In this paper we study a class of transonic flows with shocks in a two-dimensional variable-area duct for the steady full Euler system, which is a more precise description of compressible inviscid flows. The flow is supersonic at the entrance of the duct, whose boundaries are suitable perturbations of straight lines, while the flow becomes subsonic across a nearly flat shock front. The condition of impenetrability is posed on the boundaries. We will show that for given pressure at the exit, in general such flow patterns may not exist except when the pressure at the exit satisfies an additional restriction: Its mean value has already been determined by the state of the flow at the entrance and the geometry of the duct. Precisely, to ensure the stability of such transonic shocks, the pressure at the exit can be given only apart from a constant difference, that is, it should contain an unknown constant to be solved simultaneously with the flow fields in the duct. The proof reveals that the requirement of conservation of mass in the duct is closely connected to this phenomenon (see Remark 8.1 in section 8.1).

On the other hand, given pressure at the exit is a physically well accepted condition for flows in nozzles [12]. So our result indicates that the transonic shock we investigated here is unstable and not likely to be observed in practice. However, since the flow fields of the transonic shock we studied here are relatively simple, it may help us gain some insight into understanding those more complicated transonic shocks appearing, for example, in de Laval nozzles. Note that all the works cited above on transonic shocks and [7], [8], [29] are devoted to the study of the class of transonic shocks we investigate here.

In this paper we also discuss, from the mathematical point of view, the well-posedness or ill-posedness of a transonic shock problem in variable-area ducts if other conditions are given at the exit. It is shown that for given density, entropy, Mach number, or the velocity component parallel to the axis of the duct, the problem is in general ill-posed; however, it is well-posed for the given velocity component, which is perpendicular to the axis of the duct. For a list of such results, see section 11.

We remark that in [8] Chen has discussed the special case when the boundaries of the duct are straight lines and the flow has certain symmetric properties, while the upstream supersonic flow is perturbed. The author [29] has also investigated the case for flows in a cylinder with cylindrical symmetry by a different method from [8], and the radial velocity vanishing condition was posed at the exit. In [7] Chen and Yuan developed the methods initiated in [29] and solved the transonic shock problem for the three-dimensional steady full Euler system under the periodic conditions on the lateral boundary of the duct, and hence obtained the solution of the transonic shock problem in a three-dimensional duct with a constant square section under certain assumptions on the symmetry of the coming flow. The ill-posedness for given pressure at the exit is also demonstrated in detail there. However, due to the special structure of the two-dimensional stationary Euler system, we developed a different and more powerful approach here and obtained more results.

Now we comment on several difficulties which lie in the transonic shock problem we investigate presently. First is the treatment of the shock front, which is a free boundary and should be determined with the solutions (the subsonic states of the

gas flows) simultaneously. Fruitful techniques have been developed in [1], [2], [3], [8], [20] to deal with the type of free boundaries we meet here. In a rough way, those techniques allow us, by suitable reformulation of the Rankine–Hugoniot jump conditions, to construct a boundary modifying mapping, whose fixed point is the desired free boundary. The definition of the boundary modifying mapping involves solving a series of nonlinear fixed boundary problems.

Second, the steady full Euler system is a hyperbolic-elliptic composite system for subsonic flow. For such a system, classical techniques such as energy estimates, maximum principle, and estimates of fundamental solutions, are not valid in a straightforward way. One needs to separate the "elliptic part" and "hyperbolic part" appropriately to use the classical theory of elliptic and hyperbolic differential equations. To cope with the curved boundary, we also write the system in Lagrangian coordinates by virtue of the law of conservation of mass, and then decompose it into a 2×2 system (which is elliptic for subsonic flow, hyperbolic for supersonic flow, and of mixed type for transonic flow) and two algebraic equations (one is Bernoulli's law and the other is the invariance of entropy along streamlines for C^1 flows). This simplifies greatly the Euler system and enables us to study the transonic shock problem comprehensively. For example, one of the merits of this approach is that it avoids loss of derivatives. We remark that this formulation may be used to study other smooth flow patterns in ducts. Such a technic has already been used by Chen to study a flat Mach configuration in [11] and by Fang to study the transonic shocks attached to a curved wedge [14].

Third, later on we will find out that we need to solve an elliptic system in a rectangular domain. It is well known that the corners may cause singularities in the solutions (even the well-posedness; see an example in [30]), which in turn affect the regularity of the shock front, and then the smoothness of the boundary itself, and then may cause new trouble in the regularity of solutions. Another feature is that the "hyperbolic part" may transport the singularity at the corners produced by the "elliptic part" to other points in the domain. We are lucky that we can use weighted Hölder spaces and the results established in [16] by Gilbarg, Hörmander and in [21] by Lieberman to overcome this difficulty.

Fourth, as mentioned above, it turns out we are in fact dealing with an ill-posed problem if we give directly the pressure at the exit. We will show its relation to the Neumann boundary problems for Poisson equations and determine appropriate boundary conditions to make such a problem well-posed.

We will use the following well-known Banach contraction mapping principle twice to solve the transonic shock problem:

> *Any contractive mapping on a complete metric space has one and only one fixed point.*

To find the transonic shock front, we will show that the boundary modifying mapping is contractive (see section 10). However, to define the boundary modifying mapping, we need again the Banach contraction mapping principle to show that a series of nonlinear fixed boundary problems are uniquely solvable under some hypothesis (see section 9). Due to our great efforts contributed to simplify the original problem (section 3–7), obtaining the necessary estimates is straightforward and not hard work.

The paper is organized as follows. In section 2 we rigorously formulate the problem of transonic shocks in variable-area ducts (denoted as problem (**A**)) and state our main results, i.e., Theorem 2.6. In section 3 we write the Euler system in Lagrangian coordinates, which also transform the curved boundaries of ducts into straight lines.

In section 4 we decompose the resulted system into the "elliptic part" and "hyperbolic part" and in section 5 we show the existence of supersonic flow in the ducts. In section 6 we formulate a free boundary problem (denoted as problem (**B**)) and then reduce it to a set of fixed boundary problems (denoted as problem (**C**)) and a boundary modifying problem. In section 7, by rewriting the Rankine–Hugoniot jump conditions we express problem (**C**) in an equivalent but more transparent form (denoted as problem (**D**)). Section 8 is devoted to the linearized version of problem (**D**). In section 9 we solve problem (**C**) by the Banach contraction mapping principle. In section 10 we construct the boundary modifying mapping and show that it has a fixed point by using the Banach contraction mapping principle once again, thus finishing the proof of our main results, Theorem 2.6. The last section of this paper, section 11, is devoted to well-posedness or ill-posedness of the transonic shock problem (**A**) for various conditions given at the exits of the ducts. The detailed proofs of these results are omitted since they can be done in the same spirit as the proof of Theorem 2.6, but we have sketched out the main points.

2. Formulation of the transonic shock problem and main results.

2.1. Problem (A) and background solution. The Euler system, which models two-dimensional inviscid steady gas flow, is of the form

$$\begin{cases} \nabla \cdot \mathbf{m} = 0, \\ \nabla \cdot \left(\dfrac{\mathbf{m} \otimes \mathbf{m}}{\rho} \right) + \nabla p = 0, \end{cases} \tag{2.1}$$

with Bernoulli's law

$$\frac{1}{2}\mathbf{u}^2 + i = \text{const}, \tag{2.2}$$

where ρ, p, i are the density, pressure, and enthalpy of the fluid, while $\mathbf{u} = (u, v)$ and $\mathbf{m} = \rho\mathbf{u}$ are the velocity and the momentum density vector, respectively. The first equation in (2.1) is the conservation of mass, the second is the conservation of momentum, and the Bernoulli's law corresponds to the conservation of energy. Note that the const in (2.2) depends on streamlines but is invariant on the same streamline even across a shock [12].

In the case of polytropic gas $p = A(S)\rho^\gamma, \gamma \in (1, \infty)$, with S the entropy, (2.2) takes the form

$$\frac{1}{2}(u^2 + v^2) + \frac{a^2}{\gamma - 1} = \text{const}, \tag{2.3}$$

where $a = \sqrt{\gamma A(S)\rho^{\gamma-1}}$ is the local speed of sound. For C^1 flow, (2.1) can also be written as a symmetric system:

$$\begin{pmatrix} \rho u & 0 & 1 \\ 0 & \rho u & 0 \\ 1 & 0 & \frac{u}{\rho a^2} \end{pmatrix} \partial_x U + \begin{pmatrix} \rho v & 0 & 0 \\ 0 & \rho v & 1 \\ 0 & 1 & \frac{v}{\rho a^2} \end{pmatrix} \partial_y U = 0. \tag{2.4}$$

In this form, the first two equations are the conservation of momentum, and the last is the conservation of mass.

Remark 2.1. In (2.4) we have set

$$U = \begin{pmatrix} u & v & p \end{pmatrix}^t \tag{2.5}$$

as the state of the gas. Since $a^2 = \gamma p/\rho$, we may obtain ρ from (2.3) once the const in it is known. Sometimes we will also set

$$U = \begin{pmatrix} u & v & p & \rho \end{pmatrix}^t. \tag{2.6}$$

Later we will introduce

$$w = \frac{v}{u}. \tag{2.7}$$

To simplify the notation, for u nonzero we will also set U as

$$\begin{pmatrix} u & w & p \end{pmatrix}^t. \tag{2.8}$$

There will be no confusion in using U to express these vectors later.

Without loss of generality, we set $\mathbb{P} := \{(x,y) \in \mathbb{R}^2 : x \in [-1,1], 0 \le y \le \Gamma(x)\}$ to be a two-dimensional duct with variable sections, and denote the upper wall $\{y = \Gamma(x) : x \in [-1,1]\}$ as Γ_+ with $\Gamma(x)$ a positive function, and $\Gamma_- = \{y = 0 : x \in [-1,1]\}$ the lower wall. We also set $\Gamma_s = \{x = s : y \in [0, \Gamma(s)]\}$ for $s \in [-1,1]$.

We are interested in the following boundary value problem (**A**):

$$(\mathbf{A}) : \begin{cases} (2.1), (2.2) & \text{in} \quad \mathbb{P}, \\ v = 0 & \text{on} \quad \Gamma_-, \\ v - u\Gamma'(x) = 0 & \text{on} \quad \Gamma_+, \\ U = U_b^- & \text{on} \quad \Gamma_{-1}, \\ p = p_1 & \text{on} \quad \Gamma_1. \end{cases} \tag{2.9}$$

The conditions on $\Gamma_\pm$ mean that the boundary is impermeable and it is natural for ducts without holes on its boundaries. We suppose $U_b^- := \begin{pmatrix} u_b^- & 0 & p_b^- & \rho_b^- \end{pmatrix}^t$ is a constant supersonic state with $\rho_b^- > 0$ on Γ_{-1}, which represents supersonic flow entering the duct when $u_b^- > 0$. Hence the const in Bernoulli's law (2.3) is

$$c_0 = (u_b^-)^2/2 + (a_b^-)^2/(\gamma - 1)$$

and independent of streamlines. It is necessary to control the pressure at Γ_1 to obtain transonic flows in $\mathbb{P}$; otherwise the flow may be purely supersonic in $\mathbb{P}$, which is why we need the last condition in (2.9). However, the following simple but fundamental result indicates we may have trouble if we give p_1 in an arbitrary way. (Giving other conditions on Γ_1 instead of p will be discussed in section 11. In the following sections 2–10 we concentrate only on the typical case, i.e., problem (**A**).)

PROPOSITION 2.1. *For the special case $\Gamma(x) \equiv 1$, suppose the solution U to (2.9) depends only on x; then for given supersonic state U_b^-, there exists a unique constant $p_1 = p_b^+$ determined by U_b^- such that*

$$S_b : \{x = 0\} \tag{2.10}$$

is a shock front with uniform supersonic state U_b^- ahead of it (i.e., in $\{x < 0\}$) and uniform subsonic state $U_b^+ = \begin{pmatrix} u_b^+ & 0 & p_b^+ & \rho_b^+ \end{pmatrix}^t$ behind it (i.e., in $\{x > 0\}$). S_b and (U_b^-, U_b^+) make up a piecewise smooth weak entropy solution to (2.9) containing shocks. Here "uniform" means that the states $U_b^\pm$ are constant vectors.

Proof. From the one-dimensional steady Euler system it is obvious that any solution without a jump must be uniform. So $U \equiv U_b^-$ for $x \in [-1, 0]$. The Rankine–Hugoniot jump conditions (see [4, 13]) now takes the form

$$\rho u = \rho_b^- u_b^-, \quad \rho u^2 + p = \rho_b^- (u_b^-)^2 + p_b^-, \quad Eu = E_b^- u_b^-,$$

where $E = \frac{\gamma}{\gamma-1} p + \frac{1}{2}\rho |\mathbf{u}|^2$. By supersonic condition $u_b^- > a_b^-$ it is easy to get

$$\begin{aligned} u &= \frac{c_*}{u_b^-}, \qquad c_* := 2c_0 \frac{\gamma - 1}{\gamma + 1}, \\ \rho &= \frac{\rho_b^- (u_b^-)^2}{c_*}, \\ p &= \rho_b^- (u_b^-)^2 + p_b^- - c_* \rho_b^-. \end{aligned}$$

Direct calculation demonstrates that $u < a$ (subsonic) and the Lax entropy condition (see [13])

$$p > p_b^-. \tag{2.11}$$

So $U_b^+ \equiv U = (u, 0, p, S)^t$ for $x \in [0, 1]$, and thus $p_1 = p$ is uniquely determined by U_b^- as well as $U_b^\pm$. □

Remark 2.2. In the rest of this paper we call the above obtained $(U_b^\pm)$ and $S_b : \{x_0 = 0\}$ a *background solution* and denote it as $U_b = (U_b^-, U_b^+; S_b)$. Equation (2.10) is used to fix the position of the shock front since we may set $x = c$ for any $c \in (-1, 1)$ as the shock front and obtain the same $U_b^\pm$. One may also observe from the above result that the pressure $p = p_1$ at Γ_1 is necessary, though it cannot be given arbitrarily. The main result of this paper, Theorem 2.6 below, shows that for two-dimensional flow this observation is also valid.

2.2. Function spaces. Although the background solution provides us with some useful information, however, when $\Gamma(x)$ is slightly curved, rigorously solving problem (**A**) still involves several difficulties, as mentioned in the introduction. For subsonic flow, the steady Euler system is of hyperbolic-elliptic composite type: it has a real (generalized) eigenvalue of multiplicity 1 and a pair of conjugate complex eigenvalues. Due to conservation of mass we can introduce the Lagrangian transformation to reduce the original equations to two algebraic equations (Bernoulli's law and constancy of entropy along streamlines for C^1 flows) and a 2×2 system of partial differential equations, which is hyperbolic for supersonic flow, elliptic for subsonic flow, and of mixed type for transonic flow. Thus to obtain the subsonic flow behind the shock front S, we have to confront elliptic boundary value problems on rectangular domains

$$\Omega = \Big\{(x, y) : 0 \le y \le \Gamma(x), f(y) \le x \le 1\Big\}, \tag{2.12}$$

where $x = f(y)$ is the equation of the shock front S which satisfies $f(0) = 0$. Suppose S and Γ_+ intersect at the point $\Sigma_4 = (x_*, y_*)$. It is well known that the corners

$$\Sigma_1 = (0, 0), \quad \Sigma_2 = (1, 0), \quad \Sigma_3 = (1, \Gamma(1)), \quad \Sigma_4 = (x_*, y_*) \tag{2.13}$$

in general will cause singularities to the solutions, and the popular Schauder theory for $C^{2,\alpha} (\alpha \in (0, 1))$ domains (see [15]) may be invalid. The loss of regularity at the corners will also influence the regularity of the shock front S itself, which in turn has

an effect on the smoothness of the domain Ω, and thus may cause new trouble when solving the elliptic problems. The hyperbolic part may also transport the singularities at corners to other points in the duct. Fortunately, Gilbarg and Hörmander [16] and Lieberman [21] have established the *intermediate Schauder estimates* to attack elliptic problems on nonsmooth domain (see also the Notes of Chapter 6 in [15]), and their theory is powerful enough to handle our dilemma. Following their ideas, we introduce the function spaces $H_a^{(b)}(\Omega)$, $H_a^{'b}[0,y_*]$ to describe precisely the regularity of our desired subsonic flow and the transonic shock front, respectively. Our definition is a little different from theirs, but due to the boundary regularity estimates (Lemmas 6.18 and 6.29 in [15]), there is no problem later in using their theorems. Note that in the following we always suppose that $0 \le k < a = k+\alpha \le k+1, a+b > 0$, with k an integer and $\alpha \in (0,1]$ for such spaces.

The Banach spaces $H_a^{'(b)}[0,y_*]$ is defined as follows. A function f on $[0,y_*]$ is in $H_a^{'(b)}[0,y_*]$ if and only if

$$\|f\|_{a;[0,y_*]}^{'(b)} := \sup_{\delta>0} \delta^{a+b} \|f\|_{C^a[\delta,y_*-\delta]} < \infty, \tag{2.14}$$

with C^a here the usual Hölder space $C^{k,\alpha}$. We define $\|\cdot\|_{a;[0,y_*]}^{'(b)}$ as the norm of $H_a^{'(b)}[0,y_*]$.

The Banach space $H_a^{(b)}(\Omega)$ is by definition the set of functions ϕ defined on Ω with the property that

$$\|\phi\|_{a;\Omega}^{(b)} := \sup_{\delta>0} \delta^{a+b} \|\phi\|_{C^a(\Omega_\delta)} < \infty, \tag{2.15}$$

where

$$\Omega_\delta := \Big\{ P = (\bar\xi,\bar\eta) \in \Omega : \text{distance}(P,\Gamma^{\pm}) > \delta \Big\}. \tag{2.16}$$

Here Ω as in (2.12) with $f \in H_a^{'(b)}[0,y_*]$, while $\Gamma^+ := \{(x,\Gamma(x)) : x_* \le x \le 1\}, \Gamma^- := \{(x,0) : 0 \le x \le 1\}$ are, respectively, the upper and lower boundary of Ω.

Notice that the Lagrangian transformation also has the advantage that it straightens the curved boundary since it straightens the streamlines. So later by introducing certain homeomorphisms $\Phi : \Omega \to [0,1;0,1]$ which are of class $H_a^{(b)}(\Omega)$ with $b < -1$, we will actually solve elliptic boundary problems on the square $[0,1;0,1]$. For simplicity, we write $H_a^{(b)}([0,1;0,1])$ as $H_a^{(b)}$, and $H_a^{'(b)}[0,1]$ as $H_a^{'(b)}$. The corresponding norms are simply denoted as $\|\cdot\|_a^{(b)}, \|\cdot\|_a^{'(b)}$, respectively. By direct calculations one can verify the following.

PROPOSITION 2.2. *Suppose $b < -1$, Ω as before, $u \in H_a^{(b)}$, and $\Phi : \Omega \to [0,1;0,1]$ satisfy $\Phi \in H_a^{(b)}(\bar\Omega;\mathbb{R}^2)$. Then $u \circ \Phi \in H_a^{(b)}(\bar\Omega)$ and*

$$\| u \circ \Phi \|_{H_a^{(b)}(\bar\Omega)} \le C \| u \|_{H_a^{(b)}}, \tag{2.17}$$

where $C = C\big(n, \| \Phi \|_{H_a^{(b)}(\bar\Omega;\mathbb{R}^n)}\big)$.

A similar result also holds for $H_a^{'(b)}$. This means that the homeomorphisms introduced later (including the Lagrangian transformation) will not influence our resultant estimates.

We list here several useful properties of spaces $H_a^{(b)}$ (they also hold for $H_a^{'(b)}$) which are used later to obtain estimates of certain nonlinear terms. The proof and more information about this class of weighted Hölder spaces can be found in [16].

PROPOSITION 2.3.

$$\|\nabla\phi\|_{a-1}^{(1+b)} \le C\,\|\phi\|_a^{(b)} \qquad \text{if} \quad a>1, \tag{2.18}$$

$$\|\phi\|_a^{(b)} \le C\,\|\phi\|_a^{(b')} \qquad \text{if} \quad b'\le b. \tag{2.19}$$

PROPOSITION 2.4. *If $0\le a'\le a, a'+b\geqslant 0$, and b is not an integer ≤ 0, then*

$$\|\phi\|_{a'}^{(b)} \le C\,\|\phi\|_a^{(b)}. \tag{2.20}$$

PROPOSITION 2.5. *If $0\le c_j\le a+b, a\geqslant 0$, then*

$$\|\phi\psi\|_a^{(b)} \le C(\|\phi\|_a^{(b-c_1)}\,\|\psi\|_0^{(c_1)} + \|\phi\|_0^{(c_2)}\,\|\psi\|_a^{(b-c_2)}). \tag{2.21}$$

2.3. Main results. There are two main results in this paper. Now we can state precisely the first one as the following theorem. Another is indicated in Remark 2.6. For details, see section 11.

THEOREM 2.6. *There exists a $\varepsilon_0>0$ such that if*

$$\|\Gamma(x)-1\|_{C^5[-1,1]} \le \varepsilon < \varepsilon_0, \tag{2.22}$$

$$\frac{\mathrm{d}^k(\Gamma(x)-1)}{\mathrm{d}x^k}\Big|_{x=-1} = 0, \quad k=0,1,2,3,4,5, \tag{2.23}$$

then there is a unique $e\in\mathbb{R}$ with

$$|e| < C_0\varepsilon \tag{2.24}$$

such that (2.9) *with*

$$p_1 = p_b^+ + e \tag{2.25}$$

has a unique weak entropy solution $(U_-,U_+;S)$ with the following properties:

(i) *U_- is supersonic, U_+ is subsonic, and S is the shock front separating U_- and U_+ with entropy condition.*

(ii) *$S: x=f(y)$, $y\in[0,y_*]$, with y_* satisfying $y_*=\Gamma(f(y_*))$ and*

$$f(0)=0. \tag{2.26}$$

(iii) *For some $\alpha\in(0,1)$, the following estimates hold:*

$$\left\|U_- - U_b^-\right\|_{C^{3,\alpha}(\mathbb{P}_-)} < C_0\varepsilon, \tag{2.27}$$

$$\left\|U_+ - U_b^+\right\|_{2+\alpha;\Omega}^{(-\alpha)} < C_0\varepsilon, \tag{2.28}$$

$$\|f\|_{3+\alpha;[0,y_*]}^{'(-1-\alpha)} < C_0\varepsilon. \tag{2.29}$$

Here ε_0, C_0 are constants depending only on U_b, and we have

$$\mathbb{P}_- := \{(x,y)\in\mathbb{P} : x < f(y)\},$$

with Ω the same as in (2.12).

Remark 2.3. We suppose (2.26) holds to fix the position of the shock front. This is necessary, as indicated by the translation invariance along the x axis for the background solution: for the same p_1 in Proposition 2.1 at the exit, the position of the shock cannot be uniquely determined (see also Remark 2.2 and [4], [28]). We note that this phenomena is different from those transonic shocks observed in de Laval nozzles.

Remark 2.4. Equation (2.25) may be replaced by

$$p_1 = p_b^+ + g(y) + e \tag{2.30}$$

with e a constant to be determined simultaneously with U for any $g \in C^{2,\alpha}[0, \Gamma(1)]$ with small norm. There is no additional difficulty in the proof. Giving pressure at the exit in this way implies that the value of the pressure at the exit can be given only apart from a constant difference. We note that e in most cases does not vanish, as was shown by Proposition 2.1 if g is a nonzero number: it has already been determined by the coming upstream flow and the shape of the duct and g. This implies that for given pressure at the exit of the duct the transonic shock problem is ill-posed. As can be seen from the background solution, the ill-posedness is not related to the fact that we fixed the position of the shock.

Remark 2.5. Our proof can be modified to treat the case when the upstream supersonic flow at the entrance of the duct is also perturbed slightly if certain orders of compatibility conditions hold at the entrance, and a similar result can be proved. The major difference is that the constant in Bernoulli's law may be different on different streamlines. In [7] we have studied this case for the three-dimensional Euler system.

Remark 2.6. We note that the method developed in this paper provides us with more information than just presented in Theorem 2.6. It indicates clearly the well-posedness of giving v, w at Γ_1; ill-posedness of giving u, ρ, S, or the Mach number $M = |\mathbf{u}|/a$ as well as p there will be discussed in detail in section 11.

Remark 2.7. We emphasize here that the uniqueness of transonic shock in Theorem 2.6 is proved only in the class of functions satisfying properties (i)–(iii) listed there. The "global uniqueness" is an interesting open problem. Noting the nonuniqueness of transonic shocks claimed by Smith in [26] and symmetry breaking phenomena discussed by Kuz'min [19] and references therein, rigorous analysis of uniqueness or nonuniqueness of certain problems in aerodynamics is very important to understand some widely used models in practice and numerical simulations.

3. Euler equations in Lagrangian coordinates. The Euler equations (2.1), (2.2) are difficult to handle directly. In this section we use conservation of mass to write them in Lagrangian coordinates, which simplifies the geometry of the domain, as well as the "hyperbolic" part of the Euler system, as will be shown in the next section.

Set

$$w = \frac{v}{u}, \tag{3.1}$$

and denote the integral curves of

$$\begin{cases} \dfrac{\mathrm{d}\hat{y}(x,h)}{\mathrm{d}x} = w(x, \hat{y}(x,h)), \\ \hat{y}(0,h) = h \end{cases} \tag{3.2}$$

by

$$\begin{cases} x = \xi, \\ \hat{y} = \hat{y}(\xi, h). \end{cases} \tag{3.3}$$

(These are exactly streamlines.) Let

$$\eta = \eta(x, h) = \int_{\hat{y}(x,0)}^{\hat{y}(x,h)} \rho u(x, y) \mathrm{d}y \tag{3.4}$$

be the flux of mass between two such curves. Then by using the first equation in (2.1) we have

$$\begin{aligned} \partial_x \eta = & \rho u(x, \hat{y}(x, h)) \frac{\partial \hat{y}(x, h)}{\partial x} \\ & - \rho u(x, \hat{y}(x, 0)) \frac{\partial \hat{y}(x, 0)}{\partial x} - \int_{\hat{y}(x,0)}^{\hat{y}(x,h)} \partial_y (\rho v(x, y)) \mathrm{d}y \\ = & \, 0. \end{aligned} \tag{3.5}$$

Hence $\eta = \eta(-1, h)$ and $\eta(-1, 0) = 0$. Thus if

$$\frac{\partial \eta(0, h)}{\partial h} = \rho u(0, \hat{y}(0, h)) \frac{\partial \hat{y}(0, h)}{\partial h} = \rho u(0, \hat{y}(0, h)) \neq 0, \tag{3.6}$$

we may obtain the inverse function $h = h(\eta)$ of $\eta = \eta(-1, h)$ and $h(0) = 0$. Set

$$y(x, \eta) = \hat{y}(x, h(\eta)); \tag{3.7}$$

then (3.4) becomes

$$\eta = \int_{y(x,0)}^{y(x,\eta)} \rho u(x, s) \mathrm{d}s, \tag{3.8}$$

and by differentiating it with η one has

$$\frac{\partial y}{\partial \eta} = \frac{1}{\rho u}. \tag{3.9}$$

Now we introduce the following Lagrangian transformation $(x, y) \mapsto (\xi, \eta)$:

$$\begin{cases} x = \xi, \\ y = y(\xi, \eta). \end{cases} \tag{3.10}$$

Then by

$$\frac{\partial (x, y)}{\partial (\xi, \eta)} = \begin{pmatrix} 1 & 0 \\ w & \frac{1}{\rho u} \end{pmatrix}, \tag{3.11}$$

we have

$$\frac{\partial (\xi, \eta)}{\partial (x, y)} = \begin{pmatrix} 1 & 0 \\ -\rho v & \rho u \end{pmatrix}; \tag{3.12}$$

thus

$$\begin{cases} \partial_x = \partial_\xi - \rho v \partial_\eta, \\ \partial_y = \rho u \partial_\eta. \end{cases} \tag{3.13}$$

So a little computation shows that (2.1) or (2.4) may be written as conservation laws

$$\begin{cases} \partial_\xi(\frac{1}{\rho u}) - \partial_\eta w = 0 & \text{(conservation of mass)}, \\ \partial_\xi(u + \frac{p}{\rho u}) - \partial_\eta(pw) = 0 & \text{(conservation of momentum along } \xi), \\ \partial_\xi v + \partial_\eta p = 0 & \text{(conservation of momentum along } \eta), \end{cases} \tag{3.14}$$

or as symmetric system

$$A\partial_\xi U + B\partial_\eta U = 0, \tag{3.15}$$

with

$$A = \begin{pmatrix} u & 0 & \frac{1}{\rho} \\ 0 & u & 0 \\ \frac{1}{\rho} & 0 & \frac{u}{\rho^2 a^2} \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 0 & -v \\ 0 & 0 & u \\ -v & u & 0 \end{pmatrix} \tag{3.16}$$

and

$$U = \begin{pmatrix} u & v & p \end{pmatrix}^t. \tag{3.17}$$

The above transformation is valid if and only if

$$\rho u \neq 0. \tag{3.18}$$

Note that in (3.16) the last equation corresponds to conservation of mass.

Next we consider boundary conditions on $\Gamma_\pm$. By (2.9) and (3.2) (and uniqueness of solutions to Cauchy problems of ODEs) $\Gamma_\pm$ are streamlines. Thus Γ_- in the (ξ, η) coordinates is

$$\tilde{\Gamma}_- : \ \eta = 0, \quad \xi \in [-1, 1], \tag{3.19}$$

while Γ_+ is

$$\tilde{\Gamma}_+ : \ \eta = \eta_0 = \int_0^1 \rho u(-1, s) \mathrm{d}s, \quad \xi \in [-1, 1]. \tag{3.20}$$

In the latter, without loss of generality we always suppose that $\eta_0 \equiv 1$ by suitable normalization of the unit of the coming flow. The corresponding boundary conditions are

$$\begin{cases} w = 0 & \text{on} \quad \tilde{\Gamma}_-, \\ w = \Gamma'(\xi) & \text{on} \quad \tilde{\Gamma}_+. \end{cases} \tag{3.21}$$

Since the shock front may be curved, with the equation

$$\xi = \psi(\eta), \quad \eta \in [0, 1], \tag{3.22}$$

we introduce further the following transformation $\mathbf{\Phi}_\psi : (\xi, \eta) \mapsto (\bar{\xi}, \bar{\eta})$ to straighten the shock front:

$$\begin{cases} \bar{\xi} = \dfrac{\xi - \psi(\eta)}{1 - \psi(\eta)}, \\ \bar{\eta} = \eta, \end{cases} \quad \text{or} \quad \begin{cases} \xi = (1 - \psi(\bar{\eta}))\bar{\xi} + \psi(\bar{\eta}), \\ \eta = \bar{\eta}. \end{cases} \tag{3.23}$$

So

$$(\bar{\xi}, \bar{\eta}) \in [0, 1; 0, 1]$$

and

$$\begin{cases} \dfrac{\partial}{\partial \xi} = \dfrac{1}{1 - \psi(\bar{\eta})} \dfrac{\partial}{\partial \bar{\xi}}, \\ \dfrac{\partial}{\partial \eta} = \dfrac{\partial}{\partial \bar{\eta}} + \dfrac{(\bar{\xi} - 1)\psi'(\bar{\eta})}{1 - \psi(\bar{\eta})} \dfrac{\partial}{\partial \bar{\xi}}. \end{cases} \tag{3.24}$$

Thus (3.15) becomes

$$\bar{A}\partial_{\bar{\xi}} U + \bar{B}\partial_{\bar{\eta}} U = 0, \tag{3.25}$$

with

$$\bar{A} = A + (\bar{\xi} - 1)\psi'(\bar{\eta})B, \quad \bar{B} = (1 - \psi(\bar{\eta}))B. \tag{3.26}$$

Finally, note that after passing the shock front, (3.21) in the $(\bar{\xi}, \bar{\eta})$ coordinates is

$$\begin{cases} w = 0 & \text{on} \quad \bar{\Gamma}_- := \{(\bar{\xi}, 0) : \bar{\xi} \in [0, 1]\}, \\ w = \Gamma'((1 - \psi(1))\bar{\xi} + \psi(1)) & \text{on} \quad \bar{\Gamma}_+ := \{(\bar{\xi}, 1) : \bar{\xi} \in [0, 1]\}. \end{cases} \tag{3.27}$$

4. Decomposition of elliptic-hyperbolic composite system. The idea involved in this section to write (3.25) as separate elliptic and hyperbolic equations is rudimentary. Let λ be a generalized eigenvalue of $\bar{B}$ with respect to $\bar{A}$:

$$\det(\lambda \bar{A} - \bar{B}) = 0, \tag{4.1}$$

and let the corresponding generalized left (row) eigenvector be l, i.e.,

$$l\bar{B} = \lambda l \bar{A}, \tag{4.2}$$

then multiply (3.25) from the left by l to get

$$l\bar{A}(\partial_{\bar{\xi}} + \lambda \partial_{\bar{\eta}})U = 0. \tag{4.3}$$

Now suppose λ (and thus l) is complex:

$$\lambda = \lambda_R + i\lambda_I, \quad l = l_R + i l_I, \quad i = \sqrt{-1}; \tag{4.4}$$

then (4.3) is equivalent to

$$\begin{cases} l_R \bar{A}\partial_I U + l_I \bar{A}\partial_R U = 0, \\ l_R \bar{A}\partial_R U - l_I \bar{A}\partial_I U = 0, \end{cases} \tag{4.5}$$

with

$$\partial_R = \partial_{\bar\xi} + \lambda_R \partial_{\bar\eta}, \qquad \partial_I = \lambda_I \partial_{\bar\eta}. \tag{4.6}$$

So roughly speaking, the real eigenvalue λ corresponds to the hyperbolic equation (4.3) while the complex λ and its conjugation $\bar\lambda$ correspond to the elliptic system (4.5).

System (3.25) has a real eigenvalue λ_0 and a pair of complex eigenvalues $\lambda = \lambda_R \pm i\lambda_I$ if the Mach number $M = |\mathbf{u}|/a < 1$ (the computation is straightforward and we omit it):

$$\lambda_0 = 0, \tag{4.7}$$

$$\lambda_R = -\frac{(1-\psi)\big((\bar\xi-1)\psi'(u^2+v^2) - \frac{v}{\rho}\big)}{\frac{1}{\rho^2}\left(\frac{u^2}{a^2}-1\right) - (\bar\xi-1)^2\psi'^2(u^2+v^2) + \frac{2}{\rho}(\bar\xi-1)\psi' v}, \tag{4.8}$$

$$\lambda_I = \frac{(1-\psi)\frac{u}{\rho}\sqrt{1-M^2}}{\frac{1}{\rho^2}\left(\frac{u^2}{a^2}-1\right) - (\bar\xi-1)^2\psi'^2(u^2+v^2) + \frac{2}{\rho}(\bar\xi-1)\psi' v}. \tag{4.9}$$

Here and in the following we write $\psi = \psi(\bar\eta)$, $\psi' = \psi'(\bar\eta)$. The corresponding left eigenvectors are

$$l_0 = \begin{pmatrix} u & v & 0 \end{pmatrix}, \tag{4.10}$$

$$l_R = \begin{pmatrix} \frac{\lambda_R}{\rho} - \lambda_R(\bar\xi-1)v\psi' + (1-\psi)v & \lambda_R(\bar\xi-1)\psi' u - (1-\psi)u & -\lambda_R u \end{pmatrix}, \tag{4.11}$$

$$l_I = \begin{pmatrix} \frac{\lambda_I}{\rho} - \lambda_I(\bar\xi-1)v\psi' & \lambda_I(\bar\xi-1)\psi' u & -\lambda_I u \end{pmatrix}. \tag{4.12}$$

Thus

$$l_0\bar A = \begin{pmatrix} u^2 & uv & \frac{u}{\rho} \end{pmatrix}, \tag{4.13}$$

$$l_R\bar A = \begin{pmatrix} (1-\psi)uv & -(1-\psi)u^2 & 0 \end{pmatrix}, \tag{4.14}$$

$$l_I\bar A = \begin{pmatrix} 0 & 0 & -(1-\psi)u\frac{\sqrt{1-M^2}}{\rho} \end{pmatrix}. \tag{4.15}$$

By (4.3), (4.7), and (4.13) we get the hyperbolic equation

$$\frac{1}{2}\partial_{\bar\xi}(u^2+v^2) + \frac{1}{\rho}\partial_{\bar\xi} p = 0 \tag{4.16}$$

if $u \neq 0$. On the other hand, from Bernoulli's law (2.3) one gets

$$\frac{1}{2}\partial_{\bar\xi}(u^2+v^2) + \frac{1}{\gamma-1}\partial_{\bar\xi} a^2 = 0;$$

hence

$$\frac{1}{\rho}\partial_{\bar\xi} p - \frac{1}{\gamma-1}\partial_{\bar\xi} a^2 = 0.$$

By $p = A(S)\rho^\gamma, a^2 = \gamma A(S)\rho^{\gamma-1}$ the above equation is actually the constancy of entropy along streamlines for C^1 solutions

$$\partial_{\bar\xi}\left(\frac{p}{\rho^\gamma}\right) = 0. \tag{4.17}$$

Similarly, we can write (4.5) as

$$\begin{cases} \partial_{\bar\xi} p + \lambda_R \partial_{\bar\eta} p - \beta_1 \partial_{\bar\eta} w = 0, \\ \partial_{\bar\xi} w + \beta_2 \partial_{\bar\eta} p + \lambda_R \partial_{\bar\eta} w = 0, \end{cases} \tag{4.18}$$

with

$$\begin{cases} \beta_1 = -\dfrac{(1-\psi)u^3}{\frac{1}{\rho^2}\left(\frac{u^2}{a^2}-1\right) - (\bar\xi-1)^2\psi'^2(u^2+v^2) + \frac{2}{\rho}(\bar\xi-1)\psi' v}, \\ \beta_2 = -\dfrac{\frac{1}{u\rho^2}(1-\psi)(1-M^2)}{\frac{1}{\rho^2}\left(\frac{u^2}{a^2}-1\right) - (\bar\xi-1)^2\psi'^2(u^2+v^2) + \frac{2}{\rho}(\bar\xi-1)\psi' v}. \end{cases} \tag{4.19}$$

When $M < 1$, (4.18) is an elliptic system. However, for $M > 1$, i.e., supersonic flow, we can also carry out similar calculations to obtain (4.18), which is a hyperbolic system. Thus if

$$\det \begin{pmatrix} l_0 \\ l_R \\ l_I \end{pmatrix} = (1-\psi)\lambda_I u(u^2+v^2) \tag{4.20}$$

is nonzero, (4.17) and (4.18) are equivalent to (3.25) for C^1 solutions. This is true if

$$\rho u \neq 0, \quad M \neq 1, \quad u \neq a, \qquad \|\psi\|_{C^1} \ll 1. \tag{4.21}$$

Remark 4.1. The first equation in (4.18) is in essence the conservation of mass. In fact, it is obtained by multiplying (3.25) from the left by l_I. Notice that the third argument in l_I is nonzero and the last equation in (3.25) is the conservation of mass.

5. Existence of supersonic flow. In this section we always set $\psi \equiv 0$, and we will use (4.18) to show existence and uniqueness of supersonic flow in the duct $\mathbb{P}$ when its boundary is slightly curved, without considering the conditions at the exit. Now (4.18) is

$$\partial_\xi \begin{pmatrix} w \\ p \end{pmatrix} + \begin{pmatrix} \varpi & \beta \\ \kappa & \varpi \end{pmatrix} \partial_\eta \begin{pmatrix} w \\ p \end{pmatrix} = 0, \tag{5.1}$$

with

$$\varpi = \frac{\rho v a^2}{u^2 - a^2}, \quad \beta = \frac{a^2(M^2-1)}{u(u^2-a^2)}, \quad \kappa = \frac{\rho^2 a^2 u^3}{u^2-a^2}.$$

Consider the following mixed initial-boundary value problem:

$$\begin{cases} (5.1) & \text{in} \quad \tilde{\mathbb{P}} = [-1,1]\times[0,1], \\ p = p_b^- & \text{on} \quad \tilde\Gamma_{-1} : \xi = -1, \\ w = 0 & \text{on} \quad \tilde\Gamma_{-1} : \xi = -1, \\ w = 0 & \text{on} \quad \tilde\Gamma_- : \eta = 0, \\ w = \Gamma'(\xi) & \text{on} \quad \tilde\Gamma_+ : \eta = 1, \end{cases} \tag{5.2}$$

where

$$p = d_0 \rho^\gamma, \quad \text{or} \quad \rho = \left(\frac{p}{d_0}\right)^{\frac{1}{\gamma}}, \tag{5.3}$$

$$u = \left\{ \frac{2}{1+w^2} \left(c_0 - \frac{\gamma d_0}{\gamma - 1} \left(\frac{p}{d_0} \right)^{\frac{\gamma-1}{\gamma}} \right) \right\}^{\frac{1}{2}}, \tag{5.4}$$

with

$$d_0 = p_b^- / (\rho_b^-)^\gamma. \tag{5.5}$$

Equation (5.3) originates from (4.17), and (5.4) comes from Bernoulli's law (2.3) and (5.3).

Remark 5.1. The system (5.1) is genuinely nonlinear in a neighborhood of U_b^-. Direct computation shows that the eigenvalues are

$$\lambda_\pm = \varpi \pm \sqrt{\beta\kappa} = \frac{\rho a^2}{u^2 - a^2}(v \pm u\sqrt{M^2 - 1}), \tag{5.6}$$

and the corresponding left (resp., right) eigenvectors $l_\pm$ ($r_\pm$) are

$$l_\pm = \begin{pmatrix} \pm\sqrt{\kappa} & \sqrt{\beta} \end{pmatrix}, \tag{5.7}$$

$$r_\pm = \begin{pmatrix} \pm\sqrt{\beta} & \sqrt{\kappa} \end{pmatrix}^t. \tag{5.8}$$

Thus

$$\nabla\lambda_\pm \cdot r_\pm(U_b^-) = \frac{1}{2}(1+\gamma) \frac{\rho u^4 \sqrt{u}}{(u^2 - a^2)^2} \bigg|_{U = U_b^-} \neq 0. \tag{5.9}$$

Set $W = (w, p)^t$. The characteristic form of (5.1) is

$$(\sqrt{\kappa}, \sqrt{\beta})(\partial_\xi + (\varpi + \sqrt{\beta\kappa})\partial_\eta)W = 0, \tag{5.10}$$

$$(-\sqrt{\kappa}, \sqrt{\beta})(\partial_\xi + (\varpi - \sqrt{\beta\kappa})\partial_\eta)W = 0. \tag{5.11}$$

THEOREM 5.1. *There exists a positive ε_0 such that if* (2.22) *and* (2.23) *hold, then problem* (5.2) *has a unique solution* (w, p) *satisfying*

$$\|w\|_{C^{3,\alpha}(\tilde{\mathbb{P}})} + \left\|p - p_b^-\right\|_{C^{3,\alpha}(\tilde{\mathbb{P}})} \leq C_0\varepsilon. \tag{5.12}$$

The constants ε_0, C_0 depend solely on U_b^-, and $\alpha \in (0,1)$ may be arbitrary.

COROLLARY 5.2. *Under the same assumptions of Theorem* 5.1*, by* (3.1)*,* (5.3)*,* (5.4)*, and* (5.12) *we also have*

$$\left\|u - u_b^-\right\|_{C^{3,\alpha}(\mathbb{P})} + \|v\|_{C^{3,\alpha}(\mathbb{P})} + \left\|\rho - \rho_b^-\right\|_{C^{3,\alpha}(\mathbb{P})} + \left\|p - p_b^-\right\|_{C^{3,\alpha}(\mathbb{P})} \leq C_0\varepsilon. \tag{5.13}$$

Remark 5.2. Hereafter we denote the u, v, p, ρ, w, S obtained in Theorem 5.1 and Corollary 5.2 as $u_-, v_-, p_-, \rho_-, w_-, S_-$ in accordance with the notation in Theorem 2.6.

The proof of Theorem 5.1 is standard; it just needs a little modification of the proof of Theorem 3.3 in Chapter 4 of [20] (p. 180). (We may get local existence directly by this theorem.) In fact, if the boundary condition is a small perturbation of zero, then the existence can be semiglobal. It means that the life span of the smooth solution depends on the smallness of the perturbation of boundary data. In other words, the life span can be larger than any given number, provided the perturbation is small enough.

Remark 5.3. For $\Gamma'(\xi) < 0$ and the case when perturbation is not small, Chen has proved in [10] that the solution may blow up in finite distance from the entrance and shocks will appear.

6. Free boundary problem (B) and fixed boundary problem (C).

6.1. Problem (B). Knowing the supersonic flow, now we are in the position to determine the shock front and the subsonic state behind it simultaneously, satisfying the restrictions of pressure at the exit. We formulate it as the free boundary problem (**B**).

Let

$$S : \xi = \psi(\eta), \qquad \eta \in [0, 1], \tag{6.1}$$

be the shock front. By (3.14) the following Rankine–Hugoniot jump conditions [12] should hold across S:

$$-\left[\frac{1}{\rho u}\right] = [w]\ \psi'(\eta), \tag{6.2}$$

$$-\left[u + \frac{p}{\rho u}\right] = [pw]\ \psi'(\eta), \tag{6.3}$$

$$[v] = [p]\ \psi'(\eta). \tag{6.4}$$

By (6.4) we have

$$\psi'(\eta) = \frac{[v]}{[p]}. \tag{6.5}$$

Due to Remark 2.3 concerning (2.26), we set

$$\psi(0) = 0. \tag{6.6}$$

Substituting (6.5) in (6.2) and (6.3), we have

$$G_1(U, U_-) := [w][uw] + \left[\frac{1}{\rho u}\right][p] = 0, \tag{6.7}$$

$$G_2(U, U_-) := [pw][uw] + \left[u + \frac{p}{\rho u}\right][p] = 0. \tag{6.8}$$

Here $U := \begin{pmatrix} u & w & p \end{pmatrix}^t$, and $U_- := \begin{pmatrix} u_- & w_- & p_- \end{pmatrix}^t$ with $U_- = U_-(\psi(\eta), \eta)$. Note that (6.5), (6.7), and (6.8) are equivalent to (6.2)–(6.4) provided $[p] \neq 0$, which is guaranteed by (2.11) if the perturbations are small.

Problem (**B**) can be stated now as the following:

Find $U, \psi(\eta)$ and a real number e such that
(i) $\psi(\eta)$ satisfies (6.1), (6.5), (6.6);
(ii) (6.7), (6.8) hold on S;
(iii) $w = 0$ on $\tilde{\Gamma}_-$;
(iv) $w = \Gamma'(\xi)$ on $\tilde{\Gamma}_+$;
(v) $p = p_b^+ + e$ on $\tilde{\Gamma}_1$.
(vi) Set $\Omega_\psi := \{(\xi, \eta) : \eta \in [0, 1], \psi(\eta) \leq \xi \leq 1\}$; then (4.17), (4.18) should hold in Ω_ψ as well as Bernoulli's law (2.3).

6.2. Problem (C). The idea of dealing with problem (**B**) is, roughly speaking, by iteration: first we fix the boundary and solve a fixed boundary problem, use (6.5), (6.6) to update the boundary, and then solve another fixed boundary problem, etc.

Set

$$\mathcal{S}_\sigma = \Big\{\psi(\eta) \in H^{'(-1-\alpha)}_{3+\alpha}[0,1] : \|\psi\|^{'(-1-\alpha)}_{3+\alpha;[0,1]} \le \sigma, \psi(0) = 0\Big\} \tag{6.9}$$

with

$$\sigma \le \sigma_0 < \frac{1}{2}. \tag{6.10}$$

For any $\psi \in \mathcal{S}_\sigma$, we may use transformation (3.23), which is of class $H^{(-1-\alpha)}_{3+\alpha;\Omega_\psi}$, to state the fixed boundary problem $(\mathbf{C}_\psi)$ as follows:

Find U and $e \in \mathbb{R}$ such that
(i) (4.17), (4.18), and (2.3) hold in $\Omega := [0,1] \times [0,1]$;
(ii) (3.27) holds on $\bar{\Gamma}_\pm$;
(iii) (6.7), (6.8) hold on $\bar{\xi} = 0$;
(iv) $p = p_b^+ + e$ holds on $\bar{\xi} = 1$.

Now if problem $(\mathbf{C}_\psi)$ is uniquely solvable, with the solution U_ψ, then by the Cauchy problem of the ODE (note that $\eta = \bar{\eta}$)

$$\begin{cases} \tilde{\psi}'(\eta) = \frac{[v_\psi]}{[p_\psi]}, \\ \tilde{\psi}(0) = 0, \end{cases} \tag{6.11}$$

later (section 10) we will construct a mapping $\Psi : \mathcal{S}_\sigma \to \mathcal{S}_\sigma$ given by $\Psi(\psi) = \tilde{\psi}$ if ε_0 in Theorem 2.6 is small. Clearly the fixed point $\bar{\psi}$ of Ψ corresponds to the desired shock front in problem $(\mathbf{B})$, and the solution $U_{\bar{\psi}}$ obtained by problem $(\mathbf{C}_{\bar{\psi}})$ is the subsonic state we are looking for. We call Ψ the *boundary modifying mapping*.

7. Problem (D): An equivalent form of problem (C). This section is devoted to writing problem $(\mathbf{C}_\psi)$ in an equivalent, but more transparent and tractable, form called problem $(\mathbf{D}_\psi)$. This is a nonlinear boundary problem for nonlinear systems.

We first deal with the boundary conditions. Since $G_i(U_b^+, U_b^-) = 0$ for $i = 1, 2$ holds, we may write (6.7), (6.8) as

$$\begin{aligned} &\nabla_+ G_i(U_b^+, U_b^-) \cdot (U - U_b^+) \\ &\quad = \nabla_+ G_i(U_b^+, U_b^-) \cdot (U - U_b^+) - (G_i(U, U_b^-) - G_i(U_b^+, U_b^-)) \\ &+ (G_i(U, U_b^-) - G_i(U, U_-)) \\ &\quad := g_i(U, U_-), \end{aligned} \tag{7.1}$$

where $\nabla_+ G_i(U, U_-)$ is the gradient of $G_i(U, U_-)$ with respect to the variables U. By direct calculations (note that here by Bernoulli's law we consider ρ as a function of p, w, u),

$$\begin{aligned} \nabla_+ G_i(U_b^+, U_b^-) &= \left.\frac{\partial(G_1, G_2)(U, U_-)}{\partial(u, w, p)}\right|_{(U,U_-)=(U_b^+, U_b^-)} \\ &= \begin{pmatrix} a_1 & 0 & b_1 \\ a_2 & 0 & b_2 \end{pmatrix} \end{aligned} \tag{7.2}$$

with

$$\begin{aligned}
a_1 &= -\frac{2c_0+u^2}{2c_0-u^2}\cdot\frac{[p]}{\rho u^2}\Big|_{(U_b^+,U_b^-)}\\
&= -\frac{2c_0+{u_b^+}^2}{2c_0-{u_b^+}^2}\cdot\frac{p_b^+-p_b^-}{\rho_b^+{u_b^+}^2},\\
b_1 &= -\frac{[p]}{\rho up}\Big|_{(U_b^+,U_b^-)},\\
a_2 &= [p]\left(\frac{1}{\gamma}-\frac{p}{\rho u^2}\right)\Big|_{(U_b^+,U_b^-)},\\
b_2 &= \left[u+\frac{p}{\rho u}\right]\Big|_{(U_b^+,U_b^-)}\\
&= 0.
\end{aligned}$$

Thus

$$d_1 := \det\begin{pmatrix} a_1 & b_1\\ a_2 & b_2\end{pmatrix} = \frac{[p]^2}{\rho up}\left(\frac{1}{\gamma}-\frac{p}{\rho u^2}\right)\Big|_{(U_b^+,U_b^-)} = -\frac{[p]^2}{\gamma\rho up}\left(\frac{a^2}{u^2}-1\right)\Big|_{(U_b^+,U_b^-)} \neq 0,$$

and we may rewrite (7.1) as

$$p-p_b^+ = \frac{1}{d_1}(a_1g_2-a_2g_1) := h_1(U,U_-), \tag{7.3}$$

$$u-u_b^+ = \frac{1}{d_1}(b_2g_1-b_1g_2) := h_2(U,U_-). \tag{7.4}$$

They should hold on $\bar{\xi}=0$.

Next we manipulate the equations. In the following we denote the value of U on $\bar{\xi}=0$ as U_0. For example, by (7.3), (7.4), $p_0 = h_1 + p_b^+, u_0 = h_2 + u_b^+$.

Now by (4.17) and Bernoulli's law (2.3) we get

$$\rho_0 = \frac{\gamma}{\gamma-1}\cdot\frac{p_0}{c_0-\frac{1}{2}u_0^2(1+w_0^2)}, \tag{7.5}$$

$$\rho = \rho_0\left(\frac{p}{p_0}\right)^{\frac{1}{\gamma}}, \tag{7.6}$$

$$u = \left\{\frac{2}{1+w^2}\cdot\left(c_0-\frac{\gamma}{\gamma-1}\cdot\frac{p}{\rho}\right)\right\}^{\frac{1}{2}}, \tag{7.7}$$

while w, p may be solved from (4.18).

Let

$$\lambda_i := \beta_i|_{U=U_b^+,\psi=0} \qquad \text{for} \quad i=1,2, \tag{7.8}$$

with β_i defined as in (4.19), and let

$$f_1(U,\psi) = -\lambda_R\partial_{\bar{\eta}}p + (\beta_1-\lambda_1)\partial_{\bar{\eta}}w, \tag{7.9}$$

$$f_2(U,\psi) = -\lambda_R\partial_{\bar{\eta}}w + (\lambda_2-\beta_2)\partial_{\bar{\eta}}p; \tag{7.10}$$

then λ_i is positive and we may write (4.18) as

$$\begin{cases} \partial_{\bar\xi} p - \lambda_1 \partial_{\bar\eta} w = f_1(U,\psi), \\ \partial_{\bar\xi} w + \lambda_2 \partial_{\bar\eta} p = f_2(U,\psi). \end{cases} \tag{7.11}$$

For subsonic flow this is a first order nonlinear elliptic system.

So far problem (**C**) may be expressed in the following equivalent way if (4.21) holds.

Problem (**D1**)—boundary value problem for a first order elliptic system:

$$\begin{cases} \partial_{\bar\xi} p - \lambda_1 \partial_{\bar\eta} w = f_1(U,\psi) & \text{in} \quad \Omega, \\ \partial_{\bar\xi} w + \lambda_2 \partial_{\bar\eta} p = f_2(U,\psi) & \text{in} \quad \Omega, \\ p = p_b^+ + h_1(U,U_-) & \text{on} \quad \bar\xi = 0, \\ p = p_b^+ + e & \text{on} \quad \bar\xi = 1, \\ w = 0 & \text{on} \quad \bar\eta = 0, \\ w = \Gamma'((1-\psi(1))\bar\xi + \psi(1)) & \text{on} \quad \bar\eta = 1. \end{cases} \tag{7.12}$$

Problem (**D2**)—algebraic equations (recall that $U_0 = U|_{\bar\xi=0}$):

$$\begin{cases} u_0 = u_b^+ + h_2(U,U_-), \\ p_0 = p_b^+ + h_1(U,U_-), \\ \rho_0 = \dfrac{\gamma}{\gamma-1} \cdot \dfrac{p_0}{c_0 - \frac{1}{2}u_0^2(1+w_0^2)}, \\ \rho = \rho_0 \left(\frac{p}{p_0}\right)^{\frac{1}{\gamma}}, \\ u = \left\{ \frac{2}{1+w^2} \cdot \left(c_0 - \frac{\gamma}{\gamma-1} \cdot \frac{p}{\rho} \right) \right\}^{\frac{1}{2}}. \end{cases} \tag{7.13}$$

We call the above two coupled problems problem ($\mathbf{D}_\psi$) (or problem (**D**) for simplicity). The equivalence for smooth solutions is obvious from the deductions in the above sections.

8. Solving linearized problem (D). It is nature and standard to use iteration methods, such as the Banach contraction mapping principle, to solve problem (**D**). Thus in this section we concentrate on the related "linearized" problems.

8.1. Linearized problem (D1). Problem **D1** solves $\bar p, \bar w$, and $e \in \mathbb{R}$ satisfying

$$\begin{cases} \partial_{\bar\xi} \bar p - \lambda_1 \partial_{\bar\eta} \bar w = f_1 & \text{in} \quad \Omega, \\ \partial_{\bar\xi} \bar w + \lambda_2 \partial_{\bar\eta} \bar p = f_2 & \text{in} \quad \Omega, \\ \bar p = p_b^+ + h_1 & \text{on} \quad \bar\xi = 0, \\ \bar p = p_b^+ + e & \text{on} \quad \bar\xi = 1, \\ \bar w = 0 & \text{on} \quad \bar\eta = 0, \\ \bar w = g(\bar\xi) & \text{on} \quad \bar\eta = 1, \end{cases} \tag{8.1}$$

where f_1, f_2, h_1, g are suitable nonhomogeneous terms. This is a boundary value problem on a domain with a piecewise smooth boundary, so we need a generalized version of the usual Schauder theory for elliptic equations.

We may separate problem (8.1) into the following two problems:

$$\begin{cases} \partial_{\bar\xi}\bar p_1 - \lambda_1\partial_{\bar\eta}\bar w_1 = f_1 & \text{in} \quad \Omega, \\ \partial_{\bar\xi}\bar w_1 + \lambda_2\partial_{\bar\eta}\bar p_1 = 0 & \text{in} \quad \Omega, \\ \bar p_1 = p_b^+ + h_1 & \text{on} \quad \bar\xi = 0, \\ \bar p_1 = p_b^+ + e & \text{on} \quad \bar\xi = 1, \\ \bar w_1 = 0 & \text{on} \quad \bar\eta = 0, \\ \bar w_1 = g(\bar\xi) & \text{on} \quad \bar\eta = 1; \end{cases} \tag{8.2}$$

$$\begin{cases} \partial_{\bar\xi}\bar p_2 - \lambda_1\partial_{\bar\eta}\bar w_2 = 0 & \text{in} \quad \Omega, \\ \partial_{\bar\xi}\bar w_2 + \lambda_2\partial_{\bar\eta}\bar p_2 = f_2 & \text{in} \quad \Omega, \\ \bar p_2 = 0 & \text{on} \quad \bar\xi = 0, \\ \bar p_2 = 0 & \text{on} \quad \bar\xi = 1, \\ \bar w_2 = 0 & \text{on} \quad \bar\eta = 0, \\ \bar w_2 = 0 & \text{on} \quad \bar\eta = 1. \end{cases} \tag{8.3}$$

Then

$$\bar p = \bar p_1 + \bar p_2, \qquad \bar w = \bar w_1 + \bar w_2 \tag{8.4}$$

is the solution of problem (8.1). Since Ω is simply connected, we may introduce potentials $\phi_1(\bar\xi,\bar\eta), \phi_2(\bar\xi,\bar\eta)$ such that

$$\partial_{\bar\xi}\phi_1 = -\lambda_2(\bar p_1 - p_b^+), \qquad \partial_{\bar\eta}\phi_1 = \bar w_1, \tag{8.5}$$

$$\partial_{\bar\xi}\phi_2 = \lambda_1\bar w_2, \qquad \partial_{\bar\eta}\phi_2 = \bar p_2, \tag{8.6}$$

and write (8.2), (8.3) as

$$\begin{cases} \frac{1}{\lambda_2}\partial_{\bar\xi}^2\phi_1 + \lambda_1\partial_{\bar\eta}^2\phi_1 = -f_1 & \text{in} \quad \Omega, \\ \partial_{\bar\xi}\phi_1 = -\lambda_2 h_1 & \text{on} \quad \bar\xi = 0, \\ \partial_{\bar\xi}\phi_1 = -\lambda_2 e & \text{on} \quad \bar\xi = 1, \\ \partial_{\bar\eta}\phi_1 = 0 & \text{on} \quad \bar\eta = 0, \\ \partial_{\bar\eta}\phi_1 = g(\bar\xi) & \text{on} \quad \bar\eta = 1; \end{cases} \tag{8.7}$$

$$\begin{cases} \frac{1}{\lambda_1}\partial_{\bar\xi}^2\phi_2 + \lambda_2\partial_{\bar\eta}^2\phi_2 = f_2 & \text{in} \quad \Omega, \\ \phi_2 = 0 & \text{on} \quad \partial\Omega. \end{cases} \tag{8.8}$$

Equation (8.8) is the Dirichlet problem for Poisson equations. By Theorem 7.2 and Remark (2) following it in [16], and Theorem 1.4 in [21], we know there is a unique solution ϕ_2 and

$$\|\phi_2\|_{3+\alpha}^{(-1-\alpha)} \le C\,\|f_2\|_{1+\alpha}^{(1-\alpha)}, \tag{8.9}$$

where C depends only on U_b and σ_0, and $\alpha \in (0,\alpha_0)$ may be arbitrary for a fixed α_0.

Next we consider (8.7), which is actually the Neumann problem for Poisson equations:

$$\begin{cases} \triangle\phi = f & \text{in} \quad \Omega, \\ \frac{\partial\phi}{\partial\nu} = g & \text{on} \quad \partial\Omega, \end{cases}$$

where ν is the unit outward normal of $\partial\Omega$. It is well known that such a problem is solvable if and only if

$$\int_\Omega f \ \mathrm{d}\bar{\xi}\mathrm{d}\bar{\eta} = \int_{\partial\Omega} g \ \mathrm{d}s. \tag{8.10}$$

This is in essence the reason why we have to introduce the number e in the pressure giving at the exit of the duct.

Applying (8.10) to (8.7), we get

$$\int_\Omega f_1 \ \mathrm{d}\bar{\xi}\mathrm{d}\bar{\eta} = \int_0^1 (e - h_1) \ \mathrm{d}\bar{\eta} - \lambda_1 \int_0^1 g(\bar{\xi}) \ \mathrm{d}\bar{\xi};$$

thus if we take

$$e = \int_\Omega f_1 \ \mathrm{d}\bar{\xi}\mathrm{d}\bar{\eta} + \lambda_1 \int_0^1 g(\bar{\xi}) \ \mathrm{d}\bar{\xi} + \int_0^1 h_1 \ \mathrm{d}\bar{\eta}, \tag{8.11}$$

(8.7) is solvable, and any two solutions differ only from a constant.

Now if (8.11) holds, then by Theorem 1.4 in [21] there exists a unique solution ϕ_1 to (8.7) with $\phi_1(0,0) = 0$, and furthermore the following estimate holds for $\alpha \in (0, \alpha_1)$ with a fixed $\alpha_1 \in (0,1)$:

$$\|\phi_1\|_{3+\alpha}^{(-1-\alpha)} \le C\Big(\|f_1\|_{1+\alpha}^{(1-\alpha)} + \|g\|_{C^{2+\alpha}[0,1]} + \|h_1\|_{2+\alpha}^{\prime(-\alpha)} \Big). \tag{8.12}$$

So finally by (8.4)–(8.6), (8.9), and (8.12) we get

$$\begin{aligned} &\big\|\bar{p} - p_b^+\big\|_{2+\alpha}^{(-\alpha)} + \|\bar{w}\|_{2+\alpha}^{(-\alpha)} + |e| \\ &\le C\Big(\|f_1\|_{1+\alpha}^{(1-\alpha)} + \|f_2\|_{1+\alpha}^{(1-\alpha)} + \|g\|_{C^{2+\alpha}[0,1]} + \|h_1\|_{2+\alpha}^{\prime(-\alpha)} \Big). \end{aligned} \tag{8.13}$$

Remark 8.1. An important observation is that the first equation in (8.1), which is responsible for the well-posedness or ill-posedness of the transonic shock problem under pressure giving on the exit, is in essence the equation of conservation of mass, as can be checked by tracing its origin. This fact can be seen more clearly by using another completely different method which was developed in [7].

8.2. "Linearized" problem (D2). This problem solves (recall that $U_0 = U|_{\bar{\xi}=0}$):

$$\begin{cases} \bar{u}_0 = u_b^+ + h_2(U, U_-), \\ \bar{p}_0 = p_b^+ + h_1(U, U_-), \\ \bar{\rho}_0 = \dfrac{\gamma}{\gamma - 1} \cdot \dfrac{\bar{p}_0}{c_0 - \frac{1}{2}\bar{u}_0^2(1 + \bar{w}_0^2)}, \\ \bar{\rho} = \bar{\rho}_0 \left(\frac{\bar{p}}{\bar{p}_0}\right)^{\frac{1}{\gamma}}, \\ \bar{u} = \left\{ \frac{2}{1+\bar{w}^2} \cdot \left(c_0 - \frac{\gamma}{\gamma - 1} \cdot \frac{\bar{p}}{\bar{\rho}} \right) \right\}^{\frac{1}{2}}. \end{cases} \tag{8.14}$$

9. Solution of problem (C). With the above preparations, we solve in this section problem (**D**) (i.e., problem (**C**)) by the Banach contraction mapping principle.

Set

$$\mathcal{O}_\delta := \Big\{U = (u, w, p, \rho)^t : \big\|u - u_b^+\big\|_{2+\alpha}^{(-\alpha)} + \|w\|_{2+\alpha}^{(-\alpha)} + \big\|p - p_b^+\big\|_{2+\alpha}^{(-\alpha)} + \big\|\rho - \rho_b^+\big\|_{2+\alpha}^{(-\alpha)} \le \delta\Big\}, \tag{9.1}$$

with

$$\delta < \delta_0 \tag{9.2}$$

and δ_0 a constant depending only on U_b such that our preparations in the preceding sections are valid. $\mathcal{O}_\delta$ is a closed subset of Banach space $(H_{2+\alpha}^{(-\alpha)})^4$. By Proposition 2.2 the norm here is in fact equivalent to that used in Theorem 2.6. We will construct a mapping $\mathcal{T}$ from $\mathcal{O}_\delta$ to $\mathcal{O}_\delta$ by problem (**D**) and show this mapping contracts when ε_0 (the perturbation of the wall of the duct) is small.

For any $U = (u, w, p, \rho)^t \in \mathcal{O}_\delta$, substitute

$$f_1 = f_1(U, \psi), \tag{9.3}$$

$$f_2 = f_2(U, \psi), \tag{9.4}$$

$$h_1 = h_1(U, U_-), \tag{9.5}$$

$$g(\bar\xi) = \Gamma'((1 - \psi(1))\bar\xi + \psi(1)) \tag{9.6}$$

in problem (**D1**), with $f_i(U, \psi)(i = 1, 2)$ as in (7.9), (7.10) and $h_1(U, U_-)$ defined by (7.3). By (2.18)–(2.21) and (7.1), (7.9), (7.10) we have the following estimates for $i = 1, 2$:

$$\|f_i(U, \psi)\|_{1+\alpha}^{(1-\alpha)} \le C(\delta^2 + \delta\sigma), \tag{9.7}$$

$$\|h_i(U, U_-)\|_{2+\alpha}^{'(-\alpha)} \le C(\delta^2 + \varepsilon). \tag{9.8}$$

$$\|g\|_{C^{2,\alpha}[0,1]} \le C\varepsilon. \tag{9.9}$$

We may get unique $\bar p, \bar w, e$ from problem (**D1**), and by (8.13) we have

$$\big\|\bar p - p_b^+\big\|_{2+\alpha}^{(-\alpha)} + \|\bar w\|_{2+\alpha}^{(-\alpha)} + |e| \le C(\delta^2 + \delta\sigma + \varepsilon). \tag{9.10}$$

Now consider problem (**D2**). By (8.14) and analyticity of each expression, we easily obtain that

$$\big\|\bar u - u_b^+\big\|_{2+\alpha}^{(-\alpha)} \le C(\delta^2 + \delta\sigma + \varepsilon), \tag{9.11}$$

$$\big\|\bar\rho - \rho_b^+\big\|_{2+\alpha}^{(-\alpha)} \le C(\delta^2 + \delta\sigma + \varepsilon). \tag{9.12}$$

So far we obtained the unique $\bar U := (\bar p, \bar u, \bar w, \bar\rho)^t$ from $U = (p, u, w, \rho)^t \in \mathcal{O}_\delta$ and have the estimate

$$\big\|\bar p - p_b^+\big\|_{2+\alpha}^{(-\alpha)} + \|\bar w\|_{2+\alpha}^{(-\alpha)} + \big\|\bar u - u_b^+\big\|_{2+\alpha}^{(-\alpha)} + \big\|\bar\rho - \rho_b^+\big\|_{2+\alpha}^{(-\alpha)} + |e| \le C(\delta^2 + \delta\sigma + \varepsilon). \tag{9.13}$$

Now choosing ε_0, σ_0 such that

$$C\delta_0 \le \frac{1}{4}, \tag{9.14}$$

$$C\sigma_0 \le \frac{1}{4}, \tag{9.15}$$

and

$$\delta = 2C\varepsilon, \tag{9.16}$$

we get

$$\|\bar{p} - p_b^+\|_{2+\alpha}^{(-\alpha)} + \|\bar{w}\|_{2+\alpha}^{(-\alpha)} + \|\bar{u} - u_b^+\|_{2+\alpha}^{(-\alpha)} + \|\bar{\rho} - \rho_b^+\|_{2+\alpha}^{(-\alpha)} + |e| \le \delta. \tag{9.17}$$

Thus the mapping $\mathcal{T} : U = (u, w, p, \rho)^t \mapsto \bar{U} = (\bar{u}, \bar{w}, \bar{p}, \bar{\rho})^t$ maps $\mathcal{O}_\delta$ into $\mathcal{O}_\delta$.

What is left is to show the contraction of $\mathcal{T}$. For $i = 1, 2$, suppose

$$\psi^{(i)} \in \mathcal{S}_\sigma,$$

$$U^{(i)} = (u^{(i)}, w^{(i)}, p^{(i)}, \rho^{(i)})^t \in \mathcal{O}_\delta,$$

and denote

$$\bar{U}^{(i)} = (\bar{u}^{(i)}, \bar{w}^{(i)}, \bar{p}^{(i)}, \bar{\rho}^{(i)})^t = \mathcal{T}((u^{(i)}, w^{(i)}, p^{(i)}, \rho^{(i)})^t),$$

$$U_-^{(i)} = U_-(\psi^{(i)}(\bar{\eta}), \bar{\eta}), \tag{9.18}$$

$$g^{(i)} = \Gamma'((1 - \psi^{(i)}(1))\bar{\xi} + \psi^{(i)}(1)). \tag{9.19}$$

Recall that $\|U_- - U_b^-\|_{C^{3,\alpha}(\mathbb{P})} \le C_0\varepsilon$; we get

$$\left\|U_-^{(1)} - U_-^{(2)}\right\|_{2+\alpha}^{'(-\alpha)} \le C\varepsilon \left\|\psi^{(1)} - \psi^{(2)}\right\|_{2+\alpha}^{'(-\alpha)} \le C\varepsilon \left\|\psi^{(1)} - \psi^{(2)}\right\|_{3+\alpha}^{'(-1-\alpha)}.$$

Then direct calculation shows that for $j = 1, 2$,

$$\begin{aligned} &\left\|f_j(U^{(1)}, \psi^{(1)}) - f_j(U^{(2)}, \psi^{(2)})\right\|_{1+\alpha}^{(1-\alpha)} \\ &\le C(\delta + \sigma)\Big(\left\|U^{(1)} - U^{(2)}\right\|_{2+\alpha}^{(-\alpha)} + \left\|\psi^{(1)} - \psi^{(2)}\right\|_{3+\alpha}^{'(-1-\alpha)} \Big), \end{aligned} \tag{9.20}$$

$$\begin{aligned} &\left\|h_j(U^{(1)}, U_-^{(1)}) - h_j(U^{(2)}, U_-^{(2)})\right\|_{2+\alpha}^{'(-\alpha)} \\ &\le C(\delta + \varepsilon)\Big(\left\|U^{(1)} - U^{(2)}\right\|_{2+\alpha}^{(-\alpha)} + \left\|\psi^{(1)} - \psi^{(2)}\right\|_{3+\alpha}^{'(-1-\alpha)} \Big). \end{aligned} \tag{9.21}$$

$$\left\|g^{(1)} - g^{(2)}\right\|_{C^{2,\alpha}[0,1]} \le C\varepsilon \left\|\psi^{(1)} - \psi^{(2)}\right\|_{3+\alpha}^{'(-1-\alpha)}. \tag{9.22}$$

Thus by solving corresponding problem (**D**) we get

$$\begin{aligned} &\left\|\bar{U}^{(1)} - \bar{U}^{(2)}\right\|_{2+\alpha}^{(-\alpha)} \\ &\le C(\delta + \sigma + \varepsilon)\Big(\left\|U^{(1)} - U^{(2)}\right\|_{2+\alpha}^{(-\alpha)} + \left\|\psi^{(1)} - \psi^{(2)}\right\|_{3+\alpha}^{'(-1-\alpha)} \Big). \end{aligned} \tag{9.23}$$

For $\psi^{(1)} = \psi^{(2)} = \psi$, we obtain contraction of $\mathcal{T}$ by choosing $\delta_0, \varepsilon_0, \sigma_0$ such that

$$C(\varepsilon_0 + \delta_0 + \sigma_0) < \frac{1}{2}. \tag{9.24}$$

This solves problem ($\mathbf{C}_\psi$) for any $\psi \in \mathcal{S}_\sigma$ with σ_0 small.

10. Solution of problem (B): Determination of shock front. For any $\psi \in \mathcal{S}_\sigma$, we have solved problem $(\mathbf{C}_\psi)$ to obtain the unique solution U_ψ. Now by solving the Cauchy problem

$$\begin{cases} \tilde{\psi}'(\eta) = \frac{[v_\psi]}{[p_\psi]}, \\ \tilde{\psi}(0) = 0, \end{cases} \tag{10.1}$$

we constructed a mapping by $\Psi(\psi) = \tilde{\psi}$.

Obviously we have

$$\left\|\tilde{\psi}\right\|_{3+\alpha}^{'(-1-\alpha)} \le C(\delta+\varepsilon) \le C\varepsilon \tag{10.2}$$

by using (9.16). Taking

$$\sigma = C\varepsilon, \tag{10.3}$$

we then have $\Psi : \mathcal{S}_\sigma \mapsto \mathcal{S}_\sigma$ provided ε_0 is sufficiently small.

For $\psi^{(i)} \in \mathcal{S}_\sigma$, $i = 1, 2$, denote $U^{(i)}$ as $U_{\psi^{(i)}}$; then by (9.23) (recall now that $\bar{U}^{(i)} = U^{(i)}$) one gets

$$\left\|U^{(1)} - U^{(2)}\right\|_{2+\alpha}^{(-\alpha)} \le C(\delta+\sigma+\varepsilon) \left\|\psi^{(1)} - \psi^{(2)}\right\|_{3+\alpha}^{'(-1-\alpha)}; \tag{10.4}$$

thus

$$\begin{aligned} &\left\|\tilde{\psi}^{(1)} - \tilde{\psi}^{(2)}\right\|_{3+\alpha}^{'(-1-\alpha)} \\ &\le C \left\|U^{(1)} - U^{(2)}\right\|_{2+\alpha}^{(-\alpha)} + C\varepsilon \left\|\psi^{(1)} - \psi^{(2)}\right\|_{3+\alpha}^{'(-1-\alpha)} \\ &\le C(\delta+\sigma+\varepsilon) \left\|\psi^{(1)} - \psi^{(2)}\right\|_{3+\alpha}^{'(-1-\alpha)}. \end{aligned} \tag{10.5}$$

If (9.24) holds, Ψ contracts on $\mathcal{S}_\sigma$. By the Banach contraction mapping principle we know the free boundary problem $(\mathbf{B})$ is uniquely solvable. Combining this result and Theorem 5.1, we proved Theorem 2.6.

Remark 10.1. We explain here further why the uniqueness claimed in Theorem 2.6 holds. By (10.5) we see the fixed point, i.e., the transonic shock front $\bar{\psi}$ is unique. Uniqueness for nonlinear problem $(\mathbf{D}_{\bar{\psi}})$ in section 9 (thus problem $(\mathbf{C}_{\bar{\psi}})$) follows from the contraction argument of the mapping $\mathcal{T}$ defined on the line after estimate (9.17) (consult (9.23) with the case $\psi^{(1)} = \psi^{(2)} = \bar{\psi}$). Moreover, uniqueness of constant e for nonlinear problem $(\mathbf{D}_{\bar{\psi}})$ follows by writing the nonlinear problem as a linear problem (8.1) with right-hand sides defined by (9.3)–(9.6), and then using uniqueness of e for linear problem (8.1). Thus the subsonic flow is also unique.

11. Discussion on well-posedness or ill-posedness for other conditions given at the exit of duct. In this section we discuss the well-posedness or ill-posedness of transonic shock problem $(\mathbf{A})$ if other conditions are given at the exit of the duct. Our tool is the well-posedness or ill-posedness of the corresponding boundary value problem for elliptic systems (8.1). We remark that all the results listed below can be proved rigorously in the same fashion as we have done for giving

pressure at the exit before. We just sketch out the key points that are needed for such proofs.

1. As have been shown above (in section 8), given p at Γ_1 corresponds to the Neumann problem for Poisson equations. So in general for given pressure at the exit, problem (**A**) is ill-posed.

2. However, if we give w at the exit, then we need to solve a mixed boundary value problem for Poisson equations with Dirichlet data nonempty. It is well known that such a problem is well-posed; i.e., we can give w at the exit in an arbitrary way and also obtain a unique solution (although we require that $w|_{\Gamma_1}$ should be small since we are dealing with a small perturbation problem). So for w given at the exit, problem (**A**) is well-posed.

3. For arbitrarily given $v = g$ at the exit, Problem (**A**) is still well-posed. In fact, this corresponds to given

$$w = \frac{g}{u}$$

for any $U = (u, v, p, \rho)^t \in \mathcal{O}_\delta$ in the linearized problem (**D1**). The linearized problem (**D1**) is then uniquely solvable, and the contraction by

$$w^{(1)} - w^{(2)} = g\frac{u^{(1)} - u^{(2)}}{u^{(1)}u^{(2)}}$$

is still available, since g is small.

4. For given entropy $S = g$ at the exit, problem (**A**) is ill-posed. In fact, by constancy of entropy along streamlines behind the shock front, we get

$$\frac{p_0}{\rho_0^\gamma} = g.$$

Now by the third equation in (7.13), one has

$$w_0 = \left\{ 2\frac{c_0 - p_0\frac{\gamma}{\gamma-1}\left(\frac{g}{p_0}\right)^{\frac{1}{\gamma}}}{u_0^2} \right\}^{\frac{1}{2}}.$$

Since p_0, u_0 are known, we obtain both p_0 and w_0 on $\bar{\xi} = 0$. This means we encounter an initial-boundary value problem for the elliptic system (i.e., the first two equations in (8.1) or (7.12)). It is well known that such problems are ill-posed.

5. For giving Mach number $M = g$ at the exit, Problem (**A**) is ill-posed. Indeed, by Bernoulli's law (2.3) we have

$$\gamma\frac{p}{\rho} = a^2 = \frac{c_0}{\frac{1}{\gamma-1} + \frac{1}{2}g^2}.$$

From constancy of entropy we get

$$\frac{p}{\rho^\gamma} = \frac{p_0}{\rho_0^\gamma},$$

where ρ_0 can be expressed by the third equation in (7.13). Thus we can solve the above two equations to obtain

$$p = p_0 h,$$

where

$$h = \left\{ \frac{c_0}{(c_0 - \frac{1}{2}u_0^2(1+w_0^2))(1+\frac{1}{2}(\gamma-1)g^2)} \right\}^{\frac{\gamma}{\gamma-1}}.$$

Thus we get

$$p - p_b^+ = (p_0 - p_b^+)h + p_b^+(h-1).$$

Notice that

$$h(U_b^+) = 1$$

and

$$\|h-1\| \le C(\|u_0 - u_b^+\| + \|g - M_b^+\| + \|w_0\|^2).$$

(Note here that w_0 is itself small and that fortunately w_0^2 appears in the expression of h. This observation is of crucial importance!) With such an estimate in hand, the remaining work is the same as giving pressure at the exit. Thus problem (**A**) is not well-posed for the given arbitrary Mach number at the exit of the duct.

6. For given arbitrary density $\rho = g$ at the exit, problem (**A**) is not well-posed. From constancy of entropy we have

$$p = \frac{p_0 g^\gamma}{\rho_0^\gamma}.$$

Due to the third equation in (7.13), we get

$$p = \left(\frac{\gamma}{\gamma-1}\right)^\gamma p_0^{1-\gamma} g^\gamma \left(c_0 - \frac{1}{2}u_0^2(1+w_0^2)\right)^\gamma.$$

The left analysis is the same as in **5**.

7. For given $u = g$ at the exit, problem (**A**) is still ill-posed. By Bernoulli's law we get

$$\frac{p}{\rho} = \frac{\gamma-1}{\gamma}\Big(c_0 - \frac{1}{2}g^2(1+w_1^2)\Big);$$

here w_1 is the value of w restricted on $\bar{\xi} = 1$. Using constancy of entropy we also have

$$\frac{p}{\rho^\gamma} = \frac{p_0}{\rho_0^\gamma}.$$

By the expressions of ρ_0 (the third equation in (7.13)) we can solve from the above two equations that

$$p = p_0 \left(\frac{c_0 - \frac{1}{2}g^2(1+w_1^2)}{c_0 - \frac{1}{2}u_0^2(1+w_0^2)}\right)^{\frac{\gamma}{\gamma-1}}.$$

Note w_0, w_1 are small quantities and appeared as squares in the above expressions; u_0, p_0 are known and are second order terms as shown in section 9. Thus we can use similar methods as above to show the ill-posedness of problem (**A**).

Remark 11.1. All the above results may be surprising at first glance. However, a deep consideration of the background solution suggests these results are natural, since for the one-dimensional case, S, p, ρ, M, u have already been completely determined.

Acknowledgments. The author would like to thank Shuxing Chen, Yongqian Zhang, and Beixiang Fang for their generous help in doing this work.

CHEMICAL KINETICS ON SURFACES: A SINGULAR LIMIT OF A REACTION-DIFFUSION SYSTEM*

G. FIBICH†, I. GANNOT‡, A. HAMMER§, AND S. SCHOCHET†

Abstract. We show that chemical kinetics relations can be used to describe processes that involve binding and dissociation reactions that take place on surfaces. From a mathematical perspective, the problem we study is a singular limit of a reaction-diffusion system in which one of the variables concentrates on a lower-dimensional set in the limit, while the other continues to diffuse in a fixed domain.

Key words. chemical kinetics, surface, binding, dissociation, singular limit, invariant region

DOI. 10.1137/050633767

1. Introduction.

Numerous biological processes involve binding and dissociation reactions that take place on surfaces. For example, in *antibody-antigen* interactions, antibodies immobilize and agglutinate infectious agents by binding to specific receptors located on the surface of antigens [1, 19, 22]. Additional examples include the binding of proteins to cell membranes either to initiate transduction of external signals into the cell (*signal transduction*) or to open the ion channels of the membrane (see, e.g., [18]); the binding of microbiological cultures to attachment sites on the inner walls of flow reactors [12]; and the phenomenon of surface plasmon resonance, which involves interactions of biopolymers with various ligands [13].

A natural way to model surface reactions is to adapt the standard chemical-kinetics approach used for reactions occurring in volumes. This means that the binding rate for surface reactions is assumed to be proportional to the product of the volumetric concentration of the reactant at the surface and the surface concentration of the binding sites [18, 20]. There is a methodological problem with this approach, however, since chemical-kinetics relations are usually derived under the assumption that reactions take place in a volume, in which the two reactants are well mixed.

Our goal here is to justify the use of chemical-kinetics relations for reactions that take place on surfaces. To do so, we will first construct a volumetric model in which the binding sites, and hence also the binding and dissociation reactions, take place in a narrow volumetric layer around the surface. We will then show that as the width of the binding sites layer shrinks to zero, the volumetric model reduces to a surface model, in which binding sites are located on the surface, and for which the reactions are still described by chemical-kinetics relations.

From a mathematical perspective, the problem we study is a singular limit of a

reaction-diffusion system. The problem here differs from the widely studied case of thin domains (see, e.g., [10]) in that here only one of the variables concentrates on a lower-dimensional set in the limit, while the other continues to diffuse in a fixed domain.

In this study we analyze the problem of chemical kinetics on surfaces in the context of a mathematical model for a novel in-vivo imaging technique for identifying and locating cancerous tumors, which are sphere-like, isolated, three-dimensional objects, with a smooth boundary.[1] This model consists of a diffusion equation in the volume surrounding the tumor, and binding and dissociation reactions that take place on the tumor surface. We note, however, that the methodology developed in this study, namely, the study of "surface models" as the limit of "volumetric models," can be applied to other models that involve binding and dissociation reactions on surfaces. Moreover, our approach may also be relevant to problems in combustion (e.g., burning of coal) in which the reactions take place between one or more species (e.g., coal) that are confined to narrow regions near the reactor boundaries and other species that are free to diffuse over larger domains (e.g., oxygen) [2].

The paper is organized as follows. In section 2 we construct two mathematical models, a surface model and a volumetric model. In section 3 we present a heuristic derivation of the surface model from the volumetric model. This is done by taking the limit as the width of the volumetric layer tends to zero while assuming that the limits of the concentrations exist in appropriate senses. For further clarity, we consider only the radially symmetric case. In section 4 we rigorously prove that solutions of the volumetric model converge to those of the surface model, without assuming radial symmetry. Finally, in section 5 we comment briefly on the possibility of extending our results to other models.

2. Mathematical models.

2.1. Fluorophore-antibody imaging. Our interest in this problem originated from the need to model a novel in-vivo imaging technique for identifying and locating cancerous tumors [11]. This method is based on one of the immune system responses to tumors, which is the concentration of white blood cells, known as T cells, around the tumor. These T cells have receptors which are specific to some antibodies of the immune system. The imaging technique involves selecting an antibody with high specificity to T cells [3], artificially conjugating it with a fluorescent marker compound, and injecting the fluorescenated antibodies into the suspected tumor area [5, 6, 7, 8, 9]. After some time, the fluorescenated antibodies, hereinafter denoted *markers*, will diffuse away from the tumor area, except for those that are bound to the T cell receptors around the tumor. Hence, when an external laser excitation is applied, the fluorescence of the markers indicates the location of the tumor.

The mathematical model that we use to describe the method of fluorophore-antibody imaging involves diffusion of markers in the tissue, binding of markers to T cells receptors (binding sites), and dissociation of markers that are already bound to sites. The methodology developed in this study can, however, be extended to more complex models that allow for diffusion of markers into the tissue area, advection effects, etc.

To simplify the presentation, in this section we assume that the tumor is the radially symmetric ball $0 \le r < r_{tumor}$, where r is the radial distance from the tumor

[1] This corresponds to the common solid tumors such as breast, lung, and sarcoma, at the early stages of the tumor (i.e., before it develops a nonsmooth surface).

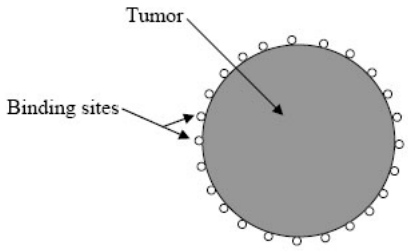

FIG. 1. *The surface model. Binding sites are located on the boundary of the tumor.*

center. The assumption of radial symmetry is reasonable for young, small-size tumors. Our results, however,are also valid for more advanced tumors, which are half-spheres or isolated, three-dimensional lumps, so long that their boundary remains smooth (see section 4). For simplicity we also assume that the initial markers distribution is radially symmetric.

2.2. The surface model. We first develop a surface model in which the T cell binding sites are located on the tumor surface (see Figure 1). In the tissue area, the motion of the markers is governed by the diffusion equation

$$\frac{\partial M(r,t)}{\partial t} = D\Delta M(r,t), \qquad 0 < t, \quad r_{tumor} < r < \infty, \tag{1}$$

where $M(r,t)$ is the volumetric concentration of the free (i.e., unbound) markers, and D is the diffusion coefficient of markers in the tissue. The initial condition for (1) is

$$M(r,0) = M_0(r), \tag{2}$$

where $M_0(r)$ is the initial concentration of markers.

Let us assume that chemical-kinetics relations can be used to model the reactions that take place on a surface. Then the free sites concentration at the tumor surface ($r = r_{tumor}$) is governed by the equation

$$\frac{\partial S(t)}{\partial t} = k_d^{sur}[S_{tot} - S(t)] - k_b^{sur} M(r_{tumor}, t) S(t), \tag{3}$$

where $S(t)$ denotes the free sites concentration, k_b^{sur} and k_d^{sur} are the binding and dissociation rate constants, respectively, and S_{tot} is the total concentration of sites, both free and occupied. Equation (3) shows that the free sites concentration increases as a result of dissociation of marker-site complexes and decreases as a result of binding of free markers to binding sites. The dissociation rate is linearly proportional to the bound sites concentration, $[S_{tot} - S(t)]$. Under the assumption of chemical kinetics, the binding rate is linearly proportional to the concentration of free binding sites, $S(t)$, and also linearly proportional to the concentration of free markers on the tumor boundary, $M(r_{tumor}, t)$.

We assume that before the injection of markers (i.e., at $t = 0$), all binding sites are unoccupied, so the initial condition for the sites equation is given by the total sites concentration S_{tot}, i.e.,

$$S(0) = S_{tot}. \tag{4}$$

We now derive the boundary conditions for the markers at the tumor boundary. Markers may be either free (i.e., in the tissue area) or bound (to T cell binding sites). If we assume that a single marker binds to a single site, then the concentration of bound markers on the surface equals $S_{tot} - S(t)$. In view of the fact that the total area of the tumor surface is $4\pi r_{tumor}^2$, the total number of bound markers is then $4\pi r_{tumor}^2 [S_{tot} - S(t)]$. Thus, the global conservation of markers is given by

$$\underset{\text{bound markers}}{4\pi r_{tumor}^2 [S_{tot} - S(t)]} + \underset{\text{free markers}}{4\pi \int_{r_{tumor}}^{\infty} M(r,t)\, r^2 dr} = \underset{\text{total markers}}{4\pi \int_{r_{tumor}}^{\infty} M_0(r)\, r^2 dr}.$$

Differentiating this equation with respect to t, and using (1) and the formula for Δ in polar coordinates, shows that

$$\begin{aligned} r_{tumor}^2 \frac{\partial S(t)}{\partial t} &= \int_{r_{tumor}}^{\infty} \frac{\partial M(r,t)}{\partial t}\, r^2 dr \\ &= D \int_{r_{tumor}}^{\infty} \Delta M(r,t)\, r^2 dr = D \int_{r_{tumor}}^{\infty} \left[\frac{\partial^2 M}{\partial r^2} + \frac{2}{r} \frac{\partial M}{\partial r} \right] r^2 dr \\ &= D \int_{r_{tumor}}^{\infty} \frac{\partial \left[r^2 \frac{\partial M}{\partial r} \right]}{\partial r} dr = -D r_{tumor}^2 \frac{\partial M}{\partial r}(r_{tumor}, t), \end{aligned} \tag{5}$$

provided that the concentration of markers decays sufficiently rapidly at large distances so that they have no flux at infinity. Upon substituting in the value of $\frac{\partial S(t)}{\partial t}$ from (3) we find that the boundary condition at the tumor surface is given by

$$\frac{\partial M}{\partial r}(r_{tumor}, t) = \frac{1}{D} \{ k_b^{sur} M(r_{tumor}, t) S(t) - k_d^{sur} [S_{tot} - S(t)] \}. \tag{6}$$

2.3. The volumetric model. As mentioned in the introduction, there is a methodological problem with the surface model since we used chemical-kinetics relations to model surface reactions; see (3). In order to avoid this problem, we now adopt a different approach and assume that the T cell binding sites are located in a narrow volumetric layer around the tumor (see Figure 2). This approach also has a physiological justification. Indeed, data collected in histological staining experiments show that T cells are not located strictly on the tumor surface but rather in a thin volumetric layer around the tumor (see Figure 3). The existence of a layer of T-lymphocytes (CD3 positive cells) around the tumor was also reported in, e.g., [4, 25].

Let ε denote the width of the volumetric layer in which binding sites are located. Then the volume density $S_{\text{tot}}^{\varepsilon}(r)$ of total binding sites vanishes identically for $r > r_{tumor} + \varepsilon$, i.e.,

$$S_{\text{tot}}^{\varepsilon}(r) \equiv 0 \qquad \text{for } r > r_{tumor} + \varepsilon. \tag{7}$$

Of course this implies that the density $S^{\varepsilon}(t,r)$ of free binding sites also vanishes for $r > r_{tumor} + \varepsilon$.

The equation of evolution for the concentration $M^{\varepsilon}(t,r)$ of free markers now takes the form

$$\begin{aligned} \frac{\partial M^{\varepsilon}(r,t)}{\partial t} &= D \Delta M^{\varepsilon}(r,t) + k_d^{vol} [S_{\text{tot}}^{\varepsilon}(r) - S^{\varepsilon}(r,t)] - k_b^{vol} M^{\varepsilon}(r,t) S^{\varepsilon}(r,t), \\ & 0 < t, \quad r_{tumor} < r < \infty, \end{aligned} \tag{8}$$

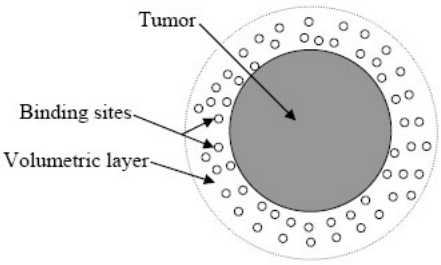

FIG. 2. *The volumetric model. Binding sites are located in a thin volumetric layer around the tumor.*

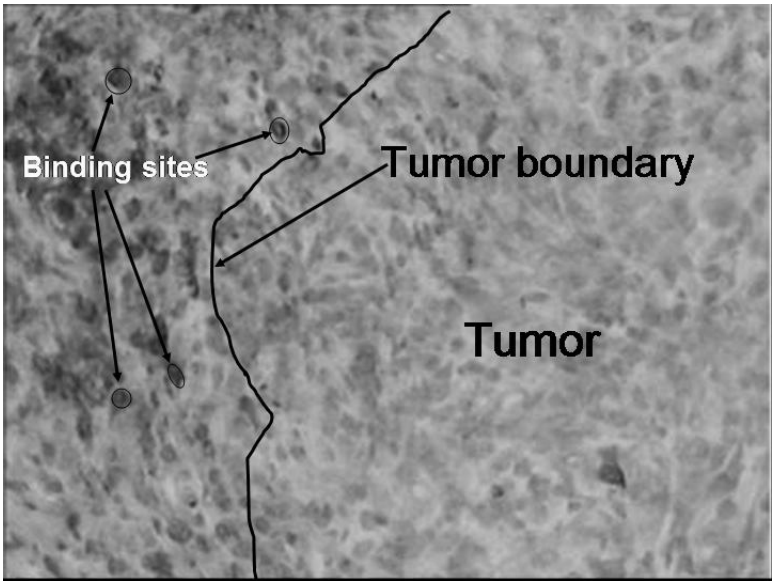

FIG. 3. *Histological staining of a 5-day old tumor squamous cell carcinoma in the oral cavity (mag. X200). Binding sites (stained in black) can be seen to the left of the solid line. Figure supplied by Dr. Gallya Gannot, National Institutes of Health, Bethesda, MD.*

where k_b^{vol} and k_d^{vol} are the volumetric model binding and dissociation rate constants, respectively. The first term on the right is the diffusion term, the second term describes the dissociation of marker-site complexes, and the third term describes the creation of these complexes. Note that in contrast to (3), there is no problem with using chemical-kinetics relations.

The rate of change of the free sites concentration is derived using chemical-kinetics relations, as was done for (3) of the surface model, yielding

$$\frac{\partial S^{\varepsilon}(r,t)}{\partial t} = k_d^{vol}\left[S_{\text{tot}}^{\varepsilon}(r) - S^{\varepsilon}(r,t)\right] - k_b^{vol} M^{\varepsilon}(r,t) S^{\varepsilon}(r,t). \tag{9}$$

The only difference is that now these reactions take place in a volumetric layer rather than on a surface as in the previous model.

As in the surface model, we assume that at time $t = 0$ all the binding sites are unoccupied. Therefore, the initial condition for the free sites concentration is given

by

$$S^\varepsilon(r,0) = S^\varepsilon_{\text{tot}}(r). \tag{10}$$

The initial distribution of markers will be assumed to be the same as for the surface model:

$$M^\varepsilon(r,0) = M_0(r), \tag{11}$$

independently of ε. We also assume that markers cannot diffuse into the tumor. Therefore, at the tumor surface we impose the no-flux boundary condition

$$\frac{\partial M^\varepsilon(r,t)}{\partial r}(r_{tumor},t) = 0. \tag{12}$$

3. Heuristic justification of the surface model from the volumetric model. We now show, under some scientifically natural assumptions, that as the width ε of the binding sites layer goes to zero the volumetric model reduces to the surface model.

As already mentioned, we assume that both models have the same initial distribution of markers, and that in both models all the sites are unoccupied at time $t = 0$. We also assume that both models have the same total number of sites, i.e.,

$$\underbrace{4\pi \int_{r_{tumor}}^{\infty} S^\varepsilon_{\text{tot}}(r)\, r^2\, dr}_{\substack{\text{total number of sites} \\ \text{for the volumetric model}}} = \underbrace{4\pi r^2_{tumor} S_{tot}}_{\substack{\text{total number of sites} \\ \text{for the surface model}}}. \tag{13}$$

Next, we assume that the solution $M^\varepsilon(r,t)$, $S^\varepsilon(r,t)$ of the volumetric model (7)–(12) and the solution $M(r,t)$, $S(t)$ of the surface model (1)–(4), (6) exist for all positive time and are unique.

Finally, we assume that as ε tends to zero both the concentration $M^\varepsilon(r,t)$ of markers in the volumetric model and the radial integral of the concentration $S^\varepsilon(r,t)$ of free sites in that model tend to definite values. In other words, we assume that

$$M^0(r,t) := \lim_{\varepsilon\to 0} M^\varepsilon(r,t) \quad \text{and} \quad \mathcal{S}^0(t) := \frac{1}{r^2_{tumor}} \lim_{\varepsilon\to 0} \int_{r_{tumor}}^{\infty} S^\varepsilon(r,t)\, r^2\, dr \tag{14}$$

exist. Furthermore, we assume that in the region $r > r_{tumor}$ those equations may be differentiated and integrated as often as needed, and that the order of the resulting derivatives, integrals, and limits may be freely interchanged.

PROPOSITION 3.1. *Under the above assumptions, the limits* (14) *of the volumetric model are the solution of the surface model with the same binding and dissociation constants. In other words,*

$$M^0(r,t) \equiv M(r,t), \tag{15}$$

and

$$\mathcal{S}^0(t) \equiv S(t), \tag{16}$$

the latter of which may also be expressed as

$$\lim_{\varepsilon\to 0} S^\varepsilon(r,t) \equiv S(t)\cdot\delta(r - r_{tumor}),$$

where δ is the Dirac δ function.

Proof. Since $S^{\varepsilon}_{\text{tot}}(r)$ is nonnegative, (7) plus (13) implies that

$$\lim_{\varepsilon\to 0} S^{\varepsilon}_{\text{tot}}(r) = S_{tot}\cdot\delta(r - r_{tumor}). \tag{17}$$

Similarly, since

$$0 \le S^{\varepsilon}(r,t\,) \le S^{\varepsilon}_{\text{tot}}(r), \tag{18}$$

it follows from (7) plus (14) that

$$\lim_{\varepsilon\to 0} S^{\varepsilon}(r,t) = \mathcal{S}^0(t)\cdot\delta(r - r_{tumor}), \tag{19}$$

and (17)–(19) imply further that

$$0 \le \mathcal{S}^0(t) \le S_{tot}.$$

We now show that for $r > r_{tumor}$ and $t \ge 0$, (15)–(16) hold, by showing that M^0 and $\mathcal{S}^0$ satisfy the surface model equations (1)–(4), (6).

Integrating both sides of (9) and taking the limit as $\varepsilon \to 0$ gives

$$\begin{aligned}
&\frac{1}{r^2_{tumor}}\lim_{\varepsilon\to 0}\int_{r_{tumor}}^{\infty}\frac{\partial S^{\varepsilon}(r,t)}{\partial t}\; r^2\,dr\\
&= \frac{1}{r^2_{tumor}}\lim_{\varepsilon\to 0}\int_{r_{tumor}}^{\infty} k_d^{vol}\left[S^{\varepsilon}_{\text{tot}}(r) - S^{\varepsilon}(r,t)\right]\; r^2\,dr\\
&\quad -\frac{1}{r^2_{tumor}}\lim_{\varepsilon\to 0}\int_{r_{tumor}}^{\infty} k_b^{vol} M^{\varepsilon}(r,t)S^{\varepsilon}(r,t)\; r^2\,dr.
\end{aligned}$$

Combining the above with (14), (17), and (19) gives

$$\mathcal{S}^0_t = k_d^{vol}\left[S_{tot} - \mathcal{S}^0\right] - k_b^{vol} M^0(r_{tumor},t)\mathcal{S}^0, \tag{20}$$

which corresponds to (3).

Similarly, in light of (14), (17), and (19) the limit $\varepsilon \to 0$ of the volumetric markers equation (8) yields

$$\frac{\partial M^0(r,t)}{\partial t} = D\Delta M^0(r,t) \qquad \text{for } r > r_{tumor}, \tag{21}$$

which is the analogue of (1).

From (10), (13), and (14) it follows that

$$\mathcal{S}^0(0) = S_{tot}.$$

More simply, (11) plus (14) implies

$$M^0(r,0) = M_0(r).$$

These two equations correspond to (4) and (2).

Finally, we derive the boundary condition for M^0 at $r = r_{tumor}$. In contrast to the assumed differentiability of the limits (14) for $r > r_{tumor}$, on the boundary we must expect that

$$\frac{\partial M^0}{\partial r}\Big|_{r_{tumor}} \ne \lim_{\varepsilon\to 0}\frac{\partial M^{\varepsilon}}{\partial r}\Big|_{r_{tumor}} = 0.$$

Indeed, although we assume, as in the surface model, that the markers cannot diffuse into the tumor, the existence of binding sites on the boundary effectively results in "disappearance" of markers at $r = r_{tumor}$. Hence, in the surface model the boundary $r = r_{tumor}$ is absorbing.

To derive the correct boundary condition there, we first note that the conservation law for the total number of markers may be written as

$$\frac{d}{dt}\frac{1}{r_{tumor}^2}\int_{r_{tumor}}^{\infty}\{M^\varepsilon(r,t)+[S^\varepsilon_{\rm tot}(r)-S^\varepsilon(r,t)]\}\ r^2\,dr=0,$$

since $M^\varepsilon(r,t)$ and $[S^\varepsilon_{\rm tot}(r)-S^\varepsilon(r,t)]$ are the concentrations of free and bound markers, respectively. Taking the limit as $\varepsilon\to 0$ and using (14), (17), and (19) gives

$$\frac{d}{dt}\left\{\frac{1}{r_{tumor}^2}\int_{r_{tumor}}^{\infty}M^0(r,t)\ r^2\,dr+\left[S_{tot}-\mathcal{S}^0\right]\right\}=0.$$

Therefore, by (14), (21), (20), and a calculation similar to (5) we get

$$\begin{aligned}\frac{\partial M^0(r_{tumor},t)}{\partial r}&=-\frac{1}{D}\frac{\partial \mathcal{S}^0}{\partial t}\\&=-\frac{1}{D}k_d^{vol}\left[S_{tot}-S^0(r,t)\right]+\frac{1}{D}k_b^{vol}M^0(r_{tumor},t)S^0(r,t),\end{aligned}$$

in accordance with (6). ∎

4. Rigorous justification of the surface model from the volumetric model. We now present a rigorous derivation of the surface model as the limit of the volumetric model. Unlike in sections 2 and 3, we do not make the assumption of radial symmetry.

4.1. Equations and results. When radial symmetry is not assumed we may write the equations governing the concentrations of unbound markers M^ε and unoccupied sites S^ε in the volumetric model in the form

$$M^\varepsilon_t(t,x)=D\Delta M^\varepsilon+k_d\,(S^\varepsilon_{\rm tot}(x)-S^\varepsilon)-k_bS^\varepsilon M^\varepsilon, \tag{22}$$

$$S^\varepsilon_t(t,x)=k_d\,(S^\varepsilon_{\rm tot}(x)-S^\varepsilon)-k_bS^\varepsilon M^\varepsilon. \tag{23}$$

Here x is a vector in $\mathbb{R}^d$ for some $d>1$ and $S^\varepsilon_{\rm tot}(x)$ is the total concentration of sites, which depends only on x since the sites are still assumed to remain stationary. Equations (22)–(23) are to hold in a smooth domain Ω in $\mathbb{R}^d$ whose inner surface $\partial_i\Omega$ is the boundary of the region occupied by the tumor. In order to reduce the technical complications we will assume that Ω is bounded, and its outer boundary, far from the tumor, will be denoted $\partial_o\Omega$. See Figure 4. However, the case when Ω is the entire exterior of the tumor surface $\partial_i\Omega$ could also be treated; in particular, the theorem on invariant regions (Theorem 3 below) is still valid in that case.

The total concentration of sites is clearly nonnegative, i.e.,

$$S^\varepsilon_{\rm tot}(x)\ge 0. \tag{24}$$

Also, since the sites are located near the surface of the tumor,

$$S^\varepsilon_{\rm tot}(x)=0\quad \text{for } d(x,\partial_i\Omega)>\varepsilon, \tag{25}$$

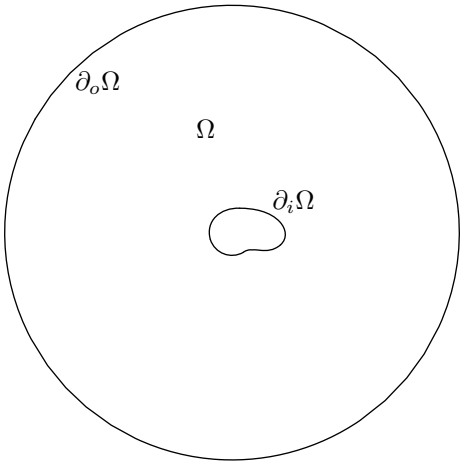

FIG. 4. *The domain Ω and its inner and outer boundaries $\partial_i\Omega$ and $\partial_o\Omega$.*

where $d(x, \partial_i\Omega)$ is the distance from a point x to the interior region Ω_i occupied by the tumor. We shall also assume that

$$S^{\varepsilon,0}_{\text{tot}}(y) := \int_0^\varepsilon S^\varepsilon_{\text{tot}}(y + \tau\nu)\, d\tau \text{ converges uniformly to some } S^0_{\text{tot}}(y) \text{ as } \varepsilon \to 0, \tag{26}$$

where ν denotes the unit normal on $\partial_i\Omega$ pointing into Ω. Note that conditions (24)–(26) are satisfied when $S^\varepsilon_{\text{tot}}(y + \tau\nu) = \frac{1}{\varepsilon}\phi(y)\psi(\frac{\tau}{\varepsilon})$, where ϕ and ψ are nonnegative continuous functions and $\psi(s)$ vanishes for $s > 1$.

The boundary condition for M^ε is

$$\nu \cdot \nabla M^\varepsilon = 0 \qquad \text{on } \partial\Omega, \tag{27}$$

which means that markers do not leave the region Ω. The initial conditions are

$$S^\varepsilon(0, x) = S^\varepsilon_{\text{tot}}(x), \tag{28}$$

which means that all sites are originally unoccupied, and

$$M^\varepsilon(0, x) = M_0(x) \geq 0. \tag{29}$$

Furthermore, we will assume that

$$S^\varepsilon_{\text{tot}}(x) M_0(x) \equiv 0, \tag{30}$$

i.e., that initial locations of the markers and sites do not overlap. Physically this is another expression of the assumption that time zero occurs before the sites start to become occupied, since if the marker and site locations overlapped at time zero, then some sites would have become occupied before then. Mathematically it avoids having an initial layer in which the site-occupation reaction would quickly reduce the size of the reaction term down to order one.

The local-in-time existence of a unique solution to (22)–(23), (27)–(29) can be obtained via the method of [23], by substituting the Green's function for the Neumann boundary value problem for $u_t = D\Delta u$ in place of the whole-space Green's function

in [23, eq. (2.7)]. Furthermore, the uniform bounds on the solution obtained in the next subsection imply that solution exists for all positive time.

The equations for the surface model are

$$M_t = D\Delta M \tag{31}$$

in Ω,

$$\nu \cdot \nabla M = \frac{k_d \left(S^0_{\rm tot}(x) - S\right) - k_b S M}{D} \tag{32}$$

on the inner boundary $\partial_i\Omega$ bounding the tumor region, (27) on the outer boundary $\partial_o\Omega$, and

$$S_t = k_d \left(S^0_{\rm tot}(y) - S\right) - k_b S M \tag{33}$$

on the inner boundary $\partial_i\Omega$. Although the existence of solutions to the surface model could be obtained by an appropriate adaptation of the method used for the volumetric model, we will obtain existence here as a by-product of our convergence result.

Our main result is that solutions of the volumetric model converge to those of the boundary model as the parameter ε tends to zero.

THEOREM 1. *Assume that S^ε_{tot} satisfies* (24)–(26). *Let $(M^\varepsilon, S^\varepsilon)$ be the solution of* (22)–(23) *and* (27) *having initial data of the form* (28)–(29) *belonging to $C^2(\overline{\Omega})$ and satisfying* (30). *Then as $\varepsilon \to 0$, M^ε and*

$$\mathcal{S}^\varepsilon(y,t) := \int_0^\varepsilon S^\varepsilon(y + \tau\nu, t)\, d\tau \tag{34}$$

converge to the unique solution (M, S) of (31) *and* (33) *satisfying* (32) *on $\partial_i\Omega$ and* (27) *on $\partial_o\Omega$ and having initial data* (29) *and $S(0,y) = S^0_{tot}(y)$.*

In the next subsection we will prove some uniform bounds that will be used in the subsequent subsection to take the limit as $\varepsilon \to 0$. Those uniform bounds also imply an upper bound for the fraction of sites that are occupied at any time.

THEOREM 2. *The ratio*

$$\frac{\int_\Omega \left[S^\varepsilon_{tot}(x) - S^\varepsilon(x,t)\right]\, dx}{\int_\Omega S^\varepsilon_{tot}(x)\, dx}$$

of occupied sites to total sites is never more than

$$\frac{k_b \max_{x\in\Omega} M_0(x)}{k_d + k_b \max_{x\in\Omega} M_0(x)}. \tag{35}$$

4.2. Uniform estimates.

4.2.1. Invariant regions. In order to be able to take the limit of the solutions as $\varepsilon \to 0$, we need certain uniform bounds on those solutions. Some of the required bounds follow from the theory of invariant domains. See [24, Chap. 14] for an introduction and references. The version we will apply, in which the hypotheses have been weakened somewhat, is the following special case of [21, Thm. 3].

THEOREM 3. *Assume that the following hold:*

1. *Domain: Ω is either a smooth bounded domain or the exterior of a smooth bounded domain.*

2. *Smoothness:* $u := (u_1, \ldots, u_p)$ *is continuous on* $[0,T] \times \overline{\Omega}$, *and* u_t, u_{x_j}, *and* $u_{x_j x_k}$ *are continuous on* $(0,T) \times \Omega$.
3. *PDE:* u *satisfies the system*

$$\partial_t u_j - d_j \Delta u_j = f_j(t,x,u) \tag{36}$$

for $0 < t < T \leq \infty$ *and* $x \in \Omega$, *where* $d_j \geq 0$ *and* $f_j \in C^1$.
4. *Region: The region* $\mathcal{R} := \{u \mid a_j \leq u_j \leq b_j\}$ *is invariant for the system of ODEs obtained by setting every* d_j *in* (36) *to zero, i.e.,* $f_j \leq 0$ *when* $u_j = b_j$ *and* $a_k \leq u \leq b_k$ *for each* $k \neq j$, *and* $f_j \geq 0$ *when* $u_j = a_j$ *and* $a_k \leq u \leq b_k$ *for each* $k \neq j$.
5. *Initial condition:* $u(0,x) = u_0(x)$ *for* $x \in \Omega$, *where* $u_0(x) \in \mathcal{R}$ *for all such* x.
6. *Boundary condition:* $\partial_\nu u = 0$ *for* $0 < t < T$ *and* $x \in \partial\Omega$, *where* ν *denotes the exterior normal on the boundary* $\partial\Omega$.
7. *Behavior at infinity: If* Ω *is unbounded, then* $u(t,x) = o(|x|^2)$ *as* $x \to \infty$.

Then the solution $u(t,x)$ *remains in* $\mathcal{R}$ *for* $0 \leq t \leq T$ *and* $x \in \overline{\Omega}$.

The region that we wish to show to be invariant for (22)–(23) depends on x, as will be apparent below, so Theorem 3 does not apply directly. That theorem could be extended to the case of x-dependent invariant regions either by using the fact that the S-component does not diffuse or via the approach of [15]. However, it will in any case be convenient to transform our system via

$$N^\varepsilon = 1 + \frac{k_b M^\varepsilon}{k_d}, \qquad R^\varepsilon = \frac{S^\varepsilon}{S^\varepsilon_{\rm tot}(x)}, \tag{37}$$

which yields equations whose invariant sets will not depend on x. Although $S^\varepsilon_{\rm tot}(x)$ vanishes in much of the domain Ω, which makes $R^\varepsilon(0,x)$ undefined, the initial condition (28) implies that $R^\varepsilon(0,x) \equiv 1$ where $S^\varepsilon_{\rm tot}(x)$ is nonzero, so the initial data for R^ε extend naturally to

$$R^\varepsilon(0,x) = 1. \tag{38}$$

The initial data

$$N^\varepsilon(0,x) = 1 + \frac{k_b M_0(x)}{k_d} \tag{39}$$

for N^ε are obtained directly from those of M via the transformation (37).

In terms of the new variables N^ε and R^ε, system (22)–(23) becomes

$$N^\varepsilon_t = D\Delta N^\varepsilon + k_b S^\varepsilon_{\rm tot}(x)\left[1 - N^\varepsilon R^\varepsilon\right], \tag{40}$$

$$R^\varepsilon_t = k_d\left[1 - N^\varepsilon R^\varepsilon\right]. \tag{41}$$

The boundary condition (27) becomes

$$\nu \cdot \nabla N^\varepsilon = 0 \qquad \text{on } \partial\Omega. \tag{42}$$

LEMMA 4. *Suppose that* N^ε *and* R^ε *satisfy the system* (40)–(41) *plus the boundary condition* (42) *and have initial data* (38)–(39). *Define* $N_{\max} := \max N^\varepsilon(0,x)$. *Then*

$$1 \leq N^\varepsilon \leq N_{\max}, \qquad \tfrac{1}{N_{\max}} \leq R^\varepsilon \leq 1. \tag{43}$$

Proof. The vector field $(k_b S^\varepsilon_{\rm tot}(x)(1 - N^\varepsilon R^\varepsilon), k_d(1 - N^\varepsilon R^\varepsilon))$ points left and down at points above the curve $R^\varepsilon = \frac{1}{N^\varepsilon}$, and up and to the right below that curve. For

any k, that curve intersects the rectangle $1 \le N^\varepsilon \le k$, $\frac{1}{k} \le R^\varepsilon \le 1$ at the upper left and lower right corners, and so points inwards everywhere on the boundary of that rectangle, except at those corners, where it vanishes. Since $M_0(x) \ge 0$, the initial data (39) for N^ε satisfy $N^\varepsilon(0,x) \ge 1$, while the initial data for R^ε are identically one. Thus, the initial data lie in the rectangle (43). Now apply Theorem 3. ∎

Translating the bounds (43) back into the original variables $(M^\varepsilon, S^\varepsilon)$ yields Theorem 2.

In order to obtain convergence of solutions as $\varepsilon \to 0$ it is necessary to obtain estimates for derivatives as well. However, since $S^\varepsilon_{\rm tot}(x)$ and its derivatives are not uniformly bounded, it is not convenient to estimate the evolution of spatial derivatives of N^ε. But $S^\varepsilon_{\rm tot}(x)$ is independent of time, so we can obtain estimates for time derivatives; a spatial estimate will then be obtained by using the theory of elliptic PDEs.

LEMMA 5. *Let N^ε and R^ε satisfy the conditions of Lemma* 4. *Suppose in addition that condition* (30) *holds and that for some $\tilde b_\pm$,*

$$\tilde b_- \le D\Delta N_0(x) \le \tilde b_+. \tag{44}$$

Then for some b_-, b_+, B_-, and B_+

$$b_- \le N^\varepsilon_t \le b_+, \qquad B_- \le R^\varepsilon_t \le B_+. \tag{45}$$

Proof. Since the equation for R^ε is an ODE, a uniform bound on its time derivative follows from the bounds for N^ε and R^ε; i.e., the second half of (45) holds. Taking the time derivative of (40) for N^ε and substituting for the time derivative of R^ε from (41) yields

$$(N^\varepsilon_t)_t = D\Delta(N^\varepsilon_t) - k_b R^\varepsilon S^\varepsilon_{\rm tot}(x)\left[(N^\varepsilon_t) + \frac{k_d N^\varepsilon(1-N^\varepsilon R^\varepsilon)}{R^\varepsilon}\right]. \tag{46}$$

The bounds (43) imply both a lower bound $\hat b_-$ and an upper bound $\hat b_+$ for the expression $\frac{k_d N^\varepsilon(1-N^\varepsilon R^\varepsilon)}{R^\varepsilon}$ appearing in (46). Condition (30) implies that $N^\varepsilon_t(0,x) = D\Delta N^\varepsilon(0,x)$, so the bounds (44) imply the same bounds for $N^\varepsilon_t(0,x)$. Define $b_- := \min\{\hat b_-, \tilde b_-\}$ and $b_+ := \max\{\hat b_+, \tilde b_+\}$. Since differentiating (42) with respect to time shows that $\nu\cdot\nabla(N^\varepsilon_t)$ also vanishes on the boundary, another application of Theorem 3 shows that the first half of (45) holds. ∎

4.2.2. Elliptic estimate. Solving (40) for ΔN^ε yields

$$\Delta N^\varepsilon = \frac{N^\varepsilon_t - k_b S^\varepsilon_{\rm tot}(x)\,[1 - N^\varepsilon R^\varepsilon]}{D}. \tag{47}$$

Although the right side of (47) is not known to be uniformly bounded, it is a uniformly bounded function times the known expression $S^\varepsilon_{\rm tot}(x)$ plus a bounded function. This will allow us to obtain uniform estimates for N^ε and R^ε in an appropriate Hölder space, and also to determine the behavior of $\nu\cdot\nabla N^\varepsilon$ near the boundary.

DEFINITION 6. *Let Ω be a domain in $\mathbb{R}^d$, let $B_r(x_0)$ denote the ball of radius r centered at x_0, and suppose that $1 \le p \le \infty$. A measurable function f belongs to the Morrey space $\mathcal{M}^p(\Omega)$ if*

$$\|f\|_{\mathcal{M}^p} := \sup_{x_0\in\Omega}\sup_{r>0} \frac{\int_{B_r(x_0)\cap\Omega} |f(x)|\,dx}{r^{d(1-1/p)}} < \infty. \tag{48}$$

An easy calculation shows that $L^p(\Omega) \subset \mathcal{M}^p(\Omega)$ [9, sect. 7.9]. However, the reverse is not true. In particular, although $S^\varepsilon_{\rm tot}$ is uniformly bounded in L^p only for $p = 1$, its structural properties (24)–(26) ensure that $S^\varepsilon_{\rm tot}$, and hence also $g(x)S^\varepsilon_{\rm tot}$ for any bounded g, belong to $\mathcal{M}^d(\Omega)$.

LEMMA 7. *Suppose that S^ε_{tot} satisfies* (24)–(26) *and that $g^\varepsilon(x)$ is uniformly bounded. Then for some fixed constant c,*

$$\|g^\varepsilon(x)S^\varepsilon_{\rm tot}(x)\|_{\mathcal{M}^d} \le c. \tag{49}$$

Proof. Since g^ε is bounded it suffices to prove estimate (49) for $g^\varepsilon \equiv 1$. Since assumptions (24)–(26) imply that the total number of sites $\int_\Omega S^\varepsilon(x)\,dx$ is uniformly bounded, for any positive δ

$$\sup_{x_0\in\Omega}\sup_{r\ge\delta}\frac{\int_{B_r(x_0)}|S^\varepsilon_{\rm tot}(x)|\,dx}{r^{d(1-1/p)}}$$

is uniformly bounded. By picking δ small enough so that the map

$$(y,\tau)\mapsto y+\tau\nu(y) \tag{50}$$

is one to one $\partial_i\Omega\times[0,\delta]$ and satisfies $|[y_1+\tau_1\nu(y_1)]-[y_2+\tau_2\nu(y_2)]|\ge c|y_1-y_2|$ there for some fixed positive c, we obtain that the intersection of the support of $S^\varepsilon_{\rm tot}$ with any ball $B_r(x_0)$ of radius at most δ is contained in a set of the form $\{y+\tau\nu(y)\mid y\in \partial_i\Omega\cap B_{kr}(y_0),\ \tau\in[0,\delta]\}$. Assumption (26) implies that the integral of $S^\varepsilon_{\rm tot}$ over such a set is bounded by a constant times the volume of a ball of radius kr in dimension $d-1$, which is a constant times r^{d-1}. Combining this with the bound for $r\ge\delta$ yields (49). ∎

Although integration against the Green's function for the Laplacian does not map L^1 into C^0 since functions in L^1 can tend weakly to a delta function, it does map $\mathcal{M}^p$ for p sufficiently large into the space $C^{0,\alpha}$ of Hölder-continuous functions for some appropriate positive α. We begin with a general result.

LEMMA 8. *Suppose that $f\in\mathcal{M}^p$ with $p>1$. Then for $\mu>\frac{1}{p}$, $Tf(x):=\int_\Omega\frac{f(y)}{|x-y|^{d(1-\mu)}}\,dy$ belongs to $C^{0,\alpha}$ for $\alpha<\min\{1,d(\mu-\frac{1}{p})\}$, where d is the spatial dimension. Furthermore, the $C^{0,\alpha}$ seminorm of Tf is bounded by a constant times the $\mathcal{M}^p$ norm of f.*

Proof. By interpolating between the elementary inequalities

$$\left|\frac{1}{|x_1-y|^\beta}-\frac{1}{|x_2-y|^\beta}\right|\le\left[\frac{1}{|x_1-y|^\beta}+\frac{1}{|x_2-y|^\beta}\right]$$

and

$$\left|\frac{1}{|x_1-y|^\beta}-\frac{1}{|x_2-y|^\beta}\right|\le c|x_1-x_2|\left[\frac{1}{|x_1-y|^{\beta+1}}+\frac{1}{|x_2-y|^{\beta+1}}\right],$$

we obtain that for any $\gamma\in[0,1]$,

$$\left|\frac{1}{|x_1-y|^\beta}-\frac{1}{|x_2-y|^\beta}\right|\le c(\gamma)|x_1-x_2|^\gamma\left[\frac{1}{|x_1-y|^{\beta+\gamma}}+\frac{1}{|x_2-y|^{\beta+\gamma}}\right]. \tag{51}$$

Pick $\alpha\in(0,1)$ such that $\alpha<d(\mu-\frac{1}{p})$. Applying (51) with $\gamma=\alpha$ and $\beta=d(1-\mu)$ yields

$$|[Tf](x_1)-[Tf](x_2)|\le c(\alpha)|x_1-x_2|^\alpha\sum_{j=1}^2\int_\Omega\frac{1}{|x_j-y|^{d(1-\lceil\mu-\frac{\alpha}{d}\rceil)}}f(y)\,dy. \tag{52}$$

Since $\mu - \frac{\alpha}{d} > \frac{1}{p}$ by construction, the integrals on the right side of (52) are bounded by [9, Lem. 7.18]. ∎

Using Lemma 8 we can show that N^ε and R^ε are uniformly bounded in some Hölder space.

LEMMA 9. *Under the conditions of Lemma* 5*, for bounded times the solutions* N^ε *and* R^ε *are uniformly bounded in* $C^{0,\alpha}$ *for* $\alpha < 1$.

Proof. Let G be the Neumann Green's function for the Laplacian in Ω, so that for any f having mean zero, the solutions to $\Delta u = f$ in Ω, $\frac{\partial u}{\partial \nu} = 0$ on $\partial\Omega$, are $u(x) = \int_\Omega G(x,y) f(y)\, dy + c$. The singularity of G when $x = y$ is of the same order as the Newtonian potential, i.e., $\frac{1}{|x-y|^{d-2}}$, or $\log(|x-y|)$ when $d = 2$. Since the smooth part of G makes a smooth contribution to u, it suffices to show that $\int_\Omega \frac{1}{|x-y|^{d(1-\mu)}} \Delta N^\varepsilon(y)\, dy$ belongs to $C^{0,\alpha}$ for $\alpha < 1$, where $\mu = \frac{2}{d}$ for $d > 2$ and is arbitrarily close to one for $d = 2$.

Now any bounded function belongs to $\mathcal{M}^\infty$ and hence also to $\mathcal{M}^p$ for any $p < \infty$. Hence (47) plus the bounds for N^ε, R^ε, and N_t^ε and Lemma 7 implies that ΔN^ε belongs to $\mathcal{M}^d$.

Lemma 8 therefore shows that $\int_\Omega \frac{1}{|x-y|^{d(1-\mu)}} \Delta N^\varepsilon(y)\, dy$ belongs to $C^{0,\alpha}$ for $\alpha < d(\frac{2}{d} - \frac{1}{d}) = 1$, and that its $C^{0,\alpha}$ seminorm is uniformly bounded. ∎

4.3. Taking the limit. By Ascoli's theorem, the uniform bounds obtained in the previous subsection imply the convergence along subsequences as $\varepsilon \to 0$.

COROLLARY 10. *Under the conditions of Lemma* 5*, for every sequence of values of* ε *there is a subsequence for which* N^ε *and* R^ε *converge uniformly in* Ω *for bounded times. The limits* N *and* R *satisfy the same bounds* (43) *as* N^ε *and* R^ε.

We first consider the limit in terms of the variables (N, R).

LEMMA 11. *The limits* (N, R) *satisfy*

$$N_t = D\Delta N \tag{53}$$

in Ω,

$$\nu \cdot \nabla N = \frac{k_b S_{tot}^0(y)(1 - NR)}{D} \tag{54}$$

on the inner boundary $\partial_i\Omega$ *bounding the tumor region,* (42) *on the outer boundary* $\partial_o\Omega$*, and*

$$R_t = k_d(1 - NR) \tag{55}$$

in $\overline{\Omega}$*, including in particular, on the inner boundary* $\partial_i\Omega$*. The initial values of* N *and* R *are the same as for the original system.*

Proof. Taking the weak limit of the PDE (40) yields (53) within the domain Ω, since N_t^ε converges weakly to N_t and the reaction term tends to zero in every compact subset of Ω. Since R^ε satisfies an ODE, the convergence of N^ε and R^ε implies that the limits satisfy (55). Since the convergence of N^ε and R^ε is uniform in time as well as space, their limits have the same initial values.

Finally, in order to obtain (54), let Ω_δ denote the subset of Ω whose distance to the inner boundary $\partial_i\Omega$ is less than δ. For sufficiently small δ, $\Omega_\delta = \{y + \tau\nu \mid y \in \partial_i\Omega,\ 0 < \tau < \delta\}$. The boundary of Ω_δ is then the disjoint union of $\partial_i\Omega$, and the set $\partial_\delta\Omega$ of points in Ω whose distance to $\partial_i\Omega$ is exactly δ. Since (53) implies that N is smooth in Ω, the derivative $\frac{\partial N}{\partial \nu}$ of N with respect to the outer normal on $\partial_\delta\Omega$ is well defined. As before, let $y(x)$ denote the mapping sending $x = y + \tau\nu$ to y.

By Green's formula, for any smooth function ψ

$$\int_{\partial_\delta\Omega}\psi(y(x))\frac{\partial N^\varepsilon}{\partial\nu}=\int_{\Omega_\delta}\psi\Delta N^\varepsilon-N^\varepsilon\Delta\psi+\int_{\partial_\delta\Omega}N^\varepsilon\frac{\partial\psi(y(x))}{\partial\nu} \tag{56}$$

since both $\frac{\partial N^\varepsilon}{\partial\nu}$ and $\frac{\partial\psi(y(x))}{\partial\nu}$ vanish on $\partial_i\Omega$.

Since $\frac{\partial\psi(y(x))}{\partial\nu}$ vanishes on $\partial_i\Omega$, it is $O(\delta)$ on $\partial_\delta\Omega$. Also, since N^ε is uniformly bounded and the volume of Ω_δ is $O(\delta)$, $\int_{\Omega_\delta}N^\varepsilon\Delta\psi=O(\delta)$. Similarly, upon substituting (47) into (56), the term involving N_t^ε contributes $O(\delta)$. Hence

$$\int_{\partial_\delta\Omega}\psi(y(x))\frac{\partial N^\varepsilon}{\partial\nu}=-\int_{\Omega_\delta}\psi(y(x))\frac{k_bS_{\rm tot}^\varepsilon(x)\,[1-N^\varepsilon R^\varepsilon]}{D}+O(\delta). \tag{57}$$

Now take the limit as first $\varepsilon\to0$ and then $\delta\to0$. The left side of (57) tends to $\int_{\partial_i\Omega}\psi(y)\frac{\partial N}{\partial\nu}$. Since the term $O(\delta)$ on the right side is uniform in ε, it contributes nothing to the combined limit. Hence

$$\begin{aligned}\int_{\partial_i\Omega}\psi(y)\frac{\partial N}{\partial\nu}\,d\sigma(y)&=-\lim_{\delta\to0}\lim_{\varepsilon\to0}\int_{\Omega_\delta}\psi(y(x))\frac{k_bS_{\rm tot}^\varepsilon(x)\,[1-N^\varepsilon R^\varepsilon]}{D}\,dx\\&=-\lim_{\delta\to0}\lim_{\varepsilon\to0}\int_{\Omega_\varepsilon}\psi(y(x))\frac{k_bS_{\rm tot}^\varepsilon(x)\,[1-N^\varepsilon R^\varepsilon]}{D}\,dx\\&=-\lim_{\delta\to0}\lim_{\varepsilon\to0}\int_{\partial_i\Omega}\psi(y)\int_0^\varepsilon\frac{k_bS_{\rm tot}^\varepsilon(y+\tau\nu)\,[1-N^\varepsilon(y+\tau\nu)R^\varepsilon(y+\tau\nu)]}{D}\,d\tau\,d\sigma(y),\end{aligned} \tag{58}$$

where we have used the fact that the difference between dx and $d\tau\,d\sigma(y)$ tends to zero with the distance from the boundary. Since the total integral of $S_{\rm tot}^\varepsilon$ is uniformly bounded, and $N^\varepsilon R^\varepsilon$ converge uniformly, we may replace that expression in (58) with its limit NR. In addition, $N(y+\tau\nu)R(y+\tau\nu)=N(y)R(y)+o(1)$, so in fact

$$\begin{aligned}&\int_{\partial_i\Omega}\psi(y)\frac{\partial N}{\partial\nu}\,d\sigma(y)\\&\quad=-\int_{\partial_i\Omega}\psi(y)\frac{k_b\,[1-N(y)R(y)]}{D}\left[\lim_{\varepsilon\to0}\int_0^\varepsilon S_{\rm tot}^\varepsilon(y+\tau\nu)\,d\tau\right]d\sigma(y)\\&\quad=-\int_{\partial_i\Omega}\psi(y)\frac{k_b\,[1-N(y)R(y)]}{D}S_{\rm tot}^{\varepsilon,0}(y)\,d\sigma(y)\\&\quad=-\int_{\partial_i\Omega}\psi(y)\frac{k_b\,[1-N(y)R(y)]}{D}S_{\rm tot}^0(y)\,d\sigma(y)\end{aligned} \tag{59}$$

by assumption (26). Since ψ is an arbitrary smooth function, (59) implies (54). ∎

In order to obtain convergence of the full sequence $(N^\varepsilon,R^\varepsilon)$ without restricting to some subsequence, it suffices to show that the limit obtained along different subsequences is unique.

LEMMA 12. *A bounded solution of* (53) *in* Ω, (54) *and* (55) *on the inner boundary* $\partial_i\Omega$, *and* (42) *on the outer boundary, with given initial data, is unique.*

Proof. Suppose that (N_j,R_j), $j=1,2$, are solutions having the same initial data. Define $N:=N1-N_2$ and $R:=R_1-R_2$. Multiplying the difference of (53) for N_1 and N_2 by N, integrating over Ω, and adding the integral over $\partial_i\Omega$ of R times the

difference of (55) for R_1 and R_2 yields

$$\begin{aligned}(60)\qquad &\frac{d}{dt}\frac{1}{2}\left[\int_\Omega N^2\,dx+\int_{\partial_i\Omega}R^2\,d\sigma(y)\right]\\ &\qquad=-D\int_\Omega\nabla N^2-\int_{\partial_i\Omega}\left[\frac{k_bS^0(y)}{D}N+k_dR\right]\,[R_1N+N_2R]\,d\sigma(y).\end{aligned}$$

Since both R_1 and N_2 are bounded and strictly positive, the elementary inequality $-c_1x^2+c_2xy-c_3y^2\le c_4y^2$ allows us to reduce (60) to

$$\begin{aligned}(61)\qquad &\frac{d}{dt}\frac{1}{2}\left[\int_\Omega N^2\,dx+\int_{\partial_i\Omega}R^2\,d\sigma(y)\right]\le c\int_{\partial_i\Omega}R^2\,d\sigma(y)\\ &\qquad\le c\cdot\frac{1}{2}\left[\int_\Omega N^2\,dx+\int_{\partial_i\Omega}R^2\,d\sigma(y)\right].\end{aligned}$$

Since $N\equiv0$ and $R\equiv0$ initially, (61) shows that they remain zero for all time. ∎

We are finally ready to prove the main result in terms of the original variables M^ε and S^ε.

Proof of Theorem 1. Lemma 12 implies the convergence of N^ε and R^ε to N and R holds without restricting to a subsequence. Upon transforming back to the variable M, (53) becomes (31). In view of the uniform convergence of R^ε, (26) implies the convergence of (34) to $S^0_{\text{tot}}R$, so (54)–(55) yield (32)–(33). The convergence of the initial data is obtained similarly. ∎

5. Possible extensions. In this study we have aimed to give both heuristic and rigorous justifications for using the laws of chemical kinetics to describe binding and dissociation reactions that take place on surfaces. Our results were obtained, however, for a specific model involving a single reaction taking place on the boundary, with purely diffusive dynamics away from the boundary. Furthermore, a more realistic model of the fluorophore-antibody–based imaging studied here should also include advection effects to account for the continuous drainage of the interstitial fluid. Other chemical and biological systems involve more complicated interactions, possibly including several reactions on the boundary. To what extent can our methods be applied in these more general situations?

Since both our heuristic and rigorous analyses implicitly or explicitly require uniform bounds on reaction concentrations or ratios, our methods seem to require the presence of an invariant region for the reaction dynamics. Models of a variety of chemical and biological systems for which the existence of such regions have been deduced or assumed have been studied [14, 16, 17].

Additional restrictions must be placed on reactants that concentrate at the boundary surface. First, the reaction terms must be at most linear in those reactants. In terms of our heuristic analysis, this condition arises because the volumetric concentrations of those reactants tend to Dirac delta functions, which makes superlinear functions of those concentrations diverge to infinity even when considered in the sense of distributions. In our rigorous analysis linearity is needed in order for the second change of variables in (37) to be helpful.

That reaction terms be at most linear in "surface" reactants seems to be a necessary condition for our results to hold, rather than a technical limitation. The presence of a superlinear growth term would make the reaction blow up as the reactant concentrates at the boundary, while superlinear decay terms would make reactions disappear in the limit.

Our methods can accommodate advection terms involving the "volumetric" reactants that do not concentrate at the boundary (e.g., advection of markers). Note, however, that our analysis does not apply to models that allow for advection or even diffusion of the "surface" reactants. Indeed, such advection or diffusion terms would change the model substantially, since they would cause the "surface" reactants to leave the region near the boundary.

NONUNIFORM AVERAGE SAMPLING AND RECONSTRUCTION OF SIGNALS WITH FINITE RATE OF INNOVATION*

QIYU SUN†

Abstract. From an average (ideal) sampling/reconstruction process, the question arises whether the original signal can be recovered from its average (ideal) samples and, if so, how. We consider the above question under the assumption that the original signal comes from a prototypical space modeling signals with a finite rate of innovation, which includes finitely generated shift-invariant spaces, twisted shift-invariant spaces associated with Gabor frames and Wilson bases, and spaces of polynomial splines with nonuniform knots as its special cases. We show that the displayer associated with an average (ideal) sampling/reconstruction process, which has a well-localized average sampler, can be found to be well-localized. We prove that the reconstruction process associated with an average (ideal) sampling process is robust, locally behaved, and finitely implementable, and thus we conclude that the original signal can be approximately recovered from its incomplete average (ideal) samples with noise in real time. Most of our results in this paper are new even for the special case when the original signal comes from a finitely generated shift-invariant space.

Key words. average sampling, ideal sampling, signals with finite rate of innovation, shift-invariant spaces

1. Introduction.

Modern digital data processing of functions (or signals or images) uses a discretized version of the original function that is obtained by (average) sampling on a discrete set [2]. The classical model is the Shannon sampling and reconstruction on the band-limited space B_Ω, the space of all square-integrable functions on the real line with their Fourier transform supported in $[-\Omega, \Omega]$. From the Shannon sampling theorem, sampling a function f in B_π on the uniform grid $\mathbf{Z}$ yields an ℓ^2 sequence $(f(k))_{k\in\mathbf{Z}}$, and conversely the original function f can be recovered from its sampling data $\{f(k), k \in \mathbf{Z}\}$ by the following reconstruction formula:

$$f(x) = \sum_{k\in\mathbf{Z}} f(k)\mathrm{sinc}(x-k),\ x \in \mathbf{R}, \tag{1.1}$$

where the sinc function is defined by $\mathrm{sinc}(x) = \frac{\sin \pi x}{\pi x}$. The above sampling and reconstruction theorem gives a framework for converting analogue signals into sequences, which can be processed digitally and converted back into analogue signals via the reconstruction formula (1.1). For the ideal sampling and reconstruction on the band-limited space and the finitely generated shift-invariant spaces, there is an extensive literature (see, for example, the recent review papers [2, 57] and monographs [12, 14, 43]).

In most physical circumstances, due to the nonideal acquisition device at the sampling location, it is not realistic to measure the sample $f(\gamma)$ of the original signal f in a space V at the location γ exactly. So a better assumption is that the sampled data are of the form $\langle f, \psi_\gamma\rangle$,

$$A:\ V \ni f \longmapsto (\langle f, \psi_\gamma\rangle)_{\gamma\in\Gamma}, \tag{1.2}$$

where ψ_γ, to be known as the *average sampling functional*, reflects the characteristic of the nonideal acquisition device at the sampling location γ. We call the above sampling process an *average sampling process*, and call the collection $\Psi := \{\psi_\gamma, \gamma \in \Gamma\}$ of average sampling functionals an *average sampler*. Clearly, the average sampling process becomes an ideal sampling process if the delta function δ_γ is used as the average sampling functional ψ_γ on every sampling location γ.

An easy model for the average sampling process is the discretization of the blurring process encountered in many practical situations, such as in the process of a remote camera imaging a scene and an observer viewing the sampled image [59]. For the average sampling and reconstruction on the band-limited space and on the finitely generated shift-invariant spaces, the reader may refer [1, 4, 5, 6, 22, 25, 28, 53, 54, 55, 61] and references cited therein.

The question arises from the average sampling process whether the original function can be recovered from its average samples and, if so, how. Specifically, the first part of the above question, which will be discussed in section 4, can be described as follows: Given a class of functions V on $\mathbf{R}^d$, find conditions on the average sampler $\Psi = \{\psi_\gamma : \gamma \in \Gamma\}$ under which any function f in V can be reconstructed uniquely and stably from its average samples $\{\langle f, \psi_\gamma\rangle : \gamma \in \Gamma\}$.

The second part of the above question arising from the average sampling process is the reconstruction process from the average (ideal) samples:

$$D : (c_\gamma)_{\gamma\in\Gamma} \longmapsto \sum_{\gamma\in\Gamma} c_\gamma \tilde{\psi}_\gamma \in V \tag{1.3}$$

such that

$$DAf = f \quad \text{for all} \quad f \in V. \tag{1.4}$$

Here for each $\gamma \in \Gamma$, the function $\tilde{\psi}_\gamma$, to be known as the *display block* at the location γ, reflects the characteristic of the display device at the sampling location γ. We call the above reconstruction process an *average reconstruction process* and the collection $\Psi := \{\tilde{\psi}_\gamma,\ \gamma \in \Gamma\}$ of display blocks an *displayer*.

For the efficiency and stability of the reconstruction process (1.3), (1.4) to recover a function f in the space V from its averaging samples $\{\langle f, \psi_\gamma\rangle, \gamma \in \Gamma\}$ or from its ideal samples $\{f(\gamma), \gamma \in \Gamma\}$, we require the corresponding displayer $\tilde{\Psi} := \{\tilde{\psi}_\gamma, \gamma \in \Gamma\}$ to be *well-localized*, and the average sampling/reconstruction process (1.3), (1.4) to be *robust, local-behaved*, and *finitely implementable*. In this paper, we show that those natural requirements for the average (ideal) sampling/reconstruction process would be met when signals in the space V have a finite rate of innovation and the average sampler Ψ is well-localized; see section 2.3 for our reasons for considering sampling/reconstruction of signals with a finite rate of innovation. Here a signal is said to have a *finite rate of innovation* if it has a finite degree of freedom per unit of time; see [23, 34, 40, 42, 45, 46, 58].

The paper is organized as follows. We divide section 2 into five subsections. In the first three subsections, we make some basic assumptions on the sampling set Γ, the average sampler $\Psi = \{\psi_\gamma, \gamma \in \Gamma\}$, and the space V, which is where the original function f for the average sampling/reconstruction process comes from. Briefly, we assume that the sampling set Γ is a relatively separated subset of $\mathbf{R}^d$, the average sampler Ψ is well-localized in the sense that every average sampling functional ψ_γ in the average sampler Ψ is essentially located in a neighborhood of $\gamma \in \Gamma$, and the space V is the space $V_q(\Phi, \Lambda)$, that is, as originally introduced in [52] for modeling

signals with a finite rate of innovation. In the last two subsections, we recall some basic properties of the space $V_q(\Phi,\Lambda)$ from [52], and introduce a simplified model of our average (ideal) sampling/reconstruction process for the readers' convenience.

Since each display block $\tilde{\psi}_\gamma$ in the displayer $\tilde{\Psi} := \{\tilde{\psi}_\gamma, \gamma\in\Gamma\}$ reflects the characteristic of the display device at the sampling location $\gamma, \gamma\in\Gamma$, it is reasonable to *require* that for each $\gamma\in\Gamma$, the display block $\tilde{\psi}_\gamma$ be essentially supported in a neighborhood of the sampling location γ. In section 3, derived from a general theorem for localized frames (see [8, Theorem 1], [24, Theorem 3.6], and [32, Theorem 13]), it is shown that such a requirement would be met for average (ideal) sampling in the space $V_2(\Phi,\Lambda)$ if the average sampler Ψ and the generator Φ for the space $V_2(\Phi,\Lambda)$ are well-localized (Theorems 3.1 and 3.2); see Remark 3.1 for a more general formulation of the well-localization of a displayer. The well-localization of displayers will play a crucial role in our study of stable average sampling in $V_r(\Phi,\Lambda)$ with $r\neq 2$ (Corollary 3.4), the robustness and local convergence of the reconstruction process from average (ideal) samples (Theorems 5.1–5.3 and 6.1–6.3), and exponential convergence of an iterative algorithm for the reconstruction process from average (ideal) samples (Theorems 7.1 and 7.2).

In section 4, we find conditions on the average sampling sampler $\Psi = \{\psi_\gamma : \gamma\in\Gamma\}$ (respectively, on the ideal sampling set Γ) under which any function f in $V_2(\Phi,\Lambda)$ can be reconstructed uniquely and stably from its average samples $\{\langle f,\psi_\gamma\rangle : \gamma\in\Gamma\}$ (respectively, from its ideal samples $\{f(\gamma),\gamma\in\Gamma\}$); see Theorems 4.1 and 4.2.

In the average (ideal) sampling/reconstruction process, we should bring the following situations into our consideration: the average samples $\{\langle f,\psi_\gamma\rangle : \gamma\in\Gamma\}$ may involve some noises (caused by, for example, measurement, storage, or transmission), and the average sampler Ψ may not be exactly the same as the one we expect (because of the mathematical modeling or the measurement of the acquisition device). In section 5, we consider the numerical stability of the reconstruction process (1.3), (1.4). We show that if the average sampler Ψ and the generator Φ for the space $V_2(\Phi,\Lambda)$ are well-localized, then the reconstruction process (1.3), (1.4) for $f\in V_2(\Phi,\Lambda)$ is stable under the corruption of the average (ideal) sampling data, and under the perturbation of averaging samplers, ideal sampling sets and the displayers; see Theorems 5.1, 5.2, and 5.3 for details. Then we conclude that the reconstruction process (1.3), (1.4) for $f\in V_2(\Phi,\Lambda)$ is *robust*.

By the reconstruction process (1.3), (1.4), any function f in the space V can be recovered fully when its average (ideal) sampling data are received completely. In some situations (such as when data missing are in the transmission and in the real-time reconstruction process), we are required to recover the original function (signal) partially from incomplete (ideal) average samples. We observe from the well-localization of the average sampler Ψ and of the ideal sampling set Γ that the average sampling data $\langle f,\psi_\gamma\rangle$ and the ideal sampling data $f(\gamma)$ catch the information of the function f essentially in a neighborhood of the sampling location γ for every $\gamma\in\Gamma$, which implies that the average (ideal) sampling procedure is locally behaved. So a natural question is whether the reconstruction procedure is locally behaved, or particularly whether a function $f\in V_2(\Phi,\Lambda)$ on a certain region K can be recovered approximately (or exactly) from the average sampling data $\langle f,\psi_\gamma\rangle$ and the ideal sampling data $f(\gamma)$ for the sampling location γ in a neighborhood of that region. In section 6, it is proved that for any bounded region K, the original function in the space $V_2(\Phi,\Lambda)$ can be approximately recovered from its average (ideal) samples in an R-neighborhood $B(K,R) = \{y : \inf_{x\in K}|y-x|\le R\}$ of that region K via a finite algorithm (see

Theorems 6.1 and 6.2 for details), and moreover that the local convergence rate of the local reconstruction procedure is almost the same as the rate of polynomial (subexponential) decay of the generator Φ and of the average sampler Ψ. Therefore we conclude that the reconstruction process (1.3), (1.4) for $f \in V_2(\Phi, \Lambda)$ is *locally behaved* and *finitely implementable* (hence it could lead possibly to a real-time reconstruction algorithm) when the average sampler Ψ and the generator Φ are well-localized. As a by-product of the local reconstruction theorems, we obtain a necessary condition on the location Γ of average (ideal) sampling devices, which states that, for a stable average (ideal) sampling/reconstruction procedure on the space $V_2(\Phi, \Lambda)$, there exists a positive constant R_0 such that for any domain $K \subset \mathbf{R}^d$, the number of average (ideal) sampling devices located in R_0-neighborhood $B(K, R_0)$ of that domain K should exceed the degrees of freedom of the space $V_2(\Phi, \Lambda)$ in the domain K; see Theorem 6.3 for details. The above necessary condition, which is usually known as the density property, is established in [3] for the ideal sampling on the B-spline space (see [2, 3] and references cited therein for nonuniform sampling on the band-limited space, and see [8, 9] for nonuniform Gabor system).

In the average (ideal) sampling/reconstruction process, we need an efficient and fast numerical algorithm that recovers any function $f \in V_r(\Phi, \Lambda)$ from its average sampling values $\langle f, \psi_\gamma \rangle, \gamma \in \Gamma$, or from its ideal sampling values $f(\gamma), \gamma \in \Gamma$. In section 7, we modify the standard Richardson–Landweber iterative frame algorithm to implement the reconstruction process (1.3), (1.4) for signals $f \in V_r(\Phi, \Lambda)$ when average (ideal) samples are received completely, and show that the new iterative algorithm converges exponentially for any initial data in ℓ^r and that the limit agrees with the signal in the space $V_r(\Phi, \Lambda)$ whenever the initial data are obtained from average (ideal) sampling of that signal (see [2, 6, 22] for convergence results similar to the standard Richardson–Landweber iterative frame algorithm in the shift-invariant setting). The Richardson–Landweber iterative algorithm is easily implemented, but it provides slow convergence in general. Relaxation and acceleration techniques, such as the conjugate gradient acceleration, help to alleviate the convergence problem [29, 30], but their consideration is beyond the scope of this paper and will be discussed in a subsequent paper.

The proofs of all results are collected in section 8.

In this paper, an uppercase letter C, if unspecified, denotes an absolute constant which may be different at different occurrences.

2. Preliminaries.

2.1. The sampling set Γ. Every γ in the sampling set Γ is used as the location of a (non-)ideal sampling acquisition device, which has the average sampling characteristic ψ_γ. Then reasonable assumptions on the sampling set Γ are that only finitely many such sampling acquisition devices are located in any unit interval, and that the distribution of those devices is almost location invariant. So in this paper, we make the following basic assumption on the sampling set Γ:

(i) *The sampling set Γ is a relatively separated subset of $\mathbf{R}^d$.*

Here, given a subset $X = \{x_j\}$ of $\mathbf{R}^d$, we say that X is *relatively separated* if there exists a positive constant $D(X)$ such that

$$\sum_{x_j \in X} \chi_{x_j + [0,1]^d}(x) \le D(X) \quad \text{for all } x \in \mathbf{R}^d. \tag{2.1}$$

2.2. The average sampler Ψ. We say that a positive function u on $\mathbf{R}^d$ is a *weight* if it is continuous, symmetric, and satisfies $1 = u(0) \le u(x) < \infty$ for

all $x \in \mathbf{R}^d$, and the inequality $u(x+y) \le u(x)v(y), x, y \in \mathbf{R}^d$, holds for another continuous function v on $\mathbf{R}^d$. The model examples of weights convenient for our consideration of the sampling/reconstruction process are the *polynomial weights*

$$u_\alpha(x) = (1+|x|)^\alpha \tag{2.2}$$

with $\alpha \ge 0$, and the *subexponential weights*

$$e_{D,\delta}(x) = \exp(D|x|^\delta) \tag{2.3}$$

with $D > 0$ and $\delta \in (0,1)$.

Given $1 \le p, q \le \infty$, a weight u, a relatively separated subset Γ of $\mathbf{R}^d$, and a family $\Psi = \{\psi_\gamma : \gamma \in \Gamma\}$ of functions on $\mathbf{R}^d$, we define $\|\Psi\|_{q,p,u}$ by

$$\begin{aligned}\|\Psi\|_{q,p,u} := &\sup_{\gamma\in\Gamma} \big\| \big(\|\psi_\gamma(\cdot)u(\cdot-\gamma)\|_{L^q(k+[0,1]^d)}\big)_{k\in\mathbf{Z}^d}\big\|_{\ell^p(\mathbf{Z}^d)} \\ &+ \sup_{k\in\mathbf{Z}^d} \big\| \big(\|\psi_\gamma(\cdot)u(\cdot-\gamma)\|_{L^q(k+[0,1]^d)}\big)_{\gamma\in\Gamma}\big\|_{\ell^p(\Gamma)},\end{aligned} \tag{2.4}$$

where, as usual, $\|\cdot\|_{L^q(K)}$ denotes the usual L^q norm on the space $L^q(K)$ of all q-integrable functions on a measurable set K, and $\|\cdot\|_{\ell^p(X)}$ (or $\|\cdot\|_{\ell^p}$ for short) is the usual $\ell^p(X)$ norm on the space of all q-summable sequences on the index set X. For $q = p = \infty$, it is obvious that $\|\Psi\|_{q,p,u} < \infty$ if and only if $|\psi_\gamma(x)| \le \|\Psi\|_{q,p,u}(u(x-\gamma))^{-1}$ for all $x \in \mathbf{R}^d$ and $\gamma \in \Gamma$. In general, for the family of functions $\Psi = \{\psi_\gamma : \gamma \in \Gamma\}$ with $\|\Psi\|_{q,p,u} < \infty$, each function $\psi_\gamma, \gamma \in \Gamma$, is an L^q function "locally" and a weighted L^p function centered at γ "globally." Therefore for each $\gamma \in \Gamma$, the function ψ_γ in the collection $\Psi := \{\psi_\gamma, \gamma \in \Gamma\}$ with $\|\Psi\|_{q,p,u} < \infty$ can be thought of as essentially supported in a neighborhood of $\gamma \in \Gamma$.

For the average sampler $\Psi = \{\psi_\gamma : \gamma \in \Gamma\}$, each average sampling functional ψ_γ reflects the characteristic of the nonideal acquisition device at the location $\gamma \in \Gamma$, and hence it should be essentially supported in a neighborhood of the sampling location γ. So we make the following basic assumption on the average sampler Ψ:

(ii) *The average sampler* $\Psi = \{\psi_\gamma : \gamma \in \Gamma\}$ *satisfies*

$$\|\Psi\|_{q,p,u} < \infty \tag{2.5}$$

for some $1 \le p, q \le \infty$, *and weight* u.

We interpret any average sampler that satisfies the basic assumption (ii) as having *polynomial* (*subexponential*) *decay*, due to the interpretation of the collection Ψ of average sampling functional $\psi_\gamma, \gamma \in \Gamma$, with $\|\Psi\|_{q,p,u} < \infty$ and the model assumption on the weight u that is convenient for our consideration of the sampling/reconstruction process in which u is a polynomial weight u_α or a subexponential weight $e_{D,\delta}$.

Remark 2.1. For adapting to different average (ideal) sampling situations, we add some flexibility to the basic assumption (ii) on the average sampler Ψ with variable exponents p and q and weights u. For instance, we may use $q = 1$ for approximating ideal sampling ($\psi_\gamma \approx \delta_\gamma$; see [6]), $q = 2$ for frame sampling (for instance, $\Psi = \{\phi(\cdot - k), k \in \mathbf{Z}^d\}$ for frame sampling in the shift-invariant space $V_2(\phi)$ generated by ϕ, [7, 13, 39, 52]), $q = \infty$ in local blurring or local averaging (for instance, $\psi_\gamma = h(\cdot-\gamma)$ for some compactly supported phase function h, [5, 25, 59]), and the subexponential weight $e_{D,\delta}$ for oversampling band-limited signals [35].

Remark 2.2. Given $p \in [1,\infty]$, a weight u, and two relatively separated subsets Γ, Γ' of $\mathbf{R}^d$, we define the *matrix algebra* $\mathcal{A}_{p,u}(\Gamma,\Gamma')$ *of Schur class* by

$$\mathcal{A}_{p,u}(\Gamma,\Gamma') := \big\{A := (A(\gamma,\gamma'))_{\gamma\in\Gamma,\gamma'\in\Gamma'} : \|A\|_{\mathcal{A}_{p,u}} < \infty\big\}, \tag{2.6}$$

where

$$\|A\|_{\mathcal{A}_{p,u}} := \sup_{\gamma\in\Gamma} \big\|\big(A(\gamma,\gamma')u(\gamma-\gamma')\big)_{\gamma'\in\Gamma'}\big\|_{\ell^p(\Gamma')} + \sup_{\gamma'\in\Gamma'} \big\|\big(A(\gamma,\gamma')u(\gamma-\gamma')\big)_{\gamma\in\Gamma}\big\|_{\ell^p(\Gamma)}$$

(see, e.g., [32, 37, 51]). Then the basic assumption $\|\Psi\|_{q,p,u} < \infty$ on the average sampler Ψ is characterized by

$$\|\Psi\|_{q,p,u} < \infty \text{ if and only if } (\|\psi_\gamma\|_{L^q(k+[0,1]^d)})_{\gamma\in\Gamma,k\in\mathbf{Z}^d} \in \mathcal{A}_{p,u}(\Gamma,\mathbf{Z}^d). \tag{2.7}$$

For the basic assumption $\|\Psi\|_{q,p,u} < \infty$ with different exponents p, q and weights u, we have the following results, which will be used frequently in the proofs:

$$\|\Psi\|_{q_1,p,u} \le C\|\Psi\|_{q_2,p,u} \tag{2.8}$$

if $q_1 \le q_2$, and

$$\|\Psi\|_{q,p_1,u} \le C\|\Psi\|_{q,p_2,v} \tag{2.9}$$

if $p_1 \le p_2$ and $\|uv^{-1}\|_{L^r} < \infty$, where $1/r = 1/p_1 - 1/p_2$; see [52] for details.

2.3. The space V in which functions are sampled and recovered. The band-limited space $B_\Omega, \Omega > 0$, is a prototypical space for sampling theory and for signal processing in the classical band-limited model [2]. By the Whittaker representation theorem, the band-limited space B_π is spanned by the shifted sinc function $\mathrm{sinc}(x-k) := \frac{\sin\pi(x-k)}{\pi(x-k)}, k \in \mathbf{Z}$, using ℓ^2 coefficients, i.e., $B_\Omega = \{\sum_{k\in\mathbf{Z}} c(k)\mathrm{sinc}(x-k) : (c(k)) \in \ell^2\}$.

Since the sinc function has infinite support and slow decay at infinity, the band-limited space is often unsuitable for numerical implementations (see, e.g., [2, 35]). Hence people consider other models that retain some of the *simplicity* and *structure* of the band-limited model, but are more *amenable* to numerical implementation and are more *flexible* for approximate real data (see [2, 11, 15, 36, 56] and references cited therein).

Other than the band-limited model, a widely used model is the finitely generated shift-invariant model; see, e.g., [1, 2, 4, 5, 6, 19, 28, 41, 53, 54, 55]. Here the finitely generated shift-invariant space $V_q(\phi_1,\dots,\phi_N)$, that has functions $\phi_1,\dots,\phi_N$ on $\mathbf{R}^d$ as its generators, is defined by

$$V_q(\phi_1,\dots,\phi_N) := \left\{ \sum_{n=1}^N \sum_{k\in\mathbf{Z}^d} c_n(k)\phi_n(\cdot-k) : (c_n(k))_{k\in\mathbf{Z}^d} \in \ell^q, 1 \le n \le N \right\}, \tag{2.10}$$

where $1 \le q \le \infty$ (see, e.g., [7, 13, 16, 21, 39] for the applications of finitely generated shift-invariant spaces in wavelet analysis and approximation theory). Clearly the finitely generated shift-invariant space $V_q(\phi_1,\dots,\phi_N)$ becomes the band-limited space B_π if we let $q = 2, N = 1$, and $\phi_1 = \mathrm{sinc}$.

The space $V_q(\Phi,\Lambda)$,

$$V_q(\Phi,\Lambda) := \left\{ \sum_{\lambda\in\Lambda} c(\lambda)\phi_\lambda : \ \big\|(c(\lambda))_{\lambda\in\Lambda}\big\|_{\ell^q(\Lambda)} < \infty \right\}, \tag{2.11}$$

that was recently introduced by the author in [52] is a new model (other than the above band-limited model and shift-invariant model), where $1 \le q \le \infty$, Λ is a relatively separated subset of $\mathbf{R}^d$, and $\Phi = \{\phi_\lambda, \lambda \in \Lambda\}$ satisfies $\|\Phi\|_{q,p,u} < \infty$ for

some $1 \le p, q \le \infty$ and some weight u. We call Φ the *generator* of the space $V_q(\Phi, \Lambda)$, and call Λ the *location of the generator*.

The prototypical space $V_q(\Phi, \Lambda)$ has shift-invariant spaces, twisted shift-invariant spaces generated by (non-)uniform Gabor frame system (or Wilson basis) in the time-frequency analysis (see, e.g., [8, 17, 26, 38, 47] and references cited therein), and spaces of polynomial splines (which are widely used as approximating spaces in data fitting problems and operator-equation problems [15, 36, 48]) as its special cases. Particularly the space $V_q(\Phi, \Lambda)$ and the shift-invariant space $V_q(\phi_1, \dots, \phi_N)$ are related as follows:

$$V_q(\Phi, \Lambda) = V_q(\phi_1, \dots, \phi_N) \tag{2.12}$$

and

$$\|\Phi\|_{q,p,u} < \infty \text{ if and only if } \phi_1, \dots, \phi_N \in W_q(L_{p,u}) \tag{2.13}$$

if we let $\Lambda := \{x_1, \dots, x_N\} + \mathbf{Z}^d$ and $\phi_\lambda := \phi_n(\cdot - k)$ if $\lambda = x_n + k$ for some $k \in \mathbf{Z}^d$, where $\{x_1, \dots, x_N\}$ is a discrete set in $\mathbf{R}^d/\mathbf{Z}^d$; see [52] for details. Here we recall that the *Wiener amalgam space* $W_q(L_{p,u})$, which consists of functions that are "locally" in L^q and "globally" in weighted L^p space with weight u [2], is defined by

$$W_q(L_{p,u}) := \Big\{ f : \ \|f\|_{W_q(L_{p,u})} := \big\| \big(\|fu\|_{L^q(k+[0,1]^d)} \big)_{k \in \mathbf{Z}^d} \big\|_{\ell^p(\mathbf{Z}^d)} < \infty \Big\}. \tag{2.14}$$

The prototypical space $V_q(\Phi, \Lambda)$ is suitable for modeling signals with a finite rate of innovations [23, 34, 40, 42, 44, 45, 46, 58] in, for instance, (i) stream of pulses $\sum_l a_l p(t - t_l)$ found in global positioning system (GPS) applications and cellular radio, where $p(t)$ is the antenna transmit pulse shape; (ii) stream of different pulses $\sum_l a_l p_l(t - t_l)$ found in modeling ultra wide-band, where different incoming paths are subjected to different frequency-selective attenuations; (iii) band-limited signals with additive shot noise $\sum_{k \in \mathbf{Z}} c(k)\mathrm{sinc}(t - k) + \sum_l d(l)\delta(t - t_l)$; (iv) sum of band-limited signals and nonuniform spline signals, convenient for modeling electrocardiogram signals.

The prototypical space $V_q(\Phi, \Lambda)$ retains some of the simplicity and structure of a finitely generated shift-invariant space of the form (2.10), is *amenable* to numerical implementation (see sections 5, 6, and 7), and is more *flexible* for approximating real data than the band-limited model and the shift-invariant model (see [52] for details).

So in this paper, we make the following basic assumption on the space V in which functions are sampled and recovered:

(iii) *The space V is of the form $V_q(\Phi, \Lambda)$, where $1 \le q \le \infty$, Λ is a relatively separated subset of $\mathbf{R}^d$, and $\Phi = \{\phi_\lambda : \lambda \in \Lambda\}$ is a family of functions on $\mathbf{R}^d$ satisfying $\|\Phi\|_{q,p,u} < \infty$ for some $1 \le p \le \infty$ and weight u.*

Remark 2.3. Signals in the space $V := V_q(\Phi, \Lambda)$, which satisfies the above basic assumption (iii), have a finite rate of innovation because a signal $f = \sum_{\lambda \in \Lambda} c(\lambda)\phi_\lambda \in V_q(\Phi, \Lambda)$ on a unit interval $t + [-1/2, 1/2)^d$ is essentially determined by the coefficients $c(\lambda)$ with $\lambda \in t + [-1/2, 1/2)^d$ because of the well-localization property of the generator Φ, and the total number of the locations $\lambda \in \Lambda$ on the unit interval $t + [-1/2, 1/2)^d$ is bounded by some constant C_0 independent of the center t of the unit interval due to the relative separatedness of the location Λ of the generator Φ.

Remark 2.4. We provide some flexibility on the assumption $\|\Phi\|_{q,p,u} < \infty$ on the generator Φ of the space $V_q(\Phi, \Lambda)$ for adapting to different modeling situations. For instance, we may use $q = 1$ and $p = \infty$ when modeling slow-varying signals with shot noises [58], $1 \le p, q \le \infty$ when modeling signals in a finitely generated shift-invariant space [2], and $q = \infty$ and $1 \le p \le \infty$ for decomposing a time signal via (non-)uniform Gabor frame system or Wilson basis [26].

2.4. The space $V_q(\Phi,\Lambda)$ for modeling signals with a finite rate of innovations. Let $\delta_{\lambda\lambda'}$ stand for the usual Kronecker symbol. For a Hilbert space H with $E=\{e_\lambda,\lambda\in\Lambda\}$ being its Riesz basis, we say that $E^d=\{e_\lambda^d:\ \lambda\in\Lambda\}\subset H$ is a *dual Riesz basis* of E if E^d is a Riesz basis of H and $\langle e_\lambda,e_{\lambda'}^d\rangle=\delta_{\lambda\lambda'}$ for all $\lambda,\lambda'\in\Lambda$, and we say that $E^o=\{e_\lambda^o:\ \lambda\in\Lambda\}$ is an *orthonormal basis* for H if E^o is a basis of H and $\langle e_\lambda^o,e_{\lambda'}^o\rangle=\delta_{\lambda\lambda'}$ for all $\lambda,\lambda'\in\Lambda$.

Let $1\le p\le\infty$. We say that a weight u is *p-admissible* if there exist a weight v and two positive constants $D:=D(u)\in(0,\infty)$ and $\theta:=\theta(u)\in(0,1)$ such that

$$u(x+y)\le D(u(x)v(y)+v(x)u(y))\quad\text{for all } x,y\in\mathbf{R}^d, \tag{2.15}$$

$$\|(vu^{-1})\|_{L^{p'}}\le D,\ \text{and} \tag{2.16}$$

$$\inf_{\tau>0}\|v\|_{L^1(B(\tau))}+t\|vu^{-1}\|_{L^{p'}(\mathbf{R}^d\setminus B(\tau))}\le Dt^\theta\quad\text{for all } t\ge1, \tag{2.17}$$

where $p'=p/(p-1)$ and $B(\tau)=\{x\in\mathbf{R}^d:|x|\le\tau\}$. The p-admissibility of a weight u is a technical condition in [51] for establishing the Wiener lemma for matrix algebras of Schur class and of Sjöstrand class; see also Lemmas 8.1 and 8.2. It is verified in [51] that the polynomial weight u_α with $\alpha>d(1-1/p)$ and the subexponential weight $e_{D,\delta}$ with $D>0$ and $\delta\in(0,1)$ are p-admissible weights. The reader may refer to those two model examples for simplification; see also subsection 2.5.

Now we recall some properties of the space $V_q(\Phi,\Lambda)$ in [52]; see, e.g., [2, 39] for similar results for our familiar shift-invariant setting.

PROPOSITION 2.1 (see [52]). *Let $1\le q\le\infty$, $u_\alpha(x):=(1+|x|)^\alpha,\alpha\ge0$, be the polynomial weights, Λ be a relatively separated subset of $\mathbf{R}^d$, $\Phi=\{\phi_\lambda,\lambda\in\Lambda\}$ satisfy $\|\Phi\|_{q,1,u_0}<\infty$, and $V_q(\Phi,\Lambda)$ be defined as in* (2.11). *Then $V_q(\Phi,\Lambda)\subset L^q$. Moreover,*

$$\Big\|\sum_{\lambda\in\Lambda}c(\lambda)\phi_\lambda\Big\|_{L^r}\le C\big\|\big(c(\lambda)\big)_{\lambda\in\Lambda}\big\|_{\ell^r(\Lambda)}\|\Phi\|_{q,1,u_0} \tag{2.18}$$

for every sequence $(c(\lambda))_{\lambda\in\Lambda}\in\ell^r(\Lambda)$ with $1\le r\le q$, and

$$\big\|\big(\langle f,\phi_\lambda\rangle\big)_{\lambda\in\Lambda}\big\|_{\ell^r(\Lambda)}\le C\|f\|_{L^r}\|\Phi\|_{q,1,u_0} \tag{2.19}$$

for all $f\in L^r$ with $q/(q-1)\le r\le\infty$.

PROPOSITION 2.2 (see [52]). *Let $2\le q\le\infty$, $1\le p\le\infty$, u be a p-admissible weight, Λ be a relatively separated subset of $\mathbf{R}^d$, $\Phi=\{\phi_\lambda,\lambda\in\Lambda\}$ be a family of functions on $\mathbf{R}^d$, $V_2(\Phi,\Lambda)$ be as in* (2.11), *and the frame operator S on $V_2(\Phi,\Lambda)$ be defined by*

$$Sf=\sum_{\lambda\in\Lambda}\langle f,\phi_\lambda\rangle\phi_\lambda,\quad f\in V_2(\Phi,\Lambda). \tag{2.20}$$

Assume that Φ is a Riesz basis for $V_2(\Phi,\Lambda)$ and satisfies $\|\Phi\|_{q,p,u}<\infty$. Then $S^{-1}\Phi:=\{S^{-1}\phi_\lambda:\lambda\in\Lambda\}$ is a dual Riesz basis of Φ, $S^{-1/2}\Phi:=\{S^{-1/2}\phi_\lambda:\lambda\in\Lambda\}$ is an orthonormal basis of $V_2(\Phi,\Lambda)$, and $\|S^{-1}\Phi\|_{q,p,u}+\|S^{-1/2}\Phi\|_{q,p,u}<\infty$. If we further assume that Λ is a lattice, and that the generator Φ of the space $V_2(\Phi,\Lambda)$ is enveloped by a function in the Wiener amalgam space $W_\infty(L_{p,u})$ (hence $\|\Phi\|_{q,p,u}\le\|\Phi\|_{\infty,p,u}\le C\|h\|_{W_\infty(L_{p,u})}<\infty$), i.e., $|\phi_\lambda(x)|\le h(x-\lambda)$ for some $h\in W_\infty(L_{p,u})$, then so are dual Riesz basis $S^{-1}\Phi$ and orthonormal basis $S^{-1/2}\Phi$.

Remark 2.5. Let $1 \le p, r \le \infty$; we say that a weight u is (p,r)-*admissible* (or we say that $w(x,y) := u(x-y)$ is a (p,r)-admissible translation-invariant weight [51]) if there exist a weight v and two positive constants $D \in (0,\infty)$ and $\theta \in (0,1)$ such that (2.15), (2.16), and

$$\inf_{\tau>0} \|v\|_{L^{r'}(B(\tau))} + t\|vu^{-1}\|_{L^{p'}(\mathbf{R}^d \setminus B(\tau))} \le Dt^{\theta} \quad \text{for all } t \ge 1 \tag{2.21}$$

hold, where $p' = p/(p-1)$ and $r' = r/(r-1)$. Clearly the p-admissibility of a weight agrees with its (p,∞)-admissibility. Since for any weight v it holds that $\|v\|_{L^{r'}(B(\tau))} \le C\|v\|_{L^1(B(\tau))}$ for all $\tau \ge 1$, we then conclude that p-admissibility of a weight implies its (p,r)-admissibility for any $1 \le r \le \infty$.

2.5. Model. The reader may consider the following model for simplification:

(i) The generator $\Phi := \{\phi_\lambda, \lambda \in \Lambda\}$ of the space $V_r(\Phi,\Lambda)$ is enveloped by some function g in the Wiener amalgam space $W_q(L_{p,u})$ with $2 \le q \le \infty$, i.e.,

$$|\phi_\lambda(x)| \le g(x-\lambda) \quad \text{for all } x \in \mathbf{R}^d \text{ and } \lambda \in \Lambda. \tag{2.22}$$

(The above envelopment assumption (2.22) for the generator Φ implies that the basic assumption (iii) $\|\Phi\|_{q,p,u} < \infty$ for the generator Φ is satisfied. The converse is true in the shift-invariant setting, $V_r(\Phi,\Lambda) = V_r(\phi_1,\dots,\phi_N)$; particularly, the above envelopment property for the generator Φ of the space $V_r(\Phi,\Lambda)$ is equivalent to the basic assumption (iii) $\|\Phi\|_{q,p,u} < \infty$, and also equivalent to the property that the generators $\phi_1,\dots,\phi_N$ of the space $V_2(\phi_1,\dots,\phi_N)$ belong to the Wiener amalgam space $W_q(L_{p,u})$. The envelopment assumption (2.22) for the generator Φ is not satisfied when the space $V_q(\Phi,\Lambda)$ is used for modeling slow-varying signals with shot noises [42].)

(ii) The average sampler $\Psi = \{\psi_\gamma : \gamma \in \Gamma\}$ is enveloped by some function h in the Wiener amalgam space $W_{q^*}(L_{p,u})$ with $q/(q-1) \le q^* \le \infty$, i.e.,

$$|\psi_\gamma(x)| \le h(x-\gamma) \quad \text{for all } x \in \mathbf{R}^d \text{ and } \gamma \in \Gamma. \tag{2.23}$$

(The above envelopment assumption (2.23) for the average sampler Ψ implies that the basic assumption (ii) $\|\Psi\|_{q^*,p,u} < \infty$ for the average sampler Ψ is satisfied. The above envelopment assumption (2.23) for the average sampler Ψ is not satisfied when it is a family of approximating delta functionals with variable width [28].)

(iii) The weight u in the above envelopment assumptions on the generator Φ and the average sampler Ψ is the polynomial weight $u_\alpha(x) := (1+|x|)^\alpha$ with $\alpha > d(1-1/p)$ or the exponential weight $e_{D,\delta}(x) := \exp(D|x|^\delta)$ with $D > 0$ and $\delta \in (0,1)$.

Remark 2.6. Given an exponent $p \in [1,\infty]$, a weight u, and two relatively separated subsets Γ, Γ' of $\mathbf{R}^d$, we define the *matrix algebra* $\mathcal{C}_{p,u}(\Gamma,\Gamma')$ *of Sjöstrand class* by

$$\mathcal{C}_{p,u}(\Gamma,\Gamma') := \big\{A := (A(\gamma,\gamma'))_{\gamma,\gamma'\in\Gamma},\ \|A\|_{\mathcal{C}_{p,u}} < \infty\big\}, \tag{2.24}$$

where

$$\|A\|_{\mathcal{C}_{p,u}} := \|(Au)_*(k))_{k\in\mathbf{Z}^d}\|_{\ell^p}$$

and

$$(Au)_*(k) = \sup_{\gamma\in m+[-1/2,1/2)^d, \gamma'\in m+k+[-1/2,1/2)^d, m\in\mathbf{Z}^d} |A(\gamma,\gamma')u(\gamma-\gamma')|,\ k \in \mathbf{Z}^d$$

(see, e.g., [8, 10, 27, 49, 51]). For the case when $q = \infty, 1 \le p \le \infty$, and Γ is a lattice, the envelopment property (2.23) for the average sampler $\Psi := \{\psi_\gamma,\ \gamma \in \Gamma\}$ is characterized by $(\|\psi_\gamma\|_{L^q(\mu+[0,1]^d)})_{\gamma,\mu\in\Gamma} \in \mathcal{C}_{p,u}(\Gamma,\Gamma)$. Here a subset X of $\mathbf{R}^d$ is said to be a *lattice* if $1 \le \sum_{x_j\in X} \chi_{x_j+[0,1]^d}(x) \le D(X)$ for all $x \in \mathbf{R}^d$ and some $D(X) < \infty$.

3. Well-localized displayer. Let $1 \le q \le \infty$ and V be a subspace of L^q. We say that Γ, a subset of $\mathbf{R}^d$, is a *stable ideal sampling set* for the space V if there exist two positive constants A, B such that

$$A\|f\|_{L^q} \le \|(f(\gamma))_{\gamma\in\Gamma}\|_{\ell^q(\Gamma)} \le B\|f\|_{L^q} \quad \text{for all } f \in V, \tag{3.1}$$

and that $\Psi = \{\psi_\gamma : \gamma \in \Gamma\}$, a family of average sampling functionals, is a *stable averaging sampler* for the space V if there exist two positive constants A', B' such that

$$A'\|f\|_{L^q} \le \|(\langle f, \psi_\gamma\rangle)_{\gamma\in\Gamma}\|_{\ell^q(\Gamma)} \le B'\|f\|_{L^q} \quad \text{for all } f \in V \tag{3.2}$$

(see [5]). From the above definitions of a stable ideal sampling set Γ and a stable average sampler Ψ, we have that any function $f \in V$ can be reconstructed uniquely and stably from its samples $\{f(\gamma) :\ \gamma \in \Gamma\}$ if Γ is a stable ideal sampling set for V, and similarly that any function $f \in V$ can be reconstructed uniquely and stably from its average samples $\{\langle f, \psi_\gamma\rangle :\ \gamma \in \Gamma\}$ if Ψ is a stable averaging sampler for V.

For average (ideal) sampling on the space $V_2(\Phi, \Lambda)$, derived from a general theorem for localized frames (see [8, Theorem 1], [24, Theorem 3.6], and [32, Theorem 13]), we have the following well-localization results for its displayer (Theorems 3.1 and 3.2); see Remark 3.1 for a more general formulation of the well-localization of a displayer. From those results, it concludes that the displayer $\tilde\Psi$ associated with a stable (ideal) averaging sampler Ψ has the same polynomial (subexponential) decay when both the average sampler Ψ and the generator Φ for the space $V_2(\Phi, \Lambda)$ have polynomial (subexponential) decay.

THEOREM 3.1. *Let $2 \le q \le \infty, q/(q-1) \le q^* \le \infty, 1 \le r \le q, 1 \le p \le \infty$, u be a p-admissible weight, the subsets Λ, Γ of $\mathbf{R}^d$ be relatively separated, the generator $\Phi = \{\phi_\lambda : \lambda \in \Lambda\}$ satisfy*

$$\|\Phi\|_{q,p,u} < \infty, \tag{3.3}$$

the average sampler $\Psi = \{\psi_\gamma : \gamma \in \Gamma\}$ satisfy

$$\|\Psi\|_{q^*,p,u} < \infty, \tag{3.4}$$

and the space $V_r(\Phi, \Lambda)$ be as in (2.11). Assume that Φ is a Riesz basis of $V_2(\Phi, \Lambda)$ and that Ψ is a stable averaging sampler for $V_2(\Phi, \Lambda) \subset L^2$. Then there exists a displayer $\tilde\Psi = \{\tilde\psi_\gamma : \gamma \in \Gamma\} \subset V_1(\Phi, \Lambda)$ such that

$$\|\tilde\Psi\|_{q,p,u} < \infty, \tag{3.5}$$

and

$$f = \sum_{\gamma\in\Gamma} \langle f, \psi_\gamma\rangle \tilde\psi_\gamma \quad \text{for all } f \in V_r(\Phi, \Lambda). \tag{3.6}$$

If we further assume that Λ is a lattice and that the generator Φ and the average sampler Ψ are enveloped by some functions in the Wiener amalgam space $W_\infty(L_{p,u})$, then so is the displayer $\tilde\Psi$.

THEOREM 3.2. *Let $1 \le p, r \le \infty$, u be a p-admissible weight, the subsets Λ, Γ of $\mathbf{R}^d$ be relatively separated, $\Phi = \{\phi_\lambda : \lambda \in \Lambda\}$ be a family of continuous functions on $\mathbf{R}^d$ that satisfies*

$$\|\Phi\|_{\infty,p,u} < \infty, \tag{3.7}$$

and the space $V_r(\Phi, \Lambda)$ be as in (2.11). *Assume that Φ is a Riesz basis of $V_2(\Phi, \Lambda)$, and that Γ is a stable ideal sampling set for $V_2(\Phi, \Lambda) \subset L^2$. Then there exists a displayer $\tilde{\Psi} = \{\tilde{\psi}_\gamma : \gamma \in \Gamma\}$ such that $\tilde{\Psi} \subset V_1(\Phi, \Lambda)$, $\|\tilde{\Psi}\|_{\infty,p,u} < \infty$, and*

$$f = \sum_{\gamma\in\Gamma} f(\gamma)\tilde{\psi}_\gamma \quad \text{for all } f \in V_r(\Phi, \Lambda). \tag{3.8}$$

If we further assume that Γ is a lattice and that Φ is enveloped by a function in the Wiener amalgam space $W_\infty(L_{p,u})$, then so is the displayer $\tilde{\Psi}$.

Remark 3.1. For the well-localization of the displayer $\tilde{\Psi}$, the following general principle can be derived from theorems for localized frames (see [8, Theorem 1], [24, Theorem 3.6], and [32, Theorem 13]): Let Λ and Γ be two index sets, and let the families $\mathcal{A}(\Lambda) = \{(a(\lambda, \lambda'))_{\lambda,\lambda'\in\Lambda}\}$ and $\mathcal{A}(\Gamma, \Lambda) = \{(a(\gamma, \lambda))_{\gamma\in\Gamma,\lambda\in\Lambda}\}$ of infinite matrices have the following algebraic properties that (i) $\mathcal{A}(\Lambda)$ is an inverse-closed matrix algebra in $\mathcal{B}(\ell^2(\Lambda))$ (the space of all bounded operators on $\ell^2(\Lambda)$), (ii) $A^T A \in \mathcal{A}(\Lambda)$ for any $A \in \mathcal{A}(\Gamma, \Lambda)$, and (iii) $AB \in \mathcal{A}(\Gamma, \Lambda)$ for any $A \in \mathcal{A}(\Gamma, \Lambda)$ and $B \in \mathcal{A}(\Lambda)$. Then on the space $V_2(\Phi, \Lambda)$ whose generator $\Phi := (\phi_\lambda)_{\lambda\in\Lambda}$ is a frame, there exists an $\mathcal{A}(\Gamma, \Lambda)$-localized displayer $\tilde{\Psi} := (\tilde{\psi}_\gamma)_{\gamma\in\Gamma}$ associated with a stable average sampling processing

$$V_2(\Phi, \Lambda) \ni f \longmapsto \langle f, \Psi\rangle \in \ell^2(\Gamma) \tag{3.9}$$

whose average sampler $\Psi := (\psi_\gamma)_{\gamma\in\Gamma}$ is $\mathcal{A}(\Gamma, \Lambda)$-localized. Here we say that $\Psi := (\psi_\gamma)_{\gamma\in\Gamma}$ is $\mathcal{A}(\Gamma, \Lambda)$-localized on $V_2(\Phi, \Lambda)$ if $A_{\Psi,\Phi} := (\langle\psi_\gamma, \phi_\lambda\rangle)_{\gamma\in\Gamma,\lambda\in\Lambda} \in \mathcal{A}(\Gamma, \Lambda)$ and $A_{\Psi,\tilde{\Phi}} := (\langle\psi_\gamma, \tilde{\phi}_\lambda\rangle)_{\gamma\in\Gamma,\lambda\in\Lambda} \in \mathcal{A}(\Gamma, \Lambda)$, where $\tilde{\Phi} = (\tilde{\phi}_\lambda)_{\lambda\in\Lambda}$ is the dual frame generator $\tilde{\Phi}$ associated with the frame Φ. Thus the well-localization for the displayer in Theorems 3.1 and 3.2 becomes essentially a concrete example of the above general principle (particularly in Theorems 3.1 and 3.2, the Schur class $\mathcal{A}_{p,u}(\Gamma, \Lambda)$ and the Sjöstrand class $\mathcal{C}_{p,u}(\Gamma, \Lambda)$ are used as $\mathcal{A}(\Gamma, \Lambda)$ in the above principle, and $\mathcal{A}_{p,u}(\Lambda, \Lambda)$ and $\mathcal{C}_{p,u}(\Lambda, \Lambda)$ as $\mathcal{A}(\Lambda)$). The well-localization of the displayer in the above principle and the localization of the dual frame in the theory of frames are equivalent since for the case when $\Psi \in V_2(\Phi, \Lambda)$ (otherwise replacing Ψ with the projection $P\Psi$ of Ψ on $V_2(\Phi, \Lambda)$; see Remark 3.2 below) the stability of the average sampling process (3.9) is equivalent to the frame property for Ψ, and the displayer $A_{\Psi,\Phi}(A_{\Psi,\Phi}^T A_{\Psi,\Phi})^\dagger\Phi$ associated with the average sampling processing (3.9) is the canonical dual frame associated with the frame Ψ, where $(A_{\Psi,\Phi}^T A_{\Psi,\Phi})^\dagger$ is the pseudo-inverse of the matrix $A_{\Psi,\Phi}^T A_{\Psi,\Phi}$. Therefore the above principle for the well-localization of a displayer is established (i) in [8, Theorem 1] for the case when $\Psi = \Phi$, $\Gamma = \Lambda$, $\mathcal{A}(\Lambda, \Lambda)$, and $\mathcal{A}(\Lambda)$ are the Sjöstrand class $\mathcal{C}_{1,0}(\Lambda, \Lambda)$ defined by

$$\mathcal{C}_{1,0}(\Lambda, \Lambda) = \left\{(c(\lambda, \lambda')_{\lambda,\lambda'\in\Lambda} : \left(\sup_{a(\lambda)-a(\lambda')=g\in G} |c(\lambda, \lambda')|\right)_{g\in G} \in \ell^1(G)\right\},$$

where G is an additive discrete group of the form $B_0\mathbf{Z}^d \times (\mathbf{Z}^{d'}/B_1\mathbf{Z}^{d'})$ for some nonsingular diagonal matrices B_0 and B_1, and $a : \Lambda \to G$ is a map with $\sup_{g\in G} \#\{\lambda \in \Lambda : \ a(\lambda) = g\} < \infty$; (ii) in [24, Theorem 3.6] for the case when $\Psi = \Phi$, $\Gamma = \Lambda$, $\mathcal{A}(\Lambda, \Lambda)$ and $\mathcal{A}(\Lambda)$ are a solid, inverse-closed, involute Banach algebra; and (iii) in [32, Theorem 13] for the case that $\Lambda = \mathbf{Z}^d$, Γ is a relative separated subset of $\mathbf{R}^d$, $\mathcal{A}(\Lambda) = \mathcal{A}$, and $\mathcal{A}(\Gamma, \Lambda) = \{(a(\gamma, k))_{\gamma\in\Gamma,k\in\mathbf{Z}^d} : \ (\tilde{a}(m, n))_{m,n\in\mathbf{Z}^d} \in \mathcal{A}\}$, where $\mathcal{A}$ is a solid, inverse-closed, involute Banach algebra, and

$$\tilde{a}(m, n) = \begin{cases} \sup_{\gamma\in(m+[0,1)^d)\cap\Gamma} |a(\gamma, n)| & \text{if } (m + [0, 1)^d) \cap \Gamma \neq \emptyset, \\ 0 & \text{if } (m + [0, 1)^d) \cap \Gamma = \emptyset. \end{cases}$$

The above principle for the well-localization of the displayer can be derived from [32, Theorem 13] with identical proof.

Remark 3.2. Let $\Phi = \{\phi_\lambda : \lambda \in \Lambda\}$ and $\Psi = \{\psi_\gamma : \gamma \in \Gamma\}$ be as in either Theorem 3.1 or Theorem 3.2, and let $S^{-1}\Phi = \{S^{-1}\phi_\lambda : \lambda \in \Lambda\}$ be the dual Riesz basis for the space $V_2(\Phi, \Lambda)$ in Proposition 2.2. By Propositions 2.1 and 2.2, the operator P defined by $Pf := \sum_{\lambda\in\Lambda}\langle f, S^{-1}\phi_\lambda\rangle\phi_\lambda$ is a projection operator from L^2 to $V_2(\Phi, \Lambda)$. We can extend the domain of the projection operator P so that $P\psi_\gamma$ is well defined for every sampling functional ψ_γ in the average sampling case and for the delta functional δ_γ in the ideal sampling case. Moreover, $\langle f, \psi_\gamma\rangle = \langle f, P\psi_\gamma\rangle$ for all $\gamma \in \Gamma$ and $f \in V_2(\Phi, \Lambda)$. We then have that if Ψ is a stable average sampler, then $P\Psi = \{P\psi_\gamma : \gamma \in \Gamma\}$ is a frame of $V_2(\Phi, \Lambda)$; that is, there exist two positive constants $A, B > 0$ such that

$$A\|f\|_2 \le \|(\langle f, P\psi_\gamma\rangle)_{\gamma\in\Gamma}\|_{\ell^2(\Gamma)} \le B\|f\|_2 \quad \text{for all } f \in V_2(\Phi, \Lambda). \tag{3.10}$$

So by the general frame theory, a displayer $\tilde{\Psi} \subset V_2(\Phi, \Lambda)$, which *may or may not* have polynomial (subexponential) decay, can be constructed, while we show in Theorems 3.1 and 3.2 that a displayer $\tilde{\Psi}$ can be constructed to has polynomial (subexponential) decay whenever the generator Φ and the average sampler Ψ have it. The reader may refer to [2] and references cited therein for the connection among average (ideal) sampling, reproducing kernel Hilbert space, and frame theory in the shift-invariant setting.

By Theorems 3.1 and 3.2, we have the following corollary for the uniform sampling in the familiar shift-invariant space.

COROLLARY 3.3. *Let $1 \le p \le \infty, 2 \le q \le \infty, 1 \le r \le q, q/(q-1) \le q^* \le \infty$, u be the polynomial weight u_α with $\alpha > d(1 - 1/p)$ or the subexponential weight $e_{D,\delta}$ with $D > 0$ and $\delta \in (0, 1)$, and $\phi_1, \dots, \phi_N \in W_q(L_{p,u})$, and $\Phi = \{\phi_n(\cdot - k) : \ 1 \le n \le N, k \in \mathbf{Z}^d\}$ be a Riesz basis of $V_2(\phi_1, \dots, \phi_N)$. Then we have that*

(i) *if $\psi_1, \dots, \psi_L \in W_{q^*}(L_{p,u})$, and $\Psi := \{\psi_l(\cdot-k) : 1 \le l \le L, k \in \mathbf{Z}^d\}$ is a stable average sampler for $V_2(\phi_1, \dots, \phi_N)$, then there exist functions $\tilde{\psi}_1, \dots, \tilde{\psi}_L \in W_q(L_{p,u})$ such that $f = \sum_{l=1}^L \sum_{k\in\mathbf{Z}^d}\langle f, \psi_l(\cdot - k)\rangle\tilde{\psi}_l(\cdot - k)$ holds for all $f \in V_r(\phi_1, \dots, \phi_N)$.*

(ii) *if $\phi_1, \dots, \phi_N$ are continuous functions in $W_\infty(L_{p,u})$, and $X_0 + \mathbf{Z}^d$ is a stable ideal sampling set for $V_2(\phi_1, \dots, \phi_N)$, where $X_0 = \{x_1, \dots, x_L\} \subset [0, 1)^d$, then there exist continuous functions $\tilde{\psi}_1, \dots, \tilde{\psi}_L \in W_\infty(L_{p,u})$ such that $f = \sum_{l=1}^L \sum_{k\in\mathbf{Z}^d} f(x_l + k)\tilde{\psi}_l(\cdot - k)$ holds for all $f \in V_r(\phi_1, \dots, \phi_N)$.*

Remark 3.3. For the shift-invariant setting $V_2(\Phi, \Lambda) = V_2(\phi_1, \dots, \phi_N)$ for some functions $\phi_1, \dots, \phi_N$, it is shown in [28] that if the generator $\phi_1, \dots, \phi_N$ satisfies $|\phi_n(x)| \le C_0(1 + |x|)^{-\alpha}$ for all $1 \le n \le N$ and $x \in \mathbf{R}^d$, (i.e., $\|\Phi\|_{\infty,\infty,u_\alpha} < \infty$, where $\Phi := \{\phi_n(\cdot - k), \ 1 \le n \le N, k \in \mathbf{Z}^d\}$), and if the average sampling functional

ψ_γ is supported in $\gamma + [-a, a]$ and $\|\psi_\gamma\|_{L^1} \le C_0$ for some positive constants C_0 and a (which implies that $\|\Psi\|_{1,\infty,u} < \infty$ for any weight u, where $\Psi := \{\psi_\gamma,\ \gamma \in \Gamma\}$), then the corresponding displayer $\tilde{\Psi} := \{\tilde{\psi}_\gamma : \gamma \in \Gamma\}$ can be chosen to satisfy $|\tilde{\psi}_\gamma(x)| \le C_1(1 + |x - \gamma|)^{-\alpha}$ for some positive constant C_1 (i.e., $\|\tilde{\Psi}\|_{\infty,\infty,u_\alpha} < \infty$). A similar result for the ideal sampling process is also established in [28]. The above results for the average (ideal) sampling process follow from Theorems 3.1 and 3.2 with $p = q = \infty, q^* = 1, u = u_\alpha$, and $V_2(\Phi, \Lambda)$ being a finitely generated shift-invariant space. Other than those exponents p, q, q^* and weight u mentioned above, the results in Theorems 3.1 and 3.2 are new even for our familiar shift-invariant setting.

By Theorems 3.1 and 3.2, we have the following result for the stability of the average sampler Ψ in the space $V_r(\Phi, \Lambda) \subset L^r$ with $r \ne 2$, which can also derived from [24, Theorem 2.7] and [28, Theorem 10].

COROLLARY 3.4. *Let $2 \le q \le \infty, 1 \le p \le \infty$, u be a p-admissible weight, and the subsets Λ, Γ of $\mathbf{R}^d$ be relatively separated. Then we have that*

(i) *if Φ is a Riesz basis of $V_2(\Phi, \Lambda)$ and satisfies* (3.3)*, and if Ψ is a stable averaging sampler for $V_2(\Phi, \Lambda) \subset L^2$ and satisfies* (3.4) *for some $q/(q-1) \le q^* \le \infty$, then the stable average sampler Ψ for $V_2(\Phi, \Lambda)$ is also a stable averaging sampler for $V_r(\Phi, \Lambda) \subset L^r$ for all $q^*/(q^*-1) \le r \le q$.*

(ii) *if the family $\Phi = \{\phi_\lambda : \lambda \in \Lambda\}$ of continuous functions on $\mathbf{R}^d$ is a Riesz basis of $V_2(\Phi, \Lambda)$ and satisfies* (3.7)*, and if Γ is a stable ideal sampling set for $V_2(\Phi, \Lambda)$, then the ideal sampling set Γ for $V_2(\Phi, \Lambda)$ is also a stable ideal sampling set for $V_r(\Phi, \Lambda) \subset L^r$ for all $1 \le r \le \infty$.*

Remark 3.4. By Corollary 3.4, the stability of the average (ideal) sampler for $V_2(\Phi, \Lambda) \subset L^2$ implies the stability of the average (ideal) sampler for $V_r(\Phi, \Lambda) \subset L^r$ with $r \ne 2$. Such an implication can also be derived from [24, Theorem 2.7] and [28, Theorem 10], where the formulation of localized frames are used. (The author thank the anonymous referee for pointing out that derivation.) The above implication is observed in [22, 28] for the shift-invariant setting under slightly stronger assumptions on the average sampler Ψ, the generator Φ, and the nonuniform sampling set Γ than the ones in Corollary 3.4. As for the case when the average sampler and the generator are identical and when the grid Λ and the sampling set Γ are $\mathbf{Z}^d$, the above implication has long been known (and even the converse is also true); see, for instance, [7, 39].

4. Stability of the average (ideal) sampling/reconstruction process. For a matrix $A := (A(\lambda, \lambda'))_{\lambda \in \Lambda, \lambda \in \Lambda'}$, we define its transpose A^* by $A^* := (\overline{A(\lambda, \lambda')})_{\lambda' \in \Lambda', \lambda \in \Lambda}$. For a space $V_2(\Phi, \Lambda)$ generated by $\Phi := \{\phi_\lambda, \lambda \in \Lambda\}$, an average sampling on the space $V_2(\Phi, \Lambda)$ with the average sampler $\Psi := \{\psi_\gamma, \gamma \in \Gamma\}$, and an ideal sampling on the space $V_2(\Phi, \Lambda)$ with the sampling set Γ, we define the subspace H of ℓ^2 by

$$H = \{(\langle f, \phi_\lambda \rangle)_{\lambda \in \Lambda} :\ f \in V_2(\Phi, \Lambda)\}, \tag{4.1}$$

and two Gram matrices $A_{\Psi,\Phi}$ and $A_{\delta_\Gamma,\Phi}$ by

$$A_{\Psi,\Phi} = \big(\langle \psi_\gamma, \phi_\lambda \rangle\big)_{\gamma \in \Gamma, \lambda \in \Lambda} \tag{4.2}$$

and

$$A_{\delta_\Gamma,\Phi} = \big(\phi_\lambda(\gamma)\big)_{\gamma \in \Gamma, \lambda \in \Lambda}. \tag{4.3}$$

THEOREM 4.1. *Let $2 \le q \le \infty, q/(q-1) \le q^* \le \infty; q^*/(q^*-1) \le r \le q; 1 \le p \le \infty$; u be a p-admissible weight; the subsets Λ, Γ of $\mathbf{R}^d$ be relatively separated; the*

generator $\Phi = \{\phi_\lambda : \lambda \in \Lambda\}$ *satisfy* $\|\Phi\|_{q,p,u} < \infty$*; the average sampler* $\Psi = \{\psi_\gamma : \gamma \in \Gamma\}$ *satisfy* $\|\Psi\|_{q^*,p,u} < \infty$*; and the space* $V_r(\Phi, \Lambda)$*, the subspace* H *of* ℓ^2*, and the matrix* $A_{\Psi,\Phi}$ *be as in* (2.11), (4.1)*, and* (4.2)*, respectively. Assume that* Φ *is a frame of* $V_2(\Phi, \Lambda)$*. Then* Ψ *is a stable averaging sampler for* $V_2(\Phi, \Lambda) \subset L^2$ *if and only if there exists a positive constant* C *such that*

$$C^{-1}\|c\|^2_{\ell^2(\Lambda)} \le \langle (A_{\Psi,\Phi})^* A_{\Psi,\Phi} c, c\rangle \le C\|c\|^2_{\ell^2(\Lambda)} \text{ for all } c \in H. \tag{4.4}$$

THEOREM 4.2. *Let* $1 \le p, r \le \infty$*;* u *be a* p*-admissible weight; the subsets* Λ, Γ *of* $\mathbf{R}^d$ *be relatively separated;* $\Phi = \{\phi_\lambda : \lambda \in \Lambda\}$ *be a family of continuous functions on* $\mathbf{R}^d$ *that satisfies* (3.7)*; and the space* $V_r(\Phi, \Lambda)$*, the space* H*, and the matrix* $A_{\delta_\Gamma,\Phi}$ *be as in* (2.11)*,* (4.1)*, and* (4.3)*, respectively. Assume that* Φ *is a frame of* $V_2(\Phi, \Lambda)$*. Then* Γ *is a stable ideal sampling set for* $V_2(\Phi, \Lambda)$ *if and only if there exists a positive constant* C *such that*

$$C^{-1}\|c\|^2_{\ell^2(\Lambda)} \le \langle (A_{\delta_\Gamma,\Phi})^* A_{\delta_\Gamma,\Phi} c, c\rangle \le C\|c\|^2_{\ell^2(\Lambda)} \text{ for all } c \in H. \tag{4.5}$$

Remark 4.1. For the uniform average sampling on finitely generated shift-invariant spaces, that is, $V_2(\Phi, \Lambda) = V_2(\phi_1, \dots, \phi_N)$ and $\Psi = \{\psi_l(\cdot - k), 1 \le l \le L, k \in \mathbf{Z}^d\}$ for some functions $\phi_n, 1 \le n \le N$, and $\psi_l, 1 \le l \le L$, the matrix $(A_{\Psi,\Phi})^* A_{\Psi,\Phi}$ in (4.4) can be written as

$$(A_{\Psi,\Phi})^* A_{\Psi,\Phi} = \left(\sum_{l=1}^{N} \sum_{j \in \mathbf{Z}^d} \langle \phi_n(\cdot - k), \psi_l(\cdot - j)\rangle \langle \psi_l(\cdot - j), \phi_{n'}(\cdot - k')\rangle \right)_{(n,k),(n',k') \in \{1,\dots,N\} \times \mathbf{Z}^d}.$$

Due to the shift-invariant structure of the matrix $(A_{\Psi,\Phi})^* A_{\Psi,\Phi}$, we may use the Fourier technique to interpret (4.4) in Theorem 4.1 as

$$C^{-1} G(\xi) \le A_{as}(\xi) \le C G(\xi) \text{ a.e. } \xi \in \mathbf{R}^d, \tag{4.6}$$

where the Fourier transform $\hat{f}$ of an integrable function f is defined by $\hat{f}(\xi) = \int_{\mathbf{R}^d} f(x) e^{-ix\xi} dx$, and the $N \times N$ matrices $G(\xi)$ and $A_{as}(\xi)$ are defined by

$$G(\xi) = \left(\sum_{k \in \mathbf{Z}^d} \widehat{\phi}_n(\xi + 2k\pi) \overline{\widehat{\phi}_{n'}(\xi + 2k\pi)} \right)_{1 \le n, n' \le N}$$

and

$$A_{as}(\xi) = \sum_{l=1}^{L} \sum_{k,k' \in \mathbf{Z}^d} \left(\widehat{\phi}_n(\xi + 2k\pi) \overline{\widehat{\psi}_l(\xi + 2k\pi)} \widehat{\psi}_l(\xi + 2k'\pi) \overline{\widehat{\phi}_{n'}(\xi + 2k'\pi)} \right)_{1 \le n, n' \le N}.$$

The above characterization (4.6) of the stable averaging sampler Ψ is given in [5] under weaker assumptions on the generator $\phi_1, \dots, \phi_N$ and the average sampler $\psi_1, \dots, \psi_L$ than the ones for the generator Φ and the average sampler Ψ in Theorem 4.1.

Remark 4.2. For the uniform ideal sampling on a single generated shift-invariant space, that is, $V_2(\Phi, \Lambda) = V_2(\phi)$ and $\Gamma = \mathbf{Z}^d$, the matrix $(A_{\delta_\Gamma,\Phi})^* A_{\delta_\Gamma,\Phi}$ in (4.5) can be

written as $(A_{\delta_\Gamma,\Phi})^* A_{\delta_\Gamma,\Phi} = (\sum_{j\in\mathbf{Z}^d} \phi(j-k)\phi(j-k'))_{k,k'\in\mathbf{Z}^d}$. Similar to the uniform average sampling case, we may use the Fourier technique to interpret (4.5) in Theorem 4.2 as follows: $C^{-1} \le |\sum_{k\in\mathbf{Z}^d} \widehat{\phi}(\xi+2k\pi)| \le C$ for almost all $\xi \in \mathbf{R}^d$, which was given in [60].

Remark 4.3. For the characterization of the stable average sampler and stable ideal sampling set for various spaces, there is an extensive literature (see, for instance, the recent review papers [2, 57] and monographs [12, 14, 43] for ideal sampling, and [1, 2, 4, 5, 6, 28, 53, 54, 55] for average sampling).

5. Robustness of the reconstruction process. For the numerical stability of the reconstruction formulas (3.6) and (3.8) when the average (ideal) sampling data and the displayer are corrupted, for instance, by the noise in the measurement, we have the following result.

THEOREM 5.1. *Let $p, q, q^*, r, u, \Lambda, \Gamma, \Phi, \Psi, \tilde{\Psi}$ be as either in Theorem* 3.1 *or in Theorem* 3.2. *Assume that the original function f belongs to $V_r(\Phi,\Lambda)$, and that $G = \{g_\gamma : \gamma\in\Gamma\}$ and $\tilde{\Psi}' = \{\tilde{\psi}'_\gamma : \gamma\in\Gamma\}$ are the corrupted average sampling data and displayer, respectively. Then there exists a positive constant C (independent of f, G, and $\tilde{\Psi}'$) such that*

$$\begin{aligned}\left\| f - \sum_{\gamma\in\Gamma} g_\gamma \tilde{\psi}'_\gamma \right\|_r &\le C\|(g_\gamma - \langle f, \psi_\gamma\rangle)_{\gamma\in\Gamma}\|_{\ell^r(\Gamma)} \|\tilde{\Psi}\|_{q,p,u} \\ &\quad + C\|\tilde{\Psi} - \tilde{\Psi}'\|_{q,p,u} \|(g_\gamma)_{\gamma\in\Gamma}\|_{\ell^r(\Gamma)}. \end{aligned} \tag{5.1}$$

For the numerical stability of the reconstruction processes (3.6) and (3.8) when there is certain perturbation for the average sampler and for the ideal sampling set, we have the following results.

THEOREM 5.2. *Let $p, q, q^*, u, \Lambda, \Gamma, \Phi, \Psi, \tilde{\Psi}, V_q(\Phi,\Lambda)$ be as in Theorem* 3.1. *Then there exist a sufficiently small positive number δ_0 and a positive constant C such that any average sampler $\Psi' = \{\psi'_\gamma : \gamma\in\Gamma\}$ with the property that*

$$\|\Psi' - \Psi\|_{q^*,p,u} \le \delta_0 \tag{5.2}$$

is a stable average sampler for the space $V_2(\Phi,\Lambda)$, and the corresponding displayer $\tilde{\Psi}'$ satisfies

$$\|\tilde{\Psi}' - \tilde{\Psi}\|_{q^*,p,u} \le C\|\Psi' - \Psi\|_{q^*,p,u}. \tag{5.3}$$

THEOREM 5.3. *Let $p, u, \Lambda, \Gamma, \Phi, \tilde{\Psi}, V_q(\Phi,\Lambda)$ be as in Theorem* 3.2. *Assume that $\Phi_\delta = \{\phi_{\gamma,\delta} : \gamma\in\Gamma\}$ satisfies*

$$\|\Phi_\delta\|_{\infty,p,u} \to 0 \text{ as } \delta\to 0, \tag{5.4}$$

where $\phi_{\gamma,\delta}(x) = \sup_{|t|\le\delta} |\phi_\gamma(x+t) - \phi_\gamma(x)|$. Then there exist a sufficiently small positive number δ_0 and a positive constant C such that any sampling set $\Gamma' := \{\gamma+\delta_\gamma : \gamma\in\Gamma\}$ with $\sup_{\gamma\in\Gamma}|\delta_\gamma| \le \delta_0$ is a stable ideal sampling set for the space $V_2(\Phi,\Lambda)$, and the corresponding displayer $\tilde{\Psi}'$ satisfies $\|\tilde{\Psi}' - \tilde{\Psi}\|_{\infty,p,u} \le C\|\Phi_{\delta_0}\|_{\infty,p,u}$.

By Theorems 5.2 and 5.3, we have the following results about perturbation for nonuniform average (ideal) sampling on a finitely generated shift-invariant space.

COROLLARY 5.4. *Let $1 \le p \le \infty, 2 \le q \le \infty, q/(q-1) \le q^* \le \infty$; u be the polynomial weight u_α with $\alpha > d(1-1/p)$ or the subexponential weight $e_{D,\delta}$ with*

$D > 0$ and $\delta \in (0,1)$, $\phi_1, \ldots, \phi_N \in W_q(L_{p,u})$; Γ be a relatively separated subset of $\mathbf{R}^d$; and $\Phi := \{\phi_n(\cdot - k),\ \ 1 \le n \le N, k \in \mathbf{Z}^d\}$ be a Riesz basis of the shift-invariant space $V_2(\phi_1, \ldots, \phi_N)$. Then

(i) *if $\psi_1, \ldots, \psi_L \in W_{q^*}(L_{p,u})$, and $\Psi := \{\psi_l(\cdot - \gamma),\ 1 \le l \le L, \gamma \in \Gamma\}$ is a stable average sampler for $V_2(\phi_1, \ldots, \phi_N)$, then there exists a positive constant δ_0 such that for any functions $\theta_1, \ldots, \theta_L$ with $\sum_{l=1}^{L} \|\psi_l - \theta_l\|_{W_{q^*}(L_{p,u})} \le \delta_0$, their generating average sampler $\Theta := \{\theta_l(\cdot - \gamma),\ 1 \le l \le L, \gamma \in \Gamma\}$ is a stable average sampler for $V_2(\phi_1, \ldots, \phi_N)$.*

(ii) *if $\phi_1, \ldots, \phi_N$ are continuous functions in $W_\infty(L_{p,u})$, and Γ is a stable ideal sampling set for $V_2(\phi_1, \ldots, \phi_N)$, then there exists a positive constant δ_0 such that any relatively separated set $\tilde{\Gamma} = \{\gamma + \delta_\gamma : \gamma \in \Gamma\}$ with $\sup_{\gamma \in \Gamma} |\delta_\gamma| \le \delta_0$ is a stable ideal sampling set for $V_2(\phi_1, \ldots, \phi_N)$.*

Remark 5.1. From Corollary 5.4, we see that for the shift-invariant setting, the stability of the nonuniform average (ideal) sampling is preserved under small perturbation. Such a phenomenon is observed in [19, 41, 57] for the ideal sampling process in the band-limited spaces and the finite-generated shift-invariant spaces, and in [4] for the average sampling process in the finitely generated shift-invariant spaces. We use a different approach than the ones in [4, 19, 41, 57] to consider the perturbation problem, and then the stability under small perturbation is shown to be preserved under weak assumptions on the generator Φ and the average sampler Ψ; see, for instance, [4] in which such a preservation is established only for the case when $q = \infty, q^* = 1, p = 1$, and $u = u_0$.

Remark 5.2. Unlike in the shift-invariant setting, the stability of the ideal sampling set is not preserved under small perturbation in our general setting, or in other words, assumption (5.4) in Theorem 5.3 cannot be eliminated if we expect that the stability of the ideal sampling set is preserved under small perturbation. For instance, let $\Lambda = \mathbf{Z}$ and $\Phi := \{\phi_k(x) := h(2(x-k))\cos^2(4k\pi(x-k)) : k \in \mathbf{Z}\}$, where $h(x) = \max(1 - |x|, 0)$ is the hat function. For the space $V_2(\Phi, \mathbf{Z})$ generated by that family of functions Φ, we see that $f(k) = c(k), k \in \mathbf{Z}$, for any $f = \sum_{k \in \mathbf{Z}} c(k)\phi_k \in V_2(\Phi, \mathbf{Z})$. Thus $\|f\|_2 \le \|(f(k))_{k \in \mathbf{Z}}\|_{\ell^2(\mathbf{Z})} \le 4\|f\|_2$ for all $f \in V_2(\Phi, \mathbf{Z})$, where we have also used the facts that $\phi_k, k \in \mathbf{Z}$, are supported in $k + [-1/2, 1/2]$ and satisfy $\frac{1}{4} \le \|\phi_k\|_2 \le 1$. This shows that $\mathbf{Z}$ is a stable sampling set for $V_2(\Phi, \mathbf{Z})$. Noting that $f(k + 1/(8k)) = 0, k \in \mathbf{Z}$, for any $f = \sum_{k \in \mathbf{Z}} c(k)\phi_k \in V_2(\Phi, \mathbf{Z})$, we then conclude that for *any* $0 < \delta < 1/2$, the small perturbation $\mathbf{Z}_\delta = \{k + (-1)^k \min(\delta, 1/(8|k|)),\ 0 \ne k \in \mathbf{Z}\}$ of the stable sampling set $\mathbf{Z}$ is *not* a stable sampling set for $V_2(\Phi, \Lambda)$. Moreover, assumption (5.4) does not hold for that family of functions Φ, since for any $\delta > 0$,

$$\|\Phi_\delta\|_{q,p,\alpha} \ge \|\phi_k - \phi_k\left(\cdot + \frac{1}{8k}\right)\|_{L^q(k+[0,1])} \ge \frac{1}{2}\int_0^{1/4} |\cos 8k\pi x| dx \ge \frac{1}{16},$$

where the integer k is chosen so that $8k\delta \ge 1$.

6. Locally finite reconstruction process. For a bounded set K and a positive number R, we let $B(K, R) := \{y \in \mathbf{R}^d : \inf_{x \in K} |y - x| \le R\}$ be the R-neighborhood of the set K. For an average sampling process on the space $V_r(\Phi, \Lambda)$ with the average sampler $\Psi := \{\psi_\gamma, \gamma \in \Gamma\}$, we define the *locally finite reconstruction approximation* of a function $f \in V_r(\Phi, \Lambda)$ on a bounded set K using average sampling data on the R-neighborhood $B(K, R)$ of the set K by

$$\tilde{f}^a_{K,R} = \sum_{\gamma \in \Gamma \cap B(K,R)} \langle f, \psi_\gamma \rangle \tilde{\psi}^a_{\gamma,K,R}, \tag{6.1}$$

where

$$\tilde{\psi}^a_{\gamma,K,R} = \sum_{\lambda_1,\lambda_2\in B(K,2R)} \langle \psi_\gamma, \phi_{\lambda_1}\rangle (\tilde{A}_{\Psi,\Phi,K,R})^{-1}(\lambda_1,\lambda_2)\phi_{\lambda_2} \tag{6.2}$$

and

$$\tilde{A}_{\Psi,\Phi,K,R} = \left(\sum_{\gamma\in\Gamma\cap B(K,4R)} \langle \phi_\lambda, \psi_\gamma\rangle\langle \psi_\gamma, \phi_{\lambda'}\rangle \right)_{\lambda,\lambda'\in B(K,3R)}. \tag{6.3}$$

Similarly for the ideal sampling process on the space $V_r(\Phi,\Lambda)$ with the sampling set Γ, we define the locally finite reconstruction approximation of a function $f\in V_r(\Phi,\Lambda)$ on a bounded set K using the ideal sampling data on the R-neighborhood $B(K,R)$ of the set K by

$$\tilde{f}^i_{K,R} = \sum_{\gamma\in\Gamma\cap B(K,R)} f(\gamma)\tilde{\psi}^i_{\gamma,K,R}, \tag{6.4}$$

where

$$\tilde{\psi}^i_{\gamma,K,R} = \sum_{\lambda_1,\lambda_2\in B(K,2R)} \phi_{\lambda_1}(\gamma)(\tilde{A}_{\delta_\Gamma,\Phi,K,R})^{-1}(\lambda_1,\lambda_2)\phi_{\lambda_2} \tag{6.5}$$

and

$$\tilde{A}_{\Psi,\Phi,K,R} = \left(\sum_{\gamma\in\Gamma\cap B(K,4R)} \phi_\lambda(\gamma)\phi_{\lambda'}(\gamma) \right)_{\lambda,\lambda'\in B(K,3R)}. \tag{6.6}$$

For any bounded set K, we observe that the locally finite reconstruction approximation $\tilde{f}^a_{K,R}$ for the average sampling/reconstruction process and $\tilde{f}^i_{K,R}$ for the ideal sampling/reconstruction process are obtained by using the samples in a finite neighborhood of that set K with finitely many steps. Then we conclude from Theorems 6.1 and 6.2 that the locally finite reconstruction approximation could be possibly used in the real-time reconstruction by selecting the parameter R properly.

Using an idea similar to the finite section method in frame theory (see, e.g., [18, 20, 35]), we have the following locally finite reconstruction approximation for the average (ideal) sampling/reconstruction process.

THEOREM 6.1. *Let $p,q,q^*,r,u,\Lambda,\Gamma,\Phi,\Psi,\tilde{\Psi}$ be as in Theorem* 3.1*, and let $\tilde{f}^a_{K,R}$ be defined as in* (6.1) *for any bounded set K, positive number $R\ge 1$, and function $f\in V_r(\Phi,\Lambda)$. Then there exists a positive constant C (independent of the bounded set K, the positive number $R\ge 1$, and the function $f\in V_r(\Phi,\Lambda)$) such that*

$$\begin{aligned}\|\tilde{f}^a_{K,R} - f\|_{L^r(K)} &\le C\|u^{-1}\|^2_{L^{p'}(\mathbf{R}^d\setminus B(R))}\|(\langle f,\psi_\gamma\rangle)_{\gamma\in\Gamma}\|_{\ell^r(\Gamma)}\\ &\quad + C\|u^{-1}\|_{L^{p'}(\mathbf{R}^d\setminus B(R))}\|(\langle f,\psi_\gamma\rangle)_{\gamma\in\Gamma\setminus B(K,R)}\|_{\ell^r(\Gamma\setminus B(K,R))}\end{aligned} \tag{6.7}$$

holds for any bounded set K, any positive number $R\ge 1$, and any $f\in V_r(\Phi,\Lambda)$.

THEOREM 6.2. *Let $p,r,u,\Lambda,\Gamma,\Phi,\tilde{\Psi}$ be as in Theorem* 3.2*, and let $\tilde{f}^i_{K,R}$ be defined as in* (6.4) *for any bounded set K, positive number $R\ge 1$, and function $f\in V_r(\Phi,\Lambda)$. Then there exists a positive constant C (independent of the bounded set K, the positive number $R\ge 1$, and the function $f\in V_r(\Phi,\Lambda)$) such that*

$$\begin{aligned}\|\tilde{f}^i_{K,R} - f\|_{L^r(K)} &\le C\|u^{-1}\|^2_{L^{p'}(\mathbf{R}^d\setminus B(R))}\|(f(\gamma))_{\gamma\in\Gamma}\|_{\ell^r(\Gamma)}\\ &\quad + C\|u^{-1}\|_{L^{p'}(\mathbf{R}^d\setminus B(R))}\|(f(\gamma))_{\gamma\in\Gamma\setminus B(K,R)}\|_{\ell^r(\Gamma\setminus B(K,R))}\end{aligned} \tag{6.8}$$

holds for any bounded set K, any positive number $R \geq 1$, and any $f \in V_r(\Phi, \Lambda)$.

As a by-product of Theorems 6.1 and 6.2, we have the following result about the location of (non-)ideal sampling devices.

THEOREM 6.3. *Let $p, q, q^*, r, u, \Lambda, \Gamma, \Phi, \Psi, \tilde{\Psi}$ be as in either Theorem* 3.1 *or Theorem* 3.2. *Then there exists a positive constant R_0 such that for any bounded set K, the number of (non-)ideal sampling devices located in $B(K, R_0)$ exceeds the degrees of freedom of the space $V_2(\Phi, \Lambda)$ in the domain K, that is,*

$$\#(\Gamma \cap B(K, R_0)) \geq \#(\Lambda \cap K), \tag{6.9}$$

where $\#(E)$ denotes the cardinality of a set E.

Remark 6.1. If $V_2(\Phi, \Lambda)$ is a shift-invariant space generated by a compactly supported continuous function ϕ, then one may verify that the matrix $\big(\sum_{\gamma\in\Gamma} \phi_\lambda(\gamma)\phi_{\lambda'}(\gamma)\big)$ associated with the ideal sampling on Γ is a band-limited matrix. Furthermore for the case when finite truncation of that matrix is invertible (which is true if ϕ is a B-spline and Γ is a sampling set with sampling density strictly less than the optimal density; see [3, 4]), Gröchenig and Schwab [33] proposed an efficient local reconstruction algorithm to recover the original function in a domain *exactly*, instead of *approximately* as in Theorems 6.1 and 6.2, from its samples in a neighborhood of that domain. Comparing with the locally perfect recovery in [33], we see that the locally finite approximation in Theorems 6.1 and 6.2 works for the well-localized average sampling process as well as the ideal sampling process, and for most signals with a finite rate of innovation instead of signals of B-spline type.

Remark 6.2. The density property (6.9) in Corollary 6.3 is established in [3] for the ideal sampling of signals in a B-spline space; that is, $V_2(\Phi, \Lambda)$ is the shift-invariant space generated by the integer shifts of a B-spline. The reader may refer to [2] for similar results for average (ideal) sampling in the band-limited space, and to [8, 9] for the nonuniform Gabor system.

7. The Richardson–Landweber iterative reconstruction process. Let Φ be the generator of the space $V_2(\Phi, \Lambda)$, Ψ be an average sampler, and Γ be an ideal sampling set. We define an iterative reconstruction algorithm from average sampling data $(a_\gamma)_{\gamma\in\Gamma} \in \ell^r$ by

$$\begin{cases} f_0 = A^{-2} \sum_{\gamma\in\Gamma,\lambda\in\Lambda} a_\gamma \langle \psi_\gamma, \phi_\lambda\rangle \phi_\lambda, \\ f_n = f_0 + f_{n-1} - A^{-2} T_{as} f_{n-1} \text{ if } n \geq 1, \end{cases} \tag{7.1}$$

where A is a positive parameter and the operator T_{as} is defined by

$$T_{as} f = \sum_{\gamma\in\Gamma,\lambda\in\Lambda} \langle f, \psi_\gamma\rangle \langle \psi_\gamma, \phi_\lambda\rangle \phi_\lambda. \tag{7.2}$$

Similarly we define an iterative reconstruction algorithm from ideal sampling data $(a_\gamma)_{\gamma\in\Gamma} \in \ell^r$ by

$$\begin{cases} f_0 = A^{-2} \sum_{\gamma\in\Gamma,\lambda\in\Lambda} a_\gamma \phi_\lambda(\gamma) \phi_\lambda, \\ f_n = f_0 + f_{n-1} - A^{-2} T_{is} f_{n-1}, \ n \geq 1, \end{cases} \tag{7.3}$$

where A is a positive parameter and the operator T_{is} is defined by

$$T_{is} f = \sum_{\gamma\in\Gamma,\lambda\in\Lambda} f(\gamma) \phi_\lambda(\gamma) \phi_\lambda. \tag{7.4}$$

Since the operators A_{as} in (7.2) and A_{is} in (7.4) can be written as $T_{as} = T_\Phi A^*_{\Psi,\Phi} A_{\Psi,\Phi}(T_\Phi)^{-1}$ and $T_{is} = T_\Phi A^*_{\delta_\Gamma,\Phi} A_{\delta_\Gamma,\Phi}(T_\Phi)^{-1}$, where $T_\Phi : (c(\lambda)) \longmapsto \sum_{\lambda\in\Lambda} c(\lambda)\phi_\lambda$, we then have that the iterative reconstruction algorithms from average sampling data and from ideal sampling data are equivalent to the familiar Richardson–Landweber iterative algorithms for the positive operators $A^*_{\Psi,\Phi}A_{\Psi,\Phi}$ and $A^*_{\delta_\Gamma,\Phi}A_{\delta_\Gamma,\Phi}$ on $\ell^2(\Lambda)$, respectively. For the iterative reconstruction algorithms from average sampling data and from ideal sampling data, we have the following exponential convergence for signals in $V_r(\Phi,\Lambda)$.

THEOREM 7.1. *Let $p, q, q^*, r, u, \Lambda, \Gamma, \Phi, \Psi, V_r(\Phi,\Lambda)$ be as in Theorem* 3.1. *We assume that the parameter A in* (7.1) *is a positive constant larger than the operator norm of the matrix $A_{\Psi,\Phi}$ from $\ell^2(\Lambda)$ to $\ell^2(\Gamma)$. Then the sequence $\{f_n, n \ge 1\}$ in* (7.1) *converges to a function f_∞ in $V_r(\Phi,\Lambda)$ in the L^r norm exponentially for any initial data $(a_\gamma)_{\gamma\in\Gamma} \in \ell^r$; that is, there exist two positive constants $C \in (0,\infty)$ and $s \in (0,1)$ such that*

$$\|f_n - f_\infty\|_r \le Cs^n \|(a_\gamma)_{\gamma\in\Gamma}\|_{\ell^r(\Gamma)} \quad \text{for all } n \ge 1. \tag{7.5}$$

Furthermore if the initial data $(a_\gamma)_{\gamma\in\Gamma}$ are obtained from average sampling a function f in $V_r(\Phi,\Lambda)$, that is, $a_\gamma = \langle f, \psi_\gamma\rangle$ for all $\gamma \in \Gamma$, then the limit function f_∞ of the sequence $\{f_n, n \ge 1\}$ agrees with the original function f.

THEOREM 7.2. *Let $p, r, u, \Lambda, \Gamma, \Phi, V_q(\Phi,\Lambda)$ be as in Theorem* 3.2. *Assume that the parameter A in* (7.3) *is a positive constant larger than the operator norm of the matrix $A_{\delta_\Gamma,\Phi} := (\phi_\lambda(\gamma))_{\gamma\in\Gamma,\lambda\in\Lambda}$ from $\ell^2(\Lambda)$ to $\ell^2(\Gamma)$. Then the sequence $\{f_n, n \ge 1\}$ in* (7.3) *converges to a function $f_\infty \in V_r(\Phi,\Lambda)$ in the L^r norm exponentially. Moreover if $a_\gamma = f(\gamma), \gamma \in \Gamma$, holds for some $f \in V_r(\Phi,\Lambda)$, then $f_\infty = f$.*

Remark 7.1. For $\Phi = \{\phi_\lambda : \lambda \in \Lambda\}$, we let P be the projection operator from L^2 to $V_2(\Phi,\Lambda)$; see Remark 3.2. Then for the average sampling/reconstruction process with Ψ as its average sampler (resp., the ideal sampling/reconstruction process with Γ as its sampling set), $P\Psi := \{P\psi_\gamma,\ \psi_\gamma \in \Psi\}$ (resp., $P\delta_\Gamma := \{P\delta_\gamma,\ \gamma \in \Gamma\}$) is a frame for $V_2(\Phi,\Lambda)$, and hence the corresponding frame algorithm is the familiar Richardson–Landweber iterative algorithm for the positive operator $(A_{\Phi,\Phi})^{-1/2}A^*_{\Psi,\Phi}A_{\Psi,\Phi}(A_{\Phi,\Phi})^{-1/2}$ (resp., $(A_{\Phi,\Phi})^{-1/2}A^*_{\delta_\Gamma,\Phi}A_{\delta_\Gamma,\Phi}(A_{\Phi,\Phi})^{-1/2}$) on the space $\ell^2(\Lambda)$; see [2]. Clearly the iterative frame algorithm becomes the iterative algorithm proposed in this article when Φ is an orthonormal basis of $V_2(\Phi,\Lambda)$. In general, we need more computation for each iterative step of the iterative frame algorithm than that of the iterative algorithm in the paper. The consideration of which iterative algorithm converges faster, and of other implementations of the reconstruction process associated with the average (ideal) sampling/reconstruction process, is beyond the scope of this paper and will be discussed in a subsequent paper. By the general frame theory, the iterative frame algorithm associated with the average (ideal) sampling/reconstruction process on the space $V_2(\Phi,\Lambda) \subset L^2$ converges exponentially. Similar to the proofs of Theorems 7.1 and 7.2, we have the exponential convergence of the iterative frame algorithm on the space $V_r(\Phi,\Lambda)$ with $r \ne 2$, under the assumption that $p, q, q^*, r, u, \Lambda, \Lambda, \Phi, \Psi$ are as in Theorems 3.1 or 3.2. The above exponential convergence theorem for the iterative frame algorithm is established in [2, 22] for the shift-invariant setting with some minor additional assumptions on the exponents p, q, q^* and weight u.

8. Proofs. In this section, we collect the proofs of all theorems and corollaries stated in Sections 3, 4, 5, 6, and 7.

8.1. Proof of Theorem 3.1. Unlike in the study of average (ideal) sampling signals in a shift-invariant space, the main obstacle when considering well-localization of the displayer comes from the nongroup structure on the generator Φ and the average sampler Ψ, which makes the standard approach from Fourier analysis inapplicable. In the proof of Theorem 3.1, we will use the procedure used in the study of localized frames (see [8, 24, 31, 32, 37, 50, 51, 52] and references cited therein) with some nonessential modification (see also Remark 3.1). For the completeness of this paper, we include a complete proof.

For a matrix $A = (a(\lambda, \lambda'))_{\lambda,\lambda' \in \Lambda}$, we denote by $\|A\|_{\mathcal{B}^2}$ its operator norm on $\ell^2(\Lambda)$. To prove Theorem 3.1, we recall some properties of the matrix algebras of the Schur class $\mathcal{A}_{p,u}(\Lambda, \Lambda')$ and of the Sjöstrand class $\mathcal{C}_{p,u}(\Lambda, \Lambda)$ in [51]. The third property in Lemmas 8.1 and 8.2 below is usually known as Wiener's lemma; see, for instance, [8, 10, 24, 27, 31, 32, 37, 49, 50, 51] and references cited therein for its recent development and various applications.

LEMMA 8.1 (see [51]). *Let $1 \le p \le \tilde{p} \le \infty$, u and $\tilde{u}$ be weights, and $\Lambda, \Lambda', \Lambda''$ be relatively separated subsets of $\mathbf{R}^d$. Then the following statements are true:*

(i) *If $\|u\tilde{u}^{-1}\|_{L^r} < \infty$, where $r = p\tilde{p}/(\tilde{p} - p)$, then*

$$\|A\|_{\mathcal{A}_{p,u}} \le C\|A\|_{\mathcal{A}_{\tilde{p},\tilde{u}}} \quad \text{for all } A \in \mathcal{A}_{\tilde{p},\tilde{u}}(\Lambda, \Lambda'). \tag{8.1}$$

(ii) *If there exists another weight v such that (2.15) and (2.16) hold, then*

$$\|AB\|_{\mathcal{A}_{p,u}} \le C\|A\|_{\mathcal{A}_{p,u}}\|B\|_{\mathcal{A}_{p,u}} \tag{8.2}$$

for all $A \in \mathcal{A}_{p,u}(\Lambda, \Lambda')$ and $B \in \mathcal{A}_{p,w}(\Lambda', \Lambda'')$, where

$$AB := \left(\sum_{\lambda' \in \Lambda'} A(\lambda, \lambda')B(\lambda', \lambda'') \right)_{\lambda \in \Lambda, \lambda'' \in \Lambda''}.$$

(iii) *If u is a p-admissible weight and A is a matrix in $\mathcal{A}_{p,u}(\Lambda, \Lambda)$ satisfying*

$$\|Ac\|_{\ell^2} \ge D_0\|c\|_{\ell^2} \text{ for all } c \in \ell^2 \tag{8.3}$$

for some positive constant D_0, then the inverse A^{-1} of the matrix A belongs to $\mathcal{A}_{p,u}(\Lambda, \Lambda)$.

(iv) *If u is a p-admissible weight, then there exist positive constants $C_1, C_2 \in (0, \infty)$ and $\theta \in (0, 1)$ such that the following estimate holds for all $A \in \mathcal{A}_{p,u}(\Lambda, \Lambda)$:*

$$\|A^n\|_{\mathcal{A}_{p,u}} \le \left(C_1 \frac{\|A\|_{\mathcal{A}_{p,u}}}{\|A\|_{\mathcal{B}^2}} \right)^{C_2 n^\theta} \|A\|_{\mathcal{B}^2}^n, \ n \ge 1. \tag{8.4}$$

LEMMA 8.2 (see [51]). *Let $1 \le p \le \tilde{p} \le \infty$, u and $\tilde{u}$ be weights on $\mathbf{R}^d$, and Λ be a lattice of $\mathbf{R}^d$. Then the following statements are true:*

(i) *If $\|u\tilde{u}^{-1}\|_{L^r} < \infty$, where $r = p\tilde{p}/(\tilde{p} - p)$, then*

$$\|A\|_{\mathcal{C}_{p,u}} \le C\|A\|_{\mathcal{C}_{\tilde{p},\tilde{u}}} \quad \text{for all } A \in \mathcal{C}_{\tilde{p},\tilde{u}}(\Lambda, \Lambda). \tag{8.5}$$

(ii) *If there exists another weight v such that (2.15) and (2.16) hold, then*

$$\|AB\|_{\mathcal{C}_{p,u}} \le C\|A\|_{\mathcal{C}_{p,u}}\|B\|_{\mathcal{C}_{p,u}} \quad \text{for all } A, B \in \mathcal{C}_{p,u}(\Lambda, \Lambda). \tag{8.6}$$

(iii) *If u is a p-admissible weight on $\mathbf{R}^d$ and if A is a matrix in $\mathcal{C}_{p,u}(\Lambda,\Lambda)$ that satisfies* (8.3)*, then the inverse A^{-1} of the matrix A belong to $\mathcal{C}_{p,u}(\Lambda,\Lambda)$.*

Now we are ready to start the proof of Theorem 3.1.

Proof of Theorem 3.1. By Proposition 2.2, without loss of generality, we may assume that Φ is an orthonormal basis of $V_2(\Phi,\Lambda)$ for otherwise replacing Φ with $S^{-1/2}\Phi$. Therefore

$$\big\|c\big\|_{\ell^2(\Lambda)} = \bigg\|\sum_{\lambda\in\Lambda} c(\lambda)\phi_\lambda\bigg\|_2 \quad \text{for all } c := \big(c(\lambda)\big)_{\lambda\in\Lambda} \in \ell^2(\Lambda) \tag{8.7}$$

and

$$f = \sum_{\lambda\in\Lambda} \langle f,\phi_\lambda\rangle\phi_\lambda \quad \text{for all } f \in V_2(\Phi,\Lambda). \tag{8.8}$$

From (2.8), (3.3), and (3.4), it follows that $\|\Psi\|_{q/(q-1),p,u} + \|\Phi\|_{q,p,u} < \infty$. This, together with (2.7), Lemma 8.1, and the trivial estimate

$$|A_{\Psi,\Phi}(\gamma,\lambda)| \le \sum_{k\in\mathbf{Z}^d} \|\psi_\gamma\|_{L^{q/(q-1)}(k+[0,1]^d)} \|\phi_\lambda\|_{L^q(k+[0,1)^d)},$$

proves that the matrix $A_{\Psi,\Phi} = (A_{\Psi,\Phi}(\gamma,\lambda))_{\gamma\in\Gamma,\lambda\in\Lambda}$ in (4.2) belongs to $\mathcal{A}_{p,u}(\Gamma,\Lambda)$:

$$A_{\Psi,\Phi} \in \mathcal{A}_{p,u}(\Gamma,\Lambda). \tag{8.9}$$

Furthermore, there exists a positive constant C such that

$$\|A_{\Psi,\Phi}\|_{\mathcal{A}_{p,u}} \le C\|\Psi\|_{q/(q-1),p,u}\|\Phi\|_{q,p,u}. \tag{8.10}$$

Clearly the transpose A^* of a matrix $A \in \mathcal{A}_{p,u}$ has the same $\mathcal{A}_{p,u}$ norm as the one of the matrix A,

$$\|A^*\|_{\mathcal{A}_{p,u}} = \|A\|_{\mathcal{A}_{p,u}}. \tag{8.11}$$

Combining (8.2), (8.9), and (8.11) then yields

$$A^*_{\Psi,\Phi}A_{\Psi,\Phi} \in \mathcal{A}_{p,u}(\Lambda,\Lambda). \tag{8.12}$$

For the matrix $A_{\Psi,\Phi}$, we obtain from (8.7) and the stable assumption on the averaging sampler Ψ that

$$C^{-1}\|c\|_2 \le \bigg\|\bigg(\sum_{\lambda\in\Lambda} A_{\Psi,\Phi}(\gamma,\lambda)c(\lambda)\bigg)_{\gamma\in\Gamma}\bigg\|_{\ell^2(\Gamma)} \le C\|c\|_2 \tag{8.13}$$

for any $\ell^2(\Lambda)$-sequence $c = (c(\lambda))_{\lambda\in\Lambda}$.

Combining (8.2), (8.12), and (8.13), and applying Lemma 8.1 to the matrix $A^*_{\Psi,\Phi}A_{\Psi,\Phi}$, we conclude that

$$(A^*_{\Psi,\Phi}A_{\Psi,\Phi})^{-1} \in \mathcal{A}_{p,u}(\Lambda,\Lambda). \tag{8.14}$$

Let

$$R := A_{\Psi,\Phi}(A^*_{\Psi,\Phi}A_{\Psi,\Phi})^{-1}, \tag{8.15}$$

write $R = (R(\gamma,\lambda))_{\gamma\in\Gamma,\lambda\in\Lambda}$, and define $\tilde{\Psi} := \{\tilde{\psi}_\gamma : \gamma \in \Gamma\}$ by

$$\tilde{\psi}_\gamma = \sum_{\lambda\in\Lambda} R(\gamma,\lambda)\phi_\lambda, \quad \gamma \in \Gamma. \tag{8.16}$$

Now we prove that $\tilde{\Psi}$ satisfies all requirements of the displayer associated with the average sampler Ψ. By (8.2), (8.9), and (8.14), we have

$$R \in \mathcal{A}_{p,u}(\Gamma,\Lambda). \tag{8.17}$$

This implies that the sequence $(R(\gamma,\lambda))_{\lambda\in\Lambda} \in \ell^1(\Lambda)$ for any $\gamma \in \Gamma$, and hence $\tilde{\Psi} \subset V_1(\Phi,\Lambda)$.

From (2.7), (8.2), (8.17), and the trivial estimate for $\tilde{\Psi}$: $\|\tilde{\psi}_\gamma\|_{L^q(k+[0,1]^d)} \le \sum_{\lambda\in\Lambda}|R(\gamma,\lambda)|\|\psi_\lambda\|_{L^q(k+[0,1]^d)}$, we have

$$\|\tilde{\Psi}\|_{q,p,u} \le C\|R\|_{\mathcal{A}_{p,u}}\|\Phi\|_{q,p,u} < \infty. \tag{8.18}$$

For any $f \in V_2(\Phi,\lambda)$, it follows from (8.8), (8.15), and (8.17) that

$$\begin{aligned}
&\left(\left\langle \sum_{\gamma\in\Gamma}\langle f,\psi_\gamma\rangle\tilde{\psi}_\gamma, \phi_\lambda\right\rangle\right)_{\lambda\in\Lambda}\\
&\quad= \left(\sum_{\lambda_1\in\Lambda}\langle f,\phi_{\lambda_1}\rangle \times \sum_{\lambda_2\in\Lambda}\langle\phi_{\lambda_2},\phi_\lambda\rangle\left(\sum_{\gamma\in\Gamma}A^*_{\Psi,\Phi}(\lambda_1,\gamma)R(\gamma,\lambda_2)\right)\right)_{\lambda\in\Lambda}\\
&\quad= \left(\sum_{\lambda_1\in\Lambda}\langle f,\phi_{\lambda_1}\rangle\langle\phi_{\lambda_1},\phi_\lambda\rangle\right)_{\lambda\in\Lambda} = \big(\langle f,\phi_\lambda\rangle\big)_{\lambda\in\Lambda}.
\end{aligned} \tag{8.19}$$

This proves the reconstruction formula (3.6) for $r = 2$,

$$f = \sum_{\gamma\in\Gamma}\langle f,\psi_\gamma\rangle\tilde{\psi}_\gamma \quad \text{for any } f \in V_2(\Phi,\Lambda). \tag{8.20}$$

For $1 \le r < \infty$, we obtain from (2.8), (2.9), (8.2), (8.9), (8.17), and Proposition 2.1 that

$$\begin{aligned}
&\left\|\sum_{\gamma\in\Gamma}\sum_{\lambda,\lambda'\in\Lambda}|c(\lambda)| \times |\langle\phi_\lambda,\psi_\gamma\rangle| \times |R(\gamma,\lambda')| \times |\phi_{\lambda'}|\right\|_{L^r}\\
&\quad\le C\|c\|_{\ell^r(\Lambda)}\|A_{\Psi,\Phi}\|_{\mathcal{A}_{p,u}}\|R\|_{\mathcal{A}_{p,u}}\|\Phi\|_{r,p,u}\\
&\quad\le C\|c\|_{\ell^r(\Lambda)}\|A_{\Psi,\Phi}\|_{\mathcal{A}_{p,u}}\|R\|_{\mathcal{A}_{p,u}}\|\Phi\|_{q,p,u} < \infty
\end{aligned} \tag{8.21}$$

for any sequence $c := (c(\lambda))_{\lambda\in\Lambda} \in \ell^r(\Lambda)$. Then for $1 \le r < \infty$, the reconstruction formula (3.6) follows easily from (8.20), (8.21), and the density of $\ell^2 \cap \ell^r$ in ℓ^r.

For $r=\infty$, we have that $p=\infty$. Take $c=(c(\lambda))_{\lambda\in\Lambda}\in\ell^\infty(\Lambda)$. We let $f=\sum_{\lambda\in\Lambda}c(\lambda)\phi_\lambda$ and $f_{k,\tau}=\sum_{|\lambda-k|\le\tau}c(\lambda)\phi_\lambda$ for $\tau\ge 1$. Then there exists a positive constant C (independent of $k\in\mathbf{Z}^d$ and $\tau\ge 1$) such that

$$\begin{aligned}\sup_{x\in k+[0,1]^d}|f(x)-f_{k,\tau}(x)|&\le\sum_{|\gamma-k|>\tau}|c(\lambda)|\sup_{x\in k+[0,1]^d}|\phi_\lambda(x)|\\&\le C\|c\|_{\ell^\infty(\Lambda)}\|\Phi\|_{\infty,p,u}\|u^{-1}\|_{L^{p'}(\mathbf{R}^d\setminus B(\tau))}\end{aligned}$$

and

$$\begin{aligned}&\sup_{x\in k+[0,1]^d}\Big|\sum_{\gamma\in\Gamma}\langle f-f_{k,\tau},\psi_\gamma\rangle\tilde{\psi}_\gamma(x)\Big|\\&\le\|c\|_{\ell^\infty}\Bigg(\sum_{|\gamma-k|\ge\tau/2,\gamma\in\Gamma}\sum_{\lambda\in\Lambda}+\sum_{\gamma\in\Gamma}\sum_{|\lambda-\gamma|\ge\tau/2,\lambda\in\Lambda}\Bigg)|\langle\phi_\lambda,\psi_\gamma\rangle|\sup_{x\in k+[0,1]^d}|\tilde{\psi}_\gamma(x)|\\&\le C\|c\|_{\ell^\infty(\Lambda)}\|A_{\Psi,\Phi}\|_{\mathcal{A}_{p,u}}\|\tilde{\Psi}\|_{\infty,p,u}\|u^{-1}\|_{L^{p'}(\mathbf{R}^d\setminus B(\tau/2))}.\end{aligned}$$

The above two estimates, together with (8.20), lead to

$$\begin{aligned}&\sup_{x\in k+[0,1]^d}\Big|f(x)-\sum_{\gamma\in\Gamma}\langle f,\psi_\gamma\rangle\tilde{\psi}_\gamma(x)\Big|\\&=\sup_{x\in k+[0,1]^d}\Big|(f-f_{k,\tau})(x)-\sum_{\gamma\in\Gamma}\langle f-f_{k,\tau},\psi_\gamma\rangle\tilde{\psi}_\gamma(x)\Big|\\&\le C\|c\|_{\ell^\infty(\Lambda)}\|u^{-1}\|_{L^{p'}(\mathbf{R}^d\setminus B(\tau/2))}\to 0\text{ as }\tau\to\infty\end{aligned}$$

for all $k\in\mathbf{Z}^d$, where we have used assumption (2.17) to obtain the last limit. This proves the reconstruction formula (3.6) for $r=\infty$, and hence completes the verification that the collection $\tilde{\Psi}$ in (8.16) is the desired displayer associated with the average sampler Ψ.

Now we prove that the displayer $\tilde{\Psi}$ in (8.16) is enveloped by a function in $W_\infty(L_{p,u})$ when Λ is a lattice, and the average sampler Ψ and the generator Φ for the space $V_2(\Phi,\Lambda)$ are enveloped by some functions $g,h\in W_\infty(L_{p,u})$, respectively. Let $A_{\Psi,\Phi}=(A_{\Psi,\Phi}(\gamma,\lambda))_{\gamma\in\Gamma,\lambda\in\Lambda}$ be as in (4.2). Then for any $\lambda\in m+[-1/2,1/2)^d$ and $\lambda'\in m'+[-1/2,1/2)^d$ with $m,m'\in\mathbf{Z}^d$,

$$\begin{aligned}|(A^*_{\Psi,\Phi}A_{\Psi,\Phi})(\lambda,\lambda')|&\le\sum_{k,l\in\mathbf{Z}^d}\sum_{\mu\in\Gamma}\|h(\cdot+\lambda-k)\|_{L^\infty([0,1]^d)}\|g(\cdot+\mu-k)\|_{L^\infty([0,1]^d)}\\&\qquad\times\|g(\cdot+\mu-l)\|_{L^\infty([0,1]^d)}\|h(\cdot+\lambda'-l)\|_{L^\infty([0,1]^d)}\\&\le C\sum_{k,l,n\in\mathbf{Z}^d}\|h(\cdot+m-k)\|_{L^\infty([-1,2]^d)}\|g(\cdot+n-k)\|_{L^\infty([-1,2]^d)}\\&\qquad\times\|g(\cdot+n-l)\|_{L^\infty([-1,2]^d)}\|h(\cdot+m'-l)\|_{L^\infty([-1,2]^d)}\\&\le d(m-m')\end{aligned}$$

for some sequence $(d(m))_{m\in\mathbf{Z}^d}$ with $(d(m)u(m))_{m\in\mathbf{Z}^d}\in\ell^p$. This implies that

$$A^*_{\Psi,\Phi}A_{\Psi,\Phi}\in\mathcal{C}_{p,u}(\Lambda,\Lambda).\tag{8.22}$$

Therefore using (8.13) and (8.22), and applying Lemma 8.2 to the matrix $A^*_{\Psi,\Phi}A_{\Psi,\Phi}$, we conclude that

$$(A^*_{\Psi,\Phi}A_{\Psi,\Phi})^{-1} \in \mathcal{C}_{p,u}(\Lambda,\Lambda). \tag{8.23}$$

Let R be the matrix in (8.15) and $\tilde{\Psi} := \{\tilde{\psi}_\gamma, \gamma \in \Gamma\}$ be the displayer defined in (8.16). Then for $\gamma \in k + [0,1)^d$ and $x \in l + [0,1)^d$,

$$\begin{aligned}
|\tilde{\psi}_\gamma(x)| &\le \sum_{\lambda,\lambda'\in\Lambda}\sum_{m\in\mathbf{Z}^d} \|g(\cdot+\gamma-m)\|_{L^\infty([0,1]^d)}\|h(\cdot+\lambda'-m)\|_{L^\infty([0,1]^d)} \\
&\quad \times |(A^*_{\Psi,\Phi}A_{\Psi,\Phi})^{-1}(\lambda',\lambda)|h(x-\lambda) \\
&\le C \sum_{n,n',m\in\mathbf{Z}^d} \|g\|_{L^\infty(m-k+[-1,2]^d)}\|h\|_{L^\infty(m-n'+[-1,2]^d)} \\
&\quad \times b(n-n') \sup_{y\in l-n+[-1,2]^d} |h(y)| \le c(k-l),
\end{aligned}$$

where $(b(k))_{k\in\mathbf{Z}^d}$ and $(c(k))_{k\in\mathbf{Z}^d}$ are sequences with $(b(k)u(k))_{k\in\mathbf{Z}^d}$ and $(c(k)u(k))_{k\in\mathbf{Z}^d}$ belonging to ℓ^p. This proves that $\tilde{\Psi} := \{\tilde{\psi}_\gamma, \gamma \in \Gamma\}$ is enveloped by some function in $W_\infty(L_{p,u})$, and hence completes the proof. □

8.2. Proof of Theorem 3.2. By (3.7) and the relative separatedness of the sets Γ and Λ, the matrix $A_{\delta_\Gamma,\Phi} = (\phi_\lambda(\gamma))_{\gamma\in\Gamma,\lambda\in\Lambda}$ in (4.3) belongs to $\mathcal{A}_{p,u}(\Gamma,\Lambda)$. Then we may reach the conclusion of Theorem 3.2 using the same argument as the one in the proof of Theorem 3.1, except we replace the average sampler Ψ with the ideal sampler δ_Γ. We omit the details of the proof here. □

8.3. Proof of Theorem 4.1. Let S be the frame operator (2.20) on the space $V_2(\Phi,\Lambda)$. By the frame assumption on the generator Φ, we have

$$C^{-1}\|f\|_2 \le \|Sf\|_2 \le C\|f\|_2 \quad \text{for all } f \in V_2(\Phi,\Lambda) \tag{8.24}$$

and

$$C^{-1}\|f\|_2 \le \big\|\big(\langle f,\phi_\lambda\rangle\big)_{\lambda\in\Lambda}\big\|_{\ell^2(\Lambda)} \le C\|f\|_2 \quad \text{for all } f \in V_2(\Phi,\Lambda). \tag{8.25}$$

Then the conclusion follows from (8.24), (8.25), and

$$\langle A^*_{\Psi,\Phi}A_{\Psi,\Phi}c, c\rangle = \big\|\big(\langle Sf,\psi_\gamma\rangle\big)_{\gamma\in\Gamma}\big\|^2_{\ell^2(\Lambda)}$$

for any $c = (\langle f,\phi_\lambda\rangle)_{\lambda\in\Lambda}$, where $f \in V_2(\Phi,\Lambda)$. □

8.4. Proof of Theorem 4.2. Note that $\langle A^*_{\delta_\Gamma,\Phi}A_{\delta_\Gamma,\Phi}c, c\rangle = \|(Sf(\gamma))_{\gamma\in\Gamma}\|^2_{\ell^2(\Lambda)}$ for $c = (\langle f,\phi_\lambda\rangle)_{\lambda\in\Lambda}$, where $f \in V_2(\Phi,\Lambda)$. This, together with (8.24) and (8.25), proves the conclusion. □

8.5. Proof of Theorem 5.1. The estimate (5.1) follows from (3.6), (3.8), Proposition 2.1, and the following inequality:

$$\left|f - \sum_{\gamma\in\Gamma} g_\gamma\tilde{\psi}'_\gamma\right| \le \sum_{\gamma\in\Gamma}|\langle f,\psi_\gamma\rangle - g_\gamma||\tilde{\psi}_\gamma| + \sum_{\gamma\in\Gamma}|g_\gamma||\tilde{\psi}_\gamma - \tilde{\psi}'_\gamma|. \qquad \square$$

8.6. Proof of Theorem 5.2. Let $A_{\Psi,\Phi}$ and $A_{\Psi',\Phi}$ be the Gram matrices as in (4.2). Then there exists a positive constant C independent of the average samplers Ψ' and Ψ by (2.8) and (8.10) such that

$$\begin{aligned}\|A_{\Psi,\Phi}-A_{\Psi',\Phi}\|_{\mathcal{A}_{p,u}} &= \|A_{\Psi-\Psi',\Phi}\|_{\mathcal{A}_{p,u}}\\ &\le C\|\Psi-\Psi'\|_{q/(q-1),p,\alpha}\|\Phi\|_{q,p,u} \le C\|\Psi-\Psi'\|_{q^*,p,u}\|\Psi\|_{q,p,u}.\end{aligned} \tag{8.26}$$

This, together with (8.2), yields the following estimate:

$$\|(A_{\Psi,\Phi})^*A_{\Psi,\Phi}-(A_{\Psi',\Phi})^*A_{\Psi',\Phi}\|_{\mathcal{A}_{p,u}} \le C\|\Psi-\Psi'\|_{q^*,p,u}, \tag{8.27}$$

which then implies that

$$\begin{aligned}&\|((A_{\Psi',\Phi})^*A_{\Psi',\Phi})^{-1}-((A_{\Psi,\Phi})^*A_{\Psi,\Phi})^{-1}\|_{\mathcal{A}_{p,u}}\\ &\quad\le C\|((A_{\Psi,\Phi})^*A_{\Psi,\Phi})^{-1}\|_{\mathcal{A}_{p,u}}\\ &\qquad\times\sum_{k=1}^{\infty}\Big\|\Big(\big((A_{\Psi,\Phi})^*A_{\Psi,\Phi}\big)^{-1}\big((A_{\Psi,\Phi})^*A_{\Psi,\Phi}-(A_{\Psi',\Phi})^*A_{\Psi',\Phi}\big)\Big)^k\Big\|_{\mathcal{A}_{p,u}}\\ &\quad\le C\|((A_{\Psi,\Phi})^*A_{\Psi,\Phi})^{-1}\|_{\mathcal{A}_{p,u}}\\ &\qquad\times\sum_{k=1}^{\infty}\big(C\|((A_{\Psi,\Phi})^*A_{\Psi,\Phi})^{-1}\|_{\mathcal{A}_{p,u}}\|\big((A_{\Psi,\Phi})^*A_{\Psi,\Phi}-(A_{\Psi',\Phi})^*A_{\Psi',\Phi}\big)\|_{\mathcal{A}_{p,u}}\big)^k\\ &\quad\le C\sum_{k=1}^{\infty}\big(C\|\Psi-\Psi'\|_{q^*,p,u}\big)^k \le \frac{C^2\|\Psi-\Psi'\|_{q^*,p,u}}{1-C\|\Psi-\Psi'\|_{q^*,p,u}} \le \frac{C^2\delta_0}{1-C\delta_0}<\infty\end{aligned}$$

when δ_0 in (5.2) is sufficiently small, where we have used the estimates in (5.2), (8.2), (8.14), and (8.27). This proves that $((A_{\Psi',\Phi})^*A_{\Psi',\Phi})^{-1}\in\mathcal{A}_{p,u}(\Lambda,\Lambda)$ as δ_0 in (5.2) is sufficiently small. Moreover using the argument in the proof of Theorem 3.1, we conclude that Ψ' is a stable average sampler for the space $V_2(\Phi,\Lambda)$, and

$$\|R'-R\|_{p,\alpha} \le C\|\Psi-\Psi'\|_{q^*,p,\alpha} \tag{8.28}$$

for some positive constant C, where $R'=A_{\Psi',\Phi}((A_{\Psi',\Phi})^*A_{\Psi',\Phi})^{-1}=(R'(\gamma,\lambda))_{\gamma\in\Gamma,\lambda\in\Lambda}$ and $R=A_{\Psi,\Phi}((A_{\Psi,\Phi})^*A_{\Psi,\Phi})^{-1}=(R(\gamma,\lambda))_{\gamma\in\Gamma,\lambda\in\Lambda}$. Therefore the displayers $\tilde{\Psi}'=\{\tilde{\psi}'_\gamma:\gamma\in\Gamma\}$ and $\tilde{\Psi}=\{\tilde{\psi}_\gamma:\gamma\in\Gamma\}$ associated with the stable average samplers Ψ' and Ψ, respectively, which are defined by $\psi'_\gamma=\sum_{\lambda\in\Lambda}R'(\gamma,\lambda)\phi_\lambda$ and $\psi_\gamma=\sum_{\lambda\in\Lambda}R(\gamma,\lambda)\phi_\lambda$, $\gamma\in\Gamma$, satisfy

$$\|\tilde{\Psi}'-\tilde{\Psi}\|_{q^*,p,u} \le C\|R-R'\|_{\mathcal{A}_{p,u}}\|\Phi\|_{q^*,p,u} \le C\|\Psi-\Psi'\|_{q^*,p,u}. \tag{8.29}$$

Hence (5.3) follows. □

8.7. Proof of Theorem 5.3. We can use the same technique as the one in the proof of Theorem 5.2, except the matrices $A_{\Psi,\Phi}$ and $A_{\Psi',\Phi}$ and the estimate (8.26) are replaced with the matrices $A_{\delta_\Gamma,\Phi}=(\phi_\lambda(\gamma))_{\gamma\in\Gamma,\lambda\in\Lambda}$ and $A_{\delta_{\Gamma'},\Phi}=(\phi_\lambda(\gamma+\delta_\gamma))_{\gamma\in\Gamma,\lambda\in\Lambda}$, and the estimate $\|A_{\delta_\Gamma,\Phi}-A_{\delta_{\Gamma'},\Phi}\|_{\mathcal{A}_{p,u}}\le\|\Phi_{\delta_0}\|_{\infty,p,u}$ for sequences $\{\delta_\gamma\}$ with $\sup_{\gamma\in\Gamma}|\delta_\gamma|\le\delta_0$, respectively. We omit the details of the proof here. □

8.8. Proof of Corollary 5.4. The first conclusion follows from Theorem 5.2 and the equivalence between $\sum_{l=1}^{L}\|\theta_n\|_{W_{q^*}(L_{p,u})}$ and $\|\Theta\|_{q*,p,\alpha}$, where $\Theta=\{\theta_l(\cdot-\gamma):1\le l\le L,\gamma\in\Gamma\}$.

For any continuous function ϕ in $W_\infty(L_{p,u})$, there exist continuous functions $\phi_n, n \ge 1$, with compact support such that $\lim_{n\to\infty} \|\phi_n - \phi\|_{W_\infty(L_{p,u})} = 0$. Therefore the modulus of continuity $\omega(\phi,\delta)(x) := \sup_{|t|\le\delta} |\phi(x+t) - \phi(x)|$ of the continuous function ϕ in $W_\infty(L_{p,u})$ has the property that $\|\omega(\phi,\delta)\|_{W_\infty(L_{p,u})} \to 0$ as $\delta \to 0$ [2]. This together with (2.13) and Theorem 5.3 proves the second conclusion. □

8.9. Proof of Theorem 6.1. For average sampling on the space $V_r(\Phi,\Lambda)$ with the average sampler $\Psi := \{\psi_\gamma, \gamma \in \Gamma\}$, we introduce two local reconstruction approximations of a function $f \in V_r(\Phi,\Lambda)$ on a bounded set K using average sampling data on the R-neighborhood $B(K,R)$ of the set K by

$$f_{K,R} = \sum_{\gamma\in\Gamma\cap B(K,R)} \langle f, \psi_\gamma\rangle \tilde{\psi}_\gamma \tag{8.30}$$

and

$$f^1_{K,R} = \sum_{\gamma\in\Gamma\cap B(K,R)} \langle f, \psi_\gamma\rangle \tilde{\psi}^1_{\gamma,K,R}, \tag{8.31}$$

where

$$\tilde{\psi}_\gamma = \sum_{\lambda_1,\lambda_2\in\Lambda} \langle \psi_\gamma, \phi_{\lambda_1}\rangle (A^*_{\Psi,\Phi}A_{\Psi,\Phi})^{-1}(\lambda_1,\lambda_2)\phi_{\lambda_2}$$

and

$$\tilde{\psi}^1_{\gamma,K,R} = \sum_{\lambda_1,\lambda_2\in B(K,2R)\cap\Lambda} \langle \psi_\gamma, \phi_{\lambda_1}\rangle (A^*_{\Psi,\Phi}A_{\Psi,\Phi})^{-1}(\lambda_1,\lambda_2)\phi_{\lambda_2}.$$

For a bounded domain K and a positive number $R > 0$, define the projection matrices $P_{K,R}$ and $Q_{K,R}$ by

$$(P_{K,R}c)(\lambda) = \begin{cases} c(\lambda) & \text{if } \lambda \in \Lambda\cap B(K,R), \\ 0 & \text{if } \lambda \notin \Lambda\cap B(K,R) \end{cases}$$

for any $c := (c(\lambda))_{\lambda\in\Lambda}$, and

$$(Q_{K,R}d)(\gamma) = \begin{cases} d(\gamma) & \text{if } \gamma \in \Gamma\cap B(K,R), \\ 0 & \text{if } \gamma \notin \Gamma\cap B(K,R) \end{cases}$$

for any $d := (d(\gamma))_{\gamma\in\Gamma}$.

To prove Theorem 6.1, we need the following estimates for $f - f_{K,R}$ and $f_{K,R} - f^1_{K,R}$.

LEMMA 8.3. *Let $p, q, q^*, r, u, \Lambda, \Gamma, \Phi, \Psi, \tilde{\Psi}$ be as in Theorem 3.1, and set $p' = p/(p-1)$. Then there exists a positive constant C (independent of the bounded set K, the positive number $R \ge 1$, and the function $f \in V_r(\Phi,\Lambda)$) such that*

$$\|f_{K,R} - f\|_{L^r(K)} \le C\|u^{-1}\|_{L^{p'}(\mathbf{R}^d\setminus B(R))} \|(\langle f, \psi_\gamma\rangle)_{\gamma\in\Gamma\setminus B(K,R)}\|_{\ell^r(\Gamma\setminus B(K,R))} \tag{8.32}$$

and

$$\|f_{K,R} - f^1_{K,R}\|_{L^r(K)} \le C\|u^{-1}\|^2_{L^{p'}(\mathbf{R}^d\setminus B(R))} \|(\langle f, \psi_\gamma\rangle)_{\gamma\in B(K,R)}\|_{\ell^r(B(K,R))} \tag{8.33}$$

for any compact set K, any positive number $R \ge 1$, and any $f \in V_r(\Phi,\Lambda)$.

Proof. Let $\tilde{K} \subset \mathbf{Z}^d$ be the minimal subset of $\mathbf{Z}^d$ such that $K \subset \tilde{K} + [0,1)^d$. For $1 \le r \le q$ and $r < \infty$,

$$\begin{aligned}
\|f - f_{K,R}\|_{L^r(K)}^r &= \left\| \sum_{\gamma \notin \Gamma_{K,R}} \langle f, \psi_\gamma \rangle \tilde{\psi}_\gamma \right\|_{L^r(K)}^r \\
&\le \int_{\tilde{K}+[0,1]^d} \left(\sum_{\gamma \notin \Gamma_{K,R}} |\langle f, \psi_\gamma \rangle|^r |\tilde{\psi}_\gamma(x)| \right) \times \left(\sum_{\gamma \notin \Gamma_{K,R}} |\tilde{\psi}_\gamma(x)| \right)^{r-1} dx \\
&\le \sum_{\gamma \notin \Gamma_{K,R}} |\langle f, \psi_\gamma \rangle|^r \sum_{k \in \tilde{K}} \|\tilde{\psi}_\gamma\|_{L^r(k+[0,1]^d)} \times \left(\sum_{\gamma \notin \Gamma_{K,R}} \|\tilde{\psi}_\gamma\|_{L^r(k+[0,1]^d)} \right)^{r-1} \\
&\le \|(\langle f, \psi_\gamma \rangle)_{\gamma \in \Gamma \setminus \Gamma_{K,R}}\|_{\ell^r(\Gamma \setminus \Gamma_{K,R})}^r \times \left(\sup_{\gamma \notin \Gamma_{K,R}} \sum_{k \in \tilde{K}} \|\tilde{\phi}_\gamma\|_{L^r(k+[0,1]^d)} \right) \\
&\quad \times \left(\sup_{k \in \tilde{K}} \sum_{\gamma \notin \Gamma_{K,R}} \|\tilde{\psi}_\gamma\|_{L^r(k+[0,1]^d)} \right)^{r-1} \qquad (8.34)
\end{aligned}$$

where we set $\Gamma_{K,R} = \Gamma \cap B(K,R)$. Then for all $r \in [1,\infty)$ with $1 \le r \le q$, we have

$$\begin{aligned}
\|f - f_{K,R}\|_{L^r(K)} &\le C \|(\langle f, \psi_\gamma \rangle)_{\gamma \in \Gamma \setminus \Gamma_{K,R}}\|_{\ell^r(\Gamma \setminus \Gamma_{K,R})} \\
&\quad \times \|u\|_{L^{p'}(\mathbf{R}^d \setminus B(R))} \|\tilde{\Psi}\|_{r,p,u}. \qquad (8.35)
\end{aligned}$$

For $r = \infty$, it follows from $r \le q$ that $q = \infty$. Then using standard modification to the estimate (8.35), we obtain

$$\begin{aligned}
\|f - f_{K,R}\|_{L^\infty(K)} &\le C \|(\langle f, \psi_\gamma \rangle)_{\gamma \in \Gamma \setminus \Gamma_{K,R}}\|_{\ell^\infty(\Gamma \setminus \Gamma_{K,R})} \\
&\quad \times \|u\|_{L^{p'}(\mathbf{R}^d \setminus B(R))} \|\tilde{\Psi}\|_{\infty,p,u}. \qquad (8.36)
\end{aligned}$$

Then the local estimate (8.32) follows from (8.18), (8.35), and (8.36).

Set $R_{\Phi,r} = (\|\phi_\lambda\|_{L^r(k+[0,1]^d)})_{\lambda \in \Lambda, k \in \mathbf{Z}^d}$ and $|A| = (|a_{\lambda,\lambda'}|)$ for a matrix $A = (a_{\lambda,\lambda'})$. Then it follows from (2.7), (2.9), and Lemma 8.1 that

$$\begin{aligned}
&\sup_{k \in \tilde{K}} \sum_{\gamma \in B(K,R) \cap \Gamma} \|\tilde{\psi}_\gamma - \tilde{\psi}^1_{\gamma,K,R}\|_{L^r(k+[0,1]^d)} \\
&\qquad + \sup_{\gamma \in B(K,R) \cap \Gamma} \sum_{k \in \tilde{K}} \|\tilde{\psi}_\gamma - \tilde{\psi}^1_{\gamma,K,R}\|_{L^r(k+[0,1]^d)} \\
&\le C \left(\sup_{k \in \tilde{K}} \sum_{\gamma \in B(K,R) \cap \Gamma} + \sup_{\gamma \in B(K,R) \cap \Gamma} \sum_{k \in \tilde{K}} \right) \\
&\qquad \left(\sum_{\lambda \in B(K,2R) \cap \Lambda} \sum_{\lambda' \in \Lambda \setminus B(K,2R)} + \sum_{\lambda \in \Lambda \setminus B(K,2R)} \sum_{\lambda' \in \Lambda} \right) \\
&\qquad |\langle \psi_\gamma, \phi_\lambda \rangle| \, |(A^*_{\Psi,\Phi} A_{\Psi,\Phi})^{-1}(\lambda,\lambda')| \, \|\phi_{\lambda'}\|_{L^r(k+[0,1]^d)} \\
&\le C \|Q_{K,R} \, |A_{\Psi,\Phi}| \, P_{K,2R} \, |(A^*_{\Psi,\Phi} A_{\Psi,\Phi})^{-1}| \, (I - P_{K,2R}) R_{\Phi,r} P_{K,1}\|_{\mathcal{A}_{1,u_0}} \\
&\quad + C \|Q_{K,R} \, |A_{\Psi,\Phi}| \, (I - P_{K,2R}) \, |(A^*_{\Psi,\Phi} A_{\Psi,\Phi})^{-1}| \, R_{\Phi,r} P_{K,1}\|_{\mathcal{A}_{1,u_0}} \\
&\le C \|u\|^2_{L^{p'}(\mathbf{R}^d \setminus B(R))} \| \, |A_{\Psi,\Phi}| \, P_{K,2R} \, |(A^*_{\Psi,\Phi} A_{\Psi,\Phi})^{-1}| \, \|_{\mathcal{A}_{p,u}} \|R_{\Phi,r}\|_{\mathcal{A}_{p,u}} \\
&\quad + C \|u\|^2_{L^{p'}(\mathbf{R}^d \setminus B(R))} \|A_{\Psi,\Phi}\|_{\mathcal{A}_{p,u}} \| \, |(A^*_{\Psi,\Phi} A_{\Psi,\Phi})^{-1}| \, R_{\Phi,r}\|_{\mathcal{A}_{p,u}} \\
&\le C \|u\|^2_{L^{p'}(\mathbf{R}^d \setminus B(R))} \|A_{\Psi,\Phi}\|_{\mathcal{A}_{p,u}} \|(A^*_{\Psi,\Phi} A_{\Psi,\Phi})^{-1}\|_{\mathcal{A}_{p,u}} \|\Phi\|_{r,p,u}. \qquad (8.37)
\end{aligned}$$

This together with (8.10) and (8.14) proves (8.33). □

To prove Theorem 6.1, we need another lemma.

LEMMA 8.4. *Let $p, q, q^*, r, u, \Lambda, \Gamma, \Phi, \Psi, \tilde{\Psi}$ be as in Theorem 3.1, and $A_{\Psi,\Phi}$ be as in (4.2). Then there exist positive constants C and δ_0 (independent of the bounded set K and the positive number $R \geq 1$) such that*

$$\begin{aligned} &\|P_{K,2R}(A^*_{\Psi,\Phi}A_{\Psi,\Phi})^{-1}P_{K,2R} - P_{K,2R}R_{\Psi,\Phi,K,3R}P_{K,2R}\|_{\mathcal{A}_{1,u_0}} \\ &\quad \leq C\|u\|^2_{L^{p'}(\mathbf{R}^d\setminus B(R))} \end{aligned} \tag{8.38}$$

holds for all bounded sets K and all positive numbers R with $\|u\|_{L^{p'}(\mathbf{R}^d\setminus B(R))} \leq \delta_0$, where $R_{\Psi,\Phi,K,3R}$ is the generalized inverse of the matrix $P_{K,3R}\tilde{A}_{\Psi,\Phi,K,R}P_{K,3R}$, that is, $R_{\Psi,\Phi,K,3R}P_{K,3R}\tilde{A}_{\Psi,\Phi,K,R}P_{K,3R} = P_{K,3R}$ and $P_{K,3R}R_{\Psi,\Phi,K,3R}P_{K,3R} = R_{\Psi,\Phi,K,3R}$.

Proof. By (8.13), for any $A \geq (\|A^*_{\Psi,\Phi}A_{\Psi,\Phi}\|_{\mathcal{B}^2})^{1/2}$ there exists a matrix $B \in \mathcal{A}_{p,u}(\Lambda,\Lambda)$ such that

$$A^*_{\Psi,\Phi}A_{\Psi,\Phi} = A^2(I - B) \tag{8.39}$$

and

$$\|B\|_{\mathcal{B}^2} < 1, \tag{8.40}$$

where I is the usual unit matrix. By (8.4), (8.40), and the estimates $\|P_{K,3R}BP_{K,3R}\|_{\mathcal{B}^2} \leq \|B\|_{\mathcal{B}^2}$ and $\|P_{K,3R}BP_{K,3R}\|_{\mathcal{A}_{p,u}} \leq \|B\|_{\mathcal{A}_{p,u}}$, we have

$$\|B^k\|_{\mathcal{A}_{p,u}} + \|(P_{K,3R}BP_{K,3R})^k\|_{\mathcal{A}_{p,u}} \leq C\bigg(\frac{\|B\|_{\mathcal{B}^2}+1}{2}\bigg)^k,\ k \geq 1. \tag{8.41}$$

Therefore for $k \geq 2$,

$$\begin{aligned} &\bigg\|P_{K,2R}\sum_{k=1}^{\infty}B^kP_{K,2R} - P_{K,2R}\sum_{k=1}^{\infty}(P_{K,3R}BP_{K,3R})^kP_{K,2R}\bigg\|_{\mathcal{A}_{1,u_0}} \\ &\leq \sum_{k=2}^{\infty}\sum_{l=0}^{k-2}\|P_{K,2R}(P_{K,3R}BP_{K,3R})^lB(I-P_{K,3R})B^{k-1-l}P_{K,2R}\|_{\mathcal{A}_{1,u_0}} \\ &\leq C\sum_{k=2}^{\infty}\sum_{l=0}^{k-2}\|P_{K,2R}(P_{K,3R}BP_{K,3R})^lB(I-P_{K,3R})\|_{\mathcal{A}_{1,u_0}} \\ &\qquad\qquad \times\|(I-P_{K,3R})B^{k-1-l}P_{K,2R}\|_{\mathcal{A}_{1,u_0}} \\ &\leq C\|u\|^2_{L^{p'}(\mathbf{R}^d\setminus B(R))}\sum_{k=2}^{\infty}\sum_{l=0}^{k-2}\|(P_{K,3R}BP_{K,3R})^lB\|_{\mathcal{A}_{p,u}}\|B^{k-1-l}\|_{\mathcal{A}_{p,u}} \\ &\leq C\|u\|^2_{L^{p'}(\mathbf{R}^d\setminus B(R))}\|B\|_{\mathcal{A}_{p,u}}\sum_{k=2}^{\infty}(k-1)\bigg(\frac{\|B\|_{\mathcal{B}^2}+1}{2}\bigg)^{k-1} \\ &\leq C\|u\|^2_{L^{p'}(\mathbf{R}^d\setminus B(R))}, \end{aligned} \tag{8.42}$$

where we have used (8.40) and (8.41) to obtain the last inequality.

Write

$$P_{K,3R}\tilde{A}_{\Psi,\Phi,K,R}P_{K,3R} = P_{K,3R}A^*_{\Psi,\Phi}Q_{K,4R}A_{\Psi,\Phi}P_{K,3R} = A^2(P_{K,3R} - B'), \tag{8.43}$$

where A is the positive constant in (8.39). Since

$$\begin{aligned}&\|P_{K,3R}A^*_{\Psi,\Phi}Q_{K,4R}A_{\Psi,\Phi}P_{K,3R}-P_{K,3R}A^*_{\Psi,\Phi}A_{\Psi,\Phi}P_{K,3R}\|_{\mathcal{B}^2}\\&\quad\le\|P_{K,3R}A^*_{\Psi,\Phi}Q_{K,4R}A_{\Psi,\Phi}P_{K,3R}-P_{K,3R}A^*_{\Psi,\Phi}A_{\Psi,\Phi}P_{K,3R}\|_{\mathcal{A}_{1,u_0}}\\&\quad\le C\|u\|^2_{L^{p'}(\mathbf{R}^d\setminus B(R))}\|A_{\Psi,\Phi}\|^2_{\mathcal{A}_{p,u}},\end{aligned}\tag{8.44}$$

we have that

$$\|P_{K,3R}BP_{K,3R}-B'\|_{\mathcal{B}^2}\le D_0\|u\|^2_{L^{p'}(\mathbf{R}^d\setminus B(R))}\|A_{\Psi,\Phi}\|^2_{\mathcal{A}_{p,u}}\le\frac{1-\|B\|_{\mathcal{B}^2}}{3},\tag{8.45}$$

when $\|u\|^2_{L^{p'}(\mathbf{R}^d\setminus B(R))}\le\delta_0$ for some sufficiently small positive number δ_0, where D_0 is a positive constant. Therefore

$$\|(B')^k\|_{\mathcal{A}_{p,u}}\le C\bigg(\frac{\|B\|_{\mathcal{B}^2}+1}{2}\bigg)^k,\quad k\ge1,\tag{8.46}$$

by (8.4), (8.40), and (8.45). Similar to the argument in the proof of the estimate (8.42), we have

$$\begin{aligned}&\bigg\|P_{K,2R}\sum_{k=1}^{\infty}(B')^kP_{K,2R}-P_{K,2R}\sum_{k=1}^{\infty}(P_{K,3R}BP_{K,3R})^kP_{K,2R}\bigg\|_{\mathcal{A}_{1,u_0}}\\&\quad\le\sum_{k=1}^{\infty}\sum_{l=0}^{k-1}\|(B')^l(B'-P_{K,3R}BP_{K,3R})(P_{K,3R}BP_{K,3R})^{k-1-l}\|_{\mathcal{A}_{1,u_0}}\\&\quad\le C\|u\|^2_{L^{p'}(\mathbf{R}^d\setminus B(R)}\|A_{\Psi,\Phi}\|_{\mathcal{A}_{p,u}}\sum_{k=1}^{\infty}k\bigg(\frac{\|B\|_{\mathcal{B}^2}+1}{2}\bigg)^k\le C\|u\|^2_{L^{p'}(\mathbf{R}^d\setminus B(R))},\end{aligned}\tag{8.47}$$

where the second inequality follows from (8.41), (8.44), (8.45), and (8.46). Combining (8.39), (8.42), (8.43), and (8.47) proves the desired estimate (8.38). □

Now we start to prove Theorem 6.1.

Proof of Theorem 6.1. By Lemma 8.4,

$$\sup_{\lambda\in B(K,2R)}\sum_{\lambda'\in B(K,2R)}|(A^*_{\Psi,\Phi}A_{\Psi,\Phi})^{-1}(\lambda,\lambda')-(\tilde A_{\Psi,\Phi,K,R})^{-1}(\lambda,\lambda')|\le C\|u\|^2_{L^{p'}(\mathbf{R}^d\setminus B(R))},$$

which, together with (8.9) and Lemma 8.1, implies that

$$\begin{aligned}&\bigg(\sup_{k\in\tilde K}\sum_{\gamma\in B(K,R)\cap\Gamma}+\sup_{\gamma\in B(K,R)\cap\Gamma}\sum_{k\in\tilde K}\bigg)\|\tilde\psi^a_{\gamma,K,R}-\tilde\psi^1_{\gamma,K,R}\|_{L^r(k+[0,1]^d)}\\&\quad\le C\|u\|^2_{L^{p'}(\mathbf{R}^d\setminus B(R))}.\end{aligned}\tag{8.48}$$

Therefore estimate (6.7) follows from (8.48), Proposition 2.1, and Lemma 8.3. □

8.10. Proof of Theorem 6.2. Theorem 6.2 can be proved using an argument similar to the one in the proof of Theorem 6.1, except the average sampler Ψ is replaced with the ideal sampler δ_Γ. We omit the details of the proof here. □

8.11. Proof of Theorem 6.3. For any bounded set K, we let

$$V_2(\Phi, \Lambda\cap K)=\bigg\{\sum_{\lambda\in\Lambda\cap K} c(\lambda)\phi_\lambda,\ \sum_{\lambda\in\Lambda\cap K}|c(\lambda)|^2<\infty\bigg\}.$$

By the Riesz assumption on Φ,

$$C^{-1}\|c\|_{\ell^2(\Lambda\cap K)}\le\bigg\|\sum_{\lambda\in\Lambda\cap K} c(\lambda)\phi_\lambda\bigg\|_{L^2(\mathbf{R}^d)}\le C\|c\|_{\ell^2(\Lambda\cap K)} \tag{8.49}$$

for any sequence $c:=(c(\lambda))_{\lambda\in\Lambda\cap K}$. For any $R\ge 1$, it follows by the localization assumption on the generator Φ that

$$\begin{aligned}&\bigg\|\sum_{\lambda\in\Lambda\cap K} c(\lambda)\phi_\lambda\bigg\|^2_{L^2(\mathbf{R}^d\setminus B(K,R))}\\ &\quad\le\sum_{\lambda\in\Lambda\cap K}|c(\lambda)|^2\sum_{k\in\mathbf{Z}^d\setminus B(K,R-1)}\|\phi_\lambda\|_{L^2(k+[0,1]^d)}\bigg(\sum_{\lambda'\in\Lambda\cap K}\|\phi_{\lambda'}\|_{L^2(k+[0,1]^d)}\bigg)\\ &\quad\le C\|\Phi\|^2_{2,p,u}\|u^{-1}\|^2_{L^{p'}(\mathbf{R}^d\setminus B(R))}\sum_{\lambda\in\Lambda\cap K}|c(\lambda)|^2.\end{aligned} \tag{8.50}$$

We recall that

$$\|u^{-1}\|_{L^{p'}(\mathbf{R}^d\setminus B(R))}\to 0\text{ as }R\to\infty \tag{8.51}$$

by (2.17). Therefore by (8.49), (8.50), and (8.51), there exist positive constants C and R_1 such that

$$C^{-1}\|c\|_{\ell^2(\Lambda\cap K)}\le\bigg\|\sum_{\lambda\in\Lambda\cap K} c(\lambda)\phi_\lambda\bigg\|_{L^2(B(K,R_1))}\le C\|c\|_{\ell^2(\Lambda\cap K)} \tag{8.52}$$

for all sequences $c:=(c(\lambda))_{\lambda\in\Lambda\cap K}$.

Set $K_1=B(K,R_1)$. For the average sampling/reconstruction process, there exists a positive constant C by Theorem 6.1 and Lemma 8.1 such that for any $R\ge 1$ and $f=\sum_{\lambda\in\Lambda\cap K}c(\lambda)\phi_\lambda$,

$$\begin{aligned}\|\tilde f^a_{K_1,R}-f\|_{L^2(K_1)}&\le C\|u^{-1}\|_{L^{p'}(\mathbf{R}^d\setminus B(R))}\|(\langle f,\psi_\gamma\rangle)_{\gamma\in\Gamma}\|_{\ell^2(\Gamma)}\\ &\le C\|u^{-1}\|_{L^{p'}(\mathbf{R}^d\setminus B(R))}\|A_{\Psi,\Phi}\|_{\mathcal{A}_{p,u}}\bigg(\sum_{\lambda\in\Lambda\cap K}|c(\lambda)|^2\bigg)^{1/2}.\end{aligned} \tag{8.53}$$

Similarly for the ideal sampling/reconstruction procedure, there exists a positive constant C such that for any $R\ge 1$ and $f=\sum_{\lambda\in\Lambda\cap K}c(\lambda)\phi_\lambda$,

$$\|\tilde f^i_{K_1,R}-f\|_{L^2(K_1)}\le C\|u^{-1}\|_{L^{p'}(\mathbf{R}^d\setminus B(R))}\|A_{\delta_\Gamma,\Phi}\|_{\mathcal{A}_{p,u}}\bigg(\sum_{\lambda\in\Lambda\cap K}|c(\lambda)|^2\bigg)^{1/2}. \tag{8.54}$$

Therefore there exists a positive constant R_2 independent of K by (8.9) and (8.51)–(8.54) so that

$$C^{-1}\bigg(\sum_{\lambda\in\Lambda\cap K}|c(\lambda)|^2\bigg)^{1/2}\le\|f^a_{K_1,R_2}\|_{L^2(K_1)}\le C\bigg(\sum_{\lambda\in\Lambda\cap K}|c(\lambda)|^2\bigg)^{1/2} \tag{8.55}$$

for the average sampling/reconstruction process, and

$$C^{-1}\left(\sum_{\lambda\in\Lambda\cap K}|c(\lambda)|^2\right)^{1/2}\le\|f^i_{K_1,R_2}\|_{L^2(K_1)}\le C\left(\sum_{\lambda\in\Lambda\cap K}|c(\lambda)|^2\right)^{1/2} \tag{8.56}$$

for the ideal sampling/reconstruction process. Therefore conclusion (6.9) follows by letting $R_0=R_1+R_2$. □

8.12. Proof of Theorem 7.1. Let $A_{\Psi,\Phi}$ be as in (4.2), and the matrix $B\in\mathcal{A}_{p,u}(\Lambda,\Lambda)$ be as in (8.39) and (8.40). Write the sequence $(a_\gamma)_{\gamma\in\Gamma}$ as a vector, to be denoted by a, and the family of functions Φ as a vector, which is still denoted by Φ. We claim that

$$f_n=\sum_{k=0}^n a^TA_{\Psi,\Phi}B^k\Phi,\quad n\ge0, \tag{8.57}$$

where a^T denotes the transpose of the vector a. The above claim is obviously true for $n=0$. Inductively we assume that the claim is true for n. By (7.1), (8.39), and the inductive hypothesis, we have

$$\begin{aligned}f_{n+1}&=a^TA_{\Psi,\Phi}\Phi+\sum_{k=0}^n a^TA_{\Psi,\Phi}B^k\Phi-A^{-2}\sum_{k=0}^n a^TA_{\Psi,\Phi}B^kA^*_{\Psi,\Phi}A_{\Psi,\Phi}\Phi\\&=a^TA_{\Psi,\Phi}\Phi+\sum_{k=0}^n a^TA_{\Psi,\Phi}B^k\Phi-\sum_{k=0}^n a^TA_{\Psi,\Phi}B^k(I-B)\Phi\\&=\sum_{k=0}^{n+1}a^TA_{\Psi,\Phi}B^k\Phi.\end{aligned}$$

This proves claim (8.57) by induction.

By (8.9), (8.41), (8.57), and Proposition 2.1, we have

$$\begin{aligned}\|f_{n+1}-f_n\|_r&=\|a^TA_{\Psi,\Phi}B^{n+1}\Phi\|_r\\&\le C\|a\|_{\ell^r(\Gamma)}\|A_{\Psi,\Phi}\|_{\mathcal{A}_{p,u}}\|B^{n+1}\|_{\mathcal{A}_{p,u}}\|\Phi\|_{q,p,u}\\&\le C\left(\frac{\|B\|_{\mathcal{B}^2}+1}{2}\right)^n\|a\|_{\ell^r(\Gamma)}\quad\text{for all } n\ge0,\end{aligned} \tag{8.58}$$

where $a:=(a_\gamma)_{\gamma\in\Gamma}$. The first conclusion then follows from (8.58).

Now we assume that the initial data $a:=(a_\gamma)_{\gamma\in\Gamma}$ are obtained from average sampling a function $f\in V_r(\Phi,\Lambda)$. Taking limits at both sides of $f_n=f_0+f_{n-1}-A^{-2}T_{as}f_{n-1}$ and using the Riesz property of Φ, we obtain

$$\sum_{\gamma\in\Gamma}\langle f-f_\infty,\psi_\gamma\rangle\langle\psi_\gamma,\phi_\lambda\rangle=0\ \text{ for all } \lambda\in\Lambda. \tag{8.59}$$

Write

$$f-f_\infty=\sum_{\lambda\in\Lambda}d_\lambda\phi_\lambda \tag{8.60}$$

for some ℓ^r sequence $d=(d_\lambda)_{\lambda\in\Lambda}$. We then may write (8.59) as

$$d^TA^*_{\Psi,\Phi}A_{\Psi,\Phi}=0. \tag{8.61}$$

Combining (8.13), (8.60), and (8.61) leads to the second conclusion of the theorem that the limit function f_∞ agrees with the original function f. □

8.13. Proof of Theorem 7.2. We may use the same argument as in the proof of Theorem 7.1 with standard modification, for instance, the matrix $A_{\Psi,\Phi}$ in the proof of Theorem 7.1 by the matrix $A_{\delta_\Gamma,\Phi} := (\phi_\lambda(\gamma))_{\gamma\in\Gamma,\lambda\in\Lambda}$. We omit the details of the proof here. □

Acknowledgments. The author would like to thank Professors A. Aldroubi, K. Gröchenig, and D. Han for their help in preparing this paper. The author also thanks the anonymous referees for their valuable comments and suggestions which led to an improvement of the results and the presentation in the paper. In particular, the author thanks the anonymous referee for the suggestion that leads to the general principle in Remark 3.1 for the well-localization of the displayer, and for pointing out that the results in Theorems 3.1 and 3.2 can be derived from theorems for localized frames in [8, 24, 32].

ON THE PARTIAL DIFFERENTIAL EQUATIONS OF ELECTROSTATIC MEMS DEVICES: STATIONARY CASE*

NASSIF GHOUSSOUB† AND YUJIN GUO†

Abstract. We analyze the nonlinear elliptic problem $\Delta u = \frac{\lambda f(x)}{(1+u)^2}$ on a bounded domain Ω of R^N with Dirichlet boundary conditions. This equation models a simple electrostatic micro-electromechanical system (MEMS) device consisting of a thin dielectric elastic membrane with boundary supported at 0 above a rigid ground plate located at -1. When a voltage—represented here by λ—is applied, the membrane deflects towards the ground plate, and a snap-through may occur when it exceeds a certain critical value λ^* (pull-in voltage). This creates a so-called pull-in instability, which greatly affects the design of many devices. The mathematical model leads to a nonlinear parabolic problem for the dynamic deflection of the elastic membrane, which will be considered in a forthcoming paper. Here, we focus on the stationary equation and on estimates for λ^* in terms of material properties of the membrane, which can be fabricated with a spatially varying dielectric permittivity profile f. Applying analytical and numerical techniques, we establish upper and lower bounds for λ^* in terms of the volume and shape of the domain, the dimension of the ambient space, as well as the permittivity profile. We analyze the first branch of stable steady states when $\lambda < \lambda^*$ and prove that a semistable (extremal) solution exists at $\lambda = \lambda^*$ in dimension $1 \le N \le 7$, and that classical extremal solutions may not exist for dimension $N \ge 8$. More refined properties of stable steady states—such as regularity, stability, uniqueness, multiplicity, energy estimates, and comparison results—are also established. The analysis of branches of unstable solutions is more elaborate and is tackled in the companion paper [P. Esposito, N. Ghoussoub, and Y. Guo, *Comm. Pure Appl. Math.*, (2006), to appear].

Key words. MEMS, pull-in voltage, power law permittivity profile, minimal solutions

1. Introduction.

Micro-electromechanical systems (MEMS) are often used to combine electronics with microsize mechanical devices in the design of various types of microscopic machinery. MEMS devices have therefore become key components of many commercial systems, including accelerometers for airbag deployment in automobiles, ink jet printer heads, optical switches, chemical sensors, and so on (see, for example, [20]). The key component of many modern MEMS is a simple idealized electrostatic device consisting of a thin and deformable elastic membrane that is held fixed along its boundary and which lies above a rigid grounded plate. This elastic membrane is modeled as a dielectric with a small but finite thickness. The upper surface of the membrane is coated with a negligibly thin metallic conducting film. When a voltage V is applied to the conducting film, the thin dielectric membrane deflects towards the bottom plate, and when V is increased beyond a certain critical value V^*—known as the pull-in voltage—the steady state of the elastic membrane is lost and proceeds to touchdown or snap through at a finite time, creating the so-called pull-in instability.

A mathematical model of the physical phenomena, leading to a partial differential

equation for the dimensionless dynamic deflection of the membrane, was derived and analyzed in [10] and [12]. In the damping-dominated limit, and using a narrow-gap asymptotic analysis, the dimensionless dynamic deflection $u = u(x,t)$ of the membrane on a bounded domain Ω in R^2 is found to satisfy the following parabolic problem:

$$\begin{aligned} \frac{\partial u}{\partial t} &= \Delta u - \frac{\lambda f(x)}{(1+u)^2} \quad \text{for} \quad x \in \Omega, \\ u(x,0) &= 0 \qquad\qquad\qquad\quad \text{for} \quad x \in \Omega, \\ u(x,t) &= 0 \qquad\qquad\qquad\quad \text{for} \quad x \in \partial\Omega. \end{aligned} \tag{1.1}$$

The initial condition in (1.1) assumes that the membrane is initially undeflected and that the voltage is suddenly applied to the upper surface of the membrane at time $t = 0$. The parameter $\lambda > 0$ in (1.1) characterizes the relative strength of the electrostatic and mechanical forces in the system, and is given in terms of the applied voltage V by $\lambda = \frac{\varepsilon_0 V^2 L^2}{2T_e d^3}$, where d is the undeflected gap size, L is the length scale of the membrane, T_e is the tension of the membrane, and ε_0 is the permittivity of free space in the gap between the membrane and the bottom plate. From now on we shall use the parameter λ and λ^* to represent the applied voltage V and pull-in voltage V^*, respectively. Referred to as the *permittivity profile*, $f(x)$ in (1.1) is defined by the ratio $f(x) = \frac{\varepsilon_0}{\varepsilon_2(x)}$, where $\varepsilon_2(x)$ is the dielectric permittivity of the thin membrane.

There are several issues that must be considered in the actual design of MEMS devices. Typically one of the primary goals is to achieve the maximum possible stable deflection before touchdown occurs, which is referred to as the *pull-in distance* (cf. [12] and [19]). Another consideration is to increase the stable operating range of the device by improving the pull-in voltage λ^* subject to the constraint that the range of the applied voltage is limited by the available power supply. Such improvements in the stable operating range are important for the design of certain MEMS devices such as microresonators. One way of achieving larger values of λ^*, while simultaneously increasing the pull-in distance, was studied in [19] and [12] and consists of introducing a spatially varying dielectric permittivity $\varepsilon_2(x)$ of the membrane. The idea is to locate the region where the membrane deflection would normally be largest under a spatially uniform permittivity, and then make sure that a new dielectric permittivity $\varepsilon_2(x)$ is largest—and consequently the profile $f(x)$ smallest—in that region.

Pelesko studied in [19] the steady states of (1.1), when $f(x)$ is assumed to be bounded away from zero, i.e., $0 < C \le f(x) \le 1$ for all $x \in \Omega$. He established in this case an upper bound for λ^*, and derived numerical results for the power-law permittivity profile, from which the larger pull-in voltage and thereby the larger pull-in distance, existence, and multiplicity of the steady states were observed. From the strictly mathematical point of view, it turned out that—at least for $f \equiv 1$—there already exist in the literature many interesting results concerning the properties of the branch of semistable solutions for Dirichlet boundary value problems of the form $-\Delta u = \lambda h(u)$, where h is a regular nonlinearity (e.g., $h(u) = e^u$ or $(1+u)^p$ for $p > 1$). See, for example, the seminal papers [8, 14, 15] and also [6] for a survey on the subject and an exhaustive list of related references. After a first version of this paper was circulated, X. Cabre informed us that even the case of singular nonlinearities involved in MEMS devices had already been considered in [4] and in a more general context in [17].

Recently, Guo, Pan, and Ward studied in [12] the dynamic behavior of (1.1), which is also of great practical interest. They considered a more general class of profiles $f(x)$, where the membrane is allowed to be perfectly conducting, i.e., $0 \le$

$f(x) \le 1$ for all $x \in \Omega$, with $f(x) > 0$ on a subset of positive measure of Ω. By using both analytical and numerical techniques, they obtained larger pull-in voltage λ^* and larger pull-in distance for different classes of varying permittivity profiles. Besides the above practical considerations, the model turned out to be a very rich source of interesting mathematical phenomena. Numerics give lots of information and point to many conjectures, but the available arsenal of nonlinear analysis and PDE techniques can tackle only a precious few, even in the case of power-law permittivity profiles $f(x) = |x|^\alpha$.

This paper is a first in a series where we try to provide a rigorous mathematical analysis for various phenomena related to this model, which were observed numerically. Estimates on the pull-in voltage λ^* depend on the size and geometry of the domain, but also on the dimension of the ambient space and the permittivity profile f. A similar dependence occurs for the refined properties of steady states—such as regularity, stability, uniqueness, multiplicity, energy estimates, and comparison results. The same complexity carries to the dynamic case, where issues related to the "touchdown profile"—in finite or infinite time—or to global convergence towards a stable steady state present many interesting mathematical challenges.

In this first paper, we focus on the stable and semistable stationary deflections of the membrane, while the unstable case is considered in [9], and the dynamic case in [11]. For convenience, we shall set $v = -u$ in such a way that our discussion will center on the following elliptic problem:

$$(S)_\lambda \qquad -\Delta v = \frac{\lambda f(x)}{(1-v)^2} \quad \text{and} \quad 0 < v < 1 \ \text{ for } x \in \Omega\,, \ \text{ while } v = 0 \ \text{ on } \ \partial\Omega.$$

Throughout the paper and unless mentioned otherwise, solutions for $(S)_\lambda$ will be taken in the classical sense. The permittivity profile f will be allowed to vanish somewhere, and will be assumed to satisfy

$$\begin{aligned} &f \in C^\alpha(\bar\Omega) \quad \text{for some } \alpha \in (0,1],\ 0 \le f \le 1, \text{ and} \\ &f > 0 \quad \text{on a subset of } \Omega \text{ of positive measure.} \end{aligned} \tag{1.2}$$

This paper is organized as follows. In section 2 we mainly show the existence of a specific pull-in voltage and study its dependence on the size and shape of the domain as well as on the permittivity profile. These monotonicity properties will help us establish in section 3 new lower and upper bound estimates on the pull-in voltage. We shall write $|\Omega|$ for the volume of a domain Ω in R^N and $P(\Omega) := \int_{\partial\Omega} ds$ for its "perimeter," with ω_N referring to the volume of the unit ball $B_1(0)$ in R^N. We denote by μ_Ω the first eigenvalue of $-\Delta$ on $H_0^1(\Omega)$, and by ϕ_Ω the corresponding positive eigenfunction normalized with $\int_\Omega \phi_\Omega dx = 1$.

THEOREM 1.1. *Assume that f is a function satisfying* (1.2) *on a bounded domain Ω; then there exists a finite pull-in voltage $\lambda^* := \lambda^*(\Omega, f) > 0$ such that we have the following:*

1. *If $0 \le \lambda < \lambda^*$, there exists at least one solution for $(S)_\lambda$.*
2. *If $\lambda > \lambda^*$, there is no solution for $(S)_\lambda$.*
3. *The following bounds on λ^* hold for any bounded domain Ω:*

$$\max\left\{\frac{8N}{27},\ \frac{6N-8}{9}\right\} \frac{1}{\sup_\Omega f} \left(\frac{\omega_N}{|\Omega|}\right)^{\frac{2}{N}} \le \lambda^*(\Omega), \tag{1.3}$$

$$\min\left\{\bar\lambda_1 := \frac{4\mu_\Omega}{27 \inf\limits_{x\in\Omega} f(x)}, \bar\lambda_2 := \frac{\mu_\Omega}{3\int_\Omega f\phi_\Omega\, dx}\right\} \ge \lambda^*(\Omega). \tag{1.4}$$

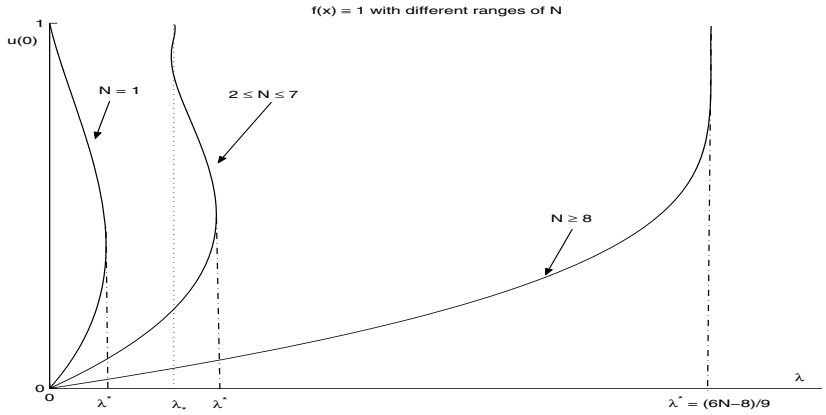

FIG. 1.1. *Plots of $u(0)$ versus λ for the constant permittivity profile $f(x) \equiv 1$ defined in the unit ball $B_1(0) \subset R^N$ with different ranges of N. In the case of $N \geq 8$, we have $\lambda^* = (6N-8)/9$.*

4. *If Ω is a strictly star-shaped domain, that is if $x \cdot \nu(x) \geq a > 0$ for all $x \in \partial\Omega$, where $\nu(x)$ is the unit outer normal at $x \in \partial\Omega$, and if $f \equiv 1$, then*

$$\lambda^*(\Omega) \leq \bar{\lambda}_3 = \frac{(N+2)^2 P(\Omega)}{8aN|\Omega|}.$$

In particular, if $\Omega = B_1(0) \subset R^N$, then we have the bound

$$\lambda^*(B_1(0)) \leq \frac{(N+2)^2}{8}.$$

5. *If $f(x) \equiv |x|^\alpha$ with $\alpha \geq 0$ and Ω is a ball of radius R, then we have*

$$\lambda^*(B_R, |x|^\alpha) \geq \max\left\{\frac{4(2+\alpha)(N+\alpha)}{27R^{(2+\alpha)}}, \frac{(2+\alpha)(3N+\alpha-4)}{9R^{(2+\alpha)}}\right\}. \tag{1.5}$$

Moreover, if $N \geq 8$ and $0 \leq \alpha \leq \alpha^{**}(N) := \frac{4-6N+3\sqrt{6}(N-2)}{4}$, we have

$$\lambda^*(B_1, |x|^\alpha) = \frac{(2+\alpha)(3N+\alpha-4)}{9}. \tag{1.6}$$

In section 3.3 we give some numerical estimates on λ^* to compare them with the analytic bounds given in Theorem 1.1 above. Note that the upper bound $\bar{\lambda}_1$ is relevant only when f is bounded away from 0, while the upper bound $\bar{\lambda}_2$ is valid for all permittivity profiles. However, the order between these two upper bounds can vary in general. For example, in the case of exponential permittivity profiles of the form $f(x) = e^{\alpha(|x|^2-1)}$ on the unit disc, one can see that $\bar{\lambda}_1$ is a better upper bound than $\bar{\lambda}_2$ for small α, while the reverse holds true for larger values of α. The lower bounds in (1.3) and (1.5) can be improved in small dimensions, but they are optimal—at least for the ball—in dimension larger than 8.

We also consider issues of uniqueness and multiplicity of solutions for $(S)_\lambda$ with $0 < \lambda \leq \lambda^*$. The bifurcation diagrams in Figure 1.1 show the complexity of the situation, even in the radially symmetric case. One can see that the number of branches—and of solutions—is closely connected to the space dimension, a fact that

we establish analytically in section section 4, by focussing on the very first branch of solutions considered to be "minimal" in the following way.

DEFINITION 1.2. *A solution $u_\lambda(x)$ of $(S)_\lambda$ is said to be minimal if for any other solution u of $(S)_\lambda$ we have $u_\lambda(x) \le u(x)$ for all $x \in \Omega$.*

One can also consider for any solution u of $(S)_\lambda$ the linearized operator at u defined by $L_{u,\lambda} = -\Delta - \frac{2\lambda f(x)}{(1-u)^3}$ and its eigenvalues $\{\mu_{k,\lambda}(u); k = 1, 2, \ldots\}$. The first eigenvalue is then simple and is given by

$$\mu_{1,\lambda}(u) = \inf \left\{ \langle L_{u,\lambda}\phi, \phi \rangle_{H_0^1(\Omega)} \, ; \, \phi \in C_0^\infty(\Omega), \int_\Omega |\phi(x)|^2 dx = 1 \right\}.$$

Stable solutions (*resp.*, *semi-stable solutions*) of $(S)_\lambda$ are those solutions u such that $\mu_{1,\lambda}(u) > 0$ (*resp.*, $\mu_{1,\lambda}(u) \ge 0$). Our main results in this direction can be stated as follows.

THEOREM 1.3. *Assume that f is a function satisfying* (1.2) *on a bounded domain Ω, and consider $\lambda^* := \lambda^*(\Omega, f)$ as defined in Theorem* 1.1. *Then the following hold:*

1. *For any $0 \le \lambda < \lambda^*$ there exists a unique minimal solution u_λ of $(S)_\lambda$ such that $\mu_{1,\lambda}(u_\lambda) > 0$. Moreover, for each $x \in \Omega$ the function $\lambda \to u_\lambda(x)$ is strictly increasing and differentiable on $(0, \lambda^*)$.*
2. *If $1 \le N \le 7$, then one has $\sup_{\lambda \in (0,\lambda^*)} \| u_\lambda \|_\infty < 1$, and consequently $u^* = \lim_{\lambda \uparrow \lambda^*} u_\lambda$ exists in $C^{2,\alpha}(\bar{\Omega})$ and is a solution for $(S)_{\lambda^*}$ such that $\mu_{1,\lambda^*}(u^*) = 0$. In particular, u^*—often referred to as the extremal solution of problem $(S)_\lambda$—is unique.*
3. *On the other hand, if $N \ge 8$, $f(x) = |x|^\alpha$ with $0 \le \alpha \le \alpha^{**}(N) := \frac{4-6N+3\sqrt{6}(N-2)}{4}$, and Ω is the unit ball, then the extremal solution is necessarily $u^*(x) = 1 - |x|^{\frac{2+\alpha}{3}}$ and is therefore singular.*

We note that, in general, the function u^* exists in any dimension, does solve $(S)_{\lambda^*}$ in a suitable weak sense, and is the unique solution in an appropriate class. The above theorem says that it is, however, a classical solution in dimensions $1 \le N \le 7$, and this will allow us to start another branch of nonminimal (unstable) solutions. Indeed, we show in section 5—following ideas of Crandall and Rabinowitz [8]—that, for $1 \le N \le 7$ and for λ close enough to λ^*, there exists a unique second branch U_λ of solutions for $(S)_\lambda$, bifurcating from u^*, with

$$\mu_{1,\lambda}(U_\lambda) < 0 \quad \text{while } \mu_{2,\lambda}(U_\lambda) > 0. \tag{1.7}$$

In the companion paper [9], we shall provide a variational (mountain pass) characterization of these unstable solutions, and more importantly we establish—under the same dimension restriction as above—a compactness result along the second branch of unstable solutions leading to a—nonzero—second bifurcation point.

Issues of uniqueness, multiplicity, and other qualitative properties of the solutions for $(S)_\lambda$ are still far from being well understood, even in the radially symmetric case which we consider in section 6. Some of the classical work of Joseph and Lundgren [14] and many that followed can be adapted to this situation when the permittivity profile is constant. However, the case of a power-law permittivity profile $f(x) = |x|^\alpha$ defined in a unit ball already presents a much richer situation. In section 6 we present some numerical evidence for various conjectures relating to this case, some of which have been tackled in [9]. A detailed and involved analysis of compactness along the unstable branches will be discussed there, as well as some information about the second bifurcation point.

2. The pull-in voltage. In this section, we establish the existence and some monotonicity properties for the pull-in voltage λ^*, which is defined as

$$\lambda^*(\Omega, f) = \sup\{\lambda > 0 \mid (S)_\lambda \text{ possesses at least one solution}\}. \tag{2.1}$$

2.1. Existence of the pull-in voltage. For any bounded domain Γ in R^N, we denote by μ_Γ the first eigenvalue of $-\Delta$ on $H_0^1(\Gamma)$ and by ψ_Γ the corresponding positive eigenfunction normalized with $\sup_{x\in\Gamma}\psi_\Gamma = 1$. We also associate with any domain Ω in R^N the following parameter:

$$\nu_\Omega = \sup\Big\{\mu_\Gamma H(\inf_\Omega \psi_\Gamma);\ \Gamma \text{ domain of } R^N,\ \Gamma \supset \bar{\Omega}\Big\}, \tag{2.2}$$

where H is the function $H(t) = \frac{t(t+1+2\sqrt{t})}{(t+1+\sqrt{t})^3}$.

THEOREM 2.1. *Assume that f is a function satisfying* (1.2) *on a bounded domain Ω in R^N; then there exists a finite pull-in voltage $\lambda^* := \lambda^*(\Omega, f) > 0$ such that*

1. *if $\lambda < \lambda^*$, there exists at least one solution for $(S)_\lambda$;*
2. *if $\lambda > \lambda^*$, there is no solution for $(S)_\lambda$.*

Moreover, we have the lower bound

$$\lambda^*(\Omega, f) \geq \frac{\nu_\Omega}{\sup_{x\in\Omega} f(x)}. \tag{2.3}$$

Proof. We need to show that $(S)_\lambda$ has at least one solution when $\lambda < \frac{\nu_\Omega}{\sup_\Omega f(x)}$. It is clear that $u \equiv 0$ is a subsolution of $(S)_\lambda$ for all $\lambda > 0$. To construct a super-solution, consider a bounded domain $\Gamma \supset \bar{\Omega}$ with smooth boundary, and let $(\mu_\Gamma, \psi_\Gamma)$ be its first eigenpair normalized in such a way that

$$\sup_{x\in\Gamma}\psi_\Gamma(x) = 1 \quad \text{and} \quad \inf_{x\in\Omega}\psi_\Gamma(x) := s_1 > 0.$$

We construct a supersolution in the form $\psi = A\psi_\Gamma$, where A is a scalar to be chosen later. First, we must have $A\psi_\Gamma \geq 0$ on $\partial\Omega$ and $0 < 1 - A\psi_\Gamma < 1$ in Ω, which requires that $0 < A < 1$. We also require

$$-\Delta\psi - \frac{\lambda f(x)}{(1-A\psi)^2} \geq 0 \quad \text{in } \Omega, \tag{2.4}$$

which can be satisfied as long as $\mu_\Gamma A\ \psi_\Gamma \geq \frac{\lambda \sup_\Omega f(x)}{(1-A\ \psi_\Gamma)^2}$ in Ω or

$$\lambda \sup_\Omega f(x) < \beta(A,\Gamma) := \mu_\Gamma \inf\{g(sA);\ s \in [s_1(\Gamma), 1]\}, \tag{2.5}$$

where $g(s) = s(1-s)^2$. In other words, $\lambda^* \sup_\Omega f(x) \geq \sup\{\beta(A,\Gamma);\ 0 < A < 1,\ \Gamma \supset \bar{\Omega}\}$, and therefore it remains to show that

$$\nu_\Omega = \sup\{\beta(A,\Gamma);\ 0 < A < 1, \Gamma \supset \bar{\Omega}\}. \tag{2.6}$$

For that, we note first that $\inf_{s\in[s_1,1]} g(As) = \min\big\{g(As_1), g(A)\big\}$. We also have that $g(As_1) \leq g(A)$ if and only if $A^2(s_1^3 - 1) - 2A(s_1^2 - 1) + (s_1 - 1) \leq 0$, which happens if and only if $A^2(s_1^2 + s_1 + 1) - 2A(s_1 + 1) + 1 \geq 0$ or if and only if either $A \leq A_-$ or $A \geq A_+$, where

$$A_+ = \frac{s_1 + 1 + \sqrt{s_1}}{s_1^2 + 1 + s_1} = \frac{1}{s_1 + 1 - \sqrt{s_1}}, \qquad A_- = \frac{s_1 + 1 - \sqrt{s_1}}{s_1^2 + 1 + s_1} = \frac{1}{s_1 + 1 + \sqrt{s_1}}.$$

Since $A_- < 1 < A_+$, we get that

$$G(A) = \inf_{s\in[s_1,1]} g(As) = \begin{cases} g(As_1) & \text{if } 0 \le A \le A_-, \\ g(A) & \text{if } A_- \le A \le 1. \end{cases} \tag{2.7}$$

We now have that $\frac{dG}{dA} = g'(As_1)s_1 \ge 0$ for all $0 \le A \le A_-$. And since $A_- \ge \frac{1}{3}$, we have $\frac{dG}{dA} = g'(A) \le 0$ for all $A_- \le A \le 1$. It follows that

$$\begin{aligned} \sup_{0<A<1} \inf_{s\in[s_1,1]} g(As) &= \sup_{0<A<1} G(A) = G(A_-) = g(A_-) \\ &= \frac{1}{s_1+1+\sqrt{s_1}}\left(1 - \frac{1}{s_1+1+\sqrt{s_1}}\right)^2 \\ &= \frac{s_1(s_1+1+2\sqrt{s_1})}{(s_1+1+\sqrt{s_1})^3} = H\left(\inf_\Omega \psi_\Gamma\right), \end{aligned}$$

which proves our lower estimate.

Now we know that $\lambda^* > 0$, so we can pick $\lambda \in (0, \lambda^*)$ and use the definition of λ^* to find a $\bar\lambda \in (\lambda, \lambda^*)$ such that $(S)_{\bar\lambda}$ has a solution $u_{\bar\lambda}$; i.e.,

$$-\Delta u_{\bar\lambda} = \tfrac{\bar\lambda f(x)}{(1-u_{\bar\lambda})^2},\ 0 \le u_{\bar\lambda} < 1, \text{ on } \Omega \quad \text{and} \quad u_{\bar\lambda} = 0 \text{ on } \partial\Omega,$$

and in particular $-\Delta u_{\bar\lambda} \ge \frac{\lambda f(x)}{(1-u_{\bar\lambda})^2}$ on Ω, which then implies that $u_{\bar\lambda}$ is a supersolution of $(S)_\lambda$. Since $u \equiv 0$ is a subsolution of $(S)_\lambda$, we can again conclude that there is a solution u_λ of $(S)_\lambda$.

It is also easy to show that λ^* is finite, since if $(S)_\lambda$ has at least one solution $0 < u < 1$, then, by integrating against the first (positive) eigenfunction ϕ_Ω, we get

$$\begin{aligned} +\infty > \mu_\Omega \ge \mu_\Omega \int_\Omega u\phi_\Omega &= -\int_\Omega u\Delta\phi_\Omega = -\int_\Omega \phi_\Omega \Delta u \\ &= \lambda \int_\Omega \frac{\phi_\Omega f}{(1-u)^2} dx \ge \lambda \int_\Omega \phi_\Omega f\, dx \end{aligned} \tag{2.8}$$

and therefore $\lambda^* < +\infty$. The definition of λ^* implies that there is no solution of $(S)_\lambda$ for any $\lambda > \lambda^*$. □

2.2. Monotonicity results for the pull-in voltage. In this subsection, we give a more precise characterization of λ^*, namely as the endpoint for the branch of minimal solutions. This will allow us to establish various monotonicity properties for λ^* that will help in the estimates given in the next subsections. First we give a recursive scheme for the construction of minimal solutions.

THEOREM 2.2. *Assume that f is a function satisfying* (1.2) *on a bounded domain Ω in R^N; then for any $0 < \lambda < \lambda^*(\Omega, f)$ there exists a unique minimal positive solution u_λ for $(S)_\lambda$. It is obtained as the limit of the sequence $\{u_n(\lambda; x)\}$ constructed recursively as follows: $u_0 \equiv 0$ in Ω and, for each $n \ge 1$,*

$$\begin{aligned} -\Delta u_n &= \frac{\lambda f(x)}{(1-u_{n-1})^2}, \quad x \in \Omega; \\ 0 \le u_n < 1, \quad x \in \Omega; &\qquad u_n = 0, \qquad x \in \partial\Omega. \end{aligned} \tag{2.9}$$

Proof. Let u be any positive solution for $(S)_\lambda$, and consider the sequence $\{u_n(\lambda;x)\}$ defined in (2.9). Clearly $u(x) > u_0 \equiv 0$ in Ω, and whenever $u(x) \geq u_{n-1}$ in Ω, then

$$-\Delta(u-u_n) = \lambda f(x)\left[\frac{1}{(1-u)^2} - \frac{1}{(1-u_{n-1})^2}\right] \geq 0, \quad x \in \Omega\,; \quad u-u_n = 0, \quad x \in \partial\Omega.$$

The maximum principle and an immediate induction yield that $1 > u(x) \geq u_n$ in Ω for all $n \geq 0$. In a similar way, the maximum principle implies that the sequence $\{u_n(\lambda;x)\}$ is monotone increasing. Therefore, $\{u_n(\lambda;x)\}$ converges uniformly to a positive solution $u_\lambda(x)$, satisfying $u(x) \geq u_\lambda(x)$ in Ω, which is a minimal positive solution of $(S)_\lambda$. It is also clear that u_λ is unique in this class of solutions. □

Remark 2.1. Let $g(x,\xi,\Omega)$ be Green's function of the Laplace operator, with $g(x,\xi,\Omega) = 0$ on $\partial\Omega$. Then the iteration in (2.9) can be replaced by $u_0 \equiv 0$ in Ω, and for each $n \geq 1$,

$$u_n(\lambda;x) = \lambda \int_\Omega \frac{f(\xi)g(x,\xi,\Omega)}{(1-u_{n-1}(\lambda;\xi))^2} d\xi, \quad x \in \Omega\,; \qquad u_n(\lambda;x) = 0, \quad x \in \partial\Omega. \tag{2.10}$$

The same reasoning as above yields that $\lim_{n\to\infty} u_n(\lambda;x) = u_\lambda(x)$ for all $x \in \Omega$.

The above construction of solutions yields the following monotonicity result for the pull-in voltage.

PROPOSITION 2.3. *If $\Omega_1 \subset \Omega_2$ and if f is a function satisfying* (1.2) *on Ω_2, then $\lambda^*(\Omega_1) \geq \lambda^*(\Omega_2)$ and the corresponding minimal solutions satisfy $u_{\Omega_1}(\lambda,x) \leq u_{\Omega_2}(\lambda,x)$ on Ω_1 for every $0 < \lambda < \lambda^*(\Omega_2)$.*

Proof. Again the method of sub/supersolutions immediately yields that $\lambda^*(\Omega_1) \geq \lambda^*(\Omega_2)$. Now consider, for $i = 1, 2$, the sequences $\{u_n(\lambda,x,\Omega_i)\}$ on Ω_i defined by (2.10), where $g(x,\xi,\Omega_i)$ are the corresponding Green's functions on Ω_i. Since $\Omega_1 \subset \Omega_2$, we have that $g(x,\xi,\Omega_1) \leq g(x,\xi,\Omega_2)$ on Ω_1. Hence, it follows that

$$u_1(\lambda,x,\Omega_2) = \lambda \int_{\Omega_2} f(\xi)g(x,\xi,\Omega_2)d\xi \geq \lambda \int_{\Omega_1} f(\xi)g(x,\xi,\Omega_1)d\xi = u_1(\lambda,x,\Omega_1)$$

on Ω_1. By induction we conclude that $u_n(\lambda,x,\Omega_2) \geq u_n(\lambda,x,\Omega_1)$ on Ω_1 for all n. On the other hand, since $u_n(\lambda,x,\Omega_2) \leq u_{n+1}(\lambda,x,\Omega_2)$ on Ω_2 for n, we get that $u_n(\lambda,x,\Omega_1) \leq u_{\Omega_2}(\lambda,x)$ on Ω_1, and we are done. □

We also note the following easy comparison results, and we omit the details.

COROLLARY 2.4. *Suppose that $f_1, f_2 : \Omega \to R$ are two functions satisfying* (1.2) *and such that $f_1(x) \leq f_2(x)$ on Ω; then $\lambda^*(\Omega,f_1) \geq \lambda^*(\Omega,f_2)$, and for $0 < \lambda < \lambda^*(\Omega,f_2)$ we have $u_1(\lambda,x) \leq u_2(\lambda,x)$ on Ω, where $u_1(\lambda,x)$ (resp., $u_2(\lambda,x)$) are the unique minimal positive solution of*

$$-\Delta u = \frac{\lambda f_1(x)}{(1-u)^2} \ \left(\textit{resp.}, -\Delta u = \frac{\lambda f_2(x)}{(1-u)^2}\right) \textit{ on } \Omega \quad \textit{and} \quad u = 0 \textit{ on } \partial\Omega.$$

Moreover, if $f_2(x) > f_1(x)$ on a subset of positive measure, then $u_1(\lambda,x) < u_2(\lambda,x)$ for all $x \in \Omega$.

The following result is similar to Theorem 4.10 of [2], which deals only with nonsingular nonlinearities. It can, however, be extended to our setting, but the adaptation of the proof is left to the interested reader.

PROPOSITION 2.5. *For any bounded domain Γ in R^N and any function f satisfying* (1.2) *on Γ, we have $\lambda^*(\Gamma,f) \geq \lambda^*(B_R,f^*)$, where $B_R = B_R(0)$ is the Euclidean ball in R^N with radius $R > 0$ and with volume $|B_R| = |\Gamma|$, and where f^* is the Schwarz symmetrization of f.*

3. Estimates for the pull-in voltage. While the lower bound in (2.3) is useful to prove existence, it is not easy to compute. The following subsection gives more computationally accessible lower estimates for λ^*.

3.1. Lower bounds for λ^*.

PROPOSITION 3.1. *Assume that f is a function satisfying* (1.2) *on a bounded domain Ω in R^N; then we have the following lower bound:*

$$\lambda^*(\Omega, f) \geq \max\left\{\frac{8N}{27}, \frac{6N-8}{9}\right\}\frac{1}{\sup_\Omega f}\left(\frac{\omega_N}{|\Omega|}\right)^{\frac{2}{N}}. \tag{3.1}$$

Moreover, if $f(x) \equiv |x|^\alpha$ with $\alpha \geq 0$ and Ω is a ball of radius R, then we have

$$\lambda^*(B_R, |x|^\alpha) \geq \max\left\{\frac{4(2+\alpha)(N+\alpha)}{27}, \frac{(2+\alpha)(3N+\alpha-4)}{9}\right\}R^{-(2+\alpha)}. \tag{3.2}$$

Finally, if $N \geq 8$ and $0 \leq \alpha \leq \alpha^{**}(N) := \frac{4-6N+3\sqrt{6}(N-2)}{4}$, we have

$$\lambda^*(B_1, |x|^\alpha) = \frac{(2+\alpha)(3N+\alpha-4)}{9}. \tag{3.3}$$

Proof. Setting $R = \left(\frac{|\Omega|}{\omega_N}\right)^{\frac{1}{N}}$, it suffices—in view of Proposition 2.5 and since $\sup_{B_R} f^* = \sup_\Omega f$—to show that

$$\lambda^*(B_R, f^*) \geq \max\left\{\frac{8N}{27R^2\sup_\Omega f^*}, \frac{6N-8}{9R^2\sup_\Omega f^*}\right\} \tag{3.4}$$

for the case where $\Omega = B_R$. In fact, the function $w(x) = \frac{1}{3}(1 - \frac{|x|^2}{R^2})$ satisfies on B_R

$$-\Delta w = \frac{2N}{3R^2} = \frac{2N(1-\frac{1}{3})^2}{3R^2}\frac{1}{(1-\frac{1}{3})^2} \geq \frac{8N}{27R^2\sup_\Omega f}\frac{f(x)}{[1-\frac{1}{3}(1-\frac{|x|^2}{R^2})]^2}$$
$$= \frac{8N}{27R^2\sup_\Omega f}\frac{f(x)}{(1-w)^2}.$$

So for $\lambda \leq \frac{8N}{27R^2\sup_\Omega f}$, w is a supersolution of $(S)_\lambda$ in B_R. Since, on the other hand, $w_0 \equiv 0$ is a subsolution of $(S)_\lambda$ and $w_0 \leq w$ in B_R, then there exists a solution of $(S)_\lambda$ in B_R, which proves a part of (3.4).

A similar computation applied to the function $v(x) = 1 - (\frac{|x|}{R})^{\frac{2}{3}}$ shows that v is also a supersolution as long as $\lambda \leq \frac{6N-8}{9R^2\sup_\Omega f}$.

In order to prove (3.2), it suffices to note that $w(x) = \frac{1}{3}\left(1 - \frac{|x|^{2+\alpha}}{R^{2+\alpha}}\right)$ is a supersolution for $(S)_\lambda$ on B_R, provided $\lambda \leq \frac{4(2+\alpha)(N+\alpha)}{27R^{2+\alpha}}$, and that $v(x) = 1 - (\frac{|x|}{R})^{\frac{2+\alpha}{3}}$ is a supersolution for $(S)_\lambda$ on B_R, provided $\lambda \leq \frac{(2+\alpha)(3N+\alpha-4)}{9R^{2+\alpha}}$.

In order to complete the proof of Proposition 3.1, we need to establish that the function $u^*(x) = 1 - |x|^{\frac{2+\alpha}{3}}$ is the extremal function as long as $N \geq 8$ and $0 \leq \alpha \leq \alpha^{**}(N) = \frac{4-6N+3\sqrt{6}(N-2)}{4}$. This will then yield that for such dimensions and these values of α, the voltage $\lambda = \frac{(2+\alpha)(3N+\alpha-4)}{9}$ is exactly the pull-in voltage λ^*.

First, it is easy to check that u^* is a $H_0^1(\Omega)$-weak solution of $(S)_{\lambda^*}$. Since $\|u^*\|_\infty = 1$, and by the characterization of Theorem 5.1 below, we need to prove only that

$$\int_\Omega |\nabla\phi|^2 \geq \int_\Omega \frac{2\lambda|x|^\alpha}{(1-u^*)^3}\phi^2 \quad \text{for all } \phi \in H_0^1(\Omega). \tag{3.5}$$

However, Hardy's inequality gives for $N \geq 2$ that $\int_{B_1} |\nabla\phi|^2 \geq \frac{(N-2)^2}{4}\int_{B_1} \frac{\phi^2}{|x|^2}$ for any $\phi \in H_0^1(B_1)$, which means that (3.5) holds whenever $2\lambda^* \leq \frac{(N-2)^2}{4}$ or, equivalently, if $N \geq 8$ and $0 \leq \alpha \leq \alpha^{**} = \frac{4-6N+3\sqrt{6}(N-2)}{4}$. □

Remark 3.1. The above lower bounds can be improved at least in low dimensions. First note that if $N > \frac{12+\alpha}{5}$, then $\lambda_2 = \frac{(2+\alpha)(3N+\alpha-4)}{9}$ is the better lower bound and is actually sharp on the ball as soon as $N \geq 8$ and $\alpha \leq \alpha^{**}$. For lower dimensions, the best lower bounds are more complicated even when one considers supersolutions of the form $v(x) = a(1-(\frac{|x|}{R})^k)$ and optimizes $\lambda(a,k,R)$ over a and k. For example, in the case where $\alpha = 0$, $N = 2$, and $R = 1$, one can see that a better lower bound can be obtained via the supersolution $v(x) = \frac{1}{2.4}(1-|x|^{1.6})$.

3.2. Upper bounds for λ^*. We note that (2.8) already yields a finite upper bound for λ^*. However, Pohozaev-type arguments can be used to establish better and more computable upper bounds. In this subsection, we establish the upper estimates claimed in Theorem 1.1. For a general domain Ω, the following upper bounds on $\lambda^*(\Omega)$ were established in Theorem 3.1 of [19] and in Theorem 2.2 of [12], respectively.

PROPOSITION 3.2. (1) *Assume that f is a function satisfying* (1.2) *on a bounded domain Ω in R^N such that* $\inf_\Omega f > 0$*; then*

$$\lambda^*(\Omega, f) \leq \bar{\lambda}_1 \equiv \frac{4\mu_\Omega}{27}\left(\inf_\Omega f\right)^{-1}. \tag{3.6}$$

(2) *If we only suppose that $f > 0$ on a set of positive measure, then*

$$\lambda^*(\Omega, f) \leq \bar{\lambda}_2 \equiv \frac{\mu_\Omega}{3}\left(\int_\Omega f\phi_\Omega\, dx\right)^{-1}. \tag{3.7}$$

If, in addition, $\Omega \subset R^N$ is a strictly star-shaped domain around 0, then we can prove the following estimate.

PROPOSITION 3.3. *Suppose $f \equiv 1$ and that $\Omega \subset R^N$ is a strictly star-shaped smooth domain such that $x \cdot \nu \geq a > 0$ for $x \in \partial\Omega$, where ν is the unit outer normal to $\partial\Omega$, then*

$$\lambda^*(\Omega) \leq \bar{\lambda}_3 = \frac{(N+2)^2 P(\Omega)}{8aN|\Omega|}. \tag{3.8}$$

In particular, if Ω is the Euclidean unit ball in R^N, then we have the bound

$$\lambda^*(B_1(0)) \leq \frac{(N+2)^2}{8}.$$

Proof. Recall Pohozaev's identity: If u is a solution of

$$\Delta u + \lambda g(u) = 0 \quad \text{for } x \in \Omega\,; \qquad u = 0 \quad \text{for } x \in \partial\Omega,$$

then

$$N\lambda\int_\Omega G(u)dx-\frac{N-2}{2}\lambda\int_\Omega ug(u)dx=\frac{1}{2}\int_{\partial\Omega}(x\cdot\nu)\left(\frac{\partial u}{\partial\nu}\right)^2 ds, \tag{3.9}$$

where $G(u)=\int_0^u g(s)ds$. Applying this with $g(u)=\frac{1}{(1-u)^2}$ and $G(u)=\frac{u}{1-u}$ yields

$$\begin{aligned}\frac{\lambda}{2}\int_\Omega\frac{u(N+2-2Nu)}{(1-u)^2}dx&=\frac{1}{2}\int_{\partial\Omega}(x\cdot\nu)\left(\frac{\partial u}{\partial\nu}\right)^2 ds\\&\geq\frac{a}{2P(\Omega)}\left(\int_{\partial\Omega}\frac{\partial u}{\partial\nu}ds\right)^2\\&=\frac{a}{2P(\Omega)}\left(-\int_\Omega\Delta udx\right)^2\\&=\frac{a\lambda^2}{2P(\Omega)}\left(\int_\Omega\frac{dx}{(1-u)^2}\right)^2,\end{aligned} \tag{3.10}$$

where we have used the divergence theorem and Hölder's inequality

$$\int_{\partial\Omega}\frac{\partial u}{\partial\nu}ds\leq\left(\int_{\partial\Omega}\left(-\frac{\partial u}{\partial\nu}\right)^2 ds\right)^{1/2}\left(\int_{\partial\Omega}ds\right)^{1/2}.$$

Since

$$\begin{aligned}\int_\Omega\frac{u(N+2-2Nu)}{(1-u)^2}dx&=\int_\Omega\left[-2N\left(u-\frac{N+2}{4N}\right)^2+\frac{(N+2)^2}{8N}\right]\frac{1}{(1-u)^2}dx\\&\leq\frac{(N+2)^2}{8N}\int_\Omega\frac{dx}{(1-u)^2},\end{aligned}$$

we deduce from (3.10) that

$$\frac{(N+2)^2}{8N}\geq\frac{a\lambda}{P(\Omega)}\int_\Omega\frac{dx}{(1-u)^2}\geq\frac{a\lambda|\Omega|}{P(\Omega)},$$

which implies the upper bound (3.8) for λ^*.

Finally, for the special case where $\Omega=B_1(0)\subset R^N$, we have $a=1$ and $\frac{P(B_1(0))}{\omega_N}=N$ and hence the bound $\lambda^*(B_1(0))\leq\bar\lambda_3=\frac{(N+2)^2}{8}$. □

3.3. Numerical estimates for λ^*. In the computations below we shall consider two choices for the domain Ω,

$$\Omega:[-1/2,1/2]\quad\text{(slab)},\qquad\Omega:x^2+y^2\leq 1\quad\text{(unit disk)}. \tag{3.11}$$

Simple calculations yield that

$$\begin{aligned}&\mu_\Omega=\pi^2,&&\phi_\Omega=\frac{\pi}{2}\sin\left[\pi\left(x+\frac{1}{2}\right)\right]\quad\text{(slab)},\\&\mu_\Omega=z_0^2\approx 5.783,&&\phi_\Omega=\frac{z_0}{J_1(z_0)}J_0(z_0|x|)\quad\text{(unit disk)}.\end{aligned} \tag{3.12}$$

Here J_0 and J_1 are Bessel functions of the first kind, and $z_0 \approx 2.4048$ is the first zero of $J_0(z)$. The bounds $\bar{\lambda}_1$ and $\bar{\lambda}_2$ can be evaluated by substituting (3.12) into (3.6) and (3.7). Notice that $\bar{\lambda}_2$ is, in general, determined only up to a numerical quadrature. Using Newton's method and COLSYS [1], one can also solve the boundary value problem $(S)_\lambda$ and numerically calculate λ^* as the saddle-node point for the following two choices of the permittivity profile:

$$\begin{array}{lllll} \text{slab}: & f(x)=|2x|^\alpha \quad \text{(power-law)}; & f(x)=e^{\alpha(x^2-1/4)} & \text{(exponential)}, \\ \text{unit disk}: & f(x)=|x|^\alpha \quad \text{(power-law)}; & f(x)=e^{\alpha(|x|^2-1)} & \text{(exponential)}, \end{array}$$

where $\alpha \geq 0$. Table 3.1 contains numerical values for λ^* in the case of exponential profiles, while Table 3.2 deals with power-law profiles. What is remarkable is that $\bar{\lambda}_1$ and $\bar{\lambda}_2$ are not comparable even when f is bounded away from 0 and that neither one of them provides the optimal value for λ^*. This leads us to conjecture that there should be a better estimate for λ^*, one involving the distribution of f in Ω, as opposed to the infimum or its average against the first eigenfunction ϕ_Ω.

4. The branch of minimal solutions. The branch of minimal solutions corresponds to the lowest branch in the bifurcation diagram, the one connecting the origin point $\lambda = 0$ to the first fold at $\lambda = \lambda^*$. In this section, we analyze further the properties of this branch. To do so, we consider for each solution u of $(S)_\lambda$ the operator $L_{u,\lambda} = -\Delta - \frac{2\lambda f}{(1-u)^3}$ associated with the linearized problem around u. We denote by $\mu_1(\lambda, u)$ the smallest eigenvalue of $L_{u,\lambda}$, that is, the one corresponding to the following Dirichlet eigenvalue problem:

$$-\Delta\phi - \frac{2\lambda f(x)}{(1-u)^3}\phi = \mu\phi, \quad x \in \Omega; \qquad \phi = 0, \qquad x \in \partial\Omega. \tag{4.1}$$

In other words,

$$\mu_1(\lambda,u)=\inf_{\phi\in H_0^1(\Omega)}\frac{\int_\Omega\left\{|\nabla\phi|^2-2\lambda f(1-u)^{-3}\phi^2\right\}dx}{\int_\Omega\phi^2dx}.$$

4.1. Spectral properties of minimal solutions. We start with the following crucial lemma, which shows among other things that semistable solutions are necessarily minimal solutions.

LEMMA 4.1. *Let f be a function satisfying* (1.2) *on a bounded domain Ω in R^N, and let $\lambda^*:=\lambda^*(\Omega,f)$. Suppose that u is a positive solution of $(S)_\lambda$, and consider any (classical) supersolution v of $(S)_\lambda$, that is,*

$$-\Delta v\ge\frac{\lambda f(x)}{(1-v)^2}\quad\text{and}\quad 0\le v(x)<1,\quad x\in\Omega;\quad v=0,\ \ x\in\partial\Omega. \tag{4.2}$$

If $\mu_1(\lambda,u)>0$, then $v\ge u$ on Ω, and if $\mu_1(\lambda,u)=0$, then $v\equiv u$ on Ω.

Proof. For a given λ and $x\in\Omega$, use the fact that $f(x)\ge 0$ and that $t\to\frac{\lambda f(x)}{(1-t)^2}$ is convex on $(0,1)$ to obtain

$$-\Delta(u+\tau(v-u))-\frac{\lambda f(x)}{[1-(u+\tau(v-u))]^2}\ge 0,\quad x\in\Omega, \tag{4.3}$$

for $\tau\in[0,1]$. Note that (4.3) is an identity at $\tau=0$, which means that the first derivative of the left-hand side for (4.3) with respect to τ is nonnegative at $\tau=0$; i.e.,

$$-\Delta(v-u)-\frac{2\lambda f(x)}{(1-u)^3}(v-u)\ge 0,\quad x\in\Omega;\quad v-u=0,\quad x\in\partial\Omega. \tag{4.4}$$

Thus, the maximal principle implies that if $\mu_1(\lambda,u)>0$, we have $v\ge u$ on Ω, while if $\mu_1(\lambda,u)=0$, we have

$$-\Delta(v-u)-\frac{2\lambda f(x)}{(1-u)^3}(v-u)=0,\quad x\in\Omega. \tag{4.5}$$

The second derivative of the left-hand side for (4.3) with respect to τ is therefore nonnegative at $\tau=0$; i.e.,

$$-\frac{6\lambda f(x)}{(1-u)^4}(v-u)^2\ge 0,\quad x\in\Omega. \tag{4.6}$$

From (4.6) we deduce that $v\equiv u$ in $\Omega\setminus\Omega_0$, where $\Omega_0=\{x\in\Omega:\ f(x)=0\text{ for }x\in\Omega\}$. On the other hand, (4.5) reduces to $-\Delta(v-u)=0$ for $x\in\Omega_0$, while $v-u=0$ on $\partial\Omega_0$, which implies $v\equiv u$ on Ω_0. Hence if $\mu_1(\lambda,u)=0$, then $v\equiv u$ on Ω. □

THEOREM 4.2. *Assume that f is a function satisfying* (1.2) *on a bounded domain Ω in R^N, and consider the branch $\lambda\to u_\lambda$ of minimal solutions on $(0,\lambda^*)$. Then the following hold:*

1. *For each $x\in\Omega$, the function $\lambda\to u_\lambda(x)$ is differentiable and strictly increasing on $(0,\lambda^*)$.*
2. *For each $\lambda\in(0,\lambda^*)$, u_λ is a stable solution and $\lambda\to\mu_{1,\lambda}:=\mu_1(\lambda,u_\lambda)$ is decreasing on $(0,\lambda^*)$.*

Proof. Consider $\lambda_1<\lambda_2<\lambda^*$, their corresponding minimal positive solutions u_{λ_1} and u_{λ_2}, and let u^* be a positive solution for $(S)_{\lambda_2}$. For the monotone increasing series $\{u_n(\lambda_1;x)\}$ defined in (2.9), we then have $u^*>u_0(\lambda_1;x)\equiv 0$, and if $u_{n-1}(\lambda_1;x)\le u^*$

in Ω, then

$$-\Delta(u^*-u_n) = f(x)\left[\frac{\lambda_2}{(1-u^*)^2}-\frac{\lambda_1}{(1-u_{n-1})^2}\right] \geq 0, \quad x \in \Omega\,; \quad u^*-u_n = 0, \quad x \in \partial\Omega.$$

So we have $u_n(\lambda_1;x) \leq u^*$ in Ω. Therefore, $u_{\lambda_1} = \lim_{n\to\infty} u_n(\lambda_1;x) \leq u^*$ in Ω, and in particular $u_{\lambda_1} \leq u_{\lambda_2}$ in Ω. Therefore, $\frac{du_\lambda(x)}{d\lambda} \geq 0$ for all $x \in \Omega$.

That $\lambda \to \mu_{1,\lambda}$ is decreasing follows easily from the variational characterization of $\mu_{1,\lambda}$, the monotonicity of $\lambda \to u_\lambda$, as well as the monotonicity of $(1-u)^{-3}$ with respect to u.

Now we define $\lambda^{**} = \sup\{\lambda;\ u_\lambda \text{ is a stable solution for } (S)_\lambda\}$. It is clear that $\lambda^{**} \leq \lambda^*$, and to show equality it suffices to prove that there is no minimal solution for $(S)_\mu$ with $\mu > \lambda^{**}$. For that, suppose w is a minimal solution of $(S)_{\lambda^{**}+\delta}$ with $\delta > 0$; then we would have, for $\lambda \leq \lambda^{**}$,

$$-\Delta w = \frac{(\lambda^{**}+\delta)f(x)}{(1-w)^2} \geq \frac{\lambda f(x)}{(1-w)^2}, \quad x \in \Omega.$$

Since for $0 < \lambda < \lambda^{**}$ the minimal solutions u_λ are stable, it follows from Lemma 4.1 that $1 > w \geq u_\lambda$ for all $0 < \lambda < \lambda^{**}$. Consequently, $\underline{u} = \lim_{\lambda \nearrow \lambda^{**}} u_\lambda$ exists in $C^1(\Omega)$ and is a solution for $(S)_{\lambda^{**}}$. Now from the definition of λ^{**}, we necessarily have $\mu_{1,\lambda^{**}} = 0$; hence by again applying Lemma 4.1, we obtain that $w \equiv \underline{u}$ and $\delta = 0$ on Ω, which is a contradiction, and hence $\lambda^{**} = \lambda^*$.

Since each u_λ is stable, then by setting $F(\lambda, u_\lambda) := -\Delta - \frac{\lambda f}{(1-u_\lambda)^2}$, we get that $F_{u_\lambda}(\lambda, u_\lambda)$ is invertible for $0 < \lambda < \lambda^*$. It then follows from the implicit function theorem that $u_\lambda(x)$ is differentiable with respect to λ.

Finally, by differentiating $(S)_\lambda$ with respect to λ, and since $\lambda \to u_\lambda(x)$ is non-decreasing, we get

$$-\Delta\frac{du_\lambda}{d\lambda} - \frac{2\lambda f(x)}{(1-u_\lambda)^3}\frac{du_\lambda}{d\lambda} = \frac{f(x)}{(1-u_\lambda)^2} \geq 0, \quad x \in \Omega\,; \quad \frac{du_\lambda}{d\lambda} \geq 0, \quad x \in \partial\Omega.$$

Applying the strong maximum principle, we conclude that $\frac{du_\lambda}{d\lambda} > 0$ on Ω for all $0 < \lambda < \lambda^*$. □

Remark 4.1. Lemma 3 of [8] yields $\mu_1(1,0)$ as an upper bound for λ^{**}—at least in the case where $\inf_\Omega f > 0$ on Ω. Since $\lambda^{**} = \lambda^*$, this gives another upper bound for λ^* in our setting. Note, however, that in the case where $f \equiv 1$, we have $\mu_1(1,0) = \frac{\mu_\Omega}{2}$, while the estimate in Theorem 1.1 gives $\frac{4\mu_\Omega}{27}$ for an upper bound.

4.2. Energy estimates and regularity. We start with the following easy observations.

LEMMA 4.3. *Let f be a function satisfying* (1.2) *on a bounded domain Ω in R^N.*

1. *Any (weak) solution u in $H_0^1(\Omega)$ of $(S)_\lambda$ then satisfies $\int_\Omega \frac{f}{(1-u)^2}dx < \infty$.*
2. *If $\inf_\Omega f > 0$ and $N \geq 3$, then any solution u such that $f/(1-u) \in L^{3N/2}$ is a classical solution.*

Proof. (1) Since $u \in H_0^1(\Omega)$ is a positive solution of $(S)_\lambda$, we have

$$\int_\Omega \frac{\lambda f}{(1-u)^2} - \int_\Omega \frac{\lambda f}{1-u} = \int_\Omega \frac{\lambda u f}{(1-u)^2} = \int_\Omega |\nabla u|^2 =: C < +\infty,$$

which implies that

$$\int_\Omega \frac{\lambda f}{(1-u)^2} \le C + \int_\Omega \frac{\lambda f}{1-u} \le C + \int_\Omega \left[C\varepsilon \frac{\lambda f}{(1-u)^2} + \frac{C}{\varepsilon} f \right] \le C + C\varepsilon \int_\Omega \frac{\lambda f}{(1-u)^2}$$

with $\varepsilon > 0$. Therefore, by choosing $\varepsilon > 0$ small enough, we conclude that $\int_\Omega \frac{f}{(1-u)^2} < \infty$.

(2) Suppose u is a weak solution such that $\frac{f(x)}{(1-u)^3} \in L^p(\Omega)$, which means that $\frac{f(x)}{(1-u)^2} \in L^{3p/2}(\Omega)$. By Sobolev's theorem we can already deduce that $u \in C^{0,\alpha}$ with $\alpha = 2 - \frac{2N}{3p}$. To get more regularity, it suffices to show that $u < 1$ on Ω, but then if not, we consider $x_0 \in \bar{\Omega}$ such that $u(x_0) = \|u\|_{C(\bar{\Omega})} = 1$; then we have $|1 - u(x)| = |u(x_0) - u(x)| \le C|x_0 - x|^\alpha$ on $\bar{\Omega}$. This inequality shows that if $p \ge \frac{N}{2}$, then we have

$$\infty > \int_\Omega \left(\frac{f(x)}{(1-u)^3} \right)^p dx \ge C' \int_\Omega |x - x_0|^{-3p\alpha} dx = C' \int_\Omega |x - x_0|^{-N} dx = \infty,$$

a contradiction, which implies that we must have $\|u\|_{C(\bar{\Omega})} < 1$. □

Note that the above argument cannot be applied to the case where $f(x) \ge 0$ vanishes on Ω, and therefore we have to use the iterative scheme outlined in the next theorem.

THEOREM 4.4. *Let f be a function satisfying (1.2) on a bounded domain Ω in R^N. Then for any constant $C > 0$ there exists $0 < K(C, N) < 1$ such that a positive weak solution u of $(S)_\lambda$ $(0 < \lambda < \lambda^*)$ is a classical solution and $\| u \|_{C(\Omega)} \le K(C, N)$, provided that*

1. *$N = 1$ and $\| \frac{f}{(1-u)^3} \|_{L^1(\Omega)} \le C$,*
2. *$N \ge 2$ and $\| \frac{f}{(1-u)^3} \|_{L^{N/2}(\Omega)} \le C$.*

Proof. We prove this lemma by considering the following three cases separately.

(1) If $N = 1$, then for any $I > 0$ we write using the Sobolev inequality with constant $K(1) > 0$,

$$\begin{aligned}
&K(1) \parallel (1-u)^{-1} - 1 \parallel_{L^\infty}^2 \\
&\quad \le \int_\Omega \left| \nabla [(1-u)^{-1} - 1] \right|^2 \\
&\quad = \frac{\lambda}{3} \int_\Omega f(1-u)^{-2} [(1-u)^{-3} - 1] \\
&\quad \le CI + C \int_{\{(1-u)^{-3} \ge I\}} 8f(1-u)^{-2} \\
&\qquad + C \int_{\{(1-u)^{-3} \ge I\}} f \left[\frac{1}{(1-u)^3} + \frac{2}{(1-u)^2} + \frac{4}{1-u} \right] \left[(1-u)^{-1} - 1 \right]^2 \\
&\quad \le CI + C + C \parallel (1-u)^{-1} - 1 \parallel_{L^\infty(\{(1-u)^{-3} \ge I\})}^2 \int_{\{(1-u)^{-3} \ge I\}} \frac{f}{(1-u)^3} \\
&\quad \le CI + C + C\varepsilon(I) \parallel (1-u)^{-1} - 1 \parallel_{L^\infty}^2,
\end{aligned} \tag{4.7}$$

with $\varepsilon(I) = \int_{\{(1-u)^{-3}\geq I\}} \frac{f}{(1-u)^3}$, where Lemma 4.3(1) is applied in the second inequality. From the assumption $f/(1-u)^3 \in L^1(\Omega)$, we have $\varepsilon(I) \to 0$ as $I \to \infty$. We now choose I such that $\varepsilon(I) \leq \frac{K(1)}{2C}$, so that the above estimates implier that $\| (1-u)^{-1} - 1 \|_{L^\infty} < C$. Standard regularity theory for elliptic problems now implies that $1/(1-u) \in C^{2,\alpha}(\Omega)$. Therefore, u is classical, and there exists a constant $K(C,N)$ which can be taken strictly less than 1 such that $\| u \|_{C(\Omega)} \leq K(C,N) < 1$.

(2) Assuming $N = 2$, we need to show that

$$(1-u)^{-1} \in L^p(\Omega) \quad \text{for any } p > 1. \tag{4.8}$$

Fix $p > 1$ and let us introduce $T_k u = \min\{u, 1-k\}$, the truncated function of u at level $1-k$, $0 < k < 1$. For k small, we take $(1-T_k u)^{-1} - 1 \in H_0^1(\Omega)$ as a test function for $(S)_\lambda$:

$$\int_\Omega \frac{|\nabla T_k u|^2}{(1-T_k u)^2} = \int_\Omega \frac{\lambda f(x)}{(1-u)^2}((1-T_k u)^{-1} - 1) \leq \int_\Omega \frac{\lambda f(x)}{|1-u|^3} \leq C < +\infty. \tag{4.9}$$

Since now $\log\left(\frac{1}{1-T_k u}\right) \in H_0^1(\Omega)$, by the Moser–Trudinger inequality and (4.9) we get that for any $p > 1$

$$\int_\Omega (1-T_k u)^{-p} \leq C_1 exp\left(\frac{p^2}{16\pi}\int_\Omega \left|\nabla \log\left(\frac{1}{1-T_k u}\right)\right|^2\right) \leq C_2,$$

where C_1, C_2 denote positive constants depending only on p and C. Taking the limit as $k \to 0$ and using that $u \leq 1$, we get the validity of (4.8).

(3) The case when $N > 2$ is more elaborate, and we first show that $(1-u)^{-1} \in L^q(\Omega)$ for all $q \in (1,\infty)$. Since $u \in H_0^1(\Omega)$ is a solution of $(S)_\lambda$, we already have $\int_\Omega \frac{f}{(1-u)^2} < C$. Now we proceed by iteration to show that if $\int_\Omega \frac{f}{(1-u)^{2+2\theta}} < C$ for some $\theta \geq 0$, then $\int_\Omega \frac{1}{(1-u)^{2^*(1+\theta)}} < C$.

Indeed, for any constant $\theta \geq 0$ and $\ell > 0$ we choose a test function $\phi = [(1-u)^{-3} - 1]\min\{(1-u)^{-2\theta}, \ell^2\}$. By applying this test function to both sides of $(S)_\lambda$, we have

$$\begin{aligned}
&\lambda \int_\Omega f(1-u)^{-2}[(1-u)^{-3} - 1]\min\{(1-u)^{-2\theta}, \ell^2\} \\
&= \int_\Omega \nabla u \cdot \nabla\big[\big((1-u)^{-3} - 1\big)\min\{(1-u)^{-2\theta}, \ell^2\}\big] \\
&= 3\int_\Omega |\nabla u|^2 (1-u)^{-4}\min\{(1-u)^{-2\theta}, \ell^2\} \\
&\quad + 2\theta \int_{\{(1-u)^{-\theta} \leq \ell\}} |\nabla u|^2 (1-u)^{-2\theta-1}[(1-u)^{-3} - 1].
\end{aligned} \tag{4.10}$$

We now suppose $\int_\Omega \frac{f}{(1-u)^{2+2\theta}} < C$. We then obtain from (4.10) and the fact that

$\frac{1}{(1-u)^5} \le C_I \frac{1}{(1-u)^3}(\frac{1}{1-u}-1)^2$ whenever $(1-u)^{-3} \ge I > 1$ that

$$
\begin{aligned}
&\int_\Omega \left|\nabla[\big((1-u)^{-1}-1\big)\min\{(1-u)^{-\theta},\ell\}]\right|^2 \\
&= 2\int_\Omega |\nabla u|^2(1-u)^{-4}\min\{(1-u)^{-2\theta},\ell^2\} \\
&\quad + 2\theta^2\int_{\{(1-u)^{-\theta}\le\ell\}} |\nabla u|^2(1-u)^{-2\theta-1}\left[\frac{1}{(1-u)^3}+\frac{1}{1-u}-\frac{2}{(1-u)^2}\right] \\
&\le C\lambda\int_\Omega f(1-u)^{-2}[(1-u)^{-3}-1]\min\{(1-u)^{-2\theta},\ell^2\} \\
&\le CI + C\int_{\{(1-u)^{-3}\ge I\}} f(1-u)^{-3}\big[(1-u)^{-1}-1\big]^2\min\{(1-u)^{-2\theta},\ell^2\} \\
&\le CI + C\left[\int_{\{(1-u)^{-3}\ge I\}}\left(\frac{f}{(1-u)^3}\right)^{\frac{N}{2}}\right]^{\frac{2}{N}} \\
&\qquad \times\left[\int_{\{(1-u)^{-3}\ge I\}}\big(\big[(1-u)^{-1}-1\big]\min\{(1-u)^{-\theta},\ell\}\big)^{\frac{2N}{N-2}}\right]^{\frac{N-2}{N}} \\
&\le CI + C\varepsilon(I)\int_\Omega \left|\nabla[\big((1-u)^{-1}-1\big)\min\{(1-u)^{-\theta},\ell\}]\right|^2
\end{aligned}
\tag{4.11}
$$

with $\varepsilon(I) = \big[\int_{\{(1-u)^{-3}\ge I\}}\big(\frac{f}{(1-u)^3}\big)^{\frac{N}{2}}\big]^{\frac{2}{N}}$.

From the assumption $f/(1-u)^3 \in L^{\frac{N}{2}}(\Omega)$ we have $\varepsilon(I)\to 0$ as $I\to\infty$. We now choose I such that $\varepsilon(I) = \frac{1}{2C}$, and the above estimates imply that

$$
\int_{\{(1-u)^{-\theta}\le\ell\}} \left|\nabla[(1-u)^{-\theta-1}-(1-u)^{-\theta}]\right|^2 \le CI,
$$

where the bound is uniform with respect to ℓ. This estimate leads to

$$
\begin{aligned}
&\frac{1}{(\theta+1)^2}\int_{\{(1-u)^{-\theta}\le\ell\}} \left|\nabla[(1-u)^{-\theta-1}]\right|^2 = \int_{\{(1-u)^{-\theta}\le\ell\}} (1-u)^{-2\theta-4}\left|\nabla u\right|^2 \\
&\le CI + C\int_{\{(1-u)^{-\theta}\le\ell\}} (1-u)^{-2\theta-3}\left|\nabla u\right|^2 \\
&\le CI + \int_{\{(1-u)^{-\theta}\le\ell\}} \big[C\varepsilon(1-u)^{-2\theta-4} + C/\varepsilon\big]\left|\nabla u\right|^2 \\
&\le CI + C/\varepsilon + C\varepsilon\int_{\{(1-u)^{-\theta}\le\ell\}} (1-u)^{-2\theta-4}\left|\nabla u\right|^2
\end{aligned}
$$

with $\varepsilon > 0$. This means that for $\varepsilon > 0$ sufficiently small

$$
\int_{\{(1-u)^{-\theta}\le\ell\}} \left|\nabla(1-u)^{-\theta-1}\right|^2 = \int_{\{(1-u)^{-\theta}\le\ell\}} (\theta+1)^2(1-u)^{-2\theta-4}\left|\nabla u\right|^2 < C.
$$

Thus we can let $\ell\to\infty$, and we get that $(1-u)^{-\theta-1} \in H^1(\Omega) \hookrightarrow L^{2^*}(\Omega)$, which means that $\int_\Omega \frac{1}{(1-u)^{2^*(1+\theta)}} < C$.

By iterating the above argument for $\theta_i+1=\frac{N}{N-2}(\theta_{i-1}+1)$ for $i\geq 1$ and starting with $\theta_0=0$, we find that $1/(1-u)\in L^q(\Omega)$ for all $q\in(1,\infty)$.

Standard regularity theory for elliptic problems applies again to give that $1/(1-u)\in C^{2,\alpha}(\Omega)$. Therefore, u is a classical solution, and there exists a constant $0<K(C,N)<1$ such that $\|u\|_{C(\Omega)}\leq K(C,N)<1$. □

THEOREM 4.5. *For any dimension $1\leq N\leq 7$ there exists a constant $0<C(N)<1$ independent of λ such that for any $0<\lambda<\lambda^*$ the minimal solution u_λ satisfies $\|u_\lambda\|_{C(\Omega)}\leq C(N)$.*

Consequently, $u^*=\lim_{\lambda\uparrow\lambda^*}u_\lambda$ exists in the topology of $C^{2,\alpha}(\bar\Omega)$ with $0<\alpha<1$. It is the unique classical solution for $(S)_{\lambda^*}$ and satisfies $\mu_{1,\lambda^*}(u^*)=0$.

This result—which yields Theorem 1.3(2)—will follow from the following uniform energy estimate on the minimal solutions u_λ.

PROPOSITION 4.6. *There exists a constant $C(p)>0$ such that for $\lambda\in(0,\lambda^*)$ the minimal solution u_λ satisfies $\|\frac{f}{(1-u_\lambda)^3}\|_{L^p(\Omega)}\leq C(p)$ as long as $p<1+\frac{4}{3}+2\sqrt{\frac{2}{3}}$.*

Proof. Since minimal solutions are stable, we have

$$\lambda\int_\Omega\frac{2f(x)}{(1-u_\lambda)^3}w^2dx\leq-\int_\Omega w\Delta w dx=\int_\Omega|\nabla w|^2dx \tag{4.12}$$

for all $0<\lambda<\lambda^*$ and nonnegative $w\in H_0^1(\bar\Omega)$. Setting

$$w=(1-u_\lambda)^i-1>0,\quad\text{where } -2-\sqrt{6}<i<0, \tag{4.13}$$

then (4.12) becomes

$$i^2\int_\Omega(1-u_\lambda)^{2i-2}|\nabla u_\lambda|^2dx\geq\lambda\int_\Omega\frac{2[1-(1-u_\lambda)^i]^2f(x)}{(1-u_\lambda)^3}dx. \tag{4.14}$$

On the other hand, multiplying $(S)_\lambda$ by $\frac{i^2}{1-2i}[(1-u_\lambda)^{2i-1}-1]$ and applying integration by parts yields that

$$i^2\int_\Omega(1-u_\lambda)^{2i-2}|\nabla u_\lambda|^2dx=\lambda\frac{i^2}{2i-1}\int_\Omega\frac{[1-(1-u_\lambda)^{2i-1}]f(x)}{(1-u_\lambda)^2}dx. \tag{4.15}$$

Hence (4.14) and (4.15) reduce to

$$\begin{aligned}&\frac{\lambda\,i^2}{2i-1}\int_\Omega\frac{f(x)}{(1-u_\lambda)^2}dx-2\lambda\int_\Omega\frac{f(x)}{(1-u_\lambda)^3}dx+4\lambda\int_\Omega\frac{f(x)}{(1-u_\lambda)^{3-i}}dx\\&\quad\geq\lambda\left(2+\frac{i^2}{2i-1}\right)\int_\Omega\frac{f(x)}{(1-u_\lambda)^{3-2i}}dx.\end{aligned} \tag{4.16}$$

From the choice of i in (4.13) we have $2+\frac{i^2}{2i-1}>0$. So (4.16) and Holder's inequality imply that

$$\begin{aligned}\int_\Omega\frac{f(x)}{(1-u_\lambda)^{3-2i}}dx&\leq C\int_\Omega\frac{f(x)}{(1-u_\lambda)^{3-i}}dx\\&\leq C\left(\int_\Omega\left|\frac{f^{\frac{3-i}{3-2i}}}{(1-u_\lambda)^{3-i}}\right|^{\frac{3-2i}{3-i}}dx\right)^{\frac{3-i}{3-2i}}\cdot\left(\int_\Omega\left|f^{\frac{-i}{3-2i}}\right|^{\frac{3-2i}{-i}}dx\right)^{\frac{-i}{3-2i}}\\&\leq C\left(\int_\Omega\frac{f(x)}{(1-u_\lambda)^{3-2i}}dx\right)^{\frac{3-i}{3-2i}}.\end{aligned} \tag{4.17}$$

It follows that $\int_\Omega \frac{f(x)}{(1-u_\lambda)^{3-2i}}dx \le C$, and therefore we have

$$\int_\Omega \left|\frac{f(x)}{(1-u_\lambda)^3}\right|^{\frac{3-2i}{3}} dx = \int_\Omega f^{\frac{-2i}{3}} \cdot \frac{f}{(1-u_\lambda)^{3-2i}}dx \le C\int_\Omega \frac{f}{(1-u_\lambda)^{3-2i}}dx \le C. \tag{4.18}$$

In view of (4.13) we finally get that $\| \frac{f(x)}{(1-u_\lambda)^3} \|_{L^p} \le C$, where $p = \frac{3-2i}{3} \le 1 + \frac{4}{3} + 2\sqrt{\frac{2}{3}}$. □

Proof of Theorem 4.5. The existence of u^* as a classical solution follows from Proposition 4.6 and Theorem 4.4, as long as $\frac{N}{2} < 1 + \frac{4}{3} + 2\sqrt{\frac{2}{3}}$, which happens when $N \le 7$.

Since $\mu_{1,\lambda} > 0$ on the minimal branch for any $\lambda < \lambda^*$, we have the limit $\mu_{1,\lambda^*} \ge 0$. If now $\mu_{1,\lambda^*} > 0$, the implicit function theorem could be applied to the operator $L_{u_{\lambda^*},\lambda^*}$ and would allow the continuation of the minimal branch $\lambda \mapsto u_\lambda$ of classical solutions beyond λ^*, which is a contradiction, and hence $\mu_{1,\lambda^*} = 0$. The uniqueness in the class of classical solutions then follows from Lemma 4.1.

5. Uniqueness and multiplicity of solutions. We first note that in view of the monotonicity in λ and the uniform boundedness of the first branch of solutions, the extremal function defined by $u^*(x) = \lim_{\lambda\uparrow\lambda^*} u_\lambda(x)$ always exists and can always be considered as a solution for $(S)_{\lambda^*}$ in a generalized sense. Now if there exists $0 < C < 1$ such that $\| u_\lambda \|_{C(\Omega)} \le C$ for each $\lambda < \lambda^*$—just like in the case where $1 \le N < 8$—then we have seen in Theorem 4.5 that u^* is unique among the classical solutions. In the sequel, we tackle the important case when u^* is a weak solution (i.e., in $H_0^1(\Omega)$) of $(S)_{\lambda^*}$ but with the possibility that $\|u^*\|_\infty = 1$.

5.1. Uniqueness of the solution at $\lambda = \lambda^*$. We shall borrow ideas from [3, 5, 16], where the authors deal with the case of regular nonlinearities. However, unlike those papers, where solutions are considered in a very weak sense, we consider here a more focused and much simpler situation. We establish the following useful characterization of the extremal solution.

THEOREM 5.1. *Assume that f is a function satisfying* (1.2) *on a bounded domain Ω in R^N. For $\lambda > 0$, consider $u \in H_0^1(\Omega)$ to be a weak solution of $(S)_\lambda$ (in the $H_0^1(\Omega)$ sense) such that $\| u \|_{L^\infty(\Omega)} = 1$. Then the following assertions are equivalent:*

1. *$\mu_{1,\lambda} \ge 0$; that is, u satisfies $\int_\Omega |\nabla\phi|^2 \ge \int_\Omega \frac{2\lambda f(x)}{(1-u)^3}\phi^2$ for all $\phi \in H_0^1(\Omega)$.*
2. *$\lambda = \lambda^*$ and $u = u^*$.*

We need the following uniqueness result.

PROPOSITION 5.2. *Let $f \in C(\bar\Omega)$ be a nonnegative function. Let u_1, u_2 be two $H_0^1(\Omega)$-weak solutions of $(S)_\lambda$ so that $\mu_{1,\lambda}(u_i) \ge 0$ for $i = 1, 2$. Then $u_1 = u_2$ almost everywhere (a.e.) in Ω.*

Proof. For any $\theta \in [0, 1]$ and $\phi \in H_0^1(\Omega)$, $\phi \ge 0$, we have that

$$\begin{aligned} I_{\theta,\phi} :&= \int_\Omega \nabla\big(\theta u_1 + (1-\theta)u_2\big)\nabla\phi - \int_\Omega \frac{\lambda f(x)}{\big(1-\theta u_1 - (1-\theta)u_2\big)^2}\phi \\ &= \lambda\int_\Omega f(x)\left(\frac{\theta}{(1-u_1)^2} + \frac{1-\theta}{(1-u_2)^2} - \frac{1}{\big(1-\theta u_1 - (1-\theta)u_2\big)^2}\right)\phi \ge 0 \end{aligned}$$

due to the convexity of $u \to 1/(1-u)^2$. Since $I_{0,\phi} = I_{1,\phi} = 0$, the derivative of $I_{\theta,\phi}$ at $\theta = 0, 1$ provides

$$\int_\Omega \nabla\big(u_1 - u_2\big)\nabla\phi - \int_\Omega \frac{2\lambda f(x)}{\big(1-u_2\big)^3}(u_1-u_2)\phi \geq 0,$$

$$\int_\Omega \nabla\big(u_1 - u_2\big)\nabla\phi - \int_\Omega \frac{2\lambda f(x)}{\big(1-u_1\big)^3}(u_1-u_2)\phi \leq 0,$$

for any $\phi \in H_0^1(\Omega)$, $\phi \geq 0$. Testing the first inequality on $\phi = (u_1-u_2)^-$ and the second one on $(u_1-u_2)^+$, we get that

$$\int_\Omega \left[|\nabla(u_1-u_2)^-|^2 - \frac{2\lambda f(x)}{(1-u_2)^3}\big((u_1-u_2)^-\big)^2\right] \leq 0,$$

$$\int_\Omega \left[|\nabla(u_1-u_2)^+|^2 - \frac{2\lambda f(x)}{(1-u_1)^3}\big((u_1-u_2)^+\big)^2\right] \leq 0.$$

Since $\mu_{1,\lambda}(u_1) \geq 0$, we have

(1) either $\mu_{1,\lambda}(u_1) > 0$ and then $u_1 \leq u_2$ a.e.,

(2) or $\mu_{1,\lambda}(u_1) = 0$, which then gives $\int_\Omega \nabla(u_1-u_2)\nabla\bar\phi - \int_\Omega \frac{2\lambda f(x)}{(1-u_1)^3}(u_1-u_2)\bar\phi = 0$, where $\bar\phi = (u_1-u_2)^+$. Since $I_{\theta,\bar\phi} \geq 0$ for any $\theta \in [0,1]$ and $I_{1,\bar\phi} = \partial_\theta I_{1,\bar\phi} = 0$, we get that $\partial^2_{\theta\theta} I_{1,\bar\phi} = -\int_\Omega \frac{6\lambda f(x)}{(1-u_1)^4}((u_1-u_2)^+)^3 \geq 0$. Letting $Z_0 = \{x \in \Omega : f(x) = 0\}$, we clearly have $(u_1-u_2)^+ = 0$ a.e. in $\Omega \setminus Z_0$, and from the above we obtain $\int_\Omega |\nabla(u_1-u_2)^+|^2 = 0$. Hence, $u_1 \leq u_2$ a.e. in Ω. The same argument applies to prove the reversed inequality, and the proof is complete. □

Since $\| u_\lambda \| < 1$ for any $\lambda \in (0, \lambda^*)$, we need—in order to prove Theorem 5.1—to show only that $(S)_\lambda$ does not have any $H_0^1(\Omega)$-weak solution for $\lambda > \lambda^*$. By the definition of λ^*, this is already true for classical solutions. We shall now extend this property to the class of weak solutions by means of the following result.

PROPOSITION 5.3. *If w is a $H_0^1(\Omega)$-weak solution of $(S)_\lambda$, then for any $\varepsilon \in (0,1)$ there exists a classical solution w_ε of $(S)_{\lambda(1-\varepsilon)}$.*

Proof. First we prove that for any $\psi \in C^2([0,1])$ concave function so that $\psi(0) = 0$ we have that

$$\int_\Omega \nabla\psi(w)\nabla\varphi \geq \int_\Omega \frac{\lambda f}{(1-w)^2}\dot\psi(w)\varphi \tag{5.1}$$

for any $\varphi \in H_0^1(\Omega)$, $\varphi \geq 0$. Indeed, by the concavity of ψ we get

$$\begin{aligned}\int_\Omega \nabla\psi(w)\nabla\varphi = \int_\Omega \dot\psi(w)\nabla w\nabla\varphi &= \int_\Omega \nabla w\nabla\left(\dot\psi(w)\varphi\right) - \int_\Omega \ddot\psi(w)\varphi|\nabla w|^2 \\ &\geq \int_\Omega \frac{\lambda f(x)}{(1-w)^2}\dot\psi(w)\varphi\end{aligned}$$

for any $\varphi \in C_0^\infty(\Omega)$, $\varphi \geq 0$, and by density we get (5.1) for any $\varphi \in H_0^1(\Omega)$, $\varphi \geq 0$.

Now let $\varepsilon \in (0,1)$, and define $\psi_\varepsilon(w) := 1 - \big(\varepsilon + (1-\varepsilon)(1-w)^3\big)^{\frac{1}{3}}$ for $0 \leq w \leq 1$. Since $\psi_\varepsilon \in C^2([0,1])$ is a concave function, $\psi_\varepsilon(0) = 0$, and since $\dot\psi_\varepsilon(w) = (1-\varepsilon)$

$\frac{g(\psi_\varepsilon(w))}{g(w)}$, where $g(s) := (1-s)^{-2}$, we obtain from (5.1) that for any $\varphi \in H_0^1(\Omega)$, $\varphi \geq 0$,

$$\int_\Omega \nabla\psi_\varepsilon(w)\nabla\varphi \geq \int_\Omega \frac{\lambda f(x)}{(1-w)^2}\dot{\psi}_\varepsilon(w)\varphi = \lambda(1-\varepsilon)\int_\Omega f(x)g\big(\psi_\varepsilon(w)\big)\varphi$$
$$= \int_\Omega \frac{\lambda(1-\varepsilon)f(x)}{(1-\psi_\varepsilon(w))^2}\varphi.$$

Hence, $\psi_\varepsilon(w)$ is a $H_0^1(\Omega)$-weak supersolution of $(S)_{\lambda(1-\varepsilon)}$ so that $0 \leq \psi_\varepsilon(w) \leq 1-\varepsilon^{\frac{1}{3}} < 1$. Since 0 is a subsolution for any $\lambda > 0$, we get the existence of a $H_0^1(\Omega)$-weak solution w_ε of $(S)_{\lambda(1-\varepsilon)}$ so that $0 \leq w_\varepsilon \leq 1-\varepsilon^{\frac{1}{3}}$. By standard elliptic regularity theory, w_ε is a classical solution of $(S)_{\lambda(1-\varepsilon)}$. □

5.2. Uniqueness of low energy solutions for small voltage. We now focus on the uniqueness when λ is small. We first define nonminimal solutions for $(S)_\lambda$ as follows.

DEFINITION 5.4. *A solution $0 \leq u < 1$ is said to be a nonminimal positive solution of $(S)_\lambda$ if there exist another positive solution v of $(S)_\lambda$ and a point $x \in \Omega$ such that $u(x) > v(x)$.*

LEMMA 5.5. *Suppose u is a nonminimal solution of $(S)_\lambda$ with $\lambda \in (0, \lambda^*)$. Then $\mu_1(\lambda, u) < 0$, and the function $w = u - u_\lambda$ is in the negative space of $L_{u,\lambda} = -\Delta - \frac{2\lambda f(x)}{(1-u)^3}$.*

Proof. For a fixed $\lambda \in (0, \lambda^*)$, let u_λ be the minimal solution of $(S)_\lambda$. We have $w = u - u_\lambda \geq 0$ in Ω, and $-\Delta w - \frac{\lambda(2-u-u_\lambda)f}{(1-u)^2(1-u_\lambda)^2}w = 0$ in Ω. Hence the strong maximum principle yields that $u_\lambda < u$ in Ω.

Let $\Omega_0 = \{x \in \Omega : f(x) = 0\}$ and $\Omega/\Omega_0 = \{x \in \Omega : f(x) > 0\}$. Direct calculations give that

$$-\Delta(u-u_\lambda) - \frac{2\lambda f(u-u_\lambda)}{(1-u)^3} = \lambda f\left[\frac{1}{(1-u)^2} - \frac{1}{(1-u_\lambda)^2} - \frac{2(u-u_\lambda)}{(1-u)^3}\right]$$
$$= 0, \ \ x \in \Omega_0\,; \quad < 0, \ x \in \Omega/\Omega_0. \tag{5.2}$$

From this we get

$$\langle L_{u,\lambda}w, w\rangle = \lambda\int_{\Omega/\Omega_0} f(x)(u-u_\lambda)$$
$$\cdot\left[\frac{1}{(1-u)^2} - \frac{1}{(1-u_\lambda)^2} - \frac{2}{(1-u)^3}(u-u_\lambda)\right]dx < 0. \tag{5.3}$$

Now we are able to prove the following uniqueness result.

THEOREM 5.6. *For every $M > 0$ there exists $0 < \lambda_1^*(M) < \lambda^*$ such that for $\lambda \in (0, \lambda_1^*(M))$ the equation $(S)_\lambda$ has a unique solution v satisfying the following:*

1. $\|\frac{f}{(1-v)^3}\|_1 \leq M$ *and the dimension* $N = 1$,
2. $\|\frac{f}{(1-v)^3}\|_{1+\epsilon} \leq M$ *for some* $\epsilon > 0$ *and* $N = 2$,
3. $\|\frac{f}{(1-v)^3}\|_{N/2} \leq M$ *and* $N > 2$.

Proof. For any fixed $\lambda \in (0, \lambda^*)$, let u_λ be the minimal solution of $(S)_\lambda$, and suppose $(S)_\lambda$ has a nonminimal solution u. The preceding lemma then gives

$$\int_\Omega |\nabla(u-u_\lambda)|^2 dx < \int_\Omega \frac{2\lambda(u-u_\lambda)^2 f(x)}{(1-u)^3}dx.$$

This implies in the case where $N > 2$ that

$$C(N)\left(\int_\Omega |u-u_\lambda|^{\frac{2N}{N-2}}dx\right)^{\frac{N-2}{N}} < \lambda\int_\Omega \frac{2f(x)}{|1-u|^3}|u-u_\lambda|^2dx$$
$$\le 2\lambda\left(\int_\Omega \left|\frac{f}{|1-u|^3}\right|^{\frac{N}{2}}\right)^{\frac{2}{N}}\left(\int_\Omega |u-u_\lambda|^{\frac{2N}{N-2}}\right)^{\frac{N-2}{N}}$$
$$\le 2\lambda M^{\frac{2}{N}}\left(\int_\Omega (u-u_\lambda)^{\frac{2N}{N-2}}dx\right)^{\frac{N-2}{N}},$$

which is a contradiction if $\lambda < \frac{C(N)}{2M^{\frac{2}{N}}}$ unless $u \equiv u_\lambda$. If $N = 1$, then we write

$$C(1)\|(u-u_\lambda)\|_\infty^2 < \lambda\int_\Omega \frac{2f(x)}{(1-u)^3}(u-u_\lambda)^2dx \le 2\lambda\|(u-u_\lambda)\|_\infty^2\int_\Omega \frac{f}{(1-u)^3}dx,$$

and the proof follows. A similar proof holds for dimension $N = 2$. □

Remark 5.1. The above gives uniqueness for small λ among all solutions that either stay away from 1 or those that approach it slowly. We do not know whether, if λ is small enough, any positive solution v of $(S)_\lambda$ satisfies $\int_\Omega (1-v)^{-\frac{3N}{2}}dx \le M$ for some uniform bound M independent of λ. Numerical computations do show that we may have uniqueness for small λ—at least for radially symmetric solutions—as long as $N \ge 2$.

5.3. Second solutions around the bifurcation point. Our next result is quite standard.

LEMMA 5.7. *Suppose there exists* $0 < C < 1$ *such that* $\|u_\lambda\|_{C(\bar\Omega)} \le C$ *for each* $\lambda < \lambda^*$. *Then there exists* $\delta > 0$ *such that the solutions of* $(S)_\lambda$ *near* $(\lambda^*, u_{\lambda^*})$ *form a curve* $\rho(s) = \{(\bar\lambda(s), v(s)) : |s| < \delta\}$, *and the pair* $(\bar\lambda(s), v(s))$ *satisfies*

$$\bar\lambda(0) = \lambda^*,\ \bar\lambda'(0) = 0,\ \bar\lambda''(0) < 0, \quad \textit{and} \quad v(0) = u_{\lambda^*},\ v'(0)(x) > 0 \textit{ in } \Omega. \tag{5.4}$$

In particular, if $1 \le N \le 7$, *then for* λ *close enough to* λ^* *there exists a unique second branch* U_λ *of solutions for* $(S)_\lambda$, *bifurcating from* u^*, *such that* $\mu_{1,\lambda}(U_\lambda) < 0$ *while* $\mu_{2,\lambda}(U_\lambda) > 0$.

Proof. The proof is similar to a related result of Crandall and Rabinowitz (cf. [7, 8]) so we will be brief. First, the assumed upper bound on u_λ in C^1 and standard regularity theory shows that if $f \in C(\bar\Omega)$, then $\|u_\lambda\|_{C^{2,\alpha}(\bar\Omega)} \le C < 1$ for some $0 < \alpha < 1$ (while if $f \in L^\infty$, then $\|u_\lambda\|_{C^{1,\alpha}(\bar\Omega)} \le C < 1$). It follows that $\{(\lambda, u_\lambda)\}$ is precompact in the space $R \times C^{2,\alpha}$, and hence we have a limiting point $(\lambda^*, u_{\lambda^*})$, as desired. Since $\frac{\lambda^* f(x)}{(1-u_{\lambda^*})^2}$ is nonnegative, Theorem 3.2 of [7] characterizes the solution set of $(S)_\lambda$ near $(\lambda^*, u_{\lambda^*})$: $\bar\lambda(0) = \lambda^*$, $\bar\lambda'(0) = 0$, $v(0) = u_{\lambda^*}$, and $v'(0) > 0$ in Ω. The same computation as in Theorem 4.8 in [7] gives that $\bar\lambda''(0) < 0$. In particular, if $1 \le N \le 7$, then our Theorem 4.5 gives the compactness of $u^* = u_{\lambda^*}$, and the theory of Crandall and Rabinowitz in [8] then implies that, for λ close enough to λ^*, there exists a unique second branch U_λ of solutions for $(S)_\lambda$, bifurcating from u^*, such that $\mu_{1,\lambda}(U_\lambda) < 0$ while $\mu_{2,\lambda}(U_\lambda) > 0$. □

Remark 5.2. A version of these results will be established variationally in the companion paper [9]. Indeed, we shall give there a variational characterization for both the stable and unstable solutions u_λ, U_λ in the following sense: For $1 \le N \le 7$, there exists $\delta > 0$ such that for any $\lambda \in (\lambda^* - \delta, \lambda^*)$ the minimal solution u_λ is a local minimum for some regularized energy functional $J_{\varepsilon,\lambda}$ on the space $H_0^1(\Omega)$, while the second solution U_λ is a mountain pass for the functional $J_{\varepsilon,\lambda}$.

6. Radially symmetric case and power-law permittivity profiles. In this section, we discuss issues of uniqueness and multiplicity of solutions for $(S)_\lambda$ when Ω is a symmetric domain and when f is a radially symmetric permittivity profile. Here, one can again define the corresponding pull-in voltage $\lambda_r^*(\Omega, f)$ requiring the solutions to be radially symmetric, that is,

$$\lambda_r^*(\Omega, f) = \sup\{\lambda;\ (S)_\lambda \text{ has a radially symmetric solution}\}.$$

PROPOSITION 6.1. *Let Ω be a symmetric domain, and let f be a nonnegative bounded radially symmetric permittivity profile on Ω; then the minimal solutions of $(S)_\lambda$ are necessarily radially symmetric, and consequently $\lambda_r^*(\Omega, f) = \lambda^*(\Omega, f)$. Moreover, if Ω is a ball, then any radial solution of $(S)_\lambda$ attains its maximum at 0.*

Proof. It is clear that $\lambda_r^*(\Omega, f) \le \lambda^*(\Omega, f)$, and the reverse will be proved if we establish that every minimal solution of $(S)_\lambda$ with $0 < \lambda < \lambda^*(\Omega, f)$ is radially symmetric. This is a straightforward application of the recursive scheme defined in Theorem 2.2, which gives a radially symmetric function at each step, and therefore the resulting limiting function—which is the minimal solution—is radially symmetric.

For any radially symmetric $u(r)$ of $(S)_\lambda$ defined in the ball of radius R, we have $u_r(0) = 0$ and

$$-u_{rr} - \frac{N-1}{r}u_r = \frac{\lambda f}{(1-u)^2} \qquad \text{in } (0, R).$$

Multiplying by r^{N-1}, we get that $-\frac{d(r^{N-1}u_r)}{dr} = \frac{\lambda f r^{N-1}}{(1-u)^2} \ge 0$, and therefore $u_r < 0$ in $(0, R)$ since $u_r(0) = 0$. This shows that $u(r)$ attains its maximum at 0. ∎

The bifurcation diagrams shown in the introduction actually reflect the radially symmetric situation, and our emphasis in this section is on whether there is a better chance to analyze mathematically the higher branches of solutions in this case. Now some of the classical work of Joseph and Lundgren [14] and many that followed can be adapted to this situation when the permittivity profile is constant. However, the case of a power-law permittivity profile $f(x) = |x|^\alpha$ defined in a unit ball already presents a much richer situation. We now present various analytical and numerical evidence for various conjectures relating to this case, some of which are established rigorously in [9].

Power-law permittivity profiles. Consider the domain Ω to be a unit ball $B_1(0) \subset R^N$ $(N \ge 1)$, and let $f(x) = |x|^\alpha$ $(\alpha \ge 0)$. We analyze in this case the branches of radially symmetric solutions of $(S)_\lambda$ for $\lambda \in (0, \lambda^*]$. In this case, $(S)_\lambda$ reduces to

$$-u_{rr} - \frac{N-1}{r}u_r = \frac{\lambda r^\alpha}{(1-u)^2}, \quad 0 < r \le 1, \quad u'(0) = 0, \quad u(1) = 0. \tag{6.1}$$

Here $r = |x|$ and $0 < u = u(r) < 1$ for $0 < r < 1$. Looking first for a solution of the form $u(r) = 1 - \beta w(P)$ with $P = \gamma r$, where $\gamma,\ \beta > 0$, equation (6.1) implies that $\gamma^2\beta(w'' + \frac{N-1}{P}w') = \frac{\lambda P^\alpha}{\beta^2\gamma^\alpha}\frac{1}{w^2}$. We set $w(0) = 1$ and $\lambda = \gamma^{2+\alpha}\beta^3$. This yields the following initial value problem:

$$w'' + \frac{N-1}{P}w' = \frac{P^\alpha}{w^2}, \quad P > 0\,; \qquad w'(0) = 0,\ w(0) = 1. \tag{6.2}$$

Since $u(1) = 0$ we have $\beta = 1/w(\gamma)$, where $w(\gamma)$ is a solution of (6.2). Therefore, we conclude that

$$u(0) = 1 - \frac{1}{w(\gamma)}, \qquad \lambda = \frac{\gamma^{2+\alpha}}{w^3(\gamma)}. \tag{6.3}$$

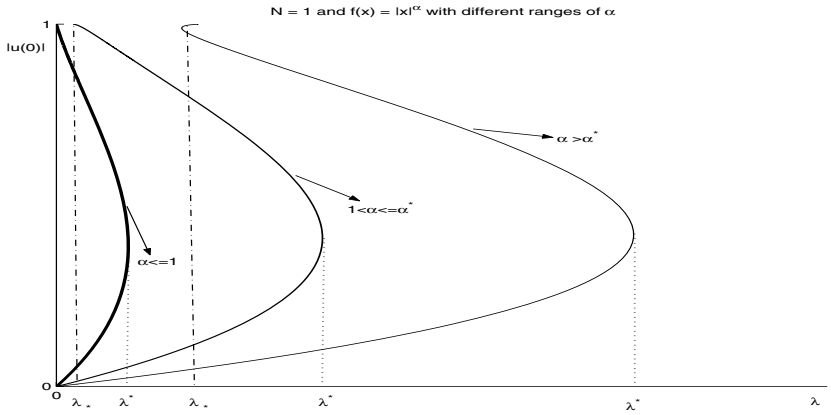

FIG. 6.1. *Plots of $u(0)$ versus λ for the power-law permittivity profile $f(x) = |x|^\alpha$ ($\alpha \geq 0$) defined in the slab domain ($N = 1$). The numerics point to a constant $\alpha^* > 1$ (analytically given in* (6.10)*) such that the bifurcation diagrams are greatly different for different ranges of α: $0 \leq \alpha \leq 1$, $1 < \alpha \leq \alpha^*$, and $\alpha > \alpha^*$.*

As was done in [19], one can numerically integrate the initial value problem (6.2) and use the results to compute the complete bifurcation diagram for (6.1). We show such a computation of $u(0)$ versus λ defined in (6.3) for the slab domain ($N = 1$) in Figure 6.1. In this case, one observes from the numerical results that when $N = 1$ and $0 \leq \alpha \leq 1$, there exist exactly two solutions for $(S)_\lambda$ whenever $\lambda \in (0, \lambda^*)$. On the other hand, the situation becomes more complex for $\alpha > 1$ as $u(0) \to 1$. This leads to the question of determining the asymptotic behavior of $w(P)$ as $P \to \infty$. Towards this end, we proceed as follows.

Setting $\eta = \log P$ and $w(P) = P^B V(\eta) > 0$ for some positive constant B, we obtain from (6.2) that

$$P^{B-2}V'' + (2B + N - 2)P^{B-2}V' + B(B + N - 2)P^{B-2}V = \frac{P^{\alpha-2B}}{V^2}. \tag{6.4}$$

Choosing $B - 2 = \alpha - 2B$ so that $B = (2 + \alpha)/3$, we get that

$$V'' + \frac{3N + 2\alpha - 2}{3}V' + \frac{(2 + \alpha)(3N + \alpha - 4)}{9}V = \frac{1}{V^2}. \tag{6.5}$$

We can already identify from this equation the following regime.

Case 1. Assume that

$$N = 1 \quad \text{and} \quad 0 \leq \alpha \leq 1. \tag{6.6}$$

In this case, there is no equilibrium point for (6.5), which means that the bifurcation diagram vanishes at $\lambda = 0$, from which one infers that in this case there exist exactly two solutions for $\lambda \in (0, \lambda^*)$ and just one for $\lambda = \lambda^*$.

Case 2. N and α satisfy either one of the following conditions:

$$\begin{array}{l} N = 1 \quad \text{and} \quad \alpha > 1, \\ N \geq 2. \end{array} \tag{6.7}$$

There exists then an equilibrium point V_e of (6.5) which must be positive and satisfies

$$V_e^3 = \frac{9}{(2 + \alpha)(3N + \alpha - 4)} > 0. \tag{6.8}$$

Linearizing around this equilibrium point by writing $V = V_e + Ce^{\sigma\eta},\ 0 < C \ll 1$, we obtain that $\sigma^2 + \frac{3N+2\alpha-2}{3}\sigma + \frac{(2+\alpha)(3N+\alpha-4)}{3} = 0$. This reduces to

$$\begin{aligned} &\sigma_\pm = -\frac{3N+2\alpha-2}{6} \pm \frac{\sqrt{\triangle}}{6}, \quad \text{where} \\ &\triangle = -8\alpha^2 - (24N-16)\alpha + (9N^2 - 84N + 100). \end{aligned} \tag{6.9}$$

We note that $\sigma_\pm < 0$ whenever $\triangle \geq 0$. Now define

$$\alpha^* = -\frac{1}{2} + \frac{1}{2}\sqrt{\frac{27}{2}}, \qquad \alpha^{**} = \frac{4 - 6N + 3\sqrt{6}(N-2)}{4} \quad (N \geq 8). \tag{6.10}$$

Next, we discuss different ranges of N and α in terms of their effect on the sign of $\triangle$.

Case 2.A. N and α satisfy either one of the following:

$$\begin{aligned} &N = 1 \quad \text{with } 1 < \alpha \leq \alpha^*, \\ &N \geq 8 \quad \text{with } 0 \leq \alpha \leq \alpha^{**}. \end{aligned} \tag{6.11}$$

In this case, we have $\triangle \geq 0$ and $V \sim (\frac{9}{(2+\alpha)(3N+\alpha-4)})^{\frac{1}{3}} + C_1 e^{-\frac{3N+2\alpha-2-\sqrt{\triangle}}{6}\eta} + \cdots$ as $\eta \to +\infty$. Further, we conclude that $w \sim P^{\frac{2+\alpha}{3}}(\frac{9}{(2+\alpha)(3N+\alpha-4)})^{\frac{1}{3}} + C_1 P^{-\frac{N-2}{2}+\frac{\sqrt{\triangle}}{6}} + \cdots$ as $P \to +\infty$. In both cases, the branch monotonically approaches the value 1 as $\eta \to +\infty$. Moreover, since $\lambda = \gamma^{2+\alpha}/w^3(\gamma)$, we have

$$\lambda \sim \lambda_* = \frac{(2+\alpha)(3N+\alpha-4)}{9} \qquad \text{as } \gamma \to \infty, \tag{6.12}$$

which is another important critical threshold for the voltage.

In the case (6.11) illustrated by Figure 6.1, we have $\lambda_* < \lambda^*$, and the number of solutions increases but remains finite as λ approaches λ_*. On the other hand, in the case of (6.11) illustrated by Figure 6.2(bottom), we have $\lambda_* = \lambda^*$, and there seems to be only one branch of solutions.

Case 2.B. N and α satisfy any one of the following three conditions:

$$\begin{aligned} &N = 1 \quad \text{with } \alpha > \alpha^*, \\ &2 \leq N \leq 7 \quad \text{with } \alpha \geq 0, \\ &N \geq 8 \quad \text{with } \alpha > \alpha^{**}. \end{aligned} \tag{6.13}$$

In this case, we have $\triangle < 0$ and

$$V \sim \left(\frac{9}{(2+\alpha)(3N+\alpha-4)}\right)^{\frac{1}{3}} + C_1 e^{-\frac{3N+2\alpha-2}{6}\eta} cos\left(\frac{\sqrt{-\triangle}}{6}\eta + C_2\right) + \cdots \quad \text{as} \quad \eta \to +\infty.$$

We also have

$$w \sim P^{\frac{2+\alpha}{3}}\left(\frac{9}{(2+\alpha)(3N+\alpha-4)}\right)^{\frac{1}{3}} + C_1 P^{-\frac{N-2}{2}} cos\left(\frac{\sqrt{-\triangle}}{6} logP + C_2\right) + \cdots \quad \text{as } P \to +\infty, \tag{6.14}$$

and from the fact that $\lambda = \gamma^{2+\alpha}/w^3(\gamma)$ we get again that $\lambda \sim \lambda_* = \frac{(2+\alpha)(3N+\alpha-4)}{9}$ as $\gamma \to \infty$. Note the oscillatory behavior of $w(P)$ in (6.14) for large P, which means that

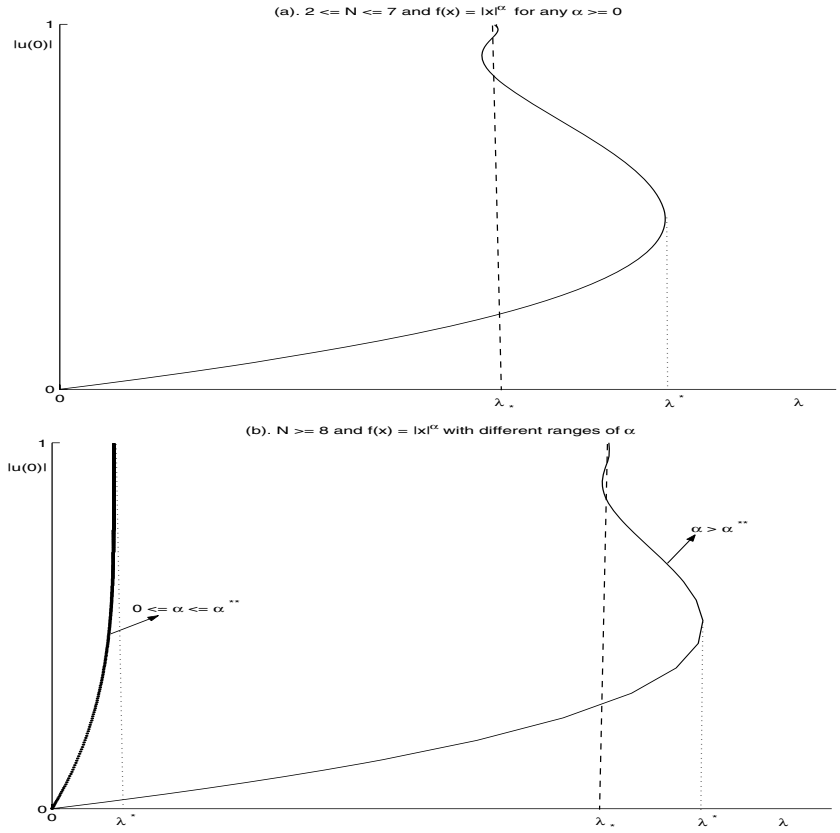

FIG. 6.2. *Top figure: Plots of $u(0)$ versus λ for the power-law permittivity profile $f(x) = |x|^\alpha$ ($\alpha \geq 0$) defined in the unit ball $B_1(0) \subset R^N$ with $2 \leq N \leq 7$. In this case, $u(0)$ oscillates around the value λ_* defined in* (6.12)*, and u^* is regular. Bottom figure: Plots of $u(0)$ versus λ for the power-law permittivity profile $f(x) = |x|^\alpha$ ($\alpha \geq 0$) defined in the unit ball $B_1(0) \subset R^N$ with $N \geq 8$. The characters of the bifurcation diagrams depend on different ranges of α: when $0 \leq \alpha \leq \alpha^{**}$, there exists a unique solution for $(S)_\lambda$ with $\lambda \in (0, \lambda^*)$ and u^* is singular; when $\alpha > \alpha^{**}$, $u(0)$ oscillates around the value λ_* defined in* (6.12) *and u^* is regular.*

$u(0)$ is expected to oscillate around the value $\lambda_* = \frac{(2+\alpha)(3N+\alpha-4)}{9}$ as $P \to \infty$. The diagrams below point to the existence of a sequence $\{\lambda_i\}$ satisfying $\lambda_0 = 0$, $\lambda_1 = \lambda^*$, $\lambda_{2k} \nearrow \lambda_*$, $\lambda_{2k-1} \searrow \lambda_*$ as $k \to \infty$ and such that exactly $2k+1$ solutions for $(S)_\lambda$ exist when $\lambda \in (\lambda_{2k}, \lambda_{2k+2})$, while there are exactly $2k$ solutions when $\lambda \in (\lambda_{2k+1}, \lambda_{2k-1})$. Furthermore, $(S)_\lambda$ has infinitely multiple solutions at $\lambda = \lambda_*$.

The three cases (6.13) considered here for N and α are illustrated by the diagrams in Figures 6.1, 6.2(top), and 6.2(bottom), respectively.

Acknowledgments. We are grateful to Michael. J. Ward for introducing us to the PDE models for electrostatic MEMS devices, and to Louis Nirenberg for leading us to the pioneering work of Joseph and Lundgren and the related papers of Crandall and Rabinowitz. Special thanks go to Pierpaolo Esposito for his thorough reading of the manuscript, which led to many improvements, and to Xavier Cabre for pointing out the related paper of Mignot and Puel, and for providing his own recent preprints on the subject.

ASYMPTOTICS OF THE POISSON PROBLEM IN DOMAINS WITH CURVED ROUGH BOUNDARIES*

ALEXANDRE L. MADUREIRA† AND FRÉDÉRIC VALENTIN†

Abstract. Effective boundary conditions (wall laws) are commonly employed to approximate PDEs in domains with rough boundaries, but it is neither easy to design such laws nor to estimate the related approximation error. A two-scale asymptotic expansion based on a domain decomposition result is used here to mitigate such difficulties, and as an application we consider the Poisson equation. The proposed scheme considers rough curved boundaries and allows a complete asymptotic expansion for the solution, highlighting the influence of the boundary curvature. The derivation and estimation of high order effective conditions is a corollary of such development. Sharp estimates for first and second order wall law approximations are considered for different Sobolev norms and show superior convergence rates in the interior of the domain. A numerical test illustrates several of the results obtained here.

Key words. Poisson equation, rough boundary, effective boundary conditions, asymptotic expansion, wall laws, curved domain

1. Introduction.

In several applications, it is necessary to solve PDEs in domains with boundaries that are rough. Analytic solutions are rarely available, and direct numerical computations are usually out of reach since the rapidly varying wrinkles and the domain have different length scales. The traditional remedy is to pose special boundary conditions on a mollified domain to capture the geometrical influence of the wrinkles. The development of such conditions is cumbersome in general, and modeling error estimates can be out of reach. The aim of this paper is to investigate and explicate such issues.

Problems posed on domains with rough boundary pervade many fields of research. In aerodynamics, aircrafts and space shuttles are often covered with tiles, hence their walls have an array of periodic gaps [22].

Similarly, small air injecting nozzles are periodically introduced over wings of aircrafts to decrease the drag [6]. Another interesting example in the fluid mechanics is the flow field around golf balls, in which the wrinkles associated to the curvature decrease the gap between the air-pressure behind and in front of the ball. Finally, in hemodynamics, the cell surfaces of the endothelium modifies the wall shear stress produced by the blood flow, and realistic computer simulations must take this effect into account [32].

To avoid discretizing such intricate boundaries, practitioners start resorting to *wall laws*, which are effective boundary conditions that try to emulate the effect of the wrinkles without actually resolving them. Ingenious methods were developed, some in ad hoc fashion, but many of them based on firm mathematical ground.

Nonetheless, even when mathematics played a significant role and error estimates were found, some qualitative aspects of the resulting models that were observed numerically were missed by the theory. For instance, close to the wrinkles, the exact solution wiggles, where the model solution does not. Hence the approximation there is precarious in the H^1 norm, but fine in the L^2 norm. However, far from the boundary, where the solution is "smooth," a better approximation occurs, even when derivatives are considered. Previously, some authors considered some of these effects, but it seems hard to generalize their results to other operators, or to second order, curvature dependent approximations.

There are several papers devoted to finding good wall laws as well as the corresponding modeling errors estimates. Most of the articles fit in the framework of two-scale asymptotic expansions [14, 23, 29, 30]. For fluids, [9, 11] deal with the Stokes equations, and [5, 7, 13, 24] focus on the steady and unsteady incompressible Navier–Stokes equations. An interesting alternative way to derive effective boundary conditions is based on domain decomposition strategies as introduced in [3] for the Laplace operator, and extended to other operators [4, 7]; see also [31] for a survey and [10, 27, 28] for related techniques and problems.

The previous references considered the wrinkles to be laid upon a flat line or surface, or considered first order approximations only. In [1] first and second order models for diffraction of an electromagnetic wave by a cylindrical curved grating were considered, and some H^1 norm estimates were obtained. The references [2, 20, 21] also developed wall laws for wave scattering problems.

We extend here the results of [25], where we considered first and second order wall laws for general curved boundaries. We estimate the modeling errors in the L^2 and H^1 norms, both on the whole domain and in its interior, confirming several numerical predictions. Our mathematical framework mixes two-scale asymptotic expansions and domain decomposition ideas. Using such procedure, wall laws of arbitrary order come by naturally, and we derive first and second order effective boundary conditions. Local boundary fitted coordinates expose how the exact solution depends on the curvature of the boundary (in a sense that we make clear in what follows). This is crucial to develop high order models, which depend on the curvature. We believe that our approach is quite general and can handle more sophisticated operators.

We now outline the contents of this paper. In the next section, we introduce basic definitions and highlight the main ingredients of the approach. Section 3 presents wall laws of different orders, along with error estimates and a summary of effective conditions. Section 4 contains the development of the asymptotic expansion, and the details necessary to define the boundary layer terms are in section 5. The errors associated with the asymptotic expansion are considered in section 6. Finally, in section 7 we validate the models numerically.

We now briefly introduce and explain some basic notation that we use throughout this paper. As usual, if D is an open set, then ∂D denotes its boundary, $\overline{D}$ its closure, $L^2(D)$ is the set of square integrable functions in D, and $H^s(D)$ is the corresponding Sobolev space of order s, for a real number s. We denote the norms of those spaces by $\|\cdot\|_{L^2(D)}$ and $\|\cdot\|_{H^s(D)}$. Also, the symbol $\cdot|_D$ denotes the restriction of a function to the domain D. Without loss of generality, we have chosen to work in two dimensions. Nonetheless, all that follows can be generalized to the three-dimensional case. Bold fonts indicate two-dimensional vectors, and the symbol $\partial_{\boldsymbol{n}}$ indicates the (outward) normal derivative with respect to the domain Ω_s. Similarly, ∂_x denotes the derivative with respect to the variable x, etc. We denote by c a generic constant (not necessarily

the same in all occurrences) which is independent of ε, but may depend on Ω_s and Sobolev norms of f.

2. Definitions and main results. We denote the domain of interest by $\Omega^\varepsilon \subset \mathbb{R}^2$, which is open, bounded, and ε-dependent. Here, ε indicates the length scale of the roughness element. It is convenient to consider $\Omega^\varepsilon = \Omega_s \cup \Omega_r^\varepsilon \cup \Gamma$, where the limit domain Ω_s is open and ε-independent, the open set Ω_r^ε depends on ε with $\Omega_s \cap \Omega_r^\varepsilon = \emptyset$, and the interface $\Gamma = \partial\Omega_s \cap \partial\Omega_r^\varepsilon$. The precise definition of these subdomains follow.

We assume that Ω_s has its boundary $\partial\Omega_s$ constituted of two disjoint parts, a smooth inner boundary Γ, and a Lipschitz-continuous outer boundary. We arc length parameterize the smooth curve Γ by an ε-independent function $\boldsymbol{\psi} : \mathbb{R} \to \mathbb{R}^2$, which is periodic with period L, and injective in $(0, L)$. In other words, Γ is a simple closed curve with length L, and it bounds a region of the plane, which we call its interior. We orient Γ in such a way that it is positively oriented, i.e., going along the direction of increasing parameter, the interior of the curve stays on the left. We assume that $\varepsilon = L/N$, for some positive integer N.

The domain Ω_r^ε has Γ as its outer boundary and Γ_r^ε as its inner boundary. The curve Γ_r^ε, which is also closed, is defined as a perturbation of Γ, and is parameterized by

$$\boldsymbol{\psi}^\varepsilon(\theta) = \boldsymbol{\psi}(\theta) + \varepsilon\big[d_0 - \psi_r(\varepsilon^{-1}\theta)\big]\,\boldsymbol{n}(\theta),$$

where $\boldsymbol{n}$ is the normal vector pointing towards the interior of Γ, and $d_0 > 1$ is such that $d_0\varepsilon$ is smaller than the minimum radius of curvature of Γ. The function $\psi_r : \mathbb{R} \to \mathbb{R}$ is independent of ε, Lipschitz-continuous with $\psi_r(0) = 0$, and periodic with period 1. Without loss of generality, we assume that $\|\psi_r\|_{L^\infty(\mathbb{R})} = 1$. Formally,

$$\Omega_r^\varepsilon \,=\, \{\, \mathbf{x} = \boldsymbol{\psi}(\theta) + (\varepsilon\, d_0 - \rho)\, \boldsymbol{n}(\theta) \,:\, \theta \in [0, L),\, \rho \in (\varepsilon\, \psi_r(\varepsilon^{-1}\theta), \varepsilon\, d_0)\,\}.$$

Hence, Ω^ε has its boundary constituted of two parts, a rough inner boundary Γ_r^ε, and a Lipschitz-continuous outer boundary that is independent of ε and does not intersect Γ. Note that Γ splits the original domain Ω^ε into two regions Ω_s and Ω_r^ε, one ε-independent, and the other containing the wrinkles. The subdomain Ω_r^ε is the set of points between Γ and Γ_r^ε, and Ω_s is the ε-independent domain comprehended between Γ and the outer boundary of Ω^ε. This is the set of all points at least "slightly away" from the wrinkles. See Figure 1. Finally, we denote a typical point in it by $\mathbf{x} = (x_1, x_2)$.

We consider the problem

$$\begin{aligned} -\Delta\, u^\varepsilon &= f \quad \text{in } \Omega^\varepsilon, \\ u^\varepsilon &= 0 \quad \text{on } \partial\Omega^\varepsilon, \end{aligned} \tag{1}$$

where f has support in Ω_s.

It is clear that the solution u^ε depends in a nontrivial way on the small parameter ε. It is our goal to unfold this dependence and show how to develop models for (1). It is possible to expand u^ε in a formal power series with respect to ε. This expansion is far from trivial since it has to take into account effects from the wrinkles as well as from the curvature. To focus on the main steps of our approach, we start by presenting the first few terms of this expansion, and only in Ω_s. The details of the asymptotics are considered in section 4.

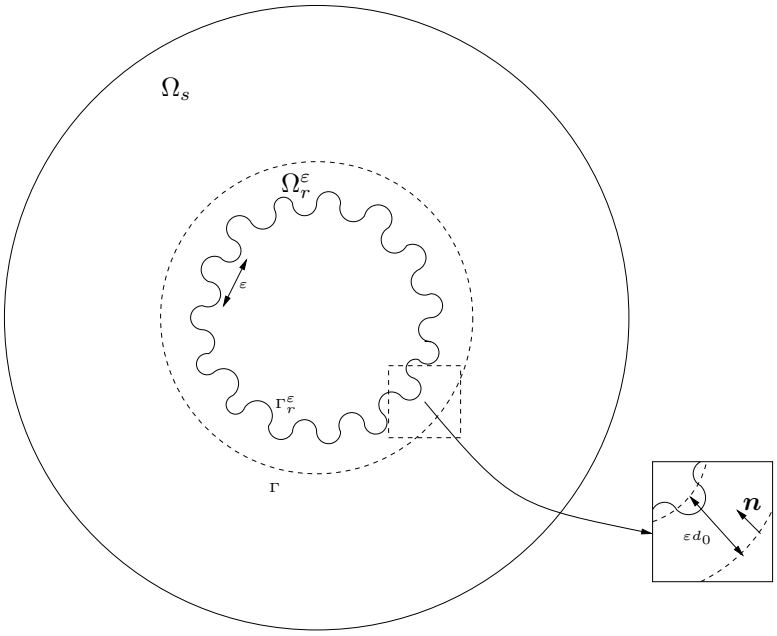

FIG. 1. *The domain* Ω^ε.

The asymptotic expansion of u^ε in Ω_s is a formal combination of an ε-independent part and a highly oscillatory part which decays exponentially to zero away from Γ,

$$u^\varepsilon \sim u^0 + \varepsilon\, u^1 + \varepsilon\, W^{1,0} + \dots \quad \text{in } \Omega_s. \tag{2}$$

While u^0, u^1 are ε-independent, the oscillatory function $W^{1,0}$ depends on ε, but only in a trivial manner.

It is natural to define the first term of the asymptotic such that

$$\begin{aligned} -\Delta\, u^0 &= f \quad \text{in } \Omega_s, \\ u^0 &= 0 \quad \text{on } \partial\Omega_s. \end{aligned} \tag{3}$$

To continue the description of the expansion, it is necessary to introduce a *cell problem*. This is no different from other singularly perturbed problems, perhaps elliptic PDEs with highly oscillatory coefficients being the most notorious. Such cell problems are a essential part in up-scaling procedures and brings information related to the small scale geometry into the large scale behavior of the solution.

In the present case, the cell problem is defined in the semi-infinite strip Ω_r, which "contains" the geometry of the wrinkles,

$$\Omega_r = \{\, (\hat\theta, \hat\rho) \in \mathbb{R}^2 \,:\, \hat\theta \in (0,1),\, \hat\rho \in (\psi_r(\hat\theta), +\infty)\,\},$$

i.e., Ω_r occupies the region delimited by straight lateral boundaries at $\hat\theta = 0$ and $\hat\theta = 1$, and by the lower boundary $\Gamma_r = \{\, (\hat\theta, \psi_r(\hat\theta)) \,:\, \hat\theta \in (0,1)\,\}$; see Figure 2.

We define $C^\infty_{per}(\Omega_r)$ by restricting to Ω_r the functions in $C^\infty(\mathbb{R}^2)$ which are one-periodic with respect to $\hat\theta$. Let $H^1_{per}(\Omega_r)$ be the closure of $C^\infty_{per}(\Omega_r)$ with respect to the $H^1(\Omega_r)$ norm. We also introduce the space of exponentially decaying functions

$$S(\Omega_r) = \{ w \in H^1_{per}(\Omega_r) \,:\, w\, e^{\alpha\hat\rho} \in H^1(\Omega_r) \text{ for some } \alpha > 0 \}\,.$$

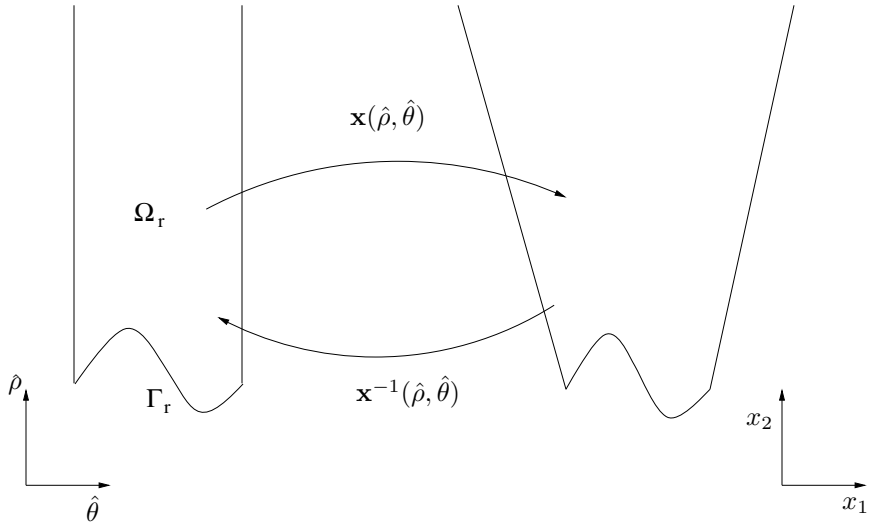

FIG. 2. *The cell domain.*

The following result guarantees that certain Poisson problems posed in Ω_r are well posed, and the solutions have nice properties. The reference [5] deals with related questions for the Stokes operator.

LEMMA 1. *Let $F \in S^*(\Omega_r)$, the dual space of $S(\Omega_r)$. Then there is a unique solution $w \in H^1_{loc}(\Omega_r)$ that is one-periodic with respect to $\hat{\theta}$, and such that $\nabla w \in L^2(\Omega_r)$, and*

$$\begin{aligned} (\partial_{\hat{\theta}\hat{\theta}} + \partial_{\hat{\rho}\hat{\rho}})w &= F \quad \text{in } \Omega_r, \\ w &= \hat{\rho} \quad \text{on } \Gamma_r. \end{aligned} \tag{4}$$

Moreover, there exists a unique constant z such that $w - z \in S(\Omega_r)$, and, if $F \equiv 0$,

$$z \leq \|\psi_r\|_{L^\infty(\mathbb{R})}.$$

Proof. A simple modification of the beautiful arguments of [8, Lemma 4.4] guarantees well posedness and yields a proof of the decaying behavior of the solution towards a constant. Assume now that w is harmonic, and for $t \geq \|\psi_r\|_{L^\infty(\mathbb{R})}$, let $\gamma_t = (0,1) \times \{t\}$. Then Green's identity yields that $\int_{\gamma_t} \partial_{\boldsymbol{n}} w$ is constant with respect to t. Letting $t \to \infty$, we have that actually $\int_{\gamma_t} \partial_{\boldsymbol{n}} w = 0$ for all $t \geq \|\psi_r\|_{L^\infty(\mathbb{R})}$. Using again Green's identity in $S_{t,\tilde{t}} = (0,1) \times (t,\tilde{t})$, for $\tilde{t} > t \geq \|\psi_r\|_{L^\infty(\mathbb{R})}$, we gather that

$$\int_{\partial S_{t,\tilde{t}}} w\, \partial_{\boldsymbol{n}}\, \hat{\rho} = \int_{\partial S_{t,\tilde{t}}} \hat{\rho}\, \partial_{\boldsymbol{n}}\, w = 0.$$

Thus $\int_{\gamma_t} w = \int_{\gamma_{\tilde{t}}} w$, and letting $\tilde{t} \to \infty$, we see that $z = \int_{\gamma_t} w$. Then $z \leq \|w\|_{L^\infty(\gamma_t)}$, and we conclude from the maximum principle [17] that $z \leq \|\psi_r\|_{L^\infty(\mathbb{R})}$. ∎

Remark 1. Note that $S^*(\Omega_r)$ contains, for instance, functions that grow at most algebraically with respect to $\hat{\rho}$.

We define $w^{0,0} \in S(\Omega_r)$, and the constant $z^{0,0}$ as the solution of

$$\begin{aligned} (\partial_{\hat{\theta}\hat{\theta}} + \partial_{\hat{\rho}\hat{\rho}})\, w^{0,0} &= 0 \quad \text{in } \Omega_r, \\ w^{0,0} &= \hat{\rho} - z^{0,0} \quad \text{on } \Gamma_r. \end{aligned} \tag{5}$$

It follows immediately from Lemma 1 that (5) is well defined. Both $z^{0,0}$ and $w^{0,0}$ are related to the boundary layers that naturally appear in the original problem.

To incorporate the influence of the cell problem into the asymptotic expansion (2), we introduce boundary fitted coordinates (θ, ρ) for points "close enough" to Γ; see [12]. Let ρ_0 be a positive number smaller than the minimum radius of curvature of Γ. For a given $\theta \in [0, L)$ and $\rho \in (\varepsilon\, \psi_r(\varepsilon^{-1}\theta), \varepsilon\, d_0 + \rho_0)$, we have

$$\mathbf{x}(\theta, \rho) = \boldsymbol{\psi}(\theta) + (\varepsilon\, d_0 - \rho)\, \boldsymbol{n}(\theta) \in \Omega^\varepsilon.$$

Note that $|\rho - \varepsilon\, d_0| = \operatorname{dist}(\mathbf{x}, \Gamma)$ is the distance between $\mathbf{x}$ and Γ and that the above map defines a local diffeomorphism. The change of coordinates $\mathbf{x} \to (\rho, \theta)$ is not well defined globally in Ω^ε, but only for points with distance from Γ smaller than the minimum radius of curvature of Γ.

In such a new system of coordinates, we simply write the normal derivative of u^0 at a point $\mathbf{x} \in \Gamma$ as $\partial_{\boldsymbol{n}}\, u^0(\theta, \varepsilon\, d_0)$, where θ is such that $\mathbf{x} = \boldsymbol{\psi}(\theta)$. We set

$$W^{1,0}(\theta, \rho) = \Upsilon(\varepsilon d_0 + \rho)\, w^{0,0}(\varepsilon^{-1}\theta, \varepsilon^{-1}\rho)\, \partial_{\boldsymbol{n}}\, u^0(\theta, \varepsilon\, d_0) \tag{6}$$

in the formal expansion (2), where $\Upsilon(\cdot)$ is a smooth ε-independent cutoff function, such that $\Upsilon(\rho)$ equals one if ρ is smaller than a fixed number smaller than ρ_0, and vanishes for $\rho \geq \rho_0$. For instance, we may set Υ identically equal to one in $(-\infty, \rho_0/3]$ and vanishing in $[\rho_0, +\infty)$. The following estimates follow from standard regularity results and scaling arguments (see also Lemma 3):

$$\|W^{1,0}\|_{L^2(\Omega^\varepsilon)} \leq c\, \varepsilon^{1/2}, \qquad \|W^{1,0}\|_{H^1(\Omega^\varepsilon)} \leq c\, \varepsilon^{-1/2}. \tag{7}$$

Finally, let

$$\begin{gathered} -\Delta\, u^1 = 0 \quad \text{in } \Omega_s, \\ u^1 = \left(-d_0 + z^{0,0}\right)\, \partial_{\boldsymbol{n}}\, u^0 \quad \text{on } \Gamma, \qquad u^1 = 0 \quad \text{on } \partial\Omega_s \backslash \Gamma. \end{gathered} \tag{8}$$

Albeit (2) is formal, we show below (Theorem 4) that if

$$e = u^\varepsilon - u^0 - \varepsilon\, u^1 - \varepsilon\, W^{1,0},$$

then there exists an ε-independent constant c such that

$$\|e\|_{H^1(\Omega_s)} \leq c\, \varepsilon^{3/2}. \tag{9}$$

Several other estimates follow from a combination of (9), the triangle inequality, and (7). For instance, we easily find that

$$\|u^\varepsilon - u^0 - \varepsilon\, u^1\|_{H^1(\Omega_s)} \leq \|e\|_{H^1(\Omega_s)} + \|\varepsilon\, W^{1,0}\|_{H^1(\Omega_s)} \leq c\, \varepsilon^{1/2}, \tag{10}$$

$$\|u^\varepsilon - u^0 - \varepsilon\, u^1\|_{L^2(\Omega_s)} \leq \|e\|_{H^1(\Omega_s)} + \|\varepsilon\, W^{1,0}\|_{L^2(\Omega_s)} \leq c\, \varepsilon^{3/2}. \tag{11}$$

The culprit for the low convergence rates in some of the estimates above are the boundary layers. Hence, *interior estimates*, i.e., estimates that bound the errors in domains that are away from the boundary ought to show better rates. It is possible to obtain such estimates by adding a higher order boundary layer term similar to (6) to the expansion. The new term, which we denote by $\breve{\mathrm{W}}$, behaves like $W^{1,0}$, i.e., decays exponentially fast to zero with ρ/ε, and

$$\|\breve{W}\|_{L^2(\Omega^\varepsilon)} \leq c\, \varepsilon^{1/2}, \qquad \|\breve{W}\|_{H^1(\Omega^\varepsilon)} \leq c\, \varepsilon^{-1/2}.$$

TABLE 1
Relative error convergence rates for a zeroth order model.

quantity	$L^2(\Omega_s)$ error	$L^2(\Omega_s^{int})$ error
u	$O(\varepsilon)$	$O(\varepsilon)$
∇u	$O(\varepsilon^{1/2})$	$O(\varepsilon)$

For the sake of simplicity, we do not describe $\check{W}$ now. Such a function is defined after two different cell problems are solved; see (19) and (20). It is now possible to derive a better estimate in the H^1 norm:

$$\|u^\varepsilon - u^0 - \varepsilon\, u^1 - \varepsilon\, W^{1,0} - \varepsilon^2\, \check{W}\|_{H^1(\Omega_s)} \le c\,\varepsilon^2. \tag{12}$$

Finally, let $\Omega_s^{int} \subset \Omega_s$ be such that $\overline{\Omega_s^{int}} \cap \overline{\Gamma} = \emptyset$. Then

$$\begin{aligned} &\|u^\varepsilon - u^0 - \varepsilon\, u^1\|_{H^1(\Omega_s^{int})} \\ &\le \|u^\varepsilon - u^0 - \varepsilon\, u^1 - \varepsilon\, W^{1,0} - \varepsilon^2\, \check{W}\|_{H^1(\Omega_s)} + \|\varepsilon\, W^{1,0}\|_{H^1(\Omega_s^{int})} + \|\varepsilon^2\, \check{W}\|_{H^1(\Omega_s^{int})} \le c\,\varepsilon^2. \end{aligned} \tag{13}$$

Note in (13) that the exponential decay of both $W^{1,0}$ and $\check{W}$ guarantees that their $H^1(\Omega_s^{int})$ norms are also exponentially small and hence bounded by $c\,\varepsilon^2$.

3. Derivation of wall laws.

3.1. Zeroth order wall law. A first attempt to approximate u^ε would use u^0. It immediately follows from (10), (11) and regularity estimates for u^1 that

$$\begin{aligned} \|u^\varepsilon - u^0\|_{H^1(\Omega_s)} &\le \|u^\varepsilon - u^0 - \varepsilon\, u^1\|_{H^1(\Omega_s)} + \|\varepsilon\, u^1\|_{H^1(\Omega_s)} \le c\,\varepsilon^{1/2}, \\ \|u^\varepsilon - u^0\|_{L^2(\Omega_s)} &\le \|u^\varepsilon - u^0 - \varepsilon\, u^1\|_{L^2(\Omega_s)} + \|\varepsilon\, u^1\|_{L^2(\Omega_s)} \le c\,\varepsilon. \\ \|u^\varepsilon - u^0\|_{L^2(\Omega_s^{int})} &\le \|u^\varepsilon - u^0 - \varepsilon\, u^1\|_{H^1(\Omega_s^{int})} + \|\varepsilon\, u^1\|_{H^1(\Omega_s)} \le c\,\varepsilon. \end{aligned}$$

The $O(\varepsilon^{1/2})$ error in the $H^1(\Omega_s)$ norm is due to the inability of this approximation to capture the oscillatory behavior of the solution close to the wrinkles. This explains the better performance in the $L^2(\Omega_s)$ and interior norms. Table 1 presents various relative error estimates with respect to ε, including interior estimates.

3.2. First order wall law. Inspired by (2), (10)–(13), we would like to approximate u^ε by the first terms of its asymptotic expansion, but without solving the PDEs that define these terms. A first step in this direction is to consider only the functions that actually have influence in the interior of the domain, i.e., we assume

$$u^\varepsilon \approx u^0 + \varepsilon\, u^1. \tag{14}$$

Thus, over Γ, from (3), (8), and (14),

$$u^\varepsilon \approx \varepsilon\,(-d_0 + z^{0,0})\,\partial_{\boldsymbol{n}}\, u^0, \qquad \partial_{\boldsymbol{n}}\, u^\varepsilon \approx \partial_{\boldsymbol{n}}\, u^0 + \varepsilon\, \partial_{\boldsymbol{n}}\, u^1. \tag{15}$$

So

$$u^\varepsilon + \varepsilon\,(d_0 - z^{0,0})\,\partial_{\boldsymbol{n}}\, u^\varepsilon \approx \varepsilon^2\,(d_0 - z^{0,0})\,\partial_{\boldsymbol{n}}\, u^1,$$

TABLE 2
Relative error convergence rates for a first order model.

quantity	$L^2(\Omega_s)$ error	$L^2(\Omega_s^{int})$ norm error
u	$O(\varepsilon^{3/2})$	$O(\varepsilon^2)$
∇u	$O(\varepsilon^{1/2})$	$O(\varepsilon^2)$

on Γ, and this amount can be small enough for certain applications. We define then $\bar{u} \in H^1(\Omega_s)$ approximating u^ε in Ω_s by

$$\begin{aligned} -\Delta\,\bar{u} &= f \quad \text{in } \Omega_s, \\ \bar{u} + \varepsilon\,(d_0 - z^{0,0})\,\partial_{\boldsymbol{n}}\,\bar{u} &= 0 \quad \text{on } \Gamma, \qquad \bar{u} = 0 \quad \text{on } \partial\Omega_s\backslash\Gamma. \end{aligned} \tag{16}$$

It follows from Lemma 1 that $z^{0,0} \leq \|\psi_r\|_{L^\infty(\mathbb{R})}$, and since $\|\psi_r\|_{L^\infty(\mathbb{R})} = 1 < d_0$, the difference $d_0 - z^{0,0}$ is positive. Thus (16) is well posed for all positive ε.

To estimate the modeling error, we first note that if $\bar{e} = \bar{u} - u^0 - \varepsilon\,u^1$, then

$$\begin{aligned} -\Delta\,\bar{e} &= 0 \quad \text{in } \Omega_s, \\ \bar{e} + \varepsilon\,(d_0 - z^{0,0})\,\partial_{\boldsymbol{n}}\,\bar{e} &= -\varepsilon^2\,(d_0 - z^{0,0})\,\partial_{\boldsymbol{n}}\,u^1 \quad \text{on } \Gamma, \qquad \bar{e} = 0 \quad \text{on } \partial\Omega_s\backslash\Gamma. \end{aligned} \tag{17}$$

It follows from regularity estimates [16, Theorem 4.24] that there exists an ε-independent constant c such that

$$\|\bar{e}\|_{H^1(\Omega_s)} \leq c\,\varepsilon^2.$$

The modeling error estimates are then as follows:

$$\|u^\varepsilon - \bar{u}\|_{H^1(\Omega_s)} \leq \|u^\varepsilon - u^0 - \varepsilon\,u^1\|_{H^1(\Omega_s)} + \|\bar{u} - u^0 - \varepsilon\,u^1\|_{H^1(\Omega_s)} \leq c\,\varepsilon^{1/2},$$

where we used the triangle inequality and (10).

Analogously, using (11), (13), we obtain L^2 and interior estimates

$$\|u^\varepsilon - \bar{u}\|_{L^2(\Omega_s)} \leq c\,\varepsilon^{3/2} \qquad \|u^\varepsilon - \bar{u}\|_{H^1(\Omega_s^{int})} \leq c\,\varepsilon^2.$$

We summarize the convergence results in Table 2.

3.3. Second order wall law. The derivation of higher order approximations to u^ε follows the same *modus operandi* as in the previous subsection. We first consider only the terms that have influence away from Γ_r^ε and assume that

$$u^\varepsilon \approx u^0 + \varepsilon\,u^1 + \varepsilon^2\,u^2. \tag{18}$$

To define the term u^2 above we introduce two new cell problems, seeking $w^{1,0}$ and $w^{1,1}$ in $S(\Omega_r)$, and the constants $z^{1,0}$ and $z^{1,1}$ satisfying

$$-(\partial_{\hat{\theta}\hat{\theta}} + \partial_{\hat{\rho}\hat{\rho}})\,w^{1,0} = \chi - \partial_{\hat{\rho}}\,w^{0,0} + 2\,\hat{\rho}\,\partial_{\hat{\theta}\hat{\theta}}\,w^{0,0} \quad \text{in } \Omega_r, \qquad w^{1,0} = -z^{1,0} \quad \text{on } \Gamma_r, \tag{19}$$

$$-(\partial_{\hat{\theta}\hat{\theta}} + \partial_{\hat{\rho}\hat{\rho}})\,w^{1,1} = 2\,\partial_{\hat{\theta}}\,w^{0,0} \quad \text{in } \Omega_r, \qquad w^{1,1} = z^{1,1} \quad \text{on } \Gamma_r, \tag{20}$$

where $\chi(\hat{\rho}) = 1$ if $\hat{\rho} < d_0$, and $\chi(\hat{\rho}) = 0$ if $\hat{\rho} \geq d_0$. The previous cell problems are well posed, as Lemma 1 guarantees. The expression of $\check{W}$ mentioned on page 1455 is as follows:

$$\begin{aligned}\check{W}(\theta,\rho) = \Upsilon(\varepsilon d_0+\rho)\big[&w^{1,0}(\varepsilon^{-1}\theta,\varepsilon^{-1}\rho)\kappa(\theta)\,\partial_{\boldsymbol{n}}\,u^0(\theta,\varepsilon\,d_0)\\ &+ w^{1,1}(\varepsilon^{-1}\theta,\varepsilon^{-1}\rho)\partial_\theta\,\partial_{\boldsymbol{n}}\,u^0(\theta,\varepsilon\,d_0) + w^{0,0}(\varepsilon^{-1}\theta,\varepsilon^{-1}\rho)\,\partial_{\boldsymbol{n}}\,u^1(\theta,\varepsilon\,d_0)\big],\end{aligned}$$

where $\kappa(\theta)$ is the curvature of Γ at the point $\boldsymbol{\psi}(\theta)$.

Next, we define u^2 by

$$\begin{gathered}-\Delta\,u^2 = 0 \quad \text{in } \Omega_s,\\ u^2 = (-d_0+z^{0,0})\,\partial_{\boldsymbol{n}}\,u^1 + z^{1,0}\kappa\,\partial_{\boldsymbol{n}}\,u^0 + z^{1,1}\partial_\theta\,\partial_{\boldsymbol{n}}\,u^0 \quad \text{on } \Gamma, \qquad u^2 = 0 \quad \text{on } \partial\Omega_s\backslash\Gamma,\end{gathered}$$

and the estimates below follow:

$$\|u^\varepsilon - u^0 - \varepsilon\,u^1 - \varepsilon^2\,u^2\|_{H^1(\Omega_s)} \leq c\,\varepsilon^{1/2}, \tag{21}$$

$$\|u^\varepsilon - u^0 - \varepsilon\,u^1 - \varepsilon^2\,u^2\|_{L^2(\Omega_s)} \leq c\,\varepsilon^{3/2}, \tag{22}$$

$$\|u^\varepsilon - u^0 - \varepsilon\,u^1 - \varepsilon^2\,u^2\|_{H^1(\Omega_s^{int})} \leq c\,\varepsilon^{3}. \tag{23}$$

If (18) holds, then

$$\begin{aligned}u^\varepsilon &\approx \varepsilon\,(-d_0+z^{0,0}+\varepsilon\,z^{1,0}\kappa)\,\partial_{\boldsymbol{n}}\,u^0 + \varepsilon^2\,(-d_0+z^{0,0})\,\partial_{\boldsymbol{n}}\,u^1 + \varepsilon^2\,z^{1,1}\partial_\theta\,\partial_{\boldsymbol{n}}\,u^0\\ &= \varepsilon\,(-d_0+z^{0,0}+\varepsilon\,z^{1,0}\kappa)\,\partial_{\boldsymbol{n}}\,u^0 + \varepsilon^2\,(-d_0+z^{0,0})\,\partial_{\boldsymbol{n}}\,u^1 + \varepsilon^2\,\frac{z^{1,1}}{-d_0+z^{0,0}}\partial_\theta u^1\end{aligned}$$

over Γ, where we used from (8) that $\partial_\theta u^1 = (-d_0+z^{0,0})\partial_\theta\,\partial_{\boldsymbol{n}}\,u^0$ to obtain the last equality. We also have

$$\partial_{\boldsymbol{n}}\,u^\varepsilon \approx \partial_{\boldsymbol{n}}\,u^0 + \varepsilon\,\partial_{\boldsymbol{n}}\,u^1 + \varepsilon^2\,\partial_{\boldsymbol{n}}\,u^2, \qquad \partial_\theta u^\varepsilon \approx \partial_\theta u^0 + \varepsilon\,\partial_\theta u^1 + \varepsilon^2\,\partial_\theta u^2,$$

over Γ. Hence,

$$\begin{aligned}u^\varepsilon + (\varepsilon\,d_0 - \varepsilon\,z^{0,0} - \varepsilon^2\,z^{1,0}\,\kappa)\,\partial_{\boldsymbol{n}}\,u^\varepsilon - \varepsilon^2\,\frac{z^{1,1}}{-d_0+z^{0,0}}\,\partial_\theta u^\varepsilon &\approx -\varepsilon^3\,z^{1,0}\,\kappa\,\partial_{\boldsymbol{n}}\,u^1\\ - \varepsilon^3(-d_0+z^{0,0}+\varepsilon\,z^{1,0}\,\kappa)\,\partial_{\boldsymbol{n}}\,u^2 - \varepsilon^3\,\frac{z^{1,1}}{-d_0+z^{0,0}}\,\partial_\theta u^1 - \varepsilon^4\,\frac{z^{1,1}}{-d_0+z^{0,0}}\,\partial_\theta u^2.&\end{aligned}$$

So we define $\bar{\bar{u}} \in H^1(\Omega_s)$ approximating u^ε in Ω_s by

$$\begin{gathered}-\Delta\,\bar{\bar{u}} = f \quad \text{in } \Omega_s,\\ \bar{\bar{u}} + (\varepsilon\,d_0 - \varepsilon\,z^{0,0} - \varepsilon^2\,z^{1,0}\,\kappa)\,\partial_{\boldsymbol{n}}\,\bar{\bar{u}} - \varepsilon^2\,\frac{z^{1,1}}{-d_0+z^{0,0}}\,\partial_\theta\bar{\bar{u}} = 0 \quad \text{on } \Gamma,\\ \bar{\bar{u}} = 0 \quad \text{on } \partial\Omega_s\backslash\Gamma.\end{gathered} \tag{24}$$

Since Γ is a closed curve,

$$\int_\Gamma \bar{\bar{u}}\partial_\theta\bar{\bar{u}}\,d\theta = 0,$$

TABLE 3
Relative error convergence rates for a second order model.

quantity	$L^2(\Omega_s)$ error	$L^2(\Omega_s^{int})$ norm error
u	$O(\varepsilon^{3/2})$	$O(\varepsilon^3)$
∇u	$O(\varepsilon^{1/2})$	$O(\varepsilon^3)$

and for ε small enough the well posedness of (24) follows from Lemma 1 and the Lax–Milgram's lemma. To estimate the modeling error we first define $\bar{\bar{e}} = \bar{\bar{u}} - u^0 - \varepsilon\, u^1 - \varepsilon^2\, u^2$. Thus

$$
\begin{aligned}
&-\Delta\, \bar{\bar{e}} = 0 \quad \text{in } \Omega_s,\\
&\bar{\bar{e}} + (\varepsilon\, d_0 - \varepsilon\, z^{0,0} - \varepsilon^2\, z^{1,0}\kappa)\ \partial_{\boldsymbol{n}}\, \bar{\bar{e}} - \varepsilon^2\, \frac{z^{1,1}}{-d_0 + z^{0,0}}\, \partial_\theta \bar{\bar{e}} = -\varepsilon^3 z^{1,0}\, \kappa\ \partial_{\boldsymbol{n}}\, u^1\\
&-\varepsilon^3\, (-d_0 + z^{0,0} + \varepsilon\, z^{1,0}\, \kappa)\ \partial_{\boldsymbol{n}}\, u^2 - \varepsilon^3\, \frac{z^{1,1}}{-d_0 + z^{0,0}}\, \partial_\theta u^1 - \varepsilon^4\, \frac{z^{1,1}}{-d_0 + z^{0,0}}\, \partial_\theta u^2 \quad \text{on } \Gamma,\\
&\bar{\bar{e}} = 0 \quad \text{on } \partial\Omega_s \backslash \Gamma.
\end{aligned}
$$

Regularity estimates [16, Theorem 4.24] guarantee the existence of an ε-independent constant c such that

$$\|\bar{\bar{e}}\|_{H^1(\Omega_s)} \leq c\, \varepsilon^3.$$

Using the triangle inequality and (21), it is possible to estimate the $H^1(\Omega_s)$ norm modeling error,

$$\|u^\varepsilon - \bar{\bar{u}}\|_{H^1(\Omega_s)} \leq \|u^\varepsilon - u^0 - \varepsilon\, u^1 - \varepsilon^2\, u^2\|_{H^1(\Omega_s)} + \|\bar{\bar{u}} - u^0 - \varepsilon\, u^1 - \varepsilon^2\, u^2\|_{H^1(\Omega_s)} \leq c\, \varepsilon^{1/2}.$$

Analogously, using (22), (23), we obtain L^2 and interior estimates,

$$\|u^\varepsilon - \bar{\bar{u}}\|_{L^2(\Omega_s)} \leq c\, \varepsilon^{3/2} \qquad \|u^\varepsilon - \bar{\bar{u}}\|_{H^1(\Omega_s^{int})} \leq c\, \varepsilon^3.$$

These results are displayed in Table 3.

3.4. Summary: The proposed effective problems. The first order boundary value problem in Ω_s is the following: find $\bar{u} \in H^1(\Omega_s)$ such that

$$
\begin{aligned}
&-\Delta\, \bar{u} = f \quad \text{in } \Omega_s,\\
&\partial_{\boldsymbol{n}}\, \bar{u} = -\frac{1}{\varepsilon\, (d_0 - z^{0,0})}\, \bar{u} \quad \text{on } \Gamma, \qquad \bar{u} = 0 \quad \text{on } \partial\Omega_s \backslash \Gamma,
\end{aligned}
\tag{25}
$$

where $z^{0,0}$ is obtained from (5). For error estimates, see Table 2.

The second order boundary value problem in Ω_s is: find $\bar{\bar{u}} \in H^1(\Omega_s)$ such that

$$
\begin{aligned}
&-\Delta\, \bar{\bar{u}} = f \quad \text{in } \Omega_s,\\
&\partial_{\boldsymbol{n}}\, \bar{\bar{u}} = -C_1^\varepsilon\, \bar{\bar{u}} + C_2^\varepsilon\, \partial_\theta \bar{\bar{u}} \quad \text{on } \Gamma, \qquad \bar{\bar{u}} = 0 \quad \text{on } \partial\Omega_s \backslash \Gamma,
\end{aligned}
\tag{26}
$$

with

$$C_1^\varepsilon = \frac{1}{\varepsilon\, (d_0 - z^{0,0} - \varepsilon\, z^{1,0}\, \kappa)}, \quad C_2^\varepsilon = \frac{\varepsilon\, z^{1,1}}{(d_0 - z^{0,0} - \varepsilon\, z^{1,0}\, \kappa)(z^{0,0} - d_0)},$$

and where $z^{0,0}$ is computed from (5), and $z^{1,0}$, $z^{1,1}$ from (19), (20). For error estimates, see Table 3.

4. Asymptotic expansion definition. We now find and justify the terms presented previously. Consider a formal asymptotic expansion in the general form

$$u^\varepsilon \sim u^0 + \varepsilon\, u^1 + \varepsilon^2\, u^2 + \cdots + W^{BL}(\varepsilon) \quad \text{in } \Omega_s. \tag{27}$$

Here, $W^{BL}(\varepsilon)$ corresponds to the oscillatory part of the solution, which dies away exponentially fast with the distance to the boundary. Our procedure to find out the terms in the expansion uses a domain decomposition result that we state below.

It is convenient to introduce the jump function $[\![\cdot]\!]$ that assigns the *absolute value* of the jump over the interface Γ.

LEMMA 2. *Let Ω^ε, Ω_s, Ω_r^ε, and Γ be as above. Then there exists an ε-independent constant c such that*

$$\begin{aligned}\|e\|_{H^1(\Omega_r^\varepsilon)} + \|e\|_{H^1(\Omega_s)} \\ \leq c\left(\|\Delta e\|_{L^2(\Omega_r^\varepsilon)} + \|\Delta e\|_{L^2(\Omega_s)} + \|[\![e]\!]\|_{H^{1/2}(\Gamma)} + \|[\![\partial_{\boldsymbol{n}} e]\!]\|_{H^{-1/2}(\Gamma)}\right)\end{aligned} \tag{28}$$

whenever $e|_{\Omega_r^\varepsilon} \in H^1(\Omega_r^\varepsilon)$, $\Delta e|_{\Omega_r^\varepsilon} \in L^2(\Omega_r^\varepsilon)$, and $e|_{\Omega_s} \in H^1(\Omega_s)$, $\Delta e|_{\Omega_s} \in L^2(\Omega_s)$, with $e = 0$ on $\partial\Omega_r^\varepsilon \backslash \Gamma \cup \partial\Omega_s \backslash \Gamma$.

Proof. We first define

$$e^- = e|_{\Omega_r^\varepsilon}, \qquad e^+ = e|_{\Omega_s}.$$

It follows from Green's identity that

$$\begin{aligned}\int_{\Omega_r^\varepsilon} |\nabla e^-|^2\, d\mathbf{x} &= -\int_{\Omega_r^\varepsilon} e^-\, \Delta e^-\, d\mathbf{x} - < e^-, \partial_{\boldsymbol{n}} e^- >_{H^{1/2}(\Gamma)\times H^{-1/2}(\Gamma)}, \\ \int_{\Omega_s} |\nabla e^+|^2\, d\mathbf{x} &= -\int_{\Omega_s} e^+\, \Delta e^+\, d\mathbf{x} + < e^+, \partial_{\boldsymbol{n}} e^+ >_{H^{1/2}(\Gamma)\times H^{-1/2}(\Gamma)},\end{aligned}$$

where $< \cdot, \cdot >_{H^{1/2}(\Gamma)\times H^{-1/2}(\Gamma)}$ indicates the duality pairing between $H^{1/2}(\Gamma)$ and $H^{-1/2}(\Gamma)$. Combining both identities and then adding and subtracting the quantity $< e^-, \partial_{\boldsymbol{n}} e^+ >_{H^{1/2}(\Gamma)\times H^{-1/2}(\Gamma)}$, we gather that

$$\begin{aligned}|e^-|^2_{H^1(\Omega_r^\varepsilon)} + |e^+|^2_{H^1(\Omega_s)} = -\int_{\Omega_r^\varepsilon} e^-\, \Delta e^-\, d\mathbf{x} - \int_{\Omega_s} e^+\, \Delta e^+\, d\mathbf{x} \\ + < e^-, \partial_{\boldsymbol{n}} e^+ - \partial_{\boldsymbol{n}} e^- >_{H^{1/2}(\Gamma)\times H^{-1/2}(\Gamma)} + < e^+ - e^-, \partial_{\boldsymbol{n}} e^+ >_{H^{1/2}(\Gamma)\times H^{-1/2}(\Gamma)}.\end{aligned}$$

When estimating the above quantities, a delicate question is how the constants depend on the domains. For $u \in H^{1/2}(\Gamma)$ and $v \in H^{-1/2}(\Gamma)$, the inequality

$$< u, v >_{H^{1/2}(\Gamma)\times H^{-1/2}(\Gamma)} \leq \|u\|_{H^{1/2}(\Gamma)} \|v\|_{H^{-1/2}(\Gamma)}$$

comes by naturally by inducing the operator norm in $H^{-1/2}(\Gamma)$. Thus, with the aid of the Cauchy–Schwarz inequality it follows that

$$\begin{aligned}|e^-|^2_{H^1(\Omega_r^\varepsilon)} + |e^+|^2_{H^1(\Omega_s)} \leq \|e^-\|_{L^2(\Omega_r^\varepsilon)} \|\Delta e^-\|_{L^2(\Omega_r^\varepsilon)} + \|e^+\|_{L^2(\Omega_s)} \|\Delta e^+\|_{L^2(\Omega_s)} \\ + \|e^-\|_{H^{1/2}(\Gamma)} \|[\![\partial_{\boldsymbol{n}} e]\!]\|_{H^{-1/2}(\Gamma)} + \|[\![e]\!]\|_{H^{1/2}(\Gamma)} \|\partial_{\boldsymbol{n}} e^+\|_{H^{-1/2}(\Gamma)}.\end{aligned}$$

Next, let Ω' be the interior of Γ, i.e., the open domain circumvented by Γ. Hence $\Omega_r^\varepsilon \subset \Omega'$, and since the trace of e vanishes on Γ_r^ε, the extension (by zero) operator

$$P : \{v \in H^1(\Omega_r^\varepsilon) :\ v = 0 \text{ on } \Gamma_r^\varepsilon\} \to H^1(\Omega')$$

given by $Pv = v$ in Ω_r^ε and $Pv = 0$, otherwise, is an isometry [26, 19]. By construction, P preserves L^2 norms as well and we gather the trace and Poincaré inequalities,

$$\|v\|_{H^{1/2}(\Gamma)} \le c\|Pv\|_{H^1(\Omega')} = c\|v\|_{H^1(\Omega_r^\varepsilon)} \tag{29}$$

$$\|v\|_{L^2(\Omega_r^\varepsilon)} = \|Pv\|_{L^2(\Omega')} \le c|Pv|_{H^1(\Omega')} = c|v|_{H^1(\Omega_r^\varepsilon)} \tag{30}$$

for all $v \in H^1(\Omega_r^\varepsilon)$, where the constant c is independent of ε.

Using now the trace inequality $\|v\|_{H^{1/2}(\Gamma)} \le c\|v\|_{H^1(\Omega_s)}$ for all $v \in H^1(\Omega_s)$ and (29), it follows that

$$\begin{aligned} |e^-|^2_{H^1(\Omega_r^\varepsilon)} + |e^+|^2_{H^1(\Omega_s)} \le{}& (\|\Delta e^-\|_{L^2(\Omega_r^\varepsilon)} + \|\Delta e^+\|_{L^2(\Omega_s)})\|e\|_{L^2(\Omega^\varepsilon)} \\ &+ \|e^-\|_{H^1(\Omega_r^\varepsilon)}\|[\![\partial_{\boldsymbol{n}} e]\!]\|_{H^{-1/2}(\Gamma)} + c\|[\![e]\!]\|_{H^{1/2}(\Gamma)}\|e^+\|_{H^1(\Omega_s)}. \end{aligned} \tag{31}$$

To conclude the proof, it is enough to use in (31) the Poincaré inequality in Ω_r^ε given by (30) and also in Ω_s. □

We shall apply Lemma 2 repeatedly with e being the difference between u^ε and a truncated asymptotic expansion. Hence, to make such a difference as small as possible, we ought to minimize the L^2 norm of Δe in Ω_r^ε and Ω_s and control the jumps of both e and $\partial_{\boldsymbol{n}} e$ over Γ.

A natural choice for the first term of the asymptotic of u^ε is u^0 given by (3), plus the condition $u^0 = 0$ in $\overline{\Omega_r^\varepsilon}$. Applying Lemma 2 with $e = u^\varepsilon - u^0$, we see that the source of error is the normal derivative jump $[\![\partial_{\boldsymbol{n}} u^0]\!]$. We remedy this by adding $\varepsilon\,\zeta^1$ to the asymptotic, where

$$\zeta^1(\mathbf{x}) = \begin{cases} -\varepsilon^{-1}\rho\ \partial_{\boldsymbol{n}} u^0(\theta, d_0\,\varepsilon) & \text{in } \Omega_r^\varepsilon, \\ 0 & \text{in } \Omega_s. \end{cases}$$

The function ζ^1 defined as above satisfies the following properties:

1. $\zeta^1 \equiv 0$ outside Ω_r^ε,
2. $[\![\varepsilon\,\partial_{\boldsymbol{n}}\,\zeta^1]\!] \equiv |\,\partial_{\boldsymbol{n}}\,u^0|$ on Γ,
3. $\zeta^1 = \psi_r(\varepsilon^{-1}\theta)\ \partial_{\boldsymbol{n}}\,u^0(\theta, d_0\,\varepsilon)$ on Γ_r^ε.

So, in general, the correction of the jump of the normal derivative on Γ violates the zero Dirichlet condition at Γ_r^ε.

Proceeding with the computations, we have to add a boundary corrector to compensate for the value of ζ^1 on Γ_r^ε. This is nontrivial since a "typical" boundary corrector does not decay to zero; see Lemma 1 and (5). A similar, but actually simpler situation occurs for the asymptotics of plates [18]. Thus, we add a boundary corrector that is the sum of two functions and is given by $\varepsilon\left[W^1(\varepsilon) + \chi_r^\varepsilon Z^1(\varepsilon)\right]$. One part, corresponding to $W^1(\varepsilon)$, decays exponentially fast to zero with $\varepsilon^{-1}\rho$ and undulates with $\varepsilon^{-1}\theta$. The other part, corresponding to $Z^1(\varepsilon)$, depends only on θ and is nonzero only in Ω_r^ε. Hence,

$$-\Delta\, W^1(\varepsilon) = \chi_r^\varepsilon\,\Delta\left[\zeta^1 + Z^1(\varepsilon)\right] \quad \text{in } \Omega^\varepsilon, \tag{32}$$

$$W^1(\varepsilon) = -\zeta^1 - Z^1(\varepsilon) \quad \text{on } \Gamma_r^\varepsilon, \tag{33}$$

and the characteristic function of Ω_r^ε is given by χ_r^ε, where

$$\chi_r^\varepsilon(\rho) = \begin{cases} 1 & \text{if } \rho < \varepsilon d_0, \\ 0 & \text{otherwise.} \end{cases}$$

At first sight, finding $W^1(\varepsilon)$ and $Z^1(\varepsilon)$ satisfying (32), (33) seems (at least!) as hard as solving the original problem (1). Nevertheless, it is possible to make use of the periodicity of the wrinkles, and formally recast (32), (33) as a sequence of ε-independent problems which are easier to solve. We write

$$W^1(\varepsilon) \sim W^{1,0} + \varepsilon\, W^{1,1} + \varepsilon^2\, W^{1,2} + \cdots, \tag{34}$$

$$Z^1(\varepsilon) \sim Z^{1,0} + \varepsilon\, Z^{1,1} + \varepsilon^2\, Z^{1,2} + \cdots. \tag{35}$$

We shall impose on Γ_r^ε that $W^{1,0} = -\zeta^1 - Z^{1,0}$ and that $W^{1,j} = -Z^{1,j}$ for $j \neq 0$. We postpone the precise definition of these terms for now, but add, formally, the term $\varepsilon\, \chi_r^\varepsilon(\mathbf{x}) Z^{1,0}(\theta) + \varepsilon\, W^{1,0}(\theta, \varepsilon^{-1}\theta, \varepsilon^{-1}\rho)$ to the asymptotic. The remaining terms of the expansion for $W^1(\varepsilon)$, $Z^1(\varepsilon)$ shall be added as we continue to develop the expansion.

So far the asymptotic reads as

$$\begin{cases} \varepsilon\, \zeta^1 + \varepsilon\, W^{1,0} + \varepsilon\, Z^{1,0} & \text{in } \Omega_r^\varepsilon, \\ u^0 + \varepsilon\, W^{1,0} & \text{in } \Omega_s. \end{cases} \tag{36}$$

Note that now the normal derivative of the difference between u^ε and the expression in (36) has zero jump on Γ, but the difference itself has nontrivial jump equal to $-d_0\, \varepsilon\, \partial_{\boldsymbol{n}}\, u^0 + \varepsilon\, Z^{1,0}$ on Γ. Such error no longer depends on the fast variable and it can be corrected adding to the asymptotic expansion a new term that depends only on the slow variable.

We continue to define the terms of the expansion, this time trying to cancel out the error due to the jump of the expression in (36) on Γ. Consider u^1 the solution of

$$\begin{gathered} -\Delta\, u^1 = 0 \quad \text{in } \Omega_s, \\ u^1 = -d_0\, \partial_{\boldsymbol{n}}\, u^0 + Z^{1,0} \quad \text{on } \Gamma, \qquad u^1 = 0 \quad \text{on } \partial\Omega_s \backslash \Gamma, \qquad u^1 = 0 \quad \text{on } \Omega_r^\varepsilon. \end{gathered} \tag{37}$$

Remark 2. Although (37) looks different from (8), it is not. In fact, $Z^{1,0} = z^{0,0}\, \partial_{\boldsymbol{n}}\, u^0$, but that will become clear later.

Adding $\varepsilon\, u^1$ to the expansion corrects the previous error, but results in a jump in the normal derivative across Γ. Mimicking what we did before, we add $\varepsilon^2\, \zeta^2$ to the expansion, where

$$\zeta^2(\mathbf{x}) = -\varepsilon^{-1} \rho\, \chi_r^\varepsilon(\rho)\, \partial_{\boldsymbol{n}}\, u^1(\theta, d_0\varepsilon).$$

Ideally the next contribution would be $\varepsilon^2 \big[W^2(\varepsilon) + \chi_r^\varepsilon Z^2(\varepsilon)\big]$, where

$$-\Delta\, W^2(\varepsilon) = \chi_r^\varepsilon\, \Delta \big[\zeta^2 + Z^2(\varepsilon)\big] \quad \text{in } \Omega^\varepsilon, \tag{38}$$

$$W^2(\varepsilon) = -\zeta^2 - Z^2(\varepsilon) \quad \text{on } \Gamma_r^\varepsilon. \tag{39}$$

As in (34), (35),

$$W^2(\varepsilon) \sim W^{2,0} + \varepsilon\, W^{2,1} + \varepsilon^2\, W^{2,2} + \cdots, \tag{40}$$

$$Z^2(\varepsilon) \sim Z^{2,0} + \varepsilon\, Z^{2,1} + \varepsilon^2\, Z^{2,2} + \cdots. \tag{41}$$

On Γ_r^ε we shall have $W^{2,0} = -\zeta^2 - Z^{2,0}$, and $W^{2,j} = -Z^{2,j}$ for $j \neq 0$. Then, we simply add $\varepsilon^2 \big[W^{1,1} + W^{2,0} + \chi_r^\varepsilon \big(Z^{1,1} + Z^{2,0}\big)\big]$ to our asymptotic expansion. Note that terms in ε^2 corresponding to the expansions for $W^1(\varepsilon)$, $Z^1(\varepsilon)$ are included now.

At this point, the asymptotic reads as

$$(42)\quad \begin{cases} \varepsilon\,\zeta^1+\varepsilon^2\,\zeta^2+\varepsilon\,W^{1,0}+\varepsilon\,Z^{1,0}+\varepsilon^2\left(W^{1,1}+W^{2,0}\right)+\varepsilon^2\left(Z^{1,1}+Z^{2,0}\right) & \text{in } \Omega_r^\varepsilon,\\ u^0+\varepsilon\,u^1+\varepsilon\,W^{1,0}+\varepsilon^2\left(W^{1,1}+W^{2,0}\right) & \text{in } \Omega_s. \end{cases}$$

The expansion pattern should be clear by now, and the successive terms are defined in similar manner. In general, after the kth step, the asymptotic expansion reads as

$$(43)\quad \begin{cases} \zeta_{k,\varepsilon}+W_{k,\varepsilon}^{BL}+Z_{k,\varepsilon} & \text{in } \Omega_r^\varepsilon,\\ u_{k-1,\varepsilon}^{smooth}+W_{k,\varepsilon}^{BL} & \text{in } \Omega_s, \end{cases}$$

where $\zeta_{k,\varepsilon}(\theta,\rho)=\varepsilon\,\zeta^1+\cdots+\varepsilon^k\,\zeta^k$, and $\zeta^i=-\varepsilon^{-1}\rho\,\chi_r^\varepsilon\;\partial_{\boldsymbol{n}}\,u^{i-1}(\theta,d_0\varepsilon)$. Also,

$$W_{k,\varepsilon}^{BL}=\varepsilon\,W^{1,0}+\varepsilon^2\left(W^{1,1}+W^{2,0}\right)+\cdots+\varepsilon^k\left(W^{1,k-1}+W^{2,k-2}+\cdots+W^{k,0}\right),$$
$$Z_{k,\varepsilon}=\chi_r^\varepsilon\left[\varepsilon\,Z^{1,0}+\varepsilon^2\left(Z^{1,1}+Z^{2,0}\right)+\cdots+\varepsilon^k\left(Z^{1,k-1}+Z^{2,k-2}+\cdots+Z^{k,0}\right)\right].$$

Here, although we did not fully define these functions yet, $W^{i,j}$, $Z^{i,j}$ depend only on u^{i-1}, $W^{i,j-1},\cdots,W^{i,0}$ and $Z^{i,j-1},\cdots,Z^{i,0}$. Also, we shall have on Γ_r^ε that

$$W^{i,0}=-\zeta^i-Z^{i,0},\qquad W^{i,j}=-Z^{i,j}\quad\text{for } j\neq 0.$$

Finally, $u_{k-1,\varepsilon}^{smooth}=u^0+\varepsilon\,u^1+\cdots+\varepsilon^{k-1}\,u^{k-1}$, where u^0 is as in (3), and for i positive,

$$\begin{gathered} -\Delta\,u^i=0\quad\text{in } \Omega_s,\\ u^i=-d_0\;\partial_{\boldsymbol{n}}\,u^{i-1}+Z^{1,i-1}+Z^{2,i-2}+\cdots+Z^{i,0}\quad\text{on } \Gamma,\qquad u^i=0\quad\text{on } \partial\Omega_s\backslash\Gamma,\\ u^i=0\quad\text{in } \Omega_r^\varepsilon. \end{gathered}$$

5. The boundary corrector problem. We now analyze the boundary corrector problem, as (32), (33) and (38), (39), in more detail. The presence of the curvature makes this problem cumbersome and a lot of insight can be gained by studying the zero curvature case first; see [5] and references therein.

Consider the problem

$$(44)\quad -\Delta\,w(\varepsilon)=\chi_r^\varepsilon\;\Delta\left[-\varepsilon^{-1}\rho\,\phi(\theta)+z(\varepsilon)\right]\quad\text{in } \Omega^\varepsilon,$$
$$(45)\quad w(\varepsilon)=\varepsilon^{-1}\rho\,\phi(\theta)-z(\varepsilon)\quad\text{on } \Gamma_r^\varepsilon.$$

Here, ϕ is a given function of θ only. The function $z(\varepsilon)$ is unknown a priori, but it is introduced to guarantee that $w(\varepsilon)$ decays exponentially to zero with ρ. It is desirable to have $z(\varepsilon)$ as simple as possible, and it suffices to assume $z(\varepsilon)$ independent of ρ.

Although ϕ is not necessarily periodic, we try to make use of the periodicity of the wrinkles, and recast the corrector problem as a sequence of problems in periodic domains. Using the stretched coordinates $(\hat\theta,\hat\rho)=(\varepsilon^{-1}\theta,\varepsilon^{-1}\rho)$, we seek solutions that are product of functions in the stretched coordinates with functions of θ only. With this in mind, we write the Laplacian of a function in the form $v(\mathbf{x})=h(\hat\theta,\hat\rho)\,g(\theta)$ as

$$\begin{aligned}(46)\quad -\Delta\,v=&-\varepsilon^{-2}\left(\partial_{\hat\theta\hat\theta}h+\partial_{\hat\rho\hat\rho}h\right)g+\varepsilon^{-1}\left(\kappa\,\partial_{\hat\rho}\,h-2\,\kappa\,\hat\rho\,\partial_{\hat\theta\hat\theta}\,h\right)g-\varepsilon^{-1}2\,\partial_{\hat\theta}\,h\,g'\\ &-\sum_{j=0}^{\infty}\varepsilon^j\,\hat\rho^j\left[\left(\;\hat\rho\;\;a_1^{j+1}\,\partial_{\hat\rho}\,h+a_3^{j+1}\,\hat\rho\,\partial_{\hat\theta}\,h+a_2^{j+2}\,\hat\rho^2\,\partial_{\hat\theta\hat\theta}\,h\right)g+\left(a_3^j\,h+2\,a_2^{j+1}\,\hat\rho\,\partial_{\hat\theta}\,h\right)g'\right.\\ &\left.+\,a_2^j\,h\,g''\right],\end{aligned}$$

where

$$a_1^j = -[\kappa(\theta)]^{j+1}, \quad a_2^j = (j+1)\,[\kappa(\theta)]^j, \quad a_3^j = \frac{j(j+1)}{2}\,[\kappa(\theta)]^{j-1}\,\kappa'(\theta),$$

and we recall that κ is the curvature of Γ.

From (46), and using that $z(\varepsilon)$ is independent of ρ,

$$\begin{aligned} -\Delta[\varepsilon^{-1}\rho\,\phi(\theta)] &= \varepsilon^{-1}\kappa\,\phi - \sum_{j=0}^{\infty}\varepsilon^j\,\hat{\rho}^j\,\left[\hat{\rho}\,a_1^{j+1}\,\phi + \hat{\rho}(a_3^j\,\phi' + a_2^j\,\phi'')\right], \\ \Delta\,z(\varepsilon) &= \sum_{j=0}^{\infty}\varepsilon^j\,\hat{\rho}^j\,\left[a_3^j\,\partial_\theta z(\varepsilon) + a_2^j\,\partial_{\theta\theta}\,z(\varepsilon)\right]. \end{aligned} \tag{47}$$

Assuming the expansion

$$z(\varepsilon) \sim z^0 + \varepsilon\,z^1 + \varepsilon^2\,z^2 + \cdots \tag{48}$$

and using the formal identity

$$\sum_{j=0}^{\infty}\sum_{i=0}^{\infty}\varepsilon^{i+j}\,c_j\,d_i = \sum_{j=0}^{\infty}\sum_{k=0}^{j}\varepsilon^j\,c_k\,d_{j-k}, \tag{49}$$

we gather from (47), (48), (49) the identity

$$\begin{aligned} \Delta\left[-\varepsilon^{-1}\rho\,\phi + z(\varepsilon)\right] = \varepsilon^{-1}\,\kappa\,\phi + \sum_{j=0}^{\infty}\varepsilon^j\,\Big\{ &-\hat{\rho}^j\,\left[\hat{\rho}\,a_1^{j+1}\,\phi + \hat{\rho}\,(a_3^j\,\phi' + a_2^j\,\phi'')\right] \\ &+ \sum_{k=0}^{j}\hat{\rho}^k\,\left(a_3^k\,\partial_\theta z^{j-k} + a_2^k\,\partial_{\theta\theta}\,z^{j-k}\right)\Big\}. \end{aligned} \tag{50}$$

Assuming the expansion

$$w(\varepsilon) \sim w^0 + \varepsilon\,w^1 + \varepsilon^2\,w^2 + \cdots \tag{51}$$

and that $w^0(\theta,\rho) = w^{0,0}(\hat{\theta},\hat{\rho})\,\phi(\theta)$ and $z^0(\theta) = z^{0,0}\,\phi(\theta)$, where $z^{0,0}$ is a constant, we gather that (44), (45), (46), and (50) lead to (5).

It is clear that w^0, z^0 do not satisfy (44) exactly, but only the highest order (with power ε^{-2}) term. In fact, if ϕ is smooth, it follows from usual regularity estimates and a scaling argument that

$$\left\|\Delta\big(\Upsilon w^0\big) - \varepsilon^{-1}\chi_r^\varepsilon\;\Delta\big(\rho\,\phi - z^0\big)\right\|_{L^2(\Omega^\varepsilon)} \leq c\,\varepsilon^{-1/2}.$$

Here, as in page 1455, we need the cutoff function Υ, since w^0 is not well defined all over Ω^ε.

The remainder shall be corrected by the equations defining w^1, w^2, etc. Note also that defining w^0 as a product between $w^{0,0}$ and ϕ allows us to impose periodic boundary conditions in the PDE defining $w^{0,0}$. This trick reduces the original boundary corrector problem (44), (45) to a much easier to solve *sequence of cell problems*.

Continuing the procedure with the aid of (46), we set

$$w^1(\theta,\rho) = w^{1,0}(\hat{\theta},\hat{\rho})\,\kappa(\theta)\,\phi(\theta) + w^{1,1}(\hat{\theta},\hat{\rho})\,\phi'(\theta),$$

and $z^1(\theta) = z^{1,0}\,\kappa(\theta)\,\phi(\theta) + z^{1,1}\,\phi'(\theta)$, where $w^{1,0}$ and $w^{1,1} \in S(\Omega_r)$, and $z^{1,0}$ and $z^{1,1}$ are constants such that (19), (20) holds.

Now, $w^0 + \varepsilon\, w^1$ is a better approximate solution to (44) since,

$$\big\|\Delta\big[\Upsilon\big(w^0 + \varepsilon\, w^1\big)\big] - \varepsilon^{-1}\chi_r^\varepsilon\ \Delta\big(\rho\,\phi - z^0\big)\big\|_{L^2(\Omega^\varepsilon)} \le c\,\varepsilon^{1/2}.$$

It is easy to see that the right-hand sides of the equations become more involved as we proceed. The crucial point is to note that in the above cases, the equations do not involve the nonperiodic terms ϕ, κ or their derivatives.

Proceeding in a similar manner, we define w^2, w^3, etc., and

$$\big\|\Delta\big[\Upsilon\big(w^0 + \varepsilon\, w^1 + \cdots + \varepsilon^k\, w^k\big)\big] - \varepsilon^{-1}\chi_r^\varepsilon\ \Delta\big(\rho\,\phi - z^0\big)\big\|_{L^2(\Omega^\varepsilon)} \le c\,\varepsilon^{k-1/2}. \tag{52}$$

Finally, it follows from our computations that

$$w \sim w^{0,0}\,\phi + \varepsilon\,(w^{1,0}\,\kappa\,\phi + w^{1,1}\,\phi') + \varepsilon^2 \cdots, \tag{53}$$

$$z \sim z^{0,0}\,\phi + \varepsilon\,(z^{1,0}\,\kappa\,\phi + z^{1,1}\,\phi') + \varepsilon^2 \cdots. \tag{54}$$

In terms of the expansions for the boundary corrector for our original problem, see (32)–(35), we define

$$\begin{aligned}
W^{1,0}(\mathbf{x}) &= \Upsilon(\rho)\, w^{0,0}(\hat\theta,\hat\rho)\ \partial_{\boldsymbol{n}}\, u^0(\theta, d_0\,\varepsilon),\\
W^{1,1}(\mathbf{x}) &= \Upsilon(\rho)\,[w^{1,0}(\hat\theta,\hat\rho)\,\kappa(\theta)\ \partial_{\boldsymbol{n}}\, u^0(\theta, d_0\,\varepsilon) + w^{1,1}\,(\hat\theta,\hat\rho)\,\partial_\theta\,\partial_{\boldsymbol{n}}\, u^0(\theta, d_0\,\varepsilon)],\\
Z^{1,0}(\theta) &= z^{0,0}\ \partial_{\boldsymbol{n}}\, u^0(\theta, d_0\,\varepsilon),\\
Z^{1,1}(\theta) &= z^{1,0}\,\kappa(\theta)\ \partial_{\boldsymbol{n}}\, u^0(\theta, d_0\,\varepsilon) + z^{1,1}\,\partial_\theta\,\partial_{\boldsymbol{n}}\, u^0(\theta, d_0\,\varepsilon),
\end{aligned} \tag{55}$$

etc. Similarly, from (38)–(41), we define

$$\begin{aligned}
W^{2,0}(\mathbf{x}) &= \Upsilon(\rho)\, w^{0,0}(\hat\rho,\hat\theta)\ \partial_{\boldsymbol{n}}\, u^1(\theta, d_0\,\varepsilon),\\
W^{2,1}(\mathbf{x}) &= \Upsilon(\rho)\,[w^{1,0}(\hat\theta,\hat\rho)\,\kappa(\theta)\ \partial_{\boldsymbol{n}}\, u^1(\theta, d_0\,\varepsilon) + w^{1,1}\,(\hat\theta,\hat\rho)\,\partial_\theta\ \partial_{\boldsymbol{n}}\, u^1(\theta, d_0\,\varepsilon)],\\
Z^{2,0}(\theta) &= z^{0,0}\ \partial_{\boldsymbol{n}}\, u^1(\theta, d_0\,\varepsilon),\\
Z^{2,1}(\theta) &= z^{1,0}\,\kappa(\theta)\ \partial_{\boldsymbol{n}}\, u^1(\theta, d_0\,\varepsilon) + z^{1,1}\,\partial_\theta\,\partial_{\boldsymbol{n}}\, u^1(\theta, d_0\,\varepsilon),
\end{aligned}$$

and so on.

6. Convergence estimate. In this section we estimate the difference between a truncated asymptotic expansion and the exact solution. To bound such difference, some a priori estimates are necessary, thus the regularity of the terms in the expansion is worthy of consideration. The results below are based on standard regularity estimates [15].

The boundary layer terms $w^{i,j}$ solve Poisson problems of the form (4), and we assume first that Ω_r is a convex polygon. Then $w^{0,0} \in H^2(\Omega_r)$. For $i > 1$, it follows from (46) that the right-hand side of the Poisson problem for $w^{i,j}$ depends on a linear combination of $w^{k,l}$, $\partial_{\hat\rho} w^{k,l}$, $\partial_{\hat\theta} w^{k,l}$, $\partial_{\hat\theta\hat\theta} w^{k,l}$, where $k < i$. Thus, $w^{i,j} \in H^2(\Omega_r)$. Similarly, if Ω_r is a nonconvex polygon with largest angle equal to ω, then $w^{i,j} \in H^s(\Omega_r)$ for all $s < 1 + \pi/\omega$. Note that the regularity results above depend *only* on the geometry of Ω_r and not on f. On the other hand, the regularity of $W^{i,j}$ depends on f, since it also depends on the u^i; see, e.g., (55).

Concerning the regularity of u^i, we rely on smoothness of Ω_s to conclude from (3) that $\|u_0\|_{H^{m+2}(\Omega_s)} \le c\|f\|_{H^m(\Omega_s)}$ for all real m, where c depends only on Ω_s. Since

u^i is harmonic for i positive, its regularity is determined by its Dirichlet boundary condition on Γ. Using (46), (50), we gather that the boundary condition for u^i depends, among other more regular terms, on $\partial_\theta^j \, \partial_{\boldsymbol{n}} \, u^{i-j-1}$, for $j = 0, \ldots, i-1$. Thus, an induction argument leads to the existence of a constant c depending only on Ω_s and m such that $\|u^i\|_{H^{m+2-i}(\Omega_s)} \leq c\|f\|_{H^m(\Omega_s)}$, for all real m.

Standard scaling arguments lead to the result below.

LEMMA 3. *Assume that f is a smooth function with support in Ω_s. Then, for every integers i, j, there exists a constant c such that*

$$\|W^{i,j}\|_{L^2(\Omega^\varepsilon)} \leq c\,\varepsilon^{1/2}, \qquad \|W^{i,j}\|_{H^1(\Omega^\varepsilon)} \leq c\,\varepsilon^{-1/2},$$
$$\|Z^{i,j}\|_{H^1(\Omega_r^\varepsilon)} + \|\zeta^i\|_{H^1(\Omega_r^\varepsilon)} \leq c\,\varepsilon^{1/2}, \qquad \|u^i\|_{H^1(\Omega_s)} \leq c.$$

The constant c might depend on f, Ω_s, and Ω_r, but it is independent of ε.

Considering now the truncated expansion as in (43), we define the error

$$e_k = \begin{cases} u^\varepsilon - \zeta_{k,\varepsilon} - W_{k,\varepsilon}^{BL} - Z_{k,\varepsilon} & \text{in } \Omega_r^\varepsilon, \\ u^\varepsilon - u_{k-1,\varepsilon}^{smooth} - W_{k,\varepsilon}^{BL} & \text{in } \Omega_s. \end{cases} \tag{56}$$

Aiming to use Lemma 2, we first note that e_k vanishes on $\partial\Omega^\varepsilon$. Also, the jumps across Γ are such that

$$[\![e_k]\!] = 0, \qquad [\![\partial_{\boldsymbol{n}} \, e_k]\!] = \varepsilon^k |\, \partial_{\boldsymbol{n}} \, u^k|. \tag{57}$$

Estimating $\Delta \, e_k$ is nontrivial since e_k is not harmonic in general. Indeed,

$$-\Delta \, e_k = \begin{cases} \Delta \big[\zeta_{k,\varepsilon} + W_{k,\varepsilon}^{BL} + Z_{k,\varepsilon}\big] & \text{in } \Omega_r^\varepsilon, \\ \Delta \, W_{k,\varepsilon}^{BL} & \text{in } \Omega_s. \end{cases}$$

It follows from the construction of $W_{k,\varepsilon}^{BL}$ in section 5, (52), and Lemma 3, that

$$\|\, \Delta \, e_k\|_{L^2(\Omega^\varepsilon)} \leq c\,\varepsilon^{k-1/2}. \tag{58}$$

With the above estimates it is not hard to prove the following result, which shows the rate of convergence in ε of the asymptotic expansion.

THEOREM 4. *For any positive integer k there exists a constant c such that the difference between the truncated asymptotic expansion and the original solution measured in the original domain is bounded as follows:*

$$\|e_k\|_{H^1(\Omega_s)} + \|e_k\|_{H^1(\Omega_r^\varepsilon)} \leq c\,\varepsilon^{k+1/2}. \tag{59}$$

Proof. From Lemmas 2 and 3 and estimates (57), (58), we have that

$$\|e_k\|_{H^1(\Omega_s)} + \|e_k\|_{H^1(\Omega_r^\varepsilon)} \leq c\,\varepsilon^{k-1/2}. \tag{60}$$

Although the above estimate is not sharp, it is not hard to improve it. In fact,

$$\begin{aligned} \|e_k\|_{H^1(\Omega_s)} + \|e_k\|_{H^1(\Omega_r^\varepsilon)} \leq{}& \|e_{k+1}\|_{H^1(\Omega_s)} + \|e_{k+1}\|_{H^1(\Omega_r^\varepsilon)} \\ &+ \|e_{k+1} - e_k\|_{H^1(\Omega_s)} + \|e_{k+1} - e_k\|_{H^1(\Omega_r^\varepsilon)} \leq c\,\varepsilon^{k+1/2}, \end{aligned}$$

where we used (60) and Lemma 3 to obtain the last inequality. ∎

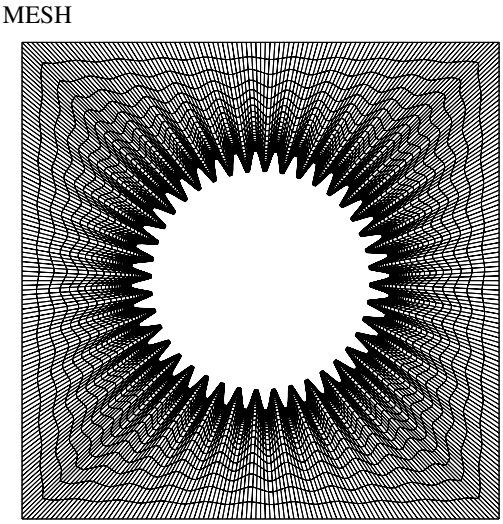

FIG. 3. *Mesh of rough domain.*

7. Numerical validation: Rough cylinder. We consider $\Omega_s \subset \mathbb{R}^2$ as the two-dimensional region having as outer boundary a square of size 4 and as inner boundary a circle of radius 1.15. Formally we have

$$\Omega_s = \{\mathbf{x} = (x_1, x_2) \in \mathbb{R}^2 \,:\, |\mathbf{x}| > 1.15,\, |x_i| < 2,\, i = 1, 2\}.$$

We define the rough domain as having the same square as outer boundary and a "perturbed" circle as the inner boundary. We lay upon a circle of unitary radius 20 periodic wrinkles of height 0.1. Thus $d_0\varepsilon = 0.15$. The test considered is a variation of (1), where $f = 0$, and $u = 1$ at the outer boundary. We obtain an "exact" solution by fully discretizing the rough domain with a refined mesh shown in Figures 3 and 4. We remark that the polygonal appearance of the boundary in Figure 4 is deceiving and results from approximation a smooth domain using polygonal meshes. Equations (25) yield the first order solution, and (26) yield the second order solution. Figures 5 and 6 show the isolines and profiles of the solutions for the first and second order cell problems (5) and (19). Note that we plot only $w^{1,0}$, since $z^{1,1} = 1.0 \times 10^{-5}$ and can be disregarded in the computations. The computed effective constants are $z^{0,0} = 0.77$ and $z^{1,0} = 0.27$. In Figure 7 we plot the level curves for the exact solution and the second order approximation. In Figures 8, 9, and 10 we compare the profiles of the exact solution with the first and second order approximations, at different heights above the wrinkles. It is possible to see that the second order approximation yields the best results, as predicted by the theory.

8. Conclusions. We investigated in this paper the problem of developing and estimating wall laws for problems defined in domains with rough and curved boundaries. For the sake of simplicity, the Poisson problem was considered. We developed a general methodology consisting of a two-scale expansion technique based on a domain decomposition result and obtained high order effective boundary conditions. Numerical tests accompanied the several sharp error estimates presented for first and second order approximations. In particular, this work proves that to obtain accurate

numerical results, the curvature must be considered.

Our approach can be carried over to more sophisticated operators and to higher dimensions, yielding then a general procedure to develop and estimate effective boundary conditions.

Acknowledgments. The authors thank the anonymous referees for several corrections and suggestions.

OPTIMAL TRACING OF VISCOUS SHOCKS IN SOLUTIONS OF VISCOUS CONSERVATION LAWS*

WEN SHEN† AND MEE REA PARK†

Abstract. This paper contains a qualitative study of a scalar conservation law with viscosity: $u_t + f(u)_x = u_{xx}$. We consider the problem of identifying the location of viscous shocks, thus obtaining an optimal finite dimensional description of solutions to the viscous conservation law. We introduce a nonlinear functional whose minimizers yield the viscous traveling profiles which optimally fit the given solution. We prove that outside an initial time interval and away from times of shock interactions, our functional remains very small, i.e., the solution can be accurately represented by a finite number of viscous traveling waves.

Key words. optimal viscous shock tracing, viscous conservation laws, viscous traveling shocks, data compression, finite dimensional representation

1. Introduction.

Consider a scalar conservation law with viscosity

$$u_t + f(u)_x = u_{xx}\,. \tag{1.1}$$

We assume that the flux f is smooth and genuinely nonlinear, so that $f''(u) \geq \kappa > 0$ for every u. Our main interest here is how to identify the emergence of viscous shocks in a solution, and how to optimally trace their locations and strengths.

More generally, one may ask the following question. Assume that a particular solution $u = u(t,x)$ has already been computed. If we are allowed only a finite number of parameters to describe its most relevant features, what is the best way to compress the information? In the literature, the problem of finite dimensional approximation of a dynamical system has been studied mainly by looking at ω-limit sets [T]. Several results, valid for evolution equations of parabolic type, provide estimates on the dimension of an attractor. Of course, this yields a bound on the number of parameters needed to describe the evolution of the system asymptotically as $t \to +\infty$.

In the present paper, the focus is different. Namely, we seek a finite dimensional description which is accurate not only in the asymptotic limit as $t \to +\infty$ but also in the transient regime. For solutions to a scalar, viscous conservation law, this transient behavior is actually the most interesting feature that can be observed. On the other hand, at least in the case of convex flux, the ω-limit set is rather trivial. The asymptotic limit of any solution $t \mapsto u(t,\cdot)$ can be described in terms of the solution of a Riemann problem, i.e., either a single rarefaction or a viscous shock wave. For general theory on hyperbolic conservation laws, we refer to the books [Sm, B, S].

The problem of optimal location of viscous shock profiles was mentioned also in [W]. In this connection, we introduce a scalar functional whose minimizers identify the strengths and locations of viscous shock profiles present in the solution. We also

prove that outside a set of times with finite measure, at all other times our functional has very small values. In other words, the description of the solution profile $u(t,\cdot)$ in terms of finitely many viscous shocks is accurate, for most times t. The exceptional set consists of an initial time interval and times at which shock interactions occur; see Figure 1.

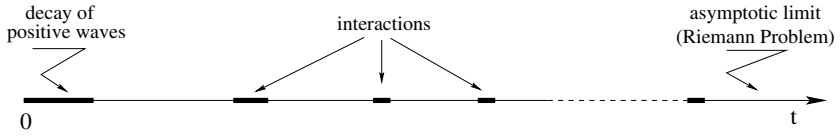

FIG. 1. *The exceptional set of times where the finite dimensional representation is not accurate.*

2. The main result. We consider here the single conservation law with viscosity

$$u_t + f(u)_x = u_{xx}\,. \tag{2.1}$$

We fix $M > 0$ and let $\mathcal{F}_M$ denote the set of all solutions to the Cauchy problem for (2.1) with initial data

$$u(0,x) = \bar u(x) \tag{2.2}$$

satisfying

$$\text{Tot.Var.}\{\bar u\} \leq M\,, \qquad\qquad \|\bar u\|_{\mathbf{L}^\infty} \leq M\,. \tag{2.3}$$

We shall assume that the flux f is $\mathcal{C}^2$ and strictly convex, so that $f''(u) > 0$ for all $u \in \mathbb{R}$. In particular, this implies that there exist constants κ, κ',

$$0 < \kappa \leq f''(u) \leq \kappa' \qquad\qquad \text{for all } u \in [-M, M]\,. \tag{2.4}$$

In essence, what we want to show is the following. Apart from a small set of times $J \subset [0,\infty[$, the profile $u(t,\cdot)$ of any solution of (2.1) can be accurately described in terms of the superposition of finitely many traveling viscous shocks. Indeed, the assumption (2.4) of genuine nonlinearity implies that all rarefaction waves will decay within an initial time interval. Moreover, in regions where the gradient u_x is large and negative, viscous shock profiles will form. These can travel for a long time without much changing their shape, except when they interact with each other. The set J of exceptional times where our description is not accurate will thus include an initial time interval and also the intervals where wave interactions occur. Much of the following analysis aims at making rigorous the above claims.

For every $u^- > u^+$ and $y \in \mathbb{R}$, let $\omega^{(u^\pm, y)}$ be the unique viscous shock profile joining the states u^-, u^+, centered at y. This profile can be found as the unique solution to the ODE

$$\omega' = f(\omega) - \sigma\,\omega - \big[f(u^-) - \sigma u^-\big]\,, \qquad\qquad \sigma = \frac{f(u^-) - f(u^+)}{u^- - u^+}\,, \tag{2.5}$$

satisfying the additional conditions

$$\omega''(y) = 0\,, \qquad\qquad \omega(-\infty) = u^-, \qquad \omega(+\infty) = u^+. \tag{2.6}$$

Notice that the last two identities in (2.6) follow from (2.5) and the convexity of f. Given any solution $u \in \mathcal{F}_M$ of the conservation law, for each $t > 0$ we introduce a description based on optimal location of shock profiles. Fix an integer $N \geq 1$ and let $\omega_i = \omega^{(u_i^{\pm}, y_i)}$ be the ith viscous shock profile we try to fit in. We consider the functional

$$\mathcal{J}\big(u(t),\ \omega_1, \ldots, \omega_N\big) \doteq \sum_{i=1}^{N} \int_{\mathbb{R}} \Big|u(t,x) - \omega_i(x)\Big| \cdot \big|\omega_{i,x}(x)\big|^2 \, dx + \int_{\mathbb{R}} \left|u_x(t,x) - \sum_{i=1}^{N} \omega_{i,x}(x)\right|^2 dx\,. \tag{2.7}$$

Notice that the first integral measures the distance between u and the traveling viscous shock ω_i, multiplied by a weight function $|\omega_{i,x}|^2$ which is vanishingly small away from the center of the ith shock. The second integral measures how well the derivative u_x is approximated by derivatives of traveling shock profiles. See Figure 2 for an illustration of fitting two viscous shocks in a solution.

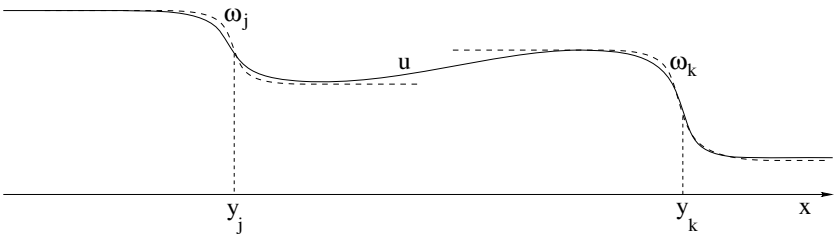

FIG. 2. *Fitting two viscous shocks ω_j, ω_k in a solution.*

If we fix a priori the complexity of our description, i.e., the integer N, how small can we render the integral $\mathcal{J}$? This problem can be formulated as

$$\inf_{\omega_1, \ldots, \omega_N} \mathcal{J}\big(u(t), \omega_1, \ldots, \omega_N\big)\,, \tag{2.8}$$

where the infimum is taken over all N-tuples of traveling shock profiles $\omega_i = \omega^{(u_i^{\pm}, y_i)}$, for some states $u_i^- > u_i^+$ and $y_i \in \mathbb{R}$. Notice that if we choose $\omega_i \equiv 0$ for $i = 1, \ldots, N$ (i.e., all traveling waves of zero amplitude), then the first integral in (2.7) vanishes because trivially $\omega_{i,x} \equiv 0$. However, in this case the second integral equals $\big\|u_x(t,\cdot)\big\|^2_{\mathbf{L}^2}$, which is of order Tot.Var.$(u)^3$ due to regularization and can be large.

To estimate the quantity in (2.8), an intuitive argument goes as follows. Set $\delta = M/N$, where M is given in (2.3). Since the total variation of $u(t)$ is bounded by M, there can be at most N shock profiles of strength $\geq \delta$. Each one of these can be traced accurately. In addition, there may be an arbitrarily large number of smaller shocks, say, of strengths σ_j, $j \geq 1$, with

$$\sigma_j \leq \delta\,, \qquad \sum_j \sigma_j \leq M\,. \tag{2.9}$$

Each shock which is not traced produces an error in the second integral of (2.7) of the order

$$\int \big|\omega_{j,x}(x)\big|^2 \, dx = \mathcal{O}(1) \cdot \sigma_j^3\,. \tag{2.10}$$

Because of (2.9) we thus expect that the minimum of $\mathcal{J}$ is approximately

$$\mathcal{J}_{\min} \approx \mathcal{O}(1) \cdot M\delta^2 = \mathcal{O}(1) \cdot \frac{M^3}{N^2}\,. \tag{2.11}$$

The estimate (2.11) should indeed hold outside an initial time interval, where positive waves will decay, and away from interaction times. Our main results are as follows.

THEOREM 2.1. *Assume $f''(u) \geq \kappa > 0$ for every $u \in \mathbb{R}$. Let $u \in \mathcal{F}_M$ be a solution of the viscous conservation law* (2.1)*, and fix $N \geq 1$. Then, for every $t > 0$, the minimization problem* (2.8) *has at least one solution.*

THEOREM 2.2. *There exist constants α (uniformly valid for all $N \geq 1$ and $u \in \mathcal{F}_M$) and $\beta = \beta_{N,M}$ (depending only on N and M) such that*

$$\mathcal{J}_{\min}\big(u(t)\big) \leq \alpha \cdot \frac{1}{N^2} \tag{2.12}$$

for all $t \in [0, \infty[\,\setminus I^u$ for an exceptional set I^u of times, with meas$(I^u) \leq \beta$.

The remainder of the paper contains a proof of the above two theorems. We remark that Theorem 2.1 states the existence of a minimizer for the scalar function $\mathcal{J} : \mathbb{R}^{3N} \mapsto \mathbb{R}$. Since $\mathcal{J}$ is continuous and positive, the result would be trivial if $\mathcal{J}(y) \to \infty$ as $|y| \to \infty$. However, it is easily seen that this coercivity condition fails. The heart of the proof consists in showing that, if $\{X^{(m)}\}_{m\geq 1}$ is a minimizing sequence with $|X^{(m)}| \to \infty$, then a second minimizing sequence $\tilde{X}^{(m)}$ can be defined (in terms of $X^{(m)}$) whose elements remain uniformly bounded.

The proof of Theorem 2.2 involves a deeper argument. With a solution of the viscous equation (2.1) we associate a curve γ moving in the plane. By results in [BB, BB1, BB2], the total area swept by this curve in its motion is a priori bounded in terms of a monotone decreasing area functional $Q(u)$. We then show that at every time t where the rate of decrease $\frac{d}{dt}Q(u(t))$ is sufficiently small, the inequality (2.12) holds.

We remark that in (2.8), the integer N is fixed. Of course, one could let N vary and look at the minimization problem

$$\min_{N\geq 0} \inf_{\omega_1,\ldots,\omega_N} \Big\{\epsilon\, N + \mathcal{J}\big(u(t),\, \omega_1, \ldots, \omega_N\big)\Big\}\,. \tag{2.13}$$

Here the first term penalizes the complexity of the description, adding a cost for each new viscous profile. The small constant $\epsilon > 0$ acts as a threshold parameter. Small viscous shock waves, whose strength $\|\omega_x\|^2_{\mathbf{L}^2}$ is of order $< \epsilon$, will not be traced. From Theorem 2.1 it immediately follows that the problem (2.13) also admits a global minimizer. This can be interpreted as an optimal description of the solution profile $u(t, \cdot)$ as superposition of traveling viscous shocks.

3. Proof of Theorem 2.1.

Step 1. At any fixed time $t > 0$, the solution $u(t, \cdot)$ of the viscous conservation law (2.1) is a C^1 function with bounded total variation. We shall prove, more generally, that the functional $\mathcal{J}(u;\, \omega_1, \ldots, \omega_N)$ admits a global minimum for every $\mathcal{C}^1$ function $u : \mathbb{R} \mapsto \mathbb{R}$ with bounded variation.

Step 2. Recall that $\omega_k \doteq \omega^{(u_k^{\pm}, y_k)}$. Observing that the traveling wave profiles ω_k as well as their derivatives $\omega_{k,x}$ depend continuously on the scalar parameters $u_k^-,\ u_k^+,\ y_k$ $(k = 1, \ldots, N)$, we have to prove that the continuous scalar function $\mathcal{J}(u; \cdot) : \mathbb{R}^{3N} \mapsto \mathbb{R}$ admits a global minimum.

Since $\mathcal{J} \geq 0$, this function has a nonnegative infimum $\mathcal{J}^{min}$. We can thus construct a minimizing sequence in $\mathbb{R}^{3N}$, converging to J^{min}, say,

$$\left\{ X^{(m)} \doteq \left(y_1^{(m)},\, u_1^{(m)+},\, u_1^{(m)-}, \ldots,\, y_N^{(m)},\, u_N^{(m)+},\, u_N^{(m)-} \right);\ \ m \geq 1 \right\}. \tag{3.1}$$

By possibly taking a subsequence, we can assume that each component of the vector $X^{(m)} \in \mathbb{R}^{3N}$ either converges to a finite limit or else diverges to $\pm\infty$.

Step 3. If

$$\sup_{m\geq 1} \left\{ \left| y_k^{(m)} \right| + \left| u_k^{(m)+} \right| + \left| u_k^{(m)-} \right| \right\} < \infty$$

for each $k = 1, \ldots, N$, then the entire minimizing sequence $\{X^{(m)}\}_{m\geq 1}$ is bounded in $\mathbb{R}^{3N}$. By our previous assumption, it converges to some limit

$$\bar{X} = \left(\bar{y}_1,\, \bar{u}_1^+,\, \bar{u}_1^-, \ldots,\, \bar{y}_N,\, \bar{u}_N^+,\, \bar{u}_N^- \right).$$

By continuity, we thus have $\mathcal{J}(u;\, \bar{X}) = \mathcal{J}^{min}$, proving the existence of a minimizer.

Step 4. In general, however, one cannot guarantee the minimizing sequence to be bounded, because the function $\mathcal{J}(u\,;\,\cdot)$ is not coercive on $\mathbb{R}^{3N}$. We shall thus adopt an alternative strategy. Assume that for some index j,

$$\lim_{m\to\infty} \left\{ \left| y_j^{(m)} \right| + \left| u_j^{(m)+} \right| + \left| u_j^{(m)-} \right| \right\} = \infty\,.$$

Consider the new sequence

$$\tilde{X}^{(m)} \doteq \left(\tilde{y}_1^{(m)},\, \tilde{u}_1^{(m)+},\, \tilde{u}_1^{(m)-}, \ldots,\, \tilde{y}_N^{(m)},\, \tilde{u}_N^{(m)+},\, \tilde{u}_N^{(m)-} \right),$$

obtained by setting the parameters of the jth traveling profile to zero. More precisely, for every $m \geq 1$ we set

$$\begin{aligned} &\left(\tilde{y}_i^{(m)},\, \tilde{u}_i^{(m)+},\, \tilde{u}_i^{(m)-} \right) = \left(y_i^{(m)},\, u_i^{(m)+},\, u_i^{(m)-} \right) \qquad \text{if } \ i \neq j\,, \\ &\left(\tilde{y}_j^{(m)},\, \tilde{u}_j^{(m)+},\, \tilde{u}_j^{(m)-} \right) = (0,0,0)\,. \end{aligned}$$

We claim that

$$\limsup_{m\to\infty} \mathcal{J}(u;\, \tilde{X}^{(m)}) \leq \lim_{m\to\infty} \mathcal{J}(u;\, X^{(m)})\,. \tag{3.2}$$

If the original sequence had k unbounded components, say, for $j \in \{i_1, i_2, \ldots, i_k\} \subset \{1, 2, \ldots, N\}$, the above construction yields a new minimizing sequence having $k-1$ unbounded components. By induction, in a finite number of steps we obtain a minimizing sequence where all components are bounded. Hence, by Step 3, a global minimizer exists.

Step 5. It now remains to show that (3.2) holds. Equivalently, for every $\varepsilon > 0$ we will prove that

$$\limsup_{m\to\infty} \mathcal{J}(u;\, \tilde{X}^{(m)}) \leq \lim_{m\to\infty} \mathcal{J}(u;\, X^{(m)}) + \varepsilon\,. \tag{3.3}$$

We shall consider different cases.

Case 1. Assume that, as $m \to \infty$,

$$\|\omega_{j,x}^{(m)}\|_{\mathbf{L}^2} \to 0\,. \tag{3.4}$$

By the assumption $f''(u) \geq \kappa > 0$, the strict convexity of the flux function implies

$$\|\omega_{j,x}^{(m)}\|_{\mathbf{L}^\infty} \to 0\,. \tag{3.5}$$

In this case, observing that $\omega_{i,x}^{(m)} \leq 0$ because all viscous shock profiles are decreasing, we have the estimate

$$\begin{aligned}
&\int_{-\infty}^{\infty} \left| u_x - \sum_{i=1}^{N} \omega_{i,x}^{(m)} \right|^2 dx \\
&\qquad \geq \int_{-\infty}^{\infty} \left| u_x - \sum_{i \neq j} \omega_{i,x}^{(m)} \right|^2 dx - 2 \int_{-\infty}^{\infty} |u_x| \cdot \left| \omega_{j,x}^{(m)} \right| dx \\
&\qquad \geq \int_{-\infty}^{\infty} \left| u_x - \sum_{i \neq j} \omega_{i,x}^{(m)} \right|^2 dx - 2 \cdot \|u_x\|_{\mathbf{L}^1} \cdot \left\| \omega_{j,x}^{(m)} \right\|_{\mathbf{L}^\infty}.
\end{aligned}$$

Here we used the elementary inequality $(a-b-c)^2 \geq (a-b)^2 - 2|ac|$, valid whenever b and c have the same sign. Therefore,

$$\lim_{m\to\infty} \int_{-\infty}^{\infty} \left| u_x - \sum_{i=1}^{N} \omega_{i,x}^{(m)} \right|^2 dx \;\geq\; \limsup_{m\to\infty} \int_{-\infty}^{\infty} \left| u_x - \sum_{i \neq j} \omega_{i,x}^{(m)} \right|^2 dx\,, \tag{3.6}$$

provided that (3.4) holds. Clearly, (3.6) implies (3.2). Notice that the condition (3.4) is certainly satisfied if $u^{(m)+}$ and $u^{(m)-}$ remain uniformly bounded and $|u^{(m)+} - u^{(m)-}| \to 0$.

Case 2. Assume that

$$\liminf_{m\to\infty} \left\| \omega_{j,x}^{(m)} \right\|_{\mathbf{L}^2} \doteq \delta_2 > 0\,. \tag{3.7}$$

This breaks down into three different subcases.

Case 2a. We have the limits $|y_j^{(m)}| \to \infty$ while $u_j^{(m)+} \to u_j^+$, $u_j^{(m)-} \to u_j^-$. To fix the ideas, assume $y_j^{(m)} \to +\infty$. Observe that in this case $\delta_2 = \|\omega_{j,x}\|_{\mathbf{L}^2}$, where ω_j is a viscous shock profile connecting u_j^- with u_j^+. Given $\varepsilon > 0$, choose L so large that

$$\left(\int_L^{\infty} |u_x|^2 \, dx \right)^{1/2} \;<\; \frac{\varepsilon}{2\,\delta_2}\,.$$

We then have the estimate

$$\begin{aligned}
&\int_{-\infty}^{\infty} \left| u_x - \sum_{i=1}^{N} \omega_{i,x}^{(m)} \right|^2 dx \\
&\quad \geq \int_{-\infty}^{\infty} \left| u_x - \sum_{i\neq j} \omega_{i,x}^{(m)} \right|^2 dx - 2\int_{-\infty}^{L} |u_x| \cdot \left|\omega_{j,x}^{(m)}\right| \, dx - 2\int_{L}^{\infty} |u_x| \cdot \left|\omega_{j,x}^{(m)}\right| \, dx \\
&\quad \geq \int_{-\infty}^{\infty} \left| u_x - \sum_{i\neq j} \omega_{i,x}^{(m)} \right|^2 dx - 2\left(\int_{-\infty}^{L} |u_x| \, dx\right) \cdot \sup_{x<L} \left|\omega_{j,x}^{(m)}(x)\right| \\
&\qquad\qquad - 2\left(\int_{L}^{\infty} |u_x|^2 \, dx\right)^{1/2} \cdot \left\|\omega_{j,x}^{(m)}\right\|_{\mathbf{L}^2} .
\end{aligned}$$

Observing that

$$\lim_{m\to\infty} \sup_{x<L} \left|\omega_{j,x}^{(m)}(x)\right| = 0\,, \qquad\qquad \lim_{m\to\infty} \left\|\omega_{j,x}^{(m)}\right\|_{\mathbf{L}^2} = \delta_2$$

from the above estimate we deduce

$$\liminf_{m\to\infty} \int_{-\infty}^{\infty} \left| u_x - \sum_{i=1}^{N} \omega_{i,x}^{(m)} \right|^2 dx \;\geq\; \liminf_{m\to\infty} \int_{-\infty}^{\infty} \left| u_x - \sum_{i\neq j} \omega_{i,x}^{(m)} \right|^2 dx - 2\frac{\varepsilon}{2\delta_2}\delta_2\,.$$

This clearly implies (3.3).

Case 2b. Assume that both sequences $u_j^{(m)+}$ and $u_j^{(m)-}$ diverge to $+\infty$. The case where they both tend to $-\infty$ is entirely similar. We then have

$$\begin{aligned}
&\liminf_{m\to\infty} \int_{-\infty}^{\infty} \left|u - \omega_j^{(m)}\right| \cdot \left|\omega_{j,x}^{(m)}\right|^2 dx \\
&\qquad \geq \lim_{m\to\infty} \left(\inf_{x\in\mathbb{R}} \left|u(x) - \omega_j^{(m)}(x)\right| \right) \cdot \left\|\omega_{j,x}^{(m)}\right\|_{\mathbf{L}^2}^2 \;=\; \infty\,.
\end{aligned}$$

Hence the original sequence was not minimizing. This contradiction shows that this case cannot happen.

Case 2c. Assume that the strength of the jth traveling wave becomes arbitrarily large as $m\to\infty$, so that $u_j^{(m)-} - u_j^{(m)+} \to \infty$. In this case, it is easy to check that $\mathcal{J}(u\,;\, X^{(m)}) \to \infty$. Indeed, let $K \doteq \|u\|_{\mathbf{L}^\infty}$. We then have

$$\liminf_{m\to\infty} \int_{-\infty}^{\infty} \left|u - \omega_j^{(m)}\right| \cdot \left|\omega_{j,x}^{(m)}\right|^2 dx \geq \liminf_{m\to\infty} \int_{\left|\omega_j^{(m)}(x)\right|>K+1} \left|\omega_{j,x}^{(m)}\right|^2 dx\,.$$

Obviously, this integral diverges to infinity. Indeed, let's consider the case when

$$\lim_{m\to\infty} u^{(m)-} = +\infty\,.$$

For the case when $\lim_{m\to\infty} u^{(m)+} = -\infty$ it is entirely similar. We have

$$\begin{aligned}
&\liminf_{m\to\infty} \int_{\left|\omega_j^{(m)}(x)\right|>K+1} \left|\omega_{j,x}^{(m)}\right|^2 dx \;\geq\; \liminf_{m\to\infty} \int_{\omega_j^{(m)}(x)>K+1} \left|\omega_{j,x}^{(m)}\right|^2 dx \\
&\qquad \geq \liminf_{m\to\infty} \min_{\omega_j^{(m)}(x)>K+1} \left|\omega_{j,x}^{(m)}\right| \cdot \int_{\omega_j^{(m)}(x)>K+1} \left|\omega_{j,x}^{(m)}\right| dx \;=\; \infty.
\end{aligned}$$

This proves that the original sequence was not minimizing. We again conclude that this case cannot happen. This completes the proof of Theorem 2.1. □

4. Proof of Theorem 2.2. We shall rewrite the parabolic equation (2.1) using a different set of variables:

$$v = f(u) - u_x\,, \qquad \tau = t\,, \qquad \eta = u\,. \tag{4.1}$$

This change of variable was first introduced in [BB] and then used in later papers [BB1, BB2]. For each fixed time $t > 0$, the solution of (2.1)–(2.2) is smooth. The map

$$x \mapsto \gamma^t(x) \doteq \big(u(t,x)\,,\ v(t,x)\big) \tag{4.2}$$

parameterizes a curve γ^t in the u-v plane. To see how this curve evolves in time, from (2.3) one obtains

$$v_t + f'(u)v_x = v_{xx}\,. \tag{4.3}$$

On regions where $u_x \neq 0$ we can now use (τ, η) as independent variables, instead of (t, x). From (4.1) and (4.3) we obtain

$$u_x = f(u) - v\,, \qquad v_\eta = \frac{v_x}{u_x}\,, \qquad v_{\eta\eta} = \frac{v_{xx}}{u_x^2} - \frac{v_x}{u_x^3}\,u_{xx}\,,$$

$$v_\tau = v_t - \frac{u_t}{u_x}\,v_x = (v_{xx} - f'(u)v_x) - \frac{v_x}{u_x}\,(u_{xx} - f'(u)u_x) = v_{xx} - \frac{u_{xx}}{u_x}\,v_x\,.$$

Therefore

$$v_\tau = (u_x)^2 v_{\eta\eta} = \big(v - f(\eta)\big)^2 v_{\eta\eta}\,. \tag{4.4}$$

In particular, the curve $\gamma = \gamma(\tau, \eta) = (\eta, v(\tau, \eta))$ evolves in the direction of the curvature and its total length is monotone decreasing in time. Another functional which is monotonically decreasing in time is the area functional

$$Q(\gamma) \doteq \frac{1}{2}\int\!\!\int_{\eta<\tilde\eta} \Big|\gamma_\eta(\eta) \wedge \gamma_\eta(\tilde\eta)\Big|\,d\eta d\tilde\eta, \tag{4.5}$$

defined as the double integral of a wedge product. In terms of the original coordinates u, x, we have

$$\begin{aligned} Q(u) = \int\!\!\int_{x<\tilde x} &|u_x(\tilde x)\cdot[f'(u(x))\cdot u_x(x) - u_{xx}(x)] \\ &-u_x(x)\cdot[f'(u(\tilde x))\cdot u_x(\tilde x) - u_{xx}(\tilde x)]|\;dxd\tilde x\,. \end{aligned} \tag{4.6}$$

All these calculations, (4.1)–(4.6), can be found in [BB, BB1]. As proved in [BB1], the decrease of the functional Q controls the area swept by the curve γ in its motion.

By parabolic regularization estimates, at time $t = 1$ we now have

$$Q\big(u(1)\big) \leq C_1 \tag{4.7}$$

for some constant C_1, uniformly valid for all solutions $u \in \mathcal{F}_M$. Therefore

$$\begin{aligned}\int_1^\infty \int \big(v - f(\eta)\big)^2 |v_{\eta\eta}|\, d\eta d\tau \;&\leq\; \int_1^\infty \int \big|v_\tau(\tau,\eta)\big|\, d\eta d\tau \\ &\leq \int_1^\infty -\left\{\frac{d}{dt} Q\big(u(t)\big)\right\} dt \;\leq\; Q\big(u(1)\big) \;\leq\; C_1\,. \end{aligned} \tag{4.8}$$

As a consequence, for any given $\varepsilon > 0$, there exists a set of times $I^u \subset [1, \infty[$ with

$$\text{meas}(I^u) \leq C_1/\varepsilon \tag{4.9}$$

such that

$$\int \big(v(t,\eta) - f(\eta)\big)^2 \cdot \big|v_{\eta\eta}(t,\eta)\big|\, d\eta \leq \varepsilon \qquad \text{for all } t \geq 1, t \notin I^u. \tag{4.10}$$

In addition, the assumption (2.4) of genuine nonlinearity yields the well-known decay estimate $u_x(t,x) \leq (\kappa t)^{-1}$, hence

$$-\infty < u_x(t,x) \leq \varepsilon, \qquad\qquad x \in \mathbb{R}\,, \tag{4.11}$$

for all $t \geq (\kappa\varepsilon)^{-1}$. To achieve a proof of Theorem 2.2, it now suffices to show that at every time t where (4.10)–(4.11) hold with some $\varepsilon > 0$ sufficiently small, the profile of $u(t,\cdot)$ can be suitably approximated by a finite superposition of viscous shock profiles, and (2.12) holds.

As before, set $\delta \doteq M/N$. We can single out finitely many disjoint intervals $I_k = [a_k, b_k]$, $k = 1, \ldots, \nu$, such that

$$\min_{x \in I_k} u_x(t,x) \leq -7\delta^2 \quad \text{for all} \quad k\,,$$

$$u_x(t,x) \leq u_x(t,a_k) = u_x(t,b_k) = -2\delta^3 \quad \text{for all} \quad x \in I_k\,, \tag{4.12}$$

$$u_x(t,x) > -7\delta^2 \quad \text{for all} \quad x \notin I_1 \cup \cdots \cup I_\nu\,. \tag{4.13}$$

The images of these intervals through the mapping $x \mapsto \gamma(x)$ are graphs of functions $v = v^{(k)}(\eta)$, say, with $\eta \in [b_k', a_k'] \doteq \big[u(b_k), u(a_k)\big]$; see Figure 3. For each k we now choose a point $x_k \in [a_k, b_k]$ such that

$$-m_k \;\doteq\; u_x(t,x_k) \;=\; \min_{a_k \leq x \leq b_k} u_x(t,x) \tag{4.14}$$

and call γ^k the segment in the u-v plane with endpoints on the graph of the function f, tangent to the graph of the function $v^{(k)}$ at the point $c_k \doteq u(t,x_k)$, as in Figure 4. Let $u_k^+ < u_k^-$ be the points where γ^k intersects the graph of f, and call ω_k the unique viscous traveling wave profile satisfying

$$\begin{gathered} \omega(-\infty) = u_k^-\,, \quad \omega(\infty) = u_k^+\,, \\ \omega' = f(\omega) - \sigma_k\,\omega - \big[f(u_k^-) - \sigma_k u_k^-\big]\,, \quad \sigma_k = \frac{f(u_k^-) - f(u_k^+)}{u_k^- - u_k^+} = f'\big(u(t,x_k)\big)\,, \\ \omega(x_k) = u(t,x_k)\,, \quad f'(\omega(x_k)) = \sigma_k\,. \end{gathered} \tag{4.15}$$

It is important to notice that, by the previous construction, the image of the one-to-one map

$$x \mapsto \Big(\omega_k(x)\,,\; f\big(\omega_k(x)\big) - \omega_{k,x}(x)\Big)$$

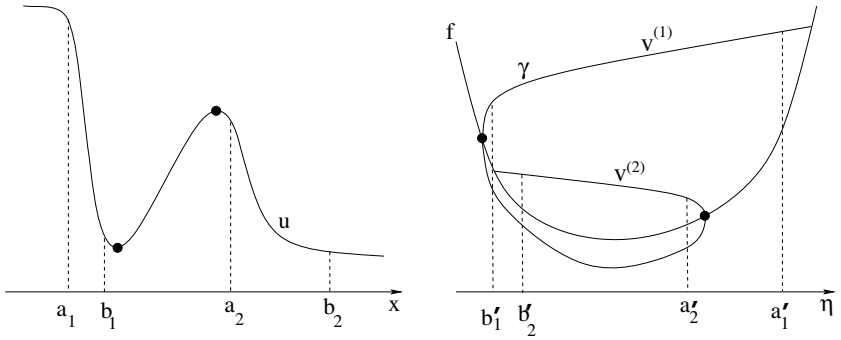

FIG. 3. *Example of a solution of the viscous conservation law and the corresponding curve in the $v-\eta$ plane.*

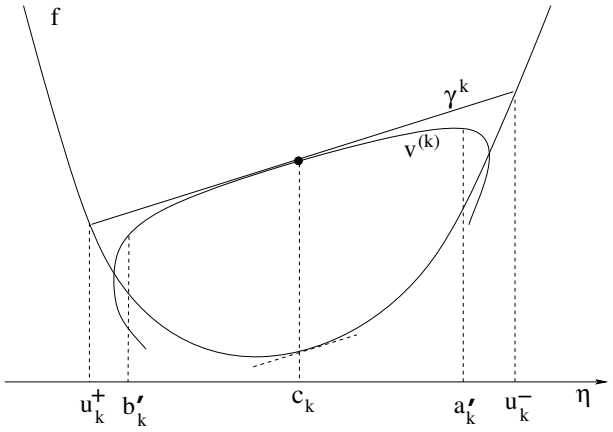

FIG. 4. *Fitting in a viscous shock ω_k, illustrated in the $v-\eta$ plane.*

is precisely the segment γ^k. Moreover, the tangency condition and the maximality condition (4.14) imply that, at $x = x_k$,

$$u_x(t,x_k) = \omega_{k,x}(x_k)\,, \qquad\qquad u_{xx}(t,x_k) = \omega_{k,xx}(x_k) = 0\,.$$

Geometrically, this means that both $u(t,\cdot)$ and $\omega_k(\cdot)$ have an inflection point at $x = x_k$. We now recall that, by (4.10),

$$\sum_k \int_{b'_k}^{a'_k} \Big(v^{(k)}(\eta) - f(\eta)\Big)^2 \cdot \Big|v^{(k)}_{\eta\eta}(t,\eta)\Big|\, d\eta \;\leq\; \varepsilon\,. \tag{4.16}$$

Restricted to the region where $u_x \leq -\delta^3$, the previous inequality implies the key estimate

$$\sum_{k=1}^{\nu} \int_{\{v^{(k)}(\eta)-f(\eta)\geq\delta^3\}} \Big|v^{(k)}_{\eta\eta}(t,\eta)\Big|\, d\eta \;\leq\; \frac{\varepsilon}{\delta^6}\,. \tag{4.17}$$

Since $\varepsilon > 0$ can be chosen arbitrarily small, according to (4.17) every function $v^{(k)}$ is almost affine, hence its graph is very well approximated by the tangent line γ^k. Reverting to the original variables t, x, this in turn implies that $u(t,\cdot)$ is closely approximated by the corresponding traveling profile ω_k on the appropriate interval $x \in [a_k, b_k]$.

LEMMA 4.1. *Assume that the flux function satisfies*

$$0 < \kappa \le f''(u) \le \kappa' \qquad \text{for all } u \in \mathbb{R}\,. \tag{4.18}$$

Then for every $\varepsilon' > 0$ there exists $\varepsilon > 0$ small enough so that (4.17) *implies the following:*

$$\|u - \omega_k\|_{\mathbf{L}^\infty([a_k,b_k])} \le \varepsilon'\,, \quad \|u - \omega_k\|^2_{H^1([a_k,b_k])} \le \varepsilon' \quad \text{for all } k\,. \tag{4.19}$$

Moreover,

$$u(t,a_k) - u(t,b_k) \ge \sqrt{\frac{m_k}{\kappa'}}\,, \tag{4.20}$$

$$\sup_{x \notin [a_k,b_k]} |\omega_{k,x}(x)| \le 3\delta^3\,, \tag{4.21}$$

$$\int_{\mathbb{R}\setminus[a_k,b_k]} |\omega_{k,x}(x)|\,dx \le \frac{6\delta^2}{\sqrt{\kappa}}\,. \tag{4.22}$$

Proof. By choosing $\varepsilon > 0$ sufficiently small, we can assume that the $\mathcal{C}^1$ distance

$$\left\| v^{(k)} - \gamma^k \right\|_{\mathcal{C}^1\left([b'_k,a'_k]\right)} \tag{4.23}$$

is as small as we like. By (4.12), when $x \in [a_k,b_k]$ we have $u_x \le -2\delta^3$. The map $x \mapsto u(x)$ is thus invertible on each interval $[a_k,b_k]$. The two norms in (4.19) can both be estimated in terms of the distance (4.23).

We now prove (4.20). Using (4.23) and recalling (4.12), by taking $\varepsilon > 0$ sufficiently small we can assume that

$$\begin{aligned} \gamma^k(a'_k) - f(a'_k) &\le v^{(k)}(a'_k) - f(a'_k) + \|v^{(k)} - \gamma^k\|_{\mathcal{C}^0} \le 3\delta^3\,, \\ \gamma^k(b'_k) - f(b'_k) &\le v^{(k)}(b'_k) - f(b'_k) + \|v^{(k)} - \gamma^k\|_{\mathcal{C}^0} \le 3\delta^3\,. \end{aligned}$$

The inequality (4.20) now follows from a simple geometrical inequality (see Figure 5(a)). If $f'' < \kappa'$ and γ is a linear function such that

$$\gamma(a') - f(a') \le 3\delta^3, \qquad \gamma(b') - f(b') \le 3\delta^3, \qquad \gamma(c) - f(c) = m_k\,,$$

for some points $b' < c < a'$, then

$$a' - b' \ge \sqrt{\frac{2(m_k - 3\delta^3)}{\kappa'}}\,.$$

Since we are assuming $\delta < 1$, $m_k \ge 7\delta^2 > 2(3\delta^3)$, from the previous inequality we deduce

$$a'_k - b'_k \ge \sqrt{\frac{m_k}{\kappa'}}\,,$$

proving (4.20).

The inequality (4.21) follows from

$$\sup_{x \notin [a_k,b_k]} |\omega_{k,x}(x)| = \max\left\{|\omega_{k,x}(a'_k)|\,,\ |\omega_{k,x}(b'_k)|\right\} \le 2\delta^3 + \left\| v^{(k)} - \gamma^k \right\|_{\mathcal{C}^1([b'_k,a'_k])} \le 3\delta^3\,.$$

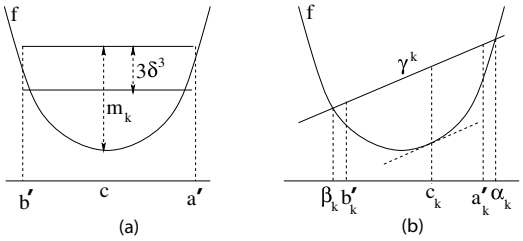

FIG. 5. *Some geometrical properties of convex functions.*

To prove (4.22), call α_k, β_k the points where the line γ^k intersects the graph of f, as in Figure 5(b). Then

$$\int_{\mathbb{R}\setminus[a_k,b_k]} |\omega_{k,x}(x)|\, dx = (\alpha_k - a'_k) + (b'_k - \beta_k)\,.$$

Consider the function $g(u) \doteq \gamma^k(u) - f(u)$. Clearly, we have

$$g(c_k) = \max_u g(u) \geq 7\delta^2,$$

and c_k is the midpoint of the interval $[\beta_k, \alpha_k]$. Assuming $f'' \geq \kappa$, then

$$a'_k - c_k \geq \frac{1}{2}\sqrt{\frac{4(m_k - 3\delta^3)}{\kappa}}.$$

Recalling that

$$g(a'_k) \leq 3\delta^3\,, \qquad g(b'_k) \leq 3\delta^3\,, \qquad g'' = -f'' \leq -\kappa\,,$$

we conclude that

$$-g'(a'_k) = -\int_{c_k}^{a'_k} g''(u)\, du \geq \kappa(a'_k - c_k) \geq \sqrt{\kappa(m_k - 3\delta^3)}.$$

Recalling that $m_k \geq 7\delta^2$ and $\delta < 1$, we obtain

$$\alpha_k - a'_k \leq \frac{3\delta^3}{\sqrt{\kappa(m_k - 3\delta^3)}} \leq \frac{6\delta^3}{\sqrt{8\kappa\delta^2}} \leq \frac{3\delta^2}{\sqrt{\kappa}}\,.$$

The estimate for $b'_k - \beta_k$ is totally similar. Together, these yield (4.22). The proof of the lemma is completed. □

As approximations to $u(t,\cdot)$ we now choose the N traveling profiles ω_k in the above list, corresponding to the N largest values of m_k, say, $m_1 \geq m_2 \geq \cdots \geq m_N$. Notice that (4.20) implies

$$N\sqrt{\frac{m_N}{\kappa'}} \leq M\,, \qquad\qquad m_N \leq \kappa' \left(\frac{M}{N}\right)^2.$$

Hence

$$|u_x(t,x)| \leq \kappa' \left(\frac{M}{N}\right)^2, \qquad\qquad x \notin \bigcup_{k=1}^{N} [a_k, b_k]\,. \tag{4.24}$$

Using the estimates (4.19)–(4.21) we now check that the functional $\mathcal{J}$ at (2.7) is small, as claimed by Theorem 2.2. The first half of the right-hand side in (2.7) can be estimated as

$$\begin{aligned}
&\sum_{k=1}^N \int_{\mathbb{R}} |u(t,x)-\omega_k(x)|\cdot|\omega_{k,x}(x)|^2\,dx\\
&\quad=\sum_{k=1}^N\left(\int_{x\in[a_k,b_k]}+\int_{x\notin[a_k,b_k]}\right)|u(t,x)-\omega_k(x)|\cdot|\omega_{k,x}(x)|^2\,dx\\
&\quad\leq \sum_k \|u-\omega_k\|_{\mathbf{L}^\infty([a_k,b_k])}\cdot\|\omega_{k,x}\|^2_{\mathbf{L}^2(\mathbb{R})}\\
&\qquad+\sum_k\Big(\|u\|_{\mathbf{L}^\infty(\mathbb{R})}+\|\omega_k\|_{\mathbf{L}^\infty(\mathbb{R})}\Big)\sup_{x\notin[a_k,b_k]}|\omega_{k,x}(x)|\cdot\int_{\mathbb{R}\setminus[a_k,b_k]}|\omega_{k,x}(x)|\,dx\\
&\quad\leq \mathcal{O}(1)\cdot N\,\varepsilon'+N\cdot 2M\cdot 3\delta^3\frac{6\delta^2}{\sqrt{\kappa}}\;=\;\mathcal{O}(1)\cdot\frac{1}{N^4}\,.
\end{aligned}$$

For the second half of the right-hand side of (2.7), we can use the inequality $(a+b)^2\leq 2(a^2+b^2)$, valid for all real numbers of a,b, and we get

$$\begin{aligned}
&\int_{\mathbb{R}}\left|u_x(t,x)-\sum_{k=1}^N\omega_{k,x}(x)\right|^2dx\\
&=\sum_k\int_{a_k}^{b_k}\left|u_x(t,x)-\sum_{k=1}^N\omega_{k,x}(x)\right|^2dx+\int_{\mathbb{R}\setminus\cup_k[a_k,b_k]}\left|u_x(t,x)-\sum_{k=1}^N\omega_{k,x}(x)\right|^2dx\\
&\leq\sum_k\int_{a_k}^{b_k}\left(|u_x(t,x)-\omega_{k,x}(x)|+\sum_{j\neq k}|\omega_{j,x}(x)|\right)^2dx\\
&\qquad+\int_{\mathbb{R}\setminus\cup_k[a_k,b_k]}\left(|u_x(t,x)|+\sum_k|\omega_{k,x}(x)|\right)^2dx\\
&\leq 2\sum_k\left\{\int_{a_k}^{b_k}|u_x(t,x)-\omega_{k,x}(x)|^2\,dx+\int_{a_k}^{b_k}\left(\sum_{j\neq k}|\omega_{j,x}(x)|\right)^2dx\right\}\\
&\qquad+2\int_{\mathbb{R}\setminus\cup_k[a_k,b_k]}\left[|u_x(t,x)|^2+\left(\sum_k|\omega_{k,x}(x)|\right)^2\right]dx\\
&\leq I_1+I_2+I_3+I_4\,,
\end{aligned}$$

where

$$I_1=2\sum_k|u-\omega_k|_{H^1([a_k,b_k])}\,,$$

$$I_2 = 2\sum_j \left(\sum_{k\neq j} \int_{a_k}^{b_k} |\omega_{j,x}(x)|^2 \, dx \right) \;\leq\; 2\sum_j \int_{\mathbb{R}\setminus[a_j,b_j]} |\omega_{j,x}(x)|^2 \, dx$$
$$\leq\; 2\sum_j \left\{ \sup_{x\notin[a_j,b_j]} |\omega_{j,x}(x)| \cdot \int_{\mathbb{R}\setminus[a_j,b_j]} |\omega_{j,x}(x)| \, dx \right\},$$
$$I_3 = 2\left\{ \sup_{x\notin\cup[a_k,b_k]} |u_x(t,x)| \right\} \cdot \int_{\mathbb{R}} |u_x(t,x)| \, dx\,,$$
$$I_4 = 2\sum_k \left\{ \sup_{x\notin[a_k,b_k]} |\omega_{k,x}(x)| \right\} \cdot \int_{\mathbb{R}\setminus\cup_k[a_k,b_k]} \sum_k |\omega_{k,x}(x)| \, dx\,.$$

Using the estimates in Lemma 4.1 and (4.24), we get

$$I_1 \leq 2N\varepsilon'\,,$$
$$I_2 \leq 2N\, 3\delta^3\, \frac{6\delta^2}{\sqrt{\kappa}}\,,$$
$$I_3 \leq 2\kappa' \frac{M^2}{N^2}\, M\,,$$
$$I_4 \leq 2\cdot N3\delta^3 \cdot N\, \frac{6\delta^2}{\sqrt{\kappa}}\,.$$

Note that I_1 measures how well the viscous shock profile matches the solution on the interval $[a_k, b_k]$, and this term is arbitrarily small. I_2 measures the H_1 norm of the viscous shock waves outside the interval $[a_k, b_k]$, and it is of $\mathcal{O}(1)/N^4$. And I_3 is the sum of all the shock waves that are not represented. This is the largest term here, and is of $\mathcal{O}(1)/N^2$. Finally, I_4 is similar to I_2, and is of $\mathcal{O}(1)/N^3$. In summary, we have

$$\int_{\mathbb{R}} \left| u_x(t,x) - \sum_{k=1}^{N} \omega_{k,x}(x) \right|^2 dx \;\leq\; \mathcal{O}(1)\cdot\frac{1}{N^2}\,.$$

Putting these two parts together, we get the desired result.

5. Concluding remarks. For solutions to the conservation law (2.1), the transient behavior is nontrivial and can last an arbitrarily long time. This happens because we are considering solutions defined on the whole real line. On the other hand, if the equation is restricted to a bounded interval, say,

$$u_t + f(u)_x = u_{xx}, \qquad x \in]a,b[\,, \tag{5.1}$$

with boundary conditions

$$u(a) = \alpha\,, \qquad u(b) = \beta\,, \tag{5.2}$$

then all solutions would converge at an exponential rate to a unique steady state $w(\cdot)$.

Indeed, from basic theory of parabolic equations [H] it follows that there exists a unique function $w : [a,b] \mapsto \mathbb{R}$ which satisfies the two-point boundary value problem

$$f(w)_x = w_{xx}\,, \qquad w(a) = \alpha\,, \qquad w(b) = \beta\,. \tag{5.3}$$

Linearizing (5.1) around the steady state w, one obtains the existence of some $\delta > 0$ such that, for every initial data $\bar{u} \in \mathbf{L}^2$ the corresponding solution of (5.1)–(5.2) satisfies

$$\|u(t) - w\|_{\mathcal{C}^k([a,b])} \leq C\, e^{-\delta t}.$$

Here one can choose a constant C uniformly valid on bounded subsets of $\mathbf{L}^2$. After an initial time interval, the long-term behavior of the solution is thus trivial.

In the case of a bounded domain, the corresponding equation (4.4) in the (η, v) variables must be supplemented with the boundary conditions

$$v_\eta(\alpha) = v_\eta(\beta) = 0\,.$$

The unique steady state solution of (5.3) corresponds to a constant function:

$$v(\eta) \equiv \kappa \qquad \text{for all } \eta \in [\alpha,\, \beta]\,.$$

Observing that

$$b - a = \int_\alpha^\beta \frac{1}{u_x}\, du = \int_\alpha^\beta \frac{1}{f(\eta) - v(\eta)}\, d\eta\,,$$

one can uniquely determine the constant κ from the relation

$$b - a = \int_\alpha^\beta \frac{1}{f(\eta) - \kappa}\, d\eta\,.$$

Acknowledgments. The authors are grateful to Prof. Alberto Bressan at the same department for proposing the problem and for many useful discussions. We also want to thank one of the referees for carefully reading through the paper and for various remarks.

SYNCHRONIZATION OF A STOCHASTIC REACTION-DIFFUSION SYSTEM ON A THIN TWO-LAYER DOMAIN*

TOMÁS CARABALLO†, IGOR D. CHUESHOV‡, AND PETER E. KLOEDEN§

Abstract. A system of semilinear parabolic stochastic partial differential equations with additive space-time noise is considered on the union of thin bounded tubular domains $D_{1,\varepsilon} := \Gamma \times (0, \varepsilon)$ and $D_{2,\varepsilon} := \Gamma \times (-\varepsilon, 0)$ joined at the common base $\Gamma \subset \mathbb{R}^d$, where $d \geq 1$. The equations are coupled by an interface condition on Γ which involves a reaction intensity $k(x', \varepsilon)$, where $x = (x', x_{d+1}) \in \mathbb{R}^{d+1}$ with $x' \in \Gamma$ and $|x_{d+1}| < \varepsilon$. Random influences are included through additive space-time Brownian motion, which depend only on the base spatial variable $x' \in \Gamma$ and not on the spatial variable x_{d+1} in the thin direction. Moreover, the noise is the same in both layers $D_{1,\varepsilon}$ and $D_{2,\varepsilon}$. Limiting properties of the global random attractor are established as the thinness parameter of the domain $\varepsilon \to 0$, i.e., as the initial domain becomes thinner, when the intensity function possesses the property $\lim_{\varepsilon \to 0} \varepsilon^{-1} k(x', \varepsilon) = +\infty$. In particular, the limiting dynamics is described by a single stochastic parabolic equation with the averaged diffusion coefficient and a nonlinearity term, which essentially indicates synchronization of the dynamics on both sides of the common base Γ. Moreover, in the case of nondegenerate noise we obtain stronger synchronization phenomena in comparison with analogous results in the deterministic case previously investigated by Chueshov and Rekalo [*EQUADIFF*-2003, F. Dumortier et al., eds., World Scientific, Hackensack, NJ, 2005, pp. 645–650; *Sb. Math.*, 195 (2004), pp. 103–128].

1. Introduction.

Let $D_{1,\varepsilon}$ and $D_{2,\varepsilon}$ be thin bounded domains in $\mathbb{R}^{d+1}$, where $d \geq 1$, of the form

$$D_{1,\varepsilon} = \Gamma \times (0, \varepsilon), \qquad D_{2,\varepsilon} = \Gamma \times (-\varepsilon, 0),$$

where $0 < \varepsilon \leq 1$ and Γ is a bounded C^2-domain in $\mathbb{R}^d$. We write $x \in D_\varepsilon := D_{1,\varepsilon} \cup D_{2,\varepsilon}$ as $x = (x', x_{d+1})$, where $x' \in \Gamma$ and $x_{d+1} \in (0, \varepsilon)$ or $x_{d+1} \in (-\varepsilon, 0)$, and will not distinguish between the sets $\Gamma \times \{0\} \subset \mathbb{R}^{d+1}$ and $\Gamma \subset \mathbb{R}^d$.

We consider the following system of semilinear parabolic equations:

$$\frac{\partial}{\partial t} U^i - \nu_i \Delta U^i + a U^i + f_i(U^i) + h_i(x) = \dot{W}(t, x'), \quad t > 0, \ \ x \in D_{i,\varepsilon}, \ \ i = 1, 2, \tag{1}$$

with the initial data

$$U^i(0, x) = U_0^i(x), \qquad x \in D_{i,\varepsilon}, \ \ i = 1, 2, \tag{2}$$

where the $\dot{W}(t,x')$ is a Gaussian white noise depending on the spatial variable $x' \in \Gamma$ (but not on the x_{d+1} spatial variable).

We assume that U^1 and U^2 satisfy the Neumann boundary conditions

$$\big(\nabla U^i, n_i\big) = 0, \qquad x \in \partial D_{i,\varepsilon} \setminus \Gamma, \quad i = 1,2, \tag{3}$$

on the external part of the boundary of the compound domain D_ε, where n is the outer normal to ∂D_ε, and a matching condition on Γ of the form

$$\begin{aligned} \left(-\nu_1 \frac{\partial U^1}{\partial x_{d+1}} + k(x',\varepsilon)(U^1 - U^2)\right)\Big|_\Gamma &= 0, \\ \left(\nu_2 \frac{\partial U^2}{\partial x_{d+1}} + k(x',\varepsilon)(U^2 - U^1)\right)\Big|_\Gamma &= 0. \end{aligned} \tag{4}$$

Here the above constants ν_i and a are positive numbers.

We impose the following assumptions:

- for $i = 1,2$ the function $f_i \in C^1(\mathbb{R})$ possesses the property $f_i'(v) \geq -c$ for all $v \in \mathbb{R}$ and also satisfies the relations

$$v f_i(v) \geq a_0 |v|^{p+1} - c, \quad |f_i'(v)| \leq a_1 |v|^{p-1} + c, \quad v \in \mathbb{R}, \tag{5}$$

  where a_j and c are positive constants and $1 \leq p < 3$;
- $h_i \in H^1(D_{i,1})$, $i = 1,2$;
- the interface reaction intensity $k(x',\varepsilon)$ satisfies

$$k(\cdot,\varepsilon) \in L^\infty(\Gamma), \quad k(x',\varepsilon) > 0 \text{ for } x' \in \Gamma,\ \varepsilon \in (0,1],$$

  and

$$\lim_{\varepsilon \to 0} \frac{1}{\varepsilon} k(x',\varepsilon) = +\infty,\ x' \in \Gamma, \text{ in Lebesgue measure (see Remark 1.1)}; \tag{6}$$

- $W(t)$, $t \in \mathbb{R}$, is a two-sided $L_2(\Gamma)$-valued Wiener process with covariance operator $K = K^* \geq 0$ such that

$$\operatorname{tr}\Big[K\left(-\Delta_N + 1\right)^{2\beta-1}\Big] < \infty \quad \text{for some} \quad \beta > \max\left\{1\,,\ \frac{d}{4}\right\}, \tag{7}$$

  where Δ_N is the Laplace operator in $L_2(\Gamma)$ with the Neumann boundary conditions on $\partial\Gamma$. We denote by $(\Omega, \mathcal{F}, \mathbb{P})$ the corresponding probability space, and by $\dot{W} \equiv \partial_t W$ the generalized derivative with respect to t.

Remark 1.1. Our main example of the interface reaction intensity is the following function:

$$k(x',\varepsilon) = \varepsilon^\alpha k_0(x') \in L^\infty(\Gamma), \quad k_0(x') > 0 \quad \text{for } x' \in \Gamma,\ \varepsilon \in (0,1],$$

for some $\alpha \in [0,1)$. We also note that the convergence in (Lebesgue) measure to infinity means that

$$\lim_{\varepsilon \to 0} \operatorname{Leb}\left\{x' \in \Gamma\ :\ \varepsilon^{-1} k(x',\varepsilon) \leq N\right\} = 0 \ \text{ for any } \ N > 0.$$

Problem (1)–(4) is a model for a reaction-diffusion system consisting of two components filling thin contacting layers $D_{1,\varepsilon}$ and $D_{2,\varepsilon}$ separated by a penetrable membrane Γ. Reaction of the components is possible on the surface Γ only, and the reaction

intensity $k(x', \varepsilon)$ depends on the thickness of the domains filled by the reactants. The deterministic version of the model was considered by Chueshov and Rekalo [12, 13], while Rekalo [27] investigated the special case of identical equations in both layers with $k(\varepsilon, x)$ independent of ε. The stochastic version considered in the present paper allows for irregularities and random effects on the separating membrane.

Hale and Raugel [21, 22] initiated the analysis of asymptotic dynamics of deterministic semilinear reaction-diffusion equations on thin domains. Some extensions of their results can be also found in [16] and [26]. In all these papers, a reaction-diffusion equation is endowed with homogeneous Neumann boundary conditions. To our knowledge stochastic evolution equations have not previously been investigated on thin domains.

In this paper we investigate the pathwise asymptotic behavior of the above stochastic evolution system by converting it into a system of pathwise random partial differential equations (PDEs) to which deterministic methods can be applied in a pathwise manner.

Our main result deals with properties of random (global) pullback attractors for the random dynamical system generated by (1)–(4) in $L_2(D_\varepsilon)$. In particular, we prove that these pullback attractors are closely related to the corresponding object for the problem

$$\frac{\partial}{\partial t}U - \nu\Delta_{x'}U + aU + f(U) + h(x') = \dot{W}(t, x'), \qquad t > 0, \;\; x' \in \Gamma, \tag{8}$$

on the spatial domain Γ with the Neumann boundary conditions on $\partial\Gamma$. Here we denote

$$\nu = \frac{\nu_1 + \nu_2}{2}, \quad f(U) = \frac{f_1(U) + f_2(U)}{2}, \quad h(x') = \frac{h_1(x', 0) + h_2(x', 0)}{2}. \tag{9}$$

This is essentially a statement about the synchronization of the dynamics of the system in the two thin layers at the level of global pullback attractors. Since, in principle, a global attractor can be a rather complicated set, the synchronization at this level does not imply that *any* pair of trajectories becomes asymptotically synchronized. However, in the case of nondegenerate noise ($Kh = 0$ if and only if $h = 0$ and the image of K is dense in $L_2(\Gamma)$) we can prove, in contrast with the deterministic counterpart, that the global pullback attractor for (8) is a singleton. This means that we also have asymptotic synchronization in our system at the level of trajectories. Thus we observe a stronger synchronizing effect of a nondegenerate stochastic noise in the system under consideration.

The synchronization of stochastic stationary solutions (i.e., single-valued random attractors) of finite dimensional stochastic systems was considered in [5]. See also [1, 23] for similar results in deterministic nonautonomous systems and [7, 28] for autonomous infinite dimensional systems.

The synchronization of coupled systems is a ubiquitous phenomenon in the biological and physical science and is also known to occur in a number of social science contexts. A descriptive account of its diversity of occurrence can be found in the recent book of Strogatz [32], which contains an extensive list of references. In particular, synchronization provides an explanation for the emergence of spontaneous order in the dynamical behavior of coupled systems, which in isolation may exhibit chaotic dynamics. It has been shown to persist in the presence of environmental noise provided that appropriate concepts of random attractors and stochastic stationary solutions are used instead of their deterministic counterparts [5]. As mentioned above, in this

paper we will see that the presence of additive noise can lead to a strengthening of the synchronization, i.e., at the level of trajectories rather than attractors, which does not occur in the absence of noise.

Since most of our analysis is a pathwise analysis applied to pathwise defined random PDEs, i.e., with the stationary Ornstein–Uhlenbeck process appearing as a space-time dependent coefficient, it is reasonable to expect that similar results will also hold for other kinds of noise, for example, with fractional Brownian motion in the original stochastic partial differential equations (SPDEs). The results will be presented in a forthcoming paper.

The paper is organized as follows. We start with preliminary section 2 containing background material from the theory of random systems which we need to state and discuss our main results in section 3. Further sections are devoted to the proof of our main theorem, Theorem 3.1.

2. Random dynamical systems. In order to formulate our results we need some notation and results from the theory of random dynamical systems (with continuous time) and random attractors.

Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a probability space and let $(\mathcal{X}, d_{\mathcal{X}})$ be a complete separable metric (Polish) space. Arnold [2] defined a random dynamical system (RDS) (θ, ϕ) on $\Omega \times \mathcal{X}$ in terms of a metric dynamical system θ on Ω, which represents the noise driving the system, and a cocycle mapping $\phi : \mathbb{R}_+ \times \Omega \times \mathcal{X} \to \mathcal{X}$, which represents the dynamics in the state space $\mathcal{X}$ and satisfies the following properties:

1. $\phi(0, \omega)\phi_0 = \phi_0$ for all $\phi_0 \in \mathcal{X}$ and $\omega \in \Omega$;
2. $\phi(s + t, \omega)\phi_0 = \phi(s, \theta_t\omega)\phi(t, \omega)\phi_0$ for all s, $t \geq 0$, $\phi_0 \in \mathcal{X}$, and $\omega \in \Omega$;
3. $(t, \phi_0) \mapsto \phi(t, \omega)\phi_0$ is continuous for each $\omega \in \Omega$; and
4. $\omega \mapsto \phi(t, \omega)\phi_0$ is $\mathcal{F}$-measurable for all $(t, \phi_0) \in \mathbb{R}_+ \times \mathcal{X}$.

We recall that a metric dynamical system $\theta \equiv (\Omega, \mathcal{F}, \mathbb{P}, \{\theta_t, t \in \mathbb{R}\})$ is a family of measure-preserving transformations $\{\theta_t : \Omega \mapsto \Omega, t \in \mathbb{R}\}$ such that

(i) $\theta_0 = id, \theta_t \circ \theta_s = \theta_{t+s}$ for all $t, s \in \mathbb{R}$;

(ii) the map $(t, \omega) \mapsto \theta_t\omega$ is measurable, and $\theta_t\mathbb{P} = \mathbb{P}$ for all $t \in \mathbb{R}$.

RDSs (with continuous time) are generated by differential equations with random coefficients or stochastic differential equations with a unique and global solution, as well as by infinite dimensional stochastic evolution equations with additive noise. We refer to [2] for more details on the general theory of RDS theory.

To construct an RDS in our case we first need to associate a metric dynamical system θ with the Wiener process W on $(\Omega, \mathcal{F}, \mathbb{P})$ with values in $L_2(\Gamma)$. The probability measure $\mathbb{P}$ of this process can be realized on $\mathcal{F} = \mathcal{B}(C_0(\mathbb{R}, L_2(\Gamma)))$, where $C_0(\mathbb{R}, L_2(\Gamma))$ is the Fréchet space of continuous functions on $\mathbb{R}$ with values in $L_2(\Gamma)$ which are zero at time zero. For this realization we introduce the flow $(\theta_t)_{t\in\mathbb{R}}$ given by the *Wiener shift*

$$\theta_t\omega(\cdot) = \omega(\cdot + t) - \omega(t), \quad t \in \mathbb{R}. \tag{10}$$

Interpreting the above Wiener process in the canonical sense $W(\cdot, \omega) = \omega(\cdot)$, it follows that (10) is the well-known helix property of a Wiener process:

$$W(t + s, \omega) - W(s, \omega) = W(t, \theta_s\omega), \quad s, t \in \mathbb{R}, \quad \omega \in \Omega.$$

We now introduce the Ornstein–Uhlenbeck process as a stationary solution of the linear stochastic evolution equation

$$\frac{\partial}{\partial t}U = \nu\Delta_{x'}U - aU + \dot{W}(t, x'), \qquad t > 0, \;\; x' \in \Gamma,$$

on the spatial domain Γ with Neumann boundary conditions on $\partial\Gamma$. Here, as above, we denote $\nu = (\nu_1 + \nu_2)/2$. This process $\eta(t)$ can be written in the form

$$\eta(t,\omega) := \left(\int_{-\infty}^{t} e^{-(t-\tau)A_0} dW(\tau)\right)(\omega), \tag{11}$$

where $A_0 = -\nu\Delta_N + a$ and Δ_N is the Laplace operator in $L_2(\Gamma)$ with the Neumann boundary conditions on $\partial\Gamma$. The integral in (11) exists as an operator stochastic integral (see, e.g., [24] or [19]) We can also involve a perfection procedure to define $\eta(t,\omega) \equiv \bar{\eta}(\theta_t\omega)$ for *all* $\omega \in \Omega$ (for details see [14]). Moreover, under condition (7), $t \mapsto \bar{\eta}(\theta_t\omega)$ is continuous from $\mathbb{R}$ into $D(A_0^{\beta'}) \subset H^{2\beta'}(\Gamma)$ for each $\omega \in \Omega$, where $\beta' \in [0,\beta)$ is arbitrary, and the *temperedness* condition

$$\sup_{t\in\mathbb{R}}\{\| A_0^{\beta'}\bar{\eta}(\theta_t\omega) \| e^{-\gamma|t|}\} < \infty \quad \forall\ \gamma > 0,\ \omega \in \Omega,$$

is satisfied. We also note that under condition (7), since $H^s(\Gamma) \subset C(\overline{\Gamma})$ for $s > d/2$, we have that $t \mapsto \bar{\eta}(\theta_t\omega)$ is a pathwise continuous tempered process with values in $D(A_0) \cap C(\overline{\Gamma})$. In particular

$$\bar{\eta}(\theta_t\omega) \in C\left(\mathbb{R}; C(\overline{\Gamma}) \cap \left\{\psi \in H^2(\Gamma) : \psi \text{ satisfies Neumann b.c. on } \partial\Gamma\right\}\right) \tag{12}$$

for every $\omega \in \Omega$. We will use this observation later.

We recall the following definition of a random set (see [2] or [4]).

DEFINITION 2.1 (random set). *Let $\mathcal{X}$ be a Polish space with a metric $d_{\mathcal{X}}$. A multifunction $\omega \mapsto D(\omega) \neq \emptyset$ is said to be a* random set *if the mapping $\omega \mapsto \operatorname{dist}_{\mathcal{X}}(v, D(\omega))$ is measurable for any $v \in \mathcal{X}$, where $\operatorname{dist}_{\mathcal{X}}(v,B)$ is the distance in $\mathcal{X}$ between the element v and the set $B \subset \mathcal{X}$. For ease of notation we denote the random set $\omega \mapsto D(\omega)$ by $\widehat{D}$ or $\{D(\omega)\}$. If $D(\omega)$ is closed for each $\omega \in \Omega$, then $\widehat{D}$ is called a* random closed set*, while if $D(\omega)$ is a compact set for all $\omega \in \Omega$, then $\widehat{D}$ is called a* random compact set*. A random set $\{D(\omega)\}$ is said to be* tempered *if there exists a $v_0 \in \mathcal{X}$ such that $D(\omega) \subset \{v \in \mathcal{X} : d_{\mathcal{X}}(v, v_0) \le r(\omega)\}$ for all $\omega \in \Omega$, where the random variable $r(\omega) > 0$ is tempered, i.e.,*

$$\sup_{t\in\mathbb{R}}\{r(\theta_t\omega)e^{-\gamma|t|}\} < \infty \quad \forall\ \gamma > 0,\ \omega \in \Omega.$$

We denote by $\mathcal{D}$ the collection of all tempered random sets in $\mathcal{X}$.

Below we also need the concept of a random attractor for RDSs (see, e.g., [2, 17, 18, 29] and the references therein), which extends the corresponding definition of a global attractor in autonomous systems (cf. [3, 9, 33], for example).

DEFINITION 2.2. *Let (θ,ϕ) be an RDS with the phase space $\mathcal{X}$. A random closed set $\{\mathfrak{A}(\omega)\}$ from $\mathcal{D}$ is said to be a* random pullback attractor *for (θ,ϕ) in $\mathcal{D}$ if* (i) *$\widehat{\mathfrak{A}}$ is an invariant set, i.e., $\phi(t,\omega)\mathfrak{A}(\omega) = \mathfrak{A}(\theta_t\omega)$ for $t \ge 0$ and $\omega \in \Omega$, and* (ii) *$\widehat{\mathfrak{A}}$ is pullback attracting in $\mathcal{D}$, i.e.,*

$$\lim_{t\to+\infty} d_{\mathcal{X}}\{\varphi(t,\theta_{-t}\omega)D(\theta_{-t}\omega)\,|\,\mathfrak{A}(\omega)\} = 0, \quad \omega \in \Omega,$$

for all $\widehat{D} \in \mathcal{D}$, where $d_{\mathcal{X}}\{A|B\} = \sup_{a\in A}\operatorname{dist}_{\mathcal{X}}(a,B)$.

Note that a pullback attractor is also a weak *forward* attractor; i.e., we have that

$$\lim_{t\to+\infty}\int_{\Omega} d_{\mathcal{X}}\{\varphi(t,\omega)D(\omega)\,|\,\mathfrak{A}(\theta_t\omega)\}\mathbb{P}(d\omega) = 0 \quad \forall\widehat{D} \in \mathcal{D}.$$

If the random attractor consists of singleton sets, i.e., $\mathfrak{A}(\omega) = \{X^*(\omega)\}$ for some random variable X^* with $X^*(\omega) \in \mathcal{X}$, then $X_t^*(\omega) := X^*(\theta_t\omega))$ is a stationary stochastic process on $\mathcal{X}$.

The following result [18] ensures the existence of a random attractor for an RDS on a Polish space.

THEOREM 2.3. *Let (θ, ϕ) be a continuous or discrete time RDS on $\Omega \times \mathcal{X}$ such that $\phi(t, \omega, \cdot) : \mathcal{X} \to \mathcal{X}$ is a compact operator for each fixed $t > 0$ and $\omega \in \Omega$. If there exists a tempered random set $\widehat{\mathfrak{B}} = \{\mathfrak{B}(\omega), \omega \in \Omega\}$ and a $T_{\widehat{D},\omega} \geq 0$ such that*

$$\phi(t, \theta_{-t}\omega)D(\theta_{-t}\omega) \subset \mathfrak{B}(\omega) \qquad \forall t \geq T_{\widehat{D},\omega},$$

for every tempered random set $\widehat{D}$, then the RDS (θ, ϕ) has a random pullback attractor $\widehat{\mathfrak{A}} = \{\mathfrak{A}(\omega), \omega \in \Omega\}$ with the component subsets defined for each $\omega \in \Omega$ by

$$\mathfrak{A}(\omega) = \bigcap_{s>0} \overline{\bigcup_{t \geq s} \phi(t, \theta_{-t}\omega)\mathfrak{B}(\theta_{-t}\omega)}^{d_{\mathcal{X}}}.$$

The family $\{\mathfrak{B}(\omega)\}$ is called a pullback absorbing random set for the RDS.

3. Main results. Now we are in position to state our main results which we formulate in the theorem below. This says that the limiting dynamics of the system (1)–(4) is given by that of the averaged system (8) on Γ, which one can interpret as the synchronization of dynamics of the original system on the two sides of the membrane Γ. In addition, if the system is the same on both sides of the membrane, then the limiting behavior is independent of the thinness parameter ε when it is sufficiently small.

THEOREM 3.1. *Under the conditions above the following assertions hold.*

1. *Problem* (1)–(4) *generates an RDS $(\theta, \bar{\phi}_\varepsilon)$ in the space*

$$\mathcal{H}_\varepsilon = L_2(D_{1,\varepsilon}) \oplus L_2(D_{2,\varepsilon}) \sim L_2(D_\varepsilon)$$

with the metric dynamical system θ generated by the Wiener process W and the cocycle $\bar{\phi}_\varepsilon$ defined by the formula $\bar{\phi}_\varepsilon(t, \omega)U_0 = U(t, \omega)$, where $U(t, \omega) = (U^1(t, \omega); U^2(t, \omega))$ is a strong (in the sense of stochastic equations [19]*) solution to problem* (1)–(4) *and $U_0 = (U_0^1; U_0^2)$.*

2. *Similarly, problem* (8) *generates an RDS $(\theta, \bar{\phi}_0)$ in the space $L_2(\Gamma)$.*
3. *The cocycles $\bar{\phi}_\varepsilon$ converge to $\bar{\phi}_0$ in the sense that*

$$\lim_{\varepsilon \to 0} \sup_{t \in [0,T]} \frac{1}{\varepsilon} \int_{D_\varepsilon} |\bar{\phi}_\varepsilon(t, \omega)v - \bar{\phi}_0(t, \omega)v|^2 dx = 0 \quad \forall \omega \in \Omega,$$

for any $v(x) \in \mathcal{H}_\varepsilon$ independent of the variable x_{d+1}, and for any $T > 0$.

4. *These RDS $(\theta, \bar{\phi}_\varepsilon)$ and $(\theta, \bar{\phi}_0)$ have random compact pullback attractors $\{\bar{\mathfrak{A}}^\varepsilon(\omega)\}$ and $\{\bar{\mathfrak{A}}^0(\omega)\}$ in their corresponding phase spaces. Moreover, if the correlation operator K of the Wiener process W is nondegenerate in the sense that* (i) *$Kh = 0$ if and only if $h = 0$, and* (ii) *the image of K is dense in $L_2(\Gamma)$, then the attractor $\{\bar{\mathfrak{A}}^0(\omega)\}$ is a singleton, i.e., $\bar{\mathfrak{A}}^0(\omega) = \{\bar{v}_0(\omega)\}$, where $\bar{v}_0(\omega)$ is a tempered random variable with values in $L_2(\Gamma)$.*
5. *The attractors $\{\bar{\mathfrak{A}}^\varepsilon(\omega)\}$ are upper semicontinuous as $\varepsilon \to 0$ in the sense that*

$$\lim_{\varepsilon \to 0} \sup_{v \in \bar{\mathfrak{A}}^\varepsilon(\omega)} \left\{ \inf_{v_0 \in \bar{\mathfrak{A}}^0(\omega)} \frac{1}{\varepsilon} \int_{D_\varepsilon} |v(x', x_{d+1}) - v_0(x')|^2 dx \right\} = 0 \quad \forall \omega \in \Omega. \tag{13}$$

6. *In addition, if*

$$\begin{aligned} &\nu_1 = \nu_2 := \nu, \quad f_1(U) = f_2(U) := f(U), \\ &h_1(x', x_{d+1}) = h(x'), \quad h_2(x', x_{d+1}) = h(x'); \end{aligned} \tag{14}$$

$f(U)$ is globally Lipschitz, i.e., there exists a constant $L > 0$ such that

$$|f(U) - f(V)| \le L|U - V|, \quad U, V \in \mathbb{R}, \tag{15}$$

and also that

$$k(x', \varepsilon) > k_\varepsilon \text{ for } x' \in \Gamma,\ \varepsilon \in (0, 1]; \quad \text{and} \quad \lim_{\varepsilon \to 0} \varepsilon^{-1} k_\varepsilon = +\infty, \tag{16}$$

then there exists $\varepsilon_0 > 0$ such that for all $\varepsilon \in (0, \varepsilon_0]$ the global random pullback attractor $\{\bar{\mathfrak{A}}^\varepsilon(\omega)\}$ for $(\theta, \bar{\phi}_\varepsilon)$ has the form

$$\bar{\mathfrak{A}}^\varepsilon(\omega) \equiv \left\{ v(x', x_{d+1}) \equiv v_0(x') \ : \ v_0 \in \bar{\mathfrak{A}}^0(\omega) \right\},$$

where $\{\bar{\mathfrak{A}}^0(\omega)\}$ is the random pullback attractor for the RDS $(\theta, \bar{\phi}_0)$.

Remark 3.2. In the case when $\bar{\mathfrak{A}}^0(\omega) = \{\bar{v}_0(\omega)\}$ is a singleton, relation (13) turns into the equality

$$\lim_{\varepsilon \to 0} \sup_{v \in \bar{\mathfrak{A}}^\varepsilon(\omega)} \left\{ \frac{1}{\varepsilon} \int_{D_\varepsilon} |v(x', x_{d+1}, \omega) - \bar{v}_0(x', \omega)|^2 dx \right\} = 0 \quad \forall \omega \in \Omega.$$

In particular, this implies that for any $U_0, U_0^* \in \mathcal{H}_\varepsilon$ we have that

$$\lim_{\varepsilon \to 0} \limsup_{t \to +\infty} \left\{ \frac{1}{\varepsilon} \| \bar{\phi}_\varepsilon(t, \theta_{-t}\omega) U_0 - \bar{\phi}_\varepsilon(t, \theta_{-t}\omega) U_0^* \|^2_{L_2(D_\varepsilon)} \right\} = 0 \quad \forall \omega \in \Omega, \tag{17}$$

where we can omit the $\lim_{\varepsilon \to 0}$ under conditions (14)–(16). Thus we obtain the synchronization effect not only at the level of global attractors (see (13)) but also at the level of trajectories in relation (17). We emphasize that this *double* synchronization phenomenon is not true for the deterministic ($K \equiv 0$) counterpart of the problem. In the latter case the global attractor for (8) (without the noise $\dot{W}$) is not a single point when the reaction term $au + f(u)$ has several roots, and thus (17) cannot be true for *all* initial data. In this case we have synchronization at the level of the global attractors only.

Remark 3.3. The statements of Theorem 3.1 deal with the case when the intensity interaction $k(x', \varepsilon)$ between layers is asymptotically strong enough (see condition (6)). However, similarly to [12, 13] we can also consider the case when the limit in (6) is finite by assuming that

$$\lim_{\varepsilon \to 0} \varepsilon^{-1} k(x', \varepsilon) = k(x') \quad \text{strongly in } L_2(\Gamma) \tag{18}$$

for some bounded nonnegative function $k(x') \in L_2(\Gamma)$. In this case the limiting problem for (1)–(4) is a system of two parabolic SPDEs on Γ of the form

$$\frac{\partial}{\partial t} U^i - \nu_i \Delta_{x'} U^i + aU^i + f_i(U^i) + k(x')(-1)^{i+1}(U^1 - U^2) + h_i(x', 0) = \dot{W}(t, x'), \tag{19}$$

where $i = 1, 2$ and $(t; x') \in \mathbb{R}_+ \times \Gamma$, with the Neumann boundary condition on $\partial\Gamma$. Using the same method as for the case (6) in combination with deterministic arguments given in [13] for a particular case of (18), one can prove upper semicontinuity of $\{\bar{\mathfrak{A}}^\varepsilon(\omega)\}$ in the limit $\varepsilon \to 0$ in the case (18). However we will not present the case because (i) our main point of interest is the phenomenon of synchronization, and (ii) under condition (18) synchronization is possible only in some very special cases.

The proof of Theorem 3.1 is given in the remaining sections of the paper. To begin, in section 4 the problem is reformulated in terms of pathwise random PDEs on a scaled domain and appropriate function spaces are introduced. Then we show that (1)–(4) generates an RDS. In section 5 the existence of a random pullback attractor is proved. Then in section 5.1 the limiting dynamics on finite time intervals as $\epsilon \to 0$ is established, and in section 7 the upper continuous dependence of the attractors as $\epsilon \to 0$ is shown. Finally, in section 8 the synchronization of the systems for fixed $\epsilon > 0$ is considered.

4. Generation of an RDS by the two-layer problem.

4.1. Equivalent random PDEs. We introduce the new dependent variables V^i (which are also stochastic processes):

$$V^i(t, x, \omega) := U^i(t, x', x_{d+1}, \omega) - \bar{\eta}(\theta_t\omega, x'), \quad t > 0, \ \ x = (x', x_{d+1}) \in D_{i,\varepsilon}, \ \ i = 1, 2,$$

where $\bar{\eta}(\omega, x')$ is given by (11) after perfection. Let

$$\begin{aligned} h_1(x, \omega) &= -\frac{1}{2}(\nu_1 - \nu_2)\Delta\bar{\eta}(\omega) + h_1(x), \\ h_2(x, \omega) &= \frac{1}{2}(\nu_1 - \nu_2)\Delta\bar{\eta}(\omega) + h_2(x). \end{aligned} \tag{20}$$

Then equations (1)–(4) can be transformed into the pathwise random semilinear parabolic PDEs

$$\partial_t V^i - \nu_i\Delta V^i + aV^i + f_i\left(V^i + \bar{\eta}(\theta_t\omega)\right) + h_i(x, \theta_t\omega) = 0, \quad t > 0, \ x \in D_{i,\varepsilon}, \tag{21}$$

for $i = 1, 2$, with the random initial data

$$V^i(0, x, \omega) = U_0^i(x) - \bar{\eta}(\omega), \qquad x \in D_{i,\varepsilon}, \ \ i = 1, 2. \tag{22}$$

Since the Ornstein–Uhlenbeck process $\bar{\eta}(\theta_t\omega; x')$ does not depend on x_{d+1}, due to (12) we obtain the Neumann boundary conditions

$$\left(\nabla V^i(x), n_i(x)\right) = 0, \qquad x \in \partial D_{i,\varepsilon} \setminus \Gamma, \quad i = 1, 2, \tag{23}$$

on the external part of the boundary of the compound domain D_ε, where n is the outer normal to ∂D_ε. Condition (4) turns into a matching condition on Γ of the form

$$\begin{aligned} \left(-\nu_1\frac{\partial V^1}{\partial x_{d+1}} + k(x', \varepsilon)(V^1 - V^2)\right)\Big|_\Gamma &= 0, \\ \left(\nu_2\frac{\partial V^2}{\partial x_{d+1}} + k(x', \varepsilon)(V^2 - V^1)\right)\Big|_\Gamma &= 0, \end{aligned} \tag{24}$$

which is now pathwise random and homogeneous.

4.2. Scaling and functional spaces. It is convenient to deal with a fixed domain where every equation is defined for $\varepsilon > 0$. Let us introduce the new coordinates $(x, y) \in \mathbb{R}^{d+1}$, as follows:

$$x = x', \quad x \in \Gamma, \quad y = \varepsilon^{-1} x_{d+1}, \quad y \in (-1, 1).$$

In so doing, we transform the domain D_ε into $D = D_1 \cup D_2$, where $D_1 = \Gamma \times (0, 1)$, $D_2 = \Gamma \times (-1, 0)$; the operator $\nabla = (\nabla_{x'}$ and $\partial_{x_{d+1}})$ into $\nabla_\varepsilon = (\nabla_x, \varepsilon^{-1}\partial_y)$; and $\Delta = \Delta_{x'} + \partial^2_{x_{d+1}}$ into $\Delta_\varepsilon = \Delta_x + \varepsilon^{-2}\partial_{yy}$. Problem (21)–(24) takes the form

$$\partial_t v^i - \nu_i \Delta_\varepsilon v^i + a v^i + f_i(v^i + \bar{\eta}) + h_i^\varepsilon(x, y, \theta_t \omega) = 0, \quad t > 0, \ (x, y) \in D_i, \tag{25}$$

for $i = 1, 2$, with the initial data

$$v^i(0, x, y) = V_0^i(x, y), \quad (x, y) \in D_i, \quad i = 1, 2, \tag{26}$$

and the boundary conditions

$$\left.\frac{\partial v^i}{\partial n_i}\right|_{\partial D_i \setminus \Gamma} = 0, \quad i = 1, 2, \tag{27}$$

$$\left.\left(\nu_i \frac{\partial v_i}{\partial y} - \varepsilon k(x, \varepsilon)(v_1 - v_2)\right)\right|_{y=0} = 0, \quad i = 1, 2. \tag{28}$$

Here $h_i^\varepsilon(x, y, \omega) = h_i(x, \varepsilon y, \omega)$ and n_i is the outward normal to the boundary ∂D_i. A solution $V(t, x', x_{d+1})$ to problem (21)–(24) is expressed in terms of a solution $v(t, x, y)$ to problem (25)–(28) by the formula $V(t, x', x_{d+1}) = v(t, x', \varepsilon^{-1} x_{d+1})$.

Let us introduce the space

$$\mathcal{H} = L^2(D_1) \oplus L^2(D_2) \simeq L^2(D)$$

endowed with the norm $\|u\|^2 \equiv \|u_1\|^2_{L^2(D_1)} + \|u_2\|^2_{L^2(D_2)}$, where $u = (u_1; u_2)$, $u_i \equiv u|_{D_i}$, and let us define a family of Sobolev spaces

$$\mathcal{H}^1_\varepsilon = H^1(D_1) \oplus H^1(D_2), \quad \varepsilon \in (0, 1],$$

endowed with the norm

$$\|u\|^2_{1,\varepsilon} \equiv \sum_{i=1}^{2} \left(\|u_i\|^2_{H^1(D_i)} + \varepsilon^{-2} \|\partial_y u_i\|^2_{L^2(D_i)} \right).$$

Every element $v \in H^1(\Gamma) \oplus H^1(\Gamma)$ can be extended naturally to an element $u \in \mathcal{H}^1_\varepsilon$ by the formula $u_i(x, y) \equiv v_i(x)$, $(x, y) \in D_i$, $i = 1, 2$; in what follows, this will be done without further comment.

4.3. Abstract representation. Now we represent problem (25)–(27) in the abstract form. To do this we first consider the bilinear form

$$\begin{aligned} a_\varepsilon(u, v) \quad &= \sum_{i=1}^{2} \nu_i \left[(\nabla_x u_i, \nabla_x v_i)_{L^2(D_i)} + \frac{1}{\varepsilon^2} (\partial_y u_i, \partial_y v_i)_{L^2(D_i)} \right] + a \cdot (u, v)_{\mathcal{H}} \\ &+ \frac{1}{\varepsilon} \int_\Gamma k(x, \varepsilon)(u_1(x, 0) - u_2(x, 0))(v_1(x, 0) - v_2(x, 0))\, dx, \end{aligned}$$

defined on the elements $u = (u_1; u_2)$, $v = (v_1; v_2)$ of the space $\mathcal{H}^1_\varepsilon = H^1(D_1) \oplus H^1(D_2)$. One can show that $a_\varepsilon(u, v)$ is a closed symmetric form in $\mathcal{H}$ possessing the property

$$c_0 \sum_{i=1,2} \|u\|^2_{H^1(D_i)} \le c_1 \|u\|^2_{1,\varepsilon} \le a_\varepsilon(u, u), \quad u \in \mathcal{H}^1_\varepsilon. \tag{29}$$

Here and in what follows we drop the subscript ε in constants which can be chosen independently of $\varepsilon \in (0, 1]$. Therefore, there exists a unique positive self-adjoint operator A_ε such that $\mathcal{D}(A_\varepsilon) \subset \mathcal{H}^1_\varepsilon$ and

$$a_\varepsilon(u, v) = (A_\varepsilon u, v)_{\mathcal{H}}, \quad u \in \mathcal{D}(A_\varepsilon),\ v \in \mathcal{H}^1_\varepsilon.$$

It can be shown that

$$\mathcal{D}(A_\varepsilon) = \big\{u \in H^2(D_1) \oplus H^2(D_2)\ :\ u \text{ satisfies (27) and (28)}\big\}$$

and also that

$$A_\varepsilon u = (-\nu_1 \Delta_\varepsilon u_1 + a u_1,\ -\nu_2 \Delta_\varepsilon u_2 + a u_2), \quad u = (u_1, u_2) \in \mathcal{D}(A_\varepsilon).$$

Moreover, $\mathcal{D}(A^{1/2}_\varepsilon) = \mathcal{H}^1_\varepsilon$, $a_\varepsilon(u, u) = \|A^{1/2}_\varepsilon u\|^2$. For more details concerning the operator A_ε we refer to [13].

Now we can rewrite the pathwise random PDE in problem (25)–(28) in the abstract form

$$\frac{d}{dt} v + A_\varepsilon v = B(v, \theta_t \omega), \quad v|_{t=0} = v_0, \tag{30}$$

in the space $\mathcal{H}$, where

$$B(v, \omega) = \begin{cases} -f_1(v^1 + \bar\eta(\omega)) - h_1(x, \varepsilon y, \omega), & y > 0, \\ -f_2(v^2 + \bar\eta(\omega)) - h_2(x, \varepsilon y, \omega), & y < 0. \end{cases}$$

4.4. Generation of an RDS. By the same method as in [25] (see also [30, Chap. 3]) one can prove that there exists a deterministic constant M such that the nonlinear mapping $A_\varepsilon - B(\cdot, \omega) + M$ is a maximal monotone operator on $\mathcal{D}(A_\varepsilon)$. This observation makes it possible (some details can be found in [8, Chap. 15] for the general nonautonomous case) to prove that for each $\omega \in \Omega$ and $v_0 \in \mathcal{H}$ on any time interval $[0, T]$ there exists a unique weak solution $v(t, \omega)$ to (30) from the class

$$L_{p+1}(0, T; L_{p+1}(D)) \cap L_2(0, T; \mathcal{H}^1_\varepsilon) \cap C(0, T; \mathcal{H}).$$

Since this solution can be constructed as a limit of the corresponding Galerkin approximations, the mapping $(t; \omega) \mapsto v(t, \omega)$ is measurable. Moreover, it is easy to derive from the uniqueness property that the mapping $\phi_\varepsilon(t, \omega) : \mathcal{H} \mapsto \mathcal{H}$ defined by the relation $\phi_\varepsilon(t, \omega) v_0 = v(t, \omega)$, where $v(t, \omega)$ solves (30), satisfies the cocycle property. Thus (30) generates an RDS.

Now using inverse transformation we define the cocycle $\bar\phi_\varepsilon$ for problem (1)–(4) by the formula

$$\bar\phi_\varepsilon(t, \omega) = R^{-1}_\varepsilon(\theta_t \omega) \circ \phi_\varepsilon(t, \omega) \circ R_\varepsilon(\omega),$$

where $R_\varepsilon(\omega) : L_2(D_\varepsilon) \mapsto L_2(D)$ is an affine random mapping of the form

$$[R_\varepsilon(\omega) U](x, y) = U(x, \varepsilon y) - \bar\eta(\omega), \quad U \in L_2(D_\varepsilon).$$

This proves the first statement in Theorem 3.1.

It is clear that $R_\varepsilon(\omega)$ maps tempered random sets in $L_2(D_\varepsilon)$ into tempered sets in $L_2(D)$. Therefore all other statements of Theorem 3.1 can be easily reformulated as statements concerning the RDS $(\theta, \phi_\varepsilon)$ generated by the random evolution equation in (30). In our further considerations we deal with this RDS $(\theta, \phi_\varepsilon)$.

5. Random pullback attractors. In this section we prove the existence of a random pullback attractor for problem (25)–(28) for every *fixed* $\varepsilon \in (0, 1]$ and also for the limiting problem (8).

5.1. The case $\varepsilon > 0$. We first want to emphasize that we do not use any information concerning the behavior of the intensity $k(x', \varepsilon)$ as $\varepsilon \to 0$, and hence our results in this subsection cover both of the cases (6) and (18).

Our main result in this section is the following assertion.

PROPOSITION 5.1. *In the space $\mathcal{H}$ the RDS $(\theta, \phi_\varepsilon)$ generated by problem* (25)–(28) *possesses a compact pullback attractor $\widehat{\mathfrak{A}}^\varepsilon$ which belongs to the space $\mathcal{H}^1_\varepsilon$. Moreover, there exists a tempered random variable $R(\omega)$, which does not depend on ε, such that*

$$\mathfrak{A}^\varepsilon(\omega) \subset \left\{ v \in \mathcal{H}^1_\varepsilon \ : \ a_\varepsilon(v, v) + \|v\|^{p+1}_{L_{p+1}(D)} \le R^2(\omega) \right\}, \quad \omega \in \Omega. \tag{31}$$

We split the proof into several lemmata which are also important for the limit transition on finite time intervals.

LEMMA 5.2 (pullback dissipativity). *The RDS $(\theta, \phi_\varepsilon)$ is pullback dissipative in $\mathcal{D}$; i.e., there exists a tempered random variable $R(\omega) > 0$ such that for any random set $\widehat{D}$ from $\mathcal{D}$ we can find $t_0(\omega, \widehat{D}) > 0$ for which*

$$\|\phi_\varepsilon(t, \theta_{-t}\omega)U\|_{\mathcal{H}} \le R(\omega) \quad \forall\ U \in D(\theta_{-t}\omega),\ t \ge t_0(\omega, \widehat{D}).$$

Thus the random ball $B_0(\omega) = \{U \in \mathcal{H} : \|U\|_{\mathcal{H}} \le R(\omega)\}$ is pullback absorbing. This ball is also forward invariant and absorbing if we take

$$R^2(\omega) = c_1 \int_{-\infty}^0 e^{c_0 \tau} \left(1 + \|\bar\eta(\theta_\tau\omega)\|^{p+1}_{L_{p+1}(\Gamma)} + \|\bar\eta(\theta_\tau\omega)\|^2_{H^1(\Gamma)} \right) d\tau,$$

with appropriate $c_0 > 0$ and $c_1 > 0$ independent of $\varepsilon \in (0, 1]$.

Proof. The calculations below are formal, but can be justified by considering Galerkin approximations.

Multiplying (25) by v^i in $L_2(D_i)$ for $i = 1, 2$, after some calculations we obtain that

$$\frac{1}{2}\frac{d}{dt}\|v\|^2_{\mathcal{H}} + a_\varepsilon(v, v) + \sum_{i=1,2} \left[\int_{D_i} f_i(v^i + \bar\eta) v^i dx + (h^\varepsilon, v^i)_{L_2(D_i)} \right] = 0. \tag{32}$$

From (5) we have that

$$\begin{aligned}
(f_i(v^i + \bar\eta), v^i) &= \int_{D_i} f(v^i) v^i dx + \int_{D_i} \left[\int_0^1 f_i'(v^i + \lambda\bar\eta) d\lambda \right] \bar\eta v^i dx \\
&\ge a_0 \|v^i\|^{p+1}_{L_{p+1}(D_i)} - c_1 \int_{D_i} \left(1 + |v^i|^{p-1} + |\bar\eta|^{p-1} \right) |\bar\eta| |v^i| dx - c_2 \\
&\ge \frac{a_0}{2} \|v^i\|^{p+1}_{L_{p+1}(D_i)} - b_0 \left(1 + \|\bar\eta\|^{p+1}_{L_{p+1}(\Gamma)} \right) \qquad (33)
\end{aligned}$$

and from (20) and (29) we also have that

$$\sum_{i=1,2}(h^\varepsilon, v^i)_{L_2(D_i)} \le C\left(\|\bar\eta\|_{H^1(\Gamma)} + \sum_{i=1,2}\|h\|_{H^1(D_i)}\right)[a_\varepsilon(v,v)]^{1/2}. \tag{34}$$

Now from (32)–(34) we obtain that

$$\frac{d}{dt}\|v\|^2_{\mathcal{H}} + a_\varepsilon(v,v) + a_0\|v\|^{p+1}_{L_{p+1}(D)} \le R_0^2(\theta_t\omega), \tag{35}$$

where

$$R_0^2(\omega) = c\left(1 + \|\bar\eta(\omega)\|^{p+1}_{L_{p+1}(\Gamma)} + \|\bar\eta(\omega)\|^2_{H^1(\Gamma)}\right). \tag{36}$$

Since $a_\varepsilon(v,v) \ge c_0\|v\|^2_{\mathcal{H}} + \frac{1}{2}a_\varepsilon(v,v)$, by differentiating $e^{\nu_* t}\|v\|^2_{\mathcal{H}}$, taking into account (35), and integrating, we have that

$$\|v(t)\|^2_{\mathcal{H}} + \int_0^t e^{-\nu_*(t-\tau)}V^0_\varepsilon(v(\tau))d\tau \le \|v_0\|^2_{\mathcal{H}}e^{-\nu_* t} + \int_0^t e^{-\nu_*(t-\tau)}R_0^2(\theta_\tau\omega)d\tau, \tag{37}$$

for any $0 < \nu_* \le c_0$, where $R_0(\omega)$ is given by (36) and

$$V^0_\varepsilon(v) = \frac{1}{2}a_\varepsilon(v,v) + a_0\|v\|^{p+1}_{L_{p+1}(D)}. \tag{38}$$

This allows us to complete the proof of Lemma 5.2. □

LEMMA 5.3 (compact absorbing set). *For each $\varepsilon \in (0,1]$ there exists a compact, forward invariant tempered absorbing set.*

Proof. Multiplying (25) by $\partial_t v^i$ in $L_2(D_i)$ we find that

$$\begin{aligned}&\partial_t\Psi_\varepsilon(v(t)) + \|\partial_t v(t)\|^2_{\mathcal{H}}\\ &+ \sum_{i=1,2}\int_{D_i}\left[f(v^i+\bar\eta) - f(v^i)\right]\partial_t v^i dxdy + \int_D h^\varepsilon\partial_t v^i dxdy = 0,\end{aligned} \tag{39}$$

where

$$\Psi_\varepsilon(u) = \frac{1}{2}a_\varepsilon(u,u) + \sum_{i=1}^2\int_{D_i}F_i(u^i)\,dxdy, \quad u = (u^1;u^2) \in \mathcal{H}^1_\varepsilon. \tag{40}$$

Here $F_i(u) = \int_0^u f_i(\xi)d\xi$. It is clear from the assumptions concerning f_i that

$$\begin{aligned}&\left|\sum_{i=1,2}\int_{D_i}\left[f(v^i+\bar\eta) - f(v^i)\right]\partial_t v^i dxdy\right|\\ &\le c\sum_{i=1,2}\int_{D_i}\left|f(v^i+\bar\eta) - f(v^i)\right|^2 dxdy + \frac{1}{4}\|\partial_t v(t)\|^2_{\mathcal{H}}\\ &\le c_1 + c_2\int_D|v|^{p+1}\,dxdy + c_3\left[|\bar\eta|^{p+1}_{L_{p+1}(\Gamma)} + |\bar\eta|^{p_*}_{L_{p_*}(\Gamma)}\right] + \frac{1}{4}\|\partial_t v(t)\|^2_{\mathcal{H}},\end{aligned}$$

where $p_* = 2(p+1)/(3-p)$. We also have that

$$\left|\int_D h^\varepsilon\partial_t v^i dxdy\right| \le c_1 + c_2\|\bar\eta\|^2_{H^2(\Gamma)} + \frac{1}{4}\|\partial_t v(t)\|^2_{\mathcal{H}}$$

Therefore from (39) we have that

$$\partial_t \Psi_\varepsilon(v(t)) + \frac{1}{2}\|\partial_t v(t)\|^2_{\mathcal{H}} \leq c_1 + c_2\|v\|^{p+1}_{L_{p+1}(D)} + c_3\left(\|\bar\eta\|^2_{H^2(\Gamma)} + |\bar\eta|^{p+1}_{L_{p+1}(\Gamma)} + |\bar\eta|^{p_*}_{L_{p_*}(\Gamma)}\right). \tag{41}$$

Consequently, choosing positive constants b_0 and b_1 in an appropriate way one can see that

$$V_\varepsilon(u) := b_0\|u\|^2_{\mathcal{H}} + \Psi_\varepsilon(u) + b_1 \tag{42}$$

with Ψ_ε given by (40) satisfies the relations

$$c_0 V^0_\varepsilon(v) \leq V_\varepsilon(v) \leq c_1\left[1 + V^0_\varepsilon(v)\right] \tag{43}$$

with $V^0_\varepsilon(v)$ given by (38). Moreover, due to (35) we can choose b_0 and b_1 such that

$$\frac{d}{dt}V_\varepsilon(v) + \gamma V_\varepsilon(v) + \frac{1}{2}\|\partial_t v_\varepsilon(t)\|^2_{\mathcal{H}} \leq R_1^2(\theta_t\omega), \tag{44}$$

with positive γ, where

$$R_1^2(\omega) = c\left(1 + \|\bar\eta(\omega)\|^{p+1}_{L_{p+1}(\Gamma)} + |\bar\eta(\omega)|^{p_*}_{L_{p_*}(\Gamma)} + \|\bar\eta(\omega)\|^2_{H^2(\Gamma)}\right), \quad p_* = \frac{2p+2}{3-p}. \tag{45}$$

We note that $R_1(\omega)$ is a tempered random variable because $t \mapsto \bar\eta(\theta_t\omega)$ is a tempered process with values in $H^2(\Gamma) \cap C(\overline{\Gamma})$. From (44) we have that

$$V_\varepsilon(v(t)) \leq e^{-\gamma(t-s)}V_\varepsilon(v(s)) + \int_s^t e^{-\gamma(t-\tau)}R_1^2(\theta_\tau\omega)d\tau, \quad t \geq s. \tag{46}$$

By (43) we also have

$$V^0_\varepsilon(v(t)) \leq c_1 e^{-\gamma(t-s)}V^0_\varepsilon(v(s)) + c_2\int_s^t e^{-\gamma(t-\tau)}R_1^2(\theta_\tau\omega)d\tau, \quad t \geq s.$$

Therefore using (37) after integration with respect to s over the interval $[0,t]$ we obtain

$$V^0_\varepsilon(v(t)) \leq \frac{c_1}{t}\|v_0\|^2_{\mathcal{H}}e^{-\gamma_* t} + c_2\left(1 + \frac{1}{t}\right)\int_0^t e^{-\gamma_*(t-\tau)}R_1^2(\theta_\tau\omega)d\tau, \quad t > 0, \tag{47}$$

for some $0 < \gamma_* \leq \gamma$. Relations (46) and (47) makes it possible to conclude that there exists a tempered random variable $R_*(\omega)$ such that the set

$$\mathfrak{B}(\omega) = \left\{v : V_\varepsilon(v) \leq R_*^2(\omega)\right\} \tag{48}$$

is forward invariant and absorbing. It is clear that $\mathfrak{B}(\omega)$ is compact in $\mathcal{H}$ for each $\omega \in \Omega$. Moreover, $R_*^2(\omega)$ does not depend on ε. □

Completion of the proof of Proposition 5.1. The proof follows from Theorem 2.3 and Lemmata 5.2 and 5.3. Relation (31) follows from (47), (48), and properties of the functionals V^0_ε and V_ε given in (38), (42), and (43).

Remark 5.4. It also follows from (44) and (37) that

$$\int_0^t \tau e^{-\gamma_*(t-\tau)}\|\partial_t v_\varepsilon(\tau)\|^2_{\mathcal{H}} d\tau \le c_1\|v_0\|^2_{\mathcal{H}} e^{-\gamma_* t} + c_2\int_0^t (1+\tau)e^{-\gamma_*(t-\tau)} R_1^2(\theta_\tau\omega)d\tau, \tag{49}$$

for all $t \ge 0$, where $\gamma_* > 0$. Below we will also need the next lemma.

LEMMA 5.5. *For any initial data $v, v_* \in \mathcal{H}$ we have the estimate*

$$\|\phi_\varepsilon(t,\omega)v - \phi_\varepsilon(t,\omega)v_*\|_{\mathcal{H}} \le c_1 e^{c_2 t}\|v - v_*\|_{\mathcal{H}}, \quad \omega \in \Omega, \tag{50}$$

where c_1 and c_2 do not depend on $\omega \in \Omega$ and $\varepsilon \in (0,1]$.

Proof. We use the same method as in Lemma 5.2 by considering the difference of two solutions and relying on the property

$$\big(f_i(v^i + \bar\eta) - f_i(v^i_* + \bar\eta)\big)\,(v^i - v^i_*) \ge -c_0|v^i - v^i_*|^2,$$

where c_0 does not depend on ω and ε. ∎

5.2. Limiting system. The same change of unknown variable $U = v + \bar\eta$ transforms equation (8) into the following random PDE on Γ:

$$\begin{cases} \partial_t v - \nu\Delta v + av + f(v + \bar\eta(\theta_t\omega)) + h(x') = 0, \quad t > 0,\ x' \in \Gamma, \\ \\ \frac{\partial v}{\partial n}\big|_{\partial\Gamma} = 0,\ v|_{t=0} = v_0, \end{cases} \tag{51}$$

where ν, $f(v)$, and h are given by (9). The same argument as in section 4 allows us to prove that problem (51) generates an RDS (θ, ϕ_0) in the space $L_2(\Gamma)$ and thus to establish Theorem 3.1(2).

The following assertion states the existence of a pullback attractor for this RDS (θ, ϕ_0).

PROPOSITION 5.6. *In the space $L_2(\Gamma)$, problem* (51) *generates an RDS (θ, ϕ_0) possessing a compact pullback attractor $\{\mathfrak{A}^0(\omega)\}$ which belongs to the space $H^1(\Gamma)$. If the correlation operator K possesses the properties* (i) *$Kh = 0$ if and only if $h = 0$ and* (ii) *the image of K is dense in $L_2(\Gamma)$, then the attractor $\{\mathfrak{A}^0(\omega)\}$ is a singleton; i.e., there exists a tempered random variable $v_0(\omega)$ with values in $H^1(\Gamma)$ such that $\mathfrak{A}^0(\omega) = \{v_0(\omega)\}$ for all $\omega \in \Omega$.*

Proof. To prove the existence of the attractor we argue exactly as in Proposition 5.1 and we do not repeat it again.

As for the second part, we first note that the RDS (θ, ϕ_0) is *monotone*; i.e., the property $v(x) \le v_*(x)$ for almost all $x \in \Gamma$ implies that

$$[\phi_0(t,\omega)v](x) \le [\phi_0(t,\omega)v_*](x) \quad \text{for almost all} \quad x \in \Gamma,$$

for all $t > 0$, and for $\omega \in \Omega$. This monotonicity property can be established by the standard (pathwise) argument (see, e.g., [31]). We also refer to [10] for a general discussion of monotone RDSs. Our next step is to apply a result from [15] which states that, under some conditions, the global pullback attractor of a monotone RDS consists of a single random equilibrium. The main hypothesis in [15] is the weak convergence of distributions of the process $t \mapsto \phi_0(t,\omega)v$ to some limiting probability measure. In our case we can guarantee this property because the noise $\dot W$ is nondegenerate in the phase space of the system (θ, ϕ_0). We refer to [15, subsection 4.5] for details. ∎

Propositions 5.1 and 5.6 imply Theorem 3.1(4).

Remark 5.7. Although it is possible to prove that the RDS $(\theta, \phi_\varepsilon)$ generated by problem (25)–(28) is also monotone, we cannot apply the result from [15] to prove that $\hat{\mathfrak{A}}^\varepsilon$ is a single equilibrium. The point is that the noise $\dot{W}$ is nondegenerate in $L_2(\Gamma)$ (the phase space of the system (θ, ϕ_0)), but it is *degenerate* in $\mathcal{H} = L_2(D)$ (the phase space for $(\theta, \phi_\varepsilon)$), and hence we cannot guarantee the weak convergence of distributions of the process $t \mapsto \phi_\varepsilon(t, \omega)U_0$. Thus the pullback attractor $\hat{\mathfrak{A}}^\varepsilon$ may contain more than one equilibrium. The same conclusion is valid for problem (19). One can prove that (19) generates a monotone RDS with a compact pullback attractor, but to conclude that this attractor is a random equilibrium we need the nondegeneracy of the noise in $L_2(\Gamma) \times L_2(\Gamma)$, which is obviously not true for this case.

Remark 5.8. 1. It is clear from the argument in the proof of Lemma 5.5 that

$$\|\phi_0(t, \omega)v - \phi_0(t, \omega)v_*\|_{L_2(\Gamma)} \le c_1 e^{c_2 t}\|v - v_*\|_{L_2(\Gamma)}, \quad \omega \in \Omega, \tag{52}$$

for some constants c_1 and c_2 independent of ω, where $v, v_* \in L_2(\Gamma)$.

2. Since $L_2(\Gamma)$ can be embedded naturally into $L_2(D) \sim \mathcal{H}$ as the subspace of functions independent of y, we can consider the cocycle ϕ_0 as a mapping from $L_2(\Gamma)$ into $\mathcal{H}$. Therefore we can compare it with ϕ_ε. Below we also consider the image $\widetilde{\mathfrak{A}}^0(\omega)$ of $\mathfrak{A}^0(\omega)$ under this embedding.

6. Limit transition on finite time intervals. Our main result in this section is the following theorem, which implies the third statement in Theorem 3.1.

THEOREM 6.1. *For any time interval we have that*

$$\lim_{\varepsilon \to 0} \sup_{t \in [\delta, T]} \|\phi_\varepsilon(t, \omega)v - \phi_0(t, \omega)v_*\|_{\mathcal{H}} = 0 \quad \forall \delta \in (0, T), \tag{53}$$

where $v_* = \langle v \rangle := \frac{1}{2}\int_{-1}^{1} v(x, y)dy$. *If* v *does not depend on* y, *i.e.,* $v = v_*$, *then*

$$\lim_{\varepsilon \to 0} \sup_{t \in [0, T]} \|\phi_\varepsilon(t, \omega)v - \phi_0(t, \omega)v_*\|_{\mathcal{H}} = 0. \tag{54}$$

Proof. Let $w_\varepsilon(t) = \phi_\varepsilon(t, \omega)v$. It follows from (37), (47), and (49) that

$$\sup_{t \in [0, T]} \sum_{i=1,2} \|w^i_\varepsilon(t)\|^2_{L_2(D_i)} + \int_0^T \|w^i_\varepsilon(t)\|^2_{H^1(D_i)}dt \le C_T(\omega), \tag{55}$$

and, for every $\delta > 0$,

$$\sup_{t \in [\delta, T]} \sum_{i=1,2} \|w^i_\varepsilon(t)\|^2_{H^1(D_i)} + \sum_{i=1,2} \int_\delta^T \|\partial_t w^i_\varepsilon(t)\|^2_{L_2(D_i)}dt \le C_{T,\delta}(\omega), \tag{56}$$

$$\frac{1}{\varepsilon^2}\left[\sup_{t \in [\delta, T]} \sum_{i=1,2} \|\partial_y w^i_\varepsilon(t)\|^2_{L_2(D_i)} + \sum_{i=1,2} \int_0^T \|\partial_y w^i_\varepsilon(t)\|^2_{L_2(D_i)}dt\right] \le C_{T,\delta}(\omega). \tag{57}$$

Moreover, we have that

$$\sup_{t \in [\delta, T]} \int_\Gamma \frac{k(x', \varepsilon)}{\varepsilon}|w^1_\varepsilon(t) - w^2_\varepsilon(t)|^2dx' + \int_0^T dt \int_\Gamma \frac{k(x', \varepsilon)}{\varepsilon}|w^1_\varepsilon(t) - w^2_\varepsilon(t)|^2dx' \le C_{T,\delta}(\omega) \tag{58}$$

for all intervals $[0,T]$ and $\varepsilon \in (0,1]$. Therefore, using relations (55)–(57) and Aubin's compactness theorem we can conclude that there exist a pair of functions

$$u_i \in C(\delta, T; L^2(\Gamma)) \cap L^\infty(\delta, T; H^1(\Gamma)), \quad i = 1,2, \quad \forall \delta > 0$$

and a sequence $\{\varepsilon_n\}$ such that

$$\lim_{n\to\infty} \sum_{i=1,2} \sup_{t\in[\delta,T]} \|w^i_{\varepsilon_n}(t) - u_i(t)\|_{L_2(D_i)} = 0. \tag{59}$$

Moreover, we also have weak convergence in $L_2(0,T;H^1(D))$. One can also see from (58) and (6) that $u_1(t) = u_2(t) \equiv u(t)$ on the set Γ. Considering a variational form of (25)–(28), one can show that $u(t)$ solves problem (51). The corresponding argument is exactly the same as in [13] for the deterministic case and therefore we do not give details here. Thus (53) follows from (59) and from the uniqueness theorem for (51).

To prove (54) we first consider $v \equiv v_*$ from the space $H^1(\Gamma) \cap L_{p+1}(\Gamma)$. In this case relying on (46) with $s = 0$ and using the fact that $V_\varepsilon(v)$ does not depend on ε for this choice of v, we can easily prove estimates (56) and (57) with $\delta = 0$. Thus the same argument as above gives (54) for $v \equiv v_*$ from $H^1(\Gamma) \cap L_{p+1}(\Gamma)$. To obtain (54) for $v_* \in L_2(\Gamma)$ we use an appropriate approximation procedure and relations (50) and (52). □

Remark 6.2. By a standard argument we can prove that (53) and (54) hold uniformly with respect to v in every compact set.

Remark 6.3. Since the arguments given in Lemmata 5.2 and 5.3 do not depend on the behavior of $k(x,\varepsilon)$ as $\varepsilon \to 0$, the estimates in (55)–(58) hold for *both* cases (6) and (18). Thus, in the latter case, we can also conclude from (55)–(57) that w^1_ε and w^2_ε converge to some functions u^1 and u^2 defined on Γ. However, in that case we cannot prove that u^1 and u^2 are the same because under condition (18) estimate (58) does not lead to the conclusion. In the case (18) the same arguments as in [12, 13] give us the convergence of $\bar{\phi}_\varepsilon(t,\omega)$ generated by (1)–(4) to the cocycle generated by (19).

7. Upper semicontinuity of attractors. In this section we prove the following assertion, which is our first result on synchronization.

THEOREM 7.1. *Let $\{\mathfrak{A}^\varepsilon(\omega)\}$ be the global random pullback attractor for the RDS $(\theta, \phi_\varepsilon)$ generated by* (25)–(28). *Then*

$$\lim_{\varepsilon\to 0} \sup \left\{ \operatorname{dist}_{\mathcal{H}} \left(u, \widetilde{\mathfrak{A}}^0(\omega) \right) \,:\, u \in \mathfrak{A}^\varepsilon(\omega) \right\} = 0 \quad \forall \omega \in \Omega, \tag{60}$$

where $\widetilde{\mathfrak{A}}^0(\omega) = \left\{ J(v) \,:\, v \in \mathfrak{A}^0(\omega) \right\} \subset \mathcal{H}$. Here $\{\mathfrak{A}^0(\omega)\}$ is the random pullback attractor for the RDS (θ, ϕ_0) and $J : L_2(\Gamma) \mapsto L_2(D) = \mathcal{H}$ is the natural embedding operator.

Proof. Assume that (60) does not hold for some $\omega \in \Omega$. Then there exist a sequence $\{\varepsilon_n\}$ with $\varepsilon_n \to 0$ and a sequence $u_n \in \mathfrak{A}^{\varepsilon_n}(\omega)$ such that

$$\operatorname{dist}_{\mathcal{H}}(u_n, \widetilde{\mathfrak{A}}^0(\omega)) \geq \delta > 0 \quad \forall\, n = 1,2,\ldots. \tag{61}$$

By the invariance property of the attractor $\mathfrak{A}^{\varepsilon_n}(\omega)$, for every $t > 0$ there exists $v^t_n \in \mathfrak{A}^{\varepsilon_n}(\theta_{-t}\omega)$ such that $u_n = \phi_{\varepsilon_n}(t, \theta_{-t}\omega) v^t_n$. Since $\mathfrak{A}^{\varepsilon_n}(\omega)$ is compact and estimate (31) holds, we can assume that there exist u_* and v^t_* in $H^1(D_1) \oplus H^1(D_2)$ such that

$$\lim_{n\to\infty} \|u_n - u_*\|_{\mathcal{H}} = 0, \quad \lim_{n\to\infty} \|v^t_n - v^t_*\|_{\mathcal{H}} = 0. \tag{62}$$

As in the proof of Theorem 6.1 one can see that

$$u_* = \tilde{u} \oplus \tilde{u}, \quad v_*^t = \tilde{v}^t \oplus \tilde{v}^t,$$

where $\tilde{u}, \tilde{v}^t \in H^1(\Gamma)$. Therefore, if we show that $\tilde{u} \in \mathfrak{A}^0(\omega)$, then we obtain a contradiction to (61).

It follows from Lemma 5.5 and Theorem 6.1 that

$$\tilde{u} = \phi_0(t, \theta_{-t}\omega)\tilde{v}^t.$$

However, it follows from (31) and (62) that $\tilde{v}^t \in B_0(\theta_{-t}\omega)$, where

$$B_0(\omega) = \left\{ v \in H^1(\Gamma) \,:\, \|v\|_{H^1(\Gamma)} \le \tilde{R}(\omega) \right\},$$

where $\tilde{R}(\omega)$ is a tempered random variable. Thus we have that

$$\tilde{u} \in \phi_0(t, \theta_{-t}\omega)B_0(\theta_{-t}\omega) \quad \text{for every} \quad t > 0.$$

Since $\phi_0(t, \theta_{-t}\omega)B_0(\theta_{-t}\omega) \to \mathfrak{A}^0(\omega)$ as $t \to \infty$, this implies that $\tilde{u} \in \mathfrak{A}^0(\omega)$. □

Theorem 3.1(5) follows from Theorem 7.1.

Remark 7.2. In the case (18), similarly to the deterministic case (see [12, 13]), we can prove the upper convergence of the pullback attractors $\hat{\mathfrak{A}}^\varepsilon$ to the corresponding object for the RDS generated by (19). We also refer to [6] and to the references therein for a general study of upper semicontinuity of random and nonautonomous attractors.

8. Synchronization for fixed $\varepsilon > 0$. Now we consider the case when the equations are the same in both domains; i.e., we assume that relations (14), (15), and (16) hold.

Under conditions (14) the cocycle ϕ_ε has a deterministic forward *invariant* subspace $\mathcal{L}$ in $\mathcal{H}$ consisting of functions which are independent of the variable y, i.e.,

$$\mathcal{L} = \{u(x,y) \in L_2(D) \,:\, u(x,y) \equiv u(x,0) \equiv v \in L_2(\Gamma)\}.$$

It is clear that $\phi_\varepsilon(t,\omega)\mathcal{L} \subset \mathcal{L}$ and $\phi_\varepsilon(t,\omega) \equiv \phi_0(t,\omega)$ on $\mathcal{L}$.

THEOREM 8.1. *Under conditions* (14), (15), *and* (16) *there exists* $\varepsilon_0 > 0$ *such that for all* $\varepsilon \in (0, \varepsilon_0]$ *the global random pullback attractor* $\mathfrak{A}^\varepsilon(\omega)$ *for* $(\theta, \phi_\varepsilon)$ *has the form*

$$\mathfrak{A}^\varepsilon(\omega) \equiv \widetilde{\mathfrak{A}}^0(\omega) = \left\{ J(v) \,:\, v \in \mathfrak{A}^0(\omega) \right\} \subset \mathcal{H}, \tag{63}$$

where $J : L_2(\Gamma) \mapsto L_2(D) = \mathcal{H}$ *is the natural embedding operator and* $\mathfrak{A}^0(\omega)$ *is the random pullback attractor for the RDS* (θ, ϕ_0).

Proof. Let P be the orthoprojector in $\mathcal{H}$ onto $\mathcal{L}$. This operator has the form

$$(Pu)(x,y) = \frac{1}{2}\int_{-1}^{1} u(x,\xi)d\xi, \quad u \in \mathcal{H} \sim L_2(D).$$

Let $Q = 1 - P$. Both of the operators P and Q map the domain $\mathcal{D}(A_\varepsilon)$ of the operator A_ε into itself and commute with A_ε. Therefore it follows from (30) that Qv_ε satisfies the equation

$$\frac{d}{dt}Qv_\varepsilon + A_\varepsilon Qv_\varepsilon = QB(v_\varepsilon, \theta_t\omega), \quad Qv|_{t=0} = Qv_0. \tag{64}$$

Multiplying this equation by Qv_ε we obtain

$$\frac{1}{2}\frac{d}{dt}\|Qv_\varepsilon\|^2_{\mathcal{H}} + a_\varepsilon(Qv_\varepsilon, Qv_\varepsilon)_{\mathcal{H}} = (QB(v_\varepsilon, \theta_t\omega), Qv_\varepsilon)_{\mathcal{H}}. \tag{65}$$

From (15) we have that

$$\begin{aligned}(QB(v_\varepsilon, \theta_t\omega), Qv_\varepsilon)_{\mathcal{H}} &= \int_D \left[f(v_\varepsilon(x,y)) - \frac{1}{2}\int_{-1}^1 f(v_\varepsilon(x,\xi))d\xi\right] Qv_\varepsilon(x,y)dxdy \\ &\le \frac{L}{2}\int_D \int_{-1}^1 |v_\varepsilon(x,y) - v_\varepsilon(x,\xi)|\, Qv_\varepsilon(x,y)d\xi dxdy \\ &\le \frac{L}{\sqrt{2}}\left[\int_\Gamma dx \int_{-1}^1 dy \int_{-1}^1 d\xi\, |v_\varepsilon(x,y) - v_\varepsilon(x,\xi)|^2\right]^{1/2} \|Qv_\varepsilon\|_{\mathcal{H}}.\end{aligned}$$

If we add and subtract Pv_ε in the expression under the integral, then we easily arrive at the relation

$$(QB(v_\varepsilon, \theta_t\omega), Qv_\varepsilon)_{\mathcal{H}} \le 2L\|Qv_\varepsilon\|^2_{\mathcal{H}}. \tag{66}$$

Thus from (65) we obtain that

$$\frac{1}{2}\frac{d}{dt}\|Qv_\varepsilon\|^2_{\mathcal{H}} + a_\varepsilon(Qv_\varepsilon, Qv_\varepsilon)_{\mathcal{H}} \le 2L\|Qv_\varepsilon\|^2_{\mathcal{H}}. \tag{67}$$

LEMMA 8.2. *Under conditions* (14) *and* (16) *we have that*

$$\limsup_{\varepsilon\to 0}\left\{\frac{a_\varepsilon(Qv_\varepsilon, Qv_\varepsilon)_{\mathcal{H}}}{\|Qv_\varepsilon\|^2_{\mathcal{H}}} \ : v \in \mathcal{H}^1_\varepsilon\right\} = +\infty. \tag{68}$$

Proof. Basically we use the same calculations of the spectrum of A_ε as in [11]. □

Lemma 8.2 implies that there exists $\varepsilon_0 > 0$ such that

$$\frac{d}{dt}\|Qv_\varepsilon\|^2_{\mathcal{H}} + \gamma_0\|Qv_\varepsilon\|^2_{\mathcal{H}} \le 0$$

for all $0 < \varepsilon \le \varepsilon_0$ and for some $\gamma_0 > 0$. Therefore,

$$\|Qv_\varepsilon(t)\|^2_{\mathcal{H}} \le \|Qv_\varepsilon(0)\|^2_{\mathcal{H}} e^{-\gamma_0 t}, \quad t \ge 0.$$

This implies that the subspace $\mathcal{L}$ attracts all tempered sets (in both the forward and the pullback sense) with exponential (deterministic) speed. Since $\phi_\varepsilon(t,\omega) \equiv \phi_0(t,\omega)$ on $\mathcal{L}$, this implies (63). □

Theorem 8.1 implies Theorem 3.1(6).

EFFECTIVE MACROSCOPIC DYNAMICS OF STOCHASTIC PARTIAL DIFFERENTIAL EQUATIONS IN PERFORATED DOMAINS*

WEI WANG†, DAOMIN CAO†, AND JINQIAO DUAN‡

Dedicated to Philip Holmes on the occasion of his 60th birthday

Abstract. An effective macroscopic model for a stochastic microscopic system is derived. The original microscopic system is modeled by a stochastic partial differential equation (SPDE) defined on a domain perforated with small holes or heterogeneities. The homogenized effective model is still an SPDE but defined on a unified domain without holes. The solutions of the microscopic model are shown to converge to those of the effective macroscopic model in probability distribution as the size of holes diminishes to zero. Moreover, the long time effectivity of the macroscopic system, in the sense of *convergence in probability distribution*, and the effectivity of the macroscopic system, in the sense of *convergence in energy*, are also proved.

Key words. stochastic PDEs, effective macroscopic model, stochastic homogenization, white noise, probability distribution, perforated domain

DOI. 10.1137/050648766

1. Introduction.

In recent years there has been an explosive growth of activities in multiscale modeling of complex phenomena in many areas, including material science, climate dynamics, chemistry, and biology [15, 31]. Stochastic partial differential equations (SPDEs or stochastic PDEs)—evolutionary equations containing noises—arise naturally as mathematical models of multiscale systems under random influences. In fact, the need to include stochastic effects in mathematical modeling of realistic physical phenomena has become widely recognized in, for example, condensed matter physics, climate and geophysical sciences, and materials sciences. But implementing this idea poses some challenges both in theory and in computation [17, 33].

This paper is devoted to the effective macroscopic dynamics of microscopic systems modeled by parabolic SPDEs in perforated media which exhibit small-scale heterogeneities. One example of such microscopic systems of interest is composite materials with microscopic heterogeneities under the impact of external random fluctuations. The heterogeneity scale is taken to be much smaller than the macroscopic scale, which is equivalent, here, to assuming that the heterogeneities are evenly distributed. From a mathematical point of view, one can assume that microscopic heterogeneities (holes) are periodically placed in the media. This periodicity can be represented by a small positive parameter ϵ (i.e., the period). In fact we work on the space-time cylinder $D_\epsilon \times (0,T)$, with $T > 0$, and D_ϵ is the spatial domain obtained by removing a number N_ϵ of holes, of size ϵ, periodically distributed, from a fixed

domain D. When taking $\epsilon \to 0$, the holes inside D are smaller and smaller and their numbers go to ∞. This signifies that the heterogeneities become finer and finer.

There has been much work done on the homogenization problem for the deterministic systems defined in such perforated domains or other heterogeneous media; see, for example, [6, 24, 25, 28, 29, 30] for heat transfer in a composite material, [6, 8, 11] for the wave propagation in a composite material, and [21, 23] for the fluid flow in porous media. For an introduction to homogenization, see [2, 9, 18, 27].

Recently there also has been work done on homogenization of partial differential equations (PDEs) in the random context; see [19, 22, 26] for PDEs with random coefficients, and see [5, 35, 36] for PDEs in randomly perforated domains. Also see the survey book [18] about the homogenization results in a random context. A basic assumption in these texts is the ergodic hypotheses on the coefficients for the passing of the limit of $\epsilon \to 0$. Note that the microscopic models in these works are PDEs with random coefficients, so-called random PDEs, instead of stochastic PDEs.

In the present paper, the microscopic model is an SPDE defined in a perforated domain. Homogenization techniques are employed to derive an effective, simplified, macroscopic model. Homogenization is a formal mathematic procedure for deriving macroscopic models from microscopic systems. It has been applied to a variety of problems including composite materials modeling, porous media, and climate modeling; see [9, 10, 18, 27]. Homogenization provides effective macroscopic behavior of the systems with microscopic heterogeneities for which direct numerical simulations are usually too expensive.

We consider a spatially extended system, where stochastic effects are taken into account in the model equation, defined on a deterministic domain but perforated with small scale holes. Specifically, we study a class of SPDEs driven by white noise on a perforated domain in the following form:

$$du_\epsilon(t) = (\mathcal{A}_\epsilon u_\epsilon + F_\epsilon(x,t))dt + G_\epsilon(x,t)dW(t), \quad 0 < t < T, \quad \epsilon > 0, \tag{1.1}$$

which will be described in detail in the next section. For the general theory of SPDEs we refer to [12]. The goal here is to derive the homogenized equation (effective equation), which is still an SPDE, for (1.1) by the homogenization techniques in the sense of *probability*.

Homogenization theory has been developed for deterministic systems, and a compactness discussion for the solutions $\{u_\epsilon\}_\epsilon$ in some function space is a key step in various homogenization approaches [9]. However, due to the appearance of the stochastic term in the above microscopic system considered in this paper, such compactness result does not hold for this stochastic system. Fortunately the compactness in the sense of probability, that is, the tightness of the distributions for $\{u_\epsilon\}$, still holds. So one appropriate approach is to homogenize the stochastic system in the sense of probability. The goal in this paper is to derive an effective macroscopic equation for the above microscopic system by homogenization in the sense of probability. It is shown that the solution u_ϵ of the microscopic or heterogeneous system converges to that of the macroscopic or homogenized system as $\epsilon \downarrow 0$ in probability distribution. This means that the distribution of $\{u_\epsilon\}_\epsilon$ weakly converges, in some appropriate space, to the distribution of a stochastic process which solves the macroscopic effective equation. Moreover, the long time effectivity of the homogenized macroscopic system is demonstrated; that is, the solution $u_\epsilon(t)$ is shown to converge to the stationary solution of the homogenized equation as $t \to \infty$ and $\epsilon \downarrow 0$ in the sense of probability distribution.

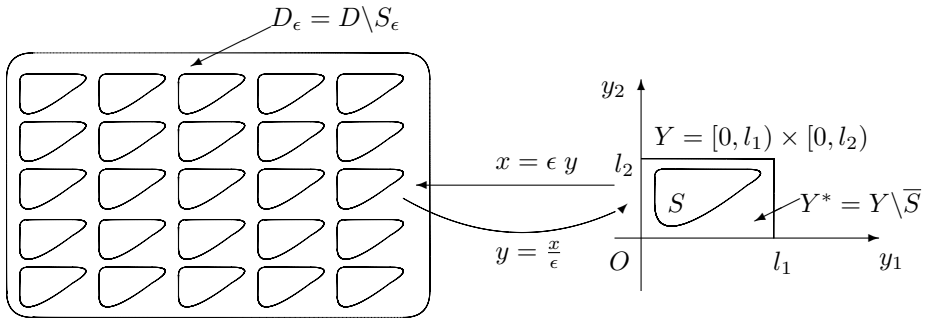

FIG. 1. *Geometric setup in* R^2.

Furthermore, the effectivity of the macroscopic system in the sense of convergence in energy is also shown.

In our approach, one difficulty is that the spatial domain is changing as $\epsilon \to 0$. To overcome this we use the extension operator introduced in [8] and introduce a new probability space depending on a parameter in which the solution is uniformly bounded. One novelty here is that the original microscopic model is a stochastic PDE, instead of a random PDE, as studied by others; see e.g., [19, 26, 7].

This paper is organized as follows. The problem formulation is stated in section 2. Section 3 is devoted to basic properties of the microscopic system. The effective macroscopic equation is derived in section 4. The long time effectivity of the homogenized macroscopic system is considered in section 6. Finally, the effectivity of the macroscopic system in the sense of convergence in energy is shown in section 5. Moreover, in the appendix we present the explicit expression of the homogenization matrix.

2. Problem formulation. Let D be an open bounded set in R^n, $n \geq 2$, with smooth boundary ∂D and $\epsilon > 0$ a small parameter. Let $Y = [0, l_1) \times [0, l_2) \times \cdots \times [0, l_n)$ be a representative (cubic) cell in R^n and S an open subset of Y with smooth boundary ∂S, such that $\overline{S} \subset Y$. Write $l = (l_1, l_2, \ldots, l_n)$. Define $\epsilon S = \{\epsilon y : y \in S\}$. Denote by $S_{\epsilon,k}$ the translated image of ϵS by kl, $k \in Z^n$, $kl = (k_1 l_1, k_2 l_2, \ldots, k_n l_n)$. Also let S_ϵ be the set of all the holes contained in D and $D_\epsilon = D\backslash S_\epsilon$. Then D_ϵ is a periodically perforated domain with holes of the same size as period ϵ. We assume that the holes do not intersect with the boundary ∂D, which implies that $\partial D_\epsilon = \partial D \cup \partial S_\epsilon$. See Figure 1 for the case $n = 2$. This assumption allows us to avoid technicalities, and the results of our paper will remain valid without this assumption; see [1].

In what follows we use the notation

$$Y^* = Y\backslash\overline{S}, \quad \vartheta = \frac{|Y^*|}{|Y|}$$

with $|Y|$ and $|Y^*|$ the Lebesgue measure of Y and Y^*, respectively. Also denote by $\tilde{v}$ the zero extension to the whole D for any function defined on D_ϵ:

$$\tilde{v} = \begin{cases} v & \text{on } D_\epsilon, \\ 0 & \text{on } S_\epsilon. \end{cases}$$

Now for $T > 0$ fixed final time, we consider the following Itô-type nonautonomous SPDE defined on the perforated domain D_ϵ in R^n:

$$du_\epsilon(x,t) = \Big(\operatorname{div}\big(A_\epsilon(x)\nabla u_\epsilon(x,t)\big) + f_\epsilon(x,t)\Big)dt + g_\epsilon(t)dW(t) \quad \text{in } D_\epsilon \times (0,T), \tag{2.1}$$

$$u_\epsilon = 0 \text{ on } \partial D \times (0,T), \tag{2.2}$$

$$\frac{\partial u_\epsilon}{\partial \nu_{A_\epsilon}} = 0 \text{ on } \partial S_\epsilon \times (0,T), \tag{2.3}$$

$$u_\epsilon(0) = u_\epsilon^0 \text{ in } D_\epsilon, \tag{2.4}$$

where the matrix A_ϵ is

$$A_\epsilon = \Big(a_{ij}\Big(\frac{x}{\epsilon}\Big)\Big)_{ij},$$

and

$$\frac{\partial \cdot}{\partial \nu_{A_\epsilon}} = \sum_{ij} a_{ij}\Big(\frac{x}{\epsilon}\Big)\frac{\partial \cdot}{\partial x_j} n_i$$

with n the exterior unit normal vector on the boundary ∂D_ϵ.

We make the following assumptions on the coefficients:

1. $a_{ij} \in L^\infty(R^n)$, $i,j = 1,\dots,n$;
2. $\sum_{i,j=1}^n a_{ij}\xi_i\xi_j \geq \alpha \sum_{i=1}^n \xi_i^2$ for $\xi \in R^n$ and α a positive constant;
3. a_{ij} are Y-periodic.

Furthermore we assume that

$$f_\epsilon \in L^2(D_\epsilon \times [0,T]), \tag{2.5}$$

and for $0 \leq t \leq T$, $g_\epsilon(t)$ is a linear operator from ℓ^2 to $L^2(D_\epsilon)$ defined as

$$g_\epsilon(t)k = \sum_{i=1}^\infty g_\epsilon^i(x,t)k_i, \quad k = (k_1,k_2,\dots) \in \ell^2,$$

where $g_\epsilon^i(x,t) \in L^2(D_\epsilon \times [0,T])$, $i = 1,2,\dots$, are measurable functions with

$$\sum_{i=1}^\infty |g_\epsilon^i(x,t)|^2_{L^2(D_\epsilon)} < C_T, \quad t \in [0,T], \tag{2.6}$$

for some positive constant C_T independent of ϵ. In (2.1), $W(t) = (W_1(t), W_2(t), \dots)$ is a Wiener process in ℓ^2 with covariance operator $Q = Id_{\ell^2}$, and $\{W_i(t) : i = 1,2,\dots\}$ are mutually independent real valued standard Wiener processes on a complete probability space $(\Omega, \mathcal{F}, \mathbf{P})$ with a canonical filtration $(\mathcal{F}_t)_{t\geq 0}$. Then

$$|g_\epsilon(t)|^2_{\mathcal{L}_2^Q} = \sum_{i=1}^\infty |g_\epsilon^i(x,t)|^2_{L^2(D_\epsilon)} < C_T, \quad t \in [0,T]. \tag{2.7}$$

Here $\mathcal{L}_2^Q$ is the space of Hilbert–Schmit operators [12, 16]. Denote by $\mathbf{E}$ the expectation operator with respect to $\mathbf{P}$.

The following compactness result [20] will be used in our approach. Let $\mathcal{X} \subset \mathcal{Y} \subset \mathcal{Z}$ be three reflective Banach spaces and $\mathcal{X} \subset \mathcal{Y}$ with compact and dense embedding. Define the Banach space as

$$G = \left\{ v : v \in L^2(0,T;\mathcal{X}), \frac{dv}{dt} \in L^2(0,T;\mathcal{Z}) \right\}$$

with norm

$$|v|_G^2 = \int_0^T |v(s)|_{\mathcal{X}}^2 ds + \int_0^T \left| \frac{dv}{ds}(s) \right|_{\mathcal{Z}}^2 ds, \quad v \in G.$$

LEMMA 2.1. *If B is bounded in G, then it is precompact in $L^2(0,T;\mathcal{Y})$.*

Let $\mathcal{S}$ be a Banach space and $\mathcal{S}'$ be the strong dual space of $\mathcal{S}$. We recall the definitions and some properties of weak convergence and weak* convergence [34].

DEFINITION 2.2. *A sequence $\{s_n\}$ in $\mathcal{S}$ is said to converge weakly to $s \in \mathcal{S}$ if $\forall s' \in \mathcal{S}'$,*

$$\lim_{n\to\infty} (s', s_n)_{\mathcal{S}',\mathcal{S}} = (s', s)_{\mathcal{S}',\mathcal{S}},$$

which is written as $s_n \rightharpoonup s$ weakly in $\mathcal{S}$. Note that (s', s) denotes the value of the continuous linear functional s' at the point s.

LEMMA 2.3 (Eberlein–Shmulyan). *Assume that $\mathcal{S}$ is reflexive and let $\{s_n\}$ be a bounded sequence in $\mathcal{S}$. Then there exists a subsequence $\{s_{nk}\}$ and $s \in \mathcal{S}$ such that $s_{nk} \rightharpoonup s$ weakly in $\mathcal{S}$ as $k \to \infty$. If all the weakly convergent subsequence of $\{s_n\}$ has the same limit s, then the whole sequence $\{s_n\}$ weakly converges to s.*

DEFINITION 2.4. *A sequence $\{s'_n\}$ in $\mathcal{S}'$ is said to converge weakly* to $s' \in \mathcal{S}'$ if $\forall s \in \mathcal{S}$,*

$$\lim_{n\to\infty} (s'_n, s)_{\mathcal{S}',\mathcal{S}} = (s', s)_{\mathcal{S}',\mathcal{S}},$$

which is written as $s'_n \rightharpoonup s'$ weakly* in $\mathcal{S}'$.

LEMMA 2.5. *Assume that the dual space $\mathcal{S}'$ is reflexive and let $\{s'_n\}$ be a bounded sequence in $\mathcal{S}'$. Then there exists a subsequence $\{s'_{nk}\}$ and $s' \in \mathcal{S}'$ such that $s'_{nk} \rightharpoonup s'$ weakly* in $\mathcal{S}'$ as $k \to \infty$. If all the weakly* convergent subsequence of $\{s'_n\}$ has the same limit s', then the whole sequence $\{s'_n\}$ weakly* converges to s'.*

We also use the following definition of the weak convergence of the Borel probability measures on $\mathcal{S}$; for more details we refer to [14].

DEFINITION 2.6. *Let $\{\mu_\epsilon\}_\epsilon$ be a family of Borel probability measures on the Banach space $\mathcal{S}$. We say μ_ϵ weakly converges to a Borel measure μ on $\mathcal{S}$ if*

$$\int_{\mathcal{S}} h d\mu_\epsilon \to \int_{\mathcal{S}} h d\mu \ \text{ as } \ \epsilon \downarrow 0$$

for any $h \in C_b(\mathcal{S})$, the space of bounded continuous functions on $\mathcal{S}$.

In the following, for a fixed $T > 0$, we always denote by C_T a constant independent of ϵ.

3. Basic properties of the microscopic model. In this section we will present some estimates of the solutions of microscopic model (2.1), useful for the tightness result of the distributions of solution processes in some appropriate space.

Let $H = L^2(D)$ and $H_\epsilon = L^2(D_\epsilon)$. Define the space

$$V_\epsilon = \{u \in H^1(D_\epsilon), u|_{\partial D} = 0\}$$

provided with the norm

$$|v|_{V_\epsilon} = |\nabla_{A_\epsilon} v|_{\oplus_n H_\epsilon} = \left| \left(\sum_{j=1}^n a_{ij}\Big(\frac{x}{\epsilon}\Big) \frac{\partial v}{\partial x_j} \right)_{i=1}^n \right|_{\oplus_n H_\epsilon}.$$

This norm is equivalent to the usual $H^1(D_\epsilon)$-norm, with an embedding constant independent of ϵ, due to the assumptions on a_{ij} in the last section. Here $\oplus_n$ denotes the direct sum of the Hilbert spaces with a usual direct sum norm. Let

$$\mathcal{D}(\mathcal{A}_\epsilon) = \left\{ v \in V_\epsilon : \operatorname{div}(A_\epsilon \nabla v) \in H_\epsilon \text{ and } \left.\frac{\partial v}{\partial \nu_{A_\epsilon}}\right|_{\partial S_\epsilon} = 0 \right\}$$

and define operator $\mathcal{A}_\epsilon v = \operatorname{div}(A_\epsilon \nabla v)$ for $v \in \mathcal{D}(\mathcal{A}_\epsilon)$. Then system (2.1)–(2.4) can be written as the following abstract stochastic evolutionary equation:

$$du_\epsilon = (\mathcal{A}_\epsilon u_\epsilon + f_\epsilon)dt + g_\epsilon dW, \quad u_\epsilon(0) = u_\epsilon^0. \tag{3.1}$$

By the assumptions on a_{ij}, operator $\mathcal{A}_\epsilon$ generates a strongly continuous semigroup $S_\epsilon(t)$ on H_ϵ. The solution of (3.1) can then be written in the mild sense as

$$u_\epsilon(t) = S_\epsilon(t)u_\epsilon^0 + \int_0^t S_\epsilon(t-s)f_\epsilon(s)ds + \int_0^t S_\epsilon(t-s)g_\epsilon(s)dW(s). \tag{3.2}$$

The variational formulation is

$$\begin{aligned} \big(du_\epsilon(t), v\big)_{H_\epsilon^{-1}, V_\epsilon} &= \left(-\int_{D_\epsilon} A_\epsilon(x)\nabla u_\epsilon(x,t)\nabla v(x)dx + \int_{D_\epsilon} f_\epsilon(x,t)v(x)dx \right) dt \\ &\quad + \int_{D_\epsilon} g_\epsilon(x,t)v(x)dW(t), \quad \text{in } \mathcal{D}'(0,T), \quad v \in V_\epsilon, \end{aligned} \tag{3.3}$$

with $u_\epsilon(0,x) = u_\epsilon^0(x)$.

For the well-posedness of system (3.1) we have the following result.

THEOREM 3.1 (global well-posedness of the microscopic model). *Assume that* (2.5) *and* (2.7) *hold. Let* u_ϵ^0 *be an* $\big(\mathcal{F}_0, \mathcal{B}(H_\epsilon)\big)$*-measurable random variable. Then system* (3.1) *has a unique mild solution* $u \in L^2\big(\Omega, C(0,T;H_\epsilon) \cap L^2(0,T;V_\epsilon)\big)$*, which is also a weak solution in the following sense:*

$$\begin{aligned} &(u_\epsilon(t), v)_{H_\epsilon} \\ &= (u_\epsilon^0, v)_{H_\epsilon} + \int_0^t (\mathcal{A}_\epsilon u_\epsilon(s), v)_{H_\epsilon} ds + \int_0^t (f_\epsilon, v)_{H_\epsilon} ds + \int_0^t (g_\epsilon dW, v)_{H_\epsilon} \end{aligned} \tag{3.4}$$

for $t \in [0,T)$ *and* $v \in V_\epsilon$*. Moreover, if* u_ϵ^0 *is independent of* $W(t)$ *with* $\mathbf{E}|u_\epsilon^0|_{H_\epsilon}^2, < \infty$*, then*

$$\mathbf{E}|u_\epsilon(t)|_{H_\epsilon}^2 + \mathbf{E}\int_0^t |u_\epsilon(s)|_{V_\epsilon}^2 ds \le \mathbf{E}|u_\epsilon^0|_{H_\epsilon}^2 + C_T \quad \textit{for } t \in [0,T], \tag{3.5}$$

and

$$\mathbf{E}\int_0^t |\dot{u}_\epsilon(s)|^2_{H_\epsilon^{-1}} ds \le C_T(\mathbf{E}|u_\epsilon^0|^2_{H_\epsilon} + 1) \ \textit{for} \ t \in [0,T]. \tag{3.6}$$

If we further assume that

$$|\nabla_{A_\epsilon} g_\epsilon(t)|^2_{\mathcal{L}_2^Q} = \sum_{i=1}^{\infty} |\nabla_{A_\epsilon} g_\epsilon^i(t)|^2_{\oplus_n H_\epsilon} \le C_T, \ \ \textit{for}\, t \in [0,T] \tag{3.7}$$

and $u_\epsilon^0 \in V_\epsilon$ *with* $\mathbf{E}|u_\epsilon^0|^2_{V_\epsilon} < \infty$, *then*

$$\mathbf{E}|u_\epsilon(t)|^2_{V_\epsilon} + \mathbf{E}\int_0^t |\mathcal{A}_\epsilon u_\epsilon(s)|^2_{H_\epsilon} ds \le \mathbf{E}|u_\epsilon^0|^2_{V_\epsilon} + C_T \ \ \textit{for} \ t \in [0,T]. \tag{3.8}$$

Moreover, system (3.1) *is well-posed on* $[0,\infty)$ *when*

$$f_\epsilon \in L^2(0,\infty; H_\epsilon), \ \ g_\epsilon \in L^2(0,\infty; \mathcal{L}_2^Q). \tag{3.9}$$

Proof. By assumption (2.7), we have

$$|g_\epsilon(t)|^2_{\mathcal{L}_2^Q} = \sum_{i=1}^{\infty} |g_\epsilon^i(t,x)|^2_{H_\epsilon} < \infty.$$

Then the classical result of [12] yields the local existence of u_ϵ. Applying the stochastic Fubini theorem, it is easy to verify that the local mild solution is also a weak solution.

Now we give the following a priori estimate which yields the existence of a weak solution on $[0,T]$, provided (2.5) and (2.7) hold.

Applying the Itô formula to $|u_\epsilon|^2$, we obtain

$$d|u_\epsilon(t)|^2_{H_\epsilon} - 2(\mathcal{A}_\epsilon u_\epsilon, u_\epsilon)_{H_\epsilon} dt = 2(f_\epsilon, u_\epsilon)_{H_\epsilon} dt + 2(g_\epsilon dW, u_\epsilon)_{H_\epsilon} + |g_\epsilon|^2_{\mathcal{L}_2^Q} dt. \tag{3.10}$$

By the assumption on a_{ij}, we see that

$$-(\mathcal{A}_\epsilon u_\epsilon, u_\epsilon)_{H_\epsilon} \ge \lambda |u_\epsilon|^2_{H_\epsilon}$$

for some constant $\lambda > 0$ independent of ϵ. Then integrating (3.10) with respect to t yields

$$\begin{aligned} &|u_\epsilon(t)|^2_{H_\epsilon} + \int_0^t |u_\epsilon|^2_{V_\epsilon} ds \\ &\quad \le |u_\epsilon^0|^2_{H_\epsilon} + \lambda^{-1}|f_\epsilon|^2_{L^2(0,T;H_\epsilon)} + \int_0^t (g_\epsilon dW, u_\epsilon)_{H_\epsilon} ds + \int_0^t |g_\epsilon|^2_{\mathcal{L}_2^Q} ds. \end{aligned}$$

Taking expectation on both sides of the above inequality, we derive (3.5).

In a similar way, application of the Itô formula to $|u_\epsilon|^2_{V_\epsilon} = |\nabla_{A_\epsilon} u_\epsilon|^2_{\oplus_n H_\epsilon}$ results in the relation

$$\begin{aligned} &d|u_\epsilon(t)|^2_{V_\epsilon} + 2(\mathcal{A}_\epsilon u_\epsilon, \mathcal{A}_\epsilon u_\epsilon)_{H_\epsilon} dt \\ &\qquad = -2(f_\epsilon, \mathcal{A}_\epsilon u_\epsilon)_{H_\epsilon} dt - 2(g_\epsilon dW, \mathcal{A}_\epsilon u_\epsilon)_{H_\epsilon} + |\nabla_{A_\epsilon} g_\epsilon|^2_{\mathcal{L}_2^Q} dt. \end{aligned} \tag{3.11}$$

Integrating both sides of (3.11), and by the Cauchy–Schwarz inequality, it is easily to obtain

$$|u_\epsilon(t)|^2_{V_\epsilon} + \int_0^t |\mathcal{A}_\epsilon u_\epsilon|^2_{H_\epsilon} ds \\ \leq |u_\epsilon(0)|^2_{V_\epsilon} + |f_\epsilon|^2_{L^2(0,T;H_\epsilon)} - 2\int_0^t (g_\epsilon dW, \mathcal{A}_\epsilon u_\epsilon)_{H_\epsilon} ds + \int_0^t |\nabla_{A_\epsilon} g_\epsilon|^2_{\mathcal{L}_2^Q} ds,$$

Then taking the expectation, we derive (3.8). By (3.3) and the property of the stochastic integral we easily have (3.6).

Thus, by the above estimates, the solution can be extended to $[0, \infty)$ if (3.9) holds. The proof is complete. □

We recall a probability concept. Let z be a random variable taking values in a Banach space $\mathcal{S}$, namely, $z: \Omega \to z$. Denote by $\mathcal{L}(z)$ the distribution (or law) of z. In fact, $\mathcal{L}(z)$ is a Borel probability measure on $\mathcal{S}$ defined as [12]

$$\mathcal{L}(z)(A) = \mathbf{P}\{\omega : z(\omega) \in A\},$$

for every event (i.e., a Borel set) A in the Borel σ-algebra $\mathcal{B}(\mathcal{S})$, which is the smallest σ-algebra containing all open balls in $\mathcal{S}$.

As stated in section 1, for the SPDE (2.1) we aim at deriving an effective equation in the sense of probability. A solution u_ϵ may be regarded as a random variable taking values in $L^2(0,T;H_\epsilon)$. So for a solution u_ϵ of (2.1)–(2.4) defined on $[0,T]$, we focus on the behavior of the distribution of u_ϵ in $L^2(0,T;H_\epsilon)$ as $\epsilon \to 0$. For this purpose, the tightness [14] of distributions is needed. Note that the function space changes with ϵ, which is a difficulty in obtaining the tightness of distributions. Thus, we will treat $\{\mathcal{L}(u_\epsilon)\}_{\epsilon>0}$ as a family of distributions on $L^2(0,T;H)$ by extending u_ϵ to the whole domain D. Recall that the distribution (or law) of u_ϵ is defined as

$$\mathcal{L}(u_\epsilon)(A) = \mathbf{P}\{\omega : u_\epsilon(\cdot,\cdot,\omega) \in A\}$$

for Borel set A in $L^2(0,T;H_\epsilon)$. First, we define an extension operator P_ϵ in the following lemmas.

In the following we denote by $\mathbf{L}(\mathcal{X},\mathcal{Y})$ the space of a bounded linear operator from Banach space $\mathcal{X}$ to Banach space $\mathcal{Y}$.

LEMMA 3.2. *There exists a bounded linear operator*

$$\hat{Q} \in \mathbf{L}(H^k(Y^*), H^k(Y)), \quad k = 0, 1,$$

such that

$$|\nabla \hat{Q} v|_{\oplus_n L^2(Y)} \leq C |\nabla v|_{\oplus_n L^2(Y^*)}, \quad v \in H^1(Y^*),$$

for some constant $C > 0$.

For the proof of Lemma 3.2 see [8].

In the following lemma we define an extension operator P_ϵ in terms of the above bounded linear operator $\hat{Q}$.

LEMMA 3.3. *There exists an extension operator*

$$P_\epsilon \in \mathbf{L}\big(L^2(0,T;H^k(D_\epsilon)), L^2(0,T;H^k(D))\big), \quad k = 0, 1,$$

such that for any $v \in H^k(D_\epsilon)$,

(1) $P_\epsilon v = v$ *on* $D_\epsilon \times (0,T)$,
(2) $|P_\epsilon v|_{L^2(0,T;H)} \le C_T |v|_{L^2(0,T;H_\epsilon)}$,
(3) $|\nabla_{A_\epsilon}(P_\epsilon v)|_{L^2(0,T;\oplus_n L^2(D))} \le C_T |\nabla_{A_\epsilon} v|_{L^2(0,T;\oplus_n L^2(D_\epsilon))}$,
where C_T *is a constant independent of* ϵ.

Proof. If $\varphi \in H^k(D_\epsilon)$, then

$$\varphi_\epsilon(y) = \frac{1}{\epsilon}\varphi(\epsilon\, y)$$

belongs to $H^k(Y_l^*)$ with Y_l^* the translation of Y^* for some $l \in R^n$. Define

$$\hat{Q}_\epsilon \varphi(x) = \epsilon(\hat{Q}\varphi_\epsilon)\left(\frac{x}{\epsilon}\right). \tag{3.12}$$

Now for $\varphi \in L^2(0,T;H^k(D_\epsilon))$, we define

$$(P_\epsilon\varphi)(x,t) = [\hat{Q}_\epsilon\varphi(t,\cdot)]\Big(\frac{x}{\epsilon}\Big) = \epsilon[\hat{Q}\varphi_\epsilon(t,\cdot)]\Big(\frac{x}{\epsilon}\Big).$$

It is known [8] that the operator $P_\epsilon \in \mathbf{L}\big(L^2(0,T;H^k(D_\epsilon)), L^2(0,T;H^k(D))\big)$, $k = 0,1$, and satisfies conditions (1)–(3) listed in the lemma. This completes the proof. ∎

Remark 3.4. In Lemma 2.1 of [8], the operator P_ϵ defined in $\mathbf{L}(L^\infty(0,T;H^k(D_\epsilon)), L^\infty(0,T;H^k(D)))$, $k = 0,1$, coincides with the operator defined in Lemma 3.3 above.

Remark 3.5. The estimates in Theorem 3.1 for u_ϵ also hold for $P_\epsilon u_\epsilon$. In fact estimates (3.5) and (3.8) are easily derived due to the property of the operator of P_ϵ. Since the operator P_ϵ is defined on $L^2(0,T;H^k(D_\epsilon)$, $k = 0,1$, we define

$$P_\epsilon \dot{u}_\epsilon \equiv \mathcal{A}_\epsilon P_\epsilon u_\epsilon + \tilde{f}_\epsilon + \tilde{g}_\epsilon \dot{W} \ \text{ on } D \times (0,T).$$

By the property of P_ϵ and the estimates of u_ϵ, it is easy to see that

$$P_\epsilon \dot{u}_\epsilon = (\dot{P_\epsilon u_\epsilon}) \ \text{ in } D_\epsilon \times (0,T)$$

and

$$\mathbf{E}|P_\epsilon \dot{u}_\epsilon|_{L^2(0,T;H^{-1})} \le \mathbf{E}|\dot{u}_\epsilon|_{L^2(0,T;H_\epsilon^{-1})}.$$

4. Effective macroscopic model. We now derive the effective macroscopic model for the original model (2.1). Let $u_\epsilon \in L^2(0,T;H_\epsilon)$ be the solution of system (2.1)–(2.4). Then by the estimates in Theorem 3.1, Remark 3.5, and the Chebyshev inequality [12, 14], it is clear that for any $\delta > 0$ there is a bounded set $K_\delta \subset G$ with the spaces $\mathcal{X}$, $\mathcal{Y}$, and $\mathcal{Z}$ in Lemma 2.1 (and in the paragraph immediately before it) replaced by $H_0^1(D)$, H, and $H^{-1}(D)$, respectively, such that

$$\mathbf{P}\{P_\epsilon u_\epsilon \in K_\delta\} > 1 - \delta.$$

Thus, K_δ is compact in $L^2(0,T;H)$ by Lemma 2.1. Then $\{\mathcal{L}(P_\epsilon u_\epsilon)\}_\epsilon$ is tight in $L^2(0,T;H)$. The Prokhorov theorem and the Skorohod embedding theorem [12] assure that for any sequence $\{\epsilon_j\}$ with $\epsilon_j \to 0$ as $j \to \infty$, there exists a subsequence $\{\epsilon_{j(k)}\}$, random variables $\{\hat{u}_{\epsilon_{j(k)}}\} \subset L^2(0,T;H_{\epsilon_{j(k)}})$ and $u \in L^2(0,T;H)$ defined on a new probability space $(\widehat{\Omega}, \widehat{\mathcal{F}}, \widehat{\mathbf{P}})$, such that

$$\mathcal{L}(P_{\epsilon_{j(k)}}\hat{u}_{\epsilon_{j(k)}}) = \mathcal{L}(P_{\epsilon_{j(k)}} u_{\epsilon_{j(k)}})$$

and

$$P_{\epsilon_{j(k)}}\hat{u}_{\epsilon_{j(k)}} \to u \ \text{ in } \ L^2(0,T;H) \ \text{ as } \ k \to \infty,$$

for almost all $\omega \in \widehat{\Omega}$. Moreover, $P_{\epsilon_{j(k)}}\hat{u}_{\epsilon_{j(k)}}$ solves system (2.1)–(2.4) with W replaced by Wiener process $\widehat{W}_k$ defined on the probability space $(\widehat{\Omega}, \widehat{\mathcal{F}}, \widehat{\mathbf{P}})$ with the same distribution as W. The limit u is unique; see [4, p. 333]. In the following, we will determine the limiting equation (homogenized effective equation) that u satisfies and see that the limiting equation is independent of ϵ. After this is done we see that $\mathcal{L}(u_\epsilon)$ weakly converges to $\mathcal{L}(u)$ as $\epsilon \downarrow 0$.

We always assume the following conditions

$$\tilde{f}_\epsilon \rightharpoonup f \ \text{ weakly in } \ L^2(0,T;H) \text{ as } \epsilon \to 0, \tag{4.1}$$

and

$$\tilde{g}^i_\epsilon \rightharpoonup g^i \ \text{ weakly in } \ L^2(0,T;H) \text{ as } \epsilon \to 0. \tag{4.2}$$

Define a new probability space $(\Omega_\delta, \mathcal{F}_\delta, \mathbf{P}_\delta)$ as

$$\Omega_\delta = \{\omega \in \Omega : u_\epsilon(\omega) \in K_\delta\},$$

$$\mathcal{F}_\delta = \{F \cap \Omega_\delta : F \in \mathcal{F}\},$$

and

$$\mathbf{P}_\delta(F) = \frac{\mathbf{P}(F \cap \Omega_\delta)}{\mathbf{P}(\Omega_\delta)} \ \text{ for } \ F \in \mathcal{F}_\delta.$$

Denote by $\mathbf{E}_\delta$ the expectation operator with respect to $\mathbf{P}_\delta$.

Now we restrict the system on the probability space $(\Omega_\delta, \mathcal{F}_\delta, \mathbf{P}_\delta)$. In the following discussion we aim at obtaining $L^2(\Omega_\delta)$ convergence for any $\delta > 0$, which means the convergence in probability [3, 14].

From the estimates (3.5), (3.6), Remark 3.5, and the compact embedding of $G \hookrightarrow L^2(0,T;H)$, there exists a subsequence of u_ϵ in K_δ, still denoted by u_ϵ, such that for a fixed $\omega \in \Omega_\delta$,

$$P_\epsilon u_\epsilon \rightharpoonup u \ \text{ weakly}^* \text{ in } \ L^\infty(0,T;H), \tag{4.3}$$

$$P_\epsilon u_\epsilon \rightharpoonup u \ \text{ weakly in } \ L^2(0,T;H^1), \tag{4.4}$$

$$P_\epsilon u_\epsilon \to u \ \text{ strongly in } \ L^2(0,T;H), \tag{4.5}$$

$$P_\epsilon \dot{u}_\epsilon \rightharpoonup \dot{u} \ \text{ weakly in } \ L^2(0,T;H^{-1}). \tag{4.6}$$

Define

$$\xi_\epsilon = \left(\sum_{j=1}^n a_{ij}\Big(\frac{x}{\epsilon}\Big)\frac{\partial u_\epsilon}{\partial x_j}\right) = A_\epsilon \nabla u_\epsilon$$

which satisfies

$$-\text{div } \xi_\epsilon = f_\epsilon + g_\epsilon \dot{W} - \dot{u}_\epsilon \ \ in \ \ D_\epsilon \times (0,T), \tag{4.7}$$

$$\xi_\epsilon \cdot n = 0 \ \text{ on } \ \partial S_\epsilon \times (0,T). \tag{4.8}$$

By the hypothesis of a_{ij} and the fact that $(\tilde{u}_\epsilon)_\epsilon$ is bounded in $L^2(0,T;H_0^1)$, we have

$$\tilde{\xi}_\epsilon \rightharpoonup \xi \ \text{ weakly in } \ L^2(0,T;\oplus_n H). \tag{4.9}$$

We make use of Tartar's method of oscillating test functions to determine the limiting equation [9].

Note that

$$\begin{aligned}\int_0^T\int_D \tilde{\xi}_\epsilon\cdot\nabla v\varphi dxdt &= \int_0^T\int_D \tilde{f}_\epsilon v\varphi dxdt + \sum_{i=1}^\infty \int_0^T\int_D \tilde{g}_\epsilon^i v dx\varphi dW_i(t)\\ &\quad + \int_0^T\int_D P_\epsilon u_\epsilon \chi D_\epsilon \dot{\varphi} v dxdt\end{aligned} \tag{4.10}$$

$\forall\ v\in H_0^1(D)$ and $\varphi\in\mathcal{D}(0,T)$. We pass to the limit in (4.10) as $\epsilon\to 0$. Due to the facts

$$P_\epsilon u_\epsilon \to u \ \text{ strongly in } \ L^2(0,T;H), \tag{4.11}$$

$$\chi_{D_\epsilon} \rightharpoonup \vartheta \ \text{ weakly}^* \ \text{ in } \ L^\infty(D), \tag{4.12}$$

and the estimate

$$\mathbf{E}\Big|\sum_{i=1}^\infty \int_0^T\int_D \tilde{g}_\epsilon^i v dx\varphi dW_i(t)\Big|^2 \le \sum_{i=1}^\infty |\tilde{g}_\epsilon^i|^2_{L^2(0,T;H)} |v\varphi|^2_{L^2(0,T;H)},$$

by assumption (4.2) we see that

$$\sum_{i=1}^\infty \int_0^T\int_D \tilde{g}_\epsilon^i v dx\varphi dW_i(t) \to \sum_{i=1}^\infty \int_0^T\int_D g^i v dx\varphi dW_i(t), \ \text{ in } \ L^2(\Omega).$$

Thus, letting $\epsilon\to 0$ in (4.10), and since $L^2(\Omega_\delta)$ is a subspace of $L^2(\Omega)$, one finds that in $L^2(\Omega_\delta)$

$$\begin{aligned}\int_0^T\int_D \xi\cdot\nabla v\varphi dxdt &= \int_0^T\int_D f v\varphi dxdt + \sum_{i=1}^\infty \int_0^T\int_D g^i v dx\varphi dW_i(t)\\ &\quad + \int_0^T\int_D \vartheta u\dot{\varphi} v dxdt.\end{aligned} \tag{4.13}$$

Hence

$$-\text{div}\ \xi(x,t) = f(x,t) + g(x,t)\dot{W} - \vartheta\dot{u} \ \text{ in } \ D\times(0,T). \tag{4.14}$$

In the following we identify the limit ξ. We follow the approach of the deterministic case for the elliptic problem with homogeneous Neumann boundary condition [9].

For any $\lambda\in R^n$, let w_λ be the solution of

$$-\sum_{j=1}^n \frac{\partial}{\partial y_j}\left(\sum_{i=1}^n a_{ij}(y)\frac{\partial w_\lambda}{\partial y_i}\right) = 0 \ \text{ in } \ Y^*, \tag{4.15}$$

$$w_\lambda - \lambda\cdot y \quad \text{is } \ Y\text{-periodic}, \tag{4.16}$$

$$\frac{\partial w_\lambda}{\partial \nu_A} = 0 \ \text{ on } \ \partial S, \tag{4.17}$$

and define

$$w_\lambda^\epsilon = \epsilon(\hat{Q}w_\lambda)\Big(\frac{x}{\epsilon}\Big),$$

where $\hat{Q}$ is as in Lemma 3.2. Then we have [9]

$$w_\lambda^\epsilon \rightharpoonup \lambda \cdot x \ \text{ weakly in } \ H^1(D), \tag{4.18}$$

$$\nabla w_\lambda^\epsilon \rightharpoonup \lambda \ \text{ weakly in } \ \oplus_n L^2(D). \tag{4.19}$$

Now we define

$$(\eta_j^\lambda(y))_j = \left(\sum_{i=1}^n a_{ji}(y)\frac{\partial w_\lambda(y)}{\partial y_i}\right)_j, \ \ y \in Y^*,$$

and $(\eta_\epsilon^\lambda)(x) = (\eta_j^\lambda(x/\epsilon))_j = A_\epsilon^t \nabla w_\lambda^\epsilon$. Then

$$-\text{div}\, \tilde{\eta}_\epsilon^\lambda = 0 \ \text{ in } \ D, \tag{4.20}$$

and due to (4.18) and (4.19)

$$\tilde{\eta}_\epsilon^\lambda \rightharpoonup \mathcal{M}_Y(\eta^\lambda) \ \text{ weakly in } \ L^2(D). \tag{4.21}$$

It is easy to see that $\mathcal{M}_Y(\eta^\lambda) = B^t\lambda$ with $B^t = (\beta_{ji})$ a constant matrix, which is determined in the appendix.

Using test function $\varphi v w_\lambda^\epsilon$ with $\varphi \in \mathcal{D}(0,T)$, $v \in \mathcal{D}(D)$ in (4.10) and multiplying both sides of (4.20) with $\varphi v P_\epsilon u_\epsilon$, we thus obtain

$$\begin{aligned}
&\int_0^T\int_D \tilde{\xi}_\epsilon \cdot \nabla v\varphi w_\lambda^\epsilon dxdt + \int_0^T\int_{D_\epsilon} \xi_\epsilon \cdot \nabla w_\lambda^\epsilon v\varphi dxdt \\
&- \int_0^T\int_D \tilde{\eta}_\epsilon^\lambda \cdot \nabla v\varphi P_\epsilon u_\epsilon dxdt - \int_0^T\int_D \tilde{\eta}_\epsilon^\lambda \cdot \nabla(P_\epsilon u_\epsilon) v\varphi dxdt \\
&= \int_0^T\int_D \tilde{f}_\epsilon \varphi v w_\lambda^\epsilon dxdt + \sum_{i=1}^\infty \int_0^T\int_D \tilde{g}_\epsilon^i v w_\lambda^\epsilon dx\varphi dW_i(t) + \int_0^T\int_D P_\epsilon u_\epsilon \chi_{D_\epsilon}\dot{\varphi} v w_\lambda^\epsilon dxdt.
\end{aligned}$$

Then by the definition of ξ_ϵ, η_ϵ^λ and assumptions (4.1), (4.2), using the convergences (4.9), (4.11), (4.12), (4.18), (4.19) and (4.21), we have in $L^2(\Omega_\delta)$

$$\begin{aligned}
&\int_0^T\int_D \xi \cdot \nabla v\varphi\lambda \cdot x dxdt - \int_0^T\int_D B^t\lambda \cdot \nabla v\varphi u dxdt \\
&\quad = \int_0^T\int_D f\varphi v\lambda \cdot x dxdt + \sum_{i=1}^\infty \int_0^T\int_D g^i v\lambda \cdot x dx\varphi dW_i(t) + \int_0^T\int_D \vartheta u v\dot{\varphi}\lambda \cdot x dxdt.
\end{aligned}$$

That is,

$$\begin{aligned}
&\int_0^T\int_D \xi \cdot \nabla(v\lambda \cdot x)\varphi dxdt - \int_0^T\int_D \xi \cdot \lambda v\varphi dxdt - \int_0^T\int_D B^t\lambda \cdot \nabla v\varphi u dxdt \\
&\quad = \int_0^T\int_D f\varphi v\lambda \cdot x dxdt + \sum_{i=1}^\infty \int_0^T\int_D g^i v\lambda \cdot x dx\varphi dW_i(t) + \int_0^T\int_D \vartheta u v\dot{\varphi}\lambda \cdot x dxdt.
\end{aligned}$$

Then by using (4.13) with the test function replaced by $v\lambda \cdot x\varphi$, one has

$$\int_0^T \int_D \xi \cdot \lambda v\varphi dxdt = \int_0^T \int_D B^t\lambda \cdot \nabla u\varphi v dxdt,$$

which yields

$$\xi \cdot \lambda = B^t\lambda \cdot \nabla u = B\nabla u \cdot \lambda.$$

Then

$$\xi = B\nabla u$$

since λ is arbitrary. Then u satisfies the equation

$$\vartheta du = \big(\mathrm{div}(B\nabla u) + f\big)dt + gdW(t). \tag{4.22}$$

Assume that

$$\tilde{u}_\epsilon^0 \rightharpoonup u^0, \text{ weakly in } H \text{ as } \epsilon \to 0. \tag{4.23}$$

We now determine the initial value by suitable test functions. In fact, taking $v \in \mathcal{D}(D)$ and $\varphi \in \mathcal{D}([0,T])$ with $\varphi(T) = 0$, we have

$$\begin{aligned}\int_0^T \int_D \tilde{\xi}_\epsilon \cdot \nabla v\varphi dxdt = &\int_0^T \int_D \tilde{f}_\epsilon v\varphi dxdt + \sum_{i=0}^{\infty} \int_0^T \int_D \tilde{g}\epsilon^i v dx\varphi dW_i(t)\\ &- \int_0^T \int_D \tilde{u}_\epsilon v\dot{\varphi} dxdt + \int_D \tilde{u}_\epsilon^0 \varphi(0) v dx.\end{aligned}$$

Now let $\epsilon \to 0$. Noticing that

$$\begin{aligned}\int_0^T \int_D \tilde{u}_\epsilon v\dot{\varphi} dxdt &= \int_0^T \int_D \chi_{D\epsilon} P_\epsilon \tilde{u}_\epsilon v\dot{\varphi} dxdt \to \int_0^T \int_D \vartheta u v\dot{\varphi} dxdt\\ &= -\int_0^T \int_D \vartheta \dot{u} v\varphi dxdt + \int_D \vartheta u(0)\varphi(0) v dx\end{aligned}$$

by (4.14), we have

$$u(0) = \frac{u^0}{\vartheta}.$$

Here one should notice that the above result is in the sense of $L^2(\Omega_\delta)$. Then the above analysis yields

$$\lim_{\epsilon \to 0} \mathbf{E}_\delta |P_\epsilon u_\epsilon - u|^2_{L^2(0,T;H)} = 0 \tag{4.24}$$

and

$$\lim_{\epsilon \to 0} \mathbf{E}_\delta \int_0^T \int_D (\mathcal{A}_\epsilon P_\epsilon u_\epsilon - B\nabla u) v\varphi dxdt = 0 \tag{4.25}$$

for any $v \in \mathcal{D}(D)$ and $\varphi \in \mathcal{D}([0,T])$.

Now we are in the position to present the homogenized effective equation in the following theorem.

THEOREM 4.1 (effective macroscopic model). *For any $T > 0$, assume that* (4.1), (4.2), *and* (4.23) *hold. Let u_ϵ be the solution of* (2.1)–(2.4). *Then the distribution $\mathcal{L}(P_\epsilon u_\epsilon)$ converges weakly to μ in the space of probability measures on $L^2(0,T;H)$ as $\epsilon \downarrow 0$, with μ being the distribution of u, which is the solution of the following homogenized effective SPDE*

$$\vartheta du = \big(\operatorname{div}(B\nabla u) + f\big)dt + gdW(t) \quad \text{in } D \times (0,T), \tag{4.26}$$

$$u = 0 \text{ on } \partial D \times (0,T), \tag{4.27}$$

$$u(x,0) = \frac{u^0}{\vartheta} \quad \text{in } D, \tag{4.28}$$

where the constant coefficient $\vartheta = \frac{|Y^*|}{|Y|}$ is defined in the beginning of section 2, *and the effective matrix $B = (\beta_{ij})$ is determined by* (7.4) *in the appendix at the end of this paper. Moreover, the coefficients f, g and initial datum u^0 are defined in* (4.1), (4.2), *and* (4.23), *respectively.*

Remark 4.2. This theorem implies that the macroscopic model (4.26) is an effective approximation for the microscopic model (2.1), on any finite time interval $0 < t < T$, in the sense of probability distribution. In other words, if we intend to numerically simulate the microscopic model up to finite time, we could use the macroscopic model as an approximation when ϵ is sufficiently small.

Remark 4.3. Due to the appearance of the stochastic integral term (see (4.10)), this theorem on weak convergence of probability measures does not follow from the deterministic homogenization results and the mild formulation (3.2).

Remark 4.4. The SPDE (4.26) is defined on the homogenized domain D. By the analysis in [12], for any fixed $T > 0$, the macroscopic system (4.26)–(4.28) is well-posed, as long as $f \in L^2(0,T;H)$ and $g \in L^2(0,T;\mathcal{L}_2^Q)$.

Proof of Theorem 4.1. Noticing the arbitrariness of δ, we see that this is a direct result of the analysis of the first part in this section by the Skorohod theorem and the $L^2(\Omega_\delta)$ convergence of $P_\epsilon u_\epsilon$ on $(\Omega_\delta, \mathcal{F}_\delta, \mathbf{P}_\delta)$. □

We finish this section with the following remark.

Remark 4.5. Note that there are several papers on effective dynamics for PDEs with random coefficients (so-called random PDEs, not stochastic PDEs); see [19, 26, 32] and references therein. In [19, 26], a random PDE is obtained as the homogenized effective equation for a random system with fast or small scales on its time or spatial variable. The distribution of the solution of the heterogeneous system converges weakly to that of the homogenized equation. However, in [32], the effective equation is obtained as an averaged deterministic equation for a random system with fast scales in time. The fluctuation of the solution of the random equation around the solution of the averaged equation converges to a generalized Ornstein–Uhlenbeck process in distribution. In the present paper, the original microscopic model is an SPDE (i.e., PDE with white noise) and the effective macroscopic equation is still an SPDE.

5. Long time effectivity of the macroscopic model. In this section we consider the long time effectivity of the homogenized system (4.26) in the autonomous case, i.e., when f_ϵ and g_ϵ (and thus f and g) are independent of time t. It is proved in section 4 that for fixed $T > 0$ the macroscopic behavior of the microscopic system (2.1)–(2.4) can be approximated by the macroscopic model (4.26) in the sense of probability distribution. In fact we can show the long time approximation. More

specifically, we now prove that in the sense of distribution, all solutions of (2.1)–(2.4) converge to the unique stationary solution of (4.26) as $T \to \infty$ and $\epsilon \to 0$, under the assumption that $f_\epsilon \in H_\epsilon$ and $g_\epsilon^i \in V_\epsilon$ are *independent* of time t and

$$\sum_{i=1}^{\infty} |\nabla_{A_\epsilon} g_\epsilon^i(x)|^2_{\oplus_n H_\epsilon} < C^*. \tag{5.1}$$

Here C^* is a positive constant independent of ϵ.

By the above assumptions, as well as the properties of a_{ij} and β_{ij}, a standard argument (see [13, section 6]) yields that the system (3.1) and (4.26) have unique stationary solutions $u_\epsilon^*(x,t)$ and $u^*(x,t)$, defined for $t > 0$. We denote by μ_ϵ^* and μ^* the distributions of $P_\epsilon u_\epsilon^*$ and u^* in the space H, respectively. Then if $\mathbf{E}|u_\epsilon^0|^2 < \infty$ and $\mathbf{E}|u^0|^2 < \infty$,

$$\Big| \int_H h d\mu_\epsilon(t) - \int_H h d\mu_\epsilon^* \Big| \le C(u_\epsilon^0) e^{-\gamma t}, \ \ t > 0, \tag{5.2}$$

$$\Big| \int_H h d\mu(t) - \int_H h d\mu^* \Big| \le C(u^0) e^{-\gamma t}, \ \ t > 0, \tag{5.3}$$

for some constant $\gamma > 0$ and any $h : H \to R^1$ with $\sup|h| \le 1$ and $\mathrm{Lip}(h) \le 1$. Here $\mu_\epsilon(t) = \mathcal{L}(P_\epsilon u_\epsilon(t, u_\epsilon^0))$, $\mu(t) = \mathcal{L}(u(t, \frac{u^0}{\vartheta}))$, and $C(u_\epsilon^0)$ and $C(u^0)$ are positive constants depending only on the initial values u_ϵ^0 and u^0, respectively. The above convergence also yields that $\mu_\epsilon(t)$ and $\mu(t)$ weakly converge to μ_ϵ^* and μ^*, respectively, as $t \to \infty$.

We will give some additional a priori estimates which are uniform with respect to ϵ to ensure the tightness of the stationary distributions. For Banach space U and $p > 1$, we define $W^{1,p}(0,T;U)$ as the space of functions $h \in L^p(0,T;U)$ such that

$$|h|^p_{W^{1,p}(0,T;U)} = |h|^p_{L^p(0,T;U)} + \Big|\frac{dh}{dt}\Big|^p_{L^p(0,T;U)} < \infty.$$

For any $\alpha \in (0,1)$, define $W^{\alpha,p}(0,T;U)$ as the space of function $h \in L^p(0,T;U)$ such that

$$|h|^p_{W^{\alpha,p}(0,T;U)} = |h|^p_{L^p(0,T;U)} + \int_0^T \int_0^T \frac{|h(t) - h(s)|^p_U}{|t-s|^{1+\alpha p}} ds dt < \infty.$$

For $\rho \in (0,1)$, we denote by $C^\rho(0,T;U)$ the space of functions $h : [0,T] \to \mathcal{X}$ that are Hölder continuous with exponent ρ.

In the remaining part of this section, we always assume that f_ϵ and g_ϵ^i are independent of time t with (5.1) holding. For $T > 0$ denote by $\mathbf{u}_{\epsilon,T}^*$ (respectively, $\mathbf{u}_T^*$) the distribution of stationary process $P_\epsilon u_\epsilon^*(\cdot)$ (respectively, $u^*(\cdot)$) in the space $L^2(0,T;H^1)$. Then we have the following result.

LEMMA 5.1. *For any $T > 0$ the family $\mathbf{u}_{\epsilon,T}^*$ is tight in the space $L^2(0,T;H^{2-\iota})$ with $\iota > 0$.*

Proof. Since u_ϵ^* is stationary, by (3.8), we see that

$$\mathbf{E}|u_\epsilon^*|^2_{L^2(0,T;H_\epsilon^2)} < C_T. \tag{5.4}$$

Now represent u_ϵ^* in the form

$$u_\epsilon^*(t) = u_\epsilon^*(0) + \int_0^t \mathcal{A}_\epsilon u_\epsilon^*(s) ds + \int_0^t f_\epsilon(x) ds + \int_0^t g_\epsilon(x) dW(s).$$

Also by the stationarity of u_ϵ^* and (3.8) we obtain

$$\mathbf{E}\Big|\int_0^t \mathcal{A}_\epsilon P_\epsilon u_\epsilon^*(s)ds + \int_0^t \tilde{f}_\epsilon(x)ds\Big|^2_{W^{1,2}(0,T;H)} \le C_T. \tag{5.5}$$

Let $M_\epsilon(s,t) = \int_s^t \tilde{g}_\epsilon(x)dW(s)$. By Lemma 7.2 of [12] and the Hölder inequality, we derive that

$$\begin{aligned}\mathbf{E}|M_\epsilon(s,t)|^4_{V_\epsilon} \le c\left(\int_s^t |\nabla_{A_\epsilon}\tilde{g}_\epsilon(x)|^2_{\mathcal{L}_2^Q}d\tau\right)^2 &\le K(t-s)\int_s^t |\nabla_{A_\epsilon}\tilde{g}_\epsilon(x)|^4_{\mathcal{L}_2^Q}d\tau \\ &\le KC^{*2}|t-s|^2\end{aligned}$$

for $t \in [s,T]$, where K is a positive constant independent of ϵ, s, and t. Then

$$\mathbf{E}\int_0^T |M_\epsilon(0,t)|^4_{V_\epsilon}dt \le C_T \tag{5.6}$$

and

$$\mathbf{E}\int_0^T\int_0^T \frac{|M_\epsilon(0,t)-M_\epsilon(0,s)|^4_{V_\epsilon}}{|t-s|^{1+4\alpha}}dsdt \le C_T. \tag{5.7}$$

Combining (5.4)–(5.7) and the compact embedding of

$$L^2(0,T;H^2)\cap W^{1,2}(0,T;H) \subset L^2(0,T;H^{2-\iota})$$

and

$$L^2(0,T;H^2)\cap W^{\alpha,4}(0,T;H^1) \subset L^2(0,T;H^{2-\iota}),$$

we obtain the tightness of $\mathbf{u}^*_{\epsilon,T}$. This completes the proof. □

The above lemma directly yields the following result.

COROLLARY 5.2. *The family $\{\mu_\epsilon^*\}$ is tight in the space H^1.*

By Lemma 5.1, for any fixed $T > 0$, the Skorohod embedding theorem asserts that for any sequence $\{\epsilon_n\}_n$ with $\epsilon_n \to 0$ as $n \to \infty$, there is a subsequence $\{\epsilon_{n(k)}\}_k$, a new probability space $(\overline{\Omega}, \overline{\mathcal{F}}, \overline{\mathbf{P}})$, and random variables $\overline{u}^*_{\epsilon_{n(k)}} \in L^2(0,T;V_\epsilon)$, $\overline{u}^* \in L^2(0,T;H^1)$, such that

$$\mathcal{L}(P_\epsilon \overline{u}^*_{\epsilon_{n(k)}}) = \mathbf{u}^*_{\epsilon_{n(k)},T}, \quad \mathcal{L}(\overline{u}^*) = \mathbf{u}^*_T,$$

and

$$\overline{u}^*_{\epsilon_{n(k)}} \to \overline{u}^* \text{ in } L^2(0,T;H^1) \text{ as } k \to \infty.$$

Moreover, $\overline{u}^*_{\epsilon_{n(k)}}$ (respectively, $\overline{u}^*$) is the unique stationary solution of (3.1) (respectively, (4.26)) with W replaced by $\overline{W}_k$ (respectively, $\overline{W}$). $\overline{W}_k$ and $\overline{W}$ are some Wiener processes defined on $(\overline{\Omega}, \overline{\mathcal{F}}, \overline{\mathbf{P}})$ with the same distribution as W. Then by the analysis of section 4 and the uniqueness of the invariant measure,

$$\mathbf{u}^*_{\epsilon,T} \rightharpoonup \mathbf{u}^*_T \text{ as } \epsilon \to 0$$

for any $T > 0$.

To show the long time effectivity, let $u_\epsilon(t)$, $t \geq 0$, be a weak solution of system (2.1)–(2.4), and define $u_\epsilon^t(\cdot) = u_\epsilon(t+\cdot)$ which is in the space $L^2_{loc}(R_+; V_\epsilon)$ by Theorem 3.1. Then by (5.2)

$$\mathcal{L}(P_\epsilon u_\epsilon^t(\cdot)) \rightharpoonup \mathcal{L}(P_\epsilon u_\epsilon^*(\cdot)), \quad t \to \infty,$$

in the space of probability measures on $L^2_{loc}(R_+; H^1)$. From the above analysis we draw the following result which implies the long time effectivity of the homogenized effective equation (4.26).

THEOREM 5.3 (long time effectivity of the macroscopic model). *Assume that $f_\epsilon \in H_\epsilon$ and $g_\epsilon^i \in V_\epsilon$ are independent of time t with* (5.1) *being satisfied, and further assume that* (4.1) *and* (4.2) *hold in H. Denote by $u_\epsilon(t)$, $t \geq 0$, the solution of* (2.1)–(2.4) *and by u^* the unique stationary solution of* (4.26). *Then*

$$\lim_{\epsilon \downarrow 0} \lim_{t \to \infty} \mathcal{L}(P_\epsilon u_\epsilon^t(\cdot)) = \mathcal{L}(u^*(\cdot)), \tag{5.8}$$

where the limits are understood in the sense of weak convergence of Borel probability measures in the space $L^2_{loc}(R_+; H^1)$. That is, the solution of (2.1)–(2.4) *converges to the stationary solution of* (4.26) *in probability distribution as $t \to \infty$ and $\epsilon \to 0$.*

Remark 5.4. This theorem implies that the macroscopic model (4.26) is an effective approximation for the microscopic model (2.1), on a very long time scale. In other words, if we intend to numerically simulate the long time behavior of the microscopic model, we could just simulate the macroscopic model as an approximation when ϵ is sufficiently small.

6. Effectivity in energy convergence. In sections 4 and 5, we have considered finite time and long time effectivity of the macroscopic model (4.26), in the sense of convergence in probability distribution. In this section we focus on the finite time effectivity of the macroscopic model (4.26), but in the sense of convergence in energy. Namely, we show that the solution of the microscopic model (2.1) or (3.1) converges to the solution of the macroscopic model (4.26), in an energy norm.

Let u_ϵ be a weak solution of (3.1) and u be a weak solution of (4.26). We introduce the following energy functionals:

$$\mathcal{E}^\epsilon(u_\epsilon)(t) = \frac{1}{2}\mathbf{E}|\tilde{u}_\epsilon|_H^2 + \mathbf{E}\int_0^t \int_D \chi_{D_\epsilon} A_\epsilon \nabla\big(P_\epsilon u_\epsilon(x,\tau)\big)\nabla\big(P_\epsilon u_\epsilon(x,\tau)\big)dxd\tau \tag{6.1}$$

and

$$\mathcal{E}^0(u)(t) = \frac{1}{2}\mathbf{E}|u|_H^2 + \mathbf{E}\int_0^t \int_D B\nabla u(x,\tau)\nabla u(x,\tau)dxd\tau. \tag{6.2}$$

By the Itô formula, it is clear that

$$\mathcal{E}^\epsilon(u_\epsilon)(t) = \frac{1}{2}\mathbf{E}|\tilde{u}_\epsilon^0|_H^2 + \mathbf{E}\int_0^t \int_D \tilde{f}_\epsilon(x,\tau)\tilde{u}_\epsilon(x,\tau)dxd\tau + \frac{1}{2}\mathbf{E}\int_0^t |\tilde{g}_\epsilon(x,\tau)|^2_{\mathcal{L}_2^Q} d\tau$$

and

$$\mathcal{E}^0(u)(t) = \frac{1}{2}\mathbf{E}|u^0|_H^2 + \mathbf{E}\int_0^t \int_D f(x,\tau)u(x,\tau)dxd\tau + \frac{1}{2}\mathbf{E}\int_0^t |g(x,\tau)|^2_{\mathcal{L}_2^Q} d\tau.$$

Then we have the following result on effectivity of the macroscopic model in the sense of convergence in energy.

THEOREM 6.1 (effectivity in energy convergence). *Assume that* (4.1) *and* (4.2) *hold. If*

$$\tilde{u}_\epsilon^0 \to u^0 \ \text{ strongly in } \ H \ \text{ as } \epsilon \to 0,$$

then

$$\mathcal{E}^\epsilon(u_\epsilon) \to \mathcal{E}^0(u) \quad \text{in } \ C([0,T]) \ \text{ as } \epsilon \to 0.$$

Proof. By the analysis of section 4, for any $\delta > 0$, $u_\epsilon \to u$ strongly in $L^2(0,T;H)$ on Ω_δ, and then by the arbitrariness of δ, it is easy to see that

$$\mathbf{E}\int_0^t \int_D \tilde{f}_\epsilon(x,\tau)\tilde{u}_\epsilon(x,\tau)dxd\tau \to \mathbf{E}\int_0^t \int_D f(x,\tau)u(x,\tau)dxd\tau \ \text{ for } t \in [0,T].$$

Then by $\tilde{g}_\epsilon \rightharpoonup g$ weakly in $L^2(0,t;\mathcal{L}_2^Q)$, we have

$$\mathcal{E}^\epsilon(u_\epsilon)(t) \to \mathcal{E}^0(u)(t) \ \text{ for any } \ t \in [0,T]. \tag{6.3}$$

We now need only show that $\{\mathcal{E}^\epsilon(u_\epsilon)(t)\}_\epsilon$ is equicontinuous, as then the Ascoli–Arzela theorem [14] will imply the result in the theorem.

In fact, given any $t \in [0,T]$, and $h > 0$ small enough, we have

$$\begin{aligned}
&|\mathcal{E}^\epsilon(u_\epsilon)(t+h) - \mathcal{E}^\epsilon(u_\epsilon)(t)| \\
&\quad \le \Big|\mathbf{E}\int_t^{t+h}\int_D \tilde{f}_\epsilon(x,\tau)\tilde{u}_\epsilon(x,\tau)dxd\tau\Big| + \mathbf{E}\int_t^{t+h} |\tilde{g}_\epsilon(x,\tau)|^2_{\mathcal{L}_2^Q} d\tau \\
&\quad \le \mathbf{E}\left\{|\tilde{f}_\epsilon|_{L^2(0,T;H)}\int_t^{t+h} |\tilde{u}_\epsilon(x,\tau)|_H^2 dxd\tau\right\} + \mathbf{E}\int_t^{t+h} |\tilde{g}_\epsilon(x,\tau)|^2_{\mathcal{L}_2^Q} d\tau.
\end{aligned}$$

Noting that $\tilde{u}_\epsilon \in L^2(0,T;H)$ a.s. and (2.7), we have

$$|\mathcal{E}^\epsilon(u_\epsilon)(t+h) - \mathcal{E}^\epsilon(u_\epsilon)(t)| \to 0 \ \text{ as } h \to 0,$$

uniformly on ϵ, which means the equicontinuity of the family $\{\mathcal{E}^\epsilon(u_\epsilon)\}_\epsilon$. This completes the proof. ∎

7. Appendix: The homogenized matrix. In this appendix, we give the explicit expression of the homogenized matrix B; for more details see [9]. Let χ^i, $i = 1,\dots,n$, be the solutions of

$$-\sum_{l,k=1}^n \frac{\partial}{\partial y_l}\left(a_{kl}\frac{\partial(\chi^i - y_i)}{\partial y_k}\right) = 0 \ \text{ in } \ Y^*, \tag{7.1}$$

$$\sum_{l,k=1}^n a_{kl}\frac{\partial(\chi^i - y_i)}{\partial y_k} n_l = 0 \ \text{ on } \partial S, \tag{7.2}$$

$$\chi^i \ \text{ is } \ Y\text{-periodic}. \tag{7.3}$$

It is easy to calculate that $\chi^i = -w_{e_i} + e_i$ with $\{e_i\}_{i=1}^n$ the canonical basis of R^n. Then

$$\beta_{ij} = \frac{1}{|Y|}\int_Y \sum_{k=1}^n a_{kj}\frac{\partial w_{e_i}}{\partial y_k}dy = \frac{1}{|Y|}\int_Y a_{ij}dy - \frac{1}{|Y|}\int_Y \sum_{k=1}^n a_{kj}\frac{\partial \chi_i}{\partial y_k}dy. \tag{7.4}$$

Moreover, the operator $B = (\beta_{ij})$ satisfies the uniform ellipticity condition: there is a constant $b > 0$ such that

$$\sum_{i,j=1}^{n} \beta_{ij}\xi_i\xi_j \geq b\sum_{i=1}^{n} \xi_i^2 \quad \text{for } \xi = (\xi_1, \ldots, \xi_n) \in R^n.$$

Acknowledgments. The authors thank the referees for very helpful suggestions and comments.

LOCAL SMOOTHING AND LOCAL SOLVABILITY FOR THIRD ORDER DISPERSIVE EQUATIONS*

HERBERT KOCH† AND JEAN-CLAUDE SAUT‡

Abstract. Two-dimensional deep water waves can be described by various third order dispersive equations, modifying and generalizing the KdV equations as well as nonlinear Schrödinger equations. We establish local well-posedness for initial data $u_0 \in H^{3/2}(\mathbb{R}^2)$ for many of the proposed models using local smoothing estimates with respect to the forcing term and the initial data.

Key words. third order dispersive equations, local smoothing, nonlinear waves

1. Introduction. The weakly nonlinear dynamics of a quasi-monochromatic wave train propagating at the surface of water can be described by nonlinear Schrödinger-type equations. This has been established in one dimension and two dimensions by Zakharov [19] for infinitely deep water and by Hasimoto and Ono [10] in the one-dimensional finite depth case. They obtained the cubic nonlinear Schrödinger equation. For nearly one-dimensional wave trains in finite depth water, Davey and Stewartson [4] and Djordjevic and Redekopp [7] derived the so-called Davey–Stewartson systems for, respectively, purely gravity and gravity-capillary waves. Those systems involve a wave-induced mean flow resulting in a nonlocal nonlinear Schrödinger equation. They reduce to the cubic nonlinear Schrödinger equation in the infinitely deep water limit. Let a be a typical wave amplitude and k be the modulus of the mean wave number. All the models above are found by a perturbation analysis up to $O(\varepsilon^3)$ when $\varepsilon = k\,a \ll 1$ is the wave steepness.

Taking perturbation analysis one step further to $O(\varepsilon^4)$, Dysthe [8] has derived a system which improves significantly upon the results on the stability of finite amplitude waves in infinite depth. One of the dominant new effects is the wave-induced mean flow with potential Φ. Solving the equation for Φ in terms of the complex amplitude of the wave packet allows one to put the Dysthe system (in dimensionless variables) in the following form (see [9]):

$$\begin{aligned} 2i\left(\frac{\partial A}{\partial t}+\frac{1}{2}\frac{\partial A}{\partial x}\right)+\frac{1}{2}\frac{\partial^2 A}{\partial y^2}-\frac{1}{4}\frac{\partial^2 A}{\partial x^2}-A|A|^2=\frac{i}{8}\left(\frac{\partial^3}{\partial x^3}-6\frac{\partial^3}{\partial x\partial y^2}\right)A \\ +\frac{i}{2}A\left(A\frac{\partial\overline{A}}{\partial x}-\overline{A}\frac{\partial A}{\partial x}\right)-\frac{5i}{2}|A|^2\frac{\partial A}{\partial x}+AR_1\frac{\partial}{\partial x}|A|^2, \end{aligned} \tag{1.1}$$

where R_1 is the Riesz transform in $\mathbb{R}^2$, that is,

$$F(R_1\psi)=i\frac{\xi_1}{|\xi|}\hat{\psi}.$$

Here F and $\hat{\psi}$ denote the Fourier transform.

The usual nonlinear Schrödinger equation (NLS) is obtained by neglecting the right-hand side of (1.1), which is of order ε^4 in the dimensional variables. Note that going one step further in the perturbation introduces higher dispersive terms as well as new nonlinear ones.

A similar derivation of the fourth order (in ε) evolution equations for the amplitude of a train of nonlinear gravity-capillary waves on the surface of an ideal fluid of infinite depth was performed by Hogan [11]. The equation reads

$$\begin{aligned} 2i\left(\frac{\partial A}{\partial t}+c_g\frac{\partial A}{\partial x}\right)+p\frac{\partial^2 A}{\partial x^2}+q\frac{\partial^2 A}{\partial y^2}-\gamma|A|^2A=-is\frac{\partial^3 A}{\partial x\partial y^2}-ir\frac{\partial^3 A}{\partial x^3} \\ -iuA^2\frac{\partial\overline{A}}{\partial x}+iv|A|^2\frac{\partial A}{\partial x}+AR_1\frac{\partial}{\partial x}|A|^2, \end{aligned} \tag{1.2}$$

where c_g is the group velocity and γ, p, q, s, r, u, and v are real parameters depending on the surface tension parameter. Note that q and s are strictly positive, while p can achieve both signs (in particular, the sign is negative for purely gravity waves as in the Dysthe system and positive for purely capillary waves). We refer to the survey of Dias and Kharif [6] for a more complete description of the models of water waves.

Similar problems occur in nonlinear optics (see, for instance, [20]), in particular in the modeling of the dynamics of femtosecond laser pulses in a nonlinear media with temporal dispersion. The evolution of the complex envelope $E(x,y,z,t)$ of the field is described by the third order NLS

$$i\frac{\partial}{\partial z}E+(1-i\varepsilon_1\partial_t)\Delta_\perp E-\frac{\partial^2 E}{\partial t^2}-i\varepsilon_2\frac{\partial^3 E}{\partial t^3}+(1+i\varepsilon_1\partial_t)g(|E|^2)E=0, \tag{1.3}$$

where $\Delta_\perp=\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}$ is the transverse Laplacian and $\varepsilon_2\in\mathbb{R}$, $\varepsilon_1>0$, and typically, $g(z)=z$. As is usual in nonlinear optics, the evolution variable (which plays, mathematically, the role of time, whereas t will be treated as spatial variable later) is z. The transverse Laplacian accounts for diffraction, while the second and third time derivatives describe group velocity and third order dispersion.

Very little is known concerning the Cauchy problem for (1.1)–(1.3). The only results available are local existence for analytic Cauchy data for (1.1) and (1.2) by de Bouard [5], and, very recently, well-posedness in $H^3(\mathbb{R}^2)$ by Chihara [3], who applies techniques developed for derivative nonlinear Schrödinger equations to these third order equations.

Sharp estimates on the fundamental solution of the linearization of (1.2) at 0 have been recently derived in [2]. They lead naturally to Strichartz estimates. Because of the presence of derivatives in the nonlinear terms, Strichartz estimates do not suffice by themselves to obtain the local well-posedness of (1.2) by a contraction argument.

The aim of this paper is to give a proof of local well-posedness of (1.2) and (1.3) in two space dimensions for data in the Sobolev space $H^{3/2}$ by a contraction argument involving spaces related to the local smoothing properties of the group associated to the linear equation

$$\begin{aligned} iu_t+P(D)u &= f && \text{in } \mathbb{R}^n\times\mathbb{R}, \\ u(x,0) &= u_0(x) && \text{for } x\in\mathbb{R}^n, \end{aligned} \tag{1.4}$$

where $P(D)$ is a differential operator of order $\kappa\geq 2$ with real symbol $p(\xi)$. Let p_κ be the part of degree κ.

Assumption. We assume that there exist $c_1, c_2 > 0$ such that

$$|\nabla p(\xi)| \geq c_1 |\xi|^{\kappa-1} - c_2. \tag{1.5}$$

Straightforward calculations show that (1.5) is satisfied for problem (1.1). It is satisfied for (1.2) provided s and r are nonzero and for (1.3) if ε_1 and ε_2 are nonzero.

Let

$$\tilde{Q}_x = \left\{ y | \max_j |x_j - y_j| \leq \frac{1}{2} \right\}$$

and, for $T > 0$,

$$Q_{x,T} = \tilde{Q}_x \times [0, T].$$

The local smoothing estimate is the following.

PROPOSITION 1.1. *Suppose that p satisfies* (1.5). *Let $T > 0$. Then we have*

$$\sup_x \|(1-\Delta)^{\frac{\kappa-1}{4}} u\|_{L^2(Q_{x,T})} + \sup_{0\leq t\leq T} \|u(t)\|_{L^2} \leq c \left(\|u_0\|_{L^2} + \sum_{k\in\mathbb{Z}^n} \|(1-\Delta)^{-\frac{\kappa-1}{4}} f\|_{L^2(Q_{k,T})} \right).$$

Note that the cubes $Q_{k,T}$ cover $\mathbb{R}^n \times (0,T)$. We apply it with $\kappa = 3$ and $n = 2$ to construct a solution to

$$\begin{array}{rcll} iu_t + P(D)u &=& f(u, \partial_\nu u) & \text{in } \mathbb{R}^2 \times \mathbb{R}, \\ u(x,0) &=& u_0(x) & \text{for } x \in \mathbb{R}^2, \end{array} \tag{1.6}$$

where P is of order 3, ν is a unit vector in $\mathbb{R}^2$, and, with the Riesz transform R_ν defined by the Fourier multiplier $\frac{\xi\cdot\nu}{|\xi|}$ and with real or complex constants a_j,

$$f(u, \partial_\nu u) = a_0 |u|^2 u + a_1 u^2 \partial_\nu \bar{u} + a_2 |u|^2 \partial_\nu u + a_3 u \partial_\nu R_\nu |u|^2. \tag{1.7}$$

Note that in (1.3) z becomes the time variable and t a spatial variable. In most models the L^2 norm is preserved. This is the case when

$$a_0, a_3 \in \mathbb{R}, \qquad a_1, a_2 \in i\mathbb{R}. \tag{1.8}$$

We fix a smooth compactly supported function ϕ, identically 1 on $\tilde{Q}_0$.

DEFINITION 1.2. *We define the function spaces $X_{t_0} \subset C([0,t_0]; H^{3/2}(\mathbb{R}^2))$ and Y_{t_0} through the norms*

$$\begin{aligned} \|u\|_{X_{t_0}} = {} & \sup_{0\leq t\leq t_0} \|u(t)\|_{H^{3/2}(\mathbb{R}^2)} + \sup_{x\in\mathbb{R}^2} \|(1-\Delta)_x^{5/4} u\|_{L^2(Q_{x,t_0})} \\ & + t_0^{-1/2} \left(\sum_{k\in\mathbb{Z}^2} \sup_{0\leq t\leq t_0} \left(\|\phi(.-k)u(t)\|^2_{H^{1/2}(\mathbb{R}^2)} - \|\phi(.-k)u(0)\|^2_{H^{1/2}(\mathbb{R}^2)} \right) \right)^{1/2} \end{aligned} \tag{1.9}$$

and

$$\|f\|_{Y_{t_0}} = \inf_{f_1+f_2=f} \left\{ \sum_{k\in\mathbb{Z}^2} \|(1-\Delta)^{-1/4} f_1\|_{L^2(Q_{k,t_0})} + \int_0^{t_0} \|f_2(\tau)\|_{H^{3/2}(\mathbb{R}^2)} d\tau \right\}.$$

After these preparations we can formulate the main result.

THEOREM 1.3. *Suppose that p satisfies* (1.5) *and that the nonlinearity is of the form* (1.7). *Given $c > 1$ there exists $t_0 \sim c^{-2}$ such that for $u_0 \in H^{3/2}(\mathbb{R}^2)$ with $\|u_0\|_{H^{3/2}} \leq c$ there exists a unique solution $u \in X_{t_0}$ to* (1.6) *and* (1.7) *with initial value u_0. Moreover, the map $H^{\frac{3}{2}}(\mathbb{R}^2) \to X_{t_0}, u_0 \to u$ is analytic. In the particular case of* (1.2) *and* (1.3) *we have, furthermore, $\|u(t)\|_{L^2(\mathbb{R}^2)} = \|u_0\|_{L^2(\mathbb{R}^2)}$.*

Proposition 1.1 is proved in section 2 by a reduction to a one-dimensional estimate. In section 3 we prove the main result, which implies in particular that the Cauchy problem for (1.1), for (1.2) if s and r are nonzero, and for (1.3) if ε_1 and ε_2 are nonzero and $g(z) = z$, is locally well-posed for data in $H^{3/2}(\mathbb{R}^2)$. It is likely that one could consider data in Sobolev spaces of lower order by using the Strichartz estimates of [1] and maximal function estimates. Note that for solutions of (1.2) and (1.3) the L^2 norm is formally conserved, which could possibly be used to get global existence from local existence in $L^2(\mathbb{R}^2)$ since $L^2(\mathbb{R}^2)$ is a critical space for scaling. The dispersive estimates obtained in [2] might be useful to establish global existence for small data.

2. Local smoothing estimates. In this part we consider dispersive equations in all space dimensions and of all orders. Local smoothing estimates with respect to the initial data for general dispersive equations are well known; see, for example, [13]. There are fewer results concerning the smoothing property with respect to the forcing term f. As far as we know, such results have been established in the case when $\kappa = 2$ (Schrödinger-type equations) [18, 16], in one space dimension for all κ [15, 14, 17], and more recently, by Hoshiro [12] who established related local smoothing estimates using arguments which are very different from those in this section.

Let a, b, $s \in \mathbb{R}$ and $b \neq 0$. Then by the residue theorem we have

$$\frac{1}{2\pi i} \int_{\mathbb{R}} \frac{e^{is\sigma}}{\sigma - a - ib}\, d\sigma = \begin{cases} 0 & \text{if } bs < 0, \\ e^{ias - bs} & \text{if } bs > 0. \end{cases} \tag{2.1}$$

This simple identity has important and simple consequences for similar integrals for polynomials.

LEMMA 2.1. *Let $p(\sigma)$ be a real polynomial of degree κ. Then for all real $\varepsilon \neq 0$,*

$$\left| \frac{1}{2\pi i} \int_{\mathbb{R}} \frac{e^{is\sigma} p'(\sigma)}{p(\sigma) - i\varepsilon}\, d\sigma \right| \leq \kappa.$$

Proof. We may assume without loss of generality that the degree κ is at least 1. Let $b_i \in \mathbb{C}$, $i = 1, \ldots, m \leq \kappa$, be the zeros of the polynomial $p - i\varepsilon$ of multiplicity N_i. Then

$$\frac{p'}{p - i\varepsilon} = \sum_{i=1}^{m} \frac{N_i}{s - b_i}.$$

No zero of $p - i\varepsilon$ is real, and the assertion follows from the previous calculation (2.1).

There is even a precise formula for $\varepsilon \to 0$. Let $H(s) = 1$ for $s < 0$ and 0 otherwise. Then

$$\lim_{\varepsilon \to 0+} \int_{\mathbb{R}} \frac{e^{is\sigma} p'(\sigma)}{p(\sigma) - i\varepsilon}\, d\sigma = \sum_{j=1}^{k_1} N_j e^{ia_j s} H(\pm s) + \sum_{\{j : \operatorname{Im} a_j s > 0\}} N_j e^{ia_j s},$$

where the first sum is over all zeros on the real line and the second one over all zeros where the imaginary part is positive. The sign in $H(\pm s)$ is determined by the sign of the imaginary part of the root of $p - i0$. □

Let p be a real polynomial of degree κ in $\mathbb{R}^n$. We denote the group generated by $P(D)$ by $S(t)$, which has the kernel function

$$k(x,t) = \begin{cases} 0 & \text{if } t \le 0, \\ \frac{1}{(2\pi)^n} \int e^{ix\xi + itp(\xi)}\, d\xi & \text{otherwise,} \end{cases}$$

where the integral is a standard oscillatory integral, and

$$Kf(x,t) = \int_{-\infty}^{t} \int_{\mathbb{R}^n} k(x-y, t-s) f(y,s) dy\, ds.$$

Then

$$i(\tau - p(\xi))\hat{Kf}(\xi,\tau) = \hat{f}(\xi,\tau)$$

and

$$k(x,t) = \lim_{\varepsilon > 0, \varepsilon \to 0} F^{-1}\Big(\frac{1}{\tau + p(\xi) - i\varepsilon}\Big).$$

In what follows we fix a unit vector $v \in \mathbb{R}^n$ and define for $r \in \mathbb{R}$ the n-dimensional hyperplane

$$\mathcal{H}^v_r = \{(x,t) | \langle v, x\rangle = r\}. \tag{2.2}$$

Let u and f be measurable functions. We define function spaces by their norm

$$\begin{aligned} \|u\|_{L^\infty(\mathbb{R}, L^2(\mathcal{H}^v))} &= \operatorname*{ess\,sup}_r \|u|_{\mathcal{H}^v_r}\|_{L^2(\mathcal{H}^v_r)}, \\ \|f\|_{L^1(\mathbb{R}, L^2(\mathcal{H}^v))} &= \int_{\mathbb{R}} \|u|_{\mathcal{H}^v_{r'}}\|_{L^2(\mathcal{H}^v_{r'})} dr'. \end{aligned}$$

Let p_v be the derivative of the symbol p in direction v.

LEMMA 2.2. *The following inequality holds for all τ and all ξ perpendicular to v and ε small:*

$$\Big\| F^v\Big[\frac{p_v}{\tau + p(\xi) - i\varepsilon}\Big]\Big\|_{L^\infty(\mathbb{R})} \le \sqrt{2\pi}\kappa,$$

where F^v is the partial inverse Fourier transform in the direction of v.

Proof. We fix $(\xi,\tau) \in \mathcal{H}^v$ and set

$$q(\sigma) = \tau + p(\xi + \sigma v)$$

which is a polynomial of order at most κ. The assertion follows now from Lemma 2.1. □

THEOREM 2.3. *Let $A = p_v(D)$ be the differential operator defined by the Fourier multiplier p_v. Suppose that $f \in L^1(\mathbb{R}; L^2(\mathcal{H}^v_r))$. Then*

$$\sup_r \|(AKf)|_{\mathcal{H}^v_r}\|_{L^2(\mathcal{H}^v_r)} \le \sqrt{2\pi}\kappa \int_{\mathbb{R}} \|f|_{\mathcal{H}^v_{r'}}\|_{L^2(\mathcal{H}^v_{r'})}\, dr'.$$

Proof. The Fourier transform of K is

$$\lim_{\varepsilon \to 0} \frac{1}{\tau + p(\xi) - i\varepsilon}.$$

The Fourier transform in the direction v satisfies the desired bounds. Hence, if $f \in L^2(\mathcal{H}^v)$ and $r', r \in \mathbb{R}$, then

$$\|K(\delta_{r'}(.)f)|_{\mathcal{H}^v_r}\|_{L^2(\mathcal{H}^v_r)} \le \sqrt{2\pi}\kappa\|f|_{\mathcal{H}^v_{r'}}\|_{L^2(\mathcal{H}^v_{r'})},$$

where δ denotes the Dirac measure, because this map is defined by a bounded Fourier multiplier. Integration with respect to r' yields the desired result. □

We consider the initial boundary value problem

$$i\partial_t u - P(D)u = f, \qquad u(.,0) = u_0,$$

where we assume that

$$|p_v(D)|^{-1/2} f \in L^1(\mathbb{R}; L^2(\mathcal{H}^v))$$

and $u(0) = u_0 \in L^2$. If $f = 0$, then there is a unique solution in $C(\mathbb{R}; L^2(\mathbb{R}^n))$. Then formally the solution for positive t is given by

$$u(t) = k(.,t) * u_0 + \int_0^t k(.,t-s) * f(.,s)ds.$$

In what follows we study this solution.

PROPOSITION 2.4. *We have*

$$\sup_t \|u(t)\|_{L^2} + (2\pi)^{-1/4}\kappa^{-1/2}\||p_v|^{1/2}(D)u\|_{L^\infty(\mathbb{R},L^2(\mathcal{H}^v))} \le \|u_0\|_{L^2} + (2\pi)^{1/4}\sqrt{\kappa}\||p_v|^{-1/2}(D)f)\|_{L^1(\mathbb{R},L^2(\mathcal{H}^v))}.$$

It is part of the statement that the left-hand side is finite if the right-hand side is finite.

Proof. There are four estimates to prove. We suppose that f is defined on $\mathbb{R}^n \times \mathbb{R}$. The estimate

$$(2\pi)^{-1/4}\kappa^{-1/2}\||p_v|^{1/2}(D)u\|_{L^\infty(\mathbb{R},L^2(\mathcal{H}^v))} \le (2\pi)^{1/4}\sqrt{\kappa}\||p_v|^{-1/2}(D)f\|_{L^1(\mathbb{R},L^2(\mathcal{H}^v))}$$

for $u(t) = \int_{-\infty}^t S(t-s)f(s)\,ds$ is the content of Theorem 2.3.

The estimate

$$\sup_t \|u(t)\|_{L^2} \le (2\pi)^{1/4}\sqrt{\kappa}\||p_v|^{-1/2}(D)f\|_{L^1(\mathbb{R},L^2(\mathcal{H}^v))}$$

follows from

$$\|u(0)\|_{L^2} \le (2\pi)^{1/4}\sqrt{\kappa}\||p_v|^{-1/2}(D)f\|_{L^1(\mathbb{R},L^2(\mathcal{H}^v))} \tag{2.3}$$

for $u = Kf$. More precisely we define

$$T_1 : L^1(\mathbb{R}; L^2(\mathcal{H}^v \cap \{t < 0\})) \to L^2(\mathbb{R}^n),$$
$$T_1 f = (Kf)(0),$$

and

$$T_2 : L^2(\mathbb{R}^n) \to L^\infty(\mathbb{R}; L^2(\mathcal{H}^v \cap \{t < 0\})),$$
$$T_2(u_0)(t) = S(-t)u_0.$$

Then

$$T_2 = T_1^*$$

since

$$\begin{aligned}\int_{\mathbb{R}^n}\int_{-\infty}^{0} T_2 v\overline{f}\,dt\,dx &= \int_0^\infty \int_{\mathbb{R}^n} S(-t)v\overline{f(-t)}dxdt\\ &= \int_{\mathbb{R}^n} v\int_0^\infty \overline{S(t)f(-t)}dt\,dx\\ &= \int_{\mathbb{R}^n} v\overline{T_1(f)}dx.\end{aligned}$$

We observe that the kernel of K is supported in the half space $t \le 0$, and hence we may assume that f is supported in the same half space. On the other hand, if f is supported in the half space $\{t \le 0\}$, and $t > 0$, then

$$Kf(t) = T_2T_1f(-t).$$

Hence, the bounds for T_1 and T_2 follow by an application of Theorem 2.3.

Now we define

$$v(t) = u(t) - \int_{-\infty}^{t} S(t-s)f(s)\,ds,$$

and we obtain

$$i\partial_t v - P(D)v = 0,$$

$$v(0) = u_0 - \int_{-\infty}^{0} S(-s)f(s)\,ds.$$

The theorem is proved if we show $\|v(t)\|_{L^2} = \|v(0)\|_{L^2}$ and

$$\|v\|_{L^\infty(\mathbb{R},L^2(\mathcal{H}^v)\cap\{t>0\})} \le (2\pi)^{1/4}\sqrt{\kappa}\|v(0)\|_{L^2}.$$

The first estimate follows from the energy equality and the second from the estimate for T_2. □

In what follows we will need an elementary estimate. We study

$$i\partial_t v - P(D)v = f,$$

where p is a real polynomial of order κ in n variables. We recall that

$$\tilde{Q}_x := \left\{ y \in \mathbb{R}^2 : \max\{|x_i - y_i|\} \le \frac{1}{2} \right\} \quad \text{and } Q_{x,t_0} = \tilde{Q}_x \times (0,t_0).$$

LEMMA 2.5. *Let $\phi \in C_0^\kappa(\mathbb{R}^n)$ be supported in $B_R(x)$. Then*

$$\left|\|\phi v(t)\|_{L^2}^2 - \|\phi v(0)\|_{L^2}^2\right| \le 4t\int_0^t \|\phi f(s)\|_{L^2}^2 ds + c\int_0^t \|v(s)\|^2_{H^{\frac{\kappa-1}{2}}(B_R(x))}\,ds.$$

Proof. We write

$$\begin{aligned}\|\phi v(t)\|_{L^2}^2 - \|\phi v(0)\|_{L^2}^2 = &\int_0^t \langle \phi v(s), -i\phi f(s) - i\phi P(D)v(s)\rangle\\ &+ \langle -i\phi f(s) - i\phi P(D)v(s), \phi v(s)\rangle ds\end{aligned}$$

and estimate

$$\int_0^t |\langle \phi v(s), \phi f(s)\rangle| ds \le 2t \int_0^t \|\phi f(s)\|_{L^2}^2 + (8t)^{-1} \int_0^t \|\phi v(s)\|_{L^2}^2,$$

where the last term is controlled by $\sup_{0\le s\le t} 8^{-1}\|\phi v(s)\|_{L^2}^2$. Moreover, since $P(D)$ is self-adjoint,

$$\begin{aligned}\langle \phi v(s), \phi P(D) v(s)\rangle - \langle \phi P(D) v(s), \phi v(s)\rangle \\ = \langle \phi v(s), [\phi, P(D)] v(s)\rangle - \langle [\phi, P(D)] v(s), \phi v(s)\rangle.\end{aligned}$$

Clearly $[\phi, P(D)]$ is an operator of order $\kappa - 1$, and we can distribute the derivatives on both terms. □

Now we are in a position to formulate the local smoothing estimate.

PROPOSITION 2.6. *Suppose that p satisfies* (1.5). *Let $T > 0$. Then we have*

$$\sup_x \|(1-\Delta)^{\frac{\kappa-1}{4}} u\|_{L^2(Q_{x,T})} + \sup_{0\le t\le T} \|u(t)\|_{L^2} \lesssim \|u_0\|_{L^2} + \sum_{k\in\mathbb{Z}^n} \|(1-\Delta)^{-\frac{\kappa-1}{4}} f\|_{L^2(Q_{k,T})}.$$

Proof. We fix a finite number of unit vectors v_i, $1 \le i \le M$, such that

$$\sum_{j=1}^M |p_{v_j}| \ge \delta |\xi|^{\kappa-1}$$

for ξ sufficiently large. We choose $\eta \in C^\infty(\mathbb{R})$ to be identically 0 in $[-\delta/n, \delta/n]$, 1 outside $[-2\delta/n, 2\delta/n]$, and define

$$p_j(\xi) = p_{v_j}(\xi)\eta(p_{v_j}(\xi)(1+|\xi|^2)^{1-\kappa}).$$

By construction,

$$\delta|\xi|^{\kappa-1} \le n \sum |p_j(\xi)|$$

for $|\xi| \gg 1$. This inequality may fail, however, in a bounded set. If $p_j(\xi)$ is small, then we do not obtain a gain in the local smoothing estimate. We use the function η to localize the local smoothing estimates to values of ξ, where we gain in the local smoothing estimate.

By the previous arguments, we may assume $u(0) = 0$ because we obtain the dependence on the initial data by a T-T^* argument, as above, from the smoothing with respect to forcing. Let x be given. We fix a smooth function ψ, identically 1 on $\tilde{Q}_x$, supported in a hypercube of twice the size of $\widetilde{Q}_x$. Then it suffices to bound

$$\|(1-\Delta)^{\frac{\kappa-1}{4}}(\psi u)\|_{L^2((0,T)\times\mathbb{R}^n)}.$$

Clearly for fixed t, with $\bar{Q}_x$, respectively, $\bar{Q}_{x,T}$, the hypercube of twice the spatial scale of $\tilde{Q}_x$, and F the spatial Fourier transform,

$$\begin{aligned}\|(1-\Delta)^{\frac{\kappa-1}{4}}(\psi u)\|_{L^2(\mathbb{R}^n)}^2 &= \langle |\xi|^{\kappa-1} F(\psi u), F(\psi u)\rangle \\ &\lesssim \sum_j \langle |p_j(D_x)|(\psi u), \psi u\rangle + \|(1-\Delta)^{-\frac{\kappa-1}{4}} \psi u\|_{L^2} \\ &\lesssim \sum_j \|\psi |p_j|^{1/2} u\|_{L^2(\mathbb{R}^n)}^2 + \|(1-\Delta)^{\frac{\kappa-3}{4}} u\|_{L^2(\bar{Q}_x)}^2.\end{aligned} \tag{2.4}$$

Integration over t together with the bound of Theorem 2.3 gives

$$\begin{aligned}\|(1-\Delta)^{\frac{\kappa-1}{4}}\psi u\|_{L^2(\bar{Q}_{x,T})} \lesssim & \|(1-\Delta)^{\frac{\kappa-3}{4}}u\|_{L^2(\bar{Q}_{x,T})} \\ & + \sum_{k\in\mathbb{Z}^2}\sum_j \|(|p_j|^{1/2}/|p_{v_j}|)(D_x)|f\|_{L^2(Q_{k,T})} \\ \lesssim & \|(1-\Delta)^{\frac{\kappa-3}{4}}u\|_{L^2(\bar{Q}_{x,T})} + \sum_j\sum_{k\in\mathbb{Z}^2}\|(1-\Delta)^{-\frac{\kappa-1}{4}}f\|_{L^2(Q_{k,T})}.\end{aligned}$$

Now, with H^s the standard Sobolev space, we denote the space of function with values in $H^s(Q_x)$ by $L^2(H^s(Q_{x,T}))$. Since the kernel of $1-\Delta$ decays exponentially, and by compact embeddings, we obtain for some $\delta>0$ and all $\varepsilon>0$

$$\begin{aligned}\|(1-\Delta)^{\frac{\kappa-3}{4}}u\|_{L^2(Q_{x,T})} \le & c_1\sum_{k\in\mathbb{Z}^2} e^{-\delta|x-k|}\|u\|_{L^2(H^{\frac{\kappa-3}{2}}(Q_{k,T}))} \\ \le & c_2\sup_{k\in\mathbb{Z}^2}\|u\|_{L^2(H^{\frac{\kappa-3}{2}}(Q_{x+k,T}))} \\ \le & \sup_k \varepsilon\|u\|_{L^2(H^{\frac{\kappa-1}{2}}(Q_{k,T}))} + c_\varepsilon\|u\|_{L^2(H^{-\frac{\kappa-1}{2}}(Q_{k,T}))} \\ \le & \sup_k \varepsilon\|(1-\Delta)^{\frac{\kappa-1}{4}}u\|_{L^2(Q_{k,T})} + c_\varepsilon\|(1-\Delta)^{-\frac{\kappa-1}{4}}u\|_{L^2(Q_{k,T})}.\end{aligned}$$

We take the sup with respect to x and choose ε small to arrive at

$$\begin{aligned}\sup_x\|(1-\Delta)^{\frac{\kappa-1}{4}}u\|_{L^2(Q_{x,T})} \lesssim & \sup_x\|(1-\Delta)^{-\frac{\kappa-1}{4}}u\|_{L^2(Q_{x,T})} \\ & + \sum_{k\in\mathbb{Z}^n}\|(1-\Delta)^{-\frac{\kappa-1}{4}}f\|_{L^2(Q_{k,T})}.\end{aligned}$$

Using Lemma 2.5 for $(1-\Delta)^{-\frac{\kappa-1}{4}}u$, since $u(0)=0$, we may bound

$$\begin{aligned}\sup_x\|(1-\Delta)^{-\frac{\kappa-1}{4}}u\|_{L^2(Q_{x,T})} & \lesssim T^{\frac12}\sup_x\sup_t\|(1-\Delta)^{-\frac{\kappa-1}{4}}u(t)\|_{L^2(Q_x)} \\ & \lesssim T^{1/2}\sup_x\|(1-\Delta)^{-\frac{\kappa-1}{4}}f\|_{L^2(Q_{x,T})} + T^{1/2}\sup_x\|u\|_{L^2(Q_{x,T})} \\ & \lesssim T^{1/2}\sup_x\|(1-\Delta)^{-\frac{\kappa-1}{4}}f\|_{L^2(Q_{x,T})} + T^{1/2}\sup_x\|(1-\Delta)^{\frac{\kappa-1}{4}}u\|_{L^2(Q_{x,T})}.\end{aligned}$$

We choose T small to absorb the last term and obtain

$$\sup_x\|(1-\Delta)^{\frac{\kappa-1}{4}}u\|_{L^2(Q_{x,T})} \lesssim \|u_0\|_{L^2(\mathbb{R}^n)} + \sum_{k\in\mathbb{Z}^2}\|(1-\Delta)^{-\frac{\kappa-1}{4}}f\|_{L^2(Q_{k,T})}.$$

Next we shall add $\sup_t\|u(t)\|_{L^2}$ on the left-hand side. That this can be done follows from the standard energy estimate if $f=0$; hence we can reduce our attention to the case $u_0=0$. Let $\tilde{Y}$ and $\tilde{X}$ be the spaces defined by $\sum_k\|(1-\Delta)^{-\frac{\kappa-1}{4}}f\|_{L^2(Q_{k,T})}$ and $\sup_k\|(1-\Delta)^{\frac{\kappa-1}{4}}u\|_{L^2(Q_{k,T})}$, respectively. Let $K: L^2\ni u_0\to u\in\tilde{X}$ be the map from u_0 to the solution u to the homogeneous equation with initial data u_0. Its adjoint is the map $K^*: Y\ni f\to u(T)\in L^2$ which maps the right-hand side to the solution with zero initial data evaluated at time T. Thus K^* is bounded since K is bounded if T is small. The arguments work uniformly for small T and we obtain the claimed bound for small T. This last restriction is removed by an iterative application of the estimate on small time intervals. □

From now on we restrict ourselves to $\kappa=3$ and $n=2$.

LEMMA 2.7. *Suppose that* $|\nabla p(\xi)| \sim |\xi|^2$ *for large* ξ,

$$iu_t - P(D)u = f \text{ in } \mathbb{R}^2 \times (0,T), \tag{2.5}$$

and $u(0) = u_0 \in H^{3/2}(\mathbb{R}^2)$. *Then*

$$\|u\|_{X_{t_0}} \lesssim \|u_0\|_{H^{3/2}(\mathbb{R}^2)} + \|f\|_{Y_{t_0}}.$$

Proof. Proposition 2.6 implies

$$\sup_{0\le t\le t_0} \|u\|_{H^1} + \sup_{x\in\mathbb{R}^2} \|D_x^2 u\|_{L^2(Q_{x,t_0})} \lesssim \|D_x u_0\|_{L^2} + \inf_{f_1+f_2=f} \left(\sum_{k\in\mathbb{Z}^2} \|f_1\|_{L^2(Q_{k,t_0})} + \int_0^{t_0} \|f_2(t)\|_{L^2} \right).$$

We apply $(1-\Delta)^{1/4}$ to (2.5) and obtain

$$\sup_{0\le t\le t_0} \|u\|_{H^{3/2}(\mathbb{R}^2)} + \sup_{x\in\mathbb{R}^2} \|(1-\Delta)^{5/4} u\|_{L^2(Q_{x,t_0})} \lesssim \|u_0\|_{H^{3/2}(\mathbb{R}^2)} + \|f\|_{Y_{t_0}}.$$

We combine this inequality with Lemma 2.5 and choose $\phi \in C_0^\infty(\mathbb{R}^2)$, which is identically 1 in $[-1,1]^2$ and supported in $[-2,2]^2$. Then by Lemma 2.5

$$\sum_{k\in\mathbb{Z}^2} \left| \|\phi(x-k)u(t)\|_{L^2}^2 - \|\phi(x-k)u(0)\|_{L^2}^2 \right| \lesssim t \int_0^t \|f(s)\|_{L^2}^2 ds + \int_0^t \|u\|_{H^1(\mathbb{R}^n)}^2 ds.$$

We apply this estimate to $(1-\Delta)^{1/4}u$. The commutators $[(1-\Delta)^{1/4}, \phi]$ are of order $-1/2$. Their kernels decay quickly and the corresponding terms can be easily controlled. Hence,

$$t_0^{-1} \sum_{k\in\mathbb{Z}^2} \left| \|\phi(x-k)u(t)\|_{H^{1/2}(\mathbb{R}^2)}^2 - \|\phi(x-k)u(0)\|_{H^{1/2}(\mathbb{R}^2)}^2 \right| \lesssim \int_0^t \|f(s)\|_{H^{1/2}(\mathbb{R}^2)}^2 ds + \sup_{0\le t\le t_0} \|u(t)\|_{H^{3/2}(\mathbb{R}^2)}^2.$$

This completes the proof. □

3. The main result. Here we study the problem

$$iu_t - P(D)u = f(u), \qquad u(x,0) = u_0(x),$$

where the symbol $p(\xi)$ satisfies (1.5) and where f is as in (1.7). We can write the problem in the form

$$f(u) = F[u,u,u]$$

with

$$F[u,v,w] = \frac{1}{6}\left(f(u+v+w) + f(u) + f(v) + f(w) - f(u+v) - f(u+w) - f(v+w)\right),$$

where F is symmetric and linear in each argument. A typical term is

$$F[u,v,w] = u\partial_\nu R_\nu(vw) + v\partial_\nu R_\nu(wu) + w\partial_\nu R_\nu(uv). \tag{3.1}$$

After these preparations we turn to the proof of Theorem 1.3.

Proof. We will choose $w_0 \in H^4(\mathbb{R}^2)$ below and define w as the solution to

$$iw_t - P(D)w = 0, \qquad u(0,x) = w_0(x).$$

Instead of u we search the solution to

$$iv_t - P(D)v = f(v+w), \qquad v(0) = u_0 - w_0$$

by a fixed point argument. As a by-product of the proof we will obtain Lipschitz—and even analytic—dependence on the initial data.

Clearly by Sobolev's embedding

$$\|D_x^2 w\|_{L^\infty(\mathbb{R}\times\mathbb{R}^2)} \lesssim \|w_0\|_{H^4(\mathbb{R}^2)}.$$

Let $c_0 = \|u_0\|_{H^{3/2}}$. We choose ε small and $w_0 \in H^4(\mathbb{R}^2)$ with $\|u_0 - w_0\|_{H^{1/2}} \le \varepsilon$, $\|u_0 - w_0\|_{H^{3/2}} \lesssim 2c_0$, and $\|w_0\|_{H^4(\mathbb{R}^2)} \lesssim c_0^{5/2}\varepsilon^{-3/2}$. The result will follow from Lemma 2.7 and from the following.

LEMMA 3.1. *Suppose that $f = f(u, \nabla u)$ is of the form* (1.7). *Then, with F related to f as in* (3.1), *if $t_0 \le 1$,*

$$\begin{aligned}\|F[u,v,w]\|_{Y_{t_0}} \lesssim &\Big(\|u(0)\|_{H^{1/2}} + t_0^{\frac12}\|u\|_{X_{t_0}}\Big)\Big(\|v(0)\|_{H^{1/2}} + t_0^{\frac12}\|v\|_{X_{t_0}}\Big)\|w\|_{X_{t_0}}\\ &+ \Big(\|v(0)\|_{H^{1/2}} + t_0^{\frac12}\|v\|_{X_{t_0}}\Big)\Big(\|w(0)\|_{H^{1/2}} + t_0^{\frac12}\|w\|_{X_{t_0}}\Big)\|u\|_{X_{t_0}}\\ &+ \Big(\|w(0)\|_{H^{1/2}} + t_0^{\frac12}\|w\|_{X_{t_0}}\Big)\Big(\|u(0)\|_{H^{1/2}} + t_0^{\frac12}\|u\|_{X_{t_0}}\Big)\|v\|_{X_{t_0}}.\end{aligned}$$

Proof. It suffices to show that

$$\|f(u)\|_{Y_{t_0}} \le c\Big(\|u(0)\|_{H^{1/2}}^2 + t_0\|u\|_{X_{t_0}}^2\Big)\|u\|_{X_{t_0}}. \tag{3.2}$$

This can be seen either by polarization or by checking the proof below.

It suffices to estimate the L^2 norm of $(1-\Delta)^{1/4}f$ in cylinders as in (3.2). More precisely, since by a Sobolev embedding

$$\|h(s)\|_{H^{1/2}(\tilde{Q}_x)} \le \|h(s)\|_{W^{1,4/3}(\tilde{Q}_x)},$$

we have to show that

$$\sum_{k\in\mathbb{Z}^2} \||g| + |\nabla g|\|_{L^{4/3}(Q_k)} \le c\Big(\|u(0)\|_{H^{1/2}} + t_0^{1/2}\|u\|_{X_{t_0}}^2\Big)^2\|u\|_{X_{t_0}}, \tag{3.3}$$

where g is one of the following terms:

$$u^3,\ u^2\partial_\nu u,\ u\partial_\nu R_\nu|u|^2. \tag{3.4}$$

The treatment of $u\partial_\nu R_\nu|u|^2$ is typical and contains all the difficulties. For clarity we first consider the term $\nabla(u^2Du)$. By Hölder's inequality,

$$\|\nabla(u^2(s)Du(s))\|_{L^{4/3}(\tilde{Q}_x)} \lesssim \|u(s)\|_{L^8(\tilde{Q}_x)}^2\|D^2u(s)\|_{L^2(\tilde{Q}_x)} + \|u(s)\|_{L^8(\tilde{Q}_x)}\|\nabla u\|_{L^{16/5}(\tilde{Q}_x)}^2,$$

and by interpolation,

$$\|\nabla u\|_{L^{16/5}(\tilde{Q}_x)}^2 \lesssim \|u\|_{L^8(\tilde{Q}_x)}(\|u\|_{L^2(\tilde{Q}_x)} + \|D^2u\|_{L^2(\tilde{Q}_x)});$$

hence

$$\int_0^{t_0} \|\nabla(u^2(s)Du(s))\|^2_{L^{4/3}(\tilde{Q}_x)}ds \lesssim \int_0^{t_0} \|u(s)\|^4_{L^8(\tilde{Q}_x)}(\|u\|^2_{L^2(\tilde{Q}_x)} + \|D^2u(s)\|^2_{L^2(\tilde{Q}_x)})ds$$
$$\leq c_1 \int_0^{t_0} \|u(s)\|^4_{H^{1/2}(\tilde{Q}_x)}\|u(s)\|^2_{H^{5/2}(\tilde{Q}_x)}ds$$
$$\leq c_2 \sup_{0\leq t\leq t_0} \|(1-\Delta)^{1/4}u(t)\|^2_{L^2(\tilde{Q}_x)}\|(1-\Delta)^{5/4}u\|_{L^2(Q_{x,t_0})},$$

and thus, by the definition of the spaces X_{t_0},

$$\sum_{k\in Z^2}\left\{\int_0^t \|u^2(s)Du(s)\|^2_{H^{1/2}(\tilde{Q}_k)}ds\right\} \leq c\Big(\|(1-\Delta)^{1/4}u(0)\|_{L^2} + t_0^{1/2}\|u\|_{X_{t_0}}\Big)^2\|u\|_{X_{t_0}}.$$

We now turn to the most difficult term

$$\sum_k \|\nabla(u\partial_\nu R_\nu|u|^2)\|_{L^2([0,t_0],L^{4/3}(Q_k))}.$$

There are two terms to control:

$$\sum_k \|(\nabla u)\partial_\nu R_\nu|u|^2\|_{L^2([0,t_0],L^{4/3}(Q_k))} \tag{3.5}$$

and

$$\sum_k \|u\nabla\partial_\nu R_\nu|u|^2\|_{L^2([0,t_0],L^{4/3}(Q_k))}. \tag{3.6}$$

By Hölder's inequality, for fixed t,

$$\|(\nabla u)\partial_\nu R_\nu|u|^2\|_{L^{4/3}(Q_k)} \lesssim \|\nabla u\|_{L^{16/5}(Q_k)}\|\partial_\nu R_\nu|u|^2\|_{L^{16/7}}.$$

The kernel $K(x,y)$ of $\partial_\nu R_\nu$ decays fast for $|x-y|\to\infty$,

$$|K(x,y)| \leq c|x-y|^{-3};$$

hence we estimate

$$\|\partial_\nu R_\nu|u|^2\|_{L^{\frac{16}{7}}(Q_k)} \lesssim \sum_{\bar{k}}(1+|k-\bar{k}|)^{-3}\sup_{\bar{k}}\|u\|^2_{L^2(Q_k)} + \sum_{|k-\bar{k}|\leq 2}\|\partial_\nu|u|^2\|_{L^{\frac{16}{7}}(Q_{\bar{k}})}.$$

Now we proceed as above and bound $\sum_k \|\nabla(u\partial_v R_v|u|^2)\|_{L^2([0,t_0],L^{4/3}(Q_k))}$ following the arguments above. □

We complete the proof of Theorem 1.3 using Lemmas 2.7 and 3.1. First we obtain

$$\|w\|_{X_{t_0}} \leq c(n)\|w_0\|_{H^{3/2}} \leq c(n)c_0.$$

Let $J: X_{t_0}\to X_{t_0}, J:\tilde{v}\to v$, be defined as a solution to

$$v_t + P(D)v = f(w+\tilde{v}), \qquad v(0) = u_0 - w_0.$$

Then by Lemmas 2.7 and 3.1,

(3.7)
$$\|v\|_{X_{t_0}} \lesssim c_0 + \Big(\|w_0\|_{H^{1/2}} + \|u_0 - w_0\|_{H^{1/2}} + t_0^{1/2}(\|w_0\|_{H^{3/2}} + \|\tilde v\|_{X_{t_0}})\Big)^2(\|w_0\|_{H^{3/2}} + \|\tilde v\|_{X_{t_0}})$$
$$\lesssim c_0 + t_0(c_0 + \|\tilde v\|_{X_{t_0}})^3.$$

We shall see that this map is a contraction—at least if we decrease t_0 if necessary. The lower bound on the life span follows from (3.7).

Let

$$v_t^j + P(D)v^j = f(w + \tilde v^j), \qquad v^j(0) = u_0 - w_0,$$

for $j = 1, 2$. We expand the trilinear term

$$f(w + \tilde v^2) - f(w + \tilde v^1) = 3F[w, w, \tilde v^2 - \tilde v^1] + 3F[w, \tilde v^2 + \tilde v^1, \tilde v^2 - \tilde v^1]$$
$$+ F[\tilde v^2 + \tilde v^1, \tilde v^2 + \tilde v^1, \tilde v^2 - \tilde v^1].$$

It is straightforward to estimate

$$\|F[w(t), w(t), \tilde v^2 - \tilde v^1]\|_{L^1(H^{3/2})} \lesssim t_0^{1/2}\|w_0\|_{H^4}^2\|\tilde v^2 - \tilde v^1\|_{X_{t_0}},$$

and hence,

$$\|v^2 - v^1\|_{X_{t_0}} \le \gamma\|\tilde v^2 - \tilde v^1\|_{X_{t_0}},$$

where γ can be chosen as

$$\gamma \sim t_0^{1/2}\|w_0\|_{H^4}^2 + (\|w_0\|_{H^{1/2}} + t_0^{1/2}\|w\|_{X_{t_0}} + \mu)\mu \lesssim t_0^{1/2}c_0^5\varepsilon^{-3} + (c_0 + \mu)\mu$$

with

$$\mu = \varepsilon + t_0^{1/2}(\|\tilde v^2\|_{X_{t_0}} + \|\tilde v^1\|_{X_{t_0}}).$$

Suppose that $\|\tilde v^j\|_{X_{t_0}} \le R$ with $R > c_0$. Then

$$\|v^2 - v^1\|_{X_{t_0}} \le \frac{1}{2}\|\tilde v^2 - \tilde v^1\|_{X_{t_0}}$$

provided $\varepsilon R \ll 1$, $t_0^{1/2}R^2 \ll 1$, $t_0^{1/2}(c_0 + 1) \ll 1$ and $t_0 \ll c_0^{-10}\varepsilon^6$. Given R we can satisfy all these inequalities. Let $R_0 = \|J(0)\|_{X_{t_0}}$, $R \ge 2R_0$, and ε, t_0 be as above. Then

$$\|J(\tilde v)\|_{X_{t_0}} \le R_0 + \frac{1}{2}R \le R$$

if $\|\tilde v\|_{X_{t_0}} \le R$ and $\|\tilde v(0)\|_{H^{1/2}(\mathbb{R}^2)} \le \varepsilon$. Now J maps this ball into itself and is a contraction. The same argument gives uniqueness of solutions in that class. Finally, we may reinterpret the considerations above as an application of the implicit function theorem with analytic nonlinearities, which implies analytic dependence on the initial data. □

By similar arguments one could establish the local well-posedness of (1.3) for $n = 3$ in $\mathbb{R}^3$ in the cubic case for initial data in $H^2(\mathbb{R}^2)$, provided ε_1 and ε_2 are nonzero.

RESONANCE AND INTERIOR LAYERS IN AN INHOMOGENEOUS PHASE TRANSITION MODEL*

MANUEL DEL PINO†, MICHAŁ KOWALCZYK‡, AND JUNCHENG WEI§

Abstract. We consider the problem $\varepsilon^2\Delta u + (u - a(x))(1 - u^2) = 0$ in Ω, $\frac{\partial u}{\partial \nu} = 0$ on $\partial\Omega$, where Ω is a smooth and bounded domain in $\mathbb{R}^2$, $-1 < a(x) < 1$. Assume that $\Gamma = \{x \in \Omega, a(x) = 0\}$ is a closed, smooth curve contained in Ω in such a way that $\Omega = \Omega_+ \cup \Gamma \cup \Omega_-$ and $\frac{\partial a}{\partial n} > 0$ on Γ, where n is the outer normal to Ω_+. Fife and Greenlee [*Russian Math. Surveys*, 29 (1974), pp. 103–131] proved the existence of an interior transition layer solution u_ε which approaches -1 in Ω_- and $+1$ in Ω_+, for *all* ε sufficiently small. A question open for many years has been whether an interior transition layer solution approaching 1 in Ω_- and -1 in Ω_+ exists. In this paper, we answer this question affirmatively when $n = 2$, provided that ε is small and away from certain critical numbers. A main difficulty is a resonance phenomenon induced by a large number of small critical eigenvalues of the linearized operator.

1. Introduction and statement of main result.

Let Ω be a bounded, smooth domain in $\mathbb{R}^2$. In the gradient theory of phase transitions it is common to seek critical points in $H^1(\Omega)$ of energy of the form

$$J_\varepsilon(u) = \frac{\varepsilon}{2}\int_\Omega |\nabla u|^2 + \varepsilon^{-1}\int_\Omega W(x,u),$$

where $W(x,\cdot)$ is a double-well potential with exactly two strict local minimizers at $u = +1$ and $u = -1$, which also correspond to trivial local minimizers of J_ε in $H^1(\Omega)$. For simplicity of exposition we shall restrict ourselves to a potential of the form

$$W(x,u) = \int_{-1}^{u} (s^2 - 1)(s - a(x))ds, \tag{1.1}$$

for a smooth function $a(x)$ with

$$-1 < a(x) < 1 \text{ for all } x \in \Omega.$$

Critical points of J_ε correspond to solutions of the problem

$$\begin{cases} \varepsilon^2\Delta u + (u - a(x))(1 - u^2) = 0 & \text{in } \Omega, \\ \frac{\partial u}{\partial \nu} = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.2}$$

where $\varepsilon > 0$ is a small parameter and ν denotes unit outer normal to $\partial\Omega$. The function $u(x)$ represents a continuous realization of the phase present in a material confined to the region Ω at the point x which, except for a narrow region, is expected to take values close to $+1$ or -1. Of interest are, of course, nontrivial steady state configurations in which the two phases coexist.

The case $a \equiv 0$ corresponds to the standard Allen–Cahn equation [6]

$$\begin{cases} \varepsilon^2 \Delta u + u(1-u^2) = 0 & \text{in } \Omega, \\ \frac{\partial u}{\partial \nu} = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.3}$$

for which extensive literature on transition layer solutions is available; see, for instance, [4, 17, 18, 24] and the references therein. We observe that in this case, $+1$ and -1 are both global minimizers of the potential (1.1). We are interested in an inhomogeneous situation in which $+1$ is the absolute minimizer of $W(x,\cdot)$ in one region of the domain, while -1 is such a minimizer in its complement. More precisely, we shall assume that the set

$$\Gamma = \{x \in \Omega \ / \ a(x) = 0\}$$

is a smooth, simple, closed curve in Ω which separates the domain into two disjoint components,

$$\Omega = \Omega_- \cup \Omega_+ \cup \Gamma \tag{1.4}$$

such that

$$a(x) < 0 \ \text{ in } \Omega_+, \quad a(x) > 0 \ \text{ in } \Omega_-, \quad \frac{\partial a}{\partial n} > 0 \ \text{ on } \Gamma\,. \tag{1.5}$$

Observe in particular that for the potential (1.1) we have

$$W(x,-1) < W(x,+1) \quad \text{in } \Omega_-, \quad W(x,+1) < W(x,-1) \quad \text{in } \Omega_+\,.$$

Thus, if one considers a global minimizer u_ε for J_ε, which exists by standard arguments, then u_ε should minimize $W(x,u)$; namely, u_ε should intuitively have the following asymptotic behavior as $\varepsilon \to 0$:

$$u_\varepsilon \to -1 \text{ in } \Omega_-, \quad u_\varepsilon \to +1 \text{ in } \Omega_+. \tag{1.6}$$

A solution u_ε to problem (1.2) with these characteristics was constructed, and precisely described, by Fife and Greenlee [15] in 1974 via matching asymptotic and bifurcation arguments.

Supersubsolutions were later used by Angenent, Mallet-Paret, and Peletier in the one-dimensional case [7] for construction and classification of stable solutions. Radial solutions were found variationally by Alikakos and Simpson [5]. The construction of the Fife–Greenlee solution allowing Γ to be any closed subset of Ω in any dimension was given by the first author in [10]. Further constructions have been found recently by Dancer and Yan [9] and Do Nascimento [13]. In particular, it was found in [9] that this solution is precisely a minimizer of J_ε. Related results can be found in [1, 3].

On the other hand, a solution exhibiting a transition layer in the *opposite direction*, namely,

$$u_\varepsilon \to +1 \text{ in } \Omega_-, \qquad u_\varepsilon \to -1 \text{ on } \Omega_+, \tag{1.7}$$

has been believed to exist for many years. Hale and Sakamoto [19] established the existence of this solution in the one-dimensional case, while this was done in the radial case in a ball in [11]; see also [8]. The opposite direction layer (1.7) in this scalar problem is meaningful in finding transition layer solutions in pattern-formation–reaction-diffusion systems such as the Gierer–Meinhardt system with saturation; see [11, 14, 25, 28, 27] and the references therein. While the singular perturbation methods used in these one-dimensional or radial equations and systems do not see a substantial difference between the stable and unstable layers, except for the sign of the principal $O(\varepsilon)$ eigenvalue of the linearization, one faces a dramatically different situation in higher-dimensional, nonsymmetric situations. This is clearly seen when linearizing around a spherically symmetric solution like (1.7), as bifurcations of nonradial solutions along certain infinite discrete sets of values for $\varepsilon \to 0$ take place, as established in [27]. In particular, the radial solution has a large ε-dependent Morse index. This poses an important difficulty for a general construction. A phenomenon of this type was previously observed in the one-dimensional case by Alikakos, Bates, and Fusco [2] in a construction of solutions with any prescribed Morse index.

In this paper we are able to prove that the opposite-layer solution (1.7) exists as long as ε remains properly away from a set of critical values. More precisely, there is an explicit number $\lambda_* > 0$ such that given $c > 0$, if ε is sufficiently small and satisfies the gap condition

$$|k^2\varepsilon - \lambda_*| \geq c\sqrt{\varepsilon} \quad \text{for all } k \in \mathbb{N}, \tag{1.8}$$

then a solution u_ε with the required concentration property indeed exists. In other words, this will be the case whenever ε is small and away from the critical numbers $\frac{\lambda_*}{k^2}$, in the sense that for fixed and arbitrarily small $c < \lambda_*$,

$$\varepsilon \notin \left[\frac{\lambda_*}{k^2} - \frac{c}{k^3}\,,\, \frac{\lambda_*}{k^2} + \frac{c}{k^3} \right] \quad \text{for all } k \in \mathbb{N}.$$

Here λ_* is defined by

$$\lambda_* = \frac{1}{3\pi^2 \int_{\mathbb{R}} H_x^2 dx} \left(\int_\Gamma \sqrt{\frac{\partial a}{\partial \nu}} \right)^2, \tag{1.9}$$

where $H(y)$ is the unique heteroclinic solution of

$$H'' + H - H^3 = 0,\ H(0) = 0,\ H(\pm\infty) = \pm 1. \tag{1.10}$$

We can now state our main result.

THEOREM 1. *Given $c > 0$, there exists $\varepsilon_0 > 0$ such that for all $\varepsilon < \varepsilon_0$ satisfying the gap condition* (1.8), *problem* (1.2) *has a solution u_ϵ satisfying*

$$u_\varepsilon(x) \to +1 \quad in \quad \Omega_-, \quad u_\varepsilon(x) \to -1 \quad in \quad \Omega_+$$

as $\varepsilon \to 0$.

Much more accurate information on the solution will be provided by its construction; in particular, its shape near Γ is governed by the heteroclinic solution H, in the sense that

$$u_\varepsilon(x) \sim H\left(\frac{t - \varepsilon f(\theta)}{\varepsilon} \right),$$

where f is a bounded function of θ, a choice of arclength coordinate of Γ, and t is the (signed) normal coordinate along the outer normal to Ω_+ on Γ.

The main difficulty in the construction of the interior layer solution in the opposite direction is the appearance of a large number of small *critical eigenvalues*, or *resonance*. This kind of phenomenon has been dealt with in various problems, for example, in the study of periodic orbits for strongly attractive potentials [21, 29] and in boundary concentrations for singularly perturbed Neumann problems [22, 23]. It also arises in our previous work [12] on the construction of a concentrating solution on weighted geodesics for nonlinear Schrodinger equations. The scheme employed here follows the general lines set in [12].

More precisely, the solution to the full problem is roughly decomposed into the form

$$u_\varepsilon(x) = H\left(s - f(\varepsilon z)\right) + \phi_1\left(s - f(\varepsilon z)\right) + \tilde{\phi}(s, z), \tag{1.11}$$

where $x = (t, \theta) = (\varepsilon s, \varepsilon z)$, $t = \varepsilon s$ is the signed distance to Γ, $\theta = \varepsilon z$ is the arclength coordinate of Γ whose length is l, f is an l-periodic function left as a parameter, and ϕ_1 is the correction term to be defined, while $\tilde{\phi}(s, z)$ is $L^2(ds)$-orthogonal for each z to $H_s(s - f(\varepsilon z))$. Solving first in $\tilde{\phi}$ a natural projected problem, where the linear operator is uniformly invertible, the resolution of the full problem becomes reduced to a nonlinear, nonlocal second order system of differential equations in f which turns out to be directly solvable thanks to the assumptions made. This approach is familiar when the parameter f lies in a finite-dimensional space (as in the papers [5, 9, 13, 19]), corresponding this time to adjusting infinitely many parameters. To stress the difference in the radial case, we note that the parameter f is just a single number. The analysis we make takes special advantage through Fourier analysis of the fact that the objects to be adjusted are one-variable functions, while we still believe that the current approach may be modified to the higher-dimensional case. We also believe that the gap condition may be improved to size ε^q, any $q > \frac{1}{2}$.

Additionally we point out the following:

1. The results of Theorem 1 remain true when Ω is an unbounded domain, for instance, $\Omega = \mathbb{R}^2$. Indeed, our proofs, and in particular the matching argument below, can easily be adapted to handle this case.

2. The method and results presented in Theorem 1 can be generalized to more general bistable equations of the form

$$\varepsilon^2 \Delta u - h(x, u, \varepsilon) = 0 \text{ in } \Omega, \quad \varepsilon \frac{\partial u}{\partial \nu} - \sigma(x, \epsilon) u = f(x, \epsilon) \text{ on } \partial\Omega,$$

as treated originally by Fife and Greenlee [15].

3. Our general approach seems also to work when $N = 3$. It will be an interesting problem to consider $N \geq 4$. Note that there is no restriction of dimension in the construction of Fife–Greenlee solutions (1.6); see [10].

The organization of this paper is as follows. In section 2, we set up the local coordinates near Γ and transform (1.2) into a new equation in the stretched variable (s, z). We then introduce the first correction term ϕ_1 and estimate the errors. In section 3, we use a gluing procedure to reduce the nonlinear problem to one on the infinite cylinder and another one away from the interface. Then we solve the inner problem modulo the projections in section 4 and the full problem modulo projections in section 5. In section 6 and section 7, we derive a nonlinear ODE for f, which will be solved in section 8 using the gap condition.

2. The setup near the curve. Let $\Gamma = \{x \in \Omega, a(x) = 0\}$ be a simple, closed, smooth curve in $\Omega \subset \mathbb{R}^2$ and let $\ell = |\Gamma|$ denote its total length. We consider the natural parameterization $\gamma(\theta)$ of Γ with positive orientation, where θ denotes the arclength parameter measured from a fixed point of Γ. Let $\nu(\theta)$ denote outer unit normal to Γ. Points y which are δ_0-close Γ for sufficiently small δ_0 can be represented in the form

$$y = \gamma(\theta) + t\,\nu(\theta), \quad |t| < \delta_0,\ \theta \in [0, \ell)\,, \tag{2.1}$$

where map $y \mapsto (t, \theta)$ is a local diffeomorphism. By slight abuse of notation we denote $a(t, \theta)$ to actually mean $a(y)$ for y in (2.1). Let $k(\theta)$ denote the curvature of Γ.

Stretching variables, absorbing ε from Laplace's operator, and replacing $u(y)$ with $u(\varepsilon y)$, (1.2) becomes

$$\Delta u + (u - a(\varepsilon y))(1 - u^2) = 0 \text{ in } \Omega_\varepsilon, \qquad \frac{\partial u}{\partial \nu} = 0 \text{ on } \partial\Omega_\varepsilon, \tag{2.2}$$

where $\Omega_\varepsilon = \frac{\Omega}{\varepsilon}$.

Let $(s, z) = \varepsilon^{-1}(t, \theta)$ be the natural stretched coordinates associated with the curve $\Gamma_\varepsilon = \varepsilon^{-1}\Gamma$, now defined for

$$z \in [0, \varepsilon^{-1}\ell), \quad s \in (-\varepsilon^{-1}\delta_0, \varepsilon^{-1}\delta_0). \tag{2.3}$$

Equation (2.2) for u expressed in these coordinates becomes

$$u_{zz} + u_{ss} + B_1(u) + B_2(u) + u - u^3 = 0, \tag{2.4}$$

in the region (2.3), where

$$B_1(u) = -u_{zz}\left[1 - \frac{1}{(1 + \varepsilon k(\varepsilon z)s)^2}\right] + \frac{\varepsilon k(\varepsilon z)u_s}{1 + \varepsilon k(\varepsilon z)s} - \frac{\varepsilon^2 s\, k'(\varepsilon z)u_z}{(1 + \varepsilon k(\varepsilon z)s)^3},$$

$$B_2(u) = -a(\varepsilon s, \varepsilon z)(1 - u^2).$$

For further reference, it is convenient to expand B_1 in the form

$$B_1(u) \,=\, (\varepsilon k(\varepsilon z) - \varepsilon^2 s k^2(\varepsilon z))u_s \,+\, B_0(u), \tag{2.5}$$

where

$$B_0(u) \,=\, \varepsilon^2 s a_1(\varepsilon s, \varepsilon z)u_z + \varepsilon s a_2(\varepsilon s, \varepsilon z)u_{zz} + \varepsilon^3 s^2 a_3(\varepsilon s, \varepsilon z)u_s, \tag{2.6}$$

for certain smooth functions $a_j(t, \theta), j = 1, 2, 3$. Observe that all terms in the operator B_1 have ε as a common factor.

We consider now a further change of variables in (2.4). Let $f(\theta)$ be a twice differentiable, ℓ-periodic function whose exact form is to be specified later (see (2.25)). We define $v(x, z)$ by the relation

$$u(s, z) = v(\,x\,,\,z), \quad x = s - f(\varepsilon z). \tag{2.7}$$

We want to express (2.4) in terms of these new coordinates. We compute

$$u_s = v_x, \quad u_{ss} = v_{xx}, \tag{2.8}$$

$$u_z = v_x(-f)_z + v_z, \tag{2.9}$$

$$u_{zz} = v_{xx}|f_z|^2 + 2v_{xz}(-f)_z + v_x\,(-f)_{zz} + v_{zz}. \tag{2.10}$$

In order to write down the equation it is also convenient to expand

$$a(\varepsilon s, \varepsilon z) = a(0, \varepsilon z) + a_t(0, \varepsilon z)\varepsilon s + \frac{1}{2}a_{tt}(0, \varepsilon z)\varepsilon^2 s^2 + a_4(\varepsilon s, \varepsilon z)\varepsilon^3 s^3 \tag{2.11}$$

for a smooth function $a_4(t, \theta)$. It turns out that u solves (2.4) if and only if v defined by (2.7) solves

$$S(v) \equiv v_{zz} + v_{xx} + B_3(v) + B_4(v) + v - v^3 = 0, \tag{2.12}$$

where $B_3(v)$ is a linear differential operator defined by

$$\begin{aligned} B_3(v) = &\left[\varepsilon k - \varepsilon^2 k^2\,(\,x + f\,)\right]\, v_x \\ &+ \left[\varepsilon^2\,|f'|^2\, v_{xx} - 2\varepsilon f' v_{xz} - \varepsilon^2 f'' v_x\right] \\ &+ B_5(v), \end{aligned}$$

with

$$B_5(v) = B_0(u) - a_4(\varepsilon s, \varepsilon z)\varepsilon^3 s^3(1 - v^2) \tag{2.13}$$

and

$$B_4(v) = -\left[\varepsilon a_t\,(x + f) + \frac{\varepsilon^2}{2}a_{tt}\,(x + f)^2\right]\,(1 - v^2). \tag{2.14}$$

$B_0(u)$ is the operator in (2.6), where the derivatives are expressed in terms of the formulas (2.8)–(2.10), a_4 is given by (2.11), and s is replaced with $x + f$.

Let $H(x)$ denote the unique positive solution of (1.10). Then, taking $H(x)$ as a first approximation, the error produced is of ε times a function with exponential decay. Let us be more precise. We need to identify both the terms of order ε and those of order ε^2:

$$\begin{aligned} S(H) = B_3(H) + B_4(H) = &\left[\varepsilon k - \varepsilon^2 k^2\,(\,x + f\,)\right]\, H_x \\ &+ \left[\,\varepsilon^2 |f'|^2\, H_{xx} - \varepsilon^2 f'' H_x\,\right] \\ &- \left[\varepsilon a_t\,(x + f) + \frac{\varepsilon^2}{2}a_{tt}\,(x + f)^2\right]\,(1 - H^2) + B_5(H), \end{aligned}$$

where

$$B_5(H) = B_0(H) - \varepsilon^3 s^3 a_4(\varepsilon s, \varepsilon z)(1 - H^2).$$

Gathering terms of order ε and ε^2 we get

$$\begin{aligned} S(H) = &-\varepsilon a_t x(1-H^2) \\ &+\varepsilon\left[kH_x - a_t f(1-H^2)\right] \\ &-\varepsilon^2\left[k^2(xH_x) - |f'|^2 H_{xx} + a_{tt} f x(1-H^2)\right] \\ &-\varepsilon^2\left[k^2 f H_x + f'' H_x + \frac{a_{tt}}{2}[x^2+f^2](1-H^2)\right] \\ &\qquad + B_6(H) \\ = &\,\varepsilon S_1 + \varepsilon S_2 + \varepsilon^2 S_3 + \varepsilon^2 S_4 + B_6(H)\,. \end{aligned}$$

Let us observe that, grouped this way, the quantities S_1, S_3 are odd functions of x while S_2, S_4 are even. In addition, $B_6(H)$ is a term of order ε^3 times an exponentially decaying function. We want now to construct a further approximation to a solution which eliminates the terms of order ε in the error. If ϕ represents such an approximation, then we see that

$$S(H+\phi) = S(H) + L_0(\phi) + B_7(\phi) + N_0(\phi),$$

where

$$L_0(\phi) = \phi_{zz} + \phi_{xx} + (1-3H^2)\phi, \tag{2.15}$$

$$B_7(\phi) = B_3(H+\phi) + B_4(H+\phi) - B_3(H) - B_4(H), \tag{2.16}$$

and

$$N_0(\phi) = -3H\phi^2 - \phi^3. \tag{2.17}$$

We write

$$\begin{aligned} S(H+\phi) = &\,[\varepsilon(S_1+S_2) + \phi_{xx} + (1-3H^2)\phi] \\ &+\varepsilon^2 S_3 + \varepsilon^2 S_4 + B_6(H) + \phi_{zz} + B_7(\phi) + N_0(\phi). \end{aligned} \tag{2.18}$$

We choose $\phi = \phi_1$ in order to eliminate the term between brackets in the above expression. Namely, for fixed z, we need a solution of

$$-\phi_{xx} + (3H^2-1)\phi = \varepsilon(S_1+S_2), \quad \phi(\pm\infty) = 0.$$

As it is well known, this problem is solvable provided that

$$\int_{-\infty}^{\infty} (S_1+S_2)H_x\,dx = 0. \tag{2.19}$$

Furthermore, the solution is unique under the constraint

$$\int_{-\infty}^{\infty} \phi H_x\,dx = 0. \tag{2.20}$$

We compute

$$\int_{-\infty}^{\infty} (S_1+S_2)H_x\,dx = \int_{-\infty}^{\infty} S_2 H_x\,dx = k\int_{-\infty}^{\infty} H_x^2 - a_t f \int_{-\infty}^{\infty} (1-H^2)H_x,$$

where

$$\int_{-\infty}^{\infty}(1-H^2)H_x=\frac{4}{3}.$$

Since $a_t(0,\theta)\neq 0$, we have that the first approximation of f should be

$$f_0(\theta)=c_0\frac{k(\theta)}{a_t(0,\theta)},\quad \text{where } c_0=\frac{3\int_{\mathbb{R}}H_x^2}{4}.$$

The solution has the form

$$\phi_1=\phi_{11}+\phi_{12}, \tag{2.21}$$

where

$$\phi_{11}=\varepsilon a_{11}(\varepsilon z)H_1(x),\quad \phi_{12}=\varepsilon f_0(\varepsilon z)a_{12}(\varepsilon z)H_2(x), \tag{2.22}$$

$$a_{11}=a_t(0,\theta),\quad a_{12}=k(\theta),$$

H_1 is the unique odd function satisfying

$$-H_{1,xx}-H_1+3H^2H_1=x(1-H^2), \tag{2.23}$$

and H_2 is the unique even solution satisfying

$$-H_{2,xx}-H_2+3H^2H_2=H_x-c_0(1-H^2),\quad \int_{\mathbb{R}}H_2H_x\,dx=0. \tag{2.24}$$

Let us now choose f:

$$f(\theta)=f_0(\theta)+\mathbf{f}(\theta). \tag{2.25}$$

In all what follows, we will assume the validity of the following constraints on the parameter $\mathbf{f}$:

$$\|\mathbf{f}\|\equiv\varepsilon\|\mathbf{f}^{''}\|_{L^2(0,\ell)}+\sqrt{\varepsilon}\|\mathbf{f}'\|_{L^2(0,\ell)}+\|\mathbf{f}\|_{L^\infty(0,\ell)}\leq\varepsilon, \tag{2.26}$$

so that

$$\|\mathbf{f}\|_{L^\infty(0,\ell)}\leq\varepsilon,\quad \|\mathbf{f}'\|_{L^2(0,\ell)}\leq\sqrt{\varepsilon},\quad \|\mathbf{f}''\|_{L^2(0,\ell)}\leq 1. \tag{2.27}$$

By interpolation, it also holds that

$$\|\mathbf{f}'\|_{L^\infty(0,\ell)}\leq\sqrt{\varepsilon}. \tag{2.28}$$

We now take our basic approximation to a solution to the problem near the curve Γ_ε to be

$$f(\theta)=f_0(\theta)+\mathbf{f}(\theta),\qquad \mathtt{H}=H+\phi_1. \tag{2.29}$$

Substituting $\phi=\phi_1$ in (2.18), we can compute the new error:

$$\begin{aligned}E_1&=S(\mathtt{H})=S(H+\phi_1)\\&=\varepsilon(S_1+S_2)+\phi_{1,xx}+(1-3H^2)\phi_1\\&\quad+\varepsilon^2S_3+\varepsilon^2S_4+B_6(H)+\phi_{1,zz}+B_7(\phi_1)+N_0(\phi_1)\\&=-\varepsilon a_t\mathbf{f}(1-H^2)+\varepsilon^2S_3+\varepsilon^2S_4+B_6(H)+\phi_{1,zz}+B_7(\phi_1)+N_0(\phi_1).\end{aligned} \tag{2.30}$$

Observe that since ϕ_1 and $\mathbf{f}$ are of size $O(\varepsilon)$, all terms above carry ε^2 in front. Observe also that all functions involved are expressed in (x,z) variables, and the natural domain for those variables is the infinite strip

$$\mathcal{S} = \{-\infty < x < \infty, \quad 0 < z < \ell/\varepsilon\}.$$

We now want to measure the size of the error in the $L^2(\mathcal{S})$ norm.

Note that

$$\| - \varepsilon a_t \mathbf{f}(1-H^2) + \varepsilon^2 S_3 + \varepsilon^2 S_4\|_{L^2(\mathcal{S})} \leq C\varepsilon^{\frac{3}{2}}. \tag{2.31}$$

A rather delicate term in the cubic remainder $B_6(H)$ is the one carrying $\mathbf{f}''$ since in reality we shall only assume a uniform bound on $\|\mathbf{f}''\|_{L^2(0,\ell)}$. For instance, one term arising from $B_6(H)$ can be written as

$$R = \varepsilon^3 (x+f) f''(\varepsilon z) a_2(\varepsilon(x+f), \varepsilon z) H_x(x), \quad f = f_0 + \mathbf{f},$$

with a_2 smooth (see (2.6)). Observe that

$$\int_{\mathcal{S}} |R|^2 \leq C\varepsilon^6 \int_0^{\frac{\ell}{\varepsilon}} |f''(\varepsilon z)|^2 dz = \varepsilon^5 \|f''\|^2_{L^2(0,\ell)}.$$

Hence

$$\|R\|_{L^2(\mathcal{S})} \leq C\varepsilon^{\frac{5}{2}} \|f''\|_{L^2(0,\ell)}.$$

Since ϕ_1 can be bounded by $C\varepsilon|x|^2 e^{-c|x|}$ for large $|x|$, we obtain that

$$\|B_7(\phi_1)\|_{L^2(\mathcal{S})} \leq C\varepsilon^{\frac{3}{2}} \ .$$

A similar bound holds for the term $N_0(\phi_1)$:

$$\|N_0(\phi_1)\|_{L^2(\mathcal{S})} \leq C\varepsilon^{\frac{3}{2}}. \tag{2.32}$$

In summary, we have

$$\|S(H+\phi_1)\|_{L^2(\mathcal{S})} \leq C\varepsilon^{\frac{3}{2}}. \tag{2.33}$$

We set up the full problem in the form $S(\mathtt{H}+\phi) = 0$, which takes the form near the curve,

$$S(\mathtt{H}+\phi) = L_0(\phi) + B_8(\phi) + E_1 + N_1(\phi) = 0, \tag{2.34}$$

where $E_1 = S(\mathtt{H})$ and

$$L_0(\phi) = \phi_{xx} + \phi_{zz} + (1 - 3\mathtt{H}^2)\phi \ , \tag{2.35}$$

$$B_8(\phi) = B_7(\phi+\phi_1) - B_7(\phi_1), \tag{2.36}$$

$$N_1(\phi) = N_0(\phi+\phi_1) - N_0(\phi_1). \tag{2.37}$$

We recall that the description made here is only local. However, we will be able to reduce the problem to one qualitatively similar to that of the above form in the infinite strip.

3. The matching procedure. We follow [12] to perform a procedure that we refer to as an infinite-dimensional Liapunov–Schmidt reduction (see the explanations at the end of this section). Since it is quite similar to that of [12], we shall only sketch the proofs.

First, we need to match solutions near and outside Γ. The idea is to solve the problem outside a tubular neighborhood of Γ and then to reduce the problem to an infinite strip.

Let $\mathtt{H}(y)$ denote the first approximation constructed near the curve in the coordinate $y = (y_1, y_2)$ in $\mathbb{R}^2$. Let $\delta < \delta_0/100$ be a fixed number. We consider a smooth cut-off function $\eta_\delta(t)$ such that $\eta_\delta(t) = 1$ if $|t| < \delta$ and $= 0$ if $|t| > 2\delta$. Denote as well $\eta^\varepsilon_\delta(s) = \eta_\delta(\varepsilon|s|)$, where s is the normal coordinate to Γ_ε. We define our first global approximation to be simply

$$\mathbf{H}(y) = \begin{cases} \eta^\varepsilon_{3\delta}(s)(\mathtt{H}+1) - 1 \text{ if } y \in \Omega_+, \\ \eta^\varepsilon_{3\delta}(s)(\mathtt{H}-1) + 1 \text{ if } y \in \mathbb{R}^2 \setminus \Omega_+. \end{cases}$$

Denote $S(u) = \Delta u + (u - a(\varepsilon s, \varepsilon z))(1 - u^2)$ for $u = \mathbf{H} + \tilde\phi$. Then $S(\mathbf{H} + \tilde\phi) = 0$ if and only if

$$\tilde L(\tilde\phi) = \tilde E + \tilde N(\tilde\phi), \tag{3.1}$$

where

$$\begin{aligned} \tilde E &= -S(\mathbf{H}), \\ \tilde L(\tilde\phi) &= \Delta\tilde\phi + [1 - 3\mathbf{H}^2 + 2a(\varepsilon y)\mathbf{H}]\tilde\phi, \end{aligned}$$

and

$$\tilde N(\tilde\phi) = -3\mathbf{H}(\tilde\phi)^2 - (\tilde\phi)^3 + a(\varepsilon y)(\tilde\phi)^2.$$

We further separate $\tilde\phi$ in the following form:

$$\tilde\phi = \eta^\varepsilon_{3\delta}\phi + \psi,$$

where, in coordinates (x, z), we assume that ϕ is defined in the whole strip $\mathcal{S}$. We want

$$\tilde L(\eta^\varepsilon_{3\delta}\phi) + \tilde L(\psi) = \tilde E + \tilde N(\eta^\varepsilon_{3\delta}\phi + \psi).$$

We achieve this if the pair (ψ, ϕ) satisfies the following nonlinear coupled system:

$$\eta^\varepsilon_{3\delta}\tilde L(\phi) = \eta^\varepsilon_\delta\tilde E + \eta^\varepsilon_\delta\tilde N(\eta^\varepsilon_{3\delta}\phi + \psi) - 3\eta^\varepsilon_\delta(1 - \mathbf{H}^2)\psi, \tag{3.2}$$

$$\begin{aligned} &\Delta\psi - 2(1 - a\mathbf{H})\psi + 3(1 - \eta^\varepsilon_\delta)(1 - \mathbf{H}^2)\,\psi = (1 - \eta^\varepsilon_\delta)\,\tilde E - 2\varepsilon\nabla\eta^\varepsilon_{3\delta}\,\nabla\phi \\ &\quad - 2\varepsilon^2(\Delta\eta^\varepsilon_{3\delta})\,\phi + (1 - \eta^\varepsilon_\delta)\,\tilde N(\,\eta^\varepsilon_{3\delta}\,\phi + \psi\,), \end{aligned} \tag{3.3}$$

where ϕ is defined globally on $\mathcal{S}$ and ψ is defined in Ω_ε and is required to satisfy the Neumann boundary condition.

Notice that the operator $\tilde L$ in the strip $\mathcal{S}$ may be taken as any compatible extension outside the $6\delta/\varepsilon$-neighborhood of the curve.

What we want to do next is to reduce the problem to one in the strip. To do this, we solve, given a small ϕ, problem (3.3) for ψ. This can be done in an elementary way: Let us observe first that since $|a(x)| < 1$, we have

$$\gamma_0^2 = \min_{x\in\bar{\Omega}} 2(1 - |a(x)|) > 0. \tag{3.4}$$

Since $1-\mathbf{H}^2$ is exponentially small for $|s| > \delta\varepsilon^{-1}$, where s is the normal coordinate to Γ_ε, then the problem

$$\Delta\psi - 2(1 - a(\varepsilon y)\mathbf{H})\psi + 3(1 - \eta_\delta^\varepsilon)(1 - \mathbf{H}^2)\psi = h, \text{ in } \Omega, \quad \frac{\partial\psi}{\partial\nu} = 0 \text{ on } \partial\Omega_\varepsilon, \tag{3.5}$$

has a unique bounded solution ψ whenever $\|h\|_\infty < +\infty$. Moreover,

$$\|\psi\|_\infty \le C\|h\|_\infty.$$

Assume now that ϕ satisfies the following decay condition:

$$|\nabla\phi(y)| + |\phi(y)| \le e^{-\frac{\gamma}{\varepsilon}} \quad \text{for } |s| > \frac{\delta}{\varepsilon}. \tag{3.6}$$

Since $\tilde{N}$ has a power-like behavior with power greater than one, a direct application of the contraction mapping principle yields that problem (3.3) has a unique (small) solution $\psi = \psi(\phi)$ with

$$\|\psi(\phi)\|_\infty \le Ce^{-\delta/\varepsilon} + C\varepsilon[\,\|\phi\|_{L^\infty(|s|>\delta\varepsilon^{-1})} + \|\nabla\phi\|_{L^\infty(|s|>\delta\varepsilon^{-1})}\,],$$

where with some abuse of notation by $\{|s| > \delta/\varepsilon\}$ we denote the complement of the δ/ε-neighborhood of Γ_ε. The nonlinear operator ψ satisfies a Lipschitz condition of the form

$$\|\psi(\phi_1) - \psi(\phi_2)\|_\infty \le C\varepsilon[\,\|\phi_1 - \phi_2\|_{L^\infty(|s|>\delta\varepsilon^{-1})} + \|\nabla(\phi_1 - \phi_2)\|_{L^\infty(|s|>\delta\varepsilon^{-1})}\,].$$

The full problem has been reduced to solving the (nonlocal) problem in the infinite strip $\mathcal{S}$,

$$L_2(\phi) = \eta_\delta^\varepsilon\tilde{E} + \eta_\delta^\varepsilon\tilde{N}(\eta_{3\delta}^\varepsilon\phi + \psi(\phi)) - 3\eta_\delta^\varepsilon(1 - \mathbf{H}^2)\psi(\phi), \tag{3.7}$$

for a $\phi \in H^2(\mathcal{S})$ satisfying condition (3.6). Here L_2 denotes a linear operator that coincides with $\tilde{L}$ on the region $|s| < 10\delta/\varepsilon$.

We shall define this operator next. The operator $\tilde{L}$ for $|s| > 20\delta/\varepsilon$ is given in coordinates (x, z) by

$$L_1(\phi) = \phi_{xx} + \phi_{zz} + (1 - 3\mathtt{H}^2)\phi.$$

We extend it for functions ϕ defined in the entire strip $\mathcal{S}$, in terms of (x, z), as follows:

$$L_2(\phi) = L_1(\phi) + 2\chi\,(\varepsilon|x|)a(\varepsilon s, \varepsilon z)\mathtt{H}\phi + \chi\,(\varepsilon|x|)B_1(\phi), \tag{3.8}$$

where $\chi\,(r)$ is a smooth cut-off function which equals 1 for $r < 10\delta$ and vanishes identically for $r > 20\delta$.

Rather than solving problem (3.1) directly, we shall do it in steps. We consider the following projected problem in $H^2(\mathcal{S})$: Given $f = f_0 + \mathbf{f}$, with $\mathbf{f}$ satisfying bounds (2.26), find functions $\phi \in H^2(\mathcal{S})$, c such that

$$L_2(\phi) = \eta_\delta^\varepsilon \tilde{E} + N_2(\phi) + c(\varepsilon z)\chi_\delta^\varepsilon H_x \quad \text{in } \mathcal{S}, \tag{3.9}$$

$$\phi(x,0) = \phi(x,\ell/\varepsilon), \quad \phi_z(x,0) = \phi_z(x,\ell/\varepsilon), \quad -\infty < x < +\infty, \tag{3.10}$$

$$\int_{-\infty}^{\infty} \phi(x,z)\, H_x(x)\, dx = 0, \quad 0 < z < \frac{\ell}{\varepsilon}. \tag{3.11}$$

Here $N_2(\phi) = \eta_\delta^\varepsilon \tilde{N}(\eta_{3\delta}^\varepsilon \phi + \psi(\phi)) - 3\eta_\delta^\varepsilon(1 - \mathtt{H}^2)\psi(\phi)$ and $\chi_\delta^\varepsilon(x) = \chi_1(\varepsilon|x|/\delta)$, where $\chi_1(t)$ is a cut-off function equal to 1 for $|t| < 1/2$ and equal to 0 for $|t| > 1$.

We will prove that this problem has a unique solution whose norm is controlled by the L^2 norm of $\eta_\delta^\varepsilon \tilde{E} = E_1 = S(\mathtt{H})$. The main step here is to show bounded invertibility of a suitable perturbation of the operator L_2. The proof of this fact is a combination of an a priori estimate (Lemma 4.1) with an application of the Fredholm alternative (Lemma 4.2). After this first step, our task is to adjust the parameter $\mathbf{f}$ in such a way that c is identically zero. As we will see, this turns out to be equivalent to solving a nonlocal, nonlinear, second order differential equation for $\mathbf{f}$ under periodic boundary conditions. This system is solvable in a region where the bound (2.26) holds.

We call the entire procedure described above as *infinite-dimensional Lyapunov–Schmidt reduction* because of its analogy to a method devised by Floer and Weinstein [16] in a finite-dimensional context for a related problem. In a finite-dimensional setting, the main step in this method, which corresponds to adjustment of a parameter to make $c = 0$, is also known as *quasi-invariant manifold reduction*. The whole scheme has been refined and widely used in singular perturbation elliptic problems.

We will carry out the outlined program in the next sections. To solve (3.9)–(3.11) we need to investigate invertibility of L_2 in the L^2-H^2 setting under periodic boundary conditions and orthogonality conditions.

4. Invertibility of L_2. Let L_2 be the operator defined in $H^2(\mathcal{S})$ by (3.8). In this section we study the linear problem

$$L_2(\phi) = h + c(\varepsilon z)\chi_\delta^\varepsilon H_x \quad \text{in } \mathcal{S}, \tag{4.1}$$

$$\phi(x,0) = \phi(x,\ell/\varepsilon), \quad \phi_z(x,0) = \phi_z(x,\ell/\varepsilon), \quad -\infty < x < +\infty, \tag{4.2}$$

$$\int_{-\infty}^{\infty} \phi(x,z)\, H_x(x)\, dx = 0, \quad 0 < z < \frac{\ell}{\varepsilon} \tag{4.3}$$

for a given $h \in L^2(\mathcal{S})$. Our main result in this section is the following.

PROPOSITION 4.1. *If δ in the definition of L_2 is chosen sufficiently small, then there exists a constant $C > 0$, independent of ε, such that for all small ε, problem* (4.1)–(4.3) *has a unique solution $\phi = T(h)$, which satisfies the estimate*

$$\|\phi\|_{H^2(\mathcal{S})} \le C\|h\|_{L^2(\mathcal{S})}.$$

For the proof of this result we need the validity of the corresponding assertion for a simpler operator which does not depend on δ. Let us consider the problem

$$\mathtt{L}(\phi) = \phi_{ss} + \phi_{zz} + (1 - 3H^2)\phi = h \quad \text{in } \mathcal{S}, \tag{4.4}$$

$$\phi(x,0) = \phi(x,\ell/\varepsilon), \quad \phi_z(x,0) = \phi_z(x,\ell/\varepsilon), \quad -\infty < x < +\infty, \tag{4.5}$$

$$\int_{-\infty}^{\infty} \phi(x,z)\, H_x(x)\, dx = 0, \quad 0 < z < \frac{\ell}{\varepsilon}. \tag{4.6}$$

LEMMA 4.1. *There exists a constant $C > 0$, independent of ε such that the solutions of* (4.4)–(4.6) *satisfy the a priori estimate*

$$\|\phi\|_{H^2(\mathcal{S})} \le C\|h\|_{L^2(\mathcal{S})}.$$

Proof. Let us consider Fourier series decompositions for h and ϕ of the form

$$\phi(x,z) = \sum_{k=0}^{\infty} \left[\phi_{1k}(x)\cos\left(\frac{2\pi k}{\ell}\varepsilon z\right) + \phi_{2k}(x)\sin\left(\frac{2\pi k}{\ell}\varepsilon z\right)\right],$$

$$h(x,z) = \sum_{k=0}^{\infty} \left[h_{1k}(x)\cos\left(\frac{2\pi k}{\ell}\varepsilon z\right) + h_{2k}(x)\sin\left(\frac{2\pi k}{\ell}\varepsilon z\right)\right].$$

Then we have the validity of the equations

$$-\frac{4\pi^2 k^2 \varepsilon^2}{l^2}\phi_{lk} + \mathtt{L}_0(\phi_{lk}) = h_{lk}, \quad x \in \mathbb{R}, \tag{4.7}$$

with orthogonality conditions

$$\int_{-\infty}^{\infty} \phi_{lk}\, H_x\, dx = 0. \tag{4.8}$$

We have denoted here

$$\mathtt{L}_0(\phi_{lk}) = \phi_{lk,xx} + (1-3H^2)\phi_{lk}.$$

Let us consider the bilinear form in $H^1(\mathbb{R})$ associated with the operator $\mathtt{L}_0$, namely,

$$B(\psi,\psi) = \int_{-\infty}^{\infty} [|\psi_x|^2 + (3H^2-1)|\psi|^2]\, dx\ .$$

Since (4.8) holds, we conclude that

$$C[\|\phi_{lk}\|^2_{L^2(\mathbb{R})} + \|\phi_{lk,x}\|^2_{L^2(\mathbb{R})}] \le B(\phi_{lk},\phi_{lk}) \tag{4.9}$$

for a constant $C > 0$ independent of l, k. Using this fact and (4.7) we conclude with the estimate

$$(1+k^4\varepsilon^4)\|\phi_{lk}\|^2_{L^2(\mathbb{R})} + \|\phi_{lk,x}\|^2_{L^2(\mathbb{R})} \le C\|h_{lk}\|^2_{L^2(\mathbb{R})}.$$

In particular, we see from (4.7) that ϕ_{lk} satisfies an equation of the form

$$-\phi_{lk,xx} + 2\phi_{lk} = \tilde{h}_{lk}, \quad x \in \mathbb{R},$$

where $\|\tilde{h}_{lk}\|_{L^2(\mathbb{R})} \le C\|h_{lk}\|_{L^2(\mathbb{R})}$. Hence it follows that additionally we have the estimate

$$\|\phi_{lk,xx}\|^2_{L^2(\mathbb{R})} \le C\|h_{lk}\|^2_{L^2(\mathbb{R})}. \tag{4.10}$$

Adding up estimates (4.9), (4.10) in k and l we conclude that

$$\|D^2\phi\|^2_{L^2(\mathcal{S})} + \|D\phi\|^2_{L^2(\mathcal{S})} + \|\phi\|^2_{L^2(\mathcal{S})} \le C\|h\|^2_{L^2(\mathcal{S})},$$

which ends the proof. ∎

We consider now the following problem: Given $h \in L^2(\mathcal{S})$, find functions $\phi \in H^2(\mathcal{S})$, $c \in L^2(0,\ell)$ such that

$$\mathtt{L}(\phi) \;=\; h \;+\; c(\varepsilon z)\chi_\delta^\varepsilon H_x \quad \text{in } \mathcal{S}, \tag{4.11}$$

$$\phi(x,0) = \phi(x,\ell/\varepsilon), \quad \phi_z(x,0) = \phi_z(x,\ell/\varepsilon), \quad -\infty < x < +\infty, \tag{4.12}$$

$$\int_{-\infty}^{\infty} \phi(x,z)\, H_x(x)\, dx = 0, \quad 0 < z < \frac{\ell}{\varepsilon}. \tag{4.13}$$

LEMMA 4.2. *Problem* (4.11)–(4.13) *possesses a unique solution. Moreover,*

$$\|\phi\|_{H^2(\mathcal{S})} \le C\|h\|_{L^2(\mathcal{S})}.$$

Proof. To establish existence, we assume that

$$h(x,z) = \sum_{k=0}^{\infty} \left[h_{1k}(x)\cos\left(\frac{2\pi k}{\ell}\varepsilon z\right) \;+\; h_{2k}(x)\sin\left(\frac{2\pi k}{\ell}\varepsilon z\right)\right]$$

and consider the problem of finding $\phi_{lk} \in H^1(\mathbb{R})$, and constants c_{lk}, such that

$$-\frac{4\pi^2 k^2 \varepsilon^2}{l^2}\phi_{lk} + L_0(\phi_{lk}) = h_{lk} + c_{lk}\chi_\delta^\varepsilon H_x, \quad x \in \mathbb{R},$$

and

$$\int_{-\infty}^{\infty} \phi_{lk}\, H_x\, dx = 0.$$

Fredholm's alternative yields that this problem is solvable with the choices

$$c_{lk} = -\frac{\int_{-\infty}^{\infty} h_{lk} H_x dx}{\int_{-\infty}^{\infty} H_x^2 \chi_\delta^\varepsilon dx}.$$

Observe in particular that

$$\sum_{k=0}^{\infty} |c_{lk}|^2 \le C\varepsilon\|h\|^2_{L^2(\mathcal{S})}. \tag{4.14}$$

Finally, define

$$\phi(x,z) = \sum_{k=0}^{\infty} \left[\phi_{1k}(x)\cos\left(\frac{2\pi k}{\ell}\varepsilon z\right) \;+\; \phi_{2k}(x)\sin\left(\frac{2\pi k}{\ell}\varepsilon z\right)\right],$$

and correspondingly

$$c(z) = \sum_{k=0}^{\infty} \left[c_{1k}\cos\left(\frac{2\pi k}{\ell} z\right) \;+\; c_{2k}\sin\left(\frac{2\pi k}{\ell} z\right)\right].$$

The estimate (4.14) gives that $c(\varepsilon z)\chi_\delta^\varepsilon H_x$ has the $L^2(\mathcal{S})$ norms controlled by that of h. The a priori estimates of the previous lemma tell us that the series for ϕ is convergent in $H^2(\mathcal{S})$ and defines a unique solution for the problem with the desired bounds. ∎

Proof of Proposition 4.1. Problem (4.1)–(4.3) can be reduced to a small perturbation of a problem of the form (4.11)–(4.13) in which Lemma 4.2 is applicable. In fact, we have

$$L_2(\phi) = \mathtt{L}(\phi) + \tilde{B}(\phi), \tag{4.15}$$

where

$$\tilde{B}(\phi) = 3(\mathtt{H}^2 - 3H^2)\phi + 2\chi(\varepsilon|x|)a(\varepsilon s, \varepsilon z)\phi + \chi(\varepsilon|x|)B_1(\phi).$$

In the operator $B_1(\phi)$, consider for instance the following term involving f'':

$$B_f(\phi) = \varepsilon^2 f''(\varepsilon z)\phi_x.$$

Then we have

$$\|B_f(\phi)\|^2_{L^2(\mathcal{S})} \le \varepsilon^3 \int_0^\ell |f''(\theta)|^2 d\theta \left(\sup_z \int_{-\infty}^{\infty} |\phi_x(x,z)|^2 \, dx \right).$$

Let $\varphi(z) = \int_{-\infty}^{\infty} |\phi_x(x,z)|^2 dx$. Then

$$\begin{aligned} \sup_z \varphi(z) &\le \varepsilon \int_{\mathcal{S}} |\phi_x|^2 + 2 \int_{\mathcal{S}} |\phi_x||\phi_{xz}| \\ &\le \frac{1}{2} \sup_z \varphi(z) + 4\varepsilon^{-1} \int_{\mathcal{S}} |\phi_{xz}|^2 + \varepsilon \int_{\mathcal{S}} |\phi_x|^2. \end{aligned}$$

Hence

$$\varphi(z) \le C\varepsilon^{-1} \|\phi\|^2_{H^2(\mathcal{S})}, \tag{4.16}$$

so that finally

$$\|B_f(\phi)\|_{L^2(\mathcal{S})} \le C\varepsilon \|f''\|_{L^2(0,\ell)}.$$

For other terms the analysis follows in a simpler way. In fact we get

$$\|\tilde{B}(\phi)\|_{L^2(\mathcal{S})} \le C\delta \|\phi\|_{H^2(\mathcal{S})}.$$

This last estimate is a rather straightforward consequence of the fact that $|\varepsilon s| < 20\delta$ wherever the operator $\chi(\varepsilon|x|)B_1$ is supported, and $|a(\varepsilon s, \varepsilon z)| \le C\delta$ in $\mathcal{S}$. Thus, by reducing δ if necessary, we apply the invertibility result of Lemma 4.2. This concludes the proof. □

5. Solving the nonlinear intermediate problem. In this section we will solve problem (3.9)–(3.11). For brevity we let $E_2 = \eta^\varepsilon_\delta \tilde{E}$.

Notice that

$$\|E_2\|_{L^2(\mathcal{S})} \le C\varepsilon^{\frac{3}{2}}.$$

For further reference, it is useful to point out the Lipschitz dependence of the term of error E_2 on the parameters $\mathbf{f}$ for the norms defined in (2.26). We have the validity of the estimate

$$\|E_2(\mathbf{f}_1) - E_2(\mathbf{f}_2)\|_{L^2(\mathcal{S})} \le C\varepsilon^{\frac{1}{2}} [\|\mathbf{f}_1 - \mathbf{f}_2\|]. \tag{5.1}$$

Let T be the operator defined by Proposition 4.1. Then the equation is equivalent to the fixed point problem

$$\phi = T(E_2 + N_2(\phi)) \equiv \mathcal{A}(\phi). \tag{5.2}$$

The operator T has a useful property: Assume h has support contained in $|x| \leq \frac{\delta}{\varepsilon}$. Then by elliptic estimates, $\phi = T(h)$ satisfies the estimate

$$|\phi(x,z)| + |\nabla\phi(x,z)| \leq \|\phi\|_\infty e^{-\frac{\gamma_0\delta}{\varepsilon}} \quad \text{for } |x| > \frac{\delta}{\varepsilon}. \tag{5.3}$$

Now we recall that the operator $\psi(\phi)$ satisfies, as seen directly from its definition,

$$\|\psi(\phi)\|_{L^\infty} \leq C\left[\,\|\,|\nabla\phi| + |\phi|\,\|_{L^\infty(|s|>\frac{\delta}{\varepsilon})} + e^{-\frac{\gamma_0\delta}{\varepsilon}}\right], \tag{5.4}$$

and also the Lipschitz condition

$$\|\psi(\phi_1) - \psi(\phi_2)\|_{L^\infty} \leq C\left[\,\|\,|\nabla(\phi_1-\phi_2)| + |\phi_1-\phi_2|\,\|_{L^\infty(|s|>\frac{\delta}{\varepsilon})}\right]; \tag{5.5}$$

here $s = x + f$. These facts will allow us to construct a region where the contraction mapping principle applies. As we have said,

$$\|E_2\|_{L^2(\mathcal{S})} \leq C_* \varepsilon^{\frac{3}{2}}$$

for certain constant $C_* > 0$. We consider the following closed, bounded subset of $H^2(\mathcal{S})$:

$$\mathcal{B} = \left\{ \phi \in H^2(\mathcal{S}) \;\middle|\; \begin{array}{l} \|\phi\|_{H^2(\mathcal{S})} \leq D\varepsilon^{\frac{3}{2}}, \\ \|\,|\phi| + |\nabla\phi|\,\|_{L^\infty(|s|>\frac{\delta}{\varepsilon})} \leq \|\phi\|_{H^2(\mathcal{S})} e^{-\frac{\gamma_0\delta}{2\varepsilon}} \end{array} \right\}.$$

We claim that if the constant D is fixed sufficiently large, then the map $\mathcal{A}$ defined in (5.2) is a contraction from B into itself.

Let us analyze the Lipschitz character of the nonlinear operator $N_2(\phi)$, involved in $\mathcal{A}$ for functions in $\mathcal{B}$. Arguing as in [12], we have the following Lipschitz estimates for $N_2(\phi)$:

$$\|N_2(\phi_1) - N_2(\phi_2)\|_{L^2(\mathcal{S})} \leq C\varepsilon^{\frac{3}{2}} \|\phi_1 - \phi_2\|_{H^2(\mathcal{S})}. \tag{5.6}$$

Now let $\phi \in \mathcal{B}$; then $\varphi = \mathcal{A}(\phi)$ satisfies

$$\|\varphi\|_{H^2(\mathcal{S})} \leq C_* \varepsilon^{\frac{3}{2}} \|T\|.$$

Choosing any number $D > C_*\|T\|$ we get that for small ε

$$\|\varphi\|_{H^2(\mathcal{S})} \leq D\varepsilon^{\frac{3}{2}}.$$

On the other hand we have

$$\|\varphi\|_{L^\infty(\mathcal{S})} \leq C\|\varphi\|_{H^2(\mathcal{S})}.$$

But φ satisfies an equation of the form $L_2(\varphi) = h$ with h compactly supported. Hence φ belongs to $\mathcal{B}$ thanks to the discussion above. $\mathcal{A}$ is clearly a contraction mapping thanks to (5.6). We conclude that $\mathcal{A}$ has a unique fixed point in $\mathcal{B}$.

We recall that the error E_2 and the operator T themselves carry the function $\mathbf{f}$ as a parameter. A tedious but straightforward analysis of all terms involved in the differential operator and in the error yield that this dependence is indeed Lipschitz with respect to the H^2 norm (for each fixed ε). Indeed, emphasizing now the dependence of L_2 on $\mathbf{f}$ we can write

$$L_{2,\mathbf{f}_1}(\phi(\mathbf{f}_1)) - L_{2,\mathbf{f}_2}(\phi(\mathbf{f}_2)) = L_{2,\mathbf{f}_1}[\phi(\mathbf{f}_1) - \phi(\mathbf{f}_2)] + [L_{2,\mathbf{f}_1} - L_{2,\mathbf{f}_2}](\phi(\mathbf{f}_1))$$

and use the theory just developed to estimate $\phi(\mathbf{f}_1) - \phi(\mathbf{f}_2)$. Taking advantage of the Lipschitz character of the error term $E_2(\mathbf{f})$, we can show the Lipschitz character of T, and we find

$$\|T_{\mathbf{f}_1} - T_{\mathbf{f}_2}\| \le C\varepsilon\|\mathbf{f}_1 - \mathbf{f}_2\|.$$

Hence

$$\|\phi(\mathbf{f}_1) - \phi(\mathbf{f}_2)\|_{H^2(\mathcal{S})} \le C\varepsilon\|\mathbf{f}_1 - \mathbf{f}_2\|. \tag{5.7}$$

We summarize the result we have obtained in the following.

PROPOSITION 5.1. *There is a number $D > 0$ such that for all sufficiently small ε and all $\mathbf{f}$ satisfying* (2.26)*, problem* (3.9)–(3.11) *has a unique solution $\phi = \phi(\mathbf{f})$ which satisfies*

$$\|\phi\|_{H^2(\mathcal{S})} \le D\varepsilon^{\frac{3}{2}},$$
$$\| \, |\phi| + |\nabla\phi| \, \|_{L^\infty(|s|>\frac{\delta}{\varepsilon})} \le \|\phi\|_{H^2(\mathcal{S})} e^{-\frac{\gamma_0\delta}{2\varepsilon}}.$$

Besides, ϕ depends Lipschitz continuously on $\mathbf{f}$ in the sense of estimate (5.7).

Next we carry out the second part of the program, which is to set up an equation for $\mathbf{f}$, which is equivalent to making c identically zero. The equation is obtained by simply integrating the equation (only in x) against H_x. It is therefore of crucial importance to carry out computations of the terms $\int_{\mathbb{R}} E_2 H_x \, dx$. We do that in the next section.

6. Estimates for projections of the error. In this section we carry out some estimates for the terms $\int_{\mathbb{R}} E_2 H_x \, dx$, where $E_2 = \eta_\delta^\varepsilon E_1$ and E_1 was defined as in (2.30). Observe that it suffices to evaluate $\int_{\mathbb{R}} E_1 H_x \, dx$ instead since the difference $E_2 - E_1$ is exponentially small in ε. Notice that the odd terms in x in E_1 do not contribute to the value of the integral since H_x is an even function.

We recall

$$S(H+\phi_1) = -\varepsilon a_t \mathbf{f}(1-H^2) + \varepsilon^2 S_3 + \varepsilon^2 S_4 + B_6(H) + \phi_{1,zz} + B_7(\phi_1) + N_0(\phi_1),$$

where S_3 is an odd function, S_4 is an even function, and $B_6(H)$ is of order ε^3. Thus, we see that

$$\begin{aligned}
&\int_{\mathbb{R}} S(H+\phi_1)H_x \\
&\quad = -\varepsilon a_t \mathbf{f} \int_{\mathbb{R}} (1-H^2)H_x \\
&\qquad -\varepsilon^2 \left\{ \mathbf{f}'' \int_{\mathbb{R}} H_x^2 + \mathbf{f}\left[k^2 \int_{\mathbb{R}} H_x^2 + a_{tt} f_0 \int_{\mathbb{R}} (1-H^2)H_x \right] \right. \\
&\qquad\qquad \left. + \frac{\mathbf{f}^2}{2} a_{tt} \int_{\mathbb{R}} (1-H^2)H_x dx \right\} \\
&\qquad + \int_{\mathbb{R}} N_0(\phi_1)H_x + \int_{\mathbb{R}} B_7(\phi_1)H_x + \varepsilon^2 \gamma_0(\varepsilon z) + \varepsilon^3 b_{1\varepsilon}\mathbf{f}'' + \varepsilon^3 b_{2\varepsilon}\,.
\end{aligned}$$

Here and below we denote by $b_{l\varepsilon}$, $l = 1, 2$, generic, uniformly bounded continuous functions of the form

$$b_{l\varepsilon} = b_{l\varepsilon}(z, \mathbf{f}(\varepsilon z), \mathbf{f}'(\varepsilon z)),$$

where additionally $b_{1\varepsilon}$ is uniformly Lipschitz in its last two arguments. Here and below, functions $\gamma_j(\theta), j = 0, 1, 2, \ldots$, are C^2 smooth in its argument $\theta \in (0, \ell)$.

Next we estimate $\int_{\mathbb{R}} N_0(\phi_1)H_x$. This term is to main order of the form $\int_{\mathbb{R}} H\phi_1^2 H_x$. Since ϕ_1 doesn't depend on $\mathbf{f}$, we have

$$\int_{\mathbb{R}} N_0(\phi_1)H_x = \varepsilon^2\gamma_1(\varepsilon z).$$

Now, let us consider $\int_{\mathbb{R}} B_7(\phi_1)H_x$. All terms in this expression, with the exception of the terms of size ε in B_7, carry in the L^2 norm as functions of $\theta = \varepsilon z$ powers 3 or higher. Thus, we find

$$\begin{aligned}\int_{\mathbb{R}} B_7(\phi_1)H_x &= \varepsilon \int_{\mathbb{R}} \left[k\phi_{1,x} - a_t(0, \varepsilon z)(x + f)\phi_1\right] H_x \ + O(\varepsilon^3) \\ &= -\varepsilon^2 \mathbf{f} a_t(0, \varepsilon z) \int_{\mathbb{R}} \phi_1 H_x \, dx + \varepsilon^2\gamma_2(\varepsilon z) + \varepsilon^3 b_{3\varepsilon} f^{''} + \varepsilon^3 b_{4\varepsilon},\end{aligned}$$

where $b_{3\varepsilon}$ is uniformly Lipschitz in $\mathbf{f}$ and $\mathbf{f}^{'}$.

In summary, we have established that

$$\begin{aligned}\int_{\mathbb{R}} S(H + \phi_1)H_x \, dx = -\left[\varepsilon^2(\mathbf{f}''(\varepsilon z) + \gamma_3(\varepsilon z)\mathbf{f}\ ) + \varepsilon \mathbf{f}\gamma_4(\varepsilon z)\right] \int_{\mathbb{R}} H_x^2 \\ + \varepsilon^2\gamma_5(\varepsilon z) + \varepsilon^3[b_{5\varepsilon}\mathbf{f}'' + b_{6\varepsilon}],\end{aligned} \tag{6.1}$$

where γ_4 is given by

$$\gamma_4(\theta) = \frac{a_t(0, \theta) \int_{\mathbb{R}} (1 - H^2)H_x}{\int_{\mathbb{R}} H_x^2}, \tag{6.2}$$

and $b_{5\varepsilon}$ is uniformly Lipschitz in $\mathbf{f}$ and $\mathbf{f}^{'}$.

7. Projections of terms involving ϕ. We will estimate next the terms that involve ϕ in (3.9)–(3.11) integrated against H_x. We call the sum of them $\varphi(\phi)$:

$$\begin{aligned}\varphi = -2 \int_{\mathbb{R}} \chi(\varepsilon|x|)a(\varepsilon s, \varepsilon z)\phi H_x \, dx \\ - \int_{\mathbb{R}} \chi(\varepsilon|x|)B_8(\phi)H_x \, dx + \int_{\mathbb{R}} N_2(\phi)H_x \, dx \\ + 3 \int_{\mathbb{R}} [\mathtt{H}^2 - H^2]\phi H_x \, dx = \sum_{i=1}^{4} \varphi_i.\end{aligned}$$

Let $\varphi_1(\varepsilon z) = -2 \int_{\mathbb{R}} a(\varepsilon s, \varepsilon z)\chi(\varepsilon|x|)\phi H_x$. Then it is easy to see that

$$\int_0^{\ell} |\varphi_1(\theta)|^2 d\theta \le C\varepsilon^3 \|\phi\|^2_{H^2(S)},$$

and hence

$$\|\varphi_1\|_{L^2(0,\ell)} \le C\varepsilon^3.$$

The Lipschitz continuity of φ_1 follows from the Lipschitz continuity of ϕ.

Next we let $\varphi_2(\varepsilon z) = \int_{\mathbb{R}} B_1(\phi)\chi(\varepsilon|x|)H_x$. We make the following observation: All terms in $B_1(\phi)$ carry ε and involve powers of x times derivatives of powers of $0, 1$ or two orders of ϕ. The conclusion is that since H_x has exponential decay, then

$$\int_0^\ell |\varphi_2(\theta)|^2 d\theta \le C\varepsilon^3 \|\phi\|^2_{H^2(S)}.$$

Hence

$$\|\varphi_2\|_{L^2(0,\ell)} \le C\varepsilon^3.$$

To prove the Lipschitz regularity of φ_2, we single out one less regular terms in $B_8(\phi)$. The one whose coefficient depends on $\mathbf{f}''$ explicitly has the form

$$\varphi_{2*} = \varepsilon^2 \mathbf{f}'' \int_{\mathbb{R}} \phi_x H_x = -\varepsilon^2 \mathbf{f}'' \int_{\mathbb{R}} \phi H_{xx}.$$

Since ϕ has Lipschitz dependence on $\mathbf{f}$ in the form (5.7), we see that this is transmitted from Sobolev's embedding into

$$\|\phi(\mathbf{f}_1) - \phi(\mathbf{f}_2)\|_{L^\infty(\mathcal{S})} \le C\varepsilon^{\frac{3}{2}} \|\mathbf{f}_1 - \mathbf{f}_2\|,$$

from where it follows

$$\|\varphi_{2*}(\mathbf{f}_1) - \varphi_{2*}(\mathbf{f}_2)\|_{L^2(0,\ell)} \le C\varepsilon^{1+\alpha} \|\mathbf{f}_1 - \mathbf{f}_2\|.$$

The remainder $\varphi_2 - \varphi_{2*}$ actually defines for fixed ε a compact operator for $\mathbf{f}$ in $L^2(0,\ell)$. This is a consequence of the fact that weak convergence in $H^2(\mathcal{S})$ implies local strong convergence in $H^1(\mathcal{S})$, and the same is the case for $H^2(0,\ell)$ and $C^1[0,\ell]$. If $\mathbf{f}_j$ are weakly convergent sequences in $H^2(0,\ell)$, then clearly the functions $\phi(\mathbf{f}_j)$ constitute a bounded sequence in $H^1(\mathcal{S})$. In the above remainder one can integrate by parts, if necessary, once in x. Averaging against H_x, which decays exponentially, localizes the situation, and the desired fact follows.

We observe also that $\varphi_3(\varepsilon z) = \int_{\mathbb{R}} N_2(\phi) H_x$ can be estimated similarly. Using the definition of $N_2(\phi)$ and the exponential decay of H_x we obtain

$$\|\varphi_3\|_{L^2(0,\ell)} \le C\varepsilon^{\frac{1}{2}} \|\phi\|^2_{H^2(\mathcal{S})} \le C\varepsilon^3.$$

Let us consider now

$$\varphi_4(\varepsilon z) = \int_{\mathbb{R}} 3[\mathtt{H}^2 - H^2]\phi H_x.$$

Since $\mathtt{H} = H + \phi_1$ and ϕ_1 can be estimated as

$$|\phi_1(x,z)| \le C\varepsilon(|x|^2 + 1)\, e^{-c|x|},$$

we easily see that

$$\|\varphi_4\|_{L^2(0,\ell)} \le C\varepsilon^{\frac{3}{2}} \|\phi\|_{H^2(\mathcal{S})} \le C\varepsilon^3 .$$

These terms define compact operators similarly as before.

In summary, we have

$$\|\varphi(\phi)\|_{L^2(0,\ell)} \le C\varepsilon^3. \tag{7.1}$$

8. The reduced equation for f: Proof of the theorem. In this section we set up an equation relating $\mathbf{f}$ such that for the solution ϕ of (3.9)–(3.10) obtained via Proposition 5.1 one has that the coefficient $c(\varepsilon z)$ is identically zero. To achieve this we multiply first the equation against H_x and integrate only in x. The equation $c = 0$ is then equivalent to the relation

$$\int_{\mathbb{R}} E_2 H_x dx + \varphi(\phi) = 0.$$

Using the estimates in the previous sections we then find that these relations are equivalent to the following nonlinear, nonlocal, differential equation for $\mathbf{f}$:

$$\mathcal{L}(\mathbf{f}) \equiv \varepsilon \mathbf{f}'' + (\varepsilon\gamma_3 + \gamma_4)\mathbf{f} = \varepsilon\gamma_5(\varepsilon z) + \varepsilon^2 M_\varepsilon. \tag{8.1}$$

We further set

$$\mathbf{f} = \varepsilon \frac{\gamma_5}{\gamma_4 + \varepsilon\gamma_3} + \hat{\mathbf{f}}.$$

Then (8.1) becomes a nonlocal equation for $\hat{\mathbf{f}}$,

$$\mathcal{L}(\hat{\mathbf{f}}) \equiv \varepsilon \hat{\mathbf{f}}'' + (\varepsilon\gamma_3 + \gamma_4)\hat{\mathbf{f}} = \varepsilon^2 M_\varepsilon. \tag{8.2}$$

The operators $M_\varepsilon = M_\varepsilon(\hat{\mathbf{f}})$ can be decomposed into the following form:

$$M_\varepsilon(\hat{\mathbf{f}}) = A_\varepsilon(\hat{\mathbf{f}}) + K_\varepsilon(\hat{\mathbf{f}}),$$

where K_ε is uniformly bounded in $L^2(0,\ell)$ for $\hat{\mathbf{f}}$ satisfying constraints (2.26) and is also compact. The operator A_ε is Lipschitz in this region:

$$\|A_\varepsilon(\hat{\mathbf{f}}_1) - A_\varepsilon(\hat{\mathbf{f}}_2)\|_{L^2(0,\ell)} \le C\varepsilon \|\hat{\mathbf{f}}_1 - \hat{\mathbf{f}}_2\|.$$

The functions $\gamma_i, i = 1, 2$, are smooth. Furthermore, we have

$$\gamma_4 = \frac{4}{3}\left(\int_{\mathbb{R}} H_x^2\right)^{-1} a_t(0,\theta) > 0.$$

We will solve now (8.2). First we need to use assumption (1.8) to deal with the invertibility of $\mathcal{L}$. We have the following lemma.

LEMMA 8.1. *Assume that condition* (1.8) *holds. If $d \in L^2(0,\ell)$, then there is a unique solution $\hat{\mathbf{f}} \in H^2(0,\ell)$ of $\mathcal{L}(\hat{\mathbf{f}}) = d$ which is ℓ-periodic and satisfies*

$$\varepsilon\|\hat{\mathbf{f}}''\|_{L^2(0,\ell)} + \sqrt{\varepsilon}\|\hat{\mathbf{f}}'\|_{L^2(0,\ell)} + \|\hat{\mathbf{f}}\|_{L^\infty(0,\ell)} \le C\varepsilon^{-1/2}\|d\|_{L^2(0,\ell)}.$$

Moreover, if d is in $H^2(0,\ell)$, then

$$\varepsilon\|\hat{\mathbf{f}}''\|_{L^2(0,\ell)} + \|\hat{\mathbf{f}}'\|_{L^2(0,\ell)} + \|\hat{\mathbf{f}}\|_{L^\infty(0,\ell)} \le C[\|d''\|_{L^2(0,\ell)} + \|d'\|_{L^2(0,\ell)}] + C\|d\|_{L^2(0,\ell)}.$$

Let us accept for the moment the validity of this result and let us conclude the proof of the theorem. From the contraction mapping principle, the equation

$$\mathcal{L}\hat{\mathbf{f}} = g$$

is uniquely solvable for $\hat{\mathbf{f}}$ satisfying (2.26) if $\|g\|_2 < \varepsilon^{\frac{3}{2}+\rho}$ for some $\rho > 0$. The desired result for the full problem (8.2) then follows directly from Schauder's fixed point theorem. In fact, refining the fixed point region, we can actually get $\|\hat{\mathbf{f}}\| = O(\varepsilon^{3/2})$ for the solution.

Proof of Lemma 8.1. We consider the boundary value problem

$$\mathcal{L}(\hat{\mathbf{f}}) = d, \quad \hat{\mathbf{f}}(0) = \hat{\mathbf{f}}(\ell), \qquad \hat{\mathbf{f}}'(0) = \hat{\mathbf{f}}'(\ell). \tag{8.3}$$

We notice that it suffices to show Lemma 8.1 with

$$\mathcal{L}_1(\hat{\mathbf{f}}) = \varepsilon\beta^{-2}\hat{\mathbf{f}}'' + \hat{\mathbf{f}},$$

where $\beta = \sqrt{\gamma_4}$. We make the following *Liouville transformation* (cf. [20]):

$$\begin{aligned}
&\ell_0 = \int_0^\ell \beta(\theta)d\theta, \quad t = \frac{\int_0^\theta \beta(\theta)d\theta}{\ell_0}\pi, \quad \lambda_0 = \frac{\ell_0^2}{\pi^2},\\
&\Psi(\theta) = (\beta(\theta))^{-\frac{1}{2}}, \quad y(t) = \Psi^{-1}(\theta)\hat{\mathbf{f}}(\theta), \quad q(t) = \frac{\ell_0^2}{\pi^2}\frac{\Psi_{\theta\theta}}{\beta^2\Psi},\\
&\tilde{d}(t) = \Psi^{-1}(\theta)d(\theta).
\end{aligned}$$

Then (8.3) with $\mathcal{L}$ replaced by $\mathcal{L}_1$ is transformed into

$$\tilde{\mathcal{L}}_2(y) = \varepsilon(y'' + q(t)y) + \lambda_0 y = \tilde{d}, \quad y(0) = y(\pi), \qquad y'(0) = y'(\pi), \tag{8.4}$$

and it then suffices to establish the estimates in Lemma 8.1 for the solution of this problem in terms of the corresponding norms of $\tilde{d}$. It is standard that the eigenvalue problem

$$y'' + q(t)y + \lambda y = 0, \quad y(0) = y(\pi), \qquad y'(0) = y'(\pi) \tag{8.5}$$

has an infinite sequence of eigenvalues λ_k, $k \geq 0$, with an associated orthonormal basis in $L^2(0,\pi)$, $\{y_k\}$, constituted by eigenfunctions. A result in [20] provides asymptotic expressions as $k \to +\infty$ for these eigenvalues and eigenfunctions, which turn out to correspond to those for $q \equiv 0$. We have

$$\sqrt{\lambda_k} = 2k + O\Big(\frac{1}{k^3}\Big), \quad k \to \infty. \tag{8.6}$$

Problem (8.4) is then solvable if and only if $\lambda_k\varepsilon \neq \lambda_0$ for all $k \geq 1$. In such a case, the solution to (8.3) then can be written as

$$y(t) = \sum_{k=1}^{\infty} \frac{\tilde{d}_k}{\lambda_0 - \lambda_k\varepsilon} y_k(t)$$

with this series convergent in L^2. Hence

$$\|y\|^2_{L^2(0,\pi)} = \sum_{k=0}^{\infty} \frac{|\tilde{d}_k|^2}{(\lambda_0 - \lambda_k\varepsilon)^2}.$$

We then choose ε such that

$$|4k^2\varepsilon - \lambda_0| \;\geq\; c\sqrt{\varepsilon} \tag{8.7}$$

for all k, where c is small. This corresponds precisely to condition (1.8). From (8.6) we then find that $|\lambda_0 - \lambda_k\varepsilon| \geq \frac{c}{2}\sqrt{\varepsilon}$ if ε is also sufficiently small. It follows that $\|y\|_{L^2(0,\pi)} \leq C\varepsilon^{-\frac{1}{2}}\|\tilde{d}\|_{L^2(0,\pi)}$. Next we notice that

$$\begin{aligned}|y(t)| &\leq \sum_{k=1}^{\infty}\left|\frac{\tilde{d}_k y_k(t)}{\lambda_0 - \lambda_k\varepsilon}\right| \\ &\leq \left(\sum_{k=1}^{\infty}\tilde{d}_k^2 y_k^2(t)\right)^{1/2}\left(\sum_{k=1}^{\infty}\frac{1}{(\lambda_0 - \lambda_k\varepsilon)^2}\right)^{1/2} \\ &\leq \frac{C}{\sqrt{\varepsilon}}\|\tilde{d}\|_{L^2(0,\pi)};\end{aligned}$$

hence the L^∞ estimate for y follows, and thus we get

$$\varepsilon\|y'\|_{L^2(0,\pi)} + \|y\|_{L^\infty(0,\pi)} \leq C\varepsilon^{-\frac{1}{2}}\|\tilde{d}\|_{L^2(0,\pi)}.$$

Observe also that

$$\|y'\|^2_{L^2(0,\pi)} \leq C\sum_{k=0}^{\infty}|\tilde{d}_k|^2\frac{1+|\lambda_k|}{(\lambda_0 - \lambda_k\varepsilon)^2} \leq C\sum_{k=0}^{\infty}(1+k^4)|\tilde{d}_k|^2.$$

Besides, if d is in $H^2(0,\pi)$ with $d(0) = d(\pi)$, $d'(0) = d'(\pi)$, then the sum $\sum_k k^4 d_k^2$ is finite and bounded by the H^2 norm of d. This and the equation automatically imply

$$\varepsilon\|y''\|_{L^2(0,\pi)} + \|y'\|_{L^2(0,\pi)} + \|y\|_{L^\infty(0,\pi)} \leq C\|\tilde{d}\|_{H^2(0,\pi)},$$

and the proof is complete. □

Remark 8.1. In section 3 of [26], an equivalent form of (8.2) was also derived for a system of singularly perturbed elliptic equations on N-dimensional domains ($N \geq 2$). There it was assumed that $\gamma_4(\theta) < 0$ (condition (A7) in [26]). It was also observed that when $\gamma_4 > 0$, there is a resonance of eigenvalues hitting 0.

Acknowledgments. We thank one of the referees for pointing out [26] to us. We also thank the second referee for valuable comments regarding the bibliography and the history of the problem as well as for a careful and insightful revision of the manuscript.

EXPONENTIAL HOMOGENIZATION OF LINEAR SECOND ORDER ELLIPTIC PDEs WITH PERIODIC COEFFICIENTS*

VLADIMIR KAMOTSKI†, KARSTEN MATTHIES‡, AND VALERY P. SMYSHLYAEV‡

Abstract. A problem of homogenization of a divergence-type second order uniformly elliptic operator is considered with arbitrary bounded rapidly oscillating periodic coefficients, either with periodic "outer" boundary conditions or in the whole space. It is proved that if the right-hand side is Gevrey regular (in particular, analytic), then by optimally truncating the full two-scale asymptotic expansion for the solution one obtains an approximation with an exponentially small error. The optimality of the exponential error bound is established for a one-dimensional example by proving the analogous lower bound.

Key words. homogenization, elliptic equation, exponential asymptotics, Gevrey regularity, and analyticity

1. Introduction.

Classical homogenization theory describes the relation of solutions $u^\varepsilon(x)$ of boundary value problems with rapidly oscillating coefficients to solutions $u_0(x)$ of a homogenized problem, i.e., a problem without rapidly oscillating coefficients. In appropriate function spaces convergence can be established as $\varepsilon \to 0$ (with ε describing the period or wavelength of the coefficients' oscillations); see, e.g., [1, 2, 3, 4] and the references therein. For particular homogenization problems, e.g., for those described by linear second order elliptic PDEs with periodic coefficients, the rate of convergence with respect to ε can often also be determined, see, e.g., [4, 5, 6, 7]. The order of convergence can sometimes be improved further by constructing higher order correctors. The presence of a boundary creates additional "boundary layers," which substantially complexifies the problem of constructing the higher order terms; see, e.g., [5, 3, 4, 8, 9]. However, in the absence of the boundary, either for a problem with outer periodicity conditions or in the whole space (away from the spectrum), higher order terms can often be explicitly constructed. In particular, under the assumptions of sufficient regularity of the coefficients and the right-hand side of the equation, it is possible to construct and rigorously justify a full two-scale asymptotic expansion for $u^\varepsilon(x)$, i.e., to establish the error bounds both for linear problems (e.g., [3, 10]) and even for appropriate nonlinear ones [11].

The above can be referred to, in the context of homogenization, as "homogenization in all orders," by analogy with "asymptotics in all orders": by appropriately

truncating the infinite asymptotic series one arrives at an asymptotic approximation to the actual solution u^ε with accuracy of any desirable polynomial order in ε as $\varepsilon \to 0$. We address in this paper the question of homogenization "beyond all orders," i.e., with an exponentially small error, via an optimal truncation of the (generally divergent) asymptotic expansion. The ideas of exponential asymptotics have been intensively developed in the recent literature (see, e.g., [12] and the references therein); however, not that much progress has been achieved in this direction specifically for problems of averaging and more specifically of homogenization. An exponential averaging technique was developed for ODEs by Neishtadt [13] and recently adjusted to PDEs with a temporal [14] and then *one-dimensional spatial* oscillations [15].

To the best of our knowledge, the present work represents the first example of a rigorous analytic exponential averaging for truly *multidimensional spatial oscillations*, i.e., for multidimensional homogenization. On the other hand, exponentially accurate approximations are potentially relevant to the problem of achieving exponentially convergent numerical schemes for homogenization; see, e.g., [16].

We consider the abovementioned "classical" elliptic homogenization problems with periodic coefficients, both for the case of periodic boundary conditions and in the whole space. We will assume that the right-hand side is sufficiently regular (not only infinitely smooth as required for constructing the full asymptotic expansion, but additionally "Gevrey regular," in particular, analytic). Then we show that one obtains an approximation with an exponentially small error by optimally truncating the full two-scale asymptotic series for the solution. Importantly, the above exponential bounds are sharp in the sense that we establish analogous lower bounds for the error in an explicit but rather generic one-dimensional example.

The Gevrey regularity techniques have proved useful in exploring exponentially small effects in different problems, for example, in diffraction/scattering for describing the wave field in the shadow [17] and the asymptotic distribution of resonances [18], and in the one-dimensional exponential averaging [14, 15] for controlling the effect of Galerkin approximation of PDEs via ODEs. In the present work, however, the Gevrey regularity allows us to control the error of the truncation of a full asymptotic expansion both with respect to the short period or wavelength of the oscillations ε and the large number n of the terms in the truncated asymptotic series.

The next section gives a precise formulation of the problems and the statements of the main results, which are Theorems 1 and 1′, and specifically the exponential error bounds (17) and (19). The rest of the paper is devoted to the proof of the theorems, as well as of the optimality of the estimates (17) and (19) for an explicit one-dimensional example; see Theorem 5. In particular, for analytic right-hand sides $f(x)$, in Theorems 1 and 5, the exponential bounds (17) and (79) hold with $\beta = 1$, with the "rate" of decay (the constants C_2 and $\tilde{C}_2$) related to the imaginary part of the "nearest" singularity in the analytic continuation of $f(x)$ for complex x; see Remark 7.

2. Statement of the problem and main results. We consider a family of differential operators with rapidly oscillating periodic coefficients:

$$(L^\varepsilon u)(x) := -\nabla \cdot \left(A\left(\frac{x}{\varepsilon}\right) \nabla u \right)(x). \tag{1}$$

The matrix $A(y) = (A_{ij}(y))_{ij} \in L^\infty(\mathbb{T})$, $i, j = 1, \dots, d$, where $\mathbb{T} = \mathbb{R}^d/\mathbb{Z}^d$, $d \geq 1$, is a d-dimensional torus, is assumed to be symmetric[1] and uniformly elliptic; i.e.,

[1]The assumption of the symmetry of matrix $A(y)$ holds in most physically relevant examples, but could be waived for the purposes of this paper: the stated results would still hold at the expense of a slightly more complicated algebra in the exposition.

$A_{ij}(y) = A_{ji}(y)$ for any i, j and $y \in \mathbb{T}$ and there exists $\nu_0 > 0$ such that for all $\xi \in \mathbb{R}^d$ and $y \in \mathbb{T}$

$$A_{ij}(y)\xi_i\xi_j \geq \nu_0|\xi|^2. \tag{2}$$

Here and throughout the paper we use the Einstein summation convention with respect to repeated indices.

The main problem considered in this paper is for the right-hand side f being infinitely smooth and periodic with a "fixed" period chosen to be equal to unity and having zero mean, with the solution also required to have zero mean and to satisfy the periodic boundary conditions; cf. [3, 10]. Namely, assuming $\varepsilon^{-1} \in \mathbb{N}$ to be a large integer, we address the following homogenization problem: for a given f with zero-mean value

$$\langle f \rangle := \int_{\mathbb{T}} f(x)\,dx = 0, \tag{3}$$

we seek a solution to the problem

$$(L^\varepsilon u^\varepsilon)(x) = f(x) \text{ in } \mathbb{T}, \tag{4}$$

$$\langle u^\varepsilon \rangle := \int_{\mathbb{T}} u^\varepsilon(x)\,dx = 0. \tag{5}$$

Equation (4) is a "classical" model of periodic homogenization, physically corresponding to, e.g., stationary heat conduction, electric conductivity, linear elasticity in anti-plane shear, etc.

For a special class of functions f, namely for Gevrey regular functions, we will construct an exponentially accurate asymptotic approximation to u^ε. Thus, we adopt the following definition (cf., e.g., [20], [21]).

DEFINITION 1. *We say that a $C^\infty(\mathbb{T})$ function f is β-Gevrey regular, where $\beta \geq 1$, if there exists $B > 0$ such that for all $l \in \mathbb{N}$*

$$\|f\ ;\ H^l(\mathbb{T})\| \leq B^l(l!)^\beta, \tag{6}$$

where B may depend on f but is independent of l. We use notation $f \in \mathcal{G}^\beta(\mathbb{T})$.

Here and below we use the scale of Sobolev spaces $H^l(\mathbb{X})$, $l \in \mathbb{N}$, on a Riemannian manifold $\mathbb{X}$, with the norm

$$\|f\ ;\ H^l(\mathbb{X})\| = \sum_{|k|=l} \|D^k f\ ;\ L^2(\mathbb{X})\| + \|f\ ;\ L^2(\mathbb{X})\|, \tag{7}$$

where $\|\cdot\ ;\ L^2(\mathbb{X})\|$ is the standard L^2 norm on $\mathbb{X}$, and we adopt the following conventional multi-index notation: $k = (k_1, \ldots, k_d) \in \mathbb{Z}_+^d$, where $\mathbb{Z}_+ := \mathbb{N} \cup \{0\}$ is the set of nonnegative integers; $|k| := k_1 + \cdots + k_d$; and $D^k := \partial^{|k|}/\partial x_1^{k_1} \ldots \partial x_d^{k_d}$. We will also deal with $H^{-1}(\mathbb{X})$ norms, defined as duals to the space $H_0^1(\mathbb{X})$ of functions from $H^1(\mathbb{X})$ with zero mean.

Definition 1 gives one of several equivalent definitions of the Gevrey "extreme regularity" class $\mathcal{G}^\beta$ (see also [19]). In particular, for $\beta = 1$ the functions are from $\mathcal{G}^\beta$ if and only if they are real analytic; for $\beta > 1$ the functions are infinitely smooth but not necessarily analytic. A conventional way of clarifying these relations is by reformulating them in the Fourier space. For the above $\mathbb{T}$-periodic functions f, when represented by their Fourier series

$$f(x) = \sum_{p \in \mathbb{Z}^d} f_p \exp(2i\pi p \cdot x), \tag{8}$$

a sufficient condition for f to belong to $\mathcal{G}^\beta$ is for its Fourier coefficients f_p to decay exponentially with the "rate" $|p|^{1/\beta}$; i.e.,

$$|f_p| \le c_1 \exp\left(-c_2|p|^{1/\beta}\right) \tag{9}$$

with some p-independent positive constants c_1 and c_2. The latter is well known and can be seen, for example, by applying the Plancherel theorem to (7), using (9), then replacing the resulting series by "asymptotically equivalent" integrals, and finally employing the Stirling asymptotic formulae; see, e.g., [29, (6.1.37)]. Throughout the paper we will use various minor modifications of the direct implication of the Stirling formula for

$$\Gamma(z) := \int_0^\infty \exp(-s)s^{z-1}ds,\ z>0;\ \Gamma(l+1)=l!,\ l\in\mathbb{N}, \tag{10}$$

which we display below for the reader's convenience:

$$A_1\left(\frac{z}{e}\right)^{z-1/2} \le \Gamma(z) \le A_2\left(\frac{z}{e}\right)^{z-1/2},\quad z\ge 1, \tag{11}$$

with some "universal" constants A_1 and A_2.

Notice that for real-analytic f (9) holds with $\beta=1$, and the rate of exponential decay c_2 is determined by the absolute value of the imaginary part of the "nearest" singularity in the analytic continuation.

For any fixed $\varepsilon>0$ the problem (4)–(5) is a well-posed elliptic problem which has a unique solution $u^\varepsilon\in H^1(\mathbb{T})$. Given $n\in\mathbb{Z}_+$ we seek an approximation to this solution in the standard form of the appropriately truncated two-scale asymptotic series (cf., e.g., [3]):

$$u^{\varepsilon,n}(x) = \sum_{m=0}^{n+2}\varepsilon^m u^{(m)}\left(x,\frac{x}{\varepsilon}\right), \tag{12}$$

where the functions $u^{(m)}(x,y)$ are required to be periodic in the "fast" variable y. It is known that for the present problem one can construct in this way a full asymptotic expansion with $u^{(m)}$ adopting the following form (see, e.g., [3, 10]):

$$u^{(m)}(x,y) = \sum_{l=0}^{m}\sum_{|k|=l} N_k(y)D_x^k\, v_{m-l}(x), \tag{13}$$

where $N_0(y)\equiv 1$ and $N_k(y)$ are periodic solutions of the "main" ($|k|=1$) and "higher order" ($|k|>1$) "canonical" unit cell problems in the "fast" variable y. The functions $v_s(x)$, $s\ge 0$, solve certain recurrent systems of equations in the "slow" variable x (see [3]), which are briefly reviewed in the next section.

Before formulating the main result, for convenience of the future referencing, we combine (12) and (13) to give

$$u^{\varepsilon,n}(x) = \sum_{l=0}^{n+2}\varepsilon^l\sum_{|k|=l} N_k\left(\frac{x}{\varepsilon}\right)D_x^k\, V^{(n-l+2)}(x,\varepsilon). \tag{14}$$

The slowly varying part in (14) is a partial sum of the formal asymptotic series $V^{(\infty)}(x,\varepsilon)$ (see (29)):

$$V^{(M)}(x,\varepsilon) := \sum_{s=0}^{M} \varepsilon^s v_s(x). \tag{15}$$

The main results of the present paper are the following.

THEOREM 1. *Suppose $A \in L^\infty(\mathbb{T})$ and satisfies (2), and $f \in \mathcal{G}^\beta(\mathbb{T}), \beta \geq 1, \langle f \rangle = 0$. Let u^ε be the unique solution of (4)–(5). Then there exist ε-independent constants $C_1 > 0$, $C_2 > 0$, $\kappa_1 > 0$, and $\kappa_2 > \kappa_1$, such that for any n satisfying*

$$\kappa_1 \varepsilon^{-1/\beta} \leq n \leq \kappa_2 \varepsilon^{-1/\beta} \tag{16}$$

the approximation (14) has the error bound

$$\|u^\varepsilon - u^{\varepsilon,n} \ ; \ H^1(\mathbb{T})\| \leq C_1 \exp(-C_2 \varepsilon^{-\frac{1}{\beta}}). \tag{17}$$

The above result may be interpreted in the sense that if the (generally divergent) asymptotic series (12) is, for sufficiently small ε, "optimally" truncated by choosing $n = n(\varepsilon)$ according to (16), for example, $n(\varepsilon) = \left[\kappa_2 \varepsilon^{-1/\beta}\right]$ with the square brackets denoting the entire part, then this produces an exponentially small error in the sense of (17).

Note also that for less regular f the earlier results on the polynomial rather than exponential error (see, e.g., [5, Thm. 11.1], [3, section 4.2, Thm. 2]) will be a by-product of our analysis: if, e.g., f has a finite regularity in the scale of Sobolev spaces, say f belongs to $H^M(\mathbb{T})$ but does not belong to $H^{M+1}(\mathbb{T})$ for some M, one can construct only finitely many terms in the expansion (12). As a result one obtains only an error bound of polynomial order ε^n with a finite n related to M. On the other hand, if one assumes $f \in C^\infty$ but makes no assumption on the "rate" of growth of its H^l norms when $l \to \infty$, one does reproduce the "homogenization in all orders" with an error bound $C_n \varepsilon^n$ for any n. However, in the latter case one has no control on the growth of C_n as $n \to \infty$, which disallows any possible further "a priori" improvement of the error bound.

Let us also note that Theorem 1 can be generalized further in a number of ways. Assuming higher regularity of the coefficients A_{ij}, one can get in (17) the same rate of convergence but in stronger norms. One can also consider another case without the boundary for a "shifted" operator $L^\varepsilon + 1$ in entire $\mathbb{R}^d$ rather than for L^ε in a fixed domain with periodic boundary condition. Then the same exponential estimate holds; i.e., the following theorem can be obtained adapting the proof of Theorem 1 with minor changes.

THEOREM 1′. *Suppose $A \in L^\infty(\mathbb{T})$ and satisfies (2); $f \in \mathcal{G}^\beta(\mathbb{R}^d), \beta \geq 1$, i.e., $f \in C^\infty(\mathbb{R}^d)$ and there exists $B > 0$ such that for all $l \in \mathbb{N}, \|f \ ; \ H^l(\mathbb{R}^d)\| \leq B^l (l!)^\beta$. Let $u^\varepsilon \in H^1(\mathbb{R}^d)$ be the unique solution of*

$$(L^\varepsilon + 1) u^\varepsilon = f. \tag{18}$$

Then there exist ε-independent constants $C_1 > 0$, $C_2 > 0$, $\kappa_1 > 0$, and $\kappa_2 > \kappa_1$, such that for any n satisfying $\kappa_1 \varepsilon^{-1/\beta} \leq n \leq \kappa_2 \varepsilon^{-1/\beta}$ the corresponding asymptotic approximation of the form (12) has the error bound

$$\|u^\varepsilon - u^{\varepsilon,n} \ ; \ H^1(\mathbb{R}^d)\| \leq C_1 \exp(-C_2 \varepsilon^{-\frac{1}{\beta}}). \tag{19}$$

Note that in the latter case the explicit structure of the two-scale asymptotics (12) is slightly different from that of (14); see (57).

We expect similar results to be valid also for *nonlinear* elliptic divergence operators (cf. [11]). Accounting for the presence of a boundary is in general a difficult open problem; cf. [8, 9].

The proof of the theorems will be divided into three steps. First we derive a priori estimates on appropriate norms of the coefficients N_k and v_s in suitable functional spaces for fixed k and s in section 3. Then, in section 4, we estimate the right-hand side error term $L^\varepsilon u^{\varepsilon,n} - f$ for fixed n and ε (in the H^{-1} norm). In section 5 we translate this into the error estimates for $u^{\varepsilon,n(\varepsilon)} - u^\varepsilon$ via analysis of the "mean" and standard ellipticity estimates, and finally "minimize" the error by an optimal choice of $n(\varepsilon)$ dependence on ε. This establishes the desired exponential error bound and hence proves Theorem 1. Proof of Theorem 1′ follows the same strategy with minor technical alterations listed in Remark 2 immediately following the proof of Theorem 1.

Optimality of the exponential error bound (17) is proved in section 6 for an explicit one-dimensional example; see Theorem 5.

3. Recurrent relations and a priori estimates. We briefly describe the procedure for determining the coefficients in (14) and (15) (see, e.g., [3, 10] for the detailed derivation in a slightly different notation). Below, we give one possible way to summarize it.

First, the infinite series version of (14),

$$u^\varepsilon(x) \sim \sum_{l=0}^{\infty} \varepsilon^l \sum_{|k|=l} N_k\left(\frac{x}{\varepsilon}\right) D_x^k V^\infty(x,\varepsilon), \tag{20}$$

is formally substituted into (4). After appropriate differentiations and re-grouping the terms with equal powers of ε (treating at this stage $V^\infty(x,\varepsilon)$ as a "whole") we arrive at

$$\sum_{l=0}^{\infty} \varepsilon^{l-2} \sum_{|k|=l} \left\{L_y^1 N_k(y) - T_k(y)\right\}_{y=x/\varepsilon} D^k V^\infty(x,\varepsilon) \sim f(x), \tag{21}$$

where

$$N_0(y) \equiv 1, \quad T_0(y) \equiv 0, \tag{22}$$

and

$$|k| = 1 : T_k(y) = A_{ij,j}(y), \ k = e_i, \tag{23}$$

$$|k| \geq 2 : T_k(y) = \sum_{\substack{i,j=1,\dots,d \\ k'=k-e_i\geq 0}} \left((A_{ij}N_{k'})_{,j} + A_{ij}N_{k',j}\right)(y) + \sum_{\substack{i,j=1,\dots,d \\ k''=k-e_i-e_j\geq 0}} A_{ij}(y)N_{k''}(y). \tag{24}$$

Here we denote by e_i the unit ith axis vector in $\mathbb{Z}^d$ and adopt the standard convention denoting derivatives by the indices following the comma in the subscript; $k \geq 0$ for a multi-index k means $k_i \geq 0$ for any $1 \leq i \leq d$ ($k > 0$ will mean $k \geq 0$ and $k_i > 0$ for some i, with $k' < k$ meaning $k - k' > 0$, etc.).

We then require the "coefficients" $\left\{L_y^1 N_k(y) - T_k(y)\right\}$ in (21) to be independent of the fast variable y, i.e., to be equal to constants which are denoted by $-h_k$. This

implies that N_k are solutions to the following "cell problems" for $|k| \geq 1$:

$$L_y^1 N_k = T_k(y) - h_k \text{ in } \mathbb{T}, \tag{25}$$

$$\langle N_k \rangle = 0, \tag{26}$$

with periodic conditions for N_k.

The solvability condition for (25)–(26) implies, necessarily, that h_k are the mean values of T_k over the periodicity cell:

$$h_k = \langle T_k \rangle. \tag{27}$$

Combining (21) with (25) yields an infinite order formal asymptotic equation for the "slow" part $V^\infty(x,\varepsilon)$:

$$-\sum_{l=0}^{\infty} \varepsilon^{l-2} \sum_{|k|=l} h_k D^k V^\infty(x,\varepsilon) \sim f(x). \tag{28}$$

A formal asymptotic solution of (28) is in turn sought in the form of an "infinite order" version of (15):

$$V^\infty(x,\varepsilon) \sim \sum_{s=0}^{\infty} \varepsilon^s v_s(x). \tag{29}$$

The substitution of (29) into (28) with subsequent rearrangements and equating terms with the same powers of ε yields

$$-A^{\text{hom}}_{i,j=1} v_{s,ij}(x) = f_s(x), \tag{30}$$

$$\langle v_s \rangle = 0, \tag{31}$$

with the right-hand sides

$$f_0 = f, \tag{32}$$

$$f_s = \sum_{l=3}^{s+2} \sum_{|k|=l} h_k D_x^k v_{s-l+2}, \ s \geq 1. \tag{33}$$

In (30) $A^{\text{hom}} = \left(A^{\text{hom}}_{ij}\right)_{i,j=1}^d$ is a "classical" homogenized matrix, which is known to be positive definite (with the same ellipticity constant ν_0 as in (2)) and symmetric:

$$A^{\text{hom}}_{ij} = \langle A_{ij} \rangle + \langle A_{is} N_{e_j,s} \rangle = \begin{cases} h_{e_i+e_j}, & i = j, \\ \frac{1}{2} h_{e_i+e_j}, & i \neq j. \end{cases}$$

Notice that (30) is uniquely solvable for any $s \geq 0$: a necessary and sufficient condition for the solvability is $\langle f_s \rangle = 0$ which does hold for $s = 0$ by assumption (3) and for $s \geq 1$ by (33). The slowly varying terms v_s are hence found recurrently as solutions to *homogenized* equations (30) with constant coefficients on a torus $\mathbb{T}$.

The relations (22)–(27) and (30)–(33) are hence sufficient for uniquely identifying all N_k and v_s, respectively. Then the so-defined asymptotic "double series" (20), (29) provides a full asymptotic expansion of the solution $u^\varepsilon(x)$ "in all orders": in particular, its truncation $u^{\varepsilon,n}$ produces an error of polynomial order in ε (see, e.g., [3, section 4.2, Thm. 2] or section 4 below).

We next aim at estimating the quantities

$$\mathcal{N}^{(l)} := \max_{|k|=l} \|N_k \ ; \ H^1(\mathbb{T})\|, \tag{34}$$

$$\mathcal{V}^{(s,m)} := \|v_s \ ; \ H^m(\mathbb{T})\|. \tag{35}$$

We will prove the following lemma.

LEMMA 2. *Under the assumptions of Theorem* 1 *the following estimates hold for all* $l, s, m \in \mathbb{N} \cup \{0\}$: (i)

$$\mathcal{N}^{(l)} \le \left(M_{\mathcal{N}}\right)^l, \tag{36}$$

(ii)

$$\mathcal{V}^{(s,m)} \le \sum_{k=0}^{s} \left(M_{\mathcal{V}}\right)^{k+1} \|f \ ; \ H^{m+k}(\mathbb{T})\| \tag{37}$$

for appropriate constants $M_{\mathcal{N}}$ *and* $M_{\mathcal{V}}$, *depending only on* $\|A \ ; \ L^\infty(\mathbb{T})\|$ *and the ellipticity constant* ν_0 *(see* (2)*).*

Proof. Further on we will use the abbreviated notation $|\cdot|_l := \|\cdot \ ; \ H^l(\mathbb{T})\|$, $l \ge -1$ ($|\cdot|_0 := \|\cdot \ ; \ L^2(\mathbb{T})\|$) and denote by C, M_1, M_2, etc. various positive constants whose precise values are insignificant and can change during the proof.

(i) Due to the standard ellipticity estimates we have

$$|v|_1 \le C(\nu_0)|G|_0 \tag{38}$$

for a solution of $L^1 v = \nabla \cdot G$, $\langle v \rangle = 0$ with arbitrary $G \in \left(L^2(\mathbb{T})\right)^d$. So we deduce from (22)–(24), (25)–(26), and (27) for $|k| \ge 2$ that

$$|N_k|_1 \le C(\nu_0)\|A \ ; L^\infty(\mathbb{T})\| \left(\sum_{k'<k, \, |k-k'|=1} |N_{k'}|_1 + \sum_{k''<k, |k-k''|=2} |N_{k''}|_0 \right). \tag{39}$$

The latter reads in terms of (34) as

$$\mathcal{N}^{(l)} \le M_1 \mathcal{N}^{(l-1)} + M_2 \mathcal{N}^{(l-2)}, \quad l \ge 2, \tag{40}$$

and implies (36) by induction: from (22) we have $\mathcal{N}^{(0)} = 1$ and, due to (23) and (38), $\mathcal{N}^{(1)} \le C(\nu_0)\|A \ ; L^\infty(\mathbb{T})\| \le M_1$. Therefore choosing $M_{\mathcal{N}} > \max\{1, M_1 + (M_2)^{1/2}\}$ we arrive at (36).

(ii) Now turning to v_s, due to (30)–(33) we estimate for $s \ge 1$ and $m \ge 1$

$$|v_s|_m \le C(A^{\mathrm{hom}}) \sum_{l=3}^{s+2} \sum_{|k|=l} |h_k| |D_x^k v_{s-l+2}|_{m-2}. \tag{41}$$

This can be established, e.g., using again the ellipticity estimates applied to (30), which being an elliptic equation with constant coefficients can be differentiated m times. Applying also a version of the Poincaré inequality, which in our choice of the domain and the norms (see (7)) is the obvious estimate

$$\|g; H^k(\mathbb{T})\| \le \|g; H^l(\mathbb{T})\|, \ k \le l, \tag{42}$$

we conclude that $C(A^{\mathrm{hom}})$ can be chosen independently of m.

Since (24) and (27) obviously imply that $\max_{|k|=l}|h_k| \le C\left(\mathcal{N}^{(l-1)}+\mathcal{N}^{(l-2)}\right)$, from (41) we arrive after a straightforward manipulation at

$$\mathcal{V}^{(s,m)} \le C\sum_{r=1}^{s}\mathcal{N}^{(r+1)}r^{d-1}\mathcal{V}^{(s-r,m+r)}. \tag{43}$$

The latter in turn, combined with (36), implies that with large enough M_0

$$\mathcal{V}^{(s,m)} \le \sum_{r=1}^{s}M_0^r\mathcal{V}^{(s-r,m+r)}. \tag{44}$$

Let us finally show by induction in s that the latter is sufficient to deduce (37) with some $M_{\mathcal{V}} > 2M_0$. Indeed for $s=0$, due to (30) for all $m \ge 0$, we have $|v_0|_m \le |v_0|_{m+2} \le M_3|f|_m$ with M_3 independent of m, implying (37). Now we proceed with the induction step: suppose (37) holds for $s=0,\dots,S$ with a constant $M_{\mathcal{V}} > \max\{2M_0, M_3\}$. Then due to (44) we have

$$\begin{aligned}\mathcal{V}^{(S+1,m)} &\le \sum_{r=1}^{S+1}M_0^r\mathcal{V}^{(S+1-r,m+r)} \le \sum_{r=1}^{S+1}\sum_{k=0}^{S+1-r}M_0^rM_{\mathcal{V}}^{k+1}|f|_{m+r+k}\\ &\le \sum_{q=1}^{S+1}M_{\mathcal{V}}^{q+1}|f|_{m+q}\sum_{r=1}^{q}\left(\frac{M_0}{M_{\mathcal{V}}}\right)^r,\end{aligned}$$

which by our choice of $M_{\mathcal{V}}$ implies (37) for $s=S+1$. ∎

4. Remainder estimates. Next we derive estimates for the error in the right-hand side of the original equation (4) as a result of substitution into its left-hand side of the truncated asymptotic ansatz $u^{\varepsilon,n}$; see (12)–(15). The following lemma is in effect an implication of the above described formal asymptotic construction: it is supplemented by a more accurate bookkeeping of the structure of the remainder term $R^{\varepsilon,n}$ (as needed for purposes of this work), which is bound, by the construction, to contain only the terms of orders ε^{n+1} and ε^{n+2} for fixed n and small ε; cf. [3, 10].

LEMMA 3. *Under the assumptions of Theorem* 1 *one has* $L^\varepsilon u^{\varepsilon,n} = f + R^{\varepsilon,n}$ *with* $R^{\varepsilon,n} \in H^{-1}(\mathbb{T})$, *and*

$$\begin{aligned}R^{\varepsilon,n} = -\varepsilon^{n+1}\Bigg(&\sum_{l=0}^{n+2}\sum_{|k|=l}\left(\left(A_{ij}N_k\right)_{,j}+A_{ij}N_{k,j}\right)D_{x_i}D_x^kv_{n-l+2}\\ &+\sum_{l=0}^{n+1}\sum_{|k|=l}A_{ij}N_kD_{x_ix_j}D_x^k(v_{n-l+1}+\varepsilon v_{n-l+2})\\ &+\varepsilon\sum_{|k|=n+2}A_{ij}N_kD_{x_ix_j}D_x^kv_0\Bigg)\end{aligned} \tag{45}$$

(denoting $D_{x_i} := \partial/\partial x_i$, $D_{x_ix_j} := \partial^2/(\partial x_i\partial x_j)$*).*

Proof. The proof is a straightforward calculation by substituting the expansion (14), (15) into (4). We notice that since $A_{ij} \in L^\infty(\mathbb{T})$, $N_k \in H^1(\mathbb{T})$, and $v_s \in C^\infty(\mathbb{T})$,

all the "product" terms in (45) are in $H^{-1}(\mathbb{T})$. For example,

$$\begin{aligned}(\,(A_{ij}N_k)_{,j}\,)\left(\frac{x}{\varepsilon}\right)D_{x_i}D_x^kV^{(n-l+2)}(x,\varepsilon) &= \varepsilon\frac{\partial}{\partial x_j}\left((A_{ij}N_k)\left(\frac{x}{\varepsilon}\right)D_{x_i}D_x^kV^{(n-l+2)}(x,\varepsilon)\right)\\ &\quad -\varepsilon\left((A_{ij}N_k)\left(\frac{x}{\varepsilon}\right)D_{x_ix_j}D_x^kV^{(n-l+2)}(x,\varepsilon)\right),\end{aligned}\tag{46}$$

with the first term in the latter expression being a derivative of an L^2 function and the last one an L^2 function itself.

The terms up to order $O(\varepsilon^n)$ equal f by (14), (15), (30), (32), and (33). Via direct inspection,

$$\begin{aligned}(L^\varepsilon u^{\varepsilon,n})(x) &= -\nabla\cdot\left(A\left(\frac{x}{\varepsilon}\right)\nabla u^{\varepsilon,n}\right)(x)\\ &= -\nabla\cdot\left(A\left(\frac{x}{\varepsilon}\right)\nabla\sum_{l=0}^{n+2}\varepsilon^l\sum_{|k|=l}N_k\left(\frac{x}{\varepsilon}\right)D_x^k\,V^{(n-l+2)}(x,\varepsilon)\right)\\ &= \sum_{l=0}^{n+2}\varepsilon^{l-2}\sum_{|k|=l}(L_y^1N_k)\left(\frac{x}{\varepsilon}\right)D_x^kV^{(n-l+2)}(x,\varepsilon)\\ &\quad -\sum_{l=0}^{n+2}\varepsilon^{l-1}\sum_{|k|=l}(\,(A_{ij}N_k)_{,j}+A_{ij}N_{k,j}\,)\left(\frac{x}{\varepsilon}\right)D_{x_i}D_x^kV^{(n-l+2)}(x,\varepsilon)\\ &\quad -\sum_{l=0}^{n+2}\varepsilon^{l}\sum_{|k|=l}(A_{ij}N_k)\left(\frac{x}{\varepsilon}\right)D_{x_ix_j}D_x^kV^{(n-l+2)}(x,\varepsilon).\end{aligned}$$

Now we replace $V^{(n-l+2)}(x,\varepsilon)$ by $V^{(n-l+1)}(x,\varepsilon)+\varepsilon^{n-l+2}v_{n-l+2}$ in the second term and by $V^{(n-l)}(x,\varepsilon)+\varepsilon^{n-l+1}v_{n-l+1}+\varepsilon^{n-l+2}v_{n-l+2}$ in the last term; see (15). These "remainders" containing v_{n-l+1} and v_{n-l+2} as well as the term corresponding to $l=n+2$ in the last sum, all being of order ε^{n+1} and ε^{n+2}, produce exactly $R^{\varepsilon,n}$. Therefore we have

$$\begin{aligned}(L^\varepsilon u^{\varepsilon,n})(x) &= R^{\varepsilon,n}+\sum_{l=0}^{n+2}\varepsilon^{l-2}\sum_{|k|=l}(L_y^1N_k)\left(\frac{x}{\varepsilon}\right)D_x^kV^{(n-l+2)}(x,\varepsilon)\\ &\quad -\sum_{l=0}^{n+1}\varepsilon^{l-1}\sum_{|k|=l}(\,(A_{ij}N_k)_{,j}+A_{ij}N_{k,j}\,)\left(\frac{x}{\varepsilon}\right)D_{x_i}D_x^kV^{(n-l+1)}(x,\varepsilon)\\ &\quad -\sum_{l=0}^{n}\varepsilon^{l}\sum_{|k|=l}(A_{ij}N_k)\left(\frac{x}{\varepsilon}\right)D_{x_ix_j}D_x^kV^{(n-l)}(x,\varepsilon).\end{aligned}$$

Now we change the summation indices in the two latter terms to obtain the first $n+2$ terms of the series (21)

$$\begin{aligned}(L^\varepsilon u^{\varepsilon,n})(x) &= R^{\varepsilon,n}+\sum_{l=2}^{n+2}(L_y^1N_k-T_k)D^kV^{(n-l+2)}\\ &= R^{\varepsilon,n}-\sum_{l=2}^{n+2}\varepsilon^{l-2}\sum_{|k|=l}h_kD^kV^{(n-l+2)}=f+R^{\varepsilon,n},\end{aligned}$$

having used in the last equality (30)–(33). ∎

Using the above formula (45) for the remainder term, we estimate $R^{\varepsilon,n}$ with an explicit dependence on both ε and n as in the following lemma ($[\cdot]$ denotes the entire part).

LEMMA 4. *Under the assumptions of Theorem* 1, *there exist* C_3, ε_0 *such that for all* n *and all* $0 < \varepsilon < \varepsilon_0$ *the remainder term* $R^{\varepsilon,n}$ *can be estimated as follows:*

$$\|R^{\varepsilon,n};\ H^{-1}(\mathbb{T})\| \le C_3^n \varepsilon^{n+1} \|f;\ H^{n+5+[d/2]}(\mathbb{T})\|. \tag{47}$$

Proof. Here we combine the formula for the error term in Lemma 3 with the estimates in Lemma 2. To estimate the H^{-1} norm of the aggregates like $((A_{ij}N_k)D^{|k|+1}v)_{,j}$ (see (46)) and $A_{ij}N_kD^{|k|+2}v$ we need to ensure that $D^{|k|+2}v$ is in L^∞. By the Sobolev embedding theorems this holds if $v \in H^{|k|+3+[d/2]}$. Therefore

$$\begin{aligned}
\|R^{\varepsilon,n};\ H^{-1}(\mathbb{T})\| = \Bigg\| & \varepsilon^{n+1} \Bigg(\sum_{l=0}^{n+2} \sum_{|k|=l} \big((A_{ij}N_k)_{,j} + A_{ij}N_{k,j} \big) D_{x_i} D_x^k v_{n-l+2} \\
& + \sum_{l=0}^{n+1} \sum_{|k|=l} A_{ij}N_k D_{x_i,x_j} D_x^k (v_{n-l+1} + \varepsilon v_{n-l+2}) \\
& + \varepsilon \sum_{|k|=n+2} A_{ij}N_k D_{x_i,x_j} D_x^k v_0 \Bigg);\ H^{-1}(\mathbb{T}) \Bigg\| \\
\le \varepsilon^{n+1} \Bigg(& C \sum_{l=0}^{n+2} l^{d-1} \|A; L^\infty\| \mathcal{N}^{(l)} \mathcal{V}^{(n-l+2,l+3+[d/2])} \\
& + C \sum_{l=0}^{n+1} l^{d-1} \|A; L^\infty\| \mathcal{N}^{(l)} \Big(\mathcal{V}^{(n-l+1,l+3+[d/2])} \\
& \qquad + \varepsilon \mathcal{V}^{(n-l+2,l+3+[d/2])} \Big) \\
& + C\varepsilon n^{d-1} \|A; L^\infty\| \mathcal{N}^{(n+2)} \mathcal{V}^{(0,n+5+[d/2])} \Bigg) \\
\le C\varepsilon^{n+1} & \Big(\max\{M_{\mathcal{N}}, M_{\mathcal{V}}\} \Big)^{n+2} n^d \|f; H^{n+5+[d/2]}\|.
\end{aligned}$$

Here we have used again the Poincaré inequality (42). An appropriate choice of C_3 yields the result. ∎

Remark 1. The last lemma could also be used to rederive results for finite regularity f, or smooth f, which are not necessarily in any Gevrey space $\mathcal{G}^\beta$. If, for example, f has finite regularity, i.e., $f \in H^M(\mathbb{T})$ and $f \notin H^{M+1}(\mathbb{T})$ for some M, then, as the above procedure demonstrates, only a finite number of terms in the asymptotic expansion can be constructed, and the H^{-1} norms can be bounded only for $n < M - 4 - d/2$. If, however, $f \in C^\infty(\mathbb{T})$, but no assumptions are made on the rate of growth of its H^l norms for large l, the estimate (47) still holds for any n, but there is no control over the growth of the Sobolev norms of f with n in the right-hand side of (47). The latter would prevent us from improving the polynomial "asymptotics in all orders" any further. This highlights the importance of the Gevrey extreme regularity of f for the exponential error bounds.

5. Proof of Theorem 1. The proof of the theorem is now essentially a corollary of Lemma 4, the estimates (6) holding due to the assumption of Gevrey regularity

of f and standard elliptic regularity theory. Let us first introduce a "normalized" approximation

$$\tilde{u}^{\varepsilon,n} := u^{\varepsilon,n} - \langle u^{\varepsilon,n} \rangle. \tag{48}$$

By the elliptic regularity theory for all n we have

$$\|\tilde{u}^{\varepsilon} - u^{\varepsilon,n} \,;\, H^1(\mathbb{T})\| \le C \|R^{\varepsilon,n};\, H^{-1}(\mathbb{T})\|. \tag{49}$$

Using Lemma 4, we obtain

$$\|\tilde{u}^{\varepsilon} - u^{\varepsilon,n} \,;\, H^1(\mathbb{T})\| \le C C_3^n \varepsilon^{n+1} \|f; H^{n+4+[d/2]}\|. \tag{50}$$

Let us next show that the mean $\langle u^{\varepsilon,n} \rangle$ can also be estimated in a similar way. Due to representations (12), (13) we have

$$\langle u^{\varepsilon,n} \rangle = \sum_{m=0}^{n+2} \varepsilon^m \sum_{l=0}^{m} \sum_{|k|=l} \left\langle N_k \left(\frac{x}{\varepsilon} \right) D_x^k \, v_{m-l}(x) \right\rangle. \tag{51}$$

Note that $\langle N_k \rangle = 0$; therefore for any $s > 0$ the functions $\left((-\Delta_y)^{-s} N_k(\cdot)\right)(y)$ and $\left((-\Delta_x)^{-s} N_k(\frac{\cdot}{\varepsilon})\right)(x)$ are correctly defined functions with zero mean, using, for example, the Fourier representation for $(-\Delta_y)$ on a torus $\mathbb{T}$. Moreover, they are linked via

$$\left((-\Delta_x)^{-s} N_k \left(\frac{\cdot}{\varepsilon} \right)\right)(x) = \varepsilon^{2s} \left((-\Delta_y)^{-s} N_k(\cdot)\right) \left(\frac{x}{\varepsilon} \right) \tag{52}$$

(recall $\varepsilon^{-1} \in \mathbb{N}$). Thus, integrating (51) by parts sufficiently many times, we get

$$\begin{aligned} &\langle u^{\varepsilon,n} \rangle \\ &= \sum_{m=0}^{n+2} \varepsilon^m \sum_{l=0}^{m} \sum_{|k|=l} \varepsilon^{n+2-m} \left\langle \left((-\Delta_y)^{-\frac{n+2-m}{2}} N_k \right) \left(\frac{x}{\varepsilon} \right) (-\Delta_x)^{\frac{n+2-m}{2}} D_x^k \, v_{m-l}(x) \right\rangle. \end{aligned} \tag{53}$$

Now, via the Cauchy–Schwartz inequality,

$$|\langle u^{\varepsilon,n} \rangle| \le \varepsilon^{n+2} \sum_{m=0}^{n+2} \sum_{l=0}^{m} \sum_{|k|=l} \|(-\Delta_y)^{-\frac{n+2-m}{2}} N_k;\, L^2(\mathbb{T})\| \, \|v_{m-l};\, H^{n+2-m+l}(\mathbb{T})\|. \tag{54}$$

Therefore, applying the Poincaré inequality (42) to the first norm and then using estimates (36), (37) of Lemma 2, we have

$$\begin{aligned} |\langle u^{\varepsilon,n} \rangle| &\le \varepsilon^{n+2} \sum_{m=0}^{n+2} \sum_{l=0}^{m} C l^{d-1} \left(\sup_{|k|=l} \|N_k;\, H^1\| \right) \sum_{p=0}^{m-l} M_{\mathcal{V}}^{p+1} \|f; H^{n+2-m+l+p}\| \\ &\le \varepsilon^{n+2} \|f; H^{n+2}\| \sum_{m=0}^{n+2} \sum_{l=0}^{m} C l^d M_{\mathcal{N}}^l \sum_{p=0}^{m-l} M_{\mathcal{V}}^{p+1} \\ &\le \varepsilon^{n+2} \|f; H^{n+2}\| \sum_{m=0}^{n+2} \sum_{l=0}^{m} C l^d M_{\mathcal{N}}^l M_{\mathcal{V}}^{m-l}, \end{aligned}$$

and therefore

$$|\langle u^{\varepsilon,n}\rangle| \le \varepsilon^{n+2} C C_4^n \|f; H^{n+2}\|. \tag{55}$$

Combining the latter with (50) we finally get

$$\|u^\varepsilon - u^{\varepsilon,n}\ ;\ H^1(\mathbb{T})\| \le C C_5^n \varepsilon^{n+1} \|f; H^{n+5+[d/2]}\| \tag{56}$$

for small enough ε with an appropriate constant $C_5 > 0$.

Further, by (6), $\|f; H^{n+5+[d/2]}\| \le B^{n+5+[d/2]}((n+5+[d/2])!)^\beta$. Using the Stirling formula (11) for the factorial (implying $M! = \Gamma(M+1) \le C M^{M+1/2} e^{-M}$ for any $M \in \mathbb{N}$ with some $C > 0$), we obtain

$$\begin{aligned}
&\|u^\varepsilon - u^{\varepsilon,n}\ ;\ H^1(\mathbb{T})\| \\
&\le C C_5^n \varepsilon^{n+1} B^{n+5+[d/2]} (n+5+[d/2])^{(n+5+[d/2])\beta} e^{-\beta(n+5+[d/2])} n^{1/2} \\
&\le C \varepsilon^{n+1} (C_6 B)^n n^{n\beta} = C\varepsilon \exp(n \ln(n^\beta C_6 B \varepsilon)).
\end{aligned}$$

Thus, we get the desired decay of this norm if the logarithm in the latter exponent is uniformly negative. The latter can be assured by choosing $n(\varepsilon) \in (\kappa_1 \varepsilon^{-1/\beta}, \kappa_2 \varepsilon^{-1/\beta})$ with any choice of constants κ_1 and κ_2 such that $0 < \kappa_1 < \kappa_2 < (C_6 B)^{-1/\beta}$. Indeed, we then estimate

$$\|u^{\varepsilon,n(\varepsilon)} - u^\varepsilon\ ;\ H^1(\mathbb{T})\| \le C\varepsilon \exp[(\kappa_1 \ln(\kappa_2^\beta C_6 B))\varepsilon^{-1/\beta}],$$

which implies (17) by choosing $C_1 = C$ and $C_2 = -\kappa_1 \ln(\kappa_2^\beta C_6 B) > 0$. The theorem is proved. □

Remark 2 (on the proof of Theorem 1′). The proof of Theorem 1′ conceptually follows the above proof of Theorem 1. We briefly sketch the proof emphasizing only the most significant alterations to the above argument. First note that, although we still use the asymptotic series (12) for the approximation, its precise structure slightly differs from (14); namely, (12) is now represented in the following form:

$$u^{\varepsilon,n}(x) = \sum_{l=0}^{n+2} \varepsilon^l \sum_{s=0}^{[\frac{l}{2}]} \sum_{|k|=l-2s} N_k^{(s)}\left(\frac{x}{\varepsilon}\right) D_x^k V^{(n-l+2)}(x,\varepsilon). \tag{57}$$

For $N_k^{(s)}$, analogously to (25), (26), one deduces the recurrence relations

$$L_y^1 N_k^{(s)} = T_k^{(s)}(y) - h_k^{(s)} - N_k^{(s-1)}, \qquad \langle N_k^{(s)}\rangle = 0,\ s \ge 0, \tag{58}$$

assuming henceforth that $N_k^{(-1)} \equiv 0$. If $|k| \ge 2$, then one finds

$$T_k^{(s)} = \sum_{\substack{i,j=1,\dots,d \\ k'=k-e_i\ge 0}} \left((A_{ij} N_{k'}^{(s)})_{,j} + A_{ij} N_{k',j}^{(s)}\right) + \sum_{\substack{i,j=1,\dots,d \\ k''=k-e_i-e_j\ge 0}} A_{ij} N_{k''}^{(s)}, \tag{59}$$

and otherwise

$$|k| = 1, k = e_i: \quad T_k^{(s)} = (A_{ij} N_0^{(s)})_{,j} + A_{ij} N_{0,j}^{(s)}, \tag{60}$$

$$k = 0: \quad T_k^{(s)} = 0,\ \ N_0^{(0)} \equiv 1. \tag{61}$$

Further, in all the cases $h_k^{(s)} = \langle T_k^{(s)} \rangle$, except $h_0^{(1)} = -1$. Obviously one has $N_k^{(0)} = N_k$ (see (22)–(26)), and thus by induction in s one finds all $N_k^{(s)}$. Now let us introduce $\mathfrak{N}_q = \max_{|k|+2s=q} |N_k^{(s)}|_1$. Due to (59) we obviously have $|T_k^{(s)} - h_k^{(s)}|_{-1} \le C(\mathfrak{N}_{|k|+2s-1} + \mathfrak{N}_{|k|+2s-2})$. The basic elliptic estimate (38) for the problem (58) still holds and therefore implies that $\mathfrak{N}_q \le M_1 \mathfrak{N}_{q-1} + M_2 \mathfrak{N}_{q-2}$, which gives an exponential estimate of growth of $\mathfrak{N}_q$: with large enough $M_{\mathfrak{N}}$ for all $q \ge 0$

$$\mathfrak{N}_q \le (M_{\mathfrak{N}})^q. \tag{62}$$

Turning now to evaluation of $v_s(x)$, substituting the expansion (57) into (18) we observe that $V^{(\infty)}(x,\varepsilon)$ formally satisfies

$$\left(-A_{ij}^{\hom} D_{ij} + 1 + \sum_{l=3}^{\infty} \varepsilon^{l-2} \sum_{s=0}^{[\frac{l}{2}]} \sum_{|k|=l-2s} h_k^{(s)} D_x^k \right) V^{\infty}(x,\varepsilon) = f(x) \ \text{ in } \mathbb{R}^d; \tag{63}$$

therefore we have

$$-A_{ij}^{\hom} v_{s,ij} + v_s = f_s \ \text{ in } \mathbb{R}^d, \tag{64}$$

where

$$f_0 = f, \tag{65}$$

$$f_s = \sum_{l=3}^{s+2} \sum_{r=0}^{[\frac{l}{2}]} \sum_{|k|=l-2r} h_k^{(r)} D_x^k v_{s-l+2}, \ s \ge 1. \tag{66}$$

The latter differs from (33) only by the presence of lower order derivatives, and without any significant alteration one deduces an exponential estimate (37) in very much the same way as in Lemma 2. As a result, introducing $\mathfrak{V}^{(s,m)} = \|v_s;\ H^m(\mathbb{R}^d)\|$ with large enough $M_{\mathfrak{V}}$, we get by induction in s an estimate

$$\mathfrak{V}^{(s,m)} \le \sum_{k=0}^{s} (M_{\mathfrak{V}})^{k+1} \|f\ ;\ H^{m+k}(\mathbb{R}^d)\|. \tag{67}$$

The remainder estimate is bound to be of order ε^{n+1}, and with some minor technical alteration of the argument in section 4 one also gets

$$\|R^{\varepsilon,n}; H^{-1}(\mathbb{R}^d)\| \le C\varepsilon^{n+1} M^n \|f; H^{n+5+[d/2]}(\mathbb{R}^d)\|. \tag{68}$$

Finally, repeating the argument at the beginning of this section (omitting the consideration of the mean), employing appropriate modifications of the Poincaré inequality, ellipticity estimates, Sobolev embedding, etc. from (68), and the fact that $f \in \mathcal{G}^{\beta}(\mathbb{R}^d)$, one finally deduces Theorem 1′.

Remark 3. Note that as formulated the theorems admit some further sharpening: for example, one can replace $H^1(\mathbb{T})$ norm in (17) with $W^{1,p}(\mathbb{T})$ norm, where $p \in (2, p_0(d,\nu_0))$ with some $p_0(d,\nu_0) > 2$. Indeed, as can be seen from the structure of our argument, we select a functional space according to the fundamental ellipticity estimate (38), whereas the latter (38) can be refined in the case of bounded measurable coefficients and the right-hand side being the divergence of an L^{∞} (vector-)function (see, e.g., [22, Chapter 6]).

Remark 4. The proof of the theorems has been via a straightforward "bookkeeping" of the terms in the full two-scale asymptotic expansion (20)–(29). On the other hand, this is known to be related to the so-called spectral method in homogenization and closely related "Bloch approximation" approach; see, e.g., [24, 25, 26, 27, 28, 6]. There is no doubt that these spectral methods are capable of at least reestablishing the background results on the "homogenization in all orders" (i.e., approximations with arbitrary high order polynomial error bounds). An interesting further prospect would be to interpret the results presented here on *exponential* homogenization in terms of underlying analytic spectral properties of the Floquet–Bloch operator with periodic coefficients.

6. On the optimality of the exponential error (17): An example. In this section we demonstrate that the main exponential error bound (17) of Theorem 1 for $\|u^\varepsilon - u^{\varepsilon,n}\ ;\ H^1(\mathbb{T})\|$ is "optimal" for a particular class of one-dimensional examples. Namely, we show that by whatever choice of the truncation $n(\varepsilon)$ the error bound (17) cannot be improved apart from "optimizing" the choice of constants C_1 and C_2. This is done by proving an analogous exponential lower bound for the error; see (79). The latter is obtained by an optimal truncation $n(\varepsilon)$ of lower bounds derived for each n and ε, which in turn is observed to be delivered by $n(\varepsilon)$ within the range (16). In this sense the exponential error bound (17) is sharp.

We consider the following one-dimensional example. Consider elliptic problem

$$-\frac{d}{dx}\left(a(x/\varepsilon)\frac{d}{dx}u(x)\right) = f(x), \tag{69}$$

with one-periodic boundary conditions, $\langle u\rangle = \langle f\rangle = 0$, $\varepsilon = 1/N$, $N \in \mathbb{N}$, which is the one-dimensional version of the problem (4)–(5), with unique solution $u^\varepsilon(x)$. To be specific, let us consider[2]

$$a(y) = \frac{1}{3/2 - \cos(2\pi y - \pi/4)}. \tag{70}$$

We fix arbitrary $\beta \geq 1$ and assume the right-hand side f to be an infinitely differentiable real-valued 1-periodic function with real nonnegative Fourier coefficients f_k (hence $f_{-k} = f_k$), i.e.,

$$f(x) = \sum_{k\in\mathbb{Z},k\neq 0} f_k \exp(2i\pi kx) = 2\sum_{k=1}^{\infty} f_k \cos(2\pi kx), \quad f_k \geq 0. \tag{71}$$

We further assume that f satisfies the "converse" inequality to (6) determining β-Gevrey regular functions; i.e., there exists $b > 0$ such that

$$\|f\ ;\ H^l(\mathbb{T})\| \geq b^l (l!)^\beta \quad \text{for all } l \in \mathbb{N}. \tag{72}$$

In particular, for "sharp" β-Gevrey regular functions both (6) and (72) hold simultaneously:

$$b^l (l!)^\beta \leq \|f\ ;\ H^l(\mathbb{T})\| \leq B^l (l!)^\beta, \quad 0 < b \leq B < +\infty, \quad \text{for all } l \in \mathbb{N}. \tag{73}$$

[2]The analysis of this section can be generalized in a straightforward way to more general $a(y)$, for example, $a(y) = (a_0 - a_1\cos(2\pi y) - a_2 \sin(2\pi y))^{-1}$, $a_0 > 0$, $a_1 \neq 0$, $a_2 \neq 0$, $a_1^2 + a_2^2 < a_0^2$. We do not pursue maximal generality to avoid unnecessary further algebraic complications.

A sufficient condition for f to satisfy (73) is for its Fourier coefficients f_k to decay exponentially with the "rate" $|k|^{1/\beta}$, i.e.,

$$A_1 \exp(-B_1|k|^{1/\beta}) \le f_k \le A_2 \exp(-B_2|k|^{1/\beta}) \tag{74}$$

with positive A_1, A_2, B_1, and B_2.

To see that such f satisfies (73) one can first apply the Plancherel theorem to definition (7), implying

$$\begin{aligned}(2\pi)^{2l} A_1 \sum_{k\in\mathbb{N}} \exp(-2B_1 k^{1/\beta}) k^{2l} \le (2\pi)^{2l} \sum_{k\in\mathbb{N}} k^{2l} f_k^2 \le \|f;\ H^l(\mathbb{T})\|^2 \\ \le 4(2\pi)^{2l} \sum_{k\in\mathbb{N}} k^{2l} f_k^2 \le 4(2\pi)^{2l} A_2 \sum_{k\in\mathbb{N}} \exp(-2B_2 k^{1/\beta}) k^{2l}. \end{aligned} \tag{75}$$

Then one can notice that the sums in (75) can be further bounded both from above and from below as follows: there exist l-independent positive constants D_1 and D_2 such that

$$\begin{aligned} D_1 \beta (2B_1)^{-\beta(2l+1)} \Gamma((2l+1)\beta) = D_1 \int_0^\infty \exp(-2B_1 s^{1/\beta}) s^{2l} ds \\ \le \sum_{k\in\mathbb{N}} \exp(-2B_1 k^{1/\beta}) k^{2l} \le \sum_{k\in\mathbb{N}} \exp(-2B_2 k^{1/\beta}) k^{2l} \\ \le D_2 l \int_0^\infty \exp(-2B_2 s^{1/\beta}) s^{2l} ds = D_2 l \beta (2B_2)^{-\beta(2l+1)} \Gamma((2l+1)\beta). \end{aligned} \tag{76}$$

(A way to establish (76) is by noticing that the series, asymptotically for large l, coincides to the main order with the integral.) Finally, by the application of the Stirling formula (11) we obtain $D_3^{2l}(l!)^{2\beta} \le \Gamma((2l+1)\beta) \le D_4^{2l}(l!)^{2\beta}$ with l-independent D_3, D_4, which implies (73).

An example of a function f satisfying (71) and (73) is

$$f(x) = \sum_{k\in\mathbb{Z}, k\neq 0} \exp(-|k|^{1/\beta}) \exp(2i\pi k x). \tag{77}$$

In particular, for $\beta = 1$

$$f(x) = 2\,\mathrm{Re} \sum_{k=1}^{\infty} \exp(k(2i\pi x - 1)) = \frac{2e\cos(2\pi x) - 2}{(e^2+1) - 2e\cos(2\pi x)} \tag{78}$$

is clearly analytic, with poles at $x = \pm i/(2\pi) + n$, $n \in \mathbb{Z}$.

We formulate the following optimality theorem for the above one-dimensional case.

THEOREM 5. *For any f satisfying* (74) *with $B_1 = B_2$ there exist positive constants $\tilde{C}_1$ and $\tilde{C}_2$ such that the following lower error bound for the exact solution u^ε of the problem* (69)–(70) *and its asymptotic approximation $u^{\varepsilon,n}$ holds for any $n \in \mathbb{N}$ and any $\varepsilon = 1/N$, $N \in \mathbb{N}$:*

$$\|u^\varepsilon - u^{\varepsilon,n}\ ;\ H^1(\mathbb{T})\| \ge \tilde{C}_1 \exp(-\tilde{C}_2 \varepsilon^{-\frac{1}{\beta}}). \tag{79}$$

Proof. In the one-dimensional case, the general recurrence relations (22)–(27), (30)–(33) for the correctors N_k, the "homogenized coefficients" h_k, and "slowly varying" parts v_s specialize to simple ODEs (see, e.g., [23, section 1F]), which can be

solved explicitly.[3] In particular, the equations (25)–(26) for the "main corrector" N_1 specialize to

$$\frac{d}{dy}N_1(y) = \frac{a^{-1}(y)}{\langle a^{-1}\rangle} - 1 = \frac{2}{3}\left(\frac{3}{2} - \cos\left(2\pi y - \frac{\pi}{4}\right)\right) - 1 = -\frac{2}{3}\cos\left(2\pi y - \frac{\pi}{4}\right), \tag{80}$$

implying $N_1(y) = -(3\pi)^{-1}\sin(2\pi y - \pi/4)$. All the higher order correctors N_k, $k \geq 2$, have a similar form, due to the recurrence relations

$$\frac{d}{dy}N_k = -N_{k-1} \tag{81}$$

(the latter also immediately follows by direct substitution of (20) into (69)). As a result,

$$\begin{aligned} N_{2m}(y) &= (-1)^m \frac{\cos(2\pi y - \pi/4)}{3\pi(2\pi)^{2m-1}} = (-1)^m 2^{1/2}\frac{\cos(2\pi y) + \sin(2\pi y)}{3(2\pi)^{2m}}, \quad m \geq 1, \\ N_{2m+1}(y) &= (-1)^{m+1}\frac{\sin(2\pi y - \pi/4)}{3\pi(2\pi)^{2m}} = (-1)^m 2^{1/2}\frac{\cos(2\pi y) - \sin(2\pi y)}{3(2\pi)^{2m+1}}, \quad m \geq 0. \end{aligned} \tag{82}$$

Further, v_0 is given by homogenized equation (30) ($s = 0$) specializing in the one-dimensional case to

$$-h_2\,\frac{d^2}{dx^2}v_0 = f, \tag{83}$$

where $h_2 = A^{\mathrm{hom}} = \langle a^{-1}\rangle^{-1} = 2/3$. Furthermore, in the one-dimensional case $h_k = 0$ for all $k \geq 3$ via a straightforward analysis of the recurrent relations (23)–(27) (see, e.g., [23, section 1F]). The latter immediately implies via (30) and (33) that $v_k = 0$ for all $k \geq 1$. Taking the above into account specializes the remainder term (45) in Lemma 3 to

$$\begin{aligned} R^{\varepsilon,n}(x) &= -\varepsilon^{n+1}\left(\left(aN'_{n+2} + a'N_{n+2}\right)\left(\frac{x}{\varepsilon}\right)D^{n+3}v_0(x)\right. \\ &\qquad \left. +\varepsilon a\left(\frac{x}{\varepsilon}\right)N_{n+2}\left(\frac{x}{\varepsilon}\right)D^{n+4}v_0(x)\right) \\ &= -\frac{d}{dx}\left(\varepsilon^{n+2}a\left(\frac{x}{\varepsilon}\right)N_{n+2}\left(\frac{x}{\varepsilon}\right)D^{n+3}v_0(x)\right) = -\frac{d}{dx}\Phi^{\varepsilon,n}(x), \end{aligned} \tag{84}$$

where

$$\Phi^{\varepsilon,n}(x) := \varepsilon^{n+2}a\left(\frac{x}{\varepsilon}\right)N_{n+2}\left(\frac{x}{\varepsilon}\right)D^{n+3}v_0(x). \tag{85}$$

Employing in the above the explicit solutions (82) for N_k and (83) for v_0, we arrive at

$$\begin{aligned} \Phi^{\varepsilon,n}(x) &= \frac{(-1)^{n/2}\varepsilon^{n+2}(\cos(2\pi x/\varepsilon) + \sin(2\pi x/\varepsilon))}{2^{1/2}(2\pi)^{n+2}\,[3/2 - \cos(2\pi x/\varepsilon - \pi/4)]}D^{n+1}f(x), \ n = 2m,\ m \geq 1, \\ \Phi^{\varepsilon,n}(x) &= \frac{(-1)^{(n+1)/2}\varepsilon^{n+2}(\cos(2\pi x/\varepsilon) - \sin(2\pi x/\varepsilon))}{2^{1/2}(2\pi)^{n+2}\,[3/2 - \cos(2\pi x/\varepsilon - \pi/4)]}D^{n+1}f(x), \ n = 2m+1,\ m \geq 0. \end{aligned} \tag{86}$$

(87)

[3] We remark that the present one-dimensional case is integrable, and an alternative but related approach for analyzing the error term in the asymptotics is from the exact solution; see Remark 5.

From (84), by the definition of the H^{-1} norm, we have

$$\|R^{\varepsilon,n};\ H^{-1}\|^2 \geq C\|\Phi^{\varepsilon,n} - \langle\Phi^{\varepsilon,n}\rangle;\ L^2\|^2 = C\left(\|\Phi^{\varepsilon,n};\ L^2\|^2 - \left|\int_0^1 \Phi^{\varepsilon,n}(x)dx\right|^2\right) \tag{88}$$

(recalling that C denotes constants whose precise value is insignificant).

With the aim of further bounding (88) from below, we introduce for any given $\varepsilon = 1/N$ and n functions $h_N(x)$ as follows:

$$\begin{aligned} h_N(x) = h(Nx) &= \frac{\cos(2\pi Nx) + \sin(2\pi Nx)}{[3/2 - \cos(2\pi Nx - \pi/4)]},\ N = 2m, \\ h_N(x) = h(Nx) &= \frac{\cos(2\pi Nx) - \sin(2\pi Nx)}{[3/2 - \cos(2\pi Nx - \pi/4)]},\ N = 2m+1. \end{aligned} \tag{89}$$

We prove the following lemma.

LEMMA 6. *There exists a constant C such that for any f satisfying* (71) *and for all n and N*

$$\|h_N D^{n+1} f;\ L^2\|^2 \geq C\|D^{n+1} f;\ L^2\|^2. \tag{90}$$

Proof. Choosing first n to be even, $n = 2m$, notice that

$$\begin{aligned} \|h_N(x)D^{n+1}f(x);\ L^2\|^2 &:= \int_0^1 \frac{(\cos(2\pi Nx) + \sin(2\pi Nx))^2}{[3/2 - \cos(2\pi Nx - \pi/4)]^2} \left(D^{n+1}f\right)^2 dx \\ &\geq \frac{4}{25}\int_0^1 (\cos(2\pi Nx) + \sin(2\pi Nx))^2 \left(D^{n+1}f\right)^2 dx \\ &= \frac{4}{25}\|\left(\cos(2\pi Nx) + \sin(2\pi Nx)\right) D^{n+1}f(x);\ L^2\|^2. \end{aligned}$$

We next notice that for n even and for f given by (71) $D^{n+1}f$ is represented by a sine Fourier series, implying that $\cos(2\pi Nx)D^{n+1}f(x)$ and $\sin(2\pi Nx)D^{n+1}f(x)$ are orthogonal in $L^2(0,1)$ and hence

$$\|\left(\cos(2\pi Nx) + \sin(2\pi Nx)\right) D^{n+1}f(x);\ L^2\|^2 \geq \|\cos(2\pi Nx)D^{n+1}f(x);\ L^2\|^2.$$

Further,

$$\begin{aligned} g_{Nn}(x) := \cos(2\pi Nx)D^{n+1}f(x) &= \frac{1}{2}\sum_{k\in\mathbb{Z}} \left(e^{2i\pi Nx} + e^{-2i\pi Nx}\right)(2i\pi k)^{n+1} f_k e^{2i\pi kx} \\ &= \frac{1}{2}\sum_{m\in\mathbb{Z}} e^{2i\pi mx}\left[(i2\pi(m-N))^{n+1} f_{m-N} + (i2\pi(m+N))^{n+1} f_{m+N}\right]. \end{aligned}$$

Hence, applying the Plancherel theorem,

$$\begin{aligned}\|g_{Nn}(x);\ L^2\|^2 &= \frac{(2\pi)^{2n+2}}{4}\sum_{m\in\mathbb{Z}}\left[(m-N)^{n+1}f_{m-N}+(m+N)^{n+1}f_{m+N}\right]^2\\ &\geq \frac{(2\pi)^{2n+2}}{4}\sum_{m=N+1}^{\infty}\left[(m-N)^{n+1}f_{m-N}+(m+N)^{n+1}f_{m+N}\right]^2\\ &\geq \frac{(2\pi)^{2n+2}}{4}\sum_{m=N+1}^{\infty}\left((m-N)^{n+1}f_{m-N}\right)^2 = \frac{(2\pi)^{2n+2}}{4}\sum_{m=1}^{\infty}\left(m^{n+1}f_m\right)^2\\ &= \frac{(2\pi)^{2n+2}}{8}\sum_{m\in\mathbb{Z}}\left(m^{n+1}f_m\right)^2 = \frac{1}{8}\|D^{n+1}f(x);\ L^2\|^2.\end{aligned}$$

In the latter we have used the nonnegativity of Fourier coefficients f_k, their symmetry ($f_{-k}=f_k$), and the fact that $\langle f\rangle = 0$ (hence $f_0=0$).

The above proves the lemma for even n. The proof for odd n is fully analogous, with the sign alteration between the "sine" and "cosine" terms, then noticing that $D^{n+1}f$ is represented by a cosine Fourier series, and then using the orthogonality and neglecting the sine term as before. ∎

We next aim at showing that, at least for sufficiently large n, the last term in the right-hand side of (88) can be bounded from the above as in (90) but with a smaller constant.

LEMMA 7. *For any f satisfying* (74) *with $B_1 = B_2$ there exists $n_0 > 0$ such that for all $n > n_0$ and all N*

$$\left\langle h_N(x)D^{n+1}f(x)\right\rangle^2 := \left|\int_0^1 h_N(x)D^{n+1}f(x)dx\right|^2 \leq \frac{1}{2}C\|D^{n+1}f(x);\ L^2\|^2, \tag{91}$$

where C is same as in Lemma 6.

Proof. The Fourier series of $h_N(x)$ has the form

$$h_N(x) = \sum_{\ell\in\mathbb{Z}} h_\ell \exp(i2\pi N\ell x), \tag{92}$$

with $\{h_\ell\}$ being two possible sets of (rapidly decaying) Fourier coefficients (for N even and odd, according to (89)), independent of N for all $\ell\in\mathbb{Z}$. Then,

$$\begin{aligned}\left\langle h_N(x)D^{n+1}f(x)\right\rangle^2 &= \left|\sum_{\ell\in\mathbb{Z}} h_\ell(2\pi N\ell)^{n+1}f_{-N\ell}\right|^2\\ &\leq (2\pi)^{2n+2}\max_{k\in\mathbb{N}}\left(k^{2n+2}f_k^2\right)\left(\sum_{\ell\in\mathbb{Z}}|h_\ell|\right)^2 \leq H(2\pi)^{2n+2}\max_{t\geq 0}\phi_n(t)\\ &\leq H(2\pi)^{2n+2}\left(\frac{\beta}{eB_1}(n+1)\right)^{2\beta(n+1)}, \qquad (93)\end{aligned}$$

where

$$\phi_n(t) := t^{2n+2}\exp\left(-2B_1t^{1/\beta}\right) \tag{94}$$

and H is independent of N and n.

On the other hand, we have

$$\begin{aligned}\|D^{n+1}f;\ L^2\|^2 &= (2\pi)^{2n+2}\sum_{k\in\mathbb{Z}} k^{2n+2}f_k^2 \geq A_1(2\pi)^{2n+2}\sum_{k\in\mathbb{Z}}\phi_n(|k|)\\ &\geq 2A_1(2\pi)^{2n+2}\left(\int_0^\infty \phi_n(t)dt - \max_{t\geq 0}\phi_n(t)\right)\\ &= 2A_1(2\pi)^{2n+2}\left(\int_0^\infty \phi_n(t)dt - \left(\frac{\beta}{eB_1}(n+1)\right)^{2\beta(n+1)}\right) \qquad (95)\end{aligned}$$

using the fact that $\phi_n(t)$, $t\geq 0$, has a single maximum for any n. Further, we estimate

$$\int_0^\infty \phi_n(t)dt = \beta(2B_1)^{-\beta(2n+3)}\Gamma((2n+3)\beta) \geq C\left(\frac{\beta}{eB_1}(n+1)\right)^{2\beta(n+1)} n^{\beta-1/2} \qquad (96)$$

with some $C>0$, having used

$$\Gamma((2n+3)\beta) \geq c\left(\frac{(2n+3)\beta}{e}\right)^{(2n+3)\beta-1/2} \qquad (97)$$

with some $c>0$ which is a direct implication of the Stirling formula (11), and then performing further straightforward manipulations.

Comparing finally (93) with (95) and (96), we conclude that

$$\left\langle h_N(x)D^{n+1}f(x)\right\rangle^2 \leq cn^{1/2-\beta}\|D^{n+1}f(x);\ L^2\|^2$$

with some $c>0$, and hence (91) holds with appropriate choice of n_0. □

Now we complete the proof of Theorem 5. Let C be a constant from Lemma 6 and let n_0 be as in Lemma 7. Denote

$$\begin{aligned}G_{nN} &:= \|h_N(x)D^{n+1}f(x);\ L^2\|^2 - \left\langle h_N(x)D^{n+1}f(x)\right\rangle^2\\ &= \int_0^1 \left(h_N(x)D^{n+1}f(x) - \left\langle h_N(x)D^{n+1}f(x)\right\rangle\right)^2 dx > 0. \qquad (98)\end{aligned}$$

(G_{nN} is strictly positive for any n and N since $h_N(x)D^{n+1}f(x)$ is not a constant: h_N vanishes at some points, but $D^{n+1}f(x)$ is clearly not identically zero.)

By Lemmas 6 and 7, for any N and for any $n>n_0$

$$G_{nN} \geq \frac{1}{2}C\|D^{n+1}f(x);\ L^2\|^2. \qquad (99)$$

Further, for any $0<n\leq n_0$

$$\lim_{N\to\infty} G_{nN} = C_1\|D^{n+1}f(x);\ L^2\|^2, \qquad (100)$$

where

$$C_1 := \left\langle \left(h_N - \langle h_N\rangle\right)^2\right\rangle > 0$$

is N-independent positive constant by (89). (A standard way to establish (100) is to subtract from h_N^2 and h_N in (98) their means, represent the resulting zero-mean

periodic functions as derivatives of other periodic functions, and then integrate by parts.) It follows from (100) that there exists $C_2 > 0$ such that

$$G_{nN} \geq C_2 \| D^{n+1} f(x);\ L^2 \|^2$$

for any N and for any $n \leq n_0$. Combining the latter with (99) implies that

$$G_{nN} \geq C_3 \| D^{n+1} f(x);\ L^2 \|^2 \tag{101}$$

for all n and N with $C_3 = \min(C/2, C_2)$.

Next, from (86)–(87)

$$\| \Phi^{\varepsilon,n}(x) - \langle \Phi^{\varepsilon,n} \rangle ;\ L^2 \|^2 = \frac{1}{4} \left(\frac{\varepsilon}{2\pi} \right)^{2n+4} G_{nN} \geq C_4 \left(\frac{\varepsilon}{2\pi} \right)^{2n+4} \| D^{n+1} f(x);\ L^2 \|^2. \tag{102}$$

Using again the lower bounds in (95)–(97) implies

$$\| D^{n+1} f(x);\ L^2 \|^2 \geq C_5^n n^{2\beta n}$$

with some $C_5 > 0$, which combined with (102) yields

$$\| \Phi^{\varepsilon,n}(x) - \langle \Phi^{\varepsilon,n} \rangle ;\ L^2 \| \geq C_6^n \varepsilon^{n+2} n^{\beta n}. \tag{103}$$

Now, by uniform continuity of L^ε as an operator from H^1 to H^{-1}, we have

$$\| u^{\varepsilon,n} - u^\varepsilon \ ;\ H^1(\mathbb{T}) \| \geq \| u^{\varepsilon,n} - \langle u^{\varepsilon,n} \rangle - u^\varepsilon \ ;\ H^1(\mathbb{T}) \| \geq C \| R^{\varepsilon,n}(x);\ H^{-1} \|. \tag{104}$$

Combining this with (88) and (103) implies

$$\| u^{\varepsilon,n} - u^\varepsilon \ ;\ H^1(\mathbb{T}) \| \geq C_7^n \varepsilon^{n+2} n^{\beta n}. \tag{105}$$

We can now "optimize" the lower bound (105) for any fixed small ε by choosing $n = n(\varepsilon)$ so that the right-hand side of (105) is minimized:

$$\| u^{\varepsilon,n} - u^\varepsilon \ ;\ H^1(\mathbb{T}) \| \geq \varepsilon^2 \min_{t \geq 1} \left[(C_7 \varepsilon)^t t^{\beta t} \right]. \tag{106}$$

The latter minimum is attained at

$$t = e^{-1} (C_7 \varepsilon)^{-1/\beta}; \tag{107}$$

substituting this back into (106), we finally obtain a lower bound of the form

$$\| u^{\varepsilon,n} - u^\varepsilon \ ;\ H^1(\mathbb{T}) \| \geq \varepsilon^2 \exp\left[-\beta e^{-1} (C_7 \varepsilon)^{-1/\beta} \right]. \tag{108}$$

Finally, since obviously there exists such a positive constant $\tilde{C}_1$ such that $\varepsilon^2 > \tilde{C}_1 \exp(-\varepsilon^{1/\beta})$ for any $0 < \varepsilon \leq 1$, (108) implies (79) for any $0 < \varepsilon \leq 1$, for example, with the above $\tilde{C}_1$ and $\tilde{C}_2 = \beta e^{-1} C_7^{-1/\beta} + 1$. The theorem is proved. □

We conclude from Theorem 5 that up to the choice of the constants $C_1, C_2 > 0$, the main error estimate (17) in Theorem 1 is sharp, at least for the above one-dimensional case. Note also that the above lower bound (79) was obtained by "optimizing" the lower bound (105) for a given small ε by choosing $n = n(\varepsilon)$ in the range given by

(107), which is consistent with (16) for the upper bound. In this sense, the range of truncation given by (16) is also "optimal."

Remark 5. Notice that the present one-dimensional case is "integrable" and that Theorem 5 could have been alternatively derived from the exact solution of (69):

$$u^\varepsilon(x) = \int_0^x (F(s) - A^\varepsilon)\, a^{-1}\left(\frac{s}{\varepsilon}\right) ds \; - \; B^\varepsilon, \tag{109}$$

where $F(x) := -\int_0^x f(t)dt$ is periodic, $A^\varepsilon := \langle F(\cdot)a^{-1}(\cdot/\varepsilon)\rangle\langle a^{-1}\rangle^{-1}$, and $B^\varepsilon := \int_0^1 (F(s)-A^\varepsilon)a^{-1}(s/\varepsilon)(1-s)ds$. One then employs $a^{-1}(x/\varepsilon) = \langle a^{-1}\rangle + \varepsilon\langle a^{-1}\rangle \frac{d}{dx} N_1(x/\varepsilon)$ (cf. (80)), in (109) and integrates by parts. Then employing iteratively (81) and integrating by parts n times is expected to explicitly reproduce $u^{\varepsilon,n}$, with the rest being the "error term." The latter would then still have to be analyzed in a fashion similar if not identical to that in the above proofs (the details are omitted).

Remark 6. The same arguments (Lemmas 6 and 7) can be used to obtain lower bounds of finite order in ε if $f \in H^M$ but $f \notin H^{M+1}$ for some $M \in \mathbb{N}$. Namely, on one hand, only a finite number of terms in the asymptotic expansion can be constructed. On the other hand, for each such n (from a finite set) a lower bound of the form (105) holds with appropriate choice of C_7. Optimizing finally with respect to the final set of lower bounds (105), one arrives at an unimprovable polynomial lower bound. On the other hand, if $f \in C^\infty(\mathbb{T})$ and is not from any Gevrey-type class with no other control on the growth of its H^l norms for large l (equivalently, on $\|D^{n+1}f; L^2\|$ for large n), there is no control on the "coefficients" multiplying ε^{n+2} in the error bounds for large n (cf. (104), (86)–(88)), which does not allow us to improve the homogenization in all orders any further. This indicates the importance of the Gevrey extreme regularity of f for the exponential lower bounds.

Remark 7. For analytic $f(x)$ Theorems 1 and 5, i.e., the exponential upper bound (17) and lower bound (79), respectively, both hold with $\beta = 1$. The "rate" of the exponential decay is then determined by the values of the constants C_2 and $\tilde{C}_2$ in (17) and (79). By tracing back the proofs of both theorems, one observes that these constants are dependent on the rate of the exponential decay of the Fourier coefficients of f, i.e., by the constants c_2 in (9) and B_1 in (74). On the other hand, for analytic f, the latter constants are directly related to the "width" of analytic continuation of $f(x)$ into the complex plane off the real axis, i.e., the absolute value of the imaginary part of the "first singularity"; for example, f in (78) has a pole in $x = \pm i/(2\pi)$, corresponding to $B_1 = 1$. In this sense one could argue that the rate of exponential error bound for analytic f is determined by the nearest singularity in the analytic continuation.

MAGNETIC FIELD-INDUCED INSTABILITIES IN LIQUID CRYSTALS*

FANGHUA LIN† AND XING-BIN PAN‡

Abstract. We use the Landau–de Gennes model to investigate the magnetic field-induced instabilities in liquid crystals. In particular, we examine the change of weak and strong stabilities in the pure smectic states and in the pure nematic states. Motivated by de Gennes' discovery on the analogies between liquid crystals and superconductors, we introduce critical magnetic fields $H_{\rm s}$ and $H_{\rm sh}$. The pure smectic states lose their global minimality (strong stability) at $H_{\rm s}$ and lose their local minimality (weak stability) at $H_{\rm sh}$. We also examine the change of stability in the pure nematic states. We show in the case of equal elastic coefficients that a liquid crystal in a sufficiently strong magnetic field will not be in a pure nematic state, which exhibits a significant difference between the Landau–de Gennes model for liquid crystals and the Ginzburg–Landau model for superconductivity.

Key words. liquid crystal, phase transition, critical magnetic field, Landau–de Gennes model

1. Introduction.

A liquid crystal configuration will change its stability under applied electric or magnetic fields. The classical mathematical description of transitions of stabilities in nematic liquid crystals under applied magnetic fields is given by introducing a magnetic energy density $-\chi(\mathbf{H}\cdot\mathbf{n})^2$ to the classical Oseen–Frank energy density $F_N(\mathbf{n},\nabla\mathbf{n})$ of nematic liquid crystals to obtain a modified energy functional (one may call it *the Oseen–Frank model with magnetic effect*):

$$\int_\Omega \{F_N(\mathbf{n},\nabla\mathbf{n}) - \chi(\mathbf{H}\cdot\mathbf{n})^2\}dx.$$

Here $\mathbf{n}:\bar\Omega\to\mathbb{S}^2$ denotes the *director field* of the nematic liquid crystals, $\mathbf{H}$ is an applied magnetic field, and χ is a positive parameter; see [E], [dGP, p. 287], [K], [HKL], and [CL]. It was widely accepted that adding the term $\chi(\mathbf{H}\cdot\mathbf{n})^2$ into the Oseen–Frank energy is only a lower order perturbation from an analysis point of view and that one does not expect substantially new phenomena. The physical phenomena, however, say otherwise (see [LL, section 2.2]).

In this paper we consider the influence of magnetic fields on the states of liquid crystals and on phase transitions from a nematic state to a smectic state. We shall work in the framework of the Landau–de Gennes theory [dGP]. According to this theory, the states and phase transitions of nematic to smectic liquid crystals can be described by the minimizers $(\psi,\mathbf{n})$ of Landau–de Gennes energy, where ψ is a complex-valued function called *order parameter* and $\mathbf{n}$ is the director field. This model was proposed by de Gennes when he discovered the analogies of liquid crystals

and superconductors; see [dG], [dGP]. To understand the effects of magnetic fields on liquid crystals, including nematics and smectics phase transitions, we follow the earlier work of Ericksen [E] by introducing the term $-\chi(\mathbf{H}\cdot\mathbf{n})^2$ to the Landau–de Gennes model to get a modified energy functional (which one may refer to as the *Landau–de Gennes model with magnetic effect*). We then examine the behavior of minimizers of the functional when the applied magnetic fields vary. Throughout this paper we consider the strong anchoring condition, which is simply the Dirichlet boundary condition on the director fields:

$$\mathbf{n} = \mathbf{u}_0 \quad \text{on } \partial\Omega,$$

where $\mathbf{u}_0 \in C^1(\partial\Omega, \mathbb{S}^2)$. As in [HKL], we can drop the divergence term (surface energy) in the Oseen–Frank energy. For simplicity, we also assume, as in [P2], [P4], that the bend and twist coefficients in the Oseen–Frank energy functional are equal: $K_2 = K_3$. This leads to a simplified form of the Landau–de Gennes energy functional with an applied magnetic field

(1.1)
$$\mathcal{E}[\psi,\mathbf{n}] = \int_\Omega \left\{ |\nabla_{q\mathbf{n}}\psi|^2 + \frac{\kappa^2}{2}(1-|\psi|^2)^2 + K_1|\operatorname{div}\mathbf{n}|^2 + K_2|\operatorname{curl}\mathbf{n}|^2 - \chi(\mathbf{H}\cdot\mathbf{n})^2 \right\} dx,$$

where κ, K_1, K_2, and χ are positive constants and q is a real number. Without loss of generality we shall always assume that $q \geq 0$. We may write the functional as

$$\mathcal{E}[\psi,\mathbf{n}] = \mathcal{G}[\psi,\mathbf{n}] + \mathcal{F}[\mathbf{n}] - \int_\Omega \chi(\mathbf{H}\cdot\mathbf{n})^2 dx,$$

where

$$\mathcal{F}[\mathbf{n}] = \int_\Omega \{K_1|\operatorname{div}\mathbf{n}|^2 + K_2|\operatorname{curl}\mathbf{n}|^2\} dx$$

is the simplified Oseen–Frank energy for nematics and

$$\mathcal{G}[\psi,\mathbf{n}] = \int_\Omega \left\{ |\nabla_{q\mathbf{n}}\psi|^2 + \frac{\kappa^2}{2}(1-|\psi|^2)^2 \right\} dx$$

is the Ginzburg–Landau energy of smectics. The functional $\mathcal{E}$ is well defined in the space

$$W^{1,2}(\Omega,\mathbb{C}) \times W^{1,2}(\Omega,\mathbb{S}^2,\mathbf{u}_0),$$

where $W^{1,2}(\Omega,\mathbb{C})$ is the usual Sobolev space of complex valued functions and

$$W^{1,2}(\Omega,\mathbb{S}^2,\mathbf{u}_0) = \{\mathbf{u}\in W^{1,2}(\Omega,\mathbb{R}^3) :\ |\mathbf{u}(x)| = 1 \text{ a.e. in } \Omega,\ \mathbf{u} = \mathbf{u}_0 \text{ on } \partial\Omega\}.$$

Analysis shows that the minimizers of $\mathcal{E}$ undergo complicated changes when the applied fields vary, indicating that magnetic fields have a very important influence on phase transitions of liquid crystals. To make our presentations more explicit so that one can compare our analysis with numerical computations as well as physical experiments, in this paper (except in section 2) we shall restrict ourselves to a simple situation where the applied field $\mathbf{H}$ and the boundary data $\mathbf{u}_0$ are a pair of constant vectors orthogonal to each other; i.e., we assume that

(1.2)
$$\mathbf{H} = \sigma\mathbf{h}, \qquad \mathbf{u}_0 = \mathbf{e},$$

where σ is a positive number measuring the strength of the applied magnetic field and $\mathbf{h}$ and $\mathbf{e}$ are unit vectors such that $\mathbf{h} \cdot \mathbf{e} = 0$. The energy functional can then be rewritten as

$$\mathcal{E}[\psi, \mathbf{n}] = \mathcal{G}[\psi, \mathbf{n}] + \mathcal{F}[\mathbf{n}] - \chi\sigma^2 \int_\Omega (\mathbf{h} \cdot \mathbf{n})^2 dx. \tag{1.3}$$

We shall write

$$\begin{aligned} \mathcal{F}_{\sigma\mathbf{h}}[\mathbf{n}] &= \mathcal{F}[\mathbf{n}] - \chi\sigma^2 \int_\Omega (\mathbf{h} \cdot \mathbf{n})^2 dx \\ &= \int_\Omega \{K_1 |\operatorname{div} \mathbf{n}|^2 + K_2 |\operatorname{curl} \mathbf{n}|^2 - \chi\sigma^2 (\mathbf{h} \cdot \mathbf{n})^2\} dx. \end{aligned}$$

Under the above assumptions, one can easily see that the energy functional $\mathcal{E}$ has two families of trivial critical points. One is given by

$$\psi = 0, \quad \mathbf{n} = \mathbf{n}_\sigma, \tag{1.4}$$

where $\mathbf{n}_\sigma$ is a global minimizer of $\mathcal{F}_{\sigma\mathbf{h}}$:

$$\mathcal{F}_{\sigma\mathbf{h}}[\mathbf{n}_\sigma] = \inf_{\mathbf{n} \in W^{1,2}(\Omega, \mathbb{S}^2, \mathbf{e})} \mathcal{F}_{\sigma\mathbf{h}}[\mathbf{n}].$$

The second family is

$$\psi = ce^{iq\mathbf{e}\cdot\mathbf{x}}, \quad \mathbf{n} = \mathbf{e}, \tag{1.5}$$

where c is an arbitrary complex number such that $|c| = 1$. Following de Gennes' view on the analogies of superconductors and liquid crystals, we may compare the family (1.4) with the normal state of superconductors and call them *pure nematic states* and compare the family (1.5) with the Meissner state of superconductors and call them *pure smectic states*. We shall see in section 5 (Lemma 5.1) that $\mathbf{n}_\sigma = \mathbf{e}$ if σ is below a critical field $H_{\mathrm{n}}(0)$. Hence for $0 \le \sigma < H_{\mathrm{n}}(0)$, the only pure nematic state is $(0, \mathbf{e})$.

In this paper we shall introduce critical magnetic fields H_{sh} and H_{s}, where the pure smectic states change their weak stability (local minimality) at H_{sh} and change their strong stability (global minimality) at H_{s}.

One of the main goals of the paper is to show that

(i) if $0 \le \sigma < H_{\mathrm{s}}(\kappa, q)$, the pure smectic states are the only global minimizers of the functional $\mathcal{E}$;

(ii) if $H_{\mathrm{s}}(\kappa, q) < \sigma < H_{\mathrm{sh}}(q)$, the pure smectic states are local minimizers but not global minimizers; and

(iii) if $\sigma > H_{\mathrm{sh}}(q)$, the pure smectic states are not local minimizers.

We shall also give a criterion to test the minimality of the pure nematic states.

One believes that the critical field H_{sh} given here is an analogy of the superheating field of superconductors.[1] One may also expect existence of a critical magnetic field for liquid crystals that is an analogy of the upper critical magnetic field H_{C_3} for type II superconductors.[2] However, we are not able to provide a formal result to verify that

[1] See recent mathematical research on the superheating field for cylindrical superconductors by Chapman [Ch2], Lin and Du [LD], and Pan and Kwek [PK] and for bulk superconductors by Bates and Pan [BP].

[2] Nucleation of superconductivity and the upper critical field for type II superconductors have been studied by many mathematicians in recent years, among them Chapman [Ch1], Bauman, Phillips, and Tang [BPT], Bernoff and Sternberg [BS], Lu and Pan [LP1], [LP2], Helffer and Pan [HP], Helffer and Morame [HM1], [HM2], and Pan [P1], [P3].

this simple analogy exists, as liquid crystals and superconductors may have different responses in strong magnetic fields. In fact, when applied magnetic fields are above H_{C_3}, superconductors will be in the normal state, i.e., the normal state is the global minimizer of the Ginzburg–Landau functional. However, a liquid crystal under very strong magnetic fields may not be in a pure nematic state. Indeed, in section 5, we will give a proof of this conclusion in the case that $K_1 = K_2$.

Besides the normal and Meissner states, a superconductor may be in the so-called mixed state or in the surface superconducting state. Liquid crystals may also have many phases. Naturally, one is interested in various intermediate states of liquid crystals that can be described by nontrivial minimizers of $\mathcal{E}$. One also wishes to understand phase transitions between these states, as applied magnetic fields vary. We leave these problems to the future.

The outline of this paper is as follows. In section 2 we recall the concept of weak stability used by Cohen and Luskin [CL]. In section 3 we examine the weak instability in pure smectic states induced by external magnetic fields, and we introduce the critical magnetic field $H_{\rm sh}$. In section 4 we introduce the critical field $H_{\rm s}$. We also introduce an auxiliary field $H_{\rm n}$ and show that $H_{\rm s} \le H_{\rm n} \le H_{\rm sh}$. We then discuss the properties of these critical fields. In section 5 we examine the minimality of the pure nematic states. We then prove in the case of equal elastic coefficients that a liquid crystal under a strong magnetic field may not be in a pure nematic state.

We should point out that there exist many mathematical research works on liquid crystals done by physicists and mathematicians; see, for instance, [dGP], [K], [B], [E], [HKL], [L1], [L2], [L3], [LL], and the references therein. The magnetic field-induced instabilities and the Freedericksz transitions of nematic liquid crystals have been investigated in some simple cases by Cohen and Luskin [CL] and Atkin and Stewart [AS1], [AS2]. For recent work on the Landau–de Gennes model we refer to [Ca] and [BCLP].

2. Weak stability of critical points. In this section we consider the functional $\mathcal{E}$ defined in (1.1) for a general magnetic field $\mathbf{H}$. Following the earlier works [H], [CT], and [CL], we define the weak stability of critical points of $\mathcal{E}$ as follows.

DEFINITION 2.1. *$(\psi_0, \mathbf{n}_0) \in W^{1,2}(\Omega, \mathbb{C}) \times W^{1,2}(\Omega, \mathbb{S}^2, \mathbf{u}_0)$ is called a critical point of the functional $\mathcal{E}$ if for any $\phi \in W^{1,2}(\Omega, \mathbb{C})$ and $\mathbf{v} \in W_0^{1,2}(\Omega, \mathbb{R}^3) \cap L^\infty(\Omega, \mathbb{R}^3)$, we have*

$$\frac{d}{dt}\Big|_{t=0} \mathcal{E}[\psi_t, \mathbf{n}_t] = 0;$$

here

$$\psi_t = \psi_0 + t\phi, \qquad \mathbf{n}_t = \frac{\mathbf{n}_0 + t\mathbf{v}}{|\mathbf{n}_0 + t\mathbf{v}|}. \tag{2.1}$$

A critical point $(\psi_0, \mathbf{n}_0)$ is said to be weakly stable if for any $\phi \in W^{1,2}(\Omega, \mathbb{C})$ and $\mathbf{v} \in W_0^{1,2}(\Omega, \mathbb{R}^3) \cap L^\infty(\Omega, \mathbb{R}^3)$, there exists a positive number T depending on ϕ and $\mathbf{v}$ such that for all $0 < t < T$ it holds that

$$\mathcal{E}[\psi_0, \mathbf{n}_0] \le \mathcal{E}[\psi_t, \mathbf{n}_t].$$

For ψ_t and $\mathbf{n}_t$ given in (2.1), computations show that (also see [CL])

$$\begin{aligned} &\mathbf{n}_t = \mathbf{n}_0 + t\mathbf{n}_1 + t^2\mathbf{n}_2 + O(t^3), \qquad \text{where} \\ &\mathbf{n}_1 = \mathbf{v} - (\mathbf{v}\cdot\mathbf{n}_0)\mathbf{n}_0, \\ &\mathbf{n}_2 = -(\mathbf{v}\cdot\mathbf{n}_0)\mathbf{v} + \frac{1}{2}\big[3(\mathbf{v}\cdot\mathbf{n}_0)^2 - |\mathbf{v}|^2\big]\mathbf{n}_0, \end{aligned} \tag{2.2}$$

and

$$\begin{aligned}\nabla_{q\mathbf{n}_t}\psi_t &= \nabla_{q\mathbf{n}_0}\psi_0 + t\Phi_1 + t^2\Phi_2 + O(t^3), \qquad \text{where}\\ \Phi_1 &= \nabla_{q\mathbf{n}_0}\phi - iq\mathbf{n}_1\psi_0,\\ \Phi_2 &= -iq(\mathbf{n}_1\phi + \mathbf{n}_2\psi_0).\end{aligned} \tag{2.3}$$

For small t, we have

$$\begin{aligned}&\mathcal{G}[\psi_t,\mathbf{n}_t] = \mathcal{G}[\psi_0,\mathbf{n}_0]\\ &+ 2t\int_\Omega\Big\{\Re[\overline{\nabla_{q\mathbf{n}_0}\phi}\nabla_{q\mathbf{n}_0}\psi_0 - \kappa^2\bar\phi(1-|\psi_0|^2)\psi_0] - q\mathbf{n}_1\Im(\bar\psi_0\nabla_{q\mathbf{n}_0}\psi_0)\Big\}dx\\ &+ t^2\int_\Omega\Big\{|\Phi_1|^2 - \kappa^2(1-|\psi_0|^2)|\phi|^2 + 2\kappa^2(\Re(\bar\phi\psi_0))^2 - 2q\Im[(\mathbf{n}_1\bar\phi + \mathbf{n}_2\bar\psi_0)\nabla_{q\mathbf{n}_0}\psi_0]\Big\}dx\\ &+ O(t^3);\end{aligned}$$

$$\begin{aligned}&\mathcal{F}[\mathbf{n}_t] = \mathcal{F}[\mathbf{n}_0] + 2t\int_\Omega\{K_1\mathrm{div}\,\mathbf{n}_0\,\mathrm{div}\,\mathbf{n}_1 + K_2\mathrm{curl}\,\mathbf{n}_0\cdot\mathrm{curl}\,\mathbf{n}_1\}dx\\ &+ t^2\int_\Omega\big\{K_1[(\mathrm{div}\,\mathbf{n}_1)^2 + 2\mathrm{div}\,\mathbf{n}_0\,\mathrm{div}\,\mathbf{n}_2] + K_2[|\mathrm{curl}\,\mathbf{n}_1|^2 + 2\mathrm{curl}\,\mathbf{n}_0\cdot\mathrm{curl}\,\mathbf{n}_2]\big\}dx\\ &+ O(t^3);\end{aligned}$$

and

$$\begin{aligned}\int_\Omega(\mathbf{H}\cdot\mathbf{n}_t)^2dx &= \int_\Omega(\mathbf{H}\cdot\mathbf{n}_0)^2dx + 2t\int_\Omega(\mathbf{H}\cdot\mathbf{n}_0)(\mathbf{H}\cdot\mathbf{n}_1)dx\\ &\quad + t^2\int_\Omega\{(\mathbf{H}\cdot\mathbf{n}_1)^2 + 2(\mathbf{H}\cdot\mathbf{n}_0)(\mathbf{H}\cdot\mathbf{n}_2)\}dx.\end{aligned}$$

So

$$\begin{aligned}\mathcal{E}[\psi_t,\mathbf{n}_t] &= \mathcal{E}[\psi_0,\mathbf{n}_0]\\ &+ 2t\left\{\mathcal{A}(\psi_0,\mathbf{n}_0;\phi,\mathbf{v}) - \chi\int_\Omega(\mathbf{H}\cdot\mathbf{n}_0)(\mathbf{H}\cdot\mathbf{n}_1)dx\right\}\\ &+ t^2\left\{\mathcal{B}(\psi_0,\mathbf{n}_0;\phi,\mathbf{v}) - \chi\int_\Omega\{(\mathbf{H}\cdot\mathbf{n}_1)^2 + 2(\mathbf{H}\cdot\mathbf{n}_0)(\mathbf{H}\cdot\mathbf{n}_2)\}dx\right\}\\ &+ O(t^3),\end{aligned} \tag{2.4}$$

where

$$\begin{aligned}\mathcal{A}(\psi_0,\mathbf{n}_0;\phi,\mathbf{v}) &= \int_\Omega\Big\{\Re[\overline{\nabla_{q\mathbf{n}_0}\phi}\nabla_{q\mathbf{n}_0}\psi_0 - \kappa^2\bar\phi(1-|\psi_0|^2)\psi_0] - q\mathbf{n}_1\Im(\bar\psi_0\nabla_{q\mathbf{n}_0}\psi_0)\\ &\qquad + K_1\mathrm{div}\,\mathbf{n}_0\,\mathrm{div}\,\mathbf{n}_1 + K_2\mathrm{curl}\,\mathbf{n}_0\cdot\mathrm{curl}\,\mathbf{n}_1\Big\}dx\end{aligned} \tag{2.5}$$

and

$$\begin{aligned}&\mathcal{B}(\psi_0,\mathbf{n}_0;\phi,\mathbf{v})\\ &= \int_\Omega\Big\{|\nabla_{q\mathbf{n}_0}\phi - iq\mathbf{n}_1\psi_0|^2 - \kappa^2(1-|\psi_0|^2)|\phi|^2 + 2\kappa^2[\Re(\bar\phi\psi_0)]^2\\ &\quad - 2q\Im[(\mathbf{n}_1\bar\phi + \mathbf{n}_2\bar\psi_0)\nabla_{q\mathbf{n}_0}\psi_0] + K_1[(\mathrm{div}\,\mathbf{n}_1)^2 + 2\mathrm{div}\,\mathbf{n}_0\,\mathrm{div}\,\mathbf{n}_2]\\ &\quad + K_2[|\mathrm{curl}\,\mathbf{n}_1|^2 + 2\mathrm{curl}\,\mathbf{n}_0\cdot\mathrm{curl}\,\mathbf{n}_2]\Big\}dx.\end{aligned} \tag{2.6}$$

Therefore we have the following conclusions.

LEMMA 2.2. *$(\psi_0, \mathbf{n}_0) \in W^{1,2}(\Omega, \mathbb{C}) \times W^{1,2}(\Omega, \mathbb{S}^2, \mathbf{u}_0)$ is a critical point of the functional $\mathcal{E}$ if and only if for any $\phi \in W^{1,2}(\Omega, \mathbb{C})$ and $\mathbf{v} \in W_0^{1,2}(\Omega, \mathbb{R}^3) \cap L^\infty(\Omega, \mathbb{R}^3)$ it holds that*

$$\mathcal{A}(\psi_0, \mathbf{n}_0; \phi, \mathbf{v}) - \chi \int_\Omega (\mathbf{H} \cdot \mathbf{n}_0)(\mathbf{H} \cdot \mathbf{n}_1) dx = 0. \tag{2.7}$$

If a critical point $(\psi_0, \mathbf{n}_0) \in W^{1,2}(\Omega, \mathbb{C}) \times W^{1,2}(\Omega, \mathbb{S}^2, \mathbf{u}_0)$ is weakly stable, then for any $\phi \in W^{1,2}(\Omega, \mathbb{C})$ and $\mathbf{v} \in W_0^{1,2}(\Omega, \mathbb{R}^3) \cap L^\infty(\Omega, \mathbb{R}^3)$ we have

$$\mathcal{B}(\psi_0, \mathbf{n}_0; \phi, \mathbf{v}) \geq \chi \int_\Omega \{(\mathbf{H} \cdot \mathbf{n}_1)^2 + 2(\mathbf{H} \cdot \mathbf{n}_0)(\mathbf{H} \cdot \mathbf{n}_2)\} dx. \tag{2.8}$$

Remark 2.1. From (2.7) we see that if $(\psi, \mathbf{n})$ is a critical point of $\mathcal{E}$, then it satisfies the equation

$$\begin{cases} -\nabla_{q\mathbf{n}}^2 \psi = \kappa^2 (1 - |\psi|^2)\psi & \text{in } \Omega, \\ \nabla_{q\mathbf{n}} \psi \cdot \nu = 0 & \text{on } \partial\Omega. \end{cases} \tag{2.9}$$

3. Magnetic field-induced instability: Loss of local minimality of pure smectic states. Henceforth, we assume $\mathbf{H} = \sigma \mathbf{h}$ and $\mathbf{u}_0 = \mathbf{e}$ as in (1.2), where σ is a positive number, $\mathbf{h}$ and $\mathbf{e}$ are unit vectors such that $\mathbf{h} \cdot \mathbf{e} = 0$, and we assume the functional $\mathcal{E}$ is given by (1.3). We shall examine, in this section, the weak stability of the critical points given in (1.5) that correspond with a pure smectic state. For any $\mathbf{v} \in W_0^{1,2}(\Omega, \mathbb{R}^3) \cap L^\infty(\Omega, \mathbb{R}^3)$, let ψ_t and $\mathbf{n}_t$ be defined by (2.1). In the present case we have

$$\mathbf{n}_1 = \mathbf{v} - (\mathbf{v} \cdot \mathbf{e})\mathbf{e}, \qquad \mathbf{H} \cdot \mathbf{n}_1 = \sigma(\mathbf{v} \cdot \mathbf{h}).$$

Using Lemma 2.2 we conclude that if the critical point $(\psi_0, \mathbf{n}_0) = (ce^{iq\mathbf{e}\cdot\mathbf{x}}, \mathbf{e})$ given in (1.5) is weakly stable, then for any $\phi \in W^{1,2}(\Omega, \mathbb{C})$ and $\mathbf{v} \in W_0^{1,2}(\Omega, \mathbb{R}^3) \cap L^\infty(\Omega, \mathbb{R}^3)$ there holds that

$$\mathcal{B}(\psi_0, \mathbf{n}_0; \phi, \mathbf{v}) \geq \chi\sigma^2 \int_\Omega |\mathbf{v} \cdot \mathbf{h}|^2 dx. \tag{3.1}$$

Note that $W_0^{1,2}(\Omega, \mathbb{R}^3) \cap L^\infty(\Omega, \mathbb{R}^3)$ is dense in $W_0^{1,2}(\Omega, \mathbb{R}^3)$. If the above inequality holds for all $\mathbf{v} \in W_0^{1,2}(\Omega, \mathbb{R}^3) \cap L^\infty(\Omega, \mathbb{R}^3)$, then it must hold for all $\mathbf{v} \in W_0^{1,2}(\Omega, \mathbb{R}^3)$.

With the particular choice of $\mathbf{H}$ and $\mathbf{n}_0$ given in (1.2), we can simplify the expression of $\mathcal{B}(\psi_0, \mathbf{n}_0; \phi, \mathbf{v})$. Since

$$\nabla_{q\mathbf{n}_0} \psi_0 = 0, \qquad |\psi_0| = 1,$$

we have

$$\begin{aligned} &\mathcal{B}(\psi_0, \mathbf{n}_0; \phi, \mathbf{v}) \\ &= \int_\Omega \{|\nabla_{q\mathbf{n}_0} \phi - iq\mathbf{n}_1\psi_0|^2 + 2\kappa^2(\Re(\bar{\phi}\psi_0))^2 + K_1|\operatorname{div} \mathbf{n}_1|^2 + K_2|\operatorname{curl} \mathbf{n}_1|^2\} dx. \end{aligned}$$

For any $\phi \in W^{1,2}(\Omega, \mathbb{C})$, one can always write

$$\phi = icqe^{iq\mathbf{n}_0\cdot\mathbf{x}} u, \qquad \text{where} \quad u \in W^{1,2}(\Omega, \mathbb{C}).$$

Thus

$$\nabla_{q\mathbf{n}_0}\phi - iq\mathbf{n}_1\psi_0 = icqe^{iq\mathbf{n}_0\cdot x}(\nabla u - \mathbf{n}_1),$$
$$\Re(\bar{\phi}\psi_0) = |c|^2\Re(iqu) = -q\Im(u).$$

Here we have used the condition $|c| = 1$. Let us change the notation by writing $\mathbf{w}$ for $\mathbf{n}_1$, namely,

$$\mathbf{n}_1 = \mathbf{w} \in W_0^{1,2}(\Omega, \mathbb{R}^3), \qquad \mathbf{w}(x)\cdot\mathbf{e} = 0 \quad \text{in } \Omega.$$

Then one has

$$\mathcal{B}(\psi_0, \mathbf{n}_0; \phi, \mathbf{v}) = \int_\Omega \{q^2|\nabla u - \mathbf{w}|^2 + 2\kappa^2 q^2(\Im(u))^2 + K_1|\operatorname{div}\mathbf{w}|^2 + K_2|\operatorname{curl}\mathbf{w}|^2\}dx.$$

Obviously, if $(\phi, \mathbf{v})$ is such that $\mathcal{B}(\psi_0, \mathbf{n}_0; \phi, \mathbf{v})/\|\mathbf{v}\cdot\mathbf{h}\|^2_{L^2(\Omega)}$ is minimal, then

$$u = -\frac{i}{cq}e^{-iq\mathbf{n}_0\cdot\mathbf{x}}\phi$$

is real-valued. Thus it suffices to consider u as a real-valued function for our purposes, and we write

$$\mathcal{B}(\psi_0, \mathbf{n}_0; \phi, \mathbf{v}) = B(u, \mathbf{w}),$$

where

$$B(u, \mathbf{w}) = \int_\Omega \{q^2|\nabla u - \mathbf{w}|^2 + K_1|\operatorname{div}\mathbf{w}|^2 + K_2|\operatorname{curl}\mathbf{w}|^2\}dx. \tag{3.2}$$

We define now a nonnegative number $H_{\rm sh}$ as follows.

DEFINITION 3.1. *Given $q \geq 0$, $K_1 > 0$, $K_2 > 0$, and a pair of mutually orthogonal unit vectors $\mathbf{h}$ and $\mathbf{e}$, we define $H_{\rm sh} = H_{\rm sh}(q, K_1, K_2, \Omega, \mathbf{h}, \mathbf{e})$ by*

$$H_{\rm sh}^2 = \frac{1}{\chi}\inf\left\{\frac{q^2\|\nabla u - \mathbf{w}\|^2_{L^2(\Omega)} + \mathcal{F}[\mathbf{w}]}{\int_\Omega |\mathbf{h}\cdot\mathbf{w}|^2 dx} : (u, \mathbf{w}) \in W^{1,2}(\Omega)\times W_0^{1,2}(\Omega, \mathbb{R}^3),\ \mathbf{w}(x)\cdot\mathbf{e} = 0 \text{ in } \Omega\right\}. \tag{3.3}$$

From the above discussion we have the next lemma.

LEMMA 3.2. *Under condition* (1.2)*, the pure smectic states lose their weak stability when σ increases to the critical value $H_{\rm sh}$. More precisely, a pure smectic state is weakly stable if $|\sigma| < H_{\rm sh}$, and it is not weakly stable if $|\sigma| > H_{\rm sh}$.*

We may further simplify the expression in the right-hand side of (3.3). Note that if $(u, \mathbf{w})$ is a minimizer of $H_{\rm sh}$, then

$$u = \xi_{\mathbf{w}},$$

where $\xi_{\mathbf{w}}$ is a solution of

$$\Delta\xi_{\mathbf{w}} = \operatorname{div}\mathbf{w} \quad \text{in } \Omega, \qquad \frac{\partial\xi_{\mathbf{w}}}{\partial\nu} = \gamma_\nu\mathbf{w} \quad \text{on } \partial\Omega, \qquad \int_\Omega \xi_{\mathbf{w}}dx = 0, \tag{3.4}$$

where $\gamma_\nu \mathbf{w}$ is the trace of $\mathbf{w}$ on the boundary, which is equal to the restriction of $\nu \cdot \mathbf{w}$ on $\partial\Omega$ when $\mathbf{w}$ is smooth. Moreover,

$$\int_\Omega |\nabla \xi_{\mathbf{w}} - \mathbf{w}|^2 dx = \omega(\mathbf{w})|\Omega|,$$

where

$$\omega(\mathbf{w}) = \inf_{\xi \in W^{1,2}(\Omega)} \fint_\Omega |\nabla \xi - \mathbf{w}|^2 dx. \tag{3.5}$$

Write

$$B(\mathbf{w}) = B(\xi_{\mathbf{w}}, \mathbf{w}). \tag{3.6}$$

Obviously we have, for any $b > 0$,

$$\xi_{b\mathbf{w}} = b\xi_{\mathbf{w}}.$$

Thus

$$B(b\mathbf{w}) = bB(\mathbf{w}).$$

We have therefore verified

$$H_{\rm sh}^2 = \frac{1}{\chi} \inf \Big\{ B(\mathbf{w}) : \ \mathbf{w} \in W_0^{1,2}(\Omega, \mathbb{R}^3), \ \mathbf{w}(x) \cdot \mathbf{e} = 0 \text{ in } \Omega, \ \|\mathbf{h} \cdot \mathbf{w}\|_{L^2(\Omega)} = 1 \Big\}. \tag{3.7}$$

Note that the minimizers $(\psi_0, \mathbf{n}_0)$ given in (1.5) contain a complex number c. However, $B(u, \mathbf{w})$ and $B(\mathbf{w})$ are independent of c.

In the following, we write $H_{\rm sh}$ by $H_{\rm sh}(q)$ to emphasize the dependence on the parameter q. We will see in section 5 that the critical value $H_{\rm sh}(0)$ is particularly interesting:

$$H_{\rm sh}^2(0) = \frac{1}{\chi} \inf \big\{ \mathcal{F}[\mathbf{w}] : \ \mathbf{w} \in W_0^{1,2}(\Omega, \mathbb{R}^3), \ \mathbf{w}(x) \cdot \mathbf{e} = 0 \text{ in } \Omega, \ \|\mathbf{h} \cdot \mathbf{w}\|_{L^2(\Omega)} = 1 \big\}. \tag{3.8}$$

PROPOSITION 3.3. *$H_{\rm sh}(q) > 0$ and it is achieved. For fixed K_1, K_2, Ω, $\mathbf{h}$, $\mathbf{e}$, we have*

$$\lim_{q \to +\infty} H_{\rm sh}(q) = \infty. \tag{3.9}$$

Proof. Step 1. Let $\mathbf{w}_j \in W_0^{1,2}(\Omega, \mathbb{R}^3)$ and $\xi_j = \xi_{\mathbf{w}_j}$ be such that

$$\mathbf{w}_j \cdot \mathbf{e} = 0 \quad \text{in } \Omega, \quad \|\mathbf{w}_j \cdot \mathbf{h}\|_{L^2(\Omega)} = 1, \quad B(\mathbf{w}_j) \to \chi H_{\rm sh}^2 \quad \text{as } j \to \infty.$$

Since $\mathbf{w}_j \in W_0^{1,2}(\Omega, \mathbb{R}^3)$, we have

$$\int_\Omega |\nabla \mathbf{w}_j|^2 dx = \int_\Omega \{|\operatorname{div} \mathbf{w}_j|^2 + |\operatorname{curl} \mathbf{w}_j|^2\} dx \le \frac{1}{\min\{K_1, K_2\}} B(\mathbf{w}_j) \le C.$$

Hence $\{\mathbf{w}_j\}$ is bounded in $W_0^{1,2}(\Omega, \mathbb{R}^3)$. After passing to a subsequence we may assume that, as $j \to \infty$,

$$\mathbf{w}_j \to \mathbf{w}_0 \quad \text{weakly in } W_0^{1,2}(\Omega, \mathbb{R}^3) \text{ and strongly in } L^2(\Omega, \mathbb{R}^3).$$

Then $\mathbf{w}_0(x)\cdot\mathbf{e}=0$ for a.e. $x\in\Omega$. We also have

$$\int_\Omega |\nabla\xi_j-\mathbf{w}_j|^2dx\le\frac{1}{q^2}B(\mathbf{w}_j)\le C.$$

From this and the fact $\int_\Omega\xi_j dx=0$, we see that $\{\xi_j\}$ is bounded in $W^{1,2}(\Omega)$. Note that

$$\|\operatorname{div}\mathbf{w}_j\|^2_{L^2(\Omega)}\le C(\Omega)\|\mathbf{w}_j\|^2_{W^{1,2}(\Omega)}\le C,$$

and $\mathbf{w}_j=\mathbf{0}$ on $\partial\Omega$. Applying elliptic estimates to (3.4) for ξ_j with $\mathbf{w}=\mathbf{w}_j$, we find that $\{\xi_j\}$ is bounded in $W^{2,2}(\Omega)$. Passing to a subsequence we have $\xi_j\to\xi_0$ weakly in $W^{2,2}(\Omega)$ and strongly in $W^{1,2}(\Omega)$ as $j\to\infty$, and ξ_0 satisfies (3.4) for $\mathbf{w}=\mathbf{w}_0$. Thus $\xi_0=\xi_{\mathbf{w}_0}$. Hence we have proved that

$$B(\mathbf{w}_0)=B(\xi_{\mathbf{w}_0},\mathbf{w}_0)\le\liminf_{j\to\infty}B(\xi_j,\mathbf{w}_j)=\chi H^2_{\rm sh}.$$

On the other hand, since $\|\mathbf{w}_0\cdot\mathbf{h}\|_{L^2(\Omega)}=\lim_{j\to\infty}\|\mathbf{w}_j\cdot\mathbf{h}\|_{L^2(\Omega)}=1$, we have

$$B(\mathbf{w}_0)\ge\chi H^2_{\rm sh}(q).$$

Thus $\mathbf{w}_0$ is a minimizer of $B(\mathbf{w})$, i.e., $(\xi_0,\mathbf{w}_0)$ achieves $H_{\rm sh}(q)$. It in turn implies that $H_{\rm sh}(q)>0$.

Step 2. Suppose $H_{\rm sh}(q)\le c$ for all q. We may assume $\mathbf{e}=\mathbf{e}_1$. Let us choose $q_j\to+\infty$ and choose $u_j\in W^{1,2}(\Omega)$ and $\mathbf{w}_j\in W^{1,2}_0(\Omega,\mathbb{R}^3)$ such that $\int_\Omega u_j dx=0$, $\mathbf{e}_1\cdot\mathbf{w}_j=0$, and $(u_j,\mathbf{w}_j)$ achieves $H_{\rm sh}(q_j)$. Thus

$$\int_\Omega\{q_j^2|\nabla u_j-\mathbf{w}_j|^2+K_1|\operatorname{div}\mathbf{w}_j|^2+K_2|\operatorname{curl}\mathbf{w}_j|^2\}dx\le\chi c^2\int_\Omega(\mathbf{h}\cdot\mathbf{w}_j)^2dx.$$

In particular, one has $\|\operatorname{div}\mathbf{w}_j\|_{L^2(\Omega)}\le C$ and $\|\operatorname{curl}\mathbf{w}_j\|_{L^2(\Omega)}\le C$. Recall that for a bounded and simply connected domain with smooth boundary, the following inequality holds:

(3.10)
$$\|\mathbf{B}\|_{H^{k+1}(\Omega)}\le C(\Omega,k)\left\{\|\operatorname{div}\mathbf{B}\|_{H^k(\Omega)}+\|\operatorname{curl}\mathbf{B}\|_{H^k(\Omega)}+\left\|\begin{matrix}\nu\cdot\mathbf{B}\\ \nu\times\mathbf{B}\end{matrix}\right\|_{H^{k+1/2}(\partial\Omega)}\right\},$$

where $\left\|\begin{smallmatrix}\nu\cdot\mathbf{B}\\ \nu\times\mathbf{B}\end{smallmatrix}\right\|_{H^{k+1/2}(\partial\Omega)}$ means either $\|\nu\cdot\mathbf{B}\|_{H^{k+1/2}(\partial\Omega)}$ or $\|\nu\times\mathbf{B}\|_{H^{k+1/2}(\partial\Omega)}$; see Theorem 3 on p. 209 and Proposition 6 on p. 237 in [DL]. Since $\mathbf{w}_j\in W^{1,2}_0(\Omega,\mathbb{R}^3)$, from the above inequalities we see that $\{\mathbf{w}_j\}$ is bounded in $W^{1,2}_0(\Omega,\mathbb{R}^3)$. After passing to a subsequence we may assume that

$$\mathbf{w}_j\to\hat{\mathbf{w}}\quad\text{weakly in } W^{1,2}_0(\Omega,\mathbb{R}^3)\text{ and strongly in } L^4(\Omega,\mathbb{R}^3)\text{ as } j\to\infty.$$

In particular, $\|\hat{\mathbf{w}}\|_{L^2(\Omega)}=1$. Since $\|\nabla u_j-\mathbf{w}_j\|_{L^2(\Omega)}=O(q_j^{-1})$ and $\mathbf{w}_j\to\hat{\mathbf{w}}$ strongly in $L^2(\Omega,\mathbb{R}^3)$, we conclude that

$$u_j\to\hat u\quad\text{strongly in } W^{1,2}(\Omega)\quad\text{and } \nabla\hat u=\hat{\mathbf{w}}.$$

In particular, $\frac{\partial\hat u}{\partial x_1}=\mathbf{e}_1\cdot\nabla\hat u=\mathbf{e}_1\cdot\hat{\mathbf{w}}=0$, and hence $\hat u=\hat u(x_2,x_3)$. On the other hand, via the $W^{2,2}$-estimates for u_j's described in the first step, one concludes that

$\nabla\hat{u} = \mathbf{w} = \mathbf{0}$ on $\partial\Omega$. These two facts together imply that $\nabla\hat{u} = \mathbf{0}$ on the whole Ω, and hence $\mathbf{w} = \nabla\hat{u} = \mathbf{0}$, which contradicts the fact that $\|\hat{\mathbf{w}}\|_{L^2(\Omega)} = 1$. This completes the proof. □

Now we derive the Euler–Lagrange equation for the minimizers of $H_{\rm sh}$. We can rotate the coordinate system and assume without loss of generality that $\mathbf{h} = \mathbf{e}_1$ and $\mathbf{u}_0 = \mathbf{e}_3$. Hence

$$\mathbf{H} = \sigma\mathbf{e}_1 = (\sigma, 0, 0), \qquad \mathbf{u}_0 = \mathbf{e}_3 = (0, 0, 1),$$

and

$$\mathbf{w} = (w_1, w_2, 0), \qquad \mathbf{w} \cdot \mathbf{h} = w_1.$$

Define an operator

$$P : \mathbb{R}^3 \to \mathbb{R}^2, \quad P(x_1, x_2, x_3) = (x_1, x_2).$$

Let $\mathbf{w} = (w_1, w_2, 0)$ be a minimizer of $H_{\rm sh}$. Then $\mathbf{w}$ satisfies the following Euler–Lagrange equations:

$$\begin{cases} P(-K_1\nabla\operatorname{div}\mathbf{w} + K_2\operatorname{curl}^2\mathbf{w} + q^2(\mathbf{w} - \nabla\xi_{\mathbf{w}})) = (\chi H_{\rm sh}^2 w_1, 0) & \text{in } \Omega, \\ \mathbf{w} = \mathbf{0} \quad \text{on } \partial\Omega. \end{cases}$$

In the special case when $K_1 = K_2 \equiv K$ we have

$$\begin{cases} -K\Delta w_1 + (q^2 - \chi H_{\rm sh}^2) w_1 = q^2 \partial_1 \xi_{\mathbf{w}}, \\ -K\Delta w_2 + q^2 w_2 = q^2 \partial_2 \xi_{\mathbf{w}} & \text{in } \Omega, \\ w_1 = w_2 = 0 & \text{on } \partial\Omega. \end{cases} \tag{3.11}$$

We would like to point out that (3.7) defines a minimization problem under the pointwise orthogonality condition

$$\mathbf{w}(x) \cdot \mathbf{e} = 0 \quad \text{for all } x \in \Omega. \tag{3.12}$$

It is the orthogonality condition (3.12) that makes the minimization problem for $H_{\rm sh}$ interesting. In particular, from (3.9) we see that, for fixed $\mathbf{h}$, $\mathbf{e}$, K_1 and $K_2 > 0$, $H_{\rm sh}(q)$ diverges as $q \to \infty$. In contrast, if we consider a similar minimization problem formulated by removing the orthogonality condition (3.12) from the definition of $H_{\rm sh}(q)$ and define $\tilde{H}(q) = \tilde{H}(q, K_1, K_2, \Omega, \mathbf{h})$ by

$$\tilde{H}^2(q) = \frac{1}{\chi} \inf \left\{ B(\mathbf{w}) : \ \mathbf{w} \in W_0^{1,2}(\Omega, \mathbb{R}^3), \ \ \|\mathbf{h} \cdot \mathbf{w}\|_{L^2(\Omega)} = 1 \right\},$$

then there exists a constant C independent of q such that

$$\tilde{H}(q) \le C \left(\frac{K_1}{\chi} \right)^{1/2} \quad \text{for all } q. \tag{3.13}$$

To prove (3.13), we assume $\mathbf{h} = \mathbf{e}_1$. For any $u \in W^{2,2}(\Omega)$ such that $\nabla u = 0$ on $\partial\Omega$, take $\mathbf{w} = \nabla u$. Then

$$B(\nabla u) = B(u, \nabla u) = K_1 \|\Delta u\|_{L^2(\Omega)}^2.$$

Therefore (3.13) holds with C defined by

$$C = \inf \left\{ \frac{\|\Delta u\|_{L^2(\Omega)}^2}{\|\partial_1 u\|_{L^2(\Omega)}^2} : \ u \in W^{2,2}(\Omega), \ \ \nabla u = 0 \text{ on } \partial\Omega \right\}.$$

4. Magnetic field-induced instabilities: Loss of global minimality of pure smectic states. In this section we examine the change of the global minimality of the pure smectic states when the applied magnetic fields vary. For a pure smectic state $(\psi_0, \mathbf{n}_0)$ given in (1.5), we have

$$\mathbf{h} \cdot \mathbf{n}_0 \equiv 0 \quad \text{in } \Omega, \qquad \mathcal{E}[\psi_0, \mathbf{n}_0] = 0.$$

Now we consider a global minimizer $(\psi, \mathbf{n})$ of the functional $\mathcal{E}$ in the space $W^{1,2}(\Omega, \mathbb{C}) \times W^{1,2}(\Omega, \mathbb{S}^2, \mathbf{u}_0)$. A simple computation shows that if the global minimizer $(\psi, \mathbf{n})$ is not a pure smectic state, then $\mathbf{h} \cdot \mathbf{n} \not\equiv 0$ in Ω, and $\mathcal{E}[\psi, \mathbf{n}] \leq \mathcal{E}[\psi_0, \mathbf{n}_0] \leq 0$. (See Lemma 5.1 for a similar discussion for minimizers of the functional $\mathcal{F}_{\sigma \mathbf{h}}$.) Therefore

$$\mathcal{G}[\psi, \mathbf{n}] + \mathcal{F}[\mathbf{n}] \leq \chi \sigma^2 \int_\Omega (\mathbf{h} \cdot \mathbf{n})^2 dx.$$

This observation leads to the following definition.

DEFINITION 4.1. *Given $q \geq 0$, $\kappa > 0$, $K_1 > 0$, $K_2 > 0$, and given a pair of mutually orthogonal unit vectors $\mathbf{h}$ and $\mathbf{e}$, the critical magnetic field $H_{\rm s} = H_{\rm s}(q, \kappa, K_1, K_2, \Omega, \mathbf{h}, \mathbf{e})$ is defined by*

$$H_{\rm s}^2 = \frac{1}{\chi} \inf \left\{ \frac{\mathcal{G}[\psi, \mathbf{n}] + \mathcal{F}[\mathbf{n}]}{\int_\Omega (\mathbf{h} \cdot \mathbf{n})^2 dx} : \ (\psi, \mathbf{n}) \in W^{1,2}(\Omega, \mathbb{C}) \times W^{1,2}(\Omega, \mathbb{S}^2, \mathbf{e}), \ \mathbf{h} \cdot \mathbf{n} \not\equiv 0 \right\}. \tag{4.1}$$

The critical field $H_{\rm s}$ can be used to test whether the pure smectic states are global minimizers. If we fix the parameters κ, q, K_1, and K_2, then the pure smectic states remain as global minimizers for small σ, and they lose the global minimality when σ increases and reaches the critical field $H_{\rm s}$.

LEMMA 4.2. *Under the above assumptions we have the following:*

(i) *If there exists a global minimizer $(\psi, \mathbf{n})$ that is not a pure smectic state, then $\sigma \geq H_{\rm s}$.*

(ii) *If $\sigma > H_{\rm s}$, then the global minimizers are not pure smectic states.*

(iii) *If $0 \leq \sigma < H_{\rm s}$, then the only global minimizers are the pure smectic states.*

In the following, we write $H_{\rm s}$ as $H_{\rm s}(\kappa, q)$ to emphasize its dependence on the parameters κ and q. Note that the pure smectic states lose their global minimality at the critical magnetic field $H_{\rm s}(\kappa, q)$ and lose their local minimality at the critical magnetic field $H_{\rm sh}(q)$. So we always have

$$0 < H_{\rm s}(\kappa, q) \leq H_{\rm sh}(q).$$

To get a better estimate of $H_{\rm s}(q)$, we define a number $H_{\rm n}$ which is closely related to $H_{\rm s}$ as follows.

DEFINITION 4.3. *The number $H_{\rm n} = H_{\rm n}(q, K_1, K_2, \Omega, \mathbf{h}, \mathbf{e})$ is defined by*

$$H_{\rm n}^2 = \frac{1}{\chi} \inf \left\{ \frac{q^2 \|\nabla u - \mathbf{n}\|_{L^2(\Omega)}^2 + \mathcal{F}[\mathbf{n}]}{\int_\Omega (\mathbf{h} \cdot \mathbf{n})^2 dx} : \right. \\ \left. (u, \mathbf{n}) \in W^{1,2}(\Omega) \times W^{1,2}(\Omega, \mathbb{S}^2, \mathbf{e}), \ \mathbf{h} \cdot \mathbf{n} \not\equiv 0 \right\}. \tag{4.2}$$

In the following we write $H_{\rm n}$ as $H_{\rm n}(q)$ to emphasize its dependence on q. In particular,

$$H_{\rm n}^2(0) = \frac{1}{\chi} \inf \left\{ \frac{\mathcal{F}[\mathbf{n}]}{\int_\Omega (\mathbf{h} \cdot \mathbf{n})^2 dx} : \ \mathbf{n} \in W^{1,2}(\Omega, \mathbb{S}^2, \mathbf{e}), \ \mathbf{h} \cdot \mathbf{n} \not\equiv 0 \right\}. \tag{4.3}$$

Note that $H_{\rm n}(0)$ depends on K_1, K_2, Ω, $\mathbf{h}$, and $\mathbf{e}$.

LEMMA 4.4. *$H_{\rm s}(\kappa,0)$ is independent of κ. In fact we have*

$$H_{\rm s}(\kappa,0)=H_{\rm n}(0)\quad \textit{for all } \kappa. \tag{4.4}$$

For any κ and q we have

$$H_{\rm s}(\kappa,q)\geq H_{\rm n}(0). \tag{4.5}$$

Proof. To verify (4.4), we take $\psi=1$ as a test function. Equation (4.5) follows from (4.4) and the definition of $H_{\rm s}(\kappa,q)$ immediately. ∎

The following theorem gives the relations between $H_{\rm s}(\kappa,q)$, $H_{\rm n}(q)$, and $H_{\rm sh}(q)$.

THEOREM 4.5. *Assume Ω is a simply connected and bounded domain with smooth boundary.*

(i) *For all $\kappa>0$, $q\geq 0$, we have*

$$0<H_{\rm s}(\kappa,q)\leq H_{\rm n}(q)\leq H_{\rm sh}(q). \tag{4.6}$$

(ii) *For any κ and q, if $H_{\rm s}(\kappa,q)<H_{\rm sh}(q)$, then $H_{\rm s}(\kappa,q)$ is achieved.*

(iii) *For any $q\geq 0$, if $H_{\rm n}(q)<H_{\rm sh}(q)$, then $H_{\rm n}(q)$ is achieved (and hence $H_{\rm s}(\kappa,q)<H_{\rm sh}(q)$ and $H_{\rm s}(\kappa,q)$ is achieved).*

Proof of (i). The inequality $H_{\rm s}(\kappa,q)\leq H_{\rm n}(q)$ is easy to verify. In fact, for any $\phi\in W^{1,2}(\Omega)$ and $\mathbf{n}\in W^{1,2}(\Omega,\mathbb{S}^2,\mathbf{e})$ with $\mathbf{h}\cdot\mathbf{n}\not\equiv 0$, choose $(e^{iq\phi},\mathbf{n})$ as a test function for $H_{\rm s}(\kappa,q)$. It is easy to show that

$$H_{\rm s}^2(\kappa,q)\leq\frac{1}{\chi}\frac{q^2\|\nabla\phi-\mathbf{n}\|^2_{L^2(\Omega)}+\mathcal{F}[\mathbf{n}]}{\int_\Omega(\mathbf{h}\cdot\mathbf{n})^2dx}.$$

Then we take infimum for all such $(\phi,\mathbf{n})$ to get the inequality $H_{\rm s}(\kappa,q)\leq H_{\rm n}(q)$.

To prove $H_{\rm n}(q)\leq H_{\rm sh}(q)$, let $u\in W^{1,2}(\Omega)$ and $\mathbf{w}\in W_0^{1,2}(\Omega,\mathbb{R}^3)\cap L^\infty(\Omega,\mathbb{R}^3)$, with $\mathbf{e}\cdot\mathbf{w}\equiv 0$ in Ω and $\mathbf{h}\cdot\mathbf{w}\not\equiv 0$. Set

$$\phi_t=\mathbf{e}\cdot\mathbf{x}+tqu,\qquad \mathbf{n}_t=\frac{\mathbf{e}+t\mathbf{w}}{|\mathbf{e}+t\mathbf{w}|}=\mathbf{e}+t\mathbf{w}+O(t^2).$$

Then

$$\begin{aligned}
&q^2\|\nabla\phi_t-\mathbf{n}_t\|^2_{L^2(\Omega)}+\mathcal{F}[\mathbf{n}_t]\\
&=t^2\{q^2\|\nabla u-\mathbf{w}+O(t)\|^2_{L^2(\Omega)}+\mathcal{F}[\mathbf{w}+O(t)]\}\\
&=t^2\{q^2\|\nabla u-\mathbf{w}\|^2_{L^2(\Omega)}+\mathcal{F}[\mathbf{w}]\}+O(t^3),\\
&\int_\Omega(\mathbf{h}\cdot\mathbf{n}_t)^2dx=t^2\int_\Omega(\mathbf{h}\cdot\mathbf{w})^2dx+O(t^3).
\end{aligned}$$

Hence

$$\frac{q^2\|\nabla\phi_t-\mathbf{n}_t\|^2_{L^2(\Omega)}+\mathcal{F}[\mathbf{n}_t]}{\int_\Omega(\mathbf{h}\cdot\mathbf{n}_t)^2dx}=\frac{q^2\|\nabla u-\mathbf{w}\|^2_{L^2(\Omega)}+\mathcal{F}[\mathbf{w}]}{\int_\Omega(\mathbf{h}\cdot\mathbf{w})^2dx}+O(t).$$

Letting $t\to 0$ we get

$$\chi H_{\rm n}^2(q)\leq\frac{q^2\|\nabla u-\mathbf{w}\|^2_{L^2(\Omega)}+\mathcal{F}[\mathbf{w}]}{\int_\Omega(\mathbf{h}\cdot\mathbf{w})^2dx}.$$

Then we take infimum in the right-hand side to get

$$\chi H_{\rm n}^2(q) \le \inf\left\{ \frac{q^2\|\nabla u - \mathbf{w}\|^2_{L^2(\Omega)} + \mathcal{F}[\mathbf{w}]}{\int_\Omega (\mathbf{h}\cdot\mathbf{w})^2 dx} : \right.$$
$$\left. u \in W^{1,2}(\Omega),\ \mathbf{w} \in W_0^{1,2}(\Omega,\mathbb{R}^3)\cap L^\infty(\Omega,\mathbb{R}^3),\ \mathbf{e}\cdot\mathbf{w}\equiv 0,\ \mathbf{h}\cdot\mathbf{w}\not\equiv 0 \right\}.$$

Since $W_0^{1,2}(\Omega,\mathbb{R}^3)\cap L^\infty(\Omega,\mathbb{R}^3)$ is dense in $W_0^{1,2}(\Omega,\mathbb{R}^3)$, we conclude that $H_{\rm n}(q) \le H_{\rm s}(q)$.

To prove $H_{\rm s}(\kappa,q) > 0$, recall that $H_{\rm sh}(q) > 0$. If $H_{\rm s}(\kappa,q) = H_{\rm sh}(q)$, then we have $H_{\rm s}(\kappa,q) > 0$; if $H_{\rm s}(\kappa,q) < H_{\rm sh}(q)$, then from conclusion (ii), which we shall prove below, we know that $H_{\rm s}(\kappa,q)$ is achieved. Assume $(\psi,\mathbf{n})$ achieves $H_{\rm s}(\kappa,q)$ and suppose $H_{\rm s}(\kappa,q) = 0$. Then

$$\mathcal{G}[\psi,\mathbf{n}] + \mathcal{F}[\mathbf{n}] = \chi H_{\rm s}^2(\kappa,q)\int_\Omega (\mathbf{h}\cdot\mathbf{n})^2 dx = 0, \qquad \mathbf{h}\cdot\mathbf{n}\not\equiv 0.$$

Thus $\mathbf{n}$ satisfies

$$\operatorname{div}\mathbf{n} = 0, \quad \operatorname{curl}\mathbf{n} = \mathbf{0}, \quad |\mathbf{n}(x)| = 1 \quad \text{a.e. in } \Omega, \quad \mathbf{n} = \mathbf{e} \quad \text{on } \partial\Omega.$$

Since Ω is simply connected, $\mathbf{n}$ is a constant vector and hence must be equal to $\mathbf{e}$ since $\mathbf{n} = \mathbf{e}$ on $\partial\Omega$. (See step 1.1 in the proof of Theorem 3.6 in [P2].) Then $\mathbf{h}\cdot\mathbf{n} \equiv 0$, which contradicts the assumption that $\mathbf{h}\cdot\mathbf{n} \not\equiv 0$.

Proof of (ii). In the following we assume $H_{\rm s}(\kappa,q) < H_{\rm sh}(q)$ and prove that $H_{\rm s}(\kappa,q)$ is achieved.

Step 1. Let $\{(\psi_j,\mathbf{n}_j)\}$ be a minimizing sequence for $H_{\rm s}(\kappa,q)$. Then

$$\mathcal{G}[\psi_j,\mathbf{n}_j] + \mathcal{F}[\mathbf{n}_j] = (\chi H_{\rm s}^2(\kappa,q) + o(1))\int_\Omega (\mathbf{h}\cdot\mathbf{n}_j)^2 dx. \tag{4.7}$$

Since $|\mathbf{h}\cdot\mathbf{n}_j| \le 1$, the right-hand side in (4.7) is bounded. Thus $\{\operatorname{div}\mathbf{n}_j\}$ and $\{\operatorname{curl}\mathbf{n}_j\}$ are bounded in $L^2(\Omega)$. Since $|\mathbf{n}_j| = 1$ a.e. and $\mathbf{n}_j = \mathbf{e}$ on the boundary, from (3.10) we see that $\{\mathbf{n}_j\}$ is bounded in $W^{1,2}(\Omega,\mathbb{R}^3)$. Therefore we can pass to a subsequence and assume that, as $j\to\infty$,

$$\mathbf{n}_j \to \hat{\mathbf{n}} \quad \text{weakly in } W^{1,2}(\Omega,\mathbb{R}^3) \text{ and strongly in } L^2(\Omega,\mathbb{R}^3).$$

It follows that $|\hat{\mathbf{n}}(x)| = \lim_{j\to\infty}|\mathbf{n}_j(x)| = 1$ for a.e. $x\in\Omega$ and $\hat{\mathbf{n}} = \mathbf{e}$ on $\partial\Omega$. Thus $\hat{\mathbf{n}} \in W^{1,2}(\Omega,\mathbb{S}^2,\mathbf{e})$. On the other hand, (4.7) implies that $\{|\nabla_{q\mathbf{n}_j}\psi_j|\}$ is bounded in $L^2(\Omega)$ and $\{\psi_j\}$ is bounded in $L^4(\Omega)$. Then from

$$\|\nabla\psi_j\|_{L^2(\Omega)} = \|\nabla_{q\mathbf{n}_j}\psi_j + iq\mathbf{n}_j\psi_j\|_{L^2(\Omega)} \le \|\nabla_{q\mathbf{n}_j}\psi_j\|_{L^2(\Omega)} + \|q\mathbf{n}_j\psi_j\|_{L^2(\Omega)}$$

we see that $\{\psi_j\}$ is bounded in $W^{1,2}(\Omega,\mathbb{C})$. Passing to subsequence again we assume that, as $j\to\infty$,

$$\psi_j \to \hat{\psi} \quad \text{weakly in } W^{1,2}(\Omega,\mathbb{C}) \text{ and strongly in } L^4(\Omega).$$

Taking limit in (4.7) we find

$$\mathcal{G}[\hat{\psi},\hat{\mathbf{n}}] + \mathcal{F}[\hat{\mathbf{n}}] \le \liminf_{j\to\infty}\{\mathcal{G}[\psi_j,\mathbf{n}_j] + \mathcal{B}F[\mathbf{n}_j]\} = \chi H_{\rm s}^2(\kappa,q)\int_\Omega (\mathbf{h}\cdot\hat{\mathbf{n}})^2 dx. \tag{4.8}$$

If $\mathbf{h}\cdot\hat{\mathbf{n}}\not\equiv 0$, then (4.8) implies that $(\hat{\psi},\hat{\mathbf{n}})$ achieves $H_{\rm s}(\kappa,q)$.

In the next two steps we shall prove that if $H_{\rm s}(\kappa,q)<H_{\rm sh}(q)$, then we must have $\mathbf{h}\cdot\hat{\mathbf{n}}\not\equiv 0$.

Step 2. In the following we assume $\mathbf{h}\cdot\hat{\mathbf{n}}\equiv 0$. Then from (4.8) we see that $\operatorname{div}\hat{\mathbf{n}}=0$ and $\operatorname{curl}\hat{\mathbf{n}}=\mathbf{0}$ in Ω. Since Ω is simply connected, $|\hat{\mathbf{n}}(x)|=1$ a.e. in Ω, and $\hat{\mathbf{n}}=\mathbf{e}$ on $\partial\Omega$, we have $\hat{\mathbf{n}}\equiv\mathbf{e}$. (See step 1.1 in the proof of Theorem 3.6 in [P2].) From (4.8) we also see that

$$\nabla\hat{\psi}-iq\mathbf{e}\hat{\psi}=0,\quad |\hat{\psi}|=1. \tag{4.9}$$

We claim that

$$\hat{\psi}=ce^{iq\mathbf{e}\cdot\mathbf{x}}$$

for some complex number c with $|c|=1$. In fact, since $\hat{\psi}\neq 0$, for any $x_0\in\Omega$, there exists a neighborhood of x_0, say, $U(x_0)$, on which $\hat{\psi}$ has a representation $\hat{\psi}=fe^{iq\phi}$ with $f>0$. The condition $|\hat{\psi}|=1$ implies $f=1$. From the first equality in (4.9) we have $\nabla\phi=\mathbf{e}$. So on $U(x_0)$ we have $\hat{\psi}=ce^{iq\mathbf{e}\cdot\mathbf{x}}$ for some complex number c with $|c|=1$. Since Ω is connected, the constant c does not depend on x_0. So the claim is true.

In the following, for simplicity we assume $c=1$ and

$$\psi=e^{iq\mathbf{e}\cdot\mathbf{x}}.$$

Recall that $\mathbf{h}\cdot\mathbf{n}_j\not\equiv 0$, so $\mathbf{n}_j\not\equiv\mathbf{e}$. Let us write

$$\mathbf{n}_j=\mathbf{e}+\varepsilon_j\mathbf{w}_j,\qquad \psi_j=e^{iq\mathbf{e}\cdot\mathbf{x}}(1+iq\varepsilon_j g_j), \tag{4.10}$$

where

$$\begin{aligned}&\varepsilon_j=\|\mathbf{n}_j-\mathbf{e}\|_{W^{1,2}(\Omega)}>0,\\ &\mathbf{w}_j\in W_0^{1,2}(\Omega,\mathbb{R}^3),\qquad \|\mathbf{w}_j\|_{W^{1,2}(\Omega)}=1.\end{aligned}$$

We shall estimate $\mathbf{w}_j$ and g_j.

Since $\mathbf{w}_j\in W_0^{1,2}(\Omega,\mathbb{R}^3)$, we have

$$\begin{aligned}1&=\int_\Omega\{|\nabla\mathbf{w}_j|^2+|\mathbf{w}_j|^2\}dx\le C\int_\Omega|\nabla\mathbf{w}_j|^2dx\\ &=C\int_\Omega\{|\operatorname{div}\mathbf{w}_j|^2+|\operatorname{curl}\mathbf{w}_j|^2\}dx\le\frac{C}{\min\{K_1,K_2\}}\mathcal{F}[\mathbf{w}_j]\\ &=\frac{C}{\varepsilon_j^2\min\{K_1,K_2\}}\mathcal{F}[\mathbf{n}_j],\end{aligned}$$

so

$$\varepsilon_j^2\le\frac{C}{\min\{K_1,K_2\}}\mathcal{F}[\mathbf{n}_j]=o(1).$$

Since $\{\mathbf{w}_j\}$ is bounded in $W_0^{1,2}(\Omega,\mathbb{R}^3)$, after passing to a subsequence again we may assume that, as $j\to\infty$,

$$\mathbf{w}_j\to\hat{\mathbf{w}}\quad\text{weakly in } W_0^{1,2}(\Omega,\mathbb{R}^3),\quad\text{strongly in } L^4(\Omega,\mathbb{R}^3).$$

Moreover,

$$1 = |\mathbf{n}_j(x)|^2 = |\mathbf{e} + \varepsilon_j \mathbf{w}_j(x)|^2 = 1 + 2\varepsilon_j \mathbf{e}\cdot\mathbf{w}_j(x) + \varepsilon_j^2 |\mathbf{w}_j(x)|^2,$$

so

$$\mathbf{e}\cdot\mathbf{w}_j(x) = -\frac{\varepsilon_j}{2}|\mathbf{w}_j(x)|^2 \to 0 \quad \text{strongly in } L^2(\Omega).$$

Thus

$$\mathbf{e}\cdot\hat{\mathbf{w}}(x) = 0 \quad \text{for a.e. } x \in \Omega. \tag{4.11}$$

Using (4.10) we compute

$$\begin{aligned} &|\nabla_{q\mathbf{n}_j}\psi_j|^2 = q^2\varepsilon_j^2 |\nabla g_j - (1 + iq\varepsilon_j g_j)\mathbf{w}_j|^2, \\ &|\psi_j|^2 = 1 + q\varepsilon_j(-2\Im(g_j) + q\varepsilon_j |g_j|^2). \end{aligned}$$

Using these and (4.7), (4.11) we get

$$\begin{aligned} &(\chi H_{\mathrm{s}}^2(\kappa, q) + o(1)) \int_\Omega (\mathbf{h}\cdot\mathbf{w}_j)^2 dx \\ =&\frac{1}{\varepsilon_j^2}\int_\Omega (\mathbf{h}\cdot\mathbf{n}_j)^2 dx = \frac{1}{\varepsilon_j^2}\mathcal{G}[\psi_j, \mathbf{n}_j] + \frac{1}{\varepsilon_j^2}\mathcal{F}[\mathbf{n}_j] \\ =&\int_\Omega \left\{ q^2 |\nabla g_j - (1 + iq\varepsilon_j g_j)\mathbf{w}_j|^2 + \frac{\kappa^2}{2} q^2 (-2\Im(g_j) + q\varepsilon_j |g_j|^2)^2 \right\} dx + \mathcal{F}[\mathbf{w}_j]. \end{aligned} \tag{4.12}$$

In particular, we have

$$\int_\Omega |\nabla g_j - \psi_j e^{-iq\mathbf{e}\cdot\mathbf{x}}\mathbf{w}_j|^2 dx = \int_\Omega |\nabla g_j - (1 + iq\varepsilon_j g_j)\mathbf{w}_j|^2 dx \le C_1.$$

So

$$\begin{aligned} \|\nabla g_j\|_{L^2(\Omega)} \le& \|\nabla g_j - \psi_j e^{-iq\mathbf{e}\cdot\mathbf{x}}\mathbf{w}_j\|_{L^2(\Omega)} + \|\psi_j e^{-iq\mathbf{e}\cdot\mathbf{x}}\mathbf{w}_j\|_{L^2(\Omega)} \\ \le& C_1 + \|\psi_j \mathbf{w}_j\|_{L^2(\Omega)} \le C_1 + \|\psi_j\|_{W^{1,2}(\Omega)} \|\mathbf{w}_j\|_{W^{1,2}(\Omega)} \le C_2. \end{aligned}$$

We now write

$$\tilde{g}_j = g_j - b_j, \qquad b_j = \fint_\Omega g_j dx.$$

To estimate $\tilde{g}_j$, we note that $\fint_\Omega \tilde{g}_j dx = 0$ and use the Poincaré inequality to get

$$\|\tilde{g}_j\|_{L^2(\Omega)} \le C\|\nabla \tilde{g}_j\|_{L^2(\Omega)} \le C_3.$$

Then we use the Sobolev inequality to get

$$\|\tilde{g}_j\|_{L^4(\Omega)} \le C\|\tilde{g}_j\|_{W^{1,2}(\Omega)} \le C_4. \tag{4.13}$$

Thus

$$\|\tilde{g}_j \mathbf{w}_j\|_{L^2(\Omega)} \le C\|\tilde{g}_j\|_{L^4(\Omega)} \|\mathbf{w}_j\|_{W^{1,2}(\Omega)} \le C_5.$$

To estimate b_j, we note that

$$\psi_j = e^{iq\mathbf{e}\cdot\mathbf{x}}(1+iq\varepsilon_j g_j) = \hat{\psi} + iq\varepsilon_j g_j e^{iq\mathbf{e}\cdot\mathbf{x}}.$$

So we have

$$iq\varepsilon_j g_j = e^{-iq\mathbf{e}\cdot\mathbf{x}}(\psi_j - \hat{\psi}) \to 0 \quad \text{in } L^4(\Omega);$$

hence

$$\varepsilon_j g_j \to 0 \quad \text{in } L^4(\Omega),$$

and

$$\varepsilon_j b_j = \varepsilon_j g_j - \varepsilon_j \tilde{g}_j = o(1). \tag{4.14}$$

Now we have

$$\begin{aligned}
&\|\nabla g_j - (1+iq\varepsilon_j g_j)\mathbf{w}_j\|_{L^(\Omega)} \\
=&\|\nabla \tilde{g}_j - (1+iq\varepsilon_j b_j)\mathbf{w}_j - iq\varepsilon_j \tilde{g}_j \mathbf{w}_j\|_{L^2(\Omega)} \\
=&\|\nabla \tilde{g}_j - (1+iq\varepsilon_j b_j)\mathbf{w}_j\|_{L^2(\Omega)} + O(\varepsilon_j \|\tilde{g}_j \mathbf{w}_j\|_{L^2(\Omega)}) \\
=&\|\nabla \tilde{g}_j - (1+iq\varepsilon_j b_j)\mathbf{w}_j\|_{L^2(\Omega)} + O(\varepsilon_j).
\end{aligned}$$

Set

$$u_j = \frac{\tilde{g}_j}{1+iq\varepsilon_j b_j}.$$

Then we use (4.14) to get

$$\begin{aligned}
&\|\nabla g_j - (1+iq\varepsilon_j g_j)\mathbf{w}_j\|^2_{L^(\Omega)} \\
=&|1+iq\varepsilon_j b_j|^2 \|\nabla u_j - \mathbf{w}_j\|^2_{L^2(\Omega)} + O(\varepsilon_j^2) \\
=&(1+o(1))\|\nabla u_j - \mathbf{w}_j\|_{L^2(\Omega)} + o(1).
\end{aligned}$$

Since the left-side term in the above equalities is bounded, we see that

$$\|\nabla u_j - \mathbf{w}_j\|_{L^2(\Omega)} \le C_5,$$

which implies

$$\|\nabla u_j\|_{L^2(\Omega)} \le C_6.$$

Since $\int u_j dx = 0$, we apply the Poincaré inequality to conclude that $\{u_j\}$ is bounded in $W^{1,2}(\Omega, \mathbb{C})$. Passing to a subsequence again we may assume that

$$u_j \to \hat{u} \quad \text{weakly in } W^{1,2}(\Omega, \mathbb{C}) \text{ and strongly in } L^2(\Omega).$$

Now we go back to (4.12) and find

$$\begin{aligned}
&(\chi H_s^2 + o(1)) \int_\Omega (\mathbf{h}\cdot\mathbf{w}_j)^2 dx \\
=&\int_\Omega \left\{ q^2(1+o(1))|\nabla u_j - \mathbf{w}_j|^2 + \frac{\kappa^2}{2} q^2 (-2\Im(g_j) + q\varepsilon_j |g_j|^2)^2 \right\} dx + \mathcal{F}[\mathbf{w}_j].
\end{aligned}$$

Hence

$$q^2\|\nabla u_j - \mathbf{w}_j\|^2_{L^2(\Omega)} + \mathcal{F}[\mathbf{w}_j] \le (\chi H_{\rm s}^2(\kappa, q) + o(1)) \int_\Omega (\mathbf{h}\cdot\mathbf{w}_j)^2 dx. \tag{4.15}$$

Letting $j \to \infty$ we find

$$q^2\|\nabla \hat{u} - \hat{\mathbf{w}}\|^2_{L^2(\Omega)} + \mathcal{F}[\hat{\mathbf{w}}] \le \chi H_{\rm s}^2(\kappa, q) \int_\Omega (\mathbf{h}\cdot\hat{\mathbf{w}})^2 dx. \tag{4.16}$$

Step 3. We claim that

$$\mathbf{h}\cdot\hat{\mathbf{w}} \not\equiv 0.$$

Suppose the claim were false. Then $\mathbf{h}\cdot\hat{\mathbf{w}} \equiv 0$ on Ω. Since $\mathbf{w}_j \to \hat{\mathbf{w}}$ strongly in $L^2(\Omega, \mathbb{R}^3)$, we have, as $j \to \infty$,

$$\int_\Omega (\mathbf{h}\cdot\mathbf{w}_j)^2 dx \to 0.$$

From (4.15) we have

$$\|\operatorname{div}\mathbf{w}_j\|_{L^2(\Omega)} \to 0, \qquad \|\operatorname{curl}\mathbf{w}_j\|_{L^2(\Omega)} \to 0,$$

and from (4.16),

$$\operatorname{div}\hat{\mathbf{w}} = 0 \quad \text{and} \quad \hat{\mathbf{w}} = \nabla\hat{u} \quad \text{in } \Omega, \qquad \hat{\mathbf{w}} = \mathbf{0} \quad \text{on } \partial\Omega.$$

Hence

$$\Delta\hat{u} = 0 \quad \text{in } \Omega, \qquad \nabla\hat{u} = \mathbf{0} \quad \text{on } \partial\Omega.$$

The maximum principle for harmonic functions yields that $\hat{u}$ is constant on Ω, and hence $\mathbf{w} = \mathbf{0}$. Thus

$$\mathbf{w}_j \to \mathbf{0} \quad \text{strongly in } L^2(\Omega, \mathbb{R}^3).$$

Since $\mathbf{w}_j \in W_0^{1,2}(\Omega, \mathbb{R}^3)$, from (3.10) we have

$$\|\mathbf{w}_j\|_{W^{1,2}(\Omega)} \le C(\|\operatorname{div}\mathbf{w}_j\|_{L^2(\Omega)} + \|\operatorname{curl}\mathbf{w}_j\|_{L^2(\Omega)} + \|\mathbf{w}_j\|_{L^2(\Omega)}) \to 0,$$

which contradicts the assumption $\|\mathbf{w}_j\|_{W^{1,2}(\Omega)} = 1$. So the claim is true.

Using the claim, (4.11), and (4.16) we have

$$\chi H_{\rm s}^2(\kappa, q) \ge \frac{q^2\|\nabla\hat{u} - \hat{\mathbf{w}}\|^2_{L^2(\Omega)} + \mathcal{F}[\hat{\mathbf{w}}]}{\int_\Omega (\mathbf{h}\cdot\hat{\mathbf{w}})^2 dx} \ge \chi H_{\rm sh}(q).$$

Thus we must have

$$H_{\rm s}(\kappa, q) = H_{\rm sh}(q).$$

In other words, under the assumption $H_{\rm s}(\kappa, q) < H_{\rm sh}(q)$, we must have $\mathbf{h}\cdot\hat{\mathbf{n}} \not\equiv 0$, and hence we use the result proved in Step 1 to conclude that $H_{\rm s}(\kappa, q)$ is achieved. Now conclusion (ii) is proved.

The proof of conclusion (iii) is similar to the proof of (ii) and hence is omitted. □

5. Magnetic field-induced instabilities in pure nematic states. In this section we examine the local minimality as well as global minimality of the pure nematic states given in (1.4). Note that $(0, \mathbf{n})$ is a critical point of the functional $\mathcal{E}$ if and only if $\mathbf{n}$ is a critical point of the functional $\mathcal{F}_{\sigma\mathbf{h}}$. Let

$$\begin{aligned} &C(\sigma) \equiv C(\sigma, K_1, K_2, \mathbf{h}, \mathbf{e}) = \inf_{\mathbf{n}\in W^{1,2}(\Omega,\mathbb{S}^2,\mathbf{e})} \mathcal{F}_{\sigma\mathbf{h}}[\mathbf{n}], \\ &\mathcal{M}(\sigma) \equiv \mathcal{M}(\sigma, K_1, K_2, \mathbf{h}, \mathbf{e}) = \{\mathbf{n} \in W^{1,2}(\Omega, \mathbb{S}^2, \mathbf{e}) :\ \mathcal{F}_{\sigma\mathbf{h}}[\mathbf{n}] = C(\sigma)\}. \end{aligned} \tag{5.1}$$

If $\mathbf{n} \in \mathcal{M}(\sigma)$, then $(0, \mathbf{n})$ is a critical point of $\mathcal{E}$.

We first look for a criterion for $\mathbf{n}$ to be a global minimizer of $\mathcal{F}_{\sigma\mathbf{h}}$ in the set $W^{1,2}(\Omega, \mathbb{S}^2, \mathbf{e})$. If $\mathbf{n}$ is a minimizer of $\mathcal{F}_{\sigma\mathbf{h}}$, then $\mathbf{n}$ satisfies the Euler–Lagrange equation

$$\begin{cases} -K_1 \nabla \operatorname{div} \mathbf{n} + K_2 \operatorname{curl}^2 \mathbf{n} = \chi\sigma^2(\mathbf{h}\cdot\mathbf{n})\mathbf{h} + \lambda(x)\mathbf{n} & \text{in } \Omega, \\ \mathbf{n} = \mathbf{e} \quad \text{on } \partial\Omega, \end{cases} \tag{5.2}$$

where $\lambda(x)$ is a function of x which is dependent on $\mathbf{n}$. By a simple computation we find

$$\begin{aligned} \lambda(x) &= \mathbf{n}\cdot[-K_1\nabla\operatorname{div}\mathbf{n} + K_2 \operatorname{curl}^2 \mathbf{n}] - \chi\sigma^2(\mathbf{h}\cdot\mathbf{n})^2 \\ &= K_2|\nabla\mathbf{n}|^2 + (K_1 - K_2)[(\operatorname{div}\mathbf{n})^2 - \operatorname{div}((\operatorname{div}\mathbf{n})\mathbf{n})] - \chi\sigma^2(\mathbf{h}\cdot\mathbf{n})^2. \end{aligned}$$

In the particular case where $K_1 = K_2 = K$, we have

$$\begin{cases} -\Delta\mathbf{n} = |\nabla\mathbf{n}|^2\mathbf{n} + \dfrac{\chi\sigma^2}{K}[(\mathbf{h}\cdot\mathbf{n})\mathbf{h} - (\mathbf{h}\cdot\mathbf{n})^2\mathbf{n}] & \text{in } \Omega, \\ \mathbf{n} = \mathbf{e} \quad \text{on } \partial\Omega. \end{cases} \tag{5.3}$$

Since $\mathbf{h}\cdot\mathbf{e} = 0$, the constant vector $\mathbf{e}$ is a critical point of $\mathcal{F}_{\sigma\mathbf{h}}$ for all σ. The following lemma gives a simple criterion for $\mathbf{n} = \mathbf{e}$ to be a global minimizer. Recall the numbers $H_{\mathrm{sh}}(0)$ and $H_{\mathrm{n}}(0)$ defined in (3.8) and (4.3), respectively, and recall that we have

$$0 < H_{\mathrm{n}}(0) \le H_{\mathrm{sh}}(0).$$

LEMMA 5.1. (i) *If $0 \le \sigma < H_{\mathrm{n}}(0)$, then $\mathbf{n} = \mathbf{e}$ is the only global minimizer of $\mathcal{F}_{\sigma\mathbf{h}}$ in $W^{1,2}(\Omega, \mathbb{S}^2, \mathbf{e})$.*

(ii) *If $H_{\mathrm{n}}(0) < H_{\mathrm{sh}}(0)$ and if $H_{\mathrm{n}}(0) < \sigma < H_{\mathrm{sh}}(0)$, then $\mathbf{n} = \mathbf{e}$ is not a global minimizer of $\mathcal{F}_{\sigma\mathbf{h}}$ in $W^{1,2}(\Omega, \mathbb{S}^2, \mathbf{e})$, but it is weakly stable (a local minimizer).*

(iii) *If $\sigma > H_{\mathrm{sh}}(0)$, then $\mathbf{n} = \mathbf{e}$ is not weakly stable.*

Lemma 5.1 shows that if K_1 and K_2 are fixed, the constant critical point $\mathbf{n} = \mathbf{e}$ remains as a global minimizer for small σ, and it loses the global minimality when σ increases and reaches $H_{\mathrm{n}}(0)$.

Proof of Lemma 5.1. We first note that $\mathcal{F}_{\sigma\mathbf{h}}[\mathbf{e}] = 0$. If $\mathbf{n}$ is a global minimizer, then $\mathcal{F}_{\sigma\mathbf{h}}[\mathbf{n}] \le \mathcal{F}_{\sigma\mathbf{h}}[\mathbf{e}] = 0$. If $\mathbf{h}\cdot\mathbf{n} \equiv 0$, then from

$$\mathcal{F}_{\sigma\mathbf{h}}[\mathbf{n}] = \int_\Omega \{K_1|\operatorname{div}\mathbf{n}|^2 + K_2|\operatorname{curl}\mathbf{n}|^2\}dx \le \mathcal{F}_{\sigma\mathbf{h}}[\mathbf{e}] = 0$$

we see that $\operatorname{div}\mathbf{n} = 0$ and $\operatorname{curl}\mathbf{n} = \mathbf{0}$ on Ω. Since Ω is simply connected and $|\mathbf{n}| = 1$, $\mathbf{n}$ must be a constant vector, and it must be equal to $\mathbf{e}$ since $\mathbf{n} = \mathbf{e}$ on $\partial\Omega$.

Therefore a nonconstant global minimizer $\mathbf{n}$ must satisfy $\mathbf{h}\cdot\mathbf{n}\not\equiv 0$. From

$$0=\mathcal{F}_{\sigma\mathbf{h}}[\mathbf{e}]\geq\mathcal{F}_{\sigma\mathbf{h}}[\mathbf{n}]=\mathcal{F}[\mathbf{n}]-\chi\sigma^2\int_\Omega(\mathbf{h}\cdot\mathbf{n})^2dx,$$

we have

$$\sigma^2\geq\frac{1}{\chi}\frac{\mathcal{F}[\mathbf{n}]}{\int_\Omega(\mathbf{h}\cdot\mathbf{n})^2dx}\geq H_{\rm n}^2(0).$$

Thus if $0\leq\sigma<H_{\rm n}(0)$, then the only global minimizer is $\mathbf{n}=\mathbf{e}$.

Next, assume $\sigma>H_{\rm n}(0)$. Take $\tilde{\mathbf{n}}\in W^{1,2}(\Omega,\mathbb{S}^2,\mathbf{e})$ such that $\mathbf{h}\cdot\tilde{\mathbf{n}}\not\equiv 0$ on Ω and

$$\frac{1}{\chi}\frac{\mathcal{F}[\tilde{\mathbf{n}}]}{\int_\Omega(\mathbf{h}\cdot\tilde{\mathbf{n}})^2dx}<H_{\rm n}(0)^2+\delta<\sigma^2.$$

Then

$$\mathcal{F}_{\sigma\mathbf{h}}[\tilde{\mathbf{n}}]=\mathcal{F}[\tilde{\mathbf{n}}]-\chi\sigma^2\int_\Omega(\mathbf{h}\cdot\tilde{\mathbf{n}})^2dx<\mathcal{F}[\tilde{\mathbf{n}}]-\chi(H_{\rm n}(0)^2+\delta)\int_\Omega(\mathbf{h}\cdot\tilde{\mathbf{n}})^2dx<0.$$

Hence

$$\inf\{\mathcal{F}_{\sigma\mathbf{h}}[\mathbf{n}]:\ \mathbf{n}\in W^{1,2}(\Omega,\mathbb{S}^2,\mathbf{e})\}<0,$$

and the constant map $\mathbf{n}=\mathbf{e}$ is not a global minimizer.

To finish the proof, we use the definition of weak stability given in section 2 to derive the conclusion about weak stability of $\mathbf{n}=\mathbf{e}$ for $0<\sigma<H_{\rm sh}(0)$ and instability for $\sigma>H_{\rm sh}(0)$. □

Let us consider next the following question: If $\mathbf{n}_\sigma\in\mathcal{M}(\sigma,K_1,K_2,\mathbf{h},\mathbf{e})$ is a global minimizer of $\mathcal{F}_{\sigma\mathbf{h}}$, when is $(0,\mathbf{n}_\sigma)$ a global minimizer of the functional $\mathcal{E}$? To answer this question, let $\mu=\mu(q\mathbf{n})$ denote the lowest eigenvalue of the following equation:

$$-\nabla_{q\mathbf{n}}^2\phi=\mu\phi\quad\text{in }\Omega,\quad\nabla_{q\mathbf{n}}\phi\cdot\nu=0\quad\text{on }\partial\Omega. \tag{5.4}$$

Note that

$$\mu(q\mathbf{n})=\inf_{\phi\in W^{1,2}(\Omega,\mathbb{C})}\frac{\|\nabla_{q\mathbf{n}}\phi\|^2_{L^2(\Omega)}}{\|\phi\|^2_{L^2(\Omega)}}.$$

Define

$$\mu_*(q,\sigma)\equiv\mu_*(q,\sigma,K_1,K_2,\mathbf{h},\mathbf{e})=\inf_{\mathbf{n}\in\mathcal{M}(\sigma,K_1,K_2,\mathbf{h},\mathbf{e})}\mu(q\mathbf{n}). \tag{5.5}$$

LEMMA 5.2. (i) *If $(\psi,\mathbf{n})$ is a global minimizer of $\mathcal{E}$ which is not a pure nematic state, then $\mu(q\mathbf{n})<\kappa^2$.*

(ii) *If $\mu_*(q,\sigma)<\kappa^2$, then the pure nematic states are not global minimizers of $\mathcal{E}$.*

Proof. To prove (i), we note that if $(\psi,\mathbf{n})$ is a global minimizer, and if $\psi=0$, then we must have $\mathbf{n}\in\mathcal{M}(\sigma)$, and hence $(\psi,\mathbf{n})=(0,\mathbf{n})$ is a pure nematic state. Thus if $(\psi,\mathbf{n})$ is not a pure nematic state, then $\psi\not\equiv 0$. Choose $\mathbf{n}_\sigma\in\mathcal{M}(\sigma)$. We have

$$\mathcal{G}[\psi,\mathbf{n}]+\mathcal{F}_{\sigma\mathbf{h}}[\mathbf{n}]\leq\mathcal{G}[0,\mathbf{n}_\sigma]+\mathcal{F}_{\sigma\mathbf{h}}[\mathbf{n}_\sigma];$$

hence

$$\int_\Omega \left\{ |\nabla_{q\mathbf{n}}\psi|^2 - \kappa^2|\psi|^2 + \frac{\kappa^2}{2}|\psi|^4 \right\} dx \le \mathcal{F}_{\sigma\mathbf{h}}[\mathbf{n}_\sigma] - \mathcal{F}_{\sigma\mathbf{h}}[\mathbf{n}] \le 0,$$

so

$$\int_\Omega \{|\nabla_{q\mathbf{n}}\psi|^2 - \kappa^2|\psi|^2\} dx \le -\frac{\kappa^2}{2}\int_\Omega |\psi|^4 dx < 0.$$

Thus

$$\mu(q\mathbf{n}) \le \frac{\|\nabla_{q\mathbf{n}}\psi\|^2_{L^2(\Omega)}}{\|\psi\|^2_{L^2(\Omega)}} < \kappa^2.$$

To prove (ii), note that for a pure smectic state $(0, \mathbf{n}_\sigma)$ we have $\mathcal{E}[0, \mathbf{n}_\sigma] = \frac{\kappa^2}{2}|\Omega|$. If $\mu_*(q,\sigma) < \kappa^2$, we choose $\mathbf{n} \in \mathcal{M}(\sigma)$ such that $\mu(q\mathbf{n}) < \kappa^2$ and let ϕ be an eigenfunction of $-\nabla^2_{q\mathbf{n}}$ associated with $\mu(q\mathbf{n})$. Then we choose $(t\phi, \mathbf{n})$ as a test function for $\mathcal{E}$ and find $\mathcal{E}[t\phi, \mathbf{n}] < \frac{\kappa^2}{2}|\Omega|$ if t is small. So a global minimizer $(\psi, \mathbf{n})$ must satisfy $\mathcal{E}[\psi, \mathbf{n}] < \frac{\kappa^2}{2}|\Omega|$, and hence it cannot be a pure nematic state. ∎

PROPOSITION 5.3. *If $0 \le \sigma \le H_{\mathrm{n}}(0)$ and $\kappa > 0$, or if $\sigma > H_{\mathrm{n}}(0)$ and $\mu_*(q,\sigma) < \kappa^2$, then the pure nematic states are not global minimizers of $\mathcal{E}$.*

Proof. We note that if $0 \le \sigma < H_{\mathrm{n}}(0)$, then from Lemma 5.1 we have $\mathcal{M}(\sigma) = \{\mathbf{e}\}$; and if $\sigma = H_{\mathrm{n}}(0)$, then we have $\mathbf{e} \in \mathcal{M}(\sigma)$. It is easy to see that $\mu(q\mathbf{e}) = 0$ with associated eigenfunction $\psi = e^{iq\mathbf{e}\cdot\mathbf{x}}$. Thus $\mu_*(q,\sigma) \le \mu(q\mathbf{e}) = 0 < \kappa^2$ for any $\kappa > 0$. Then the conclusion follows from Lemma 5.2(ii).

When $\sigma > H_{\mathrm{n}}(0)$ and $\mu_*(q,\sigma) < \kappa^2$, the conclusion was proved in Lemma 5.2. ∎

Note that the conclusion of Proposition 5.3 for the case $0 \le \sigma < H_{\mathrm{n}}(0)$ is a direct consequence of Lemma 4.2(iii). In fact, for any q we have $H_{\mathrm{s}}(\kappa, q) \ge H_{\mathrm{n}}(0)$. If $0 \le \sigma < H_{\mathrm{n}}(0)$, then $0 \le \sigma < H_{\mathrm{s}}(\kappa, q)$, and the pure smectic states are global minimizers with energy equal to zero. But the pure nematic state $(0, \mathbf{e})$ has energy $\frac{\kappa^2}{2}|\Omega|$, and so it cannot be a global minimizer.

Let us define

$$\sigma_*(\kappa, q) = \inf\{\sigma > 0 : \ \mu_*(q,\sigma) \ge \kappa^2\},$$
$$Q_*(\kappa, \sigma) = \inf\{q > 0 : \ \mu_*(q,\sigma) \ge \kappa^2\}.$$

From Proposition 5.3, when $\sigma > H_{\mathrm{n}}(0)$, we have the following statement about the global minimality of the pure nematic states.

Claim. In the following cases, the pure nematic states are not global minimizers of $\mathcal{E}$:

(i) $0 < \sigma < \sigma_*(\kappa, q)$, *for given κ and q.*
(ii) $\kappa^2 > \mu_*(q,\sigma)$, *for given q and σ.*
(iii) $0 \le q < Q_*(\kappa,\sigma)$, *for given κ and σ.*

Our next question arises in a comparison of liquid crystals with superconductivity. Recall that type II superconductors will always stay in the normal state if the applied magnetic field is sufficiently strong. Considering the analogies of liquid crystals to superconductors, one might expect that a liquid crystal would be in a pure nematic state if the applied magnetic field is sufficiently strong. However, this is not true. In fact we have the next theorem.

THEOREM 5.4. *Fix q, κ, K_1, K_2, $\mathbf{h}$, and $\mathbf{e}$, with $K_1 = K_2$. When σ is sufficiently large, the pure nematic states are not global minimizers.*

The conclusion of Theorem 5.4 reveals an *important difference in the responses to applied magnetic fields for smectic liquid crystals and for superconductors.* For superconductors, a sufficiently strong applied magnetic field will penetrate the material and destroy superconductivity. In contrast, smectic liquid crystals in an applied magnetic field also undergo phase transitions, but the applied magnetic field will not completely destroy the smectic structure, and the molecules of the liquid crystals will not be completely layered and aligned along the direction of the applied magnetic field.

To prove Theorem 5.4 we shall establish estimates of $C(\sigma)$ (see (5.1)) and $\mu_*(q,\sigma)$ (see (5.5)) for large σ.

LEMMA 5.5. (i) *For large σ we have*

$$C(\sigma) \le -\chi|\Omega|\sigma^2 + C_1\sigma, \tag{5.6}$$

where $C_1 > 0$ depends only on K_1, K_2, $\mathbf{h}$, $\mathbf{e}$, and Ω.

(ii) *Let $\mathbf{n}_\sigma$ be a global minimizer of $\mathcal{F}_{\sigma\mathbf{h}}$. Then*

$$|\mathbf{h}\cdot\mathbf{n}_\sigma(x)| \to 1 \quad \text{in } L^2(\Omega) \text{ as } \sigma\to\infty.$$

(iii) *If $K_1 = K_2$, then $\mathbf{h}\cdot\mathbf{n}_\sigma(x)$ converges in $L^2(\Omega)$ to 1 or to -1 as $\sigma\to\infty$.*

Proof. After rotating the coordinate system we may assume that $\mathbf{h} = \mathbf{e}_3$ and $\mathbf{e} = \mathbf{e}_1$. Then for any $\mathbf{n} = (n_1, n_2, n_3) \in W^{1,2}(\Omega, \mathbb{S}^2, \mathbf{e})$ we may write

$$\mathcal{F}_{\sigma\mathbf{h}}[\mathbf{n}] = \mathcal{J}_\sigma[\mathbf{n}] - \chi|\Omega|\sigma^2,$$

where

$$\mathcal{J}_\sigma[\mathbf{n}] = \int_\Omega \{K_1|\operatorname{div}\mathbf{n}|^2 + K_2|\operatorname{curl}\mathbf{n}|^2 + \chi\sigma^2(n_1^2+n_2^2)\}dx. \tag{5.7}$$

Step 1. Proof of (i). We estimate the lower bound of $\mathcal{J}_\alpha$ for large σ. Let us consider a test map of the form

$$\mathbf{n} = (\cos\phi, 0, \sin\phi),$$

where ϕ is a smooth function and $\phi = 0$ on $\partial\Omega$. Hence $\mathbf{n} = \mathbf{e}_1$ on $\partial\Omega$. We compute

$$\operatorname{div}\mathbf{n} = \partial_1 n_1 + \partial_3 n_3 = -\sin\phi\partial_1\phi + \cos\phi\partial_3\phi,$$
$$\operatorname{curl}\mathbf{n} = (\partial_2 n_3, \partial_3 n_1 - \partial_1 n_3, -\partial_2 n_1) = (\cos\phi\partial_2\phi, -\sin\phi\partial_3\phi - \cos\phi\partial_1\phi, -\sin\phi\partial_2\phi).$$

So we have

$$\mathcal{J}_\sigma[\mathbf{n}] = J_\sigma[\phi] \equiv \int_\Omega f_\sigma(\phi)dx,$$

where

$$f_\sigma(\phi) = K_1|\sin\phi\partial_1\phi - \cos\phi\partial_3\phi|^2 + K_2|\partial_2\phi|^2 + K_2|\sin\phi\partial_3\phi + \cos\phi\partial_1\phi|^2 + \chi\sigma^2\cos^2\phi.$$

Note that

$$|\sin\phi\partial_1\phi - \cos\phi\partial_3\phi|^2 \le |\partial_1\phi|^2 + |\partial_3\phi|^2,$$
$$|\sin\phi\partial_3\phi + \cos\phi\partial_1\phi|^2 \le |\partial_1\phi|^2 + |\partial_3\phi|^2.$$

So

$$f_\sigma(\phi) \le K_1(|\partial_1\phi|^2 + |\partial_3\phi|^2) + K_2|\nabla\phi|^2 + \chi\sigma^2\cos^2\phi.$$

For small $\varepsilon > 0$, let

$$\Omega_\varepsilon = \{x \in \Omega : \ \mathrm{dist}(x, \partial\Omega) < \varepsilon\}, \qquad \Omega^\varepsilon = \{x \in \Omega : \ \mathrm{dist}(x, \partial\Omega) \ge \varepsilon\}.$$

Then we split $J_\sigma[\phi]$ into two parts:

$$J_\sigma[\phi] = J_{\sigma 1}[\phi] + J_{\sigma 2}[\phi],$$

where

$$J_{\sigma 1}[\phi] = \int_{\Omega_\varepsilon} f_\sigma(\phi)dx, \qquad J_{\sigma 2}[\phi] = \int_{\Omega^\varepsilon} f_\sigma(\phi)dx.$$

We choose ϕ such that

$$\phi = \frac{\pi}{2} \text{ in } \Omega^\varepsilon, \quad \phi = 0 \text{ on } \partial\Omega, \quad |\nabla\phi| \le \frac{C}{\varepsilon} \quad \text{on } \Omega.$$

Then $J_{\sigma 2}[\phi] = 0$, and

$$J_{\sigma 1}[\phi] \le \int_{\Omega_\varepsilon} \{(K_1 + K_2)|\nabla\phi|^2 + \chi\sigma^2\cos^2\phi\}dx \le \left[\frac{C^2(K_1 + K_2)}{\varepsilon^2} + \chi\sigma^2\right]|\Omega_\varepsilon|.$$

When $\partial\Omega$ is smooth, there exists $C_0 > 0$ only depending on $\partial\Omega$ such that for all small $\varepsilon > 0$ we have

$$|\Omega_\varepsilon| \le C_0\varepsilon.$$

Therefore

$$J_\sigma[\phi] = J_{\sigma 1}[\phi] \le \frac{C_0}{\varepsilon}[C^2(K_1 + K_2) + \chi\sigma^2\varepsilon^2].$$

For large σ we choose

$$\varepsilon = \frac{C}{\sigma}\sqrt{\frac{K_1 + K_2}{\chi}}$$

and find

$$J_\sigma[\phi] \le 2\sigma C_0 C\sqrt{\chi(K_1 + K_2)}.$$

This yields estimate (5.6).

Step 2. *Proof of* (ii). From (i) we have

$$\mathcal{J}_\sigma[\mathbf{n}_\sigma] = \int_\Omega \{K_1|\mathrm{div}\,\mathbf{n}_\sigma|^2 + K_2|\mathrm{curl}\,\mathbf{n}_\sigma|^2 + \chi\sigma^2|\mathbf{n}'_\sigma|^2\}dx \le C\sigma,$$

where $\mathbf{n}'_\sigma = (n_{\sigma 1}, n_{\sigma_2}, 0)$. Thus, as $\sigma \to \infty$,

$$\int_\Omega |\mathbf{n}'_\sigma|^2 dx \le \frac{C}{\sqrt{\sigma}} \to 0,$$

namely,

$$\int_\Omega (1-|n_{\sigma 3}|^2)dx \to 0.$$

So $|n_{\sigma 3}| \to 1$ in $L^1(\Omega)$. Since $|n_{\sigma 3}(x)| \le 1$ a.e., we use the Lebesgue dominated convergence theorem to conclude that $|n_{\sigma 3}| \to 1$ in $L^p(\Omega)$ for any $1 < p < \infty$.

Step 3. Now we assume $\mathbf{h} = \mathbf{e}_3$, $\mathbf{e} = \mathbf{e}_1$, and $K_1 = K_2 = K$. We prove that the minimizer $\mathbf{n}_\sigma$ has the following property: $\mathbf{n}_{\sigma 3}$ does not change sign, namely, either $\mathbf{n}_{\sigma 3}$ is always positive, or it is always negative, or it is identically equal to zero.

Now the Euler–Lagrange equation reads

$$\begin{cases} -\Delta \mathbf{n} = |\nabla \mathbf{n}|^2 \mathbf{n} + b^2\sigma^2[n_3\mathbf{e}_3 - n_3^2\mathbf{n}] & \text{in } \Omega, \\ \mathbf{n} = \mathbf{e}_1 & \text{on } \partial\Omega, \end{cases} \tag{5.8}$$

where

$$b^2 = \frac{\chi}{K}.$$

To investigate the behavior of the minimizers for large σ, we borrow the proof from [HL, Lemma 2.2]. For simplicity we drop the subscript σ and let $\mathbf{n} = (n_1, n_2, n_3)$ denote a minimizer. Set $\mathbf{u} = (n_1, n_2, |n_3|)$. Since $n_3 \in W^{1,2}(\Omega)$, we have $|\nabla |n_3|| = |\nabla n_3|$ a.e., and so $|n_3| \in W^{1,2}(\Omega)$. Note that $n_3 = 0$ on $\partial\Omega$. Hence $\mathbf{u} \in W^{1,2}(\Omega, \mathbb{S}^2, \mathbf{e})$, and

$$\int_\Omega |\nabla \mathbf{u}|^2 dx = \int_\Omega |\nabla \mathbf{n}|^2 dx.$$

Since $K_1 = K_2 = K$, we have

$$\mathcal{J}_\sigma[\mathbf{n}] = \int_\Omega \{K|\nabla \mathbf{n}|^2 + \chi\sigma^2(n_1^2 + n_2^2)\}dx.$$

Thus $\mathbf{u}$ is also a global minimizer of $\mathcal{F}_{\sigma\mathbf{h}}$, and hence it is a weak solution of (5.8). In particular, $u_3 = |n_3| \ge 0$, and it is a weak solution of

$$\begin{cases} -\Delta u_3 = |\nabla \mathbf{n}|^2 u_3 + b^2\sigma^2(u_3 - u_3^3) & \text{in } \Omega, \\ u_3 = 0 & \text{on } \partial\Omega. \end{cases}$$

Thus

$$-\Delta u_3 = |\nabla \mathbf{n}|^2 u_3 + b^2\sigma^2(1 - u_3^2)u_3 \ge 0.$$

So u_3 satisfies

$$\Delta u_3 \le 0 \quad \text{in } \Omega, \quad u_3 = 0 \quad \text{on } \partial\Omega.$$

Using the weak Harnack inequality for bounded nonnegative superharmonic functions, we have

$$\operatorname{ess\,inf}_{B_{\theta R}} u_3 \ge c\left(\fint_{B_R} u_3^p dx\right)^{1/p} \quad \text{for all } B_R \subset \Omega,$$

where p is some positive number. Thus if $u_3 \not\equiv 0$, then $u_3 > 0$ in Ω, namely, either $n_3 > 0$ everywhere in Ω or $n_3 < 0$ everywhere in Ω.

Step 4. *Proof of* (iii). Assume $K_1 = K_2 = K$. From Step 2 we see that, for large σ, $n_{\sigma 3} \not\equiv 0$; from Step 3, $n_{\sigma 3}$ does not change its sign. We may assume $n_{\sigma 3} > 0$. Then, as $\sigma \to \infty$, $n_{\sigma 3} \to 1$ in $L^2(\Omega)$ and $\mathbf{n}'_\sigma \to \mathbf{0}$ in $L^2(\Omega, \mathbb{R}^3)$. Thus $\mathbf{n}_\sigma \to \mathbf{e}_3$ in $L^2(\Omega, \mathbb{R}^3)$. □

Proof of Theorem 5.4. Assume $K_1 = K_2 = K$. Without loss of generality we assume $\mathbf{h} = \mathbf{e}_3$ and $\mathbf{e} = \mathbf{e}_1$. Let $\mathbf{n}_\sigma$ be a global minimizer of $\mathcal{F}_{\sigma \mathbf{h}}$. We estimate $\mu(q\mathbf{n}_\sigma)$ for large σ. From Lemma 5.5, we may pass to a subsequence and assume that $\mathbf{n}_\sigma \to \mathbf{e}_3$ strongly in $L^2(\Omega, \mathbb{R}^3)$. Take $\phi = e^{iqx_3}$. We have, as $\sigma \to \infty$,

$$\int_\Omega |\nabla_{q\mathbf{n}_\sigma} \phi|^2 dx = q^2 \int_\Omega |\mathbf{n}_\sigma - \mathbf{e}_3|^2 dx \to 0,$$

$$\mu(q\mathbf{n}_\sigma) \le \frac{\|\nabla_{q\mathbf{n}_\sigma} \phi\|^2_{L^2(\Omega)}}{\|\phi\|^2_{L^2(\Omega)}} = \frac{q^2 \|\mathbf{n}_\sigma - \mathbf{e}_3\|^2_{L^2(\Omega)}}{|\Omega|} \to 0.$$

So for any $\kappa > 0$, we have $\mu(q\mathbf{n}_\sigma) < \kappa^2$ for all large σ. Hence $\mu_*(q, \sigma) < \kappa^2$ for all large σ. From Lemma 5.2 we conclude that for any given κ, there exists $\hat{\sigma}$ depending on κ such that, for all $\sigma > \hat{\sigma}$, the pure nematic states are not global minimizers. □

A MATHEMATICAL ANALYSIS OF THE OPTIMAL EXERCISE BOUNDARY FOR AMERICAN PUT OPTIONS*

XINFU CHEN† AND JOHN CHADAM†

Abstract. We study a free boundary problem arising from American put options. In particular we prove existence and uniqueness for this problem, and we derive and rigorously prove high order asymptotic expansions for the early exercise boundary near expiry. We provide four approximations for the boundary: one is explicit and is valid near expiry (weeks); two others are implicit involving inverse functions and are accurate for longer time to expiry (months); the fourth is an ODE initial value problem which is very accurate for all times to expiry, is extremely stable, and hence can be solved instantaneously on any computer. We further provide an ode iterative scheme which can reach its numerical fixed point in five iterations for all time to expiry. We also provide a large time (equivalent to regular expiration times but large interest rate and/or volatility) behavior of the exercise boundary. To demonstrate the accuracy of our approximations, we present the results of a numerical simulation.

Key words. early exercise boundary, existence and uniqueness, numerical and analytical approximations

AMS subject classifications. 91B28, 35R35, 45G05

DOI. 10.1137/S0036141003437708

1. Introduction.

With the Black–Scholes hypothesis of log-normal stock prices, the price $P(S,T)$ for an American put option on a share of price S at time T can be formulated as the solution to following free boundary problem (cf. [27]):

$$(P)\quad \begin{cases} P_T + \frac{1}{2}\sigma^2 S^2 P_{SS} + r\,S\,P_S - r\,P = 0 & \text{for } T < T_F,\ S > S_f(T), \\ P(S,T) = E - S,\quad P_S(S,T) = -1 & \text{for } T < T_F,\ S \le S_f(T), \\ S_f(T_F) = E,\quad P(S,T_F) = \max\{0, E-S\} & \text{for } T = T_F,\ S > 0. \end{cases}$$

Here E is the exercise (strike) price, T_F the expiration time, σ the constant volatility, r the constant risk-free interest rate, and $S = S_f(T)$ the free boundary separating regions of optimally holding and exercising.

There is a considerable literature on the optimal exercise boundary, both analytical and numerical; see, for example, [1, 2, 3, 4, 6, 14, 15, 16, 18, 20, 21, 24, 25, 26] and the references therein. A recent list of references, together with numerical approximations, can be found in [1, 8, 24].

For notational simplicity, we write problem (P) in a nondimensional form. Let

$$k = 2r/\sigma^2,\quad S = E\,e^x,\quad T = T_F - 2t/\sigma^2\ ,\quad P(S,T) = E\,p(x,t),\quad S_f(T) = E\,e^{s(t)}.$$

Then problem (P) becomes, for the transformed price $p(x,t)$ and the optimal exercise

boundary $x = s(t)$,

$$
(1.1)\qquad \begin{cases} p_t - p_{xx} - (k-1)p_x + k\,p = 0 & \text{for } t > 0,\ x > s(t), \\ p(x,t) = 1 - e^x,\ p_x(x,t) = -e^x & \text{for } t > 0,\ x \le s(t), \\ s(0) = 0, \qquad p(x,0) = \max\{1 - e^x, 0\} & \text{for } t = 0,\ x \in \mathbb{R}, \\ p(x,t) > \max\{1 - e^x, 0\} & \text{for } t > 0,\ x > s(t). \end{cases}
$$

The last condition corresponds to the physical condition $P > E - S$ when $S > S_f(T)$. Though not necessary, we include this condition in (1.1) to make the definition of the free boundary clearer.

Unlike the American call option with dividend where $s(t) \sim -2\sqrt{t\alpha}$ with α being a constant [27] when the (continuous) dividend rate is less than the risk-free interest rate, here for the put option, α becomes unbounded as $t \searrow 0$ (i.e., $T \nearrow T_F$), leading to difficulties in the theoretical analysis, numerical simulation, and accurate pricing and strategic trading during this extremely volatile period, i.e., the period in which the relation between the asset and option prices is rapidly varying.

Although the analysis to be presented is quite technical, the high accuracy of the ensuing global estimates for the location of the early exercise boundary is important for practitioners. Knowing the location of the early exercise boundary a priori makes the pricing of American style financial derivatives amenable by Monte Carlo simulation, which is the preferred systematic method of fund managers with thousands of instruments. In addition to the practical importance of these estimates, the technical methods to obtain them are also of theoretical interest. Since the methods do not use the convexity of the free boundary (we have proven the convexity of the free boundary for problem (P) in a separate paper [7]), they serve as a prototype for problems with nonconvex free boundary problems. We expect this to be the most likely case in finance since even for the closely related problem (P) on a dividend-paying asset, numerical simulations by Detemple suggest (private communication) that the early exercise boundary may not be convex for all choices of the parameters.

In recent developments, Kuske and Keller [18], Bunch and Johnson [5], and Stamicar et al. [25] derived independently the following similar asymptotic expansions for $\alpha(t) := s^2(t)/(4t)$:

$$
\begin{aligned}
&\text{(KK)} && 9\pi k^2\, t\, \alpha^2\, e^{2\alpha} &&\sim 1\ , \\
&\text{(BJ)} && 4k^2\, t\, \alpha\, e^{2\alpha} &&\sim 1 - k^2/[2(1+k)^2]\ , \\
&\text{(SSC)} && 4\pi k^2\, t\, e^{2\alpha} &&\sim 1
\end{aligned}
$$

for all sufficiently small positive t. Regardless of their differences, all these asymptotics capture the dominant behavior $\lim_{t\searrow 0} \frac{2\alpha(t)}{|\log t|} = 1$ that was rigorously established by Barles et al. [4]. Nevertheless, any two of the asymptotics (KK), (BJ), and (SSC) cannot hold simultaneously at the next order. For example, by taking logarithms, (SSC) implies that $2\alpha(t) \sim |\log(t)| - \log(4\pi k^2)$, while (KK) implies $2\alpha(t) \sim |\log(t)| - \log(9\pi k^2)$ with additional log log corrections from the α^2 term. Similarly, (BJ) implies yet another constant term along with log log corrections.

On the other hand, due to the singularity of problem (1.1) near the origin, numerical simulations are very difficult, and typical methods such as the binomial or trinomial tree methods can hardly capture any asymptotic behavior of $\alpha(t)$ more accurately than the above approximations.

One purpose of this paper is to give a complete and rigorous mathematical justification to show that indeed (SSC) is the correct asymptotic behavior of $\alpha(t)$ as $t \searrow 0$. In addition, we shall prove rigorously that as $t \searrow 0$, $\alpha(t) = s^2(t)/(4t)$ has the more general asymptotic expansion

(1.2)
$$\alpha(t) = -\xi - \frac{1}{2\xi} + \frac{1}{8\xi^2} + \frac{17}{24\xi^3} - \frac{51}{64\xi^4} - \frac{287}{120\xi^5} + \frac{199}{32\xi^6} + O(\xi^{-7}), \quad \xi := \log\sqrt{4\pi k^2 t}.$$

Due to our particular choice of ξ, this expansion does not have a constant term and also does not depend otherwise on any parameters. This differentiates it from the behavior obtained in (KK) and (BJ) that give other constants and log log rather than inverse log corrections. Please see Remark 3.2 and section 7.2 for further discussions of this point.

Another purpose of this paper is to provide the following noniterative approximations to $s(t)$ for both small and large t:

$$\text{(expl)} \quad \alpha = -\xi - \frac{1}{2(\xi - a)} + \frac{1/8 + a/2}{(\xi - a)^2}, \qquad a = 0.96621\ldots,$$

$$\text{(imp1)} \quad \xi = -\alpha - \log\left\{1 - \frac{1}{2(\alpha+1)} - \frac{1}{2(\alpha+1)^2}\right\},$$

$$\text{(imp2)} \quad \xi = -\alpha - \log\left\{\tfrac{2}{\sqrt{\pi}}\textstyle\int_0^{\sqrt{\alpha}} e^{-z^2} dz\right\} + \log\tfrac{e^{\alpha} + 2k\log(1+1/k)\, e^{1/\alpha}}{e^{\alpha} + e^{1/\alpha}},$$

$$\text{(ODE)} \quad \tfrac{d}{dt}s(t) = \tfrac{s(t)}{2kt}\Gamma(s(t), t), \qquad \Gamma(z,t) := \tfrac{1}{2\sqrt{\pi t}} e^{-z^2/(4t) - (k-1)z/2 - (k+1)^2 t/4}.$$

There have also been many contributions to the study of early exercise boundaries for American options with dividends; see, for example, Evans et al. [11] and Knessl [17]. An earlier theoretical work using a variational approach for American options with multiple assets as well as a numerical algorithm for the pricing problem was supplied by Jaillet et al. [15]. By contrast, the main focus of this paper is to give a complete treatment, with particular attention on the singular behavior of the optimal exercise boundary near expiry, for the simplest nontrivial case of the American put without dividends. It is expected that analysis similar to ours can be carried over, with appropriate modifications, to the case with other payoffs, dividends, and/or multiple assets. On the other hand, as mentioned earlier, even in the closely related case of problem (P) on a dividend-paying asset, the dependence of the near expiring behavior, and possibly the convexity, on the choice of parameters suggests that the necessary modifications may be subtle.

The explicit approximation (expl) and the first implicit approximation (imp1) are derived directly from the asymptotic expansion (1.2); they are fourth order in the sense that for small t, the α values calculated from (expl) or (imp1) have error of order $O(|\xi|^{-4})$. Our numerical simulation (cf. [8]) shows that both (expl) and (imp1) are far better than any straightforward truncations of (1.2) (assuming $T_F - T$ is larger than 1 second) both in accuracy and in the length of interval of validity of the formulas. For our running example (cf. Figure 7.1), where $E = 1$, $r = 0.1/\text{year}$ and $\sigma = 0.25/\sqrt{\text{year}}$, the approximation (expl) is accurate for $T_F - T$ less than several weeks and (imp1) is accurate for $T_F - T$ less than several months.

The second implicit approximation (imp2) is an interpolation of the small time behavior $\alpha \approx -\xi$ and large time behavior $s(t) \approx \log[(1+k)/k]$ derived from Merton's solution for the infinite horizon problem for American put [22]. In general (imp2) is

better than (imp1). For our running example, the error of the approximation (imp2) is less than 2×10^{-3} for $T_F - T$ up to 3 years.

The ODE approximation is to be solved with an initial condition compatible with the limit $\alpha + \xi \to 0$ as $\xi \to -\infty$. In numerical implementation, it is transformed to an equation for α in the $\xi = \log\sqrt{4\pi k^2 t}$ variable and the initial condition is approximated by $\alpha|_{\xi=\xi_0} = -\xi_0 - 1/(2\xi_0)$, where ξ_0 is a large negative number, say, $\xi_0 = -10$. Numerical simulation shows that this ODE initial value problem is very stable and highly insensitive to any change of initial conditions, and hence can be solved instantaneously on any computer. The ODE approximation is better than any of the above three. For our running example, its error is less than 5×10^{-5} when $T_F - T$ is less than 2 months, 10^{-3} when $T_F - T$ less than 1 year, and 6×10^{-3} for all $T_F - T > 0$. We would like to point out that our ODE approximation has already surpassed those numerical approximations from the standard binomial or trinomial tree methods (with 1000 division points), which are typically used in literature as the "exact" solutions for comparisons; see the curve marked Bino in Figure 7.1.

The ODE approximation is derived from the following exact system:

$$\text{(1.3)} \qquad \begin{cases} \dot{s}(t) = \frac{s(t)}{2kt}\,\Gamma(s(t),t)\big\{1 + m(t)\big\}, \\ m(t) = k\displaystyle\int_0^t \left\{\frac{s(t)-s(\tau)}{t-\tau}\,\frac{2t}{s(t)} - 1\right\}\frac{\Gamma(s(t)-s(\tau),t-\tau)}{\Gamma(s(t),t)}\,d\,s(\tau). \end{cases}$$

From this system, we obtain an iterative scheme. Starting with the ODE approximation (corresponding to $m \equiv 0$), successively solve (1.3) with m evaluated at the previous iteration of s. As it turns out, this iteration converges very rapidly; a numerical fixed point (difference less than 10^{-7}) is obtained after only five iterations. The first iteration takes less than 1 minute and the total of five iterations takes less than 10 minutes (on a Sparc server). See Figure 7.1 for the error estimate of the first three iterations.

Note that $t = \sigma^2(T_F - T)/2 = r(T_F - T)/k$ is large when σ and/or r are large. Hence, to include cases where r and/or σ are large, we also provide a long time behavior of s. For large t,

$$\text{(long)} \qquad s(t) \sim s_\infty \exp\left\{\hat{m}\int_{(k+1)^2 t/4}^{\infty} \rho^{-3/2} e^{-\rho}\,d\rho\right\},$$

$$s_\infty = s(\infty) = \log[k/(1+k)],$$

$$\hat{m} = \frac{k+1}{4\sqrt{\pi}}\int_0^\infty \frac{s(\tau)}{s_\infty}\exp\left\{\frac{k-1}{2}(s(\tau) - s_\infty) + \frac{(k+1)^2}{4}\tau\right\} d\,s(\tau).$$

Here $\hat{m}$ can be calculated approximately by using the ODE approximation for s, which is instantaneous since we can do so by solving ODE. When (long) is incorporated with our noniterative schemes such as ODE, we can instantaneously obtain reliable approximate values of $s(t)$ for any t and any parameters r and σ; see Figure 7.1 for $r = 0.1/\text{year}$ and $\sigma = 0.25/\sqrt{\text{year}}$, and see [8] for other values of the parameters.

This paper is organized as follows. In section 2, we briefly establish, for mathematical completeness, the well-posedness of problem (1.1) via a classical variational approach [12]. We show that the solution (p, s) to (1.1) exists and is unique, that $s(t)$ is continuous and nondecreasing, and as $t \to \infty$, $(s(t), p(\cdot, t)) \to (s_\infty, p_\infty(\cdot))$, the solution to the infinite horizon problem [22]. During the review and revision of this manuscript, an alternative proof of the existence and uniqueness appeared in the literature [23].

In section 3 we derive several integral and integrodifferential equations for s by using the fundamental solution Γ for the linear parabolic PDE for p; in particular we derive (1.3).

Sections 4 through 6 are devoted to showing that (1.3) has a solution $s(\cdot)$ with $\alpha := s^2(t)/(4t)$ satisfying the asymptotic behavior (1.2). In section 4, we transform (1.3) into an equation of the form

$$(\mathbf{I} + \mathbf{L})[u'] + G(u, \xi) = F[u], \tag{1.4}$$

where $u = u(\xi) = \alpha(t) = s^2(t)/(4t)$, $\xi = \log\sqrt{4\pi k^2 t}$, $\mathbf{I}$ is the identity operator, $\mathbf{L}$ a linear operator defined in (4.5), $F[u]$ a small nonlinear operator, and G a function. In section 5 we show that the operator $(\mathbf{I}+\mathbf{L})$ is invertible from C^0 to C^0 and that $\mathbf{L}[\phi]$ is always 1/2 more differentiable than ϕ, although $\|\phi - \mathbf{L}[\phi]\|_{C^0((-\infty,\xi])} \to 0$ as $\xi \to -\infty$ for any uniformly continuous function ϕ. In section 6, we first establish the existence of a unique solution to (1.4), with $F[u]$ replaced by any known small function, in a finite interval $\xi \in (-j, \xi_0]$ for any j and some fixed negative large constant ξ_0. To take the limit $j \to \infty$, we show that (1.4), in a finite interval $[-j, \xi_0]$ or half finite interval $(-\infty, \xi_0]$, possesses a comparison principle, which allows us to construct sub and super solutions to sandwich the solutions. We let $j \to \infty$ to obtain solutions of (1.4) with given known F. A Schauder's fixed point theorem then can be used to establish the existence of a solution to (1.4). Uniqueness of the solution follows from the well-posedness result of section 3. The asymptotic expansion (1.2) is proved by the comparison principle and construction of sub and super solutions.

Finally, in section 7 we derive our approximation formula mentioned earlier and, for the purpose of illustration, provide a numerical simulation to support the advantages of our new approximations.

We repeat that recently we have shown [7] that the optimal boundary is convex; see also [10]. Using this property, many of the proofs here can be greatly simplified. Nevertheless, the method provided here is general enough to be extended to many similar option problems where the optimal exercise boundaries may not be convex.

2. Well-posedness of problem (P). In this section we establish the well–posedness of the free boundary problem (1.1). Though many techniques and results are standard and may be cited from references, we still provide a certain degree of detail for completeness of the paper.

For convenience, we denote by $\mathfrak{L}$ the operator

$$\mathfrak{L}[p] = p_{xx} + (k-1)p_x - k\,p.$$

LEMMA 2.1. *Let $p(x,t)$, together with a free boundary $x = s(t)$, be a solution to* (1.1). *Then*

$$\begin{cases} \min\{p - p_0, p_t - \mathfrak{L}[p]\} = 0 & \text{in } \ \mathbb{R} \times (0,\infty), \\ p(x,0) = p_0(x) := \max\{1 - e^x, 0\} & \forall\ x \in \mathbb{R}. \end{cases} \tag{2.1}$$

The proof follows from a straightforward verification and is omitted.

THEOREM 2.2. *There exists a unique solution p to* (2.1). *Define $s(t) = \sup\{x | p(x,t) = p_0(x)\}$ for all $t > 0$. Then* (i) *$s(\cdot)$ is a strictly decreasing continuous function on $(0,\infty)$,* (ii) *$\lim_{t\searrow 0} s(t) = 0$,* (iii) *$p(x,t) > p_0(x)$ for all $x > s(t)$ and $t > 0$, and $p(x,t) = p_0(x)$ for all $x \le s(t)$ and $t \ge 0$, and* (iv) *(p, s) solves* (1.1).

Proof. The existence of a unique solution p follows from a well-developed parabolic theory for obstacle problems; see, for example, [12, Chap. 1, sec. 8]. Here for completeness and for the existence of $s(\cdot)$, we provide the main idea of the proof.

Uniqueness. Let p_1 and p_2 be arbitrary two solutions to (2.1). Denote $\gamma_i = (\partial_t - \mathfrak{L})p_i \geq 0$. Then

$$(p_1 - p_2)\{(p_1 - p_2)_t - \mathfrak{L}[(p_1 - p_2)]\} = (p_1 - p_2)(\gamma_1 - \gamma_2) \leq 0 \quad \text{in } \mathbb{R} \times (0, \infty)$$

since $\gamma_1 = 0$ when $p_1 - p_2 > 0$ (as $p_1 > p_2 \geq p_0$) and $\gamma_2 = 0$ when $p_1 - p_2 < 0$. Integrating the above inequality over $x \in \mathbb{R}$ and using the Gronwall's inequality, one concludes that $p_1 \equiv p_2$.

Existence. For every $\varepsilon > 0$, let $q^\varepsilon(x,t)$ be the solution to the semilinear parabolic Cauchy problem

$$\begin{cases} q^\varepsilon_t - \mathfrak{L}[q^\varepsilon] = \beta_\varepsilon(q^\varepsilon - p^\varepsilon_0) & \text{in } \mathbb{R} \times (0, \infty), \\ q^\varepsilon(\cdot, 0) = p^\varepsilon_0(\cdot) := \rho^\varepsilon * p_0 & \text{on } \mathbb{R} \times \{0\}, \end{cases}$$

where $\rho^\varepsilon(z) := \varepsilon^{-1}\rho(\varepsilon^{-1}z)$ with $\rho(\cdot)$ being a smooth and nonnegative mollifier of unit integral over $\mathbb{R}^1$, and $\beta_\varepsilon(\cdot)$ is any nonnegative, bounded, and smooth function defined on $\mathbb{R}$ with the properties

$$\beta'_\varepsilon(z) \leq 0 \ \text{ for all } \ z \in \mathbb{R}, \qquad \beta_\varepsilon(0) = k, \quad \text{and } \ \beta_\varepsilon(z) = 0 \ \text{ for } \ z > \varepsilon.$$

Existence of a unique smooth solution q^ε follows from standard parabolic PDE theory; see, for example, [13]. To take the limit $\varepsilon \to 0$ to obtain a solution to (2.1), we need to establish a few ε-independent a priori estimates for q^ε.

Differentiating the differential equation with respect to t gives $(\partial_t - \mathfrak{L} - \beta'_\varepsilon)q^\varepsilon_t = 0$ in $\mathbb{R} \times (0, \infty)$. When $t = 0$, $q^\varepsilon_t(\cdot, 0) = \mathfrak{L}[p^\varepsilon_0] + \beta_\varepsilon(0) \geq 0$ in $\mathbb{R}^1$ since $\beta_\varepsilon(0) = k$ and in the distributional sense $\mathfrak{L}[p_0] \geq -k$ which implies $\mathfrak{L}[p^\varepsilon_0] = \rho^\varepsilon * \mathfrak{L}[p_0] \geq -k$. Therefore, by comparison, $q^\varepsilon_t > 0$ on $\mathbb{R} \times [0, \infty)$.

Also one can show that p^ε_0 is a subsolution and $\mathbf{1}$ is a supersolution so that $p^\varepsilon_0 < q^\varepsilon < 1$ in $\mathbb{R} \times (0, \infty)$.

Note that $p^\varepsilon_0 < q^\varepsilon$ implies $\beta^\varepsilon(q^\varepsilon - p^\varepsilon_0) \in [0, k)$ on $\mathbb{R} \times (0, \infty)$. Consequently, by local PDE regularity estimates, the set $\{q^\varepsilon\}_{0<\varepsilon<1}$ is bounded in $C^{\beta,\beta/2}(\mathbb{R} \times [0, \infty)) \cap W^{2,1}_r((-R, R) \times (0, R) \setminus (-\delta, \delta) \times (0, \delta))$ for every $\beta \in (0, 1)$, $r > 1$, $\delta > 0$, and $R > \delta$. Hence, there exist $\gamma \in L^\infty(\mathbb{R} \times (0, \infty))$ and $p \in C^{\beta,\beta/2}(\mathbb{R} \times [0, \infty)) \cap W^{2,1}_{r,\mathrm{loc}}(\mathbb{R} \times [0, \infty) \setminus (0, 0))$ such that, along some sequence $\varepsilon \searrow 0$, $\beta_\varepsilon(q^\varepsilon - p^\varepsilon_0) \to \gamma$ weakly in $L^r(B_R(0) \times (0, R))$, and $q^\varepsilon \to p$ strongly in $C^{\beta,\beta/2}([-R, R] \times [0, R])$ and weakly in $W^{2,1}_r((-R, R) \times (0, R) \setminus ((-\delta, \delta) \times (0, \delta))$ for every $r > 1, \beta \in (0, 1), \delta > 0$ and $R > \delta$. Taking the limit of the differential equation for q^ε along that convergent sequence, we conclude that $p(\cdot, 0) = p_0(\cdot)$ and

$$p_t - \mathfrak{L}[p] = \gamma \in [0, k], \quad p \geq p_0, \quad p_t \geq 0 \qquad \text{in } \mathbb{R} \times (0, \infty).$$

Since $q^\varepsilon \to p$ locally uniformly, $p(x_0, t_0) - p_0(x_0) > 0$ implies $q^\varepsilon > p^\varepsilon_0 + \varepsilon$, i.e., $\beta^\varepsilon(q^\varepsilon - p^\varepsilon) = 0$, in a ε-independent neighborhood of (x_0, t_0) for all sufficiently small positive ε in the sequence, and therefore, $\gamma = 0$ in a neighborhood of (x_0, t_0). Thus p is a solution to (2.1).

The free boundary. Let $\mathbf{C} := \{(x,t) \in \mathbb{R} \times [0, \infty) \mid p(x,t) = p_0(x)\}$ be the contact set in the obstacle problem terminology. Since $p_t \geq 0$, there exists a

(semicontinuous) function $T : \mathbb{R} \to [0, \infty) \cup \{\infty\}$, such that $\mathbf{C} = \{(x, t) \mid x \in \mathbb{R}^1, 0 \le t \le T(x)\}$.

Since $p_t - \mathfrak{L}[p] = \gamma \ge 0$ in $\mathbb{R} \times (0, \infty)$, a comparison principle implies that $p > 0$ in $\mathbb{R} \times (0, \infty)$. It then follows that $T(x) = 0$ for all $x > 0$ since $p_0(x) = 0$ for all $x \ge 0$.

Now we show that $T(\cdot)$ is nonincreasing. Indeed, if $T(x_0) > 0$, then defining a new function $\tilde{p}$ by $\tilde{p} = p$ in $[x_0, \infty) \times [0, T(x_0)]$ and $\tilde{p} = p_0$ in $(-\infty, x_0] \times [0, T(x_0)]$, one can verify that $\tilde{p}$ is a solution to (2.1) in $\mathbb{R} \times [0, T(x_0)]$, so that, by uniqueness, $p = \tilde{p}$. Consequently, $(-\infty, x_0] \times [0, T(x_0)] \in \mathbf{C}$, and therefore $T(x) \ge T(x_0)$ for all $x \le x_0$. Thus $T(\cdot)$ is nonincreasing.

Next we show that $T(x)$ is strictly decreasing for $x \le 0$. Suppose this is not true. Then for some $x_2 < x_1 \le 0$, $T(x_2) = T(x_1) < \infty$. Consequently, $p(\cdot, t_0) = p_0(\cdot)$ in $[x_2, x_1]$ and $p > p_0$ in $(x_2, \infty) \times (T(x_2), \infty)$. It then follows that $p_t - \mathfrak{L}[p] = \gamma \equiv 0$ in $(x_2, \infty) \times (T(x_2), \infty)$. Since p_0 is smooth in (x_2, x_1), so is p in $(x_2, x_1) \times [T(x_2), \infty)$. Thus $p_t(\frac{x_1+x_2}{2}, T(x_2)) = \mathfrak{L}[p_0](\frac{x_1+x_2}{2}) = -k$, contradicting $p_t \ge 0$. Hence, $T(x)$ is strictly decreasing on $(-\infty, 0]$.

It then follows that the function $t = T(x)$ for $x \le 0$ admits an inverse $x = s(t)$ defined for all $t \ge 0$ and is nondecreasing. As inverse functions of strictly monotonic functions are continuous, $s(\cdot)$ is continuous. Note that $T(x) = 0$ for $x > 0$ and $T(x) > 0$ for $x < 0$ implies that $s(0) = 0$.

Finally we verify that $s(t)$ is strictly decreasing. In fact, if $s(t)$ is a constant over an interval $[t_1, t_2]$, then $p_t - \mathfrak{L}[p] = 0$ in $(s(t_1), \infty) \times (t_1, t_2)$ and $p(s(t_1), t) = p_0(s(t_1))$ for all $t \in [t_1, t_2]$, so that $p \in C^\infty([s(t_1), \infty) \times (t_1, t_2))$. As $p_t \ge (\not\equiv) 0$ and $(\partial_t - \mathfrak{L})p_t = 0$ in $[s(t_1), \infty) \times (t_1, t_2)$, the Hopf lemma then gives $p_{tx} > 0$ on $\{s(t_1)+\} \times (t_1, t_2)$, which implies that $p_x(s(t)+, t)$ is strictly increasing for $t \in (t_1, t_2)$. On the other hand, $p \in W^{2,1}_{r,loc}(\mathbb{R} \times (0, \infty))$ for any $r > 1$ and the definition of $s(\cdot)$ implies that $p_x(s(t), t) = p_{0x}(s(t_1))$ is a constant for all $t \in (t_1, t_2)$, and we have a contradiction. Hence, $s(t)$ is strictly decreasing. This completes the proof. □

THEOREM 2.3. *There exists a unique solution (p, s) to (1.1). In addition, $p \in W^{2,1}_{r,loc}(\mathbb{R} \times [0, \infty) \setminus (0, 0))$ for any $r > 1$, and $p > 0$, $p_t \ge 0$, and $p_x < 0$ in $\mathbb{R} \times (0, \infty)$. Furthermore, $s(\cdot)$ is continuous and strictly decreasing and as $t \to \infty$,*

$$s(t) \to s_\infty := \log(1 + 1/k), \tag{2.2}$$

$$p(x, t) \to p_\infty(x) := \begin{cases} 1 - e^x & \text{if } x \le s_\infty, \\ (1 - e^{s_\infty})e^{-k(x - s_\infty)} & \text{if } x > s_\infty. \end{cases} \tag{2.3}$$

Proof. We need only show the assertions (2.2), (2.3), and $p_x < 0$ in $\mathbb{R} \times (0, \infty)$ since the rest follows from Lemma 2.1 and the proof of Theorem 2.2. As $\gamma = k$ for $x < s(t)$ and $= 0$ for $x > s(t)$, $(\partial_t - \mathfrak{L})[p_x] = \gamma_x \le 0$ in the distributional sense. A strong maximum principle then implies that $p_x < 0$ in $\mathbb{R} \times (0, \infty)$. It remains to show (2.2) and (2.3).

First of all, we can use comparison to show that $p(\cdot, t) < p_\infty(\cdot)$ for all $t \ge 0$. This inequality implies, by the definition of s, that $s(t) > s_\infty$ for all $t > 0$.

Next, as we know that $p_t(\cdot, \cdot) \ge 0$ and $s(\cdot)$ is strictly decreasing, the existence of an upper bound $p_\infty(\cdot)$ for $p(\cdot, t)$ and a lower bound s_∞ for $s(\cdot)$ then implies that the limits $p^*(\cdot) = \lim_{t\to\infty} p(\cdot, t)$ and $s^* = \lim_{t\to\infty} s(t)$ exist. From the differential equation, we can derive that $\mathfrak{L}[p^*] = 0$ in (s^*, ∞), $p^* = p_0$ in $(-\infty, s^*]$, and $p^* \in W^2_{r,loc}(\mathbb{R})$ for any $r > 1$. Solving for (p^*, s^*) from these relations we find that $s^* = s_\infty$ and $p^*(\cdot) = p_\infty(\cdot)$. This completes the proof. □

Remark 2.1. The limit $(s_\infty, p_\infty(\cdot))$ is the classical solution of Merton [22] for the infinite horizon problem for American puts.

Remark 2.2. That $s(t)$ is not differentiable at $t = 0$ is due to the nonsmoothness of the initial data $p(\cdot, 0) = p_0 = \max\{1 - e^x, 0\}$. To see this, consider the hodograph transformation: Let $x = X(z, t)$ be the inverse function of $z = p_x(x, t) + e^x$. Then $s(t) = X(0, t)$, and $X(z, t)$ solves the following initial Neumann boundary value problem for a quasi-linear parabolic PDE:

$$\begin{cases} X_t - \frac{1}{X_z^2} X_{zz} + (k-1) - kzX_z = 0 \quad \text{for } z > 0, t > 0, \\ X_z(0, t) = 1/k \quad \text{for } \ t > 0, \\ X(\cdot, 0) = \max\{0, \log(z)\} \quad \forall z > 0. \end{cases} \tag{2.4}$$

This problem is highly singular since $X(z, 0) = 0$ for $z \in (0, 1)$, which is due to the fact that $-p_{0x}(0)$ has a jump from 0 to 1.

It is important to note that if the initial data $X(z, 0) = \max\{0, \log(z)\}$ is replaced by $X^\varepsilon(z, 0)$, a smooth function with positive slope, the resulting solution satisfies $X_z^\varepsilon > 0$ on $[0, \infty) \times [0, \infty)$. Our numerical simulation (not shown here) indicates that a numerical scheme based on (2.4) is much better than the binomial or trinomial tree method.

From (2.4), we see that if for some $\beta > 0$, $s(t)$ is $C^{1+\beta}$ near some $t = t_0 > 0$, then $s(\cdot) \in C^\infty((t_0, \infty))$. Indeed, s in $C^{1+\beta}$ near t_0 implies $p(x, t)$ in $C^{2+\beta, 1+\beta/2}$ in a neighborhood of $\mathbb{R} \times \{t_0\}$, so that $X(\cdot, t_0)$ is in $C^{1+\beta}([0, \infty))$. With a more detailed a priori estimate on the previous ε problem one can show that $(p_x + e^x)_x > 0$ so $X_z(\cdot, t_0) > 0$ on $[0, \infty)$. A maximum principle for the equation for X_z can be used to show that $X_z > 0$ on $[0, \infty) \times [t_0, \infty)$. Since the Neumann boundary value $X_z(0, t) = 1/k$ is a constant function, a boot strap argument and a classical local Hölder estimate for quasi-linear parabolic equation (see for example, [19]) then implies that $X \in C^\infty([0, \infty) \times (t_0, \infty))$. In particular, $s(t) = X(0, t)$ is also in $C^\infty((t_0, \infty))$.

In the subsequent sections, we shall show (by a totally different method) that $s(\cdot) \in C^2((0, \delta))$ for some $\delta > 0$, so that $s \in C^\infty((0, \infty))$.

3. Integral representation for the free boundary $x = s(t)$. In this section, we use the Green's representation for solutions of the linear parabolic PDE in (1.1) to derive, for the free boundary $x = s(t)$, several integral and integrodifferential equations, including (1.3), which is to be solved later to establish the asymptotic behavior of $s(t)$ for small positive t.

We denote by $\Gamma(x, t)$ the fundamental solution to the operator $\partial_t - \mathfrak{L}$; more precisely,

$$\begin{aligned} \Gamma(x, t) &= \frac{1}{2\sqrt{\pi t}} \exp\left\{ -\frac{[x + (k-1)t]^2}{4t} - kt \right\} \\ &= \frac{1}{2\sqrt{\pi t}} \exp\left\{ -\frac{[x + (k+1)t]^2}{4t} + x \right\}. \end{aligned} \tag{3.1}$$

Since $(\partial_t - \mathfrak{L})[p] = \gamma$ in $L^r_{loc}(\mathbb{R} \times (0, \infty))$ for any $r > 1$ and $\gamma = k$ for $x < s(t)$ and $\gamma = 0$ for $x > s(t)$, the Green's identity gives, for the unique solution (p, s) of (1.1),

$$p(x, t) = \int_{-\infty}^{0} (1 - e^y)\Gamma(x - y, t)\, dy + k \int_0^t \int_{-\infty}^{s(t-\tau)} \Gamma(x - y, \tau)\, dy d\tau \quad x \in \mathbb{R}, t > 0. \tag{3.2}$$

It is worth mentioning that the first integral on the right-hand side is the price for the European put option because $e^{kt}\Gamma(x - y, t)dy$ is the probability that at expiry

the stock price (after scaling) is y, for which the option has value $e^{-kt}\max\{1-e^y,0\}$. Consequently, the second integral in (3.2) is the extra value (premium) of the American put option over the European put option, if the option is exercised optimally (i.e., exercise the option as soon as the (scaled) stock price s is below $s(t)$).

LEMMA 3.1. *Let $s\in C^0([0,\infty))\cap C^1((0,\infty))\cap W^{1,1}((0,1))$ be any function and $p(x,t)$ be defined as in (3.2). Set $p_0(x)=\max\{1-e^x,0\}$. Then for all $t>0$ and $x\neq 0$ and $x\neq s(t)$,*

$$
\begin{aligned}
(3.3)\quad p(x,t) &= p_0(x)+\int_0^t\left\{\Gamma(x,\tau)-k\int_{s(t-\tau)}^0\Gamma(x-y,\tau)dy\right\}d\tau,\\
p_x(x,t) &= p_{0x}(x)+\int_0^t\Big\{\Gamma_x(x,\tau)+k\,\Gamma(x,\tau)-k\,\Gamma(x-s(t-\tau),\tau)\Big\}d\tau,\\
p_t(x,t) &= \Gamma(x,t)+k\int_0^t\Gamma(x-s(t-\tau),\tau)\dot s(t-\tau)\,d\tau,\\
p_{xx}(x,t) &= p_{0xx}(x)+\Gamma(x,t)+\int_0^t\Big\{\Gamma_x(x,\tau)+k\Gamma(x,\tau)-k\,\Gamma_x(x-s(t-\tau),\tau)\Big\}d\tau,\\
p_{xt}(x,t) &= \Gamma_x(x,t)+k\int_0^t\Gamma_x(x-s(t-\tau),\tau)\dot s(t-\tau)\,d\tau.
\end{aligned}
$$

Consequently, (p,s) solves (1.1) if and only if s satisfies one of the following equations, for all $t>0$:

$$
\begin{aligned}
(3.4)\quad &\int_0^t\Gamma(s(t),\tau)d\tau=k\int_0^t\int_{s(t-\tau)}^0\Gamma(s(t)-y,\tau)dyd\tau,\\
(3.5)\quad &\int_0^t\Big\{\Gamma_x(s(t),\tau)+k\,\Gamma(s(t),\tau)\Big\}d\tau=k\int_0^t\Gamma(s(t)-s(t-\tau),\tau)\,d\tau,\\
(3.6)\quad &\Gamma(s(t),t)=-k\int_0^t\Gamma(s(t)-s(t-\tau),\tau)\dot s(t-\tau)\,d\tau,\\
(3.7)\quad &\Gamma(s(t),t)=\frac{k}{2}+k\int_0^t\Big\{\Gamma_x(s(t)-s(t-\tau),\tau)-\Gamma(s(t)-s(t-\tau),\tau)\Big\}\,d\tau,\\
(3.8)\quad &\dot s(t)=-\frac{2\Gamma_x(s(t),t)}{k}-2\int_0^t\Gamma_x(s(t)-s(t-\tau),\tau)\dot s(t-\tau)\,d\tau.
\end{aligned}
$$

THEOREM 3.2. *Let $s\in C^1((0,\infty))\cap C^0([0,\infty))$ be nonpositive and $\alpha(t)=s^2(t)/(4t)$. Assume that as $t\searrow 0$, $\alpha(t)=[-1+o(1)]\log\sqrt{t}$ and $t\,\dot\alpha(t)=O(1)$. Then s, together with p defined in (3.2), solve (1.1) if and only if s satisfies the integrodifferential equation, for all $t>0$,*

$$
(3.9)\qquad \dot s(t)=\frac{s(t)\Gamma(s(t),t)}{2kt}+\int_0^t\Big\{\frac{s(t)-s(t-\tau)}{\tau}-\frac{s(t)}{2t}\Big\}\Gamma(s(t)-s(t-\tau),\tau)\dot s(t-\tau)\,d\tau.
$$

One notices that (3.9) is exactly equivalent to (1.3).

Remark 3.1. Since $\Gamma_x(x,t)=-\frac{x+(k-1)t}{2t}\Gamma(x,t)$, adding (3.8) and (3.6) multiplied by $\frac{\lambda s(t)+2(k-1)t}{2kt}$ gives

$$
(3.10)\qquad \dot s(t)=\frac{(2-\lambda)s\Gamma(s,t)}{2kt}+\int_0^t\Big\{\frac{s(t)-s(t-\tau)}{\tau}-\frac{\lambda s(t)}{2t}\Big\}\Gamma(s(t)-s(t-\tau),\tau)\dot s(t-\tau)\,d\tau.
$$

Setting $\lambda = 1$ gives (3.9) or (1.3). We choose the particular value $\lambda = 1$ is to make the integral as small as possible, because the most significant contribution of the integral comes from small τ and when τ is small, $\frac{s(t)-s(t-\tau)}{\tau} \approx s'(t) = \frac{s(t)}{2t}[1 + \frac{t\dot{\alpha}(t)}{\alpha}] \approx \frac{s(t)}{2t}$. Indeed, the cancellation is even stronger than this. A linear combination of equations (3.6)–(3.8) shows that the integral on the right-hand side of (3.9) is equal to

$$\int_0^t \Big\{ \frac{\dot{s}(t) + \dot{s}(t-\tau)}{2} \frac{s(t) - s(t-\tau)}{\tau} - \dot{s}(t)\dot{s}(t-\tau) + \tfrac{k+1}{2}\dot{s}(t) \Big\} \Gamma(s(t) - s(t-\tau), \tau)\, d\tau.$$

Due to the strong cancellation of the first two terms in the integrand, the ratio $m(t)$ of the integral and the first term on the right-hand side of (3.9) can be expanded as $0 + 0\xi^{-1} + 0\xi^{-2} + \frac{1}{4}\xi^{-3} + O(\xi^{-4})$, where $\xi = \log[\sqrt{4\pi k^2 t}]$. Thus, we can drop the integral in (3.9) to obtain the ODE in section 1 approximating $s(t)$ accurately for small as well as large t (when t is large, $\dot{s}(t) = O(t^{-3/2}e^{-(k+1)^2 t/4})$ is exponentially small).

Remark 3.2. From (3.4) one can immediately obtain a rough estimate for $s(t)$ for small t. In fact, since $\int_{-\infty}^0 \Gamma(y,t)\, dy = \frac{1}{2}e^{-kt}$, the double integral in (3.4) can be written as $\theta(t)\, kt$ with $\theta(t) \in (0, 1/2)$. Also since $\Gamma(s(t), t) = \frac{1+o(1)}{\sqrt{4\pi t}} e^{-s(t)^2/(4t)}$ for small t, $\int_0^t \Gamma(s(t), \tau)\, d\tau = \frac{[1+o(1))]\sqrt{t\,\alpha}}{\sqrt{\pi}} \int_{\sqrt{\alpha}}^\infty \eta^{-2} e^{-\eta^2}\, d\eta$, where $\alpha = s^2/(4t)$. Thus (3.4) gives $\lim_{t\searrow 0} \alpha(t) = \infty$. Consequently, $\int_{\sqrt{\alpha}}^\infty \eta^{-2} e^{-\eta^2} d\eta = \frac{1}{2}\alpha^{-3/2} e^{-\alpha}(1 + O(\alpha^{-1}))$ and, from (3.4),

$$\alpha^{-1} e^{-\alpha}[1 + O(\alpha^{-1})] = \sqrt{4\pi k^2 t}\, \theta(t)\ .$$

Hence α is of order at least $O(|\log t|)$. One can further calculate, assuming $\alpha = [-1 + o(1)] \log \sqrt{t}$, that $\theta = \alpha^{-1}(1 + o(1))$. It then follows that $\alpha = |\log \sqrt{4\pi k^2 t}|(1 + o(1))$, a conjecture first made correctly in [25]. It is worth mentioning here that $\theta(t) \approx \alpha^{-1}$ eliminates any $\log|\log t|$ corrections (as suggested in [18] and [5]) to the leading order approximation $\alpha \approx -\log[\sqrt{t}]$ for small t.

The smallness of $\theta(t)$ results from the strong cancellation of the integral $k\int_0^t \int_{-\infty}^{s(t-\tau)} \Gamma(x - y, \tau) dy d\tau$ which represents the extra value of the American put over the European put, and the integral $-k\int_0^t \int_{-\infty}^0 \Gamma(x - y, \tau) dy d\tau = p_0 * \Gamma(\cdot, t) - \{p_0 + \int_0^t \Gamma(x, \tau) d\tau\}$ which relates to that part of the premium added on to the European put to account for the possibility that the future stock price drops below x. It seems to us that this strong cancellation was not observed in [18], resulting in $\log|\log t|$ terms appearing in their expansion of α.

The asymptotic behavior $\alpha = -\log\sqrt{4\pi k^2 t} + o(1)$ for small t can also be similarly derived from (3.5).

Remark 3.3. Equation (3.6) or (3.7) can be used to derive an interesting and highly nontrivial limit: $\lim_{t\to 0} \Gamma(s(t), t) = k$. Indeed, using the change of variable $\eta = \frac{s(t-\tau)-s(t)}{2\sqrt{\tau}}$, one obtains from (3.6)

$$\Gamma(s(t), t) = k[\ 1 + o(1)\ ] \int_0^{\sqrt{\alpha}} \frac{2e^{-\eta^2}}{\sqrt{\pi}} \Big(2 - \frac{s(t) - s(t-\tau)}{\dot{s}(t-\tau)\tau}\Big)^{-1} d\eta = k + o(1)$$

since when τ/t is small, $\frac{s(t)-s(t-\tau)}{\dot{s}(t-\tau)\tau} \approx 1$, whereas when τ/t is not small, $\eta \gg 1$ so that $\frac{s(t)-s(t-\tau)}{\dot{s}(t-\tau)\tau}$ can be replaced by 1 as an approximation.

Remark 3.4. A system exactly equivalent to (3.7) was derived in [25] and was used to derive formally (SSC) in section 1. The system was also used to obtain accurate approximations of s for small t, via an iteration scheme: starting with $s \equiv 0$, update s by solving (3.7) with the right-hand side evaluated at a previous s. Nevertheless, this scheme does not seem to converge, although its first several iterations converge rapidly (for small t); for more details, see [8, 25]. This is one of our reasons for deriving (3.9) and using it to analyze $s(t)$ theoretically and also numerically.

Remark 3.5. The nonpositivity assumption on s for the integrodifferential equation in (3.9) is important since if s is a solution, then when $k = 1$, $\hat{s} = -s$ is also a solution.

Proof of Lemma 3.1. Since $\Gamma(\cdot, 0)$ is the Delta function,

$$\int_{-\infty}^{0} (1 - e^y)\Gamma(x - y, t)\, dy = p_0(x) + \int_0^t \int_{-\infty}^{0} p_0(y)\Gamma_\tau(x - y, \tau) dy d\tau$$
$$= p_0(x) + \int_0^t \left\{ \Gamma(x, \tau) - k \int_{-\infty}^{0} \Gamma(x - y, \tau)\, dy \right\} d\tau$$

by using $\Gamma_\tau(x - y, \tau) = \Gamma_{xx} + (k - 1)\Gamma_x - k\Gamma$ and integrating by parts. Substituting this identity into (3.2) we obtain (3.3). The rest of the equations, for p_x, p_t, p_{xx}, and p_{xt}, follow by differentiating (3.3) (a substitution $\Gamma_{xx} + k\Gamma_x = \Gamma_\tau + \Gamma_x + k\Gamma$ is needed for p_{xx}). We remark that all the integrals are convergent due to the regularity assumption we made on s. It remains to show the second part of the lemma.

First we assume that (p, s) solves (1.1). Then $p(x, t) - p_0(x)$, as well as all its derivatives, vanish when $x < s(t)$. Thus, letting $x \nearrow s(t)$ we obtain from the equations for $p, p_x, p_t, p_{xx} - p_x$, and p_{xt} the corresponding equations asserted. Here, in taking the limits for p_{xx} and p_{xt}, we need the following fact: for any continuous function f,

$$\lim_{x \to s(t)\pm} \int_0^t \Gamma_x(x - s(t - \tau), \tau) f(t - \tau)\, d\tau = \mp \frac{f(t)}{2} + \int_0^t \Gamma_x(s(t) - s(t - \tau), \tau) f(t - \tau)\, d\tau.$$

Next we assume that s satisfies one of the equations in the second part of the lemma and show that (p, s) solves (1.1). First we notice that p satisfies $p(\cdot, 0) = p_0(\cdot)$ and for $t > 0$, $p_t - \mathfrak{L}[p] = 0$ for $x > s(t)$, and $= k$ for $x < s(t)$. In addition, $p \in W^{2,1}_{r,loc}(\mathbb{R} \times [0, \infty) \setminus \{(0, 0)\})$ for any $r > 0$. From the equations we derived for p, p_x, p_t, p_{xx}, and p_{xt}, we see that the equations in the second part of the lemma are, respectively, equivalent to the conditions $p = p_0$, $p_x = p_{0x}$, $p_t = 0$, $p_{xx} - p_x = p_{0xx} - p_{0x}$, and $p_{xt} = 0$ at $(s(t)-, t)$ for all $t > 0$. Each of these conditions provides, by the uniqueness of solutions of the initial boundary value problem of the parabolic equation $p_t - \mathfrak{L}[p] = k$ in the set $\{(x, t) \mid x \le s(t), t > 0\}$, that $p \equiv p_0$ in the set, which implies that (p, s) satisfies all the equations (1.1). Also, (p, s) satisfies all the other integral equations we derived.

It remains to show that $p > p_0$ when $x > s(t)$. That $p \in W^{2,1}_r$ for any r implies that $p \in C^{1+\beta,(\beta+1)/2}$ so $p_0 = p$ and $p_{0x} = p_x$ on $x = s(t)$. Now the function $q := (p - p_0)_x$ satisfies $q_t - \mathfrak{L}[q] = 0$. In addition, $q = 0$ and $q_x = k > 0$ on $x = s(t)$. Using lap number theory, one concludes that the number of zeroes of $q(\cdot, t)$ is nonincreasing. One can show that for sufficiently small positive t, $q(\cdot, t) = 0$ has exactly one root in $(s(t), \infty)$, so that $q(\cdot, t) = 0$ has at most one root for all $t > 0$. Consequently, $q(\cdot, t) = 0$ has exactly one root in $(s(t), \infty)$. Thus, starting from $s(t)$, $p(\cdot, t) - p_0(\cdot, t)$ first increases, then decreases to zero as $x \to \infty$; i.e. $p > p_0$ for all $x > s(t)$. This completes the proof. ∎

Proof of Theorem 3.2. Assume that (p, s) solves (1.1). Then $p_{xt} = p_t = 0$ at $(s(t)-, t)$ for all $t > 0$. Equation (3.9) then follows from $p_{xt} + \frac{s(t)+2(k-1)t}{4t} p_t = 0$ at $(s(t)-, t)$.

Now we assume that s satisfies (3.9) and show that (p, s) solves (1.1). We need only show that $p_t = 0$ for all $x < s(t)$. Note that p defined in (3.2) is smooth (enough in our subsequent analysis) in the set $\{(x,t) \mid x \le s(t)-, t > 0\}$, and (3.9) implies $p_{xt} + \frac{s(t)+2(k-1)t}{4t} p_t = 0$ at $(s(t)-, t)$ for all $t > 0$. Since $\frac{s(t)+2(k-1)t}{4t} \sim -\frac{\sqrt{\alpha(t)}}{\sqrt{4t}}$ is negative and p_t is singular near the origin, we cannot directly apply a standard parabolic PDE theory to conclude that $p_t = 0$ for $x < s(t)$ and all $t \ge 0$.

Differentiating the equation $p_t - \mathfrak{L}[p] = k$ with respect to t, multiplying the resulting equation by p_t, and integrating over $(-\infty, s(t))$ we obtain, after integration by parts and the substitution $p_{xt} = -\frac{s(t)+2(k-1)t}{4t} p_t$ at the boundary $x = s(t)-$,

$$\frac{1}{2}\frac{d}{dt}\int_{-\infty}^{s(t)} p_t^2 dx + \int_{-\infty}^{s(t)} (p_{xt}^2 + k\, p_t^2) dx$$
$$= \Big\{ \frac{\dot s(t)}{2} - \frac{s(t)}{4t} \Big\} p_t^2(s(t)-, t) = -\frac{\sqrt{t}\,\dot\alpha(t)}{2\sqrt{\alpha(t)}} p_t^2(s(t)-, t)$$

by the definition $\alpha(t) = s^2/(4t)$. Using $p_t^2(s(t)-, t) = \int_{-\infty}^{s(t)} 2 p_t p_{xt} dx \le \int_{-\infty}^{s(t)} (\delta p_t^2 + \delta^{-1} p_{xt}^2) dx$ with $\delta = |\frac{t\dot\alpha(t)}{2\sqrt{\alpha(\tau)}}|$ and canceling the integral involving p_{xt}^2 on both sides we then obtain

$$\frac{d}{dt}\int_{-\infty}^{s(t)} p_t^2(x,t) dx \le \frac{t(\dot\alpha(t))^2}{2\alpha(t)} \int_{-\infty}^{s(t)} p_t^2(x,t) dx \quad \text{for all } t > 0.$$

Solving the differential inequality over (ε, t) $(0 < \varepsilon < t)$ then gives

$$\int_{-\infty}^{s(t)} p_t^2(x,t)\, dx \le \exp\left\{ \int_\varepsilon^t \frac{\tau \dot\alpha^2(\tau)}{2\alpha(\tau)}\, d\tau \right\} \int_{-\infty}^{s(\varepsilon)} p_t^2(x,\varepsilon)\, dx. \tag{3.11}$$

We now show that the right-hand side approaches zero as $\varepsilon \searrow 0$.

First, using the assumptions on α we can calculate

$$\exp\left\{ \int_\varepsilon^t \frac{\tau \dot\alpha^2(\tau)}{2\alpha(\tau)}\, d\tau \right\} \le |\log \varepsilon|^{O(1)}. \tag{3.12}$$

Next we estimate $\int_{-\infty}^{s(\varepsilon)} p_t^2(x,\varepsilon) dx$ by using the representation of p_t in Lemma 3.1. First we consider the integral in the representation of p_t. Observe that our assumption on α implies $\dot s(\varepsilon-\tau) < 0$ and $[s(\varepsilon) - s(\varepsilon-\tau) + (k-1)\tau] < 0$ for all small ε and $\tau \in (0, \varepsilon)$. Therefore, for all $x < s(\varepsilon)$, $\Gamma(x - s(\varepsilon - \tau), \tau) \le C \exp\{-\frac{[x-s(\varepsilon)]^2}{4\varepsilon}\} \tau^{-1/2} \exp\{-\frac{[s(\varepsilon)-s(\varepsilon-\tau)]^2}{4\tau}\}$, where C is independent of ε. Hence, with a change of variable $\tau \to \eta$ via $\eta = [s(\varepsilon-\tau) - s(\varepsilon)]/(2\sqrt{\tau})$ $(d\eta = -\frac{\dot s(\varepsilon-\tau) d\tau}{2\sqrt{\tau}} (1 - \frac{s(\varepsilon)-s(\varepsilon-\tau)}{2\tau \dot s(\varepsilon-\tau)})$, we can estimate

$$0 < -\int_0^\varepsilon \Gamma(x - s(\varepsilon-\tau), \tau) \dot s(\varepsilon-\tau)\, d\tau \le C \exp\{-\tfrac{[x-s(\varepsilon)]^2}{4\varepsilon}\} \int_0^{\sqrt{\alpha(\varepsilon)}} \frac{e^{-\eta^2}}{1 - \frac{s(\varepsilon)-s(\varepsilon-\tau)}{2\tau\dot s(\varepsilon-\tau)}}\, d\eta$$
$$\le C \exp\{-\tfrac{[x-s(\varepsilon)]^2}{4\varepsilon}\}$$

since the assumption on α implies that $0 < \frac{s(\varepsilon)-s(\varepsilon-\tau)}{2\tau\dot{s}(\varepsilon-\tau)} < \frac{3}{4}$ for all small ε and $\tau \in (0,\varepsilon)$. It then follows from the representation for p_t in Lemma 3.1 that

$$\int_{-\infty}^{s(\varepsilon)} p_t(x,\varepsilon)^2 dx \le \int_{-\infty}^{s(\varepsilon)} \Big\{ 2\Gamma^2(x,\varepsilon) + C\exp\{-\tfrac{[x-s(\varepsilon)]^2}{2\varepsilon}\}\Big\}$$
$$\le C\Big\{ \varepsilon^{-1/2} \int_{\sqrt{\alpha(\varepsilon)}}^{\infty} e^{-2\eta^2} d\eta + \sqrt{\varepsilon}\Big\}$$

by using $\Gamma(x,\varepsilon) \le C\varepsilon^{-1/2}\exp\{-\frac{x^2}{4\varepsilon}\}$ and a change of variable $x = -2\sqrt{\varepsilon}\eta$. Since $\alpha(\varepsilon) = -\frac{1}{2}\log\varepsilon + O(1)$ for small ε, $\int_{\sqrt{\alpha(\varepsilon)}}^{\infty} e^{-2\eta^2}\, d\eta = [1+O(\alpha(\varepsilon)^{-1})]e^{-2\alpha(\varepsilon)}/(4\sqrt{\alpha(\varepsilon)}) = O(\varepsilon)$. Hence, $\int_{-\infty}^{s(\varepsilon)} p_t^2(x,\varepsilon) = O(\sqrt{\varepsilon})$. Substituting this last estimate and (3.12) into (3.11) and sending $\varepsilon \searrow 0$ we then conclude that $\int_{-\infty}^{s(t)} p_t^2(x,t) = 0$ for any $t > 0$. This implies that $p_t = 0$ for all $x < s(t)$, thereby completing the proof of the theorem. □

4. Asymptotic behavior of $s(t)$. In this section, we study the integrodifferential equation (3.9) for small t.

4.1. Reformulation of the problem. To study (3.9), it is convenient to study the function $s^2(t)/(4t)$ in the $\log(t)$ scale. For this purpose, we change variables from (s,t) to (u,ξ) by

$$\begin{cases} t = \frac{1}{4\pi k^2} e^{2\xi}, \\ s(t) = -2\sqrt{t\, u(\xi)}, \end{cases} \quad \Leftrightarrow \quad \begin{cases} \xi = \log\sqrt{t} + \log\sqrt{4\pi k^2}, \\ u(\xi) = s^2(t)/(4t)\ (=\alpha(t)). \end{cases}$$

To transform the integrodifferential equation (3.9) into the new unknown $u(\xi)$, we bear in mind that we are interested in small t, i.e., large negative ξ. Also, one expects $u(\xi) = -\xi - O(\xi^{-1})$ and $u'(\xi) = -1 + O(\xi^{-2})$. The absence of a constant term in the expansion of $u(\xi)$ is due to the presence of the particularly chosen constant $4\pi k^2$ in the definition of ξ.

In the sequel, $' = \frac{d}{d\xi}$ and $F[u](\xi)$ denotes the value at ξ of the function $F[u]$ when F is an operator.

Now we transform (3.9) into the new variables (u,ξ). Simple substitution yields

$$s(t)\Big\{\dot{s}(t) - \frac{s(t)}{2kt}\,\Gamma(s(t),t)\ \Big\} = u'(\xi) + G(u(\xi),\xi),$$
$$G(u,\xi) := 2u\Big(1 - \exp\{-u - \xi + \tfrac{(k-1)\sqrt{u}e^{\xi}}{2k\sqrt{\pi}} - \tfrac{(k+1)^2 e^{2\xi}}{16k^2\pi}\}\Big). \tag{4.1}$$

To convert the integral in (3.9), we notice that the singularity on the exponent looks like $\xi\ z$, where $z = \frac{(\sqrt{t}-\sqrt{t-\tau})^2}{\tau}$ if we were to suppose $s(t) \sim \sqrt{4t}\xi$. This suggests the use of the change of variable from τ to z via $\tau = \frac{4zt}{(1+z)^2}$. Then

$$z = \tfrac{\tau}{(\sqrt{t}+\sqrt{t-\tau})^2} = \tfrac{(\sqrt{t}-\sqrt{t-\tau})^2}{\tau}, \qquad \eta := \log\sqrt{4\pi k^2(t-\tau)} = \xi + \log\tfrac{1-z}{1+z}.$$

For notational simplicity, we write $u = u(\xi)$, $\hat{u} = u(\eta)$, and $\hat{u}' = u'(\eta)$. Then $s(t) = -2\sqrt{tu}$, $s(t-\tau) = -2\sqrt{(t-\tau)\hat{u}}$, $\dot{s}(t-\tau) = -\frac{\sqrt{\hat{u}}}{\sqrt{t-\tau}}[1 + \hat{u}'/(2\hat{u})]$, and

$$s(t)\int_0^t \Big(\frac{s(t)}{2t} - \frac{s(t)-s(t-\tau)}{\tau}\Big)\,\dot{s}(t-\tau)\,\Gamma(s(t)-s(t-\tau),\tau)\,d\tau$$
$$= \int_0^1 \Big\{\frac{1+z^2}{z}\sqrt{u} - \frac{1-z^2}{z}\sqrt{\hat{u}}\Big\}\Big\{1 + \frac{\hat{u}'}{2\hat{u}}\Big\}\frac{\sqrt{\hat{u}}\sqrt{-\xi}\,e^{\xi z - b}}{\sqrt{\pi z}}dz,$$

where

$$b = \log\sqrt{-\xi/u} + (u+\xi)z + \log[1+z]$$
$$+ \tfrac{1-z}{2}\{u-\hat{u}\} + \tfrac{1-z^2}{4z}\{\sqrt{u}-\sqrt{\hat{u}}\}^2 - \tfrac{(k-1)e^{\xi}}{2k\sqrt{\pi}}\{\sqrt{u} - \tfrac{1-z}{1+z}\sqrt{\hat{u}}\} + \tfrac{(k+1)^2 z e^{2\xi}}{4k^2\pi(1+z)^2}. \tag{4.2}$$

One observes that $\eta - \xi = \log\frac{1-z}{1+z} \sim 2z$ for small z. This suggests that we can approximate $\hat{u} = u(\eta)$ by $u(\xi - 2z)$. Hence, writing $(\frac{1+z^2}{z}\sqrt{u} - \frac{1-z^2}{z}\sqrt{\hat{u}})\sqrt{\hat{u}}$ as $\frac{u-u(\xi-2z)}{2z} + \frac{u(\xi-2z)-\hat{u}}{2z} - \frac{(\sqrt{u}-\sqrt{\hat{u}})^2}{2z} + z(\sqrt{u\hat{u}} + \hat{u})$, we can transform (3.9) (multiplied by $s(t)$) to

$$u'(\xi) + \int_0^1 \frac{u(\xi) - u(\xi-2z)}{2z}\frac{\sqrt{-\xi}e^{\xi z}}{\sqrt{\pi z}}\,dz + G(u(\xi),\xi) = F[u](\xi), \tag{4.3}$$

where $G(u,\xi)$ is as in (4.1) and the operator F is defined by

$$F[u](\xi) = -\int_0^1 \Big\{f_1 + f_2 + \hat{u}' f_3\Big\}\,dz\,, \tag{4.4}$$
$$f_1 = \Big\{\tfrac{u-u(\xi-2z)}{2z}(e^{-b}-1) + \tfrac{u(\xi-2z)-\hat{u}}{2z}e^{-b} - \tfrac{(\sqrt{u}-\sqrt{\hat{u}})^2}{2z}e^{-b}\Big\}\,\tfrac{\sqrt{-\xi}e^{\xi z}}{\sqrt{\pi z}},$$
$$f_2 = z(\sqrt{u\hat{u}} + \hat{u})\,\tfrac{\sqrt{-\xi}e^{\xi z - b}}{\sqrt{\pi z}},$$
$$f_3 = \Big\{\tfrac{1+z^2}{z}\sqrt{\tfrac{u}{\hat{u}}} - \tfrac{1-z^2}{z}\Big\}\tfrac{\sqrt{-\xi}e^{\xi z - b}}{\sqrt{\pi z}}.$$

Now we introduce a linear operator $\mathbf{L} : \phi \to \mathbf{L}[\phi]$ by

$$\mathbf{L}[\phi](\xi) = \int_0^1 \Big(\frac{1}{z}\int_0^z \phi(\xi - 2\zeta)d\zeta\Big)\frac{\sqrt{-\xi}e^{\xi z}}{\sqrt{\pi z}}\,dz\,.$$
$$= \int_0^1 \phi(\xi-2\zeta)\varrho(\xi,\zeta)\,d\zeta, \quad \varrho(\xi,\zeta) := \int_\zeta^1 \frac{\sqrt{-\xi}e^{\xi z}}{z\sqrt{\pi z}}\,dz\,. \tag{4.5}$$

Then equation (3.9) or (4.3) can be written as, for $\xi < 0$ (i.e., $t < 1/(4\pi k^2)$),

$$(\mathbf{I} + \mathbf{L})[u'](\xi) + G(u(\xi),\xi) = F[u](\xi), \tag{4.6}$$

where $\mathbf{I}$ represents the identity operator.

THEOREM 4.1. *Assume that $k > 0$. Then there exists a constant $\xi_0 < 0$ such that* (4.6) *admits a unique positive solution $u(\cdot) \in C^2((-\infty,\xi_0])$ having the asymptotic expansion, as $\xi \to -\infty$,*

$$u(\xi) = u_0(\xi) + O(\xi^{-4}), \quad u_0 := -\xi - \frac{1}{2\xi} + \frac{1}{8\xi^2} + \frac{17}{24\xi^3}. \tag{4.7}$$

4.2. Proof of Theorem 4.1. We use the following Schauder's fixed point theorem:

> *A continuous map $\mathbf{T}$ from a compact and convex subset $\mathbf{D}$ of a Banach space $\mathbf{X}$ to $\mathbf{D}$ possesses at least a fixed point.*

To apply this theorem, we define, for some negative constant ξ_0 to be chosen later,

$$\mathbf{X} = C^1((-\infty,\xi_0])\,, \qquad \|v\|_{\mathbf{X}} := \sup_{\xi\in(-\infty,\xi_0]}\{|v(\xi)| + |v'(\xi)|\}\,,$$
$$\mathbf{D} = \{v \in \mathbf{X} \;|\; |v(\xi)| + |v'(\xi)| + |v''(\xi)| \le |\xi|^{-1} \;\; \forall\,\xi \in (-\infty,\xi_0]\}\,.$$

The uniform decay of derivatives of functions in $\mathbf{D}$ ensures that $\mathbf{D}$ is compact and convex in $\mathbf{X}$. We also need two technical lemmas.

LEMMA 4.2. *Let u_0 be as in* (4.7). *There exists a positive constant C_0, depending only on k, such that for every $\xi_0 \le -2$ and every $u \in \{u_0\} + \mathbf{D}$, the function $F[u](\cdot)$ defined in* (4.4) *is continuous differentiable on $(-\infty, \xi_0]$ and*

$$\left|F[u](\xi) + 1\right| + \left|\frac{d}{d\xi}F[u](\xi)\right| \le C_0|\xi|^{-2} \qquad \forall\, \xi \in (\infty, \xi_0]\ . \tag{4.8}$$

LEMMA 4.3. *Let C_0 be as in the previous lemma. There exist a positive constant $M(C_0)$ and a negative constant $\Xi(C_0) \le -2$ such that if $\xi_0 \le \Xi[C_0]$ and $f \in C^1((-\infty, \xi_0])$ satisfies*

$$|f(\xi) + 1| + |f'(\xi)| \le C_0|\xi|^{-2} \qquad \forall \xi \in (-\infty, \xi_0],$$

then there exists a unique solution $w \in C^2((-\infty, \xi_0])$ to

$$(P1) \quad \begin{cases} (\mathbf{I} + \mathbf{L})[w'](\xi) + G(w(\xi), \xi) = f(\xi) & \forall\, \xi \in (-\infty, \xi_0], \\ \lim_{\xi \to -\infty}(w(\xi) + \xi) = 0\ . \end{cases} \tag{4.9}$$

In addition, the solution satisfies, for u_0 defined as in (4.7),

$$|w(\xi) - u_0(\xi)| + |w'(\xi) - u_0'(\xi)| + |\xi|^{-1}\ |w''(\xi) - u_0''(\xi)| \le M(C_0)|\xi|^{-3} \quad \forall\, \xi \le \xi_0.$$

Proof of Theorem 4.1. We choose $\xi_0 = \min\{\Xi[C_0], -M(C_0)\}$, where $C_0, M(C_0)$ and $\Xi[C_0]$, depending only on k, are as in the previous two lemmas.

For every $v \in \mathbf{D}$, we define $\mathbf{T}[v] = w - u_0$, where w is the solution to (4.9) with $f := F[u_0 + v]$. By Lemma 4.2 and Lemma 4.3, $\mathbf{T}$ is well defined. In addition, from the estimates for w and the definition of ξ_0, $\mathbf{T}[v] \in \mathbf{D}$; i.e., $\mathbf{T}$ maps $\mathbf{D}$ into itself.

Now we show that $\mathbf{T} : \mathbf{D} \subset \mathbf{X} \to \mathbf{X}$ is continuous. For this purpose, let v_j, $j = 1, 2, \ldots, \infty$, be functions in $\mathbf{D}$ such that $v_j \to v_\infty$ in $\mathbf{X} = C^1((-\infty, \xi_0])$ as $j \to \infty$. We want to show that $\mathbf{T}[v_j] \to \mathbf{T}[v_\infty]$ in $\mathbf{X}$. As every member of $\{\mathbf{T}[v_j]\}_{j=1}^{\infty}$ is in $\mathbf{D}$, which is compact in $\mathbf{X}$, any subsequence of $\{\mathbf{T}[v_j]\}$ has a subsubsequence convergent to a limit, say, $\tilde{v}$, in $\mathbf{X}$. Since along that subsubsequence, $F[u_0 + v_j] \to F[u_0 + v_\infty]$, $(\mathbf{T}[v_j])' \to \tilde{v}'$, and $\mathbf{L}[(u_0 + \mathbf{T}[v_j])'\ ] \to \mathbf{L}[(u_0 + \tilde{v})']$ in $C^0((-\infty, \xi_0])$, we conclude by taking the limit of the integrodifferential equation satisfied by $\mathbf{T}[v_j]$ that $u_0 + \tilde{v}$ is a solution to (4.9) with $f = F[u_0 + v_\infty]$. It then follows by uniqueness of (4.9) that $\tilde{v} = \mathbf{T}[v_\infty]$. Consequently, the whole sequence $\{\mathbf{T}[v_j]\}$ converges to $\mathbf{T}[v_\infty]$ in $\mathbf{X}$. Thus, $\mathbf{T}$ is continuous. The Schauder fixed point theorem then shows that $\mathbf{T}$ has at least one fixed point, which, after adding u_0, gives a solution to (4.3).

Finally, by Theorem 3.2, such a solution u is unique. This proves Theorem 4.1. ∎

4.3. Proof of Lemma 4.2. For notational simplicity, in the sequel, $O(f)$ stands for a quantity satisfying $|O(f)| \le C|f|$, where C is a positive constant depending only on k.

Since $u - u_0 \in \mathbf{D}$, $|u'(\xi) + 1| \le 2/|\xi|$, so that, by the mean value theorem and the definition $\eta = \xi + \log\frac{1-z}{1+z}$,

$$u - \hat{u} = u(\xi) - u(\eta) = u'(\xi - \theta)\{\xi - \eta\} = [1 + O(|\xi|^{-1})]\log\tfrac{1-z}{1+z}.$$

It then follows from the Lebesgue dominated convergence theorem that $F \in C^1((-\infty, \xi_0])$. It remains to estimate $F[u]$ and its derivative.

Note that b, defined in (4.2), is uniformly bounded in $z \in (0,1)$ and $\xi \in (-\infty, \xi_0]$. When $z \in [1/2, 1]$, the term $e^{\xi z} < e^{\xi/2}$ is exponential small in terms of $\xi < \xi_0 \le -2$. All other terms are of order $\log[1-z]$, so the total contribution of the integral for $z \in [1/2, 1]$ is exponential small in ξ. Thus, we need only pay attention when $z \in (0, 1/2]$.

First we estimate f_1. That $u - u_0 \in \mathbf{D}$ and $\eta - \xi = \log \frac{1-z}{1+z} = -2z + (z^2)$ implies $b = O(z^2 + z|\xi|^{-1} + \xi^{-2})$ so that $|f_1| = O(z^2 + z|\xi|^{-1} + \xi^{-2}) \frac{\sqrt{-\xi} e^{\xi z}}{\sqrt{\pi z}}$. Note that for every $\xi < 0$ and $i > -1/2$,

$$\int_0^1 z^i \frac{\sqrt{-\xi} e^{\xi z}}{\sqrt{\pi z}}\, dz \le \frac{|\xi|^{-i}}{\sqrt{\pi}} \int_0^\infty z^{i-1/2} e^{-z}\, dz = O(|\xi|^{-i}).$$

It then follows that $\int_0^1 |f_1| dz = O(\xi^{-2})$. A direct differentiation also shows that $\int_0^1 |\frac{d}{d\xi} f_1|\, dz = O(\xi^{-2})$ since $u'' = O(|\xi|^{-1})$.

Similarly, we can show that $\int_0^1 (|\hat{u}' f_3| + |\frac{d}{d\xi} \hat{u}' f_3|) dz = O(\xi^{-2})$.

For the integral involving f_2, we write $\sqrt{u\hat{u}} + \hat{u} = 2u - \frac{1}{2}(\sqrt{u} - \sqrt{\hat{u}})^2 - \frac{3}{2}(u - \hat{u}) = -2\xi + O(|\xi|^{-1} + |\xi|^{-1} \log^2 \frac{1+z}{1-z} + \log \frac{1+z}{1-z})$. Hence, $\int_0^1 f_2\, dz = \int_0^1 \frac{-2z\xi\sqrt{-\xi} e^{\xi z}}{\sqrt{\pi z}}\, dz + O(|\xi|^{-2}) = -1 + O(\xi|^{-2})$. A differentiation also gives $|\int_0^1 \frac{d}{d\xi} f_2\, dz| = O(\xi^{-2})$. This completes the proof. □

Remark 4.1. The integral in (3.10) is of size $|\xi|/s(t)$ if $\lambda \neq 1$. When $\lambda = 1$, this integral is of size $(\mathbf{L}[u'] - F[u])/s(t) = O(\xi^{-2})/s(t)$ since $u' = -1 + O(\xi^{-2})$ and $\mathbf{L}[u'] = -1 + O(\xi^{-2})$. Hence, the ratio of the integral and the first term on the right-hand side of (3.9) is of size $O(\xi^{-3})$; see Remark 3.1.

4.4. Idea for the proof of Lemma 4.3. To complete the proof of Theorem 4.1, it remains to prove Lemma 4.3, which will be done in the next two sections. Here we provide the main idea of the proof.

We first investigate in section 5 the linear operator $\mathbf{L}$. In particular, we show that the inverse operator $(\mathbf{I} + \mathbf{L})^{-1}$ is a bounded operator from C^0 to C^0. Also, we show that $\mathbf{L}[\phi]$ is always $1/2$ more differentiable than ϕ.

Then in section 6, we study, for any large integer j, an initial value problem $(\mathrm{P1})_j$ of the integrodifferential equation in (P1) in the interval $[-j, \xi_0]$ with "initial value" $w = u_0$ in $(-\infty, -j]$. The existence of a solution follows from a standard Picard iteration technique.

To obtain certain desired behavior of the solution of $(\mathrm{P1})_j$, we find that $(\mathrm{P1})_j$, as well as (P1), satisfy a comparison principle: larger initial data and larger source term produce larger solutions. Because of the large positive derivative $\frac{\partial}{\partial u} G(u_0, \xi) \sim 2|\xi|$, this comparison principle allows us to construct sub and super solutions of the form $u_0 \pm M|\xi|^{-3}$ to sandwich the solution to $(\mathrm{P1})_j$. Thus, we can take the limit $j \to \infty$ to obtain a solution to (P1) with the desired asymptotic behavior. Uniqueness of solutions to (P1) also follows from the comparison principle.

5. The operator L. In this section we study the operator $\mathbf{L}$ defined in (4.5).

LEMMA 5.1. *There exists a universal positive constant c_0 such that for every $\xi_0 \le -2$,*

$$\begin{aligned} c_0 \|\phi\|_{C^0(-\infty,\xi_0])} &\le \|(\mathbf{I} + \mathbf{L})[\phi]\|_{C^0(-\infty,\xi_0])} \\ &\le 2\|\phi\|_{C^0((-\infty,\xi_0])} \quad \forall\, \phi \in C^0((-\infty, \xi_0])\,. \end{aligned} \tag{5.1}$$

Consequently, $\mathbf{I}+\mathbf{L}$ *admits a bounded inverse* $(\mathbf{I}+\mathbf{L})^{-1}$ *from* $C^0((-\infty,\xi_0])$ *to itself and*

$$\tfrac{1}{2} \le \| \, (\mathbf{I}+\mathbf{L})^{-1} \, \|_{C^0((-\infty,\xi_0]\to C^0((-\infty,\xi_0])} \le \tfrac{1}{c_0}. \tag{5.2}$$

Proof. The second inequality in (5.1) follows easily from the first definition of $\mathbf{L}$ (one line above (4.5)).

To prove the first inequality, we make a scaling change a change of variables $z \to Z/|\xi|$ and $\zeta \to \theta/|\xi|$. Then $\mathbf{L}[\phi]$ in (4.5) can be written as

$$\mathbf{L}[\phi](\xi) = \int_0^{-\xi} \phi(\xi + 2\theta/\xi)\varrho_1(\xi,\theta)\,d\theta, \quad \varrho_1(\xi,\theta) = \int_\theta^{-\xi} \frac{e^{-Z}}{Z\sqrt{\pi Z}}\,dZ.$$

To prove the first inequality in (5.1), we notice that $\mathbf{L}$ is linear, so that we can without loss of generality assume $\|\phi\|_{C^0} = 1 = \sup_{\xi<\xi_0}\phi(\xi)$.

Let $j \ge 2$ be any integer, and let $\xi_j \in (-\infty,\xi_0]$ be a point such that $\phi(\xi_j) \ge 1 - 1/j$. Since $\int_0^{-\xi_j} \varrho_1(\xi_j,\theta) < 1$ for any $m \in (0,1/2)$,

$$\begin{aligned}
&(\mathbf{I}+\mathbf{L})[\phi](\xi_j) \\
&\quad \ge \int_0^{-\xi_j} \Big\{1 + \phi(\xi_j + 2\theta/\xi_j)\Big\}\varrho_1(\xi_j,\theta)\,d\theta - \frac{1}{j} \ge m\varrho_1(\xi_j,1)\{1 - A(\xi_j,m)\} - \frac{1}{j},
\end{aligned}$$

where $A(\xi,m) = \text{measure}\{\theta \in [0,1] \;\big|\; \phi(\xi + 2\theta/\xi) + 1 < m\}$. Suppose $A(\xi_j,m) > 0$. Then there is a unique $\hat{\xi}_j \in (\xi_j + 2/\xi_j, \xi_j)$ such that $\phi(\xi) + 1 > m$ in $(\hat{\xi}_j,\xi_j]$ and $\phi(\hat{\xi}_j) + 1 = m$. Since $\hat{\xi}_j + 2/\hat{\xi}_j < \xi_j + 2/\xi_j$,

$$\begin{aligned}
A(\xi_j,m) &= \frac{\xi}{2}\text{measure}\{z \in [\xi_j + 2/\xi_j, \xi_j] \mid \phi(z) < m-1\} \\
&\le \frac{\xi}{2}\text{measure}\{z \in [\hat{\xi}_j + 2/\xi_j, \hat{\xi}_j] \mid \phi(z) < m-1\} = \frac{\xi}{\hat{\xi}} A(\hat{\xi}_j,m) \leqslant A(\hat{\xi}_j,m).
\end{aligned}$$

Hence

$$\begin{aligned}
-(\mathbf{I}+\mathbf{L})[\phi](\hat{\xi}_j) &= 1 - m - \mathbf{L}[\phi](\hat{\xi}_j) \ge -m + \int_0^{-\hat{\xi}_j} \{1 - \phi(\hat{\xi}_j + 2\theta/\hat{\xi}_j)\}\varrho_1(\hat{\xi}_j,\theta)\,d\theta \\
&\ge -m + (2-m)A(\hat{\xi}_j,m)\varrho_1(\hat{\xi}_j,1) \ge -m + (2-m)A(\xi_j,m)\varrho_1(\xi_j,1) \\
&\ge \varrho(\xi_j,1)[-m + (1-m)A(\xi_j,m)].
\end{aligned}$$

It then follows that, regardless of the size of $A(\xi_j,m)$,

$$\begin{aligned}
\|(\mathbf{I}+\mathbf{L})[\phi]\|_{C^0} + \tfrac{1}{j} &\ge \varrho_1(\xi_j,1)\max\Big\{m[1 - A(\xi_j,m)], -m + (2-m)A(\xi_j,m)\Big\} \\
&\ge \varrho_1(-2,1)m(1-m).
\end{aligned}$$

Sending $j \to \infty$ and taking $m = 1/2$ we then conclude that (5.1) holds with $c_0 = \varrho_1(-2,1)/4$.

The invertibility of $\mathbf{I}+\mathbf{L}$ and the estimate (5.2) follow from (5.1) and the Hahn–Banach theorem. ∎

Next, we show that $\mathbf{L}[\phi]$ is 1/2 more differentiable than ϕ.

LEMMA 5.2. *For every $\beta \in [0,1]$, there exists a positive constant $C(\beta)$ such that*

$$\|\phi\|_{C^0([a-2,b])} + C(\beta)\sqrt{|a|}\ [\phi]_{\beta,[a-2,b]} \ \geq \ \begin{cases} [\ \mathbf{L}[\phi]\ ]_{\beta+1/2,[a,b]} & \text{if } \beta \in [0,1/2), \\ [\mathbf{L}[\phi]\ ]^*_{1,[a,b]} & \text{if } \beta = 1/2, \\ [(\mathbf{L}[\phi])'\ ]_{\beta-1/2,[a,b]} & \text{if } \beta \in (1/2,1], \end{cases} \tag{5.3}$$

where $[\psi]^*_{1,[a,b]} := \sup_{a\leq\xi_2<\xi_1\leq b} \frac{|\psi(\xi_2)-\psi(\xi_1)|}{|\xi_2-\xi_1|\ \max\{1,|\log(\xi_1-\xi_2)|\}}$ *and*

$$[\psi]_{\beta,[c,d]} = \sup_{c\leq\xi_2<\xi_1\leq d} \frac{|\psi(\xi_2)-\psi(\xi_1)|}{|\xi_2-\xi_1|^\beta} \quad \forall \beta \in [0,1]. \tag{5.4}$$

We remark that $\mathbf{L}[\phi](\xi)$ depends only on values of ϕ in $[\xi-2,\xi]$. Also the factor $\sqrt{|a|}$ on the left-hand side of (5.3) is necessary since $\lim_{\xi\to\infty}\{\mathbf{L}[\phi](\xi)-\phi(\xi)\}=0$ for any bounded and uniformly continuous function ϕ.

Proof. Let ξ_1 and ξ_2 be any numbers such that $a \leq \xi_2 < \xi_1 \leq b$. Set $h = \xi_1 - \xi_2$. Since $\|\mathbf{L}\|_{C^0\to C^0} \leq 1$, we need only consider the case $h < 1/4$. Also, $\mathbf{L}[\mathbf{1}](\xi) = \int_0^{-\xi} \varrho(\xi,\theta)d\theta = \int_0^{-\xi} \frac{e^{-z}}{\sqrt{\pi z}}\,dz$, so that $\|\mathbf{L}[\mathbf{1}]\|_{C^1} \leq 1$. Hence, by considering the function $\phi(\xi) - \phi(\xi_2)\mathbf{1}$ if necessary, we can assume that $\phi(\xi_2) = 0$.

First, we consider the case $\beta \in [0,1/2]$. Using (4.5) and changing of variable $\zeta \to \zeta + h/2$ for the integral for $\mathbf{L}[\phi](\xi_1)$ we have

$$\begin{aligned} \mathbf{L}[\phi](\xi_2) - \mathbf{L}[\phi](\xi_1) = &\int_0^{1-h/2} \phi(\xi_2-2\zeta)\Big\{\varrho(\xi_2,\zeta) - \varrho(\xi_1,\zeta+h/2)\Big\}\,d\zeta \\ &+ \int_{1-h/2}^1 \phi(\xi_2-2\zeta)\varrho(\xi_2,\zeta)\,d\zeta - \int_0^{h/2} \phi(\xi_1-2\zeta)\varrho(\xi_1,\zeta)\,d\zeta\ . \end{aligned}$$

Now $\phi(\xi_2)=0$ implies $|\phi(\xi_2-2\zeta)| \leq [\phi]_\beta |2\zeta|^\beta$ for all $\zeta \in [0,1]$ and $|\phi(\xi_1-2\zeta)| \leq h^\beta [\phi]_\beta$ for all $\zeta \in [0,h/2]$. Hence, $|\mathbf{L}[\phi](\xi_2) - \mathbf{L}[\phi](\xi_1)|$ is bounded by

$$\begin{aligned} [\phi]_\beta\ \Bigg\{ &\int_0^{1-h/2} (2\zeta)^\beta \Big|\varrho(\xi_1-h,\zeta) - \varrho(\xi_1,\zeta+h/2)\Big|\,d\zeta \\ &+ \int_{1-h/2}^1 \varrho(\xi_2,\zeta)\,d\zeta + \int_0^{h/2} h^\beta \varrho(\xi_1,\zeta)\,d\zeta \Bigg\}. \end{aligned} \tag{5.5}$$

Note that $\varrho(\xi,\zeta) < \sqrt{|\xi|/\pi}\int_\zeta^1 z^{-3/2}dz \leq 2\sqrt{|\xi|}\zeta^{-1/2}$. The last two integrals are bounded by $O(1)\sqrt{|\xi_2|}h^{\beta+1/2}$ when $\beta \in [0,1/2]$. Also

$$\begin{aligned} |\varrho(\xi_1-h,\zeta) - \varrho(\xi_1,\zeta+h/2)| \leq &\int_{\zeta+h/2}^1 \frac{|\sqrt{|\xi_1-h|}e^{(\xi_1-h)z} - \sqrt{\xi_1}e^{\xi_1 z}|}{\sqrt{\pi z^3}}dz \\ &+ \int_\zeta^{\zeta+h/2} \frac{\sqrt{|\xi_1-h|}e^{(\xi_1-h)z}}{\sqrt{\pi z^3}}dz \end{aligned}$$

The first integral is bounded by $O(1)\sqrt{|\xi_2|}h\zeta^{-1/2}$ whereas the second integral is bounded by

$$O(1)\sqrt{|\xi_2|}\Big(\frac{1}{\sqrt{\zeta+h/2}} - \frac{1}{\sqrt{\zeta}}\Big) = \frac{O(1)\sqrt{|\xi_2|}\ \ h/2}{\sqrt{\zeta}\sqrt{\zeta+h/2}(\sqrt{\zeta+h/2}+\sqrt{\zeta})} = \frac{O(1)\sqrt{|\xi_2|}\,h}{\zeta\sqrt{\zeta+h/2}}.$$

Finally, note that

$$\int_0^1 \frac{\zeta^\beta h}{\zeta\sqrt{\zeta+h/2}}d\zeta = h^{\beta+1/2}\int_0^{1/h}\frac{z^{\beta-1}}{\sqrt{z+1/2}}dz = \begin{cases} O(\beta)h^{\beta+1/2} & \text{if } \beta\in(0,1/2),\\ O(1)h|\log h| & \text{if } \beta = 1/2.\end{cases}$$

Therefore, the quantity in (5.5) is bounded by $C(\beta)\sqrt{|\xi_2|}[\phi]_\beta h^{\beta+1/2}$ if $\beta\in[0,1/2)$ and by $C(\beta)\sqrt{|\xi_2|}[\phi]_\beta h\,|\log h|$ if $\beta = 1/2$. This proves (5.3) for the case $\beta\in[0,1/2]$.

Next we consider $\beta\in(1/2,1]$. Set $\Phi(\xi) = \int_{\xi_2}^{\xi}\phi(\eta)\,d\eta$. Then

$$\mathbf{L}[\phi] = \int_0^1 \frac{\Phi(\xi)-\Phi(\xi-2z)}{2z}\frac{\sqrt{-\xi}e^{\xi z}}{\sqrt{\pi z}},$$

and

$$\frac{d}{d\xi}\mathbf{L}[\phi](\xi) = \int_0^1 \frac{\phi(\xi)-\phi(\xi-2z)}{2z}\frac{\sqrt{-\xi}e^{\xi z}}{\sqrt{\pi z}}\,dz + \frac{1}{2\xi}\int_0^1 \frac{\Phi(\xi)-\Phi(\xi-2z)}{2z}\frac{(1+2\xi z)\sqrt{-\xi}e^{\xi z}}{\sqrt{\pi z}}\,dz =: \mathrm{I}(\xi)+\mathrm{II}(\xi)\,.$$

Note that $\frac{d}{d\xi}\mathrm{II}(\xi)$ is bounded by $[\phi]_\beta$ since $\Phi' = \phi$ and $|\phi(\xi)-\phi(\xi-2z)|\le[\phi]_\beta(2z)^\beta$ and $\beta>1/2$. It remains to consider $I(\cdot)$. We write

$$I(\xi_1)-I(\xi_2) = \int_0^1 \frac{\phi(\xi_1)-\phi(\xi_1-2z)-\phi(\xi_2)+\phi(\xi_2-2z)}{2z}\frac{\sqrt{-\xi_1}e^{\xi_1 z}}{\sqrt{\pi z}}\,dz + \int_0^1 \frac{\phi(\xi_2)-\phi(\xi_2-2z))}{2z}\,\frac{\sqrt{-\xi_1}e^{\xi_1 z}-\sqrt{-\xi_2}e^{\xi_2 z}}{\sqrt{\pi z}}\,dz.$$

Since $|\phi(\xi_2)-\phi(\xi_2-2z)|\le[\phi]_\beta(2z)^\beta$ with $\beta>1/2$, the second integral is bounded by $h[\phi]_\beta|\xi_1|^{-\beta}\int_0^\infty(1+Z)Z^{\beta-3/2}e^{-Z}\,dZ \le Ch[\phi]_\beta|\xi_1|^{-\beta}$. To estimate the first integral, we use

$$|\phi(\xi_1)-\phi(\xi_1-2z)-\phi(\xi_2)+\phi(\xi_2-2z)|\le 2[\phi]_\beta\min\{h^\beta,(2z)^\beta\}$$

so that the first integral is bounded by

$$2[\phi]_\beta\int_0^\infty \frac{\min\{(2z)^\beta,h^\beta\}}{2z}\frac{\sqrt{-\xi_2}e^{\xi_2 z}}{\sqrt{\pi z}}\,dz \le C\sqrt{-\xi_2}[\phi]_\beta h^{\beta-1/2}.$$

In summary, we have $|\frac{d}{d\xi}\mathbf{L}[\phi](\xi_1)-\frac{d}{d\xi}\mathbf{L}[\phi](\xi_2)|\le C[\phi]_\beta\sqrt{-\xi_2}h^{\beta-1/2}$. This completes the proof. ∎

Remark 5.1. With the same technique, one can show that for any positive non-integer β, $\mathbf{L}[\phi]\in C^\beta$ if $\phi\in C^{\beta-1/2}$. Also we can show that $F[u]$ defined in (4.4) is always 1/2 more differentiable that u', assuming that $u\sim-\xi+o(1/\xi)$. We omit the details.

6. Proof of Lemma 4.3.

6.1. The truncated problem. We first study problem (P1) in a finite interval $[-j,\xi_0]$:

$$(\mathrm{P1})_j \qquad \begin{cases} (\mathbf{I}+\mathbf{L})[w'](\xi)+G(w(\xi),\xi) = f(\xi) & \forall\,\xi\in(-j,\xi_0],\\ w(\xi) = u_0(\xi) & \forall\xi\in(-\infty,-j]\,.\end{cases} \tag{6.1}$$

Since we aim for positive solutions, we extend $G(w,\xi)$ for negative w by 0.

LEMMA 6.1. *Let $-j < \xi_0 \le -2$, $f(\cdot)$ be any continuous function on $[-j, \xi_0]$, and u_0 be any differentiable function on $(-\infty, \xi_0]$. Then $(\mathrm{P1})_j$ admits a unique solution $w \in C^1([-j+, \xi_0])$.*

Proof. We first note that $\mathbf{L}[w'] = \int_0^1 \frac{w(\xi)-w(\xi-2z)}{2z} \frac{\sqrt{-\xi}e^{\xi z}}{\sqrt{\pi z}}\, dz$, so that $\|\mathbf{L}[w']\|_{C^0([-j,\xi])}$ $\le C_j [w]_{3/4,[-j-2,\xi]}$ for all $\xi \in [-j, \xi_0]$, where $C_j = j^{1/4} \int_0^\infty Z^{-3/4} e^{-Z} dZ$ and $[\phi]_{\beta,[a,b]}$ is as in (5.4). We remark that if $\phi(a) = 0$, then $[\phi]_{0,[a,b]} \ge \|\phi\|_{C^0([a,b])} := \sup_{\xi\in[a,b]} |\phi(\xi)|$.

Next we note that the function $G(w, \xi)$, after extension by 0 for negative w, is bounded, uniformly in $\xi \in [-j, \xi_0]$ and $u \in [-M, M]$ for every $M > 0$. Also $L_j = \sup_{\xi\in[-j,0], w\ge 0} |G_w(w, \xi)| < \infty$.

We now use the Picard iteration to establish the existence and uniqueness. Starting with $w_0 \equiv u_0$, we successively define w_i, $i = 1, 2, \ldots$, by $w_i = u_0$ in $(-\infty, -j]$ and

$$w_i(\xi) = u_0(-j) + \int_{-j}^{\xi} \Big\{ f(\hat\xi) - G(w_{i-1}(\hat\xi), \hat\xi) - \mathbf{L}[w'_{i-1}](\hat\xi) \Big\} d\hat\xi, \quad \xi \in [-j, \xi_0].$$

Taking the difference of the equations (and also their derivative) for w_{i+1} and w_i we obtain for all $i \ge 1$ and all $\xi \in (-j, \xi_0]$

$$[w_{i+1} - w_i]_{0,[-j,\xi]} \le L \int_{-j}^{\xi} \Big\{ [w_i - w_{i-1}]_{0,[-j,\hat\xi]} + [w_i - w_{i-1}]_{3/4,[-j,\hat\xi]} \Big\} d\hat\xi,$$
$$[w_{i+1} - w_i]_{1,[-j,\xi]} \le L \Big\{ [w_i - w_{i-1}]_{0,[-j,\xi]} + [w_i - w_{i-1}]_{3/4,[-j,\xi]} \Big\},$$

where $L = \max\{C_j, L_j\}$. Since $[\phi]_{3/4,[a,b]} \le ([\phi]_{1,[a,b]})^{3/4} ([\phi]_{0,[a,b]})^{1/4}$ for any ϕ and any interval $[a, b]$, mathematical induction then gives for $\beta = 0, 3/4, 1$ and all $i \ge 2$

$$[w_{i+1} - w_i]_{\beta,[-j,\xi]} \le \frac{M^i (\xi + j)^{i/4}}{(i\,!)^{1/4}} \Big(\frac{i}{4(\xi + j)} \Big)^{\beta} \qquad \forall \xi \in (-j, \xi_0]$$

for some sufficiently large constant M depending only on j and u_0. Following the rest steps of the Picard iteration method (see, for example, [9]), we then complete the proof. □

To take the limit $j \to \infty$ for solutions of $(P1)_j$, we need certain estimates. This will be done via a comparison principle and construction of sub and super solutions.

6.2. The comparison principle. For convenience, we introduce a nonlinear operator $\mathbf{N}$ defined by

$$\mathbf{N}[w](\xi) = (\mathbf{I} + \mathbf{L})[w'](\xi) + G(w(\xi), \xi)\,. \tag{6.2}$$

LEMMA 6.2 (comparison principle). *Let $\xi_0 \le -2$ be any number and w_1 and w_2 be two (piecewise) continuous differentiable functions on $(-\infty, \xi_0]$ satisfying the following:*

(i) $\min\{w_1, w_2\} \ge 3/2$ *in* $(-\infty, \xi_0]$;

(ii) *there exists* $j \in \{\infty\} \cup (-\xi_0, \infty)$ *such that*

$$\mathbf{N}[w_1](\xi) \ge \mathbf{N}[w_2](\xi) \quad \forall\, \xi \in (-j, \xi_0]$$

and $\liminf_{\xi\to-\infty}\{w_1(\xi) - w_2(\xi)\} \ge 0$ *if* $j = \infty$, *and* $w_1(\xi) \ge w_2(\xi)$ *on* $(-\infty, -j]$ *if* $j < \infty$.

Then $w_1(\xi) \ge w_2(\xi)$ *for all* $\xi \in (-\infty, \xi_0]$.

Proof. Let $\varepsilon \in (0, 1/4)$ be any constant. We define

$$\xi_\varepsilon = \sup\{\xi \le \xi_0 \mid w_1 + \varepsilon > w_2 \ \text{ in } \ (-\infty, \xi)\}.$$

The "initial condition" in assumption (ii) implies that ξ_ε is well defined and $\xi_\varepsilon > -j$. We claim that $\xi_\varepsilon = \xi_0$. In fact, if this is not true, then $w_2 < w_1 + \varepsilon$ in $(-\infty, \xi_\varepsilon)$, and at $\xi = \xi_\varepsilon$, $w_2 = w_1 + \varepsilon$ and $w_2' \ge w_1'$. In addition, $G(w_2(\xi_\varepsilon), \xi_\varepsilon) = G(w_1(\xi_\varepsilon) + \varepsilon, \xi_\varepsilon) > G(w_1(\xi_\varepsilon), \xi_\varepsilon)$ since $w_1(\xi_\varepsilon) = -\varepsilon + \max\{w_1(\xi_\varepsilon), w_2(\xi_\varepsilon)\} > 5/4$ and $G_w(w, \xi) > 0$ when $w > 5/4$. Hence

$$\begin{aligned}
&\mathbf{N}[w_1](\xi_\varepsilon) \\
&\quad = w_1'(\xi_\varepsilon) + \int_0^1 \frac{\{w_1(\xi_\varepsilon) + \varepsilon\} - \{w_1(\xi_\varepsilon - 2z) + \varepsilon\}}{2z} \frac{\sqrt{-\xi_\varepsilon} e^{\xi_\varepsilon z}}{\sqrt{\pi z}} dz + G(w_1(\xi_\varepsilon), \xi_\varepsilon) \\
&\quad < w_2'(\xi_\varepsilon) + \int_0^1 \frac{w_2(\xi_\varepsilon) - w_2(\xi_\varepsilon - 2z)}{2z} \frac{\sqrt{-\xi_\varepsilon} e^{\xi_\varepsilon z}}{\sqrt{\pi z}}\, dz + G(w_2(\xi_\varepsilon), \xi_\varepsilon) = \mathbf{N}[w_2](\xi_\varepsilon),
\end{aligned}$$

which contradicts the assumption that $\mathbf{N}[w_1] \ge \mathbf{N}[w_2]$ in $(-j, \xi_0]$. This contradiction shows that $\xi_\varepsilon = \xi_0$; namely, $w_1(\xi) + \varepsilon \ge w_2(\xi)$ in $(-\infty, \xi_0]$. Sending ε to 0 we then obtain the assertion of the lemma. □

One notices that the condition (i) is used only to ensure that $G_w(w, \xi) > 0$ for any $w \ge \max\{w_1, w_2\}$.

For later applications, we also provide the following maximum principle.

LEMMA 6.3 (maximum principle). *Let $L(\cdot)$ be a continuous and uniformly positive function on $(-\infty, \xi_0]$ and W be a Lipschitz continuous functions on $(-\infty, \xi_0]$ satisfying*

$$(\mathbf{I} + \mathbf{L})[W'](\xi) + L(\xi) W(\xi) \ge 0 \quad \forall \xi \in (-\infty, \xi_0], \qquad \inf_{\xi \le \xi_0} W(\xi) > -\infty.$$

Then $W \ge 0$ on $(-\infty, \xi_0]$.

The proof follows closely the proof for the previous lemma and is omitted.

6.3. Estimates for solutions of $(\mathbf{P1})_j$. Let C_0 be the constant in Lemma 4.2.

LEMMA 6.4. *There exists a large negative constant $\Xi_1(C_0)$ such that if $\xi_0 \le \Xi_1(C_0)$ and $f(\cdot) \in C^0((-\infty, \xi_0])$ satisfying*

$$|f(\xi) + 1| \le C_0 \xi^{-2}, \tag{6.3}$$

then the unique solution w to $(\mathrm{P1})_j$ with $u_0 = -\xi - \frac{1}{2}\xi^{-1} + \frac{3}{8}\xi^{-2} + \frac{17}{24}\xi^{-3}$ satisfies

$$|w(\xi) - u_0| \le (1 + \tfrac{1}{2} C_0) |\xi|^{-3} \qquad \forall \xi \in (-\infty, \xi_0], \tag{6.4}$$

$$|w'(\xi) - u_0'| \le \frac{2C_0 + 2}{c_0} \xi^{-2} \qquad \forall \xi \in (-\infty, \xi_0]. \tag{6.5}$$

Proof. Let $w_\pm = u_0 \mp M\xi^{-3}$, where $M > 0$ is to be determined. Then $\frac{w_\pm(\xi) - w_\pm(\xi - 2z)}{2z}$ $= w_\pm'(\xi) + z\, O(|\xi|^{-3})$. It then follows that $\mathbf{L}[w_\pm'] = \int_0^1 \frac{w_\pm(\xi) - w_\pm(\xi - 2z)}{2z} \frac{\sqrt{-\xi} e^{\xi z}}{\sqrt{\pi z}}\, dz =$ $w_\pm'(\xi) + O(|\xi|^{-4})$. Consequently,

$$\begin{aligned}
&\mathbf{N}[w_\pm] - f(\xi) = (\mathbf{I} + \mathbf{L})[w_\pm'] + G(w_\pm, \xi) - f(\xi) \\
&= 2w_\pm'(\xi) + 2w_\pm(1 - e^{-w_\pm - \xi}) - f(\xi) + O(|\xi|^{-4}) \\
&= -1 - f(\xi) \pm 2M\xi^{-2} + O(|\xi|^{-3}).
\end{aligned}$$

Hence, taking $M = C_0/2 + 1$ and $\Xi_1[C_0]$ large enough, we have $\pm\mathbf{N}[w_\pm] > 0$ in $(-\infty, \xi_0]$. The comparison principle then gives $w_- \le w \le w_+$ in $(-\infty, \xi_0]$ and therefore also (6.4). In addition,

$$(\mathbf{I}+\mathbf{L})[w' - u_0'](\xi) = f(\xi) - G(w(\xi), \xi) - 2u_0' + O(|\xi|^{-4}) = O(\xi^{-2}).$$

The estimate (6.5) then follows from the boundedness of $\|(\mathbf{I}+\mathbf{L})^{-1}\|_{C^0 \to C^0}$. □

Now we are ready to prove Lemma 4.3.

6.4. Proof of Lemma 4.3. Let C_0 and $\Xi_1(C_0)$ be as in Lemmas 4.2 and 6.4, respectively. Let $\xi_0 \le \Xi_1(C_0]$.

For each integer $j > |\xi_0|$, let w_j be the solution to $(P1)_j$. From Lemma 6.4, we know that we can extract a subsequence from $\{w_j\}_{j>|\xi_0|}$, which converges to w in $C^\beta((-\infty, \xi_0])$ for any $\beta \in (0,1)$ and some Lipschitz continuous function w satisfying the estimates (6.4) and (6.5). Consequently, $G(w_j(\cdot), \cdot) \to G(w(\cdot), \cdot)$ in $C^0((-\infty, \xi_0])$. Also, from the expression $\mathbf{L}[w_j'](\xi) = \int_0^1 \frac{w_j(\xi) - w_j(\xi - 2z)}{2z} \frac{\sqrt{-\xi} e^{\xi z}}{\sqrt{\pi z}}\, dz$ we see that $\mathbf{L}[w_j'] \to \mathbf{L}[w']$ uniformly in $(-\infty, \xi_0]$. Hence, from $w_j' = f - \mathbf{L}[w_j'] - G(w_j, \cdot)$, we conclude that $w_j(\cdot)' \to w'(\cdot)$ in $C^0((-\infty, \xi_0])$ and w is a $C^1((-\infty, \xi_0])$ solution to (P1). Uniqueness of the solution to (P1) follows from the comparison principle, i.e., Lemma 6.2 with $j = \infty$.

It remains to show that $w \in C^2$ and to estimate w'' and w' (better than (6.5)).

First, $f(\cdot) + G(w(\cdot), \cdot)$ is differentiable. Also, that $w' \in C^0$ and Lemma 5.2 implies that $\mathbf{L}[w'] \in C^{1/2}$ so that $w' = f - G(w, \cdot) - \mathbf{L}[w'] \in C^{1/2}$. Repeating this process, we then conclude that $w \in C^2$.

Once we know that w is C^2, we can differentiate the equation for w to obtain

$$(\mathbf{I}+\mathbf{L})[w''] + L(\xi)w' = f_\xi - G_\xi(w, \xi) - \psi,$$

where $L(\xi) = G_w(w(\xi), \xi))$ and $\psi = \int_0^1 \frac{w(\xi) - w(\xi - 2z)}{2z} \frac{\sqrt{-\xi} e^{\xi z}}{\sqrt{\pi z}} \left\{ \frac{1}{\xi} + z \right\} dz = O(\xi^{-2})$ since $w' = -1 + O(|\xi|^{-1})$.

Using the estimate (6.4) and the definition of G in (4.1) we see that $L(\xi) = G_w(w, \xi) = -2\xi - 1 - 2\xi^{-1} + O(|\xi|^{-2})$ and $G_\xi = -2\xi - 1 - \xi^{-1} + O(\xi^{-2})$. Since $(\mathbf{I}+\mathbf{L})[u_0''] = O(|\xi|^{-3})$ we have $(\mathbf{I}+\mathbf{L})[(w - u_0)''] + L(\xi)(w - u_0)' = f_\xi - G_\xi - \psi - L(\xi)u_0' + O(|\xi|^{-3}) = O(\xi^{-2})$ by the assumption on f_ξ.

Now we can use the maximum principle (Lemma 6.3) to estimate $(u - u_0)'$ and $(u - u_0)''$. For large constant M to be determined, set $W_\pm = -M\xi^{-3} \pm (u - u_0)'$. Then $(\mathbf{I}+\mathbf{L})[W'] + L(\xi)W = 2M\xi^{-2} + O(1)|\xi|^{-2} + O(|\xi|^{-3})$, where $O(1)$ depends only on C_0. Hence, taking M large (depending only on C_0) such that $M + O(1) = 1$ and then taking $\Xi(C_0)$ large enough negative, we have, when $\xi_0 \le \Xi(C_0)$, that $W_\pm > 0$ in $(-\infty, \xi_0]$, i.e., $|(w - u_0)'| \le M|\xi|^{-3}$. (Note the improvement over (6.5).) In addition, from $(\mathbf{I}-\mathbf{L})[(w - u_0)''] = O(|\xi|^{-2}) - L(w - u_0)' = O(|\xi|^{-2})$ and the boundedness of $(\mathbf{I}+\mathbf{L})^{-1}$ we conclude that $(w - u_0)'' = O(\xi^{-2})$. This completes the proof of Lemma 4.3 and also of Theorem 4.1. □

Remark 6.1. Using the same argument as in problem $(P1)_j$ (the Picard iteration), one can extend the solution u of (4.3) to $\xi \in (-\infty, \infty)$.

Remark 6.2. With the preceding argument for the C^2 differentiability of w, one can actually show that solution u to (4.3) is C^∞. To do this, one writes the equation as

$$u' + \mathbf{L}[u'] + \mathbf{L}_1^u[u'] = (F[u] + \mathbf{L}_1^u[u']) - G(u, \cdot),$$

where $\mathbf{L}_1^u[\phi'] = \int_0^1 \phi'(\eta) f_3\, dz$ is the part of $F[u]$ involving the integral of $u'(\eta)f_3$. Then the right-hand side of the equation is always 1/2 more differentiable than that of u'. As the operator norm from $C^0((\infty,\xi])$ to $C^0((-\infty,\xi])$ of $\mathbf{L}_1^u$ is of order $|\xi|^{-1}$, one sees that $(\mathbf{I}+\mathbf{L}+\mathbf{L}_1^u)^{-1}$ is bounded from C^0 to C^0. It then follows from a boot strap argument that $u \in C^\infty$. See also Remark 2.2.

6.5. Higher order expansions.

THEOREM 6.5. *There exist constants $c_1, c_2, c_3, \ldots$ such that as $\xi \to -\infty$, the unique solution to* (P1) *has the asymptotic expansion $u \sim -\xi + \sum_{i=1}^\infty c_i \xi^{-i}$; in particular,* (1.2) *holds (with $\alpha(t)$ replaced by $u(\xi)$).*

Proof.

Construction of the asymptotic expansion. First, we can replace $G(u,\xi)$ defined in (4.1) by $2u(1-e^{-u-\xi})$ since the terms dropped are of order $O(|\xi|e^\xi)$. Similarly, we can drop the exponentially small terms in b defined in (4.2). (These are equivalent to replacing the fundamental solution $\Gamma(x,t)$ in (3.2) by $\frac{1}{2\sqrt{\pi t}}e^{-x^2/(4t)}$.) Writing (4.6) as $G(u,\xi) = F[u] - (\mathbf{I}+\mathbf{L})[u]$ and solving for u we obtain

$$u(\xi) = -\xi - \log\left\{1 + \frac{(\mathbf{I}+\mathbf{L})[u'] - F[u]}{2u(\xi)}\right\}.$$

Starting with $u = \xi + O(1)$ and successively replacing u on the right-hand side by its previous expansion, we then obtain expansions of all order. The key here is that the right-hand side produces a unique $n+1$th order expansion, if an nth order expansion of u is given, because of the denominator $2u(\xi)$.

With the help of Mathematica's symbolic package, we obtain, in particular, the expansion (1.2); see www.math.pitt.edu/~xfc.

Rigorous verification of the expansion.

For every $n \ge 2$, set $u_n = -\xi + \sum_{i=1}^n c_i \xi^{-i}$ and define

$$\mathbf{X}_n = \left\{ w \in C^1((-\infty,\xi_n]) \,\middle|\, |(w-u_n)(\xi)| + \tfrac{1}{|\xi|}|(w-u_n)'(\xi)| \le M_n|\xi|^{-n-1} \ \forall\ \xi \le \xi_n \right\}.$$

We shall use mathematical induction to show that for every integer $n \ge 2$, $u \in \mathbf{X}_n$ provided that we take ξ_n and M_n large enough.

Suppose $u \in \mathbf{X}_n$. Then one can verify that $F[u]-F[u_n] = O(|\xi|^{-n-1})$. In deriving this, we need

$$u(\xi)-u(\eta) = \int_\xi^\eta u'(\hat\xi)\, d\hat\xi = \int_\xi^\eta (u_n' + O(|\xi|^{-n})\, d\hat\xi = u_n(\xi) - u_n(\eta) + |\xi-\eta|O(|\xi|^{-n}).$$

Now define $w_\pm = u_{n+1} \pm M|\xi|^{-n-2}$, where M is to be determined. We can calculate $\mathbf{N}[w_\pm] := (\mathbf{I}+\mathbf{L})[w_\pm'] + G(w_\pm,\xi) = \mathbf{N}[u_{n+1}] \pm 2M|\xi|^{-n-1} + O(|\xi|^{-n-2})$ since $L(\xi) := G_w(u,\xi) = 2|\xi| + O(1)$.

From the construction of u_{n+1}, we have $\mathbf{N}[u_{n+1}] = F[u_n] + O(|\xi|^{-n-1})$, and we then conclude that $\mathbf{N}[w_\pm] - \mathbf{N}[u] = F[u_n] - F[u] \pm 2M|\xi|^{-n-1} + O(1)|\xi|^{-n-1} = 2 \pm M|\xi|^{-n-1} + O(1)|\xi|^{-n-1}$, where $O(1)$ is independent of M if ξ is large enough. Hence, there exist a large constant M_{n+1} and large negative constant ξ_{n+1} such that for $M = M_{n+1}$, $\pm(\mathbf{N}[u] - \mathbf{N}[w_\pm]) > 0$ in $(-\infty,\xi_{n+1})]$. Therefore, by comparison, $w_- < u < w_+$, i.e., $|u-u_{n+1}| \le M_{n+1}|\xi|^{-n-2}$ for all $\xi \le \xi_{n+1}$. We take M large enough. With this estimate, we also obtain $(\mathbf{I}+\mathbf{L})[(u-u_{n+1})'] = \{\mathbf{N}[u]-\mathbf{N}[u_{n+1}]\} - \{G(u,\xi)-G(u_{n+1},\xi)\} = O(|\xi|^{-n-1})$. Consequently, by the boundedness of $(\mathbf{I}+\mathbf{L})^{-1}$, $|u'-u_{n+1}| = O(|\xi|^{-n-1})$. Thus, $u \in \mathbf{X}_{n+1}$. This completes the proof. ∎

Remark 6.3. We did not include the second order derivative of u in the definition of $\mathbf{X}_n$ since we do not intend to establish the estimate for u''. On the other hand, we do need to include the second order derivative of u in $\mathbf{X}$ in the proof of Theorem 4.1 to make the set $\mathbf{D}$ compact in $\mathbf{X}$.

7. Approximations of the early exercise boundary. In applications, one needs to find quickly the early exercise boundary

$$S_f(T) = Ee^{s(t)}, \quad s(t) = -2\sqrt{t\,\alpha(t)}, \quad \alpha(t) = u(\xi),$$
$$\xi = \log\sqrt{4\pi k^2 t},\ k = 2r\sigma^{-2}, \quad t = \tfrac{1}{2}\sigma^2(T_F - T)$$

of the American put option. As mentioned in the introduction, there have been a number of theoretical approximations; see, for example, [25], [18], [5], and [2, 3, 14]. In this section we derive our new approximations mentioned in section 1 as well as provide numerical comparisons. In what follows, σ^2 and r are measured in annualized units, i.e., have units 1/year.

7.1. An explicit approximation near expiry. One notices that expansions such as (1.2) cannot be used for $\xi \geq 0$ (equivalent to $t \geq 1/(4\pi k^2)$ or $T_F - T > \sigma^2/(8\pi r^2)$). Indeed, our numerical evidence [8] shows that approximations based on the truncations of (1.2) break down much earlier, and higher order expansions approximate $s(t)$ better than the second order only if $T_F - T$ is shorter than a few minutes and, therefore, are of no practical use. In this aspect, the best choice for practical estimation of $S_f(T)$ near expiry is the second order approximation $u(\xi) \approx -\xi - \frac{1}{2\xi}$. It is good for $T_F - T$ less than a week when $\sigma = 0.25/\sqrt{\text{year}}, r = 0.1/\text{year}$. Nevertheless, we still want to use (1.2) to obtain better approximations.

We recall that the particular choice of the constant $4\pi k^2$ in the definition of $\xi = \log\sqrt{t} + \log\sqrt{4\pi k^2}$ is to eliminate the constant term in the expansion of $u(\xi)$. If we use another variable such as $\hat{\xi} = \log\sqrt{Bt}$ and expand u in terms of $1/\hat{\xi}$, then the corresponding expansions make sense for all $t < 1/B$. Based on this idea, for any $a > 0$, we expand $u(\xi)$ as $u = -\xi - \frac{1}{2(\xi-a)} + \frac{1/8+a/2}{(\xi-a)^2} + \frac{17/24-a/4-a^2/2}{(\xi-a)^3} + \cdots$. Being equivalent to (1.2) as $\xi \to -\infty$, this new expansion, however, can be evaluated for all $t < e^a/(4\pi k^2)$. In particular, taking $a = 0.96621$ to be the positive root to $17/24 - a/4 - a^2/2 = 0$ and truncating the expansion at the fourth order, we obtain (expl) in section 1. Numerical evidence shows that this new approximation (expl) is better than any of the straightforward truncations of (1.2), both in accuracy and in the length of the interval of validity. For $\sigma = 0.25/\sqrt{\text{year}}$ and $r = 0.1/\text{year}$, the approximation is very accurate for $T_F - T$ less than 1 month.

7.2. An implicit/series approximation. We can extend further the above idea. We seek approximations which meet two requirements: (i) they are valid asymptotic expansions as $\xi \to -\infty$, and (ii) they are analytic for all $\xi \in \mathbb{R}$. We find that such approximations can be easily obtained if we regard ξ as function of u, i.e., the inverse function of $\xi = \xi(u)$.

For every $a > 0$, we convert (1.2) into its equivalent form $\xi = -u - \log\{1 - \frac{1}{2(u+a)} - \frac{a}{2(u+a)^2} + \frac{1-a^2}{2(u+a)^2} + \cdots\}$. Hence, taking $a = 1$ and truncating the expansion at the fourth order, we obtain the implicit formula (imp1) in section 1. As a special advantage, this expansion is meaningful for all time since for every $\xi \in \mathbb{R}$, there is a unique u solving (imp1) and $\xi \to \infty$ as $u \to 0$, which is compatible with the fact that $u = \frac{s(t)^2}{4t} \to 0$ as $\xi = \log\sqrt{4\pi k^2 t} \to \infty$. Our numerical experiments in [8] show that

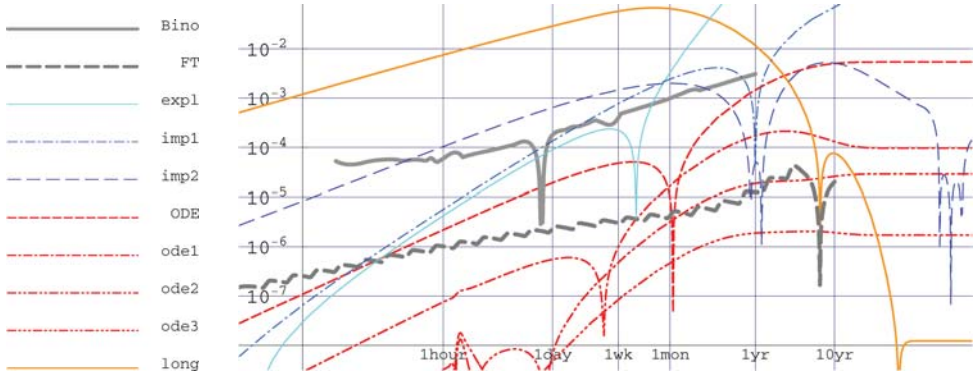

FIG. 7.1. *Error (in* $\log_{10}$*) of approximations for* $r = 0.1$ *and* $\sigma = 0.25$.

(impl1) is much better than (expl). It is reasonably good for $T_F - T$ as long as one year when $\sigma = 0.25$ and $r = 0.1$. See Figure 7.1.

7.3. Implicit/interpolation approximation. The approximation (impl1) is based on the asymptotic expansion (1.2) which concerns *only* the behavior of $s(t)$ near expiry. We now derive an approximation which incorporates as well the asymptotic behavior of u for large $t = e^{2\xi}/(4\pi k^2)$.

Using (3.6) and the change of variable $\tau \to z$ via $z = (s(t) - s(t-\tau))/(2\sqrt{\tau})$ we obtain

$$e^{-u-\xi} = \frac{2}{\sqrt{\pi}} \int_0^{\sqrt{u}} e^{-z^2} \theta_1(t,z)\theta_2(t,z)\, dz =: \frac{2\theta(t)}{\sqrt{\pi}} \int_0^{\sqrt{u}} e^{-z^2}\, dz, \tag{7.1}$$

where

$$\theta_1(t,z) = \Big\{2 - \frac{s(t) - s(t-\tau)}{\tau\, s'(t-\tau)}\Big\}^{-1}, \qquad \theta_2(t,z) = \exp\{\tfrac{(k-1)s(t-\tau)}{2} + \tfrac{(k+1)^2(t-\tau)}{4}\}.$$

Note that $\theta_1(t,0) = 1$ and $\theta(t,\sqrt{u}) = 1/2$. Also, $\lim_{t\to 0} \theta_2(t,z) = 1$ uniformly in z and $\lim_{t\to 0} \theta_1(t,z) = 1$ for any fixed finite z. Hence $\lim_{t\to 0} \theta(t) = 1$; cf. Remark 3.3.

Now we consider $\theta(t)$ for large t. From Theorem 2.3, we obtain $u = s^2(t)/(4t) \approx \log^2[1 + 1/k]/(4t)$, and $1/\theta(t) = \frac{2}{\sqrt{\pi}} e^{u+\xi} \int_0^{\sqrt{u}} e^{-z^2} dz \approx 2k \log[1 + 1/k]$ for large t (or ξ). Once we know the behavior of $\theta(t)$ for small and large t, we can approximate $\theta(t)$ for any t by interpolation. Without considering any more detailed behavior of θ for intermediate sizes of t, we choose, for simplicity, the approximation

$$\frac{1}{\theta(t)} \approx \frac{\theta(0)e^u + \theta(\infty)e^{1/u}}{e^u + e^{1/u}} = \frac{e^u + 2k\log(1 + 1/k)e^{1/u}}{e^u + e^{1/u}}.$$

Substituting this approximation into (7.1) and taking the log of both sides, we then obtain (imp2) in section 1. Figure 7.1 shows that (imp2) is better than (impl1) when $T_F - T$ is larger than 1 month (for $r = 0.1$ and $\sigma = 0.25$). When $T_F - T$ is less than a month, (impl1) is better than (imp2) since for small t, (impl1) is a fourth order approximation whereas (imp2) is only first order.

We remark that (impl1) can be revised to provide approximations which have higher order (as $t \to 0$) than (imp2), yet still capture the asymptotic behavior $s(t) \sim s_\infty$ for large t.

7.4. An ODE approximation. The ODE approximation in section 1 is obtained by neglecting the integral in (3.10). In the (u,ξ) variable, it can be written as

$$(7.2)\quad \begin{cases} \dfrac{1}{2u}\dfrac{du}{d\xi} = \exp\Big\{ -u-\xi+\frac{(k-1)\sqrt{u}e^{\xi}}{2k\sqrt{\pi}} - \frac{(k+1)^2e^{2\xi}}{16k^2\pi}e^{2\xi}\Big\} - 1 \quad \text{for} \quad \xi\in\mathbb{R}^1, \\ \lim_{\xi\to-\infty}\{u(\xi)+\xi\} = 0. \end{cases}$$

In numerically solving this ODE problem, the initial condition can be taken as $u|_{\xi=\xi_0} = -\xi_0 - \frac{1}{2\xi_0}$ for large negative ξ_0, say, $\xi_0 = -7$. This initial value problem is extremely stable with respect to the initial condition. Indeed, solutions with initial conditions $u|_{\xi=-7} = 1, 7, 10$ are indistinguishable when $\xi = -6$, since the initial difference decays with a speed $e^{-(\xi-\xi_0)G_w(u_0,\xi)} \approx e^{-2|\xi_0|(\xi-\xi_0)}$. Also, the computing time is almost instantaneous. Our numerical simulations indicate that this ODE approximation is better than any of the previous three algebraic approximations and is very accurate for a variety of parameter ranges of σ and r and almost all time $t > 0$.

7.5. An ODE iterative scheme. For the purpose of numerical comparison of the accuracy of theoretical approximations, highly accurate solutions for $s(t)$ are needed. Such solutions can be obtain by an iteration based on (3.10). We write (3.10) as (1.3). Asymptotic expansion gives for small t, $m(t) = 0 + 0\xi^{-1} + 0\,\xi^{-2} + \frac{1}{4}\,\xi^{-3} + O(\xi^{-4}) \approx \frac{1}{4}\xi^{-3}$, and for large t,

$$m(t) \approx m(\infty) = k\int_0^\infty \Big\{1 - \frac{2s(\tau)}{s(\infty)}\Big\}\exp\left\{\frac{(k-1)}{2}s(\tau) + \frac{(k+1)^2}{4}\tau\right\}\dot{s}(\tau)\,d\tau.$$

We remark that the integral is finite since letting t in (3.6) approach ∞ gives the identity

$$1 = -k\int_0^\infty \exp\left\{\frac{(k-1)}{2}s(\tau) + \frac{(k+1)^2}{4}\tau\right\}\dot{s}(\tau)\,d\tau.$$

Hence, $|m(\infty)| < 1$. Our numerical simulation shows that $m(t)$ changes sign exactly once, and this occurs near $\xi = 0$; for $r = 0.1$ and $\sigma = 0.25$, the minimum of $m(t)$ is $-0.003\ldots$, which occurs near $\xi = -5$, and the maximum is $0.17\ldots$, which is attained at $\xi = \infty$. From here, we can see why the ODE approximation (approximating m by 0) is very accurate for all $t > 0$.

The ODE iterative scheme that we propose is as follows: update s by solving (1.3) for s with $m(t)$ evaluated at a previous s; more precisely, $m^{(0)}(t) \equiv 0$, and for $n = 0, 1, \ldots$, $s^{(n)}(t) = -2\sqrt{t\,u^{(n)}(t)}$, where

$$(7.3)\quad \begin{cases} \dfrac{du^{(n)}}{d\log\sqrt{4\pi k^2 t}} = 2u^{(n)}\Big\{\frac{1+m^{(n)}}{\sqrt{4\pi k^2 t}}\exp\Big[\frac{k-1}{2}\sqrt{t\,u^{(n)}} - u^{(n)} - \frac{(k+1)^2}{4}t\Big] - 1\Big\}, \quad t \ge \delta, \\ u^{(n)}(\delta) = -\frac{1}{2}\log[4\pi k^2\delta] - \frac{1}{2}\log^{-1}[4\pi k^2\delta]), \end{cases}$$

$$m^{(n+1)}(t) = \begin{cases} ks^{(n)}(\delta) + \int_\delta^t \Big\{\frac{s^{(n)}(t)-s^{(n)}(\tau)}{t-\tau}\frac{2t}{s^{(n)}(t)} - 1\Big\}\frac{k\Gamma(s^{(n)}(t)-s^{(n)}(\tau),t-\tau)}{\Gamma(s^{(n)}(t),t)}\dot{s}^{(n)}(\tau)\,d\tau, & t \ge \delta_1, \\ \frac{1}{4}\log^{-3}\sqrt{4\pi k^2 t}, & t\in[\delta,\delta_1], \end{cases}$$

where δ and δ_1 are small numbers, say, $\delta = e^{-27}$ and $\delta_1 = e^{-18}$. The ODE for u is solved in the $\xi = \log\sqrt{4\pi k^2 t}$ variable, and a change of variable $\tau = t\eta^2$ is used in evaluating the integral for m. For $t \in [\delta_1, t_{\max}]$ ($t_{\max} = e^5$ will make $s(t_{\max})$ within 0.1% of s_∞), an increasing number, say, $32, 48, 72, 108, \ldots$, of points evenly distributed on the $\log t$ scale can be used to interpolate the function $m^{(1)}(t), m^{(2)}(t), m^{(3)}(t), \ldots$. In general, three iterations will provide a solution of relative error less than 10^{-5}, for all t, and five iterations will produce a numerical fixed point, which costs a total of less than 10 minutes of computing time on a Sparc server.

7.6. An approximation for large time. Although options with very long expiry rarely exist in practice, it is still useful to find the long time behavior (more precise than $S_f \approx Ek/(1+k)$) of the optimal exercise boundary since the scaling $t = \frac{\sigma^2}{2}(T_F - T) = \frac{r}{k}(T_F - T)$ tells us that short time expiration can be considered as long if r or σ is large. For this reason, we provide an approximation for large time, so that when incorporated with our ODE and/or implicit approximations, it will provide instantaneously a reliable approximation valid for all t and consequently for all ranges of σ and r.

Approximating $\Gamma(s(t), t)\{1 + m(t)\}$ on the right-hand side of (1.3) by $\frac{1+m(\infty)}{2\sqrt{\pi t}}$ $e^{-\frac{(1-k)}{2}s(\infty) - \frac{(k+1)^2}{4}t}$ and integrating the resulting approximation from t to ∞ we obtain (long) in section 1. As the ODE solution is a good approximation, $\hat{m}$ in (long) can be approximately calculated by using the ODE approximation for $s^{(0)}(\tau)$ in the integral; the computing time for this approximation is almost instantaneous since we can do so for $s^{(0)}$.

7.7. A numerical example. To give the reader an idea of the accuracy of our approximations, we provide in Figure 7.1 the results of a numerical simulation with typical parameters $E = 1$ (dollar), $r = 0.1$ (1/year), $\sigma = 0.25$ ($1/\sqrt{\text{year}}$), and $k = 2r/\sigma^2 = 3.2$.

In Figure 7.1, the vertical axis is $\log_{10}$ (errors) (with labeling being the actual size of the errors) of the various approximations for the optimal exercise boundary $S_f(T)$, whereas the horizontal axis is the time to expiry ($(T_F - T)$) in the log scale. In calculating the errors, the "exact" solution to which all the approximations are compared is actually the fifth iteration of (7.3), which is a numerical fixed point to (3.9). The labels stand for the binomial tree method (Bino), the front tracking (FT) and extrapolation methods (www.math.pitt.edu/˜xfc), the explicit approximation (expl), the implicit/series approximation (imp1), the implicit/interpolation approximation (imp2), the ODE approximation (ODE), the iterative ODE approximation (7.3) of the first, second, and third iterations, and the large time approximation (long). All the cusps (except those near the right and lower edges of the figure) are the points where errors change sign (since $\log_{10}(\text{error}) = -\infty$ at these points). The nonsmoothness of the curve marked imp2 near the right edge of the figure is due to the inefficiency of our Newton method in finding the roots u of (imp2) for large t. The bumps of ode2 and ode3 at the lower edge of the figure are numerical round-off errors.

The classical binomial and/or trinomial tree methods are typically used in the literature to find solutions to serve as the exact solutions with which approximations are to be compared. In calculating the optimal boundary $S_f(T)$, the point where the functions $P(S,T)$ and $E - S$ depart (tangentially), these tree methods are computing-time extensive. Depending on the initial guess of S_f, for each given T, it takes, with the number of division points $n = 1000$, about 5 to 20 minutes to find $S_f(T)$. The complexity of the method is $O(n^2)$ and the error is of order $O(\frac{\log n}{n})$. The solution

used in the figure contains 50 different sample Ts so that it takes about 10 hours of computing time.

The front tracking method that one of the authors designed has the same complexity $O(n^2)$ and error $O(\frac{\ln n}{n})$ as that of the binomial tree method. However, one can use solutions obtained with divisions $n, n/2$, and $n/4$, respectively, to extrapolate a much more accurate solution, as one can see from the significant difference between the curves marked Bino and FT. Given a fixed time $T_{\max}$, it takes, with $n = 2000$, about 15 minutes to find $S_f(T)$ for all $(T_F - T) \le T_{\max}$. The solution used in the figure is actually the union of solutions for $T_F - T$ in the interval $(\frac{1}{2}T_{\max}, T_{\max}]$ with $T_{\max} = 10/2^i$ (year) for $i = 0, 1, \ldots, 25$, and therefore, it takes a total of 10 computing hours.

As mentioned earlier, the ODE approximation is almost instantaneous. From the figure, one can see that the ODE approximation has already surpassed that obtained from the binomial method (with 1000 division). For the ODE iterative scheme, the computing time for the first iteration takes about 1 minute. To finish the fifth iteration takes a total of about 10 minutes.

Acknowledgment. The authors would like to express their appreciation to the referees for their valuable comments and suggestions.

YOUNG MEASURES AND ORDER-DISORDER TRANSITION IN STATIONARY FLOW OF LIQUID CRYSTALS*

MARIA-CARME CALDERER† AND ALEXANDER PANCHENKO‡

Abstract. We study a system of nonlinear second order ordinary differential equations modeling Poiseuille flow of liquid crystals with variable degree of orientation, at the limit of large Ericksen number. The system is singularly perturbed and degenerate, and as a result the solutions are highly oscillatory. We obtain the relations satisfied by the Young measures generated by sequences of weak solutions, and show that the persistent oscillations are encoded in the Young measure generated by the molecular alignment variable. The effective equations correspond to the macroscopic isotropic Newtonian flow with a liquid crystalline microstructure indicating a remnant alignment.

Key words. Nematic liquid crystals, Young measures, non-Newtonian flows, singular perturbations, effective viscosity

1. Introduction.

In this article we study stationary flow of nematic liquid crystals with large Ericksen number, $\mathcal{E}$, in terms of the Young measures generated by sequences of weak solutions of the governing equations. It is experimentally well known that liquid crystal flows with large Ericksen number present a high density of defects and texture which increases with increasing values of $\mathcal{E}$ (cf. [19], [11], [16], [13], and [18]).

The system that we analyze consists of ordinary differential equations for the variable fields $s(x)$, $\phi(x)$, and $v(x)$, with $x \in [-1,1]$ with $\mathbf{R}^2 \times (-1,1)$, representing the domain of the flow. The governing system is highly nonlinear, nonautonomous and singularly perturbed with respect to the small parameter $\mu = \mathcal{E}^{-1}$. Its principal part as well as the boundary conditions become degenerate at $s = 0$. These combined features result in a highly oscillatory behavior of weak solutions. The goal of the present analysis is to encode oscillations persistent at the limit $\mu \to 0$ into Young measures.

We study a plane Poiseuille flow, which is driven by a prescribed pressure gradient, with vanishing velocity field at the boundary. The variable ϕ corresponds to the angle between the unit molecular director, $\mathbf{n} = (\sin\phi, 0, \cos\phi)$, and the velocity, $\mathbf{v} = (0, 0, v(x))$, of the flow. The variable degree of orientation, $s \in (-\frac{1}{2}, 1)$, gives the quality of alignment of the molecules with the director field, with $s = 1$ corresponding to perfect alignment, and $s = -\frac{1}{2}$ describing the case with molecules placed on a plane perpendicular to $\mathbf{n}$. Especially relevant to the present study is the isotropic case, $s = 0$, with randomly oriented molecules. Points, lines or planes in the flow region with $s = 0$ correspond to nematic liquid crystal defects, with undefined ϕ. Moreover, ϕ becomes discontinuous across defect lines and planes. The variables s and $\mathbf{n}$ correspond to an

eigenvalue and eigenvector, respectively, of the optically uniaxial and traceless order tensor Q. The latter represents a second order moment of the molecular orientation field of a rigid polymer.

The equations that we analyze follow from those derived by Ericksen to model flow of liquid crystals with variable degree of orientation [8]. They yield the Leslie–Ericksen equations when the order parameter s is taken to be a nonzero constant. Relevant features of the model include the Helmholtz free energy and the viscous, anisotropic, stress tensor. The latter is characterized by a set of anisotropic viscosity functions, $\alpha_i(s)$, $1 \leq i \leq 6$, known as Leslie coefficients (in particular, $\frac{1}{2}\alpha_4(0)$ represents the Newtonian viscosity). The free energy density is of the form $a_1|\nabla s|^2 + a_2 s^2|\nabla \mathbf{n}|^2 + \mathcal{J}^{-1} f(s)$, with a_1, a_2 and $\mathcal{J}$ denoting positive, dimensionless material parameters. The scalar function $f(s)$ represents a multiwell potential, favoring special directions of alignment at equilibrium. As a result of the elastic and viscous contributions to the model, the nature of the flow is fully non-Newtonian.

The flow behavior is determined mostly by three nondimensional parameter groups, the *Reynolds* number $\mathcal{R}$, the *Interface* number $\mathcal{I}$, and the *Ericksen* number $\mathcal{E}$. The latter measures the ratio of the viscous torque of the flow with respect to the elastic one. The condition of $\mathcal{E}$ being large corresponds to flow with large pressure gradient, and also to the case of viscous torque dominating the elastic one. The parameter $\mathcal{I}$ is associated with the free energy required to maintain defects in the flow, and it corresponds to the quotient of the bulk elastic energy and the gradient part of the Helmholtz free energy. The quantity $\mathcal{J}^{-1} = \mathcal{I}\mathcal{E}^{-1}$ appears as a coefficient in the free energy, as previously indicated. The derivation of the model studied in this article, the physical and nondimensional parameter groups, can be found in [3], [4], and [5].

We observe that s identically zero is not a solution of the problem. For an arbitrary flow domain, the bulk isotropic state, $s \equiv 0$, can only be realized at equilibrium, if permitted by the boundary conditions. In the case of Poiseuille flow, prescribing a nonzero pressure gradient excludes $s = 0$ from being an equilibrium solution. Consequently, one of the main outcomes of our study is to show that the isotropic state can be nearly realized in an effective sense.

Intuitively, one expects that for large Ericksen number, viscosity effects are dominant and therefore, the molecular alignment (associated with $s \neq 0$) is destroyed. The absence of alignment is indicated by $s = 0$. In this sense, the limit of large Ericksen number should represent the transition from order to disorder. In section 5, we show (Theorem 5.1) that there is indeed a sequence of generalized solutions such that in the limit $\mu \to 0$, s tends to zero uniformly and v becomes the Newtonian velocity field of Poiseuille flow. This alone would indicate a perfect isotropic limit. However, the Young measure generated by ϕ satisfies the additional moment relations, indicating a residual molecular alignment. Although at a macroscopic scale the flow is isotropic, a liquid crystalline microstructure is present. The oscillatory behavior of solutions at the limit of large Ericksen number was numerically detected by the simulations performed in [14]. This provided the motivation for the present study.

In addition to the governing system being singularly perturbed as $\mu \to 0$, it becomes degenerate at $s = 0$. One mathematical difficulty is that standard methods of analysis of singular perturbations [7] cannot be readily applied here. On the other hand, owing to the singularly perturbed nature of the system, a priori bounds for the derivatives are not uniform in μ and therefore, embedding theorems cannot be applied to obtain compactness of s. We overcome these difficulties by constructing tight bounds in terms of supersolutions and subsolutions. They are both solutions of a

classical variational problem for particle motion in a central force field [1]. The upper and lower bounds on s so obtained tend to 0 as $\mu \to 0$, which entails compactness. This leads to partial stability in the sense that s converges to zero uniformly as $\mu \to 0$, while ϕ oscillates with increasing frequency.

Another interesting aspect of the system being driven to degeneracy at the limit $\mu \to 0$ manifests itself in the prescription of boundary conditions. Since the system is of second order with respect to s and ϕ, one expects that both $s(\pm 1)$ and $\phi'(\pm 1)$ (or $\phi(\pm 1)$) should be prescribed. We choose $s(\pm 1) = \mu$. However, in passing to the limit $\mu \to 0$, we find that the boundary conditions $\phi'(\pm 1)$ cannot be freely chosen, but depend on $s(\pm 1)$. In addition, $|\phi'(\pm 1)| \to \infty$ as $\mu \to 0$, in agreement with the fact that our limiting process amounts to creating a boundary defect. The unboundedness of ϕ' causes ϕ to be undefined at the defect location as expected. So, boundary values for the angular variable become redundant at the limit. The choice of $s(\pm 1) = \mu$ does not detract from generality. Our purpose is to study the oscillatory phenomenon on the bulk and avoid boundary layer contributions that would appear in the case that s is not driven to zero at the boundary. These contributions could be incorporated in the current analysis using the techniques previously developed in [3], [4], and [5], but we do not attempt such an analysis here.

The article is organized as follows. Following section 1, the statement of the problem is presented in section 2. We developed a priori bounds and necessary conditions for Young measures in section 3. The main technical result of the paper is stated in section 4, with Theorem 4.3 being the focus of the work. A discussion of the effective equations is presented in section 5, with Theorem 5.1 stating the physical conclusions.

2. Formulation of the problem. We study the following system of differential equations on the interval $I = (-1, 1)$:

$$\mu \left(a_1 s'' - a_2 s(\phi')^2\right) = G_1(s, \phi, x), \tag{2.1}$$

$$\mu a_2 (s^2 \phi')' = G_2(s, \phi, x), \tag{2.2}$$

where

$$G_1(s, \phi, x) = \frac{1}{2}\beta_1(s) g^{-1}(s, \phi) x \sin 2\phi + \frac{1}{\mathcal{J}} \frac{df}{ds}(s), \tag{2.3}$$

$$G_2(s, \phi, x) = \frac{1}{2}(\gamma_1(s) + \gamma_2(s) \cos 2\phi) g^{-1}(s, \phi) x. \tag{2.4}$$

Equations (2.1)–(2.4) model plane Poiseuille flow of nematic liquid crystals with variable degree of orientation. The previously introduced functions $s(x)$ and $\phi(x)$ are the unknown fields of the problem. In (2.1)–(2.4), $'$ denotes derivative with respect to the independent variable $x \in I$. The boundary conditions are prescribed as follows:

$$s(-1) = \mu, \quad s(1) = \mu, \tag{2.5}$$

$$\phi'(-1) = A(\mu), \quad \phi'(1) = B(\mu). \tag{2.6}$$

As mentioned in section 1, $A(\mu)$ and $B(\mu)$ cannot be arbitrarily prescribed for sufficiently small $\mu > 0$. The system (2.1)–(2.4) contains positive scalar parameters μ, $\mathcal{J}$, a_1, and a_2 discussed in section 1. For more details on these quantities, see [3], [4], and [5].

Let $\tau > 0$ be a given material parameter. We suppose that β_1, γ_1, and γ_2 are smooth functions of s on the interval $(-\frac{1}{2}, 1)$, and that $g(s, \phi)$ is also smooth. We

assume that the following hypotheses hold:

$$\beta_1 < 0, \quad \gamma_1 > 0, \tag{2.7}$$

$$\gamma_1(s) = O(s^2), \quad \gamma_2(s) = O(s) \quad \text{for } s \text{ close to } 0, \tag{2.8}$$

$$g(s,\phi) \geq \tau > 0. \tag{2.9}$$

It follows from assumptions (2.8) and (2.9) that $\frac{1}{s}G_2(s)$ is a smooth function of s and satisfies

$$\frac{1}{s}G_2(s) = O(1), \tag{2.10}$$

for $|s|$ small. Equations (2.1)–(2.9) completely describe the problem studied in the paper. The key observation that enables us to overcome the lack of uniform bounds mentioned in section 1 is as follows. If the right-hand sides of (2.1) and (2.2) are replaced with $\frac{1}{\mathcal{J}}df/ds$ and zero, respectively, and, in addition, $a_1 = a_2$, one obtains the classical system modeling motion of a particle in a central force field with potential $-\frac{1}{\mathcal{J}}f(s)$ (see, e.g., [1]). In that case, the variable x is time and $s(x), \phi(x)$ are the radial and angular particle coordinates, respectively. This system has two first integrals: the angular momentum and the total mechanical energy, which make the problem completely integrable. In this paper, this classical system (with different potentials) is used to construct sub- and supersolutions of (2.1), (2.2) (see the proof of Theorem 4.3).

In the remainder of this section we outline the derivation of the governing system from the Leslie–Ericksen equations studied previously in [3], [4], and [5]). The equations considered in these papers are as follows:

$$\mu\left(a_1 s'' - a_2 s(\phi')^2\right) = \beta_1(s)v' \sin\phi\cos\phi + \frac{1}{\mathcal{J}}\frac{df}{ds}(s) \tag{2.11}$$

$$\mu a_2(s^2\phi')' = \left(\gamma_1(s) + \gamma_2(s)\cos 2\phi\right)v' \tag{2.12}$$

$$\frac{1}{\mathcal{R}}(g(s,\phi)v')' = 1, \tag{2.13}$$

Equation (2.13) corresponds to the balance of linear momentum. Its right-hand side represents the prescribed pressure gradient and $\mathcal{R}$ is the Reynolds number. Since we are interested in the behavior of solutions when $\mathcal{E}$ is large and the Reynolds number $\mathcal{R}$ is moderate, there is no loss of generality in assuming $\mathcal{R} = 1$. The function $\beta_1(s)$ is a Leslie coefficient, and $\gamma_1(s), \gamma_2(s)$, and $g(s,\phi)$ are given in terms of $\alpha_i(s)$, $i = 1, \ldots, 5$, as follows:

$$\gamma_1 := \alpha_3 - \alpha_2, \quad \gamma_2 := \alpha_2 + \alpha_3, \tag{2.14}$$

$$\begin{aligned} g(s,\phi) = {} & \frac{1}{2}\alpha_4(s) + \alpha_1(s)\sin^2\phi\cos^2\phi \\ & + \frac{1}{2}(\alpha_5 - \alpha_2)(s)\sin^2\phi + \frac{1}{2}\alpha_3(s)\cos^2\phi. \end{aligned} \tag{2.15}$$

In section 5, we shall make use of the fact (see, e.g., [3], [4], and [5]) that $\alpha_j(0) = 0$ for $j \neq 4$. This implies

$$g(0,\phi) = \frac{1}{2}\alpha_4(0) > 0, \tag{2.16}$$

where $\frac{1}{2}\alpha_4(0)$ is the Newtonian viscosity. The second law of thermodynamics requires that the system be dissipative. This imposes inequality restrictions on the Leslie coefficients $\beta_1(s)$ and $\alpha_i(s)$ (see [12]). As a consequence, we have that $\beta_1 < 0, \gamma_1 > 0$ and

$$g(s,\phi) \geq 0, \quad s \in \left[-\frac{1}{2}, 1\right], \quad \phi \in \mathbf{R}. \tag{2.17}$$

For the forthcoming analysis, we will impose a stronger assumption (2.9), where $\tau > 0$ is a material parameter related to the Newtonian viscosity. Such a strict inequality is an immediate consequence of $\mathcal{E} \neq 0$ [3]. Additional assumptions on Leslie coefficients consistent with kinetic theory of polymers are discussed in [3] and [4].

Next, we solve (2.13) for the velocity v, obtaining

$$v'(x) = (x + C)g^{-1}(s(x), \phi(x)), \tag{2.18}$$

where C is a constant of integration. The boundary conditions $v(\pm 1) = 0$ imply that

$$v(x) = \int_{-1}^{x} tg^{-1}(s(t), \phi(t))\, dt + C \int_{-1}^{x} g^{-1}(s(t), \phi(t))\, dt,$$

and

$$C = -\left(\int_{-1}^{1} g^{-1}(s(t), \phi(t))\, dt\right)^{-1} \int_{-1}^{1} tg^{-1}(s(t), \phi(t))\, dt. \tag{2.19}$$

It should be noted that C is a functional of s, ϕ taking constant values for a given flow. A calculation using the positivity of g yields $-1 < C \leq 1$. Postulating translational invariance of the equations, it is not difficult to show that there exists an interval J (which may be different for different μ) such that $C = 0$ when the equations are considered on J. Calculations involving C are analogous to those with the remaining terms. So, without loss of generality, we will set $C = 0$ in the equations. We also point out that this does not change the qualitative behavior of solutions because of the translational invariance. Combining (2.11), (2.12), and (2.18), we obtain the reduced system (2.1)–(2.4).

3. A priori bounds and necessary conditions for Young measures. In this section we introduce the concept of Young measures generated by sequences of weak solutions of the problem. We derive integral identities and a priori estimates satisfied by weak solutions. Passing to the limit $\mu \to 0$ in the weak formulation of the equations yields algebraic momentum relations satisfied by the Young measures. Such relations can be appropriately interpreted as the effective equations of the system.

A weak solution of the system (2.1)–(2.2) is a pair of functions (s, ϕ) such that $s \in W^{1,2}(I)$, $s\phi \in W^{1,2}(I)$, and for all test functions $h \in C_0^1(I)$, the integral identities

$$-\mu a_1 \int_I s'h'dx - \mu a_2 \int_I s(\phi')^2 h dx = \int_I G_1 h dx, \tag{3.1}$$

$$-\mu a_2 \int_I s^2 \phi' h' dx = \int_I G_2 h dx \tag{3.2}$$

hold, where the right-hand sides G_1 and G_2 are given by (2.3) and (2.4), respectively.

For each $\mu > 0$, existence of weak solutions satisfying $s \in (-\frac{1}{2}, 1), |\phi| \leq \frac{\pi}{2}$ together with the boundary conditions (2.5), (2.6) can obtained using the existence theorem in [2].

3.1. L^2-bounds. The L^2-estimates will be obtained from the following proposition.

PROPOSITION 3.1. *Let s, ϕ be a sufficiently smooth solution of* (2.1) *and* (2.2). *Then the following identities hold:*

$$-\mu a_1 \int_I |s'|^2\,dx + \mu a_1(s's(1) - s's(-1)) - \mu a_2 \int_I s^2(\phi')^2\,dx = \int_I G_1(x,s,\phi)s\,dx, \tag{3.3}$$

$$-\mu a_2 \int_I s^2(\phi')^2 dx + \mu a_2((s^2\phi'\phi)(1) - (s^2\phi'\phi)(-1)) = \int_I G_2(x,s,\phi)\phi dx. \tag{3.4}$$

Proof. Multiplying (2.1) by s and integrating by parts yields

$$\mu a_1 \int_I (s')^2 dx + \mu a_1(s's(1) - s's(-1)) + \mu a_2 \int_I s^2|\phi'|^2 dx = \int_I G_1(x,s,\phi)s dx.$$

Likewise, multiplication of (2.2) by ϕ and integration by parts yields (3.4). ∎

The uniform boundedness of G_1 and G_2 with respect to μ follows from the analogous property of s and ϕ. If, in addition, the boundary terms $b_1(\mu) \equiv \mu a_1(s(1)s'(1) - s(-1)s'(-1))$ and $b_2(\mu) \equiv \mu a_2((s^2\phi'\phi)(1) - (s^2\phi'\phi)(-1))$ are also uniformly bounded, then the identities (3.3) and (3.4) yield the following uniform a priori bounds:

$$\begin{aligned} \mu^{\frac{1}{2}} \|s'\|_{L^2(I)} &\le C, \\ \mu^{\frac{1}{2}} \|s\phi'\|_{L^2(I)} &\le C, \end{aligned} \tag{3.5}$$

where $C > 0$ is independent of μ.

Note that $b_1(\mu)$ and $b_2(\mu)$ vanish when $s(\pm 1) = 0$. Otherwise, if $s'(\pm 1)$ and $\phi'(\pm 1)$ do not grow too fast as $\mu \to 0$, and s and ϕ are uniformly bounded, then $b_1(\mu)$ and $b_2(\mu)$ are also uniformly bounded. Such a statement follows from the estimates on the boundary layer terms valid for a large class of boundary conditions. Indeed, near the boundary $x = \pm 1$, s can be well approximated by a boundary layer term S, satisfying $S(x) = O(e^{\frac{-|x-1|}{\mu^{1/2}}})$, for μ close to 0 (cf. [3] and [4]). Moreover,

$$|s'(\pm 1)| \le \frac{C}{\mu^{1/2}}, \tag{3.6}$$

where C is independent of μ. A related property of the solutions of the governing equations for small μ is the oscillatory behavior of s about $s = 0$ on the interval I; an estimate on the number of oscillations gives $N = O(\mu^{-\frac{1}{2}})$. Moreover, the first and the last zeroes of s in I approach the boundary as $\mu \to 0$ [2]. Numerical simulations of such a behavior are presented in [14].

3.2. Momentum relations for Young measures. The estimates (3.5) allow for some control of the oscillations and yield existence of the microscopic length scale $l \sim \mu^{1/2}|I|$. Unfortunately, the bounds on the derivatives are not uniform in μ, so

it is not possible to extract subsequences convergent weakly in $W^{1,2}(I)$ as $\mu \to 0$. Since s, ϕ are bounded pointwise, we can extract subsequences weak-*convergent in $L^\infty(I)$, and hence weakly convergent in $L^2(I)$. However, this convergence cannot be improved to strong convergence due to high oscillatory behavior of s and ϕ. Such behavior is appropriately encoded in the Young measure generated by sequences of weak solutions [20]. In [17] this measure is defined as follows.

DEFINITION 1. *A Young (parameterized) measure is a family of probability measures $\lambda = \{\lambda_x\}_{x\in\Omega}$ associated with a sequence of functions $f_j : \Omega \subset \mathbf{R}^N \to \mathbf{R}^m$ such that*

(i) $\mathrm{supp}(\lambda_x) \subset \mathbf{R}^m$;

(ii) *λ_x depend measurably on $x \in \Omega$, which means that for any continuous function $\phi : \mathbf{R}^N \to \mathbf{R}$, the function*

$$\bar{\phi}(x) = \int \phi(y) d\lambda_x(y) = \langle \phi(y), \lambda_x(y) \rangle$$

is (Lebesgue) measurable;

(iii) *if the sequence $\phi(f_j)$ converges weakly in $L^p(\Omega)$, $1 \le p < \infty$ (weak-$\star$ in $L^\infty(\Omega)$), then the weak limit is the function*

$$\bar{\phi}(x) = \int \phi(\xi) d\lambda_x(\xi).$$

In what follows, we use the following facts about Young measures. The first [17, Theorem 6.2] is the existence theorem.

THEOREM 3.2. *Let $\Omega \subset \mathbf{R}^N$ be a (Lebesgue) measurable set and let $z_j : \Omega \to \mathbf{R}^m$ be measurable functions such that*

$$\sup_j \int_\Omega g(|z_j|) dx < \infty,$$

where $g : [0, \infty]$ is a continuous, nondecreasing function such that $\lim_{t\to\infty} g(t) = \infty$.

Then there exists a subsequence, not relabeled, and a family of probability measures, $\lambda = \{\lambda_x\}_{x\in\Omega}$ (the associated Young measure) with the property that whenever the sequence $\{\psi(x, z_j(x))\}$ is weakly convergent in $L^1(\Omega)$ for any Caratheodory function $\psi(x, \xi) : \Omega \times \mathbf{R}^m \to [-\infty, \infty]$, the weak limit is the function

$$\bar{\psi}(x) = \int_{\mathbf{R}^m} \psi(x, \xi) d\lambda_x(\xi).$$

The second fact concerns Young measures generated by sequences of vector functions, for which strong convergence holds for some of the components, but not for all of them [17, Proposition 6.13].

THEOREM 3.3. *Let $z_j = (u_j, v_j) : \Omega \to \mathbf{R}^d \times \mathbf{R}^m$ be a bounded sequence in $L^p(\Omega)$ such that $\{u_j\}$ converges strongly to u in $L^p(\Omega)$. If $\lambda = \{\lambda_x\}_{x\in\Omega}$ is the Young measure associated with z_j, then $\lambda_x = \delta_{u(x)} \otimes \nu_x$ for (Lebesgue) almost all $x \in \Omega$, where $\{\nu_x\}_{x\in\Omega}$ is the Young measure corresponding to $\{v_j\}$.*

Young measures provide a description of the weak limits of the nonweakly continuous functions G_1 and G_2 in (2.1) and (2.2). We denote by λ_x the Young measure associated with the sequences of weak solutions (s^μ, ϕ^μ). By definition, for any

continuous function H on $[-1/2,1]\times[-\pi/2,\pi/2]$, the sequence $H(s^\mu,\phi^\mu)$ converges weakly-* to

$$\bar{H}(x)=\int_{-1/2}^{1}\int_{-\pi/2}^{\pi/2}H(s,\phi)d\lambda_x(s,\phi).$$

It is a well known fact [17] that Young measures are in general difficult to compute. In particular, there is no general method for derivation of conditions imposed on Young measures by the nonlinear differential constraints on generating sequences. Available results concern sequences generated by gradients [10]. A generalization of [10] to sequences solving certain constant-coefficient linear partial differential equations is obtained in [9].

In the present case it is possible to derive some necessary conditions for Young measures passing to the limit in the integral identities (3.1) and (3.2). In the next proposition we use notation $a=(a_2/a_1)^{1/2}$.

PROPOSITION 3.4. *Let λ_x be the Young measure generated by a sequence of weak solutions (s^μ,ϕ^μ) satisfying the estimates* (3.5). *Then for any test function $h\in C_0^1(I)$, the following relations hold:*

$$\int\left(G_1(x,y,z)\sin az+\frac{1}{ay}G_2(x,y,z)\cos az\right)d\lambda_x(y,z)h(x)dx=0, \tag{3.7}$$

$$\int\left(G_1(x,y,z)\cos az-\frac{1}{ay}G_2(x,y,z)\sin az\right)d\lambda_x(y,z)h(x)dx=0. \tag{3.8}$$

Proof. Let $w(x)$ be a test function. In the integral identities (3.1), we first replace h with the test function $\sin(a\phi)w$. Next, we formally substitute $\frac{1}{s}a\cos(a\phi)w$ for h in (3.2) and add the resulting identities. This yields,

$$-\mu a_1\int(s\sin a\phi)'w'dx=\int\left(G_1\sin a\phi+\frac{1}{as}G_2\cos a\phi\right)wdx. \tag{3.9}$$

To justify the use of $\frac{1}{s}a\cos(a\phi)w$ as a test function, we point out that $\frac{1}{s}G_2$ is a smooth function of s and satisfies (2.10). Thus, the right-hand side of the previous equation is well defined. This allows us to approximate $\frac{1}{s}$ by a sequence of test functions and then pass to the limit in the resulting integral identities.

The estimates (3.5) on derivatives yield

$$\|\,\mu^{1/2}(s\sin a\phi)'\,\|_{L^2(I)}\le C$$

with C independent of μ. Hence the integral on the left tends to zero as $\mu\to 0$. Using the definition of Young measures to pass to the limit in the right-hand side we obtain the first equation in (3.7).

Next, using $\cos a\phi w$ as a test function in (3.1) and $-\frac{A}{s}\sin a\phi w$ in (3.2) and summing up, we have

$$-\mu a_1\int(s\cos a\phi)'w'\,dx=\int\left(G_1\cos a\phi-\frac{1}{as}G_2\sin a\phi\right)w\,dx. \tag{3.10}$$

Again, the limit of the integral on the left is zero. Passing to the limit in (3.10) yields the second equation in (3.7). ∎

Remark 3.1. The method of proof is based on the following formal procedure. Consider the original system (2.1)–(2.2):

$$\mu(a_1 s'' - a_2 s(\phi')^2) = G_1(x, s, \phi),$$
$$\mu a_2 (s^2 \phi')' = G_2(x, s, \phi).$$

If we multiply the first equation of the system by $\sin a\phi$, the second equation by $1/s \cos a\phi$, and add the resulting equations, we obtain

$$\mu a_1 (s \sin a\phi)'' = G_1 \sin a\phi + \frac{G_2}{s} \cos a\phi. \tag{3.11}$$

Similarly, multiplying the first equation by $\cos a\phi$, the second one by $-1/s \sin a\phi$, and adding the results, we get

$$\mu a_1 (s \cos a\phi)'' = G_1 \cos a\phi - \frac{G_2}{s} \sin a\phi. \tag{3.12}$$

The momentum relations from the proposition are obtained by passing to the limit (in the sense of distributions) in the integral identities corresponding to the system (3.11), (3.12), and thus they are the effective equations for this new system. Moreover, relations (3.7), (3.8) are also effective equations for the original system, since their solutions satisfy the differential equations almost everywhere, and, for each $\mu > 0$, the zero sets of the functions $\cos a\phi$, $\sin a\phi$, and s can be shown to be countable by standard Sturm–Liouville results as in [2].

Remark 3.2. It is interesting to ask to what extent the relations from the proposition characterize Young measures generated by sequences of weak solutions of (2.1) and (2.2). The measures in question satisfy (3.7) and (3.8), but these conditions are far from being sufficient, since they can be obtained for Young measures generated by different equations. These equations may contain, for instance, terms with linear combinations of higher-order derivatives of s and $s\phi'$ multiplied by sufficiently large powers of μ.

4. Generalized solutions and isotropic defects. In this section, we construct generalized solutions s^μ, ϕ^μ from a special class of weak solutions. Generalized solutions are such that s^μ approaches 0, uniformly on I, and ϕ^μ is bounded and presents multiple jump discontinuities. Such jump discontinuities may correspond to isotropic (plane) defects in stationary three dimensional flow.

The numerical experiments carried out in [14] indicate partial stability, which means that $s^\mu \to 0$ as $\mu \to 0$, and ϕ^μ oscillates with a frequency of the order of $\mu^{-1/2}$. In this subsection, we obtain sufficient conditions for such type of behavior. For this, we appeal to results from the theory of ordinary differential equations; the main technical tool is Nagumo's theorem [15], (stated as Theorem 4.1). This theorem provides sufficient conditions for existence of solutions satisfying pointwise upper and lower bounds, constructed from sub- and supersolutions. This result allows us to prove Theorem 4.3 on existence of partially stable solutions.

The strategy of the proof of Theorem 4.3 is as follows. First, we consider arbitrary solutions satisfying boundary conditions that depend on μ (see Theorem 4.3 for the precise formulation). Then, we show that among these, there is a large class of boundary conditions for which s^μ is bounded by a multiple of μ. Nagumo's theorem guarantees existence of such solutions. To apply the theorem, we first show that sub- and supersolutions of the system can be constructed from solutions of a classical variational problem that models the motion of a particle in a central force field.

The solutions of the variational systems depend on the first integral parameters. By appropriate choice of the parameters, we find sub- and supersolutions satisfying the desired bounds. An additional difficulty that we encounter is that Nagumo's theorem concerns classical solutions, while the present system may have singularities near the points where $s = 0$. We deal with this problem by examining solutions only on the set where the absolute value of s^μ is larger than μ, and then use upper and lower bounds to demonstrate that, on this set, $|s^\mu| \le 2\mu$.

Nagumo's theorem concerns solutions of the Dirichlet problem on the interval $[a, b]$ for a single second order equation

$$\begin{aligned} u'' &= F(x, u, u'), \\ u(a) &= u_0, \qquad u(b) = u_1. \end{aligned} \tag{4.1}$$

Assume that F is a continuous function of its arguments satisfying the condition

$$F(x, u, z) = O(|z|^2) \ \text{ as } \quad |z| \to \infty \tag{4.2}$$

for all (x, u) in a rectangle $[a, b] \times [\alpha, \beta]$. The following theorem is due to Nagumo [15].

THEOREM 4.1. *Suppose that F satisfies* (4.2)*, and there exist functions $\alpha(x), \beta(x)$ with the properties*

(i) $\alpha, \beta \in C^2([a, b])$;
(ii) $\alpha(x) \le \beta(x)$;
(iii) $\alpha'' \ge F(x, \alpha, \alpha')$, $\beta'' \le F(x, \beta, \beta')$;
(iv) $\alpha(a) \le u_0 \le \beta(a)$, $\alpha(b) \le u_1 \le \beta(b)$. *Then the problem* (4.1) *has a solution $u(x) \in C^2([a, b])$ such that*

$$\alpha(x) \le u(x) \le \beta(x) \tag{4.3}$$

on $[a, b]$.

This theorem has been used by Howes and Chang [7] to study stability of singularly perturbed ODE. We note that condition (4.2) is not the most general one (see [7] for other types of conditions), but it is sufficient for our purpose. We point out that stability conditions for systems studied in [7] do not apply to the present case, since the vector solution (s, ϕ) is not expected to be stable.

According to this theorem, to show that $s^\mu \to 0$, it is enough to construct sequences of bounds $\alpha^\mu(x), \beta^\mu(x)$ for solutions s^μ of (2.1) which converge to zero uniformly on I. Since we are dealing with a system, the bounds for s must be uniform in ϕ. First, we consider the case when $\frac{1}{\mathcal{J}}$ tends to infinity as μ approaches zero.

THEOREM 4.2. *We assume that hypotheses* (2.7)–(2.9) *are satisfied. Let*

$$\frac{1}{\mathcal{J}(\mu)} \to \infty \quad \text{as} \quad \mu \to 0.$$

Suppose that $f \in C^1(-\frac{1}{2}, 1)$ has an isolated local minimum at $s = 0$ and ϕ is an arbitrary differentiable function on I.

Then, there exist a decreasing sequence $\{\mu_n\} \subset (0, 1]$, $\mu_n \to 0$ as $n \to \infty$ and sequences of real numbers $\mathcal{L}_n$ and $\mathcal{M}_n$, such that for every n, there exists a solution s_n to the scalar boundary value problem

$$\mu_n a_1 s'' = \mu_n a_2 s(\phi')^2 - \frac{1}{2}\beta_1(s)x\frac{\sin 2\phi}{g(s, \cos 2\phi)} + \frac{1}{\mathcal{J}(\mu_n)}\frac{df}{ds}(s), \tag{4.4}$$

$$s(-1) = \mathcal{L}_n, \quad s(1) = \mathcal{M}_n,$$

with the property that $s_n \to 0$, *as* $n \to \infty$, *uniformly on* I. *Moreover, the rate of convergence is independent of* ϕ.

Proof. By the assumptions on f, there exists a fixed interval E, containing zero, such that $\frac{df}{ds} > 0$ for $s > 0$, and $\frac{df}{ds} < 0$ for $s < 0$. Let us choose a strictly decreasing sequence $\{\sigma_n\} \subset E$, $\sigma_n > 0$, and such that $\lim_{n\to\infty} \sigma_n = 0$. Likewise, we select an increasing sequence $\{\alpha_n\} \subset E$, $\alpha_n < 0$, and such that $\lim_{n\to\infty} \alpha_n = 0$. For each positive integer n, we can find a real number $\mu_n > 0$ such that

$$\mu a_2 \sigma_n (\phi')^2 + \frac{1}{\mathcal{J}}(\mu)\frac{df}{ds}(\sigma_n) - \frac{1}{2}\beta_1(\sigma_n)x\frac{\sin 2\phi}{g(s,\cos 2\phi)} \geq 0 \quad \text{and}$$

$$\mu a_2 \alpha_n (\phi')^2 + \frac{1}{\mathcal{J}}(\mu)\frac{df}{ds}(\alpha_n) - \frac{1}{2}\beta_1(\alpha_n)x\frac{\sin 2\phi}{g(s,\cos 2\phi)} \leq 0$$

for all $0 < \mu \leq \mu_n$. Indeed, by assumptions (2.7)–(2.9), the last term on the left-hand side of the previous expressions is bounded by a constant $\frac{1}{2}\frac{m}{\tau}$, where $m > 0$ is a bound on $x\beta_1$. For each $n > 0$, we now choose $\alpha_n < \mathcal{L}_n, \mathcal{M}_n < \sigma_n$. The conclusion follows from Theorem 4.1, if we use the constant functions σ_n and α_n as, respectively, upper and lower bounds. ∎

Remark 4.1. We point out that the condition $\mathcal{J} \to 0$ (i.e., $\frac{1}{\mathcal{J}} \to \infty$) as $\mu \to 0$ represents the Leslie–Ericksen limit of the theory, that is the case when the liquid crystal is described by the director $\mathbf{n}$, with the order parameter taking a constant value corresponding to a critical point of the bulk energy $f(s)$.

Next, we consider the more subtle case of $\frac{1}{\mathcal{J}}$ bounded. We assume that $\frac{1}{\mathcal{J}}$ and f satisfy the following conditions:

(i) $\frac{1}{\mathcal{J}}(\mu)$ is bounded by a constant M for all $\mu \leq 1$,
(ii) $f(s) \in C^2(-\frac{1}{2}, 1)$,
(iii) there exist $a, b \in (-\frac{1}{2}, 1)$ such that $|\frac{df}{ds}(s)| \leq M$ for $s \in [a, b]$, $\frac{df}{ds}(s) > 0$ on $(b, 1)$ and $\frac{df}{ds}(s) < 0$ on $(-\frac{1}{2}, a)$.

We observe that the last condition on f may allow several potential wells between $s = -\frac{1}{2}$ and $s = 1$. This may include pure nematic liquid crystals as well as compounds (see [6, chapter 1]).

THEOREM 4.3. *We assume that hypotheses* (2.7)–(2.9) *are satisfied. Suppose that conditions* (i), (ii), *and* (iii) *are fulfilled. Consider sequences* $\{s^\mu, \phi^\mu\}$ *of weak solutions of* (2.1)–(2.2) *such that*

$$s(-1) = s(1) = \mu \tag{4.5}$$

hold. Then there exist $A(\mu), B(\mu) \in \mathbf{R}$ *such that sequences* $\{s^\mu, \phi^\mu\}$ *additionally satisfying*

$$(\phi^\mu)'(-1) = A(\mu), \quad (\phi^\mu)'(1) = B(\mu), \tag{4.6}$$

have the property that $s^\mu \to 0$ *as* $\mu \to 0$, *uniformly on* I.

Proof. Fix $\mu > 0$ and consider solutions (s, ϕ) of the problem

$$\mu a_1 s'' = \mu a_2 s(\phi')^2 - \frac{\beta_1 x \sin 2\phi}{2g(s,\phi)} + \frac{1}{\mathcal{J}}\frac{df}{ds}(s), \tag{4.7}$$

$$\mu a_2 (s^2\phi')' = \frac{x}{g}(\gamma_1(s) + \gamma_2(s)\cos 2\phi), \tag{4.8}$$

satisfying boundary conditions (4.5) and (4.6), with the values $A(\mu)$ and $B(\mu)$ to be specified later. Although this solution is weak, the estimates (3.5) imply continuity of s.

First, we integrate (4.8) to obtain

$$s^2(x)\phi'(x) = \frac{1}{\mu a_2}(\mu^2 A + p(x)), \tag{4.9}$$

where

$$p(x) = \int_{-1}^{x} \frac{y}{g(s(y),\phi(y))}(\gamma_1(s(y)) + \gamma_2(s(y))\cos 2\phi(y))\, dy. \tag{4.10}$$

Next, we represent I as the union of the sets $E^+ = \{x \in I : s > \mu\}$, $E^- = \{x \in I : s < \mu\}$ and $E_0 = \{x \in I : |s| \le \mu\}$, and define s^+ and s^- to be restrictions of s to E^+, E^-, respectively. Since E^+ is open, it can be represented as $E^+ = \cup_{j=1}^{\infty} I_j$, where $I_j = (a_j, b_j)$ are open intervals, and $s(a_j) = s(b_j) = \mu$. Let us consider the system (4.7), (4.8) on some interval I_j. Since $s \ge \mu$ on I_j, we can obtain s from (4.9) and substitute it into (4.7):

$$\mu a_1 s'' = \frac{1}{\mu a_2 s^3}\left(\mu^2 A + p(x)\right)^2 + \frac{\beta_1(s) x \sin 2\phi}{2g(s,\phi)} + \frac{1}{\mathcal{J}}\frac{df}{ds}(s). \tag{4.11}$$

From now on, the strategy of the proof is as follows.

1. Use Nagumo's theorem to construct, for each choice of ϕ, a solution u of (4.11) on I_j, satisfying the boundary conditions (4.5), and such that $-2\mu \le u \le 2\mu$ on I_j. To obtain existence of u, we shall choose A, B sufficiently large. The same choice of A, B works for all I_j, which provides u on E^+. The analogous argument yields existence of u on E^-.
2. Once the choice of A, B is made, the boundary conditions (4.5), (4.6) are specified, and we obtain a particular solution (S, Φ) of (4.7) and (4.8).
3. We prove that u, corresponding to the choice $\phi = \Phi$ in (4.11), coincides with S on the intervals where $|S| > \mu$. This gives an upper bound on S.
4. For each μ, define $s^\mu = S$, $\phi^\mu = \Phi$.

Now we begin implementing the previously described strategy. First, note that the right-hand side of (4.11) is a continuous function of s when $x \in I_j$, and the Nagumo condition (4.2) is satisfied, since the right-hand side is independent of s'. The bounds on u must be independent of the choice of ϕ, which would allow us to adjust ϕ later on when $A = \phi'(-1)$ is chosen. We begin with the construction of the upper bound. To construct the bound, we use the comparison variational system

$$\mu a_1 q'' = \mu a_2 q(\psi')^2 - \frac{dh}{dq}(q), \tag{4.12}$$

$$\mu a_2 (q^2\psi')' = 0. \tag{4.13}$$

This system is classical (see [1]), at least when $a_1 = a_2$. It describes the motion of a particle in a central force field with the potential h. In that case, x denotes time and q, ψ represent the radial and angular particle coordinates, respectively. The following properties of (4.12) and (4.13) are well known. The system has two first integrals, the angular momentum and the total energy, respectively:

$$M = q^2\psi',$$
$$E = \frac{1}{2}\mu a_1 (q')^2 + \frac{1}{2}\mu a_2 q^2 (\psi')^2 + h(q).$$

Combining these two equations allows us to rewrite

$$E = \frac{1}{2}\mu a_1 (q')^2 + V(q), \quad \text{where}$$
$$V(q) = \frac{1}{2}\mu a_2 \frac{M^2}{q^2} + h(q)$$

is the effective potential energy. The evolution of q is described by the autonomous differential equation

$$\mu a_1 q'' = \mu a_2 \frac{M^2}{q^3} - \frac{dh}{dq}(q). \tag{4.14}$$

We point out that it is possible to choose E, M, and h (nonuniquely) so that $V(q)$ has a minimum at $q_0 = 3/2\mu$, and such that the solution, $q(x)$ remains close to q_0 for all $x \in I_j$; in such a case, there are positive constants c_1, c_2, with the property that $c_1\mu \le q \le c_2\mu$ and $c_1 > 1, c_2 < 2$. The function q is an upper bound for u provided the inequality

$$\mu a_2 \frac{M^2}{q^3} - h'(q) \le \frac{1}{\mu a_2 q^3}\left(\mu^2 A - C_1\right)^2 - \frac{C_2}{\tau} + \frac{1}{\mathcal{J}}\frac{df}{ds}(q) \tag{4.15}$$

holds. Here the constant C_1 denotes an upper bound of $|p(x)|$ and C_2 an upper bound of $|\beta_1(q)x|$. Since $q > 0$, the right-hand side of (4.15) is dominated by that of (4.11). We point out that C_1 and C_2 are independent of s, ϕ, and μ. We also note that, since $q \in (c_1\mu, c_2\mu)$, the second and third terms in the right-hand side of (4.15) are bounded independent of μ. So, in order to satisfy inequality (4.15), it is sufficient to choose $A(\mu)$ large enough so that

$$(\mu^2 A - C_1)^2 - (\mu a_2)^2 M^2 \ge K, \tag{4.16}$$

where $K > 0$ is independent of μ. Then, for $\mu \in (0, 1]$, the first term in the right-hand side is dominant. We observe that the condition (4.16) is independent of the choice of the interval I_j, so it will remain the same when we consider different intervals. This completes the construction of the upper bound.

The construction of the lower bound is similar. We only need to choose q to be negative with the absolute value on the order of μ. Since the power of q in the dominant term is odd, we obtain a lower bound $q \ge -2\mu$. Now by Nagumo's theorem, for each choice of ϕ, there exists u such that the pair u, ϕ solves the (4.11) and such that $|u| \le 2\mu$ holds on each I_j, which means that we have u defined on E^+.

Next, a slight modification of the preceding argument provides existence of the solution u on E^-. Since A has already been determined, we can now determine B using (4.5) and (4.9). Specifically, set

$$B = \frac{1}{\mu^3 a_2}(\mu^2 A + C_1). \tag{4.17}$$

So the boundary conditions A and B of ϕ' are now specified. Thus, solving the system (4.7), (4.8) subject to boundary conditions (4.5) and (4.6) yields a solution (S, Φ).

We observe from relations (4.16) and (4.17) that the quantities A and B are independent of the particular choice of s used in the definition of the level sets $E^{\pm}$.

We now consider the sets $E^{\pm}$ corresponding to the fields (S, Φ). Arguing as above, we construct the solution u, on the new sets $E^{\pm}$, and denote the restrictions of S to

E^+ (E^-) by S^+ (S^-). Next, we show that u and S^+ are equal on I_j. Suppose, otherwise, that $S^+ \geq u$ on some interval $L \subset I_j$ and $S^+ = u$ at the endpoints of L. Consider the function $v = S^+ - u$. Substituting u, S^+ into (4.7) and subtracting the resulting equations we find that

$$\mu a_1 v'' = \mu a_2 v(\Phi')^2 - \frac{1}{2}\left(\frac{\beta_1(S^+)}{g(S^+,\Phi)} - \frac{\beta_1(u)}{g(u,\Phi)}\right) x \sin 2\Phi + \frac{1}{\mathcal{J}}\left(\frac{df}{ds}(S^+) - \frac{df}{ds}(u)\right). \tag{4.18}$$

Since $\frac{\beta_1}{g(s,\Phi)}$ is Lipschitz in s, we note that $|\left(\frac{\beta_1(S^+)}{g(S^+,\Phi)} - \frac{\beta_1(u)}{g(u,\Phi)}\right) x \sin 2\Phi| \leq C_g|v|$, holds, where C_g is independent of the choice of I_j. Furthermore, for μ sufficiently close to zero, because of condition (iii), $\frac{df}{ds}(u)$ belongs to the interval on which $\frac{df}{ds}$ and $\frac{d^2f}{ds^2}$ are bounded. Now if S^+ is also in that interval, then using condition (ii), we can write $|\frac{df}{ds}(S^+) - \frac{df}{ds}(u)| \leq C_f v$, where C_f is independent of I_j. Otherwise, if S^+ is large, $\frac{df}{ds}(S^+) > |\frac{df}{ds}(u)|$, by condition (iii). Hence, the right-hand side of (4.18) is positive, for all nonnegative v. Then (4.18) implies that $v'' \geq 0$ on L. Hence, v is a convex function on L which is nonnegative and satisfies zero boundary conditions. Thus, v must be identically zero on L.

Similarly, we prove that if $u \geq S^+$ on some interval, then in fact $u = S^+$. From this and the continuity of S^+, we conclude that $u = S^+$ on I_j and the original solution S satisfies the inequalities

$$\mu \leq S \leq 2\mu \tag{4.19}$$

on I_j. Since the analogous arguments apply to all intervals in E^+, we obtain that S satisfies the inequality (4.19) in E^+. Moreover, $|S| \leq \mu$ in E_0. It remains to prove that $-2\mu \leq S \leq -\mu$ on E^-. The proof is analogous to that in the case of E^+.

Finally, for each $\mu \in (0, 1]$, define $s^\mu = S$, $\phi^\mu = \Phi$, since $|s^\mu| \leq 2\mu$ on I and the sequence s^μ converges to zero uniformly as $\mu \to 0$. □

Remark 4.2. Equations (4.16) and (4.17) suggest that $A = O(\mu^{-2}), B = O(\mu^{-3})$ as $\mu \to 0$.

Remark 4.3. The second part of the proof provides a partial uniqueness argument for solutions of the system (2.1)–(2.4), with the boundary conditions satisfying (4.16), (4.17). It seems that such an argument can be used to prove uniqueness for each fixed $\mu > 0$. This will be the subject of future research.

The proof of the previous theorem brings out some relevant physical aspects of the problem as well as related mathematical issues. The former arguments strongly reflect the interplay between the mechanisms responsible for the oscillatory behavior of solutions and the degenerate nature of the boundary conditions for s close to 0. (Let us recall that ϕ is undefined when $s = 0$.) In order to illustrate such features, let us consider the boundary value problem with prescribed nonzero boundary conditions on s, and also prescribed values of ϕ'. If we now allow the boundary values of s to approach 0, it is natural to expect that the boundary values of ϕ' cannot be independently chosen. This is indeed the nature of Theorem 4.3. Specifically, the restriction on $\phi'(\pm 1)$ imposed by $s(\pm 1) = \mu$ with μ small is contained in inequality (4.16).

A consequence of the fact that $\phi'(\pm 1)$ is large, as indicated by (4.16), is that ϕ' is positive on I, so ϕ is increasing on the intervals of continuity. Consequently, ϕ may be large in such intervals. In order to ensure boundedness of ϕ, we will make

use of the shift invariance of the system (2.1)–(2.2). Indeed, if s, ϕ is a solution, then $s, \phi + k\pi$ is also a solution for any integer k. Starting with an increasing $\tilde{\phi}$, we can split the interval I into subintervals on which $k\pi \le \tilde{\phi} \le (k+1)\pi$ and, then define ϕ by shifting appropriately on each subinterval. The function ϕ obtained in such a fashion will be bounded, rapidly oscillating and discontinuous. We will refer to solutions with rapidly oscillating discontinuous ϕ as generalized to distinguish them from the weak solutions. The discontinuities of ϕ are associated with liquid crystal defects.

COROLLARY 4.4. *Let $\tilde{s}^\mu, \tilde{\phi}^\mu$ be a sequence of weak solutions constructed in Theorem* 4.3. *Then there exists a sequence of generalized solutions s^μ, ϕ^μ such that*

(i) $s^\mu \to 0$ *uniformly on* I;
(ii) $|\phi^\mu| \le \frac{\pi}{2}$;
(iii) *for each $\mu > 0$, the support of the distribution $(\tilde{\phi}^\mu)' - (\phi^\mu)'$ is a finite set of points;*
(iv) *for any $h \in C_0^1(I)$, s^μ, ϕ^μ satisfies the integral identities*

$$\mu a_1 \int_I (s^\mu)' h'\, dx - \mu a_2 \int_I s^\mu ((\phi^\mu)')^2 h\, dx = \int_I G_1(s^\mu, \phi^\mu) h\, dx, \tag{4.20}$$

$$\mu a_2 \int_I (s^\mu)^2 (\tilde{\phi}^\mu)' h'\, dx = \int_I G_2(s^\mu, \phi^\mu) h\, dx.$$

Proof. Let J be the largest integer such that $\phi(-1) \ge J\pi - \frac{\pi}{2}$. The interval I can be represented as a union of N_μ disjoint intervals I_k, $k = 0, 1, 2, \dots N_\mu$, such that $x \in I_k$ when

$$\pi(J+k) - \frac{\pi}{2} \le \phi(x) < \pi(J+k) + \frac{\pi}{2},$$

holds. Starting with $\tilde{s}^\mu, \tilde{\phi}^\mu$, we define s^μ, ϕ^μ as follows:

$$s^\mu = \tilde{s}^\mu,$$
$$\phi^\mu = \tilde{\phi}^\mu - \pi(J+k)$$

for $x \in I_k$. Note that the distributional derivative of ϕ^μ is not locally integrable. However, we have

$$(\phi^\mu)' = (\tilde{\phi}^\mu)'$$

when both are restricted to the complement of the set of the endpoints of I_k.

Next, we observe that $G_l(s, \phi) = G_l(s, \phi + m\pi)$, where $l = 1, 2$ and m is an integer. Hence, replacing $\tilde{\phi}^\mu$ by ϕ^μ in the right-hand sides of the integral identities for the weak solutions which yields (4.20). ∎

Remark 4.4. Note that, in general, it is not possible to replace $(\tilde{\phi}^\mu)'$ by $(\phi^\mu)'$ in the left-hand side of the second identity.

5. Effective configurations. The limiting process yields effective governing equations and configurations of Newtonian Poiseuille flow, with constant viscosity. However, additional equations associated to microstructural phenomena also arise at the limit. They may be related to the occurrence of remnant ordered states on a microscopic scale.

Let us first recall (2.11)–(2.13) and the definition of g:

$$g(s, \phi) = \frac{1}{2}\alpha_4(s) + \alpha_1(s) \sin^2\phi \cos^2\phi + \frac{1}{2}(\alpha_5 - \alpha_2)(s) \sin^2\phi + \frac{1}{2}\alpha_3(s) \cos^2\phi. \tag{5.1}$$

If $\{s^\mu, \phi^\mu\}$ is a sequence of functions such that $s^\mu \to 0$ uniformly, then by (2.16)

$$g(s^\mu, \phi^\mu) \to \frac{1}{2}\alpha_4(0),$$

uniformly on I, as μ approaches zero. Up to a subsequence, the solution v_μ of (2.13) tends to a limit v_0 strongly in $L^2(I)$, and weakly in $W^{1,2}(I)$. Hence, the product $g(s^\mu, \phi^\mu)v'_\mu$ converges to $\frac{1}{2}\alpha_4(0)v'_0$ weakly in $L^2(I)$. This implies that v_0 satisfies the effective equation

$$\eta_{\text{eff}} v''_0 = 1, \tag{5.2}$$

which is the Newtonian Poiseuille flow with constant effective viscosity $\eta_{\text{eff}} = \frac{1}{2}\alpha_4(0)$. When the Ericksen number is large and the Reynolds number is of order 1, the typical viscosity is much larger than the typical elasticity. It is natural to expect that alignment of the molecules will be destroyed by the diffusion, so that liquid crystal flow is that of an isotropic liquid with a constant viscosity. If that were the case, (5.2) would be the only effective equation of the limiting flow. Rigorous analysis suggests, however, that one should also consider the Young measure ν_x generated by the sequence ϕ^μ. In Remark 5.1, following the proof of Theorem 5.1, we explain that ν_x is nontrivial, which means that it cannot have the form $\delta(z-\bar{\phi}(x))$ for any function $\bar{\phi}(x)$. Since localization of ν_x at $\bar{\phi}$ signals strong convergence, this implies that the sequence ϕ^μ cannot converge strongly. Therefore, ν_x must describe "possible disordered states" compatible with the boundary conditions and macroscopic flow.

Combining Theorem 3.3 and Proposition 3.4 with the partial stability Theorem 4.3, we obtain the following theorem.

THEOREM 5.1. *Let $\tilde{s}^\mu, \tilde{\phi}^\mu$ be a sequence of weak solutions from Theorem* 4.3 *satisfying the a priori estimates*

$$\| \tilde{s}' \|_{L^2(I)} \le C,$$
$$\| \tilde{s}\tilde{\phi}' \|_{L^2(I)} \le C,$$

with C independent of μ. Let (s^μ, ϕ^μ) be a corresponding sequence of generalized solutions. Then, up to a subsequence,

(i) *$s^\mu \to 0$ uniformly on I;*

(ii) *the sequence ϕ^μ generates a Young measure ν_x satisfying moment relations*

$$\int_{-1}^{1}\int_{-\pi/2}^{\pi/2}\left(G_1(0,z,x)\sin az - \frac{1}{a}\frac{G_2}{z}(0,z,x)\cos az\right)d\nu_x(z)h(x)\,dx = 0, \tag{5.3}$$
$$\int_{-1}^{1}\int_{-\pi/2}^{\pi/2}\left(G_1(0,z,x)\cos az + \frac{1}{a}\frac{G_2}{z}(0,z,x)\sin az\right)d\nu_x(z)h(x)\,dx = 0,$$

for each $h \in C_0^1(I)$. In (5.3), *$a = (a_2/a_1)^{1/2}$;*

(iii) *the sequence $s((\tilde{\phi}^\mu)')^2$ converges to a measure ρ in the sense of distributions. Moreover,*

$$\rho = \int_{-\pi/2}^{\pi/2} G_1(0,z,x)d\nu_x(z). \tag{5.4}$$

Proof. Part (i) follows directly from Theorem 4.3. Since s^μ converges to zero in L^2, the corresponding Young measure is $\delta(y)$. Hence, part (ii) follows from Theorem 3.3 and momentum relations in Proposition 3.4.

Next, consider the integral identity

$$-\mu a_1 \int_I s' h' dx + \mu a_2 \int_I s(\phi')^2 h \, dx = \int_I G_1(x, s, \phi) h \, dx.$$

Since $\|s'\|_{L^2(I)} \leq C\mu^{-1/2}$ with C independent of μ, the first integral on the left converges to zero as $\mu \to 0$. The integral in the right-hand side converges to

$$\int_I \int_{-\pi/2}^{\pi/2} G_1(0, z, x) d\nu_x(z) h(x) dx.$$

This yields,

$$\lim_{\mu \to 0} \int_I s(\phi')^2 h \, dx = \int_I \int_{-\pi/2}^{\pi/2} G_1(0, z, x) d\nu_x(z) h(x) \, dx$$

for all $h \in C_0^1(I)$. Since this space is dense in $C_0(I)$, the equality above holds for all $h \in C_0(I)$. Hence, the distributional limit of $s(\phi')^2$ is a Radon measure ρ such that

$$\int_I h d\rho = \int_I h \int_{-\pi/2}^{\pi/2} G_1(0, z, x) d\nu_x(z) dx$$

for all $h \in C_0(I)$. ∎

Remark 5.1. Strong convergence of ϕ^μ is incompatible with the moment relations (5.3). If strong convergence takes place, then $\nu_x(z) = \delta(x - \bar{\phi}(x))$ for some function $\bar{\phi}$ (the strong limit). If that were the case, then from (5.3) we would obtain

$$G_1(0, \bar{\phi}, x) \sin a\bar{\phi} - \frac{1}{a} \left(\frac{G_2}{s} \right) (0, \bar{\phi}, x) \cos a\bar{\phi} = 0, \tag{5.5}$$

$$G_1(0, \bar{\phi}, x) \cos a\bar{\phi} + \frac{1}{a} \left(\frac{G_2}{s} \right) (0, \bar{\phi}, x) \sin a\bar{\phi} = 0, \tag{5.6}$$

and thus

$$G_1(0, \bar{\phi}, x) = 0, \tag{5.7}$$

$$\left(\frac{G_2}{s} \right) (0, \bar{\phi}, x) = 0. \tag{5.8}$$

This means that $s = 0, \phi = \bar{\phi}$ is an equilibrium solution of (2.1, 2.2). Direct computation shows that $s = 0$ cannot be an equilibrium solution for any $\bar{\phi}$.

6. Conclusions. We study the oscillatory behavior of the solutions of the governing equations modeling Poiseuille flow of liquid crystals with variable degree of orientation, at the limit of large Ericksen number $\mathcal{E}$. The governing equations are singularly perturbed and highly degenerate. The oscillations of s occur about the isotropic value $s = 0$, and at points where s vanishes the angle of alignment ϕ is discontinuous and ϕ' becomes unbounded. This situation corresponds to the presence of defects in the flow. We obtain necessary condition for the Young measures generated

by sequences of solutions and show that the persistent oscillatory behavior is encoded in the Young measure generated by ϕ. We prove a partial stability result establishing uniform convergence of s to 0 as $\mu = \mathcal{E}^{-1} \to 0$ and the increasingly oscillatory behavior of ϕ. Compactness of s allows us to pass to the limit in the governing system and obtain the effective equations. The latter consist of the Newtonian flow equation together with the algebraic relations for the Young measure generated by ϕ. This suggest that macroscopically the flow is isotropic and Newtonian with a remaining liquid crystalline microstructure.

STABILITY OF COMPRESSIBLE VORTEX SHEETS IN STEADY SUPERSONIC EULER FLOWS OVER LIPSCHITZ WALLS*

GUI-QIANG CHEN†, YONGQIAN ZHANG‡, AND DIANWEN ZHU§

Abstract. We are concerned with the stability of compressible vortex sheets in two-dimensional steady supersonic Euler flows over Lipschitz walls under a BV boundary perturbation, since steady supersonic Euler flows are important in many physical situations. It is proved that steady compressible vortex sheets in supersonic flow are stable in structure globally, even under the BV perturbation of the Lipschitz walls. In order to achieve this, we develop a modified Glimm difference scheme and identify a Glimm-type functional to obtain the required BV estimates by incorporating the Lipschitz boundary and the strong vortex sheets naturally and by tracing the interaction not only between the boundary and weak waves but also between the strong vortex sheets and weak waves. Then these estimates are employed to establish the convergence of the approximate solutions to a global entropy solution and the corresponding approximate strong vortex sheets to a strong compressible vortex sheet of the entropy solution. The asymptotic stability of entropy solutions in the flow direction is also established.

1. Introduction.

We are concerned with the stability of compressible vortex sheets in steady supersonic Euler flows over Lipschitz walls under a BV boundary perturbation. The two-dimensional steady supersonic Euler flows are generally governed by

$$\begin{cases} (\rho u)_x + (\rho v)_y = 0, \\ (\rho u^2 + p)_x + (\rho uv)_y = 0, \\ (\rho uv)_x + (\rho v^2 + p)_y = 0, \\ (\rho u(E + p/\rho))_x + (\rho v(E + p/\rho))_y = 0, \end{cases} \tag{1.1}$$

where (u, v) is the velocity, ρ the density, p the scalar pressure, and

$$E = \frac{1}{2}(u^2 + v^2) + e(\rho, p)$$

the total energy with internal energy e, a given function of (ρ, p) defined through thermodynamical relations. The other two thermodynamic variables are the temperature T and the entropy S. If (ρ, S) are chosen as the independent variables, then we have the constitutive relations

$$(e, p, T) = (e(\rho, S), p(\rho, S), T(\rho, S)), \tag{1.2}$$

governed by

$$TdS = de - \frac{p}{\rho^2} d\rho. \tag{1.3}$$

For an ideal gas,

$$p = R\rho T, \qquad e = c_v T, \qquad \gamma = 1 + \frac{R}{c_v} > 1, \tag{1.4}$$

and

$$p = p(\rho, S) = \kappa \rho^\gamma \exp(S/c_v), \qquad e = \frac{\kappa}{\gamma - 1} \rho^{\gamma - 1} \exp(S/c_v) = \frac{RT}{\gamma - 1}, \tag{1.5}$$

where R, κ, and c_v are all positive constants.

If the flow is isentropic (i.e., $S = \text{const.}$), then the pressure p is a function of density ρ, $p = p(\rho)$, and the flow is governed by the following simpler isentropic Euler equations:

$$\begin{cases} (\rho u)_x + (\rho v)_y = 0, \\ (\rho u^2 + p)_x + (\rho uv)_y = 0, \\ (\rho uv)_x + (\rho v^2 + p)_y = 0. \end{cases} \tag{1.6}$$

For polytropic isentropic gases, by scaling, the pressure-density relation can be expressed as

$$p(\rho) = \rho^\gamma / \gamma, \qquad \gamma > 1. \tag{1.7}$$

For the isothermal flow, $\gamma = 1$. The quantity

$$c = \sqrt{p_\rho(\rho, S)}$$

is defined as the sonic speed and, for polytropic gases, $c = \sqrt{\gamma p/\rho}$.

System (1.1) or (1.6) governing a supersonic flow (i.e., $u^2 + v^2 > c^2$) has all real eigenvalues and is hyperbolic in the flow direction, while system (1.1) or (1.6) governing a subsonic flow (i.e., $u^2 + v^2 < c^2$) has complex eigenvalues and is elliptic-hyperbolic mixed and composite (cf. [4, 5]).

We are interested in whether steady compressible vortex sheets in supersonic flow are always stable in supersonic flow under the BV perturbation of the Lipschitz walls. Multidimensional steady supersonic Euler flows are important in many physical situations (cf. Courant and Friedrichs [8]). In particular, when the upstream flow is a uniform steady flow above the plane wall in $x < 0$ all the time, the flow downstream above a Lipschitz wall in $x > 0$ is governed by a steady Euler flow after a sufficiently long time. Furthermore, since steady Euler flows are asymptotic states and may be global attractors of the corresponding unsteady Euler flows, it is important to establish

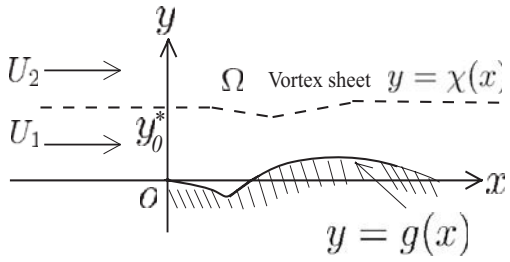

FIG. 1. *Stability of the compressible vortex sheet in supersonic flow.*

the existence of steady Euler flows and understand their qualitative behavior to shed light on the long-time asymptotic behavior of the unsteady compressible Euler flows, one of the most fundamental problems in mathematical fluid dynamics which is still widely open. In this paper we focus on the existence and behavior of such global supersonic Euler flows, especially the nonlinear stability of strong compressible vortex sheets in the supersonic Euler flows, under the BV perturbation of the Lipschitz walls.

For concreteness, we will analyze the problem in the region over the Lipschitz wall for the supersonic Euler flows governed by system (1.1) for $U = (u, v, p, \rho)$ and by (1.6) for $U = (u, v, \rho)$, respectively. Then we have the following:

(i) There exists a Lipschitz function $g \in Lip(\mathbb{R}_+; \mathbb{R})$ with $g(0) = 0$, $g'(0+) = 0$, $g'_\infty = \lim_{x\to\infty} g'(x+)$, and $g' \in BV(\mathbb{R}_+; \mathbb{R})$ such that

$$TV(g'(\cdot)) < \varepsilon \qquad \text{for some constant } \varepsilon > 0, \tag{1.8}$$

$$\Omega = \{(x, y) : y > g(x),\, x \geq 0\}, \quad \Gamma = \{(x, y) : y = g(x),\, x \geq 0\},$$

and $\mathbf{n}(x\pm) = \frac{(-g'(x\pm),1)}{\sqrt{(g'(x\pm))^2+1}}$ are the outer normal vectors to Γ at the points $x\pm$, respectively (see Figure 1).

(ii) The upstream flow consists of one straight vortex sheet $y = y_0^* > 0$ and two constant vectors U_1 when $0 < y < y_0^*$ and U_2 when $y > y_0^* > 0$ satisfying

$$v_1 = v_2 = 0, \qquad u_i > c_i > 0,\ i = 1, 2,$$

where $c_i = \sqrt{\gamma p_i/\rho_i}$ is the sonic speed of state U_i, $i = 1, 2$.

With this setup, the vortex sheet problem can be formulated into the following problem of initial-boundary value type for system (1.1).

Cauchy condition:

$$U|_{x=0} = \begin{cases} U_1, & 0 < y < y_0^*, \\ U_2, & y > y_0^*. \end{cases} \tag{1.9}$$

Boundary condition:

$$(u, v) \cdot \mathbf{n} = 0 \qquad \text{on } \Gamma. \tag{1.10}$$

The main theorem of this paper is the following.

MAIN THEOREM (existence and stability). *There exist $\varepsilon_0 > 0$ and $C > 0$ such that if* (1.8) *holds for $\varepsilon \leq \varepsilon_0$, then there exists a pair of functions*

$$U \in BV_{loc}(\Omega) \cap L^\infty(\Omega), \qquad \chi \in Lip(\mathbb{R}_+; \mathbb{R}_+)$$

with $\chi(0) = y_0^*$ *such that the following hold:*

(i) U *is a global entropy solution of system* (1.1)*, or* (1.6)*, in* Ω *with the initial-boundary data* (1.9)–(1.10) *that is satisfied in the trace sense and*

$$TV\{U(x,\cdot) : [g(x),\infty)\} \le C\,TV(g'(\cdot)) \qquad \text{for every } x \in [0,\infty). \tag{1.11}$$

(ii) *The curve* $\{y = \chi(x)\}$ *is a strong vortex sheet with* $\chi(x) > g(x)$ *for any* $x > 0$*,*

$$\sup_{g(x)<y<\chi(x)} |U(x,y) - U_1| \le C\varepsilon, \qquad \sup_{y>\chi(x)} |U(x,y) - U_2| \le C\varepsilon, \tag{1.12}$$

and

$$\lim_{x\to\infty} \sup\{|v(x,y)/u(x,y) - g'_\infty| : y > g(x)\} + \lim_{x\to\infty} |\chi'(x) - g'_\infty| = 0. \tag{1.13}$$

(iii) *There exists a constant* $p_\infty > 0$ *such that*

$$\lim_{x\to\infty} \sup\{|p(x,y) - p_\infty| : y > g(x)\} = 0. \tag{1.14}$$

This theorem indicates that the strong vortex sheets in supersonic flow are nonlinearly stable globally in structure.

In order to establish this theorem, we first develop a modified Glimm scheme whose mesh grids are designed to follow the slope of the Lipschitz boundary, which is different from the standard case with rectangular mesh grids, so that the lateral Riemann building blocks contain only one wave emanating from the mesh points on the boundary. For the adiabatic Euler flow determined by (1.1), the essential estimate is on the strength δ_1 of the reflected 1-wave when the weak 4-wave with strength α_4 hits the strong vortex sheet from below. We obtain that the key bound on the reflection coefficient in front of α_4 in the estimate of δ_1 is strictly less than one, i.e.,

$$\delta_1 = \beta_1 + K_{11}\alpha_4 + O(1)|\beta_1|(|\alpha_2| + |\alpha_3|), \qquad |K_{11}| < 1.$$

The estimate on the interaction between the boundary and weak waves is also crucial.

Based on the construction of the modified Glimm scheme and the new interaction estimates, we successfully identify a Glimm-type functional by incorporating the Lipschitz wall and the strong vortex sheet naturally and by tracing the interactions not only between the boundary and weak waves but also between the strong vortex sheet and weak waves, so that the Glimm-type functional monotonically decreases in the flow direction. Another essential estimate is to trace the approximate strong vortex sheets in order to establish the nonlinear stability and asymptotic behavior of the strong vortex sheet in supersonic flow in the downstream direction under the BV boundary perturbation. Condition (1.8) may be relaxed so that the total variation of $g'(x)$ is allowed to be relatively larger than the small L^∞ norm of $g'(x)$ by combining the analysis in this paper with the arguments in [21, 22].

We observe that the stability of contact discontinuities for the Cauchy problem for strictly hyperbolic systems under a BV perturbation has been studied by Sablé-Tougeron [18] and Corli and Sablé-Tougeron [9]. In particular, the reflection coefficients, such as K_{11} here, are required to be less than one, which is the stability condition for the mixed problem in the strip $(0,1)$ in the earlier works; see, e.g., Sablé-Tougeron [18]. The essential difference between system (1.1) as analyzed in sections 2–5 here and strictly hyperbolic systems as considered in [9, 18] is that two of the four characteristic eigenvalues coincide and have two linearly independent

eigenvectors which determine the compressible vortex sheets so that two independent parameters are required to describe precisely these vortex sheets. Furthermore, our physical boundary condition for the initial-boundary value problem is the slip-wall boundary condition on the nonflat boundary whose slope function is allowed to be discontinuous, i.e., the characteristic boundary condition on the *nonflat, nonsmooth* boundary, which is different from the initial-boundary value problem over the *flat* boundary considered in [18]. For our case, additional nonlinear waves are produced by the boundary vertices, A_k, so that careful estimates on boundary reflection and interaction for nonlinear waves are required to match the slip-wall boundary condition and to be incorporated into the functional naturally.

We further remark that our Glimm-type functional has additional ingredients, in comparison with that used in Corli and Sablé-Tougeron [9] and Sablé-Tougeron [18]. More precisely, in this paper, the linear part of the functional has a new term, $L_0(J)$, to control the new waves produced by the flow moving around the boundary vertices, A_k. The linear part of the functional is shown to be decreasing near the vortex sheet and the boundary, in addition to controlling the quadratic part. The proof of the decreasing of the linear part makes full use of the following facts:

(i) $L_0(J)$ is strictly decreasing along the boundary.

(ii) If a 1-wave interacts with the boundary or the vortex sheet, it disappears and a new wave is produced, which implies the strict decreasing of L_1^i near the boundary and vortex sheet. The same is true when a 2-wave interacts with the vortex sheet.

Then, combining these two facts with the estimates on the coefficients K_{ij} and K_{bi} in the wave interactions and reflections, we succeed in assigning different weights to the strengths of the waves so that the linear part is strictly decreasing. With the careful design of the linear part, which is different from that in [18, 9], we simply use the same quadratic part as that used in Glimm [11] (see also [14, 15, 19]) in our Glimm-type functional, which sufficiently controls the linear part in the regions (1) and (2). For more details, see section 4.

It would be interesting and important to clarify the connections between the stability of steady compressible vortex sheets and long-time asymptotic stability of unsteady compressible vortex sheets in supersonic flow, since the nonlinear instabilities of compressible vortex sheets may develop in a short-time or some intermediate-time regime under certain situations. For this, we refer the reader to Miles [17], Artola and Majda [1, 2, 3], Woodward [24], and the references cited therein.

In this paper we first focus on the adiabatic Euler flows in sections 2–5 and then study the isentropic Euler flows in section 6. In section 2, we study the lateral and classical Riemann problems and analyze the properties of the Riemann solutions to the adiabatic Euler equations (1.1), which are essential for the interaction estimates among the nonlinear waves and the wall in section 3 and for the existence and behavior of entropy solutions of the problem in sections 4–5. In section 3, we make estimates on the wave interactions and reflections on the boundary and the strong vortex sheet, respectively. In section 4, we develop a modified Glimm scheme to construct the approximate solutions and establish necessary estimates for them in the approximate domains. In section 5, we establish the convergence of approximate solutions to a global entropy solution and prove the nonlinear stability and asymptotic behavior of the strong vortex sheet over the Lipschitz wall. In section 6, we extend the analysis and approach to establish the existence and behavior of two-dimensional steady supersonic flows governed by the isentropic Euler equations.

2. Riemann problems and Riemann solutions. In this section, we study the lateral and classical Riemann problems and analyze the properties of the Riemann solutions to the adiabatic Euler system (1.1), which are essential not only for the interaction estimates among the nonlinear waves and the Lipschitz wall but also for the existence and behavior of solutions of our problem in sections 3–5.

2.1. Euler equations. The Euler system can be written in the following conservation form:

$$W(U)_x + H(U)_y = 0, \tag{2.1}$$

where $U = (u, v, p, \rho)$, $W(U) = (\rho u, \rho u^2 + p, \rho uv, \rho u(h + \frac{u^2+v^2}{2}))$, and $H(U) = (\rho v, \rho uv, \rho v^2 + p, \rho v(h + \frac{u^2+v^2}{2}))$ with $h = \frac{\gamma p}{(\gamma-1)\rho}$. For a smooth solution $U(x, y)$, system (2.1) is equivalent to

$$\nabla_U W(U)U_x + \nabla_U H(U)U_y = 0. \tag{2.2}$$

Then the eigenvalues of (2.1) are the roots of the fourth order polynomial,

$$\det(\lambda \nabla_U W(U) - \nabla_U H(U)), \tag{2.3}$$

that is, the solutions of the equation

$$(v - \lambda u)^2 \left((v - \lambda u)^2 - c^2(1 + \lambda^2)\right) = 0,$$

where $c = \sqrt{\gamma p/\rho}$ is the sonic speed. If the flow is supersonic (i.e., $u^2 + v^2 > c^2$), system (1.1) is hyperbolic. In particular, when $u > c$, system (1.1) has four eigenvalues in the x-direction,

$$\lambda_j = \frac{uv + (-1)^j c\sqrt{u^2 + v^2 - c^2}}{u^2 - c^2}, \ \ j = 1, 4; \qquad \lambda_i = v/u, \ \ i = 2, 3, \tag{2.4}$$

and the four corresponding linearly independent eigenvectors:

$$\begin{aligned} &\mathbf{r}_j = \kappa_j(-\lambda_j, 1, \rho(\lambda_j u - v), \rho(\lambda_j u - v)/c^2)^\top, \quad j = 1, 4, \\ &\mathbf{r}_2 = (u, v, 0, 0)^\top, \qquad \mathbf{r}_3 = (0, 0, 0, \rho)^\top, \end{aligned} \tag{2.5}$$

where κ_j are chosen so that $\mathbf{r}_j \cdot \nabla\lambda_j = 1$ since the jth-characteristic fields are genuinely nonlinear, $j = 1, 4$. Note that the second and third characteristic fields are always linearly degenerate: $\mathbf{r}_j \cdot \nabla\lambda_j = 0, j = 2, 3$. We also point out that, at the unperturbed states $U_i = (u_i, 0, p_i, \rho_i)$ for $i = 1, 2$,

$$\lambda_2(U_i) = \lambda_3(U_i) = 0, \quad \lambda_1(U_i) = -c_i/\sqrt{u_i^2 - c_i^2} = -\lambda_4(U_i) < 0 \ \text{ for } i = 1, 2.$$

Definition 2.1 (entropy solutions). *A BV function $U = U(x, y)$ is called an entropy solution of problem* (1.1) *and* (1.9)–(1.10) *provided that*

(i) *U is a weak solution of* (1.1) *and satisfies* (1.9)–(1.10) *in the trace sense;*

(ii) *U satisfies the entropy inequality*

$$(\rho uS)_x + (\rho vS)_y \geq 0 \tag{2.6}$$

in the sense of distributions in Ω including the boundary.

Remark 2.1. The entropy inequality (2.6) for our steady case directly follows from the Clausius inequality in the time-dependent case,

$$(\rho S)_t + (\rho u S)_x + (\rho v S)_y \geq 0,$$

under the assumption that the solution (u, v, p, ρ) is independent of time t. Furthermore, by a direct but tedious calculation, when $u > c$, the function $\eta = -\rho u S$ as an entropy function of system (1.1) is a strictly convex function of the conserved variables

$$w = (w_1, w_2, w_3, w_4) = (\rho u, \rho u^2 + p, \rho u v, \rho u(E + p/\rho)).$$

2.2. Wave curves in the phase space. In this subsection, we analyze some basic properties of nonlinear waves. We consider the problem for $u > c$ in the state space, especially in the neighborhoods of U_1 and U_2. We first seek the self-similar solutions to (1.1),

$$(u, v, p, \rho)(x, y) = (u, v, p, \rho)(\xi), \qquad \xi = y/x,$$

which connect to a state $U_0 = (u_0, v_0, p_0, \rho_0)$. Then we have

$$\det\left(\xi \nabla_U W(U) - \nabla_U H(U)\right) = 0, \tag{2.7}$$

which implies

$$\xi = \lambda_i = v/u, \quad i = 2, 3, \quad \text{or} \quad \xi = \lambda_j = \frac{uv + (-1)^j c\sqrt{u^2 + v^2 - c^2}}{u^2 - c^2}, \quad j = 1, 4.$$

Plugging $\xi = \lambda_i$ into (2.7), we obtain

$$dp = 0, \qquad v du - u dv = 0,$$

which yields the vortex sheet curves $C_i(U_0)$ in the phase space:

$$C_i(U_0): \quad p = p_0, \quad w = v/u = v_0/u_0, \qquad i = 2, 3, \tag{2.8}$$

which describe compressible vortex sheets. More precisely, we have

$$C_2(U_0): U = (u_0 e^{\sigma_2}, v_0 e^{\sigma_2}, p_0, \rho_0)^\top \tag{2.9}$$

with strength σ_2 and slope v_0/u_0, which is determined by

$$\begin{cases} \frac{dU}{d\sigma_2} = \mathbf{r}_2(U), \\ U|_{\sigma_2 = 0} = U_0, \end{cases}$$

and

$$C_3(U_0): U = (u_0, v_0, p_0, \rho_0 e^{\sigma_3})^\top \tag{2.10}$$

with strength σ_3 and slope v_0/u_0, which is determined by

$$\begin{cases} \frac{dU}{d\sigma_3} = \mathbf{r}_3(U), \\ U|_{\sigma_3 = 0} = U_0. \end{cases}$$

Remark 2.2. The full Euler system (1.1) has two contact discontinuities that coincide as a single vortex sheet in the physical xy-plane. However, in the phase space

$U = (u, v, p, \rho)$, to describe this vortex sheet precisely, it requires two independent parameters, since there are two linearly independent eigenvectors corresponding to the repeated eigenvalues $\lambda_2 = \lambda_3 = v/u$ of the two linearly degenerate fields.

Plugging $\xi = \lambda_j$ into (2.7), we get the jth-rarefaction wave curve $R_j(U_0), j = 1, 4$, in the phase space through U_0:

(2.11)
$$R_j(U_0): \ dp = c^2 d\rho, \ du = -\lambda_j dv, \ \rho(\lambda_j u - v)dv = dp \quad \text{for } \rho < \rho_0, \ u > c, \quad j = 1, 4.$$

Similarly, the Rankine–Hugoniot conditions for (1.1) are

$$s[\rho u] = [\rho v], \tag{2.12}$$

$$s[\rho u^2 + p] = [\rho uv], \tag{2.13}$$

$$s[\rho uv] = [\rho v^2 + p], \tag{2.14}$$

$$s\left[\rho u\left(h + \frac{u^2 + v^2}{2}\right)\right] = \left[\rho v\left(h + \frac{u^2 + v^2}{2}\right)\right], \tag{2.15}$$

where the jump symbol $[\cdot]$ stands for the value of the quantity of the front state minus that of the back state.

Then we have

$$(v_0 - su_0)^2\left((v_0 - su_0)^2 - \overline{c}^2(1 + s^2)\right) = 0,$$

where $\overline{c}^2 = \frac{c_0^2}{b}\frac{\rho}{\rho_0}$ and $b = \frac{\gamma+1}{2} - \frac{\gamma-1}{2}\frac{\rho}{\rho_0}$. This implies

$$s = s_i = v_0/u_0, \quad i = 2, 3, \tag{2.16}$$

or

$$s = s_j = \frac{u_0 v_0 + (-1)^j \overline{c}\sqrt{u_0^2 + v_0^2 - \overline{c}^2}}{u_0^2 - \overline{c}^2}, \quad j = 1, 4, \tag{2.17}$$

where $u_0 > \overline{c}$ for small shocks.

Plugging $s_i, i = 2, 3$, into (2.12)–(2.15), we get the same $C_i(U_0), i = 2, 3$, as defined in (2.9)–(2.10); while plugging $s_j, j = 1, 4$, into (2.12)–(2.15), we obtain the jth-shock wave curve $S_j(U_0), j = 1, 4$, through U_0:

$$S_j(U_0): \ [p] = \frac{c_0^2}{b}[\rho], \ [u] = -s_j[v], \ \rho_0(s_j u_0 - v_0)[v] = [p] \quad \text{for } \rho > \rho_0, \ u > c, \quad j = 1, 4,$$

where $\rho_0 < \rho$ is equivalent to the entropy condition (2.6) on the shock wave.

Note that $S_j(U_0)$ contacts with $R_j(U_0)$ at U_0 up to second order.

2.3. Lateral Riemann problem. It has been shown in [8] that when the angle between the flow direction of the front state and the wall at a boundary vertex is smaller than π and larger than the extreme angle determined by the incoming flow state and $\gamma \geq 1$, then a unique 4-shock forms, which separates the front state from the supersonic back state; when the angle between the flow direction of the front state and the wall at a boundary vertex is larger than π and less than an extreme angle, then a 4-rarefaction wave forms, which emanates from the vertex (see Figure 2). This indicates that when the angle between the flow direction of the front state and the wall at a boundary vertex is near π, the lateral Riemann problem is always uniquely solvable. For the detail, see Figure 3 and Proposition 3.3; also see Courant and Friedrichs [8].

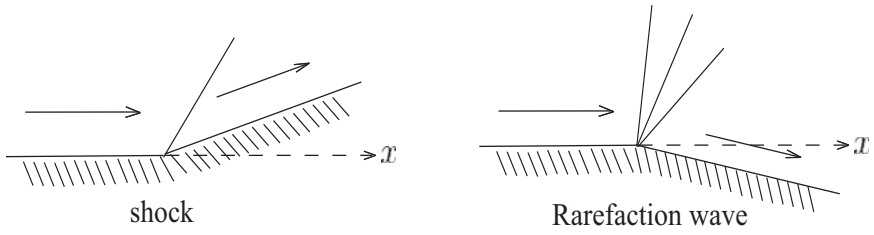

FIG. 2. *Lateral Riemann solutions.*

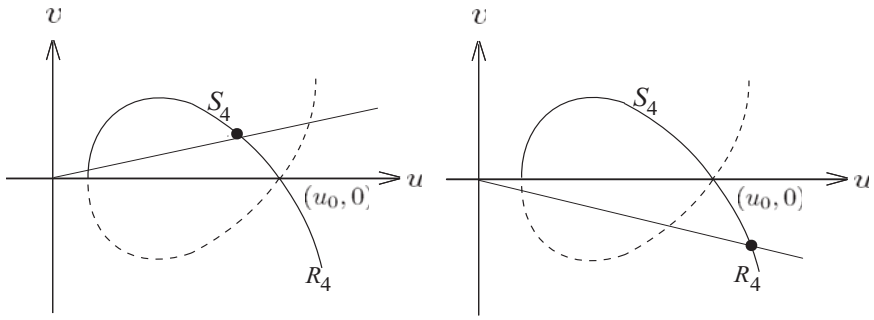

FIG. 3. *Wave curves in the (u, v)-plane for the lateral Riemann problem.*

2.4. Riemann problem involving only weak waves. Consider the Riemann problem for (2.1):

$$U|_{x=x_0} = \begin{cases} U_a, & y > y_0, \\ U_b, & y < y_0, \end{cases} \tag{2.18}$$

where U_a and U_b are the constant states which are regarded as the *above* state and *below* state with respect to the line $y = y_0$, respectively.

Following Lax [13], we can parameterize any physically admissible wave curve in a neighborhood of any constant state U_0, $O_\varepsilon(U_0)$, by $\alpha_j \mapsto \Phi_j(\alpha_j; U_b)$, with $\Phi_j \in C^2$ and $\Phi_j|_{\alpha_j=0} = U_b$ and $\partial_{\alpha_j}\Phi_j|_{\alpha_j=0} = \mathbf{r}_j(U_b)$. For $j = 1, 4$, the case $\alpha_j > 0$ corresponds to a rarefaction wave, while the case $\alpha_j < 0$ corresponds to a shock wave. Notice that, for system (1.1), we have the explicit formulas for Φ_2 and Φ_3 to describe the vortex sheets by two independent parameters (σ_2, σ_3):

$$\Phi_2(\sigma_2, U_b) = (u_b e^{\sigma_2}, v_b e^{\sigma_2}, p_b, \rho_b), \qquad \Phi_3(\sigma_3, U_b) = (u_b, v_b, p_b, \rho_b e^{\sigma_3}).$$

For simplicity, we set $\Phi(\alpha_4, \alpha_3, \alpha_2, \alpha_1; U_b) := \Phi_4(\alpha_4; \Phi_3(\alpha_3; \Phi_2(\alpha_2; \Phi_1(\alpha_1; U_b))))$. We also denote by $O_\varepsilon(W)$ a universal neighborhood that is a ball with radius $M\varepsilon > 0$ and center W, where $M > 0$ is a universal constant depending only on the parameters in the system and possibly the boundary function $g(x)$ (starting section 4.2), which may be different at each occurrence. Then we have the following lemma.

LEMMA 2.2. *There exists $\varepsilon > 0$ such that, for any states $U_a, U_b \in O_\varepsilon(U_0)$, the Riemann problem* (2.18) *admits a unique admissible solution consisting of four elementary waves. In addition, the state U_a can be represented by*

$$U_a = \Phi(\alpha_4, \alpha_3, \alpha_2, \alpha_1; U_b)$$

with $\Phi|_{\alpha_1=\alpha_2=\alpha_3=\alpha_4=0} = U_b$ and $\partial_{\alpha_i}\Phi|_{\alpha_1=\alpha_2=\alpha_3=\alpha_4=0} = \mathbf{r}_i(U_b), i = 1, 2, 3, 4.$

Furthermore, we find that the renormalization factors $\kappa_j(U), j = 1, 4$, in (2.5) are positive in a neighborhood $O_\varepsilon(U_0)$ of any state $U_0 = (u_0, 0, p_0, \rho_0)$ with $u_0 > c_0$, which is either U_1 or U_2 below.

LEMMA 2.3. *At any state $U_0 = (u_0, 0, p_0, \rho_0)$ with $u_0 > c_0$,*

$$\kappa_1(U_0) = \kappa_4(U_0) = 1/\left(\nabla_U \lambda_j \cdot (-\lambda_j, 1, \rho u \lambda_j, \rho u \lambda_j / c^2)|_{U=U_0}\right) > 0,$$

which implies $\kappa_j(U) > 0$ for any $U \in O_\varepsilon(U_0)$ with small $\varepsilon > 0$ since $\kappa_j(U)$ are continuous for $j = 1, 4$.

In fact, at the state $U_0 = (u_0, 0, p_0, \rho_0)$, it is straightforward to see that

$$\nabla_U \lambda_j \cdot (-\lambda_j, 1, \rho u \lambda_j, \rho u \lambda_j / c^2)|_{U=U_0} > 0, \qquad j = 1, 4.$$

Therefore, we have $\kappa_1(U_0) = \kappa_4(U_0) > 0$, which implies that $\kappa_j(U) > 0$, $j = 1, 4$, for any state $U \in O_\varepsilon(U_0)$ with small $\varepsilon > 0$.

2.5. Riemann problem involving the strong vortex sheets. For simplicity, we use the notation $\{U_b, U_a\} = (\alpha_1, \alpha_2, \alpha_3, \alpha_4)$ to denote $U_a = \Phi(\alpha_4, \alpha_3, \alpha_2, \alpha_1; U_b)$ throughout the paper. For any $U_b \in O_\varepsilon(U_1)$ and $U_a \in O_\varepsilon(U_2)$, we also use $\{U_b, U_a\} = (0, \sigma_2, \sigma_3, 0)$ to denote the strong vortex sheet that connects U_b and U_a with strength (σ_2, σ_3). That is,

$$U_m = \Phi_2(\sigma_2; U_b) := (u_b e^{\sigma_2}, v_b e^{\sigma_2}, p_b, \rho_b)^\top, \; U_a = \Phi_3(\sigma_3; U_m) := (u_m, v_m, p_m, \rho_m e^{\sigma_3})^\top.$$

In particular, we note that

$$U_2 = (u_2, 0, p_2, \rho_2)^\top = (u_1 e^{\sigma_{20}}, 0, p_1, \rho_1 e^{\sigma_{30}})^\top.$$

We write $G(\sigma_3, \sigma_2; U_b) = \Phi_3(\sigma_3; \Phi_2(\sigma_2; U_b))$ for short for any $U_b \in O_\epsilon(U_1)$. Then we have the following.

LEMMA 2.4. *The vector function $G(\sigma_3, \sigma_2; U_b)$ satisfies*

$$G_{\sigma_2}(\sigma_3, \sigma_2; U_b) = (u_b e^{\sigma_2}, v_b e^{\sigma_2}, 0, 0)^\top, \qquad G_{\sigma_3}(\sigma_3, \sigma_2; U_b) = (0, 0, 0, \rho_b e^{\sigma_3})^\top,$$

and

$$\nabla_U G(\sigma_3, \sigma_2; U_b) = \operatorname{diag}(e^{\sigma_2}, e^{\sigma_2}, 1, e^{\sigma_3}).$$

These can be easily obtained from direct calculations and are thus omitted.

The following lemma is essential to estimate the strengths of reflected weak waves in the interaction between the strong vortex sheet and weak waves (see the proofs for Propositions 3.4–3.5).

LEMMA 2.5. *For the plane vortex sheet with the lower state $U_1 = (u_1, 0, p_1, \rho_1)$, upper state $U_2 = (u_2, 0, p_1, \rho_2)$, and strength $(\sigma_{20}, \sigma_{30})$,*

$$\det(\mathbf{r}_4(U_2), G_{\sigma_3}(\sigma_{30}, \sigma_{20}; U_1), G_{\sigma_2}(\sigma_{30}, \sigma_{20}; U_1), \nabla_U G(\sigma_{30}, \sigma_{20}; U_1) \cdot \mathbf{r}_1(U_1)) > 0.$$

This can be obtained by the following direct calculations:

$$\begin{aligned}
&\det(\mathbf{r}_4(U_2), G_{\sigma_3}(\sigma_{30}, \sigma_{20}; U_1), G_{\sigma_2}(\sigma_{30}, \sigma_{20}; U_1), \nabla_U G(\sigma_{30}, \sigma_{20}; U_1) \cdot \mathbf{r}_1(U_1)) \\
&= \kappa_1(U_1)\kappa_4(U_2) \begin{vmatrix} -\lambda_4(U_2) & 0 & u_1 e^{\sigma_{20}} & e^{\sigma_{20}}(-\lambda_1(U_1)) \\ 1 & 0 & 0 & e^{\sigma_{20}} \\ \rho_2 u_2 \lambda_4(U_2) & 0 & 0 & \rho_1 u_1 \lambda_1(U_1) \\ \frac{\rho_2 u_2 \lambda_4(U_2)}{c_2^2} & \rho_1 e^{\sigma_{30}} & 0 & e^{\sigma_{30}} \frac{\rho_1 u_1 \lambda_1(U_1)}{c_1^2} \end{vmatrix} \\
&= \kappa_1(U_1)\kappa_4(U_2)\rho_1^2 u_1^2 e^{\sigma_{20}+\sigma_{30}}(\lambda_4(U_2)e^{2\sigma_{20}+\sigma_{30}} + \lambda_4(U_1)) > 0.
\end{aligned}$$

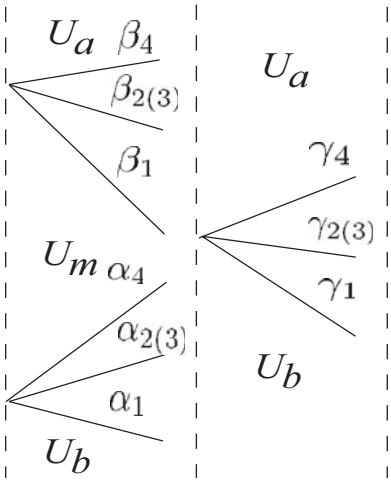

FIG. 4. *Weak wave interactions.*

3. Estimates on wave interactions and reflections. We now make estimates on wave interactions, especially near the strong vortex sheet, and wave reflections on the wall.

3.1. Estimates on weak wave interactions. We first estimate the interactions among weak waves. We will use the following elementary identity, whose proof is straightforward.

LEMMA 3.1. *If $f \in C^2(\mathbb{R}^2)$, then, for any $(x,y) \in \mathbb{R}^2$,*

$$f(x,y) - f(x,0) - f(0,y) + f(0,0) = xy \int_0^1 \int_0^1 f_{xy}(rx, sy) dr ds. \tag{3.1}$$

PROPOSITION 3.2. *Suppose that U_b, U_m, and U_a are three states in a small neighborhood of U_0 with $\{U_b, U_m\} = (\alpha_1, \alpha_2, \alpha_3, \alpha_4)$, $\{U_m, U_a\} = (\beta_1, \beta_2, \beta_3, \beta_4)$, and $\{U_b, U_a\} = (\gamma_1, \gamma_2, \gamma_3, \gamma_4)$ (cf. Figure 4). Then*

$$\gamma_i = \alpha_i + \beta_i + O(1)\triangle(\alpha, \beta), \tag{3.2}$$

where $\triangle(\alpha,\beta) = |\alpha_4||\beta_1| + |\alpha_3||\beta_1| + |\alpha_2||\beta_1| + |\alpha_4||\beta_2| + |\alpha_4||\beta_3| + \sum_{j=1,4} \triangle_j(\alpha,\beta)$ with

$$\triangle_j(\alpha,\beta) = \begin{cases} 0, & \alpha_j \geq 0,\ \beta_j \geq 0; \\ |\alpha_j||\beta_j|, & \text{otherwise.} \end{cases}$$

The proof of this proposition is standard, whose simple proof can be found in Temple [20] or Chen, Zhang, and Zhu [7]; also see Dafermos [10].

3.2. Estimates on the weak wave reflections on the boundary. Denote by $\{C_k\}_{k=0}^{\infty}$ the points $\{(a_k, b_k)\}_{k=0}^{\infty}$ in the xy-plane with $a_{k+1} > a_k > 0$ (cf. Figure 5). Set

$$\begin{aligned} &\omega_{k,k+1} = \arctan\left(\frac{b_{k+1} - b_k}{a_{k+1} - a_k}\right), \quad \omega_k = \omega_{k,k+1} - \omega_{k-1,k}, \quad \omega_{-1,0} = 0, \\ &\Omega_{k+1} = \{(x,y) : x \in [a_k, a_{k+1}],\ y > b_k + (x - a_k)\tan(\omega_{k,k+1})\}, \\ &\Gamma_{k+1} = \{(x,y) : x \in (a_k, a_{k+1}),\ y = b_k + (x - a_k)\tan(\omega_{k,k+1})\}, \end{aligned} \tag{3.3}$$

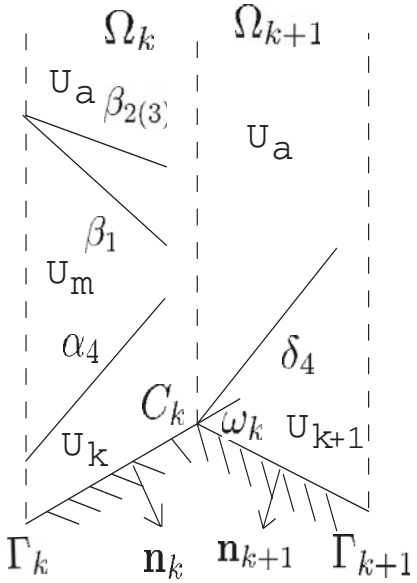

FIG. 5. *Weak wave reflections on the boundary.*

and the outer normal vector to Γ_k:

$$\mathbf{n}_{k+1} = \frac{(b_{k+1}-b_k, a_k - a_{k+1})}{\sqrt{(b_{k+1}-b_k)^2+(a_{k+1}-a_k)^2}} = (\sin(\omega_{k,k+1}), -\cos(\omega_{k,k+1})). \tag{3.4}$$

We consider the initial-boundary value problem

$$\begin{cases} (2.1) & \text{in } \Omega_{k+1}, \\ U|_{x=a_k} = U_a, & \\ (u,v)\cdot \mathbf{n}_{k+1} = 0 & \text{on } \Gamma_{k+1}, \end{cases} \tag{3.5}$$

where U_a is a constant state.

PROPOSITION 3.3. *Let* $\{U_m, U_a\} = (\beta_1, \beta_2, \beta_3, 0)$ *and* $\{U_k, U_m\} = (0,0,0,\alpha_4)$ *with*

$$(u_k, v_k)\cdot \mathbf{n}_k = 0.$$

Then there exists a unique solution U_{k+1} *of problem* (3.5) *such that*

$$\{U_{k+1}, U_a\} = (0,0,0,\delta_4)$$

and $U_{k+1}\cdot(\mathbf{n}_{k+1},0,0) = 0$. *Furthermore,*

$$\delta_4 = \alpha_4 + K_{b1}\beta_1 + K_{b2}\beta_2 + K_{b3}\beta_3 + K_{b0}\omega_k,$$

where K_{b1}, K_{b2}, K_{b3}, *and* K_{b0} *are* C^2*-functions of* β_3, β_2, β_1, α_4, ω_{k+1}, *and* U_a *satisfying*

$$K_{b1}|_{\{\omega_k=\alpha_4=\beta_1=\beta_2=\beta_3=0, U_a=U_1\}} = 1, \qquad K_{bi}|_{\{\omega_k=\alpha_4=\beta_1=\alpha_2=\beta_3=0, U_a=U_1\}} = 0,\ i=2,3,$$

and K_{b0} *is bounded. In particular,* $K_{b0} < 0$ *at the origin.*

Proof. First, by the implicit function theorem, similar to Lemma 2.2, we have $U_k = \Psi(\alpha_1, \alpha_2, \alpha_3, \alpha_4; U_a)$ for the C^2-function $\Psi = \Phi^{-1}$ and $\Psi_{\alpha_j}|_{\alpha_1=\alpha_2=\alpha_3=\alpha_4=0} = -\mathbf{r}_j(U_a)$, $j = 1, 2, 3, 4$. Then it suffices to find the solution to

$$\Psi(0,0,0,\alpha_4; \Psi(\beta_1,\beta_2,\beta_3,0;U_a)) \cdot (\mathbf{n}_k, 0, 0) = \Psi(0,0,0,\delta_4;U_a)\cdot(\mathbf{n}_{k+1},0,0). \tag{3.6}$$

Since

$$\begin{aligned}&\partial_{\delta_4}(\Psi(0,0,0,\delta_4;U_a)\cdot(\mathbf{n}_{k+1},0,0))|_{\{\delta_4=0,U_a=U_1,\omega_{k,k+1}=0\}}\\ &= -\kappa_1(U_1)(-\lambda_1(U_1), 1, \rho_1\lambda_1(U_1)u_1, \rho_1\lambda_1(U_1)u_1/c_1^2)\cdot(0,1,0,0) < 0,\end{aligned}$$

we know from the implicit function theorem that δ_4 can be solved as a C^2-function of β_3, β_2, β_1, α_4, ω_k, $\omega_{k,k+1}$, and U_a. Since $\omega_{k,k+1}$ and U_a are constant here, we write $\delta_4 = \delta_4(\omega_k, \beta_3, \beta_2, \beta_1, \alpha_4)$ without specific indication of the dependence on U_a and $\omega_{k,k+1}$.

Again, from (3.1), we can obtain

$$\begin{aligned}&\delta_4(\omega_k,\beta_3,\beta_2,\beta_1,\alpha_4)\\ &= \delta_4(\omega_k,\beta_3,\beta_2,\beta_1,\alpha_4) - \delta_4(0,\beta_3,\beta_2,\beta_1,\alpha_4) + \delta_4(0,\beta_3,\beta_2,\beta_1,\alpha_4)\\ &\quad - \delta_4(0,0,\beta_2,\beta_1,\alpha_4) + \delta_4(0,0,\beta_2,\beta_1,\alpha_4) - \delta_4(0,0,0,\beta_1,\alpha_4)\\ &\quad + \delta_4(0,0,0,\beta_1,\alpha_4) - \delta_4(0,0,0,0,\alpha_4) + \delta_4(0,0,0,0,\alpha_4)\\ &= K_{b0}\omega_k + K_{b3}\beta_3 + K_{b2}\beta_2 + K_{b1}\beta_1 + \alpha_4.\end{aligned}$$

Differentiating (3.6) with respect to β_1, β_2, and β_3, respectively, and letting $\omega_k = \beta_3 = \beta_2 = \beta_1 = \alpha_4 = 0$ and $U_a = U_1$, we have

$$\mathbf{r}_1(U_1)\cdot(0,1,0,0) = \partial_{\beta_1}\delta_4\,\mathbf{r}_4(U_1)\cdot(0,1,0,0),$$

$$\mathbf{r}_2(U_1)\cdot(0,1,0,0) = \partial_{\beta_2}\delta_4\,\mathbf{r}_4(U_1)\cdot(0,1,0,0),$$

and

$$\mathbf{r}_3(U_1)\cdot(0,1,0,0) = \partial_{\beta_3}\delta_4\,\mathbf{r}_4(U_1)\cdot(0,1,0,0).$$

Hence we have

$$K_{b1}|_{\{\omega_k=\beta_3=\beta_2=\beta_1=\alpha_4=0,\ U_a=U_1\}} = 1, \qquad K_{b2}|_{\{\omega_k=\beta_3=\beta_2=\beta_1=\alpha_4=0,\ U_a=U_1\}} = 0,$$

and $K_{b3}|_{\{\omega_k=\beta_3=\beta_2=\beta_1=\alpha_4=0,\ U_a=U_1\}} = 0$. It is clear that $K_{b0} = \partial_{\omega_k}\delta_4$ is bounded. Differentiating (3.6) with respect to ω_k, we find that, at the origin, $K_{b0} = \partial_{\omega_k}\delta_4| = -u_1/\kappa_4(U_1) < 0$. This completes the proof. ∎

3.3. Estimates on the interaction between the strong vortex sheet and weak waves. There are two cases depending on how the strong vortex sheet and the weak waves interact. The first case is when the weak waves approach the strong vortex sheet from below, as in Figure 6. Then we have the following.

PROPOSITION 3.4. *Let $U_b, U_m \in O_\epsilon(U_1)$ and $U_a \in O_\epsilon(U_2)$ with*

$$\{U_b, U_m\} = (0, \alpha_2, \alpha_3, \alpha_4), \qquad \{U_m, U_a\} = (\beta_1, \sigma_2, \sigma_3, 0).$$

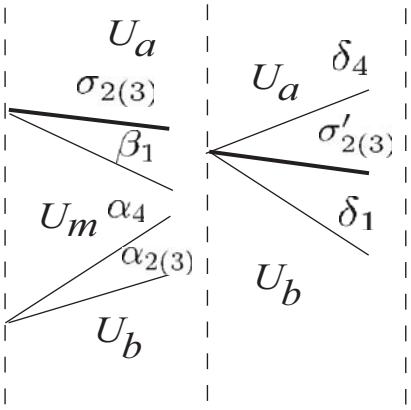

FIG. 6. *Weak waves approach the strong vortex sheet from below.*

Then there exists a unique $(\delta_1, \sigma_2', \sigma_3', \delta_4)$ *such that the Riemann problem* (2.18) *admits an admissible solution that consists of a weak* 1*-wave of strength* δ_1*, a strong vortex sheet of strength* (σ_2', σ_3')*, and a weak* 4*-wave of strength* δ_4*:*

$$\{U_b, U_a\} = (\delta_1, \sigma_2', \sigma_3', \delta_4).$$

Moreover,

$$\begin{aligned}
&\delta_1 = \beta_1 + K_{11}\alpha_4 + O(1)\Delta', \quad \delta_4 = K_{14}\alpha_4 + O(1)\Delta',\\
&\sigma_2' = \sigma_2 + \alpha_2 + K_{12}\alpha_4 + O(1)\Delta', \quad \sigma_3' = \sigma_3 + \alpha_3 + K_{13}\alpha_4 + O(1)\Delta',
\end{aligned}$$

where $\Delta' = |\beta_1|(|\alpha_2| + |\alpha_3|)$*,* $|K_{11}|_{\{\alpha_4=\alpha_3=\alpha_2=0, \sigma_2'=\sigma_{20}, \sigma_3'=\sigma_{30}\}} < 1$*, and* $\sum_{j=2}^4 |K_{1j}|$ *is bounded.*

Proof. We need to find the solution $(\delta_1, \sigma_2', \sigma_3', \delta_4)$ as a function of α_2, α_3, α_4, β_1, σ_2, σ_3, and U_b to

$$\Phi_4(\delta_4; G(\sigma_3', \sigma_2'; \Phi_1(\delta_1; U_b))) = G(\sigma_3, \sigma_2; \Phi_1(\beta_1, \Phi(\alpha_4, \alpha_3, \alpha_2, 0; U_b))). \tag{3.7}$$

Lemma 2.5 implies

$$\begin{aligned}
&\det\left(\frac{\partial \Phi_4(\delta_4; G(\sigma_3', \sigma_2'; \Phi_1(\delta_1; U_b)))}{\partial(\delta_4, \sigma_3', \sigma_2', \delta_1)}\right)\Bigg|_{\{\delta_4=\delta_1=0, \sigma_2'=\sigma_{20}, \sigma_3'=\sigma_{30}\}}\\
&= \det(\mathbf{r}_4(U_2), G_{\sigma_3}(\sigma_{30}, \sigma_{20}; U_1), G_{\sigma_2}(\sigma_{30}, \sigma_{20}; U_1), \nabla_U G(\sigma_{30}, \sigma_{20}; U_1) \cdot \mathbf{r}_1(U_1)) > 0.
\end{aligned}$$

Therefore, $(\delta_1, \sigma_2', \sigma_3', \delta_4)$ can be solved as a C^2-function of $(\alpha_2, \alpha_3, \alpha_4, \beta_1, \sigma_2, \sigma_3; U_b)$ uniquely. That is,

$$\sigma_i' = \sigma_i'(\alpha_2, \alpha_3, \alpha_4, \beta_1, \sigma_2, \sigma_3), \ i = 2, 3; \qquad \delta_j = \delta_j(\alpha_2, \alpha_3, \alpha_4, \beta_1, \sigma_2, \sigma_3), \ j = 1, 4,$$

where we have omitted U_b for simplicity. Using Lemma 3.1(i), we have

$$\begin{aligned}
\delta_1 &= \delta_1(\alpha_2, \alpha_3, \alpha_4, \beta_1, \sigma_2, \sigma_3) - \delta_1(\alpha_2, \alpha_3, 0, \beta_1, \sigma_2, \sigma_3) + \delta_1(\alpha_2, \alpha_3, 0, \beta_1, \sigma_2, \sigma_3)\\
&= K_{11}\alpha_4 + \beta_1 + O(1)(|\beta_1||\alpha_2| + |\beta_1||\alpha_3|),\\
\delta_4 &= \delta_4(\alpha_2, \alpha_3, \alpha_4, \beta_1, \sigma_2, \sigma_3) - \delta_4(\alpha_2, \alpha_3, 0, \beta_1, \sigma_2, \sigma_3) + \delta_4(\alpha_2, \alpha_3, 0, \beta_1, \sigma_2, \sigma_3)\\
&= K_{14}\alpha_4 + O(1)(|\beta_1||\alpha_2| + |\beta_1||\alpha_3|),\\
\sigma_i' &= \sigma_i'(\alpha_2, \alpha_3, \alpha_4, \beta_1, \sigma_2, \sigma_3) - \sigma_i'(\alpha_2, \alpha_3, 0, \beta_1, \sigma_2, \sigma_3) + \sigma_i'(\alpha_2, \alpha_3, 0, \beta_1, \sigma_2, \sigma_3)\\
&= K_{1i}\alpha_4 + \alpha_i + \sigma_i + O(1)(|\beta_1||\alpha_2| + |\beta_1||\alpha_3|), \qquad i = 2, 3,
\end{aligned}$$

where

$$K_{1i} = \int_0^1 \partial_{\alpha_4}\sigma_i'(\alpha_2, \alpha_3, \theta\alpha_4, \beta_1, \sigma_2, \sigma_3)d\theta, \quad i = 2, 3,$$
$$K_{1j} = \int_0^1 \partial_{\alpha_4}\delta_j(\alpha_2, \alpha_3, \theta\alpha_4, \beta_1, \sigma_2, \sigma_3)d\theta, \quad j = 1, 4.$$

When $\beta_1 = \alpha_4 = \alpha_3 = \alpha_2 = 0$, $\sigma_2 = \sigma_{20}$, and $\sigma_3 = \sigma_{30}$, it is clear that $|\partial_{\alpha_4}(\delta_1, \delta_4)|$ and $|\partial_{\alpha_4}(\sigma_2', \sigma_3')|$ are bounded. We can further claim that $|\partial_{\alpha_4}\delta_1| < 1$, which can be seen as follows:

Differentiate (3.7) with respect to α_4 and let $\beta_1 = \alpha_4 = \alpha_3 = \alpha_2 = 0$, $\sigma_2 = \sigma_{20}$, and $\sigma_3 = \sigma_{30}$. We obtain

$$\begin{aligned}
&\nabla_U G(\sigma_{30}, \sigma_{20}; U_1) \cdot \mathbf{r}_4(U_1)\\
&= \partial_{\alpha_4}\delta_4\, \mathbf{r}_4(U_2) + \partial_{\alpha_4}\sigma_3'\, G_{\sigma_3}(\sigma_{30}, \sigma_{20}; U_1)\\
&\quad + \partial_{\alpha_4}\sigma_2'\, G_{\sigma_2}(\sigma_{30}, \sigma_{20}; U_1) + \partial_{\alpha_4}\delta_1\, \nabla_U G(\sigma_{30}, \sigma_{20}; U_1) \cdot \mathbf{r}_1(U_1).
\end{aligned}$$

By Lemma 2.5, we have

$$\begin{aligned}
&|\partial_{\alpha_4}\delta_1|\\
&= \left|\frac{\det(\mathbf{r}_4(U_2), G_{\sigma_3}(\sigma_{30}, \sigma_{20}; U_1), G_{\sigma_2}(\sigma_{30}, \sigma_{20}; U_1), \nabla_U G(\sigma_{30}, \sigma_{20}; U_1) \cdot \mathbf{r}_4(U_1))}{\det(\mathbf{r}_4(U_2), G_{\sigma_3}(\sigma_{30}, \sigma_{20}; U_1), G_{\sigma_2}(\sigma_{30}, \sigma_{20}; U_1), \nabla_U G(\sigma_{30}, \sigma_{20}; U_1) \cdot \mathbf{r}_1(U_1))}\right|\\
&= \left|\frac{\kappa_4(U_2)\kappa_4(U_1)\rho_1^2 u_1^2 e^{\sigma_{20}+\sigma_{30}}(\lambda_4(U_2)e^{2\sigma_{20}+\sigma_{30}} - \lambda_4(U_1))}{\kappa_4(U_2)\kappa_1(U_1)\rho_1^2 u_1^2 e^{\sigma_{20}+\sigma_{30}}(\lambda_4(U_2)e^{2\sigma_{20}+\sigma_{30}} - \lambda_1(U_1))}\right|\\
&= \left|\frac{\lambda_4(U_2)e^{2\sigma_{20}+\sigma_{30}} - \lambda_4(U_1)}{\lambda_4(U_2)e^{2\sigma_{20}+\sigma_{30}} + \lambda_4(U_1)}\right| < 1.
\end{aligned}$$

This completes the proof. □

Remark 3.1. The essential feature of system (1.1) is that the reflection coefficient K_{11} is less than one, which also appears as the stability condition in [9, 18] for the strictly hyperbolic case.

The second case is when the weak waves approach the strong vortex sheet from above, as in Figure 7. By symmetry, we can easily obtain the following.

PROPOSITION 3.5. *Let $U_b \in O_\epsilon(U_1)$ and $U_m, U_a \in O_\epsilon(U_2)$ with*

$$\{U_b, U_m\} = (0, \sigma_2, \sigma_3, \alpha_4), \qquad \{U_m, U_a\} = (\beta_1, \beta_2, \beta_3, 0).$$

Then there exists a unique $(\delta_1, \sigma_2', \sigma_3', \delta_4)$ such that the Riemann problem (2.18) admits an admissible solution that consists of a weak 1-wave of strength δ_1, a strong vortex sheet of strength (σ_2', σ_3'), and a weak 4-wave of strength δ_4, that is,

$$\{U_b, U_a\} = (\delta_1, \sigma_2', \sigma_3', \delta_4).$$

Moreover,

$$\begin{aligned}
&\delta_1 = K_{21}\beta_1 + O(1)\Delta'', \quad \sigma_2' = \sigma_2 + \beta_2 + K_{22}\beta_1 + O(1)\Delta'',\\
&\sigma_3' = \sigma_3 + \beta_3 + K_{23}\beta_1 + O(1)\Delta'', \quad \delta_4 = \alpha_4 + K_{24}\beta_1 + O(1)\Delta'',
\end{aligned}$$

where $\sum_{j=1}^4 |K_{2j}|$ is bounded and $\Delta'' = |\alpha_4|(|\beta_2| + |\beta_3|)$.

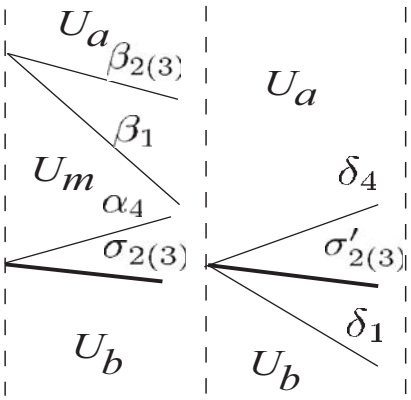

FIG. 7. *Weak waves approach the vortex sheet from above.*

4. Approximate solutions. In this section, we develop a modified Glimm difference scheme to construct a family of approximate solutions and establish their necessary estimates for the initial-boundary value problem (1.1) and (1.9)–(1.10) in the corresponding approximate domains $\Omega_{\Delta x}$.

4.1. A modified Glimm scheme. To define the scheme more clearly, we first use the fact that the boundary is a perturbation of the straight wall, that is,

$$\sup_{x\geq 0}|g'(x)|<\varepsilon \qquad \text{for sufficiently small } \varepsilon>0.$$

For any $\Delta x\geq 0$, set $a_k:=k\Delta x$ and $b_k:=y_k=g(k\Delta x)$ in (3.3) and (3.4), and follow the notation in subsection 3.2 (also see Figure 5). Then

$$m:=\sup_{k>0}\left\{\frac{y_k-y_{k-1}}{\Delta x}\right\}<\varepsilon. \tag{4.1}$$

Define

$$\Omega_{\Delta x}=\bigcup_{k\geq 1}\Omega_{\Delta x,k},$$

where $\Omega_{\Delta x,k}=\{(x,y):(k-1)\Delta x<x\leq k\Delta x, y>y_{k-1}+(x-(k-1)\Delta x)\tan(\omega_{k-1,k})\}$. Choose $\Delta y>0$ such that the Courant–Friedrichs–Lewy-type condition holds:

$$\frac{\Delta y-m\Delta x}{\Delta x}<\max_{j=1,4}\left(\sup_{U\in O_\varepsilon(U_1)\cup O_\varepsilon(U_2)}|\lambda_j(U)|\right).$$

Define

$$b_{k,n}=(2n+1+\theta_k)\Delta y+y_k,$$

where θ_k is randomly chosen in $(-1,1)$. Then we choose

$$P_{k,n}=(k\Delta x,b_{k,n}),\qquad k\geq 0,\quad n=0,1,2,\dots,$$

to be the mesh points and define the approximate solutions $U_{\Delta x,\theta}$ in $\Omega_{\Delta x}$ for any $\theta=(\theta_0,\theta_1,\theta_2,\dots)$ in an inductive way:

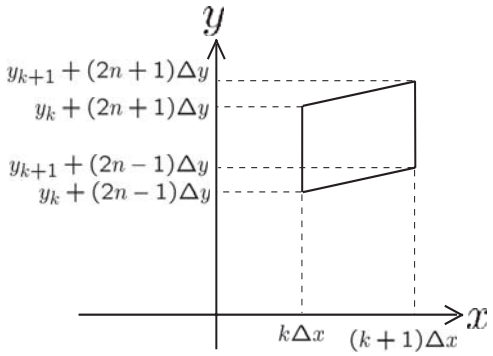

FIG. 8. *Diamond* $T_{k,n}$.

For $k=0$, we define $U_{\Delta x,\theta}$ in $\{0\le x<\Delta x\}\cap\Omega_{\Delta x}$ starting from

$$U_{\Delta x,\theta}|_{x=0,y>0}=\begin{cases} U_1, & 0<y<y_0^*,\\ U_2, & y>y_0^*.\end{cases}$$

Assume that $U_{\Delta x,\theta}$ has been constructed in $\{0\le x<k\Delta x\}$. Denoting, for $n\ge 1$,

$$U^0_{k,n}(y):=U_{\Delta x,\theta}(k\Delta x-,b_{k,n})\qquad \text{if } y\in(y_k+2n\Delta y,y_k+(2n+2)\Delta y),$$

then we define $U_{\Delta x,\theta}$ in $\{k\Delta x\le x<(k+1)\Delta x\}$ as follows: We first solve the following lateral Riemann problem in the diamond $T_{k,0}$, whose vertices are $((k+1)\Delta x,y_{k+1})$, $((k+1)\Delta x,y_{k+1}+\Delta y)$, $(k\Delta x,y_k)$, and $(k\Delta x,y_k+\Delta y)$:

$$\begin{cases} W(U_k)_x+H(U_k)_y=0 & \text{in } T_{k,0},\\ U_k|_{x=k\Delta x}=U^0_{k,n}, & \\ (u_k,v_k)\cdot\mathbf{n}_k=0 & \text{on } \Gamma_k.\end{cases}$$

We thus obtain the lateral Riemann solution U_k in $T_{k,0}$ as constructed in section 2.3 and define

$$U_{\Delta x,\theta}=U_k\qquad\text{in } T_{k,0}.$$

Then we solve the following Riemann problem in each diamond $T_{k,n}$ for $n\ge 1$, whose vertices are $((k+1)\Delta x,y_{k+1}+(2n-1)\Delta y)$, $((k+1)\Delta x,y_{k+1}+(2n+1)\Delta y)$, $(k\Delta x,y_k+(2n-1)\Delta y)$, and $(k\Delta x,y_k+(2n+1)\Delta y)$ (see Figure 8):

$$\begin{cases} W(U_k)_x+H(U_k)_y=0 & \text{in } T_{k,n},\\ U_k|_{x=k\Delta x}=U^0_{k,n}.\end{cases}$$

We obtain the Riemann solution $U_k(x,y)$ in $T_{k,n}$ as constructed in sections 2.4–2.5 and define

$$U_{\Delta x,\theta}=U_k\qquad\text{in } T_{k,n},\ n\ge 1.$$

In this way, we have constructed the approximate solutions $U_{\Delta x,\theta}(x,y)$ globally provided that we can obtain a uniform bound of the approximate solutions.

4.2. Glimm-type functional and its bounds. In this section, we prove that the approximate solutions can be well defined in $\Omega_{\Delta x}$ indeed via the steps in section 4.1 by providing a uniform bound for them. First, we introduce the following lemma.

LEMMA 4.1.

(i) *If* $\{U_b, U_a\} = (\alpha_1, \alpha_2, \alpha_3, \alpha_4)$ *with* $U_b, U_a \in O_\varepsilon(U_i)$ *for fixed* $i = 1$ *or* 2, *then*

$$|U_b - U_a| \le B_1(|\alpha_1| + |\alpha_2| + |\alpha_3| + |\alpha_4|)$$

with $B_1 = \max_{i=1,2,1\le j\le 4} \big(\sup_{U\in O_\varepsilon(U_i)} |\partial_{\alpha_j}\Phi(\alpha_4, \alpha_3, \alpha_2, \alpha_1; U)|\big)$.

(ii) *For any* $\sigma_j \in O_{\hat\varepsilon}(\sigma_{j0})$ *so that* $G(\sigma_3, \sigma_2, U_b) \subset O_\varepsilon(U_2)$ *when* $U_b \in O_\varepsilon(U_1)$ *for some* $\hat\varepsilon = \hat\varepsilon(\varepsilon) \to 0$ *as* $\varepsilon \to 0$,

$$|G(\sigma_3, \sigma_2, U_b) - G(\sigma_{30}, \sigma_{20}, U_b)| \le \tilde B(|\sigma_3 - \sigma_{30}| + |\sigma_2 - \sigma_{20}|)$$

with $\tilde B = \max_{j=2,3} \big(\sup_{\sigma_j\in O_{\hat\varepsilon}(\sigma_{j0})} |G'_{\sigma_j}(\sigma_3, \sigma_2, U_b)|\big)$.

Next, we show that $U_{\Delta x,\theta}$ can be globally defined. Assume that $U_{\Delta x,\theta}$ has been defined in $\{x < k\Delta x\} \cap \Omega_{\Delta x}$ by the steps in section 4.1 and assume that the following conditions are satisfied:

$$C_1(k-1): \begin{cases} \text{In each } \Omega_{\Delta x,j} \text{ for } 0 \le j \le k-1, \text{ there is a strong vortex sheet } \chi^{(j)} \\ \text{in } U_{\Delta x,\theta} \text{ with strength } (\sigma_2^{(j)}, \sigma_3^{(j)}) \text{ so that } \sigma_i^{(j)} \in O_{\hat\varepsilon}(\sigma_{i0}), \text{ which} \\ \text{divides } \Omega_{\Delta x,j} \text{ into two parts: } \Omega^{(1)}_{\Delta x,j} \text{ and } \Omega^{(2)}_{\Delta x,j}, \text{ where } \Omega^{(1)}_{\Delta x,j} \text{ is} \\ \text{the part bounded by } \chi^{(j)} \text{ and } \Gamma_j, \text{ where } \Omega_{\Delta x,j} \text{ and } \Gamma_j \text{ are defined} \\ \text{by (3.3)}; \end{cases}$$

$$C_2(k-1): U_{\Delta x,\theta}|_{\Omega^{(1)}_{\Delta x,j}} \in O_\varepsilon(U_1) \text{ and } U_{\Delta x,\theta}|_{\Omega^{(2)}_{\Delta x,j}} \in O_\varepsilon(U_2),\ 0 \le j \le k-1;$$

$$C_3(k-1): \begin{cases} \{\chi^{(j)}\}_{j=0}^{k-1} \text{ forms } \chi_{\Delta x,\theta} : y = \chi_{\Delta x,\theta}(x), \text{ called an approximate} \\ \text{vortex sheet, emanating from point } (0, y_0^*). \end{cases}$$

Here and in what follows, we always denote by $\chi^{(j)}$ the strong vortex sheet front with strength $(\sigma_2^{(j)}, \sigma_3^{(j)})$. Then we prove that $U_{\Delta x,\theta}$ can be defined in $\Omega_{\Delta x,k}$ and satisfies $C_1(k), C_2(k)$, and $C_3(k)$.

From the construction steps in section 4.1, we first define $U_{\Delta x,\theta}$ and the strong vortex sheet $\chi^{(k)}$ in $\Omega_{\Delta x,k}$ so that there exists a diamond $\Lambda_{k,n(k)}$ such that $\chi^{(k-1)}$ enters $\Lambda_{k,n(k)}$ and $\chi^{(k)}$ emanates from the center of $\Lambda_{k,n(k)}$. We extend $\chi_{\Delta x,\theta}$ to $\Omega_{\Delta x,k}$ such that $\chi_{\Delta x,\theta} = \chi^{(k)}$ in $\Omega_{\Delta x,k}$ and define $\Omega^{(1)}_{\Delta x,j}$ and $\Omega^{(2)}_{\Delta x,j}$ in the same way as in $C_1(k-1)$. Then it suffices to impose some conditions so that $C_2(k-1)$ holds and $\sigma_i^{(k)} \in O_{\hat\varepsilon}(\sigma_{i0}), i = 2, 3$.

To achieve this, we will establish the bound on the total variation of $U_{\Delta x,\theta}$ on a class of space-like curves. Denote

$$N(\theta_{k+1}, n) = \begin{cases} P_{k+1,n} & \text{if } \theta_{k+1} \le 0, \\ P_{k+1,n-1} & \text{if } \theta_{k+1} > 0, \end{cases} \qquad S(\theta_k, n) = \begin{cases} P_{k-1,n-1} & \text{if } \theta_k \le 0, \\ P_{k-1,n} & \text{if } \theta_k > 0. \end{cases}$$

Then we introduce the following.

DEFINITION 4.2. *A* j*-mesh curve* J *is defined to be an unbounded space-like curve lying in the strip* $\{(j-1)\Delta x \le x \le (j+1)\Delta x\}$ *and consisting of the segments of the form* $P_{k,n-1}N(\theta_{k+1}, n)$, $P_{k,n-1}S(\theta_k, n)$, $S(\theta_k, n)P_{k,n}$, *and* $N(\theta_{k+1}, n)P_{k,n}$.

This means that we connect the mesh point $P_{k,n}$ by two line segments to the two mesh points $P_{k-1,n-1}$ and $P_{k-1,n}$ if $\theta_k \le 0$, or we connect the mesh point $P_{k,n}$ by two line segments to the two mesh points $P_{k-1,n}$ and $P_{k-1,n+1}$ if $\theta_k > 0$ (see Figure 9).

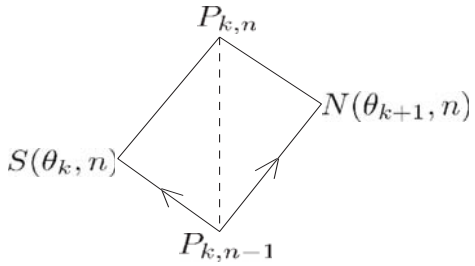

FIG. 9. *Interaction diamond $\Lambda_{k,n}$ and orientation of the segments.*

Clearly, for any $k > 0$, each k-mesh curve I divides the plane $\mathbb{R}^2$ into part I^+ and part I^-, where I^- is the one containing the set $\{x < 0\}$. As in Glimm [11], we also partially order these mesh curves by saying $J > I$ if every point of the mesh curve J is either on I or contained in I^+, and we call J an immediate successor to I if $J > I$ and every mesh point of J except one is on I.

With such mesh curves J, we associate the Glimm-type functional $F_s(J)$ on J.

DEFINITION 4.3. *We define*

$$F_s(J) = C^*(|\sigma_2^J - \sigma_{20}| + |\sigma_3^J - \sigma_{30}|) + F(J)$$

with

$$\begin{aligned}
&F(J) = L(J) + KQ(J),\\
&L(J) = L^1(J) + L^2(J),\\
&L^1(J) = K_1^* L_0(J) + K_{11}^* L_1^1(J) + K_{12}^* L_2^1(J) + K_{13}^* L_3^1(J) + L_4^1(J),\\
&L^2(J) = K_{21}^* L_1^2(J) + K_{22}^* L_2^2(J) + K_{23}^* L_3^2(J) + K_{24}^* L_4^2(J),\\
&Q(J) = \sum\{|\alpha_i||\beta_j| \ : \ \textit{both } \alpha_i \textit{ and } \beta_j \textit{ cross } J \textit{ and approach}\},
\end{aligned}$$

and $L_0(J) = \sum\{|\omega(C_k)| \ : \ C_k \in \Omega_J\}$,

$$L_j^i(J) = \sum\{|\alpha_j| \ : \ \alpha_j \textit{ crosses } J \textit{ in region (i)}\}, \quad i = 1, 2, \ j = 1, 2, 3, 4,$$

where K and C^* will be defined later, while Ω_J is the set of the corner points C_k lying in J^+, i.e.,

$$\Omega_J = \{C_k \in J^+ \cap \partial\Omega_{\Delta x} \ : \ k \geq 0\},$$

(σ_2^J, σ_3^J) stands for the strength of the strong vortex sheet crossing J, and $K_1^*, K_{11}^*, K_{12}^*$, and K_{13}^* for the constants associated with region (1), and $K_{21}^*, K_{22}^*, K_{23}^*$, and K_{24}^* for the constants associated with region (2) which satisfy the following conditions:

$$K_1^* > |K_{b0}|, \quad K_{1j}^* > |K_{bj}|, \qquad j = 1, 2, 3,$$

and

$$K_{24}^* < \frac{1 - |K_{11}|K_{11}^*}{|K_{14}|}, \quad K_{21}^* > |K_{21}|K_{11}^* + |K_{24}|K_{24}^*,$$

while K_{12}^*, K_{13}^*, K_{22}^*, and K_{23}^* are arbitrarily large positive constants. These conditions can be achieved from our discussions of the properties of K_{bj}, K_{1j}, and K_{2j}, $j = 1, 2, 3, 4$, as in Propositions 3.3–3.5 in section 3.

From now on, we denote by $M > 0$ a universal constant, depending only on the parameters in the system and the boundary function $g(x)$, which may be different at each occurrence, and $O(1)$ is the quantity that is bounded by M. Now we prove the decreasing property of our functional F_s. We first have the following.

PROPOSITION 4.4. *Suppose that the boundary function $g(x)$ satisfies* (4.1)*, and I and J are two k-mesh curves such that J is an immediate successor of I. Suppose that*

$$\left|U_{\Delta x,\theta}|_{I\cap(\,\Omega^{(i)}_{\Delta x,k-1}\cup\,\Omega^{(i)}_{\Delta x,k})}-U_i\right|<\varepsilon,\ i=1,2;\qquad |\sigma_j^I-\sigma_{j0}|<\hat{\varepsilon}(\varepsilon),\ j=2,3,$$

for some $\hat{\varepsilon}(\varepsilon)>0$ determined in Lemma 4.1*. Then there exist constants $\tilde{\varepsilon}>0, K>0$, and $C^*>1$, depending only on the parameters in system* (1.6) *and states U_1 and U_2, such that if $F_s(I)\le\tilde{\varepsilon}$, then*

$$F_s(J)\le F_s(I),$$

and hence

$$\left|U_{\Delta x,\theta}|_{J\cap(\,\Omega^{(i)}_{\Delta x,k-1}\cup\,\Omega^{(i)}_{\Delta x,k})}-U_i\right|<\varepsilon,\ i=1,2;\quad |\sigma_j^J-\sigma_{j0}|<\hat{\varepsilon}(\varepsilon),\ j=2,3.$$

Proof. Let Λ be the diamond that is formed by I and J. We can always assume that $I=I_0\cup I'$ and $J=J_0\cup J'$ such that $\partial\Lambda=I'\cup J'$. We divide our proof into four cases depending on the location of the diamond.

Case 1 (interior weak-weak interaction). Λ lies in the interior of $\Omega_{\Delta x}$ and does not touch $\chi_{\Delta x,\theta}$ so that only weak waves enter Λ. We prove only the case when Λ is in between $\partial\Omega_{\Delta x}$ and $\chi_{\Delta x,\theta}$ since the proof is similar when Λ is above $\chi_{\Delta x,\theta}$. Denote $Q(\Lambda)=\Delta(\alpha,\beta)$, where $\Delta(\alpha,\beta)$ is as defined in Proposition 3.2.

Then

$$L^1(J)-L^1(I)\le(1+K_{11}^*+K_{12}^*+K_{13}^*)MQ(\Lambda),$$

and

$$\begin{aligned}&Q(J)-Q(I)\\&=\left(Q(I_0)+\sum_{i=2}^4Q(\gamma_i,I_0)\right)-\left(Q(I_0)+Q(\Lambda)+\sum_{i=2}^4Q(\alpha_i,I_0)+\sum_{i=2}^4Q(\beta_i,I_0)\right)\\&=Q(O(1)Q(\Lambda),I_0)-Q(\Lambda)=(O(1)L(I_0)-1)Q(\Lambda)\le-\frac{1}{2}Q(\Lambda),\end{aligned}$$

since $L(I_0)\ll 1$. Hence

$$\begin{aligned}F(J)-F(I)&=L(J)-L(I)+K(Q(J)-Q(I))\\&\le\left((1+K_{11}^*+K_{12}^*+K_{13}^*)M-\frac{K}{2}\right)Q(\Lambda)\\&\le-\frac{1}{4}Q(\Lambda)\end{aligned}$$

by choosing suitably large K.

Case 2 (near the boundary). The diamond Λ touches the approximate boundary $\partial\Omega_{\Delta x}$, but not the strong vortex sheet $\chi_{\Delta x,\theta}$. Then $\Omega_J=\Omega_I\backslash\{C_k\}$ for certain k and $\sigma_j^I=\sigma_j^J, j=2,3$.

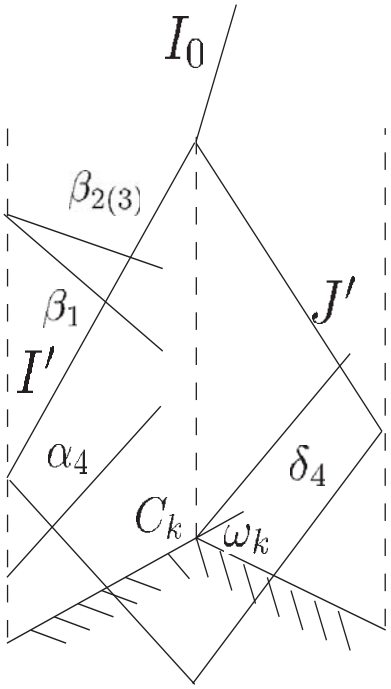

FIG. 10. *Case* 2: *near the boundary.*

Let δ_4 be the weak 4-wave going out of Λ through J', and let $\alpha_4, \beta_1, \beta_2$, and β_3 be the weak waves entering Λ through I', as shown in Figure 10. Then

$$
\begin{aligned}
&L_0(J) - L_0(I) = -|\omega_k|,\\
&L_i^1(J) - L_i^1(I) = \sum_{\gamma_i \text{ crosses } I_0} |\gamma_i| - \left(|\beta_i| + \sum_{\gamma_i \text{ crosses } I_0} |\gamma_i| \right) = -|\beta_i|, \quad i = 1,2,3,\\
&L_4^1(J) - L_4^1(I) = \left(|\delta_4| + \sum_{\gamma_4 \text{ crosses } I_0} |\gamma_4| \right) - \left(|\alpha_4| + \sum_{\gamma_4 \text{ crosses } I_0} |\gamma_4| \right)\\
&\qquad\qquad = |\delta_4| - |\beta_4| \le |K_{b1}||\beta_1| + |K_{b2}||\beta_2| + |K_{b3}||\beta_3| + |K_{b0}||\omega_{k+1}|,
\end{aligned}
$$

where the last step is from Proposition 3.3. Therefore, we have

$$L(J) - L(I) \le (|K_{b0}| - K_1^*)|\omega_{k+1}| + (|K_{b1}| - K_{11}^*)|\beta_1| + (|K_{b2}| - K_{12}^*)|\beta_2| + (|K_{b3}| - K_{13}^*)|\beta_3|.$$

Then, from our requirement in Definition 4.3, we have

$$L(J) \le L(I).$$

Notice that $F_s(I) \le \epsilon'$ implies $L(I) \le \epsilon'$. Hence, the higher order term $Q(I)$ can always be bounded by the linear term $L(I)$, and we can easily conclude $F(J) \le F(I)$.

Case 3. The diamond Λ covers a part of $\partial\Omega_{\Delta x}$, and $S_*(\sigma_{(k-1)})$ emanates from C_{k-1} and enters Λ.

Case 3.1 (near the strong vortex sheet I). We first investigate the situation when Λ lies in region (1) and the strong vortex sheet $\chi^{(k-1)}$ enters Λ. Then $\chi^{(k)}$ is generated from the inside of Λ, $\sigma_j^I = \sigma_j^{(k-1)}$, and $\sigma_j^J = \sigma_j^{(k)}$, $j = 2, 3$.

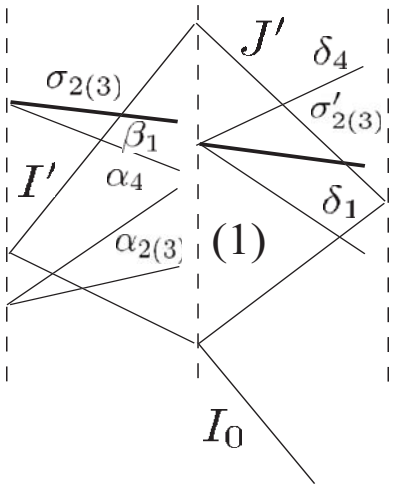

FIG. 11. *Case* 3.1: *near the strong vortex sheet* (I).

Let δ_4 and δ_1 be the weak waves going out of Λ through J', and let $\beta_1, \alpha_4, \alpha_3$, and α_2 be the weak waves entering Λ through I', as shown in Figure 11. Then

$$\begin{aligned}
L_4^2(J) - L_4^2(I) &= \left(|\delta_4| + \sum_{\gamma_4 \text{ crosses } I_0} |\gamma_4| \right) - \sum_{\gamma_4 \text{ crosses } I_0} |\gamma_4| \\
&= |\delta_4| \le |K_{14}||\alpha_4| + O(1)|\beta_1|(|\alpha_2| + |\alpha_3|), \\
L_1^1(J) - L_1^1(I) &= \left(|\delta_1| + \sum_{\gamma_1 \text{ crosses } I_0} |\gamma_1| \right) - \left(|\beta_1| + \sum_{\gamma_1 \text{ crosses } I_0} |\gamma_1| \right) \\
&= |\delta_1| - |\beta_1| \le |K_{11}||\alpha_4| + O(1)|\beta_1|(|\alpha_2| + |\alpha_3|), \\
L_j^1(J) - L_j^1(I) &= \sum_{\gamma_j \text{ crosses } I_0} |\gamma_j| - \left(|\alpha_j| + \sum_{\gamma_j \text{ crosses } I_0} |\gamma_j| \right) = -|\alpha_j|, \quad j = 2, 3, 4.
\end{aligned}$$

The above inequalities are from Propositions 3.4–3.5. Hence,

$$L(J) - L(I) \le (|K_{14}|K_{14}^* + |K_{11}|K_{11}^* - 1)|\alpha_4| - (K_{12}^* + O(1)|\beta_1|)|\alpha_2| - (K_{13}^* + O(1)|\beta_1|)|\alpha_3|$$

with $|K_{14}|K_{24}^* + |K_{11}|K_{11}^* - 1 < 0$ by our appropriate choice of the constants.

Furthermore, since the higher order term $Q(I)$ can always be bounded by the linear term $L(I)$ and

$$|\sigma_2^J - \sigma_2^I| + |\sigma_3^J - \sigma_3^I| \le (|K_{12}| + |K_{13}|)|\alpha_4| + (1 + O(1)|\beta_1|)|\alpha_2| + (1 + O(1)|\beta_1|)|\alpha_3|$$

with $|K_{12}|$ and $|K_{13}|$ bounded, we can choose C^* suitably small such that

$$F_s(J) - F_s(I) \le C^*(|\sigma_2^J - \sigma_2^I| + |\sigma_3^J - \sigma_3^I|) + F(J) - F(I) \le 0.$$

Therefore, we have $F_s(J) \le F_s(I)$.

Case 3.2 (near the strong vortex sheet II). Now, we investigate the second situation when Λ lies in region (2) and the strong vortex sheet $\chi^{(k-1)}$ enters Λ. Then $\chi^{(k)}$ is generated from the interior of Λ, $\sigma_j^I = \sigma_j^{(k-1)}$, and $\sigma_j^J = \sigma_j^{(k)}$.

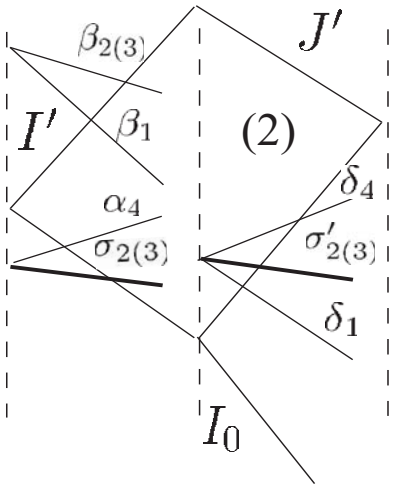

FIG. 12. *Case* 3.2: *near the strong vortex sheet* (II).

Let δ_4 and δ_1 be the weak waves going out of Λ through J', and let β_1, β_2, and β_3 be the weak waves entering Λ through I', as shown in Figure 12. Then

$$\begin{aligned}
L_1^1(J)-L_1^1(I) &= \left(|\delta_1|+\sum_{\gamma_1 \text{ crosses } I_0}|\gamma_1|\right)-\sum_{\gamma_1 \text{ crosses } I_0}|\gamma_1| \\
&= |\delta_1| \le |K_{21}||\beta_1|+O(1)(|\alpha_4||\beta_2|+|\alpha_4||\beta_3|), \\
L_4^2(J)-L_4^2(I) &= \left(|\delta_4|+\sum_{\gamma_4 \text{ crosses } I_0}|\gamma_4|\right)-\left(|\alpha_4|+\sum_{\gamma_4 \text{ crosses } I_0}|\gamma_4|\right) \\
&= |\delta_4|-|\alpha_4| \le |K_{24}||\beta_1|+O(1)(|\alpha_4||\beta_2|+|\alpha_4||\beta_3|), \\
L_j^2(J)-L_j^2(I) &= \sum_{\gamma_j \text{ crosses } I_0}|\gamma_j|-\left(|\beta_j|+\sum_{\gamma_j \text{ crosses } I_0}|\gamma_j|\right)=-|\beta_j|, \quad j=1,2,3.
\end{aligned}$$

The above inequalities are from Propositions 3.4–3.5. Hence

$$L(J)-L(I) \le (|K_{21}|K_{11}^*+|K_{24}|K_{24}^*-K_{21}^*)|\beta_1|-(K_{22}^*+O(1)|\alpha_4|)|\beta_2|-(K_{23}^*+O(1)|\alpha_4|)|\beta_3|$$

with $|K_{21}|K_{11}^*+|K_{24}|K_{24}^*-K_{21}^*<0$ by our appropriate choice of the constants.

Similar to the analysis for Case 3.1, we again have $F_s(J)\le F_s(I)$.

Then, from Lemma 4.1, there exists $\tilde\epsilon>0$ such that, when $F(I)<\tilde\epsilon$, we have $|U-U_1|<\epsilon$, or $|U-U_2|<\epsilon$. □

Let I_k be the k-mesh curve lying in $\{(j-1)\Delta x\le x\le j\Delta x\}$. From Proposition 4.4, we obtain the following theorem for any $k\ge 1$.

THEOREM 4.5. *Suppose that the boundary function $g(x)$ satisfies* (4.1). *Let ε, $\tilde\varepsilon$, $\hat\varepsilon(\varepsilon)$, K, and C^* be the constants specified in Proposition* 4.4. *If the induction hypotheses $C_1(k-1)$, $C_2(k-1)$, and $C_3(k-1)$ hold and if $F_s(I_{k-1})\le\tilde\varepsilon$, then*

$$\left|U_{\Delta x,\theta}\big|_{\Omega^{(i)}_{\Delta x,k}}-U_i\right|<\varepsilon,\ i=1,2; \qquad U_{\Delta x,\theta}|_{x<0}=\begin{cases} U_1, & y<y_0^*,\\ U_2, & y>y_0^*,\end{cases}$$

$$|\sigma_j^{(k)}-\sigma_{j0}|<\hat\varepsilon(\varepsilon),\ j=2,3,$$

and

$$F_s(I_k) \le F_s(I_{k-1}). \tag{4.2}$$

Moreover, we obtain the following.

THEOREM 4.6. *There exists $\varepsilon > 0$ such that if $TV(g'(\cdot)) < \varepsilon$, then, for any $\theta \in \prod_{k=0}^{\infty}(-1,1)$ and every $\Delta x > 0$, the modified Glimm scheme defines a family of global approximate solutions $U_{\Delta x,\theta}$ and the corresponding approximate strong vortex sheet fronts $\chi_{\Delta x,\theta}$ in $\Omega_{\Delta x,\theta}$ which satisfy $C_1(k-1)$, $C_2(k-1)$, $C_3(k-1)$, and (4.2) for any $k \ge 1$. In addition,*

$$TV\{U_{\Delta x,\theta}(k\Delta x-,\cdot) : [y_k,\infty)\} < M\,TV(g'(\cdot))$$

for any $k \ge 0$ and

$$|\chi_{\Delta x,\theta}(x+h) - \chi_{\Delta x,\theta}(x)| \le M|h| + 2\Delta x$$

for any $x \ge 0$ and $h > 0$.

4.3. Estimates on the approximate vortex sheets. We use the notation and estimates in the previous section and define

$$s_{\Delta x,\theta}(x) = \left.\frac{v_{\Delta x,\theta}}{u_{\Delta x,\theta}}\right|_{\{y=\chi_{\Delta x,\theta}\}} = s^{(k)}|_{\{y=\chi_{\Delta x,\theta}\}} \qquad \text{if } x \in (k\Delta x,(k+1)\Delta x],$$

$$E_{\Delta x,\theta}(\Lambda) \begin{cases} Q(\Lambda) & \text{for Case 1,} \\ |\omega_k| + |\beta_1| + |\beta_2| + |\beta_3| & \text{for Case 2,} \\ |\alpha_4| & \text{for Case 3.1,} \\ |\beta_1| & \text{for Case 3.2.} \end{cases}$$

Let $L_{\Delta x,\theta}(\Gamma_b)$ be the sum of the strengths of 4-waves leaving Γ_b, and let $L^2_{\Delta x,\theta}$ and $L^1_{\Delta x,\theta}$ be the sum of the strengths of all 4-waves and all 1-waves, respectively, leaving the vortex sheet $\chi_{\Delta x,\theta}$. Then, by Proposition 4.4, we have the following lemma.

LEMMA 4.7. *There exists a constant M_1, independent of $\Delta x, \theta$, and $U_{\Delta x,\theta}$, such that*

$$\sum_{\Lambda} E_{\Delta x,\theta}(\Lambda) \le M_1,$$

where the summation is over all the diamonds.

Then we have the following lemma.

LEMMA 4.8. *There exist constants M_2 and M_3, independent of $\Delta x, \theta$, and $U_{\Delta x,\theta}$, such that*

$$L^2_{\Delta x,\theta} + L^1_{\Delta x,\theta} \le M_2, \qquad TV(s_{\Delta x,\theta}) \le M_3.$$

5. Global entropy solutions. In this section we establish the convergence of the approximate solutions to a global entropy solution and prove the nonlinear stability and asymptotic behavior of the strong vortex sheet under the BV perturbation.

5.1. Convergence of the approximate solutions. Let the line $x = a > 0$ intersect $\partial\Omega_{\Delta x} = \cup_{k\geq 1}\{\overline{C_{k-1}C_k}\}$ at point $(a, p_a^{\Delta x})$. Similarly to [26], by Theorem 4.6, we have the following lemma.

LEMMA 5.1. *For any $h > 0$ and $x \geq 0$, there exists a constant M independent of $\Delta x, \theta$, and h such that*

$$\int_0^\infty |U_{\Delta x,\theta}(x+h, y+p_{x+h}^{\Delta x}) - U_{\Delta x,\theta}(x, y+p_x^{\Delta x})|dy \leq M|h|.$$

Denote

$$J(\theta, \Delta x, \phi) = \sum_{k=1}^{\infty}\int_0^\infty \phi(k\Delta x, y+y_k)\cdot(U_{\Delta x,\theta}(k\Delta x+, y+y_k) - U_{\Delta x,\theta}(k\Delta x-, y+y_k))dy,$$

where $\phi \in C_0^\infty(\mathbb{R}^2;\mathbb{R}^4)$. Following the steps in [11], we have the following.

LEMMA 5.2. *There exist a null set $N \subset \Pi_{k=0}^{\infty}(-1,1)$ and a subsequence $\{\Delta x_j\}_{j=1}^{\infty} \subset \{\Delta x\}$, which tends to 0, such that*

$$J(\theta, \Delta x_j, \phi) \longrightarrow 0 \qquad \text{when } \Delta x_j \to 0$$

for any $\theta \in \Pi_{k=0}^{\infty}(-1,1)\backslash N$ and $\phi \in C_0^\infty(\mathbb{R}^2;\mathbb{R}^4)$.

To establish the main theorem, we need to estimate the slope of the approximate strong vortex sheet fronts. Let

$$\tilde{d}_k = \frac{s^{(k-1)}\Delta x - (y_k - y_{k-1})}{\Delta y} \quad \text{and} \quad d_k = \begin{cases} \tilde{d}_k - 1 & \text{if } \tilde{d}_k > 0, \\ \tilde{d}_k + 1 & \text{if } \tilde{d}_k < 0. \end{cases}$$

Then, by the choice of Δx and $\{y_k\}$ and by Lemma 4.8, we find that $d_k \in (-1,1)$, which depends only on $\{\theta_l\}_{l=1}^{k-1}$. Thus we define

$$I(x, \Delta x, \theta) = \sum_{k=1}^{[x/\Delta x]} I_k(\Delta x, \theta),$$

where $I_k(\Delta x, \theta) = \mathbf{1}_{(-1,d_k)}(\theta_k)(d_k - 1)\Delta y + \mathbf{1}_{(d_k,1)}(\theta_k)(d_k+1)\Delta y$, $\mathbf{1}_A$ denotes the characteristic function of the set A, and $[x/\Delta x]$ denotes the largest integer less than or equal to $x/\Delta x$. Notice that $I_k(\Delta x, \theta)$ is the jump of the function $y = \chi_{\Delta x,\theta}(x)$ at $x = k\Delta x$ and is a measurable function of $(\Delta x, \theta)$, which depends only on $U_{\Delta x,\theta}|_{\{0\leq x\leq k\Delta x\}}$ and $\{\theta_l\}_{l=0}^{k}$.

LEMMA 5.3.

(i) *For any $x \geq 0$, $\Delta x > 0$, and $\theta \in \Pi_{k=0}^{\infty}(-1,1)$, we have*

$$\chi_{\Delta x,\theta}(x) = -I(x, \Delta x, \theta) + \int_0^x s_{\Delta x,\theta}(s)ds.$$

(ii) *There is a null set N_1 and a subsequence $\{\Delta_l\}_{l=1}^{\infty} \subset \{\Delta x_j\}_{j=1}^{\infty}$ such that*

$$\int_0^\infty e^{-x}|I(x, \Delta_l, \theta)|^2 dx \longrightarrow 0 \qquad \text{when } \Delta_l \to 0$$

for any $\theta \in \Pi_{k=0}^{\infty}(-1,1)\backslash N_1$.

Proof. Part (i) can be obtained by a direct calculation. We will focus only on part (ii). As in [11], let $d\theta = \Pi_{k=0}^{\infty}(d\theta_k/2)$. Then, for any $l > j$, we have

$$\int I_l I_j d\theta = \int \left(I_j \int I_l d\theta_l \right) \Pi_{i=1}^{l-1} d\theta_i = 0.$$

Therefore, we can deduce

$$\int |I(x, \Delta x, \theta)|^2 d\theta = \sum_{k=1}^{[x/\Delta x]} \int |I_k(\Delta x, \theta)|^2 d\theta \le 4 \left| \frac{\Delta y}{\Delta x} \right|^2 x \Delta x.$$

Then, by choosing a subsequence $\{\Delta_l\}_{l=1}^{\infty} \subset \{\Delta x_j\}_{j=1}^{\infty}$ with $\sum_{l=0}^{\infty} \Delta_l < \infty$ as in Lemma 5.2, we arrive at (ii). ∎

Then, by Theorem 4.6 and Lemmas 5.1–5.2, we have the following theorem.

THEOREM 5.4 (existence and stability). *There exist $\varepsilon > 0$ and $C > 0$ such that if* (1.8) *holds, then, for each $\theta \in (\Pi_{k=0}^{\infty}(-1, 1))\backslash(N \cup N_1)$, there exists a subsequence $\{\Delta_l\}$ of mesh sizes with $\Delta_l \to 0$ as $l \to \infty$ and a pair of functions $U_\theta \in BV(\Omega; O_\varepsilon(U_1) \cup O_\varepsilon(U_2))$ and $\chi_\theta \in Lip(\mathbb{R}_+; \mathbb{R}_+)$ with $\chi_\theta(0) = y_0^*$ such that*

(i) *$U_{\Delta_l,\theta}(x, \cdot)$ converges to $U_\theta(x, \cdot)$ in $L^1(g(x), \infty)$ for every $x > 0$, and U_θ is a global entropy solution of problem* (1.6) *and* (1.9)–(1.10) *in Ω and satisfies* (1.11) *and the initial-boundary data* (1.9)–(1.10) *in the trace sense;*

(ii) *$\chi_{\Delta_l,\theta}$ converges to χ_θ uniformly in any bounded x-interval such that* (1.12) *holds;*

(iii) *$s_{\Delta_l,\theta}$ converges to $s_\theta \in BV([0, \infty))$ a.e. with $|s_\theta| \le \hat{\varepsilon} \le \epsilon$ and*

$$\chi_\theta'(x) = s_\theta(x).$$

In addition, if θ is equidistributed, then $\chi_\theta(x) > g(x)$ for any $x > 0$ and the Rankine–Hugoniot conditions hold a.e. along the curve $\{y = \chi_\theta(x)\}$.

The proofs of (i) and (ii) and the convergence proof of $s_{\Delta_l,\theta}$ in (iii) can be carried out in the same way as in the standard cases (see [6, 11, 12, 25]) by using the structure of the approximate solutions. In particular, for any $\varphi \in C_0^{\infty}(\mathbb{R}^2; \mathbb{R})$,

$$\begin{aligned} &\int_{\Omega_{\Delta_x,\theta}} (\rho^{\Delta x,\theta} u^{\Delta x,\theta} \varphi_x + \rho^{\Delta x,\theta} v^{\Delta x,\theta} \varphi_y) dx dy \\ &= \int_{\Omega} \chi_{\Omega_{\Delta x,\theta}} (\rho^{\Delta x,\theta} u^{\Delta x,\theta} \varphi_x + \rho^{\Delta x,\theta} v^{\Delta x,\theta} \varphi_y) dx dy \end{aligned}$$

weak-star converges, and hence the initial condition is satisfied by the trace theorem for BV functions (cf. [23]). Similarly, the boundary condition can be shown to be satisfied. The equality in (iii) can be deduced from section 4.3 and the result on the convergence of $\{\chi_{\Delta_l,\theta}\}$ and $\{s_{\Delta_l,\theta}\}$.

5.2. Asymptotic behavior of the strong vortex sheet in the flow direction. As in Theorem 5.4, let $\theta \in (\Pi_{k=0}^{\infty}(-1, 1))\backslash(N \cup N_1)$ be equidistributed, and let U_θ be the solution and χ_θ its vortex sheet, respectively. By Theorem 5.4, we conclude that the solution U_θ contains at most countable vortex sheets, shocks, and points of wave interactions. Moreover, we can modify the solution U_θ such that U_θ is continuous except on the vortex sheets, shocks, and points of wave interactions (see [10, 12, 16]). Then we have the following lemma.

LEMMA 5.5. *The total variation of $(p_\theta, v_\theta/u_\theta)$ is sufficiently small above the Lipschitz wall and*

$$\lim_{x\to\infty} TV\{(p_\theta(x,\cdot), v_\theta(x,\cdot)/u_\theta(x,\cdot)) : (g(x),\infty)\} = 0.$$

Proof. Let $\{\Delta_l\}$ be the sequence given as in Theorem 5.4, and let $E_{\Delta_l,\theta}(\Lambda)$ and $Q_{\Delta_l,\theta}(\Lambda)$ be the quantities defined in Lemma 4.8. As in [12], we denote by $dE_{\Delta_l,\theta}$ the measures assigning to $E_{\Delta_l,\theta}(\Lambda)$ to the center of Λ.

The boundedness of $E_{\Delta_l,\theta}(\Lambda)$ in Lemma 4.7 implies the compactness of $\{dE_{\Delta_l,\theta}\}$. Then we can select its subsequence (still denoted by itself) so that, when $\Delta_l \to 0$, the limit

$$dE_{\Delta_l,\theta} \to dE_\theta$$

exists in the weak-star topology in the measure space and is finite on Ω. Therefore, for any $\delta > 0$, we can choose $x_\delta > 0$ independent of $\{U_{\Delta_l,\theta}\}$ and $\{\Delta_l\}$ such that, for any $l > 0$,

$$\sum_{k\geq[x_\delta/\Delta_l]} E_{\lambda,\theta}(\Lambda_{k,n}) < \delta.$$

Moreover, let $X^1_\delta = (x_\delta, y^1_\delta)$ (*or* $X^4_\delta = (x_\delta, y^4_\delta)$) be the point lying in $\chi_{\Delta_l,\theta}$ (or $\partial\Omega_{\Delta_k}$, respectively). Let $\chi^4_{\Delta_l,\theta}$ be the minimum approximate 4-characteristics in $U_{\Delta_l,\theta}$ emanating from the point X^1_δ, and $\chi^1_{\Delta_l,\theta}$ the maximum approximate 1-characteristics in $U_{\Delta_l,\theta}$ emanating from the point X^4_δ. From the construction of approximate solutions, we have

$$|\chi^j_{\Delta_l,\theta}(x+h) - \chi^j_{\Delta_l,\theta}(x)| \leq B(|h| + \Delta_l), \qquad j = 1, 4,$$

for some constant B independent of Δx and θ. Then, for $\theta \in \prod_{k=0}^{\infty}[-1,1]\backslash N$, we can select a subsequence (still denoted by) $\{\Delta_l\}$ such that

$$\chi^j_{\Delta_l,\theta} \to \chi^j_\theta \qquad \text{uniformly on every bounded interval as } \Delta_l \to 0$$

for some $\chi^j_\theta \in Lip$ with $(\chi^j_\theta)'$ bounded.

Let the characteristics $y = \chi^4_\theta(x)$ and $y = \chi^1_\theta(x)$ intersect $\partial\Omega$ and $y = \chi_\theta(x)$, respectively, at $(t^4_\delta, \chi_\theta(t^4_\delta))$ and $(t^1_\delta, \chi_\theta(t^1_\delta))$ for some t^4_δ and t^1_δ. Then, since the velocity ratio v/u and the pressure p are invariant across the vortex sheet, by the approximate conservation laws for the weak 1-waves and 4-waves, we can deduce in the same way as in [12] that

$$TV\{v_{\Delta_l,\theta}(x-,\cdot)/u_{\Delta_l,\theta}(x-,\cdot) \ : \ (g_l(x), \chi_{\Delta_l,\theta}(x))\} < M\,\delta$$

and

$$TV\{p_{\Delta_l,\theta}(x-,\cdot) \ : \ (g_l(x), \chi_{\Delta_l,\theta}(x))\} < M\,\delta$$

for $x > 2(t^1_\delta + t^4_\delta)$, where M is independent of δ, x, $U_{\Delta_l,\theta}$, and Δ_l.

Thus, taking the limit as $\Delta_l \to 0$ and using Theorem 5.4 and the regularity of U_θ yields that, for $x > 2(t^1_\delta + t^4_\delta)$,

$$TV\{v_\theta(x-,\cdot)/u_\theta(x-,\cdot) \ : \ (g(x), \chi_\theta(x))\} < M\,\delta,$$

$$TV\{p_\theta(x-,\cdot)\ :\ (g(x),\chi_\theta(x))\} < M\,\delta.$$

The corresponding estimates above the strong vortex sheet can be obtained similarly. This completes the proof. ∎

THEOREM 5.6.

(i) *Let* $g'_\infty = \lim_{x\to\infty} g'(x+)$. *Then*

$$\lim_{x\to\infty} \sup\{|v_\theta(x,y)/u_\theta(x,y) - g'_\infty|\ :\ y > g(x)\} + \lim_{x\to\infty} |\chi'_\theta(x) - g'_\infty| = 0.$$

(ii) *There exists a constant* p_∞ *such that*

$$\lim_{x\to\infty} \sup\{|p_\theta(x,y) - p_\infty|\ :\ y > g(x)\} = 0.$$

Proof. Let $U_{l,\theta} = U_{\Delta_l,\theta}$, $\sigma_{l,\theta} = \sigma_{\Delta_l,\theta}$, and $\chi_{l,\theta} = \chi_{\Delta_l,\theta}$, where Δ_l is chosen as in the proof of Lemma 5.5. Following the construction of approximate solutions, we conclude that, for every $x > 0$,

$$v_{l,\theta}/u_{l,\theta}|_{\Gamma_k} = (y_{k+1} - y_k)/\Delta x = g'(\eta_k)$$

for some $\eta_k \in (k\Delta x, (k+1)\Delta x)$. Then, choosing x_δ so that $|g'(x+) - g'(\infty)| < \delta$ for $x > x_\delta$, we have

$$\begin{aligned}&\sup\{|v_{l,\theta}(x,y)/u_{l,\theta}(x,y) - g'_\infty|\ :\ g(x) < y < \chi_\theta(x)\}\\ &\le TV\{v_{l,\theta}(x,\cdot)/u_{l,\theta}(x,\cdot)\ :\ (g(x),\chi_\theta(x))\} + M\delta \qquad \text{for } x > 2x_\delta.\end{aligned}$$

Therefore, taking the limit as $\Delta_l \to 0$, by Theorem 5.4 and Lemma 5.5, and by the regularity of U_θ, we can deduce part (i) for $g(x) < y < \chi_\theta(x)$. The case $y > \chi_\theta(x)$ can be proved similarly.

Part (ii) can be obtained similarly by using Lemma 5.5. ∎

6. Isentropic Euler flows over Lipschitz walls. In this section, we study the isentropic Euler equations (1.6) for steady supersonic flows, which can be written in the following conservation form:

$$W(U)_x + H(U)_y = 0, \qquad U = (u, v, \rho), \tag{6.1}$$

with

$$W(U) = (\rho u, \rho u^2 + p, \rho uv), \quad H(U) = (\rho v, \rho uv, \rho v^2 + p).$$

As in section 1, the problem of supersonic Euler flows governed by (6.1) over Lipschitz walls can be formulated as problem (1.9)–(1.10) for system (6.1) in the region above the wall.

DEFINITION 6.1 (entropy solutions). *A BV function* $U = U(x,y)$ *is called an entropy solution of problem* (6.1) *and* (1.9)–(1.10) *provided that*

(i) U *is a weak solution of* (6.1) *and satisfies* (1.9)–(1.10) *in the trace sense;*

(ii) U *satisfies the entropy inequality*

$$(\rho u(E + p(\rho)/\rho))_x + (\rho v(E + p(\rho)/\rho))_y \le 0 \tag{6.2}$$

in the sense of distributions in Ω *including the boundary.*

Remark 6.1. The entropy inequality (6.2) for the steady case directly follows from the energy inequality in the time-dependent isentropic case,

$$(\rho E)_t + (\rho u(E + p(\rho)/\rho))_x + (\rho v(E + p(\rho)/\rho))_y \le 0,$$

under the assumption that the solution (u, v, p, ρ) is independent of time t. Furthermore, by a straightforward calculation, the function $\eta = \rho u(E + p(\rho)/\rho)$ as an entropy function of system (6.1) is a strictly convex function of the conserved variables $W = (w_1, w_2, w_3) = (\rho u, \rho u^2 + p, \rho uv)$ when $u > c$.

6.1. Riemann problems and Riemann solutions. When $u > c$, the eigenvalues of system (6.1) are

$$\lambda_j = \frac{uv + (-1)^{\frac{j+1}{2}} c\sqrt{u^2 + v^2 - c^2}}{u^2 - c^2}, \quad j = 1, 3; \qquad \lambda_2 = v/u, \tag{6.3}$$

where $c^2 = \sqrt{p'(\rho)}$.

When the flow is supersonic (i.e., $u^2 + v^2 > c^2$), system (6.1) is hyperbolic and, when $u > c$, the corresponding eigenvectors are

$$\mathbf{r}_2 = (u, v, 0)^\top, \quad \mathbf{r}_j = \kappa_j(-\lambda_j, 1, \rho(\lambda_j u - v)/c^2)^\top, \ j = 1, 3,$$

where κ_j are chosen so that $\mathbf{r}_j \cdot \nabla\lambda_j = 1$ since the j-characteristic fields are genuinely nonlinear, $j = 1, 3$. Note that the second characteristic field is always linearly degenerate: $\mathbf{r}_2 \cdot \nabla\lambda_2 = 0$.

6.1.1. Wave curves in the phase space. Similarly as in section 2, the vortex sheet curve $C_2(U_0)$ through U_0 with strength σ_2 is

$$C_2(U_0) : U = (u, v, \rho)^\top = (u_0 e^{\sigma_2}, v_0 e^{\sigma_2}, \rho_0)^\top, \tag{6.4}$$

determined by

$$\begin{cases} \frac{dU}{d\sigma_2} = \mathbf{r}_2(U), \\ U|_{\sigma_2 = 0} = U_0, \end{cases}$$

which describes a compressible vortex sheet. Moreover, the jth-rarefaction wave curve $R_j(U_0)$ in the phase space through U_0 is

$$R_j(U_0) : \quad du = -\lambda_j dv, \quad \rho(\lambda_j u - v)dv = dp \qquad \text{for } \rho < \rho_0,\ u > c, \qquad j = 1, 3. \tag{6.5}$$

It is easy to check that $\frac{d\lambda_j}{d\rho}$ along $R_j(U_0), j = 1, 3$, satisfy

$$\frac{d\lambda_1}{d\rho}\bigg|_{R_1(U_0)} < 0, \quad \frac{d\lambda_3}{d\rho}\bigg|_{R_3(U_0)} > 0.$$

Similarly, the Rankine–Hugoniot conditions for (6.1) are

$$s[\rho u] = [\rho v], \tag{6.6}$$

$$s[\rho u^2 + p] = [\rho uv], \tag{6.7}$$

$$s[\rho uv] = [\rho v^2 + p]. \tag{6.8}$$

Then we have

$$s = s_2 = v_0/u_0, \qquad s = s_j = \frac{u_0v_0 + (-1)^{\frac{j+1}{2}}\overline{c}\sqrt{u_0^2 + v_0^2 - \overline{c}^2}}{u_0^2 - \overline{c}^2},\ j = 1, 3,$$

where $\overline{c}^2 = \frac{\rho}{\rho_0}\frac{[p]}{[\rho]}$.

Plugging s_2 into (6.6)–(6.8), we get the same $C_2(U_0)$, as defined in (6.4); while plugging $s_j, j = 1, 3$, into (6.6)–(6.8), we get the jth-shock wave curve $S_j(U_0)$ through U_0:

$$S_j(U_0): \quad [u] = -s_j[v], \quad \rho_0(s_ju_0 - v_0)[v] = [p] \quad \text{for } \rho > \rho_0,\ u > c, \quad j = 1, 3.$$

Notice that $S_j(U_0)$ contacts with $R_j(U_0)$ at U_0 up to second order and

$$\frac{ds_1}{d\rho}\bigg|_{S_1(U_0)} < 0, \qquad \frac{ds_3}{d\rho}\bigg|_{S_3(U_0)} > 0.$$

LEMMA 6.2. *At the state $U_0 = (u_0, 0, \rho_0)$ with $u_0 > c_0$, $\kappa_1(U_0) = \kappa_3(U_0) > 0$, which implies $\kappa_j(U) > 0$ for any state $U \in O_\varepsilon(U_0)$ with small $\varepsilon > 0$, since κ_j are continuous for $j = 1, 3$.*

6.1.2. Riemann problem involving strong vortex sheets. For any $U_b \in O_\varepsilon(U_1)$ and $U_a \in O_\varepsilon(U_2)$, we also use $\{U_b, U_a\} = (0, \sigma_2, 0)$ to denote the strong vortex sheet that connects U_b with U_a with strength σ_2. Then

$$U_a = \Phi_2(\sigma_2; U_b) = (u_be^{\sigma_2}, v_be^{\sigma_2}, \rho_b)^\top.$$

LEMMA 6.3. *The vector function $\Phi_2(\sigma_2; U_b)$ satisfies*

$$\partial_{\sigma_2}\Phi_2(\sigma_2; U_b) = (u_be^{\sigma_2}, v_be^{\sigma_2}, 0)^\top \quad \text{and} \quad \nabla_U\Phi_2(\sigma_2; U_b) = \operatorname{diag}(e^{\sigma_2}, e^{\sigma_2}, 1).$$

Furthermore, we have the following essential lemma for any 2-straight vortex sheet with below state $U_1 = (u_1, 0, \rho_1)$, above state $U_2 = (u_2, 0, \rho_1)$, and strength σ_{20}.

LEMMA 6.4. $\det(\mathbf{r}_3(U_2), \partial_{\sigma_2}\Phi_2(\sigma_{20}; U_1), \nabla_U\Phi_2(\sigma_{20}; U_1)\cdot\mathbf{r}_1(U_1)) > 0$.

This can be seen as follows:

$$\begin{aligned}
&\det(\mathbf{r}_3(U_2), \partial_{\sigma_2}\Phi_2(\sigma_{20}; U_1), \nabla_U\Phi_2(\sigma_{20}; U_1)\cdot\mathbf{r}_1(U_1))\\
&= \kappa_1(U_1)\kappa_3(U_2)\begin{vmatrix} -\lambda_3(U_2) & u_1e^{\sigma_{20}} & e^{\sigma_{20}}(-\lambda_1(U_1))\\ 1 & 0 & e^{\sigma_{20}}\\ \frac{\rho_1u_2\lambda_3(U_2)}{c_2^2} & 0 & \frac{\rho_1u_1\lambda_1(U_1)}{c_1^2}\end{vmatrix}\\
&= \frac{1}{c_1^2}\rho_1u_1^2e^{\sigma_{20}}\kappa_1(U_1)\kappa_3(U_2)(\lambda_3(U_2)e^{2\sigma_{20}} + \lambda_3(U_1)) > 0.
\end{aligned}$$

6.2. Estimates on wave interactions and reflections. Now we make essential estimates as in section 3. The interaction estimates are similar and the corresponding Figures 5–7 are the same except that the 2, 3-vortex sheets and 4-wave in section 3 are now replaced by a 2-vortex sheet and 3-wave, respectively.

6.2.1. Estimates on the weak wave reflections on the boundary. We use the same notation as in section 3.2 for $C_k(a_k, b_k)$ with $a_{k+1} > a_k > 0$, $\omega_{k,k+1}$, ω_k, Ω_k, Γ_k, and the outer normal vector $\mathbf{n}_k$ to Γ_k (cf. Figure 5). Then we consider the initial-boundary value problem with constant state U_a:

$$\begin{cases} (6.1) & \text{in } \Omega_{k+1}, \\ U|_{x=a_k} = U_a, & \\ (u, v) \cdot \mathbf{n}_{k+1} = 0 & \text{on } \Gamma_{k+1}. \end{cases}$$

PROPOSITION 6.5. *Let* $\{U_a, U_m\} = (\alpha_3, \alpha_2, 0)$ *and* $\{U_m, U_k\} = (0, 0, \beta_1)$ *with*

$$(u_k, v_k) \cdot \mathbf{n}_k = 0.$$

Then there exists U_{k+1} *such that*

$$\{U_a, U_{k+1}\} = (0, 0, \delta_3) \qquad \text{and} \qquad (u_{k+1}, v_{k+1}) \cdot \mathbf{n}_{k+1} = 0.$$

Furthermore,

$$\delta_3 = \beta_1 + K_{b3}\alpha_3 + K_{b2}\alpha_2 + K_{b0}\omega_k,$$

where K_{b3}, K_{b2}, *and* K_{b0} *are* C^2*-functions of* $(\alpha_3, \alpha_2, \beta_1, \omega_k; U_a)$ *satisfying*

$$K_{b3}|_{\{\omega_k=\alpha_3=\alpha_2=\beta_1=0, U_a=U_1\}} = 1, \qquad K_{b2}|_{\{\omega_k=\alpha_3=\alpha_2=\beta_1=0, U_a=U_1\}} = 0,$$

and K_{b0} *is bounded.*

6.2.2. Estimates on the interaction between the strong vortex sheet and weak waves. Again, we have to consider the two cases depending on how the vortex sheet and the weak waves interact. See Figures 6 and 7.

The first case is when the weak waves approach the vortex sheet from below. We have the following proposition.

PROPOSITION 6.6. *Let* $U_b, U_m \in O_\epsilon(U_1)$ *and* $U_a \in O_\epsilon(U_2)$ *with*

$$\{U_b, U_m\} = (0, \alpha_2, \alpha_3), \qquad \{U_m, U_a\} = (\beta_1, \sigma_2, 0).$$

Then there exists a unique $(\delta_1, \sigma_2', \delta_3)$ *such that the Riemann problem* (2.18) *admits an admissible solution that consists of a weak* 1*-wave of strength* δ_1*, a strong vortex sheet of strength* σ_2'*, and a weak* 3*-wave of strength* δ_3*, that is,*

$$\{U_b, U_a\} = (\delta_1, \sigma_2', \delta_3).$$

Moreover,

$$\begin{aligned} &\delta_1 = \beta_1 + K_{11}\alpha_3 + O(1)|\beta_1||\alpha_2|, \qquad \delta_3 = K_{13}\alpha_3 + O(1)|\beta_1||\alpha_2|, \\ &\sigma_2' = \sigma_2 + \alpha_2 + K_{12}\alpha_3 + O(1)|\beta_1||\alpha_2|, \end{aligned}$$

where

$$|K_{11}|_{\{\alpha_3=\alpha_2=0, \sigma_2'=\sigma_{20}\}} = \left|\frac{\lambda_3(U_2)e^{\sigma_{20}} - \lambda_3(U_1)}{\lambda_3(U_2)e^{\sigma_{20}} + \lambda_3(U_1)}\right| < 1, \quad K_{12} \text{ and } K_{13} \text{ are bounded.}$$

We need to find the solution $(\delta_1, \sigma_2', \delta_3)$ as a function of $(\alpha_2, \alpha_3, \beta_1, \sigma_2; U_b)$ to

$$\Phi_2(\sigma_2; \Phi_1(\beta_1; \Phi_3(\alpha_3, \alpha_2, 0; U_b))) = \Phi_3(\delta_3; \Phi_2(\sigma_2'; \Phi_1(\delta_1; U_b))). \tag{6.9}$$

Lemma 6.4 implies

$$\det\left(\frac{\partial\Phi_3(\delta_3,\Phi_2(\sigma_2';\Phi_1(\delta_1,U_b)))}{\partial(\delta_3,\sigma_2',\delta_1)}\right)\Bigg|_{\{\delta_1=0,\sigma_2'=\sigma_{20}\}}$$
$$=\det(\mathbf{r}_3(U_2),\partial_{\sigma_2}\Phi_2(\sigma_{20};U_1),\nabla_U\Phi_2(\sigma_{20};U_1)\cdot\mathbf{r}_1(U_0))>0.$$

Therefore, $(\delta_3,\sigma_2',\delta_1)$ can be solved as a C^2-function of $(\alpha_2,\alpha_3,\beta_1,\sigma_2;U_b)$ uniquely, i.e., $\delta_i=\delta_i(\alpha_2,\alpha_3,\beta_1,\sigma_2;U_b)$, $i=1,3$, and $\sigma_2'=\sigma_2'(\alpha_2,\alpha_3,\beta_1,\sigma_2;U_b)$. Then we can follow the proof of Proposition 3.3 to obtain our desired result.

The second case is when the weak waves approach the vortex sheet from above. By symmetry, we can easily obtain the following.

PROPOSITION 6.7. *Let $U_b\in O_\epsilon(U_1)$ and $U_a,U_m\in O_\epsilon(U_2)$ with*

$$\{U_b,U_m\}=(0,\sigma_2,\alpha_3),\qquad \{U_m,U_a\}=(\beta_1,\beta_2,0).$$

Then there exists a unique $(\delta_1,\sigma_2',\delta_3)$ such that the Riemann problem (2.18) *admits an admissible solution that consists of a weak* 1*-wave of strength δ_1, a vortex sheet of strength σ_2', and a weak* 3*-wave of strength δ_3, that is,*

$$\{U_b,U_a\}=(\delta_1,\sigma_2',\delta_3).$$

Moreover,

$$\delta_1=K_{21}\beta_1+O(1)|\alpha_3||\beta_2|,\quad \delta_3=\alpha_3+K_{23}\beta_1+O(1)|\alpha_3||\beta_2|,$$
$$\sigma_2'=\sigma_2+\beta_2+K_{22}\beta_1+O(1)|\alpha_3||\beta_2|,$$

where $\sum_{j=1}^3|K_{2j}|$ is bounded.

6.3. Approximate solutions. Similarly to section 4, we can construct globally defined, modified Glimm approximate solutions $U_{\Delta x,\theta}$ in the approximate domains (see Figure 8). We need to estimate $U_{\Delta x,\theta}$ on a class of space-like curves, i.e., j-mesh curves J as introduced in Definition 4.2. To achieve this, we now define the Glimm-type functional.

DEFINITION 6.8. *We define*

$$F_s(J)=C^*|\sigma_2^J-\sigma_{20}|+F(J)$$

with

$$F(J)=L(J)+KQ(J),$$
$$L(J)=L^1(J)+L^2(J),$$
$$L^1(J)=K_1^*L_0(J)+K_{11}^*L_1^1(J)+K_{12}^*L_2^1(J)+L_3^1(J),$$
$$L^2(J)=K_{21}^*L_1^2(J)+K_{22}^*L_2^2(J)+K_{23}^*L_3^2(J),$$
$$Q(J)=\sum\{|\alpha_i||\beta_j|\ :\ \textit{both } \alpha_i \textit{ and } \beta_j \textit{ cross } J \textit{ and approach}\},$$

and $L_0(J)=\sum\{|\omega(C_k)|\ :\ C_k\in\Omega_J\}$,

$$L_j^i(J)=\sum\{|\alpha_j|\ :\ \alpha_j \textit{ crosses } J \textit{ in region (i)}\},\quad i=1,2;\ j=1,2,3,$$

where K and C^* are chosen later, while Ω_J is the set of the corner points C_k lying in J^+, that is,

$$\Omega_J=\{C_k\in J^+\cap\partial\Omega_{\Delta x}\ :\ k\ge 0\},$$

σ_2^J stands for the strength of the strong vortex sheet crossing J, K_1^*, K_{11}^*, and K_{12}^* are the constants associated with region (1)*, K_{21}^*, K_{22}^*, and K_{23}^* are the constants associated with region* (2)*, which satisfy the conditions*

$$K_1^* > |K_{b0}|, \qquad K_{1i}^* > |K_{bi}|, \quad i = 1, 2,$$

and

$$K_{23}^* < \frac{1 - |K_{11}|K_{11}^*}{|K_{13}|}, \quad K_{21}^* > |K_{21}|K_{11}^* + |K_{23}|K_{23}^*,$$

while K_{12}^* and K_{22}^* are arbitrarily large positive constants. These conditions can be achieved from our discussions of the properties of K_{bj} and K_{sj}, $j = 1, 2$, as in Propositions 6.5–6.7 *in section* 6.2*.*

The rest can be done in the same way as in the previous sections by choosing suitable K and C^*, so we omit the details here.

Acknowledgment. The second author thanks the Department of Mathematics of Northwestern University for its hospitality during his visit.

GLOBAL EXISTENCE OF CLASSICAL SOLUTIONS FOR A HAPTOTAXIS MODEL*

CHRISTOPH WALKER† AND GLENN F. WEBB†

Abstract. A system of nonlinear partial differential equations modeling haptotaxis is investigated. The model arises in cell migration processes involved in tumor invasion. The existence of unique global classical solutions is proved.

Key words. haptotaxis, diffusion, global existence, uniqueness, classical solutions

AMS subject classifications. 92C17, 92D25, 35G25

DOI. 10.1137/060655122

1. Introduction.

Models of complex dynamic biological processes frequently involve systems of nonlinear partial differential equations for production, growth, decay, interaction, and spatial movement. For models that include spatial movement the equations typically contain both diffusion and taxis terms. Our goal in this paper is to examine the issues of global existence and uniqueness for a model involving spatial movement and haptotaxis. The term *haptotaxis* originated with S. B. Carter in 1965: "... the movement of a cell is controlled by the relative strengths of its peripheral adhesions, and that movements directed in this way, together with the influence of patterns of adhesion on cell shape are responsible for the arrangement of cells into complex and ordered tissues" [8]. Cell movement in morphogenesis, inflammation, wound healing, tumor invasion, and other migrations are the result of haptotactic responses of cells to differential adhesion strengths [8, 9].

The haptotaxis model we investigate here is a simplified version of a model proposed by Anderson [5] in 2005 to describe tumor invasion into surrounding tissue (see also [6]). The model involves four key components of the process: tumor cells, surrounding tissue macromolecules, degradative enzymes, and oxygen. The model in [5] hybridizes continuum partial differential equations and cellular automata formulations to incorporate cell cycle elements, and a similar model in [7] uses continuum cell age structure for the same purpose. Both of these investigations model other features of tumor invasion, including the role of quiescent cells and the evolution of mutated cell lines of increasingly invasive aggressiveness. Our objective is to investigate the simplified system of four nonlinear partial differential equations which underlie the models in [5] and [7]. The mathematical formulation of haptotaxis is similar to that of more familiar chemotaxis processes for which we refer to the survey article [16] and the extensive list of references therein. Haptotaxis in tumor growth, however, possesses unique features in that the movement of tumor cells is directed to the bound (i.e., nondiffusible) extracellular environment, which supplies essential oxygen and available space, as it is degraded by the tumor-produced degradative enzyme. The mathematical difficulty in treating haptotaxis in this context is that the

†Department of Mathematics, Vanderbilt University, 1326 Stevenson Center, Nashville, TN 37240 (christoph.walker@vanderbilt.edu, glenn.f.webb@vanderbilt.edu). The work of the second author was supported by PHS-NIH grant 1P50CA113007-01.

haptotaxis term is nonlinearly dependent on the tumor cells through the diffusion of the degradative enzyme produced by these cells.

We make the following assumptions: The tumor is contained in a region of tissue Ω. The dependent variables of the model are as follows: $p(x,t)$ is the density of tumor cells at $x \in \Omega$ at time t, $m(x,t)$ is the concentration of matrix degradative enzyme (MDE) at $x \in \Omega$ at time t, $f(x,t)$ is the density of extracellular matrix macromolecules at $x \in \Omega$ at time t, and $w(x,t)$ is the concentration of oxygen at $x \in \Omega$ at time t. The equations of the model are as follows:

$$(H_1) \qquad \partial_t f = -\underbrace{a(x)\, m\, f}_{\text{degradation}},$$

$$(H_2) \qquad \partial_t m = \underbrace{\alpha\, \Delta m}_{\text{diffusion}} + \underbrace{d(x)\, p}_{\text{production}} - \underbrace{b(x)\, m}_{\text{decay}},$$

$$(H_3) \qquad \partial_t p = \underbrace{\beta\, \Delta p}_{\text{cell motility}} - \underbrace{\nabla \cdot (p\, \chi(f)\, \nabla f)}_{\text{haptotaxis}} - \underbrace{\theta(x,w)\, p}_{\text{cell death}} + \underbrace{\varrho(x,w)\, p}_{\text{cell division}},$$

$$(H_4) \qquad \partial_t w = \underbrace{\gamma\, \Delta w}_{\text{diffusion}} + \underbrace{g(x)\, f}_{\text{production}} - \underbrace{\omega(x,p)\, w}_{\text{uptake}} - \underbrace{e(x)\, w}_{\text{decay}}$$

for $(t,x) \in (0,\infty) \times \Omega$ supplemented with Neumann boundary conditions

$$(H_5) \qquad \partial_\nu m = \partial_\nu p - p\chi(f)\partial_\nu f = \partial_\nu w = 0 \quad \text{on } \partial\Omega$$

and initial conditions

$$(H_6) \qquad f(0) = f^0, \quad m(0) = m^0, \quad p(0) = p^0, \quad w(0) = w^0.$$

It seems that (H_1)–(H_6) have not been considered analytically thus far, but rather related equations of the form

$$\partial_t f = h(p,f), \tag{1}$$

$$\partial_t p = \beta\, \Delta p - \nabla \cdot \big(p\, \chi(f)\, \nabla f\big) \tag{2}$$

have attracted attention, in particular the case

$$h(p,f) = \sigma\, p\, f^r \quad \text{with} \quad \sigma = \pm 1 \quad \text{and} \quad r > 0. \tag{3}$$

We refer to [13] for the case of general functions h satisfying suitable hypotheses. As for (1), (2) with h of the form (3), we refer to [10, 11, 12, 17, 19, 20, 21, 23], where existence of solutions and phenomena such as blowup or stability of steady states are investigated depending on the sign of σ, on r, and on the sensitivity χ.

We point out that our model differs from (1), (2), (3) with $\sigma = -1$, in that the ordinary differential equation in (H_1) is coupled to (H_3) via the "intermediate" equation (H_2).

Solving (H_3) or (2) classically requires that f have second order derivatives (with respect to x) in some L_q-space. In our model the regularity of f is determined by m for which one has a smoothing effect due to (H_2). This induces the regularity that allows us to derive an L_q-bound on p, which is sufficient to deduce global existence for $n \le 3$ and without smallness assumptions on the initial data. As for (1)–(3), the

regularity of f is determined by p. Thus, the second order derivatives of p should also be in L_q. Local existence and uniqueness of "smooth" solutions for (1)–(3) can be obtained using maximal regularity for the p-equation (2). However, global existence then requires estimates on p that are stronger than L_q-estimates and which are far from obvious.

In order to state our main result regarding the solvability of (H_1)–(H_6) we assume that Ω is a bounded and smooth domain in $\mathbb{R}^n$, $n \le 3$, and that the diffusion coefficients α, β, and γ are positive constants. Concerning the data in (H_1)–(H_4) we assume throughout that there exists some $s > 0$ such that

$$\begin{cases} a \in W^2_\infty(\Omega) \ , \quad \partial_\nu a = 0 \text{ on } \partial\Omega \ , \\ b \, , \, d \in C^s(\bar\Omega) \ , \quad g \, , \, e \in L_\infty(\Omega) \ , \end{cases} \tag{4}$$

and that all functions are nonnegative. We also assume that

$$\chi \in C^1(\mathbb{R}^+) \ , \qquad \chi \ge 0 \ , \qquad \chi \text{ and } \chi' \text{ are globally Lipschitz continuous.} \tag{5}$$

Furthermore, regarding ϱ, θ, $\omega \in C(\bar\Omega \times \mathbb{R}, \mathbb{R}^+)$ we suppose that, for some $c_0 > 0$,

$$|\phi(x,\eta) - \phi(x,\bar\eta)| \le c_0 \, |\eta - \bar\eta| \ , \quad x \in \Omega \ , \quad \eta \, , \, \bar\eta \in \mathbb{R} \ , \quad \phi \in \{\varrho, \theta, \omega\} \ . \tag{6}$$

Note that this implies, for some $c > 0$,

$$|\phi(x,\eta)| \le c \, (1 + |\eta|) \ , \quad x \in \Omega \ , \quad \eta \in \mathbb{R} \ , \quad \phi \in \{\varrho, \theta, \omega\} \ . \tag{7}$$

To simplify the notation we put $\vartheta := \varrho - \theta$.

For brevity of notation we set $L_q := L_q(\Omega)$ and $W^\tau_q := W^\tau_q(\Omega)$ for $1 \le q \le \infty$ and $\tau \ge 0$. Moreover, we denote by $W^\tau_{q,\mathcal{B}} := W^\tau_{q,\mathcal{B}}(\Omega)$ the Sobolev–Slobodeckii spaces including the Neumann boundary conditions, that is,

$$W^\tau_{q,\mathcal{B}} := \begin{cases} \left\{ u \in W^\tau_q \, ; \, \partial_\nu u = 0 \right\} \ , & \tau > 1 + 1/q \ , \\ W^\tau_q \ , & 0 \le \tau < 1 + 1/q \ . \end{cases}$$

If $J \subset \mathbb{R}^+$ is an interval containing 0, we set $\dot J := J \setminus \{0\}$.

We shall prove then the following result.

THEOREM 1.1. *Let assumptions* (4)–(6) *be satisfied, and let* $(1 \vee n/2) < q < \infty$ *and* $2\delta \in (0,2) \setminus \{1 + 1/q\}$. *Given any nonnegative initial value*

$$(f^0, m^0, p^0, w^0) \in W^2_{q,\mathcal{B}} \times W^{2\delta}_{q,\mathcal{B}} \times L_q \times L_q$$

there exists a global nonnegative solution (f, m, p, w) *to* (H_1)–(H_6) *such that*

$$\begin{aligned} & f \in C(\mathbb{R}^+, W^2_{q,\mathcal{B}}) \cap C^1(\dot{\mathbb{R}}^+, W^2_{q,\mathcal{B}}) \ , \\ & m \in C(\mathbb{R}^+, W^{2\delta}_{q,\mathcal{B}}) \cap C(\dot{\mathbb{R}}^+, W^2_{q,\mathcal{B}}) \cap C^1(\dot{\mathbb{R}}^+, L_q) \ , \\ & p \in C(\mathbb{R}^+, L_q) \cap C(\dot{\mathbb{R}}^+, W^2_{q,\mathcal{B}}) \cap C^1(\dot{\mathbb{R}}^+, L_q) \ , \\ & w \in C(\mathbb{R}^+, L_q) \cap C(\dot{\mathbb{R}}^+, W^2_{q,\mathcal{B}}) \cap C^1(\dot{\mathbb{R}}^+, L_q) \ . \end{aligned}$$

This solution satisfies

$$t^\eta \, \|p(t)\|_{W^{2\eta}_q} \to 0 \quad \text{and} \quad t^\lambda \, \|m(t)\|_{W^2_q} \to 0 \quad \text{as} \quad t \to 0^+ \tag{8}$$

for all (η, λ) *such that*

$$n/q < 2\eta < 2\ , \quad 2\eta \geq 1\ , \quad (1-\delta) \vee \eta \leq \lambda < 1\ , \tag{9}$$

and it is the only solution satisfying (8) *for some* (η, λ) *as in* (9).

Remarks 1.2. (a) Except for (H_1), which lacks a smoothing effect due to diffusion, the regularity assumptions on the initial values and the restriction on the integrability index q seem to be fairly weak. In particular, we do not impose bounded initial values or assume that $q > n$, and also the Sobolev regularity on m^0 can be arbitrary low.

(b) The no-flux boundary condition on p in (H_5) is correct from a modeling point of view, since neither diffusion nor haptotaxis should change the tumor mass. Notice that it reduces to a Neumann boundary condition $\partial_\nu p(t) = 0$ provided that $\partial_\nu f(t) = 0$. The latter is guaranteed due to the imposed Neumann boundary conditions on f^0 and a. Thus, these assumptions decouple p and f on the boundary.

(c) The solution depends continuously on the initial value in the sense stated in Proposition 3.1.

(d) The local existence and uniqueness statement of the theorem above is also true for space dimensions $n > 3$ as it follows from the proof given below.

We state the following simplified version of the above theorem for the particular case $q > n$.

COROLLARY 1.3. *Let* a, b, d, e, g *be nonnegative constants and suppose* (5), (6). *If* $q > n$, *then problem* (H_1)–(H_6) *has, for any nonnegative initial value*

$$(f^0, m^0, p^0, w^0) \in X := W_q^2 \times W_q^1 \times W_q^1 \times L_q$$

such that $\partial_\nu f^0 = 0$, *a unique global nonnegative classical solution* (f, m, p, w) *in the space* $C(\mathbb{R}^+, X)$.

A proof of Corollary 1.3 could be obtained by applying the general semigroup theory for semilinear parabolic problems. However, we shall point out that Theorem 1.1 actually ensures existence and uniqueness of classical solutions under considerably weaker assumptions on the integrability index q but also on the regularity of the initial values p^0 and m^0. Also note that any classical solution belonging to $C(\mathbb{R}^+, X)$ satisfies (8) for some (η, λ) as in (9). In this sense, the uniqueness (and existence) result stated in Theorem 1.1 is more general than in Corollary 1.3.

The outline of this paper is as follows: In section 2 we collect some auxiliary results which are used in the proof of local existence and uniqueness of solutions in section 3. Section 4 is devoted to positivity of solutions, and in section 5 we prove global existence. In section 6 some numerical examples are given in order to illustrate the role of haptotaxis in spatial movement. In section 7 we summarize our results.

2. Preliminaries. In what follows, we denote for $1 < q < \infty$ by $\Delta := \Delta_q$ the Laplace operator defined on $W^2_{q,\mathcal{B}}$ and observe that it generates a positive, strongly continuous analytic semigroup $\{e^{t\Delta}\,;\, t \geq 0\}$ of contractions on L_q [1, 22]. Moreover, we will use the inequality

$$\|e^{t\Delta}\|_{\mathcal{L}(W^{2\sigma}_{q,\mathcal{B}}, W^{2\tau}_{q,\mathcal{B}})} \leq c(T)\, t^{\sigma-\tau}\ , \quad 0 < t \leq T\ , \tag{10}$$

which is true provided that $0 \leq 2\sigma \leq 2\tau \leq 2$ with $2\sigma, 2\tau \neq 1 + 1/q$, where $c(T)$ depends on the involved parameters. We also use the inequality

$$\|e^{t\Delta}\|_{\mathcal{L}(L_q, L_p)} \leq\ c(T)\, t^{-(1/q-1/p)n/2}\ , \quad t \in (0, T]\ , \tag{11}$$

for $1 < q \leq p \leq \infty$. Given $\xi > 0$ we then put $U_\xi(t) := e^{t\xi\Delta}$. Furthermore, for any measurable function $u : \dot{J} \to L_q$ we set

$$U_\xi \star u(t) := \int_0^t U_\xi(t-s)\, u(s)\ \mathrm{d}s\ , \quad t \in \dot{J}\ ,$$

whenever these integrals exist. If E is a Banach space and $\mu \in \mathbb{R}$, we denote by $BC_\mu(\dot{J}, E)$ the Banach space of all functions $u : \dot{J} \to E$ such that $\big(t \mapsto t^\mu u(t)\big)$ is bounded and continuous from $\dot{J}$ into E, equipped with the norm

$$u \mapsto \|u\|_{C_\mu(\dot{J},E)} := \sup_{t\in\dot{J}} t^\mu \, \|u(t)\|_E\ .$$

We write $C_\mu(\dot{J}, E)$ for the closed linear subspace consisting of all u satisfying $t^\mu u(t) \to 0$ in E as $t \to 0^+$. Note that $C_\nu((0,T], E) \hookrightarrow C_\mu((0,T], E)$ for $\nu \leq \mu$ and $T > 0$.

For later use we state the following auxiliary result on pointwise multiplication.

LEMMA 2.1. *Suppose that $n/q < 2\eta$ with $2\eta \geq 1$ and let $0 < 2r < (s \wedge 2\eta)$. Then pointwise multiplication is a continuous mapping*

(i) $W_q^{2\eta} \times L_q \to L_q$,
(ii) $W_q^{2\eta-1} \times W_q^1 \to L_q$,
(iii) $C^s(\bar{\Omega}) \times W_q^{2\eta} \to W_q^{2r}$.

Proof. (i) follows from the embedding $W_q^{2\eta} \hookrightarrow L_\infty$, while statements (ii) and (iii) are easy consequences of [2, Thm. 4.1]. □

Evidently, given suitable functions $f^0 = f^0(x)$ and $m = m(x,t)$, the solution to (H_1) is

$$F_1(m) := F_1[f^0](m) := \left[t \mapsto \exp\left(-\int_0^t am(s)\mathrm{d}s\right) f^0\right]\ .$$

Note then that the gradient and the Laplacian take the form

$$\nabla F_1(m)(t) = \exp\left(-\int_0^t am(s)\mathrm{d}s\right)\left[\nabla f^0 - \int_0^t \nabla(am)(s)\mathrm{d}s\, f^0\right] \tag{12}$$

and

$$\begin{aligned}\Delta F_1(m)(t) = \exp\left(-\int_0^t am(s)\mathrm{d}s\right)\Big[&\Delta f^0 - \int_0^t \Delta(am)(s)\mathrm{d}s\, f^0 \\ &+ \Big|\int_0^t \nabla(am)(s)\mathrm{d}s\Big|^2 f^0 - 2\int_0^t \nabla(am)(s)\mathrm{d}s\cdot\nabla f^0\Big]\ .\end{aligned} \tag{13}$$

In particular, (12) warrants that $\partial_\nu F_1(m)(t) = 0$ provided $\partial_\nu f^0 = \partial_\nu m(t) = 0$ for all t since $a \in W^2_{\infty,\mathcal{B}}$. Furthermore, F_1 has the following properties.

LEMMA 2.2. *For $0 < T \leq T_0$ put $I := [0,T]$. If $(1 \vee n/2) < q < \infty$ and $f^0 \in W^2_{q,\mathcal{B}}$, there holds*

(i) *$F_1(m) \in C^1(I, W^2_{q,\mathcal{B}})$ for $m \in C(I, W^2_{q,\mathcal{B}})$;*
(ii) *$F_1(m) \in C(I, W^2_{q,\mathcal{B}})$ for $m \in C_\mu(\dot{I}, W^2_{q,\mathcal{B}})$ and $\mu < 1$, and for $R_0 > 0$ there exists a constant $k := k(T_0, R_0) > 0$ such that*

$$\|F_1(m) - F_1(\bar{m})\|_{C(I,W^2_{q,\mathcal{B}})} \leq k\, \|f^0\|_{W_q^2}\, T^{1-\mu}\, \|m - \bar{m}\|_{C_\mu(\dot{I},W^2_{q,\mathcal{B}})}$$

provided $\|m\|_{C_\mu(\dot{I},W^2_{q,\mathcal{B}})}$, $\|\bar{m}\|_{C_\mu(\dot{I},W^2_{q,\mathcal{B}})} \leq R_0$.

Proof. (i) Fix $m \in C(I, W^2_{q,\mathcal{B}}) \hookrightarrow C(I, L_\infty)$ and temporarily set $F_1 := F_1(m)$. Owing to Lemma 2.1, (4), and (13) we deduce $(1+\Delta)F_1 \in C(I, L_q)$, from which it follows that $F_1 \in C(I, W^2_{q,\mathcal{B}})$ since $\partial_\nu F_1 = 0$. Clearly, this implies $F_1 \in C^1(I, W^2_{q,\mathcal{B}})$ owing to $\partial_t F_1 = -amF_1$ and the fact that pointwise multiplication is a continuous mapping from $W^2_{q,\mathcal{B}} \times W^2_{q,\mathcal{B}}$ into $W^2_{q,\mathcal{B}}$.

(ii) Given $m, \bar m \in C_\mu(\dot I, W^2_{q,\mathcal{B}})$ with norm less than $R_0 > 0$, we have

$$\int_0^t \|m(s)\|_\infty \,\mathrm{d}s \,\le\, c \int_0^t \|m(s)\|_{W^2_q} \,\mathrm{d}s \,\le\, c(R_0)\, t^{1-\mu} \,, \quad t \in I \,.$$

This yields for $0 \le t \le T$

$$\begin{aligned} \|F_1(m)(t) - F_1(\bar m)(t)\|_{L_q} \,&\le\, c(T_0, R_0) \int_0^t \|m(s) - \bar m(s)\|_\infty \,\mathrm{d}s\, \|f^0\|_{L_q} \\ &\le\, c(T_0, R_0)\, \|f^0\|_{L_q}\, T^{1-\mu}\, \|m - \bar m\|_{C_\mu(\dot I, W^2_{q,\mathcal{B}})} \,. \end{aligned}$$

Similarly, Lemma 2.1 and (13) entail

$$\|\Delta F_1(m)(t) - \Delta F_1(\bar m)(t)\|_{L_q} \,\le c(T_0, R_0)\, \|f^0\|_{W^2_q}\, T^{1-\mu}\, \|m - \bar m\|_{C_\mu(\dot I, W^2_{q,\mathcal{B}})}$$

for $0 \le t \le T$, and the assertion follows. □

LEMMA 2.3. *Let $1 < q < \infty$, $2\sigma \in (0,2) \setminus \{1 + 1/q\}$ and $T, \xi > 0$. Then*

(i) *$U_\xi u := [t \mapsto U_\xi(t)u] \in C_\sigma\big((0,T], W^{2\sigma}_{q,\mathcal{B}}\big)$ for $u \in L_q$;*

(ii) *$U_\xi u = [t \mapsto U_\xi(t)u] \in C_{1-\sigma}\big((0,T], W^2_{q,\mathcal{B}}\big)$ for $u \in W^{2\sigma}_{q,\mathcal{B}}$.*

Proof. The proof of [4, Prop. 6] is easily adapted to the case (i). In much the same way one shows (ii). □

3. Local existence and uniqueness. In the following we use the abbreviations

$$\begin{aligned} S(m,p) \,&:=\, d\,p \,-\, b\,m \,, \\ Q(f,p,w) \,&:=\, -\nabla \cdot \big(p\,\chi(f)\,\nabla f\big) \,+\, \vartheta(w)\,p \,, \\ R(f,p,w) \,&:=\, -\,e\,w \,-\, \omega(p)\,w \,+\, g\,f \,. \end{aligned}$$

Here and below we denote by $\vartheta(w)$ and $\omega(p)$ the Nemitskii operators of $\vartheta(\cdot, w)$ and $\omega(\cdot, p)$, respectively; that is, we set $\phi(u) := [x \mapsto \phi(x, u(x))]$ for $\phi \in \{\vartheta, \omega\}$ and $u : \Omega \to \mathbb{R}$.

The proof of the existence and uniqueness statement of Theorem 1.1 is based on the next result.

PROPOSITION 3.1. *Let $1 < q < \infty$ and $n/q < 2\eta \le 2\xi \le 2\mu < 2$ with $2\eta \ge 1$. Given $B \ge 1$ there exists $T := T(B) > 0$ such that, for any*

$$u^0 := \big(f^0, m^0, p^0, w^0\big) \in E := W^2_{q,\mathcal{B}} \times W^{2(1-\mu)}_{q,\mathcal{B}} \times L_q \times L_q$$

with $\|u^0\|_E \le B$, the problem

$$\text{(M)} \qquad \begin{cases} f(t) = \exp\big(-\int_0^t am(s)\mathrm{d}s\big) f^0 \,, & t \in I \,, \\ m(t) = U_\alpha(t)\, m^0 \,+\, U_\alpha \star S(m,p)(t) \,, & t \in I \,, \\ p(t) = U_\beta(t)\, p^0 \,+\, U_\beta \star Q(f,p,w)(t) \,, & t \in I \,, \\ w(t) = U_\gamma(t)\, w^0 \,+\, U_\gamma \star R(f,p,w)(t) \,, & t \in I \,, \end{cases}$$

has a unique solution

$$u := (f,m,p,w) \in \mathcal{V}_T := C(I,W^2_{q,\mathcal{B}}) \times C_\mu(\dot I,W^2_{q,\mathcal{B}}) \times C_\xi(\dot I,W^{2\eta}_{q,\mathcal{B}}) \times C(I,L_q)\ ,$$

where $I := [0,T]$. Moreover, the solution depends continuously on the initial value in the sense that if $\bar u \in \mathcal{V}_T$ denotes the solution corresponding to $\bar u^0 \in E$ with $\|\bar u^0\|_E \le B$, then $\bar u \to u$ in $\mathcal{V}_T$ as $\bar u^0 \to u^0$ in E.

Proof. Given $T \in (0,1]$ we put

$$W_T := C\big([0,T],W^2_{q,\mathcal{B}}\big)\ ,\quad X_T := C_\mu\big((0,T],W^2_{q,\mathcal{B}}\big)\ ,$$
$$Y_T := C_\xi\big((0,T],W^{2\eta}_{q,\mathcal{B}}\big)\ ,\quad Z_T := C\big([0,T],L_q\big)\ ,$$

so that $\mathcal{V}_T = W_T \times X_T \times Y_T \times Z_T$. For $u^0 = \big(f^0,m^0,p^0,w^0\big) \in E$ it then follows from Lemma 2.3 that

$$V^0 := \big(f^0,U_\alpha m^0,U_\beta p^0,U_\gamma w^0\big) \in \mathcal{V}_T\ .$$

Defining

$$F_2(m,p) := U_\alpha m^0 + U_\alpha \star S(m,p)\ ,$$
$$F_3(f,p,w) := U_\beta p^0 + U_\beta \star Q(f,p,w)\ ,$$
$$F_4(f,p,w) := U_\gamma w^0 + U_\gamma \star R(f,p,w)\ ,$$

and

$$F(u) := F(f,m,p,w) := \big(F_1(m),F_2(m,p),F_3(f,p,w),F_4(f,p,w)\big)\ ,$$

problem (M) can be recast as a fixed point problem of the form $F(u) = u \in \mathcal{V}_T$. In order to solve this problem, we first recall that Lemma 2.2(ii) implies that there exists for any given $R_0 > 0$ a constant $c(R_0) > 0$ with

$$\|F_1(m) - F_1(\bar m)\|_{W_T} \le c(R_0)\,T^{1-\mu}\,\|m-\bar m\|_{X_T} \tag{14}$$

provided $m\,,\,\bar m \in X_T$ with $\|m\|_{X_T}\,,\,\|\bar m\|_{X_T} \le R_0$ and $\|f^0\|_{W^2_{q,\mathcal{B}}} \le R_0$. We fix r such that $0 < 2r < (s \wedge 2\eta \wedge (1+1/q))$, where $s > 0$ is given in (4). For $m \in X_T$ and $p \in Y_T$ we derive from Lemma 2.1(iii), (10), and (4)

(15)
$$\begin{aligned}\|U_\alpha \star S(m,p)(t)\|_{W^2_q} &\le c\int_0^t \|U_\alpha(t-s)\|_{\mathcal{L}(W^{2r}_{q,\mathcal{B}},W^2_{q,\mathcal{B}})}\big(\|p(s)\|_{W^{2\eta}_q} + \|m(s)\|_{W^2_q}\big)\,\mathrm{d}s\\ &\le c\,t^{r-\xi}\,\mathsf{B}(r,1-\xi)\,\|p\|_{Y_T} + c\,t^{r-\mu}\,\mathsf{B}(r,1-\mu)\,\|m\|_{X_T}\ ,\end{aligned}$$

where B denotes the beta function. Therefore,

$$\|F_2(m,p) - F_2(\bar m,\bar p)\|_{X_T} \le c\,T^r\,(\|p-\bar p\|_{Y_T} + \|m-\bar m\|_{X_T}) \tag{16}$$

for $m,\bar m \in X_T$ and $p,\bar p \in Y_T$. Next observe that

$$\nabla\cdot\big(p\,\chi(f)\,\nabla f\big) = p\,\chi(f)\,\Delta f + \chi(f)\,\nabla p\cdot\nabla f + p\,\chi'(f)\,|\nabla f|^2;$$

hence

$$\|\nabla\cdot\big(p\,\chi(f)\,\nabla f\big)\|_{L_q}\ \le\ c\,\|p\|_{W_q^{2\eta}}\,(1+\|f\|_{W_q^2}^3)\ ,\quad p\in W_{q,\mathcal{B}}^{2\eta}\ ,\quad f\in W_{q,\mathcal{B}}^2\ ,$$

by Lemma 2.1 and (5). Given $f\in W_T$, $p\in Y_T$, and $w\in Z_T$ we thus compute, using (10) and (7),

(17)
$$\begin{aligned}\|U_\beta\star Q(f,p,w)(t)\|_{W_q^{2\eta}}\le c\int_0^t\|U_\beta(t-s)\|_{\mathcal{L}(L_q,W_{q,\mathcal{B}}^{2\eta})}\Big\{&\|p(s)\|_{W_q^{2\eta}}\left(1+\|f(s)\|_{W_q^2}^3\right)\\&+\left(1+\|w(s)\|_{L_q}\right)\|p(s)\|_{W_q^{2\eta}}\Big\}\,\mathrm{d}s\\\le\ c\,t^{1-\eta-\xi}\,\mathsf{B}(1-\eta,1-\xi)\,\|p\|_{Y_T}&\left(1+\|f\|_{W_T}^3+\|w\|_{Z_T}\right)\ .\end{aligned}$$

Similarly, for $f,\bar f\in W_T$, $p,\bar p\in Y_T$, and $w,\bar w\in Z_T$ we obtain

(18)
$$\begin{aligned}\|F_3(f,p,w)\ -\ F_3(\bar f,\bar p,\bar w)\|_{Y_T}\ \le&\,c\,T^{1-\eta}\,\|p\|_{Y_T}\left(1+\|f\|_{W_T}+\|\bar f\|_{W_T}\right)^2\|f-\bar f\|_{W_T}\\&+c\,T^{1-\eta}\left(1+\|\bar f\|_{W_T}^3+\|w\|_{Z_T}\right)\|p-\bar p\|_{Y_T}\\&+c\,T^{1-\eta}\,\|p\|_{Y_T}\,\|w-\bar w\|_{Z_T}\ .\end{aligned}$$

Given $f,\bar f\in W_T$, $p,\bar p\in Y_T$, and $w,\bar w\in Z_T$ analogous computations show that

(19)
$$\begin{aligned}\|F_4(f,p,w)-F_4(\bar f,\bar p,\bar w)\|_{Z_T}\ \le&\,c\,T^{1-\xi}\left(1+\|\bar p\|_{Y_T}\right)\|w-\bar w\|_{Z_T}\\&+\ c\,T^{1-\xi}\,\|w\|_{Z_T}\,\|p-\bar p\|_{Y_T}\\&+\ c\,T\,\|f-\bar f\|_{W_T}\ .\end{aligned}$$

Combining (14), (16), (18), (19), and defining $\lambda:=(1-\mu)\wedge r\wedge(1-\xi)>0$ we find a constant $\kappa(R_0)>0$ such that

$$\|F(u)-F(\bar u)\|_{\mathcal{V}_T}\ \le\ \kappa(R_0)\,T^\lambda\left(1+\|u\|_{\mathcal{V}_T}+\|\bar u\|_{\mathcal{V}_T}\right)\|u-\bar u\|_{\mathcal{V}_T}\ ,\tag{20a}$$

$$\|F(u)-V^0\|_{\mathcal{V}_T}\ \le\ \kappa(R_0)\,T^\lambda\left(1+\|u\|_{\mathcal{V}_T}\right)\|u\|_{\mathcal{V}_T}\ ,\tag{20b}$$

provided $u=(f,m,p,w)$, $\bar u=(\bar f,\bar m,\bar p,\bar w)\in\mathcal{V}_T$ are such that $\|m\|_{X_T},\|\bar m\|_{X_T}\le R_0$ and $\|f^0\|_{W_q^2}\le R_0$, where $R_0>0$ and $T\in(0,1]$ are arbitrary. Put

$$\mathcal{K}:=1+\sup_{0<t\le1}\left(t^\mu\,\|U_\alpha(t)\|_{\mathcal{L}(W_{q,\mathcal{B}}^{2(1-\mu)},W_{q,\mathcal{B}}^2)}\ +\ t^\xi\,\|U_\beta(t)\|_{\mathcal{L}(L_q,W_{q,\mathcal{B}}^{2\eta})}\right),$$

which is a finite constant according to (10), and let $R_0:=(1+\mathcal{K})B$ for $B\ge1$ given. Choose then $T:=T(B)\in(0,1]$ such that

$$\kappa(R_0)\,(1+R_0)\,R_0\,T^\lambda\ \le\ \frac12\quad\text{and}\quad k(1,R_0)\,B\,T^{1-\mu}\ \le\frac14\ ,\tag{21}$$

the constant $k(1,R_0)>0$ stemming from Lemma 2.2(ii). Notice that, in particular, for $u^0=\big(f^0,m^0,p^0,w^0\big)\in E$ with $\|u^0\|_E\le B$, there holds

$$\|V^0\|_{\mathcal{V}_T}\le\mathcal{K}\,B\ ,\quad V^0=\big(f^0,U_\alpha m^0,U_\beta p^0,U_\gamma w^0\big)\ .$$

Denoting by $\mathcal{B}_T$ the closed ball in $\mathcal{V}_T$ with center V^0 and radius B, we hence have

$$\|u\|_{\mathcal{V}_T} \le (1+\mathcal{K})\, B = R_0 , \quad u \in \mathcal{B}_T .$$

Therefore, in view of (20a), (20b), and (21), the mapping $F : \mathcal{B}_T \to \mathcal{B}_T$ is a contraction (with contraction constant less than $1/2$), which implies the existence of a unique solution to problem (M) for any $u^0 = \big(f^0, m^0, p^0, w^0\big) \in E$ with $\|u^0\|_E \le B$. If $\bar{u}^0 = \big(\bar{f}^0, \bar{m}^0, \bar{p}^0, \bar{w}^0\big) \in E$ with $\|\bar{u}^0\|_E \le B$ is another initial value, there exists a corresponding unique solution $\bar{u} = \big(\bar{f}, \bar{m}, \bar{p}, \bar{w}\big) \in \mathcal{V}_T$ satisfying $\|\bar{u}\|_{\mathcal{V}_T} \le R_0$. Defining

$$\tilde{F} := (F_2, F_3, F_4) \quad \text{and} \quad \bar{V}^0 := \big(\bar{f}^0, U_\alpha \bar{m}^0, U_\beta \bar{p}^0, U_\gamma \bar{w}^0\big)$$

we derive from (20a), (20b), and Lemma 2.2(ii) that

$$\begin{aligned}
\|u - \bar{u}\|_{\mathcal{V}_T} &\le \|F_1[f^0](m) - F_1[\bar{f}^0](\bar{m})\|_{W_T} + \|\tilde{F}(u) - \tilde{F}(\bar{u})\|_{X_T \times Y_T \times Z_T} \\
&\quad + \|U_\alpha(m^0 - \bar{m}^0)\|_{X_T} + \|U_\beta(p^0 - \bar{p}^0)\|_{Y_T} + \|U_\gamma(w^0 - \bar{w}^0)\|_{Z_T} \\
&\le k(1, R_0)\|f^0\|_{W^2_{q,\mathcal{B}}}\, T^{1-\mu}\, \|m - \bar{m}\|_{X_T} + k(1, R_0)\, \|\bar{m}\|_{X_T}\, \|f^0 - \bar{f}^0\|_{W^2_{q,\mathcal{B}}} \\
&\quad + \frac{1}{2}\, \|u - \bar{u}\|_{\mathcal{V}_T} + \|V^0 - \bar{V}^0\|_{\mathcal{V}_T} .
\end{aligned}$$

But then, due to (21),

$$\|u - \bar{u}\|_{\mathcal{V}_T} \le c(R_0)\, \|V^0 - \bar{V}^0\|_{\mathcal{V}_T} \le c(R_0)\, \mathcal{K}\, \|u^0 - \bar{u}^0\|_E ,$$

whence $\bar{u} \to u$ in $\mathcal{V}_T$ as $\bar{u}^0 \to u^0$ in E. This proves the proposition. □

We now focus on the existence of a unique maximal solution to (H_1)–(H_6) enjoying the regularity properties stated in Theorem 1.1.

Let $(1 \vee n/2) < q < \infty$ and $2\delta \in (0,2) \setminus \{1 + 1/q\}$ be given. Fix η and λ such that $n/q < 2\eta < 2$ with $2\eta \ge 1$ and $(1-\delta) \vee \eta \le \lambda < 1$ and put $(\xi, \mu) := (\eta, \lambda)$. Then, for $\big(f^0, m^0, p^0, w^0\big) \in W^2_{q,\mathcal{B}} \times W^{2\delta}_{q,\mathcal{B}} \times L_q \times L_q$, Proposition 3.1 ensures the existence of $T > 0$ and a unique solution

$$u = (f, m, p, w) \in C([0,T], W^2_{q,\mathcal{B}}) \times C_\mu((0,T], W^2_{q,\mathcal{B}}) \times C_\xi((0,T], W^{2\eta}_{q,\mathcal{B}}) \times C([0,T], L_q)$$

to problem (M). As in (17),

$$\|U_\beta \star Q(f,p,w)(t)\|_{L_q} \le c(T)\, t^{1-\xi} \to 0 \quad \text{as} \quad t \to 0^+ ,$$

and therefore

$$p = U_\beta\, p^0 + U_\beta \star Q(f,p,w) \in C([0,T], L_q)$$

is a mild L_q-solution to (H_3). From this and the identity

$$m = U_\alpha\, m^0 + U_\alpha \star S(m,p)$$

we obtain that $m \in C([0,T], W^{2\delta}_{q,\mathcal{B}})$ is a mild L_q-solution to (H_2). Clearly, $w \in C([0,T], L_q)$ is a mild L_q-solution to (H_4).

Next we show that these mild solutions are actually classical solutions. First, we fix $\varepsilon \in (0,T]$ and set $I := [0, T-\varepsilon]$. Then

$$f_\varepsilon := f(\cdot + \varepsilon) \in C(I, W^2_{q,\mathcal{B}}) , \qquad m_\varepsilon := m(\cdot + \varepsilon) \in C(I, W^2_{q,\mathcal{B}}) ,$$
$$p_\varepsilon := p(\cdot + \varepsilon) \in C(I, W^{2\eta}_{q,\mathcal{B}}) , \qquad w_\varepsilon := w(\cdot + \varepsilon) \in C(I, L_q) .$$

Furthermore, Lemma 2.2(i) warrants $f_\varepsilon \in C^1(I, W^2_{q,\mathcal{B}})$ and thus, letting $\varepsilon \to 0^+$, we obtain $f \in C^1((0,T], W^2_{q,\mathcal{B}})$. Next, $h_\varepsilon := S(m_\varepsilon, p_\varepsilon) \in C(I, W^{2r}_{q,\mathcal{B}})$ with $r > 0$ sufficiently small by Lemma 2.1(iii). Therefore, observing that $W^{2r}_{q,\mathcal{B}}$ is a (real) interpolation space between L_q and $W^2_{q,\mathcal{B}}$ (cf. [24]) and taking into account that m_ε is a mild L_q-solution to the linear problem

$$\dot{M} - \alpha \Delta M = h_\varepsilon(t) \ , \quad t \in \dot{I} \ , \qquad M(0) = m_\varepsilon(0) \in W^2_{q,\mathcal{B}} \ ,$$

we conclude that $m_\varepsilon \in C^1(\dot{I}, L_q) \cap C(I, W^2_{q,\mathcal{B}})$ since mild solutions to linear problems are unique; see [3, II.Thm. 1.2.2]. Letting $\varepsilon \to 0^+$ we deduce that m is a classical solution to (H_2) possessing the same regularity properties as m_ε on $(0,T]$. Next, define $j_\varepsilon := Q(f_\varepsilon, p_\varepsilon, w_\varepsilon) \in C(I, L_q)$ and notice that p_ε is a mild L_q-solution to the linear problem

$$\dot{P} - \beta \Delta P = j_\varepsilon(t) \ , \quad t \in \dot{I} \ , \qquad P(0) = p_\varepsilon(0) \in W^{2\eta}_{q,\mathcal{B}} \ . \tag{22}$$

Thus, $p_\varepsilon \in C^\varrho(I, W^{2\sigma}_{q,\mathcal{B}})$ with $2\eta > 2\sigma > n/q$ and $2\sigma \ge 1$, where $\varrho := \eta - \sigma > 0$ owing to [3, II.Thm. 5.3.1]. Clearly, due to $k_\varepsilon := R(f_\varepsilon, p_\varepsilon, w_\varepsilon) \in C(I, L_q)$ and (10) we have

$$w_\varepsilon \ = \ U_\gamma \, w_\varepsilon(0) \ + \ U_\gamma \star k_\varepsilon \in C(I, W^{2\nu}_{q,\mathcal{B}}) \ , \quad \nu < 1 \ .$$

Applying again [3, II.Thm. 5.3.1] we obtain $w_\varepsilon \in C^\varrho(I, L_q)$. From (6) and the fact that $f_\varepsilon \in C^1(I, W^2_{q,\mathcal{B}})$ and $p_\varepsilon \in C^\varrho(I, W^{2\sigma}_{q,\mathcal{B}})$ it follows that $k_\varepsilon \in C^\varrho(I, L_q)$; hence, as above, $w_\varepsilon \in C^1(\dot{I}, L_q) \cap C(\dot{I}, W^2_{q,\mathcal{B}})$ by [3, II.Thm. 1.2.2], which ensures that w is a classical solution to (H_4) with the corresponding regularity properties. Moreover, recalling that $2\sigma > n/q$ with $2\sigma \ge 1$ and invoking Lemma 2.1, we deduce $j_\varepsilon \in C^\varrho(I, L_q)$ thanks to (5). Due to [3, II.Thm. 1.2.2] and (22) this implies that p_ε belongs to $C^1(\dot{I}, L_q) \cap C(\dot{I}, W^2_{q,\mathcal{B}})$, whence $p \in C^1((0,T], L_q) \cap C((0,T], W^2_{q,\mathcal{B}})$ is a classical solution to (H_3).

Let us now prove that this solution is unique in the sense stated in Theorem 1.1. Suppose therefore that there exist two solutions $(\tilde{f}, \tilde{m}, \tilde{p}, \tilde{w})$ and $(\bar{f}, \bar{m}, \bar{p}, \bar{w})$ to (H_1)–(H_6) on some interval $[0,T]$ satisfying

$$\tilde{f} \, , \, \bar{f} \in C\big([0,T], W^2_{q,\mathcal{B}}\big) \ , \qquad \tilde{w} \, , \, \bar{w} \in C\big([0,T], L_q\big) \ ,$$

$$\tilde{m} \in C_{\tilde{\lambda}}\big((0,T], W^2_{q,\mathcal{B}}\big) \ , \qquad \bar{m} \in C_{\bar{\lambda}}\big((0,T], W^2_{q,\mathcal{B}}\big) \ ,$$

$$\tilde{p} \in C_{\tilde{\eta}}\big((0,T], W^{2\tilde{\eta}}_{q,\mathcal{B}}\big) \ , \qquad \bar{p} \in C_{\bar{\eta}}\big((0,T], W^{2\bar{\eta}}_{q,\mathcal{B}}\big)$$

for some $n/q < 2\tilde{\eta}$, $2\bar{\eta} < 2$ with $2\tilde{\eta}$, $2\bar{\eta} \ge 1$ and $\tilde{\lambda}$, $\bar{\lambda} < 1$. Defining

$$\eta := \tilde{\eta} \wedge \bar{\eta} \ , \qquad \xi := \tilde{\eta} \vee \bar{\eta} \ , \qquad \mu := \tilde{\lambda} \vee \bar{\lambda} \vee \xi \vee (1 - \delta)$$

we obtain two solutions to (M) such that both $\tilde{m}, \bar{m}$ belong to $C_\mu((0,T], W^2_{q,\mathcal{B}})$ and both $\tilde{p}, \bar{p}$ belong to $C_\xi((0,T], W^{2\eta}_{q,\mathcal{B}})$, where $n/q < 2\eta \le 2\xi \le 2\mu < 2$ with $2\eta \ge 1$. Making T smaller if necessary, Proposition 3.1 guarantees that $(\tilde{f}, \tilde{m}, \tilde{p}, \tilde{w})$ coincides with $(\bar{f}, \bar{m}, \bar{p}, \bar{w})$ on $[0,T]$.

Evidently, local uniqueness warrants that we may extend the solution (f,m,p,w) constructed above to a maximal solution on an interval $J := [0,t^+)$. Since, according to Proposition 3.1, the local existence time $T > 0$ can be chosen uniformly with respect to initial values that are bounded in $W^2_{q,\mathcal{B}} \times W^{2\delta}_{q,\mathcal{B}} \times L_q \times L_q$, we surely have

$$\limsup_{t \nearrow t^+} \big\| \big(f(t),m(t),p(t),w(t)\big) \big\|_{W^2_q \times W^{2\delta}_q \times L_q \times L_q} \;=\; \infty \tag{23}$$

in the case that $t^+ < \infty$.

Summing up, we have shown thus far that problem (H_1)–(H_6) admits a maximal solution being unique and possessing the regularity properties in the sense stated in Theorem 1.1. Moreover, this solution satisfies (8) and, if $t^+ < \infty$, then (23) also holds.

Remark 3.2. Given $p^0 \in W^{2\eta}_{q,\mathcal{B}}$ with $n/q < 2\eta < 2$ and $2\eta \geq 1$ there holds $p \in C(J, W^{2\eta}_{q,\mathcal{B}})$. In particular, one may choose $2\eta = 1$ if $q > n$; see Corollary 1.3. This readily follows by taking $C([0,T], W^{2\eta}_{q,\mathcal{B}})$ as state space for p instead of the weighted space $C_\xi((0,T], W^{2\eta}_{q,\mathcal{B}})$ in the above proof.

4. Positivity. Using ideas as in [18] we now show positivity of the solution corresponding to positive initial values. Given

$$\big(f^0,m^0,p^0,w^0\big) \in W^2_{q,\mathcal{B}} \times W^{2\delta}_{q,\mathcal{B}} \times L_q \times L_q$$

such that $f^0 \geq 0$, $m^0 \geq 0$, $p^0 \geq 0$, and $w^0 \geq 0$ (a.e. on Ω) let (f,m,p,w) denote the maximal solution on J constructed in the previous section. Then obviously $f(t) \geq 0$ on Ω for $t \in J$.

First suppose that $q > (n \vee 2)$ and $p^0, w^0 \in W^2_{q,\mathcal{B}}$. Fix $T \in \dot{J}$ and $n/q < 2\sigma < 1$. Then choose $\eta \in \big(1/2, 1-\sigma\big)$ and observe that $p \in C_\eta(\dot{J}, W^{2\eta}_{q,\mathcal{B}})$ in view of (8). Analogously to (17) it follows from Lemma 2.1 that

$$\|U_\beta \star Q(f,p,w)(t)\|_{W^{2\sigma}_q} \;\leq\; c(T)\, t^{1-\sigma-\eta} \;\longrightarrow 0 \quad \text{as} \quad t \to 0^+ \;,$$

and consequently

$$p \;=\; U_\beta\, p^0 \;+\; U_\beta \star Q(f,p,w) \in C([0,T], W^{2\sigma}_{q,\mathcal{B}}) \hookrightarrow C([0,T]\times\bar{\Omega}) \;.$$

Similarly, there holds

$$w \;=\; U_\gamma\, w^0 \;+\; U_\gamma \star R(f,p,w) \in C([0,T], W^{2\sigma}_{q,\mathcal{B}}) \hookrightarrow C([0,T]\times\bar{\Omega}) \;,$$

and thus, in particular,

$$\vartheta(w) \in C([0,T]\times\bar{\Omega}) \;. \tag{24}$$

According to [18, p. 451] there exist a function $H \in C^2(\mathbb{R})$ and a constant $c_0 > 0$ such that $H(z) = 0$ for $z \geq 0$ and $H(z) > 0$ for $z < 0$ and such that

$$0 \;\leq\; H''(z)\, z^2 \;\leq\; c_0\, H(z) \;, \quad z \in \mathbb{R} \;,$$

and

$$0 \;\leq\; H'(z)\, z \;\leq\; c_0\, H(z) \;, \quad z \in \mathbb{R} \;.$$

Define $M \in C^1((0,T]) \cap C([0,T])$ as

$$M(t) := \int_\Omega H\big(p(t,x)\big)\, \mathrm{d}x\ , \quad t \in [0,T]\ .$$

Owing to $\partial_\nu p(t) = \partial_\nu f(t) = 0$ we deduce from (H_3) that

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}t} M(t) \ &= \ \int_\Omega H'(p) \left(\beta \Delta p - \nabla \cdot \big(p\, \chi(f)\, \nabla f \big) + \vartheta(w)\, p \right) \mathrm{d}x \\ &= \ -\beta \int_\Omega H''(p)\, |\nabla p|^2 \ \mathrm{d}x \ + \ \int_\Omega H''(p)\, p\, \chi(f)\, \nabla p \cdot \nabla f \ \mathrm{d}x \\ &\quad + \ \int_\Omega H'(p)\, \vartheta(w)\, p \ \mathrm{d}x. \end{aligned}$$

Therefore, since

$$|p\, \chi(f)\, \nabla p \cdot \nabla f| \ \le \ \frac{\beta}{2}\, |\nabla p|^2 \ + \ \frac{1}{2\beta}\, p^2\, \chi(f)^2\, |\nabla f|^2$$

we infer from (7) and the fact that both f and ∇f belong to $C([0,T] \times \bar{\Omega})$, from (24), and the properties of the function H that

$$\frac{\mathrm{d}}{\mathrm{d}t} M(t) \le c(T) M(t)\ , \quad t \in (0,T]\ .$$

Thus $M(0) = 0$ ensures $M(t) = 0$ for $t \in [0,T]$, that is, $p(t) \ge 0$ on Ω for $t \in [0,T]$. It is then straightforward to prove that $m(t) \ge 0$ and $w(t) \ge 0$ on Ω for $t \in [0,T]$. But $T > 0$ was arbitrary, so the desired positivity follows.

Finally, to show positivity in the general case $q > (1 \vee n/2)$ we approximate $p^0, w^0 \in L_q$ by nonnegative smooth functions and use the continuous dependence of the solution on the initial value provided by Proposition 3.1.

5. Global existence. It remains only to prove global existence. We denote by (f, m, p, w) the maximal nonnegative solution on $J = [0, t^+)$ corresponding to the nonnegative initial value

$$\big(f^0, m^0, p^0, w^0\big) \in W^2_{q,\mathcal{B}} \times W^{2\delta}_{q,\mathcal{B}} \times L_q \times L_q\ .$$

We first claim that it suffices to prove

$$\sup_{t \in J \cap [0,T]} \|p(t)\|_{L_q} \ < \ \infty\ , \quad T > 0\ , \tag{25}$$

in order to conclude that $t^+ = \infty$. Indeed, suppose that (25) holds for any $T > 0$ and set $J_T := J \cap [0,T]$. Replacing the solution by the shifted solution $(f_\varepsilon, m_\varepsilon, p_\varepsilon, w_\varepsilon)$ introduced in the existence proof in section 3, we may assume without loss of generality that all m, p, w belong to $C(J, W^2_{q,\mathcal{B}}) \cap C^1(J, L_q)$, in particular that $m^0 \in W^2_{q,\mathcal{B}}$. Observe then that $w \in L_\infty(J_T, L_\infty)$ as it follows from (H_4) since $w(t) \ge 0$ and $\|f(t)\|_\infty \le \|f^0\|_\infty$. Next, since $b \in L_\infty$, we may choose $\lambda > 0$ sufficiently large such that $-(\lambda + b - \alpha\Delta)$ has bounded imaginary powers with angle strictly less than $\pi/2$ (for instance, see [3, III.Ex. 4.7.3(d), III.Thm. 4.8.7]). Therefore, defining $n(t) := e^{-\lambda t} m(t)$ and noticing that

$$\dot{n} \ + \ (\lambda + b - \alpha\Delta)\, n \ = \ d\, e^{-\lambda t}\, p(t) \ =: \ z(t)\ , \quad n(0) \ = \ m^0 \in W^2_{q,\mathcal{B}}\ ,$$

it follows from [3, III.Thm. 4.10.7] that $n \in L_q(J_T, W^2_{q,\mathcal{B}})$ since $z \in L_\infty(J_T, L_q)$ by (25) and $n(0) \in W^2_{q,\mathcal{B}}$. But then

$$\int_0^t \|m(s)\|_{W^2_q} \, \mathrm{d}s \, \le \, c(T) \, , \quad t \in J_T \, ,$$

and we deduce from (13) that $f \in L_\infty(J_T, W^2_{q,\mathcal{B}})$. Finally, owing to $p \in L_\infty(J_T, L_q)$, (10), and Gronwall's inequality we conclude from (H_2) that $m \in L_\infty(J_T, W^{2\delta}_{q,\mathcal{B}})$. Consequently, combining all the estimates on f, m, p, and w we see that the blowup criterion (23) implies $t^+ = \infty$ since $T > 0$ was arbitrary. Therefore, (25) is indeed sufficient to conclude global existence.

To derive the desired L_q-bound on p we employ a change of variable of the form $p \mapsto \frac{p}{\phi(f)}$, where ϕ solves

$$\phi'(z) \, = \, \frac{\chi(z)}{\beta} \, \phi(z) \, , \quad z > 0 \, , \qquad \phi(0) = 1 \, .$$

This device has been used in [11, 12, 14] for equations of the form (1), (2), (3) and leads in our case to the equation in divergence form

$$\frac{\mathrm{d}}{\mathrm{d}t} \frac{p}{\phi(f)} \, = \, \frac{\beta}{\phi(f)} \, \nabla \cdot \left(\phi(f) \, \nabla \frac{p}{\phi(f)} \right) \, + \, \vartheta(w) \, \frac{p}{\phi(f)} \, + \, \frac{a}{\beta} \, \chi(f) \, f \, m \, \frac{p}{\phi(f)} \, . \tag{26}$$

Global existence is then an easy consequence of the following proposition, where the basic idea of its proof is adapted from [11]. We point out here again that in our case, the coupling of (H_1) and (H_3) via (H_2) allows us to derive the a priori estimate for p (which does not seem to be possible without a smallness condition on the initial value in the case of (1), (2), (3) with $\sigma = -1$; see [11]).

PROPOSITION 5.1. *Suppose that* $\|p(t)\|_{L_\rho} \le c(T)$, $t \in J_T := J \cap [0, T]$, *for some* $\rho \in [1, q)$ *and suppose there exists* $\varrho \in (\rho, 2\rho \wedge q]$ *such that*

$$\varrho \left(\frac{n}{\rho} - 2 \right) \, < \, 2 \left(\rho - 1 + \frac{2\rho}{n} \right) \, . \tag{27}$$

Then $\|p(t)\|_{L_\varrho} \le c(T)$ *for* $t \in J_T$.

Proof. We first observe that (27) allows to fix $r > 1$ such that

$$\frac{n\varrho}{n\varrho + 2\rho} \, < \, \frac{1}{r} \, < \, 1 + \frac{2}{n} - \frac{1}{\rho} \, . \tag{28}$$

If $\varrho \ge 2$, we set $\mu := 0$; otherwise we fix $\mu \in (0, 1)$. Then we put $p_\mu := p + \mu \ge \mu$ and note that

$$\nabla \left(\frac{p_\mu}{\phi(f)} \right)^{\varrho/2} \, = \, \frac{\varrho}{2} \, \left(\frac{p_\mu}{\phi(f)} \right)^{\varrho/2-1} \, \nabla \frac{p_\mu}{\phi(f)}$$

by the chain rule. Hence $\left(\frac{p_\mu}{\phi(f)}\right)^{\varrho/2} \in W^1_2$ since $W^1_q \hookrightarrow L_2$ due to $q > n/2$. Moreover, $\partial_\nu \frac{p_\mu}{\phi(f)} = 0$ owing to $\partial_\nu p = \partial_\nu f = 0$. Thus, given any $\Lambda \in C^2\big((0, \infty)\big)$ we derive

from (26)

$$
\begin{aligned}
&\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega \phi(f)\,\Lambda\left(\frac{p_\mu}{\phi(f)}\right)\,\mathrm{d}x\\
&\quad=\beta\int_\Omega \Lambda'\left(\frac{p_\mu}{\phi(f)}\right)\,\nabla\cdot\left(\phi(f)\,\nabla\frac{p_\mu}{\phi(f)}\right)\,\mathrm{d}x+\int_\Omega \Lambda'\left(\frac{p_\mu}{\phi(f)}\right)\,\vartheta(w)\,p\,\mathrm{d}x\\
&\qquad+\frac{1}{\beta}\int_\Omega \Lambda'\left(\frac{p_\mu}{\phi(f)}\right)\,a\,m\,\chi(f)\,f\,p\,\mathrm{d}x-\frac{1}{\beta}\int_\Omega \Lambda\left(\frac{p_\mu}{\phi(f)}\right)\,a\,m\,\chi(f)\,f\,\phi(f)\,\mathrm{d}x\\
&\qquad+\mu\int_\Omega \Lambda'\left(\frac{p_\mu}{\phi(f)}\right)\,\nabla\cdot\left(\chi(f)\nabla f\right)\,\mathrm{d}x+\frac{\mu}{\beta}\int_\Omega \Lambda'\left(\frac{p_\mu}{\phi(f)}\right)\,a\,m\,\chi(f)\,f\,\mathrm{d}x\\
&\quad=-\beta\int_\Omega \Lambda''\left(\frac{p_\mu}{\phi(f)}\right)\,\phi(f)\,\left|\nabla\frac{p_\mu}{\phi(f)}\right|^2\,\mathrm{d}x\\
&\qquad+\frac{1}{\beta}\int_\Omega a\,m\,\chi(f)\,f\left[p\,\Lambda'\left(\frac{p_\mu}{\phi(f)}\right)-\phi(f)\,\Lambda\left(\frac{p_\mu}{\phi(f)}\right)\right]\,\mathrm{d}x\\
&\qquad+\int_\Omega \Lambda'\left(\frac{p_\mu}{\phi(f)}\right)\,\vartheta(w)\,p\,\mathrm{d}x-\mu\int_\Omega \Lambda''\left(\frac{p_\mu}{\phi(f)}\right)\,\chi(f)\,\nabla\frac{p_\mu}{\phi(f)}\cdot\nabla f\,\mathrm{d}x\\
&\qquad+\frac{\mu}{\beta}\int_\Omega \Lambda'\left(\frac{p_\mu}{\phi(f)}\right)\,a\,m\,\chi(f)\,f\,\mathrm{d}x
\end{aligned}
$$

for $t\in J$. In particular, taking $\Lambda(z)=z^\varrho$ we have

(29)

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega \phi(f)\,\left(\frac{p_\mu}{\phi(f)}\right)^\varrho\,\mathrm{d}x\;\le\;&-4\,\beta\,\frac{\varrho-1}{\varrho}\int_\Omega \phi(f)\,\left|\nabla\left(\frac{p_\mu}{\phi(f)}\right)^{\varrho/2}\right|^2\,\mathrm{d}x\\
&+S_0\int_\Omega m\,\left(\frac{p_\mu}{\phi(f)}\right)^\varrho\,\mathrm{d}x\\
&+\varrho\,\|\vartheta(w)\|_\infty\int_\Omega \phi(f)\,\left(\frac{p_\mu}{\phi(f)}\right)^\varrho\,\mathrm{d}x\\
&+\mu\,\varrho\,(\varrho-1)\|\chi(f)\|_\infty\int_\Omega \left(\frac{p_\mu}{\phi(f)}\right)^{\varrho-2}\,\left|\nabla\frac{p_\mu}{\phi(f)}\cdot\nabla f\right|\,\mathrm{d}x\\
&+\mu\,S_0\int_\Omega m\,\left(\frac{p_\mu}{\phi(f)}\right)^{\varrho-1}\,\mathrm{d}x
\end{aligned}
$$

for $t\in J$, where

$$
S_0\;:=\;\frac{\varrho-1}{\beta}\,\|a\|_\infty\sup_{0<z<\|f^0\|_\infty}\left(z\,\chi(z)\,\phi(z)\right)\;<\;\infty
$$

since $\|f(t)\|_\infty\le\|f^0\|_\infty$ and $\|\vartheta(w)\|_\infty<\infty$ on J_T due to $w\in L_\infty(J_T,L_\infty)$. Next, we use the second inequality of (28), (11), the given L_ρ-bound on p, and Gronwall's inequality to derive from (H_2) that

$$
\|m(t)\|_{L_{r'}}\;\le\;c(T)\;,\quad t\in J_T\;,
$$

where r' denotes the dual exponent of r. Hence, taking into account that the first inequality of (28) warrants the following version of the Gagliardo–Nirenberg inequality (see [15, p. 37])

$$\|\cdot\|_{L_{2r}}^{2r} \le c_0 \|\cdot\|_{L_{2\rho/\varrho}}^{2(r-1)} \|\cdot\|_{W_2^1}^2 ,$$

applying Young's inequality, and using once again the given L_ρ-bound on p, it follows for $\varepsilon > 0$ that

$$\begin{aligned} S_0 \int_\Omega m \left(\frac{p_\mu}{\phi(f)}\right)^\varrho \,\mathrm{d}x &\le c(\varepsilon) \int_\Omega m^{r'} \,\mathrm{d}x + \varepsilon \int_\Omega \left(\frac{p_\mu}{\phi(f)}\right)^{\varrho r} \,\mathrm{d}x \\ &\le c(T,\varepsilon) + \varepsilon \left\| \left(\frac{p_\mu}{\phi(f)}\right)^{\varrho/2} \right\|_{L_{2r}}^{2r} \\ &\le c(T,\varepsilon) + \varepsilon\, c_0 \left\| \frac{p_\mu}{\phi(f)} \right\|_{L_\rho}^{\varrho(r-1)} \left\| \left(\frac{p_\mu}{\phi(f)}\right)^{\varrho/2} \right\|_{W_2^1}^2 \\ &\le c(T,\varepsilon) + c(T,\varepsilon) \int_\Omega \left(\frac{p_\mu}{\phi(f)}\right)^\varrho \,\mathrm{d}x \\ &\quad + \varepsilon\, c(T) \int_\Omega \left| \nabla \left(\frac{p_\mu}{\phi(f)}\right)^{\varrho/2} \right|^2 \,\mathrm{d}x . \end{aligned}$$

We can estimate the last term in (29) similarly, since

$$\begin{aligned} \mu\, S_0 \int_\Omega m \left(\frac{p_\mu}{\phi(f)}\right)^{\varrho-1} \,\mathrm{d}x &\le \mu\, c(T,\varepsilon) + \mu\, c(T,\varepsilon) \int_\Omega \left(\frac{p_\mu}{\phi(f)}\right)^\varrho \,\mathrm{d}x \\ &\quad + \mu\, \varepsilon\, c(T) \int_\Omega \left| \nabla \left(\frac{p_\mu}{\phi(f)}\right)^{\varrho/2} \right|^2 \,\mathrm{d}x . \end{aligned}$$

In the case that $\varrho < 2$ we have by Young's inequality for $\delta > 0$

$$\begin{aligned} \mu\, \varrho\, (\varrho-1) \|\chi(f)\|_\infty &\int_\Omega \left(\frac{p_\mu}{\phi(f)}\right)^{\varrho-2} \left| \nabla \frac{p_\mu}{\phi(f)} \cdot \nabla f \right| \,\mathrm{d}x \\ &\le \delta\, \mu\, \frac{\varrho^2}{4} \int_\Omega \left(\frac{p_\mu}{\phi(f)}\right)^{\varrho-2} \left| \nabla \frac{p_\mu}{\phi(f)} \right|^2 \,\mathrm{d}x \\ &\quad + \mu\, c(\delta) \int_\Omega \left(\frac{p_\mu}{\phi(f)}\right)^{\varrho-2} |\nabla f|^2 \,\mathrm{d}x \\ &\le \mu\, \delta \int_\Omega \left| \nabla \left(\frac{p_\mu}{\phi(f)}\right)^{\varrho/2} \right|^2 \,\mathrm{d}x + \mu^{\varrho-1}\, c(\delta) \int_\Omega \phi(f)^{\varrho-2} |\nabla f|^2 \,\mathrm{d}x . \end{aligned}$$

Therefore, due to $\phi(f) \ge 1$ and $\mu < 1$, we infer from (29) by combining the above

estimates that for all $t \in J_T$

(30)
$$\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega \phi(f)\,\left(\frac{p_\mu}{\phi(f)}\right)^\varrho\,\mathrm{d}x \le c(T,\varepsilon) + c(T,\varepsilon)\int_\Omega \phi(f)\,\left(\frac{p_\mu}{\phi(f)}\right)^\varrho\,\mathrm{d}x + \left(\varepsilon\,c(T) + \delta - 4\,\beta\,\frac{\varrho-1}{\varrho}\right)\int_\Omega \left|\nabla\left(\frac{p_\mu}{\phi(f)}\right)^{\varrho/2}\right|^2\,\mathrm{d}x + \mu^{\varrho-1}\,c(\delta)\int_\Omega \phi(f)^{2-\varrho}\,|\nabla f|^2\,\mathrm{d}x\ .$$

We then choose $\varepsilon > 0$ and $\delta > 0$ sufficiently small so that the term involving the gradient of $\frac{p_\mu}{\phi(f)}$ becomes negative. Recalling that $\|\phi(f)\|_\infty \le c\big(\|f^0\|_\infty\big)$ on J_T, that $\nabla f(t) \in L_2$, and that $p \in C^1(J, L_q)$ we may then let $\mu \to 0^+$ and use Lebesgue's theorem to obtain

$$\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega \phi(f)\,\left(\frac{p}{\phi(f)}\right)^\varrho\,\mathrm{d}x \le c(T) + c(T)\int_\Omega \phi(f)\,\left(\frac{p}{\phi(f)}\right)^\varrho\,\mathrm{d}x$$

for all $t \in J_T$ since $1 < \varrho \le q$. Thus, we conclude $\|p(t)\|_{L_\varrho} \le c(T)$ for $t \in J_T$. □

We are now in a position to prove that indeed $J = \mathbb{R}^+$. Since p is nonnegative, $\|\vartheta(w(t))\|_\infty \le c(T)$, and $\partial_\nu p(t) = \partial_\nu f(t) = 0$ for $t \in J_T$ it follows that $\|p(t)\|_{L_1} \le c(T)$, $t \in J_T$, by integrating (H_3). Therefore, we may apply Proposition 5.1 successively to derive $\|p(t)\|_{L_q} \le c(T)$ for $t \in J_T$; hence $J = \mathbb{R}^+$ according to (25). Consequently, the proof of Theorem 1.1 is complete.

6. Numerical examples. We illustrate the theoretical results above with numerical examples (a numerical treatment of a more general model is given in [7]). The parameters for the example are chosen for illustrative purposes.

The region Ω is $[0,6] \times [0,6] \subset \mathbb{R}^2$, the parameters are $a(x) \equiv 5.0$, $\alpha = .01$, $d(x) \equiv 1.0$, $b(x) \equiv 1.0$, $\beta = .01$, $\chi(f) \equiv 0.0$, or $\chi(f) \equiv 0.4$, $\theta(x,w) \equiv 0.1$, $\varrho(x,w) = 2.0\,w/(1.0+w)$, $\gamma = 0.1$, $e(x) \equiv 1.0$, $\omega(x,p) = 2.0\,p/(1.0+p)$, $g(x) \equiv 5.0$, and the initial conditions are

$$f^0(x) = 0.05\,\cos\big((10.0\,\pi/36.0)\,x_1^2\big)\,\sin\big((13.0\,\pi/72.0)\,x_2^2\big) + 0.3\ ,$$
$$p^0(x) = 5.0\,\max\big\{0.3 - (x_1-3.0)^2 - (x_2-3.0)^2\,,\,0.0\big\}\,,$$

$m^0(x) = p^0(x)$, and $w^0(x) = 4.0\,f^0(x)$, where $x = (x_1, x_2)$. The normalized tumor density is initially distributed symmetrically in a circle. The normalized extracellular matrix density is immobile and heterogeneous above a uniform background value. The haptotactic parameter χ is an indicator of the relative strength of cell-matrix adhesion, and the value of χ increases through successive mutations of the tumor cell lines, as tumor cells gain greater capacity to invade the surrounding bound substrate [5]. We provide two choices for the haptotaxis parameter χ to demonstrate this increase in χ. In Figures 1, 2, 3 the value of χ is 0.0, so that all movement of cells is due only to cell motility. In Figures 4, 5, 6 the value of χ is 0.4, so that movement of cells is due to both cell motility and haptotactic directed attraction. The simulations demonstrate that haptotaxis produces a profound distinction in the spatial behavior in the two cases. Without haptotaxis the tumor expands slowly and symmetrically (Figures 1 and 2) as the total population declines (Figure 3). With haptotaxis the

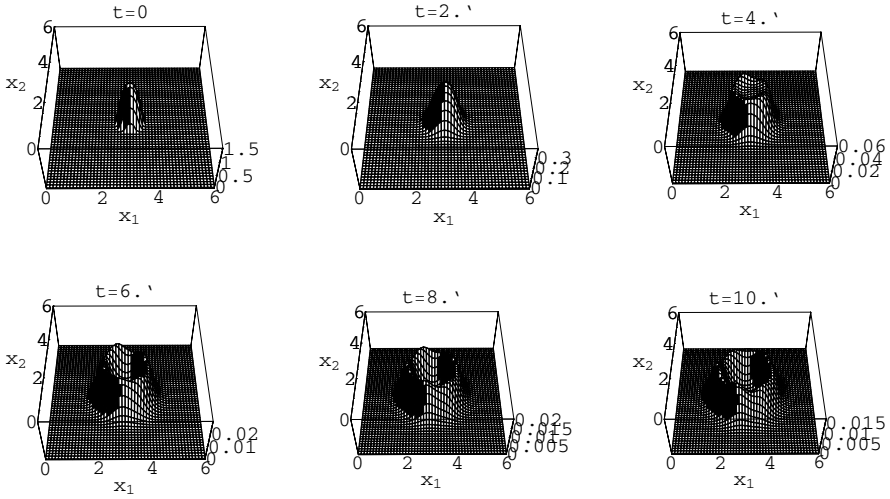

FIG. 1. *The normalized tumor cell density for various times in the case without haptotaxis ($\chi = 0.0$). The tumor slowly expands nearly symmetrically as it decreases in total mass. The interior of the tumor becomes necrotic as tumor cells consume and exhaust the supply of oxygen furnished by the extracellular matrix.*

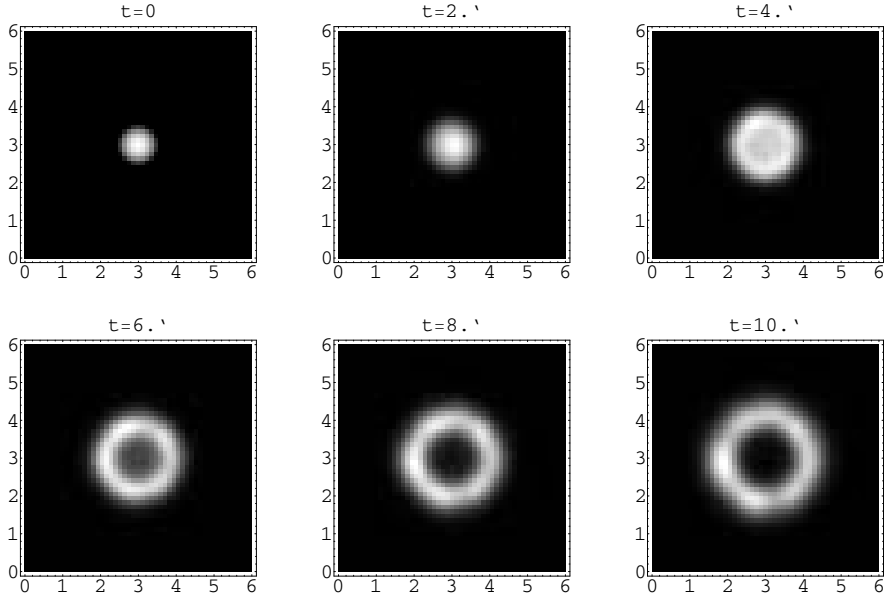

FIG. 2. *The density plots in the (x_1, x_2)-coordinate system of the tumor cell distributions in Figure* 1 *($\chi = 0.0$).*

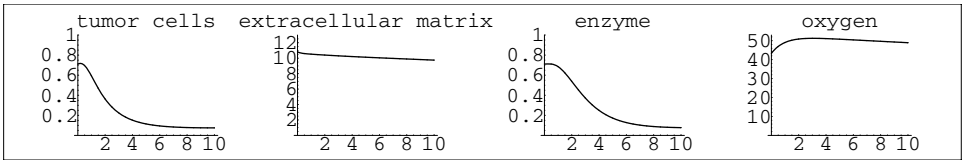

FIG. 3. *The total populations in the case without haptotaxis ($\chi = 0.0$): $\int_\Omega p(x,t)\mathrm{d}x$, $\int_\Omega f(x,t)\mathrm{d}x$, $\int_\Omega m(x,t)\mathrm{d}x$, $\int_\Omega w(x,t)\mathrm{d}x$ as functions of time. The total tumor mass eventually shrinks to a very low value.*

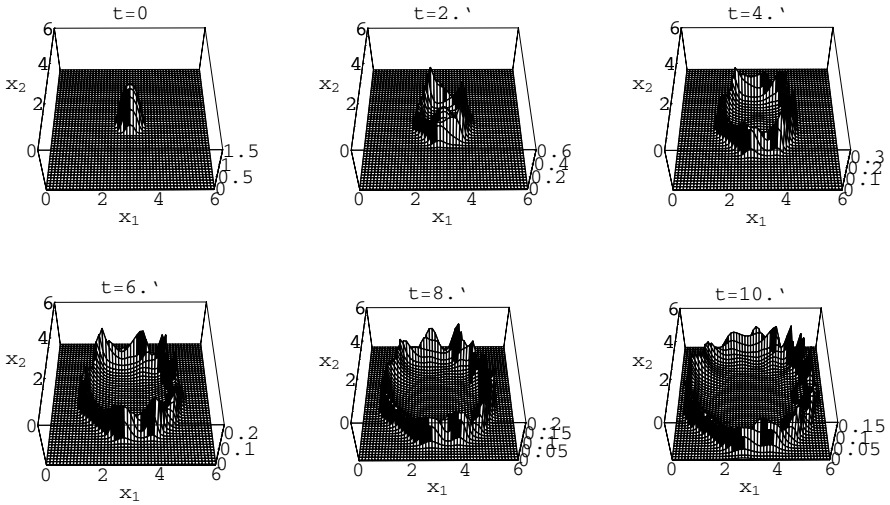

FIG. 4. *The normalized tumor cell density for various times in the case with haptotaxis ($\chi = 0.4$). The tumor expands more rapidly and asymmetrically as it increases in total mass.*

tumor spreads much more rapidly and asymmetrically (Figures 4 and 5) as the total tumor cell population increases (Figure 6) for a time. The distinction of the two cases demonstrates the importance of haptotaxis in the ability of tumors to invade surrounding tissue.

7. Summary. In Theorem 1.1 we have proven the existence of unique classical global solutions to the model of tumor growth (H_1)–(H_6). The model describes the spatial invasion of a tumor mass into its surrounding extracellular matrix. A key feature of the model is that the migration of tumor cells is due primarily to haptotaxis-directed movement. The interpretation of haptotaxis in tumor growth is that cell movement is controlled by the differential strengths of cell-cell adhesion gradients. Haptotaxis differs from chemotaxis in that the directed migration of the tumor cells toward concentrations of the extracellular macromolecules is mediated by a diffusive enzyme produced by the tumor cells. This enzyme degrades the matrix macromolecules, which produce the oxygen essential for tumor growth, and thus alters patterns of tumor movement and proliferation. The haptotaxis process in the model produces technical complications, but also yields the regularity of solutions essential in the analysis. We have demonstrated the role of haptotaxis in two numerical examples. In the first example, without haptotaxis, the only spatial movement of tumor

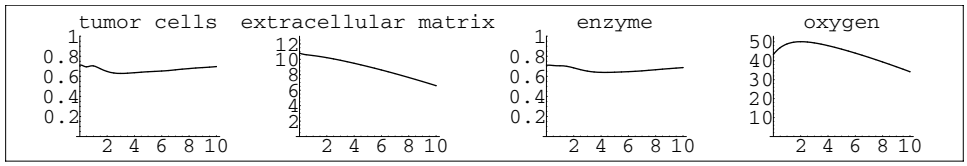

FIG. 6. *The total populations in the case with haptotaxis (*$\chi = 0.4$*):* $\int_\Omega p(x,t)\mathrm{d}x$*,* $\int_\Omega f(x,t)\mathrm{d}x$*,* $\int_\Omega m(x,t)\mathrm{d}x$*,* $\int_\Omega w(x,t)\mathrm{d}x$ *as functions of time. The total tumor mass grows for an interval of time.*

cells is due to cell motility modeled by diffusion. In this example the tumor invades slowly and decreases in total tumor mass. In the second example, with all parameters the same as in the first example, but with the addition of haptotaxis, the tumor invades more rapidly and with increasing total tumor mass. Both examples show the characteristic interior necrosis of tumor cells due to exhaustion of the oxygen supply, but the effect is much more pronounced with haptotaxis. The utilization of oxygen by the tumor cell population is critical in understanding the distinction of the two examples. If the oxygen concentration is constant in time, then the evolution of the total tumor mass is independent of haptotaxis. If the oxygen concentration evolves in time due to tumor consumption and degradation of its source, then haptotaxis-directed spatial migration enables a more efficient utilization of the environmental resources and results in a more aggressive invasion of the tumor into the surrounding tissue.

THE DISTRIBUTION OF SURFACE SUPERCONDUCTIVITY ALONG THE BOUNDARY: ON A CONJECTURE OF X. B. PAN*

YANIV ALMOG† AND BERNARD HELFFER‡

Abstract. We consider the Ginzburg–Landau model of superconductivity in two dimensions in the large κ limit. For applied magnetic fields weaker than the onset field H_{C_3} but greater than H_{C_2} it is well known that the superconductivity order parameter decays exponentially fast away from the boundary. It has been conjectured by X. B. Pan that this surface superconductivity solution converges pointwise to a constant along the boundary. For applied fields that are in some sense between H_{C_2} and H_{C_3}, we prove that the solution indeed converges to a constant but in a much weaker sense.

Key words. superconductivity, surface, Ginzburg–Landau

AMS subject classifications. 82D55

1. Introduction.

The Ginzburg–Landau energy functional of superconductivity is given in the form

$$\mathcal{J}(\Psi, A) = \int_\Omega \left(-|\Psi|^2 + \frac{|\Psi|^4}{2} + |h - h_{ex}|^2 + \left| \left(\frac{i}{\kappa}\nabla + A \right) \Psi \right|^2 \right) dx_1 dx_2, \tag{1.1}$$

in which $\Omega \subset\subset \mathbb{R}^2$ is smooth, and Ψ is the (complex) superconducting order parameter, such that $|\Psi|$ varies from $|\Psi| = 0$ (when the material is at a normal state) to $|\Psi| = 1$ (for the purely superconducting state). The magnetic vector potential is denoted by A (the magnetic field is, then, given by $h = \nabla \times A$), h_{ex} is the constant applied magnetic field, and κ is the Ginzburg–Landau parameter which is a property of the material. The functional $\mathcal{J}$ is invariant under the gauge transformation

$$\Psi \to e^{i\kappa\eta}\Psi,\ A \to A + \nabla\eta, \tag{1.2}$$

where η is a smooth function. We focus here on the properties, for a given h_{ex}, of the global minimizers[1] (Ψ_κ, A_κ) of $\mathcal{J}$ in $H^1(\Omega, \mathbb{C}) \times H^1(\Omega, \mathbb{R}^2)$ for type II superconductors (for which $\kappa > 1/\sqrt{2}$). Note that every global minimizer actually represents an orbit of minimizers associated to the group of transformations (1.2).

1.1. The onset of superconductivity.

It is known both from experiments [18] and rigorous analysis [13] that for a sufficiently strong magnetic field the normal state ($\Psi \equiv 0$, $h = h_{ex}$) would prevail. If the field is then decreased, there is a critical field, depending on the sample's geometry, where the material would enter the superconducting state. For samples with boundaries, this field is known as the onset

[1]We could have actually written more precisely $(\Psi_{\kappa,h_{ex}}, A_{\kappa,h_{ex}})$ but will omit the reference to h_{ex} in order to avoid cumbersome notation.

critical field (or nucleation field) and is called H_{C_3}. This leads to the definition (cf. [19, 15, 10], for instance)

$$H_{C_3}(\kappa) = \inf\{h_{ex} > 0 : (0, \hat{A}) \text{ is the unique global minimizer of } \mathcal{J}\}, \tag{1.3}$$

where $\hat{A} : \Omega \to \mathbb{R}^2$ satisfies $\nabla \times \hat{A} = h_{ex}$. The minimizer $(0, \hat{A})$ is unique in the sense that any other minimizer is gauge equivalent to it, i.e., it should be in the form $(0, \hat{A} + \nabla\eta)$. We note that for our choice of scaling in (1.1) we have $H_{C_3} \sim \frac{\kappa}{\beta_0}$ as $\kappa \to \infty$ for smooth Ω [17], where β_0 is approximately 0.59.

The simplest case in which the bifurcation from the normal state $(0, \hat{A})$ to the superconducting one was described is the case of a half-plane [20]. The analysis in this case is one dimensional: the linearized Ginzburg–Landau equations were solved on $\mathbb{R}_+$. A similar situation occurs in two dimensions: it was proved in [17] and [7] that the bifurcating mode in $\mathbb{R}^2_+$ is one dimensional and that the value of H_{C_3} is exactly the same as in the one-dimensional case.

In addition, Saint-James and de Gennes [20] found that superconductivity appears first near the boundary for a half-plane, i.e., the order parameter Ψ_κ decays exponentially fast away from the boundary. This phenomenon, which appears only in the presence of boundaries, is therefore called surface superconductivity. It was later proved for general two-dimensional domains with smooth boundaries [17, 7], that as the domain's scale tends to infinity the onset field tends to de Gennes' value, and that Ψ_κ decays exponentially fast away from the boundary.

Another related problem that has been considered in the literature is the distribution of $|\Psi_\kappa|$ along the boundary near the critical field. In [4], this distribution was formally obtained. This led to the conjecture that $|\Psi_\kappa|$ should be maximal at the point of maximal curvature along the boundary. This was indeed proved a few years later [15, 16, 11, 12]. Furthermore, it was shown that Ψ_κ decays exponentially fast away from the points of maximal curvature along the boundary.

1.2. Weakly nonlinear analysis. Suppose now that h_{ex} is further decreased below H_{C_3}. While the minimizer Ψ_κ still decays exponentially fast away from the boundary much after the nucleation in the highly nonlinear regime when $\kappa < h_{ex} < H_{C_3}$ [1, 19, 2], the exponential decay along the boundary disappears quite rapidly as h_{ex} decreases. More precisely, if we introduce the distance to the nucleation field ρ by

$$\rho(\kappa) = H_{C_3}(\kappa) - h_{ex},$$

then exponential rate of decay along the boundary (far from the points of maximal curvature) is guaranteed only when

$$\rho(\kappa) \xrightarrow[\kappa\to\infty]{} 0.$$

Furthermore, it was proved in [10] that if ρ satisfies

$$\lim_{\kappa\to\infty} \rho(\kappa) = \infty; \quad \lim_{\kappa\to\infty} \frac{\rho(\kappa)}{\kappa^{1/2}} = 0,$$

then there exists $u \in \mathcal{S}(\overline{\mathbb{R}^+})$ such that

$$\int_\Omega \left| |\Psi_\kappa(x)|^2 - \frac{\rho}{\kappa} u\left(\frac{\kappa}{\sqrt{\lambda}}\, t(x)\right)\right|^2 dx = o(\rho\kappa^{-3}), \tag{1.4}$$

where $t = d(x, \partial\Omega)$, $\lambda = \kappa/h_{ex}$.

This leaves open the situation when $\rho(\kappa)/\kappa^{\frac{1}{2}}$ does not tend to 0 as $\kappa \to \infty$ and in particular becomes of the order of $\kappa^{\frac{1}{2}}$. It is this last case which will be considered in this article.

1.3. Highly nonlinear analysis: Pan's conjecture. Given some $\lambda \in]\beta_0, 1[$, let $(\kappa_n, h_{ex}^n)_{n\in\mathbb{N}}$ denote a pair of sequences satisfying

$$\lim_{n\to+\infty} \kappa_n = \infty; \quad \lim_{n\to+\infty} \frac{\kappa_n}{h_{ex}^n} = \lambda.$$

In the above $\beta_0 = \lim_{\kappa\to\infty} \kappa/H_{C_3}(\kappa)$ (we provide a better definition of β_0 in the next section). In [19, Conjecture 1], Pan conjectures the existence of a function $]\beta_0, 1[\ni \lambda \mapsto C(\lambda) \in \mathbb{R}^+$ such that, for any sequence as above,

$$|\Psi_{\kappa_n}(x)| \to C(\lambda)\ \forall x \in \partial\Omega. \tag{1.5}$$

While the conjecture appears to be correct in its essence—any minimizer, as the results in [10] and in the present contribution suggest, does tend in some weak sense to a constant along the boundary—we believe that either the convergence assumed in (1.5) cannot be uniform, or else that the global minimizer must be discontinuous in h_{ex} and κ. Let us sketch the heuristic arguments supporting this belief. We first write the Euler–Lagrange equations associated with (1.1) (or the Ginzburg–Landau equations):

$$\left(\frac{i}{\kappa}\nabla + A_\kappa\right)^2 \Psi_\kappa = \Psi_\kappa \left(1 - |\Psi_\kappa|^2\right), \tag{1.6a}$$

$$-\nabla \times \nabla \times A_\kappa = \frac{i}{2\kappa}\left(\Psi_\kappa^* \nabla\Psi_\kappa - \Psi_\kappa \nabla\Psi_\kappa^*\right) + |\Psi_\kappa|^2 A_\kappa. \tag{1.6b}$$

If $|\Psi_\kappa| > 0$ for all $x \in \partial\Omega$ (and this is indeed the case if we assume uniform convergence in (1.5)), then we can divide (1.6b) by $|\Psi_\kappa|^2$ and integrate over $\partial\Omega$ (the measure on $\partial\Omega$ being denoted by ds), to obtain the existence of an integer $N(\Psi_\kappa)$ such that

$$\int_{\partial\Omega} \frac{\nabla \times (h_\kappa - h_{ex})}{|\Psi|^2} ds + \int_\Omega h_\kappa\, dx = \frac{2\pi}{\kappa} N(\Psi_\kappa),$$

where $h_\kappa = \nabla \times A_\kappa$ is the induced magnetic field. The integer $N(\Psi_\kappa) \in \mathbb{Z}$ is the winding number (or the degree) of Ψ_κ around $\partial\Omega$, which is invariant under the transformation (1.2) since η must be smooth.

In [9] it is proved that Ψ_κ vanishes at isolated points or curves which should end on $\partial\Omega$. If $|\Psi_\kappa|$ does not vanish on the boundary, as implied by (1.5), then it is clear that Ψ_κ can vanish only at isolated points. Thus, we can conclude that $N(\Psi_\kappa)$ is the number of vortices of Ψ_κ, including multiplicities, in Ω.

In [16], it is proved (see [19] for an extension to the case which is considered here) that, for any $\epsilon_0 > 0$, there exist $C > 0$ and κ_0, such that, if $\kappa/h_{ex} \in [\beta_0 + \epsilon_0, 1 - \epsilon_0]$ and $\kappa \geq \kappa_0$, then

$$\|h - h_{ex}\|_{L^\infty(\Omega)} + \|\nabla(h_\kappa - h_{ext})\|_{L^\infty(\Omega)} \leq C.$$

Hence there exists a constant C such that

$$\left| N(\Psi_\kappa) - \kappa h_{ex} \frac{|\Omega|}{2\pi} \right| \leq C\kappa. \tag{1.7}$$

Suppose now that the minimizer is unique when varying h_{ex} and κ as above. It is in this case reasonable to think that (Ψ_κ, A_κ) varies continuously. If there exist κ_0, $\epsilon_1 > 0$ and $C > 0$ such that

$$|\Psi_\kappa| \geq \frac{1}{C} \text{ on } \partial\Omega \; \forall \kappa \geq \kappa_0 \text{ s. t. } \frac{\kappa}{h_{ex}} \in [\lambda - \epsilon_1, \lambda + \epsilon_1]$$

(which would be a consequence of a uniform version of (1.5)), then $N(\Psi_\kappa)$ must be fixed, by continuity, for all $\kappa \geq \kappa_0$ such that $\kappa/h_{ex} \in [\lambda - \epsilon_1, \lambda + \epsilon_1]$, and this is in contradiction with (1.7).

The above argument works not only for (ψ_κ, A_κ) but for any solution of (1.6). If indeed critical points of (1.1) are continuous functions of κ and h_{ex} in this regime, then (1.7) would contradict another conjecture of Pan (Conjecture 2 in [19]), implying that any solution of (1.6) converges to a constant along the boundary when $\kappa \to \infty$ and $\kappa/h_{ex} \in (\beta_0, 1)$. While the existence of continuous branches of critical points appears to be reasonable, two counterexamples come to mind while discussing the continuity of the global minimizer.

1. Serfaty [21] proves, for much lower external fields, that a large number of local minimizers of (1.1) in a disc, characterized by different winding numbers, exist for sufficiently large κ whenever $\frac{1}{C}\kappa^{-1} \leq h_{ex} \leq C\kappa^{\alpha-1}$ for some $0 < \alpha < 1$. In this regime of applied magnetic field values the magnetic field is nonuniform inside the domain, and hence the vortices are kept near the disc's center, which minimizes the magnetic field term in (1.1).
   While in the present case h_{ex} and κ have the same order, if we allow for an $O(1)$ change in the applied magnetic field we might still encounter a global minimizer which turns into a local minimizer (or a critical point) and vice versa. Thus, this result suggests that the contradiction between (1.7) and the convergence to a uniform constant along the boundary might be explained by arguing that the global minimizer is discontinuous. However, unlike the case discussed in [21], no equivalent mechanism which keeps the vortices away from the boundary is presently known as the magnetic field uniformly converges to h_{ex} in Ω [2].
2. Bauman, Phillips, and Tang [3] found radially symmetric solutions of the linearized version of (1.6). These solutions are characterized by a "fat" vortex at the disc's center. The degree of the vortex is determined, to leading order in the large κ limit, by the magnetic flux through the disc. Thus, there is a sequence of critical flux values where the bifurcating mode changes its winding number. It is shown in [3] that the bifurcating mode is locally stable near the bifurcation for κ large enough.
   Based on the results in [3] one can argue that the minimizer undergoes an abrupt change when the flux varies around one of the above critical values (and when κ is appropriately tuned to guarantee that weakly nonlinear analysis still holds). However, this result seems to follow from the special geometry, and, in general, for different geometries or away from the linear regime, nothing would hold the vortices in the center.

1.4. Statement of the main result. In the present contribution we focus on the case

$$\lim_{\kappa\to\infty} \frac{h_{ex}(\kappa)}{\kappa} = \frac{1}{\lambda},$$

with λ close to β_0. We prove the following theorem.

THEOREM 1.1. *Let $\delta > 0$ be sufficiently small, so that $t = d(x, \partial\Omega)$ is a smooth function of x for $0 \le t \le \delta$, and let*

$$\Omega_\delta = \left\{ x \in \bar{\Omega} \,:\, d(x, \partial\Omega) \le \delta \right\}.$$

Then there exist $\epsilon > 0$, a function

$$[0, +\infty[\times]\beta_0, \beta_0 + \epsilon[\ni (\tau, \lambda) \mapsto U(\tau, \lambda) \in \mathbb{R}^+,$$

a constant $C > 0$, and κ_0, such that, for $\kappa \ge \kappa_0$ and $h_{ex} = \frac{\kappa}{\lambda}$ with $\lambda \in]\beta_0, \beta_0 + \epsilon[$,

$$\int_{\Omega_\delta} \left[|\Psi_\kappa(x)|^2 - U\left(\frac{\kappa}{\sqrt{\lambda}} t(x), \lambda \right) \right]^2 dx_1 dx_2 \le \frac{C}{\kappa^2}, \tag{1.8a}$$

$$\int_{\partial\Omega} \left[\left| \Psi_\kappa \big/_{\partial\Omega} \right|^2 - U(0, \lambda) \right]^2 ds \le \frac{C}{\kappa^{1/2}}. \tag{1.8b}$$

The function $U(\tau, \lambda)$ is defined for $\tau \in \overline{\mathbb{R}^+}$ by

$$U(\tau, \lambda) = |f_{\zeta(\lambda)}(\tau; \lambda)|^2,$$

where $f_z(\tau; \lambda)$ and $\zeta(\lambda)$ are associated to minimizers of a family of one-dimensional problems, which will be analyzed in section 2. The second statement in the theorem gives the $L^2(\partial\Omega)$ convergence of $|\Psi_\kappa|^2$ to a constant and is consequently a weak form of Pan's conjecture.

The rest of the contribution is arranged as follows.

In section 2 we consider a one-dimensional differential operator and prove that it is positive for $\beta_0 < \lambda < \beta_0 + \epsilon$. In section 3 we use the results of section 2 to analyze a simplified two-dimensional minimization problem, which was proved in [19] to be a good approximation of the full Ginzburg–Landau model for $\beta_0 < \lambda < 1$. The last section gives the proof of Theorem 1.1.

2. A one-dimensional problem. Let

$$\beta(z) = \inf_{\phi \in H^1_{mag}(]0,\infty[) \setminus \{0\}} \frac{\int_0^\infty |\phi'(\tau)|^2 + (\tau + z)^2 |\phi(\tau)|^2 \, d\tau}{\int_0^\infty |\phi(\tau)|^2 \, d\tau}. \tag{2.1}$$

Here

$$H^1_{mag}(]0, +\infty[) = \{ u \in L^2(]0, +\infty[) \,,\; u' \in L^2(]0, +\infty[) \text{ and } \tau u \in L^2(]0, +\infty[) \}.$$

It is well known (see [5]) that $\beta(z)$ has a unique local minimum at $z_0 < 0$, where

$$\beta(z_0) = \beta_0 = z_0^2.$$

Furthermore, $\beta(z) \xrightarrow[z \to \infty]{} \infty$ and $\beta(z) \xrightarrow[z \to -\infty]{} 1$. Clearly, for $\beta_0 < \lambda < 1$ there exist $z_1(\lambda) < z_0 < z_2(\lambda)$, such that

$$]z_1(\lambda), z_2(\lambda)[= \beta^{-1}([\beta_0, \lambda[).$$

It is also easy to show [6] that

$$\beta''(z_0) = -2 z_0 \phi^2(0) > 0, \tag{2.2}$$

where ϕ is the minimizer of (2.1) whose $L^2(\mathbb{R}_+)$ norm is unity.

Let $f_z(\tau;\lambda)$ denote the minimizer of

$$\mathcal{E}_{z,\lambda}(\phi) = \int_0^\infty |\phi'(\tau)|^2 + (\tau+z)^2|\phi(\tau)|^2 + \frac{\lambda}{2}|\phi(\tau)|^4 - \lambda|\phi(\tau)|^2\, d\tau \tag{2.3}$$

in $H^1_{mag}(]0,\infty[)$. The Euler–Lagrange equation associated with (2.3) is

$$-f_z''(\tau;\lambda) + (\tau+z)^2 f_z(\tau;\lambda) = \lambda f_z(\tau;\lambda)(1-f_z(\tau;\lambda)^2). \tag{2.4}$$

It has been proved in [19, Theorems 3.1 and 3.3] that whenever $z_1(\lambda) < z < z_2(\lambda)$, there exists a unique positive global minimizer to (2.3). Furthermore, let

$$b(z,\lambda) = \inf_{\varphi\in H^1_{mag}(]0,\infty[)} \mathcal{E}_{z,\lambda}(\varphi). \tag{2.5}$$

Then there exists $\zeta(\lambda)\in\,]z_1(\lambda), z_2(\lambda)[$, where $z\mapsto b(z,\lambda)$ attains its minimum over $\mathbb{R}$,

$$b(\zeta(\lambda),\lambda) = \inf_z b(z,\lambda).$$

Moreover,

$$\int_0^\infty (\tau+\zeta(\lambda))|f_{\zeta(\lambda)}(\tau;\lambda)|^2\, d\tau = 0. \tag{2.6}$$

Remark 2.1. Note that when $z\notin\,]z_1(\lambda), z_2(\lambda)[$, then $b(z,\lambda)=0$, and the minimizer of $\mathcal{E}_{z,\lambda}$ is the 0-function. In particular,

$$b(\zeta(\lambda),\lambda) < 0 \ \text{ if } \lambda > \beta_0.$$

The following lemma will play a crucial role in the analysis of the two-dimensional problem in section 3.

LEMMA 2.2. *Let*

$$\gamma(\alpha,\lambda) = \inf_{\phi\in H^1_{mag}(]0,\infty[)} \frac{\int_0^\infty |\phi'(\tau)|^2 + (\tau+\zeta+\alpha)^2|\phi(\tau)|^2 - \lambda(1-f_\zeta(\tau;\lambda)^2)|\phi(\tau)|^2\, d\tau}{\int_0^\infty |\phi(\tau)|^2\, d\tau}, \tag{2.7}$$

with $\zeta=\zeta(\lambda)$.

Then there exists $\epsilon>0$ *such that, for* $\lambda\in[\beta_0,\beta_0+\epsilon[$,

$$\min_{\alpha\in\mathbb{R}} \gamma(\alpha,\lambda) = 0. \tag{2.8}$$

Proof. We divide the proof into three steps.

Step 1. $\gamma(0,\lambda) = \gamma_\alpha(0,\lambda) = 0$.

Let $\mathbb{R}_+ \ni \tau\mapsto u(\tau;\alpha,\lambda)$ denote the positive minimizer of (2.7), whose $L^2(\mathbb{R}_+)$ norm is one. Then u satisfies

$$-u''(\tau;\alpha,\lambda) + (\tau+\alpha+\zeta)^2 u(\tau;\alpha,\lambda) - \lambda(1-f_\zeta(\tau;\lambda)^2)u(\tau;\alpha,\lambda) = \gamma(\alpha,\lambda)u(\tau;\alpha,\lambda), \tag{2.9a}$$

$$u'(0;\alpha,\lambda) = 0. \tag{2.9b}$$

For $\alpha = 0$, we multiply (2.9a) by f_ζ and integrate over $\mathbb{R}_+$ to obtain

$$\gamma(0,\lambda)\int_0^\infty f_\zeta(\tau;\lambda)u(\tau;\alpha,\lambda)\,d\tau = 0.$$

Since both u and f_ζ are positive, we have using (2.4),

$$\gamma(0,\lambda) = 0, \quad u(\tau,0,\lambda) = \frac{f_\zeta(\tau;\lambda)}{\|f_\zeta\|_2}, \tag{2.10}$$

where, for $p \in [1,+\infty]$, $\|\cdot\|_p = \|\cdot\|_{L^p(\mathbb{R}_+)}$. Next, we differentiate (2.9) with respect to α to obtain, having in mind (2.4),

$$-u''_\alpha + (\tau+\alpha+\zeta)^2 u_\alpha - \lambda(1-f_\zeta^2)u_\alpha = \gamma u_\alpha + \gamma_\alpha u - 2(\tau+\alpha+\zeta)u, \tag{2.11a}$$

$$u'_\alpha(0) = 0, \tag{2.11b}$$

where $u_\alpha(\tau;\alpha,\lambda) = (\frac{\partial u}{\partial\alpha})(\tau;\alpha,\lambda)$ and $\gamma_\alpha(\alpha,\lambda) = \frac{\partial\gamma}{\partial\alpha}(\alpha,\lambda)$. Multiplying (2.11a) by u and integrating by parts, we obtain

$$\gamma_\alpha(\alpha,\lambda) = 2\int_0^\infty (\tau+\alpha+\zeta(\lambda))|u(\tau;\alpha,\lambda)|^2\,d\tau. \tag{2.12}$$

In view of (2.6) and (2.10), we thus have

$$\gamma_\alpha(0,\lambda) = 0. \tag{2.13}$$

Step 2.

$$\exists\epsilon_1 > 0 :\ \lambda < \beta_0 + \epsilon_1 \Rightarrow \gamma_{\alpha\alpha}(0,\lambda) > \frac{1}{2}\beta''(z_0) > 0. \tag{2.14}$$

To prove the above statement we notice that $z_1(\lambda) \uparrow z_0$ and $z_2(\lambda) \downarrow z_0$ as $\lambda \to \beta_0$. Hence, since $z_1(\lambda) < \zeta(\lambda) < z_2(\lambda)$, we have

$$\zeta(\lambda) \xrightarrow[\lambda\to\beta_0]{} z_0. \tag{2.15}$$

Moreover, one gets from the fact that f_z is a minimizer the property that

$$\mathcal{E}_{z,\lambda}(f_z) \le 0.$$

From this inequality and (2.1) we easily obtain

$$\frac{1}{2}||f_z||_4^4 \le \frac{(\lambda-\beta_0)}{\lambda}||f_z||_2^2,$$

$$||(\tau+z)f_z||_2^2 \le \lambda||f_z||_2^2, \tag{2.16}$$

and

$$||f_z||_{H^1}^2 \le (\lambda+1)||f_z||_2^2.$$

Let $z = \zeta(\lambda)$. Since $|\zeta(\lambda)|$ is bounded in some right semineighborhood of β_0, it follows immediately from (2.16) that for R large enough we get

$$||f_\zeta||_2^2 \le 2||f_\zeta||_{L^2(]0,R[)}^2.$$

We now observe that

$$||f_\zeta||_4^4 \leq C(\lambda-\beta_0)||f_\zeta||^2_{L^2(]0,R[)} \leq C(\lambda-\beta_0)R^{\frac{1}{2}}||f_\zeta||_4^2.$$

This first gives that

$$||f_\zeta||_4 \leq \tilde{C}(\lambda-\beta_0)^{\frac{1}{2}},$$

and hence that

$$||f_\zeta||_2 \leq \hat{C}(\lambda-\beta_0)^{\frac{1}{2}}.$$

By interpolation, we obtain

$$||f_\zeta||_\infty \leq C||f_\zeta||_2^{\frac{1}{2}}\ ||f'_\zeta||_2^{\frac{1}{2}} \leq C'(\lambda-\beta_0)^{\frac{1}{4}}, \tag{2.17}$$

which implies that

$$\lim_{\lambda\to\beta_0} \|f_{\zeta(\lambda)}(\,\cdot\,;\lambda)\|_\infty = 0.$$

Substituting the above and (2.15) into (2.7) yields

$$\gamma(\alpha,\lambda) \xrightarrow[\lambda\to\beta_0]{} \beta(\alpha+z_0),$$

where the convergence is uniform on every compact set in $\mathbb{R}$. Since γ is holomorphic in α, its derivatives must uniformly converge as well, and hence

$$\gamma_{\alpha\alpha}(\alpha,\lambda) \xrightarrow[\lambda\to\beta_0]{} \beta''(\alpha+z_0), \tag{2.18}$$

from which (2.14) easily follows. We note that a tedious calculation shows that

$$\gamma_{\alpha\alpha}(0,\lambda) = -2\zeta\frac{f_\zeta^2(0;\lambda)}{\|f_\zeta\|_2^2} + \frac{6\lambda^2}{\|f_\zeta\|_2^2}\int_0^\infty f_\zeta^6(\tau;\lambda)\,d\tau\ - \frac{2\lambda}{3}\int_0^\infty f_\zeta^4(\tau;\lambda)[\lambda-(\tau+\zeta)^2]d\tau,$$

with $\zeta=\zeta(\lambda)$, from which one can easily prove (2.14) as well.

From (2.14) we obtain that

$$\exists\alpha_0>0:\ \lambda<\beta_0+\epsilon_1 \Rightarrow \gamma(\alpha,\lambda)\geq 0\ \forall|\alpha|\leq\alpha_0.$$

The last step would thus be to prove the above statement for $|\alpha|>\alpha_0$.

Step 3. Proof of (2.8).

From the definition of γ (2.7), it follows that

$$\gamma(\alpha,\lambda)\geq\beta(\zeta+\alpha)-\lambda.$$

Clearly, for any $\alpha_1>0$, there exists $\epsilon_2>0$, such that, if $\lambda\leq\beta_0+\epsilon_2$, then $[z_1(\lambda),z_2(\lambda)]\subset[z_0-\alpha_1,z_0+\alpha_1]$. We now take $\alpha_1=\alpha_0$. This gives that $\beta(\zeta+\alpha)\geq\lambda$ for all $|\alpha|\geq\alpha_0$, and (2.8) follows. □

3. On two-dimensional models on half cylinders. We can now prove the following theorem.

THEOREM 3.1. *For $\omega \in]0,+\infty[$ and $\lambda \in [\beta_0,+\infty[$, let us consider the functional*

$$\mathcal{H}_\omega \ni \psi \mapsto E_\omega(\psi,\lambda) = \int_{-\pi/\omega}^{\pi/\omega}\int_0^\infty \left[|(i\nabla + \xi_1 \hat{i}_2)\psi|^2 + \frac{1}{2}\lambda|\psi|^4 - \lambda|\psi|^2\right] d\xi_1 d\xi_2, \tag{3.1}$$

where

$$|(i\nabla + \xi_1\hat{i}_2)\psi|^2 = |i\partial_{\xi_1}\psi|^2 + |(i\partial_{\xi_2} + \xi_1)\psi|^2,$$

and

$$\mathcal{H}_\omega = \Big\{\psi \in H^1_{mag}\big(\mathbb{R}_+\times]-L,L[,\mathbb{C}\big)\ \forall L>0 \ \Big|\ \exists z\in\mathbb{R}:\ \psi(\xi_1,\xi_2+2\pi/\omega) = e^{-iz\frac{2\pi}{\omega}}\psi(\xi_1,\xi_2)\Big\}.$$

Let ψ_λ be the function

$$(\mathbb{R}_+\times\mathbb{R}) \ni (\xi_1,\xi_2) \mapsto \psi_\lambda(\xi_1,\xi_2) := e^{-i\zeta(\lambda)\xi_2} f_{\zeta(\lambda)}(\xi_1;\lambda). \tag{3.2}$$

Then there exists $\epsilon > 0$ such that

$$E_\omega(\psi,\lambda) \geq E_\omega(\psi_\lambda,\lambda)\ \forall\lambda\in]\beta_0,\beta_0+\epsilon[,\ \forall\omega>0, \quad \text{and } \forall\psi\in\mathcal{H}_\omega. \tag{3.3}$$

Remark 3.2. Clearly ψ_λ is in $\mathcal{H}_\omega$ (take $z=\zeta(\lambda)$). Hence, the theorem states that ψ_λ is the global minimizer of E_ω in $\mathcal{H}_\omega$.

Proof. Consider first functions in $\mathcal{H}_\omega$ which are given in the form

$$(\xi_1,\xi_2) \mapsto \psi(\xi_1,\xi_2) := f_\zeta(\xi_1;\lambda)e^{-i\zeta\xi_2}v, \tag{3.4}$$

with v periodic,

$$v(\xi_1,\xi_2) = v(\xi_1,\xi_2+2\pi/\omega), \tag{3.5}$$

and

$$\zeta = \zeta(\lambda).$$

Then

$$E_\omega(\psi,\lambda) = \int_{-\pi/\omega}^{\pi/\omega}\int_0^\infty \left[|(i\nabla + (\xi_1+\zeta)\hat{i}_2)f_\zeta v|^2 + \frac{1}{2}\lambda|f_\zeta v|^4 - \lambda|f_\zeta v|^2\right] d\xi_1 d\xi_2.$$

Clearly,

$$\begin{aligned}\int_{-\pi/\omega}^{\pi/\omega}\int_0^\infty |(i\nabla + (\xi_1+\zeta)\hat{i}_2)f_\zeta v|^2\, d\xi_1 d\xi_2 \\ = \int_{-\pi/\omega}^{\pi/\omega}\int_0^\infty \Big[|v|^2\big[|f_\zeta'|^2 + (\xi_1+\zeta)^2|f_\zeta|^2\big] + f_\zeta^2|\nabla v|^2 + \frac{1}{2}(f_\zeta^2)'\frac{\partial}{\partial\xi_1}(|v|^2) \\ + i(\xi_1+\zeta)f_\zeta^2\left(\bar{v}\frac{\partial v}{\partial\xi_2} - v\frac{\partial\bar{v}}{\partial\xi_2}\right)\Big] d\xi_1 d\xi_2.\end{aligned}$$

Furthermore, integration by parts and (2.4) yield

$$\int_{-\pi/\omega}^{\pi/\omega}\int_0^\infty \left[|v|^2\left[|f_\zeta'|^2+(\xi_1+\zeta)^2|f_\zeta|^2\right]+\frac{1}{2}(f_\zeta^2)'\frac{\partial}{\partial\xi_1}(|v|^2)\right]d\xi_1 d\xi_2 = \lambda\int_{-\pi/\omega}^{\pi/\omega}\int_0^\infty |v|^2 f_\zeta^2(1-f_\zeta^2)\,d\xi_1 d\xi_2. \tag{3.6}$$

Hence,

$$\begin{aligned}\Delta E_\omega &= E_\omega(\psi,\lambda)-E_\omega(f_\zeta e^{-i\zeta\xi_2},\lambda)\\ &= \int_{-\pi/\omega}^{\pi/\omega}\int_0^\infty f_\zeta^2\left[|\nabla v|^2+i(\xi_1+\zeta)\left(\bar v\frac{\partial v}{\partial\xi_2}-v\frac{\partial\bar v}{\partial\xi_2}\right)\right]d\xi_1 d\xi_2\\ &\quad+\frac{1}{2}\int_{-\pi/\omega}^{\pi/\omega}\int_0^\infty f_\zeta(\xi_1;\lambda)^4(1-|v(\xi_1,\xi_2)|^2)^2\,d\xi_1 d\xi_2.\end{aligned}$$

Using (3.5), we can write

$$v(\xi_1,\xi_2)=\sum_{n=-\infty}^{\infty} v_n(\xi_1)e^{in\omega\xi_2}.$$

Then

$$\Delta E_\omega = \sum_{n=-\infty}^{\infty}\int_0^\infty f_\zeta(\xi_1;\lambda)^2\left[|v_n'(\xi_1)|^2+(n^2\omega^2+2n\omega\xi_1)|v_n(\xi_1)|^2\right]d\xi_1 + \frac{1}{2}\int_{-\pi/\omega}^{\pi/\omega}\int_0^\infty f_\zeta(\xi_1;\lambda)^4(1-|v(\xi_1,\xi_2)|^2)^2\,d\xi_1 d\xi_2. \tag{3.7}$$

Consider now the functional

$$u\mapsto \mathcal{J}(u,\alpha)=\int_0^\infty |f_\zeta(\xi_1;\lambda)|^2\left[|u'(\xi_1)|^2+[\alpha^2+2\alpha(\xi_1+\zeta)]|u(\xi_1)|^2\right]d\xi_1.$$

Substituting $w(\xi_1)=f_\zeta(\xi_1;\lambda)\,u(\xi_1)$ and utilizing (2.4), we obtain

$$\begin{aligned}\int_0^\infty |f_\zeta(\xi_1)|^2|u'(\xi_1)|^2\,d\xi_1 &= \int_0^\infty\left[-\left(w^2\frac{f_\zeta'}{f_\zeta}\right)'+w^2\frac{f_\zeta''}{f_\zeta}+|w'|^2\right]d\xi_1\\ &= \int_0^\infty\left[|w'|^2+[(\xi_1+\zeta)^2-\lambda(1-f_\zeta^2)]|w|^2\right]d\xi_1.\end{aligned}$$

Consequently,

$$\mathcal{J}(w/f_\zeta,\alpha)=\int_0^\infty\left(|w'|^2+[(\xi_1+\zeta+\alpha)^2-\lambda(1-f_\zeta^2)]|w|^2\right)d\xi_1\ge\gamma(\alpha,\lambda)\int_0^\infty|w|^2\,d\xi_1.$$

Combining the above with (3.7), we obtain

$$\Delta E_\omega\ge\sum_{n=-\infty}^{\infty}\gamma(n\omega,\lambda)\int_0^\infty f_\zeta^2|v_n|^2\,d\xi_1+\frac{1}{2}\int_{-\pi/\omega}^{\pi/\omega}\int_0^\infty f_\zeta^4(1-|v|^2)^2\,d\xi_1 d\xi_2\ge 0,$$

which proves, using (2.8), inequality (3.3) for every function in $\mathcal{H}_\omega$ satisfying (3.4).

Note for later use that this implies

(3.8)
$$|E_\omega(\psi,\lambda) - E_\omega(f_\zeta\, e^{-i\zeta\xi_2},\lambda)| \geq \frac{1}{2}\int_{-\pi/\omega}^{\pi/\omega}\int_0^\infty f_\zeta(\xi_1;\lambda)^4(1-|v(\xi_1,\xi_2)|^2)^2\, d\xi_1 d\xi_2.$$

To prove (3.3) for all $\psi \in \mathcal{H}_\omega$, we consider now functions of the form

(3.9) $$(\xi_1,\xi_2) \mapsto \psi_0(\xi_1,\xi_2) = f_\zeta(\xi_1;\lambda)e^{-iz\xi_2}v, \text{ with } v(\xi_1,\xi_2) = v(\xi_1,\xi_2+2\pi/\omega).$$

Consider first the case when $\omega \in \mathbb{R}_+$ satisfies

(3.10) $$\frac{\zeta - z}{\omega} = \frac{p}{q} \text{ for some pair } (p,q) \in \mathbb{Z}\times\mathbb{N}.$$

Clearly, if ψ_0 satisfies (3.9) for some $\omega \in \mathbb{R}_+$, then it also satisfies (3.9) for $\omega/\hat{q}$, for every $\hat{q} \in (\mathbb{N}\setminus\{0\})$. Moreover, it is easy to show that

(3.11) $$E_{\omega/\hat{q}}(\psi_0) = \hat{q}E_\omega(\psi_0),\ E_{\omega/\hat{q}}(\psi_\lambda) = \hat{q}E_\omega(\psi_\lambda).$$

We now choose $\hat{q} = q$, and observe that, according to (3.10), $\hat{\omega} = \omega/q$ satisfies

(3.12) $$\frac{\zeta - z}{\hat{\omega}} \in \mathbb{Z}.$$

But in this case, ψ_0 admits the representation (3.4), and hence

$$E_{\hat{\omega}}(\psi_0) \geq E_{\hat{\omega}}(\psi_\lambda).$$

Coming back to ω and using (3.11), we have the proof of (3.3) when ω satisfies (3.10) (with the additional condition that z is fixed).

The proof of (3.3) in the general case follows immediately from the density of the rational numbers in $\mathbb{R}$. □

4. Surface superconductivity. Let $\mathcal{J}$ be given by (1.1). Let (Ψ_κ, A_κ) denote a minimizer of $\mathcal{J}$ in $H^1(\Omega,\mathbb{C})\times H^1(\Omega,\mathbb{R}^2)$. We prove in this section that $|\Psi_\kappa|^2$ is nearly a constant along the boundary, in $L^2(\partial\Omega)$ sense, as $\kappa\to\infty$, and for

$$\beta_0 < \lambda = \frac{\kappa}{h_{ex}} < \beta_0 + \epsilon,$$

where ϵ is defined in (2.8).

To this end we need to adapt the results in [19]. Then let

(4.1) $$x = \mathcal{F}(t,s)$$

denote a diffeomorphism from

$$D(\delta) = \{(s,t)\ :\ |s| \leq |\partial\Omega|/2,\ 0 \leq t \leq \delta\}$$

to

$$\Omega_\delta = \left\{x \in \bar{\Omega}\ :\ d(x,\partial\Omega) \leq \delta\right\}.$$

In the previous equation $t = d(x,\partial\Omega)$ and s denotes the arclength along $\partial\Omega$.

In order to formulate and prove the results of this section it is necessary to fix a specific gauge for (ψ_κ, A_κ). To this end we first define the magnetic potential P_κ to be the solution of

$$\begin{cases} \nabla \times P_\kappa = \nabla \times A_\kappa - h_{ex} & \text{in } \Omega, \\ \nabla \cdot P_\kappa = 0 & \text{in } \Omega, \\ P_\kappa \cdot \hat{\nu} = 0 & \text{in } \partial\Omega \end{cases} \tag{4.2}$$

(see, for example, [8] for the proof of existence of a unique solution for (4.2)). Moreover, the map associating the solution P_κ of (4.2) to the field $(h_\kappa - h_{ex})$ is linear continuous from $L^p(\Omega)$ into $W^{1,p}(\Omega)$ for any $p \in [1, +\infty[$, and, using the Sobolev injection theorem, one can show that

$$||P_\kappa||_{L^\infty(\Omega)} \leq C_\Omega \, ||\nabla \times A_\kappa - h_{ex}||_{L^\infty(\Omega)}. \tag{4.3}$$

Then let $e_1 = -\hat{\nu}$ denote an inward unit normal vector on $\partial\Omega$ and let e_2 denote a unit tangential vector. Further, let

$$g = \mathrm{Det}(D\mathcal{F}) = 1 - t\kappa_r(s),$$

where κ_r denotes the local curvature on $\partial\Omega$. Let (see [19]) F be any vector potential such that $\nabla \times F = h_{ex}$ and let a be defined by

$$a = a_1 e_1 + a_2 e_2 = [F \cdot e_1]e_1 + [gF \cdot e_2]e_2. \tag{4.4}$$

By [14], or the appendix in [12], there exists $\hat{A}_\kappa$ such that if we substitute $F = \hat{A}_\kappa$ in (4.4), we obtain

$$a_1(s,t) = 0; \quad a_2(s,t) = h_{ex}[c_2 + t - t^2\kappa_r(s)],$$

where

$$c_2 = \frac{|\Omega|}{|\partial\Omega|}.$$

The gauge in (1.2) is now fixed by the condition that the $\hat{A}_\kappa$ has in the new coordinates the normal form given above and that A_κ satisfies

$$A_\kappa - \hat{A}_\kappa = P_\kappa.$$

We now introduce the change of variables

$$(\xi_1, \xi_2) = \left(\frac{\kappa}{\sqrt{\lambda}} t, \, \frac{\kappa}{\sqrt{\lambda}} s \right) \tag{4.5}$$

and prove the following lemma.

LEMMA 4.1. *Let*

$$\tilde{\Psi}_\kappa(\xi_1, \xi_2) = \begin{cases} \Psi_\kappa(\frac{\sqrt{\lambda}}{\kappa}\xi_1, \frac{\sqrt{\lambda}}{\kappa}\xi_2) e^{-ic_2\xi_2} & \text{for } 0 \leq \xi_1 \leq \frac{\kappa}{\sqrt{\lambda}}\delta, \\ \Psi_\kappa(\kappa\delta/\sqrt{\lambda}, \xi_2) e^{-ic_2\xi_2} e^{-(\xi_1 - \kappa\delta/\sqrt{\lambda})} & \text{for } \xi_1 \geq \frac{\kappa}{\sqrt{\lambda}}\delta, \end{cases}$$

where $c_2 = c_2(\Omega)$, and let

$$\omega_\kappa = \frac{2\pi\sqrt{\lambda}}{\kappa|\partial\Omega|}.$$

Then, as κ tends to $+\infty$,

$$\mathcal{J}(\Psi_\kappa, A_\kappa) \geq \frac{1}{\kappa^2} E_{\omega_\kappa}(\tilde{\Psi}_\kappa, \lambda) + \mathcal{O}(1/\kappa^2). \tag{4.6}$$

We will later prove (see (4.18)), that $\left|E_{\omega_\kappa}(\tilde{\Psi}_\kappa, \lambda)\right| \geq C\kappa$, and hence the correction term on the right-hand side of (4.6) is much smaller than the first term as $\kappa \to \infty$.

Proof. In [2] (see also [16]) it was proved that for $\lambda < 1$, there exists $\mu > 0$ such that

$$|\nabla(\nabla \times A_\kappa)| \leq Ce^{-\mu\kappa d(x,\partial\Omega)}. \tag{4.7}$$

Consequently, for $x \in \Omega_\delta$, we have

$$|\nabla \times A_\kappa - h_{ex}|(x) \leq \int_0^{d(x,\partial\Omega)} |\nabla(\nabla \times A_\kappa)(t, s(x))| dt \leq C \int_0^\infty e^{-\mu\kappa t} dt.$$

Hence, there exists $C_1 > 0$ such that

$$\|\nabla \times A_\kappa - h_{ex}\|_{L^\infty(\Omega_\delta)} \leq \frac{C_1}{\kappa}.$$

In view of (4.7) we can state the above inequality for the $L^\infty(\Omega)$ norm of $\nabla \times A_\kappa - h_{ex}$, and thus (4.3) gives that, for some $C_2 > 0$,

$$\|A_\kappa - \hat{A}_\kappa\|_{L^\infty(\Omega)} \leq \frac{C_2}{\kappa}.$$

Hence, for some $C_3 > 0$,

$$\int_\Omega |\nabla \times A_\kappa - h_{ex}|^2 \, dx_1 dx_2 \leq \frac{C_3}{\kappa^2}, \tag{4.8}$$

and

$$\begin{aligned}
&\int_\Omega \left| \left(\frac{i}{\kappa}\nabla + A_\kappa \right) \Psi_\kappa \right|^2 dx = \int_\Omega \left| \left(\frac{i}{\kappa}\nabla + \hat{A}_\kappa \right) \Psi_\kappa \right|^2 dx \\
&+ \int_\Omega |\Psi_\kappa|^2 |A_\kappa - \hat{A}_\kappa|^2 \, dx \; + \; \int_\Omega (A_\kappa - \hat{A}_\kappa) \cdot \left[\frac{i}{\kappa} (\overline{\Psi_\kappa} \nabla \Psi_\kappa - \Psi_\kappa \nabla \overline{\Psi_\kappa}) + 2\hat{A}_\kappa \right] dx \\
&\geq \int_\Omega \left| \left(\frac{i}{\kappa}\nabla + \hat{A}_\kappa \right) \Psi_\kappa \right|^2 dx \; - 2||A_\kappa - \hat{A}_\kappa||_{L^\infty(\Omega)} \, ||\Psi_\kappa||_{L^\infty} \int_\Omega \left| \left(\frac{i}{\kappa}\nabla + \hat{A}_\kappa \right) \Psi_\kappa \right| dx.
\end{aligned}$$

In [2] it is shown that

$$|\Psi_\kappa| + \left| \left(\frac{i}{\kappa}\nabla + \hat{A}_\kappa \right) \Psi_\kappa \right| \leq Ce^{-\mu\kappa d(x,\partial\Omega)} \tag{4.9}$$

for some $\mu > 0$ when $\lambda < 1$. Hence,

$$\int_\Omega \left| \left(\frac{i}{\kappa}\nabla + A_\kappa \right) \Psi_\kappa \right|^2 dx \geq \int_\Omega \left| \left(\frac{i}{\kappa}\nabla + \hat{A}_\kappa \right) \Psi_\kappa \right|^2 dx \; - \frac{C}{\kappa^2}. \tag{4.10}$$

Combining (4.8) and (4.10) we obtain

$$\mathcal{J}(\Psi_\kappa, A_\kappa) \geq \int_\Omega \left(\left| \left(\frac{i}{\kappa}\nabla + \hat{A}_\kappa \right) \Psi_\kappa \right|^2 + \frac{1}{2}|\Psi_\kappa|^4 - |\Psi_\kappa|^2 \right) dx \; - \frac{C}{\kappa^2}. \tag{4.11}$$

Using the coordinates (4.1) we obtain

$$\int_{\Omega_\delta} \left(\left| \left(\frac{i}{\kappa}\nabla + \hat{A}_\kappa \right) \Psi_\kappa \right|^2 + \frac{1}{2}|\Psi_\kappa|^4 - |\Psi_\kappa|^2 \right) dx_1 dx_2$$

$$= \int_{D(\delta)} \left\{ \frac{1}{\kappa^2} \left| \frac{\partial \Psi_\kappa}{\partial t} \right|^2 + \frac{1}{g^2} \left| \left(\frac{i}{\kappa}\frac{\partial}{\partial s} + a_2 \right) \Psi_\kappa \right|^2 + \frac{1}{2}|\Psi_\kappa|^4 - |\Psi_\kappa|^2 \right\} g \, ds dt.$$

Applying the transformation (4.5), we obtain

$$\int_0^{\frac{\kappa\delta}{\sqrt{\lambda}}} d\xi_1 \int_{-\frac{\kappa|\partial\Omega|}{2\sqrt{\lambda}}}^{\frac{\kappa}{2\sqrt{\lambda}|\partial\Omega|}} d\xi_2 \frac{\tilde{g}}{\kappa^2}$$

$$\times \left\{ \left| \frac{\partial \tilde{\Psi}_\kappa}{\partial \xi_1} \right|^2 + \frac{1}{\tilde{g}^2} \left| \left(i\frac{\partial}{\partial \xi_2} + \xi_1 - \kappa_r(s)\frac{\sqrt{\lambda}}{\kappa}\xi_1^2 \right) \tilde{\Psi}_\kappa \right|^2 + \frac{1}{2}\lambda|\tilde{\Psi}_\kappa|^4 - \lambda|\tilde{\Psi}_\kappa|^2 \right\},$$

where $\tilde{g}$ is defined by

$$\tilde{g}(\xi_1, \xi_2) = 1 - \frac{\sqrt{\lambda}}{\kappa}\xi_1 \kappa_r(\sqrt{\lambda}\xi_2/\kappa).$$

Since by (4.9), there exist $\tilde{\mu} > 0$ and $\tilde{C}$ such that on $[\, 0, \frac{\kappa\delta}{\sqrt{\lambda}} \,[\times] - \frac{\kappa|\partial\Omega|}{2\sqrt{\lambda}}, +\frac{\kappa|\partial\Omega|}{2\sqrt{\lambda}} \,[$,

$$\left| \left(i\frac{\partial}{\partial \xi_2} + \xi_1 - \kappa_r(\sqrt{\lambda}\xi_2/\kappa)\frac{\sqrt{\lambda}}{\kappa}\xi_1^2 \right) \tilde{\Psi}_\kappa \right|^2 + |\xi_1|^2 |\tilde{\Psi}_\kappa|^2 \leq \tilde{C}\, e^{-\tilde{\mu}\xi_1},$$

there exist $\mu > 0$ and C such that

$$\left| \left(i\frac{\partial}{\partial \xi_2} + \xi_1 \right) \tilde{\Psi}_\kappa \right|^2 \leq C e^{-\mu\xi_1}.$$

We thus obtain

$$\int_0^{\frac{\kappa}{\sqrt{\lambda}}\delta} d\xi_1 \int_{-\frac{\kappa}{2\sqrt{\lambda}}|\partial\Omega|}^{\frac{\kappa}{2\sqrt{\lambda}}|\partial\Omega|} d\xi_2 \frac{1}{\tilde{g}} \left| \left(i\frac{\partial}{\partial \xi_2} + \xi_1 - \kappa_r(\sqrt{\lambda}\xi_2/\kappa)\frac{\sqrt{\lambda}}{\kappa}\xi_1^2 \right) \tilde{\Psi}_\kappa \right|^2$$

$$= \int_0^\infty d\xi_1 \int_{-\frac{\kappa}{2\sqrt{\lambda}}|\partial\Omega|}^{\frac{\kappa}{2\sqrt{\lambda}}|\partial\Omega|} d\xi_2 \left| \left(i\frac{\partial}{\partial \xi_2} + \xi_1 \right) \tilde{\Psi}_\kappa \right|^2 + \mathcal{O}(1).$$

Using the above arguments for the remaining terms yields

$$\mathcal{J}(\Psi_\kappa, \hat{A}_\kappa) = \frac{1}{\kappa^2} \int_0^{\frac{\kappa}{\sqrt{\lambda}}\delta} d\xi_1 \int_{-\frac{\kappa}{2\sqrt{\lambda}}|\partial\Omega|}^{\frac{\kappa}{2\sqrt{\lambda}}|\partial\Omega|} d\xi_2$$

$$\times \left(\left| \frac{\partial \tilde{\Psi}_\kappa}{\partial \xi_1} \right|^2 + \left| \left(i\frac{\partial}{\partial \xi_2} + \xi_1 \right) \tilde{\Psi}_\kappa \right|^2 + \frac{1}{2}\lambda|\Psi_\kappa|^4 - \lambda|\Psi_\kappa|^2 \right) + \mathcal{O}(\kappa^{-2}),$$

so

$$\mathcal{J}(\Psi_\kappa, \hat{A}_\kappa) = \frac{1}{\kappa^2} E_{\omega_\kappa}(\tilde{\Psi}_\kappa, \lambda) + \mathcal{O}(\kappa^{-2}). \tag{4.12}$$

Combining (4.12) with (4.11) yields (4.6). □

We can now prove the main result of this work.

Proof of Theorem 1.1. Let $\hat{\psi}_{\lambda,\kappa} : \Omega_\delta \to \mathbb{C}$ be given by

$$\hat{\psi}_{\lambda,\kappa}(x) = \psi_\lambda\left(\frac{\kappa}{\sqrt{\lambda}} t(x)\right) \exp\left\{-ic_2\left(\frac{\kappa}{\sqrt{\lambda}} s(x)\right)\right\}.$$

Further, let $\chi : \mathbb{R}_+ \to [0,1]$ denote a smooth cutoff function satisfying

$$\chi(t) = \begin{cases} 1 & t \le \frac{1}{2}, \\ 0 & t \ge 1. \end{cases}$$

Then $\chi\big(t(x)/\delta\big)\hat{\psi}_{\lambda,\kappa}(x)$ is in $H^1(\Omega, \mathbb{C})$, and it is not difficult to show that

$$\mathcal{J}(\Psi_\kappa, A_\kappa) \le \mathcal{J}(\hat{\psi}_{\lambda,\kappa}, \hat{A}_\kappa) = -\frac{C_\lambda |\partial\Omega|}{\kappa\sqrt{\lambda}} + \mathcal{O}(\kappa^{-2}), \tag{4.13a}$$

where

$$C_\lambda = -\frac{\omega}{2\pi} E_\omega(\psi_\lambda, \lambda). \tag{4.13b}$$

By Theorem 3.1 there exists $\epsilon > 0$ such that, for $\beta_0 < \lambda < \beta_0 + \epsilon$, we have, for all ω,

$$C_\lambda = -\frac{\omega}{2\pi} \inf_{\psi \in \mathcal{H}_\omega} E_\omega(\psi, \lambda). \tag{4.14}$$

Note that this implies, in particular,

$$C_\lambda = -\lim_{\omega \to 0} \frac{\omega}{2\pi} \inf_{\psi \in \mathcal{H}_\omega} E_\omega(\psi, \lambda). \tag{4.15}$$

Combining (4.6) and (4.13) we obtain

$$\mathcal{J}(\Psi_\kappa, A_\kappa) = -\frac{C_\lambda |\partial\Omega|}{\kappa\sqrt{\lambda}} + \mathcal{O}(\kappa^{-2}), \tag{4.16}$$

In [19, Lemma 7.3], Pan proves (4.16), for any fixed $\beta_0 < \lambda < 1$, by using as a test functions the unknown minimizer of E_{ω_κ} in $\mathcal{H}_{\omega_\kappa}$ instead of ψ_λ, and (4.15) as the definition of C_λ. He also proves (4.16) when $\lambda(\kappa) \to \lambda$ (with $\lambda(\kappa) = \frac{\kappa}{h_{ex}(\kappa)}$) but with an additional $\mathcal{O}([\lambda(\kappa) - \lambda]/\kappa)$ error. Note that when $\lambda = \beta_0$, this result is no more useful since $C_{\beta_0} = 0$, and hence the leading order term of $\mathcal{J}$ is unknown in this case (see [10] for results in this case).

By (2.5) and (3.3), we have

$$C_\lambda = -b(\zeta(\lambda), \lambda),$$

which shows that $C_\lambda > 0$ for every $\beta_0 < \lambda < 1$. Consequently, we have by (4.6) and (4.16),

$$E_{\omega_\kappa}(\tilde{\Psi}_\kappa, \lambda) \le E_{\omega_\kappa}(\psi_\lambda, \lambda) + C. \tag{4.17}$$

Thus, by (4.13b)

$$E_{\omega_\kappa}(\tilde{\Psi}_\kappa,\lambda) \leq -C_\lambda \frac{|\partial\Omega|}{\sqrt{\lambda}}\kappa + C,$$

which proves that indeed

$$\left|E_{\omega_\kappa}(\tilde{\Psi}_\kappa,\lambda)\right| \geq C\kappa, \tag{4.18}$$

and that the correction term on the right-hand side of (4.6) is much smaller than the leading order term.

Let w_κ be defined by

$$\tilde{\Psi}_\kappa(\xi_1,\xi_2) = f_\zeta(\xi_1;\lambda) w_\kappa(\xi_1,\xi_2)\, e^{-ic_2\xi_2}.$$

Clearly, w_κ is periodic in ξ_2. Thus, by (3.8), we get

$$\left|E_{\omega_\kappa}(\tilde{\Psi}_\kappa,\lambda) - E_{\omega_\kappa}(\psi_\lambda,\lambda)\right| \geq \frac{1}{2}\int_{-\pi/\omega_\kappa}^{\pi/\omega_\kappa} d\xi_2 \int_0^\infty d\xi_1\, |f_\zeta|^4 (1-|w_\kappa|^2)^2.$$

Consequently, there exists $C_0 > 0$ such that

$$\int_{-\pi/\omega_\kappa}^{\pi/\omega_\kappa} d\xi_2 \int_0^\infty d\xi_1 |f_\zeta|^4 (1-|w_\kappa|^2)^2 \leq C_0,$$

and hence, for suitable constants C_1 and C_2,

$$\int_{\Omega_\delta} [|\Psi_\kappa|^2 - |\hat{\psi}_{\lambda,\kappa}|^2]^2\, dx \leq \frac{C_1}{\kappa^2}\int_{-\pi/\omega_\kappa}^{\pi/\omega_\kappa} d\xi_2 \int_0^\infty d\xi_1\, |f_\zeta|^4 (1-|w_\kappa|^2)^2 \leq \frac{C_2}{\kappa^2},$$

which proves (1.8a).

To prove (1.8b), we first notice that it is proved in [2] that

$$|\Psi_\kappa| + \frac{1}{\kappa}|\nabla\Psi_\kappa| \leq C,$$

and using the explicit form of $\hat{\psi}_{\lambda,\kappa}$, we obtain

$$\left|\nabla(|\Psi_\kappa|^2 - |\hat{\psi}_{\lambda,\kappa}|^2)\right| \leq C\kappa. \tag{4.19}$$

Evidently, as a consequence of the mean value formula, there exist $C > 0$ and $\delta_0 > 0$, such that, for every $0 < \delta' \leq \delta_0$, there exists $0 \leq \delta'' \leq \delta'$ such that

$$\int_{t=\delta''} \left[\, |\Psi_\kappa|^2 - |\hat{\psi}_{\lambda,\kappa}|^2 \,\right]^2 ds \leq \frac{C}{\delta'}\int_{\Omega_{\delta'}} \left[\, |\Psi_\kappa|^2 - |\hat{\psi}_{\lambda,\kappa}|^2 \,\right]^2 dx_1 dx_2.$$

Furthermore, by (4.19), we have

$$\int_{\partial\Omega} \left[\, |\Psi_\kappa|^2 - |\hat{\psi}_{\lambda,\kappa}|^2 \,\right]^2 ds \leq C\int_{t=\delta''} [|\Psi_\kappa|^2 - |\hat{\psi}_{\lambda,\kappa}|^2]^2\, ds \;+\; C\kappa\delta''.$$

Consequently, there exists $C > 0$ such that

$$\int_{\partial\Omega} \left[\, |\Psi_\kappa|^2 - |\hat{\psi}_{\lambda,\kappa}|^2 \,\right]^2 ds \leq \frac{C}{\delta'}\frac{1}{\kappa^2} + C\kappa\delta'.$$

Choosing $\delta' = \kappa^{-3/2}$ proves (1.8b). ∎

Finally, we compare Theorem 1.1 with the results in [10, Remark 1.5]. As was already stated in the introduction, when $\rho(\kappa) = o(\kappa^{1/2})$ and tends to ∞ as $\kappa \to +\infty$, (1.4) holds. The function u in (1.4) is given by

$$u(\tau) = \beta_0 \frac{|u_0(\tau)|^2}{\|u_0\|_4^4},$$

u_0 denoting the minimizer of (2.1).

We first note that, since as $\lambda \to \beta_0$, we have

$$f_{\zeta_\lambda}^2(\tau) \sim \frac{\lambda - \beta_0}{\beta_0^2} u(\tau),$$

and since

$$\frac{\lambda - \beta_0}{\beta_0^2} \sim \frac{\rho}{\kappa} \quad \text{as } \kappa \to \infty,$$

(1.4) and (1.8a) match. The error in (1.4) is substantially smaller than in (1.8a). The difference is explained by the fact that ψ_κ itself is small on $\partial\Omega$ when $\lambda \to \beta_0$. Thus, if we extrapolate the error term in (1.4) to external fields for which $\rho/\kappa \approx 1$, it becomes $\mathcal{O}(\kappa^{-2})$ exactly as in (1.8a).

Acknowledgments. The authors wish to thank the European program HPRN-CT-2002-00274 (Front Singularities) and their Scientists in Charge in France, Haim Brezis and Danielle Hilhorst, for providing support for the visit of the first author at the University of Paris XI in February 2005.

QUASI-LINEAR THERMOELASTICITY SYSTEM ARISING IN SHAPE MEMORY MATERIALS*

SHUJI YOSHIKAWA†, IRENA PAWŁOW‡, AND WOJCIECH M. ZAJĄCZKOWSKI§

Abstract. In this paper we establish the global existence and uniqueness of a solution for the three-dimensional and two-dimensional forms of the quasi-linear thermoelasticity system which arises as a mathematical model of shape memory alloys. The system represents a multidimensional version with viscosity and capillarity of the well-known Falk model for one-dimensional martensitic phase transitions. In the setup considered by Pawłow and Zajączkowski [*Math. Methods Appl. Sci.,* 28 (2005), pp. 407–442; 551–592], some conditions have been required for the nonlinear term. In the present paper we improve the result by imposing less restrictive assumptions.

Key words. quasi-linear parabolic equations, maximal regularity, shape memory, thermoelastic

1. Introduction.

We consider the following initial-boundary value problem in quasi-linear thermoelasticity:

$$(\mathrm{TE})_d \begin{cases} u_{tt} + \kappa QQu - \nu Qu_t = \nabla \cdot F_{,\varepsilon}(\varepsilon,\theta), \\ [c_v - F_{,\theta\theta}(\varepsilon,\theta)\theta]\theta_t - k\Delta\theta = \theta F_{,\theta\varepsilon}(\varepsilon,\theta) : \varepsilon_t + \nu(A\varepsilon_t) : \varepsilon_t & \text{in } \Omega_T, \\ u = Qu = \nabla\theta \cdot n = 0 & \text{on } S_T, \\ u(0,x) = u_0(x),\ u_t(0,x) = u_1(x),\ \theta(0,x) = \theta_0(x) \geq 0 & \text{in } \Omega, \end{cases}$$

where $\Omega \subset \mathbb{R}^d$ $(d = 2, 3)$ is a bounded domain with a smooth boundary $\partial\Omega$, $\Omega_T = (0,T] \times \Omega$, and $S_T = [0,T] \times \partial\Omega$. Let $u = (u_i) \in \mathbb{R}^d$ denote the displacement vector, $\varepsilon = (\varepsilon_{ij})$ with $\varepsilon_{ij}(u) = \frac{1}{2}(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i})$ the linearized strain tensor, θ the absolute temperature, and $F \in \mathbb{R}$ the elastic energy density. The capillarity term QQu with constant coefficient $\kappa > 0$ corresponds to interaction effects on phase interfaces. The coefficients ν, c_v, and k are positive constants corresponding to the viscosity coefficient, caloric specific heat, and the heat conductivity, respectively.

We use the notation $F_{,\varepsilon} = (\frac{\partial F}{\partial \varepsilon_{ij}})$, $F_{,\theta} = \frac{\partial F}{\partial \theta}$, and $\tilde{\varepsilon} : \varepsilon = \sum_{i,j=1}^{d} \tilde{\varepsilon}_{ij}\varepsilon_{ij}$. We define the linearized elasticity operator Q by the following second order differential operator:

$$Qu = \mu\Delta u + (\lambda + \mu)\nabla(\nabla \cdot u),$$

where λ and μ are the Lamé constants such that

$$\mu > 0 \quad \text{and} \quad d\lambda + 2\mu > 0. \tag{1.1}$$

The fourth order tensor A represents linear isotropic Hooke's law, defined by

$$A_{ijkl} := \lambda\delta_{ij}\delta_{kl} + \mu(\delta_{ik}\delta_{jl} + \delta_{il}\delta_{jk}).$$

We note that the tensor has the following symmetry properties:

$$A_{ijkl} = A_{klij}, \quad A_{ijkl} = A_{jikl}, \quad A_{ijkl} = A_{ijlk},$$

and the relation $Qu = \nabla\cdot\varepsilon(u)A$ holds. Assumption (1.1) ensures the strong ellipticity of the operator Q and the following inequality:

$$a_*|\varepsilon|^2 \le (A\varepsilon) : \varepsilon \le a^*|\varepsilon|^2,$$

where $a_* = \min\{d\lambda + 2\mu, 2\mu\}$ and $a^* = \max\{d\lambda + 2\mu, 2\mu\}$. In this article, we consider the following structure of the elastic energy density:

(A) $F(\varepsilon,\theta) = G(\theta)H(\varepsilon) + \overline{H}(\varepsilon)$ such that

(i) $G \in \mathrm{C}^3(\mathbb{R},\mathbb{R})$ is as follows:

$$G(\theta) = \begin{cases} C_1\theta & \text{if } \theta \in [0,\theta_1], \\ \varphi(\theta) & \text{if } \theta \in [\theta_1,\theta_2], \\ C_2\theta^r & \text{if } \theta \in [\theta_2,\infty), \end{cases}$$

where $\varphi \in \mathrm{C}^3(\mathbb{R},\mathbb{R})$, $\varphi'' \le 0$, and C_1 and C_2 are positive constants for some fixed θ_1, θ_2 satisfying $0 < \theta_1 < \theta_2 < \infty$. We extend G defined on $\mathbb{R}$ as an odd function.

(ii) $H \in \mathrm{C}^3(\mathbb{S}^2,\mathbb{R})$ satisfies the condition $H(\varepsilon) \ge 0$, where $\mathbb{S}^2$ denotes the set of symmetric second order tensors in $\mathbb{R}^d$.

(iii) $\overline{H} \in \mathrm{C}^3(\mathbb{S}^2,\mathbb{R})$ satisfies $\overline{H}(\varepsilon) \ge -C_3$, where C_3 is some real number.

(iv) $H(\varepsilon)$ and $\overline{H}(\varepsilon)$ satisfy the following growth conditions:

$$\begin{aligned} &|H_{,\varepsilon}(\varepsilon)| \le C|\varepsilon|^{K_1-1}, \quad |H_{,\varepsilon\varepsilon}(\varepsilon)| \le C|\varepsilon|^{K_1-2}, \quad |H_{,\varepsilon\varepsilon\varepsilon}(\varepsilon)| \le C|\varepsilon|^{K_1-3}, \\ &|\overline{H}_{,\varepsilon}(\varepsilon)| \le C|\varepsilon|^{K_2-1}, \quad |\overline{H}_{,\varepsilon\varepsilon}(\varepsilon)| \le C|\varepsilon|^{K_2-2}, \quad |\overline{H}_{,\varepsilon\varepsilon\varepsilon}(\varepsilon)| \le C|\varepsilon|^{K_2-3} \end{aligned}$$

for large $|\varepsilon|$.

Here we note that the regularity assumption for $H(\varepsilon)$ and $\overline{H}(\varepsilon)$ ensures that there exists a positive constant M such that

$$|H_{,\varepsilon}(\varepsilon)| + |H_{,\varepsilon\varepsilon}(\varepsilon)| + |H_{,\varepsilon\varepsilon\varepsilon}(\varepsilon)| + |\overline{H}_{,\varepsilon}(\varepsilon)| + |\overline{H}_{,\varepsilon\varepsilon}(\varepsilon)| + |\overline{H}_{,\varepsilon\varepsilon\varepsilon}(\varepsilon)| \le M$$

for small $|\varepsilon|$. Under the above structure of nonlinearity the system $(\mathrm{TE})_d$ can be rewritten as follows:

$$u_{tt} + \kappa QQu - \nu Qu_t = \nabla\cdot[G(\theta)H_{,\varepsilon}(\varepsilon) + \overline{H}_{,\varepsilon}(\varepsilon)], \tag{1.2}$$

$$c_v\theta_t - k\Delta\theta = \theta G''(\theta)\theta_t H(\varepsilon) + \theta G'(\theta)\partial_t H(\varepsilon) + \nu(A\varepsilon_t) : \varepsilon_t \quad \text{in } \Omega_T, \tag{1.3}$$

$$u = Qu = \nabla\theta\cdot n = 0 \quad \text{on } S_T, \tag{1.4}$$

$$u(0,x) = u_0(x), \quad u_t(0,x) = u_1(x), \quad \theta(0,x) = \theta_0(x) \ge 0 \quad \text{in } \Omega. \tag{1.5}$$

In this paper we show the unique global existence of a solution for (1.2)–(1.5) under the following power of nonlinearity:

$$0 \le r < \frac{5}{6}, \qquad 0 \le K_1, K_2 < 6, \qquad 6r + K_1 < 6 \tag{1.6}$$

in the 3-D case, and

$$0 \le r < 1, \qquad 0 \le K_1, K_2 < \infty \tag{1.7}$$

in the 2-D case.

Before discussing the result of this paper more precisely we shall explain the related results and the physical background of this model. In [10], Falk presents the Landau–Ginzburg type theory using the shear strain $\varepsilon := \partial_x u$ as an order parameter to describe the martensitic-austenitic phase transitions occurring in 1-D shape memory allows (SMAs). There are many papers related to 1-D SMAs (e.g., [2], [3], [6], [12], [16], [17], and [24]). The system $(\mathrm{TE})_d$ is a generalization of the 1-D Falk model with internal viscosity to the 3-D case. The Helmholtz free energy density takes the following form:

$$\widetilde{F}(\varepsilon, \nabla\varepsilon, \theta) = F_0(\theta) + F(\varepsilon, \theta) + |Qu|^2,$$
$$F_0(\theta) = -c_v\theta\log(\theta/\theta_3) + c_v\theta + \tilde{c},$$

and the stress tensor is given by

$$\sigma = \frac{\delta\widetilde{F}}{\delta\varepsilon} + \nu A\varepsilon_t,$$

where $\tilde{c}$ and θ_3 denote the positive physical constants. System $(\mathrm{TE})_d$ can be derived by an argument similar to that in the 1-D case (see [5]). For more details on the derivation of this system, we refer to [19]. In [11], Falk and Konopka give the form of the elastic energy density F as follows:

$$F(\varepsilon, \theta) = \sum_{i=1}^{3} \alpha_i^2(\theta - \theta_c)J_i^2(\varepsilon) + \sum_{i=1}^{5} \alpha_i^4(\theta - \theta_c)J_i^4(\varepsilon) + \sum_{i=1}^{2} \alpha_i^6 J_i^6(\varepsilon), \tag{1.8}$$

where α_i^k, θ_c are constants and J_i^k denote certain kth order monomials with respect to (ε_{ij}). Here we remark that in the 1-D case the elastic energy density takes the following form:

$$F_{1D}(\varepsilon, \theta) = \alpha_1\varepsilon^2(\theta - \theta_c) - \alpha_2\varepsilon^4 + \alpha_3\varepsilon^6, \tag{1.9}$$

where $\varepsilon := \partial_x u$ and α_i, θ_c are positive constants. Comparing (1.8) with the 1-D form (1.9), we see that in the 3-D case, $H(\varepsilon)$ must be fourth order with respect to ε. This causes some difficulties in the mathematical treatment of system (1.2)–(1.5). Moreover, the difficulties arise also from the fact that the useful embedding $H^1 \hookrightarrow L^\infty$ does not hold in the multidimensional case. There had been no papers on the solvability of this system with the Falk–Konopka elastic energy density (1.8), $r = 1$, $K_1 = 4$, and $K_2 = 6$. Then Pawłow and Żochowski [20] studied the energy density F under several stronger assumptions than (1.8), namely, lower order powers of nonlinearity. Moreover, for the simplification of treatments, they first considered the semilinearized equations of the quasi-linear system $(\mathrm{TE})_d$:

$$(\mathrm{SLTE})_d \begin{cases} u_{tt} + \kappa QQu - \nu Qu_t = \nabla \cdot F_{,\varepsilon}(\varepsilon, \theta), & \\ c_v\theta_t - k\Delta\theta = \theta F_{,\theta\varepsilon}(\varepsilon, \theta) : \varepsilon_t + \nu(A\varepsilon_t) : \varepsilon_t & \text{in } \Omega_T, \\ u = Qu = \nabla\theta \cdot n = 0 & \text{on } S_T, \\ u(0, x) = u_0(x),\ u_t(0, x) = u_1(x),\ \theta(0, x) = \theta_0(x) \ge 0 & \text{in } \Omega, \end{cases}$$

which is the model $(\mathrm{TE})_d$ with removed quasi-linear term $\theta G''(\theta)\theta_t H(\varepsilon)$. They showed the unique global existence of a sufficiently smooth solution for $(\mathrm{SLTE})_d$ under the following assumptions on the nonlinearity:

$$0 \le r < \frac{1}{2}, \qquad 0 \le K_1 \le \left(\frac{1}{2} - r\right) K_2 + 1, \qquad 0 \le K_2 \le \frac{7}{2} \tag{1.10}$$

in the 3-D case, and

$$0 \le r < \frac{1}{2}, \qquad 0 \le K_1 \le \left(\frac{1}{2} - r\right) K_2 + 1, \qquad 0 \le K_2 < \infty \tag{1.11}$$

in the 2-D case. In addition, due to the applied parabolic decomposition of the elasticity system, they assumed the condition $0 < 2\sqrt{\kappa} \le \nu$ between viscosity and capillarity. Such an assumption, however, does not seem realistic for SMA viscosity effects which are negligibly small. In [25] the unique global existence of the solution to $(\mathrm{SLTE})_3$ in a larger class is proved by using the contraction mapping principle. The result is proved without conditions between κ and ν, and the class of nonlinearities is generalized to $K_2 < 6$. The first two assumptions in (1.10) are present due to the semilinearization which causes the absence of energy conservation law (Lemma 4.1 below). Recently, Pawłow and Zajączkowski [21] have proved the unique global existence for the quasi-linear system (1.2)–(1.5) under the assumptions

$$\begin{gathered} 0 < r < \frac{2}{3}, \quad 0 < K_1 < \frac{15}{4} \ \text{ and } \ 15r + 4K_1 = 15 \ \text{ if } \ K_1 > 1, \\ 0 < K_2 \le \frac{9}{2}, \quad 0 < 2\sqrt{\kappa} \le \nu. \end{gathered} \tag{1.12}$$

The latter, restrictive condition between viscosity and capillarity has been removed by the above mentioned authors in [23]. The aim of the present paper is to prove the unique global existence of a solution to system (1.2)–(1.5) under weaker assumptions than (1.12). More precisely, we admit the nonlinearity specified in (1.6), (1.7) and arbitrary positive coefficients of capillarity $\kappa > 0$ and viscosity $\nu > 0$. Unfortunately, our result still does not cover the physically realistic case (1.8).

Here we add some remarks on the 2-D case. The results of [20] include the 2-D case of the semilinearized problem $(\mathrm{SLTE})_2$. The unique global existence for the 2-D quasilinear system $(\mathrm{TE})_2$ is established in [22] under the assumption

$$0 \le r < \frac{7}{8}, \qquad 0 \le K_1 < \infty, \qquad 0 \le K_2 < \infty. \tag{1.13}$$

In [26] the unique global existence for $r = 1$ is proved under other strong assumptions. Roughly speaking, the restrictions in [26] are such that $K_1 = 0$ and that the energy of initial data $\|u_0\|_{H^2} + \|u_1\|_{L^2} + \|\theta_0\|_{L^1}$ is sufficiently small. We note that if we take $r = 1$, then the quasi-linear term $\theta G''(\theta)H(\varepsilon)\theta_t$ of (1.3) does not appear. We also describe the result for the 2-D case in section 5 of this paper. We show that the system $(\mathrm{TE})_2$ has a unique global solution under assumptions (1.7). Comparing these assumptions with (1.13), we see that the restriction for r is weaker; nevertheless we cannot admit $r = 1$.

We now introduce some notation and function spaces. Throughout this paper C and Λ are positive constants independent of time T and depending on time T, respectively. In particular, we may use Λ instead of $\Lambda(\|(u_0, u_1, \theta_0)\|_X)$ for some X if there is no danger of confusion.

- $L^p(\Omega_T) = L^p_T L^p = L^p(0,T;L^p(\Omega))$ is the standard Lebesgue space. We often use the notation $L^p(\Omega_I) = L^p_I L^p$ for some interval I.
- $W^{2l,l}_p(\Omega_T)$ is the Sobolev space equipped with the norm

$$\|u\|_{W^{2l,l}_p(\Omega_T)} := \sum_{j=0}^{2l} \sum_{2r+|\alpha|=j} \|D_t^r D_x^\alpha u\|_{L^p(\Omega_T)},$$

  where $D_t := i\frac{\partial}{\partial t}$, $D_x^\alpha = \prod_{\alpha=\alpha_1+\alpha_2+\alpha_3} D_k^{\alpha_k}$, and $D_k := i\frac{\partial}{\partial x_k}$ for multi-index $\alpha = (\alpha_i)_{i=1}^n$.

- $H^j(\Omega) := W^j_2(\Omega)$, where W^j_p is the Sobolev space equipped with the norm $\|u\|_{W^j_p(\Omega)} := \sum_{|\alpha|\le j} \|D_x^\alpha u\|_{L^p(\Omega)}$.
- $B^s_{p,q} = B^s_{p,q}(\Omega)$ is the Besov space. Namely, $B^s_{p,q} := [L^p(\Omega), W^j_p(\Omega)]_{s/j,q}$, where $[X,Y]_{s/j,q}$ is the real interpolation space. For more details we refer to [1] by Adams and Fournier.
- $\mathrm{C}^{\alpha,\alpha/2}(\Omega_T)$ is the Hölder space: the set of all continuous functions in Ω_T satisfying the Hölder condition in x with exponent α, and in t with exponent $\alpha/2$.

We now state the main result of this paper.

THEOREM 1.1. *Let the positive physical constants κ, ν, c_v, and k be fixed arbitrarily. Assume that* $\min_\Omega \theta_0 \ge 0$ *and* (1.6) *holds. Then, given* $5 < p \le q < \infty$, *for any* $T > 0$ *and* $(u_0, u_1, \theta_0) \in B^{4-2/p}_{p,p} \times B^{2-2/p}_{p,p} \times B^{2-2/q}_{q,q} =: U(p,q)$, *there exists at least one solution* (u,θ) *to* (1.2)–(1.5) *satisfying*

$$(u,\theta) \in W^{4,2}_p(\Omega_T) \times W^{2,1}_q(\Omega_T) =: V_T(p,q).$$

Moreover, if we assume $\min_\Omega \theta_0 = \theta_* > 0$, *then there exists a positive constant* ω *such that*

$$\theta \ge \theta_* \exp(-\omega t) \qquad \text{in } \Omega_T.$$

For completeness we recall also the uniqueness result which follows by repeating the arguments of the corresponding result in [22, section 6].

THEOREM 1.2. *In addition to the assumptions of Theorem* 1.1, *suppose that* $F(\varepsilon,\theta) \in \mathrm{C}^4(\mathbb{S}^2 \times \mathbb{R}^+, \mathbb{R})$. *Then the solution* $(u,\theta) \in V_T(p,q)$ *to* (1.2)–(1.5) *constructed above is unique.*

We prove Theorem 1.1 by using the Leray–Schauder fixed point principle. The key estimates are the maximal regularity estimate for (1.2), and the classical energy estimate and the parabolic De Giorgi method for (1.3). In general, the derivative of a solution is less regular than the right-hand side of the corresponding equation. However, for parabolic equations such a loss of regularity does not occur, as in the case of elliptic equations. The estimate ensuring this regularity is called the maximal regularity. For more precise information on the maximal regularity we refer to [4], and for more recent topics of the maximal L^p-regularity we refer to [9]. Since the maximal regularity theory is limited to linear parabolic equations, we cannot use it directly for the quasi-linear equation (1.3). To obtain the higher order a priori estimates we apply the classical energy methods and the parabolic De Giorgi method (see [14], [15]). Using these methods we can show the Hölder continuity of θ. By virtue of such regularity, we arrive at the estimate in a higher Sobolev norm.

In section 2 we list several preliminary results which are used in the paper. In section 3 we prove the unique global existence of the solution for certain truncated

version of problem (1.2)–(1.5). To this purpose we use the Leray–Schauder fixed point principle. In section 4 we show that the solution of $(\mathrm{TE})_3$ coincides with the solution of the truncated problem constructed in section 3 for a sufficiently large truncation level L. In section 5 we consider the 2-D system $(\mathrm{TE})_2$.

2. Preliminaries. In this section, we present some auxiliary results which will be used in the subsequent sections.

LEMMA 2.1 (maximal regularity).

(i) *Let $p \in (1,\infty)$. Denote by u the solution of the linear problem*

$$\begin{cases} u_{tt} + \kappa QQu - \nu Qu_t = \nabla \cdot f & \text{in } \Omega_T, \\ u = Qu = 0 & \text{on } S_T, \\ u(0,x) = u_0(x), \quad u_t(0,x) = u_1(x) & \text{in } \Omega. \end{cases}$$

Then the following estimates hold:

$$\|u\|_{W_p^{4,2}(\Omega_T)} \le C \left(\|u_0\|_{B_{p,p}^{4-\frac{2}{p}}} + \|u_1\|_{B_{p,p}^{2-\frac{2}{p}}} + \|\nabla \cdot f\|_{L^p(\Omega_T)} \right) \tag{2.1}$$

for any $(u_0,u_1) \in B_{p,p}^{4-2/p} \times B_{p,p}^{2-2/p}$ and $\nabla \cdot f \in L^p(\Omega_T)$, and

$$\|\nabla u\|_{W_p^{2,1}(\Omega_T)} \le C \left(\|u_0\|_{B_{p,p}^{3-\frac{2}{p}}} + \|u_1\|_{B_{p,p}^{1-\frac{2}{p}}} + \|f\|_{L^p(\Omega_T)} \right) \tag{2.2}$$

for any $(u_0,u_1) \in B_{p,p}^{3-2/p} \times B_{p,p}^{1-2/p}$ and $f \in L^p(\Omega_T)$.

(ii) *Let $q \in (1,\infty)$. Assume that $\rho(x)$ is Hölder continuous in Ω such that $\inf_\Omega \rho > 0$. Denote by θ the solution of the linear problem*

$$\begin{cases} \theta_t - \rho \Delta \theta = g & \text{in } \Omega_T, \\ n \cdot \nabla \theta = 0 & \text{on } S_T, \\ \theta(0,x) = \theta_0(x) & \text{in } \Omega. \end{cases}$$

Then the following estimate holds:

$$\|\theta\|_{W_q^{2,1}(\Omega_T)} \le C \left(\|\theta_0\|_{B_{q,q}^{2-\frac{2}{q}}} + \|g\|_{L^q(\Omega)} \right) \tag{2.3}$$

for any $\theta_0 \in B_{q,q}^{2-2/q}$, where C depends on $\inf_\Omega \rho$.

For the proof of (i) we refer to [25, Lemma 2.1, Proposition 2.4], and (ii) is the particular case of [13, Examples 3.2, A), 2)]. Next, we recall the useful space-time embedding lemma.

LEMMA 2.2 (embedding [14, Lemma II.3.3]). *Let $f \in W_p^{2l,l}(\Omega_T)$. Then, for $l \in \mathbb{Z}^+$ and multi-index α, it follows that*

$$\|D_t^r D_x^\alpha f\|_{L^q(\Omega_T)} \le C\delta^{l-\psi} \|f\|_{W_p^{2l,l}(\Omega_T)} + C\delta^{-\psi} \|f\|_{L^p(\Omega_T)}, \tag{2.4}$$

provided $q \ge p$ and $\psi := r + \frac{|\alpha|}{2} + \frac{d+2}{2}(\frac{1}{p} - \frac{1}{q}) \le l$. If $\varphi := r + \frac{|\alpha|}{2} + \frac{d+2}{2p} < l$, then

$$\|D_t^r D_x^\alpha f\|_{L^\infty(\Omega_T)} \le C\delta^{l-\varphi} \|f\|_{W_p^{2l,l}(\Omega_T)} + C\delta^{-\varphi} \|f\|_{L^p(\Omega_T)}; \tag{2.5}$$

moreover, $D_t^r D_x^\alpha f$ is Hölder continuous. Here, $\delta \in (0, \min(T, \zeta^2)]$, ζ is the altitude of the cone in the statement of the cone condition satisfied by Ω.

LEMMA 2.3. *Let φ be given as in* (A)(i). *Then the function $\varphi(s)$ satisfies*

$$\varphi(s) - s\varphi'(s) \geq 0 \tag{2.6}$$

for any $s \in [\theta_1, \theta_2]$.

Proof. Putting $f(s) = \varphi(s) - s\varphi'(s)$, we have $f'(s) = -s\varphi''(s) \geq 0$ and $f(\theta_1) = 0$. Then $f(s) = \varphi(s) - s\varphi'(s) \geq 0$ in $[\theta_1, \theta_2]$. □

To show Theorem 1.1 we apply the Leray–Schauder fixed point principle. We recall it here in one of its equivalent formulations for the reader's convenience .

THEOREM 2.4 (Leray–Schauder fixed point principle [8]). *Let X be a Banach space. Assume that $\Phi : [0,1] \times X \to X$ is a map with the following properties:*

(L1) *For any fixed $\tau \in [0,1]$ the map $\Phi(\tau, \cdot) : X \to X$ is compact.*

(L2) *For every bounded subset $\mathcal{B}$ of X, the family of maps $\Phi(\cdot, \xi) : [0,1] \to X$, $\xi \in \mathcal{B}$, is uniformly equicontinuous.*

(L3) *$\Phi(0, \cdot)$ has precisely one fixed point in X.*

(L4) *There is a bounded subset $\mathcal{B}$ of X such that any fixed point in X of $\Phi(\tau, \cdot)$ is contained in $\mathcal{B}$ for every $0 \leq \tau \leq 1$.*

Then $\Phi(1, \cdot)$ has at least one fixed point in X.

3. Truncated problem. To prove the existence theorem we first consider the following truncated problem $(\mathrm{TE})_3^L$:

$$u_{tt} + \kappa QQu - \nu Qu_t = \Gamma_L\Big(\nabla \cdot [G(\theta)H_{,\varepsilon}(\varepsilon) + \overline{H}_{,\varepsilon}(\varepsilon)]\Big), \tag{3.1}$$

$$\begin{aligned} &c_v\theta_t - k\Delta\theta = \theta G''(\theta)\theta_t H(\varepsilon) + \theta G'(\theta)\partial_t H(\varepsilon) + \nu(A\varepsilon_t) : \varepsilon_t && \text{in } \Omega_T, \\ &u = Qu = \nabla\theta \cdot n = 0 && \text{on } S_T, \\ &u(0,x) = u_0(x), \quad u_t(0,x) = u_1(x), \quad \theta(0,x) = \theta_0(x) \geq 0 && \text{in } \Omega, \end{aligned} \tag{3.2}$$

where

$$\Gamma_L(x) = \begin{cases} x & \text{if } |x| \leq L, \\ L\frac{x}{|x|} & \text{if } |x| \geq L. \end{cases}$$

THEOREM 3.1. *Fix L and $5 < p \leq q < \infty$. Assume that $\theta_0 \geq 0$,* (1.6) *holds, and $F(\varepsilon, \theta) \in \mathrm{C}^4(\mathbb{S}^2 \times \mathbb{R}^+, \mathbb{R})$. Then for any $T > 0$ and $(u_0, u_1, \theta_0) \in U(p,q)$, there exists a unique solution (u_L, θ_L) to $(\mathrm{TE})_3^L$ satisfying $(u_L, \theta_L) \in V_T(p,q)$.*

Proof of Theorem 3.1. We apply Theorem 2.4 to the map Φ_τ^L from $V_T(p,q)$ into $V_T(p,q)$,

$$\Phi_\tau^L : (\bar{u}, \bar{\theta}) \mapsto (u, \theta), \qquad \tau \in [0,1],$$

defined by means of the following initial-boundary value problems:

$$\begin{aligned} &u_{tt} + \kappa QQu - \nu Qu_t = \tau\Gamma_L\Big(\nabla \cdot [G(\bar{\theta})H_{,\varepsilon}(\bar{\varepsilon}) + \overline{H}_{,\varepsilon}(\bar{\varepsilon})]\Big), \\ &c_v\theta_t - k\Delta\theta = \tau\left\{\bar{\theta}G''(\bar{\theta})\theta_t H(\varepsilon) + \bar{\theta}G'(\bar{\theta})\partial_t H(\varepsilon) + \nu(A\varepsilon_t) : \varepsilon_t\right\} && \text{in } \Omega_T, \\ &u = Qu = \nabla\theta \cdot n = 0 && \text{on } S_T, \\ &u(0,x) = \tau u_0(x), \quad u_t(0,x) = \tau u_1(x), \quad \theta(0,x) = \tau\theta_0(x) && \text{in } \Omega, \end{aligned}$$

where $\bar{\varepsilon} = \varepsilon(\bar{u})$. A fixed point of $\Phi_\tau^L(1, \cdot)$ in $V_T(p,q)$ is the desired solution of the system $(\mathrm{TE})_3^L$. Therefore to prove the existence statement it is sufficient to check

that the map Φ_τ^L satisfies assumptions (L1)–(L4) of Theorem 2.4. Noting that Γ_L is Lipschitz continuous, we can check assumptions (L1), (L2), and (L3) in the same way as that in [21, section 3]. Then it is sufficient to check assumption (L4), namely, to derive a priori bounds for a fixed point of the solution map Φ_τ^L. Without loss of generality we may set $\tau = 1$. Hence, from now on our purpose is to obtain a priori bounds for $(\mathrm{TE})_3^L$. To this end we prepare several lemmas. If there is no danger of confusion, we write for simplicity (u, θ) instead of (u_L, θ_L).

LEMMA 3.2 (maximum principle). *Let* $(u_0, u_1, \theta_0) \in B^{4-2/p}_{p,p} \times B^{2-2/p}_{p,p} \times L^2$ *for* $p > 5$. *Assume that* $\min_\Omega \theta_0 \geq 0$. *Then the solution* θ *to* $(\mathrm{TE})_3^L$ *is nonnegative almost everywhere in* Ω_T.

Proof. It follows from the maximal regularity (2.1) for (3.1) that

$$
\begin{aligned}
&\|u\|_{W_p^{4,2}(\Omega_T)} \\
&\quad \leq C\left(\|u_0\|_{B^{4-2/p}_{p,p}} + \|u_1\|_{B^{2-2/p}_{p,p}} + \|\Gamma_L\left\{\nabla\cdot[G(\bar\theta)H_{,\varepsilon}(\bar\varepsilon) + \overline{H}_{,\varepsilon}(\bar\varepsilon)]\right\}\|_{L^p(\Omega_T)}\right) \\
&\quad \leq C(\|u_0\|_{B^{4-2/p}_{p,p}} + \|u_1\|_{B^{2-2/p}_{p,p}} + L|\Omega_T|^{\frac{1}{p}}) \\
&\quad \leq \Lambda(L).
\end{aligned} \tag{3.3}
$$

Then taking $p > 5$, by Lemma 2.2 we have

$$
\|\varepsilon\|_{L^\infty(\Omega_T)} + \|\varepsilon_t\|_{L^\infty(\Omega_T)} \leq \Lambda(L) < \infty. \tag{3.4}
$$

Therefore it holds that

$$
\|\partial_t H(\varepsilon)\|_{L^\infty(\Omega_T)} \leq \|\varepsilon_t\|_{L^\infty(\Omega_T)}\|\varepsilon\|^{K_1-1}_{L^\infty(\Omega_T)} \leq \Lambda(L)
$$

for $K_1 > 1$. Since $\sup_{\varepsilon\in\mathbb{S}} |H_{,\varepsilon}(\varepsilon)| \leq M$ for $K_1 \leq 1$, we conclude that

$$
\|\partial_t H(\varepsilon)\|_{L^\infty(\Omega_T)} \leq \Lambda(L) \tag{3.5}
$$

for every $K_1 \geq 0$. From now on, throughout this section we shall write $\Lambda = \Lambda(L)$.

Multiplying (3.2) by $\theta_- := \min\{\theta, 0\}$ and integrating over Ω, we have

$$
\begin{aligned}
&\frac{c_v}{2}\frac{d}{dt}\int_\Omega \theta_-^2 dx + k\int_\Omega |\nabla\theta_-|^2 dx \\
&\qquad = \int_\Omega [\theta_-\theta G''(\theta)\theta_t H(\varepsilon) + \theta_-\theta G'(\theta)\partial_t H(\varepsilon) + \nu\theta_- A\varepsilon_t : \varepsilon_t]\, dx \\
&\qquad = \frac{d}{dt}\int_\Omega H(\varepsilon)G_2(\theta_-)dx + \int_\Omega \overline{G}_2(\theta_-)\partial_t H(\varepsilon)dx + \int_\Omega \nu\theta_- A\varepsilon_t : \varepsilon_t dx,
\end{aligned}
$$

where $G_2(\theta) = \theta^2 G'(\theta) - \overline{G}_2(\theta)$ and $\overline{G}_2(\theta) = 2\int_0^\theta sG'(s)ds$. We have $G_2(0) = 0$ and $G_2'(y) = y^2 G''(y) \geq 0$ for $y \leq 0$, because G'' is the odd function such that $G''(y) \leq 0$ for $y \geq 0$. Then $G_2(y) \leq 0$ for $y \geq 0$. Hence, we have

$$
-\int_\Omega H(\varepsilon)G_2(\theta_-)dx \geq 0.
$$

It follows from (1.1) that

$$
\int_\Omega \nu\theta_- A\varepsilon_t : \varepsilon_t dx \leq \nu a_* \int_\Omega \theta_- |\varepsilon_t|^2 dx \leq 0.
$$

Noting that $\overline{G}_2(\theta) = \frac{1}{2}C_1\theta^2$ for $\theta \in [-\theta_1, \theta_1]$, we have $\sup_{s\in\mathbb{R}} \frac{|\overline{G}_2(s)|}{s^2} \le C$. Therefore we conclude that

$$\begin{aligned}\int_\Omega \overline{G}_2(\theta_-)\partial_t H(\varepsilon)dx &\le \int_\Omega |\theta_-|^2 \frac{|\overline{G}_2(\theta_-)|}{|\theta_-|^2}|\partial_t H(\varepsilon)|dx \\ &\le \Lambda\|\theta_-\|_{L^2}^2.\end{aligned}$$

Consequently, we have

$$\frac{d}{dt}\left(c_v\|\theta_-(t)\|_{L^2}^2 - \int_\Omega H(\varepsilon)G_2(\theta_-)dx\right) \le \Lambda\left(c_v\|\theta_-(t)\|_{L^2}^2 - \int_\Omega H(\varepsilon)G_2(\theta_-)dx\right).$$

Using the Gronwall inequality we obtain

$$\begin{aligned}\|\theta_-(t)\|_{L^2}^2 &\le \|\theta_-(t)\|_{L^2}^2 - \int_\Omega H(\varepsilon)G_2(\theta_-)dx \\ &\le \Lambda e^{\Lambda t}\left(\|\theta_-(0)\|_{L^2}^2 - \int_\Omega H(\varepsilon(0))G_2(\theta_-(0))dx\right) \\ &= 0,\end{aligned}$$

which completes the proof. □

LEMMA 3.3. *Let $l > 2$ be an arbitrary integer. Assume that $r \le 1$. Then for any $(u_0, u_1, \theta_0) \in B^{4-2/p}_{p,p} \times B^{2-2/p}_{p,p} \times L^l =: U_1(l)$, the solution (u, θ) to $(\mathrm{TE})^L_3$ satisfies*

$$\|\theta\|_{L^\infty_T L^l} \le \Lambda,$$

where $\Lambda = \Lambda(T, \|(u_1, u_2, \theta_0)\|_{U_1(l)})$. Moreover, if $(u_0, u_1, \theta_0) \in U_1(\infty)$, then we have

$$\|\theta\|_{L^\infty(\Omega_T)} \le \Lambda,$$

where $\Lambda = \Lambda(T, \|(u_1, u_2, \theta_0)\|_{U_1(\infty)})$.

Proof. Multiplying (3.2) by θ^{l-1} and integrating over Ω, we have

$$\begin{aligned}&\frac{c_v}{l}\frac{d}{dt}\|\theta\|_{L^l}^l + k(l-1)\int_\Omega \theta^{l-2}|\nabla\theta|^2 dx \\ &\quad= \int_\Omega \left(\theta^l G''(\theta)\theta_t H(\varepsilon) + \theta^l G'(\theta)\partial_t H(\varepsilon) + \nu\theta^{l-1}A\varepsilon_t : \varepsilon_t\right)dx \\ &\quad= \frac{d}{dt}\int_\Omega G_l(\theta)H(\varepsilon)dx + \int_\Omega \overline{G}_l(\theta)\partial_t H(\varepsilon)dx + \nu\int_\Omega \theta^{l-1}A\varepsilon_t : \varepsilon_t dx,\end{aligned} \tag{3.6}$$

where $G_l(\theta) = \theta^l G'(\theta) - \overline{G}_l(\theta)$ and $\overline{G}_l(\theta) = l\int_0^\theta s^{l-1}G'(s)ds$. Since

$$\theta^l G''(\theta) = \begin{cases} C_2 r(r-1)\theta^{l+r-2} \le 0 & \text{for } \theta \ge \theta_2, \\ \theta^l\varphi''(\theta) \le 0 & \text{for } \theta_1 \le \theta \le \theta_2, \\ 0 & \text{for } \theta \le \theta_1, \end{cases} \tag{3.7}$$

we have $G_l'(\theta) = \theta^l G''(\theta) \le 0$ for $\theta \ge 0$ and $G_l'(0) = 0$. Thereby, we obtain

$$G_l(\theta) \le 0 \quad \text{for} \quad \theta \ge 0. \tag{3.8}$$

We put

$$\hat{\theta} = \theta \left(1 - \frac{lG_l(\theta)H(\varepsilon)}{c_v \theta^l}\right)^{1/l}.$$

We note that $\hat{\theta} \geq \theta$ due to (3.8). Since $\sup_{s\in[0,\infty)} |G'(s)| =: M < \infty$, we have

$$|\overline{G}_l(\theta)| = \left| l \int_0^\theta s^{l-1} G'(s) ds \right| \leq C\theta^l$$

and

$$|G_l(\theta)| \leq M\theta^l + |\overline{G}_l(\theta)| \leq C\theta^l.$$

In view of (3.4) and (3.5) we obtain

$$\left| \int_\Omega \overline{G}_l(\theta) \partial_t H(\varepsilon) dx \right| \leq C \|\theta^l\|_{L^1(\Omega)} \|\partial_t H(\varepsilon)\|_{L^\infty(\Omega)} \leq \Lambda \|\theta\|^l_{L^l(\Omega)}$$

and

$$\int_\Omega \theta^{l-1} A\varepsilon_t : \varepsilon_t \leq C \|\varepsilon_t\|^2_{L^\infty(\Omega)} \|\theta\|^{l-1}_{L^{l-1}(\Omega)} \leq \Lambda \|\theta\|^{l-1}_{L^l(\Omega)}.$$

Since $\frac{1}{l}\partial_t \|\hat{\theta}\|^l_{L^l} = \|\hat{\theta}\|^{l-1}_{L^l} \partial_t \|\hat{\theta}\|_{L^l}$, it follows from (3.6) that

$$\begin{aligned} \frac{d}{dt}\|\hat{\theta}\|_{L^l(\Omega)} &\leq \Lambda \|\theta\|_{L^l(\Omega)} + \Lambda \\ &\leq \Lambda \|\hat{\theta}\|_{L^l(\Omega)} + \Lambda. \end{aligned}$$

Thus by the Gronwall inequality we have

$$\|\hat{\theta}\|_{L^\infty_T L^l} \leq \Lambda \|\hat{\theta}_0\|_{L^l} + \Lambda. \tag{3.9}$$

Since

$$\begin{aligned} \hat{\theta}_0 &= \theta_0 \left(1 - \frac{lG_l(\theta_0)H(\varepsilon_0)}{c_v \theta_0^l}\right)^{1/l} \\ &\leq \theta_0 \left(1 + \frac{lM\Lambda}{c_v}\right)^{1/l}, \end{aligned}$$

we can obtain the first assertion. Here we note that the constant Λ in (3.9) is independent of l. Therefore taking a limit as $l \to \infty$ we can obtain the second assertion. This completes the proof. □

LEMMA 3.4. *Let T be arbitrarily fixed. Assume that $r \leq 1$. Then for any $(u_0, u_1, \theta_0) \in B^{4-2/p}_{p,p} \times B^{2-2/p}_{p,p} \times H^1 =: U_2$, the solution (u, θ) to $(\mathrm{TE})^L_3$ satisfies*

$$\|\theta\|_{W^{2,1}_2(\Omega_T)} \leq \Lambda,$$

where Λ depends on T and $\|(u_0, u_1, \theta_0)\|_{U_2}$.

Proof. By using Lemma 3.3, thanks to $\theta_0 \in H^1 \hookrightarrow L^2$, we have

$$\|\theta\|_{L^\infty_T L^2} \leq \Lambda. \tag{3.10}$$

Since $\theta G''(\theta) \le 0$ from (3.7) for $l = 1$, the following estimate holds true:

$$\iint_{\Omega_T} \theta_t^2 \theta G''(\theta) H(\varepsilon) dxdt \le 0. \tag{3.11}$$

Multiplying (3.2) by θ_t and integrating over Ω_T, we have

$$\begin{aligned}
&c_v \|\theta_t\|^2_{L^2(\Omega_T)} + \frac{k}{2}\|\nabla\theta\|^2_{L^\infty_T L^2} \\
&\quad \le \frac{k}{2}\|\theta_0\|^2_{H^1} + \iint_{\Omega_T} \theta_t^2 \theta G''(\theta) H(\varepsilon) dxdt \\
&\qquad + \iint_{\Omega_T} \theta_t \theta G'(\theta) \partial_t H(\varepsilon) dxdt + \iint_{\Omega_T} \nu \theta_t A\varepsilon_t : \varepsilon_t dxdt \\
&\quad \le \frac{k}{2}\|\theta_0\|^2_{H^1} + \Lambda \|\theta_t\|_{L^2(\Omega_T)} \|\theta\|^r_{L^\infty_T L^2} \|\partial_t H(\varepsilon)\|_{L^\infty(\Omega_T)} \\
&\qquad + \Lambda \|\theta_t\|_{L^\infty_T L^2} \|\varepsilon_t\|^2_{L^\infty(\Omega_T)} \\
&\quad \le \frac{k}{2}\|\theta_0\|^2_{H^1} + \frac{c_v}{2}\|\theta_t\|^2_{L^2(\Omega_T)} + \Lambda,
\end{aligned}$$

thanks to (3.4), (3.5), (3.10), and (3.11). Therefore we arrive at

$$\|\theta_t\|_{L^2(\Omega_T)} + \|\nabla\theta\|_{L^\infty_T L^2} \le \Lambda(\|(u_0, u_1, \theta_0)\|_{U_2}).$$

Next, multiplying (3.2) by $\frac{-\Delta\theta}{c_v - \theta G''(\theta) H(\varepsilon)}$ and integrating over Ω, we get

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|\nabla\theta(t)\|^2_{L^2} + \int_\Omega \frac{k(\Delta\theta)^2}{c_v - \theta G''(\theta) H(\varepsilon)} dx \\
&\quad = -\int_\Omega \frac{\Delta\theta}{c_v - \theta G''(\theta) H(\varepsilon)} \left(\theta G'(\theta) \partial_t H(\varepsilon) + \nu A\varepsilon_t : \varepsilon_t\right) dx.
\end{aligned}$$

Here we remark that

$$c_v \le c_v - \theta G''(\theta) H(\varepsilon) \le c_v + M\Lambda,$$

where $0 \le \sup_{\theta \ge 0}(-\theta G''(\theta)) =: M < \infty$. Then integrating over $[0, t]$ for $t \le T$, we conclude with the estimate

$$\begin{aligned}
&\|\nabla\theta(t)\|^2_{L^2} + \frac{2k}{c_v + \Lambda M}\|\Delta\theta\|^2_{L^2(\Omega_T)} \\
&\quad \le \|\nabla\theta_0\|^2_{L^2} + 2\|\Delta\theta\|_{L^2(\Omega_T)} \left\|\theta G'(\theta)\partial_t H(\varepsilon) + \nu A\varepsilon_t : \varepsilon_t\right\|_{L^2(\Omega_T)} \\
&\quad \le \|\nabla\theta_0\|^2_{L^2} + \frac{k}{(c_v + \Lambda M)}\|\Delta\theta\|^2_{L^2(\Omega_T)} \\
&\qquad + \frac{c_v + \Lambda M}{k}\Big(\Lambda\|\theta\|_{L^\infty_T L^2}\|\partial_t H(\varepsilon)\|_{L^\infty(\Omega_T)} + \Lambda\|\varepsilon_t\|_{L^\infty(\Omega_T)}\Big)^2 \\
&\quad \le \frac{k}{(c_v + \Lambda M)}\|\Delta\theta\|^2_{L^2(\Omega_T)} + \Lambda.
\end{aligned}$$

Consequently, we arrive at the desired result. □

The same procedure as in [21, Lemma 6.1] allows us to conclude that $\theta \in \mathrm{C}^{\alpha,\alpha/2}(\Omega_T)$ for some Hölder exponent $0 < \alpha < 1$ depending on T, $\sup_\Omega \theta_0$, and $\|\theta\|_{L^\infty(\Omega_T)}$. The proof relies on the classical parabolic De Giorgi method. For more precise information on this method we refer to [14, Chapter II, section 7] and [15, Chapter VI, section 12]. Here we note that ε is Hölder continuous due to Lemma 2.2.

LEMMA 3.5 (see [21, Lemma 6.1]). *Assume that $k = \sup_\Omega \theta_0 < \infty$. Suppose that*

$$\|\varepsilon\|_{W_s^{2,1}(\Omega_T)} + \|\theta\|_{W_2^{2,1}(\Omega_T)} + \|\theta\|_{L^\infty(\Omega_T)} \le \Lambda \tag{3.12}$$

holds for any $s \in (1,\infty)$. Then $\theta \in \mathrm{C}^{\alpha,\alpha/2}(\Omega_T)$ with Hölder exponent $\alpha \in (0,1)$ depending on Λ and k.

LEMMA 3.6. *Assume that* (3.12) *holds. Then for any $(u_0,u_1,\theta_0) \in U(p,q)$ and $5 < p,q < \infty$ we have*

$$\|(u,\theta)\|_{V_T(p,q)} = \|u\|_{W_p^{4,2}(\Omega_T)} + \|\theta\|_{W_q^{2,1}(\Omega_T)} \le \Lambda,$$

where Λ depends on $\|(u_0,u_1,\theta_0)\|_{U(p,q)}$ and T.

Proof. We can construct a unique timelocal solution $(u,\theta) \in W_p^{4,2}(\Omega_{\widetilde{T}}) \times W_q^{2,1}(\Omega_{\widetilde{T}})$ of $(\mathrm{TE})_3^L$ for sufficiently small $\widetilde{T} < T$, using the result of Clément and Li [7] (see also [27, Lemma 3.3.7]). Then from the embedding we have $\theta \in \mathrm{C}([0,\widetilde{T}] \times \Omega)$. By combining this regularity result with Lemma 3.5, we obtain $\theta \in \mathrm{C}^{\alpha,\alpha/2}([0,T] \times \Omega)$.

For brevity of notation we denote $c_v - \theta G''(\theta)H(\varepsilon)$ by $c_0(\varepsilon,\theta)$, and $\theta G'(\theta)\partial_t H(\varepsilon) + \nu(A\varepsilon_t) : \varepsilon_t$ by $R(\varepsilon,\theta)$. Then (1.3) can be rewritten as

$$c_0(\varepsilon_0,\theta_0)\theta_t - \Delta\theta = (c_0(\varepsilon_0,\theta_0) - c_0(\varepsilon,\theta))\theta_t + R(\varepsilon,\theta).$$

By the assumptions we have

$$\begin{aligned}\|R(\varepsilon,\theta)\|_{L^q(\Omega_T)} &\le C\|\theta\|_{L^\infty(\Omega_T)}^r \|H_{,\varepsilon}(\varepsilon)\|_{L^\infty(\Omega_T)} \|\varepsilon_t\|_{L^q(\Omega_T)} + C\|\varepsilon_t\|_{L^{2q}(\Omega_T)}^2 \\ &\le \Lambda.\end{aligned}$$

From the Hölder continuity it follows that

$$\|c_0(\varepsilon_0,\theta_0) - c_0(\varepsilon,\theta)\|_{L^\infty(\Omega_{T_1})} \le K T_1^{\frac{\alpha}{2}},$$

where K is the Hölder constant independent of T_1. Here $T_1 \ll T$ will be determined later.

Next, we show that $1/c_0(\varepsilon,\theta)(x,T_2)$ is Hölder continuous with respect to the space variable for T_2 fixed in $[0,T]$. We remark that

$$\mathcal{G}(y) := yG''(y) \le M$$

and $\mathcal{G} \in \mathrm{C}^1$ is Lipschitz continuous. Then we have

$$\begin{aligned}
&\left|\frac{1}{c_0}(x,T_2)-\frac{1}{c_0}(x',T_2)\right| \\
&= \left|\frac{\mathcal{G}(\theta(x',T_2))H(\varepsilon(x',T_2))-\mathcal{G}(\theta(x,T_2))H(\varepsilon(x,T_2))}{\{c_v-\mathcal{G}(\theta(x,T_2))H(\varepsilon(x,T_2))\}\{c_v-\mathcal{G}(\theta(x',T_2))H(\varepsilon(x',T_2))\}}\right| \\
&\le \frac{1}{c_v^2}|\{\mathcal{G}(\theta(x',T_2))H(\varepsilon(x',T_2))-\mathcal{G}(\theta(x,T_2))H(\varepsilon(x',T_2))\} \\
&\qquad +\{\mathcal{G}(\theta(x,T_2))H(\varepsilon(x',T_2))-\mathcal{G}(\theta(x,T_2))H(\varepsilon(x,T_2))\}| \\
&\le \frac{1}{c_v^2}|H(\varepsilon(x',T_2))|\,|\mathcal{G}(\theta(x',T_2))-\mathcal{G}(\theta(x,T_2))| \\
&\qquad +\frac{1}{c_v^2}|\mathcal{G}(\theta(x,T_2))|\,|H(\varepsilon(x',T_2))-H(\varepsilon(x,T_2))| \\
&\le \Lambda K|x-x'|^\alpha + CM|x-x'|^\alpha \\
&\le \Lambda|x-x'|^\alpha,
\end{aligned}$$

where Λ is independent of T_2. Therefore $[1/c_0(\varepsilon,\theta)](x,T_2)$ is Hölder continuous for any $T_2 \in [0,T]$. Moreover, we have $\sup_{\Omega_T}[1/c_0(\varepsilon,\theta)] \ge 1/(c_v+M\Lambda)$. These conditions ensure that $\frac{1}{c_0(\varepsilon(T_2),\theta(T_2))}\Delta$ has the maximal regularity property according to (2.3). Hence, taking $T_1 = (\frac{1}{2\Lambda(K,M,T)K})^{\frac{1}{\alpha}}$, we have

$$\begin{aligned}
\|\theta\|_{W_q^{2,1}(\Omega_{T_1})} &\le \Lambda(K,M,T)\Big(\|c_0(\varepsilon_0,\theta_0)-c_0(\varepsilon,\theta)\|_{L^\infty(\Omega_{T_1})}\|\theta_t\|_{L^q(\Omega_{T_1})} \\
&\qquad +\|R(\varepsilon,\theta)\|_{L^q(\Omega_{T_1})}+\|\theta_0\|_{B^{2-2/q}_{q,q}(\Omega)}\Big) \\
&\le \frac{1}{2}\|\theta_t\|_{L^q(\Omega_{T_1})}+\Lambda+\Lambda\|\theta_0\|_{B^{2-2/q}_{q,q}(\Omega)},
\end{aligned}$$

which yields

$$\|\theta\|_{W_q^{2,1}(\Omega_{T_1})} \le \Lambda+\Lambda\|\theta_0\|_{B^{2-2/q}_{q,q}(\Omega)}.$$

Here we remark that

$$\|\theta(T_1)\|_{B^{2-2/q}_{q,q}} \le C(T_1)\|\theta\|_{W_q^{2,1}(\Omega_{T_1})} \le C(T_1)\left(\Lambda+\Lambda\|u_0\|_{B^{2-2/q}_{q,q}}\right)$$

thanks to the embedding $W_q^{2,1}(\Omega_{T_1}) \hookrightarrow BUC([0,T_1],B^{2-\frac{2}{q}}_{q,q})$ (see [4], [18]). Then similarly for the interval $[T_1,2T_1]$ we have

$$\|\theta\|_{W_q^{2,1}(\Omega_{[T_1,2T_1]})} \le \Lambda+\Lambda\|u(T_1)\|_{B^{2-2/q}_{q,q}} \le \Lambda+\Lambda\|u_0\|_{B^{2-2/q}_{q,q}} \le \Lambda.$$

Repeating the same operation yields

$$\|\theta\|_{W_q^{2,1}(\Omega_{[kT_1,(k+1)T_1]})} \le \Lambda.$$

Summing the inequalities from $k=0$ to $k=m$ satisfying $(m+1)T_1 > T$ and $mT_1 \le T$, we conclude that

$$\|\theta\|_{W_q^{2,1}(\Omega_T)} \le \Lambda.$$

Next we estimate the norm $\|u\|_{W_p^{4,2}(\Omega_T)}$. From Lemma 2.2 it follows that

$$\|\nabla\theta\|_{L^\infty(\Omega_T)} + \|\nabla\varepsilon\|_{L^\infty(\Omega_T)} \le \Lambda$$

for $q > 5$. Therefore, by virtue of the maximal regularity (2.1), we have

$$\begin{aligned}
&\|u\|_{W_p^{4,2}(\Omega_T)} \\
&\quad\le C\|(u_0,u_1,0)\|_{U(p,q)} + \|\nabla\cdot(G(\theta)H_{,\varepsilon}(\varepsilon))\|_{L^p(\Omega_T)} + \|\nabla\cdot\overline{H}_{,\varepsilon}(\varepsilon)\|_{L^p(\Omega_T)} \\
&\quad\le C\|(u_0,u_1,0)\|_{U(p,q)} + \Lambda\|\nabla\theta\|_{L^\infty(\Omega_T)}\|G'(\theta)\|_{L^\infty(\Omega_T)}\|H_{,\varepsilon}(\varepsilon)\|_{L^\infty(\Omega_T)} \\
&\qquad + \Lambda\|\theta\|^r_{L^\infty(\Omega_T)}\|\nabla\varepsilon\|_{L^\infty(\Omega_T)}\|H_{,\varepsilon\varepsilon}(\varepsilon)\|_{L^\infty(\Omega_T)} + \Lambda\|\nabla\varepsilon\|_{L^\infty(\Omega_T)}\|\overline{H}_{,\varepsilon\varepsilon}(\varepsilon)\|_{L^\infty(\Omega_T)} \\
&\quad\le \Lambda(\|(u_0,u_1,0)\|_{U(p,q)}),
\end{aligned}$$

which completes the proof. □

Proof of Theorem 3.1 (*continuation*). The assumption (L4) is satisfied thanks to Lemma 3.6 and estimate (3.3). Then the existence of a solution to problem $(\mathrm{TE})_3^L$ results from Theorem 2.4. Noting that Γ_L is Lipschitz continuous, we can obtain the uniqueness result by repeating the arguments of [22, section 6]. We remark also that the assumption $p \le q$ is required to show (L1); see [21]. Thereby the proof of Theorem 3.1 is completed. □

4. Proof of Theorem 1.1 (existence). The idea of the proof consists of showing that the solution (u_L, θ_L) to $(\mathrm{TE})_3^L$ constructed in section 3 satisfies also the original system (1.2)–(1.5) for sufficiently large truncation size L. To this purpose, assuming that there exists a sufficiently smooth solution of problem (1.2)–(1.5) such that $\theta \ge 0$, we derive for it a sequence of a priori estimates which are independent of L.

LEMMA 4.1 (energy inequality). *Assume that* $\theta \ge 0$ *a.e. in* Ω_T, $K_2 \le 6$, *and* $6r + K_1 \le 6$. *Then for any* $t \in [0,T]$ *a smooth solution of* (1.2)–(1.5) *satisfies*

$$\|\theta(t)\|_{L^1(\Omega)} + \|u_t(t)\|_{L^2(\Omega)} + \|Qu(t)\|_{L^2(\Omega)} \le C(\|(u_0,u_1,\theta_0)\|_{H^2\times L^2\times L^1}). \tag{4.1}$$

Proof. Multiplying (1.2) by u_t and integrating the resulting equation with respect to the space variable, we have

$$\frac{d}{dt}\left(\frac{1}{2}\|u_t\|^2_{L^2} + \frac{\kappa}{2}\|Qu\|^2_{L^2} + \int_\Omega \overline{H}(\varepsilon)dx\right) + \nu\int_\Omega (A\varepsilon_t) : \varepsilon_t dx = -\int_\Omega G(\theta)\frac{\partial}{\partial t}H(\varepsilon)dx.$$

Integrating (1.3) over Ω, we obtain

$$c_v\frac{d}{dt}\int_\Omega \theta dx = \nu\int_\Omega (A\varepsilon_t) : \varepsilon_t dx + \int_\Omega \theta G'(\theta)\frac{\partial}{\partial t}H(\varepsilon)dx + \int_\Omega \theta G''(\theta)\theta_t H(\varepsilon)dx.$$

Combining these equalities, we deduce

$$\begin{aligned}
&\frac{d}{dt}\left(\frac{1}{2}\|u_t\|^2_{L^2} + \frac{\kappa}{2}\|Qu\|^2_{L^2} + c_v\int_\Omega \theta dx + \int_\Omega \overline{H}(\varepsilon)dx\right) \\
&\quad= \int_\Omega \left(\theta G'(\theta)\frac{\partial}{\partial t}H(\varepsilon) + \theta G''(\theta)\theta_t H(\varepsilon) - G(\theta)\frac{\partial}{\partial t}H(\varepsilon)\right)dx \\
&\quad= -\frac{d}{dt}\int_\Omega \overline{G}(\theta)H(\varepsilon)dx,
\end{aligned}$$

where $\overline{G}(\theta) = G(\theta) - \theta G'(\theta)$. Consequently,

$$\frac{d}{dt}\left(\frac{1}{2}\|u_t\|_{L^2}^2 + \frac{\kappa}{2}\|Qu\|_{L^2}^2 + c_v\int_\Omega \theta dx + \int_\Omega \overline{H}(\varepsilon)dx + \int_\Omega \overline{G}(\theta)H(\varepsilon)dx\right) = 0.$$

Here we recall that $\theta \geq 0$ and $H(\varepsilon) \geq 0$. By the structure of $G(\theta)$, the function $\overline{G}(\theta)$ is as follows:

$$\overline{G}(r) = \begin{cases} 0 & \text{if } \theta \in [0, \theta_1], \\ \varphi(\theta) - \theta\varphi'(\theta) & \text{if } \theta \in [\theta_1, \theta_2], \\ C_2(1-r)\theta^r & \text{if } \theta \in [\theta_2, \infty). \end{cases}$$

According to Lemma 2.3 we have $\overline{G}(\theta) \geq 0$. Consequently, it follows from (A)(iii) that

$$\begin{aligned} &\frac{1}{2}\|u_t(t)\|_{L^2}^2 + \frac{\kappa}{2}\|u(t)\|_{H^2}^2 + c_v\|\theta(t)\|_{L^1} \\ &\quad \leq \frac{1}{2}\|u_0\|_{H^2}^2 + \frac{\kappa}{2}\|u_1\|_{L^2}^2 + c_v\|\theta_0\|_{L^1} + \int_\Omega |\overline{H}(\varepsilon_0)|dx + C_3|\Omega| \\ &\qquad + \int_{\{\theta_2 \geq \theta_0 \geq \theta_1\}\cap\Omega} [\varphi(\theta_0) - \theta_0\varphi'(\theta_0)]H(\varepsilon_0)dx + C_2(1-r)\int_{\{\theta_0 > \theta_2\}\cap\Omega} \theta_0^r H(\varepsilon_0)dx, \end{aligned}$$

where $\varepsilon_0 = \varepsilon(u_0)$. Since the smooth function $\varphi(s) - s\varphi'(s)$ is bounded for $s \in [\theta_1, \theta_2]$, it follows that

$$\begin{aligned} \int_{\{\theta_2 \geq \theta_0 \geq \theta_1\}\cap\Omega} [\varphi(\theta_0) - \theta_0\varphi'(\theta_0)]H(\varepsilon_0)dx &\leq C\int_\Omega |\varepsilon_0|^{K_1}dx \\ &\leq C\|u_0\|_{H^2}^{K_1} \end{aligned}$$

for $K_1 \leq 6$,

$$\begin{aligned} \int_{\{\theta_0 > \theta_2\}\cap\Omega} \theta_0^r H(\varepsilon_0)dx &\leq C\|\theta_0\|_{L^1}^r \|\varepsilon_0\|_{L^{\frac{K_1}{1-r}}}^{K_1} \\ &\leq C\|\theta_0\|_{L^1}^r \|u_0\|_{H^2}^{K_1} \end{aligned}$$

for $6r + K_1 \leq 6$, and

$$\int_\Omega |\overline{H}(\varepsilon_0)|dx \leq \|u_0\|_{H^2}^{K_2}$$

for $K_2 \leq 6$. Hence, we conclude the assertion. □

LEMMA 4.2. *Let T be fixed. Assume that $\theta \geq 0$ a.e. in Ω_T and (1.6) holds. Then for any $(u_0, u_1, \theta_0) \in B^{19/8}_{16/5,16/5} \times B^{3/8}_{16/5,16/5} \times L^2 =: U_3$, the solution (u, θ) to (1.2)–(1.5) satisfies*

$$\|\varepsilon\|_{W^{2,1}_{16/5}(\Omega_T)} + \|\nabla\theta\|_{L^2(\Omega_T)} + \|\theta\|_{L^\infty_T L^2} \leq \Lambda, \tag{4.2}$$

where Λ depends on T and $\|(u_0, u_1, \theta_0)\|_{U_3}$. Moreover,

$$\|\varepsilon\|_{L^\infty(\Omega_T)} + \|\theta\|_{L^{10/3}(\Omega_T)} \leq \Lambda. \tag{4.3}$$

Proof. We remark that $\|(u_0,u_1,\theta_0)\|_{H^2\times L^2\times L^1}\le C\|(u_0,u_1,\theta_0)\|_{U_3}$ (see [1]). From the Gagliardo–Nirenberg inequality and Lemma 4.1 it follows that

$$\begin{aligned}\|\varepsilon\|_{L^{5p}(\Omega_T)} &\le C\left\|\|\varepsilon\|^{\frac{4}{5}}_{L^6(\Omega)}\|\varepsilon\|^{\frac{1}{5}}_{W^2_p(\Omega)}\right\|_{L^{5p}_T}\\ &\le C\|\varepsilon\|^{\frac{4}{5}}_{L^\infty_T L^6}\|\varepsilon\|^{\frac{1}{5}}_{W^{2,1}_p(\Omega_T)}\\ &\le C\|u\|^{\frac{4}{5}}_{L^\infty_T H^2}\|\varepsilon\|^{\frac{1}{5}}_{W^{2,1}_p(\Omega_T)}\\ &\le C\|\varepsilon\|^{\frac{1}{5}}_{W^{2,1}_p(\Omega_T)}\end{aligned} \tag{4.4}$$

and

$$\begin{aligned}\|\theta\|_{L^{\frac{8}{3}}(\Omega_T)} &\le C\left\|\|\theta\|^{\frac{1}{4}}_{L^1(\Omega)}\|\theta\|^{\frac{3}{4}}_{H^1(\Omega)}\right\|_{L^\infty_T}\\ &\le C\|\theta\|^{\frac{1}{4}}_{L^\infty_T L^1}\|\theta\|^{\frac{3}{4}}_{L^2_T H^1}\\ &\le \Lambda(\|\nabla\theta\|_{L^2(\Omega_T)}+\|\theta\|_{L^\infty_T L^2})^{\frac{3}{4}}.\end{aligned} \tag{4.5}$$

It follows from (4.4) that

$$\|\overline{H}_{,\varepsilon}(\varepsilon)\|_{L^{\frac{16}{5}}(\Omega_T)}\le C\|\varepsilon\|^{K_2-1}_{L^{16}(\Omega_T)}\le\Lambda\|\varepsilon\|^{\frac{K_2-1}{5}}_{W^{2,1}_{\frac{16}{5}}(\Omega_T)}\le\frac{1}{4}\|\varepsilon\|_{W^{2,1}_{\frac{16}{5}}(\Omega_T)}+\Lambda$$

for $K_2\in[1,6)$, and

$$\|\overline{H}_{,\varepsilon}(\varepsilon)\|_{L^{\frac{16}{5}}(\Omega_T)}\le M|\Omega_T|^{\frac{5}{16}}\le\Lambda$$

for $K_2\in[0,1)$.

We first consider the case of $K_1\ge 1$. Applying the growth condition and the Young inequality, we have

$$\begin{aligned}&\|G(\theta)H_{,\varepsilon}(\varepsilon)\|_{L^{\frac{16}{5}}(\Omega_T)}\\ &\quad\le\|\theta\|^r_{L^{\frac{8}{3}}(\Omega_T)}\|\varepsilon\|^{K_1-1}_{L^{\frac{16(K_1-1)}{5-6r}}(\Omega_T)}+\sup_{\theta\in[0,\theta_2]}|G(\theta)|\|\varepsilon\|^{K_1-1}_{L^{\frac{16(K_1-1)}{5}}(\Omega_T)}\\ &\quad\le\Lambda\|\theta\|^r_{L^{\frac{8}{3}}(\Omega_T)}\|\varepsilon\|^{K_1-1}_{L^{16}(\Omega_T)}+\Lambda\|\varepsilon\|^{K_1-1}_{L^{16}(\Omega_T)}\end{aligned}$$

for $6r+K_1\le 6$ (and $K_1\le 6$). Then

$$\begin{aligned}&\|\theta\|^r_{L^{8/3}(\Omega_T)}\|\varepsilon\|^{K_1-1}_{L^{16}(\Omega_T)}+\|\varepsilon\|^{K_1-1}_{L^{16}(\Omega_T)}\\ &\quad\le\Lambda(\|\nabla\theta\|_{L^2(\Omega_T)}+\|\theta\|_{L^\infty_T L_2})^{3r/4}\|\varepsilon\|^{(K_1-1)/5}_{W^{2,1}_{16/5}(\Omega_T)}+\Lambda\|\varepsilon\|^{(K_1-1)/5}_{W^{2,1}_{16/5}(\Omega_T)}\\ &\quad\le\frac{1}{4}\|\varepsilon\|_{W^{2,1}_{16/5}(\Omega_T)}+\Lambda(\|\nabla\theta\|_{L^2(\Omega_T)}+\|\theta\|_{L^\infty_T L_2})^{15r/4(6-K_1)}+\Lambda\end{aligned}$$

for $6r+K_1<6$ (and $K_1<6$). From the maximal regularity (2.2) it follows that

$$\begin{aligned}&\|\varepsilon\|_{W^{2,1}_{16/5}(\Omega_T)}\\ &\quad\le C\|(u_0,u_1,\theta_0)\|_{U_3}+\|G(\theta)H_{,\varepsilon}(\varepsilon)\|_{L^{16/5}(\Omega_T)}+\|\overline{H}_{,\varepsilon}(\varepsilon)\|_{L^{16/5}(\Omega_T)}\\ &\quad\le C\|(u_0,u_1,\theta_0)\|_{U_3}+\Lambda+\Lambda(\|\nabla\theta\|_{L^2(\Omega_T)}+\|\theta\|_{L^\infty_T L_2})^{15r/4(6-K_1)}.\end{aligned} \tag{4.6}$$

Next, multiplying (1.3) by θ and integrating over Ω, we have

$$
\begin{aligned}
&\frac{c_v}{2}\frac{d}{dt}\|\theta(t)\|_{L^2}^2 + k\|\nabla\theta\|_{L^2}^2 \\
&\quad = \int_\Omega \theta^2 G''(\theta)\theta_t H(\varepsilon)dx + \int_\Omega \theta^2 G'(\theta)\partial_t H(\varepsilon)dx + \nu\int_\Omega \theta A\varepsilon_t : \varepsilon_t dx \\
&\quad = \int_\Omega G_2'(\theta)\theta_t H(\varepsilon)dx + \int_\Omega G_2(\theta)\partial_t H(\varepsilon)dx + 2\int_\Omega \overline{G}_2(\theta)\partial_t H(\varepsilon)dx \\
&\qquad + \nu\int_\Omega \theta A\varepsilon_t : \varepsilon_t dx \\
&\quad = \frac{d}{dt}\int_\Omega G_2(\theta)H(\varepsilon)dx + 2\int_\Omega \overline{G}_2(\theta)\partial_t H(\varepsilon)dx + \nu\int_\Omega \theta A\varepsilon_t : \varepsilon_t dx,
\end{aligned}
\tag{4.7}
$$

where $G_2(\theta)$ and $\overline{G}_2(\theta)$ are given in the proof of Lemma 3.2. Recall that

$$
G_2(\theta) = \frac{C_2 r(r-1)}{r+1}\theta^{r+1} \le 0 \quad \text{and} \quad \overline{G}_2(\theta) = \frac{2C_2 r}{r+1}\theta^{r+1} \quad \text{for } \theta \ge \theta_2,
$$

and

$$
\sup_{\theta\in[0,\theta_2]} |G_2(\theta)| + \sup_{\theta\in[0,\theta_2]} |\overline{G}_2(\theta)| =: M < \infty.
$$

Then we have

$$
\begin{aligned}
&-\int_\Omega G_2(\theta)H(\varepsilon)dx \\
&\quad = -\int_{\Omega\cap\{\theta\ge\theta_2\}} G_2(\theta)H(\varepsilon)dx - \int_{\Omega\cap\{\theta_1\le\theta\le\theta_2\}} G_2(\theta)H(\varepsilon)dx \\
&\quad \ge -M\int_\Omega |H(\varepsilon)|dx.
\end{aligned}
$$

Hence, integrating (4.7) with respect to the time variable, we obtain

$$
\begin{aligned}
&\frac{c_v}{2}\|\theta\|_{L_T^\infty L^2}^2 + k\|\nabla\theta\|_{L^2(\Omega_T)}^2 \\
&\quad \le \frac{c_v}{2}\|\theta_0\|_{L^2}^2 + \|\overline{G}_2(\theta)\partial_t H(\varepsilon)\|_{L^1(\Omega_T)} + \nu\|\theta A\varepsilon_t : \varepsilon_t\|_{L^1(\Omega_T)} \\
&\qquad + M\sup_{t\in[0,T]}\int_\Omega |H(\varepsilon(t))|dx + \int_\Omega |G_2(\theta_0)H(\varepsilon_0)|dx.
\end{aligned}
$$

By (4.4), (4.5), and the assumptions we infer that

$$
\begin{aligned}
\|\theta^{r+1}\partial_t H(\varepsilon)\|_{L^1(\Omega_T)} &\le \Lambda\|\theta\|_{L^{8/3}(\Omega_T)}^{r+1}\|u\|_{W^{2,1}_{16/5}(\Omega_T)}\|\varepsilon\|_{L^{16}(\Omega_T)}^{K_1-1} \\
&\le \Lambda(\|\nabla\theta\|_{L^2(\Omega_T)} + \|\theta\|_{L_T^\infty L_2})^{\frac{3(r+1)}{4}}\|u\|_{W^{2,1}_{16/5}(\Omega_T)}^{1+(K_1-1)/5},
\end{aligned}
$$

$$
\begin{aligned}
\|\theta A\varepsilon_t : \varepsilon_t\|_{L^1(\Omega_T)} &\le C\|\theta\|_{L^{\frac{8}{3}}(\Omega_T)}\|\varepsilon_t\|_{L^{\frac{16}{5}}(\Omega_T)}^2 \\
&\le \Lambda(\|\nabla\theta\|_{L^2(\Omega_T)} + \|\theta\|_{L_T^\infty L_2})^{\frac{3}{4}}\|\varepsilon_t\|_{\frac{16}{5}(\Omega_T)}^2,
\end{aligned}
$$

$$
\int_\Omega |H(\varepsilon(t))|dx \le C\|u(t)\|_{H^2}^{K_1} \le \Lambda,
$$

and

$$\begin{aligned}\|\theta_0^{r+1}H(\varepsilon_0)\|_{L^1(\Omega)} &\le C\|\theta_0\|_{L^2(\Omega)}^{r+1}\|\varepsilon_0\|_{L^{\frac{2K_1}{1-r}}(\Omega)}^{K_1}\\ &\le C\|\theta_0\|_{L^2(\Omega)}^{r+1}\|u_0\|_{H^2(\Omega)}^{K_1}.\end{aligned}$$

Consequently, we arrive at

$$\begin{aligned}&\|\theta\|_{L_T^\infty L^2}^2+\|\nabla\theta\|_{L^2(\Omega_T)}^2\\ &\quad\le \Lambda(\|(u_0,u_1,\theta_0)\|_{U_3})+\Lambda(\|\nabla\theta\|_{L^2(\Omega_T)}+\|\theta\|_{L_T^\infty L_2})^{\frac{3(r+1)}{4}}\|\varepsilon\|_{W^{2,1}_{\frac{16}{5}}(\Omega_T)}^{\frac{4}{5}+\frac{K_1}{5}}\\ &\qquad+\Lambda(\|\nabla\theta\|_{L^2(\Omega_T)}+\|\theta\|_{L_T^\infty L_2})^{\frac{3}{4}}\|\varepsilon_t\|_{L^{\frac{16}{5}}(\Omega_T)}^2.\end{aligned}\tag{4.8}$$

Substituting (4.6) into (4.8) yields

$$\begin{aligned}\|\theta\|_{L_T^\infty L^2}^2+\|\nabla\theta\|_{L^2(\Omega_T)}^2 &\le \Lambda(\|(u_0,u_1,\theta_0)\|_{U_3})\\ &+\Lambda(\|\nabla\theta\|_{L^2(\Omega_T)}+\|\theta\|_{L_T^\infty L_2})^{\frac{3(r+1)}{4}}\left(\|(u_0,u_1,\theta_0)\|_{U_3}+\|\nabla\theta\|_{L^2(\Omega_T)}^{\frac{15r}{4(6-K_1)}}\right)^{\frac{4}{5}+\frac{K_1}{5}}\\ &+\Lambda(\|\nabla\theta\|_{L^2(\Omega_T)}+\|\theta\|_{L_T^\infty L_2})^{\frac{3}{4}}\left(\|(u_0,u_1,\theta_0)\|_{U_3}+\|\nabla\theta\|_{L^2(\Omega_T)}^{\frac{15r}{4(6-K_1)}}\right)^2.\end{aligned}$$

Here from the assumption $6r+K_1<6$ it follows that

$$\begin{aligned}\frac{3(r+1)}{4}+\frac{15r}{4(6-K_1)}\left(\frac{4}{5}+\frac{K_1}{5}\right)=\frac{30r+3(6-K_1)}{4(6-K_1)}<\frac{5(6-K_1)+3(6-K_1)}{4(6-K_1)}=2,\\ \frac{3}{4}+\frac{30r}{4(6-K_1)}<\frac{3}{4}+\frac{5}{4}=2.\end{aligned}$$

Thus we conclude that

$$\|\theta\|_{L_T^\infty L^2}+\|\nabla\theta\|_{L^2(\Omega_T)}\le\Lambda(\|(u_0,u_1,\theta_0)\|_{U_3})+\Lambda\|\nabla\theta\|_{L^2(\Omega_T)}^{1-}.$$

Here we use $p-$ to denote a number less than p. Hence, by the Young inequality, we have

$$\|\theta\|_{L_T^\infty L^2}+\frac{1}{2}\|\theta\|_{L^2(\Omega_T)}\le\Lambda(\|(u_0,u_1,\theta_0)\|_{U_3}).$$

Substituting the above inequality into (4.6), we deduce also the following:

$$\|\varepsilon\|_{W^{2,1}_{16/5}(\Omega_T)}\le\Lambda(\|(u_0,u_1,\theta_0)\|_{U_3}).$$

Next, we consider the case when $0\le K_1\le 1$ and $0\le r<5/6$. In this case it follows that

$$|H_{,\varepsilon}(\varepsilon)|\le C<\infty.$$

By an argument similar to the one presented above we have

$$\begin{aligned}\|\varepsilon\|_{W^{2,1}_{16/5}(\Omega_T)} &\le \|(u_0,u_1,0)\|_{U_3}+\|G(\theta)H_{,\varepsilon}(\varepsilon)\|_{L^{16/5}(\Omega_T)}\\ &\le \|(u_0,u_1,0)\|_{U_3}+C\|\theta\|_{L^{\frac{16r}{5}}(\Omega_T)}^r+C\sup_{\theta\in[0,\theta_2]}G(\theta)\\ &\le \|(u_0,u_1,0)\|_{U_3}+\Lambda\|\theta\|_{L^{\frac{8}{3}}(\Omega_T)}^r+C.\end{aligned}\tag{4.9}$$

Noting that

$$\|\theta^{r+1}\partial_t H(\varepsilon)\|_{L^1(\Omega_T)} \le \Lambda\|\theta\|^{r+1}_{L^{8/3}(\Omega_T)}\|u\|_{W^{2,1}_{16/5}(\Omega_T)},$$

we obtain

$$\begin{aligned}
&\|\theta\|^2_{L^\infty_T L^2} + \|\nabla\theta\|^2_{L^2(\Omega_T)}\\
&\quad\le \|\theta_0\|^2_{L^2} + \|\theta^{r+1}\partial_t H(\varepsilon)\|_{L^1(\Omega_T)} + \|\theta A\varepsilon_t : \varepsilon_t\|_{L^1(\Omega_T)}\\
&\qquad + M\sup_{t\in[0,T]}\int_\Omega |H(\varepsilon(t))|dx + \int_\Omega |G_2(\theta_0)H(\varepsilon_0)|dx\\
&\quad\le \Lambda(\|(u_0,u_1,\theta_0)\|_{U_3}) + \Lambda\|\theta\|^{r+1}_{L^{8/3}(\Omega_T)}\|u\|_{W^{2,1}_{16/5}(\Omega_T)}\\
&\qquad + C\|\theta\|_{L^{8/3}(\Omega_T)}\|u\|^2_{W^{2,1}_{16/5}(\Omega_T)}\\
&\quad\le \Lambda(\|(u_0,u_1,\theta_0)\|_{U_3}) + \Lambda(\|\nabla\theta\|_{L^2(\Omega_T)} + \|\theta\|_{L^\infty_T L^2})^{3(2r+1)/4}.
\end{aligned}$$

Since $3(2r+1)/4 < 2$, we arrive at the desired estimate (4.2).

The estimate (4.3) follows with the help of the embeddings

$$\|\varepsilon\|_{L^\infty(\Omega_T)} \le \Lambda\|\varepsilon\|_{W^{2,1}_{16/5}(\Omega_T)}$$

and the inequality

$$\|\theta\|_{L^{10/3}(\Omega_T)} \le C\left\|\|\theta\|^{2/5}_{L^2(\Omega)}\|\theta\|^{3/5}_{H^1(\Omega)}\right\|_{L^{10/3}_T} \le C\|\theta\|^{2/5}_{L^\infty_T L^2}\|\theta\|^{3/5}_{L^2H^1}.$$

This completes the proof. □

LEMMA 4.3. *Let T be any fixed. Assume that $\theta \ge 0$ a.e. in Ω_T and (1.6) holds. Then for any $(u_0,u_1,\theta_0) \in B^{5/2}_{4,4}\times B^{1/2}_{4,4}\times H^1 = U_4$ the following estimate holds:*

$$\|\varepsilon\|_{W^{2,1}_4(\Omega_T)} + \|\nabla\theta\|_{L^\infty_T L^2} + \|\theta\|_{W^{2,1}_2(\Omega_T)} \le \Lambda,$$

where the constant Λ depends on T and $\|(u_0,u_1,\theta_0)\|_{U_4}$. Moreover, we have

$$\|\nabla\theta\|_{L^{10/3}(\Omega_T)} + \|\theta\|_{L^{10}(\Omega_T)} + \|\nabla\varepsilon\|_{L^{20}(\Omega_T)} \le \Lambda.$$

Proof. Remark that $U_4 \hookrightarrow U_3$. Using (4.3) we have

$$\|G(\theta)H_{,\varepsilon}(\varepsilon)\|_{L^4(\Omega_T)} \le \begin{cases}\Lambda\|\theta\|^r_{L^{10/3}(\Omega_T)}\|\varepsilon\|^{K_1-1}_{L^\infty(\Omega_T)} \le \Lambda & \text{if } K_1 \ge 1,\\ \Lambda\sup|H_{,\varepsilon}|\|\theta\|^r_{L^{10/3}(\Omega_T)} \le \Lambda & \text{if } K_1 \le 1\end{cases} \tag{4.10}$$

for $r \le 5/6$. Then from the maximal regularity (2.2) it follows that

$$\|\varepsilon\|_{W^{2,1}_4} \le \|(u_0,u_1,\theta_0)\|_{U_4} + \|G(\theta)H_{,\varepsilon}(\varepsilon)\|_{L^4} \le \Lambda. \tag{4.11}$$

Multiplying (1.3) by θ_t and integrating over Ω_T, we get

$$\begin{aligned}
&c_v\|\theta_t\|^2_{L^2(\Omega_T)} + \frac{k}{2}\|\nabla\theta\|^2_{L^\infty_T L^2} \\
&\quad\le \frac{k}{2}\|\theta_0\|^2_{H^1} + \iint_{\Omega_T} \theta_t^2 \theta G''(\theta) H(\varepsilon) dxdt \\
&\qquad + \iint_{\Omega_T} \theta_t \theta G'(\theta)\partial_t H(\varepsilon) dxdt + \iint_{\Omega_T} \theta_t A\varepsilon_t : \varepsilon_t dxdt \\
&\quad\le \frac{k}{2}\|\theta_0\|^2_{H^1} + C\|\theta_t\|_{L^2(\Omega_T)}\|\theta^r H_{,\varepsilon}(\varepsilon)\|_{L^4}\|\varepsilon_t\|_{L^4} + C\|\theta_t\|_{L^2}\|\varepsilon_t\|^2_{L^4} \\
&\quad\le \frac{k}{2}\|\theta_0\|^2_{H^1} + \Lambda(\|(u_0,u_1,\theta_0)\|_{U_4})\|\theta_t\|_{L^2(\Omega_T)} \\
&\quad\le \Lambda(\|(u_0,u_1,\theta_0)\|_{U_4}) + \frac{1}{2}\|\theta_t\|^2_{L^2(\Omega_T)},
\end{aligned}$$

where we applied (3.11), (4.10), and (4.11). Therefore we arrive at

$$\|\varepsilon\|_{W^{2,1}_4(\Omega_T)} + \|\theta_t\|_{L^2(\Omega_T)} + \|\nabla\theta\|_{L^\infty_T L^2} \le \Lambda(\|(u_0,u_1,\theta_0)\|_{U_4}). \tag{4.12}$$

Next, multiplying (1.3) by $\frac{-\Delta\theta}{c_v - \theta G''(\theta)H(\varepsilon)}$ and integrating over Ω, we obtain

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|\nabla\theta(t)\|^2_{L^2} + \int_\Omega \frac{k|\Delta\theta|^2}{c_v - \theta G''(\theta)H(\varepsilon)} dx \\
&\quad\le \int_\Omega \frac{\Delta\theta}{c_v - \theta G''(\theta)H(\varepsilon)} \left(\theta G'(\theta)\partial_t H(\varepsilon) + \nu A\varepsilon_t : \varepsilon_t\right) dx.
\end{aligned}$$

Here we recall that

$$c_v \le c_v - \theta G''(\theta)H(\varepsilon) \le c_v + M\Lambda,$$

where $0 \le \sup_{\theta\ge 0}(-\theta G''(\theta)) =: M < \infty$. Then integrating the above inequality with respect to the time variable, we conclude that

$$\begin{aligned}
&\|\nabla\theta(t)\|^2_{L^2} + \frac{2k}{c_v + \Lambda M}\|\Delta\theta\|^2_{L^2(\Omega_T)} \\
&\quad\le \|\nabla\theta_0\|^2_{L^2} + \frac{k}{c_v + \Lambda M}\|\Delta\theta\|^2_{L^2(\Omega_T)} \\
&\qquad + \frac{c_v + \Lambda M}{k}\left\|\theta G'(\theta)\partial_t H(\varepsilon) + A\varepsilon_t : \varepsilon_t\right\|^2_{L^2(\Omega_T)} \\
&\quad\le \Lambda + \frac{k}{c_v + \Lambda M}\|\Delta\theta\|^2_{L^2(\Omega_T)} + \Lambda(M)\|\theta^r H_{,\varepsilon}(\varepsilon)\|_{L^4(\Omega_T)}\|\varepsilon_t\|_{L^4(\Omega_T)} \\
&\qquad + \Lambda(M)\|\varepsilon_t\|^2_{L^4(\Omega_T)} \\
&\quad\le \Lambda + \frac{k}{2(1+\Lambda M)}\|\Delta\theta\|^2_{L^2(\Omega_T)}
\end{aligned}$$

due to (4.10) and (4.11). Consequently, we obtain the first assertion.

With the help of Lemma 2.2, we also obtain estimate

$$\|\nabla\theta\|_{L^{10/3}(\Omega_T)} + \|\theta\|_{L^{10}(\Omega_T)} + \|\nabla\varepsilon\|_{L^{20}(\Omega_T)} \le \Lambda\left(\|\theta\|_{W^{2,1}_2(\Omega_T)} + \|\varepsilon\|_{W^{2,1}_4(\Omega_T)}\right) \le \Lambda,$$

which completes the proof. □

LEMMA 4.4. *Let T be arbitrary fixed and $p \in [20/9, 10/3]$ fixed. Assume that $\theta \geq 0$ a.e. in Ω_T and (1.6) holds. Then for any $(u_0, u_1, \theta_0) \in B^{4-2/p}_{p,p} \times B^{2-2/p}_{p,p} \times H^1 =: U_5(p)$, the solution (u, θ) to (1.2)–(1.5) satisfies*

$$\|u\|_{W^{4,2}_p(\Omega_T)} \leq \Lambda,$$

where Λ depends on T and $\|(u_0, u_1, \theta_0)\|_{U_5(p)}$.

Proof. Since the embedding $B^{4-\frac{2}{p}}_{p,p} \hookrightarrow B^{\frac{5}{2}}_{4,4}$ holds for any $\frac{20}{9} \leq p$, by Lemma 4.3 we find that

$$\begin{aligned}\|\varepsilon\|_{W^{2,1}_4(\Omega_T)} + \|\theta\|_{W^{2,1}_2(\Omega_T)} &\leq \Lambda \left(\|(u_0, u_1, \theta_0)\|_{B^{5/2}_{4,4} \times B^{1/2}_{4,4} \times H^1} \right) \\ &\leq \Lambda \left(\|(u_0, u_1, \theta_0)\|_{B^{4-2/p}_{p,p} \times B^{2-2/p}_{p,p} \times H^1} \right).\end{aligned}$$

For any $p \leq \frac{10}{3}$ we have

$$\begin{aligned}\|\nabla \cdot (G(\theta) H_{,\varepsilon}(\varepsilon))\|_{L^p(\Omega_T)} &\leq \Lambda \|\nabla \theta\|_{L^{10/3}(\Omega_T)} \|G'(\theta)\|_{L^\infty(\Omega_T)} \|H_{,\varepsilon}(\varepsilon)\|_{L^\infty(\Omega_T)} \\ &\quad + \Lambda \|\theta\|^r_{L^{10}(\Omega_T)} \|\nabla \varepsilon\|_{L^{20}(\Omega_T)} \|H_{,\varepsilon\varepsilon}(\varepsilon)\|_{L^\infty(\Omega_T)} \\ &\leq \Lambda\end{aligned}$$

and

$$\|\nabla \cdot \overline{H}_{,\varepsilon}(\varepsilon)\|_{L^p(\Omega_T)} \leq \Lambda \|\nabla \varepsilon\|_{L^{20}(\Omega_T)} \|\overline{H}_{,\varepsilon\varepsilon}(\varepsilon)\|_{L^\infty(\Omega_T)} \leq \Lambda,$$

thanks to Lemmas 4.2 and 4.3. Then from the maximal regularity (2.1) it follows that

$$\begin{aligned}\|u\|_{W^{4,2}_p(\Omega_T)} &\leq C \|(u_0, u_1, 0)\|_{U_5(p)} \\ &\quad + C(\|\nabla \cdot (G(\theta) H_{,\varepsilon}(\varepsilon))\|_{L^p(\Omega_T)} + \|\nabla \cdot \overline{H}_{,\varepsilon}(\varepsilon)\|_{L^p(\Omega_T)}) \\ &\leq \Lambda.\end{aligned}$$

This completes the proof. □

LEMMA 4.5. *Let T be arbitrary fixed, $l > 2$ integer, and $p \in (1, \infty)$. Assume that $\theta \geq 0$ a.e. in Ω_T and (1.6) holds. Then for any $(u_0, u_1, \theta_0) \in B^{17/5}_{10/3,10/3} \times B^{7/5}_{10/3,10/3} \times (L^l \cap H^1) =: U_6(l)$, the solution (u, θ) to (1.2)–(1.5) satisfies*

$$\|\theta\|_{L^\infty_T L^l_x} \leq \Lambda,$$

where $\Lambda = \Lambda(T, \|(u_0, u_1, \theta_0)\|_{U_6(l)})$. Moreover, if $(u_0, u_1, \theta_0) \in U_6(\infty)$, then

$$\|\theta\|_{L^\infty(\Omega_T)} \leq \Lambda,$$

where $\Lambda = \Lambda(T, \|(u_0, u_1, \theta_0)\|_{U_6(\infty)})$, and for $(u_0, u_1, \theta_0) \in (B^{3-2/p}_{p,p} \cap B^{17/5}_{10/3,10/3}) \times (B^{1-2/p}_{p,p} \cap B^{7/5}_{10/3,10/3}) \times (L^\infty \cap H^1) =: U_7(p)$, it holds that

$$\|\varepsilon\|_{W^{2,1}_p(\Omega_T)} \leq \Lambda,$$

where $\Lambda = \Lambda(T, \|(u_0, u_1, \theta_0)\|_{U_7(p)})$.

Proof. The same operation as in the proof of Lemma 3.3 yields

$$\begin{aligned}&\frac{c_v}{l} \frac{d}{dt} \|\hat{\theta}\|^l_{L^l} + k(l-1) \int_\Omega \theta^{l-2} |\nabla \theta|^2 dx \\ &\qquad = \int_\Omega \overline{G}_l(\theta) \partial_t H(\varepsilon) dx + \nu \int \theta^{l-1} A \varepsilon_t : \varepsilon_t dx.\end{aligned} \tag{4.13}$$

Here we recall that $G_l(\theta) = \theta^l G'(\theta) - \overline{G}_l(\theta)$, $\overline{G}_l(t) = l\int_0^\theta s^{l-1}G'(s)ds$ and

$$\hat{\theta} = \theta\left(1 - \frac{lG_l(\theta)H(\varepsilon)}{c_v\theta^l}\right)^{1/l} \geq \theta. \tag{4.14}$$

Since $\|H_{,\varepsilon}(\varepsilon)\|_{L^\infty(\Omega_T)} = \Lambda < \infty$ from (4.3), we have

$$\begin{aligned}\left|\int_\Omega \overline{G}_l(\theta)\partial_t H(\varepsilon)dx\right| &\leq C\|\theta^{l-1}\|_{L^1(\Omega)}\|\theta\|_{L^\infty(\Omega)}\|\varepsilon_t\|_{L^\infty(\Omega)}\|H_{,\varepsilon}(\varepsilon)\|_{L^\infty(\Omega)}\\ &\leq \Lambda\|\theta\|_{L^l(\Omega)}^{l-1}\|\theta\|_{H^2(\Omega)}\|\varepsilon_t\|_{L^\infty(\Omega)}.\end{aligned}$$

Therefore we conclude from (4.13) that

$$\frac{c_v}{l}\frac{d}{dt}\|\hat{\theta}\|_{L^l(\Omega)}^l \leq \Lambda\|\varepsilon_t\|_{L^\infty(\Omega)}\|\theta\|_{H^2(\Omega)}\|\theta\|_{L^l(\Omega)}^{l-1} + C\|\varepsilon_t\|_{L^\infty(\Omega)}^2\|\theta\|_{L^l(\Omega)}^{l-1}. \tag{4.15}$$

Here note that the equality $\partial_t\|\hat{\theta}\|_{L^l(\Omega)}^l = l\|\hat{\theta}\|_{L^l(\Omega)}^{l-1}\partial_t\|\hat{\theta}\|_{L^l(\Omega)}$, the Sobolev embedding, and Lemma 4.4 yield estimates

$$\begin{aligned}\|\varepsilon_t\|_{L_T^2L^\infty} \leq \Lambda\|\varepsilon_t\|_{L_T^2W^1_{10/3}} \leq \Lambda\|u\|_{W^{4,2}_{10/3}(\Omega_T)} \leq \Lambda,\\ \|\theta\|_{L_T^2H^2} \leq \|\theta\|_{W_2^{2,1}(\Omega_T)} \leq \Lambda,\end{aligned}$$

where Λ is independent of l. Thus, integrating (4.15) with respect to the time variable gives

$$\begin{aligned}\|\hat{\theta}\|_{L_T^\infty L^l} &\leq \|\hat{\theta}_0\|_{L^l} + \Lambda\|\varepsilon_t\|_{L_T^2L^\infty}\|\theta\|_{L_T^2H^2} + \Lambda\|\varepsilon_t\|_{L_T^2L^\infty}^2\\ &\leq \Lambda + \|\hat{\theta}_0\|_{L^l}.\end{aligned}$$

In view of the inequality $\hat{\theta}_0 \leq \theta_0\,(1 + lM\Lambda/c_v)^{1/l}$, the desired result can be obtained. For the $W_p^{2,1}$-norm of ε, we find that

$$\begin{aligned}\|\varepsilon\|_{W_p^{2,1}} &\leq C\|(u_0,u_1,0)\|_{U_7(p)} + \Lambda\|\theta\|_{L^\infty(\Omega_T)}^r\|H_{,\varepsilon}(\varepsilon)\|_{L^\infty(\Omega_T)} + \Lambda\|\overline{H}_\varepsilon(\varepsilon)\|_{L^\infty(\Omega_T)}\\ &\leq \Lambda\end{aligned}$$

for $p \in (1,\infty)$, by virtue of the maximal regularity (2.2). This completes the proof. □

Using again Lemma 3.4, we can also prove the Hölder continuity of θ. The Hölder continuity of ε is ensured on account of Lemma 2.2. Hence from Lemma 3.6 we can obtain the bounds in higher Sobolev norms; i.e., for $5 < p, q < \infty$,

$$\|(u,\theta)\|_{V_T(p,q)} = \|u\|_{W_p^{4,2}(\Omega_T)} + \|\theta\|_{W_q^{2,1}(\Omega_T)} \leq \Lambda =: \widehat{\Lambda}, \tag{4.16}$$

where $\widehat{\Lambda}$ is independent of L.

This a priori estimate says that if there exists a solution to problem $(\mathrm{TE})_3$ such that $\theta \geq 0$, then this solution satisfies estimate (4.16). Let us consider now problem $(\mathrm{TE})_3^L$ from section 3, assuming that the truncation size L is sufficiently large such that

$$\left|\nabla\cdot[G(\theta)H_{,\varepsilon}(\varepsilon) + \overline{H}_{,\varepsilon}(\varepsilon)]\right| \leq \widehat{\Lambda}^{K_1+r-1} + \widehat{\Lambda}^{K_2-1} \ll L.$$

In this case we may regard Γ_L as the identity operator because the internal part of Γ_L in (3.1) is smaller than L. Therefore the unique solution (u_L,θ_L) to $(\mathrm{TE})_3^L$ satisfies (4.16) for large L. In other words, the $V_T(p,q)$-norm bound for (u_L,θ_L) does not depend on L. Hence (u_L,θ_L) satisfies also the original system $(\mathrm{TE})_3$.

The positivity of θ follows by the same argument as the proof of Lemma 3.1 in [22]. This completes the proof of Theorem 1.1.

5. 2-D case. In this section we consider the solvability of 2-D system $(\mathrm{TE})_2$. We prove the following theorem.

THEOREM 5.1. *Fix $4 < p \le q < \infty$. Assume that $\min_\Omega \theta_0 \ge 0$, $\nu > 0$, and* (A) *with* (1.7). *Then for any $T > 0$ and $(u_0, u_1, \theta_0) \in U(p, q)$, there exists at least one solution (u, θ) to $(\mathrm{TE})_2$ satisfying $(u, \theta) \in V_T(p, q)$.*

Moreover, if we assume $\min_\Omega \theta_0 = \theta_* > 0$, then there exists a positive constant ω such that

$$\theta \ge \theta_* \exp(-\omega t) \qquad \text{in } \Omega_T.$$

THEOREM 5.2. *In addition to the assumptions of Theorem* 1.1, *suppose that $F(\varepsilon, \theta) \in \mathrm{C}^4(\mathbb{S}^2 \times \mathbb{R}^+, \mathbb{R})$. Then the solution $(u, \theta) \in V_T(p, q)$ to $(\mathrm{TE})_2$ constructed above is unique.*

Proof of Theorem 5.1. With the exception of a priori bounds, the result follows by the same procedure as in the proof of the 3-D case. Thus it remains to check the bounds corresponding to Lemmas 4.1, 4.2, and 4.3 under assumption (A) with (1.7).

LEMMA 5.3 (energy inequality). *Assume that $\theta \ge 0$ a.e. in Ω_T and* (1.7) *holds. Then for any $t \in [0, T]$ the smooth solution of $(\mathrm{TE})_2$ satisfies*

$$\|\theta(t)\|_{L^1(\Omega)} + \|u_t(t)\|_{L^2(\Omega)} + \|Qu(t)\|_{L^2(\Omega)} \le C(\|(u_0, u_1, \theta_0)\|_{H^2 \times L^2 \times L^1}).$$

Proof. The same operation as in the proof of Lemma 4.1 yields

$$\frac{d}{dt}\left(\frac{1}{2}\|u_t\|_{L^2}^2 + \frac{\kappa}{2}\|Qu\|_{L^2}^2 + c_v \int_\Omega \theta dx + \int_\Omega \overline{H}(\varepsilon) dx + \int_\Omega \overline{G}(\theta) H(\varepsilon) dx\right) = 0,$$

where $\overline{G}(\theta) = G(\theta) - \theta G'(\theta)$. Here we recall that $\theta \ge 0$, $H(\varepsilon) \ge 0$, and $\overline{G}(\theta) \ge 0$. Consequently, it follows from (A)(iii) that

$$\begin{aligned}
&\frac{1}{2}\|u_t\|_{L_T^\infty L^2}^2 + \frac{\kappa}{2}\|u\|_{L_T^\infty H^2}^2 + c_v \|\theta\|_{L_T^\infty L^1} \\
&\quad \le \frac{\kappa}{2}\|u_0\|_{H^2}^2 + \frac{1}{2}\|u_1\|_{L^2}^2 + c_v\|\theta_0\|_{L^1} + \int_\Omega \left\{|\overline{H}(\varepsilon_0)| + |\overline{G}(\theta_0) H(\varepsilon_0)|\right\} dx + C_3|\Omega|,
\end{aligned}$$

where $\varepsilon_0 = \varepsilon(u_0)$. From the Sobolev embedding it holds that

$$\|\varepsilon_0\|_{L^s(\Omega)} \le C\|u_0\|_{H^2(\Omega)} \tag{5.1}$$

for any $s \in [1, \infty)$. Then we have

$$\begin{aligned}
\int_\Omega |\overline{G}(\theta_0) H(\varepsilon_0)| dx &\le C\|\theta_0\|_{L^1(\Omega)}^r \|\varepsilon_0\|_{L^{\frac{K_1}{1-r}}(\Omega)}^{K_1} \\
&\le C\|\theta_0\|_{L^1(\Omega)}^r \|u_0\|_{H^2}^{K_1}
\end{aligned}$$

for $r < 1$ and $K_1 < \infty$, and

$$\begin{aligned}
\int_\Omega \overline{H}(\varepsilon_0) dx &\le \|\varepsilon_0\|_{L^{K_2}}^{K_2} \\
&\le C\|u_0\|_{H^2}^{K_2}
\end{aligned}$$

for $K_2 < \infty$. This completes the proof. ∎

LEMMA 5.4. *Let T and $p \in [2,4)$ be fixed. Assume that* (1.7) *holds. Then for any* $(u_0, u_1, \theta_0) \in B^{3-2/p}_{p,p} \times B^{1-2/p}_{p,p} \times L^2 =: U_3'(p)$, *the solution* (u, θ) *to* $(\mathrm{TE})_2$ *satisfies*

$$\|\varepsilon\|_{W^{2,1}_p(\Omega_T)} + \|\nabla\theta\|_{L^2(\Omega_T)} + \|\theta\|_{L^\infty_T L^2} \le \Lambda, \tag{5.2}$$

where Λ *depends on* T *and* $\|(u_0, u_1, \theta_0)\|_{U_3'(p)}$. *Moreover, we have*

$$\|\varepsilon\|_{L^\infty(\Omega_T)} + \|\theta\|_{L^p(\Omega_T)} \le \Lambda. \tag{5.3}$$

Proof. We first show (5.2) for p such that $p < 3$. From the Sobolev inequality (5.1) and Lemma 5.3, it follows that

$$\|\varepsilon\|_{L^s(\Omega_T)} \le \Lambda \|u\|_{L^\infty_T H^2} \le \Lambda$$

for every $s < \infty$, and hence we obtain

$$\|H_{,\varepsilon}\|_{L^s(\Omega_T)} + \|\overline{H}_{,\varepsilon}\|_{L^s(\Omega_T)} \le \Lambda \tag{5.4}$$

for any K_1, $K_2 < \infty$. Moreover, by using the Hölder inequality, we have

$$\|\theta\|_{L^p(\Omega_T)} \le C \left\| \|\theta\|^{1-2/p}_{L^1} \|\theta\|^{2/p}_{L^{2/(3-p)}} \right\|_{L^p_T} \le C \|\theta\|^{1-2/p}_{L^\infty_T L^1} \|\theta\|^{2/p}_{L^2_T H^1} \le \Lambda \|\theta\|^{2/p}_{L^2_T H^1} \tag{5.5}$$

for $p \in [2,3)$.

We fix $\bar{p}$ such that $r + 2 < \bar{p} < 3$. From (5.4), (5.5), and the maximal regularity (2.2) it follows that

$$\begin{aligned}
&\|\varepsilon\|_{W^{2,1}_{\bar{p}}(\Omega_T)} \\
&\quad \le C\|(u_0, u_1, \theta_0)\|_{U_3'(\bar{p})} + C\|G(\theta)H_{,\varepsilon}(\varepsilon)\|_{L^{\bar{p}}(\Omega_T)} + C\|\overline{H}_{,\varepsilon}(\varepsilon)\|_{L^{\bar{p}}(\Omega_T)} \\
&\quad \le \Lambda + C\|\theta\|^r_{L^{\bar{p}}(\Omega_T)} \|H_{,\varepsilon}(\varepsilon)\|_{L^{\frac{\bar{p}}{(1-r)}}(\Omega_T)} + C\|\overline{H}_{,\varepsilon}(\varepsilon)\|_{L^{\bar{p}}(\Omega_T)} \\
&\quad \le \Lambda + \Lambda \|\theta\|^{\frac{2r}{\bar{p}}}_{L^2_T H^1}.
\end{aligned} \tag{5.6}$$

Next, the same operation as in the proof of Lemma 4.2 yields

$$\begin{aligned}
&\frac{c_v}{2}\|\theta\|^2_{L^\infty_T L^2} + k\|\nabla\theta\|^2_{L^2(\Omega_T)} \\
&\quad \le \frac{c_v}{2}\|\theta_0\|^2_{L^2} + \|\overline{G}_2(\theta)\partial_t H(\varepsilon)\|_{L^1(\Omega_T)} + \nu\|\theta A\varepsilon_t : \varepsilon_t\|_{L^1(\Omega_T)} \\
&\qquad + M \sup_{t\in[0,T]} \int_{\Omega_T} |H(\varepsilon(t))|dx + \int_\Omega |G_2(\theta_0)H(\varepsilon_0)|dx.
\end{aligned}$$

By (5.4), (5.5), and (5.6) we have

$$\begin{aligned}
\|\theta^{r+1}\partial_t H(\varepsilon)\|_{L^1(\Omega_T)} &\le \Lambda \|\theta\|^{r+1}_{L^{\bar{p}}(\Omega_T)} \|\varepsilon\|_{W^{2,1}_{\bar{p}}(\Omega_T)} \|H_{,\varepsilon}(\varepsilon)\|_{L^{\frac{\bar{p}}{\bar{p}-(r+2)}}(\Omega_T)} \\
&\le \Lambda \|\theta\|^{\frac{2(r+1)}{\bar{p}}}_{L^2_T H^1} \left(\Lambda + \|\theta\|^{\frac{2r}{\bar{p}}}_{L^2_T H^1} \right)
\end{aligned}$$

for $\bar{p} > r+2$,

$$\begin{aligned}\|\theta A\varepsilon_t : \varepsilon_t\|_{L^1(\Omega_T)} &\le \Lambda\|\theta\|_{L^{\bar{p}}(\Omega_T)}\|\varepsilon_t\|^2_{L^{\frac{2\bar{p}}{\bar{p}-1}}(\Omega_T)} \\ &\le \Lambda\|\theta\|^{\frac{2}{\bar{p}}}_{L^2_T H^1}\left(\Lambda + \|\theta\|^{\frac{4r}{\bar{p}}}_{L^2_T H^1}\right),\end{aligned}$$

$$\int_\Omega |H(\varepsilon(t))|dx \le C\|u(t)\|^{K_1}_{H^2} \le \Lambda,$$

and

$$\begin{aligned}\|\theta_0^{r+1}H(\varepsilon_0)\|_{L^1(\Omega)} &\le C\|\theta_0\|^{r+1}_{L^2(\Omega)}\|\varepsilon_0\|^{K_1}_{L^{\frac{2K_1}{1-r}}(\Omega)} \\ &\le C\|\theta_0\|^{r+1}_{L^2(\Omega)}\|u_0\|^{K_1}_{H^2(\Omega)}.\end{aligned}$$

Consequently, we arrive at

$$\|\theta\|^2_{L^\infty_T L^2} + \|\nabla\theta\|^2_{L^2(\Omega_T)} \le \Lambda(\|(u_0,u_1,\theta_0)\|_{U_3'(p)}) + \Lambda\|\theta\|^{\frac{2(2r+1)}{\bar{p}}}_{L^2_T H^1}.$$

Since $2r+1 < r+2 < \bar{p}$, by using the Young inequality we have

$$\|\theta\|_{L^\infty_T L^2} + \|\nabla\theta\|_{L^2(\Omega_T)} \le \Lambda(\|(u_0,u_1,\theta_0)\|_{U_3'(p)}). \tag{5.7}$$

Substituting (5.7) into (5.6), we obtain (5.2) for $p < 3$.

We shall show the rest of the proof. Taking $p \in [2,4)$, by the same operation as (5.5) we have

$$\|\theta\|_{L^p(\Omega_T)} \le C\|\theta\|^{1-2/p}_{L^\infty_T L^2}\|\theta\|^{2/p}_{L^2_T H^1} \le \Lambda$$

for $p < 4$ thanks to (5.7). Then from (2.2) we conclude that

$$\begin{aligned}\|\varepsilon\|_{W^{2,1}_p} &\le \Lambda + \|\theta\|^r_{L^p}\|H_{,\varepsilon}(\varepsilon)\|_{L^{\frac{p}{(1-r)}}} + \|\overline{H}_{,\varepsilon}(\varepsilon)\|_{L^p} \\ &\le \Lambda.\end{aligned}$$

This completes the proof. □

LEMMA 5.5. *Let T be any fixed. Assume that* (1.7) *holds. Then for any $(u_0,u_1,\theta_0) \in B^{5/2}_{4,4} \times B^{1/2}_{4,4} \times H^1 = U_4'$ the following estimate holds:*

$$\|\varepsilon\|_{W^{2,1}_4(\Omega_T)} + \|\nabla\theta\|_{L^\infty_T L^2} + \|\theta\|_{W^{2,1}_2(\Omega_T)} \le \Lambda,$$

where constant Λ depends on T and $\|(u_0,u_1,\theta_0)\|_{U_4'}$. Moreover, we have

$$\|\nabla\theta\|_{L^4(\Omega_T)} + \|\theta\|_{L^s(\Omega_T)} + \|\nabla\varepsilon\|_{L^s(\Omega_T)} \le \Lambda$$

for any $s < \infty$.

Proof. It follows from Lemma 5.4 and (2.2) that

$$\begin{aligned}\|\varepsilon\|_{W^{2,1}_4(\Omega_T)} &\le C\|(u_0,u_1,\theta_0)\|_{U_4'} + C\|\theta\|^r_{L^{4r}}\|H_{,\varepsilon}(\varepsilon)\|_{L^\infty(\Omega_T)} \\ &\quad + C\|\overline{H}_{,\varepsilon}(\varepsilon)\|_{L^\infty(\Omega_T)} \\ &\le \Lambda\end{aligned} \tag{5.8}$$

thanks to $r < 1$. The same operation as in the proof of Lemma 4.3 yields

$$\begin{aligned} c_v\|\theta_t\|^2_{L^2(\Omega_T)} + \frac{k}{2}\|\nabla\theta\|^2_{L^\infty_T L^2} &\le \frac{k}{2}\|\theta_0\|^2_{H^1} + C\|\theta_t\|_{L^2(\Omega_T)}\|\theta^r H_{,\varepsilon}(\varepsilon)\|_{L^4(\Omega_T)}\|\varepsilon_t\|_{L^4(\Omega_T)} \\ &\quad + C\|\theta_t\|_{L^2(\Omega_T)}\|\varepsilon_t\|^2_{L^4(\Omega_T)} \\ &\le \Lambda + \frac{c_v}{2}\|\theta_t\|^2_{L^2(\Omega_T)} \end{aligned}$$

on account of (5.3) and (5.8). Therefore, we arrive at the estimate

$$\|\varepsilon\|_{W^{2,1}_4(\Omega_T)} + \|\theta_t\|_{L^2(\Omega_T)} + \|\nabla\theta\|_{L^\infty_T L^2} \le \Lambda(\|(u_0, u_1, \theta_0)\|_{U'_4}).$$

Moreover, applying the same argument as in the proof of Lemma 4.3, we get

$$\|\Delta\theta\|_{L^2(\Omega_T)} \le \Lambda.$$

This completes the proof of the first assertion. With the help of Lemma 2.2 we obtain the second assertion. This completes the proof of Lemma 5.5. □

From a modification similar to that presented in section 4 we can derive the estimate

$$\|(u,\theta)\|_{V_T(p,q)} = \|u\|_{W^{4,2}_p(\Omega_T)} + \|\theta\|_{W^{2,1}_q(\Omega_T)} \le \Lambda.$$

Hence the proof of Theorem 5.1 are completed. □

NONLINEAR ASYMPTOTIC STABILITY OF THE SEMISTRONG PULSE DYNAMICS IN A REGULARIZED GIERER–MEINHARDT MODEL*

ARJEN DOELMAN†, TASSO J. KAPER‡, AND KEITH PROMISLOW§

Abstract. We use renormalization group (RG) techniques to prove the nonlinear asymptotic stability for the semistrong regime of two-pulse interactions in a regularized Gierer–Meinhardt system. In the semistrong limit the localized activator pulses interact strongly through the slowly varying inhibitor. The interaction is not tail-tail as in the weak interaction limit, and the pulse amplitudes and speeds change as the pulse separation evolves on algebraically slow time scales. In addition the point spectrum of the associated linearized operator evolves with the pulse dynamics. The RG approach employed here validates the interaction laws of quasi-steady two-pulse patterns obtained formally in the literature, and establishes that the pulse dynamics reduce to a closed system of ordinary differential equations for the activator pulse locations. Moreover, we fully justify the reduction to the nonlocal eigenvalue problem (NLEP) showing that the large difference between the quasi-steady NLEP operator and the operator arising from linearization about the pulse is controlled by the resolvent.

1. Introduction.

Pulse solutions are the building blocks for the analysis of complex patterns in reaction-diffusion equations. Within the proper scaling limit, the dynamics exhibited by many reaction-diffusion systems is governed by the interactions of localized solutions of pulse type. A prototypical example is given by the spatio-temporal chaotic dynamics of the one-dimensional Gray–Scott system for which numerical simulations indicate that the chaotic dynamics originate from the interactions and bifurcations of pulse solutions [13].

In the context of singularly perturbed equations in one spatial dimension, there is a well-developed literature addressing the existence and stability of stationary pulse solutions based on the geometric singular perturbation theory and the Evans function methods (see [15, 5] and the references therein). There is no such general theory for pulse interactions. In fact, strong pulse interactions, and especially the phenomena of pulse-replication and annihilation, have been studied computationally, but are not yet understood mathematically. On the other hand, there are methods to study the behavior of pulses in the weak interaction limit where the pulses are so greatly separated that they can be considered at leading order as copies of a solitary pulse. In this regime the exponentially weak interactions affect only the position of the pulses and have no leading order influence on their shape or stability (see [8, 9, 14, 15] and

the references therein).

Recently, an intermediate concept has been introduced in the context of singularly perturbed equations, the semistrong interaction case (see [6, 16] and the references therein). The semistrong regime exists in systems whose components decay at asymptotically distinct rates, so that some of the components of the system approach the trivial background state between pulses, while others do not. Moreover, the pulse positions, amplitudes, and shapes change at rates that are algebraically small in the perturbation parameter (see Figure 1.1) and may bifurcate due to the interactions [6, 16].

Up to now the semistrong pulse interaction has only been studied formally (see Remark 1.3). In this paper we show that the semistrong interaction fits naturally into the framework of the renormalization group (RG) methods developed to study the stability of slowly evolving patterns [14, 12]. For the Gierer–Meinhardt equations, the geometric singular perturbation theory shows that the activator-inhibitor interaction reduces the highly diffusive inhibitor to a local constant within each activator pulse. The value of this constant determines the activator pulse interactions, in particular causing the pulse amplitudes to depend upon the pulse positions, which evolve on an $\mathcal{O}(\frac{1}{\varepsilon^4})$ time scale. The RG analysis makes these statements rigorous, in particular fully justifying the reductions made in the nonlocal eigenvalue problem (NLEP) analysis which arises in the linear stability analysis of the pulses.

The singular perturbation theory typically constructs a family of pulse type patterns which are approximate solutions of a given system of equations [2, 3, 6, 11, 16]. The solutions are characterized by parameters $\vec{p} \in \mathbb{R}^k$, which are often—but not exclusively—pulse locations. The linearizing about the global manifold of slowly evolving pulse patterns for a particular choice of parameters $\vec{p}$ allows one to decompose the phase space into tangential (or active) and normal (or decaying) modes. In the RG approach, rather than using the exact linearization, reduced linearized operators are identified at a discrete family of base points on the manifold. These form a loose covering of approximate tangent planes, much like the scales of a fish form a piecewise linear envelope of the underlying body. In the current setting this

gives two specific advantages: first, in a neighborhood of each base point we identify a temporally constant linearized operator and associated phase space decomposition, and second, we are free to modify the governing linear operator in ways that simplify the analysis. For the Gierer–Meinhardt equations, the singularly perturbed structure of the linearized operators makes them strongly contractive on certain regions of the phase space. This permits a nontrivial replacement of spatially varying potentials with delta functions, affording dramatic simplification to the analysis of the principle linear operator. Indeed we replace the exact linearization with a putatively $\mathcal{O}(\varepsilon^{-2})$ "perturbation." This reduced linear operator gives rise to exactly the NLEP operators introduced previously in the formal linear stability analysis, [2, 6, 16], and justifies the observation that, at the linear level, the inhibitor equation averages perturbations into a mean-field.

The RG method shows that the NLEP operators control the flow in a neighborhood of the pulse configurations, generating a thin absorbing set in the phase space. Moreover, we recover the leading order pulse evolution by projecting the flow onto the tangent plane of the manifold of two-pulse solutions. In this paper we consider only two-pulse solutions. Although there are no new conceptual features, the generalization to N-pulses is technical. In particular, determining the amplitudes of each pulse within an N-pulse configuration requires a nontrivial nonlinear computation, and the stability of the underlying pattern will depend sensitively upon the pulse amplitudes and separations. These issues have been studied numerically in [11] and the construction and interaction of N-pulses on bounded domains has been considered in [16]. However, the nonlinear aspects of the stability approach we developed here generalizes directly from the two-pulse to the N-pulse case. Our methods can also be applied to the weak and semistrong N-pulse interactions in classes of singularly perturbed reaction-diffusion equations as considered in [6] and in [17] on bounded domains. Nevertheless, interesting additional issues may emerge in specific settings, such as the semistrong evolution of pulses in the Gray–Scott equation (see [4]) in which the essential spectrum is asymptotically close to the origin.

The main result of this paper addresses the semistrong evolution of two-pulse solutions Φ, given in (2.5), of the regularized Geirer–Meinhardt equation (2.3). The solutions are parameterized by pulse positions $\Gamma = (\Gamma_1, \Gamma_2)^t$, with pulse separation $\Delta\Gamma = |\Gamma_1 - \Gamma_2|$. In the application at hand the RG approach models the impact of transient initial perturbations on the semistrong pulse evolution, and after the decay of the transients, recovers the formal pattern evolution at leading order. For the Gierer–Meinhardt equation the semistrong regime is comprised of pulses whose separations satisfy $\Delta\Gamma > \Delta\Gamma^*(\mu)$, where $\Delta\Gamma^* = \mathcal{O}(\varepsilon^{-2})$ is defined in (3.37) of Proposition 3.4. For $\Delta\Gamma < \Delta\Gamma^*$ one enters the strong interaction regime, where the two-pulse solution has quasi-stationary eigenvalues which are incompatible with the two-pulse manifold, and pulse splitting bifurcations are observed. Our approach works uniformly for the weak, $\Delta\Gamma \gg \varepsilon^{-2}$, and semistrong interactions, recovering prior results [8, 9, 14, 15], for the weak interaction limit.

We introduce the norm $\|\cdot\|_X$ on $H^1 \times H^1$ defined by

$$\|G\|_X = \varepsilon\|G_1\|_{L^2} + \varepsilon^{-1}\|\partial_\xi G_1\|_{L^2} + \|G_2\|_{H^1}, \tag{1.1}$$

and remark that it controls the L^∞ norm uniformly,

$$\|G_1\|_{L^\infty} \leq (2\|G_1\|_{L^2}\|\partial_\xi G_1\|_{L^2})^{\frac{1}{2}} \leq \varepsilon\|G_1\|_{L^2} + \varepsilon^{-1}\|\partial_\xi G_1\|_{L^2} \leq \|G\|_X. \tag{1.2}$$

We next state our main theorem for the pulses in the semistrong interaction regime.

THEOREM 1.1. *Let ε be sufficiently small, let $\mu > \mu_{\rm Hopf}$, and let the pulse separation satisfy $\Delta\Gamma > \Delta\Gamma^*(\mu)$, where $\mu_{\rm Hopf}$ and $\Delta\Gamma^*(\mu)$ are given in Proposition* 3.4. *The manifold $\mathcal{M}$ of two-pulse solutions* (2.6) *of the regularized Gierer–Meinhardt equation* (2.3) *is asymptotically exponentially stable up to $\mathcal{O}(\varepsilon^3)$. That is, there exists M and $\nu > 0$, independent of ε, such that for all initial data $\vec{U}_0$ sufficiently close to the $\mathcal{M}$, the corresponding solution $\vec{U} = (U, V)^t$ of the regularized Gierer–Meinhardt equations can be decomposed as*

$$\vec{U}(\xi, t) = \Phi_\Gamma + W(\xi, t), \tag{1.3}$$

where the parameters $\Gamma(t)$ of the two-pulse solution Φ evolve at leading order according to (4.17). *Moreover, the remainder W satisfies*

$$\|W\|_X \leq M(e^{-\nu t}\|W_0\|_X + \varepsilon^3). \tag{1.4}$$

In particular, after the perturbation W has decayed to $\mathcal{O}(\varepsilon^3)$, the pulse evolution is given by the ordinary differential equations (4.75) *which are equivalent at leading order to*

$$\frac{d}{dt}\Delta\Gamma = \varepsilon^2\sqrt{\mu}\frac{e^{-\varepsilon^2\Delta\Gamma\sqrt{\mu}}}{1 + e^{-\varepsilon^2\Delta\Gamma\sqrt{\mu}}}. \tag{1.5}$$

Since the pulses are repelling, Theorem 1.1 governs the evolution of all two-pulse solutions in the semistrong or the weak interaction regime. That is, any two-pulse solutions with $\Delta\Gamma(0) > \Delta\Gamma^*(\mu)$ will evolve according to (1.5) for all subsequent time.

Remark 1.2. The pulse dynamics (1.5) were obtained formally in [6].

Remark 1.3. In [2, 3], slowly-modulated two-pulse solutions were constructed for the Gray–Scott model on the infinite line, along with ODEs for the pulse positions, using the method of multiple scales. Various bifurcations, including the bifurcation to self-replicating two-pulse solutions, were identified. Moreover, the NLEP method, which was initially developed for studying the stability of stationary, one-pulse solutions (see [5] and the references therein) was (formally) extended in [2] to the stability analysis of two-pulse solutions. For the generalized Gierer–Meinhardt equations on bounded domains, [11] presents ODEs for N-spike quasi-equilibrium solutions in the semistrong and weak interaction regimes. Also, the NLEP method is employed to formally derive explicitly computable stability criterions. Further formal study of the instabilities (competition and oscillatory) for two-pulse solutions of the Gierer–Meinhardt equations has been reported in [16]. The analysis is primarily on a bounded domain, and results for the infinite line—some of which extend those reported in [2, 3]—are obtained by taking the domain to be large. Semistrong pulse interactions have also been studied in [6] for a large class of reaction-diffusion equations, including for the generalized Gierer–Meinhardt equations the Gray–Scott model, the Thomas equations, the Schnakenberg model, and others. Conditions were derived to determine formally whether adjacent pulses attract or repel, and the interactions between stationary and dynamically-evolving N-pulse solutions were studied.

2. The two-pulse solutions of the Gierer–Meinhardt equations. As proposed the Gierer–Meinhardt model, [10], has an artificial singularity in its nonlinear term, which suggests infinite production of the activator, V, in the absence of the inhibitor, U. While the singular model can be studied by working with exponentially weighted norms which preserve positivity of the inhibitor, the behavior of the

model for small concentrations bears little resemblance to chemical reality. Moreover, the singularity has an exponentially small impact on both the two-pulse construction and their evolution. To avoid clouding the analysis, we truncate the superfluous singularity of the Gierer–Meinhardt reaction term, replacing it with a variation of the classic Rice–Hertzfeld mechanism typical of complex reactions with inhibition steps; see chapter 26 of [1]. In the slow spatial variable x, the regularized Gierer–Meinhardt equation is given by

$$\begin{cases} U_t = \frac{1}{\varepsilon^2} U_{xx} - \mu U + \frac{1}{\varepsilon^2} V^2, \\ V_t = \varepsilon^2 V_{xx} - V + \frac{V^2}{\kappa(U)}, \end{cases} \tag{2.1}$$

where $U(x,t), V(x,t) : \mathbb{R} \times \mathbb{R}^+ \to \mathbb{R}$, $\mu > 0$ is the main (bifurcation) parameter, and $\varepsilon > 0$ is asymptotically small, $0 < \varepsilon \ll 1$. The regularizing function κ takes the form

$$\kappa(s) = \begin{cases} s & \text{if } s > 2\delta, \\ \delta & \text{if } 0 < s < \delta, \end{cases} \tag{2.2}$$

and is smooth for $s \in (\delta, 2\delta)$, with derivative uniformly less than two. In the absence of the inhibitor, U, the production rate of the activator V reduces to V^2/δ, where δ is a small parameter. The regularization introduces an $\mathcal{O}(e^{-\varepsilon^{-2}|\ln \delta|})$ perturbation to the pulse dynamics. The fast spatial scale is defined by $\xi = \frac{x}{\varepsilon}$, so that (2.1) transforms into

$$\begin{cases} U_t = \frac{1}{\varepsilon^4} U_{\xi\xi} - \mu U + \frac{1}{\varepsilon^2} V^2, \\ V_t = V_{\xi\xi} - V + \frac{V^2}{\kappa(U)}. \end{cases} \tag{2.3}$$

We denote the right-hand side of (2.3) by $F(U,V)$. Since the regularizing term has only an exponentially small impact on the pulse construction we carry over the asymptotic results for the singular Gierer–Meinhardt equation without modification.

PROPOSITION 2.1. *The construction and spectral analysis of pulse solutions for the classical GM model given in* [5] *and the construction and formal dynamics of semistrong two-pulses given in* [6] *hold up to exponentially small terms for the regularized models* (2.1)–(2.3).

2.1. Notation. We write $f = g + \mathcal{O}(\varepsilon)$ in norm $\|\cdot\|$ if

$$\|f - g\| \leq c\varepsilon, \tag{2.4}$$

and assume the $\|\cdot\|_X$ norm if no norm is specified. The solution (U,V) of the Gierer–Meinhardt equation is denoted $\vec{U}$. The two-pulse solutions are denoted by $\Phi_\Gamma = (U_0 + \varepsilon^2 U_2 + \cdots, V_0 + \varepsilon^2 V_2 + \cdots)^t$, while the initial data of the Gierer–Meinhardt equation is given by $\vec{U}_0$. We denote by $\|f\|_{\widehat{L}^p}$ and $\|f\|_{\widehat{H}^2}$ the L^p and H^2 norms of the Fourier transform of f. We remark that $\|f\|_{L^\infty} \leq c\|f\|_{\widehat{L}^1}$ and, conversely, $\|f\|_{\widehat{L}^\infty} \leq c\|f\|_{L^1}$, and, in particular, that the delta function resides in $\widehat{L}^\infty$ but is not in L^1. Also the norm $\|\langle x\rangle f\|_{L^1}$ with $\langle x\rangle \equiv 1 + |x|$ controls the L^∞ norm of the derivative of the Fourier transform of f. We denote the mass of a function f by $\overline{f} = \int_{-\infty}^{\infty} f \, d\xi$. The quantity $[\vec{F}]_k$ will denote the kth component of the vector $\vec{F}$ when less cumbersome notation is not available.

2.2. Asymptotic pulse solutions. Within the semistrong pulse regime the two pulses interact strongly through the inhibitor component, U, and weakly through the activator, V. The asymptotic family of semistrong two-pulse solutions is parameterized by the pulse location $\Gamma \in \mathcal{K} = \{(\Gamma_1, \Gamma_2) \Big| \Gamma_1 < \Gamma_2, |\Gamma_1 - \Gamma_2| \geq \Delta\Gamma^*(\mu)\}$, where $\Delta\Gamma^*(\mu)$ is defined in Proposition 3.4. We denote the two-pulse solution by $\Phi_\Gamma(\xi)$ which we expand as

$$\Phi_\Gamma(\xi) = \begin{pmatrix} \Phi_{\Gamma,1} \\ \Phi_{\Gamma,2} \end{pmatrix} = \begin{pmatrix} U_0(\xi;\Gamma) + \varepsilon^2 U_2(\xi;\Gamma) + \varepsilon^4 U_4(\xi;\Gamma) \\ V_0(\xi;\Gamma) + \varepsilon^2 V_2(\xi;\Gamma) \end{pmatrix}, \tag{2.5}$$

and define the manifold $\mathcal{M} \subset H^1 \times H^1$ of two-pulse solutions by

$$\mathcal{M} = \{\Phi_\Gamma \big| \Gamma \in \mathcal{K}\}. \tag{2.6}$$

We first describe the leading order terms $(U_0, V_0)^t$ which were derived in [6]. Full resolution of the pulse dynamics of the renormalization procedure of section 4 requires a more accurate description of the two-pulse solution which requires the construction of the higher order corrections, outlined in Lemma 2.1.

The V-components of the two-pulse solutions are centered around the pulse-positions $\xi = \Gamma_k(t)$, where

$$\Gamma_1(t) = \Gamma_0 - \varepsilon^2 \int_0^t \hat{c}(s)ds, \;\; \Gamma_2(t) = \Gamma_0 + \varepsilon^2 \int_0^t \hat{c}(s)ds. \tag{2.7}$$

In the two-pulse configuration each pulse moves away from their mutual center Γ_0 with equal and opposite speed given by

$$\hat{c} = \frac{1}{2}\sqrt{\mu} \frac{e^{-\varepsilon^2 \Delta\Gamma\sqrt{\mu}}}{1 + e^{-\varepsilon^2 \Delta\Gamma\sqrt{\mu}}}, \tag{2.8}$$

where $\Delta\Gamma = \Delta\Gamma(t) = |\Gamma_1 - \Gamma_2|$; see (1.5).

The leader order term, V_0, of the V component of Φ_Γ is given by the sum of two one-pulses

$$V_0(\xi;\Gamma(t)) = \phi_1 + \phi_2, \tag{2.9}$$

where for $k = 1, 2$ the one-pulse solution is

$$\phi_k(\xi) = \frac{3}{2} A(\Gamma) \operatorname{sech}^2 \frac{1}{2}(\xi - \Gamma_k(t)). \tag{2.10}$$

A key distinction between the semistrong interaction depicted here and the weak pulse interaction is that the pulse amplitude, $A(\Gamma)$, depends nontrivially upon the pulse separation, $\Delta\Gamma = |\Gamma_1 - \Gamma_2|$, via

$$A(\Gamma) = \frac{\sqrt{\mu}}{3} \frac{1}{1 + e^{-2\varepsilon^2 \Delta\Gamma\sqrt{\mu}}}. \tag{2.11}$$

The pulse regions $\mathcal{I}_k = \mathcal{I}_k(t)$, $k = 1, 2$, are defined as regions outside which V_0 is exponentially small, and such that U_0 remains constant at leading order over a pulse region. We set the width of the pulse regions to be $\mathcal{O}(1/\sqrt{\varepsilon})$, i.e., we define

$$\mathcal{I}_k = \left(\Gamma_k(t) - \frac{1}{\sqrt{\varepsilon}}, \Gamma_k(t) + \frac{1}{\sqrt{\varepsilon}}\right), \;\; k = 1, 2. \tag{2.12}$$

The choice of pulse region width is somewhat arbitrary but standard. Another distinguishing feature of the semistrong pulse interaction is that the slowly varying U-component of Φ_Γ is not the sum of two one-pulses. To the left of $\mathcal{I}_1$ and to the right of $\mathcal{I}_2$, $U_0(x,t)$ decays slowly, while in the region between $\mathcal{I}_1$ and $\mathcal{I}_2$ it is cosh-like, but again on the slow, spatial scale,

(2.13)
$$U_0(\xi;\Gamma) = \begin{cases} Ae^{\varepsilon^2\sqrt{\mu}(\xi-\Gamma_1)} & \text{for } \xi < \Gamma_1 - \varepsilon^{-\frac{1}{2}}, \\ A\dfrac{\cosh \varepsilon^2\sqrt{\mu}\,(\xi - (\Gamma_1+\Gamma_2)/2)}{\cosh \varepsilon^2\sqrt{\mu}\Delta\Gamma/2} & \text{for } \Gamma_1 + \varepsilon^{-\frac{1}{2}} < \xi < \Gamma_2 - \varepsilon^{-\frac{1}{2}}, \\ Ae^{-\varepsilon^2\sqrt{\mu}(\xi-\Gamma_2)} & \text{for } \Gamma_2 + \varepsilon^{-\frac{1}{2}} < \xi. \end{cases}$$

As defined above, U_0 would be nonsmooth if extended into the pulse regions $\mathcal{I}_k$. Rather we define the U-component of the two-pulse solution inside $\mathcal{I}_k$ as $U_0+\varepsilon^2 U_2(\xi)$, where $U_0 \equiv A$, and $U_2(\xi)$ is a solution of $U_{\xi\xi} + \phi_k^2 = 0$; see (2.3). Using (2.13) as boundary or matching conditions and the pulse amplitude (2.11), we find

(2.14)
$$U_0 + \varepsilon^2 U_2(\xi;\Gamma) = A + \varepsilon^2 \begin{cases} A[\sqrt{\mu} - 3A](\xi - \Gamma_1) - \int_{\Gamma_1}^{\xi}\int_{\Gamma_1}^{\xi_1} \phi_1^2(\xi_2)\,d\xi_2\,d\xi_1 & \text{for } \xi \in \mathcal{I}_1, \\ A[\sqrt{\mu} - 3A](\xi - \Gamma_2) - \int_{\Gamma_2}^{\xi}\int_{\Gamma_2}^{\xi_1} \phi_2^2(\xi_2)\,d\xi_2\,d\xi_1 & \text{for } \xi \in \mathcal{I}_2, \end{cases}$$

which gives that $U_0 + \varepsilon^2 U_2(\xi) \in C^1 \cap H^2$. The C^1-smoothness of $U_0 + \varepsilon^2 U_2(\xi)$ is equivalent to the amplitude-pulse separation relation (2.11), i.e. $U_0 + \varepsilon^2 U_2(\xi)$ can be smooth only for $A(\Gamma)$ given by (2.11).

Relations (2.7), (2.8), (2.9), (2.10), (2.11), (2.13), and (2.14) give a leading order description of the two-pulse solution $\Phi_\Gamma(\xi)$. The corrections $U_4(\xi)$ and $V_2(\xi)$ can be obtained by a straightforward regular asymptotic expansion and are both defined only in the pulse regions $\mathcal{I}_{1,2}$ (see (2.23) in the proof of Lemma 2.1 below). The residual of Φ_Γ,

$$\mathbf{R} = \mathbf{F}(\Phi_\Gamma) = \begin{pmatrix} F_1(\Phi_\Gamma) \\ F_2(\Phi_\Gamma) \end{pmatrix}, \tag{2.15}$$

is determined by the right-hand side of (2.3), denoted by $(F_1, F_2)^t$, evaluated at Φ_Γ. Obtaining L^1- and L^2-estimates on the residual is a key step to controlling the remainder in the renormalization process.

LEMMA 2.1. *For the residual* $\mathbf{R} = \mathbf{F}(\Phi_\Gamma)$ *defined in* (2.15) *we have*

$$\sup_{\mathbb{R}} |F_2(\Phi_\Gamma)| = \mathcal{O}(\varepsilon^2), \quad \sup_{\mathbb{R}\setminus\mathcal{I}_1\cup\mathcal{I}_2} |F_1(\Phi_\Gamma)| = \mathcal{O}(\varepsilon^4), \quad \sup_{\mathcal{I}_1\cup\mathcal{I}_2} |F_1(\Phi_\Gamma)| = \mathcal{O}(\varepsilon\sqrt{\varepsilon}). \tag{2.16}$$

More specifically

$$R_2(\Gamma) = \varepsilon^2 \hat{c}\,(\phi_1' - \phi_2') + \mathcal{O}(\varepsilon^4) \text{ in } L^2(\mathbb{R}), \tag{2.17}$$

while

$$\|R_1(\Gamma)\|_{L^1} = \mathcal{O}(\varepsilon). \tag{2.18}$$

The $\mathcal{O}(\varepsilon\sqrt{\varepsilon})$ bound on F_1 in (2.16) and the $\mathcal{O}(\varepsilon)$ bound on R_1 in (2.18) deteriorate to $\mathcal{O}(\varepsilon^{-\frac{1}{2}})$ bounds, if we do not introduce the leading order corrections $\varepsilon^4 U_4$ and $\varepsilon^2 V_2$ in (2.5). Moreover, (2.17) no longer holds in that case. On the other hand, the bounds on $R_2(\Gamma)$ given in the lemma are sharp. The bounds on $R_1(\Gamma)$ may be sharpened, but this does not lead to any improvements in the renormalization analysis of section 4.

Proof. In [6], Φ_Γ is constructed as the solution of the classical Gierer–Meinhardt system

$$\begin{cases} -\varepsilon^6 \hat{c}_k U_\xi = U_{\xi\xi} - \varepsilon^4 \mu U + \varepsilon^2 V^2, \\ -\varepsilon^2 \hat{c}_k V_\xi = V_{\xi\xi} - V + \frac{V^2}{U} \end{cases} \tag{2.19}$$

with $\hat{c}_1 = -\hat{c} < 0$ for $\xi < \Gamma_0$ and $\hat{c}_2 = \hat{c} > 0$ for $\xi < \Gamma_0$, and $\hat{c} = \hat{c}(t)$ as in (2.8). Note the factor ε^4 difference between the right-hand sides of the U-equation here and in (2.3). We may employ a regular perturbation expansion, writing

$$\begin{aligned} U(\xi,t) &= U_0(\xi;\Gamma) + \varepsilon^2 U_2(\xi;\Gamma) + \varepsilon^4 U_4(\xi;\Gamma) + \varepsilon^6 U_r(\xi,t;\varepsilon^2), \\ V(\xi,t) &= V_0(\xi;\Gamma) + \varepsilon^2 V_2(\xi;\Gamma) + \varepsilon^4 V_r(\xi,t;\varepsilon^2), \end{aligned} \tag{2.20}$$

where A, U_2, and V_0 are given in (2.9), (2.10), (2.11), (2.13), (2.14), and U_4 and V_2 have already been introduced in (2.5). Likewise, we expand F_1 and F_2 (Proposition 2.1),

$$\begin{aligned} F_1(\Phi_\Gamma) &= \frac{1}{\varepsilon^2}\left[U_{2,\xi\xi} + V_0^2\right] + \left[U_{4,\xi\xi} - \mu U_0 + 2V_0V_2\right] \\ &\quad + \varepsilon^2\left[U_{r,\xi\xi} - \varepsilon^4\mu U_r - F_{1,r}^{\mathrm{inh}}(U_2, V_{0,2,r};\varepsilon^2)\right], \\ F_2(\Phi_\Gamma) &= \left[V_{0,\xi\xi} - V_0 + \frac{V_0^2}{U_0}\right] + \varepsilon^2\left[L_{22}V_2 - \frac{V_0^2U_2}{U_0^2}\right] \\ &\quad + \varepsilon^4\left[L_{22}V_r - F_{2,r}^{\mathrm{inh}}(U_{0,2,4}, \varepsilon^2 U_r, V_{0,2}, \varepsilon^2 V_r;\varepsilon^2)\right], \end{aligned} \tag{2.21}$$

where

$$L_{22}V = V_{\xi\xi} - V + \frac{V_0^2}{U_0}V, \tag{2.22}$$

and the expressions for $F_{1,r}^{\mathrm{inh}}(U_2, V_{0,2,r};\varepsilon^2)$ and $F_{2,r}^{\mathrm{inh}}(U_{0,2,4}, \varepsilon^2 U_r, V_{0,2}, \varepsilon^2 V_r;\varepsilon^2)$ follow directly by substitution of (2.20) in (2.3). We obtain by (2.19) the following equations for U_4 and V_2:

$$U_{4,\xi\xi} = \mu U_0 - 2V_0V_2, \quad L_{22}V_2 = \frac{V_0^2U_2}{U_0^2} - \hat{c}_k V_{0,\xi}, \tag{2.23}$$

for $\xi \in \mathcal{I}_{1,2}$. These equations can be solved uniquely by application of the natural boundary/matching conditions. Note that $U_4(\xi)$ grows as $(\xi - \Gamma_{1,2})^2$ for $|\xi - \Gamma_{1,2}| \gg 1$ and that V_2 decays exponentially to 0 as $|\xi - \Gamma_{1,2}| \gg 1$ (see (2.9)). The equations for the remainders $U_r(\xi,t;\varepsilon^2)$ and $V_r(\xi,t;\varepsilon^2)$ are given by

$$\begin{aligned} U_{r,\xi\xi} - \varepsilon^4\mu U_r &= F_{1,r}^{\mathrm{inh}}(U_2, V_{0,2,r};\varepsilon^2) - \hat{c}_k U_{0,\xi} - \varepsilon^2\hat{c}_k U_{2,\xi} - \varepsilon^4\hat{c}_k U_{4,\xi} - \varepsilon^6\hat{c}_k U_{r,\xi}, \\ L_{22}V_r &= F_{2,r}^{\mathrm{inh}}(U_{0,2,4}, \varepsilon^2 U_r, V_{0,2}, \varepsilon^2 V_r;\varepsilon^2) - \hat{c}_k V_{2,\xi} - \varepsilon^2\hat{c}_k V_{r,\xi}, \end{aligned} \tag{2.24}$$

for $\xi \in \mathbb{R}$. It is a straightforward procedure to check that $|V_r|$ and $|F^{\text{inh}}_{2,r}|$ are uniformly bounded for $\xi \in \mathbb{R}$; in fact, both V_r and $F^{\text{inh}}_{2,r}$ decay exponentially to 0 as $|\xi - \Gamma_{1,2}(t)| \gg 1$. Together with the definitions of V_0 and V_2 ((2.9) and (2.23)), substitution of this result in the second equation of (2.21) yields (2.17). This also implies the results on $F_2(\Phi_\Gamma)$ in (2.16).

Outside the pulse regions $\mathcal{I}_k$, all $V_{0,2,r}$ components are exponentially small, and U_0 is constructed as a solution of the equation $U_{\xi\xi} - \varepsilon^4 \mu U = 0$; see (2.13). Therefore, the correction U_r to U_0 in the U-component of the two-pulse solution also varies like $\varepsilon^2 \xi$, and U_2 and U_4 may be taken to be identically zero outside $\mathcal{I}_k$. This implies by (2.21) and (2.24) that outside $\mathcal{I}_k$

$$F_1(\Phi_\Gamma) = -\varepsilon^2 \hat{c}_k U_{0,\xi} = \mathcal{O}(\varepsilon^4).$$

Since U_r decays for $\xi \to \pm\infty$ with the same slow rate as U_0, we find

$$\int_{\mathbb{R}\setminus\mathcal{I}_1\cup\mathcal{I}_2} |F_1(\Phi_\Gamma)|\, d\xi = \frac{1}{\varepsilon^2} \times \mathcal{O}(\varepsilon^4) = \mathcal{O}(\varepsilon^2).$$

Inside $\mathcal{I}_k$, we conclude from (2.24) and the fact that U_2 grows linearly with $(\xi - \Gamma_i)$ (see (2.14)) that U_r may grow as $(\xi - \Gamma_i)^3$. Nevertheless, both $U_{r,\xi\xi}$ and $F^{\text{inh}}_{1,r}(U_2, V_{0,2,r}; \varepsilon^2)$ only grow linearly in $(\xi - \Gamma_i)$. Since the width of the $\mathcal{I}_k$ interval is $\mathcal{O}(1/\sqrt{\varepsilon})$ (see (2.12)) we deduce from (2.21) and (2.24) that $\sup_{\mathcal{I}_1\cup\mathcal{I}_2} |F_1(\Phi_\Gamma)| = \mathcal{O}(\varepsilon\sqrt{\varepsilon})$ (2.16). Hence, by (2.12),

$$\int_{\mathcal{I}_k} |F_1(\Phi_\Gamma)|\, d\xi = \frac{1}{\sqrt{\varepsilon}} \times \mathcal{O}(\varepsilon\sqrt{\varepsilon}) = \mathcal{O}(\varepsilon),$$

which yields the L^1-bound (2.18). ∎

3. Linearization and the reduced operators. In a neighborhood of the two-pulse manifold $\mathcal{M}$ we decompose the solutions of (2.3) as

$$\begin{pmatrix} U \\ V \end{pmatrix} = \Phi_\Gamma + W(\xi, t), \tag{3.1}$$

where the remainder $W = (W_1, W_2)^t$ and Γ is taken as a function of time. In terms of the remainder introduced in (3.1), the GM equation (2.3) can then be written as

$$W_t + \frac{\partial \Phi}{\partial \Gamma}\dot{\Gamma} = \mathbf{R} + L_\Gamma W + \mathcal{N}(W), \tag{3.2}$$

where R is the residual (2.15) and L_Γ is the linearization of F about Φ_Γ, given by

$$L_\Gamma = \begin{pmatrix} \epsilon^{-4}\partial_\xi^2 - \mu & 2\varepsilon^{-2}\Phi_{\Gamma,2} \\ -\dfrac{\Phi_{\Gamma,2}^2 \kappa'(\Phi_{\Gamma,1})}{\kappa(\Phi_{\Gamma,1})^2} & \partial_\xi^2 - 1 + 2\dfrac{\Phi_{\Gamma,2}}{\kappa(\Phi_{\Gamma,1})} \end{pmatrix}. \tag{3.3}$$

In the linear operator above $\kappa(\Phi_{\Gamma,1}) = \Phi_{\Gamma,1}$ except for those ξ for which $\Phi_{\Gamma,2}(\xi) = \mathcal{O}(e^{-\varepsilon^{-2}|\ln\delta|})$. Thus the perturbation to the linearization introduced by the regularization is compact and exponentially small. The final term, $\mathcal{N}(W)$, representing the nonlinearity is given at leading order by

$$\mathcal{N}(W) = \begin{pmatrix} \epsilon^{-2} W_2^2 \\ \mathcal{O}(W_2^2) + \mathcal{O}(V_0 W_1 W_2) + \mathcal{O}(V_0^2 W_1^2) \end{pmatrix}. \tag{3.4}$$

From the asymptotic form of the pulse solution given in (2.9), (2.11), and (2.13), we calculate that

$$\varepsilon^2 \left\| \frac{\partial U_0}{\partial \Gamma_k} \right\|_{L^1} + \varepsilon \left\| \frac{\partial U_0}{\partial \Gamma_k} \right\|_{L^2} + \left\| \frac{\partial U_0}{\partial \Gamma_k} \right\|_{L^\infty} = \mathcal{O}(\varepsilon^2), \tag{3.5}$$

while

$$\frac{\partial V_0}{\partial \Gamma_k} = -\phi_k' + \mathcal{O}(\varepsilon^2), \tag{3.6}$$

in L^2.

3.1. The reduced linearization. A key step in the RG treatment is the replacement of the exact linear operator with a reduced operator whose spectral and semigroup properties are easier to analyze, yet such that the difference between the exact and the reduced operator, the secularity, does not lead to growth of the remainder W. Due to the contractivity of the L_{11} component of L_Γ, the two-pulse potential which comprises the L_{12} component can be replaced with δ functions located at each pulse position. The mass of the delta function is chosen to equal the mass of the product of the original potential and the function it operates upon. We also replace the exact two-pulse solution Φ_Γ with its leading order approximation $(U_0, V_0)^t$. With these reductions the linearized operator becomes

$$\tilde{L}_\Gamma = \begin{pmatrix} \epsilon^{-4}\partial_\xi^2 - \mu & 2\varepsilon^{-2}\big(\delta_{\Gamma_1} \otimes \phi_1 + \delta_{\Gamma_2} \otimes \phi_2\big) \\ -\dfrac{V_0^2}{A^2} & \partial_\xi^2 - 1 + 2\dfrac{V_0}{A} \end{pmatrix}, \tag{3.7}$$

where the tensor product of f_1 and f_2 is defined by

$$(f_1 \otimes f_2)\, W = (f_2, W)_{L^2} f_1. \tag{3.8}$$

In particular, $\delta_{\Gamma_k} \otimes \phi_k$ represents the tensor product of the δ function centered at $\xi = \Gamma_k$ with ϕ_k. In the analysis below we use the notation

$$\alpha_k(W) = (\phi_k, W)_{L^2}, \tag{3.9}$$

for $k = 1, 2$. The scalar operators that appear in the upper left entry, respectively lower right, of the matrix $\tilde{L}$ (3.7) will be denoted by L_{11}, respectively L_{22}; see (2.22). The reduced operator is ostensibly an $\mathcal{O}(\varepsilon^{-2})$ perturbation of the original operator. However, it is immediately clear that they share the same essential spectrum

$$\sigma_{\text{ess}} = \{\lambda \in \mathbb{R} : \lambda \leq \max(-1, -\mu)\}. \tag{3.10}$$

3.2. The point spectrum. The two-pulse profiles which comprise the manifold $\mathcal{M}$ are not stationary solutions, and as such it is not self-consistent to determine their linear stability in terms of the spectrum of the associated linearized operator. We say that the two-pulse solution Φ_Γ is *spectrally compatible* with the manifold $\mathcal{M}$ if the spectrum of the associated linear operator can be decomposed into a part contained within the left-half complex plane and a finite-dimensional part whose associated eigenspace approximates the tangent plane of $\mathcal{M}$ at Γ.

To determine the point spectrum of $\tilde{L}$ we invert the U component of the eigenvalue equation, and eliminate the inhibitor from the activator equation, reducing the

eigenvalue problem to a scalar equation for the activator component of the eigenfunction. We call this the NLEP equation (see (3.23)) and denote the corresponding linear operator by $\mathcal{L}(\lambda, \Delta\Gamma)$. The NLEP operator controls the point spectrum of $\tilde{L}$ to leading order.

PROPOSITION 3.1. *Up to multiplicity we have* $\sigma_p(\tilde{L}) = \{\lambda | \mathrm{Ker}(\mathcal{L}(\lambda)) \neq 0\}(1 + \mathcal{O}(\varepsilon^2))$. *That is, for each eigenvalue* $\lambda \in \sigma_p(\tilde{L})$ *with corresponding eigenvector* $\Psi = (\Psi_1, \Psi_2)^t$, *there is a* $\lambda_{\mathcal{L}}$ *and corresponding* ψ *such that* $\mathcal{L}(\lambda_{\mathcal{L}})\psi = \lambda_{\mathcal{L}}\psi$, $|\lambda - \lambda_{\mathcal{L}}| = \mathcal{O}(\varepsilon^2)$ *with* $\Psi_2 = \psi(1 + \mathcal{O}(\varepsilon^2))$ *and* Ψ_1 *given by* (3.12) *up to* $\mathcal{O}(\varepsilon^2)$. *Moreover, the small eigenvalues of* $\tilde{L}$ *and* $\mathcal{L}$ *are both exponentially small.*

Proof. The eigenvalue problem for the reduced operator is written as

$$\tilde{L}\Psi = \lambda\Psi, \tag{3.11}$$

where $\Psi = (\Psi_1, \Psi_2)^t$ is a possibly complex two-vector. Since $L_{11} - \lambda$ is invertible for $\lambda \notin (-\infty, -\mu]$, we may solve for Ψ_1 as

$$\Psi_1 = -2\varepsilon^{-2}\big(\alpha_1(L_{11} - \lambda)^{-1}\delta_{\Gamma_1} + \alpha_2(L_{11} - \lambda)^{-1}\delta_{\Gamma_2}\big), \tag{3.12}$$

where the $\alpha_k = (\phi_k, \Psi_2)_{L^2}$ are as yet undetermined. From the Fourier transform we find

$$\widehat{\Psi}_1(k) = \frac{2}{\sqrt{2\pi}}\frac{\varepsilon^2\big(\alpha_1 e^{ik\Gamma_1} + \alpha_2 e^{ik\Gamma_2}\big)}{k^2 + \varepsilon^4(\mu + \lambda)}. \tag{3.13}$$

From the integral relation

$$\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} e^{-ik\xi}\frac{\varepsilon^2 e^{ik\Gamma}}{k^2 + \varepsilon^4(\mu + \lambda)} = \sqrt{\frac{\pi}{2(\mu + \lambda)}}e^{-\varepsilon^2\sqrt{\mu+\lambda}|\xi - \Gamma|}, \tag{3.14}$$

we may invert the Fourier transform of Ψ_1 explicitly,

$$\Psi_1(\xi, t) = \alpha_1 H(\lambda, \xi - \Gamma_1) + \alpha_2 H(\lambda, \xi - \Gamma_2), \tag{3.15}$$

where

$$H(\lambda, x) = \frac{1}{\sqrt{\mu + \lambda}}e^{-\varepsilon^2|x|\sqrt{\mu+\lambda}}. \tag{3.16}$$

Eliminating Ψ_1, the equation for Ψ_2 reduces to

$$(L_{22} - \lambda)\Psi_2 = \frac{V_0^2}{A^2}\Psi_1; \tag{3.17}$$

see also (2.22). Since Ψ_1 is a slowly varying function of ξ, while each term in V_0 decays exponentially to zero at an $\mathcal{O}(1)$ rate in ξ, we may reduce the equation for Ψ_2 to

$$(L_{22} - \lambda)\Psi_2 = \frac{V_0^2}{A^2}\left(\alpha_1 H(\lambda, \xi - \Gamma_1) + \alpha_2 H(\lambda, \xi - \Gamma_2)\right) \tag{3.18}$$

$$= \frac{\phi_1^2 + \phi_2^2}{A^2}\left(\alpha_1 H(\lambda, \xi - \Gamma_1) + \alpha_2 H(\lambda, \xi - \Gamma_2)\right) + \mathcal{O}(e^{-\Delta\Gamma}) \tag{3.19}$$

$$= \frac{1}{A^2\sqrt{\mu + \lambda}}\left[\phi_1^2\left(\alpha_1 + \alpha_2 E\right) + \phi_2^2\left(\alpha_1 E + \alpha_2\right)\right] + \mathcal{O}(\varepsilon^2), \tag{3.20}$$

where

$$E = E(\Delta\Gamma;\lambda) = e^{-\varepsilon^2\sqrt{\mu+\lambda}\Delta\Gamma}. \tag{3.21}$$

In the tensor product notation this is written as

$$(L_{22}-\lambda)\Psi_2 = \frac{1}{A^2\sqrt{\mu+\lambda}}\left[\phi_1^2\otimes(\phi_1+E\phi_2)+\phi_2^2\otimes(E\phi_1+\phi_2)\right]\Psi_2. \tag{3.22}$$

We define the NLEP operator as

$$\mathcal{L}(\lambda,\Delta\Gamma) = L_{22} - \frac{1}{A^2\sqrt{\mu+\lambda}}\left[\phi_1^2\otimes(\phi_1+E\phi_2)+\phi_2^2\otimes(E\phi_1+\phi_2)\right]. \tag{3.23}$$

This is a compact perturbation of L_{22} and thus is Fredholm, with the same essential spectrum, but is no longer self-adjoint. Indeed its adjoint exchanges the roles of the potentials in each tensor product. ∎

PROPOSITION 3.2. *Except for the exponentially small eigenvalues, the point spectrum of the NLEP operator $\mathcal{L}$ is given, up to multiplicity, by the zeros of the equation*

$$\mathcal{R}(\lambda) - 3\frac{\sqrt{\mu+\lambda}}{\sqrt{\mu}}\frac{1+e^{-\varepsilon^2\sqrt{\mu}\Delta\Gamma}}{1\pm e^{-\varepsilon^2\sqrt{\mu+\lambda}\Delta\Gamma}} = 0, \tag{3.24}$$

where $\mathcal{R}$ is an explicitly known meromorphic function on $\mathbf{C}\backslash(-\infty,-1]$ given by (3.33).

Proof. The spectrum of the NLEP operator $\mathcal{L}$ can be determined explicitly as the zeros of an analytic equation using the methods developed in [5], which we outline below. We introduce $w_h(\xi)\geq 0$ as the scaled homoclinic solution of

$$w_{\xi\xi} - w + w^2 = 0 \tag{3.25}$$

with its maximum at $\xi = 0$. For $k = 1,2$ we introduce the translates $w_{h,k}(\xi) = w_h(\xi-\Gamma_k)$. Since $\phi_k(\xi) = Aw_{h,k}(\xi)$, (2.10) and (3.22) can be written as

$$\frac{d^2\Psi_2}{d\xi^2} - \left[(1+\lambda) - 2(w_{h,1}+w_{h,2})\right]\Psi_2 = \frac{1}{\sqrt{\mu+\lambda}}\left[w_{h,1}^2(\alpha_1+\alpha_2E)+w_{h,2}^2(\alpha_1E+\alpha_2)\right], \tag{3.26}$$

where $\alpha_k = \alpha_k(\Psi_2)$ (3.9). Since the potential of both the Schrödinger operator on the left-hand side of the equation and the inhomogeneous term on the right-hand side consists of disjoint parts localized about Γ_1 and Γ_2, it is natural to decompose Ψ_2 into

$$\Psi_2 = \psi_1(\xi) + \psi_2(\xi), \tag{3.27}$$

where ψ_k is localized about Γ_k and decays exponentially as ξ moves away from Γ_k. Equation (3.26) is equivalent, up to exponentially small terms, to the coupled system

$$\begin{cases} \dfrac{d^2\psi_1}{d\xi^2} - \left[(1+\lambda) - 2w_{h,1}\right]\psi_1 = \dfrac{w_{h,1}^2}{\sqrt{\mu+\lambda}}(\alpha_1+\alpha_2E), \\ \dfrac{d^2\psi_2}{d\xi^2} - \left[(1+\lambda) - 2w_{h,2}\right]\psi_2 = \dfrac{w_{h,2}^2}{\sqrt{\mu+\lambda}}(\alpha_1E+\alpha_2). \end{cases} \tag{3.28}$$

We define $\bar{\psi} = \bar{\psi}(\xi;\lambda)$ as the uniquely determined bounded solution of

$$\frac{d^2\psi}{d\xi^2} - [(1+\lambda) - 2w_h]\,\psi = w_h^2, \tag{3.29}$$

and its translates $\bar{\psi}_k(\xi)$ are defined by $\bar{\psi}_k(\xi) = \bar{\psi}(\xi - \Gamma_k)$. The functions $\bar{\psi}$ can be determined explicitly; see [5].

We first consider the solution of (3.29) for $\lambda \notin \sigma_{\rm red} = \{\frac{5}{4}, 0, -\frac{3}{4}\} \cup (-\infty, -1]$, the spectrum of the operator

$$L_{\rm red} = \frac{d^2}{d\xi^2} - (1 - 2w_h(\xi)). \tag{3.30}$$

Clearly,

$$\psi_1(\xi) = C_1\bar{\psi}_1(\xi), \;\; \psi_2(\xi) = C_2\bar{\psi}_2(\xi) \tag{3.31}$$

for some constants C_k that depend on λ and $\Delta\Gamma$. Recalling that here $\alpha_k = (\phi_k, \Psi_2)_{L^2}$ and using (3.27), we find

$$\begin{aligned} \alpha_k &= \int_{-\infty}^{\infty} \phi_k(\psi_1 + \psi_2)d\xi = \int_{-\infty}^{\infty} Aw_{h,k}(C_1\bar{\psi}_1 + C_2\bar{\psi}_2)d\xi \\ &= AC_k \int_{-\infty}^{\infty} w_{h,k}\bar{\psi}_k d\xi = AC_k \int_{-\infty}^{\infty} w_h\bar{\psi}d\xi \end{aligned} \tag{3.32}$$

up to asymptotically small corrections. The quantity

$$\mathcal{R}(\lambda) \equiv \int_{-\infty}^{\infty} w_h\bar{\psi}d\xi \tag{3.33}$$

is meromorphic for $\lambda \in \mathbb{C}\backslash(-\infty, -1]$, with poles at $\lambda = \frac{5}{4}$ and $\lambda = -\frac{3}{4}$; see [5]. Note that in [5] a more general function, $\mathcal{R}(\lambda;\beta_1,\beta_2)$, has been defined and studied; (3.33) is related to [5] by $\mathcal{R}(\lambda) = 216\mathcal{R}(\lambda;2,2)$. The system (3.28) can be written as

$$\begin{cases} \dfrac{d^2\psi_1}{d\xi^2} - [(1+\lambda) - 2w_{h,1}]\,\psi_1 = \dfrac{Aw_{h,1}^2\mathcal{R}}{\sqrt{\mu+\lambda}}\,(C_1 + C_2E)\,, \\ \dfrac{d^2\psi_2}{d\xi^2} - [(1+\lambda) - 2w_{h,2}]\,\psi_2 = \dfrac{Aw_{h,2}^2\mathcal{R}}{\sqrt{\mu+\lambda}}\,(C_1E + C_2)\,. \end{cases} \tag{3.34}$$

Comparing the equations for $\psi_{1,2}(\xi)$ to (3.29), we obtain the following relations for C_1 and C_2:

$$C_1 = \frac{A\mathcal{R}}{\sqrt{\mu+\lambda}}\,(C_1 + C_2E)\,, \;\; C_2 = \frac{A\mathcal{R}}{\sqrt{\mu+\lambda}}\,(C_1E + C_2)\,, \tag{3.35}$$

or, equivalently,

$$\begin{pmatrix} \dfrac{A\mathcal{R}}{\sqrt{\mu+\lambda}} - 1 & \dfrac{AE\mathcal{R}}{\sqrt{\mu+\lambda}} \\ \dfrac{AE\mathcal{R}}{\sqrt{\mu+\lambda}} & \dfrac{A\mathcal{R}}{\sqrt{\mu+\lambda}} - 1 \end{pmatrix} \begin{pmatrix} C_1 \\ C_2 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}. \tag{3.36}$$

For (3.26) to have nontrivial solutions the determinant of the matrix on the left-hand side of (3.36) must be zero. Isolating $\mathcal{R}(\lambda)$ from the resulting expression and using

(2.11) and (3.21), we obtain (3.24) whose zeros are the eigenvalues of the NLEP equation (3.22), up to multiplicity, outside of $\sigma_{\rm red}$. These eigenvalues lie on curves $\lambda(\Delta\Gamma)$, parametrized by the pulse separation.

For $\lambda \in \sigma_{\rm red}$ we analyze the eigenvalue equation case by case. For $\lambda = -\frac{3}{4}$ or $\frac{5}{4}$, (3.29) does not have a bounded solution since the right-hand side is not orthogonal to the kernel of the $L_{\rm red}$, and so these values cannot be eigenvalues. However, the eigenfunction $\frac{d}{d\xi}w_h$ of $L_{\rm red}$ at $\lambda = 0$ is L^2 orthogonal to w_h. Equation (3.32) implies that $\alpha_1 = \alpha_2 = 0$ and the system (3.28) has a double eigenvalue at $\lambda = 0$ with a two-dimensional eigenspace spanned by $\{\frac{d}{d\xi}w_h(\xi - \Gamma_1), \frac{d}{d\xi}w_h(\xi - \Gamma_2)\}$. These eigenvalues do not occur as solutions of (3.24), rather they correspond to exponentially small eigenvalues of the original NLEP system (3.22), whose corresponding eigenfunctions, derived in Lemma 3.7, form the key spectral projection onto the active tangent plane. ∎

Remark 3.3. Proposition 3.2 is equivalent to Principle Result 5.3 of [16].

We identify conditions on μ and Γ such that the reduced linearized operator, $\tilde{L}_\Gamma$, is spectrally compatible with the manifold $\mathcal{M}$ of two-pulse solutions.

PROPOSITION 3.4. *For each* $\Delta\Gamma \in (0, \infty)$, *the* NLEP *eigenvalue problem* (3.22) *has two exponentially small eigenvalues, denoted* $\lambda_\pm$, *and* 4 *or* 6 *eigenvalues* $\lambda_+^{j_+}(\Delta\Gamma)$ *and* $\lambda_-^{j_-}(\Delta\Gamma)$, $j_\pm = 1, \ldots, J_\pm, J_\pm = J_\pm(\mu) = 2$ or 3. *There exists a unique* $\mu_{\rm Hopf} > 0$ *such that for all* $\mu > \mu_{\rm Hopf}$, *there is a* $\Delta\Gamma^*(\mu)$ *and a* $\nu > 0$ *such that*

$$\mathrm{Re}[\lambda_\pm^{j_\pm}(\Delta\Gamma)] < -\nu < 0 \ \text{ for all } \ \Delta\Gamma \geq \Delta\Gamma^*(\mu),\ j_\pm = 1, \ldots, J_\pm.$$

For all $\mu > \mu_{\rm TP} \approx 0.62$ (*the tangent point*), $\Delta\Gamma^*$ *takes the exact form*

$$\Delta\Gamma^*(\mu) = \frac{1}{\varepsilon^2\sqrt{\mu}}\log 3, \tag{3.37}$$

while for $\mu \in (\mu_{\rm Hopf}, \mu_{\rm TP})$, $\Delta\Gamma^*(\mu)$ *increases with decreasing* μ, *with* $\Delta\Gamma^*(\mu) \to \infty$ *as* $\mu \downarrow \mu_{\rm Hopf}$.

Since the two pulses of $\Phi_\Gamma(\xi)$ move away from each other (see (2.7), (2.8)), this result implies that the spectrum of the NLEP operator $\mathcal{L}$ remains in the stable half-plane for all $t \geq 0$ if $\Delta\Gamma(0) > \Delta\Gamma^*$.

Proof. We can distinguish two limits, $\Delta\Gamma \to \infty$ and $\Delta\Gamma \downarrow 0$. The first case represents the situation in which the two pulses of $\Phi_\Gamma(\xi)$ are so far apart that the two-pulse solution can be considered as two one-pulse solutions, i.e., the two-pulse solution is in the weak interaction limit. In this limit, (3.24) reduces to

$$\mathcal{R}(\lambda) = 3\frac{\sqrt{\mu + \lambda}}{\sqrt{\mu}}, \tag{3.38}$$

for both $\lambda_\pm(\Delta\Gamma)$. This is the relation that determines the point spectrum of the solitary one-pulse solution of (2.1), independent of the regularization. It was shown in Theorem 5.11 of [5] that there exists a unique $\mu_{\rm Hopf} > 0$ such that all solutions of (3.38) have $\mathrm{Re}(\lambda) < 0$ for $\mu > \mu_{\rm Hopf}$ and that (3.22) always has incompatible eigenvalues if $\mu < \mu_{\rm Hopf}$. Numerical evaluation shows that $\mu_{\rm Hopf} \approx 0.36$. Moreover, (3.38) has 2 or 3 nontrivial eigenvalues, i.e., $\lambda \neq 0$, depending on μ; the third (compatible) eigenvalue is created in an edge bifurcation as μ increases through $\mu_{\rm edge} \approx 0.77$ [5]. There also are 2 or 3 curves $\lambda_+^{j_+}(\Delta\Gamma)$ and $\lambda_-^{j_-}(\Delta\Gamma)$, i.e., $j_\pm = 1, \ldots, J_\pm$, $J_\pm(\mu) = 2$, respectively 3, for $\mu < \mu_{\rm edge}$, respectively $> \mu_{\rm edge}$. The eigenvalues $\lambda_\pm^3(\Delta\Gamma)$ are real and $\lambda_\pm^3(\Delta\Gamma) < -\frac{3}{4}$.

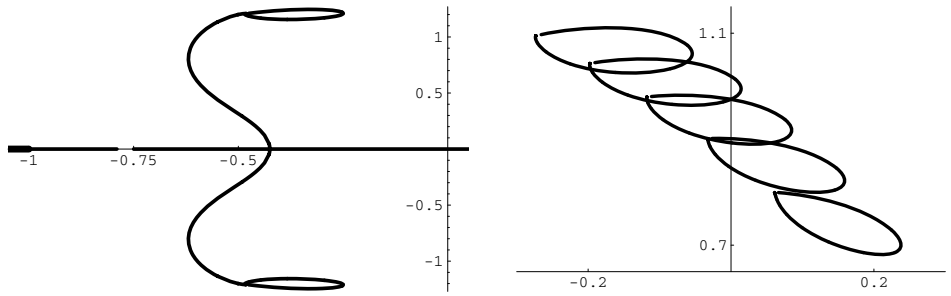

FIG. 3.1. (a) *The orbits of the zeroes* $\lambda(\Delta\Gamma)$ *of* (3.24) *plotted parametrically in the complex plane as a function of* $\Delta\Gamma$ *for* $\mu = 1$. *The eigenvalues* $\lambda_+^{1,2}(\Delta\Gamma)$ *are closed loops attached to the homoclinic limit* $\lambda \approx -0.48 + 1.20i$; *the curves* $\lambda_-^{1,2}(\Delta\Gamma)$ *approach the homoclinic point in the limit* $\Delta\Gamma \to \infty$, *but* $\lambda_-^{1,2}(\Delta\Gamma)$ *collide on the real axis, becoming real as* $\Delta\Gamma$ *decreases approaching the limits* $\lambda_-^{1,2}(\Delta\Gamma) \to -\frac{3}{4}, \frac{5}{4}$ *as* $\Delta\Gamma \to 0$. *The third pair of eigenvalues satisfies* $\lambda_\pm^3(\Delta\Gamma) < -\frac{3}{4}$ *with* $\lambda_-^3(\Delta\Gamma)$ *disappearing into the essential spectrum of* (3.22) *as* $\Delta\Gamma$ *decreases through a critical value. All eigenvalues* $\lambda_\pm^{1,2,j}(\Delta\Gamma)$ *have negative real part for* $\Delta\Gamma > \Delta\Gamma^*(1)$ *given by* (3.37). (b) *The closed* $\lambda_+^1(\Delta\Gamma)$*-loops for five values of* μ: $\mu = 0.7 > \mu_{\rm TP}$, $\mu = 0.6, 0.5, 0.4 \in (\mu_{\rm Hopf}, \mu_{\rm TP})$, *and* $\mu = 0.3 < \mu_{\rm Hopf}$. *The* $\Delta\Gamma$*-region* $(\Delta\Gamma_+^{1,*}(\mu), \Delta\Gamma_+^{2,*}(\mu))$ *in which* $Re[\lambda_+^1(\Delta\Gamma)] > 0$ *grows as* $\mu \in (\mu_{\rm Hopf}, \mu_{\rm TP})$ *decreases, so that* $\Delta\Gamma^*(\mu) = \Delta\Gamma_+^{2,*}(\mu)$ *for* $\mu < \mu^* \in (\mu_{\rm Hopf}, \mu_{\rm TP})$.

For small values of $\Delta\Gamma$ there are two mechanisms to generate incompatible point spectrum, one which occurs for $\mu > \mu_{\rm TP}$ and the other for $\mu \in (\mu_{\rm Hopf}, \mu_{\rm TP})$. The first occurs when the eigenvalues λ_-^1 and λ_-^2 collide and become real. Indeed, in the limit $\Delta\Gamma \downarrow 0$, it follows from Proposition 3.2 that $\lambda_+^{1,2}(\Delta\Gamma)$ again approaches a solution of (3.38), i.e., the $\lambda_+^{1,2}(\Delta\Gamma)$-branches are closed curves. On the other hand, $|\mathcal{R}(\lambda_-^{1,2}(\Delta\Gamma))|$ becomes unbounded in this limit. By evaluation of (3.24), we see that $\mathcal{R}(\lambda)$ becomes unbounded as $\lambda_-^1(\Delta\Gamma) \to -\frac{3}{4}$, the stable pole of $\mathcal{R}(\lambda)$, and as $\lambda_-^2(\Delta\Gamma) \to +\frac{5}{4}$, the other, unstable pole of $\mathcal{R}(\lambda)$. The passage of the real eigenvalue $\lambda_-^2(\Delta\Gamma)$ through zero corresponds to $\Delta\Gamma$ given by (3.37) since $\mathcal{R}(0) = 6$ [5]. In particular, the eigenvalue problem (3.22) has incompatible eigenvalues for all $\Delta\Gamma < \log 3/(\varepsilon^2\sqrt{\mu})$, for $\mu > \mu_{\rm TP}$.

In the second case, the $\lambda_+^{1,2}(\Delta\Gamma)$-branches may cross through the imaginary axis. For the tangent point value, $\mu = \mu_{\rm TP}$, the $\lambda_+^{1,2}$ curves are tangent to the imaginary axis. For $\mu \in (\mu_{\rm Hopf}, \mu_{\rm TP})$, a part of the closed, complex conjugate $\lambda_+^{1,2}(\Delta\Gamma)$-curves lies in the unstable half-plane, while the endpoints of the curve, i.e., the eigenvalues associated to the stationary homoclinic one-pulse limit, lie in the stable half-plane; see Figure 3.1(b). More specifically, $\mathrm{Re}[\lambda_+^{1,2}(\Delta\Gamma)] > 0$ for $\Delta\Gamma \in (\Delta\Gamma_+^{1,*}(\mu), \Delta\Gamma_+^{2,*}(\mu))$, where

$$\lim_{\mu\to\mu_{\rm Hopf}} \Delta\Gamma_+^{1,*}(\mu) = 0, \quad \lim_{\mu\to\mu_{\rm Hopf}} \Delta\Gamma_+^{2,*}(\mu) = \infty,$$
$$\lim_{\mu\to\mu_{\rm TP}} \Delta\Gamma_+^{1,*}(\mu) = \lim_{\mu\to\mu_{\rm TP}} \Delta\Gamma_+^{2,*}(\mu) \approx \frac{1.32}{\varepsilon^2},$$

so that $\Delta\Gamma^*(\mu) = \Delta\Gamma_+^{2,*}(\mu) > \log 3/(\varepsilon^2\sqrt{\mu})$ for $\mu \in (\mu_{\rm Hopf}, \mu_+^*)$ for a certain $\mu_+^* \in (\mu_{\rm Hopf}, \mu_{\rm TP})$. □

The orbits of the eigenvalues λ of (3.22) as function of $\Delta\Gamma$ can be determined by a direct evaluation of $\mathcal{R}(\lambda)$ [5]; see Figure 3.1.

Remark 3.5. Competition instabilities and synchronous oscillatory instabilities were identified for the Gierer–Meinhardt equations in [17, 16]; see, especially, section

5.2 of [16]. The presence of these two instabilities is related to the two multipliers in the NLEP, as also found here.

Remark 3.6. Proposition 3.4 implies that $\Phi_\Gamma(\xi)$ is not spectrally compatible with the manifold $\mathcal{M}$ if $\Delta\Gamma(0) < \Delta\Gamma^*(\mu)$. However, this lower bound on the admissible pulse separation distance does not limit the semistrong character of the pulse interaction in $\Phi_\Gamma(\xi)$, since the U-component of $\Phi_\Gamma(\xi)$ evolves on the slow $\varepsilon^2\xi$ space scale. To quantify the lower bound on pulse separation we determine the corresponding maximum value of the minimum $U_{\min}(t)$ of the inhibitor U between the two pulses $\Gamma_{1,2}$; see also Figure 1.1. Since $U_{\min}(t;\mu)$ decreases monotonically in time (by (2.11) and (2.13)), we find that a spectrally compatible two-pulse solution must satisfy

$$U_{\min}(0) < U^*_{\min}(\mu) = \frac{A(\Delta\Gamma^*)}{\cosh \varepsilon^2\sqrt{\mu}\Delta\Gamma^*/2} = \frac{3}{16}\sqrt{3\mu},$$

if $\mu > \mu_{\mathrm{TP}}$ (3.37). In the context of Figure 1.1, in which $\mu = 5$, it follows that $U_{\min}(0)$ must be less than $0.72\ldots$. The evolution shown there is thus governed by Theorem 1.1.

Remark 3.7. The lower bound (3.37) on the pulse separation distance does not contradict the pulse-splitting behavior observed in the Gierer–Meinhardt equation [7], in which a stable two-pulse solution is observed with an $\mathcal{O}(1)$ pulse separation distance at the onset of splitting. It is shown in [7] that pulse splitting only occurs for $\mu = \mathcal{O}(1/\varepsilon^4)$. For these values of μ, $\Delta\Gamma^*(\mu) = \mathcal{O}(1)$ (3.37), which implies that the two V-pulses of $\Phi_\Gamma(\xi)$ are no longer well separated. Thus, the lower bound (3.37) agrees with the analysis of [7], since it implies that μ must be $\mathcal{O}(1/\varepsilon^4)$ in order to have two-pulse solutions that are not well separated.

3.3. The resolvent estimates and the semigroup. To establish estimates on the semigroup generated by the reduced linearization $\tilde{L}$ we begin with preliminary bounds on the resolvents of L_{11} and $\mathcal{L}$ in the norms defined in section 2.1. A key point is that the resolvent of L_{11} is strongly contractive on zero-mass functions.

LEMMA 3.1. *Let $\lambda \in \mathbf{C}$ be an $\mathcal{O}(1)$ distance from $\sigma(L_{11})$ and set $g = (L_{11}-\lambda)^{-1}f$. Then the following estimates hold uniformly in λ:*

$$\varepsilon\|g\|_{L^2} + \varepsilon^{-1}\|\partial_\xi g\|_{L^2} \le c\varepsilon^2\,\|f\|_{\widehat{L}^\infty}. \tag{3.39}$$

Moreover, for small total mass, $\overline{f}$ we have the improved estimate,

$$\varepsilon\|g\|_{L^2} + \varepsilon^{-1}\|\partial_\xi g\|_{L^2} \le c\left(\varepsilon^2|\overline{f}| + \varepsilon^4\left\|<x>f\right\|_{L^1}\right). \tag{3.40}$$

Proof. We take the Fourier transform of the equation $(L_{11}-\lambda)g = f$, obtaining

$$\widehat{g}(k) = \frac{1}{\sqrt{2\pi}}\frac{\varepsilon^4\widehat{f}(k)}{k^2+\varepsilon^4(\lambda+\mu)}. \tag{3.41}$$

Assuming that $f \in \widehat{L}^\infty$, the bound

$$\left(\int_{-\infty}^{\infty}\left|\frac{\varepsilon^4}{k^2+\varepsilon^4(\lambda+\mu)}\right|^2 dk\right)^{\frac{1}{2}} \le c\varepsilon, \tag{3.42}$$

for some $c > 0$, shows that $\|g\|_{L^2} \le c\varepsilon\|f\|_{\widehat{L}^\infty}$. Replacing $\widehat{f}$ with $ik\widehat{f}$ in (3.41) and calculating an integral similar to (3.42) gives $\|\partial_\xi g\|_{L^2} \le c\varepsilon^3\|f\|_{\widehat{L}^\infty}$. Together these

results yield (3.39). In the case that f has small mass, the identify $\widehat{f}(0) = \overline{f}$ and the fact that the norm $\|\langle x\rangle f\|_{L^1}$ controls the L^∞ norm of the k-derivative of the Fourier transform of f imply that $\widehat{f}$ is uniformly Lipschitz and small at zero, and so we have the estimate

$$|\widehat{f}(k)| \leq c\frac{|\overline{f}| + |k|}{1+|k|}\|\langle x\rangle f\|_{L^1}. \tag{3.43}$$

This inequality, used in (3.41), leads to the bound (3.40). □

We define $\mathcal{V}$ to be the eigenspace associated to the two exponentially small eigenvalues $\lambda_\pm^*$ of $\mathcal{L}^\dagger$, the adjoint of $\mathcal{L}$.

LEMMA 3.2. *Assume that $\lambda \in \mathbf{C}$ is an $\mathcal{O}(1)$ distance from $\sigma(\mathcal{L})\backslash\{\lambda_+, \lambda_-\}$. Then we have the following estimate, uniformly in λ, and for $\Gamma \in \mathcal{K}$:*

$$\|(\mathcal{L}-\lambda)^{-1} f\|_{H^1} \leq c\|f\|_{L^2} \tag{3.44}$$

for all $f \perp \mathcal{V}$.

Proof. The NLEP operator $\mathcal{L}$ is a finite rank perturbation of L_{22}, a self-adjoint Schrödinger operator, and hence is Fredholm. Moreover, away from its point spectrum, $\mathcal{L}-\lambda$ is boundedly invertible with $\mathcal{O}(1)$ inverse, uniformly in $\Delta\Gamma$ for $\Gamma \in \mathcal{K}$. If $f \perp \mathcal{V}$, then $\mathcal{L}-\lambda$ is uniformly invertible for λ in a neighborhood of $\lambda_\pm$. To obtain uniformity in λ for large $|\lambda|$ we observe that the resolvent of $\mathcal{L}$ can be explicitly constructed in terms of the resolvent of the selfadjoint operator L_{22} and that this later quantity decays like $(\mathrm{dist}(\lambda, \sigma(L_{22})))^{-2}$. That the resolvent of $\mathcal{L}$ maps into H^1 follows from a classic argument by contradiction. □

To study the resolvent of $\tilde{L}$ we project off the eigenspace $\{\Psi_+, \Psi_-\}$ associated to its small eigenvalues, $\lambda_\pm$. We introduce the space $X_\Gamma = \{\vec{U} \,|\, \|\vec{U}\|_X < \infty$ and $\pi_\Gamma \vec{U} = 0\}$, where the spectral projection is given in terms of the adjoint eigenfunctions $\Psi_\pm^\dagger$ by

$$\pi_\Gamma \vec{U} = \frac{(\vec{U}, \Psi_-^\dagger)}{(\Psi_-, \Psi_-^\dagger)}\Psi_- + \frac{(\vec{U}, \Psi_+^\dagger)}{(\Psi_+, \Psi_+^\dagger)}\Psi_+. \tag{3.45}$$

The complimentary projection is $\tilde{\pi}_\Gamma = I - \pi_\Gamma$. Assuming the spectral compatibility of Φ_Γ, the space X_Γ is associated to temporally decaying solutions of the semigroup generated by $\tilde{L}_\Gamma$, while $\tilde{X}_\Gamma = \mathcal{R}\pi_\Gamma$ is the eigenspace associated to the two exponentially small eigenvalues $\lambda_\pm$. To characterize the projections we need asymptotics for these eigenfunctions.

LEMMA 3.3. *The small eigenvalue eigenfunctions have the following asymptotic form:*

$$\Psi_\pm = \begin{pmatrix} 0 \\ \phi_1' \pm \phi_2' \end{pmatrix} + \text{ exponentially small}, \tag{3.46}$$

$$\Psi_\pm^\dagger = \begin{pmatrix} 0 \\ \phi_1' \pm \phi_2' \end{pmatrix} + \mathcal{O}\left(\varepsilon^4\right), \tag{3.47}$$

in the X-norm.

Proof. The expansion for the eigenfunctions follows from classical results. For the adjoint eigenfunctions we present the case for a single pulse; the generalization to two-pulses is straightforward. The adjoint operator is given by

$$\tilde{L}_\Gamma^\dagger = \begin{pmatrix} L_{11} & -\dfrac{\phi_1^2}{A^2} \\ 2\varepsilon^{-2}\phi_1 \otimes \delta_{\Gamma_1} & L_{22} \end{pmatrix}, \tag{3.48}$$

where L_{11} and L_{22} are given in (3.7). Writing $\Psi^\dagger = (\Psi_1^\dagger, \Psi_2^\dagger)^t$ and taking λ_+^* exponentially small, we solve for the second component of $\Psi^\dagger$, noting that ϕ_1 is in the range of L_{22} since it is orthogonal to its kernel, ϕ_1',

$$\Psi_2^\dagger = \beta\phi_1' - 2\varepsilon^{-2}\Psi_1^\dagger(\Gamma_1)L_{22}^{-1}\phi_1, \tag{3.49}$$

where β is a free parameter. Solving for $\Psi_1^\dagger$ we have

$$\Psi_1^\dagger = \frac{\beta}{A^2}L_{11}^{-1}\phi_1^2\phi_1' - \frac{2\Psi_1^\dagger(\Gamma_1)}{\varepsilon^2 A^2}L_{11}^{-1}\left(\phi_1^2 L_{22}^{-1}\phi_1\right). \tag{3.50}$$

The function $\phi_1^2\phi_1'$ has zero mass, so from (3.40) we have

$$\|L_{11}^{-1}\phi_1^2\phi_1'\|_{L^\infty} \le c\varepsilon^4. \tag{3.51}$$

It can be verified that $\phi_1^2 L_{22}^{-1}\phi_1$ is a positive $\mathcal{O}(1)$ function, and thus we know $L_{11}^{-1}\left(\phi_1^2 L_{22}^{-1}\phi_1\right)\big|_{\xi=\Gamma_1}$ is nonzero and $\mathcal{O}(1)$. Evaluating (3.50) at $\xi = \Gamma_1$ and solving for $\Psi_1^\dagger(\Gamma_1)$ shows that $\Psi_1^\dagger(\Gamma_1) = \mathcal{O}(\varepsilon^6)$. Substituting this back into (3.50) and choosing $\beta = 1$ yields the equivalent of (3.47) in the one-pulse case. ∎

With these results we may estimate the resolvent of $\tilde{L}_\Gamma$ restricted to X_Γ.

PROPOSITION 3.8. *Let λ be an $\mathcal{O}(1)$ distance from $\sigma(\tilde{L})\backslash\{\lambda_+, \lambda_-\}$ and denote $G = (\tilde{L} - \lambda)^{-1}F$. For $F \in X_\Gamma$, we have the following estimates on the resolvent of $\tilde{L}$, holding uniformly in λ, and in $\Gamma \in \mathcal{K}$:*

$$\|G\|_X \le c\left(\varepsilon^2\|F_1\|_{L^1} + \|F_2\|_{L^2}\right). \tag{3.52}$$

If, in addition, the mass of F_1 is small, then we have the improved estimate

$$\|G\|_X \le c\left(\varepsilon^2|\overline{F}_1| + \varepsilon^4\| <x> F_1\|_{L^1} + \|F_2\|_{L^2}\right). \tag{3.53}$$

Proof. By analogy with the eigenvalue problem we solve for G_1:

$$G_1 = (L_{11} - \lambda)^{-1}F_1 + \alpha_1 H(\lambda, \xi - \Gamma_1) + \alpha_2 H(\lambda, \xi - \Gamma_2), \tag{3.54}$$

where H is given by (3.16), and $\alpha_k = (G_2, \phi_k)_{L^2}$, for $k = 1, 2$. The second component of G satisfies

$$(L_{22} - \lambda)G_2 = F_2 + \frac{V_0^2}{A^2}\left((L_{11} - \lambda)^{-1}F_1 + \alpha_1 H(\xi - \Gamma_1) + \alpha_2 H(\xi - \Gamma_2)\right). \tag{3.55}$$

Approximating the product $V_0^2 H$ as in the eigenvalue problem, we find the equation

$$(\mathcal{L} - \lambda)\, G_2 = F_2 + \frac{V_0^2}{A^2}(L_{11} - \lambda)^{-1}F_1, \tag{3.56}$$

where the NLEP operator $\mathcal{L}$ is defined in (3.23).

From the asymptotics on $\Psi_\pm^\dagger$ the condition $F \in X_\Gamma$ is equivalent to the right-hand side of (3.56) being orthogonal to $\mathcal{V}$. From Proposition 3.1 the point spectrum of $\tilde{L}$, less its exponentially small eigenvalues, agrees with the point spectrum of $\mathcal{L}$, less its exponentially small eigenvalues, up to $\mathcal{O}(\varepsilon^2)$. So λ is an $\mathcal{O}(1)$ distance from $\sigma(\mathcal{L})\backslash\{\lambda_\pm\}$ and the estimate (3.44) applied to (3.56) yields

$$\begin{aligned}\|G_2\|_{H^1} &\le c\left(\|F_2\|_{L^2} + \|V_0^2(L_{11} - \lambda)^{-1}F_1\|_{L^2}\right)\\ &\le c\left(\|F_2\|_{L^2} + \|(L_{11} - \lambda)^{-1}F_1\|_{L^\infty}\right).\end{aligned} \tag{3.57}$$

From (3.39) and (1.2) we find that

$$\|G_2\|_{H^1} \leq c\left(\|F_2\|_{L^2} + \varepsilon^2\|F_1\|_{L^1}\right). \tag{3.58}$$

If F_1 has small mass, then by applying (3.40) we have the improved estimate

$$\|G_2\|_{H^1} \leq c\left(\|F_2\|_{L^2} + \varepsilon^2|\overline{F}_1| + \varepsilon^4\left\|<x>F_1\right\|_{L^1}\right). \tag{3.59}$$

From (3.54) and (3.39) we find that

$$\|G_1\|_{L^2} \leq c\left(\varepsilon\|F_1\|_{L^1} + \|G_2\|_{L^2}\|H(\lambda)\|_{L^2}\right), \tag{3.60}$$

but since

$$|\widehat{H}(k,\lambda)| \leq c\left|\frac{\varepsilon^2}{k^2 + \varepsilon^4(\lambda+\mu)}\right|, \tag{3.61}$$

we have $\|H(\lambda)\|_{L^2} \leq c\varepsilon^{-1}$ and we obtain

$$\|G_1\|_{L^2} \leq c\left(\varepsilon\|F_1\|_{L^1} + \varepsilon^{-1}\|F_2\|_{L^2}\right). \tag{3.62}$$

A similar argument yields

$$\|\partial_\xi G_1\|_{L^2} \leq c\left(\varepsilon^3\|F_1\|_{L^1} + \varepsilon\|F_2\|_{L^2}\right), \tag{3.63}$$

which verifies (3.52).

If F_1 has small mass, then applying (3.40) to (3.57) yields the improved estimate

$$\|G_2\|_{H^1} \leq c\left(\|F_2\|_{L^2} + \varepsilon^2|\overline{F}_1| + \varepsilon^4\left\|<x>F_1\right\|_{L^1}\right). \tag{3.64}$$

Following the arguments laid out in (3.60)–(3.63) yields (3.53). □

Since $\tilde{L}$ is an analytic operator we can generate its semigroup from the Laplace transform of the resolvent. We fix the contour C in the complex plane as depicted in Figure 3.3 and generate the semigroup S associated to $\tilde{L}|_{X_\Gamma}$ via the contour integral

$$S(t)F = \frac{1}{2\pi i}\int_C e^{\lambda t}(\lambda - \tilde{L})^{-1}F\, d\lambda, \tag{3.65}$$

where we assume that $F \in X_\Gamma$. The semigroup inherits the following properties from the resolvent.

PROPOSITION 3.9. *Let $\mu > \mu_{\text{Hopf}}$ and $\Delta\Gamma > \Delta\Gamma^*(\mu)$ be given and let $\nu > 0$ be as given by Proposition* 3.4. *The solution $\vec{U}$ of $\vec{U} = S(t)F$, where $F \in X_\Gamma$, satisfies*

$$\|\vec{U}\|_X \leq Me^{-\nu t}\left(\varepsilon^2\|F_1\|_{L^1} + \|F_2\|_{L^2}\right), \tag{3.66}$$

for some $M > 0$ independent of $\Delta\Gamma > \Delta\Gamma^*(\mu)$. If, in addition, F_1 has small mass, then we have the improved estimate

$$\|\vec{U}\|_X \leq Me^{-\nu t}\left(\varepsilon^2|\overline{F}_1| + \varepsilon^4\| <x>F_1\|_{L^1} + \|F_2\|_{L^2}\right). \tag{3.67}$$

Proof. By Proposition 3.4, the conditions on μ and Γ imply that $\sigma(\tilde{L})\backslash\{\lambda_+, \lambda_-\}$ is contained within the interior of the contour C, and $\text{dist}(\sigma(\tilde{L}), C) = \mathcal{O}(1)$. The estimates on the semigroup follow directly from the contour integral representation (3.65) of $S(t)$, the resolvent estimates (3.52)–(3.53), and the uniformity of these estimates over the contour C. □

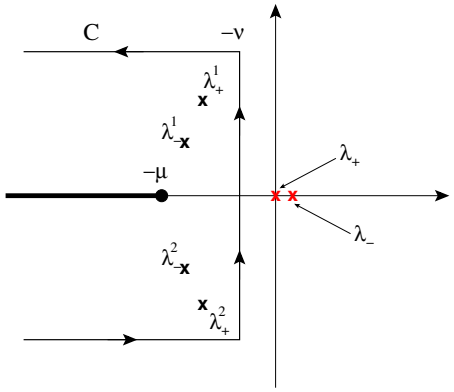

FIG. 3.2. *The spectrum $\sigma(\tilde{L})$ of the reduced operator as determined by Proposition* 3.3*, and the contour C used to generate the semigroup S. Depiction is for the case $\mu > \mu_{\mathrm{Hopf}}$ and $\Delta\Gamma > \Delta\Gamma^*(\mu)$ for which $\lambda_{\pm}^{1,2}$ are within the left-half plane and $J_{\pm} = 2$; see Proposition* 3.4*. The eigenspace corresponding to the small point spectrum $\{\lambda_{\pm}\}$ is projected away and is not contained within the contour.*

4. Nonlinear stability via the RG method. We adapt the RG method developed in [14] to the singular perturbation setting of the Gierer–Meinhardt equations. We assume at time t_0 that our initial data $\vec{U}_0$ satisfies

$$\|\Phi_{\Gamma_*} - \vec{U}_0\| \leq \delta, \tag{4.1}$$

for some $\Gamma_* \in \mathcal{K}$. The following proposition, adapted from Proposition 2.2 of [14], permits us to choose our base point Γ_0 about which we develop our local coordinate system.

PROPOSITION 4.1. *Fix $\delta \ll 1$. Given $\vec{U}_0$ and $\Gamma_* \in \mathcal{K}$ satisfying $\|W_*\|_X \leq \delta$, for $W_* \equiv \Phi_{\Gamma_*} - \vec{U}_0$, there exists $M > 0$, independent of $\vec{U}_0$ and Γ_*, and a smooth function $\mathcal{H} : X \mapsto \mathcal{K}$ such that $\Gamma = \Gamma_* + \mathcal{H}(W_*)$ satisfies*

$$W_0 \equiv \vec{U}_0 - \Phi_\Gamma \in X_\Gamma. \tag{4.2}$$

Moreover, if $W_* \in X_{\tilde{\Gamma}}$ for some $\tilde{\Gamma} \in \mathcal{K}$, then

$$|\Gamma - \Gamma_*| \leq M_0 \|W_*\|_X |\Gamma_* - \tilde{\Gamma}|. \tag{4.3}$$

Proof. Since

$$W_0 = W_* + \Phi_\Gamma - \Phi_{\Gamma_*}, \tag{4.4}$$

the condition (4.2) is equivalent to

$$0 = \pi_\Gamma W_0 = \pi_\Gamma \left(W_* + \Phi_\Gamma - \Phi_{\Gamma_*} \right). \tag{4.5}$$

Since $\Psi_\pm^\dagger$, are approximately spanned by $(0, \phi_1')^t$ and $(0, \phi_2')^t$, and $\Phi_{\Gamma,2} = V_0 + \mathcal{O}(\varepsilon^2)$, our equations $\Lambda = (\Lambda_1, \Lambda_2)^t$ are equivalent, up to $\mathcal{O}(\varepsilon^2)$, to

$$\Lambda_1(\Gamma, W_*) \equiv \Big(W_{2,*} + V_0(\Gamma) - V_0(\Gamma_*), \phi_1'(\cdot, \Gamma_1) \Big)_{L^2} = 0, \tag{4.6}$$

$$\Lambda_2(\Gamma, W_*) \equiv \Big(W_{2,*} + V_0(\Gamma) - V_0(\Gamma_*), \phi_2'(\cdot, \Gamma_2) \Big)_{L^2} = 0. \tag{4.7}$$

Since $\Lambda(\Gamma_*, 0) = 0$ and the Γ gradient of Λ given by

$$\nabla_\Gamma \Lambda\Big|_{(\Gamma=\Gamma_*, W_*=0)} = \begin{pmatrix} -\|\phi_1'\|_{L^2} & 0 \\ 0 & -\|\phi_1'\|_{L^2} \end{pmatrix} + \mathcal{O}(\varepsilon^2) \tag{4.8}$$

is uniformly invertible, the implicit function theorem guarantees the existence of a smooth function $\mathcal{H}$ which provides the solution of (4.2) and in a neighborhood about the manifold $\mathcal{M}$ defined in (2.6). The interval of existence of $\mathcal{H}$ may be chosen uniformly in Γ since the solution of (4.2) behaves smoothly as $\Delta\Gamma \to \infty$.

If, in addition, we have $W_* \in X_{\tilde{\Gamma}}$, then $(W_{2,*}, \phi_k'(\tilde{\Gamma}_k))_{L^2} = \mathcal{O}(\varepsilon^4)$ for $k = 1, 2$. We see that

$$\left|\Big(W_{2,*}, \phi_k'(\Gamma_k)\Big)_{L^2}\right| \le \left|\Big(W_{2,*}, \phi_k'(\tilde{\Gamma}_k) - \phi_k'(\Gamma_k)\Big)_{L^2}\right| \le M_0 \|W_*\|_{L^2} |\tilde{\Gamma} - \Gamma|. \qquad \square \tag{4.9}$$

4.1. The projected equations. To begin the RG procedure we freeze $\Gamma = \Gamma_0$ in X_{Γ_0}, where Γ_0 is the base point provided by Proposition 4.1, and change variables as

$$\vec{U}(t) = \Phi_\Gamma + W, \tag{4.10}$$

where $W \in X_{\Gamma_0}$ and $\Gamma = \Gamma(t)$. Comparing to (3.2), we write the evolution for the remainder W as

$$W_t + \frac{\partial \Phi}{\partial \Gamma}\dot{\Gamma} = \mathbf{R} + \tilde{L}_{\Gamma_0} W + \left(L_\Gamma - \tilde{L}_{\Gamma_0}\right) W + \mathcal{N}(W), \tag{4.11}$$

$$W(\xi, 0) = W_0, \tag{4.12}$$

where $W_0 = W_* + \Phi_{\Gamma_0} - \Phi_{\Gamma_*}$. The terms $\Delta L \equiv L_\Gamma - \tilde{L}_{\Gamma_0}$ include both the approximations made to the linear operator and the secular growth implicit in the sliding of Γ away from Γ_0.

To enforce $W \in X_{\Gamma_0}$ we impose the nondegeneracy condition $\frac{\partial}{\partial t}\pi_0 W = 0$, where $\pi_0 = \pi_{\Gamma_0}$ is given by (3.45). Since π_0 is independent of time, the nondegeneracy condition is equivalent to $\pi_0 W_t = 0$, and, moreover, as π_0 commutes with $\tilde{L}_{\Gamma_0}$ it follows that $\pi_0 \tilde{L}_{\Gamma_0} W = \tilde{L}_{\Gamma_0} \pi_0 W = 0$. The nondegeneracy condition is thus equivalent to the pair of equations obtained by projecting onto $\Psi_+^\dagger$ and $\Psi_-^\dagger$,

$$\left(\frac{\partial \Phi}{\partial \Gamma}\dot{\Gamma}, \Psi_\pm^\dagger\right)_{L^2} = \left(\mathbf{R} + \Delta L\, W + \mathcal{N}(W), \Psi_\pm^\dagger\right)_{L^2}. \tag{4.13}$$

From the form of the semistrong pulse solutions, and assuming momentarily that $\dot{\Gamma} = \mathcal{O}(\varepsilon^2)$, we calculate

$$\frac{\partial \Phi_\Gamma}{\partial \Gamma}\dot{\Gamma} = \begin{pmatrix} 0 \\ \phi_1'\dot{\Gamma}_1 + \phi_2'\dot{\Gamma}_2 \end{pmatrix} + \begin{pmatrix} \mathcal{O}(\varepsilon^3) \\ \mathcal{O}(\varepsilon^4) \end{pmatrix} \tag{4.14}$$

componentwise in the L^2 norm. Using the form of the adjoint eigenvector (3.47) and (3.6), (4.13) may be written as

$$\begin{pmatrix} \|\phi_1'\|_{L^2}^2 + \mathcal{O}(\varepsilon^4) & \|\phi_2'\|_{L^2}^2 + \mathcal{O}(\varepsilon^4) \\ \|\phi_1'\|_{L^2}^2 + \mathcal{O}(\varepsilon^4) & -\|\phi_2'\|_{L^2}^2 + \mathcal{O}(\varepsilon^4) \end{pmatrix} \dot{\Gamma} = \begin{pmatrix} \left(\mathbf{R} + \Delta L\, W + \mathcal{N}(W), \Psi_+^\dagger\right)_{L^2} \\ \left(\mathbf{R} + \Delta L\, W + \mathcal{N}(W), \Psi_-^\dagger\right)_{L^2} \end{pmatrix}. \tag{4.15}$$

Again using the asymptotic form of the adjoint eigenfunctions $\Psi^\dagger_\pm$ we may neglect the contribution from $\Psi^\dagger_{\pm,1}$ in the inner products on the right-hand side of (4.15). In particular, from the L^1 bounds on R_1 from (2.18), we have

$$(R_1, \Psi^\dagger_{\pm,1})_{L^2} \leq \|R_1\|_{L^1} \|\Psi^\dagger_{\pm,1}\|_{L^\infty} = \mathcal{O}(\varepsilon^5). \tag{4.16}$$

Inverting the matrix on the left-hand side and using the expansions for $\Psi^\dagger_{\pm,2}$, we arrive at the equations of motion for Γ which show explicitly the coupling between the remainder W and the pulse evolution,

$$\dot\Gamma_k = -\frac{(R_2 + [\Delta L\ W]_2 + \mathcal{N}_2, \phi_k'(\cdot;\Gamma_0))_{L^2}}{(\phi_k', \phi_k')_{L^2}} + \mathcal{O}(\varepsilon^5, \varepsilon^4 \|W\|_X). \tag{4.17}$$

To simplify the equation for the evolution of the remainder W, we introduce the reduced residual

$$\tilde{\mathbf{R}} = \tilde\pi_\Gamma \left(\mathbf{R} - \frac{\partial \Phi_\Gamma}{\partial \Gamma} \dot\Gamma \right), \tag{4.18}$$

and observe from the asymptotic description (2.17) of R_2 that the projection removes the leading order term from the second component of the residual. By Lemma 2.1, the reduced residual enjoys the estimates

$$\|\tilde R_1\|_{L^1} \leq \mathcal{O}(\varepsilon), \tag{4.19}$$

$$\|\tilde R_2\|_{L^2} \leq \mathcal{O}(\varepsilon^4). \tag{4.20}$$

The evolution for the remainder W is now given by

$$W_t = \tilde{\mathbf{R}} + \tilde L_0 W + \tilde\pi_0 \left(\Delta L\ W + \mathcal{N} \right), \tag{4.21}$$

$$W(\xi, t_0) = W_0, \tag{4.22}$$

where $\tilde L_0 = \tilde L_{\Gamma_0}$ and $\tilde\pi_0 = I - \pi_{\Gamma_0}$. The point of the reduction of the Gierer–Meinhardt equation (2.3) to the projected residual equation (4.21), in the case of two-pulse dynamics, is that the asymptotically relevant and the asymptotically negligible terms are now evident. The evolution for W is controlled by the first two terms on the right-hand side of (4.21); we will show that the last two terms are asymptotically irrelevant, until $\Gamma - \Gamma_0$ is so large that the secularity implicit in ΔL forces an update of Γ_0.

4.2. Decay of the remainder. We identify the duration of each renormalization interval and quantify the decay of the remainder W over this interval. To control the dynamics we introduce the quantities

$$T_0(t) = \sup_{t_0 < s < t} e^{\nu(s-t_0)} \|W(s)\|_X, \tag{4.23}$$

$$T_1(t) = \sup_{t_0 < s < t} |\Gamma(s) - \Gamma_0|. \tag{4.24}$$

The first enforces the decay of the remainder W, and the second measures the distance the pulse positions have moved from their frozen base point. The variation of constants formula applied to (4.21) yields the solution

$$W(\xi, t) = S(\Delta t) W_0 + \int_{t_0}^t S(t-s)(\tilde R + \tilde\pi_0 \left(\Delta L\ W + \mathcal{N} \right)) \, ds, \tag{4.25}$$

where we have introduced $\Delta t = t - t_0$.

To estimate the distance that the pulse locations Γ have moved from the base point Γ_0 we examine the equations (4.17). We break ΔL into secular and reductive parts $\Delta L = \Delta L_s + \Delta L_r$, where $\Delta L_s = L_\Gamma - L_{\Gamma_0}$ and $\Delta L_r = L_{\Gamma_0} - \tilde{L}_{\Gamma_0}$, and remark that

$$\|[\Delta L\ W]_2\|_{L^2} \le \|\,[\Delta L_s\, W]_2\,\|_{L^2} + \|\,[\Delta L_r\, W]_2\,\|_{L^2} \tag{4.26}$$

$$\le c\left(|\Gamma - \Gamma_0| + \varepsilon^2\right)\|W\|_{L^2} \tag{4.27}$$

$$\le c(T_1(t) + \varepsilon^2)e^{-\nu(t-t_0)}T_0(t), \tag{4.28}$$

where the estimates on ΔL_s and ΔL_r are described in more detail below. From the form (3.4) of the regularized nonlinearity it is straightforward to obtain the estimate

$$|(\mathcal{N}_2, \phi_k')_{L^2}| \le c\|W\|_X^2. \tag{4.29}$$

With these bounds in hand, the drift of the pulses is controlled by their speed,

$$T_1(t) \le \int_{t_0}^{t_0+\Delta t} |\dot{\Gamma}(s)|ds$$

$$\le \int_{t_0}^{t_0+\Delta t} c\left(\|R_2\|_{L^2} + (\varepsilon^2 + T_1(t))e^{-\nu(s-t_0)}T_0(t) + e^{-2\nu(s-t_0)}T_0^2(t)\right)ds \tag{4.30}$$

$$\le c(\varepsilon^2\Delta t + (\varepsilon^2 + T_1)T_0 + T_0^2). \tag{4.31}$$

For T_0 small enough we can eliminate T_1 from the right-hand side, and neglecting T_0 in the sum $T_0 + \Delta t$, we obtain

$$T_1 \le c(\varepsilon^2\Delta t + T_0^2). \tag{4.32}$$

Turning to bounds on the remainder, we estimate the irrelevant terms first. The secular term takes the form

$$\Delta L_s = \begin{pmatrix} 0 & 2\varepsilon^{-2}\Big(V_0(\cdot;\Gamma) - V_0(\cdot;\Gamma_0)\Big) \\ V_{12}(\cdot;\Gamma) - V_{12}(\cdot,\Gamma_0) & V_{22}(\cdot;\Gamma) - V_{22}(\cdot;\Gamma_0) \end{pmatrix}, \tag{4.33}$$

where V_{12} and V_{22} denote the potentials in the $\tilde{L}_{12}$ and $\tilde{L}_{22}$ components of $\tilde{L}$. Since each potential, V_0, V_{12}, and V_{22}, decays rapidly away from the pulse locations, the difference between the potential centered at pulse locations Γ_0 and at Γ scales like $\Gamma - \Gamma_0$ in any reasonable norm. In particular,

$$\|V_0(\cdot,\Gamma) - V_0(\cdot,\Gamma_0)\|_{H^1} + \|V_0(\cdot,\Gamma) - V_0(\cdot,\Gamma_0)\|_{L^1} \le c|\Gamma - \Gamma_0|, \tag{4.34}$$

and similarly for V_{12} and V_{22}. Using these estimates it follows directly that

$$\|[\Delta L_s\, W]_1\|_{L^1} \le c\varepsilon^{-2}\|V_0(\cdot,\Gamma) - V_0(\cdot,\Gamma_0)\|_{L^1}\|W_2\|_{L^\infty} \tag{4.35}$$

$$\le c\varepsilon^{-2}T_1\|W\|_X. \tag{4.36}$$

Similarly

$$\|[\Delta L_s\, W]_2\|_{L^2} \le c\|V_{12}(\cdot,\Gamma) - V_{12}(\cdot,\Gamma_0)\|_{H^1}\|W_1\|_X$$

$$+ \|V_{22}(\cdot,\Gamma) - V_{22}(\cdot,\Gamma_0)\|_{H^1}\|W_2\|_X \tag{4.37}$$

$$\le cT_1\|W\|_X. \tag{4.38}$$

Combining these estimates with the unweighted semigroup estimate (3.66) we find that

$$\|S(t-s)\tilde{\pi}_0(\Delta L_s\ W(s))\|_X \leq Me^{-\nu(t-s)}T_1(s)\|W\|_X. \tag{4.39}$$

The small mass version of the semigroup estimate plays a key role in controlling the reductive term $\Delta L_r\ W$ given by

$$\Delta L_r = \begin{pmatrix} 0 & 2\varepsilon^{-2}\Big(V_0 - \delta_{\Gamma_1}\otimes\phi_1(\Gamma_0) - \delta_{\Gamma_2}\otimes\phi_2(\Gamma_0)\Big) + \mathcal{O}(1) \\ \mathcal{O}(\varepsilon^2 V_0^2) & \mathcal{O}(\varepsilon^2 V_0) \end{pmatrix}, \tag{4.40}$$

where here the $\mathcal{O}$ indicates pointwise estimates. The first component of the reductive term can be decomposed as

$$[\Delta L_r\, W]_1 = \varepsilon^{-2}\left(\Sigma_1 + \Sigma_2\right), \tag{4.41}$$

where

$$\Sigma_k = \phi_k - \delta_{\Gamma_1}\otimes\phi_k + \mathcal{O}(\varepsilon^2\phi_k). \tag{4.42}$$

That is, each Σ_k decays at an $\mathcal{O}(1)$ exponential rate away from $x = \Gamma_k$, and, moreover, at leading order each component $\Sigma_k W_2$ is mass-free for $k = 1, 2$. In particular, the total mass of the 1 component of $\Delta L_r\, W$ arises only from the higher order corrections,

$$|\overline{[\Delta L_r\, W]_1}| \leq c\|W_2\|_X. \tag{4.43}$$

In the weighted norms we estimate

$$\begin{aligned} \|<x-\Gamma_k>\Sigma_k W_2\|_{L^2} &\leq \varepsilon^{-2}(\|\langle x-\Gamma_k\rangle\delta_{\Gamma_k}\|_{L^2} + \|\langle x-\Gamma_k\rangle\phi_k\|_{L^2})\|W_2\|_{L^\infty} \\ &\leq c\varepsilon^{-2}\|W\|_X, \end{aligned} \tag{4.44}$$

for $k = 1, 2$. For the second component we observe that

$$\|[\Delta L_r W]_2\|_{H^1} \leq c\varepsilon^2\|W\|_{H^1}, \tag{4.45}$$

so from the weighted semigroup estimate (3.67) we find

$$\|S(t-s)\tilde{\pi}_0(\Delta L_r\ W(s))\|_X \leq Me^{-\nu(t-s)}\varepsilon^2\|W\|_X \tag{4.46}$$

independent of the pulse spacing $\Delta\Gamma$.

Finally, for the nonlinear term given by (3.4), it is easy to verify

$$\|S(t-s)\tilde{\pi}_0\mathcal{N}\|_X \leq Me^{-\nu(t-s)}(\|W_2^2\|_{L^1} + \|W_2^2\|_{L^2} + \|W_1^2\|_{L^2}) \tag{4.47}$$

$$\leq Me^{-\nu(t-s)}\|W\|_X^2. \tag{4.48}$$

From the bounds on the reduced residual (4.19)–(4.20) and the semigroup estimate we obtain

$$\|S(t-s)\tilde{R}\|_X \leq M\varepsilon^3 e^{-\nu(t-s)}. \tag{4.49}$$

Taking the X-norm of variation of constants solution for W, (4.25), and using the estimates outlined above we obtain

(4.50)
$$\|W(t)\|_X \leq M\left(e^{-\nu\Delta t}\|W(t_0)\|_X + \int_{t_0}^{t} e^{-\nu(t-s)}\left[\varepsilon^3 + \left(\varepsilon^2 + T_1(s)\right)\|W(s)\|_X + \|W(s)\|_X^2\right] ds\right).$$

To estimate the decay of $\|W(t')\|_X$ for $t' \in (t_0, t)$ we evaluate (4.50) at $t = t'$, multiply by $e^{\nu(t'-t_0)}$, and take the sup over $t' \in (t_0, t)$ obtaining

$$T_0(t) \leq M\left(T(t_0) + \int_{t_0}^{t}\left[\varepsilon^3 e^{\nu(s-t_0)} + \left(\varepsilon^2 + T_1(t)\right)T_0(t) + e^{-\nu s}T_0(t)^2\right] ds\right) \tag{4.51}$$

$$\leq M(T_0(t_0) + \varepsilon^3 e^{\nu\Delta t} + \left(\varepsilon^2 + T_1(t)\right)\Delta t\, T_0(t) + T_0(t)^2). \tag{4.52}$$

From (4.32) we may eliminate T_1 from the T_0 estimate,

$$T_0(t) \leq M(T_0(t_0) + \varepsilon^3 e^{\nu\Delta t} + \varepsilon^2(\Delta t + (\Delta t)^2)T_0(t) + T_0(t)^2 + \Delta t\, T_0^3). \tag{4.53}$$

For $\Delta t \ll \min\left\{\varepsilon^{-1}, T_0^{-1}\right\}$ the term $M\varepsilon^2((\Delta t)^2 + \Delta t) < \frac{1}{2}$, and we may eliminate the linear term in T_0 from the right-hand side. In addition we may absorb the cubic term in T_0 into the quadratic one. With these reductions (4.53) becomes

$$T_0 \leq 2M(T_0(t_0) + \varepsilon^3 e^{\nu\Delta t} + T_0^2). \tag{4.54}$$

The quadratic equation in T_0,

$$0 = T_0(t_0) + \varepsilon^3 e^{\nu\Delta t} - \frac{1}{2M}T_0 + T_0^2, \tag{4.55}$$

has two positive real roots so long as $T_0(t_0) + \varepsilon^3 e^{\nu\Delta t} \ll 1$. The smaller of these roots, r_0, takes the form

$$r_0 = 2M(T_0(t_0) + \varepsilon^3 e^{\nu\Delta t}) + \mathcal{O}(T_0(t_0) + \varepsilon^3 e^{\nu\Delta t})^2, \tag{4.56}$$

while the larger is

$$r_1 = \frac{1}{2M} + \mathcal{O}(T_0(t_0) + \varepsilon^3 e^{\nu\Delta t}). \tag{4.57}$$

Thus if $T_0(t_0) \ll 1$ and $\varepsilon^3 e^{\nu\Delta t} \ll 1$, then there is an *excluded region*, either $0 < T_0 < r_0$ or $r_1 < T_0 < \infty$. Since $T_0(t_0) < r_0$ and T_0 is continuous in t, we see that

$$T_0(t) \leq r_0 \leq M(T_0(t_0) + \varepsilon^3 e^{\nu\Delta t}) \tag{4.58}$$

so long as

$$\Delta t \leq \frac{3\beta|\log\varepsilon|}{\nu} \tag{4.59}$$

for any fixed $\beta < 1$. This condition on Δt prevents the secularity from dominating the linear operator; in particular, it is a stronger condition on Δt than that imposed after (4.53). This implies that

$$\|W(t)\|_X \leq M(e^{-\nu(t-t_0)}\|W(t_0)\|_X + \varepsilon^3), \quad \text{for } t \in \left(t_0, t_0 + \frac{3\beta|\log\varepsilon|}{\nu}\right) \tag{4.60}$$

and, in particular, for $t_1 = t_0 + \Delta t$ we have

$$\|W(t_1)\|_X \leq M(\varepsilon^{3\beta}\|W(t_0)\|_X + \varepsilon^3). \tag{4.61}$$

4.3. The RG iteration. We break the time evolution into a series of initial value problems, tracking the decay of the remainder over the long-time scale of many RG iterations. We fix $\beta < 1$ and $\Delta t = \frac{3\beta|\log\varepsilon|}{\nu}$. The renormalization times are defined sequentially,

$$t_n = t_{n-1} + \Delta t. \tag{4.62}$$

We break the evolution of W into disjoint intervals $I_n = [t_n, t_{n+1})$. On each interval I_n we solve the initial value problem (4.21) with initial data $W(t_n) \in X_{\Gamma_n}$, with the quantities $T_{0,n}$ and $T_{1,n}$ corresponding to (4.23)–(4.24) over I_n. The renormalization map, $\mathcal{G}$, takes the initial data $W_{n-1} = W(t_{n-1})$ for the initial value problem on interval I_{n-1} and returns the initial data $W_n = W(t_n)$ for the initial value problem on the interval I_n,

$$\mathcal{G}W_{n-1} = W_n. \tag{4.63}$$

Arguing inductively, the initial data and the new base point Γ_n are obtained from $W(t_n^-)$, the end-value of the evolution of W over I_{n-1}, by applying Proposition 4.1. Indeed, we know that $W(t_n^-) \in X_{\Gamma_{n-1}}$ and so from (4.3) we have

$$|\Gamma_n - \Gamma(t_n^-)| \le M_0\|W(t_n^-)\|_X|\Gamma(t_n^-) - \Gamma(t_{n-1})| \le M_0\|W(t_n^-)\|_X T_{1,n-1}(t). \tag{4.64}$$

From the estimates on Δt and $T_{1,n-1}$, we bound the jump in Γ at renormalization by

$$|\Gamma_n - \Gamma(t_n^-)| \le M_0\left(|\log\varepsilon|\varepsilon^2 + T_{0,n-1}^2\right)\|W(t_n^-)\|_X. \tag{4.65}$$

The solution at time $t = t_n$ is independent of the decomposition,

$$\vec{U}(t_n) = \Phi_{\Gamma(t_n^-)} + W(t_n^-) = \Phi_{\Gamma_n} + W_n, \tag{4.66}$$

and we may bound the jump in W at each renormalization

$$\begin{aligned}\|W(t_n^-) - W(t_n)\|_X &= \|\Phi_{\Gamma(t_n^-)} - \Phi_{\Gamma_n}\|_X \le c|\Gamma_n - \Gamma(t_n^-)| \\ &\le M_0\left(|\log\varepsilon|\varepsilon^2 + T_{0,n-1}^2\right)\|W(t_n^-)\|_X,\end{aligned} \tag{4.67}$$

where we used the fact that U_0 is $\mathcal{O}(1)$ X-Lipschitz in Γ, as follows from (3.5) and (1.2). From (4.58), using the equality $T_{0,n-1}(t_{n-1}) = \|W_{n-1}\|_X$, we have the estimate

$$T_{0,n-1} \le M_1(\|W_{n-1}\|_X + \varepsilon^{3(1-\beta)}). \tag{4.68}$$

Combining the estimates (4.67) and (4.68) with (4.61), we obtain a bound on $\mathcal{G}W_{n-1} = W_n$,

$$\begin{aligned}\|\mathcal{G}W_{n-1}\|_X \le (1 + M_0[|\log\varepsilon|\varepsilon^2 + M_1^2(\|W(t_{n-1})\|_X + \varepsilon^{3(1-\beta)})^2]) \\ \times M(\varepsilon^{3\beta}\|W(t_{n-1})\|_X + \varepsilon^3).\end{aligned} \tag{4.69}$$

Neglecting the terms involving positive powers of ε within the first parenthesis on the left-hand side, we may bound $\|W(t_n)\|_X$ by η_n, the solution of the map

$$\eta_n = M(1 + M_2\eta^2)(\varepsilon^{3\beta}\eta_{n-1} + \varepsilon^3), \tag{4.70}$$

with $\eta_0 = \|W(\cdot, t_0)\|_X$, and $M_2 = M_0M_1^2$. It is easy to see for $\eta_0 = \mathcal{O}(1)$ and ε sufficiently small that

$$\eta_n \to \frac{M}{1 - \varepsilon^{3\beta}M}\varepsilon^3, \tag{4.71}$$

as $n \to \infty$. Since $\|W(\cdot, t_n)\|_X \le \eta_n$, the estimate (4.61) yields the result (1.4) in Theorem 1.1.

4.4. Long-time asymptotics. To recover the asymptotic pulse motion, we consider the situation where t is sufficiently large so that $\|W\|_X \leq M\varepsilon^3$. In this regime we see from (4.32) that $T_1 \leq c\varepsilon^2|\log\varepsilon|$, and hence from (4.27) that

$$\|\Delta L\ W\|_{L^2} \leq c\varepsilon^2|\log\varepsilon|\|W\|_{L^2} \leq c\varepsilon^5|\log\varepsilon|. \tag{4.72}$$

Moreover, from the form (3.4) of the nonlinearity we readily verify that

$$\|\mathcal{N}_2(W)\| \leq c\|W\|_X^2 = \mathcal{O}(\varepsilon^6). \tag{4.73}$$

In this regime the estimates (4.72) and (4.73) on the secularity and the nonlinearity show that the remainder W has an asymptotically small influence on the pulse evolution equations (4.17), which reduce to

$$\dot{\Gamma}_k(t) = -\frac{(R_2, \phi_k'(\cdot;\Gamma(t)))_{L^2}}{\|\phi_k'\|_{L^2}^2} + \mathcal{O}(|\log\varepsilon|\varepsilon^5). \tag{4.74}$$

Furthermore, the asymptotic form (2.17) for the second component of the remainder shows that

$$\dot{\Gamma}_k(t) = \varepsilon^2\hat{c}(\Gamma)\frac{(\phi_1' - \phi_2', \phi_k')_{L^2}}{\|\phi_k'\|_{L^2}^2} + \mathcal{O}(\varepsilon^4) = (-1)^{k+1}\varepsilon^2\hat{c}(\Gamma) + \mathcal{O}(\varepsilon^4), \tag{4.75}$$

where $\hat{c}(\Gamma)$ is, by construction, the position-dependent formal pulse speed given by (2.8). In particular, the pulse separation $\Delta\Gamma = \Gamma_1 - \Gamma_2$ grows as given by (1.5) while the amplitudes increase according to (2.11).

DIFFUSION LIMIT OF A SEMICONDUCTOR BOLTZMANN–POISSON SYSTEM*

NADER MASMOUDI† AND MOHAMED LAZHAR TAYEB‡

Abstract. The paper deals with the diffusion limit of the initial-boundary value problem for the multidimensional semiconductor Boltzmann–Poisson system. Here, we generalize the one-dimensional results obtained in [5] to the case of several dimensions using global renormalized solutions. The method of moments and a velocity averaging lemma are used to prove the convergence of the renormalized solutions to the semiconductor Boltzmann–Poisson system towards a global weak solution of the drift-diffusion-Poisson model.

Key words. kinetic transport equations, semiconductor Boltzmann–Poisson system, drift-diffusion model, entropy dissipation, moment method, velocity averaging lemma, renormalized solution

1. Introduction and main results. In this paper, we study the diffusion limit of the initial-boundary value problem for the semiconductor Boltzmann–Poisson system (see [24, 27]). The model we consider here is associated with a linear low density approximation of the electron-phonon collisions. In other words it is a low density approximation of the physically correct Fermi–Dirac system. When the potential is given and is smooth enough, Poupaud [27] has proved the convergence of the rescaled Boltzmann equation towards a linear drift-diffusion model. Let us recall that the drift-diffusion equation is a standard model for semiconductors physics and suited for numerical computations since it does not involve the kinetic variable v. We refer to [9, 14, 15, 24] for a discussion about drift-diffusion models.

In the one-dimensional case, the convergence results of [27] are extended in [5] to the semiconductor Boltzmann system with a Poisson coupling. In [5] the solutions considered are defined in a weak sense [1, 4, 5]. The entropy inequality and a hybrid-Hilbert expansion are used to approximate the entropy production term due to the boundary and allow the proof of the convergence of the rescaled Boltzmann equation towards the drift-diffusion for self-consistent potential. The method is based essentially on the fact that solutions to the limit system are smooth, which gives useful uniform bounds on all terms of the Hilbert expansion and then allows one to obtain a strong convergence and also to exhibit a convergence rate. The multidimensional case is different. Indeed, if we want to work with global solutions, we can only deal with solutions to the semiconductor Boltzmann–Poisson which are defined in the renormalized sense (see [11, 25]). Indeed, due to the presence of the Poisson term and the Boltzmann collision term in the equation for the density, we cannot prove global uniform bounds in any L^p space for $p > 1$. On one hand, we can see that if we remove the collision term, then we can easily get a priori estimates for f in any

$L^\infty((0,T);L^p(dxdv))$, $1 \le p \le \infty$. On the other hand, if we remove the Poisson term, then we can get a priori estimates for f in any $L^\infty((0,T);L^p(dxM^{1-p}dv))$, $1 \le p < \infty$. Hence, we can see that, mathematically, these two terms cannot be treated in the same spaces. This is one of the major mathematical difficulties of this model.

Before recalling the Boltzmann–Poisson system, let us mention that drift-diffusion models can also be derived from other singular limits. We refer, for instance, to [28] where the drift-diffusion model is derived from a Vlasov–Fokker–Planck system.

1.1. Formulation of the problem. In this paper we study the parabolic limit of the rescaled Boltzmann–Poisson system. Hence, the rescaled system, defined on the phase space $\Omega = \omega \times \mathbb{R}^d$ where $d \ge 1$, reads as follows:

$$\partial_t f^\varepsilon + \frac{1}{\varepsilon}\left(v.\nabla_x f^\varepsilon - \nabla_x(\phi^\varepsilon + \tilde{\phi}_b).\nabla_v f^\varepsilon\right) - \frac{Q(f^\varepsilon)}{\varepsilon^2} = 0, \quad (x,v) \in \Omega, \tag{1}$$

where ε is a small parameter related to the mean free path and $f^\varepsilon(t,x,v)$ denotes the electron distribution function. The time variable t is nonnegative. The position x belongs to an open set ω of $\mathbb{R}^d$, assumed to be smooth and bounded and the velocity v belongs to $\mathbb{R}^d$. This equation has to be complemented with initial and boundary conditions which take into account how particles are injected in the semiconductor device. We assume that the boundary $\partial\omega$ is sufficiently smooth. We denote by $n(x)$ the outward unit normal vector at the position $x \in \partial\omega$ and $d\sigma_x$ the Lebesgue measure on $\partial\omega$. The outgoing and incoming parts are defined as

$$\Gamma^\pm = \{(x,v) \in \partial\Omega;\ \pm v.n(x) > 0\}.$$

The initial data is assumed to be known and depend on the mean free path ε:

$$f^\varepsilon(0,x,v) = f_0^\varepsilon(x,v), \qquad (x,v) \in \Omega. \tag{2}$$

The incoming boundary data is assumed to be a well-prepared function [4, 5, 27], in the sense that

$$f^\varepsilon(t,x,v) = f_b(t,x,v) := \rho_b(t,x)M(v), \qquad (x,v) \in \Gamma^-, \tag{3}$$

where M is the normalized Maxwellian

$$M(v) = \frac{e^{-|v|^2/2}}{(2\pi)^{d/2}}$$

and $\rho_b(t,x)$ is a boundary data. The precise assumptions we choose on the initial and boundary conditions will be detailed later on. The linear operator Q describes physical conservation properties during collisions. Here, we only assume that the charge is conserved during the collision [2, 24]. A typical model for such a situation is the linear approximation of the electron-phonon interaction, given by

$$Q(f)(v) = \int_{\mathbb{R}^d} \sigma(v,v')(M(v)f(v') - M(v')f(v))dv'. \tag{4}$$

The cross section σ is assumed to be symmetric (micro-reversibility principle) and bounded from above and below:

$$\begin{cases} \sigma(v,v') = \sigma(v',v), \quad (v,v') \in \mathbb{R}^{2d}, \\ \exists\ \sigma_1,\ \sigma_2 > 0 \quad / \quad 0 < \sigma_1 \le \sigma \le \sigma_2. \end{cases} \tag{5}$$

Here, we are making another approximation by assuming that σ is bounded from below and above instead of taking delta measures concentrated on balls of constant kinetic energies (see, [3, 6]).

The mean free path is defined to be an average of the collision frequency $\lambda(v)$ given by

$$\lambda(v) = \int_{\mathbb{R}^d} \sigma(v, v')M(v')dv'.$$

Here, for all v, we have $\sigma_1 \leq \lambda(v) \leq \sigma_2$. Hence, the mean free path in (1) is of order $1/\varepsilon$. We refer to [4, 5, 27] for the detailed properties of these kinds of collision kernels. We assume that the potential ϕ^ε is self consistent:

$$\left\{ \begin{array}{l} -\Delta_x \phi^\varepsilon = \displaystyle\int_{\mathbb{R}^d} f^\varepsilon dv, \\ \phi^\varepsilon{}_{|\partial\omega} = 0. \end{array} \right. \tag{6}$$

The potential $\tilde{\phi_b}$ is given in $\overline{\omega}$. It takes into account the distribution of positive background charges.

We define the charge density ρ^ε and the current density j^ε associated to the distribution f^ε by

$$\rho^\varepsilon(t,x) = \int_{\mathbb{R}^d} f^\varepsilon(t,x,v)dv, \qquad j^\varepsilon(t,x) = \frac{1}{\varepsilon}\int_{\mathbb{R}^d} v f^\varepsilon(t,x,v)dv.$$

1.2. Assumptions and preliminaries. Throughout the paper we shall make the following assumptions and notations:

A1: $f_0^\varepsilon \geq 0$, $\displaystyle\int_\Omega f_0^\varepsilon(1+|v|^2+|\log f_0^\varepsilon|) \leq C$ and $\phi^\varepsilon(t=0)$ is bounded in $H^1(\omega)$.

A2: $(\sqrt{\rho_b}, \partial_t \rho_b) \in L^\infty_{loc}(\mathbb{R}^+;\, H^{1/2}(\partial\omega) \times L^\infty(\partial\omega))$ and the density is bounded from above and below; there exist $\underline{c}$ and $\overline{c}$ such that $0 < \underline{c} \leq \rho_b(.,x) \leq \overline{c}$, for $x \in \partial\omega$.

A3: $\tilde{\phi_b} \geq 0$ and $(\tilde{\phi_b}, \partial_t \tilde{\phi_b}) \in L^\infty_{loc}(\mathbb{R}^+;\, W^{1,\infty}(\overline{\omega}) \times L^\infty(\overline{\omega}))$.

We define the total charge (or mass), the kinetic energy, and two distances to the local equilibrium by

$$\mathcal{M}^\varepsilon(t) = \int_\Omega f^\varepsilon(t,x,v)dxdv, \qquad \mathcal{K}^\varepsilon(t) = \int_\Omega \frac{|v|^2}{2} f^\varepsilon(t,x,v)dxdv,$$

$$\mathcal{R}^\varepsilon(t) = \frac{1}{2}\int_0^t \int_\Omega \left(\sqrt{f^\varepsilon} - \sqrt{\rho^\varepsilon M}\,\right)^2 dxdvds \tag{7}$$

$$\mathcal{R}_1{}^\varepsilon(t) = \frac{1}{2}\int_0^t \int_\Omega \left(f^\varepsilon - \rho^\varepsilon M\,\right)\left(\log f^\varepsilon - \log(\rho^\varepsilon M)\,\right) dxdvds.$$

The entropy and entropy fluxes through the inflow and outflow boundaries are defined by

$$\begin{aligned} \mathcal{E}^\varepsilon(t) &= \frac{1}{2}\left\|\nabla_x \phi^\varepsilon(t)\right\|^2_{L^2(\omega)} + \int_\Omega f^\varepsilon \left(\log f^\varepsilon + \frac{|v|^2}{2} + \tilde{\phi_b}\right)(t), \\ I^\pm_\varepsilon(t) &= \int_0^t \int_{\Gamma^\pm} f^\varepsilon \left(\log f^\varepsilon + \frac{|v|^2}{2} + \phi_b\right) |v.n(x)|\, d\sigma_x dvds. \end{aligned} \tag{8}$$

We also define the quasi-Fermi level (defined on the boundary $\partial\omega$)

$$\mathcal{E}_F(t,x) = \log\left(\frac{\rho_b(t,x)}{(2\pi)^{d/2}}\right) + \tilde{\phi}_b(t,x). \tag{9}$$

Let us recall two lemmas about the collision kernel (see [27]).

LEMMA 1.1 (H-theorem). *Assume that* (5) *holds, then the operator Q is bounded in $L^1(dv)$ and satisfies for all $f \in L^1(dv)$, $f \geq 0$, and $f(|\log f| + |v|^2) \in L^1(dv)$*

$$\int_{\mathbb{R}^d} Q(f) = 0 \quad \textit{and} \quad \mathcal{H}(f) = \int_{\mathbb{R}^d} Q(f)\log\left(\frac{f}{M}\right) \leq -\frac{\sigma_1}{2}\int_{\mathbb{R}^d}\left(\sqrt{f} - \sqrt{\rho\, M}\right)^2,$$

where $\rho = \int f(v)dv$. Moreover,

$$\mathcal{H}(f) = 0 \Leftrightarrow Q(f) = 0 \Leftrightarrow f(v) = \rho\, M(v).$$

LEMMA 1.2. *Assume that* (5) *holds, then*

1. *$-Q$ is a bounded, symmetric, nonnegative operator on $L^2(\mathbb{R}^d;\ M^{-1}dv)$,*
2. *$\mathcal{K}erQ = \mathbb{R}\, M$,*
3. *$-Q$ is coercive on $\mathcal{R}(Q) = \mathcal{K}erQ^{\perp}$.*

1.3. Statement of the result. Our motivation in this work is to prove the convergence of renormalized solutions $(f^\varepsilon, \phi^\varepsilon)$ to (1–6) towards $(\rho M, \phi)$, where (ρ, ϕ) satisfies the following drift-diffusion-Poisson (DD-P) system [14, 18, 27]:

$$\text{(DD-P)} \quad \begin{cases} \partial_t\rho + \nabla_x.J(\rho,\phi) = 0, \\ J(\rho,\phi) = -\mathbf{D}[\nabla_x\rho + \rho\nabla_x(\phi + \tilde{\phi}_b)], \\ \mathbf{D} = -\displaystyle\int_{\mathbb{R}^d} v \otimes\ Q^{-1}(vM)dv > 0, \\ -\Delta_x\phi = \rho, \\ \rho(t=0) = \rho_0, \quad (\rho,\phi)\,_{|\partial\omega} = (\rho_b, 0). \end{cases}$$

DEFINITION 1.3. *We say that (ρ,ϕ) is a weak solution to the drift-diffusion-Poisson system (DD-P) if*

$$\begin{aligned} &\rho \in L^\infty(0,T;\ \mathrm{LlogL}(\omega)) \cap L^2(0,T;\ L^2(\omega)), \\ &\sqrt{\rho} \in L^2(0,T;\ H^1(\omega)), \\ &\partial_t\rho \in L^1(0,T;\ W^{-1,1}(\omega)), \\ &\phi \in L^2(0,T;\ H^1_0(\omega)). \end{aligned}$$

and (ρ,ϕ) satisfies (DD-P) in the weak sense.

We recall here the definition of the space $\mathrm{LlogL}(\omega)$,

$$\mathrm{LlogL}(\omega) = \{f | f \geq 0 \,\text{and}\, \int_\omega [\, f\,(1 + |\log f|)] \text{ is finite}\}, \tag{10}$$

and that $\rho \in L^\infty(0,T;\ \mathrm{LlogL}(\omega))$ if and only if $\int_\omega \rho(t)\,(1 + |\log\rho(t)|)\,dx \leq C$, where C is independent of $t \in (0,T)$.

We also point out that due to the fact that $\partial_t\rho \in L^1(0,T;\ W^{-1,1}(\omega))$, we deduce that ρ is continuous in time with values in $W^{-1,1}(\omega)$ and hence the initial data for ρ makes sense. The main result of this paper is the following theorem.

THEOREM 1.4. *Assume that assumptions* A1, A2, *and* A3 *hold. Let* $(f^\varepsilon, \phi^\varepsilon)$ *be a renormalized solution of* (1–6) *(in the sense of Theorem* 2.2*). Then,*

$$\begin{array}{ll} f^\varepsilon \to \rho M & \text{in } L^1((0,T)\times\Omega), \\ \phi^\varepsilon \to \phi & \text{in } L^2((0,T); W^{1,p}(\omega)) \quad \forall\, p<2, \end{array} \tag{11}$$

where (ρ, ϕ) *is a weak solution of the (DD-P). Moreover,*

$$\phi \in L^\infty(0,T;\ H_0^1(\omega)) \cap L^2(0,T;\ H^2(\omega)).$$

The proof of this theorem is as follows. In section 2, we prove the existence of renormalized solutions to the semiconductor Boltzmann–Poisson system. In section 3, we establish some a priori uniform estimates. These estimates generalize the estimates obtained in [5]. To get the convergence we argue in a different manner as in [5]. Indeed, in the one-dimensional case the energy estimate of section 3 and the convergence are deduced from a hybrid-Hilbert expansion which is based on the regularity of the limiting system. In the present case, the solution to the (DD-P) is not regular enough and the solutions of the initial system are only renormalized. Instead, the method of moment and velocity averaging are used to pass to the limit ($\varepsilon \to 0$). In section 4, we use a velocity averaging lemma to prove the compactness of the charge density ρ. In section 5, we pass to the limit weakly in the equation. In section 6, we recover the boundary condition for ρ. Finally, section 7 is devoted to the proof of the regularity estimates on (ρ, ϕ) and that the limit solution (ρ, ϕ) is a weak solution of (DD-P).

2. Existence of renormalized solutions. For the existence of renormalized solutions to the full Boltzmann–Poisson system we refer to [11, 25]. It is noteworthy that even though the Boltzmann kernel we are considering here is linear, the combination of the Boltzmann term and the Poisson term makes the existence of weak solutions to (1–6) with uniform bounds a difficult problem and we were not able to construct such kinds of solutions. This is coming from the fact that the Poisson term can be well treated in $L^p(dv)$ type of spaces whereas the linear Boltzmann term can be well treated in $L^p(M^{1-p}dv)$. This incompatibility is responsible for the lack of estimates. We notice then that the entropy bound given in (15) is not enough to give a sense to $\nabla_x \phi^\varepsilon f_\varepsilon$.

Before stating an existence theorem for (1–6) let us give a definition for renormalized solution or more precisely the definition we are going to use.

DEFINITION 2.1. *We say that* $(f^\varepsilon, \phi^\varepsilon)$ *is a renormalized solution to the semiconductor Boltzmann–Poisson system if it satisfies the following:*

1. $\forall\, \beta \in \mathcal{C}^1(\mathbb{R}^+)$, $|\beta(t)| \le C(\sqrt{t}+1)$ *and* $|\beta'(t)| \le C$, $\beta(f^\varepsilon)$ *is a weak solution of*

$$\begin{cases} \varepsilon\partial_t\beta(f^\varepsilon) + v.\nabla_x\beta(f^\varepsilon) - \nabla_v.(\nabla_x(\phi^\varepsilon + \tilde{\phi}_b)\beta(f^\varepsilon)) = \beta'(f^\varepsilon)\frac{Q(f^\varepsilon)}{\varepsilon} \\ \beta(f^\varepsilon)_{|\Gamma^-} = \beta(f_b^\varepsilon), \\ \beta(f^\varepsilon)(t=0) = \beta(f_0^\varepsilon). \end{cases} \tag{12}$$

2. $\forall\, \lambda > 0$, $\theta_{\varepsilon,\lambda} = \sqrt{f^\varepsilon + \lambda M}$ *satisfies*

$$\varepsilon\partial_t\theta_{\varepsilon,\lambda} + v.\nabla_x\theta_{\varepsilon,\lambda} - \nabla_v.[\nabla_x(\phi^\varepsilon + \tilde{\phi}_b)\theta_{\varepsilon,\lambda}] = \frac{Q(f^\varepsilon)}{2\varepsilon\theta_{\varepsilon,\lambda}} + \frac{\lambda M}{2\theta_{\varepsilon,\lambda}} v.\nabla_x(\phi^\varepsilon + \tilde{\phi}_b). \tag{13}$$

THEOREM 2.2. *The semiconductor Boltzmann–Poisson system* (1–6) *has a renormalized solution in the sense of Definition* 2.1 *which satisfies, in addition,*

1. *The continuity equation*

$$\partial_t \rho^\varepsilon + \nabla_x . j^\varepsilon = 0 \tag{14}$$

2. *The entropy inequality*

$$\left[\int_\Omega f^\varepsilon \left(\tilde{\phi}_b + \frac{|v|^2}{2} + \log f^\varepsilon\right) + \frac{1}{2}\|\nabla\phi^\varepsilon\|_{L^2}^2\right]_0^t - \frac{1}{\varepsilon^2}\int_0^t\int_\Omega Q(f^\varepsilon)\log\left(\frac{f^\varepsilon}{M}\right)$$
$$\leq \int_0^t\int_\Omega \partial_t\tilde{\phi}_b f^\varepsilon - \frac{1}{\varepsilon}\int_0^t\int_{\Gamma^+\cup\Gamma^-} f^\varepsilon\left(\phi_b + \frac{|v|^2}{2} + \log f^\varepsilon\right)(v.n(x)). \tag{15}$$

Proof. For the convenience of the reader, we give an idea of the proof in Appendix A. We also refer to [25] for more details. □

3. Uniform energy estimates.

LEMMA 3.1. *Assume that assumptions* A1, A2, *and* A3 *are satisfied. Then, any renormalized solution* $(f^\varepsilon, \phi^\varepsilon)$ *of the semiconductor Boltzmann–Poisson system* (1–6) *satisfies*

$$\mathcal{M}^\varepsilon(t) + \mathcal{K}^\varepsilon(t) + \|\nabla\phi^\varepsilon(t)\|_{L^2}^2 + \frac{\mathcal{R}_1^\varepsilon(t)}{\varepsilon^2} + \int_0^t \|j^\varepsilon(s)\|_{L^1} ds \leq C_T \tag{16}$$

uniformly in ε, *where* $\mathcal{M}^\varepsilon$, $\mathcal{K}^\varepsilon$, *and* $\mathcal{R}_1^\varepsilon$ *are defined in* (7).

Proof. Starting from the entropy inequality (15), one can write the entropy dissipation in the following form:

$$\int_{\mathbb{R}^d} Q(f^\varepsilon)\log\left(\frac{f^\varepsilon}{M}\right)dv$$
$$= -\frac{1}{2}\int_{\mathbb{R}^{2d}} \sigma M M' \left(\log\frac{f^\varepsilon(v')}{M(v')} - \log\frac{f^\varepsilon(v)}{M(v)}\right)\left(\frac{f^\varepsilon(v')}{M(v')} - \frac{f^\varepsilon(v)}{M(v)}\right)dvdv'.$$

Using the Jensen inequality,

$$\int_{\mathbb{R}^d} Q(f^\varepsilon)\log\left(\frac{f^\varepsilon}{M}\right) \leq -\frac{\sigma_1}{2}\int_{\mathbb{R}^d} M\left(\log\rho^\varepsilon - \log\frac{f^\varepsilon(v)}{M(v)}\right)\left(\rho^\varepsilon - \frac{f^\varepsilon(v)}{M(v)}\right).$$

Applying the relation

$$(a-b)\log(a/b) \geq \left(\sqrt{a} - \sqrt{b}\right)^2 \tag{17}$$

we obtain

$$-\int_0^t\int_\Omega Q(f^\varepsilon)\left(\log f^\varepsilon + \frac{|v|^2}{2}\right) \geq \sigma_1\mathcal{R}_1^\varepsilon(t) \geq \sigma_1\mathcal{R}^\varepsilon(t). \tag{18}$$

Moreover, we also have to approximate the entropy production term by the boundary $(I_\varepsilon^+ - I_\varepsilon^-)(t)$, defined in (7). We write this quantity as follows:

$$(I_\varepsilon^+ - I_\varepsilon^-) = \int_0^t\int_{\Gamma^+} |v.n|\left[f^\varepsilon(v)\log\left(\frac{f^\varepsilon(v)}{f^\varepsilon(-v)}\right) + (f^\varepsilon(v) - f^\varepsilon(-v))\,\mathcal{E}_F(s,x)\right].$$

Using the inequality $a\log(a/b) \geq a - b$ for $a, b > 0$, we obtain

$$(I_\varepsilon^+ - I_\varepsilon^-)(t) \geq \int_0^t\int_{\Gamma^+} |v.n(x)|[f^\varepsilon(v) - f^\varepsilon(-v)]\,(1 + \mathcal{E}_F(t,x))d\sigma_x\,dv\,ds. \tag{19}$$

Then, we can replace (15) according to (18) and (19) and obtain

(20)
$$[\mathcal{E}^\varepsilon(t)]_0^t + \frac{\sigma_1}{\varepsilon^2}\mathcal{R}_1^\varepsilon(t) \le \int_0^t \int_\Omega \partial_t \tilde{\phi_b} f^\varepsilon - \frac{1}{\varepsilon}\int_0^t \int_{\Gamma^+} |v.n(x)|[f^\varepsilon(v) - f^\varepsilon(-v)](1+\mathcal{E}_F),$$

where

$$\mathcal{E}^\varepsilon(t) = \frac{1}{2}\left\|\nabla_x \phi^\varepsilon(t)\right\|^2_{L^2(\omega)} + \int_\Omega f^\varepsilon \left(\log f^\varepsilon + \frac{|v|^2}{2} + \tilde{\phi_b}\right)(t)$$

and

$$\mathcal{E}_F(t,x) = \log\left(\frac{\rho_b(t,x)}{(2\pi)^{d/2}}\right) + \tilde{\phi}_b(t,x).$$

We extend the quasi-Fermi level on $\bar{\omega}$ (denoted by $\tilde{\mathcal{E}_F}$) and replace ρ_b by its harmonic extension (in $\bar{\omega}$) $\tilde{\rho}_b$. According to assumptions A2 and A3, $\nabla_x\tilde{\mathcal{E}_F}$ and $\partial_t\tilde{\mathcal{E}_F}$ defined on ω by

$$\begin{aligned}
\partial_t\tilde{\mathcal{E}_F} &= (\partial_t\tilde{\rho}_b + \tilde{\rho}_b\,\partial_t\tilde{\phi_b})/\tilde{\rho}_b,\\
\nabla_x\tilde{\mathcal{E}_F} &= (\nabla_x\tilde{\rho}_b + \tilde{\rho}_b\,\nabla_x\tilde{\phi_b})/\tilde{\rho}_b
\end{aligned}$$

are bounded. By multiplying (14) by $(1+\tilde{\mathcal{E}_F}(t,x))$ and integrating by parts, we obtain

(21)
$$\begin{aligned}
\frac{1}{\varepsilon}\int_0^t \int_{\Gamma^+} (1+\mathcal{E}_F)(f^\varepsilon(v) - f^\varepsilon(-v))|v.n(x)| &= \int_0^t\int_\omega \partial_t\tilde{\mathcal{E}_F}\ \rho^\varepsilon + \int_0^t\int_\omega \nabla_x\tilde{\mathcal{E}_F}.j^\varepsilon\\
&- \left[\int_\omega (1+\tilde{\mathcal{E}_F})\rho^\varepsilon\right]_0^t
\end{aligned}$$

and then (20) is equivalent to

$$[\mathcal{E}^\varepsilon(t)]_0^t + \frac{\sigma_1}{\varepsilon^2}\mathcal{R}_1^\varepsilon(t) \le \left[\int_\omega (1+\tilde{\mathcal{E}_F})\rho^\varepsilon\right]_0^t - \int_0^t\int_\omega \nabla_x\tilde{\mathcal{E}_F}.j^\varepsilon - \int_0^t\int_\omega \frac{\partial_t\tilde{\rho}_b}{\tilde{\rho}_b}\ \rho^\varepsilon$$

which implies, according to A1, A2, and A3, that

$$\mathcal{E}^\varepsilon(t) + \frac{\mathcal{R}_1^\varepsilon(t)}{\varepsilon^2} \le C_T\left(1 + \mathcal{M}^\varepsilon(t) + \int_0^t \mathcal{M}^\varepsilon(s)ds + \int_0^t \|j^\varepsilon(s)\|_{L^1}ds\right),$$

where C_T depends only on T. Let us estimate the current density in the following way:

$$\begin{aligned}
\int_0^t \|j^\varepsilon(s)\|_{L^1}ds &= \frac{1}{\varepsilon}\int_0^t\int_\omega \left|\int_{\mathbb{R}^d} v\left(\sqrt{f^\varepsilon} - \sqrt{\rho^\varepsilon M}\right)\left(\sqrt{f^\varepsilon} + \sqrt{\rho^\varepsilon M}\right)\right|\\
&\le \frac{1}{\varepsilon}\sqrt{\mathcal{R}^\varepsilon(t)}\left(\int_0^t\int_\Omega |v|^2\left(\sqrt{f^\varepsilon} + \sqrt{\rho^\varepsilon M}\right)^2\right)^{1/2}.
\end{aligned}$$

The Young's inequality $(\alpha\, a^2 + \frac{1}{4\alpha}b^2 \ge ab \quad \forall\,\alpha > 0)$, gives

(22)
$$\int_0^t \|j^\varepsilon(s)\|_{L^1}\,ds \le \frac{\alpha}{\varepsilon^2}\mathcal{R}^\varepsilon(t) + \frac{C_T}{4\alpha}\int_0^t (\mathcal{M}^\varepsilon(s) + \mathcal{K}^\varepsilon(s))ds,$$

where α does not depend on ε (for example, $\alpha = 1/2$). Then, one can deduce that

$$\mathcal{E}^\varepsilon(t) + \frac{\mathcal{R}_1^\varepsilon(t)}{2\varepsilon^2} \le C_T \left(1 + \mathcal{M}^\varepsilon(t) + \int_0^t \mathcal{M}^\varepsilon(s)ds + \int_0^t \mathcal{K}^\varepsilon(s)ds\right) \tag{23}$$

and bound $\mathcal{M}^\varepsilon$ and $\mathcal{K}^\varepsilon$ in terms of $\mathcal{E}^\varepsilon$ using

$$\int_\Omega f^\varepsilon \log\left(\frac{f^\varepsilon}{e^{2C_T} e^{-|v|^2/4}}\right) \ge \mathcal{M}^\varepsilon - |\omega| e \int_{\mathbb{R}^d}^{e^{2C_T}} e^{-|v|^2/4}. \tag{24}$$

Hence, we deduce that

$$\mathcal{M}^\varepsilon(t) + \mathcal{K}^\varepsilon(t) + \|\nabla_x \phi^\varepsilon(t)\|_{L^2}^2 + \frac{\mathcal{R}_1^\varepsilon(t)}{\varepsilon^2} \le C_T \left(1 + \int_0^t \mathcal{M}^\varepsilon(s)ds + \int_0^t \mathcal{K}^\varepsilon(s)ds\right).$$

The Gronwall inequality leads to a uniform bound of $\mathcal{M}^\varepsilon$, $\mathcal{K}^\varepsilon$, $\varepsilon^{-2}\mathcal{R}_1^\varepsilon$, and $\|\nabla_x \phi^\varepsilon\|_{L^2}$. Then we get the L^1-bound on j^ε using (22). □

COROLLARY 3.2. *The renormalized solution satisfies*

$$\int_\Omega f^\varepsilon(1 + |v|^2 + |log f^\varepsilon|) + \int_0^t \int_{\Gamma^+} f^\varepsilon(1 + |v|^2 + |log f^\varepsilon|)|v.n(x)| \le C_T.$$

Moreover, f^ε and its trace $f^\varepsilon_{|_{\Gamma^+}}$ are weakly, relatively compact in $L^1((0,T)\times\Omega)$ and $L^1((0,T)\times\Gamma^+, |v.n(x)|dtd\sigma_x dv)$, respectively.

Proof. Let us remark that

$$\int f^\varepsilon |\log f^\varepsilon| = \int_{f^\varepsilon \ge 1} f^\varepsilon \log f^\varepsilon - \int_{f^\varepsilon \le 1} f^\varepsilon \log f^\varepsilon. \tag{25}$$

Estimates (16), (23), and (24) imply that

$$|\mathcal{E}^\varepsilon(t)| \le C_T,$$

$$\begin{aligned} \int_{f^\varepsilon \le 1} f^\varepsilon |\log f^\varepsilon| &= -\int_{f^\varepsilon \le 1} f^\varepsilon \log(f^\varepsilon / e^{-|v|^2}) + \int |v|^2 f^\varepsilon \\ &\le \int |v|^2 f^\varepsilon dxdv + |\omega| \int e^{-|v|^2} dv \le C_T, \end{aligned}$$

and

$$\int_{f^\varepsilon \ge 1} f^\varepsilon \log f^\varepsilon \le |\mathcal{E}^\varepsilon(t)| + \int_{f^\varepsilon \le 1} f^\varepsilon |\log f^\varepsilon| \le C_T.$$

The Dunford–Pettis theorem [13] implies the weak compactness of f^ε in the mentioned space. We obtain the bound and the weak compactness of $f^\varepsilon_{|_{\Gamma^+}}$ by a similar argument. Indeed, from the entropy bound we can deduce that

$$\int_0^t \int_{\Gamma^+} |v.n(x)| \left[\frac{f^\varepsilon(v)}{\rho_b M} \log\left(\frac{f^\varepsilon(v)}{\rho_b M}\right)\right] \rho_b M(v) dv d\sigma dt \le C\varepsilon \tag{26}$$

and then we can argue as previously. □

Corollary 3.2 will be used to approximate uniformly f^ε by bounded function. Indeed, let β_δ be an approximation of the identity, namely $\beta_\delta(s) = \frac{1}{\delta}\beta(\delta s)$, where β

is a $\mathcal{C}_0^\infty$ function satisfying $\beta(s) = s$ for $s \le 1$, $0 \le \beta'(s) \le 1$ for all s and $\beta(s) = 2$ for $s \ge 3$. As a consequence of the equi-integrability of f^ε, we deduce that $(\beta_\delta(f^\varepsilon))_{\delta,\varepsilon}$ is weakly relatively compact in $L^1((0,T)\times\Omega)$. Indeed, we have

$$\int_0^T \int_\Omega |\beta_\delta(f^\varepsilon) - f^\varepsilon| \le C \int_{f^\varepsilon \ge 1/\delta} f^\varepsilon \to 0 \quad \text{as } \delta \to 0$$

and

$$\int_0^T \int_{\Gamma^+} |\beta_\delta(f^\varepsilon) - f^\varepsilon|(v.n(x)) \le \int_0^T \int_{\Gamma^+ \cap \{f^\varepsilon \ge 1/\delta\}} |f^\varepsilon|(v.n(x)) \to 0 \quad \text{as } \delta \to 0$$

uniformly in ε. Up to extraction of a subsequence, we also have

$$\begin{array}{rll} \beta_\delta(f^\varepsilon) - f^\varepsilon & \to 0 & \text{a. e. as } \delta \to 0, \\ \beta'_\delta(f^\varepsilon) & \to 1 & \text{a. e. as } \delta \to 0. \end{array}$$

More precisely,

$$\sup_{\varepsilon<1} \|\beta_\delta(f^\varepsilon) - f^\varepsilon\|_{L^1_{t,x,v}} \to 0 \qquad \text{as } \delta \to 0. \tag{27}$$

PROPOSITION 3.3. *The renormalized solution $(f^\varepsilon, \phi^\varepsilon)$ satisfies the following:*

1. *ρ^ε is weakly, relatively compact in $L^1((0,T)\times\omega)$.*
2. *$\frac{Q(f^\varepsilon)}{\varepsilon}$ is weakly, relatively compact in $L^1((0,T)\times\Omega)$.*
3. *$\nabla\phi^\varepsilon$ is relatively compact in $L^2(0,T;\ L^p(\omega))$ for all $1 \le p < 2$.*

Proof. Let $\log^+ s = \max(0, \log s)$. Applying the Jensen inequality we get

$$\rho^\varepsilon \log^+ \rho^\varepsilon = \int \left(\frac{f^\varepsilon}{M} M dv\right) \left(\log^+ \int \frac{f^\varepsilon}{M} M dv\right) \le \int f^\varepsilon \log^+ \frac{f^\varepsilon}{M} dv.$$

The uniform energy bound (16) and Corollary 3.2 lead to

$$\int_0^t \int_\omega \rho^\varepsilon (1 + \log^+ \rho^\varepsilon) \le C_T$$

which implies the $L^1((0,T)\times\omega)$ weak compactness of the sequence ρ^ε. Let us define

$$r_\varepsilon := \frac{\sqrt{f^\varepsilon} - \sqrt{\rho^\varepsilon M}}{\varepsilon \sqrt{M}}.$$

Hence, from the energy bound (16), we deduce that r_ε is bounded in $L^2((0,T)\times\Omega,\ M dt dx dv)$. Extracting a subsequence if necessary, we denote by r its weak limit. Using r_ε, we can rewrite

$$f^\varepsilon = \rho^\varepsilon M + 2\varepsilon M \sqrt{\rho^\varepsilon}\, r_\varepsilon + \varepsilon^2 r_\varepsilon^2 M$$

and

$$\frac{Q(f^\varepsilon)}{\varepsilon} = 2\sqrt{\rho^\varepsilon}\, Q(r_\varepsilon M) + \varepsilon\, Q(r_\varepsilon^2 M),$$

where $r_\varepsilon^2 M$ and $r_\varepsilon M$ are, respectively, bounded in L^1 and $L^2(M^{-1}dv)$. The operator Q is bounded in L^1 and $L^2(M^{-1}dv)$. This implies that $\frac{Q(f^\varepsilon)}{\varepsilon}$ is bounded in $L^1_{t,x,v}$ and

$$\frac{Q(f^\varepsilon)}{\varepsilon} = 2\sqrt{\rho^\varepsilon}\, Q(r_\varepsilon M) + \mathbf{O}(\varepsilon)_{L^1(0,T)\times\Omega}.$$

Moreover, let $\alpha > 0$, then

$$\int_A |\sqrt{\rho^\varepsilon}\, Q(r_\varepsilon M)| \le C \int_A \rho^\varepsilon M + \frac{1}{4C} \int_A \frac{Q^2(r_\varepsilon M)}{M}$$

and choose C such that $\frac{1}{4C} \| \frac{Q^2(r_\varepsilon M)}{M} \|_{L^1_{t,x,v}} \le \alpha/2$. For such fixed α and C the equi-integrability of $\rho^\varepsilon M$ implies

$$\exists\, \delta > 0, \forall\, A \subset (0,T) \times \Omega, \quad |A| < \delta \Rightarrow C \int_A \rho^\varepsilon M \le \alpha/2.$$

So, $\sqrt{\rho^\varepsilon}\, Q(r_\varepsilon M)$ is equi-integrable. Besides, if $\Omega_R := \omega \times B(0,R)$, then

$$\int_0^T \int_{\Omega_R^c} |\sqrt{\rho^\varepsilon}\, Q(r_\varepsilon M)| \le \|\rho^\varepsilon\|^{1/2}_{L^1_{t,x}} \left(\int_{B(O,R)^c} M dv \right)^{1/2} \left(\int_0^T \int_{\Omega_R^c} Q(r_\varepsilon M)^2 M^{-1} \right)^{1/2} \to 0$$

as R goes to infinity uniformly in ε. This proves the weak compactness of $\frac{Q(f^\varepsilon)}{\varepsilon}$ in $L^1((0,T) \times \Omega)$.

The third assertion of the proposition is a consequence of the Lions–Aubin theorem (see [22, Lemma 5.1]). Indeed, using that $\nabla_x \phi^\varepsilon$ is bounded in $L^2(0,T;\, L^2(\omega))$ and $\Delta_x \phi^\varepsilon$ is bounded in $L^2(0,T,\, L^1(\omega))$ we deduce that $\nabla_x \phi^\varepsilon$ is bounded in $L^2(0,T;\, L^2(\omega) \cap W^{r,q}(\omega))$ for some $q > 1$ and $0 < r < 1$ such that $\frac{1-r}{d} > 1 - \frac{1}{q}$. And, using that $\partial_t \nabla_x \phi^\varepsilon = \nabla_x (\Delta_x)^{-1} \nabla_x . (j^\varepsilon)$ we see that $\partial_t \nabla_x \phi^\varepsilon$ is bounded in $L^1(W^{-s,p}_{loc}(\omega))$ for some $p > 1$ and $s > d - \frac{d}{p}$. Hence, $\nabla_x \phi^\varepsilon$ is compact in $L^2(0,T;\ L^q_{loc}(\omega))$ for some $1 < q < 2$. And using that $\nabla_x \phi^\varepsilon$ is bounded in $L^2(0,T;\ L^2(\omega))$ we deduce the compactness in $L^2(0,T;\ L^p(\omega))$ for all $p < 2$. □

PROPOSITION 3.4. *r_ε is such that $\varepsilon |r_\varepsilon|^2 |v|^2 M$ is bounded in $L^1((0,T) \times \Omega)$ and $\sqrt{\varepsilon} |r_\varepsilon|^2 |v| M$ is bounded in $L^1((0,T) \times \Omega)$.*

Proof. The proof uses Young's inequality (see [7] and [23] where a similar argument is used to control the distance to the Maxwellian). Let us denote $r(z) = z \log(1+z)$ and

$$r^*(p) = \sup_{z > -1} (pz - r(z))$$

its Legendre transform. Hence $r^*(p)$ behaves like e^p when p goes to $+\infty$. Moreover, $r^*(p)$ has a superquadratic homogeneity, namely for $0 < \alpha < 1$ and $p > 0$, we have $r^*(\alpha p) \le \alpha^2 r^*(p)$. We also denote $z_\varepsilon = \frac{f^\varepsilon}{\rho_\varepsilon M} - 1$ and $z_\varepsilon = 0$ if $\rho_\varepsilon = 0$. Hence

$$\varepsilon |r_\varepsilon|^2 |v|^2 \le \frac{1}{\varepsilon} \rho_\varepsilon |z_\varepsilon| |v|^2. \tag{28}$$

By the Young inequality, we have

$$\begin{aligned} \frac{1}{\varepsilon} \rho_\varepsilon |v|^2 |z_\varepsilon| &\le \frac{4\rho_\varepsilon}{\varepsilon^2} \left[r^* \left(\frac{\varepsilon}{4} |v|^2 \right) + r(|z_\varepsilon|) \right] \\ &\le \frac{4\rho_\varepsilon}{\varepsilon^2} \left[\varepsilon^2 r^* \left(\frac{|v|^2}{4} \right) + r(z_\varepsilon) \right] \end{aligned}$$

which is clearly bounded in $L^1((0,T) \times \Omega, dt dx M dv)$ by using the growth of r^* and the entropy dissipation bound $\mathcal{R}_1^\varepsilon(t) \le C\varepsilon^2$. This proves the first assertion. Interpolating with the fact that r_ε is bounded in $L^2((0,T) \times \Omega, dt dx M dv)$, we deduce the second bound. This ends the proof of the proposition. □

4. Compactness by velocity averaging.

PROPOSITION 4.1. *The density ρ^ε is relatively compact in $L^1((0,T)\times\omega)$: there exists $\rho\in L^1((0,T)\times\omega)$ such that, up to extraction of a subsequence if necessary,*

$$\rho^\varepsilon\to\rho\quad \text{in } L^1 \text{and a.e.}$$

Using (27), it suffices to show the compactness of $(\beta_\delta(f^\varepsilon))_\varepsilon$ for all (fixed) $\delta>0$. This is a consequence of the averaging lemma (see [17, 12]) and the continuity equation.

Let us recall the following averaging lemma.

LEMMA 4.2. *Assume that h^ε is bounded in $L^2((0,T)\times\Omega)$, that h_0^ε and h_1^ε are bounded in $L^1((0,T)\times\Omega)$, and that*

$$\varepsilon\,\partial_t h^\varepsilon + v.\nabla_x h^\varepsilon = h_0^\varepsilon + \nabla_v . h_1^\varepsilon. \tag{29}$$

Then, for all $\psi\in\mathcal{C}_0^\infty(\mathbb{R}^d)$,

$$\left\|\int_{\mathbb{R}^d}(h^\varepsilon(t,x+y,v)-h^\varepsilon(t,x,v))\,\psi(v)dv\right\|_{L^1_{t,x}}\to 0 \text{ when } y\to 0 \text{ uniformly in } \varepsilon \tag{30}$$

where $h^\varepsilon(t,x,v)$ has been prolonged by 0 for $x\notin\omega$.

Remark 4.1. The above lemma only gives the compactness in the x variable of the averages in v of $h^\varepsilon(t,x,v)$. This is due to the presence of an ε in front of the time derivative in (29). We also refer to [18] and [7] for similar averaging lemmas where there is only gain of regularity in the x variable.

This lemma can be deduced from the proof of Theorem 1.8 of [8] or from the proof of Theorem 6 of [12] (see also the proof of Theorem 3 of [12]). The only difference here is the presence of the time derivative which comes with the factor ε in front and hence does not imply regularity in time as in Theorem 6 of [12]. Actually, following the proof of Theorem 3 of [12] with $q=m=1$, $p=2$, $\tau=0$, and writing the problem in the whole space $\mathbb{R}_t\times\mathbb{R}^d_x$, we can prove that $\int_{\mathbb{R}^d}\psi(v)h^\varepsilon(t,x,v)dv$ is in the Besov space $L^{r,\infty}((0,T);B^{s,r}_{\infty,\infty})$, where $r=\frac{5}{3}$ and $s=\frac{1}{5}$. For the definition of the Besov space $B^{s,r}_{\infty,\infty}$, we refer to [12]. A sketch of the proof will be given in Appendix B. This, of course, yields the compactness stated in (30).

Proof of Proposition 4.1. Let δ be a (fixed) nonnegative parameter. Let us verify that the rescaled Boltzmann equation (in the renormalized sense) satisfies the assumptions of Lemma 4.2. Indeed, $\beta_\delta(f^\varepsilon)$ is a weak solution of

$$\varepsilon\,\partial_t\beta_\delta(f^\varepsilon) + v.\nabla_x\beta_\delta(f^\varepsilon) = h_0^\varepsilon + \nabla_v.h_1^\varepsilon,$$

where

$$h_0^\varepsilon = \frac{Q(f^\varepsilon)}{\varepsilon}\beta_\delta'(f^\varepsilon)\qquad\text{and}\qquad h_1^\varepsilon = \nabla(\phi^\varepsilon+\tilde{\phi_b})\,\beta_\delta(f^\varepsilon).$$

The sequences $(\beta_\delta(f^\varepsilon))_\varepsilon$ is bounded in $L^\infty\cap L^1((0,T)\times\Omega)$ and hence in $L^2((0,T)\times\Omega)$. Moreover, h_0^ε is weakly, relatively compact in $L^1_{t,x,v}$ and by applying Holder's inequality and using the uniform bound of $\beta_\delta(f^\varepsilon)$ in L^2 (for fixed δ), we obtain

$$\|h_1^\varepsilon\|_{L^1((0,T)\times\omega;L^2(\mathbb{R}^d))}\le\frac{C}{\sqrt{\delta}}\sup_{t\le T}\|\nabla(\phi^\varepsilon+\tilde{\phi_b})(t)\|_{L^2_x}.$$

Since we are using a compactly supported function to localize in space, the L^2 bound in v also yields an L^1 bound.

Assumptions of Lemma 4.2 are satisfied and hence we get the L^1-compactness in x of $\int_{\mathbb{R}^d} \psi(v)\beta_\delta(f^\varepsilon)dv$, namely (30) holds with h^ε replaced by $\beta_\delta(f^\varepsilon)$.

Next, using that $(\beta_\delta(f^\varepsilon))_\varepsilon$ is bounded in $L^\infty(0,T;\, L^1((1+|v|^2)dxdv))$, we see that we can take $\psi(v)$ to be constant equal to 1 in (30) and hence we deduce that, after also sending δ to 0 and using the equi-integrability of f^ε, that

$$\|\rho^\varepsilon(t,x+y)-\rho^\varepsilon(t,x)\|_{L^1_{t,x}} \to 0 \text{ when } y \to 0 \text{ uniformly in } \varepsilon.$$

Finally, using that $\partial_t\rho^\varepsilon = -\nabla_x .j^\varepsilon$ is bounded in $L^1((0,T);W^{-1,1}(w))$, we deduce that ρ^ε is relatively compact in $L^1((0,T)\times\omega)$ and Proposition 4.1 is proved. □

5. Passing to the limit. Using the previous section, there exists $\rho \in L^1((0,T)\times\omega)$ such that

$$\rho^\varepsilon \to \rho \quad \text{in } L^1_{t,x} \quad \text{and a. e.}$$

The inequality $\left(\sqrt{a}-\sqrt{b}\right)^2 \le |a-b|$ leads to

$$\sqrt{\rho^\varepsilon} \to \sqrt{\rho} \quad \text{in } L^2_{t,x} \quad \text{and a. e.}$$

The entropy dissipation given by (15) leads to

$$f^\varepsilon \to \rho\, M \quad \text{in } L^1_{t,x,v} \quad \text{and a. e.} \tag{31}$$

Moreover, we have

$$\frac{Q(f^\varepsilon)}{\varepsilon} = \left(2\sqrt{\rho^\varepsilon}\, Q(r_\varepsilon\, M) + \varepsilon\, Q(r_\varepsilon^2 M)\right) \quad \rightharpoonup \quad 2\sqrt{\rho}\, Q(r\, M) \quad \text{in } L^1,$$

where r is the weak limit of r^ε in $L^2((0,T)\times\Omega,\, M(v)dtdxdv)$. So, one can pass to the limit in (13) for $\lambda > 0$, up to extraction of a subsequence, and get

$$\begin{aligned} v.\nabla_x\sqrt{(\rho+\lambda)M} - \nabla_v.(\nabla_x(\phi+\tilde{\phi_b})\sqrt{(\rho+\lambda)M}) \;&=\; \frac{\sqrt{\rho}\, Q(r\, M)}{\sqrt{(\rho+\lambda)M}} \\ &\quad + \frac{\lambda M\, v.\nabla_x(\phi+\tilde{\phi_b})}{2\sqrt{(\rho+\lambda)M}}, \end{aligned} \tag{32}$$

where $\nabla_x\phi$ is the $\mathrm{L}^2_{t,x}$-weak limit of $\nabla_x\phi^\varepsilon$. Sending λ to 0, we infer that

$$\left(\nabla_x\sqrt{\rho} + \frac{1}{2}\sqrt{\rho}\,\nabla_x(\phi+\tilde{\phi_b})\right).vM = Q(r\, M).$$

Using that $Q(r\, M)$ is bounded in $L^2((0,T)\times\Omega,\, M^{-1}(v)dtdxdv)$, we deduce that $\nabla_x\sqrt{\rho} + \frac{1}{2}\sqrt{\rho}\,\nabla_x(\phi+\tilde{\phi_b})$ is bounded in $L^2((0,T)\times\omega)$. Besides, the current density is given by

$$j^\varepsilon = 2\sqrt{\rho^\varepsilon}\int_{\mathbb{R}^d} r^\varepsilon\, vMdv + \varepsilon\int r_\varepsilon^2 vMdv.$$

Using Proposition 3.4, we deduce that

$$j^\varepsilon = 2\sqrt{\rho^\varepsilon}\int_{\mathbb{R}^d} r^\varepsilon\, vMdv + \mathbf{O}(\sqrt{\varepsilon})_{L^1((0,T)\times\Omega)} \rightharpoonup 2\sqrt{\rho}\int_{\mathbb{R}^d} r\, vMdv \quad \text{in } L^1_{t,x}.$$

The function $vM \in \mathcal{R}(Q) := \mathcal{K}erQ^{\perp}$, therefore

$$\int r\, vM\, dv = \int Q(r\, M)Q^{-1}(vM)\frac{dv}{M}$$

and

$$j^{\varepsilon} \rightharpoonup J(\rho,\phi) := 2\sqrt{\rho}\left[\int_{\mathbb{R}^d}(v\otimes Q^{-1}(vM))dv\right]\left(\nabla_x\sqrt{\rho}+\frac{1}{2}\sqrt{\rho}\,\nabla_x(\phi+\tilde{\phi}_b)\right).$$

Passing to the limit ($\varepsilon \to 0$) in (14) and the Poisson equation $-\Delta\phi^{\varepsilon} = \rho^{\varepsilon}$, we obtain

$$\begin{cases} \partial_t\rho + \nabla_x J(\rho,\phi) = 0, \\ J(\rho,\phi) = 2\sqrt{\rho}\left[-\mathbf{D}\left(\nabla_x\sqrt{\rho}+\frac{1}{2}\sqrt{\rho}\,\nabla_x(\phi+\tilde{\phi}_b)\right)\right], \\ \mathbf{D} = -\displaystyle\int_{\mathbb{R}^d}(v\otimes Q^{-1}(vM))dv \quad \text{and} \quad -\Delta_x\phi = \rho. \end{cases}$$

6. The limit boundary condition. In this section, we want to pass to the limit in the boundary condition and prove that $\rho = \rho_b$ on $\partial\omega$. First notice that from the fact that $\nabla_x\sqrt{\rho}+\frac{1}{2}\sqrt{\rho}\,\nabla_x(\phi+\tilde{\phi}_b)$ is bounded in $L^2((0,T)\times\omega)$, we deduce that $\nabla_x\sqrt{\rho}$ is bounded in $L^1((0,T)\times\omega)$ and hence the trace of $\sqrt{\rho}$ makes sense on $\partial\omega$.

For each sequence $(g_\varepsilon)_\varepsilon$, $\overline{g_\varepsilon}$ will denote the weak limit of $(g_\varepsilon)_\varepsilon$ when ε goes to zero, extracting a subsequence if necessary. In particular, $\overline{f^{\varepsilon}_{|\Gamma}}$ denotes the weak limit of $f^{\varepsilon}_{|\Gamma}$ in $L^1((0,T)\times\Gamma^+, |v.n(x)|dtd\sigma_x dv)$. We recall that $\beta_\delta(f^{\varepsilon})$ is a weak solution of the renormalized semiconductor Boltzmann equation

$$\varepsilon\partial_t\beta_\delta(f^{\varepsilon}) + v\,.\nabla_x\beta_\delta(f^{\varepsilon}) - \nabla_x(\phi^{\varepsilon}+\tilde{\phi}_b).\nabla_v\beta_\delta(f^{\varepsilon}) = \frac{Q(f^{\varepsilon})}{\varepsilon}\beta'_\delta(f^{\varepsilon}) \tag{33}$$

with the following boundary condition and initial data

$$\beta_\delta(f^{\varepsilon})_{|\Gamma^-} = \beta_\delta(\rho_b M) \quad \text{and} \quad \beta_\delta(f^{\varepsilon})_{|t=0} = \beta_\delta(f^{\varepsilon}_0).$$

Passing to the limit in (33), we infer that

$$v\,.\nabla_x\beta_\delta(\rho M) - \nabla_x(\phi+\tilde{\phi}_b).\nabla_v\beta_\delta(\rho M) = 2\sqrt{\rho}\,Q(r\,M)\beta'_\delta(\rho M). \tag{34}$$

On one hand, by using $\xi(t,x,v) \in \mathcal{C}^\infty([0,T]\times\bar{\Omega})$ as a test function in (34) we get

$$-\int_0^T\int_\Omega \beta_\delta(\rho M)v.\nabla_x\xi + \int_0^T\int_\Omega \beta_\delta(\rho M)\nabla_x(\phi+\tilde{\phi}_b).\nabla_v\xi$$

$$-\int_0^T\int_\Omega 2\sqrt{\rho}\,Q(r\,M)\beta'_\delta(\rho M)\xi + \int_0^T\int_{\partial\Omega}\xi\beta_\delta(\rho M)(v.n(x)) = 0.$$

On the other hand, using $\xi(t,x,v)$ as a test function in (33) and passing to the limit, we deduce that

$$\beta_\delta(\rho M)_{|\partial\Omega} = \overline{\beta_\delta(f^{\varepsilon})_{|\partial\Omega}}. \tag{35}$$

From Corollary 3.2, we deduce that $f^{\varepsilon}_{|\partial\Omega} \in L^\infty(0,T;\ \mathrm{LlogL}(|v.n(x)|d\sigma_x dv))$ and hence $\beta_\delta(f^{\varepsilon})_{|\partial\Omega} = \beta_\delta(f^{\varepsilon}_{|\partial\Omega}) \in L^\infty(0,T;\ \mathrm{LlogL}(|v.n(x)|d\sigma_x dv))$ uniformly in ε,δ. Hence,

$\beta_\delta(\rho M)_{|\partial\Omega}$ is uniformly bounded in $L^\infty(0,T;\ \mathrm{LlogL}(|v.n(x)|d\sigma_x dv))$ and converges to $(\rho M)_{|\partial\Omega}$ when δ goes to 0.

Using $\psi(t,x) \in \mathcal{C}^\infty([0,T]\times\bar{\omega})$ as a test function in (33) and passing to the limit, we get

$$\int_0^T \int_\Omega \beta_\delta(\rho M) v.\nabla_x \psi + \int_0^T \int_\Omega 2\sqrt{\rho}\, Q(r\, M)\beta_\delta'(\rho M)\psi = \int_0^T \int_{\Gamma^+} \psi \left(\overline{\beta_\delta(f^\varepsilon)_{|\Gamma^+}} - \beta_\delta(\rho_b M) \right) (v.n(x)).$$

Sending δ to 0 and using that

$$\int_0^T \int_\Omega \rho M v.\nabla_x \psi + \int_0^T \int_\Omega 2\sqrt{\rho}\, Q(r\, M)\psi = 0,$$

we deduce that

$$\lim_{\delta\to 0} \int_0^T \int_{\Gamma^+} \left[\overline{\beta_\delta(f^\varepsilon)_{|\Gamma^+}} - \beta_\delta(\rho_b M) \right] (v.n(x))\psi = 0. \tag{36}$$

Using (35) and the fact that

$$\int_{\mathbb{R}^d \cap \{v.n(x)\geq 0\}} M(v.n(x))dv = \frac{1}{2\pi}$$

we infer that

$$\int_0^T \int_{\partial\omega} [\rho_{|\partial\omega} - \rho_b]\psi = 0 \tag{37}$$

and hence $\rho = \rho_b$ on $\partial\omega$.

7. Regularity of the density. In this section we shall prove that the limit $\rho \in L^\infty(0,T;\ L^2(\omega))$ and that $\sqrt{\rho} \in L^2(0,T;\ H^1(\omega))$.

We assume that $\rho_b(t,x)$ is defined in the whole domain ω. We can, for instance, extend $\sqrt{\rho_b(t,x)}$ in ω as a harmonic function. Hence, $\rho_b(t,x)$ satisfies

$$\rho_b \in L^\infty((0,T)\times\omega) \quad \text{and} \quad \sqrt{\rho_b} \in L^2(0,T;\ H^1(\omega)).$$

LEMMA 7.1. *Let ω be a regular and bounded open subset of $\mathbb{R}^d$ and ρ a positive function of $L^\infty(0,T;\ L^1(\omega))$ satisfying*

$$\begin{cases} \nabla_x\sqrt{\rho} + \frac{1}{2}\nabla_x\phi\sqrt{\rho} = G \in L^2(0,T;\ L^2(\omega)), \\ -\Delta_x\phi = \rho, \\ \nabla_x\phi \in L^\infty(0,T;\ L^2), \\ \rho = \rho_b \quad \textit{on } \partial\omega. \end{cases} \tag{38}$$

Then

$$\rho \in L^2(0,T;\ L^2(\omega)), \qquad \sqrt{\rho} \in L^2(0,T;\ H^1(\omega)),$$

and

$$\nabla\phi\sqrt{\rho} \in L^2(0,T;\ L^2(\omega)).$$

Proof. The first and third equations of (38) imply that $\nabla_x\sqrt{\rho} \in L^1$ and hence the boundary condition $\rho = \rho_b$ on $\partial\omega$ makes sense. Let us take β_δ as in the proof of Corollary 3.2. But since we will deal with possibly negative values, we take $\beta_\delta(s) = \frac{1}{\delta}\beta(\delta s)$, where β is a C^∞ function satisfying $\beta(s) = s$ for $-1 \le s \le 1$, $0 \le \beta'(s) \le 1$ for all s and $\beta(s) = 2$ for $|s| \ge 3$.

We denote $\psi = \sqrt{\rho} - \sqrt{\rho_b}$. Hence

$$\nabla_x\beta_\delta(\psi) = \nabla_x\psi\,\beta'_\delta(\psi).$$

Hence, after subtracting $\sqrt{\rho_b}$ from $\sqrt{\rho}$, we can renormalize the first equation appearing in (38), it gives

$$\nabla_x\beta_\delta(\psi) + \frac{1}{2}\nabla_x\phi\beta'_\delta(\psi)\psi = \tilde{G}\beta'_\delta(\psi), \tag{39}$$

where $\tilde{G} = G - \nabla_x\sqrt{\rho_b} - \frac{1}{2}\nabla_x\phi\sqrt{\rho_b}$ is also in $L^2(0,T;\,L^2(\omega))$. Then using that for fixed $\delta > 0$

$$|\nabla_x\phi\beta'_\delta(\psi)\psi| \le \frac{1}{2\delta}|\nabla\phi| \in L^2,$$

we deduce that $\nabla_x\beta_\delta(\psi) \in L^2$ for fixed δ. Taking the L^2 norm of (39), we get

$$\|\nabla_x\beta_\delta(\psi)\|^2_{L^2} + \frac{1}{4}\|\nabla_x\phi\beta'_\delta(\psi)\psi\|^2_{L^2} + \int_0^T\int_\omega \nabla_x\phi\nabla_x\beta_\delta(\psi)\beta'_\delta(\psi)\psi \le \|\tilde{G}\|^2_{L^2}. \tag{40}$$

Let $\tilde{\beta}$ be given by $\tilde{\beta}(s) = \int_0^s \tau\beta'(\tau)^2 d\tau$ and $\tilde{\beta}_\delta(s) = \frac{1}{\delta^2}\tilde{\beta}(\delta s)$. Hence, $\tilde{\beta}_\delta(s)$ goes to $\frac{s^2}{2}$ when δ goes to 0.

Computing the third term in (40), we get

$$\int_\omega \nabla_x\phi.\nabla_x\beta_\delta(\psi)\beta'_\delta(\psi)\psi \quad = \quad \int_\omega \nabla_x\phi.\nabla_x\tilde{\beta}_\delta(\psi) = \int_\omega \rho\tilde{\beta}_\delta(\psi).$$

Hence, we deduce that for all $\delta > 0$,

$$\|\nabla_x\beta_\delta(\psi)\|^2_{L^2} + \frac{1}{4}\|\nabla_x\phi\beta'_\delta(\psi)\psi\|^2_{L^2} + \int_0^T\int_\omega \rho\tilde{\beta}_\delta(\psi) \le \|\tilde{G}\|^2_{L^2}.$$

Letting δ go to zero, we get that

$$\|\nabla_x(\sqrt{\rho} - \sqrt{\rho_b})\|^2_{L^2} + \frac{1}{4}\|\nabla_x\phi(\sqrt{\rho} - \sqrt{\rho_b})\,\|^2_{L^2} + \frac{1}{2}\int_0^T\int_\omega \rho(\sqrt{\rho} - \sqrt{\rho_b})^2 \le \|\tilde{G}\|^2_{L^2}.$$

Using that $\sqrt{\rho_b}$ is bounded, we conclude the proof of the lemma. ∎

Now, using the lemma, we can see easily that we can rewrite the current

$$J(\rho,\phi) = 2\sqrt{\rho}\left[-\mathbf{D}\left(\nabla_x\sqrt{\rho} + \frac{1}{2}\sqrt{\rho}\,\nabla_x(\phi + \tilde{\phi_b})\right)\right] = -\mathbf{D}[\nabla_x\rho + \rho\nabla_x(\phi + \tilde{\phi_b})].$$

Finally, the regularity of ϕ can be easily deduced from that of ρ and this ends the proof of Theorem 1.4.

Appendix A. Existence of renormalized solution. We present here a proof of the existence of renormalized solution to (1–6) satisfying the conditions of Theorem

2.2. We refer to [25] for the existence of renormalized solution to the Vlasov–Poisson–Boltzmann system with a nonlinear Boltzmann kernel.

To simplify the notations we take $\varepsilon = 1$. We begin by regularizing the collision operator and both Boltzmann and Poisson equations. Let us define

$$Q_R(f) = \int_{\mathbb{R}^d} \sigma_R(v, v')(Mf' - M'f)dv', \tag{41}$$

where

$$\sigma_R(v, v') = \sigma(v, v')1_{|v|\le R}(v)1_{|v'|\le R}(v'). \tag{42}$$

The regularized semiconductor Boltzmann–Poisson system reads

$$(VBP)_{\alpha,R} \qquad \begin{cases} \partial_t f_{\alpha,R} + \left(v.\nabla_x f_{\alpha,R} - \nabla_x(\phi_{\alpha,R} + \tilde{\phi}_b).\nabla_v f_{\alpha,R}\right) = Q_R(f_{\alpha,R}), \\ -(1 - \alpha\,\Delta_x)^{2m}\Delta_x\phi_{\alpha,R} = \rho_{\alpha,R} = \displaystyle\int_{|v|\le R} f_{\alpha,R}dv, \\ f_{\alpha,R}(0, x, v) = f_0(x, v), \qquad (x, v) \in \Omega, \\ f_{\alpha,R}(t, x, v) = f_b(t, x, v), \qquad (x, v) \in \Gamma^-, \\ \phi_{\alpha,R} = \Delta_x\phi_{\alpha,R} = \cdots = \Delta_x^{2m}\phi_{\alpha,R} = 0, \quad x \in \partial\omega, \end{cases}$$

where α is a nonnegative parameter and $m \in \mathbb{N}^*$. We refer to [1, 5, 29] for further details about this approximation.

A simple computation gives the following H-theorem:

LEMMA A.1. *The collision operator Q_R is bounded in L^1 and L^∞ and satisfies*

$$\int_{|v|<R} Q_R(f)dv = \int_{\mathbb{R}^d} Q_R(f)dv = 0$$

and

$$\int_{|v|<R} Q_R(f)\log\frac{f}{M} = \int_{\mathbb{R}^d} Q_R(f)log\frac{f}{M} \le -\frac{\sigma_1}{2}\int\left(\sqrt{f} - \sqrt{M\int f dv}\right)^2.$$

As a consequence of these conservation properties, one can prove, by a fixed point procedure and by using the characteristic method, that the modified system $(VBP)_{\alpha,R}$ has a weak solution $(f_{\alpha,R}, \phi_{\alpha,R})$. More precisely, multiplying the semiconductor Boltzmann equation by $(1 + |v|^2/2 + \log f_{\alpha,R})$, and integrating with respect to $dtdxdv$, we get

$$\begin{aligned} &\left[\frac{1}{2}\int_\omega |(1-\alpha\Delta)^m\nabla_x\phi_{\alpha,R}|^2(s) + \int_\Omega f_{\alpha,R}\left(\log f_{\alpha,R} + \frac{|v|^2}{2} + \tilde{\phi}_b\right)(s)\right]_0^t \\ &\int_0^t\int_{\Gamma^+} f_{\alpha,R}\left(\log f_{\alpha,R} + \frac{|v|^2}{2} + \tilde{\phi}_b\right)|v.n(x)| + \frac{\sigma_1}{2}\int_0^t\int_\Omega\left(\sqrt{f_{\alpha,R}} - \sqrt{\rho_{\alpha,R}M}\right)^2 \\ &\le \int_0^t\int_{\Gamma^-} f_b\left(\log f_b + \frac{|v|^2}{2} + \phi_b\right)|v.n(x)|. \end{aligned}$$

For fixed α, the solution is weak. One can pass to the limit $R \to \infty$ and show that

there exists a weak solution $(f_\alpha,\ \rho_\alpha,\ \phi_\alpha)$ of

$$(VBP)_\alpha \qquad \begin{cases} \partial_t f_\alpha + v.\nabla_x f_\alpha - \nabla_x(\phi_\alpha + \tilde{\phi}_b).\nabla_v f_\alpha = Q(f_\alpha), \\ -(1-\alpha\Delta_x)^{2m}\Delta_x\phi_\alpha = \rho_\alpha = \displaystyle\int_{\mathbb{R}^d} f_\alpha dv, \\ f_\alpha(0,x,v) = f_0(x,v), \qquad (x,v)\in\Omega, \\ f_\alpha(t,x,v) = f_b(t,x,v) \qquad (x,v)\in\Gamma^-, \\ \phi_\alpha = \Delta_x\phi_\alpha = \cdots = \Delta_x^{2m}\phi_\alpha = 0, \qquad x\in\partial\omega. \end{cases}$$

Moreover, this weak solution satisfies (12), (13), and (14) and

$$\left[\frac{1}{2}\int_\omega |(1-\alpha\Delta)^m\nabla_x\phi_\alpha|^2(t) + \int_\Omega f_\alpha\left(\log f_\alpha + \frac{|v|^2}{2} + \tilde{\phi}_b\right)(s)\right]_0^t$$
$$\int_0^t\int_{\Gamma^+} f_\alpha\left(\log f_\alpha + \frac{|v|^2}{2} + \phi_b\right)|v.n(x)| + \frac{\sigma_1}{2}\int_0^t\int_\Omega\left(\sqrt{f_\alpha} - \sqrt{\rho_\alpha M}\right)^2$$
$$\le \int_0^t\int_{\Gamma^-} f_b\left(\log f_b + \frac{|v|^2}{2} + \phi_b\right)|v.n(x)| \le C_T.$$

As a consequence of this identity we get the following proposition.

PROPOSITION A.2.

1. *f_α and $f_{\alpha|_{\Gamma^+}}$ are, respectively, weakly, relatively compact in $L^1((0,T)\times\Omega)$ and $L^1((0,T)\times\Gamma^+, |v.n(x)|dtd\sigma_x dv)$.*
2. *$\|\nabla_x\phi_\alpha\|_{L^2} \le \|(1-\Delta_x)^m\nabla_x\phi_\alpha\|_{L^2} \le C_T$ and $\nabla_x\phi_\alpha$ is relatively compact in $L^p((0,T)\times\omega)$ for all $p<2$.*
3. *ρ_α is relatively compact in $L^1((0,T)\times\omega)$.*

The proof of this proposition follows the same lines as the proofs of compactness given in the paper (see the proofs of Corollary 3.2 and Propositions 3.3 and 4.1). Notice, however, that we do not immediately get the compactness of f_α as in (31).

Using this proposition, we can end the proof of Theorem 2.2.

Let $f,\ \rho,\ \phi$, and j be the weak limits of subsequences of $f_\alpha,\ \rho_\alpha,\ \phi_\alpha$, and $j^\alpha = \int v f_\alpha dv$. To prove that (f,ϕ) satisfies (12) and (13), we argue as in [21] (see also [25]). The method is based on a double renormalization. First, we write the equation satisfied by $\beta_\delta(f_\alpha)$, where β_δ was defined in section 3 and then weakly pass to the limit when α goes to zero. Then, we renormalize the resulting limit equation using the function β or the function $\sqrt{s+\lambda M}$. Finally, we let α go to zero and recover (12) and (13). The continuity equation (14) can be easily deduced from the continuity equation for ρ_α and the entropy inequality (15) can be deduced from a classical convexity argument (see also [25]). This ends the proof of Theorem 2.2.

Appendix B. Sketch of the proof of Lemma 4.2. Here we would like to prove Lemma 4.2.

Step 1: First, we rewrite the problem in the whole space in t and x. This step only uses the equi-integrability of h_ε. Indeed, for α small enough, we can find C^∞ cut-off functions $\chi_1(t)$ and $\chi_2(x)$ such that $\chi_1 = 1$ on $(\alpha, T-\alpha)$ has compact support in $(0,T)$, and $\chi_2 = 1$ on $\{x\in\omega, |, \mathrm{dist}(x,\partial\omega) > \alpha$ and has compact support in ω. Denoting $\chi(t,x) = \chi_1(t)\chi_2(x)$ and $\tilde{h}^\varepsilon = \chi(t,x)h^\varepsilon$, we get

$$\varepsilon\,\partial_t\tilde{h}^\varepsilon + v.\,\nabla_x\tilde{h}^\varepsilon = \chi h_0^\varepsilon + \nabla_v\,.\,(\chi h_1^\varepsilon) + (\varepsilon\partial_t + v.\,\nabla_x)\chi h^\varepsilon. \tag{43}$$

Moreover, due to the uniform bound of h^ε in L^2, we have

$$\left\| \int_{\mathbb{R}^d} \left(h^\varepsilon(t,x,v) - \tilde{h}^\varepsilon(t,x,v) \right) \psi(v) dv \right\|_{L^1((0,T)\times\omega)} \to 0$$

when α goes to zero, uniformly in ε.

Step 2: From step 1, we see that it is enough to prove the lemma when we replace $(0,T)\times\omega$ by $\mathbb{R}_t \times \mathbb{R}^d_x$ since the extra term on the right-hand side of (43) is in L^2. Notice also that since we localize in the v variable by integrating against $\psi(v)$, the L^2 norm controls the L^1 norm. More precisely, we can prove that under the conditions of the lemma, $\int_{\mathbb{R}^d} \psi(v) h^\varepsilon(t,x,v) dv \in L^{r,\infty}((0,T); B^{s,r}_{\infty,\infty})$, where $r = \frac{5}{3}$ and $s = \frac{1}{5}$ (see [12] for the definition of the Besov space built on the Lorentz space $L^{r,\infty}$). One way of proving the bound in the Besov space is to use the Littlewood–Paley decomposition and follow the proof of Theorem 3 of [12]. The only difference is that $\xi.v$ should be replaced by $\varepsilon\tau + \xi.v$ and that we take the Fourier transform in t and x (see also Theorem 1.8 of [8]).

Here, we would like to sketch a proof which follows the idea used in [19]. Adding λh^ε to both sides of (29), we get

$$\lambda h^\varepsilon + \varepsilon\, \partial_t h^\varepsilon + v.\nabla_x h^\varepsilon = h_0^\varepsilon + \nabla_v \,.\, h_1^\varepsilon + \lambda h^\varepsilon.$$

Hence,

$$\int_{\mathbb{R}^d} h^\varepsilon(t,x,v)\psi(v)dv = T_\lambda(h_0^\varepsilon + \nabla_v \,.\, h_1^\varepsilon + \lambda h^\varepsilon), \tag{44}$$

where

$$T_\lambda g(t,x) = \int_0^\infty \int_{\mathbb{R}^d} g(t-\varepsilon s, x - sv, v) e^{-\lambda s} \phi(v) dv\, ds. \tag{45}$$

Applying Proposition 3.1 of [19], we deduce that

$$\|T_\lambda(g)\|_{L^2_t H^{1/2}_x} \le C\lambda^{-1/2} \|g\|_{L^2(\mathbb{R}\times\mathbb{R}^d\times\mathbb{R}^d)}, \tag{46}$$

$$\|T_\lambda(g)\|_{\lambda^{-2}L^1_t W^{-1,1}_x + \lambda^{-1} L^1_t L^1_x} \le C \|g\|_{L^1(\mathbb{R}_t\times\mathbb{R}^d_x; W^{-1,1}(\mathbb{R}^d))}. \tag{47}$$

Hence,

$$\int_{\mathbb{R}^d} h^\varepsilon(t,x,v)\psi(v)dv = \rho = \rho^1 + \rho^2, \tag{48}$$

where

$$\|\rho^1\|_{L^2_t H^{1/2}_x} \le C\lambda^{1/2} \|h^\varepsilon\|_{L^2}, \tag{49}$$

$$\|\rho^2\|_{\lambda^{-2}L^1_t W^{-1,1}_x + \lambda^{-1} L^1_t L^1_x} \le C(\|h_0^\varepsilon\|_{L^1} + \|h_1^\varepsilon\|_{L^1}). \tag{50}$$

This can also be written as $\rho^2 = \rho_1^2 + \rho_2^2$, where

$$\|\rho_1^2\|_{L^1_t W^{-1,1}_x} \le C\lambda^{-2}(\|h_0^\varepsilon\|_{L^1} + \|h_1^\varepsilon\|_{L^1}), \tag{51}$$

$$\|\rho_2^2\|_{L^1_t L^1_x} \le C\lambda^{-1}(\|h_0^\varepsilon\|_{L^1} + \|h_1^\varepsilon\|_{L^1}). \tag{52}$$

We would like to deduce that $\rho \in [L^2H^{1/2}, L^1W^{-1,1}]_{(1/5,\infty)}$, the real interpolation of order $(1/5,\infty)$ of the couple $(L^2H^{1/2}, L^1W^{-1,1})$. For all $t \in \mathbb{R}_+$, we define the function

$$K(t) = \inf_{a_1+a_2=\rho} \|a_1\|_{L^2H^{1/2}} + t\|a_2\|_{L^1W^{-1,1}}. \tag{53}$$

To conclude, it is enough to prove that $K(t) \leq Ct^{1/5}$. For $t > 0$, we take λ such that $t = \lambda^{5/2}$.

If $0 < t < 1$, then ρ_2^2 also satisfies $\|\rho_2^2\|_{L_t^1 W_x^{-1,1}} \leq C\lambda^{-2}$, and hence taking $a_1 = \rho^1$ and $a_2 = \rho^2$, we deduce that $K(t) \leq Ct^{1/5}$.

If $t > 1$, then we write ρ_2^2 as the sum of two terms $\rho_2^2 = \rho_3^2 + \rho_4^2$ such that $\rho_3^2 \in \lambda^{-2}L^1W^{-1,1}$ and $\rho_4^2 \in \lambda^{1/2}L^1W^{3/2,1}$. Hence, if we define

$$K_1(t) = \inf_{a_1+a_2=\rho} \|a_1\|_{L^2H^{1/2}+L^1W^{3/2,1}} + t\|a_2\|_{L^1W^{-1,1}} \tag{54}$$

we get that $K_1(t) \leq Ct^{1/5}$ by taking $a_1 = \rho^1 + \rho_4^2$ and $a_2 = \rho_1^2 + \rho_3^2$.

This proves that $\rho \in [L^2H^{1/2} + L^1W^{3/2,1}, L^1W^{-1,1}]_{(1/5,\infty)}$. This is, of course, enough to get the compactness stated in the lemma.

Acknowledgments. The second author would like to thank N. Ben Abdallah for interesting discussions and encouragements. The authors would like to thank the referee for many constructive remarks.

ON THE CONVERGENCE OF THE NO RESPONSE TEST*

ROLAND POTTHAST†

Abstract. The no response test is a new scheme in inverse problems for partial differential equations which was recently proposed in [D. R. Luke and R. Potthast, *SIAM J. Appl. Math.*, 63 (2003), pp. 1292–1312] in the framework of inverse acoustic scattering problems. The main idea of the scheme is to construct special probing waves which are small on some test domain. Then the response for these waves is constructed. If the response is small, the unknown object is assumed to be a subset of the test domain. The response is constructed from *one*, *several*, or *many* particular solutions of the problem under consideration. In this paper, we investigate the *convergence* of the no response test for the reconstruction information about inclusions D from the Cauchy values of solutions to the Helmholtz equation on an outer surface $\partial\Omega$ with $\overline{D} \subset \Omega$. We show that the one-wave no response test provides a criterion to test the analytic extensibility of a field. In particular, we investigate the construction of approximations for the set of singular points $N(u)$ of the total fields u from one given pair of Cauchy data. Thus, the no response test solves a particular version of the classical *Cauchy problem*. Also, if an infinite number of fields is given, we prove that a *multifield version* of the no response test reconstructs the unknown inclusion D. This is the first convergence analysis which could be achieved for the no response test.

Key words. inverse problems, inverse scattering, shape reconstruction, sampling method, no response test

1. Introduction.

We will study the no response test for the treatment of the following basic model problems from the theory of inverse boundary value problems.

Let Ω and D be bounded domains with boundary of class C^2, $\overline{D} \subset \Omega$ and $\Omega \setminus \overline{D}$ connected. For Ω we consider the simple situation where it is simply connected. We assume that the interior homogeneous Dirichlet problem for the Helmholtz equation in Ω does have only the trivial solution, i.e., κ is not an interior Dirichlet eigenvalue of Ω. In this case the interior Dirichlet problem for Ω can be solved with arbitrary continuous or L^2 boundary data and the solutions depend continuously on these data with respect to any C^μ-norm on compact subsets of Ω. Also, we assume that the same condition is satisfied for $\Omega \setminus \overline{D}$. In this case the following boundary value problem has a unique solution; cf. [3].

Boundary value problem. We consider a function $u \in C^2(\Omega \setminus \overline{D}) \cap C(\overline{\Omega} \setminus D)$ which satisfies the Helmholtz equation

$$\triangle u + \kappa^2 u = 0 \quad \text{in } \Omega \setminus \overline{D} \tag{1.1}$$

with boundary values

$$u = 0 \quad \text{on } \partial D. \tag{1.2}$$

For the *forward problem*, the function

$$u|_{\partial\Omega} = f \tag{1.3}$$

is given, and we look for the solution u to (1.1)–(1.3) and its normal derivative

$$\frac{\partial u}{\partial \nu} = g \tag{1.4}$$

on $\partial\Omega$. Here, the unit normal vector ν is assumed to point into the exterior of $\Omega \setminus \overline{D}$.

Inverse boundary value problem. For the inverse problem we assume that the *Cauchy data*

$$u|_{\partial\Omega} = f, \quad \left.\frac{\partial u}{\partial \nu}\right|_{\partial\Omega} = g \tag{1.5}$$

are given. The problem is to reconstruct D or to gain information about D by reconstructing a subset of D without knowledge of the boundary condition on ∂D.

The no response test. We assume that Cauchy data (1.5) of some solution u to (1.1)–(1.5) are given. For some test domain $G \subset \Omega$ the no response test calculates a *response* by probing the unknown scatterer D with special waves, for example, with single-layer potentials

$$v[\varphi](y) := \int_{\partial\Omega} \Phi(x,y)\varphi(x)ds(x), \quad y \in \Omega,\ \varphi \in L^2(\partial\Omega), \tag{1.6}$$

where the functions $v[\varphi]$ are chosen such that

$$\|v[\varphi]\|_{C^1(\overline{G})} \leq \epsilon \tag{1.7}$$

on G with some constant $\epsilon > 0$. We define

$$J(x) := \frac{1}{2}u(x) - \int_{\partial\Omega} \left(\frac{\partial u}{\partial \nu}(y)\Phi(x,y) - u(y)\frac{\partial \Phi(x,y)}{\partial \nu(y)} \right) ds(y), \quad x \in \partial\Omega, \tag{1.8}$$

and calculate the *response* of the domain D with respect to the probing function $v[\varphi]$ by

$$I(\varphi) := \int_{\partial\Omega} J(x)\varphi(x)ds(x). \tag{1.9}$$

The construction of the response is described in more detail in section 2.

The no response test uses a set $\mathcal{G}$ of sampling or test domains G, respectively. For each domain G the *maximal response* is defined as the supremum over all responses for special functions $v[\varphi]$ with (1.7). All test domains G with maximal response smaller than c_0 with some constant c_0 are called *positive* (= no response), otherwise *negative*. To obtain a reconstruction, we build the intersections

$$M_{rec} := \bigcap_{G\ positive} \overline{G} \tag{1.10}$$

of all positive test domains. The extension of the response functional to the multiwave case is described in section 2.

Convergence analysis for the no response test in different cases. For our convergence analysis we will work with admissible test domains.

DEFINITION 1.1 (admissible test domains). *Let $G \subset \Omega$ be some domain such that there is a homotopy $[0,1] \ni \lambda \mapsto G_\lambda$ with $G_0 = \Omega$ and $G_1 = G$ such that G_λ is a simply connected domain with boundary of class C^2 and $\overline{G_{\lambda_2}} \subset G_{\lambda_1}$ for $\lambda_2 > \lambda_1$. In this case G is called an* admissible *test domain.*

The results of our subsequent convergence analysis can be summarized as follows. Let G be some admissible test domain.

1. *One-wave case.* If the field u can be analytically continued into $\Omega \setminus G$, then for an arbitrary constant $c_0 > 0$ and sufficiently small $\epsilon > 0$ the domain G is positive. If u cannot be analytically continued into $\Omega \setminus \overline{G}$, then G is negative/not positive.
2. *Multiwave case.* The intersection of all positive test domains is exactly the unknown domain D.

For the *one-wave case* we will show that the no response functional is bounded from below by a constant times the derivatives of the field u in the exterior of $\overline{G}$. This is obtained by further developing techniques introduced in the framework of the *point-source method*; cf. [10], [12]. The point-source method reconstructs the total field u or its derivatives and then uses the boundary condition to find the unknown inclusion D from the knowledge of u and the boundary condition. However, the basic difference between the point-source method and the no response test is that the point-source method does calculate the field or one particular derivative, whereas the no response test estimates the behavior of the full set of Taylor coefficients.

The results show that the no response test and the *range test* [13] in principle reconstruct the same set, even though these methods use a different indicator function for the test domains. The idea of the range test is to solve the single-layer integral equation

$$\int_{\partial G} e^{-i\kappa \hat{x}\cdot y} \varphi(y) ds(y) = u^\infty(\hat{x}), \quad \hat{x} \in \mathbb{S}, \tag{1.11}$$

with $\varphi \in L^2(\partial G)$ to test whether the field u^∞ can be analytically extended up to ∂G. Both methods test for analytic extensibility.

For the convergence analysis in the *multiwave case* we will bound the no response functional by a factor times the indicator function of the *singular sources method* as introduced in [11] and [12] to obtain convergence. The singular sources scheme reconstructs the scattered field $\Psi^s(z,z)$ for an incident singular field $\Psi(\cdot,z)$ in its source point z and uses the behavior $|\Psi^s(z,z)| \to \infty$ for $z \to \partial D$.

The idea to use singular incident fields for *uniqueness results* has been employed in the work of Isakov [6] and Kirsch and Kress [7]. Corresponding *stability results* using singular sources have been derived in [11]. Also, these ideas have been transformed into a constructive *singular sources method* by the author [11], [12]. Independently, Ikehata proposed using singular waves for shape reconstruction by the *probe method*; see [5]. More recently, the probe method has been numerically realized by Erhard and Potthast [2], and the numerical behavior in the case of an impedance boundary condition was carefully investigated by Cheng, Liu, and Nakamura [1]. The convergence properties of different sampling methods have been compared and investigated by Honda et al. in [4].

2. The no response test for the boundary value problem. The goal of this section is to develop a formulation of the no response test for the inverse boundary value problem (1.1)–(1.5).

Preparations. By Green's formula the total field u can be calculated by

$$u(x) = \int_{\partial\Omega} \left(\frac{\partial u}{\partial \nu}(y)\Phi(x,y) - u(y)\frac{\partial \Phi(x,y)}{\partial \nu(y)} \right) ds(y) + \int_{\partial D} \frac{\partial u}{\partial \nu}(y)\Phi(x,y)ds(y), \quad x \in \Omega \setminus \overline{D}, \tag{2.1}$$

where we already used the boundary condition on ∂D to simplify the second integral over ∂D. Using the classical jump relations we can calculate the limit of $u(x)$ for $x \to \partial\Omega$. We obtain

$$u_-(x) = \frac{1}{2}u(x) + \int_{\partial\Omega} \left(\frac{\partial u}{\partial \nu}(y)\Phi(x,y) - u(y)\frac{\partial \Phi(x,y)}{\partial \nu(y)} \right) ds(y) + \int_{\partial D} \frac{\partial u}{\partial \nu}(y)\Phi(x,y)ds(y), \quad x \in \partial\Omega. \tag{2.2}$$

For the inverse boundary value problem the functions $u|_{\partial\Omega}$ and $\frac{\partial u}{\partial \nu}|_{\partial\Omega}$ are known. Thus, the function J defined in (1.8) can be calculated from the given data. In particular, from (2.2) we derive

$$\int_{\partial D} \frac{\partial u}{\partial \nu}(y)\Phi(x,y)ds(y) = J(x), \quad x \in \partial\Omega. \tag{2.3}$$

Now, consider the single-layer potential (1.6) with density $\varphi \in L^2(\partial\Omega)$ or $C(\partial\Omega)$. We multiply (2.3) by φ, integrate over $\partial\Omega$, and exchange the order of integration to obtain

$$\begin{aligned} \int_{\partial\Omega} \varphi(x)J(x)ds(x) &= \int_{\partial\Omega} \varphi(x) \left(\int_{\partial D} \frac{\partial u}{\partial \nu}(y)\Phi(x,y)ds(y) \right) ds(x) \\ &= \int_{\partial D} \frac{\partial u}{\partial \nu}(y) \left(\int_{\partial\Omega} \Phi(x,y)\varphi(x)ds(x) \right) ds(y) \\ &= \int_{\partial D} \frac{\partial u}{\partial \nu}(y)v(y)ds(y). \end{aligned} \tag{2.4}$$

Thus, the value of the last integral can be calculated from the given data f and g as defined in (1.5).

No response test, one-wave case. First, we consider the case where only one pair of Cauchy data $f = u|_{\partial\Omega}$, $g = \frac{\partial u}{\partial \nu}|_{\partial\Omega}$ is given on $\partial\Omega$. Let $G \subset \Omega$ be a test domain. The idea of the no response test is to construct $v[\varphi]$ given in (1.6) such that it is small on G and large outside of G.

DEFINITION 2.1. *Given some $\epsilon > 0$ let $\mathcal{M}(G,\epsilon)$ be the set of all $\varphi \in L^2(\partial\Omega)$ such that the* test functions *$v[\varphi]$ satisfy the* impulse size condition

$$\|v[\varphi]|_G\|_{C^1(\overline{G})} \le \epsilon. \tag{2.5}$$

We call this testing with impulses of maximal size ϵ on G.

In detail, the following test is carried out.

DEFINITION 2.2 (no response test, one-wave case). *Choose $\epsilon > 0$ and some constant $c_0 > 0$, and consider admissible test domains $G \subset \Omega$. For all $\varphi \in \mathcal{M}(G,\epsilon)$ calculate the functional*

$$I(\varphi) := \int_{\partial\Omega} J(x)\varphi(x)ds(x) \tag{2.6}$$

and

$$I_\epsilon(G) := \sup_{\varphi \in \mathcal{M}(G,\epsilon)} I(\varphi). \tag{2.7}$$

If $I_\epsilon(G) < c_0$, we call the domain G positive *and we say that we have* no response. *Otherwise, G is denoted as* negative, *since the response is larger than c_0.*

We define

$$I_0(G) := \lim_{\epsilon \to 0} I_\epsilon(G). \tag{2.8}$$

We will show that if u can be analytically extended into $\Omega \setminus G$, then $I_0(G) = 0$, and, conversely, the condition $I_0(G) = 0$ implies analytic extensibility into $\Omega \setminus \overline{G}$. The closure $\overline{G}$ of each test domain G with $I_0(G) = 0$ does contain the singular points $N(u)$ of the field u. Taking the intersections of the sets $\overline{G}$ for all possible test domains G with $I_0(G) = 0$ we obtain some upper estimate for this set of singular points $N(u)$ of u. The next sections will give a precise analysis of this situation. For practical reconstructions we will choose $\epsilon > 0$ and $c_0 > 0$ and obtain an approximation for $N(u)$ by the intersection of all positive test domains.

No response test, multiwave case. Now, we assume that more than one pair of Cauchy data f, g is given. Let $f(\xi), g(\xi)$ for $\xi = 1, \dots, N$ be a finite (for $N \in \mathbb{N}$) or infinite (for $N = \infty$) number of linearly independent Cauchy data. We assume that the set

$$\left\{ f(\xi) := u(\cdot, \xi)\Big|_{\partial\Omega} : \ \xi \in \mathbb{N} \right\} \tag{2.9}$$

is dense (and thus complete) in $L^2(\partial\Omega)$. Now, the functional J depends on $\xi = 1, 2, \dots, N$; i.e., we have

$$J(x,\xi) := \frac{1}{2} u(x,\xi) - \int_{\partial\Omega} \left(\frac{\partial u(y,\xi)}{\partial \nu(y)} \Phi(x,y) - u(y,\xi) \frac{\partial \Phi(x,y)}{\partial \nu(y)} \right) ds(y) \tag{2.10}$$

for $x \in \partial\Omega$ and $\xi = 1, \dots, N$. Then we formulate the following no response test for the multiwave case.

Definition 2.3 (no response test, multiwave case). *Let G be some test domain. Choose $\epsilon_1 > 0$ and some constant $c_0 > 0$. For all $\varphi \in \mathcal{M}(G, \epsilon_1)$ calculate the boundary values $v[\varphi]|_{\partial\Omega}$. With the given data $f(\xi)$, $\xi = 1, \dots, N$, find an approximation*

$$q[\alpha] := \sum_{\xi=1}^{N} \alpha_\xi f(\xi) \tag{2.11}$$

to $v[\varphi]|_{\partial\Omega}$ with

$$\| v[\varphi]|_{\partial\Omega} - q[\alpha] \|_{L^2(\partial\Omega)} \le \epsilon_2. \tag{2.12}$$

Here, we use $\alpha = (\alpha_1, \alpha_2, \dots)$ and define $\mathcal{Q}(\epsilon_2, \varphi)$ as the set of α such that (2.12) is satisfied. The size of ϵ_2 depends on the number of boundary data which are available. For $N = \infty$ the value ϵ_2 can be chosen arbitrarily small. Then, with the functional

$$I(\varphi, \alpha) := \sum_{\xi=1}^{N} \alpha_\xi \int_{\partial\Omega} J(x,\xi) \varphi(x) ds(x), \tag{2.13}$$

we calculate

$$I_{\epsilon_1,\epsilon_2}(G) := \sup_{\varphi\in\mathcal{M}(\epsilon_1),\alpha\in\mathcal{Q}(\epsilon_2,\varphi)} I(\varphi,\alpha). \tag{2.14}$$

If $I_{\epsilon_1,\epsilon_2}(G) < c_0$*, we call the domain* G positive *and we say that we have* no response. *Otherwise,* G *is denoted as* negative*, since the response is (relatively) large.*

Later, we will carry out the convergence analysis for the case where $N = \infty$. Then, analogously to the one-dimensional case, we define

$$I_{0,0}(G) := \lim_{\epsilon_1\to 0}\lim_{\epsilon_2\to 0} I_{\epsilon_1,\epsilon_2}(G). \tag{2.15}$$

We will show that $I_{0,0}(G)$ is zero if and only if $D \subset G$. If $D \not\subset G$, we obtain $I_{0,0}(G) = \infty$. Then in the multiwave case the no response test will denote exactly those domains G as positive which contain the unknown scatterer D in its interior.

3. On the *extensibility* and *singular points* of a solution to the boundary value problem. Let u be a solution to the boundary value problem (1.1)–(1.5). If the domain D has analytic boundary, it is well known (see 5.7.1 in [9]) that the field u can be analytically extended into the interior of D. The convergence of the no response test is strongly linked to the extensibility of the field u. Thus, for a proper analysis of the convergence of the no response test we need to study the extensibility of u into the interior of D.

We would like to define some type of "minimal" set M such that u can be extended into the exterior $\Omega \setminus M$ of M but not into any $\Omega \setminus N$ for $N \subset M$, $N \neq M$. However, due to the possible existence of Riemannian surfaces and the possible nonuniqueness of this extension, in general, the set M will not be well defined as a single set.

A different idea would be to test for some kind of "singular" points on a Riemannian surface. However, there are a number of different types of "singular points." One possible definition would be to consider points to be singular where one of the derivatives of the field u becomes singular. However, even if all derivatives are bounded, there might not be an analytic extension into the particular point. Further, a point z might be singular in the sense that one extension of u does have a singular derivative and there might still be some analytic extension of u into the point z along some different and complicated path. Here, we have chosen to use some kind of minimal definition. We call a point singular only if there does not exist *any* analytic continuation into this point.

Definition 3.1 (singular points of u). *Consider an analytic function in* $\Omega \setminus \overline{D}$*. We call a point* $z \in \Omega$ *a* singular point *of the field* u *if there is no analytic continuation of the field* u *into a neighborhood of* z*.*

Remark. The set of singular points might be empty. If it is not empty, it is a subset of the scattering domain $\overline{D}$, since by assumption u is analytic in $\Omega \setminus \overline{D}$. Due to the existence of different analytic extensions on Riemannian surfaces there might be many singularities of these extended fields in different points of Ω. But in singular points the field u is singular on any branch of the Riemannian surface or is not contained in these branches at all.

In this work, we will restrict our attention to the problem of testing extensibility into the exterior of some admissible test domain G. Then all points into which no analytic extension exists will be a subset of this test domain; i.e., we obtain some upper estimate for the set of singular points of the field u.

The rest of this section is used to formulate some preparations. One basic tool for the investigation of analytic extensions is Taylor's expansion of the field u.

LEMMA 3.2. *We assume that $A_e := \Omega \setminus \overline{A}$ is the open interior of the complement of some simply connected open set A with boundary of class C^2. If u is analytic in A_e and for some $\rho > 0$ the set*

$$\left\{ a_\mu(z) := \sup_{|h|=1} \rho^\mu \tfrac{|(h\cdot\nabla)^\mu u(z)|}{\mu!} : \quad \mu \in \mathbb{N} \right\} \tag{3.1}$$

of Taylor coefficients of u is uniformly bounded by a constant C for all $z \in A_e$ with $d(z, \partial\Omega) > \rho$, then u is extensible into an open neighborhood of $\overline{A_e}$; i.e., there is a set A' with $\overline{A'} \subset A$ such that u is extensible into $A'_e = \Omega \setminus \overline{A'}$.

Proof. Consider some boundary point z_0. Due to our assumption for some $\rho > 0$ the modulus of $a_\mu(z)$ is bounded for z in a neighborhood of z_0 by a constant C. Then the Taylor series

$$\sum_{\mu=0}^{\infty} \frac{1}{\mu!}((x-z)\cdot\nabla)^\mu u(z) \tag{3.2}$$

can be estimated by

$$\Big| \sum_{\mu=0}^{\infty} \frac{1}{\mu!}((x-z)\cdot\nabla)^\mu u(z) \Big| \;\le\; \sum_{\mu=0}^{\infty} a_\mu \left(\frac{|x-z|}{\rho} \right)^\mu . \tag{3.3}$$

For $|x - z| < \rho$, the series (3.3) is absolutely convergent. In this case we apply Lemma 7.2 to see that u can be analytically extended into the ball $B_\rho(z)$ of z_0. This is the case for every boundary point z.

At this point, we still might obtain different extensions of u for different boundary points z_0. However, since ∂A is of class C^2 we can choose $\tau > 0$ sufficiently small such that for each two balls $B_\tau(z_1)$ and $B_\tau(z_2)$ with $z_1, z_2 \in \partial A$ with $B_\tau(z_1) \cap B_\tau(z_2) \neq \emptyset$ the intersection $B_\tau(z_1) \cap B_\tau(z_2) \cap A_e$ is not empty and thus the extensions into the simply connected set $B_\tau(z_1) \cap B_\tau(z_2)$ are identical. ∎

4. Convergence in the one-wave case. The goal of this section is to prove the first of our two main theorems—the convergence for the one-wave case.

THEOREM 4.1. *Let G with $\overline{G} \subset \Omega$ be an admissible test domain. We have $I_0(G) = 0$ if u can be analytically extended into $\Omega \setminus G$. If u cannot be analytically extended into $\Omega \setminus \overline{G}$, then we have $I_\epsilon(G) = \infty$ for all $\epsilon > 0$ and thus $I_0(G) = \infty$.*

Proof. First, we show that if $D \subset G$, i.e., if the true inclusion D is a subset of the test domain G, then we obtain $I_0(G) = 0$. For $D \subset G$ and $v[\varphi]$ defined by (1.6) we have

$$|v[\varphi](y)| \le \epsilon, \quad y \in \partial D \subset \overline{G}. \tag{4.1}$$

Thus, from (2.4) we obtain

$$\begin{aligned} |I(\varphi)| &\le \Big| \int_{\partial D} \frac{\partial u}{\partial \nu}(y) v[\varphi](y) ds(y) \Big| \\ &\le \epsilon \int_{\partial D} \Big| \frac{\partial u}{\partial \nu}(y) \Big| ds(y) \\ &\le \epsilon c \end{aligned} \tag{4.2}$$

with some constant c. Passing to the limit $\epsilon \to 0$ we obtain $I_0(G) = 0$.

In the next step, we assume that the field u can be analytically extended up to $\mathbb{R}^m \setminus G$; i.e., u and $\frac{\partial u}{\partial \nu}$ are well defined and continuous on ∂G (cf. Figure 4.1). If we are not in the first case, then

$$D^* := D \cap (\mathbb{R}^m \setminus G) \tag{4.3}$$

is not empty. We define

$$\Gamma := \partial(G \cap D).$$

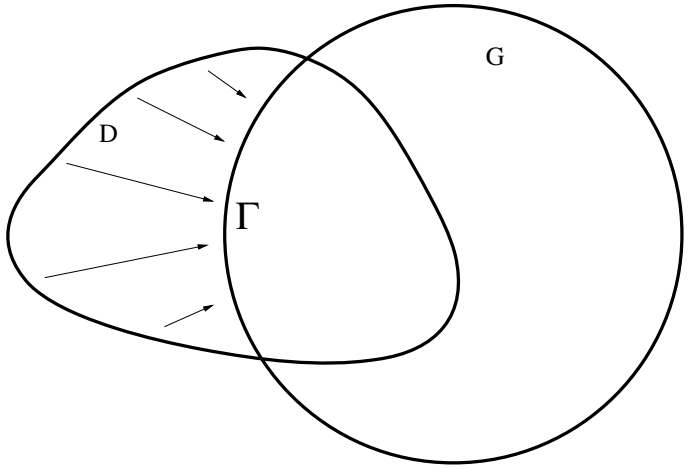

FIG. 4.1. *Domains D and G. The arrows indicate how the integration over $\partial D \setminus \overline{G}$ is transformed into an integration over Γ.*

In this case we can use $u|_{\partial D} = 0$ and apply Green's second theorem to v and u in D^* to calculate

$$\begin{aligned} &\int_{\partial D} \frac{\partial u}{\partial \nu}(y) v[\varphi](y) ds(y) \\ &= \int_{\partial D} \left(\frac{\partial u}{\partial \nu}(y) v[\varphi](y) - \frac{\partial v[\varphi]}{\partial \nu}(y) u(y) \right) ds(y) \\ &= \int_{\Gamma} \left(\frac{\partial u}{\partial \nu}(y) v[\varphi](y) - \frac{\partial v[\varphi]}{\partial \nu}(y) u(y) \right) ds(y). \end{aligned} \tag{4.4}$$

Since u and $\frac{\partial u}{\partial \nu}$ are well defined and bounded on Γ, and since

$$\|v[\varphi]\|_{C^1(\overline{G})} \to 0, \quad \epsilon \to 0, \tag{4.5}$$

the integral in (4.4) tends to zero for $\epsilon \to 0$. This proves that for u extensible into $\Omega \setminus G$ the no response test yields $I_0(G) = 0$.

In the third and final step we will show that if u cannot be analytically extended into $\Omega \setminus \overline{G}$, we have $I_0(G) = \infty$.

First, if u cannot be analytically extended into $\Omega \setminus \overline{G}$, then there must be some maximal parameter $\lambda_0 \in (0, 1)$ such that u can be analytically extended into $\Omega \setminus G_\lambda$ for all $\lambda < \lambda_0$, but not into any $\Omega \setminus G_\lambda$ for any $\lambda > \lambda_0$. Then, for all $\rho > 0$, the set (3.1) cannot be uniformly bounded for all $z \in \Omega \setminus G_{\lambda_0}$, since in this case we could construct

an analytic extension of u into the interior of G_{λ_0} and λ_0 would not be maximal. Thus, given some $\rho > 0$ there must be a point $z_0 \in \Omega \setminus G_{\lambda_0}$ (with $d(z_0, \partial\Omega) > \rho$) such that (3.1) is not uniformly bounded in any neighborhood of z_0. The point z_0 has a positive distance

$$\rho_0 := \inf_{y \in \overline{G}} |y - z_0| \tag{4.6}$$

to the set G. Given $h \in \mathbb{R}^m$ with $|h| = 1$ we define

$$\beta(z, \mu) := \sup_{y \in \overline{G}} \Big\{ (h \cdot \nabla_z)^\mu \Phi(y, z), \;\; \nabla_y (h \cdot \nabla_z)^\mu \Phi(y, z) \Big\} \tag{4.7}$$

for z in a neighborhood of z_0 and $\mu \in \mathbb{N}$. Then the $C^1(\overline{G})$-norm of the function

$$\Psi(\cdot, z) := \frac{\epsilon}{4\beta(z, \mu)} (h \cdot \nabla_z)^\mu \Phi(\cdot, z) \tag{4.8}$$

is bounded by $\epsilon/2$ for z in a neighborhood V of z_0. For later use we assume that $V \subset B_{\rho_0/2}(z_0)$.

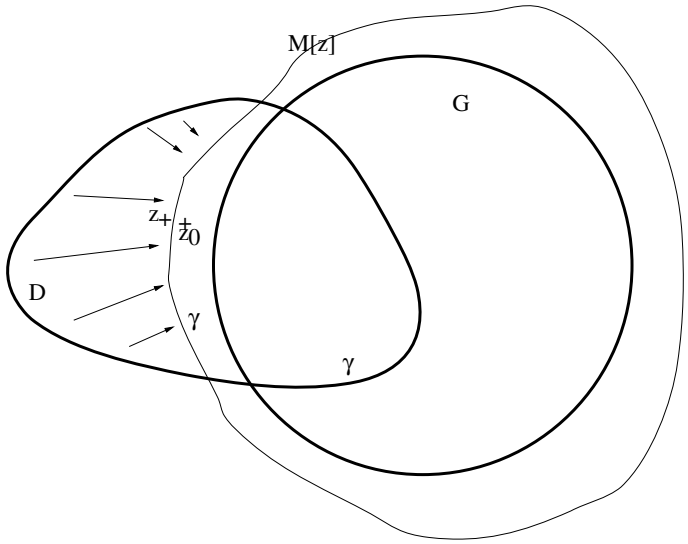

FIG. 4.2. *Domains D, G, and $M[z]$. The arrows indicate how the integration over $\partial D \setminus M[z]$ is transformed into an integration over γ.*

For $z \in V \setminus G_{\lambda_0}$ we can find a domain $M[z]$ with (1) boundary of class C^2 such that (2) the homogeneous interior Dirichlet problem for $M[z]$ has only the trivial solution, (3) u can be analytically extended into the exterior of $M[z]$, (4) $z \notin M[z]$, and (5) $M[z] \supset G$ (cf. Figure 4.2). Then the extension of u into the exterior of $M[z]$ implies that $u|_{\partial M[z]}$ and $\frac{\partial u}{\partial \nu}|_{\partial M[z]}$ are well defined.

Now, on $\overline{M[z]}$ we approximate the function $\Psi(\cdot, z)$ by a sequence $v_n[z] := v[\varphi_n]$ of single-layer potentials with density $\varphi_n \in L^2(\partial\Omega)$ as defined in (1.6), i.e., we have

$$\| v_n[z] - \Psi(\cdot, z) \|_{C^1(\overline{M[z]})} \leq \frac{1}{n}. \tag{4.9}$$

Since $G \subset M[z]$, we obtain the estimate

$$\begin{aligned} \|v_n[z]\|_{C^1(\overline{G})} &\leq \|v_n[z] - \Psi(\cdot, z)\|_{C^1(\overline{G})} + \|\Psi(\cdot, z)\|_{C^1(\overline{G})} \\ &\leq \frac{1}{n} + \frac{\epsilon}{2} \end{aligned} \tag{4.10}$$

for $z \in V \setminus N(u)$. For n sufficiently large, we have $\|v_n[z]\|_{C^1(\overline{G})} \leq \epsilon$. In this case we derive from Green's second theorem

$$\begin{aligned} &\int_{\partial D} \frac{\partial u}{\partial \nu}(y) v_n[z](y) ds(y) \\ &= \int_{\partial D} \left(\frac{\partial u}{\partial \nu}(y) v_n[z](y) - \frac{\partial v_n[z](y)}{\partial \nu} u(y) \right) ds(y) \\ &= \int_{\gamma} \left(\frac{\partial u}{\partial \nu}(y) v_n[z](y) - \frac{\partial v_n[z](y)}{\partial \nu} u(y) \right) ds(y), \end{aligned} \tag{4.11}$$

where we define $\gamma := \partial(M[z] \cap D)$ and where the normal on γ is oriented into the exterior of the closed curve. Since we have $\gamma \subset \overline{M[z]}$ in the limit $n \to \infty$ we obtain the convergence of

$$\begin{aligned} &\int_{\partial \Omega} J(x) \varphi_n(x) ds(x) \\ &= \int_{\partial D} \frac{\partial u}{\partial \nu}(y) v_n[z](y) ds(y) \\ &= \int_{\gamma} \left\{ \frac{\partial u}{\partial \nu}(y) v_n[z](y) - \frac{\partial v_n[z](y)}{\partial \nu} u(y) \right\} ds(y) \end{aligned}$$

towards the term

$$\begin{aligned} &\int_{\gamma} \left\{ \frac{\partial u}{\partial \nu}(y) \Psi(y, z) - \frac{\partial \Psi(y, z)}{\partial \nu(y)} u(y) \right\} ds(y) \\ &= \frac{\epsilon}{4\beta(z, \mu)} \int_{\gamma} \left\{ \frac{\partial u}{\partial \nu}(y) (h \cdot \nabla_z)^{\mu} \Phi(y, z) \right. \\ &\qquad \left. - \frac{\partial}{\partial \nu(y)} \left((h \cdot \nabla_z)^{\mu} \Phi(y, z) \right) u(y) \right\} ds(y) \end{aligned} \tag{4.12}$$

$$= \frac{\epsilon}{4\beta(z, \mu)} (h \cdot \nabla_z)^{\mu} u(z) - \frac{\epsilon}{4\beta(z, \mu)} (h \cdot \nabla_z)^{\mu} u_{ext}(z) \tag{4.13}$$

with

$$u_{ext}(z) := \int_{\partial \Omega} \left\{ \frac{\partial u}{\partial \nu}(y) \Phi(y, z) - \frac{\partial \Phi(y, z)}{\partial \nu(y)} u(y) \right\} ds(y). \tag{4.14}$$

As shown above for any fixed ρ the μth derivatives of u multiplied by $\rho^{|\mu|}/\mu!$ cannot be uniformly bounded for all $\mu \in \mathbb{N}$ in the neighborhood V of z_0, i.e.,

$$\forall C > 0 \ \exists \mu \in \mathbb{N} \text{ and } z \in V \setminus G_{\lambda_0} \text{ such that } \left| \frac{\rho^{\mu}}{\mu!} \cdot (h \cdot \nabla_{z_0})^{\mu} u(z) \right| \geq C. \tag{4.15}$$

For an analytic function $u(y)$ in a set V we know that for each $z \in V$ there is a neighborhood $B_{\rho}(z)$ such that

$$\sum_{\mu=0}^{\infty} \frac{((y - z) \cdot \nabla_z)^{\mu}}{\mu!} f(z) \tag{4.16}$$

is absolutely convergent towards f on $B_\rho(z)$. This yields

$$\left|(h\cdot\nabla_z)^\mu f(z)\right| \le c\frac{\mu!}{|y-z|^\mu} \tag{4.17}$$

with $h := \frac{(y-z)}{|y-z|}$ for some constant c. So due to the analyticity of the fundamental solution in z uniformly for $y \in \overline{G}$, the constant $\beta = \beta(z,\mu)$ is seen to be bounded by

$$|\beta(z,\mu)| \le c\frac{\mu!}{\rho_1^\mu}, \quad z \in V \setminus G_{\lambda_0}, \quad \mu \ge 1, \tag{4.18}$$

with some constants ρ_1 and c. Further, we remark that the exterior term (4.14) is analytic, and for ρ_1 sufficiently small the second term of (4.13) can be estimated by a constant $\tilde{c}$. Altogether, we can find sequences $(\mu_l)_{l\in\mathbb{N}} \subset \mathbb{N}, (z_l)_{l\in\mathbb{N}} \subset V$ and densities $\varphi_l \in L^2(\partial\Omega)$, $l \in \mathbb{N}$, which satisfy the impulse size condition (2.5) such that the indicator functional $I(\varphi_n)$ can be estimated from below by

$$\begin{aligned} I(\varphi_l) &= \int_{\partial D} \frac{\partial u}{\partial \nu}(y) v[\varphi_l](y) ds(y) \\ &\ge \frac{1}{c}\Big|\frac{\epsilon}{4}\frac{\rho_1^{\mu_l}}{\mu_l!}(h\cdot\nabla_z)^{\mu_l} u(z_l)\Big| - \tilde{c} \\ &\to \infty, \quad l \to \infty. \end{aligned} \tag{4.19}$$

Thus, $I_\epsilon(G)$ defined in (2.7) is unbounded and we have shown

$$I_\epsilon(G) = \infty, \quad I_0(G) = \infty, \tag{4.20}$$

which completes the proof of the theorem. □

5. Decompositions of the field u into $u = w + v$. This section contains several preparations which are needed to prove the convergence of the multiwave version of the no response test in the following section.

I. For the analysis of the multiwave case of the no response test we need the following decomposition of the field u into the sum of an *incident* field v and some *scattered field* w. Given the boundary data $f \in C(\partial\Omega)$ we define $v \in C^2(\Omega) \cap C(\overline{\Omega})$ to be the solution of the interior Dirichlet problem to the Helmholtz equation with boundary values f. Now, given a solution u to the boundary value problem (1.1)–(1.5), i.e., $u|_{\partial\Omega} = f$ and $u|_{\partial D} = 0$, we define

$$w := u - v \tag{5.1}$$

with the function v defined by its Dirichlet boundary data $f := u|_{\partial\Omega}$. The function v is considered to be some type of *incident* field, and the function w satisfies

$$w|_{\partial\Omega} = 0, \qquad w|_{\partial D} = -v|_{\partial D} \tag{5.2}$$

and is called a *scattered field*.

II. Let G be some test domain with $D \subset G$ and $z \in \Omega\setminus\overline{G}$ and consider a sequence (v_n), $n \in \mathbb{N}$, of single-layer potentials,

$$v_n := v[\varphi_n], \tag{5.3}$$

with boundary data $f_n := v[\varphi_n]$, such that

$$\|v[\varphi_n] - \beta\Phi(\cdot, z)\|_{C^1(\overline{G})} \to 0, \quad n \to \infty. \tag{5.4}$$

In particular, we obtain the convergence

$$\|v[\varphi_n] - \beta\Phi(\cdot, z)\|_{C^1(\partial D)} \to 0, \quad n \to \infty. \tag{5.5}$$

Let u_n be the solution of (1.1)–(1.5) with boundary data $\tilde{f}_n$ such that

$$\|\tilde{f}_n - f_n\|_{L^2(\partial\Omega)} \to 0 \tag{5.6}$$

for $n \to \infty$. We define

$$w_n := u_n - v_n. \tag{5.7}$$

Then we have

$$w_n|_{\partial\Omega} \to 0, \quad n \to \infty \text{ in } L^2(\partial\Omega), \tag{5.8}$$

$$w_n|_{\partial D} \to -\beta\Phi(\cdot, z), \quad n \to \infty, \text{ in } C(\partial D), \tag{5.9}$$

where the second equation is obtained via

$$\begin{aligned} \|w_n + \beta\Phi(\cdot, z)\|_{C(\partial D)} &\le \|u_n\|_{C(\partial D)} + \| - v_n + \beta\Phi(\cdot, z)\|_{C(\partial D)} \\ &\le \|v_n - \beta\Phi(\cdot, z)\|_{C(\partial D)}. \end{aligned} \tag{5.10}$$

From (5.8) and (5.9) by the unique solvability of the interior Dirichlet problem in $\Omega \setminus D$ we obtain the convergence of w_n towards some function w with

$$w|_{\partial\Omega} = 0, \tag{5.11}$$

$$w|_{\partial D} = -\beta\Phi(\cdot, z). \tag{5.12}$$

We will denote this function by $w(\cdot, z)$ to indicate the dependence on the source point z.

III. As a preparation for the next section now consider the response functional (2.13) for the multiwave case. Here, we construct $\alpha_{\xi,n}$ in such a way that

$$\left\| \sum_{\xi} \alpha_{\xi,n} u(\cdot, \xi) - f_n \right\|_{L^2(\partial\Omega)} \to 0, \quad n \to \infty, \tag{5.13}$$

for the boundary data f_n defined via (5.4). In this case using (2.4) we have

$$\begin{aligned} &\sum_{\xi} \alpha_{\xi,n} \int_{\partial\Omega} J(x, \xi)\varphi_n(x) ds(x) \\ &= \int_{\partial D} v_n(y) \sum_{\xi} \alpha_{\xi,n} \frac{\partial u(y, \xi)}{\partial \nu} ds(y) \\ &= \int_{\partial D} \sum_{\xi} \alpha_{\xi,n} \left\{ v_n(y) \frac{\partial u(y, \xi)}{\partial \nu} - \frac{\partial v_n(y)}{\partial \nu} \underbrace{u(y, \xi)}_{=0} \right\} ds(y). \end{aligned} \tag{5.14}$$

Trivial identity yields

$$\int_{\partial D}\left\{v_n(y)\frac{\partial v_n(y)}{\partial \nu}-\frac{\partial v_n(y)}{\partial \nu}v_n(y)\right\}ds(y)=0. \tag{5.15}$$

We subtract (5.15) from (5.14) to obtain

$$\begin{aligned}\sum_{\xi}\alpha_{\xi,n}\int_{\partial\Omega}J(x,\xi)\varphi_n(x)ds(x)&\\ =\int_{\partial D}\left\{v_n(y)\left(\sum_{\xi}\alpha_{\xi,n}\frac{\partial u(y,\xi)}{\partial\nu}-\frac{\partial v_n(y)}{\partial\nu}\right)\right.&\\ \left.-\frac{\partial v_n(y)}{\partial\nu}\left(\sum_{\xi}\alpha_{\xi,n}u(y,\xi)-v_n(y)\right)\right\}ds(y).&\end{aligned} \tag{5.16}$$

We define

$$u_n:=\sum_{\xi}\alpha_{\xi,n}u(\cdot,\xi),\quad n=1,2,3,\ldots. \tag{5.17}$$

By (5.13) this function u_n with $\tilde{f}_n := u_n|_{\partial\Omega}$ satisfies the condition (5.6) with v_n defined by (5.3)–(5.4). Then

$$w_n=u_n-v_n\ =\sum_{\xi=1}^{N}\alpha_{\xi,n}u(\cdot,\xi)-v_n \tag{5.18}$$

converges towards $w(\cdot)$ on ∂D, which is the scattered field for an incident point source with source point z. We remark that the function u_n is zero on ∂D and v_n is analytic and converges in $C^1(\partial D)$ towards $\beta\Phi(\cdot,z)$. By standard integral equation methods we obtain convergence of the normal derivatives on ∂D; i.e., the term

$$\frac{\partial w_n}{\partial\nu}=\frac{\partial}{\partial\nu}\Big(u_n-v_n\Big)=\sum_{\xi=1}^{N}\alpha_{\xi,n}\frac{\partial u(y,\xi)}{\partial\nu}-\frac{\partial v_n(y)}{\partial\nu} \tag{5.19}$$

converges towards $\frac{\partial w}{\partial\nu}$ on ∂D. Thus, for the functional (5.16) we have the convergence

$$\begin{aligned}&\sum_{\xi=1}^{N}\alpha_{\xi,n}\int_{\partial\Omega}J(x,\xi)\varphi_n(x)ds(x)\\ &\to\beta\int_{\partial D}\left\{\Phi(y,z)\frac{\partial w(y,z)}{\partial\nu(y)}-\frac{\partial\Phi(y,z)}{\partial\nu(y)}w(y,z)\right\}ds(y)\end{aligned} \tag{5.20}$$

for $n\to\infty$.

6. Convergence in the multiwave case. We are now prepared to prove the second of our two main theorems.

THEOREM 6.1. *Consider the multiwave case of the no response test where the condition* (2.9) *is satisfied. For some test domain G we obtain $I_{0,0}(G)=0$ if $D\subset G$ and $I_{0,0}(G)=\infty$ if $D\not\subset G$. In particular, for $D\not\subset G$ we have $I_{\epsilon_1,\epsilon_2}(G)=\infty$ for all*

$\epsilon_1, \epsilon_2 > 0$. *This proves in the limit* $\epsilon_1, \epsilon_2 \to 0$ *the convergence of the no response test for the multiwave case towards the true inclusion* D.

Proof. First, consider the case $D \subset G$. In this case, as shown in (5.16) for $\varphi \in \mathcal{M}(\epsilon_1)$ and $\alpha \in \mathcal{Q}(\epsilon_2, \varphi)$, we obtain

$$\begin{aligned}(6.1)\quad &\sum_{\xi=1}^{N} \alpha_\xi \int_{\partial\Omega} J(x,\xi)\varphi(x)ds(x) \\ &= \int_{\partial D} \left\{ v[\varphi](y) \left(\sum_{\xi} \alpha_\xi \frac{\partial u(y,\xi)}{\partial \nu} - \frac{\partial v[\varphi](y)}{\partial \nu} \right) \right. \\ &\qquad \left. - \frac{\partial v[\varphi](y)}{\partial \nu} \left(\sum_{\xi} \alpha_\xi u(y,\xi) - v[\varphi](y) \right) \right\} ds(y).\end{aligned}$$

For the multiwave version of the no response test according to (2.11) and (2.12) we have chosen the coefficients α_ξ such that the L^2-norm $\|w[\varphi]\|_{L^2(\partial\Omega)}$ of the scattered field

$$(6.2)\qquad w[\varphi] \;:=\; \sum_{\xi=1}^{N} \alpha_\xi u(\cdot,\xi) - v[\varphi]$$

is bounded by ϵ_2. By construction of the set $\mathcal{M}$ in (2.5) of Definition 2.1 and the Dirichlet boundary condition for u we further have

$$(6.3)\qquad \|w[\varphi]\|_{C(\partial D)} \le \epsilon_1, \quad \|v[\varphi]\|_{C(\partial D)} \le \epsilon_1, \quad \left\| \frac{\partial v[\varphi]}{\partial \nu} \right\|_{C(\partial D)} \le \epsilon_1.$$

By the continuity of the interior Dirichlet-to-Neumann map on ∂D in combination with classical regularity results for the normal derivative on a C^2-boundary ∂D, we obtain the estimate

$$(6.4)\qquad \left\| \frac{\partial w[\varphi]}{\partial \nu} \right\| = \left\| \sum_{\xi} \alpha_\xi \frac{\partial u(y,\xi)}{\partial \nu} - \frac{\partial v[\varphi](y)}{\partial \nu} \right\|_{C(\partial D)} \le c_1 \cdot (\epsilon_1 + \epsilon_2)$$

with some constant c_1. Thus, the functional (6.1) is bounded by

$$(6.5)\qquad c \cdot \epsilon_1 \cdot (\epsilon_1 + \epsilon_2)$$

with some constant c. We have proven that the functional $I_{\epsilon_1,\epsilon_2}(G)$ of the multiwave no response test (defined in (2.14)) is bounded. In the limit $\epsilon_1, \epsilon_2 \to 0$ we obtain convergence towards zero. This yields

$$(6.6)\qquad I_{0,0}(G) = 0.$$

Next, we assume that $D \not\subset G$. Then there is a point $z_0 \in \partial D \setminus \overline{G}$ located in the component of $\Omega \setminus (D \cup G)$ which is connected to $\partial\Omega$ and which satisfies

$$(6.7)\qquad \rho := \inf_{y \in \overline{G}} |y - z_0| > 0.$$

In this case for $z \in B_{\rho/2}(z_0) \cap (\Omega \setminus \overline{D})$ we use the construction worked out in section 5, parts II and III, but now for some test domain $M[z]$ which satisfies the conditions (1)

to (4) of section 4 and (5) $\overline{D \cup G} \subset M[z]$. This construction generates a sequence of incident fields v_n which approximate $\beta\Phi(\cdot, z)$ in $C^1(\overline{D} \cup \overline{G})$. The scattered field w_n converges towards the function defined in (5.11) and (5.12). Thus, using (5.20) we obtain

$$\begin{aligned} &\left| \sum_{\xi=1}^{N} \alpha_{\xi,n} \int_{\partial\Omega} J(x,\xi)\varphi_n(x) ds(x) \right| \\ &\to \beta \left| \int_{\partial D} \left\{ \Phi(y,z) \frac{\partial w(y,z)}{\partial \nu(y)} - \frac{\partial \Phi(y,z)}{\partial \nu(y)} w(y,z) \right\} ds(y) \right| \\ &= \beta \left| w(z,z) - \int_{\partial\Omega} \Phi(y,z) \frac{\partial w(y,z)}{\partial \nu(y)} ds(y) \right|. \end{aligned} \tag{6.8}$$

We remark that by Theorem 7.1 $w(z,z)$ is unbounded for $z \to z_0 \in \partial D$, but $\frac{\partial w(\cdot,z)}{\partial \nu}$ is bounded on $\partial\Omega$. We estimate the integral for $z \in B_{\rho/2}(z_0)$ by some constant $\tilde{c}$. For sufficiently large n this yields

$$\begin{aligned} &\left| \sum_{\xi=1}^{N} \alpha_{\xi,n} \int_{\partial\Omega} J(x,\xi)\varphi_n(x) ds(x) \right| \\ &\geq \frac{\beta}{2} \Big(\Big| w(z,z) \Big| - \tilde{c} \Big) \\ &\to \infty, \quad z \to z_0. \end{aligned} \tag{6.9}$$

Thus, we have constructed a sequence $\varphi_n \in \mathcal{M}(\epsilon_1)$ and $\alpha_n \in \mathcal{Q}(\epsilon_2, \varphi_n)$ such that $I(\varphi_n, \alpha_n)$ defined in (2.13) is unbounded. For the indicator function (2.14) this proves

$$I_{\epsilon_1,\epsilon_2}(G) = \infty \tag{6.10}$$

for all $\epsilon_1, \epsilon_2 > 0$ and thus $I_{0,0}(G) = \infty$. Hence, the proof is complete. ∎

7. Appendix. Here, our first goal is to analyze the behavior of a solution to the boundary value problem (5.11), (5.12) in the limit $z \to \partial D$.

THEOREM 7.1. *The solution $w(\cdot, z)$ of the Helmholtz equation in $\Omega \setminus \overline{D}$ with boundary values given by* (5.11), (5.12) *has the behavior*

$$|w(z,z)| \to \infty, \quad z \to \partial D. \tag{7.1}$$

Let M be a domain with $\overline{M} \subset \Omega \setminus \overline{D}$. Then we have

$$\left\| \frac{\partial w(\cdot, z)}{\partial \nu} \right\|_{C(\partial\Omega)} \leq C \tag{7.2}$$

uniformly for $z \in M$ with some constant C.

Proof. The proof is analogous to the case of obstacle scattering as worked out in detail in [12, Theorem 2.1.15 and Lemma 2.1.10]. ∎

Second, for the convenience of the reader we add some material about Taylor's series and analyticity of multidimensional functions.

LEMMA 7.2. *Consider the directional Taylor expansion*

$$u(x) = \sum_{\mu=0}^{\infty} \frac{1}{\mu!} ((x-z) \cdot \nabla)^{\mu} u(z). \tag{7.3}$$

If, for $|x-z|<\rho$, the series (3.3) *is absolutely convergent, then the function u is analytic in $B_\rho(z)$.*

Proof. First, recall the general form of the multidimensional Taylor series of u,

$$u(x)=\sum_{\xi=0}^{\infty} b_\xi (x-z)^\xi, \tag{7.4}$$

with the multi-index $\xi=(\xi_1,\dots,\xi_n)$, the coefficients

$$b_\xi=\frac{1}{\xi_1!\cdots\xi_n!}\cdot\frac{\partial^{\xi_1+\cdots+\xi_n}u(z)}{\partial z_1^{\xi_1}\cdots\partial z_n^{\xi_n}}, \tag{7.5}$$

and the multipower and multisum

$$z^\xi=z_1^{\xi_1}\cdot\ldots\cdot z_n^{\xi_n},\qquad \sum_{\xi=0}^{m}a_\xi:=\sum_{\xi_1=0}^{m_1}\cdots\sum_{\xi_n=0}^{m_n}a_{(\xi_1,\dots,\xi_n)} \tag{7.6}$$

for $m=(m_1,\dots,m_n)$. The form (7.4) is also the general local representation of an analytic function. We employ the standard formula

$$\begin{aligned}&\begin{pmatrix}\mu\\ k-1\end{pmatrix}+\begin{pmatrix}\mu\\ k\end{pmatrix}=\frac{\mu!}{(k-1)!(\mu-k+1)!}+\frac{\mu!}{k!(\mu-k)!}\\ &=\frac{\mu!}{k!(\mu-k+1)!}\{k+(\mu-k+1)\}=\frac{\mu!}{k!(\mu-k+1)!}(\mu+1)\\ &=\frac{(\mu+1)!}{k!(\mu+1-k)!}=\begin{pmatrix}\mu+1\\ k\end{pmatrix}.\end{aligned} \tag{7.7}$$

In the case of absolute convergence we are able to reorder the terms in (7.3) via the binomial formula, which in the two-dimensional case is given by

$$\Big((x_1-z_1)\partial_1+(x_2-z_2)\partial_2\Big)^\mu=\sum_{k=0}^{\mu}\begin{pmatrix}\mu\\ k\end{pmatrix}(x_1-z_1)^k(x_2-z_2)^{\mu-k}\partial_1^k\partial_2^{\mu-k}. \tag{7.8}$$

We obtain

$$\begin{aligned}&\sum_{\mu=0}^{\infty}\frac{1}{\mu!}((x-z)\cdot\nabla)^\mu u(z)\\ &=\sum_{\mu=0}^{\infty}\frac{1}{\mu!}\sum_{k=0}^{\mu}\begin{pmatrix}\mu\\ k\end{pmatrix}(x_1-z_1)^k(x_2-z_2)^{\mu-k}\partial_1^k\partial_2^{\mu-k}u(z)\\ &=\sum_{\xi_1=0}^{\infty}\sum_{\xi_2=0}^{\infty}\frac{1}{\xi_1!\xi_2!}(x_1-z_1)^{\xi_1}(x_2-z_2)^{\xi_2}\partial_1^{\xi_1}\partial_2^{\xi_2}u(z)\\ &=\sum_{\xi=0}^{\infty}b_\xi(x-z)^\xi,\end{aligned} \tag{7.9}$$

where we replaced $k=\xi_1$ and $\mu-k=\xi_2$ and observe that when $\mu=0$ to ∞ and $k=0$ to μ the variables ξ_1 and ξ_2 run through all numbers between 0 and ∞ such that each point $(\xi_1,\xi_2)\in\mathbb{N}_0\times\mathbb{N}_0$ is hit once. This proves analyticity of the function u. A proof for higher n is carried out analogously. ∎

Acknowledgments. For the completion of the proofs, discussions with Prof. Dr. Gen Nakamura and Dr. Mourad Sini, Hokkaido University, Japan, have been very important. The collaboration and interaction was a pleasure. Further, I would like to thank Prof. Dr. Simon Chandler-Wilde, Reading University, UK, and Prof. Dr. Rainer Kreß, University of Göttingen, for helpful discussions and remarks and Dr. Klaus Erhard and Dipl.-Phys. Jochen Schulz, Göttingen, for carefully reading the manuscript.

GLOBAL WEAK SOLUTIONS TO EQUATIONS OF COMPRESSIBLE MISCIBLE FLOWS IN POROUS MEDIA*

Y. AMIRAT† AND V. SHELUKHIN‡

Abstract. We study the one-dimensional equations governing compressible flows of m miscible components in a porous medium. The equations are reduced to a quasi-linear parabolic system for the discharge function P and the concentrations c_i. The equations of this system are strongly coupled since the parabolic equation for c_i contains both the second derivative c_{ixx} and the second derivative P_{xx}. We prove global weak solvability of an initial boundary-value problem both in the Eulerian and Lagrangian formulations.

Key words. porous media, compressible miscible flows, existence

DOI. 10.1137/050640321

1. Introduction. We address the question of global solvability of the one-dimensional equations which govern flows of m miscible components in porous media. For the reader's convenience, we restate the basic three-dimensional model [3], [10], [17].

The seepage velocity $\mathbf{u}(\mathbf{x}, t)$ obeys the Darcy law

$$\mathbf{u} = -\frac{k}{\mu}(\nabla p - \rho g \nabla z). \tag{1.1}$$

Here, p is the mixture pressure, ρ is the mixture density, z is the vertical component of the space-point vector $\mathbf{x}$ (we assume that z grows in the direction of the gravitation acceleration vector $\mathbf{g}$), μ is the viscosity, and k is the permeability.

When the fluid is slightly compressible, pressure and density are related by the state equation

$$\frac{d\rho}{\rho} = \nu dp,$$

where ν is the compressibility constant. Given some reference conditions, one can write the state equation as

$$\rho = \rho_r \exp(\nu(p - p_r)), \quad p_r = \text{const}, \quad \rho_r = \text{const} > 0,$$

or equivalently

$$p = \frac{1}{\nu} \ln \frac{\rho}{\kappa} \text{ with } \kappa = \rho_r e^{-\nu p_r}. \tag{1.2}$$

The mixture mass conservation law is written as

$$\frac{\partial \Phi \rho}{\partial t} + \operatorname{div}(\rho \mathbf{u}) = 0, \quad 0 \le \Phi \le 1, \tag{1.3}$$

where Φ is the porosity, the fraction of volume occupied by the fluid.

If chemical reactions do not occur, the change of volume concentration c_i of the ith component of the fluid mixture is described by the equation

$$\frac{\partial \Phi \rho c_i}{\partial t} + \operatorname{div} \mathbf{q}_i = 0, \quad (\mathbf{q}_i)_j \equiv \rho c_i u_j - \rho D_{jk} \frac{\partial c_i}{\partial x_k}, \quad i = 1, \dots, m, \quad j = 1, 2, 3. \tag{1.4}$$

The diffusion-dispersion tensor D is given by the formula

$$D_{ij} = \Phi d_m \delta_{ij} + \Phi |\mathbf{u}| \left(d_e \frac{u_i u_j}{|\mathbf{u}|^2} + d_t \left(1 - \frac{u_i u_j}{|\mathbf{u}|^2} \right) \right),$$

where d_m is the diffusion, and d_e and d_t are the dispersion coefficients.

Equations (1.1)–(1.3) cannot be solved independently of (1.4) because of the constitutive law

$$\mu = \mu(c_1, c_2, \dots, c_m). \tag{1.5}$$

The parameters $k, \nu, \Phi, d_m, d_e, d_t$ are normally assumed to be positive constants.

Due to the definition of c_i, equations (1.4) are coupled by the restrictions

$$0 \le c_i, \quad \sum_1^m c_j = 1. \tag{1.6}$$

Note that because of equality (1.6), the equation for c_m in (1.4) is a consequence of (1.3) and of the first $m-1$ equations in (1.4).

Equations (1.1)–(1.6) have many applications and serve as a basis for the computer modeling of petroleum reservoir flows, underground contamination problems, etc. [5, 6]. As for the incompressible flows, we refer the reader to the results in [4], [8], [7], [15].

One-dimensional vertical flows equations in the domain $|x| < 1$ reduce to the system

$$(\Phi \rho)_t + (\rho u)_x = 0, \quad u = -\lambda(p_x - g\rho), \quad \lambda \equiv \frac{k}{\mu}, \quad p = \frac{1}{\nu} \ln \frac{\rho}{\kappa}, \tag{1.7}$$

$$(\Phi \rho c_i)_t + (\rho c_i u)_x = (\rho D(u) c_{ix})_x, \quad D(u) \equiv \Phi(d_m + d_p |u|), \quad 1 \le i \le m-1, \tag{1.8}$$

with the restrictions

$$0 \le c_i, \quad \sum_1^{m-1} c_j \le 1. \tag{1.9}$$

Global existence of this system was studied in [2] under the Douglas–Roberts [5] assumption that the term $\rho_x c_i u$ in each equation of system (1.8) is negligible and the derivative $(\rho c_i u)_x$ can be substituted with the sum $\rho c_{ix} u + \rho c_i u_x$. Here, we perform the analysis of system (1.7)–(1.9) without any smallness hypothesis. All the mathematical difficulties to overcome stem from the fact that the vector

$$\mathbf{v} := (P, c_1, c_2, \dots, c_{m-1})^T,$$

with P standing for the fluid discharge, solves the quasi-linear parabolic system (2.1)–(2.2) in the form

$$\mathbf{v}_t = A(\mathbf{v}, \mathbf{v}_x)\mathbf{v}_{xx} + \mathbf{f}[x, \mathbf{v}, \mathbf{v}_x], \tag{1.10}$$

with a triangular $m \times m$-matrix A and with $\mathbf{f}$ being a nonlocal term containing the integral $\int_{-1}^{x} \exp(\nu P(y,t))dy$. Triangularity means that the parabolic equation for P does not contain the second derivative $\partial_{xx}c_i$, but the parabolic equation for c_i contains both the second derivatives $\partial_{xx}c_i$ and $\partial_{xx}P$. For system (1.10), a global existence theory is not yet developed. The theory of Ladyzhenskaya, Solonnikov, and Ural'ceva [13] can be applied to system (1.10) provided that A is diagonal and $A_{11} = A_{22} = \cdots = A_{mm}$. The results of Amann [1] concern the triangular matrix A, but they are valid under the assumption that some a priori estimates hold. Interestingly, triangular parabolic systems

$$\mathbf{v}_t = (B(\mathbf{v})\mathbf{v}_x)_x + (\mathbf{f}(\mathbf{v}))_x \tag{1.11}$$

arise also in the theory of three-phase capillary immiscible flows in porous media [9]. But the results obtained for system (1.11) are not applicable here, since the matrix B does not depend on $\mathbf{v}_x$.

We study system (1.7)–(1.9) in the domain

$$Q = \Omega \times (0,T), \quad \Omega = \{x : |x| < 1\}.$$

The initial and boundary-value conditions are

$$p|_{t=0} = p_0, \quad c_i|_{t=0} = c_i^0, \tag{1.12}$$

$$u|_{|x|=1} = 0, \quad \partial_x c_i|_{|x|=1} = 0, \quad 1 \le i \le m-1. \tag{1.13}$$

We denote $\rho_0 = \rho_r \exp(\nu(p_0 - p_r))$.

We assume that the mobility function $\lambda(\mathbf{c})$, $\mathbf{c} := (c_1, c_2, \dots, c_{m-1})^T$, is defined not only in the domain (1.9) but in the whole space $\mathbb{R}^{m-1}$ and

$$\lambda \in C^2(\mathbb{R}^{m-1}), \quad 0 < \lambda_0 \le \lambda(\mathbf{c}) \le \lambda_0^{-1}. \tag{1.14}$$

In what follows, we use the Sobolev spaces $W^{k,p}(\Omega)$, $W_p^{k,l}(Q)$, the Orlicz and Sobolev–Orlicz spaces $L_M(\Omega)$, $W_M^1(\Omega)$ (associated with an admissible convex function M), and the Hölder spaces $H^{k+\alpha,(k+\alpha)/2}(\bar{Q})$ [12], [11], [13]; the corresponding definitions will be restated below.

We define a *weak solution* $(u, p, \rho, \mathbf{c})$ of problem (1.7)–(1.9), (1.12), (1.13) as follows:

(i) $u \in L^\infty(0,T; L_M(\Omega)) \cap L^{3/2}(0,T; W^{1,3/2}(\Omega)) \cap L^3(Q)$;
$p, \rho \in L^\infty(0,T; W_M^1(\Omega)) \cap L^{3/2}(0,T; W^{2,3/2}(\Omega))$
$\cap L^3(0,T; W^{1,3}(\Omega)) \cap L^\infty(Q)$; $p_t, \rho_t \in L^{3/2}(Q)$;
$\mathbf{c} \in L^\infty(0,T; L^2(\Omega)) \cap L^2(0,T; W^{1,2}(\Omega))$
with $M(s) = |s|\ln(1+|s|) - |s| + \ln(1+|s|)$;

(ii) the equations

$$(\Phi\rho)_t + (\rho u)_x = 0, \quad u = -\lambda(\mathbf{c})(p_x - g\rho), \quad p = \frac{1}{\nu}\ln\frac{\rho}{\kappa},$$

hold a.e. in Q;

(iii) equations (1.8) hold weakly in the following sense:

$$\iint_{\bar{Q}} \rho\mathbf{c}(\Phi\psi_t + u\psi_x) - \rho D(u)\mathbf{c}_x\psi_x \, dxdt = -\int_\Omega \Phi\rho_0(x)\,\mathbf{c}_0(x)\psi(x,0)dx$$

for any $\psi \in C^1(\bar{Q})$ such that $\psi(x,T) = 0$.

We formulate the main result.

THEOREM 1.1. *Assume that* $p_0 \in W^{2,2}(\Omega)$, $\mathbf{c}_0 \in L^2(\Omega)$ *and that the function* $\lambda(\mathbf{c})$ *satisfies restrictions* (1.14). *Then, problem* (1.7)–(1.9), (1.12), (1.13) *has a weak solution such that* $\inf_Q \rho > 0$.

Observe that restrictions (1.9) are not included in the above definition. To justify the notion of weak solution we establish the following claim.

THEOREM 1.2. *If the weak solution* $(u, p, \rho, \mathbf{c})$ *is regular enough, it satisfies restrictions* (1.9), *provided that they are valid for the initial data* $\mathbf{c}_0$.

We comment on the proofs. The first step is the reduction of the basic equations (1.7)–(1.8) to the parabolic system

$$\Phi P_t - \lambda(\mathbf{c})|P_x|^2 = \left(\frac{\lambda(\mathbf{c})}{\nu} P_x\right) x, \tag{1.15}$$

$$\Phi \mathbf{c}_t - \lambda(\mathbf{c}) P_x \mathbf{c}_x = \Phi[(d_m + d_p|\lambda(\mathbf{c})P_x|)\mathbf{c}_x]_x + \Phi\Big(d_m + d_p|\lambda(\mathbf{c})P_x|\Big)\mathbf{c}_x \rho_x \rho^{-1}, \tag{1.16}$$

where P is the discharge function, related to the velocity u by the Darcy law $u = -\lambda(\mathbf{c})P_x$; the density ρ is given by the representation formula

$$\rho(x,t) = \kappa e^{\nu P(x,t)} \Big/ \Big(1 - \nu\kappa g \int_{-1}^{x} e^{\nu P(y,t)} dy\Big).$$

This reduction has a twofold meaning. On the one hand, it enables us to derive a number of a priori estimates like the maximum principles for P and c_i. Particularly, the claim of Theorem 1.2 follows immediately from (1.16). On the other hand, one can see that the basic equations are as difficult as the strongly coupled parabolic system (1.15)–(1.16), with (1.16) for $\mathbf{c}$ containing both the second derivative $\mathbf{c}_{xx}$ and the second derivative P_{xx}. Moreover, it becomes clear that it is impossible to obtain a regular solution without an a priori estimate

$$\|u\|_{C^0(\overline{Q})} \overset{?}{\leq} \text{const} \tag{1.17}$$

according to the existing theory of parabolic equations (see, for a example, [13]).

The a priori estimates obtained are those which correspond to item (i) of the definition of weak solution. They do not guarantee the bound (1.17); this is why our results concern only the weak solutions.

Starting from system (1.15)–(1.16), we construct approximate solutions and study their compactness.

As follows from a priori estimates, the last term in (1.16) belongs to only $L^1(Q)$. Thus, one cannot substitute this equation by Galerkin approximation equations. In this sense, (1.8) is better. But there is an obstacle in the study of the system

$$\Phi P_t - \lambda(\mathbf{c})|P_x|^2 = \left(\frac{\lambda(\mathbf{c})}{\nu} P_x\right) x, \quad (\Phi\rho\mathbf{c})_t + (\rho\mathbf{c}u)_x = (\rho D(u)\mathbf{c}_x)_x. \tag{1.18}$$

Whatever approximation $(P_n, \mathbf{c}_n)$, the functions $\mathbf{c}_n$ should converge a.e. in Q in order to pass to the limit in the equation $u_n = -\lambda(\mathbf{c}_n)P_{nx}$. With the estimate $\|\mathbf{c}_n\|_{L^2(0,T;W^{1,2}(\Omega))} \leq b$ at hand, one could prove the convergence of $\mathbf{c}_n$ a.e. in Q by the Aubin–Lions compactness theorem [14] if there were an estimate of $\mathbf{c}_{nt}$ in some weak norm. From (1.8), one can obtain such an estimate for the time derivative

$(\Phi\rho_n\mathbf{c}_n)_t$, but not for the time derivative $\mathbf{c}_{nt}$. Moreover, the presence of the density ρ makes (1.8) a degenerate parabolic equation for $\mathbf{c}$, and the problem of existence of Galerkin approximations also becomes more complicated.

To avoid these technical difficulties, we propose another approach. Its main ingredient is the passage to the Lagrangian variables $(x,t) \to (\xi,t)$ by the formulas (2.6) and (2.7) below. In the new variables, system (1.18) reads

$$\nu P_t = \Phi\rho(\lambda(\mathbf{c})\rho P_\xi)_\xi, \quad \mathbf{c}_t = \Phi(\rho^2 D\mathbf{c}_\xi)_\xi, \quad \rho = \kappa e^{\nu P + \nu g(1+\xi)/\Phi}. \tag{1.19}$$

We define approximate solutions $(P_n(\xi,t), \mathbf{c}_n(\xi,t))$, by the semi-Galerkin method, in the sense that P_n and $\mathbf{c}_n$ solve the first equation in (1.19) exactly and solve the second equation approximately (see section 4).

It is an advantage of system (1.19) that P_n and $\mathbf{c}_n$ enjoy the same a priori estimates (except (1.9)) as the solution $(P(\xi,t), \mathbf{c}(\xi,t))$ itself, including the estimates for the time derivatives of P_n and $\mathbf{c}_n$. One more advantage is the straightforward estimate $\inf_Q \rho > 0$.

Thus, we first prove global solvability of system (1.19) (Theorem 5.1), equipped with the corresponding initial and boundary conditions. Then, the same result for system (1.18) (Theorem 5.2) is obtained by the inverse change of variables $(\xi,t) \to (x,t)$. Theorem 1.1 is an easy consequence of Theorem 5.2.

Though any regular solution of (1.19) satisfies the restrictions (1.9), it is not true for the approximate concentrations $\mathbf{c}_n$ since they do not exactly solve the second equation in (1.19). Due to the technique developed in [16], there is a possibility of deriving properties (1.9) for the weak solutions using only the weak formulation (see item (iii) in the definition of weak solution). But to apply this technique one needs estimate (1.17). Thus, the validity of properties (1.9) for the weak solution is an open problem.

2. Different settings of the problem. First, we show that the basic flow equations can be formulated as a quasi-linear parabolic system. We introduce the fluid discharge function P as follows:

$$P := p - \frac{g(1+\xi)}{\Phi}, \quad \xi(x,t) := \Phi\int_{-1}^{x} \rho(y,t)dy - 1.$$

Here, ξ is the mass Lagrange variable. For simplicity we assume that

$$\Phi\int_{-1}^{1} \rho_0(x)dx = 2.$$

Due to the mass conservation law and the boundary condition $u|_{|x|=1} = 0$, we have

$$\Phi\int_{-1}^{1} \rho(x,t)dx = 2.$$

Hence, $\xi(\cdot,t)$ maps Ω onto itself, and $\xi(\pm1,t) = \pm1$.

By (1.7)–(1.8) and the formulas

$$u = -\lambda P_x, \quad \rho_x = \nu\rho p_x, \quad p_x = P_x + g\rho, \quad p_t = P_t + \Phi^{-1} g\,\lambda\rho P_x,$$

one can verify that P and $\mathbf{c}$ solve the parabolic system

$$\Phi P_t - \lambda(\mathbf{c})P_x^2 = \left(\frac{\lambda(\mathbf{c})}{\nu}P_x\right)x, \tag{2.1}$$

$$\Phi\mathbf{c}_t + u\mathbf{c}_x = (D(u)\mathbf{c}_x)_x + D(u)\mathbf{c}_x\rho_x\rho^{-1}, \tag{2.2}$$

with u, ρ, and D given by the representation formulas

$$u = -\lambda(\mathbf{c})P_x, \quad \rho(x,t) = \frac{\kappa e^{\nu P(x,t)}}{1 - \nu\kappa g \int_{-1}^{x} e^{\nu P(y,t)} dy}, \quad D = \Phi(d_m + d_p|u|). \tag{2.3}$$

The boundary and initial conditions are

$$\begin{aligned} &P_x|_{|x|=1} = 0, \quad \mathbf{c}_x|_{|x|=1} = 0, \\ &P|_{t=0} = p_0 - g\int_{-1}^{x} \rho_0(y)dy, \quad \mathbf{c}|_{t=0} = \mathbf{c}_0(x). \end{aligned} \tag{2.4}$$

All the formulas (2.1)–(2.4) can be obtained by simple calculations. We comment only on the derivation of the representation formula for the density which is the second one in (2.3). Since $\xi_x = \Phi\rho$, one can write the definition of P as

$$g\kappa\nu e^{\nu P} = \nu g\rho e^{-\nu g(\xi+1)/\Phi} = -e^{-\nu g/\Phi}\frac{\partial}{\partial x}e^{-\nu g\xi/\Phi}. \tag{2.5}$$

Then we integrate (2.5) with respect to the x variable to obtain

$$1 - g\kappa\nu \int_{-1}^{x} e^{\nu P(y,t)} dy = e^{-\nu g(\xi+1)/\Phi}.$$

Now the representation formula for density results from this relation and the first equality in (2.5).

In what follows we use a Lagrange formulation of the problem. The change of variables $(x,t) \to (\xi,t)$ maps the cylinder $Q = \Omega \times (0,T)$ onto itself and

$$\xi_x = \Phi\rho, \quad \xi_t = -\rho u, \quad \xi|_{x=\pm 1} = \pm 1. \tag{2.6}$$

Observe that the Jacobian of the transformation is equal to $\Phi\rho$. The inverse transformation $(\xi,t) \to (x,t)$ satisfies the equalities

$$\Phi\rho x_\xi = 1, \quad \Phi x_t = u, \quad x|_{\xi=\pm 1} = \pm 1. \tag{2.7}$$

Let $\tilde{f}(\xi,t)$ stand for the transformation of a given function $f(x,t)$:

$$\tilde{f}(\xi,t) = f(x(\xi,t),t).$$

By formulas (2.6) and (2.7), we have

$$\tilde{f_t} = f_t + uf_x/\Phi, \quad \tilde{f_\xi} = \frac{f_x}{\rho\Phi}, \quad x(\xi,t) = \int_{-1}^{\xi} \frac{1}{\tilde{\rho}(y,t)\Phi}\, dy - 1.$$

Now, omitting "˜" one can write the flow equations in the Lagrange variables as

$$\begin{aligned} &(\rho^{-1})_t = u_\xi, \quad u = -\Phi\lambda(\mathbf{c})\rho P_\xi, \quad P = p - \frac{g(1+\xi)}{\Phi}, \quad p = \frac{1}{\nu}\ln\frac{\rho}{\kappa}, \\ &\mathbf{c}_t = \Phi(\rho^2 D\mathbf{c}_\xi)_\xi, \quad D = \Phi(d_m + d_p|u|), \quad u|_{|\xi|=1} = 0. \end{aligned}$$

The parabolic system (2.1), (2.2) is written as

$$\nu P_t = \Phi\rho(\lambda(\mathbf{c})\rho P_\xi)_\xi, \quad \mathbf{c}_t = \Phi(\rho^2 D(u)\mathbf{c}_\xi)_\xi, \tag{2.8}$$

with

$$\rho = \kappa e^{\nu P + \nu g(1+\xi)/\Phi}, \quad D(u) = \Phi(d_m + d_p|u|), \quad u = -\Phi\lambda(\mathbf{c})\rho P_\xi. \tag{2.9}$$

The boundary and initial conditions are

$$\begin{aligned} &P_\xi|_{|\xi|=1} = 0, \quad \mathbf{c}_\xi|_{|\xi|=1} = 0, \\ &P|_{t=0} = P_0(x(\xi,0)) \equiv \tilde{P}_0(\xi), \quad \mathbf{c}|_{t=0} = \mathbf{c}_0(x(\xi,0)) \equiv \tilde{\mathbf{c}}_0(\xi), \end{aligned} \tag{2.10}$$

where the function $x(\xi, 0)$ can be calculated via the equality

$$\xi = \Phi \int_{-1}^{x(\xi,0)} \rho_0(y)dy - 1.$$

Observe that system (2.8) can be written in a conservative form:

$$v_t = \Phi\left(\frac{\lambda(\mathbf{c})v_\xi}{\nu\, v^2}\right)\xi + \left(\frac{g\lambda(\mathbf{c})}{v}\right)\xi, \quad \mathbf{c}_t = \Phi\left(\frac{D\mathbf{c}_\xi}{v^2}\right)\xi \tag{2.11}$$

by passing to the variables v and $\mathbf{c}$, where $v = 1/\rho$ is the specific volume.

Thus, starting from the flow equations, we have obtained three parabolic systems. We claim that each of these systems is equivalent to the basic flow equations. Let us verify that claim for system (2.1), (2.2). The verification for the other systems is similar.

It is enough to show that, given a solution $(P, \mathbf{c})$ of (2.1), (2.2), the functions ρ and u, defined by (2.3), solve the equations

$$\Phi\rho_t + (\rho u)_x = 0, \quad u = -\lambda(p_x - g\rho), \quad p = \frac{1}{\nu}\ln\frac{\rho}{\kappa}. \tag{2.12}$$

By definition (2.3) of u, it follows from (2.1) that

$$\Phi P_t + uP_x + u_x/\nu = 0. \tag{2.13}$$

Hence,

$$\Phi(e^{\nu P})_t + (ue^{\nu P})_x = 0.$$

Denoting $R = \int_{-1}^{x} e^{\nu P(y,t)}dy$, we see that R solves the transport equation

$$\Phi R_t + uR_x = 0 \tag{2.14}$$

and is linked with ρ by the equality

$$\rho = -\frac{1}{g\nu}\frac{\partial}{\partial x}\ln(1 - \kappa\nu g R).$$

Integrating the latter equation with respect to the x variable, we obtain that

$$1 - \kappa\nu g R = e^{-\nu g z}, \quad z := \int_{-1}^{x} \rho(y,t)dy.$$

Thus, we have proved that

$$P = \frac{1}{\nu}\ln\frac{\rho}{\kappa} - g\int_{-1}^{x}\rho(y,t)dy \quad \text{or} \quad \rho = \kappa e^{\nu P + \nu g z}.$$

We calculate

$$e^{\nu g z}\Big(\Phi\rho_t + (\rho u)_x\Big) = \kappa\nu e^{\nu g z}(\Phi P_t + uP_x + u_x/\nu) + \nu g z e^{\nu g z}(\Phi z_t + u z_x).$$

Observe that z, being a function of R, solves the transport equation (2.14). Hence, the first equation in (2.12) results from (2.13).

3. A priori estimates. In what follows, the norms in $L^q(\Omega)$ and $L^r(0,T;L^q(\Omega))$ are denoted by $\|\cdot\|_q$ and $\|\cdot\|_{r,q,}$, respectively.

We assume that the solutions to the basic flow equations are regular enough. It permits us to use any of the parabolic systems described above. If the change of variables $(x,t) \to (\xi,t)$ is regular, the solvability of the problem in the Euler setting (system (2.1)–(2.4)) implies the solvability of the problem in the Lagrange setting (system (2.8)–(2.10)), and vice versa. But it does not mean that the study of one system is as easy as the study of the other. Since the change of variables depends on the solution, systems (2.1)–(2.4) and (2.8)–(2.10) are completely different nonlinear systems. In fact, we do not tackle system (2.1)–(2.4) directly. First, we prove the solvability of system (2.8)–(2.10) and then we do it for system (2.1)–(2.4) via the change of variables. The main reason is that approximate solutions of the Eulerian system do not enjoy as many estimates as those of the Lagrangian system.

First, we consider the problem in the Lagrange setting.

LEMMA 3.1. *The discharge function satisfies the maximum principle*

$$\underline{P} \equiv \inf_{\Omega} \tilde{P}_0(\xi) \le P(\xi,t) \le \sup_{\Omega} \tilde{P}_0(\xi) \equiv \overline{P} \quad \forall (\xi,t) \in Q. \tag{3.1}$$

Proof. Given a function $F(P)$, $F \in C^2_{loc}(\mathbb{R})$, we multiply the first equation in (2.8) by $vF'(P)$, $v := \rho^{-1}$, and integrate the result over the domain $\Omega \times (0,\tau)$, $0 < \tau \le T$, to arrive at the equality

$$\int_\Omega v(\xi,\tau)F(P(\xi,\tau))d\xi + \frac{\Phi}{\nu}\int_0^\tau \int_\Omega \lambda\rho P_\xi^2(F'' - \nu F')d\xi dt = \int_\Omega v_0 F(P_0)d\xi. \tag{3.2}$$

Here, we have used the equation $v_t = u_\xi$. The continuous function

$$F_1(P) = \begin{cases} 0, & P < \overline{P} + \varepsilon, \\ \big(e^{\nu(P-\overline{P}-\varepsilon)} - 1\big)/\nu, & P \ge \overline{P} + \varepsilon, \end{cases}$$

solves the equation $F''(P) - \nu F'(P) = 0$ everywhere except at the point $P = \overline{P} + \varepsilon$.

For any $\delta > 0$, let $\theta_\delta(r)$ be a standard mollifier:

$$\theta_\delta(r) = \theta(r/\delta)/\delta, \quad \theta \in C^\infty(\mathbb{R}), \quad \theta \ge 0, \quad \operatorname{supp}\theta \subset [-1,1], \quad \int_{\mathbb{R}} \theta(r)dr = 1.$$

Clearly, the function $F_{1\delta} = F_1 * \theta_\delta$ enjoys the properties

$$F_{1\delta} \in C^\infty(\mathbb{R}),$$
$$F_{1\delta} \to F_1 \quad \text{in} \quad C_{\text{loc}}(\mathbb{R}), \quad \text{and} \quad F''_{1\delta}(P) - \nu F'_{1\delta}(P) \to 0 \quad \text{if} \quad P \ne \overline{P} + \varepsilon.$$

Let us take $F(P) = F_{1\delta}(P)$ in (3.2) and send δ to 0. Observe that $P_\xi(\xi,t) = 0$ a.e. at the set where $P(\xi,t) = \overline{P} + \varepsilon$. Hence, by the Lebesgue theorem,

$$\int_0^\tau \int_\Omega \lambda\rho P_\xi^2 \Big(F''_{1\delta}(P) - \nu F'_{1\delta}(P)\Big)d\xi dt \to 0 \quad \text{as} \quad \delta \to 0.$$

On the other hand, by the choice of F_1,

$$\int_\Omega v(\xi,\tau)F_{1\delta}(P(\xi,\tau))d\xi \to \int_\Omega v(\xi,\tau)F_1(P(x,\tau))d\xi, \quad \int_\Omega v_0 F_{1\delta}(P_0)d\xi \to 0,$$

as $\delta \to 0$. Thus, $\int_\Omega v(\xi,\tau)F_1(P(\xi,\tau))d\xi = 0$ for any $\tau \geq 0$. This implies that $P \leq \overline{P} + \varepsilon$. Since ε is arbitrary, the estimate $P \leq \overline{P}$ follows.

Next, we take the function $F(P)$ in (3.2) equal to $F_2(P)$, with F_2 such that

$$F_2 \in C^2_{\rm loc}(\mathbb{R}), \quad F_2'' \geq 0, \quad F_2' \leq 0, \quad F_2(P) = 0 \quad \text{if} \quad P \leq \underline{P}.$$

Due to this choice, we obtain $P \geq \underline{P}$. Estimates (3.1) are established. ∎

Consequence. It follows from the density representation formula (2.9) that

$$\underline{\rho} \equiv \kappa e^{\nu \underline{P}} \leq \rho \leq \kappa e^{\nu \overline{P} + 2\nu g/\Phi} \equiv \overline{\rho}.$$

LEMMA 3.2. *The function P_ξ satisfies the estimate*

$$\sup_{t\geq 0} \int_\Omega |P_\xi| d\xi \leq \int_\Omega |\tilde{P}_{0\xi}| d\xi. \tag{3.3}$$

Proof. Denoting $z = P_\xi$, we obtain from (2.8) the following equation for z:

$$\nu z_t = (\Phi \rho(\lambda\rho z)_\xi)_\xi.$$

Given $\delta > 0$, we multiply this equation by $M_1'(\lambda\rho z)$, where $M_1(s) = (s^2+\delta^2)^{1/2}$ is a smooth approximation of $|s|$, and integrate the result over $\Omega \times (0,t)$. We obtain

$$\int_0^t \int_\Omega \frac{\nu z_t \lambda\rho z}{((\lambda\rho z)^2+\delta^2)^{1/2}} + \frac{\delta^2\, \Phi\rho |(\lambda\rho z)_\xi|^2}{((\lambda\rho z)^2+\delta^2)^{3/2})}\, d\xi d\tau = 0.$$

In the limit as $\delta \to 0$ we have

$$\int_0^t \int_\Omega z_t \,\mathrm{sign}(\lambda\rho z)\, d\xi d\tau = \int_0^t \int_\Omega z_t \,\mathrm{sign}(z)\, d\xi d\tau = \int_0^t \frac{d}{d\tau} \int_\Omega |z|\, d\xi d\tau \leq 0,$$

from which follows (3.3). ∎

LEMMA 3.3. *The function* $\mathbf{c}$ *satisfies the estimate*

$$\sup_{t\geq 0} \int_\Omega |\mathbf{c}|^2 d\xi + \Phi \int_0^t \int_\Omega \rho^2 D |\mathbf{c}_\xi|^2 d\xi d\tau \leq \int_\Omega |\mathbf{c}_0|^2 d\xi.$$

Proof. It follows immediately if one multiplies the second equation in (2.8) by $\mathbf{c}$ and integrate the result over $\Omega \times (0,t)$. ∎

Let us now introduce the convex function

$$M(U) = |U| \ln(1+|U|) - |U| + \ln(1+|U|). \tag{3.4}$$

One can easily verify that

$$M'(U) = \ln(1+|U|)\,\mathrm{sign} U, \quad M''(U) = (1+|U|)^{-1}.$$

Below, b (with or without a subscript) indicates a generic constant, depending only on some bounds of the initial data, which will probably take on different values in different occurrences.

We have the following result.

LEMMA 3.4. *The function*

$$U = -\Phi\rho P_\xi$$

satisfies the estimates

$$\|U\|_{L^\infty(0,T;L_M(\Omega))} \le b, \quad \|U\|_{3,3} \le b,$$
$$\|U_\xi\|_{3/2,3/2} \le b, \quad \|U\|_{2,\infty} \le b,$$

where $L_M(\Omega)$ denotes the Orlicz space associated with the function M defined by (3.4)*, and b is a constant depending only on Φ, ν, g, $\underline{\rho}$, $\overline{\rho}$, and the function λ.*

Proof. By differentiation with respect to ξ, it follows from the first equation in (2.8) that the function U solves the equation

$$U_t + \rho U(\lambda U)_\xi = \Phi\nu^{-1}\rho\,(\rho(\lambda U)_\xi)_\xi. \tag{3.5}$$

We multiply (3.5) by $vM'(U)$, where $v = 1/\rho$, and integrate the result over Ω using the equalities $v_t = u_\xi$ and $u = \lambda U$. This gives

$$\frac{d}{dt}\int_\Omega vM(U)\,d\xi = \int_\Omega (\lambda U)_\xi\,(M(U) - UM'(U))\,d\xi \\ -\Phi\nu^{-1}\int_\Omega M''(U)U_\xi\rho(\lambda U)_\xi\,d\xi.$$

The last equality can be written in the form

$$\frac{d}{dt}\int_\Omega vM(U)d\xi + \int_\Omega \Phi\nu^{-1}\rho\lambda U_\xi^2 M''(U)\,d\xi \\ = -\int_\Omega \Phi\nu^{-1}\rho\lambda_\xi U U_\xi M''(U)\,d\xi + \int_\Omega \lambda U^2 U_\xi M''(U)\,d\xi. \tag{3.6}$$

We denote

$$J_1 = \int_\Omega \Phi\nu^{-1}\rho\lambda U_\xi^2 M''(U)\,d\xi, \quad J_2 = -\int_\Omega \Phi\nu^{-1}\rho\lambda_\xi U U_\xi M''(U)\,d\xi,$$
$$J_3 = \int_\Omega \lambda U^2 U_\xi M''(U)\,d\xi.$$

By the Young inequality, we have

$$|J_2| \le J_1/2 + b_1\int_\Omega \frac{U^2|\mathbf{c}_\xi|^2}{1+|U|}d\xi \le J_1/2 + b_2\int_\Omega \rho^2 D|\mathbf{c}_\xi|^2 d\xi. \tag{3.7}$$

To estimate J_3 we write it in the form

$$J_3 = \int_\Omega \lambda F(U)_\xi d\xi = -\int_\Omega \lambda_\xi F(U)d\xi,$$

where the function F is chosen in such a way that $F(0) = 0$, $F'(U) = M''(U)U^2$, and $|F(U)| \le U^2/2$. Then, by the Young inequality,

$$|J_3| \le \delta\int_\Omega |U|^3 d\xi + b_{1\delta}\int_\Omega |U||\lambda_\xi|^2\,d\xi,$$
$$\le \delta\int_\Omega |U|^3 d\xi + b_{2\delta}\int_\Omega |U||c_\xi|^2\,d\xi$$
$$\le \delta\int_\Omega |U|^3 d\xi + b_{3\delta}\int_\Omega \rho^2 D|\mathbf{c}_\xi|^2 d\xi \text{ for any } \delta > 0.$$

On the other hand,

$$|U(\xi,t)|^3 = |U(\xi,t)|\,|\int_{-1}^{\xi} U_\xi(y,t)dy\,|^2,$$

and then

$$\int_\Omega |U(\xi,t)|^3\,d\xi \le \int_\Omega \frac{U_\xi^2}{1+|U|}\,d\xi\Big(\int_\Omega |U(\xi,t)|\,d\xi\Big)\Big(\int_\Omega (1+|U|)\,d\xi\Big). \tag{3.8}$$

Thus,

$$\begin{aligned}|J_3| \le \delta \int_\Omega \frac{U_\xi^2}{1+|U|}\,d\xi\Big(\int_\Omega |U(\xi,t)|\,d\xi\Big)\Big(\int_\Omega (1+|U|)\,d\xi\Big)\\ + b_{3\delta}\int_\Omega \rho^2 D|\mathbf{c}_\xi|^2 d\xi \text{ for any } \delta>0.\end{aligned} \tag{3.9}$$

Choosing δ small enough and applying Lemma 3.2 we infer from (3.6), (3.7), and (3.9) that

$$\|U\|_{L^\infty(0,T;L_M(\Omega))} \le b, \quad \iint_{\mathrm{Q}} \frac{U_\xi^2}{1+|U|}\,d\xi dt \le b.$$

From (3.8) and Lemma 3.2, we deduce that

$$\iint_{\mathrm{Q}} |U(\xi,t)|^3\,d\xi dt \le b.$$

Then, by the Young inequality we have

$$\begin{aligned}\iint_{\mathrm{Q}} |U_\xi|^{3/2}\,d\xi dt &= \iint_{\mathrm{Q}} \frac{|U_\xi|^{3/2}(1+|U|)^{3/4}}{(1+|U|)^{3/4}}\,d\xi dt\\ &\le \left(\iint_{\mathrm{Q}} \frac{|U_\xi|^2}{(1+|U|)} d\xi dt\right)^{3/4}\left(\iint_{\mathrm{Q}} (1+|U|)^3\,d\xi dt\right)^{1/4} \le b.\end{aligned}$$

By the same token,

$$U(\xi,t)^2 = 2\int_{-1}^{\xi} \frac{UU_\xi(1+|U|)^{1/2}}{(1+|U|)^{1/2}}\,dy.$$

Hence,

$$\sup_{\xi\in\Omega}\int_0^T |U(\xi,t|^2\,dt \le \iint_{\mathrm{Q}}\left(|U|^2+|U|^3+\frac{|U_\xi|^2}{(1+|U|)}\right)d\xi dt \le b.$$

Lemma 3.4 is proved. □

Let us summarize the above estimates. From the above lemmas one may conclude that any solution satisfies the estimates

$$\begin{aligned}&b^{-1} \le P,\rho,v \le b, \quad \||U|^{1/2}\mathbf{c}_\xi\|_{2,2} \le b,\\ &\|\mathbf{c}\|_{\infty,2} \le b, \quad \|\mathbf{c}\|_{L^2(0,T;W^{1,2}(\Omega))} \le b,\\ &\|U\|_{L^\infty(0,T;L_M(\Omega))} \le b, \quad \|U\|_{3,3} \le b,\end{aligned} \tag{3.10}$$

$$\|U_\xi\|_{3/2,3/2} \le b, \quad \|U\|_{2,\infty} \le b, \tag{3.11}$$

where the constant b depends only on $\|\mathbf{c}_0\|_2$, $\underline{\rho}$, $\overline{\rho}$, and $\|\rho_{0\xi}\|_{L_M(\Omega)}$.

Finally, we remark that

$$0 \le c_i, \quad \sum_1^{m-1} c_j \le 1 \tag{3.12}$$

if the functions $\mathbf{c}$ is regular and the initial data $\mathbf{c}_0$ satisfy the same conditions. Estimates (3.12) are easily derived from the second equation in (2.8) by the maximum principle, and they imply that the functions c_i $(1 \le i \le m-1)$ stand for volume fractions.

Because of the estimates $b^{-1} \le \rho \le b$, one can conclude that estimates (3.10) and (3.11) remain valid in the Euler setting for the solutions $(P(x,t), \mathbf{c}(x,t))$ of problem (2.1)–(2.4) in the following sense:

$$\begin{aligned}
&b^{-1} \le P, \rho \le b, \quad \||U|^{1/2}\mathbf{c}_x\|_{2,2} \le b,\\
&\|\mathbf{c}\|_{\infty,2} \le b, \quad \|\mathbf{c}\|_{L^2(0,T;W^{1,2}(\Omega))} \le b,\\
&\|U\|_{L^\infty(0,T;L_M(\Omega))} \le b, \quad \|U\|_{3,3} \le b,\\
&\|U_x\|_{3/2,3/2} \le b, \quad \|U\|_{2,\infty} \le b,
\end{aligned}$$

where $U = -P_x$.

4. Approximate solutions. We study problem (2.8)–(2.10), applying the semi-Galerkin method. Given a smooth basis $(w_i)_{i\ge1}$ in $L^2(\Omega)$, we define an approximate solution $(P_n(\xi,t), \mathbf{c}_n(\xi,t))$ by the following scheme. We look for each component c_{in}, $(i = 1, \dots, m-1)$ of the concentration vector $\mathbf{c}_n$ in the form

$$c_{in}(\xi,t) = \sum_{j=1}^{n} \alpha_j^{in}(t) w_j(\xi), \quad \alpha_{in} = (\alpha_1^{in}, \dots, \alpha_n^{in}),$$

and we find $\mathbf{c}_n$, P_n, ρ_n, and U_n from the equations

$$\frac{d}{dt}\int_\Omega c_{in} w_j \, d\xi + \int_\Omega \rho_n^2 D_n c_{in\xi} w_{j\xi} \, d\xi = 0, \quad j = 1, 2, \dots, n, \tag{4.1}$$

$$c_{in}|_{t=0} = c_{in}^{(0)}(\xi) \equiv \sum_{j=1}^{n} \alpha_{0j}^{in} w_j(\xi), \tag{4.2}$$

$$D_n = \Phi(d_m + d_p|u_n|), \quad \rho_n = \kappa e^{\nu P_n + \nu g(1+\xi)/\Phi}, \quad u_n = -\Phi\lambda(\mathbf{c}_n)\rho_n P_{n\xi}, \tag{4.3}$$

$$\nu P_{nt} = \Phi\rho_n(\lambda(\mathbf{c}_n)\rho_n P_{n\xi})_\xi, \quad P_{n\xi}|_{|\xi|=1} = 0, \quad P_n|_{t=0} = \tilde{P}_0(\xi). \tag{4.4}$$

Here, $\mathbf{c}_n^{(0)} \to \tilde{\mathbf{c}}_0$ in $L^2(\Omega)$ as $n \to \infty$.

To simplify notation in this section, we omit the index n and we assume that the function c stands for any component c_i of $\mathbf{c}_n$ and that the vector $\alpha = (\alpha_1, \dots, \alpha_n)$ stands for $(\alpha_1^{in}, \dots, \alpha_n^{in})$.

First, we prove that the approximate solution $(P(\xi,t), \mathbf{c}(\xi,t))$ exists locally in time. To this end we consider the ball

$$B(T) = \left\{ \alpha(t) \in C([0,T]; \mathbb{R}^n) : \max_{0<t<T} |\alpha(t) - \alpha_0| \le 1 \right\}$$

in $C([0,T]; \mathbb{R}^n)$, and we introduce the operator

$$\mathcal{A} : B(T) \to C([0,T]; \mathbb{R}^n), \quad \mathcal{A}\hat{\alpha} = \alpha,$$

by the following scheme. Given $\hat{\alpha} \in B(T)$, we first solve the parabolic problem (4.4) for $\hat{P}$, with the components c_{in} of the vector $\mathbf{c}_n$ substituted by

$$\hat{c} = \sum_{j=1}^{n} \hat{\alpha}_j(t) w_j, \quad \hat{\lambda} := \lambda(\hat{\mathbf{c}}),$$

and with $\hat{\rho}$ given by the second formula in (4.3). Then we take $\hat{u} = -\Phi \hat{\lambda} \hat{\rho} \hat{P}_\xi$ and find α from the ODE which is (4.1) and (4.2) for $c = \sum_{j=1}^{n} \alpha_j(t) w_j$, with ρ and u substituted by $\hat{\rho}$ and $\hat{u}$.

We denote by $W_M^1(\Omega)$ the Sobolev–Orlicz space

$$W_M^1(\Omega) = \{f(x) : f \in L_M(\Omega), \quad \partial_x f \in L_M(\Omega)\}$$

associated with an admissible convex function $M : \mathbb{R} \to \mathbb{R}$.

The Hölder space $H^{2k+\beta, k+\beta/2}(\overline{Q})$ consists of continuous functions $f(x,t)$ such that $\partial^{2l} f(x,t)/\partial x^{2l}, \partial^l f(x,t)/\partial t^l \in C(\overline{Q})$, $0 \le l \le k$, and

$$\sup_{|x_i| \le 1,\, 0 \le t \le T} \frac{|\partial^{2k} f/\partial x^{2k}(x_1,t) - \partial^{2k} f/\partial x^{2k}(x_2,t)|}{|x_1 - x_2|^\beta} < \infty,$$

$$\sup_{0 \le t_i \le T,\, |x| \le 1} \frac{|\partial^k f/\partial t^k(x,t_1) - \partial^k f/\partial t^k(x,t_2)|}{|t_1 - t_2|^{\beta/2}} < \infty.$$

For more details on the above spaces we refer the reader to [13].

To justify the scheme (4.1)–(4.4), we prove the following.

LEMMA 4.1. *Assume that*

$$\lambda_0 \le \hat{\lambda} \le \lambda_0^{-1}, \quad \hat{\lambda}_\xi \in L^2(0,T; W_0^{1,2}(\Omega)), \quad \tilde{P}_0 \in W_M^1(\Omega), \tag{4.5}$$

where $W_0^{1,2}(\Omega)$ is the closure of $\mathcal{D}(\Omega)$ in $W^{1,2}(\Omega)$ and the function M is given by (3.4). *Then, the problem*

$$\begin{aligned} &\nu P_t = \Phi \rho (\hat{\lambda} \rho P_\xi)_\xi, \quad \rho = \kappa e^{\nu P + \nu g(1+\xi)/\Phi}, \\ &P_\xi|_{|\xi|=1} = 0, \quad P|_{t=0} = \tilde{P}_0(\xi), \end{aligned} \tag{4.6}$$

has a unique solution with the properties

$$\underline{P} \le P \le \overline{P}, \quad P_\xi \in L^\infty(0,T; L_M(\Omega)) \cap L^3(Q), \quad P_{\xi\xi}, P_t \in L^{3/2}(Q).$$

Moreover,

$$\|P_{\xi\xi}, P_t\|_{3/2,3/2} + \|P_\xi\|_{L^\infty(0,T;L_M(\Omega))} + \|P_\xi\|_{3,3} \le b,$$

where the constant b depends only on $\lambda_0, \underline{P}, \overline{P}$ and on the norms $\|\tilde{P}_0\|_{W_M^1(\Omega)}$ and $\|\hat{\lambda}_\xi\|_{L^2(0,T;W_0^{1,2}(\Omega))}$.

Proof. Let (λ_δ) be a sequence of functions from the set

$$\begin{aligned} &\lambda_0 \le \lambda \le \lambda_0^{-1}; \quad \lambda, \lambda_\xi, \lambda_t, \lambda_{t\xi} \in C(\overline{Q}); \\ &\lambda_\xi|_{|\xi|=1} = 0, \quad \lambda, \lambda_\xi \in H^{1+\beta,(1+\beta)/2}(\overline{Q}) \quad (0 < \beta < 1), \end{aligned} \tag{4.7}$$

and such that

$$\lambda_\delta \to \hat{\lambda} \text{ in } L^2(0,T;W^{2,2}(\Omega)) \text{ as } \delta \to 0.$$

Let $P_{\delta 0}(\xi)$ be a sequence from $H^{3+\beta}(\Omega)$ such that

$$P_{\delta 0} \to \tilde{P}_0 \text{ in } W^1_M(\Omega) \text{ as } \delta \to 0.$$

We also assume that the compatibility conditions

$$\frac{\partial}{\partial \xi}\left(\rho_{\delta 0}\frac{\partial}{\partial \xi}\left(\lambda_{\delta 0}\rho_{\delta 0}\frac{\partial}{\partial \xi}P_{\delta 0}\right)\right)|_{|\xi|=1} = 0 \tag{4.8}$$

are fulfilled.

Let us consider problem $(4.6)_\delta$, which is (4.6) with λ and $\tilde{P}_0$ substituted by λ_δ and $P_{\delta 0}$, respectively. By Theorem 7.4 of [13, Chapter V], there is a unique solution $P_\delta \in H^{3+\beta,(3+\beta)/2}(\overline{Q})$ of $(4.6)_\delta$. By the arguments applied in Lemmas 3.1 and 3.2, one obtains the estimates

$$\underline{P} \le P_\delta \le \overline{P}, \quad \underline{\rho} \le \rho_\delta \le \overline{\rho}, \quad \sup_{t\ge 0}\int_\Omega |P_{\delta\xi}|\,d\xi \le \int_\Omega |P_{\delta 0\xi}|\,d\xi.$$

It follows from Lemma 3.4 (see equality (3.6)) that the function $U_\delta = -\Phi\rho_\delta P_{\delta\xi}$ satisfies the equality

$$\begin{aligned}&\frac{d}{dt}\int_\Omega v_\delta M(U_\delta)\,d\xi + \int_\Omega \Phi\nu^{-1}\rho_\delta\lambda_\delta U^2_{\delta\xi}M''(U_\delta)\,d\xi\\ &= \int_\Omega \Phi\nu^{-1}\rho_\delta\lambda_{\delta\xi}U_\delta U_{\delta\xi}M''(U_\delta)\,d\xi + \int_\Omega (\lambda_\delta U_\delta)^2 U_{\delta\xi}M''(U_\delta)\,d\xi.\end{aligned} \tag{4.9}$$

We denote

$$J^\delta_1 = \int_\Omega \Phi\nu^{-1}\rho_\delta\lambda_\delta U^2_{\delta\xi}M''(U_\delta)\,d\xi, \quad J^\delta_2 = \int_\Omega \Phi\nu^{-1}\rho_\delta\lambda_{\delta\xi}U_\delta U_{\delta\xi}M''(U_\delta)\,d\xi,$$
$$J^\delta_3 = \int_\Omega (\lambda_\delta U_\delta)^2 U_{\delta\xi}M''(U_\delta).$$

We have

$$|J^\delta_2| \le J^\delta_1/2 + b_1\int_\Omega \lambda^2_{\delta\xi}|U_\delta|d\xi,$$

$$|J^\delta_3| \le \eta\int_\Omega |U_\delta|^3 d\xi + b_{1\eta}\int_\Omega |U_\delta||\lambda^2_{\delta\xi}\,d\xi \text{ for any } \eta > 0.$$

Observe that

$$\int_\Omega \lambda^2_{\delta\xi}|U_\delta|d\xi \le 2\int_\Omega \lambda^2_{\delta\xi\xi}d\xi\int_\Omega |U_\delta|d\xi.$$

Then, as in the proof of Lemma 3.4, we obtain

$$\|P_{\delta\xi}\|_{L^\infty(0,T;L_M(\Omega))} + \|P_{_\delta\xi\xi}\|_{3/2,3/2} + \|P_{_\delta\xi}\|_{3,3} + \|P_{_\delta\xi}\|_{2,\infty} \le b, \tag{4.10}$$

uniformly in δ.

Observe also that

$$\int_\Omega |\lambda_\xi|^3 d\xi \le 2 \int_\Omega |\lambda_\xi| d\xi \int_\Omega |\lambda_{\xi\xi}|^2 d\xi, \tag{4.11}$$

for any function $\lambda(\xi)$ such that $\lambda_\xi|_{|\xi|=1} = 0$. Hence, it follows from $(4.6)_\delta$ that the time derivative $P_{\delta t}$ satisfies the estimate

$$\|P_{\delta t}\|_{3/2,3/2} \le b,$$

uniformly in δ.

By the compact imbedding of $W^{1,3/2}(Q)$ into $L^{3/2}(Q)$, there is a subsequence (P_{δ_k}) and a function $P \in W^{1,3/2}(Q)$ such that $P_{\delta_k} \to P$ in $L^{3/2}(Q)$. Since P_{δ_k} is bounded in $L^\infty(Q)$, $P_{\delta_k} \to P$ in $L^q(Q)$ for any $1 \le q < \infty$, by interpolation. Clearly, $\rho_{\delta_k} \to \rho$ in $L^q(Q)$ as well.

Let us consider the function $V_\delta := v_{\delta\xi}$ which solves (see (2.11)) the equation

$$V_{\delta t} = \Phi\nu^{-1}(\rho_\delta^2 \lambda_\delta V_\delta)_{\xi\xi} + (\rho_\delta g \lambda_\delta)_{\xi\xi}.$$

From the above estimates it follows that

$$\|V_\delta\|_{L^{3/2}(0,T;W^{1,3/2}(\Omega))} + \|V_{\delta t}\|_{L^3(0,T;W^{-2,3}(\Omega))} \le b.$$

Hence, by the Aubin–Lions compactness theorem [14] one may assume that $P_{\delta_k\xi} \to P_\xi$ in $L^{3/2}(Q)$. Moreover, by estimates (4.10) and interpolation, $P_{\delta_k\xi} \to P_\xi$, $\rho_{\delta_k\xi} \to \rho_\xi$ in $L^q(Q)$, for any $1 \le q < 3$.

Let us show that the limit function P solves problem (4.6). Equation $(4.6)_\delta$ is written as

$$\nu P_{\delta t} = \Phi\rho_\delta\Big(\lambda_{\delta\xi}\rho_\delta P_{\delta\xi} + \lambda_\delta \rho_{\delta\xi} P_{\delta\xi} + \lambda_\delta \rho_\delta P_{\delta\xi\xi}\Big). \tag{4.12}$$

We claim that each term converges in $\mathcal{D}'(Q)$. Let us consider the last term. Denote for simplicity $P_\delta = P_{\delta_k}$. We write the decomposition equality

$$\lambda_\delta \rho_\delta^2 P_{\delta\xi\xi} = \lambda\rho^2 P_{\delta\xi\xi} + (\rho_\delta - \rho)(\rho_\delta + \rho)\lambda_\delta P_{\delta\xi\xi} + \rho^2(\lambda_\delta - \lambda)P_{\delta\xi\xi} \equiv \sum_{i=1}^3 J_i^\delta.$$

By (4.10), $P_{\delta\xi\xi} \to P_{\xi\xi}$ weakly in $L^{3/2}(Q)$. On the other hand, due to (4.11), $\lambda_{\delta\xi} \to \lambda_\xi$ in $L^3(Q)$. Hence,

$$\int_Q J_1^\delta \varphi \, d\xi \to \int_Q \lambda\rho^2 P_{\xi\xi}\varphi \, d\xi, \quad \int_Q J_2^\delta \varphi \, d\xi \to 0, \quad \int_Q J_3^\delta \varphi \, d\xi \to 0$$

for any $\varphi \in \mathcal{D}(Q)$.

One can study the convergence of the other terms of (4.12) similarly. Thus, the limit function P solves problem (4.6). Observe that equality (4.6) is valid also as equality of functions in $L^{3/2}(Q)$; hence the function v ($v = 1/\rho$) calculated via formula $(4.6)_2$ solves (2.11) in the same sense.

Let us prove uniqueness. Given two solutions v_1 and v_2 of equation (2.11), with the boundary conditions $v_{i\xi}|_{|\xi|=1} = 0$, we denote $v = v_1 - v_2$, $\rho = \rho_1 - \rho_2$. The function v solves the parabolic problem

$$v_t = \Phi\nu^{-1}(\rho_1^2 \hat\lambda v_\xi)_\xi + \Phi\nu^{-1}(\hat\lambda v_{2\xi}\rho(\rho_1 + \rho_2))_\xi + (g\hat\lambda\rho)_\xi, \; v_\xi|_{|\xi|=1} = 0, \; v|_{t=0} = 0.$$

We multiply this equation by the function $M_1'(v) = v/(v^2+\delta^2)^{1/2}$, a smooth approximation of $\operatorname{sign}(v)$, and integrate the result over $\Omega \times (0,t)$. It follows that

$$\begin{aligned}\int_\Omega M_1(v(t))d\xi + \underbrace{\Phi\nu^{-1}\int_0^t\int_\Omega M_1''(v)\rho_1^2\hat\lambda v_\xi^2\,d\xi d\tau}\\ = -\int_0^t\int_\Omega M_1''(v)\rho\hat\lambda v_\xi\Big(\Phi\nu^{-1}v_{2\xi}(\rho_1+\rho_2)+g\Big)\,d\xi d\tau\\ \le \underbrace{\cdots}/2 + b\int_0^t\int_\Omega M_1''(v)\rho^2(1+v_{2\xi}^2)\,d\xi d\tau.\end{aligned}$$

Observe that $0 \le M_1''(v)v^2 \le \delta$, $v_{2\xi}^2 \in L^{3/2}(Q)$, $\rho = -\rho_1\rho_2 v$. Hence, in the limit $\delta \to 0$ we obtain that $\int_\Omega |v(t)|\,d\xi \le 0$. Lemma 4.1 is proved. □

By the previous lemma, the operator $\mathcal{A}$, defined by the right-hand side of the equality

$$\alpha_j = \alpha_{0j} + (M^{-1})_{ij}\int_0^t\int_\Omega \hat\rho^2\hat D\hat c_\xi w_{i\xi}d\xi d\tau \equiv (\mathcal{A}\hat\alpha)_j, \quad M_{ij} = \int_\Omega w_i w_j d\xi$$

is well defined. Moreover, it is compact since it maps $B(T)$ on a bounded set of $W^1(0,T)$. Observe that all the norms in the n-dimensional space spanned by the basis function w_j, $j = 1,\dots,n$, are equivalent. Clearly, $\mathcal{A}$ maps $B(T_n)$ into itself provided T_n is small enough. Consequently, one can use the Schauder theorem to conclude that there exists at least one fixed point α. Thus, problem (4.1)–(4.4) has a local solution.

Now, this procedure can be iterated as many times as necessary to reach $T_n = T$ as long as there is a bound on α independent of T_n. The existence of such a bound follows from the equality

$$\frac{d}{dt}\int_\Omega c_{in}^2 d\xi + \int_\Omega \rho_n^2 D_n c_{in\xi}^2 d\xi = 0,$$

which is valid for any fixed point α. Indeed, by integration we have

$$\sup_{t\ge0}\int_\Omega c_{in}^2(t)d\xi + \int_0^t\int_\Omega \rho_n^2 D_n c_{in\xi}^2 d\xi \le \limsup_{n\to\infty}\int_\Omega |c_{in}^{(0)}(\xi)|^2 d\xi.$$

Hence, an approximate solution defined by (4.1)–(4.4) exists globally.

Let us show that the regularity of $P_n(\xi,t)$ can be improved provided that the initial datum $\tilde P_0(\xi)$ is more regular than in Lemma 4.1.

LEMMA 4.2. *Assume that $\tilde P_0(\xi)$ belongs to $W^{2,2}(\Omega)$. Then*

$$P_n \in L^\infty(0,T;W^{2,2}(\Omega)) \cap L^2(0,T;W^{3,2}(\Omega)), \quad \frac{\partial^2 P_n}{\partial t\partial\xi} \in L^2(Q).$$

Moreover, the functions $U_n = -\Phi\rho_n P_{n\xi}$ and $V_n = v_{n\xi}$ solve the parabolic problems

$$\begin{aligned}&U_{nt} + \rho_n U_n(\lambda(\mathbf{c}_n)U_n)_\xi = \Phi\nu^{-1}\rho_n(\,\rho_n(\lambda(\mathbf{c}_n)U_n)_\xi\,)_\xi,\\ &U_n|_{|\xi|=1} = 0, \quad U_n|_{t=0} = -\Phi\tilde\rho_0(\xi)\tilde P_0(\xi),\end{aligned} \tag{4.13}$$

and

$$\begin{aligned}&V_{nt} = \Phi\nu^{-1}(\rho_n^2\lambda(\mathbf{c}_n)V_n)_{\xi\xi} + (\rho_n g\lambda(\mathbf{c}_n))_{\xi\xi}.\\ &V_n|_{|\xi|=1} = 0, \quad V_n|_{t=0} = \tilde v_{0\xi}(\xi).\end{aligned} \tag{4.14}$$

The differential equations (4.13) *and* (4.14) *hold as equalities of functions from* $L^2(Q)$.

Proof. Let (λ_δ) be a sequence satisfying conditions (4.7) and such that

$$\lambda_\delta \to \lambda(\mathbf{c}_n) \text{ in } W^1(0,T;C^2(\overline{\Omega})) \text{ as } \delta \to 0.$$

Let $P_{\delta 0}(\xi)$ be a sequence from $H^{3+\beta}(\Omega)$ such that

$$P_{\delta 0} \to \tilde{P}_0 \text{ in } W^{2,2}(\Omega) \text{ as } \delta \to 0.$$

Assume that the compatibility conditions (4.8) are fulfilled. We consider the parabolic problem $(4.4)_\delta$, which is problem (4.4) with $\lambda(\mathbf{c}_n)$ and $\tilde{P}_0$ substituted by λ_δ and $P_{\delta 0}$, respectively. By Theorem 7.4 of [13, Chapter V], there is a unique solution $P_\delta \in H^{3+\beta,(3+\beta)/2}(\overline{Q})$ of $(4.4)_\delta$.

The function $U_\delta = -\Phi\rho_\delta P_{\delta\xi}$ solves the parabolic equation

$$U_{\delta t} + \rho_\delta U_\delta(\lambda_\delta U_\delta)_\xi = \Phi\nu^{-1}\rho_\delta(\rho_\delta(\lambda_\delta U_\delta)_\xi)_\xi. \tag{4.15}$$

Due to the choice of λ_δ, one can obtain, by the same arguments as in Lemma 4.1, the following estimates:

$$\underline{\rho} \le \rho_\delta \le \overline{\rho}, \quad \|P_{\delta t}\|_{3/2,3/2} \le b, \tag{4.16}$$

$$\|U_\delta\|_{L^\infty(0,T;L_M(\Omega))} + \|U_{\delta\xi}\|_{3/2,3/2} + \|U_\delta\|_{3,3} + \|U_\delta\|_{2,\infty} \le b \tag{4.17}$$

uniformly in δ.

The function $V_\delta := v_{\delta\xi}$ solves the equation

$$V_{\delta t} = \Phi\nu^{-1}(\rho_\delta^2\lambda_\delta V_\delta)_{\xi\xi} + (\rho_\delta g\lambda_\delta)_{\xi\xi}. \tag{4.18}$$

We multiply it by V_δ^3 and integrate the result over Ω to obtain

$$\frac{1}{4}\frac{d}{dt}\int_\Omega V_\delta^4\,d\xi + \overbrace{3\Phi\nu^{-1}\int_\Omega \rho_\delta^2\lambda_\delta V_\delta^2 V_{\delta\xi}^2\,d\xi}^{\ddots} = 6\Phi\nu^{-1}\int_\Omega \rho_\delta^3\lambda_\delta V_\delta^4 V_{\delta\xi}\,d\xi$$
$$+ 3\int_\Omega \rho_\delta^2 V_\delta^3 V_{\delta\xi}(g\lambda_\delta - \Phi\nu^{-1}\lambda_{\delta\xi})\,d\xi - 3g\int_\Omega \rho_\delta\lambda_{\delta\xi}V_\delta^2 V_{\delta\xi}\,d\xi \equiv \sum_{i=1}^3 J_i.$$

We estimate

$$J_1 + J_2 \le \overbrace{\cdots}/4 + b_1(\|U_\delta\|_\infty^2 + 1)\int_\Omega V_\delta^4\,d\xi, \quad J_3 \le \overbrace{\cdots}/4 + b_2\|U_\delta\|_2^2.$$

Due to estimates (4.17), one concludes that

$$\frac{d}{dt}\int_\Omega V_\delta^4\,d\xi \le f_1(t)\int_\Omega V_\delta^4\,d\xi + f_2(t),$$

with the functions f_i bounded in $L^1(0,T)$ uniformly in δ. By Gronwall's lemma it follows that

$$\|V_\delta, U_\delta\|_{\infty,4} \le b, \quad \|V_\delta V_{\delta\xi}, U_\delta U_{\delta\xi}\|_{2,2} \le b \tag{4.19}$$

uniformly in δ. Observe that some constants b in this proof may depend on n.

With such estimates at hand, we multiply (4.15) by $U_{\delta\xi\xi}$ and integrate the result over Ω to obtain

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_\Omega U_{\delta\xi}^2 d\xi + \underbrace{\Phi\nu^{-1}\int_\Omega \rho_\delta^2\lambda_\delta U_{\delta\xi\xi}^2 d\xi}\\
&= -\int_\Omega \rho_\delta U_{\delta\xi}U_{\delta\xi\xi}\Big([\Phi\nu^{-1}(\rho_\delta\lambda_\delta)_\xi + \lambda_\delta U_\delta] + [\Phi\nu^{-1}(\rho_{\delta\xi}\lambda_{\delta\xi} + \rho_\delta\lambda_{\delta\xi\xi}) + \lambda_{\delta\xi}U_\delta]\Big)d\xi\\
&\le \underbrace{\cdots}/2 + b\int_\Omega (1 + U_\delta^4 + U_{\delta\xi}^2U_\delta^2)\,d\xi.
\end{aligned}$$

Hence,

$$\|U_{\delta\xi}, V_{\delta\xi}\|_{\infty,2} \le b, \quad \|U_{\delta\xi\xi}, V_{\delta\xi\xi}, U_{\delta t}, V_{\delta t}\|_{2,2} \le b \tag{4.20}$$

uniformly in δ.

Due to estimates (4.16), (4.17), (4.19), and (4.20), and the uniqueness of solutions of problem (4.4), one can prove by the arguments of Lemma 4.1 that $P_\delta \to P_n$ in the same sense as in Lemma 4.1. Moreover,

$$U_{\delta\xi} \to U_{n\xi}, \quad U_{\delta\xi\xi} \to U_{n\xi\xi}, \quad U_{\delta t} \to U_{nt} \text{ weakly in } L^2(Q),$$

and

$$U_\delta \to U_n \text{ strongly in } L^q(Q) \text{ for any } 1 \le q < 4.$$

The similar convergences are valid for the sequence V_δ:

$$V_{\delta\xi} \to V_{n\xi}, \quad V_{\delta\xi\xi} \to V_{n\xi\xi}, \quad V_{\delta t} \to V_{nt} \text{ weakly in } L^2(Q),$$

and

$$V_\delta \to V_n \text{ strongly in } L^q(Q) \text{ for any } 1 \le q < 4.$$

The above claims of convergence enable us to pass to the limit, as $\delta \to 0$, in (4.15) and (4.18). Lemma 4.2 is proved. □

Consequence. It follows easily from the above lemma that the function $z_n = P_{n\xi}$ solves the equation

$$\nu z_{nt} = (\Phi\rho_n(\lambda(\mathbf{c}_n)\rho_n z_n)_\xi)_\xi \tag{4.21}$$

in $L^2(Q)$.

5. Global solvability. We argue by a compactness method. To this end we use estimates independent of n for the approximate solutions $(P_n, \mathbf{c}_n)$, defined by (4.1)–(4.4). It is an advantage of the semi-Galerkin method that all the a priori estimates obtained in section 3 are also valid for $(P_n, \mathbf{c}_n)$:

$$b^{-1} \le P_n, \rho_n \le b, \quad \||u_n|^{1/2}\mathbf{c}_{n\xi}\|_{2,2} \le b,$$

$$\|\mathbf{c}_n\|_{\infty,2} \le b, \quad \|\mathbf{c}_n\|_{L^2(0,T;W^{1,2}(\Omega))} \le b, \tag{5.1}$$

$$\|P_{n\xi}\|_{L^\infty(0,T;L_M(\Omega))} \le b, \quad \|P_{n\xi}\|_{3,3} \le b,$$

$$\|P_{n\xi}\|_{2,\infty} \le b, \quad \|P_{n\xi\xi}, P_{nt}\|_{3/2,3/2} \le b, \tag{5.2}$$

uniformly in n. By the Young inequality, one can derive from (5.1), (5.2) that

$$\|D_n \mathbf{c}_{n\xi}\|_{3/2,3/2} \le b,$$

uniformly in n. It follows from (4.21) that

$$\left\| \frac{\partial}{\partial t} P_{n\xi} \right\|_{L^{3/2}(0,T;\, W^{-1,3/2}(\Omega))} \le b, \tag{5.3}$$

uniformly in n.

To derive the estimate

$$\|\mathbf{c}_{nt}\|_{L^{3/2}(0,T;\,(W^{2,2}(\Omega))^*)} \le b, \tag{5.4}$$

we choose the basis $(w_j)_{j\ge 1}$, defined as

$$w_{j\xi\xi} = -\lambda_j w_j, \quad w_{j\xi}|_{|\xi|=1} = 0.$$

Clearly, $w_j = \cos(\pi(j-1)\xi)$ and $\lambda_j = \pi^2(j-1)^2$.

Denote by $\mathcal{P}_n$ the projection of $L^2(\Omega)$ onto X_n, the subspace of $L^2(\Omega)$, spanned by $w_1, \dots, w_n$. Observe that

$$\|(\mathcal{P}_n w)_{\xi\xi}\|_2^2 = \sum_{j=1}^{n} \lambda_j^2 \beta_j^2 \le \sum_{j=1}^{\infty} \lambda_j^2 \beta_j^2 = \|w_{\xi\xi}\|_2^2, \quad w = \sum_{j=1}^{\infty} \beta_j w_j,$$

and the norm of w in $W^{2,2}(\Omega)$ is equivalent to $(\|w\|_2^2 + \|w_{\xi\xi}\|_2^2)^{1/2}$.

One can write equality (4.1) as

$$\frac{d}{dt} \int_\Omega c_{in}(\mathcal{P}_n w)\, d\xi + \int_\Omega \rho_n^2 D_n c_{in\xi} (\mathcal{P}_n w)_\xi \, d\xi = 0 \quad \forall w \in W^{2,2}(\Omega).$$

Now it follows that

$$|\langle \mathbf{c}_{nt}, w\rangle| \le \overline{\rho}^2 \|D_n \mathbf{c}_{n\xi}\|_{3/2} \|(\mathcal{P}_n w)_\xi\|_3.$$

Observe that

$$\|(\mathcal{P}_n w)_\xi\|_3 \le b_1 \|(\mathcal{P}_n w)_\xi\|_{W^{1,2}(\Omega)} \le b_2 \|\mathcal{P}_n w\|_{W^{2,2}(\Omega)} \le b_3 (\|\mathcal{P}_n w\|_2^2 + \|(\mathcal{P}_n w)_{\xi\xi}\|_2^2)^{1/2}$$

$$\le b_3 (\|w\|_2^2 + \|w_{\xi\xi}\|_2^2)^{1/2} \le b_4 \|w\|_{W^{2,2}(\Omega)}.$$

Hence,

$$\|\mathbf{c}_{nt}(t)\|_{(W^{2,2}(\Omega))^*} \le b \|D_n(t) \mathbf{c}_{n\xi}(t)\|_{3/2}.$$

Thus, estimate (5.4) is established.

THEOREM 5.1. *Assume that $\tilde{P}_0 \in W^{2,2}(\Omega)$, $\tilde{\mathbf{c}}_0 \in L^2(\Omega)$, and function $\lambda(\mathbf{c})$ satisfies restrictions* (1.14). *Then, problem* (2.8)–(2.10) *has a solution $(P(\xi,t), \mathbf{c}(\xi,\mathbf{t}))$ with the properties*

$$\underline{\rho} \le \rho \le \overline{\rho},\ P_t \in L^{3/2}(Q),$$
$$P \in L^\infty(0,T; W_M^1(\Omega)) \cap L^{3/2}(0,T; W^{2,3/2}(\Omega)) \cap L^2(0,T; W^{1,\infty}(\Omega))$$
$$\cap\ L^3(0,T; W^{1,3}(\Omega)) \cap L^\infty(Q), \quad \mathbf{c} \in L^\infty(0,T; L^2(\Omega)) \cap L^2(0,T;\, W^{1,2}(\Omega)),$$

where the function M is given by (3.4). *The first equation in* (2.8) *holds as an equality of functions in* $L^{3/2}(Q)$. *The second equation in* (2.8) *holds weakly:*

$$\iint_{\mathrm{Q}} \left(\mathbf{c}\Psi_t - \Phi\rho^2 D\mathbf{c}_\xi \Psi_\xi\right) d\xi dt = -\int_\Omega \tilde{\mathbf{c}}_0 \Psi(\xi,0) d\xi \tag{5.5}$$

for any $\Psi \in C^1(\bar{Q})$ *such that* $\Psi(\xi,T)=0$.

Proof. The uniform bounds $(5.1)_4$ and (5.4) imply by the Aubin–Lions theorem that there are a subsequence, still denoted $(\mathbf{c})_n$, and a function $\mathbf{c}$, such that $\mathbf{c}_n \to \mathbf{c}$ a.e. in Q, and $\mathbf{c}_n \to \mathbf{c}$ strongly in $L^2(Q)$ and weakly in $L^2(0,T;W^{1,2}(\Omega))$. Hence $\lambda(\mathbf{c}_n) \to \lambda(\mathbf{c})$ a.e. in Q and strongly in $L^q(Q)$ for any $q \in [1,\infty)$.

The uniform bound $\|P_n\|_{W^{1,3/2}(Q)} \le b$ and the compact imbedding of $W^{1,3/2}(Q)$ into $L^{3/2}(Q)$ imply that, up to a subsequence, there is a function $P \in W^{1,3/2}(Q)$ such that $P_n \to P$, $\rho_n \to \rho$ strongly in $L^q(Q)$, for any $q \in [1,3/2)$. Since $\underline{P} \le P \le \overline{P}$, one can also obtain by an interpolation argument that $P_n \to P$, $\rho_n \to \rho$ strongly in $L^q(Q)$ for any $q \in [1,\infty)$.

It follows from (5.2) that

$$P_{n\xi\xi} \to P_{\xi\xi}, \quad P_{nt} \to P_t, \text{ weakly in } L^{3/2}(Q).$$

Due to estimates (5.3) and $(5.2)_4$, one concludes that $P_{n\xi} \to P_\xi$ in $L^{3/2}(Q)$. Since $\|P_{n\xi}\|_{3,3} \le b$, one has by interpolation that $P_{n\xi} \to P_\xi$ in $L^q(Q)$, for any $q \in [1,3)$.

As for the function $u_n = -\Phi\rho_n\lambda(\mathbf{c}_n)P_{n\xi}$, one has by the above token that $u_n \to u$ in $L^q(Q)$, for any $q \in [1,3)$. Hence, $|u_n|\,\mathbf{c}_{n\xi} \to |u|\,\mathbf{c}_\xi$ in $\mathcal{D}'(Q)$.

The convergences described above enable us to pass to the limit, as $n \to \infty$, in (4.1)–(4.4). The proof of Theorem 5.1 is complete. ∎

The next result concerns the problem in the Euler setting.

THEOREM 5.2. *Assume that* $P_0 \in W^{2,2}(\Omega)$, $\mathbf{c}_0 \in L^2(\Omega)$, *and the function* $\lambda(\mathbf{c})$ *satisfies restrictions* (1.14). *Then, problem* (2.1)–(2.4) *has a solution* $(P(x,t),\mathbf{c}(x,t))$ *with the properties*

$$\begin{aligned}
&\underline{\rho} \le \rho \le \overline{\rho}, P_t \in L^{3/2}(Q),\\
&P \in L^\infty(0,T;W^1_M(\Omega)) \cap L^{3/2}(0,T;W^{2,3/2}(\Omega)) \cap L^2(0,T;W^{1,\infty}(\Omega))\\
&\quad \cap\, L^3(0,T;W^{1,3}(\Omega)) \cap L^\infty(Q), \quad \mathbf{c} \in L^\infty(0,T;L^2(\Omega)) \cap L^2(0,T;W^{1,2}(\Omega)),
\end{aligned}$$

where the function M is given by (3.4). *Equation* (2.1) *holds as an equality of functions from* $L^{3/2}(Q)$. *Equation* (2.2) *holds weakly:*

$$\iint_{\mathrm{Q}} \rho\mathbf{c}(\Phi\psi_t + u\psi_x) - \rho D\mathbf{c}_x\psi_x \, dxdt = -\int_\Omega \Phi\rho_0(x)\mathbf{c}_0(x)\psi(x,0)dx, \tag{5.6}$$

for any $\psi \in C^1(\bar{Q})$ *such that* $\psi(x,T)=0$.

Proof. Let $(\tilde{P}(\xi,t),\tilde{\mathbf{c}}(\xi,t))$ be a solution in the Lagrange setting given by Theorem 5.1. The function $\tilde{\rho}(\xi,t)$ enables us to define the Euler variables by the formulae

$$x(\xi,t) = \Phi^{-1}\int_{-1}^{\xi} \tilde{v}(y,t)dy - 1, \quad x_\xi = \Phi^{-1}\tilde{v}, \quad x_t = \Phi^{-1}\tilde{u}.$$

Clearly,

$$x \in C(\bar{Q}) \cap L^2(0,T;W^{2,3/2}(\Omega)), \quad x_t \in L^3(Q) \cap L^{3/2}(0,T;W^{1,3/2}(\Omega)).$$

The inverse function $\xi(x,t)$ enjoys the same regularity as a function of the variables x and t.

One can verify that the functions

$$P(x,t) = \tilde{P}(\xi,t)|_{\xi=\xi(x,t)}, \quad \mathbf{c}(x,t) = \tilde{\mathbf{c}}(\xi,t)|_{\xi=\xi(x,t)}$$

solve the equations

$$\Phi P_t + uP_x = \left(\frac{\lambda(\mathbf{c})}{\nu} P_x\right) x, \quad u = -\lambda(\mathbf{c})P_x$$

a.e. in Q.

Let us verify that the functions $P(x,t)$ and $\mathbf{c}(x,t)$ solve (5.6). First, we observe that, by a continuity argument, the functions $\tilde{P}(\xi,t)$ and $\tilde{\mathbf{c}}(\xi,t)$ satisfy (5.5) for all $\Psi \in L^2(Q)$ such that $\Psi_t \in L^2(Q)$, $\Psi_\xi \in L^3(Q)$, and $\Psi(\xi,T) = 0$. Observe that because of the inclusion $\Psi_t \in L^2(Q)$, the function Ψ belongs to $C([0,T];L^2(\Omega))$ and Ψ has traces at $t = \text{const}$.

Given an arbitrary function $\psi(x,t)$ such that $\psi \in C^1(\bar{Q})$, $\psi(x,T) = 0$, let us consider the sum of integrals

$$J = \iint_{\mathrm{Q}} \Big(\rho\mathbf{c}(\Phi\psi_t + u\psi_x) - \rho D\mathbf{c}_x\psi_x\Big)\, dxdt + \int_\Omega \mathbf{c}_0(x)\psi(x,0)\, dx.$$

Denoting $\Psi(\xi,t) = \psi(x,t)|_{x=x(\xi,t)}$, and making the change of variables $(x,t) \to (\xi,t)$, we have

$$J = \iint_{\mathrm{Q}} \Big(\tilde{\mathbf{c}}\Psi_t - \Phi\tilde{\rho}^2\tilde{D}\tilde{\mathbf{c}}_\xi\Psi_\xi\Big)\, d\xi dt + \int_\Omega \tilde{\mathbf{c}}_0\Psi(\xi,0)\, d\xi,$$

where

$$\Psi_t = \Phi^{-1}\psi_x(x(\xi,t),t)\tilde{u}(\xi,t) + \psi_t(x(\xi,t),t) \in L^2(Q),$$

$$\Psi_\xi = \Phi^{-1}\psi_x(x(\xi,t),t)\tilde{v}(\xi,t) \in L^3(Q),$$

and $\Psi(\xi,0) = \psi(x(\xi,0),0) \in L^2(\Omega)$. Clearly, Ψ belongs to $C([0,T];L^2(\Omega))$. Thus, $J = 0$ and the theorem is proved. □

A LOSING ESTIMATE FOR THE IDEAL MHD EQUATIONS WITH APPLICATION TO BLOW-UP CRITERION*

MARCO CANNONE†, QIONGLEI CHEN‡, AND CHANGXING MIAO‡

Abstract. In this paper we study the blow-up criterion of smooth solution to the ideal MHD equations in $\mathbb{R}^n$. By means of the Fourier frequency localization and Bony paraproduct decomposition, we show a losing estimate for the ideal MHD equations and apply it to establish an improved blow-up criterion of smooth solutions. As a special case, we recover a previous result of Planchon for the incompressible Euler equations.

Key words. ideal MHD equations, blow-up, Littlewood–Paley decomposition, Besov space

AMS subject classifications. 76W05, 35B65

DOI. 10.1137/060652002

1. Introduction.

We are concerned with the blow-up phenomena of smooth solutions to the ideal MHD equations in $\mathbb{R}^n$:

$$\text{(IMHD)}\quad \begin{cases} u_t + u\cdot\nabla u = -\nabla p - \frac{1}{2}\nabla b^2 + b\cdot\nabla b, \\ b_t + u\cdot\nabla b = b\cdot\nabla u, \\ \nabla\cdot u = \nabla\cdot b = 0, \\ u(0,x) = u_0(x), \quad b(0,x) = b_0(x), \end{cases} \tag{1.1}$$

where $x\in\mathbb{R}^n, t\geq 0$, u, b describes the flow velocity vector and the magnetic field vector, respectively, p is a scalar pressure, while u_0 and b_0 are the given initial velocity and initial magnetic field with $\nabla\cdot u_0 = \nabla\cdot b_0 = 0$, $b^2 = |b|^2$.

By the standard energy method [12], it is known that for $(u_0, b_0)\in H^s(\mathbb{R}^3)$, $s\geq 3$, there exists $T>0$ such that the Cauchy problem (1.1) has a unique smooth solution $(u(t,x), b(t,x))$ on $[0,T)$ satisfying

$$(u,b)\in C([0,T); H^s)\cap C^1([0,T); H^{s-1}).$$

However, in contrast to the Euler equation (when $b=0$), the global existence of smooth solutions to the inviscid MHD equations is not known even in two dimensions. Later on, Caflisch, Klapper and Steele [3] extended the well-known result of Beale–Kato–Majda [2] for the incompressible Euler equations to the three dimensional IMHD equations. They showed precisely that if the smooth solution (u,b) satisfies the condition

$$\int_0^T \|\nabla\times u\|_{L^\infty} + \|\nabla\times b\|_{L^\infty} dt < \infty, \tag{1.2}$$

then the solution (u,b) can be extended beyond $t=T$, namely, for some $T<\tilde{T}$, $(u,b)\in C([0,\tilde{T});H^s)\cap C^1([0,\tilde{T});H^{s-1})$. In other words, let $[0,T)$ be the maximal time interval to the smooth solution (u,b) for (IMHD); then (u,b) blows up at T iff

$$\lim_{\varepsilon\to 0}\int_{\varepsilon_0}^{T-\varepsilon}\|\nabla\times u\|_{L^\infty}+\|\nabla\times b\|_{L^\infty}dt=\infty\qquad\forall\ 0\le\varepsilon_0<T. \tag{1.3}$$

Recently, Zhang and Liu [17] refined the blow-up condition (1.3) to

$$\lim_{\varepsilon\to 0}\int_{\varepsilon_0}^{T-\varepsilon}\|\nabla\times u\|_{\dot{B}^0_{\infty,\infty}}+\|\nabla\times b\|_{\dot{B}^0_{\infty,\infty}}dt=\infty\quad\forall\ 0\le\varepsilon_0<T.$$

Here and thereafter, $\dot{B}^s_{p,q}$ denotes the homogenous Besov space, whose definition will be given in section 2.

Recently, for the incompressible Euler equations,

$$\text{(IE)}\qquad\begin{cases}u_t+u\cdot\nabla u+\nabla p=0,\\ \nabla\cdot u=0,\\ u(0,x)=u_0(x),\end{cases} \tag{1.4}$$

Planchon [14] was able to relax previous blow-up conditions such as

$$\lim_{\varepsilon\to 0}\int_{\varepsilon_0}^{T-\varepsilon}\|\omega(t)\|_\infty dt=\infty\qquad\forall\ 0\le\varepsilon_0<T\qquad\text{(see, e.g., [2])},$$
$$\lim_{\varepsilon\to 0}\int_{\varepsilon_0}^{T-\varepsilon}\|\omega(t)\|_{BMO}dt=\infty\qquad\forall\ 0\le\varepsilon_0<T\qquad\text{(see, e.g., [10])},$$
$$\lim_{\varepsilon\to 0}\int_{\varepsilon_0}^{T-\varepsilon}\|\omega(t)\|_{\dot{B}^0_{\infty,\infty}}dt=\infty\qquad\forall\ 0\le\varepsilon_0<T\qquad\text{(see, e.g., [11])},$$

and he established an improved blow-up criterion in the framework of mixed time-space Besov spaces. His result is the following: there exists a positive constant M_0 such that if

$$\lim_{\varepsilon\to 0}\sup_{j\in\mathbb{Z}}\int_{T-\varepsilon}^{T}\|\Delta_j\omega(t)\|_\infty dt\ge M_0, \tag{1.5}$$

then u cannot be continued beyond $t=T$. Here $\omega=\nabla\times u$ is the vorticity and Δ_j denotes a frequency localization operator at $|\xi|\approx 2^j$; see section 2 for the definition.

Inspired by [14], we want to obtain the corresponding result for the IMHD equations. Unfortunately, the method of [16, 14] does not apply directly, since there is not enough evidence to show if the solution u remains smooth past time T from the deduced inequality (see the last inequality in [14]). More precisely, we cannot infer that $f(T)$ can be dominated by $f(T-\varepsilon)$ from the following inequality:

$$f(T)\le f(T-\varepsilon)+\delta(\varepsilon)f(T)\log(1+f(T)),$$

where $\delta(\varepsilon)$ is a function such that $\delta(\varepsilon)\to 0$ when ε tends to zero.

To overcome this difficulty, we first obtain a losing estimate for the IMHD equations (1.1), which is motivated by [7, 8], and further establishes a blow-up criterion of smooth solution for the IMHD equations (1.1). Let us point out that losing estimates

might be of independent interest, as they can be used to establish improved blow-up criteria of smooth solutions for the incompressible Navier–Stokes equations

$$\text{(NS)} \quad \begin{cases} u_t - \nu\Delta u + u\cdot\nabla u + \nabla p = 0, \\ \nabla\cdot u = 0, \\ u(0,x) = u_0(x), \end{cases} \tag{1.6}$$

and MHD equations with dissipation and resistance

$$\text{(MHD)} \quad \begin{cases} u_t - \nu\Delta u + u\cdot\nabla u = -\nabla p - \frac{1}{2}\nabla b^2 + b\cdot\nabla b, \\ b_t - \eta\Delta u + u\cdot\nabla b = b\cdot\nabla u, \\ \nabla\cdot u = \nabla\cdot b = 0, \\ u(0,x) = u_0(x), \quad b(0,x) = b_0(x). \end{cases} \tag{1.7}$$

We will prove the losing estimate for the IMHD equation (1.1) is the following theorem.

THEOREM 1.1. *Let (u,b) be a smooth solution to* (1.1) *with $(u_0,b_0)\in B^s_{p,q}$, $s>\frac{n}{p}+1$, $1\le p,q<\infty$. Then there exists a positive constant $C_0>0$ such that for $\lambda\ge C_0$,*

$$\mathcal{M}(u)+\mathcal{M}(b)\lesssim \|u_0\|_{\dot B^s_{p,q}}+\|b_0\|_{\dot B^s_{p,q}}, \tag{1.8}$$

where

$$\mathcal{M}(f)\triangleq \Big\|\sup_{t\in[0,T)} 2^{js-\Psi_\lambda(t)}\|\Delta_j f(t)\|_p\Big\|_{\ell^q(\mathbb{Z})} \quad \textit{with}$$

$$\Psi_\lambda(t',t)\triangleq \lambda\int_{t'}^{t}\|\nabla u(t'')\|_\infty+\|\nabla b(t'')\|_\infty dt'' \quad \textit{and} \quad \Psi_\lambda(t)=\Psi_\lambda(0,t).$$

As an application to Theorem 1.1, and inspired by [14], we obtain a similar blow-up criterion for the IMHD equations (1.1).

THEOREM 1.2. *Let $(u_0,b_0)\in B^s_{p,q}$, $s>\frac{n}{p}+1$, $1\le p,q<\infty$. Suppose that $(u,b)\in C([0,T);B^s_{p,q})\cap C^1([0,T);B^{s-1}_{p,q})$ is the smooth solution to* (1.1). *There exists an absolute constant $M>0$ such that*

(i) *If*

$$\limsup_{\varepsilon\to 0}\sum_{j\in\mathbb{Z}}\int_{T-\varepsilon}^{T}(\|\Delta_j(\nabla\times u)\|_\infty+\|\Delta_j(\nabla\times b)\|_\infty)dt=\delta<M, \tag{1.9}$$

then $\delta=0$, and the solution (u,b) can be extended past time $t=T$.

(ii) *If*

$$\limsup_{\varepsilon\to 0}\sum_{j\in\mathbb{Z}}\int_{T-\varepsilon}^{T}(\|\Delta_j(\nabla\times u)\|_\infty+\|\Delta_j(\nabla\times b)\|_\infty)dt\ge M, \tag{1.10}$$

then the solution blows up at $t=T$.

Remark 1.1. In Theorem 1.2, M can be viewed as a threshold of blow-up. Planchon gave an exact explanation for the appearance of M; see [14] for details.

Remark 1.2. Note that $B^{s-1}_{p,q}$ is a Banach algebra for $s>\frac{n}{p}+1$. One can easily prove that there exists a unique smooth solution $(u,b)\in C([0,T);B^s_{p,q})\cap C^1([0,T);B^{s-1}_{p,q})$ to (1.1) by standard method; see [16] for details.

Remark 1.3. (i) In the case of $b = 0$, (IMHD) can be read as the incompressible Euler equations (IE), and what is proved in [14] is a straightforward consequence of Theorem 1.2.

(ii) Making use of losing estimate techniques, we can establish an improved blow-up criterion of smooth solution in the framework of mixed time-space Besov space for the incompressible Navier–Stokes equations (NS) and MHD equations (MHD).

Notation. Throughout the paper, C stands for a "harmless" constant, and we will use the notation $A \lesssim B$ as an equivalent to $A \leq CB$, $A \approx B$ as $A \lesssim B$ and $B \lesssim A$.

2. Preliminaries. Let us recall the Littlewood–Paley decomposition (see also [1, 15]) and then establish a certain kind of logarithmic Sobolev inequalities in the framework of mixed time-space Besov space. Let $\mathcal{S}(\mathbb{R}^3)$ be the Schwartz class of rapidly decreasing functions. Given $f \in \mathcal{S}(\mathbb{R}^n)$, its Fourier transform $\mathcal{F}f = \hat{f}$ is defined by

$$\hat{f}(\xi) = (2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} e^{-ix\cdot\xi} f(x)dx.$$

Choose two nonnegative radial functions χ, $\varphi \in \mathcal{S}(\mathbb{R}^n)$, supported in $B = \{\xi \in \mathbb{R}^n, |\xi| \leq \frac{4}{3}\}$ and $\mathcal{C} = \{\xi \in \mathbb{R}^n, \frac{3}{4} \leq |\xi| \leq \frac{8}{3}\}$, respectively, such that

$$\chi(\xi) + \sum_{j\geq 0} \varphi(2^{-j}\xi) = 1, \quad \xi \in \mathbb{R}^n,$$
$$\sum_{j\in\mathbb{Z}} \varphi(2^{-j}\xi) = 1, \quad \xi \in \mathbb{R}^n\backslash\{0\}.$$

Setting $\varphi_j(\xi) = \varphi(2^{-j}\xi)$, one easily verifies that $\operatorname{supp}\varphi_j \cap \operatorname{supp}\varphi_{j'} = \emptyset$ if $|j - j'| \geq 2$ and $\operatorname{supp}\chi \cap \operatorname{supp}\varphi_j = \emptyset$ if $j \geq 1$. Let $h = \mathcal{F}^{-1}\varphi$ and $\tilde{h} = \mathcal{F}^{-1}\chi$; we define the dyadic blocks as follows:

$$\Delta_j f = \varphi(2^{-j}D)f = 2^{jn} \int_{\mathbb{R}^n} h(2^j y)f(x - y)dy,$$
$$S_j f = \sum_{k\leq j-1} \Delta_k f = \chi(2^{-j}D)f = 2^{jn} \int_{\mathbb{R}^n} \tilde{h}(2^j y)f(x - y)dy.$$

Informally, $\Delta_j = S_j - S_{j-1}$ is a frequency projection to the annulus $\{|\xi| \approx 2^j\}$, while S_j is a frequency projection to the ball $\{|\xi| \lesssim 2^j\}$.

Making use of Littlewood–Paley's decomposition, we give the definition of the homogenous Besov space. Let $s \in \mathbb{R}, 1 \leq p, q \leq \infty$; the homogenous Besov space $\dot{B}^s_{p,q}$ is defined by

$$\dot{B}^s_{p,q} = \{f \in \mathcal{Z}'(\mathbb{R}^n); \|f\|_{\dot{B}^s_{p,q}} < \infty\},$$

where

$$\|f\|_{\dot{B}^s_{p,q}} = \begin{cases} \Big(\displaystyle\sum_{j=-\infty}^{\infty} 2^{jsq} \|\Delta_j f\|_p^q \Big)^{\frac{1}{q}} & \text{for} \quad q < \infty, \\ \displaystyle\sup_{j\in\mathbb{Z}} 2^{js} \|\Delta_j f\|_p & \text{for} \quad q = \infty, \end{cases}$$

and $\mathcal{Z}'(\mathbb{R}^n)$ denotes the dual space of $\mathcal{Z}(\mathbb{R}^n) = \{f \in \mathcal{S}(\mathbb{R}^n); \partial^\alpha \hat{f}(0) = 0; \forall \alpha \in \mathbb{N}^n \text{ multi-index}\}$ and can be identified by the quotient space of $\mathcal{S}'/\mathcal{P}$ with the polynomials space $\mathcal{P}$.

For $s > 0$, we define the inhomogeneous Besov space as

$$B^s_{p,q} = \{f \in \mathcal{S}'(\mathbb{R}^n);\ \|f\|_{B^s_{p,q}} < \infty\},$$

where

$$\|f\|_{B^s_{p,q}} = \|f\|_p + \|f\|_{\dot{B}^s_{p,q}}.$$

For details, we refer to [1, 15].

In addition to normal time-space Besov space such as $L^r(I; B^s_{p,q})$ or $L^r(I; \dot{B}^s_{p,q})$, we also use another kind of mixed time-space Besov space, used previously in [6]; see also [4]. Let $s \in \mathbb{R}, 1 \le r, p, q \le \infty$, $0 < T \le +\infty$; the space $\widetilde{L}^r_T(\dot{B}^s_{p,q})$ is defined by

$$\widetilde{L}^r_T(\dot{B}^s_{p,q}) = \{f \in \mathcal{D}'((0,T); \mathcal{Z}'(\mathbb{R}^n));\ \|f\|_{\widetilde{L}^r_T(\dot{B}^s_{p,q})} < \infty\},$$

where

$$\|f\|_{\widetilde{L}^r_T(\dot{B}^s_{p,q})} = \left\| 2^{js} \left(\int_0^T \|\Delta_j f(t)\|_p^r dt \right)^{\frac{1}{r}} \right\|_{\ell^q}.$$

Before establishing logarithmic Sobolev inequality in the framework of mixed time-space Besov space, we introduce two well-known lemmas which will be used repeatedly in this paper.

LEMMA 2.1 (Bernstein's estimates). *Let $1 \le p \le q \le \infty$. Assume that $f \in L^p$; then there exist constants C independent of f, j such that*

$$\operatorname{supp}\hat{f} \subset \{|\xi| \lesssim 2^j\} \Rightarrow \|\partial^\alpha f\|_q \le C 2^{j|\alpha| + jn(\frac{1}{p} - \frac{1}{q})} \|f\|_p, \tag{2.1}$$

$$\operatorname{supp}\hat{f} \subset \{|\xi| \approx 2^j\} \Rightarrow \|f\|_p \le C 2^{-j|\alpha|} \sup_{|\beta| = |\alpha|} \|\partial^\beta f\|_p. \tag{2.2}$$

This lemma is classic and for a proof, see [13].

LEMMA 2.2 (commutator estimate). *Let $j \in \mathbb{Z}$, $1 \le p \le \infty$. Assume that $f \in L^p$, $\nabla g \in L^\infty$; then there exists a positive constant C independent of f, g, and j such that*

$$\|[\Delta_j,\, g] f\|_p \le C 2^{-j} \|\nabla g\|_\infty \|f\|_p. \tag{2.3}$$

The proof is rather standard and can be found in [5, 7, 14].

Now we are in the position to prove a certain kind of logarithmic Sobolev inequalities initiated in [14] in terms of mixed time-space Besov space, which will play an important role in the proof of Theorem 1.1 as well.

PROPOSITION 2.1. *Let $1 \le p < \infty$, $1 \le q \le \infty$, and $s > \frac{n}{p} + 1$. Assume that $f \in \widetilde{L}^1_T(\dot{B}^0_{\infty,\infty}) \cap L^\infty_T(B^{s-1}_{p,q})$. Then the following inequality holds:*

$$\int_0^T \|f(t)\|_\infty dt \le C \left(1 + \sup_j \int_0^T \|\Delta_j f\|_\infty dt (1 + \log^+(T \|f\|_{L^\infty_T(B^{s-1}_{p,q})})) \right), \tag{2.4}$$

where $\log^+ x = \log x$, for $x > 1$; $\log^+ x = 0$, for $x \le 1$; and C is an absolute constant independent of f, T.

Proof. Using the Littlewood–Paley decomposition, we decompose f as follows:

$$f = S_{-N} f + \sum_{j=-N}^{N} \Delta_j f + \sum_{j>N} \Delta_j f \triangleq f_1 + f_2 + f_3,$$

where N is a positive integer to be chosen later. We first estimate f_1. It follows from (2.1) that

$$\int_0^T \|f_1\|_\infty dt \le \int_0^T 2^{-N\frac{n}{p}} \|S_{-N} f\|_p dt \le CT 2^{-N\frac{n}{p}} \|f\|_p. \tag{2.5}$$

Second, it is obvious that

$$\int_0^T \|f_2\|_\infty dt \le (2N+1) \sup_j \int_0^T \|\Delta_j f\|_\infty dt. \tag{2.6}$$

Finally, we turn to f_3. In view of (2.1) together with the definition of Besov space, it follows that

$$\begin{aligned} \int_0^T \|f_3\|_\infty dt &\le \int_0^T \sum_{j>N} 2^{j(\frac{n}{p}-s+1)} 2^{j(s-1)} \|\Delta_j f\|_p dt \\ &\le CT 2^{-N(s-\frac{n}{p}-1)} \|f\|_{L^\infty_T(B^{s-1}_{p,q})}, \end{aligned} \tag{2.7}$$

where we have used the Hölder inequality in the last inequality of (2.7).

Combining (2.5)–(2.7) and setting $\alpha = \min(\frac{n}{p}, s - \frac{n}{p} - 1)$, one easily verifies that

$$\int_0^T \|f\|_\infty dt \le C \left(T 2^{-\alpha N} \|f\|_{L^\infty_T(B^{s-1}_{p,q})} + N \sup_j \int_0^T \|\Delta_j f\|_\infty dt \right). \tag{2.8}$$

Now we choose N such that $T 2^{-\alpha N} \|f\|_{L^\infty_T(B^{s-1}_{p,q})} \le 1$, i.e.,

$$N \ge \frac{\log(T \|f\|_{L^\infty_T(B^{s-1}_{p,q})})}{\alpha \log 2}.$$

Then our desired estimate (2.4) follows from the above inequality and (2.8). ∎

3. A losing a priori estimate. Let us begin with the proof of Theorem 1.1.

Proof of Theorem 1.1. We first consider the symmetrized IMHD equations rewritten in terms of the classical Elsasser variables [9]. Denote

$$\begin{cases} z^+ = u + b, \\ z^- = u - b. \end{cases}$$

Then (IMHD) can be reduced to

$$(\mathrm{IMHD})_* \quad \begin{cases} \partial_t z^+ + (z^- \cdot \nabla) z^+ = -\nabla \pi, \\ \partial_t z^- + (z^+ \cdot \nabla) z^- = -\nabla \pi, \\ \mathrm{div} z^+ = \mathrm{div} z^- = 0, \\ z^+(0) = z_0^+ = u_0 + b_0, \quad z^-(0) = z_0^- = u_0 - b_0, \end{cases} \tag{3.1}$$

where $\pi = p + \frac{1}{2} b^2$.

Let (z^+, z^-) be a smooth solution to $(\mathrm{IMHD})_*$ with $(z_0^+, z_0^-) \in \dot{B}^s_{p,q}$, $s > \frac{n}{p} + 1$, $1 \le p, q < \infty$. Then the proof of Theorem 1.1 can be reduced to establish the following estimate: for λ sufficient large, such as $\lambda > C_0$, there holds

$$\alpha_T^q + \beta_T^q \lesssim \|z_0^+\|^q_{\dot{B}^s_{p,q}} + \|z_0^-\|^q_{\dot{B}^s_{p,q}}, \tag{3.2}$$

where $\alpha_T = \|\alpha_{j,T}\|_{\ell^q}$, $\beta_T = \|\beta_{j,T}\|_{\ell^q}$ and

$$\alpha_{j,T} = \sup_{t\in[\,0,T)} 2^{js-\Phi_\lambda(t)}\|\Delta_j z^+(t)\|_p,$$
$$\beta_{j,T} = \sup_{t\in[\,0,T)} 2^{js-\Phi_\lambda(t)}\|\Delta_j z^-(t)\|_p \quad \text{with}$$
$$\Phi_\lambda(t',t) \triangleq \lambda\int_{t'}^{t} \|\nabla z^+(t'')\|_\infty + \|\nabla z^-(t'')\|_\infty dt'' \quad \text{and} \quad \Phi_\lambda(t) = \Phi_\lambda(0,t).$$

Denote $\mathbb{P}$ the matrix operator with entries $(\delta_{ij} - R_iR_j)$; here δ_{ij} is the Kronecker symbol and R_i, R_j are Riesz transforms. As such $\mathbb{P}$ is the well-known projection onto divergence-free vector fields. Applying $\mathbb{P}$ to two sides of (3.1) and taking the operation Δ_j on both sides of the resulting equations, we get

$$\begin{cases} \partial_t z_j^+ + \mathbb{P}\Delta_j((z^-\cdot\nabla)z^+) = 0, \\ \partial_t z_j^- + \mathbb{P}\Delta_j((z^+\cdot\nabla)z^-) = 0, \end{cases} \tag{3.3}$$

where

$$z_j = \Delta_j z.$$

Multiplying the first equation of (3.3) by $|z_j^+|^{p-2}z_j^+$ and the second one by $|z_j^-|^{p-2}z_j^-$, integrating the resulting equations in $\mathbb{R}^n$ with respect to the space variable gives

$$\begin{cases} \dfrac{1}{p}\dfrac{d}{dt}\|z_j^+\|_p^p = -\displaystyle\int_{\mathbb{R}^n} \mathbb{P}\Delta_j((z^-\cdot\nabla)z^+)\,|z_j^+|^{p-2}z_j^+ dx, \\ \dfrac{1}{p}\dfrac{d}{dt}\|z_j^-\|_p^p = -\displaystyle\int_{\mathbb{R}^n} \mathbb{P}\Delta_j((z^+\cdot\nabla)z^-)\,|z_j^-|^{p-2}z_j^- dx. \end{cases}$$

In what follows, we need to estimate the convection terms

$$\int_{\mathbb{R}^n} \mathbb{P}\Delta_j((z^-\cdot\nabla)z^+)\,|z_j^+|^{p-2}z_j^+ dx \quad \text{and} \quad \int_{\mathbb{R}^n} \mathbb{P}\Delta_j((z^+\cdot\nabla)z^-)\,|z_j^-|^{p-2}z_j^- dx. \tag{3.4}$$

We only deal with the first term appearing in (3.4), as the second one can be treated in the same way. Now we decompose $((z^-\cdot\nabla)z^+)$ as a paraproduct

$$\begin{aligned}(z^-\cdot\nabla)z^+ &= \sum_k (S_{k-1}z^-\cdot\nabla)z_k^+ + \sum_k (z_k^-\cdot\nabla)S_{k-1}z^+ + \sum_{|k-k'|\le 1}(z_{k'}^-\cdot\nabla)z_k^+ \\ &\triangleq I_1 + I_2 + I_3. \end{aligned} \tag{3.5}$$

It is easy to see that we only need to preserve the vector structure for I_1. For the remaining two terms one can forget about vectors and think of them as scalar.

• I_2 estimates. Applying the Hölder inequality in conjunction with the boundedness of $\mathbb{P}$ on L^p $(1 < p < \infty)$, we get

$$\left|\int_{\mathbb{R}^n} \mathbb{P}\Delta_j(I_2)|z_j^+|^{p-2}z_j^+ dx\right| \lesssim \sum_{k\sim j}\|\nabla S_{k-1}z^+\|_\infty\|z_k^-\|_p\|z_j^+\|_p^{p-1}, \tag{3.6}$$

where $k\sim j$ stands for $|k-j|\le 1$ owing to the support conditions.

• I_3 estimates. Noting that $\nabla\cdot z_j^{\pm}=0$, one easily shows that

$$\int_{\mathbb{R}^n}\mathbb{P}\Delta_j(I_3)|z_j^+|^{p-2}z_j^+dx=\sum_{1\le\ell\le n}\int_{\mathbb{R}^n}\Delta_j\Big(\sum_{j\lesssim k\sim k'}\mathbb{P}\nabla\cdot(z_{k'}^-\otimes z_k^+)\Big)^{(\ell)}|z_j^{+(\ell)}|^{p-2}z_j^{+(\ell)}dx.$$

If $p\ge 2$, integrating by parts together with the Hölder inequality yields

$$\Big|\int_{\mathbb{R}^n}\mathbb{P}\Delta_j(I_3)|z_j^+|^{p-2}z_j^+dx\Big|\lesssim(p-1)\sum_{j\lesssim k\sim k'}\|z_{k'}^-\|_p\|z_k^+\|_p\|z_j^+\|_p^{p-2}\|\nabla z_j^+\|_\infty. \tag{3.7}$$

If $p<2$, it follows by the Hölder inequality

$$\Big|\int_{\mathbb{R}^n}\mathbb{P}\Delta_j(I_3)|z_j^+|^{p-2}z_j^+dx\Big|\lesssim\sum_{j\lesssim k\sim k'}\|\nabla z_k^+\|_\infty\|z_{k'}^-\|_p\|z_j^+\|_p^{p-1}. \tag{3.8}$$

• I_1 estimates. Observe that

$$\begin{aligned}\mathbb{P}\Delta_j\sum_k(S_{k-1}z^-\cdot\nabla)z_k^+&=\mathbb{P}\Delta_j(S_{j-1}z^-\cdot\nabla)\sum_{k\sim j}z_k^++\mathbb{P}\Delta_j\sum_{k\sim k'\sim j}(z_{k'}^-\cdot\nabla)z_k^+\\&\triangleq II_1+II_2.\end{aligned}$$

We have by the Hölder inequality

$$\Big|\int_{\mathbb{R}^n}II_2|z_j^+|^{p-2}z_j^+dx\Big|\lesssim\sum_{k\sim k'\sim j}\|\nabla z_k^+\|_\infty\|z_{k'}^-\|_p\|z_j^+\|_p^{p-1}. \tag{3.9}$$

Furthermore, we can rewrite II_1 as

$$II_1=\sum_{1\le\ell\le n}C_\ell\partial_\ell\sum_{k\sim j}z_k^++(S_{j-1}z^-\cdot\nabla)\mathbb{P}\Delta_j\sum_{k\sim j}z_k^+\triangleq III_1+III_2,$$

where C_ℓ is the commutator denoted by

$$C_\ell=[\mathbb{P}\Delta_j,\,S_{j-1}z^{-(\ell)}Id].$$

It is easy to see $\sum_{k\sim j}\mathbb{P}\Delta_jz_k^+=z_j^+$. Making use of $\mathrm{div}z_j^+=0$ and integrating by parts, we have

$$\begin{aligned}\int_{\mathbb{R}^n}III_2|z_j^+|^{p-2}z_j^+dx&=\sum_{1\le\ell\le n}\int_{\mathbb{R}^n}S_{j-1}z^{-(\ell)}\partial_\ell z_j^+|z_j^+|^{p-2}z_j^+dx\\&=\sum_{1\le\ell\le n}\int_{\mathbb{R}^n}\partial_\ell(S_{j-1}z^{-(\ell)}z_j^+)|z_j^+|^{p-2}z_j^+dx\\&=-(p-1)\sum_{1\le\ell\le n}\int_{\mathbb{R}^n}S_{j-1}z^{-(\ell)}z_j^+\partial_\ell z_j^+|z_j^+|^{p-2}dx,\end{aligned}$$

which implies that

$$\int_{\mathbb{R}^n}III_2|z_j^+|^{p-2}z_j^+dx=0. \tag{3.10}$$

On the other hand, from the commutator estimate (2.3), we obtain

$$\left|\int_{\mathbb{R}^n} III_1|z_j^+|^{p-2}z_j^+dx\right| \lesssim \|\nabla S_{j-1}z^-\|_\infty\|z_j^+\|_p^p. \tag{3.11}$$

Combining (3.6)–(3.7) and (3.9)–(3.11), we infer that

$$\begin{aligned}\frac{1}{p}\frac{d}{dt}\|z_j^+\|_p^p &\lesssim \sum_{k\sim j}\Big(\|\nabla S_{j-1}z^+\|_\infty\|z_k^-\|_p\|z_j^+\|_p^{p-1}+\|\nabla S_{j-1}z^-\|_\infty\|z_k^+\|_p\|z_j^+\|_p^{p-1}\Big)\\ &\quad+\sum_{j\lesssim k'\sim k}\|z_k^+\|_p\|z_{k'}^-\|_p\|z_j^+\|_p^{p-2}\|\nabla z_j^+\|_\infty\\ &\lesssim \sum_{k\sim j}\Big(\|\nabla z^+\|_\infty\|z_k^-\|_p\|z_j^+\|_p^{p-1}+\|\nabla z^-\|_\infty\|z_k^+\|_p\|z_j^+\|_p^{p-1}\Big)\\ &\quad+\sum_{j\lesssim k'\sim k}\|z_k^+\|_p\|z_{k'}^-\|_p\|z_j^+\|_p^{p-2}\|\nabla z^+\|_\infty,\end{aligned}$$

where use has been made of the inequalities $\|\nabla S_{j-1}z^+\|_\infty\le\|\nabla z^+\|_\infty$ and $\|\nabla z_k^+\|_\infty\le\|\nabla z^+\|_\infty$ to derive the second estimate. Thus we deduce

$$\begin{aligned}\frac{d}{dt}\|z_j^+\|_p^2 &\lesssim \sum_{k\sim j}\Big(\|\nabla z^+\|_\infty\|z_k^-\|_p+\|\nabla z^-\|_\infty\|z_k^+\|_p\Big)\|z_j^+\|_p\\ &\quad+\sum_{j\lesssim k'\sim k}\|z_k^+\|_p\|z_{k'}^-\|_p\|\nabla z^+\|_\infty,\end{aligned}$$

which implies

$$\begin{aligned}\frac{d}{dt}\|z_j^+\|_p^q &\lesssim \frac{q}{2}\sum_{k\sim j}\Big(\|\nabla z^+\|_\infty\|z_k^-\|_p+\|\nabla z^-\|_\infty\|z_k^+\|_p\Big)\|z_j^+\|_p^{q-1}\\ &\quad+\frac{q}{2}\sum_{j\lesssim k'\sim k}\|z_k^+\|_p\|z_{k'}^-\|_p\|\nabla z^+\|_\infty\|z_j^+\|_p^{q-2}.\end{aligned}\tag{3.12}$$

In the same way as leading to (3.12), we have for z_j^-

$$\begin{aligned}\frac{d}{dt}\|z_j^-\|_p^q &\lesssim \frac{q}{2}\sum_{k\sim j}\Big(\|\nabla z^-\|_\infty\|z_k^+\|_p+\|\nabla z^+\|_\infty\|z_k^-\|_p\Big)\|z_j^-\|_p^{q-1}\\ &\quad+\frac{q}{2}\sum_{j\lesssim k'\sim k}\|z_k^-\|_p\|z_{k'}^+\|_p\|\nabla z^-\|_\infty\|z_j^-\|_p^{q-2}.\end{aligned}\tag{3.13}$$

Integrating (3.13) over $[0,t)$ with respect to time variable τ, and then multiplying by $2^{q(js-\Phi_\lambda(t))}$ both sides of the resulting inequality, we get

$$\begin{aligned}2^{q(js-\Phi_\lambda(t))}\|z_j^+\|_p^q(t) &\lesssim 2^{jqs}\|z_j^+\|_p^q(0)+\int_0^t 2^{-q\Phi_\lambda(\tau,t)}(\|\nabla z^+\|_\infty+\|\nabla z^-\|_\infty)(\tau)\\ &\quad\times\Big(\sum_{k\sim j}2^{q(js-\Phi_\lambda(\tau))}\|z_j^+(\tau)\|_p^{q-1}(\|z_k^-\|_p+\|z_k^+\|_p)(\tau)+\sum_{j\lesssim k'\sim k}2^{2(j-k)s}\\ &\quad\times 2^{ks-\Phi_\lambda(\tau)}\|z_k^+\|_p 2^{k's-\Phi_\lambda(\tau)}\|z_{k'}^-\|_p 2^{(q-2)(js-\Phi_\lambda(\tau))}\|z_j^+\|_p^{q-2}\Big)d\tau.\end{aligned}$$

Taking the supremum over $[0,T)$ on both sides of the above inequality, we deduce that

$$\alpha_{j,T}^q \lesssim \alpha_{j,0}^q + \sup_{t\in[0,T)} \int_0^t 2^{-q\Phi_\lambda(\tau,t)}(\|\nabla z^+\|_\infty + \|\nabla z^-\|_\infty)(\tau)d\tau \bigg(\alpha_{j,T}^{q-1} \sum_{k\sim j}(\beta_{k,T}+\alpha_{k,T})$$

$$+\alpha_{j,T}^{q-2} \sum_{j\lesssim k'\sim k} 2^{2(j-k)s}\alpha_{k,T}\beta_{k',T}\bigg). \tag{3.14}$$

Moreover, integrating by parts yields

$$\int_0^t 2^{-q\Phi_\lambda(\tau,t)}(\|\nabla z^+\|_\infty + \|\nabla z^-\|_\infty)(\tau)d\tau \le \frac{1}{q\lambda\log 2}. \tag{3.15}$$

• When $q \ge 2$. Taking the sum over j of (3.14); then using the above estimate and Hölder inequality leads to

$$\alpha_T^q \lesssim \|z_0^+\|_{\dot B^s_{p,q}}^q + \frac{1}{q\lambda\log 2}(\alpha_T^{q-1}\beta_T + \alpha_T^q), \tag{3.16}$$

where use has been made of the $\ell^1 \to \ell^{\frac{q}{2}}$ convolution to the second sum of the right side of (3.14). Let us go back to (3.13); arguing similarly as in deriving (3.16), we obtain

$$\beta_T^q \lesssim \|z_0^-\|_{\dot B^s_{p,q}}^q + \frac{1}{q\lambda\log 2}(\beta_T^{q-1}\alpha_T + \beta_T^q). \tag{3.17}$$

Summing up (3.16) and (3.17), together with the Hölder inequality, yields

$$\alpha_T^q + \beta_T^q \lesssim \|z_0^+\|_{\dot B^s_{p,q}}^q + \|z_0^-\|_{\dot B^s_{p,q}}^q + \frac{1}{q\lambda\log 2}(\alpha_T^q + \beta_T^q). \tag{3.18}$$

Now if we choose λ large enough such that

$$\lambda \gtrsim \frac{2}{q\log 2}, \tag{3.19}$$

then

$$\alpha_T^q + \beta_T^q \lesssim \|z_0^+\|_{\dot B^s_{p,q}}^q + \|z_0^-\|_{\dot B^s_{p,q}}^q. \tag{3.20}$$

• When $q < 2$. One may substitute (3.7) by (3.8) in the estimate of I_3. It is not hard to verify that

$$\alpha_{j,T}^q \lesssim \alpha_{j,0}^q + \sup_{t\in[0,T)} \int_0^t 2^{-q\Phi_\lambda(\tau,t)}(\|\nabla z^+\|_\infty + \|\nabla z^-\|_\infty)(\tau)d\tau \bigg(\alpha_{j,T}^{q-1} \sum_{k\sim j}(\beta_{k,T}+\alpha_{k,T})$$

$$+\alpha_{j,T}^{q-1} \sum_{j\lesssim k'\sim k} 2^{(j-k)s}\beta_{k',T}\bigg).$$

By exactly the same procedure as the case of $q \ge 2$, we can get the required estimate (3.2). This completes the proof of Theorem 1.1. □

4. The blow-up criterion. In this section, we want to prove Theorem 1.2.

Proof of Theorem 1.2. Assume that

$$\limsup_{\varepsilon\to 0}\sup_{j}\int_{T-\varepsilon}^{T}(\|\Delta_j\omega\|_\infty+\|\Delta_j J\|_\infty)dt=\delta<M. \tag{4.1}$$

Then the solution (u,b) of (IMHD) can be extended past time $t=T$, where $\omega=\nabla\times u$ and $J=\nabla\times b$ are the vorticity with respect to u and b, respectively. This fact is equivalent to the blow-up criterion (1.9) in Theorem 1.2.

Let $(u,b)\in C_T(B^s_{p,q})$, $s>\frac{n}{p}+1$, $1\le p,q<\infty$ be the smooth solution to (IMHD); then (z^+,z^-) is the smooth solution to $(\mathrm{IMHD})_*$ and (4.1) can be read as

$$\limsup_{\varepsilon\to 0}\sup_{j}\int_{T-\varepsilon}^{T}(\|\Delta_j(\nabla\times z^+)\|_\infty+\|\Delta_j(\nabla\times z^-)\|_\infty)dt=\delta<2M. \tag{4.2}$$

Thanks to the Biot–Savard law,

$$\nabla u=(-\Delta)^{-1}\nabla\nabla\times\omega,\quad \nabla b=(-\Delta)^{-1}\nabla\nabla\times J,$$

and $\|R_k\Delta_j f\|_p\le C_0\|\Delta_j f\|_p$, $(1\le p\le\infty)$; it follows that (4.2) is equivalent to

$$\limsup_{\varepsilon\to 0}\sup_{j}\int_{T-\varepsilon}^{T}(\|\Delta_j\nabla z^+\|_\infty+\|\Delta_j\nabla z^-\|_\infty)dt=\delta_0<2C_0M, \tag{4.3}$$

where C_0 is a constant from the boundedness of Riesz transform R_k, $1\le k\le n$.

We are now in position to set the blow-up criterion. In order to do this, let us estimate

$$\|z^+(t)\|_p\le\|z_0^+\|_p+\int_0^t\|\nabla z^+(\tau)\|_\infty\|z^-(\tau)\|_p d\tau.$$

Multiplying by $2^{-\Phi_\lambda(t)}$, both sides of the above inequality yield

$$2^{-\Phi_\lambda(t)}\|z^+(t)\|_p\lesssim\|z_0^+\|_p+\int_0^t 2^{-\Phi_\lambda(\tau,t)}\|\nabla z^+(\tau)\|_\infty 2^{-\Phi_\lambda(\tau)}\|z^-(\tau)\|_p d\tau.$$

This along with (3.15) implies that

$$\sup_{t\in[0,T)}2^{-\Phi_\lambda(t)}\|z^+(t)\|_p\lesssim\|z_0^+\|_p+\frac{1}{\lambda\log 2}\sup_{[0,T)}2^{-\Phi_\lambda(t)}\|z^-(t)\|_p.$$

An analogous argument leading to the above estimate allows us to get

$$\sup_{t\in[0,T)}2^{-\Phi_\lambda(t)}\|z^-(t)\|_p\lesssim\|z_0^-\|_p+\frac{1}{\lambda\log 2}\sup_{[0,T)}2^{-\Phi_\lambda(t)}\|z^+(t)\|_p.$$

If $\lambda\gtrsim\frac{2}{\log 2}$, then

$$\sup_{t\in[0,T)}2^{-\Phi_\lambda(t)}(\|z^+(t)\|_p+\|z^-(t)\|_p)\lesssim\|z_0^+\|_p+\|z_0^-\|_p. \tag{4.4}$$

Let us define

$$\gamma_T\triangleq\sup\left((\alpha_T^q+\beta_T^q)^{\frac{1}{q}},\ \sup_{[0,T)}2^{-\Phi_\lambda(t)}(\|z^+(t)\|_p+\|z^-(t)\|_p)\right).$$

This together with (3.2) and (4.4) implies that

$$\gamma_T \lesssim \|z_0^+\|_{B^s_{p,q}} + \|z_0^-\|_{B^s_{p,q}}.$$

In particular, we have

$$\|z^+(t)\|_{B^s_{p,q}} + \|z^-(t)\|_{B^s_{p,q}} \lesssim 2^{\Phi_\lambda(t)}(\|z_0^+\|_{B^s_{p,q}} + \|z_0^-\|_{B^s_{p,q}}) \quad \forall\, t \in [0,T), \tag{4.5}$$

where

$$\Phi_\lambda(t) = \lambda \int_0^t (\|\nabla z^+\|_\infty + \|\nabla z^-\|_\infty)(\tau) d\tau.$$

Applying Proposition 2.1 with $f(t) = \nabla z^+$ and $f(t) = \nabla z^-$, respectively, and collecting the resulting inequalities, we have

$$\begin{aligned}\int_0^t (\|\nabla z^+\|_\infty + \|\nabla z^-\|_\infty)(\tau) d\tau \lesssim 1 + \sup_j \int_0^t (\|\Delta_j \nabla z^+\|_\infty + \|\Delta_j \nabla z^-\|_\infty) d\tau \\ \times \bigg(1 + \log^+(t\|z^+\|_{L^\infty_t(B^s_{p,q})} + t\|z^-\|_{L^\infty_t(B^s_{p,q})})\bigg).\end{aligned} \tag{4.6}$$

For the sake of convenience, we denote that

$$\zeta(T) \triangleq \sup_{[0,T)} \big\|z^+(t)\big\|_{B^s_{p,q}} + \sup_{[0,T)} \big\|z^-(t)\big\|_{B^s_{p,q}}.$$

Putting (4.6) into (4.5), then taking supremum over $[0,T)$ with respect to t, we have

$$\zeta(T) \lesssim 2^{\lambda\bigg(1 + \sup_j \int_0^T (\|\Delta_j \nabla z^+\|_\infty + \|\Delta_j \nabla z^-\|_\infty) d\tau (1 + \log^+(T\zeta(T)))\bigg)} \zeta(0).$$

We should point out that the above inequality still holds if the time interval $[0,T)$ is replaced by $[T-\varepsilon, T)$. Thanks to condition (4.3), we deduce that

$$\zeta(T) \lesssim 2^{\lambda \sup_j \int_{T-\varepsilon}^T (\|\Delta_j \nabla z^+\|_\infty + \|\Delta_j \nabla z^-\|_\infty) d\tau \log^+(\varepsilon\zeta(T))} \zeta(T-\varepsilon).$$

Setting $Z(T) \triangleq \log(e + \zeta(T))$, we finally have

$$Z(T) \le C\lambda \sup_j \int_{T-\varepsilon}^T (\|\Delta_j \nabla z^+\|_\infty + \|\Delta_j \nabla z^-\|_\infty) d\tau Z(T) + Z(T-\varepsilon). \tag{4.7}$$

If we choose $M = \frac{1}{2CC_0\lambda}$, the condition (4.3) ensures the term $\lambda \sup_j \int_{T-\varepsilon}^T (\|\Delta_j \nabla z^+\|_\infty + \|\Delta_j \nabla z^-\|_\infty) d\tau < \frac{1}{C\lambda}$ when $\varepsilon \to 0$, which implies that

$$Z(T) \lesssim Z(T-\varepsilon).$$

Hence we have the $B^s_{p,q}$ regularity for the solution at $t = T$ and the solution can be continued after $t = T$. This completes the proof of Theorem 1.2. ∎

THE EFFECT OF INHIBITOR ON THE PLASMID-BEARING AND PLASMID-FREE MODEL IN THE UNSTIRRED CHEMOSTAT*

JIANHUA WU†, HUA NIE†, AND GAIL S. K. WOLKOWICZ‡

Abstract. This paper deals with a chemostat model with an inhibitor in the context of competition between plasmid-bearing and plasmid-free organisms. First, sufficient conditions for coexistence of the steady-state are determined. Second, the effects of the inhibitor are considered. It turns out that the parameter μ, which represents the effect of the inhibitor, plays a very important role in deciding the number of the coexistence solutions. The results show that if μ is sufficiently large this model has at least two coexistence solutions provided that the maximal growth rate a of u lies in a certain range and has only one unique asymptotically stable coexistence solution when a belongs to another range. Finally, extensive simulations are done to complement the analytic results. The main tools used here include degree theory in cones, bifurcation theory, and perturbation technique.

Key words. chemostat, coexistence solution, perturbation theory, stability

1. Introduction.

The chemostat is a common model in microbial ecology. It is used as an ecological model of a simple lake, as a model of waste treatment, and as a model for commercial production of fermentation processes. It is important in ecology because the parameters are readily measurable and, thus, the mathematical results are readily testable. For a general discussion of competitive systems see [29], while a detailed mathematical description of competition in the chemostat can be found in [30].

Our study focuses on a chemostat model in the context of competition between plasmid-bearing and plasmid-free organisms. This issue has recently received considerable attention. The theoretical literature on this model includes Ryder and DiBiaso [25], Stephanopoulos and Lapidus [28], Hsu, Waltman, and Wolkowicz [17], Lu and Hadeler [22], Levin [20], Luo and Hsu [18], and Macken, Levin, and Waldstätter [23]. In industry, genetically altered organisms are frequently used to manufacture a desired product, for instance, a pharmaceutical. The alteration is accomplished by introducing a piece of DNA into the cell in the form of a plasmid. The burden imposed on the cell by the task of production can result in the genetically altered (the plasmid-bearing) organism being a less able competitor than the plasmid-free organism. Unfortunately, the plasmid can be lost in the reproductive process. Thus, it is possible for the plasmid-free organism to take over the culture. To avoid "capture" of the process by the plasmid-free organism, the obvious choice is to alter the medium in such a way as to favor the plasmid-bearing organism. An example of this would be to introduce an antibiotic into the feed bottle. See [10, 15, 16] for a detailed biological and chemical background. Models in this direction have been studied in Lenski and Hattingh [21], Hsu and Waltman [13, 15, 16], Hsu, Luo, and Waltman [12], Nie and Wu [24], and the references therein.

This paper is concerned with the competition model between plasmid-bearing and plasmid-free organisms in the unstirred chemostat in the presence of an inhibitor. Here the plasmid-bearing organism devotes a partition of its resource to produce an inhibitor, which diminishes the growth rate of the plasmid-free organism but does not reduce that of the plasmid-bearing organism. The pioneering work on this model is that of Hsu and Waltman in [15]. They proposed an ODE model (see [15]) based on the study of Chao and Levin [1] and Levin [20]. Moreover, they obtained some results on the global asymptotic behavior. In our current paper, we allow a heterogeneous environment and so we remove the well-stirred hypothesis and consider the corresponding PDE system. Let $s(x,t)$ be the nutrient concentration at time t; let $u(x,t)$ and $v(x,t)$ be the concentrations of the plasmid-bearing and plasmid-free organisms in the culture vessel, respectively, and let $p(x,t)$ be the concentration of the inhibitor. Then using similar arguments as in [6, 14, 34, 32, 24] the model in the unstirred case takes the form

$$\begin{aligned}
&s_t = ds_{xx} - \tfrac{1}{r}auf_1(s) - \tfrac{1}{r}bvf_2(s)e^{-\mu p}, && x\in(0,1), t>0,\\
&u_t = du_{xx} + a(1-q-k)uf_1(s), && x\in(0,1), t>0,\\
&v_t = dv_{xx} + bvf_2(s)e^{-\mu p} + aquf_1(s), && x\in(0,1), t>0,\\
&p_t = dp_{xx} + akuf_1(s), && x\in(0,1), t>0
\end{aligned}$$

with boundary conditions and initial conditions

$$\begin{aligned}
&s_x(0,t) = -s^0, s_x(1,t) + \gamma s(1,t) = 0, && t>0,\\
&u_x(0,t) = u_x(1,t) + \gamma u(1,t) = 0, && t>0,\\
&v_x(0,t) = v_x(1,t) + \gamma v(1,t) = 0, && t>0,\\
&p_x(0,t) = p_x(1,t) + \gamma p(1,t) = 0, && t>0\\
&s(x,0) = s_0(x) \geq 0, && p(x,0) = p_0(x) \geq 0, \not\equiv 0,\\
&u(x,0) = u_0(x) \geq 0, \not\equiv 0, && v(x,0) = v_0(x) \geq 0, \not\equiv 0,
\end{aligned}$$

where $s^0 > 0$ is the input concentration of the nutrient, which is assumed to be constant; d is the diffusion rate of the chemostat; r is the growth yield constant and a, b are the maximal growth rates of the plasmid-bearing and plasmid-free organisms (without an inhibitor), respectively. The response functions are denoted by $f_i(s) = s/(k_i + s), i = 1, 2$, where k_i are the Michaelis–Menten constants. The term $e^{-\mu p}$ used by Lenski and Hattingh in [21] represents the degree of inhibition of p on the growth rate of v, where $\mu > 0$ is a constant and represents the effect of the inhibitor on v. The constant q is the fraction of plasmid lost, and k is the fraction of consumption devoted to the production of the inhibitor. Hence, $0 < q, k < 1$, and $1 - q - k > 0$. γ is a positive constant. In this model, the corresponding yield constants are assumed to be equal, just as in [17, 15, 20].

For the sake of convenience, by nondimensionalizing the parameters, which are indicated below with bars, $\bar{s} = s/s^0, \bar{u} = u/rs^0, \bar{v} = v/rs^0, \bar{p} = p/rs^0, \bar{k}_i = k_i/s^0, \bar{\mu} = rs^0\mu, f_i(\bar{s}) = f_i(s^0\bar{s})$, we can rewrite this model in the form

$$\begin{aligned}
&s_t = ds_{xx} - auf_1(s) - bvf_2(s)e^{-\mu p}, && x\in(0,1), t>0,\\
&u_t = du_{xx} + a(1-q-k)uf_1(s), && x\in(0,1), t>0,\\
&v_t = dv_{xx} + bvf_2(s)e^{-\mu p} + aquf_1(s), && x\in(0,1), t>0,\\
&p_t = dp_{xx} + akuf_1(s), && x\in(0,1), t>0,\\
&s_x(0,t) = -1, s_x(1,t) + \gamma s(1,t) = 0, && t>0,\\
&u_x(0,t) = u_x(1,t) + \gamma u(1,t) = 0, && t>0,\\
&v_x(0,t) = v_x(1,t) + \gamma v(1,t) = 0, && t>0,\\
&p_x(0,t) = p_x(1,t) + \gamma p(1,t) = 0, && t>0,\\
&s(x,0) = s_0(x) \geq 0, && p(x,0) = p_0(x) \geq 0, \not\equiv 0,\\
&u(x,0) = u_0(x) \geq 0, \not\equiv 0, && v(x,0) = v_0(x) \geq 0, \not\equiv 0.
\end{aligned} \tag{1.1}$$

For simplicity, we drop the bars over the nondimensional quantities.

Introduce the new variables $\Phi(x,t) = s + u + v + p$ and $\Psi(x,t) = p - cu$ into (1.1), where $c = k/(1-q-k)$. Then one can argue in exactly the same way as in [24, 33, 34, 36] to conclude that the limiting system of (1.1) may be written as

$$\text{(PP)}\quad \begin{aligned} &u_t = du_{xx} + a(1-q-k)uf_1(z-(1+c)u-v), && x\in(0,1), t>0,\\ &v_t = dv_{xx} + bvf_2(z-(1+c)u-v)e^{-\mu cu}\\ &\qquad +aquf_1(z-(1+c)u-v), && x\in(0,1), t>0,\\ &u_x(0,t) = u_x(1,t) + \gamma u(1,t) = 0, && t>0,\\ &v_x(0,t) = v_x(1,t) + \gamma v(1,t) = 0, && t>0,\\ &u(x,0) = u_0(x) \geq 0, \not\equiv 0,\ v(x,0) = v_0(x) \geq 0, \not\equiv 0, && x\in[0,1], \end{aligned}$$

where $z(x) = (1+\gamma)/\gamma - x, (1+c)u_0(x) + v_0(x) \leq z(x), \not\equiv z(x)$.

The purpose of the present paper is to investigate nonnegative steady-state solutions of system (1.1) and the effect of the inhibitor on coexistence states of this system. Thus we will concentrate on the simplified elliptic system:

$$\text{(EP)}\quad \begin{aligned} &du'' + a(1-q-k)uf_1(z-(1+c)u-v) = 0, && x\in(0,1),\\ &dv'' + bvf_2(z-(1+c)u-v)e^{-\mu cu} + aquf_1(z-(1+c)u-v) = 0,\\ &u'(0) = u'(1) + \gamma u(1) = 0, \qquad v'(0) = v'(1) + \gamma v(1) = 0, \end{aligned}$$

which is obtained from the steady-state system of (1.1) by introducing the variables $\Phi(x) = s + u + v + p$ and $\Psi(x) = p - cu$. Since the proof is standard, we omit it here. Interested readers can refer to [14, 24, 32, 33, 34] for details.

We are mainly interested in coexistence states of (EP), that is, the positive solutions of (EP). Hence, we redefine the response functions as follows:

$$\bar{f}_i(s) = \begin{cases} f_i(s), & s \geq 0,\\ \tan^{-1}(2s/k_i + 1) - \pi/4, & s < 0. \end{cases}$$

It is easily seen that $\bar{f}_i \in C^1(-\infty, +\infty)$. We will denote $\bar{f}_i(s)$ by $f_i(s)$ for the sake of simplicity.

This work is motivated by numerical simulations that seem to indicate that, when the parameters sit in a certain range, there exists a coexistence solution of (EP). More interestingly, it is possible that (EP) has exactly two coexistence solutions if v is a better competitor than u and the parameter μ is suitably large. From the biological standpoint, the numerical results mean that the inhibitor plays an important role in determining the number of coexistence solutions of (EP). As mentioned before, the main purpose of this paper is to determine when the numerical results hold and confirm them rigorously.

Turning now to a description of the main results, we start by introducing some notation and recalling some well-known facts. Let λ_1, σ_1 be, respectively, the principal eigenvalues of the problems

$$\begin{aligned} &d\varphi_1'' + \lambda_1 f_1(z)\varphi_1 = 0 \ \text{ in } \ (0,1), \quad \varphi_1'(0) = \varphi_1'(1) + \gamma\varphi_1(1) = 0;\\ &d\psi_1'' + \sigma_1 f_2(z)\psi_1 = 0 \ \text{ in } \ (0,1), \quad \psi_1'(0) = \psi_1'(1) + \gamma\psi_1(1) = 0, \end{aligned}$$

with the corresponding positive eigenfunctions uniquely determined by the normalization $\max_{[0,1]}\varphi_1 = \max_{[0,1]}\psi_1 = 1$. It is well known (see [14, 33]) that, if $a \leq \lambda_1/(1-q-k)$, the boundary value problem

$$\text{(1.2)}\quad du'' + a(1-q-k)uf_1(z-u) = 0, \qquad x\in(0,1), \qquad u'(0) = u'(1) + \gamma u(1) = 0$$

has zero as its unique nonnegative solution, and if $a > \lambda_1/(1-q-k)$, then it has a unique positive solution, which is denoted by ϑ and satisfies the following properties.

(A) $0 < \vartheta < z$.

(B) ϑ is continuously differentiable for $a \in (\lambda_1/(1-q-k), +\infty)$ and is pointwise increasing when a increases.

(C) $\lim_{a\to\lambda_1/(1-q-k)} \vartheta = 0$ uniformly for $x \in (0,1)$, and $\lim_{a\to\infty} \vartheta = z(x)$ for almost every $x \in (0,1)$.

(D) Let $L_a = d\frac{d^2}{dx^2} + a(1-q-k)(f_1(z-\vartheta) - \vartheta f_1'(z-\vartheta))$ be the linear operator of the above equation at ϑ. Then L_a is a differential operator in $C_B^2([0,1]) = \{u \in C^2([0,1]) : u'(0) = u'(1) + \gamma u(1) = 0\}$, and all eigenvalues of L_a are strictly negative.

Remark 1. For the other steady-state one-species problem

$$dv'' + bvf_2(z-v) = 0, \qquad x \in (0,1), \qquad v'(0) = v'(1) + \gamma v(1) = 0,$$

we have the same outcomes. Since we will need this later, we denote the unique positive solution by θ and the linear operator by $L_b = d\frac{d^2}{dx^2} + b(f_2(z-\theta) - \theta f_2'(z-\theta))$.

Next, we introduce $\hat{\lambda}_1$ as the principal eigenvalue of

$$d\hat{\varphi}_1'' + \hat{\lambda}_1 f_1(z-\theta)\hat{\varphi}_1 = 0 \ \text{ in } \ (0,1), \ \ \hat{\varphi}_1'(0) = \hat{\varphi}_1'(1) + \gamma\hat{\varphi}_1(1) = 0,$$

with the corresponding eigenfunction $\hat{\varphi}_1$ normalized by $\max_{[0,1]} \hat{\varphi}_1 = 1$.

Now we are ready to state the main results of this paper, which give analytic confirmation of some of the numerical results.

THEOREM 1.1. (EP) *has a coexistence solution if either* (i) $a > \lambda_1/(1-q-k)$, $b < \sigma_1$ *or* (ii) $a > \hat{\lambda}_1/(1-q-k)$, $b > \sigma_1$.

THEOREM 1.2. *Suppose* $b > \sigma_1$. *Then for any* $\epsilon > 0$ *small and any* $A \geq \frac{\hat{\lambda}_1}{1-q-k}$, *there exists* $M = M(\epsilon, A)$ *large such that for* $\mu \geq M$,

(i) *if* $a \in [\lambda_1/(1-q-k) + \epsilon, \hat{\lambda}_1/(1-q-k))$, *there exist at least two coexistence solutions of* (EP);

(ii) *if* $a \in [\hat{\lambda}_1/(1-q-k), A]$, *there exists a unique coexistence solution of* (EP), *and it is asymptotically stable.*

THEOREM 1.3. *Suppose* $b > \sigma_1$. *Then there exist* $\epsilon_0 > 0$ *small and* $M_0 > 0$ *large, both independent of* a, *such that if* $a \in [\hat{\lambda}_1/(1-q-k) - \epsilon_0, \hat{\lambda}_1/(1-q-k))$ *and* $\mu \geq M_0$, *then* (EP) *has exactly two coexistence solutions, one asymptotically stable and the other unstable.*

The main tools in proving Theorems 1.1–1.3 include degree theory and bifurcation theory. A crucial point of the proof for Theorems 1.2 and 1.3 is to make use of the limiting equations of (EP) which are obtained by letting $\mu \to \infty$ formally in (EP). It turns out that one of the limiting problems can be understood fully. For the other limiting problem, we can also attain some properties. Finally, perturbation theory leads to the main results of this paper.

The contents of the present paper are as follows: In section 2, some preliminary results are given which are needed in the later sections. In section 3, we consider the general case and prove Theorem 1.1. For the case μ large, the uniqueness and non-uniqueness of the coexistence solutions to (EP) are obtained in section 4. The stability is also obtained for some cases. Finally, in section 5, some numerical simulations are given complementing the analytical results.

2. Preliminaries. We begin by providing the following well-known lemmas as preliminaries without proofs. They are useful for obtaining the results in this paper.

LEMMA 2.1 (see [9, 19]). *Suppose* $q(x) \in C(\overline{\Omega})$ *and* $q(x) > 0$ *on* $\overline{\Omega}$ *in the eigenvalue problem*

$$\triangle\phi + \lambda q(x)\phi = 0, \qquad x \in \Omega, \qquad \frac{\partial\phi}{\partial n} + \gamma(x)\phi = 0, \qquad x \in \partial\Omega, \tag{2.1}$$

where $\gamma(x) \in C(\partial\Omega)$ *and* $\gamma(x) \geq 0$. *Then all eigenvalues of* (2.1) *can be listed in order*

$$0 < \lambda_1(q(x)) < \lambda_2(q(x)) \leq \cdots \to \infty$$

with the corresponding eigenfunctions $\phi_1, \phi_2, \ldots$, *where* $\phi_1 > 0$ *on* $\overline{\Omega}$, *and the principal eigenvalue*

$$\lambda_1(q) = \inf_{\phi} \frac{\int_\Omega |\nabla\phi|^2 dx + \int_{\partial\Omega} \gamma(x)\phi^2 ds}{\int_\Omega q(x)\phi^2 dx}$$

is simple. Moreover, the comparison principle holds: $\lambda_j(q_1) \leq \lambda_j(q_2)$ *for* $j \geq 1$ *if* $q_1 \geq q_2$ *on* $\overline{\Omega}$, *and strict inequality holds if* $q_1(x) \not\equiv q_2(x)$.

LEMMA 2.2 (see [27]). *Suppose* $q \in C(\overline{\Omega})$, $\gamma(x) \in C(\partial\Omega)$, *and* $\gamma(x) \geq 0$. *Let* $\sigma_1(q)$ *be the first eigenvalue of the problem* $-\triangle\omega + q\omega = \lambda\omega, x \in \Omega$, $\frac{\partial\omega}{\partial n} + \gamma(x)\omega = 0, x \in \partial\Omega$. *Then* $\sigma_1(q)$ *depends continuously on* q, *and* $q_1 \leq q_2, q_1 \not\equiv q_2$ *imply* $\sigma_1(q_1) < \sigma_1(q_2)$.

LEMMA 2.3 (see [31]). *Let* $q(x) \in C(\overline{\Omega})$ *and* $q(x) + p > 0$ *on* $\overline{\Omega}$ *with* $p > 0$, *and let* η_1 *be the first eigenvalue of the eigenvalue problem*

$$-\triangle\varphi - q(x)\varphi = \eta\varphi, \qquad x \in \Omega, \qquad \frac{\partial\varphi}{\partial n} + \gamma(x)\varphi = 0, \qquad x \in \partial\Omega,$$

where $\gamma(x) \in C(\partial\Omega)$ *and* $\gamma(x) \geq 0$. *If* $\eta_1 > 0$ *(or* $\eta_1 < 0$*), then the eigenvalue problem*

$$-\triangle\varphi + p\varphi = t(q(x) + p)\varphi, \qquad x \in \Omega, \qquad \frac{\partial\varphi}{\partial n} + \gamma(x)\varphi = 0, \qquad x \in \partial\Omega$$

has no eigenvalue less than or equal to 1 *(or has eigenvalues less than* 1*).*

Now, we introduce some more notation that will be used throughout this paper. Let X be a real Banach space, and let $W \subset X$ be a closed convex set. W is called a wedge provided that $\alpha W \subset W$ for all $\alpha \geq 0$. A wedge W is said to be a cone if $W \cap \{-W\} = 0$. Let $y \in W$, and define a wedge

$$W_y := \mathrm{cl}\{x \in X | y + \nu x \in W \ \text{ for some } \ \nu > 0\},$$

where "cl" means the closure of the set. Let S_y be the maximal linear subspace of X contained in W_y. Assume that T is a compact and Fréchet differentiable operator on X such that $y \in W$ is a fixed point of T and $T(W) \subseteq W$. Then the Fréchet derivative $T'(y)$ of T at y leaves W_y and S_y invariant (see [4, 26]). If there exists a closed linear subspace X_y of X such that $X = S_y \oplus X_y$ and W_y is generating, then the index of T at y can be found by analyzing certain eigenvalue problems in X_y and S_y as follows. Let $Q : X \to X_y$ be the projection operator of X_y along S_y. In view of Theorems 2.1 and 2.2 of [26], $\mathrm{index}_W(T, y)$ exists if the Fréchet derivative $T'(y)$ of T at y has no nonzero fixed point in W_y. Furthermore,

(1) $\mathrm{index}_W(T, y) = 0$ if $Q \circ T'(y)$ has an eigenvalue $\lambda > 1$;

(2) $\mathrm{index}_W(T, y) = \mathrm{index}_{S_y}(T'(y), 0)$ if $Q \circ T'(y)$ has no such eigenvalues.

Here $\mathrm{index}_{S_y}(T'(y), 0)$ is the index of the linear operator $T'(y)$ at 0 in the space S_y.

Next, we derive some a priori estimates for positive solutions of (EP). For an accurate estimate for positive solutions of (EP), we first consider the boundary value problem

$$\begin{aligned} &dv'' + bvf_2(z-v) + \tfrac{aq\vartheta}{1+c} f_1(z-v) = 0,\ x \in (0,1), \\ &v'(0) = v'(1) + \gamma v(1) = 0. \end{aligned} \tag{2.2}$$

LEMMA 2.4. *There exists a unique positive solution of* (2.2), *denoted by* $\bar{v}(x)$, *which satisfies* $0 < \bar{v}(x) < z$. *In particular,* $\theta < \bar{v}(x) < z$ *if* $b > \sigma_1$.

Proof. First, we claim that if $v(x)$ is a positive solution of (2.2), then $0 < v(x) < z$ and that, in addition, if $b > \sigma_1$, then $\theta < v(x) < z$. Indeed, let $\omega = z - v$. Then

$$d\omega'' - bvf_2(\omega) - \frac{aq\vartheta}{1+c} f_1(\omega) = 0, \qquad x \in (0,1), \qquad \omega'(0) = -1, \qquad \omega'(1) + \gamma\omega(1) = 0.$$

Suppose $\inf_{x\in[0,1]} \omega(x) = \omega(x_0) < 0$. Then $x_0 \notin (0,1)$. Otherwise, $\omega''(x_0) \geq 0$. By the previous equation for ω, we have $d\omega''(x_0) = bv(x_0)f_2(\omega(x_0)) + \frac{aq\vartheta(x_0)}{1+c} f_1(\omega(x_0)) < 0$, a contradiction. If $x_0 = 0$, then $\omega'(x_0) \geq 0$, contradicting the boundary condition $\omega'(0) = -1$. Similarly, we can see that $x_0 = 1$ is also impossible. Hence, one must have $\omega \geq 0, \not\equiv 0$ on [0, 1].

Assume $\omega(x_0) = 0$ for some point $x_0 \in [0,1]$. Then $x_0 = 0$ or 1 by the strong maximum principle. On the other hand, from the Hopf boundary lemma, it is easy to see that both $x = 0$ and 1 are impossible, which implies $\omega > 0$ on [0, 1]. That is, $v < z$ on [0, 1]. Moreover, since

$$dv'' + bvf_2(z-v) + \frac{aq\vartheta}{1+c} f_1(z-v) > dv'' + bvf_2(z-v),$$

it is easy to see that $v > \theta$ if $b > \sigma_1$. Hence, our assertion holds.

On the other hand, for sufficiently small $\delta > 0$, $\delta\varphi_1, z$ are the sub- and supersolutions of (2.2), respectively. It follows from the existence-comparison theorem for elliptic systems that the minimal and maximal solutions v_1, v_2 to (2.2) exist and satisfy the relation $\delta\varphi_1 < v_1 \leq v_2 < z$. Next, we show that $v_1 \equiv v_2$, to obtain the uniqueness. Since v_1, v_2 are the solutions of (2.2),

$$\begin{aligned} dv_1'' + bv_1 f_2(z-v_1) + \tfrac{aq\vartheta}{1+c} f_1(z-v_1) = 0, \\ dv_2'' + bv_2 f_2(z-v_2) + \tfrac{aq\vartheta}{1+c} f_1(z-v_2) = 0. \end{aligned}$$

Multiplying the first equation by v_2 and the second equation by v_1 and considering the integral $I = \int_0^1 d(v_1'' v_2 - v_2'' v_1)dx$, we have

$$\int_0^1 bv_1v_2(f_2(z-v_1) - f_2(z-v_2))dx + \frac{aq}{1+c}\int_0^1 \vartheta[v_2 f_1(z-v_1) - v_1 f_1(z-v_2)]dx = 0.$$

By the monotonity of $f_i (i = 1, 2)$ and since $v_1 \leq v_2$, we have $v_1 \equiv v_2$. □

The next lemma gives a priori estimates for positive solutions of (EP).

LEMMA 2.5. *Assume* (u, v) *is a nonnegative solution of* (EP) *with* $u \not\equiv 0$ *and* $v \not\equiv 0$. *Then*

1) $0 < u < \frac{\vartheta}{1+c} < \frac{z}{1+c}, 0 < v \leq \bar{v} < z$ *on* [0, 1], *where* $\bar{v}$ *defined by Lemma* 2.4;
2) $(1+c)u + v < z$ *on* [0, 1];
3) $a > \frac{\lambda_1}{1-q-k}$.

Proof. Clearly, $u > 0$ on $[0, 1]$ by the strong maximum principle and Hopf boundary lemma. Since $0 = du'' + a(1-q-k)uf_1(z-(1+c)u-v) \le du'' + a(1-q-k)uf_1(z-(1+c)u)$, it is easy to check that $u \le \frac{\vartheta}{1+c}$ and $a > \frac{\lambda_1}{1-q-k}$. Moreover, one can find that $u < \frac{\vartheta}{1+c}$ because $v \not\equiv 0$.

For v, we have

$$\begin{aligned} 0 &= dv'' + bvf_2(z-(1+c)u-v)e^{-\mu cu} + aquf_1(z-(1+c)u-v) \\ &\le dv'' + bvf_2(z-v) + \tfrac{aq\vartheta}{1+c}f_1(z-v). \end{aligned}$$

By Lemma 2.4 and the strong maximum principle, it follows that $0 < v \le \bar{v} < z$. It remains to show that $(1+c)u + v < z$ on $[0, 1]$. This proof is similar to the proof of Lemma 4.2 in [33] and so is omitted here. ∎

3. Existence of coexistence solutions. The goal of this section is to discuss the existence of coexistence solutions of (EP) in the general case and to establish Theorem 1.1.

In order to use the functional analytic framework of degree theory we introduce the spaces

$$\begin{aligned} &X = C([0,1]) \times C([0,1]), \\ &D = \{(u,v) \in X | u \le \tfrac{\vartheta}{1+c}, v \le \max_{[0,1]} \bar{v} + 1\}, \\ &W = \{(u,v) \in X | u \ge 0, v \ge 0 \ \text{ for } \ x \in [0,1]\}, \\ &D' = (\text{int}D) \cap W. \end{aligned}$$

Then W is a cone of X and D' is a bounded open set in W.

We consider the system

$$\begin{aligned} &du'' + \tau a(1-q-k)uf_1(z-(1+c)u-v) = 0, \\ &dv'' + \tau bvf_2(z-(1+c)u-v)e^{-\mu cu} + \tau aquf_1(z-(1+c)u-v) = 0, \\ &u'(0) = u'(1) + \gamma u(1) = 0, \quad v'(0) = v'(1) + \gamma v(1) = 0, \end{aligned} \tag{3.1}$$

where $\tau \in [0,1]$. Assume (u_τ, v_τ) is a nonnegative solution of (3.1). Then it is not hard to show that $u_\tau < \frac{\vartheta}{1+c}, v_\tau \le \bar{v}$ for all $\tau \in [0,1]$.

Since $f_1(z-(1+c)u-v) \ge f_1(z-(1+c)u) - K_1 v$ for some positive constant $K_1 > 0$, we can define $\mathcal{A}_\tau : X \to X, \tau \in [0,1]$ as

$$\begin{aligned} \mathcal{A}_\tau(u,v) = \ & (-d\tfrac{d^2}{dx^2} + M)^{-1}(\tau a(1-q-k)ug_1(u,v) + Mu, \\ & \tau bvg_2(u,v) + \tau aqug_1(u,v) + Mv) \end{aligned}$$

where $(-d\frac{d^2}{dx^2} + M)^{-1}$ is the inverse operator of $-d\frac{d^2}{dx^2} + M$ subject to the boundary conditions $u'(0) = u'(1) + \gamma u(1) = 0$, $g_1(u,v) = f_1(z-(1+c)u-v)$, $g_2(u,v) = f_2(z-(1+c)u-v)e^{-\mu cu}$, and M is large enough such that $M + \tau a(1-q-k)g_1(u,v) > 0$ and $M + \tau bg_2(u,v) - \tau aquK_1 > 0$ for all $(u,v) \in D'$ and $\tau \in [0,1]$. Clearly, $\mathcal{A}_\tau$ is compact. Let $\mathcal{A} = \mathcal{A}_1$. Then $\mathcal{A} : D' \to W$ is continuously differentiable. It follows from Lemma 2.5 that (EP) has nonnegative solutions if and only if the operator $\mathcal{A}$ has a fixed point in D'. Moreover, $\mathcal{A}_\tau$ has no fixed point on $\partial D'$. By the homotopic invariance of the degree, we obtain

$$\text{index}(\mathcal{A}, D', W) = \text{index}(\mathcal{A}_\tau, D', W) = \text{index}(\mathcal{A}_0, D', W) = \text{index}_W(\mathcal{A}_0, (0,0)).$$

By some standard calculations, we can obtain $\text{index}_W(\mathcal{A}_0, (0,0)) = 1$. Hence, we have the following.

LEMMA 3.1. $\text{index}(\mathcal{A}, D', W) = 1$.

LEMMA 3.2. (i) *Suppose* $a \neq \frac{\lambda_1}{1-q-k}$ *and* $b \neq \sigma_1$. *Then* $\text{index}_W(\mathcal{A}, (0,0)) = 1$ *if* $a < \frac{\lambda_1}{1-q-k}$ *and* $b < \sigma_1$, *and* $\text{index}_W(\mathcal{A}, (0,0)) = 0$ *if* $a > \frac{\lambda_1}{1-q-k}$ *or* $b > \sigma_1$.

(ii) $\text{index}_W(\mathcal{A}, (0,\theta)) = 1$ *if* $a < \frac{\hat{\lambda}_1}{1-q-k}$, *and* $\text{index}_W(\mathcal{A}, (0,\theta)) = 0$ *if* $a > \frac{\hat{\lambda}_1}{1-q-k}$.

Since the proof of this Lemma is very lengthy and quite standard, we include the proof in Appendix A. Now, we turn to prove Theorem 1.1.

Proof of Theorem 1.1. (i) If $a > \lambda_1/(1-q-k)$ and $b < \sigma_1$, then (EP) has no semitrivial nonnegative solution. In view of Lemmas 3.1 and 3.2, $\text{index}_W(\mathcal{A}, D') = 1$ and $\text{index}_W(\mathcal{A}, (0,0)) = 0$, which implies that $\mathcal{A}$ must have a positive fixed point in D'. That is, (EP) has a positive solution in D'.

(ii) If $a > \hat{\lambda}_1/(1-q-k), b > \sigma_1$, then (EP) has a semitrivial nonnegative solution $(0,\theta)$. Suppose $\mathcal{A}$ has no positive fixed point in D'. Then by Lemma 3.1 and the additivity of index,

$$\text{index}_W(\mathcal{A}, (0,0)) + \text{index}_W(\mathcal{A}, (0,\theta)) = \text{index}_W(\mathcal{A}, D') = 1.$$

However, by Lemma 3.2, $\text{index}_W(\mathcal{A}, (0,0)) = 0$, and $\text{index}_W(\mathcal{A}, (0,\theta)) = 0$ in this case, a contradiction. Hence there must exist a positive solution of (EP) in D'. This completes the proof. □

4. The effect of inhibitor. The purpose of this section is to examine the effect of the inhibitor on the multiple coexistence states. In view of the model, the effect of the inhibitor increases as the parameter μ increases. Motivated by the numerical simulations, we consider only the case of $b > \sigma_1$ and μ large enough. Using a perturbation technique, we show that the system has two positive solutions if μ is sufficiently large and the other parameters sit in some suitable range.

First of all, we observe that if a is bounded away from $\lambda_1/(1-q-k)$ and μ is large, positive solutions to (EP) are of two types. More precisely, let (u,v) be any positive solution of (EP); then either (u,v) is close to a positive solution of the problem

$$\begin{aligned} &du'' + a(1-q-k)uf_1(z-(1+c)u-v) = 0, \qquad x \in (0,1),\\ &dv'' + aquf_1(z-(1+c)u-v) = 0, \qquad x \in (0,1),\\ &u'(0) = u'(1) + \gamma u(1) = 0, \qquad v'(0) = v'(1) + \gamma v(1) = 0, \end{aligned} \tag{4.1}$$

or $(\mu u, v)$ is close to a positive solution of the problem

$$\begin{aligned} &d\omega'' + a(1-q-k)\omega f_1(z-v) = 0, \qquad x \in (0,1),\\ &dv'' + bvf_2(z-v)e^{-c\omega} = 0, \qquad x \in (0,1),\\ &\omega'(0) = \omega'(1) + \gamma\omega(1) = 0, \qquad v'(0) = v'(1) + \gamma v(1) = 0. \end{aligned} \tag{4.2}$$

Since the above two equations play an important role in determining the coexistence solutions of (EP), we first study positive solutions of (4.1) and (4.2).

LEMMA 4.1. *Assume* $a > \lambda_1/(1-q-k)$. *Then there exists a unique positive solution* $((1-q-k)\vartheta, q\vartheta)$ *of* (4.1), *and it is linearly asymptotically stable.*

Proof. Suppose that $(u,v) > 0$ solves (4.1). Let $\omega = qu - (1-q-k)v$. Then we have

$$d\omega'' = 0, \qquad \omega'(0) = \omega'(1) + \gamma\omega(1) = 0,$$

which implies $\omega \equiv 0$. That is, $v = \frac{q}{1-q-k}u$. Substituting $v = \frac{q}{1-q-k}u$ into the first

equation of (4.1), we obtain that

$$\begin{aligned} &du'' + a(1-q-k)uf_1\left(z - \frac{u}{1-q-k}\right) = 0, \qquad x \in (0,1),\\ &u'(0) = u'(1) + \gamma u(1) = 0. \end{aligned}$$

Then $u = (1-q-k)\vartheta$ due to $a > \lambda_1/(1-q-k)$, and $v = q\vartheta$. That is, (4.1) has a unique positive solution $((1-q-k)\vartheta, q\vartheta)$. It remains to establish the stability. For this purpose, noting that $c = k/(1-q-k)$, we consider the linearized eigenvalue problem

$$\begin{aligned} &d\phi'' + a(1-q-k)[f_1(z-\vartheta) - (1-q)\vartheta f_1'(z-\vartheta)]\phi\\ &\quad -a(1-q-k)^2\vartheta f_1'(z-\vartheta)\psi = -\eta\phi,\\ &d\psi'' + aq[f_1(z-\vartheta) - (1-q)\vartheta f_1'(z-\vartheta)]\phi - aq(1-q-k)\vartheta f_1'(z-\vartheta)\psi = -\eta\psi,\\ &\phi'(0) = \phi'(1) + \gamma\phi(1) = 0, \qquad \psi'(0) = \psi'(1) + \gamma\psi(1) = 0. \end{aligned} \tag{4.3}$$

Let $\omega = q\phi - (1-q-k)\psi$. Then

$$d\omega'' = -\eta\omega, \qquad \omega'(0) = \omega'(1) + \gamma\omega(1) = 0.$$

If $\omega \not\equiv 0$, then $\eta > 0$. If $\omega \equiv 0$, then $\psi = \frac{q\phi}{1-q-k}$, which leads to

$$\begin{aligned} &d\phi'' + a(1-q-k)(f_1(z-\vartheta) - \vartheta f_1'(z-\vartheta))\phi = -\eta\phi,\\ &\phi'(0) = \phi'(1) + \gamma\phi(1) = 0. \end{aligned}$$

From Lemma 2.2, $\sigma_1(a(1-q-k)(f_1(z-\vartheta) - \vartheta f_1'(z-\vartheta))) < \sigma_1(a(1-q-k)f_1(z-\vartheta)) = 0$. Hence, we can claim that $\eta > 0$. Therefore, (4.3) has no eigenvalue η with $Re\eta \le 0$ and so the stability follows. □

LEMMA 4.2. *Suppose $b > \sigma_1$ fixed. Then* (4.2) *has a positive solution if and only if $\frac{\lambda_1}{1-q-k} < a < \frac{\hat\lambda_1}{1-q-k}$. Moreover, all positive solutions of* (4.2) *are unstable.*

Proof. Suppose (ω, v) is a positive solution of (4.2). Then $a(1-q-k) = \lambda_1(f_1(z-v)) > \lambda_1(f(z)) = \lambda_1$. On the other hand,

$$0 = dv'' + bvf_2(z-v)e^{-c\omega} < dv'' + bvf_2(z-v),$$

which means $v < \theta$. Thus, $a(1-q-k) = \lambda_1(f_1(z-v)) < \lambda_1(f_1(z-\theta)) = \hat\lambda_1$. Hence, if (4.2) has a positive solution, then $\frac{\lambda_1}{1-q-k} < a < \frac{\hat\lambda_1}{1-q-k}$.

Next, we show that (4.2) has a positive solution if $\lambda_1/(1-q-k) < a < \hat\lambda_1/(1-q-k)$. To this end, we first prove that for any given $A > \hat\lambda_1/(1-q-k)$, there exists a constant $C > 0$ such that $\|\omega\|_\infty < C$ for any nonnegative solution of (4.2) with $a \in (\lambda_1/(1-q-k), A]$. At first, one can find that (4.2) has only two nonnegative solutions $(0,0)$ and $(0,\theta)$ if $a \ge \hat\lambda_1/(1-q-k)$. It remains to show that any positive solution (ω, v) of (4.2) with $\frac{\lambda_1}{1-q-k} < a < \frac{\hat\lambda_1}{1-q-k}$ satisfies $\|\omega\|_\infty < C$. Suppose this is not true. Then we may assume that there exists $a_i \to a \in [\lambda_1/(1-q-k), \hat\lambda_1/(1-q-k)]$, (ω_i, v_i) positive solutions of (4.2) with $a = a_i$ and $\|\omega_i\|_\infty \to \infty$. Set $\tilde v_i = v_i/\|v_i\|_\infty, \tilde\omega_i = \omega_i/\|\omega_i\|_\infty$. Then

$$\begin{aligned} &d\tilde\omega_i'' + a_i(1-q-k)\tilde\omega_i f_1(z - \|v_i\|_\infty\tilde v_i) = 0,\\ &d\tilde v_i'' + b\tilde v_i f_2(z-v_i)e^{-c\|\omega_i\|_\infty\tilde\omega_i} = 0,\\ &\tilde\omega_i'(0) = \tilde\omega_i'(1) + \gamma\tilde\omega_i(1) = 0, \qquad \tilde v_i'(0) = \tilde v_i'(1) + \gamma\tilde v_i(1) = 0. \end{aligned}$$

By L^p estimates and the Sobolev embedding theorem, we may assume $\tilde{\omega}_i \to \tilde{\omega} \geq 0, \not\equiv 0$, $\tilde{v}_i \to \tilde{v} \geq 0, \not\equiv 0$ in $C^1([0,1])$, and $\tilde{\omega}$ satisfies

$$d\tilde{\omega}'' + a(1-q-k)\tilde{\omega} f_1(z - B\tilde{v}) = 0, \quad \tilde{\omega}'(0) = \tilde{\omega}'(1) + \gamma\tilde{\omega}(1) = 0,$$

where $B = \lim_{i\to\infty} \|v_i\|_\infty < \infty$. (In view of the equation for v_i and $0 < v_i < \theta$, this limit exists by passing to a subsequence.) Thus $\tilde{\omega} > 0$ on $[0, 1]$ by the strong maximum principle and Hopf boundary lemma. Hence $e^{-c\omega_i} = e^{-c\|\omega_i\|_\infty \tilde{\omega}_i} \to 0$ as $i \to \infty$, which implies $v_i \to 0$, and $\tilde{v}$ satisfies

$$d\tilde{v}'' = 0, \quad \tilde{v}'(0) = \tilde{v}'(1) + \gamma\tilde{v}(1) = 0.$$

Thus $\tilde{v} \equiv 0$. This is a contradiction to $\tilde{v} \not\equiv 0$ and $\|\tilde{v}\|_\infty = 1$.

Let $\tilde{D} = \{(\omega, v) \in W : \|\omega\|_\infty \leq C + 1, \|v\|_\infty \leq \sup_{[0,1]} z + 1\}$,

$$B_\tau(\omega, v) = \left(-d\frac{d^2}{dx^2} + M\right)^{-1} \left(\tau(1-q-k)\omega f_1(z-v) + M\omega,\ bvf_2(z-v)e^{-c\omega} + Mv\right),$$

where W defined in section 3 is the positive cone of X and M is sufficiently large such that $M + \tau(1-q-k)f_1(z-v) > 0$ and $M + bf_2(z-v)e^{-c\omega} > 0$ for all $(\omega, v) \in \tilde{D}$ and $\tau \in (\lambda_1/(1-q-k), A]$.

By virtue of our a priori estimates and the homotopic invariance property of the fixed point index, we obtain $\text{index}_W(B_\tau, \tilde{D}) \equiv \text{const}$ for $\tau > \lambda_1/(1-q-k)$. On the other hand, if $a > \hat{\lambda}_1/(1-q-k)$, then (4.2) has only two nonnegative solutions $(0,0)$ and $(0,\theta)$. Hence for $\tau \in (\hat{\lambda}_1/(1-q-k), A]$, $\text{index}_W(B_\tau, \tilde{D}) = \text{index}_W(B_\tau, (0,0)) + \text{index}_W(B_\tau, (0,\theta))$. Next, we calculate the index of the two nonnegative solutions.

Let $B'_\tau(0,0)$ be the Fréchet derivative of B_τ at $(0,0)$. Then

$$B'_\tau(0,0)(\omega, v) = \left(-d\frac{d^2}{dx^2} + M\right)^{-1} (\tau(1-q-k)\omega f_1(z) + M\omega,\ bvf_2(z) + Mv)$$

for each $(\omega, v) \in X$. Therefore, an eigenvector (ω, v) of $B'_\tau(0,0)$ satisfies

$$\begin{aligned}
&-d\omega'' + M\omega = \tfrac{1}{\lambda}(\tau(1-q-k)f_1(z) + M)\omega,\\
&-dv'' + Mv = \tfrac{1}{\lambda}(bf_2(z) + M)v,\\
&\omega'(0) = \omega'(1) + \gamma\omega(1) = 0, \qquad v'(0) = v'(1) + \gamma v(1) = 0.
\end{aligned}$$

Since $b > \sigma_1, \tau > \lambda_1/(1-q-k)$, it is easy to check that $I - B'_\tau(0,0)$ is invertible in $W_{(0,0)} = \{(\omega, v) \in X : \omega \geq 0, v \geq 0\}$. Moreover, a similar argument as in the proof of Lemma 3.2 (see Appendix A) shows that $B'_\tau(0,0)$ has eigenvalues larger than 1. It follows from Theorem 2.2 of [26] that $\text{index}_W(B_\tau, (0,0)) = 0$ for $\tau > \lambda_1/(1-q-k)$.

Let $B'_\tau(0,\theta)$ denote the Fréchet derivative of B_τ at $(0,\theta)$. Then $B'_\tau(0,\theta)(\omega, v) = (-d\frac{d^2}{dx^2} + M)^{-1}(\tau(1-q-k)\omega f_1(z-\theta) + M\omega, b(f_2(z-\theta) - \theta f'_2(z-\theta))v - bc\theta f_2(z-\theta)\omega + Mv)$ for each $(\omega, v) \in X$. In order to apply Theorem 2.2 of [26], we introduce the notation $y = (0,\theta), W_y = \{(\omega, v) \in X : \omega \geq 0\}, S_y = \{(0, v) : v \in C_B([0,1])\}$, and $X_y = \{(\omega, 0) \in X : \omega \in C_B([0,1])\}$. Then $X = S_y \oplus X_y$ with projection Q given by $(\omega, v) \to (\omega, 0)$.

Suppose $(\omega, v) \in W_y$ is a fixed point of $B'_\tau(0,\theta)$. Then (ω, v) satisfies

$$\begin{aligned}
&d\omega'' + \tau(1-q-k)\omega f_1(z-\theta) = 0,\\
&dv'' + b(f_2(z-\theta) - \theta f'_2(z-\theta))v - bc\theta f_2(z-\theta)\omega = 0,\\
&\omega'(0) = \omega'(1) + \gamma\omega(1) = 0, \qquad v'(0) = v'(1) + \gamma v(1) = 0.
\end{aligned}$$

It is easy to check that $I - B'_\tau(0,\theta)$ is invertible in W_y as long as $\tau \neq \hat{\lambda}_1/(1-q-k)$. Hence, $\text{index}_W(B_\tau,(0,\theta))$ is well defined if $\tau \neq \hat{\lambda}_1/(1-q-k)$. Next, we determine the index of B_τ at $(0,\theta)$. In view of the definition $Q(\omega,v)=(\omega,0)$, every eigenfunction of $Q\circ B'_\tau(0,\theta)$ has the form $(\omega,0)$, where ω is a nonzero solution of the equation

$$-d\omega'' + M\omega = \frac{1}{\lambda}(\tau(1-q-k)f_1(z-\theta)+M)\omega,\ \omega'(0)=\omega'(1)+\gamma\omega(1)=0.$$

We can proceed further as in the proof of Lemma 3.2 (see Appendix A) to show that $\text{index}_W(B_\tau,(0,\theta))=0$ if $\tau>\hat{\lambda}_1/(1-q-k)$ and $\text{index}_W(B_\tau,(0,\theta))=1$ if $\tau<\hat{\lambda}_1/(1-q-k)$. Hence, for any $\tau \in (\hat{\lambda}_1/(1-q-k), A]$, $\text{index}_W(B_\tau,\tilde{D}) = \text{index}_W(B_\tau,(0,0)) + \text{index}_W(B_\tau,(0,\theta)) = 0$. Meanwhile, by the homotopic invariance property of the fixed point index, we can claim that $\text{index}_W(B_\tau,\tilde{D})\equiv 0$ for any $\tau \in (\lambda_1/(1-q-k), A]$. However, for $\lambda_1/(1-q-k) < \tau < \hat{\lambda}_1/(1-q-k)$, $\text{index}_W(B_\tau,(0,0)) + \text{index}_W(B_\tau,(0,\theta)) = 1 \neq \text{index}_W(B_\tau,\tilde{D})$, which implies B_τ has at least a positive fixed point in $\tilde{D}$ for $\lambda_1/(1-q-k)<\tau<\hat{\lambda}_1/(1-q-k)$. Namely, (4.2) has a positive solution when $a \in (\lambda_1/(1-q-k), \hat{\lambda}_1/(1-q-k))$.

It remains to prove the instability of any positive solution (ω_0, v_0) of (4.2). To this end, let us consider the eigenvalue problem

$$\begin{aligned} &d\varphi'' + a(1-q-k)f_1(z-v_0)\varphi - a(1-q-k)\omega_0 f_1'(z-v_0)\psi + \eta\varphi = 0,\\ &d\psi'' + b[f_2(z-v_0) - v_0 f_2'(z-v_0)]e^{-c\omega_0}\psi - cbv_0 f_2(z-v_0)e^{-c\omega_0}\varphi + \eta\psi = 0,\\ &\varphi'(0)=\varphi'(1)+\gamma\varphi(1)=0, \qquad \psi'(0)=\psi'(1)+\gamma\psi(1)=0. \end{aligned} \tag{4.4}$$

It is well known (see, e.g., [11]) that one can put this eigenvalue problem in the context of spectral theory of compact strongly positive operators with respect to the order cone $P=\{(\varphi,\psi)\in X : \varphi\geq 0, \psi\leq 0\}$. In particular, by the Krein–Rutman theorem [5, 11], one can show (4.4) has an eigenvalue η_1, which has the following properties: it is real, algebraically simple, and all other eigenvalues have their real part greater than η_1. Moreover, η_1 corresponds to an eigenfunction (φ,ψ) in the interior of P, and it is the only eigenvalue with an eigenfunction in P. Thus it is called the principal eigenvalue of (4.4). The linearized stability criterion for (ω_0, v_0) can be expressed in terms of the principal eigenvalue: (ω_0, v_0) is asymptotically stable if $\eta_1 > 0$; it is unstable if $\eta_1 < 0$. On the other hand, multiplying the first equation of (4.4) by ω_0 and integrating, we obtain

$$\eta_1\int_0^1 \varphi\omega_0 dx = a(1-q-k)\int_0^1 \omega_0^2 f_1'(z-v_0)\psi dx.$$

Noting that (φ,ψ) belongs to the interior of P, we must have $\eta_1<0$, which implies the instability. □

The rest of this section is devoted to the proof of Theorems 1.2 and 1.3, which are important in understanding the effect of the inhibitor on the number of the coexistence solutions. In order to establish Theorem 1.2, we need the following technical results.

LEMMA 4.3. *For any $\epsilon>0$ small, there exists $M=M(\epsilon)$ large such that if $a\geq\lambda_1/(1-q-k)+\epsilon$, $\mu\geq M$,* (EP) *has a positive solution $(\tilde{u},\tilde{v})$ which satisfies*

$$(1-\delta)(1-q-k)\vartheta \leq \tilde{u} \leq (1-q-k)\vartheta,\quad (1-\delta)q\vartheta \leq \tilde{v} \leq (q+\delta)\vartheta, \tag{4.5}$$

where ϑ are the unique positive solutions of (1.2)*, and $0<\delta\leq\delta_0$, where $\delta_0>0$ is small such that $(1+\delta_0)\vartheta < z$ on $[0,1]$.*

Proof. Suppose that (u, v) solves (EP). Let $\chi = (1-q-k)v - qu$. Then (u, χ) satisfies

$$\begin{aligned} &du'' + a(1-q-k)uf_1(z - \tfrac{u+\chi}{1-q-k}) = 0,\\ &d\chi'' + b(\chi + qu)f_2(z - \tfrac{u+\chi}{1-q-k})e^{-\mu c u} = 0, \end{aligned} \tag{4.6}$$

with the usual boundary conditions. Since $0 < \vartheta < z$ on $[0, 1]$, we can claim that there exists $\delta_0 > 0$ small such that $(1+\delta_0)\vartheta < z$ on $[0, 1]$. Set

$$\Sigma = \{(u, \chi) \in X : (1-\delta_0)(1-q-k)\vartheta \le u \le (1-q-k)\vartheta,\ 0 \le \chi \le \delta_0(1-q-k)\vartheta\}.$$

Next, we show (4.6) is quasi-monotone decreasing [35] on Σ provided that μ is large enough. Clearly, $h_1(u, \chi) = a(1-q-k)uf_1(z - \frac{u+\chi}{1-q-k})$ is quasi-monotone decreasing on Σ. On the other hand, let $h_2(u, \chi) = b(\chi + qu)f_2(z - \frac{u+\chi}{1-q-k})e^{-\mu c u}$. Then

$$\frac{\partial h_2(u,\chi)}{\partial u} = be^{-\mu cu}[qf_2(z - \tfrac{u+\chi}{1-q-k}) - \tfrac{\chi+qu}{1-q-k}f_2'(z - \tfrac{u+\chi}{1-q-k}) - \mu c(\chi + qu)f_2(z - \tfrac{u+\chi}{1-q-k})].$$

Recalling that $(1+\delta_0)\vartheta < z$ on $[0, 1]$, it is easy to see that $\frac{\partial h_2(u,\chi)}{\partial u} < 0$ on Σ provided that μ is large enough. That is, $h_2(u, \chi)$ is quasi-monotone decreasing on Σ provided that μ is large enough.

Let $(\bar{u}, \underline{\chi}) = ((1-q-k)\vartheta(a), 0)$ and $(\underline{u}, \bar{\chi}) = ((1-\delta)(1-q-k)\vartheta, \delta(1-q-k)\vartheta)$. By the super- and subsolution method, it suffices to show that $(\bar{u}, \underline{\chi})$ and $(\underline{u}, \bar{\chi})$ are pairs of super-sub solutions of (4.6) for large μ. That is, we need to show that the inequalities

$$\begin{aligned} &d\bar{u}'' + a(1-q-k)\bar{u}f_1(z - \tfrac{\bar{u}+\underline{\chi}}{1-q-k}) \le 0,\\ &d\underline{\chi}'' + b(\underline{\chi} + q\bar{u})f_2(z - \tfrac{\bar{u}+\underline{\chi}}{1-q-k})e^{-\mu c\bar{u}} \ge 0 \end{aligned}$$

and

$$\begin{aligned} &d\underline{u}'' + a(1-q-k)\underline{u}f_1(z - \tfrac{\underline{u}+\bar{\chi}}{1-q-k}) \ge 0,\\ &d\bar{\chi}'' + b(\bar{\chi} + q\underline{u})f_2(z - \tfrac{\underline{u}+\bar{\chi}}{1-q-k})e^{-\mu c\underline{u}} \le 0 \end{aligned}$$

hold. It is trivial to check the inequalities for $\bar{u}, \underline{\chi}$, and $\underline{u}$. For $\bar{\chi}$ to satisfy the above inequality, it suffices to have

$$e^{-\mu c(1-\delta)(1-q-k)\vartheta} \le \frac{\delta a(1-q-k)(k_2+z-\theta)}{b((1-q)\delta+q)(k_1+z-\theta)}.$$

It is well known that there exists $B > 1$ large enough such that $Bk_1 > k_2$. Hence, $\frac{k_2+z-\theta}{k_1+z-\theta} > \frac{k_2}{Bk_1}$. Since $a \ge \lambda_1/(1-q-k) + \epsilon$ and $\vartheta = \vartheta(a) \ge \vartheta(\frac{\lambda_1}{1-q-k} + \epsilon)$, we need to have only

$$e^{-\mu c(1-\delta)(1-q-k)\vartheta(\frac{\lambda_1}{1-q-k}+\epsilon)} \le \frac{\delta[\lambda_1 + \epsilon(1-q-k)]k_2}{b((1-q)\delta+q)Bk_1},$$

where $\vartheta(\frac{\lambda_1}{1-q-k}+\epsilon)$ is the unique positive solution of (1.2) with $a = \frac{\lambda_1}{1-q-k}+\epsilon$. Clearly, this inequality holds as long as μ is sufficiently large. Namely, as long as μ is large enough, we have

$$d\bar{\chi}'' + b(\bar{\chi} + q\underline{u})f_2\left(z - \frac{\underline{u}+\bar{\chi}}{1-q-k}\right)e^{-\mu c\underline{u}} \le 0.$$

Thus $(\bar{u}, \underline{\chi})$ and $(\underline{u}, \bar{\chi})$ are the order upper and lower solutions of (4.6). It follows the existence-comparison theorem for elliptic systems that (4.6) has a solution $(\tilde{u}, \tilde{\chi})$, which satisfies

$$(1-\delta)(1-q-k)\vartheta \le \tilde{u} \le (1-q-k)\vartheta, \quad 0 \le \tilde{\chi} \le \delta(1-q-k)\vartheta.$$

Noting that $v = \frac{\chi+qu}{1-q-k}$, we know that (EP) has a positive solution $(\tilde{u}, \tilde{v})$, which satisfies (4.5). □

LEMMA 4.4. *For any $\epsilon > 0$ small and any $A > \lambda_1/(1-q-k)$, there exists $M = M(\epsilon, A) > 0$ large such that if $a \in (\lambda_1/(1-q-k) + \epsilon, A]$ and $\mu \ge M$, then any positive solution of* (EP) *that satisfies* (4.5) *is nondegenerate and linearly stable.*

Proof. If $a \in (\lambda_1/(1-q-k) + \epsilon, A]$ and (u, v) satisfies (4.5), then it is easy to see that (EP) is a regular perturbation of (4.1) when μ is large. Since (4.1) has a unique positive solution $((1-q-k)\vartheta, q\vartheta)$ which is linearly stable, this lemma follows from a standard regular perturbation argument. □

As noted before, the next lemma shows rigorously that the positive solutions to (EP) are of two types.

LEMMA 4.5. *Suppose $a_i \to a \in (\frac{\lambda_1}{1-q-k}, +\infty), \mu_i \to \infty$, and (u_i, v_i) is a positive solution of* (EP) *with $(a, \mu) = (a_i, \mu_i)$. Then for large i, either (u_i, v_i) is close to $((1-q-k)\vartheta, q\vartheta)$ or $(\mu_i u_i, v_i)$ is close to (ω, v) in $C^1([0,1]) \times C^1([0,1])$, where (ω, v) is a positive solution of* (4.2). *Moreover, if $a_i \ge \frac{\hat{\lambda}_1}{1-q-k}$ for all large i and $a_i \to a$, then (u_i, v_i) converges to $((1-q-k)\vartheta, q\vartheta)$ in the C^1 norm.*

Proof. We argue by contradiction. Suppose we can find $a_i \to a \in (\frac{\lambda_1}{1-q-k}, +\infty)$, $\mu_i \to \infty$, and positive solution (u_i, v_i) bounded away from $((1-q-k)\vartheta, q\vartheta)$ and any positive solution of (4.2). First, by Lemma 2.5, $0 \le (1+c)u_i + v_i < z(x)$. Hence, by elliptic regularity and the Sobolev embedding theorems, we may assume the existence of a subsequence (if necessary), such that $u_i \to u$ and $v_i \to v$ in $C^1([0,1])$ for some $u, v \in C_B^1([0,1])$. Set $\omega_i = \mu_i u_i$ and $\chi_i = (1-q-k)v_i - qu_i$. Then (ω_i, χ_i) satisfies

$$\begin{aligned} &d\omega_i'' + a_i(1-q-k)\omega_i f_1(z-(1+c)u_i - v_i) = 0, \\ &d\chi_i'' + b(1-q-k)v_i f_2(z-(1+c)u_i - v_i)e^{-c\omega_i} = 0, \end{aligned} \tag{4.7}$$

with the usual boundary conditions. By passing to a subsequence, we have two possibilities.

Case a: $\mu_i \|u_i\|_\infty \to \infty$. In this case, one must have $\chi_i \to 0$. Indeed, it suffices to show $e^{-c\omega_i} \to 0$ almost everywhere in (0, 1) as $i \to \infty$. Let $\tilde{\omega}_i = \omega_i / \|\omega_i\|_\infty$. Then $\tilde{\omega}_i$ satisfies

$$-d\tilde{\omega}_i'' = a_i(1-q-k)\tilde{\omega}_i f_1(z-(1+c)u_i - v_i), \quad \tilde{\omega}_i'(0) = \tilde{\omega}_i'(1) + \gamma\tilde{\omega}_i(1) = 0.$$

By L^p estimates and the Sobolev embedding theorem, we may assume $\tilde{\omega}_i \to \tilde{\omega} \ge 0, \not\equiv 0$ in $C^1([0,1])$, and $\tilde{\omega}$ satisfies

$$-d\tilde{\omega}'' = a(1-q-k)\tilde{\omega} f_1(z-(1+c)u - v), \quad \tilde{\omega}'(0) = \tilde{\omega}'(1) + \gamma\tilde{\omega}(1) = 0.$$

Here $0 \le (1+c)u + v \le z$ because $0 < (1+c)u_i + v_i < z$. Therefore, $\tilde{\omega} > 0$ on [0, 1] by the strong maximum principle and Hopf boundary lemma. Thus $e^{-c\omega_i} = e^{-c\|\omega_i\|_\infty \tilde{\omega}_i} \to 0$ as $i \to \infty$, which implies $\chi_i \to 0$. Hence, $(1-q-k)v = qu$, and

$$du'' + a(1-q-k)uf_1\left(z - \frac{u}{1-q-k}\right) = 0, \qquad u'(0) = u'(1) + \gamma u(1) = 0.$$

This implies $u \equiv 0$ or $u = (1-q-k)\vartheta$. If $u \equiv 0$, then $v = \frac{q}{1-q-k}u \equiv 0$. That is, $(u_i, v_i) \to (0,0)$ as $i \to \infty$. Hence, $\tilde{u}_i = u_i/\|u_i\|_\infty$ satisfies

$$d\tilde{u}_i'' + a_i(1-q-k)\tilde{u}_i f_1(z-(1+c)u_i - v_i) = 0, \quad \tilde{u}_i'(0) = \tilde{u}_i'(1) + \gamma\tilde{u}_i(1) = 0.$$

Similarly, by L^p estimates and the Sobolev embedding theorem, we may assume that $\tilde{u}_i \to \tilde{u} \geq 0, \not\equiv 0$ in C^1, and in view of the strong maximum principle, $\tilde{u} > 0$ and satisfies

$$d\tilde{u}'' + a(1-q-k)\tilde{u}f_1(z) = 0, \quad \tilde{u}'(0) = \tilde{u}'(1) + \gamma\tilde{u}(1) = 0,$$

which means $a = \lambda_1/(1-q-k)$, a contradiction. Hence $u = (1-q-k)\vartheta$ and $v = q\vartheta$, which contradicts our assumption.

Case b: $\mu_i\|u_i\|_\infty$ is uniformly bounded, which implies $u_i \to 0$ as $i \to \infty$. Hence, $\chi_i = (1-q-k)v_i - qu_i \to (1-q-k)v$. Since ω_i is uniformly bounded, by the equation for ω_i, we may assume that $\omega_i \to \omega$ in $C^1([0,1])$. It follows from (4.7) that (ω, v) satisfies (4.2). If $\omega \geq 0, \not\equiv 0$, then the strong maximum principle tells us that $\omega > 0$. On the other hand, we claim that $v > 0$ on [0, 1]. Otherwise,

$$d\omega'' + a(1-q-k)\omega f_1(z) = 0, \qquad x \in (0,1), \qquad \omega'(0) = \omega'(1) + \gamma\omega(1) = 0,$$

which implies $a = \lambda_1/(1-q-k)$, a contradiction. Hence, (a, ω, v) is a positive solution of (4.2), which contradicts our assumption that (a_i, ω_i, v_i) is bounded away from any positive solution of (4.2). Therefore, we must have $\omega \equiv 0$. It follows that $v \equiv 0$ or $v = \theta$. Suppose $v \equiv 0$. Then $v_i \to 0$ and $\tilde{\omega}_i = \omega_i/\|\omega_i\|_\infty$ satisfies

$$d\tilde{\omega}_i'' + a_i(1-q-k)\tilde{\omega}_i f_1(z-(1+c)u_i - v_i) = 0, \quad \tilde{\omega}_i'(0) = \tilde{\omega}_i'(1) + \gamma\tilde{\omega}_i(1) = 0.$$

By L^p estimates and the Sobolev embedding theorem, we may assume $\tilde{\omega}_i \to \tilde{\omega} \geq 0, \not\equiv 0$ in $C^1([0,1])$, and by virtue of the strong maximum principle, $\tilde{\omega} > 0$ satisfies

$$d\tilde{\omega}'' + a(1-q-k)\tilde{\omega}f_1(z) = 0, \quad \tilde{\omega}'(0) = \tilde{\omega}'(1) + \gamma\tilde{\omega}(1) = 0,$$

which means $a = \lambda_1/(1-q-k)$, a contradiction. Thus $(\omega_i, v_i) \to (0, \theta)$, and hence $a_i(1-q-k) = \lambda_1(f_1(z-(1+c)u_i - v_i)) \to \lambda_1(f_1(z-\theta)) = \hat{\lambda}_1$. That is, $a_i \to \hat{\lambda}_1/(1-q-k)$. On the other hand, we can show that (4.2) has a positive solution branch bifurcating from $(a, \omega, v) = (\hat{\lambda}_1/(1-q-k), 0, \theta)$ (see Lemma 4.7). Hence, we can find $a = \tilde{a}_i \to \hat{\lambda}_1/(1-q-k)$ such that (4.2) with $a = \tilde{a}_i$ has a positive solution $(\tilde{\omega}_i, \tilde{v}_i)$ converging in L^∞ to $(0, \theta)$. Thus $(a_i, \mu_i u_i, v_i)$ is close to $(\tilde{a}_i, \tilde{\omega}_i, \tilde{v}_i)$ for i large. This again contradicts our assumption. This finishes the proof of the first part of this lemma.

Now, we prove that if $a_i \geq \hat{\lambda}_1/(1-q-k)$ for all large i and $a_i \to a$ as $i \to \infty$, then $(u_i, v_i) \to ((1-q-k)\vartheta, q\vartheta)$. Again we use an indirect argument. We suppose that this is not true. Then by the first part of this lemma and by choosing a subsequence if necessary, we may assume that $(\mu_i u_i, v_i)$ is close to a positive solution of (4.2). This implies $u_i \to 0$ as $i \to \infty$. We divide the arguments into two cases: (i) $a > \hat{\lambda}_1/(1-q-k)$ and (ii) $a = \hat{\lambda}_1/(1-q-k)$.

In case (i), suppose for any $\epsilon > 0$, there exists $a_i \to a \geq \hat{\lambda}_1/(1-q-k) + \epsilon$ such that $u_i \to 0$ as $\mu_i \to \infty$. Then $\omega_i = \mu_i u_i, \chi_i = (1-q-k)v_i - qu_i$ satisfy (4.7). Passing to a subsequence, we have two possibilities.

Case a: $\|\omega_i\|_\infty = \mu_i \|u_i\|_\infty \to \infty$. Noting Lemma 2.5, we claim that $\chi_i \to 0$ as before, which means $v_i = \frac{\chi_i + qu_i}{1-q-k} \to 0$. Let $\tilde{u}_i = u_i/\|u_i\|_\infty$. Then by L^p estimates and the Sobolev embedding theorem, we may assume $\tilde{u}_i \to \tilde{u}$ in $C^1([0,1])$, and by the strong maximum principle, $\tilde{u} > 0$. Moreover, $\tilde{u}$ satisfies

$$d\tilde{u}'' + a(1-q-k)\tilde{u}f_1(z) = 0, \qquad \tilde{u}'(0) = \tilde{u}'(1) + \gamma\tilde{u}(1) = 0,$$

which implies $a = \lambda_1/(1-q-k)$, a contradiction.

Case b: $\|\omega_i\|_\infty = \mu_i\|u_i\|_\infty \leq C$. Then by using a priori estimates for v_i (see Lemma 2.5), we may assume that $(\omega_i, v_i) \to (\omega, v)$ in $C^1([0,1])$, where $\omega, v \geq 0$ on [0, 1]. Noting that $\chi_i = (1-q-k)v_i - qu_i$ and $u_i \to 0$, one has $\chi_i \to (1-q-k)v$. It follows from the equations in (4.7) that (ω, v) satisfies (4.2). Namely, (ω, v) is exactly the nonnegative solution of (4.2). If $\omega \geq 0, \not\equiv 0$, then by the strong maximum principle, $\omega > 0$. Hence, $(\hat{\lambda}_1 <) a(1-q-k) = \lambda_1(f_1(z-v))$, which implies $v \not\equiv 0$. It follows from the strong maximum principle that $v > 0$. This contradicts Lemma 4.2; that is, (4.2) has no positive solution provided that $a > \hat{\lambda}_1/(1-q-k)$. Therefore, $\omega \equiv 0$ and $v = \theta$ (the possibility $v \equiv 0$ can be ruled out by similar arguments as in the proof of the first part of this lemma). Set $\tilde{u}_i = u_i/\|u_i\|_\infty$. A similar argument shows that $a = \hat{\lambda}_1/(1-q-k)$, a contradiction. Therefore, our assertion holds.

In case (ii), since $a_i \to \hat{\lambda}_1/(1-q-k)$ and $u_i \to 0$, one can assert that $v_i \to \theta$ and $\mu_i u_i \to 0$ in C^1 norm. Indeed, let $\tilde{u}_i = u_i/\|u_i\|_\infty$. Then $\tilde{u}_i$ satisfies

$$d\tilde{u}_i'' + a_i(1-q-k)\tilde{u}_i f_1(z-(1+c)u_i - v_i) = 0, \quad \tilde{u}_i'(0) = \tilde{u}_i'(1) + \gamma\tilde{u}_i(1) = 0.$$

Similarly, we may suppose $\tilde{u}_i \to \tilde{u}$ in $C^1([0,1])$ and $\tilde{u} > 0$ satisfies

$$d\tilde{u}'' + \hat{\lambda}_1\tilde{u}f_1(z-v) = 0, \quad \tilde{u}'(0) = \tilde{u}'(1) + \gamma\tilde{u}(1) = 0, \tag{4.8}$$

which implies $v \not\equiv 0$; otherwise, $\hat{\lambda}_1 = \lambda_1$, a contradiction. Noting that $a_i \to \hat{\lambda}_1/(1-q-k), u_i \to 0, v_i \to v \not\equiv 0$, and

$$dv_i'' + bv_i f_2(z-(1+c)u_i - v_i)e^{-c\mu_i\|u_i\|_\infty\tilde{u}_i} + a_i q u_i f_1(z-(1+c)u_i - v_i) = 0,$$

we can show that $\mu_i\|u_i\|_\infty$ is uniformly bounded. Hence we may assume that $\mu_i u_i \to \omega$ in $C^1([0,1])$ for some $\omega \geq 0$. Letting $i \to \infty$, we must have $dv'' + bvf_2(z-v) \geq 0$, which means $v \leq \theta$. Multiplying (4.8) by $\hat{\varphi}_1$, integrating over [0, 1], and applying Green's formula, we obtain

$$\hat{\lambda}_1 \int_0^1 \tilde{u}\hat{\varphi}_1(f_1(z-v) - f_1(z-\theta))dx = 0,$$

which implies $v = \theta$ since $v \leq \theta$. Moreover, $\tilde{u} = \hat{\varphi}_1$. That is, $v_i \to \theta$. Next, we show $\omega \equiv 0$. If $\omega \geq 0, \not\equiv 0$, then $\omega > 0$ by the strong maximum principle. Noting that $a_i \to \hat{\lambda}_1/(1-q-k), u_i \to 0, v_i \to \theta, \mu_i u_i \to \omega$, we have

$$d\theta'' + b\theta f_2(z-\theta)e^{-c\omega} = 0, \quad \theta'(0) = \theta'(1) + \gamma\theta(1) = 0.$$

This means $b = \lambda_1(f_2(z-\theta)e^{-c\omega}) > \lambda_1(f_2(z-\theta)) = b$, a contradiction. Hence our assertion holds. Next, we show $(1+c)u_i + v_i < \theta$ for large i. Let $Q_i = (1+c)u_i + v_i$.

Clearly, $Q_i \to \theta$, and

$$dQ_i'' + a_i u_i f_1(z - Q_i) + b v_i f_2(z - Q_i) e^{-c\mu_i u_i} = 0, \quad Q_i'(0) = Q_i'(1) + \gamma Q_i(1) = 0.$$

Hence

$$\begin{aligned}
&dQ_i'' + bQ_i f_2(z - Q_i) \\
&= u_i[b(1+c)f_2(z - Q_i) - a_i f_1(z - Q_i)] + b v_i f_2(z - Q_i)[1 - e^{-c\mu_i u_i}] \\
&= u_i[b(1+c)f_2(z - Q_i) - a_i f_1(z - Q_i) + b v_i f_2(z - Q_i) c\mu_i + O(\mu_i^2 u_i)] \\
&= u_i[b(1+c)f_2(z - Q_i) - a_i f_1(z - Q_i) + (bcv_i f_2(z - Q_i) + O(\mu_i u_i))\mu_i].
\end{aligned}$$

Since $\mu_i u_i \to 0$ and $\mu_i \to \infty$, we have $dQ_i'' + bQ_i f_2(z - Q_i) > 0$ for large i, which implies $Q_i < \theta$ for large i.

Now multiplying the equation for u_i by $\hat{\varphi}_1$ and integrating over [0, 1], we obtain

$$\int_0^1 [a_i(1 - q - k)f_1(z - Q_i) - \hat{\lambda}_1 f_1(z - \theta)]\hat{\varphi}_1 u_i dx = 0.$$

Since $a_i(1 - q - k) \geq \hat{\lambda}_1$ and $f_1(z - Q_i) > f_1(z - \theta)$ for large i, $\int_0^1 [a_i(1 - q - k)f_1(z - Q_i) - \hat{\lambda}_1 f_1(z - \theta)]\hat{\varphi}_1 u_i dx > 0$ for all large i, a contradiction. Hence $(u_i, v_i) \to ((1 - q - k)\vartheta, q\vartheta)$ in the C^1 norm when $a_i \geq \frac{\hat{\lambda}_1}{1-q-k}$ for all large i, $a_i \to a$, and $\mu_i \to \infty$. □

LEMMA 4.6. (i) *For any* $A \geq \frac{\hat{\lambda}_1}{1-q-k}$, *there exists* $M > 0$ *large such that if* $\mu > M$ *and* $a \in [\frac{\hat{\lambda}_1}{1-q-k}, A]$, *then any positive solution* (u, v) *of* (EP) *is nondegenerate and linearly asymptotically stable, and* $\mathrm{index}_W(\mathcal{A}, (u, v)) = 1$.

(ii) *For any* $\epsilon, \delta > 0$ *small, there exists* $M_{\epsilon,\delta} > 0$ *large such that if* $a \in [\frac{\lambda_1}{1-q-k} + \epsilon, \frac{\hat{\lambda}_1}{1-q-k})$ *and* $\mu \geq M_{\epsilon,\delta}$ *and if* (u, v) *is a positive solution of* (EP), *then either* (a) $\|u - (1 - q - k)\vartheta\|_{C^1} + \|v - q\vartheta\|_{C^1} < \delta$ *or* (b) $\|\mu u - \tilde{\omega}\|_{C^1} + \|v - \tilde{v}\|_{C^1} + \|a - \tilde{a}\|_{C^1} < \delta$, *where* $(\tilde{\omega}, \tilde{v})$ *is a positive solution of* (4.2) *with* $a = \tilde{a}$. *Moreover, if* (a) *occurs, then* (u, v) *is nondegenerate linearly asymptotically stable and* $\mathrm{index}_W(\mathcal{A}, (u, v)) = 1$.

Proof. (i) We prove the nondegeneracy and linear stability first. For this purpose, we consider the linearized eigenvalue problem

$$\begin{aligned}
&d\phi'' + a(1 - q - k)[f_1(z - (1+c)u - v) - (1+c)uf_1'(z - (1+c)u - v)]\phi \\
&\quad - a(1 - q - k)uf_1'(z - (1+c)u - v)\psi = -\eta\phi, \\
&d\psi'' + [b(f_2(z - (1+c)u - v) - vf_2'(z - (1+c)u - v))e^{-\mu cu} \\
&\quad - aquf_1'(z - (1+c)u - v)]\psi \\
&\quad - bv[f_2'(z - (1+c)u - v)(1+c) + \mu c f_2(z - (1+c)u - v)]e^{-\mu cu}\phi \\
&\quad + aq[f_1(z - (1+c)u - v) - (1+c)uf_1'(z - (1+c)u - v)]\phi = -\eta\psi, \\
&\phi'(0) = \phi'(1) + \gamma\phi(1) = 0, \qquad \psi'(0) = \psi'(1) + \gamma\psi(1) = 0.
\end{aligned}$$

By Lemma 4.5, (EP) has no positive solution with a small u component when $a \in [\frac{\hat{\lambda}_1}{1-q-k}, A]$ and μ is large. Therefore, we can establish this assertion by a simple variant of the proof of Lemma 4.4.

Next, we prove the statement concerning the fixed point index. Since any positive solution (u, v) to (EP) is nondegenerate, we have

$$\mathrm{index}_W(\mathcal{A}, (u, v)) = \mathrm{index}_X(\mathcal{A}, (u, v)) = \mathrm{index}_X(\mathcal{A}'(u, v), (0, 0)).$$

Let $Q_t(\phi,\psi) = (-d\frac{d^2}{dx^2} + M)^{-1}(f,g)$, where $0 \le t \le 1$ and

$$\begin{aligned} f = \;& a(1-q-k)[f_1(z-(1+c)u-v) - (1+c)uf_1'(z-(1+c)u-v)]\phi + M\phi \\ & -ta(1-q-k)uf_1'(z-(1+c)u-v)\psi, \\ g = \;& [b(f_2(z-(1+c)u-v) - vf_2'(z-(1+c)u-v))e^{-\mu cu} \\ & -taquf_1'(z-(1+c)u-v)]\psi + M\psi \\ & -bv[(1+c)f_2'(z-(1+c)u-v) + \mu cf_2(z-(1+c)u-v)]e^{-\mu cu}\phi \\ & +aq[f_1(z-(1+c)u-v) - (1+c)uf_1'(z-(1+c)u-v)]\phi. \end{aligned}$$

Then there exists a neighborhood $U_\delta \subset X$ of $(0,0)$ such that Q_t has no fixed point on ∂U_δ provided μ is large enough. Moreover, we can choose U_δ such that $\mathcal{A}'(u,v)(\phi,\psi) = (\phi,\psi)$ has only the solution $(\phi,\psi) = (0,0)$ in U_δ. By similar arguments as in Lemma 2.5 in [7] and Theorem 3.1 in [8], we can show $\operatorname{index}_X(\mathcal{A}'(u,v),(0,0)) = \operatorname{index}_X(\mathcal{A}'(u,v),U_\delta) = \operatorname{index}_X(Q_1,U_\delta) = \operatorname{index}_X(Q_0,U_\delta) = \operatorname{index}_X(Q_0,(0,0)) = 1$. Hence $\operatorname{index}_W(\mathcal{A},(u,v)) = 1$.

(ii) The statement on the location of the positive solutions follows directly from Lemma 4.5. The other statements are proved in the same way as in (i) above. □

Proof of Theorem 1.2. (i) For any $\epsilon > 0$ small, let $M = \max\{M(\epsilon), M(\epsilon, \hat{\lambda}_1/(1-q-k))\}$, where $M(\epsilon), M(\epsilon,\hat{\lambda}_1/(1-q-k))$ are given by Lemmas 4.3 and 4.4, respectively. Assume that for $\mu \ge M$ and $a \in [\lambda_1/(1-q-k)+\epsilon, \hat{\lambda}_1/(1-q-k))$, (EP) has only a unique positive solution $(\tilde{u},\tilde{v})$ as shown in Lemma 4.3. In view of Lemma 4.4, $I - \mathcal{A}'(\tilde{u},\tilde{v})$ is invertible in X and $\mathcal{A}'(\tilde{u},\tilde{v})$ has no real eigenvalue greater than one, where $\mathcal{A}'(\tilde{u},\tilde{v})$ is the Fréchet derivative of $\mathcal{A}$ at $(\tilde{u},\tilde{v})$. We can argue in the same way as in the proof of Theorem 3.1 in [8] to draw a conclusion that $\operatorname{index}_W(\mathcal{A},(\tilde{u},\tilde{v})) = 1$. By virtue of Lemmas 3.1 and 3.2, it follows that

$$1 = \operatorname{index}_W(\mathcal{A},D') = \operatorname{index}_W(\mathcal{A},(0,0)) + \operatorname{index}_W(\mathcal{A},(0,\theta)) + \operatorname{index}_W(\mathcal{A},(\tilde{u},\tilde{v})) = 2.$$

This contradiction completes the proof.

(ii) It follows from Lemma 4.6 that for any $A \ge \frac{\hat{\lambda}_1}{1-q-k}$, there exists $M > 0$ large such that any positive solution (u,v) of (EP) is nondegenerate and linearly asymptotically stable for $a \in [\frac{\hat{\lambda}_1}{1-q-k}, A]$ and $\mu \ge M$. Hence, it suffices to show the uniqueness. Set $D_1 = \{(u,v) \in X : \frac{(1-q-k)}{2}\vartheta < u < \frac{\vartheta}{1+c}, \frac{q}{2}\vartheta < v < \max_{[0,1]}\bar{v} + 1\}$, and define $F_\tau : D_1 \to W$ by

$$F_\tau(u,v) = \left(-d\frac{d^2}{dx^2} + K\right)^{-1}(a(1-q-k)ug_1(u,v)+Ku,\ \tau bvg_2(u,v)+aqug_1(u,v)+Kv),$$

where $\tau \in [0,1]$, $g_1(u,v) = f_1(z-(1+c)u-v)$, $g_2(u,v) = f_2(z-(1+c)u-v)e^{-\mu cu}$, and K is large enough such that $K+a(1-q-k)g_1(u,v) > 0$ and $K+\tau bg_2(u,v)-aquK_1 > 0$ (K_1 is given in section 3) for all $(u,v) \in D_1$ and $\tau \in [0,1]$. Clearly, F_τ is a compact and continuously differentiable operator. Moreover, it follows from Lemma 4.5 that there exists $M > 0$ large such that if $\mu \ge M$ and $a \in [\hat{\lambda}_1/(1-q-k), A]$, then any positive solution (u,v) of (EP) is close to $((1-q-k)\vartheta, q\vartheta)$. Hence, $(u,v) \in D_1$ for $a \in [\hat{\lambda}_1/(1-q-k), A]$ and $\mu \ge M$. Namely, if $a \in [\hat{\lambda}_1/(1-q-k), A]$ and $\mu \ge M$, then (u,v) is a positive solution of (EP) if and only if it is a fixed point of F_1 in D_1. Again by Lemma 4.5, F_τ has no fixed point on ∂D_1 for $a \in [\hat{\lambda}_1/(1-q-k), A]$ and $\mu \ge M$. Therefore, $\operatorname{index}_W(F_\tau, D_1) \equiv$ const. In particular, $\operatorname{index}_W(F_1,D_1) = \operatorname{index}_W(F_0,D_1)$. It is easy to show that F_0 has a unique fixed point $((1-q-k)\vartheta, q\vartheta)$ in D_1 and $\operatorname{index}_W(F_0,D_1) = \operatorname{index}_W(F_0,((1-q-k)\vartheta, q\vartheta)) = 1$. Hence, $\operatorname{index}_W(F_1,D_1) = 1$.

As mentioned before, from Lemma 4.6, we know that, for $\mu > M$ and $a \in [\hat{\lambda}_1/(1-q-k), A]$, all fixed points of F_1 in D_1 are nondegenerate and linearly stable. Hence by a compactness argument it is easy to show that there are at most finitely many fixed points of F_1, which are denoted by $\{(u_i, v_i)\}_{i=1}^n$. By Lemma 4.6 again, $\text{index}_W(\mathcal{A}, (u_i, v_i)) = 1$. In view of the additivity property of the fixed point index, we have for $a \in [\hat{\lambda}_1/(1-q-k), A]$

$$n = \sum_{i=1}^{n} \text{index}_W(F_1, (u_i, v_i)) = \text{index}_W(F_1, D_1) = 1.$$

Hence for $\mu \geq M$ and $a \in [\hat{\lambda}_1/(1-q-k), A]$, (EP) has only a unique positive solution and it is stable. The proof of Theorem 1.2 is completed. □

Next we wish to establish Theorem 1.3, but first we give the following lemma, which is crucial in proving Theorem 1.3.

LEMMA 4.7. *There exists $\epsilon > 0$ small such that if $\hat{\lambda}_1/(1-q-k) - \epsilon \leq a < \hat{\lambda}_1/(1-q-k)$, then* (4.2) *has a unique positive solution.*

Proof. Here, we prove this lemma by the local bifurcation theorem of Crandall and Rabinowitz [3]. We regard a as the bifurcation parameter and try to construct a positive solution branch from the semitrivial nonnegative solution branch $\{(a, 0, \theta) : a \in R^+\}$.

After some standard calculations, we obtain that $(\hat{\lambda}_1/(1-q-k), 0, \theta)$ is a bifurcation point. Close to this bifurcation point, (4.2) has a positive solution $(a(s), s(\hat{\varphi}_1 + \Phi(s)), \theta + s(\chi_1 + \Psi(s)))$ $(0 < s \ll 1)$, where $a(0) = \hat{\lambda}_1/(1-q-k), \chi_1 = bcL_b^{-1}(\theta f_2(z-\theta)\hat{\varphi}_1) < 0, \Phi(0) = \Psi(0) = 0$. Putting this positive solution into the first equation of (4.2), dividing by s, and differentiating with respect to s, it follows that the derivative of $a(s)$ with respect to s at $s = 0$ is less than 0. That is, $a'(0) < 0$, which implies the positive solution bifurcation branch is to the left. Namely, there exists $\epsilon > 0$ sufficiently small such that if $\hat{\lambda}_1/(1-q-k) - \epsilon \leq a < \hat{\lambda}_1/(1-q-k)$, then (4.2) has a positive solution with the form of $(a(s), s(\hat{\varphi}_1 + \Phi(s)), \theta + s(\chi_1 + \Psi(s)))$ $(0 < s \ll 1)$. Furthermore, it is unique as long as ϵ is sufficiently small. In fact, it is also unstable. We leave the proof of this assertion to the reader. □

Proof of Theorem 1.3. First we show that for large μ (EP) has a unique asymptotically stable positive solution which is close to $((1-q-k)\vartheta, q\vartheta)$. In fact, if we choose $\delta > 0$ small enough in Lemma 4.6, then by Lemma 4.6 any positive solution of (EP) close to $((1-q-k)\vartheta, q\vartheta)$ is nondegenerate and linearly stable. Next, by a simple variant of the proof of part (ii) of Theorem 1.2, we can find that (EP) has only one positive solution of type (a), and it is asymptotically stable.

On the other hand, we can show that (EP) has a unique unstable positive solution of type (b). If this assertion holds, then by Lemma 4.6 our proof is completed. Hence, our main task is to establish this assertion.

Suppose (u, v) is a positive solution of type (b) of (EP). It follows from Lemmas 4.6 and 4.7; $(\mu u, v)$ is close to (ω, v), where (ω, v) is the unique positive solution of (4.2). Hence to prove the uniqueness, it suffices to show that, for $a \in [\hat{\lambda}_1/(1-q-k) - \epsilon_0, \hat{\lambda}_1/(1-q-k))$ and $\mu \geq M_0$, there is a unique pair $(\mu u, v)$ close to (ω, v) for certain ϵ_0 and M_0.

Set $\hat{u} = \mu u, \epsilon = \frac{1}{\mu}$, and consider the following problem with the usual boundary conditions

$$\begin{aligned} &d\hat{u}'' + a(1-q-k)\hat{u}f_1(z-(1+c)\epsilon\hat{u}-v) = 0, \qquad x \in (0,1), \\ &dv'' + bvf_2(z-(1+c)\epsilon\hat{u}-v)e^{-c\hat{u}} + aq\epsilon\hat{u}f_1(z-(1+c)\epsilon\hat{u}-v) = 0. \end{aligned} \tag{4.9}$$

Clearly, (u, v) is a solution of (EP) if and only if $(\mu u, v)$ is a solution of (4.9) with $\epsilon = 1/\mu$. Thus it suffices to prove the uniqueness of (4.9). For fixed $\epsilon \geq 0$, regarding a as a bifurcation parameter, we see that $(\hat{\lambda}_1/(1-q-k), 0, \theta)$ is a simple bifurcation point of (4.9). By virtue of a variant of Theorem 1 in Crandall and Rabinowitz [2], there exists $\delta_1 > 0$ and C^1 curves

$$\Gamma_\epsilon = \{(a(\epsilon, s), \hat{u}(\epsilon, s), v(\epsilon, s)) : 0 < s < \delta_1\}, \qquad 0 \leq \epsilon \leq \delta_1,$$

such that if $0 \leq \epsilon \leq \delta_1$, then all positive solutions of (4.9) close to $(\hat{\lambda}_1/(1-q-k), 0, \theta) = (a(0,0), \hat{u}(0,0), v(0,0))$ lie on the curve Γ_ϵ. Hence, we need show only that for fixed ϵ, Γ_ϵ uniformly cover an a-range: $a \in [\hat{\lambda}_1/(1-q-k) - \epsilon_0, \hat{\lambda}_1/(1-q-k))$ only once for suitably chosen ϵ_0. It is easy to obtain

$$\frac{\partial a}{\partial s}(0,0) = \frac{\hat{\lambda}_1 \int_0^1 \hat{\varphi}_1 f_1'(z-\theta)\chi_1}{(1-q-k)\int_0^1 \hat{\varphi}_1^2 f_1(z-\theta)} < 0$$

based on $\chi_1 = L_b^{-1}(bc\theta f_2(z-\theta)\hat{\varphi}_1) < 0$. By taking δ_1 small, we may assume that $\frac{\partial a}{\partial s}(\epsilon, s) < 0$ for $0 \leq \epsilon, s \leq \delta_1$. Hence $\hat{\lambda}_1/(1-q-k) - a(0, \delta_1) = a(0,0) - a(0,\delta_1) > 0$. Since $a(\epsilon, s)$ is continuous, there exists $\delta \in (0, \delta_1]$ such that $\epsilon_0 = \min_{0 \leq \epsilon \leq \delta}(\hat{\lambda}_1/(1-q-k) - a(\epsilon, \delta_1)) > 0$. Therefore, if $a \geq \hat{\lambda}_1/(1-q-k) - \epsilon_0$, then $a(\epsilon, \delta_1) \leq a$ for any $\epsilon \in [0, \delta]$. This shows that for each $\epsilon \in [0, \delta]$, Γ_ϵ covers the a-range $[\hat{\lambda}_1/(1-q-k) - \epsilon_0, \hat{\lambda}_1/(1-q-k))$. Moreover, since $\frac{\partial a}{\partial s}(\epsilon, s) < 0$ for $0 \leq \epsilon, s \leq \delta_1$, each curve covers the range only once. By taking $M_0 = 1/\delta$, we see that, for $\mu \geq M_0$ and $\hat{\lambda}_1/(1-q-k) - \epsilon_0 \leq a < \hat{\lambda}_1/(1-q-k)$, (EP) has exactly one positive solution of type (b).

It remains to show the instability. A simple computation shows that η is an eigenvalue of the linearization of (EP) at (u, v) with eigenfunction (ϕ, ψ) if and only if it is an eigenvalue of that of (4.9) with $\epsilon = 1/\mu$ at $(\mu u, v)$ with eigenfunction $(\mu\phi, \psi)$. Hence it suffices to show that the linearization of (4.9) has a negative eigenvalue at any point on the bifurcation curves Γ_ϵ. This follows from a simple application of a variant of Theorem 1.16 in Crandall and Rabinowitz [3]. More precisely, by Lemma 1.3 in [3], we can obtain a variant of Corollary 1.13 there. That is, there exist $\tau > 0$ and C^1 functions $\gamma : (\hat{\lambda}_1/(1-q-k) - \tau, \hat{\lambda}_1/(1-q-k) + \tau) \times (-\tau, \tau) \to R^1$ and $\beta : (-\tau, \tau) \times (-\tau, \tau) \to R^1$ such that $\gamma(a, \epsilon)$ is a simple eigenvalue of the linearization of (4.9) at $(a, 0, \theta)$ and $\beta(s, \epsilon)$ is a simple eigenvalue of the linearization of (4.9) at $(a, u, v) = (a(\epsilon, s), \hat{u}(\epsilon, s), v(\epsilon, s))$ with $0 \leq \epsilon, s \leq \tau$. Moreover, $\gamma(\hat{\lambda}_1/(1-q-k), \epsilon) = \beta(0, \epsilon) = 0$. It is easy to check that, in fact, $\gamma(a, \epsilon)$ is a simple eigenvalue of

$$d\phi'' + a(1-q-k)\phi f_1(z-\theta) = -\gamma(a, \epsilon)\phi$$

with the usual boundary conditions. Hence, $\frac{\partial \gamma}{\partial a}(\hat{\lambda}_1/(1-q-k), \epsilon) < 0$ because of the monotone property. Then it follows from Theorem 1.16 in [3] that $\beta(s, 0) \sim -s\frac{\partial a}{\partial s}(0, s)\frac{\partial \gamma}{\partial a}(\hat{\lambda}_1/(1-q-k), 0)$ for $0 < s \ll 1$, which implies $\beta(s, 0) < 0$ and the positive solution of type (b) of (EP) is unstable. This completes the proof of Theorem 1.3. □

5. Numerical simulation. In this section, we present some results of our numerical simulations that complement the analytic results of the previous sections. All computations in this section are performed with Matlab.

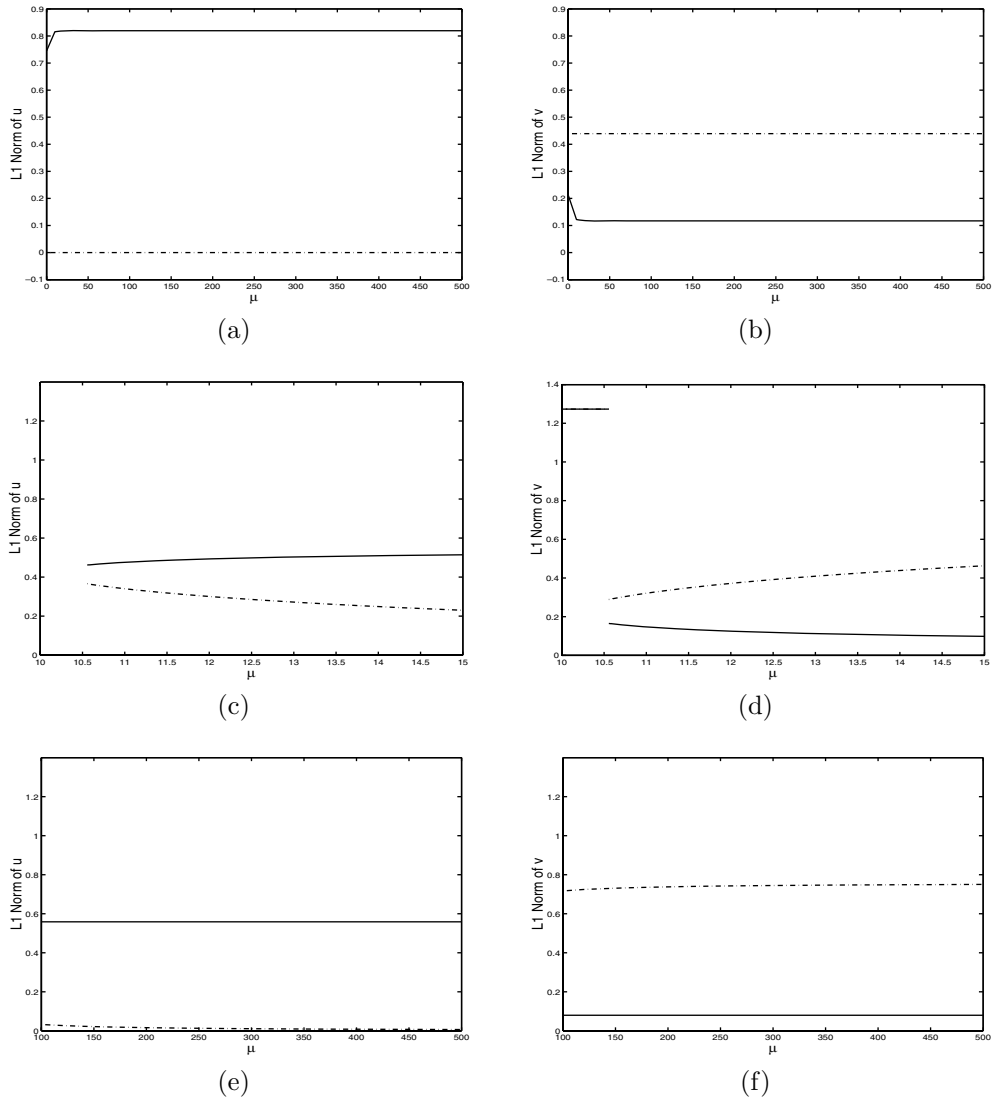

FIG. 1. *Effect of μ:* (a) *and* (b) *are the bifurcation diagrams of u and v, respectively, with respect to μ with the parameters $a = 4, b = 1.5$. Here the two solid lines in* (a) *and* (b) *represent the L^1 norm of components u and v of the stable coexistence solution (u, v), respectively. The two dashed lines in* (a) *and* (b) *represent the L^1 norm of components 0 and θ of the unstable semitrivial nonnegative solution $(0, \theta)$, respectively. Similarly, the pair of* (c) *and* (d) *and the pair of* (e) *and* (f) *are the bifurcation diagrams of u and v, respectively, with respect to μ all with $a = 2.5, b = 5$. Here solid lines denote the stable solutions and dashed lines represent the unstable solutions. Note that $\mu \in [10, 15]$ in* (c) *and* (d) *and that $\mu \in [100, 500]$ in* (e) *and* (f). *The aim of plotting in the above domain is to explicitly show the change tendency of u and v.*

Several parameters are common for all simulations: the diffusion rate $d = 1.0$ and parameters $k_1 = 1, k_2 = 1.1, \gamma = 1, q = 0.1$, and $k = 0.2$. The other parameters are varied in order to illustrate different outcomes. In Figures 1 and 2, the vertical axis is the L_1 norm of u or v. In Figures 3 and 4, the coexistence solutions to (PP) are plotted.

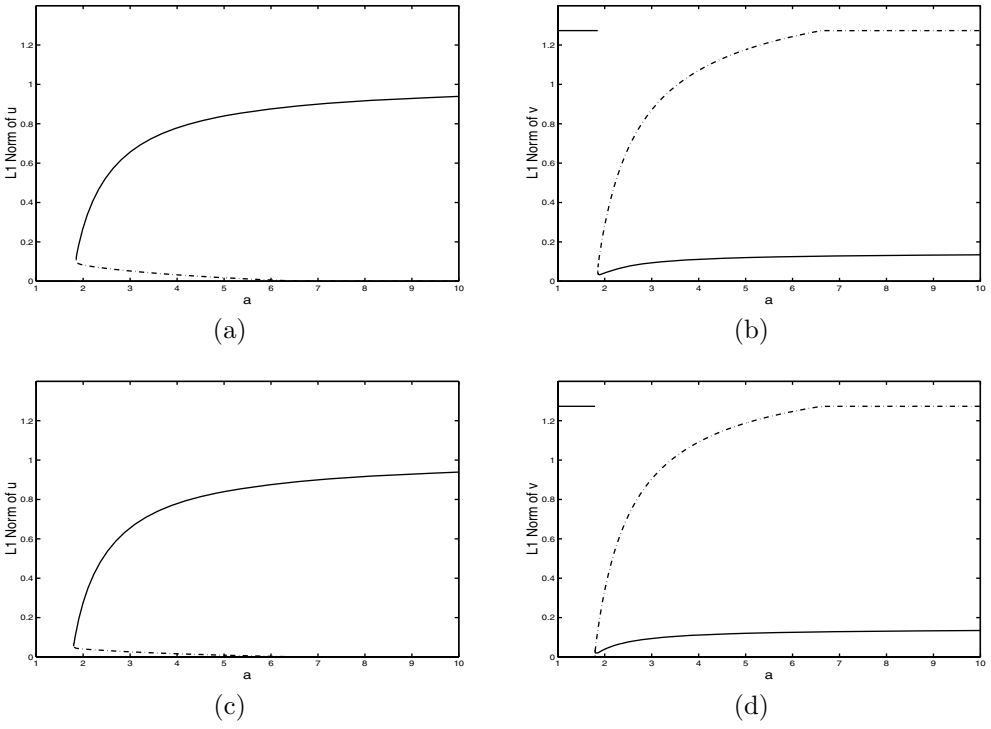

FIG. 2. *Bifurcation diagrams with respect to a:* (a) *and* (b) *with* $\mu = 50, b = 5$ *and* (c) *and* (d) *with* $\mu = 100, b = 5$ *also represent the bifurcation graphs of* u *and* v *with respect to* a*, respectively. Here solid lines denote the stable solutions and dashed lines represent the unstable solutions.*

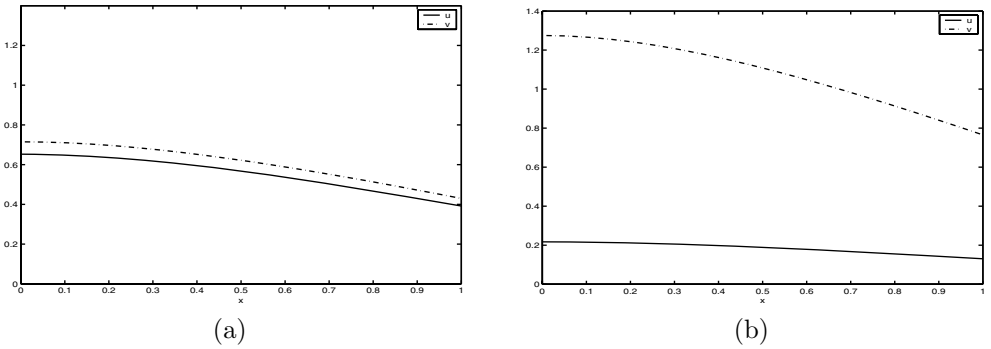

FIG. 3. *Two coexistence solutions of* (PP) *with* $\mu = 1, a = 6.4, b = 5$*. This indicates* (PP) *also has two coexistence solutions when* μ *is not large.*

The simulations presented below illustrate the following major outcomes of the plasmid-bearing and plasmid-free competition in the unstirred chemostat with an internal inhibitor.

(1) If u is a better competitor than v, there exists only a unique globally stable coexistence state of (PP) for any $\mu > 0$ (see Figures 1(a) and 1(b)). That is, if u is a better competitor, then it cannot eliminate its competitor but forces the existence of a coexistence state. This reflects the difference between the plasmid model and the standard competition model in the chemostat.

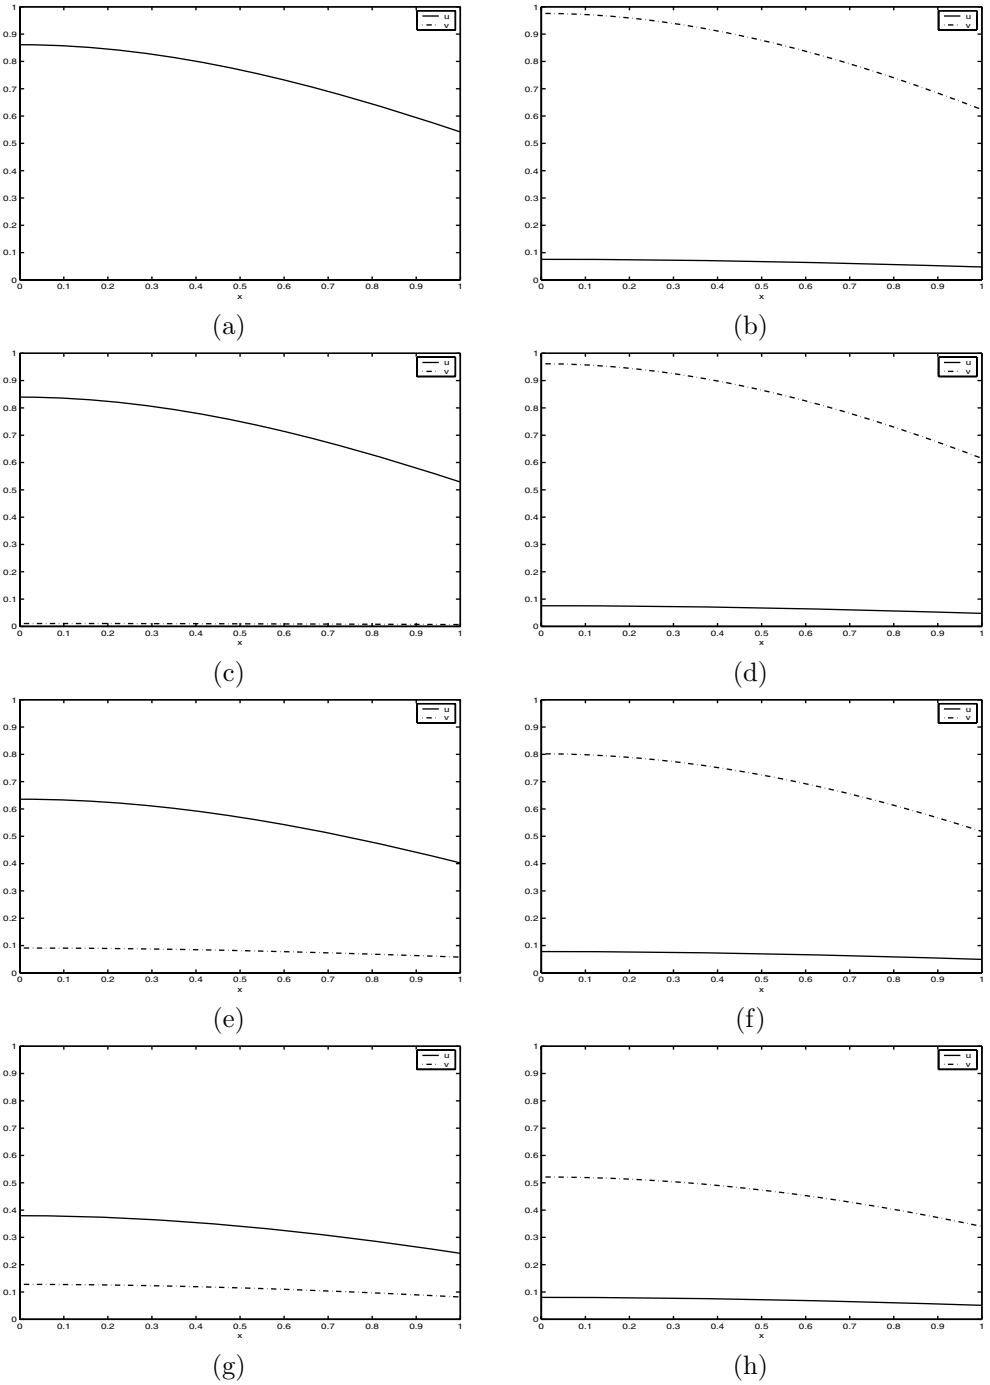

FIG. 4. *The difference between the plasmid model and the standard chemostat competition model in the presence of inhibitor:* (a) *and* (b) *with* $q = 0$, (c) *and* (d) *with* $q = 0.01$, (e) *and* (f) *with* $q = 0.1$, *and* (g) *and* (h) *with* $q = 0.2$. *Here* $a = 2.5, b = 5, \mu = 50$. *The simulations suggest that for large* μ *the plasmid model* $(q > 0)$ *has two coexistence solutions; one asymptotically stable,* (c), (e), *and* (g) *with* $q = 0.01, 0.1, 0.2$, *respectively, and the others unstable,* (d), (f) *and* (h) *with* $q = 0.01, 0.1, 0.2$, *respectively. However, the basic chemostat model* $(q = 0)$ *seems to have only one unstable coexistence solution,* (b). *Moreover, when* $q \to 0+$, *the stable coexistence solution of* (PP) *goes to the semitrivial nonnegative solution* $(\vartheta, 0)$, (a).

(2) If u is a weaker competitor than v, then there exists a unique number $\mu^* > 0$ such that if $\mu < \mu^*$ there is no coexistence state of (PP) and the semitrivial nonnegative solution $(0, \theta)$ is globally stable; if $\mu > \mu^*$ there are exactly two coexistence states of (PP) (see Figures 1(c)–(f)). One is asymptotically stable, and the theoretical results and plenty of numerical analysis strongly suggest the other coexistence state is the most possibly unstable. Namely, if v is the better competitor, then it will eliminate u unless the effect of the inhibitor is sufficiently large, reflected by the condition $\mu > \mu^*$. This result exactly indicates that the inhibitor can help the genetically altered (plasmid-bearing) organism to avoid capture of the process by the plasmid-free organism.

(3) If μ is sufficiently large and b suitably large, then there exists a unique constant $a_\mu > \frac{\lambda_1}{1-q-k}$ such that (PP) has exactly two coexistence states for $a_\mu < a < \frac{\hat{\lambda}_1}{(1-q-k)}$: one asymptotically stable and the other (most possibly) unstable. Meanwhile, the semitrivial nonnegative solution $(0, \theta)$ is stable as well. But for $a \geq \frac{\hat{\lambda}_1}{(1-q-k)}$, (PP) has only a unique coexistence state, and it is asymptotically stable (see Figure 2). The simulations indicate that it is also globally stable, but we cannot give a rigorous proof. Furthermore, a_μ goes to $\frac{\lambda_1}{1-q-k}$ when $\mu \to \infty$, which is just consistent with our analytic outcomes.

(4) In fact, (PP) may also have two coexistence states in the case that μ is not large enough. For example, taking the parameters $\mu = 1, a = 6.4$, and $b = 5$ and the same parameters as above, (PP) has two positive solutions; see Figure 3. Moreover, the simulations also suggest that the coexistence solution in Figure 3(a) is asymptotically stable and the coexistence solution in Figure 3(b) is (most possibly) unstable.

(5) We discuss the difference between the plasmid model and the standard chemostat competition model in the presence of inhibitor. In (1), we mention the difference between the above two kinds of chemostat models when the plasmid-bearing organism is a better competitor. Here, we mainly concentrate on the case that the plasmid-bearing organism is a weaker competitor than the plasmid-free organism. It is easy to see that the introduction of the plasmid-free organism destroys the competitive property of the system. However, it is this property of the plasmid model that leads to the complex dynamical behavior. Now, numerical simulations help us understand this; see Figure 4. Take the parameters $a = 2.5, b = 5$, and $\mu = 50$ and the same parameters as before except that $q = 0, 0.01, 0.1, 0.2$ for Figures 4(a)–(h). Simulations convince us that when the effect of the inhibitor is very large, represented by large μ, if $q = 0$, that is, for the standard chemostat model with inhibitor, there is only one positive coexistence solution (see Figure 4(b)). Moreover, both the analytic results and many numerical simulations convince us that it is unstable. But once $q > 0$, the plasmid model has one asymptotically stable coexistence solution (see Figures 4(c), 4(e), 4(g)) and one (most likely) unstable coexistence solution (see Figures 4(d), 4(f), 4(h)).

Appendix A. In this section, we give the proof of Lemma 3.2.

Proof. (i) Let $y = (0, 0)$. By computation $W_y = \{(u, v) \in X : u \geq 0, v \geq 0\}$, $S_y = (0, 0)$. Hence $X_y = X$, and $Q = I$ (I is the identity operator in X). We first examine the eigenvalues of $\mathcal{A}'(0, 0)$, where $\mathcal{A}'(0, 0)$ is the Fréchet derivative of $\mathcal{A}$ with respect to (u, v) at $(0, 0)$. By direct computation,

$$\mathcal{A}'(0,0)(u,v) = \left(-d\frac{d^2}{dx^2} + M\right)^{-1} \times (a(1-q-k)uf_1(z) + Mu,\ bvf_2(z) + Mv + aquf_1(z))$$

for each $(u,v)\in X$. Hence an eigenvector (u,v) of $\mathcal{A}'(0,0)$ satisfies

$$\begin{aligned}&-du'' + Mu = \tfrac{1}{\lambda}(a(1-q-k)f_1(z)+M)u,\\ &-dv'' + Mv = \tfrac{1}{\lambda}((bf_2(z)+M)v + aquf_1(z)),\\ &u'(0)=u'(1)+\gamma u(1)=0, \qquad v'(0)=v'(1)+\gamma v(1)=0.\end{aligned}$$

It is easy to see that $I-\mathcal{A}'(0,0)$ is invertible in W_y since $a\neq \lambda_1/(1-q-k)$ and $b\neq\sigma_1$.

If $u\equiv 0$, then λ is an eigenvalue of

$$-dv'' + Mv = \frac{1}{\lambda}(bf_2(z)+M)v,\ v'(0)=v'(1)+\gamma v(1)=0. \tag{A.1}$$

Let η_1 be the principal eigenvalue of

$$-d\omega'' - bf_2(z)\omega = \eta_1\omega,\quad \omega'(0)=\omega'(1)+\gamma\omega(1)=0.$$

Then $\eta_1>0$ if $b<\sigma_1$, and $\eta_1<0$ if $b>\sigma_1$. It follows from Lemma 2.3 that if $b<\sigma_1$, then (A.1) has no eigenvalue larger than or equal to 1; if $b>\sigma_1$, then (A.1) has eigenvalues larger than 1. Namely, $\mathcal{A}'(0,0)$ has no eigenvalue larger than or equal to 1 with the corresponding eigenvector of the form $(0,v)$ if $b<\sigma_1$; $\mathcal{A}'(0,0)$ has eigenvalues larger than 1 with the corresponding eigenvector of the form $(0,v)$ if $b>\sigma_1$.

If $u\not\equiv 0$, then λ is an eigenvalue of

$$-du'' + Mu = \frac{1}{\lambda}(a(1-q-k)f_1(z)+M)u, \qquad u'(0)=u'(1)+\gamma u(1)=0.$$

By Lemma 2.3, we know that if $a<\lambda_1/(1-q-k)$, then $\mathcal{A}'(0,0)$ has no eigenvalue larger than or equal to 1 with the associated eigenfunction (u,v), where $u\not\equiv 0$; if $a>\lambda_1/(1-q-k)$, then $\mathcal{A}'(0,0)$ has eigenvalues larger than 1 with the associated eigenfunction $(u,v)(u\not\equiv 0)$. Hence, by Theorem 2.2 in [26], $\operatorname{index}_W(\mathcal{A},(0,0))=1$ if $a<\lambda_1/(1-q-k)$ and $b<\sigma_1$, and $\operatorname{index}_W(\mathcal{A},(0,0))=0$ if $a>\lambda_1/(1-q-k)$ or $b>\sigma_1$.

(ii) Let $y=(0,\theta)$. By computation,

$$W_y=\{(u,v)\in X: u\geq 0\},\ S_y=\{(0,v): v\in C_B([0,1])\}.$$

Define $X_y=\{(u,0): u\in C_B([0,1])\}$. Then $X=S_y\oplus X_y$ with projection Q given by $(u,v)\to(u,0)$. We first determine the existence of $\operatorname{index}_W(\mathcal{A},(0,\theta))$. Let $\mathcal{A}'(0,\theta)$ denote the Fréchet derivative of $\mathcal{A}$ with respect to (u,v) at $(0,\theta)$. Then

$$\mathcal{A}'(0,\theta)(u,v)=\left(\left(-d\frac{d^2}{dx^2}+M\right)^{-1}g(u,v),\ \left(-d\frac{d^2}{dx^2}+M\right)^{-1}(h_1(u,v)+h_2(u,v))\right)$$

for $(u,v)\in X$, where

$$\begin{aligned}&g(u,v)=(a(1-q-k)f_1(z-\theta)+M)u,\\ &h_1(u,v)=(-b(1+c)\theta f_2'(z-\theta)-b\mu c\theta f_2(z-\theta)+aqf_1(z-\theta))u,\\ &h_2(u,v)=(b(f_2(z-\theta)-\theta f_2'(z-\theta))+M)v.\end{aligned}$$

Let $(u,v)\in W_y$ be a fixed point of $\mathcal{A}'(0,\theta)$. Then (u,v) satisfies

$$\begin{aligned}&du'' + a(1-q-k)uf_1(z-\theta)=0,\\ &dv'' + b(f_2(z-\theta)-\theta f_2'(z-\theta))v\\ &\quad=(b(1+c)\theta f_2'(z-\theta)+b\mu c\theta f_2(z-\theta)-aqf_1(z-\theta))u.\end{aligned}$$

Clearly, if $a \neq \hat{\lambda}_1/(1-q-k)$, then $u \equiv v \equiv 0$. That is, $I - \mathcal{A}'(0,\theta)$ is invertible in W_y, and $\text{index}_W(\mathcal{A},(0,\theta))$ is well defined. Next, we consider the eigenvalues of $Q \circ \mathcal{A}'(0,\theta)$. By virtue of definition $Q(u,v) = (u,0)$, every eigenvector of $Q \circ \mathcal{A}'(0,\theta)$ has the form $(u,0)$, where u is a nonzero solution of the equation

$$-du'' + Mu = \frac{1}{\lambda}(a(1-q-k)f_1(z-\theta) + M)u, \qquad u'(0) = u'(1) + \gamma u(1) = 0.$$

Let η_1 be the first eigenvalue of

$$-d\omega'' - a(1-q-k)\omega f_1(z-\theta) = \eta_1\omega, \qquad \omega'(0) = \omega'(1) + \gamma\omega(1) = 0.$$

Then $\eta_1 > 0$ if $a < \hat{\lambda}_1/(1-q-k)$; $\eta_1 < 0$ if $a > \hat{\lambda}_1/(1-q-k)$. It follows from Lemma 2.3 that $Q \circ \mathcal{A}'(0,\theta)$ has no eigenvalue larger than or equal to 1 if $a < \hat{\lambda}_1/(1-q-k)$; $Q \circ \mathcal{A}'(0,\theta)$ has an eigenvalue larger than 1 if $a > \hat{\lambda}_1/(1-q-k)$. In view of Theorem 2.2 in [26], $\text{index}_W(\mathcal{A},(0,\theta)) = 0$ if $a > \hat{\lambda}_1/(1-q-k)$; $\text{index}_W(\mathcal{A},(0,\theta)) = \text{index}_{S_y}(\mathcal{A}'(0,\theta),(0,0)) = (-1)^\sigma$ if $a < \hat{\lambda}_1/(1-q-k)$. Here σ is the sum of multiplicities of the eigenvalues λ of $\mathcal{A}'(0,\theta)$ restricted in S_y such that $\lambda > 1$.

It remains to prove that $\text{index}_W(\mathcal{A},(0,\theta)) = 1$ for $a < \hat{\lambda}_1/(1-q-k)$. It suffices to show $\sigma = 0$. Suppose λ is an eigenvalue of $\mathcal{A}'(0,\theta)$ in S_y with the corresponding eigenvector (u,v). Then $u = 0$ and v is a nonzero solution of the equation

$$-dv'' + Mv = \frac{1}{\lambda}(b(f_2(z-\theta) - \theta f_2'(z-\theta)) + M)v, \qquad v'(0) = v'(1) + \gamma v(1) = 0. \tag{A.2}$$

It follows from Lemma 2.3 that (A.2) has no eigenvalue larger than or equal to 1, which implies $\sigma = 0$ and $\text{index}_W(\mathcal{A},(0,\theta)) = \text{index}_{S_y}(\mathcal{A}'(0,\theta),(0,0)) = 1$. The proof of this lemma is completed. □

SINGULAR LIMIT PROBLEM FOR SOME ELLIPTIC SYSTEMS*

YOSHIHITO OSHITA†

Abstract. For the sharp interface problem arising in the singular limit of some elliptic systems, we prove the existence and the nondegeneracy of solutions whose interface is a distorted circle in a two-dimensional bounded domain without any assumption on the symmetry of the domain.

Key words. sharp interface, singular perturbation, elliptic system

1. Introduction.

We consider

$$\begin{cases} -\Delta v = \mathbf{1}_{\Omega^+} - m & \text{in } \Omega, \\ \dfrac{\partial v}{\partial n} = 0 & \text{on } \partial\Omega, \\ \beta v + \kappa = 0 & \text{on } \Gamma, \end{cases} \tag{1.1}$$

where $\Omega \subset \mathbb{R}^2$ is a bounded domain with the smooth boundary $\partial\Omega$, $\partial/\partial n$ is the normal derivative on $\partial\Omega$, Ω^+ is an open set in Ω, $\Gamma = \partial\Omega^+ \subset \Omega$ is a C^2-curve embedded in Ω, κ is the curvature of Γ, $\beta > 0$ is a parameter, $m \in (0,1)$ is a constant, and $\mathbf{1}_{\Omega^+}$ denotes the characteristic function of Ω^+.

This problem comes from the following reaction-diffusion systems:

$$u_\tau = \epsilon^2 \Delta u + f(u) - \mu v, \qquad v_\tau = \Delta v + g(u,v), \tag{1.2}$$

where $u = u(y,\tau)$ and $v = v(y,\tau)$ are real-valued functions on $(y,\tau) \in \mathbb{R}^2 \times \mathbb{R}^+$; $\epsilon, \mu > 0$ are positive constants; $f \in C^1(\mathbb{R})$ is a function satisfying $f(i) = 0$, $f'(i) < 0$ $(i = 0, 1)$, $f(a) = 0$, $f'(a) > 0$ with $a \in (0,1)$, and $f(s) = -W'(s)$ with $W \in C^2(\mathbb{R})$ being a double-equal-well potential satisfying

$$W(0) = W(1) = 0 < W(s) \quad \forall s \in \mathbb{R}\backslash\{0,1\},$$
$$W''(0)W''(1) > 0;$$

and $g \in C^1(\mathbb{R}^2)$ is a function such that $g(1,0) = 1 - m > 0$, $g(-1,0) = -m < 0$. It follows $\int_0^1 f(s)\,ds = 0$.

A typical example of (f,g) is the FitzHugh–Nagumo type: $f(s) = s(s-a)(1-s)$, $g(u,v) = u - \gamma v - m$ ($\gamma \geq 0$ is a nonnegative constant). The general case is referred to as the activator-inhibitor system.

The system (1.2) describes the reaction and the diffusion phenomena of substances. When the ratio of the diffusion constants, ϵ^2, is extremely small, very interesting stationary patterns, such as stripes or spots, often appear. As a mathematical approach to understanding this pattern formation, we consider the limit $\epsilon \to 0$. Then

usually the domain is divided into two regions, and the remaining part becomes a thin layer. In some cases, the width of the internal transition layer approaches 0 in the limit, and the discontinuity surface inside the domain, which is called the sharp interface, appears. Recently very fine layered patterns of (1.2) have attracted a great deal of attention. See [4, 13, 14]. We consider this fine pattern which has the space scale of $\epsilon^{1/3}$ order. This is the unique scale that the order of the two driving forces of the sharp interface, the inhibitor v and the curvature of the sharp interface, balances. See [11]. This scale also appeared in [4]. After rescaling

$$x = \frac{y}{\epsilon^{1/3}}, \qquad t = \epsilon^{4/3}\tau, \qquad \varepsilon = \epsilon^{2/3},$$

we obtain

$$\begin{cases} u_t = \Delta u + \dfrac{1}{\varepsilon^2}(f(u) - \mu v), \\ \varepsilon^3 v_t = \Delta v + \varepsilon g(u, v). \end{cases} \tag{1.3}$$

We consider the stationary solutions of (1.3) subject to the homogeneous Neumann boundary condition:

$$\begin{cases} -\varepsilon^2 \Delta u = f(u) - \mu v & \text{in } \Omega, \\ -\Delta v = \varepsilon g(u, v) & \text{in } \Omega, \\ \dfrac{\partial u}{\partial n} = \dfrac{\partial v}{\partial n} = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.4}$$

where $\Omega \subset \mathbb{R}^2$ is a bounded domain with the smooth boundary $\partial\Omega$.

The reduced equation in the singular limit $\varepsilon \to 0$ becomes

$$\begin{cases} -\Delta v_1 = \mathbf{1}_{\Omega^+} - m & \text{in } \Omega, \\ \dfrac{\partial v_1}{\partial n} = 0 & \text{on } \partial\Omega, \\ \frac{\mu}{\sigma} v_1 + \kappa = 0 & \text{on } \Gamma, \end{cases} \tag{RP}$$

where Ω^+ is an open set in Ω such that $\Gamma = \partial\Omega^+$ is a curve embedded in Ω and $\mathbf{1}_{\Omega^+}$ denotes the characteristic function of Ω^+. Here $u \to \mathbf{1}_{\Omega^+}$, $v/\varepsilon \to v_1$ as $\varepsilon \to 0$. See Appendix A of this paper or [12].

The associated functional becomes

$$J[\Gamma] = \sigma|\Gamma| + \frac{\mu}{2}\int_\Omega |\nabla v_1|^2 \, dx,$$

where $|\Gamma|$ is the length of Γ and v_1 is a solution to

$$\begin{cases} -\Delta v_1 = \mathbf{1}_{\Omega^+} - m & \text{in } \Omega, \\ \dfrac{\partial v_1}{\partial n} = 0 & \text{on } \partial\Omega. \end{cases}$$

See Lemma 3.4 in section 3.

Essentially the same equation as (RP) was obtained in [12] by using the matched expansion method. Once you have a "nondegenerate" solution of (RP) in some sense, you can find a layered solution for the singular perturbation problem (1.4) with $g(u, v) = u - m$ and $\mu = 1$. See Appendix B.

For the reduction from the parabolic system to the sharp interface model, see [17]. In the case of the FitzHugh–Nagumo type, the functional $J[\Gamma]$ can also be obtained mathematically by using the notion of the Gamma convergence. See [14].

The direct method of calculus of variations implies the existence of global minimizers of $J[\Gamma]$. This gives a solution of (RP). However, it is usually difficult to know the profile and the nondegeneracy of the global minimizers. Here we consider the problem of finding a solution of (RP) that does not necessarily correspond to the global minimizers. The radially symmetric case for related problems is studied in [5, 6, 12, 15, 16, 18]. We do not assume any symmetry of the domain.

In order to state the result, we define the Green's function and its harmonic part.

DEFINITION 1.1. *For each $y \in \Omega$, let $G(x,y)$ be the solution to*

$$\begin{cases} -\Delta_x G(x,y) = \delta(x-y) - \dfrac{1}{|\Omega|}, & x \in \Omega, \\ \dfrac{\partial G}{\partial n_x}(x,y) = 0, & x \in \partial\Omega, \\ \displaystyle\int_\Omega G(x,y)\,dx = 0. \end{cases}$$

Set

$$G(x,y) = -\frac{1}{2\pi}\log|x-y| + \frac{|x-y|^2}{4|\Omega|} + H(x,y), \quad x,y \in \Omega.$$

Then it is known that $H(x,y)$ is symmetric and harmonic in both x and y. Let $\mathcal{H}(x) = H(x,x)$.

We define the following two conditions.

(A1) $0 \in \Omega$ is a strict local minimum point of $\mathcal{H}$. More precisely, there exists a neighborhood U of 0 in Ω such that $\mathcal{H}(0) < \mathcal{H}(x)$ for all $x \in U\backslash\{0\}$.

(A2) $0 \in \Omega$ is a nondegenerate critical point of $\mathcal{H}$.

Remark. When $\Omega = \{x \in \mathbb{R}^2\,;\, |x| < 1\}$, $x = 0$ is a unique minimum point of $\mathcal{H}$, and both (A1) and (A2) are satisfied. Indeed, we have $\mathcal{H}(x) = -\frac{1}{2\pi}\log(1-|x|^2) + \frac{|x|^2}{2\pi} + \mathcal{H}(0)$, and hence $\frac{\partial^2\mathcal{H}}{\partial x_i \partial x_j}(0) = \frac{2}{\pi}\delta_{ij}$.

The regular part of Green's function subject to the homogeneous Dirichlet boundary condition has a unique nondegenerate minimum point when $\Omega \subset \mathbb{R}^2$ is convex (see [2]). The regular part of Green's function subject to the homogeneous Neumann boundary condition is considered in [7].

We denote by d_{H} the Hausdorff metric

$$d_{\mathrm{H}}(K_1,K_2) = \max[\sup\{\mathrm{dist}(x,K_2)\,;\, x \in K_1\}, \sup\{\mathrm{dist}(y,K_1)\,;\, y \in K_2\}],$$

$S_r(0) = \{x \in \mathbb{R}\,;\, |x| = r\}$, and $B_r(0) = \{x \in \mathbb{R}\,;\, |x| < r\}$.

THEOREM 1.1. *Assume that* (A1) *or* (A2) *holds. If*

$$r_0 := \sqrt{\frac{m|\Omega|}{\pi}} < \mathrm{dist}(0,\partial\Omega),$$

then there exists a constant $\beta_0 > 0$ such that (1.1) *has a solution*

$$\begin{cases} \Gamma = \Gamma_\beta, \\ v = v_\beta, \\ \Omega^+ = \Omega^+_\beta \end{cases}$$

for all $\beta < \beta_0$ satisfying $d_{\mathrm{H}}(\Gamma_\beta, S_{r_0}(0)) \to 0$ as $\beta \to 0$.

This paper is organized as follows. In section 2, we prepare some preliminaries and notations. In section 3, we prove Theorem 1.1, and in section 4, we consider the linearized nondegeneracy of the problem.

2. Notation. We identify 2π-periodic functions on $\mathbb{R}$ with the functions on $S^1 = \{x \in \mathbb{R}^2\,;\, |x| = 1\} \cong \mathbb{R}/2\pi\mathbb{Z}$. For $q \in C^2(S^1)$, we use the following notation:

$$\dot{q}(\omega) = \frac{dq}{d\omega}(\omega) = \frac{d}{d\theta} q(\cos\theta, \sin\theta), \quad \omega = (\cos\theta, \sin\theta) \in S^1$$

and

$$\ddot{q}(\omega) = \frac{d^2q}{d\omega^2}(\omega) = \frac{d^2}{d\theta^2} q(\cos\theta, \sin\theta), \quad \omega = (\cos\theta, \sin\theta) \in S^1.$$

We set $X = C^2(S^1)$,

$$\|q\|_X = \max_{\omega\in S^1} |q(\omega)| + \max_{\omega\in S^1} |\dot{q}(\omega)| + \max_{\omega\in S^1} |\ddot{q}(\omega)|,$$

$Y = C(S^1)$, and

$$\|q\|_Y = \max_{\omega\in S^1} |q(\omega)|.$$

For $q_1, q_2 \in L^2(S^1)$, denote

$$\langle q_1, q_2\rangle = \int_{S^1} q_1(\omega) q_2(\omega)\, d\omega = \int_0^{2\pi} q_1(\cos\theta, \sin\theta) q_2(\cos\theta, \sin\theta)\, d\theta$$

and $\|q_1\|^2 = \langle q_1, q_1\rangle$.

Let $\Pi_{n^2} : L^2(S^1) \to L^2(S^1)$ denote the projections with respect to $\langle\cdot,\cdot\rangle$ onto $\operatorname{span}\{\cos i\theta, \sin i\theta\,;\, i = 0, 1, \dots, n\}$ for $n = 0, 1, \dots$. Let $\Pi_{n^2}^{\perp} = \mathbf{Id} - \Pi_{n^2}$.

Define $\Phi_0(\omega) = 1/\sqrt{2\pi}$, $\Phi_1(\omega) = \omega_1/\sqrt{\pi}$, and $\Phi_2(\omega) = \omega_2/\sqrt{\pi}$ for $\omega = (\omega_1, \omega_2) \in S^1$. Then $\Pi_0^{\perp}, \Pi_1^{\perp}$ are the projections onto the orthogonal complements of $\operatorname{span}\{\Phi_0\}$ and $\operatorname{span}\{\Phi_i\,;\, i = 0, 1, 2\}$, respectively.

3. Proof of Theorem 1.1. For brevity's sake, we assume that $r_0 = 1 < \operatorname{dist}(0, \partial\Omega)$.

For $\ell > 0$, define

$$X_\ell = \{q \in X\,;\, \|q\|_X \le \ell\}.$$

We can choose a constant $\delta \in (0, 1/2)$ such that $B_{1+\delta}(0) \subset \Omega$ by the assumption. For $q \in X_{\delta/2}$, define

$$\Gamma(q) = \{\sqrt{1 + q(\omega)}\,\omega\,;\, \omega \in S^1\},$$

$$\Omega^+(q) = \{r\omega\,;\, 0 \le r \le \sqrt{1 + q(\omega)}, \omega \in S^1\}.$$

Let $q \in X_{\delta/2} \cap \Pi_0^{\perp} X$. Then $\Gamma(q) \subset \Omega$, and $|\Omega^+(q)| = \pi$. Indeed since $\sqrt{1+q} \le 1 + \frac{1}{2}q \le 1 + \frac{\delta}{4}$, we have $\Gamma(q) \subset B_{1+\delta/2}(0) \subset \Omega$. In addition, since $\langle q, 1\rangle = 0$, we have

$$|\Omega^+(q)| = \int_{S^1} \int_0^{\sqrt{1+q(\omega)}} r\, dr d\omega = \int_{S^1} \frac{1 + q(\omega)}{2}\, d\omega = \pi.$$

Let M_β be the map from $X_{\delta/2}$ to Y defined by

$$M_\beta(q)(\omega) = K(q)(\omega) + \beta \int_{\Omega^+(q)} G(\sqrt{1+q(\omega)}\omega, y)\, dy, \qquad \omega \in S^1$$

for $q \in X_{\delta/2}$, where

$$K(q) = \frac{1 + q + \frac{3\dot{q}^2}{4(1+q)} - \frac{1}{2}\ddot{q}}{\left[1 + q + \frac{\dot{q}^2}{4(1+q)}\right]^{3/2}}$$

is the curvature of $\Gamma(q)$. Indeed, set $x_1(\theta) = r(\theta)\cos\theta$, $x_2(\theta) = r(\theta)\sin\theta$ with

$$r(\theta) = \sqrt{1 + q(\cos\theta, \sin\theta)}.$$

Then the curvature of $\Gamma(q)$ can be computed as follows.

$$\frac{\dot{x}_1\ddot{x}_2 - \ddot{x}_2\dot{x}_1}{(\dot{x}_1^2 + \dot{x}_2^2)^{3/2}} = \frac{r^2 + 2\dot{r}^2 - r\ddot{r}}{(r^2 + \dot{r}^2)^{3/2}} = \frac{1 + q + \frac{3\dot{q}^2}{4(1+q)} - \frac{1}{2}\ddot{q}}{\left[1 + q + \frac{\dot{q}^2}{4(1+q)}\right]^{3/2}}.$$

In order to solve (1.1), we need prove only the following.

PROPOSITION 3.1. *Suppose either* (A1) *or* (A2) *holds. If* $1 = \sqrt{m|\Omega|/\pi} < \operatorname{dist}(0, \partial\Omega)$, *then there exists a constant* $\beta_0 > 0$ *such that* $\Pi_0^\perp M_\beta(q) = 0$ *has a solution* $q = q_\beta \in X_{\delta/2} \cap \Pi_0^\perp X$ *for all* $\beta \in (0, \beta_0)$ *satisfying* $q_\beta \to 0$ *in* X *as* $\beta \to 0$.

Indeed, if $q \in X_{\delta/2} \cap \Pi_0^\perp X$ is a solution of $\Pi_0^\perp M_\beta(q) = 0$, then there exists a constant C_1 such that

$$M_\beta(q) \equiv C_1.$$

Now set

$$v(x) = \int_{\Omega^+(q)} G(x, y)\, dy - \frac{1}{\beta} C_1, \quad x \in \Omega.$$

Then v satisfies

$$\begin{cases} -\Delta v = \mathbf{1}_{\Omega^+(q)} - m & \text{in } \Omega, \\ \dfrac{\partial v}{\partial n} = 0 & \text{on } \partial\Omega. \end{cases}$$

Hence we see that

$$\Gamma = \Gamma(q), \quad v(x) = \int_{\Omega^+(q)} G(x, y)\, dy - \frac{1}{\beta} C_1, \quad \Omega^+ = \Omega^+(q)$$

solves our (1.1) and completes the proof of Theorem 1.1.

3.1. Proof of Proposition 3.1. First we construct approximate solutions and prepare some lemmas. Next we find a solution by decomposing the equation $\Pi_0^\perp M_\beta(q) = 0$ into the system of equations:

1. $\Pi_1^\perp M_\beta(q) = 0$,
2. $(\Pi_1 - \Pi_0) M_\beta(q) = 0$.

Approximate solutions. We shall construct approximate solutions. Fix $\eta = (\eta_1, \eta_2) \in \mathbb{R}^2$ ($|\eta| < 1$). For $\omega \in S^1$, $r = \eta \cdot \omega + \sqrt{1 + (\eta \cdot \omega)^2 - |\eta|^2}$ is the solution of $|r\omega - \eta| = 1, r > 0$. Now set

$$q(\omega; \eta) := 2(\eta \cdot \omega)^2 - |\eta|^2 + 2(\eta \cdot \omega)\sqrt{1 + (\eta \cdot \omega)^2 - |\eta|^2} \quad \text{for } \omega \in S^1.$$

Then $\Gamma(q(\cdot; \eta))$ is a circle of radius 1 with center at η. Also it is easy to see that $\langle q(\cdot; \eta), \Phi_0 \rangle = 0$. Set

$$\xi_i = \langle q(\cdot; \eta), \Phi_i \rangle, \quad i = 1, 2. \tag{3.1}$$

Noting that $q(\omega; \eta) + |\eta|^2 - 2(\eta \cdot \omega)\sqrt{1 + q(\omega; \eta)} = 0$, it follows that

$$\xi_i = 2\sqrt{\pi} \sum_{j=1}^{2} \eta_j \langle \sqrt{1 + q(\omega; \eta)} \Phi_j, \Phi_i \rangle, \quad i = 1, 2.$$

Then we have $\langle q(\cdot; 0), \Phi_i \rangle = 0$, $i = 1, 2$, and $\partial \xi_i / \partial \eta_j(0) = 2\sqrt{\pi} \langle \Phi_j, \Phi_i \rangle = 2\sqrt{\pi} \delta_{ij}$. From the inverse mapping theorem, we conclude that there exists a neighborhood $U_1 \subset \mathbb{R}^2$ of 0 and a smooth map $P = (P_1, P_2)$ on U_1 such that $\xi_i = \langle q(\cdot; P(\xi)), \Phi_i \rangle$ for $\xi = (\xi_1, \xi_2) \in U_1$. Set $\psi_\xi = q(\cdot; P(\xi))$ for $\xi \in U_1$. Taking a smaller U_1 if necessary, we may assume the following.

LEMMA 3.1. *For any $\xi = (\xi_1, \xi_2) \in U_1$, there holds $\psi_\xi \in X_{\delta/4} \cap \Pi_0^\perp X$,*

$$\Pi_1 \psi_\xi = \xi_1 \Phi_1 + \xi_2 \Phi_2,$$

and $\Gamma(\psi_\xi) = \{\omega \sqrt{1 + \psi_\xi(\omega)}\,;\, \omega \in S^1\}$ is a circle of radius 1 with center at $P(\xi) \in \mathbb{R}^2$. Moreover P is smooth, $P(0) = 0$, and $\partial P_i / \partial \xi_j(0) = (2\sqrt{\pi})^{-1} \delta_{ij}$.

Since $K(\psi_\xi) \equiv 1$, we have $M_\beta(\psi_\xi) = 1 + O(\beta)$, and hence $\Pi_0 M_\beta(\psi_\xi) = \langle 1 + O(\beta), \Phi_0 \rangle \Phi_0 = 1 + O(\beta)$. Thus we have the following.

PROPOSITION 3.2. $\Pi_0^\perp M_\beta(\psi_\xi) = O(\beta)$ *as $\beta \to 0$ uniformly in $\xi \in U_1$.*

Linearization. For $t > -1$, $p \in \mathbb{R}$, and $s \in \mathbb{R}$, set

$$L(t, p, s) = \frac{1 + t + \frac{3p^2}{4(1+t)} - \frac{1}{2}s}{\left[1 + t + \frac{p^2}{4(1+t)}\right]^{3/2}}. \tag{3.2}$$

Then K is C^1 on $X_{\delta/2}$, and there hold

$$K'(q)\zeta = L_s(q, \dot{q}, \ddot{q})\ddot{\zeta} + L_p(q, \dot{q}, \ddot{q})\dot{\zeta} + L_t(q, \dot{q}, \ddot{q})\zeta \quad \text{for } \zeta \in X. \tag{3.3}$$

Moreover since

$$M_\beta(q)(\omega) = K(q)(\omega) + \beta \int_{S^1} \int_{-1}^{q(\hat{\omega})} G(\sqrt{1 + q(\omega)}\omega, \sqrt{1 + \hat{q}}\hat{\omega}) \frac{d\hat{q}}{2} d\hat{\omega}, \qquad \omega \in S^1$$

for $q \in X_{\delta/2}$, we see that M_β is also C^1 and

$$\begin{aligned}
[M'_\beta(q)\zeta](\omega) &= [K'(q)\zeta](\omega) + \frac{\beta}{2}\int_{S^1} G(\sqrt{1+q(\omega)}\omega, \sqrt{1+q(\hat\omega)}\hat\omega)\zeta(\hat\omega)\,d\hat\omega \\
&\quad + \beta\zeta(\omega)\int_{S^1}\int_{-1}^{q(\hat\omega)} \frac{\nabla_x G(\sqrt{1+q(\omega)}\omega, \sqrt{1+\hat q}\hat\omega)\cdot\omega}{2\sqrt{1+q(\omega)}}\,\frac{d\hat q}{2}\,d\hat\omega \\
&= \frac{d}{d\omega}[L_s(q,\dot q,\ddot q)\dot\zeta] + L_t(q,\dot q,\ddot q)\zeta \\
&\quad + \frac{\beta}{2}\int_{S^1} G(\sqrt{1+q(\omega)}\omega, \sqrt{1+q(\hat\omega)}\hat\omega)\zeta(\hat\omega)\,d\hat\omega \\
&\quad + \frac{\beta\zeta(\omega)}{2\sqrt{1+q(\omega)}}\int_{\Omega^+(q)} \omega\cdot\nabla_x G(\sqrt{1+q(\omega)}\omega, y)\,dy, \quad \omega \in S^1
\end{aligned} \tag{3.4}$$

for $q \in X_{\delta/2}$ and $\zeta \in X$.

LEMMA 3.2. *$\langle K'(q)\zeta_1, \zeta_2\rangle = \langle \zeta_1, K'(q)\zeta_2\rangle$, and $\langle M'_\beta(q)\zeta_1, \zeta_2\rangle = \langle \zeta_1, M'_\beta(q)\zeta_2\rangle$ for all $\zeta_1, \zeta_2 \in X$.*

Proof. Since

$$\begin{aligned}
L_s(q,\dot q,\ddot q) &= -\frac{1}{2}\left[1+q+\frac{\dot q^2}{4(1+q)}\right]^{-3/2}, \\
L_p(q,\dot q,\ddot q) &= \frac{3\dot q}{16}\left\{4 - \frac{\dot q^2}{(1+q)^2} + \frac{2\ddot q}{1+q}\right\}\left[1+q+\frac{\dot q^2}{4(1+q)}\right]^{-5/2},
\end{aligned}$$

we have $\frac{d}{d\omega}L_s(q,\dot q,\ddot q) = L_p(q,\dot q,\ddot q)$. Hence it follows that for $\zeta \in X$

$$\begin{aligned}
K'(q)\zeta &= L_s(q,\dot q,\ddot q)\ddot\zeta + L_p(q,\dot q,\ddot q)\dot\zeta + L_t(q,\dot q,\ddot q)\zeta \\
&= \frac{d}{d\omega}[L_s(q,\dot q,\ddot q)\dot\zeta] + L_t(q,\dot q,\ddot q)\zeta.
\end{aligned} \tag{3.5}$$

The assertion of the Lemma follows from (3.5) and (3.4). ∎

PROPOSITION 3.3. *There exists a constant $C > 0$, independent of small β, such that*

$$\|M'_\beta(q) - M'_\beta(\psi_\xi)\|_{\mathcal{L}(X,Y)} \le Ca^{1/3}$$

for any q in $\{q \in X_{\delta/2}\,;\, \|q-\psi_\xi\|_X \le a\}$, $a \le \delta/4$, and $\xi \in U_1$.

Proof. We shall show that there exists a constant $C > 0$, independent of small β, such that

$$\|M'_\beta(q)\zeta - M'_\beta(\psi_\xi)\zeta\|_Y \le Ca^{1/3}\|\zeta\|_X$$

for any q in $\{q \in X_{\delta/2}\,;\, \|q-\psi_\xi\|_X \le a\}$, $a \le \delta/4$, $\xi \in U_1$, and $\zeta \in X$.

Let $q \in X_{\delta/2}, \|q-\psi_\xi\|_X \le a$, $a \le \delta/4$, $\xi \in U_1$, and $\zeta \in X$. In this proof, for the sake of notational simplicity, we will use the same letters C to denote some positive constants, independent of q, ξ, a, ζ, whose values may vary from line to line.

From the expression (3.3) and the fact that L is smooth in $(-1,\infty)\times\mathbb{R}\times\mathbb{R}$, we easily see that

$$\|K'(q)\zeta - K'(\psi_\xi)\zeta\|_X \le Ca\|\zeta\|_Y. \tag{3.6}$$

Next let

$$v(x) = \int_{\Omega^+(q)} G(x,y)\,dy,$$
$$v_\xi(x) = \int_{\Omega^+(\psi_\xi)} G(x,y)\,dy.$$

Then since $\|\mathbf{1}_{\Omega^+(q)} - \mathbf{1}_{\Omega^+(\psi_\xi)}\|_{L^3(\Omega)} \le C\|q-\psi_\xi\|^{1/3}_{L^\infty(S^1)} \le Ca^{1/3}$, it follows from elliptic estimates and the Sobolev embedding theorem that $v, v_\xi \in W^{2,3}(\Omega) \subset C^{1,1/3}(\bar\Omega)$, $\|v - v_\xi\|_{C^1(\bar\Omega)} \le Ca^{1/3}$, and $\|v\|_{C^{1,1/3}(\bar\Omega)} < \infty$. Then since

$$\begin{aligned}
&\frac{\omega\cdot\nabla v(\sqrt{1+q(\omega)}\omega)}{\sqrt{1+q(\omega)}} - \frac{\omega\cdot\nabla v_\xi(\sqrt{1+\psi_\xi(\omega)}\omega)}{\sqrt{1+\psi_\xi(\omega)}}\\
&= \frac{\omega\cdot\nabla v(\sqrt{1+\psi_\xi(\omega)}\omega) - \omega\cdot\nabla v_\xi(\sqrt{1+\psi_\xi(\omega)}\omega)}{\sqrt{1+\psi_\xi(\omega)}}\\
&\quad + \frac{\omega\cdot\nabla v(\sqrt{1+\psi_\xi(\omega)}\omega)}{\sqrt{1+q(\omega)}} - \frac{\omega\cdot\nabla v(\sqrt{1+\psi_\xi(\omega)}\omega)}{\sqrt{1+\psi_\xi}}\\
&\quad + \frac{\omega\cdot\nabla v(\sqrt{1+q(\omega)}\omega) - \omega\cdot\nabla v(\sqrt{1+\psi_\xi(\omega)}\omega)}{|\sqrt{|1+q(\omega)} - \sqrt{1+\psi_\xi(\omega)}|^{1/3}} \frac{|\sqrt{|1+q(\omega)} - \sqrt{1+\psi_\xi(\omega)}|^{1/3}}{\sqrt{1+q(\omega)}},
\end{aligned}$$

we have

$$\sup_{\omega\in S^1}\left|\frac{\omega\cdot\nabla v(\sqrt{1+q(\omega)}\omega)}{\sqrt{1+q(\omega)}} - \frac{\omega\cdot\nabla v_\xi(\sqrt{1+\psi_\xi(\omega)}\omega)}{\sqrt{1+\psi_\xi(\omega)}}\right| \le Ca^{1/3}. \tag{3.7}$$

On the other hand let

$$w_\xi(x) = \int_{S^1} G\left(x, \sqrt{1+\psi_\xi(\hat\omega)}\hat\omega\right)\zeta(\hat\omega)\,d\hat\omega.$$

Then w_ξ is the solution to

$$\int_\Omega \nabla w_\xi\cdot\nabla\varphi\,dx = A_{\psi_\xi}\varphi := \int_{S^1}\zeta(\hat\omega)\varphi\left(\sqrt{1+\psi_\xi(\hat\omega)}\hat\omega\right)\,d\hat\omega - \frac{1}{|\Omega|}\int_{S^1}\zeta\int_\Omega\varphi$$

for all $\varphi\in W^{1,3/2}(\Omega)$. Here

$$A_{\psi_\xi} : \varphi \mapsto \int_{S^1}\zeta(\hat\omega)\varphi\left(\sqrt{1+\psi_\xi(\hat\omega)}\hat\omega\right)\,d\hat\omega - \frac{1}{|\Omega|}\int_{S^1}\zeta\int_\Omega\varphi$$

is a bounded linear functional on $W^{1,3/2}(\Omega)$. Indeed for $\varphi\in W^{1,3/2}(\Omega)$, we have

$$\begin{aligned}
&\left|\int_{S^1}\zeta(\hat\omega)\varphi\left(\sqrt{1+\psi_\xi(\hat\omega)}\hat\omega\right)\,d\hat\omega\right|\\
&\qquad\le \left(\int_{S^1}\left|\varphi\left(\sqrt{1+\psi_\xi(\hat\omega)}\hat\omega\right)\right|^{3/2}d\hat\omega\right)^{2/3}\left(\int_{S^1}|\zeta(\hat\omega)|^3\,d\hat\omega\right)^{1/3}\\
&\qquad\le (2\pi)^{1/3}\|\zeta\|_Y\|\tilde\varphi\|_{L^{3/2}(S^1)}\\
&\qquad\le C\|\zeta\|_Y\|\tilde\varphi\|_{W^{1,3/2}(B_1(0))} \le C\|\zeta\|_Y\|\varphi\|_{W^{1,3/2}(\Omega)},
\end{aligned}$$

where $\tilde{\varphi}(x) = \varphi\big(\sqrt{1+\psi_\xi(x/|x|)}\,x\big)$ and hence $A_{\psi_\xi} \in W^{-1,3}(\Omega)$ and $\|A_{\psi_\xi}\|_{W^{-1,3}(\Omega)} \le C\|\zeta\|_Y$. Then by elliptic estimates, we see that $w_\xi \in W^{1,3}(\Omega)$, and there exists a positive constant C, independent of $\xi \in U_1$, such that $\|w_\xi\|_{W^{1,3}(\Omega)} \le C\|\zeta\|_Y$.

Let

$$w(x) = \int_{S^1} G\left(x, \sqrt{1+q(\hat{\omega})}\hat{\omega}\right)\zeta(\hat{\omega})\,d\hat{\omega},$$
$$A_q : \varphi \mapsto \int_{S^1} \zeta(\hat{\omega})\varphi\left(\sqrt{1+q(\hat{\omega})}\hat{\omega}\right)\,d\hat{\omega}.$$

Then similarly we have $w \in W^{1,3}(\Omega)$ and $A_q \in W^{-1,3}(\Omega)$.

In addition, we estimate for $\varphi \in W^{1,3/2}(\Omega)$,

$$\begin{aligned}
|A_q\varphi - A_{\psi_\xi}\varphi| &= \left|\int_{S^1} \zeta(\hat{\omega})\varphi\left(\sqrt{1+q(\hat{\omega})}\hat{\omega}\right) - \zeta(\hat{\omega})\varphi\left(\sqrt{1+\psi_\xi(\hat{\omega})}\hat{\omega}\right)\,d\hat{\omega}\right| \\
&= \left|\int_{S^1}\int_{\sqrt{1+\psi_\xi(\hat{\omega})}}^{\sqrt{1+q(\hat{\omega})}} \varphi_r(r\hat{\omega})\zeta(\hat{\omega})\,dr\,d\hat{\omega}\right| \\
&\le \frac{\|\zeta\|_Y}{\sqrt{1-\delta/2}}\int_D |\varphi_r|\,dx \\
&\le \frac{\|\zeta\|_Y}{\sqrt{1-\delta/2}}\left(\int_D |\varphi_r|^{3/2}\,dx\right)^{2/3}\left(\int_D dx\right)^{1/3} \\
&\le \frac{(\pi a)^{1/3}}{\sqrt{1-\delta/2}}\|\zeta\|_Y\|\varphi\|_{W^{1,3/2}(\Omega)},
\end{aligned}$$

where

$$\begin{aligned}
D = \Bigg\{ & r\omega \in \Omega\,; \\
& \min\left(\sqrt{1+\psi_\xi(\omega)}, \sqrt{1+q(\omega)}\right) \le r \le \max\left(\sqrt{1+\psi_\xi(\omega)}, \sqrt{1+q(\omega)}\right), \omega \in S^1 \Bigg\}
\end{aligned}$$

and $\varphi_r(r\omega) = \omega\cdot\nabla\varphi(r\omega)$. We then have $\|A_q - A_{\psi_\xi}\|_{W^{-1,3}(\Omega)} \le Ca^{1/3}\|\zeta\|_Y$, and thus by elliptic estimates, $\|w - w_\xi\|_{L^\infty(\Omega)} \le Ca^{1/3}\|\zeta\|_Y$.

Therefore we have

$$\begin{aligned}
&\left|w\left(\sqrt{1+q(\omega)}\omega\right) - w_\xi\left(\sqrt{1+\psi_\xi(\omega)\omega}\right)\right| \\
&\le \left|w_\xi\left(\sqrt{1+\psi_\xi(\omega)\omega}\right) - w_\xi\left(\sqrt{1+q(\omega)}\omega\right)\right| \\
&\qquad + \left|w_\xi\left(\sqrt{1+q(\omega)}\omega\right) - w\left(\sqrt{1+q(\omega)}\omega\right)\right| \\
&\le Ca^{1/3}\|\zeta\|_Y
\end{aligned}$$

and hence

$$\sup_{\omega\in S^1}\left|w\left(\sqrt{1+q(\omega)}\omega\right) - w_\xi\left(\sqrt{1+\psi_\xi(\omega)\omega}\right)\right| \le Ca^{1/3}\|\zeta\|_Y. \tag{3.8}$$

Our assertion follows from (3.4), (3.6), (3.7), and (3.8). ∎

LEMMA 3.3. *For $\zeta \in X$,*

$$K'(0)\zeta = -\frac{1}{2}\left\{\ddot{\zeta} + \zeta\right\}.$$

Proof. From a simple computation, we have $L_t(0,0,0) = L_s(0,0,0) = -\frac{1}{2}$, $L_p(0,0,0) = 0$, and thus

$$K'(0)\zeta = L_s(0,0,0)\ddot{\zeta} + L_p(0,0,0)\dot{\zeta} + L_t(0,0,0)\zeta = -\frac{1}{2}\left\{\ddot{\zeta} + \zeta\right\}$$

for $\zeta \in X$. □

Note that (i) $\{\frac{1}{2}(n^2-1)\}_{n=0,1,2,\ldots}$ are the set of all the eigenvalues of $K'(0)$, (ii) the eigenspace associated with the eigenvalue $\frac{1}{2}(n^2-1)$ is $\operatorname{span}\{\cos n\theta, \sin n\theta\}$, and (iii) $K'(0)$ maps $\Pi_1^{\perp}X$ onto $\Pi_1^{\perp}Y$.

PROPOSITION 3.4. *There exists a constant C and a neighborhood $U_2 \subset U_1$ of 0, independent of small β, such that for all $\zeta \in \Pi_1^{\perp}X$ and $\xi \in U_2$,*

$$\|\Pi_1^{\perp} M'_{\beta}(\psi_{\xi})\zeta\|_Y \geq C\|\zeta\|_X.$$

Proof. Assume by contrary that there exist $\beta_n > 0$, $\zeta_n \in \Pi_1^{\perp}X$, and $\xi_n \in U_1$ such that $\|\zeta_n\|_X = 1$, $\lim_{n\to\infty}\beta_n = 0$, $\lim_{n\to\infty}\xi_n = 0$, and

$$\lim_{n\to\infty} \|\Pi_1^{\perp} M'_{\beta_n}(\psi_{\xi_n})\zeta_n\|_Y = 0.$$

We write ψ_n instead of ψ_{ξ_n} for simplicity. Taking a subsequence if necessary, we may assume that $\zeta_n \to \zeta$ in C^1 and $\psi_n \to 0$ in X. By Proposition 3.3,

$$\|M'_{\beta_n}(\psi_n) - M'_{\beta_n}(0)\| \leq C\|\psi_n\|_X^{1/3}$$

for n large. Hence

$$\|M'_{\beta_n}(\psi_n)\zeta_n - M'_{\beta_n}(0)\zeta_n\|_Y \leq C\|\psi_n\|_X^{1/3}.$$

Since

$$\Pi_1^{\perp} M'_{\beta_n}(0)\zeta_n = \Pi_1^{\perp} M'_{\beta_n}(\psi_n)\zeta_n - \Pi_1^{\perp}(M'_{\beta_n}(\psi_n)\zeta_n - M'_{\beta_n}(0)\zeta_n)$$

and

$$M'_{\beta}(0)\zeta = K'(0)\zeta + O(\beta)\zeta,$$

we have

$$\lim_{n\to\infty} \|\Pi_1^{\perp} K'(0)\zeta_n\|_Y = \lim_{n\to\infty} \|\Pi_1^{\perp} M'_{\beta_n}(\psi_{\xi_n})\zeta_n\|_Y = 0.$$

Then we have, for any $\varphi \in \Pi_1^{\perp}X$,

$$0 = \lim_{n\to\infty} \int_{S^1} \varphi \Pi_1^{\perp} K'(0)\zeta_n = \lim_{n\to\infty} \int_{S^1} \zeta_n \Pi_1^{\perp} K'(0)\varphi = \int_{S^1} \zeta \Pi_1^{\perp} K'(0)\varphi$$

since $\zeta_n \to \zeta$ in C^1. Since $K'(0)\varphi \in \Pi_1^{\perp}Y$ and $K'(0)\Pi_1^{\perp}X = \Pi_1^{\perp}Y$, we then have $\zeta = 0$. Thus we conclude that $\zeta_n \to 0$ in C^1, and it follows from $\|\zeta_n\|_X \leq \|\ddot{\zeta}_n + \zeta_n\|_Y + \|\dot{\zeta}_n\|_Y + 2\|\zeta_n\|_Y$ that

$$\frac{1}{2} = \frac{1}{2}\lim_{n\to\infty} \|\zeta_n\|_X \leq \lim_{n\to\infty} \|K'(0)\zeta_n\|_Y = \lim_{n\to\infty} \|\Pi_1^{\perp} K'(0)\zeta_n\|_Y = 0.$$

This is a contradiction and completes the proof. □

Energy functional.

DEFINITION 3.1. *For $q \in X_{\delta/2}$, define*

$$E_\beta[q] := \frac{1}{\beta}|\Gamma(q)| + \frac{1}{2}\int_\Omega |\nabla v|^2\,dx,$$

where

$$v(x) = \int_{\Omega^+(q)} G(x,y)\,dy, \quad x \in \Omega.$$

Note that

$$\begin{aligned}\int_\Omega |\nabla v|^2\,dx &= -\int_\Omega v\Delta v\,dx = \int_\Omega v(\mathbf{1}_{\Omega^+(q)} - m)\,dx \\ &= \int_{\Omega^+(q)}\int_{\Omega^+(q)} G(x,y)\,dxdy. \end{aligned} \tag{3.9}$$

LEMMA 3.4. *Let $T : \mathbb{I} \to X_{\delta/2}$ be a C^1-map from an open interval $\mathbb{I} \subset \mathbb{R}$ to $X_{\delta/2}$. Then*

$$\frac{d}{dt}E_\beta[T(t)] = \frac{1}{2\beta}\langle M_\beta(q), T'(t)\rangle, \tag{3.10}$$

$$\frac{d}{dt}|\Gamma(T(t))| = \frac{1}{2}\langle K(T(t)), T'(t)\rangle. \tag{3.11}$$

Proof. We write $q = T(t)$, $\zeta = T'(t)$, $R = \sqrt{1 + T(t)}$, and $\partial R/\partial t = \zeta/(2R)$. Then

$$|\Gamma(q)| = \int_{S^1} \sqrt{R^2 + \dot{R}^2}\,d\omega.$$

Since

$$\frac{R}{\sqrt{R^2+\dot{R}^2}} - \frac{d}{d\omega}\frac{\dot{R}}{\sqrt{R^2+\dot{R}^2}} = R\frac{R^2 + 2\dot{R}^2 - R\ddot{R}}{\left[R^2+\dot{R}^2\right]^{3/2}} = RK(q),$$

we have

$$\begin{aligned}\frac{d}{dt}|\Gamma(q)| &= \int_{S^1} RK(q)\frac{\partial R}{\partial t}\,d\omega \\ &= \frac{1}{2}\langle K(q), \zeta\rangle. \end{aligned} \tag{3.12}$$

Next let

$$v(x) = \int_{\Omega^+(q)} G(x,y)\,dy, \quad x \in \Omega.$$

Then from (3.9), we have

$$\int_\Omega |\nabla v|^2\,dx = \int_{S^1}\int_{S^1}\int_0^{R(\varphi)}\int_0^{R(\omega)} G(r\omega, s\varphi)rs\,drdsd\omega d\varphi,$$

and thus

$$\frac{d}{dt}\int_\Omega |\nabla v|^2\,dx = \int_{S^1}\int_{S^1}\left\{R(\varphi)\frac{\partial R}{\partial t}(\varphi)\int_0^{R(\omega)} G(r\omega,\varphi R(\varphi))r\,dr \right.$$
$$\left. + R(\omega)\frac{\partial R}{\partial t}(\omega)\int_0^{R(\varphi)} G(\omega R(\omega),s\varphi)s\,ds\right\}d\omega d\varphi$$
$$= \int_{S^1} v(R(\omega)\omega)\zeta\,d\omega. \tag{3.13}$$

Here we used the identities $G(x,y)=G(y,x)$ and

$$\frac{d}{dt}\int_0^{a(t)}\int_0^{b(t)} f(r,s)\,drds = a'(t)\int_0^{b(t)} f(r,a(t))\,dr + b'(t)\int_0^{a(t)} f(b(t),s)\,ds.$$

Hence (3.10) follows from (3.12) and (3.13). □

We apply the following Lemma used in [1, 8, 9, 10].

LEMMA 3.5. *Let X,Y be Banach spaces, $a>0$, $B_a = B_a(z) = \{z\in X\,;\,\|z-z_0\|\le a\}$. Suppose that F is a C^1-map of B_a into Y with $F'(z_0)$ invertible and satisfying, for some $0<\vartheta<1$,*

$$\|F'(z_0)^{-1}F(z_0)\| \le (1-\vartheta)a,$$
$$\|F'(z_0)^{-1}\|\,\|F'(z)-F'(z_0)\| \le \vartheta \quad \forall z\in B_a.$$

Then there is a unique solution in B_a of $F(z)=0$.

Completion of the proof. Define a map $F_\beta(\cdot) = \Pi_1^\perp M_\beta(\psi_\xi+\cdot)$ from $X_{\delta/4}\cap\Pi_1^\perp X$ to $\Pi_1^\perp Y$. Then we can take $a(\beta)>0$ such that $a(\beta)=O(\beta)$ as $\beta\to 0$ and $\|F'_\beta(\psi_\xi)^{-1}F_\beta(\psi_\xi)\|\le\frac{a(\beta)}{2}$. Then we see that for sufficiently small β,

$$\|F'_\beta(\psi_\xi)^{-1}\|\|F'_\beta(\psi_\xi+v)-F'_\beta(\psi_\xi)\| \le \frac{1}{2}$$

for all $v\in X_{a(\beta)}\cap\Pi_1^\perp X$. Then applying Lemma 3.5, we deduce that there exists a function $q^\perp_{\beta,\xi}\in X_{a(\beta)}\cap\Pi_1^\perp X$ solving

$$0 = F(q^\perp_{\beta,\xi}) = \Pi_1^\perp M_\beta(\psi_\xi + q^\perp_{\beta,\xi}). \tag{3.14}$$

Now $\Pi_0^\perp M_\beta(\psi_\xi+q^\perp_{\beta,\xi})=0$ if and only if $\langle M_\beta(\psi_\xi+q^\perp_{\beta,\xi}),\Phi_i\rangle=0$ for $i=1,2$. It follows from Lemma 3.4 and (3.14) that

$$\frac{\partial}{\partial\xi_i}E_\beta[\psi_\xi+q^\perp_{\beta,\xi}] = \frac{1}{2\beta}\langle M_\beta(\psi_\xi+q^\perp_{\beta,\xi}),\Phi_i\rangle,\quad i=1,2. \tag{3.15}$$

We have the following.

LEMMA 3.6. *There hold*

$$E_\beta[\psi_\xi+q^\perp_{\beta,\xi}] - \frac{2\pi}{\beta} = \frac{\pi}{16} + \frac{\pi^2}{8|\Omega|} + \frac{\pi^2}{2}\mathcal{H}(P(\xi)) + o(1), \tag{3.16}$$

and

$$\frac{\partial}{\partial\xi_i}E_\beta[\psi_\xi+q^\perp_{\beta,\xi}] = \frac{\pi^2}{2}\sum_{j=1}^2\frac{\partial\mathcal{H}}{\partial x_j}(P(\xi))\frac{\partial P_j}{\partial\xi_i}(\xi) + o(1),\quad i=1,2, \tag{3.17}$$

as $\beta\to 0$ uniformly in $\xi\in U_2$.

Proof. First we prove (3.16). It follows from (3.12) that

$$|\Gamma(\psi_\xi + q^\perp_{\beta,\xi})| = |\Gamma(\psi_\xi)| + \frac{1}{2}\langle 1, q^\perp_{\beta,\xi}\rangle + o(\|q^\perp_{\beta,\xi}\|_X) = 2\pi + o(\beta) \tag{3.18}$$

as $\beta \to 0$. In addition, we see that

$$\int_{\Omega^+(\psi_\xi + q^\perp_{\beta,\xi})}\int_{\Omega^+(\psi_\xi + q^\perp_{\beta,\xi})} G(x,y)\,dxdy = \int_{\Omega^+(\psi_\xi)}\int_{\Omega^+(\psi_\xi)} G(x,y)\,dxdy + o(1)$$

as $\beta \to 0$. Hence we need prove only

$$E_\beta[\psi_\xi] = \frac{2\pi}{\beta} + \frac{\pi}{16} + \frac{\pi^2}{8|\Omega|} + \frac{\pi^2}{2}\mathcal{H}(P(\xi)), \quad \xi \in U_2. \tag{3.19}$$

By the translation invariance, we have

$$\int_{\Omega^+(\psi_\xi)}\int_{\Omega^+(\psi_\xi)} \log|x-y|\,dxdy = \int_{\Omega^+(0)}\int_{\Omega^+(0)} \log|x-y|\,dxdy = -\frac{1}{4}\pi^2.$$

Similarly using the translation invariance and the fact that there holds

$$\int_{\Omega^+(0)} x \cdot y\,dx = 0$$

for any $y \in \mathbb{R}^2$, we have

$$\begin{aligned}\int_{\Omega^+(\psi_\xi)}\int_{\Omega^+(\psi_\xi)} |x-y|^2\,dxdy &= \int_{\Omega^+(0)}\int_{\Omega^+(0)} |x-y|^2\,dxdy \\ &= \int_{\Omega^+(0)}\int_{\Omega^+(0)} (|x|^2 + |y|^2)\,dxdy = \pi^2.\end{aligned}$$

In addition, by the mean value theorem for harmonic functions, we have

$$\int_{\Omega^+(\psi_\xi)}\int_{\Omega^+(\psi_\xi)} H(x,y)\,dxdy = \pi^2\mathcal{H}(P(\xi)).$$

Hence (3.19) follows and so does (3.16).

Next we prove (3.17). By Lemma 3.4 and (3.14), we see that

$$\begin{aligned}\frac{1}{\beta}\langle M_\beta(\psi_\xi + q^\perp_{\beta,\xi}), \Phi_i\rangle &= \frac{1}{\beta}\left\langle M_\beta(\psi_\xi + q^\perp_{\beta,\xi}), \frac{\partial\psi_\xi}{\partial\xi_i}\right\rangle \\ &= \frac{1}{\beta}\left\langle M_\beta(\psi_\xi), \frac{\partial\psi_\xi}{\partial\xi_i}\right\rangle + \frac{1}{\beta}\left\langle M'_\beta(\psi_\xi)q^\perp_{\beta,\xi}, \frac{\partial\psi_\xi}{\partial\xi_i}\right\rangle + o(1) \qquad (3.20)\end{aligned}$$

as $\beta \to 0$. By Lemma 3.4, we have

$$\frac{1}{\beta}\left\langle M_\beta(\psi_\xi), \frac{\partial\psi_\xi}{\partial\xi_i}\right\rangle = 2\frac{\partial}{\partial\xi_i}E_\beta[\psi_\xi]. \tag{3.21}$$

Noting that $K'(\psi_\xi)\frac{\partial\psi_\xi}{\partial\xi_i} \equiv 0$ since $K(\psi_\xi) \equiv 1$, it follows from Lemma 3.2 that

$$\begin{aligned}\frac{1}{\beta}\left\langle M'_\beta(\psi_\xi)q^\perp_{\beta,\xi}, \frac{\partial\psi_\xi}{\partial\xi_i}\right\rangle &= \frac{1}{\beta}\left\langle K'(\psi_\xi)q^\perp_{\beta,\xi}, \frac{\partial\psi_\xi}{\partial\xi_i}\right\rangle + O(\beta) \\ &= \frac{1}{\beta}\left\langle q^\perp_{\beta,\xi}, K'(\psi_\xi)\frac{\partial\psi_\xi}{\partial\xi_i}\right\rangle + O(\beta) \\ &= O(\beta) \qquad (3.22)\end{aligned}$$

as $\beta \to 0$. Thus (3.17) follows from (3.15), (3.19), (3.20), (3.21), and (3.22). ∎

Since

$$\begin{aligned}\frac{\partial}{\partial\xi_k}\sum_{j=1}^{2}\frac{\partial\mathcal{H}}{\partial x_j}(P(\xi))\frac{\partial P_j}{\partial\xi_i}(\xi)\bigg|_{\xi=0}&\\ &=\sum_{j,n=1}^{2}\frac{\partial^2\mathcal{H}}{\partial x_j\partial x_n}(0)\frac{\partial P_n}{\partial\xi_k}(0)\frac{\partial P_j}{\partial\xi_i}(0)+\sum_{j=1}^{2}\frac{\partial\mathcal{H}}{\partial x_j}(0)\frac{\partial P_j}{\partial\xi_i\partial\xi_k}(0)\\ &=\frac{1}{4\pi}\frac{\partial^2\mathcal{H}}{\partial x_i\partial x_k}(0),\end{aligned}$$

it follows from (3.15) and (3.17) that if $\frac{\partial^2\mathcal{H}}{\partial x_i\partial x_k}(0)$ is nondegenerate, then there exists a $\xi_\beta\in U_2$ such that $\langle M_\beta(\psi_{\xi_\beta}+q^{\perp}_{\beta,\xi_\beta}),\Phi_i\rangle=0$ $(i=1,2)$ and $\lim_{\beta\to0}\xi_\beta=0$. Thus $\psi_{\xi_\beta}+q^{\perp}_{\beta,\xi_\beta}$ is a solution of $\Pi_0^{\perp}M_\beta(\cdot)=0$.

If 0 is a strict local minimum point of $\mathcal{H}$, it follows from (3.15) and (3.16) that there exists a $\xi_\beta\in U_2$ such that $\langle M_\beta(\psi_{\xi_\beta}+q^{\perp}_{\beta,\xi_\beta}),\Phi_i\rangle=0$ $(i=1,2)$ and $\lim_{\beta\to0}\xi_\beta=0$. The proof is complete. □

4. Linearized nondegeneracy. In this section, we continue to use the notation defined in section 3. Throughout this section, we assume that there exists a compact subset $\mathcal{N}\subset\Omega$ satisfying $\operatorname{dist}(\mathcal{N},\partial\Omega)>1$. We linearize the equation around $\boldsymbol{P}+\Gamma(q)=\{\boldsymbol{P}+\sqrt{1+q(\omega)}\omega\,;\,\omega\in S^1\}$ for $\boldsymbol{P}\in\mathcal{N}$. Set

$$M_\beta(q\,;\boldsymbol{P})(\omega):=K(q)(\omega)+\beta\int_{\boldsymbol{P}+\Omega^+(q)}G(\boldsymbol{P}+\sqrt{1+q(\omega)}\omega,y)\,dy,\qquad\omega\in S^1$$

for $q\in X_{\delta/2}$, where $\boldsymbol{P}+\Omega^+(q)$ is the region surrounded by $\boldsymbol{P}+\Gamma(q)$.

THEOREM 4.1. *Suppose that*

(B1) *for every small $\beta>0$, there exist $\tilde q_\beta\in X$ and $\boldsymbol{P}\in\mathcal{N}$ such that*

$$(\Pi_4-\Pi_1)M_\beta(\tilde q_\beta\,;\boldsymbol{P})=0,$$

(B2) $\|\tilde q_\beta\|_X=O(\beta)$ *as* $\beta\to0$, *and*

(B3) *the Hessian matrix $\big(\frac{\partial^2\mathcal{H}}{\partial x_i\partial x_j}(\boldsymbol{P})\big)_{1\le i,j\le2}$ of $\mathcal{H}$ is nondegenerate for any $\boldsymbol{P}\in\mathcal{N}$.*

Then for sufficiently small β, $\mathcal{L}=\Pi_0^{\perp}M'_\beta(\tilde q_\beta\,;\boldsymbol{P})$ is nondegenerate in the sense that $\mathcal{L}\zeta=0$, $\int_{S^1}\zeta\,d\omega=0$ implies that $\zeta=0$.

Let $q_\beta=\psi_{\xi_\beta}+q^{\perp}_{\beta,\xi_\beta}$ be a solution obtained in Proposition 3.1. If you define $\tilde q_\beta$ such as $\Gamma(\psi_{\xi_\beta}+q^{\perp}_{\beta,\xi_\beta})=P(\xi_\beta)+\Gamma(\tilde q_\beta)$, then (B1) with $\boldsymbol{P}=P(\xi_\beta)$ and (B2) hold. Thus we have the following.

COROLLARY 4.1. *Suppose* (A2). *Then the solution obtained in Theorem* 1.1 *is nondegenerate in the sense of Theorem* 4.1.

Proof of Theorem 4.1. For brevity's sake, we write $q=\tilde q_\beta$. Set

$$\begin{aligned}B(\zeta,\zeta)=&\int_{S^1}[-L_s(q,\dot q,\ddot q)\dot\zeta^2+L_t(q,\dot q,\ddot q)\zeta^2]\,d\omega\\ &+\frac{\beta}{2}\int_{S^1}\int_{S^1}\zeta(\omega)G(\boldsymbol{P}+\sqrt{1+q(\omega)}\omega,\boldsymbol{P}+\sqrt{1+q(\hat\omega)}\hat\omega)\zeta(\hat\omega)\,d\omega d\hat\omega\\ &+\frac{\beta}{2}\int_{S^1}d\omega\frac{\zeta(\omega)^2}{\sqrt{1+q(\omega)}}\int_{\boldsymbol{P}+\Omega^+(q)}\omega\cdot\nabla_xG(\boldsymbol{P}+\sqrt{1+q(\omega)}\omega,y)\,dy\end{aligned}\tag{4.1}$$

for $\zeta \in H^1(S^1)$. We regard $\mathcal{L}$ as the operator on $\Pi_0^\perp H^2(S^1)$ satisfying $B(\zeta,\zeta) = \langle \mathcal{L}\zeta, \zeta\rangle$ for all $\zeta \in \Pi_0^\perp H^2(S^1)$.

LEMMA 4.1. *Suppose* (B2). *Let* $\lambda_1 \le \lambda_2 \le \lambda_3 \le \cdots$ *be the eigenvalues of* $\mathcal{L} : \Pi_0^\perp H^2(S^1) \to \Pi_0^\perp L^2(S^1)$ *and* $\zeta_i \in \Pi_0^\perp H^2(S^1)$ *be the normalized eigenfunctions associated with* λ_i. *Then*

$$\lambda_1 = \inf_{\zeta \in \Pi_0^\perp H^1(S^1), \|\zeta\|=1} B(\zeta,\zeta) = B(\zeta_1,\zeta_1) = O(\beta), \tag{4.2}$$

$$\lambda_2 = \inf_{\substack{\zeta \in \Pi_0^\perp H^1(S^1), \|\zeta\|=1 \\ \zeta \perp \zeta_1}} B(\zeta,\zeta) = B(\zeta_2,\zeta_2) = O(\beta), \tag{4.3}$$

$$\lambda_3 = \inf_{\substack{\zeta \in \Pi_0^\perp H^1(S^1), \|\zeta\|=1 \\ \zeta \perp \mathrm{span}\{\zeta_1,\zeta_2\}}} B(\zeta,\zeta) = B(\zeta_3,\zeta_3) = \frac{3}{2} + O(\beta). \tag{4.4}$$

Proof. The characterization of eigenvalues of $\mathcal{L}$ comes from the min-max principle of eigenvalues:

$$\lambda_i = \inf_{V_i \in \mathcal{S}_i} \max_{\substack{\zeta \in V_i \\ \|\zeta\|=1}} B(\zeta,\zeta), \quad i = 1,2,\ldots, \tag{4.5}$$

where $\mathcal{S}_i$ is the set of all i-dimensional subspace in $\Pi_0^\perp H^1(S^1)$. We need show only that $\lambda_i = \frac{1}{2}\left(\left[\frac{i+1}{2}\right]^2 - 1\right) + O(\beta)$ for $i = 1,2,\ldots$, where $[\frac{i+1}{2}]$ denotes the largest integer which is less than or equal to $\frac{i+1}{2}$.

We see that there exists a constant C such that $B(\zeta,\zeta) \ge \langle K'(0)\zeta,\zeta\rangle - C\beta\|\zeta\|^2 - C\beta\|\dot\zeta\|^2 \ge \frac{1}{2}(\|\dot\zeta\|^2 - \|\zeta\|^2) - C\beta\|\zeta\|^2 - C\beta\|\dot\zeta\|^2$ for all $\zeta \in H^1(S^1)$ and all small β.

For any $V_i \in \mathcal{S}_i$, let $V_{i+1} = V_i \oplus \mathrm{span}\{1\} \in \mathcal{T}_{i+1}$. Note that there holds

$$\left[\frac{i+1}{2}\right]^2 = \inf_{W_{i+1} \in \mathcal{T}_{i+1}} \max_{\substack{\zeta \in W_{i+1} \\ \|\zeta\|=1}} \left\|\dot\zeta\right\|^2,$$

where $\mathcal{T}_{i+1}$ is the set of all $(i+1)$-dimensional subspace in $H^1(S^1)$. It follows that $\max_{\zeta \in V_{i+1}} \|\dot\zeta\|^2/\|\zeta\|^2 \ge [\frac{i+1}{2}]^2$. This means that there exists a $\zeta^* \in V_{i+1}$ such that $\|\dot{\zeta^*}\|^2 \ge [\frac{i+1}{2}]^2$ and $\|\zeta^*\| = 1$. Setting $\zeta^* = \Pi_0\zeta^* + \zeta^\perp$, we have $0 < \|\zeta^\perp\| \le 1$ since $\|\dot{\zeta^\perp}\|^2 = \|\dot{\zeta^*}\|^2$ and $\|\zeta^*\|^2 = (\Pi_0\zeta^*)^2 + \|\zeta^\perp\|^2$. Then $\zeta^{**} = \frac{\zeta^\perp}{\|\zeta^\perp\|}$ satisfies $\zeta^{**} \in V_i$, $\|\zeta^{**}\| = 1$, and $\|\dot{\zeta^{**}}\|^2 \ge [\frac{i+1}{2}]^2$. Hence $\max_{\substack{\zeta \in V_i \\ \|\zeta\|=1}} B(\zeta,\zeta) \ge B(\zeta^{**},\zeta^{**}) \ge (\frac{1}{2} - C\beta)\|\dot{\zeta^{**}}\|^2 - (\frac{1}{2} + C\beta)\|\zeta^{**}\|^2 \ge ([\frac{i+1}{2}]^2 - 1)/2 - C([\frac{i+1}{2}]^2 + 1)\beta$. Hence we conclude that $\lambda_i \ge \frac{1}{2}\left([\frac{i+1}{2}]^2 - 1\right) + O(\beta)$.

On the other hand, let $V_1 = \mathrm{span}\{\cos\theta\}$ and

$$V_i = \begin{cases} \mathrm{span}\{\cos j\theta, \sin j\theta\,;\, j = 1,\ldots,n\} & \text{if } i = 2n \\ \mathrm{span}\{\cos j\theta, \sin j\theta, \cos(n+1)\theta\,;\, j = 1,\ldots,n\} & \text{if } i = 2n+1. \end{cases}$$

Then we see that $V_i \in \mathcal{S}_i$ and

$$\max_{\substack{\zeta \in V_i \\ \|\zeta\|=1}} \left\|\dot\zeta\right\|^2 = \left[\frac{i+1}{2}\right]^2.$$

Therefore we have

$$\begin{aligned} \lambda_i \le \max_{\substack{\zeta \in V_i \\ \|\zeta\|=1}} B(\zeta,\zeta) &\le \max_{\substack{\zeta \in V_i \\ \|\zeta\|=1}} \left\{ \frac{1}{2}\left(\left\|\dot\zeta\right\|^2 - \|\zeta\|^2\right) + C\beta\|\zeta\|^2 \right\} \\ &\le \frac{1}{2}\left(\left[\frac{i+1}{2}\right]^2 - 1\right) + O(\beta). \end{aligned}$$

The proof is complete. □

LEMMA 4.2.

1. *There hold* $L_{ts}(0,0,0) = L_{tt}(0,0,0) = L_{pp}(0,0,0) = \frac{3}{4}$ *and* $L_{ss}(0,0,0) = L_{ps}(0,0,0) = L_{tp}(0,0,0) = 0$ *(the definition of* $L(t,p,s)$ *is* (3.2)*).*
2. *There hold*

$$\int_{S^1} d\omega \Phi_j(\omega)\Phi_k(\omega)\omega \cdot \nabla_x H(\boldsymbol{P}+\omega,\boldsymbol{P}) = \frac{1}{2}\frac{\partial^2 H}{\partial x_j \partial x_k}(x,y)\Big|_{x=y=\boldsymbol{P}} \tag{4.6}$$

and

$$\int_{S^1}\int_{S^1} \Phi_j(\omega)H(\boldsymbol{P}+\omega,\boldsymbol{P}+\hat{\omega})\Phi_k(\hat{\omega})\, d\omega d\hat{\omega} = \pi\frac{\partial^2 H}{\partial x_j \partial y_k}(x,y)\Big|_{x=y=\boldsymbol{P}} \tag{4.7}$$

for each $j,k = 1,2$.

3. *Suppose* (B1) *and* (B2) *hold. Then*

$$\lim_{\beta\to 0}\frac{1}{\beta}\langle \dot{q}\Phi_k, \dot{\Phi}_j\rangle = -\frac{\pi}{3}\frac{\partial^2 H}{\partial x_j \partial x_k}(x,y)\Big|_{x=y=\boldsymbol{P}} \tag{4.8}$$

for each $j,k = 1,2$.

Proof. Part 1 follows from a simple computation.

By Green's theorem and the mean value theorem for harmonic functions,

$$\begin{aligned}\int_{S_r} ds_x \frac{\partial H}{\partial x_j}(\boldsymbol{P}+x,\boldsymbol{P})x_k &= r\int_{S_r} ds_x \frac{\partial H}{\partial x_j}(\boldsymbol{P}+x,\boldsymbol{P})\frac{x_k}{r}\\ &= r\int_{B_r}\frac{\partial^2 H}{\partial x_j \partial x_k}(\boldsymbol{P}+x,\boldsymbol{P})\, dx\\ &= \pi r^3 \frac{\partial^2 H}{\partial x_j \partial x_k}(\boldsymbol{P},\boldsymbol{P}),\end{aligned} \tag{4.9}$$

and hence

$$\begin{aligned}\int_{B_1}\frac{\partial H}{\partial x_j}(\boldsymbol{P}+x,\boldsymbol{P})x_k\, dx &= \int_0^1 dr\int_{S_r} ds_x \frac{\partial H}{\partial x_j}(\boldsymbol{P}+x,\boldsymbol{P})x_k\\ &= \int_0^1 \pi r^3\, dr \frac{\partial^2 H}{\partial x_j \partial x_k}(\boldsymbol{P},\boldsymbol{P})\\ &= \frac{\pi}{4}\frac{\partial^2 H}{\partial x_j \partial x_k}(\boldsymbol{P},\boldsymbol{P}).\end{aligned} \tag{4.10}$$

It then follows from Green's theorem that

$$\begin{aligned}&\pi\int_{S^1} d\omega \Phi_j(\omega)\Phi_k(\omega)\omega\cdot\nabla_x H(\boldsymbol{P}+\omega,\boldsymbol{P})\\ &\qquad = \sum_{i=1}^2 \int_{S^1}\omega_i\omega_j\omega_k \frac{\partial H}{\partial x_i}(\boldsymbol{P}+\omega,\boldsymbol{P})\, d\omega\\ &\qquad = \int_{B_1}\frac{\partial H}{\partial x_j}(\boldsymbol{P}+x,\boldsymbol{P})x_k + \frac{\partial H}{\partial x_k}(\boldsymbol{P}+x,\boldsymbol{P})x_j\, dx\\ &\qquad = \frac{\pi}{2}\frac{\partial^2 H}{\partial x_j \partial x_k}(\boldsymbol{P},\boldsymbol{P}),\end{aligned} \tag{4.11}$$

and thus (4.6) follows.

By Green's theorem and the mean value theorem, we have

$$\begin{aligned}
\pi \int_{S^1}\int_{S^1} \Phi_j(\omega) H(\boldsymbol{P}+\omega, \boldsymbol{P}+\hat{\omega})\Phi_k(\hat{\omega})\, d\omega d\hat{\omega} & \\
&= \int_{S^1}\int_{S^1} H(\boldsymbol{P}+x, \boldsymbol{P}+\hat{x}) x_j \hat{x}_k \, ds_x ds_{\hat{x}} \\
&= \int_{S^1}\int_{B_1} \frac{\partial H(\boldsymbol{P}+x, \boldsymbol{P}+\hat{x})}{\partial \hat{x}_k} x_j \, ds_x d\hat{x} \\
&= \pi \int_{S^1} x_j \frac{\partial H}{\partial \hat{x}_k}(\boldsymbol{P}+x, \boldsymbol{P}) ds_x \\
&= \pi \int_{B_1} \frac{\partial^2 H}{\partial x_j \partial \hat{x}_k}(\boldsymbol{P}+x, \boldsymbol{P}) dx \\
&= \pi^2 \frac{\partial^2 H}{\partial x_j \partial \hat{x}_k}(\boldsymbol{P}, \boldsymbol{P}). \qquad (4.12)
\end{aligned}$$

Thus (4.7) follows.

On the other hand,

$$\begin{aligned}
\langle \dot{q}\Phi_k, \dot{\Phi}_j\rangle &= -\langle q, \dot{\Phi}_k \dot{\Phi}_j\rangle - \langle q, \Phi_k \ddot{\Phi}_j\rangle \\
&= -\langle q, \dot{\Phi}_j \dot{\Phi}_k\rangle + \langle q, \Phi_j \Phi_k\rangle \\
&= \left\langle q, 2\Phi_j\Phi_k - \frac{\delta_{jk}}{\pi}\right\rangle. \qquad (4.13)
\end{aligned}$$

Set $\Phi_{jk} = 2\Phi_j\Phi_k - \frac{\delta_{jk}}{\pi}$. From Lemmas 3.3 and 3.2 we have

$$\langle q, \Phi_{jk}\rangle = \frac{2}{3}\langle q, K'(0)\Phi_{jk}\rangle = \frac{2}{3}\langle K'(0)q, \Phi_{jk}\rangle. \qquad (4.14)$$

Since $\langle M_\beta(q\,;\boldsymbol{P}), \Phi_{jk}\rangle = 0$ by (B1), we have $\langle M_\beta(0\,;\boldsymbol{P}), \Phi_{jk}\rangle + \langle M'_\beta(0\,;\boldsymbol{P})q, \Phi_{jk}\rangle = o(\beta)$. Noting (B2), we see that

$$\begin{aligned}
\lim_{\beta\to 0}\left\langle \frac{K'(0)q}{\beta}, \Phi_{jk}\right\rangle &= -\int_{S^1}\int_{B_1} G(\boldsymbol{P}+\omega, \boldsymbol{P}+y)\, dy \Phi_{jk}(\omega)\, d\omega \\
&= -\pi \int_{S^1} G(\boldsymbol{P}+\omega, \boldsymbol{P})\Phi_{jk}(\omega)\, d\omega \\
&= -\pi \int_{S^1} H(\boldsymbol{P}+\omega, \boldsymbol{P})\Phi_{jk}(\omega)\, d\omega. \qquad (4.15)
\end{aligned}$$

On the other hand, it follows from (4.10) and Green's theorem that

$$\begin{aligned}
\pi \int_{S^1} d\omega \Phi_j(\omega)\Phi_k(\omega) H(\boldsymbol{P}+\omega, \boldsymbol{P}) &= \int_{S^1} d\omega \omega_j \omega_k H(\boldsymbol{P}+\omega, \boldsymbol{P}) \\
&= \int_{B_1} \frac{\partial H}{\partial x_j}(\boldsymbol{P}+x, \boldsymbol{P}) x_k + \delta_{jk} H(\boldsymbol{P}+x, \boldsymbol{P})\, dx \\
&= \frac{\pi}{4}\frac{\partial^2 H}{\partial x_j \partial x_k}(\boldsymbol{P}, \boldsymbol{P}) + \delta_{jk}\pi H(\boldsymbol{P}, \boldsymbol{P}). \qquad (4.16)
\end{aligned}$$

Thus by (4.13), (4.15), (4.14), and (4.16), we conclude that

$$\lim_{\beta\to 0}\frac{1}{\beta}\langle\dot{q}\Phi_j,\dot{\Phi}_k\rangle = -\frac{2}{3}\pi\int_{S^1} H(\boldsymbol{P}+\omega,\boldsymbol{P})\left(2\Phi_j\Phi_k-\frac{\delta_{jk}}{\pi}\right)d\omega$$

$$= -\frac{\pi}{3}\frac{\partial^2 H}{\partial x_j\partial x_k}(\boldsymbol{P},\boldsymbol{P}). \tag{4.17}$$

The proof of (4.8) is complete. □

LEMMA 4.3. *Suppose* (B1) *and* (B2) *hold. Then there exists an orthogonal matrix* $(c_{ij})_{1\le i,j\le 2}$ *such that for* $i=1,2$, $\zeta_i^R=\zeta_i-(c_{1i}\Phi_1+c_{2i}\Phi_2)$ *satisfies* $\|\zeta_i^R\|^2=O(\beta)$ *as* $\beta\to 0$. *In addition, there holds*

$$\sum_{k=1}^{2}\frac{\pi}{4}\frac{\partial^2\mathcal{H}}{\partial x_j\partial x_k}(\boldsymbol{P})c_{ki} = o(1)+\frac{\lambda_i}{\beta}c_{ji} \tag{4.18}$$

for each $i,j=1,2$.

Proof. Set

$$\Phi_1 = d_{11}\zeta_1+d_{12}\zeta_2+\zeta_1^{\perp}, \tag{4.19}$$

$$\Phi_2 = d_{21}\zeta_1+d_{22}\zeta_2+\zeta_2^{\perp}, \tag{4.20}$$

where $\zeta_i^{\perp}\in\Pi_0^{\perp}H^2(S^1)$ and $\zeta_i^{\perp}\perp\operatorname{span}\{\zeta_1,\zeta_2\}$ for $i=1,2$. Then we have, for $i=1,2$,

$$\begin{aligned} O(\beta) &= B(\Phi_i,\Phi_i)\\ &= \langle\mathcal{L}\Phi_i,\Phi_i\rangle\\ &= d_{i1}^2\lambda_1+d_{i2}^2\lambda_2+\langle\mathcal{L}\zeta_i^{\perp},\zeta_i^{\perp}\rangle\\ &\ge O(\beta)+\|\zeta_i^{\perp}\|^2 \end{aligned} \tag{4.21}$$

and thus $\|\zeta_i^{\perp}\|^2=O(\beta)$. On the other hand, we have $1=d_{i1}^2+d_{i2}^2+\|\zeta_i^{\perp}\|^2$ and $0=d_{11}d_{21}+d_{12}d_{22}+\langle\zeta_1^{\perp},\zeta_2^{\perp}\rangle$. Hence we see that there exists an orthogonal matrix (c_{ij}) such that $d_{ij}=c_{ij}+O(\sqrt{\beta})$. Then since

$$\begin{aligned} \begin{pmatrix}\zeta_1\\ \zeta_2\end{pmatrix}-\begin{pmatrix}c_{11}&c_{21}\\ c_{12}&c_{22}\end{pmatrix}\begin{pmatrix}\Phi_1\\ \Phi_2\end{pmatrix} &= \begin{pmatrix}c_{11}&c_{21}\\ c_{12}&c_{22}\end{pmatrix}\begin{pmatrix}c_{11}-d_{11}&c_{12}-d_{12}\\ c_{21}-d_{21}&c_{22}-d_{22}\end{pmatrix}\begin{pmatrix}\zeta_1\\ \zeta_2\end{pmatrix}\\ &\quad -\begin{pmatrix}c_{11}&c_{21}\\ c_{12}&c_{22}\end{pmatrix}\begin{pmatrix}d_{10}\zeta_0+\zeta_1^{\perp}\\ d_{20}\zeta_0+\zeta_2^{\perp}\end{pmatrix}, \end{aligned} \tag{4.22}$$

$\zeta_i^R=\zeta_i-\sum_{k=1}^{2}c_{ki}\Phi_k$ satisfies the desired estimate. This completes the proof of the first part of Lemma 4.3.

Multiplying Φ_j to $\lambda_i\zeta_i=\mathcal{L}\zeta_i$ and integrating over S^1, we have $\lambda_i\langle\zeta_i,\Phi_j\rangle=\langle\mathcal{L}\zeta_i,\Phi_j\rangle$. Substituting $\zeta_i=\sum_{k=1}^{2}c_{ki}\Phi_k+\zeta_i^R$, we then have

$$\begin{aligned} \lambda_i c_{ji}+\lambda_i\langle\zeta_i^R,\Phi_j\rangle &= \sum_{k=1}^{2}c_{ki}\langle\mathcal{L}\Phi_k,\Phi_j\rangle+\langle\mathcal{L}\zeta_i^R,\Phi_j\rangle\\ &= \sum_{k=1}^{2}c_{ki}\langle\mathcal{L}\Phi_k,\Phi_j\rangle+\langle\zeta_i^R,\mathcal{L}\Phi_j\rangle, \end{aligned} \tag{4.23}$$

and hence $\sum_{k=1}^{2} c_{ki}\langle \mathcal{L}\Phi_k, \Phi_j\rangle = \lambda_i c_{ji} + o(\beta)$ by $\lambda_i = O(\beta)$, $\mathcal{L}\Phi_j = K'(0)\Phi_j + O(\beta) = O(\beta)$, and $\zeta_i^R = O(\sqrt{\beta})$. We need prove only that

$$\lim_{\beta\to 0} \frac{1}{\beta}\langle \mathcal{L}\Phi_k, \Phi_j\rangle = \frac{\pi}{4}\frac{\partial^2 \mathcal{H}}{\partial x_j \partial x_k}(\boldsymbol{P}). \tag{4.24}$$

Since $K''(0)(q_1, q_2) = \frac{3}{4}(\ddot{q}_1 q_2 + \dot{q}_1\dot{q}_2 + q_1 q_2 + q_1\ddot{q}_2)$ by Lemma 4.2 part 1 and $K'(0)\Phi_k = -\frac{1}{2}\{\ddot{\Phi}_k + \Phi_k\} = 0$, integrating by parts yields

$$\begin{aligned}
\langle K'(q)\Phi_k, \Phi_j\rangle &= \langle K'(0)\Phi_k, \Phi_j\rangle + \langle K''(0)(q, \Phi_k), \Phi_j\rangle + o(\beta) \\
&= \frac{3}{4}\langle \ddot{q}\Phi_k + \dot{q}\dot{\Phi}_k + q\Phi_k + q\ddot{\Phi}_k, \Phi_j\rangle + o(\beta) \\
&= -\frac{3}{4}\langle \dot{q}\Phi_k, \dot{\Phi}_j\rangle + o(\beta). \qquad (4.25)
\end{aligned}$$

Hence by (4.8), we have

$$\lim_{\beta\to 0} \frac{1}{\beta}\langle K'(q)\Phi_k, \Phi_j\rangle = \frac{\pi}{4}\frac{\partial^2 H}{\partial x_j \partial x_k}(\boldsymbol{P}, \boldsymbol{P}). \tag{4.26}$$

On the other hand, we have

$$\begin{aligned}
&\lim_{\beta\to 0}\int_{S^1}\int_{S^1} \Phi_j(\omega) G(\boldsymbol{P} + \sqrt{1+q(\omega)}\omega, \boldsymbol{P} + \sqrt{1+q(\hat{\omega})}\hat{\omega})\Phi_k(\hat{\omega})\, d\omega d\hat{\omega} \\
&\qquad = \int_{S^1}\int_{S^1} \Phi_j(\omega) G(\boldsymbol{P} + \omega, \boldsymbol{P} + \hat{\omega})\Phi_k(\hat{\omega})\, d\omega d\hat{\omega} \\
&\qquad = \frac{1}{2}\delta_{jk} - \frac{\pi}{2|\Omega|}\delta_{jk} + \pi\frac{\partial^2 H}{\partial x_j \partial y_k}(\boldsymbol{P}, \boldsymbol{P}). \qquad (4.27)
\end{aligned}$$

Here we used (4.7),

$$-\frac{1}{2\pi}\int_{S^1} \log|\omega - \hat{\omega}|\Phi_j(\hat{\omega})\, d\hat{\omega} = \frac{1}{2}\Phi_j(\omega), \tag{4.28}$$

and

$$\begin{aligned}
\int_{S^1} \frac{|\omega - \hat{\omega}|^2}{4}\Phi_j(\hat{\omega})\, d\hat{\omega} &= \int_{B_1} \frac{y_j - \omega_j}{2\sqrt{\pi}}\, dy \\
&= -\frac{\pi}{2}\Phi_j(\omega). \qquad (4.29)
\end{aligned}$$

Moreover,

$$\begin{aligned}
&\lim_{\beta\to 0}\int_{S^1} \Phi_j(\omega)\frac{\Phi_k(\omega)}{\sqrt{1+q(\omega)}}\int_{\Omega^+(q)} \omega\cdot\nabla_x G(\boldsymbol{P} + \sqrt{1+q(\omega)}\omega, \boldsymbol{P} + y)\, dy \\
&\qquad = \int_{S^1} d\omega \Phi_j(\omega)\Phi_k(\omega)\int_{B_1} \omega\cdot\nabla_x G(\boldsymbol{P} + \omega, \boldsymbol{P} + y)\, dy \\
&\qquad = -\frac{1}{2}\delta_{jk} + \frac{\pi}{2|\Omega|}\delta_{jk} + \frac{\pi}{2}\frac{\partial^2 H}{\partial x_j \partial x_k}(\boldsymbol{P}, \boldsymbol{P}). \qquad (4.30)
\end{aligned}$$

Here we used

$$\begin{aligned}\int_{S^1} d\omega\Phi_j(\omega)\Phi_k(\omega)\int_{B_1}\omega\cdot\nabla_x H(\boldsymbol{P}+\omega,\boldsymbol{P}+y)\,dy&\\ =\pi\int_{S^1} d\omega\Phi_j(\omega)\Phi_k(\omega)\omega\cdot\nabla_x H(\boldsymbol{P}+\omega,\boldsymbol{P})&\\ =\frac{\pi}{2}\frac{\partial^2 H}{\partial x_j\partial x_k}(\boldsymbol{P},\boldsymbol{P})\qquad\text{by (4.6)},&\end{aligned}$$

$$-\frac{1}{2\pi}\nabla_x\int_{B_1}\log|x-y|\,dy=-\frac{x}{2},$$

and

$$\nabla_x\int_{B_1}\frac{|x-y|^2}{4}\,dy=\frac{\pi}{2}x.$$

Consequently by (4.26), (4.27), and (4.30), we have

$$\lim_{\beta\to 0}\frac{1}{\beta}\langle\mathcal{L}\Phi_k,\Phi_j\rangle=\frac{\pi}{2}\frac{\partial^2 H}{\partial x_j\partial y_k}(\boldsymbol{P},\boldsymbol{P})+\frac{\pi}{2}\frac{\partial^2 H}{\partial x_j\partial x_k}(\boldsymbol{P},\boldsymbol{P})=\frac{\pi}{4}\frac{\partial^2\mathcal{H}}{\partial x_j\partial x_k}(\boldsymbol{P}),\tag{4.31}$$

and the proof is complete. □

Completion of the proof of Theorem 4.1. Assume by contrary that there exists a sequence ζ_β such that $\mathcal{L}\zeta_\beta=0$, $\|\zeta_\beta\|=1$, and $\int_{S^1}\zeta_\beta\,d\omega=0$. This means that ζ_β is an eigenfunction of $\mathcal{L}$ associated with the eigenvalue 0. We see that for sufficiently small β, either λ_1 or λ_2 is equal to 0. Then by Lemma 4.3, we have $\zeta_\beta=c_1\Phi_1+c_2\Phi_2+\zeta^R$ such that $(c_1,c_2)\in S^1$ and $\|\zeta^R\|^2=O(\beta)$, and

$$\sum_{k=1}^{2}\frac{\partial^2\mathcal{H}}{\partial x_j\partial x_k}(\boldsymbol{P})c_k=o(1)\quad\text{for } j=1,2$$

as $\beta\to 0$. Taking a subsequence if necessary, we may assume that $(c_1,c_2)\to(\hat{c}_1,\hat{c}_2)\in S^1$ and

$$\sum_{k=1}^{2}\frac{\partial^2\mathcal{H}}{\partial x_j\partial x_k}(\boldsymbol{P})\hat{c}_k=0\quad\text{for } j=1,2.$$

It follows from (B3) that $\hat{c}_1=\hat{c}_2=0$. This is a contradiction and completes the proof.

Appendix A. Formal derivation of reduced problem. We shall formally deduce the reduced problem. If we assume $u\to u_0$ and $v\to v_0$ in the limit $\varepsilon\to 0$, we have

$$f(u_0)=\mu v_0,\quad \Delta v_0=0\quad\text{in }\Omega,$$

$$\frac{\partial v_0}{\partial n}=0\quad\text{on }\partial\Omega.$$

Hence v_0 is a constant. Now assume that v_0 is close to 0 and

$$u_0=f_1^{-1}(\mu v_0)\mathbf{1}_{\Omega^+}+f_0^{-1}(\mu v_0)\mathbf{1}_{\Omega^-},$$

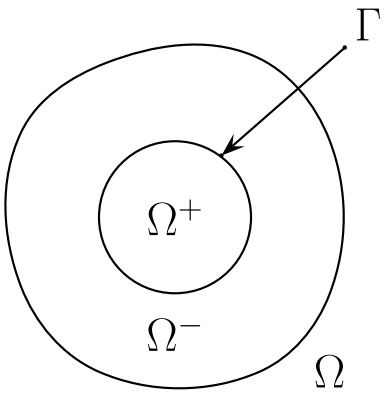

FIG. 1. *Sharp interface* Γ *and the domain* Ω.

where Ω^+, Ω^- are mutually disjoint open sets in Ω such that $\Gamma = \Omega \backslash (\Omega^+ \cup \Omega^-)$ is a curve embedded in Ω, $\mathbf{1}_{\Omega^\pm}$ denote the characteristic functions of $\Omega^\pm$, and $u = f_i^{-1}(v)$ are the inverse functions of $v = f(u)$ near $u = i$ $(i = 0, 1)$, respectively. We call Γ the sharp interface (see Figure 1). We shall identify the profile of u near Γ.

It is known that there exists a constant $\tau > 0$, depending on f, such that for any $v \in (-\tau, \tau)$, the equation for u, $u_t = u_{xx} + f(u) - v$, has a traveling wave solution $u(x,t) = Q(x - ct\,; v)$ with the speed $c = c(v)$ and the profile $Q = Q(\xi; v)$. More precisely, $c(v)$ and $Q(\xi; v)$ for $v \in (-\tau, \tau), \xi \in \mathbb{R}$ satisfy

$$\begin{cases} \ddot{Q} + c(v)\dot{Q} + f(Q) - v = 0 \quad \text{in } \mathbb{R}, \\ \lim_{\xi \to -\infty} Q(\xi; v) = f_1^{-1}(v), \\ \lim_{\xi \to +\infty} Q(\xi; v) = f_0^{-1}(v), \\ c(0) = 0. \end{cases}$$

Here $\dot{}$ means $d/d\xi$. See, for example, [3]. Near the sharp interface Γ, consider the function

$$u(x) = Q\left(\frac{d(x)}{\varepsilon}; v\right),$$

where $d = d(x)$ is the signed distance function from Γ such that $d(x) > 0$ if $x \in \Omega^-$ and $d(x) < 0$ if $x \in \Omega^+$. If the above function satisfies the first equation of (1.4) for each prescribed v, noting that $|\nabla d| = 1$, there holds

$$\ddot{Q} + \varepsilon(\Delta d)\dot{Q} + f(Q) - \mu v = 0.$$

Since Δd is equal to the curvature κ of Γ on the interface Γ (here we choose the sign such that $\kappa > 0$ when Ω^+ is a disk), it follows that

$$c(\mu v) = \varepsilon\kappa \qquad \text{on } \Gamma.$$

Since $c(0) = 0$ by the assumption, we may assume that $v_0 = 0$ and $u_0 = \mathbf{1}_{\Omega^+}$.

Next we consider the higher order term. Assume

$$v = \varepsilon v_1 + O(\varepsilon^2).$$

Then we obtain the reduced problem

$$\text{(A.1)}\qquad \begin{cases} -\Delta v_1 = g(u_0,0) = \mathbf{1}_{\Omega^+} - m & \text{in } \Omega, \\ \dfrac{\partial v_1}{\partial n} = 0 & \text{on } \partial\Omega, \\ \mu c'(0) v_1 = \kappa & \text{on } \Gamma. \end{cases}$$

Since it is easily seen that $c'(0) = -\frac{1}{\sigma} < 0$ with

$$\sigma = \int_0^1 \sqrt{2W(s)}\, ds = \int_{-\infty}^{\infty} [\dot{Q}(\xi;0)]^2\, d\xi,$$

(A.1) becomes (RP) with $\beta = \mu/\sigma$.

Appendix B. Layered solutions for elliptic systems. In this section, we will show that (1.4) with $g(u,v) = u - m$, $\mu = 1$ has a layered solution from Theorem 1.2 of [12].

The equation $v = f(u)$ has three solutions $f_0^{-1}(v) < f_a^{-1}(v) < f_1^{-1}(v)$ for small $|v|$, where $u = f_i^{-1}(v)$ is the inverse function of $v = f(u)$ near $u = i$ $(i = 0, a, 1)$. We then have $f_u(f_i^{-1}(v)) < 0$ $(i = 0, 1)$, and $J(0) = 0$, $J'(0) = -1$, where $J(v) := \int_{f_0^{-1}(v)}^{f_1^{-1}(v)} [f(s) - v]\, ds$. Thus the assumptions (A1)–(A3) of [12] are satisfied.

We use the notation in sections 2 and 3. Under the assumption (A2), we consider the solution $q \in X_{\delta/2}$ of $\Pi_0^{\perp} M_\beta(q) = 0$ obtained in Proposition 3.1. For brevity's sake, we assume that (B1) holds with $\boldsymbol{P} = 0$. Then, $\Pi_0^{\perp} M'_\beta(q)\zeta = 0$ and $\zeta \in \Pi_0^{\perp} X$ implies that $\zeta = 0$.

Let $(\Gamma(q), v, \Omega^+(q))$ be a corresponding solution of (1.1). We write $\Gamma^* = \Gamma(q)$, $\Omega^+ = \Omega^+(q)$, and $\Omega^- = \Omega \backslash (\Omega^+ \cup \Gamma^*)$.

Set $r = r(\theta) = \sqrt{1 + q(\theta)}$. Let

$$\mathbf{e}_1 = \left(\frac{\dot{r}\cos\theta - r\sin\theta}{\sqrt{r^2 + \dot{r}^2}}, \frac{\dot{r}\sin\theta + r\cos\theta}{\sqrt{r^2 + \dot{r}^2}} \right)$$

be a unit tangent vector on Γ^* and

$$\mathbf{e}_2 = \left(-\frac{\dot{r}\sin\theta + r\cos\theta}{\sqrt{r^2 + \dot{r}^2}}, \frac{\dot{r}\cos\theta - r\sin\theta}{\sqrt{r^2 + \dot{r}^2}} \right)$$

be the unit normal vector on Γ^* which points the interior of Ω^+.

Set $V^+ = v|_{\Omega^+}$ and $V^- = v|_{\Omega^-}$. Then $-\Delta V^+ = 1 - m$ in Ω^+, $\beta V^+ + \kappa = 0$ on Γ^*, $-\Delta V^- = -m$ in Ω^-, $\beta V^- + \kappa = 0$ on Γ^*, and $\partial V^-/\partial n = 0$ on $\partial\Omega$. Moreover $\partial V^+/\partial \mathbf{e}_2 = \partial V^-/\partial \mathbf{e}_2$ on Γ^* since $v \in W^{2,\infty}(\Omega) \subset C^1(\Omega)$. Thus (A4) of [12] is satisfied.

By a bootstrap argument, q is smooth and so is Γ^*. Fix $\alpha \in (0,1)$. For any $I \in C^{2,\alpha}(\Gamma^*)$, let $w^{\pm}$ be the unique solution to

$$\begin{cases} \Delta w^+ = 0 & \text{in } \Omega^+, \\ w^+ = I & \text{on } \Gamma^* \end{cases}$$

and

$$\begin{cases} \Delta w^- = 0 & \text{in } \Omega^-, \\ \frac{\partial w^-}{\partial n} = 0 & \text{on } \partial\Omega, \\ w^- = I & \text{on } \Gamma^*, \end{cases}$$

respectively.

Let $Z(x) = \frac{\partial w^-}{\partial \mathbf{e}_2}(x) - \frac{\partial w^+}{\partial \mathbf{e}_2}(x)$ for $x \in \Gamma^*$. Then it follows from Green's theorem that $w^+(x) = \int_{\Gamma^*} G(x,y)Z(y)\,ds_y + \frac{1}{|\Omega|}(\int_{\Omega^+} w^+\,dx + \int_{\Omega^-} w^-\,dx)$ for $x \in \Omega^+$, $w^-(x) = \int_{\Gamma^*} G(x,y)Z(y)\,ds_y + \frac{1}{|\Omega|}(\int_{\Omega^+} w^+\,dx + \int_{\Omega^-} w^-\,dx)$ for $x \in \Omega^-$, and $I(x) = \int_{\Gamma^*} G(x,y)Z(y)\,ds_y + \frac{1}{|\Omega|}(\int_{\Omega^+} w^+\,dx + \int_{\Omega^-} w^-\,dx)$ for $x \in \Gamma^*$. Moreover we see that $\int_{\Omega^+} \nabla w^+ \cdot \nabla\varphi\,dx + \int_{\Omega^-} \nabla w^- \cdot \nabla\varphi\,dx = \int_{\Gamma^*} Z\varphi\,ds$ for all $\varphi \in C^\infty(\bar\Omega)$. Let $\mathcal{S} : C^{2,\alpha}(\Gamma^*) \to C^{1,\alpha}(\Gamma^*)$ be the linear map defined by $\mathcal{S}(I) = Z$. Then $\mathcal{S}$ has one dimensional kernel which is spanned by $I \equiv \text{const}$, and $\mathrm{Im}(\mathcal{S}) = \{Z \in C^{1,\alpha}(\Gamma^*)\,;\, P(Z) = 0\}$, where P is a projection defined by $P(Z) = \frac{1}{|\Gamma^*|}\int_{\Gamma^*} Z\,ds$ for $Z \in C^\alpha(\Gamma^*)$.

On the other hand, for $Z \in C^{1,\alpha}(\Gamma^*)$, define $w(x) = \int_{\Gamma^*} G(x,y)Z(y)\,ds_y$ for $x \in \Omega$. Then we see that $\Delta w(x) = \frac{1}{|\Omega|}\int_{\Gamma^*} Z\,ds$ for $x \in \Omega^\pm$. Moreover there holds $\int_\Omega \nabla w \cdot \nabla\varphi\,dx = \int_{\Gamma^*} Z\varphi\,ds - \frac{1}{|\Omega|}\int_{\Gamma^*} Z\,ds\int_\Omega \varphi\,dx$ for all $\varphi \in C^\infty(\bar\Omega)$. Let $\mathcal{T} : C^{1,\alpha}(\Gamma^*) \to C^{2,\alpha}(\Gamma^*)$ be the linear operator defined by $\mathcal{T}(Z) = w|_{\Gamma^*}$. Then $\mathcal{S}(\mathbf{Id} - P)\mathcal{T} = \mathbf{Id}$ on $\{Z \in C^{1,\alpha}(\Gamma^*)\,;\, P(Z) = 0\}$, and $(\mathbf{Id} - P)\mathcal{T}\mathcal{S} = \mathbf{Id}$ on $\{I \in C^{2,\alpha}(\Gamma^*)\,;\, P(I) = 0\}$.

Let

$$\ell = \int_0^\theta \sqrt{r^2 + \dot r^2}\,d\theta$$

be the arc-length parameter of Γ^*. We change the variable θ into ℓ and regard functions of ℓ as functions on Γ^*.

PROPOSITION B.1. *For any $\zeta \in \Pi_0^\perp X$,*

$$M'_\beta(q)\zeta = \tilde{\mathcal{L}}Z := \frac{d^2Z}{d\ell^2} + \kappa^2 Z + \beta(\nabla v \cdot \mathbf{e}_2)Z - \beta\mathcal{T}(Z),$$

where

$$Z(\ell) = -\frac{\zeta(\theta)}{2\sqrt{r^2 + \dot r^2}}.$$

Proof. For small $|\tau|$, set

$$Q(\theta,\tau) = q(\theta) + \tau\zeta(\theta), \quad R(\theta,\tau) = \sqrt{1 + q(\theta) + \tau\zeta(\theta)}.$$

Let $\Theta(\tau)$ be the continuous function satisfying that $R(\Theta(\tau),\tau)(\cos\Theta(\tau), \sin\Theta(\tau))$ is on the normal line of $\Gamma(q)$ at $r(\theta)(\cos\theta, \sin\theta)$, and that $\Theta(0) = \theta$. Then we have

$$\left.\frac{d}{d\tau}\right|_{\tau=0} R(\Theta(\tau),\tau)(\cos\Theta(\tau), \sin\Theta(\tau)) \cdot \mathbf{e}_1 = 0,$$

which implies that

$$\frac{d\Theta}{d\tau}(0) = \frac{\dot r}{r\sqrt{r^2 + \dot r^2}} Z(\ell)$$

and

$$\left.\frac{d}{d\tau}\right|_{\tau=0} R(\Theta(\tau),\tau)(\cos\Theta(\tau), \sin\Theta(\tau)) = Z\mathbf{e}_2.$$

Hence Z is the normal velocity of the evolution of curves $\tau \mapsto \Gamma(Q(\cdot,\tau))$.

We see that

$$M'_\beta(q)\zeta = L_s(q,\dot q,\ddot q)\ddot\zeta + L_p(q,\dot q,\ddot q)\dot\zeta + L_t(q,\dot q,\ddot q)\zeta + \frac{\beta}{2}\frac{\nabla v\cdot\omega}{r}\zeta + \frac{\beta}{2}\int_{S^1} G(x,r(\hat\omega)\hat\omega)\zeta(\hat\omega)\,d\hat\omega\Big|_{x=r(\cos\theta,\sin\theta)}.$$

First we have

$$\begin{aligned}\nabla v\cdot\omega &= (\omega\cdot\mathbf{e}_1)(\nabla v\cdot\mathbf{e}_1) + (\omega\cdot\mathbf{e}_2)(\nabla v\cdot\mathbf{e}_2)\\ &= \frac{\dot r}{\sqrt{r^2+\dot r^2}}(\nabla v\cdot\mathbf{e}_1) - \frac{r}{\sqrt{r^2+\dot r^2}}(\nabla v\cdot\mathbf{e}_2),\end{aligned}$$

$$\nabla v\cdot\mathbf{e}_1 = \frac{\partial v}{\partial \ell} = -\frac{1}{\beta}\frac{d\kappa}{d\ell} = -\frac{1}{\beta}\frac{d\kappa}{d\theta}\frac{1}{\sqrt{r^2+\dot r^2}},$$

and thus

$$\begin{aligned}\frac{\beta}{2}\frac{\nabla v\cdot\omega}{r}\zeta &= \frac{\beta}{2}\frac{\dot r}{r\sqrt{r^2+\dot r^2}}(\nabla v\cdot\mathbf{e}_1)\zeta - \frac{\beta}{2}\frac{\nabla v\cdot\mathbf{e}_2}{\sqrt{r^2+\dot r^2}}\zeta\\ &= \frac{\dot r}{r\sqrt{r^2+\dot r^2}}\frac{d\kappa}{d\theta}Z - \frac{\beta}{2}\frac{\nabla v\cdot\mathbf{e}_2}{\sqrt{r^2+\dot r^2}}\zeta\\ &= \frac{\dot r}{r\sqrt{r^2+\dot r^2}}\frac{d\kappa}{d\theta}Z + \beta(\nabla v\cdot\mathbf{e}_2)Z.\end{aligned}$$

Hence

$$M'_\beta(q)\zeta = I_1 + I_2 + I_3,$$

where

$$\begin{aligned}I_1 &:= L_s\ddot\zeta + L_p\dot\zeta + L_t\zeta + \frac{\dot r}{r\sqrt{r^2+\dot r^2}}\frac{d\kappa}{d\theta}Z,\\ I_2 &:= \beta(\nabla v\cdot\mathbf{e}_2)Z,\\ I_3 &:= \frac{\beta}{2}\int_{S^1} G(x,r(\hat\omega)\hat\omega)\zeta(\hat\omega)\,d\hat\omega\Big|_{x=r(\cos\theta,\sin\theta)}.\end{aligned}$$

Then by change of variable, we have

$$\frac{\beta}{2}\int_{S^1} G(x,r(\hat\omega)\hat\omega)\zeta(\hat\omega)\,d\hat\omega = -\beta\int_{\Gamma^*} G(x,y)Z(y)\,ds_y$$

for $x\in\Gamma^*$, and thus $I_3 = -\beta\mathcal{T}(Z)$.

Next using

$$\begin{aligned}L_s\ddot\zeta + L_p\dot\zeta + L_t\zeta &= \frac{\partial}{\partial\tau}\Big|_{\tau=0} L(q+\tau\zeta,\dot q+\tau\dot\zeta,\ddot q+\tau\ddot\zeta)\\ &= \frac{\partial}{\partial\tau}\Big|_{\tau=0}\frac{R^2+2\dot R^2 - R\ddot R}{(R^2+\dot R^2)^{3/2}}\end{aligned}$$

and

$$\left.\frac{\partial R}{\partial \tau}\right|_{\tau=0} = -\frac{\sqrt{r^2+\dot r^2}}{r} Z,$$

we obtain

$$I_1 = L_s\ddot\zeta + L_p\dot\zeta + L_t\zeta + \frac{\dot r}{r\sqrt{r^2+\dot r^2}}\frac{d\kappa}{d\theta} Z = \frac{d^2 Z}{d\ell^2} + \kappa^2 Z \tag{B.1}$$

after lengthy computations. The claim of Proposition B.1 now follows from (B.1) and $I_3 = -\beta\mathcal{T}(Z)$. Note that

$$\begin{aligned}
&\left.\frac{d}{d\tau}\right|_{\tau=0} L(q(\Theta(\tau)) + \tau\zeta(\Theta(\tau)), \dot q(\Theta(\tau)) + \tau\dot\zeta(\Theta(\tau)), \ddot q(\Theta(\tau)) + \tau\ddot\zeta(\Theta(\tau)))\\
&\quad = L_s\ddot\zeta + L_p\dot\zeta + L_t\zeta + (L_s\dddot q + L_p\ddot q + L_t\dot q)\frac{d\Theta}{d\tau}(0)\\
&\quad = L_s\ddot\zeta + L_p\dot\zeta + L_t\zeta + \frac{d}{d\theta}L(q(\theta), \dot q(\theta), \ddot q(\theta))\frac{d\Theta}{d\tau}(0)\\
&\quad = L_s\ddot\zeta + L_p\dot\zeta + L_t\zeta + \frac{\dot r}{r\sqrt{r^2+\dot r^2}}\frac{d\kappa}{d\theta} Z.
\end{aligned}$$

Hence the left-hand side of (B.1) is the derivative of the curvature at the point along the normal direction. □

PROPOSITION B.2. *There exists a constant $C > 0$ such that*

$$\|(\mathbf{Id} - P)\tilde{\mathcal{L}} Z\|_{C^\alpha} \ge C\|Z\|_{C^{2,\alpha}}$$

for any $Z \in C^{2,\alpha}(\Gamma^*)$ with $\int_{\Gamma^*} Z\, ds = 0$.

Proof. Suppose not. Then there exists a sequence $Z_n \in C^{2,\alpha}(\Gamma^*)$ with $\int_{\Gamma^*} Z_n\, ds = 0$, $\|Z_n\|_{C^{2,\alpha}} = 1$, and $\|(\mathbf{Id} - P)\tilde{\mathcal{L}} Z\|_{C^\alpha} \to 0$. Then taking a subsequence if necessary, we may assume that $Z_n \to Z$ in C^1. Then

$$\frac{d^2 Z_n}{d\ell^2} \to (\mathbf{Id} - P)(-\kappa^2 Z - \beta(\nabla v \cdot \mathbf{e}_2)Z + \beta\mathcal{T}(Z))$$

in C^α and thus uniformly. Hence $Z_n \to Z$ in $C^{2,\alpha}$ and $(\mathbf{Id} - P)\tilde{\mathcal{L}} Z = 0$. Setting $\zeta(\theta) = -2\sqrt{r^2+\dot r^2} Z(\ell)$, it follows from Proposition B.1 that $\Pi_0^\perp M'_\beta(q)\zeta = 0$. Then by the nondegeneracy, we have $\zeta = 0$ and thus $Z = 0$. It follows that $0 = \|Z\|_{C^{2,\alpha}} = \lim_{n\to\infty}\|Z_n\|_{C^{2,\alpha}} = 1$. This is a contradiction, and the proof is complete. □

It follows from Proposition B.2 that the linear operator $(\mathbf{Id} - P)\tilde{\mathcal{L}}$ has a bounded inverse from $\{Z \in C^\alpha(\Gamma^*)\,;\, P(Z) = 0\}$ to $\{Z \in C^{2,\alpha}(\Gamma^*)\,;\, P(Z) = 0\}$. Therefore (A5) of [12] is satisfied and Theorem 1.2 of [12] can be applied for (1.4) with $g(u, v) = u - m$ and $\mu = 1$.

STRONG INSTABILITY OF STANDING WAVES FOR THE NONLINEAR KLEIN–GORDON EQUATION AND THE KLEIN–GORDON–ZAKHAROV SYSTEM*

MASAHITO OHTA† AND GROZDENA TODOROVA‡

Abstract. The orbital instability of ground state standing waves $e^{i\omega t}\phi_\omega(x)$ for the nonlinear Klein–Gordon equation has been known in the domain of all frequencies ω for the supercritical case and for frequencies strictly less than a critical frequency ω_c in the subcritical case. We prove the strong instability of ground state standing waves for the entire domain above. For the case when the frequency is equal to the critical frequency ω_c we prove strong instability for all radially symmetric standing waves $e^{i\omega_c t}\varphi(x)$. We prove similar strong instability results for the Klein–Gordon–Zakharov system.

1. Introduction and main results. We study the strong instability of standing wave solutions $e^{i\omega t}\varphi(x)$ for the nonlinear Klein–Gordon equation of the form

$$\partial_t^2 u - \Delta u + u = |u|^{p-1}u, \quad (t,x) \in \mathbb{R}\times\mathbb{R}^N, \tag{1.1}$$

where $N \geq 2$, $1 < p < 1 + 4/(N-2)$, $-1 < \omega < 1$, and $\varphi \in H^1(\mathbb{R}^N)$ is a nontrivial solution of

$$-\Delta\varphi + (1-\omega^2)\varphi - |\varphi|^{p-1}\varphi = 0, \quad x \in \mathbb{R}^N. \tag{1.2}$$

We also study the same problem for the Klein–Gordon–Zakharov (KGZ) system

$$\partial_t^2 u - \Delta u + u + nu = 0, \quad (t,x) \in \mathbb{R}\times\mathbb{R}^N, \tag{1.3}$$

$$c_0^{-2}\partial_t^2 n - \Delta n = \Delta(|u|^2), \quad (t,x) \in \mathbb{R}\times\mathbb{R}^N, \tag{1.4}$$

where $N = 2, 3$, and $c_0 > 0$ is a constant. The system (1.3)–(1.4) describes the interaction of a Langumiur wave and an ion acoustic wave in a plasma. The complex valued function u denotes the fast time scale component of an electric field raised by electrons, and the real valued function n denotes the deviation of ion density (see [34, 4, 8]).

From the result of Ginibre and Velo [10], the Cauchy problem for (1.1) is locally well-posed in the energy space $X := H^1(\mathbb{R}^N) \times L^2(\mathbb{R}^N)$. Thus, for any $(u_0, u_1) \in X$ there exists a unique solution $\vec{u} := (u, \partial_t u) \in C([0, T_{\max}); X)$ of (1.1) with $\vec{u}(0) = (u_0, u_1)$ such that either $T_{\max} = \infty$ (global existence) or $T_{\max} < \infty$ and $\lim_{t\to T_{\max}}$

$\|\vec{u}(t)\|_X = \infty$ (finite time blowup). Moreover, the solution $u(t)$ satisfies the conservation laws of energy and charge:

$$E(\vec{u}(t)) = E(u_0, u_1), \quad Q(\vec{u}(t)) = Q(u_0, u_1), \quad t \in [0, T_{\max}),$$

where

$$E(u, v) = \frac{1}{2}\|v\|_2^2 + \frac{1}{2}\|\nabla u\|_2^2 + \frac{1}{2}\|u\|_2^2 - \frac{1}{p+1}\|u\|_{p+1}^{p+1}, \tag{1.5}$$

$$Q(u, v) = \operatorname{Im} \int_{\mathbb{R}^N} \overline{u} v \, dx. \tag{1.6}$$

Let $\phi_\omega \in H^1(\mathbb{R}^N)$ be the ground state (the least energy solution) of (1.2). We refer to [2, 30] for the existence of ϕ_ω, and to [13] for the uniqueness of ϕ_ω. The stability of standing waves $e^{i\omega t}\phi_\omega$ for (1.1) has been studied by many authors. First, we consider the orbital stability of $e^{i\omega t}\phi_\omega$. Shatah [27] proves that $e^{i\omega t}\phi_\omega$ is orbitally stable if $p < 1 + 4/N$ and $\omega_c < |\omega| < 1$, where

$$\omega_c = \sqrt{\frac{p-1}{4 - (N-1)(p-1)}}. \tag{1.7}$$

Shatah and Strauss [29] prove that $e^{i\omega t}\phi_\omega$ is orbitally unstable when $p < 1 + 4/N$ and $|\omega| < \omega_c$ or when $p \geq 1 + 4/N$ and $|\omega| < 1$. Here, we say that a standing wave solution $e^{i\omega t}\varphi$ is orbitally stable for (1.1) if for any $\varepsilon > 0$ there exists $\delta > 0$ such that if $(u_0, u_1) \in X$ satisfies $\|(u_0, u_1) - (\varphi, i\omega\varphi)\|_X < \delta$, then the solution $u(t)$ of (1.1) with $\vec{u}(0) = (u_0, u_1)$ exists globally and satisfies

$$\sup_{t \geq 0} \inf_{\theta \in \mathbb{R}, y \in \mathbb{R}^N} \|\vec{u}(t) - e^{i\theta}(\varphi(\cdot + y), i\omega\varphi(\cdot + y))\|_X < \varepsilon.$$

Otherwise, $e^{i\omega t}\varphi$ is said to be orbitally unstable.

Next, we consider instability of $e^{i\omega t}\phi_\omega$ in a stronger sense. Berestycki and Cazenave [1] prove that the ground state standing wave $e^{i\omega t}\phi_\omega$ for (1.1) is very strongly unstable (see Definition 1 below) when the frequency $\omega = 0$ (see also [14, 26]). Shatah [28] proves that the ground state standing wave $e^{i\omega t}\phi_\omega$ for nonlinear Klein–Gordon equations with general nonlinearity is strongly unstable (see Definition 2 below) when $\omega = 0$ and $N \geq 3$. Recently, the authors [23] proved that the ground state standing wave $e^{i\omega t}\phi_\omega$ for (1.1) is very strongly unstable when $|\omega| \leq \sqrt{(p-1)/(p+3)}$ and $N \geq 3$. Here, we give the definitions of very strong instability and strong instability.

Definition 1 (very strong instability). *We say that $e^{i\omega t}\varphi$ is very strongly unstable for (1.1) if for any $\varepsilon > 0$ there exists $(u_0, u_1) \in X$ such that $\|(u_0, u_1) - (\varphi, i\omega\varphi)\|_X < \varepsilon$ and the solution $u(t)$ of (1.1) with $\vec{u}(0) = (u_0, u_1)$ blows up in finite time.*

Definition 2 (strong instability). *We say that $e^{i\omega t}\varphi$ is strongly unstable for (1.1) if for any $\varepsilon > 0$ there exists $(u_0, u_1) \in X$ such that $\|(u_0, u_1) - (\varphi, i\omega\varphi)\|_X < \varepsilon$ and the solution $u(t)$ of (1.1) with $\vec{u}(0) = (u_0, u_1)$ either blows up in finite time or exists globally and satisfies $\limsup_{t\to\infty} \|\vec{u}(t)\|_X = \infty$.*

Note that, by the definitions, if $e^{i\omega t}\varphi$ is very strongly unstable, then it is strongly unstable, and that if $e^{i\omega t}\varphi$ is strongly unstable, then it is orbitally unstable.

Before stating our main results, we recall instability results for the nonlinear Schrödinger equation

$$i\partial_t u + \Delta u + |u|^{p-1}u = 0, \quad (t, x) \in \mathbb{R} \times \mathbb{R}^N. \tag{1.8}$$

Let $\omega > 0$ and $\phi_\omega \in H^1(\mathbb{R}^N)$ be the ground state of

$$-\Delta\varphi + \omega\varphi - |\varphi|^{p-1}\varphi = 0, \quad x \in \mathbb{R}^N. \tag{1.9}$$

It is known that for any $\omega > 0$ the standing wave solution $e^{i\omega t}\phi_\omega$ for (1.8) is orbitally stable when $1 < p < 1 + 4/N$, and it is very strongly unstable when $1 + 4/N < p < 1 + 4/(N-2)$ (see [1, 7, 33]). Moreover, for the critical case $p = 1 + 4/N$, for any $\omega > 0$ and any nontrivial solution $\varphi \in H^1(\mathbb{R}^N)$ of (1.9), it is known that the standing wave $e^{i\omega t}\varphi$ is very strongly unstable for (1.8) (see [32]). For general theory of orbital stability and instability of solitary waves, we refer to Grillakis, Shatah, and Strauss [11, 12]. We state our main results.

THEOREM 1. *Let $N \geq 2$, $1 < p < 1+4/(N-2)$, $\omega \in (-1, 1)$, and ϕ_ω be the ground state of* (1.2). *Assume that $|\omega| \leq \omega_c$ if $p < 1 + 4/N$, where the critical frequency ω_c is given by* (1.7). *Then, the standing wave $e^{i\omega t}\phi_\omega$ for the nonlinear Klein–Gordon equation* (1.1) *is strongly unstable in the sense of Definition* 2.

Can we refine further this instability result? Namely, can we prove in certain cases that the standing wave $e^{i\omega t}\phi_\omega$ for (1.1) is very strongly unstable in the sense of Definition 1? The result of Cazenave [5] answers this question for the restricted range for the exponent p of nonlinearity $1 < p \leq 5$ for $N = 2$ and $1 < p \leq N/(N-2)$ for $N \geq 3$. Cazenave proves that any global solution $u(t)$ of (1.1) is uniformly bounded in X, i.e., $\sup_{t\geq 0} \|\vec{u}(t)\|_X < \infty$, if $1 < p \leq 5$ and $N = 2$, and if $1 < p \leq N/(N-2)$ and $N \geq 3$. Therefore, for this range of the exponent p, Theorem 1 together with the result of Cazenave gives us a very strong instability result in the sense of Definition 1 for ground state standing waves $e^{i\omega t}\phi_\omega$ of (1.1). Using an argument in Merle and Zaag [18], we can extend the result of Cazenave and prove the uniform boundedness of global solutions of (1.1) in X when $1 < p < 1+4/(N-1)$ and $N \geq 2$. The following lemma holds.

LEMMA 2. *Let $N \geq 2$ and $1 < p < 1 + 4/(N-1)$. If $\vec{u} \in C([0,\infty), X)$ is a global solution of* (1.1), *then $\sup_{t\geq 0} \|\vec{u}(t)\|_X < \infty$.*

Therefore, from Theorem 1 and Lemma 2, we deduce the following.

COROLLARY 3. *In addition to the assumptions in Theorem* 1, *let $1 < p \leq 1 + 4/(N-1)$ if $N = 2, 3$, and that $1 < p < 1+4/(N-1)$ if $N \geq 4$. Then, the ground state standing wave $e^{i\omega t}\phi_\omega$ for* (1.1) *is very strongly unstable in the sense of Definition* 1.

Remark. Let us mention that when the exponent p of nonlinearity is in the range $1 + 4/(N-1) < p < 1 + 4/(N-2)$ we are unable to give better instability results than those in Theorem 1 for ground state standing waves $e^{i\omega t}\phi_\omega$ of (1.1) for large frequencies $|\omega| > \sqrt{(p-1)/(p+3)}$. The very strong instability result for small frequencies $|\omega| \leq \sqrt{(p-1)/(p+3)}$ and $N \geq 3$ is given in [23]. The following theorem is an important contribution of Kenji Nakanishi on the very strong instability in this area for large p and large frequencies ω.

THEOREM A (due to Kenji Nakanishi). *Let $N \geq 2$, $1+4/N \leq p < 1+4/(N-2)$, $|\omega| < 1$, and ϕ_ω be the ground state of* (1.2). *Then, the standing wave $e^{i\omega t}\phi_\omega$ for the nonlinear Klein–Gordon equation* (1.1) *is very strongly unstable in the sense of Definition* 1.

This way, we have the entire picture for the very strong instability of ground state standing waves.

For the critical frequency $\omega = \omega_c$ in the case $1 < p < 1 + 4/N$, we can prove a much more general instability result for standing waves which are not necessarily related to the ground state.

THEOREM 4. *Let $N \geq 2$, $1 < p < 1 + 4/N$, and $\varphi \in H^1(\mathbb{R}^N)$ be any nontrivial, radially symmetric solution of (1.2) with $\omega = \omega_c$. Then, the standing wave solution $e^{i\omega_c t}\varphi$ of (1.1) is very strongly unstable in the sense of Definition 1. The same assertion is true for $\omega = -\omega_c$.*

For the existence of infinitely many radially symmetric solutions of (1.2), we refer to [3]. As mentioned above, a similar result of Theorem 4 is known for the nonlinear Schrödinger equation (1.8) in the critical case $p = 1+4/N$ without assuming the radial symmetry of the solution of (1.9) and the restriction on space dimensions $N \geq 2$ (see [32]).

The proofs of Theorems 1 and 4 are based on using local versions of the virial-type identities. To prove strong instability of the ground state for the case when $\omega = 0$ and $N \geq 3$, Shatah in [28] considers a local version of the following identity:

$$\frac{d}{dt}\,\mathrm{Re}\int_{\mathbb{R}^N} x\cdot\nabla u\partial_t\bar{u}\,dx = NK_1(\vec{u}(t)), \tag{1.10}$$
$$K_1(u,v) := -\frac{1}{2}\|v\|_2^2 + \left(\frac{1}{2}-\frac{1}{N}\right)\|\nabla u\|_2^2 + \frac{1}{2}\|u\|_2^2 - \frac{1}{p+1}\|u\|_{p+1}^{p+1}.$$

Since the integral in the left-hand side of (1.10) is not well defined on the energy space X, one needs to approximate the weight function x in (1.10) by suitable bounded functions. To control error terms by the approximation, initial perturbations are restricted to being radially symmetric, and the decay estimate for radially symmetric functions in $H^1(\mathbb{R}^N)$,

$$\|w\|_{L^\infty(|x|\geq m)} \leq Cm^{-(N-1)/2}\|w\|_{H^1}, \tag{1.11}$$

(see [30]) is employed. The assumption $N \geq 2$ is needed here. In the case $N = 1$, we expect similar very strong instability results for the standing waves. This kind of approach has been also used for blowup problems of the nonlinear Schrödinger equation (1.8) (see, e.g., [21, 22, 15, 16, 17, 19, 20]).

In the proof of Theorem 1 for the case $p \geq 1 + 4/N$, we use a local version of the virial identity

$$-\frac{d}{dt}\,\mathrm{Re}\int_{\mathbb{R}^N}\{2x\cdot\nabla u + Nu\}\partial_t\bar{u}\,dx = P(u(t)), \tag{1.12}$$

where

$$P(u) := 2\|\nabla u\|_2^2 - \frac{N(p-1)}{p+1}\|u\|_{p+1}^{p+1}. \tag{1.13}$$

Namely, instead of the left-hand side of (1.12), which is not well defined in the energy space X, we use (2.6) with conveniently chosen weights (see the beginning of section 2).

Note that (1.12) follows from (1.10) and

$$\frac{1}{2}\frac{d^2}{dt^2}\|u(t)\|_2^2 = \frac{d}{dt}\,\mathrm{Re}\int_{\mathbb{R}^N} u\partial_t\bar{u}\,dx = -K_2(\vec{u}(t)), \tag{1.14}$$
$$K_2(u,v) = -\|v\|_2^2 + \|\nabla u\|_2^2 + \|u\|_2^2 - \|u\|_{p+1}^{p+1},$$

and that the functional P appears in the virial identity for the nonlinear Schrödinger equation (1.8):

$$\frac{d^2}{dt^2}\|xu(t)\|_2^2 = 4P(u(t)). \tag{1.15}$$

The case $p < 1+4/N$ is more delicate. Here we use a local version of the identity

$$-\frac{d}{dt}\,\mathrm{Re}\int_{\mathbb{R}^N}\{2x\cdot\nabla u+(N+\alpha)u\}\partial_t\bar{u}\,dx = K(\vec{u}(t)), \tag{1.16}$$

where $\alpha := 4/(p-1)-N$ and

$$K(u,v) := -\alpha\|v\|_2^2+\alpha\|u\|_2^2+(\alpha+2)\left\{\|\nabla u\|_2^2-\frac{2}{p+1}\|u\|_{p+1}^{p+1}\right\} \tag{1.17}$$

(cf. [29, page 185]). Note that

$$\begin{aligned} K(u,v) &= P(u)+\alpha K_2(u,v)\\ &= -2(\alpha+1)\|v-i\omega u\|_2^2+2(\alpha+2)(E-\omega Q)(u,v)\\ &\qquad -2\alpha\omega Q(u,v)-2\{1-(\alpha+1)\omega^2\}\|u\|_2^2, \end{aligned} \tag{1.18}$$

and that $1-(\alpha+1)\omega^2>0$ if $|\omega|>\omega_c$, and correspondingly $1-(\alpha+1)\omega^2=0$ if $|\omega|=\omega_c$. Again instead of the left-hand side of (1.16), we use (2.7) with conveniently chosen weights.

Next, we consider the KGZ system (1.3)–(1.4). The well-posedness of the Cauchy problem for (1.3)–(1.4) in the energy space is studied by Ozawa, Tsutaya, and Tsutsumi [25]. Here, the energy space Y is defined by $Y = H^1(\mathbb{R}^N)\times L^2(\mathbb{R}^N)\times L^2(\mathbb{R}^N)\times \dot{H}^{-1}(\mathbb{R}^N)$. When $N=3$ and $c_0\neq 1$, it is proved in [25] that for any $(u_0,u_1,n_0,n_1)\in Y$ there exists a unique solution $\mathbf{u} := (u,\partial_t u,n,\partial_t n)\in C([0,T_{\max});Y)$ of (1.3)–(1.4) with initial data $\mathbf{u}(0)=(u_0,u_1,n_0,n_1)$ satisfying the conservation laws of the energy $H(\mathbf{u}(t))=H(\mathbf{u}(0))$ and the charge $Q(\mathbf{u}(t))=Q(\mathbf{u}(0))$ for all $t\in[0,T_{\max})$, where Q is defined by (1.6) and

$$\begin{aligned} H(u,v,n,\nu) = \frac{1}{2}\|v\|_2^2+\frac{1}{4c_0^2}\|\nu\|_{\dot{H}^{-1}}^2\\ +\frac{1}{2}\|\nabla u\|_2^2+\frac{1}{2}\|u\|_2^2+\frac{1}{4}\|n\|_2^2+\frac{1}{2}\int_{\mathbb{R}^N}|u|^2n\,dx. \end{aligned} \tag{1.19}$$

The case when $N=3$ and $c_0=1$ is treated in [24, 31], where the global small data solutions result is presented. For the case $N=2$, by using the idea of the paper of Ozawa, Tsutaya, and Tsutsumi [25] we can prove the local well-posedness of the Klein–Gordon–Zakharov system (1.3)–(1.4) in the energy space Y for all $c_0>0$.

We study instability of standing wave solutions

$$(u_\omega(t,x),n_\omega(t,x)) = (e^{i\omega t}\phi_\omega(x),-|\phi_\omega(x)|^2)$$

for (1.3)–(1.4), where $-1<\omega<1$, $N=2,3$, and $\phi_\omega\in H^1(\mathbb{R}^N)$ is the ground state of

$$-\Delta\varphi+(1-\omega^2)\varphi-|\varphi|^2\varphi=0,\quad x\in\mathbb{R}^N. \tag{1.20}$$

By a similar method as in the proof of Theorem 1 for the case $p\geq 1+4/N$ together with an argument in Merle [17] for the Zakharov system, we have the following.

THEOREM 5. *Let $N=2,3$, $\omega\in(-1,1)$, ϕ_ω be the ground state of* (1.20)*, and $c_0\neq 1$ if $N=3$. Then, the standing wave $(e^{i\omega t}\phi_\omega,-|\phi_\omega|^2)$ of KGZ system* (1.3)–(1.4) *is strongly unstable in the following sense. For any $\lambda>1$, the solution $\mathbf{u}(t)$ of* (1.3)–(1.4) *with initial data $\mathbf{u}(0)=(\lambda\phi_\omega,\lambda i\omega\phi_\omega,-\lambda^2|\phi_\omega|^2,0)$ either blows up in finite time or exists globally and satisfies $\limsup_{t\to\infty}\|\mathbf{u}(t)\|_Y=\infty$.*

Remark. It is known (see [4, Theorem 3]) that the negative initial energy $H(\mathbf{u}(0))$ implies that the solution $\mathbf{u}(t)$ of (1.3)–(1.4) either blows up in finite time or blows up in infinite time, namely the solution exists globally and satisfies the asymptotic condition $\limsup_{t\to\infty} \|\mathbf{u}(t)\|_Y = \infty$. Since the energy

$$H(\lambda\phi_\omega, \lambda i\omega\phi_\omega, -\lambda^2|\phi_\omega|^2, 0) > 0$$

for λ close to 1, the result in [4] is not applicable to Theorem 5.

Next, we consider the very strong instability of $(e^{i\omega t}\phi_\omega, -|\phi_\omega|^2)$ for (1.3)–(1.4). Since (1.4) of the KGZ system is massless, it seems difficult to obtain the uniform boundedness of global solutions for (1.3)–(1.4) similar to Lemma 2. Therefore, for the standing wave $(e^{i\omega t}\phi_\omega, -|\phi_\omega|^2)$ we do not deduce a very strong instability similar to the instability result in Corollary 3 of Theorem 1. However, using the method in our previous paper [23], we obtain the following very strong instability result for small frequencies.

THEOREM 6. *Let $N = 3$, $c_0 \neq 1$, $|\omega| < 1/\sqrt{3}$, and ϕ_ω be the ground state of* (1.20). *Then, the standing wave $(e^{i\omega t}\phi_\omega, -|\phi_\omega|^2)$ of the KGZ system* (1.3)–(1.4) *is very strongly unstable in the following sense. For any $\lambda > 1$, the solution $\mathbf{u}(t)$ of* (1.3)–(1.4) *with the initial data $\mathbf{u}(0) = (\lambda\phi_\omega, \lambda i\omega\phi_\omega, -\lambda^2|\phi_\omega|^2, 0)$ blows up in finite time.*

Remark. In Theorem 6, the case $\omega = 0$ is proved by Gan and Zhang [9].

The plan of this paper is as follows. In section 2, we prove Theorems 1 and 4 and Lemma 2 for the nonlinear Klein–Gordon equation (1.1). The proof of Theorem A is given at the end of section 2. Section 3 is devoted to applications to the KGZ system (1.3)–(1.4), and we prove Theorems 5 and 6.

2. Proof of theorems for the nonlinear Klein–Gordon equation (1.1). In this section, we first prove Theorems 1 and 4.

We start with a convenient choice of the weight functions, as follows. Let $\Phi \in C^2([0,\infty))$ be a nonnegative function such that

$$\Phi(r) = \begin{cases} N & \text{for} \quad 0 \le r \le 1, \\ 0 & \text{for} \quad r \ge 2, \end{cases} \qquad \Phi'(r) \le 0 \ \text{ for } \ 1 \le r \le 2.$$

For $m > 0$, we put

$$\Phi_m(r) = \Phi\left(\frac{r}{m}\right), \quad \Psi_m(r) = \frac{1}{r^{N-1}} \int_0^r s^{N-1}\Phi_m(s)\, ds. \tag{2.1}$$

Then, Φ_m and Ψ_m satisfy the following properties.

LEMMA 7. *For $m > 0$, we have*

$$\Phi_m(r) = N, \quad \Psi_m(r) = r, \quad 0 \le r \le m, \tag{2.2}$$

$$\Psi_m'(r) + \frac{N-1}{r}\Psi_m(r) = \Phi_m(r), \quad r \ge 0, \tag{2.3}$$

$$|\Phi_m^{(k)}(r)| \le \frac{C}{m^k}, \quad r \ge 0, \ k = 0, 1, 2, \tag{2.4}$$

$$\Psi_m'(r) \le 1, \quad r \ge 0. \tag{2.5}$$

Proof. Properties (2.2)–(2.4) follow from definition (2.1). We show (2.5). Integrating by parts implies

$$Nr^{N-1}\Psi_m(r) = \int_0^r Ns^{N-1}\Phi_m(s)\, ds = r^N\Phi_m(r) - \int_0^r s^N\Phi_m'(s)\, ds.$$

Thus, by (2.3), we have

$$\Psi_m'(r) = \Phi_m(r) - \frac{N-1}{r}\Psi_m(r) = \frac{1}{N}\Phi_m(r) + \frac{N-1}{Nr^N}\int_0^r s^N \Phi_m'(s)\,ds.$$

Since $\Phi_m(r) \le N$ and $\Phi_m'(r) \le 0$ for $r \ge 0$, we have (2.5). □

LEMMA 8. *Let $u(t)$ be a radially symmetric solution of (1.1), and put*

$$I_m^1(t) = 2\,\mathrm{Re}\int_{\mathbb{R}^N} \Psi_m \partial_r u \partial_t \overline{u}\,dx + \mathrm{Re}\int_{\mathbb{R}^N} \Phi_m u \partial_t \overline{u}\,dx, \tag{2.6}$$

$$I_m^2(t) = I_m^1(t) + \alpha\,\mathrm{Re}\int_{\mathbb{R}^N} u\partial_t \bar{u}\,dx, \tag{2.7}$$

where $\alpha := 4/(p-1) - N$. Then, there exists a constant $C_0 > 0$ independent of m such that

$$-\frac{d}{dt}I_m^1(t) \le P(u(t)) + \frac{N(p-1)}{p+1}\int_{|x|\ge m} |u(t,x)|^{p+1}\,dx + \frac{C_0}{m^2}\|u(t)\|_2^2, \tag{2.8}$$

$$-\frac{d}{dt}I_m^2(t) \le K(\vec{u}(t)) + \frac{N(p-1)}{p+1}\int_{|x|\ge m} |u(t,x)|^{p+1}\,dx + \frac{C_0}{m^2}\|u(t)\|_2^2 \tag{2.9}$$

for all $t \in [0, T_{\max})$.

Proof. We multiply (1.1) by $\Psi_m\overline{\partial_r u}$ and by $\Phi_m \overline{u}$, respectively, and have

$$\begin{aligned}-\frac{d}{dt}2\,\mathrm{Re}\int_{\mathbb{R}^N}\Psi_m\partial_r u\partial_t\overline{u}\,dx &= \int_{\mathbb{R}^N}\left(\Psi_m' + \frac{N-1}{r}\Psi_m\right)|\partial_t u|^2\,dx \\ &+ \int_{\mathbb{R}^N}\left(\Psi_m' - \frac{N-1}{r}\Psi_m\right)|\nabla u|^2\,dx - \int_{\mathbb{R}^N}\left(\Psi_m' + \frac{N-1}{r}\Psi_m\right)|u|^2\,dx \\ &+ \frac{2}{p+1}\int_{\mathbb{R}^N}\left(\Psi_m' + \frac{N-1}{r}\Psi_m\right)|u|^{p+1}\,dx\end{aligned}$$

and

$$\begin{aligned}-\frac{d}{dt}\,\mathrm{Re}\int_{\mathbb{R}^N}\Phi_m u\partial_t\overline{u}\,dx &= -\int_{\mathbb{R}^N}\Phi_m|\partial_t u|^2\,dx - \frac{1}{2}\int_{\mathbb{R}^N}\Delta\Phi_m|u|^2\,dx \\ &+ \int_{\mathbb{R}^N}\Phi_m|\nabla u|^2\,dx + \int_{\mathbb{R}^N}\Phi_m|u|^2\,dx - \int_{\mathbb{R}^N}\Phi_m|u|^{p+1}\,dx.\end{aligned}$$

By (2.3) in Lemma 7, we have the identity

$$-\frac{d}{dt}I_m^1(t) = 2\int_{\mathbb{R}^N}\Psi_m'|\nabla u|^2\,dx - \frac{p-1}{p+1}\int_{\mathbb{R}^N}\Phi_m|u|^{p+1}\,dx - \frac{1}{2}\int_{\mathbb{R}^N}\Delta\Phi_m|u|^2\,dx.$$

The inequality (2.8) follows from Lemma 7. Finally, (2.9) follows from (2.8), (1.14), and (1.18). □

First, we consider the case $p \ge 1 + 4/N$. We define the functional

$$J_\omega(u) = \frac{1}{2}\|\nabla u\|_2^2 + \frac{1-\omega^2}{2}\|u\|_2^2 - \frac{1}{p+1}\|u\|_{p+1}^{p+1}, \tag{2.10}$$

and consider the constrained minimization problem

$$d_\omega^1 = \inf\{J_\omega(u) : u \in H^1(\mathbb{R}^N)\setminus\{0\},\ P(u) = 0\} \tag{2.11}$$

and the set

$$\mathcal{R}^1_\omega = \{(u,v) \in X : (E-\omega Q)(u,v) < d^1_\omega,\ P(u) < 0\}, \tag{2.12}$$

where E and Q are the energy and the charge, respectively, and the functional P is defined by (1.13).

Note that

$$(E-\omega Q)(u,v) = J_\omega(u) + \frac{1}{2}\|v - i\omega u\|_2^2, \tag{2.13}$$

$$P(u) = 2\partial_\lambda J_\omega(\lambda^{N/2}u(\lambda\cdot))|_{\lambda=1}. \tag{2.14}$$

LEMMA 9. *Let $N \geq 2$, $1 + 4/N \leq p < 1 + 4/(N-2)$, and $\omega \in (-1,1)$. Then, we have the following:*

(i) $J_\omega(u) - \frac{1}{N(p-1)}P(u) > d^1_\omega$ *for all* $u \in H^1(\mathbb{R}^N)$ *satisfying* $P(u) < 0$.

(ii) *The minimization problem* (2.11) *is attained at the ground state* ϕ_ω *of* (1.2).

(iii) $\lambda(\phi_\omega, i\omega\phi_\omega) \in \mathcal{R}^1_\omega$ *for all* $\lambda > 1$.

Proof. (i) We put

$$\begin{aligned} J^1_\omega(u) &:= J_\omega(u) - \frac{1}{N(p-1)}P(u) \\ &= \left\{\frac{1}{2} - \frac{2}{N(p-1)}\right\}\|\nabla u\|_2^2 + \frac{1-\omega^2}{2}\|u\|_2^2. \end{aligned} \tag{2.15}$$

Note that $1/2 - 2/N(p-1) \geq 0$ by the assumption $p \geq 1 + 4/N$. Let $u \in H^1(\mathbb{R}^N)$ satisfy $P(u) < 0$. Then, we have $u \neq 0$, and there exists $\lambda_1 \in (0,1)$ such that $P(\lambda_1 u) = 0$. By (2.11), we have $d^1_\omega \leq J_\omega(\lambda_1 u) = J^1_\omega(\lambda_1 u) < J^1_\omega(u)$.

(ii) For the case $p > 1 + 4/N$, see [6, Proposition 8.2.4], and for $p = 1 + 4/N$, see [19, Proposition 2.5].

(iii) By (2.13), we have

$$\begin{aligned} &(E-\omega Q)(\lambda(\phi_\omega, i\omega\phi_\omega)) = J_\omega(\lambda\phi_\omega) \\ &= \lambda^2\left(\frac{1}{2}\|\nabla\phi_\omega\|_2^2 + \frac{1-\omega^2}{2}\|\phi_\omega\|_2^2\right) - \frac{\lambda^{p+1}}{p+1}\|\phi_\omega\|_{p+1}^{p+1}. \end{aligned}$$

Since $J_\omega(\phi_\omega) = d^1_\omega$, $\partial_\lambda J_\omega(\lambda\phi_\omega)|_{\lambda=1} = 0$, and $\partial^2_\lambda J_\omega(\lambda\phi_\omega)|_{\lambda=1} < 0$, we have $(E - \omega Q)(\lambda(\phi_\omega, i\omega\phi_\omega)) < d^1_\omega$ for all $\lambda > 1$. Similarly, we have $P(\lambda\phi_\omega) < 0$ for all $\lambda > 1$. Hence, we have $\lambda(\phi_\omega, i\omega\phi_\omega) \in \mathcal{R}^1_\omega$ for all $\lambda > 1$. □

LEMMA 10. *Suppose that $N \geq 2$, $1 + 4/N \leq p < 1 + 4/(N-2)$, and $\omega \in (-1,1)$. If $(u_0, u_1) \in \mathcal{R}^1_\omega$, then the solution $u(t)$ of* (1.1) *with $\vec{u}(0) = (u_0, u_1)$ satisfies*

$$-\frac{1}{N(p-1)}P(u(t)) > d^1_\omega - (E-\omega Q)(u_0,u_1), \quad t \in [0, T_{\max}). \tag{2.16}$$

Proof. First, we show that $P(u(t)) < 0$ for all $t \in [0, T_{\max})$. Suppose that there exists $t_1 \in (0, T_{\max})$ such that $P(u(t_1)) = 0$ and $P(u(t)) < 0$ for $t \in [0, t_1)$. Then, by Lemma 9(i) and (2.15), we have

$$\left\{\frac{1}{2} - \frac{2}{N(p-1)}\right\}\|\nabla u\|_2^2 + \frac{1-\omega^2}{2}\|u(t)\|_2^2 > d^1_\omega > 0, \quad t \in [0, t_1).$$

Thus, we have $u(t_1) \neq 0$. Therefore, by (2.11), we have $d^1_\omega \leq J_\omega(u(t_1))$. Meanwhile, since $(u_0, u_1) \in \mathcal{R}^1_\omega$, E and Q are conserved, and by (2.13), we have $J_\omega(u(t_1)) \leq$

$(E-\omega Q)(\vec{u}(t_1)) < d_\omega^1$. This is a contradiction. Hence, we have $P(u(t)) < 0$ for all $t \in [0, T_{\max})$. From this fact, Lemma 9(i) and (2.13), we obtain (2.16). □

Proof of Theorem 1 *for the case* $p \geq 1 + 4/N$. Let $\lambda > 1$ be fixed and denote

$$\delta := \frac{N(p-1)}{2}\{d_\omega^1 - (E-\omega Q)(\lambda(\phi_\omega, i\omega\phi_\omega))\}.$$

Then, by Lemma 9(iii), we have $\delta > 0$. Suppose that the solution $u(t)$ of (1.1) with $\vec{u}(0) = \lambda(\phi_\omega, i\omega\phi_\omega)$ exists for all $t \in [0, \infty)$ and is uniformly bounded in X, i.e.,

$$M_1 := \sup_{t\geq 0} \|\vec{u}(t)\|_X < \infty. \tag{2.17}$$

Since $u(t)$ is radially symmetric in x for all $t \geq 0$, we define $I_m^1(t)$ for $u(t)$ by (2.6). By (1.11) and (2.17), we have

$$\begin{aligned}&\int_{|x|\geq m} |u(t,x)|^{p+1}\,dx \leq \|u(t)\|_{L^\infty(|x|\geq m)}^{p-1}\|u(t)\|_2^2\\ &\leq Cm^{-(N-1)(p-1)/2}\|u(t)\|_{H^1}^{p+1} \leq CM_1^{p+1}m^{-(N-1)(p-1)/2}\end{aligned}$$

for all $t \geq 0$ and $m > 0$. Note that we assume $N \geq 2$. Thus, there exists $m_0 > 0$ such that

$$\sup_{t\geq 0}\left(\frac{N(p-1)}{p+1}\int_{|x|\geq m_0} |u(t,x)|^{p+1}\,dx + \frac{C_0}{m_0^2}\|u(t)\|_2^2\right) < \delta.$$

Thus, by Lemmas 8 and 10, we have

$$\begin{aligned}&\frac{d}{dt}I_{m_0}^1(t)\\ &\geq -P(u(t)) - \left(\frac{N(p-1)}{p+1}\int_{|x|\geq m_0} |u(t,x)|^{p+1}\,dx + \frac{C_0}{m_0^2}\|u(t)\|_2^2\right)\\ &\geq 2\delta - \delta = \delta\end{aligned}$$

for all $t \geq 0$. Therefore, we have $\lim_{t\to\infty} I_{m_0}^1(t) = \infty$. On the other hand, there exists a constant $C = C(m_0) > 0$ such that $I_{m_0}^1(t) \leq C\|\vec{u}(t)\|_X^2 \leq CM_1^2$ for all $t \geq 0$. This is a contradiction. Hence, for any $\lambda > 1$, the solution $u(t)$ of (1.1) with $\vec{u}(0) = \lambda(\phi_\omega, i\omega\phi_\omega)$ either blows up in finite time or exists for all $t \geq 0$ and $\limsup_{t\to\infty} \|\vec{u}(t)\|_X = \infty$. This completes the proof of Theorem 1 for the case $p \geq 1 + 4/N$. □

Next, we consider the case $p < 1 + 4/N$. For this case, we need a different variational characterization of the ground state ϕ_ω of (1.2) from that for the case $p \geq 1 + 4/N$. We define the functional

$$K_\omega^0(u) = \alpha(1-\omega^2)\|u\|_2^2 + (\alpha+2)\left\{\|\nabla u\|_2^2 - \frac{2}{p+1}\|u\|_{p+1}^{p+1}\right\},$$

and consider the constrained minimization problem

$$d_\omega^0 = \inf\{J_\omega(u) : u \in H^1(\mathbb{R}^N) \setminus \{0\},\ K_\omega^0(u) = 0\} \tag{2.18}$$

and the set

$$\mathcal{R}_\omega^0 = \{(u,v) \in X : (E-\omega Q)(u,v) < d_\omega^0,\ K_\omega^0(u) < 0\}, \tag{2.19}$$

where $\alpha = 4/(p-1) - N > 0$. Note that

$$K_\omega^0(u) = 2\partial_\lambda J_\omega(\lambda^\beta u(\lambda\cdot))|_{\lambda=1}, \quad \beta = \frac{\alpha+N}{2} = \frac{2}{p-1}. \tag{2.20}$$

LEMMA 11. *Let $N \geq 2$, $1 < p < 1 + 4/N$, and $\omega \in (-1,1)$. Then, we have the following:*

(i) $\frac{1-\omega^2}{\alpha+2}\|u\|_2^2 > d_\omega^0$ *for all* $u \in H^1(\mathbb{R}^N)$ *satisfying* $K_\omega^0(u) < 0$.

(ii) *The minimization problem* (2.18) *is attained at the ground state* ϕ_ω *of* (1.2).

(iii) $\lambda(\phi_\omega, i\omega\phi_\omega) \in \mathcal{R}_\omega^0$ *for all* $\lambda > 1$.

Proof. First, we note that

$$J_\omega(u) - \frac{1}{2(\alpha+2)}K_\omega^0(u) = \frac{1-\omega^2}{\alpha+2}\|u\|_2^2, \tag{2.21}$$

$$d_\omega^0 = \inf\left\{\frac{1-\omega^2}{\alpha+2}\|u\|_2^2 : u \in H^1(\mathbb{R}^N)\setminus\{0\},\ K_\omega^0(u) = 0\right\}. \tag{2.22}$$

(i) Let $u \in H^1(\mathbb{R}^N)$ satisfy $K_\omega^0(u) < 0$. Then, we have $u \neq 0$, and there exists $\lambda_1 \in (0,1)$ such that $K_\omega^0(\lambda_1 u) = 0$. By (2.18), we have

$$d_\omega^0 \leq \frac{1-\omega^2}{\alpha+2}\|\lambda_1 u\|_2^2 < \frac{1-\omega^2}{\alpha+2}\|u\|_2^2.$$

(ii) Note that $d_\omega^0 \geq 0$ by (2.22). Let $\{u_j\} \subset H^1(\mathbb{R}^N)$ be a minimizing sequence for (2.18). By considering the Schwarz symmetrization of u_j, we can assume that $\{u_j\} \subset H_{rad}^1(\mathbb{R}^N)$. We refer to [2, Appendix A.III] for the definition and basic properties of the Schwarz symmetrization. By (2.22), we see that $\{u_j\}$ is bounded in $L^2(\mathbb{R}^N)$. Moreover, by $K_\omega^0(u_j) = 0$ and the Gagliardo–Nirenberg inequality, we have

$$\begin{aligned}&(\alpha+2)\|\nabla u_j\|_2^2 + \alpha(1-\omega^2)\|u_j\|_2^2\\ &= \frac{2(\alpha+2)}{p+1}\|u_j\|_{p+1}^{p+1} \leq C\|u_j\|_2^{p+1-\theta}\|\nabla u_j\|_2^\theta,\end{aligned}$$

where $\theta = (p-1)N/2$. Since $p < 1+4/N$, we see that $\theta < 2$ and that $\{u_j\}$ is bounded in $H^1(\mathbb{R}^N)$. Therefore, there exist a subsequence of $\{u_j\}$ (we still denote it by the same letter) and $w \in H_{rad}^1(\mathbb{R}^N)$ such that $u_j \rightharpoonup w$ weakly in $H^1(\mathbb{R}^N)$ and $u_j \to w$ strongly in $L^{p+1}(\mathbb{R}^N)$. Here, we used the fact that the embedding $H_{rad}^1(\mathbb{R}^N) \hookrightarrow L_{rad}^q(\mathbb{R}^N)$ is compact for $2 < q < 2 + 4/(N-2)$ (see [30]). Next, we show that $w \neq 0$. Suppose that $w = 0$. Then, by $K_\omega^0(u_j) = 0$ and the strong convergence $u_j \to 0$ in $L^{p+1}(\mathbb{R}^N)$, we see that $u_j \to 0$ in $H^1(\mathbb{R}^N)$. On the other hand, by $K_\omega^0(u_j) = 0$ and the Sobolev inequality, we have

$$\begin{aligned}&(\alpha+2)\|\nabla u_j\|_2^2 + \alpha(1-\omega^2)\|u_j\|_2^2 = \frac{2(\alpha+2)}{p+1}\|u_j\|_{p+1}^{p+1}\\ &\leq C\{(\alpha+2)\|\nabla u_j\|_2^2 + \alpha(1-\omega^2)\|u_j\|_2^2\}^{(p+1)/2}.\end{aligned}$$

Since $u_j \neq 0$, we have $\|u_j\|_{H^1} \geq C$ for some $C > 0$. This is a contradiction. Thus, we see that $w \in H^1(\mathbb{R}^N)\setminus\{0\}$. Therefore, by (2.21) and (2.22), we have

$$d_\omega^0 \leq \frac{1-\omega^2}{\alpha+2}\|w\|_2^2 \leq \liminf_{j\to\infty}\frac{1-\omega^2}{\alpha+2}\|u_j\|_2^2 = \liminf_{j\to\infty} J_\omega(u_j) = d_\omega^0,$$

and $K_\omega^0(w) \le \liminf_{j\to\infty} K_\omega^0(u_j) = 0$. Moreover, by (i), we have $K_\omega^0(w) = 0$. Therefore, w attains (2.22) and (2.18). Since w attains (2.18), there exists a Lagrange multiplier $\eta \in \mathbb{R}$ such that

$$J'_\omega(w) = \frac{\eta}{2(\alpha+2)}(K_\omega^0)'(w). \tag{2.23}$$

That is, w satisfies

$$-(1-\eta)\Delta w + (1-\omega^2)\left(1 - \frac{\alpha}{\alpha+2}\eta\right) w - (1-\eta)|w|^{p-1}w = 0 \tag{2.24}$$

in $H^{-1}(\mathbb{R}^N)$. First, we show that $\eta < 1$. Suppose that $\eta \ge 1$. Then, by (2.24) and $K_\omega^0(w) = 0$, we have

$$\begin{aligned}
0 &= (1-\eta)\|\nabla w\|_2^2 + (1-\omega^2)\left(1 - \frac{\alpha}{\alpha+2}\eta\right)\|w\|_2^2 - (1-\eta)\|w\|_{p+1}^{p+1} \\
&= \frac{(\eta-1)(p-1)}{2}\|\nabla w\|_2^2 + \frac{\alpha(p-1)(1-\omega^2)}{2(\alpha+2)}\left\{\eta - 1 + \frac{4}{\alpha(p-1)}\right\}\|w\|_2^2 \\
&\ge \frac{2(1-\omega^2)}{\alpha+2}\|w\|_2^2 > 0.
\end{aligned}$$

This is a contradiction. Thus, we have $\eta < 1$. Since we have

$$1 - \eta > 0, \quad (1-\omega^2)\left(1 - \frac{\alpha}{\alpha+2}\eta\right) > 0$$

in (2.24), by [6, Theorem 8.1.1], we have $x \cdot \nabla w \in H^1(\mathbb{R}^N)$. Therefore, by (2.23), we have

$$\begin{aligned}
0 = K_\omega^0(w) &= 2\partial_\lambda J_\omega(\lambda^\beta w(\lambda\cdot))|_{\lambda=1} = 2\langle J'_\omega(w), x\cdot\nabla w + \beta w\rangle \\
&= \frac{\eta}{\alpha+2}\langle (K_\omega^0)'(w), x\cdot\nabla w + \beta w\rangle = \frac{\eta}{\alpha+2}\partial_\lambda K_\omega^0(\lambda^\beta w(\lambda\cdot))|_{\lambda=1},
\end{aligned}$$

where $\beta = (\alpha+N)/2$. Moreover, by $K_\omega^0(w) = 0$, we have

$$\begin{aligned}
&\partial_\lambda K_\omega^0(\lambda^\beta w(\lambda\cdot))|_{\lambda=1} \\
&= \alpha^2(1-\omega^2)\|w\|_2^2 + (\alpha+2)^2\left\{\|\nabla w\|_2^2 - \frac{2}{p+1}\|w\|_{p+1}^{p+1}\right\} \\
&= -2\alpha(1-\omega^2)\|w\|_2^2 < 0.
\end{aligned}$$

Thus, we have $\eta = 0$. Therefore, w satisfies $J'(w) = 0$ and $K_\omega^2(w) = 0$, where

$$K_\omega^2(u) := \langle J'_\omega(u), u\rangle = \|\nabla u\|_2^2 + (1-\omega^2)\|u\|_2^2 - \|u\|_{p+1}^{p+1}.$$

Since ϕ_ω attains

$$\inf\{J_\omega(u) : u \in H^1(\mathbb{R}^N)\setminus\{0\},\ K_\omega^2(u) = 0\}$$

(see, e.g., [23, Lemma 3]), we have $J_\omega(\phi_\omega) \le J_\omega(w)$. On the other hand, ϕ_ω satisfies $K_\omega^0(\phi_\omega) = 0$, and we have $d_\omega^0 = J_\omega(w) \le J_\omega(\phi_\omega)$. Hence, ϕ_ω attains (2.18).

(iii) The proof is similar to that of Lemma 9(iii), and we omit it. □

LEMMA 12. *Suppose that* $N \geq 2$, $1 < p < 1 + 4/N$, *and* $\omega \in (-1, 1)$. *If* $(u_0, u_1) \in \mathcal{R}^0_\omega$, *then the solution* $u(t)$ *of* (1.1) *with* $\vec{u}(0) = (u_0, u_1)$ *satisfies*

$$\frac{1-\omega^2}{\alpha+2}\|u(t)\|_2^2 > d^0_\omega, \quad t \in [0, T_{\max}).$$

Proof. The proof is similar to that for Lemma 10. We omit the details. □

Proof of Theorem 1 *for the case* $p < 1 + 4/N$. Let $\lambda > 1$ be fixed and define

$$\delta_1 = (\alpha+2)\{d^0_\omega - (E - \omega Q)(\lambda(\phi_\omega, i\omega\phi_\omega))\},$$
$$\delta_2 = \alpha\left\{\omega Q(\lambda(\phi_\omega, i\omega\phi_\omega)) - \frac{\omega^2(\alpha+2)}{1-\omega^2}d^0_\omega\right\},$$

and $\delta = \delta_1 + \delta_2$. Then, by Lemma 11(iii), we have $\delta_1 > 0$. Moreover, by Lemma 11(ii) and (2.22), we have

$$\frac{\omega^2(\alpha+2)}{1-\omega^2}d^0_\omega = \omega^2\|\phi_\omega\|_2^2 < \lambda^2\omega^2\|\phi_\omega\|_2^2 = \omega Q(\lambda(\phi_\omega, i\omega\phi_\omega)).$$

Thus, we have $\delta_2 > 0$ and $\delta > 0$. Suppose that the solution $u(t)$ of (1.1) with $\vec{u}(0) = \lambda(\phi_\omega, i\omega\phi_\omega)$ exists for all $t \in [0, \infty)$ and is uniformly bounded in X. Since $u(t)$ is radially symmetric in x for all $t \geq 0$, we define $I^2_m(t)$ for $u(t)$ by (2.7). As in the proof of Theorem 1 for the case $p \geq 1 + 4/N$, there exists $m_0 > 0$ such that

$$\sup_{t\geq 0}\left(\frac{N(p-1)}{p+1}\int_{|x|\geq m_0}|u(t,x)|^{p+1}\,dx + \frac{C_0}{m_0^2}\|u(t)\|_2^2\right) < \delta.$$

Thus, by Lemma 8, we have

$$\frac{d}{dt}I^2_{m_0}(t) \geq -K(\vec{u}(t)) - \delta, \quad t \geq 0.$$

Here, recall that we assume $|\omega| \leq \omega_c$, so we have $1 - (\alpha+1)\omega^2 \geq 0$. Thus, by (1.18) and Lemma 12, we have

$$\begin{aligned}
&-K(\vec{u}(t)) \\
&\geq -2(\alpha+2)(E-\omega Q)(\vec{u}(t)) + 2\alpha\omega Q(\vec{u}(t)) + 2\{1-(\alpha+1)\omega^2\}\|u(t)\|_2^2 \\
&\geq -2(\alpha+2)(E-\omega Q)(\vec{u}(0)) + 2\alpha\omega Q(\vec{u}(0)) + 2\{1-\omega^2-\alpha\omega^2\}\frac{\alpha+2}{1-\omega^2}d^0_\omega \\
&= 2\delta
\end{aligned}$$

for all $t \geq 0$. Therefore, we have $(d/dt)I^2_{m_0}(t) \geq \delta$ for all $t \geq 0$, and $\lim_{t\to\infty} I^2_{m_0}(t) = \infty$. The rest of the proof is the same as in the proof of Theorem 1 for the case $p \geq 1 + 4/N$, and we omit the details. □

Proof of Theorem 4. Let us first note that identity (1.18) contains the reason that in Theorem 4 we can allow any radially symmetric solutions of (1.2), unlike the case of Theorem 1 where we can treat only the ground state of (1.2). Namely, when $\omega = \omega_c$ we have $1 - (\alpha+1)\omega_c^2 = 0$, and therefore the identity (1.18) does not contain the norm $\|u\|_2^2$. Let us recall that in Theorem 1 we control this norm by using the variational characterization of the ground state.

Let $\varphi \in H^1(\mathbb{R}^N) \setminus \{0\}$ be a radially symmetric solution of (1.2) with $\omega = \omega_c$. Let $\lambda > 1$ and put

$$\delta = \alpha\omega_c Q(\lambda(\varphi, i\omega_c\varphi)) - (\alpha+2)(E - \omega_c Q)(\lambda(\varphi, i\omega_c\varphi)).$$

Since $J'_{\omega_c}(\varphi) = 0$, we have $(E - \omega_c Q)(\lambda(\varphi, i\omega_c\varphi)) = J_{\omega_c}(\lambda\varphi) < J_{\omega_c}(\varphi)$ for $\lambda > 1$. Moreover, we have $\omega_c Q(\lambda(\varphi, i\omega_c\varphi)) = \omega_c^2\lambda^2\|\varphi\|_2^2 > \omega_c^2\|\varphi\|_2^2$ for $\lambda > 1$. Thus, we have

$$\delta > \alpha\omega_c^2\|\varphi\|_2^2 - (\alpha+2)J_{\omega_c}(\varphi) = -\frac{1}{2}K^0_{\omega_c}(\varphi) - \{1 - (\alpha+1)\omega_c^2\}\|\varphi\|_2^2.$$

By [6, Theorem 8.1.1], we have $x \cdot \nabla\varphi \in H^1(\mathbb{R}^N)$. Therefore, by (2.20) and by $J'_{\omega_c}(\varphi) = 0$, we have

$$K^0_{\omega_c}(\varphi) = 2\langle J'_{\omega_c}(\varphi), x \cdot \nabla\varphi + \beta\varphi\rangle = 0.$$

Moreover, since $(\alpha+1)\omega_c^2 = 1$, we have $\delta > 0$. Suppose that the solution $u(t)$ of (1.1) with $\vec{u}(0) = \lambda(\varphi, i\omega_c\varphi)$ exists for all $t \in [0, \infty)$ and is uniformly bounded in X. Since $u(t)$ is radially symmetric in x for all $t \geq 0$, we define $I^2_m(t)$ for $u(t)$ by (2.7). As in the proof of Theorem 1 for the case $p \geq 1 + 4/N$, there exists $m_0 > 0$ such that

$$\sup_{t\geq 0}\left(\frac{N(p-1)}{p+1}\int_{|x|\geq m_0}|u(t,x)|^{p+1}\,dx + \frac{C_0}{m_0^2}\|u(t)\|_2^2\right) < \delta.$$

Thus, by Lemma 8, we have

$$\frac{d}{dt}I^2_{m_0}(t) \geq -K(\vec{u}(t)) - \delta, \quad t \geq 0.$$

Moreover, by (1.18) and $(\alpha+1)\omega_c^2 = 1$, we have

$$\begin{aligned}
&-K(\vec{u}(t))\\
&\geq -2(\alpha+2)(E - \omega_c Q)(\vec{u}(t)) + 2\alpha\omega_c Q(\vec{u}(t)) + 2\{1 - (\alpha+1)\omega_c^2\}\|u(t)\|_2^2\\
&\geq -2(\alpha+2)(E - \omega_c Q)(\vec{u}(0)) + 2\alpha\omega_c Q(\vec{u}(0)) = 2\delta
\end{aligned}$$

for all $t \geq 0$. Therefore, we have $(d/dt)I^2_{m_0}(t) \geq \delta$ for all $t \geq 0$, and $\lim_{t\to\infty} I^2_{m_0}(t) = \infty$. On the other hand, there exists a constant $C = C(m_0) > 0$ such that $I^2_{m_0}(t) \leq C\|\vec{u}(t)\|_X^2 \leq C$ for all $t \geq 0$. This is a contradiction. Therefore, for any $\lambda > 1$, the solution $u(t)$ of (1.1) with $\vec{u}(0) = \lambda(\varphi, i\omega_c\varphi)$ either blows up in finite time or exists for all $t \geq 0$ and $\limsup_{t\to\infty}\|\vec{u}(t)\|_X = \infty$. Finally, by Lemma 2, if $u(t)$ exists for all $t \geq 0$, then $\sup_{t\geq 0}\|\vec{u}(t)\|_X < \infty$. Hence, $u(t)$ blows up in finite time. This completes the proof. □

Proof of Lemma 2. By Proposition 3.1 and Lemma 3.5 in [5], we have

$$\sup_{t\geq 0}\|u(t)\|_2 < \infty, \tag{2.25}$$

$$\sup_{t\geq 0}\int_t^{t+1}\|\vec{u}(s)\|_X^2\,ds < \infty. \tag{2.26}$$

By (2.26) and the conservation of energy E, we have

$$C_1 := \sup_{t\geq 0}\int_t^{t+1}\|u(s)\|_{p+1}^{p+1}\,ds < \infty. \tag{2.27}$$

Note that the estimates (2.25), (2.26), and (2.27) hold true for $1 < p < 1 + 4/(N-2)$. In what follows, we use an argument in Merle and Zaag [18]. First, for $r = (p+3)/2$, we show

$$\sup_{t\geq 0}\|u(t)\|_r < \infty. \tag{2.28}$$

Indeed, by (2.27) and the mean value theorem, for any $t \geq 0$ there exists $\tau(t) \in [t, t+1]$ such that

$$\|u(\tau(t))\|_{p+1}^{p+1} = \int_t^{t+1} \|u(s)\|_{p+1}^{p+1}\, ds \leq C_1. \tag{2.29}$$

Since $2 < r < p+1$, it follows from (2.25) and (2.29) that $\sup_{t\geq 0} \|u(\tau(t))\|_r < \infty$. Moreover, for any $t \geq 0$, we have

$$\begin{aligned}
&\|u(t)\|_r^r - \|u(\tau(t))\|_r^r = \int_{\tau(t)}^t \frac{d}{ds}\|u(s)\|_r^r\, ds \\
&\leq C \int_t^{t+1} \int_{\mathbb{R}^N} |u(s,x)|^{r-1} |\partial_s u(s,x)|\, dx\, ds \\
&\leq C \int_t^{t+1} \left(\|u(s)\|_{2(r-1)}^{2(r-1)} + \|\partial_s u(s)\|_2^2 \right) ds.
\end{aligned}$$

Since $2(r-1) = p+1$, by (2.26), (2.27), and $\sup_{t\geq 0} \|u(\tau(t))\|_r < \infty$, we have (2.28). Next, by the Gagliardo–Nirenberg inequality, we have

$$\|u(t)\|_{p+1} \leq C \|u(t)\|_r^{1-\theta} \|\nabla u(t)\|_2^{\theta},$$

where

$$\frac{1}{p+1} = \theta \left(\frac{1}{2} - \frac{1}{N} \right) + \frac{1-\theta}{r}.$$

Since we assume $p < 1 + 4/(N-1)$, we have $(p+1)\theta < 2$. Thus, by (2.28), there exists a constant $C_2 > 0$ such that

$$\frac{2}{p+1} \|u(t)\|_{p+1}^{p+1} \leq C_2 + \frac{1}{2} \|\nabla u(t)\|_2^2, \quad t \geq 0.$$

Moreover, by the conservation of energy E, for any $t \geq 0$ we have

$$\begin{aligned}
\|\vec{u}(t)\|_X^2 &= 2E(\vec{u}(0)) + \frac{2}{p+1} \|u(t)\|_{p+1}^{p+1} \\
&\leq 2E(\vec{u}(0)) + C_2 + \frac{1}{2} \|\nabla u(t)\|_2^2,
\end{aligned}$$

which implies $\|\vec{u}(t)\|_X^2 \leq 4E(\vec{u}(0)) + 2C_2$. This completes the proof. □

We conclude this section with the proof of Theorem A.

Proof of Theorem A (due to Kenji Nakanishi). Following the proof of Theorem 1, take the radially symmetric solution $u(t,r)$ $(r = |x|)$ starting from $(u(0), \partial_t u(0)) = \lambda(\phi_\omega, i\omega\phi_\omega)$ with $\lambda > 1$, and assume by contradiction that it exists for all $t \geq 0$. Then Cazenave's estimate (2.26) implies that there exists $M < \infty$ such that for all $T > 0$

$$\int_T^{T+1} \int_{\mathbb{R}^N} |\partial_t u|^2 + |\nabla u|^2 + |u|^2 dx dt \leq M. \tag{2.30}$$

Hence for any positive integer j, there exists $T_j \in [j-1, j]$ such that

$$\int_{\mathbb{R}^N} |\partial_t u|^2 + |\nabla u|^2 + |u|^2 dx|_{t=T_j} \leq M.$$

By Lemmas 8, 9, and 10, there exists $\delta > 0$ such that for any $m > 1$ and $t > 0$ we have

$$\frac{d}{dt} I_m^1(t) \geq 2\delta - R_m(t), \quad R_m(t) := \frac{N(p-1)}{p+1} \int_{|x|\geq m} |u|^{p+1} dx + \frac{C}{m^2} \|u(t)\|_2^2,$$

where I_m^1 is defined by (2.6). Here and below, C is a positive constant, which may depend only on p and N. Integrating in t, we get

$$I_m^1(T_{j+2}) - I_m^1(T_j) \geq 2\delta - \int_{T_j}^{T_{j+2}} R_m(t) dt,$$

since $T_{j+2} - T_j \geq 1$. Notice that (2.30) is enough to control the error term R_m uniformly in j. To see this, let $\chi(t,r) \in C^\infty(\mathbb{R}^2)$ satisfy $\chi(t,r) = 1$ when $|t| \leq 2$ and $|r| \geq 1$, and $\chi(t,r) = 0$ if $|t| \geq 4$ or $|r| \leq 1/2$. For any $m > 1$ and $T > 4$, let $v(t,r) = \chi(t - T, r/m)u(t,|r|)$. Then we have

$$\int_{\mathbb{R}^2} |\partial_t v|^2 + |\partial_r v|^2 + |v|^2 dr dt \leq Cm^{1-N} \int_{T-4}^{T+4} \int_{\mathbb{R}^N} |\partial_t u|^2 + |\nabla u|^2 + |u|^2 dx dt \leq 8Cm^{1-N} M.$$

Hence the Sobolev embedding $H^1(\mathbb{R}^2) \subset L^{p+1}(\mathbb{R}^2)$ implies that

$$\int_{T-2}^{T+2} \int_{|x|\geq m} |u|^{p+1} dx dt \leq C \sum_{j=0}^{\infty} \int_{T-2}^{T+2} (2^j m)^{N-1} \int_{r \geq 2^j m} |u|^{p+1} dr dt \leq Cm^{-(p-1)(N-1)/2} M^{(p+1)/2}.$$

Therefore choosing m sufficiently large, we obtain

$$I_m^1(T_{j+2}) - I_m^1(T_j) \geq \delta$$

for all $j \geq 4$, which contradicts the global bound

$$I_m^1(T_j) \leq Cm \int_{\mathbb{R}^N} |\partial_t u|^2 + |\partial_r u|^2 + |u|^2 dx|_{t=T_j} \leq CmM.$$

This completes the proof. □

3. Proof of theorems for the KGZ system. In this section, we prove Theorems 5 and 6.

Proof of Theorem 5. Let $\lambda > 1$ and put

$$\tilde{d}_\omega = (H - \omega Q)(\phi_\omega, i\omega\phi_\omega, -|\phi_\omega|^2, 0),$$
$$\delta = N\{\tilde{d}_\omega - (H - \omega Q)(\lambda\phi_\omega, \lambda i\omega\phi_\omega, -\lambda^2|\phi_\omega|^2, 0)\},$$

where H and Q are defined by (1.19) and (1.6), respectively. In the same way as in Lemma 9(iii), we see that $\delta > 0$. Suppose that the solution $\mathbf{u}(t)$ of (1.3)–(1.4) with $\mathbf{u}(0) = (\lambda\phi_\omega, \lambda i\omega\phi_\omega, -\lambda^2|\phi_\omega|^2, 0)$ exists globally and satisfies $M := \sup_{t\geq 0} \|\mathbf{u}(t)\|_Y < \infty$. Note that since the initial data is radially symmetric, the solution $\mathbf{u}(t)$ is also

radially symmetric for all $t \geq 0$. Following Merle [17], we introduce the function $w(t) := -(-\Delta)^{-1}\partial_t n(t)$, and for $m > 0$ we consider the function

$$\tilde{I}_m(t) = I_m^1(t) + \frac{1}{c_0^2}\int_{\mathbb{R}^N} \Psi_m n(t)\partial_r w(t)\,dx,$$

where $I_m^1(t)$ is defined by (2.6) and Φ_m and Ψ_m are given by (2.1). Note that since $\partial_t n(t) \in \dot{H}^{-1}(\mathbb{R}^N)$, we see that $w(t) \in \dot{H}^1(\mathbb{R}^N)$ and $\|\partial_t n\|_{\dot{H}^{-1}} = \|\nabla w\|_2$. By the same computations as in Lemma 8, we have

$$\begin{aligned}-\frac{d}{dt}\tilde{I}_m(t) &= 2\int_{\mathbb{R}^N} \Psi_m'|\nabla u|^2\,dx + \frac{1}{2}\int_{\mathbb{R}^N}\Phi_m(n^2 + 2|u|^2 n)\,dx \\ &\quad -\frac{1}{2}\int_{\mathbb{R}^N}\Delta\Phi_m|u|^2\,dx + \frac{1}{2c_0^2}\int_{\mathbb{R}^N}\left(\Psi_m' - \frac{N-1}{r}\Psi_m\right)|\nabla w|^2\,dx.\end{aligned}$$

By Lemma 7, we have

$$\begin{aligned}&\int_{\mathbb{R}^N}\Psi_m'|\nabla u|^2\,dx \leq \|\nabla u(t)\|_2^2, \\ &-\frac{1}{2}\int_{\mathbb{R}^N}\Delta\Phi_m|u|^2\,dx \leq \frac{C_1}{m^2}\|u(t)\|_2^2 \leq \frac{C_1 M^2}{m^2}, \\ &\int_{\mathbb{R}^N}\left(\Psi_m' - \frac{N-1}{r}\Psi_m\right)|\nabla w|^2\,dx \leq \|\nabla w(t)\|_2^2 = \|\partial_t n(t)\|_{\dot{H}^{-1}}.\end{aligned}$$

Moreover, we have

$$\begin{aligned}&\int_{\mathbb{R}^N}\Phi_m(n^2 + 2|u|^2 n)\,dx \\ &= \int_{\mathbb{R}^N}\Phi_m(n + |u|^2)^2\,dx - \int_{\mathbb{R}^n} N|u|^4\,dx + \int_{\mathbb{R}^n}(N - \Phi_m)|u|^4\,dx \\ &\leq N\|n + |u|^2\|_2^2 - N\|u\|_4^4 + \int_{|x|\geq m}(N - \Phi_m)|u|^4\,dx,\end{aligned}$$

and by (1.11) we have

$$\begin{aligned}&\frac{1}{2}\int_{|x|\geq m}(N - \Phi_m)|u|^4\,dx \leq C\|u(t)\|_{L^\infty(|x|\geq m)}^2\|u(t)\|_2^2 \\ &\leq \frac{C_2}{m^{N-1}}\|u(t)\|_{H^1}^4 \leq \frac{C_2 M^4}{m^{N-1}}.\end{aligned}$$

Therefore, we have

$$-\frac{d}{dt}\tilde{I}_m(t) \leq \tilde{P}(\mathbf{u}(t)) + \frac{C_1 M^2}{m^2} + \frac{C_2 M^4}{m^{N-1}} \tag{3.1}$$

for all $t \geq 0$, where we put

$$\tilde{P}(u, v, n, \nu) = 2\|\nabla u\|_2^2 - \frac{N}{2}\|u\|_4^4 + \frac{N}{2}\|n + |u|^2\|_2^2 + \frac{1}{2c_0^2}\|\nu\|_{\dot{H}^{-1}}^2.$$

Note that

$$\begin{aligned}(H-\omega Q)(u,v,n,\nu)&-\frac{1}{2N}\tilde{P}(u,v,n,\nu)\\&=\frac{1}{2}\|v-i\omega u\|_2^2+\left(1-\frac{1}{N}\right)\frac{1}{4c_0^2}\|\nu\|_{\dot{H}^{-1}}^2+\left(\frac{1}{2}-\frac{1}{N}\right)\|\nabla u\|_2^2+\frac{1-\omega^2}{2}\|u\|_2^2\\&\geq\left(\frac{1}{2}-\frac{1}{N}\right)\|\nabla u\|_2^2+\frac{1-\omega^2}{2}\|u\|_2^2.\end{aligned}$$

Using this inequality, in the same way as in Lemmas 9 and 10, we see that

$$-\tilde{P}(\mathbf{u}(t))\geq 2N\{\tilde{d}_\omega-(H-\omega Q)(\mathbf{u}(0))\}=2\delta \tag{3.2}$$

holds for all $t\geq 0$. Therefore, taking $m_1>0$ such that

$$\frac{C_1M^2}{m_1^2}+\frac{C_2M^4}{m_1^{N-1}}<\delta,$$

by (3.1) and (3.2), we have $(d/dt)\tilde{I}_{m_1}(t)\geq\delta$ for all $t\geq 0$, and $\lim_{t\to\infty}\tilde{I}_{m_1}(t)=\infty$. The rest of the proof is the same as in the proof of Theorem 1 for the case $p\geq 1+4/N$, and we omit the details. □

Proof of Theorem 6. Let $\lambda>1$. Suppose that the solution $\mathbf{u}(t)$ of (1.3)–(1.4) with $\mathbf{u}(0)=(\lambda\phi_\omega,\lambda i\omega\phi_\omega,-\lambda^2|\phi_\omega|^2,0)$ exists globally. By the assumption $|\omega|<1/\sqrt{3}$, we can take α such that $2\omega^2/(1-\omega^2)<\alpha<1$. For such an α, we consider a function defined by

$$I_\alpha(t)=\frac{1}{2}\left\{\|u(t)\|_2^2+\frac{\alpha}{c_0^2}\|n(t)\|_{\dot{H}^{-1}}^2\right\}.$$

Note that since $n(0)=-\lambda^2|\phi_\omega|^2\in L^1(\mathbb{R}^3)\cap L^2(\mathbb{R}^3)\subset\dot{H}^{-1}(\mathbb{R}^3)$ and $\partial_t n\in C([0,\infty);\dot{H}^{-1}(\mathbb{R}^3))$, we see that $n\in C^1([0,\infty);\dot{H}^{-1}(\mathbb{R}^3)\cap L^2(\mathbb{R}^3))$. Then, we have

$$\begin{aligned}\frac{d}{dt}I_\alpha(t)&=\mathrm{Re}\langle u(t),\partial_t u(t)\rangle_{L^2}+\frac{\alpha}{c_0^2}\langle n(t),\partial_t n(t)\rangle_{\dot{H}^{-1}}\\&=\mathrm{Re}\langle u(t),\partial_t u(t)-i\omega u(t)\rangle_{L^2}+\frac{\alpha}{c_0^2}\langle n(t),\partial_t n(t)\rangle_{\dot{H}^{-1}}\end{aligned}$$

and

$$\begin{aligned}\frac{d^2}{dt^2}I_\alpha(t)=\|\partial_t u(t)\|_2^2+\frac{\alpha}{c_0^2}\|\partial_t n(t)\|_{\dot{H}^{-1}}^2-\|\nabla u(t)\|_2^2-\|u(t)\|_2^2\\-\alpha\|n(t)\|_2^2-(1+\alpha)\int_{\mathbb{R}^3}|u(t,x)|^2n(t,x)\,dx.\end{aligned}$$

Thus, we have

$$\begin{aligned}&\frac{d^2}{dt^2}I_\alpha(t)+2(1+\alpha)(H-\omega Q)(\mathbf{u}(0))-2\omega Q(\mathbf{u}(0))\\&=(2+\alpha)\|\partial_t u(t)-i\omega u(t)\|_2^2+\left(2+\frac{1-\alpha}{2\alpha}\right)\frac{\alpha}{c_0^2}\|\partial_t n(t)\|_{\dot{H}^{-1}}^2\\&\qquad+K_{\omega,\alpha}(u(t),n(t)),\end{aligned}$$

where we put

$$K_{\omega,\alpha}(u,n)=\alpha\left\{\|\nabla u\|_2^2+\left(1-\omega^2-\frac{2}{\alpha}\omega^2\right)\|u\|_2^2+\frac{1-\alpha}{2\alpha}\|n\|_2^2\right\}.$$

Here, we define

$$\begin{aligned}
&J_\omega(u,n)=\frac{1}{2}\|\nabla u\|_2^2+\frac{1-\omega^2}{2}\|u\|_2^2+\frac{1}{4}\|n\|_2^2+\frac{1}{2}\int_{\mathbb{R}^3}|u(x)|^2n(x)\,dx,\\
&K^1_{\omega,\alpha}(u,n)=\partial_\lambda J_\omega(\lambda u,\lambda^{2\alpha}n)|_{\lambda=1}\\
&=\|\nabla u\|_2^2+(1-\omega^2)\|u\|_2^2+\alpha\|n\|_2^2+(1+\alpha)\int_{\mathbb{R}^3}|u|^2n\,dx,\\
&K^2_{\omega,\alpha}(u,n)=2\partial_\lambda J_\omega(\lambda^{(1-\alpha)/\alpha}u(\cdot/\lambda),n(\cdot/\lambda))|_{\lambda=1}\\
&=\frac{2-\alpha}{\alpha}\|\nabla u\|_2^2+\frac{2+\alpha}{\alpha}(1-\omega^2)\|u\|_2^2\\
&\qquad\qquad+\frac{3}{2}\|n\|_2^2+\frac{2+\alpha}{\alpha}\int_{\mathbb{R}^3}|u|^2n\,dx,
\end{aligned}$$

and put

$$\begin{aligned}
&J^1_{\omega,\alpha}(u,n)=J_\omega(u,n)-\frac{1}{2(1+\alpha)}K^1_{\omega,\alpha}(u,n)\\
&=\frac{\alpha}{1+\alpha}\left\{\frac{1}{2}\|\nabla u\|_2^2+\frac{1-\omega^2}{2}\|u\|_2^2+\frac{1-\alpha}{4\alpha}\|n\|_2^2\right\},\\
&J^2_{\omega,\alpha}(u,n)=J_\omega(u,n)-\frac{\alpha}{2(2+\alpha)}K^2_{\omega,\alpha}(u,n)\\
&=\frac{\alpha}{2+\alpha}\left\{\|\nabla u\|_2^2+\frac{1-\alpha}{2\alpha}\|n\|_2^2\right\},\\
&\theta=1-\frac{2\omega^2}{(1-\omega^2)\alpha}.
\end{aligned}$$

Then, we have $0<\theta<1$ and

$$K_{\omega,\alpha}(u,n)=2(1+\alpha)\theta J^1_{\omega,\alpha}(u,n)+(2+\alpha)(1-\theta)J^2_{\omega,\alpha}(u,n).$$

Moreover, in a similar way as in Lemmas 3 and 4 in [23], we can prove that $J^j_{\omega,\alpha}(u(t),n(t))\geq\tilde{d}_\omega$ for all $t\geq0$ and $j=1,2$. Therefore, we have

$$\begin{aligned}
K_{\omega,\alpha}(u(t),n(t))&\geq\{2(1+\alpha)\theta+(2+\alpha)(1-\theta)\}\,\tilde{d}_\omega\\
&=2\left(1+\alpha-\frac{\omega^2}{1-\omega^2}\right)\tilde{d}_\omega
\end{aligned}$$

for all $t\geq0$. Moreover, since we have $\tilde{d}_\omega=(1-\omega^2)\|\phi_\omega\|_2^2$, putting $\beta=\min\{2+\alpha,2+(1-\alpha)/2\alpha\}$, we have

$$\begin{aligned}
\frac{d^2}{dt^2}I_\alpha(t)&\geq\beta\left\{\|\partial_tu(t)-i\omega u(t)\|_2^2+\frac{\alpha}{c_0^2}\|\partial_tn(t)\|^2_{\dot{H}^{-1}}\right\}\\
&\quad+2(1+\alpha)\{\tilde{d}_\omega-(H-\omega Q)(\mathbf{u}(0))\}+2\omega Q(\mathbf{u}(0))-2\omega^2\|\phi_\omega\|_2^2
\end{aligned}$$

for all $t \geq 0$. Since $\beta > 2$, $(H - \omega Q)(\mathbf{u}(0)) < \tilde{d}_\omega$, and $\omega Q(\mathbf{u}(0)) > \omega^2 \|\phi_\omega\|_2^2$ for all $\lambda > 1$, by the standard concavity argument, we see that there exists $T_1 \in (0, \infty)$ such that $\lim_{t \to T_1 - 0} I_\alpha(t) = \infty$. This is a contradiction. Hence, for all $\lambda > 1$, the solution $\mathbf{u}(t)$ of (1.3)–(1.4) with $\mathbf{u}(0) = (\lambda\phi_\omega, \lambda i\omega\phi_\omega, -\lambda^2|\phi_\omega|^2, 0)$ blows up in finite time. This completes the proof. □

POISSON–NERNST–PLANCK SYSTEMS FOR ION CHANNELS WITH PERMANENT CHARGES*

BOB EISENBERG† AND WEISHI LIU‡

Abstract. Ionic channels and semiconductor devices use atomic scale structures to control macroscopic flows from one reservoir to another. The one-dimensional steady-state Poisson-Nernst-Planck (PNP) system is a useful representation of these devices, but experience shows that describing the reservoirs as boundary conditions is difficult. We study the PNP system for two types of ions with three regions of piecewise constant permanent charge, assuming the Debye number is large, because the electric field is so strong compared to diffusion. Reservoirs are represented by the outer regions with permanent charge zero. If the reciprocal of the Debye number is viewed as a singular parameter, the PNP system can be treated as a singularly perturbed system that has two limiting systems: inner and outer systems (termed fast and slow systems in geometric singular perturbation theory). A complete set of integrals for the inner system is presented that provides information for boundary and internal layers. Application of the exchange lemma from geometric singular perturbation theory gives rise to the existence and (local) uniqueness of the solution of the singular boundary value problem near each singular orbit. A set of simultaneous equations appears in the construction of singular orbits. Multiple solutions of such equations in this or similar problems might explain a variety of multiple valued phenomena seen in biological channels, for example, some forms of gating, and might be involved in other more complex behaviors, for example, some kinds of active transport.

Key words. singular perturbation, boundary layers, internal layers

1. Introduction.

Electrodiffusion, the diffusion and migration of electric charge, plays a central role in a wide range of our technology and science [53, 11, 54, 14, 15, 67, 41]: semiconductor technology controls the migration and diffusion of quasi-particles of charge in transistors and integrated circuits [75, 62, 71], chemical sciences deal with charged molecules in water [11, 19, 8, 26, 9, 10], all of biology occurs in plasmas of ions and charged organic molecules in water [3, 16, 33, 72]. It is no coincidence that the physics of electrodiffusion is of such general importance: systems of moving charge have a richness of behavior that can be sometimes easily controlled by boundary conditions [67, 71], and the goal of technology (and much of physical science) is to control systems to allow useful behavior.

Control is important to the medical and biological sciences as well. Medicine seeks to control disease and help life. Evolution controls life by selecting those organisms that successfully reproduce. Organisms control their internal environment and external behavior to make reproduction possible, often using electrodiffusion for the mechanism of control [72, 33]. Whatever the reason, it is a fact that nearly all biology occurs in ultrafiltrates of blood called plasmas, in which ions move much as they move in gaseous plasmas, or as quasi-particles move in semiconductors [21, 22, 23, 24].

The pun between the medical and physical meanings of "plasma" is useful and surprisingly precise.

In semiconductor and biological devices, macroscopic flows of charges are driven through tiny (atomic scale) channels that link one macroscopic reservoir to another. The reservoirs are macroscopic regions in which the concentration of charges is nearly constant (because the dimensions of the reservoirs are macroscopic and so the total number of charges is hardly changed by the flows) and electrical potentials are nearly constant too. The electrical resistance of the macroscopic region is so small that only a tiny electrical potential gradient is needed to drive significant flow of charge in the reservoir. The electric field is strong throughout these systems and only a few charges (ions) are needed to create significant electrical potentials, compared to the enormous number of ions (10^{23}, Avogadro's number) needed to create chemical potentials (and diffusion). That is why the Debye number is so large (see systems (1) and (5)). Semiconductors and evolution take advantage of the strength of the electric field. Engineers and biophysicists control flow by setting the electric potential at the boundaries called terminals, contacts, or baths.

The flow through the atomic scale channel is affected by other variables besides the applied boundary potentials, namely, by the shape of the pore in the channel (through which permanently charged ions flow) and the distribution of permanent and induced (i.e., polarization) charge on the wall of the channel as well as the mobility of ions [49, 25, 17, 40, 32]. A precise description and understanding of flow on an atomic scale is daunting. Enormous numbers of variables are needed to describe atomic scale trajectories that have a fundamental time scale 10^{-16} sec and length scale 10^{-10} m compared to biological function that is typically much slower than 10^{-5} sec. It is not clear what to do with this number of variables and trajectories even if they could be computed accurately or with known inaccuracies.

We are fortunate that description on the atomic time scale is unnecessary. What is needed in fact is a reduced description that focuses attention on the properties that control function in technology and biology. This reduced description needs to describe channel structure on the atomic scale of distance, in all likelihood, but it needs to describe flows and reservoirs only on the macroscopic scale.

Reduced descriptions of this type are familiar in engineering where they are called device equations. Semiconductor manufacturers produce the device behaviors they need by choosing particular structures of permanent charge, using as little atomic structure as possible, so cost is minimized. Device behaviors are described by device equations. It is device equations that we seek as we try to understand and control ion channels (and molecular machines of biology in general).

Device equations are most useful when they predict complex behaviors realistically while using only a few parameters with fixed values (that do not need to be changed to describe the complex behaviors). Fortunately, electrodiffusion allows rich behavior with simple device equations and a fixed set of parameters. Remarkably, the diverse (technologically important) behavior of transistors can be described by simple conservation laws and constitutive relations, the Poisson–Nernst–Planck (PNP) equations using fixed values of parameters. A single transistor can behave as many different devices, each with its own device equation, and this rich behavior can be described quite well by the PNP equations with a fixed set of parameters. Different values of the boundary potentials (i.e., power supply voltages) move the solution of the equations into different domains, each with its own device equation.

The PNP system of equations has been analyzed mathematically to some extent, but the equations have been simulated and computed to a much larger extent [18, 6,

16, 38, 49, 4, 17, 66, 36, 37, 40, 2, 20, 31, 55, 56, 1, 13, 70, 65, 29, 30, 43, 7]. Computational and experimental experience with a variety of PNP-like systems shows that the existing mathematical analysis is unsatisfactory. It is clear from these simulations that macroscopic reservoirs must be included in the mathematical formulation to describe the actual behavior of channels (or useful transistors) [60, 32, 31, 12, 59, 57, 58, 34, 29]. Macroscopic boundary conditions that describe such reservoirs introduce boundary layers of concentration and charge. If those boundary layers reach into the part of the device performing atomic control, they dramatically affect its behavior. Boundary layers of charge are particularly likely to create artifacts over long distances because the electric field spreads a long way. Indeed, transistors, channels, transporters, and receptors are actually built so that the contacts, electrodes, and control systems that maintain the reservoirs are quite distant and distinct from the channel.

In this paper, we construct and analyze the minimal model that includes reservoirs and channels and start the study of its mathematical properties. We begin with simple setups and conditions using geometric singular perturbation theory to extract powerful results. In particular, we consider three regions, two of which are reservoirs, and one of which is the narrow channel (with permanent charge, i.e., doping). And we consider only two species of current carriers. Nonetheless, we find quite complex behavior showing clearly that the reservoirs are inextricably linked to the channel and cannot be replaced by simple boundary conditions. We find general properties of the system and hints that somewhat more complicated systems (with several regions of permanent charge of different density and/or sign) carrying multiple ionic species (with different valence, i.e., with different permanent charge on each type of ion) may have quite rich behavior. Such rich behavior is apparent in biology where channels switch ("gate") between different values of current (one value nearly zero) and where transporters couple the flow of different types of ions in an extremely important, quite robust, but nearly unknown way.

The rest of the paper is organized as follows. In section 2, we begin with a description of a three-dimensional PNP system as the model for ion flow through an ion channel and discuss a one-dimensional reduction as the maximal radius of cross-sections of the channel approaching zero. We then identify the problem to be studied in this paper: steady-states of boundary value problems of the one-dimensional PNP system. In section 3, we cast our problem in the language of geometric singular perturbation theory. By introducing new dependent variables, we write the PNP system as a singularly perturbed system of first order equations. Making use of the inner and outer limiting systems, we then construct singular orbits for the PNP boundary value problem. In section 4, we apply geometric singular perturbation theory to show that, for small $\epsilon > 0$, there is a true solution shadowing each singular orbit. We conclude the paper by a general remark in section 5.

2. Three-dimensional model PNP system and a one-dimensional reduction. We now briefly describe the model PNP system of equations. As discussed above, the key features of an ion channel are the shape of its pore and the distribution of the permanent charge along its interior wall. As a first approximation, we consider a special ion channel modeled by

$$\Omega_\mu = \{(x, y, z) : 0 < x < 1,\ y^2 + z^2 < g^2(x, \mu)\},$$

where g is a smooth function satisfying

$$g(x, 0) = 0 \ \text{ and } \ g_0(x) = \frac{\partial g}{\partial \mu}(x, 0) > 0 \ \text{ for } \ x \in [0, 1].$$

The small parameter μ measures the maximal radius of cross-sections of the channel. The boundary $\partial\Omega_\mu$ of Ω_μ consists of three portions:

$$\begin{aligned}\mathcal{L}_\mu &= \{(x,y,z) \in \partial\Omega_\mu : x = 0\},\\ \mathcal{R}_\mu &= \{(x,y,z) \in \partial\Omega_\mu : x = 1\},\\ \mathcal{M}_\mu &= \{(x,y,z) \in \partial\Omega_\mu : y^2 + z^2 = g^2(x,\mu)\}.\end{aligned}$$

Here, $\mathcal{L}_\mu$ and $\mathcal{R}_\mu$ are viewed as the two ends of the reservoirs and $\mathcal{M}_\mu$ the wall of the channel and the reservoirs.

Then the model employed for flow through the channel is the PNP system (see [5] for a derivation from Boltzmann transport equation; see [66] for a derivation including correlations from coupled Langevin–Poisson equations; see [11, p. 773, eq. 26.64] for the classical description of the system at thermodynamic equilibrium, when all fluxes are zero):

$$\begin{aligned}\Delta\phi &= -\lambda\left(\sum_{i=1}^{n}\alpha_i c_i + Q\right),\\ \frac{\partial c_i}{\partial t} &= D_i\nabla\cdot(\nabla c_i + \alpha_i c_i\nabla\phi),\end{aligned} \tag{1}$$

where ϕ is the electric potential; c_i's are the concentrations of the n species, and α_i's are the valences, i.e., charge on one ion; D_i's are the diffusion constants; λ is the Debye number; and Q is the distribution of the permanent charge along the interior wall of the channel.

As mentioned in the introduction, the concentrations of the ions and the electrical potential in the reservoirs are nearly constants, and the wall of the channel is assumed to be perfectly insulated. We thus assume the following boundary conditions:

$$\begin{gathered}\phi|_{\mathcal{L}_\mu} = \nu_0, \quad \phi|_{\mathcal{R}_\mu} = 0, \quad c_i|_{\mathcal{L}_\mu} = L_i, \quad c_i|_{\mathcal{R}_\mu} = R_i,\\ \frac{\partial\phi}{\partial\mathbf{n}}\Big|_{\mathcal{M}_\mu} = \frac{\partial c_k}{\partial\mathbf{n}}\Big|_{\mathcal{M}_\mu} = 0,\end{gathered} \tag{2}$$

where ν_0, L_i, R_i are constants and $\mathbf{n}$ is the outward unit normal vector to $\mathcal{M}_\mu$.

We remark that, typically in the reservoirs, one imposes electroneutrality conditions: $\alpha L_1 - \beta L_2 = 0$ and $\alpha R_1 - \beta R_2 = 0$. In this case, there will be no boundary layers at the two ends although there will be internal layers *where* the permanent charge Q jumps. For mathematical interest, we use the slightly more general boundary conditions.

In [52], for $n = 2$ with $Q = 0$, we obtained the following limiting one-dimensional PNP system as $\mu \to 0$:

$$\begin{aligned}\frac{1}{g_0^2}\frac{\partial}{\partial x}\left(g_0^2\frac{\partial}{\partial x}\phi\right) &= -\lambda(\alpha_1 c_1 + \alpha_2 c_2),\\ \frac{\partial c_1}{\partial t} &= \frac{D_1}{g_0^2}\frac{\partial}{\partial x}\left(g_0^2\frac{\partial}{\partial x}c_1 + \alpha_1 c_1 g_0^2\frac{\partial}{\partial x}\phi\right),\\ \frac{\partial c_2}{\partial t} &= \frac{D_2}{g_0^2}\frac{\partial}{\partial x}\left(g_0^2\frac{\partial}{\partial x}c_2 + \alpha_2 c_2 g_0^2\frac{\partial}{\partial x}\phi\right)\end{aligned} \tag{3}$$

on $x \in (0,1)$ with the boundary conditions

$$\phi(t,0) = \nu_0, \quad \phi(t,1) = 0, \quad c_i(t,0) = L_i, \quad c_i(t,1) = R_i. \tag{4}$$

In particular, we showed that the attractors $\mathcal{A}_\mu$ of (1) and (2) are upper semicontinuous at $\mu = 0$ to the attractor $\mathcal{A}_0$ of (3) and (4). One-dimensional PNP systems of the form (3) also arise in treatments based on the density functional theory of statistical mechanics [31]. The motivation for such a mathematical treatment is that, first of all, the one-dimensional system is much simpler; second, if the one-dimensional limiting system is structurally stable (i.e., if the global dynamics is robust), then the dynamics for the system on the three-dimensional domain with small μ is essentially the same as that of the limiting one-dimensional system. There is a well-established framework for verification of structural stability although it is by no means trivial. A key step is to understand the behavior of the steady-state of the limiting one-dimensional system.

In light of the above result and discussion, we will then study steady-states of the one-dimensional PNP system for two species of current carriers with valences $\alpha > 0$ and $-\beta < 0$, including now a permanent charge:

$$\begin{aligned} \epsilon^2 h^{-1}(x)\frac{d}{dx}\left(h(x)\frac{d}{dx}\phi\right) &= -(\alpha c_1 - \beta c_2 + Q(x)), \quad \frac{dJ_i}{dx} = 0, \\ h(x)\frac{dc_1}{dx} + \alpha c_1 h(x)\frac{d\phi}{dx} &= -J_1, \\ h(x)\frac{dc_2}{dx} - \beta c_2 h(x)\frac{d\phi}{dx} &= -J_2, \end{aligned} \tag{5}$$

with the boundary conditions

$$\phi(0) = \nu_0, \quad c_i(0) = L_i; \quad \phi(1) = 0, \quad c_i(1) = R_i. \tag{6}$$

Here J_i is the total flux of the ith ion, $Q(x)$ is the permanent charge along the channel, $h(x) = g_0^2(x)$, and ϵ is related to λ via $\lambda = \epsilon^{-2}$.

Many mathematical papers have been written about the existence and uniqueness of solutions of the boundary value problems, and numerical algorithms have been developed to approximate solutions even for high-dimensional systems (see, e.g., [39, 42, 61, 44]). Under the assumption that $\epsilon \ll 1$, the problem can be viewed as a singular perturbation one. In particular, for $\alpha = \beta = 1$, $h(x) = 1$, and $Q(x) = 0$, the boundary value problem for the one-dimensional PNP system (5) was studied in [7] using the method of matched asymptotic expansions as well as numerical simulations, which provide a good quantitative understanding of the problem with one region without permanent charge. In [51], assuming $\epsilon \ll 1$ but for general α, β, $h(x) = 1$ and $Q(x) = 0$, the boundary value problem was treated using geometric theory for singularly perturbed problems (see, e.g., [27, 45, 47, 50]).

We use the geometric framework in paper [51] to investigate PNP systems with multiple regions of permanent charge and with multiple ions. A major difference of the model studied in this paper from those previously studied is the inclusion of multiple regions of permanent charge. The focus will be on the simple case of two ions and two reservoirs (i.e., two regions without permanent charge). The idea is to construct singular orbits for the boundary value problem and apply geometric singular perturbation theory to obtain, for $\epsilon > 0$ small, solutions near singular orbits. Issues of the existence and multiplicity of singular orbits are reduced to the properties of a set of nonlinear algebraic equations (43). To our surprise, for the simple case we study, multiple solutions for the boundary value problem are shown to exist. This contrasts to what was suspected in some early works (see, for example, [63, 64]) which expressed the (entirely reasonable) opinion that multiple solutions cannot occur for the simple

structure of permanent charge considered here. The set of equations (43) governs the multiplicity of solutions to the boundary value problem. We will thoroughly examine the set of algebraic equations in the future.

3. A dynamical system framework and a construction of singular orbits. We will rewrite the PNP system into a standard form for singularly perturbed systems and convert the boundary value problem to a connecting problem.

Denote the derivative with respect to x by overdot and introduce $u = \epsilon\dot{\phi}$ and $\tau = x$. System (5) becomes

$$\begin{aligned} &\epsilon\dot{\phi} = u, \quad \epsilon\dot{u} = \beta c_2 - \alpha c_1 - Q(\tau) - \epsilon\frac{h'(\tau)}{h(\tau)}u, \\ &\epsilon\dot{c}_1 = -\alpha c_1 u - \epsilon h^{-1}(\tau)J_1, \\ &\epsilon\dot{c}_2 = \beta c_2 u - \epsilon h^{-1}(\tau)J_2, \\ &\dot{J}_1 = \dot{J}_2 = 0, \quad \dot{\tau} = 1. \end{aligned} \tag{7}$$

We will treat system (7) as a dynamical system of phase space $\boldsymbol{R}^7$ with state variables $(\phi, u, c_1, c_2, J_1, J_2, \tau)$. The introduction of the extra state variable $\tau = x$ and the τ-equation seems to add complications to the problem, but this has a great advantage that we will explain shortly.

For $\epsilon > 0$, the rescaling $x = \epsilon\xi$ of the independent variable x gives rise to an equivalent system

$$\begin{aligned} &\phi' = u, \quad u' = \beta c_2 - \alpha c_1 - Q(\tau) - \epsilon\frac{h'(\tau)}{h(\tau)}u, \\ &c_1' = -\alpha c_1 u - \epsilon h^{-1}(\tau)J_1, \\ &c_2' = \beta c_2 u - \epsilon h^{-1}(\tau)J_2, \\ &J_1' = J_2' = 0, \quad \tau' = \epsilon, \end{aligned} \tag{8}$$

where prime denotes the derivative with respect to the variable ξ.

For $\epsilon > 0$, systems (7) and (8) have exactly the same phase portrait. But their limits at $\epsilon = 0$ are different and, very often, the two limiting systems provide complementary information on state variables. Therefore, the main task of singularly perturbed problems is to patch the limiting information together to form a solution for the entire $\epsilon > 0$ system. In terms of asymptotic expansions, system (7) and its limit at $\epsilon = 0$ will be used to study *outer or regular layer* solutions. We will call this system the *outer system* and its limit at $\epsilon = 0$ the *outer limit system*. System (8) and its limit at $\epsilon = 0$ will be used to study *inner or singular layer* solutions, and we call the system the *inner system* and its limit system at $\epsilon = 0$ the *inner limit system*. By *a singular orbit*, we mean a continuous and piecewise smooth curve in $\boldsymbol{R}^7$ that is a union of finitely many orbits of the outer limit system or inner limit system. In the theory of geometric singular perturbations, viewing the independent variables x and ξ as slow and fast time variables, the outer system is called the *slow system*, the inner system is called the *fast system*, and a singular orbit is a union of *slow* and *fast* orbits.

Let B_L and B_R be the subsets of the phase space $\boldsymbol{R}^7$ defined by

$$B_L = \{(\nu_0, u, L_1, L_2, J_1, J_2, 0) \in \boldsymbol{R}^7 : \text{ arbitrary } u, J_1, J_2\}, \tag{9}$$

$$B_R = \{(0, u, R_1, R_2, J_1, J_2, 1) \in \boldsymbol{R}^7 : \text{ arbitrary } u, J_1, J_2\}. \tag{10}$$

Then the boundary value problem is equivalent to a *connecting problem*, namely, finding a solution of (7) or (8) from B_L to B_R. To see this, suppose that $(\phi, u, c_1, c_2, J_1, J_2, \tau)$ is an orbit starting at a point on B_L and ending at a point on B_R. Due to the definitions of B_L and B_R, the starting point automatically has $x = \tau = 0$ with the assigned values for ϕ, c_1, and c_2 at $x = 0$, and the ending point has $x = \tau = 1$ with the assigned values for ϕ, c_1, and c_2 at $x = 1$. This solution $(\phi, u, c_1, c_2, J_1, J_2, \tau)$ satisfies the boundary condition automatically. Most importantly, when we *arbitrarily* rescale the independent variable x, the phase portrait will remain the same. Therefore, in searching for a solution from B_L to B_R, we can apply any rescaling of the independent variable x, even a rescaling that depends on each individual solution. (We will use a rescaling that is different for each solution when we derive the system (34) from system (33).) This is the significant advantage of introducing $\tau = x$ and $\dot{\tau} = 1$ promised earlier. The idea of converting a boundary value problem to a connecting one is now rather standard in applied dynamical systems.

In this paper, we will consider the case where the outer regions are reservoirs and the permanent charge is constant along the channel; that is,

$$Q(x) = \begin{cases} 0 & \text{for } 0 < x < a, \\ Q & \text{for } a < x < b, \\ 0 & \text{for } b < x < 1, \end{cases}$$

where Q is a constant. The intervals $[0, a]$ and $[b, 1]$ are the reservoirs, and the interval $[a, b]$ is the channel.

We will be interested in solutions of the connecting problem for system (7) or (8) from B_L to B_R defined in (9) and (10). In view of the jump of Q at $x = a$ and $x = b$, the best one can hope is that the solution is continuous and piecewise differentiable. We therefore require our solutions to be *continuous and piecewise differentiable*. The continuity of u implies that ϕ, c_1, and c_2 are differentiable. Our requirement is motivated by two considerations: (i) the dissipation present in the full PNP system (that includes time evolution) improves the regularity of solutions; in particular, the attractor contains regular solutions. Steady-state solutions, being in the attractor, should have the regularity imposed; (ii) if the requirement is relaxed, say, only requiring ϕ, c_1, c_2 to be piecewise differentiable, then one can preassign any value for (ϕ, c_1, c_2) at any partition points $0 < x_1 < x_2 < \cdots < x_k < 1$ and construct solutions over each subinterval and piece them together to create a solution over $[0, 1]$ with the preassigned values for (ϕ, c_1, c_2) at the partition points. (This assertion follows from the work in [7, 51].) It is clear that the only relevant solutions are those in which ϕ, c_1, c_2 are differentiable.

Our construction of a solution involves two main steps: the first step is to construct a singular orbit to the connecting problem, and the second step is to apply geometric singular perturbation theory to show that there is a unique solution near the singular orbit for $\epsilon > 0$ and small. Here we will give a detailed explanation for the first step and leave the explanation of the second step to section 4.

To construct a singular orbit, we first construct a singular orbit on each of the subinterval $[0, a]$, $[a, b]$, and $[b, 1]$. The reason to split the interval $[0, 1]$ into three subintervals is simply because the permanent charge $Q(x)$ has jumps at $x = a$ and $x = b$. To be able to construct a singular orbit on each subinterval, we need to preassign the values of ϕ, c_1, and c_2 at $x = a$ and $x = b$. Suppose, for the moment, that $\phi = \phi^a$, $c_1 = c_1^a$, and $c_2 = c_2^a$ at $x = a$, and that $\phi = \phi^b$, $c_1 = c_1^b$, and $c_2 = c_2^b$

at $x = b$. Those *six* unknown values

$$\phi^a,\ c_1^a,\ c_2^a;\ \phi^b,\ c_1^b,\ c_2^b \tag{11}$$

will be determined along our construction of a singular orbit on the whole interval $[0, 1]$.

1. On the left subinterval $[0, a]$ where $Q = 0$ or there is no permanent charge, we construct a singular orbit for the boundary value problem with (ϕ, c_1, c_2, τ) being

$$(\nu_0, L_1, L_2, 0) \text{ at } x = 0 \text{ and } (\phi^a, c_1^a, c_2^a, a) \text{ at } x = a.$$

   The orbit consists of two boundary layers Γ_l^0 and Γ_l^a and one regular layer Λ_l. In particular, given (ϕ^a, c_1^a, c_2^a), the flux densities J_1^l, J_2^l and the value $u_l(a)$ are uniquely determined (see section 3.1).
2. On the middle subinterval $[a, b]$, we construct a singular orbit for the boundary value problem with (ϕ, c_1, c_2, τ) being

$$(\phi^a, c_1^a, c_2^a, a) \text{ at } x = a \text{ and } (\phi^b, c_1^b, c_2^b, b) \text{ at } x = b.$$

   The orbit consists of two boundary layers Γ_m^a and Γ_m^b and one regular layer Λ_m. In particular, given (ϕ^a, c_1^a, c_2^a) and (ϕ^b, c_1^b, c_2^b), the flux densities J_1^m, J_2^m and the values $u_m(a)$ and $u_m(b)$ are uniquely determined (see section 3.2).
3. On the right subinterval $[b, 1]$, we construct a singular orbit for the boundary value problem with (ϕ, c_1, c_2, τ) being

$$(\phi^b, c_1^b, c_2^b, b) \text{ at } x = b \text{ and } (0, R_1, R_2, 1) \text{ at } x = 1.$$

   The orbit again consists of two boundary layers Γ_r^b and Γ_r^1 and one regular layer Λ_r. In particular, given (ϕ^b, c_1^b, c_2^b), the flux densities J_1^r, J_2^r and the value $u_r(b)$ are uniquely determined (see section 3.3).
4. Finally, for a singular orbit on the whole interval $[0, 1]$, we require that

$$J_1^l = J_1^m = J_1^r, \quad J_2^l = J_2^m = J_2^r, \quad u_l(a) = u_m(a), \quad u_m(b) = u_r(b).$$

   This consists of *six* conditions. *The number of conditions is exactly the same as the number of unknown values in* (11) (see section 3.4).
   The qualitative properties of these six equations and conditions are of great importance. It turns out that they can have multiple solutions. Different solutions yield different amounts of current for otherwise identical conditions, suggesting that each level might correspond to a different functional state of a transporter, or a different gating state of a channel. Indeed, it seems likely that more complex systems than those considered here would be described by similar systems of equations with multiple solutions. Interesting and very important properties of channels and transporters—each corresponding to a quite distinct device with a quite distinct input-output relation and device equation—might arise this way in systems including Ca^{2+} or in systems with multiple regions of nonzero permanent charge, or in systems with branched, Y-shaped, or adjacent interacting channels.

Remark 3.1. We call Γ_l^a, Γ_m^a, Γ_m^b, and Γ_r^b boundary layers because, relative to each subinterval, they are boundary layers. But, relative to the whole interval $[0, 1]$, they should be termed *internal layers*.

3.1. Singular orbit on $[0, a]$ where $Q(x) = 0$. We consider the case with zero permanent charge on the subinterval $[0, a]$ because $[0, a]$ is viewed as one of the reservoirs. The nonzero Q over the subinterval $[a, b]$ will affect the solution on $[0, a]$ and on $[b, 1]$. This effect will show up when we impose *matching* conditions on ϕ^a, c_1^a, and c_2^a to construct the singular orbit over the *whole* interval $[0, 1]$.

Following the discussion above, we set $\phi(a) = \phi^a$, $c_1(a) = c_1^a$, and $c_2(a) = c_2^a$, where ϕ^a, c_i^a are unknown values to be determined later on. Now let

$$B_a = \{(\phi^a, u, c_1^a, c_2^a, J_1, J_2, a) \in \boldsymbol{R}^7 : u, J_i \text{ arbitrary}\}.$$

In this part, we will construct a singular orbit that connects B_L to B_a. Two boundary layers will be constructed in section 2.1.1 followed by the construction of the regular layer in section 2.1.2. The permanent charge Q is zero in both constructions.

If we set $\epsilon = 0$ in system (7) with $Q(x) = 0$, we get the outer limit system and, in particular, $u = 0$ and $\alpha c_1 = \beta c_2$. The set

$$\mathcal{Z}_l = \{u = 0, \alpha c_1 = \beta c_2\}$$

will be called *the outer manifold*. In the theory of geometric singular perturbations, $\mathcal{Z}_l$ is called *the slow manifold* because if x and ξ are viewed as time variables, the evolution on $\mathcal{Z}_l$ is characterized by the time variable ξ, which is slow.

Remark 3.2. In systems (7) and (8), there appear to be four fast equations and three slow equations. Typically, one would expect a three-dimensional slow manifold. But, in this specific problem, the slow manifold is five-dimensional. This fact indicates some degeneracy of the slow flow, which is reflected in sections 3.1.2 and 3.2.2. The exchange lemma applied in the proof of Theorem 4.1 in section 4 is still valid. In fact, it applies to singular perturbation problems of more general forms than standard ones (see, e.g., [46, p. 562, Remark 1]).

The geometric method for a construction of singular orbits on each of the subintervals $[0, a]$, $[a, b]$, and $[b, 1]$ is the same. Let us explain the approach for constructing the singular orbit that connects B_L to B_a on $[0, a]$ (see Figure 1). Generally, the outer manifold $\mathcal{Z}_l$ will not intersect B_L and B_a. Since every outer or regular layer orbit lies entirely on the outer manifold $\mathcal{Z}_l$, it will not intersect B_L and B_a; that is, it cannot satisfy the boundary conditions. Two boundary or inner layers need to be introduced to connect boundaries B_L and B_a with the outer layer solution on $\mathcal{Z}_l$. These boundary layers should satisfy the inner limit system. The boundary layer orbit Γ_l^0 at $x = 0$ will connect B_L to $\mathcal{Z}_l$. It must lie on the stable manifold $W^s(\mathcal{Z}_l)$; that is, it belongs to the intersection $M_L \cap W^s(\mathcal{Z}_l)$, where M_L is the collection of orbits starting from points on B_L. Similarly, the boundary layer Γ_l^a at $x = a$ will connect $\mathcal{Z}_l$ to B_a and it must lie on the unstable manifold $W^u(\mathcal{Z}_l)$; that is, it belongs to the intersection $M_l^a \cap W^u(\mathcal{Z}_l)$, where M_l^a is the collection of orbits starting from points on B_l^a.

The first step in the construction examines the stability of the outer manifold $\mathcal{Z}_l$ by linearizing along $\mathcal{Z}_l$. ($\mathcal{Z}_l$ is the set of equilibria of the inner limit system.) It turns out that the outer manifold $\mathcal{Z}_l$ has a stable manifold $W^s(\mathcal{Z}_l)$ and an unstable manifold $W^u(\mathcal{Z}_l)$. The next step is to check whether $W^s(\mathcal{Z}_l)$ intersects B_L and whether $W^u(\mathcal{Z}_l)$ intersects B_a. This requires concrete knowledge of the *global* behavior of $W^s(\mathcal{Z}_l)$ and $W^u(\mathcal{Z}_l)$, and the information from the linearization is not enough. Neither is abstract dynamical systems theory (since the inner limit system is *nonlinear*). Luckily, we discovered a complete set of integrals for the inner limit system (see Proposition 3.2). The set of integrals reflects the intrinsic *mathematical*

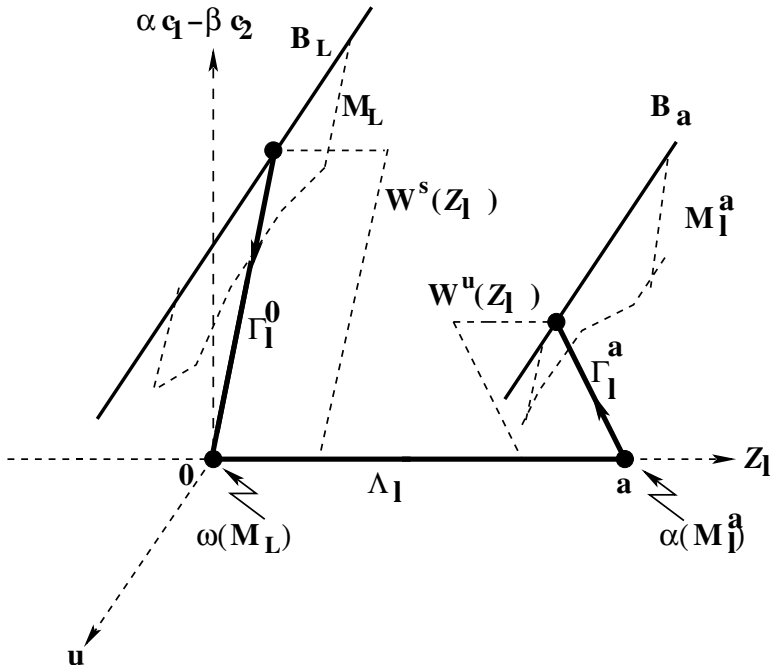

FIG. 1. *Schematic picture of the singular orbit (solid curves) on* $[0,a]$*: one left boundary layer* Γ_l^0*, one regular layer* Λ_l*, and one right boundary layer* Γ_l^a*.*

structure of this particular electrodiffusion system, the channel problem. This mathematical special structure implies particular specific physical and chemical properties of the ion channel. It is irresistible, albeit speculative, to suspect that the special mathematical structure produces biologically important properties of the channel. In that sense, the mathematical structure of the problem provides one possible "device equation" for the channel system.

It is this set of integrals in Proposition 3.2 that allows us to give a complete, global description of the inner limit dynamics; in particular, we are able to establish the required intersections $M_L \cap W^s(\mathcal{Z}_l)$ and $M_l^a \cap W^u(\mathcal{Z}_l)$ and are also able to identify the so-called ω-limit set $\omega(M_L \cap W^s(\mathcal{Z}_l))$ and the α-limit set $\alpha(M_l^a \cap W^u(\mathcal{Z}_l))$ of the intersections. The intersections give the set of candidates for the boundary layers (consisting of two parameter families of inner orbits parameterized by J_1 and J_2). The foot points $\omega(M_L \cap W^s(\mathcal{Z}_l))$ and $\alpha(M_l^a \cap W^u(\mathcal{Z}_l))$ (each parameterized by J_1 and J_2 also) on $\mathcal{Z}_l$ provide the (reduced) boundary conditions for the outer solutions. It turns out there is only one outer orbit Λ_l that connects $\omega(M_L \cap W^s(\mathcal{Z}_l))$ to $\alpha(M_l^a \cap W^u(\mathcal{Z}_l))$ and also determines the pair (J_1, J_2) uniquely. The desired singular orbit connecting B_L to B_a on $[0,a]$ is formed by this outer orbit Λ_l together with the two boundary layers Γ_l^0 and Γ_l^a that are uniquely determined by the pair (J_1, J_2).

We remind the reader that the singular orbit to be constructed on this subinterval with zero permanent charge will *not* be complete *until* the unknowns in (11) are determined through matching conditions implicitly posed by the permanent charge Q on the *whole* interval $[0,1]$, including the channel region where the permanent charge is not zero. The entire system is coupled and must be solved together, suggesting the source of difficulties with earlier treatments, which tried to replace the reservoirs with

boundary conditions. The importance of the coupling of different intervals suggests that the shapes of antechambers commonly found in biological channels may be important to their function. It is interesting that synthetic nanochannels acquire some properties of biological channels when they are built with antechambers of specific shape [68, 69].

3.1.1. Inner dynamics on $[0, a]$: Boundary layers or inner solutions. We start with the examination of boundary layers on the interval $[0, a]$ where $Q = 0$. These will be studied using the inner limit system obtained by setting $\epsilon = 0$ in (8):

$$\begin{aligned} &\phi' = u, \quad u' = \beta c_2 - \alpha c_1, \\ &c_1' = -\alpha c_1 u, \\ &c_2' = \beta c_2 u, \\ &J_1' = J_2' = 0, \quad \tau' = 0. \end{aligned} \tag{12}$$

This inner limit system describes what a chemist would call (thermodynamic) equilibrium. The reader should be warned that the word "equilibrium" is used widely, albeit informally, in computational electronics to describe a system *not* at thermodynamic equilibrium, namely, a system in which the distribution of velocities is a displaced Maxwellian, with displacement given by the flux (in appropriate units). Only when the flux of every species is zero is the "equilibrium" of computational electronics a thermodynamic equilibrium.

The set of equilibria of (12), that is, the set of points at which the vector field of (12) vanishes, is precisely $\mathcal{Z}_l = \{u = 0, \alpha c_1 = \beta c_2\}$. The linearization at points $(\phi, 0, c_1, c_2, J_1, J_2, \tau) \in \mathcal{Z}_l$ is

$$\begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & -\alpha & \beta & 0 & 0 & 0 \\ 0 & -\alpha c_1 & 0 & 0 & 0 & 0 & 0 \\ 0 & \beta c_2 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

This linearization is similar to the Green–Kubo expansion used by physical chemists to describe a nonequilibrium system close to equilibrium [11, 48, 74, 76]. Of course, such a linearization is useful only around some specific (operating) point; here the thermodynamic operating point with zero fluxes. To study nonlinear behavior far from the thermodynamic operating point, one must do a linearization around other points, at which fluxes are not zero. Such analyses have not been attempted, as far as we know for the PNP system, or in physical chemistry in general, perhaps because the locations and properties of operating points other than the thermodynamic one are hard to specify simply. Linearization around general *nonequilibrium* operating points is a crucial method in electrical engineering and has been used to design nonlinear circuits since the invention of electron valves—i.e., vacuum tubes—in the 1930s.

The linearized system has five zero eigenvalues whose generalized eigenspace is the tangent space of the five-dimensional outer manifold $\mathcal{Z}_l$ of equilibria. The two other eigenvalues are $\pm\sqrt{(\alpha + \beta)\alpha c_1} \neq 0$ whose eigenvectors are not tangent to $\mathcal{Z}_l$.

In this sense, $\mathcal{Z}_l$ is called *normally hyperbolic*. The theory of normally hyperbolic invariant manifolds (e.g., [27]) states that

(i) there is a six-dimensional stable manifold $W^s(\mathcal{Z}_l)$ of $\mathcal{Z}_l$ that consists of points approaching $\mathcal{Z}_l$ in forward time;

(ii) there is a six-dimensional unstable manifold $W^u(\mathcal{Z}_l)$ of $\mathcal{Z}_l$ that consists of points approaching $\mathcal{Z}_l$ in backward time;

(iii) $\mathcal{Z}_l$ as well as $W^s(\mathcal{Z}_l)$ and $W^u(\mathcal{Z}_l)$ persists for $\epsilon > 0$ small; that is, for $\epsilon > 0$ small, there exist invariant manifolds $\mathcal{Z}_l^\epsilon$, $W^s(\mathcal{Z}_l^\epsilon)$, and $W^u(\mathcal{Z}_l^\epsilon)$, close to their counterparts.

What this result suggests is that, for a singular orbit connecting B_L to B_a, the boundary layer at $x = 0$ must lie in $M_L \cap W^s(\mathcal{Z}_l)$ and the boundary layer at $x = a$ must lie in $M_l^a \cap W^u(\mathcal{Z}_l)$, where M_L is the collection of orbits from B_L in forward time under the flow of system (12) and M_l^a is the collection of orbits from B_a in backward time under the flow of system (12). This is precisely what we will show.

DEFINITION 3.1. *A smooth function $H : \boldsymbol{R}^n \to \boldsymbol{R}$ is called* an integral *of system $\frac{d}{dt}z = f(z)$, $z \in \boldsymbol{R}^n$, if $\frac{d}{dt}[H(z(t))] = 0$ whenever $z(t)$ is a solution.*

For a system on $\boldsymbol{R}^n$, if there are $(n-1)$ (independent) integrals, then any orbits can be theoretically determined by the intersections of $(n-1)$ level sets of the integrals.

PROPOSITION 3.2. *System* (12) *has the following six integrals:*

$$H_1 = e^{\alpha\phi}c_1, \quad H_2 = e^{-\beta\phi}c_2, \quad H_3 = c_1 + c_2 - \frac{1}{2}u^2,$$
$$H_4 = J_1, \quad H_5 = J_2, \quad H_6 = \tau.$$

Proof. The proof can be verified directly. ∎

The reader seeking physical insight is reminded that α is the valence (i.e., charge) of the ions with number density c_1; $(-\beta)$ is the charge of the ions with number density c_2, $u = \epsilon\dot{\phi}$, $\tau = x$; and ϵ is the Debye length.

These integrals allow one to completely understand the boundary layers (at $x = 0, a$) and characterize landing points of boundary layers on the outer manifold $\mathcal{Z}_l$. The information on landing points is crucial because it provides the boundary conditions that allow the regular layer to connect boundary layers.

COROLLARY 3.3. (i) *Let $\phi = \phi^L$ be the unique solution of*

$$\alpha L_1 e^{\alpha(\nu_0-\phi)} - \beta L_2 e^{-\beta(\nu_0-\phi)} = 0, \quad \textit{that is, } \phi^L = \nu_0 - \frac{1}{\alpha+\beta}\ln\frac{\beta L_2}{\alpha L_1},$$

and let

$$c_1^L = \frac{1}{\alpha}(\alpha L_1)^{\frac{\beta}{\alpha+\beta}}(\beta L_2)^{\frac{\alpha}{\alpha+\beta}}, \quad c_2^L = \frac{1}{\beta}(\alpha L_1)^{\frac{\beta}{\alpha+\beta}}(\beta L_2)^{\frac{\alpha}{\alpha+\beta}}.$$

The stable manifold $W^s(\mathcal{Z}_l)$ intersects B_L transversally at points with

$$\begin{aligned} u_0 &= [sgn(\phi^L - \nu_0)]\sqrt{2(L_1+L_2) - 2(L_1 e^{\alpha(\nu_0-\phi^L)} + L_2 e^{-\beta(\nu_0-\phi^L)})} \\ &= [sgn(\alpha L_1 - \beta L_2)]\sqrt{2\left(L_1 + L_2 - \frac{\alpha+\beta}{\alpha\beta}(\alpha L_1)^{\frac{\beta}{\alpha+\beta}}(\beta L_2)^{\frac{\alpha}{\alpha+\beta}}\right)} \end{aligned} \tag{13}$$

and arbitrary J_i's, where sgn is the sign function (see Figure 1*).*

Let $\phi = \phi^{a,l}$ be the unique solution of

$$\alpha c_1^a e^{\alpha(\phi^a-\phi)} - \beta c_2^a e^{-\beta(\phi^a-\phi)} = 0, \quad \textit{that is, } \phi^{a,l} = \phi^a - \frac{1}{\alpha+\beta}\ln\frac{\beta c_2^a}{\alpha c_1^a},$$

and let

$$c_1^{a,l} = \frac{1}{\alpha}(\alpha c_1^a)^{\frac{\beta}{\alpha+\beta}}(\beta c_2^a)^{\frac{\alpha}{\alpha+\beta}}, \quad c_2^{a,l} = \frac{1}{\beta}(\alpha c_1^a)^{\frac{\beta}{\alpha+\beta}}(\beta c_2^a)^{\frac{\alpha}{\alpha+\beta}}.$$

The unstable manifold $W^u(\mathcal{Z}_l)$ intersects B_a transversally at points with

$$\begin{aligned} u_l(a) &= [sgn(\phi^a - \phi^{a,l})]\sqrt{2(c_1^a + c_2^a) - 2(c_1^a e^{\alpha(\phi^a-\phi^{a,l})} + c_2^a e^{-\beta(\phi^a-\phi^{a,l})})} \\ &= [sgn(\beta c_2^a - \alpha c_1^a)]\sqrt{2\left(c_1^a + c_2^a - \frac{\alpha+\beta}{\alpha\beta}(\alpha c_1^a)^{\frac{\beta}{\alpha+\beta}}(\beta c_2^a)^{\frac{\alpha}{\alpha+\beta}}\right)} \end{aligned} \tag{14}$$

and arbitrary J_i's (see Figure 1*).*

(ii) *Potential boundary layers Γ_l^0 at $x = 0$ are determined up to (J_1, J_2) as follows: the ϕ-component satisfies the Hamiltonian system*

$$\phi'' + \alpha L_1 e^{\alpha(\nu_0-\phi)} - \beta L_2 e^{-\beta(\nu_0-\phi)} = 0,$$

together with $\phi(0) = \nu_0$ and $\phi(\xi) \to \phi^L$ as $\xi \to \infty$, $u(\xi) = \phi'(\xi)$, and

$$c_1(\xi) = L_1 e^{\alpha(\nu_0-\phi(\xi))}, \quad c_2(\xi) = L_2 e^{-\beta(\nu_0-\phi(\xi))}.$$

Similarly, potential boundary layers Γ_l^a at $x = a$ are determined in the following way: the ϕ-component satisfies the Hamiltonian system

$$\phi'' + \alpha c_1^a e^{\alpha(\phi^a-\phi)} - \beta c_2^a e^{-\beta(\phi^a-\phi)} = 0,$$

together with $\phi(0) = \phi^a$ and $\phi(\xi) \to \phi^{a,l}$ as $\xi \to -\infty$, $u(\xi) = \phi'(\xi)$, and

$$c_1(\xi) = c_1^a e^{\alpha(\phi^a-\phi(\xi))}, \quad c_2(\xi) = c_2^a e^{-\beta(\phi^a-\phi(\xi))}.$$

(iii) *Let $N_L = M_L \cap W^s(\mathcal{Z}_l)$ and $N_l^a = M_l^a \cap W^u(\mathcal{Z}_l)$. Then,*

$$\omega(N_L) = \left\{\left(\phi^L, 0, c_1^L, c_2^L, J_1, J_2, 0\right) : \text{ all } J_1, J_2\right\},$$

$$\alpha(N_l^a) = \left\{\left(\phi^{a,l}, 0, c_1^{a,l}, c_2^{a,l}, J_1, J_2, a\right) : \text{ all } J_1, J_2\right\},$$

where ϕ^L, c_1^L, c_2^L, $\phi^{a,l}$, $c_1^{a,l}$, and $c_2^{a,l}$ are given explicitly as in part (i)*.*

Proof. We provide a proof for the first part that is related to the boundary layer on the left in each statement.

Let $z(\xi) = (\phi(\xi), u(\xi), c_1(\xi), c_2(\xi), J_1(\xi), J_2(\xi), \tau(\xi))$ be a solution of system (12) with $z(0) \in B_L$ and $z(\xi) \in W^s(\mathcal{Z}_l)$. Then, $J_i(\xi) = J_i$, $\tau(\xi) = 0$ for all ξ, $z(\xi) \to z(\infty) = (\phi^L, 0, c_1^L, c_2^L, J_1, J_2, 0) \in \mathcal{Z}_l$ for some ϕ^L and c_i^L with $\alpha c_1^L = \beta c_2^L$, and

$$\phi(0) = \nu_0, \quad c_1(0) = L_1, \quad c_2(0) = L_2.$$

Using the integrals H_1 and H_2, we have

$$e^{\alpha\phi} c_1 = e^{\alpha\nu_0} L_1, \quad e^{-\beta\phi} c_2 = e^{-\beta\nu_0} L_2.$$

Therefore,

$$c_1 = L_1 e^{\alpha(\nu_0-\phi)}, \quad c_2 = L_2 e^{-\beta(\nu_0-\phi)}. \tag{15}$$

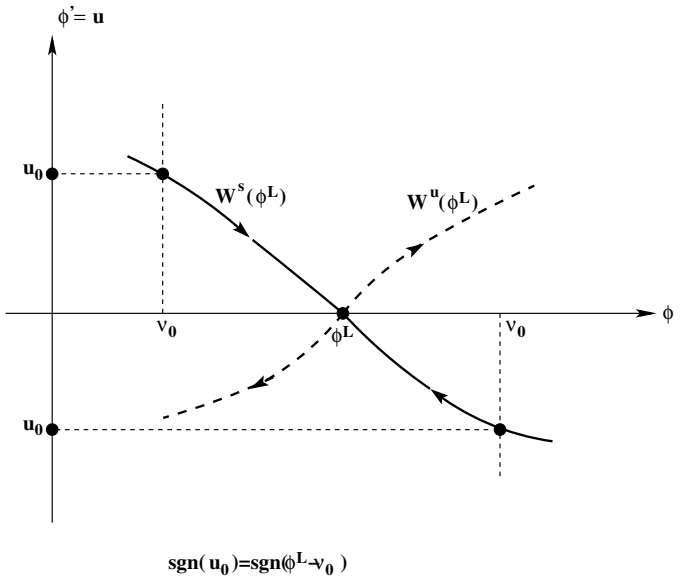

FIG. 2. *The stable manifold $W^s(\phi^L)$ of the equilibrium $(\phi^L, 0)$ is the solid curve, and the unstable manifold $W^u(\phi^L)$ is the dashed curve. The left branch of $W^s(\phi^L)$ has positive u-coordinates, and the right branch has negative u-coordinates; e.g., if $(\phi, u) \in W^s(\phi^L)$, then sign$[u]$ = sign$[\phi^L - \phi]$.*

Taking the limit as $\xi \to \infty$, we have

$$c_1^L = L_1 e^{\alpha(\nu_0 - \phi^L)}, \quad c_2^L = L_2 e^{-\beta(\nu_0 - \phi^L)}.$$

In view of the relation $\alpha c_1^L = \beta c_2^L$, one has

$$\alpha L_1 e^{\alpha(\nu_0 - \phi^L)} = \beta L_2 e^{-\beta(\nu_0 - \phi^L)} \text{ or } \phi^L = \nu_0 - \frac{1}{\alpha + \beta} \ln \frac{\beta L_2}{\alpha L_1}.$$

Hence,

$$c_1^L = \frac{1}{\alpha} (\alpha L_1)^{\frac{\beta}{\alpha+\beta}} (\beta L_2)^{\frac{\alpha}{\alpha+\beta}}, \quad c_2^L = \frac{1}{\beta} (\alpha L_1)^{\frac{\beta}{\alpha+\beta}} (\beta L_2)^{\frac{\alpha}{\alpha+\beta}}.$$

Since $\phi'' = \beta c_2 - \alpha c_1$, (15) implies that ϕ satisfies the Hamiltonian equation

$$\phi'' + \alpha L_1 e^{\alpha(\nu_0 - \phi)} - \beta L_2 e^{-\beta(\nu_0 - \phi)} = 0$$

with $\phi(0) = \nu_0$ and $\phi(\xi) \to \phi^L$ as $\xi \to \infty$. The Hamiltonian is

$$H(\phi, u) = \frac{u^2}{2} - L_1 e^{\alpha(\nu_0 - \phi)} + L_2 e^{-\beta(\nu_0 - \phi)}.$$

In terms of ϕ and $u = \phi'$, the equation becomes

$$\phi' = u, \quad u' = \beta L_2 e^{-\beta(\nu_0 - \phi)} - \alpha L_1 e^{\alpha(\nu_0 - \phi)}. \tag{16}$$

The Hamiltonian system has a unique equilibrium $(\phi^L, 0)$ with ϕ^L given above. If $W^s(\phi^L)$ is the stable manifold of $(\phi^L, 0)$, then it is the restriction of $W^s(\mathcal{Z}_l)$ to the (ϕ, u)-plane. In order to have $(\nu_0, u_0) \in W^s(\phi^L)$ (see Figure 2), $H(\phi^L, 0) = H(\nu_0, u_0)$

and one has the expression for u_0 in (13). To determine the sign of u_0, note that the left branch of the stable manifold $W^s(\phi^L)$ lies above the ϕ-axis and hence that $\nu_0 < \phi^L$ implies $u_0 > 0$; similarly, if $\nu_0 > \phi^L$, then $u_0 < 0$. □

Remark 3.3. We claim that the quantities under the square root in the displays (13) and (14) are nonnegative. In fact, quite interestingly, the nonnegativeness is equivalent to Young's inequality

$$\frac{a^p}{p} + \frac{b^q}{q} \geq ab \text{ for } a, b \geq 0, \ \frac{1}{p} + \frac{1}{q} = 1; \text{ “ = ” holds if and only if } a^p = b^q.$$

Take (13) for example. If we set

$$a = (\alpha L_1)^{\frac{\beta}{\alpha+\beta}}, \quad b = (\beta L_2)^{\frac{\alpha}{\alpha+\beta}}, \quad p = \frac{\alpha+\beta}{\beta}, \quad q = \frac{\alpha+\beta}{\alpha},$$

then

$$L_1 + L_2 - \frac{\alpha+\beta}{\alpha\beta}(\alpha L_1)^{\frac{\beta}{\alpha+\beta}}(\beta L_2)^{\frac{\alpha}{\alpha+\beta}} = \frac{\alpha+\beta}{\alpha\beta}\left(\frac{a^p}{p} + \frac{b^q}{q} - ab\right).$$

Thus, the quantity is always nonnegative and it is zero if and only if $\alpha L_1 = \beta L_2$.

3.1.2. Outer dynamics on $[0, a]$: Regular layers or outer solutions. We now construct regular layers or outer solutions on $\mathcal{Z}_l$ that connect $\omega(N_L)$ to $\alpha(N_l^a)$. We find that the outer flow on $\mathcal{Z}_l$ is itself a singular perturbation problem. To see this, we zoom in on an $O(\epsilon)$-neighborhood of $\mathcal{Z}_l$ by blowing up the u and $\alpha c_1 - \beta c_2$ coordinates; that is, we make a scaling $u = \epsilon p$ and $\beta c_2 - \alpha c_1 = \epsilon q$. System (7) becomes

$$\begin{aligned}
&\dot{\phi} = p, \quad \epsilon\dot{p} = q - \epsilon\frac{h'(\tau)}{h(\tau)}p,\\
&\epsilon\dot{q} = (\alpha(\alpha+\beta)c_1 + \epsilon\beta q)p - h^{-1}(\tau)(\beta J_2 - \alpha J_1),\\
&\dot{c}_1 = -\alpha c_1 p - h^{-1}(\tau)J_1,\\
&\dot{J}_i = 0, \quad \dot{\tau} = 1,
\end{aligned} \tag{17}$$

which is indeed a singular perturbation problem due to the factor ϵ in front of $\dot{p}$ and $\dot{q}$. Its limit, as $\epsilon \to 0$, is

$$\begin{aligned}
&\dot{\phi} = p, \quad 0 = q,\\
&0 = \alpha(\alpha+\beta)c_1 p - h^{-1}(\tau)(\beta J_2 - \alpha J_1),\\
&\dot{c}_1 = -\alpha c_1 p - h^{-1}(\tau)J_1,\\
&\dot{J}_i = 0, \quad \dot{\tau} = 1.
\end{aligned} \tag{18}$$

For this system, the outer manifold is

$$\mathcal{S}_l = \left\{ p = \frac{\beta J_2 - \alpha J_1}{\alpha(\alpha+\beta)h(\tau)c_1}, \ q = 0 \right\}.$$

The outer limit dynamics on $\mathcal{S}_l$ is

$$\begin{aligned}
&\dot{\phi} = \frac{\beta J_2 - \alpha J_1}{\alpha(\alpha+\beta)h(\tau)c_1},\\
&\dot{c}_1 = -\frac{\beta(J_1 + J_2)}{(\alpha+\beta)h(\tau)},\\
&\dot{J}_i = 0, \quad \dot{\tau} = 1.
\end{aligned} \tag{19}$$

Remark 3.4. Following the suggestion of one of the referees, we give a sketch of an alternative and more standard way of deriving the outer limit dynamics (19).

Introduce $\hat{q} = \beta c_2 - \alpha c_1$. In terms of the variables $(\phi, u, \hat{q}, c_1, J_i, \tau)$, system (8) (with $Q = 0$) becomes

$$\begin{aligned} &\phi' = u, \quad u' = \hat{q} - \epsilon \frac{h'(\tau)}{h(\tau)} u, \\ &\hat{q}' = (\alpha(\alpha+\beta)c_1 + \beta\hat{q})u - \epsilon h^{-1}(\tau)(\beta J_2 - \alpha J_1), \\ &c_1' = -\alpha c_1 u - \epsilon h^{-1}(\tau) J_1, \\ &J_i' = 0, \quad \tau' = \epsilon. \end{aligned} \tag{20}$$

For $\epsilon = 0$, the set $\{u = \hat{q} = 0\}$ is a normally hyperbolic invariant manifold consisting of equilibria. By Fenichel's theory, the manifold persists for $\epsilon > 0$ small and is given by

$$u = \epsilon A(\phi, c_1, J_i, \tau) + O(\epsilon^2), \quad \hat{q} = \epsilon B(\phi, c_1, J_i, \tau) + O(\epsilon^2).$$

Using the invariance of the manifold and substituting the above expressions for u and $\hat{q}$ into system (20), one obtains

$$B = O(\epsilon), \quad A = \frac{\beta J_2 - \alpha J_1}{\alpha(\alpha+\beta)h(\tau)c_1} + O(\epsilon).$$

System (20) on the perturbed invariant manifold can be obtained by substituting the expression of u and $\hat{q}$ with the approximations of A and B above. It reads as follows:

$$\begin{aligned} &\phi' = \epsilon \frac{\beta J_2 - \alpha J_1}{\alpha(\alpha+\beta)h(\tau)c_1} + O(\epsilon^2), \\ &c_1' = -\epsilon \frac{\beta(J_1 + J_2)}{(\alpha+\beta)h(\tau)} + O(\epsilon^2), \\ &J_i' = 0, \quad \tau' = \epsilon. \end{aligned} \tag{21}$$

The corresponding outer dynamics is

$$\begin{aligned} &\dot{\phi} = \frac{\beta J_2 - \alpha J_1}{\alpha(\alpha+\beta)h(\tau)c_1} + O(\epsilon), \\ &\dot{c}_1 = -\frac{\beta(J_1 + J_2)}{(\alpha+\beta)h(\tau)} + O(\epsilon), \\ &\dot{J}_i = 0, \quad \dot{\tau} = 1. \end{aligned} \tag{22}$$

Its limiting dynamics at $\epsilon = 0$ is exactly system (19).

The outer limit dynamics (33) in section 3.2.2 can also be derived this way.

The solution of (19) with the initial condition $(\phi^L, c_1^L, J_1, J_2, 0)$ that corresponds to the point $(\phi^L, 0, c_1^L, c_2^L, J_1, J_2, 0) \in \omega(N_L)$ is

$$\begin{aligned} \tau(x) &= x, \quad c_1(x) = c_1^L - \frac{\beta(J_1+J_2)}{\alpha+\beta} \int_0^x h^{-1}(s) ds, \\ \phi(x) &= \phi^L + \frac{\beta J_2 - \alpha J_1}{\alpha(\alpha+\beta)} \int_0^x h^{-1}(s) c_1^{-1}(s) ds \\ &= \phi^L - \frac{\beta J_2 - \alpha J_1}{\alpha\beta(J_1+J_2)} \int_0^x \frac{\dot{c}_1(s)}{c_1(s)} ds \quad ((19) \text{ is used here}) \\ &= \phi^L - \frac{\beta J_2 - \alpha J_1}{\alpha\beta(J_1+J_2)} \ln \frac{c_1(x)}{c_1^L}. \end{aligned}$$

Recall that we are looking for solutions that belong to $\alpha(N_l^a)$ when $\tau = a$. Evaluating the solution at $\tau = x = a$, we have

$$c_1^{a,l} = c_1^L - \frac{\beta(J_1+J_2)}{\alpha+\beta}\int_0^a h^{-1}(s)ds,$$
$$\phi^{a,l} = \phi^L - \frac{\beta J_2 - \alpha J_1}{\alpha\beta(J_1+J_2)}\ln\frac{c_1^{a,l}}{c_1^L};$$

in particular,

$$J_1 = \frac{(c_1^L - c_1^{a,l})}{\int_0^a h^{-1}(s)ds}\left(1 + \frac{\alpha(\phi^L - \phi^{a,l})}{\ln c_1^L - \ln c_1^{a,l}}\right),$$
$$J_2 = \frac{(c_2^L - c_2^{a,l})}{\int_0^a h^{-1}(s)ds}\left(1 - \frac{\beta(\phi^L - \phi^{a,l})}{\ln c_2^L - \ln c_2^{a,l}}\right). \tag{23}$$

We have used the relations $\alpha c_1^L = \beta c_2^L$ and $\alpha c_1^{a,l} = \beta c_2^{a,l}$ to get this more symmetric form for J_2.

The regular layer Λ_l is given by

$$\begin{aligned}
&\phi(x) = \phi^L - \frac{\beta J_2 - \alpha J_1}{\alpha\beta(J_1+J_2)}\ln\frac{c_1(x)}{c_1^L},\\
&u(x) = 0, \quad \alpha c_1(x) = \beta c_2(x),\\
&c_1(x) = c_1^L - \frac{\beta(J_1+J_2)}{\alpha+\beta}\int_0^x h^{-1}(s)ds,\\
&\tau(x) = x
\end{aligned} \tag{24}$$

with J_1 and J_2 determined by (23).

To summarize, for given values (ϕ^a, c_1^a, c_2^a), we have constructed a unique singular orbit on the left subinterval $[0,a]$ that connects B_L to B_a. It consists of two boundary layer orbits Γ_l^0 from the point $(\nu_0, u_0, L_1, L_2, J_1, J_2, 0) \in B_L$ to the point $(\phi^L, 0, c_1^L, c_2^L, J_1, J_2, 0) \in \omega(N_L) \subset \mathcal{Z}_l$ and Γ_l^a from the point $(\phi^{a,l}, 0, c_1^{a,l}, c_2^{a,l}, J_1, J_2, a) \in \alpha(N_l^a) \subset \mathcal{Z}_l$ to the point $(\phi^a, u_l(a), c_1^a, c_2^a, J_1, J_2, a) \in B_a$, and a regular layer Λ_l on $\mathcal{Z}_l$ that connects the two foot points $(\phi^L, 0, c_1^L, c_2^L, J_1, J_2, 0) \in \omega(N_L)$ and $(\phi^{a,l}, 0, c_1^{a,l}, c_2^{a,l}, J_1, J_2, a) \in \alpha(N_l^a)$ of the two boundary layers.

3.2. Singular orbits on $[a,b]$ with $Q(x) = Q$. We now construct a singular orbit on the subinterval $[a,b]$ viewed as the channel where the permanent charge $Q(x) = Q$ is a nonzero constant. The construction is nearly the same as that for singular orbits on $[0,a]$.

We set $\phi(b) = \phi^b$, $c_1(b) = c_1^b$, and $c_2(b) = c_2^b$, where ϕ^b, c_i^b are unknowns to be determined later. Let

$$B_b = \{(\phi^b, u, c_1^b, c_2^b, J_1, J_2, b) \in \boldsymbol{R}^7 : \text{ arbitrary } u, J_1, J_2\}.$$

The singular orbit to be constructed will be a connecting orbit from B_a to B_b over $[a,b]$.

3.2.1. Inner dynamics on $[a,b]$: Boundary layers or inner solutions. By setting $\epsilon = 0$ in system (7) with $Q(x) = Q$, we get $u = 0$ and $\alpha c_1 + Q = \beta c_2$. The outer manifold is

$$\mathcal{Z}_m = \{u = 0, \alpha c_1 + Q = \beta c_2\}.$$

In terms of ξ, we obtain the inner system of (7):

$$\begin{aligned}
&\phi' = u, \quad u' = \beta c_2 - \alpha c_1 - Q - \epsilon \frac{h'(\tau)}{h(\tau)} u,\\
&c_1' = -\alpha c_1 u - \epsilon h^{-1}(\tau) J_1,\\
&c_2' = \beta c_2 u - \epsilon h^{-1}(\tau) J_2,\\
&J_1' = J_2' = 0, \quad \tau' = \epsilon.
\end{aligned} \tag{25}$$

The limiting system at $\epsilon = 0$ is

$$\begin{aligned}
&\phi' = u, \quad u' = \beta c_2 - \alpha c_1 - Q,\\
&c_1' = -\alpha c_1 u,\\
&c_2' = \beta c_2 u,\\
&J_1' = J_2' = 0, \quad \tau' = 0.
\end{aligned} \tag{26}$$

The set of equilibria of (26) is precisely $\mathcal{Z}_m$, and $\mathcal{Z}_m$ is normally hyperbolic with a six-dimensional stable manifold $W^s(\mathcal{Z}_m)$ and a six-dimensional unstable manifold $W^u(\mathcal{Z}_m)$. The manifolds $\mathcal{Z}_m$, $W^s(\mathcal{Z}_m)$, and $W^s(\mathcal{Z}_m)$ persist for $\epsilon > 0$ small.

PROPOSITION 3.4. (i) *System* (26) *has the following six integrals:*

$$\begin{aligned}
&H_1 = e^{\alpha\phi} c_1, \quad H_2 = e^{-\beta\phi} c_2, \quad H_3 = c_1 + c_2 - \frac{1}{2}u^2 - Q\phi,\\
&H_4 = J_1, \quad H_5 = J_2, \quad H_6 = \tau.
\end{aligned}$$

(ii) *Let $\phi = \phi^{a,m}$ be the unique solution of*

$$\alpha c_1^a e^{\alpha(\phi^a - \phi)} - \beta c_2^a e^{-\beta(\phi^a - \phi)} + Q = 0, \tag{27}$$

and let

$$c_1^{a,m} = e^{\alpha(\phi^a - \phi^{a,m})} c_1^a, \quad c_2^{a,m} = e^{-\beta(\phi^a - \phi^{a,m})} c_2^a.$$

The stable manifold $W^s(\mathcal{Z}_m)$ intersects B_a transversally at points with

(28)

$$\begin{aligned}
&u_m(a)\\
&= [sgn(\phi^{a,m} - \phi^a)] \sqrt{2c_1^a(1 - e^{\alpha(\phi^a - \phi^{a,m})}) + 2c_2^a(1 - e^{-\beta(\phi^a - \phi^{a,m})}) - 2Q(\phi^a - \phi^{a,m})}.
\end{aligned}$$

and arbitrary J_i's.

Let $\phi = \phi^{b,m}$ be the unique solution of

$$\alpha c_1^b e^{\alpha(\phi^b - \phi)} - \beta c_2^b e^{-\beta(\phi^b - \phi)} + Q = 0, \tag{29}$$

and let

$$c_1^{b,m} = e^{\alpha(\phi^b - \phi^{b,m})} c_1^b, \quad c_2^{b,m} = e^{-\beta(\phi^b - \phi^{b,m})} c_2^b.$$

The unstable manifold $W^u(\mathcal{Z}_m)$ intersects B_b transversally at points with

(30)

$$u_m(b) = [sgn(\phi^b - \phi^{b,m})]\sqrt{2c_1^b(1 - e^{\alpha(\phi^b-\phi^{b,m})}) + 2c_2^b(1 - e^{-\beta(\phi^b-\phi^{b,m})}) - 2Q(\phi^b - \phi^{b,m})}.$$

and arbitrary J_i's.

(iii) *Potential boundary layers Γ_m^a at $x = a$ can be determined in the following way: the ϕ-component satisfies the Hamiltonian system*

$$\phi'' + \alpha c_1^a e^{\alpha(\phi^a-\phi)} - \beta c_2^a e^{-\beta(\phi^a-\phi)} + Q = 0,$$

together with $\phi(0) = \phi^a$ and $\phi(\xi) \to \phi^{a,m}$ as $\xi \to \infty$, $u(\xi) = \phi'(\xi)$, and

$$c_1(\xi) = c_1^a e^{\alpha(\phi^a-\phi(\xi))}, \quad c_2(\xi) = c_2^a e^{-\beta(\phi^a-\phi(\xi))}.$$

Similarly, potential boundary layers Γ_m^b at $x = b$ can be determined in the following way: the ϕ-component satisfies the Hamiltonian system

$$\phi'' + \alpha c_1^b e^{\alpha(\phi^b-\phi)} - \beta c_2^b e^{-\beta(\phi^b-\phi)} + Q = 0,$$

together with $\phi(0) = \phi^b$ and $\phi(\xi) \to \phi^{b,m}$ as $\xi \to -\infty$, $u(\xi) = \phi'(\xi)$, and

$$c_1(\xi) = c_1^b e^{\alpha(\phi^b-\phi(\xi))}, \quad c_2(\xi) = c_2^b e^{-\beta(\phi^b-\phi(\xi))}.$$

(iv) *Let $N_m^a = M_m^a \cap W^s(\mathcal{Z}_m)$ and $N_m^b = M_m^b \cap W^u(\mathcal{Z}_m)$, where M_m^a is the collection of orbits from B_a in forward time under the flow* (26) *and M_m^b is the collection of orbits from B_b in backward time under the flow* (26)*. Then,*

$$\omega(N_m^a) = \{(\phi^{a,m}, 0, c_1^{a,m}, c_2^{a,m}, J_1, J_2, a) : \text{ all } J_i\},$$
$$\alpha(N_m^b) = \{(\phi^{b,m}, 0, c_1^{b,m}, c_2^{b,m}, J_1, J_2, b) : \text{ all } J_i\}.$$

Remark 3.5. To show that the quantity under the square root in the display (28) is nonnegative, we assume $c_1^a > 0$ and $c_2^a > 0$ for the moment and let

$$f(x) = c_1^a + c_2^a - c_1^a e^{\alpha(\phi^a-x)} - c_2^a e^{-\beta(\phi^a-x)} - Q(\phi^a - x).$$

Then,

$$f'(x) = \alpha c_1^a e^{\alpha(\phi^a-x)} - \beta c_2^a e^{-\beta(\phi^a-x)} + Q$$

and

$$f''(x) = -\alpha^2 c_1^a e^{\alpha(\phi^a-x)} - \beta^2 c_2^a e^{-\beta(\phi^a-x)} < 0.$$

Therefore $f(x)$ is concave downward. Note that $f'(x) \to +\infty$ as $x \to -\infty$ and $f'(x) \to -\infty$ as $x \to +\infty$. Hence, $f(x)$ has a unique critical point and it must have a global maximum at this critical point. Since $x = \phi_m^a$ is the critical point, we have

$$f(\phi_m^a) \geq f(\phi^a) = 0.$$

By continuity, we have $f(\phi_m^a) \geq 0$ even if $c_1^a = 0$ and/or $c_2^a = 0$. Similarly, the quantity under the square root in the display (30) is nonnegative.

3.2.2. Outer dynamics on $[a, b]$: Regular layers or outer solutions. We now study the flow in the vicinity of the outer manifold $\mathcal{Z}_m$. Following the treatment of the outer flow on $\mathcal{Z}_l$ in section 3.1.2 (see also Remark 3.4), we make a scaling $u = \epsilon p$ and $\beta c_2 - \alpha c_1 - Q = \epsilon q$. System (7) becomes

$$
\begin{aligned}
&\dot{\phi} = p, \quad \epsilon \dot{p} = q - \epsilon \frac{h'(\tau)}{h(\tau)} p,\\
&\epsilon \dot{q} = ((\alpha+\beta)\alpha c_1 + \beta Q + \epsilon \beta q)p - h^{-1}(\tau)(\beta J_2 - \alpha J_1),\\
&\dot{c}_1 = -\alpha c_1 p - h^{-1}(\tau) J_1,\\
&\dot{J}_1 = \dot{J}_2 = 0, \quad \dot{\tau} = 1.
\end{aligned}
\tag{31}
$$

Its limit, as $\epsilon \to 0$, is

$$
\begin{aligned}
&\dot{\phi} = p, \quad 0 = q,\\
&0 = ((\alpha+\beta)\alpha c_1 + \beta Q)p - h^{-1}(\tau)(\beta J_2 - \alpha J_1),\\
&\dot{c}_1 = -\alpha c_1 p - h^{-1}(\tau) J_1,\\
&\dot{J}_i = 0, \quad \dot{\tau} = 1.
\end{aligned}
\tag{32}
$$

For this system, the outer manifold is

$$
\mathcal{S}_m = \left\{ p = \frac{\beta J_2 - \alpha J_1}{h(\tau)((\alpha+\beta)\alpha c_1 + \beta Q)},\ q = 0 \right\}.
$$

The outer limit dynamics on $\mathcal{S}_m$ is governed by system (32), which reads as follows:

$$
\begin{aligned}
\dot{\phi} &= \frac{\beta J_2 - \alpha J_1}{h(\tau)((\alpha+\beta)\alpha c_1 + \beta Q)},\\
\dot{c}_1 &= -\frac{(\beta J_2 - \alpha J_1)\alpha c_1}{h(\tau)((\alpha+\beta)\alpha c_1 + \beta Q)} - h^{-1}(\tau) J_1\\
&= -\frac{\alpha\beta(J_1 + J_2)c_1 + \beta Q J_1}{h(\tau)((\alpha+\beta)\alpha c_1 + \beta Q)},\\
\dot{J}_i &= 0, \quad \dot{\tau} = 1.
\end{aligned}
\tag{33}
$$

Since $h(\tau) > 0$ and $\beta c_2 = \alpha c_1 + Q > 0$, system (33) has the same phase portrait as that of the following system obtained by multiplying $h(\tau)((\alpha+\beta)\alpha c_1 + \beta Q)$ on the right-hand side of system (33) (here we see the reason why $\tau = x$ and $\dot{\tau} = 1$ were introduced into the analysis; see (7)):

$$
\begin{aligned}
&\frac{d}{dy}\phi = \beta J_2 - \alpha J_1,\\
&\frac{d}{dy} c_1 = -\alpha\beta(J_1 + J_2)c_1 - \beta Q J_1,\\
&\frac{d}{dy} J_i = 0, \quad \frac{d}{dy}\tau = h(\tau)((\alpha+\beta)\alpha c_1 + \beta Q).
\end{aligned}
\tag{34}
$$

The solution with the initial condition $(\phi^{a,m}, c_1^{a,m}, J_1, J_2, a)$ that corresponds to the point $(\phi^{a,m}, 0, c_1^{a,m}, c_2^{a,m}, J_1, J_2, a) \in \omega(N_m^a)$ is

$$
\begin{aligned}
&\phi(y) = \phi^{a,m} + (\beta J_2 - \alpha J_1)y,\\
&c_1(y) = e^{-\alpha\beta(J_1+J_2)y}c_1^{a,m} - \frac{QJ_1}{\alpha(J_1+J_2)}\left(1 - e^{-\alpha\beta(J_1+J_2)y}\right),\\
&\int_a^\tau h^{-1}(s)ds = (\alpha+\beta)\alpha\int_0^y c_1 ds + \beta Q y \qquad (35)\\
&\qquad = \frac{(\alpha+\beta)c_1^{a,m}}{\beta(J_1+J_2)}\left(1 - e^{-\alpha\beta(J_1+J_2)y}\right)\\
&\qquad\quad - \frac{(\alpha+\beta)QJ_1}{J_1+J_2}\left(y - \frac{1}{\alpha\beta(J_1+J_2)}\left(1 - e^{-\alpha\beta(J_1+J_2)y}\right)\right) + \beta Q y.
\end{aligned}
$$

We are looking for solutions to reach $\alpha(N_m^b)$; that is, whenever $\tau(y) = b$, we require $\phi(y) = \phi^{b,m}$ and $c_1(y) = c_1^{b,m}$. Assume $\tau(y_0) = b$ for some $y_0 > 0$. Then, $\phi(y_0) = \phi^{b,m}$ and $c_1(y_0) = c_1^{b,m}$, and hence,

$$
\begin{aligned}
&\phi^{b,m} = \phi^{a,m} + (\beta J_2 - \alpha J_1)y_0,\\
&c_1^{b,m} = e^{-\alpha\beta(J_1+J_2)y_0}c_1^{a,m} - \frac{QJ_1}{\alpha(J_1+J_2)}\left(1 - e^{-\alpha\beta(J_1+J_2)y_0}\right),\\
&\int_a^b h^{-1}(s)ds = \frac{(\alpha+\beta)c_1^{a,m}}{\beta(J_1+J_2)}\left(1 - e^{-\alpha\beta(J_1+J_2)y_0}\right) \qquad (36)\\
&\qquad - \frac{(\alpha+\beta)QJ_1}{J_1+J_2}\left(y_0 - \frac{1}{\alpha\beta(J_1+J_2)}\left(1 - e^{-\alpha\beta(J_1+J_2)y_0}\right)\right) + \beta Q y_0.
\end{aligned}
$$

System (36) is equivalent to

$$
\begin{aligned}
&\phi^{b,m} = \phi^{a,m} + (\beta J_2 - \alpha J_1)y_0,\\
&c_1^{b,m} = e^{-\alpha\beta(J_1+J_2)y_0}c_1^{a,m} - \frac{QJ_1}{\alpha(J_1+J_2)}\left(1 - e^{-\alpha\beta(J_1+J_2)y_0}\right), \qquad (37)\\
&J_1 + J_2 = \frac{\alpha(\alpha+\beta)(c_1^{a,m} - c_1^{b,m}) - \alpha\beta Q(\phi^{a,m} - \phi^{b,m})}{\alpha\beta\int_a^b h^{-1}(s)ds}.
\end{aligned}
$$

Therefore, the outer or regular layer solution Λ_m on $[a, b]$ is given by (35) with J_1 and J_2 determined by (37). Together with the boundary layers Γ_m^a and Γ_m^b in statement (iii) of Proposition 3.4, this gives the singular orbit on the interval $[a, b]$.

3.3. Singular orbits on $[b, 1]$ with $Q(x) = 0$. The construction of singular orbits on $[b, 1]$ is virtually identical to the construction of singular orbits on $[0, a]$ in section 3.1. We will state only the results for later use.

3.3.1. Inner dynamics on $[b, 1]$: Boundary layers or inner solutions. The inner limit system is

$$
\begin{aligned}
&\phi' = u, \quad u' = \beta c_2 - \alpha c_1,\\
&c_1' = -\alpha c_1 u,\\
&c_2' = \beta c_2 u, \qquad (38)\\
&J_1' = J_2' = 0, \quad \tau' = 0.
\end{aligned}
$$

The outer manifold is

$$\mathcal{Z}_r = \{u = 0, \alpha c_1 = \beta c_2\}.$$

It consists of equilibria of system (38) and is normally hyperbolic with a six-dimensional stable manifold $W^s(\mathcal{Z}_r)$ and a six-dimensional unstable manifold $W^u(\mathcal{Z}_r)$. Concerning the boundary layers, we have the following proposition.

PROPOSITION 3.5. (i) *System* (38) *has the following six integrals:*

$$H_1 = e^{\alpha\phi}c_1, \quad H_2 = e^{-\beta\phi}c_2, \quad H_3 = c_1 + c_2 - \frac{1}{2}u^2,$$
$$H_4 = J_1, \quad H_5 = J_2, \quad H_6 = \tau.$$

(ii) *Let* $\phi = \phi^{b,r}$ *be the unique solution of*

$$\alpha c_1^b e^{\alpha(\phi^b - \phi)} - \beta c_2^b e^{-\beta(\phi^b - \phi)} = 0, \quad \textit{that is, } \phi^{b,r} = \phi^b - \frac{1}{\alpha+\beta}\ln\frac{\beta c_2^b}{\alpha c_1^b},$$

and let

$$c_1^{b,r} = \frac{1}{\alpha}(\alpha c_1^b)^{\frac{\beta}{\alpha+\beta}}(\beta c_2^b)^{\frac{\alpha}{\alpha+\beta}}, \quad c_2^{b,r} = \frac{1}{\beta}(\alpha c_1^b)^{\frac{\beta}{\alpha+\beta}}(\beta c_2^b)^{\frac{\alpha}{\alpha+\beta}}.$$

The stable manifold $W^s(\mathcal{Z}_r)$ *intersects* B_b *transversally at points with*

$$u_r(b) = [sgn(\alpha c_1^b - \beta c_2^b)]\sqrt{2\left(c_1^b + c_2^b - \frac{\alpha+\beta}{\alpha\beta}(\alpha c_1^b)^{\frac{\beta}{\alpha+\beta}}(\beta c_2^b)^{\frac{\alpha}{\alpha+\beta}}\right)} \tag{39}$$

and arbitrary J_i*'s.*

Let $\phi = \phi^R$ *be the unique solution of*

$$\alpha R_1 e^{-\alpha\phi} - \beta R_2 e^{\beta\phi} = 0, \quad \textit{that is, } \phi^R = -\frac{1}{\alpha+\beta}\ln\frac{\beta R_2}{\alpha R_1},$$

and let

$$c_1^R = \frac{1}{\alpha}(\alpha R_1)^{\frac{\beta}{\alpha+\beta}}(\beta R_2)^{\frac{\alpha}{\alpha+\beta}}, \quad c_2^R = \frac{1}{\beta}(\alpha R_1)^{\frac{\beta}{\alpha+\beta}}(\beta R_2)^{\frac{\alpha}{\alpha+\beta}}.$$

The unstable manifold $W^u(\mathcal{Z}_r)$ *intersects* B_R *transversally at points with*

$$u_1 = [sgn(\beta R_2 - \alpha R_1)]\sqrt{2\left(R_1 + R_2 - \frac{\alpha+\beta}{\alpha\beta}(\alpha R_1)^{\frac{\beta}{\alpha+\beta}}(\beta R_2)^{\frac{\alpha}{\alpha+\beta}}\right)} \tag{40}$$

and arbitrary J_i*'s.*

(iii) *Potential boundary layers* Γ_r^b *at* $x = b$ *can be determined in the following way: the* ϕ*-component satisfies the Hamiltonian system*

$$\phi'' + \alpha c_1^b e^{\alpha(\phi^b - \phi)} - \beta c_2^b e^{-\beta(\phi^b - \phi)} = 0,$$

together with $\phi(0) = \phi^b$ *and* $\phi(\xi) \to \phi^{b,r}$ *as* $\xi \to \infty$, $u(\xi) = \phi'(\xi)$, *and*

$$c_1(\xi) = c_1^b e^{\alpha(\phi^b - \phi(\xi))}, \quad c_2(\xi) = c_2^b e^{-\beta(\phi^b - \phi(\xi))}.$$

Similarly, potential boundary layers Γ_r^1 at $x = 1$ can be determined in the following way: the ϕ-component satisfies the Hamiltonian system

$$\phi'' + \alpha R_1 e^{-\alpha\phi} - \beta R_2 e^{\beta\phi} = 0,$$

together with $\phi(0) = 0$ and $\phi(\xi) \to \phi^R$ as $\xi \to -\infty$, $u(\xi) = \phi'(\xi)$, and

$$c_1(\xi) = R_1 e^{-\alpha\phi(\xi)}, \quad c_2(\xi) = R_2 e^{\beta\phi(\xi)}.$$

(iv) *Let $N_r^b = M_r^b \cap W^s(\mathcal{Z}_r)$ and $N_R = M_R \cap W^u(\mathcal{Z}_r)$, where M_r^b is the collection of orbits from B_b in forward time under the flow* (38) *and M_R is the collection of orbits from B_R in backward time under the flow* (38). *Then,*

$$\omega(N_r^b) = \{(\phi^{b,r}, 0, c_1^{b,r}, c_2^{b,r}, J_1, J_2, b) : \text{ all } J_i\},$$
$$\alpha(N_R) = \left\{\left(\phi^R, 0, c_1^R, c_2^R, J_1, J_2, 1\right) : \text{ all } J_i\right\}.$$

3.3.2. Outer dynamics on $[b, 1]$: Regular layers or outer solutions. We now examine the existence of regular layers or outer solutions that connect $\omega(N_r^b)$ to $\alpha(N_R)$. Following exactly the same analysis as in section 3.1.2, we find that the outer limit dynamics is

$$\begin{aligned} \dot{\phi} &= \frac{\beta J_2 - \alpha J_1}{(\alpha+\beta)\alpha h(\tau) c_1}, \\ \dot{c}_1 &= -\frac{\beta(J_1 + J_2)}{(\alpha+\beta)h(\tau)}, \\ \dot{J}_i &= 0, \quad \dot{\tau} = 1, \end{aligned} \tag{41}$$

and the outer solution Λ_r on $[b, 1]$ with the initial condition $(\phi^{b,r}, c_1^{b,r}, J_1, J_2, b)$ that corresponds to the point $(\phi^{b,r}, 0c_1^{b,r}, c_2^{b,r}, J_1, J_2, b) \in \omega(N_r^b)$ is given by

$$\begin{aligned} \phi(\xi) &= \phi^{b,r} - \frac{\beta J_2 - \alpha J_1}{\alpha\beta(J_1 + J_2)} \ln \frac{c_1(\xi)}{c_1^{b,r}}, \\ u(\xi) &= 0, \quad \alpha c_1(\xi) = \beta c_2(\xi), \\ c_1(\xi) &= c_1^{b,r} - \frac{\beta(J_1 + J_2)}{\alpha + \beta} \int_b^\xi h^{-1}(s) ds, \\ \tau(\xi) &= \xi. \end{aligned}$$

The outer solution Λ_r hits the point $(\phi^R, 0, c_1^R, c_2^R, J_1, J_2, 1) \in \alpha(N_R)$ if and only if

$$\begin{aligned} J_1 &= \frac{c_1^{b,r} - c_1^R}{\int_b^1 h^{-1}(s) ds} \left(1 + \frac{\alpha(\phi^{b,r} - \phi^R)}{\ln c_1^{b,r} - \ln c_1^R}\right), \\ J_2 &= \frac{c_2^{b,r} - c_2^R}{\int_b^1 h^{-1}(s) ds} \left(1 - \frac{\beta(\phi^{b,r} - \phi^R)}{\ln c_2^{b,r} - \ln c_2^R}\right). \end{aligned} \tag{42}$$

The outer solution Λ_r together with the inner solutions Γ_r^b and Γ_r^1 in statement (iii) of Proposition 3.5 gives the singular orbit on $[b, 1]$.

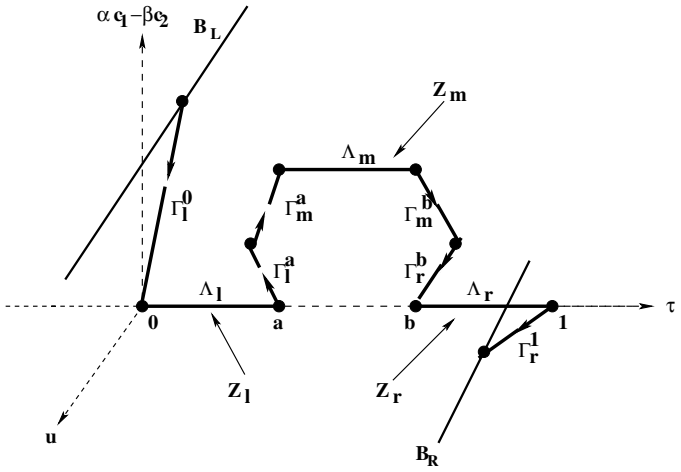

FIG. 3. *Schematic picture of the singular orbit (solid curves): left boundary layer Γ_l^0; right boundary layer Γ_r^1; four internal layers Γ_l^a, Γ_m^a, Γ_m^b, and Γ_r^b, and three regular layers Λ_l, Λ_m, and Λ_r.*

3.4. Matching and singular orbits on [0, 1]. A singular orbit on the whole interval $[0,1]$ will be the union of the singular orbits constructed on each of the subintervals (see Figure 3). The matching conditions are $u_l(a) = u_m(a)$, $u_m(b) = u_r(b)$, and J_1 and J_2 have to be the same on all subintervals; that is, from formulas (14), (23), (27), (28), (29), (30), (37), (39), and (42),

$$
\begin{aligned}
\alpha c_1^a e^{\alpha(\phi^a-\phi^{a,m})} - \beta c_2^a e^{-\beta(\phi^a-\phi^{a,m})} + Q &= 0,\\
\alpha c_1^b e^{\alpha(\phi^b-\phi^{b,m})} - \beta c_2^b e^{-\beta(\phi^b-\phi^{b,m})} + Q &= 0,\\
\frac{\alpha+\beta}{\beta} c_1^{a,l} &= c_1^a e^{\alpha(\phi^a-\phi^{a,m})} + c_2^a e^{-\beta(\phi^a-\phi^{a,m})} + Q(\phi^a-\phi^{a,m}),\\
\frac{\alpha+\beta}{\beta} c_1^{b,r} &= c_1^b e^{\alpha(\phi^b-\phi^{b,m})} + c_2^b e^{-\beta(\phi^b-\phi^{b,m})} + Q(\phi^b-\phi^{b,m}),\\
J_1 &= \frac{(c_1^L - c_1^{a,l})}{\int_0^a h^{-1}(s)ds}\left(1 + \frac{\alpha(\phi^L-\phi^{a,l})}{\ln c_1^L - \ln c_1^{a,l}}\right)\\
&= \frac{c_1^{b,r} - c_1^R}{\int_b^1 h^{-1}(s)ds}\left(1 + \frac{\alpha(\phi^{b,r}-\phi^R)}{\ln c_1^{b,r} - \ln c_1^R}\right),\\
J_2 &= \frac{(c_2^L - c_2^{a,l})}{\int_0^a h^{-1}(s)ds}\left(1 - \frac{\beta(\phi^L-\phi^{a,l})}{\ln c_2^L - \ln c_2^{a,l}}\right)\\
&= \frac{c_2^{b,r} - c_2^R}{\int_b^1 h^{-1}(s)ds}\left(1 - \frac{\beta(\phi^{b,r}-\phi^R)}{\ln c_2^{b,r} - \ln c_2^R}\right),\\
\phi^{b,m} &= \phi^{a,m} + (\beta J_2 - \alpha J_1)y_0,\\
c_1^{b,m} &= e^{-\alpha\beta(J_1+J_2)y_0} c_1^{a,m} - \frac{QJ_1}{\alpha(J_1+J_2)}\left(1 - e^{-\alpha\beta(J_1+J_2)y_0}\right),\\
J_1 + J_2 &= \frac{\alpha(\alpha+\beta)(c_1^{a,m} - c_1^{b,m}) - \alpha\beta Q(\phi^{a,m}-\phi^{b,m})}{\alpha\beta\int_a^b h^{-1}(s)ds},
\end{aligned}
\tag{43}
$$

where

$$
\begin{aligned}
c_1^L &= \frac{1}{\alpha}(\alpha L_1)^{\frac{\beta}{\alpha+\beta}}(\beta L_2)^{\frac{\alpha}{\alpha+\beta}}, \quad c_2^L = \frac{1}{\beta}(\alpha L_1)^{\frac{\beta}{\alpha+\beta}}(\beta L_2)^{\frac{\alpha}{\alpha+\beta}},\\
c_1^{a,l} &= \frac{1}{\alpha}(\alpha c_1^a)^{\frac{\beta}{\alpha+\beta}}(\beta c_2^a)^{\frac{\alpha}{\alpha+\beta}}, \quad c_2^{a,l} = \frac{1}{\beta}(\alpha c_1^a)^{\frac{\beta}{\alpha+\beta}}(\beta c_2^a)^{\frac{\alpha}{\alpha+\beta}},\\
c_1^{b,r} &= \frac{1}{\alpha}(\alpha c_1^b)^{\frac{\beta}{\alpha+\beta}}(\beta c_2^b)^{\frac{\alpha}{\alpha+\beta}}, \quad c_2^{b,r} = \frac{1}{\beta}(\alpha c_1^b)^{\frac{\beta}{\alpha+\beta}}(\beta c_2^b)^{\frac{\alpha}{\alpha+\beta}},\\
c_1^{a,m} &= e^{\alpha(\phi^a-\phi^{a,m})}c_1^a, \quad c_1^{b,m} = e^{\alpha(\phi^b-\phi^{b,m})}c_1^b.
\end{aligned}
$$

Recall that $h(x) = g_0^2(x)$, where $g_0(x)$ is the radius of the cross-section of the channel at x, Q is the concentration of the permanent charge over the interval $[a, b]$, (ϕ^a, c_1^a, c_2^a) and (ϕ^b, c_1^b, c_2^b) are the unknown values preassigned at $x = a$ and $x = b$, and J_1 and J_2 are the unknown values for the flux densities of the two types of ions.

There are also three auxiliary unknowns $\phi^{a,m}$, $\phi^{b,m}$, and y_0 in the set of equations (43). The total number of unknowns in (43) is eleven, which matches the total number of equations.

A qualitative important question is whether the set of nonlinear equations (43) has a unique solution. Next, we will consider a special case and demonstrate that (43) can have multiple solutions.

3.4.1. $\alpha = \beta = 1$, and $a = 1/3$, $b = 2/3$, and $h = 1$. We now consider a special case where $\alpha = \beta = 1$. It turns out that the nonlinear system of algebraic equations (43) in eleven unknowns can be reduced to a single algebraic equation with only one unknown. Further restrictions that $a = 1/3$, $b = 2/3$, and $h = 1$ will be posted later merely for simplicity.

Set $c_1^a c_2^a = A^2$, $c_1^b c_2^b = B^2$, $L_1 L_2 = L^2$, $R_1 R_2 = R^2$, and $Q = 2Q_0$. From the first two equations in (43), one has

$$
\begin{aligned}
\phi^a - \phi^{a,m} &= \ln \frac{\sqrt{Q_0^2 + A^2} - Q_0}{c_1^a},\\
\phi^b - \phi^{b,m} &= \ln \frac{\sqrt{Q_0^2 + B^2} - Q_0}{c_1^b}.
\end{aligned}
$$

System (43) becomes

$$
\begin{aligned}
A &= \sqrt{Q_0^2 + A^2} + Q_0 \ln \frac{\sqrt{Q_0^2 + A^2} - Q_0}{c_1^a},\\
B &= \sqrt{Q_0^2 + B^2} + Q_0 \ln \frac{\sqrt{Q_0^2 + B^2} - Q_0}{c_1^b},\\
J_1 &= \frac{L - A}{\int_0^a h^{-1}(s)ds} \cdot \frac{\nu_0 - \phi^a + \ln L_1 - \ln c_1^a}{\ln L - \ln A}\\
&= \frac{B - R}{\int_b^1 h^{-1}(s)ds} \cdot \frac{\phi^b + \ln c_1^b - \ln R_1}{\ln B - \ln R},
\end{aligned}
$$

$$
\begin{aligned}
J_2 &= \frac{L-A}{\int_0^a h^{-1}(s)ds}\left(2-\frac{\nu_0-\phi^a+\ln L_1-\ln c_1^a}{\ln L-\ln A}\right)\\
&= \frac{B-R}{\int_b^1 h^{-1}(s)ds}\left(2-\frac{\phi^b+\ln c_1^b-\ln R_1}{\ln B-\ln R}\right),\\
(J_2-J_1)y_0 &= \phi^b-\phi^a+\ln\frac{c_1^b(\sqrt{Q_0^2+A^2}-Q_0)}{c_1^a(\sqrt{Q_0^2+B^2}-Q_0)},\\
J_1+J_2 &= \frac{2(\sqrt{Q_0^2+A^2}-\sqrt{Q_0^2+B^2})-2Q_0(J_1-J_2)y_0}{\int_a^b h^{-1}(s)ds},\\
\sqrt{Q_0^2+B^2}-Q_0 &= e^{-(J_1+J_2)y_0}\left(\sqrt{Q_0^2+A^2}-Q_0\right)\\
&\quad -\frac{2Q_0J_1}{J_1+J_2}\left(1-e^{-(J_1+J_2)y_0}\right).
\end{aligned}
\tag{44}
$$

Add the J_1 and J_2 equations in (44) to get

$$
J_1+J_2 = 2\frac{L-A}{\int_0^a h^{-1}} = 2\frac{B-R}{\int_b^1 h^{-1}};\ \text{hence, } B=\frac{\int_b^1 h^{-1}}{\int_0^a h^{-1}}(L-A)+R.
$$

The first two equations in (44) give

$$
\begin{aligned}
c_1^a &= \left(\sqrt{Q_0^2+A^2}-Q_0\right)\exp\left\{\frac{\sqrt{Q_0^2+A^2}-A}{Q_0}\right\},\\
c_1^b &= \left(\sqrt{Q_0^2+B^2}-Q_0\right)\exp\left\{\frac{\sqrt{Q_0^2+B^2}-B}{Q_0}\right\}.
\end{aligned}
\tag{45}
$$

The first two equations together with $(J_2-J_1)y_0$ and the J_1+J_2 equations give

$$
J_1+J_2 = 2\frac{L-A}{\int_0^a h^{-1}} = 2\frac{B-R}{\int_b^1 h^{-1}} = 2\frac{A-B-Q_0(\phi^a-\phi^b)}{\int_a^b h^{-1}}.
$$

Hence,

$$
J_1+J_2 = 2\frac{L-R-Q_0(\phi^a-\phi^b)}{\int_0^1 h^{-1}},
$$

$$
\phi^b-\phi^a = \frac{(L-A)\int_0^1 h^{-1}-(L-R)\int_0^a h^{-1}}{Q_0\int_0^a h^{-1}},
\tag{46}
$$

and

$$
\begin{aligned}
(J_2-J_1)y_0 &= \phi^b-\phi^a-\ln\frac{\sqrt{Q_0^2+B^2}-Q_0}{c_1^b}+\ln\frac{\sqrt{Q_0^2+A^2}-Q_0}{c_1^a}\\
&= \frac{(L-A)\int_0^1 h^{-1}-(L-R)\int_0^a h^{-1}}{Q_0\int_0^a h^{-1}}+\ln\frac{(\sqrt{Q_0^2+A^2}-Q_0)c_1^b}{(\sqrt{Q_0^2+B^2}-Q_0)c_1^a}\\
&= \frac{(L-A)\int_a^b h^{-1}}{Q_0\int_0^a h^{-1}}+\frac{\sqrt{Q_0^2+B^2}-\sqrt{Q_0^2+A^2}}{Q_0}.
\end{aligned}
$$

Using

$$\frac{L-A}{\int_0^a h^{-1}} = \frac{B-R}{\int_b^1 h^{-1}}$$

and the second equality in the J_1 equation in (44), one has

$$\frac{\nu_0 - \phi^a + \ln L_1 - \ln c_1^a}{\ln L - \ln A} = \frac{\phi^b + \ln c_1^b - \ln R_1}{\ln B - \ln R}.$$

Hence,

$$\frac{\phi^b + \ln c_1^b - \ln R_1}{\ln B - \ln R} = \frac{\nu_0 + \phi^b - \phi^a + \ln(L_1 c_1^b) - \ln(R_1 c_1^a)}{\ln(BL) - \ln(AR)}.$$

The latter together with (46) and (45) gives

$$\begin{aligned}\phi^b &= \frac{\ln \frac{B}{R}}{\ln \frac{BL}{AR}} \left(\nu_0 + \ln \frac{L_1 c_1^b}{R_1 c_1^a} + \frac{(L-A)\int_0^1 h^{-1} - (L-R)\int_0^a h^{-1}}{Q_0 \int_0^a h^{-1}} \right) + \ln \frac{R_1}{c_1^b} \\ &= \frac{\ln \frac{B}{R}}{\ln \frac{BL}{AR}} \left(\nu_0 + \ln \frac{L_1(\sqrt{Q_0^2+B^2} - Q_0)}{R_1(\sqrt{Q_0^2+A^2} - Q_0)} + \frac{\sqrt{Q_0^2+B^2} - \sqrt{Q_0^2+A^2}}{Q_0} \right. \\ &\quad \left. + \frac{(L-A)\int_a^b h^{-1}}{Q_0 \int_0^a h^{-1}} \right) + \ln R_1 - \ln\left(\sqrt{Q_0^2+B^2} - Q_0\right) - \frac{\sqrt{Q_0^2+B^2} - B}{Q_0}.\end{aligned}$$

Note that all the variables in (44) can be expressed in terms of A. Substituting into the last equation in (44) we will get an equation $F(A) = 0$ in the variable A only. The expression of $F(A)$ is complicated but can be explicitly given.

We now suppose further that $a = 1/3$, $b = 2/3$, and $h = 1$. Then,

$$B = L + R - A, \quad J_1 + J_2 = 6(L - A), \tag{47}$$

$$c_1^a = \left(\sqrt{Q_0^2+A^2} - Q_0\right) \exp\left\{ \frac{\sqrt{Q_0^2+A^2} - A}{Q_0} \right\},$$

$$c_1^b = \left(\sqrt{Q_0^2+B^2} - Q_0\right) \exp\left\{ \frac{\sqrt{Q_0^2+B^2} - B}{Q_0} \right\},$$

$$\phi^b - \phi^a = \frac{2L + R - 3A}{Q_0},$$

$$\begin{aligned}\phi^b = {} & \frac{\ln \frac{B}{R}}{\ln \frac{BL}{AR}} \left(\nu_0 + \ln \frac{L_1(\sqrt{Q_0^2+B^2} - Q_0)}{R_1(\sqrt{Q_0^2+A^2} - Q_0)} + \frac{\sqrt{Q_0^2+B^2} - \sqrt{Q_0^2+A^2} + L - A}{Q_0} \right) \\ & + \ln R_1 - \ln\left(\sqrt{Q_0^2+B^2} - Q_0\right) - \frac{\sqrt{Q_0^2+B^2} - B}{Q_0},\end{aligned}$$

$$J_2 - J_1 = 6(L-A) - \frac{6(L-A)}{\ln \frac{BL}{AR}} \left(\nu_0 + \ln \frac{L_1(\sqrt{Q_0^2+B^2} - Q_0)}{R_1(\sqrt{Q_0^2+A^2} - Q_0)} \right) - \frac{6(L-A)(\sqrt{Q_0^2+B^2} - \sqrt{Q_0^2+A^2} + L - A)}{Q_0 \ln \frac{BL}{AR}},$$

$$(J_2 - J_1) y_0 = \frac{\sqrt{Q_0^2+B^2} - \sqrt{Q_0^2+A^2} + L - A}{Q_0}.$$

The final equation involving the only unknown A is $F(A) = 0$, where

$$F(A) = e^{K(A)} \left(\sqrt{Q_0^2+A^2} - \frac{Q_0(J_2-J_1)}{6(L-A)} \right) + \frac{Q_0(J_2-J_1)}{6(L-A)} - \sqrt{Q_0^2+B^2}, \tag{48}$$

where

$$K(A) = -6(L-A) \frac{\sqrt{Q_0^2+B^2} - \sqrt{Q_0^2+A^2} + L - A}{Q_0(J_2-J_1)},$$

$B = L + R - A$, and $J_2 - J_1$ is given above.

To summarize, for the special case where

$$\alpha = \beta = 1, \quad a = 1/3, \quad b = 2/3, \quad h = 1,$$

the set of nonlinear algebraic equations is equivalent to $F(A) = 0$, where $F(A)$ is given in (48). The formula $F(A)$, although terribly complicated, involves only one unknown $A = \sqrt{c_1^a c_2^a}$. Other parameters in $F(A)$ are L_1, $L = \sqrt{L_1 L_2}$, R_1, $R = \sqrt{R_1 R_2}$, ν_0, and Q_0.

For $L = L_1 = 2$, $R = R_1 = 3$, $Q = 2Q_0 = 2$, and $\nu_0 = -20$, we find, numerically, two solutions of $F(A) = 0$: $A_1 = 0.6858357$ and $A_2 = 2$ (the latter is a removable singularity of the functions $F(A)$, J_i's, ϕ^b, and ϕ^a).

Once a feasible value for A is determined, all the unknowns will be determined. We then get a singular orbit that consists of nine pieces $\Gamma_l^0 \cup \Lambda_l \cup \Gamma_l^a \cup \Gamma_m^a \cup \Lambda_m \cup \Gamma_m^b \cup \Gamma_r^b \cup \Lambda_r \cup \Gamma_r^1$ (see Figure 3).

4. Main results and numerical simulations. Any solution of the set of algebraic equations determines a singular orbit for the connecting problem. Once a singular orbit is constructed, we apply geometric singular perturbation theory to show that, for $\epsilon > 0$ small, there is a unique solution that is close to the singular orbit. Before giving the precise statement of our result and its proof, let us explain the ideas behind it.

Let $\Gamma_l^0 \cup \Lambda_l \cup \Gamma_l^a \cup \Gamma_m^a \cup \Lambda_m \cup \Gamma_m^b \cup \Gamma_r^b \cup \Lambda_r \cup \Gamma_r^1$ be a singular orbit to the connecting problem (7) associated to B_L and B_R. For $\epsilon > 0$ small, let $M_L(\epsilon)$ be the forward trace of B_L under the flow of system (7) or, equivalently, system (8). To establish the existence of a unique solution to the boundary value problem near the singular orbit, we will show that $M_L(\epsilon)$ intersects B_R transversally in a neighborhood of the singular orbit.

Roughly speaking, the evolution of $M_L(\epsilon)$ from $x = 0$ to $x = 1$ undergoes the following nine stages with each stage guided by one of the nine pieces of the singular orbit (see Figure 3):

(l1) Along Γ_l^0: Since B_L intersects $W^s(\mathcal{Z}_l)$ transversally, $M_L(\epsilon)$ will first follow the orbit Γ_l^0 towards the vicinity of $\mathcal{Z}_l$ under the inner limit flow (12) near $x = 0$.

(l2) Along Λ_l: Once $M_L(\epsilon)$ gets close to $\mathcal{Z}_l$, the outer limit flow (19) takes over, and $M_L(\epsilon)$ will then follow the outer flow on $\mathcal{Z}_l$ or $\mathcal{S}_l$ along the orbit Λ_l towards the hypersurface $\{x = a\}$.

(l3) Along Γ_l^a: Near but before $\{x = a\}$, $M_L(\epsilon)$ will leave the vicinity of $\mathcal{Z}_l$, follow the orbit Γ_l^a under the inner limit flow (12) near $x = a$, and hit the hypersurface $\{x = a\}$.

(m1) Along Γ_m^a: Upon hitting the hypersurface $\{x = a\}$, the flow switches to the inner limit flow (26) with $Q(x) = Q$. $M_L(\epsilon)$ then follows Γ_m^a towards the vicinity of $\mathcal{Z}_m$.

(m2) Along Λ_m: Once $M_L(\epsilon)$ gets close to $\mathcal{Z}_m$, the outer limit flow (33) takes over, and $M_L(\epsilon)$ will then follow the outer flow on $\mathcal{Z}_m$ or $\mathcal{S}_m$ along the orbit Λ_m towards the hypersurface $\{x = b\}$.

(m3) Along Γ_m^b: Near but before $\{x = b\}$, $M_L(\epsilon)$ will leave the vicinity of $\mathcal{Z}_m$, follow the orbit Γ_m^b under the inner limit flow (26) near $x = b$, and hit the hypersurface $\{x = b\}$.

(r1) Along Γ_r^b: Upon hitting the hypersurface $\{x = b\}$, the flow switches to the inner limit flow (38) with $Q(x) = 0$. $M_L(\epsilon)$ then follows Γ_r^b towards the vicinity of $\mathcal{Z}_r$.

(r2) Along Λ_r: Once $M_L(\epsilon)$ gets close to $\mathcal{Z}_r$, the outer limit flow (41) takes over, and $M_L(\epsilon)$ will then follow the outer flow on $\mathcal{Z}_r$ or $\mathcal{S}_r$ along the orbit Λ_r towards the hypersurface $\{x = 1\}$.

(r3) Along Γ_r^1: Near but before $\{x = 1\}$, $M_L(\epsilon)$ will leave the vicinity of $\mathcal{Z}_r$ and follow the orbit Γ_r^1 under the inner limit flow (38) near $x = 1$. If it hits B_R, then we get our solution.

The main task is to justify the above description of the stages that $M_L(\epsilon)$ undergoes. The exchange lemma—see, for example, [47, 45, 46, 50, 51, 73]—of geometric singular perturbation theory is a result that precisely characterizes the configuration of $M_L(\epsilon)$ during its evolution through the above stages. To apply this abstract theory, one need only verify certain transversality conditions of some limiting objects.

We now state our results and provide a proof using the geometric singular perturbation theory described above.

THEOREM 4.1. *Let* $\Gamma_l^0 \cup \Lambda_l \cup \Gamma_l^a \cup \Gamma_m^a \cup \Lambda_m \cup \Gamma_m^b \cup \Gamma_r^b \cup \Lambda_r \cup \Gamma_r^1$ *be a singular orbit to the connecting problem* (7) *associated to* B_L *and* B_R. *Then, for* $\epsilon > 0$ *small, the boundary value problem* (5) *and* (6) *has a unique continuous and piecewise smooth solution near the singular orbit.*

Proof. For $\epsilon > 0$ small, choose $\delta > 0$ small. Let

$$B_L(\delta) = \{(\nu_0, u, L_1, L_2, J_1, J_2, 0) : |u - u_0| < \delta, |J_i - J_i^0| < \delta\},$$

and let $M_L(\epsilon)$ be the forward trace of $B_L(\delta)$ under the flow of system (7) or, equivalently, system (8). To prove the theorem, we need to show that $M_L(\epsilon)$ intersects B_R transversally in a neighborhood of the singular orbit. Indeed, if we let $M_R(\epsilon)$ be the backward trace of B_R near the singular orbit, then $M_L(\epsilon)$ and $M_R(\epsilon)$ intersect transversally too. The transversality implies that $\dim(M_L(\epsilon) \cap M_R(\epsilon)) =$

$\dim M_L(\epsilon) + \dim M_R(\epsilon) - 7 = 1$. Therefore, the intersection $M_L(\epsilon) \cap M_R(\epsilon)$ consists of precisely one solution to the boundary value problem, and the solution is near the singular orbit.

To establish the transversal intersection of $M_L(\epsilon)$ with B_R near the singular orbit, we apply the exchange lemma successively along the stages described above. The first application of the exchange lemma verifies the descriptions for stages (l1), (l2), and (l3); the second one for stages (m1), (m2), and (m3); and the last application verifies the descriptions for stages (r1), (r2), and (r3).

Note that $\dim B_L(\delta) = 3$. Since the fast flow is not tangent to $B_L(\delta)$, one has $\dim M_L(\epsilon) = 4$. The transversality of the intersection $B_L \cap W^s(\mathcal{Z}_l)$ along Γ_l^0 implies the transversality of the intersection $M_L(0) \cap W^s(\mathcal{Z}_l)$. The exchange lemma implies that $M_L(\epsilon)$ will first follow Γ_l^0 towards $N_L \subset \mathcal{Z}_l$, then follow $N_L \cdot x$ in the vicinity of Λ_l towards $x = a$, and leave the vicinity of $\mathcal{Z}_l$. And upon exit, $M_L(\epsilon)$ is C^1 $O(\epsilon)$-close to $W^u(N_L \times (a - \delta, a))$ in the vicinity of Γ_l^a.

Denote the intersection of $W^u(N_L \times (a - \delta, a))$ with $\{x = a\}$ by $I(a)$. Then $I(a)$ intersects $W^s(\mathcal{Z}_m)$ transversally for the flow (26). Let $K(a)$ be the forward trace of $I(a)$ under (25). The exchange lemma implies that $M_L(\epsilon)$ will first follow $K(a)$ in the vicinity of Γ_m^a towards $N_m^a \subset \mathcal{Z}_m$, then follow $N_m^a \cdot x$ in the vicinity of Λ_m towards $x = b$, and leave the vicinity of $\mathcal{Z}_m$. And upon exit, $M_L(\epsilon)$ is C^1 $O(\epsilon)$-close to $W^u(N_m^a \times (b - \delta, b))$ in the vicinity of Γ_m^b.

Denote the intersection of $W^u(N_m^a \times (b - \delta, b))$ with $\{x = b\}$ by $I(b)$. Then $I(b)$ intersects $W^s(\mathcal{Z}_r)$ transversally for the flow (38). Let $K(b)$ be the forward trace of $I(b)$ under the full system. Then exchange lemma implies that $M_L(\epsilon)$ will first follow $K(b)$ in the vicinity of Γ_r^b towards $N_r^b \subset \mathcal{Z}_r$, then follow $N_r^b \cdot x$ in the vicinity of Λ_r towards $x = 1$, and leave the vicinity of $\mathcal{Z}_r$. And upon exit, $M_L(\epsilon)$ is C^1 $O(\epsilon)$-close to $W^u(N_R \times (1 - \delta, 1))$ in the vicinity of Γ_r^1.

In summary, after three applications of the exchange lemma, we determine that $M_L(\epsilon)$ is C^1 $O(\epsilon)$-close to $W^u(N_R \times (1 - \delta, 1))$ in the vicinity of Γ_r^1. Since $W^u(N_R \times (1 - \delta, 1))$ intersects B_R transversally along Γ_r^1, we have shown that $M_L(\epsilon)$ intersects B_R transversally. The proof is complete. □

Numerical simulations are performed for $A_1 = 0.6858357$ and $A_2 = 2$ (see Figures 4 and 5). The following properties of the two solutions are predicted from the analytical results and can be observed from the numerical simulations:

(i) For both A_1 and A_2, approximately $c_2(x) - c_1(x) = Q(x)$ for $x \in (0, 1)$ except around $x = 1/3$ and $x = 2/3$—the jumping points of Q.

(ii) For $A_2 = L$, $J_1 + J_2 = 0$ from (47). As a consequence of (19) and (41), $c_1(x) = c_2(x) = L = 2$ for $x \in (0, 1/3)$ and $c_1(x) = c_2(x) = R = 3$ for $x \in (2/3, 1)$. The decreasing behavior of $c_1(x) = c_2(x)$ for $x \in (0, 1/3) \cup (2/3, 1)$ can be also predicted from that of the singular orbit corresponding to A_1.

(iii) There is a significant difference between the two solutions for $A_1 \neq L$ and $A_2 = L$: the solution for A_1 has two internal layers with limit orbits Γ_l^a and Γ_m^a at $x = a = 1/3$ that match at a point on B_a (see Figure 3); the solution for A_2 has only one internal layer $\Gamma_l^a = \Gamma_m^a$ at $x = 1/3$. This analytical consequence is not clearly shown in the figures but is indicated by the different behaviors of the ϕ-component: for A_1, with the extra transition through B_a, the layers near $x = 1/3$ are smoother than the one layer for A_2. The same remarks are true for the two solutions near $x = b = 2/3$.

5. Remarks. The defining equation $F(A) = 0$ in (48) that determines multiplicity of steady-states of the PNP system should be investigated thoroughly.

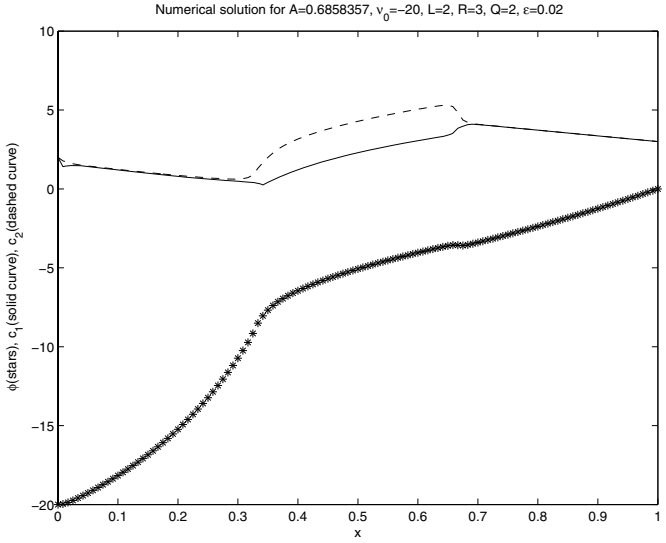

FIG. 4. *ϕ (stars), c_1 (solid curve), and c_2 (dashed curve) for $A_1 = 0.6858357$ with $L_1 = L_2 = 2$, $R_1 = R_2 = 3$, $Q = 2Q_0 = 2$, $\nu_0 = -20$, and $\epsilon = 0.02$.*

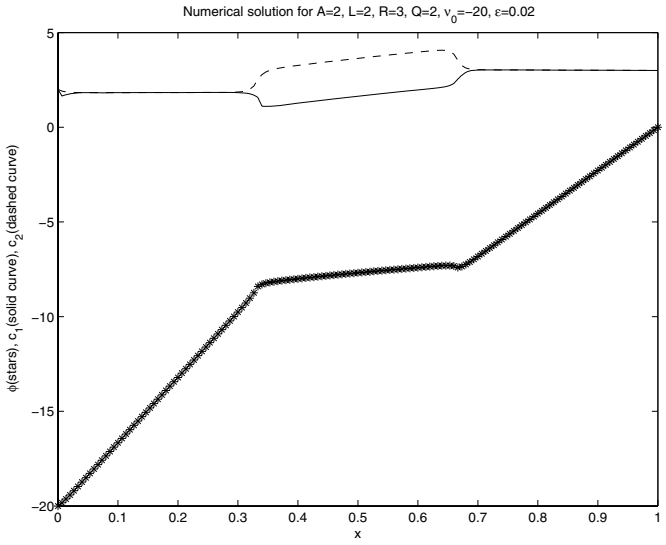

FIG. 5. *ϕ (stars), c_1 (solid curve), and c_2 (dashed curve) for $A_2 = 2$ with $L_1 = L_2 = 2$, $R_1 = R_2 = 3$, $Q = 2Q_0 = 2$, $\nu_0 = -20$, and $\epsilon = 0.02$.*

This could be studied using bifurcation theory of dynamical systems and numerical tools (e.g., AUTO) due to the presence of multiple parameters (L_i, R_i, ν_0, Q, etc. should be viewed as perturbation parameters). Another important problem is the stability of each solution in the full time evolution PNP system. Both multiplicity and stability have important biological consequences for ion channels. Single channels are in fact often defined in the laboratory by their characteristic current signal which switches from one nearly zero level ("the closed channel") to another nonzero level ("the open channel") in a random telegraph signal, with brief incomplete

spiky interruptions. Different types of channels perform their functions by controlling the open probability and/or mean duration of the stochastic signal. These gating phenomena are central to the biological function of channels and are almost always explained by saying the channel changes shape ("conformation") when it switches current level. Another explanation could be that the steady-state solutions of the PNP equations themselves have multiple solutions, and the different current levels correspond to those different solutions. Because the actual current data is stochastic, it is not clear whether the "open channel" state is stationary or not. Indeed, the open probability and/or duration of the open state might be stochastic representations of the instability of the PNP equations. Ion channels also act (in many cases) as if they have two spatially distinct gates, one of which is normally open and the other normally closed. The opening and closing processes of these gates do not overlap in ion channels so there is always a time when both gates are open and current flows through the channel. The stability properties of the equations may determine many of these gating properties. It is hard to see how the stability properties of the equations (and underlying physics) could not be involved to some significant extent, even if that gating is modulated by other processes and involves additional physics or conformational changes. Finally, there is a vitally important class of "channel" proteins in which the two gates open and close in ping pong fashion, so current can never flow right through the channel pore. These channels form mediated transporters of the greatest biological importance. It is hard to imagine that the stability of multiple solutions of the PNP equations (and the underlying physics) is not involved in the correlated gating properties of transporters, even if that gating is modulated by other processes and involves additional physics or even conformational changes.

Clearly our methods will be challenged when we try to extend them to other geometries of channels, multiple regions with nonzero permanent charges, and the even more important problems of three or more ions of different charge (e.g., Na^+, Ca^{2+}, Cl^-). The depletion layers that then occur allow the wide diversity of devices (from amplifier, to limiter, to multiplier, etc.) that can be built from a single PNP transistor, and that can be described by numerical solutions of the PNP equations [67, 35, 41, 28, 71, 34]. An alarming diversity of treatments must arise from any perturbation analysis of PNP systems because such a diversity of real devices actually exist and are built on that (physical and intellectual) substrate! Existing mathematical analysis of the PNP equations will need to be extended to show how those different devices can be built on one substrate. That is to say, analysis is needed to show how different devices arise from different values of the boundary potential but just one set of differential equations (and boundary equations), with one set of parameters (other than boundary potentials). Many useful applications in the design of channels and semiconductors depend on this analysis.

Acknowledgments. The authors are grateful to the anonymous referees whose suggestions have in our opinion, significantly improved the paper. We thank Feng He for the numerical simulations.

COMPLEX SPHERICAL WAVES FOR THE ELASTICITY SYSTEM AND PROBING OF INCLUSIONS*

GUNTHER UHLMANN† AND JENN-NAN WANG‡

Abstract. We construct complex geometrical optics solutions for the isotropic elasticity system concentrated near spheres. We then use these special solutions, called complex spherical waves, to identify inclusions embedded in an isotropic, inhomogeneous, elastic background.

Key words. complex spherical waves, elasticity system, inverse problem

1. Introduction.

Let $\Omega \subset \mathbb{R}^3$ be an open bounded domain with smooth boundary. The domain Ω is modeled as an inhomogeneous, isotropic, elastic medium characterized by the Lamé parameters $\lambda(x)$ and $\mu(x)$. Assume that $\lambda(x) \in C^2(\overline{\Omega})$, $\mu(x) \in C^4(\overline{\Omega})$ and the following inequalities hold:

$$\mu(x) > 0 \quad \text{and} \quad \lambda(x) + 2\mu(x) > 0 \quad \forall\, x \in \overline{\Omega} \quad \text{(strong ellipticity)}. \tag{1.1}$$

We consider the static isotropic elasticity system without sources:

$$\mathcal{L}u := \nabla \cdot (\lambda(\nabla \cdot u)I + 2\mu\ \mathrm{Sym}(\nabla u)) = 0 \quad \text{in} \quad \Omega, \tag{1.2}$$

where $\mathrm{Sym}(A) = (A + A^T)/2$ denotes the symmetric part of the matrix $A \in \mathbb{C}^{3\times 3}$. Equivalently, if we denote $\sigma(u) = \lambda(\nabla \cdot u)I + 2\mu\ \mathrm{Sym}(\nabla u)$ to be the stress tensor, then (1.2) becomes

$$\mathcal{L}u = \nabla \cdot \sigma = 0 \quad \text{and} \quad \Omega.$$

On the other hand, since the Lamé parameters are differentiable, we can also write (1.2) in the nondivergence form

$$\mathcal{L}u = \mu\Delta u + (\lambda + \mu)\nabla(\nabla \cdot u) + \nabla\lambda\nabla \cdot u + 2\mathrm{Sym}(\nabla u)\nabla\mu = 0 \quad \text{in} \quad \Omega. \tag{1.3}$$

Special types of solutions for elliptic equations or systems have played an important role in inverse problems since the pioneering work of Calderón [2]. In 1987, Sylvester and Uhlmann [21] introduced complex geometrical optics solutions to solve the inverse boundary value problem for the conductivity equation. For system (1.2), complex geometrical optics solutions were constructed in [5], using [4], and in [16], [17], and [18]. In [16], [17], and [18] the authors introduced an intertwining technique using pseudodifferential operators. In both [5] and [16], [17], [18], the phase functions of the complex geometrical optics solutions are linear. Other types of special solutions,

called oscillating-decaying solutions, were constructed for general elliptic systems in [19] and [20]. These oscillating-decaying solutions have been used in solving inverse problems, particularly in detecting inclusions and cavities [19].

In developing the theory for inverse boundary value problems with partial or local measurements, the authors of [7] and [14] gave, respectively, approximate complex geometrical optics solutions concentrated near hyperplanes and near hemispheres for the Schrödinger equation. In [14], the construction was based on hyperbolic geometry and was applied in [8] to construct complex geometrical optics solutions for the Schrödinger equation where the real part of the phase function is a radial function, i.e., its level surfaces are spheres. They call these solutions *complex spherical waves*. The hyperbolic geometry approach does not work for the Laplacian with first order perturbations such as the Schrödinger equation with magnetic potential and the isotropic elasticity equation (1.2) (see below). Recently, complex geometrical optics solutions with more general phase functions were constructed in [15] for the Schrödinger equation and in [3] for the Schrödinger equation with magnetic potential. The method used in [15] and [3] relies on Carleman-type estimates, which is a more flexible tool in treating lower order perturbations. Hence, we shall apply the method in [15] and [3] to construct complex geometrical optics solutions for (1.2) with the real part of the phase function being a radial function, i.e., complex spherical waves.

With these complex spherical waves at hand, we can study the inverse problem of detecting unknown inclusions inside an elastic body with known isotropic background medium. The investigation of this inverse problem is motivated by [8], in which the same problem was treated for the conductivity equation. There are several results, both theoretical and numerical, concerning the object identification problem by boundary measurements for the conductivity equation. We will not try to give a full account of these developments here. For detailed references, we refer to [8]. For the elasticity system, we will compare our result to some existing ones. In [10], Ikehata generalized his *probe method* to the isotropic elasticity system. Ikehata's probe method is based on singular solutions and Runge's approximation property (which is closely related to the unique continuation property). These ideas are due to Isakov [13]. On the other hand, for the general (anisotropic) elasticity system, a reconstruction method using oscillating-decaying solutions was given by the authors in [19]. The method in [19] shares the same spirit as Ikehata's *enclosure method* (see Ikehata's survey article [9]). Both methods enable us to reconstruct the support function of the inclusion by the Dirichlet-to-Neumann map. It should be noted that Runge's property was used in [19]. Ikehata's results on the enclosure method did not rely on Runge's property because he used the Laplacian as the background and explicit complex geometrical optics solutions are available for this case. Our approach here lies between the method in [19] and Ikehata's enclosure method in the sense that we treat the isotropic elasticity without using Runge's property. Furthermore, since we probe the region by complex spherical waves, it is possible to recover some concave parts of inclusions. Also, as in [8], we can localize the measurements with these complex spherical waves.

This paper is organized as follows. In section 2, (1.2) or (1.3) is transformed to a system of dimension four, and a Carleman estimate is derived for the new system. The construction of complex spherical waves for (1.2) is given in section 3. The study of the inverse problem is carried out in section 4.

2. Carleman estimate and its consequence. It suffices to work with system (1.3) here. Since the leading order of (1.3) is strongly coupled, we want to find

a reduced system whose leading part is decoupled (precisely, the Laplacian), and solutions of (1.3) can be constructed more easily. We will use the reduced system derived by Ikehata [11]. This reduction had already been mentioned in [22]. Let $W = \binom{w}{g}$ satisfy

$$PW := \Delta \begin{pmatrix} w \\ g \end{pmatrix} + \tilde{A}_1(x) \begin{pmatrix} \nabla g \\ \nabla \cdot w \end{pmatrix} + \tilde{A}_0(x) \begin{pmatrix} w \\ g \end{pmatrix} = 0, \tag{2.1}$$

where

$$\tilde{A}_1(x) = \begin{pmatrix} 2\mu^{-1/2}(-\nabla^2 + \Delta)\mu^{-1} & -\nabla \log \mu \\ 0 & \frac{\lambda+\mu}{\lambda+2\mu}\mu^{1/2} \end{pmatrix}$$

and

$$\tilde{A}_0(x) = \begin{pmatrix} -\mu^{-1/2}(2\nabla^2 + \Delta)\mu^{1/2} & 2\mu^{-5/2}(\nabla^2 - \Delta)\mu \ \nabla\mu \\ -\frac{\lambda-\mu}{\lambda+2\mu}(\nabla\mu^{1/2})^T & -\mu\Delta\mu^{-1} \end{pmatrix}.$$

Here $\nabla^2 f$ is the Hessian of the scalar function f. Then

$$u := \mu^{-1/2}w + \mu^{-1}\nabla g - g\nabla\mu^{-1}$$

satisfies (1.3). A similar form was also used in [5] for studying the inverse boundary value problem for the isotropic elasticity system.

With (2.1) at hand, we now consider the matrix operator $P_h = -h^2 P$. More precisely, we have

$$P_h = (hD)^2 + ihA_1(x) \begin{pmatrix} hD \\ hD\cdot \end{pmatrix} + h^2 A_0,$$

where $D = -i\nabla$, $A_1 = -\tilde{A}_1$, and $A_0 = -\tilde{A}_0$. Later on we shall denote the matrix operator

$$iA_1(x) \begin{pmatrix} hD \\ hD\cdot \end{pmatrix} = A_1(x, hD).$$

To construct complex geometrical optics solutions, we will follow closely the papers [3] and [15]. The construction here is simpler than the one given in [16], [17], where the technique of intertwining operators was first introduced. Furthermore, we do not need to work with C^∞ coefficients here. As in [3] and [15], we will use semiclassical Weyl calculus. Our goal here is to derive a Carleman estimate with semiclassical H^{-2} norm for P_h.

The conjugation of P_h with $e^{\varphi/h}$ is given by

$$e^{\varphi/h} \circ P_h \circ e^{-\varphi/h} = (hD + i\nabla\varphi)^2 + hA_1(x, hD + i\nabla\varphi) + h^2 A_0(x).$$

We first consider the leading operator $(hD + i\nabla\varphi)^2$ and denote

$$(hD + i\nabla\varphi)^2 = A + iB,$$

where $A = (hD)^2 - (\nabla\varphi)^2$ and $B = \nabla\varphi \circ hD + hD \circ \nabla\varphi$. The Weyl symbols of A and B are given as

$$a(x,\xi) = \xi^2 - (\nabla\varphi)^2 \quad \text{and} \quad b(x,\xi) = 2\nabla\varphi \cdot \xi,$$

respectively. Let Ω_0 be an open bounded domain such that $\bar{\Omega} \subset \Omega_0$. Accordingly, we extend λ and μ to Ω_0 by preserving their smoothness. We now let φ have nonvanishing gradient in Ω_0 and be a limit Carleman weight in Ω_0:

$$\{a, b\} = 0 \quad \text{when} \quad a = b = 0,$$

i.e.,

$$\langle \varphi'' | \nabla\varphi \otimes \nabla\varphi + \xi \otimes \xi \rangle = 0 \quad \text{when} \quad \xi^2 = (\nabla\varphi)^2 \text{ and } \nabla\varphi \cdot \xi = 0.$$

In order to get positivity in proving the Carleman estimate, we will modify the weight φ as in [3] and [15]. Let us denote $\varphi_\varepsilon = \varphi + h\varphi^2/(2\varepsilon)$, where $\varepsilon > 0$ will be chosen later. Also, we denote a_ε and b_ε to be the corresponding symbols as φ is replaced by φ_ε. Then one can easily check that

$$\{a_\varepsilon, b_\varepsilon\} = \frac{4h}{\varepsilon}\left(1 + \frac{h}{\varepsilon}\varphi\right)^2 (\nabla\varphi)^4 > 0 \quad \text{when} \quad a_\varepsilon = b_\varepsilon = 0.$$

Arguing as in [15], we get

$$\{a_\varepsilon, b_\varepsilon\} = \frac{4h}{\varepsilon}\left(1 + \frac{h}{\varepsilon}\varphi\right)^2 (\nabla\varphi)^4 + \alpha(x) a_\varepsilon + \beta(x,\xi) b_\varepsilon,$$

where $\beta(x,\xi)$ is linear in ξ. Therefore, at the operator level, we have

$$\begin{aligned} i[A_\varepsilon, B_\varepsilon] = {} & \frac{4h^2}{\varepsilon}\left(1 + \frac{h}{\varepsilon}\varphi\right)^2 (\nabla\varphi)^4 + \frac{h}{2}(\alpha \circ A_\varepsilon + A_\varepsilon \circ \alpha) \\ & + \frac{h}{2}(\beta^w \circ B_\varepsilon + B_\varepsilon \circ \beta^w) + h^3 c(x), \end{aligned} \tag{2.2}$$

where β^w denotes the Weyl quantization of β.

With the help (2.2), we now can estimate

$$\|(A_\varepsilon + iB_\varepsilon)V\|^2 = \|A_\varepsilon V\|^2 + \|B_\varepsilon V\|^2 + i\langle B_\varepsilon V | A_\varepsilon V\rangle - i\langle A_\varepsilon V | B_\varepsilon V\rangle$$

for $V \in C_0^\infty(\Omega)$. Here and below, we define the norm $\|\cdot\|$ and the inner $\langle \cdot \mid \cdot \rangle$ in terms of $L^2(\Omega)$. Integrating by parts, we conclude

$$\langle B_\varepsilon V | A_\varepsilon V\rangle = \langle A_\varepsilon B_\varepsilon V | V\rangle \quad \text{and} \quad \langle A_\varepsilon V | B_\varepsilon V\rangle = \langle B_\varepsilon A_\varepsilon V | V\rangle. \tag{2.3}$$

On the other hand, we observe that

$$\|h\nabla V\|^2 = \langle A_\varepsilon V | V\rangle + \|\sqrt{(\nabla\varphi)} V\|^2 \lesssim \|A_\varepsilon V\|^2 + \|V\|^2 \tag{2.4}$$

and the obvious estimate

$$\|(h\nabla)^2 V\|^2 \lesssim \|A_\varepsilon V\|^2 + \|V\|^2. \tag{2.5}$$

Using (2.2), (2.3), (2.4), and (2.5) gives

$$\begin{aligned} & \|(A_\varepsilon + iB_\varepsilon)V\|^2 \\ & \gtrsim \|A_\varepsilon V\|^2 + \|B_\varepsilon V\|^2 + \frac{h^2}{\varepsilon}\|V\|^2 - h(\|A_\varepsilon V\|\|V\| + \|B_\varepsilon V\|\|h\nabla V\|) \\ & \gtrsim \|A_\varepsilon V\|^2 + \|B_\varepsilon V\|^2 + \frac{h^2}{\varepsilon}\|V\|^2 - \frac{1}{2}\|A_\varepsilon V\|^2 - \frac{h^2}{2}\|V\|^2 - \frac{1}{2}\|B_\varepsilon V\|^2 \\ & \quad - \frac{h^2}{2}(\|A_\varepsilon V\|^2 + \|V\|^2) \\ & \gtrsim \left(1 - O\left(\frac{h^2}{\varepsilon}\right)\right)\|A_\varepsilon V\|^2 + \frac{h^2}{\varepsilon}(\|A_\varepsilon V\|^2 + \|V\|^2). \end{aligned}$$

Thus, taking h and ε ($h \ll \varepsilon$) sufficiently small, we arrive at

$$\|(A_\varepsilon + iB_\varepsilon)V\|^2 \gtrsim \frac{h^2}{\varepsilon}(\|V\|^2 + \|h\nabla V\|^2 + \|(h\nabla)^2 V\|^2),$$

namely,

$$\|(A_\varepsilon + iB_\varepsilon)V\|^2 \gtrsim \frac{h^2}{\varepsilon}\|V\|^2_{H^2_h(\Omega)}. \tag{2.6}$$

Here we define the semiclassical Sobolev norms

$$\|v\|^2_{H^m_h(\Omega)} = \sum_{|\alpha|\le m} \|(h\nabla)^\alpha v\|^2 \quad \forall\ m \in \mathbb{N}$$

and

$$\|v\|^2_{H^s_h(\mathbb{R}^3)} = \int (1 + |h\xi|^2)^s |\hat{v}(\xi)|^2 d\xi = \|\langle hD\rangle^s v\|^2 \quad \forall\ s \in \mathbb{R}.$$

Now let Ω_1 be open and $\bar{\Omega} \subset \Omega_1 \subset \Omega_0$. The estimate (2.6) also holds for $V \in C_0^\infty(\Omega_1)$. Then, as done in [3], we can obtain that

$$\frac{h^2}{\varepsilon}\|V\|^2_{H^2_h(\mathbb{R}^3)} \lesssim \|(A_\varepsilon + iB_\varepsilon)\langle hD\rangle^2 V\|^2_{H^{-2}_h(\mathbb{R}^3)}. \tag{2.7}$$

To add the first order perturbation $hA_{1,\varepsilon}V + h^2A_0V = hA_1(x, hD + i\nabla\varphi_\varepsilon)V + h^2A_0V$ into (2.7), we note that

$$\|(hA_{1,\varepsilon} + h^2A_0)\langle hD\rangle^2 V\|^2_{H^{-2}_h(\mathbb{R}^3)} \lesssim h^2\|V\|^2_{H^1_h(\mathbb{R}^3)}. \tag{2.8}$$

In view of (2.8), we get from (2.7) that

$$\|(A_\varepsilon + iB_\varepsilon + hA_{1,\varepsilon} + h^2A_0)\langle hD\rangle^2 V\|^2_{H^{-2}_h(\mathbb{R}^3)} \gtrsim h^2\|\langle hD\rangle^2 V\|^2, \tag{2.9}$$

provided $\varepsilon \ll 1$. Transforming back to the original operator, (2.9) is equivalent to

$$\|\langle hD\rangle^2 V\| \lesssim h\|e^{\phi_\varepsilon/h}Pe^{-\varphi_\varepsilon/h}\langle hD\rangle^2 V\|_{H^{-2}_h(\mathbb{R}^3)} \tag{2.10}$$

for $V \in C_0^\infty(\Omega_1)$.

Let $\chi \in C_0^\infty(\Omega_1)$ with $\chi = 1$ on Ω and $W \in C_0^\infty(\Omega)$. Substituting $V = \chi\langle hD\rangle^{-2}W$ into (2.10) and using the property that

$$\|(1-\chi)\langle hD\rangle^{-2}W\|_{H^s_h} = O(h^\infty)\|W\|$$

for any $s \in \mathbb{R}$, we get that

$$\|W\| \lesssim h\|e^{\phi_\varepsilon/h}Pe^{-\varphi_\varepsilon/h}W\|_{H^{-2}_h(\mathbb{R}^3)}. \tag{2.11}$$

Now since $e^{\varphi_\varepsilon/h} = e^{\varphi^2/\varepsilon}e^{\varphi/h}$ and $e^{\varphi^2/\varepsilon} = O(1)$, (2.11) becomes

$$\|W\| \lesssim h\|e^{\phi/h}Pe^{-\varphi/h}W\|_{H^{-2}_h(\mathbb{R}^3)}. \tag{2.12}$$

Note that (2.12) also holds when φ is replaced by $-\varphi$. Therefore, by the Hahn–Banach theorem, we have the following existence theorem.

THEOREM 2.1. *For h sufficiently small, for any $F \in L^2(\Omega)$, there exists $V \in H^2_h(\Omega)$ such that*

$$e^{\varphi/h}P_h(e^{-\varphi/h}V) = F$$

and $h\|V\|_{H^2_h(\Omega)} \lesssim \|F\|_{L^2(\Omega)}$.

3. Construction of complex spherical waves. In this section we will construct complex spherical waves for the elasticity system (1.3). We apply the method of [3] and [15] to our system here. We will work with the reduced system (2.1). Let ψ be a solution of the eikonal equation

$$a(x, \nabla\psi) = b(x, \nabla\psi) = 0 \quad \forall\ x \in \Omega,$$

i.e.,

$$\begin{cases} (\nabla\psi)^2 = (\nabla\varphi)^2 \\ \nabla\varphi \cdot \nabla\psi = 0 \end{cases} \quad \forall\ x \in \Omega. \tag{3.1}$$

Since $\{a, b\} = 0$ on $a = b = 0$, there exists a solution to (3.1). To construct complex spherical waves, we choose the limit Carleman weight

$$\varphi(x) = \log|x - x_0| \quad \text{for} \quad x_0 \notin \overline{\mathrm{ch}(\Omega)};$$

then a solution of (3.1) is

$$\psi(x) = \frac{\pi}{2} - \arctan \frac{\omega \cdot (x - x_0)}{\sqrt{(x - x_0)^2 - (\omega \cdot (x - x_0))^2}} = d_{\mathbb{S}^2}\left(\frac{x - x_0}{|x - x_0|}, \omega\right),$$

where $\mathrm{ch}(\Omega) :=$ convex hull of Ω and $\omega \in \mathbb{S}^2$ such that $\omega \neq (x - x_0)/|x - x_0|$ for all $x \in \overline{\Omega}$ [3]. We can be more explicit in the choices of φ and ψ. In fact, by suitable translation and rotation, we can take $x_0 = 0$, $\omega = (1, 0, 0)$ and set $z = x_1 + i|x'|$ with $x' = (x_2, x_3)$; then $\varphi + i\psi = \log z$ (see [3, Remark 3.1]). Having found ψ, we look for $U = e^{-(\varphi+i\psi)/h}(L + R)$ satisfying

$$(-h^2\Delta + h^2 A_1(x, D) + h^2 A_0(x))U = 0 \quad \text{in} \quad \Omega.$$

Equivalently, we need to solve

$$e^{(\varphi+i\psi)/h} P_h(e^{-(\varphi+i\psi)/h}(L + R)) = 0 \quad \text{in} \quad \Omega.$$

We can compute that

$$\begin{aligned} &e^{(\varphi+i\psi)/h} P_h e^{-(\varphi+i\psi)/h} \\ &= ((hD - \nabla\psi)^2 - (\nabla\varphi)^2) + i(\nabla\varphi \cdot (hD - \nabla\psi) + (hD - \nabla\psi) \cdot \nabla\varphi) \\ &\quad + h^2 A_1(x, D) + hA_1(x, i\nabla\varphi - \nabla\psi) + h^2 A_0 \\ &= h(-\nabla\psi \cdot D - D \cdot \nabla\psi + i\nabla\varphi \cdot D + iD \cdot \nabla\varphi + A_1(x, i\nabla\varphi - \nabla\psi)) + P_h \\ &= hQ + P_h, \end{aligned}$$

where $Q = -\nabla\psi \cdot D - D \cdot \nabla\psi + i\nabla\varphi \cdot D + iD \cdot \nabla\varphi + A_1(x, i\nabla\varphi - \nabla\psi)$. Hence we want to find L, independent of h, so that

$$QL = 0 \quad \text{in} \quad \Omega. \tag{3.2}$$

Equation (3.2) is a system of Cauchy–Riemann type. In fact, in view of the choices of φ and ψ above, (3.2) is equivalent to

$$\partial_{\bar{z}} L + \widetilde{A}(z, \theta)L = 0 \quad \text{in} \quad \Omega, \tag{3.3}$$

where $\widetilde{A}(z,\theta)$ is a C^2 matrix-valued function. Here we have used the cylindrical coordinates for $\mathbb{R}^3$, i.e., $x=(x_1,r,\theta)\in\mathbb{R}\times\mathbb{R}_+\times\mathbb{S}^1$, and $z=x_1+ir$. Using the results in [4], [6], or [18], one can find an invertible 4×4 matrix $G(x)\in C^2(\overline{\Omega})$ satisfying (3.2). For the sake of clarity, we outline the proof of the existence of G. We refer to, for example, [6, pp. 59–60] for more detailed arguments. It suffices to consider (3.3). Let $M>0$ satisfy $\overline{\Omega}\subset\{(x_1,r,\theta):|x_1|\le M,\ 0\le r\le M,\ \theta\in\mathbb{S}^1\}:=\mathcal{U}$. Without restriction, we can assume that (3.3) holds in $\mathcal{U}$ by suitably extending the matrix $\widetilde{A}$. By using cut-off functions with sufficiently small supports, one can show that G exists near $z_0=x_1^0+ir_0$, with $|x_1^0|<M, 0<r_0<M$, and depends C^2 smoothly on θ for all $\theta\in\mathbb{S}^1$. To construct a global invertible G in $\mathcal{U}$, we simply patch local solutions together with the help of Cartan's lemma.

So L can be chosen from columns of G. Then R is required to satisfy

$$e^{\varphi/h}P_h(e^{-(\varphi+i\psi)/h}R)=-e^{-i\psi/h}P_hL. \tag{3.4}$$

Note that $\|e^{-i\psi/h}P_hL\|\lesssim h^2$. Thus Theorem 2.1 implies that

$$\|e^{-i\psi/h}R\|_{H_h^2(\Omega)}\lesssim h, \tag{3.5}$$

which leads to

$$\|\partial^\alpha R\|_{L^2(\Omega)}\lesssim h^{1-|\alpha|}\quad\text{for}\quad|\alpha|\le2. \tag{3.6}$$

So if we write $L=\binom{\ell}{d}$ and $R=\binom{r}{s}$ with $\ell,r\in\mathbb{C}^3$, then

$$w=e^{-(\varphi+i\psi)/h}(\ell+r)\quad\text{and}\quad g=e^{-(\varphi+i\psi)/h}(d+s),$$

where r and s satisfy the estimate (3.6). Therefore, $u=\mu^{-1/2}w+\mu^{-1}\nabla g-g\nabla\mu^{-1}$ is the complex spherical wave for (1.3).

Remark 3.1. Even though the four-vector $\binom{\ell}{d}$ is nonzero in Ω, we cannot conclude that both ℓ and d never vanish in Ω. However, for any point $y\in\Omega$, it is easy to show that there exists a small ball $B_\delta(y)$ of y with $B_\delta(y)\subset\Omega$ such that one can find a pair of ℓ and d which does not vanish in $B_\delta(y)$. We will use this fact in studying our inverse problem in the next section.

4. Probing for inclusions. In this section we shall apply the complex spherical waves we constructed above to the problem of identifying the inclusion embedded inside an elastic body with isotropic medium. We now begin to set up the problem. Let D be an open subset of Ω with Lipschitz boundary satisfying the facts that $D\subset\subset\Omega$ and $\Omega\setminus\overline{D}$ is connected. Assume that $\lambda_0(x)\in C^2(\overline{\Omega})$ and $\mu_0(x)\in C^4(\overline{\Omega})$ satisfy the strong convexity condition, i.e.,

$$3\lambda_0(x)+2\mu_0(x)>0\quad\text{and}\quad\mu_0(x)>0\quad\forall\ x\in\overline{\Omega}. \tag{4.1}$$

It is obvious that (4.1) implies (1.1). On the other hand, we assume that $\widetilde{\lambda}(x)$, $\widetilde{\mu}(x)$ are two essentially bounded functions such that either

$$\widetilde{\mu}\ge0\quad\text{and}\quad3\widetilde{\lambda}+2\widetilde{\mu}\ge0\quad\text{a.e. in}\quad D$$

or

$$\widetilde{\mu}\le0\quad\text{and}\quad3\widetilde{\lambda}+2\widetilde{\mu}\le0\quad\text{a.e. in}\quad D.$$

For our inverse problem here, we shall also assume appropriate jump conditions across ∂D:

$$\text{For } y \in \partial D, \text{ there exists a ball } B_\epsilon(y) \text{ such that one of the following conditions holds:}$$
$$\begin{cases} (\mu+): & \widetilde{\mu} > \epsilon,\ 3\widetilde{\lambda} + 2\widetilde{\mu} \geq 0 \\ (\lambda+): & \widetilde{\mu} = 0,\ \widetilde{\lambda} > \epsilon \\ (\mu-): & \widetilde{\mu} < -\epsilon,\ 3\widetilde{\lambda} + 2\widetilde{\mu} \leq 0 \\ (\lambda-): & \widetilde{\mu} = 0,\ \widetilde{\lambda} < -\epsilon \end{cases} \quad \forall\ x \in B_\epsilon(y) \cap D. \tag{4.2}$$

To make sure that the forward problem is well-posed, we suppose that $\lambda = \lambda_0 + \chi_D\widetilde{\lambda}$ and $\mu = \mu_0 + \chi_D\widetilde{\mu}$ satisfy (4.1) a.e. in Ω, where χ_D is the characteristic function of D. Therefore, for any $f \in H^{1/2}(\partial\Omega)$, there exists a unique (weak) solution u to

$$\begin{cases} \mathcal{L}_D u = 0 & \text{in} \quad \Omega, \\ u = f & \text{on} \quad \partial\Omega. \end{cases}$$

Here the elastic operator $\mathcal{L}_D$ is defined in terms of λ and μ. The Dirichlet-to-Neumann map related to $\mathcal{L}_D$ is now defined as

$$\Lambda_D : f \to \sigma(u)\nu|_{\partial\Omega},$$

where ν is the unit outer normal of $\partial\Omega$ and for $x \in \partial\Omega$

$$\sigma(u) = \lambda(\nabla \cdot u)I + 2\mu\ \mathrm{Sym}(\nabla u) = \lambda_0(\nabla \cdot u)I + 2\mu_0\ \mathrm{Sym}(\nabla u).$$

Now assume that all parameters are known except $\widetilde{\lambda}$, $\widetilde{\mu}$, and D. The inverse problem is to determine D by Λ_D. This inverse problem was studied by Ikehata [10] with the so-called probe method. However, as we mentioned in the introduction, this method relies on Runge's approximation property, which is difficult to realize in practice. In this paper we approach this inverse problem from a different viewpoint. We would like to get partial information of D by local measurements. Our main tool is the use of complex spherical waves to probe for the inclusions. One of the advantages of our method is that we do not need Runge's property, and we can quickly determine roughly where the inclusion is located by only a few measurements that can be advantageous in practical applications.

We first derive some integral inequalities that we need. Let Λ_0 be the Dirichlet-to-Neumann map related to $\mathcal{L}_0$, where $\mathcal{L}_0$ is the elastic operator defined in terms of λ_0 and μ_0. Assume that u_0 is the solution of

$$\begin{cases} \mathcal{L}_0 u_0 = 0 & \text{in} \quad \Omega, \\ u_0 = f & \text{on} \quad \partial\Omega. \end{cases} \tag{4.3}$$

Then we have the following inequalities:

$$\begin{aligned} &\int_D \left\{ \frac{3\lambda_0 + 2\mu_0}{3(3\lambda + 2\mu)} \big(3\widetilde{\lambda} + 2\widetilde{\mu}\big)|\nabla \cdot u_0|^2 + 2\frac{\mu_0}{\mu}\widetilde{\mu} \left| \mathrm{Sym}(\nabla u_0) - \frac{\nabla \cdot u_0}{3} I \right|^2 \right\} dx \\ &\leq\ \langle (\Lambda_D - \Lambda_0) f, \overline{f} \rangle \\ &\leq \int_D \left\{ \frac{3\widetilde{\lambda} + 2\widetilde{\mu}}{3} |\nabla \cdot u_0|^2 + 2\widetilde{\mu} \left| \mathrm{Sym}(\nabla u_0) - \frac{\nabla \cdot u_0}{3} I \right|^2 \right\} dx \end{aligned} \tag{4.4}$$

(see [10, Proposition 5.1]). The plan now is to plug complex spherical waves u_0 given in Ω with parameters $h > 0$ and $t > 0$, denoted by $u_{0,h,t}$, into (4.4). For brevity, we will suppress the subscript 0 and denote $u_{0,h,t} = u_{h,t}$. We set $u_{h,t} = e^{\log t/h} v$ and $v_h = \mu_0^{-1/2} w + \mu_0^{-1} \nabla g - g \nabla \mu_0^{-1}$ with $w = e^{-(\varphi+i\psi)/h}(\ell + r)$ and $g = e^{-(\varphi+i\psi)/h}(d+s)$, where $W = \binom{w}{g}$ satisfies $PW = 0$ in Ω with λ, μ being replaced by λ_0, μ_0 (see (2.1)). Recall that r and s satisfy (3.6). Furthermore, for any $x \in \Omega$, we can choose a neighborhood of x such that $\ell(x)$ and $d(x)$ never vanish in such a neighborhood. In view of (4.4), we need to compute $\nabla \cdot u_{h,t}$ and $\mathrm{Sym}(\nabla u_{h,t})$ in detail. We note that

$$\Delta g = -\mu_0^{1/2} \frac{\lambda_0 + \mu_0}{\lambda_0 + 2\mu_0} \nabla \cdot w + b_0 \cdot w + c_0 g, \tag{4.5}$$

where (b_0, c_0) is the bottom row of A_0. From (4.5) we have

$$\begin{aligned}
&\nabla \cdot v_h \\
&= \nabla \mu_0^{-1/2} \cdot w + \mu_0^{-1/2} \nabla \cdot w + \nabla \mu_0^{-1} \cdot \nabla g + \mu_0^{-1} \Delta g - \nabla g \cdot \nabla \mu_0^{-1} - g \Delta \mu_0^{-1} \\
&= \nabla \mu_0^{-1/2} \cdot w + \mu_0^{-1/2} \nabla \cdot w + \mu_0^{-1} \Delta g - g \Delta \mu_0^{-1} \\
&= (\nabla \mu_0^{-1/2} + \mu_0^{-1} b_0) \cdot w + \mu_0^{-1/2} \left(1 - \frac{\lambda_0 + \mu_0}{\lambda_0 + 2\mu_0}\right) \nabla \cdot w + (\mu_0^{-1} c_0 - \Delta \mu_0^{-1}) g \\
&= e^{-(\varphi+i\psi)/h} \left\{ (\nabla \mu_0^{-1/2} + \mu_0^{-1} b_0) \cdot (\ell + r) - \mu_0^{-1/2} \left(1 - \frac{\lambda_0 + \mu_0}{\lambda_0 + 2\mu_0}\right) \frac{\nabla \varphi + i \nabla \psi}{h} \cdot (\ell + r) \right. \\
&\quad \left. + \mu_0^{-1/2} \left(1 - \frac{\lambda_0 + \mu_0}{\lambda_0 + 2\mu_0}\right) \nabla \cdot (\ell + r) + (\mu_0^{-1} c_0 - \Delta \mu_0^{-1})(d + s) \right\}.
\end{aligned} \tag{4.6}$$

Next we observe that

$$\mathrm{Sym}(\nabla v_h) = \mathrm{Sym}(\nabla \mu_0^{-1/2} \otimes w) + \mu_0^{-1/2} \mathrm{Sym}(\nabla w) + \mu_0^{-1} \nabla^2 g - g \nabla^2 \mu_0^{-1}$$

and hence

$$\begin{aligned}
&\mathrm{Sym}(\nabla v_h) \\
&= e^{-(\varphi+i\psi)/h} \left\{ \mathrm{Sym}(\nabla \mu_0^{-1/2} \otimes (\ell + r)) - \frac{1}{h} \mu_0^{-1/2} \mathrm{Sym}((\nabla \varphi + i \nabla \psi) \otimes (\ell + r)) \right. \\
&\quad + \mu_0^{-1/2} \mathrm{Sym}(\nabla(\ell + r)) + \mu_0^{-1} \nabla^2 (d + s) - \mu_0^{-1} \frac{1}{h} (d + s) \nabla^2 (\varphi + i\psi) \\
&\quad - \mu_0^{-1} \frac{2}{h} \mathrm{Sym}(\nabla(\varphi + i\psi) \otimes \nabla(d + s)) + \mu_0^{-1} \frac{1}{h^2} \nabla(\varphi + i\psi) \otimes \nabla(\varphi + i\psi)(d + s) \\
&\quad \left. - (d + s) \nabla^2 \mu_0^{-1} \right\},
\end{aligned} \tag{4.7}$$

where $(a \otimes b)_{jk} = (a_j b_k)$ for $1 \le j, k \le 3$.

We are now in a position to discuss the inverse problem. Recall that $\varphi = \log|x - x_0|$ with $x_0 \notin \overline{\mathrm{ch}(\Omega)}$. Let $f_{h,t}$ be the boundary value of $u_{h,t}$ on $\partial\Omega$ and denote

$$E(h, t) = |\langle (\Lambda_D - \Lambda_0) f_{h,t}, \overline{f_{h,t}} \rangle|.$$

Our main result for the inverse problem is the following.

THEOREM 4.1. *Assume that the jump condition* (4.2) *holds. For* $t > 0$ *and sufficiently small* h*, we have the following:*

(i) *If* $\operatorname{dist}(D, x_0) =: d_0 > t$*, then* $E(h,t) \le Ca^{1/h}$ *for some constants* $C > 0$ *and* $a < 1$*.*

(ii) *If* $d_0 < t$*, then* $E(h,t) \ge Cb^{1/h}$ *for some constants* $C > 0$ *and* $b > 1$ *with appropriate choices of* $f_{h,t}$*.*

(iii) *If* $\overline{D} \cap \overline{B_t(x_0)} = y$*, then*

$$\begin{cases} C'h^{-1} \le E(h,t) \le Ch^{-3} \text{ if } (\mu\pm) \text{ holds near } y, \\ C'h \le E(h,t) \le Ch^{-1} \text{ if } (\lambda\pm) \text{ holds near } y, \end{cases} \tag{4.8}$$

provided ℓ *and* d *of* $u_{h,t}$ *do not vanish near* y*.*

Proof. To prove the theorem, we simply substitute $u_{h,t}$ into (4.4). The key observation comes from (4.6) and (4.7). We consider only the cases $(\mu+)$ and $(\lambda+)$ of (4.2) here. The same arguments work for $(\mu-)$ and $(\lambda-)$ of (4.2). The only change is to use integral inequalities obtained by multiplying "$-$" on (4.4). If $(\mu+)$ holds, then the leading terms of two integrals in (4.4) come from $\operatorname{Sym}(\nabla u_{h,t})$ and are determined by

$$\frac{1}{h^4}\left(\frac{t}{|x-x_0|}\right)^{2/h}((\nabla\varphi)^2 + (\nabla\psi)^2)^2|d|^2 = \frac{4}{h^4}\left(\frac{t}{|x-x_0|}\right)^{2/h}(\nabla\varphi)^4|d|^2. \tag{4.9}$$

On the other hand, if $(\lambda+)$ holds, then the leading terms in those integrals in (4.4) come from $\nabla \cdot u_{h,t}$ and are governed by

$$\frac{2}{h^2}\left(\frac{t}{|x-x_0|}\right)^{2/h}(\nabla\varphi)^2|\ell|^2. \tag{4.10}$$

Using (4.4), (4.9), and (4.10), the proof of (i) follows easily from

$$E(h,t) \le C\frac{1}{h^4}\left(\frac{t}{d_0}\right)^{2/h} \quad \text{when } (\mu+) \text{ holds}$$

and

$$E(h,t) \le C\frac{1}{h^2}\left(\frac{t}{d_0}\right)^{2/h} \quad \text{when } (\lambda+) \text{ holds.}$$

For the proof of (ii), we pick a small ball $B_\delta \subset\subset B_t(x_0) \cap D$ such that the jump conditions $(\mu+)$ or $(\lambda+)$ hold in B_δ and $\ell(x)$, $d(x)$ of $u_{h,t}$ never vanish in $B_\delta(x)$. The latter property is guaranteed by Remark 3.1. For such choice of ℓ and d, the Dirichlet data is a priori given by

$$f_{h,t} = u_{h,t}|_{\partial\Omega} = e^{(\log t - \varphi - i\psi)/h}(\ell + d)|_{\partial\Omega}.$$

Thus, argued as above, we have that either

$$E(h,t) \ge C\frac{1}{h^4}\left(\frac{t}{d_0}\right)^{2/h} \quad \text{when } (\mu+) \text{ holds}$$

or

$$E(h,t) \geq C\frac{1}{h^2}\left(\frac{t}{d_0}\right)^{2/h} \quad \text{when } (\lambda+) \text{ holds,}$$

which implies (ii).

Now let $y \in \overline{D} \cap \overline{B_t(x_0)}$ and choose a ball $B_\epsilon(y)$ such that (4.2) holds and $\ell(x)$, $d(x)$ of $u_{h,t}$ never vanish in $B_\epsilon(y) \cap D$. Pick a small cone with vertex at y, say Γ, so that there exists an $\eta > 0$ satisfying

$$\Gamma_\eta := \Gamma \cap \{0 < |x-y| < \eta\} \subset B_\epsilon(y) \cap D.$$

We observe that if $x \in \Gamma_\eta$ with $|x-y| = \rho < \eta$, then $|x-x_0| \leq \rho + t$, i.e.,

$$\frac{1}{|x-x_0|} \geq \frac{1}{\rho+t}.$$

Thus, for the case $(\mu+)$, we get that from (4.4) and (4.9)

$$\begin{aligned} E(h,t) &\geq C\frac{1}{h^4}\int_D \widetilde{\mu}^2(\nabla\varphi)^4|d|^2\left(\frac{t}{|x-x_0|}\right)^{2/h} dx \\ &\geq C\epsilon\frac{1}{h^4}\int_0^\eta \left(\frac{t}{\rho+t}\right)^{2/h}\rho^2 d\rho \\ &\geq C\epsilon h^{-1}. \end{aligned} \tag{4.11}$$

On the other hand, we can choose a cone $\widetilde{\Gamma}$ with vertex at x_0 such that $\overline{D} \subset \widetilde{\Gamma} \cap \{|x-x_0| > t\}$. Hence, we can estimate

$$\begin{aligned} E(h,t) &\leq C\frac{1}{h^4}\int_{\widetilde{\Gamma}\cap\{t<|x-x_0|<t+\eta\}}\left(\frac{t}{|x-x_0|}\right)^{2/h} dx \\ &\quad + C\frac{1}{h^4}\int_{\widetilde{\Gamma}\cap\{t+\eta\leq|x-x_0|\}}\left(\frac{t}{|x-x_0|}\right)^{2/h} dx \\ &\leq C\frac{1}{h^4}\int_t^{t+\eta}\left(\frac{t}{r}\right)^{2/h} r^2 dr + O\left(\left(\frac{t}{t+\eta}\right)^{2/h}\right) \\ &\leq Ch^{-3}. \end{aligned} \tag{4.12}$$

Combining (4.11) and (4.12) yields the first estimate of (4.8). Using similar arguments, we can get the second estimate of (4.8) for the case $(\lambda+)$. □

Remark 4.1. (1) Using Theorem 4.1, we can clearly determine whether the probing front $\{|x-x_0| = t\}$ intersects the inclusion. In view of (iii) of the theorem, it is also possible to determine whether we have material jumps in μ or λ when the front touches the boundary of the inclusion.

(2) In the proofs of (ii) and (iii) we need to choose ℓ and d, which are nonvanishing in small subdomains of Ω. Since ℓ and d depend only on the known background medium, they can be chosen to be nonvanishing near any point in Ω at our disposal. In fact, it suffices to take ℓ and d, which are nonvanishing near the probe front $\{|x-x_0| = t\}$. Different choices of ℓ and d will give rise to different Dirichlet data $f_{h,t}$ and therefore different measurements.

(3) In real applications, we believe that the concerns in (ii) and (iii) can be ignored.

Taking advantage of the decay of the complex spherical waves in the region $\{|x - x_0| > t\}$, we can localize the measurements, which is of great practical value. Let $\phi_{\delta,t}(x) \in C_0^\infty(\mathbb{R}^3)$ satisfy

$$\phi_{\delta,t}(x) = \begin{cases} 1 & \text{on} \quad B_{t+\delta/2}(x_0), \\ 0 & \text{on} \quad \mathbb{R}^3 \setminus \overline{B_{t+\delta}(x_0)}, \end{cases}$$

where $\delta > 0$ is sufficiently small. Now we are going to use the measurements $f_{\delta,h,t} = \phi_{\delta,t} f_{h,t} = \phi_{\delta,t} u_{h,t}|_{\partial\Omega}$. Clearly, the measurements $f_{\delta,h,t}$ are localized on $B_{t+\delta}(x_0) \cap \partial\Omega$. Let us define

$$E_\delta(h,t) = |\langle (\Lambda_D - \Lambda_0) f_{\delta,h,t}, \overline{f_{\delta,h,t}} \rangle|.$$

THEOREM 4.2. *The statements of Theorem* 4.1 *are valid for* $E_\delta(h,t)$.

Proof. The main idea is to prove that the error caused by the remaining part of the measurement $(1 - \phi_{\delta,t}) f_{h,t} =: g_{\delta,h,t}$ is exponentially small. Let $w_{\delta,h,t}$ be the solution of (4.3) with boundary value $g_{\delta,h,t}$. We now want to compare $w_{\delta,h,t}$ with $(1 - \phi_{\delta,t}) u_{h,t}$. To this end, we first observe that

$$\begin{cases} \mathcal{L}_0((1 - \phi_{\delta,t}) u_{h,t} - w_{\delta,h,t}) = \mathcal{L}_0((1 - \phi_{\delta,t}) u_{h,t}), \\ (1 - \phi_{\delta,t}) u_{h,t} - w_{\delta,h,t} = 0 \quad \text{on} \quad \partial\Omega. \end{cases}$$

Since

$$\|\mathcal{L}_0((1 - \phi_{\delta,t}) u_{h,t})\|_{L^2(\Omega)} \le C\beta^{1/h}$$

for some $0 < \beta < 1$, we have that

$$\|(1 - \phi_{\delta,t}) u_{h,t} - w_{\delta,h,t}\|_{H^1(\Omega)} \le C\beta^{1/h}. \tag{4.13}$$

Using (4.4) for $\langle (\Lambda_D - \Lambda_0) g_{\delta,h,t}, \overline{g_{\delta,h,t}} \rangle$ with u_0 being replaced by $w_{\delta,h,t}$, we get from (4.13) and the decaying property of $u_{h,t}$ that

$$|\langle (\Lambda_D - \Lambda_0) g_{\delta,h,t}, \overline{g_{\delta,h,t}} \rangle| \le C\widetilde{\beta}^{1/h}$$

for some $0 < \widetilde{\beta} < 1$.

Now we first consider (i) of Theorem 4.1 for $E_\delta(h,t)$. We begin with the case $(\mu+)$ of (4.2). In view of the first inequality of (4.4), we see that

$$0 \le \langle (\Lambda_D - \Lambda_0)(\zeta f_{\delta,h,t} \pm \zeta^{-1} g_{\delta,h,t}), \overline{\zeta f_{\delta,h,t} \pm \zeta^{-1} g_{\delta,h,t}} \rangle$$

for any $\zeta > 0$, which leads to

$$\begin{aligned} &|\langle (\Lambda_D - \Lambda_0) f_{\delta,h,t}, \overline{g_{\delta,h,t}} \rangle + \langle (\Lambda_D - \Lambda_0) g_{\delta,h,t}, \overline{f_{\delta,h,t}} \rangle| \\ &\le \zeta^2 \langle (\Lambda_D - \Lambda_0) f_{\delta,h,t}, \overline{f_{\delta,h,t}} \rangle + \zeta^{-2} \langle (\Lambda_D - \Lambda_0) g_{\delta,h,t}, \overline{g_{\delta,h,t}} \rangle. \end{aligned} \tag{4.14}$$

It now follows from $f_{h,t} = f_{\delta,h,t} + g_{\delta,h,t}$ and (4.14) with $\zeta = 1/\sqrt{2}$ that

$$\begin{aligned} &\frac{1}{2} \langle (\Lambda_D - \Lambda_0) f_{\delta,h,t}, \overline{f_{\delta,h,t}} \rangle \\ &\le \langle (\Lambda_D - \Lambda_0) g_{\delta,h,t}, \overline{g_{\delta,h,t}} \rangle + \langle (\Lambda_D - \Lambda_0) f_{h,t}, \overline{f_{h,t}} \rangle \\ &\le C\widetilde{\beta}^{1/h} + \langle (\Lambda_D - \Lambda_0) f_{h,t}, \overline{f_{h,t}} \rangle. \end{aligned} \tag{4.15}$$

So from (i) of Theorem 4.1, the same statement holds for $E_\delta(h,t)$. Other cases of (4.2) are treated similarly.

Next we consider (ii) and (iii) of Theorem 4.1 for $E_{\delta,h,t}$. As before, we treat only $(\mu+)$ of (4.2). Choosing $\zeta = 1$ in (4.14), we get that

$$\begin{aligned} &\frac{1}{2}\langle(\Lambda_D - \Lambda_0)f_{h,t}, \overline{f_{h,t}}\rangle \\ &\leq \langle(\Lambda_D - \Lambda_0)g_{\delta,h,t}, \overline{g_{\delta,h,t}}\rangle + \langle(\Lambda_D - \Lambda_0)f_{\delta,h,t}, \overline{f_{\delta,h,t}}\rangle \\ &\leq C\widetilde{\beta}^{1/h} + \langle(\Lambda_D - \Lambda_0)f_{\delta,h,t}, \overline{f_{\delta,h,t}}\rangle. \end{aligned} \tag{4.16}$$

Therefore, (ii) of Theorem 4.1 and (4.16) imply that the same fact is true for $E_\delta(h,t)$. Finally, combining (4.15) and (4.16) yields statement (iii) for $E_\delta(h,t)$. The proof is now complete. □

Remark 4.2. With the help of Theorem 4.2, when parts of ∂D are near the boundary $\partial\Omega$, it is possible to detect some points of ∂D from only a few measurements taken from a very small region of $\partial\Omega$.

To end this section, we provide an algorithm of the method.

Step 1. Pick a point x_0 near $\mathrm{ch}(\Omega)$. Construct complex spherical waves $u_{h,t}$.

Step 2. Draw two balls $B_t(x_0)$ and $B_{t+\delta}(x_0)$. Set the Dirichlet data $f_{\delta,h,t} = \phi_{\delta,t}u_{h,t}|_{\partial\Omega}$. Measure the Neumann data $\Lambda_D f_{\delta,h,t}$ over the region $B_{t+\delta}(x_0) \cap \partial\Omega$.

Step 3. Calculate $E_\delta(h,t) = \langle(\Lambda_D - \Lambda_0)f_{\delta,h,t}, f_{\delta,h,t}\rangle$. If $E(h,t)$ tends to zero as $h \to 0$, then the probing front $\{|x - x_0| = t\}$ does not intersect the inclusion. Increase t and compute $E_\delta(h,t)$ again.

Step 4. If $E_{\delta,h,t}$ increases to ∞ as $h \to 0$, then the front $\{|x - x_0| = t\}$ intersects the inclusion. Decrease t to make a more accurate estimate of ∂D.

5. Conclusion. In this work we have constructed complex spherical waves or complex geometrical optics solutions for the elasticity system with isotropic inhomogeneous medium. We used these special solutions to investigate the inverse problem of identifying inclusions with localized measurements. Numerical realization of this method would be an interesting project. The same method should work for identifying cavities.

Acknowledgment. This work was done when the second author was visiting the Department of Mathematics at the University of Washington. He would like to thank this institute for its warm hospitality.

A CLASS OF FREE BOUNDARY PROBLEMS WITH ONSET OF A NEW PHASE*

PATRICK GUIDOTTI†

Abstract. A class of diffusion-driven free boundary problems is considered which is characterized by the initial onset of a phase and by an explicit kinematic condition for the evolution of the free boundary. By a domain fixing change of variables it naturally leads to coupled systems comprising a singular parabolic initial boundary value problem and a Hamilton–Jacobi equation. Even though the one-dimensional case has been thoroughly investigated, results as basic as well-posedness and regularity have so far not been obtained for its higher-dimensional counterpart. In this paper a recently developed regularity theory for abstract singular parabolic Cauchy problems is utilized to obtain the first well-posedness results for the free boundary problems under consideration. The derivation of elliptic regularity results for the underlying static singular problems will play an important role.

Key words. free boundary problem, kinematic condition, singular parabolic and elliptic equations, well-posedness, existence, regularity

1. Introduction.

In this paper we consider a class of one phase free boundary problems (FBPs) characterized by the initial onset of a phase. Such FBPs arise in the description of diffusion in polymers, for instance. Under physically natural conditions, these problems lead to a formulation in which the phase is initially absent. This feature manifests itself mathematically in that some of the equations in the nonlinear system become singular (if they are written in a fixed reference domain). In spite of the fact that these types of problems have been intensively studied in the literature over an extended period of time, only one publication deals with the singular case considered here in more than one space dimension. The simplifying assumption that the phase be initially nonempty is typically added to avoid the mathematical complications stemming from the singularity. The one-dimensional case has, however, been thoroughly investigated [9, 10, 11, 8, 7, 14] in the specific context of diffusion in polymers and, more generally, for diffusion-driven FBPs (see [18, 12], for instance). The methods used for the one-dimensional case rely on the explicit use of the heat kernel to reduce the problem to the boundary. This approach cannot be used in higher dimensions because the singular behavior induced by the initial condition on the FBP cannot be decoupled from the diffusion operator. This is due to the fact that the free boundary has a nontrivial geometry in this case and to the fact that fundamental solutions (evolution operators) have not been studied for singular parabolic problems for which the singularity affects the underlying elliptic operator in an anisotropic way. The higher-dimensional problem has recently been studied in [16] but only in its simpler quasi-stationary form. [16] established well-posedness for the problem in a class of functions which needs to be carefully crafted and leads to an asymptotic expansion for the singularity which is valid in the corresponding topologies and has practical relevance (cf. [7, 14]). Regularity results, maximal regularity in particular, for singular

parabolic equations play a crucial role in this paper and have been recently obtained by the author in [13], where a construction of the evolution operator is given for a wide class of singular parabolic problems. Maximal regularity is needed because the full problem will be solved by reduction to a model problem and perturbation about it. Since the ensuing perturbation is of maximal order (both in the singularity and differentiation) optimal regularity results are necessary. Previous abstract results were obtained in [15, 21], but they do not apply to the situation considered here because their validity does not cover the case of spaces of classical pointwise regularity, nor the case in which the singularity affects the equations anisotropically. Classical pointwise regularity is needed in the analysis proposed here since the singular parabolic equation is coupled to a Hamilton–Jacobi-type equation modeling the front's dynamics. It has long been observed, as mentioned above, that one-dimensional techniques cannot be extended to the higher-dimensional case. Summarizing, the presence of singular coefficients and the coupling to a Hamilton–Jacobi equation are two of the characterizing features of the problem under consideration. They make its analysis more difficult and delicate than that of the related but different classical Stefan problem. This paper therefore offers a successful approach that fully overcomes these difficulties.

The unknowns of the problem are a function $u : \Omega_t \to \mathbb{R}$ defined on the open domain $\Omega_t \subset \mathbb{R}^{n+1} \ni (x, y)$ and its unknown boundary Γ_t. The function u measures the concentration of the penetrant in the case of diffusion in polymers. Many geometries can be chosen for the domain Ω_t. Here a strip-like setting is chosen where the domain is bounded by a fixed lower and an upper moving hypersurface denoted by Γ_0 and Γ_t, respectively. Other configurations, like annulus-type domains, are possible and interesting, and the results obtained here would apply to those since they all would lead to the same local model problems. The system of equations satisfied by (u, Γ_t) proposed in [17] and generalizing [1, 6] then reads

$$\varepsilon u_t - \triangle_{x,y} u = 0 \qquad \text{in } \bigcup_{t>0} \{t\} \times \Omega_t \,, \tag{1.1}$$

$$u = g \qquad \text{on } (0,\infty) \times \Gamma_0 \,, \tag{1.2}$$

$$-\partial_{\nu_t} u = (1 + \varepsilon u) V \qquad \text{on } \bigcup_{t>0} \{t\} \times \Gamma_t \,, \tag{1.3}$$

$$V = (1 + \delta \, \mathrm{H}_t) u \qquad \text{on } \bigcup_{t>0} \{t\} \times \Gamma_t \,, \tag{1.4}$$

$$\Gamma_t\big|_{t=0} = \Gamma_0 \qquad \text{at } t = 0 \,. \tag{1.5}$$

In the above equations V denotes the front speed in normal (outward) direction ν_t, and H_t denotes its mean curvature. The function $g > 0$ describes the concentration profile of a reservoir of the diffusing molecule, whereas the positive constants ε, δ arise in the nondimensionalization process. They measure the deviation from a threshold concentration of the penetrant and the strength of the curvature term, respectively. Condition (1.3) models conservation of mass across the free boundary, whereas condition (1.4) is a phenomenological law which is capable of capturing the behavior observed in experiments known as case II or anomalous diffusion. The curvature term naturally appears if one assumes the front speed to be proportional to the local average concentration in a reference ball of radius $\delta > 0$ rather than to its pointwise value. The system is clearly nonlinear, and even if the boundary conditions were linear, it still would be. Indeed, two different solutions have different domains of definitions and cannot be added. This typical feature of FBPs becomes apparent after the simple

change of variables

$$(\tau,\xi,\eta)=\left(t,x,\frac{y}{s(t,x)}\right),\qquad \hat{u}(\tau,\xi,\eta)=u\big(\tau,\xi,\eta s(\tau,\xi)\big),$$

which transforms the problem to a corresponding one on a fixed domain. To do so, it is assumed that the fixed boundary of the unknown domain is given by

$$\Gamma_0=\mathbb{R}^{n-1}\times\{0\}$$

and that the unknown moving boundary can be described as the graph of a function $s(t,\cdot)$. The latter assumption is motivated by (initial) condition (1.5). In the new variables, the domain becomes the strip

$$S=\mathbb{R}^{n-1}\times[0,1]$$

with the obvious boundaries denoted by Γ_j, $j=0,1$. Using the old notation for the new variables, the system now reads

(1.6)
$$\varepsilon u_t-\triangle_x u-\frac{1+y^2|\nabla s|^2}{s^2}\partial_y^2 u=\varepsilon y\frac{\dot{s}}{s}\partial_y u-2y\frac{1}{s}\big(\nabla s\big|\partial_y\nabla u\big)-y\frac{s\triangle s-2|\nabla s|^2}{s^2}\partial_y u,$$

(1.7)
$$u=g \qquad \text{on } \Gamma_0,$$

(1.8)
$$-\frac{1+|\nabla s|^2}{s}\partial_y u=(1+\varepsilon u)\dot{s}-\big(\nabla s\big|\nabla u\big) \qquad \text{on } \Gamma_1,$$

(1.9)
$$\dot{s}=\sqrt{1+|\nabla s|^2}(1+\delta\,\mathrm{H}_t)u \qquad \text{on } \Gamma_1,$$

(1.10)
$$s(0,\cdot)=0.$$

In [16] the quasi-stationary approximation ($\varepsilon=0$) in two space dimensions was considered in the presence or absence of the mean curvature term in two space dimensions. Here there is no restriction on the spatial dimension, and the full evolutionary problem is analyzed but the curvature effects are neglected ($\delta=0$).

The main result of this paper is establishing the well-posedness of system (1.6)–(1.10). To do so, appropriate function spaces have to be used which are able to capture the regularity of the solution as well as its asymptotic behavior at the origin. The choice of function spaces is limited by the simultaneous presence of a singular parabolic problem and a Hamilton–Jacobi equation. Spaces of classical regularity are better suited for the latter and thus reduce the freedom of choice for the parabolic problem. A compromise can be reached by using spaces of classical Hölder regularity in space and of singular Hölder behavior in time. A number of preparatory results are needed; they are formulated in the next section. In section 3 elliptic and parabolic results for singular equations will be derived which play a crucial role in the existence proof given in the last section.

2. Preliminaries and setting. In order to obtain existence results for system (1.6)–(1.10) a linearization procedure will be used in combination with maximal regularity results for the relevant linearized problems. The presence of the singularity complicates the analysis significantly since the relevant regularity results are not available and need to be derived first. The linearization procedure is meant to capture the leading order terms of the differential operators at the origin with respect to both their differentiation order and their singularity degree.

Of interest in this paper are classical solutions. If such a solution existed, one would be able to guess from (1.7) and (1.9)–(1.10) that

$$s(t,x) \approx t\, g(x) \quad \text{for } t \approx 0\,.$$

This indicates that the relevant model problem which captures the leading order behavior of (1.6)–(1.8) has the form

$$\varepsilon u_t - \triangle_x u - \frac{1}{t^2 c^2(x)}\partial_y^2 u = f(t,x,y) \text{ in } (0,\infty)\times S\,, \tag{2.1}$$

$$u = g(t,x) \quad \text{ on } (0,\infty)\times \Gamma_0\,, \tag{2.2}$$

$$\frac{1}{t}\partial_y u = h(t,x) \quad \text{ on } (0,\infty)\times \Gamma_1\,, \tag{2.3}$$

where in the situation at hand g is independent of the time variable and $c = g$. The more general case of c independent of g is, however, of interest and motivates the different notation. For reasons which can be guessed and will become apparent later, both parabolic ($\varepsilon = 1$) and elliptic ($\varepsilon = 0$) regularity results are needed in the analysis of (2.1)–(2.3). The main ingredients needed to derive such regularity results are vector-valued Fourier multiplier theorems and the use of spaces of singularly Hölder continuous functions in the time variable and the construction of an evolution operator for singular families of generators. The first are crucial in the analysis of the elliptic problem with time frozen, and the latter allow for the quantitative characterization of the singular behavior in the origin ($t = 0$) both in the elliptic and parabolic cases (where maximal regularity results are needed).

For the sake of completeness the formulation of the relevant Fourier multiplier theorem and the definition of the classes of singular Hölder continuous functions needed in the analysis are given here. The basic observation illuminating the reason for their combined use will also be presented in this section.

Assume that E is a given Banach space and that $T > 0$ and $\beta \in (0,1)\ [\cup\{1-\}]$. Then the standard Hölder (Lipschitz) space is given by

$$\mathrm{C}^{\beta}\big([0,T],E\big) := \left\{ f \in \mathrm{C}\big([0,T],E\big) \,\middle|\, [u]_{\beta,[0T]} := \sup_{t\neq s} \frac{|u(t)-u(s)|}{|t-s|^{\beta}} < \infty \right\}$$

with norm

$$\|\cdot\|_{\beta} = \|\cdot\|_{\infty,[0,T]} + [\cdot]_{\beta,[0,T]}\,.$$

If $\beta = 1$ is chosen, one obtains the space of Lipschitz continuous functions. To distinguish it from the space of continuously differentiable functions the notational device $\beta = 1-$ is used. This means that $\beta = 1$ for all practical purposes except in the notation for the space which becomes C^{1-}. Singular counterparts are given by

$$\mathrm{C}^{\beta}_{\beta}\big((0,T],E\big) := \big\{ f \in \mathrm{B}\big((0,T],E\big) \,\big|\, [t \mapsto t^{\beta} u(t)] \in \mathrm{C}^{\beta}\big((0,T],E\big)\big\} \tag{2.4}$$

with weighted norm defined through

$$\|\cdot\|_{\beta,\beta} := \|u\|_{\infty,(0,T]} + [(\cdot)^{\beta} u]_{\beta,(0,T]}\,.$$

The symbol denoting the time interval in the notation for the norm will be dropped in what follows with the understanding that the interval of definition does not contain

the origin for singular spaces, whereas it does for regular ones. The following closed subspace of regular Hölder functions will also be useful:

$$\mathrm{C}_0^\beta([0,T],E) := \big\{ f \in \mathrm{C}^\beta\big([0,T],E\big) \,\big|\, f(0)=0 \big\}\,.$$

The vector-valued Fourier multiplier theorem which is needed here can be found in [2, Theorem 6.2]. We reproduce it here for the ease of the reader. The symbol class

$$\mathcal{S}^m(E_0,E_1) := \Big\{ a \in \mathrm{C}^{n+1}\big(\mathbb{R}^n\setminus\{0\},\mathcal{L}(E_0,E_1)\big) \,\Big|\, \sup_{\xi\in\mathbb{R}^n} \big|[1+|\xi|^2]^{(m+|\alpha|)/2}\partial^\alpha a(\xi)\big|_{\mathcal{L}(E_0,E_1)} < \infty\,,\ |\alpha|\le n+1 \Big\}, \tag{2.5}$$

where E_0 and E_1 are Banach spaces and $m\in\mathbb{Z}$, is instrumental in the formulation of the result. Given a symbol $a\in\mathcal{S}^m(E_0,E_1)$, an operator can be associated to it by

$$a(D) := \mathcal{F}^{-1} a\,\mathcal{F}$$

through conjugation with the vector-valued Fourier transform

$$\mathcal{F} \in \mathcal{L}_{is}\Big(\mathcal{S}\big(\mathbb{R}^n,E_j\big)\Big) \cap \mathcal{L}_{is}\Big(\mathcal{S}'\big(\mathbb{R}^n,E_j\big)\Big)\,,\quad j=0,1\,,$$

where $\mathcal{S}$ and $\mathcal{S}'$ are the operator-valued Schwartz spaces of fast decaying test functions and of tempered distributions, respectively. They are endowed with their natural topology.

THEOREM 2.1 (see [2, Theorem 6.2]). *Suppose that $\mathcal{B}\in\{B,\mathring{B},b\}$ and that $m\in\mathbb{R}$. Then*

$$\big[a\mapsto a(D)\big] \in \mathcal{L}\Big(\mathrm{S}^m(E_0,E_1),\mathcal{L}\big(\mathcal{B}^s_{p,q}(\mathbb{R}^n,E_0),\mathcal{B}^{s+m}_{p,q}(\mathbb{R}^n,E_1)\big)\Big)$$

for $s\in\mathbb{R}$ and $p,q\in[1,\infty]$.

The symbol B denotes the regular Besov spaces, whereas $\mathring{B}^s_{p,q}$ and $b^s_{p,q}$ denote the closures of $\mathcal{S}$ and $B^{s+1}_{p,q}$ in $B^s_{p,q}$, respectively. Various equivalent definitions are given in [2]. Here only regular Besov spaces with $p=q=\infty$ of positive fractional order $s\in\mathbb{R}^+\setminus\mathbb{N}$ are used, in which case one has

$$B^s_{\infty,\infty} = \mathrm{BUC}^s(\mathbb{R}^n,E)\,,$$

where the space on the right is the standard space of bounded and uniformly Hölder continuous functions given by

$$\mathrm{BUC}^s(\mathbb{R}^n,E) := \big\{ f\in\mathrm{BUC}^{[s]}(\mathbb{R}^n,E) \,\big|\, \partial^\alpha f\in\mathrm{BUC}^{s-[s]}(\mathbb{R}^n,E)\ \forall\,|\alpha|\le[s]\,\big\}\,.$$

A crucial observation connecting the dilation of symbols of type (2.5) and singular Hölder spaces was already obtained in [16]. It allows one to deal with singular elliptic and, eventually, singular parabolic boundary value problems.

PROPOSITION 2.2 (see [16, Lemma 2.5]). *Assume that $a\in\mathrm{S}^m(E_0,E_1)$ for some $m\in\mathbb{Z}$. Then*

$$\big[t\mapsto t^m\sigma_t a\big] \in \mathrm{C}_1^{1-}\big((0,T],\mathrm{S}^m(E_0,E_1)\big)$$

for $\sigma_t(a) := a(t\cdot)$.

Remark 2.1. A straightforward adaptation of the proof given in [16] of Proposition 2.2 also shows that

$$\big[t \mapsto t^m \sigma_t a\big] \in \mathrm{C}^{1-}\big([0,T], \mathrm{S}^{m-1}(E_0, E_1)\big).$$

The importance of this proposition lies in the fact that multiplication of singularly Hölder continuous functions is well defined and continuous as a map defined in various combinations of spaces

$$\mathrm{C}^\alpha_\alpha \times \mathrm{C}^\beta_\beta \to \mathrm{C}^\beta_\beta, \tag{2.6}$$

$$\mathrm{C}^\alpha_\alpha \times \mathrm{C}^\beta_0 \to \mathrm{C}^\beta_0, \tag{2.7}$$

$$\mathrm{C}^\alpha_0 \times \mathrm{C}^\beta_0 \to \mathrm{C}^\beta_{-\alpha}, \tag{2.8}$$

$$\mathrm{C}^\alpha_0 \times \mathrm{C}^\beta_\beta \to \mathrm{C}^\beta_{\beta-\alpha} \tag{2.9}$$

for $\alpha, \beta \in (0,1) \cup \{1-\}$ and $\beta \le \alpha$. The proof is elementary and can be found in [16] along with the (natural) definition of the spaces for negative lower indices.

Finally, optimal regularity results are yet another essential ingredient in dealing with the full nonlinear problem. They provide maximal regularity results for the relevant class of singular parabolic problems in classes of singularly Hölder continuous functions which are, as they need to be, perfectly compatible with the corresponding results for singular elliptic problems in the same class of functions. The result needed here has been derived in [13] and is formulated in the next theorem. It gives conditions for the well-posedness of the singular abstract Cauchy problem

$$\dot u - A(t)u = f(t)\,, \quad t > 0, \tag{2.10}$$

for a Banach space–valued function $u : (0,T] \to E_0$ and a singular family of "elliptic operators" A (that is, of generators of analytic semigroups). The symbol $\mathcal{H}^-(E_0, \omega)$ denotes the class of generators of exponentially decaying semigroups which are not necessarily strongly continuous (as introduced by [20]).

THEOREM 2.3 (see [13, Corollary 3.3]). *Assume that A satisfies the assumptions*

$$\text{(i) } A(t) \in \mathcal{H}^-(E_0, \omega)\,, \quad t > 0\,, \tag{2.11}$$

$$\text{(ii) } \|\big[A(t) - A(s)\big]A^{-1}(\tau)\|_{\mathcal{L}(E_0)} \le c\frac{t-s}{t} \text{ and}$$

$$\|\big[A(t) - A(s)\big](-A)^{-\rho}(\tau)\|_{\mathcal{L}(E_0)} \le c(t-s)\,, \tag{2.12}$$

$$\text{(iii) } \lim_{t\to 0} A^{-1}(t) = 0\,, \tag{2.13}$$

for some $\rho \in (1,2)$ and $0 < \tau \le s \le t \le T$. Let $f \in \mathrm{C}^\beta_\gamma\big((0,T], E_0\big)$ for some $\beta \in (0,1)$ and $\gamma = 0, \beta$. Then (2.10) *has a unique solution $u \in \mathrm{C}^\beta_\gamma\big((0,T], E_0\big)$ satisfying*

$$\dot u, Au \in \mathrm{C}^\beta_\gamma \quad \text{and} \quad \|\dot u\|_{\beta,\gamma} + \|Au\|_{\beta,\gamma} \le c\|f\|_{\beta,\gamma}\,,$$

where $\|\cdot\|_{\beta,0} = \|\cdot\|_\beta$.

Using a combination of elliptic and parabolic estimates, it will be possible to obtain a satisfactory regularity theory for (2.1)–(2.3). The latter will be used in the analysis of the full evolution system (1.6)–(1.10) for $\delta = 0$.

3. Elliptic and parabolic estimates. In order to use the results presented in the previous section in the analysis of (1.6)–(1.10), appropriate function spaces have to be chosen in which to work. The choice can typically be justified by balancing the regularities in the nonlinear equations in such a way that a fixed point argument can be applied to the set of equations. Whereas a variety of function spaces of Sobolev type are available for dealing with elliptic and parabolic problems, the fact that the system of interest contains a Hamilton–Jacobi equation for the evolution of s, which, in turn, appears in differentiated form as a coefficient in the equations for the evolution of u, restricts the choice to spaces of classical regularity for s. It is indeed impossible to work in Sobolev–Slobodeckii spaces for u as the loss of regularity incurred in taking traces on the boundary cannot be made up for by (1.9), which does not possess any regularizing effect. It becomes clear that spaces of classical regularity for both u and s need to be chosen. In order to use the Fourier multiplier Theorem 2.1 the choice is therefore reduced to spaces of bounded uniformly continuous functions in the x-variable. As far as the y-variable is concerned a good choice is given by the space of continuous functions, as will become clear later. The "base" space E_0 for u is therefore chosen as

$$E_0 := \mathrm{BUC}^{1+\alpha}\big(\mathbb{R}^n, \mathrm{C}(0,1)\big) \tag{3.1}$$

for $\alpha \in (0,1)$ and where $\mathrm{C}(0,1)$ denotes the standard space of continuous functions on $[0,1]$. The space with one less regularity degree in x would seem like a more natural choice, but the choice made here makes it much easier to deal with inhomogeneous Neumann boundary conditions such as (1.8). This point will become clear later in the analysis in section 3.3. In view of the singular nonautonomous nature of the problem, the standard procedures [19] for dealing with inhomogeneous (nonlinear) boundary conditions cannot be utilized.

It follows that a proper choice of "base" space for the full evolutionary problem is given by

$$\mathbb{E}_0 := \mathrm{C}^{\beta}_{\beta}\Big((0,T], \mathrm{BUC}^{1+\alpha}\big(\mathbb{R}^n, \mathrm{C}(0,1)\big)\Big) \tag{3.2}$$

for u and by

$$\mathbb{S} := \mathrm{C}^{1+\beta}\big([0,T], \mathrm{BUC}^{2+\alpha}(\mathbb{R}^n)\big) \cap \mathrm{C}^{\beta}\big([0,T], \mathrm{BUC}^{3+\alpha}(\mathbb{R}^n)\big) \tag{3.3}$$

for s. A closer look at the underlying elliptic problem ($\varepsilon = 0$) is necessary in order to better deal with the inhomogeneous boundary terms in (2.1)–(2.3). The operator $-\triangle_x - \frac{1}{t^2 g^2(x)}\partial_y^2$ has clearly nonconstant coefficients, and multiplier Theorem 2.1 is formulated only in the translation invariant case. It therefore needs to be shown that localization arguments apply in the operator-valued setting considered here.

The first step, however, is to obtain regularity results in the constant coefficient case.

3.1. The elliptic case: Constant coefficients. Consider problem (2.1)–(2.3) and assume that $\varepsilon = 0$ and that c is a constant which can be assumed to be 1 without loss of generality. Then taking a Fourier transform in the x-variables, one obtains a parameter-dependent boundary value problem for $\hat{u}$ which can be solved explicitly. The solution has the structure

$$\hat{u}(t,\xi,\cdot) = t^2\sigma_t c(\xi,\cdot)\hat{f} + t\sigma_t b(\xi,\cdot)\hat{h} + \sigma_t a(\xi,\cdot)\hat{g}, \tag{3.4}$$

where σ_t denotes dilation by $t>0$ and the operator-valued symbols a,b,c are given by

$$a(\xi,\cdot)\;=\;\frac{\cosh\big(|\xi|(1-\cdot)\big)}{\cosh(|\xi|)}\,,\;b(\xi,\cdot)\;=\;\frac{\sinh(|\xi|\cdot)}{|\xi|\cosh(|\xi|)}\,,\;c(\xi,\cdot)\;=\;\big(|\xi|^2+C\big)^{-1}\,. \tag{3.5}$$

The first two symbols have to be considered as multiplication operator–valued with respect to the variable y, whereas the last contains the sectorial operator C which is the operator $-\partial_y^2$ on $\mathrm{C}(0,1)$ with domain

$$\mathrm{dom}(C)=\{u\in\mathrm{C}^2(0,1)\,|\,u(0)=0\,,\;\partial_y u(1)=0\}=:\mathrm{C}^2_{0,0}(0,1)\,. \tag{3.6}$$

The spaces

$$\mathrm{C}^k_0:=\{u\in\mathrm{C}^k(0,1)\,|\,u(0)=0\}\,,\quad k=0,1,$$

will also be needed. Proposition 2.2 can be used in combination with the multiplications (2.6)–(2.9) to obtain regularity results in weighted Hölder spaces, provided (3.5) are in the appropriate symbol class.

THEOREM 3.1. *The symbols* (3.5) *satisfy*

$$\begin{aligned}
&a\in\mathcal{S}^0\big(\mathrm{C}(0,1),\mathrm{C}(0,1)\big)\,,\\
&b\in\mathcal{S}^k\big(\mathrm{C}(0,1),\mathrm{C}^{1-k}_0(0,1)\big)\,,\\
&c\in\mathcal{S}^j\big(\mathrm{C}(0,1),\mathrm{C}^{2-j}_{0,0}(0,1)\big)
\end{aligned}$$

for $k=0,1$ and $j=0,1,2$. The notation for the spaces has to be interpreted so that boundary conditions are imposed only if enough regularity is available but otherwise disregarded.

Proof. Take the last symbol first. It is known that the operator C is sectorial and invertible (cf. [19]). It follows that

$$\|(|\xi|^2+C)^{-1}\|_{\mathcal{L}(\mathrm{C},\mathrm{C}^{2-j})}\le\,c\frac{1}{1+|\xi|^j}\,,\quad j=0,1,2. \tag{3.7}$$

As for the derivatives, it is seen by induction that, for $\xi\neq 0$,

$$\partial^\alpha(|\xi|^2+C)^{-1}=(|\xi|^2+C)^{-1}\sum_{|\beta|\le|\alpha|}p_{\alpha,\beta}(\xi)(|\xi|^2+C)^{-|\beta|}$$

for polynomials $p_{\alpha,\beta}$ of degree at most $|\beta|$. The estimate therefore follows from (3.7). Next consider the "boundary symbols" a and b. A simple series expansion reveals that both symbols are actually analytic functions of ξ^2 (and y of course). It follows that they are smooth for all $\xi\in\mathbb{R}^n$ in spite of appearances. It is therefore legitimate to concentrate on the decay properties of the symbols without necessarily using the nowhere vanishing weight $(1+|\xi|^2)^{1/2}$ needed in the definition of the symbol class. Observe that both are smooth functions of y regardless of ξ. Consequently they define multiplication operators for $\mathrm{C}^{2-k}(0,1)$ and $k=0,1,2$. Also observe that, for b, the smoothing effect in x is due to the decay in ξ. They clearly satisfy the required boundary conditions. They further satisfy the relations

$$\begin{aligned}
\partial_y b(\xi,y)&=a(\xi,1-y)\,,\qquad \partial_y^2 b(\xi,y)=|\xi|^2 b(\xi,y)\,,\\
\partial_y a(\xi,y)&=-|\xi|^2 b(\xi,1-y)\,,\qquad \partial_y^2 a(\xi,y)=|\xi|^2 a(\xi,y)\,,
\end{aligned}$$

which make it easier to derive their mapping and symbol properties from one another. For instance, if it were known that $a, b \in \mathcal{S}^0(\mathrm{C}, \mathrm{C})$, the first relation would imply that $\partial_y b \in \mathcal{S}^0(\mathrm{C}, \mathrm{C})$ and therefore that $b \in \mathcal{S}^0(\mathrm{C}, \mathrm{C}^1)$. The last one, on the same assumptions, would show that $a \in \mathcal{S}^{-2}(\mathrm{C}, \mathrm{C}^2)$. More details are now given for the analysis of symbol a. Corresponding claims for the symbol b can be obtained by similar calculations. The claim is that $a \in \mathcal{S}^0(C, C)$. It is plain that

$$\sup_{\xi \in \mathbb{R}^n} \sup_{y \in [0,1]} |a(\xi, y)| < \infty \,.$$

As for the first derivatives in ξ one has

$$\begin{aligned} \partial_j a(\xi, y) &= \frac{\xi_j}{|\xi|} \frac{1}{\cosh(|\xi|)} \big[(1-y) \sinh(|\xi|(1-y)) - \tanh(|\xi|) \cosh(|\xi|(1-y)) \big] \\ &= \frac{\xi_j}{|\xi|} a(\xi, y) \underbrace{\big[(1-y) \tanh(|\xi|(1-y)) - \tanh(|\xi|) \big]}_{=: d(\xi, y)} \,. \end{aligned} \tag{3.8}$$

The maximum in y is taken either on the boundary $y = 0, 1$ or in the interior. On the boundary it either vanishes or is exponentially decaying in $|\xi|$. It therefore only needs to be controlled in the interior to conclude its estimation. Only the term in brackets on the right-hand side in the first line of (3.8) depends on y. Setting its first y-derivative equal to zero, one arrives at the equation

$$\frac{\tanh(|\xi|(1-y))}{(1-y)|\xi|} = \frac{1}{|\xi| \tanh(|\xi|) - 1},$$

which, for $|\xi|$ large, is asymptotic to

$$\frac{1}{(1-y)|\xi|} \sim \frac{1}{|\xi|} \,.$$

Thus the maximum is located at $y \sim \frac{1}{|\xi|}$ for large $|\xi|$. As for the maximal value for large $|\xi|$ one has

$$\partial_j a \left(\xi, \frac{1}{|\xi|} \right) \sim \frac{\xi_j}{|\xi|} a \left(\xi, \frac{1}{|\xi|} \right) \frac{1}{|\xi|}, \tag{3.9}$$

which entails the desired estimate

$$\sup_{x \in \mathbb{R}^n} \sup_{y \in [0,1]} (1 + |\xi|^2)^{1/2} |\partial_j a(\xi, y)| < \infty \,.$$

Equation (3.9) follows from

$$\left(1 - \frac{1}{|\xi|} \right) \tanh(|\xi| - 1) - \tanh(|\xi|), \tag{3.10}$$

observing that $\tanh(s) = 1$ up to exponentially small terms in s for $s > 0$ large, that is,

$$|\tanh(s) - 1| \leq c e^{-3s} \; s > 0 \,.$$

The second derivative satisfies

$$\partial_i \partial_j a(\xi, y) = \frac{\xi_i \xi_j}{|\xi|^3} a(\xi, y) d(\xi, y) + \frac{\xi_j \xi_j}{|\xi|^2} a(\xi, y) d^2(\xi, y) + \frac{\xi_j}{|\xi|} a(\xi, y) \partial_j d(\xi, y).$$

The first term on the right-hand side can be seen to decay like $1/|\xi|^2$ in view of the explicit prefactor and the estimate obtained for the first derivative (3.8). The second and third terms add up to

$$\frac{\xi_i\xi_j}{|\xi|^2}a(\xi,y)\big[(1-y)^2-1-2(1-y)\tanh(|\xi|)\tanh(|\xi|(1-y))+2\tanh^2(|\xi|)\big].$$

Similar calculations to those performed for the first derivative show that the maximum is now attained at

$$y\sim\frac{2}{|\xi|},$$

and it amounts to

$$\partial_i\partial_j a\left(\xi,\frac{2}{|\xi|}\right)-\frac{\xi_i\xi_j}{|\xi|^3}a\left(\xi,\frac{2}{|\xi|}\right)d\left(\xi,\frac{2}{|\xi|}\right)\sim\frac{4}{|\xi|^2}\,.$$

The latter follows from

$$\left(1-\frac{2}{|\xi|}\right)^2-1-2\left(1-\frac{2}{|\xi|}\right)\tanh(|\xi|-2)\tanh(|\xi|)+2\tanh^2(|\xi|)\sim\frac{4}{|\xi|^2},$$

which uses (3.10) again. In conclusion, it is obtained that

$$\sup_{\xi\in\mathbb{R}^n}\sup_{y\in[0,1]}(1+|\xi|^2)|\partial_i\partial_j a(\xi,y)|<\infty\,.$$

Comparing this with the proof of [16, Lemma 2.2], we see that the arguments are almost identical. The only differences are the additional factors like $\frac{\xi_j}{|\xi|}$ for the first derivative or $\frac{\xi_i\xi_j}{|\xi|^3}$ and $\frac{\xi_i\xi_j}{|\xi|^2}$ for the second. Terms containing these can always be handled through their explicit dependence on ξ and the estimates from previous derivatives. The inductive argument used in [16] can therefore be adapted to the current situation and leads to the desired result. □

Combining these results with Theorem 2.1, Proposition 2.2, and (2.6)–(2.9), we obtain the next important theorem. To simplify its formulation we introduce the abbreviated notation

$$\mathrm{C}^?_?\,\mathrm{BUC}^?\,\mathrm{C}^?_{?,?}$$

for the function spaces

$$\mathrm{C}^?_?\Big((0,T],\mathrm{BUC}^?\big(\mathbb{R}^n,\mathrm{C}^?_{?,?}(0,1)\big)\Big),$$

where the question marks can be substituted by any of the relevant regularity and singularity parameters.

THEOREM 3.2. *Let $\alpha,\beta\in(0,1)$ and $\gamma=0,\beta$. Given*

$$(f,g,h)\in\mathrm{C}^\beta_\gamma\,\mathrm{BUC}^{1+\alpha}\,\mathrm{C}\times\mathrm{C}^\beta_\gamma\,\mathrm{BUC}^{3+\alpha}\times\mathrm{C}^\beta_\gamma\,\mathrm{BUC}^{2+\alpha},$$

there exists a unique solution u of (2.1)–(2.3) *for $c\equiv$ const which belongs to the space*

$$\mathbb{E}_1:=\left\{u\in\mathbb{E}_0\,\Big|\,\partial_x^\alpha\left(\frac{\partial_y}{t}\right)^j u\in\mathbb{E}_0\ \textit{for}\ |\alpha|,j=0,1,2,\ \textit{s.t.}\ |\alpha|+j\le 2\right\},$$

where

$$\mathbb{E}_0 := \mathrm{C}^{\beta}_{\gamma}\,\mathrm{BUC}^{1+\alpha}\,\mathrm{C}\,.$$

It is given by

$$u = \underbrace{\mathcal{F}^{-1}t^2\sigma_t c\mathcal{F}}_{=:A(t)^{-1}} f + \underbrace{\mathcal{F}^{-1}t\sigma_t b\mathcal{F}}_{=:R_N(t)} h + \underbrace{\mathcal{F}^{-1}\sigma_t a\mathcal{F}}_{=:R_D(t)} g\,.$$

Modulo the singularity, the terms in the above representation clearly point to their asymptotic behavior at the origin. This result needs to be extended to the nonconstant coefficient case. This is done in the next section.

Remark 3.1. To make it easier to refer back to the above result in the case $\gamma = 0$, the corresponding spaces will be denoted by $\mathbb{E}_{k,0}$, $k = 0, 1$.

3.2. The elliptic nonconstant coefficient case. In this section we adapt an abstract formulation of a localization argument proposed by Angenent in [5] (see also [4, 3]) for $\mathbb{R}^n$ to cover the case of boundary value problems in an operator-valued context. It is used in combination with the Fourier multiplier Theorem 2.1 to give the basic regularity results needed for the singular elliptic boundary value problem underlying (2.1)–(2.3) in the case of constant coefficients. It should be observed that localization arguments rely on perturbation results for differential operators by lower order terms. These are small compared to the leading order operator only in a qualitative sense. Perturbation results can therefore only be applied for the resolvents with large λ where the decay properties of the inverse to the leading order operator yield smallness of the lower order terms. The structure of the singular operators considered here can be exploited in order to avoid shifting the leading order operator and in order to obtain direct invertibility results. The standard argument of course shows that nonconstant coefficient operators are sectorial whenever their constant coefficient counterpart is (see [5]). This remains valid here and can be used if the time variable is kept fixed.

The goal of this section is to extend the validity of Theorem 3.2 to the nonconstant coefficient singular boundary value problem

$$\left(\mathcal{A}(t), \gamma_0, \frac{1}{t}\gamma_1\partial_y\right) : \mathbb{E}_1 \to \mathbb{E}_0 \times \partial\mathbb{E}_1, \tag{3.11}$$

where $\mathcal{A}(t)$ is the elliptic operator driving the evolution in (2.1) and the "boundary space" $\partial\mathbb{E}_1$ is defined by

$$\partial\mathbb{E}_1 = \mathrm{C}^{\beta}_{\gamma}\,\mathrm{BUC}^{3+\alpha} \times \mathrm{C}^{\beta}_{\gamma}\,\mathrm{BUC}^{2+\alpha} =: \partial_D\mathbb{E}_1 \times \partial_N\mathbb{E}_1\,, \quad \gamma = 0, \beta\,. \tag{3.12}$$

Observe that Theorem 3.2 simply states that the above singular boundary value problem has a bounded inverse in the given topologies and for constant coefficients. The localization procedure proposed in [5] is abstract and is based on the concept of resolution. A resolution of a Banach space E is simply a triple (F, ε, δ), where F is a Banach space and the maps $\delta : E \to F$ and $\varepsilon : F \to E$ satisfy $\varepsilon \circ \delta = \mathrm{id}_E$. The operator δ plays the role of the localizing operator, whereas ε resynthesizes the local contributions. If the space E has subspaces of interest, they should correspond to "similar subspaces" of F and should be left invariant by the resolution maps. The localization operator can be constructed as follows:

$$\delta : \mathbb{E}_j \to \oplus_{k\in\mathbb{Z}}\mathbb{F}^k_j\,, \quad u \mapsto (u_k)_{k\in\mathbb{Z}^n} := (u\varphi_{k,r})_{k\in\mathbb{Z}^n}\,, \quad j = 0, 1,$$

where $\mathbb{F}_j^k = \mathbb{E}_j$ for $k \in \mathbb{Z}^n$ and the sequence space $\oplus_{k\in\mathbb{Z}}\mathbb{F}_j^k$ is endowed with the supremum norm $\sup_{k\in\mathbb{Z}} \|u_k\|_{\mathbb{F}_j}$. The maps $(\varphi_{k,r}^2)_{k\in\mathbb{Z}^n}$ are chosen as to form a smooth resolution of the identity in $\mathbb{R}^n$,

$$\sum_{k\in\mathbb{Z}^n} \varphi_{k,r}^2 \equiv 1,$$

subordinated to a cover by cubes $Q_{k\in\mathbb{Z}^n,r}$ of fixed side length $r > 0$ obtained by translation and dilation of the standard cube of side size $r = 1$ centered at the origin. The support of $\varphi_{k,r}$ should contain $Q_{k,r}$ and be contained in the union of at most finitely many adjacent cubes. The synthesis operator is then given by

$$\varepsilon : \oplus_{k\in\mathbb{Z}}\mathbb{F}_j^k \to \mathbb{E}_j\,, \quad (u_k)_{k\in\mathbb{Z}^n} \mapsto \sum_{k\in\mathbb{Z}^n} u_k\varphi_{k,r},$$

in which case the relation defining a resolution is clearly satisfied. Observe that the mappings δ and ε are continuous. The idea is to define an operator on $\oplus_{k\in\mathbb{Z}}\mathbb{F}_1$ which parallels the boundary value problem (3.11) and to use its inverse to approximate the desired inverse of (3.11) via the use of the maps ε and δ. Define the operator $(\mathcal{A}', \mathcal{B}')$ on $\oplus_{k\in\mathbb{Z}}\mathbb{F}_1$ through

$$(\mathcal{A}^k, \mathcal{B}^k)u_k = \left(-\triangle_x u_k - \frac{1}{t^2 c_k(x)}\partial_y^2 u_k, \gamma_0 u_k, \frac{1}{t}\gamma_1\partial_y u_k\right),$$

where $c_k|_{\mathrm{supp}(\varphi_{k,r})} = c|_{\mathrm{supp}(\varphi_{k,r})}$ and c_k is otherwise smoothly extended without increasing its norm to the whole space (the details of the extension procedure can be found in [4, 3]). The boundary value problem $(\mathcal{A}^k, \mathcal{B}^k)$ can be made arbitrarily close to a constant coefficient one, say, by substituting c_k by $c_k(x_k)$ and making r small. It is therefore invertible and enjoys the properties claimed in Theorem 3.2. The diagonal operator $(\mathcal{A}', \mathcal{B}')$ is then invertible itself and maps $\oplus_{k\in\mathbb{Z}}\big[\mathbb{F}_1 \times \partial\mathbb{F}_1\big]$ to $\oplus_{k\in\mathbb{Z}}\mathbb{F}_0$, where $\partial\mathbb{F}_1$ is defined in the obvious way. Denote by $\begin{bmatrix} A'(t)^{-1} & R'_D(t) & R'_N(t)\end{bmatrix}$ its inverse. Then

$$\varepsilon \begin{bmatrix} A'(t)^{-1} & R'_D(t) & R'_N(t)\end{bmatrix} \delta \tag{3.13}$$

should represent an approximation to the solution operator for the singular boundary value problem (2.1)–(2.3). In order to show this, it needs to be shown that (3.13) is an approximate left and right inverse. Starting with the latter, compute

$$\begin{bmatrix} \mathcal{A}(t) \\ \gamma_0 \\ \frac{1}{t}\gamma_1\partial_y \end{bmatrix} \varepsilon \begin{bmatrix} A'(t)^{-1} & R'_D(t) & R'_N(t)\end{bmatrix} \delta \tag{3.14}$$

$$= \begin{bmatrix} \mathrm{id}_{\mathbb{E}_0} + [\mathcal{A}(t), \varepsilon]A'(t)^{-1}\delta & [\mathcal{A}(t)\,, \varepsilon]\, R'_D(t)\delta & [\mathcal{A}(t)\,, \varepsilon]\, R'_N(t)\delta \\ 0 & \mathrm{id}_{\gamma_0\mathbb{E}_1} & 0 \\ 0 & 0 & \mathrm{id}_{\gamma_1\partial_y\mathbb{E}_1} \end{bmatrix},$$

where $[\mathcal{A}(t), \varepsilon] = \mathcal{A}(t)\varepsilon - \varepsilon\mathcal{A}(t)'$. Invertibility would follow if

$$\mathrm{id}_{\mathbb{E}_0} + [\mathcal{A}(t), \varepsilon]A'(t)^{-1}\delta \tag{3.15}$$

were invertible. Here the specific structure of the operator $\mathcal{A}(t)$ needs to be exploited since standard perturbation arguments would only allow us to show that the resolvent

$\mathcal{R}(\lambda, \mathcal{A})$ exists for large enough λ, in which case the lower order commutator term is small. The commutator term (3.15) can be computed to give

$$\sum_{k\in\mathbb{Z}^n} \left[2(\nabla\varphi_{k,r}|\nabla\cdot) + \triangle\varphi_{k,r}\cdot\right] \left[-\triangle_x - \frac{1}{t^2c_k^2(x)}\partial_y^2\right]^{-1} \varphi_k f\,. \tag{3.16}$$

To see that the inverse appearing in (3.16) does indeed exist on the desired spaces, observe that $r > 0$ can be chosen such that

$$-\triangle_x - \frac{1}{t^2c_k^2(x)}\partial_y^2 + \triangle_x + \frac{1}{t^2c_k^2(x_k)}\partial_y^2 = \left[\frac{1}{c_k^2(x)} - \frac{1}{c_k^2(x_k)}\right]\frac{1}{t^2}\partial_y^2$$

is small in $\mathcal{L}(\mathbb{E}_1, \mathbb{E}_0)$. The realization A^k of $\mathcal{A}^k$ with homogeneous boundary conditions is therefore invertible, and the constant coefficient estimates of Theorem 3.2 carry over to it (with larger constants, of course). Now, the estimates

$$\left\|2\nabla\varphi_{k,r}\nabla\left[-\triangle_x - \frac{1}{t^2c_k^2(x)}\partial_y^2\right]^{-1}\right\|_{\mathcal{L}(\mathbb{E}_0)} \le cT \quad \text{and}$$

$$\left\|\triangle\varphi_{k,r}\left[-\triangle_x - \frac{1}{t^2c_k^2(x)}\partial_y^2\right]^{-1}\right\|_{\mathcal{L}(\mathbb{E}_0)} \le cT^2$$

show that the commutator is indeed small, at least for T small enough. Here the decay properties of the resolvent as $t \to 0$ are used as a substitute for making λ large in the standard argument. Heuristically this makes sense, since making t small, just as making λ large, makes the operator "more and more elliptic." This is due to the specific nature of the singular operator. Since the difficulty of the problem stems from the origin, making T small does not in any way weaken the result.

Next it needs to be shown that (3.13) is also a good approximation for a left inverse. To that end, observe that

$$u - \varepsilon\big(\mathcal{A}'(t), \mathcal{B}'(t)\big)^{-1}\delta\big(\mathcal{A}(t), \mathcal{B}(t)\big)u$$

is the same as

$$u - \left(\varepsilon A'(t)^{-1}\delta\mathcal{A}(t)u + \varepsilon R'_D(t)\delta\gamma_0 u + \varepsilon R'_N(t)\delta\gamma_1\frac{\partial_y}{t}u\right) = \varepsilon A'(t)^{-1}[\mathcal{A}(t), \delta]u \tag{3.17}$$

because

$$u = \varepsilon A'(t)^{-1}\mathcal{A}'(t)\delta u + \varepsilon R'_D(t)\delta\gamma_0 u + \varepsilon R'_N(t)\gamma_1\frac{\partial_y}{t}u$$

by definition. The notation

$$[\mathcal{A}(t), \delta] = \mathcal{A}'(t)\delta - \delta\mathcal{A}(t)$$

was used in (3.17). It follows that

$$\varepsilon\big(\mathcal{A}'(t), \mathcal{B}'(t)\big)^{-1}\delta\big(\mathcal{A}(t), \mathcal{B}(t)\big) = \mathrm{id}_{\mathbb{E}_1} - \varepsilon A'(t)^{-1}[\mathcal{A}(t), \delta].$$

The term containing the commutator is lower order and can be estimated just as before, exploiting the structure of $\mathcal{A}(t)$ in order to yield the invertibility of

$$\mathrm{id}_{\mathbb{E}_1} - \varepsilon A'(t)^{-1}[\mathcal{A}(t), \delta]$$

and, thus, a left inverse for the singular boundary value problem. The result is summarized in the next theorem.

THEOREM 3.3. *Let $\alpha,\beta\in(0,1)$, $\gamma=0,\beta$, and $0<c_0\le c\in \mathrm{BUC}^{1+\alpha}$. Given*

$$(f,g,h)\in \mathrm{C}^{\beta}_{\gamma}\,\mathrm{BUC}^{1+\alpha}\,\mathrm{C}\times \mathrm{C}^{\beta}_{\gamma}\,\mathrm{BUC}^{3+\alpha}\times \mathrm{C}^{\beta}_{\gamma}\,\mathrm{BUC}^{2+\alpha},$$

there exists a unique solution u of (2.1)–(2.3) which belongs to the space

$$\mathbb{E}_1:=\left\{u\in\mathbb{E}_0\,\Big|\,\partial_x^{\alpha}\left(\frac{\partial_y}{t}\right)^{j}u\in\mathbb{E}_0 \text{ for } |\alpha|,j=0,1,2 \text{ s.t. } |\alpha|+j\le 2\right\},$$

where

$$\mathbb{E}_0:=\mathrm{C}^{\beta}_{\gamma}\,\mathrm{BUC}^{1+\alpha}\,\mathrm{C}\,.$$

It naturally splits into three components,

$$u=\tilde A(t)^{-1}f+\tilde R_N(t)h+\tilde R_D(t)g,$$

with the same asymptotic behavior at the origin as in the constant coefficient case and where

$$\tilde A(t)^{-1}f=\big(\mathcal{A}(t),\mathcal{B}(t)\big)^{-1}(f,0,0)\,,\quad \tilde R_D(t)g=\big(\mathcal{A}(t),\mathcal{B}(t)\big)^{-1}(0,g,0),$$
$$\text{and } \tilde R_N(t)h=\big(\mathcal{A}(t),\mathcal{B}(t)\big)^{-1}(0,0,h),$$

respectively.

Proof. The only part of the proof missing is for the claim about the asymptotic behavior of the solution. It is obtained using the representation

$$\begin{bmatrix} T & -T[\mathcal{A}(t),\varepsilon]\,R_D'(t)\delta & -T[\mathcal{A}(t),\varepsilon]\,R_N'(t)\delta\\ 0 & \mathrm{id}_{\gamma_0\mathbb{E}_1} & 0\\ 0 & 0 & \mathrm{id}_{\gamma_1\partial_y\mathbb{E}_1}\end{bmatrix}$$

for the inverse of

$$\begin{bmatrix} \mathrm{id}_{\mathbb{E}_0}-[\mathcal{A}(t),\varepsilon]A'(t)^{-1}\delta & [\mathcal{A},\varepsilon]R_D'(t)\delta & [\mathcal{A}(t),\varepsilon]R_N'(t)\delta\\ 0 & \mathrm{id}_{\gamma_0\mathbb{E}_1} & 0\\ 0 & 0 & \mathrm{id}_{\gamma_1\partial_y\mathbb{E}_1}\end{bmatrix},$$

where $T=\big[\mathrm{id}_{\mathbb{E}_0}-[\mathcal{A}(t),\varepsilon]A'(t)^{-1}\delta\big]^{-1}$, the factorization of the resolvent implied by (3.14) and the mapping properties for the operators involved which follow from the symbol analysis combined with Theorem 2.1, Proposition 2.2, and (2.6)–(2.9). Take, for instance, the entry $T\mathcal{A}(t)\,\varepsilon\,R_D'(t)\delta$. The claim follows from

$$T\in\mathcal{L}(\mathbb{E}_0),\quad \mathcal{A}\in\mathcal{L}(\mathbb{E}_1,\mathbb{E}_0),\quad \text{and}\quad \varepsilon R_D'\delta\in\mathcal{L}(\partial_D\mathbb{E}_1,\mathbb{E}_1)\,.\qquad \square$$

From now on the tildes on the solution operators of the nonconstant coefficient case will be omitted. Since the corresponding operators in the constant coefficient case will no longer be used in the analysis, no confusion seems likely.

3.3. The parabolic problem. It is now possible to return to the analysis of the model problem (2.1)–(2.3) for $\varepsilon = 1$. If the boundary conditions are homogeneous, then Theorem 2.3 gives existence and regularity of a solution $u \in \mathbb{E}_1$ whenever $f \in \mathbb{E}_0$. The notation $\mathbb{E}_1$ (see Theorem 3.2) has been used so far to describe the regularity space of the singular elliptic boundary value problem. In the parabolic case the same notation indicates the space

$$\mathbb{E}_1 := \left\{ u \in \mathbb{E}_0 \,\middle|\, \partial_t u \in \mathbb{E}_0\,,\ \partial_x^\alpha \left(\frac{\partial_y}{t}\right)^j u \in \mathbb{E}_0 \text{ for } |\alpha|, j = 0,1,2,\ \text{s.t. } |\alpha| + j \le 2 \right\}$$

in accordance with Theorem 2.3. To obtain optimal regularity results for

$$A(t) = \triangle_x + \frac{1}{t^2 c^2(x)} C$$

it is therefore sufficient to check that conditions (2.11)–(2.13) are satisfied. The operator C was defined in (3.6). Freezing coefficient arguments such as those in [4, 3] or [5] show that $A(t)$ does indeed generate an analytic semigroup on E_0 for each fixed $t > 0$, which is exponentially decaying since C is invertible (see also the beginning paragraph of subsection 3.2). Estimates (2.12)–(2.13) follow from the regularity theory developed in the previous section and the fact that $A(t)$ generates an exponentially decaying analytic semigroup. The latter makes it possible, in particular, to define the fractional power appearing in (2.12) (see [19] for more details). Condition (2.13) follows from

$$\|A(t)^{-1}\|_{\mathcal{L}(\mathbb{E}_0)} \le cT^2,$$

which, in turn, follows from the observation that $(\frac{1}{c^2(x)} C)^{-1}$ is bounded in $\mathbb{E}_0$ and from

$$A(t)^{-1} = t^2 \left(t^2 \triangle_x + \frac{1}{c^2(x)} C \right)^{-1}.$$

The first condition in (2.12) follows from

$$\big[A(t) - A(s)\big] A(\tau)^{-1} = \frac{(t^2 - s^2)\tau^2}{t^2 s^2} \frac{C}{c^2(x)} \left[-\tau^2 \triangle_x + \frac{C}{c^2(x)} \right]^{-1}$$

and the fact that

$$\left\| \frac{C}{c^2(x)} \left[-\tau^2 \triangle_x + \frac{C}{c^2(x)} \right]^{-1} \right\|_{\mathcal{L}(\mathbb{E}_0)}$$

is uniformly bounded for $\tau \in (0, T]$. The second condition in (2.12) follows similarly by using abstract mapping properties of fractional powers and, in particular, that

$$\left\| \left[-\tau^2 \triangle_x + \frac{C}{c^2(x)} \right]^{-\rho+1} \right\|_{\mathcal{L}(\mathbb{E}_0)} \le c\,.$$

It remains to be shown that problem (2.1)–(2.3) can be solved for inhomogeneous boundary conditions as well. The result is formulated in the next theorem.

THEOREM 3.4. *Let* $c \in \mathrm{BUC}^{1+\alpha}$ *and*

(3.18)
$$f \in \mathbb{E}_0\,, \quad g \in \mathrm{C}^{\beta}_{\beta}\,\mathrm{BUC}^{3+\alpha} \cap \mathrm{C}^{1+\beta}_{\beta}\,\mathrm{BUC}^{1+\alpha}\,, \quad h \in \mathrm{C}^{\beta}_{\beta}\,\mathrm{BUC}^{2+\alpha} \cap \mathrm{C}^{1+\beta}_{\beta}\,\mathrm{BUC}^{\alpha}\,.$$

Then there exists a unique solution $u \in \mathbb{E}_1$ *of* (2.1)–(2.3).

Proof. It can be assumed without loss of generality that $f \equiv 0$. Looking for a solution u in the form

$$u = v + R_D(t)g + R_N(t)h,$$

one obtains that v satisfies

$$\dot v - A(t)v = \frac{d}{dt}\big[R_D(t)g + R_N(t)h\big]\,.$$

Using (2.1)–(2.3), it can be checked that

$$\frac{d}{dt}\big[R_D(t)g\big] = \frac{2}{t}A(t)^{-1}\triangle_x R_D(t)g + R_D(t)\dot g,$$
$$\frac{d}{dt}\big[R_N(t)h\big] = \frac{2}{t}A(t)^{-1}\triangle_x R_N(t)h + \frac{1}{t}R_N(t)h + R_N(t)\dot h\,.$$

The regularity results obtained in the previous section combined with the assumptions then imply that

$$\left\{t \mapsto \frac{d}{dt}\left[R_D(t)g + R_N(t)h\right]\right\} \in \mathbb{E}_0\,.$$

Take, for instance, $\big[t \mapsto \frac{2}{t}A(t)^{-1}\triangle_x R_D(t)g\big]$ and observe that

$$R_D \in \mathcal{L}(\partial_D\mathbb{E}_1, \mathbb{E}_1)\,, \quad \triangle_x \in \mathcal{L}(\mathbb{E}_1, \mathbb{E}_0), \quad \text{and} \quad \left[t \mapsto \frac{2}{t}A(t)^{-1}\right] \in \mathcal{L}(\mathbb{E}_0)$$

or $R_D(t)\dot g$, in which case the stated regularity follows from

$$\dot g \in \gamma_0\mathbb{E}_0 \quad \text{and} \quad R_D \in \mathcal{L}(\gamma_0\mathbb{E}_0, \mathbb{E}_0).$$

The fact that $R_D \in \mathcal{L}(\gamma_0\mathbb{E}_0, \mathbb{E}_0)$ has not been explicitly proven but can be obtained by symbol analysis and freezing coefficients along the lines of sections 3.1 and 3.2. The claim then follows from Theorem 2.3. □

4. The Hamilton–Jacobi equation. Consider the Hamilton–Jacobi equation

$$s_t - \sqrt{1 + |\nabla s|^2}\, v = 0 \quad \text{in } (0,\infty)\times\mathbb{R}^n\,, \tag{4.1}$$
$$s(0,\cdot) \equiv 0 \quad \text{on } \mathbb{R}^n \tag{4.2}$$

for a given $v \in \mathrm{C}^{\beta}\,\mathrm{BUC}^{3+\alpha}$ satisfying $v(0,\cdot) = g$. The method of characteristics allows one to recast this Hamilton–Jacobi equation as a system of ODEs in the following manner:

$$\dot t = 1\,, \qquad t(0) = 0\,, \tag{4.3}$$
$$\dot x = -\frac{p}{\sqrt{1+|p|^2}}\, v(t,x)\,, \qquad x(0) = \rho \in \mathbb{R}^n\,, \tag{4.4}$$
$$\dot z = r - \frac{|p|^2}{\sqrt{1+|p|^2}}\, v(t,x)\,, \quad z(0) = 0\,, \tag{4.5}$$
$$\dot r = \sqrt{1+|p|^2}\,\partial_t v(t,x)\,, \qquad r(0) = g(\rho), \tag{4.6}$$
$$\dot p = \sqrt{1+|p|^2}\,\nabla_x v(t,x)\,, \qquad p(0) = 0\,. \tag{4.7}$$

This system is easily seen to reduce to

$$\dot{x} = -\frac{p}{\sqrt{1+|p|^2}}\, v(t,x)\,, \quad x(0) = \rho \in \mathbb{R}^n\,, \tag{4.8}$$

$$\dot{p} = \sqrt{1+|p|^2}\, \nabla_x v(t,x)\,, \quad p(0) = 0, \tag{4.9}$$

as all other unknowns can be obtained after solving this reduced system. The assumption on v makes it possible to solve this system on a possibly small time interval $[0,T]$ which is independent of $\rho \in \mathbb{R}^n$. Exploiting the regularity assumption on v, it can easily be seen that the flow mapping

$$(X_t, P_t) : \mathbb{R}^{2n} \to \mathbb{R}^{2n}\,, \quad (\rho,\eta) \mapsto \big(x(t,\rho,\eta), p(t,\rho,\eta)\big)$$

satisfies

$$[t \mapsto (X_t, P_t)] \in \mathrm{C}^\beta\, \mathrm{BUC}^{2+\alpha}(\mathbb{R}^{2n}, \mathbb{R}^{2n}),$$

where the map is obtained by solving system (4.8)–(4.9) with the second initial condition substituted by $p(0) = \eta$. It is clearly a flow of diffeomorphisms. Furthermore, since an equation satisfied by $(D_\rho x, D_\rho p)$ is easily derived from (4.8)–(4.9) and since

$$\big(D_\rho x(0,\rho,\eta), D_\rho p(0,\rho,\eta)\big) = (\mathrm{id}_{\mathbb{R}^n}, 0)\,,$$

it follows that $D_\rho X_t(\rho, 0)$ satisfies

$$\|\,\mathrm{id}_{\mathbb{R}^n} - D_\rho X_t(\rho,0)\| \le \frac{1}{2}$$

uniformly in $\rho \in \mathbb{R}^n$. This implies that $X_t(\cdot, 0)$ is a diffeomorphism and yields uniform estimates for the inverse of X_t. It follows that

$$[t \mapsto (X_t)^*]\,,\ [t \mapsto (X_t)_*] \in \mathrm{C}^\beta\, \mathcal{L}(\mathrm{BUC}^{2+\alpha}), \tag{4.10}$$

where we denoted the pull-back and push-forward with X_t by $(X_t)^*$ and $(X_t)_*$, respectively. Moreover, these operators are uniformly bounded in the norm in a small time interval.

THEOREM 4.1. *Assume that $v \in \mathrm{C}^\beta\, \mathrm{BUC}^{3+\alpha}$ is given with $v(0) = g \in \mathrm{BUC}^{3+\alpha}$. Then, for $T > 0$ small enough, there exists a unique solution s of (4.1)–(4.2) on $[0,T]$ with*

$$s \in \mathrm{C}^{1+\beta}\, \mathrm{BUC}^{2+\alpha} \cap \mathrm{C}^\beta\, \mathrm{BUC}^{3+\alpha}\ .$$

The existence interval is independent of v in a neighborhood of g. Furthermore, if $v_1, v_2 \in \mathrm{C}^\beta\, \mathrm{BUC}^{3+\alpha}$ are such that $v_1(0) = v_2(0) = g$, then

$$\begin{aligned}\|s_1 - s_2\|_{\mathrm{C}^{1+\beta}\,\mathrm{BUC}^{2+\alpha} \cap \mathrm{C}^\beta\,\mathrm{BUC}^{3+\alpha}} \\ \le\ cT\, \|v_1 - v_2\|_{\mathrm{C}^\beta\,\mathrm{BUC}^{3+\alpha}} + c\, \|v_1 - v_2\|_{\mathrm{C}^\beta\,\mathrm{BUC}^{2+\alpha}}\,.\end{aligned} \tag{4.11}$$

Proof. The solution can be computed by solving the reduced system of characteristic equations (4.8)–(4.9), which produces in particular the diffeomorphisms X_t. A minimal interval of existence can be chosen independently of the initial conditions thanks to the assumptions on v. Next

$$\nabla_x s(t,x) = p\big(t, X_t^{-1}(x), 0\big),$$

together with the discussion preceding the formulation of the theorem, in particular (4.10), shows that

$$s \in \mathrm{C}^{\beta}\,\mathrm{BUC}^{3+\alpha}\ .$$

The desired time regularity has to be backed out from (4.5)–(4.6). The time derivative appearing on the right-hand side of (4.6) is obviously not welcome in view of the assumptions made on v. It is, however, possible to rewrite the term containing said time derivative while integrating the equation to read

$$\begin{aligned}(4.12)\quad r(t,x) &= \sqrt{1+|p(t,x)|^2}v\big(t,x\big)\\ &\quad -\int_0^t [v\nabla_x v\cdot p]\big(\tau, X_\tau(X_t^{-1}(x))\big)\,d\tau - \int_0^t \left[\frac{|p|^2}{\sqrt{1+|p|^2}}v\right]\big(\tau, X_\tau(X_t^{-1}(x))\big)\,d\tau\,.\end{aligned}$$

The solution s can then be obtained by one further integration from (4.5). By (4.10) and the regularity assumption on v it then follows that

$$s \in \mathrm{C}^{1+\beta}\,\mathrm{BUC}^{2+\alpha}\ .$$

The use of this argument needs to be justified. This can be done by substituting v by a regularized version of it which is differentiable in time and for which the partial integration used to obtain (4.12) can safely be performed. Letting it converge back to the original function v produces a function satisfying the modified equation. Since the solution of the original problem can be constructed by solving only the reduced problem (4.8)–(4.9), no trouble is encountered in taking the limit.

The additional estimate follows from the characteristic system (4.3)–(4.7), the regularity assumptions on v_1, v_2, and the fact that $v_1(0) - v_2(0) = 0$. □

5. Existence result. The local existence result for regular solutions of (1.1)–(1.5) is based on the analysis of (1.6)–(1.10). The regularity theory for linear singular elliptic and parabolic problems described in the previous sections and the analysis for the Hamilton–Jacobi equation performed in the last section will be the main tools. It should be kept in mind that $\varepsilon = 1$ without loss of generality. To better highlight the structure of the problem and the use of the linear regularity theory, it is convenient to rewrite (1.6)–(1.8) using (1.9) in the form

$$\dot u - \widetilde{\mathcal{A}}(t)u = \overline{\mathcal{A}}(s)u \quad \text{in } S, \tag{5.1}$$

$$u = g \qquad \text{on } \Gamma_0, \tag{5.2}$$

$$\frac{1}{t}\partial_y u = H(s,u) \text{ on } \Gamma_1, \tag{5.3}$$

where $\widetilde{\mathcal{A}}(t) = \triangle_x + \frac{1}{t^2 g^2(x)}\partial_y^2 + \frac{y}{t}\partial_y$ and the operator $\overline{\mathcal{A}}(s)$ is defined by

$$\begin{aligned}\overline{\mathcal{A}}(s)u = \left[\frac{1+y^2|\nabla s|^2}{s^2} - \frac{1}{t^2 g^2(x)}\right]\partial_y^2 u + y\left[\frac{\dot s}{s} - \frac{1}{t}\right]\partial_y u - 2y\frac{1}{s}\big(\nabla s\big|\partial_y\nabla u\big)\\ - y\frac{s\triangle s - 2|\nabla s|^2}{s^2}\partial_y u\end{aligned}$$

and $H(s,u)$ is given by

$$H(s,u) = \frac{s}{t}\frac{1}{1+|\nabla s|^2}\big(\nabla s\big|\nabla u\big) - \frac{s}{t}\frac{1}{\sqrt{1+|\nabla s|^2}}u(1+u)\,,$$

respectively.

Remark 5.1. It should be observed that the operator family $\widetilde{\mathcal{A}}(t)$ does not coincide with the one considered in the sections devoted to elliptic and parabolic regularity theory and denoted by $A(t)$. It is, however, easy to check that it enjoys the same "singular" elliptic regularity theory, as a perturbation argument shows:

$$\widetilde{A}(t) = A(t)\left[\mathrm{id}_{\mathbb{E}_1} + A^{-1}(t)\frac{y}{t}\partial_y\right] = \left[\mathrm{id}_{\mathbb{E}_0} + \frac{y}{t}\partial_y A^{-1}(t)\right] A(t).$$

Associated with the new family, there will be boundary solution operators $\widetilde{R}_D(t)$ and $\widetilde{R}_N(t)$ with corresponding mapping properties. These new boundary operators are actually given by

$$\widetilde{R}_D(t) = R_D(t) + \widetilde{A}(t)^{-1}\left[\frac{y}{t}\partial_y R_D(t)\right] \quad \text{and} \quad \widetilde{R}_N(t) = R_N(t) + \widetilde{A}(t)^{-1}\left[\frac{y}{t}\partial_y R_N(t)\right],$$

where R_D and R_N are the original boundary operators. From now on the old notation will apply to the new operators.

Assume now that $s \in \mathbb{S}$, that is, that $s \in \mathrm{C}^{1+\beta}\,\mathrm{BUC}^{2+\alpha} \cap \mathrm{C}^{\beta}\,\mathrm{BUC}^{3+\alpha}$ is chosen in a small ball about the function $[t \mapsto tg(x)]$ (in the natural norm of $\mathbb{S}$) and satisfying

$$s(0) = 0\,, \qquad \dot{s}(0) = g\,. \tag{5.4}$$

It can be verified that the operator $\overline{\mathcal{A}}(s) \in \mathcal{L}(\mathbb{E}_1, \mathbb{E}_0)$ is small in the operator norm if the time interval length $T > 0$ is chosen small (this is the reason the modified operator $\widetilde{A}(t)$ is introduced; see Remark 5.1). This structure will be useful in the proof of the following existence result.

THEOREM 5.1. *Let $s \in \mathbb{S}$ be given with the above properties* (5.4)*, $g \in \mathrm{BUC}^{4+\alpha}$, and let $T > 0$ be small. Then there exists a unique solution $u \in \mathbb{E}_1$ of* (5.1)–(5.3)*, which is the fixed point of the operator*

$$\Phi_1(u) = v + R_D(t)g + R_N(t)H(s,u),$$

where v solves

$$\dot{v} - A(t)v = \overline{\mathcal{A}}(s)u - \frac{2}{t}A^{-1}(t)\left[\triangle_x + \frac{y}{t}\partial_y\right]\left[R_D(t)g + R_N(t)H(s,u)\right]. \tag{5.5}$$

Moreover, for $s_1, s_2 \in \mathbb{S}$, the estimates

$$\begin{aligned} \|\gamma_1 u_1 - \gamma_1 u_2\|_{\mathrm{C}^{\beta}\,\mathrm{BUC}^{3+\beta}} &\le c\|s_1 - s_2\|_{\mathbb{S}^{\beta}}\,, \\ \|\gamma_1 u_1 - \gamma_1 u_2\|_{\mathrm{C}^{\beta}\,\mathrm{BUC}^{2+\beta}} &\le cT^{\beta}\|s_1 - s_2\|_{\mathbb{S}^{\beta}} \end{aligned} \tag{5.6}$$

hold.

Proof. As already pointed out, the existence proof relies on maximal regularity results obtained in the previous sections, which are at the heart of the matter and now make it possible to use a simple Banach fixed point argument. The fixed point u will be looked for in the set $\{u \in \overline{\mathbb{B}}_{\mathbb{E}_1}(g,r) \mid u(0) = g\}$ for positive r to be fixed later. This set is endowed with the $\mathbb{E}_1$ topology and is therefore complete. It is easy but tedious to show that $v, R_N(t)H(s,u)$ are in $\mathbb{E}_1 \cap \mathbb{E}_{0,0}$. The first regularity claim follows directly from Theorems 3.3 and 3.4 both for v and $R_N(t)H(s,u)$. The vanishing property for v follows from its regularity using the equations it satisfies. Its regularity readily implies that $\partial_y^2 v(t=0) \equiv 0$. Since v satisfies homogeneous boundary conditions

$$v(y=0) = 0 = \partial_y v(y=1)$$

it then is $v(t=0)\equiv 0$. As for the boundary term $R_N(t)H(s,u)$ it follows from

$$\frac{1}{t}R_N(t)\in\mathcal{L}\big(\mathrm{C}_0^\beta\,\mathrm{BUC}^{1+\alpha},\mathbb{E}_{0,0}\big)$$

combined with

$$tH(s,u)\in\mathrm{C}_0^\beta\,\mathrm{BUC}^{1+\alpha}$$

or, alternatively, also from the equations. Finally, the equations also imply that

$$\partial_y^2R_D(0)g\equiv 0\,,\quad R_D(0)g(y=0)=g\,,\quad \partial_yR_D(0)g(y=1)=0\,.$$

It clearly follows that $R_D(0)g\equiv g$. Summarizing, it is obtained that $\Phi_1(u)(0)=g$. Next a norm estimate for $\Phi_1(u)-g$ is needed. The term $R_D(t)g-g$ can be estimated by some fixed constant r_1. As for the other boundary term, one has that

$$\left\|\frac{R_N(t)}{t}[tH(s,u)]\right\|_{\mathbb{E}_1}\ \le\ cr(1+r)T^\beta\|s\|_{\mathbb{S}},$$

and it can therefore be made arbitrarily small by reducing the interval length. The above estimate is possible since the map $[t\mapsto tH(s,u)]$ vanishes at the origin in view of the properties of s. Next v has to be estimated. Most terms can simply be estimated in a way that they produce a factor T^β and can be made arbitrarily small by interval length reduction. This is due to the fact that

$$\|v\|_{\mathbb{E}_1}\le\|\big(\partial_t-A(t)\big)^{-1}\|_{\mathcal{L}(\mathbb{E}_0,\mathbb{E}_1)}\|F(s,u)\|_{\mathbb{E}_0},$$

where $F(s,u)$ summarizes the terms on the right-hand side of (5.5), and the specifics of F. Consider, for instance, the first term $\overline{\mathcal{A}}(s)u$. Since $\overline{\mathcal{A}}(s)$ vanishes at the origin, it can be seen that

$$\|\overline{\mathcal{A}}(s)\|_{\mathcal{L}(\mathbb{E}_1,\mathbb{E}_0)}\le cT^\beta\|\dot s\|_{\mathcal{S}},$$

which implies the claimed estimate. The estimate for the second term follows from the fact that

$$\left\|\frac{1}{t}A(t)^{-1}\right\|_{\mathcal{L}(\mathbb{E}_0)}\le cT$$

and the general mapping properties of the operators involved. All remaining terms but one can be handled similarly. All terms in $\frac{d}{dt}[tH(s,u)]$ containing either s or ∇s are going to lead to more terms vanishing at the origin. The term

$$\frac{R_N(t)}{t}\left[\frac{\dot s}{\sqrt{1+|\nabla s|^2}}u(1+u)\right]$$

behaves slightly differently and needs separate consideration since $\dot s u(1+u)/\sqrt{1+|\nabla s|^2}$ does not vanish at the origin. Rewriting this term as

$$\frac{R_N(t)}{t}\left[\frac{\dot s}{\sqrt{1+|\nabla s|^2}}u(1+u)-g^2(1+g)\right]+\frac{R_N(t)}{t}[g^2(1+g)]$$

and using the fact that $u(0) = g$ up to vanishing terms of type T^β, it follows that

$$\left\| \frac{R_N(t)}{t} \left[\frac{\dot{s}}{\sqrt{1+|\nabla s|^2}} u(1+u) \right] \right\|_{\mathbb{E}_0} \leq r_2 + cr^2 T^\beta \|s\|_{\mathbb{S}},$$

where the constant r_2 is given by

$$r_2 = \left\| \big(\partial_t - A(t)\big)^{-1} \frac{R_N(t)}{t} [g^2(1+g)] \right\|_{\mathbb{E}_1}.$$

It follows that Φ_1 is a self-map if r is chosen to satisfy $r > r_1 + r_2$ and the time interval length is sufficiently small. It is important to observe that all estimates have constants which are independent of s in the chosen neighborhood.

Next it needs to be shown that Φ_1 is a contraction. The calculations are very similar to the above. The terms

$$\Phi(u_1) - \Phi_1(u_2) = v_1 - v_2 + R_N(t)\big[H(s,u_1) - H(s,u_2)\big]$$

need to be estimated. The difference $v_1 - v_2$ satisfies

$$v_1 - v_2 = \big(\partial_t - A(t)\big)^{-1}\big[F(s,u_1) - F(s,u_2)\big].$$

Maximal regularity yields that

$$\|v_1 - v_2\|_{\mathbb{E}_1} = \|\big(\partial_t - A(t)\big)^{-1}\big[F(s,u_1) - F(s,u_2)\big]\|_{\mathbb{E}_1} \leq c\,\|F(s,u_1) - F(s,u_2)\|_{\mathbb{E}_0}$$

so that only the last term needs to be estimated. As for the other summand, an estimate for

$$\|R_N(t)\big[H(s,u_1) - H(s,u_2)\big]\|_{\mathbb{E}_1}$$

needs to be established. Using similar estimates to those for the self-map property and observing that all the terms not vanishing at the origin drop out since they do not depend on the unknowns, one arrives at

$$\|\Phi_1(s,u_1) - \Phi_1(s,u_2)\|_{\mathbb{E}_1} \leq cT^\beta \|u_1 - u_2\|_{\mathbb{E}_1}$$

with a constant which is independent of s in the chosen neighborhood. Existence of a unique fixed point follows by making the interval length short enough.

Next observe that any solution actually satisfies

$$\gamma_1 u = \gamma_1 R_D(t) g + \gamma_1 [v + R_N(t) H(s,u)] \in \mathrm{C}^\beta\,\mathrm{BUC}^{3+\alpha} \tag{5.7}$$

by Remark 2.1 since $g \in \mathrm{BUC}^{4+\alpha}$. This follows from

$$v = \big(\partial_t - A(t)\big)^{-1}\left[F(s,u) + \frac{1}{t} R_N(t) g^2(1+g)\right] - \big(\partial_t - A(t)\big)^{-1} \frac{1}{t} R_N(t) g^2(1+g)$$

and

$$R_N(t)H(s,u) = R_N(t)[H(s,u) - g^2(1+g)] + R_N(t)g^2(1+g),$$

where the first terms on the right-hand sides above belong to $\mathbb{E}_{1,0}$ and the second ones are not singular due to the regularity of g, and therefore of $g^2(1+g)$, combined

with Remark 2.1. The first continuous dependence result follows along the lines of the above estimates from the fact that the solution to the initial boundary value problem depends smoothly (linearly) on the interior and boundary data $\overline{\mathcal{A}}(s)u$ and $H(s,u)$. The only difference stems from the fact that a stronger norm is now estimated which leads to the absence of the factor T^β in front of $\|s_1 - s_2\|_{\mathbb{S}}$. This factor can be regained if a weaker norm is estimated in view of the "desingularizing" properties of $[\partial_t - A(t)]^{-1}$, which leads to the stated continuous dependence estimate. The estimates are based on

$$\begin{aligned}\|\gamma_1 u_1 - \gamma_1 u_2\|_{\mathrm{C}^\beta\,\mathrm{BUC}^{3+\beta}} &\le \|\gamma_1\Phi_1(s_1,u_1) - \gamma_1\Phi_1(s_2,u_2)\|_{\mathrm{C}^\beta\,\mathrm{BUC}^{3+\beta}}\\ &\le \|\gamma_1\Phi_1(s_1,u_1) - \gamma_1\Phi_1(s_1,u_2)\|_{\mathrm{C}^\beta\,\mathrm{BUC}^{3+\beta}}\\ &\quad + \|\gamma_1\Phi_1(s_1,u_2) - \gamma_1\Phi_1(s_2,u_2)\|_{\mathrm{C}^\beta\,\mathrm{BUC}^{3+\beta}}.\end{aligned}$$

The estimate for the first term of $\overline{\mathcal{A}}(s_1) - \overline{\mathcal{A}}(s_2)$ is typical. It gives

$$\begin{aligned}&\left\|\left[\frac{t^2}{s_1^2}(1+y^2|\nabla s_1|^2) - \frac{t^2}{s_2^2}(1+y^2|\nabla s_2|^2)\right]\frac{\partial_y^2}{t^2}\right\|_{\mathcal{L}(\mathbb{E}_1,\mathbb{E}_{0,0})}\\ &\qquad\le \left\|\frac{t^2}{s_1^2}(1+y^2|\nabla s_1|^2) - \frac{t^2}{s_2^2}(1+y^2|\nabla s_2|^2)\right\|_{\mathrm{C}^\beta\,\mathrm{BUC}^{1+\alpha}\,\mathrm{C}}\left\|\frac{\partial_y^2}{t^2}\right\|_{\mathcal{L}(\mathbb{E}_1,\mathbb{E}_0)},\end{aligned}$$

which easily entails the claim since

$$\begin{aligned}&\left\|\frac{t^2}{s_1^2}(1+y^2|\nabla s_1|^2) - \frac{t^2}{s_2^2}(1+y^2|\nabla s_2|^2\right\|_{\mathrm{C}^\beta\,\mathrm{BUC}^{1+\alpha}\,\mathrm{C}}\\ &\qquad\le c\big(\|\dot s_1 - \dot s_2\|_{\mathrm{C}^\beta\,\mathrm{BUC}^{1+\alpha}} + \|s_1 - s_2\|_{\mathrm{C}^\beta\,\mathrm{BUC}^{2+\alpha}}\big) \le c\|s_1 - s_2\|_{\mathcal{S}}\,.\end{aligned}$$

One is eventually led to

$$\|\gamma_1 u_1 - \gamma_1 u_2\|_{\mathrm{C}^\beta\,\mathrm{BUC}^{3+\alpha}} \le\ cT^\beta\|u_1 - u_2\|_{\mathbb{E}_1} + \|s_1 - s_2\|_{\mathcal{S}^\beta},$$

from which the claim follows since the first term on the right can be absorbed on the left-hand side. □

All pieces are now in place in order to show existence for the original system of equations (1.6)–(1.10). By denoting with $u = \Phi_1(s)$ the solution of (1.6)–(1.8) for a given $s \in \mathcal{S}$, it follows that

$$u \in \mathbb{E}_1 \quad\text{and}\quad \gamma_1 u \in \mathrm{C}^\beta\,\mathrm{BUC}^{3+\alpha}\,.$$

Decomposition (5.7) shows that u is in a given neighborhood of g for any choice of $s \in \mathcal{S}$ in a neighborhood of $[t \mapsto tg(x)]$. Similarly let $\Phi_2(u)$ be the solution of (1.9)–(1.10) constructed in section 4. In this case, if $u \in \mathbb{E}_1$ with $\gamma_1 u \in \mathrm{C}^\beta\,\mathrm{BUC}^{3+\alpha}$, $\Phi_2(u) \in \mathcal{S}$ will be in a neighborhood of $tg(x)$ for u in a neighborhood of g. It follows that a solution to the full problem can be found by producing a fixed point s for the map $\Phi := \Phi_2 \circ \Phi_1$ and defining $u := \Phi_1(s)$. We summarize in the following theorem.

THEOREM 5.2. *For any given $g \in \mathrm{BUC}^{4+\alpha}$ such that $g(x) \ge g_0 > 0$, $x \in \mathbb{R}^n$, there exists a unique local solution (u,s) of the free boundary problem* (1.6)–(1.10) *such that*

$$\begin{aligned}u, \dot u, \partial_x^\alpha\frac{1}{t^k}\partial_y^k u \in \mathrm{C}^\beta_\beta\,\mathrm{BUC}^{1+\alpha}\,\mathrm{C}\ \textit{ for } 0 \le |\alpha| + k \le 2,\\ \gamma_1 u \in \mathrm{C}^\beta\,\mathrm{BUC}^{3+\alpha},\ \textit{and}\\ s \in \mathrm{C}^{1+\beta}\,\mathrm{BUC}^{2+\alpha} \cap \mathrm{C}^\beta\,\mathrm{BUC}^{3+\alpha}\,.\end{aligned}$$

Furthermore

$$u = R_D(t)g + R_N(t)H(s,u) + v,$$

where v is a solution of (5.5) *and the different terms have different asymptotic behavior in the origin. They behave, respectively, like t^k for $k = 0, 1, 2$ modulo the singular behavior built into the space chosen.*

Proof. Making the time interval as small as needed and choosing $r > 0$ large enough, it can be seen that (Φ_1, Φ_2) is a self-map on the complete set

$$\{u \in \overline{\mathbb{B}}_{\mathbb{E}_1}(0,r) \,|\, u(0) = g\} \times \{s \in \overline{\mathbb{B}}_{\mathbb{S}}(gt, g_0/2) \,|\, s(0) = 0\,,\ \dot{s}(0) = g\}\,,$$

where the additional requirements $u(0) \equiv g\,,\ s(0) = 0\,,\ \dot{s}(0) \equiv g$ are included in the definition of the balls. Combining the estimates of Theorems 4.1 and 5.1, it follows that

$$\|\Phi(s_1) - \Phi(s_2)\|_{\mathbb{S}^\beta} \le c\,T^\beta\,\|s_1 - s_2\|_{\mathbb{S}^\beta}$$

and the contraction principle can be applied to obtain existence. ∎

Remark 5.2. It should be pointed out that this is the first well-posedness result for this class of singular FBPs in more than one space dimension for the full evolutionary problem. A companion result for the quasi-stationary approximation ($\varepsilon = 0$) has previously been obtained in [16].

ON MULTIPLE RADIAL SOLUTIONS OF A SINGULARLY PERTURBED NONLINEAR ELLIPTIC SYSTEM*

EDWARD NORMAN DANCER†, XIAOFENG REN‡, AND SHUSEN YAN§

Abstract. We study radial solutions of a singularly perturbed nonlinear elliptic system of the FitzHugh–Nagumo type. In a particular parameter range, we find a large number of layered solutions. First we show the existence of solutions whose layers are well separated from each other and also separated from the origin and the boundary of the domain. Some of these solutions are local minimizers of a related functional while the others are critical points of saddle type. Although the local minimizers may be studied by the Γ-convergence method, the reduction procedure presented in this paper gives a more unified approach that shows the existence of both local minimizers and saddle points. Critical points of both types are all found in the reduced finite dimensional problem. The reduced finite dimensional problem is solved by a topological degree argument. Next we construct solutions with odd numbers of layers that cluster near the boundary, again using the reduction method. In this case the reduced finite dimensional problem is solved by a maximization argument.

1. Introduction.

We consider the singularly perturbed elliptic system

$$\begin{cases} -\epsilon^2 \Delta u + f(u) + \epsilon\gamma v = 0 \ \text{ in } \Omega, \\ -\Delta v + v - u = 0 \ \text{ in } \Omega, \\ \partial_\nu u = \partial_\nu v = 0 \ \text{ on } \partial\Omega \end{cases} \tag{1.1}$$

on a smooth bounded domain Ω. The perturbation parameter ϵ is positive and small. The outward normal derivatives of u and v on the boundary of Ω are denoted by $\partial_\nu u$ and $\partial_\nu v$, respectively.

The nonlinear function f in (1.1) is the cubic polynomial

$$f(u) = (u-a)\left(u - \frac{a+b}{2}\right)(u-b). \tag{1.2}$$

It has three zeros a, $\frac{a+b}{2}$, and b, in the increasing order. The function is balanced in the sense that

$$\int_a^b f(q)\, dq = 0. \tag{1.3}$$

The nonlinearity in the system (1.1) is of the FitzHugh–Nagumo type. It was originally proposed to study nerve impulses [10, 18]. The phenomenon that is modeled

is the control of the electrical potential across a cell membrane. This control is done by the change of flow of the ionic channels of the cell membrane. This results in the change in potential which is used to send electrical signals between cells. This is readily observed in muscle and other excitable cells. The two variables in the system are the excitable variable u and the recovery variable v. The dynamics of the two variables are described by the reaction-diffusion system

$$\begin{cases} u_t = \epsilon^2 \Delta u - f(u) - \epsilon\gamma v, \\ \kappa v_t = \Delta v - v + u, \\ \partial_\nu u = \partial_\nu v = 0 \ \text{ on } \partial\Omega. \end{cases} \tag{1.4}$$

Steady state solutions of (1.1) often have layered structures. In most parts of the domain Ω, a solution u is close to a or b. However, there exist small regions in Ω where the value of u changes abruptly from a to b. These regions are called transition layers or interfaces.

The parameter range in this paper differs from the more extensively studied one where ϵ does not appear in the $\epsilon\gamma v$ term in the first equation of (1.1) (see, for example, [4, 3, 5, 7, 6, 9, 14, 11, 12, 20, 19, 21, 24]). We will show that the parameter range considered in this paper typically gives solutions with a finite number of interior layers. In the parameter range without ϵ in the $\epsilon\gamma v$ term, the number of interior layers of a solution typically approaches infinity as $\epsilon \to 0$ (see [4, 17, 23, 1] for this type of phenomenon). The reason for this difference is that with ϵ in $\epsilon\gamma v$ there is less impact from the coupling effect with v, and hence there are fewer layers in a solution.

If we solve the second equation in (1.1) for v in terms of u with the boundary condition $\partial_\nu v = 0$ on $\partial\Omega$, i.e., $v = (1-\Delta)^{-1}u$, and substitute the solution into the first equation, we obtain the equation for u:

$$-\epsilon^2 \Delta u + f(u) + \epsilon\gamma(1-\Delta)^{-1}u = 0 \text{ in } \Omega, \quad \partial_\nu u = 0 \text{ on } \partial\Omega. \tag{1.5}$$

This integro-differential equation can be viewed as the Euler–Lagrange equation of the functional

$$I_\epsilon(u) = \int_\Omega \left\{ \frac{\epsilon^2}{2}|\nabla u|^2 + W(u) + \frac{\epsilon\gamma}{2}|(1-\Delta)^{-1/2}u|^2 \right\} dx. \tag{1.6}$$

Here W is an antiderivative of f; i.e.,

$$W(u) = \int_a^u f(q)\, dq. \tag{1.7}$$

Note that $W(u) \geq 0$ for all $u \in (-\infty, \infty)$ and $W(u) = 0$ if and only if $u = a$ or $u = b$. Note that $(1-\Delta)^{-1/2}$ is a nonlocal linear operator. One first defines $(1-\Delta)^{-1}$ so that $v = (1-\Delta)^{-1}$ is the solution of

$$-\Delta v + v = u \text{ in } \Omega, \ \partial_\nu v = 0 \text{ on } \partial\Omega.$$

Since $(1-\Delta)^{-1}$ is a positive operator from $L^2(\Omega)$ to itself, we define $(1-\Delta)^{-1/2}$ to be the positive square root of $(1-\Delta)^{-1}$.

The fast inhibitor limit of (1.4) is the parabolic-elliptic system

$$\begin{cases} u_t = \epsilon^2 \Delta u - f(u) - \epsilon\gamma v, \\ 0 = \Delta v - v + u, \\ \partial_\nu u = \partial_\nu v = 0 \ \text{ on } \partial\Omega \end{cases} \tag{1.8}$$

obtained by setting $\kappa = 0$ in (1.4). This is the gradient flow of I_ϵ in the $L^2(\Omega)$ space. Finding and classifying the critical points of I_ϵ (solutions of (1.1)) help us understand the behavior of (1.8).

In this paper we look for radial solutions of (1.1) on a unit ball in R^n:

$$\Omega = \{x \in R^n : |x| < 1\}. \tag{1.9}$$

The functional I_ϵ is therefore defined in the admissible set of radial $W^{1,2}$ functions:

$$\{u \in W^{1,2}(\Omega) : u = u(|x|)\}. \tag{1.10}$$

In the first part of the paper, we study layered solutions whose interfaces are well separated and away from the origin and the boundary. We prove two theorems.

THEOREM 1.1. *Let $a < 0 < b$ and K be a positive integer. There exists $\gamma_0 > 0$ such that for each $\gamma > \gamma_0$, there exists $\epsilon_0 > 0$ so that when $\epsilon \in (0, \epsilon_0)$ there are four solutions, each of which has K interfaces. Two of the four solutions, if denoted by u_ϵ^a, satisfy $\lim_{\epsilon\to 0} u_\epsilon^a(0) = a$, and the other two, if denoted by u_ϵ^b, satisfy $\lim_{\epsilon\to 0} u_\epsilon^b(0) = b$.*

THEOREM 1.2.

1. *If $a < b < 0$ and $\gamma > \frac{(n-1)\tau}{(b-a)a}$, there exists $\epsilon_0 > 0$ such that for each $\epsilon < \epsilon_0$, there is a one-interface solution u_ϵ with the property $\lim_{\epsilon\to 0} u_\epsilon(0) = b$.*
2. *If $0 < a < b$ and $\gamma > \frac{(n-1)\tau}{(b-a)a}$, there exists $\epsilon_0 > 0$ such that for each $\epsilon < \epsilon_0$, there is a one-interface solution u_ϵ with the property $\lim_{\epsilon\to 0} u_\epsilon(0) = a$.*

The constant τ here is a positive number, often called the surface tension. It is given in (2.5). The proof of Theorem 1.1 uses a type of Lyapunov–Schmidt reduction procedure tailored for singular perturbation problems. It consists of two steps. First we reduce I_ϵ to a functional Q_ϵ that is defined on a finite dimensional set. This set is really the coordinates of interfaces. In this step we construct a family of approximate solutions with K interfaces whose coordinates serve as parameters. The family is a finite dimensional submanifold of the admissible set of I_ϵ. Near each approximate solution we find a function that "solves" (1.5) in a direction that is more or less perpendicular to the submanifold. These functions are again parameterized by their interfaces and they form an improved finite dimensional submanifold. The restriction of I_ϵ on this new submanifold is Q_ϵ, which is viewed as a function of the interfaces. As a consequence of this construction, we show that a critical point of Q_ϵ is a solution of (1.5).

In the second step of the proof, we look for critical points of Q_ϵ. We show that $\epsilon^{-1}Q_\epsilon$ converges in C^1_{loc} to a function J as $\epsilon \to 0$. When γ is sufficiently large, J has a minimum. Near this local minimum Q_ϵ also has a minimum for small ϵ. The topological degree of J and hence that of Q_ϵ are shown to be 0. We then conclude that when γ is large, there are at least two critical points of Q_ϵ.

The proof of Theorem 1.2 is similar. After the same reduction procedure, we show that when γ is large, the reduced problem J has one maximum in $\mathcal{A}_1^b$ if $a < b < 0$ and one maximum in $\mathcal{A}_1^a$ if $0 < a < b$.

Another purpose of this paper is to illustrate the power and limitation of the Γ-convergence theory [8, 16, 15, 13] applied to this problem. Consider the case covered in Theorem 1.1. The limit J of the reduced problem Q_ϵ can be easily identified in the Γ-convergence theory. If one can show that the minimum of J is isolated, then a local minimizer of I_ϵ exists according to the theory. For small values of K ($K = 1$ or $K = 2$), we are able to show that the minimum is indeed isolated. For general K this also appears to be true, but we do not have a proof.

Regarding the second critical point of J, which is found by the topological degree argument on Q_ϵ, one in general cannot derive from the Γ-convergence theory that there exists another critical point of I_ϵ corresponding to the second critical point of J. This is because the Γ-convergence theory addresses only isolated local minima of J but not other types of critical points of J.

Similarly, in the case covered by Theorem 1.2 the maximum of J in $\mathcal{A}_1^a$ and the maximum in $\mathcal{A}_1^b$ do not yield solutions of (1.1) by the Γ-convergence theory. This paper shows that the nonminimum critical points all correspond to solutions of (1.5). They are saddle points of (1.6).

In the second part of the paper we further demonstrate the effectiveness of the Lyapunov–Schmidt reduction method. We construct solutions with a number of interfaces that cluster near the boundary $r = 1$. Namely, we prove the following result.

THEOREM 1.3. *Suppose that $\gamma \geq 0$ and $a < b$. For any nonnegative integer k, there exists an $\epsilon_0 > 0$ such that for each $\epsilon \in (0, \epsilon_0]$, (1.1) has a solution u_ϵ, which has $2k + 1$ interfaces near the boundary $r = 1$. Moreover, $u_\epsilon \to b$ uniformly in $B_{1-\delta}(0)$ for any $\delta > 0$ small if $b > 0$, and $u_\epsilon \to a$ uniformly in $B_{1-\delta}(0)$ for any $\delta > 0$ small if $a < b \leq 0$.*

Here the $2k + 1$ layers are all close to the boundary $r = 1$. The distance between two successive interfaces is of order $\epsilon \log \frac{1}{\epsilon}$, and the distances between these interfaces and the boundary $r = 1$ are also of order $\epsilon \log \frac{1}{\epsilon}$. After reduction the problem becomes a finite dimensional maximization problem with respect to the interfaces. The solution constructed from this maximization procedure is again of saddle type.

In Theorem 1.3 the nonlocal term $\epsilon\gamma(1-\Delta)^{-1}u$ does not play a central role. The existence of solutions with layers clustering near the boundary is valid with ($\gamma > 0$) or without ($\gamma = 0$) the nonlocal term. See also the result in [2] for the unbalanced case. The existence of interior layer solutions (Theorems 1.1 and 1.2) is different. Our results show that to have solutions of multiple interior layers we must have sufficient nonlocality, i.e., γ must be large enough.

The organization of our paper serves these two purposes. In section 2 we recall how J is derived from the Γ-convergence theory. We show that the topological degree of J is always 0 in the case $a < 0 < b$. For large γ we show that J has a minimum and consequently there is another critical point of J. The main work starts in section 3, where we reduce the study of I_ϵ to that of the finite dimensional problem Q_ϵ. Then in section 4 we show that $\epsilon^{-1}Q_\epsilon$ converges to J in C^1_{loc} and prove Theorems 1.1 and 1.2.

In section 5 another reduction is used to prove Theorem 1.3. We again derive a reduced functional of the interfaces. This time the interfaces are close to each other and to the boundary (all the distances are of order $\epsilon \log \frac{1}{\epsilon}$). As the interfaces vary in this range the functional varies by a quantity that is much smaller than ϵ. This compares differently from the situation discussed in Theorems 1.1 and 1.2. We show that the reduced problem is maximized at an interior point.

The conditions on a, b, and γ in the three theorems are used when we solve the reduced problems. In the case of Theorem 1.1 J has many critical points, and in the case of Theorem 1.2 J has only one critical point. In the case of Theorem 1.3 we will solve the reduced problem by showing that it has an interior maximum point. To achieve this goal, the assumption on the sign of b is essential.

We use C to denote constants independent of ϵ. Their values may vary from line to line. The $L^p(\Omega)$ norm, $p \in [1, \infty]$, of a function is denoted by $\|\cdot\|_p$.

2. The Γ-limit. The limiting problem J is easily identified in the Γ-convergence theory. Other than the expression of J and its properties, given in Lemmas 2.3 and 2.4,

the details of the Γ-convergence and its consequences are not needed in this paper. Therefore, we omit the proofs of the statements in this section, with the exception of Lemmas 2.3 and 2.4. The interested reader may reconstruct them with the help of the references we provide.

The Γ-limit J of $\epsilon^{-1}I_\epsilon$ is defined on the admissible set

$$\{u \in BV(\Omega, \{a, b\}) : u = u(|x|)\}, \tag{2.1}$$

where $BV(\Omega, \{a, b\})$ is the set of functions of bounded variation which take values only in $\{a, b\}$. The set (2.1) consists of such functions that are radial.

A function in (2.1) has either a finite number of interfaces or infinitely many interfaces. If it has finite, say, K, interfaces, there exist $r_1, r_2, \dots, r_K$, with $0 < r_1 < r_2 < \cdots < r_K < 1$, that divide the interval $(0, 1)$ into $(0, r_1)$, (r_1, r_2), $\dots$,(r_{K-1}, r_K), $(r_K, 1)$, and

$$u(r) = a \text{ on } (0, r_1), \ = b \text{ on } (r_1, r_2), \ = a \text{ on } (r_2, r_3), \dots \tag{2.2}$$

or

$$u(r) = b \text{ on } (0, r_1), \ = a \text{ on } (r_1, r_2), \ = b \text{ on } (r_2, r_3), \dots . \tag{2.3}$$

In the case of (2.2) we say that $u \in \mathcal{A}_K^a$ and in the case of (2.3) we say that $u \in \mathcal{A}_K^b$. On $\mathcal{A}_K^a$ and $\mathcal{A}_K^b$ the Γ-limit J is given by

$$J(u) = \omega_{n-1}\tau \sum_{j=1}^{K} r_j^{n-1} + \frac{\omega_{n-1}\gamma}{2} \int_0^1 |(1-\Delta)^{-1/2}u|^2 \, r^{n-1} dr. \tag{2.4}$$

Here we denote the area of the $n-1$ dimensional unit sphere by ω_{n-1}. The constant τ in (2.4) is given by

$$\tau = \int_a^b \sqrt{2W(q)}\, dq. \tag{2.5}$$

A function in (2.1) may also have infinite interfaces. Then the interfaces must accumulate at the origin. Otherwise, if there were a cluster point not at the origin, the total length of the interfaces would be infinite and u could not be in (2.1). Hence there exists a *decreasing* sequence $r_1, r_2, \dots$, such that $1 > r_1 > r_2 > \dots$ and $\lim_{j\to\infty} r_j = 0$, and either

$$u = \begin{cases} a & \text{on} \quad (r_1, 1), \\ b & \text{on} \quad (r_2, r_1), \\ a & \text{on} \quad (r_3, r_2) \\ \dots \end{cases} \tag{2.6}$$

or

$$u = \begin{cases} b & \text{on} \quad (r_1, 1), \\ a & \text{on} \quad (r_2, r_1), \\ b & \text{on} \quad (r_3, r_2) \\ \dots . \end{cases} \tag{2.7}$$

In this case J is defined by (2.4) with $\sum_{j=1}^{K}$ replaced by $\sum_{j=1}^{\infty}$. Because u is assumed to have bounded variation, this infinite sum converges.

Now we have J which is defined in (2.1). But I_ϵ is defined in a different set (1.10). We trivially extend both to

$$\{u \in L^2(\Omega) : u = u(|x|)\}, \tag{2.8}$$

the radial L^2-functions, by setting $I_\epsilon(u) = \infty$ if u is in (2.8) but not in (1.10) and similarly $J(u) = \infty$ if u is in (2.8) but not in (2.1). In (2.8) distance is measured by the L^2 norm $\|\cdot\|_2$.

The Γ-convergence of $\epsilon^{-1}I_\epsilon$ to J is characterized by the two properties of the following lemma.

LEMMA 2.1. *As $\epsilon \to 0$, $\epsilon^{-1}I_\epsilon$ Γ-converges to J in the following sense:*

1. *For every family of functions ϕ_ϵ in (2.8) with $\lim_{\epsilon\to 0}\|\phi_\epsilon - \phi\|_2 = 0$, $\liminf_{\epsilon\to 0}\epsilon^{-1}I_\epsilon(\phi_\epsilon) \geq J(\phi)$.*
2. *For every ϕ in (2.8), there is a family of functions ϕ_ϵ in (2.8) such that $\lim_{\epsilon\to 0}\|\phi_\epsilon - \phi\|_2 = 0$ and $\limsup_{\epsilon\to 0}\epsilon^{-1}I_\epsilon(\phi_\epsilon) \leq J(\phi)$.*

One important consequence of the Γ-convergence of $\epsilon^{-1}I_\epsilon$ is the following existence result.

LEMMA 2.2. *If $u_0 \in \mathcal{A}_K^a$ (or $\mathcal{A}_K^b$, respectively) is an isolated local minimum of J in $\mathcal{A}_K^a$ (or $\mathcal{A}_K^b$, respectively), for sufficiently small ϵ, there exists a local minimizer u_ϵ of I_ϵ, and $\lim_{\epsilon\to 0}\|u_\epsilon - u_0\|_2 = 0$.*

These two lemmas may be proved by mimicking the argument in Ren and Wei [22]. Lemma 2.2 suggests that we look for minima of J in $\mathcal{A}_K^a$ and $\mathcal{A}_K^b$. We do this in the rest of this section. Moreover, we will also find critical points of J that are not local minima.

Let $G = G(r, s)$ be the Green's function

$$-G_{rr} - \frac{n-1}{r}G_r + G = \delta(r - s). \tag{2.9}$$

Note that $G(r, s)$ is not symmetric in r and s, but $r^{n-1}G(r, s)$ is. We define

$$v(r) = \int_0^1 G(r, s)u(s)\,ds \tag{2.10}$$

to be the solution of

$$-v_{rr} - \frac{n-1}{r}v_r + v = u. \tag{2.11}$$

When it is in $\mathcal{A}_K^a$ or $\mathcal{A}_K^b$, u is determined by its jump points $r_1, r_2, \ldots, r_K$, which we term interfaces. Collectively we set $\mathbf{r} = (r_1, r_2, \ldots, r_K)$. Because u depends on $\mathbf{r}$, we often write $u = u(r; \mathbf{r})$ and correspondingly $v = v(r; \mathbf{r})$.

The nonlocal part of J may be rewritten as

$$\int_0^1 |(1-\Delta)^{-1/2}u(\cdot;\mathbf{r})|^2\, r^{n-1}dr = \int_0^1 v(r;\mathbf{r})u(r;\mathbf{r})\, r^{n-1}dr. \tag{2.12}$$

We view J as a function of $\mathbf{r}$: $J = J(\mathbf{r})$. Now we compute the derivative of J. Note that

$$\begin{aligned}\frac{\partial}{\partial r_1}\int_0^1 v(r)u(r)\, r^{n-1}dr &= \frac{\partial}{\partial r_1}\left[\int_0^{r_1} v(r)a\, r^{n-1}dr + \int_{r_1}^{r_2} v(r)b\, r^{n-1}dr + \ldots\right] \\ &= (a-b)v(r_1)r_1^{n-1} + \int_0^1 \frac{\partial v(r;\mathbf{r})}{\partial r_1}u(r;\mathbf{r})\, r^{n-1}dr. \end{aligned} \tag{2.13}$$

Because

$$\frac{\partial v(r;\mathbf{r})}{\partial r_1} = \frac{\partial}{\partial r_1}\left[\int_0^{r_1} G(r,s)a\,ds + \int_{r_1}^{r_2} G(r,s)b\,ds + \dots\right]$$

$$= (a-b)G(r,r_1), \tag{2.14}$$

we find

$$\begin{aligned}
&\frac{\partial}{\partial r_1}\int_0^1 v(r)u(r)\,r^{n-1}dr \\
&\quad = (a-b)v(r_1)r_1^{n-1} + (a-b)\int_0^1 G(r,r_1)u(r;\mathbf{r})\,r^{n-1}dr \\
&\quad = (a-b)v(r_1)r_1^{n-1} + (a-b)\int_0^1 G(r_1,r)u(r;\mathbf{r})\,r_1^{n-1}dr \\
&\quad = (a-b)v(r_1)r_1^{n-1} + (a-b)v(r_1)r_1^{n-1} \;=\; 2(a-b)v(r_1)r_1^{n-1}. \qquad (2.15)
\end{aligned}$$

We have used the symmetry of $r^{n-1}G(r,r_1)$. For a general r_j we have

$$\frac{\partial}{\partial r_j}\int_0^1 v(r)u(r)\,r^{n-1}dr = 2(-1)^j(b-a)v(r_j;\mathbf{r})r_j^{n-1}. \tag{2.16}$$

Therefore

$$\frac{\partial J(\mathbf{r})}{\partial r_j} = \omega_{n-1}[(n-1)\tau r_j^{n-2} + \gamma(b-a)(-1)^j v(r_j;\mathbf{r})r_j^{n-1}], \quad \mathbf{r}\in\mathcal{A}_K^a. \tag{2.17}$$

The gradient of J in $\mathcal{A}_K^b$ is a bit different:

$$\frac{\partial J(\mathbf{r})}{\partial r_j} = \omega_{n-1}[(n-1)\tau r_j^{n-2} + \gamma(a-b)(-1)^j v(r_j;\mathbf{r})r_j^{n-1}], \quad \mathbf{r}\in\mathcal{A}_K^b. \tag{2.18}$$

The existence of critical points of J depends on a, b, and γ. We consider the following three cases:

- *Case* I. $a < b < 0$.
- *Case* II. $0 < a < b$.
- *Case* III. $a < 0 < b$.

The first two cases are relatively simple. We have the following result.

LEMMA 2.3.

1. *If $a < b < 0$ and $\gamma > \gamma_I$ where*

$$\gamma_I = \frac{(n-1)\tau}{(a-b)b}, \tag{2.19}$$

there is a local maximum in $\mathcal{A}_1^b$. There are no critical points in other classes.

2. *If $0 < a < b$ and $\gamma > \gamma_{II}$ where*

$$\gamma_{II} = \frac{(n-1)\tau}{(b-a)a}, \tag{2.20}$$

there is a local maximum in $\mathcal{A}_1^a$. There are no critical points in other classes.

Proof. We consider only case I, for case II may be similarly handled. Note that $u \le 0$ implies that $v < 0$. In each $\mathcal{A}_K^a$, $K \ge 1$, $\frac{\partial J}{\partial r_1} > 0$. There is no critical point in $\mathcal{A}_K^a$. In $\mathcal{A}_K^b$ for $K \ge 2$, $\frac{\partial J}{\partial r_2} > 0$. So there is no critical point in $\mathcal{A}_K^b$, $K \ge 2$. The only class left is $\mathcal{A}_1^b$. In this class

$$\frac{\partial J}{\partial r_1} = \omega_{n-1} r_1^{n-2}[(n-1)\tau - \gamma(a-b)v(r_1; r_1)r_1].$$

The quantity inside the brackets is $(n-1)\tau$ when $r_1 = 0$ and $(n-1)\tau - \gamma(a-b)v(1) = (n-1)\tau - \gamma(a-b)b$ when $r_1 = 1$. Hence when $\gamma > \gamma_I$ there is a local maximum of J in $\mathcal{A}_1^b$, where γ_I is given in (2.19). Here since when $b = 0$, $\gamma_I = \infty$, the condition $\gamma > \gamma_I$ can be satisfied only when $b < 0$. □

Case III is the most interesting. We have the following lemma.

LEMMA 2.4. *Suppose $a < 0 < b$.*

1. *When γ is sufficiently large, J attains a global minimum in $\mathcal{A}_K^a$ (or $\mathcal{A}_K^b$)—not on the boundary of $\mathcal{A}_K^a$ (or $\mathcal{A}_K^b$).*
2. *Given $\gamma' > 0$ and any compact subset $\mathcal{K}'$ of $\mathcal{A}_K^a$ (or $\mathcal{A}_K^b$) one can find a compact subset $\mathcal{K}$, such that $\mathcal{K}' \subset \mathcal{K}$ and for all $\gamma \in [0, \gamma']$ the topological degree of* grad J on $\mathcal{K}$ about $\vec{0}$ is zero.
3. When γ is large, there exist at least two critical points of J in each $\mathcal{A}_K^a$ (or $\mathcal{A}_K^b$).

Proof. To prove part 1, we note that as far as the minimum is concerned the condition that γ is large is equivalent to the condition that τ is small. Or J can be considered as a perturbation of the function

$$J_0(\mathbf{r}) = \frac{\omega_{n-1}\gamma}{2} \int_0^1 |((1-\Delta)^{-1/2} u(\cdot; \mathbf{r}))^2|\, r^{n-1} dr, \quad \mathbf{r} \in \mathcal{A}_K^a \text{ (or } \mathcal{A}_K^b). \tag{2.21}$$

We recall that $\mathcal{A}_K^a$ (and, similarly, $\mathcal{A}_K^b$) is identified with

$$\{\mathbf{r} = (r_1, \dots, r_K) : 0 < r_1 < \cdots < r_K\}$$

so that the boundary of $\mathcal{A}_K^a$ is not included in $\mathcal{A}_K^a$. We study J_0 on the boundary of $\mathcal{A}_K^a$ (the case $\mathcal{A}_K^b$ is left to the reader), which consists of three pieces: (1) $r_1 = 0$, (2) $r_K = 1$, and (3) $r_j = r_{j+1}$ for some $j = 1, 2, \dots, K-1$.

In $\mathcal{A}_K^a$,

$$\frac{\partial J_0}{\partial r_j} = \omega_{n-1}\gamma(b-a)(-1)^j v(r_j; \mathbf{r}) r_j^{n-1}. \tag{2.22}$$

If the minimum of J_0 is achieved on $r_1 = 0$, say, at $\mathbf{r} = (0, r_2, r_3, \dots)$, then

$$v(r_2; \mathbf{r}) = v(r_3; \mathbf{r}) = \cdots = v(r_K; \mathbf{r}) = 0.$$

However, $v(r_2; \mathbf{r}) = 0$ and $u(r; \mathbf{r}) = b > 0$ for $r \in (0, r_2)$ imply that $v(r; \mathbf{r}) > 0$ for $r \in [0, r_2)$ by the maximum principal. Then at this $\mathbf{r}$

$$\frac{\partial J_0(\mathbf{r})}{\partial r_1} = -\omega_{n-1}\gamma(b-a)v(0; \mathbf{r}) < 0. \tag{2.23}$$

This means that the gradient of J_0 points outward at this $\mathbf{r}$. Then $\mathbf{r}$ cannot be a minimum point.

If the minimum of J is achieved at $\mathbf{r} = (r_1, r_2, \dots, r_{K-1}, 1)$ on the boundary piece $r_N = 1$, then

$$v(r_1; \mathbf{r}) = v(r_2; \mathbf{r}) = \cdots = v(r_{K-1}; \mathbf{r}) = 0.$$

Since for $r \in (r_{K-1}, 1)$,

$$u(r; \mathbf{r}) = \begin{cases} a < 0 & \text{if } K \text{ is odd,} \\ b > 0 & \text{if } K \text{ is even,} \end{cases}$$

$v(r_{K-1}; \mathbf{r}) = 0$ implies that $v(r)$ is negative if K is odd and positive if K is even on $(r_{K-1}, 1]$. Then

$$\frac{\partial J_0}{\partial r_K} = \gamma(b-a)(-1)^K v(1; \mathbf{r}) > 0. \tag{2.24}$$

Hence the gradient of J points outward at this $\mathbf{r}$ and it cannot be the minimum.

If the minimum of J is achieved at a boundary point $\mathbf{r}$ on $r_j = r_{j+1}$, we have two possibilities. First we may have $\mathbf{r} = (r_1, r_2, \dots, r_{j-1}, r_j, r_{j+1}, r_{j+2}, \dots, r_K)$ with $r_1 < r_2 < \cdots < r_{j-1} < r_j = r_{j+1} < r_{j+2} < \cdots < r_K$. This means two interfaces coincide but other interfaces stay separate. Then

$$v(r_1; \mathbf{r}) = \cdots = v(r_{j-1}; \mathbf{r}) = v(r_{j+2}; \mathbf{r}) = \cdots = v(r_K; \mathbf{r}) = 0.$$

When $r \in (r_{j-1}, r_{j+2})$,

$$u(r; \mathbf{r}) = \begin{cases} a < 0 & \text{if } j \text{ is odd,} \\ b > 0 & \text{if } j \text{ is even.} \end{cases}$$

Then, since $v(r_{j-1}; \mathbf{r}) = v(r_{j+2}; \mathbf{r}) = 0$ for $r \in (r_{j-1}, r_{j+2})$, $v(r; \mathbf{r})$ is negative if j is odd and positive if j is even by the maximal principal. Note that at the minimum $\mathbf{r}$ the outward normal direction is $\nu = (0, 0, \dots 0, 1, -1, 0, \dots, 0)$, where 1 is the jth entry and -1 the $(j+1)$th entry. The directional derivative along ν is

$$\begin{aligned} \frac{\partial J}{\partial \nu} &= \gamma(b-a)[(-1)^j v(r_j; \mathbf{r}) r_j^{n-1} - (-1)^{j+1} v(r_{j+1}; \mathbf{r}) r_{j+1}^{n-1}] \\ &= 2\gamma(b-a)(-1)^j v(r_j; \mathbf{r}) r_j^{n-1} > 0. \end{aligned}$$

Hence $\mathbf{r}$ cannot be the minimum.

In this case there is also the possibility that more than two interfaces collapse at one point, where the minimum is attained—for example, at $\mathbf{r}$ where $r_1 < r_2 < \cdots < r_{j-2} < r_{j-1} = r_j = r_{j+1} < r_{j+2} < \cdots < r_K$. However, this point can be viewed as a point on the boundary of $\mathcal{A}^a_{K-1}$. We can make an induction assumption that in every $\mathcal{A}^a_N$ or $\mathcal{A}^b_N$ with $N \le K-1$, the minimum of J_0 is not achieved on the boundary. Therefore this possibility needs no consideration.

Therefore the minimum of J_0 is achieved on a compact subset of $\mathcal{A}^a_K$. Hence for large γ, the minimum of J is also achieved inside $\mathcal{A}^a_K$.

To prove part 2, we treat γ in J as a parameter for the homotopy argument. We consider the topological degree of $\operatorname{grad} J$. We are given a compact subset $\mathcal{K}'$ of $\mathcal{A}^a_K$ and γ in $[0, \gamma']$.

First we show that grad J is not $\vec{0}$ on the boundary of some compact $\mathcal{K} \supset \mathcal{K}'$. When $\gamma = 0$,

$$\frac{\partial J}{\partial r_j} = (n-1)\omega_{n-1}\tau r_j^{n-2}, \tag{2.25}$$

which is not 0 anywhere in $\mathcal{A}_K^a$. When $\gamma > 0$, we consider the three pieces of the boundary of $\mathcal{A}_K^a$ again.

Although on the piece $r_1 = 0$ of the boundary $\partial J/\partial r_1 = 0$ if $n > 2$, we move slightly away from $r_1 = 0$ and consider small and positive r_1. Then

$$\frac{\partial J}{\partial r_1} = (n-1)\omega_{n-1}\tau r_1^{n-2} + \gamma O(r_1^{n-1}) > 0. \tag{2.26}$$

Hence grad J is not $\vec{0}$ when r_1 is positive and small.

On the second piece $\mathbf{r}_K = 1$,

$$\frac{\partial J}{\partial r_{K-1}} = (n-1)\omega_{n-1}\tau r_{K-1}^{n-2} + \omega_{n-1}\gamma(b-a)(-1)^{K-1}v(r_{K-1};\mathbf{r})r_{K-1}^{n-1}, \tag{2.27}$$

$$\frac{\partial J}{\partial r_K} = (n-1)\omega_{n-1}\tau + \omega_{n-1}\gamma(b-a)(-1)^{K}v(1;\mathbf{r}). \tag{2.28}$$

For $r \in (r_{K-1}, 1)$, $u(r;\mathbf{r}) = a < 0$ if K is odd and $u(r;\mathbf{r}) = b > 0$ if K is even. If $\frac{\partial J}{\partial r_{K-1}} = 0$, then $v(r_{K-1};\mathbf{r})$ is negative if K is odd and positive if K is even. Then for $r \in [r_{K-1}, 1]$, $v(r;\mathbf{r})$ is negative if K is odd and positive if K is even. In particular, $v(1;\mathbf{r})$ is negative if K is odd and positive if K is even. Then $\frac{\partial J}{\partial r_K}$ is always positive. Hence grad J is not $\vec{0}$ on the second piece of the boundary.

On the third piece of the boundary $r_j = r_{j+1}$,

$$\frac{\partial J}{\partial r_j} = (n-1)\omega_{n-1}\tau r_j^{n-2} + \omega_{n-1}\gamma(b-a)(-1)^{j}v(r_j;\mathbf{r})r_j^{n-1}, \tag{2.29}$$

$$\frac{\partial J}{\partial r_{j+1}} = (n-1)\omega_{n-1}\tau r_j^{n-2} + \omega_{n-1}\gamma(b-a)(-1)^{j+1}v(r_j;\mathbf{r})r_j^{n-1}. \tag{2.30}$$

These two partial derivatives cannot simultaneously be 0. Hence grad J is not $\vec{0}$ on the third piece of the boundary.

Now we can find a compact subset $\mathcal{K} \supset \mathcal{K}'$ of $\mathcal{A}_K^a$ so that for all $\gamma \in [0, \gamma']$, grad J is not $\vec{0}$ on the boundary of $\mathcal{K}$. Consequently we can define the topological degree of grad J in $\mathcal{K}$ about $\vec{0}$:

$$\mathrm{Deg}\,(\mathrm{grad}\, J, \mathcal{K}, \vec{0}). \tag{2.31}$$

Note that in part 2 of the lemma, γ is allowed to be 0. This is important, because when $\gamma = 0$, grad $J \neq \vec{0}$ in $\mathcal{A}_K^a$. Hence $\mathrm{Deg}\,(\mathrm{grad}\, J, \mathcal{K}, \vec{0}) = 0$ when $\gamma = 0$. By the invariance of the degree under continuous deformation, $\mathrm{Deg}\,(\mathrm{grad}\, J, \mathcal{K}, \vec{0}) = 0$ for all $\gamma \in [0, \gamma']$. This proves part 2 of the lemma.

The third part of the lemma follows from parts 1 and 2. For large γ, there is a minimum, say, $\mathbf{r}_*$, in $\mathcal{A}_K^a$. This gives one critical point of J. If this is the only critical point of J in $\mathcal{A}_K^a$, we can find an open ball $\mathcal{B}_\eta(\mathbf{r}_*)$ of radius η centered at $\mathbf{r}_*$ whose

closure is a subset of $\mathcal{A}_K^a$. Let $\mathcal{K}$ be a compact subset of $\mathcal{A}_K^a$ given in part 2 of the lemma, and it is large enough to contain $\mathcal{B}_\eta(\mathbf{r}_*)$ as a subset. Then

$$\text{Deg}\,(\text{grad}\,J, \mathcal{K}, \vec{0}) = \text{Deg}\,(\text{grad}\,J, \overline{\mathcal{B}}_\eta(\mathbf{r}_*), \vec{0}) + \text{Deg}\,(\text{grad}\,J, \mathcal{K}\backslash\mathcal{B}_\eta(\mathbf{r}_*), \vec{0}). \tag{2.32}$$

We know that $\text{Deg}\,(\text{grad}\,J, \mathcal{K}, \vec{0}) = 0$ from part 2. Also $\text{Deg}\,(\text{grad}\,J, \mathcal{B}_\eta(\mathbf{r}_*), \vec{0}) = 1$ because the minimum $\mathbf{r}_*$ is the only critical point in $\mathcal{B}_\eta(\mathbf{r}_*)$. Therefore $\text{Deg}\,(\text{grad}\,J, \mathcal{K}\backslash\mathcal{B}_\eta(\mathbf{r}_*), \vec{0}) = -1 \neq 0$. There is another critical point in $\mathcal{K}\backslash\mathcal{B}_\eta(\mathbf{r}_*)$. □

The reader is probably tempted to combine Lemmas 2.2 and 2.4. Since there is a minimum of J in $\mathcal{A}_K^a$ when γ is large, one would like to show that this minimum is isolated and then following Lemma 2.2 conclude that I_ϵ has a local minimizer near the minimum of J. When $K = 1$ or $K = 2$, it is indeed easy to show that the local minimum of J is isolated. However, for general K, we do not have a proof.

Moreover, in part 3 of Lemma 2.4 we have also found another critical point of J for large γ. This critical point is in general not a local minimum of J. Lemma 2.2 is hence not applicable.

Similarly, the local maxima found in Lemma 2.3 are not of much use in the Γ-convergence theory.

To make use of all the critical points of J found in Lemmas 2.3 and 2.4, we now abandon the Γ-convergence theory and proceed differently. Our new reduction approach may roughly be regarded as a convergence theory at the C^2 level, while the Γ-convergence theory is at the C^0 level. Using this argument we will be able to prove that in case III there are at least two critical points of I_ϵ with K interfaces when γ is sufficiently large (see Theorem 1.1). Similarly, in cases I and II there is a critical point of I_ϵ with one interface if γ is large (see Theorem 1.2).

3. Lyapunov–Schmidt reduction procedure. The Lyapunov–Schmidt reduction procedure involves the first and second derivatives of I_ϵ. For this reason we vaguely regard it as a reduction theory at the C^2 level.

We construct a manifold $\mathcal{M}$ of approximate solutions parameterized by $\mathbf{r} = (r_1, r_2, \dots, r_K)$. First define

$$s(r; \mathbf{r}) = a \text{ in } (0, r_1),\ b \text{ in } (r_1, r_2),\ a \text{ in } (r_2, r_3),\ \dots, \tag{3.1}$$

which gives a profile away from the interfaces. Clearly $s(\cdot; \mathbf{r}) \in \mathcal{A}_K^a$. We also identify the domain of $\mathbf{r}$ with $\mathcal{A}_K^a$. From now to the end of the paper we construct the two solutions in Theorem 1.1 that satisfy $\lim_{\epsilon\to 0} u_\epsilon^a(0) = a$ and the solution in part 2 of Theorem 1.2. Similar arguments can give the other solutions, starting with an $s(\cdot; \mathbf{r}) \in \mathcal{A}_K^b$. We leave the details to the reader.

The interface profile is the solution $H(t)$ of the differential equation

$$-H_{tt} + f(H) = 0,\ H(-\infty) = a,\ H(\infty) = b,\ H(0) = \frac{a+b}{2}. \tag{3.2}$$

$H(t)$ approaches a (or b, respectively) exponentially fast as t tends to $-\infty$ (or ∞, respectively) in the sense that there exist positive C_1, C_2 so that

$$0 < H(t) - a < C_1 e^{C_2 t} \text{ if } t < 0, \text{ and } 0 < b - H(t) < C_1 e^{-C_2 t} \text{ if } t > 0. \tag{3.3}$$

Near r_j we use $H((r - r_j)/\epsilon)$ if j is odd, or $H(-(r - r_j)/\epsilon)$ if j is even.

The outer approximation $s(\cdot;\mathbf{r})$ and the inner approximation H must be connected by a smooth cut-off function χ to make

$$w(r;\mathbf{r}) = \sum_{j=1}^{K} \chi(r-r_j) H\left((-1)^{j+1}\frac{r-r_j}{\epsilon}\right) + \left(1-\sum_{j=1}^{K}\chi(r-r_j)\right) s(r;\mathbf{r}), \tag{3.4}$$

where χ is defined to be

$$\chi(r) = \begin{cases} 1 & \text{in} \quad (-\epsilon^\alpha, \epsilon^\alpha), \\ 0 & \text{in} \quad \mathbf{R}\backslash(-2\epsilon^\alpha, 2\epsilon^\alpha). \end{cases} \tag{3.5}$$

The exponent α in (3.5) satisfies

$$0 < \alpha < 1. \tag{3.6}$$

χ satisfies

$$\chi = O(1),\ \chi' = O(\epsilon^{-\alpha}),\ \chi'' = O(\epsilon^{-2\alpha}). \tag{3.7}$$

The manifold $\mathcal{M}$ is

$$\mathcal{M} = \{w(\cdot;\mathbf{r}) :\ \mathbf{r} \in \mathcal{A}_K^a\}, \tag{3.8}$$

which is parameterized by $\mathbf{r}$ in $\mathcal{A}_K^a$.

We define two function spaces $\mathcal{X}$ and $\mathcal{Y}$,

$$\mathcal{X} = \{u \in W^{2,2}(\Omega) : u = u(|x|),\ u_r(1) = 0\};\quad \mathcal{Y} = \{q \in L^2(\Omega) : q = q(|x|)\}, \tag{3.9}$$

and a nonlinear operator $S_\epsilon : \mathcal{X} \to \mathcal{Y}$ by

$$S_\epsilon(u) = -\epsilon^2\Delta u + f(u) + \epsilon\gamma(1-\Delta)^{-1}u. \tag{3.10}$$

Equation (1.5) is $S_\epsilon(u) = 0$.

LEMMA 3.1. *$S_\epsilon(w) = O(\epsilon)$ locally uniformly in $\mathbf{r}$ and γ. More precisely, for each compact subset $\mathcal{K}$ of $\mathcal{A}_K^a$ and $[\gamma_1,\gamma_2]$, $0 < \gamma_1 < \gamma_2$, there exist $C > 0$ and $\epsilon_0 > 0$ such that for all $\mathbf{r} \in \mathcal{K}$, $\gamma \in [\gamma_1,\gamma_2]$ and $\epsilon < \epsilon_0$, $\|S_\epsilon(w(\cdot;\mathbf{r}))\|_\infty \le C\epsilon$.*

Proof. Given $\mathcal{K}$ and $[\gamma_1,\gamma_2]$, we let $\mathbf{r} \in \mathcal{K}$ and $\gamma \in [\gamma_1,\gamma_2]$. Then

$$\begin{aligned} S_\epsilon(w) &= -\epsilon^2\left(w_{rr} + \frac{n-1}{r}w_r\right) + f(w) + \epsilon\gamma(1-\Delta)^{-1}w \\ &= (-\epsilon^2 w_{rr} + f(w)) - \epsilon^2\frac{n-1}{r}w_r + \epsilon\gamma(1-\Delta)^{-1}w \\ &= O(e^{-C/\epsilon}) + O(\epsilon) + O(\epsilon) \ =\ O(\epsilon). \end{aligned} \tag{3.11}$$

The lemma follows. ∎

For each $j = 1, 2, \ldots, K$, let us define

$$h_j(r) = H'\left(\frac{r-r_j}{\epsilon}\right)\kappa\left(\frac{r-r_j}{\sqrt{\epsilon}}\right) = H'\left(\frac{r-r_j}{\epsilon}\right) + O(e^{-C/\sqrt{\epsilon}}), \tag{3.12}$$

where κ is a smooth, even, cut-off function

$$\kappa(s) = \begin{cases} 1 & \text{if } |s| \le 1, \\ 0 & \text{if } |s| \ge 2. \end{cases} \tag{3.13}$$

Here $O(e^{-C/\sqrt{\epsilon}})$ is an exponentially small quantity with respect to ϵ because of the exponentially fast decay rate of H': $H'(t) \le C_1 e^{-C_2|t|}$. Therefore $h_j'(0) = h_j'(1) = 0$, $\|h_j' - \epsilon^{-1} H''(\frac{\cdot - r_j}{\epsilon})\|_\infty = O(\epsilon^{-C/\sqrt{\epsilon}})$, and $\|h_j'' - \epsilon^{-2} H'''(\frac{\cdot - r_j}{\epsilon})\|_\infty = O(\epsilon^{-C/\sqrt{\epsilon}})$. Note that h_j depends on $\mathbf{r}$ so we sometimes write it as $h_j(r; \mathbf{r})$.

At each $w(\cdot; \mathbf{r})$ of the manifold we define the space

$$\mathcal{F}_{\mathbf{r}} = \{\phi \in \mathcal{X} : \ \phi \perp h_j, \ j = 1, 2, \dots, K\}, \tag{3.14}$$

where $\perp$ is defined from the inner product

$$\langle A, B \rangle = \int_0^1 A(r) B(r)\, r^{n-1} dr. \tag{3.15}$$

Then $w_{\mathbf{r}} + \mathcal{F}_{\mathbf{r}}$ is a subset of $\mathcal{X}$, which we call the $\mathbf{r}$-fiber of $\mathcal{M}$ in $\mathcal{X}$. Define $\mathcal{E}_{\mathbf{r}}$ to be the subspace

$$\mathcal{E}_{\mathbf{r}} = \{q \in \mathcal{Y} : \ q \perp h_j, \ j = 1, 2, \dots, K\} \tag{3.16}$$

of $\mathcal{Y}$. Let the projection from $\mathcal{Y}$ to $\mathcal{E}_{\mathbf{r}}$ be $\pi_{\mathbf{r}} : \mathcal{Y} \to \mathcal{E}_{\mathbf{r}}$, defined by

$$\pi_{\mathbf{r}}(q) = q - \sum_{j=1}^{K} \frac{\langle q, h_j \rangle}{\|h_j\|_2^2} h_j. \tag{3.17}$$

At each $w(\cdot; \mathbf{r})$ we look for a $\phi(\cdot; \mathbf{r}) \in \mathcal{F}_{\mathbf{r}}$ so that

$$\pi_{\mathbf{r}} \circ S_\epsilon(w(\cdot; \mathbf{r}) + \phi(\cdot; \mathbf{r})) = 0. \tag{3.18}$$

This means that we solve $S_\epsilon(u) = 0$ in the fiber direction. For each $\phi \in \mathcal{F}_{\mathbf{r}}$ we expand

$$S_\epsilon(w + \phi) = S_\epsilon(w) + L_{\mathbf{r}}(\phi) + R_{\mathbf{r}}(\phi), \tag{3.19}$$

where the linearized operator of S_ϵ at $w(\cdot; \mathbf{r})$ is denoted by $L_{\mathbf{r}}$: $\mathcal{X} \to \mathcal{Y}$, defined by

$$L_{\mathbf{r}}\phi := -\epsilon^2 \left(\phi_{rr} + \frac{n-1}{r} \phi_r \right) + f'(w(r; \mathbf{r}))\phi + \epsilon\gamma(1 - \Delta)^{-1}\phi, \tag{3.20}$$

and the remainder is

$$R_{\mathbf{r}}(\phi) = f(w + \phi) - f(w) - f'(w)\phi. \tag{3.21}$$

Then (3.18) is written as

$$\pi_{\mathbf{r}} \circ S_\epsilon(w) + \pi_{\mathbf{r}} \circ L_{\mathbf{r}}(\phi) + \pi_{\mathbf{r}} \circ R_{\mathbf{r}}(\phi) = 0. \tag{3.22}$$

Regarding the linear operator $\pi_{\mathbf{r}} \circ L_{\mathbf{r}}$,

$$\pi_{\mathbf{r}} \circ L_{\mathbf{r}} : \mathcal{F}_{\mathbf{r}} \to \mathcal{E}_{\mathbf{r}} \tag{3.23}$$

(note that it is defined on $\mathcal{F}_{\mathbf{r}}$—not on $\mathcal{X}$), we have the following lemma.

LEMMA 3.2.

1. *There exists $C_1 > 0$ independent of ϵ such that $\|\phi\|_\infty \le C_1 \|\pi_{\mathbf{r}} \circ L_{\mathbf{r}}(\phi)\|_\infty$ for all $\phi \in \mathcal{F}_{\mathbf{r}}$. In particular, $\pi_{\mathbf{r}} \circ L_{\mathbf{r}}$ is one-to-one from $\mathcal{F}_{\mathbf{r}}$ to $\mathcal{E}_{\mathbf{r}}$.*
2. *$\pi_{\mathbf{r}} \circ L_{\mathbf{r}}$ is onto from $\mathcal{F}_{\mathbf{r}}$ to $\mathcal{E}_{\mathbf{r}}$.*

Proof. To prove part 1 we argue by contradiction. Suppose the conclusion is false. Then there exists $\psi_\epsilon \in \mathcal{F}_{\mathbf{r}}$ for each ϵ such that $\|\psi_\epsilon\|_\infty = 1$ and along a subsequence of $\epsilon \to 0$,

$$\|\pi_{\mathbf{r}} \circ L_{\mathbf{r}}(\psi_\epsilon)\|_\infty \to 0. \tag{3.24}$$

To simplify notation, we write ψ instead of ψ_ϵ. We rewrite (3.24) as

$$-\epsilon^2 \left(\psi_{rr} + \frac{n-1}{r}\psi_r\right) + f'(w)\psi + \epsilon\gamma(1-\Delta)^{-1}\psi - \sum_{j=1}^{K} \beta_j h_j = o(1) \tag{3.25}$$

for some $\beta_j \in \mathbf{R}$. More specifically, β_j are given by

$$\beta_j = \frac{\langle L_{\mathbf{r}}(\psi), h_j \rangle}{\|h_j\|_2^2}. \tag{3.26}$$

We must estimate the size of β_j. To this end we multiply (3.25) by h_k and integrate. Then

$$\begin{aligned} &\int_0^1 \left[\left(-\epsilon^2 \left(\psi_{rr} + \frac{n-1}{r}\psi_r\right) + f'(w)\psi + \epsilon\gamma(1-\Delta)^{-1}\psi\right) h_k\right] r^{n-1} dr \\ &\quad + \sum_{j=1}^{K} \beta_j \langle h_j, h_k \rangle = o(\epsilon), \end{aligned} \tag{3.27}$$

Simple calculations simplify the second part on the left side, so

$$\begin{aligned} &\int_0^1 \left[\left(-\epsilon^2 \left(\psi_{rr} + \frac{n-1}{r}\psi_r\right) + f'(w)\psi + \epsilon\gamma(1-\Delta)^{-1}\psi\right) h_k\right] r^{n-1} dr \\ &\quad + \sum_{j=1}^{K} \beta_j (\epsilon\tau r_j^{n-1}\delta_{jk} + O(\epsilon^2)) = o(\epsilon), \end{aligned} \tag{3.28}$$

where $\delta_{jk} = 1$ if $j \ne k$ and 0 if $j = k$. Also we have used the fact that

$$\tau = \int_{\mathbf{R}} (H')^2 \, dt. \tag{3.29}$$

This τ is the same as the one given in (2.5). These two expressions give the same value because of (3.2), which H satisfies, and its first integral

$$-\frac{1}{2}(H'(t))^2 + W(H(t)) = 0. \tag{3.30}$$

The first part of the left side of (3.28) is estimated as follows:

(3.31)

$$\int_0^1 \left[\left(-\epsilon^2\left(\psi_{rr}+\frac{n-1}{r}\psi_r\right)+f'(w)\psi+\epsilon\gamma(1-\Delta)^{-1}\psi\right)h_k\right] r^{n-1}dr$$
$$=\int_0^1\left(-\epsilon^2\left(h_k''+\frac{n-1}{r}h_k'\right)\psi+f'(w)h_k\psi\right)r^{n-1}dr+\epsilon\gamma\int_0^1((1-\Delta)^{-1}\psi)h_k\,r^{n-1}dr$$
$$=\int_0^1 -\epsilon^2\frac{n-1}{r}h_k'\psi\,r^{n-1}dr+O(\epsilon^2)\;=\;O(\epsilon^2).$$

This simplifies (3.28) to

$$\sum_{j=1}^{2N}\beta_j(\epsilon\tau\delta_{jk}+O(\epsilon^2))=o(\epsilon). \tag{3.32}$$

Hence

$$\beta_j=o(1). \tag{3.33}$$

Let $y\in[0,1]$ such that, without loss of generality, $\psi(y)=\|\psi\|_\infty=1$. We claim that $y-r_j=O(\epsilon)$ for some j. Otherwise, at y,

$$\begin{aligned}L_{\mathbf{r}}(\psi)(y)&=-\epsilon^2\Delta\psi(y)+f'(w(y))\psi(y)+\epsilon\gamma((1-\Delta)^{-1}\psi)(y)\\&\geq 0+f'(w(y))+\epsilon\gamma((1-\Delta)^{-1}\psi)(y)\\&=f'(w(y))+O(\epsilon)\;=\;f'(a)+o(1).\end{aligned} \tag{3.34}$$

Combining (3.33) and (3.34), we obtain

$$\pi_{\mathbf{r}}\circ L_{\mathbf{r}}(\psi)(y)\geq f'(a)-\sum_{j=1}^{K}\beta_j h_j(y)+o(1)\geq f'(0)+o(1), \tag{3.35}$$

which contradicts (3.24).

We have thus proved that $y-\xi_j=O(\epsilon)$ for some j, along a subsequence of $\epsilon\to 0$. Define $\Psi(t)=\psi(r_j+\epsilon t)$. Then (3.25) and (3.33) imply

$$-\Psi''+f'(w_{\mathbf{r}}(r_j+\epsilon t))\Psi=o(1) \tag{3.36}$$

uniformly on any compact subset of $\mathbf{R}$. From here we may pass to the limit and find Ψ_∞ so that $\Psi\to\Psi_\infty$ in $C^2_{loc}(\mathbf{R})$. Moreover, $\Psi_\infty\neq 0$ since $\Psi((y-\xi_j)/\epsilon)=1$, and

$$-\Psi_\infty''+f'(H)\Psi_\infty=0. \tag{3.37}$$

The bounded solutions of this equation are scalar multiples of H'. Hence $\Psi_\infty=cH'$ for some $c\neq 0$.

On the other hand, since $\psi\in\mathcal{F}_{\mathbf{r}}$ means that $\psi\perp h_j$, we deduce that

$$\begin{aligned}0=\langle\psi,h_j\rangle&=\epsilon\int_{-r_j/\epsilon}^{(1-r_j)/\epsilon}\Psi(t)(H'(t)-O(e^{-C/\sqrt{\epsilon}}))(r_j+\epsilon t)^{n-1}\,dt\\&=\epsilon\left(cr_j^{n-1}\int_{\mathbf{R}}(H'(t))^2\,dt+o(1)\right),\end{aligned} \tag{3.38}$$

which is impossible, for $c \neq 0$. We have thus proved part 1 of the lemma.

To prove part 2 of the lemma we need to solve

$$\pi_{\mathbf{r}} \circ L_{\mathbf{r}}(\phi) = p \tag{3.39}$$

in $\mathcal{F}_{\mathbf{r}}$ for any given $p \in \mathcal{E}_{\mathbf{r}}$. By applying $\pi_{\mathbf{r}} \circ (1-\Delta)^{-1}$ to both sides of (3.39) we consider the equation

$$\pi_{\mathbf{r}} \circ (1-\Delta)^{-1} \circ \pi_{\mathbf{r}} \circ L_{\mathbf{r}}(\phi) = \pi_{\mathbf{r}} \circ (1-\Delta)^{-1} p. \tag{3.40}$$

The linear operator $\pi_{\mathbf{r}} \circ (1-\Delta)^{-1} \circ \pi_{\mathbf{r}} \circ L_{\mathbf{r}}$ on the left side maps from $\mathcal{F}_{\mathbf{r}}$ to itself. For this operator $\mathcal{F}_{\mathbf{r}}$ is viewed as a Banach space whose norm is inherited from the $W^{2,2}(\Omega)$ norm. The operator has the form

$$\epsilon^2(\text{identity operator}) + \text{compact operator}. \tag{3.41}$$

According to the Fredholm alternative, (3.40) is solvable if

$$\pi_{\mathbf{r}} \circ (1-\Delta)^{-1} \circ \pi_{\mathbf{r}} \circ L_{\mathbf{r}}(\phi) = 0 \tag{3.42}$$

has only the trivial solution. To see this we write (3.42) as

$$(1-\Delta)^{-1} \circ \pi_{\mathbf{r}} \circ L_{\mathbf{r}}(\phi) = \sum_{j=1}^{K} \alpha_j h_j \tag{3.43}$$

for some $\alpha_j \in \mathbf{R}$. Apply $1-\Delta$ to the last equation to find

$$\pi_{\mathbf{r}} \circ L_{\mathbf{r}}(\phi) = \sum_{j=1}^{K} \alpha_j (-\Delta h_j + h_j). \tag{3.44}$$

We multiply it by h_k and integrate to deduce

$$\begin{aligned} 0 &= \sum_{j=1}^{K} \alpha_j \int_{\Omega} (\nabla h_j \cdot \nabla h_k + h_j h_k)\, dx \qquad (3.45) \\ &= \alpha_k \int_{\Omega} (|\nabla h_k|^2 + h_k^2)\, dx, \ \ k = 1, 2, \dots, K, \end{aligned}$$

which implies that $\alpha_j = 0$, $j = 1, 2, \dots, K$. Then (3.44) becomes

$$\pi_{\mathbf{r}} \circ L_{\mathbf{r}}(\phi) = 0. \tag{3.46}$$

The first part of the lemma implies that $\phi = 0$.

Hence (3.40) is solvable; i.e., for any $p \in \mathcal{E}_{\mathbf{r}}$ there exist $\phi \in \mathcal{F}_{\mathbf{r}}$ and $\beta_j \in \mathbf{R}$ such that

$$(1-\Delta)^{-1} \circ \pi_{\mathbf{r}} \circ L_{\mathbf{r}}(\phi) = (1-\Delta)^{-1} p + \sum_{j=1}^{K} \beta_j h_j. \tag{3.47}$$

Apply $1-\Delta$ to the last equation to deduce

$$\pi_{\mathbf{r}} \circ L_{\mathbf{r}}(\phi) = p + \sum_{j=1}^{K} \beta_j (-\Delta h_j + h_j). \tag{3.48}$$

We again multiply by h_k and integrate to obtain

$$0 = \sum_{j=1}^{K} \beta_j \int_\Omega \nabla h_j \cdot \nabla h_k \, dx = \beta_k \epsilon \int_\Omega (|\nabla h_k|^2 + h_k^2) \, dx, \ k = 1, 2, \dots, K, \tag{3.49}$$

which implies that $\beta_j = 0$ for all $j = 1, 2, \dots, K$. Then (3.48) becomes (3.39). ∎

We are now ready to solve (3.18).

LEMMA 3.3. *There exists $\phi(\cdot; \mathbf{r}) \in \mathcal{F}_\mathbf{r}$ with $\|\phi(\cdot; \mathbf{r})\|_\infty = O(\epsilon)$ so that $\pi_\mathbf{r} \circ S_\epsilon(w(\cdot; \mathbf{r}) + \phi(\cdot; \mathbf{r})) = 0$.*

Proof. We write (3.22) in a fixed point form:

$$\phi = (\pi_\mathbf{r} \circ L_\mathbf{r})^{-1}(-\pi_\mathbf{r} \circ S_\epsilon(w) - \pi_\mathbf{r} \circ R_\mathbf{r}(\phi)). \tag{3.50}$$

We define the operator $T_\mathbf{r}$ from $\mathcal{D}(T_\mathbf{r})$ to itself,

$$T_\mathbf{r}(\phi) = (\pi_\mathbf{r} \circ L_\mathbf{r})^{-1}(-\pi_\mathbf{r} \circ S_\epsilon(w) - \pi_\mathbf{r} \circ R_\mathbf{r}(\phi)), \tag{3.51}$$

where the domain $\mathcal{D}(T_\mathbf{r})$ of $T_\mathbf{r}$ is

$$\mathcal{D}(T_\mathbf{r}) = \{\phi \in L^\infty(0,1) : \ \phi \perp h_j, \ j = 1, 2, \dots, K\}. \tag{3.52}$$

Let $\mathcal{B}_\mathbf{r}$ be a closed ball in $\mathcal{D}(T_\mathbf{r})$ defined by

$$\mathcal{B}_\mathbf{r} = \{\phi \in \mathcal{D}(T_\mathbf{r}) : \|\phi\|_\infty \le C_2 \epsilon\}, \tag{3.53}$$

where C_2 is a constant independent of ϵ to be determined soon. For every $\phi \in \mathcal{B}_\mathbf{r}$, by Lemma 3.1

$$\begin{aligned} \|T_\mathbf{r}(\phi)\|_\infty &\le C_1 \|\pi_\mathbf{r} \circ S_\epsilon(w)\|_\infty + C_1 \|\pi_\mathbf{r} \circ R_\mathbf{r}(\phi)\|_\infty \\ &\le C_3 \epsilon + C_5 (1 + O(\|\phi\|_\infty)) \|\phi\|_\infty^2 \\ &\le C_3 \epsilon + C_6 C_2^2 (1 + C_2 \epsilon) \epsilon^2, \end{aligned} \tag{3.54}$$

where we have estimated $R_\mathbf{r}(\phi)$ as

$$\|R_\mathbf{r}(\phi)\|_\infty \le 2\|f(w_\mathbf{r} + \phi) - f(w_\mathbf{r}) - f'(w_\mathbf{r})\phi\|_\infty \le C_4 (1 + O(\|\phi\|_\infty)) \|\phi\|_\infty^2 \tag{3.55}$$

for some C_4 depending only on f. In (3.54) the constants C_3 and C_6 are again independent of ϵ. If we choose C_2 to be sufficiently large, then when ϵ is small enough (3.54) is bounded by $C_2 \epsilon$. Therefore by choosing such C_2 we see that $\mathcal{D}(T_\mathbf{r})$ maps $\mathcal{B}_\mathbf{r}$ to itself.

Next we prove that $T_\mathbf{r}$ is a contraction mapping in $\mathcal{D}(T_\mathbf{r})$. Take ϕ_1 and ϕ_2 in $\mathcal{D}(T_\mathbf{r})$. Then

$$\begin{aligned} \|T_\mathbf{r}(\phi_1) - T_\mathbf{r}(\phi_2)\|_\infty &\le C_1 \|\pi_\mathbf{r} \circ (R_\mathbf{r}(\phi_1) - R_\mathbf{r}(\phi_2))\|_\infty \ \le \ C_7 \|R_\mathbf{r}(\phi_1) - R_\mathbf{r}(\phi_2)\|_\infty \\ &\le C_8 \|f(w_\mathbf{r} + \phi_1) - f(w_\mathbf{r} + \phi_2) - f'(w_\mathbf{r})(\phi_1 - \phi_2)\|_\infty \\ &\le C_8 \|f'(w_\mathbf{r} + \phi_2 + \theta(\phi_1 - \phi_2))(\phi_1 - \phi_2) - f'(w_\mathbf{r})(\phi_1 - \phi_2)\|_\infty \\ &\le C_8 \|f'(w_\mathbf{r} + \phi_2 + \theta(\phi_1 - \phi_2)) - f'(w_\mathbf{r})\|_\infty \|\phi_1 - \phi_2\|_\infty \\ &\le O(\|\phi_1\|_\infty + \|\phi_2\|_\infty) \ \|\phi_1 - \phi_2\|_\infty \\ &\le C_9 \epsilon \|\phi_1 - \phi_2\|_\infty, \end{aligned} \tag{3.56}$$

which implies that $T_\mathbf{r}$ is a contraction mapping if ϵ is sufficiently small. In these estimates $\theta = \theta(x) \in (0,1)$ comes from the mean value theorem. ∎

4. C^1-convergence of the reduced problem. We now define

$$Q_\epsilon(\mathbf{r}) = I_\epsilon(w(\cdot;\mathbf{r}) + \phi(\cdot;\mathbf{r})), \tag{4.1}$$

where $w(\cdot;\mathbf{r})$ is the approximate solution constructed in (3.4) and $\phi(\cdot;\mathbf{r})$ is given in Lemma 3.3. We may view Q_ϵ as a function defined on $\mathcal{A}_K^a$.

LEMMA 4.1. *If $\mathbf{r} \in A_K^a$ is a critical point of Q_ϵ, then $S_\epsilon(w(\cdot;\mathbf{r}) + \phi(\cdot;\mathbf{r})) = 0$.*

Proof. Let $\mathbf{r}_*$ be a critical point of Q_ϵ. Set $g(r;\mathbf{r}) = (w(\cdot;\mathbf{r}) + \phi(\cdot;\mathbf{r}))$. At $\mathbf{r} = \mathbf{r}_*$ we have, for each l,

$$\begin{aligned} 0 = \frac{\partial Q_\epsilon(\mathbf{r}_*)}{\partial r_l} &= \int_0^1 (-\epsilon^2 \Delta g + f(g) + \epsilon\gamma(1-\Delta)^{-1} g) \frac{\partial g}{\partial r_l}\, r^{n-1} dr \\ &= \sum_{m=1}^K c_m \int_0^1 h_m \frac{\partial g}{\partial r_l}\, r^{n-1} dr. \end{aligned}$$

Here we have assumed that at $\mathbf{r}_*$, $S_\epsilon(g) = \sum_{m=1}^K c_m h_m$, because $\pi_{\mathbf{r}}(S_\epsilon(g)) = 0$. The last equation asserts that the coefficients c_m satisfy a linear homogeneous system whose ml matrix entry is $\int_0^1 h_m \frac{\partial g}{\partial r_l}\, dx$ at $\mathbf{r} = \mathbf{r}_*$.

Recall that $g = w + \phi$ and $h_m \perp \phi$ for all $\mathbf{r}$. We differentiate $0 = \int_0^1 h_m \phi\, r^{n-1} dr$ with respect to r_l to obtain

$$\int_0^1 h_m \frac{\partial \phi(r;\mathbf{r})}{\partial r_l}\, r^{n-1} dr = -\int_0^1 \frac{\partial h_m(r;\mathbf{r})}{\partial r_l} \phi(r;\mathbf{r})\, r^{n-1} dr.$$

Therefore, since $\phi = O(\epsilon)$,

$$\int_0^1 h_m \frac{\partial g}{\partial r_l}\, r^{n-1} dr = \int_0^1 \left(h_m \frac{\partial w}{\partial r_l} - \frac{\partial h_m}{\partial r_l} \phi \right) r^{n-1} dr = \delta_{ml} r_l^{n-1} \int_R (H'(t))^2\, dt + O(\epsilon).$$

Therefore the coefficient matrix is nonsingular. This implies $c_m = 0$, i.e., $S_\epsilon(g(\cdot;\mathbf{r}_*)) = 0$. ∎

The reduced problem Q_ϵ, scaled by ϵ^{-1}, converges to J given in (2.4) in C^1 locally in $\mathbf{r}$ and locally in γ.

LEMMA 4.2. *Given a compact subset $\mathcal{K}$ of $\mathcal{A}_K^a$ and an interval $[\gamma_1, \gamma_2]$, with $0 < \gamma_1 < \gamma_2 < \infty$, we have that for every $\delta > 0$ there exists $\epsilon_0 > 0$ such that when $\epsilon < \epsilon_0$, $|\epsilon^{-1} Q_\epsilon(\mathbf{r}) - J(\mathbf{r})| < \delta$ and $|\text{grad } \epsilon^{-1} Q_\epsilon(\mathbf{r}) - \text{grad } J(\mathbf{r})| < \delta$ for all $\mathbf{r} \in \mathcal{K}$ and $\gamma \in [\gamma_1, \gamma_2]$.*

Proof. Given $\mathcal{K}$ and $[\gamma_1, \gamma_2]$, we let $\mathbf{r} \in \mathcal{K}$ and $\gamma \in [\gamma_1, \gamma_2]$. We first show the C^0-convergence. Expand $I_\epsilon(w(\cdot;\mathbf{r}) + \phi(\cdot;\mathbf{r}))$ to find

$$Q_\epsilon(\mathbf{r}) = I_\epsilon(w) + \int_0^1 S_\epsilon(w)\phi\, r^{n-1} dr + \frac{1}{2} \int_0^1 \phi L_{\mathbf{r}} \phi\, dx + O(\epsilon^3). \tag{4.2}$$

The equation $\pi_{\mathbf{r}} \circ S_\epsilon(w+\phi) = 0$ implies that $S_\epsilon(w+\phi) = \sum_{j=1}^K \beta_j h_j$ for some $\beta_j \in \mathbf{R}$, which can be written as

$$S_\epsilon(w) + L_{\mathbf{r}}\phi + O(\epsilon^2) = \sum_{j=1}^K \beta_j h_j. \tag{4.3}$$

Multiply (4.3) by ϕ and integrate to find

$$\int_0^1 S_\epsilon(w)\phi\, r^{n-1}dr + \int_0^1 \phi L_{\mathbf{r}}\phi\, r^{n-1}dr + O(\epsilon^3) = 0 \tag{4.4}$$

since $\phi \perp h_j$. Substituting (4.4) into (4.2), we deduce

$$Q_\epsilon(\mathbf{r}) = I_\epsilon(w) + \frac{1}{2}\int_0^1 S_\epsilon(w)\phi\, r^{n-1}dr + O(\epsilon^3). \tag{4.5}$$

By Lemma 3.1 we obtain

$$\int_0^1 S_\epsilon(w)\phi\, r^{n-1}dr = O(\epsilon^2). \tag{4.6}$$

Now (4.5) becomes

$$Q_\epsilon(\mathbf{r}) = I_\epsilon(w(\cdot;\mathbf{r})) + O(\epsilon^2). \tag{4.7}$$

So we turn our attention to $I_\epsilon(w(\cdot;\mathbf{r}))$. Note that

$$\begin{aligned} I_\epsilon(w(\cdot;\mathbf{r})) &= \omega_{n-1}\int_0^1 \left[\frac{\epsilon^2}{2}|w_r|^2 + W(w)\right] r^{n-1}dr + \frac{\omega_{n-1}\epsilon\sigma}{2}\int_0^1 |(1-\Delta)^{-1/2}w|^2\, r^{n-1}dr \\ &= \omega_{n-1}\epsilon\tau\sum_{j=1}^K r_j^{n-1} + \frac{\omega_{n-1}\epsilon\gamma}{2}\int_0^1 |(1-\Delta)^{-1/2}w|^2\, r^{n-1}dr + O(\epsilon^2) \\ &= \epsilon J(\mathbf{r}) + O(\epsilon^2). \end{aligned} \tag{4.8}$$

Before arriving at (4.8) we have used the fact that

$$\int_{\mathbf{R}} \left[\frac{1}{2}(H')^2 + W(H)\right] dt = \tau,$$

which follows from the first integral (3.30) of H and the definition of τ. Therefore,

$$Q_\epsilon(\mathbf{r}) = \epsilon J(\mathbf{r}) + O(\epsilon^2), \tag{4.9}$$

proving the convergence at the C^0 level.

Next we show the convergence of grad $(\epsilon^{-1}Q_\epsilon)$. We calculate

$$\begin{aligned} \frac{\partial Q_\epsilon(\mathbf{r})}{\partial r_j} &= \frac{\partial}{\partial r_j} I_\epsilon(w(\cdot;\mathbf{r}) + \phi(\cdot;\mathbf{r})) \\ &= \int_\Omega S_\epsilon(w+\phi)\frac{\partial(w(\cdot;\mathbf{r}) + \phi(\cdot;\mathbf{r}))}{\partial r_j}\, dx \\ &= \int_\Omega S_\epsilon(w+\phi)\frac{\partial w(\cdot;\mathbf{r})}{\partial r_j}\, dx + \int_\Omega S_\epsilon(w+\phi)\frac{\partial \phi(\cdot;\mathbf{r})}{\partial r_j}\, dx. \end{aligned} \tag{4.10}$$

We estimate the second integral in (4.10) first. Note that since $\pi_{\mathbf{r}}(S_\epsilon(w+\phi)) = 0$,

$$S_\epsilon(w+\phi) = \sum_{l=1}^K \beta_l h_l$$

for some $\beta_l \in \mathbf{R}$. Since when $l \neq m$, h_l, and h_m are supported in disjoint sets, the h_l's are perpendicular to each other. We find

$$\beta_l = \frac{\langle S_\epsilon(w+\phi), h_l\rangle}{\|h_l\|_2^2}.$$

To estimate the numerator on the right side we write

$$S_\epsilon(w+\phi) = S_\epsilon(w) + L_{\mathbf{r}}\phi + R_{\mathbf{r}}(\phi).$$

From Lemma 3.1 we find

$$|\langle S_\epsilon(w), h_l\rangle| \leq \|S_\epsilon(w)\|_\infty \|h_l\|_1 = O(\epsilon)O(\epsilon) = O(\epsilon^2).$$

From Lemma 3.3 we have

$$|\langle L_{\mathbf{r}}\phi, h_l\rangle| = |\langle L_{\mathbf{r}}h_l, \phi\rangle| \leq \|L_{\mathbf{r}}h_l\|_1 \|\phi\|_\infty = O(\epsilon^2)O(\epsilon) = O(\epsilon^3),$$

and

$$|\langle R_{\mathbf{r}}(\phi), h_l\rangle| \leq \|R_{\mathbf{r}}(\phi)\|_\infty \|h_l\|_1 = O(\epsilon^2)O(\epsilon) = O(\epsilon^3).$$

Combing the last three estimates we obtain

$$\langle S_\epsilon(w+\phi), h_l\rangle = O(\epsilon^2).$$

Since $\|h_l\|_2^2$ is of order ϵ, we deduce

$$\beta_l = O(\epsilon). \tag{4.11}$$

The fact $\phi \perp h_l$ implies, after differentiating $\langle \phi, h_l\rangle = 0$ with respect to r_j, that

$$\int_0^1 \frac{\partial \phi(r;\mathbf{r})}{\partial r_j} h_j \, r^{n-1} dr + \int_0^1 \frac{\partial h_l(r;\mathbf{r})}{\partial r_j} \phi \, r^{n-1} dr = 0. \tag{4.12}$$

Hence the second integral in (4.10) becomes

$$\begin{aligned} \int_\Omega S_\epsilon(w+\phi) \frac{\partial \phi(\cdot;\mathbf{r})}{\partial r_j}\, dx &= \sum_{l=1}^K \omega_{n-1}\beta_l \int_0^1 h_j \frac{\partial \phi}{\partial r_j}\, r^{n-1} dr \\ &= -\sum_{l=1}^K \omega_{n-1}\beta_l \int_0^1 \phi \frac{\partial h_l}{\partial r_j}\, r^{n-1} dr. \end{aligned} \tag{4.13}$$

Our estimate of β_l, (4.11), and Lemma 3.3 imply that the last quantity of (4.13) is of order ϵ^2:

$$\int_\Omega S_\epsilon(w+\phi) \frac{\partial \phi(\cdot;\mathbf{r})}{\partial r_j}\, dx = O(\epsilon^2). \tag{4.14}$$

It remains to calculate the first integral in (4.10). We again write $S_\epsilon(w+\phi) = S_\epsilon(w) + L_{\mathbf{r}}\phi + R_{\mathbf{r}}(\phi)$ so that

$$\int_\Omega S_\epsilon(w+\phi) \frac{\partial w(\cdot;\mathbf{r})}{\partial r_j}\, dx = \int_\Omega \left[S_\epsilon(w) \frac{\partial w(\cdot;\mathbf{r})}{\partial r_j} + L_{\mathbf{r}}\phi \frac{\partial w(\cdot;\mathbf{r})}{\partial r_j} + R_{\mathbf{r}}(\phi) \frac{\partial w(\cdot;\mathbf{r})}{\partial r_j} \right] dx.$$

We must separate two cases: j is odd and j is even. When j is odd, $w(r)$ is $H(\frac{r-r_j}{\epsilon})$ for r near r_j. Moreover,

$$\frac{\partial w(r;\mathbf{r})}{\partial r_j} = -\epsilon^{-1}H'\left(\frac{r-r_j}{\epsilon}\right) + O(e^{-C/\epsilon}). \tag{4.15}$$

In this case we argue as in the estimations leading to (4.11) to conclude that

$$\int_\Omega L_{\mathbf{r}}\phi \frac{\partial w(\cdot;\mathbf{r})}{\partial r_j}\,dx = O(\epsilon^2), \quad \int_\Omega R_{\mathbf{r}}(\phi)\frac{\partial w(\cdot;\mathbf{r})}{\partial r_j}\,dx = O(\epsilon^2).$$

Therefore,

(4.16)

$$\begin{aligned}
&\int_\Omega S_\epsilon(w+\phi)\frac{\partial w(\cdot;\mathbf{r})}{\partial r_j}\,dx = \int_\Omega S_\epsilon(w)\frac{\partial w(\cdot;\mathbf{r})}{\partial r_j}\,dx + O(\epsilon^2)\\
&= \omega_{n-1}\int_0^1 \left[-\epsilon^2\left(w_{rr}+\frac{n-1}{r}w_r\right) + f(w) + \epsilon\gamma(1-\Delta)^{-1}w\right]\frac{\partial w(r;\mathbf{r})}{\partial r_j}\,r^{n-1}dr\\
&\quad + O(\epsilon^2)\\
&= \omega_{n-1}\int_0^1 \left[-\epsilon^2\frac{n-1}{r}w_r + \epsilon\gamma(1-\Delta)^{-1}w\right]\left(-\epsilon^{-1}H'\left(\frac{r-r_j}{\epsilon}\right)\right)r^{n-1}dr + O(\epsilon^2)\\
&= \omega_{n-1}\int_0^1 \left[-\epsilon\frac{n-1}{r}H'\left(\frac{r-r_j}{\epsilon}\right) + \epsilon\gamma(1-\Delta)^{-1}w\right]\left(-\epsilon^{-1}H'\left(\frac{r-r_j}{\epsilon}\right)\right)r^{n-1}dr\\
&\quad + O(\epsilon^2)\\
&= \omega_{n-1}\epsilon[(n-1)\tau r_j^{n-2} - (b-a)\gamma r_j^{n-1}((1-\Delta)^{-1}w(\cdot;\mathbf{r}))(r_j)] + O(\epsilon^2).
\end{aligned}$$

Similarly when j is even, $w(r)$ is $H(-\frac{r-r_j}{\epsilon})$ for r near r_j and

$$\frac{\partial w(r;\mathbf{r})}{\partial r_j} = \epsilon^{-1}H'\left(-\frac{r-r_j}{\epsilon}\right) + O(e^{-C/\epsilon}). \tag{4.17}$$

Then

$$\begin{aligned}
&\int_\Omega S_\epsilon(w+\phi)\frac{\partial w(\cdot;\mathbf{r})}{\partial r_j}\,dx\\
&= \omega_{n-1}\epsilon[(n-1)\tau r_j^{n-2} + (b-a)\gamma r_j^{n-1}((1-\Delta)^{-1}w(\cdot;\mathbf{r}))(r_j)] + O(\epsilon^2)\\
&= \omega_{n-1}\epsilon[(n-1)\tau r_j^{n-2} + (b-a)\gamma r_j^{n-1}((1-\Delta)^{-1}s(\cdot;\mathbf{r}))(r_j)] + O(\epsilon^2). \qquad (4.18)
\end{aligned}$$

Recall that $s \in \mathcal{A}_K^a$ is the outer part of w defined in (3.1). In conclusion, by (4.10), (4.14), (4.16), (4.18), and the calculations of $\partial J/\partial r_j$ in section 2, we have that

$$\frac{\partial Q_\epsilon(\mathbf{r})}{\partial r_j} = \int_\Omega S_\epsilon(w+\phi)\frac{\partial w(\cdot;\mathbf{r})}{\partial r_j}\,dx + O(\epsilon^2) = \epsilon\frac{\partial J(\mathbf{r})}{\partial r_j} + O(\epsilon^2). \tag{4.19}$$

This proves the lemma. □

We are now ready to prove our main results.

Proof of Theorem 1.1. Lemma 2.4, part 1, asserts that J is minimized at a point in the interior of $\mathcal{A}_K^a$ if γ is large. By Lemma 4.2 we conclude that Q_ϵ has a local

minimum $\mathbf{r}_\epsilon$ in $\mathcal{A}_K^a$. As $\epsilon \to 0$, $\mathbf{r}_\epsilon$ converges, possibly along a subsequence, to $\mathbf{r}_* \in \mathcal{A}_K^a$, which is a minimizer of J. Choose a small neighborhood $\mathcal{K}_1$ of r_* so that $\mathbf{r}_\epsilon \in \mathcal{K}_1$. If there are several critical points of Q_ϵ in $\mathcal{K}_1$, we are finished. If there is only one, it is an isolated strict local minimum and hence has index 1. On the other hand, there exists a neighborhood $\mathcal{K}$ of $\mathcal{K}_1$ on which the degree of $\operatorname{grad} J$ is zero by Lemma 2.4, part 2. Hence, by continuity, the same is true for $\operatorname{grad} Q_\epsilon$ for small ϵ. Hence there must be another critical point of Q_ϵ in $\mathcal{K}$, as required. □

Proof of Theorem 1.2. We combine Lemmas 2.3 and 4.2. □

5. Solutions with layers near the boundary. In this section, we construct solutions with multiple layers near the boundary of Ω and prove Theorem 1.3. Let $m^2 = f'(a) = f'(b) = (b-a)^2/2 > 0$. First, we construct an approximate solution.

Let $\xi(t)$ be a smooth function, such that $0 \le \xi \le 1$, $\xi(t) = 0$ for $t \le \frac{1}{2}$, and $\xi = 1$ for $t \ge \frac{2}{3}$. Let $\mathbf{r} = (r_0, \bar{r}_1, r_1, \dots, \bar{r}_k, r_k) \in D_{\epsilon,k}$, where $D_{\epsilon,k}$ is the set containing all $\mathbf{r}$ satisfying

$$1 - M\epsilon \ln \frac{1}{\epsilon} < r_0 < \bar{r}_1 < r_1 < \cdots < \bar{r}_k < r_k < 1 - \alpha\epsilon \ln \frac{1}{\epsilon},$$

and

$$\bar{r}_j - r_{j-1} \ge \alpha\epsilon \ln \frac{1}{\epsilon}, \quad r_j - \bar{r}_j \ge \alpha\epsilon \ln \frac{1}{\epsilon}, \quad j = 1, \dots, k,$$

where $\alpha > 0$ is a small constant and $M > 0$ is a large constant.

Define

$$v_{\epsilon,j}(r) = (1-\xi)b + \xi(r) H\left(\frac{r_j - r}{\epsilon}\right), \quad j = 0, 1, \dots, k,$$

and

$$\bar{v}_{\epsilon,j}(r) = (1-\xi)a + \xi(r) H\left(\frac{r - \bar{r}_j}{\epsilon}\right), \quad j = 1, \dots, k.$$

It is easy to check that $v_{\epsilon,j}$ and $\bar{v}_{\epsilon,j}$ satisfy

$$-\epsilon^2 \Delta v = -f(v) + O(\epsilon^2 |v'| + \epsilon^2) = -f(v) + O(\epsilon). \tag{5.1}$$

Let

$$w_{\epsilon,k}(r) = v_{\epsilon,0} + \sum_{j=1}^{k} \big(v_{\epsilon,j} + \bar{v}_{\epsilon,j} - a - b\big).$$

Then, using (5.1), we obtain

$$\begin{aligned}
&-\epsilon^2 \Delta w_{\epsilon,k} + m^2 w_{\epsilon,k} \\
&= -\epsilon^2 \Delta v_{\epsilon,0} - \sum_{j=1}^{k} \big(\epsilon^2 \Delta v_{\epsilon,j} + \epsilon^2 \Delta \bar{v}_{\epsilon,j}\big) + m^2 w_{\epsilon,k} \\
&= -f(v_{\epsilon,0}) - \sum_{j=1}^{k} \big(f(v_{\epsilon,j}) + f(\bar{v}_{\epsilon,j})\big) + m^2 w_{\epsilon,k} \\
&\quad + \epsilon O\left(\epsilon |v'_{\epsilon,0}| + \epsilon \sum_{j=1}^{k} \big(|v'_{\epsilon,j}| + |\bar{v}'_{\epsilon,j}|\big) + \epsilon\right).
\end{aligned} \tag{5.2}$$

Since $w_{\epsilon,k}$ does not satisfy $w'_{\epsilon,k}(1)=0$, we need to make a projection as follows. Let $Pw_{\epsilon,k}$ be the solution of

$$\begin{cases} -\epsilon^2\Delta Pw_{\epsilon,k}+m^2Pw_{\epsilon,k}=-\epsilon^2\Delta w_{\epsilon,k}+m^2w_{\epsilon,k} & \text{in } \Omega,\\ (Pw_{\epsilon,k})'(1)=0. \end{cases} \tag{5.3}$$

We denote $\varphi_\epsilon = w_{\epsilon,k}-Pw_{\epsilon,k}$. Then φ_ϵ satisfies

$$\begin{cases} -\epsilon^2\Delta\varphi_\epsilon+m^2\varphi_\epsilon=0 \ \text{ in } \Omega,\\ \varphi'_\epsilon(1)=w'_{\epsilon,k}(1). \end{cases} \tag{5.4}$$

By the maximum principle, we see $\varphi_\epsilon<0$.

We have the following estimates for φ_ϵ.

LEMMA 5.1. *For any small $\theta>0$, there is a constant $C>0$, such that*

$$|\varphi_\epsilon(r)|\le Ce^{-m(1-r_k)/\epsilon}e^{-m(1-\theta)(1-r)/\epsilon}.$$

In particular,

$$|\varphi_\epsilon(r)|\le Ce^{-m(1-\theta)|r-r_k|/\epsilon}.$$

Proof. Let $G_\epsilon(Y,y)$ and $G(Y,y)$ be the Green function of $-\epsilon^2\Delta+m^2I$ in Ω and $-\Delta+m^2I$ in $\Omega_{\epsilon,y}=\{Y:\epsilon Y+y\in\Omega\}$ subject to the Neumann boundary condition, respectively. Then

$$G_\epsilon(Y,y)=\frac{1}{\epsilon^n}G\left(\frac{Y-y}{\epsilon},0\right).$$

We have

$$\varphi_\epsilon(y)=\epsilon^2\int_{\partial\Omega}G_\epsilon(Y,y)w'_{\epsilon,k}(1)\,dY.$$

This, together with $|w'_{\epsilon,k}(1)|=\epsilon^{-1}\big|\sum_{j=1}^k H'\big(\frac{1-\bar r_j}{\epsilon}\big)-\sum_{j=0}^k H'\big(\frac{1-r_j}{\epsilon}\big)\big|\le C\epsilon^{-1}e^{-m(1-r_k)/\epsilon}$, gives

$$\begin{aligned} |\varphi_\epsilon(y)| &\le C\epsilon e^{-m(1-r_k)/\epsilon}\int_{\partial\Omega}|G_\epsilon(Y,y)|dY\\ &= C\epsilon e^{-m(1-r_k)/\epsilon}\frac{1}{\epsilon^n}\int_{\partial\Omega}\left|G\left(\frac{Y-y}{\epsilon},0\right)\right|dY\\ &= Ce^{-m(1-r_k)/\epsilon}\int_{\partial\Omega_{\epsilon,y}}|G(Y,0)|\,dY\le Ce^{-m(1-r_k)/\epsilon}e^{-m(1-\theta)(1-r)/\epsilon}, \end{aligned} \tag{5.5}$$

since $G(Y,0)\sim\frac{1}{|Y|^{N-2}}$ as $|Y|\to0$, and $|G(Y,0)|\le Ce^{-m|Y|}$ as $|Y|\to+\infty$.

Since for $r\in[0,1]$ we have

$$|r-r_k|\le|1-r_k|+|r-1|=1-r_k+1-r,$$

as a result

$$|\varphi_\epsilon(y)|\le Ce^{-m(1-r_k)/\epsilon}e^{-m(1-\theta)(1-r)/\epsilon}\le Ce^{-m(1-\theta)|r-r_k|/\epsilon}.$$

So, we have proved the lemma. □

Define

$$I^*(u) = \frac{\epsilon^2}{2}\int_\Omega |Du|^2 + \int_\Omega W(u),$$

where $W(t) = \int_a^t f(s)\,ds$.

Next, we estimate $I^*\big(Pw_{\epsilon,k}\big)$. We have

PROPOSITION 5.2.

$$I^*(Pw_{\epsilon,k}) = \epsilon A r_0^{n-1} + \epsilon A \sum_{j=1}^{k} (\bar r_j^{n-1} + r_j^{n-1})$$

$$-B\epsilon \sum_{j=1}^{k} \big(e^{-m(\bar r_j - r_{j-1})/\epsilon} + e^{-m(r_j - \bar r_j)/\epsilon}\big) - B_\epsilon \omega_{n-1}\epsilon e^{-2m(1-r_k)/\epsilon}$$

$$+ \epsilon O\left(\sum_{j=1}^{k} \big(e^{-(1+\sigma)m(\bar r_j - r_{j-1})/\epsilon} + e^{-(1+\sigma)m(r_j - \bar r_j)/\epsilon}\big) + e^{-2(1+\sigma)m(1-r_k)/e} + \epsilon\right),$$

where $A > 0$ and $B > 0$ are some constants independent of ϵ, $B_\epsilon > 0$ is a constant depending on ϵ, satisfying $b_2 \ge B_\epsilon \ge b_1 > 0$ for some constants b_2 and b_1, and $\sigma > 0$ is a constant.

From Proposition 5.2, we see that there are three factors that affect the energy of $Pw_{\epsilon,k}$:

(i) The contribution from the layers is

$$\epsilon A r_0^{n-1} + \epsilon A \sum_{j=1}^{k} (\bar r_j^{n-1} + r_j^{n-1}).$$

(ii) The contribution from the interaction between the layers is

$$-B\epsilon \sum_{j=1}^{k} \big(e^{-m(\bar r_j - r_{j-1})/\epsilon} + e^{-m(r_j - \bar r_j)/\epsilon}\big).$$

(iii) The contribution from the Neumann boundary condition is

$$B_\epsilon \omega_{n-1}\epsilon e^{-2m(1-r_k)/\epsilon}.$$

So, we conclude that the energy will decrease if the layer moves away from the boundary, or the layers move toward each other, or the layer moves toward the boundary. As a result, if $I^*(Pw_{\epsilon,k})$ attains its maximum, the layers must be suitably separated and stay suitably close to the boundary.

We will prove Proposition 5.2 by proving three lemmas.

Let

$$\hat f(t) = f(t + a).$$

Then $\hat F(t) = \int_0^t \hat f(s)\,ds = W(t + a)$.

Denote $\psi_{\epsilon,j} = v_{\epsilon,j} - a$, $j = 0, \dots, k$, $\bar{\psi}_{\epsilon,j} = \bar{v}_{\epsilon,j} - a$, $j = 1, \dots, k$, and $\tilde{v}_{\epsilon,j} = \psi_{\epsilon,j} + \bar{\psi}_{\epsilon,j} - (b-a) = v_{\epsilon,j} + \bar{v}_{\epsilon,j} - b - a$, $j = 1, \dots, k$, $\tilde{v}_{\epsilon,0} = \psi_{\epsilon,0}$. So, with this notation, we see that

$$f(v_{\epsilon,j}) = \hat{f}(\psi_{\epsilon,j}), \quad f(\bar{v}_{\epsilon,j}) = \hat{f}(\bar{\psi}_{\epsilon,j}),$$

and

$$W(w_{\epsilon,k}) = \hat{F}(\bar{w}_{\epsilon,k}),$$

where $\bar{w}_{\epsilon,k} = w_{\epsilon,k} - a = \sum_{j=0}^{k} \tilde{v}_j$.

It is easy to see that

$$P\bar{w}_{\epsilon,k} = Pw_{\epsilon,k} - a.$$

Let

$$\hat{I}^*(u) = \frac{\epsilon^2}{2} \int_\Omega |Du|^2 + \int_\Omega \hat{F}(u).$$

By (5.2) and (5.3), we have

(5.6)

$$\begin{aligned}
&I^*\big(Pw_{\epsilon,k}\big) = \hat{I}^*\big(P\bar{w}_{\epsilon,k}\big) \\
&= \frac{1}{2}\int_\Omega \big(\epsilon^2 |DP\bar{w}_{\epsilon,k}|^2 + m^2 (P\bar{w}_{\epsilon,k})^2\big) + \int_\Omega \hat{F}(P\bar{w}_{\epsilon,k}) - \frac{1}{2} m^2 \int_\Omega (P\bar{w}_{\epsilon,k})^2 \\
&= \frac{1}{2}\int_\Omega \left(-\hat{f}(\psi_{\epsilon,0}) - \sum_{j=1}^{k} \big(\hat{f}(\psi_{\epsilon,j}) + \bar{f}(\hat{\psi}_{\epsilon,j})\big) + m^2 \hat{w}_{\epsilon,k} \right) P\bar{w}_{\epsilon,k} \\
&\quad + \epsilon O\left(\int_\Omega \left(\epsilon |\psi'_{\epsilon,0}| + \epsilon \sum_{j=1}^{k} (|\psi'_{\epsilon,j}| + |\bar{\psi}'_{\epsilon,j}|) \right) |Pw_{\epsilon,k}| \right) \\
&\quad + \int_\Omega \left(\hat{F}(P\bar{w}_{\epsilon,k}) - \frac{m^2}{2} (P\bar{w}_{\epsilon,k})^2 \right) \\
&= \frac{1}{2}\int_\Omega \left(-\hat{f}(\psi_{\epsilon,0}) - \sum_{j=1}^{k} \big(\hat{f}(\psi_{\epsilon,j}) + \hat{f}(\bar{\psi}_{\epsilon,j})\big) \right) \bar{w}_{\epsilon,k} + \int_\Omega \hat{F}(\bar{w}_{\epsilon,k}) \\
&\quad + \int_\Omega \left(-\hat{f}(\bar{w}_{\epsilon,k}) + \frac{1}{2} \left(\hat{f}(\psi_{\epsilon,0}) + \sum_{j=1}^{k} \big(\hat{f}(\psi_{\epsilon,j}) + \hat{f}(\bar{\psi}_{\epsilon,j})\big) \right) + \frac{1}{2} m^2 \bar{w}_{\epsilon,k} \right) \varphi_\epsilon \\
&\quad + \int_\Omega \left(\hat{F}(P\bar{w}_{\epsilon,k}) - \hat{F}(\bar{w}_{\epsilon,k}) + \hat{f}(\bar{w}_{\epsilon,k})\varphi_\epsilon - \frac{1}{2} m^2 \varphi_\epsilon^2 \right) + O(\epsilon^2) \\
&=: \hat{I}_1 + \hat{I}_2 + \hat{I}_3 + O(\epsilon^2).
\end{aligned}$$

LEMMA 5.3. *We have*

$$|\hat{I}_3| \le C\epsilon e^{-(3-\theta)m(1-r_k)/\epsilon},$$

where $\theta > 0$ is any small constant.

Proof. By definition, we have

$$\hat{I}_3 = \frac{1}{2}\int_\Omega \big(\hat{f}'(\bar{w}_{\epsilon,k})\varphi_\epsilon^2 - m^2\varphi_\epsilon^2\big) + O\left(\int_\Omega |\varphi_\epsilon|^3\right). \tag{5.7}$$

Write

$$\int_\Omega \big(\hat{f}'(\bar{w}_{\epsilon,k})\varphi_\epsilon^2 - m^2\varphi_\epsilon^2\big) = \int_{r_k<r\le 1} \big(\hat{f}'(\bar{w}_{\epsilon,k})\varphi_\epsilon^2 - m^2\varphi_\epsilon^2\big) + \int_{r\le r_k} \big(\hat{f}'(\bar{w}_{\epsilon,k})\varphi_\epsilon^2 - m^2\varphi_\epsilon^2\big)$$

$$= \int_{r_k<r\le 1} \big(\hat{f}'(\bar{w}_{\epsilon,k})\varphi_\epsilon^2 - m^2\varphi_\epsilon^2\big) + O\left(\int_{r\le r_k} \varphi_\epsilon^2\right). \tag{5.8}$$

Using Lemma 5.1, we obtain for $r \le r_k$

$$|\varphi_\epsilon(r)| \le Ce^{-m(1-r_k)/\epsilon} e^{-m(1-\theta)(1-r)/\epsilon} \le Ce^{-(2-\theta)m(1-r_k)/\epsilon}.$$

Thus,

$$\begin{aligned}\int_{r\le r_k} |\varphi_\epsilon|^2 &\le Ce^{-(2-\theta)2m(1-r_k)/\epsilon} \int_{r\le r_k} |\varphi_\epsilon|^\theta \\ &\le Ce^{-(2-\theta)2m(1-r_k)/\epsilon} \int_{r\le r_k} e^{-\theta(1-\theta)m|r-r_k|/\epsilon} \\ &\le C\epsilon e^{-(2-\theta)2m(1-r_k)/\epsilon}.\end{aligned} \tag{5.9}$$

On the other hand, for $r \ge r_k$, we have

$$\begin{aligned}\hat{f}'(\bar{w}_{\epsilon,k})\varphi_\epsilon^2 - m^2\varphi_\epsilon^2 &= \hat{f}'(\bar{w}_{\epsilon,k})\varphi_\epsilon^2 - \hat{f}'(0)\varphi_\epsilon^2 \\ &= O\big(|\bar{w}_{\epsilon,k}|\varphi_\epsilon^2\big) = O\Big(e^{-m(r-r_k)/\epsilon} e^{-(2-\theta)m(1-r_k)/\epsilon} e^{-m(2-\theta)(1-\theta)(1-r)/\epsilon} |\varphi_\epsilon^\theta|\Big) \\ &= O\Big(e^{-m(3-\theta)(1-r_k)/\epsilon} |\varphi_\epsilon^\theta|\Big).\end{aligned} \tag{5.10}$$

Using (5.10), we obtain

$$\begin{aligned}&\int_{r_k<r\le 1} \big(\hat{f}'(\bar{w}_{\epsilon,k})\varphi_\epsilon^2 - m^2\varphi_\epsilon^2\big) \\ &\qquad \le Ce^{-m(3-\theta)(1-r_k)/\epsilon} \int_\Omega |\varphi_\epsilon^\theta| \le C\epsilon e^{-m(3-\theta)(1-r_k)/\epsilon}.\end{aligned} \tag{5.11}$$

Combining (5.9) and (5.10), we are led to

$$\int_\Omega \big(\hat{f}'(\bar{w}_{\epsilon,k})\varphi_\epsilon^2 - m^2\varphi_\epsilon^2\big) = O\Big(\epsilon e^{-m(3-\theta)(1-r_k)/\epsilon}\Big). \tag{5.12}$$

Finally,

$$\begin{aligned}\int_\Omega |\varphi_\epsilon|^3 &= \int_{r_k<r\le 1} |\varphi_\epsilon|^3 + \int_{r\le r_k} |\varphi_\epsilon|^3 \le C\epsilon e^{-m(3-\theta)(1-r_k)/\epsilon} + C\epsilon e^{-(2-\theta)2m(1-r_k)/\epsilon} \\ &\le C\epsilon e^{-(3-\theta)m(1-r_k)/\epsilon}.\end{aligned} \tag{5.13}$$

Combining (5.7), (5.12), and (5.13), we obtain the result. □

LEMMA 5.4. *We have*

$$\hat{I}_1 = \epsilon A r_0^{n-1} + \epsilon A \sum_{j=1}^{k} (\bar{r}_j^{n-1} + r_j^{n-1}) - B\epsilon \sum_{j=1}^{k} \big(e^{-m(\bar{r}_j - r_{j-1})/\epsilon} + e^{-m(r_j - \bar{r}_j)/\epsilon}\big)$$

$$+ \epsilon O\left(\sum_{j=1}^{k} \big(e^{-(1+\sigma)m(\bar{r}_j - r_{j-1})/\epsilon} + e^{-(1+\sigma)m(r_j - \bar{r}_j)/\epsilon}\big) + e^{-(2+\sigma)m(1-r_k)/\epsilon} + \epsilon \right),$$

where $A = \omega_{n-1} \int_{-\infty}^{+\infty} \big(W(H(t)) - \frac{1}{2} f(H(t))H(t)\big)\, dt > 0$, $B > 0$ *is a constant, and* $\sigma > 0$ *is a small constant.*

Proof. It is easy to check that for any bounded t_1 and t_2,

$$\hat{F}(t_1 + t_2) - \hat{F}(t_1) - \hat{F}(t_2) = \hat{f}(t_1)t_2 + \big(\hat{f}(t_2) - \hat{f}'(0)t_2\big)t_1 + O\big(|t_1 t_2|^2\big).$$

Thus,

$$\hat{F}(\bar{w}_{\epsilon,k}) = \sum_{j=0}^{k} \hat{F}(\tilde{v}_{\epsilon,j}) + \sum_{i<j} \hat{f}(\tilde{v}_{\epsilon,i})\tilde{v}_{\epsilon,j} + \sum_{i=1}^{k-1} \left(\hat{f}\left(\sum_{j=i+1}^{k} \tilde{v}_{\epsilon,j} \right) - \hat{f}'(0) \sum_{j=i+k}^{k} \tilde{v}_{\epsilon,j} \right) \tilde{v}_{\epsilon,i}$$

$$+ O\left(\sum_{i \neq j} |\tilde{v}_{\epsilon,i}\tilde{v}_{\epsilon,j}|^2 \right). \tag{5.14}$$

Using (5.14), we can write

$$\hat{I}_1 = \sum_{j=0}^{k} \int_\Omega \left(\hat{F}(\tilde{v}_{\epsilon,j}) - \frac{1}{2}\hat{f}(\tilde{v}_{\epsilon,j})\tilde{v}_{\epsilon,j} \right) + \frac{1}{2} \int_\Omega \sum_{j=1}^{k} \Big(\hat{f}(\tilde{v}_{\epsilon,j}) - \hat{f}(\psi_{\epsilon,j}) - \hat{f}(\bar{\psi}_{\epsilon,j}) \Big) \bar{w}_{\epsilon,k}$$

$$+ \sum_{i=1}^{k-1} \int_\Omega \left(\hat{f}\left(\sum_{j=i+1}^{k} \tilde{v}_{\epsilon,j} \right) - \hat{f}'(0) \sum_{j=i+1}^{k} \tilde{v}_{\epsilon,j} \right) \tilde{v}_{\epsilon,i} + O\left(\sum_{i \neq j} \int_\Omega |\tilde{v}_{\epsilon,i}\tilde{v}_{\epsilon,j}|^2 \right). \tag{5.15}$$

It is easy to prove that

$$\int_\Omega |\tilde{v}_{\epsilon,i}\tilde{v}_{\epsilon,j}|^2 = \epsilon O\Big(e^{-2m|\bar{r}_j - r_i|/\epsilon}\Big), \quad j > i. \tag{5.16}$$

On the other hand, since for any $t \in (0, b-a)$,

$$\hat{f}(t) - \hat{f}'(0)t < 0,$$

we see

$$\int_\Omega \left(\hat{f}\left(\sum_{j=i+1}^{k} \tilde{v}_{\epsilon,j} \right) - \hat{f}'(0) \sum_{j=i+1}^{k} \tilde{v}_{\epsilon,j} \right) \tilde{v}_{\epsilon,i} = -(B + o(1))\epsilon e^{-m(\bar{r}_{i+1} - r_i)/\epsilon}, \tag{5.17}$$

where $o(1) \to 0$ as $\epsilon \to 0$, and

$$B = -\int_{-\infty}^{+\infty} \big(\hat{f}(H(t) - a) - \hat{f}'(0)(H(t) - a)\big) e^{-mt}\, dt > 0.$$

Since $\hat{f}(t) = -\hat{f}(b-a-t)$, we obtain

$$\begin{aligned}
&\hat{f}(\tilde{v}_{\epsilon,j}) - \hat{f}(\psi_{\epsilon,j}) - \hat{f}(\bar{\psi}_{\epsilon,j}) \\
&= -\hat{f}(b-a-\psi_{\epsilon,j}+b-a-\bar{\psi}_{\epsilon,j}) + \hat{f}(b-a-\psi_{\epsilon,j}) + \hat{f}(b-a-\bar{\psi}_{\epsilon,j}) \\
&= O\big(|(b-a-\psi_{\epsilon,j}||(b-a-\bar{\psi}_{\epsilon,j}|\big).
\end{aligned}$$

Thus, for $i \neq j$, we see

$$\int_\Omega \Big(\hat{f}(\tilde{v}_{\epsilon,j}) - \hat{f}(\psi_{\epsilon,j}) - \hat{f}(\bar{\psi}_{\epsilon,j})\Big)\tilde{v}_i = \epsilon O\left(\sum_{j=1}^{k}\big(e^{-2m|\bar{r}_j - r_{j-1}|/\epsilon} + e^{-2m|r_j-\bar{r}_j|/\epsilon}\big)\right).$$

So, we have

$$\begin{aligned}
&\sum_{j=0}^{k}\int_\Omega \left(\hat{F}(\tilde{v}_{\epsilon,j}) - \frac{1}{2}\hat{f}(\tilde{v}_{\epsilon,j})\tilde{v}_{\epsilon,j}\right) + \frac{1}{2}\int_\Omega \sum_{j=1}^{k}\Big(\hat{f}(\tilde{v}_{\epsilon,j}) - \hat{f}(\psi_{\epsilon,j}) - \hat{f}(\bar{\psi}_{\epsilon,j})\Big)\bar{w}_{\epsilon,k} \\
&= \sum_{j=0}^{k}\int_\Omega \left(\hat{F}(\tilde{v}_{\epsilon,j}) - \frac{1}{2}\hat{f}(\tilde{v}_{\epsilon,j})\tilde{v}_{\epsilon,j}\right) + \frac{1}{2}\int_\Omega \sum_{j=1}^{k}\Big(\hat{f}(\tilde{v}_{\epsilon,j}) - \hat{f}(\psi_{\epsilon,j}) - \hat{f}(\bar{\psi}_{\epsilon,j})\Big)\tilde{v}_j \\
&\quad + \epsilon O\left(\sum_{j=1}^{k}\big(e^{-2m|\bar{r}_j - r_{j-1}|/\epsilon} + e^{-2m|r_j-\bar{r}_j|/\epsilon}\big)\right) \\
&= \sum_{j=0}^{k}\int_\Omega \hat{F}(\tilde{v}_{\epsilon,j}) - \frac{1}{2}\int_\Omega \sum_{j=1}^{k}\Big(\hat{f}(\psi_{\epsilon,j}) + \hat{f}(\bar{\psi}_{\epsilon,j})\Big)\tilde{v}_j \\
&\quad + \epsilon O\left(\sum_{j=1}^{k}\big(e^{-2m|\bar{r}_j - r_{j-1}|/\epsilon} + e^{-2m|r_j-\bar{r}_j|/\epsilon}\big)\right). \qquad (5.18)
\end{aligned}$$

But from $\hat{f}(t) = -\hat{f}(b-a-t)$, we see

$$\hat{f}(\psi_{\epsilon,j})(\bar{\psi}_{\epsilon,j} - (b-a)) = \hat{f}(b-a-\psi_{\epsilon,j})(b-a-\bar{\psi}_{\epsilon,j}),$$

and

$$\hat{f}(\bar{\psi}_{\epsilon,j})(\psi_{\epsilon,j} - (b-a)) = \hat{f}(b-a-\bar{\psi}_{\epsilon,j})(b-a-\psi_{\epsilon,j}).$$

We also have

$$\begin{aligned}\hat{F}(\tilde{v}_{\epsilon,j}) &= \hat{F}(b-a-\tilde{v}_{\epsilon,j}) = \hat{F}(b-a-\psi_{\epsilon,j}+b-a-\bar{\psi}_{\epsilon,j})\\ &= \hat{F}(b-a-\psi_{\epsilon,j}) + \hat{F}(b-a-\bar{\psi}_{\epsilon,j})\\ &\quad + \frac{1}{2}\hat{f}(b-a-\psi_{\epsilon,j})(b-a-\bar{\psi}_{\epsilon,j})\\ &\quad + \frac{1}{2}\Big(\hat{f}(b-a-\bar{\psi}_{\epsilon,j}) - \hat{f}'(0)(b-a-\bar{\psi}_{\epsilon,j})\Big)(b-a-\psi_{\epsilon,j})\\ &\quad + \frac{1}{2}\hat{f}(b-a-\bar{\psi}_{\epsilon,j})(b-a-\psi_{\epsilon,j})\\ &\quad + \frac{1}{2}\Big(\hat{f}(b-a-\psi_{\epsilon,j}) - \hat{f}'(0)(b-a-\psi_{\epsilon,j})\Big)(b-a-\bar{\psi}_{\epsilon,j})\\ &\quad + O\Big(|b-a-\psi_{\epsilon,j}|^2|b-a-\bar{\psi}_{\epsilon,j}|^2\Big). \qquad (5.19)\end{aligned}$$

Using (5.19), we obtain

$$\begin{aligned}&\int_\Omega \hat{F}(\tilde{v}_{\epsilon,j}) - \frac{1}{2}\int_\Omega \Big(\hat{f}(\psi_{\epsilon,j}) + \hat{f}(\bar{\psi}_{\epsilon,j})\Big)\tilde{v}_j\\ &= \int_\Omega \left(\hat{F}(\psi_{\epsilon,j}) - \frac{1}{2}\hat{f}(\psi_{\epsilon,j})\psi_{\epsilon,j}\right) + \int_\Omega \left(\hat{F}(\bar{\psi}_{\epsilon,j}) - \frac{1}{2}\hat{f}(\bar{\psi}_{\epsilon,j})\bar{\psi}_{\epsilon,j}\right)\\ &\quad -(B+o(1))\epsilon e^{-m(r_j-\bar{r}_j)/\epsilon} + \epsilon O\left(\sum_{j=1}^k e^{-2m(r_j-\bar{r}_j)/\epsilon}\right). \qquad (5.20)\end{aligned}$$

Combining (5.15), (5.16), (5.17), (5.18), and (5.20), we obtain

$$\begin{aligned}\hat{I}_1 &= \sum_{j=0}^k \int_\Omega \left(\hat{F}(\psi_{\epsilon,j}) - \frac{1}{2}\hat{f}(\psi_{\epsilon,j})\psi_{\epsilon,j}\right) + \sum_{j=1}^k \int_\Omega \left(\hat{F}(\bar{\psi}_{\epsilon,j}) - \frac{1}{2}\hat{f}(\bar{\psi}_{\epsilon,j})\bar{\psi}_{\epsilon,j}\right)\\ &\quad - (B+o(1))\epsilon \sum_{j=1}^k \big(e^{-m(r_j-\bar{r}_j)/\epsilon} + e^{-m(\bar{r}_j-r_{j-1})/\epsilon}\big)\\ &\quad + \epsilon O\left(\sum_{j=1}^k \big(e^{-2m(r_j-\bar{r}_j)/\epsilon} + e^{-2m(\bar{r}_j-r_{j-1})/\epsilon}\big)\right). \qquad (5.21)\end{aligned}$$

Finally, let $\hat{H}(t) = H(t) - a$. Then we have

(5.22)

$$\begin{aligned}\int_\Omega \hat{F}(\psi_{\epsilon,j}) &= \omega_{n-1}\epsilon r_j^{n-1}\int_{-(1-r_j)/\epsilon}^{r_j/\epsilon} \hat{F}(\hat{H}(t))\,dt + O(\epsilon^2)\\ &= \omega_{n-1}\epsilon r_j^{n-1}\int_{-\infty}^{+\infty} \hat{F}(\hat{H}(t))\,dt - \omega_{n-1}\epsilon r_j^{n-1}\int_{-\infty}^{-(1-r_j)/\epsilon} \hat{F}(\hat{H}(t))\,dt + O(\epsilon^2),\end{aligned}$$

and

$$\int_\Omega \hat f(\psi_{\epsilon,j})\psi_{\epsilon,j} = \omega_{n-1}\epsilon r_j^{n-1}\int_{-\infty}^{+\infty} \hat f(\hat H(t))\hat H(t)\,dt - \omega_{n-1}\epsilon r_j^{n-1} \times \int_{-\infty}^{-(1-r_j)/\epsilon} \hat f(\hat H(t))\hat H(t)\,dt + O(\epsilon^2). \tag{5.23}$$

But from $\hat F(0) = \hat f(0) = 0$, we see

$$\left|\int_{-\infty}^{-(1-r_j)/\epsilon} \hat F(\hat H(t))\,dt - \frac{1}{2}\int_{-\infty}^{-(1-r_j)/\epsilon} \hat f(\hat H(t))\hat H(t)\,dt\right| \le \int_{-\infty}^{-(1-r_j)/\epsilon} \hat H^3(t)\,dt = O\left(\int_{-\infty}^{-(1-r_j)/\epsilon} e^{3mt}\,dt\right)$$

$$\le Ce^{-3m(1-r_j)/\epsilon}. \tag{5.24}$$

Combining (5.22), (5.23), and (5.24), we are led to

$$\int_\Omega \left(\hat F(\psi_{\epsilon,j}) - \frac{1}{2}\hat f(\psi_{\epsilon,j})\psi_{\epsilon,j}\right) = \omega_{n-1}\epsilon r_j^{n-1}\int_{-\infty}^{+\infty} \hat F(\hat H(t))\,dt - \frac{1}{2}\omega_{n-1}\epsilon r_j^{n-1}\int_{-\infty}^{+\infty} \hat f(\hat H(t))\hat H(t)\,dt + \epsilon O\big(\epsilon + e^{-3m(1-r_j)/\epsilon}\big)$$

$$= \omega_{n-1}\epsilon r_j^{n-1}A + \epsilon O\big(\epsilon + e^{-3m(1-r_k)/\epsilon}\big). \tag{5.25}$$

Similarly, we can obtain

$$\int_\Omega \left(\hat F(\bar\psi_{\epsilon,j}) - \frac{1}{2}\hat f(\bar\psi_{\epsilon,j})\bar\psi_{\epsilon,j}\right) = \omega_{n-1}\epsilon \bar r_j^{n-1}A + \epsilon O\big(\epsilon + e^{-3m(1-r_k)/\epsilon}\big). \tag{5.26}$$

Combining (5.21), (5.25), and (5.26), we prove this lemma. □

LEMMA 5.5. *We have*

$$\hat I_2 = -\epsilon B_\epsilon \omega_{n-1}e^{-2m(1-r_k)/\epsilon} + \epsilon O\Big(e^{-2m(1-r_k)/\epsilon} + \epsilon\Big) + \epsilon O\left(\sum_{j=1}^{k}\big(e^{-2(1+\sigma)(r_j-\bar r_j)/\epsilon} + e^{-2(1+\sigma)(\bar r_j - r_{j-1})/\epsilon}\big)\right), \tag{5.27}$$

where B_ϵ is a constant with $b_2 \ge B_\epsilon \ge b_1 > 0$, and $\sigma > 0$ is a small constant.

Proof. We have

$$\hat I_2 = \frac{1}{2}\int_\Omega \left(-\hat f(\psi_{\epsilon,0}) - \sum_{j=1}^{k}\big(\hat f(\psi_{\epsilon,j}) + \hat f(\bar\psi_{\epsilon,j})\big) + m^2\bar w_{\epsilon,k}\right)\varphi_\epsilon - \int_\Omega \left(\hat f(\bar w_{\epsilon,k}) - \hat f(\psi_{\epsilon,0}) - \sum_{j=1}^{k}\big(\hat f(\psi_{\epsilon,j}) + \hat f(\bar\psi_{\epsilon,j})\big)\right)\varphi_\epsilon$$

$$=: \hat I_{2,1} + \hat I_{2,2}. \tag{5.28}$$

It is easy to see that

$$|\hat{I}_{2,2}| \le C\epsilon \left(\sum_{j=1}^{k} \big(e^{-m(r_j-\bar{r}_j)/\epsilon} + e^{-m(\bar{r}_j-r_{j-1})/\epsilon} \big) \right) \|\varphi_\epsilon\|_\infty^{1-\theta}$$

$$\le C\epsilon \left(\sum_{j=1}^{k} \big(e^{-m(\bar{r}_j-r_{j-1})/\epsilon} + e^{-m(r_j-\bar{r}_j)/\epsilon} \big) \right) e^{-m(1-\theta)(1-r_k)/\epsilon}$$

$$\le C\epsilon \left(\sum_{j=1}^{k} \big(e^{-(1+\sigma)m(\bar{r}_j-r_{j-1})/\epsilon} + e^{-(1+\sigma)m(r_j-\bar{r}_j)/\epsilon} \big) + e^{-(2+\sigma)m(1-r_k)/\epsilon} \right). \tag{5.29}$$

On the other hand, using (5.2) and (5.4), we see

(5.30)

$$\hat{I}_{2,1} = \frac{1}{2} \int_\Omega \left(-\epsilon^2 \Delta \bar{w}_{\epsilon,k} + m^2 \bar{w}_{\epsilon,k} + \epsilon O\left(\epsilon |\psi'_{\epsilon,0}| + \epsilon \sum_{j=1}^{k} \big(|\psi'_{\epsilon,j}| + |\bar{\psi}'_{\epsilon,j}| \big) + \epsilon \right) \right) \varphi_\epsilon$$

$$= \frac{1}{2} \omega_{n-1} \epsilon^2 \big(-\bar{w}'_{\epsilon,k}(1)\varphi_\epsilon(1) + \bar{w}_{\epsilon,k}(1)\bar{w}'_{\epsilon,k}(1) \big)$$

$$+ \epsilon O\left(\int_\Omega \left(\epsilon |\psi'_{\epsilon,0}| + \epsilon \sum_{j=1}^{k} \big(|\psi'_{\epsilon,j}| + |\bar{\psi}'_{\epsilon,j}| \big) + \epsilon \right) |\varphi_\epsilon| \right)$$

$$= -B_\epsilon \omega_{n-1} \epsilon e^{-2m(1-r_k)/\epsilon} + \epsilon O\left(\int_\Omega \left(\epsilon |\psi'_{\epsilon,0}| + \epsilon \sum_{j=1}^{k} \big(|\psi'_{\epsilon,j}| + |\bar{\psi}'_{\epsilon,j}| \big) + \epsilon \right) |\varphi_\epsilon| \right),$$

where $B_\epsilon = \frac{1}{2} e^{2m(1-r_j)/\epsilon} (\epsilon \bar{w}'_{\epsilon,k}(1)\varphi_\epsilon(1) - \epsilon \bar{w}_{\epsilon,k}(1)\bar{w}'_{\epsilon,k}(1))$. By Lemma 5.1, noting that $\varphi_\epsilon < 0$, $w_{\epsilon,k}(1) \sim e^{-m(1-r_k)/\epsilon}$, and $\epsilon w'_{\epsilon,k}(1) \sim -e^{-m(1-r_k)/\epsilon}$, we see easily that there are $b_2 > b_1 > 0$, independent of ϵ, such that $b_2 \ge B_\epsilon \ge b_1$.

We have

$$\epsilon \int_\Omega |\psi'_{\epsilon,j}||\varphi_\epsilon| = \epsilon \int_{r \le r_k} |\psi'_{\epsilon,j}||\varphi_\epsilon| + \epsilon \int_{r \ge r_k} |\psi'_{\epsilon,j}||\varphi_\epsilon|$$

$$\le C\epsilon e^{-(2-\theta)m(1-r_k)/\epsilon} + C e^{-m(1-r_k)/\epsilon} \int_{r \ge r_k} e^{-m(r-r_j)/\epsilon} e^{-(1-\theta)m(1-r)/\epsilon}$$

$$\le C\epsilon e^{-(2-\theta)m(1-r_k)/\epsilon} + C e^{-(2-\theta)m(1-r_k)/\epsilon} \epsilon \ln \frac{1}{\epsilon}$$

$$\le C\big(e^{-(2+\sigma)m(1-r_k)/\epsilon} + \epsilon \big), \tag{5.31}$$

$$\epsilon \int_\Omega |\bar{\psi}'_{\epsilon,j}||\varphi_\epsilon| \le C\big(e^{-(2+\sigma)m(1-r_k)/\epsilon} + \epsilon \big), \tag{5.32}$$

and

$$\epsilon \int_\Omega |\varphi_\epsilon| \le C\big(e^{-(2+\sigma)m(1-r_k)/\epsilon} + \epsilon\big). \tag{5.33}$$

Combining (5.30), (5.31), (5.32), and (5.33), we obtain

$$\hat{I}_{2,1} = -B_\epsilon \omega_{n-1} \epsilon e^{-2m(1-r_k)/\epsilon} + \epsilon O\big(e^{-(2+\sigma)m(1-r_k)/\epsilon} + \epsilon\big). \tag{5.34}$$

So, the result follows from (5.28), (5.29), and (5.34). ∎

Proof of Proposition 5.2. The proof follows from Lemmas 5.3, 5.4, and 5.5. ∎

Now, we look at the reduction. We have

$$S_\epsilon(Pw_{\epsilon,k}) = -\epsilon^2 \Delta P w_{\epsilon,k} + f(Pw_{\epsilon,k}) + \epsilon\gamma(1-\Delta)^{-1} P w_{\epsilon,k}$$

$$= f(w_{\epsilon,k}) - f(v_{\epsilon,0}) - \sum_{j=1}^{k} \big(f(v_{\epsilon,j}) + f(\bar{v}_{\epsilon,j})\big) \tag{5.35}$$

$$+ f(Pw_{\epsilon,k}) - f(w_{\epsilon,k}) + m^2(w_{\epsilon,k} - Pw_{\epsilon,k}) + O(\epsilon) \tag{5.36}$$

$$= O\left(e^{-m(1-r_k)/\epsilon} + \sum_{j=1}^{k} \big(e^{-m(\bar{r}_j - r_{j-1})/\epsilon} + e^{-m(r_j - \bar{r}_j)/\epsilon}\big) + \epsilon\right). \tag{5.37}$$

Similar to the discussion in section 3, we can prove the following result.

LEMMA 5.6. *There is a* $\phi_\epsilon \in \mathcal{F}_{\mathbf{r}}$, *such that* $\pi_{\mathbf{r}} \circ S_\epsilon(w_{\epsilon,k} + \phi_\epsilon) = 0$. *Moreover,*

$$\|\phi_\epsilon\|_\infty \le C\left(e^{-m(1-r_k)/\epsilon} + \sum_{j=1}^{k} \big(e^{-m(\bar{r}_j - r_{j-1})/\epsilon} + e^{-m(r_j - \bar{r}_j)/\epsilon}\big) + \epsilon\right).$$

LEMMA 5.7. *We have*

$$I_\epsilon(Pw_{\epsilon,k} + \phi_\epsilon) = I_\epsilon(Pw_{\epsilon,k})$$

$$+ \epsilon O\left(e^{-(2+\sigma)m(1-r_k)/\epsilon} + \sum_{j=1}^{k} \big(e^{-(1+\sigma)m(\bar{r}_j - r_{j-1})/\epsilon} + e^{-(1+\sigma)m(r_j - \bar{r}_j)/\epsilon}\big) + \epsilon\right),$$

where $\sigma > 0$ *is a small constant.*

Proof. First, we estimate $\|\phi_\epsilon\|_2$.

We have

$$\begin{aligned}
\|\phi_\epsilon\|_2 &\le C\|S_\epsilon(Pw_{\epsilon,k})\|_2 + C\|R_{\mathbf{r}}(\phi_\epsilon)\|_2 \\
&\le C\|S_\epsilon(Pw_{\epsilon,k})\|_2 + C\|\phi_\epsilon^2\|_2 \\
&\le C\|S_\epsilon(Pw_{\epsilon,k})\|_2 + C\|\phi_\epsilon\|_\infty \|\phi_\epsilon\|_2 \\
&\le C\|S_\epsilon(Pw_{\epsilon,k})\|_2 + o(1)\|\phi_\epsilon\|_2,
\end{aligned}$$

where $o(1) = \|\phi_\epsilon\|_\infty \to 0$ as $\epsilon \to 0$. Thus,

$$\|\phi_\epsilon\|_2 \le C\|S_\epsilon(Pw_{\epsilon,k})\|_2. \tag{5.38}$$

We obtain, from (5.37),

$$\begin{aligned}\|S_\epsilon(Pw_{\epsilon,k})\|_2 &\le \|\hat f(\bar w_{\epsilon,k}) - \sum_{j=0}^{k}\hat f(\tilde v_{\epsilon,j})\|_2\\ &+ \left\|\sum_{j=1}^{k}\big(\hat f(\tilde v_{\epsilon,j}) - \hat f(\psi_{\epsilon,j}) - \hat f(\bar\psi_{\epsilon,j})\big)\right\|_2\\ &+ \|f(Pw_{\epsilon,k}) - f(w_{\epsilon,k}) + m^2(w_{\epsilon,k} - Pw_{\epsilon,k})\|_2 + C\epsilon. \qquad (5.39)\end{aligned}$$

It is easy to prove that

$$\begin{aligned}&\left\|\hat f(\bar w_{\epsilon,k}) - \sum_{j=0}^{k}\hat f(\tilde v_{\epsilon,j})\right\|_2^2\\ &\le C\epsilon\sum_{j=1}^{k}\big(e^{-(1+\sigma)m(r_j-\bar r_j)/\epsilon} + e^{-(1+\sigma)m(\bar r_j - r_{j-1})/\epsilon}\big), \qquad (5.40)\end{aligned}$$

and

$$\begin{aligned}&\left\|\sum_{j=1}^{k}\big(\hat f(\tilde v_{\epsilon,j}) - \hat f(\psi_{\epsilon,j}) - \hat f(\bar\psi_{\epsilon,j})\big)\right\|_2^2\\ &\le C\epsilon\sum_{j=1}^{k}\big(e^{-(1+\sigma)m(r_j-\bar r_j)/\epsilon} + e^{-(1+\sigma)m(\bar r_j - r_{j-1})/\epsilon}\big). \qquad (5.41)\end{aligned}$$

Moreover, from

$$f(Pw_{\epsilon,k}) - f(w_{\epsilon,k}) + m^2(w_{\epsilon,k} - Pw_{\epsilon,k}) = \big(m^2 - f'(w_{\epsilon,k})\big)\varphi_\epsilon + O(\varphi_\epsilon^2),$$

we obtain

$$\begin{aligned}&\|f(Pw_{\epsilon,k}) - f(w_{\epsilon,k}) + m^2(w_{\epsilon,k} - Pw_{\epsilon,k})\|_2^2\\ &\le C\int_\Omega \varphi_\epsilon^4 + C\int_\Omega \big(m^2 - f'(w_{\epsilon,k})\big)^2\varphi_\epsilon^2\\ &\le C\epsilon e^{-3m(1-r_k)/\epsilon} + C\int_\Omega \big(m^2 - f'(w_{\epsilon,k})\big)^2\varphi_\epsilon^2. \qquad (5.42)\end{aligned}$$

But

$$\begin{aligned}&\int_\Omega \big(m^2 - f'(w_{\epsilon,k})\big)^2\varphi_\epsilon^2\\ &\le C\int_{r\le r_k}\varphi_\epsilon^2 + C\int_{r\ge r_k}|w_{\epsilon,k} - a|\varphi_\epsilon^2\\ &\le C\epsilon e^{-(2+\sigma)m(1-r_k)/\epsilon}. \qquad (5.43)\end{aligned}$$

Combining (5.39)–(5.43), we obtain

$$\|S_\epsilon(Pw_{\epsilon,k})\|_2^2 \le C\epsilon e^{-(2+\sigma)m(1-r_k)/\epsilon} + C\epsilon\sum_{j=1}^{k}\left(e^{-(1+\sigma)m(r_j-\bar r_j)/\epsilon}+e^{-(1+\sigma)m(\bar r_j-r_{j-1})/\epsilon}\right). \tag{5.44}$$

Using (5.38), we obtain

$$\|\phi_\epsilon\|_2^2 \le C\epsilon e^{-(2+\sigma)m(1-r_k)/\epsilon} + C\epsilon\sum_{j=1}^{k}\left(e^{-(1+\sigma)m(r_j-\bar r_j)/\epsilon}+e^{-(1+\sigma)m(\bar r_j-r_{j-1})/\epsilon}\right). \tag{5.45}$$

Similar to section 4, using (5.44) and (5.45), we have

$$\begin{aligned} &I_\epsilon(Pw_{\epsilon,k}+\phi_\epsilon)\\ &= I_\epsilon(Pw_{\epsilon,k}) + O\Big(\|S_\epsilon(Pw_{\epsilon,k})\|_2\|\phi_\epsilon\|_2 + \|\phi_\epsilon\|_2^2\Big)\\ &= I_\epsilon(Pw_{\epsilon,k})\\ &\quad + \epsilon O\left(\epsilon + e^{-(2+\sigma)m(1-r_k)/\epsilon} + \sum_{j=1}^{k}\left(e^{-(1+\sigma)m(r_j-\bar r_j)/\epsilon}+e^{-(1+\sigma)m(\bar r_j-r_{j-1})/\epsilon}\right)\right). \end{aligned}$$

So we have proved this lemma. □

Proof of Theorem 1.3. We just need to consider the case $b > 0$. For $a < b \le 0$, we let $u_1 = -u$ and $v_1 = -v$. Then u_1 and v_1 will satisfy a similar system with $f_1(t) = (t+a)(t+\frac{a+b}{2})(t+b)$, and $-a > -b \ge 0$. From now on, we always assume that $b > 0$.

Consider

$$\max_{\mathbf{r}_\epsilon \in D_{\epsilon,k}} Q_\epsilon(\mathbf{r}), \tag{5.46}$$

where $Q_\epsilon(\mathbf{r}) = I_\epsilon(Pw_{\epsilon,k}+\phi_\epsilon)$.

Let $\mathbf{r}_\epsilon \in D_{\epsilon,k}$ be a maximum point of (5.46). We will prove that $\mathbf{r}_\epsilon$ is an interior point of $D_{\epsilon,k}$. So it is a critical point of $I_\epsilon(Pw_{\epsilon,k}+\phi_\epsilon)$.

Let $L > 0$ be a large number, such that $mL > 4$. Choose $\mathbf{r}_\epsilon^* \in D_{\epsilon,k}$, such that $r_k^* = 1 - L\epsilon\ln\frac{1}{\epsilon}$, $\bar r_j^* = r_j^* - L\epsilon\ln\frac{1}{\epsilon}$, and $r_{j-1}^* = \bar r_j^* - L\epsilon\ln\frac{1}{\epsilon}$. For this r_ϵ^*, using Proposition 5.2, we have

$$I^*(Pw_{\epsilon,k}) = \epsilon(2k+1)A + \epsilon O\left(\epsilon\ln\frac{1}{\epsilon}\right). \tag{5.47}$$

On the other hand, we have

$$\int_\Omega Pw_{\epsilon,k}(1-\Delta)^{-1}Pw_{\epsilon,k} = \int_\Omega b(1-\Delta)^{-1}b + O\left(\epsilon\ln\frac{1}{\epsilon}\right). \tag{5.48}$$

Combining (5.47) and (5.48), we obtain

$$Q_\epsilon(\mathbf{r}_\epsilon^*) = \epsilon(2k+1)A + \frac{1}{2}\gamma\epsilon\int_\Omega b(1-\Delta)^{-1}b + \epsilon O\left(\epsilon\ln\frac{1}{\epsilon}\right). \tag{5.49}$$

We have, from $Q_\epsilon(\mathbf{r}_\epsilon) \geq Q_\epsilon(\mathbf{r}_\epsilon^*)$,

$$\begin{aligned}
&\epsilon A r_{\epsilon,0}^{n-1} + \epsilon A\sum_{j=1}^{k}(\bar{r}_{\epsilon,j}^{n-1} + r_{\epsilon,j}^{n-1}) + \frac{1}{2}\gamma\epsilon\int_\Omega Pw_{\epsilon,k}(1-\Delta)^{-1}Pw_{\epsilon,k}\\
&-(B+o(1))\epsilon\sum_{j=1}^{k}\left(e^{-m(\bar{r}_{\epsilon,j}-r_{\epsilon,j-1})/\epsilon} + e^{-m(r_{\epsilon,j}-\bar{r}_{\epsilon,j})/\epsilon}\right)\\
&-(B_\epsilon+o(1))\omega_{n-1}\epsilon e^{-2m(1-r_{\epsilon,k})/\epsilon} + O(\epsilon^2)\\
&\geq \epsilon(2k+1)A + \frac{1}{2}\gamma\epsilon\int_\Omega b(1-\Delta)^{-1}b + \epsilon O\left(\epsilon\ln\frac{1}{\epsilon}\right).
\end{aligned} \tag{5.50}$$

Since $|b - Pw_{\epsilon,k}| \leq C\epsilon^2$ if $r \leq 1 - 2M\epsilon\ln\frac{1}{\epsilon}$, it is easy to check that

$$\int_\Omega |(1-\Delta)^{-1}(b-Pw_{\epsilon,k})|^2 \leq C\int_\Omega |b-Pw_{\epsilon,k}|^2 \leq C\epsilon\ln\frac{1}{\epsilon}.$$

As a result,

$$\begin{aligned}
&\int_\Omega b(1-\Delta)^{-1}b - \int_\Omega Pw_{\epsilon,k}(1-\Delta)^{-1}Pw_{\epsilon,k}\\
&= -2\int_\Omega (Pw_{\epsilon,k}-b)(1-\Delta)^{-1}b + \int_\Omega (Pw_{\epsilon,k}-b)(1-\Delta)^{-1}(Pw_{\epsilon,k}-b)\\
&= 2\int_\Omega (b-w_{\epsilon,k})(1-\Delta)^{-1}b + 2\int_\Omega \varphi_\epsilon(1-\Delta)^{-1}b + O\left(\epsilon^2\ln^2\frac{1}{\epsilon}\right).
\end{aligned} \tag{5.51}$$

But

$$\left|\int_\Omega \varphi_\epsilon(1-\Delta)^{-1}b\right| \leq C\int_\Omega |\varphi_\epsilon| \leq C\epsilon. \tag{5.52}$$

Combining (5.51) and (5.52), we obtain

$$\begin{aligned}
&\int_\Omega b(1-\Delta)^{-1}b - \int_\Omega Pw_{\epsilon,k}(1-\Delta)^{-1}Pw_{\epsilon,k}\\
&= 2\int_\Omega (b-w_{\epsilon,k})(1-\Delta)^{-1}b + O(\epsilon).
\end{aligned} \tag{5.53}$$

So, it follows from (5.50) and (5.53) that

$$\begin{aligned}
&\epsilon A(1-r_{\epsilon,0}^{n-1})+\epsilon A\sum_{j=1}^{k}(1-\bar{r}_{\epsilon,j}^{n-1}+1-r_{\epsilon,j}^{n-1})\\
&+\frac{1}{2}\gamma\epsilon\int_{\Omega}(b-w_{\epsilon,k})(1-\Delta)^{-1}b\\
&+(B+o(1))\epsilon\sum_{j=1}^{k}\big(e^{-m(\bar{r}_{\epsilon,j}-r_{\epsilon,j-1})/\epsilon}+e^{-m(r_{\epsilon,j}-\bar{r}_{\epsilon,j})/\epsilon}\big)\\
&+(B_\epsilon+o(1))\omega_{n-1}\epsilon e^{-2m(1-r_{\epsilon,k})/\epsilon}\\
&\le C\epsilon^2\ln\frac{1}{\epsilon}. \qquad (5.54)
\end{aligned}$$

Since all the terms in the left-hand side of (5.54) are positive, we obtain

$$1-r_{\epsilon,0}^{n-1}\le C\epsilon\ln\frac{1}{\epsilon},$$

and

$$e^{-m(\bar{r}_{\epsilon,j}-r_{\epsilon,j-1})/\epsilon},\quad e^{-m(r_{\epsilon,j}-\bar{r}_{\epsilon,j})/\epsilon},\quad e^{-2m(1-r_{\epsilon,k})/\epsilon}\le C\epsilon\ln\frac{1}{\epsilon}.$$

So $|\bar{r}_{\epsilon,j}-r_{\epsilon,j-1}|\ge c'\epsilon\ln\frac{1}{\epsilon}$, $|r_{\epsilon,j}-\bar{r}_{\epsilon,j}|\ge c'\epsilon\ln\frac{1}{\epsilon}$, $1-r_{\epsilon,0}\le C\epsilon\ln\frac{1}{\epsilon}$, and $1-r_{\epsilon,k}\ge c'\epsilon\ln\frac{1}{\epsilon}$. This shows that $\mathbf{r}_\epsilon$ is an interior point of $D_{\epsilon,k}$ if $M>0$ is large and $\alpha>0$ is small. □

Remark 5.8. In the case $b>0$, if $\gamma=0$, or $\gamma>0$ and $a\le 0$, then we can use the above techniques to show that (1.1) has a solution, which is close to $Pw_{\epsilon,k}^*$, where

$$w_{\epsilon,k}^*=\sum_{j=1}^{k-1}(v_{\epsilon,j}+\bar{v}_{\epsilon,j}-a-b)+\bar{v}_{\epsilon,k}.$$

In this case, similar to (5.54), we have

$$\begin{aligned}
&\epsilon A(1-\bar{r}_{\epsilon,k}^{n-1})+\epsilon A\sum_{j=1}^{k-1}(1-\bar{r}_{\epsilon,j}^{n-1}+1-r_{\epsilon,j}^{n-1})\\
&+\frac{1}{2}\gamma\epsilon\int_{\Omega}(a-w_{\epsilon,k}^*)(1-\Delta)^{-1}a\\
&+(B+o(1))\epsilon\sum_{j=1}^{k-1}\big(e^{-m(\bar{r}_{\epsilon,j}-r_{\epsilon,j-1})/\epsilon}+e^{-m(r_{\epsilon,j}-\bar{r}_{\epsilon,j})/\epsilon}\big)\\
&+(B_\epsilon+o(1))\omega_{n-1}\epsilon e^{-2m(1-\bar{r}_{\epsilon,k})/\epsilon}\\
&\le C\epsilon^2\ln\frac{1}{\epsilon}. \qquad (5.55)
\end{aligned}$$

We know that $a - w^*_{\epsilon,k}$ is always nonpositive. So, if $a \le 0$, the term $\int_\Omega (a - w^*_{\epsilon,k})(1 - \Delta)^{-1} a$ is nonnegative. Thus, if $\gamma = 0$, or $\gamma > 0$ and $a \le 0$, the left-hand side of (5.55) is always nonnegative. As a result, we can use (5.55) to deduce that $\mathbf{r}_\epsilon$ is an interior point of $D_{\epsilon,k}$.

WHITE NOISE HYPOTHESIS FOR UNIFORM QUANTIZATION ERRORS*

DAVID JIMENEZ†, LONG WANG‡, AND YANG WANG†

Abstract. The white noise hypothesis (WNH) assumes that in the uniform pulse code modulation (PCM) quantization scheme the errors in individual channels behave like white noise; i.e., they are independent and identically distributed random variables. The WNH is key to estimating the mean square quantization error (MSE). But is the WNH valid? In this paper we take a close look at the WNH. We show that in a redundant system the errors from individual channels can never be independent. Thus to an extent the WNH is invalid. Our numerical experiments also indicate that with coarse quantization the WNH is far from valid. However, as the main result of this paper we show that with fine quantizations the WNH is essentially valid in that the errors from individual channels become asymptotically *pairwise* independent, each uniformly distributed in $[-\Delta/2, \Delta/2)$, where Δ denotes the stepsize of the quantization.

Key words. frames, tight frame, pulse code modulation, quantization, white noise hypothesis

1. Introduction.

In processing, transmitting, and storing analogue signals it is often necessary to make atomic decompositions of the signal using a given set of *atoms*, or *dictionary* $\{\mathbf{v}_j\}$. In this approach, a signal $\mathbf{x}$ is represented as a linear combination of $\{\mathbf{v}_j\}$,

$$\mathbf{x} = \sum_j c_j \mathbf{v}_j.$$

In practice $\{\mathbf{v}_j\}$ is a finite set. Furthermore, for the purpose of error correction, recovery from data erasures or robustness, redundancy is built into $\{\mathbf{v}_j\}$; i.e., more elements than needed are in $\{\mathbf{v}_j\}$. Instead of a true basis, $\{\mathbf{v}_j\}$ is chosen to be a frame. Since $\{\mathbf{v}_j\}$ is a finite set, we may without loss of generality assume $\{\mathbf{v}_j\}_{j=1}^N$ are vectors in $\mathbb{R}^d$ with $N \geq d$.

Let $F = [\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_N]$ be the $d \times N$ matrix whose columns are $\mathbf{v}_1, \ldots, \mathbf{v}_N$. We say $\{\mathbf{v}_j\}_{j=1}^N$ is a *frame* if F has rank d. Let $\lambda_{\max} \geq \lambda_{\min} > 0$ be the maximal and minimal eigenvalues of FF^T, respectively. It is easily checked that

$$\lambda_{\min}\|\mathbf{x}\|^2 \leq \sum_{j=1}^N |\mathbf{x} \cdot \mathbf{v}_j|^2 \leq \lambda_{\max}\|\mathbf{x}\|^2. \tag{1.1}$$

$\lambda_{\max}$ and $\lambda_{\min}$ are called the *upper and lower frame bounds* for the frame, respectively. If $\lambda_{\max} = \lambda_{\min} = \lambda$, in which case $FF^T = \lambda I_d$, we call $\{\mathbf{v}_j\}_{j=1}^N$ a *tight frame* with frame constant λ. Note that any signal $\mathbf{x} \in \mathbb{R}^d$ can be easily reconstructed using the

†School of Mathematics, Georgia Institute of Technology, Atlanta, GA 30332 (djimenez@math.gatech.edu, wang@math.gatech.edu). The third author is supported in part by the National Science Foundation, grant DMS-0456538.

‡Department of Mathematics, Southern Polytechnic State University, Marietta, GA 30060 (lwang@spsu.edu).

data $\{\mathbf{x}\cdot\mathbf{v}_j\}_{j=1}^N$. Set $\mathbf{y}=[\mathbf{x}\cdot\mathbf{v}_1,\mathbf{x}\cdot\mathbf{v}_2,\ldots,\mathbf{x}\cdot\mathbf{v}_N]^T$. Then $\mathbf{y}=F^T\mathbf{x}$ and

$$(FF^T)^{-1}F\mathbf{y}=(FF^T)^{-1}FF^T\mathbf{x}=\mathbf{x}.$$

Let $G=(FF^T)^{-1}F=[\mathbf{u}_1,\mathbf{u}_2,\ldots,\mathbf{u}_N]$. The set of columns $\{\mathbf{u}_j\}_{j=1}^N$ of G is called the *canonical dual frame* of the frame $\{\mathbf{v}_j\}_{j=1}^N$. We have the reconstruction

$$\mathbf{x}=\sum_{j=1}^N(\mathbf{x}\cdot\mathbf{v}_j)\,\mathbf{u}_j. \tag{1.2}$$

If $\{\mathbf{v}_j\}_{j=1}^N$ is a tight frame with frame constant λ, then $G=\lambda^{-1}F$, and we have the reconstruction

$$\mathbf{x}=\frac{1}{\lambda}\sum_{j=1}^N(\mathbf{x}\cdot\mathbf{v}_j)\,\mathbf{v}_j. \tag{1.3}$$

In digital applications, quantizations will have to be performed. The simplest scheme is the pulse code modulation (PCM) quantization scheme, in which the coefficients $\{\mathbf{x}\cdot\mathbf{v}_j\}_{j=1}^N$ are quantized. In this paper we consider exclusively *uniform quantizations*. Let $\mathcal{A}=\Delta\mathbb{Z}$, where $\Delta>0$ is the quantization step. With uniform quantization a real value t is replaced with the value in $\mathcal{A}$ that is the closest to t. So, in our setting, t is replaced with $Q_\Delta(t)$ given by

$$Q_\Delta(t):=\left\lfloor\frac{t}{\Delta}+\frac{1}{2}\right\rfloor\Delta.$$

Thus, given a frame $\{\mathbf{v}_j\}_{j=1}^N$ and its canonical dual frame $\{\mathbf{u}_j\}_{j=1}^N$, instead of using the data $\{\mathbf{x}\cdot\mathbf{v}_j\}_{j=1}^N$ and (1.2) to obtain a perfect reconstruction, we use the data $\{Q_\Delta(\mathbf{x}\cdot\mathbf{v}_j)\}_{j=1}^N$ and obtain an imperfect reconstruction

$$\tilde{\mathbf{x}}=\sum_{j=1}^N Q_\Delta\left(\mathbf{x}\cdot\mathbf{v}_j\right)\mathbf{u}_j. \tag{1.4}$$

This raises the following question: How good is the reconstruction? This question has been studied in terms of both the worst case error and the mean square error (MSE); see, e.g., [13]. Note that the error from the reconstruction is

$$\mathbf{x}-\tilde{\mathbf{x}}=\sum_{j=1}^N\tau_\Delta\left(\mathbf{x}\cdot\mathbf{v}_j\right)\mathbf{u}_j, \tag{1.5}$$

where $\tau_\Delta(t):=t-Q_\Delta(t)=\left(\left\{\frac{t}{\Delta}+\frac{1}{2}\right\}-\frac{1}{2}\right)\Delta$, with $\{\cdot\}$ denoting the fractional part. While an a priori error bound is relatively straightforward to obtain, the MSE, $\mathrm{MSE}:=\mathcal{E}\left(\|\mathbf{x}-\tilde{\mathbf{x}}\|^2\right)$, assuming certain probability distribution for $\mathbf{x}$, is much harder. To simplify the problem, the so-called *white noise hypothesis* (WNH), is employed by engineers and mathematicians in this area (see, e.g., [2, 3, 13]). The WNH asserts the following:

- Each $\tau_\Delta\left(\mathbf{x}\cdot\mathbf{v}_j\right)$ is uniformly distributed in $[-\Delta/2,\Delta/2)$; hence it has mean 0 and variance $\Delta^2/12$.
- $\{\tau_\Delta\left(\mathbf{x}\cdot\mathbf{v}_j\right)\}_{j=1}^N$ are independent random variables.

With the WNH it is an easy derivation, which we furnish in the next section, that the MSE is given by

$$\mathcal{E}\left(\|\mathbf{x}-\tilde{\mathbf{x}}\|^2\right)=\frac{\Delta^2}{12}\sum_{j=1}^{d}\lambda_j^{-1}=\frac{\Delta^2}{12}\sum_{j=1}^{N}\|\mathbf{u}_j\|^2, \tag{1.6}$$

where $\{\lambda_j\}$ are the eigenvalues of FF^T.

Note that using (1.6) the MSE for quantization decreases by a factor of 4 if we decrease Δ by a factor of 2. It amounts to an increase in signal to noise ratio of approximately 6dB ($10\log_{10}4\approx 6$). This is often referred to as the *6dB-per-bit-rule*.

The WNH is often called *Bennett's white noise assumption* [2, 3]. Bennett studied quantization error (distortion) in his fundamental paper [4] in the scalar setting. He demonstrated that under the assumption that the scalar random variable has a smooth density, the quantization error behaves like uniformly distributed "random noise" when Δ is small, resulting in the MSE of approximately $\Delta^2/12$. Bennett also studied quantization errors in the nonuniform quantization setting, which can often be reduced to the uniform setting by the use of companders. The current interest in the WNH stems from the study of vector quantization, in which several correlated signals are quantized simultaneously such as in our setting. A vast literature on vector quantization and on vector quantization errors exists, and for an excellent and comprehensive survey on vector quantization see Gray and Neuhoff [14]. A weaker form of the WNH, which states that the error components are approximately uncorrelated in the high resolution setting, i.e., when Δ is small, is often found in engineering literature without rigorous proof (see [11] and the discussion in [22]). A rigorous proof of this weaker form of the WNH was first given in Viswanathan and Zamir [22]. More precisely, they proved that if two random variables X, Y have a joint density function, then $\frac{1}{\Delta^2}\mathcal{E}\left(\tau_\Delta(X)\tau_\Delta(Y)\right)\longrightarrow 0$ as $\Delta\to 0$. Viswanathan and Zamir also proved similar results in the nonuniform quantization setting, under much stronger assumptions.

It should be pointed out that much of the advantage of vector quantization comes from the fact that the quantizations are *not* necessarily performed independently on each channel. As a result there are many interesting and challenging mathematical problems in nonuniform vector quantization. While the focus of this paper is on uniform quantization, we hope it will be a very first step in resolving the problem in the more general setting.

The objective of this paper is a rather modest one. Given the vast literature on quantization errors and some of the general confusion regarding the WNH, this paper aims to provide a complete analysis and rigorous mathematical theorems on the behavior of quantization errors. These results are by no means difficult, and they are also rather intuitive. Nevertheless we feel there is a need to have them written. If nothing else we hope this paper will serve to clarify the WNH in the uniform quantization setting. As a very simple result we show that, under the assumption that the distribution of $\mathbf{x}$ has a density (absolutely continuous), the components of the quantization errors $\left\{\tau_\Delta\big(\mathbf{x}\cdot\mathbf{v}_j\big)\right\}_{j=1}^N$ can *never* be independent if $N>d$. However, we show that asymptotically the WNH is almost valid by proving stronger and more general results than those in [22]. More precisely, we prove that if a set of vectors $\{\mathbf{u}_1,\mathbf{u}_2,\dots,\mathbf{u}_k\}$ is linearly independent, then the normalized quantization errors $\left\{\frac{1}{\Delta}\tau_\Delta\left(\mathbf{x}\cdot\mathbf{u}_j\right)\right\}_{j=1}^k$ converge in distribution to independent and uniformly distributed random variables as $\Delta\to 0^+$. Applying this to the frame setting, we show that if the vectors $\{\mathbf{v}_j\}_{j=1}^N$ are pairwise linearly independent, then $\{\tau_\Delta\left(\mathbf{x}\cdot\mathbf{v}_j\right)\}_{j=1}^N$ becomes asymptotically *pairwise*

independent and thus *pairwise uncorrelated*, and each $\tau_\Delta(\mathbf{x}\cdot\mathbf{v}_j)$ becomes asymptotically uniformly distributed on $[-\Delta/2,\Delta/2]$. These slightly weaker assumptions are sufficient to lead to the MSE given by (1.6) asymptotically. Furthermore, we also characterize completely the asymptotic behavior of the MSE if some $\mathbf{v}_j$'s are parallel. These and other results are stated and proved in subsequent sections.

2. A priori error bound and MSE under the WNH. In this section we derive an a priori error bound and a formula for the MSE under the WNH. These results are not new. We include them for self-containment. We use the following settings throughout this section: Let $\{\mathbf{v}_j\}_{j=1}^N$ be a frame in $\mathbb{R}^d$ with corresponding frame matrix $F=[\mathbf{v}_1,\mathbf{v}_2,\dots,\mathbf{v}_N]$. The eigenvalues of FF^T are $\lambda_{\max}=\lambda_1\ge\lambda_2\ge\cdots\ge\lambda_d=\lambda_{\min}>0$. Let $\{\mathbf{u}_j\}_{j=1}^N$ be the canonical dual frame with corresponding matrix $G=(FF^T)^{-1}F$. For any $\mathbf{x}=\sum_{j=1}^N(\mathbf{x}\cdot\mathbf{v}_j)\,\mathbf{u}_j$, using the quantization alphabet $\mathcal{A}=\Delta\mathbb{Z}$, we have the PCM quantized reconstruction

$$\tilde{\mathbf{x}}=\sum_{j=1}^N Q_\Delta(\mathbf{x}\cdot\mathbf{v}_j)\,\mathbf{u}_j.$$

PROPOSITION 2.1. *For any $\mathbf{x}\in\mathbb{R}^d$ we have*

$$\|\mathbf{x}-\tilde{\mathbf{x}}\|\le\frac{1}{2}\sqrt{\frac{N}{\lambda_{\min}}}\Delta. \tag{2.1}$$

If in addition $\{\mathbf{v}_j\}_{j=1}^N$ is a tight frame with frame constant λ, then

$$\|\mathbf{x}-\tilde{\mathbf{x}}\|\le\frac{1}{2}\sqrt{\frac{N}{\lambda}}\Delta. \tag{2.2}$$

Proof. We have $\mathbf{x}-\tilde{\mathbf{x}}=\sum_{j=1}^N\tau_\Delta(\mathbf{x}\cdot\mathbf{v}_j)\,\mathbf{u}_j=G\mathbf{y}$, where $\mathbf{y}=[\tau_\Delta(\mathbf{x}\cdot\mathbf{v}_1),\dots,\tau_\Delta(\mathbf{x}\cdot\mathbf{v}_N)]^T$. Thus $\|\mathbf{x}-\tilde{\mathbf{x}}\|^2=\mathbf{y}^TG^TG\mathbf{y}\le\rho\left(G^TG\right)\|\mathbf{y}\|^2$, where $\rho(\cdot)$ denotes the spectral radius. Now $\rho(G^TG)=\rho(GG^T)=\rho((FF^T)^{-1})=\lambda_{\min}^{-1}$. Observe that $|\tau_\Delta(\mathbf{x}\cdot\mathbf{v}_j)|\le\Delta/2$. Thus $\|\mathbf{y}\|^2\le N(\Delta/2)^2$. This yields an a priori error bound (2.1). The bound (2.2) is an immediate corollary. ∎

PROPOSITION 2.2. *Under the WNH, the MSE is*

$$\mathcal{E}\left(\|\mathbf{x}-\tilde{\mathbf{x}}\|^2\right)=\frac{\Delta^2}{12}\sum_{j=1}^d\lambda_j^{-1}=\frac{\Delta^2}{12}\sum_{j=1}^N\|\mathbf{u}_j\|^2. \tag{2.3}$$

In particular, if $\{\mathbf{v}_j\}_{j=1}^N$ is a tight frame with frame constant λ, then

$$\mathcal{E}\left(\|\mathbf{x}-\tilde{\mathbf{x}}\|^2\right)=\frac{d}{12\lambda}\Delta^2. \tag{2.4}$$

Proof. Denote $G^TG=[b_{ij}]_{i,j=1}^N$ and again let $\mathbf{y}=[\tau_\Delta(\mathbf{x}\cdot\mathbf{v}_1),\dots,\tau_\Delta(\mathbf{x}\cdot\mathbf{v}_N)]^T$. Note that with the WNH, $\mathcal{E}(y_iy_j)=\mathcal{E}(\tau_\Delta(\mathbf{x}\cdot\mathbf{v}_i)\tau_\Delta(\mathbf{x}\cdot\mathbf{v}_j))=(\Delta^2/12)\delta_{ij}$. Now $\mathbf{x}-\tilde{\mathbf{x}}=G\mathbf{y}$, and hence

$$\mathcal{E}\left(\|\mathbf{x}-\tilde{\mathbf{x}}\|^2\right)=\mathcal{E}\left(\mathbf{y}^TG^TG\mathbf{y}\right)=\sum_{i,j=1}^N b_{ij}\mathcal{E}(y_iy_j)=\sum_{i=1}^N b_{ii}\frac{\Delta^2}{12}=\frac{\Delta^2}{12}\mathrm{tr}(G^TG).$$

Finally, $\operatorname{tr}(G^TG) = \sum_{j=1}^N \|\mathbf{u}_j\|^2$, and $\operatorname{tr}(G^TG) = \operatorname{tr}(GG^T) = \operatorname{tr}((FF^T)^{-1}) = \sum_{j=1}^d \lambda_j^{-1}$. ∎

Remark. The MSE formulae (2.3)–(2.4) still hold if the independence of $\{\tau_\Delta(\mathbf{x}\cdot\mathbf{v}_j)\}_{j=1}^N$ in the WNH is replaced with the weaker condition that $\{\tau_\Delta(\mathbf{x}\cdot\mathbf{v}_j)\}_{j=1}^N$ are uncorrelated.

3. A closer look at the WNH. The WNH asserts that the error components $\{\tau_\Delta(\mathbf{x}\cdot\mathbf{v}_j)\}_{j=1}^N$ are independent and identically distributed random variables. Intuitively this cannot be true if $N > d$. This is indeed the case in general. The following is a simple result.

THEOREM 3.1. *Let $\mathbf{X} \in \mathbb{R}^d$ be an absolutely continuous random vector. Let $\{\mathbf{v}_j\}_{j=1}^N$ be nonzero vectors in $\mathbb{R}^d$ with $N > d$. Then the random variables $\{\tau_\Delta(\mathbf{X}\cdot\mathbf{v}_j)\}_{j=1}^N$ are not independent.*

Proof. Let F be the frame matrix for the frame $\{\mathbf{v}_j\}$. Then $\dim(\operatorname{range}(F^T)) \le d$, and therefore $\mathcal{L}(\operatorname{range}(F^T)) = 0$, where $\mathcal{L}$ is the Lebesgue measure on $\mathbb{R}^N$. Let $\mathbf{Y} = [Y_1, \dots, Y_N]^T := F^T\mathbf{X}$, and let $\tilde{\mathbf{Y}} = [Q_\Delta(Y_1), \dots, Q_\Delta(Y_N)]^T$ be the quantized $\mathbf{Y}$. Denote $\mathbf{Z} = \mathbf{Y} - \tilde{\mathbf{Y}} = [Z_1, \dots, Z_N]^T$. Note that $Y_j = \mathbf{v}_j \cdot \mathbf{X}$, so each Y_j is absolutely continuous, and therefore so is each Z_j. If $\{Z_j\}$ are independent, then $\mathbf{Z}$ must be absolutely continuous.

Now, set $\Omega := \operatorname{range}(F^T) + \Delta\mathbb{Z}^N$. Then $\mathcal{L}(\Omega) = 0$ because $\Delta\mathbb{Z}^N$ is a countable set. However, $\mathbf{Z}$ takes values in Ω, so $P(\mathbf{Z} \in \Omega) = 1$. This contradicts the absolute continuity of $\mathbf{Z}$. ∎

Remark. Actually for Theorem 3.1 to hold we need only to assume that $\mathbf{X}$ has an absolutely continuous component, i.e., $\mathbf{X} = \mathbf{X}_c + \mathbf{X}_s$, where $\mathbf{X}_c \neq 0$ is absolutely continuous and $\mathbf{X}_s$ is singular. However, the theorem can fail without the absolute continuity condition, even if each component of $\mathbf{X}$ may be absolutely continuous. The simplest example is to take $\mathbf{X} = [X, -X]^T$, where X is any random variable and $\mathbf{v}_1 = [1, 1]^T$ and $\mathbf{v}_2 = [1, -1]^T$.

Even when $N = d$ the WNH holds only under rather strict conditions. The following is another simple result.

PROPOSITION 3.2. *Let $\mathbf{X} = [X_1, \dots, X_m]^T$ be a random vector in $\mathbb{R}^m$ whose distribution has density function $g(x_1, \dots, x_m)$.*

(1) *The error components $\{\tau_\Delta(X_j)\}_{j=1}^m$ are independent if and only if there exist complex numbers $\{\beta_j(n) : 1 \le j \le m, n \in \mathbb{Z}\}$ such that*

$$\widehat{g}\left(\frac{a_1}{\Delta}, \dots, \frac{a_m}{\Delta}\right) = \beta_1(a_1)\cdots\beta_m(a_m) \tag{3.1}$$

for all $[a_1, \dots, a_m]^T \in \mathbb{Z}^m$.

(2) *Let $h_j(t)$ be the marginal density of X_j. Then $\{\tau_\Delta(X_j)\}_{j=1}^m$ are identically distributed if and only if*

$$\sum_{n\in\mathbb{Z}} h_j(t - n\Delta) = H(t) \quad \text{a.e.}$$

for some $H(t)$ independent of j. They are uniformly distributed on $[-\Delta/2, \Delta/2]$ if and only if $H(t) = 1/\Delta$ a.e.

Proof. To prove (1) denote $\mathcal{I}_\Delta = [-\Delta/2, \Delta/2]$ and $\mathbf{Y} = [\tau_\Delta(X_1), \dots, \tau_\Delta(X_m)]^T$. Observe that $\mathbf{Y}$ has a density

$$G(\mathbf{y}) := \sum_{\mathbf{a}\in\mathbb{Z}^m} g(\mathbf{y} - \Delta\mathbf{a}) \tag{3.2}$$

for $\mathbf{y} \in \mathcal{I}_\Delta^m$. The density $G(\mathbf{y})$ is periodic with period Δ, and it is well known that its Fourier series is given by $G(\mathbf{y}) = \sum_{\mathbf{a}\in\mathbb{Z}^m} c_{\mathbf{a}} e^{2i\pi \frac{\mathbf{a}}{\Delta}\cdot\mathbf{y}}$, where $c_{\mathbf{a}} = \widehat{g}\left(\frac{\mathbf{a}}{\Delta}\right)$. But $\{Y_j\}_{j=1}^m$ are independent if and only if on $\mathcal{I}_\Delta^m$ we have $g(y_1,\dots,y_m) = g_1(y_1)\cdots g_m(y_m)$. This happens if and only if

$$\widehat{g}\left(\frac{a_1}{\Delta},\frac{a_2}{\Delta},\dots,\frac{a_m}{\Delta}\right) = h_1\left(\frac{a_1}{\Delta}\right) h_2\left(\frac{a_2}{\Delta}\right)\cdots h_m\left(\frac{a_m}{\Delta}\right)$$

for all $\mathbf{a} = [a_1,\dots,a_m]^T \in \mathbb{Z}^m$, with $h_j(\xi) = \widehat{g}_i(\xi)$. This part of the theorem is proved by setting $\beta_j(n) = h_j(n)$.

The proof of (2) follows directly from the fact that the density of $\tau_\Delta(X_j)$ is $\sum_{n\in\mathbb{Z}} h_j(t-\Delta n)$ for $t \in \mathcal{I}_\Delta$. □

Proposition 3.2 puts strong constraints on the distribution of $\mathbf{x}$ for the WNH to hold. Let $\mathbf{X} \in \mathbb{R}^d$ be a random vector with joint density $f(\mathbf{x})$. Let $\{\mathbf{v}_j\}_{j=1}^d$ be linearly independent, and let $\mathbf{Y} = [\mathbf{X}\cdot\mathbf{v}_1, \mathbf{X}\cdot\mathbf{v}_2,\dots,\mathbf{X}\cdot\mathbf{v}_d]^T$. Then the joint density of $\mathbf{Y}$ is $g(\mathbf{y}) = |\det(F)|^{-1} f\left((F^T)^{-1}\mathbf{y}\right)$, where $F = [\mathbf{v}_1,\mathbf{v}_2,\dots,\mathbf{v}_d]$. Thus, both the independence and the identical distribution assumptions in the WNH, even for $N = d$, will be false unless very exact conditions are met. For instance, if we take $\mathbf{X}$ to be Gaussian and F to be unitary, then the independence property is satisfied only when F diagonalizes the covariance matrix of $\mathbf{X}$.

COROLLARY 3.3. *Let $\mathbf{X} \in \mathbb{R}^d$ be a random vector with joint density $f(\mathbf{x})$ and $\{\mathbf{v}_j\}_{j=1}^d$ be linearly independent vectors in $\mathbb{R}^d$. Let $\mathbf{Y} = F^T\mathbf{X} = [\mathbf{X}\cdot\mathbf{v}_1,\dots,\mathbf{X}\cdot\mathbf{v}_N]^T$ and $g(\mathbf{y}) = |\det(F)|^{-1} f\left((F^T)^{-1}\mathbf{y}\right)$, where $F = [\mathbf{v}_1,\dots,\mathbf{v}_d]$.*

(1) *$\{\tau_\Delta(Y_j)\}_{j=1}^d$ are independent random variables if and only if there exist complex numbers $\{\beta_j(n) : 1 \le j \le d, n \in \mathbb{Z}\}$ such that*

$$\widehat{g}\left(\frac{a_1}{\Delta},\dots,\frac{a_d}{\Delta}\right) = \beta_1(a_1)\cdots\beta_d(a_d) \tag{3.3}$$

for all $[a_1,\dots,a_d]^T \in \mathbb{Z}^d$.

(2) *Let $h_j(t) = \int_{\mathbb{R}^{d-1}} g(x_1,\dots,x_{j-1},t,x_{j+1},\dots,x_d)\, dx_1\cdots dx_{j-1}\, dx_{j+1}\dots dx_d$. Then $\{\tau_\Delta(X_j)\}_{j=1}^d$ are identically distributed if and only if $\sum_{n\in\mathbb{Z}} h_j(t - n\Delta) = H(t)$ a.e. for some $H(t)$ independent of j. They are uniformly distributed on $[-\frac{\Delta}{2},\frac{\Delta}{2}]$ if and only if $H(t) = 1/\Delta$ a.e.*

Proof. We have only to observe that $g(\mathbf{y})$ is the density of $\mathbf{Y}$ and that h_j is the marginal density of Y_j. The corollary now follows directly from the theorem. □

From a practical point of view, with coarse quantization the MSE cannot be estimated simply by (1.6). Thus the "6-dB-per-bit" rule may not apply. We shall demonstrate this with numerical results. However, with high resolution quantization the formula (1.6) becomes increasingly accurate. We show this in the next section.

4. Asymptotic behavior of errors: Linear independence case. In many practical applications such as a music CD, fine quantizations with 16 bits or more have been adopted. Although the WNH is not valid in general, with fine quantizations we prove here that a weaker version of the WNH is close to being valid, which yields an asymptotic formula for the PCM quantized MSE. Our result here strengthens an asympototic result in [22].

We again consider the same setup as before. Let $\{\mathbf{v}_j\}_{j=1}^N$ be a frame in $\mathbb{R}^d$ with corresponding frame matrix $F = [\mathbf{v}_1,\mathbf{v}_2,\dots,\mathbf{v}_N]$. The eigenvalues of FF^T are $\lambda_{\max} = \lambda_1 \ge \lambda_2 \ge \cdots \ge \lambda_d = \lambda_{\min} > 0$. Let $\{\mathbf{u}_j\}_{j=1}^N$ be the canonical dual frame with corresponding matrix $G = (FF^T)^{-1}F$. For any $\mathbf{x} \in \mathbb{R}^d$ we have $\mathbf{x} = \sum_{j=1}^N (\mathbf{x}\cdot\mathbf{v}_j)\,\mathbf{u}_j$.

Using the quantization alphabet $\mathcal{A} = \Delta\mathbb{Z}$ we have the PCM reconstruction (1.4). Note that $\tilde{\mathbf{x}} = \tilde{\mathbf{x}}(\Delta)$ as it depends on Δ. With the WNH we obtain the MSE

$$\text{MSE} = \mathcal{E}\left(\|\mathbf{x} - \tilde{\mathbf{x}}\|^2\right) = \frac{\Delta^2}{12}\sum_{j=1}^{N}\lambda_j^{-1}.$$

To study the asymptotic behavior of the error components, we study as $\Delta \to 0^+$ the normalized quantization error

$$\frac{1}{\Delta}(\mathbf{x} - \tilde{\mathbf{x}}) = \sum_{j=1}^{N}\frac{1}{\Delta}\tau_\Delta\left(\mathbf{x}\cdot\mathbf{v}_j\right)\mathbf{u}_j. \tag{4.1}$$

THEOREM 4.1. *Let $\mathbf{X} \in \mathbb{R}^d$ be an absolutely continuous random vector. Let $\mathbf{w}_1, \ldots, \mathbf{w}_m$ be linearly independent vectors in $\mathbb{R}^d$. Then*

$$\left[\frac{1}{\Delta}\tau_\Delta\left(\mathbf{X}\cdot\mathbf{w}_1\right), \ldots, \frac{1}{\Delta}\tau_\Delta\left(\mathbf{X}\cdot\mathbf{w}_m\right)\right]^T$$

converges in distribution as $\Delta \to 0^+$ to a random vector uniformly distributed in $[-1/2, 1/2]^m$.

Proof. Denote $Y_j = \mathbf{X}\cdot\mathbf{w}_j$. Since $\{\mathbf{w}_j\}$ are linearly independent, $\mathbf{Y} = [Y_1, \ldots, Y_m]^T$ is absolutely continuous with some joint density $f(\mathbf{x})$, $\mathbf{x} \in \mathbb{R}^m$. As a consequence of (3.2) one has that the distribution of $\mathbf{Z} = [Z_1, \ldots, Z_m]^T$, where $Z_j = \frac{1}{\Delta}\tau_\Delta(Y_j) = \left\{\frac{Y_j}{\Delta} + \frac{1}{2}\right\} - \frac{1}{2}$, is

$$f_\Delta(\mathbf{x}) := \Delta^m \sum_{\mathbf{a}\in\mathbb{Z}^m} f(\Delta\mathbf{x} - \Delta\mathbf{a}) \tag{4.2}$$

for $\mathbf{x} \in [-1/2, 1/2]^m$. Again denote $\mathcal{I}_1 := [-1/2, 1/2]$. It is easy to see that $\|f_\Delta\|_{L^1(\mathcal{I}_1^m)} \le \|f\|_{L^1(\mathbb{R}^m)}$ for

$$\begin{aligned}
\|f_\Delta\|_{L^1(\mathcal{I}_1^m)} &= \int_{\mathcal{I}_1^m} |f_\Delta(\mathbf{x})|\, d\mathbf{x} \\
&\le \sum_{\mathbf{a}\in\mathbb{Z}^m}\int_{\mathcal{I}_1^m} \Delta^m \left|f(\Delta\mathbf{x} - \Delta\mathbf{a})\right|\, d\mathbf{x} \\
&= \sum_{\mathbf{a}\in\mathbb{Z}^m}\int_{\Delta{\mathcal{I}_1}^m + \Delta\mathbf{a}} \left|f\left(\mathbf{y}\right)\right|\, d\mathbf{y} \\
&= \int_{\mathbb{R}^m} \left|f\left(\mathbf{y}\right)\right|\, d\mathbf{y} \\
&= \|f\|_{L^1(\mathbb{R}^m)}.
\end{aligned}$$

Now, if $\Omega = [a_1, b_1] \times \cdots \times [a_m, b_m]$ and $f(\mathbf{x}) = \mathbf{1}_\Omega(\mathbf{x})$, then for $\mathbf{x} \in \mathcal{I}_1^m$ observe that $f_\Delta(\mathbf{x}) = \Delta^m K_\Delta$, where $K_\Delta(\mathbf{x}) = \#\{\mathbf{a} \in \mathbb{Z}^m : \Delta\mathbf{x} + \Delta\mathbf{a} \in \Omega\}$. Obviously, $K_\Delta(\mathbf{x}) = s/\Delta^m + O(\Delta^{-m+1})$, where $s = \mathcal{L}(\Omega)$ is the Lebesgue measure of Ω. Then $f_\Delta \to s\mathbf{1}_{\mathcal{I}_1^m}$ in $L^1(\mathcal{I}_1^m)$ as $\Delta \to 0^+$.

We return to the case when $f(\mathbf{x})$ is the density of $\mathbf{Y}$. For any $\varepsilon > 0$ it is possible to choose a $g(\mathbf{x}) \in L^1(\mathbb{R}^m)$ such that $\|f - g\|_{L^1} < \frac{\varepsilon}{3}$, and furthermore, $g(\mathbf{x}) = \sum_{j=1}^{N} c_j \mathbf{1}_{E_j}(\mathbf{x})$ is a simple function where $c_j \in \mathbb{R}$ and each E_j is a product

of finite intervals. Observe that $\int_{\mathbb{R}^m} g = \sum_{j=1}^N c_j \mathcal{L}(E_j)$. Since $(\mathbf{1}_{E_j})_\Delta \to \mathcal{L}(E_j)\mathbf{1}_{\mathcal{I}_1^m}$ in L^1 we have $g_\Delta \to \left(\int_{\mathbb{R}^m} g\right)\mathbf{1}_{\mathcal{I}_1^m}$ as $\Delta \to 0$. Hence there exists a $\delta > 0$ such that $\|g_\Delta - (\int_{\mathbb{R}^m} g)\mathbf{1}_{\mathcal{I}_1^m}\|_{L^1} < \varepsilon/3$ whenever $\Delta < \delta$. Now, for $\Delta < \delta$,

$$\begin{aligned}\left\|f_\Delta - \mathbf{1}_{\mathcal{I}_1^m}\right\|_{L^1(\mathcal{I}_1^m)} &= \|f_\Delta - g_\Delta\|_{L^1(\mathcal{I}_1^m)} + \left\|g_\Delta - \left(\int_{\mathbb{R}^m} g\right)\mathbf{1}_{\mathcal{I}_1^m}\right\|_{L^1(\mathcal{I}_1^m)} \\ &\quad + \left|1 - \left(\int_{\mathbb{R}^m} g\right)\right| \|\mathbf{1}_{\mathcal{I}_1^m}\|_{L^1(\mathcal{I}_1^m)} \\ &< \frac{\varepsilon}{3} + \frac{\varepsilon}{3} + \left|1 - \left(\int_{\mathbb{R}^m} g\right)\right| \\ &= \frac{2\varepsilon}{3} + \left|\left(\int_{\mathbb{R}^m} f\right) - \left(\int_{\mathbb{R}^m} g\right)\right| \\ &< \varepsilon. \qquad \square\end{aligned}$$

Remark. We in fact proved a stronger result, namely, that the densities converge in L^1. Applying the above theorem to the MSE, if $\{\mathbf{v}_j\}_{j=1}^N$ are pairwise linearly independent, then the error components $\{\tau_\Delta(\mathbf{X}\cdot\mathbf{v}_j)\}_{j=1}^N$ become asymptotically pairwise independent and each is uniformly distributed in $[-\frac{\Delta}{2}, \frac{\Delta}{2}]$.

COROLLARY 4.2. *Let $\mathbf{X} \in \mathbb{R}^d$ be an absolutely continuous random vector. If $\{\mathbf{v}_j\}_{j=1}^N$ are pairwise linearly independent, then as $\Delta \to 0^+$ we have*

$$\mathcal{E}\left(\|\mathbf{X} - \tilde{\mathbf{X}}\|^2\right) = \frac{\Delta^2}{12}\sum_{j=1}^d \lambda_j^{-1} + o(\Delta^2) = \frac{\Delta^2}{12}\sum_{j=1}^N \|\mathbf{u}_j\|^2 + o(\Delta^2). \tag{4.3}$$

Proof. As usual, denote by F and G the frame matrices associated with the frame $\{\mathbf{v}_j\}_{j=1}^N$ and the dual frame $\{\mathbf{u}_j\}_{j=1}^N$, respectively. Let $H = G^T G$, $Y_j = \mathbf{X}\cdot\mathbf{v}_j$, $Z_j = \left\{\frac{Y_j}{\Delta} + \frac{1}{2}\right\} - \frac{1}{2}$, and $\mathbf{Z} = [Z_1, \ldots, Z_N]^T$. By Theorem 4.1, $\mathcal{E}(Z_i) \to 0$ and $\mathcal{E}(Z_i Z_j) \to \frac{1}{12}\delta_{ij}$ as $\Delta \to 0^+$. Now $\mathbf{X} - \tilde{\mathbf{X}} = G\mathbf{Z}$. It follows from the proof of Proposition 2.2 that

$$\begin{aligned}\frac{1}{\Delta^2}\mathcal{E}(\|\mathbf{X} - \tilde{\mathbf{X}}\|^2) &= \mathcal{E}(\mathbf{Z}^T H \mathbf{Z}) \\ &= \mathcal{E}\left(\sum_{i,j=1}^N Z_i Z_j h_{ij}\right) \\ &= \sum_{i,j=1}^N h_{ij}\mathcal{E}(Z_i Z_j) \\ &= \frac{1}{12}\sum_{i=1}^N h_{ii} + o(1) \\ &= \frac{1}{12}\sum_{j=1}^d \lambda_j^{-1} + o(1),\end{aligned}$$

and hence

$$\mathcal{E}\left(\|\mathbf{X} - \tilde{\mathbf{X}}\|^2\right) = \frac{\Delta^2}{12}\sum_{j=1}^d \lambda_j^{-1} + o(\Delta^2) = \frac{\Delta^2}{12}\sum_{j=1}^N \|\mathbf{u}_j\|^2 + o(\Delta^2). \qquad \square$$

5. Asymptotic behavior of errors: Linear dependence case. In this section we consider the case in which some vectors in the frame may be parallel. This can happen, for example, if the frame contains redundant elements. Mathematically it would be interesting to understand how the MSE behaves as $\Delta \to 0^+$. We return to previous calculations and note that

$$\mathcal{E}(\|\mathbf{X}-\tilde{\mathbf{X}}\|^2) = \sum_{i,j=1}^{N} h_{ij}\mathcal{E}\left(\tau_\Delta(\mathbf{X}\cdot\mathbf{v}_i)\tau_\Delta(\mathbf{X}\cdot\mathbf{v}_j)\right).$$

Our main result in this section is the following theorem.

THEOREM 5.1. *Let X be an absolutely continuous real random variable. Let $\alpha \in \mathbb{R}\setminus\{0\}$. Then*

$$\lim_{\Delta\to 0^+} \frac{1}{\Delta^2}\mathcal{E}\left(\tau_\Delta(X)\tau_\Delta(\alpha X)\right) = \begin{cases} 0, & \alpha \notin \mathbb{Q}, \\ \dfrac{1}{12pq}, & \alpha = \dfrac{p}{q} \text{ and } p+q \text{ is even}, \\ -\dfrac{1}{24pq}, & \alpha = \dfrac{p}{q} \text{ and } p+q \text{ is odd}, \end{cases} \tag{5.1}$$

where p, q are coprime integers.

Proof. Denote $g(x) := \{x+\frac{1}{2}\} - \frac{1}{2}$. Let $\phi(x) \geq 0$ be an even C^∞ function such that $\operatorname{supp}(\phi) \subseteq [-1,1]$ and $\int_{\mathbb{R}} \phi = 1$. Let $g_n(x) = g * \phi_n$, where $\phi_n(x) = n\phi(nx)$. It is standard to check that

(a) $|g_n(x)| \leq 1/2$;
(b) $\operatorname{supp}(g(x) - g_n(x)) \subseteq [\frac{1}{2} - \frac{1}{n}, \frac{1}{2} + \frac{1}{n}] + \mathbb{Z}$;
(c) $g_n(x) \in C^\infty$ and is $\mathbb{Z}$-periodic; and
(d) $\int_{\mathbb{R}} g_n(x)\,dx = 0$.

$g_n(x)$ represents a small perturbation of $g(x)$ that "smoothes out" the discontinuities of $g(x)$. Now, set

$$\begin{aligned} E(\Delta) &:= \mathcal{E}\left(\frac{1}{\Delta^2}\tau_\Delta(X)\tau_\Delta(\alpha X)\right) \\ &= \mathcal{E}\left(g\left(\frac{X}{\Delta}\right) g\left(\frac{\alpha X}{\Delta}\right)\right) \\ &= \int_{\mathbb{R}} g\left(\frac{x}{\Delta}\right) g\left(\frac{\alpha x}{\Delta}\right) f(x)\,dx, \end{aligned}$$

and

$$E_n(\Delta) := \int_{\mathbb{R}} g_n\left(\frac{x}{\Delta}\right) g_n\left(\frac{\alpha x}{\Delta}\right) f(x)\,dx.$$

CLAIM. *$E_n(\Delta) \to E(\Delta)$ as $n \to \infty$ uniformly for all $\Delta > 0$.*

Proof of the claim. Let f be the density of $\mathbf{X}$. For any $\varepsilon > 0$,

$$\begin{aligned} |E_n(\Delta) - E(\Delta)| &= \left| \int_{\mathbb{R}} \left[g_n\left(\frac{x}{\Delta}\right) g_n\left(\frac{\alpha x}{\Delta}\right) - g\left(\frac{x}{\Delta}\right) g\left(\frac{\alpha x}{\Delta}\right) \right] f(x)\,dx \right| \\ &\leq \frac{1}{2}\int_{\mathbb{R}} \left| g_n\left(\frac{x}{\Delta}\right) - g\left(\frac{x}{\Delta}\right) \right| f(x)\,dx \\ &\quad + \frac{1}{2}\int_{\mathbb{R}} \left| g_n\left(\frac{\alpha x}{\Delta}\right) - g\left(\frac{\alpha x}{\Delta}\right) \right| f(x)\,dx. \end{aligned}$$

Now there exists an $M > 0$ such that $\int_{[-M,M]^c} f(x)\,dx < \frac{\varepsilon}{2}$. So

$$\int_{\mathbb{R}} \left| g_n\left(\frac{x}{\Delta}\right) - g\left(\frac{x}{\Delta}\right)\right| f(x)\,dx \le \int_{-M}^{M} \left| g_n\left(\frac{x}{\Delta}\right) - g\left(\frac{x}{\Delta}\right)\right| f(x)\,dx + \frac{\varepsilon}{2}.$$

Furthermore, let $A_n(\Delta, M) := \operatorname{supp}(g_n(x/\Delta) - g(x/\Delta)) \cap [-M, M]$. Then we have

$$A_n(\Delta, M) \subseteq \Delta\left(\left[\frac{1}{2} - \frac{1}{n}, \frac{1}{2} + \frac{1}{n}\right] + \mathbb{Z}\right) \cap [-M, M].$$

Hence $\mathcal{L}(A_n(\Delta, M)) \le \frac{2M}{\Delta} \cdot \frac{2\Delta}{n} = \frac{4M}{n}$, and thus

$$\int_{-M}^{M} \left| g_n\left(\frac{x}{\Delta}\right) - g\left(\frac{x}{\Delta}\right)\right| f(x)\,dx \le \int_{A_n(\Delta,M)} f(x)\,dx < \frac{\varepsilon}{2}$$

for $n > 4M/\varepsilon$ (which is independent of Δ). This yields

$$\int_{\mathbb{R}} \left| g_n\left(\frac{x}{\Delta}\right) - g\left(\frac{x}{\Delta}\right)\right| f(x)\,dx < \varepsilon.$$

Similarly we have

$$\int_{\mathbb{R}} \left| g_n\left(\frac{\alpha x}{\Delta}\right) - g\left(\frac{\alpha x}{\Delta}\right)\right| f(x)\,dx < \varepsilon$$

for sufficiently large n, proving the claim. □

Now consider the Fourier series of $g_n(t)$,

$$g_n(t) = \sum_{k\in\mathbb{Z}} c_k^{(n)} e^{2\pi i k t}.$$

It is well known that the Fourier series converges to $g_n(t)$ uniformly for all t; see, e.g., [24]. Furthermore, since $g_n(t)$ is C^∞ we have $|c_k^{(n)}| = o\left((|k|+1)^{-L}\right)$ for all $L > 0$, giving absolute convergence of the Fourier series. Thus

$$\begin{aligned} E_n(\Delta) &= \lim_{K\to\infty} \int_{\mathbb{R}} \Big(\sum_{|k|\le K} c_k^{(n)} e^{2\pi i k t \Delta^{-1}} \Big) \Big(\sum_{|k|\le K} c_k^{(n)} e^{2\pi i k \alpha t \Delta^{-1}} \Big) f(t)\,dt \\ &= \lim_{K\to\infty} \sum_{|k|,|\ell|\le K} c_k^{(n)} c_\ell^{(n)} \widehat{f}\Big(-\frac{k+\alpha\ell}{\Delta}\Big). \end{aligned}$$

Observe that $|\widehat{f}(\xi)| \le \|f\|_{L^1} = 1$, and $|c_k^{(n)}| = o\left((|k|+1)^{-L}\right)$ for any $L > 0$. So the series converges absolutely and uniformly in Δ. Thus

$$E_n(\Delta) = \sum_{k,\ell\in\mathbb{Z}} c_k^{(n)} c_\ell^{(n)} \widehat{f}\Big(-\frac{k+\alpha\ell}{\Delta}\Big). \tag{5.2}$$

For any $n > 0$ we have

$$\lim_{\Delta\to 0^+} E_n(\Delta) = \sum_{k,\ell\in\mathbb{Z}} c_k^{(n)} c_\ell^{(n)} \lim_{\Delta\to 0^+} \widehat{f}\Big(-\frac{k+\alpha\ell}{\Delta}\Big)$$

because the series converges absolutely and uniformly. Suppose $\alpha \notin \mathbb{Q}$. Then $k + \alpha\ell \neq 0$ if either $k \neq 0$ or $\ell \neq 0$. Thus $\left|-\frac{k+\alpha\ell}{\Delta}\right| \to \infty$ as $\Delta \to \infty$, and hence $\lim_{\Delta\to 0^+} \widehat{f}\big(-\frac{k+\alpha\ell}{\Delta}\big) = 0$ as $f \in L^1(\mathbb{R})$. Note also that $c_0^{(n)} = \int_{\mathbb{R}} g_n = 0$. It follows that

$$\lim_{\Delta\to 0^+} E_n(\Delta) = 0.$$

But $E_n(\Delta) \to E(\Delta)$ as $n \to \infty$ uniformly in Δ, which yields $E(\Delta) \to 0$ as $\Delta \to 0^+$.

Next, suppose $\alpha = \frac{p}{q}$, where $p, q \in \mathbb{Z}$, $(p, q) = 1$. We observe that $k + \alpha\ell = 0$ if and only if $k = pm$ and $\ell = -qm$ for some $m \in \mathbb{Z}$. In such a case

$$\widehat{f}\Big(-\frac{k+\alpha\ell}{\Delta}\Big) = \widehat{f}(0) = \int_{\mathbb{R}} f = 1.$$

It follows that

$$\lim_{\Delta\to 0^+} E_n(\Delta) = \sum_{m\in\mathbb{Z}} c_{pm}^{(n)} c_{-qm}^{(n)} \widehat{f}(0) = \sum_{m\in\mathbb{Z}} c_{pm}^{(n)} c_{-qm}^{(n)} = \sum_{m\in\mathbb{Z}} c_{pm}^{(n)} \overline{c_{qm}^{(n)}}.$$

For $r \in \mathbb{Z}, r \neq 0$ set

$$G_r^{(n)}(x) := \sum_{m\in\mathbb{Z}} c_{rm}^{(n)} e^{2\pi i m x}.$$

By Parseval we have

$$\lim_{\Delta\to 0} E_n(\Delta) = \Big\langle G_q^{(n)}, G_p^{(n)} \Big\rangle_{L^2([0,1])}.$$

It is easy to check that

$$G_r^{(n)} = \frac{1}{|r|} \sum_{j=0}^{|r|-1} g_n\Big(\frac{x+j}{r}\Big).$$

Hence $G_r^{(n)}$ converges in $L^2([0,1])$ to $G_r(x) := \frac{1}{|r|}\sum_{j=0}^{|r|-1} g\big(\frac{x+j}{r}\big)$, which has Fourier series $G_r(x) = \sum_{m\in\mathbb{Z}} c_{rm} e^{2\pi i m x}$ with $c_0 = 0$ and $c_k = \frac{(-1)^{k-1}}{2\pi i k}$ for $k \neq 0$. This yields

$$\lim_{n\to\infty} \lim_{\Delta\to 0^+} E_n(\Delta) = \lim_{n\to\infty} \Big\langle G_q^{(n)}, G_p^{(n)} \Big\rangle = \langle G_q, G_p \rangle = \sum_{m\in\mathbb{Z}} c_{qm} \overline{c_{pm}}.$$

Finally,

$$\begin{aligned} \sum_{m\in\mathbb{Z}} c_{qm}\overline{c_{pm}} &= \sum_{m\in\mathbb{Z}\setminus\{0\}} \Big(\frac{(-1)^{qm-1}}{2\pi i m q}\Big)\overline{\Big(\frac{(-1)^{pm-1}}{2\pi i m p}\Big)} \\ &= \frac{1}{2pq\pi^2} \sum_{m=1}^{\infty} \frac{(-1)^{(p+q)m}}{m^2}. \end{aligned}$$

Note that if $p + q$ is even then $\sum_{m=1}^{\infty} \frac{(-1)^{(p+q)m}}{m^2} = \sum_{m=1}^{\infty} \frac{1}{m^2} = \frac{\pi^2}{6}$. On the other hand, if $p + q$ is odd then $\sum_{m=1}^{\infty} \frac{(-1)^{(p+q)m}}{m^2} = \sum_{m=1}^{\infty} \frac{(-1)^m}{m^2} = -\frac{\pi^2}{12}$. The theorem follows. ∎

COROLLARY 5.2. *Let* $\mathbf{X}$ *be an absolutely continuous random vector in* $\mathbb{R}^d$, $\mathbf{w} \neq 0$, $\mathbf{w} \in \mathbb{R}^d$, *and* $\alpha \in \mathbb{R} \setminus \{0\}$. *Then*

$$\lim_{\Delta \to 0^+} \frac{1}{\Delta^2} \mathcal{E}\left(\tau_\Delta(\mathbf{w}\cdot\mathbf{X})\tau_\Delta(\alpha\mathbf{w}\cdot\mathbf{X})\right) = \begin{cases} 0, & \alpha \notin \mathbb{Q}, \\ \dfrac{1}{12pq}, & \alpha = \dfrac{p}{q} \text{ and } p+q \text{ is even}, \\ -\dfrac{1}{24pq}, & \alpha = \dfrac{p}{q} \text{ and } p+q \text{ is odd}, \end{cases} \tag{5.3}$$

where p, q *are coprime integers.*

Proof. We need only to note that $\mathbf{w}\cdot\mathbf{X}$ is an absolutely continuous random variable. The corollary follows immediately from Theorem 5.1. □

We can now characterize completely the asymptotic behavior of the MSE in all cases. For any two vectors $\mathbf{w}_1, \mathbf{w}_2 \in \mathbb{R}^d$ define $r(\mathbf{w}_1, \mathbf{w}_2)$ by

$$r(\mathbf{w}_1, \mathbf{w}_2) = \begin{cases} \dfrac{1}{pq}\mathbf{w}_1\cdot\mathbf{w}_2, & \mathbf{w}_1 = \dfrac{p}{q}\mathbf{w}_2, \text{ and } p+q \text{ is even}, \\ -\dfrac{1}{2pq}\mathbf{w}_1\cdot\mathbf{w}_2, & \mathbf{w}_1 = \dfrac{p}{q}\mathbf{w}_2, \text{ and } p+q \text{ is odd}, \\ 0, & \text{otherwise}, \end{cases}$$

where p, q are coprime integers.

COROLLARY 5.3. *Let* $\mathbf{X} \in \mathbb{R}^d$ *be an absolutely continuous random vector. Then as* $\Delta \longrightarrow 0^+$ *the MSE satisfies*

$$\mathcal{E}\left(\|\mathbf{X} - \tilde{\mathbf{X}}\|^2\right) = \frac{\Delta^2}{12}\sum_{j=1}^{d}\lambda_j^{-1} + \frac{\Delta^2}{6}\sum_{1\le i<j\le N} r(\mathbf{u}_i, \mathbf{u}_j) + o(\Delta^2). \tag{5.4}$$

Proof. In the proof of (4.2) we showed that

$$\lim_{\Delta\to 0^+}\frac{1}{\Delta^2}\mathcal{E}\left(\|\mathbf{X} - \tilde{\mathbf{X}}\|^2\right) = \sum_{i,j} h_{ij}\mathcal{E}\left(Z_i Z_j\right)$$

with the notation there. Observe that $h_{ij} = \mathbf{u}_i \cdot \mathbf{u}_j$. The result is immediate from Corollary 5.2. □

For fixed quantization step $\Delta > 0$ we shall denote

$$\mathrm{MSE}_{ideal} = \frac{\Delta^2}{12}\sum_{j=1}^{d}\lambda_j^{-1} + \frac{\Delta^2}{6}\sum_{1\le i<j\le N} r(\mathbf{u}_i, \mathbf{u}_j) \tag{5.5}$$

and call it the *ideal* MSE. If $\{\mathbf{v}_j\}_{j=1}^N$ are pairwise linearly independent, then the MSE_{ideal} is simply $\frac{\Delta^2}{12}\sum_{j=1}^{d}\lambda_j^{-1}$, the MSE under the WNH.

We should point out that even though the WNH is not true aysmpototically if some vectors in a frame are parallel, the contribution from the second part of (5.5) is often small enough that the MSE under the WNH is close enough to the ideal MSE. In the next section we shall show some numerical data comparing the actual MSE with the ideal MSE.

Appendix A. Numerical results. Here we present data from our computer experiments comparing the ideal MSE to the actual MSE. We performed Monte Carlo

simulations for several different sets of frames. We also experimented with various distributions for $\mathbf{X} \in \mathbb{R}^d$. As it turned out, we got very similar results for the distributions we used for most of the frames we tried. In the examples shown, the random vectors $\mathbf{X}$ are all chosen to be uniformly distributed in $[-5, 5]^d$.

Example A.1. Let $\{\mathbf{v}_j\}_{j=1}^N$ be the harmonic frame in $\mathbb{R}^2$, with $\mathbf{v}_j = \left[\cos\frac{2\pi j}{N}, \sin\frac{2\pi j}{N}\right]^T$. This is a tight frame with frame constant $\lambda = \frac{N}{2}$. The ideal MSE is $\frac{\Delta^2}{3N}$ for N odd. Taking $\Delta = \frac{1}{2}$, Table 1 displays the actual MSE, the ideal MSE, and the ratio between them. It shows that as N gets larger than 129, the actual MSE does not improve, which shows that the WNH is invalid for large Δ.

Example A.2. Let $\{\mathbf{v}_j\}_{j=1}^N$ be N independently and randomly generated vectors uniformly distributed on the unit sphere in $\mathbb{R}^4$. Table 2 shows the ratio between the actual MSE and the ideal MSE, where $\mathrm{MSE}_{ideal} = \frac{\Delta^2}{12}(\sum_{j=1}^d \lambda_j^{-1})$, with $\Delta = 2^{-k}$.

Example A.3. Let $\{\mathbf{v}_j\}_{j=0}^{N-1}$ be the harmonic frame in $\mathbb{R}^4$, with

$$\mathbf{v}_j = \sqrt{\frac{1}{2}}\left[\cos\frac{2\pi j}{N}, \sin\frac{2\pi j}{N}, \cos\frac{4\pi j}{N}, \sin\frac{4\pi j}{N}\right]^T.$$

This is a tight frame with frame constant $\lambda = \frac{N}{4}$, and the ideal MSE is $\frac{4\Delta^2}{3N}$. Table 3 shows the ratio between the actual MSE and the ideal MSE, where $\Delta = 2^{-k}$.

Example A.4. Let $\{\mathbf{v}_j\}_{j=1}^5$ be a frame in $\mathbb{R}^3$, with the corresponding matrix

$$F = \begin{pmatrix} 1 & 1 & 0 & 1 & 3 \\ 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \end{pmatrix}.$$

Note that the set contains many parallel vectors. The dual frame matrix is

$$\begin{pmatrix} \frac{1}{11} & 0 & 0 & \frac{1}{11} & \frac{3}{11} \\ \frac{1}{11} & -1 & 0 & \frac{1}{11} & \frac{3}{11} \\ 0 & 0 & 1 & 0 & 0 \end{pmatrix}.$$

The MSE under the WNH is $0.181818\Delta^2$ and, by our result, the ideal MSE is $0.190083\Delta^2$, which is closer to the actual MSE. The difference between the two estimates comes from the second part in (5.5). Table 4 shows the actual MSE, the ideal MSE, and the MSE under the WNH, where $\Delta = 2^{-k}$.

Acknowledgments. Several people have given us helpful suggestions on this paper. But in particular we wish to express our gratitude to the referee, who not only read the manuscript very carefully but provided us with a number of valuable suggestions, particularly on the vast engineering literature regarding vector quantization.
