PARABOLIC BEHAVIOR OF A HYPERBOLIC DELAY EQUATION*

THOMAS LAURENT†, BRIAN RIDER‡, AND MICHAEL REED†

Abstract. It is shown that the fundamental solution of a hyperbolic partial differential equation with time delay has a natural probabilistic structure, i.e., is approximately Gaussian, as $t \to \infty$. The proof uses ideas from the DeMoivre proof of the central limit theorem. It follows that solutions of the hyperbolic equation look approximately like solutions of a diffusion equation with constant convection as $t \to \infty$.

Key words. hyperbolic equation, time delay, probabilistic behavior, parabolic equation

DOI. 10.1137/040611422

1. Introduction.

It has long been known that time delays have a smoothing effect on ordinary differential equations. For example, Kolmanovskii and Myshkis [8] state that, "This property of 'solution smoothing' ... together with some other properties make retarded differential equations resemble parabolic differential equations. However, the reasons for this resemblance are not entirely clear." In this paper, we provide an analytical foundation for these ideas by studying the initial value problem for the linear hyperbolic equation

$$\frac{\partial}{\partial t}u(t,x) \; + \; c\frac{\partial}{\partial x}u(t,x) = -Au(t,x) \; + Bu(t-\tau,x), \tag{1}$$

$$u(t,x) = f(t,x) \qquad \text{for} \quad -\tau \le t \le 0, \tag{2}$$

where A and B are positive constants and τ is the time delay.

In section 2, we introduce the "fundamental solution,"

$$K(t,x) = \sum_{k=0}^{n} \gamma_k(t)\delta_{ct-ck\tau}(x) \qquad \text{for } \; n\tau \le t < (n+1)\tau, \tag{3}$$

where $n = 0, 1, 2, \ldots$, and we define $K(t,x) \equiv 0$ for $t\epsilon[-\tau, 0)$. The coefficients $\gamma_k(t)$ are defined recursively: $\gamma_0(t)$ satisfies $\gamma_0'(t) = -A\gamma_0(t)$ with $\gamma_0(0) = 1$ and

$$\gamma_k'(t) = -A\gamma_k(t) \; + \; B\gamma_{k-1}(t-\tau) \qquad \text{with } \gamma_k(k\tau) = 0. \tag{4}$$

Using standard functional analytic methods, we prove that $K(t) \equiv K(t,\cdot)$ is a continuous $\mathcal{D}'(\mathbb{R})$-valued function on $[0,\infty)$ that is differentiable except at τ. We prove that if $f(t)$ is any continuous $\mathcal{D}'(\mathbb{R})$-valued initial data on $[-\tau, 0]$, then there is a unique $\mathcal{D}'(\mathbb{R})$-valued solution of (1) given by

$$u(t) = K(t) * f(0) \; + \; B\int_{-\tau}^{0} K(t-\theta-\tau) * f(\theta)d\theta \qquad \text{for } \; t > 0. \tag{5}$$

‡Department of Mathematics, University of Colorado at Boulder, Boulder, CO 80309 (brider@euclid.colorado.edu)

If one integrates (1) with respect to x (assuming that $u(t,x) \to 0$ as $|x| \to \infty$), one obtains a solution of the retarded differential equation (RDE)

$$y'(t) = -Ay(t) + By(t-\tau) \quad \text{for } t > 0. \tag{6}$$

We shall denote the fundamental solution of (6) by $Y(t)$, i.e., $Y(t)$ is the solution with initial data equal to 1 at $t = 0$ and equal to 0 at earlier times. The general solution of (6) is given by a formula similar to (5), where $Y(t)$ replaces $K(t)$ and convolution is replaced by multiplication [7].

In section 3, the main section of the paper, we analyze the asymptotic behavior as $t \to \infty$ of the fundamental solution $K(t)$. The characteristic function of (6) is $h(\lambda) = \lambda + A - Be^{-\lambda\tau}$. The root of h with largest real part, λ_0, is real and we define $p = 1/h'(\lambda_0)$ and $\alpha = \tau c^2(1-p)p^2$. We prove that $K(t)$, after normalization, looks asymptotically like a Gaussian with standard deviation $\sigma = \sqrt{\alpha t}$ translating at speed cp. The proof depends on the combinatorics of the functions $\gamma_k(t)$ and follows many of the ideas of the DeMoivre proof of the central limit theorem.

In section 4, we assume that f is a continuous function on $[-\tau, 0]$ with values in $L^1(\mathbb{R})$. Using an appropriate seminorm, we show that asymptotically the solution $u(t)$ of (1) looks likes a weighted average of solutions of the transport heat equation,

$$\frac{\partial}{\partial t}v(t,x) \; + \; cp\frac{\partial}{\partial x}v(t,x) = \frac{\alpha}{2}\frac{\partial^2}{\partial x^2}v(t,x), \tag{7}$$

on the space scale $c\tau$.

We note that (1) has a natural interpretation in population dynamics. $u(t,x)$ is the population density in space at time t. Members of the population move to the right at speed c, die at rate A, and produce eggs at a rate B. The eggs are stationary, but after a time τ become moving members of the population. In this language, $Y(t)$ plays the role of the total population at time t. Hyperbolic equations with time delays occur frequently in ecology and cell biology [3], [9], [11], where $u(t,x)$ is the density of the population at different maturities x. Often these equations are nonlinear, boundary value problems with inhomogeneous velocities, so it is not clear whether the probabilistic methods of this study can be extended to those cases.

2. Existence, uniqueness, and representation. We denote by $\mathcal{D}(\mathbb{R})$ the usual space of test functions of compact support and by $\mathcal{D}'(\mathbb{R})$ the space of distributions. By convergence of a sequence $\mu_n \to \mu$ in $\mathcal{D}'(\mathbb{R})$, we always mean weak convergence, i.e., $\langle \mu_n, \psi \rangle \to \langle \mu, \psi \rangle$ for all $\psi \epsilon \mathcal{D}(\mathbb{R})$. For each fixed t, the sum defining $K(t)$ is finite, so it is clear that $K(t) \epsilon \mathcal{D}'(\mathbb{R})$ and the support of $K(t)$ is contained in the interval $[0, ct]$. Since we are interested in the properties of K as a function of t, we begin by summarizing briefly the basic definitions and properties of $\mathcal{D}'(\mathbb{R})$-valued functions that we use repeatedly.

A $\mathcal{D}'(\mathbb{R})$-valued function, f, is said to be *continuous* at t_o if $\langle f(t), \psi \rangle$ is continuous at t_o for all $\psi \epsilon \mathcal{D}(\mathbb{R})$.

PROPOSITION 2.1. *If f is continuous at t_o, then*

(a) *if $t_n \to t_o$, then $f(t_n) \to f(t_o)$ in $\mathcal{D}'(\mathbb{R})$.*

(b) *$\partial_x f$ is continuous at t_o.*

(c) *if $f(t)$ has support in $[0, ct]$ for each t and $v \epsilon \mathcal{D}'(\mathbb{R})$, then $f(t) * v$ is continuous at t_o.*

Proof. (a) simply reformulates the definition. Since $\langle \partial_x f(t), \psi \rangle = \langle f(t), -\partial_x \psi \rangle$, (b) is immediate. To prove (c), suppose $t_n \to t_o$. Since there is a ball $\mathbb{B}$ that

contains the supports of all the distributions $f(t_n)$ and since $f(t_n) \to f(t_o)$ in $\mathcal{D}'(\mathbb{R})$ by assumption, we conclude that $f(t_n) * v \to f(t_o) * v$ using the bicontinuity of convolution on $\mathcal{D}'(\mathbb{R}) \times \mathcal{D}'(\mathbb{R})$ [5, p. 105], [6, p. 71]. □

A $\mathcal{D}'(\mathbb{R})$-valued function, f, is said to be *differentiable* at t_o if $\langle \frac{f(t_n)-f(t_o)}{t_n-t_o}, \psi \rangle$ converges for all $\psi \epsilon \mathcal{D}(\mathbb{R})$ as $t_n \to t_o$.

PROPOSITION 2.2. *If f is differentiable at t_o, then*

(a) *there exists $f'(t_o)$ in $\mathcal{D}'(\mathbb{R})$ such that $\frac{f(t_n)-f(t_o)}{t_n-t_o} \to f'(t_o)$ in $\mathcal{D}'$.*

(b) *$\partial_x f$ is differentiable at t_o and $(\partial_x f)'(t_o) = \partial_x f'(t_o)$.*

(c) *if $f(t)$ has support in $[0, ct]$ for each t and $v \epsilon \mathcal{D}'(\mathbb{R})$, then $f(t) * v$ is differentiable at t_o and $(f(t) * v)' = f'(t) * v$.*

Proof. (a) A weakly convergent sequence in $\mathcal{D}'(\mathbb{R})$ has a limit in $\mathcal{D}'(\mathbb{R})$ [10, p. 15]. Since

$$\left\langle \partial_x \frac{f(t_n) - f(t_o)}{t_n - t_o}, \psi \right\rangle \;=\; -\left\langle \frac{f(t_n) - f(t_o)}{t_n - t_o}, \partial_x \psi \right\rangle,$$

(b) follows by taking limits. To prove (c), one writes the difference quotient and takes limits using the bicontinuity of convolution as above. □

A $\mathcal{D}'(\mathbb{R})$-valued function, f, is said to be *Riemann integrable* on $[a, b]$ if $\langle f(t), \psi \rangle$ is Riemann integrable on $[a, b]$ for all $\psi \epsilon \mathcal{D}(\mathbb{R})$.

PROPOSITION 2.3. *If f is Riemann integrable on $[a, b]$, then*

(a) *there exists an element of $\mathcal{D}'(\mathbb{R})$, denoted $\int_a^b f(t)\, dt$, such that*

$$\left\langle \int_a^b f(t)\, dt, \psi \right\rangle \;=\; \int_a^b \langle f(t), \psi \rangle \; dt \quad \textit{for all } \; \psi \, \epsilon \mathcal{D}(\mathbb{R}).$$

(b) $\partial_x \int_a^b f(t)\, dt \;=\; \int_a^b \partial_x f(t)\, dt$.

Proof. Let $\mathcal{P}_n$ be a sequence of partitions whose mesh size goes to zero as $n \to \infty$. Since $\langle \sum_{t_i \epsilon \mathcal{P}_n} f(t_i)(t_i - t_{i-1}), \psi \rangle$ converges for each ψ, $\sum_{t_i \epsilon \mathcal{P}_n} f(t_i)(t_i - t_{i-1})$ has a limit in $\mathcal{D}'(\mathbb{R})$. (b) follows, as above, by the adjoint relation for ∂_x. □

The following lemma summarizes the smoothness properties of $K(t)$.

LEMMA 2.4. *Let $K(t)$ be defined by* (3) *and* (4).

(a) *$K(t)$ is continuous on $[0, \infty)$.*

(b) *$K(t)$ is differentiable on $(0, \infty) \backslash \{\tau\}$ and*

$$K'(t) = -c\partial_x K(t) \;-\; AK(t) \;+\; BK(t - \tau) \quad \textit{for } \; t \epsilon (0, \infty) \backslash \{\tau\}. \tag{8}$$

Proof. Each $\delta_{ct-ck\tau}$ is a continuously differentiable $\mathcal{D}'(\mathbb{R})$-valued function of t and the coefficients $\gamma_k(t)$ are C^∞ functions of t since they are the solutions of ordinary differential equations with C^∞ source terms. Thus, $K(t)$ is continuously differentiable on each open interval of the form $(n\tau, (n+1)\tau)$ and we need only check the points $n\tau$ where the definition, (3), changes. Since $\gamma_n(n\tau) = 0$, for $n \geq 1$, $K(t)$ is continuous on $[0, \infty)$. Similarly, (4) shows that $\gamma_n'(n\tau) = 0$ for $n \geq 2$, which implies that $K(t)$ is differentiable at $n\tau$ for $n \geq 2$.

If $t \epsilon (0, \tau)$, then for all $\psi \epsilon \mathcal{D}(\mathbb{R})$, we know that $\langle K(t), \psi \rangle = \gamma_0(t)\psi(ct)$. Thus,

$$\begin{aligned} \frac{d}{dt}\langle K(t), \psi \rangle &= -A\gamma_0(t)\psi(ct) \;+\; c\gamma_0(t)\psi'(ct) \\ &= -A\langle K(t), \psi \rangle \;-\; c\langle \partial_x K(t), \psi \rangle. \end{aligned}$$

Since $K(t - \tau) = 0$, (8) holds.

Let $t\epsilon(n\tau,(n+1)\tau)$ for $n \geq 1$. Then,

$$\begin{aligned}\frac{d}{dt}\langle K(t),\psi\rangle &= \frac{d}{dt}\sum_{k=0}^{n}\gamma_k(t)\psi(ct-ck\tau)\\ &= -A\gamma_0(t)\psi(ct)+c\gamma_0(t)\psi'(ct)\\ &\quad+\sum_{k=1}^{n}(-A\gamma_k(t)+B\gamma_{k-1}(t-\tau))\psi(ct-ck\tau)\ +\ c\gamma_k(t)\psi'(ct-ck\tau)\\ &= -c\langle\partial_x K(t),\psi\rangle\ -\ A\langle K(t),\psi\rangle\ +\ B\langle K(t-\tau),\psi\rangle.\end{aligned}$$

The calculation for $t=(n+1)\tau$ is the same because $\gamma_{n+1}((n+1)\tau)=\gamma'_{n+1}((n+1)\tau)=0$. Thus, (8) holds on $(n\tau,(n+1)\tau]$ for all $n\geq 1$. □

LEMMA 2.5. *Let $f(t)$ be a continuous $\mathcal{D}'(\mathbb{R})$-valued function on $[-\tau,0]$. Then, the function $t\longmapsto\int_{-\tau}^{0}K(t-\theta-\tau)*f(\theta)\,d\theta$ is well defined and differentiable on $(0,\infty)$ and*

$$\text{for } t\geq\tau,\quad \frac{d}{dt}\int_{-\tau}^{0}K(t-\theta-\tau)*f(\theta)\,d\theta=\int_{-\tau}^{0}K'(t-\theta-\tau)*f(\theta)\,d\theta, \tag{9}$$

$$\begin{aligned}\text{for } t\epsilon(0,\tau),\quad \frac{d}{dt}\int_{-\tau}^{0}K(t-\theta-\tau)*f(\theta)\,d\theta &= f(t-\tau)\\ &\quad+\int_{-\tau}^{0}K'(t-\theta-\tau)*f(\theta)\,d\theta.\end{aligned} \tag{10}$$

Proof. For $n=-1,0,1,2,\ldots$, define the following regions of the $t-\theta$ plane:

$$R_n\ =\ \{(t,\theta)\mid n\tau\leq t-\theta-\tau<(n+1)\tau\quad\text{and}\quad -\tau\leq\theta\leq 0\}.$$

Since $K(t)$ is a C^∞ function of t in the open intervals $(n\tau,(n+1)\tau)$, $K(t-\theta-\tau)$ is C^∞ except on the boundaries of the regions R_n indicated by the dashed lines in Figure 1.

We suppose $\psi\epsilon\mathcal{D}$ and let T_a be the translation operator $T_a\psi(x)=\psi(x-a)$. For (t,θ) in $\bigcup_{-1}^{\infty}R_n$, we define

$$z(t,\theta)\ \equiv\ \langle K(t-\theta-\tau)*f(\theta),\psi\rangle$$

and note that $z\equiv 0$ on R_{-1} since $K(t)=0$ for $t<0$. On R_0, we have

$$\begin{aligned}z(t,\theta)&=\langle\gamma_0(t-\theta-\tau)\delta_{c(t-\theta-\tau)}*f(\theta),\psi\rangle\\ &=\gamma_0(t-\theta-\tau)\langle f(\theta),T_{-c(t-\theta-\tau)}\psi\rangle.\end{aligned}$$

Note that if $a_n\to a$, then $T_{a_n}\psi\to T_a\psi$ in $\mathcal{D}$, so by the continuity of f and the bicontinuity of $\langle\cdot,\cdot\rangle$ on $\mathcal{D}'\times\mathcal{D}$, we conclude that z is continuous on R_0. Since this is true for all $\psi\epsilon\mathcal{D}$, Proposition 2.3 assures us that for $0<t<\tau$ the integral $\int_{-\tau}^{0}K(t-\theta-\tau)*f(\theta)\,d\theta$ makes sense in $\mathcal{D}'$.

Let R_0^o denote the interior of R_0. If $(t,\theta)\epsilon R_0^o$, then $0<t-\theta-\tau<\tau$, so z is differentiable. Using the general fact [10, p. 105] that $\frac{d}{dy}\langle\mu(x),\psi(x+y)\rangle=\langle\mu(x),\psi'(x+y)\rangle$, we find

$$\begin{aligned}\frac{\partial}{\partial t}z(t,\theta)&=\gamma_0'(t-\theta-\tau)\langle f(\theta),T_{-c(t-\theta-\tau)}\psi\rangle\\ &\quad+c\gamma_0(t-\theta-\tau)\langle f(\theta),T_{-c(t-\theta-\tau)}\psi'\rangle.\end{aligned}$$

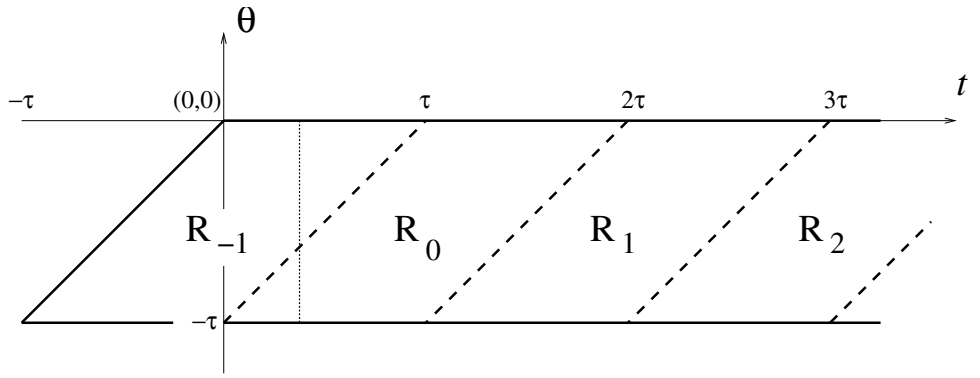

FIG. 1. *The regions R_n.*

This formula shows that $\frac{\partial}{\partial t}z(t,\theta)$ is continuous on R_0^o and can be extended continuously to the boundary of R_0^o. Thus, $\frac{\partial}{\partial t}z(t,\theta)$ is bounded in R_0^o and the usual proof (using the mean value theorem and the dominated convergence theorem) shows that

$$\frac{d}{dt}\int_{-\tau}^{0} z(t,\theta)\,d\theta = \frac{d}{dt}\int_{-\tau}^{t-\tau} z(t,\theta)\,d\theta = z(t,t-\tau)\ + \int_{-\tau}^{t-\tau}\frac{\partial}{\partial t}z(t,\theta)\,d\theta \qquad \text{for } 0<t<\tau.$$

Since this is true for all $\psi\epsilon\mathcal{D}$, Proposition 2.3 guarantees that (11) holds in $\mathcal{D}'$.

Formula (9) is proven similarly. The proof relies on the fact that z is continuous and $\frac{\partial}{\partial t}z(t,\theta)$ is bounded on $\bigcup_0^\infty R_n^o$. □

THEOREM 2.6. *Let $f:[-\tau,0]\to\mathcal{D}'$ be continuous and define*

$$u(t) = \begin{cases} K(t)*f(0)\ +\ B\int_{-\tau}^{0} K(t-\theta-\tau)*f(\theta)\,d\theta & \text{if } t>0,\\ f(t) & \text{if } -\tau\le t\le 0. \end{cases} \tag{11}$$

Then, $u(t)$ is the unique $\mathcal{D}'$-valued function that is continuous on $[-\tau,\infty)$, is differentiable on $(0,\infty)$, satisfies $u(t)=f(t)$ for $-\tau\le t\le 0$, and

$$u'(t)\ =\ -c\partial_x u(t)\ -\ Au(t)\ +\ Bu(t-\tau) \qquad \text{for } t>0. \tag{12}$$

Proof. Using the technical details from Propositions 2.1–2.3 and Lemma 2.5, the existence part of the proof is straightforward. For $t\ge\tau$,

$$\begin{aligned} u'(t) &= K'(t)*f(0)\ +\ B\int_{-\tau}^{0} K'(t-\theta-\tau)*f(\theta)\,d\theta\\ &= \{-c\partial_x K(t) - Ak(t) + BK(t-\tau)\}*f(0)\\ &\qquad + B\int_{-\tau}^{0}\{-c\partial_x K(t-\theta-\tau) - AK(t-\theta-\tau) + BK(t-\theta-2\tau)\}*f(\theta)\,d\theta\\ &= -c\partial_x u(t)\ -\ Au(t)\ +\ Bu(t-\tau), \end{aligned}$$

and for $0 < t < \tau$,

$$\begin{aligned} u'(t) &= K'(t) * f(0) \ + \ Bf(t-\tau) \ + \ B\int_{-\tau}^{t-\tau} K'(t-\theta-\tau) * f(\theta)\, d\theta \\ &= \{-c\partial_x K(t) - AK(t)\} * f(0) \ + \ Bu(t-\tau) \\ &\qquad + B\int_{-\tau}^{t-\tau} \{-c\partial_x K(t-\theta-\tau) - AK(t-\theta-\tau)\} * f(\theta)\, d\theta \\ &= -c\partial_x u(t) \ - \ Au(t) \ + \ Bu(t-\tau). \end{aligned}$$

To prove uniqueness, we need only show that $u(t) \equiv 0$ if $u(t)$ is a differentiable $\mathcal{D}'$-valued function on $(0,\infty)$ that satisfies (12) and $u(t) = 0$ for $-\tau \le t \le 0$. Let $\psi \epsilon \mathcal{D}$ and consider the function $\langle u(t), T_{ct}\psi\rangle$. By writing down the difference question and taking the limit (using the bicontinuity of $\langle\cdot,\cdot\rangle$ on $\mathcal{D}' \times \mathcal{D}$), one easily sees by using (12) that $\langle u(t), T_{ct}\psi\rangle$ is differentiable on $(0,\tau]$ and

$$\frac{d}{dt}\langle u(t), T_{ct}\psi\rangle = \langle u'(t) + c\partial_x u(t), T_{ct}\psi\rangle \tag{13}$$

$$= \langle -Au(t) + Bu(t-\tau), T_{ct}\psi\rangle \tag{14}$$

$$= -A\langle u(t), T_{ct}\psi\rangle. \tag{15}$$

Thus, for any $h > 0$, we have $\langle u(t), T_{ct}\psi\rangle = e^{-A(t-h)}\langle u(h), T_{ch}\psi\rangle$. Taking the limit as $h \to 0$ and using the continuity of u we conclude that $\langle u(t), T_{ct}\psi\rangle = 0$ for $0 \le t \le \tau$. Since this is true for all ψ, we have that $u(t) = 0$ in $\mathcal{D}'$ for $0 \le t \le \tau$. By iterating this argument, we find that $u(t) = 0$ for all $t > 0$. □

We remark that if the initial data, f, is a C^1 function on the strip $\mathbb{R} \times [-\tau, 0]$, the distribution solution is C^1 for $t > 0$ and satisfies the differential equation in the classical sense. Similarly, if f is a continuous function of t with values in $L^1(\mathbb{R})$ on $[-\tau, 0]$, then the solution $u(t)$ will be in $L^1(\mathbb{R})$ for all $t > 0$. These theorems can easily be proven by rewriting the differential equation as an integral equation and using the contraction mapping principle. Finally, consider the special case where $f(\theta) = 0$ for $\theta < 0$ and $f(0)$ is a nonnegative L^1 function. Then $u(t,\cdot)$ is the convolution of a nonnegative function with a finite linear combination of delta functions with positive coefficients, and so $u(t,\cdot)$ is nonnegative. Thus, integration in x shows that

$$||u(t,\cdot)||_1 \ = \ Y(t)||f(0)||_1,$$

where $Y(t)$ is the fundamental solution of (6).

3. The asymptotic behavior of K. The fundamental solution $K(t)$, which we denote now by K_t, is for each t a finite sum of point masses with weights $\gamma_k(t)$. K_t may be normalized to produce a proper probability measure, $\Pi_t = K_t/K_t(\mathbb{R})$, where $K_t(\mathbb{R}) = \sum_{k=0}^{n} \gamma_k(t)$ for $n\tau \le t < (n+1)\tau$. Note that $K_t(\mathbb{R}) = Y(t)$. The first form of our asymptotic result is stated in the language of convergence in distribution.

THEOREM 3.1. *Let $h(\lambda)$ be the characteristic polynomial of* (6) *and λ_0 be the root with the largest real part. Define $p = 1/h'(\lambda_0)$, $q = 1 - p$, and $\alpha = c^2\tau p^2 q$. Then,*

$$\lim_{t\to\infty} \Pi_t\Big[cpt + \sqrt{\alpha t}\ a,\ cpt + \sqrt{\alpha t}\ b\Big] = \int_a^b \frac{e^{-x^2/2}}{\sqrt{2\pi}} dx$$

for any fixed $-\infty \le a < b \le \infty$.

From a dynamical perspective, Theorem 3.1 says that, normalized to have unit mass, the fundamental solution of the equation with delay τ and speed c resembles $G_t(x) = e^{-(x-cpt)^2/2\alpha t}/\sqrt{2\pi\alpha t}$ in the sense of measures. Theorem 3.1 follows easily from a stronger result of local limit type, Theorem 3.2 below.

Consider the special sequence of times $t_n = n\tau$, $n \to \infty$. For such t_n,

$$K_{t_n} \equiv \sum_{k\in\mathbb{Z}} b_n(k)\delta_{kc\tau},$$

where the $b_n(k)$ have the following form obtained by explicitly solving the equations (4):

$$b_n(k) = \begin{cases} \frac{k^{n-k}}{(n-k)!}\xi^{-k}(B\tau)^n & \text{for } 1 \le k \le n, \\ 0 & \text{otherwise,} \end{cases}$$

where $\xi = B\tau e^{A\tau}$. We let S_n be the total mass of K_{t_n}, i.e.,

$$S_n \;=\; \sum_{k=1}^{n} b_n(k) \;=\; Y(t_n). \tag{16}$$

In these terms, Π_{t_n} can be written

$$\Pi_{t_n} = \sum_{k\in Z} \frac{b_n(k)}{S_n}\delta_{kc\tau}. \tag{17}$$

The following local theorem is the main result of this section. By *local* we mean that we have uniform control of the individual masses $b_n(\cdot)$.

THEOREM 3.2. *Let $\pi_n(\mathbb{R})$ be the lattice $\{\frac{k}{\sqrt{n}}\}$ for k ranging over the integers, and let $[pn]$ denote the integer part of pn. Then*

$$\sup_{x\in\pi_n(\mathbb{R})} \left| \sqrt{n}\frac{b_n([pn]+x\sqrt{n})}{S_n} - \frac{1}{\sqrt{2\pi p^2 q}} e^{-\frac{x^2}{2p^2q}} \right| = O\left(\sqrt{\frac{\log n}{n}}\right) \tag{18}$$

as $n \to \infty$.

As already mentioned, the proof of Theorem 3.2 is similar in spirit to the classical Demoivre–Laplace calculation leading to the (local) central limit theorem for the binomial distribution (see, for example, [4, Chap. VII, sec. 3]). Note that the error on the right-hand side of (18) compares favorably with known estimates concerning Gaussian convergence of general lattice distributions (see [1, Chap. 5]).

We break the proof of Theorem 3.2 into several steps. First, we characterize p in a different way. Then, in Lemma 3.4 we describe the shape of the distribution $b_n(\cdot)$ and show that the mass peaks at a sequence $\{m_n\}$ that is within a fixed constant of $\{np\}$, the asymptotic mean. Lemma 3.5 contains the main asymptotic estimate; we renormalize by the mass at the maximum and define

$$f_n(x) \equiv \frac{b_n(m_n + x\sqrt{n})}{b_n(m_n)}. \tag{19}$$

The heart of the proof is a set of estimates on the sequence $\{f_n(x)\}$. Finally, using the asymptotic estimate, we prove Theorem 3.2 and sketch the proof of Theorem 3.1.

LEMMA 3.3. *For*

$$\psi(x) \equiv \frac{1-x}{x} e^{\frac{1-x}{x}} \qquad \text{and} \qquad \xi \equiv B\tau e^{A\tau},$$

p is the unique solution of $\xi = \psi(x)$ lying in $(0,1)$.

Proof. Previously, p was defined as $1/h'(\lambda_0)$, where $h(\lambda) = \lambda + A - Be^{-\lambda\tau}$ and λ_0 is the unique positive root of h. It follows that $(1-p)/p = h'(\lambda_0) - 1$ in which the right-hand side may be expressed as either $\tau(\lambda_0 + A)$ or $B\tau e^{-\lambda_0\tau}$. Thus,

$$\frac{1-p}{p} = B\tau e^{-\lambda_0\tau} = B\tau e^{A\tau} e^{-\tau(\lambda_0+A)} = \xi e^{-(1-p)/p},$$

as desired. For the uniqueness, observe that $\psi(x) < 0$ for $x < 0$ and $x > 1$ and is strictly decreasing on $[0,1]$ from $+\infty$ at $x = 0$ to 0 at $x = 1$. ∎

LEMMA 3.4. *For each n, the sequence $\{b_n(k)\}$ attains its maximum at a single index, m_n, and is increasing (decreasing) to the left (right) of that point, respectively. Furthermore, there exists a constant D such that $|m_n - np| \le D$.*

Proof. Define the following approximates to ψ:

$$\psi_n(x) \equiv \left(\frac{1-x}{x+1/n}\right)\left(1+\frac{1}{nx}\right)^{n(1-x)}.$$

It may be verified that each ψ_n lies under ψ and that $\lim_{n\to\infty} \psi_n = \psi$ holds pointwise. Moreover, the ψ_n have the same shape as ψ in that they decrease strictly from $+\infty$ to 0 as x ranges from 0 to 1. As such, there is a unique $p_n \in (0,1)$ satisfying $\xi = \psi_n(p_n)$.

For $k = 1, 2, \ldots, n-1$,

$$\frac{b_n(k+1)}{b_n(k)} = \frac{1}{\xi}\left(1+\frac{1}{k}\right)^{n-k}\left(\frac{n-k}{k+1}\right) = \frac{1}{\xi}\psi_n\left(\frac{k}{n}\right),$$

and so, $b_n(k)$ is increasing on $k \le np_n$ and then decreasing on $k \ge np_n$. If we let $m_n = [p_n n]$, the smallest integer $\ge p_n n$, it is left to prove that $p - p_n = O(1/n)$.

First note that the properties of ψ_n and ψ imply that $p_n < p$ and $\lim_{n\to\infty} p_n = p$. The first follows from $\psi(p) = \xi = \psi_n(p_n) < \psi(p_n)$ along with the strict decrease of ψ; the second follows from the first and the convergence $\psi_n \to \psi$. Now, set $q_n = 1 - p_n$. Since $\xi = \psi_n(p_n)$,

$$-\log\xi + nq_n \log\left(1+\frac{1}{np_n}\right) + \log\left(\frac{q_n}{p_n+1/n}\right) = 0,$$

and using the fact that $p_n \ge p/2$ for all large enough n, an expansion yields

$$-\log\xi + \frac{q_n}{p_n} + \log\left(\frac{q_n}{p_n}\right) = O\left(\frac{1}{n}\right). \tag{20}$$

Adding $\log\xi = \log\psi(p) = \log(q/p) + (q/p)$ to (20) gives

$$\frac{p-p_n}{pp_n} + \log\left(\frac{q_n}{q}\frac{p}{p_n}\right) = O\left(\frac{1}{n}\right).$$

The fact that $p > p_n$ (and so $q < q_n$) implies that each term on the left-hand side is strictly positive. Finally, $pp_n = O(1)$, showing that $p - p_n = O(\frac{1}{n})$, and the proof is complete. ∎

LEMMA 3.5. *There exists a constant C such that*

$$\sup_{x\in\pi_n(\mathbb{R})}\left|f_n(x)-e^{-\frac{x^2}{2p^2q}}\right|\le C\frac{1}{\sqrt{n}}. \tag{21}$$

Proof. From the definition of $b_n(k)$,

$$b_n(m_n+\sqrt{n}x)=\frac{(m_n+\sqrt{n}x)^{n-m_n-\sqrt{n}x}}{(n-m_n-\sqrt{n}x)!}\xi^{-(m_n+\sqrt{n}x)}(B\tau)^n$$

for $x\in\pi_n([\frac{1-m_n}{\sqrt{n}},\frac{n-m_n}{\sqrt{n}}])$. In this range, after dividing by $b_n(m_n)$ and taking the case $x>0$ we have

(22)

$$\begin{aligned}
f_n(x)&=\left(1+\frac{\sqrt{n}x}{m_n}\right)^{n-m_n}\frac{(n-m_n)!}{(n-m_n-\sqrt{n}x)!}\frac{1}{[\xi(m_n+\sqrt{n}x)]^{\sqrt{n}x}}\\
&=\left[\left(1+\frac{\sqrt{n}x}{m_n}\right)^{n-m_n}e^{-\sqrt{n}x\frac{q}{p}}\right]\left[\prod_{0\le k\le\sqrt{n}x-1}\frac{n-m_n-k}{nq}\right]\left[\frac{np}{(m_n+\sqrt{n}x)}\right]^{\sqrt{n}x}\\
&\equiv u_n(x)\times v_n(x)\times w_n(x).
\end{aligned}$$

The second line follows after multiplying through by $e^{-\sqrt{n}x\frac{q}{p}}\ (\xi\frac{p}{q})^{\sqrt{n}x}=1$ and some algebra. If $x<0$ is desired, $v_n(x)$ should be replaced by $\prod_{1\le k\le\sqrt{n}|x|}(\frac{nq}{n-m_n+k})$. However, the asymptotic considerations are similar for either $x>0$ or $x<0$; we assume $x>0$ for the rest of the proof. We note that $f_n(x)=0$ for x outside the interval $[\frac{1-m_n}{\sqrt{n}},\frac{n-m_n}{\sqrt{n}}]$, so we define u_n,v_n, and w_n to be zero there too.

We first estimate the quantities

$$|u_n(x)-e^{-\frac{qx^2}{2p^2}}|,\quad |v_n(x)-e^{-\frac{x^2}{2q}}|,\quad \text{and } |w_n(x)-e^{-\frac{x^2}{p}}|$$

on the interval $0\le x\le M\sqrt{\log n}$ for suitable M. This interval is convenient for the tail estimates below. Using the elementary inequalities $a-a^2\le\log(1+a)\le a+a^2$ for $|a|\le 1/2$, on the range $0\le x\le\frac{p}{4}n^{\frac{1}{2}}$ we have that

$$\begin{aligned}
\log w_n(x)&\le-\sqrt{n}x\log\left(1+\frac{x}{\sqrt{n}p}-\frac{D}{n}\right)\\
&\le-\sqrt{n}x\left(\frac{x}{\sqrt{n}p}-\frac{D}{n}\right)+2\sqrt{n}x\left(\left(\frac{x}{\sqrt{n}p}\right)^2+\left(\frac{D}{n}\right)^2\right)\\
&\le-\frac{x^2}{p}+2\left(\frac{Dx}{\sqrt{n}}+\frac{x^3}{\sqrt{n}p^2}\right)
\end{aligned}$$

and,

$$\log w_n(x)\ge-\frac{x^2}{p}-2\left(\frac{Dx}{\sqrt{n}}+\frac{x^3}{\sqrt{n}p^2}\right),$$

for all large n. It follows that there exist constants c_1,c_2,c_3, so that

$$|w_n(x)-e^{-x^2/p}|\le|e^{-x^2/p}(e^{\frac{c_1}{\sqrt{n}}(1+x^3)}-1)|\le\frac{c_2}{\sqrt{n}}(1+|x|^3)e^{-x^2/p}\le\frac{c_3}{\sqrt{n}} \tag{23}$$

for all x in $[0, n^{\frac{1}{6}}]$. Of course, for n large $[0, M\sqrt{\log n}]$ is contained in both $[0, \frac{p}{4}n^{\frac{1}{2}}]$ and $[0, n^{\frac{1}{6}}]$.

For $v_n(x)$,

$$\begin{aligned}(24)\quad \log v_n(x) &\leq \sum_{0\leq k\leq \sqrt{n}x-1} \log\left(1-\frac{k-D}{nq}\right) \\ &\leq \sum_{0\leq k\leq \sqrt{n}x-1} \left(\frac{-k}{nq}+\frac{2k^2}{n^2q^2}\right)+2\frac{Dx}{\sqrt{n}} \leq -\frac{x^2}{2q}+\frac{2}{\sqrt{n}}\left(1+Dx+\frac{x^3}{q^2}\right),\end{aligned}$$

with a lower bound of the form

$$(25)\qquad \log v_n(x) \geq -\frac{x^2}{2q}-\frac{2}{\sqrt{n}}\left(1+Dx+\frac{x^3}{q^2}\right).$$

For $u_n(x)$, one expands to third order to find

$$(26)\quad -\frac{qx^2}{2p^2}-\frac{q}{\sqrt{n}p}(2Dx+x^2+8x^3) \leq \log u_n(x) \leq -\frac{qx^2}{2p^2}+\frac{q}{\sqrt{n}p}(2Dx+x^2+8x^3).$$

Given the inequalities (24), (25), and (26), an argument similar to that for $w_n(x)$ shows that both $|v_n(x) - e^{-x^2/2q}|$ and $|u_n(x) - e^{-qx^2/2p^2}|$ are $O(1/\sqrt{n})$ for $x \in [0, M\sqrt{\log n}]$. It follows that the difference between $f_n(x)$ and $e^{-x^2/2p^2q} = e^{-x^2/p}e^{-x^2/2q}e^{-qx^2/2p^2}$ is also of order $1/\sqrt{n}$ for those values of x.

Finally, we prove a global estimate

$$(27)\qquad f_n(x) \leq c_4 e^{-c_5 x^2} \equiv f^*(x) \quad \text{for } x\epsilon\mathbb{R},$$

which will give us control over the tail region $x \geq M\sqrt{\log n}$. As above, we give the proof only for $x > 0$. First,

$$\log u_n(x) = (n-m_n)\log\left(1+\frac{\sqrt{n}x}{m_n}\right)-\frac{\sqrt{n}qx}{p} \leq \left(\frac{\sqrt{n}x}{m_n}\right)\left(\frac{np-m_n}{p}\right) \leq \frac{2D}{p^2},$$

and the product defining $v_n(x)$ has only a finite number of terms greater than one independent of n. Thus, $|u_n v_n|$ is bounded by a fixed constant for all n and x. To handle w_n, first notice that if n is large enough and $x \geq 2q\sqrt{n}$, then

$$\frac{n-m_n}{\sqrt{n}} \;\leq\; q\sqrt{n}+\frac{D}{\sqrt{n}} \;\leq\; x,$$

so $w_n(x) = 0$ by definition. Also, for n large enough and any $x > 1$, we know that $\frac{x}{\sqrt{n}p}-\frac{D}{n} > 0$, so there exists a constant, c_6, such that

$$\log\left(1+\frac{x}{\sqrt{n}p}-\frac{D}{n}\right) \;\geq\; c_6\left(\frac{x}{\sqrt{n}p}-\frac{D}{n}\right) \quad \text{for } 1 \leq x \leq 2q\sqrt{n}.$$

It follows that

$$(28)\qquad w_n(x) \leq e^{-c_6 x^2/p}e^{2c_6 D^2 q} \qquad \text{for } x \geq 1 \text{ and large } n.$$

By adjusting the multiplicative constant, this Gaussian bound extends to all of $x > 0$. The bound (27) follows from boundedness of $u_n v_n$ and (28).

To obtain the tail estimate, we choose M so that $M^2 \min\{c_5, \frac{1}{2p^2q}\} \geq \frac{1}{2}$, which implies that both $f_n(x)$ and $e^{-x^2/2p^2q}$ will be of order $1/\sqrt{n}$ on $x > M\sqrt{\log n}$. This concludes the proof. ∎

Proof of Theorem 3.2. We denote $f(x) = e^{-x^2/2p^2q}$ and define

$$\tilde{f}_n(x) \equiv \frac{b_n([np] + \sqrt{n}x)}{b_n(m_n)}.$$

Since $\tilde{f}_n(x) = f_n(x - \frac{1}{\sqrt{n}}(m_n - [np]))$, Lemma 3.5 and the triangle inequality imply

$$\left|\tilde{f}_n(x) - f(x)\right| \leq C\frac{1}{\sqrt{n}} + \sup_{|\delta| \leq D/\sqrt{n}} \left|f(x) - f(x+\delta)\right| \leq C_1\frac{1}{\sqrt{n}}. \tag{29}$$

Then,

$$\begin{aligned}\sqrt{2\pi p^2 q} - \frac{S_n}{\sqrt{n}b_n(m_n)} &= \int_{-\infty}^{\infty} f(x)dx - \sum_{k=-\infty}^{\infty} \frac{1}{\sqrt{n}} f_n\left(\frac{k}{\sqrt{n}}\right) \\ &= \left[\int_{-\infty}^{\infty} f(x)dx - \sum_{k=-\infty}^{\infty} \frac{1}{\sqrt{n}} f\left(\frac{k}{\sqrt{n}}\right)\right] + \frac{1}{\sqrt{n}}\left[\sum_{k=-\infty}^{\infty}\left(f\left(\frac{k}{\sqrt{n}}\right) - f_n\left(\frac{k}{\sqrt{n}}\right)\right)\right].\end{aligned}$$

Here the first term on the right-hand side is controlled by the error in the Riemann sum, which is $(1/\sqrt{n})\int_{-\infty}^{\infty}|f'|$. For the second term, recall that we know that $|f_n(\cdot) - f(\cdot)| \leq C/\sqrt{n}$ and the bound (27) both hold. Therefore,

$$\begin{aligned}\sum_{k=-\infty}^{\infty}\left(f\left(\frac{k}{\sqrt{n}}\right) - f_n\left(\frac{k}{\sqrt{n}}\right)\right) &\leq \sum_{|k| \leq \sqrt{\ell_n n}}\left[\frac{C}{\sqrt{n}}\right] + \sum_{|k| \geq \sqrt{\ell_n n}}(c_4 e^{-c_5 k^2/n} + e^{-k^2/2np^2q}) \\ &\leq 2C\sqrt{\ell_n} + c_6\sqrt{\frac{n}{\ell_n}}e^{-c_5\ell_n},\end{aligned}$$

and taking as ℓ_n as an appropriate multiple of $\log n$ shows that

$$\left|\frac{S_n}{\sqrt{n}b_n(m_n)} - \sqrt{2\pi p^2 q}\right| \leq C_2\sqrt{\frac{\log n}{n}}. \tag{30}$$

Putting together (29) and (30) completes the proof. ∎

Finally, we conclude this section with the following proof.

Proof of Theorem 3.1. First consider $t \to \infty$ along the special sequence $t_n = n\tau$. For any $a < b$, define

$$\begin{aligned}I_n(a,b) &= \Big[cp(n\tau) + \sqrt{\alpha(n\tau)}\ a, cp(n\tau) + \sqrt{\alpha(n\tau)}\ b\Big] \\ &= c\tau\Big[np + \sqrt{p^2qn}\ a, np + \sqrt{p^2qn}\ b\Big].\end{aligned}$$

Noting that the individual masses of Π_{t_n} are positioned at a distance of $c\tau$ from each

other, we see that

$$\begin{aligned}\lim_{n\to\infty} \Pi_{t_n}\Big[I_n(a,b)\Big] &= \lim_{n\to\infty} \sum_{\sqrt{p^2qna}\le k-np\le\sqrt{p^2qnb}} \left(\frac{b_n(k)}{S_n}\right) \\ &= \lim_{n\to\infty} \frac{1}{\sqrt{n}} \sum_{x\in\pi_n[\sqrt{p^2qa},\sqrt{p^2qb}]} \left(\sqrt{n}\frac{b_n([np]+\sqrt{n}x)}{S_n}\right) \\ &= \int_{-\sqrt{p^2qa}}^{\sqrt{p^2qb}} e^{-x^2/2p^2q}\frac{dx}{\sqrt{2\pi p^2q}}\end{aligned}$$

by the dominated convergence theorem. The pointwise convergence of the integrand is the statement of Theorem 3.2, and the domination is (27). This proves the result for the special sequence $t_n = n\tau$. The general statement as $t \to \infty$ follows by interpolation and the triangle inequality. □

4. Comparison to the transport heat equation. In Theorem 3.1 we showed that normalized $\Pi_t = K_t/Y(t)$ looks more and more like

$$G_t(dx) = \frac{e^{-(x-cpt)^2/2\alpha t}}{\sqrt{2\pi\alpha t}}\,dx$$

in the sense of probability measures as $t \to \infty$. This suggests that solutions of the hyperbolic equation with time delay (1) may look like solutions of the transport heat equation (7) for t large. We will prove two theorems that express this idea. For the first, Theorem 4.2, we shall consider the special case in which the initial data, f, is zero except at $t = 0$ and $f(0)\epsilon L^1(\mathbb{R})$. General initial conditions are considered in Theorem 4.3.

For $f\epsilon L^1(\mathbb{R})$, define $U(t)$ and $V(t)$ by

$$U(t)f \;\equiv\; K_t * f \quad \text{and} \quad V(t)f \;\equiv\; G_t * f.$$

$U(t)$ is a strongly continuous family of bounded operators and $V(t)$ is a strongly continuous semigroup on $L^1(\mathbb{R})$ for $t \ge 0$; $U(t)f$ satisfies (1) and $V(t)f$ satisfies (7). Furthermore, $||U(t)f||_1 \le Y(t)||f||_1$ and $||V(t)f||_1 \le ||f||_1$, with equality in both cases if f is nonnegative. We shall see that $U(t)/Y(t)$ and $V(t)$ are "comparable" for large t on the space scale $c\tau$.

Since $K_t/Y(t)$ is, for each t, a finite sum of point measures spaced at intervals of length $c\tau$, and G_t is smooth, we need a method of comparison that integrates over intervals of length $c\tau$. Let $\mathbb{M}(\mathbb{R})$ denote the finite Borel measures on $\mathbb{R}$, and for $\mu\epsilon\mathbb{M}(\mathbb{R})$ define

$$||\mu||_{1,c\tau} \;\equiv\; \sup_{-c\tau\le a\le 0} \sum_{k\epsilon\mathbb{Z}} |\mu([a+kc\tau, a+(k+1)c\tau))|.$$

Of course, any $f\epsilon L^1(\mathbb{R})$ corresponds to a finite Borel measure, and in that case

$$||f||_{1,c\tau} \;\equiv\; \sup_{-c\tau\le a\le 0} \sum_{k\epsilon\mathbb{Z}} \left| \int_{a+kc\tau}^{a+(k+1)c\tau} f(x)\,dx \right|.$$

We begin by collecting the properties of $||\cdot||_{1,c\tau}$.

PROPOSITION 4.1.
(a) $||\cdot||_{1,c\tau}$. *is a seminorm on* $\mathbb{M}(\mathbb{R})$ *that satisfies* $||\mu||_{1,c\tau} \le ||\mu||_{\mathbb{M}(\mathbb{R})}$.
(b) *If* $\mu\epsilon\mathbb{M}(\mathbb{R})$ *and* $f\epsilon L^1(\mathbb{R})$, *then* $||\mu * f||_{1,c\tau} \le ||\mu||_{1,c\tau}\,||f||_1$.
(c) *If* $g(t)$ *is a continuous function on* $[a,b]$ *with values in* $L^1(\mathbb{R})$, *then*

$$\left\| \int_a^b g(t)\,dt \right\|_{1,c\tau} \le \int_a^b ||g(t)||_{1,c\tau}\,dt.$$

Proof. The straightforward proof of (a) is omitted. Since g is a continuous function, (c) is proven by using the sublinearity of the seminorm in the standard proof for Riemann integrals. To prove (b),

$$\begin{aligned}
||\mu * f||_{1,c\tau} &= \sup_{-c\tau\le a\le 0} \sum_{k\epsilon\mathbb{Z}} |(\mu * f)([a+kc\tau, a+(k+1)c\tau))| \\
&= \sup_{-c\tau\le a\le 0} \sum_{k\epsilon\mathbb{Z}} \left| \int_{\mathbb{R}} \mu([a+kc\tau, a+(k+1)c\tau) - y) f(y)\,dy \right| \\
&\le \int_{\mathbb{R}} \left\{ \sup_{-c\tau\le a\le 0} \sum_{k\epsilon\mathbb{Z}} |\mu([a+kc\tau, a+(k+1)c\tau) - y)| \right\} |f(y)|\,dy \\
&= ||\mu||_{1,c\tau}\,||f||_1,
\end{aligned}$$

where we have used $(\mu * f)(A) = \int_{\mathbb{R}} \mu(A-y)f(y)dy$ to obtain the second line (see [2, p. 266]). □

THEOREM 4.2. *Suppose* $f\epsilon L^1(\mathbb{R})$. *Then, there exists a constant* C *such that for* t *large,*

$$||U(t)f/Y(t) \;-\; V(t)f||_{1,c\tau} \;\le\; C\frac{\log t}{\sqrt{t}}\,||f||_1. \tag{31}$$

Proof. According to Proposition 4.1(b),

$$\begin{aligned}
||U(t)f/Y(t) \;-\; V(t)f||_{1,c\tau} &= ||(K_t/Y(t)) * f \;-\; G_t * f||_{1,c\tau} \\
&\le ||(K_t/Y(t)) \;-\; G_t||_{1,c\tau}\,||f||_1,
\end{aligned}$$

so we need only prove

$$||K_t/Y(t) \;-\; G_t||_{1,c\tau} \le C\frac{\log t}{\sqrt{t}} \tag{32}$$

for large t. As in section 3, we give the details for the special sequence $t_n = n\tau$; the proof for general t follows from the triangle inequality. We set $g(x) = e^{-x^2/2p^2q}/\sqrt{2\pi p^2 q}$ and

$$g_n(x) = \sqrt{n}\frac{b_n([np] + \sqrt{n}x)}{S_n}.$$

First, we rewrite the left-hand side of (32) so that we can use the machinery and

results of section 3:

$$
\begin{aligned}
&||K_{t_n}/Y(t_n) - G_{t_n}||_{1,c\tau} \\
&\quad = \sup_{a\in(-c\tau,0]} \sum_{k\in\mathbb{Z}} \left| \frac{b_n(k)}{S_n} - \frac{1}{\sqrt{2\pi\alpha n\tau}} \int_{a+kc\tau}^{a+(k+1)c\tau} e^{-(x-cpn\tau)^2/2\alpha n\tau}\, dx \right| \\
&\quad = \sup_{a'\in(-1,0]} \sum_{k\in\mathbb{Z}} \left| \frac{b_n(k)}{S_n} - \frac{1}{\sqrt{n}} \int_{a'+k}^{a'+(k+1)} g\Big(\frac{z-np}{\sqrt{n}}\Big) dz \right| \\
&\quad = \sup_{a''\in(-\frac{1}{\sqrt{n}},0]} \sum_{k\in\mathbb{Z}} \left| \frac{1}{\sqrt{n}} g_n\left(\frac{k}{\sqrt{n}}\right) - \int_{a''+\frac{k}{\sqrt{n}}}^{a''+\frac{k+1}{\sqrt{n}}} g\left(y + \frac{[np]-np}{\sqrt{n}}\right) dy \right| \\
&\quad \le \frac{1}{\sqrt{n}} \sum_{k\in Z} \left| g_n\left(\frac{k}{\sqrt{n}}\right) - g\left(\frac{k}{\sqrt{n}}\right) \right| \\
&\qquad + \sum_{k\in\mathbb{Z}} \int_{\frac{k}{\sqrt{n}}}^{\frac{k+1}{\sqrt{n}}} \left(\sup_{a''\in(-\frac{1}{\sqrt{n}},0]} \left| g\left(\frac{k}{\sqrt{n}}\right) - g\left(y + a'' + \frac{[np]-np}{\sqrt{n}}\right) \right| \right) dy \\
&\quad \equiv \mathcal{A}_n + \mathcal{B}_n.
\end{aligned}
$$

To estimate $\mathcal{A}_n$, recall from Theorem 3.2 that $|g_n(\frac{k}{\sqrt{n}}) - g(\frac{k}{\sqrt{n}})| \le C_1(\log\frac{n}{n})^{\frac{1}{2}}$ independently of k. Also the bound (27) for f_n translates to $g_n(x) \le c_7 e^{-c_5 x^2}$ since $\sqrt{n}b_n(m_n)/S_n$ approaches a limit (see the proof of Theorem 3.2). It follows that

$$
\mathcal{A}_n \le \frac{1}{\sqrt{n}} \sum_{|k|\le M\sqrt{n\log n}} C_1\sqrt{\frac{\log n}{n}} + \frac{1}{\sqrt{n}} \sum_{|k|\ge M\sqrt{n\log n}} \left(c_6 e^{-c_5 k^2/n} + g\left(\frac{k}{\sqrt{n}}\right)\right) = O\left(\frac{\log n}{\sqrt{n}}\right)
$$

by the choice of M. The estimate for $\mathcal{B}_n$ follows the same strategy. The function g is globally Lipschitz, and so

$$
\sup_{|c|\le\frac{2}{\sqrt{n}}} \left| g\left(\frac{k}{\sqrt{n}}\right) - g\left(\frac{k}{\sqrt{n}} + c\right)\right| \le C_2 \frac{1}{\sqrt{n}},
$$

for all k. Using this for $|k| \le M\sqrt{n\log n}$ and the decay of g for larger k, we find

$$
\mathcal{B}_n \le \sum_{|k|\le M\sqrt{n\log n}} \frac{1}{\sqrt{n}} \cdot \frac{C_2}{\sqrt{n}} + \sum_{|k|\ge M\sqrt{n\log n}} \frac{1}{\sqrt{n}} \cdot 2g\left(\frac{k-2}{\sqrt{n}}\right) = O\left(\sqrt{\frac{\log n}{n}}\right).
$$

This proves (32) and thus completes the proof of (31). □

We now consider the case in which f, the initial data for (1), is a continuous $L^1(\mathbb{R})$-valued function of t for $-\tau \le t \le 0$. Define

$$
\begin{aligned}
u(t) &= U(t)f(0) \;+\; B\int_{-\tau}^{0} U(t-\theta-\tau)f(\theta)\,d\theta \\
v(t) &= Y(t)V(t)f(0) \;+\; B\int_{-\tau}^{0} Y(t-\theta-\tau)V(t-\theta-\tau)f(\theta)\,d\theta \\
y(t) &= Y(t)||f(0)||_1 \;+\; B\int_{-\tau}^{0} Y(t-\theta-\tau)||f(\theta)||_1\,d\theta;
\end{aligned}
$$

$u(t)$ is, of course, the solution of (1) with initial condition (2). Notice that $v(t)$ is not a solution of (7) but is a weighted average of solutions to (7); it will be clear from the proof why this weighted average is natural. $y(t)$ is the solution of (6) with initial data equal to $||f(t)||_1$ for $-\tau \le t \le 0$.

THEOREM 4.3. *Suppose that f is a continuous $L^1(\mathbb{R})$-valued function of t for $-\tau \le t \le 0$, and let $u(t)$, $v(t)$, and $y(t)$ be defined as above. Then, there is a constant C_1 so that for t large enough,*

$$||u(t) - v(t)||_{1,c\tau} \le C_1 \frac{\log t}{\sqrt{t}} y(t). \tag{33}$$

Proof. We subtract $v(t)$ from $u(t)$ and apply the seminorm $||\cdot||_{1,c\tau}$. Using Proposition 4.1(c) and estimate (32), we find

$$\begin{aligned} ||u(t) - v(t)||_{1,c\tau} &\le Y(t) C \frac{\log t}{\sqrt{t}} ||f(0)||_1 \\ &\quad + B \int_{-\tau}^{0} Y(t-\theta-\tau) C \frac{\log(t-\theta-\tau)}{\sqrt{t-\theta-\tau}} ||f(\theta)||_1 \, d\theta \\ &\le C_1 \frac{\log t}{\sqrt{t}} \left\{ Y(t)||f(0)||_1 + B \int_{-\tau}^{0} Y(t-\theta-\tau)||f(\theta)||_1 \, d\theta \right\} \end{aligned}$$

for large t, which proves (33). □

Note that if $f(t)$ is a nonnegative function for all $t\epsilon[-\tau, 0]$, then $y(t) = ||u(t)||_1 = ||v(t)||_1$, so (33) estimates the relative error.

VARIATIONAL PROPERTIES OF UNBOUNDED ORDER PARAMETERS*

BO LI†

Abstract. Order parameters in physical and biological systems can sometimes become unbounded as the size of an underlying system increases. It is proposed that such a quantity be modeled as a minimizer of the energy functional

$$I_\varepsilon(u) = \fint \left[\frac{\varepsilon^2}{2} |\nabla u|^2 - \frac{1}{2} \log(1 + |u|^2) \right] dx,$$

where u is constrained by a side condition, and $\varepsilon > 0$ is a parameter that is inversely proportional to the linear size of the system. It is shown that a minimizer of I_ε exists; the minimum value of I_ε scales as $\log \varepsilon$; and both the L^2 and H^1 norms of any minimizer of I_ε are of the order $O(1/\varepsilon)$, indicating the unboundedness of the order parameter. It is also shown that the renormalized energy functionals

$$J_\varepsilon(v) = I_\varepsilon \left(\frac{v}{\varepsilon} \right) - \log \varepsilon$$

Γ-converge to the functional

$$J(v) = \fint \left(\frac{1}{2} |\nabla v|^2 - \log |v| \right) dx.$$

Minimizers of this Γ-limit for scalar order parameters with the Dirichlet boundary condition are well characterized.

Key words. order parameters, variational models, energy asymptotics, renormalized energy, Γ-convergence

1. Introduction.

Order parameters in physical and biological systems, such as population, concentration, volume fractions, magnetization vectors, directors of liquid crystals, the slope of surface height profile of thin films, etc., are mathematically scalar or vector-valued functions, or gradients of functions. An order parameter can sometimes grow unbounded as the size of an underlying system increases. An example of such an unbounded order parameter is the slope of surface of an epitaxially growing thin film in some experimental situations [5, 12, 20].

We propose to model unbounded order parameters as possible minimizers or low energy configurations of the effective free energy functional

$$\hat{I}(\hat{u}) = \fint_{\widehat{\Omega}} \left[\frac{\alpha}{2} |\nabla \hat{u}|^2 - \frac{\beta}{2} \log \left(1 + |\hat{u}|^2 \right) \right] d\hat{x}, \tag{1.1}$$

where $\widehat{\Omega} \subset \mathbb{R}^n$ for some integer $n \geq 1$ is a bounded domain, $\alpha > 0$ and $\beta > 0$ are two material constants, and the functions $\hat{u} : \widehat{\Omega} \to \mathbb{R}^m$ with some integer $m \geq 1$ are constrained by a boundary condition or some other side conditions. Here and

below, we denote $\fint_E = \frac{1}{|E|}\int_E$ for a Lebesgue measurable set $E \subseteq \mathbb{R}^n$ with a finite and nonzero Lebesgue measure $|E|$. For any $a = (a_1, \dots, a_m) \in \mathbb{R}^m$, we denote $|a| = \sqrt{\sum_{i=1}^m a_i^2}$. For a differentiable function $u = (u_1, \dots, u_m) : D \to \mathbb{R}^m$ with $D \subset \mathbb{R}^n$ an open set, we define $\nabla u : D \to \mathbb{R}^{m\times n}$ to be the $m \times n$-matrix-valued function with $\partial_{x_j} u_i(x)$ the (i, j)-entry of $\nabla u(x)$ and denote $|\nabla u(x)| = \sqrt{\sum_{i=1}^m \sum_{j=1}^n |\partial_{x_j} u_i(x)|^2}$ for $x = (x_1, \dots, x_n) \in D$.

In the special case with $\hat{u} = \nabla\hat{h}$ for some scalar function $\hat{h}$ defined on a two-dimensional domain, the functional (1.1) happens to be the Liapunov functional of the evolution equation

$$\frac{\partial\hat{h}}{\partial t} = -\alpha\Delta^2\hat{h} - \beta\nabla\cdot\left(\frac{\nabla\hat{h}}{1+|\nabla\hat{h}|^2}\right), \tag{1.2}$$

i.e., this equation is the gradient-flow induced by the functional (1.1). Equation (1.2) was first proposed phenomenologically in [12] to model the surface height profile $\hat{h}$, measured in a comoving frame, in epitaxial growth of thin films with a strong asymmetry of the adatom (adsorbed atom) attachment and detachment from lower and upper terraces to atomic step edges due to the existence of an energy barrier [4, 17, 18]. Numerical and analytical studies based on such a model have shown that the slope of the surface, $|\nabla\hat{h}|$, which is the order parameter in this case, grows unbounded, agreeing with experiments [10, 11, 12, 13, 15, 16, 21].

It is interesting to compare the energy functional (1.1) with a usual Ginzburg–Landau-type energy functional that has the term $(|\hat{u}|^2 - 1)^2$ or alike, instead of the negative logarithmic term in (1.1). Important examples of the latter include the Ginzburg–Landau energy for superconductors [3, 9] and the Cahn–Hilliard energy for phase separation [2]; both have been much studied. It is obvious that an order parameter modeled by a Ginzburg–Landau-type energy functional stays always bounded. If $|\hat{u}| \ll 1$, then by the Taylor expansion,

$$-\log(1+|\hat{u}|^2) = -|\hat{u}|^2 + \frac{1}{2}|\hat{u}|^4 + O(|\hat{u}|^6) = \frac{1}{2}(|\hat{u}|^2-1)^2 - \frac{1}{2} + O(|\hat{u}|^6).$$

Thus, both types of energy functionals have approximately the same energy landscape for admissible functions with very small magnitude. As a consequence, the zero function as a critical point is unstable in both types of models.

Intuitively, if the energy $\hat{I}(\hat{u})$ of an admissible function $\hat{u} : \widehat{\Omega} \to \mathbb{R}^m$ is very small, then the magnitude $|\hat{u}|$ of the function must be very large in some norm. But, the boundary condition (or other side conditions) and the presence of the gradient term in the energy $\hat{I}(\hat{u})$ prevent $|\hat{u}|$ from being too large. These competing mechanisms determine the magnitude of such a low energy function to be finite but to grow unbounded as the system size increases. Our primary goals of this work are to quantify such unboundedness and to characterize the asymptotic behavior of energy functionals for systems of large size.

We shall not, however, directly work with the functional $\hat{I}$ defined in (1.1). Rather, we shall first rescale the energy functional. The idea is clear for the special case that $\widehat{\Omega} = (0, \widehat{L})^n$, a cube in $\mathbb{R}^n$ of linear size $\widehat{L} > 0$: letting $u(x) = \hat{u}(\hat{x})$ with $x = \widehat{L}^{-1}\hat{x}$, one obtains that $I_\varepsilon(u) = \beta\hat{I}(\hat{u})$, where

$$I_\varepsilon(u) = \fint_\Omega \left[\frac{\varepsilon^2}{2}|\nabla u|^2 - \frac{1}{2}\log(1+|u|^2)\right] dx, \tag{1.3}$$

$\varepsilon = \sqrt{\alpha/\beta}\widehat{L}^{-1}$, and Ω is the unit cube of $\mathbb{R}^n$. Now, for a general bounded domain $\widehat{\Omega}$, one can fix some point $\hat{x}_0 \in \widehat{\Omega}$ and apply the change of variable $\hat{x} \to x = \widehat{L}^{-1}(\hat{x} - \hat{x}_0)$ with $\widehat{L}$ being the diameter of $\widehat{\Omega}$. One again obtains an equivalent variational problem with the energy functional given by (1.3), in which ε is inversely proportional to $\widehat{L}$ and $\Omega \subset \mathbb{R}^n$ is a fixed bounded domain whose diameter is independent of $\widehat{L}$.

Depending on how an underlying physical and biological system is modeled mathematically, the set of admissible functions, to be denoted by $\mathcal{H}(\Omega, \mathbb{R}^m)$, for the energy functional I_ε can be defined differently. In this work, we assume that $\Omega \subset \mathbb{R}^n$ in the definition of I_ε is a bounded domain with a Lipschitz-continuous boundary $\partial\Omega$, and define

$$\mathcal{H}(\Omega, \mathbb{R}^m) = H_0^1(\Omega, \mathbb{R}^m), \tag{1.4}$$

or

$$\mathcal{H}(\Omega, \mathbb{R}^m) = \left\{ u \in H^1(\Omega, \mathbb{R}^m) : \fint_\Omega u \, dx = 0 \right\}, \tag{1.5}$$

where $H^1(\Omega, \mathbb{R}^m)$ and $H_0^1(\Omega, \mathbb{R}^m)$ are the spaces of vector-valued functions whose components are in the usual Sobolev spaces of scalar functions $H^1(\Omega)$ and $H_0^1(\Omega)$, respectively [1, 8]. In both cases, $\mathcal{H}(\Omega, \mathbb{R}^m)$ is a closed subspace of the Hilbert space $H^1(\Omega, \mathbb{R}^m)$ that is equipped with the norm $\|u\| = \sqrt{\|u\|^2 + \|\nabla u\|^2}$ for all $u \in H^1(\Omega, \mathbb{R}^m)$, where $\|\cdot\|$ denotes the $L^2(\Omega)$-norm.

Our major results are as follows:

(1) For each $\varepsilon > 0$, there exists a minimizer of $I_\varepsilon : \mathcal{H}(\Omega, \mathbb{R}^m) \to \mathbb{R}$. Moreover, the minimum energy scales as $\log \varepsilon$, and both the L^2 and H^1 norms of any minimizer of $I_\varepsilon : \mathcal{H}(\Omega, \mathbb{R}^m) \to \mathbb{R}$ are of the order $O(1/\varepsilon)$, cf. Theorem 2.1;

(2) The renormalized energy functionals $J_\varepsilon : \mathcal{H}(\Omega, \mathbb{R}^m) \to \mathbb{R}$, defined by

$$J_\varepsilon(v) = I_\varepsilon\left(\frac{v}{\varepsilon}\right) - \log \varepsilon \qquad \forall v \in \mathcal{H}(\Omega, \mathbb{R}^m), \tag{1.6}$$

Γ-converge to the energy functional $J : \mathcal{H}(\Omega, \mathbb{R}^m) \to \mathbb{R} \cup \{\infty\}$ defined by

$$J(v) = \fint_\Omega \left(\frac{1}{2}|\nabla v| - \log |v| \right) dx, \qquad v \in \mathcal{H}(\Omega, \mathbb{R}^m), \tag{1.7}$$

cf. Theorem 3.2. Moreover, if $v_\varepsilon \in \mathcal{H}(\Omega, \mathbb{R}^m)$ for $\varepsilon > 0$ is a minimizer of $J_\varepsilon : \mathcal{H}(\Omega, \mathbb{R}^m) \to \mathbb{R} \cup \{\infty\}$, then there exists a subsequence of $\{v_\varepsilon\}_{\varepsilon>0}$ that converges *strongly* in $\mathcal{H}(\Omega, \mathbb{R}^m)$ to a minimizer of $J : \mathcal{H}(\Omega, \mathbb{R}^m) \to \mathbb{R} \cup \{\infty\}$, cf. Theorem 3.3;

(3) In the case of the scalar Dirichlet boundary-value problem, there exists a unique $v_+ \in H_0^1(\Omega)$ such that v_+ is smooth and positive in Ω, and that v_+ and $-v_+$ are the only minimizers of $J : H_0^1(\Omega) \to \mathbb{R} \cup \{\infty\}$, cf. Theorem 4.1.

The results in (1) and (2) hold also true if the set of admissible functions is $\{u \in H_0^1(\Omega, \mathbb{R}^m) : \fint_\Omega u \, dx = 0\}$, or if Ω is an open cube in $\mathbb{R}^n$ with its faces parallel to the coordinate planes and the corresponding set of admissible functions is $\{u \in H^1_{\rm per}(\Omega, \mathbb{R}^m) : \fint_\Omega u \, dx = 0\}$, where $H^1_{\rm per}(\Omega, \mathbb{R}^m)$ is the closure in $H^1(\Omega, \mathbb{R}^m)$ of the set of all C^∞, $\overline{\Omega}$-periodical functions from $\mathbb{R}^n$ to $\mathbb{R}^m$.

The heuristics behind the first part of our results is well illustrated in our previous work [13] through the calculation of trial functions with low energy using an ad hoc ansatz and the calculation of critical points of the energy functional using matched

asymptotics, with both calculations being done in a one-dimensional setting. Our results in (1) generalize those in [13] for more complicated domains and include the optimal lower bound as well as the precise asymptotics of the minimum energy.

Our results do not directly apply to continuum models, such as the Liapunov functional of the equation (1.2), of the epitaxial growth with a significant attachment-detachment asymmetry of adatoms. This is because the set of admissible functions $\hat{u}$ of the functional (1.1) is larger than the set of gradient vector fields. However, the approach developed in this work can be applied to the study of such continuum models and to obtain similar results. In particular, the large-system-size Γ-limit of the rescaled Liapunov functionals—the functional (1.3) with u replaced by ∇h for the surface height function h that models a finite energy barrier—is precisely Villain's model for an infinite energy barrier [21].

Potentially, the positive solution to the scalar Dirichlet boundary-value problem for the limiting functional can be a good alternative to the distance function in the reinitialization process of the widely used level-set numerical method [14, 19]. We will address these issues of application in separate works.

In section 2, we present and prove the results for the energy functionals $I_\varepsilon : \mathcal{H}(\Omega, \mathbb{R}^m) \to \mathbb{R}$. In section 3, we prove the Γ-convergence of the renormalized energies $J_\varepsilon : \mathcal{H}(\Omega, \mathbb{R}^m) \to \mathbb{R}$ to the functional $J : \mathcal{H}(\Omega, \mathbb{R}) \to \mathbb{R} \cup \{\infty\}$. Finally, in section 4, we characterize solutions to the scalar Dirichlet problem of infimizing the limiting energy defined in (1.7).

2. Energy asymptotics and bounds of energy minimizers. We consider the energy functionals $I_\varepsilon : \mathcal{H}(\Omega, \mathbb{R}^m) \to \mathbb{R}$, defined in (1.3) for a general domain Ω, only for $\varepsilon \in (0, 1]$, though many of our results hold true also for any $\varepsilon > 0$. For convenience, we denote $\|\!|u|\!\| = \sqrt{⨍_\Omega |u(x)|^2 dx} = (1/\sqrt{|\Omega|})\|u\|$ for all $u \in L^2(\Omega)$.

The following is our main result in this section:

THEOREM 2.1. *Let $\Omega \subset \mathbb{R}^n$ be a bounded domain with a Lipschitz-continuous boundary $\partial\Omega$. Let $\mathcal{H}(\Omega, \mathbb{R}^m)$ be defined as in* (1.4) *or* (1.5).

(1) *For each $\varepsilon \in (0, 1]$, there exists $u_\varepsilon \in \mathcal{H}(\Omega, \mathbb{R}^m)$ such that*

$$I_\varepsilon(u_\varepsilon) = \min_{u \in \mathcal{H}(\Omega, \mathbb{R}^m)} I_\varepsilon(u). \tag{2.1}$$

(2) *Let $\mu_\varepsilon = \min_{u \in \mathcal{H}(\Omega, \mathbb{R}^m)} I_\varepsilon(u)$. There exist constants C_1 and C_2 that depend only on Ω such that*

$$C_1 + \log \varepsilon \le \mu_\varepsilon \le C_2 + \log \varepsilon \qquad \forall \varepsilon \in (0, 1]. \tag{2.2}$$

Moreover, $\mu_\varepsilon - \log \varepsilon$ increases as $\varepsilon \in (0, 1]$ decreases, $\nu := \sup_{0 < \varepsilon \le 1}(\mu_\varepsilon - \log \varepsilon)$ is finite, and

$$\lim_{\varepsilon \to 0^+} (\mu_\varepsilon - \log \varepsilon) = \nu. \tag{2.3}$$

(3) *There exist constants $C_j > 0$ $(j = 3, 4, 5, 6)$ and $\varepsilon_0 \in (0, 1]$, all depending only on Ω, such that for any minimizer $u_\varepsilon \in \mathcal{H}(\Omega, \mathbb{R}^m)$ of $I_\varepsilon : \mathcal{H}(\Omega, \mathbb{R}^m) \to \mathbb{R}$ and for all $\varepsilon \in (0, \varepsilon_0]$,*

$$\frac{C_3}{\varepsilon} \le \|\!|u_\varepsilon|\!\| \le \frac{C_4}{\varepsilon}, \tag{2.4}$$

$$\frac{C_5}{\varepsilon} \le \|\!|\nabla u_\varepsilon|\!\| \le \frac{C_6}{\varepsilon}. \tag{2.5}$$

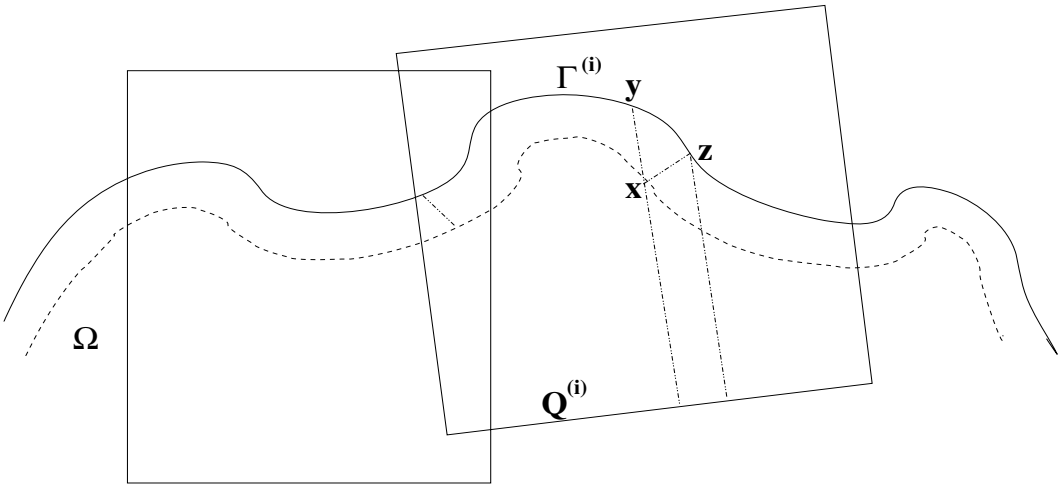

FIG. 2.2.1.

To prove this theorem, we need some preparations. We recall for any compact set $S \subset \mathbb{R}^n$ that the distance function $\text{dist}\,(\cdot, S) : \mathbb{R}^n \to \mathbb{R}$, defined by

$$\text{dist}\,(x, S) = \inf_{y \in S} |x - y| = \min_{y \in S} |x - y| \qquad \forall x \in \mathbb{R}^n,$$

is a Lipschitz-continuous function:

$$|\text{dist}\,(x, S) - \text{dist}\,(y, S)| \le |x - y| \qquad \forall x, y \in \mathbb{R}^n. \tag{2.6}$$

Moreover, it is differentiable almost everywhere in $\mathbb{R}^n$, and

$$|\nabla \text{dist}\,(x, S)| = 1 \qquad \text{a.e. } x \in \mathbb{R}^n, \tag{2.7}$$

cf. the proof of Lemma 3.2.34 in [7].

LEMMA 2.1. *If $\Omega \in \mathbb{R}^n$ is a bounded domain with a Lipschitz-continuous boundary $\partial\Omega$, then there exist constants $s_0 > 0$ and $C_0 > 0$, both depending only on Ω, such that*

$$|\{x \in \Omega : \text{dist}\,(x, \partial\Omega) \le s\}| \le C_0 s \qquad \forall s \in (0, s_0].$$

Proof. Since $\partial\Omega$ is Lipschitz-continuous, there exist finitely many Lipschitz-continuous functions $\phi^{(i)} : Q^{(i)} \to \mathbb{R}$ ($i = 1, \ldots, m$ for some integer $m \ge 1$) in local Cartesian coordinates with each $Q^{(i)} = \Pi_{j=1}^{n-1}[-\alpha_j^{(i)}, \alpha_j^{(i)}]$ for some $\alpha_j^{(i)} > 0$ ($1 \le i \le m$ and $1 \le j \le n-1$) a cube in $\mathbb{R}^{n-1}$, that satisfy the following properties (cf. Figure 2.2.1):

(1) For each i with $1 \le i \le m$, the local Cartesian coordinates $\xi^{(i)} = (\xi_1^{(i)}, \cdots, \xi_n^{(i)})$ are obtained by rotating and translating the original Cartesian coordinates $x = (x_1, \ldots, x_n)$;

(2) There exist $\alpha_n > 0$ and $\beta_n > 0$ such that for each cube $G^{(i)} := Q^{(i)} \times [-\alpha_n, \alpha_n] \subset \mathbb{R}^n$ ($1 \le i \le m$),

$$\Gamma^{(i)} := G^{(i)} \cap \partial\Omega = \left\{ \left(\hat{\xi}^{(i)}, \xi_n^{(i)} \right) \in \mathbb{R}^n : \hat{\xi}^{(i)} \in Q^{(i)},\, \xi_n^{(i)} = \phi^{(i)} \left(\hat{\xi}^{(i)} \right) \right\},$$

where $\hat{\xi}^{(i)} = \left(\xi_1^{(i)}, \ldots, \xi_{n-1}^{(i)}\right)$, and

$$U_+^{(i)} := \left\{ \left(\hat{\xi}^{(i)}, \xi_n^{(i)}\right) \in \mathbb{R}^n : \hat{\xi}^{(i)} \in Q^{(i)},\ \phi^{(i)}\left(\hat{\xi}^{(i)}\right) < \xi_n^{(i)} < \phi^{(i)}\left(\hat{\xi}^{(i)}\right) + \beta_n \right\} \subset G^{(i)} \cap \overline{\Omega}^c,$$

$$U_-^{(i)} := \left\{ \left(\hat{\xi}^{(i)}, \xi_n^{(i)}\right) \in \mathbb{R}^n : \hat{\xi}^{(i)} \in Q^{(i)},\ \phi^{(i)}\left(\hat{\xi}^{(i)}\right) - \beta_n < \xi_n^{(i)} < \phi^{(i)}\left(\hat{\xi}^{(i)}\right) \right\} \subset G^{(i)} \cap \Omega;$$

(3) The union $\cup_{i=1}^m G^{(i)}$ covers a neighborhood of the compact set $\partial\Omega$, and $\partial\Omega = \cup_{i=1}^m \Gamma_i$.

Now, since the distance function $\mathrm{dist}(\cdot, \partial\Omega) : \overline{\Omega} \to \mathbb{R}$ is Lipschitz-continuous and vanishes only on the boundary $\partial\Omega$ which is compact, by properties (2) and (3), there exists a constant $s_1 = s_1(\Omega) > 0$ such that

$$\{x \in \Omega : \mathrm{dist}\,(x, \partial\Omega) \le s_1\} \subseteq \bigcup_{i=1}^m U_-^{(i)}.$$

By this and property (3), there exist cubes $P^{(i)}$ in $\mathbb{R}^{n-1}$ with $P^{(i)} \subseteq Q^{(i)}$ $(1 \le i \le m)$ and a constant $s_0 = s_0(\Omega)$ with $0 < s_0 \le s_1$ that satisfy the following properties:

(4) For each i $(1 \le i \le m)$,

$$\{x \in \Omega : \mathrm{dist}\,(x, \partial\Omega) \le s_0\} \subseteq \bigcup_{i=1}^m V^{(i)},$$

where

$$V^{(i)} = \left\{ \left(\hat{\xi}^{(i)}, \xi_n^{(i)}\right) \in \mathbb{R}^n : \hat{\xi}^{(i)} \in \hat{P}^{(i)},\ \phi^{(i)}\left(\hat{\xi}^{(i)}\right) - \beta_n < \xi_n^{(i)} < \phi^{(i)}\left(\hat{\xi}^{(i)}\right) \right\} \subseteq U_-^{(i)};$$

(5) Let $x \in \Omega$ and $x' \in \partial\Omega$ be such that $\mathrm{dist}\,(x, \partial\Omega) = |x - x'| \le s_0$. If $x \in V^{(i)}$ for some i $(1 \le i \le m)$, then $x' \in \Gamma_i = G^{(i)} \cap \partial\Omega$.

Fix $s \in \mathbb{R}$ with $0 < s \le s_0$. Let $x \in \Omega$ be such that $\mathrm{dist}\,(x, \partial\Omega) \le s$. By property (4), we have $x \in V^{(i)}$ for some i with $1 \le i \le m$, cf. Figure 2.1. Let $\xi^{(i)} = (\hat{\xi}^{(i)}, \xi_n^{(i)})$ be the local coordinates of x in which $\hat{\xi}^{(i)} \in P^{(i)} \subseteq Q^{(i)}$. Let the point $y \in \mathbb{R}^n$ have the local coordinates $(\hat{\xi}^{(i)}, \phi^{(i)}(\hat{\xi}^{(i)}))$. Then, by property (2), $y \in \Gamma^{(i)} \subset \partial\Omega$, cf. Figure 2.1. Let $z \in \partial\Omega$ be such that $\mathrm{dist}\,(x, \partial\Omega) = |x - z| \le s$, cf. Figure 2.1. By property (5), $z \in \Gamma^{(i)} = G^{(i)} \cap \partial\Omega$. Thus, there exists $(\hat{\eta}^{(i)}, \eta_n^{(i)}) \in \Gamma^{(i)} = G^{(i)} \cap \partial\Omega$ such that $\hat{\eta}^{(i)} \in Q^{(i)}$, $(\hat{\eta}^{(i)}, \eta_n^{(i)}) = (\hat{\eta}^{(i)}, \phi^{(i)}(\hat{\eta}^{(i)}))$ are the local coordinates of z, and

$$\mathrm{dist}\,(x, \partial\Omega) = |x - z| = \left| \left(\hat{\xi}^{(i)}, \xi_n^{(i)}\right) - \left(\hat{\eta}^{(i)}, \phi^{(i)}\left(\hat{\eta}^{(i)}\right)\right) \right| \le s. \tag{2.8}$$

This implies that

$$\left|\hat{\xi}^{(i)} - \hat{\eta}^{(i)}\right| \le s. \tag{2.9}$$

Denoting by $L_i > 0$ the Lipschitz constant of the Lipschitz-continuous function $\phi^{(i)} : Q^{(i)} \to \mathbb{R}$, we have by (2.8) and (2.9) that

$$\begin{aligned} \left|\phi^{(i)}\left(\hat{\xi}^{(i)}\right) - \xi_n^{(i)}\right| &= |x - y| \\ &\le |x - z| + |y - z| \\ &\le s + \left|\hat{\xi}^{(i)} - \hat{\eta}^{(i)}\right| + \left|\phi^{(i)}\left(\hat{\xi}^{(i)}\right) - \phi^{(i)}\left(\hat{\eta}^{(i)}\right)\right| \\ &\le s + s + L_i \left|\hat{\xi}^{(i)} - \hat{\eta}^{(i)}\right| \le (2 + L_i)s. \end{aligned}$$

The arbitrariness of x now implies that

$$\{x \in \Omega : \operatorname{dist}(x, \partial\Omega) \le s\} \subseteq \bigcup_{i=1}^{m} \left\{ \left(\hat{\xi}^{(i)}, \xi_n^{(i)}\right) : \hat{\xi}^{(i)} \in \hat{Q}^{(i)},\ \phi^{(i)}(\hat{\xi}^{(i)}) - (2+L_i)s \le \xi_n^{(i)} \le \phi^{(i)}\left(\hat{\xi}^{(i)}\right) \right\}.$$

Consequently, we have

$$\begin{aligned} |\{x \in \Omega : \operatorname{dist}(x, \partial\Omega) \le s\}| &\le \sum_{i=1}^{m} \int_{\hat{Q}^{(i)}} \left[\phi^{(i)}\left(\hat{\xi}^{(i)}\right) - \left(\phi^{(i)}\left(\hat{\xi}^{(i)}\right) - (2+L_i)s \right) \right] d\hat{\xi}^{(i)} \\ &\le C_0 s, \end{aligned}$$

where $C_0 = \sum_{i=1}^{m}(2+L_i)|Q^{(i)}| > 0$, depending only on Ω, and $|Q^{(i)}|$ is the $(n-1)$-dimensional volume of $Q^{(i)}$ $(1 \le i \le m)$. □

LEMMA 2.2. *Given a bounded domain $\Omega \subset \mathbb{R}^n$ that has a Lipschitz-continuous boundary $\partial\Omega$, there exists a Lipschitz-continuous function $f : \overline{\Omega} \to \mathbb{R}$ such that*

$$f = 0 \text{ on } \partial\Omega, \quad \int_\Omega f\,dx = 0, \quad \text{and} \quad -\infty < \int_\Omega \log|f|\,dx < \infty.$$

Proof. Let $x_0 \in \Omega$ and $\rho > 0$ be such that the ball $B := B(x_0, \rho) = \{x \in \mathbb{R}^n : |x - x_0| < \rho\}$ is completely contained in Ω, i.e., $\overline{B} \subset \Omega$. For any $x \in \overline{\Omega}$, let $d(x)$ be the distance from x to the compact set $\partial\Omega \cup \partial B$ and define $f : \overline{\Omega} \to \mathbb{R}$ by

$$f(x) = \begin{cases} d(x) & \text{if } x \in \overline{\Omega} \setminus B, \\ -\gamma d(x) & \text{if } x \in B, \end{cases} \tag{2.10}$$

where $\gamma = \int_{\Omega\setminus B} d(x)\,dx / \int_B d(x)\,dx > 0$. Clearly, $f : \overline{\Omega} \to \mathbb{R}$ is continuous, $f = 0$ on $\partial\Omega$, and $\int_\Omega f(x)\,dx = 0$.

We show now that $f : \overline{\Omega} \to \mathbb{R}$ is Lipschitz-continuous. Fix $x, y \in \overline{\Omega}$. If both x and y are in B or both x and y are in $\overline{\Omega} \setminus B$, then we have by (2.6) and (2.10) that

$$|f(x) - f(y)| \le \max(1, \gamma)|x - y| \le (1+\gamma)|x - y|. \tag{2.11}$$

Assume now $x \in B$ but $y \in \overline{\Omega} \setminus B$. Choose $\delta \in \mathbb{R}$ so that $0 < \delta < 1$, the ball $B_1 := B(x_0, \rho + \delta) \subset \Omega$, and

$$0 < 2\delta < \operatorname{dist}(\partial\Omega, \overline{B}) := \inf_{x' \in \partial\Omega, y' \in \overline{B}} |x' - y'|. \tag{2.12}$$

If $y \in \overline{\Omega} \setminus B_1$, then $|x - y| \ge \delta$. Hence,

$$|f(x) - f(y)| \le \frac{2\max_{z\in\overline{\Omega}} |f(z)|}{\delta} |x - y|. \tag{2.13}$$

If $y \in B_1 \setminus B$, then

$$d(y) = \operatorname{dist}(y, \partial B) \le |x - y|.$$

Also,

$$d(x) = \operatorname{dist}(x, \partial B) \le |x - y|.$$

Thus,

$$|f(x) - f(y)| = \gamma d(x) + d(y) \le (1+\gamma)|x-y|. \tag{2.14}$$

Setting

$$L = \max\left(1+\gamma, \frac{2\max_{z\in\overline{\Omega}}|f(z)|}{\delta}\right) > 0,$$

we obtain from (2.11), (2.13), and (2.14) that

$$|f(x) - f(y)| \le L|x-y|.$$

Since $x, y \in \overline{\Omega}$ are arbitrary, the function $f : \overline{\Omega} \to \mathbb{R}$ is Lipschitz-continuous.

We show finally that $-\infty < \int_\Omega \log|f|\,dx < \infty$. Since $|f|$ is bounded from above on $\overline{\Omega}$,

$$\begin{aligned}\int_\Omega \log|f|\,dx &= \int_{\{x\in\Omega:|f(x)|<1\}} \log|f|\,dx + \int_{\{x\in\Omega:|f(x)|\ge 1\}} \log|f|\,dx \\ &\le \int_{\{x\in\Omega:|f(x)|\ge 1\}} \log|f|\,dx < \infty.\end{aligned}$$

So, we need only to show that

$$\int_\Omega \log|f|\,dx = \int_{B_1} \log|f|\,dx + \int_{\Omega\setminus B_1} \log|f|\,dx > -\infty, \tag{2.15}$$

where $B_1 = B(x_0, \rho+\delta) \subset \Omega$ is the same ball used before and $\delta > 0$ is given in (2.12).

Using (2.10) and (2.12), the polar coordinates, and a change of variables, we obtain

$$\begin{aligned}\int_{B_1} \log|f|\,dx &= \int_B \log(\gamma d(x))\,dx + \int_{B_1\setminus B} \log d(x)\,dx \\ &= |B|\log\gamma + \int_B \log|\rho - |x-x_0|\,|\,dx + \int_{B_1\setminus B} \log|\rho - |x-x_0|\,|\,dx \\ &= |B|\log\gamma + S_n\int_0^\rho r^{n-1}\log|\rho - r|\,dr + S_n\int_\rho^{\rho+\delta} r^{n-1}\log|\rho-r|\,dr \\ &> -\infty, \end{aligned} \tag{2.16}$$

where S_n is the surface area of the unit ball in $\mathbb{R}^n$.

Observe that for $x \in \Omega\setminus B_1$ with $d(x) < \delta$, we have by (2.12) that in fact $d(x) = \operatorname{dist}(x, \partial\Omega)$. Thus, by Lemma 2.1, there exists an integer $N \ge 1$ and a constant $C_0 > 0$ such that $|\omega_j| \le C_0\delta 2^{-j}$ $(j = N, \dots)$, where

$$\begin{aligned}\omega_j &:= \{x \in \Omega\setminus B_1 : 2^{-(j+1)}\delta < d(x) \le 2^{-j}\delta\} \\ &\subset \{x\in\Omega : \operatorname{dist}(x,\partial\Omega) \le 2^{-j}\delta\}, \qquad j = 0, \dots .\end{aligned}$$

Setting $E_\delta = \{x \in \Omega\setminus B_1 : d(x) > \delta\}$, we see that $\Omega\setminus B_1$ is the union of the pairwise

disjoint sets E_δ and ω_j $(j=0,\dots)$. Therefore, by the fact that $0<\delta<1$, we obtain

$$\begin{aligned}
\int_{\Omega\setminus B_1}\log|f|\,dx &= \int_{E_\delta}\log d(x)\,dx+\sum_{j=0}^{\infty}\int_{\omega_j}\log d(x)\,dx\\
&\geq |\Omega\setminus B_1|\log\delta+\sum_{j=0}^{N}|\omega_j|\log\left(2^{-(j+1)}\delta\right)+\sum_{j=N+1}^{\infty}|\omega_j|\log\left(2^{-(j+1)}\delta\right)\\
&\geq |\Omega\setminus B_1|\log\delta+|\Omega\setminus B_1|\log\left(2^{-(N+1)}\delta\right)\\
&\quad+C_0\delta\sum_{j=N+1}^{\infty}2^{-j}\log\left(2^{-(j+1)}\delta\right)\\
&= |\Omega\setminus B_1|\log\left(2^{-(N+1)}\delta^2\right)+C_0\delta\sum_{j=N+1}^{\infty}2^{-j}\left[\log\delta-(j+1)\log 2\right]\\
&> -\infty. \qquad (2.17)
\end{aligned}$$

Finally, (2.15) follows from (2.16) and (2.17). □

We are now ready to prove our main result in this section.

Proof of Theorem 2.1.

(1) Fix $\varepsilon\in(0,1]$. Recall the Poincaré inequality [1, 6, 8]

$$\|u\|\leq C_0\|\nabla u\| \qquad \forall u\in\mathcal{H}(\Omega,\mathbb{R}^m), \tag{2.18}$$

where $C_0>0$ is a constant depending only on Ω. Since $(1/s)\log(1+s)\to 0$ as $s\to\infty$, there exists $R_\varepsilon=R_\varepsilon(\Omega)>0$ such that

$$\log(1+s)\leq\frac{\varepsilon^2 s}{2C_0^2} \qquad \forall s\geq R_\varepsilon. \tag{2.19}$$

By (2.19) and (2.18), we have

$$\begin{aligned}
I_\varepsilon(u) &= \frac{\varepsilon^2}{2}\fint_\Omega|\nabla u|^2dx-\frac{1}{2|\Omega|}\int_{\{x\in\Omega:|u|^2\leq R_\varepsilon\}}\log(1+|u|^2)\,dx\\
&\quad-\frac{1}{2|\Omega|}\int_{\{x\in\Omega:|u|^2>R_\varepsilon\}}\log(1+|u|^2)\,dx\\
&\geq \frac{\varepsilon^2}{2}\fint_\Omega|\nabla u|^2dx-\frac{1}{2|\Omega|}\int_{\{x\in\Omega:|u|^2\leq R_\varepsilon\}}\log(1+R_\varepsilon)\,dx\\
&\quad-\frac{\varepsilon^2}{4C_0^2|\Omega|}\int_{\{x\in\Omega:|u|^2>R_\varepsilon\}}|u|^2dx\\
&\geq \frac{\varepsilon^2}{2}\fint_\Omega|\nabla u|^2dx-\frac{1}{2}\log(1+R_\varepsilon)-\frac{\varepsilon^2}{4C_0^2}\fint_\Omega|u|^2dx\\
&\geq \frac{\varepsilon^2}{4}\fint_\Omega|\nabla u|^2dx-\frac{1}{2}\log(1+R_\varepsilon) \qquad \forall u\in\mathcal{H}(\Omega,\mathbb{R}^m). \qquad (2.20)
\end{aligned}$$

Set $\mu_\varepsilon=\inf_{u\in\mathcal{H}(\Omega,\mathbb{R}^m)}I_\varepsilon(u)$. By (2.20), $\mu_\varepsilon>-\infty$. Let $\{u_j\}_{j=1}^\infty$ be an infimizing sequence of $I_\varepsilon:\mathcal{H}(\Omega,\mathbb{R}^m)\to\mathbb{R}$. It follows from (2.20) and (2.18) that $\{u_j\}_{j=1}^\infty$ is bounded in $\mathcal{H}(\Omega,\mathbb{R}^m)$. Thus, up to a subsequence, $u_j\rightharpoonup u_\varepsilon$ in $H^1(\Omega,\mathbb{R}^m)$ and

$u_j \to u_\varepsilon$ in $L^2(\Omega,\mathbb{R}^m)$ as $j \to \infty$ for some $u_\varepsilon \in H^1(\Omega,\mathbb{R}^m)$, where the symbol $\rightharpoonup$ and $\to$ denote the weak and strong convergence, respectively. We have in fact $u_\varepsilon \in \mathcal{H}(\Omega,\mathbb{R}^m)$, since $\mathcal{H}(\Omega,\mathbb{R}^m)$ is a closed subspace, hence a weakly closed subset, of $H^1(\Omega,\mathbb{R}^m)$.

For each $j \ge 1$, $|\nabla u_j|^2 + |\nabla u_\varepsilon|^2 \ge 2\nabla u_j \cdot \nabla u_\varepsilon$ in Ω, where the matrix dot-product is defined by $A \cdot B = \sum_{i=1}^m \sum_{j=1}^n A_{ij}B_{ij}$ for all $A = (A_{ij}), B = (B_{ij}) \in \mathbb{R}^{m\times n}$. Thus, by the weak convergence $u_j \rightharpoonup u_\varepsilon$ in $H^1(\Omega,\mathbb{R}^m)$, we have

(2.21)
$$\liminf_{j\to\infty} \fint_\Omega |\nabla u_j|^2 dx \ge \liminf_{j\to\infty} \left[2\fint_\Omega \nabla u_j \cdot \nabla u_\varepsilon \, dx - \fint_\Omega |\nabla u_\varepsilon|^2 dx \right] = \fint_\Omega |\nabla u_\varepsilon|^2 dx.$$

By the fact that $\log(1+s) \le s$ for all $s \ge 0$ and the Cauchy–Schwarz inequality, we imply from the strong convergence $u_j \to u_\varepsilon$ in $L^2(\Omega,\mathbb{R}^m)$ that

$$\begin{aligned} &\left| \fint_\Omega \left[\log(1+|u_j|^2) - \log(1+|u_\varepsilon|^2) \right] dx \right| = \left| \fint_\Omega \log\left(1 + \frac{|u_j|^2 - |u_\varepsilon|^2}{1+|u_\varepsilon|^2} \right) dx \right| \\ &\le \fint_\Omega \log\left(1 + \left| \frac{|u_j|^2 - |u_\varepsilon|^2}{1+|u_\varepsilon|^2} \right| \right) dx \le \fint_\Omega \left| \frac{|u_j|^2 - |u_\varepsilon|^2}{1+|u_\varepsilon|^2} \right| dx \\ &\le (\|\!| u_j |\!\| + \|\!| u_\varepsilon |\!\|) \|\!| u_j - u_\varepsilon |\!\| \to 0 \qquad \text{as } j \to \infty. \end{aligned} \tag{2.22}$$

This and (2.21) thus imply that

$$\mu_\varepsilon = \liminf_{j\to\infty} I_\varepsilon(u_j) \ge \fint_\Omega \left[\frac{\varepsilon^2}{2} |\nabla u_\varepsilon|^2 - \frac{1}{2}\log(1+|u_\varepsilon|^2) \right] dx = I_\varepsilon(u_\varepsilon) \ge \mu_\varepsilon,$$

leading to (2.1).

(2) Let $u_\varepsilon \in \mathcal{H}(\Omega,\mathbb{R}^m)$ be a minimizer of $I_\varepsilon : \mathcal{H}(\Omega,\mathbb{R}^m) \to \mathbb{R}$. The first variation of I_ε at u_ε then vanishes:

$$\delta I_\varepsilon(u_\varepsilon)(v) = \fint_\Omega \left(\varepsilon^2 \nabla u_\varepsilon \cdot \nabla v - \frac{u_\varepsilon v}{1+u_\varepsilon^2} \right) dx = 0 \qquad \forall v \in \mathcal{H}(\Omega,\mathbb{R}^m).$$

Choosing $v = u_\varepsilon$, we obtain that

$$\fint_\Omega |\nabla u_\varepsilon|^2 \le \frac{1}{\varepsilon^2}. \tag{2.23}$$

This and the Poincaré inequality (2.18) imply that

$$\fint_\Omega |u_\varepsilon|^2 \le \frac{C_0^2}{\varepsilon^2}. \tag{2.24}$$

Since the function $-\log(\cdot)$ is convex, Jensen's inequality and (2.24) then imply that

$$\begin{aligned} \mu_\varepsilon = I_\varepsilon(u_\varepsilon) &\ge -\frac{1}{2}\fint_\Omega \log(1+|u_\varepsilon|^2)\, dx \ge -\frac{1}{2}\log(1+\|\!| u_\varepsilon |\!\|^2) \\ &\ge -\frac{1}{2}\log\left(1 + \frac{C_0^2}{\varepsilon^2}\right) = -\frac{1}{2}\log\left(\varepsilon^2 + C_0^2\right) + \log\varepsilon \ge C_1 + \log\varepsilon, \end{aligned} \tag{2.25}$$

where $C_1 = -(1/2)\log(1+C_0^2)$.

Let $f : \overline{\Omega} \to \mathbb{R}$ be the Lipschitz-continuous function constructed in Lemma 2.2. Let $e_1 = (1, 0, \dots, 0) \in \mathbb{R}^m$ be the unit vector along the x_1-axis. Define $\hat{u}_\varepsilon = (f/\varepsilon)e_1$. Clearly, $\hat{u}_\varepsilon \in \mathcal{H}(\Omega, \mathbb{R}^m)$. Moreover,

$$\mu_\varepsilon \le I_\varepsilon(\hat{u}_\varepsilon) = \fint_\Omega \left[\frac{1}{2}|\nabla f|^2 - \frac{1}{2}\log\left(1 + \frac{|f|^2}{\varepsilon^2}\right)\right] dx \le C_2 + \log\varepsilon, \tag{2.26}$$

where

$$C_2 := \fint_\Omega \left(\frac{1}{2}|\nabla f|^2 - \log|f|\right) dx$$

is finite by Lemma 2.2. Now, (2.2) follows from (2.25) and (2.26).

Recall for each $\varepsilon \in (0, 1]$ that the renormalized energy functional, defined in (1.6), is

$$\begin{aligned} J_\varepsilon(v) &= I_\varepsilon\left(\frac{v}{\varepsilon}\right) - \log\varepsilon \\ &= \fint_\Omega \left[\frac{1}{2}|\nabla v|^2 - \frac{1}{2}\log\left(\varepsilon^2 + |v|^2\right)\right] dx \qquad \forall v \in \mathcal{H}(\Omega, \mathbb{R}^m), \end{aligned} \tag{2.27}$$

in which the variable v is scaled from the variable v/ε of the energy I_ε. It follows from (1) that for each $\varepsilon \in (0, 1]$ there exists a minimizer of $J_\varepsilon : \mathcal{H}(\Omega, \mathbb{R}^m) \to \mathbb{R}$ and the minimum value of J_ε over $\mathcal{H}(\Omega, \mathbb{R}^m)$ is

$$\nu_\varepsilon := \min_{v \in \mathcal{H}(\Omega, \mathbb{R}^m)} J_\varepsilon(v) = \mu_\varepsilon - \log\varepsilon. \tag{2.28}$$

Consequently, by (2.2), $\{\nu_\varepsilon\}_{0<\varepsilon\le 1}$ is bounded. Moreover, for each fixed $v \in \mathcal{H}(\Omega, \mathbb{R}^m)$, we have by (2.27) that $J_\varepsilon(v)$ increases as $\varepsilon \in (0, 1]$ decreases. Therefore, ν_ε increases as $\varepsilon \in (0, 1]$ decreases. This and the boundedness of $\{\nu_\varepsilon\}_{0<\varepsilon\le 1}$ imply that $\nu \in \mathbb{R}$ as defined in (2) of Theorem 2.1 is finite and that (2.3) holds true.

(3) Let again $u_\varepsilon \in \mathcal{H}(\Omega, \mathbb{R}^m)$ be a minimizer of $I_\varepsilon : \mathcal{H}(\Omega, \mathbb{R}^m) \to \mathbb{R}$. By (2.24) and (2.23), the upper bound in (2.4) and that in (2.5) hold true with $C_4 = C_0$ and $C_6 = 1$, respectively, for all $\varepsilon \in (0, 1]$. By (2.2) and Jensen's inequality, we obtain

$$C_2 + \log\varepsilon \ge \mu_\varepsilon = I_\varepsilon(u_\varepsilon) \ge -\frac{1}{2}\fint_\Omega \log\left(1 + |u_\varepsilon|^2\right) dx \ge -\frac{1}{2}\log\left(1 + \|u_\varepsilon\|^2\right),$$

leading to the lower bound in (2.4) for all $\varepsilon \in (0, e^{-C_2}/\sqrt{2}]$ with $C_3 = e^{-C_2}/\sqrt{2} > 0$. It, together with the Poincaré inequality (2.18), also implies the lower bound in (2.5) for ε in the same range with $C_5 = C_0 C_3 > 0$. Finally, letting $\varepsilon_0 = \min(1, e^{-C_2}/\sqrt{2}) \in (0, 1]$, we obtain all the desired inequalities in (2.4) and (2.5) for all $\varepsilon \in (0, \varepsilon_0]$. ∎

Remark 2.1. In the case that $\Omega = \Pi_{i=1}^n (a_i, b_i)$ with $-\infty < a_i < b_i < \infty$ $(i = 1, \dots, n)$ and the set of admissible functions is $\{u \in H^1_{\rm per}(\Omega, \mathbb{R}^m) : \fint_\Omega u\, dx = 0\}$, the upper bound (2.26) can be obtained by replacing f by $\sin(2\pi x_1/(b_1 - a_1))$.

3. Renormalized energies and their Γ-limit. We consider in this section the convergence of the renormalized energy functionals $J_\varepsilon : \mathcal{H}(\Omega, \mathbb{R}^m) \to \mathbb{R}$, defined in (2.27), to the energy functional $J : \mathcal{H}(\Omega, \mathbb{R}^m) \to \mathbb{R} \cup \{-\infty, \infty\}$, defined in (1.7).

THEOREM 3.1. *Let $\Omega \subset \mathbb{R}^n$ and $\mathcal{H}(\Omega, \mathbb{R}^m)$ be the same as in Theorem* 2.1. *We have*

$$-\infty < \inf_{v \in \mathcal{H}(\Omega, \mathbb{R}^m)} J(v) < \infty. \tag{3.1}$$

Moreover, there exists $v \in \mathcal{H}(\Omega, \mathbb{R}^m)$ *such that*

$$J(v) = \inf_{w \in \mathcal{H}(\Omega, \mathbb{R}^m)} J(w). \tag{3.2}$$

THEOREM 3.2. *Let* $\Omega \subset \mathbb{R}^n$ *and* $\mathcal{H}(\Omega, \mathbb{R}^m)$ *be the same as in Theorem* 2.1. *Let* $\{\varepsilon_j\}_{j=1}^{\infty}$ *be a decreasing sequence in* $(0, 1]$ *such that* $\lim_{j\to\infty} \varepsilon_j = 0$. *Then, the sequence of functionals* $J_{\varepsilon_j} : \mathcal{H}(\Omega, \mathbb{R}^m) \to \mathbb{R}$ $(j = 1, \dots)$ Γ*-converge with respect to the weak topology of* $\mathcal{H}(\Omega, \mathbb{R}^m)$ *to the functional* $J : \mathcal{H}(\Omega, \mathbb{R}^m) \to \mathbb{R} \cup \{\infty\}$, *i.e., the following hold true:*

(1) *If* $v_j \rightharpoonup v$ *in* $\mathcal{H}(\Omega, \mathbb{R}^m)$, *then*

$$\liminf_{j\to\infty} J_{\varepsilon_j}(v_j) \geq J(v); \tag{3.3}$$

(2) *For any* $w \in \mathcal{H}(\Omega, \mathbb{R}^m)$, *there exist* $w_j \in \mathcal{H}(\Omega, \mathbb{R}^m)$ $(j = 1, \dots)$ *such that* $w_j \rightharpoonup w$ *in* $\mathcal{H}(\Omega, \mathbb{R}^m)$ *and*

$$\lim_{j\to\infty} J_{\varepsilon_j}(w_j) = J(w).$$

THEOREM 3.3. *Let* $\Omega \subset \mathbb{R}^n$ *and* $\mathcal{H}(\Omega, \mathbb{R}^m)$ *be the same as in Theorem* 2.1. *Let* $\{\varepsilon_j\}_{j=1}^{\infty}$ *be a decreasing sequence in* $(0, 1]$ *such that* $\lim_{j\to\infty} \varepsilon_j = 0$. *For each integer* $j \geq 1$, *let* $v_j \in \mathcal{H}(\Omega, \mathbb{R}^m)$ *be a minimizer of* $J_{\varepsilon_j} : \mathcal{H}(\Omega, \mathbb{R}^m) \to \mathbb{R}$. *Then, there is a subsequence* $\{v_{j_i}\}_{i=1}^{\infty}$ *of* $\{v_j\}_{j=1}^{\infty}$ *and* $v \in \mathcal{H}(\Omega, \mathbb{R}^m)$ *that satisfy the following properties:*

(1) *As* $i \to \infty$, $v_{j_i} \to v$ (*strong convergence*) *in* $\mathcal{H}(\Omega, \mathbb{R}^m)$;
(2) $J(v) = \min_{w \in \mathcal{H}(\Omega, \mathbb{R}^m)} J(w)$;
(3) $\lim_{i\to\infty} \min_{w \in \mathcal{H}(\Omega, \mathbb{R}^m)} J_{\varepsilon_{j_i}}(w) = \min_{w \in \mathcal{H}(\Omega, \mathbb{R}^m)} J(w)$.

COROLLARY 3.1. *Let* $\Omega \subset \mathbb{R}^n$ *and* $\mathcal{H}(\Omega, \mathbb{R}^m)$ *be the same as in Theorem* 2.1.

(1) *Let* $\{\varepsilon_j\}_{j=1}^{\infty}$ *be a decreasing sequence in* $(0, 1]$ *such that* $\lim_{j\to\infty} \varepsilon_j = 0$. *For each integer* $j \geq 1$, *let* $u_j \in \mathcal{H}(\Omega, \mathbb{R}^m)$ *be a minimizer of* $I_{\varepsilon_j} : \mathcal{H}(\Omega, \mathbb{R}^m) \to \mathbb{R}$. *Then, there is a subsequence* $\{\varepsilon_{j_i} u_{j_i}\}_{i=1}^{\infty}$ *of* $\{\varepsilon_j u_j\}_{j=1}^{\infty}$ *and* $v \in \mathcal{H}(\Omega, \mathbb{R}^m)$ *that satisfy the following properties:* (i) *As* $i \to \infty$, $\varepsilon_{j_i} u_{j_i} \to v$ (*strong convergence*) *in* $\mathcal{H}(\Omega, \mathbb{R}^m)$; *and* (ii) $J(v) = \min_{w \in \mathcal{H}(\Omega, \mathbb{R}^m)} J(w)$.

(2) *We have*

$$\lim_{\varepsilon\to 0^+} \left(\min_{u \in \mathcal{H}(\Omega, \mathbb{R}^m)} I_\varepsilon(u) - \log \varepsilon \right) = \sup_{0 < \varepsilon \leq 1} \left(\min_{u \in \mathcal{H}(\Omega, \mathbb{R}^m)} I_\varepsilon(u) - \log \varepsilon \right) = \min_{w \in \mathcal{H}(\Omega, \mathbb{R}^m)} J(w).$$

We need several lemmas to prove our results.

LEMMA 3.1. *Let* $E \subset \mathbb{R}^n$ *be Lebesgue measurable with* $0 < |E| < \infty$. *Suppose* $g_j \to g$ *in* $L^1(E)$ *and* $\left\{\int_E \log |g_j|\, dx\right\}_{j=1}^{\infty}$ *is bounded. Then,* $\log |g| \in L^1(E)$ *and*

$$\liminf_{j\to\infty} \left(-\int_E \log |g_j|\, dx \right) \geq -\int_E \log |g|\, dx. \tag{3.4}$$

Proof. By the fact that $\log s \le (1/e)s$ for all $s > 0$, we have for each integer $j \ge 1$ that

$$\begin{aligned}\int_E |\log|g_j|\,|\,dx &= \int_{\{x\in E:|g_j(x)|\ge 1\}} \log|g_j|\,dx - \int_{\{x\in E:|g_j(x)|<1\}} \log|g_j|\,dx \\ &= 2\int_{\{x\in E:|g_j(x)|\ge 1\}} \log|g_j|\,dx - \int_E \log|g_j|\,dx \\ &\le \frac{2}{e}\int_E |g_j|\,dx - \int_E \log|g_j|\,dx. \end{aligned} \tag{3.5}$$

Since both $\{\int_E |g_j|\,dx\}_{j=1}^\infty$ and $\{\int_E \log|g_j|\,dx\}_{j=1}^\infty$ are bounded, we thus have

$$\sup_{j\ge 1}\int_E |\log|g_j|\,|\,dx < \infty. \tag{3.6}$$

Since $g_j \to g$ in $L^1(E)$, there exists a subsequence $\{g_{j_i}\}_{i=1}^\infty$ of $\{g_j\}_{j=1}^\infty$ such that $g_{j_i}(x) \to g(x)$ as $i \to \infty$ for a.e. $x \in E$. Consequently, by Fatou's Lemma and (3.6),

$$0 \le \int_E |\log|g|\,|\,dx = \int_E \liminf_{i\to\infty} |\log|g_{j_i}|\,|\,dx \le \liminf_{i\to\infty}\int_E |\log|g_{j_i}|\,|\,dx < \infty. \tag{3.7}$$

This implies that $\log|g| \in L^1(E)$, and, in particular, $|\{x \in E : g(x) = 0\}| = 0$.

For any $\sigma \in (0,1)$, we denote $S_\sigma = \{x \in E : 0 < |g(x)| \le \sigma\}$ and $m_\sigma = |S_\sigma|$. Since $|\log|g|\,| \ge |\log\sigma|$ on S_σ for any $\sigma \in (0,1)$, we have by (3.7) that

$$m_\sigma = \int_{S_\sigma} dx \le \int_{S_\sigma} \frac{|\log|g|\,|}{|\log\sigma|}\,dx \le \frac{1}{|\log\sigma|}\int_E |\log|g|\,|\,dx \to 0 \qquad \text{as } \sigma \to 0^+. \tag{3.8}$$

Thus, by (3.7), (3.8), and the absolute continuity of Lebesgue integrals, we obtain

$$\left|\int_{S_\sigma} \log|g|\,dx\right| \le \int_{S_\sigma} |\log|g|\,|\,dx \to 0 \qquad \text{as } \sigma \to 0^+. \tag{3.9}$$

Now, for each integer $j \ge 1$, we have by the fact that $-\log(\cdot)$ is convex and Jensen's inequality that

$$\begin{aligned} -\int_{S_\sigma} \log|g_j|\,dx &= -m_\sigma \fint_{S_\sigma} \log|g_j|\,dx \ge -m_\sigma \log\left(\fint_{S_\sigma} |g_j|\,dx\right) \\ &\ge m_\sigma \log m_\sigma - m_\sigma \log\left(\max_{i\ge 1}\|g_i\|_{L^1(E)}\right), \end{aligned} \tag{3.10}$$

in which $\max_{i\ge1}\|g_i\|_{L^1(E)} > 0$, since $g_i \to g$ in $L^1(E)$ as $i \to \infty$ and $\|g\|_{L^1(E)} \ne 0$. Thus, by (3.10) and (3.8),

$$\begin{aligned} \liminf_{j\to\infty}\left(-\int_{S_\sigma} \log|g_j|\,dx\right) &\ge m_\sigma \log m_\sigma - m_\sigma \log\left(\max_{i\ge1}\|g_i\|_{L^1(E)}\right) \\ &\to 0 \qquad \text{as } \sigma \to 0^+. \end{aligned} \tag{3.11}$$

Let $\delta > 0$. By (3.9) and (3.11), there exits $\sigma_0 \in (0,1)$ such that

$$\liminf_{j\to\infty}\left(-\int_{S_{\sigma_0}} \log|g_j|\,dx\right) \ge -\int_{S_{\sigma_0}} \log|g|\,dx - \delta. \tag{3.12}$$

Denoting $T_0 = \{x \in E : |g(x)| > \sigma_0\}$, we have by the fact that $\log(1+s) \le s$ for any $s \ge 0$ that

$$\begin{aligned}
&\left| \int_{T_0} \log |g_j| \, dx - \int_{T_0} \log |g| \, dx \right| \le \int_{T_0} \left| \log \frac{|g_j|}{|g|} \right| dx \\
&\le \int_{T_0} \log \left(1 + \left| \frac{|g_j| - |g|}{|g|} \right| \right) dx \le \int_{T_0} \frac{|g_j - g|}{\sigma_0} dx \\
&\le \frac{1}{\sigma_0} \|g_j - g\|_{L^1(E)} \to 0 \qquad \text{as } j \to \infty. \qquad (3.13)
\end{aligned}$$

It follows from (3.12) and (3.13) that

$$\liminf_{j\to\infty} \left(- \int_E \log |g_j| \, dx \right) \ge - \int_E \log |g| \, dx - \delta,$$

which implies (3.4) by the arbitrariness of $\delta > 0$. □

LEMMA 3.2. *Let $E \subset \mathbb{R}^n$ be Lebesgue measurable with $0 < |E| < \infty$ and $h \in L^1(E)$. Let $\{\varepsilon_j\}_{j=1}^\infty$ be a decreasing sequence in $(0,1]$ such that $\varepsilon_j \to 0$ as $j \to \infty$. Then,*

$$\lim_{j\to\infty} \int_E \log \sqrt{\varepsilon_j^2 + |h|^2} \, dx = \int_E \log |h| \, dx. \qquad (3.14)$$

Proof. Suppose first that $\int_E \log |h| \, dx = -\infty$. Set

$$\zeta_j = \int_E \log \sqrt{\varepsilon_j^2 + |h|^2} \, dx \qquad j = 1, \dots .$$

Then, $\{\zeta_j\}_{j=1}^\infty$ is a decreasing sequence. Thus, either $\lim_{j\to\infty} \zeta_j = -\infty$, leading to (3.14) in this case; or $\lim_{j\to\infty} \zeta_j$ exists and is finite. Suppose the latter were true. Then, $\{\zeta_j\}_{j=1}^\infty$ would be bounded from below. By the fact that $\log s \le (1/e)s$ for any $s > 0$, we have for any $j \ge 1$ that

$$\zeta_j \le \int_E \log \sqrt{1 + |h|^2} \, dx \le \frac{1}{e} \int_E \sqrt{1 + |h|^2} \, dx \le \frac{1}{e} \int_E (1 + |h|) \, dx < \infty. \qquad (3.15)$$

Thus, the sequence $\{\zeta_j\}_{j=1}^\infty$ is also bounded from above. In addition, $\sqrt{\varepsilon_j^2 + |h|^2} \to |h|$ in $L^1(E)$ as $j \to \infty$. Therefore, by Lemma 3.1, $\int_E \log |h| \, dx$ would be finite, leading to a contradiction in this case.

Suppose now that $\int_E \log |h| \, dx > -\infty$. Replacing g_j by h in (3.5), we obtain that $\log |h| \in L^1(E)$. By (3.15), $\log \sqrt{1 + |h|^2} \in L^1(E)$. Since for each $j \ge 1$,

$$\log |h| \le \log \sqrt{\varepsilon_j^2 + |h|^2} \le \log \sqrt{1 + |h|^2} \qquad \text{a.e. } E,$$

we thus obtain (3.14) in this case by Lebesgue's Dominated Convergence Theorem. □

Proof of Theorem 3.1. Let $\tau = \inf_{v \in \mathcal{H}(\Omega, \mathbb{R}^m)} J(v)$. Let $f : \overline{\Omega} \to \mathbb{R}$ be the Lipschitz-continuous function constructed in Lemma 2.2. Define $\hat{v} : \overline{\Omega} \to \mathbb{R}^m$ by $\hat{v} = f e_1$, where $e_1 = (1, 0, \dots, 0) \in \mathbb{R}^m$. Then, $\hat{v} \in \mathcal{H}(\Omega, \mathbb{R}^m)$ and $J(\hat{v}) < \infty$. Thus, $\tau < \infty$.

Since $(1/s)\log s \to 0$ as $s \to \infty$, there exists $R = R(\Omega) > 1$ such that

$$\log s \le \frac{s}{2C_0^2} \qquad \forall s \ge R, \tag{3.16}$$

where $C_0 > 0$ is the constant in the Poincaré inequality (2.18). Consequently, by (3.16) and the Poincaré inequality (2.18),

$$\begin{aligned}
J(v) &\ge \frac{1}{2}\fint_\Omega |\nabla v|^2 dx - \frac{1}{|\Omega|}\int_{\{x\in\Omega:|v|\ge 1\}} \log|v|\,dx \\
&= \frac{1}{2}\fint_\Omega |\nabla v|^2 dx - \frac{1}{2|\Omega|}\int_{\{x\in\Omega:1\le|v|^2\le R\}} \log\left(|v|^2\right)\,dx \\
&\quad - \frac{1}{2|\Omega|}\int_{\{x\in\Omega:|v|^2>R\}} \log\left(|v|^2\right)dx \\
&\ge \frac{1}{2}\fint_\Omega |\nabla v|^2 dx - \frac{1}{2|\Omega|}\int_{\{x\in\Omega:1\le|v|^2\le R\}} \log R\,dx - \frac{1}{4|\Omega|C_0^2}\int_{\{x\in\Omega:|v|^2>R\}} |v|^2 dx \\
&\ge \frac{1}{2}\fint_\Omega |\nabla v|^2 dx - \frac{1}{4C_0^2}\fint_\Omega |v|^2 dx - \frac{1}{2}\log R \\
&\ge \frac{1}{4}\fint_\Omega |\nabla v|^2 dx - \frac{1}{2}\log R \qquad \forall v \in \mathcal{H}(\Omega,\mathbb{R}^m).
\end{aligned} \tag{3.17}$$

This implies that $\tau > -\infty$. Hence, (3.1) is proved.

Let $\{v_j\}_{j=1}^\infty$ be an infimizing sequence of $J : \mathcal{H}(\Omega,\mathbb{R}^m) \to \mathbb{R}\cup\{\infty\}$. It follows from (3.17) and (2.18) that $\{v_j\}_{j=1}^\infty$ is bounded in $\mathcal{H}(\Omega,\mathbb{R}^m)$. Thus, up to a subsequence, $v_j \rightharpoonup v$ in $H^1(\Omega,\mathbb{R}^m)$ and $v_j \to v$ in $L^2(\Omega,\mathbb{R}^m)$ as $j \to \infty$ for some $v \in H^1(\Omega,\mathbb{R}^m)$. We have $v \in \mathcal{H}(\Omega,\mathbb{R}^m)$, since $\mathcal{H}(\Omega,\mathbb{R}^m)$ is weakly closed in $H^1(\Omega,\mathbb{R}^m)$.

As in the proof of Theorem 2.1, cf. (2.21), we have

$$\liminf_{j\to\infty} \fint_\Omega |\nabla v_j|^2 dx \ge \fint_\Omega |\nabla v|^2 dx. \tag{3.18}$$

Since $\{J(v_j)\}_{j=1}^\infty$ and $\{\|v_j\|\}_{j=1}^\infty$ are both bounded, the sequence

$$\left\{\int_\Omega \log|v_j|\,dx\right\}_{j=1}^\infty = \left\{\int_\Omega \frac{1}{2}|\nabla v_j|^2 dx - |\Omega| J(v_j)\right\}_{j=1}^\infty$$

is bounded. Thus, by Lemma 3.1, $\log|v| \in L^1(\Omega)$ and

$$\liminf_{j\to\infty}\left(-\fint_\Omega \log|v_j|\,dx\right) \ge -\fint_\Omega \log|v|\,dx. \tag{3.19}$$

Now, (3.2) follows from (3.18), (3.19), and the fact that $\{v_j\}_{j=1}^\infty$ is an infimizing sequence of $J : \mathcal{H}(\Omega,\mathbb{R}^m) \to \mathbb{R}\cup\{\infty\}$. □

Remark 3.1. In the case that $\Omega = \Pi_{i=1}^n (a_i, b_i)$ with $-\infty < a_i < b_i < \infty$ $(i = 1,\dots,n)$ and the set of admissible functions is $\{u \in H^1_{\rm per}(\Omega,\mathbb{R}^m) : \fint_\Omega u\,dx = 0\}$, we can still prove that $\tau < \infty$ by the same argument with f replaced by $\sin(2\pi x_1/(b_1 - a_1))$.

Proof of Theorem 3.2.

(1) Suppose $v_j \rightharpoonup v$ in $\mathcal{H}(\Omega,\mathbb{R}^m)$. We may assume that $\liminf_{j\to\infty} J_{\varepsilon_j}(v_j) < \infty$, otherwise (3.3) holds true trivially.

Notice that for each integer $j \geq 1$,

$$J_{\varepsilon_j}(v_j) \geq \fint_\Omega \left[\frac{1}{2}|v_j|^2 - \frac{1}{2}\log\left(1+|v_j|^2\right)\right] dx = I_1(v_j). \tag{3.20}$$

Thus, by (2.20) with $\varepsilon = 1$, the sequence $\{J_{\varepsilon_j}(v_j)\}_{j=1}^\infty$ is bounded from below. Let $\{v_{j_i}\}_{i=1}^\infty$ be a subsequence of $\{v_j\}_{j=1}^\infty$ such that $v_{j_i} \to v$ in $L^2(\Omega,\mathbb{R}^m)$ as $i\to\infty$ and

$$\liminf_{j\to\infty} J_{\varepsilon_j}(v_j) = \lim_{i\to\infty} J_{\varepsilon_{j_i}}(v_{j_i}) < \infty. \tag{3.21}$$

Then, the sequence $\left\{J_{\varepsilon_{j_i}}(v_{j_i})\right\}_{i=1}^\infty$ is bounded, from both above and below. Hence,

$$\left\{\int_\Omega \log\sqrt{\varepsilon_{j_i}^2+|v_{j_i}|^2}\,dx\right\}_{i=1}^\infty = \left\{\int_\Omega \frac{1}{2}|\nabla v_{j_i}|^2 dx - |\Omega| J_{\varepsilon_{j_i}}(v_{j_i})\right\}_{i=1}^\infty$$

is bounded. Moreover, $\sqrt{\varepsilon_{j_i}^2+|v_{j_i}|^2} \to |v|$ in $L^2(\Omega)$ as $i\to\infty$, since

$$\left|\sqrt{\varepsilon_{j_i}^2+|v_{j_i}|^2}-|v|\right|^2 = \varepsilon_{j_i}^2+|v_{j_i}|^2+|v|^2-2|v|\sqrt{\varepsilon_{j_i}^2+|v_{j_i}|^2} \leq \varepsilon_{j_i}^2+|v_{j_i}-v|^2 \qquad \forall i\geq 1.$$

Consequently, it follows from Lemma 3.1 that $\log|v| \in L^1(\Omega)$ and

$$\liminf_{i\to\infty}\left(-\fint_\Omega \log\sqrt{\varepsilon_{j_i}^2+|v_{j_i}|^2}dx\right) \geq -\fint_\Omega \log|v|\,dx. \tag{3.22}$$

As before, we also have

$$\liminf_{j\to\infty}\fint_\Omega |\nabla v_j|^2 dx \geq \fint_\Omega |\nabla v|^2 dx, \tag{3.23}$$

cf. (2.21) and (3.18). Now, (3.3) follows from (3.21)–(3.23).

(2) Let $w\in\mathcal{H}(\Omega,\mathbb{R}^m)$ and $w_j = w$ for all integers $j\geq 1$. The assertion of this part follows from Lemma 3.2. □

Proof of Theorem 3.3. For each integer $j\geq 1$, $\varepsilon_j v_j$ is a minimizer of $I_{\varepsilon_j}: \mathcal{H}(\Omega,\mathbb{R}^m)\to\mathbb{R}$. Thus, by (3) of Theorem 2.1, $\{v_j\}_{j=1}^\infty$ is bounded in $\mathcal{H}(\Omega,\mathbb{R}^m)$. Hence, it has a subsequence $\{v_{j_i}\}_{i=1}^\infty$ such that $v_{j_i} \rightharpoonup v$ in $\mathcal{H}(\Omega,\mathbb{R}^m)$, $v_{j_i}\to v$ in $L^2(\Omega,\mathbb{R}^m)$, and $v_{j_i}(x)\to v(x)$ for a.e. $x\in\Omega$ as $i\to\infty$ for some $v\in\mathcal{H}(\Omega,\mathbb{R}^m)$.

Since v_{j_i} is a minimizer of $J_{\varepsilon_{j_i}}:\mathcal{H}(\Omega,\mathbb{R}^m)\to\mathbb{R}$, we have for any $w'\in\mathcal{H}(\Omega,\mathbb{R}^m)$ that

$$J_{\varepsilon_{j_i}}(w') \geq J_{\varepsilon_{j_i}}(v_{j_i}) = \min_{w\in\mathcal{H}(\Omega,\mathbb{R}^m)} J_{\varepsilon_{j_i}}(w) \qquad \forall i\geq 1.$$

Consequently, we have by Lemma 3.2 and (1) of Theorem 3.2 that

$$J(w') = \lim_{i\to\infty} J_{\varepsilon_{j_i}}(w') \geq \limsup_{i\to\infty} J_{\varepsilon_{j_i}}(v_{j_i}) \geq \liminf_{i\to\infty} J_{\varepsilon_{j_i}}(v_{j_i}) \geq J(v). \tag{3.24}$$

This proves (2). Setting $w' = v$ in (3.24), we obtain that

$$\lim_{i\to\infty}\min_{w\in\mathcal{H}(\Omega,\mathbb{R}^m)} J_{\varepsilon_{j_i}}(w) = \lim_{i\to\infty} J_{\varepsilon_{j_i}}(v_{j_i}) = J(v) = \min_{w\in\mathcal{H}(\Omega,\mathbb{R}^m)} J(v), \tag{3.25}$$

proving (3).

Notice that the sequence

$$\left\{\int_\Omega \log\sqrt{\varepsilon_{j_i}^2+|v_{j_i}|^2}\,dx\right\}_{i=1}^{\infty}=\left\{\int_\Omega \frac{1}{2}|\nabla v_{j_i}|^2dx-|\Omega|J_{\varepsilon_{j_i}}(v_{j_i})\right\}_{i=1}^{\infty}$$

is bounded. Moreover, $\sqrt{\varepsilon_{j_i}^2+|v_{j_i}|^2}\to|v|$ in $L^2(\Omega)$ as $i\to\infty$. Consequently, we have by Lemma 3.1 that $\log|v|\in L^1(\Omega)$ and

$$\liminf_{i\to\infty}\left(-\int_\Omega \log\sqrt{\varepsilon_{j_i}^2+|v_{j_i}|^2}\,dx\right)\geq-\int_\Omega\log|v|\,dx. \tag{3.26}$$

Since $v_{j_i}\rightharpoonup v$ in $\mathcal{H}(\Omega,\mathbb{R}^m)$ as $i\to\infty$, we also have (cf. (2.21))

$$\liminf_{i\to\infty}\fint_\Omega|\nabla v_{j_i}|^2dx\geq\fint_\Omega|\nabla v|^2dx. \tag{3.27}$$

Now, it follows from (3.25)–(3.27) that

$$\begin{aligned}0&=\lim_{i\to\infty}J_{\varepsilon_{j_i}}(v_{j_i})-J(v)\\&\geq\left[\liminf_{i\to\infty}\fint_\Omega\frac{1}{2}|\nabla v_{j_i}|^2dx-\fint_\Omega\frac{1}{2}|\nabla v|^2dx\right]\\&\qquad+\left[\liminf_{i\to\infty}\left(-\fint_\Omega\log\sqrt{\varepsilon_{j_i}^2+|v_{j_i}|^2}\,dx\right)-\left(-\fint_\Omega\log|v|\,dx\right)\right]\\&\geq 0,\end{aligned}$$

which, together with (3.26) and (3.27), implies that

$$\liminf_{i\to\infty}\fint_\Omega|\nabla v_{j_i}|^2dx=\fint_\Omega|\nabla v|^2dx.$$

Thus,

$$\liminf_{i\to\infty}\int_\Omega|\nabla v_{j_i}-\nabla v|^2dx=\liminf_{i\to\infty}\int_\Omega\left(|\nabla v_{j_i}|^2+|\nabla v|^2-2\nabla v_{j_i}\cdot\nabla v\right)dx=0.$$

This and the Poincaré inequality (2.18) imply the strong convergence of a subsequence of $\{v_{j_i}\}_{i=1}^\infty$ to v in $\mathcal{H}(\Omega,\mathbb{R}^m)$. Thus (1) is proved. □

Proof of Corollary 3.1. Notice for any integer $j\geq1$ that u_j is a minimizer of $I_{\varepsilon_j}:\mathcal{H}(\Omega,\mathbb{R}^m)\to\mathbb{R}$ if and only if that $v_j:=\varepsilon_j u_j$ is a minimizer of $J_{\varepsilon_j}:\mathcal{H}(\Omega,\mathbb{R}^m)\to\mathbb{R}$. Thus, (1) follows from (1) and (2) of Theorem 3.3; (3) follows from (2) of Theorem 2.1 and (3) of Theorem 3.3. □

4. The scalar Dirichlet boundary-value problem. If the order parameter is a scalar function that satisfies the homogeneous Dirichlet boundary condition, then the solution of the corresponding limiting variational problem of infimizing $J:H_0^1(\Omega)\to\mathbb{R}\cup\{\infty\}$ can be well characterized. In what follows, we denote

$$\mathcal{H}_+(\Omega)=\left\{v\in H_0^1(\Omega):v(x)\geq0\text{ a.e. }x\in\Omega\right\}.$$

As usual, we also denote by $C_c^\infty(\Omega)$ the set of all $C^\infty(\Omega)$-functions that are compactly supported in Ω.

THEOREM 4.1. *Let $\Omega \subset \mathbb{R}^n$ be a bounded domain with a Lipschitz-continuous boundary $\partial\Omega$. Then, there exists $v_+ \in \mathcal{H}_+(\Omega)$ that satisfies the following properties:*

(1) *The function v_+ is the unique minimizer of $J : \mathcal{H}_+(\Omega) \to \mathbb{R} \cup \{\infty\}$. Moreover, $v_+ \in C^\infty(\Omega)$, $v_+ > 0$ in Ω,*

$$\Delta v_+ + \frac{1}{v_+} = 0 \qquad \text{in } \Omega, \tag{4.1}$$

and

$$\fint_\Omega |\nabla v_+|^2 dx = 1; \tag{4.2}$$

(2) *The two functions v_+ and $v_- := -v_+$ are the unique minimizers of $J : H_0^1(\Omega) \to \mathbb{R} \cup \{\infty\}$.*

To prove this theorem, we need the following result.

LEMMA 4.1. *Let $\Omega \subset \mathbb{R}^n$ be the same as in Theorem 4.1. Let $\varepsilon \in (0, 1]$. There exists $v_{\varepsilon+} \in \mathcal{H}_+(\Omega)$ such that*

$$J_\varepsilon(v_{\varepsilon+}) = \min_{w \in \mathcal{H}_+(\Omega)} J_\varepsilon(w) = \min_{w \in H_0^1(\Omega)} J_\varepsilon(w). \tag{4.3}$$

Moreover, $\Delta v_{\varepsilon+} \le 0$ in Ω in the sense of distributions, i.e.,

$$\int_\Omega \nabla v_{\varepsilon+} \cdot \nabla \varphi \, dx \ge 0 \qquad \forall \varphi \in C_c^\infty(\Omega) \text{ with } \varphi \ge 0 \text{ in } \Omega, \tag{4.4}$$

and

$$\fint_\Omega |\nabla v_{\varepsilon+}|^2 dx = \fint_\Omega \frac{v_{\varepsilon+}^2}{\varepsilon^2 + v_{\varepsilon+}^2} \, dx. \tag{4.5}$$

Proof. Setting $\xi_\varepsilon = \inf_{w \in \mathcal{H}_+(\Omega)} J_\varepsilon(w)$, we have by Theorem 2.1 that

$$-\infty < \min_{w \in H_0^1(\Omega)} I_\varepsilon(w) - \log \varepsilon = \min_{w \in H_0^1(\Omega)} J_\varepsilon(w) \le \xi_\varepsilon \le J_\varepsilon(0) = -\log \varepsilon < \infty.$$

Let $\{w_j\}_{j=1}^\infty \subset \mathcal{H}_+(\Omega)$ be an infimizing sequence of $J_\varepsilon : \mathcal{H}_+(\Omega) \to \mathbb{R}$. Since

$$J_\varepsilon(w_j) \ge \fint_\Omega \left[\frac{1}{2} |\nabla w_j|^2 - \frac{1}{2} \log \left(1 + |w_j|^2\right) \right] dx = I_1(w_j) \qquad \forall j \ge 1,$$

we see from (2.20) with $\mathbb{R}^m = \mathbb{R}$ and $\varepsilon = 1$, and the Poincaré inequality, that the sequence $\{w_j\}_{j=1}^\infty$ is bounded in $H^1(\Omega)$. Thus, it has a subsequence $\{w_{j_i}\}_{i=1}^\infty$ such that $w_{j_i} \rightharpoonup v_{\varepsilon+}$ in $H^1(\Omega)$ and $w_{j_i} \to v_{\varepsilon+}$ in $L^2(\Omega)$ as $i \to \infty$ for some $v_{\varepsilon+} \in H^1(\Omega)$. We have in fact $v_+ \in \mathcal{H}_+(\Omega)$, since $\mathcal{H}_+(\Omega)$ is convex and strongly closed, and hence weakly closed, in $H^1(\Omega)$. Noting that $\varepsilon > 0$ is fixed, by the same argument in the proof of Theorem 2.1, cf. (2.21) and (2.22), we obtain that $J_\varepsilon(v_{\varepsilon+}) = \xi_\varepsilon$.

For any $w \in H_0^1(\Omega)$, we have $|w| \in \mathcal{H}_+(\Omega)$ and $J_\varepsilon(|w|) = J_\varepsilon(w)$, cf. Lemmas 7.6 and 7.7 in [8]. Thus,

$$\min_{w \in H_0^1(\Omega)} J_\varepsilon(w) \le \xi_\varepsilon = J_\varepsilon(v_{\varepsilon+}) \le J_\varepsilon(|w|) = J_\varepsilon(w) \qquad \forall w \in H_0^1(\Omega).$$

This leads to (4.3).

Since $v_{\varepsilon+}$ is a minimizer of $J_\varepsilon : H_0^1(\Omega) \to \mathbb{R}$, the first variation of J_ε at $v_{\varepsilon+}$ vanishes, i.e.,

$$\delta J(v_{\varepsilon+})(\varphi) = \int_\Omega \left(\nabla v_{\varepsilon+} \cdot \nabla \varphi - \frac{v_{\varepsilon+}\varphi}{\varepsilon^2 + v_{\varepsilon+}^2} \right) dx = 0 \qquad \forall \varphi \in H_0^1(\Omega). \tag{4.6}$$

This, together with the fact that $v_{\varepsilon+} \geq 0$ a.e. Ω and that $C_c^\infty(\Omega) \subset H_0^1(\Omega)$, implies (4.4). Finally, setting $\varphi = v_{\varepsilon+}$ in (4.6), we obtain (4.5). □

Proof of Theorem 4.1.

(1) By Lemma 4.1, there exists $v_j \in \mathcal{H}_+(\Omega)$ for each integer $j \geq 1$ such that

$$J_{1/j}(v_j) = \min_{w \in \mathcal{H}_+(\Omega)} J_{1/j}(w) = \min_{w \in H_0^1(\Omega)} J_{1/j}(w), \tag{4.7}$$

$$\Delta v_j \leq 0 \qquad \text{in } \Omega \tag{4.8}$$

in the sense of distributions, cf. (4.4), and

$$⨍_\Omega |\nabla v_j|^2 dx = ⨍_\Omega \frac{v_j^2}{j^{-2} + v_j^2}\, dx. \tag{4.9}$$

By (4.7) and Theorem 3.3, there exists a subsequence $\{v_{j_i}\}_{i=1}^\infty$ of $\{v_j\}_{j=1}^\infty$ such that $v_{j_i} \to v_+$ (strong convergence) in $H^1(\Omega)$ and $v_{j_i}(x) \to v_+(x)$ a.e. $x \in \Omega$ as $i \to \infty$ for some $v_+ \in H_0^1(\Omega)$ that is a minimizer of $J : H_0^1(\Omega) \to \mathbb{R} \cup \{\infty\}$. Since $\mathcal{H}_+(\Omega)$ is weakly closed in $H^1(\Omega)$, $v_+ \in \mathcal{H}_+(\Omega)$. Moreover, since $\mathcal{H}_+(\Omega) \subset H_0^1(\Omega)$, v_+ is also a minimizer of $J : \mathcal{H}_+(\Omega) \to \mathbb{R} \cup \{\infty\}$. The fact that v_+ is the unique minimizer of $J : \mathcal{H}_+(\Omega) \to \mathbb{R} \cup \{\infty\}$ follows from the strict convexity of $J : \mathcal{H}_+(\Omega) \to \mathbb{R} \cup \{\infty\}$.

Let $\eta_+ = \operatorname{ess\,inf}_\Omega v_+$. Since $v_+ \in \mathcal{H}_+(\Omega)$, $v_+ \geq 0$ a.e. Ω. Thus, $\eta_+ \geq 0$. If $\eta_+ > 0$, then there exists $\phi_j \in C^\infty(\overline{\Omega})$ for each integer $j \geq 1$ such that $\min_{\overline{\Omega}} \phi_j \geq \eta_+/2$ $(j = 1, \dots)$ and $\phi_j \to v_+$ in $H^1(\Omega)$ as $j \to \infty$. The trace of v_+, which is the limit of $\{\phi_j\}_{j=1}^\infty$ in $L^2(\partial\Omega)$, would then be positive a.e. $\partial\Omega$. This contradicts the fact that $v_+ \in H_0^1(\Omega)$. Thus, $\operatorname{ess\,inf}_\Omega v_+ = 0$. Since $v_+ \geq 0$ is a minimizer of $J : \mathcal{H}_+(\Omega) \to \mathbb{R} \cup \{\infty\}$, $\log v_+ \in L^1(\Omega)$. Thus, we also have that $v_+(x) > 0$ a.e. $x \in \Omega$. In particular, v_+ is not a constant in Ω. Since $v_{j_i} \to v_+$ in $H^1(\Omega)$ as $i \to \infty$, we obtain by (4.8) that $\Delta v_+ \geq 0$ in Ω in the sense of distributions. Applying the Strong Maximum Principle to $L = \Delta$ and $u = v_+$ in Theorem 8.19 in [8], we see that $\operatorname{ess\,inf}_B v_+ > 0$ for any ball $B \subset\subset \Omega$. (Here and below, the notation $\omega \subset\subset \Omega$ means $\overline{\omega} \subset \Omega$.) For any open set $\Omega' \subset \mathbb{R}^n$ with $\Omega' \subset\subset \Omega$, we can cover $\overline{\Omega'}$ by finitely many balls $B_i \subset\subset \Omega$, where $i = 1, \dots, N$ for some integer $N \geq 1$, so that $\operatorname{ess\,inf}_{B_i} v_+ > 0$ for all i $(1 \leq i \leq N)$. Thus, $\delta' := \operatorname{ess\,inf}_{\Omega'} v_+ > 0$, and hence $1/v_+ \in L^\infty(\Omega')$.

Let $\varphi \in C_c^\infty(\Omega)$ with $\operatorname{supp} \varphi \subset \Omega'$ and consider $q(\delta) := J(v_+ + \delta\varphi)$ for $\delta \in \mathbb{R}$. If $|\delta| \sup_{\Omega'} |\varphi| < \delta'$, then $v_+ + \delta\varphi > 0$ a.e. in Ω', and

$$\begin{aligned} q(\delta) &= ⨍_\Omega \left[\frac{1}{2} |\nabla v_+ + \delta\varphi|^2 - \log |v_+ + \delta\varphi| \right] dx \\ &= ⨍_\Omega \frac{1}{2} |\nabla v_+ + \delta\varphi|^2 dx - \frac{1}{|\Omega|} \int_{\Omega \setminus \Omega'} \log v_+ \, dx - \frac{1}{|\Omega|} \int_{\Omega'} \log(v_+ + \delta\varphi) dx. \end{aligned}$$

Since v_+ is a minimizer of $J : H_0^1(\Omega) \to \mathbb{R} \cup \{\infty\}$, $q(\delta)$ is minimized at $\delta = 0$. Thus, $q'(0) = 0$. This leads to

$$\Delta v_+ + \frac{1}{v_+} = 0 \qquad \text{in } \Omega' \tag{4.10}$$

in the sense of distributions.

Let $\Omega'' \subset \mathbb{R}^n$ be an open set such that $\Omega'' \subset\subset \Omega' \subset\subset \Omega$. Denoting $H^k(D) = W^{k,2}(D)$ the usual Sobolev space for an open set $D \subset \mathbb{R}^n$ and an integer $k \geq 1$ [1, 8], we claim:

($*$) For any integer $k \geq 1$, there exists an open set $\Omega_k \subset \mathbb{R}^n$ such that $\Omega'' \subset\subset \Omega_k \subset\subset \Omega'$ and $v_+ \in H^{k+1}(\Omega_k)$.

Let $f := 1/v_+ \in L^\infty(\Omega')$. By (4.10), $v_+ \in H^1(\Omega')$ is a weak solution of $\Delta v_+ = f$ in Ω', i.e.,

$$\int_{\Omega'} \nabla v_+ \cdot \nabla \varphi \, dx = \int_{\Omega'} f\varphi \, dx \qquad \forall \varphi \in C_c^\infty(\Omega'). \tag{4.11}$$

By the regularity theory of elliptic boundary-value problems, cf. Theorem 8.8 in [8], we have $v_+ \in H^2(\Omega_1)$ for any open set $\Omega_1 \subset \mathbb{R}^n$ such that $\Omega'' \subset\subset \Omega_1 \subset\subset \Omega'$. Thus, the statement ($*$) is true for $k = 1$.

Suppose the statement ($*$) is also true for a general $k \geq 1$. Then, $\partial^k f \in H^1(\Omega_k)$ for any partial derivative ∂^k of order k. Replacing φ in (4.11) by $\partial^k \psi$ for any $\psi \in C_c^\infty(\Omega_k)$, one easily verifies that

$$\int_{\Omega_k} \nabla \partial^k v_+ \cdot \nabla \psi \, dx = \int_{\Omega_k} \partial^k f \psi \, dx \qquad \forall \psi \in C_c^\infty(\Omega_k),$$

i.e., $\partial^k v_+ \in H^1(\Omega_k)$ satisfies $\Delta \partial^k v_+ = \partial^k f$ in Ω_k in the sense of distributions. Therefore, by the same regularity result, there exists an open set $\Omega_{k+1} \subset \mathbb{R}^n$ with $\Omega'' \subset\subset \Omega_{k+1} \subset\subset \Omega_k \subset\subset \Omega'$ such that $\partial^k v_+ \in H^2(\Omega_{k+1})$. By suitably enlarging Ω_{k+1} if necessary, we see that $v_+ \in H^{k+2}(\Omega_{k+1})$. Hence, the statement ($*$) is true for $k+1$. Thus, it is true for any integer $k \geq 1$.

By the statement ($*$), $v_+ \in C^\infty(\Omega'')$. It then follows from the arbitrariness of Ω'' and Ω' that $v_+ \in C^\infty(\Omega)$, and that $v_+ > 0$ in Ω, since $\operatorname{ess\,sup}_{\Omega'} v_+ > 0$ for any $\Omega' \subset\subset \Omega$. Moreover, (4.1) follows from (4.10) and the arbitrariness of $\Omega' \subset\subset \Omega$. Using the fact that $v_{j_i} \to v_+$ in $H^1(\Omega)$ and that $v_{j_i}(x) \to v_+(x) > 0$ a.e. Ω, and applying Lebesgue's Dominated Convergence Theorem, we obtain (4.2) from (4.9).

(2) Clearly, both v_+ and v_- are minimizers of $J : H_0^1(\Omega) \to \mathbb{R} \cup \{\infty\}$, cf. the proof of Lemma 4.1. Assume now $\tilde{v} \in H_0^1(\Omega)$ is a minimizer of $J : H_0^1(\Omega) \to \mathbb{R} \cup \{\infty\}$. Then, $|\tilde{v}| \in \mathcal{H}_+(\Omega)$ is a minimizer of $J : \mathcal{H}_+(\Omega) \to \mathbb{R} \cup \{\infty\}$. By (1), we must have that $|\tilde{v}| = v_+$ a.e. Ω. Thus, $|\tilde{v}| \in C^\infty(\Omega)$ and $\tilde{v} > 0$ in Ω. Consequently, we have for any ball $B \subset\subset \Omega$ that $\tilde{v}(x) > 0$ for all $x \in B$ or $\tilde{v}(x) < 0$ for all $x \in B$. Therefore, for any domain $\omega \subset\subset \Omega$, $\tilde{v}(x)$ has the same sign for each $x \in \bar{\omega}$. This implies that $\tilde{v}(x) = v_+(x)$ for all $x \in \Omega$ or $\tilde{v}(x) = v_-(x)$ for all $x \in \Omega$. □

EXISTENCE OF SOLUTIONS FOR A CLASS OF IMPACT PROBLEMS WITHOUT VISCOSITY*

JEONGHO AHN† AND DAVID E. STEWART‡

Abstract. In this paper we consider dynamic frictionless impact problems of elastic materials formulated in abstract settings. The contact conditions for the impact problem are Signorini-type complementarity conditions. Using time discretization and Galerkin approximation, we investigate the convergence of numerical fully discrete trajectories to a solution of the continuous-time problem. In this way we establish the existence of solutions for a class of impact problems, some of which have been previously studied, while others have not. Most of the impact problems to which this theory can be applied are "thick" obstacle problems, although it can also be applied to a number of boundary or "thin" obstacle problems. The crucial assumption for the theory is that the cone of possible contact forces satisfies a strong pointedness condition, which can usually be related to a Sobolev embedding condition.

Key words. impact problems, dynamic obstacle problems, complementarity conditions, strongly pointed cones

1. Introduction.

In this work, we show existence of solutions for a class of dynamic impact problems which are treated from an abstract point of view. The concrete impact problems that we discuss and that are in this class are mostly "thick" obstacle problems; the solutions are functions of time $t > 0$ and $\mathbf{x} \in \Omega \subset \mathbb{R}^d$ for some d where Ω is an open domain, and the obstacle (or constraints) are applied over a subset $\Omega_1 \subset \overline{\Omega_1} \subset \Omega$. However, it is applicable to a small number of boundary contact problems. Unfortunately these do not include the wave equation with a boundary "thin" obstacle for which existence has been shown [14] or conservation of energy where Ω is a half-space [19]; the still-open case of a nonviscous elastic body with boundary contact requires further techniques beyond those described here.

In most papers on contact mechanics, the problem is cast as a variational inequality in terms of the main variable, the solution $u(t)$. This is the approach used in [9, 10, 16, 19], for example. As a result, the contact forces $N(t)$ are removed from the formulation, and their behavior remains somewhat difficult to elucidate. In this paper, we keep the contact forces as part of a complementarity formulation. In some ways this makes our approach more complicated as we now need to obtain suitable bounds on the normal contact forces. However, it means that more is known about the contact forces.

There is another aspect where this paper differs from most others on existence of solutions in contact mechanics: we are dealing with nonviscous elasticity. Thus, without contact, energy is conserved. The introduction of visco-elasticity is useful for improving the regularity of the solution; however, it makes the contact forces less

regular [3, 22, 23]. The question of the regularity of the contact forces is important as it is closely related to the question of proving energy balances. Only if the contact forces are sufficiently regular do we expect to prove that the contact forces do no work [30]. In rigid-body dynamics the contact forces are general measures and contain Dirac-δ functions; rigid-body dynamics also requires an additional parameter, the coefficient of restitution, to determine the consequences of a single impact, and to determine if energy is (possibly) conserved.

For example, consider the simple scalar problem $u_{tt} = f(t) + N(t)$ with f an integrable function, $0 \le u(t) \perp N(t) \ge 0$ for all t. Here $\mathbf{0} \le \mathbf{a} \perp \mathbf{b} \ge \mathbf{0}$ called complementarity condition implies that $\mathbf{a}, \mathbf{b} \ge \mathbf{0}$ component-wise and $\mathbf{a}^T\mathbf{b} = 0$, where we denote vectors and matrices by bold characters. Thus $\mathbf{0} \le \mathbf{a} \perp \mathbf{b} \ge \mathbf{0}$ means that for all indexes i, either $a_i = 0$ and $b_i \ge 0$, or $a_i \ge 0$ and $b_i = 0$. If $a_i > 0$, then $b_i = 0$, and conversely if $b_i > 0$, then $a_i = 0$. In our case $u(t)$ and $N(t)$ are scalars, so for all t if there is positive separation ($u(t) > 0$), there is no contact force ($N(t) = 0$); conversely, if there is a contact force ($N(t) > 0$), then there is no separation ($u(t) = 0$). Note that $u(t)$ cannot be negative (as $u(t) < 0$ would violate the no-penetration condition) while $N(t)$ cannot be negative (as $N(t) < 0$ would imply adhesion). This can be interpreted in a weak sense by requiring that u and N are nonnegative and that $\int_0^T u(t)\, N(t)\, dt = 0$.

Suppose that $u(t_*) = 0$. Then near $t = t_*$ we can set $N(t) = N_0(t) + N_* \, \delta(t - t_*)$ where N_0 is a measure without atom at t_* and δ is the Dirac-δ function. This means that $u_t(t_*^+) = u_t(t_*^-) + N_*$. Any value of N_* that exceeds $-u_t(t_*^-) \ge 0$ is permissible as then $u_t(t_*^+) > 0$ and $u(t) > 0$ for t in some interval $(t_*, t_* + \epsilon)$. For conservation of energy or an energy balance, we need $u_t(t_*^+)^2 = u_t(t_*^-)^2$; only one value of N_* will conserve energy, and yet all values of $N_* \ge -u_t(t_*^-)$ lead to solutions of the contact conditions $0 \le u(t) \perp N(t) \ge 0$. On the other hand, if $N(t) = N_0(t)$, an integrable function, then u_t is a continuous function. Thus, if $u(t_*) = 0$ in this case, $u_t(t_*) = 0$ as well, and so $\int_B u_t(t)\, N(t)\, dt = 0$ for any Borel set B, and so the contact forces do no work.

A related question is whether there should be a coefficient of restitution, as there is in rigid-body dynamics with impact. For example, the most commonly used coefficient of restitution is the Newton, or kinematic, coefficient of restitution, which is simply the negative of the ratio of the postimpact normal velocity to the preimpact normal velocity: $-u_t(t_*^+)/u_t(t_*^-)$.

Unlike the finite-dimensional case, the presence of unbounded operators means that the velocities do not necessarily have bounded variation, and care must be taken in dealing with the limits $u_t(t_*^+)$ and $u_t(t_*^-)$ in appropriate function spaces. However, it can be done in certain situations, such as a vibrating string (subject to the one-dimensional wave equation) which can contact a rigid obstacle along a portion of its length. The wave equation with an obstacle was first constructed by Amerio and Prouse [4] and was perfectly studied by Schatzman [26]. She was able to show the existence of solutions for a concave obstacle *which conserve energy*. An essential part of this was proving that $u_t(t^+, x) = -u_t(t^-, x)$ at almost every point of contact; that is, the kinematic coefficient of restitution is 1. However, the approach taken in [26] seems difficult to generalize to other contact problems.

For the sake of concreteness, we will discuss a one-dimensional vibrating string which satisfies the wave equation, fixed at endpoints $x = 0$ and $x = l$, and where contact can occur with a fixed obstacle over most of the length of the string. (Contact near the fixed endpoints will be assumed not to occur.)

We begin with the equations of motion for a body without contact:

$$\begin{aligned} u_{tt} &= -Au + f, \\ u(0) &= u^0, \\ u_t(0) &= v^0, \end{aligned}$$

where $(\cdot)_t$ denotes differentiation with respect to t, $A\colon V \to V'$ is an elliptic self-adjoint operator, V a Hilbert space, and f a constant vector in a suitable space. The results of this paper can be extended to nonconstant f; the main technical complication being obtaining suitable energy bounds for the time discretization. Incorporating contact conditions requires an obstacle represented by φ which is applied to some space W of restricted functions, a closed convex cone $K \subset W$, and a restriction or "trace" operator $\beta\colon V \to W$ which is used to identify when the solution u is "above" the obstacle: $\beta u - \varphi \in K$. In static (frictionless) contact problems, the normal contact force appears as a kind of Lagrange multiplier $N \in K^* \subset W'$, where K^* is the dual cone given by

$$K^* = \{z \mid \langle z, w\rangle \geq 0 \quad \text{for all } w \in K\}.$$

In our dynamic contact problems, we have "$N(t) \in K^*$ for all t", which must be suitably interpreted as N may be a W'-valued measure. This is transfered to V' via the adjoint of the restriction operator $\beta^*\colon W' \to V'$.

There should be a right inverse of the restriction operator (being an extension operator) $\gamma\colon W \to V$ so that $\beta\gamma\colon W \to W$ is the identity map. Note that this means that $\gamma^*\beta^*$ is the identity map on W'. This means that β is surjective and β^* is injective.

In the case of a vibrating string, $A = -\partial^2/\partial x^2$ which is defined on $H_0^1(0,l)$; the constraint on the string is that $u(t,x) - \varphi(x) \geq 0$ for all $x \in (\delta,\, l-\delta)$ for a suitable $\delta > 0$ to avoid contact near the fixed endpoints. Take $W = H^1(\delta,\, l-\delta)$. Our restriction operator $\beta\colon V \to W$ is simply given by $\beta u = u|_{(\delta,l-\delta)}$. The set K is then $\{w \in H_0^1(\delta,\, l-\delta) \mid w(x) \geq 0 \text{ for all } x \in (\delta,\, l-\delta)\}$, and K^* is the set of all nonnegative distributions in $H^{-1}(\delta,\, l-\delta)$ (and are therefore measures on $[0,\, l]$ [13]). Provided $\varphi(0),\, \varphi(l) < 0$, the energy boundedness of solutions ensures that there is a $\delta > 0$, where $u(t,x) - \varphi(x) > 0$ for all t and $x \notin (\delta, l-\delta)$. This problem was investigated by Schatzman [26] for φ concave.

It may seem unnecessary to have separate V and W spaces in this case; we could set $V = W$ and let K be a cone of functions on $(0,l)$. However, the extension of the results to show convergence of space and time discretizations assumes that K^* is the closure of K in the dual space. This does not hold if $V = W$ as then $K = \{w \in H^1(0,l) \mid w(x) \geq 0 \text{ for all } x \in [\delta, l-\delta]\}$ but $K^* = \{z \in H^{-1}(0,l) \mid z(x) \geq 0 \text{ for } x \in [\delta, l-\delta],\ z(x) = 0 \text{ for } x \in [0,\delta) \cup (l-\delta, l]\}$.

With contact the equations of motion become

$$\begin{aligned} u_{tt} &= -Au + \beta^* N(t) + f, \\ K \ni \beta u(t) - \varphi \perp N(t) &\in K^* \quad \text{for all } t \in [0,T], \end{aligned} \tag{1.1}$$

where (1.1) is called complementarity condition and it will be explained in Remark 3.1.

The impact problems have been studied in different physical situations using different approaches. In this paper, we consider the impact problems in a more general point of view which includes these problems studied in [26] and [1], and also the

Timoshenko beam (first described in [32, 33]) with Signorini contact conditions along the beam. A recent discussion of the Timoshenko beam with impact can be found in [20]. In section 4, we describe these and other impact problems in more detail. The abstract setting is described in section 3. The time discretization is given in section 5.1, and convergence of the discrete-time trajectories to a solution of our problem is proved in section 5.2 and also convergence of fully discrete trajectories is shown in section 5.3.

2. Preliminaries and functional spaces. The spaces we work are parts of a pair of *Gelfand triples* (see, for example, [35, section 17.1] for an extensive discussion of Gelfand triples):

$$V \subset H = H' \subset V'$$
$$W \subset Z = Z' \subset W',$$

where all spaces are separable Hilbert spaces, and all inclusions are dense and compact. The *pivot spaces* H and Z are typically L^2 spaces (although over different sets) while V and W are typically Sobolev spaces. Note that for a dual pair of spaces X and X' we use $\langle \cdot, \cdot \rangle_{X' \times X}$ or $\langle \cdot, \cdot \rangle$ to denote the duality pairing between X and X'; the latter form will be used where it is clear what the dual spaces are. Also inner product $(\cdot, \cdot)_H$ is used instead of $(\cdot, \cdot)_{H \times H}$. Note that the duality pairing in a Gelfand triple must be consistent with the inner product, i.e., for any $x \in H$ and $y \in V$, $\langle x, y \rangle_{V' \times V} = (x, y)_{H \times V} = (x, y)_H$. Thus the duality pairing $\langle \cdot, y \rangle_{V' \times V}$ is the continuous extension of the linear function $(\cdot, y)_{H \times V}$ or $(\cdot, y)_H$ over the largest possible subspace of V'. See [35, section 17] for the details.

For the example of a vibrating string, the pivot spaces are $H = L^2(0, l)$ and $Z = L^2(\delta, l - \delta)$; the duality pairing over H and V with V' is given by

$$\langle f, g \rangle = \int_0^l f(x)\, g(x)\, dx.$$

In order to state our existence results, we need scales of *interpolation spaces* V_θ and W_θ. While this can be done using either real or complex interpolation theories, we note that for Hilbert spaces these are equivalent to the following constructions. See, for example, Taylor [31, pp. 276–278] for complex interpolation, or Bramble and Zhang [7, Appendix B], Triebel [34, section 1.18.10], or Kuttler [15, section 22.6, exercises], for real interpolation theories. The real interpolation methods should use exponent 2 as appropriate for Hilbert spaces. Since $A \colon V \to V'$ is elliptic self-adjoint, the norm on V is equivalent to $\|u\|_A := \langle Au, u \rangle_{V' \times V}^{1/2}$.

For W we can use the natural map $J \colon W \to W'$ given by $J(w) = (\cdot, w)_{W' \times W}$ which is also elliptic and self-adjoint.

The spaces V_θ and W_θ are given by

$$V_\theta = \left\{ u \in H \mid \left\langle A^\theta u, u \right\rangle < +\infty \right\}, \quad \text{and}$$
$$W_\theta = \left\{ w \in Z \mid \left\langle J^\theta w, w \right\rangle < +\infty \right\}$$

which are inner product spaces with the inner products $(x, y)_{V_\theta} = \left\langle A^\theta x, y \right\rangle$ and $(w, z)_{W_\theta} = \left\langle J^\theta w, z \right\rangle$. Note that we will use $(\cdot, \cdot)_\theta$ for the inner product when it is clear which of the V_θ or W_θ spaces is being considered; similarly, we will use $\| \cdot \|_\theta$ for the norm in either V_θ or W_θ when the choice is clear.

Note that both V_θ and W_θ are well defined for any real number θ, and that $V = V_1$, $H = V_0$, and $V' = V_{-1}$; and the corresponding properties hold for the W_θ spaces. Note that $V_{\theta+\epsilon}$ embeds compactly in V_θ whenever $\epsilon > 0$. Furthermore, $(V_\theta)' = V_{-\theta}$ and $(W_\theta)' = W_{-\theta}$. Also continuous linear operators $F\colon X_0 \to Y_0$ and $F\colon X_1 \to Y_1$ can be extended to the continuous linear operators on the interpolation spaces, that is, $F\colon X_\theta \to Y_\theta$, $0 \le \theta \le 1$.

For the vibrating string problem, $V_\theta = \{u \in H^\theta(0,l) \mid u(0) = u(l) = 0\}$ for $\theta > 1/2$ and $H^\theta(0,l)$ otherwise. The reason for the difference is that the trace operators $u \mapsto u(0)$ and $u \mapsto u(l)$ fail to exist for $\theta \le 1/2$. Also, $W_\theta = H^\theta(\delta, l-\delta)$.

In order to obtain bounds on the contact forces, we make an assumption about the nature of the cones K and K^*.

DEFINITION 2.1. *A dual cone K^* is said to be* strongly pointed *if there exist $\kappa \in K$ and $\eta > 0$ such that for any $\zeta \in K^*$,*

$$\langle \zeta, \kappa \rangle_{W' \times W} \ge \eta \, \|\zeta\|_{W'} \, .$$

This terminology is first used in [29]; this property is equivalent to requiring that K has nonempty interior. Assuming that K^* is strongly pointed is not quite enough. In addition we need a "gap" in the scale of interpolation spaces: there should be a $\theta < 1$, $\kappa \in K$ and $\eta > 0$ such that

$$\langle \zeta, \kappa \rangle_{W_{-\theta} \times W_\theta} \ge \eta \|\zeta\|_{-\theta} \quad \text{for any } \zeta \in K^*. \tag{2.1}$$

Finally we need an additional property of the restriction operator β: there is an $\alpha < 1$, where $\beta\colon V_\alpha \to Z$ is a continuous map of Hilbert spaces.

In the case of the vibrating string problem, we can show that both of these conditions hold. Firstly, we can choose $\kappa(x) = x(l-x)$ which is positive and bounded away from zero on $[\delta, l-\delta]$. This means that

$$\begin{aligned} \langle \zeta, \kappa \rangle &= \int_{[\delta, l-\delta]} \zeta(x)\, \kappa(x)\, dx \\ &\ge \delta(l-\delta) \int_{[\delta, l-\delta]} \zeta(x)\, dx \\ &= \delta(l-\delta)\, \|\zeta\|_{\mathcal{M}[\delta, l-\delta]}. \end{aligned}$$

By the Sobolev embedding theorem (see [24, Thm. 6.91, p. 215] or [31, Prop. 3.3, p. 282]) $C[\delta, l-\delta] \supset H^\theta(\delta, l-\delta) = W_\theta$ as Banach spaces for $\theta > 1/2$. Thus by duality, $\mathcal{M}[\delta, l-\delta] \subset H^{-\theta}(\delta, l-\delta) = W_{-\theta}$ as Banach spaces, so there is a positive constant C_θ for $\theta > 1/2$, where $\|\zeta\|_{H^{-\theta}(\delta, l-\delta)} \le C_\theta \, \|\zeta\|_{\mathcal{M}[\delta, l-\delta]}$. Thus the strong pointedness assumption (2.1) holds for the vibrating string problem.

We assume that the initial displacement $u^0 \in V = V_1$ and the initial velocity $v^0 \in H = V_0$.

We introduce the following notation: if X and Y are Banach spaces, the set of all bounded linear operators from X to Y is denoted by $\mathcal{L}(X, Y)$, and, especially, $\mathcal{L}(X, X)$ is written as $\mathcal{L}(X)$.

3. Impact problem formulated in abstract setting. We seek a solution $u\colon [0, T] \to V$ satisfying the following conditions:

$$u_{tt}(t) = -Au(t) + \beta^* N(t) + f, \quad \text{in the sense of distributions,} \tag{3.1}$$

$$W \supset K \ni \beta\, u(t) - \varphi \perp N(t) \in K^* \subset W' \quad \text{for all } t \in [0, T], \tag{3.2}$$

$$u(0) = u^0, \tag{3.3}$$

$$u_t(0) = v^0. \tag{3.4}$$

Note that f does not depend on time t. The assumptions we will use throughout this paper are as follows:

(A1) We have the following Gelfand triples $V \subset H = H' \subset V'$ and $W \subset Z = Z' \subset W'$ with all spaces separable Hilbert spaces and all inclusions dense and compact.
(A2) The linear operator $A\colon V \to V'$ is elliptic and self-adjoint.
(A3) There is a linear operator $\beta\colon V \to W$ that is continuous and surjective, with a bounded right-inverse $\gamma\colon W \to V$, where $\beta\gamma = \mathrm{id}_W$.
(A4) The set $K \subset W$ is a closed convex cone, with dual cone $K^* \subset W'$.
(A5) $\varphi \in W$, $u^0 \in V$ and $v^0 \in H$.
(A6) There is $\eta > 0$, $\theta < 1$ and $\kappa \in K$, where $\langle \zeta, \kappa\rangle \geq \eta \|\zeta\|_{-\theta}$ for all $\zeta \in K^*$.
(A7) There is an $\alpha < 1$ where $\beta\colon V_\alpha \to Z$.

Note that (A6) is equivalent to requiring that the interior of K is nonempty in V_θ.

Our main result is the following theorem.

THEOREM 3.1. *Under assumptions* (A1)–(A7)*, for any $T > 0$ there is a solution (u, N) to* (3.1–3.4) *where u lies in $L^\infty(0,T;V) \cap W^{1,\infty}(0,T;H)$ and where N lies in $\mathcal{M}(0,T;W')$, the space of Borel measures on $[0,T]$ with bounded variation and values in W'.*

Remark 3.1.

(a) Note that (3.1) is interpreted in the sense of distributions in V', "$N(t) \in K^*$" is interpreted in the sense that N is a W'-valued measure with $N(B) \in K^*$ for any Borel set B, and "$\beta u - \varphi \perp N$" is interpreted in the sense that $\int_B \langle \beta u - \varphi, N\rangle = 0$ for any Borel set $B \subseteq [0,T]$.

(b) Note that since $\beta u(t) - \varphi \in K$ for all t and N is a K^*-valued measure, $\langle \beta u - \varphi, N\rangle \geq 0$ in the sense of measures. Thus if $\int_{[0,T]} \langle \beta u - \varphi, N\rangle = 0$, then $\int_B \langle \beta u - \varphi, N\rangle = 0$ for any Borel set $B \subseteq [0,T]$.

(c) The condition "$N(t) \in K^*$" for a measure N is equivalent to that used in [21] and [29].

4. Examples of dynamic frictionless impact problems. In this section, we list examples of concrete impact problems to which this abstract formulation can be applied. In section 1 we have seen the vibrating string problem with contact along the length of the string.

The Euler–Bernoulli beam equation with contact along the length of the beam can also be handled in this way. Another equation to which this approach can be applied is the Timoshenko beam with contact occurring along the length of the beam. Higher-dimensional systems require higher-order differential equations. For example, the biharmonic equation can be used for two- or three-dimensional systems with contact either on a subdomain of positive measure, or on the boundary.

The most difficult assumption to satisfy is (A6): there is a $\kappa \in K$, where $\langle \zeta, \kappa\rangle \geq \eta \|\zeta\|_{W_{-\theta}}$ for all $\zeta \in K^*$. In thick obstacle problems, $W = H^m(\Omega_1)$, where $\Omega_1 \subset \overline{\Omega_1} \subset \Omega \subset \mathbb{R}^d$. If $m > d/2$, then we have the Sobolev embedding $H^m(\Omega_1) \subset C(\overline{\Omega_1})$ and we can choose $\kappa(x) = 1$ for all $x \in \Omega_1$. Then by duality, $H^{-m}(\Omega_1) \supset \mathcal{M}(\overline{\Omega_1})$, the space of Borel measures on $\overline{\Omega_1}$. Provided K is a cone of nonnegative functions, K^* is the corresponding set of nonnegative measures. The norm on the space of measures is essentially the same as the L^1 norm, which is equal to the integral over $\overline{\Omega_1}$, which is $\langle \kappa, \zeta\rangle$. In boundary thin obstacle problems, $W = H^m(\Gamma_C)$, where $\Gamma_C \subset \partial\Omega \subset \mathbb{R}^{d-1}$, so our condition becomes $m > (d-1)/2$.

For the case of the wave equation or equations of elasticity on a domain $\Omega \subset \mathbb{R}^d$ for $d \geq 2$ the condition (A6) does not hold. The reasons are as described in the above

paragraph: we take $m = 1$ as we must take V to be a subspace of $H^1(\Omega)$ satisfying the essential homogeneous boundary conditions, and so the Sobolev embedding and the strong pointedness condition fail.

Now we introduce those problems in detail.

4.1. The wave equation in one dimension. The vibrating string problem has the formulation:

$$\begin{aligned} u_{tt} &= u_{xx} + \beta^* N(t,x) \quad \text{in } (0,T] \times (0,l), \\ 0 \le \beta u(t,x) - \varphi(x) \perp N(t,x) &\ge 0 \quad \text{in } (0,T] \times (0,l), \\ u(t,0) = u(t,l) &= 0 \quad \text{in } (0,T], \end{aligned}$$

where l is the length of a string and $\varphi(x)$ is an obstacle. Schatzman showed the existence of solutions for φ concave down; furthermore, she showed that the solutions she constructed conserved energy. However, this was done using the method of characteristics. An essential part of this work was showing that for the solutions constructed, $u_t(t^+, x) = -u_t(t^-, x)$ for almost everywhere of (t, x), where $u(t, x) = 0$. Thus it behaves as if it has a kinematic coefficient of restitution set equal to 1 for perfectly elastic impacts. However, there is no coefficient of restitution in the equations of motion. This problem has already been discussed in the introduction, and the precise characterization of the spaces V, W, etc., and the operators involved, can be found there.

The contact problem with the wave equation in one dimension and contact only at an endpoint is an old problem, and was discussed by Routh nearly a century and a half ago [25]. A more recent analysis can be found in [28]; a variation of this idea with a general point obstacle can be found in [27]. This can also be (essentially) treated in this framework, although the operator A is not coercive: it has one zero eigenvalue and all others are positive. Firstly, we take $V = H^1(0, l)$ and $W = \mathbb{R}$. Thus $Z = W_\theta = W_{-\theta} = \mathbb{R}$ for all θ. We take $K = \mathbb{R}_+$ to $K^* = \mathbb{R}_+$ and assumption (A6) holds. Assumption (A7) holds as the restriction operator $\beta u = u(0)$ is a bounded linear operator $\beta\colon V_\alpha = H^\alpha(0, l) \to Z = \mathbb{R}$ for $\alpha > 1/2$ by the usual Sobolev embedding theorems. Note that in this problem the operator $\beta^*\colon \mathbb{R} \to H^{-1}(0, l)$ is the operator $\beta^*(N) = N\,\delta$ where δ is the "Dirac-δ function" of the theory of distributions [12]. Such a term in the right-hand side of the wave equation

$$u_{tt} = u_{xx} + N(t)\,\delta(x) \quad \text{for } x \in (0, l)$$

requires less delicate treatment. If we integrate the above equation against a function $\omega \in H^1(0, l)$, we see that

$$\begin{aligned} \frac{d^2}{dt^2} \langle u, \omega \rangle &= \int_0^l u_{xx}\, \omega(x)\, dx + N(t)\, \omega(0) \\ &= u_x \omega(x)|_{x=0}^{x=l} - \int_0^l u_x\, \omega_x\, dx + N(t)\, \omega(0). \end{aligned}$$

Taking the end $x = l$ to be free, that is, to have the natural boundary condition $u_x(t, l) = 0$, we see that the appropriate boundary condition at $x = 0$ is $u_x(t, 0) = N(t)$. This is consistent with traction boundary conditions for a force $N(t)$ applied at the endpoint $x = 0$. The regularity of the solutions of these "point contact" problems is considerably better than for the problems with distributed contact.

4.2. Euler–Bernoulli beam equations. The problem of a Euler–Bernoulli beam that can contact a rigid frictionless obstacle along its length has been studied in [2, 1], both theoretically and numerically. If we assume that the beam is clamped at $x = 0$ but free at $x = l$, we get the system

$$\begin{aligned} u_{tt} &= -u_{xxxx} + \beta^* N(t,x) \quad \text{in } (0,T] \times (0,l), \\ 0 \le N(t,x) \perp \beta u(t,x) - \varphi(x) &\ge 0 \quad \text{in } (0,T] \times (0,l), \\ u(t,0) = u_x(t,0) &= 0 \quad \text{on } (0,T], \\ u_{xx}(t,l) = u_{xxx}(t,l) &\quad \text{in } (0,T]. \end{aligned}$$

As you can see, we have essential and natural boundary conditions. Notice that Euler–Bernoulli beam equation has a fourth-order differential operator. We assume that $-\varphi(0) > 0$ as for the vibrating string problem. This ensures that contact is kept away from the essential boundary $x = 0$.

More specifically, $A = \partial^4/\partial x^4$ while $V = H^2_{cf}(0,l)$ (the first subscript "c" indicates clamped boundary conditions as $x = 0$ and the second subscript "f" means free) and $W = H^2(\delta, l)$. Also $H = L^2(0,l)$ and $Z = L^2(\delta, l)$. As for the vibrating string example, we assume that $\beta : H \to Z$. One of the interesting results from the numerical study was that energy was close to being conserved even though the numerical formulation was designed to mimic inelastic impacts. It is possible to set up initial conditions for this problem which would result in dissipation of energy, but the numerical simulations seem to indicate that energy may be conserved for "most" initial conditions.

Boundary contact problems with Euler–Bernoulli beams have been investigated in other works, such as [5, 17], although the beam is typically assumed to be visco-elastic; that is, the equations of motion have the form

$$u_{tt} = -a u_{xxxx} - b\, u_{xxxxt} + f(t,x).$$

The inclusion of viscosity makes the solution u more regular (at least in space) but tends to make the normal contact force less regular. (See, for example, the results of Petrov and Schatzman [22, 23] and Ahn and Stewart [3] for a visco-elastic wave equation

$$u_{tt} = u_{xx} + b\, u_{xxt}$$

with contact at the endpoint $x = 0$.) While visco-elastic problems are not treated in this paper, the corresponding nonviscous problem with boundary contact can be dealt with in this framework.

4.3. Timoshenko beam formulation. The Timoshenko beam equations are more realistic than the Euler–Bernoulli beam equation, as is well known in engineering [32, 33]. Imposing frictionless Signorini's contact conditions along the length of the bar, we establish the following system:

$$\begin{aligned} \rho\mathcal{A}\psi_{tt} &= \mathcal{E}M\psi_{xx} + D\mathcal{A}G(w_x - \psi) \quad \text{in } (0,l) \times [0,T], \\ \rho\mathcal{A}w_{tt} &= D\mathcal{A}G(w_{xx} - \psi_x) + N(t,x) \quad \text{in } (0,l) \times [0,T], \\ 0 \le N(t,x) \perp \beta u(t,x) - \varphi(x) &\ge 0 \quad \text{in } (0,l) \times [0,T], \\ w(t,0) = \psi(t,0) &= 0 \quad \text{on } (0,T], \\ w_x(t,l) - \psi(t,l) &= 0 \quad \text{on } (0,T]. \end{aligned}$$

In this case $u(t,x) = [\psi(t,x),\, w(t,x)]^T \in \mathbb{R}^2$ and $V = H^1(0,l;\mathbb{R}^2)$. Our restriction operator $\beta : H^1(0,l;\mathbb{R}^2) \to H^1(\delta,l)$ is given by $\beta u(t,x) = w(t,x)$; note that $W = H^1(\delta,l)$. The pivot spaces are $H = L^2(0,l;\mathbb{R}^2)$ and $Z = L^2(\delta,l)$. The cone $K = \{w \in H^1(\delta,l) \mid w(x) \geq 0 \text{ for all } x \in (\delta,l)\}$. The quantity ψ is the angular rotation of the beam, while w is the vertical displacement. The physical constants involved in this equation are: ρ is the density of beam, $\mathcal{A}$ is the area of cross section of the beam, $\mathcal{E}$ is Young's modulus, M is the second moment of area, G is the modulus of elasticity of shear, and D is introduced to account for the geometric dependent distribution of shear stress.

This system behaves very similarly to the wave equation in impact, although the Euler–Bernoulli beam system can be obtained as a limit of this system as certain combinations of ρ, $\mathcal{A}$, $\mathcal{E}$, M, G and D go to infinity. Note that the approach of Schatzman for the vibrating string problem would be considerably complicated in this context by having two sets of characteristics to follow.

4.4. Thin plates in impact. The equations of motion for thin elastic plates are fourth-order equations of which the simplest uses the biharmonic operator. Incorporating frictionless contact forces over a subdomain $\Omega_1 \subset \overline{\Omega_1} \subset \Omega \subset \mathbb{R}^d$, again so as to avoid contact close to the essential boundary, we have the thick obstacle problem for a clamped boundary:

$$\begin{aligned} u_{tt} &= -\Delta^2 u + \beta^* N(t,\mathbf{x}) \quad \text{in } (0,T]\times\Omega,\\ 0 \leq \beta u(t,\mathbf{x}) - \varphi(\mathbf{x}) \perp N(t,\mathbf{x}) &\geq 0 \quad \text{on } (0,T]\times\Omega,\\ u(t,\mathbf{x}),\, \frac{\partial u}{\partial n}(t,\mathbf{x}) &= 0 \quad \text{on } (0,T]\times\partial\Omega. \end{aligned}$$

Specifically, $V = H_0^2(\Omega)$ and $H = L^2(\Omega)$, while $W = H^2(\Omega_1)$ and $Z = L^2(\Omega_1)$, and the measure of Ω_1 is strictly positive. This can be treated in our system provided $d \leq 3$. The main reason for this restriction is assumption (A6). As before, we note that this is connected to the Sobolev embedding $W_\theta = H^{2\theta}(\Omega_1) \subset C(\overline{\Omega_1})$ for $2\theta > d/2$. We can pick $1 > \theta > d/4$ provided $d \leq 3$. Then we can proceed as in the previous examples and show that $W_{-\theta} \supset \mathcal{M}(\overline{\Omega_1})$, and we can take $\kappa(\mathbf{x}) = 1$ for all $\mathbf{x} \in \Omega_1$ for the purposes of (A6).

A boundary thin obstacle problem based on the biharmonic operator can be treated by the approach here for $d \leq 3$. Let $\partial\Omega = \Gamma_D \cup \Gamma_C$ with clamped (Dirichlet) boundary conditions applied on Γ_D and the contact conditions applied on Γ_C. To avoid the problems of contact close to the essential boundary Γ_D we assume that $-\varphi$ is bounded above a positive constant on Γ_D. The boundary conditions that are applied are then

$$\begin{aligned} u(t,\mathbf{x}),\, \frac{\partial u}{\partial n}(t,\mathbf{x}) &= 0 \quad \text{for } t>0 \text{ and } \mathbf{x}\in\Gamma_D,\\ \Delta u(t,\mathbf{x}) &= 0 \quad \text{for } t>0 \text{ and } \mathbf{x}\in\Gamma_C,\\ \frac{\partial}{\partial n}\Delta u(t,\mathbf{x}) &= N(t,\mathbf{x}) \quad \text{for } t>0 \text{ and } \mathbf{x}\in\Gamma_C,\\ 0 \leq \beta u(t,\mathbf{x}) - \varphi(\mathbf{x}) \perp N(t,\mathbf{x}) &\geq 0 \quad \text{for } t>0 \text{ and } \mathbf{x}\in\Gamma_C. \end{aligned}$$

We take $V = \{u \in H^2(\Omega) \mid u|\Gamma_D = (\partial u/\partial n)|\Gamma_D = 0\}$ and $H = L^2(\Omega)$. The restriction operator $\beta\colon V \to W$ is the trace operator $H^2(\Omega) \to H^{3/2}(\Gamma_C)$. Since the dimension of Γ_C is $d-1$, we have a Sobolev embedding $H^{3/2}(\Gamma_C) \subset C(\Gamma_C)$ provided $(d-1)/2 < 3/2$; that is, provided $d \leq 3$. This means that for assumption (A6) we

can take $\kappa(\mathbf{x}) = 1$ for all $\mathbf{x} \in \Gamma_C$ provided $-\varphi(\mathbf{x}) > 0$ for all $\mathbf{x} \in \partial\Omega\backslash\Gamma_C$. This also guarantees that there is no contact within a certain small distance of $\Gamma_D = \partial\Omega\backslash\Gamma_C$.

A problem of this kind was treated numerically in [8]. The authors are not aware of any theoretical treatment of impact problems for plates of either the "thick" or "boundary thin" kinds.

5. Convergence of numerical formulation.

5.1. Time-discrete approximation. Using time discretization, we set up a numerical formulation. Our numerical scheme is to employ the midpoint rule for elasticity and the implicit Euler method for contact condition. In order to do so, we first partition time interval $[0, T]$:

$$0 = t_0 < t_1 < \cdots < t_{k-1} < t_k < t_{k+1} < \cdots < t_P = T,$$

where $h_t = t_{k+1} - t_k$ for $k \geq 0$ is the time step size. We will assume for analytical convenience that T is a multiple of h_t; that is, $h_t = T/P$ for some positive integer P. Then we denote by u^k a numerical solution of displacement $u(t_k)$, by v^k a numerical solution of velocity $v(t_k)$ and by N^k a numerical solution of contact force $N(t_k)$, respectively, at each discretized time $t_k = k \cdot h_t$. Now we establish the numerical formulation:

$$\frac{v^{k+1} - v^k}{h_t} = -\left(\frac{A\,u^{k+1} + A\,u^k}{2}\right) + \beta^* N^k + f \tag{5.1}$$

$$\frac{u^{k+1} - u^k}{h_t} = \frac{v^{k+1} + v^k}{2} \tag{5.2}$$

$$K \ni \beta u^{k+1} - \varphi \perp N^k \in K^*, \tag{5.3}$$

where the complementarity condition (5.3) implies $\left\langle N^k,\, \beta u^{k+1} - \varphi \right\rangle_{W_{-\theta}\times W_\theta} = 0$. Also we can write the numerical solution quantities as

$$u^k = \sum_{j=1}^{\infty} \left\langle u^k, \phi_j \right\rangle \phi_j,$$

$$v^k = \sum_{j=1}^{\infty} \left(v^k, \phi_j\right) \phi_j,$$

$$\beta^* N^k = \sum_{j=1}^{\infty} \left\langle \beta^* N^k, \phi_j \right\rangle \phi_j,$$

where ϕ_j forms an H-orthonormal basis and is an eigenfunction of an elliptic self-adjoint operator A. Now we define energy functional of the impact problems as

$$E[u,\, v] = \frac{1}{2}\left(\langle Au,\, u\rangle_{V'\times V} + (v,\, v)_H\right) - \langle f,\, u\rangle_{V'\times V}.$$

$\frac{1}{2}\langle Au,\, u\rangle$ is the elastic energy, $\frac{1}{2}(v,\, v)_H$ is the kinetic energy, and $-\langle f,\, u\rangle$ is the potential energy due to the external forces. In the case where $A = -\Delta$ with Dirichlet or Neumann boundary conditions, $\langle Au,\, u\rangle = \int_\Omega |\nabla u|^2 dx$.

Using (5.1) and (5.2), u^{k+1} and v^{k+1} can be expressed in terms of u^k and v^k in the following way:

$$\begin{bmatrix} u^{k+1} \\ v^{k+1} \end{bmatrix} = \left(I + h_t^2 A/4\right)^{-1} \left(\begin{bmatrix} I - h_t^2 A/4 & h_t \\ -h_t A & I - h_t^2 A/4 \end{bmatrix} \begin{bmatrix} u^k \\ v^k \end{bmatrix} + \begin{bmatrix} h_t^2/2 \\ h_t \end{bmatrix} \left(\beta^* N^k + f\right) \right). \tag{5.4}$$

5.2. Convergence theory in the semidiscrete case. We first show that we can solve the above complementarity problem.

LEMMA 5.1. *Provided $u^k \in V$ and $v^k \in H$, then there is a unique solution (u^{k+1}, v^{k+1}, N^k) to (5.1–5.3) with $u^{k+1} \in V$, $v^{k+1} \in H$ and $N^k \in W'$.*

Proof. Employing (5.4), the solution to (5.1–5.3) can be found by reducing it to the complementarity problem

$$K \ni (\beta u^k - \varphi) + h_t\,\beta(I + h_t^2 A/4)^{-1}\left[-\frac{h_t}{2}Au^k + v^k + \frac{h_t}{2}(\beta^* N^k + f)\right] \quad \perp \quad N^k \in K^*.$$

This complementarity problem is equivalent to the variational inequality: find $N^k \in K^*$ such that for all $N \in K^*$,

$$\left\langle (\beta u^k - \varphi) + h_t\,\beta(I + h_t^2 A/4)^{-1}\left[-\frac{h_t}{2}Au^k + v^k + \frac{h_t}{2}(\beta^* N^k + f)\right],\, N^k - N\right\rangle \le 0.$$

Since the operator $\beta(I + h_t^2 A/4)^{-1}\beta^*\colon W' \to W$ is elliptic and self-adjoint, we can apply the Lions–Stampacchia theorem [6, Thm. 3.1, pp. 24–29] to show that there is a unique $N^k \in W'$ satisfying these conditions. Noting that $\beta^* N^k \in V'$ and $(I + h_t^2 A/4)^{-1}\colon V' \to V$ by (5.4), we see that $u^{k+1} \in V$ and $v^{k+1} \in H$. ∎

In the discrete-time case, we will see in the next lemma that our numerical scheme ensures that energy does not increase.

LEMMA 5.2. *Suppose that numerical solutions satisfy* (5.1), (5.2) and (5.3). *Then energy does not increase.*

Proof. We claim that $E[u^{k+1}, v^{k+1}] \le E[u^k, v^k]$. Using (5.1) and (5.2), by the extension of $(\cdot,\cdot)_H$ on $V' \times V$ for $h_t > 0$ we have

$$\left(\frac{v^{k+1} - v^k}{h_t},\, \frac{v^{k+1} + v^k}{2}\right)_H = \left\langle -\left(\frac{A\,u^{k+1} + A\,u^k}{2}\right) + \beta^* N^k + f,\, \frac{u^{k+1} - u^k}{h_t}\right\rangle_{V' \times V}.$$

Thus we obtain

$$\begin{aligned}
&\frac{1}{2h_t}\left(\left(v^{k+1}, v^{k+1}\right)_H - \left(v^k, v^k\right)_H\right)\\
&= -\frac{1}{2h_t}\left(\left\langle A\,u^{k+1},\, u^{k+1}\right\rangle_{V' \times V} - \left\langle A\,u^k,\, u^k\right\rangle_{V' \times V}\right)\\
&\quad + \frac{1}{h_t}\left(\left\langle \beta^* N^k + f,\, u^{k+1}\right\rangle_{V' \times V} - \left\langle \beta^* N^k + f,\, u^k\right\rangle_{V' \times V}\right)\\
&= -\frac{1}{2h_t}\left(\left\langle A\,u^{k+1},\, u^{k+1}\right\rangle_{V' \times V} - \left\langle A\,u^k,\, u^k\right\rangle_{V' \times V}\right)\\
&\quad + \frac{1}{h_t}\left(\left\langle N^k,\, \beta u^{k+1}\right\rangle_{W' \times W} - \left\langle N^l,\, \beta u^k\right\rangle_{W' \times W}\right)\\
&\quad + \frac{1}{h_t}\left(\left\langle f,\, u^{k+1}\right\rangle_{V' \times V} - \left\langle f,\, u^k\right\rangle_{V' \times V}\right)\\
&= -\frac{1}{2h_t}\left(\left\langle A\,u^{k+1} - 2f,\, u^{k+1}\right\rangle_{V' \times V} - \left\langle A\,u^k - 2f,\, u^k\right\rangle_{V' \times V}\right)\\
&\quad + \frac{1}{h_t}\left(\left\langle N^k, \beta u^{k+1} - \varphi\right\rangle_{W' \times W} - \left\langle N^k, \beta u^k - \varphi\right\rangle_{W' \times W}\right).
\end{aligned}$$

Since $\left\langle N^k,\, \beta u^{k+1} - \varphi\right\rangle_{W' \times W} = 0$ and $\left\langle N^k,\, \beta u^k - \varphi\right\rangle_{W' \times W} \ge 0$ from the contact

condition (5.3),

$$E[u^{k+1}, v^{k+1}] = \frac{1}{2}\left(\langle Au^{k+1} - 2f,\, u^{k+1}\rangle_{V'\times V} + \left(v^{k+1}, v^{k+1}\right)_H\right)$$
$$\leq \frac{1}{2}\left(\langle Au^{k} - 2f,\, u^{k}\rangle_{V'\times V} + \left(v^{k}, v^{k}\right)_H\right) = E[u^k,\, v^k],$$

as required. ∎

Since we assumed that $u^0 \in V$ and $v^0 \in H$, the initial energy is finite, i.e., $E^0 := E(u^0,\, v^0) < \infty$. In the next Lemma, we shall see that approximate solutions at each time t_k are uniformly bounded. Notice that C represents a quantity that is independent of h and k, but the value of C will be different in each occurrence.

LEMMA 5.3. *For all $k \geq 0$,*

$$\|u^k\|_V \leq 2\,\|f\|_{V'} + \sqrt{2E^0}, \tag{5.5}$$

$$\|v^k\|_H \leq 2\,\|f\|_{V'} +^4 \sqrt{2E^0\,\|f\|_{V'}^2} + \sqrt{E^0}, \tag{5.6}$$

where $E^0 = E[u^0,\, v^0]$ is the initial energy.

Proof. From the Lemma 5.2, $E[u^k, v^k] \leq E[u^0, v^0] < \infty$ for each $k > 0$. Then we have

$$E^0 = E[u^0,\, v^0] \geq E[u^k, v^k]$$
$$= \frac{1}{2}\left(\langle u^k, A\,u^k - 2f\rangle + \left(v^k,\, v^k\right)\right)$$
$$= \frac{1}{2}\left\langle \sum_{j=1}^{\infty} u_j^k\phi_j, \sum_{j=1}^{\infty}\lambda_j u_j^k\phi_j \right\rangle + \frac{1}{2}\left(\sum_{j=1}^{\infty} v_j^k\phi_j, \sum_{j=1}^{\infty} v_j^k\phi_j\right) - \langle u^k,\, f\rangle$$
$$\geq \frac{1}{2}\left(\sum_{j=1}^{\infty}\lambda_j\left(u_j^k\right)^2 + \sum_{j=1}^{\infty}\left(v_j^k\right)^2\right) - \|u^k\|_V\,\|f\|_{V'}$$
$$= \frac{1}{2}\left(\left\|u^k\right\|_V^2 + \left\|v^k\right\|_H^2\right) - \|u^k\|_V\,\|f\|_{V'},$$

where $u_j^k = \langle u^k, \phi_j\rangle$ and $v_j^k = (v^k, \phi_j)$. Thus after some computations with quadratic equations, we see (5.5) and (5.6) which are independent of k or $h_t > 0$. ∎

Let the numerical trajectories $u_{h_t}(t)$ be linear continuous interpolant of $u_{h_t}(t_k) = u^k$ and $u_{h_t}(t_{k+1}) = u^{k+1}$ for $t \in [t_k, t_{k+1}]$. For the velocity, let $v_{h_t}(t)$ be a constant interpolant and $v_{h_t}(t) = v^{k+1}$ for $t \in (t_k, t_{k+1})$. Then $u_{h_t}(t) = u^k + \frac{1}{2}\int_{t_k}^{t}[v_{h_t}(\tau - h_t) + v_{h_t}(\tau)]\,d\tau$ for all $t \in (t_k, t_{k+1})$. In order to approach contact force $N \in \mathcal{M}(0, T; W')$, we first set up a step function $N(t) = N^k$ for $t \in [t_k, t_{k+1})$ on W'. This implies that contact force N is constant on W' for only time $t \in [t_k, t_{k+1})$. Thus it is easy to see that the approximate contact force N_{h_t} can be defined as

$$N_{h_t} = h_t \sum_{k=0}^{T/h_t - 1} \delta(t - (k+1)h_t)N^k. \tag{5.7}$$

So from Lemma 5.3, $u_{h_t} \in L^\infty(0, T; V_1)$ and $v_{h_t} \in L^\infty(0, T; H)$. Note that V_1 is compactly embedded in V_θ for any $\theta < 1$.

We now wish to bound the norm of the contact forces N_{h_t} in $\mathcal{M}(0, T; W_{-\theta})$ using the strong pointedness assumption (A6). However, we will find it convenient to work

with $\langle N^k, \beta(I + h_t^2 A/4)^{-1}\gamma\,\kappa\rangle$, instead of $\langle N^k, \kappa\rangle$, so we need an approximation result for κ.

LEMMA 5.4. *Suppose that $w \in W$. Then,*

$$\beta\left(I + h_t^2 A/4\right)^{-1}\gamma w \to w \quad \textit{in } W \quad \textit{as } h_t \downarrow 0.$$

Proof. Since $w \in W$, $\left(I + h_t^2 A/4\right)^{-1}\gamma w \in V$. Let $y = \gamma w$. Putting $y = \sum_j y_j \phi_j$, we have

$$\begin{aligned}\left\|\left(I + h_t^2 A/4\right)^{-1} y - y\right\|_V^2 &= \left\|A^{1/2}\left(\left(I + h_t^2 A/4\right)^{-1} y - y\right)\right\|_H^2 \\ &= \sum_{j=1}^{\infty}\left(\frac{h_t^2\lambda_j/4}{1 + h_t^2\lambda_j/4}\right)^2 \lambda_j y_j^2.\end{aligned}$$

Since $y \in V$, for any $\delta > 0$, there is an $n > 0$, independent of $h_t > 0$ such that $\sum_{j>n}\lambda_j y_j^2 < \delta$. Now for such n, we have

$$\sum_{j=1}^{n}\left(\frac{h_t^2\lambda_j/4}{1 + h_t^2\lambda_j/4}\right)^2 \lambda_j y_j^2 \to 0 \quad \text{as } h_t \downarrow 0. \tag{5.8}$$

On the other hand,

$$\sum_{j>n}^{\infty}\left(\frac{h_t^2\lambda_j/4}{1 + h_t^2\lambda_j/4}\right)^2 \lambda_j y_j^2 \le \sum_{j>n}^{\infty}\lambda_j y_j^2 < \delta. \tag{5.9}$$

Therefore from (5.8) and (5.9),

$$\left\|\left(I + h_t^2 A/4\right)^{-1} y - y\right\|_V \to 0 \quad \text{as } h_t \downarrow 0.$$

Thus as $h_t \downarrow 0$,

$$\begin{aligned}\left\|\beta\left(I + h_t^2 A/4\right)^{-1}\gamma w - w\right\|_W &= \left\|\beta\left(I + h_t^2 A/4\right)^{-1}\gamma w - \beta\gamma w\right\|_W \\ &= \left\|\beta\left(\left(I + h_t^2 A/4\right)^{-1} y - y\right)\right\|_W \\ &\le \|\beta\|_{\mathcal{L}(V,W)}\left\|\left(I + h_t^2 A/4\right)^{-1} y - y\right\|_V \to 0,\end{aligned}$$

as required. ∎

The above approximation result can now be used to bound the norm of N_h as a $W_{-\theta}$-valued measure.

LEMMA 5.5. *Suppose that* (A6) *holds with $\kappa \in \operatorname{int} K \subset W$. Then there is a constant C (independent of h) where*

$$\int_{[0,T]}\|N_{h_t}(t)\|_{W_{-\theta}}\,dt \le C \quad \textit{for all sufficiently small } h_t > 0.$$

Proof. Recall the matrix form (5.4). By extension of $\left(v^{k+1} - v^k, \gamma\kappa\right)_{H\times V}$ in $V' \times V$,

$$\begin{aligned}\left(v^{k+1} - v^k, \gamma\kappa\right)_{H\times V} &= \Big\langle \left(I + h_t^2 A/4\right)^{-1}\left(-h_t A u^k + \left(I - h_t^2 A/4\right) v^k\right. \\ &\quad \left. - \left(I + h_t^2 A/4\right) v^k + h_t(\beta^* N^k + f)\right), \gamma\kappa\Big\rangle_{V'\times V} \\ &= \left\langle \left(I + h_t^2 A/4\right)^{-1}\left(-h_t A u^k - \frac{h_t^2}{2} A v^k + h_t(\beta^* N^k + f)\right), \gamma\kappa\right\rangle_{V'\times V}.\end{aligned}$$

Thus we have

$$\begin{aligned} & h_t \left\langle \left(I + h_t^2 A/4\right)^{-1} \beta^* N^k,\, \gamma\kappa \right\rangle_{V' \times V} \\ & \quad = \left(v^{k+1} - v^k, \gamma\kappa\right)_H + h_t \left\langle \left(I + h_t^2 A/4\right)^{-1} A u^k,\, \gamma\kappa \right\rangle_{V' \times V} \\ & \quad + \frac{h_t^2}{2} \left\langle \left(I + h_t^2 A/4\right)^{-1} A v^k,\, \gamma\kappa \right\rangle_{V' \times V} - h_t \left\langle \left(I + h_t^2 A/4\right)^{-1} f,\, \gamma\kappa \right\rangle_{V' \times V}. \end{aligned} \tag{5.10}$$

Also it follows that

$$\begin{aligned} h_t \left\langle \left(I + h_t^2 A/4\right)^{-1} \beta^* N^k,\, \gamma\kappa \right\rangle_{V' \times V} &= h_t \left\langle \beta^* N^k,\, \left(I + h_t^2 A/4\right)^{-1} \gamma\kappa \right\rangle_{V' \times V} \\ &= h_t \left\langle N^k,\, \beta \left(I + h_t^2 A/4\right)^{-1} \gamma\kappa \right\rangle_{W' \times W}. \end{aligned} \tag{5.11}$$

Consider the second term of the right-hand side on (5.10). Since for $h_t > 0$ $\left\|(I + h_t^2 A/4)^{-1}\right\|_{\mathcal{L}(H)} = \sup_{\lambda_j \in \sigma(A)} (1 + h_t^2 \lambda_j/4)^{-1} \leq 1$, we have

$$\begin{aligned} \left| \left\langle \left(I + h_t^2 A/4\right)^{-1} A u^k,\, \gamma\kappa \right\rangle_{V' \times V} \right| &= \left| \left(\left(I + h_t^2 A/4\right)^{-1} A^{1/2} u^k,\, A^{1/2} \gamma\kappa \right)_H \right| \\ &\leq \left\| \left(I + h_t^2 A/4\right)^{-1} A^{1/2} u^k \right\|_H \left\| A^{1/2} \gamma\kappa \right\|_H \\ &\leq \left\| \left(I + h_t^2 A/4\right)^{-1} \right\|_{\mathcal{L}(H)} \left\| A^{1/2} u^k \right\|_H \left\| A^{1/2} \gamma\kappa \right\|_H \\ &\leq \left\| u^k \right\|_V \left\| \gamma\kappa \right\|_V. \end{aligned} \tag{5.12}$$

Consider the third term of the right-hand side of (5.10). Since

$$\left\|(I + h_t^2 A/4)^{-1} h_t A^{1/2}/2\right\|_{\mathcal{L}(H)} = \sup_{\lambda_j \in \sigma(A)} (h_t \lambda_j^{1/2}/2)(1 + h_t^2 \lambda_j/4)^{-1} \leq 1 \text{ for any } h_t > 0,$$

we obtain

$$\begin{aligned} & h_t \left| \left\langle \left(I + h_t^2 A/4\right)^{-1} A v^k,\, \gamma\kappa \right\rangle_{V' \times V} \right| \\ & = h_t \left| \left(\left(I + h_t^2 A/4\right)^{-1} A^{1/2} v^k,\, A^{1/2} \gamma\kappa \right)_H \right| \\ & \leq \left\| \left(I + h_t^2 A/4\right)^{-1} h_t A^{1/2} v^k \right\|_H \left\| A^{1/2} \gamma\kappa \right\|_H \\ & \leq 2 \left\| \left(I + h_t^2 A/4\right)^{-1} h_t A^{1/2}/2 \right\|_{\mathcal{L}(H)} \left\| v^k \right\|_H \left\| A^{1/2} \gamma\kappa \right\|_H \\ & \leq 2 \left\| v^k \right\|_H \left\| \gamma\kappa \right\|_V. \end{aligned} \tag{5.13}$$

Consider the fourth term of the right-hand side of (5.10). Then we have

$$\begin{aligned} h_t \left| \left\langle \left(I + h_t^2 A/4\right)^{-1} f,\, \gamma\kappa \right\rangle_{V' \times V} \right| &= h_t \left| \left(\left(I + h_t^2 A/4\right)^{-1} A^{-1/2} f,\, A^{1/2} \gamma\kappa \right)_H \right| \\ &\leq h_t \left\| \left(I + h_t^2 A/4\right)^{-1} \right\|_{\mathcal{L}(H)} \left\| A^{-1/2} f \right\|_H \left\| A^{1/2} \gamma\kappa \right\|_H \\ &\leq h_t \left\| f \right\|_{V'} \left\| \gamma\kappa \right\|_V. \end{aligned}$$

By Lemma 5.4, $\beta(I+h_t^2A/4)^{-1}\gamma\,\kappa \in \operatorname{int} K$ for sufficiently small $h_t>0$. Thus if $\|\kappa-\beta(I+h_t^2A/4)^{-1}\gamma\kappa\|_W \le \eta/2$ for sufficiently small $h_t>0$, then for all $\zeta\in K^*$,

$$\begin{aligned}&\langle\zeta,\,\kappa\rangle_{W'\times W}-\left\langle\zeta,\,\beta(I+h_t^2A/4)^{-1}\gamma\kappa\right\rangle_{W'\times W}\\&=\left\langle\zeta,\,\kappa-\beta(I+h_t^2A/4)^{-1}\gamma\kappa\right\rangle_{W'\times W}\\&\le\|\zeta\|_{W'}\left\|\kappa-\beta(I+h_t^2A/4)^{-1}\gamma\kappa\right\|_W\le\frac{\eta}{2}\|\zeta\|_{W'}.\end{aligned}$$

Since $\langle\zeta,\kappa\rangle\ge\eta\|\zeta\|_{W_{-\theta}}$, we have

$$\begin{aligned}&\eta\|\zeta\|_{W_{-\theta}}-\left\langle\zeta,\,\beta(I+h_t^2A/4)^{-1}\gamma\kappa\right\rangle_{W'\times W}\\&\le\langle\zeta,\,\kappa\rangle_{W'\times W}-\left\langle\zeta,\,\beta(I+h_t^2A/4)^{-1}\gamma\kappa\right\rangle_{W'\times W}\le\frac{\eta}{2}\|\zeta\|_{W_{-\theta}}.\end{aligned}$$

Therefore we obtain

$$\left\langle\zeta,\,\beta(I+h_t^2A/4)^{-1}\gamma\kappa\right\rangle_{W'\times W}\ge\frac{\eta}{2}\|\zeta\|_{W_{-\theta}}\quad\text{for all }\zeta\in K^*.\tag{5.14}$$

Now by (5.10) and (5.11), taking ζ as N^k, we obtain

$$\begin{aligned}&h_t\sum_{k=0}^{T/h_t-1}\left\langle N^k,\,\beta\left(I+h_t^2A/4\right)^{-1}\gamma\kappa\right\rangle_{W'\times W}\\&=\sum_{k=0}^{T/h_t-1}\left(v^{k+1}-v^k,\,\gamma\kappa\right)_{H\times V}+h_t\sum_{k=0}^{T/h_t-1}\left\langle\left(I+h_t^2A/4\right)^{-1}Au^k,\,\gamma\kappa\right\rangle_{V'\times V}\\&\quad+\frac{h_t^2}{2}\sum_{k=0}^{T/h_t-1}\left\langle\left(I+h_t^2A/4\right)^{-1}Av^k,\,\gamma\kappa\right\rangle_{V'\times V}+h_t\left\langle\left(I+h_t^2A/4\right)^{-1}f,\,\gamma\kappa\right\rangle_{V'\times V}.\end{aligned}$$

Thus using Lemma 5.3, by (5.12), (5.13), and (5.14)

$$\begin{aligned}&\frac{\eta h_t}{2}\sum_{k=0}^{T/h_t-1}\left\|N^k\right\|_{W_{-\theta}}\\&\le h_t\sum_{k=0}^{T/h_t-1}\left\langle N^k,\,\beta\left(I+h_t^2A/4\right)^{-1}\gamma\kappa\right\rangle_{W'\times W}\\&\le\|\gamma\kappa\|_H\left(\left\|v^{T/h_t}\right\|_H+\left\|v^0\right\|_H\right)+h_t\|\gamma\kappa\|_V\left(\sum_{k=0}^{T/h_t-1}\left(\left\|u^k\right\|_V+\left\|v^k\right\|_H\right)\right)\\&\quad+T\,\|f\|_{V'}\|\gamma\kappa\|_V\\&\le\|\gamma\kappa\|_H\left(\left\|v^{T/h_t}\right\|_H+\left\|v^0\right\|_H\right)+T\,\|\gamma\kappa\|_V\max_{0\le k\le T/h_t-1}\left(\left\|u^k\right\|_V+\left\|v^k\right\|_H\right)\\&\quad+T\,\|f\|_{V'}\|\gamma\kappa\|_V\\&\le C\left(\|f\|_{V'}+\sqrt{E^0}+^4\sqrt{E^0\|f\|_{V'}^2}\right),\end{aligned}\tag{5.15}$$

where C does not depend on h_t. Note that E^0 is the initial energy. Since

$$\sum_{k=0}^{T/h_t-1}\left\|N^k\right\|_{W_{-\theta}}=h_t^{-1}\int_{[0,T]}\|N_{h_t}(t)\|_{W_{-\theta}}\,dt,$$

so

$$\int_{[0,T]} \|N_{h_t}(t)\|_{W_{-\theta}} dt \le \frac{2C}{\eta}\left(\|f\|_{V'} + \sqrt{E^0} + {}^4\sqrt{E^0\,\|f\|_{V'}^2}\right) \text{ for sufficiently small } h_t > 0,$$

as required. □

For any $\sigma \in \mathbb{R}$ we define the space of Hölder continuous functions with exponent $0 < p \le 1$ in $C^p(0,T;V_\sigma)$ with norm

$$\|u\|_{C^p(0,T;V_\sigma)} = \|u\|_{C(0,T;V_\sigma)} + \sup_{t\neq s} \frac{\|u(t)-u(s)\|_{V_\sigma}}{|t-s|^p}.$$

In the next Lemma, we will see that interpolant u_{h_t} is uniformly Hölder continuous from $[0,T]$ to V_σ, $0 \le \sigma < 1$. In order to do so, we need the following inequality: for $u \in V$ we have

$$\|u\|_{V_\sigma} \le C_\sigma \|u\|_H^{1-\sigma} \|u\|_V^{\sigma}, \tag{5.16}$$

where $0 < \sigma < 1$. This inequality is presented in Kuttler [15, section 22.6, equation (62)], Triebel [34, Thm. 1.3.3(g)], and Bramble & Xu [7, Appendix A, Thms. A.1 and A.2]. Also, if $\sigma = 0$ or $\sigma = 1$, clearly (5.16) is satisfied.

LEMMA 5.6. *The discrete-time solutions u_{h_t} are uniformly Hölder continuous from $[0,T] \to V_\sigma$ with exponent $p = 1-\sigma$, where $0 \le \sigma < 1$.*

Proof. We claim that for s, $t \in [0,T]$, $\|u_{h_t}(s) - u_{h_t}(t)\|_{V_\sigma} \le C\,|s-t|^p$. Using the interpolation space bounds (5.16),

$$\begin{aligned}
\|u_{h_t}(s) - u_{h_t}(t)\|_{V_\sigma} &\le \|u_{h_t}(s) - u_{h_t}(t)\|_H^{1-\sigma}\, \|u_{h_t}(s) - u_{h_t}(t)\|_V^{\sigma} \\
&\le C_\sigma \left\| \int_s^t v_{h_t}(\tau)\, d\tau \right\|_H^{1-\sigma} \|u_{h_t}(s) - u_{h_t}(t)\|_V^{\sigma} \\
&\le C_\sigma \left(\int_s^t \|v_{h_t}(\tau)\|_H \, d\tau \right)^{1-\sigma} \left(\|u_{h_t}(s)\|_V + \|u_{h_t}(t)\|_V\right)^{\sigma}.
\end{aligned}$$

Then by the energy bounds, we obtain

$$\begin{aligned}
&\|u_{h_t}(s) - u_{h_t}(t)\|_{V_\sigma} \\
&\le C_\sigma \left(\|f\|_{V'} + \sqrt{2E^0}\right)^{\sigma} \left(2\,\|f\|_{V'} + {}^4\sqrt{2E^0\,\|f\|_{V'}^2} + \sqrt{E^0}\right)^{(1-\sigma)} |s-t|^{1-\sigma} \\
&\le C_\sigma\, |s-t|^p,
\end{aligned}$$

where C_σ is a constant independent of h_t, s and t. □

Thus we can see that the interpolant u_{h_t} is uniformly bounded in $C^p(0,T;V_\sigma)$. Now we need compactness to show that u_{h_t} converges strongly in $C([0,T];V_\sigma)$, as $h_t \downarrow 0$. The continuous linear interpolant $u_{h_t} : [0,T] \to V$ is bounded in V_σ with $\sigma < 1$, so $u_{h_t}(t)$ is in a compact subset of V_σ for all $t \in [0,T]$ and $h_t > 0$, and $u_{h_t} : [0,T] \to V_\sigma$ is an equicontinuous family. By the *Arzela–Ascoli Theorem* [18, p. 57], $C^p(0,T;V_\sigma)$ is compactly embedded in $C(0,T;V_\sigma)$ for any $\sigma < 1$.

Thus u_{h_t} has a subsequence which converges strongly in $C(0,T;V_\sigma)$. Denoting this subsequence by u_{h_t}, we restrict our attention to this subsequence.

In the next Lemma, we will see that solutions obtained by our numerical trajectories satisfy differential equations in the sense of measure.

LEMMA 5.7. *The limits (u, v, N) obtained from the numerical trajectories $(u_{h_t}, v_{h_t}, N_{h_t})$ satisfy $du/dt = v$ in $L^\infty(0, T; H)$, and the equation of motion (3.1) holds in $\mathcal{M}(0, T-\epsilon; V')$, the space of V'-valued measures on $[0, T-\epsilon]$, for any $\epsilon > 0$, where $v(0) = v^0$.*

Proof. First, we claim that $du_{h_t}/dt(t) = (v_{h_t}(t-h) + v_{h_t}(t))/2$ for all $t \neq t_k$ with u_{h_t} absolutely continuous. From (5.2) and the fact that u_{h_t} is the piecewise linear interpolant of $u_h(t_k) = u^k$ for all k, we have

$$\frac{du_{h_t}}{dt}(t) = \frac{v^{k+1} + v^k}{2} \quad \text{for all } t \in (t_k, t_{k+1}).$$

Because v_{h_t} is piecewise constant, $du_{h_t}/dt(t) = (v_{h_t}(t - h_t) + v_{h_t}(t))/2$ for $t \in (t_k,\, t_{k+1})$. Thus for any $0 \le s < t \le T$,

$$u_{h_t}(t) - u_{h_t}(s) = \int_s^t \frac{1}{2}(v_{h_t}(\tau - h_t) + v_{h_t}(\tau))\, d\tau.$$

As $u_{h_t} \to u$ in $C(0, T; V_\sigma) \subset C(0, T; H)$, and $v_{h_t} \rightharpoonup^* v$ in $L^\infty(0, T; H)$, taking limits in any convergent subsequence gives

$$u(t) - u(s) = \int_s^t v(\tau)\, d\tau,$$

and so $du/dt(t) = v(t)$ for almost all t.

We claim that for all $\xi \in \mathrm{Lip}(0, T; V)$ (the space of Lipschitz functions $[0, T] \to V$) with $\xi(T) = 0$, (u, v, N) obtained from the numerical trajectory $(u_{h_t}, v_{h_t}, N_{h_t})$ satisfies

$$\int_{[0,T]} \left\langle \frac{dv}{dt}(t),\, \xi(t) \right\rangle_{V' \times V} dt = \int_{[0,T]} \langle -Au(t) + \beta^* N(t) + f,\, \xi(t) \rangle_{V' \times V}\, dt \tag{5.17}$$

interpreted in the sense of distributions. Note that a Lipschitz function $\xi\colon [0, T] \to V$ is differentiable almost everywhere with a derivative in $L^\infty(0, T; V)$ as V has the Radon–Nikodym property [11]. Note that on $[0, T]$,

$$\frac{dv_{h_t}}{dt}(t) = \sum_{k=0}^{T/h_t - 1} \left(v^{k+1} - v^k\right) \delta\left(t - t_k\right)$$

in the sense of distributions. Then using (5.1), we have, noting that T is a multiple of h_t:

$$\begin{aligned}
&\int_{[0,T]} \left\langle \frac{dv_{h_t}}{dt}(t),\, \xi(t) \right\rangle_{V' \times V} dt \\
&= \sum_{k=0}^{T/h_t - 1} \left\langle v^{k+1} - v^k,\, \xi(t_k) \right\rangle \\
&= h_t \sum_{k=0}^{T/h_t - 1} \left\langle -A\left(\frac{u^{k+1} + u^k}{2}\right) + \beta^* N^k + f,\, \xi(t_k) \right\rangle \\
&= h_t \sum_{k=0}^{T/h_t - 1} \left\langle -A\left(\frac{u^{k+1} + u^k}{2}\right),\, \xi(t_k) \right\rangle + h_t \sum_{k=0}^{T/h_t} \left\langle \beta^* N^k + f,\, \xi(t_k) \right\rangle. \qquad (5.18)
\end{aligned}$$

Consider the first sum in (5.18). Since u_{h_t} is a piecewise linear interpolant, we obtain

$$\begin{aligned}
&h_t \sum_{k=0}^{T/h_t-1} \left\langle -A\left(\frac{u^{k+1}+u^k}{2}\right), \xi(t_k)\right\rangle \\
&= \sum_{k=0}^{T/h_t-1} \int_{t_k}^{t_{k+1}} \langle -Au_{h_t}, \xi(t_k)\rangle \, dt \\
&= \sum_{k=0}^{T/h_t-1} \int_{t_k}^{t_{k+1}} \langle -Au_{h_t}(t), \xi(t)-\xi(t)+\xi(t_k)\rangle \, dt \\
&= -\sum_{k=0}^{T/h_t-1} \int_{t_k}^{t_{k+1}} \langle Au_{h_t}(t), \xi(t)\rangle \, dt + \sum_{k=0}^{T/h_t-1} \int_{t_k}^{t_{k+1}} \langle Au_{h_t}(t), \xi(t)-\xi(t_k)\rangle \, dt \\
&= -\int_{[0,T]} \langle Au_{h_t}(t), \xi(t)\rangle \, dt + \int_{[0,T]} \langle Au_{h_t}(t), \xi(t)-\xi(h_t\lfloor t/h_t\rfloor)\rangle \, dt.
\end{aligned} \tag{5.19}$$

Consider the second sum in (5.18). Then by the similar argument to above,

$$\begin{aligned}
&h_t \sum_{k=0}^{T/h_t-1} \left\langle \beta^* N^k + f, \xi(t_k)\right\rangle \\
&= \sum_{k=0}^{T/h_t-1} \int_{t_k}^{t_{k+1}} \langle \beta^* N_{h_t}(t) + f, \xi(t_k)\rangle \, dt \\
&= \sum_{k=0}^{T/h_t-1} \int_{t_k}^{t_{k+1}} \langle \beta^* N_{h_t}(t) + f, \xi(t)\rangle \, dt + \sum_{k=0}^{T/h_t-1} \int_{t_k}^{t_{k+1}} \langle \beta^* N_h(t) + f, \xi(t_k)-\xi(t)\rangle \, dt \\
&= \int_{[0,T]} \langle \beta^* N_{h_t}(t) + f, \xi(t)\rangle \, dt + \int_{[0,T]} \langle \beta^* N_{h_t}(t) + f, \xi(h_t\lfloor t/h_t\rfloor)-\xi(t)\rangle \, dt.
\end{aligned} \tag{5.20}$$

Let C_ξ be the Lipschitz constant of ξ. Then

$$\begin{aligned}
&\left| \int_{[0,T]} \langle \beta^* N_{h_t}(t) + f, \xi(h_t\lfloor t/h_t\rfloor)-\xi(t)\rangle \, dt \right| \\
&\le \int_{[0,T]} \|\beta^* N_{h_t}(t) + f\|_{V'} \, \|\xi(h_t\lfloor t/h_t\rfloor)-\xi(t)\|_V \, dt \\
&\le C_\xi \, h_t \int_{[0,T]} \left(\|\beta^* N_{h_t}(t)\|_{V'} + \|f\|_{V'}\right) \, dt \le C \, h_t
\end{aligned}$$

for some C not depending on h_t. It follows that

$$\int_{[0,T]} \langle \beta^* N_{h_t}(t) + f, \xi(h_t\lfloor t/h_t\rfloor)-\xi(t)\rangle \, dt \to 0 \quad \text{as } h_t \downarrow 0.$$

Similarly, using the fact that Au_{h_t} is uniformly bounded in $L^\infty(0,T;V')$,

$$\int_{[0,T]} \langle Au_{h_t}(t), \xi(h_t\lfloor t/h_t\rfloor - \xi(t)\rangle \, dt \to 0 \quad \text{as } h_t \downarrow 0.$$

Extend ξ to $\xi\colon \mathbb{R} \to V$ by setting $\xi(t) = \xi(0)$ for $t < 0$ and $\xi(t) = \xi(T) = 0$ for $t > T$. Now, using integration by parts,

$$\int_{[0,T]} \left\langle \frac{dv_{h_t}}{dt}(t),\, \xi(t) \right\rangle dt = \left\langle v_{h_t}(T^+),\, \xi(T^+) \right\rangle - \left\langle v_{h_t}(0^-),\, \xi(0^-) \right\rangle - \int_0^T \left\langle v_{h_t}(t),\, \frac{d\xi}{dt}(t) \right\rangle dt.$$

But $v_{h_t}(0) = v^0$, the initial velocity, and $\xi(T^+) = \xi(T) = 0$, so

$$\int_{[0,T]} \left\langle \frac{dv_{h_t}}{dt}(t),\, \xi(t) \right\rangle dt = -\left\langle v^0,\, \xi(0) \right\rangle - \int_{[0,T]} \left\langle v_{h_t}(t),\, \frac{d\xi}{dt}(t) \right\rangle dt. \tag{5.21}$$

Since $v_{h_t} \rightharpoonup^* v$ in $L^\infty(0,T;H)$, the right-hand side of (5.21) converges to

$$-\left\langle v^0,\, \xi(0) \right\rangle - \int_{[0,T]} \left\langle v(t),\, \frac{d\xi}{dt}(t) \right\rangle dt.$$

Using integration by parts again, we see that this limit is just

$$\int_{[0,T]} \left\langle \frac{dv}{dt}(t),\, \xi(t) \right\rangle dt.$$

Now taking the weak* limits $\beta^* N_{h_t} \rightharpoonup^* \beta^* N$ in $\mathcal{M}(0,T;V')$ and $Au_{h_t} \rightharpoonup^* Au$ in $L^\infty(0,T;V')$, we get

$$\int_{[0,T]} \left\langle \frac{dv}{dt}(t),\, \xi(t) \right\rangle dt = \int_{[0,T]} \langle -Au(t) + \beta^* N(t) + f,\, \xi(t) \rangle \, dt,$$

for all $\xi \in \mathrm{Lip}(0,T;V)$, $\xi(T) = 0$. Since any function $\widetilde{\xi} \in \mathrm{Lip}(0, T-\epsilon; V)$ can be extended to a function $\xi \in \mathrm{Lip}(0,T;V)$ with $\xi(T) = 0$,

$$\begin{aligned} \frac{dv}{dt} &= -Au + \beta^* N + f \quad \text{on } [0, T-\epsilon], \\ v(0) &= v^0, \end{aligned}$$

in the sense of distributions for any $\epsilon > 0$, as desired. ∎

In the next Lemma, we will see that the limit of the numerical trajectories, as $h_t \downarrow 0$, satisfies the complementarity condition in the weak sense.

LEMMA 5.8. *Setting $\sigma = (1-\theta)\alpha + \theta$ with $\theta < 1$ and $\alpha < 1$ satisfying* (A6) *and* (A7)*, we have*

$$0 \le \int_{[0,T]} \langle N_{h_t}(t), \beta u_{h_t}(t) - \varphi \rangle_{W_{-\theta} \times W_\theta} \, dt \le C_{\theta,\sigma} h_t^{1-\sigma} \int_{[0,T]} \|N_{h_t}(t)\|_{W_{-\theta}} \, dt.$$

Proof. Let $q_{h_t}(t) = u_{h_t}(t) - u^{k+1}$ for $t_k \le t \le t_{k+1}$. Then by complementarity condition, for $t_k \le t \le t_{k+1}$ we have

$$\begin{aligned} \langle N_{h_t}(t), \beta u_{h_t}(t) - \varphi \rangle_{W_{-\theta} \times W_\theta} &= \left\langle N_{h_t}(t),\, \beta q_{h_t}(t) + \beta u^{k+1} - \varphi \right\rangle_{W_{-\theta} \times W_\theta} \\ &= \langle N_{h_t}(t),\, \beta q_{h_t}(t) \rangle_{W_{-\theta} \times W_\theta}. \end{aligned}$$

Since $\left\|N^k\right\|_{W_{-\theta}} = \|N_{h_t}(t)\|_{W_{-\theta}}$ for $t_k \le t < t_{k+1}$, we obtain

$$\begin{aligned}\int_{t_k}^{t_{k+1}} \langle N_{h_t}(t),\, \beta q_{h_t}(t)\rangle_{W_{-\theta}\times W_\theta}\, dt &= \int_{t_k}^{t_{k+1}} \left\langle N^k, \beta q_{h_t}(t)\right\rangle_{W_{-\theta}\times W_\theta} dt \\ &\le C_\theta \int_{t_k}^{t_{k+1}} \|q_{h_t}(t)\|_{V_\theta} \left\|N^k\right\|_{W_{-\theta}} dt \\ &= C_\theta \left\|N^k\right\|_{W_{-\theta}} \int_{t_k}^{t_{k+1}} \|q_{h_t}(t)\|_{V_\theta}\, dt.\end{aligned}$$

Using trapezoidal rule for the integral of linear interpolant u_{h_t} and Lemma 5.6, we have

$$\begin{aligned}\int_{t_k}^{t_{k+1}} \langle N_{h_t}(t),\, \beta q_{h_t}(t)\rangle_{W_{-\theta}\times W_\theta}\, dt &\le \frac{C_\theta}{2} \left\|N^k\right\|_{W_{-\theta}} \left\|u^{k+1} - u^k\right\|_{V_\sigma} \cdot h_t \\ &\le C_{\theta,\sigma} \left\|N^k\right\|_{W_{-\theta}} h_t^{1-\sigma} h_t.\end{aligned}$$

Thus

$$\begin{aligned}\int_{[0,T]} \langle N_{h_t}(t), \beta u_{h_t}(t) - \varphi\rangle_{W_{-\theta}\times W_\theta}\, dt &= \sum_{k=0}^{T/h_t-1} \int_{t_k}^{t_{k+1}} \langle N_{h_t}(t),\, \beta q_{h_t}(t)\rangle_{W_{-\theta}\times W_\theta}\, dt \\ &\le C_{\theta,\sigma} \sum_{k=0}^{T/h_t-1} \left\|N^k\right\|_{W_{-\theta}} h_t^{1-\sigma} h_t \\ &= C_{\theta,\sigma} h_t^{1-\sigma} \int_{[0,T]} \|N_{h_t}(t)\|_{W_{-\theta}}\, dt,\end{aligned}$$

as required. ∎

LEMMA 5.9. *Suppose that dual cone K^* is strongly pointed and $\theta < 1$ and $\sigma < 1$. Then u_{h_t} strongly converges to solution u in $C(0,T;V_\sigma)$ and N_{h_t} weakly* converges to solution N in the measure space $\mathcal{M}(0,T;W_{-\theta})$, as $h_t \downarrow 0$, and the limits satisfy complementarity condition in the weak sense.*

Proof. Let $\sigma = (1-\theta)\alpha + \theta < 1$ where $\alpha < 1$ and $\theta < 1$ from (A6) and (A7). By the Arzela–Ascoli Theorem there is a strongly convergent subsequence u_{h_t} to u in $C(0,T;V_\sigma)$. An elementary calculation and the interpolation theory of operators show that $\beta\colon V_\sigma \to W_\theta$ is a bounded linear operator. On the other hand, there is a subsequence in which N_{h_t} converges weakly* to N in $\mathcal{M}(0,T;W_{-\theta})$ by the *Alouglu's Theorem* [24, Thm. 6.62, p. 203]. Then by Lemma 5.8, as $h_t \downarrow 0$, we have

$$0 \le \int_{[0,T]} \langle N_{h_t}(t), \beta u_{h_t}(t) - \varphi\rangle_{W_{-\theta}\times W_\theta}\, dt \le C_{\theta,\sigma} h_t^{1-\sigma} \int_{[0,T]} \|N_{h_t}(t)\|_{W_{-\theta}}\, dt \to 0.$$

Since K is a closed convex cone in W, for any $\zeta \in K^*$ and $0 \le s < t \le T$, $0 \le \int_s^t \langle \zeta,\, \beta u_{h_t} - \varphi\rangle\, d\tau \to \int_s^t \langle \zeta,\, \beta u - \varphi\rangle\, d\tau$, and so $\beta u(t) - \varphi \in K$ for almost all t. Similarly, $N_{h_t} \rightharpoonup^* N \in K^*$. Thus,

$$\int_{[0,T]} \langle N_{h_t}(t), \beta u_{h_t}(t) - \varphi\rangle_{W_{-\theta}\times W_\theta}\, dt \to \int_{[0,T]} \langle N(t), \beta u(t) - \varphi\rangle_{W_{-\theta}\times W_\theta}\, dt.$$

As the integral on the left is $O(h_t^{1-\sigma})$ as $h_t \downarrow 0$, $\int_{[0,T]} \langle N(t), \beta u(t) - \varphi\rangle\, dt = 0$. This implies that the limits of the discrete-time trajectories satisfy the complementarity condition in the weak sense. The proof is complete. ∎

5.3. Convergence theory in the fully discrete case. Let $\{\psi_i \mid i = 1, \ldots, \mathcal{N}_{h_x}\}$ be a basis for a subspace $V^{h_x} \subset V$; this is the basis that is used for space discretization: $u(t_k, x) \approx \sum_{j=1}^{\mathcal{N}_{h_x}} u_j^k \psi_j(x)$ on each time t_k.

Then let $\{\Phi_i \mid \Phi_i = \beta\psi_i \text{ for } i = 1, \ldots, \mathcal{N}_{h_x}\}$ be a basis for a finite dimensional space $W_\theta^{h_x} \subset W_\theta$, and $K^{h_x} \subset K$ be the cone generated by $\{\beta\psi_i \mid 1 \le i \le \mathcal{N}_{h_x}\}$ such that $K^{h_x} \subset W_\theta^{h_x}$.

In order to show the full convergence of our numerical trajectories, we need the following conditions:

(B1) The dual cone K^* is a closure of K in $W_{-\theta}$.
(B2) For every $w \in K$, $\min_{z \in K^{h_x}} \|w - z\|_W \to 0$ as $n \to 0$.
(B3) There is a constant $C > 0$, where $\|\psi_i\|_{W_{-\theta}} \le C$ for all i, independent of $h_x > 0$.
(B4) There is a constant $C_1, C_2 > 0$, where $\left\|\mathbf{M}^{-1}\right\| \le C_1$ and $\|\mathbf{M}\| \le C_2$, independent of $h_x > 0$.
(B5) There is a constant η_1, where $\min_i \kappa_i / \max_i \kappa_i \ge \eta_1 > 0$ with $\kappa_{h_x} := \sum_{j=1}^{\mathcal{N}_{h_x}} \kappa_j \times \beta\psi_j \in W_\theta \cap K^{h_x}$, independent of $h_x > 0$.
(B6) There is a constant η_2 where $\|\boldsymbol{\kappa}\|_\infty \ge \eta_2 > 0$, independent of $h_x > 0$ ($\boldsymbol{\kappa} = (\kappa_1, \kappa_2, \ldots, \kappa_{\mathcal{N}_{h_x}})$).

Note that (B1) is a self-duality condition. Also note that we can suppose (B4), by the condition number of $\mathbf{M}$, $\mathrm{cond}(\mathbf{M}) = \left\|\mathbf{M}^{-1}\right\| \|\mathbf{M}\| \le C$ and scalar-invariance. The condition (B2) implies that we can approximate w by $z \in K^{h_x}$. We write the approximate solution $N_{h_x}^k \in K^{h_x}$ each time step t_k as

$$N_{h_x}^k = \sum_{j=1}^{\mathcal{N}_{h_x}} N_j^k \beta\psi_j,$$

where $\mathbf{N}^k = (N_1^k, N_2^k, \cdots, N_{\mathcal{N}_{h_x}}^k)^T$. In the same fashion, we write approximate solution $(u_{h_x}^k, v_{h_x}^k) \in V_\sigma^{h_x} (\subset V_\sigma) \times H^{h_x} (\subset H)$ each time step t_k as

$$u_{h_x}^k = \sum_{j=1}^{\mathcal{N}_{h_x}} u_j^k \psi_j \quad \text{and} \quad v_{h_x}^k = \sum_{j=1}^{\mathcal{N}_{h_x}} v_j^k \psi_j,$$

where $\mathbf{u}^k = (u_1^k, u_2^k, \ldots, u_{\mathcal{N}_{h_x}}^k)^T$, $\mathbf{v}^k = (v_1^k, v_2^k, \ldots, v_{\mathcal{N}_{h_x}}^k)^T$. Then we notice that approximate solutions $u_{h_t,h_x} \in C(0,T;V_\sigma)$ and $v_{h_t,h_x} \in L^\infty(0,T;H)$ in the fully discrete case.

From (5.3) the approximate solutions satisfy the complementarity condition:

$$\mathbf{0} \le \mathbf{g}^{k+1} \quad \perp \quad \mathbf{N}^k \ge \mathbf{0}, \tag{5.22}$$

where $\beta u^{k+1} - \varphi = \sum_{j=1}^{\mathcal{N}_{h_x}} \left(u_j^{k+1} - \varphi_j\right) \beta\psi_j$ and $\mathbf{g}^k = \left(g_1^k, g_2^k, \cdots, g_n^k\right)^T$ with $g_j^k = u_j^k - \varphi_j$. Then employing the fully discrete version, we have the norm of N_{h_t,h_x} as a $W_{-\theta}$-valued measure given by

$$\begin{aligned} \int_{[0,T]} \|N_{h_t,h_x}\|_{W_{-\theta}} \, dt &= h_t \sum_{k=0}^{T/h_t - 1} \left\| \sum_{j=1}^{\mathcal{N}_{h_x}} N_j^k \beta\psi_j \right\|_{W_{-\theta}} \\ &\le h_t \sum_{k=0}^{T/h_t - 1} \sum_{j=1}^{\mathcal{N}_{h_x}} \left|N_j^k\right| \|\beta\psi_j\|_{W_{-\theta}} . \end{aligned} \tag{5.23}$$

The mass matrix $\mathbf{M}$ is given by $m_{ji} = (\beta\psi_j, \beta\psi_i)_Z$. Also we assume that $\mathbf{M}$ is a positive definite. Attributed to the basis functions and mass matrix, now we modify the complementarity condition (5.22) into the alternative complementarity condition that is necessary to consider full convergence:

$$\mathbf{0} \le \mathbf{g}^{k+1} \quad \perp \quad \mathbf{M}\mathbf{N}^k \ge \mathbf{0}. \tag{5.24}$$

LEMMA 5.10. *Suppose that K^* is strongly pointed;* (B1–B6) *hold. Then we have*

$$\int_{[0,T]} \|N_{h_t,h_x}\|_{W_{-\theta}}\, dt \le C \quad \textit{for sufficiently small } h_t,\, h_x > 0,$$

where $\theta \le 1$ and C does not depend on h_t and h_x.

Proof. By Lemma 5.4, $\beta(I + h_t^2 A/4)^{-1}\gamma\omega \to \omega$ on W for any $\omega \in W$. Then we approximate κ by $\kappa_{h_x} := \sum_{j=1}^{\mathcal{N}_{h_x}} \kappa_j \beta\psi_j \in W_\theta \cap K^{h_x}$, where $\kappa_j > 0$ for any $j \ge 1$, since K is a convex cone. Recalling that (A6) is equivalent to $\kappa \in \operatorname{int} K$ in W_θ, it follows that $\kappa_{h_x} \to \kappa$ as $h_x \downarrow 0$ and $\beta(I + h_t^2 A/4)^{-1}\gamma\kappa \to \kappa$ as $h_t \downarrow 0$. Thus we choose sufficiently small $h_x > 0$ and $h_t > 0$, such that $\|\kappa_{h_x} - \kappa\|_{W_\theta} \le \eta/4$ and $\|\beta(I+h_t^2A/4)^{-1}\gamma\kappa - \kappa\|_{W_\theta} \le \eta/4$. Now employing the estimate (5.15), for sufficiently small $h_t > 0$ and $h_x > 0$ we obtain

$$\begin{aligned}
C &\ge h_t \sum_{k=0}^{T/h_t-1} \left\langle N_{h_x}^k,\, \beta\left(I + h_t^2 A/4\right)^{-1}\gamma\kappa \right\rangle_{W'\times W} \\
&\ge h_t \sum_{k=0}^{T/h_t-1} \left\langle N_{h_x}^k,\, \beta\left(I + h_t^2 A/4\right)^{-1}\gamma\kappa - \kappa + \kappa - \kappa_{h_x} + \kappa_{h_x} \right\rangle_{W'\times W} \\
&= h_t \sum_{k=0}^{T/h_t-1} \left\langle N_{h_x}^k,\, \kappa_{h_x} \right\rangle_{W'\times W} - h_t \sum_{k=0}^{T/h_t-1} \left\langle N_{h_x}^k,\, \kappa_{h_x} - \kappa \right\rangle_{W'\times W} \\
&\qquad - h_t \sum_{k=0}^{T/h_t-1} \left\langle N_{h_x}^k,\, \kappa - \beta\left(I + h_t^2 A/4\right)^{-1}\gamma\kappa \right\rangle_{W'\times W} \\
&\ge h_t \sum_{k=0}^{T/h_t-1} \left(\left\langle N_{h_x}^k,\, \kappa_{h_x} \right\rangle_{W'\times W} - \frac{\eta}{2} \left\| N_{h_x}^k \right\|_{W_{-\theta}} \right).
\end{aligned} \tag{5.25}$$

Then using (5.15) again, from (5.25)

$$h_t \sum_{k=0}^{T/h_t-1} \left\langle N_{h_x}^k,\, \kappa_{h_x} \right\rangle_{W'\times W} \le \frac{\eta h_t}{2} \sum_{k=0}^{T/h_t-1} \left\| N_{h_x}^k \right\|_{W_{-\theta}} + C \le C.$$

Thus we have

$$\begin{aligned} C &\geq h_t \sum_{k=0}^{T/h_t-1} \left\langle N_{h_x}^k,\, \kappa_{h_x} \right\rangle_{W'\times W} \\ &= h_t \sum_{k=0}^{T/h_t-1} \left(N_{h_x}^k,\, \kappa_{h_x} \right)_Z \\ &= h_t \sum_{k=0}^{T/h_t-1} \left(\sum_{j=1}^{\mathcal{N}_{h_x}} N_j^k \beta\psi_j, \sum_{i=1}^{\mathcal{N}_{h_x}} \kappa_i \beta\psi_i \right)_Z \\ &= h_t \sum_{k=0}^{T/h_t-1} \sum_{i=0}^{\mathcal{N}_{h_x}} \kappa_i \cdot (\mathbf{M}\mathbf{N}^k)_i \\ &\geq h_t \sum_{k=0}^{T/h_t-1} \sum_{i=0}^{\mathcal{N}_{h_x}} \min_{1\leq i\leq \mathcal{N}_{h_x}} \kappa_i \cdot (\mathbf{M}\mathbf{N}^k)_i. \end{aligned}$$

So it follows from condition (B5) that

$$h_t \sum_{k=0}^{T/h_t-1} \left\|\mathbf{M}\mathbf{N}^k\right\|_1 \leq \frac{C}{\eta_1 \left\|\boldsymbol{\kappa}\right\|_\infty}. \tag{5.26}$$

Therefore using (5.23) and (5.26),

$$\begin{aligned} \int_{[0,T]} \|N_{h_t,h_x}\|_{W_{-\theta}}\, dt &= h_t \sum_{k=0}^{T/h_t-1} \left\| \sum_{j=1}^{\mathcal{N}_{h_x}} N_j^k \beta\psi_j \right\|_{W_{-\theta}} \\ &\leq h_t \sum_{k=0}^{T/h_t-1} \sum_{j=1}^{\mathcal{N}_{h_x}} \left|N_j^k\right| \|\psi_j\|_{W_{-\theta}} \\ &= Ch_t \sum_{k=0}^{T/h_t-1} \left\|\mathbf{N}^k\right\|_1 \\ &= Ch_t \sum_{k=0}^{T/h_t-1} \left\|\mathbf{M}^{-1}\mathbf{M}\mathbf{N}^k\right\|_1 \\ &\leq Ch_t \sum_{k=0}^{T/h_t-1} \left\|\mathbf{M}^{-1}\right\|_1 \left\|\mathbf{M}\mathbf{N}^k\right\|_1 \\ &\leq Ch_t \sum_{k=0}^{T/h_t-1} \left\|\mathbf{M}\mathbf{N}^k\right\|_1 \\ &\leq \frac{C}{\eta_1 \cdot \eta_2} = C, \end{aligned}$$

where C does not depend on h_t and h_x. The proof is complete. ∎

As we mentioned in the semidiscrete case, in the next Lemmas we will restrict our attention to subsequences which are convergent to a solution. We note that we

require contact condition $\mathbf{MN}^k \geq \mathbf{0}$ in (5.24) rather than $\mathbf{N}^k \geq \mathbf{0}$ in (5.22), in order to show full convergence.

LEMMA 5.11. *If $\mathbf{MN}^k \geq \mathbf{0}$ and subsequence N_{h_t,h_x} weakly* converges N in the measure space $\mathcal{M}(0,T;W_{-\theta})$, then $N \in K^*$.*

Proof. Let any ξ be in $C^1(0,T;W_\theta)$. Since $N_{h_t,h_x} \rightharpoonup^* N$ as $W_{-\theta}$-valued measure, we have

$$\int_{[0,T]} \langle N_{h_t,h_x},\, \xi\rangle_{W_{-\theta}\times W_\theta}\, dt \to \int_{[0,T]} \langle N,\, \xi\rangle_{W_{-\theta}\times W_\theta}\, dt.$$

Let $\xi_{h_x}(t) = \sum_{i=1}^{\mathcal{N}_{h_x}} \xi_i(t)\psi_i \in W_\theta \cap K^{h_x}$ be the projection of ξ onto K^{h_x} with $\xi_i(t) > 0$ for all t and i. Since the convex projection is a nonexpansive mapping, ξ_{h_x} is uniformly bounded; ξ_{h_x} is also Lipschitz with the same Lipschitz constant as ξ. Then from (B2) $\xi_{h_x} \to \xi \in K$ with all t. By the standard arguments, $\|\xi_{h_x} - \xi\|_{L^\infty(0,T;W_\theta)} \to 0$ as $h_x \downarrow 0$. Therefore as $h_t \downarrow 0$ and $h_x \downarrow 0$ in suitable subsequence,

$$\int_{[0,T]} \langle N_{h_t,h_x},\, \xi_{h_x}\rangle_{W_{-\theta}\times W_\theta}\, dt \to \int_{[0,T]} \langle N,\, \xi\rangle_{W_{-\theta}\times W_\theta}\, dt. \tag{5.27}$$

Since $\mathbf{MN}^k \geq \mathbf{0}$ and $\xi_i(t) > 0$, it follows that

$$\begin{aligned}
&\int_{[0,T]} \langle N_{h_t,h_x},\, \xi_{h_x}\rangle_{W_{-\theta}\times W_\theta}\, dt \\
&= \int_{[0,T]} \left(h_t \sum_{k=0}^{T/h_t-1} \delta(t-(k+1)h_t) \sum_{j=1}^{\mathcal{N}_{h_x}} N_j^k \beta\psi_j,\, \sum_{i=1}^{\mathcal{N}_{h_x}} \xi_i(t)\beta\psi_i \right)_Z dt \\
&= h_t \sum_{k=0}^{T/h_t-1} \left(\sum_{j=1}^{\mathcal{N}_{h_x}} N_j^k \beta\psi_j,\, \sum_{i=1}^{\mathcal{N}_{h_x}} \xi_i(t_k)\beta\psi_i \right)_Z \\
&= h \sum_{k=0}^{T/h_t-1} \sum_{i=1}^{\mathcal{N}_{h_x}} \xi_i(t_k)(\mathbf{MN}^k)_i \geq 0.
\end{aligned}$$

Thus by (5.27), we have

$$0 \leq \int_{[0,T]} \langle N_{h_t,h_x},\, \xi_{h_x}\rangle_{W_{-\theta}\times W_\theta}\, dt \to \int_{[0,T]} \langle N,\, \xi\rangle_{W_{-\theta}\times W_\theta}\, dt.$$

Thus $\int_{[0,T]} \langle N,\, \xi\rangle\, dt \geq 0$. This implies that $N \in K^*$ in the W'-valued measure. ∎

We note that $du_{h_t,h_x}/dt(t) = \left(v_{h_t,h_x}(t) - v_{h_t,h_x}(t-h_t)\right)/2$ with $v_{h_t,h_x}(t) = v^0$ for $-h_t \leq t < 0$ from numerical formulation (5.2). Before we see the next Lemma, we notice that $u_{h_t,h_x} \rightharpoonup^* u$ in $L^\infty(0,T;V_\sigma)$ with $\sigma \leq 1$ and $v_{h_t,h_x} \rightharpoonup^* v$ in $L^\infty(0,T;H)$, since $L^\infty(0,T;V_\sigma) \simeq \left(L^1(0,T;V_\sigma)\right)^*$ and $L^\infty(0,T;H) \simeq \left(L^1(0,T;H)\right)^*$.

LEMMA 5.12. *Suppose that dual cone K^* is strongly pointed and $\sigma < 1$ and $\theta < 1$. Then the solution $(u,\, N)$ obtained from numerical trajectories $(u_{h_t,h_x},\, N_{h_t,h_x})$ satisfies the complementarity condition* (5.24) *in the weak sense.*

Proof. By the energy bounds in Lemma 5.3 and the similar argument to Lemma 5.6, we have

$$\begin{aligned}\|u_{h_t,h_x}(s)-u_{h_t,h_x}(t)\|_{V_\sigma} &\le \|u_{h_t,h_x}(s)-u_{h_t,h_x}(t)\|_H^{1-\sigma}\,\|u_{h_t,h_x}(s)-u_{h_t,h_x}(t)\|_V^{\sigma}\\ &\le C_\sigma\,\|(v_{h_t,h_x}(t)-v_{h_t,h_x}(t-h_t))\|_H^{1-\sigma}\\ &\quad\times\left(\|u_{h_t,h_x}(s)\|_V+\|u_{h_t,h_x}(t)\|_V\right)^{\sigma}\\ &\le C_\sigma\,|s-t|^p\,,\end{aligned}$$

where $p=1-\sigma$ and $\sigma<1$. By the Arzela–Ascoli Theorem, there is a subsequence $u_{h_t,h_x}\to u$ in $C(0,T;V_\sigma)$, as $h_t,\,h_x\downarrow 0$. Since $\beta: V_\sigma\to W_\theta$ (see Lemma 5.9) is a bounded linear operator, by (5.24) we obtain

$$\begin{aligned}&\int_{[0,T]}\langle N_{h_t,h_x},\beta u_{h_t,h_x}-\varphi_{h_x}\rangle_{W_{-\theta}\times W_\theta}\,dt\\ &=\int_{[0,T]}\left(h_t\sum_{k=0}^{T/h_t-1}\delta(t-(k+1)h_t)\sum_{j=1}^{\mathcal{N}_{h_x}}N_j^k\beta\psi_j,\ \sum_{i=1}^{\mathcal{N}_{h_x}}g_i^{k+1}\beta\psi_i\right)_Z dt\\ &=h_t\sum_{k=0}^{T/h_t-1}\left(\sum_{j=1}^{\mathcal{N}_{h_x}}N_j^k\beta\psi_j,\ \sum_{i=1}^{\mathcal{N}_{h_x}}g_i^{k+1}\beta\psi_i\right)_Z\\ &=h_t\sum_{k=0}^{T/h_t-1}(\mathbf{g}^{k+1})^T\mathbf{M}\mathbf{N}^k=0.\end{aligned}$$

Since $N_{h_t,h_x}\rightharpoonup^* N\in K^*$ and $\beta u_{h_t,h_x}-\varphi_{h_x}\to\beta u-\varphi\in K$ as measure with $h_t,\,h_x\downarrow 0$ from Lemma 5.11, taking the limit in the subsequence, it follows that

$$0=\int_{[0,T]}\langle N_{h_t,h_x},\beta u_{h_t,h_x}-\varphi_{h_x}\rangle_{W_{-\theta}\times W_\theta}\,dt\to\int_{[0,T]}\langle N,\beta u-\varphi\rangle_{W_{-\theta}\times W_\theta}\,dt.$$

The proof is complete. ∎

6. Conclusions. We have been able to show the existence of solutions for a general class of impact problems of the form

$$\begin{aligned}u_{tt}&=-Au+\beta^*N(t)+f,\\ u(0)&=u^0,\\ u_t(0)&=v^0,\\ K\ni\beta u(t)-\varphi\perp N(t)\in K^*&\quad\text{for all } t\in[0,T],\end{aligned}$$

with the last condition interpreted in a weak sense: N is a measure on $[0,T]$ with values in K^* ($\int_B N\in K^*$ for any Borel set B), $\beta u(t)-\varphi\in K$ for all t, and

$$\int_{[0,T]}\langle\beta u(t)-\varphi,\,N(t)\rangle\,dt=0,$$

with the integrand identified as a measure.

The most important assumption that was made was (A6) which is a strong pointedness assumption. The usual way in which we guarantee this is by requiring that W is a Sobolev space $H^m(\Omega_1)$ with Ω_1 a d-dimensional manifold or open set in $\mathbb{R}^d$,

where $m > d/2$ in order to get an embedding $H^{m-\epsilon}(\Omega_1) \subset C(\overline{\Omega_1})$ for some $\epsilon > 0$. This means that either m is large or d is small. Thus dynamic obstacle problems for the wave equation or the equations of elasticity in two or three dimensions (or more) cannot be treated by these methods. The incorporation of viscosity to create a visco-elastic system of equations can be used to get greater regularity in the solution u and the velocity $u_t = v$ [16]. However, it is not clear what happens to the normal contact force in such cases.

The solutions whose existence is shown are quite weak, and we cannot in general expect to prove either uniqueness or conservation of energy from such a weak solution. However, further work should improve on the regularity of the solutions (perhaps with, perhaps without, visco-elasticity) and we hope to apply the results in [30] to get conservation of energy, or at least an energy balance in which no energy losses or gains are attributed to contact forces. This is a matter for future research.

BLOW-UP AND GLOBAL ASYMPTOTICS OF THE LIMIT UNSTABLE CAHN–HILLIARD EQUATION*

J. D. EVANS†, V. A. GALAKTIONOV†, AND J. F. WILLIAMS‡

Abstract. We study the asymptotic behavior of classes of global and blow-up solutions of a semilinear parabolic equation of the "limit" Cahn–Hilliard type

$$u_t = -\Delta(\Delta u + |u|^{p-1}u) \quad \text{in } \mathbf{R}^N \times \mathbf{R}_+, \quad p > 1,$$

with bounded integrable initial data. We show that in some $\{p, N\}$-parameter ranges it admits a *countable* set of blow-up similarity patterns. The most interesting set of blow-up solutions is constructed at the first critical exponent $p = p_0 = 1 + \frac{2}{N}$, where the first simplest profile is shown to be stable. Unlike the blow-up case, we show that, for $p = p_0$, the set of global decaying source-type similarity solutions is *continuous* and determine the stable mass-branch. We prove that there exists a countable spectrum of critical exponents $\{p = p_l = 1 + \frac{2}{N+l},\ l = 0, 1, 2, \dots\}$ creating bifurcation branches, which play a key role in general description of solutions globally decaying as $t \to \infty$.

Key words. semilinear parabolic equation, similarity solutions, blow-up, asymptotic behavior

1. Introduction.

1.1. The model and discussion. In this paper we study the blow-up and the long-time asymptotic behavior of solutions of the fourth-order semilinear parabolic equation

$$u_t = -\Delta(\Delta u + u^p) \quad \text{in } \mathbf{R}^N \times \mathbf{R}_+, \quad p > 1, \quad \text{where } u^p := |u|^{p-1}u. \tag{1.1}$$

We consider the Cauchy problem for (1.1) with initial data

$$u(x, 0) = u_0(x) \quad \text{in } \mathbf{R}^N, \quad u_0 \in L^1(\mathbf{R}^N) \cap L^\infty(\mathbf{R}^N), \tag{1.2}$$

assuming in most cases that $u_0(x)$ decays exponentially as $x \to \infty$.

Equation (1.1) is a model connected with various applications. For instance, it arises as the limit case of the phenomenological, "unstable" Cahn–Hilliard equation for $N = 1$, 2 and $p = 3$, see the references in [32] and [12],

$$u_t = -(\gamma u_{xx} - u^3 + \gamma_1 u)_{xx} - \gamma_2 u.$$

It is also a reduced model from solidification theory with $N = 1$ or 2 and $p = 2$ [31, 3]. Equations of this form arise in the theory of thermo-capillary flows in thin layers of viscous fluids with free boundaries, with an anomalous dependence of the surface tension coefficient on temperature [14, 1]. Equation (1.1) also occurs as the *limit*

case as $\gamma \to 0^+$ of the Cahn–Hilliard equation with a standard double-well potential function of the form

$$
\begin{aligned}
&u_t = \nabla \cdot (\nabla (F(u) - \Delta u)), \quad \text{where} \\
&F(u) = |u|^{p-1}u - \gamma |u|^p u, \quad \text{with } \gamma > 0,
\end{aligned}
\tag{1.3}
$$

so the constant stationary state satisfies $|U_0| = \frac{1}{\gamma} \to \infty$. As usual in the similarity analysis, the present blow-up results can be applied for nonlinearities in (1.3) for sufficiently small $\gamma > 0$, i.e., for $|U_0| \gg 1$, exhibiting *intermediate* asymptotics in the sense of Zel'dovich and Barenblatt [2].

Another important class of fourth-order models related to (1.1) admitting both blow-up and decaying solutions comes from the theory of thin films and general long-wave unstable equations (see [3] and also [36]), where a typical *quasi-linear* equation takes the form

$$
u_t = -(u^n u_{xxx} + u^m u_x)_x. \tag{1.4}
$$

Equations of this form are known to admit nonnegative solutions constructed by special parabolic approximations of the nonlinear coefficients; see [4] and the references therein. Then $m = n + 2$ corresponds to the critical self-similar "conservative" case to be treated here for $n = 0$. Notice that the Cauchy problem for the uniformly parabolic equation (1.1) cannot admit compactly supported solutions and this changes some essential properties of evolution. On the other hand, one can state the same free-boundary conditions for (1.1) as for (1.4) hence admitting finite interfaces.

From the mathematical point of view, in the case of the Cauchy problem studied in the present paper, writing (1.1) in the form

$$
Pu_t = \Delta u + u^p, \tag{1.5}
$$

with the positive operator $P = (-\Delta)^{-1}$ on the right-hand side, defines a pseudo-parabolic second-order equation. Many aspects of such equations are well understood with both existence and uniqueness of local and global classical solutions and the blow-up of solutions known from the 1970's; see the first results on blow-up in [28] and the references in the surveys [15, 27].

We are mainly interested in the study of blow-up behavior of the solutions to (1.1), (1.2). In this sense (1.1) is a special model, for which (1.5) clearly indicates that, at least formally, we can expect some similarities of blow-up singularity formation phenomena to the classical semilinear heat equation from combustion theory (the solid-fuel model)

$$
u_t = \Delta u + u^p \quad \text{in } \mathbf{R}^N \times \mathbf{R}_+ \quad (p > 1). \tag{1.6}
$$

There is a huge mathematical literature, developed in the last twenty years, devoted to the study of blow-up solutions of (1.6), where in some ranges of the parameters p and N a complete description of all possible patterns has been achieved; see the references in [34, Chap. 4] and survey [15]. On the other hand, the unstable nonlinear operator in (1.1) gives the classical *porous medium equation* but posed backwards in time $u_t = -\Delta u^p$. It is not well posed and leads to blow-up of u or its derivatives in arbitrarily small times; see the concavity techniques in [29].

In standard form, (1.1) (rather than (1.5)) is a fourth-order semilinear parabolic equation. It is well known that any kind of detailed asymptotic analysis for higher-order equations is much more difficult in comparison with the second-order counterparts in view of the lack of the Maximum Principle, comparison, order-preserving semigroups and potential properties of the operators involved, etc. In this sense, we are going to show that (1.1) can be treated as an "intermediate" model between second- and fourth-order parabolic equations, where some questions of blow-up and global asymptotics, at least partially, can be studied by reasonably standard mathematical methods. Note that a completely rigorous analysis of blow-up asymptotics, comparable to that for second-order problems, is not yet available for higher-order semilinear equations such as

$$u_t = -(-\Delta)^m u + u^p, \quad m \ge 2, \tag{1.7}$$

see [6], nor for the generalized Frank–Kamenetskii equation

$$u_t = -\Delta^2 u + \mathrm{e}^u$$

with similar blow-up properties, nor for the model equation from the Semenov–Rayleigh–Benard problem with the leading operator of the form

$$u_t = -u_{xxxx} + \beta[(u_x)^3]_x + \mathrm{e}^u, \quad \beta \ge 0,$$

see [16]. The mathematical difficulties in understanding the ODE and PDE patterns increase dramatically with the order of differential operators in the equations.

1.2. The main conclusions and plan of the paper. The primary goal is to present some general principles of formation of stable generic blow-up and global asymptotics for the limit Cahn–Hilliard equation (1.1). To this end, we construct various sets of self-similar solutions of (1.1) in different ranges of the parameters p and N. We establish that, in the most interesting *conservative* critical case $p = p_0 = 1 + \frac{2}{N}$,

(i) (1.1) admits a countable discrete set of blow-up similarity solutions, and

(ii) there exists an unbounded continuous family of global similarity solutions decaying as $t \to \infty$.

We also show which of the similarity solutions are stable in a proper rescaled sense and hence describe the behavior of a wide class of more general solutions. We study the stability of the main branches of similarity solutions and discuss the sets of similarity profiles for arbitrary $p > 1$.

In the remainder of this section we discuss some basic auxiliary properties of (1.1). In section 2 we introduce the blow-up and global similarity solutions and perform a local asymptotic analysis of the corresponding ODEs. The spectral properties of the key non-self-adjoint linearized operators are described in section 3. In section 4 we present an existence analysis of blow-up similarity solutions and show that the minimal profile is an attractor for a wide set of initial data. A countable set of solutions in the critical case $p = p_0 = 1 + \frac{2}{N}$ is then constructed via a singular perturbation expansion. The non-conservative case is briefly discussed in section 5, where more general p values are considered. In section 6 we study classes of global solutions of (1.1) decaying as $t \to \infty$ and prove that, unlike the blow-up case, the family of similarity solutions at $p = p_0$ is continuous and we determine the stable branch. We also detect a sequence of critical exponents

$$p_l = 1 + \frac{2}{N + l}, \quad l = 0, 1, 2, \dots, \tag{1.8}$$

corresponding to a *transition* phenomenon between the two main classes of asymptotic patterns for the PDE (1.1). Under certain assumptions, we prove that, at each $p = p_l$, a bifurcation of similarity solutions occurs, and show that, actually, for $p \neq p_0$, p_1, the set of exponentially decaying similarity profiles is expected to be countable. Concerning possible *non-self-similar* asymptotic behavior, we show that at the same critical exponents $p = p_l$ unusual center manifold patterns occur for the limit *stable* Cahn–Hilliard equation

$$u_t = -\Delta(\Delta u - u^p), \tag{1.9}$$

where the operator on the right-hand side is monotone and coercive in $H^{-1}(\mathbf{R}^N)$, so that the Cauchy problem has a unique classical solution decaying in time, at least, for $p < \frac{N+2}{N-2}$; see [17, sect. 2].

1.3. Some preliminary results. We begin with some well-known related properties.

(a) *A potential operator and gradient system.* Equation (1.1) is uniformly parabolic with all spatial differential operators appearing in divergence form. It admits a unique, classical, local in time solution and the standard parabolic theory applies, [13]. The operator on the right-hand side of (1.1), $-\Delta(\Delta u + u^p)$, is potential in $H^{-1}(\mathbf{R}^N)$ (see [25]) and the dynamical system admits the Lyapunov function

$$E[u](t) = \frac{1}{2}\|\nabla u(t)\|_2^2 - \frac{1}{p+1}\|u(t)\|_{p+1}^{p+1}, \quad u(t) \in X = H^2(\mathbf{R}^N) \cap L^{p+1}(\mathbf{R}^N), \tag{1.10}$$

which is monotone decreasing with time on uniformly bounded orbits in X, $\frac{\mathrm{d}}{\mathrm{d}t}E[u] = -\|u_t\|_{H^{-1}}^2 \le 0$. The PDE defines a smooth gradient system in $H^{-1}(\mathbf{R}^N)$. By the gradient system theory [19], the ω-limit set of any uniformly bounded orbit,

$$\omega(u_0) = \left\{ f \in C(\mathbf{R}^N) : \exists\ \{t_k\} \to \infty \text{ such that } u(\cdot, t_k) \to\ f \ \text{ uniformly} \right\},$$

is known to consist of classical stationary solutions: $-\Delta(\Delta f + f^p) = 0$ in $\mathbf{R}^N$ for any $f \in \omega(u_0)$. If the set of stationary solutions consists of isolated equilibria, the asymptotic behavior does not essentially differ from the classical second-order theory and any bounded orbit approaches a stationary profile as $t \to \infty$. However, one can see from (1.5) that, for this problem with $p < p_S = (N+2)/(N-2)_+$ (which is the critical Sobolev exponent for the elliptic operator in (1.5)), the only admissible stationary solution is trivial, $f = 0$, so that the large-time behavior cannot be stabilization to a nonzero equilibrium. Instead, there can be blow-up or convergence to $f = 0$ with a rate as yet to be determined.

(b) *The fundamental solution and local existence.* We first need the fundamental solution of the linear fourth-order parabolic equation

$$u_t = -\Delta^2 u \quad \text{in } \mathbf{R}^N \times \mathbf{R}_+ \tag{1.11}$$

having the similarity form

$$b(x,t) = t^{-N/4}F(y), \quad y = x/t^{1/4}, \tag{1.12}$$

where the rescaled kernel F is the unique radial solution of the elliptic equation

$$\mathbf{B}F \equiv -\Delta^2 F + \frac{1}{4}y \cdot \nabla F + \frac{N}{4}F = 0 \quad \text{in } \mathbf{R}^N, \quad \text{with } \int F = 1. \tag{1.13}$$

The kernel $F = F(|y|)$ has exponential decay, oscillates as $|y| \to \infty$ and satisfies the following estimate [11, p. 47]: for some positive constants D and d,

$$|F(y)| < D\,\mathrm{e}^{-d|y|^{4/3}} \quad \text{in } \mathbf{R}^N. \tag{1.14}$$

A sharp estimate $d < 3/2^{5/2}$ is obtained from the exponential asymptotics of solutions to the ODE (1.13) as $|y| \to \infty$, such as those described in section 2.

Local existence of the unique classical solution of the Cauchy problem (1.1), (1.2) follows from the equivalent integral equation

$$u(\cdot,t) = \mathbf{M}(u) \equiv b(\cdot,t) * u_0 - \int_0^t \Delta b(\cdot,t-s) * u^p(s)\mathrm{d}s, \quad t > 0, \tag{1.15}$$

where $\mathbf{M}$ is a contraction in the metric space of continuous functions in $\mathbf{R}^N \times [0,\delta]$, $\delta > 0$ small, with the sup-norm. Using (1.12), one can see from (1.15) that any uniformly bounded solution $u(x,t)$ admits a local-in-time classical extension. Therefore, as is usual in classical parabolic theory, if blow-up of any form occurs it must do so in the L^∞-norm.

Finite-time blow-up. Despite the gradient structure, from known results on blow-up for such pseudoparabolic equations (1.5) [28], it follows that classical solutions whose initial data satisfy the energy inequality

$$E(u_0) = \frac{1}{2}\,\|\nabla u_0\|_2^2 - \frac{1}{p+1}\,\|u_0\|_{p+1}^{p+1} < 0 \tag{1.16}$$

cannot be extended beyond a finite blow-up time $T < \infty$. The problem of blow-up has been extensively studied in recent years for various higher-order quasi-linear and semilinear parabolic models, where many interesting results have been obtained; see also [32, 31, 3, 4, 5, 36] and the references therein.

2. Similarity variables for global and blow-up asymptotics. Equation (1.1) is invariant under the group of scaling transformations

$$t \mapsto \lambda t, \quad x \mapsto \lambda^{1/4} x, \quad u \mapsto \lambda^{-1/2(p-1)} u, \quad \lambda > 0.$$

This symmetry suggests the introduction of the following rescaled variables:

$$u(x,t) = [\sigma(T-t)]^{-1/2(p-1)}\theta(y,\tau), \quad y = x/[\sigma(T-t)]^{1/4}, \quad \tau = -\sigma\ln[\sigma(T-t)], \tag{2.1}$$

where σ takes the two values ± 1: $\sigma = 1$ corresponds to blow-up at the unknown blow-up time $t = T$, and $\sigma = -1$ to infinite time decay as $t \to \infty$ with a reference time T (generically, we will take $T = 0$ in this case). Without loss of generality, we suppose that the solution $u(x,t)$ blowing up at the finite time $t = T$ in the L^∞-norm, i.e.,

$$\sup_x |u(x,t)| \to \infty \text{ as } t \to T^-, \tag{2.2}$$

is such that the corresponding blow-up set $B(u_0)$ contains the origin,

$$0 \in B(u_0) = \{x \in \mathbf{R}^N : \ \exists\ \{x_n\} \to x,\ \{t_n\} \to T^- \text{ such that } u(x_n,t_n) \to \infty\}.$$

The rescaled solution $\theta(y,\tau)$ defined as in (2.1) satisfies the semilinear equation

$$\theta_\tau = \mathbf{A}(\theta) \equiv -\Delta(\Delta\theta + \theta^p) - \frac{\sigma}{4} y\cdot\nabla\theta - \frac{\sigma}{2(p-1)}\theta, \tag{2.3}$$

and we are interested in the possible asymptotic dynamics of solutions for $\tau \gg 1$.

An exact similarity solution of (1.1)

$$u_S(x,t) = [\sigma(T-t)]^{-1/2(p-1)} f(y) \tag{2.4}$$

gives an independent of τ stationary solution $f(y)$ of (2.3) leading to a fourth-order elliptic equation for the similarity profile f,

$$\mathbf{A}(f) = 0 \quad \text{in } \mathbf{R}^N. \tag{2.5}$$

It is worth mentioning that classical variational approaches do not apply to (2.5) because $\mathbf{A}$ is not a potential operator.

We restrict our attention to the case of one-dimensional or radial geometry, where (2.5) is a fourth-order ODE, and in most cases we impose symmetry conditions at the origin $y = 0$ and a suitable decay condition (possibly exponential) at infinity:

$$f'(0) = 0, \ \ f'''(0) = 0, \quad \text{and } \ f(y) \to 0 \quad \text{as } \ y \to \infty. \tag{2.6}$$

Existence of nonradial solutions to (2.5) is an interesting open problem.

2.1. Conservative similarity solutions and the first critical exponent. Under appropriate decay conditions at infinity (say, exponential), (1.1) is *conservative*:

$$\frac{\mathrm{d}}{\mathrm{d}t} \int_{\mathbf{R}^N} u \, \mathrm{d}x = - \int_{\mathbf{R}^N} \Delta(\Delta u + u^p) \, \mathrm{d}x = 0. \tag{2.7}$$

Given an exact similarity solution (2.4), and assuming that $f \in L^1(\mathbf{R}^N)$, we have that

$$\int_{\mathbf{R}^N} u_S(x,t) \, \mathrm{d}x = [\sigma(T-t)]^{-1/2(p-1)+N/4} \int_{\mathbf{R}^N} f(y) \, \mathrm{d}y, \tag{2.8}$$

which satisfies (2.7) for nonzero mass, $\int f \neq 0$, only if $p = p_0$, where

$$p_0 = 1 + \frac{2}{N} \tag{2.9}$$

is the *critical exponent* in the problem. It is interesting that p_0 coincides with the Fujita exponent for the semilinear heat equation (1.6). In fact, it is the *first* critical exponent and in section 6 we show that there exists a countable sequence of further critical exponents (1.8) corresponding to special cases of globally decaying solutions.

It follows from (2.9) that in the one-dimensional case, $N = 1$, the crucial critical case corresponds to $p = p_0 = 3$, where nonzero similarity masses can be preserved (section 4). However, we will consider other cases as well; see section 5. Moreover, from (2.8) we have

$$\text{for any } \ p \neq p_0, \quad f \in L^1 \quad \Longrightarrow \quad \int f = 0, \tag{2.10}$$

i.e., any L^1-similarity profile f has zero mass. Of course the same follows from the radial ODE (2.5) by integrating over $\mathbf{R}^N$.

2.2. Local asymptotic properties of self-similar solutions. Here we describe the possible asymptotics of small solutions to (2.5) satisfying $f(y) \to 0$ as $y \to \infty$, see (2.6). Consider the linearization of (2.5) about $f = 0$,

$$-f'''' - \frac{2(N-1)}{y} f''' - \frac{\mu}{y^2} f'' + \frac{\mu}{y^3} f' - \frac{\sigma}{4} y f' - \frac{\sigma}{2(p-1)} f = 0, \tag{2.11}$$

where $\mu = (N-1)(N-3)$. To determine the balance between the leading terms f'''' and $\frac{\sigma}{4} y f'$, we set $z = y^\alpha$ with $\alpha = \frac{4}{3}$ reducing the ODE to

$$-f'''' - a_1 f' - a_2 z^{-1} f + \mathbf{D}(z) f = 0. \tag{2.12}$$

Here $a_1 = \sigma/4\alpha^3$, $a_2 = \sigma/2(p-1)\alpha^4$ and $\mathbf{D}(z) f = \sum_{j=1}^{3} \gamma_j z^{j-4} f^{(j)}$ is a linear operator with bounded coefficients as $z \to \infty$, where the first coefficient of the derivative f' is of order $O(z^{-3})$. By the perturbation theory of linear ODEs (see Chapters III–V in [9]), we have that the leading terms of exponentially decaying solutions are described by the operator in (2.12) with constant coefficients,

$$-f'''' - a_1 f' = 0. \tag{2.13}$$

Setting $f = \mathrm{e}^{pz}$, $p \neq 0$, gives the characteristic equation $p^4 + a_1 p = 0$, when

$$p^3 = -a_1 = -\sigma/4\alpha^3 \equiv \rho_0^3(-\sigma), \quad \text{where } \rho_0 > 0. \tag{2.14}$$

There exist three roots of the form

$$p_k = \rho_0 \mathrm{e}^{i\pi(4k+\sigma+1)/6}, \quad k = 0, 1, 2, \tag{2.15}$$

where the number of roots with negative real part is two for $\sigma = -1$ and only one for $\sigma = +1$. Thus, as $y \to \infty$, there exists

(2.16) a two-dimensional stable bundle for the global case $\sigma = -1$, and

(2.17) a one-dimensional stable bundle for the blow-up case $\sigma = 1$.

This difference in the dimensionality of the stable manifold about $f = 0$ at $y = \infty$ is what distinguishes the continuous spectrum of solutions for the global case from the discrete set of blow-up solutions.

On the other hand, (2.12) also admits solutions with algebraic decay (rather than exponential) as $z \to \infty$ described by the first-order operator

$$-a_1 f' - a_2 z^{-1} f = 0 \quad \Longrightarrow \quad f(z) = A z^{-2/\alpha(p-1)}, \ \ A \neq 0.$$

Existence of solutions with such decay for the perturbed equation (2.12) is established by a standard expansion analysis by calculating solutions via a Kummer-type series converging uniformly for $z \gg 1$. For the linearized equation (2.11), the leading order behavior is algebraic,

$$f(y) = A|y|^{-2/(p-1)}(1 + o(1)) \ \ \text{as} \ \ |y| \to \infty, \quad f \in L^1 \ \ \text{iff} \ \ p < p_0, \tag{2.18}$$

with arbitrary constant $A \neq 0$. For blow-up similarity solutions (2.4), the limit-time profile is then bounded for any $x \neq 0$ and has the form

$$u_S(x, T^-) = A|x|^{-2/(p-1)}, \quad x \neq 0.$$

Clearly, for $p \geq p_0$, this is not an admissible solution for the conservative case given finite initial mass, and thus in the critical case $p = p_0$ we must have $A = 0$ and exclusively exponential decay of any similarity profiles.

3. The spectral properties of the rescaled linear operators. The structure of the rescaled equation (2.3) suggests the study of the spectral properties of the linearized operator with $\sigma = -1$ (global solutions), which is conveniently represented in a form associated with the operator in (1.13),

$$\mathbf{A}'(0) = -\Delta^2 + \frac{1}{4}\, y \cdot \nabla + \frac{1}{2(p-1)}\, I \equiv \mathbf{B} + c_* I, \quad c_* = \frac{N}{4(p-1)}(p_0 - p). \tag{3.1}$$

The spectral properties of $\mathbf{B}$ and the corresponding adjoint operator $\mathbf{B}^*$ occurring for $\sigma = 1$ will play an important role in the further asymptotic analysis of the nonlinear PDE. The operators are defined in weighted L^2-spaces with the weight functions induced by the exponential estimate of the rescaled kernel (1.14).

3.1. The point spectrum of the non-self-adjoint operator B. Note that $\mathbf{B}$ is not symmetric and does not admit a self-adjoint extension. We consider $\mathbf{B}$ in the weighted space $L^2_\rho = L^2_\rho(\mathbf{R}^N)$ with the exponentially growing weight function

$$\rho(y) = \mathrm{e}^{a|y|^\alpha} > 0 \quad \text{in } \mathbf{R}^N, \quad \text{where } \alpha = \frac{4}{3}, \tag{3.2}$$

and $a \in (0, 2d)$ (d is as in (1.14)) is a sufficiently small constant. We ascribe to $\mathbf{B}$ the domain H^4_ρ being a weighted Hilbert space with the norm

$$\|v\|^2 = \int \rho(y) \sum_{k=0}^{4} |D^k v(y)|^2 \, \mathrm{d}y,$$

induced by the corresponding inner product. From [10] we have the following result.

LEMMA 3.1. *$\mathbf{B} : H^4_\rho \to L^2_\rho$ is a bounded linear operator with the real spectrum*

$$\sigma(\mathbf{B}) = \left\{ \lambda_l = -\frac{l}{4},\ l = 0, 1, 2, \dots \right\}. \tag{3.3}$$

The eigenvalues λ_l have finite multiplicity with eigenfunctions

$$\psi_\beta(y) = \frac{(-1)^{|\beta|}}{\sqrt{\beta!}}\, D^\beta F(y), \quad \textit{with any } |\beta| = l, \tag{3.4}$$

where F is the rescaled kernel in (1.12)*, and the set of eigenfunctions $\Phi = \{\psi_\beta,\ |\beta| = 0, 1, 2, \dots\}$ is complete in L^2_ρ.*

Lemma 3.1 gives the center and stable subspaces of $\mathbf{B}$, $E^c = \mathrm{Span}\{\psi_0 = F\}$ and $E^s = \mathrm{Span}\{\psi_\beta,\ |\beta| > 0\}$.

3.2. The polynomial eigenfunctions of the adjoint operator $\mathbf{B}^*$. Consider the operator adjoint to $\mathbf{B}$,

$$\mathbf{B}^* = -\Delta^2 - \frac{1}{4}\, y \cdot \nabla, \tag{3.5}$$

which is related to $\mathbf{A}'(0)$ in (2.3) for $\sigma = 1$ (the blow-up case). We consider $\mathbf{B}^*$ in $L^2_{\rho^*}$ with the exponentially decaying weight function $\rho^*(y) = 1/\rho(y) \equiv \mathrm{e}^{-a|y|^\alpha} > 0$.

LEMMA 3.2. *$\mathbf{B}^* : H^4_{\rho^*} \to L^2_{\rho^*}$ is a bounded linear operator with the same spectrum,* (3.3)*. The eigenfunctions $\psi^*_\beta(y)$ with $|\beta| = l$ are lth order polynomials*

$$\psi^*_\beta(y) = \frac{1}{\sqrt{\beta!}} \left[y^\beta + \sum_{j=1}^{\lfloor |\beta|/4 \rfloor} \frac{1}{j!} (-\Delta)^{2j} y^\beta \right], \tag{3.6}$$

and the set $\{\psi^*_\beta\}$ is complete in $L^2_{\rho^*}$.

With this definition of the adjoint eigenfunctions, the orthonormality condition

$$\langle \psi_\beta, \psi^*_\gamma \rangle = \delta_{\beta,\gamma} \tag{3.7}$$

holds, where $\langle \cdot, \cdot \rangle$ denotes the standard (dual) L^2 inner product.

4. Blow-up similarity profiles for $p = 3$ in one dimension. The dynamics simplify for the conservative case $p = p_0 = 1 + \frac{2}{N}$ as (2.5) can be integrated once. The particular critical case

$$p = p_0 = 3 \quad \text{with} \ \ N = 1 \tag{4.1}$$

is of key importance in our analysis and highlights the typical techniques required to describe a countable set of self-similar blow-up patterns. Throughout this section we assume that (4.1) holds.

4.1. Preliminaries. In the case (4.1), the ODE (2.5) with $\sigma = 1$ for the similarity profile can be integrated once to give

$$f''' + \frac{1}{4} y f + (f^3)' = 0 \quad \text{for} \ \ y > 0, \quad f'(0) = 0, \tag{4.2}$$

where we have set the constant of integration to zero on the right-hand side. This removes the algebraically decaying mode (2.18), $f(y) = Ay^{-1}(1 + o(1))$, by looking for L^1-solutions satisfying the conservation of mass condition (2.7). It follows from (2.17) that we are left with a *one-parameter* family of exponentially decaying functions satisfying

$$f(y) = Cy^{-1/3} \mathrm{e}^{-\beta y^{4/3}} (1 + o(1)) \quad \text{as} \ y \to +\infty, \quad C \geq 0, \quad \beta = 3/4^{4/3}, \tag{4.3}$$

where the extra algebraic factor $y^{-1/3}$ is detected by a standard refined asymptotic WKBJ expansion according to the ODE theory, [9]. This asymptotic expansion fully corresponds to the linear part of the operator in (4.2) and does not depend on the cubic nonlinear term. In order to construct a solution to (4.2) we will use a shooting type argument starting from $y = \infty$. Thus, all admissible similarity profiles $f(y)$ have the asymptotic behavior (4.3) and also should satisfy the symmetry condition at the origin.

Let us now study the behavior of solutions on the manifold (4.3) parameterized by C. Denoting $f(y; C)$ as the function which satisfies (4.2) with decay from the bundle (4.3), the goal is to find the set of C such that

$$S(C) \equiv f'(0; C) = 0. \tag{4.4}$$

Because the function $S(C)$ in (4.4) is analytic in C (see below), (4.4) has at most a countable set of roots, which can accumulate at $C = \infty$ only and this actually happens. We begin with the global existence for the family $\{f(y; C)\}$.

LEMMA 4.1. *For any $C > 0$, the solution $f(y; C)$ to* (4.2), (4.3) *is well defined for all $y \in \mathbf{R}$.*

Proof. This follows from the local properties of the operator in (4.2) which are close to those for the second-order case $f'' + f^3 = 0$. Obviously, it does not admit blow-up of solutions at finite y. Integrating (4.2), $f'' = -f^3 - \frac{1}{4} \int f y \, \mathrm{d}y$, multiplying

by f' and integrating again over a sufficiently small interval near any fixed point y_0 yields

$$\begin{aligned}\frac{1}{2}\,f'^2(y) &= -\frac{1}{4}\,f^4(y) - \frac{1}{4}\int_{y_0}^{y} f'(z)\int_{y_0}^{v} f(v)v\,\mathrm{d}v\mathrm{d}z + \mathrm{const}\\ &\le \frac{1}{4}\int_{y_0}^{y} |f'(z)|\int_{y_0}^{v} |f(v)v|\,\mathrm{d}v\mathrm{d}z + \mathrm{const},\end{aligned} \tag{4.5}$$

where, by Lagrange's formula of finite increments, $|f(v)| \le |f(y_0)| + (\sup_v |f'(v)|)|v - y_0|$, the right-hand side is not more than quadratic in f'. Therefore, $f(y)$ cannot blow-up at a finite point y_* along a sequence since (4.5) guarantees that $f'(y_*)$ is finite. Obviously, this analysis applies for all $p > 1$. ∎

4.2. Existence of the first monotone blow-up similarity pattern. The proof that there exists a first, minimal $C = C_1 > 0$ such that (4.4) holds involves three steps. First, we show that in the limit as $C \to 0^+$ solutions $f(y;C)$ are strictly monotone decreasing on $[0,\infty)$ and, second, that in the other limit $C \to +\infty$ all solutions cannot be monotone. Then, by a standard continuity argument, we have that there must exist an intermediate $C = C_1 > 0$ corresponding to an admissible monotone solution.

PROPOSITION 4.2. *For all $0 < C \ll 1$, solutions $f(y;C)$ are strictly monotone decreasing in $y \ge 0$ and $f'(0;C) < 0$.*

Proof. Rescaling by setting $f = Cg$, we have

$$g''' + \frac{1}{4}yg + C^2(g^3)' = 0 \quad \text{in } \mathbf{R}_+. \tag{4.6}$$

In view of the behavior at infinity (4.3), by standard results on continuous dependence for ODEs [9], it follows that, as $C \to 0^+$,

$$f(y;C) = C(\phi_0(y) + o(1)) \quad \text{uniformly in } \mathbf{R}_+, \tag{4.7}$$

where ϕ_0 solves the linear ODE $\phi''' + \frac{1}{4}\,\phi' y = 0$ and satisfies (4.3) with $C = 1$. All the derivatives of f converge similarly. Let us now show that $\phi_0(y)$ is strictly monotone decreasing. Assume that y_i is the first (from $y = \infty$) local maximum point of ϕ_0, $\phi_0'(y_i) = 0$ and $\phi_0'(y) < 0$ on (y_i,∞). Integrating over (y_i,∞), we obtain the contradiction, $\phi_0''(y_i) = \int_{y_i}^{\infty} s\phi_0(s)\,\mathrm{d}s > 0$, thus observing an elementary feature of the Maximum Principle for such third-order equations. ∎

PROPOSITION 4.3. *There exists a $C_* > 0$ such that $f(y;C_*)$ has a local maximum point at some $y_* \ge 0$ and $f(y;C_*) > 0$ on $[y_*,\infty)$.*

Proof. Assume for contradiction that $f(y;C)$ is strictly monotone decreasing in $\mathbf{R}_+$ for all $C > 0$, and then $f(0;C) > 0$. One can see from the rescaled ODE (4.6) that the solutions $f(y;C)$ cannot be bounded for $y \in \mathbf{R}_+$ uniformly in $C > 0$. Therefore, there exists a sequence $\{C_k\} \to \infty$ such that $a_k = f(0;C_k) \to \infty$. Performing the scaling

$$f(y) = a_k g_k(z), \quad y = z/a_k, \tag{4.8}$$

we arrive at a perturbed ODE for the sequence $\{g_k(z)\}$,

$$g_k''' + (g_k^3)' = -\frac{1}{4a_k^4}\,zg_k \quad \text{for } z > 0, \quad g_k(0) = 1, \tag{4.9}$$

where $0 < g_k(z) \le 1$ and $g_k(z)$ is monotone decreasing in z. Since $\{g_k\}$ is a uniformly bounded sequence of solutions of the asymptotically perturbed ODE (4.9) with regular coefficients, by the Ascoli–Arzelá theorem and standard ODE estimates [9], we have that along a subsequence, $g_k \to \bar{g}$ uniformly on compact subsets in z, where $\bar{g}$, $0 \le \bar{g} \le 1$, must be a monotone decreasing solution of the unperturbed ODE

$$(\bar{g}'' + \bar{g}^3)' = 0, \quad \bar{g}(0) = 1. \tag{4.10}$$

Since all such solutions of (4.10) are oscillatory, which is easily checked by integrating twice, this leads to a contradiction. Therefore, there exists a sufficiently large $C_* > 0$ such that $f(y; C_*)$ is not strictly monotone in $\mathbf{R}_+$ and has a local maximum point. □

THEOREM 4.4. *There exists a constant $C_1 \in (0, C_*]$ such that (4.4) holds for $C = C_1$ and $f_1(y) = f(y; C_1)$ is a strictly monotone decreasing symmetric positive similarity profile.*

Proof. Introducing the set

$$W_1 = \{\mu > 0 : \ f(y; C) \text{ is strictly monotone decreasing in } \mathbf{R}_+ \text{ for all } C \in (0, \mu)\},$$

we have that $W_1 \ne \emptyset$ by Proposition 4.2 and W_1 is bounded above by Proposition 4.3. Hence, there exists

$$C_1 = \sup W_1 \le C_*, \tag{4.11}$$

where, by construction, $f_1(y) = f(y; C_1)$ is monotone decreasing for $y \ge 0$. By the definition of supremum in (4.11), one can see that $f_1'(y)$ must vanish at the origin, i.e., (4.4) holds. □

We now briefly describe a countable set of the similarity profiles satisfying (4.2) and (4.3) with some $C > C_1$. This construction is similar to that for the second-order ODEs from blow-up reaction-diffusion theory; see [34, pp. 190–195] and related references therein. Similar to Proposition 4.3 we show that as C increases, the function $f(y; C)$ becomes more and more oscillatory for $y > 0$. Indeed, performing the scaling (4.8) and passing to the limit $C = C_k \to \infty$, we obtain a bounded solution $\bar{g}$ satisfying (4.10) admitting oscillatory solutions only. Hence, $f(y; C)$ can have an arbitrarily large number of oscillations for $y > 0$ with $C \gg 1$. As in the proof of Theorem 4.4, for any $k = 2, 3, \dots$, we define the sets

$$W_k = \{\mu > C_{k-1} : \ f(y; C) \text{ has at most } k \text{ local extrema for } y \ge 0 \, \forall \, C \in [C_{k-1}, \mu)\}.$$

Then, once C_{k-1} is known, starting with $k = 2$, we have that $W_k \ne \emptyset$ and by the oscillatory behavior for $C \gg 1$, W_k is bounded from above. Hence, we define

$$C_k = \sup W_k > C_{k-1}, \quad k = 2, 3, \dots, \tag{4.12}$$

and by construction, $f_k(y) = f(y; C_k)$ satisfies the symmetry condition at the origin (otherwise, it is not the supremum in (4.12)).

Such a construction, while giving an infinite sequence of similarity profiles, does not describe the important properties of the functions $f_k(y)$, such as positivity (or at least "positivity dominance") and the actual distribution of local extrema and inflection points of the profiles. This will be done by a more delicate and partially formal asymptotic matching procedure.

4.3. Asymptotic construction of a countable set of similarity profiles. Here we will use the method of matched asymptotics expansions to describe the solution structure of the similarity profiles $\{f_k(y)\}$ for large k, i.e., in the limit $C_k \to \infty$. We will show that the similarity profiles will be composed of three regions. The two primary regions are an *outer region* localized near the origin, where the mass of the solution is concentrated with oscillations around a parabolic profile (see (4.20) below), and a *far-field region*, in which the solution is described by the asymptotic bundle (4.3). Joining these two regions is a narrow transition or *inner* region. The details containing the scalings and corresponding matching are given below. Because the characteristics of the family are determined by the far-field behavior, we will begin by considering refined asymptotics as $y \to \infty$.

The far-field behavior. To determine the asymptotic behavior as $y \to \infty$ in greater detail, we produce an asymptotic description of solutions from the exponential bundle (4.3). Specifically, the solution is given by the formal power series

$$f(y;C) = \sum_{n=0}^{\infty} C^{2n+1}\phi_n(y), \tag{4.13}$$

where ϕ_0 is given in (4.7) and the rest of the terms are obtained from the relation

$$\mathbf{B}^*\phi_n \equiv \phi_n''' + \frac{1}{4}\,y\phi_n = -\sum_{\substack{1\le i,j,k\le n\\ i+j+k=n+1}} (\phi_i\phi_j\phi_k)', \quad n = 2,3,\dots, \tag{4.14}$$

with the condition $\phi_n(y) = o(\phi_0(y))$ as $y \to \infty$. Using the expansion (4.3), it can be shown by direct calculation that for $y \gg 1$,

$$\phi_n(y) = \left[\gamma_n + o(y^{-1})\right]\, y^{-(4n+1)/3}\mathrm{e}^{-(2n+1)\beta y^{4/3}}, \tag{4.15}$$

with suitable constants $|\gamma_n| \le 1$. Moreover, the right-hand side of (4.15) with a sufficiently large constant γ_n gives uniform estimates of ϕ_n in $\mathbf{R}_+$, which establishes the uniform convergence of (4.13) on subsets $\{y \ge y_0\}$ with $y_0 \gg 1$. By the Weierstrass theorem, the solution $f(y;C)$ in (4.13) obtained as a uniformly converging series of analytic functions is analytic in C for $y \ge y_0$. Therefore, on extension to $y \in [0, y_0)$, as a solution of an ODE with analytic coefficients and analytic dependence on C in the Dirichlet boundary condition at $y = y_0$, it is analytic in C for any $y \ge 0$ (cf. typical analyticity results in the classical ODE theory, [9, section 8, Chapter I]). Hence, (4.4) is an analytic function having isolated zeros only and we arrive at the following conclusion.

PROPOSITION 4.5. *The problem* (4.2), (4.3) *has at most a countable set of solutions.*

The discrete nature of the function $S(C)$ will be made evident by close examination of the inner and transition regions.

A singular perturbation problem. We begin by looking for possible solutions localized in a neighborhood of the origin $y = 0$. We rescale the ODE (4.2) as (cf. (4.8))

$$f(y) = ag(z), \quad y = az, \quad \text{where } a = f(0;C), \tag{4.16}$$

with a an as yet unspecified function of C to be determined for the similarity profiles $f_k(y)$. Under the assumption that $a(C) \to \infty$ as $C \to \infty$, possibly along a

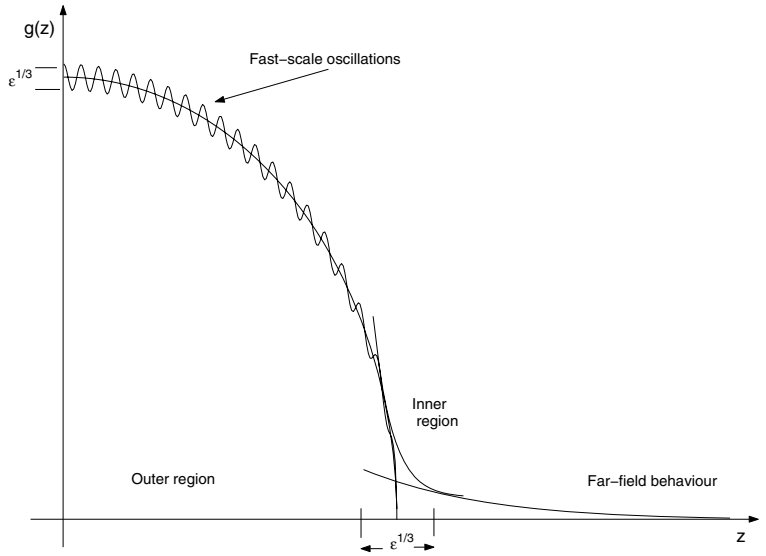

FIG. 1. *Sketch of the regions for construction of asymptotic profiles of* (4.17).

subsequence, we define

$$\varepsilon = a^{-4} \ll 1 \quad \text{for } C \gg 1.$$

Under the rescaling (4.16), (4.2) leads to a singularly perturbed ODE

$$\varepsilon g''' + \frac{1}{4} z g + (g^3)' = 0. \tag{4.17}$$

We need to describe a two-parameter family of solutions of (4.17) defined in a suitable neighborhood of the origin $z = 0$, which can be matched with the exponential bundle (4.3). In order to describe such a family, we use the method of matched asymptotic expansions and supplement the ODE (4.17) with two standard conditions

$$g(0) = 1, \quad g'(0) = 0. \tag{4.18}$$

In addition, we have

$$g''(0) = b\varepsilon^{-m}(1 + o(1)), \tag{4.19}$$

where the constant b and parameter m are as yet unspecified. The third condition (4.19) is introduced for convenience only and we show in what follows that both b and m are determined later by the matching procedure. However, their inclusion here is to emphasize that in the outer region, a faster scale is necessary in order to resolve the additional oscillatory structure as described in the proof of Proposition 4.3 by the perturbed problem (4.9).

We will show that the solution to (4.17) has a three layer structure, schematically illustrated in Figure 1, comprising

(i) an *outer region* $0 \le z < \sqrt{12}$ in which $g = O(1)$,

(ii) an *inner region* $z = \sqrt{12} + O(\varepsilon^{1/3})$ in which $g = O(\varepsilon^{1/6})$, and finally

(iii) a *third region* $z > \sqrt{12}$, where g is exponentially small (and belongs to the exponential bundle described in section 2).

The outer region. Let $g_0(z)$ be the solution of the unperturbed problem (4.17), namely,

$$\frac{1}{4} z g_0 + (g_0^3)' = 0 \quad \text{with} \quad g_0(0) = 1 \implies g_0(z) = \sqrt{1 - \frac{1}{12}\, z^2}. \tag{4.20}$$

Close to $z = 0$, we perform the linearization

$$g(z) = g_0(z) + G(Z), \tag{4.21}$$

with the fast variable $Z = z/\varepsilon^{1/2}$. Then G satisfies the equation

$$G''' + (3 g_0^2 G)' + \frac{1}{4} \varepsilon Z G + (3 g_0 G^2 + G^3)' + \varepsilon^{3/2} g_0''' = 0, \tag{4.22}$$

where $g_0^2(Z) = 1 - \frac{\varepsilon}{12}\, Z^2$. It follows that on compact subsets $0 \le Z \le c$, the principal part of (4.22) has constant coefficients,

$$G''' + 3G' + \mathcal{N}_1 = 0, \quad G(0) = G'(0) = 0, \tag{4.23}$$

where $\mathcal{N}_1 = O(\varepsilon G + G^2 + \varepsilon^2)$ on bounded smooth solutions. Therefore, by standard perturbation ODE theory [9], recalling the third condition in (4.18), the solution satisfies the following expansion as $\varepsilon \to 0$ uniformly on subsets $Z \in [0, c]$:

$$G(Z) = \theta \left(1 - \cos\left(\sqrt{3}\, Z\right)\right) + o(\theta), \tag{4.24}$$

where $\theta = \frac{1}{3}\, b \varepsilon^{1-m}$. This rigorously determines the asymptotic behavior in the region $\{z = O(\varepsilon^{1/2})\}$. For matching reasons, we need to extend the expansion (4.24) to larger subsets. This is done by introducing the new independent variable

$$t = t(Z) \equiv \int_0^Z \left(1 - \varepsilon \frac{u^2}{12}\right)^{1/2} \mathrm{d}u = \frac{1}{\varepsilon^{1/2}} \left(\frac{z}{2} \left(1 - \frac{z^2}{12}\right)^{1/2} + \sqrt{3} \sin^{-1}\left(\frac{z}{2\sqrt{3}}\right)\right), \tag{4.25}$$

and setting $G(Z) = P(t)/g_0(Z)$. This gives, similar to (4.23), an equation with constant coefficients in the principal part

$$P''' + 3P' + \mathcal{N}_2 = 0, \quad P(0) = P'(0) = 0, \tag{4.26}$$

where the perturbation $\mathcal{N}_2$, in addition to the same small terms as above from (4.23), now contains differential operators with coefficients depending on the derivatives of $g_0 = g_0(z(t))$ satisfying

$$\frac{\mathrm{d}g_0}{\mathrm{d}t} = \frac{g_0'}{t'} = O(\varepsilon^{1/2}), \quad \frac{\mathrm{d}^2 g_0}{\mathrm{d}t^2} = O(\varepsilon), \quad \frac{\mathrm{d}^3 g_0}{\mathrm{d}t^3} = O(\varepsilon^{3/2})$$

uniformly on compact subsets in $z \in [0, c]$ for any $c < \sqrt{12}$. Therefore, upon returning to the original variables $\{z,\, g\}$, the outer expansion takes the form

$$g(z) = g_0(z) + \theta \frac{1}{g_0(z)} \left(1 - \cos\sqrt{3} t\right) + \ldots \equiv g_0 + \theta g_1 + \ldots, \quad \theta = \frac{1}{3} b \varepsilon^{1-m}. \tag{4.27}$$

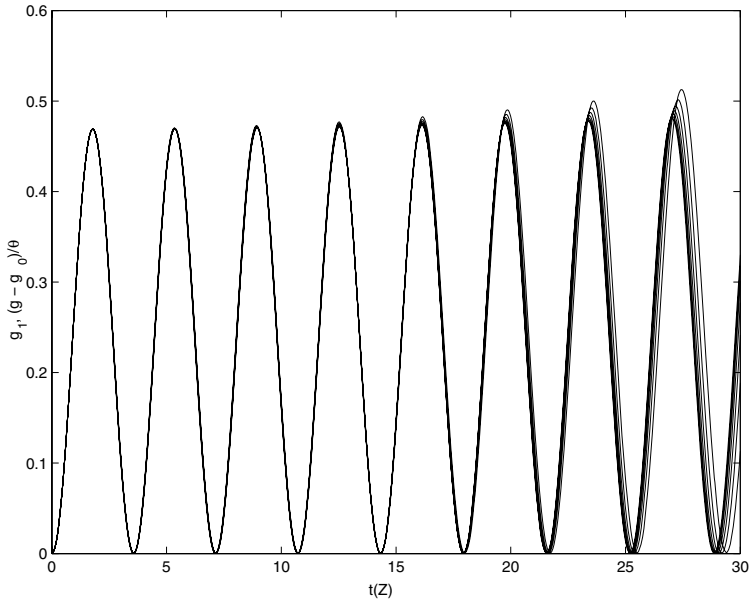

FIG. 2. *Convergence as* $\varepsilon \to 0$ *of numerical solutions of* (4.17) *to* $g_1(z,t)$ *given in* (4.27)*;* $\varepsilon \in [7.51 \cdot 10^{-4}, 1.08 \cdot 10^{-1}]$.

Note that we cannot guarantee that this expansion is valid uniformly on subsets $z \in [0, c]$ since though the principal part in (4.26) is exactly the same as in (4.23), equation (4.26) is then considered on expanding subsets in $t \in [0, c\varepsilon^{-1/2}]$ becoming unbounded as $\varepsilon \to 0$. It is worth remarking that the crucial fast scale variable (4.25) is determined by the requirement that (4.26) has constant coefficients, which fixes it to the order considered here. For first-order matching, it suffices to prescribe only the rate of deviation $O(g_0^{-1})$ of $g(z)$ from the unperturbed profile $g_0(z)$ as correctly described by the second term in (4.27). Figure 2 shows the accuracy of expansion (4.27), where we have already fixed $m = \frac{2}{3}$ (to be determined later) so that $\theta \sim \varepsilon^{1/3}$. Plotted is the first-order term g_1 from (4.27) with the full numerical solution for g scaled in the form $(g - g_0)/\varepsilon^{1/3}$.

The inner region. The outer expansion (4.27) does not reflect the far-field behavior (4.3). Thus, in order to specify the behavior for $z \approx \sqrt{12}$, we introduce the inner variables $\bar{z}$ and $R(\bar{z})$ by

$$z = \sqrt{12} + \varepsilon^{1/3}\bar{z}, \qquad g = \varepsilon^{1/6} R, \quad \text{where } R \text{ solves} \tag{4.28}$$

$$R''' + \frac{1}{4}\left(\sqrt{12} + \varepsilon^{1/3}\bar{z}\right) R + \left(R^3\right)' = 0. \tag{4.29}$$

The unperturbed equation

$$R_0''' + \frac{1}{2}\sqrt{3} R_0 + \left(R_0^3\right)' = 0 \tag{4.30}$$

admits a one-parameter family of suitable exponentially decaying solutions

$$R_0(\bar{z}) \simeq A_0 \mathrm{e}^{-3^{1/6}\bar{z}/2^{1/3}} \qquad \text{as } \ \bar{z} \to +\infty, \tag{4.31}$$

for some constant A_0, and a three-parameter family of slowly growing solutions as $\bar{z} \to -\infty$. Solutions from the bundle (4.31) satisfy

$$R_0(\bar{z}) \simeq \left(-\frac{\bar{z}}{3^{1/2}}\right)^{1/2} + \frac{\bar{a}_1}{(-\bar{z})^{1/2}}\left[1 - \bar{a}_2 \cos\left(c(-\bar{z})^{3/2}\right) - \bar{a}_3 \sin\left(c(-\bar{z})^{3/2}\right)\right], \tag{4.32}$$

where $c = 2/3^{3/4}$ and $\bar{a}_1$, $\bar{a}_2$, $\bar{a}_3$ are suitable constants. This expansion is determined in the standard way by setting $R_0 = \tilde{R}_0 + \tilde{R}_1$, where $\tilde{R}_0 = (-\bar{z})^{1/2}/3^{1/4}$ under the assumption that $|\tilde{R}_1| \ll |\tilde{R}_0|$. Then the leading linear equation for $\tilde{R}_1$ is

$$\tilde{R}_1''' + \frac{\sqrt{3}}{2}\tilde{R}_1 - \frac{1}{\sqrt{3}}\left(\bar{z}\tilde{R}_1\right)' = 0, \tag{4.33}$$

which has an exact solution in terms of the Airy functions Ai and Bi,

$$\tilde{R}_1 = c_1 Ai^2(\bar{z}) + c_2 Ai(\bar{z})Bi(\bar{z}) + c_3 Bi^2(\bar{z}), \quad c_1, c_2, c_3 \in \mathbf{R}. \tag{4.34}$$

This fact is important for the reliable numerical integration of (4.30).

Matching. To determine the sequence $\{C_k,\, k \gg 1\}$ and the corresponding values $f(0; C_k) = a(C_k)$, we now match the inner and outer solutions. Expanding the components of the outer solution (4.27) near the transition point $z = \sqrt{12}$, we have

$$g_0 \simeq \varepsilon^{1/6}\left(-\frac{\bar{z}}{3^{1/2}}\right)^{1/2}\left(1 + \varepsilon^{1/3}\frac{\bar{z}}{8 \cdot 3^{1/2}}\right), \tag{4.35}$$

(4.36)

$$g_1 \simeq \varepsilon^{-1/6}\frac{b}{3}\left(-\frac{3^{1/2}}{\bar{z}}\right)^{1/2}\left[1 - \cos\frac{\sqrt{3}t_0}{\varepsilon^{1/2}}\cos\left[c(-\bar{z})^{3/2}\right] - \sin\frac{\sqrt{3}t_0}{\varepsilon^{1/2}}\sin\left[c(-\bar{z})^{3/2}\right]\right],$$

where $t_0 = \int_0^{\sqrt{12}} \sqrt{1 - v^2/12}\,\mathrm{d}v = \frac{\sqrt{3}}{2}\pi$. Comparing the outer expansion (4.27), using (4.35) and (4.36) with the inner expansion $g = \varepsilon^{1/6}R_0 + \ldots$, where R_0 is given by (4.32), yields the matching condition $1 - m - \frac{1}{6} = \frac{1}{6}$, if full balance is to be obtained, i.e.,

$$m = \frac{2}{3}, \tag{4.37}$$

together with the coefficients

$$\bar{a}_1 = 3^{-3/4}b, \quad \bar{a}_2 = \cos\frac{3^{1/2}t_0}{\varepsilon^{1/2}} \quad \text{and} \quad \bar{a}_3 = \sin\frac{3^{1/2}t_0}{\varepsilon^{1/2}} \quad \left(t_0 = 3\sqrt{\pi}/2\right). \tag{4.38}$$

It follows that (4.37) and the first equality in (4.38) are established rigorously since we have used the "envelope" characteristic in expansion (4.27) without specifying the highly oscillatory component. In particular, (4.38) demands

$$\bar{a}_2^2 + \bar{a}_3^2 = 1. \tag{4.39}$$

To determine these values, we observe that (4.30) is translation invariant, as is the asymptotic behavior for $\bar{z} \to \infty$, but not (to leading order) as $\bar{z} \to -\infty$. To see this, we consider the solution to (4.30) as a shooting problem in the single parameter A_0.

However,

$$R_0(\bar{z}; \hat{A}_0) = R_0(\bar{z} - \bar{z}_0; A_0), \quad \text{where} \quad \hat{A}_0 = A_0 \mathrm{e}^{3^{1/6}2^{-1/3}\bar{z}_0}.$$

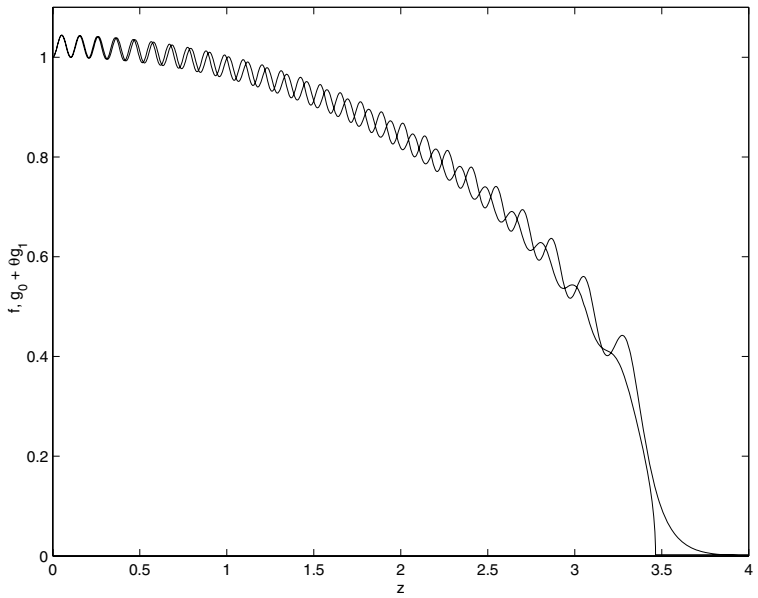

FIG. 3. *Comparison of numerical and asymptotic* (4.27) *solutions of the ODE* (4.17). *The numerical profile* $g(z)$ *exhibits the exponential decay for* $y \approx 4$.

Clearly this translation does not change the ODE although it will affect the coefficients in the far-field behavior (4.32). Denoting the new coefficients by $\hat{a}_i$, $i = 1, 2, 3$, we have to leading order that

$$\hat{a}_1 = \bar{a}_1 + \bar{z}_0/2 \cdot 3^{1/4}, \quad \hat{a}_2 = \bar{a}_2, \quad \hat{a}_3 = \bar{a}_3,$$

i.e., the translation only affects the coefficient $\bar{a}_1$ in (4.32). Thus,

$$\hat{A}_0 = A_0 \mathrm{e}^{3^{5/12} 2^{2/3} (\hat{a}_1 - \bar{a}_1)}. \tag{4.40}$$

We now seek A_0 such that the form (4.32) satisfies the constraint (4.39). From the translation argument we have that $\bar{a}_1$ is monotone decreasing in A_0, and it follows from (4.33), (4.32) that there are precisely two possible solutions which are the negatives of each other, i.e., $\bar{a}_1$ and $-\bar{a}_1$. Taking $\hat{a}_1 = -\bar{a}_1$, (4.40) gives

$$\hat{A}_0 = A_0 \mathrm{e}^{-2^{5/3} 3^{5/12} \bar{a}_1}. \tag{4.41}$$

Numerical computation gives

$$A_0 \approx 0.448\ldots, \quad \bar{a}_1 = 0.341\ldots$$

and from (4.41) we deduce the other set of values

$$A_0 \approx 0.081\ldots, \quad \bar{a}_1 = -0.341\ldots.$$

Finally, (4.38) may be used to determine the two values of b. Using the value $\bar{a}_1 \approx 0.341\ldots$ in the asymptotic expression (4.27) gives very good agreement to full numerical solutions near $z = 0$, as seen in Figure 3. In particular, the amplitude of the fast-scale oscillation is excellent.

The third region. It follows from (4.3) and (4.16) that

$$g(z) \simeq C\varepsilon^{1/3} z^{-1/3} \mathrm{e}^{-\beta z^{4/3}/\varepsilon^{1/3}} \tag{4.42}$$

is the appropriate behavior satisfying (4.17) for $z > \sqrt{12}$. Writing (4.42) in terms of the inner variable $\bar{z}$ from (4.28) gives the leading order expression

$$g(z) \simeq C\varepsilon^{1/3} 12^{-1/6} \mathrm{e}^{-\beta 12^{2/3}/\varepsilon^{1/3}} \mathrm{e}^{-3^{1/6}\bar{z}/2^{1/3}}$$

after using $\varepsilon^{1/3}\bar{z} = O(1)$. Comparing to the inner behavior (4.31) and using (4.28) gives the matching condition

$$A_0 \simeq C 12^{-1/6} \varepsilon^{1/6} \mathrm{e}^{-\beta 12^{2/3}/\varepsilon^{1/3}}. \tag{4.43}$$

Since both values of A_0 are of order $O(1)$, then

$$\varepsilon \sim \frac{3^5}{2^4}\frac{1}{(\ln C)^3} + \frac{3^6}{2^5}\frac{\ln\ln C}{(\ln C)^4} + \frac{3^6}{2^4}\frac{\ln(3^{-2/3}2A_0)}{(\ln C)^4} \quad \text{as } C \to \infty.$$

Recall that all the estimates obtained without using the highly oscillatory tails in the singular layer given by (4.27) are rigorous and asymptotically sharp. The fact that there are two values of A_0 and thus two relationships between C and ε corresponds to the two families of solutions, those with $g''(0) > 0$ or $g''(0) < 0$. Most importantly, given that asymptotically $\bar{a}_2 = \cos(3\pi/2\varepsilon^{1/2})$ and $\bar{a}_3 = \sin(3\pi/2\varepsilon^{1/2})$ in (4.38) are *unique* (up to a change in sign in both coefficients), we have that

$$3\pi/2\varepsilon^{1/2} = k\pi \pm \phi\pi(1 + o(1)), \tag{4.44}$$

for an unknown phase shift ϕ (this is a formal conclusion). Using this in the definition of $\varepsilon = a^{-4}$ gives

$$a_k = \sqrt{2k/3}(1 + o(1)) \quad \text{as } k \to \infty.$$

Also, from (4.43) this fixes the corresponding values of the expansion coefficients $C = C_k$ in (4.3) in the outer region

$$C_k \sim k^{1/3} \mathrm{e}^{3k^{2/3}/2^{2/3}} \quad \text{for } k \gg 1.$$

Using the computed values of the coefficients and expansions, we present a comparison of the numerical and asymptotic solutions in Figure 3. The slow phase-shift can be corrected by further terms in the expansion but, even to this order, we have captured the correct number of fast-scale oscillations. With $\varepsilon = 0.00083\ldots$, using only the Z variable instead of the $t(Z)$ variable given in (4.25) over-predicts the number of oscillations seen in Figure 3 by about one half.

4.4. Numerical methods.

Solution of the full ODEs. In (4.4) we introduced the shooting function S whose zeroes correspond to admissible blow-up profiles. By numerically integrating the ODE (4.2) with the far-field behavior (4.3), we have been able to approximate this function, as seen in Figure 4. An asymptotic form of the function $S(C)$ for $C \gg 1$ can be constructed by a similar matching argument by putting an extra term $\tilde{b}\sin(\sqrt{3}t)/g_0(z)$ into (4.27) ($\tilde{b} = 0$ iff $S(C) = 0$). This leads to a harder multi-parameter matching

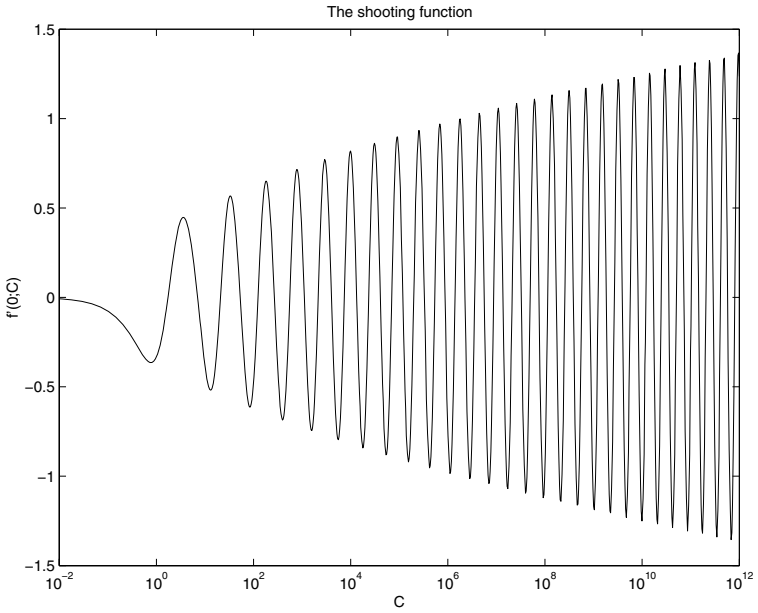

FIG. 4. *Numerical approximation to* $S(C)$ *in* (4.4).

procedure and will not be considered any further. Labeling, as above, the solutions to (4.2) corresponding to the nth zero of $S(C)$ as f_n, we find that $f_n(y)$ has precisely n maxima on $\mathbf{R}$. In Figure 5 we present the first profile f_1 given in Theorem 4.4, which has the simplest bell-shaped form. It is evolutionary stable for a broad range of initial data (see the next section). For visual clarity we separately present the profiles $\{f_{1+4n}\}$ and $\{f_{2+4n}\}$ for $n = 0, \dots, 15$.

The shooting function was approximated numerically for $0 < C \le 10^{12}$ by solving the ODE (4.2) subject to the Dirichlet condition $f(L) = C\phi_0(L)$ with L such that $f(L) = 10^{-10}$. The zeros of $S(C)$ then were used as initial guesses for a boundary value solver where now (4.2) was solved on $y \in (0, 150)$ subject to $f'(0) = 0, f(150) = 0, f'(150) = 0$. The right-hand conditions are satisfied by exponentially decaying solutions within error tolerance.

Numerical solution in the inner region. Because of the fast oscillation in (4.32) and the slow convergence to this profile (the next terms are $\mathrm{O}(1/\bar{z})$), the accurate numerical computation of the coefficients (4.43) is not straightforward; in many ways it is the most difficult numerical ODE problem in this paper. In fact, it is known that for second-order equations of the type

$$y''(t) + g(t)y(t) = 0, \quad \text{with } g(t) \to \infty \text{ as } t \to \infty$$

(of which the Airy functions are particular solutions), standard Runge–Kutta or linear multistep methods are not only poorly suited, but are incapable of producing reliable solutions in double precision arithmetic for large t [23]. As such, the values were computed using a modified magnus method employing Filon quadratures [22, 24].

Numerical solution of the PDE. The possibility of finite-time blow-up suggests that adaptive strategies in both time and space are required for reliable numerical solution to (1.1). The geometric features of this problem are also key, both the scale invariance and the preservation of mass. As such we use a scale-invariant moving-mesh

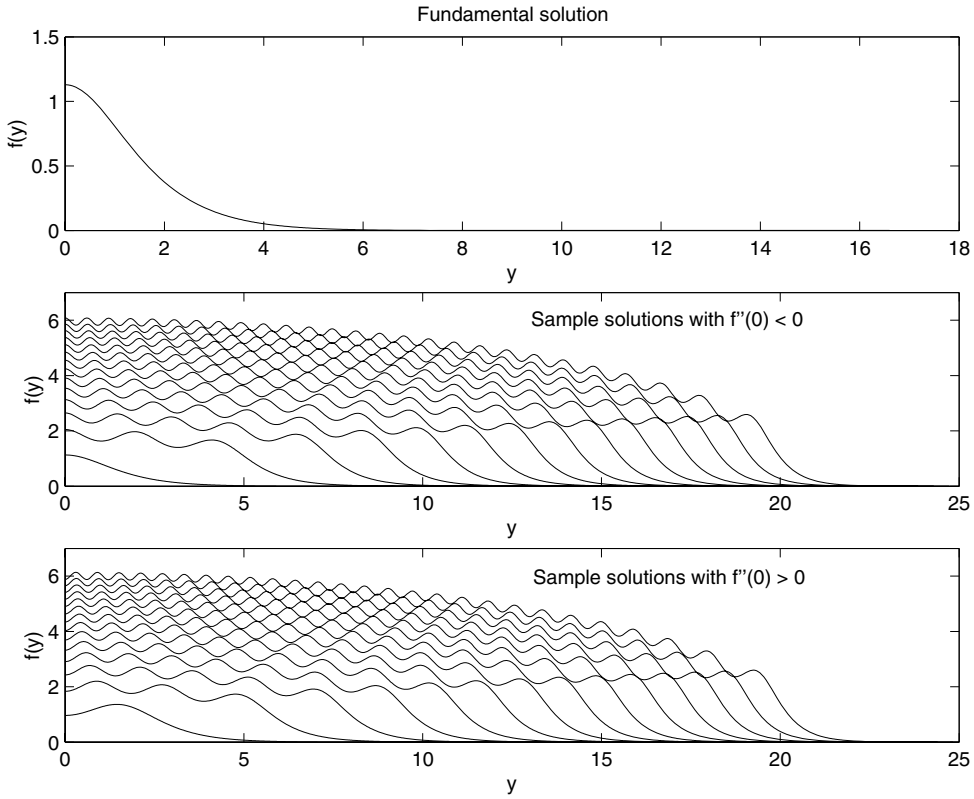

FIG. 5. *Various numerical solutions to* (4.2).

strategy which dynamically clusters the grid points where a solution indicator, in this case $|u|^3$, is large [20, 7, 21, 33, 8]. Additionally, we rescale dynamically in time and compute the physical time as part of the solution procedure [8]. This strategy does not assume any particular solution structure, but instead follows the scaling structure of the full PDE. This allows the computational grid points to move along level sets of any (emerging) similarity variable. We have also used a *conservative collocation* discretization [20, 33] which preserves the mass of the solution even into blow-up while on a moving grid.

This code is fully implicit in time and designed to solve general problems of the form $f(t, x, u, u_x, u_{xx}, u_{xxx}) = \frac{\mathrm{d}}{\mathrm{d}x} g(t, x, u, u_x, u_{xx}, u_{xxx})$ and has been used for examining many higher-order equations [6, 16, 33]. The spatial adaptive strategy has been shown to be reliable on problems for which static regridding codes have failed. For details of the code we refer to [33], while the adaptive strategy is described in [21, 7, 8].

4.5. Exponential asymptotic stability of the first blow-up pattern with profile f_1: Numerical evidence. Theorem 4.4 together with the above matching analysis for $k \gg 1$ imply that there is a discrete family of solutions to the similarity ODE (4.2), and hence a discrete set of admissible masses for the final time profiles

$$M_k = \int f_k(y)\,\mathrm{d}y, \quad k = 1, 2, \ldots . \tag{4.45}$$

We now justify that the first blow-up pattern with profile f_1 is the only stable one.

Returning to the rescaled PDE (2.3), which for $N = 1$ and $p = 3$ takes the form

$$\theta_\tau = \mathbf{A}(\theta) \equiv -\theta_{yyyy} - \frac{1}{4}(\theta y)_y - (\theta^3)_{yy}, \tag{4.46}$$

with initial data θ_0, we study the asymptotic behavior of the global orbit $\{\theta(\cdot,\tau)\}$. First we establish the following natural (but not straightforward) property of its ω-limit set $\omega(\theta_0)$.

PROPOSITION 4.6. *With the definition* (2.1) *of the rescaled solution,*

$$0 \notin \omega(\theta_0). \tag{4.47}$$

Proof. We have from (4.46) that $\mathbf{A}'(0) = \mathbf{B}^* - \frac{1}{4}\,I$ with the known spectral and other properties described in section 3.2. By Lemma 3.1, $\sigma(\mathbf{A}'(0)) = \{-\frac{k+1}{4},\ k \ge 0\}$. The principle of linearized stability [30, Chapt. 9] implies that any sufficiently small solution $\theta(y,\tau)$ decays as $\tau \to \infty$ exponentially fast and that, for some constant $C_0 > 0$,

$$|\theta(y,\tau)| \le C_0 \mathrm{e}^{-\tau/4} \quad \text{uniformly in } \mathbf{R}.$$

Then one can see from scaling (2.1) with $p = 3$ that $|u(x,t)| \le C_0$ for all $t \approx T^-$, i.e., u does not blow-up at $t = T$ contradicting the choice of blow-up time T. □

The linear part of the operator $\mathbf{A}$, $\mathbf{B}^* - \frac{1}{4}\,I$, is not self-adjoint and we do not expect that $\mathbf{A}$ is a potential operator nor that (4.46) is a gradient system. Therefore, the stability properties of the first similarity profile f_1 are studied via the spectrum of the linearized operator

$$\mathbf{A}'(f_1) = \mathbf{B}^* - \frac{1}{4}\,I - 3\frac{\mathrm{d}^2}{\mathrm{d}^2 y}(f_1^2 I), \tag{4.48}$$

which is posed in a functional setting similar to that for $\mathbf{B}^*$ introduced in section 3.

PROPOSITION 4.7. *$\mathbf{A}'(f_1) : H^4_\rho \to L^2_\rho$ is a bounded linear operator with the discrete spectrum $\sigma(\mathbf{A}'(f_1)) = \{\mu_l\}$.*

Proof. We recall that by Theorem 4.4, $f_1(y)$ has exponential decay as $y \to \infty$ so that (4.48) is a lower-order perturbation with smooth, bounded and exponentially decaying coefficients of the operator (3.1) and hence $\mathbf{A}'(f_1)$ is a bounded operator by Lemma 3.2; see [18]. In view of the known spectrum of $\mathbf{B}^*$ having compact resolvent $(\mathbf{B}^* - \lambda I)^{-1}$ in L^2_ρ [10], and by taking $(\mathbf{A}'(f_1) - cI)^{-1}$ with a large constant c, we have that the additional terms in (4.48) form a compact perturbation of the integral operator. Hence, the spectrum of $\mathbf{A}'(f_1)$ is discrete. □

Note that the two first real positive eigenvalues of $\mathbf{A}'(f_1)$ are easily calculated explicitly:

$$\mu_0 = 1,\ \ \phi_0 = (y f_1(y))' \quad \text{and} \quad \mu_1 = \frac{1}{4},\ \ \phi_1 = f_1'(y), \tag{4.49}$$

corresponding to the invariance of the original PDE (1.1) under the group of translations in t and x, respectively. As is usual in blow-up problems, since the blow-up scaling (2.1) does not admit such translations (the time T and the blow-up point $x = 0$ are fixed), these unstable modes are not available for the rescaled PDE (4.46).

A meaningful estimate of the real part of the remainder of the eigenvalues $\{\mu_l,\ l \ge 2\} \subset \mathbb{C}$ of $\mathbf{A}'(f_1)$ is nontrivial. Instead, we present a numerical calculation, from

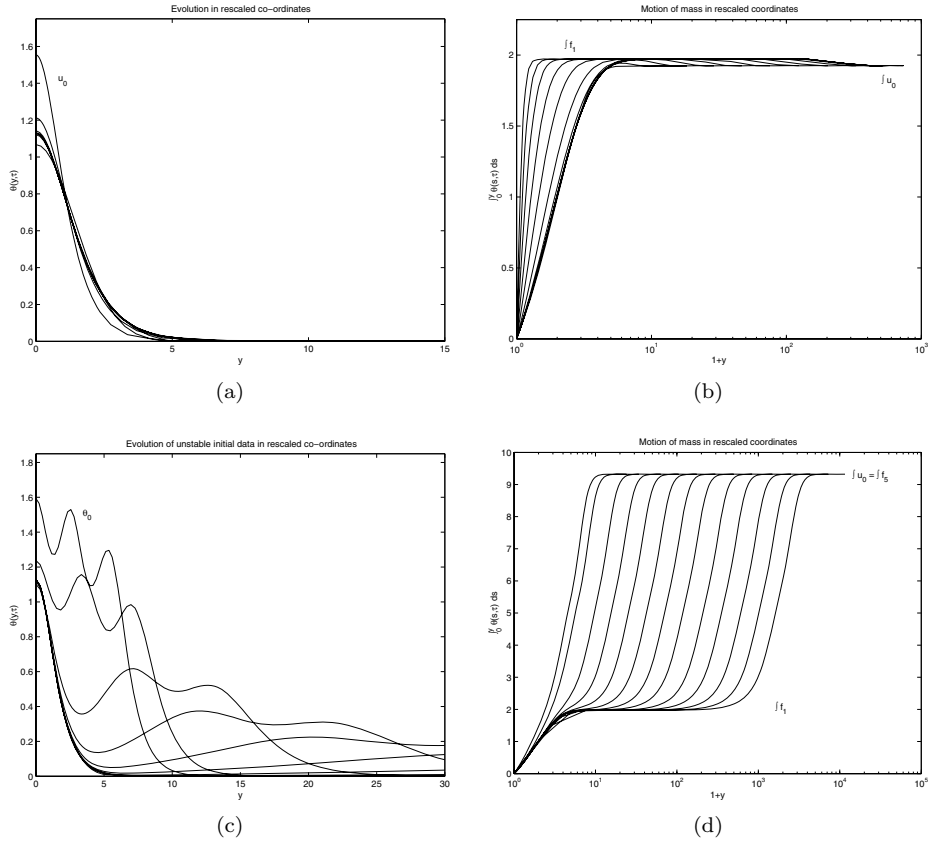

FIG. 6. *Evolution of solutions to* (1.1). (a) *Convergence to* f_1 *in rescaled coordinates.* (b) *Motion of the mass for initial mass* $\int u_0 < \int f_1$. (c) *Instability of* f_5. (d) *Motion of the mass for initial mass* $\int u_0 = \int f_5 > \int f_1$. *The rescaled coordinates are determined through the transformation* (2.1) *with* T *being taken from the numerical approximation.*

directly simulating the PDE, in Figure 6(a), where we rescale the PDE solutions according to the blow-up scaling (4.4) with $\sigma = 1$ and carefully computed blow-up time T. We have chosen symmetric monotone decreasing initial data having a smaller mass than the similarity solution,

$$\int u_0 < M_1 = \int f_1.$$

Figure 6(b) shows the time-evolution of the mass distribution ($\int_0^y \theta(s,\tau)\,\mathrm{d}s$) of this solution concentrated on intervals $[0,y]$ for $\tau \gg 1$, so that the total mass is achieved for $y = \infty$ (for $y \gg 1$ in numerical experiments), establishing convergence to M_1 (our numerical scheme was designed to preserve mass for problems of this form). In order to gain an extra positive mass to converge to f_1 uniformly on compact subsets, the rescaled solution forms two small negative humps, which disappear at $y \to \pm\infty$ as $\tau \to \infty$; see further comments below. By considering this distribution of mass one can see firstly that the numerical scheme preserves the total mass and also how the rescaled solution converges to the first similarity profile on compact sets of the rescaled spatial coordinate y.

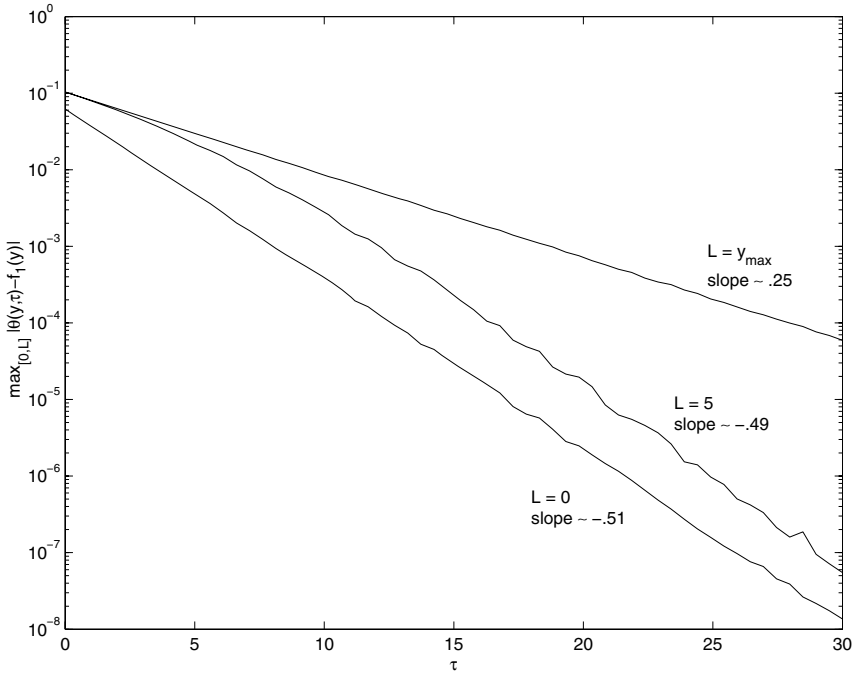

FIG. 7. *Rate of convergence to the similarity profile for $p = 3$, $N = 1$.*

From a variety of numerical experiments, we conjecture that the next eigenvalue of the linearized operator (4.48) satisfies

$$\boxed{\operatorname{Re}\mu_2 = -0.51\ldots.} \tag{4.50}$$

This eigenvalue ensures the exponential stability of the first blow-up profile f_1. We are not aware of a proof of the inequality $\operatorname{Re}\mu_2 < 0$ for operator (4.48), and, as is often happens in the operator and stability theory, we initially rely on rather delicate numerical results. This calculation is based on carefully measuring the rate of the L^∞-convergence in the rescaled coordinates over compact subsets in the similarity variable y. This is of crucial importance, since measurement over all of x shows another (wrong) estimate $\operatorname{Re}\mu_2 \simeq -\frac{1}{4}$ instead. This is understood analogously to Proposition 4.6. Indeed, solutions with mass different from the final time profile cannot, because of conservation, lose that mass, but, similarly, it cannot contribute to the final-time profile in the rescaled coordinates. This extra mass (positive or negative) is damped to zero in the rescaled coordinates as described in Proposition 4.6 and hence with exponential rate $\mathrm{e}^{-\tau/4}$. However, this is not a property of the linearized operator about the first similarity profile and such an incorrect estimate follows from the scaling (2.1), where $\frac{1}{2(p-1)} = \frac{1}{4}$ for $p = 3$. This discrepancy is indicated in Figure 7. This type of estimate can of course be made by numerical approximation of the similarity ODE and numerical evaluation of the spectrum of the numerical linearization about such solutions. However, this gives no information about more general convergence behavior.

Numerical simulation of the full PDE with stationary profiles other than f_1 shows them to be exponentially unstable and the linearized operator

$$\mathbf{A}'(f_k) = \mathbf{B}^* - \frac{1}{4}\, I - 3\frac{\mathrm{d}^2}{\mathrm{d}y^2}(f_k^2 I) \tag{4.51}$$

has eigenvalues with positive real parts. Ordering the sequence of eigenvalues $\{\mu_l\}$ such that their real parts are nonincreasing means that

$$\operatorname{Re}\mu_2 > 0 \quad \text{for all } \ k \geq 2. \tag{4.52}$$

This has been checked numerically in a number of PDE experiments with $k = 2, 3, 4$ and 5. For instance, Figures 6(c) and 6(d) displays the unstable evolution for the initial function $u_0(x)$ given by the rescaled profile $\theta_0 \simeq f_5(y)$ (with the addition of a small positive perturbation) with the larger mass $\int \theta_0 = \int f_5 > \int f_1$. Then to compensate such a positive mass-defect, two positive humps appear and move fast to infinity in the rescaled coordinates showing convergence to f_1 on compact subsets of the similarity variable y. This and similar other numerical experiments with very precise approximation clearly suggest that the similarity profiles $f_2 - f_5$ are exponentially unstable.

5. General *p*'s. The case of general p is more complicated than for the conservative case as without conservation the ODE (2.5) remains truly fourth order.

5.1. Moment conservative case $p = 2$. One seeming exception to this is the second critical exponent $p_1 = 2$, for which one can also derive a third-order ODE. These are the solutions that conserve the first moment. For simplicity, we consider only $N = 1$. Multiplying by x in the PDE (1.1) and integrating by parts, we have

$$0 = -\int_{\mathbf{R}} (u_{xx} + u^p)_{xx}\, \mathrm{d}x = \frac{\mathrm{d}}{\mathrm{d}t}\int_{\mathbf{R}} ux\, \mathrm{d}x = \frac{\mathrm{d}}{\mathrm{d}t}\left[(T-t)^{-1/2(p-1)+1/2}\int_{\mathbf{R}} \theta(y,t) y\, \mathrm{d}y\right].$$

Thus, $p = 2$ defines the exponent, for which the first moment of solutions is conserved. Generically, in $\mathbf{R}^N$ this leads to the second critical exponent $p_1 = 1 + \frac{2}{N+1}$ in the sequence (1.8) and similar to (2.10), we conclude that

$$\text{for any } \ p \neq p_1, \quad yf \in L^1 \quad \Longrightarrow \quad \int yf = 0. \tag{5.1}$$

Multiplying the ODE (2.5) in $\mathbf{R}$ with y and integrating once, we have

$$f'''y - f'' + \frac{1}{4}y^2 f + (f^2)'y - f^2 = -f''(0) - f^2(0) \equiv \frac{1}{4}A, \tag{5.2}$$

where the constant $A \in \mathbf{R}$ determines the rate of algebraic decay at infinity. Recall that from (2.18) with $p = 2$ the asymptotic algebraic behavior is

$$f(y) = Ay^{-2}(1 + o(1)) \quad \text{as } \ y \to \infty. \tag{5.3}$$

Unlike the critical case $p = 3$ (cf. (4.2)), regardless of the fact that (5.2) is a third-order ODE, we need to keep two symmetry conditions at the origin

$$f'(0) = f'''(0) = 0. \tag{5.4}$$

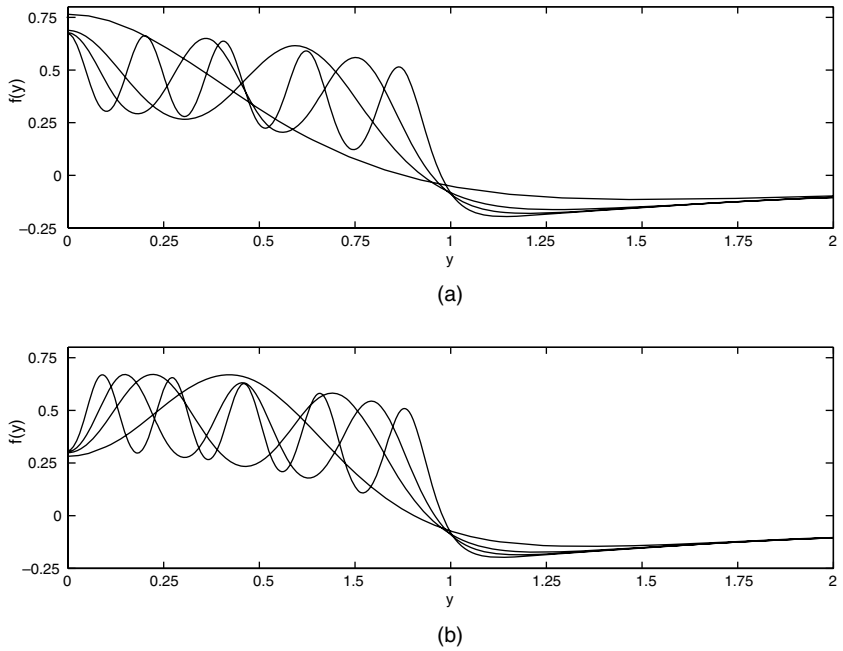

FIG. 8. (a) *Examples from the family of algebraically decaying solutions of* (5.2) *with* $f''(0) < 0$. (b) *Examples from the family of algebraically decaying solutions of* (5.2) *with* $f''(0) > 0$. *(All solutions are shown with* f *rescaled with* $(-A)^{-1/2}$*.)*

For the case $A = 0$, (5.2) may be rewritten as

$$f'' + (f^2)' + \frac{1}{4}\, yF = 0, \quad F = \int_0^y f(s)\, \mathrm{d}s.$$

Then the far-field behavior is purely exponential with a one-dimensional (1D) bundle there given in (2.17). This 1D bundle is not enough to "shoot" two boundary conditions (5.4), and we have got reliable numerical and analytical evidence that there is no exponentially decaying solution for $p = 2$.

For $A \neq 0$, solutions can again be constructed by continuation in A, but now the condition of zero mass must be enforced creating, once again, a fourth-order system. For all $A \neq 0$, we solve the ODE (5.2), (5.3) imposing the condition $\int_{\mathbf{R}} f = 0$ by setting $f(y) = F'(y)$, where F is odd, $F(0) = 0$ and $F(y) \to 0$ as $y \to \infty$, finding A such that $f'(0; A) = 0$. In Figure 8 we present example solutions with algebraic decay. These solutions are presented with f rescaled with $(-A)^{-1/2}$. The main difference from the case $p = 3$ is that now the shooting from $y = \infty$ is two-dimensional including the parameter A in (2.18) and an additional $C \in \mathbf{R}$ from the corresponding exponential bundle (2.17). This 2D asymptotic bundle is sufficient to match with two symmetry conditions (5.4) and to generate a countable set of similarity profiles $\{f_k\}$ shown in Figure 8. This 2D matching problem is more difficult than the 1D one for $p = 3$ and already exhibits typical "multidimensional" features of higher-order ODEs.

The details of a matched asymptotic construction are given in the appendix, which are now more involved than the $p = 3$ case. Figure 8 illustrates that the inner solutions have oscillations whose amplitudes are not asymptotically small (cf. (4.27)). However, we expect that an existence result similar to that in Theorem 4.4 as well

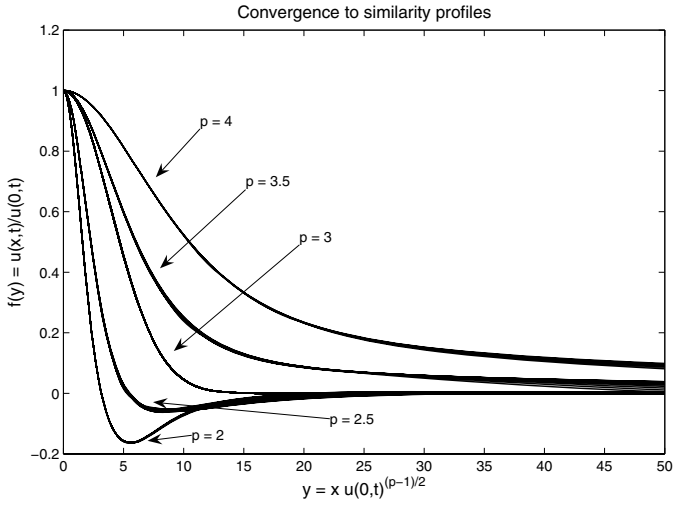

FIG. 9. *Asymptotic blow-up similarity behavior of rescaled solutions of the* $1D$ *PDE* (1.1) *for* $p \in [2, 4]$. *For each value of* p *solutions are plotted with* $u(0, t)$ *varying over 5 orders of magnitude.*

as the multiplicity analysis that follows can still be performed but become essentially more delicate.

5.2. On arbitrary $p > 1$. Finally, by direct simulation of the full PDE (1.1) with various values of $p \neq 3$, we conjecture that stable similarity profiles satisfying the ODE (2.5) govern the blow-up dynamics for all p, not just in the conservative case; see Figure 9. For instance, for $p = 2$ solutions converge exponentially fast in τ on compact subsets of y to the first fundamental *algebraically* decaying solution in Figure 8(a). Recall that, for all $p \neq 3$, precisely two symmetry conditions (5.4) should be taken into account, so we always deal with a 2D shooting by using a 2D algebraic-exponential bundle as $y \to \infty$ defined by a combination of (4.3) and (2.18),

$$f(y) = Ay^{-2/(p-1)} + \cdots + Cy^{-1/3}\mathrm{e}^{-\beta y^{4/3}} + \cdots \quad \text{as } y \to +\infty,$$

where A and C are arbitrary shooting parameters. Then the set of similarity profiles is always discrete and the first stable profile is isolated. Moreover, for such p's, a kind of singular perturbation technique similar to that in section 4 can be applied detecting, as a typical feature, countable sets of blow-up similarity profiles. A detailed similarity analysis for $p \neq 3$ and in the "singular" case $p < 1$ (with finite propagation and solutions of changing sign) will be presented in a forthcoming paper.

6. Global similarity and approximate similarity patterns. We now turn our attention to the better mathematically tractable case of global solutions. Taking $\sigma = -1$ and $T = 0$ in (2.1) yields the rescaling of global-in-time solutions. We study the asymptotic behavior as $\tau \to +\infty$ of solutions satisfying the parabolic PDE

$$\theta_\tau = \mathbf{A}(\theta) \equiv -\Delta(\Delta\theta + \theta^p) + \frac{1}{4}\, y \cdot \nabla\theta + \frac{1}{2(p-1)}\,\theta. \tag{6.1}$$

6.1. Similarity patterns for the one-dimensional equation with $p = 3$. As in the case of blow-up in section 4, we begin with the analysis of global self-similar

solutions

$$u_S(x,t) = t^{-1/4} f(y), \quad y = x/t^{1/4},$$

where f satisfies the ODE obtained from (2.5), (2.3) by integration

$$f''' - \frac{1}{4} yf + (f^3)' = 0, \quad \text{for } y > 0, \quad f'(0) = 0. \tag{6.2}$$

We are looking for profiles f with exponential decay at infinity so that these are L^1-solutions satisfying the conservation law (2.7). Recall that, unlike the blow-up case (4.2), the ODE (6.2) admits a two-dimensional exponential bundle as $y \to \infty$; see (2.16). This essentially simplifies the existence analysis and implies a continuous set of similarity profiles.

THEOREM 6.1. *The ODE problem* (6.2) *has an unbounded continuous family of exponentially decaying solutions.*

Proof. Step 1: monotonicity of solutions as $y \to \infty$. By a standard local analysis, one can check that, in addition to the two-dimensional exponential bundle of solutions mentioned in (2.16) and those with the algebraic decay (2.18), (6.2) has a three-dimensional bundle of asymptotically monotone growing solutions as $y \to \infty$

$$f(y) = \frac{y}{\sqrt{12}} + \frac{1}{y}\left(C_1 \cos\left(\frac{y^{3/2}}{3} \right) + C_2 \sin\left(\frac{y^{3/2}}{3} \right) + C_3 \right) + \cdots, \tag{6.3}$$

where C_1, C_2, C_3 are arbitrary parameters.

Step 2: the shooting argument. For a fixed constant $a \ge 0$, denote by $f(y;C)$ the solution of (6.2) with the conditions

$$f(0) = a, \quad f''(0) = C.$$

As in section 4, one can show that $f(y;C)$ is globally defined. Using the stability of the three-dimensional bundle (6.3) concentrated around the stable explicit solution

$$f_*(y) = \frac{y}{\sqrt{12}} \to \infty, \quad y \to \infty, \tag{6.4}$$

we have that there exists a sufficiently large $C_1 > 0$ such that $f(y;C)$ belongs to the bundle in (6.3) for all $C \ge C_1$. On the other hand, via symmetry by reflection, for all $-C \gg 1$, $f(y)$ approaches as $y \to \infty$ the bundle around the explicit profile $-f_*(y)$. Introducing the set

$$W = \{\mu < C_1 : \ \ f(y;C) \ \text{ belongs to (6.3) for all } C \in (\mu, C_1)\},$$

we have that there exists a finite $C = \inf W$, and by construction, $C = C(a)$ provides us with a profile $f(y;C(a))$ which belongs to the exponential bundle (2.16) as $y \to \infty$. □

Note that this implies that there exists a solution with all $f(0) = a \in \mathbf{R}$. In Figure 10 we present the bifurcation diagram with respect to mass of this continuous family of similarity profiles. As we already know, there exists another case $p = 2$, $N = 1$, where the fourth-order ODE (2.5) reduces to a simpler third-order one. The existence results here are quite similar and the family of solutions is also continuous. However, continuous families for $p = p_0$ and $p = p_1$ (quite special conservative cases associated with (1.1) in divergence form) are exceptional and these are not the generic situation for arbitrary p; see section 6.3, where discrete sets will be detected (cf. the VSSs in [17]).

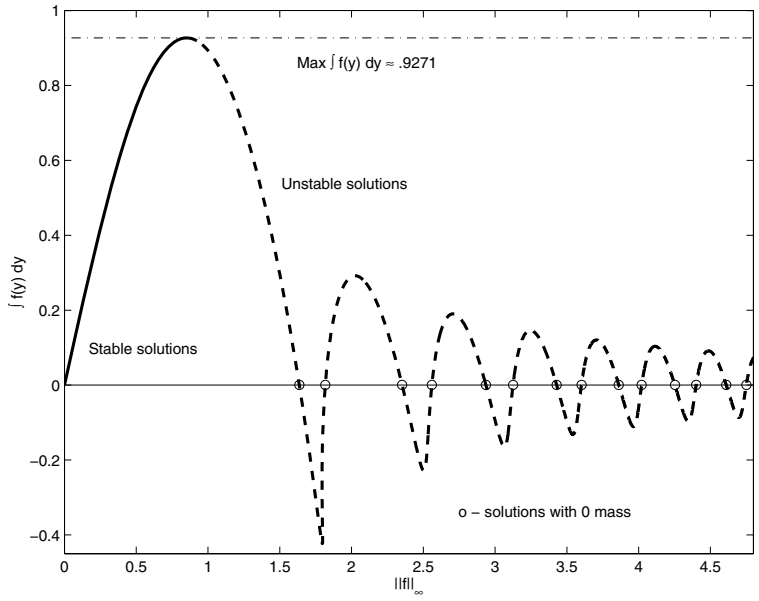

FIG. 10. *Mass bifurcation diagram.*

6.2. The minimal mass-branch is evolutionary stable. It follows from Figure 10 that, for any fixed initial mass $m_0 = \int u_0 \neq 0$, there exists a finite, or empty if

$$\boxed{|\int u_0| > m^* = 0.9271\dots},$$

set of similarity solutions with the given mass. Moreover, for $m_0 = 0$, besides $f(y) \equiv 0$, a countable family of such solutions is expected to exist that is clearly shown in Figure 10 as intersection points with the horizontal axes.

The crucial problem for such a case of multiple solutions is the stability of those solutions in the PDE sense. Let us show that the *minimal branch* in Figure 10 corresponding to the limit

$$f \to 0 \quad \text{as} \quad m_0 \to 0 \tag{6.5}$$

is stable at least for all small masses $m_0 > 0$ (or $m_0 < 0$ replacing $f \mapsto -f$). As a typical example, we perform such computations for the N-dimensional case bearing in mind that the first critical exponent is now $p = p_0 = 1 + \frac{2}{N}$. Consider the corresponding elliptic equation

$$\mathbf{A}(f) \equiv -\Delta^2 f + \frac{1}{4}\, y \cdot \nabla f + \frac{N}{4} f - \Delta f^p = 0, \quad \int f = m_0 > 0. \tag{6.6}$$

First, as an example, we establish a local result on the existence of such similarity patterns in general dimension. For $N = 2$ such a local existence was earlier established in [1] by a different technique.

PROPOSITION 6.2. *Let $p = p_0$. For any sufficiently small $m_0 > 0$,* (6.6) *admits a solution satisfying*

$$f = m_0 F + O(m_0^p) \qquad (\textit{with } F \textit{ is as in } (1.13)). \tag{6.7}$$

Proof. Setting $f = m_0 v$ and introducing operator $\mathbf{C} = \mathbf{B} - I$ with the strictly negative point spectrum, $\sigma(\mathbf{C}) = \{\lambda_l = -1 - \frac{l}{4}\}$, we consider the equivalent integral equation

$$v = \mathbf{D}(v) \equiv -\mathbf{C}^{-1} v + |m_0|^{p-1} \mathbf{C}^{-1} \Delta v^p, \tag{6.8}$$

with condition $\int v = 1$. Since $\mathbf{B}$ has compact resolvent in $L^2_\rho(\mathbf{R}^N)$ [10], we have that after a suitable smooth truncation of the nonlinearity v^p for $|v| \gg 1$ (see further comments below), $\mathbf{D}$ is a compact Hammerstein operator [25]. Since $\mathbf{D}'(0) = \mathbf{C}^{-1}$ has the simple eigenvalue $\lambda_0 = 1$, bifurcation occurs at $m_0 = 0$ and by the Lyapunov–Schmidt method [25], the solution can be represented in the form $v = F + w$, where $w \in \mathcal{L}^\perp\{F\}$. On substitution into (6.8) we obtain that $w = O(|m_0|^{p-1}) \in L^2_\rho$ is small for $|m_0| \ll 1$. Hence, w is small in H^{2m}_ρ and by the known asymptotic properties of the ODE under consideration, w is small uniformly. This means that the truncation of the unbounded nonlinearity v^p does not affect the solution bifurcating at $m_0 = 0$. Finally, we obtain the representation (6.7) in H^{2m}_ρ and uniformly in $\mathbf{R}^N$. See more details in [17, sect. 6]. □

To study the stability of the minimal branch, we consider the linearized operator

$$\mathbf{A}'(f)Y = \mathbf{B}Y - p\Delta(|f|^{p-1}Y) \equiv \mathbf{B}Y - |m_0|^{2/N} p \Delta(|F|^{p-1}Y) + \cdots . \tag{6.9}$$

For small m_0, $\mathbf{A}'(f)$ is a perturbation of $\mathbf{B}$ with the known spectrum as given in (3.3). In 1D and in the radial geometry all the eigenvalues are simple and we will denote the eigenfunctions by ψ_l instead of ψ_β with $l = |\beta|$. Similarly to Proposition 4.7, we have that $\mathbf{A}'(f)$ has a discrete spectrum which is a perturbation of that of $\mathbf{B}$ [18]. Recall that, from the orthogonality condition (3.7), $\psi_0 = F$ is the only eigenfunction of $\mathbf{B}$ with nonzero mass; see (1.13). Thus, requiring that the mass of profiles be preserved, we have to take into account perturbations of eigenvalues corresponding to perturbed eigenfunctions from $\mathcal{L}^\perp\{F\}$, i.e., of eigenvalues of $\mathbf{B}$ for $l = 1, 2, \dots$ ($l = 0$ not included). By direct calculation from (6.9), one can estimate this point spectrum given, to leading order, by

$$\sigma(\mathbf{A}'(f)) = \left\{ -\frac{l}{4} + |m_0|^{2/N} p \left\langle \Delta(|F|^{p-1}\psi_l, \psi_l^* \right\rangle + \cdots , \ l = 1, 2, \dots \right\}.$$

This guarantees that, for all small $|m_0|$, the real parts of the eigenvalues are bounded away from zero from above and that this branch is exponentially stable. Note that this expansion is not valid near the subsequent zeros of mass (other than 0) seen in Figure 10, as the L^∞-norm of such solutions is not zero for $m_0 = 0$ and hence expansion (6.7) does not hold. Therefore, other continuous monotone increasing or decreasing sub-branches are not stable.

Hence, for almost all initial data with $|\int u_0| \le m^*$, there exists the stable branch of similarity solutions that can attract the solution as $t \to \infty$. If $|\int u_0| > m^*$, then, as is seen from Figure 10, self-similar asymptotic behavior is not available and the solution is expected to blow-up in finite time.

6.3. The *p*-bifurcation diagram and asymptotic behavior. To describe the global bifurcation diagram of similarity profiles, we first determine the spectrum of critical exponents as bifurcation points. Writing the elliptic equation (2.5) in the form

$$\mathbf{B}f + c_* f = \Delta f^p \quad \text{in } \mathbf{R}^N, \quad f(y) \to 0 \text{ exponentially fast as } y \to \infty, \tag{6.10}$$

with $c_* = N(p_0 - p)/4(p-1)$, we obtain the following result.

PROPOSITION 6.3. *Let, for an integer $l \geq 0$, the eigenvalue $\lambda_l = -\frac{l}{4}$ of the operator* (3.1) *be of odd multiplicity. Then the critical exponent p_l given in* (1.8) *is a bifurcation point for the problem* (6.10).

Proof. After performing, as above, a smooth truncation of the nonlinearity f^p, the proof follows analogously to that of Proposition 6.2 (cf. Proposition 6.1 in [17]). By using the explicit representation of the resolvent of $\mathbf{B}$ [10], this differential equation reduces to an integral one with compact Hammerstein operators to which the classical bifurcation techniques apply [25]. □

Using standard bifurcation theory, we briefly describe the results calculated directly from the differential equation. By Lemma 3.1, the linear operator in (6.10) has the spectrum $\sigma(\mathbf{B}+c_*I) = \{c_* - \frac{l}{4},\, l \geq 0\}$. Therefore, any $p = p_l$ for which $c_* - \frac{l}{4} = 0$ gives the critical exponents (1.8), determines a bifurcation point for problem (6.10) provided that $\lambda_l = -\frac{l}{4}$ is of odd multiplicity (e.g., this is always true for $N = 1$ or in the radial geometry where the eigenvalues are always simple). In order to describe the local behavior of the bifurcation branches at $p \approx p_l$, we fix an l and set

$$p = p_l + \varepsilon, \quad \text{with } p_l = 1 + \frac{2}{N+l}.$$

Since $c_* = \frac{l}{4} - \mu_l\varepsilon + O(\varepsilon^2)$, with $\mu_l = \frac{1}{8}(N+l)^2$, (6.10) takes the form

$$\left(\mathbf{B} + \frac{l}{4}I\right) f - \mu_l\varepsilon f + O(\varepsilon^2) = \Delta f^p. \tag{6.11}$$

Using the Lyapunov–Schmidt method ([25, Chap. 8]) by setting $f = C\psi_l + w$, where $w \in \mathcal{L}^{\perp}\{\psi_l\}$, one can find the algebraic equation for C. Solving this, one finds that near the bifurcation point the solution takes the form

$$f = [\nu_l(p-p_l)]^{1/(p-1)}\psi_l + \cdots \quad \text{as } p \to p_l^+, \text{ where } \nu_l = -(N+l)^2/8\kappa_l \text{ and} \tag{6.12}$$

$$\kappa_l = \langle \Delta\psi_l^{p_l}, \psi_l^* \rangle = \langle \psi_l^{p_l}, \Delta\psi_l^* \rangle < 0. \tag{6.13}$$

The expansion (6.12) is posed under the crucial assumption that (6.13) holds. The strict inequality (6.13) has been checked numerically for various $l \geq 2$. It is worth mentioning that an analytical proof of (6.13) is not straightforward even in the simplest case $l = 2$, $N = 1$, where $\psi_2 = F''(y)/\sqrt{2}$, $(\psi_2^*)'' \equiv \sqrt{2}$ and $p_2 = \frac{5}{3}$, though the positivity dominance of the rescaled kernel F in the sense that $\int F = 1$ directly suggests that $\kappa_2 < 0$.

Notice however, that

$$\kappa_0 = \kappa_1 = 0 \quad \text{for all } \ N \geq 1,$$

as $\psi_0^* = 1$ and $\psi_1^*(y)$ is linear in y. Thus, the corresponding branches leave these bifurcation points vertically, suggesting a continuous family of solutions for these critical exponents described above. For $p = 3$, this has been proved in Proposition 6.2. For $p = 2$, this follows from the ODE integrated once after multiplying by y (cf. (5.2) with $A = 0$),

$$f'''y - f'' - \frac{1}{4}y^2 f + (f^2)'y - f^2 = 0. \tag{6.14}$$

Therefore, we need a single condition of odd symmetry at the origin $f(0) = 0$ since the second one $f''(0) = 0$ follows from the ODE (6.14).

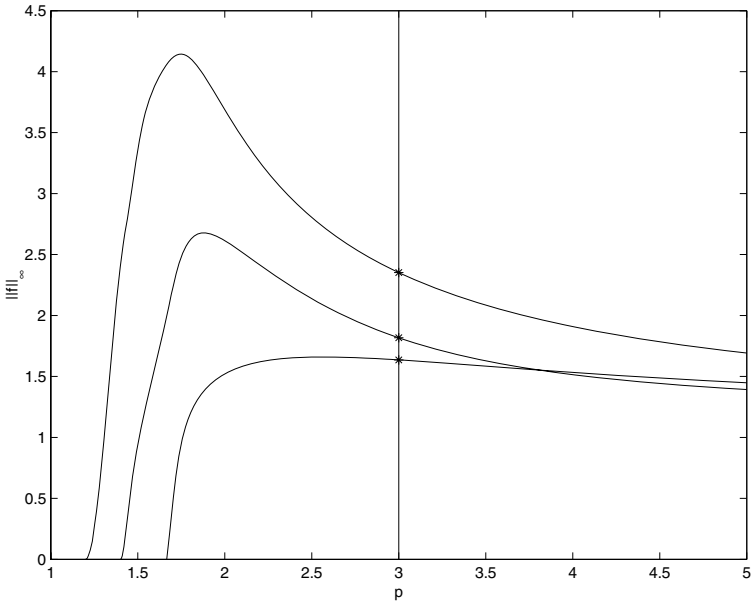

FIG. 11. *Bifurcation diagram of* (6.10) *for* $N = 1$ *with respect to* p *with even symmetry conditions at* $y = 0$. *There is a continuous branch of solutions from* $p = 3$ *and* 2 *but only a discrete set of solutions for all* $p \neq 3, 2$. *Another vertical branch of solutions bifurcates from* $p = 2$ *but with odd symmetry about* $y = 0$.

In Figure 11 we see that the remaining branches bifurcate with increasing p which is guaranteed by (6.13). Then, bearing in mind the countability of bifurcation points (1.8), Figure 11 clearly suggests that for any $p > 1$, $p \neq p_0$, p_1, there exists a countable set of solutions to (6.10). For noncoercive smooth potential operators, this is a typical result from Lusternik–Schnirel'man theory (see the classical formulation in [25, p. 381] and [26, 35] on variational methods in weighted Sobolev spaces like L^2_ρ for problems in $\mathbf{R}^N$), though problem (6.10) is not variational. The countability of solutions is not necessarily associated with the existence of a variational formulation.

It follows from (2.4) that, for $p \neq p_0$, any solution of (6.10) must have zero mass, see (2.10). The similarity profiles on all the bifurcation branches in Figure 11 satisfy (2.10). Lastly, recall from Figure 10 that there is a discrete set of μ_k such that $f(0) = \mu_k$ and $\int f_{\mu_k} = 0$. Clearly, in Figure 11 this countable set of points corresponds to intersections of the bifurcation branches with the vertical one $\{p = 3\}$. To investigate problem (6.10) numerically, we have solved the fourth-order system

$$f''' = \frac{1}{4} fy + c_* F - |f|^{p-1} f', \quad F' = f,$$

coupled with the boundary conditions

$$f'(0) = 0, \quad F(0) = 0, \quad \lim_{y \to \infty} f(y) = 0, \quad \lim_{y \to \infty} F(y) = 0,$$

as a continuation problem in $p < 3$ and $p > 3$ starting from those already known profiles at the intersection points with $\{p = 3\}$.

Figure 11 shows branching of solutions of (6.10), i.e., similarity profiles with exponential decay at infinity. Concerning possible solutions with the algebraic decay

(2.18), one can see that such functions satisfy $f \in L^1(\mathbf{R}^N)$ for $p < p_0$ so that the blow-up rate (2.4) implies the zero mass condition (2.10). We expect that there exists a continuous family of such solutions with certain domain of attraction which do not play any role for exponentially decaying initial data.

On stability of the p_2-branch for $p \in (p_2, p_0)$. Let us show that the first nonvertical branch, from $p = p_2$, is stable for $p \approx p_2^+$. This is done by estimating the real parts of the eigenvalues of the linearized operator given in (6.10), which for $l = 2$ has the form

$$\mathbf{A}'(f) = \mathbf{B} + \frac{1}{2}\, I - \varepsilon \mathbf{C} + o(\varepsilon), \quad \mathbf{C} = \mu_2 I + p_2 \nu_2 \Delta(|\psi_2|^{p_2 - 1} I), \tag{6.15}$$

where we substitute the expansion of f given by (6.12) with $l = 2$. By $\{\bar\lambda_l = \bar\lambda_l(\varepsilon)\}$, $\varepsilon = p - p_2 > 0$, we denote the discrete spectrum of $\mathbf{A}'(f)$.

For $N = 1$, due to the conservation of mass (for any $p \le p_0 = 3$) and of the first moment (for any $p \le p_1 = 2$), the first modes with positive unperturbed eigenvalues of $\mathbf{B} + \frac{1}{2} I$ ($\varepsilon = 0$), $\bar\lambda_0(0) = \frac{1}{2}$ and $\bar\lambda_1(0) = \frac{1}{4}$ are not taken into account and we need to check the perturbed third eigenvalue $\bar\lambda_2(\varepsilon)$. The same holds for $N > 1$ in the radial setting deleting all eigenvalues corresponding to nonsymmetric eigenfunctions and hence $\bar\lambda_1$. Since this unperturbed eigenvalue vanishes, $\bar\lambda_2(0) = 0$, by perturbation theory [18], the eigenvalue expansion takes the form $\bar\lambda_2(\varepsilon) = \varepsilon\rho + o(\varepsilon)$ with the eigenfunction given by $\bar\psi_2(\varepsilon) = \psi_2 + \varepsilon\varphi + o(\varepsilon)$. Substituting these approximations into the eigenvalue equation, we find

$$\mathbf{A}'(f)\bar\psi_2(\varepsilon) = \bar\lambda_2(\varepsilon)\bar\psi_2(\varepsilon),$$

and using (6.15), we obtain from the equation at $O(\varepsilon)$ that the expansion coefficients ρ and φ satisfy

$$\left(\mathbf{B} + \frac{1}{2}\, I\right)\varphi = \rho\psi_2 + \mathbf{C}\psi_2.$$

Hence, by the orthogonality condition,

$$\rho = -\langle \mathbf{C}\psi_2, \psi_2^* \rangle = -\mu_2 - \frac{1}{8}\, p_2(N+2) = -\frac{1}{8}\,(N+2)(N+3),$$

and, for small $\varepsilon = p - p_2 > 0$,

$$\bar\lambda_2(\varepsilon) = -\frac{1}{4}\,(p - p_2)(N+2)(N+3) + o(p_2 - p), \quad \text{i.e., } \operatorname{Re}\lambda_2(\varepsilon) < 0. \tag{6.16}$$

This means the exponential asymptotic stability of the similarity patterns on the p_2-bifurcation branch for all $p - p_2 > 0$ sufficiently small. We expect that the whole branch remains stable for all $p \in (p_2, p_0)$. Note that for $p = p_0$ it is not stable as Figure 10 suggests since this solution has $\|f\|_\infty \approx 1.6$ and the stable solutions have smaller L^∞-norm.

Stability of the fundamental solution for $p > p_0$. It follows from (6.10) that $c_* < 0$ for $p > p_0$ so that 0 becomes stable in the rescaled PDE (6.1). Therefore, we apply to (1.1) the scaling corresponding to the fundamental solution (1.12),

$$u(x,t) = (1+t)^{-N/4} g(y,\tau), \quad y = x/(1+t)^{1/4}, \quad \tau = \ln(1+t) \ge 0, \tag{6.17}$$

to get an exponentially perturbed equation

$$g_\tau = \mathbf{B}g - \mathrm{e}^{\gamma\tau}\Delta g^p, \tag{6.18}$$

where $\gamma = \frac{1}{4}N(p_0 - p) < 0$, if $p > p_0$. Recall that by Lemma 3.1, $\mathbf{B}$ has a one-dimensional center subspace with the eigenfunction F; see (1.13). Therefore, we arrive at a typical result in the supercritical range $p > p_0$: for all sufficiently small initial data with $m_0 = \int u_0 \neq 0$, the solution of (1.1) is global and has the same asymptotic behavior as the fundamental solution (1.12) with identical mass,

$$u(x,t) = m_0 t^{-N/4}\left[F\left(x/t^{1/4}\right) + o(1)\right] \quad \text{as } t \to \infty.$$

See rigorous analysis in [10] for (1.7) in the range $p > p_0 = 1 + \frac{2m}{N}$, which can be applied to the PDE (6.18).

6.4. Transitional non-self-similar patterns at critical exponents for the limit stable Cahn–Hilliard equation. Our analysis shows that at the bifurcation points (1.8) there occurs a transition from the linearized patterns corresponding to the stable manifold of $\mathbf{A}$ with the linearization (3.1) to the essentially nonlinear similarity patterns described in Figure 11. This is quite a general phenomenon in nonlinear parabolic equations observed in various higher-order models, [6, 10, 16, 17].

It remains to determine what happens at the critical values $p = p_l$ for the original PDE (1.1). Here one can expect some nontrivial center manifold patterns in the rescaled (6.1). It turns out that this center manifold behavior is unstable (possibly, with blow-up) for (1.1) but leads to nonsimilarity patterns for the stable (1.9). The construction of global self-similar solutions (2.4), $\sigma = -1$, is quite the same as that already considered in section 6.3 but instead of (6.10) we arrive at the equation

$$\mathbf{B}f + c_* f = -\Delta f^p. \tag{6.19}$$

Therefore, in the bifurcation analysis similar to Proposition 6.3 we obtain expansions (6.12), where $\nu_l = (N+l)^2/8\kappa_l < 0$, i.e., the branches bifurcate at $p = p_l^-$ concentrating at $p = 1^+$, and hence p is expected to decrease along them (no rigorous proof of nonlocal properties of branches is still available). A similar p-diagram occurs for very singular similarity solutions for the semilinear parabolic equations with absorption [17].

It is important to understand how such bifurcations can affect the evolution orbits of the original PDE (1.9). Consider the corresponding rescaled (6.1), which at $p = p_l$ takes the form

$$\theta_\tau = \left(\mathbf{B} + \frac{l}{4}I\right)\theta + \Delta\theta^p \quad \text{for } \tau \gg 1. \tag{6.20}$$

We fix $l \geq 1$ so that, by orthogonality, ψ_l has zero mass. By (3.3), $\mathbf{B} + \frac{l}{4}I$ has a nontrivial kernel, and therefore, by the general invariant manifold theory (see, e.g., [30]), it is natural to verify the center manifold behavior. This is expressed by looking for solutions in the form

$$\theta(\tau) = a_l(\tau)\psi_l + w(\tau), \quad \text{with } w(\tau) \in \mathcal{L}^\perp\{\psi_l\}, \tag{6.21}$$

where the center manifold dominance in the asymptotic behavior means that $w(\tau) = o(a_l(\tau))$ as $\tau \to \infty$. Substituting this expansion into (6.20) and multiplying by the adjoint eigenfunction ψ_l^* in $L^2(\mathbf{R}^N)$ yields $\dot{a}_l = \kappa_l a_l^p + o(a_l^p)$, where κ_l is as given in (6.13). Since $\kappa_l < 0$, integrating this asymptotic ODE gives

$$a_l(\tau) = [(p-1)|\kappa_l|\tau]^{-1/(p-1)}(1 + o(1)). \tag{6.22}$$

In the original $\{x,t,u\}$-variables, this defines the following asymptotic patterns for the PDE (1.1) at $p=p_l$, $l\geq 2$ as $t\to\infty$:

$$u(x,t)=C_l(t\ln t)^{-(N+l)/2}\left[\psi_l\left(y/t^{1/4}\right)+o(1)\right],\quad \text{where } C_l=[2|\kappa_l|/(N+l)]^{-(N+l)/2}.$$

Obviously, using (3.1) as the linearization in the rescaled (6.1), one can see that, in the supercritical range $p>p_l$, there exist stable manifold patterns with the behavior

$$\theta(y,\tau)=C\mathrm{e}^{-(N+l)(p-p_l)\tau/4(p-1)}[\psi_l(y)+o(1)]\quad \text{as } \tau\to\infty\quad (C\neq 0) \tag{6.23}$$

(cf. (6.21), (6.22) for $p=p_l$). The patterns (6.21), (6.22) are transitional ones at $p=p_l$ describing the exchange between the linearized stable manifold ones (6.23) and the nonlinear similarity patterns studied above. This transition phenomenon is similar to that detected in [17] for the very singular similarity solutions of the nonconservative higher-order parabolic equations $u_t=-(-\Delta)^m u-u^p$.

These transition phenomena are very difficult to detect numerically as it is only a slow logarithmic correction of an asymptotic algebraic decay rate. Moreover, it occurs only at a discrete set of nonlinearities corresponding to critical exponents $\{p_l\}$. Regardless, understanding such phenomena is crucial for the description of evolutionary completeness of patterns for this problem.

7. Summary and final conclusions. This paper has considered both blow-up and global solutions to the fourth-order semilinear parabolic equation (1.1). We have termed such an equation the limit unstable Cahn–Hilliard equation since it can arise as a limiting case of the more familiar and standard Cahn–Hilliard equation with a double-well potential function (1.3). Our attention has focused on describing the eventual patterns of similarity solutions to this equation. In the case of *blow-up*, these occur as the finite blow-up time is approached, while for the *global* solutions these occur as a large-time behavior. As such, in section 2 we presented the similarity scalings and derived the governing ODE equations for both the blow-up and global cases together with the critical value of the exponent $p=p_0=1+\frac{2}{N}$ if mass is to be conserved. Since we are interested in solutions with noncompact support (notice that a free-boundary formulation for (1.1) can give finite interfaces but we do not consider such problems concentrating on the canonical Cauchy problem in $\mathbf{R}^N\times\mathbf{R}_+$), we described in section 2.2 the possible far-field behaviors. In section 3, further preliminary results are given concerning the spectral theory of the linearized operator, which is used in the stability analysis of blow-up profiles in section 4 and plays a key role in bifurcation analysis of global similarity patterns considered in section 6.

In section 4 we provided a detailed analysis of the possible blow-up similarity profiles for the conservative case $p=p_0=1+\frac{2}{N}$ in one space dimension $N=1$, i.e., $p=p_0=3$. We conveniently parameterized the possible profiles using the free constant C that appears in the far-field behavior (4.3), and in section 4.2 gave existence results that C in fact takes an ordered countable set of values $\{C_k\}$ with $C_k>C_{k-1}$. A striking feature of the corresponding similarity profiles $\{f_k\}$ is that they posses a number of local maxima that can be related to the "index" of f_k, which increases as k increases (this can be formally associated with the Morse index or the Sturm's number of zeros of a related "eigenfunction"). In section 4.3, the method of matched asymptotic expansions was used to describe the structure of this family of profiles in the limit when C_k becomes large. A novel two-scale outer expansion was used to the capture the oscillatory behavior associated with the local maxima of the profiles satisfying a singular perturbed ODE. Importantly the asymptotics derived an explicit

expression for the values of C_k with k large. When appropriate we compared the asymptotic solution with the corresponding full numerical solution of the ODE problem to confirm its accuracy, and also in section 4.5 was described a numerical scheme for solution of the original PDE (1.1) in order to confirm convergence to our stable similarity profiles from arbitrary generic initial data. As such in section 4.5, numerical evidence was provided for the exponential stability of the first blow-up pattern f_1.

In section 5 we briefly considered blow-up in cases $p \neq p_0$. We noted the second critical exponent $p = p_1 = 1 + \frac{2}{N+1}$, in which the first moment of solutions is conserved. In this case analytical and numerical progress can be made and we again noted that, similar to the critical case $p = p_0$, we can classify the family of blow-up similarity solutions as a countable set. Matched asymptotic expansions were again used to determine the solution structure for the limiting members of this set, which is relegated to the appendix.

In section 6 we turned our attention to *global* (source-type) similarity solutions. Unlike the blow-up patterns, our main conclusion is that (1.1) admits a continuous set of similarity patterns, which can be parameterized by the mass. We proved existence and exponential stability of solutions on the minimal branch by using the classical bifurcation theory for non-self-adjoint operators, and derive a countable sequence of bifurcation exponents $\{p_l\}$, which lead to a finite number of similarity profiles for noncritical p's.

Appendix. A countable set of blow-up patterns for $p = 2$, $N = 1$. In this appendix we carry out formal asymptotic computations for the ODE (5.2), which are similar to those presented in section 4. While we again have an integrable fourth-order ODE, the calculation is now more involved. The limit $A \to -\infty$ may be considered by recasting (5.2) with (5.3) as a singular perturbation problem in a manner similar to that developed in section 4.3 for $p = 3$. Introducing the small parameter $\varepsilon > 0$ by

$$A = -\varepsilon^{-1/2},$$

the rescaling $y = \varepsilon^{-1/4}\bar{y}$ gives the following problem for $f(\bar{y})$:

$$\varepsilon \left(\frac{f''}{\bar{y}} \right)' + \varepsilon^{1/2} \left(\frac{f^2}{\bar{y}} \right)' + \frac{1}{4} f = -\frac{1}{4\bar{y}^2}, \quad \text{with} \tag{A.1}$$

$$f'(0) = 0, \qquad f''(0) + \frac{f^2(0)}{\varepsilon^{1/2}} = \frac{1}{4\varepsilon}, \quad \text{and} \tag{A.2}$$

$$f = -\frac{1}{\bar{y}^2}(1 + o(1)) \quad \text{as} \quad \bar{y} \to +\infty. \tag{A.3}$$

Here $'$ denotes $\frac{\mathrm{d}}{\mathrm{d}\bar{y}}$. In the limit $\varepsilon \to 0^+$, we obtain a four-layer structure illustrated schematically in Figure 12. We have an outer region $\bar{y} = O(1)$, in which f takes the far-field behavior (A.3), and an inner region $\bar{y} = O(\varepsilon^{1/8})$, in which $f = O(\varepsilon^{-1/4})$. This inner region is partitioned into two distinct regions, an inner 1, where $\bar{y} > \varepsilon^{1/8}\hat{a}$, and an inner 2, where $\bar{y} < \varepsilon^{1/8}\hat{a}$. The partition is through an inner inner region located at $\bar{y} = \varepsilon^{1/8}\hat{a}$, which is of width $O(\varepsilon^{3/8})$. The constant $\hat{a}$ will be shown below to be close to the location of the first singularity of a Painlevé transcendent-type equation.

The outer region $\bar{y} = O(1)$. At leading order (A.1) gives

$$f = -\frac{1}{\bar{y}^2}, \tag{A.4}$$

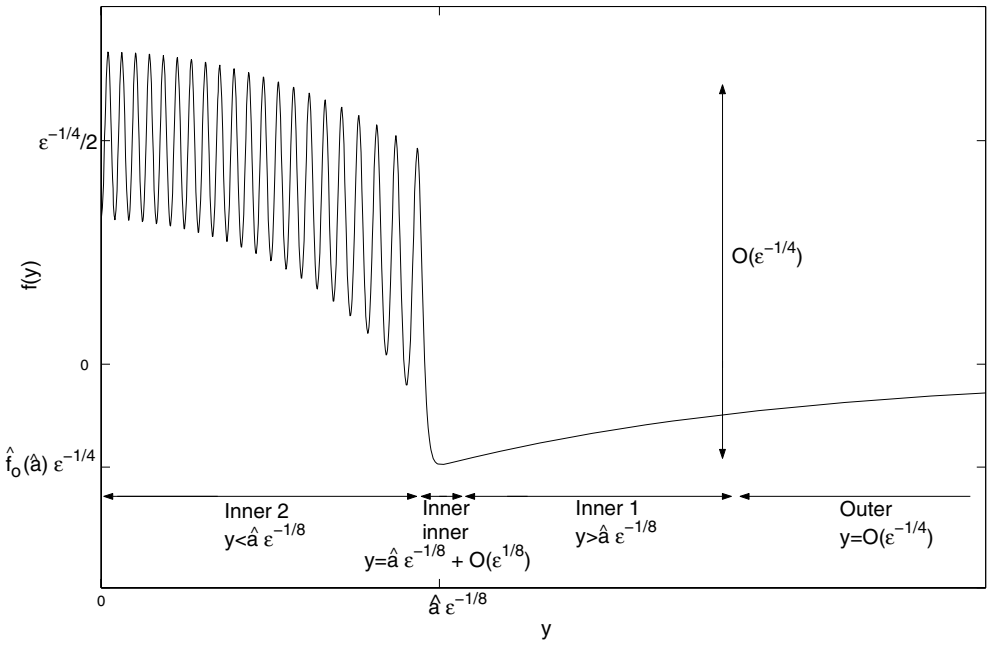

FIG. 12. *Schematic illustration of the asymptotic regions for the singular perturbation problem* (A.1)–(A.3) *expressed on the* y *variable scale.*

which obviously satisfies (A.3) but not (A.2). This gives rise to the consideration of the following inner region, in which terms involving the first derivatives of f are retrieved.

The inner 1 region $\bar{y} > \varepsilon^{1/8}\hat{a}$. Introducing the scalings

$$\bar{y} = \varepsilon^{1/8}\hat{y}, \qquad f = \varepsilon^{-1/4}\hat{f}, \quad \text{so (A.1) becomes} \tag{A.5}$$

$$\varepsilon^{1/2}\left(\frac{\hat{f}''}{\hat{y}}\right)' + \left(\frac{\hat{f}^2}{\hat{y}}\right)' + \frac{1}{4}\hat{f} = -\frac{1}{4\hat{y}^2}, \tag{A.6}$$

where $'$ now denotes $\frac{\mathrm{d}}{\mathrm{d}\hat{y}}$. Posing $\hat{f} \sim \hat{f}_0$ gives the leading order problem

$$\left(\frac{\hat{f}_0^2}{\hat{y}}\right)' + \frac{1}{4}\hat{f}_0 = -\frac{1}{4\hat{y}^2}, \quad \text{with the matching condition} \tag{A.7}$$

$$\hat{f}_0 \sim -\frac{1}{\hat{y}^2} \quad \text{as} \quad \hat{y} \to +\infty. \tag{A.8}$$

We next consider a region located at $\hat{y} = \hat{a}$ so that

$$\hat{f}_0 \sim \hat{f}_0(\hat{a}) \quad \text{as} \quad \hat{y} \to \hat{a}^+. \tag{A.9}$$

The inner inner region $\bar{y} = \varepsilon^{1/8}\hat{a} + O(\varepsilon^{3/8})$. Introducing the new variables

$$\hat{y} = \hat{a} + \varepsilon^{1/4}\hat{Y}, \qquad \hat{f} = \hat{F}, \tag{A.10}$$

we have from (A.6) that

$$\left(\frac{\hat{F}''}{(\hat{a}+\varepsilon^{1/4}\hat{Y})}\right)' + \left(\frac{\hat{F}^2}{(\hat{a}+\varepsilon^{1/4}\hat{Y})}\right)' + \frac{\varepsilon^{1/4}}{4}\left(\hat{F} + \frac{1}{(\hat{a}+\varepsilon^{1/4}\hat{Y})^2}\right) = 0, \tag{A.11}$$

where $'$ is now $\frac{\mathrm{d}}{\mathrm{d}\hat{Y}}$. Posing $\hat{F} \sim \hat{F}_0$ gives, at leading order,

$$\hat{F}_0'' + \hat{F}_0^2 = \left(\hat{f}_0(\hat{a})\right)^2, \tag{A.12}$$

after matching to (A.9). This gives the constant solution $\hat{F}_0 = \hat{f}_0(\hat{a})$ at leading order within this region.

The inner 2 region $\bar{y} < \varepsilon^{1/8}\hat{a}$. We now consider the scalings,

$$\bar{y} = \varepsilon^{1/8}\hat{y}, \qquad f = \varepsilon^{-1/4}F, \tag{A.13}$$

where $F = F(\hat{y}, Y)$ is also taken to be a function of the fast scale $\hat{y} = \varepsilon^{1/4}Y$. Defining the multiple-scales operator $\mathcal{L}$ by $\mathcal{L} = \frac{\partial}{\partial Y} + \varepsilon^{1/4}\frac{\partial}{\partial \hat{y}}$, (A.1) becomes

$$\mathcal{L}\left(\frac{1}{\hat{y}}\mathcal{L}^2 F\right) + \mathcal{L}\left(\frac{F^2}{\hat{y}}\right) + \frac{1}{4}\left(F + \frac{1}{\hat{y}^2}\right) = 0. \tag{A.14}$$

Posing $F \sim F_0 + \varepsilon^{1/4}F_1$, we have, at leading order,

$$\frac{\partial^2 F_0}{\partial Y^2} + F_0^2 = A_0(\hat{y}), \tag{A.15}$$

for some function $A_0(\hat{y})$ and at the next order,

$$\frac{\partial}{\partial Y}\left(\frac{\partial^2 F_1}{\partial Y^2} + 2F_0F_1\right) - 2\frac{\partial F_0^2}{\partial \hat{y}} + \frac{\hat{y}}{4}F_0 + 3\hat{y}^{1/3}\frac{\partial}{\partial \hat{y}}\left(\frac{A_0}{\hat{y}^{1/3}}\right) + \frac{1}{4\hat{y}} = 0. \tag{A.16}$$

The secular terms involving Y in (A.16) are removed if $3\hat{y}^{1/3}\frac{d}{d\hat{y}}\left(\frac{A_0}{\hat{y}^{1/3}}\right) = -\frac{1}{4\hat{y}}$, which gives $A_0(\hat{y}) = \frac{1}{4} - B_0\hat{y}^{1/3}$ for some constant B_0 (assumed positive). Thus F_0 satisfies

$$F_0'' + F_0^2 = \frac{1}{4} - B_0\varepsilon^{1/12}Y^{1/3}, \tag{A.17}$$

where $' = \frac{\mathrm{d}}{\mathrm{d}Y}$ and is subject to (A.2), which at leading order in the current variables becomes

$$F_0'(0) = 0, \quad F_0''(0) + F_0^2(0) = \frac{1}{4}. \tag{A.18}$$

The second condition in (A.18) is satisfied by F_0 as seen from (A.17). The equation (A.17) is noted to have movable singularities that are second-order poles. Denoting the first (i.e., smallest) positive pole location by $\hat{a}_0$, we have the local behavior,

$$F_0 \sim -\frac{6\varepsilon^{1/2}}{(\hat{a}_0 - \hat{y})^2} \quad \text{as} \quad \hat{y} \to \hat{a}_0^-. \tag{A.19}$$

Matching F_0 with $\hat{F}_0$ from the inner region requires $F_0(\hat{a}) = \hat{f}_0(\hat{a})$, where $\hat{a} < \hat{a}_0$.

It is worth remarking that the leading order solution $\hat{f}_s(\hat{y})$ in this inner 2 region on the slow scale $\hat{y}$ satisfies (A.7). As $\hat{y} \to 0^+$, the only bounded positive solution satisfying $\hat{f}_s'(0) = 0$ has the behavior,

$$\hat{f}_s \sim \frac{1}{2} - \frac{1}{8}\,\hat{y}^2 \quad \text{as} \quad \hat{y} \to 0^+.$$

For the solution satisfying this behavior, we have that $\hat{f}_s = 0$ at $\hat{y} \approx 1.6$ with $\hat{f}_s'$ unbounded which gives a first approximation for $\hat{a}$. We now have from the numerical solution of (A.7) and (A.8) the estimate $\hat{f}_0(\hat{a}) \approx -0.2$ for $\hat{a} = 1.6$. Further, imposing this condition on the two-scale approximation (A.17) suggests taking $B_0 \approx 1/4\hat{a}^{1/3}$.

Full numerical solution of (5.2) gives the values $y \approx 1.5\varepsilon^{-1/8}, f \approx -0.21\varepsilon^{-1/4}$ for the location and value of the minimum of f when $\varepsilon = 6.6 \times 10^{-9}$. This is in very good agreement with the values $\hat{a} = 1.6$, $\hat{f}_0(\hat{a}) = -0.2$ from the above asymptotics.

There are two sets of solutions to (A.17) satisfying (A.18), which are distinguished by the their values for $F(0)$. Full numerical solution of (5.2) gives the estimates $F_0(0) \approx 0.5 \pm 0.167$.

Acknowledgments. The authors would like to thank K. Promislov for several useful discussions, A. Novick-Cohen for suggestions concerning the literature, and an anonymous referee for considerable editorial input.

GLOBAL CONTINUATION IN SECOND-GRADIENT NONLINEAR ELASTICITY*

ANITA MARENO† AND TIMOTHY J. HEALEY‡

Abstract. We consider three-dimensional elastic bodies characterized by a general class of stored-energy functions dependent upon the first and second gradients of the deformation. We assume that the dependence on the higher-order term ensures strong ellipticity. With only modest assumptions on the lower-order term, we use the Leray–Schauder degree to prove the existence of global solution continua to the Dirichlet problem. With additional, physically reasonable restrictions on the stored-energy function, we then demonstrate that our global solution branch is unbounded.

Key words. nonlinear elasticity, second gradient, global continuation

DOI. 10.1137/050626065

1. Introduction.

In this work we consider the analysis of models for three-dimensional elastic bodies characterized by a general class of stored-energy functions dependent upon the first and second gradients of the deformation. We are motivated in part by the common use of second-gradient models to overcome the lack of regularity in nonlinear elasticity. Since the classical works of van der Waals [25], [29] and Cahn and Hilliard [6], the addition of small "interfacial energy" in multiwell problems associated with phase transitions is well known; see, e.g., [5], [22], [26], and references therein. Even problems within the setting of classical nonlinear elasticity (strongly elliptic) provide ample motivation for the use of higher-gradient models. For example, the potential failure of the complementing condition at the (smooth) boundary is a real impediment to existence [9], [11], [13].

We also mention the works [10] and [19]. Within the confines of one-dimensional, multiwell elasticity, these papers treat the existence of global solution branches. In particular, generalized solutions in the limit of vanishing interfacial energy are rigorously obtained. While this last difficult step is presently out of reach for three-dimensional problems, we establish a first important step in that process here, viz., the existence of unbounded solution branches for a general class of second-gradient models.

The outline of the paper is as follows: In section 2 we formulate the Dirichlet problem for a very general class of "forced" second-gradient models. We assume that the higher-order term of the stored energy function yields uniform strong ellipticity with only modest assumptions on the lower-order term. In section 3 we provide a global-continuation analysis via the Leray–Schauder degree, akin to that in [8] for classical first-gradient problems. The results are quite general, characterized by the usual two "Rabinowitz alternatives" [23] accompanied by the possibility of a bounded

solution branch that "terminates" due to the loss of local injectivity of solutions. Section 4 is the heart of the paper. We assume that the stored-energy function depends upon an interfacial-energetic term, quadratic in the second gradient of the deformation; we adopt the physically reasonable hypotheses from [12] for the lower-order term. Employing a recent uniqueness result [20, 21] for second-gradient systems and generalizing arguments from [12], we eliminate two of the "alternatives" from the general result of section 3, yielding the existence of an unbounded branch of classical injective solutions.

Notation. Throughout this work, the inner product and tensor product of $\mathbf{a}, \mathbf{b} \in \mathbb{R}^3$ are denoted as usual by $\mathbf{a} \cdot \mathbf{b}$ and $\mathbf{a} \otimes \mathbf{b}$, respectively. For second-order tensors we define the inner product by $\mathbf{A}{:}\mathbf{B} = \operatorname{tr}\left(\mathbf{A}^T\mathbf{B}\right) = A_{ij}B_{ij}$ (in Cartesian components), where tr denotes the trace and ^{T} denotes the transpose. Similarly, for third-order tensors $\mathbf{G}$ and $\mathbf{H}$ we define the inner product by $\mathbf{G} \vdots \mathbf{H} = G_{ijk}H_{ijk}$. For the most part, the third-order tensors encountered in this work are symmetric in their last two indices. Accordingly we define $V = \{\mathbf{G} : G_{ijk} = G_{ikj}\}$. For $\mathbf{G} \in V$ with components G_{ijk}, we define $\mathbf{G}^T$ to be the third-order tensor with components G_{jik}.

For Banach spaces X and Y, we let $L(X, Y)$ denote the space of bounded linear transformations from X to Y. (We let $L(X, X) \equiv L(X)$.) Then we define $GL\left(\mathbb{R}^3\right) = \{\mathbf{A} \in L(X) : \mathbf{A} \text{ is bijective}\}$, $GL^+\left(\mathbb{R}^3\right) = \left\{\mathbf{A} \in GL\left(\mathbb{R}^3\right) : \det \mathbf{A} > 0\right\}$, and $SO(3) = \left\{\mathbf{A} \in GL^+\left(\mathbb{R}^3\right) : \mathbf{A}^T = \mathbf{A}^{-1}\right\}$.

For the value of $T \in L(X, Y)$ at $x \in X$, we write $T[x]$. For a second-order tensor $\mathbf{A} \in L(\mathbb{R}^3)$, we write $\mathbf{A}\mathbf{x}$ instead of $\mathbf{A}[\mathbf{x}]$. For fourth-order tensors $\mathbf{C}$, $\mathbf{C}[\mathbf{A}]$ denotes the value of $\mathbf{C} \in L(L(\mathbb{R}^3))$ at $\mathbf{A} \in L(\mathbb{R}^3)$. Similarly, for sixth-order tensors $\mathbf{B}$, we write $\mathbf{B}[\mathbf{H}]$ for the value of $\mathbf{B}$ at a third-order tensor $\mathbf{H}$.

2. Problem formulation. We assume once and for all that an origin and an orthonormal basis have been chosen in three-dimensional Euclidean space, which we identify with the space $\mathbb{R}^3$. In this work, the reference configuration is chosen to coincide with a natural or stress-free configuration. The region occupied in the reference configuration is the closure $\bar{\Omega}$ of a domain Ω of $\mathbb{R}^3$, and we call $\bar{\Omega}$ itself the elastic body. We further assume that $\partial\Omega$ is locally of class C^5.

Deformations of the body are defined by mappings $\mathbf{f} : \bar{\Omega} \mapsto \mathbb{R}^3$ such that $\mathbf{f} \in C^2(\bar{\Omega}, \mathbb{R}^3)$ and $\nabla\mathbf{f}(\mathbf{x}) \in GL^+(\mathbb{R}^3)$. For a given deformation, we define the displacement field by $\mathbf{u}(\mathbf{x}) = \mathbf{f}(\mathbf{x}) - \mathbf{x}$ and the deformation gradient by $\mathbf{F} = \nabla\mathbf{f}(\mathbf{x}) = \mathbf{I} + \nabla\mathbf{u}(\mathbf{x}) \in GL^+(\mathbb{R}^3)$. The second gradient of $\mathbf{f}$ is denoted by $\nabla^2\mathbf{f}(\mathbf{x}) = \nabla\mathbf{F}(\mathbf{x})$, which is a third-order tensor field.

We assume that the body is subjected to a live body force $\mathbf{b}(\lambda, \mathbf{x}, \mathbf{u}, \nabla\mathbf{u})$ in Ω and a prescribed displacement $\mathbf{d}(\lambda, \mathbf{x})$ on $\partial\Omega$, where $\lambda \in \mathbb{R}$ is a loading parameter. We assume that at least one of these two fields is not identically zero and that

$$\mathbf{b}(0, \mathbf{x}, \mathbf{u}, \nabla\mathbf{u}) = \mathbf{d}(0, \mathbf{x}) \equiv \mathbf{0}. \tag{1}$$

The elastic body is presumed homogeneous and its material response is described by a stored energy function $W : V \times GL^+(\mathbb{R}^3) \to \mathbb{R}$, denoted $W(\mathbf{G}, \mathbf{F})$, such that the total internal potential energy is given by

$$E(\mathbf{f}) = \int_\Omega W(\nabla^2\mathbf{f}, \nabla\mathbf{f})\, dV. \tag{2}$$

The stored energy W is required to satisfy the principle of material objectivity:

$$W(\mathbf{Q}\mathbf{G}, \mathbf{Q}\mathbf{F}) = W(\mathbf{G}, \mathbf{F}) \text{ for all } \mathbf{Q} \in SO(3), \mathbf{G} \in V,\ \mathbf{F} \in GL^+\left(\mathbb{R}^3\right). \tag{3}$$

By a *natural* reference configuration we mean

$$\frac{\partial W(\mathbf{0},\mathbf{I})}{\partial \mathbf{G}} = \mathbf{0} \text{ and } \frac{\partial W(\mathbf{0},\mathbf{I})}{\partial \mathbf{F}} \equiv \mathbf{0}. \tag{4}$$

Furthermore, we make the following smoothness assumptions:

$$W \in C^4(V \times GL^+\left(\mathbb{R}^3\right), \mathbb{R}),$$

$$\mathbf{b} \in C^3(\mathbb{R} \times \bar{\Omega} \times \mathbb{R}^3 \times L(\mathbb{R}^3), \mathbb{R}^3),$$

$$\mathbf{d} \in C^5(\mathbb{R} \times \bar{\Omega}, \mathbb{R}^3). \tag{5}$$

We impose the geometric boundary conditions

$$\mathbf{u} = \mathbf{d} \text{ and } \frac{\partial \mathbf{u}}{\partial \mathbf{n}} = \frac{\partial \mathbf{d}}{\partial \mathbf{n}} \text{ on } \partial\Omega. \tag{6}$$

For our fourth-order problem (cf. (8) below), the conditions in (6) correspond to ideal "hard" loading. The displacement condition $(6)_1$ is common in the classical first-gradient theory, while $(6)_2$ represents the limiting case where the loading device also controls the normal derivative of the applied displacement. In plate theory, the conditions in (6) correspond to clamped edges [14].

To obtain the equilibrium equations, we calculate the first variation of $E(\mathbf{f})$ (cf. (2)) and equate it to the virtual work of the body force field $\mathbf{b}\left(\lambda, \mathbf{x}, \mathbf{u}, \nabla\mathbf{u}\right)$ acting through an admissible variation. After integrating by parts, we find the strong form of the equilibrium equations:

$$-\nabla \cdot \left(\nabla \cdot \frac{\partial W(\mathbf{G},\mathbf{F})}{\partial \mathbf{G}} - \frac{\partial W(\mathbf{G},\mathbf{F})}{\partial \mathbf{F}} \right) + \mathbf{b} = 0 \text{ in } \Omega. \tag{7}$$

Expanding (7) we obtain

$$-\mathbf{A}(\nabla^2\mathbf{u}, \mathbf{I} + \nabla\mathbf{u})[\nabla^4\mathbf{u}] + \mathbf{B}(\nabla^2\mathbf{u}, \mathbf{I} + \nabla\mathbf{u})[\nabla^3\mathbf{u}] + \mathbf{C}(\nabla^2\mathbf{u}, \mathbf{I} + \nabla\mathbf{u})[\nabla^2\mathbf{u}]$$

$$+ \mathbf{g}(\nabla^3\mathbf{u}, \nabla^2\mathbf{u}, \nabla\mathbf{u}) + \mathbf{b}\left(\lambda, \mathbf{x}, \mathbf{u}, \nabla\mathbf{u}\right) = 0 \text{ in } \Omega, \tag{8}$$

where (in components)

$$(\mathbf{A}(\mathbf{G},\mathbf{F})[\nabla^4\mathbf{u}])_i = \frac{\partial^2 W(\mathbf{G},\mathbf{F})}{\partial G_{ijk} \partial G_{lmn}} \frac{\partial^4 u_l}{\partial x_j \partial x_k \partial x_m \partial x_n},$$

$$(\mathbf{B}(\mathbf{G},\mathbf{F})[\nabla^3\mathbf{u}])_i = \frac{\partial^2 W(\mathbf{G},\mathbf{F})}{\partial F_{ij} \partial G_{klm}} \frac{\partial^3 u_k}{\partial x_j \partial x_l \partial x_m} - \frac{\partial^2 W(\mathbf{G},\mathbf{F})}{\partial F_{lm} \partial G_{ijk}} \frac{\partial^3 u_l}{\partial x_j \partial x_k \partial x_m},$$

$$(\mathbf{C}(\mathbf{G},\mathbf{F})[\nabla^2\mathbf{u}])_i = \frac{\partial^2 W(\mathbf{G},\mathbf{F})}{\partial F_{ij} \partial F_{kl}} \frac{\partial^2 u_k}{\partial x_j \partial x_l}, \tag{9}$$

and $\mathbf{g}(\cdot)$ is a vector-valued function of "higher order" in its first two arguments, viz.,

$$\mathbf{g}(\mathbf{U}, \mathbf{V}, \mathbf{W})/(|\mathbf{U}| + |\mathbf{V}|) \to \mathbf{0} \text{ as } |\mathbf{U}| + |\mathbf{V}| \to 0 \text{ for all } \mathbf{W}. \tag{10}$$

In particular, $\mathbf{g}(\cdot)$ makes no contribution to the linearization of (8) about $\mathbf{u} = \mathbf{0}$. Thus, its precise form is not important for our purposes here. Throughout this work we assume that the uniform strong ellipticity condition holds, i.e., that there exist positive constants c_1 and c_2 such that

$$c_1 \mid \mathbf{a} \mid^2 \mid \mathbf{b} \mid^4 \leq \mathbf{a} \otimes \mathbf{b} \otimes \mathbf{b} \vdots \mathbf{A}(\mathbf{G}, \mathbf{F}) [\mathbf{a} \otimes \mathbf{b} \otimes \mathbf{b}] \leq c_2 \mid \mathbf{a} \mid^2 \mid \mathbf{b} \mid^4 \tag{11}$$

for all $\mathbf{a}$,$\mathbf{b} \in \mathbb{R}^3 - \{\mathbf{0}\}$ and $(\mathbf{G}, \mathbf{F}) \in V \times GL^+ \left(\mathbb{R}^3\right)$. In addition, at the reference state, $(\mathbf{G}, \mathbf{F}) = (\mathbf{0}, \mathbf{I})$, we make the following reasonable assumptions on the coefficient tensors $\mathbf{B}, \mathbf{C}$ appearing in (8):

$$\mathbf{B}(\mathbf{0}, \mathbf{I}) = \mathbf{0}, \tag{12}$$

$$\mathbf{a} \otimes \mathbf{b} : \mathbf{C}(\mathbf{0}, \mathbf{I})[\mathbf{a} \otimes \mathbf{b}] > 0 \tag{13}$$

for all $\mathbf{a}$,$\mathbf{b} \in \mathbb{R}^3 - \{\mathbf{0}\}$.

Observe that (12) is weaker than assuming $\frac{\partial^2 W(\mathbf{0},\mathbf{I})}{\partial \mathbf{F} \partial \mathbf{G}} = \mathbf{0}$. The latter yields the physically reasonable condition that the quadratic-order coupling between $\mathbf{G}$ and $\mathbf{F}$ in $W(\mathbf{G}, \mathbf{F})$ vanishes. Of course (13) is simply the strong ellipticity condition for the classical linear elasticity tensor $\mathbf{C}(\mathbf{0}, \mathbf{I})$.

3. Existence of solution branches. For simplicity of presentation, we treat the case $\mathbf{d} \equiv \mathbf{0}$; cf. (6). The more general case is handled similarly after an appropriate change of variables; see, e.g., [8]. For $\alpha \in (0, 1)$, let $C^{m,\alpha}(\overline{\Omega}, \mathbb{R}^3)$ denote the usual Hölder space of m-times (Hölder) continuously differentiable functions, with norm $\|\cdot\|_{m,\alpha}$. The following Banach spaces play an important role in our forthcoming analysis:

$$Z = \left\{ \mathbf{u} \in C^{4,\alpha}(\bar{\Omega}, \mathbb{R}^3) : \mathbf{u} = \frac{\partial \mathbf{u}}{\partial \mathbf{n}} = 0 \text{ on } \partial\Omega \right\}; \|\mathbf{u}\|_Z \equiv \|\mathbf{u}\|_{4,\alpha},$$

$$X = \left\{ \mathbf{u} \in C^{3,\alpha}(\bar{\Omega}, \mathbb{R}^3) : \mathbf{u} = \frac{\partial \mathbf{u}}{\partial \mathbf{n}} = 0 \text{ on } \partial\Omega \right\}; \|\mathbf{u}\|_X \equiv \|\mathbf{u}\|_{\mathbf{3},\alpha},$$

$$Y = C^{0,\alpha}(\bar{\Omega}, \mathbb{R}^3); \|\mathbf{u}\|_Y \equiv \|\mathbf{u}\|_{0,\alpha}. \tag{14}$$

Since $\det \nabla \mathbf{f} > 0$ (pointwise) for a deformation $\mathbf{f} : \bar{\Omega} \to \mathbb{R}^3$, any solution of our problem (7), (6) should belong to the open subset

$$\mathcal{U} = \{\mathbf{u} \in X : \det(\mathbf{I} + \nabla \mathbf{u}) > 0 \text{ in } \bar{\Omega}\}. \tag{15}$$

In view of (1) and (4), we observe that $(\lambda, \mathbf{u}) = (0, \mathbf{0})$ is a solution (7), (6). Define $\mathcal{O}$ to be the maximal connected set in $\mathcal{U}$ containing $\mathbf{u} = \mathbf{0}$, i.e.,

$$\mathcal{O} = comp\{\mathbf{0}\} \text{ in } \mathcal{U}. \tag{16}$$

For every $\mathbf{u} \in \mathcal{O}$, we define a linear operator $L(\mathbf{u}) : Z \to Y$ via

$$L(\mathbf{u})[\mathbf{h}] \equiv -\mathbf{A}(\nabla^2 \mathbf{u}, \mathbf{I} + \nabla \mathbf{u}) \left[\nabla^4 \mathbf{h}\right] + \mathbf{B}(\nabla^2 \mathbf{u}, \mathbf{I} + \nabla \mathbf{u})[\nabla^3 \mathbf{h}]$$

$$+\,\mathbf{C}(\nabla^2\mathbf{u}, \mathbf{I}+\nabla\mathbf{u})[\nabla^2\mathbf{h}] \text{ for all } \mathbf{h}\in Z. \tag{17}$$

In view of (11), $L(\mathbf{u})$ defines a uniformly elliptic operator for any $\mathbf{u}\in\mathcal{O}$. Accordingly we have the following spectral estimate.

PROPOSITION 3.1. *There are positive constants ϵ, c_1, c_2, independent of $\mu, \mathbf{h}, \lambda, \mathbf{u}$, such that*

$$\|\mathbf{h}\|_Z \le c_1\,|\mu|^{\frac{\alpha}{4}}\,\|\,(L(\mathbf{u})-\mu I)\,[\mathbf{h}]\,\|_Y \tag{18}$$

for all $\mathbf{h}\in Z$, and for all $\mu\in\mathbb{C}$ such that $|\arg(\mu)|\le\frac{\pi}{2}+\epsilon$ and $|\mu|\ge c_2$. The mapping $I: Z\to Y$ is the identity map and $\alpha\in(0,1)$ is the Hölder exponent inherent in Z and Y.

Proof. The original L^p version of this result is due to Agmon [1]. For convenience we provide a detailed proof in the appendix for our (Hölder-space) setting (see also [30], [16]). □

By Proposition 3.1, for each $\mathbf{u}\in\mathcal{O}$, the linear operator $L(\mathbf{u})-a_oI: Z\to Y$ is injective for some sufficiently large real number $a_o > c_2$. Bijectivity of $L(\mathbf{u})-a_oI$ then follows from the Fredholm (of index zero) property. (For example, this last step is readily facilitated via a one-parameter homotopy of our operator with the vector-valued biharmonic operator, $-\Delta^2\mathbf{h}$, subject to the same homogeneous boundary conditions; cf. (6) with $\mathbf{d}\equiv\mathbf{0}$.) Next, for any $\mathbf{u}\in\mathcal{O}$, we consider the linear, uniformly elliptic boundary value problem

$$(L(\mathbf{u})-a_oI)\,[\mathbf{h}] \equiv -g(\nabla^3\mathbf{u}, \nabla^2\mathbf{u}, \nabla\mathbf{u}) - \mathbf{b}(\lambda, \mathbf{x}, \mathbf{u}, \nabla\mathbf{u}) - a_o\mathbf{u},$$

$$\mathbf{h} = \frac{\partial\mathbf{h}}{\partial\mathbf{n}} = \mathbf{0} \text{ on } \partial\Omega, \tag{19}$$

which has a unique solution, denoted $\mathbf{h}=G(\lambda,\mathbf{u})$, where $G:\mathbb{R}\times\mathcal{O}\to X$. By virtue of (5), the Schauder estimate [2] for (19), and the compact embedding $Z\to X$, we see that G is compact and continuous (*completely continuous*).

Moreover, any solution $(\lambda,\mathbf{u})\in\mathbb{R}\times\mathcal{O}$ of (7), (6) (with $\mathbf{d}\equiv\mathbf{0}$) satisfies

$$\mathbf{u} - G(\lambda,\mathbf{u}) = \mathbf{0}, \tag{20}$$

and conversely. Let $\mathcal{M}\subset\mathcal{O}$ be open and bounded. Since G is completely continuous, the Leray–Schauder degree of the mapping $\mathbf{u}\longmapsto G(\lambda,\mathbf{u})$ on $\mathcal{M}$, denoted $\deg(I-G(\lambda,\cdot),\mathcal{M},\mathbf{0})$, is well defined. Before stating the main result of this section, we need the following proposition.

PROPOSITION 3.2. *The mapping $\mathbf{u}\longmapsto G(0,\mathbf{u})$ is Frèchet differentiable at $\mathbf{u}=\mathbf{0}$, with derivative denoted by $D_uG(0,\mathbf{0})\equiv T$. The compact linear operator $T: X\to X$ is defined via the solution $\mathbf{h}=T[\mathbf{f}]$ of the linear, constant-coefficient elliptic system*

$$(L(\mathbf{0})-a_oI)\,[\mathbf{h}] \equiv -\mathbf{A}(\mathbf{0},\mathbf{I})\left[\nabla^4\mathbf{h}\right] + \mathbf{C}(\mathbf{0},\mathbf{I})\left[\nabla^2\mathbf{h}\right] - a_o\mathbf{h} \;= -a_o\mathbf{f} \text{ in } \Omega,$$

$$\mathbf{h} = \frac{\partial\mathbf{h}}{\partial\mathbf{n}} = \mathbf{0} \text{ on } \partial\Omega$$

for all $\mathbf{f}\in Y$. Moreover, for $\varepsilon>0$ sufficiently small, we have

$$\deg(I-G(0,\cdot), B_\varepsilon(\mathbf{0}), \mathbf{0}) = \pm 1, \tag{21}$$

where $B_\varepsilon(\mathbf{0}) = \{\mathbf{u} \in X : \|\mathbf{u}\| < \varepsilon\}$.

Proof. For differentiability, it suffices to show that $G(0,\mathbf{u}) - T[\mathbf{u}]$ is $o(\|\mathbf{u}\|_X)$ near $\mathbf{u} = \mathbf{0}$. We argue by contradiction, similar to the argument given in [8] (see also [24]). Namely, if the claim is not true, then there exist a positive constant α and a sequence $\mathbf{u}_j \to \mathbf{0}$ in $B_\varepsilon(\mathbf{0}) \subset X$ such that

$$\|G(0,\mathbf{u}_j) - T[\mathbf{u}_j]\| > \alpha \|\mathbf{u}_j\|_X \text{ for } j \text{ sufficiently large.} \tag{22}$$

Let $\mathbf{v}_j \equiv G(0,\mathbf{u}_j)/\|\mathbf{u}_j\|_X$ and $\mathbf{w}_j \equiv T[\mathbf{u}_j]/\|\mathbf{u}_j\|_X$, which satisfy

$$L(\mathbf{u}_j)[\mathbf{v}_j] - a_o\mathbf{v}_j = -(g(\nabla^3\mathbf{u}_j, \nabla^2\mathbf{u}_j, \nabla\mathbf{u}_j) + a_o\mathbf{u}_j)/\|\mathbf{u}_j\|_X \text{ in } \Omega,$$

and

$$L(\mathbf{0})[\mathbf{w}_j] - a_o\mathbf{w}_j = -a_o\mathbf{u}_j/\|\mathbf{u}_j\|_X \text{ in } \Omega,$$

respectively, subject to

$$\mathbf{v}_j = \mathbf{w}_j = \frac{\partial \mathbf{v}_j}{\partial \mathbf{n}} = \frac{\partial \mathbf{w}_j}{\partial \mathbf{n}} = \mathbf{0} \text{ on } \partial\Omega.$$

Clearly $\mathbf{u}_j/\|\mathbf{u}_j\|_X$ is uniformly bounded in X, and likewise, by virtue of the Schauder estimates, the sequences $\mathbf{v}_j$ and $\mathbf{w}_j$ are uniformly bounded in Z. By compact embedding, we conclude that each sequence has a convergent subsequence (not relabeled): $\mathbf{u}_j/\|\mathbf{u}_j\|_X \to \phi$ in $C^3(\bar\Omega, \mathbb{R}^3)$, $\mathbf{v}_j \to \mathbf{v}$ and $\mathbf{w}_j \to \mathbf{w}$ in $C^4(\bar\Omega, \mathbb{R}^3)$. Moreover, from (8), (9), (12), and (13), we find that $\mathbf{v}$ and $\mathbf{w}$ each satisfy the boundary value problem

$$L(\mathbf{0})[\mathbf{h}] - a_o\mathbf{h} = -a_o\phi \text{ in } \Omega,$$

$$\mathbf{h} = \frac{\partial \mathbf{h}}{\partial \mathbf{n}} = \mathbf{0} \text{ on } \partial\Omega. \tag{23}$$

By uniqueness, we conclude that $\mathbf{v} \equiv \mathbf{w}$. Hence,

$$\|\mathbf{v}_j - \mathbf{w}_j\|_X = \|G(0,\mathbf{u}_j) - T[\mathbf{u}_j]\| / \|\mathbf{u}_j\|_X \to 0 \text{ as } j \to \infty,$$

which contradicts (22).

Next, we consider the injectivity of the mapping $I - T \in L(X)$:

$$(I - T)[\mathbf{h}] = \mathbf{0} \Leftrightarrow T[\mathbf{h}] = \mathbf{h},$$

the second equation of which is equivalent to (by the definition of T; cf. also (12))

$$-\mathbf{A}(\mathbf{0},\mathbf{I})\left[\nabla^4\mathbf{h}\right] + \mathbf{C}(\mathbf{0},\mathbf{I})\left[\nabla^2\mathbf{h}\right] = \mathbf{0} \text{ in } \Omega,$$

$$\mathbf{h} = \frac{\partial \mathbf{h}}{\partial \mathbf{n}} = \mathbf{0} \text{ on } \partial\Omega. \tag{24}$$

Using (11) and (13), it is not hard to show (via the Fourier transform; cf. [28]) that the linear, *constant-coefficient*, strongly elliptic system (24) has the *unique* solution $\mathbf{h} \equiv \mathbf{0}$; i.e., $I - T$ is injective and thus bijective by the Riesz–Schauder theory. Accordingly,

$\mathbf{u} = \mathbf{0}$ is an isolated solution of (20) at $\lambda = 0$. By the linearization principle and the index formula [15], we conclude (for $\varepsilon > 0$ sufficiently small)

$$\deg(I - G(0,\cdot), B_\varepsilon(\mathbf{0}), \mathbf{0}) = \deg(I - T, B_\varepsilon(\mathbf{0}), \mathbf{0}) = \pm 1. \qquad \square$$

We also need the following characterization of the open set $\mathcal{O}$ in order to state our basic existence result: Define

$$\mathcal{O}_\delta \equiv \{\mathbf{u} \in \mathcal{O} : \det(\mathbf{I} + \nabla \mathbf{u}) > \delta \text{ in } \bar{\Omega}\}. \tag{25}$$

Observe that

$$\overline{\mathcal{O}_\delta} \subset \mathcal{O} \text{ for each } \delta > 0, \text{ and } \mathcal{O} = \cup_{\delta > 0} \mathcal{O}_\delta. \tag{26}$$

THEOREM 3.3. *Let $\Sigma \subset \mathbb{R} \times \mathcal{O}$ denote the connected component of solution pairs $(\lambda, \mathbf{u})$ of (17) containing the solution point $(0, \mathbf{0})$. Then at least one of the following holds:*

(A1) *Σ is unbounded in $\mathbb{R} \times X$;*

(A2) *$\Sigma - \{(0, \mathbf{0})\}$ is connected;*

(A3) *$\Sigma \not\subset \mathbb{R} \times \mathcal{O}_\delta$ for each $\delta > 0$.*

Proof. The proof is a straightforward generalization of a well-known argument; cf. [23]. For each fixed $\delta > 0$, we suppose that Σ is not characterized by any of the properties (A1)–(A3). We then obtain a contradiction from (21) and the homotopy invariance of the degree of $I - G$. We refer the reader to [17] for the details. $\square$

Remark 3.4. If property (A2) holds, then there are nontrivial solutions to problem (20) with null loading $\lambda = 0$. Property (A3) indicates a breakdown of local injectivity along a solution branch., viz., there is a sequence of solution points $(\lambda_j, \mathbf{u}_j) \subset \Sigma$ such that

$$\inf_{\mathbf{x} \in \bar{\Omega}} \det(\mathbf{I} + \nabla \mathbf{u}_j(\mathbf{x})) \searrow 0 \quad \text{as } j \to \infty. \tag{27a}$$

In particular, we note that Theorem 3.3 leaves open the possibility that (27a) holds without (A1) or (A2) being true. In this case the bounded branch could "terminate" at a point $(\lambda_*, \mathbf{u}_*)$ where $(\lambda_j, \mathbf{u}_j) \to (\lambda_*, \mathbf{u}_*)$ in $C^3(\bar{\Omega}, \mathbb{R}^3)$ by compact imbedding and

$$\inf_{\mathbf{x} \in \bar{\Omega}} \det(\mathbf{I} + \nabla \mathbf{u}_*(\mathbf{x})) = 0, \tag{27b}$$

which would seem to contradict (34).

Before ending this section we make an important observation: By construction, for every $(\lambda, \mathbf{u}) \in \Sigma$, the corresponding deformation $\mathbf{f}(\mathbf{x}) = \mathbf{x} + \mathbf{u}(\mathbf{x})$ satisfies $\det(\mathbf{I} + \nabla \mathbf{u}) > 0$ on $\bar{\Omega}$. Moreover, $\mathbf{f}(\mathbf{x}) = \mathbf{x} + \mathbf{d}(\lambda, \mathbf{x})$ on $\partial\Omega$. We now quote a well-known result ensuring that the deformation is injective.

COROLLARY 3.5. *Suppose that for each λ, the mapping*

$$\mathbf{x} \to \mathbf{x} + \mathbf{d}(\lambda, \mathbf{x}) \text{ is injective on } \bar{\Omega}. \tag{28}$$

Then for every $(\lambda, \mathbf{u}) \in \Sigma$, the deformation $\mathbf{f}(\mathbf{x}) = \mathbf{x} + \mathbf{u}(\mathbf{x})$ is injective on $\bar{\Omega}$.

Proof. For a proof, see [4, Theorem 5.5-2].

4. Existence of unbounded branches. In this section we make additional, physically reasonable assumptions on the stored energy function W sufficient to eliminate properties (A2) and (A3) of Theorem 3.3 on bounded solution branches, leading to the existence of unbounded solution branches to our problem. Specifically we henceforth assume that W has the form

$$W(\mathbf{F},\mathbf{G}) = \hat{W}(\mathbf{F}) + \epsilon h(\mathbf{F},\mathbf{G}) = \hat{W}(\mathbf{F}) + \frac{\epsilon}{2}\mathbf{G} \vdots \mathbf{A}(\mathbf{F})[\mathbf{G}], \tag{29}$$

where $\mathbf{G} \in V$, $\mathbf{A}(\mathbf{F})$ is a sixth-order-tensor-valued function on $GL^+(\mathbb{R}^3)$, and $\epsilon > 0$. We assume throughout that the second-gradient term is positive semidefinite, viz.,

$$h(\mathbf{F},\mathbf{G}) \geq 0 \text{ for all } \mathbf{F} \in GL^+(\mathbb{R}^3), \mathbf{G} \in V. \tag{30}$$

The specific quadratic form of the higher-gradient term in (29) is motivated, e.g., by the works of Triantafyllidis and Bardenhagen [27] and Hilgers and Pipkin [14], where ϵ is a small parameter representing a lattice length scale in the former and plate thickness in the latter. In this work ϵ plays no role. Nonetheless, we carry it along throughout as a reminder that (29) is useful in applications when ϵ is "small."

We now specialize our boundary value problem (6), (7) to (29) with null loading, i.e., $\lambda = 0$ (cf. (1)):

$$\begin{aligned} \nabla \cdot \left[-\epsilon \nabla \cdot \frac{\partial h}{\partial \mathbf{G}} + \left(\frac{\partial \hat{W}}{\partial \mathbf{F}} + \epsilon \frac{\partial h}{\partial \mathbf{F}} \right) \right] &= \mathbf{0} \text{ in } \Omega, \\ \mathbf{u} &= \mathbf{0} \text{ on } \partial\Omega, \\ \frac{\partial \mathbf{u}}{\partial n} &= \mathbf{0} \text{ on } \partial\Omega. \end{aligned} \tag{31}$$

In view of (4), observe that $\mathbf{u} \equiv \mathbf{0}$ is a solution of (31). With two additional, physically reasonable hypotheses, it turns out that $\mathbf{u} \equiv \mathbf{0}$ is the only classical solution, i.e., the only solution in $C^4(\Omega,\mathbb{R}^3) \cap C^1(\bar{\Omega},\mathbb{R}^3)$. The following is a special case of the main result in [21].

PROPOSITION 4.1. *Given* (29) *and* (30)*, assume that*

$$\hat{W}(\mathbf{I}) < \hat{W}(\mathbf{F}) \text{ for all } \mathbf{F} \in GL^+(\mathbb{R}^3) - SO(3); \tag{32}$$

i.e., $\hat{W}(\mathbf{I})$ is the global minimum of $\hat{W}(\cdot)$. Furthermore, suppose that

$$\Omega \text{ is a star-shaped domain.} \tag{33}$$

Then $\mathbf{u} \equiv \mathbf{0}$ is the only classical solution of (31).

Remark. Condition (32) ensures that $\hat{W}(\cdot)$ is quasi-convex at $\mathbf{F} = \mathbf{I}$.

An immediate consequence of Proposition 4.1 is that the solution branch $\Sigma - \{(0,\mathbf{0})\}$ has two disjoint components $\Sigma^+ \subset (0,\infty) \times X$ and $\Sigma^- \subset (-\infty,0) \times X$, separated by the hyperplane $\{0\} \times X$, which, in turn, implies the disjoint union

$$\Sigma = \Sigma^+ \cup \Sigma^- \cup \{(0,\mathbf{0})\}.$$

COROLLARY 4.2. *Assume the hypotheses of Theorem* 3.3 *and Proposition* 4.1. *Then the solution branch Σ is characterized by alternatives* (A1) *and/or* (A3) *of Theorem* 3.3.

Now we show with certain constitutive hypotheses that the branch Σ is unbounded. Here we list all of the assumptions sufficient to ensure the unboundedness of the branch.

Suppose that for some $\Psi : GL^+(\mathbb{R}^3) \to \mathbb{R}$ and $\Gamma : (0,\infty) \to \mathbb{R}$, $\hat{W}$ admits the decomposition

$$\hat{W} = \Psi(\mathbf{F}) + \Gamma(\det \mathbf{F})$$

for all $\mathbf{F} \in GL^+(\mathbb{R}^3)$,

$$\text{where } \Gamma(\det \mathbf{F}) \to \infty \text{ as } \det \mathbf{F} \searrow 0. \tag{34}$$

In addition, let

$$\Gamma \in C^3(0,\infty),\ \Psi \in\ C^3(GL^+(\mathbb{R}^3),\mathbb{R}) \cap C^2(U,\mathbb{R}),$$

$$\text{where } U = \{\mathbf{F} \in \overline{(GL^+(\mathbb{R}^3))} : ||\mathbf{F}|| < \infty\}. \tag{35}$$

We further assume that

$$\Gamma\prime(d) < 0 \text{ for } 0 < d < d_o, \text{ for some constant } d_o > 0. \tag{36}$$

We find it convenient to define the following quantities:

$$\Phi(d) = \Gamma(d) - d\Gamma^{'}(d) \text{ for all } d > 0, \tag{37}$$

$$\mathbf{P} = W\mathbf{I} - \mathbf{F}^T\left[\frac{\partial W}{\partial \mathbf{F}} - \epsilon\nabla\cdot\frac{\partial h}{\partial \mathbf{G}}\right] - \epsilon\mathbf{G}^T\frac{\partial h}{\partial \mathbf{G}}, \tag{38}$$

$$\tilde{\mathbf{P}}(\mathbf{F}) = \hat{W}\mathbf{I} - \mathbf{F}^T\frac{d\hat{W}}{d\mathbf{F}}, \tag{39}$$

$$\hat{\mathbf{P}}(\mathbf{F}) = \mathbf{F}^T\frac{d\Psi(\mathbf{F})}{d\mathbf{F}} - \Psi(\mathbf{F})\mathbf{I} \text{ for all } \mathbf{F} \in GL^+(\mathbb{R}^3). \tag{40}$$

LEMMA 4.3. *If* $(\lambda,\mathbf{u}) \in \Sigma$, *with* $J(\mathbf{x}) = \det \mathbf{F}(\mathbf{x})$ *for* $\mathbf{x} \in \bar{\Omega}$, *then*

$$\nabla(\Phi\circ J) = \nabla\cdot\hat{\mathbf{P}}(\mathbf{F}) + \mathbf{F}^T\mathbf{b}(\lambda,\mathbf{x},\mathbf{u},\nabla\mathbf{u}) + \epsilon\mathbf{F}^T\left[-\nabla\cdot\left(\nabla\cdot\frac{\partial h}{\partial \mathbf{G}}\right) + \nabla\cdot\frac{\partial h}{\partial \mathbf{F}}\right] \text{ on } \bar{\Omega}. \tag{41}$$

Proof. Using (7), (29), and (38), we see that

$$\begin{aligned}\nabla\cdot\mathbf{P} &= \nabla\cdot W\mathbf{I} - \nabla\cdot\left[\mathbf{F}^T\left(\frac{\partial W}{\partial \mathbf{F}} - \epsilon\nabla\cdot\frac{\partial h}{\partial \mathbf{G}}\right)\right] - \epsilon\nabla\cdot\left[\mathbf{G}^T\frac{\partial h}{\partial \mathbf{G}}\right]\\ &= \mathbf{F}^T\left(\epsilon\nabla\cdot\left(\nabla\cdot\frac{\partial h}{\partial \mathbf{G}}\right) - \nabla\cdot\frac{\partial W}{\partial \mathbf{F}}\right) = \mathbf{F}^T\mathbf{b}.\end{aligned}$$

By virtue of (39), this leads to

$$\nabla\cdot\mathbf{P} = \nabla\cdot\tilde{\mathbf{P}} - \epsilon\mathbf{F}^T\left[\nabla\cdot\frac{\partial h}{\partial \mathbf{F}} - \nabla\cdot\left(\nabla\cdot\frac{\partial h}{\partial \mathbf{G}}\right)\right] = \mathbf{F}^T\mathbf{b}.$$

Observing that

$$\frac{d\Gamma}{d\mathbf{F}} = \Gamma'(J)J\mathbf{F}^{-T},$$

we see using (34), (37), and (40) that $\tilde{\mathbf{P}} = -\hat{\mathbf{P}}(\mathbf{F}) + \Phi(J)\mathbf{I}$. Thus,

$$\nabla \cdot \left[-\hat{\mathbf{P}}(\mathbf{F}) + \Phi(J)\mathbf{I}\right] - \epsilon\mathbf{F}^T\left[\nabla \cdot \frac{\partial h}{\partial \mathbf{F}} - \nabla \cdot \left(\nabla \cdot \frac{\partial h}{\partial \mathbf{G}}\right)\right] = \mathbf{F}^T\mathbf{b}$$

and we obtain (41). □

Remark 4.4. Note that (38) is a second-gradient version of the elastic energy-momentum tensor. Also, (39) is the usual energy-momentum tensor for $\hat{W}$ deduced by Eshelby [7].

With these physically reasonable hypotheses in hand, we now show that Σ corresponds to an unbounded branch of solution pairs to problem (6), (8).

THEOREM 4.5. *Let the hypotheses of Theorem* 3.3*, Corollary* 3.5*, Proposition* 4.1*, and Lemma* 4.3 *hold. In addition assume the constitutive hypotheses* (34)–(36)*. Then* Σ *is a branch of globally injective solution pairs of* (6), (8) *that is unbounded in* $\mathbb{R} \times C^4(\bar{\Omega}, \mathbb{R}^3)$.

Proof. We generalize the proof in [12] in the context of our higher-gradient problem. Assume for the sake of contradiction that Σ is bounded in $\mathbb{R} \times C^4(\bar{\Omega}, \mathbb{R}^3)$. Then (A3) holds. Let $\{(\lambda_j, \mathbf{u}_j)\} \subset \Sigma$. By the Schauder estimates for (19), $\{(\lambda_j, \mathbf{u}_j)\}$ is uniformly bounded in Z (cf. (14)) and hence converges in $\mathbb{R} \times C^1(\bar{\Omega}, \mathbb{R}^3)$ by compact imbedding. We now write $\mathbf{f}_j = \mathbf{x}_j + \mathbf{u_j}$, $\mathbf{F}_j = \mathbf{I} + \nabla\mathbf{u}_j, \mathbf{G}_j = \nabla\mathbf{F}_j$, $J_j = \det\mathbf{F}_j$ on $\bar{\Omega}$. Using the triangle inequality and the conclusion of Lemma 4.3, we get

$$\|\nabla(\Phi \circ J_j)\Big\|_\infty \leq \|\frac{d\mathbf{P}(\mathbf{F}_j)}{d\mathbf{F}}\nabla^2\mathbf{u}_j\Big\|_\infty + \|\mathbf{F}_j^\top\mathbf{b}(\lambda_j, \mathbf{x}, \nabla\mathbf{u}_j, \mathbf{u}_j)\|_\infty$$

$$+ \epsilon\left\|\mathbf{F}^\top{}_j\left(\nabla \cdot \frac{\partial h(\mathbf{F}_j, \mathbf{G}_j)}{\partial \mathbf{F}} - \nabla \cdot \nabla \cdot \frac{\partial h(\mathbf{F}_j, \mathbf{G}_j)}{\partial \mathbf{G}}\right)\right\|_\infty, \tag{42}$$

where $\|\cdot\|_\infty$ denotes the supremum norm over $\bar{\Omega}$. By assumptions (35) and (37)–(40), the limit of the right-hand side of (42) is finite as $j \to \infty$. On the other hand, the left-hand side of (42) becomes unbounded as $j \to \infty$. To see this note that (27b) holds with$\|J_j\|_\infty$ bounded away from zero as $j \to \infty$. (This follows from Corollary 3.5 since $Vol(\mathbf{f}_j(\bar{\Omega})) = Vol(\bar{\Omega})$ for all j. On the other hand, if $J_j \to 0$ pointwise on $\bar{\Omega}$, then $Vol(\mathbf{f}_j(\bar{\Omega})) = \int_\Omega J_j dV \to 0$ which is a contradiction.) Consequently there are distinct points x_0 and $x_* \in \bar{\Omega}$ such that $\Phi(J_j(\mathbf{x}_o))$ remains bounded while $\Phi(J_j(\mathbf{x}_*)) \to \infty$ as $j \to \infty$. If we integrate $\nabla(\Phi \circ J_j)$ along any path in $\bar{\Omega}$ joining $\mathbf{x}_o$ and $\mathbf{x}_*$, we see from (34)–(40) that the left side of (42) grows without bound as $j \to \infty$. This is a contradiction, and we see that (A3) is possible only when Σ is unbounded. □

5. Concluding remarks. In practice (29) is often specialized further so that the sixth-order tensor-valued function $\mathbf{A}(\mathbf{F})$ is constant (i.e., independent of $\mathbf{F}$). In this case, it is not hard to show that the construction in section 3 is valid for X as defined in (14) but with the $C^{1,\alpha}(\bar{\Omega}, \mathbb{R}^3)$ topology. In particular, this leads to a strengthened version of Theorem 4.5.

Although Theorem 4.5 guarantees the existence of solutions "in the large" ("far" from the reference configuration), the absence of a priori bounds precludes global

existence of solutions. More specifically, the unbounded solution branch $\Sigma \subset \mathbb{R} \times \mathcal{O}$ may "blow up" in X for a finite value of the loading parameter $\lambda \in \mathbb{R}$. For the same reason it seems quite difficult to carry out the "singular limit of Σ" as $\epsilon \searrow 0$, as in [10], [19] in a one-dimensional setting.

Appendix. Spectral estimates.

PROPOSITION A.1. *For each* $\mathbf{u} \in \mathcal{O}$ *there exist positive constants* ϵ, c_1, c_2, *independent of* $\mu, \mathbf{h}, \lambda, \mathbf{u}$, *such that*

$$\|\mathbf{h}\|_Z \leq c_1 \mid \mu \mid^{\frac{\alpha}{4}} \| \left(A(\mathbf{u}) - \mu I\right)[\mathbf{h}] \|_Y \tag{43}$$

for all $\mathbf{h} \in Z$, *for all* $\mu \in \mathbb{C}$ *such that* $|\arg(\mu)| \leq \frac{\pi}{2} + \epsilon$ *and* $|\mu| \geq c_2$. *The mapping* $I : Z \to Y$ *is the identity map and* $\alpha \in (0,1)$ *is the Hölder exponent inherent in* Z *and* Y.

Proof. We follow the approach of Agmon [1] in the L^p setting. First we set $A(\mathbf{u}) \equiv A$, introduce a new variable t, and set $D_t = \frac{\partial}{\partial t}$. Consider the operator

$$\mathcal{L} = A - e^{i\theta} D_t^4. \tag{44}$$

For $|\theta| \leq \frac{\pi}{2} + \epsilon$, $\mathcal{L}$ is an elliptic operator of order 4 in the closure of the cylindrical domain $\Gamma = \{(\mathbf{x}, t) : \mathbf{x} \in \bar{\Omega}, t \in \mathbb{R}\}$, where ϵ depends on the constants in the definition of uniform ellipticity, and the complementing condition is satisfied for Dirichlet boundary conditions. Now we define

$$\mathbf{v}(\mathbf{x}, t) = \zeta(t) e^{i\nu t} \mathbf{h}(\mathbf{x}), \ \nu \in \mathbb{R}, \text{ and } \nu > 0,$$

and define $\Gamma_r = \bar{\Omega} \times [-r, r] \subset \mathbb{R}^4$, or the part of Γ in $\mid t \mid < r$, where $\zeta(t)$ is some fixed C^∞ function such that

$$\zeta(t) = \begin{cases} 0 & \text{for } \mid t \mid \geq 2, \\ 1 & \text{for } \mid t \mid \leq 1. \end{cases} \tag{45}$$

Applying the a priori estimate from Theorem 9.3 in [2] to $\mathbf{v}$, we obtain

$$\|\mathbf{v}\|_{4,\alpha;\Gamma_2} \leq c \left(\|\mathcal{L}\mathbf{v}\|_{0,\alpha;\Gamma_2} + \|\mathbf{v}\|_{0,\alpha;\Gamma_2} \right) \tag{46}$$

for a constant $c > 0$.

Using (44),

$$\mathcal{L}\mathbf{v} = \zeta(t) e^{i\nu t} \left(A - \nu^4 e^{i\nu t} I\right) \mathbf{h}(\mathbf{x}) + e^{i(\theta + \nu t)} \left[\sum_{k=0}^{3} \binom{4}{k} D_t^{4-k} \zeta(t) i^k \nu^k \right] \mathbf{h}(\mathbf{x}). \tag{47}$$

Since $\mathbf{v}(\mathbf{x}, t) = e^{i\nu t} \mathbf{h}(\mathbf{x})$ for $\mid t \mid \leq 1$ we obtain from (46)

(48)

$$\begin{aligned} \|e^{i\nu t} \mathbf{h}(\mathbf{x})\|_{4,\alpha;\Gamma_1} &\leq \|\mathbf{v}\|_{4,\alpha;\Gamma_2} \\ &\leq c \|\zeta(t) e^{i\nu t} \left(A - \nu^4 e^{i\nu t} I\right) \mathbf{h}(\mathbf{x})\|_{0,\alpha;\Gamma_2} \qquad (49) \\ &\quad + c \left\| e^{i(\theta + \nu t)} \left[\sum_{k=0}^{3} \binom{4}{k} D_t^{4-k} \zeta(t) i^k \nu^k \right] \mathbf{h}(\mathbf{x}) \right\|_{0,\alpha;\Gamma_2} \qquad (50) \\ &\quad + c \|\zeta(t) e^{i\nu t} \mathbf{h}(\mathbf{x})\|_{0,\alpha;\Gamma_2}. \qquad (51) \end{aligned}$$

Since $e^{i\nu t}$ is Hölder continuous, the inequality

$$\|\zeta(t)e^{i\nu t}\mathbf{h}(\mathbf{x})\ \|_{0,\alpha;\Gamma_2} \leq c_3\nu^{\alpha}\|\mathbf{h}\ \|_{0,\alpha;Y} \tag{52}$$

follows if we take ν sufficiently large.

Similarly,

$$\left\| e^{i(\theta+\nu t)} \left[\sum_{k=0}^{3} \binom{4}{k} D_t^{4-k}\zeta(t) i^k \nu^k \right] \mathbf{h}(\mathbf{x}) \right\|_{0,\alpha;\Gamma_2} \leq c_4 \sum_{k=0}^{3} \nu^{\alpha+k}\|\mathbf{h}\|_{0,\alpha;Y} \tag{53}$$

and

$$\|\zeta(t)e^{i\nu t}(A-\nu^4 e^{i\theta}I)\mathbf{h}\|_{0,\alpha;\Gamma_2} \leq c_3\nu^{\alpha}\|(A-\nu^4 e^{i\theta}I)\mathbf{h}\|_{0,\alpha;Y}. \tag{54}$$

On the other hand,

$$\|e^{i\nu t}\|_{4,\alpha;\Gamma_1} \geq \|\mathbf{h}\|_4 + c_5 \left(\sum_{k=0}^{3} \binom{4}{k} \nu^k \left[e^{i\nu t} D_x^{4-k}\mathbf{h}(\mathbf{x}) \right]_{0,\alpha;\Gamma_2} \right) \tag{55}$$

$$\geq c_6 \left(\|\mathbf{h}\|_{0,\alpha,Z} + \sum_{k=1}^{4} \nu^k \|\mathbf{h}\ \|_{4-k,\alpha,Z} \right) \tag{56}$$

$$= c_6 \sum_{k=0}^{4} \nu^k \|\mathbf{h}\|_{4-k,\alpha;Z}. \tag{57}$$

Therefore, using equations (48)−(51), (53), (54), and (55)−(57), we get

$$\sum_{k=0}^{4} \nu^k \|\mathbf{h}\|_{4-k,\alpha;Z} \leq c_1\nu^{\alpha} \left[\|(A-\nu^4 e^{i\theta}I)\mathbf{h}\|_{0,\alpha;Y} + \sum_{k=0}^{3} \nu^k \|\mathbf{h}\|_{0,\alpha;Y} \right]. \tag{58}$$

For ν sufficiently large, we may disregard the last term on the right-hand side, since it is dominated by the terms on the left-hand side. If we set $\mu = \nu^4 e^{i\theta}$, then

$$\sum_{k=0}^{4} |\mu|^{\frac{k-4}{4}} \|\mathbf{h}\|_{k,\alpha;Z} \leq c_1 |\mu|^{\frac{\alpha}{4}} \|(A-\mu I)\mathbf{h}\|_{0,\alpha;Y}$$

and (43) follows. □

SPECTRAL ANALYSIS OF TRAVELING WAVES FOR NONLOCAL EVOLUTION EQUATIONS*

PETER W. BATES† AND FENGXIN CHEN‡

Abstract. Monotone traveling waves have been shown to exist for a broad class of nonlocal bistable evolution equations. In this note we examine the spectrum of the operator obtained by linearizing about such a traveling wave and hence show that these waves are exponentially asymptotically stable, up to translation.

1. Introduction.

Perhaps the most familiar mathematical model for the evolution of phase boundaries in material science is the second order Allen–Cahn equation:

$$u_t = Du_{xx} + f(u), \tag{1.1}$$

where $D > 0$, f is a bistable function, i.e., f has exactly three roots, say, $u = \pm 1$ and $u = a \in (-1, 1)$ with $f'(\pm 1) < 0 < f'(a)$. It is well known that (1.1) has a traveling wave solution connecting $u = 1$ and $u = -1$, a solution of the form $u(x, t) = \phi(x - ct)$ for some constant c, and smooth function ϕ satisfying $\phi(\pm\infty) = \pm 1$. It is also known that the wave profile ϕ is monotone, it is unique up to translation, and it is exponentially asymptotically stable (see, e.g., [17]). This stability is in the sense that a perturbation leads to a solution converging to a translate of the wave. That result may be proved in various ways, one of which is by transforming (1.1) according to a frame moving with speed c and showing that the operator obtained by linearizing at ϕ has spectrum in the left half-plane, bounded away from the imaginary axis except for an algebraically simple eigenvalue at zero. The stability then follows from the spectral information by using abstract semigroup theory and invariant manifold/foliation results (see, e.g., [7] or [8] and [9]).

In many biological and physical settings, diffusion is not the only mechanism by which the state at one location affects the state at other locations, and it is appropriate to include in the mathematical model certain nonlocal interaction terms. Furthermore, there may be several types of long-range interactions acting at differing length scales. Thus, the reaction-diffusion equation (1.1) is replaced by a more general scalar evolution equation of the form

$$u_t - Du_{xx} - F(u, J_1 * s^1(u), \ldots, J_n * s^n(u)) = 0 \tag{1.2}$$

for all $x \in \mathbb{R}$ and $t \in \mathbb{R}^+$. Here $D \geq 0$ is a constant, $J * v(x, t) = \int_{\mathbb{R}} J(x - y)\, v(y, t)dy$ is spatial convolution, the kernels J_i are of class $C^1(\mathbb{R})$ and nonnegative,

and s^i are smooth functions, $i = 1, 2, \ldots, n$. It is further assumed that $\bar{f}(u) \equiv F(u, s^1(u), \ldots, s^n(u))$ is a smooth bistable function.

Besides the Allen–Cahn equation given above, (1.2) includes its nonlocal version, which has been the subject of several recent studies (e.g., [1], [2], [3], [4], [5], [6], [18]),

$$u_t - \lambda(J * u - u) - f(u) = 0. \tag{1.3}$$

Here $f(u)$ is a bistable function, $\lambda > 0$, $J(x) \geq 0$, and $\int_{\mathbb{R}} J = 1$.

Other physical or biological models are included in (1.2). Some identified by Chen [12] and others may be of particular interest:

- continuum limit of an interacting particle system with Glauber dynamics and Kac potential (see [15]),

  $$u_t = \tanh(\beta J * u + h) - u,$$

  where $\beta > 1$ is the reciprocal of absolute temperature and h is an external field;
- excitatory neural model (see [16]),

  $$u_t = -u + J * S(u),$$

  where $S \in C^1(\mathbb{R})$ satisfies $S'(\cdot) > 0$ in $[0, 1]$, $S(0) = 0$, $S'(0) < 1$, $S(1) = 1$, and $S'(1) < 1$;
- thalamic model (see [13]),

  $$u_t = -\beta u + \alpha(1 - u)H^\epsilon(J * S(u) - \theta),$$

  where α and β are positive constants, H^ϵ is a smooth approximation of the Heaviside function, $S' > 0$, and $\theta \in (S(0), S(1))$ is a parameter.

Existence, uniqueness, and stability of a monotone traveling wave connecting the stable homogeneous states for the nonlocal Allen–Cahn equation (1.3) were established in [6] and for the general equation (1.2) in [12] (see also [11] for the nonautonomous almost periodic case). In those works comparison methods were used to show stability. However, the spectral theory for the operator obtained by linearizing (1.2) at the traveling wave, needed for perturbation results or more precise rates of convergence, is lacking. The purpose of this note is to address this issue.

Suppose $u(x, t) = \phi(x - c_0 t)$ is a traveling wave solution of (1.2) satisfying $\phi(\pm\infty) = \pm 1$. Let $\xi = x - c_0 t$. Then (ϕ, c_0) satisfies

$$D\phi'' + c_0\phi' + F(\phi, J_1 * s^1(\phi), \ldots, J_n * s^n(\phi)) = 0 \text{ and } \phi(\pm\infty) = \pm 1 \tag{1.4}$$

for all $\xi \in \mathbb{R}$.

Let $\mathcal{L} = \mathcal{L}(\phi, c_0)$ be the linearized operator about the traveling wave ϕ, defined by

$$\begin{aligned} \mathcal{L}\psi = {} & D\psi'' + c_0\psi' + F_u(\phi, J_1 * s^1(\phi), \ldots, J_n * s^n(\phi))\psi \\ & + \sum_{i=1}^{n} F_{p_i}(\phi, J_1 * s^1(\phi), \ldots, J_n * s^n(\phi)) \cdot J_i * (s^i_u(\phi)\psi) \end{aligned} \tag{1.5}$$

on $D(\mathcal{L})$ to be specified in section 2. We prove that the spectrum of $\mathcal{L}$ consists of 0, the principle eigenvalue due to the translation invariance of the traveling waves, and the rest of it is located in the left half-plane bounded away from the imaginary axis.

As indicated above, an immediate consequence of this result is the exponential stability of traveling wave solutions. The conclusion derived from the spectral result contained in this paper when combined with the abstract theorems of [7], [8], and [9] gives more than exponential asymptotic stability, up to translation, of the traveling wave. In fact, one may conclude that the dynamics in a tubular neighborhood of the one-dimensional manifold formed by translates of the wave in the infinite dimensional phase space is foliated with codimension-one invariant stable manifolds. The leaves are transverse to the one-dimensional manifold and the dynamics is that of exponential decay to the base point, which is a suitable translate of the wave.

Even more can be said. Since the spectrum perturbs continuously, for interaction kernels $\tilde{J}_i$ near J_i but not necessarily positive, the same result holds. This is immediate from the theorems in [10] whereby the one-dimensional manifold persists as an invariant manifold, which will consist of stationary states if the $\tilde{J}_i$ are translation invariant but may have slow dynamics otherwise, with a neighborhood foliated with an invariant family of codimension-one stable manifolds with base point on the one-dimensional manifold. Comparison methods used in [12] are not applicable directly to obtain similar information when the interaction kernels are perturbed in this way.

2. Assumptions and main result. For f, J_i, and s, the following assumptions are made in [12]:

(A$_1$) $J_i(\cdot) \in C^1(\mathbb{R})$ and satisfies $J_i(\cdot) \geq 0$, $\int_{\mathbb{R}} J_i(y)dy = 1$, and $\int_{\mathbb{R}} |J_i'(y)|dy < \infty$, for $i = 1, 2, \ldots, n$. Furthermore, $\operatorname{supp} J_1 \bigcap (0, \infty) \neq \emptyset \neq \operatorname{supp} J_1 \bigcap (-\infty, 0)$.

(A$_2$) $F(u, p) = F(u, p_1, \ldots, p_n)$ and $s^1(u), \ldots, s^n(u)$ are smooth functions satisfying $F_{p_i}(u, p) \geq 0, s_u^i(u) \geq 0$, for all $(u, p) \in [-1 - \delta_0, 1 + \delta_0] \times \prod_{i=1}^n [s^i(-1 - \delta_0), s^i(1 + \delta_0)]$, and $i = 1, 2, \ldots, n$, where δ_0 is a positive constant. Furthermore, we assume $\bar{f}(\cdot) = F(\cdot, s^1(\cdot), \ldots, s^n(\cdot))$ is bistable, i.e., it has exactly three zeros ± 1 and an intermediate point q; and there exists an interval $[\alpha_1, \alpha_2] \subset (-1, 1)$ containing q such that $\bar{f}'(u) \geq 0$ for $u \in [\alpha_1, \alpha_2]$ and $\bar{f}'(u) < 0$ for $u \notin [\alpha_1, \alpha_2]$.

(A$_3$) Either (i) $D > 0$, or (ii) $F_u(u, p) < 0$ and $F_{p_1}(u, p)s_u^1(u) > 0$ on $[-1 - \delta_0, 1 + \delta_0] \times \prod_{i=1}^n [s^i(-1 - \delta_0), s^i(1 + \delta_0)]$ for some $i \in \{1, 2, \ldots, n\}$.

The following theorem is proved in [12] (see also [11]).

THEOREM 2.1. *Assume that* (A$_1$)–(A$_3$) *hold. Then*

(a) (1.2) *admits a traveling wave solution* (ϕ, c_0) *satisfying* $\phi(\pm\infty) = \pm 1$,

(b) ϕ *is strictly increasing and of class* C^1,

(c) *the traveling wave solution of* (1.2) *is unique modulo spatial translation,*

(d) *the traveling wave and its translates are an asymptotically stable family with asymptotic phase.*

Let (ϕ, c_0) be a traveling wave solution obtained in Theorem 2.1. We are going to study the spectrum of the linearized operator $\mathcal{L}$ about the traveling wave solution (ϕ, c_0) satisfying (1.4).

Let

$$X_0 = \left\{ u \in C(\mathbb{R}) \ : \ \lim_{|x| \to \infty} u(x) = 0 \right\}$$

and $\mathcal{L}$ be the linearized operator about the traveling wave (ϕ, c_0) as defined in (1.5) with domain $D(\mathcal{L})$, where $D(\mathcal{L}) = \{u \in X_0 \ : \ u', u'' \in X_0\}$ if $D > 0$; $D(\mathcal{L}) = \{u \in X_0 \ : \ u' \in X_0\}$ if $D = 0$ and $c_0 \neq 0$; and $D(\mathcal{L}) = X_0$ if $D = 0$ and $c_0 = 0$.

Let us define a normal point for an operator $\mathcal{L}$ on a Banach space to be any complex number which is in the resolvent set $\rho(\mathcal{L})$ or is an isolated eigenvalue of $\mathcal{L}$ of

finite multiplicity. The complement of the set of normal points is called the essential spectrum of $\mathcal{L}$ and is denoted by $\sigma_{ess}(\mathcal{L})$. The following is the main result of this section.

THEOREM 2.2.

(i) $\{\lambda \ : \ \mathrm{Re}\lambda \geq 0, \lambda \neq 0\} \subset \rho(\mathcal{L})$.

(ii) *0 is an algebraically simple eigenvalue with a positive eigenfunction* ϕ'.

(iii) $\sigma_{ess}(\mathcal{L}) \subset \{\lambda \ : \ Re\lambda < -\gamma_0\}$, *where* $\gamma_0 > 0$ *is a constant.*

(iv) *The adjoint operator* $\mathcal{L}^*$ *has a positive eigenfunction corresponding to the simple eigenvalue* 0.

An immediate consequence of this is the following (see [20]).

COROLLARY 2.3.

(i) *The traveling wave solution* $\phi(x - c_0 t)$ *and its translates is an exponentially stable family with asymptotic phase.*

(ii) *There exist positive constants* γ *and* C *such that*

$$\|e^{\mathcal{L}t}u\| \leq Ce^{-\gamma t}\|u\|.$$

for all u *in the range of* $\mathcal{L}$.

3. Proof of Theorem 2.2. We divide the proof of the theorem into several lemmas. We will apply comparison principle and perturbation theory to estimate the spectrum. First we need the following comparison principle (see also [11] and [12]). Here we will be assuming that $t_0 > \tau$ are fixed times, $D \geq 0$ and c_0 are constant, R_1 is an open set and $R_2 = \mathbb{R} \setminus R_1$ is the complement of R_1, $K_0(x,t) \in L^\infty(\mathbb{R} \times [\tau, t_0])$, $\hat{J}$ is an integral operator with nonnegative kernel $\hat{J}(x,y,t)$, i.e., $(\hat{J}u)(x,t) = \int_{\mathbb{R}} \hat{J}(x,y,t)u(y,t)dy$, and $\hat{J}(x,y,t) \geq 0$ satisfies $\operatorname{ess\,sup}_{x\in\mathbb{R}\ t\in[\tau,t_0]} \int_{\mathbb{R}} \hat{J}(x,y,t)dy < \infty$. Furthermore, J_1 is that mentioned in (A_1).

LEMMA 3.1 (comparison principle). *Assume that* $u \in C^1([\tau,t_0], L^\infty(\mathbb{R}))$ *and that* $u \in C([\tau,t_0], W^{1,\infty}(R_1))$ *if* $D = 0$ *and* $c_0 \neq 0$ *and* $u \in C^{1,2}((\tau,t_0] \times R_1)$ *if* $D \neq 0$. *Suppose that* $u(x,t) \geq 0$ *for all* $t \in [\tau,t_0]$ *and almost all* $x \in R_2$ *and* $u(x,t)$ *satisfies*

$$u_t - Du_{xx} - c_0 u_x - K_0(x,t)u - (\hat{J}u)(x,t) \geq 0 \tag{3.1}$$

for all $t \in (\tau,t_0]$ *and almost all* $x \in R_1$. *If* $u(x,\tau) \geq 0$ *for almost all* $x \in \mathbb{R}$, *then* $u(x,t) \geq 0$ *for all* $t \in [\tau,t_0]$ *and almost all* $x \in \mathbb{R}$. *Moreover, if* $\hat{J}(x,y,t) \geq c_1 J_1(x-y)$ *for some* $c_1 > 0$, *and* $u(\cdot,\tau) \neq 0$ *in* $L^\infty(\mathbb{R})$, *then* $u(x,t) > 0$ *for all* $t \in (\tau,t_0]$ *and almost all* $x \in R_1$.

Proof. We may assume $\tau = 0$. Let $\bar{u}(x,t) = u(x - c_0 t, t)$. Then $\bar{u}(x,t)$ satisfies (3.1) on $\bar{R}_1$ with $c_0 = 0$, $K_0(x,t)$ replaced by $\bar{K}_0(x,t) = K_0(x - c_0 t, t)$ and $\hat{J}(x,y,t)$ replaced by $\bar{J}(x,y,t) = \hat{J}(x - c_0 t, y - c_0 t, t)$, where $\bar{R}_1 = \{(x,t) \mid (x - c_0 t, t) \in R_1 \times [0,t_0]\}$.

By assumption, $\operatorname{ess\,inf}_{x\in\mathbb{R}} \bar{u}(x,t)$ is continuous. If the first conclusion of the lemma is not true, then there exist constants $\epsilon > 0, T \in (0,t_0]$ such that $\bar{u}(x,t) > -\epsilon e^{2Kt}$ for all $0 < t < T$ and almost all $x \in \mathbb{R}$, and $\operatorname{ess\,inf}_{x\in\mathbb{R}} \bar{u}(x,T) = -\epsilon e^{2KT}$, where

$$K = D + \|K_0\|_{L^\infty} + \operatorname*{ess\,sup}_{x\in\mathbb{R}\ t\in[0,t_0]} \int_{\mathbb{R}} \hat{J}(x,y,t)dy. \tag{3.2}$$

Therefore, there exist an interval $[a,b]$ and a set $S_0 \subset [a,b]$ with positive Lebesgue measure such that $\bar{u}(x,T) \leq -\frac{15}{16}\epsilon e^{2KT}$ for $x \in S_0$. Let $z(x)$ be a smooth function such that $z(x) = \min_{x\in\mathbb{R}} z(x) = 1$ for $x \in [a,b]$, $\sup_{x\in\mathbb{R}} z(x) = z(\pm\infty) = 3$, $|z'(x)| \leq 1$, and

$|z''(x)| \le 1$. Define $w_\sigma(x,t) = -\epsilon\left(\frac{3}{4} + \sigma\ z(x)\right) e^{2Kt}$ for $\sigma \in [0,1]$. Since $w_{\frac{1}{4}}(x,t) \le \bar{u}(x,t)$ for $0 \le t \le T$ and almost all $x \in \mathbb{R}$, and $w_{\frac{1}{8}}(x,T) > \bar{u}(x,T)$ for $x \in S_0$, there is a minimum $\sigma^* \in \left(\frac{1}{8}, \frac{1}{4}\right]$ such that $w_{\sigma^*}(x,t) \le \bar{u}(x,t)$ for $t \in [0,T]$ and almost all $x \in \mathbb{R}$. We claim that there exist $(x_n, t_n) \in \bar{R}_1$ and $(\bar{x}_0, \bar{t}_0)$ such that inequality (3.1), with $u, K_0, \hat{J}$ replaced by $\bar{u}, \bar{K}_0, \bar{J}$, respectively, holds for (x_n, t_n); $\lim_{n\to\infty}(x_n, t_n) = (\bar{x}_0, \bar{t}_0)$; $\lim_{n\to\infty}\{\bar{u}(x_n,t_n) - w_{\sigma^*}(x_n,t_n)\} = 0$, the essential infimum of $\bar{u}(x,t) - w_{\sigma^*}(x,t)$ on $\mathbb{R}\times[0,T]$; and $\lim_{n\to\infty}(\bar{u} - w_{\sigma^*})_t(x_n,t_n) \le 0$. If $D > 0$, we also have $\lim_{n\to\infty}(\bar{u} - w_{\sigma^*})_{xx}(x_n,t_n) \ge 0$.

We first prove the claim for $D = 0$. Let $v(x,t) = \bar{u}(x,t) - w_{\sigma^*}(x,t)$ and $\rho(t) = \operatorname{ess\,inf}_{x\in\mathbb{R}} v(x,t)$. Then $\rho(0) > 0$. Let $\bar{t}_0 = \max\{t \in (0,t_0] : \rho(\tau) > 0 \text{ for all } 0 \le \tau < t\}$. Note that $w_{\sigma^*}(\pm\infty, t) \le -\frac{9}{8}\,\epsilon e^{2Kt} < \bar{u}(x,t)$ and $\bar{u}(x,t) > w_{\sigma^*}(x,t)$ for $t \in (0,T]$ and almost all $x \in R_2 + c_0 t$. For each $t < \bar{t}_0$, since $\rho(\bar{t}_0) = 0 < \rho(t)$, there is a uniformly bounded set $A(\bar{t}_0, t) \subset R_1 + c_0 t$ of positive Lebesgue measure such that $v(x,\bar{t}_0) \le \rho(t)$ and inequality (3.1), with $u, K_0, \hat{J}$ replaced by $\bar{u}, \bar{K}_0, \bar{J}$, respectively, holds for all $x \in A(\bar{t}_0, t)$. Therefore, for $\bar{t}_n = \bar{t}_0 - \frac{1}{n}$, we have $0 \le v(x,\bar{t}_n) - v(x,\bar{t}_0) = \int_0^1 v_t(x, \bar{t}_0 + s(\bar{t}_n - \bar{t}_0))ds(\bar{t}_n - \bar{t}_0)$ for $x \in A(\bar{t}_0, \bar{t}_n)$. Therefore, there exist $t_n \in (\bar{t}_n, \bar{t}_0)$ and a bounded sequence $x_n \in A(\bar{t}_0, \bar{t}_n)$ such that $v_t(x_n, t_n) \le 0$. After taking a subsequence of x_n we may assume that the limit of x_n exists: call it $\bar{x}_0$. Then $v(x_n,t_n) \le |v(x_n,\bar{t}_0)| + |v(x_n,t_n) - v(x_n,\bar{t}_0)| \le |v(x_n,\bar{t}_0)| + \|v_t\|_{L^\infty(\mathbb{R})}(\bar{t}_0 - t_n) \to 0$, where we have used the fact that $|v(x_n,\bar{t}_0)| \le \rho(\bar{t}_n) \to 0$.

If $D > 0$, (x_n, t_n) can be chosen as the minimum point of $\bar{u}(x,t) - w_{\sigma^*}(x,t)$ in $\mathbb{R}\times[0,T]$. This proves the claim.

Therefore,

$$
\begin{aligned}
0 &\ge \lim_{n\to\infty}(\bar{u} - w_{\sigma^*})_t(x_n,t_n) - \lim_{n\to\infty} D(\bar{u} - w_{\sigma^*})_{xx}(x_n,t_n)\\
&\ge \liminf_{n\to\infty}(\bar{J}\bar{u})(x_n,t_n) + \epsilon e^{2K\bar{t}_0}\left[2K\left(\sigma^* z(\bar{x}_0) + \frac{3}{4}\right) + D\sigma^* z''(\bar{x}_0)\right] + \|K_0\|_{L^\infty} w_{\sigma^*}(\bar{x}_0,\bar{t}_0)\\
&\ge \epsilon e^{2K\bar{t}_0}\left[\frac{7}{4}\ K - \frac{1}{4}D - \frac{3}{2}\|K_0\|_{L^\infty} - \frac{3}{2}\operatorname*{ess\,sup}_{\substack{x\in\mathbb{R}\\ t\in[0,t_0]}}\int_{-\infty}^{+\infty}\hat{J}(x,y,t)dy\right] > 0,
\end{aligned}
$$

which is a contradiction. Therefore $u(x,t) \ge 0$ for almost all $x \in \mathbb{R}$ and $t \in [\tau, t_0]$.

For the conclusion of the last part of the lemma, if $D > 0$, it follows from the comparison principle of parabolic equations [19]. If $D = 0$, let $\bar{v}(x,t) = e^{Kt}\bar{u}(x,t)$. Then we have $\bar{v}_t(x,t) \ge c_1 J_1 * \bar{v}(x,t)$ for $(x,t) \in \bar{R}_1$ since $u(x,t) \ge 0$. Therefore, $\bar{v}(x,t) \ge c_1(t - t_*)J_1 * \bar{v}(x,t_*)$, where t_* is any number less than t such that $(x,t_*) \in \bar{R}_1$. After the Nth iteration, we have $\bar{v}(x,t) \ge \frac{(c_1(t-t_*))^N}{N!} J_1 * \cdots * J_1 * \bar{v}(x,t_*)$. We first consider the first case for x where t_* can be chosen to be 0. We have $\bar{v}(x,t) \ge \frac{(c_1(t-t_*))^N}{N!} J_1 * \cdots * J_1 * \bar{u}(x,0)$. If $u(x,0) \ne 0$ in $L^\infty(\mathbb{R})$, we can choose N large enough such that $J_1 * \cdots * J_1 * u(x,0) > 0$. Therefore, we have $\bar{v}(x,t) > 0$. The rest of the case is reduced to prove that $\bar{v}(x,t_*) > 0$ on a set in $R_1 + c_0 t_*$ with positive measure. After finite steps of reduction, with different choices of x and t_*, it can be reduced to the first case. This completes the proof. □

We are going to use perturbation theory to estimate the essential spectrum of $\mathcal{L}$. First, let ζ be a smooth function satisfying $\zeta(x) = 0$ for $x \le -1$, $\zeta(x) = 1$ for $x \ge 1$, and $\zeta'(x) > 0$ for $x \in (-1,1)$. Let

$$
h(\cdot) = \bar{f}'(-1)(1 - \zeta(\cdot)) + \bar{f}'(1)\zeta(\cdot), \tag{3.3}
$$

where $\bar{f}$ is defined in (A$_2$). Note that $\bar{f}'(\pm 1) < 0$, by assumption (A$_2$). Consider the operator $\mathcal{L}_0\psi$ on X_0 with domain $D(\mathcal{L}_0) = D(\mathcal{L})$ defined by

$$\mathcal{L}_0\psi = D\psi'' + c_0\psi' + h\psi + \sum_{i=1}^{n} k_i(J_i * \psi - \psi), \tag{3.4}$$

where

$$k_i(\cdot) = F_{p_i}(\phi, J_1 * s^1(\phi), \ldots, J_n * s^n(\phi))s_u^i(\phi)(\cdot) \tag{3.5}$$

for $i = 1, \ldots, n$. We also define

$$k_0(\cdot) = F_u(\phi, J_1 * s^1(\phi), \ldots, J_n * s^n(\phi))(\cdot) \tag{3.6}$$

for later use. We want to show that $\sigma_{ess}(\mathcal{L}) = \sigma_{ess}(\mathcal{L}_0)$ if $D > 0$ or $c_0 \neq 0$. First we prove the next lemma.

LEMMA 3.2. *For $\lambda \in \mathbb{C}$ satisfying $\mathrm{Re}\lambda > \max\{\bar{f}'(-1), \bar{f}'(+1)\}$, the operator $\lambda - \mathcal{L}_0 : D(\mathcal{L}_0) \to X_0$ is injective.*

Proof. Let $\lambda = \alpha + i\beta \in \mathbb{C}$ with $\alpha > \max\{\bar{f}'(-1), \bar{f}'(1)\}$ and let $u(x) = u^1(x) + iu^2(x) \in D(\mathcal{L}_0)$ be a solution of $\mathcal{L}_0 u = \lambda u$. We will prove that $u \equiv 0$.

Consider the Cauchy problem

$$v_t = \mathcal{L}_0 v - \alpha v, \tag{3.7}$$

$$v(x, 0) = u^1(x). \tag{3.8}$$

It has a unique solution $v(x,t) = u^1(x)\cos\beta t - u^2(x)\sin\beta t$.

On the other hand, since $\alpha > \max\{\bar{f}'(-1), \bar{f}'(+1)\}$, we can choose a constant $\rho_0 > 0$ such that $\alpha > \max\{\bar{f}'(-1), \bar{f}'(+1)\} + \rho_0$. Let $\bar{v}(t) = \max_{x\in\mathbb{R}} |u(x)|e^{-\rho_0 t}$. Then

$$\bar{v}_t - \mathcal{L}_0\bar{v} + \alpha\bar{v} = (-\rho_0 - h(x) + \alpha)\bar{v} \geq (\alpha - \rho_0 - \max\{\bar{f}'(-1), \bar{f}'(+1)\})\bar{v} > 0.$$

By the comparison lemma, we deduce that $|v(x,t)| \leq \bar{v}(t)$ for all $x \in \mathbb{R}$ and $t > 0$. Therefore, if $\beta = 0$, the fact that $|u^1(x)| = |v(x,t)| \leq \bar{v}(t) \to 0$ as $t \to \infty$ implies $u^1(x) \equiv 0$. The same argument applying to $u^2(x)$ yields $u^2(x) \equiv 0$. If $\beta > 0$, $|v(x,t)| = |v(x, t + 2n\pi/\beta)| \leq \bar{v}(t + 2n\pi/\beta)$. Letting $n \to \infty$, we deduce $u(x) \equiv 0$. This proves the injectivity. □

To prove the surjectivity of $\lambda - \mathcal{L}_0$, we first consider the case $D > 0$. Let $M \equiv M_m = \{u \in C(\mathbb{R}) : u(x) = 0 \text{ for } |x| \geq m\}$, where m is a positive constant, and consider the operator $\mathcal{A}_0$ on M defined by $\mathcal{A}_0 u = Du'' + c_0u' + h(x)u$ for $u \in D(\mathcal{A}_0) = M \bigcap C^2(\mathbb{R})$. We have the next lemma.

LEMMA 3.3. *If $D > 0$, then $\{\lambda : \mathrm{Re}\lambda > \max\{\bar{f}'(-1), \bar{f}'(+1)\}\} \subset \rho(\mathcal{A}_0)$.*

Proof. Similar to the proof of Lemma 3.2, we can prove that $\lambda - \mathcal{A}_0$ is injective. The lemma follows from the Fredholm theory for elliptic operators on bounded domains. □

With this preparation, we can prove the following.

LEMMA 3.4. *For $\lambda \in \mathbb{C}$ satisfying $\mathrm{Re}\lambda > \max\{\bar{f}'(-1), \bar{f}'(+1)\}$, the operator $\lambda - \mathcal{L}_0 : D(\mathcal{L}_0) \to X_0$ is surjective.*

Proof. First let us assume $D > 0$. Let θ be a smooth nonnegative function on $\mathbb{R}$ satisfying $\theta(x) = 1$ for $|x| \leq \frac{1}{2}$ and $\theta(x) = 0$ for $|x| \geq 1$. Let $\mathcal{A}_1 \equiv \mathcal{A}_{1m}$ be the operator defined by $\mathcal{A}_1 u = \mathcal{A}_0 u + \sum_{i=1}^{n} \tilde{k}_i(x)(J_i * u - u)$ for $u \in D(\mathcal{A}_1) = D(\mathcal{A}_0)$,

where $\tilde{k}_i(\cdot) = k_i(\cdot)\theta(\cdot/m)$ and m is a positive number. We will prove the surjectivity of $\mathcal{A}_1$ and let m approach the infinite to prove the surjectivety of $\lambda - \mathcal{L}_0$.

For $\lambda \in \mathbb{C}$ with $\mathrm{Re}\lambda > \max\{\bar{f}'(-1), \bar{f}'(+1)\}$, as in the proof of Lemma 3.2, one can prove that $\lambda - \mathcal{A}_1$ is injective. On the other hand, for $g \in M$, the equation

$$(\lambda - \mathcal{A}_1)u = g \tag{3.9}$$

is equivalent to $u - R(\lambda, \mathcal{A}_0)\sum_{i=1}^n \tilde{k}_i(x)(J_i * u - u) = g_1$, where $g_1 = R(\lambda, \mathcal{A}_0)g$ and $R(\lambda, \mathcal{A}_0)$ is the resolvent of $\lambda - \mathcal{A}_0$. Since $\lambda - \mathcal{A}_1$ is injective and $R(\lambda, \mathcal{A}_0)$ is compact, by the Fredholm Alternative, $u - R(\lambda, \mathcal{A}_0)\sum_{i=1}^n \tilde{k}_i(x)(J_i * u - u) = g_1$ has a solution. Therefore, for any $g \in M$, $(\lambda - \mathcal{A}_1)u = g$ has a solution.

For $g \in X_0$, let u_m be the solutions of (3.9) corresponding to $g_m = g(\cdot)\theta(\cdot/m)$. We claim that $\|u_m\|_{C(\mathbb{R})} \le C\|g\|_{C(\mathbb{R})}$ for some constant C. To prove this, suppose $\lambda = \alpha + i\beta$, $u_m(x) = u_m^1(x) + iu_m^2(x)$ and $g_m(x) = g_m^1(x) + ig_m^2(x)$. Then it is easy to verify that the problem

$$v_t - \mathcal{A}_1 v + \alpha v = g_m^1(x)\cos\beta t - g_m^2(x)\sin\beta t, \tag{3.10}$$

$$v(x,0) = u_m^1(x) \tag{3.11}$$

has the unique solution $v_m(x,t) = u_m^1(x)\cos\beta t - u_m^2(x)\sin\beta t$. Let $\bar{v}(t) = \|u_m\|_{C(\mathbb{R})}e^{-\rho_0 t} + \frac{1}{\rho_0}(1 - e^{-\rho_0 t})\|g\|_{C(\mathbb{R})}$, where $\rho_0 > 0$ is a constant satisfying $\alpha > \max\{\bar{f}'(-1), \bar{f}'(+1)\} + \rho_0$. Applying the comparison principle to $\bar{v} \pm v_m$ and using (3.10), we conclude that $|v_m(x,t)| \le \bar{v}(t) \le \|u_m\|_{C(\mathbb{R})}e^{-\rho_0 t} + \frac{1}{\rho_0}(1 - e^{-\rho_0 t})\|g\|_{C(\mathbb{R})}$. If $\beta = 0$, we have $|u_m^1(x)| = |v_m(x,t)| \le \bar{v}(t) \to \frac{1}{\rho_0}\|g\|_{C(\mathbb{R})}$ as $t \to \infty$. The same argument applies for estimate of $u^2(x)$. If $\beta \neq 0$, for each x, choose $t_n \to \infty$ such that $v_m(x,t_n) = |u_m(x)|$, implying $|u_m(x)| \le \frac{1}{\rho_0}\|g\|_{C(\mathbb{R})}$. This completes the proof of the claim.

Since $\|u_m\|_{C(\mathbb{R})}$ is uniformly bounded, there exist a function $u \in X_0$ and a subsequence, which we label the same, such that u_m converges to u in the weak $*$ topology. Note that the dual space of linear bounded functionals is represented by the space of complex Borel measures. It is easily seen that u satisfies $\lambda u - \mathcal{L}_0 u = g$ in the sense of distributions. Therefore u is a solution in the classical sense. This completes the proof of the lemma when $D > 0$.

For the case $D = 0$, we choose a positive sequence such that $\lim_{j\to\infty} D_j = 0$. Let u_j be the solutions of $-D_j u'' - c_0 u' + (\lambda - h(x)) - \sum_{i=1}^n k_i(x)(J^i * u - u) = g$. Since the proof above does not involve the size of D, we have that $\|u_j\|_{C(\mathbb{R})} \le C\|g\|_{C(\mathbb{R})}$. Again, by taking a subsequence, we can assume u_j converges to some function $u \in X_0$ in the weak $*$ topology. Similar to the above argument, we see that u is a solution to $(\lambda - \mathcal{L}_0)u = g$. This completes the proof. □

As an immediate consequence of Lemma 3.2 and 3.4, one gets $\{\lambda : \mathrm{Re}\lambda > \max\{\bar{f}'(-1), \bar{f}'(1)\}\} \subset \rho(\mathcal{L}_0)$.

Let $\mathcal{L}_1$ and $\mathcal{L}_2$ be bounded linear operators on X_0 defined by $\mathcal{L}_1 u(\cdot) = (\bar{f}'(\phi) - h)u(\cdot) = \{F_u(\phi, J_1 * s^1(\phi), \ldots, J_n * s^n(\phi)) + \sum_{i=1}^n k_i - h\}u(\cdot)$ and $\mathcal{L}_2 u(\cdot) = \sum_{i=1}^n \{F_{p_i}(\phi, J_1 * s^1(\phi), \ldots, J_n * s^n(\phi))J_i * (s_u(\phi)u) - k_i J_i * u\}(\cdot)$, respectively, for $u \in X_0$. Then we have the next lemma.

LEMMA 3.5. *Let $\lambda \in \rho(\mathcal{L}_0)$. Then if $D > 0$ or $c_0 \neq 0$, $\mathcal{L}_i(\lambda - \mathcal{L}_0)^{-1}$ is a compact operator on X_0 for $i = 1, 2$.*

Proof. Let B be a bounded closed set in X_0. Since $\|(\lambda - \mathcal{L}_0)^{-1} f\|_{C^1(\mathbb{R})} \le C\|f\|_{C(\mathbb{R})}$ if $D > 0$ or $c_0 \neq 0$, $(\lambda - \mathcal{L}_0)^{-1}B$ is bounded in $C^1(\mathbb{R})$ and therefore it is compact

in $C([-n,n])$ for all $n>0$. A diagonal argument can be used to get a sequence $\{u_k\}\subset(\lambda-\mathcal{L}_0)^{-1}B$ such that u_k converges to some u in $C([-n,n])$ for each fixed n. Note that $\mathcal{L}_iu(x)$ $(i=1,2)$ converges to zero as $|x|\to\infty$ uniformly for u in a bounded set in X_0. It easily follows that $\mathcal{L}_i(\lambda-\mathcal{L}_0)^{-1}u_k$ converges to $\mathcal{L}_i(\lambda-\mathcal{L}_0)^{-1}u$ in $C(\mathbb{R})$, respectively, for $i=1,2$. □

Now we are ready to prove Theorem 2.2(iii).

LEMMA 3.6. *There exists a positive constant γ_0 such that $\sigma_{ess}(\mathcal{L})\subset\{\lambda : \mathrm{Re}\lambda\le-\gamma_0\}$.*

Proof. Note that $\mathcal{L}=\mathcal{L}_0+\mathcal{L}_1+\mathcal{L}_2$. We know that $\sigma_{ess}(\mathcal{L}_0)\subset\{\lambda : \mathrm{Re}\lambda\le\max\{\bar f'(-1),\bar f'(1)\}\}$. If $D>0$ or $c_0\neq0$, by Lemma 3.5 and applying Theorem A.1 (p. 136) in [20], we deduce that the half-plane $\{\lambda\mid\mathrm{Re}\lambda>\max\{f'(-1),f'(1)\}\}$ consists entirely of normal points of $\mathcal{L}$ (see Lemma 3.7). This establishes the lemma with $\gamma_0=-\max\{\bar f'(-1),\bar f'(1)\}$.

For the case $D=0$ and $c_0=0$, we first show that $\lambda-\mathcal{L}$ is Fredholm with index 0 for $\lambda\in S_{\gamma_1}=\{\lambda\in\mathbb{C}:\mathrm{Re}\lambda\ge-\gamma_1\}$ for some constant $\gamma_1>0$ to be chosen. Let k_i be as defined in (3.5) and (3.6) for $i=0,1,\dots,n$. By assumption (A_3), $k_0(x)\le-\bar\delta_0<0$ for all $x\in\mathbb{R}$, where $\bar\delta_0$ is a positive constant. Since $\bar f'(\pm1)=k_0(\pm\infty)+\sum_{i=1}^n k_i(\pm\infty)<0$, by assumption (A_2), we can choose $\gamma_1>0$ such that $\lambda-k_0(x)\neq0$ for all $x\in\mathbb{R}$ and $|\sum_{i=1}^n\frac{k_i(\pm\infty)}{\lambda-k_0(\pm\infty)}|<1$ for all $\lambda\in S_{\gamma_1}$. For $\lambda\in S_{\gamma_1}$ and $i=1,2,\dots,n$, we choose smooth functions $m_i(x)$ on $\mathbb{R}$ satisfying $\lim_{x\to\pm\infty}m_i(x)=\frac{k_i(\pm\infty)}{\lambda-k_0(\pm\infty)}$ and $\sum_{i=1}^n|m_i(x)|\le\delta_1<1$, where δ_1 is a positive constant. Then, we can write

$$\begin{aligned}(\lambda-\mathcal{L})\psi&=(\lambda-k_0)\psi-\sum_{i=1}^n F_{p_i}(\phi,J_1*s^1(\phi),\dots,J_n*s^n(\phi))\cdot J_i*(s_u^i(\phi)\psi)\\&=(\lambda-k_0)\psi-\sum_{i=1}^n k_iJ_i*\psi+B_0\psi\\&=(\lambda-k_0)(B_1\psi+B_2\psi)+B_0\psi,\end{aligned}\tag{3.12}$$

where

$$\begin{aligned}B_0\psi&=\sum_{i=1}^n[k_iJ_i*\psi-F_{p_i}(\phi,J_1*s^1(\phi),\dots,J_n*s^n(\phi))J_i*(s_u^i(\phi)\psi)],\\B_1\psi&=\sum_{i=1}^n\left[m_i-\frac{k_i}{\lambda-k_0}\right]J_i*\psi,\\B_2\psi&=\psi-\sum_{i=1}^n m_iJ_i*\psi.\end{aligned}$$

By the choice of m_i, we know that the bounded linear operator B_2 is invertible on X_0. Therefore, the index of $\lambda-\mathcal{L}$ is 0 since B_0 and B_1 are compact operators on X_0.

This and the simplicity of eigenvalue 0 of $\mathcal{L}$ (see Lemma 3.8) imply that $X_0=\mathrm{Range}(\mathcal{L})\oplus N$, where N is one-dimensional. On the other hand, since 0 is an algebraically simple eigenvalue, we can take $N=\mathrm{Ker}(\mathcal{L})$ and hence $X_0=\mathrm{Range}(\mathcal{L})\oplus\mathrm{Ker}(\mathcal{L})$. Now $\mathcal{L}:\mathrm{Range}(\mathcal{L})\to\mathrm{Range}(\mathcal{L})$ is one-to-one and onto, so it has a bounded inverse. Therefore, for $|\lambda|$ small, $(\lambda-\mathcal{L})|_{\mathrm{Range}(\mathcal{L})}$ is invertible and hence if $\lambda\neq0$ with $|\lambda|$ small, $\mathcal{L}\psi=\lambda\psi$ has no nonzero solution in X_0. On the other hand, by Lemma 3.7, $\mathcal{L}\psi=\lambda\psi$ has no nonzero solution in X_0 for $\lambda\neq0$ with $\mathrm{Re}\lambda\ge0$. From this and

the fact that $\lambda - \mathcal{L}$ is Fredholm with index zero for $\lambda \in S_{\gamma_1}$, we deduce that λ is in the resolvent set of $\mathcal{L}$ for $\lambda \neq 0$ with $|\lambda|$ small or $\mathrm{Re}\lambda \geq 0$. Since $\sigma(\mathcal{L})$ is closed and bounded, we deduce that λ is in the resolvent set of $\mathcal{L}$ for $\lambda \neq 0$ with $\mathrm{Re}\lambda \geq -\gamma_0$ for some constant $\gamma_0 > 0$. □

From Lemma 3.6, we deduce that the half-plane $\{\lambda \mid \mathrm{Re}\lambda > -\gamma_0\}$ consists entirely of normal points of $\mathcal{L}$. This establishes (iii) of Theorem 2.2. The rest of the statement follows from the following lemmas.

LEMMA 3.7. $\{\lambda : \mathrm{Re}\lambda \geq 0, \lambda \neq 0\} \subset \rho(\mathcal{L})$.

Proof. It is clear that every eigenfunction of $\mathcal{L}$ in X_0 with nonzero eigenvalue is at least C^1. Suppose $\lambda = \alpha + i\beta$ satisfying $\alpha \geq 0$ and $\beta \neq 0$ is an eigenvalue with eigenfunction $u = u^1(x) + iu^2(x) \neq 0$. As in the proof of Lemma 3.2, we consider the Cauchy problem

$$v_t = \mathcal{L}v - \alpha v, \tag{3.13}$$

$$v(x,0) = u^1(x). \tag{3.14}$$

It has a solution $v(x,t) = u^1(x)\cos\beta t - u^2(x)\sin\beta t$.

Note that $v(x,t) \leq |u(x)|$ for all $x \in \mathbb{R}$ and $t \geq 0$. We claim that there is a $\tau > 0$ such that $v(x,t) \leq \tau\phi'(x)$ for all $x \in \mathbb{R}$ and $t \geq 0$. To prove this claim, let θ_0 be a constant satisfying $0 < \theta_0 < -\max\{\bar{f}'(-1), \bar{f}'(1)\}$. Since $\phi(\pm\infty) = \pm 1$, we may choose M large enough such that $F_u(\phi, J_1 * s^1(\phi), \ldots, J_n * s^n(\phi))(x) + \sum_{i=1}^n F_{p_i}(\phi, J_1 * s^1(\phi), \ldots, J_n * s^n(\phi)) J_i * (s_u^i(\phi))(x) \leq -\theta_0$ for all $|x| \geq M$ and such that $|u|$ is positive at some point $x \in [-M, M]$. Since $\phi'(x) > 0$, there exists a constant $\tau > 0$ such that $|u(x)| \leq \tau\phi'(x)$ for $|x| \leq M$. We prove that the claim holds with this choice of τ. Since $\lim_{x\to\pm\infty} u(x) = 0$, there exists a constant $\epsilon > 0$ such that $v(x,t) \leq \tau\phi'(x) + \epsilon$ for all x and $t \geq 0$. Let $\epsilon_0 = \inf\{\epsilon : v(x,t) \leq \tau\phi'(x) + \epsilon \text{ for all } x \in \mathbb{R} \text{ and } t \geq 0\}$. We prove that $\epsilon_0 = 0$. Consider the function $w(x,t) = \tau\phi'(x) + \epsilon_0 e^{-\theta_0 t}$. We have

$$\begin{aligned} w_t - \mathcal{L}w + \alpha w = {} & \epsilon_0(-\theta_0 - F_u(\phi, J_1 * s^1(\phi), \ldots, J_n * s^n(\phi))(x) \\ & - \sum_{i=1}^n F_{p_i}(\phi, J_1 * s^1(\phi), \ldots, J_n * s^n(\phi)) J_i * (s_u^i(\phi))(x)) e^{-\theta_0 t} + \alpha w \\ \geq {} & 0 \end{aligned} \tag{3.15}$$

for all $|x| > M$ and $t > 0$. Therefore w is a supersolution of (3.13) on $|x| > M$. Notice that $w(x,t) \geq v(x,t)$ for $|x| \leq M$ and $t > 0$ and $w(x,0) \geq v(x,0)$ for all x. The comparison principle (Lemma 3.1) yields $w(x,t) \geq v(x,t)$ for all x and $t > 0$. Therefore $v(x,t) = v(x, t + 2n\pi/\beta) \leq \tau\phi'(x) + \epsilon_0 e^{-\theta_0(t+2n\pi/\beta)}$ for all $n \in Z^+$, $x \in \mathbb{R}$, and $t > 0$. Letting $n \to \infty$, we get $v(x,t) \leq \tau\phi'(x)$ for all x. Therefore $\epsilon_0 = 0$ and the claim is proved.

Clearly τ_0 can be chosen such that $|u(x)| \leq \tau_0\phi'(x)$ for all $|x| \leq M$ and there is a point $x_0 \in [-M, M]$ such that $|u(x_0)| = \tau_0\phi'(x_0)$. By the comparison principle, we deduce that $v(x,t) < \tau_0\phi'(x)$ for all x and $t > 0$. If we choose t such that $u(x_0)/|u(x_0)| = e^{-i\beta t}$, then $v(x_0,t) = |u(x_0)| = \tau_0\phi'(x_0) > v(x_0,t)$, which is a contradiction. Therefore $u(x) = 0$ for all x and λ is not an eigenvalue.

Now assume that $\lambda > 0$ is an eigenvalue with an eigenfunction $u(x)$. Without loss of generality, we may assume u is real and there is a point where u is positive. Then $v(x,t) \equiv u(x)$ is a solution of (3.13) with $\alpha = \lambda > 0$ and the initial condition $v(x,0) = u(x)$. A similar argument to the above can be used to prove that $u(x) \equiv 0$ and so $\lambda > 0$ is not an eigenvalue. This completes the proof. □

LEMMA 3.8. *0 is an eigenvalue of $\mathcal{L}$ and it is algebraically simple.*

Proof. Since $(\phi(\cdot + s), c_0)$ satisfies (1.4) for each $s \in \mathbb{R}$ and $\lim_{z\to\infty} \phi(\pm z) = \pm 1$, $p = \phi'$ is a positive eigenfunction of $\mathcal{L}$ in X_0 with corresponding eigenvalue 0.

To show that 0 is a geometrically simple eigenvalue we use the comparison principle. Suppose that $\mathcal{L}v = 0$ with $v \in X_0$ and assume, without loss of generality, that $v(x_0) > 0$ for some x_0. For $\theta > 0$, let $w_\theta \equiv \theta\phi' - v$. Note that $\phi'(x) > 0$. We can choose θ large enough such that $w_\theta(x) \geq 0$ for $|x| \leq M$, where M is a constant given as in the proof of Lemma 3.7. Note that $v_\theta(x,t) \equiv w_\theta(x)$ as a function of (x,t) (it is independent of t) satisfies (3.13) with initial data $v(x,0) = w_\theta(x)$. Similar to the proof in Lemma 3.7, we deduce that $w_\theta(x) \geq 0$ for all $x \in \mathbb{R}$. Let $\theta_0 = \inf\{\theta : w_\theta(x) \geq 0\}$. We claim that $w_{\theta_0}(x) \equiv 0$. In fact, if w_{θ_0} is not identically zero, we apply the comparison principle to $v_{\theta_0}(x,t) \equiv w_{\theta_0}(x)$ to deduce that $w_{\theta_0} > 0$ for all $x \in \mathbb{R}$. Therefore there exists $\epsilon_0 > 0$ such that $w_{\theta_0-\epsilon_0}(x) \geq 0$ for $x \in [-M, M]$. This contradicts the choice of θ_0. Therefore, ϕ is a simple eigenfunction corresponding to eigenvalue 0.

To show algebraic simplicity of eigenvalue 0, suppose that there is v such that $\mathcal{L}v = -\phi'$ and recall that $\phi'(x) > 0$ on $\mathbb{R}$. Let $w_\tau \equiv v + \tau\phi'$ and note that for $\tau > 0$ and sufficiently large, $w_\tau > 0$ on $[-M, M]$ and, as we argued above, $w_\tau > 0$ on $\mathbb{R}$. Taking the infimum T of all such τ produces a function $w_T \geq 0$ on $\mathbb{R}$ and a point x_T where this function is zero. Then

$$\begin{aligned} 0 &\leq Dw_T''(x_T) + \sum_{i=1}^{n} F_{p_i}(\phi, J_1 * s^1(\phi), \cdots, J_n * s^n(\phi)) \cdot J_i * (s_u^i(\phi) w_T)(x_T) \\ &= \mathcal{L}w_T(x_T) = -\phi_0'(x_T) < 0. \end{aligned}$$

This provides the contradiction which establishes the result. ∎

Let $\mathcal{L}^*$ be the adjoint operator of $\mathcal{L}$ on X_0^*. Then we have the next lemma.

LEMMA 3.9. *The operator $\mathcal{L}^*$ on X_0^* has a positive eigenvector corresponding to the simple eigenvalue* 0.

Proof. Since 0 is a simple eigenvalue of $\mathcal{L}$, by the Fredholm theory, $\mathcal{L}^*v = 0$ has a nonzero solution v and it is unique modulo a constant multiple. For any solution $v \neq 0$ of $\mathcal{L}^*v = 0$ in X_0^*, v or $-v$ must be a positive Borel measure. To show this, if v or $-v$ is not positive, we can find a function $f \in X_0$ such that $f(x) < 0$ for all x and the dual pairing $< f, v >= 0$. Then, by the Fredholm Alternative, $\mathcal{L}u = f$ has a solution u. As before, we can choose τ such that $\tau\phi'(x) \geq -u(x)$ and $\tau\phi'(x_0) = -u(x_0)$ for some x_0. With $w(x,t) = \tau\phi'(x_0) + u(x_0)$, we have $w_t - \mathcal{L}w = -\mathcal{L}u = -f > 0$ and $w(x_0, t) = 0$, in contradiction to the strong comparison principle. ∎

LOCALIZATION FOR THE SCHRÖDINGER EQUATION IN A LOCALLY PERIODIC MEDIUM*

GRÉGOIRE ALLAIRE† AND MARIAPIA PALOMBARO‡

Abstract. We study the homogenization of a Schrödinger equation in a locally periodic medium. For the time and space scaling of semiclassical analysis we consider well-prepared initial data that are concentrated near a stationary point (with respect to both space and phase) of the energy, i.e., the Bloch cell eigenvalue. We show that there exists a localized solution which is asymptotically given as the product of a Bloch wave and of the solution of an homogenized Schrödinger equation with quadratic potential.

Key words. homogenization, localization, Bloch waves, Schrödinger

AMS subject classifications. 35B27, 35J10

1. Introduction. We study the homogenization of the following Schrödinger equation:

$$\begin{cases} \dfrac{i}{\varepsilon}\dfrac{\partial u_\varepsilon}{\partial t} - \operatorname{div}\left(A\left(x,\dfrac{x}{\varepsilon}\right)\nabla u_\varepsilon\right) + \dfrac{1}{\varepsilon^2}c\left(x,\dfrac{x}{\varepsilon}\right)u_\varepsilon = 0 & \text{in } \mathbb{R}^N\times\mathbb{R}^+, \\ u_\varepsilon(0,x) = u_\varepsilon^0(x) & \text{in } \mathbb{R}^N, \end{cases} \tag{1.1}$$

where the unknown $u_\varepsilon(t,x)$ is a complex-valued function. The coefficients $A(x,y)$ and $c(x,y)$ are real and sufficiently smooth bounded functions defined for $x\in\mathbb{R}^N$ (the macroscopic variable) and $y\in\mathbb{T}^N$ (the microscopic variable in the unit torus). The period ε is a small positive parameter which is intended to go to zero. Furthermore, the matrix A is symmetric uniformly positive definite. Of course, the usual Schrödinger equation is recovered when $A\equiv Id$, but since there is no additional difficulty, we keep the general form of (1.1) in what follows (which can be interpreted as introducing a nonflat locally periodic metric).

The scaling of (1.1) is that of semiclassical analysis (see, e.g., [5], [8], [10], [11], [12], [13], [14], [18], [19]): if the period is rescaled to 1, it amounts to looking at large time and space variables of order ε^{-1}. At least in the case when $A\equiv Id$ and $c(x,y)=c_0(x)+c_1(y)$, there is a well-known theory for the asymptotic limit of (1.1) when ε goes to zero. By using WKB asymptotic expansion or the notion of semiclassical measures (or Wigner transforms), the homogenized problem is in some sense the Liouville transport equation for a classical particle which is the limit of the wave function u_ε. In other words, for initial data living in the nth Bloch band and under some technical assumptions on the Bloch spectral cell problem (1.4), the semiclassical limit of (1.1) is given by the dynamic of the following Hamiltonian system

in the phase space $(x,\theta)\in\mathbb{R}^N\times\mathbb{T}^N$:

$$\begin{cases}\dot{x}=\nabla_\theta\lambda_n(x,\theta),\\ \dot{\theta}=-\nabla_x\lambda_n(x,\theta),\end{cases} \tag{1.2}$$

where the Hamiltonian $\lambda_n(x,\theta)$ is precisely the nth Bloch eigenvalue of (1.4) (see [8], [10], [11], [12], [13], [14], [18], [19] for more details).

Our approach to (1.1) is different since we consider special initial data that are monochromatic and have zero group velocity and zero applied force. Namely, the initial data are concentrated at a point (x^n,θ^n) of the phase space, where $\nabla_\theta\lambda_n(x^n,\theta^n)=\nabla_x\lambda_n(x^n,\theta^n)=0$. In such a case, the previous Hamiltonian system (1.2) degenerates (its solution is constant) and is unable to describe the precise dynamic of the wave function u_ε. We exhibit another limit problem which is again a Schrödinger equation with quadratic potential. In other words, we build a sequence of approximate solutions of (1.1) which are the product of a Bloch wave and of the solution of a homogenized Schrödinger equation. Furthermore, if the full Hessian tensor of the Bloch eigenvalue $\lambda_n(x,\theta)$ is positive definite at (x^n,θ^n), we prove that all the eigenfunctions of a homogenized Schrödinger equation are exponentially decreasing at infinity. In other words, we exhibit a localization phenomenon for (1.1) since we build a sequence of approximate solutions that decay exponentially fast away from x^n. The root of this localization phenomenon is the macroscopic modulation (i.e., with respect to x) of the periodic coefficients, which is similar in spirit to the randomness that causes Anderson's localization (see [9] and references therein).

Let us describe more precisely the type of well-prepared initial data that we consider. For a given point $(x^n,\theta^n)\in\mathbb{R}^N\times\mathbb{T}^N$ and a given function $v^0\in H^1(\mathbb{R}^N)$ we take

$$u_\varepsilon^0(x)=\psi_n\Big(x^n,\frac{x}{\varepsilon},\theta^n\Big)e^{2i\pi\frac{\theta^n\cdot x}{\varepsilon}}v^0\Big(\frac{x-x^n}{\sqrt{\varepsilon}}\Big), \tag{1.3}$$

where $\psi_n(x,y,\theta)$ is a so-called Bloch eigenfunction, solution of the Bloch spectral cell equation

$$-(\mathrm{div}_y+2i\pi\theta)(A(x,y)(\nabla_y+2i\pi\theta)\psi_n)+c(x,y)=\lambda_n(x,\theta)\psi_n \qquad \text{in } \mathbb{T}^N, \tag{1.4}$$

corresponding to the nth eigenvalue or energy level λ_n. The Bloch wave ψ_n is periodic with respect to y, but v^0 is not periodic, so $v^0\big(\frac{x-x^n}{\sqrt{\varepsilon}}\big)$ means that the initial data is concentrated around x^n with a support of asymptotic size $\sqrt{\varepsilon}$. The Bloch frequency $\theta^n\in\mathbb{T}^N$, the localization point $x^n\in\mathbb{R}^N$, and the energy level n are chosen such that $\lambda_n(x^n,\theta^n)$ is simple and $\nabla_x\lambda_n(x^n,\theta^n)=\nabla_\theta\lambda_n(x^n,\theta^n)=0$.

Our main result (Theorem 3.2) shows that the solution of (1.1) is approximately given by

$$u_\varepsilon(t,x)\approx\psi_n\Big(x^n,\frac{x}{\varepsilon},\theta^n\Big)e^{i\frac{\lambda_n(x^n,\theta^n)t}{\varepsilon}}e^{2i\pi\frac{\theta^n\cdot x}{\varepsilon}}v\Big(t,\frac{x-x^n}{\sqrt{\varepsilon}}\Big), \tag{1.5}$$

where v is the unique solution of the homogenized Schrödinger equation

$$\begin{cases} i\dfrac{\partial v}{\partial t}-\mathrm{div}\,(A^*\nabla v)+\mathrm{div}(vB^*z)+c^*v+vD^*z\cdot z=0 & \text{in } \mathbb{R}^N\times\mathbb{R}^+,\\ v(0,z)=v^0(z) & \text{in } \mathbb{R}^N,\end{cases} \tag{1.6}$$

where c^* is a constant coefficient and A^*, B^*, D^* are constant matrices defined by

$$A^* = \frac{1}{8\pi^2}\nabla_\theta\nabla_\theta\lambda_n(x^n,\theta^n), \quad B^* = \frac{1}{2i\pi}\nabla_\theta\nabla_x\lambda_n(x^n,\theta^n), \quad D^* = \frac{1}{2}\nabla_x\nabla_x\lambda_n(x^n,\theta^n).$$

In Proposition 3.4 we show that the homogenized problem (1.6) is well-posed since the underlying operator is self-adjoint. Furthermore, under the additional assumption that the Hessian tensor $\nabla\nabla\lambda_n(x^n,\theta^n)$ (with respect to both variables x and θ) is positive definite, we prove that (1.6) admits a countable number of eigenvalues and eigenfunctions which all decay exponentially at infinity (see Proposition 3.5). In such a case, formula (1.5) defines a family of approximate (exponentially) localized solutions of (1.1).

Let us indicate that the case of the first eigenvalue (ground state) $n = 1$ with $\theta^1 = 0$ was already studied in [3] (for the spectral problem rather than the evolution equation). The case of purely periodic coefficients (i.e., that depend only on y and not on x) is completely different and was studied in [4]. Indeed, in this latter case there is no localization effect, and one proves that, for a longer time scale (of order ε^{-1} with respect to (1.1)), the homogenized limit is again a Schrödinger equation without the drift and quadratic potential in (1.6).

2. Preliminaries. In the present section we give our main assumptions and set some notation and a few preliminary results needed in the proof of the main results in section 3.

We first assume that the coefficients $A_{ij}(x,y)$ and $c(x,y)$ are real, bounded, and Carathéodory functions (measurable with respect to y and continuous in x), which are periodic with respect to y. In other words, they belong to $C_b(\mathbb{R}^N; L^\infty(\mathbb{T}^N))$. Furthermore, the tensor $A(x,y)$ is symmetric uniformly coercive. Under these assumptions, it is well known that, for any values of the parameters $\theta \in \mathbb{T}^N$ and $x \in \mathbb{R}^N$, the cell problem (1.4) defines a compact self-adjoint operator on $L^2(\mathbb{T}^N)$, which admits a countable sequence of real increasing eigenvalues $\{\lambda_n(x,\theta)\}_{n\geq 1}$ (repeated with their multiplicity) with corresponding eigenfunctions $\{\psi_n(x,\theta,y)\}_{n\geq 1}$ normalized by

$$\|\psi_n(x,\theta,\cdot)\|_{L^2(\mathbb{T}^N)} = 1.$$

Our main assumptions are the following.

Hypothesis H1. There exist $x^n \in \mathbb{R}^N$ and $\theta^n \in \mathbb{T}^N$ such that

$$\text{(2.1)} \qquad \begin{cases} \text{(i) } \lambda_n(x^n,\theta^n) \text{ is a simple eigenvalue,} \\ \text{(ii) } (x^n,\theta^n) \text{ is a critical point of } \lambda_n(x,\theta), \\ \qquad \text{i.e., } \nabla_x\lambda_n(x^n,\theta^n) = \nabla_\theta\lambda_n(x^n,\theta^n) = 0. \end{cases}$$

Hypothesis H2. The coefficients $A(x,y)$ and $c(x,y)$ are of class C^2 with respect to the variable x in a neighborhood of $x = x^n$.

Then we set

$$A_{1,h}(y) := \frac{\partial A}{\partial x_h}(x^n,y), \quad A_{2,lh}(y) := \frac{\partial^2 A}{\partial x_l \partial x_h}(x^n,y), \quad \text{for } l,h = 1,\dots,N.$$

Similar notation is used to denote the derivatives of the function c with respect to the x-variable. With an abuse of notation we further set

$$A(y) := A(x^n,y), \quad \lambda_n := \lambda_n(x^n,\theta^n), \quad \psi_n(y) := \psi_n(x^n,y,\theta^n),$$

and analogous notation holds for all derivatives of ψ_n and λ_n with respect to the x-variable and the θ-variable evaluated at $x = x^n$ and $\theta = \theta^n$. Without loss of generality we will assume in what follows that $x^n = 0$.

Notation. For any function $\rho(y)$ defined on $\mathbb{T}^N$ we set

$$\rho^\varepsilon(z) := \rho(z/\sqrt{\varepsilon}),$$

where $z := \sqrt{\varepsilon}y \equiv x/\sqrt{\varepsilon}$. In what follows the symbols div_y and ∇_y will stand for the divergence and gradient operators which act with respect to the y-variable, while div and ∇ will indicate the divergence and gradient operators which act with respect to the z-variable. Finally, throughout this paper the Einstein summation convention is used.

Under Hypothesis H1-(i) it is a classical matter to prove that the nth eigencouple of (1.4) is smooth with respect to the variable θ in a neighborhood of $\theta = \theta^n$ (see [16]) and has the same differentiability property as the coefficients with respect to the variable x. Introducing the unbounded operator $\mathbb{A}_n(x,\theta)$ defined on $L^2(\mathbb{T}^N)$ by

$$\mathbb{A}_n(x,\theta)\psi = -(\mathrm{div}_y + 2i\pi\theta)\big(A(x,y)(\nabla_y + 2i\pi\theta)\psi\big) + c(x,y)\psi - \lambda_n(x,\theta)\psi,$$

it is easy to differentiate (1.4). Denoting by $(e_k)_{1\le k\le N}$ the canonical basis of $\mathbb{R}^N$, the first derivatives satisfy

$$\begin{aligned}\mathbb{A}_n(x,\theta)\frac{\partial\psi_n}{\partial\theta_k} &= 2i\pi e_k A(x,y)(\nabla_y + 2i\pi\theta)\psi_n \\ &\quad + (\mathrm{div}_y + 2i\pi\theta)\,(A(x,y)2i\pi e_k\psi_n) + \frac{\partial\lambda_n}{\partial\theta_k}(x,\theta)\psi_n,\end{aligned} \tag{2.2}$$

$$\begin{aligned}\mathbb{A}_n(x,\theta)\frac{\partial\psi_n}{\partial x_l} &= (\mathrm{div}_y + 2i\pi\theta)\left(\frac{\partial A}{\partial x_l}(x,\theta)(\nabla_y + 2i\pi\theta)\psi_n\right) \\ &\quad - \frac{\partial c}{\partial x_l}(x,y)\psi_n + \frac{\partial\lambda_n}{\partial x_l}(x,\theta)\psi_n.\end{aligned} \tag{2.3}$$

Similar formulas hold for second order derivatives. By integrating the cell equations for the second order derivatives against ψ_n, we obtain the following formulas that will be useful in what follows (their proofs are safely left to the reader).

LEMMA 2.1. *Assume that assumptions* H1 *and* H2 *hold true. Then the following equalities hold:*

$$\begin{aligned}&\int_{\mathbb{T}^N}\frac{1}{2\pi i}\left[A_{1,h}(\nabla_y + 2i\pi\theta^n)\frac{\partial\psi_n}{\partial\theta_k}\cdot(\nabla_y - 2i\pi\theta^n)\bar\psi_n + c_{1,h}\,\frac{\partial\psi_n}{\partial\theta_k}\bar\psi_n\right]dy \\ &\quad + \int_{\mathbb{T}^N}\left[A_{1,h}e_k\psi_n\cdot(\nabla_y - 2i\pi\theta^n)\bar\psi_n + Ae_k\frac{\partial\psi_n}{\partial x_h}\cdot(\nabla_y - 2i\pi\theta^n)\bar\psi_n\right]dy \\ &\quad - \int_{\mathbb{T}^N}\left[e_k\bar\psi_n A_{1,h}\cdot(\nabla_y + 2i\pi\theta^n)\psi_n + e_k\bar\psi_n A\cdot(\nabla_y + 2i\pi\theta^n)\frac{\partial\psi_n}{\partial x_h}\right]dy \\ &\quad - \frac{1}{2i\pi}\frac{\partial^2\lambda_n}{\partial x_h\partial\theta_k} = 0,\end{aligned} \tag{2.4}$$

$$
\begin{aligned}
(2.5)\qquad &\int_{\mathbb{T}^N}\left[A_{2,lh}(\nabla_y+2i\pi\theta^n)\psi_n\cdot(\nabla_y-2i\pi\theta^n)\bar\psi_n+\left(c_{2,lh}-\frac{\partial^2\lambda_n}{\partial x_l\partial x_h}\right)|\psi_n|^2\right]dy\\
&+\int_{\mathbb{T}^N}\left[A_{1,h}(\nabla_y+2i\pi\theta^n)\frac{\partial\psi_n}{\partial x_l}\cdot(\nabla_y-2i\pi\theta^n)\bar\psi_n+c_{1,h}\,\frac{\partial\psi_n}{\partial x_l}\bar\psi_n\right]dy\\
&+\int_{\mathbb{T}^N}\left[A_{1,l}(\nabla_y+2i\pi\theta^n)\frac{\partial\psi_n}{\partial x_h}\cdot(\nabla_y-2i\pi\theta^n)\bar\psi_n+c_{1,l}\,\frac{\partial\psi_n}{\partial x_h}\bar\psi_n\right]dy=0,
\end{aligned}
$$

(2.6)

$$
\begin{aligned}
&\int_{\mathbb{T}^N}\left[2i\pi e_kA(y)(\nabla_y+2i\pi\theta^n)\frac{\partial\psi_n}{\partial\theta_l}\bar\psi_n-\left(A(y)2i\pi e_k\frac{\partial\psi_n}{\partial\theta_l}\right)(\nabla_y-2i\pi\theta^n)\bar\psi_n\right]dy\\
&+\int_{\mathbb{T}^N}\left[2i\pi e_lA(y)(\nabla_y+2i\pi\theta^n)\frac{\partial\psi_n}{\partial\theta_k}\bar\psi_n-\left(A(y)2i\pi e_l\frac{\partial\psi_n}{\partial\theta_k}\right)(\nabla_y-2i\pi\theta^n)\bar\psi_n\right]dy\\
&-\int_{\mathbb{T}^N}\left[4\pi^2e_kA(y)e_l|\psi_n|^2+4\pi^2e_lA(y)e_k|\psi_n|^2\right]dy+\frac{\partial^2\lambda_n}{\partial\theta_l\partial\theta_k}(\theta^n)=0.
\end{aligned}
$$

We now give the variational formulations of the above cell problems, rescaled at size ε.

LEMMA 2.2. *Assume that assumptions* H1 *and* H2 *hold true, and let $\varphi(z)$ be a smooth compactly supported function defined from $\mathbb{R}^N$ into $\mathbb{C}$. Then the following equalities hold:*

$$
(2.7)\qquad \int_{\mathbb{R}^N}\left[A^\varepsilon(\nabla_y+2i\pi\theta^n)\psi_n^\varepsilon\cdot(\sqrt{\varepsilon}\nabla-2i\pi\theta^n)\bar\varphi(z)+(c^\varepsilon-\lambda_n^\varepsilon)\psi_n^\varepsilon\bar\varphi\right]dz=0,
$$

(2.8)

$$
\begin{aligned}
&\int_{\mathbb{R}^N}\left[A^\varepsilon(\nabla_y+2i\pi\theta^n)\frac{\partial\psi_n^\varepsilon}{\partial\theta_k^n}\cdot(\sqrt{\varepsilon}\nabla-2i\pi\theta^n)\bar\varphi+(c^\varepsilon-\lambda_n^\varepsilon)\frac{\partial\psi_n^\varepsilon}{\partial\theta_k^n}\bar\varphi\right]dz\\
&+\int_{\mathbb{R}^N}\left[-2\pi ie_k\cdot A^\varepsilon(\nabla_y+2i\pi\theta^n)\psi_n^\varepsilon\bar\varphi+A^\varepsilon\,2\pi ie_k\psi_n^\varepsilon\cdot(\sqrt{\varepsilon}\nabla-2i\pi\theta^n)\bar\varphi\right]dz=0,
\end{aligned}
$$

$$
\begin{aligned}
(2.9)\qquad &\int_{\mathbb{R}^N}\left[A^\varepsilon(\nabla_y+2i\pi\theta^n)\frac{\partial\psi_n^\varepsilon}{\partial x_h}\cdot(\sqrt{\varepsilon}\nabla-2i\pi\theta^n)\bar\varphi+(c^\varepsilon-\lambda_n^\varepsilon)\frac{\partial\psi_n^\varepsilon}{\partial x_h}\bar\varphi\right]dz\\
&+\int_{\mathbb{R}^N}\left[A_{1,h}^\varepsilon(\nabla_y+2i\pi\theta^n)\psi_n^\varepsilon\cdot(\sqrt{\varepsilon}\nabla-2i\pi\theta^n)\bar\varphi+c_{1,h}^\varepsilon\,\psi_n^\varepsilon\bar\varphi\right]dz=0.
\end{aligned}
$$

Proof. Formula (2.7) follows straightforwardly from (1.4), while (2.8)–(2.9) are consequences of (2.2)–(2.3). □

Finally, we recall the notion of two-scale convergence introduced in [1], [17] (which will be used with $\delta=\sqrt{\varepsilon}$).

PROPOSITION 2.3. *Let f_δ be a sequence uniformly bounded in $L^2(\mathbb{R}^N)$.*

(1) *There exists a subsequence, still denoted by f_δ, and a limit $f_0(x,y)\in L^2(\mathbb{R}^N\times\mathbb{T}^N)$ such that f_δ* two-scale converges *weakly to f_0 in the sense that*

$$
\lim_{\delta\to0}\int_{\mathbb{R}^N}f_\delta(x)\phi(x,x/\delta)\,dx=\int_{\mathbb{R}^N}\int_{\mathbb{T}^N}f_0(x,y)\phi(x,y)\,dx\,dy
$$

for all functions $\phi(x,y)\in L^2(\mathbb{R}^N;C(\mathbb{T}^N))$.

(2) *Assume further that f_δ two-scale converges weakly to f_0 and that*

$$\lim_{\delta\to 0}\|f_\delta\|_{L^2(\mathbb{R}^N)}=\|f_0\|_{L^2(\mathbb{R}^N\times\mathbb{T}^N)}.$$

Then f_δ is said to two-scale converge strongly *to its limit f_0 in the sense that, if f_0 is smooth enough, e.g., $f_0\in L^2(\mathbb{R}^N;C(\mathbb{T}^N))$, we have*

$$\lim_{\delta\to 0}\int_{\mathbb{R}^N}|f_\delta(x)-f_0(\,x,x/\delta\,)|^2\,dx=0.$$

(3) *Assume that $\delta\nabla f_\delta$ is also uniformly bounded in $L^2(\mathbb{R}^N)^N$. Then there exists a subsequence, still denoted by f_δ, and a limit $f_0(x,y)\in L^2(\mathbb{R}^N;H^1(\mathbb{T}^N))$ such that f_δ two-scale converges to $f_0(x,y)$ and $\delta\nabla f_\delta$ two-scale converges to $\nabla_y f_0(x,y)$.*

3. Main results. We begin by recalling the usual a priori estimates for the solution of the Schrödinger equation (1.1), which hold true since the coefficients are real. They are obtained by multiplying the equation successively by $\overline{u}_\varepsilon$ and $\frac{\partial\overline{u}_\varepsilon}{\partial t}$ and integrating by parts.

LEMMA 3.1. *There exists $C>0$ independent of ε such that the solution of* (1.1) *satisfies*

$$\begin{aligned}\|u_\varepsilon\|_{L^\infty(\mathbb{R}^+;L^2(\mathbb{R}^N))}&=\|u_\varepsilon^0\|_{L^2(\mathbb{R}^N)},\\ \varepsilon\|\nabla u_\varepsilon\|_{L^\infty(\mathbb{R}^+;L^2(\mathbb{R}^N))}&\le C\big(\|u_\varepsilon^0\|_{L^2(\mathbb{R}^N)}+\varepsilon\|\nabla u_\varepsilon^0\|_{L^2(\mathbb{R}^N)}\big).\end{aligned}$$

THEOREM 3.2. *Assume that assumptions* H1 *and* H2 *hold true and that the initial datum u_ε^0 is of the form* (1.3). *Then the solution of* (1.1) *can be written as*

$$u_\varepsilon(t,x)=e^{i\frac{\lambda_n t}{\varepsilon}}e^{2i\pi\frac{\theta^n\cdot x}{\varepsilon}}v_\varepsilon\Big(t,\frac{x-x^n}{\sqrt{\varepsilon}}\Big),\tag{3.1}$$

where $v_\varepsilon(t,z)$ two-scale converges strongly to $\psi_n(y)v(t,z)$; i.e.,

$$\lim_{\varepsilon\to 0}\int_{\mathbb{R}^N}\left|v_\varepsilon(t,z)-\psi_n\left(\frac{z}{\sqrt{\varepsilon}}\right)v(t,z)\right|^2dz=0,\tag{3.2}$$

uniformly on compact time intervals in $\mathbb{R}^+$, and v is the unique solution of the homogenized Schrödinger equation

$$\begin{cases}i\dfrac{\partial v}{\partial t}-\operatorname{div}(A^*\nabla v)+\operatorname{div}(vB^*z)+c^*v+vD^*z\cdot z=0 & \text{in } \mathbb{R}^N\times\mathbb{R}^+,\\ v(0,z)=v^0(z) & \text{in } \mathbb{R}^N,\end{cases}\tag{3.3}$$

where

$$A^*=\frac{1}{8\pi^2}\nabla_\theta\nabla_\theta\lambda_n(x^n,\theta^n),\quad B^*=\frac{1}{2i\pi}\nabla_\theta\nabla_x\lambda_n(x^n,\theta^n),\quad D^*=\frac{1}{2}\nabla_x\nabla_x\lambda_n(x^n,\theta^n),$$

and c^* is given by

$$\begin{aligned}c^*=\int_{\mathbb{T}^N}\Big[&A\,(\nabla_y+2i\pi\theta^n)\psi_n\cdot\frac{\partial\bar\psi_n}{\partial x_k}e_k\\ &-A(\nabla_y-2i\pi\theta^n)\frac{\partial\bar\psi_n}{\partial x_k}\cdot\psi_n\,e_k-A_{1,k}(\nabla_y-2i\pi\theta^n)\bar\psi_n\cdot\psi_n e_k\Big]dy.\end{aligned}$$

Remark 3.3. Notice that even if the tensor A^* might be noncoercive, the homogenized problem (3.3) is well posed. Indeed, the operator $\mathbb{A}^* : L^2(\mathbb{R}^N) \to L^2(\mathbb{R}^N)$ defined by

$$\mathbb{A}^*\varphi = -\mathrm{div}\,(A^*\nabla\varphi) + \mathrm{div}(\varphi B^* z) + c^*\varphi + \varphi D^* z \cdot z \tag{3.4}$$

is self-adjoint (see Proposition 3.4), and therefore by using semigroup theory (see, e.g., [6] or Chapter X in [20]), one can show that there exists a unique solution in $C(\mathbb{R}^+; L^2(\mathbb{R}^N))$, although it may not belong to $L^2(\mathbb{R}^+; H^1(\mathbb{R}^N))$.

The next result establishes the conservation of the L^2-norm for the solution v of the homogenized equation (3.3) and the self-adjointness of the operator $\mathbb{A}^*$.

PROPOSITION 3.4. *Let $v \in C(\mathbb{R}^+; L^2(\mathbb{R}^N))$ be solution to* (3.3). *Then*

$$\|v(t,\cdot)\|_{L^2(\mathbb{R}^N)} = \|v^0\|_{L^2(\mathbb{R}^N)} \quad \forall\, t \in \mathbb{R}^+. \tag{3.5}$$

Moreover, the operator $\mathbb{A}^*$ defined in (3.4) *is self-adjoint.*

Proof. We multiply (3.3) by $\bar{v}$ and take the imaginary part to obtain

$$\frac{1}{2}\frac{d}{dt}\int_{\mathbb{R}^N} |v|^2\,dz = \mathrm{Im}\left(\int_{\mathbb{R}^N} vB^* z\cdot\nabla\bar{v} - c^*|v|^2\,dz\right). \tag{3.6}$$

After integrating by parts one finds that the right-hand side of (3.6) equals

$$-\left(\frac{1}{2i}\mathrm{tr}\,B^* + \mathrm{Im}c^*\right)\int_{\mathbb{R}^N}|v|^2\,dz,$$

and therefore (3.5) is proved as soon as we show that

$$\frac{1}{2i}\mathrm{tr}\,B^* + \mathrm{Im}c^* = 0. \tag{3.7}$$

In order to do this we first rewrite the coefficients c^* and B^* in a suitable form. Denoting by $\langle\cdot,\cdot\rangle$ the Hermitian inner product in $L^2(\mathbb{T}^N)$ and using (2.2), we write

$$c^* = \frac{1}{2i\pi}\left\langle \mathbb{A}_n\frac{\partial\psi_n}{\partial\theta_k}, \frac{\partial\psi_n}{\partial x_k}\right\rangle - \int_{\mathbb{T}^N} A_{1,k}(\nabla_y - 2i\pi\theta^n)\bar{\psi}_n\cdot\psi_n e_k\,dy, \tag{3.8}$$

while by (2.2)–(2.4) it follows that

$$\begin{aligned}\frac{1}{2i\pi}\frac{\partial^2\lambda_n}{\partial x_h\partial\theta_k} =& -\frac{1}{2i\pi}\left\langle\overline{\mathbb{A}_n\frac{\partial\psi_n}{\partial\theta_k}, \frac{\partial\psi_n}{\partial x_h}}\right\rangle - \frac{1}{2i\pi}\left\langle\overline{\mathbb{A}_n\frac{\partial\psi_n}{\partial x_h}, \frac{\partial\psi_n}{\partial\theta_k}}\right\rangle \\ &+ 2i\mathrm{Im}\int_{\mathbb{T}^N} A_{1,h}(\nabla_y - 2i\pi\theta^n)\bar{\psi}_n\cdot\psi_n e_k\,dy.\end{aligned} \tag{3.9}$$

By formulas (3.8)–(3.9) it is readily seen that equality (3.7) holds true.

In order to prove the self-adjointness of the operator $\mathbb{A}^*$, one first checks that $\mathbb{A}^*$ is symmetric, which easily follows by (3.7) and the fact that $\overline{B}^* = -B^*$, and then observes that up to addition of a multiple of the identity the operator $\mathbb{A}^*$ is monotone (see, e.g., [7, Chapter VII]). ∎

In the next proposition we will denote by $\nabla\nabla\lambda_n$ the Hessian matrix of the function $\lambda_n(x,\theta)$ evaluated at the point (x^n,θ^n), namely,

$$\nabla\nabla\lambda_n = \begin{pmatrix}\nabla_x\nabla_x\lambda_n & \nabla_\theta\nabla_x\lambda_n\\ \nabla_\theta\nabla_x\lambda_n & \nabla_\theta\nabla_\theta\lambda_n\end{pmatrix}(x^n,\theta^n).$$

PROPOSITION 3.5. *Assume that the matrix $\nabla\nabla\lambda_n$ is positive definite. Then there exists an orthonormal basis $\{\varphi_n\}_{n\geq 1}$ of eigenfunctions of $\mathbb{A}^*$; moreover, for each n there exists a real constant $\gamma_n > 0$ such that*

$$e^{\gamma_n|z|}\varphi_n,\ e^{\gamma_n|z|}\nabla\varphi_n \in L^2(\mathbb{R}^N). \tag{3.10}$$

Proof. Up to shifting the spectrum of the operator $\mathbb{A}^*$, we may assume that $\mathrm{Re}(c^*) = 0$. In order to prove the existence of an orthonormal basis of eigenfunctions we introduce the inverse operator of $\mathbb{A}^*$, denoted by G^*,

$$\begin{aligned} G^* : L^2(\mathbb{R}^N) &\to L^2(\mathbb{R}^N), \\ f &\to \varphi \text{ unique solution in } H^1(\mathbb{R}^N) \text{ of} \\ \mathbb{A}^*\varphi &= f \quad \text{in } \mathbb{R}^N, \end{aligned} \tag{3.11}$$

and we show that G^* is compact. Indeed multiplication of (3.11) by $\bar\varphi$ yields

$$\int_{\mathbb{R}^N} [A^*\nabla\varphi\cdot\nabla\bar\varphi - iB^*\mathrm{Im}(\varphi z\cdot\nabla\bar\varphi) + D^*z\cdot z|\varphi|^2]\,dz = \int_{\mathbb{R}^N} f\bar\varphi\,dz. \tag{3.12}$$

Upon defining the $2N$-dimensional vector-valued function Φ,

$$\Phi := \begin{pmatrix} 2i\pi z\varphi \\ \nabla\varphi \end{pmatrix},$$

we rewrite (3.12) in agreement with this block notation:

$$\int_{\mathbb{R}^N} \frac{1}{8\pi^2}\nabla\nabla\lambda_n\Phi\cdot\overline{\Phi}\,dz = \int_{\mathbb{R}^N} f\bar\varphi\,dz.$$

By the positivity assumption on the matrix $\nabla\nabla\lambda_n$ it follows that there exists a positive constant c_0 such that

$$c_0\big(\|\nabla\varphi\|^2_{L^2(\mathbb{R}^N)} + \|z\varphi\|^2_{L^2(\mathbb{R}^N)}\big) \leq \|f\|_{L^2(\mathbb{R}^N)}\|\varphi\|_{L^2(\mathbb{R}^N)},$$

which implies by a standard argument

$$\|\varphi\|^2_{L^2(\mathbb{R}^N)} + \|\nabla\varphi\|^2_{L^2(\mathbb{R}^N)} + \|z\varphi\|^2_{L^2(\mathbb{R}^N)} \leq C\|f\|^2_{L^2(\mathbb{R}^N)},$$

from which we deduce the compactness of G^* in $L^2(\mathbb{R}^N)$-strong. Thus there exists an infinite countable number of eigenvalues for $\mathbb{A}^*$.

We are left to prove the exponential decay of the eigenfunctions (this fact is quite standard; see, e.g., [2]). Let φ_n be an eigenfunction, and let σ_n be the associated eigenvalue

$$\mathbb{A}^*\varphi_n = \sigma_n\varphi_n. \tag{3.13}$$

Let $R_0 > 0$ and $\rho \in C^\infty(\mathbb{R})$ be a real function such that $0 \leq \rho \leq 1$, $\rho(s) = 0$ for $s \leq R_0$, and $\rho(s) = 1$ for $s \geq R_0 + 1$, and for every positive integer k define $\rho_k \in C^\infty(\mathbb{R}^N)$ in the following way:

$$\rho_k(z) := \rho(|z| - k).$$

We now multiply (3.13) by $\bar{\varphi}_n \rho_k^2$ to get

$$\int_{\mathbb{R}^N} \rho_k^2 \left(A^* \nabla \varphi_n \cdot \nabla \bar{\varphi}_n - iB^* \mathrm{Im}(\varphi_n z \cdot \nabla \bar{\varphi}_n) + D^* z \cdot z |\varphi_n|^2 - \sigma_n |\varphi_n|^2 \right) dz = \int_{\mathbb{R}^N} \left(\rho_k |\varphi_n|^2 B^* z \cdot \nabla \rho_k - 2\rho_k \, \bar{\varphi}_n A^* \nabla \varphi_n \cdot \nabla \rho_k \right) dz. \tag{3.14}$$

Next remark that since the left-hand side of (3.14) is real, the right-hand side must also be real, and therefore it is equal to

$$\int_{\mathbb{R}^N} -2\rho_k \, \mathrm{Re}(\bar{\varphi}_n A^* \nabla \varphi_n) \cdot \nabla \rho_k \, dz. \tag{3.15}$$

Let B_k denote the ball of radius $R_0 + k$ and center $z = 0$, and observe that the support of $\nabla \rho_k$ is contained in $B_{k+1} \setminus B_k$. Then putting up together (3.14) and (3.15) and again using the positive definiteness of the matrix $\nabla \nabla \lambda_n$, we obtain for R_0 sufficiently large ($\sqrt{R_0} > \sigma_n$ does the job)

$$\|\varphi_n\|^2_{H^1(\mathbb{R}^N \setminus B_{k+1})} \leq c_1 \big(\|\varphi_n\|^2_{H^1(\mathbb{R}^N \setminus B_k)} - \|\varphi_n\|^2_{H^1(\mathbb{R}^N \setminus B_{k+1})} \big),$$

where c_1 is a positive constant independent of k. Thus we deduce that

$$\|\varphi_n\|^2_{H^1(\mathbb{R}^N \setminus B_{k+1})} \leq \left(\frac{c_1}{1 + c_1} \right)^k \|\varphi_n\|^2_{H^1(\mathbb{R}^N \setminus B_0)}. \tag{3.16}$$

Upon defining a positive constant $\gamma_0 > 0$ by

$$\left(\frac{c_1}{1 + c_1} \right)^k = e^{-2\gamma_0 (k + R_0)},$$

it is finally seen that (3.16) implies the estimate (3.10) for any exponent $0 < \gamma_n < \gamma_0$. □

Proof of Theorem 3.2. We rescale the space variable by introducing

$$z = \frac{x}{\sqrt{\varepsilon}},$$

and define the sequence v_ε by

$$v_\varepsilon(t, z) := e^{-i \frac{\lambda_n t}{\varepsilon}} e^{-2i\pi \frac{\theta^n \cdot x}{\varepsilon}} u_\varepsilon(t, x). \tag{3.17}$$

By the a priori estimates of Lemma 3.1 it follows that $v_\varepsilon(t, z)$ satisfies

$$\|v_\varepsilon\|_{L^\infty(\mathbb{R}^+; L^2(\mathbb{R}^N))} + \sqrt{\varepsilon} \|\nabla v_\varepsilon\|_{L^\infty(\mathbb{R}^+; L^2(\mathbb{R}^N))} \leq C,$$

and applying the compactness of two-scale convergence (see Proposition 2.3), up to a subsequence, there exists a limit $v^*(t, z, y) \in L^2(\mathbb{R}^+ \times \mathbb{R}^N; H^1(\mathbb{T}^N))$ such that v_ε and $\sqrt{\varepsilon} \nabla v_\varepsilon$ two-scale converge to v^* and $\nabla_y v^*$, respectively. Similarly, by definition of the initial data, $v_\varepsilon(0, z)$ two-scale converges to $\psi_n(y) v^0(z)$.

Although v_ε is the unknown which will pass to the limit in what follows, it is simpler to write an equation for another function, namely

$$w_\varepsilon(t, z) := e^{2i\pi \frac{\theta^n \cdot z}{\sqrt{\varepsilon}}} v_\varepsilon(t, z) = e^{-i \frac{\lambda_n t}{\varepsilon}} u_\varepsilon(t, x). \tag{3.18}$$

By (3.18) it follows that

$$\nabla w_\varepsilon = e^{2i\pi\frac{\theta^n\cdot z}{\sqrt{\varepsilon}}}\left(\nabla + 2i\pi\frac{\theta^n}{\sqrt{\varepsilon}}\right)v_\varepsilon, \tag{3.19}$$

and it can be checked that the new unknown w_ε solves the following equation:

(3.20)
$$\begin{cases} i\dfrac{\partial w_\varepsilon}{\partial t} - \operatorname{div}[A\left(\sqrt{\varepsilon}z, z/\sqrt{\varepsilon}\right)\nabla w_\varepsilon] + \dfrac{1}{\varepsilon}[c(\sqrt{\varepsilon}z, z/\sqrt{\varepsilon}) - \lambda_n]w_\varepsilon = 0 & \text{in } \mathbb{R}^N\times\mathbb{R}^+, \\ w_\varepsilon(0,z) = u_\varepsilon^0(\sqrt{\varepsilon}z) & \text{in } \mathbb{R}^N, \end{cases}$$

where the differential operators div and ∇ act with respect to the new variable z.

First step. We multiply (3.20) by the complex conjugate of

$$\varepsilon\phi\Big(t, z, \frac{z}{\sqrt{\varepsilon}}\Big)e^{2i\pi\frac{\theta^n\cdot z}{\sqrt{\varepsilon}}},$$

where $\phi(s,z,y)$ is a smooth test function defined on $\mathbb{R}^+\times\mathbb{R}^N\times\mathbb{T}^N$, with compact support in $\mathbb{R}^+\times\mathbb{R}^N$. Since this test function has compact support (fixed with respect to ε), the effect of the nonperiodic variable in the coefficients is negligible for sufficiently small ε. Therefore we can replace the value of each coefficient at $(\sqrt{\varepsilon}z, z/\sqrt{\varepsilon})$ by its Taylor expansion of order two about the point $(0, z/\sqrt{\varepsilon})$. Integrating by parts and using (3.18) and (3.19) yields

$$\begin{aligned} &-i\varepsilon\int_0^{+\infty}\!\!\int_{\mathbb{R}^N} v_\varepsilon\frac{\partial\bar\phi^\varepsilon}{\partial t}\,dt\,dz - i\varepsilon\int_{\mathbb{R}^N} v_\varepsilon(0,z)\bar\phi\Big(0,z,\frac{z}{\sqrt{\varepsilon}}\Big)\,dz \\ &\quad+\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\left[A^\varepsilon + A^\varepsilon_{1,h}\sqrt{\varepsilon}z_h + \frac{1}{2}A^\varepsilon_{2,lh}\,\varepsilon z_l z_h + o(\varepsilon)\right](\sqrt{\varepsilon}\nabla + 2i\pi\theta^n)v_\varepsilon \\ &\qquad\cdot(\sqrt{\varepsilon}\nabla - 2i\pi\theta^n)\bar\phi^\varepsilon\,dz\,dt \\ &\quad+\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\left[c^\varepsilon + c^\varepsilon_{1,h}\sqrt{\varepsilon}z_h + \frac{1}{2}c^\varepsilon_{2,lh}\,\varepsilon z_l z_h + o(\varepsilon) - \lambda_n\right]v_\varepsilon\bar\phi^\varepsilon\,dz\,dt = 0. \end{aligned}$$

Passing to the two-scale limit, we get the variational formulation of

$$-(\operatorname{div}_y + 2i\pi\theta^n)(A(y)(\nabla_y + 2i\pi\theta^n)v^*) + c(y)v^* = \lambda_n v^* \quad \text{in } \mathbb{T}^N.$$

The simplicity of λ_n implies that there exists a scalar function $v(t,z)\in L^2(\mathbb{R}^+\times\mathbb{R}^N)$ such that

$$v^*(t,z,y) = v(t,z)\psi_n(y). \tag{3.21}$$

Second step. We multiply (3.20) by the complex conjugate of

$$\Psi_\varepsilon(t,z) = e^{2i\pi\theta^n\cdot\frac{z}{\sqrt{\varepsilon}}}\left[\psi_n^\varepsilon\phi(t,z) + \sqrt{\varepsilon}\sum_{k=1}^N\left(\frac{1}{2i\pi}\frac{\partial\psi_n^\varepsilon}{\partial\theta_k}\frac{\partial\phi}{\partial z_k}(t,z) + z_k\frac{\partial\psi_n^\varepsilon}{\partial x_k}\phi(t,z)\right)\right],$$

where $\phi(t,z)$ is a smooth test function with compact support in $\mathbb{R}^+ \times \mathbb{R}^N$. We first look at those terms of the equation involving time derivatives:

(3.22)
$$\begin{aligned}
&\int_0^{+\infty}\!\!\int_{\mathbb{R}^N} i\frac{\partial w_\varepsilon}{\partial t}\bar{\Psi}_\varepsilon\,dt\,dz \\
&\quad= \int_0^{+\infty}\!\!\int_{\mathbb{R}^N} -iv_\varepsilon\left[\bar{\psi}_n^\varepsilon\frac{\partial\bar{\phi}}{\partial t}+\sqrt{\varepsilon}\sum_{k=1}^N\left(-\frac{1}{2i\pi}\frac{\partial\bar{\psi}_n^\varepsilon}{\partial\theta_k}\frac{\partial^2\bar{\phi}}{\partial t\partial z_k}+z_k\frac{\partial\bar{\psi}_n^\varepsilon}{\partial x_k}\frac{\partial\bar{\phi}}{\partial t}\right)\right]dt\,dz \\
&\qquad- i\int_{\mathbb{R}^N} v_\varepsilon(0,z)\left[\bar{\psi}_n^\varepsilon\bar{\phi}(0,z)+\sqrt{\varepsilon}\sum_{k=1}^N\left(-\frac{1}{2i\pi}\frac{\partial\bar{\psi}_n^\varepsilon}{\partial\theta_k}\frac{\partial\bar{\phi}}{\partial z_k}(0,z)+z_k\frac{\partial\bar{\psi}_n^\varepsilon}{\partial x_k}\bar{\phi}(0,z)\right)\right]dz.
\end{aligned}$$

Recalling the normalization $\int_{\mathbb{T}^N}|\psi_n|^2\,dy=1$, we find that the two-scale limit of the term on the left-hand side of (3.22) is given by the expression

$$-i\int_0^{+\infty}\!\!\int_{\mathbb{R}^N} v\frac{\partial\bar{\phi}}{\partial t}\,dz\,dt - i\int_{\mathbb{R}^N} v^0\bar{\phi}(0,z)\,dz. \tag{3.23}$$

We further decompose Ψ_ε as follows:

$$\Psi_\varepsilon=\Psi_\varepsilon^1+\Psi_\varepsilon^2\cdot z \quad\text{ with }\quad \Psi_\varepsilon^2=\sqrt{\varepsilon}e^{2i\pi\theta^n\cdot\frac{z}{\sqrt{\varepsilon}}}\sum_{k=1}^N\frac{\partial\psi_n^\varepsilon}{\partial x_k}\phi(t,z)e_k.$$

Getting rid of all terms multiplied by $o(\varepsilon)$ and taking into account (3.18) and (3.19), we next pass to the limit in the remaining terms of (3.20) multiplied by $\bar{\Psi}_\varepsilon$. The computation is similar to these in [4], but it involves new terms since ψ_n and its derivatives also depend on x. We first look at those terms which are of zero order with respect to z, namely,

(3.24)
$$\begin{aligned}
&\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\left[A^\varepsilon\nabla w_\varepsilon\cdot(\nabla\bar{\Psi}_\varepsilon^1+\bar{\Psi}_\varepsilon^2)+\frac{1}{\varepsilon}(c^\varepsilon-\lambda_n)w_\varepsilon\bar{\Psi}_\varepsilon^1\right]dz\,dt \\
&\quad=\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\left[\frac{1}{\varepsilon}A^\varepsilon\big(\sqrt{\varepsilon}\nabla+2i\pi\theta^n\big)v_\varepsilon\cdot(\nabla_y-2i\pi\theta^n)\bar{\psi}_n^\varepsilon\bar{\phi}+\frac{1}{\varepsilon}(c^\varepsilon-\lambda_n)\bar{\psi}_n^\varepsilon v_\varepsilon\bar{\phi}\right]dz\,dt \\
&\qquad-\frac{1}{2i\pi}\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\left[\frac{1}{\sqrt{\varepsilon}}A^\varepsilon\big(\sqrt{\varepsilon}\nabla+2i\pi\theta^n\big)v_\varepsilon\cdot(\nabla_y-2i\pi\theta^n)\frac{\partial\bar{\psi}_n^\varepsilon}{\partial\theta_k}\frac{\partial\bar{\phi}}{\partial z_k}\right. \\
&\qquad\qquad\left.+\frac{1}{\sqrt{\varepsilon}}(c^\varepsilon-\lambda_n)v_\varepsilon\frac{\partial\bar{\psi}_n^\varepsilon}{\partial\theta_k}\frac{\partial\bar{\phi}}{\partial z_k}\right]dz\,dt \\
&\qquad+\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\frac{1}{\sqrt{\varepsilon}}A^\varepsilon\big(\sqrt{\varepsilon}\nabla+2i\pi\theta^n\big)v_\varepsilon\cdot\bar{\psi}_n^\varepsilon\nabla\bar{\phi}\,dz\,dt \\
&\qquad+\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}-\frac{1}{2\pi i}A^\varepsilon\big(\sqrt{\varepsilon}\nabla+2i\pi\theta^n\big)v_\varepsilon\cdot\frac{\partial\bar{\psi}_n^\varepsilon}{\partial\theta_k}\nabla\frac{\partial\bar{\phi}}{\partial z_k}\,dz\,dt \\
&\qquad+\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}A^\varepsilon\big(\sqrt{\varepsilon}\nabla+2i\pi\theta^n\big)v_\varepsilon\cdot\frac{\partial\bar{\psi}_n^\varepsilon}{\partial x_k}\bar{\phi}\,e_k\,dz\,dt.
\end{aligned}$$

Using (2.7) with $\varphi=v_\varepsilon\bar{\phi}$ and (2.8) with $\varphi=v_\varepsilon\frac{\partial\bar{\phi}}{\partial z_k}$, we rewrite the first two integrals

in the right-hand side of (3.24) as follows:

$$\int_0^{+\infty}\!\!\int_{\mathbb{R}^N} -\frac{1}{\sqrt{\varepsilon}}A^\varepsilon(\nabla_y - 2i\pi\theta^n)\bar\psi_n^\varepsilon\cdot v_\varepsilon\nabla\bar\phi\,dz\,dt$$
$$+\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\left[\frac{1}{2i\pi}A^\varepsilon(\nabla_y - 2i\pi\theta^n)\frac{\partial\bar\psi_n^\varepsilon}{\partial\theta_k}\cdot v_\varepsilon\nabla\frac{\partial\bar\phi}{\partial z_k}+\frac{1}{\sqrt{\varepsilon}}A^\varepsilon e_k\cdot v_\varepsilon\frac{\partial\bar\phi}{\partial z_k}(\nabla_y - 2i\pi\theta^n)\bar\psi_n^\varepsilon\right.$$
$$\left.-\frac{1}{\sqrt{\varepsilon}}A^\varepsilon\bar\psi_n^\varepsilon e_k\cdot\big(\sqrt{\varepsilon}\nabla + 2i\pi\theta^n\big)\left(v_\varepsilon\frac{\partial\bar\phi}{\partial z_k}\right)\right]dz\,dt.$$

Combining the above terms with the other terms in (3.24) and passing to the two-scale limit in (3.24) yields

$$\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\int_{\mathbb{T}^N}\left[\frac{1}{2i\pi}A\psi_n(\nabla_y - 2i\pi\theta^n)\frac{\partial\bar\psi_n}{\partial\theta_k}\right.$$
$$\left.-\frac{1}{2i\pi}A\frac{\partial\bar\psi_n}{\partial\theta_k}(\nabla_y + 2i\pi\theta^n)\psi_n - A|\psi_n|^2e_k\right]\cdot v\nabla\frac{\partial\bar\phi}{\partial z_k}\,dy\,dz\,dt$$
$$+\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\int_{\mathbb{T}^N}A(\nabla_y + 2i\pi\theta^n)\psi_n\cdot\frac{\partial\bar\psi_n}{\partial x_k}v\bar\phi\,e_k\,dy\,dz\,dt. \tag{3.25}$$

By (2.6) it can be seen that the first integral of (3.25) equals

$$\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}A^*\nabla v\nabla\bar\phi\,dz\,dt. \tag{3.26}$$

We now focus on those terms which are linear in z:

(3.27)

$$\int_0^{+\infty}\int_{\mathbb{R}^N}\left[A^\varepsilon\nabla w_\varepsilon\cdot(\nabla\bar\Psi_\varepsilon^2 z)+\frac{1}{\varepsilon}(c^\varepsilon-\lambda_n)w_\varepsilon\bar\Psi_\varepsilon^2 z+A_{1,k}^\varepsilon\sqrt{\varepsilon}z_k\nabla w_\varepsilon\cdot(\nabla\bar\Psi_\varepsilon^1+\bar\Psi_\varepsilon^2)\right.$$
$$\left.+\frac{1}{\sqrt{\varepsilon}}c_{1,k}^\varepsilon z_k w_\varepsilon\bar\Psi_e^1\right]dz\,dt$$
$$=\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\left[\frac{1}{\sqrt{\varepsilon}}A^\varepsilon\big(\sqrt{\varepsilon}\nabla+2i\pi\theta^n\big)v_\varepsilon\cdot(\nabla_y-2i\pi\theta^n)\frac{\partial\bar\psi_n^\varepsilon}{\partial x_k}\,\bar\phi z_k\right.$$
$$\left.+\frac{1}{\sqrt{\varepsilon}}(c^\varepsilon-\lambda_n)v_\varepsilon\frac{\partial\bar\psi_n^\varepsilon}{\partial x_k}\,\bar\phi z_k\right]dz\,dt$$
$$+\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\left[\frac{1}{\sqrt{\varepsilon}}A_{1,k}^\varepsilon(\sqrt{\varepsilon}\nabla+2i\pi\theta^n)v_\varepsilon\cdot(\nabla_y-2i\pi\theta^n)\bar\psi_n^\varepsilon\,\bar\phi z_k+\frac{1}{\sqrt{\varepsilon}}c_{1,k}^\varepsilon v_\varepsilon\bar\psi_n^\varepsilon\,\bar\phi\,z_k\right]dz\,dt$$
$$+\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\left[A^\varepsilon(\sqrt{\varepsilon}\nabla+2i\pi\theta^n)v_\varepsilon\cdot\frac{\partial\bar\psi_n^\varepsilon}{\partial x_k}\nabla\bar\phi\,z_k\right.$$
$$\left.+A_{1,k}^\varepsilon(\sqrt{\varepsilon}\nabla+2i\pi\theta^n)v_\varepsilon\cdot\bar\psi_n^\varepsilon\nabla\bar\phi\,z_k\right]dz\,dt$$
$$-\frac{1}{2i\pi}\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\left[A_{1,h}^\varepsilon(\sqrt{\varepsilon}\nabla+2i\pi\theta^n)v_\varepsilon\cdot(\nabla_y-2i\pi\theta^n)\frac{\partial\bar\psi_n}{\partial\theta_k}\frac{\partial\bar\phi}{\partial z_k}\,z_h\right.$$
$$\left.+c_{1,h}^\varepsilon v_\varepsilon\frac{\partial\bar\psi_n}{\partial\theta_k}\frac{\partial\bar\phi}{\partial z_k}\,z_h\right]dz\,dt$$
$$+\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\left[\sqrt{\varepsilon}A_{1,h}^\varepsilon(\sqrt{\varepsilon}\nabla+2i\pi\theta^n)v_\varepsilon\cdot\left(-\frac{1}{2i\pi}\frac{\partial\bar\psi_n^\varepsilon}{\partial\theta_k}\nabla\frac{\partial\bar\phi}{\partial z_k}+\frac{\partial\bar\psi_n^\varepsilon}{\partial x_k}\bar\phi\,e_k\right)z_h\right]dz\,dt.$$

By (2.9) with $\varphi = v_\varepsilon \bar\phi z_k$, it can be seen that the sum of the first two integrals in the right-hand side of (3.27) gives

(3.28)
$$-\int_0^{+\infty}\int_{\mathbb{R}^N}\left(A^\varepsilon(\nabla_y - 2i\pi\theta^n)\frac{\partial\bar\psi_n^\varepsilon}{\partial x_k}\cdot v_\varepsilon\nabla(\bar\phi z_k) + A^\varepsilon_{1,k}(\nabla_y - 2i\pi\theta^n)\bar\psi_n^\varepsilon\cdot v_\varepsilon\nabla(\bar\phi z_k)\right)dz\,dt.$$

Therefore passing to the two-scale limit in (3.27), we find

$$\begin{aligned}
(3.29)\qquad &-\int_0^{+\infty}\int_{\mathbb{R}^N}\int_{\mathbb{T}^N}\Big[A(\nabla_y - 2i\pi\theta^n)\frac{\partial\bar\psi_n}{\partial x_k}\cdot v\psi_n\bar\phi\,e_k\\
&\qquad\qquad + A_{1,k}(\nabla_y - 2i\pi\theta^n)\bar\psi_n\cdot v\psi_n\bar\phi\,e_k\Big]\,dy\,dz\,dt\\
&-\int_0^{+\infty}\int_{\mathbb{R}^N}\int_{\mathbb{T}^N}\Big[A(\nabla_y - 2i\pi\theta^n)\frac{\partial\bar\psi_n}{\partial x_k}\cdot v\psi_n z_k\nabla\bar\phi\\
&\qquad\qquad + A_{1,k}(\nabla_y - 2i\pi\theta^n)\bar\psi_n\cdot v\psi_n z_k\nabla\bar\phi\Big]\,dy\,dz\,dt\\
&+\int_0^{+\infty}\int_{\mathbb{R}^N}\int_{\mathbb{T}^N}\Big[A(\nabla_y + 2i\pi\theta^n)\psi_n\cdot v\frac{\partial\bar\psi_n}{\partial x_k}z_k\nabla\bar\phi\\
&\qquad\qquad + A_{1,k}(\nabla_y + 2i\pi\theta^n)\psi_n\cdot v\bar\psi_n z_k\nabla\bar\phi\Big]\,dy\,dz\,dt\\
&-\frac{1}{2i\pi}\int_0^{+\infty}\int_{\mathbb{R}^N}\int_{\mathbb{T}^N}\Big[A_{1,h}(\nabla_y + 2i\pi\theta^n)\psi_n\cdot(\nabla_y - 2i\pi\theta^n)\frac{\partial\bar\psi_n}{\partial\theta_k}vz_h\frac{\partial\bar\phi}{\partial z_k}\\
&\qquad\qquad + c_{1,h}\psi_n\frac{\partial\bar\psi_n}{\partial\theta_k}vz_h\frac{\partial\bar\phi}{\partial z_k}\Big]\,dy\,dz\,dt.
\end{aligned}$$

By (2.4) it follows that the last integral in (3.29) is equal to

$$\begin{aligned}
(3.30)\qquad &\int_0^{+\infty}\int_{\mathbb{R}^N}\int_{\mathbb{T}^N}\Big[A_{1,h}\psi_n e_k\cdot(\nabla_y - 2i\pi\theta^n)\bar\psi_n\\
&\qquad\qquad + A\psi_n e_k\cdot(\nabla_y - 2i\pi\theta^n)\frac{\partial\bar\psi_n}{\partial x_h}\psi_n\Big]vz_h\frac{\partial\bar\phi}{\partial z_k}\;dy\,dz\,dt\\
&-\int_0^{+\infty}\int_{\mathbb{R}^N}\int_{\mathbb{T}^N}\Big[A_{1,h}\bar\psi_n e_k\cdot(\nabla_y + 2i\pi\theta^n)\psi_n\\
&\qquad\qquad + A\frac{\partial\bar\psi_n}{\partial x_h}e_k\cdot(\nabla_y + 2i\pi\theta^n)\psi_n\Big]vz_h\frac{\partial\bar\phi}{\partial z_k}\;dy\,dz\,dt\\
&-\int_0^{+\infty}\int_{\mathbb{R}^N}\int_{\mathbb{T}^N}\frac{1}{2i\pi}\frac{\partial^2\lambda_n}{\partial x_h\partial\theta_k}|\psi_n|^2vz_h\frac{\partial\bar\phi}{\partial z_k}\;dy\,dz\,dt.
\end{aligned}$$

Next notice that the first and the second lines of (3.30) cancel out with the second and the third lines of (3.29), respectively, and therefore (3.29) reduces to

$$\begin{aligned}
(3.31)\qquad &-\int_0^{+\infty}\int_{\mathbb{R}^N}\int_{\mathbb{T}^N}\Big[A(\nabla_y - 2i\pi\theta^n)\frac{\partial\bar\psi_n}{\partial x_k}\cdot v\psi_n\bar\phi\,e_k\\
&\qquad\qquad + A_{1,k}(\nabla_y - 2i\pi\theta^n)\bar\psi_n\cdot v\psi_n\bar\phi\,e_k\Big]\;dy\,dz\,dt\\
&-\int_0^{+\infty}\int_{\mathbb{R}^N}\frac{1}{2i\pi}\frac{\partial^2\lambda_n}{\partial x_h\partial\theta_k}v\frac{\partial\bar\phi}{\partial z_k}\,z_h\,dz\,dt.
\end{aligned}$$

Finally we consider all quadratic in z terms:

$$
\begin{aligned}
&\frac{1}{2}\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\left[A^\varepsilon_{2,lh}\,\varepsilon z_l z_h \nabla w_\varepsilon\cdot(\nabla\bar\Psi^1_\varepsilon+\bar\Psi^2_\varepsilon)+c^\varepsilon_{2,lh}z_l z_h w_\varepsilon\bar\Psi^1_e\right]dz\,dt\\
&\quad+\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\left[A^\varepsilon_{1,k}\sqrt{\varepsilon}z_k\nabla w_\varepsilon\cdot(z\nabla\bar\Psi^2_\varepsilon)+\frac{1}{\sqrt{\varepsilon}}c^\varepsilon_{1,k}z_k w_\varepsilon z\cdot\bar\Psi^2_\varepsilon\right]dz\,dt\\
&\quad=\frac{1}{2}\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}A^\varepsilon_{2,lh}\,\sqrt{\varepsilon}z_l z_h(\sqrt{\varepsilon}\nabla+2i\pi\theta^n)v_\varepsilon\cdot\left[\frac{1}{\sqrt{\varepsilon}}(\nabla_y-2i\pi\theta^n)\bar\psi^\varepsilon_n\bar\phi+\bar\psi^\varepsilon_n\nabla\bar\phi\right]dz\,dt\\
&\quad-\frac{1}{2}\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}A^\varepsilon_{2,lh}\,\sqrt{\varepsilon}z_l z_h(\sqrt{\varepsilon}\nabla+2i\pi\theta^n)v_\varepsilon\\
&\qquad\qquad\cdot\left[\frac{1}{2\pi i}\nabla_y\frac{\partial\bar\psi^\varepsilon_n}{\partial\theta_k}\frac{\partial\bar\phi}{\partial z_k}+\sqrt{\varepsilon}\left(\frac{1}{2i\pi}\frac{\partial\bar\psi^\varepsilon_n}{\partial\theta_k}\nabla\frac{\partial\bar\phi}{\partial z_k}+e_k\frac{\partial\bar\psi^\varepsilon_n}{\partial x_k}\bar\phi\right)\right]dz\,dt\\
&\quad+\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}A^\varepsilon_{1,h}\,z_h\Big(\sqrt{\varepsilon}\nabla+2i\pi\theta^n\Big)v_\varepsilon\cdot\left[z_k(\nabla_y-2i\pi\theta^n)\frac{\partial\bar\psi^\varepsilon_n}{\partial x_k}\bar\phi+\sqrt{\varepsilon}z_k\frac{\partial\bar\psi^\varepsilon_n}{\partial x_k}\nabla\bar\phi\right]dz\,dt\\
&\quad+\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\frac{1}{2}c^\varepsilon_{2,lh}z_l z_h v_\varepsilon\left(\bar\psi^\varepsilon_n\bar\phi-\sqrt{\varepsilon}\frac{1}{2i\pi}\frac{\partial\bar\psi^\varepsilon_n}{\partial\theta_k}\frac{\partial\bar\phi}{\partial z_k}\right)dz\,dt\\
&\quad+\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}c^\varepsilon_{1,h}z_h v_\varepsilon z_k\frac{\partial\bar\psi^\varepsilon_n}{\partial x_k}\bar\phi\,dz\,dt,
\end{aligned}
$$

which gives, on passing to the two-scale limit,

(3.32)

$$
\begin{aligned}
&\frac{1}{2}\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\int_{\mathbb{T}^N}\left[A_{2,lh}(\nabla_y+2i\pi\theta^n)\psi_n\cdot(\nabla_y-2i\pi\theta^n)\bar\psi_n+c_{2,lh}\psi_n\bar\psi_n\right]v\bar\phi\,z_l z_h\,dy\,dz\,dt\\
&+\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\int_{\mathbb{T}^N}\left[A_{1,h}(\nabla_y+2i\pi\theta^n)\psi_n\cdot(\nabla_y-2i\pi\theta^n)\frac{\partial\bar\psi_n}{\partial x_k}\right.\\
&\qquad\qquad\left.+\,c_{1,h}\psi_n\frac{\partial\bar\psi_n}{\partial x_k}\right]v\bar\phi\,z_h z_k\,dy\,dz\,dt.
\end{aligned}
$$

Now, using (2.5), we find that (3.32) reduces itself to

$$
\int_0^{+\infty}\!\!\int_{\mathbb{R}^N}\frac{1}{2}\frac{\partial^2\lambda_n}{\partial x_l\partial x_h}\,v\bar\phi\,z_l z_h\,dz\,dt. \tag{3.33}
$$

Summing up together (3.23), (3.25), (3.26), (3.31), and (3.33) yields the weak formulation of (3.3). By uniqueness of the solution of the homogenized problem (3.3), we deduce that the entire sequence v_ε two-scale converges weakly to $\psi_n(y)v(t,x)$.

It remains to prove the strong two-scale convergence of v_ε. By Lemma 3.1 we have

$$
\|v_\varepsilon(t)\|_{L^2(\mathbb{R}^N)}=\|u_\varepsilon(t)\|_{L^2(\mathbb{R}^N)}=\|u^0_\varepsilon\|_{L^2(\mathbb{R}^N)}\to\|\psi_n v^0\|_{L^2(\mathbb{R}^N\times\mathbb{T}^N)}=\|v^0\|_{L^2(\mathbb{R}^N)}
$$

by the normalization condition of ψ_n. From the conservation of energy of the homogenized equation (3.3) we have

$$
\|v(t)\|_{L^2(\mathbb{R}^N)}=\|v^0\|_{L^2(\mathbb{R}^N)},
$$

and thus we deduce the strong convergence from Proposition 2.3. □

Remark 3.6. As usual in periodic homogenization [1], [5], [15], the choice of the test function Ψ_ε in the proof of Theorem 3.2 is dictated by the formal two-scale asymptotic expansion that can be obtained for the solution w_ε of (3.20), namely,

$$w_\varepsilon(t,z) \approx e^{2i\pi\theta^n\cdot\frac{z}{\sqrt{\varepsilon}}}\left[\psi_n\left(\frac{z}{\sqrt{\varepsilon}}\right)v(t,z)+\sqrt{\varepsilon}\sum_{k=1}^{N}\left(\frac{1}{2i\pi}\frac{\partial\psi_n}{\partial\theta_k}\left(\frac{z}{\sqrt{\varepsilon}}\right)\frac{\partial v}{\partial z_k}(t,z)\right.\right.$$
$$\left.\left.+\,z_k\frac{\partial\psi_n}{\partial x_k}\left(\frac{z}{\sqrt{\varepsilon}}\right)v(t,z)\right)\right],$$

where v is the homogenized solution of (3.3). Actually the homogenized equation that one gets by the asymptotic expansion method is

$$i\frac{\partial v}{\partial t}-\operatorname{div}\left(A^*\nabla v\right)+B^*\nabla v\cdot z+\bar{c}^*v+vD^*z\cdot z=0, \tag{3.34}$$

which apparently differs from (3.3) by the following zero order term:

$$\left(\operatorname{tr}\left(\nabla_\theta\nabla_x\lambda_n\right)-4\pi\mathrm{Im}(c^*)\right)v.$$

By virtue of (3.7), the above term vanishes, so that formulas (3.34) and (3.3) are equivalent.

VISCOSITY SOLUTIONS OF INCREASING FLOWS OF SETS. APPLICATION OF THE HELE–SHAW PROBLEM FOR POWER-LAW FLUIDS*

PIERRE CARDALIAGUET† AND ELISABETH ROUY‡

Abstract. An existence and inclusion principle of viscosity solutions for increasing flows of sets is established. A typical example—the Hele–Shaw moving boundary problem for a power-law fluid—is discussed extensively.

Key words. moving boundary problems, power-law fluids, viscosity solutions

1. Introduction.

The aim of this work is to investigate a viscosity solutions approach for increasing flows of sets with velocity laws of the form

$$V_{t,x} = h(x, \Omega(t)) \qquad \forall x \in \partial\Omega(t), \tag{1}$$

where $V_{t,x}$ denotes the normal velocity to the expanding family of sets $(\Omega(t))$ and $h = h(x, \Omega(t))$ is some nonnegative velocity law depending nonlocally on the set $\Omega(t)$.

A typical example of such evolution is the Hele–Shaw approximation model of the injection of a power-law fluid between two closely situated plates. Since the fluid is supposed to be surrounded by another fluid with small viscosity, this is a one-phase moving boundary problem.

Let us denote by S the source of the injection, by $\Omega(t)$ the portion of space occupied by the fluid at time t, and by $\Sigma(t)$ the moving boundary. According to [2], [3], and [22], $\Sigma(t)$ evolves with a normal velocity $V_{t,x}$ given, at each point $x \in \Sigma(t)$, by the quasi-static equation

$$V_{t,x} = h(x, \Omega(t)), \qquad \text{where} \qquad h(x, \Omega(t)) = |\nabla u(t,x)|^{p-1}\,, \tag{2}$$

and where $u(t,x)$ satisfies at any time $t > 0$ the p-Laplace equation (with $p > 1$)

$$\begin{cases} -\text{div}\left(|\nabla u(t,x)|^{p-2}\nabla u(t,x)\right) = f(x) & \text{in } \Omega(t)\backslash S, \\ u(t,x) = 0 & \text{on } \Sigma(t), \\ u(t,x) = g(x) & \text{on } S \end{cases} \tag{3}$$

for some positive functions f and g.

In this paper, we define a notion of viscosity solutions for (1) and prove existence of such solutions. Our most important statement is the inclusion principle which holds for those generalized solutions. Our results are true under some structure condition on the velocity h that we detail further.

When $p = 2$, this example is the well-known Hele–Shaw problem. If the initial data are smooth, the evolution equation has a smooth short time solution (see [15]), but singularities generally appear in finite time. In order to define the solutions after the onset of singularities, various notions of generalized solutions have been introduced. For instance, the Hele–Shaw problem is reformulated in terms of variational inequalities via the Baiocchi transform in [14]; Hele–Shaw with surface tension is understood as the gradient flow of some functional in the space of measures in [17], while Kim proposes in [19] a definition of viscosity solutions for this problem. To the best of our knowledge, the case of $p \neq 2$ has never been studied up to now.

The main assumption we require on the velocity law $h = h(x, \Omega)$ is that it is nondecreasing with respect to Ω. Under this assumption, at least formally, the flow preserves inclusion. Namely, if $(\Omega_1(t))_t$ and $(\Omega_2(t))_t$ are two families of solutions, with $\Omega_1(0) \subset \Omega_2(0)$, then this inclusion is preserved for all time. The main result of the paper (Theorem 3.1) is that this "inclusion principle" holds true even for weak solutions when h satisfies some additional regularity conditions.

The inclusion principle is one of the key tools for constructing generalized solutions of front propagation problems: viscosity solutions in [16], [12] for the so-called level-set approach of mean curvature motion; related but more geometric viscosity solutions in [23], [4], [5]; and barrier solutions in [6], [7], and [8]. Viscosity solutions have also been introduced for the porous-medium equation [9] and for a free boundary problem motivated by combustion [20]. In [19] Kim proved the inclusion principle for the viscosity solutions of the Hele–Shaw problem when $p = 2$, $f \equiv 0$, and a particular source S. Let us underline that, although our work uses some ideas and techniques which have counterparts in [19], its point of view is completely different: the main unknown in [19] is the evolving function u (given by (3) for $p = 2$) while our unknown is the evolving family of sets. Both approaches should lead to different extensions. In that respect, we spent some effort in this paper to prove the inclusion principle for a wide class of (nonnegative) velocity laws h and not only for (2). This is completely new in this framework. Let us underline that the result could be extended to velocity laws (1) depending at each time t not only on the set $\Omega(t)$ but also on the evolving family $(\Omega(s))_{s \leq t}$.

For proving this inclusion principle we use several ideas introduced by the first author in [11] for simpler moving boundary problems. In particular, we use two basic ingredients of [11]: an equivalent definition of solutions (Proposition 2.7) and an Ilmanen interposition lemma [18]. However, proofs differ substantially. Indeed, in [11], the velocity is invariant by translation, a property which is no longer satisfied here.

We now briefly explain the organization of the paper. We first introduce the notion of viscosity solutions for the evolution equation (1) and investigate the main properties of the velocity defined by (2). Next, we state and prove the inclusion principle. Finally, we apply this inclusion principle to derive existence, uniqueness, and stability of solutions when the velocity is given by (2).

2. Definitions and preliminary results.

2.1. Definition of the solutions. Let us first fix some notations: throughout the paper $|\cdot|$ denotes the Euclidean norm (of $\mathbb{R}^N$ or $\mathbb{R}^{N+1}$, depending on the context). If K is a subset of $\mathbb{R}^N$ and $x \in \mathbb{R}^N$, then $d_K(x)$ denotes the usual distance from x to K: $d_K(x) = \inf_{y \in K} |y - x|$. Finally, we denote by $B(x, R)$ the open ball centered at x and of radius R.

We intend to study the evolution of compact hypersurfaces $\Sigma(t) = \partial\Omega(t)$ of $\mathbb{R}^N$, where $\Omega(t)$ is an open set, evolving with the following law:

$$\forall t \geq 0,\ x \in \Sigma(t),\ \ V_{t,x} = h(x, \Omega(t)), \tag{4}$$

where $V_{t,x}$ is the normal velocity of $\Omega(t)$ at the point x, and $h = h(x, \Omega)$ is defined for any $x \in \partial\Omega$ and for any open set Ω with $\mathcal{C}^{1,1}$ boundary which belongs to some class of sets $\mathcal{D}$. To fix the ideas we assume that the set $\mathcal{D}$ is of the form

$$\mathcal{D} = \big\{\Omega \subset \mathbb{R}^N \mid \Omega \text{ is open, bounded, and such that } S \subset\subset \Omega\big\}, \tag{5}$$

where S is some compact subset of $\mathbb{R}^N$. This suffices in most applications.

Our key assumption is that h is nonnegative and nondecreasing with respect to the set Ω: Namely

$$h(x, \Omega) \geq 0 \qquad \forall \Omega \in \mathcal{D} \text{ and } x \in \Omega, \tag{6}$$

and

$$\begin{gathered}\text{if } \Omega_1 \in \mathcal{D} \text{ and } \Omega_2 \in \mathcal{D},\ \Omega_1 \subset \Omega_2, \text{ and } x \in \Omega_1 \cap \partial\Omega_2,\\ \text{then } h(x, \Omega_1) \leq h(x, \Omega_2).\end{gathered} \tag{7}$$

We explain below that the assumptions above are typically satisfied for the Hele–Shaw problem described in the introduction.

From now on, we consider the graph of the evolving sets $\Omega(t)$. In order to underline the fact that it need not be smooth, we denote this graph by $\mathcal{K}$. Then $\mathcal{K}$ is a subset of $\mathbb{R}^+ \times \mathbb{R}^N$. Formally, with the notations above,

$$\mathcal{K} = \{(t, x) \text{ such that } x \in \Omega(t)\}.$$

The set $\mathcal{K}$ is our main unknown. We denote by (t, x) an element of such a set, where $t \in \mathbb{R}^+$ denotes the time and $x \in \mathbb{R}^N$ denotes the space. We set

$$\mathcal{K}(t) \ = \ \big\{x \in \mathbb{R}^N \mid (t, x) \in \mathcal{K}\big\}.$$

The closure of the set $\mathcal{K}$ in $\mathbb{R}^{N+1}$ is denoted by $\overline{\mathcal{K}}$. The closure of the complementary of $\mathcal{K}$ is denoted by $\widehat{\mathcal{K}}$:

$$\widehat{\mathcal{K}} = \overline{(\mathbb{R}^+ \times \mathbb{R}^N) \setminus \mathcal{K}}$$

and we set

$$\widehat{\mathcal{K}}(t) = \{x \in \mathbb{R}^N \mid (t, x) \in \widehat{\mathcal{K}}\}.$$

Let us go further into terminology: If $\mathcal{K}$ is a subset of $[0, +\infty) \times \mathbb{R}^N$, we say that

- $\mathcal{K}$ is a *tube* if $\forall T \geq 0$, $\overline{\mathcal{K}} \cap ([0, T] \times \mathbb{R}^N)$ is a compact subset of $\mathbb{R}^{N+1}$.
- $\mathcal{K}$ is *nondecreasing* if $\mathcal{K}(s) \subset \mathcal{K}(t)$ for any $0 \leq s \leq t$.
- $\mathcal{K}$ is *left lower semicontinuous* if

$$\forall t > 0,\ \forall x \in \mathcal{K}(t),\ \text{if } t_n \to t^-,\ \ \exists x_n \in \mathcal{K}(t_n) \text{ such that } x_n \to x.$$

- $\mathcal{K}_r$ is a *smooth tube* if $\mathcal{K}_r$ is closed in $I \times \mathbb{R}^N$ (where I is some open interval), has a nonempty interior, and $\partial\mathcal{K}_r \cap (I \times \mathbb{R}^N)$ is a $\mathcal{C}^{1,1}$ submanifold of $\mathbb{R}^{N+1}$, such that at any point $(t, x) \in \mathcal{K}_r$ the outward normal (ν_t, ν_x) to $\mathcal{K}_r$ at (t, x) satisfies $\nu_x \neq 0$. In this case the normal velocity $V^{\mathcal{K}_r}_{(t,x)}$ of $\mathcal{K}_r$ at the point $(t, x) \in \partial\mathcal{K}_r$ is given by $V^{\mathcal{K}_r}_{(t,x)} = -\nu_t/|\nu_x|$, where (ν_t, ν_x) is the outward normal to $\mathcal{K}_r$ at (t, x).

We use smooth tubes as "test sets." Namely, we say that the smooth tube $\mathcal{K}_r$ is *externally tangent* to a tube $\mathcal{K}$ at $(t,x) \in \partial\mathcal{K}$ if $\mathcal{K}_r$ is defined on some open interval I containing t, and if

$$\mathcal{K}(s) \subset \mathcal{K}_r(s) \quad \forall s \in I \quad \text{and} \quad (t,x) \in \partial\mathcal{K}_r.$$

In the same way, the smooth tube $\mathcal{K}_r$ is said to be *internally tangent* to $\mathcal{K}$ at $(t,x) \in \partial\widehat{\mathcal{K}}$ if $\mathcal{K}_r(s)$ is defined on some open interval I containing t, and if

$$\mathcal{K}_r(s) \subset \mathcal{K}(s) \quad \forall s \in I \quad \text{and} \quad (t,x) \in \partial\mathcal{K}_r.$$

We are now ready to define the viscosity solutions of (4). Recall that the set $\mathcal{D}$ is defined by (5).

DEFINITION 2.1. *Let $\mathcal{K}$ be a tube and $K_0 \subset \mathbb{R}^N$ be an initial position.*

1. *$\mathcal{K}$ is* a viscosity subsolution *to the front propagation problem* (4) *if $\mathcal{K}$ is nondecreasing, left lower semicontinuous, and $\mathcal{K}(0) \in \mathcal{D}$, and if for any smooth tube $\mathcal{K}_r$ externally tangent to $\mathcal{K}$ at some point (t,x), with $\mathcal{K}_r(t) \in \mathcal{D}$ and $t > 0$, we have*

$$V^{\mathcal{K}_r}_{(t,x)} \le h(x, \mathcal{K}_r(t)),$$

where $V^{\mathcal{K}_r}_{(t,x)}$ is the normal velocity of $\mathcal{K}_r$ at (t,x).

We say that $\mathcal{K}$ is a subsolution to the front propagation problem with initial position K_0 if $\mathcal{K}$ is a subsolution and if $\overline{\mathcal{K}}(0) \subset \overline{K_0}$.

2. *$\mathcal{K}$ is a* viscosity supersolution *to the front propagation problem if $\mathcal{K}$ is nondecreasing and $\mathcal{K}(0) \subset \mathcal{D}$, and if for any smooth tube $\mathcal{K}_r$ internally tangent to $\mathcal{K}$ at some point (t,x), with $\mathcal{K}_r(t) \in \mathcal{D}$ and $t > 0$, we have*

$$V^{\mathcal{K}_r}_{(t,x)} \ge h(x, \mathcal{K}_r(t)).$$

We say that $\mathcal{K}$ is a supersolution to the front propagation problem with initial position K_0 if $\mathcal{K}$ is a supersolution and if $\widehat{\mathcal{K}}(0) \subset \mathbb{R}^N \backslash \overline{K_0}$.

3. *Finally, we say that a tube $\mathcal{K}$ is a* viscosity solution *to the front propagation problem (with initial position K_0) if $\mathcal{K}$ is a sub- and a supersolution to the front propagation problem (with initial position K_0).*

Let us point out that, under assumptions (6) and (7), any classical solution is a viscosity solution. The previous definition has been introduced in [1] and was also used in [11].

2.2. Regularity properties of the velocity law for power-law fluids. We now investigate the main regularity properties of the velocity law for power-law fluids. This regularity shall be our guideline for the structure condition when investigating the inclusion principle. Let us recall that the velocity law h for power-law fluids is given by

$$h(x,\Omega) = |\nabla u(x)|^{p-1}, \tag{8}$$

where $u : \Omega \to \mathbb{R}$ is the solution of the following p.d.e.:

$$\text{(9)} \qquad \begin{cases} \text{(i)} & -\operatorname{div}(|\nabla u|^{p-2}\nabla u) = f & \text{in } \Omega\backslash S, \\ \text{(ii)} & u = g & \text{on } \partial S, \\ \text{(iii)} & u = 0 & \text{on } \partial\Omega, \end{cases}$$

and (i) is understood in the sense of distributions. The set S is a fixed source and we always assume above that $S \subset\subset \Omega(t)$. If $S = \emptyset$, then we omit condition (ii) in (9). We assume that

$$(10)\qquad \begin{cases} \text{(i)} & S \subset \mathbb{R}^N \text{ is bounded and equal to the closure of an open set with a } \mathcal{C}^2 \text{ boundary;} \\ \text{(ii)} & f : \mathbb{R}^N \to \mathbb{R} \text{ is continuous and bounded and either} \\ & \bullet f > 0 \text{ on } \mathbb{R}^N \text{ and } f \text{ is locally Lipschitz continuous, or} \\ & \bullet S \neq \emptyset \text{ and } f = 0 \text{ on } \mathbb{R}^N; \\ \text{(iii)} & g : S \to (0, +\infty) \text{ is } \mathcal{C}^{1,\beta} \text{ (for some } \beta \in (0,1)). \end{cases}$$

Remark 2.2. Following [21], $h(x, \Omega)$ is well defined as soon as Ω has a "smooth" boundary. More precisely, it is proved in [21] that, if Ω has a $\mathcal{C}^{1,\beta}$ boundary and if $S \subset\subset \Omega$, then the solution u is $\mathcal{C}^{1,\alpha}$ for some $\alpha \in (0, \beta)$. Moreover, the $\mathcal{C}^{1,\alpha}$ norm of u is bounded by a constant which depends only on $\|f\|_\infty$, $|g|_{1,\beta}$, p and on the $\mathcal{C}^{1,\beta}$ norm of the mapping which locally flattens the boundary of $\Omega \backslash S$.

Let us recall that $\mathcal{D}$ is defined in (5) by

$$\mathcal{D} = \{\Omega \subset \mathbb{R}^N,\ \Omega \text{ open bounded and } S \subset\subset \Omega\}.$$

The following proposition is a straightforward application of the maximum principle.

Proposition 2.3. *The function h defined by* (8) *is nonnegative and nondecreasing with respect to the inclusion, i.e., it satisfies* (6) *and* (7).

Proof of Proposition 2.3. The velocity law h is nonnegative by definition. In order to prove (7), let $\Omega_1 \in \mathcal{D}$ and $\Omega_2 \in \mathcal{D}$ be open with a $\mathcal{C}^{1,1}$ boundary, and assume that $\Omega_1 \subset \Omega_2$ and $x \in \Omega_1 \cap \partial\Omega_2$. Let u_1 and u_2 be solutions to (9) with Ω replaced by Ω_1 and Ω_2, respectively. Then u_1 and u_2 are nonnegative, and the maximum principle states that

$$u_1 \leq u_2 \qquad \text{in } \Omega_1.$$

Let ν be the outward unit normal to Ω_1 and Ω_2 at x. Since u_1 and u_2 vanish on $\partial\Omega_1$ and $\partial\Omega_2$, respectively, and are nonnegative inside Ω_1 and Ω_2, we have $\nabla u_1(x) = -|\nabla u_1(x)|\nu$ and $\nabla u_2(x) = -|\nabla u_2(x)|\nu$. Since moreover $u_1 \leq u_2$ in Ω_1, we get, for $h > 0$ small,

$$u_1(x - h\nu) = h|\nabla u_1(x)| + h\epsilon_1(h) \leq u_2(x - h\nu) = h|\nabla u_2(x)| + h\epsilon_2(h),$$

where $\epsilon_1(h) \to 0$ and $\epsilon_2(h) \to 0$ as $h \to 0^+$. Therefore, $|\nabla u_1(x)| \leq |\nabla u_2(x)|$, which proves (7). □

In order to describe the continuity properties of h, let us first recall that, if Ω is an open set with a $\mathcal{C}^{1,1}$ boundary, then the signed distance $\mathbf{d}$ defined by

$$\mathbf{d}(x) = \begin{cases} d_\Omega(x) & \text{if } x \notin \Omega, \\ -d_{\partial\Omega}(x) & \text{otherwise} \end{cases}$$

is $\mathcal{C}^{1,1}$ in a neighborhood of $\partial\Omega$. We say that a sequence Ω_n of sets with a $\mathcal{C}^{1,1}$ boundary converges to some set Ω with a $\mathcal{C}^{1,1}$ boundary if $\overline{\Omega_n}$ converges to $\overline{\Omega}$ and $\partial\Omega_n$ converges to $\partial\Omega$ for the Hausdorff distance, and if there is an open neighborhood $\mathcal{O}$ of $\partial\Omega$ such that, if $\mathbf{d}$ (resp., $\mathbf{d}_n$) is the signed distance to Ω (resp., to Ω_n), then $(\mathbf{d}_n)$ and $(\nabla\mathbf{d}_n)$ converge uniformly to $\mathbf{d}$ and $\nabla\mathbf{d}$ on $\mathcal{O}$ and if the L^∞ norms of $(\nabla^2\mathbf{d}_n)$ are uniformly essentially bounded on $\mathcal{O}$.

PROPOSITION 2.4. *The velocity h is sequentially continuous with respect to its arguments, i.e.,*

$$\begin{array}{c} \text{if } \Omega_n \text{ and } \Omega \in \mathcal{D} \text{ are open subsets of } \mathbb{R}^N \text{ with a } \mathcal{C}^{1,1} \text{ boundary,} \\ \text{such that } \Omega_n \text{ converge to } \Omega, \text{ if } x_n \in \partial\Omega_n \text{ converge to } x \in \partial\Omega, \\ \text{then } \lim_n h(x_n, \Omega_n) = h(x, \Omega). \end{array} \tag{11}$$

Proof of Proposition 2.4. Note that, if $\Omega \in \mathcal{D}$, then, for n large enough, the sets Ω_n also belongs to $\mathcal{D}$. The rest of the proposition is a straightforward application of the regularity results of [21] recalled in Remark 2.2. □

We now state some estimates on the variations of the mapping $v \to h(x+v, \Omega+v)$ for a set Ω with a smooth boundary and $x \in \partial\Omega$. The key point is that such an estimate has to be independent of the regularity of Ω. Here and below we set

$$S_r = \{x \in \mathbb{R}^N,\ d_S(x) \le r\}.$$

PROPOSITION 2.5. *Let $R > 0$ be some large constant and $r > 0$ be sufficiently small so that S_r has a $\mathcal{C}^2$ boundary. There is a constant $\lambda > 1/r$, such that, for any bounded set Ω with a $\mathcal{C}^{1,1}$ boundary such that $S_r \subset \Omega$ and $\Omega \subset B(0, R-r)$, for any $v \in \mathbb{R}^N$ with $|v| < 1/\lambda$ and any $x \in \partial\Omega$, we have*

$$\Omega + v \in \mathcal{D} \qquad \text{and} \qquad h(x+v, \Omega+v) \ge (1 - \lambda|v|)h(x, \Omega).$$

Proof of Proposition 2.5. We give the proof in the case $S \neq \emptyset$ and $f > 0$, the proof for the other cases being similar. Since $f > 0$ and f is Lipschitz continuous, we can find a constant $C_1 > 0$ such that

$$\forall x, y \in \mathbb{R}^N, \text{ with } |x|, |y| \le R,\ f(x) \ge f(y)(1 - C_1|x-y|). \tag{12}$$

Let u^+ and u_r^- be, respectively, the solutions of

$$\begin{cases} -\mathrm{div}(|\nabla u^+|^{p-2}\nabla u^+) = f & \text{in } B(0,R)\backslash S, \\ u^+ = g & \text{on } \partial S, \\ u^+ = 0 & \text{on } \partial B(0,R) \end{cases}$$

and

$$\begin{cases} -\mathrm{div}(|\nabla u_r^-|^{p-2}\nabla u_r^-) = f & \text{in } Int(S_r)\backslash S, \\ u_r^- = g & \text{on } \partial S, \\ u_r^- = 0 & \text{on } \partial S_r. \end{cases}$$

Since g is $\mathcal{C}^{1,\beta}$, and since S, S_r, and $B(0,R)$ have a $\mathcal{C}^2$ boundary, the functions u^+ and u_r^- belong to $\mathcal{C}^{1,\alpha}(\overline{\Omega})$ (for some $\alpha \in (0,\beta)$) and there is some constant $C_2 > 0$ such that u^+ and u_r^- are C_2-Lipschitz continuous, whence

$$\forall x \in S_r\backslash S\ ,\ u_r^-(x) \ge u^+(x) - 2C_2 d_S(x), \tag{13}$$

because $u^+ = u_r^-$ on ∂S. We now choose $\lambda = \max\{6C_2(p-1)/m, C_1, 2/r\}$, where $m = \min_{S_r\backslash S} u^+$. Note that m is positive.

Let $\Omega \subset \mathbb{R}^N$ be some open bounded set with a $\mathcal{C}^{1,1}$ boundary, such that $S_r \subset \Omega$ and $\Omega \subset B(0, R-r)$, and let $v \in \mathbb{R}^N$ with $|v| < 1/\lambda$. Let u be the solution of (9) with Ω and u_v be the solution of (9) with $\Omega+v$ in place of Ω. From the maximum principle,

we have $u_r^- \le u \le u^+$ and $u_r^- \le u_v \le u^+$ on $S_r\backslash S$ because $S_r \subset\subset \Omega \subset\subset B(0,R)$ and $S_r \subset\subset \Omega + v \subset\subset B(0,R)$ from the choice of $\lambda > 1/r$ and v.

Since $S_r \subset \Omega$ and $|v| < r$, we have $S \subset\subset \Omega$. We claim that

$$\frac{1}{(1-\lambda|v|)^{1/(p-1)}} u_v(x+v) \ge u(x) \qquad \forall x \in \Omega\backslash S_{|v|}. \tag{14}$$

For proving this claim, let us set $w(x) = \frac{1}{(1-\lambda|v|)^{1/(p-1)}} u_v(x+v)$ for $x \in \Omega\backslash S_{|v|}$ and let us show that

$$w \ge u \text{ on } \partial S_{|v|} \quad \text{and} \quad -\operatorname{div}(|\nabla w|^{p-2}\nabla w) \ge f \text{ on } \Omega\backslash S_{|v|}. \tag{15}$$

We have, for any $x \in \partial S_{|v|}$,

$$(1-\lambda|v|)^{1/(p-1)} w(x) = u_v(x+v) \ge u_r^-(x+v) \ge u_r^-(x) - C_2|v| \ge u^+(x) - 3C_2|v|$$

because u_r^- is C_2-Lipschitz continuous and thanks to (13). Thus,

$$(1-\lambda|v|)^{1/(p-1)} w(x) \ge u^+(x) - 3C_2|v| \ge (1-\lambda|v|)^{1/(p-1)} u^+(x)$$

because $u^+ \ge m$ in $S_r\backslash S$, $|v| < 1/\lambda$, and $\lambda \ge 6C_2(p-1)/m$. So we have proved that $w(x) \ge u^+(x) \ge u(x)$ for any $x \in \partial S_{|v|}$.

From the definition of C_1 in (12) and from the choice of λ, we have, for any $x \in \Omega\backslash S_{|v|}$,

$$-\operatorname{div}(|\nabla u_v(x+v)|^{p-2}\nabla u_v(x+v)) = f(x+v) \ge f(x)(1-\lambda|v|).$$

Thus,

$$-\operatorname{div}(|\nabla w(x)|^{p-2}\nabla w(x)) \ge f(x) \qquad \forall x \in \Omega\backslash S_{|v|}.$$

So (15) is proved, which entails (14). In particular, at any point $x \in \partial\Omega$, we have, since $w \ge u$ in $\Omega\backslash S_{|v|}$ and $w = u$ in $\partial\Omega$,

$$\begin{aligned} h(x,\Omega) &= |\nabla u(x)|^{p-1} \le |\nabla w(x)|^{p-1} \\ &= \frac{1}{1-\lambda|v|} |\nabla u_v(x+v)|^{p-1} = \frac{1}{1-\lambda|v|} h(x+v, \Omega+v). \end{aligned}$$ □

In order to prove the global existence of the solution, we need to control the growth of h, as shown in the following proposition.

PROPOSITION 2.6. *There are constants $r_0 > 0$ and $\sigma > 0$ such that*

$$\forall r \ge r_0,\ \forall x \in \partial B(0,r), \qquad h(x, B(0,r)) \le \sigma r. \tag{16}$$

Moreover, the constants r_0 and σ depend only on p, S, $\|f\|_\infty$, and $\|g\|_\infty$.

Proof of Proposition 2.6. Let us fix $r_0 > 0$ such that $S \subset\subset B(0, r_0/2^{\frac{(p-1)}{p}})$ and $\kappa = \max\{\frac{2\|g\|_\infty}{r_0^{p/(p-1)}}, \frac{\|f\|_\infty^{1/(p-1)}(p-1)}{N^{1/(p-1)}p}\}$. Let $r \ge r_0$ and u be the solution to

$$\begin{cases} -\operatorname{div}(|\nabla u|^{p-2}\nabla u) = f & \text{in } B(0,r)\backslash S, \\ u = g & \text{on } \partial S, \\ u = 0 & \text{on } \partial B(0,r). \end{cases}$$

We claim that $u \le w$ on $B(0,r)\backslash S$, where $w(x) = -\kappa|x|^{p/(p-1)} + \kappa r^{p/(p-1)}$ and $u = w$ on $\partial B(0,r)$. Indeed, $-\mathrm{div}(|\nabla w|^{p-2}\nabla w) = \kappa^{p-1}N[p/(p-1)]^{p-1} \ge f$ in $B(0,r)\backslash S$. Since $S \subset B(0, r_0/2^{(p-1)/p})$ we also have

$$\forall x \in \partial S, \quad w(x) \ge -\kappa \frac{r_0^{p/(p-1)}}{2} + \kappa r_0^{p/(p-1)} \ge \|g\|_\infty \ge g(x).$$

Finally, $u = w = 0$ on $\partial B(0,r)$ by construction. So $u \le w$ on $B(0,r)\backslash S$ and $u = w$ on $\partial B(0,r)$. This entails that $h(x, B(0,r)) = |\nabla u|^{p-1} \le |\nabla w|^{p-1} = \kappa^{p-1}[p/(p-1)]^{p-1} r$ for any $x \in \partial B(0,r)$, whence the result with $\sigma = \kappa^{p-1}[p/(p-1)]^{p-1}$. □

2.3. A preliminary result. We state here an equivalent definition for solutions of (4). This formulation is introduced in [11].

Let us set, for any compact set K, $x \in \partial K$, and $\nu \in \mathbb{R}^N$, $\nu \neq 0$,

$$h^\sharp(x, K, \nu) = \inf\{h(x, \Omega)\}, \tag{17}$$

where the infimum is taken over the sets $\Omega \in \mathcal{D}$ with a $\mathcal{C}^{1,1}$ boundary, such that $K \subset \overline{\Omega}$, $x \in \partial\Omega$ and ν is an outward normal to Ω at x. In the same way, we set

$$h^\flat(x, K, \nu) = \sup\{h(x, \Omega)\}, \tag{18}$$

where the supremum is taken over the sets $\Omega \in \mathcal{D}$ with a $\mathcal{C}^{1,1}$ boundary, such that $\Omega \subset K$, and $x \in \partial\Omega$ and ν is an outward normal to Ω at x.

We set $h^\sharp(x, K, \nu) = +\infty$ or $h^\flat(x, K, \nu) = -\infty$ if there is no set Ω with the required properties.

If A is a subset of some finite dimensional space and x belongs to A, we say that a vector ν is *a proximal normal* to A at x if the distance of $x + \nu$ to A is equal to $|\nu|$.

PROPOSITION 2.7. *Let $h = h(x, \Omega)$ satisfy* (6), (7), *and* (11). *Let $\mathcal{K}$ be a nondecreasing tube with $\mathcal{K}(0) \in \mathcal{D}$.*

Then $\mathcal{K}$ is a subsolution of the front propagation problem for h if and only if $\overline{\mathcal{K}}$ is left lower semicontinuous and if, for any $(t,x) \in \mathcal{K}$ with $t > 0$, for any proximal normal (ν_t, ν_x) to $\mathcal{K}$ at (t,x) such that $\nu_x \neq 0$, we have

$$-\frac{\nu_t}{|\nu_x|} \le h^\sharp(x, \mathcal{K}(t), \nu_x).$$

In the same way, the tube $\mathcal{K}$ is a supersolution of the front propagation problem for h if and only if, for any $(t,x) \in \widehat{\mathcal{K}}$ with $t > 0$, for any proximal normal (ν_t, ν_x) to $\widehat{\mathcal{K}}$ at (t,x) such that $\nu_x \neq 0$, we have

$$\frac{\nu_t}{|\nu_x|} \ge h^\flat(x, \mathcal{K}(t), -\nu_x).$$

Proof of Proposition 2.7. The proof is completely similar to that of Proposition 2.2 of [11]. The only difference is that our construction yields some approximation of the tube $\mathcal{K}$. We give only the main arguments for the case of subsolutions, the case of supersolutions being symmetrical. For any $\epsilon > 0$, let us set

$$\mathcal{K}^\epsilon = \{(t,x) \in \mathbb{R}^+ \times \mathbb{R}^N \mid \exists (s,y) \in \overline{\mathcal{K}} \text{ with } (t-s)^2 + |x-y|^2 \le \epsilon^2\}.$$

In [11], since h was translation invariant, $\mathcal{K}^\epsilon$ was also a subsolution of the front propagation problem. Instead here we have the following lemma.

LEMMA 2.8. *If $\mathcal{K}$ is a subsolution of the front propagation problem for h, then for any $\epsilon > 0$, $\mathcal{K}^\epsilon$ is a subsolution for h^ϵ on the time interval $[\epsilon, +\infty)$, where*

$$h^\epsilon(x, \Omega) = \sup_{|v| \le \epsilon} h(x + v, \Omega + v)$$

is defined for any bounded open set Ω with a $\mathcal{C}^{1,1}$ boundary such that $S_\epsilon \subset\subset \Omega$ and $x \in \partial K$ (where S is the compact set in the definition of $\mathcal{D}$; see (5)).

Once Lemma 2.8 is established, we can complete the proof of the proposition as in [11] by noticing that $h^\epsilon \to h$ as $\epsilon \to 0^+$, thanks to (11). □

Proof of Lemma 2.8. A straightforward application of the definition of $\mathcal{K}^\epsilon$ shows that $\mathcal{K}^\epsilon$ is nondecreasing and left lower semicontinuous. Moreover, since $S \subset\subset Int(\mathcal{K}(0)) \subset Int(\mathcal{K}(\epsilon))$, we have $S_\epsilon \subset\subset \mathcal{K}^\epsilon(\epsilon)$.

Let $\mathcal{K}_r$ be a smooth tube which is externally tangent to $\mathcal{K}^\epsilon$ at some point (t, x), with $t > \epsilon$. Since (t, x) belongs to the boundary of $\mathcal{K}^\epsilon$, there is some $(s, y) \in \overline{\mathcal{K}}$ such that

$$(t - s)^2 + |x - y|^2 = \epsilon^2.$$

Let us notice that, since $t > \epsilon$, we have $s > 0$. Now it is easy to check that the tube $\mathcal{K}_r - ((t, x) - (s, y))$ is externally tangent to $\mathcal{K}$ at (s, y). Since $\mathcal{K}$ is a subsolution, we have

$$V_{(s,y)}^{\mathcal{K}_r - ((t,x)-(s,y))} \le h(y, \mathcal{K}_r(t) - (x - y)),$$

where $V_{(s,y)}^{\mathcal{K}_r - ((t,x)-(s,y))}$ is the outward normal velocity of the smooth tube $\mathcal{K}_r - ((t, x) - (s, y))$ at (s, y). Using the definition of h^ϵ, this leads to

$$V_{(t,x)}^{\mathcal{K}_r} = V_{(s,y)}^{\mathcal{K}_r - ((t,x)-(s,y))} \le h(y, \mathcal{K}_r(t) - (x - y)) \le h^\epsilon(x, \mathcal{K}_r(t))$$

because $|x - y| \le \epsilon$. □

3. The inclusion principle. The aim of this part is to state and prove the inclusion principle for the generalized solutions of our problem.

3.1. Statement of the result. We need the following structure conditions on h:

1. $h = h(x, \Omega)$ is nonnegative and nondecreasing with respect to Ω (i.e., (6) and (7) hold),
2. h is sequentially continuous (i.e., satisfies (11)),
3. h has the following regularity property: For any $R > 0$ sufficiently large and $r > 0$ sufficiently small so that S_r has a $\mathcal{C}^2$ boundary, there are constants $\lambda > 1/r$ and $C > 0$, such that, for any compact set K with a $\mathcal{C}^{1,1}$ boundary such that $S_r \subset Int(K)$ and $K \subset B(0, R - r)$, for any $v \in \mathbb{R}^N$ with $|v| < 1/\lambda$ and any $x \in \partial K$, we have

$$(19)\quad K + v \in \mathcal{D} \qquad \text{and} \qquad h(x + v, K + v) \ge (1 - \lambda|v|)h(x, K) - C|v|.$$

Let us recall that, if $\mathcal{K}$ is a subset of $[0, +\infty) \times \mathbb{R}^N$, we set

$$\widehat{\mathcal{K}} = \overline{[0, +\infty) \times \mathbb{R}^N \backslash \mathcal{K}}.$$

THEOREM 3.1 (inclusion principle). *Under the above assumptions on h, let $\mathcal{K}_1$ be a subsolution of the front propagation problem on the interval $[0, T)$ for some $T > 0$*

and $\mathcal{K}_2$ be a supersolution on $[0,T)$. If $\mathcal{K}_1(t)$ and $\mathcal{K}_2(t)$ are nonempty for $t \in [0,T)$ and if

$$\overline{\mathcal{K}_1}(0) \cap \widehat{\mathcal{K}_2}(0) = \emptyset,$$

then

$$\forall t \in [0,T), \qquad \overline{\mathcal{K}_1}(t) \cap \widehat{\mathcal{K}_2}(t) = \emptyset.$$

Remarks.

1. Let K_1 and K_2 be bounded subsets of $\mathbb{R}^N$ such that $\overline{K_1} \subset Int(K_2)$. If $\mathcal{K}_1$ is a subsolution with initial condition K_1 and $\mathcal{K}_2$ is a supersolution with initial position K_2, then the assumption of the theorem holds: $\overline{\mathcal{K}_1}(0) \cap \widehat{\mathcal{K}_2}(0) = \emptyset$.
2. The statement $\overline{\mathcal{K}_1}(t) \cap \widehat{\mathcal{K}_2}(t) = \emptyset$ implies that $\overline{\mathcal{K}_1}(t) \subset Int(\mathcal{K}_2(t))$.
3. *Remarks on the structure conditions.* Thanks to Propositions 2.3, 2.4, and 2.5, our structure condition holds for the Hele–Shaw problem, where h is defined by (8). It is also satisfied for nonlocal evolution laws of the form

$$h(x,\Omega) = \int_\Omega \rho(x,y)dy,$$

where ρ is some nonnegative smooth and compactly supported function. This evolution equation is treated in particular in [10] and in [13] (the latter in the more general case of Neumann-type boundary conditions).

3.2. Proof of Theorem 3.1. From the definition of subsolutions, we can assume that $\mathcal{K}_1$ has a closed graph: $\overline{\mathcal{K}_1} = \mathcal{K}_1$. The main step of the proof amounts to showing that, for any $\gamma > 1$, such that $S_{\gamma-1} \subset Int(\mathcal{K}_1(0))$,

$$\forall t \in [0,T), \qquad \mathcal{K}_1(t) \cap \widehat{\mathcal{K}_2}(\gamma t) = \emptyset. \tag{20}$$

We explain how to obtain Theorem 3.1 from (20) at the very end of the proof.

For showing (20), we argue by contradiction, by assuming that there is some $\gamma > 1$ with $S_{\gamma-1} \subset Int(\mathcal{K}_1(0))$ and some $T^* \in [0,T)$ such that

$$\mathcal{K}_1(T^*) \cap \widehat{\mathcal{K}_2}(\gamma T^*) \neq \emptyset. \tag{21}$$

Since $\mathcal{K}_1(0) \cap \widehat{\mathcal{K}_2}(0) = \emptyset$, we have $T^* > 0$. We now introduce several notations: Let $R > 0$ be sufficiently large so that $\mathcal{K}_1(T) \subset B(0, R-(\gamma-1))$ and $\mathcal{K}_2(T) \subset B(0, R-(\gamma-1))$. We denote by λ and C the constants defined in (19) for R and $r := \gamma - 1 > 0$. Let us recall that $\lambda > 1/r$ and that, for any compact set K with a $\mathcal{C}^{1,1}$ boundary such that $S_r \subset Int(K)$ and $K \subset B(0, R-r)$, for any $v \in \mathbb{R}^N$ with $|v| < 1/\lambda$ and any $x \in \partial K$, we have

$$h(x+v, K+v) \geq (1-\lambda|v|)h(x,K) - C|v|. \tag{22}$$

We also set

$$\kappa = \gamma C + 1. \tag{23}$$

For any $\epsilon \in (0, \tau_0)$ and any $\sigma \in (0,1]$, we set

$$\mathcal{K}_1^{\epsilon,\sigma} = \left\{ (t,x) \in \mathbb{R}^+ \times \mathbb{R}^N \mid \exists (s,y) \in \mathcal{K}_1 \text{ with } \frac{1}{\sigma^2}(t-s)^2 + |x-y|^2 \leq \epsilon^2 e^{-2\kappa s} \right\} \tag{24}$$

and

$$\widehat{\mathcal{K}}_2^{\epsilon,\sigma} = \left\{ (t,x) \in \mathbb{R}^+ \times \mathbb{R}^N \mid \exists (s,y) \in \widehat{\mathcal{K}_2} \text{ with } \frac{1}{\sigma^2}(t-s)^2 + |x-y|^2 \le \epsilon^2 e^{-2\kappa s} \right\} \tag{25}$$

and

$$T^{\epsilon,\sigma,\gamma} = \min\{t \ge \epsilon \mid \mathcal{K}_1^{\epsilon,\sigma}(t) \cap \widehat{\mathcal{K}}_2^{\epsilon,\sigma}(\gamma t) \ne \emptyset\}.$$

Let us point out that

$$T^{\epsilon,\sigma,\gamma} \le T^* \tag{26}$$

because assumption (21) implies that $\mathcal{K}_1(T^*) \cap \widehat{\mathcal{K}_2}(\gamma T^*) \ne \emptyset$ and $\mathcal{K}_1(t) \subset \mathcal{K}_1^{\epsilon,\sigma}(t)$ and $\widehat{\mathcal{K}_2}(t) \subset \widehat{\mathcal{K}}_2^{\epsilon,\sigma}(t)$.

Let us define Π_1^σ and Π_2^σ, the projections on the sets $\mathcal{K}_1$ and $\widehat{\mathcal{K}_2}$, as follows: $\forall \sigma \in (0,1]$,

$$\Pi_1^\sigma(t,x) = \left\{ (s_1,y_1) \in \mathcal{K}_1 \;\middle|\; \begin{array}{l} \frac{1}{\sigma^2}(t-s_1)^2 + |x-y_1|^2 \\ = \inf_{(s,y)\in\mathcal{K}_1} \frac{1}{\sigma^2}(t-s)^2 + |x-y|^2 \end{array} \right\}$$

and

$$\Pi_2^\sigma(t,x) = \left\{ (s_2,y_2) \in \widehat{\mathcal{K}_2} \;\middle|\; \begin{array}{l} \frac{1}{\sigma^2}(t-s_2)^2 + |x-y_2|^2 \\ = \inf_{(s,y)\in\widehat{\mathcal{K}_2}} \frac{1}{\sigma^2}(t-s)^2 + |x-y|^2 \end{array} \right\}.$$

PROPOSITION 3.2. *One can choose ϵ and σ sufficiently small so that, for any $x \in \mathcal{K}_1^{\epsilon,\sigma}(T^{\epsilon,\sigma,\gamma}) \cap \widehat{\mathcal{K}}_2^{\epsilon,\sigma}(\gamma T^{\epsilon,\sigma,\gamma})$, for any $(s_1,y_1) \in \Pi_1^\sigma(T^{\epsilon,\sigma,\gamma},x)$, and any $(s_2,y_2) \in \Pi_2^\sigma(\gamma T^{\epsilon,\sigma,\gamma},x)$, we have $y_1 \ne x$, $y_2 \ne x$, $s_1 > 0$, and $s_2 > 0$.*

Proof of Proposition 3.2. Let us first prove that there is some positive ϵ_0 such that

$$\text{for any } \epsilon \in (0,\epsilon_0) \text{ and any } \sigma \in (0,1], \text{ we have } T^{\epsilon,\sigma,\gamma} > \epsilon. \tag{27}$$

Since $\mathcal{K}_1(0) \cap \widehat{\mathcal{K}_2}(0) = \emptyset$ and the sets $\mathcal{K}_1$ and $\widehat{\mathcal{K}_2}$ are closed in $\mathbb{R}^+ \times \mathbb{R}^N$, there is some $\tau > 0$ such that

$$\forall 0 \le s,t \le \tau,\ \mathcal{K}_1(s) \cap \widehat{\mathcal{K}_2}(t) = \emptyset.$$

Then set

$$\theta = \min\{|y_1 - y_2| \mid y_1 \in \mathcal{K}_1(s),\ y_2 \in \widehat{\mathcal{K}_2}(t),\ 0 \le s,t \le \tau\}; \tag{28}$$

then $\theta > 0$. Set $\epsilon_0 = \min\{\frac{\theta}{2}, \frac{\tau}{1+\gamma}\}$. We claim that, for any $\epsilon \in (0,\epsilon_0)$ and for any $\sigma \in (0,1]$, we have

$$\mathcal{K}_1^{\epsilon,\sigma}(\epsilon) \cap \widehat{\mathcal{K}}_2^{\epsilon,\sigma}(\gamma\epsilon) = \emptyset. \tag{29}$$

It is clearly enough to prove the result for $\sigma = 1$. We argue by contradiction. Suppose that, contrary to our claim, there is some $x \in \mathcal{K}_1^{\epsilon,1}(\epsilon) \cap \widehat{\mathcal{K}}_2^{\epsilon,1}(\gamma\epsilon)$. Then there is some $(s_1,y_1) \in \mathcal{K}_1$ and some $(s_2,y_2) \in \widehat{\mathcal{K}_2}$ such that

$$|(\epsilon,x) - (s_1,y_1)| \le \epsilon e^{-\kappa s_1} \text{ and } |(\gamma\epsilon,x) - (s_2,y_2)| \le \epsilon e^{-\kappa s_2}.$$

This implies, on the one hand, that $|y_1 - y_2| \le 2\epsilon < \theta$ and, on the other hand, that

$$0 \le s_1 \le 2\epsilon < \tau \text{ and } 0 \le s_2 \le (1+\gamma)\epsilon < \tau,$$

which is in contradiction with the definition of θ in (28). Thus, (29) is proved, which obviously implies that $T^{\epsilon,\sigma,\gamma} > \epsilon$, i.e., (27) holds.

From now on we fix $\epsilon \in (0, \epsilon_0)$. Let us first notice that $T^{\epsilon,\sigma,\gamma}$ is nondecreasing with respect to σ and is bounded by T^* thanks to (26). Let us set $\bar{t} = \lim_{\sigma \to 0^+} T^{\epsilon,\sigma,\gamma}$. Let us also define

$$\mathcal{K}_1^{\epsilon,0} = \{(t,x) \in \mathbb{R}^+ \times \mathbb{R}^N \mid \exists y \in \mathcal{K}_1(t) \text{ with } |x-y| \le \epsilon e^{-\kappa t}\}$$

and

$$\widehat{\mathcal{K}}_2^{\epsilon,0} = \{(t,x) \in \mathbb{R}^+ \times \mathbb{R}^N \mid \exists y \in \widehat{\mathcal{K}_2}(t) \text{ with } |x-y| \le \epsilon e^{-\kappa s}\}.$$

It is easily checked that

$$\bigcap_{\sigma \in (0,1]} \mathcal{K}_1^{\epsilon,\sigma} = \mathcal{K}_1^{\epsilon,0} \qquad \text{and} \qquad \bigcap_{\sigma \in (0,1]} \widehat{\mathcal{K}}_2^{\epsilon,\sigma} = \widehat{\mathcal{K}}_2^{\epsilon,0}. \tag{30}$$

Moreover, $\mathcal{K}_1^{\epsilon,0}$ and $\widehat{\mathcal{K}}_2^{\epsilon,0}$ are closed since $\mathcal{K}_1$ and $\widehat{\mathcal{K}_2}$ are. Hence, from the definition of $T^{\epsilon,\sigma,\gamma}$ and of $\bar{t}$, we have

$$\mathcal{K}_1^{\epsilon,0}(\bar{t}) \cap \widehat{\mathcal{K}}_2^{\epsilon,0}(\gamma\bar{t}) \neq \emptyset\ .$$

Let us also point out that, for any $t \in (0, \bar{t})$,

$$\mathcal{K}_1^{\epsilon,0}(t) \cap \widehat{\mathcal{K}}_2^{\epsilon,0}(\gamma t) = \emptyset \tag{31}$$

because, $\mathcal{K}_1^{\epsilon,0}(t) \subset \mathcal{K}_1^{\epsilon,\sigma}(t)$, $\widehat{\mathcal{K}}_2^{\epsilon,0}(\gamma t) \subset \widehat{\mathcal{K}}_2^{\epsilon,\sigma}(\gamma t)$, and $\mathcal{K}_1^{\epsilon,\sigma}(t) \cap \widehat{\mathcal{K}}_2^{\epsilon,\sigma}(\gamma t) = \emptyset$ as soon as $T^{\epsilon,\sigma,\gamma} > t$.

The next step of the proof amounts to showing that

$$\forall x \in \mathcal{K}_1^{\epsilon,0}(\bar{t}) \cap \widehat{\mathcal{K}}_2^{\epsilon,0}(\gamma\bar{t}),\ d_{\mathcal{K}_1(\bar{t})}(x) = \epsilon e^{-\kappa\bar{t}} \text{ and } d_{\widehat{\mathcal{K}_2}(\gamma\bar{t})}(x) = \epsilon e^{-\gamma\kappa\bar{t}}. \tag{32}$$

For proving this, we argue by contradiction, by assuming (for instance) that $d_{\mathcal{K}_1(\bar{t})}(x) < \epsilon e^{-\kappa\bar{t}}$. Then there is some $y_1 \in \mathcal{K}_1(\bar{t})$ such that $|y_1 - x| < \epsilon e^{-\kappa\bar{t}}$. Let also $y_2 \in \widehat{\mathcal{K}_2}(\gamma\bar{t})$ be such that $|y_2 - x| \le \epsilon e^{-\gamma\kappa\bar{t}}$. Since $\mathcal{K}_1$ is a subsolution, it is left lower semicontinuous. Thus, for any sequence $t_k \to \bar{t}^-$, there is some $y_1^k \to y_1$ with $y_1^k \in \mathcal{K}_1(t_k)$. In the same way, since $\mathcal{K}_2$ is a supersolution, $\widehat{\mathcal{K}_2}$ is left lower semicontinuous, and there is a sequence $y_2^k \in \widehat{\mathcal{K}_2}(\gamma t_k)$ which converges to y_2. Since $|y_1 - y_2| < \epsilon e^{-\kappa\bar{t}} + e^{-\gamma\kappa\bar{t}}$, for k large enough we still have $|y_1^k - y_2^k| \le \epsilon(e^{-\kappa t_k} + e^{-\gamma\kappa\bar{t}})$. Then it is easy to find some point $x_k \in [y_1^k, y_2^k]$ such that $|y_1^k - x_k| \le \epsilon e^{-\kappa t_k}$ and $|y_2^k - x_k| \le \epsilon e^{-\gamma\kappa\bar{t}}$, i.e., $x_k \in \mathcal{K}_1^{\epsilon,0}(t_k) \cap \widehat{\mathcal{K}}_2^{\epsilon,0}(\gamma t_k)$. This is in contradiction with (31). Hence, claim (32) is proved.

From this claim we deduce that, for $\epsilon' = \epsilon/4 < \epsilon$, we have

$$\mathcal{K}_1^{\epsilon',0}(\bar{t}) \cap \widehat{\mathcal{K}}_2^{\epsilon,0}(\gamma\bar{t}) = \emptyset.$$

Hence, there is some $\sigma_0 \in (0,1)$ such that

$$\mathcal{K}_1^{\epsilon',\sigma_0}(\bar{t}) \cap \widehat{\mathcal{K}_2}^{\epsilon,\sigma_0}(\gamma\bar{t}) = \emptyset$$

because of (30). Since $\mathcal{K}_1^{\epsilon',\sigma_0}$ and $\widehat{\mathcal{K}_2}^{\epsilon,\sigma_0}$ are closed and since $T^{\epsilon,\sigma,\gamma} \to \bar{t}$ as $\sigma \to 0^+$, we have, for any $\sigma > 0$ sufficiently small, that

$$\mathcal{K}_1^{\epsilon',\sigma_0}(T^{\epsilon,\sigma,\gamma}) \cap \widehat{\mathcal{K}_2}^{\epsilon,\sigma_0}(\gamma T^{\epsilon,\sigma,\gamma}) = \emptyset. \tag{33}$$

Let $x \in \mathcal{K}_1^{\epsilon,\sigma}(T^{\epsilon,\sigma,\gamma}) \cap \widehat{\mathcal{K}}_2^{\epsilon,\sigma}(T^{\epsilon,\sigma,\gamma})$. Then, from (33), $x \notin \mathcal{K}_1^{\epsilon',\sigma_0}(T^{\epsilon,\sigma,\gamma})$. Therefore, if $(s_1, y_1) \in \Pi_1^{\sigma}(T^{\epsilon,\sigma,\gamma}, x)$, we have

$$\frac{1}{\sigma^2}(T^{\epsilon,\sigma,\gamma} - s_1)^2 + |x - y_1|^2 \le \epsilon^2 e^{-2\kappa s_1}$$

and

$$\frac{1}{\sigma_0^2}(T^{\epsilon,\sigma,\gamma} - s_1)^2 + |x - y_1|^2 > (\epsilon')^2 e^{-2\kappa s_1}.$$

This implies that $x \neq y_1$ as soon as $\sigma < \sigma_0/2$ (recall that $\epsilon' = \epsilon/4$). So we have proved that, for any σ sufficiently small, for any $x \in \mathcal{K}_1^{\epsilon,\sigma}(T^{\epsilon,\sigma,\gamma}) \cap \widehat{\mathcal{K}}_2^{\epsilon,\sigma}(T^{\epsilon,\sigma,\gamma})$, and for any $(s_1, y_1) \in \Pi_1^{\sigma}(T^{\epsilon,\sigma,\gamma}, x)$, we have $x \neq y_1$. We can prove in the same way that, for any $(s_2, y_2) \in \Pi_2^{\sigma}(T^{\epsilon,\sigma,\gamma}, x)$, we have $y_2 \neq x$.

Finally, s_1 is positive because the inequality $\frac{1}{\sigma^2}(T^{\epsilon,\sigma,\gamma} - s_1)^2 + |x - y_1|^2 \le \epsilon e^{-2\kappa s_1}$ implies that

$$s_1 \ge T^{\epsilon,\sigma,\gamma} - \sigma\epsilon e^{-\kappa s_1},$$

where the right-hand side is positive thanks to (27). We can prove in the same way that $s_2 > 0$. □

From now on we fix $\epsilon > 0$ and $\sigma > 0$ as in Proposition 3.2 and also sufficiently small so that

$$\epsilon < 1/(2\lambda) \quad \text{and} \quad \frac{1}{(1 - 2\lambda\epsilon)} \le \gamma. \tag{34}$$

Recall that λ is defined at the beginning of the proof. Let x, (s_1, y_1), and (s_2, y_2) be as in Proposition 3.2. For simplicity, we set $t^* = T^{\epsilon,\sigma,\gamma}$.

Let us define, for any two sets U and V, the minimal distance $d(U, V)$ between U and V by

$$d(U, V) = \inf_{x \in U, y \in V} |x - y|.$$

PROPOSITION 3.3. *The point (t^*, x) belongs to the boundary of $\mathcal{K}_1^{\epsilon,\sigma}$, while the point $(\gamma t^*, x)$ belongs to the boundary of $\widehat{\mathcal{K}}_2^{\epsilon,\sigma}$. Moreover,*

$$d(\mathcal{K}_1(s_1), \widehat{\mathcal{K}_2}(s_2)) = |y_1 - y_2|.$$

In particular, $y_1 \in \partial\mathcal{K}_1(s_1)$, $y_2 \in \partial\widehat{\mathcal{K}_2}(s_2)$, and

$$\frac{1}{\sigma^2}(t^* - s_1)^2 + |x - y_1|^2 = \epsilon^2 e^{-2\kappa s_1} \quad \textit{and} \quad \frac{1}{\sigma^2}(\gamma t^* - s_2)^2 + |x - y_2|^2 = \epsilon^2 e^{-\kappa s_2}.$$

Proof of Proposition 3.3. For proving that the point (t^*, x) belongs to the boundary of $\mathcal{K}_1^{\epsilon,\sigma}$, we argue by contradiction by assuming that (t^*, x) belongs to the interior of $\mathcal{K}_1^{\epsilon,\sigma}$. Then, since $\widehat{\mathcal{K}_2}$ is left lower semicontinuous, so is $\widehat{\mathcal{K}}_2^{\epsilon,\sigma}$. Thus, for any

$t_n \to (t^*)^-$, there is some $x_n \to x$ such that $(\gamma t_n, x_n) \in \widehat{\mathcal{K}}_2^{\epsilon,\sigma}$. But, since (t^*, x) belongs to the interior of $\mathcal{K}_1^{\epsilon,\sigma}$, (t_n, x_n) also belongs to $\mathcal{K}_1^{\epsilon,\sigma}$ for n large enough. This is in contradiction with the definition of t^*.

Symmetric arguments show that the point $(\gamma t^*, x)$ belongs to the boundary of $\widehat{\mathcal{K}}_2^{\epsilon,\sigma}$. Let us now prove that $d(\mathcal{K}_1(s_1), \widehat{\mathcal{K}_2}(s_2)) = |y_1 - y_2|$. Since $y_1 \in \mathcal{K}_1(s_1)$ and $y_2 \in \widehat{\mathcal{K}_2}(s_2)$, we have $d(\mathcal{K}_1(s_1), \widehat{\mathcal{K}_2}(s_2)) \le |y_1 - y_2|$. Assume for a while that $d(\mathcal{K}_1(s_1), \widehat{\mathcal{K}_2}(s_2)) < |y_1 - y_2|$. Let $z_1 \in \mathcal{K}_1(s_1)$ and $z_2 \in \widehat{\mathcal{K}_2}(s_2)$ be such that $|z_1 - z_2| < |y_1 - y_2|$. One can choose $\rho \in (0,1)$ such that, if $x_\rho = \rho z_1 + (1-\rho) z_2$, then

$$|z_1 - x_\rho| < |y_1 - x| \text{ and } |z_2 - x_\rho| < |y_2 - x|$$

because $|z_1 - z_2| < |y_1 - y_2| \le |y_1 - x| + |y_2 - x|$. Therefore,

$$\frac{1}{\sigma^2}(t^* - s_1)^2 + |z_1 - x_\rho|^2 < \frac{1}{\sigma^2}(t^* - s_1)^2 + |y_1 - x|^2 \ \le \epsilon^2 e^{-2\kappa s_1}$$

and

$$\frac{1}{\sigma^2}(\gamma t^* - s_2)^2 + |z_2 - x_\rho|^2 < \frac{1}{\sigma^2}(\gamma t^* - s_2)^2 + |y_2 - x|^2 \ \le \epsilon^2.$$

So one can find some $t < t^*$ such that

$$\frac{1}{\sigma^2}(t - s_1)^2 + |z_1 - x_\rho|^2 \le \epsilon^2 e^{-2\kappa s_1} \text{ and } \frac{1}{\sigma^2}(\gamma t - s_2)^2 + |z_2 - x_\rho|^2 \le \epsilon^2,$$

which means that $x_\rho \in \mathcal{K}_1^{\epsilon,\sigma}(t) \cap \widehat{\mathcal{K}}_2^{\epsilon,\sigma}(\gamma t)$ and $t < t^*$. This is in contradiction with the definition of t^*. Therefore, we have proved that $d(\mathcal{K}_1(s_1), \widehat{\mathcal{K}_2}(s_2)) = |y_1 - y_2|$. □

Let us introduce two new notations:

$$(\nu_t^1, \nu_x^1) = (t^* - s_1 - \epsilon^2 \sigma^2 \kappa e^{-2\kappa s_1}, \sigma^2 (x - y_1)) \tag{35}$$

and

$$(\nu_t^2, \nu_x^2) = (\gamma t^* - s_2 - \epsilon^2 \sigma^2 \kappa e^{-2\kappa s_2}, \sigma^2 (x - y_2)). \tag{36}$$

PROPOSITION 3.4. *There is some $\rho > 0$ such that the vectors $\rho(\nu_t^1, \nu_x^1)$ and $\rho(\nu_t^2, \nu_x^2)$ are proximal normals to $\mathcal{K}_1$ at (s_1, y_1) and to $\widehat{\mathcal{K}_2}$ at (s_2, y_2), respectively.*

Proof of Proposition 3.4. We do the proof only for (ν_t^1, ν_x^1), with the proof for (ν_t^2, ν_x^2) being similar. From Proposition 3.3, (t^*, x) belongs to the boundary of $\mathcal{K}_1^{\epsilon,\sigma}$. Therefore, the set $\mathcal{K}_1$ is contained in the set

$$E = \left\{ (s, y) \in \mathbb{R}^+ \times \mathbb{R}^N, \ \frac{1}{\sigma^2}(t^* - s)^2 + |y - x|^2 \ge \epsilon^2 e^{-2\kappa s} \right\}.$$

From Proposition 3.3 again, the point (s_1, y_1) belongs to the boundary of E. Moreover, E has a smooth boundary in a neighborhood of (s_1, y_1) because the gradient of the map $(s, y) \to \epsilon^2 e^{-2\kappa s} - \frac{1}{\sigma^2}(t^* - s)^2 - |y - x|^2$ at (s_1, y_1) is

$$\left(-2\epsilon^2 \kappa e^{-2\kappa s_1} - \frac{2(s_1 - t^*)}{\sigma^2}, -2(y_1 - x) \right) = \frac{2}{\sigma^2}(\nu_t^1, \nu_x^1),$$

which does not vanish since $y_2 \neq x$ from Proposition 3.2. Therefore, this gradient is, up to some small positive multiplicative constant, a proximal normal to E at the

point (s_1, y_1). Since $\mathcal{K}_1 \subset E$ with $(s_1, y_1) \in \mathcal{K}_1$, it is also a proximal normal to $\mathcal{K}_1$ at (s_1, y_1). Since (ν_t^1, ν_x^1) is proportional to this gradient, the proof is complete. □

Since $\mathcal{K}_1$ is a subsolution and $\rho(\nu_t^1, \nu_x^1)$ is a proximal normal to $\mathcal{K}_1$ at (s_1, y_1), with $\nu_x^1 \neq 0$ and $s_1 > 0$ thanks to Proposition 3.2, Proposition 2.7 states that

$$-\frac{\nu_t^1}{|\nu_x^1|} = -\frac{t^* - s_1 - \epsilon^2\sigma^2\kappa e^{-2\kappa s_1}}{\sigma^2|x - y_1|} \leq h^\sharp(y_1, \mathcal{K}_1(s_1), \nu_x^1). \tag{37}$$

Similarly, since $\mathcal{K}_2$ is a supersolution and $\rho(\nu_t^2, \nu_x^2)$ is a proximal normal to $\widehat{\mathcal{K}_1}$ at (s_2, y_2), with $\nu_x^2 \neq 0$ and $s_2 > 0$, Proposition 2.7 also states that

$$\frac{\nu_t^2}{|\nu_x^2|} = \frac{\gamma t^* - s_2 - \epsilon^2\sigma^2\kappa e^{-2\kappa s_2}}{\sigma^2|x - y_2|} \geq h^\flat(y_2, \mathcal{K}_2(s_2), -\nu_x^2). \tag{38}$$

To proceed, we need some relations between (ν_t^1, ν_x^1) and (ν_t^2, ν_x^2).

PROPOSITION 3.5. *There is some $\theta > 0$ such that*

$$\nu_x^2 = -\theta\nu_x^1 \quad \textit{and} \quad \nu_t^2 + \epsilon^2\sigma^2\kappa e^{-2\kappa s_2} \leq -\theta(\nu_t^1 + \epsilon^2\sigma^2\kappa e^{-2\kappa s_1})/\gamma.$$

Proof of Proposition 3.5. From the definition of t^*, we know that

$$\forall \epsilon < s < t^*,\ \mathcal{K}_1^{\epsilon,\sigma}(s) \cap \widehat{\mathcal{K}}_2^{\epsilon,\sigma}(\gamma s) = \emptyset.$$

Let us now notice that the sets B_1 and B_2 defined by

$$B_1 = \left\{(s, y) \mid \frac{1}{\sigma^2}(s - s_1)^2 + |y - y_1|^2 \leq \epsilon^2 e^{-2\kappa s_1}\right\}$$

and

$$B_2 = \left\{(s, y) \mid \frac{1}{\sigma^2}(\gamma s - s_2)^2 + |y - y_2|^2 \leq \epsilon^2 e^{-2\kappa s_2}\right\}$$

are, respectively, subsets of $\mathcal{K}_1^{\epsilon,\sigma}$ and of the graph of $\widehat{\mathcal{K}}_2^{\epsilon,\sigma}(\gamma\cdot)$. Therefore,

$$\forall (s, y), \text{ if } (s, y) \in B_1 \cap B_2, \text{ then } s \geq t^*. \tag{39}$$

From Proposition 3.3, the point (t^*, x) belongs to $\partial\mathcal{K}_1^{\epsilon,\sigma}$. Hence, $(t^*, x) \in \partial B_1$. In the same way, $(\gamma t^*, x)$ belongs to $\partial\widehat{\mathcal{K}}_2^{\epsilon,\sigma}$, and so $(t^*, x) \in \partial B_2$. Therefore, (39) states that (t^*, x) is a minimum in the following problem: Minimize s over the points $(s, y) \in B_1 \cap B_2$.

The necessary conditions for this problem (for the extended Lagrangian) state that there is some $(\lambda_1, \lambda_2, \lambda_3) \in \mathbb{R}_+^3$ with $(\lambda_1, \lambda_2, \lambda_3) \neq 0$, such that

$$\lambda_1\left(\frac{1}{\sigma^2}(t^* - s_1), x - y_1\right) + \lambda_2\left(\frac{\gamma}{\sigma^2}(\gamma t^* - s_2), x - y_2\right) + \lambda_3(1, 0) = 0.$$

Using the notations (35) and (36), this is equivalent to

$$\lambda_1(\nu_t^1 + \epsilon^2\sigma^2\kappa e^{-2\kappa s_1}, \sigma^2\nu_x^1) + \lambda_2(\gamma\nu_t^2 + \epsilon^2\sigma^2\kappa e^{-2\kappa s_2}, \sigma^2\nu_x^2) + \lambda_3(\sigma^2, 0) = 0.$$

Since, from Proposition 3.2, $\nu_x^1 \neq 0$ and $\nu_x^2 \neq 0$, we have $\lambda_1 \neq 0$ and $\lambda_2 \neq 0$. Setting

$\theta = \lambda_1/\lambda_2 > 0$, we get $\nu_x^2 = -\theta\nu_x^1$ and

$$\begin{aligned}\nu_t^2 + \epsilon^2\sigma^2\kappa e^{-2\kappa s_2} &= -\frac{1}{\gamma}\left(\theta(\nu_t^1 + \epsilon^2\sigma^2\kappa e^{-2\kappa s_1}) + \frac{\lambda_3\sigma^2}{\lambda_2}\right)\\ &\le -\frac{\theta}{\gamma}(\nu_t^1 + \epsilon^2\sigma^2\kappa e^{-2\kappa s_1}). \qquad \square\end{aligned}$$

Let us now recall the Ilmanen interposition lemma [18], which plays a crucial role in our study.

LEMMA 3.6 (Ilmanen). *Let A and B be two disjoint subsets of $\mathbb{R}^N$, A being compact and B closed. Then there exists some closed set K_r with a $\mathcal{C}^{1,1}$ boundary, such that*

$$A \subset K_r \quad \textit{and} \quad K_r \cap B = \emptyset$$

and

$$d(A,B) = d(A,\partial K_r) + d(\partial K_r, B).$$

Let us apply Lemma 3.6 to $A = \mathcal{K}_1(s_1)$ and $B = \widehat{\mathcal{K}_2}(s_2)$: There exists some set K_r with a $\mathcal{C}^{1,1}$ boundary such that

$$\mathcal{K}_1(s_1) \subset K_r \quad \text{and} \quad \widehat{\mathcal{K}_2}(s_2) \cap K_r = \emptyset$$

and

$$d(\mathcal{K}_1(s_1), \widehat{\mathcal{K}_2}(s_2)) = d(\partial K_r, \mathcal{K}_1(s_1)) + d(\partial K_r, \widehat{\mathcal{K}_2}(s_2)).$$

Let us set $\rho_1 = d(\partial K_r, \mathcal{K}_1(s_1))$, $\rho_2 = d(\partial K_r, \widehat{\mathcal{K}_2}(s_2))$, and $w = \frac{y_2 - y_1}{|y_2 - y_1|}$. Let us notice that $\nu_x^1 = |\nu_x^1| w$, while $\nu_x^2 = -|\nu_x^2| w$.

PROPOSITION 3.7. *The smooth set $K_r - \rho_1 w$ is externally tangent to $\mathcal{K}_1(s_1)$ at the point y_1 and w is a normal to $K_r - \rho_1 w$ at y_1; namely,*

$$\mathcal{K}_1(s_1) \subset (K_r - \rho_1 w) \quad \textit{and} \quad y_1 \in \partial\mathcal{K}_1(s_1) \cap \partial(K_r - \rho_1 w). \tag{40}$$

In the same way, the smooth set $K_r + \rho_2 w$ is internally tangent to $\mathcal{K}_2(s_2)$ at the point y_2 and w is a normal to $K_r + \rho_2 w$ at y_2:

$$K_r + \rho_2 w \subset \widehat{\mathcal{K}_2}(s_2) \quad \textit{and} \quad y_2 \in \partial(K_r + \rho_2 w) \cap \partial\widehat{\mathcal{K}_2}(s_2). \tag{41}$$

Finally, $S \subset Int(K_r - \rho_1 w)$ and $S \subset Int(K_r + \rho_2 w)$.

Remark. The proposition states that we can estimate the quantity $h^\sharp(y_1, \mathcal{K}_1(s_1), \nu_x^1)$ by using the set $K_r - \rho_1 w$, while the estimate of $h^\flat(y_2, \mathcal{K}_2(s_2), -\nu_x^2)$ can be done by using $K_r + \rho_2 w$.

Proof of Proposition 3.7. For proving (40) and (41), let us first notice that the fact that $\mathcal{K}_1(s_1) \subset K_r$ and $d(\partial K_r, \mathcal{K}_1(s_1)) = \rho_1$ implies the inclusion $\mathcal{K}_1(s_1) \subset (K_r - \rho_1 w)$. In the same way, since $\widehat{\mathcal{K}_2}(s_2) \cap K_r = \emptyset$ and $d(\partial K_r, \widehat{\mathcal{K}_2}(s_2)) = \rho_2$, we have $K_r + \rho_2 w \subset \widehat{\mathcal{K}_2}(s_2)$.

Let $z = y_2 - \rho_2 w = y_1 + \rho_1 w$. We have $d_{\mathcal{K}_1(s_1)}(z) \le |y_1 - z| = \rho_1$ and $d_{\widehat{\mathcal{K}_2}(s_2)}(z) \le |y_2 - z| = \rho_2$. Since, from Propositions 3.3, $d(\mathcal{K}_1(s_1), \widehat{\mathcal{K}_2}(s_2)) = |y_2 - y_1|$, this leads to

$$\rho_1 + \rho_2 \ge d_{\mathcal{K}_1(s_1)}(z) + d_{\widehat{\mathcal{K}_2}(s_2)}(z) \ge d(\mathcal{K}_1(s_1), \widehat{\mathcal{K}_2}(s_2)) = |y_1 - y_2| = \rho_1 + \rho_2.$$

So

$$d_{\mathcal{K}_1(s_1)}(z) = |y_1 - z| = \rho_1 \quad \text{and} \quad d_{\widehat{\mathcal{K}_2}(s_2)}(z)|y_2 - z| = \rho_2. \tag{42}$$

This implies that $z \notin \mathbb{R}^N \backslash K_r$, since $d(\partial K_r, \mathcal{K}_1(s_1)) = \rho_1$, and that $z \notin Int(K_r)$, since $d(\partial K_r, \widehat{\mathcal{K}_2}(s_2)) = \rho_2$. Thus, $z \in \partial K_r$, and $y_1 = z - \rho_1 w \in \partial \mathcal{K}_1(s_1) \cap \partial(K_r - \rho_1 w)$, while $y_2 = z + \rho_2 w \in \partial(K_r + \rho_2 w) \cap \partial\widehat{\mathcal{K}_2}(s_2)$. Moreover, using (42) again shows that $d(\mathcal{K}_1(s_1), \partial K_r) = |y_1 - z|$. Since K_r is smooth, this implies that w (which is proportional to $z - y_1$) is a normal to K_r at z; so (40) and (41) hold.

We now prove that $S \subset Int(K_r - \rho_1 w)$ and $S \subset Int(K_r + \rho_2 w)$. Indeed, since $S \subset Int(\mathcal{K}_1(0))$ and since $\mathcal{K}_1(0) \subset (K_r - \rho_1 w)$, we have that $S \subset Int(K_r - \rho_1 w)$. Moreover, since, from the choice of ϵ in (34),

$$S_{2\epsilon} \subset Int(S_{\gamma-1}) \subset Int(\mathcal{K}_1(0)) \subset Int(\mathcal{K}_1(s_1)) \subset Int(K_r - \rho_1 w)$$

and since $\rho_1 + \rho_2 = |y_2 - y_1| \leq 2\epsilon$, we have that $S \subset Int(K_r + \rho_2 w)$. □

We are now ready to prove the main step.

Proof of (20). Considering now the definition of $h^\sharp$ (introduced before Proposition 2.7), (40) and the facts that $\nu_x^1 = |\nu_x^1| w$ is a normal to K_r at y_1 and that $S \subset Int(K_r - \rho_1 w)$ yield

$$h^\sharp(y_1, \mathcal{K}_1(s_1), \nu_x^1) \leq h(y_1, K_r - \rho_1 w). \tag{43}$$

In the same way, (41) together with the facts that $\nu_x^2 = -|\nu_x^2| w$ is a normal to K_r at y_2 and that $S \subset Int(K_r + \rho_2 w)$ implies that

$$h^\flat(y_2, \mathcal{K}_2(s_2), -\nu_x^2) \geq h(y_2, K_r + \rho_2 w). \tag{44}$$

Using inequality (22), we can estimate the difference between the right-hand sides of the two previous inequalities:

$$h(y_2, K_r + \rho_2 w) \geq (1 - 2\lambda\epsilon) h(y_1, K_r - \rho_1 w) - C\epsilon(e^{-\kappa s_1} + e^{-\kappa s_2}) \tag{45}$$

because $y_2 - y_1 = (\rho_1 + \rho_2) w$ and $|y_1 - y_2| \leq \epsilon(e^{-\kappa s_1} + e^{-\kappa s_2}) \leq 2\epsilon$ with $\epsilon < 1/(2\lambda)$. Let us also note that

$$|\nu_x^j| \leq \sigma^2 |y_j - x| \leq \sigma^2 \epsilon e^{-\kappa s_j} \qquad \text{for } j = 1, 2. \tag{46}$$

Using Proposition 3.5 and putting together (37), (38), and the three previous inequalities finally gives

$$\begin{aligned}
h(y_2, K_r + \rho_2 w) \;&\leq\; h^\flat(y_2, \mathcal{K}_2(s_2), -\nu_x^2) \quad \text{(from (44))} \\
&\leq \frac{\nu_t^2}{|\nu_x^2|} \quad \text{(from (38))} \\
&\leq -\frac{\nu_t^1 + \epsilon^2\sigma^2\kappa e^{-2\kappa s_1}}{\gamma|\nu_x^1|} - \frac{\epsilon^2\sigma^2\kappa e^{-2\kappa s_2}}{|\nu_x^2|} \quad \text{(from Proposition 3.5)} \\
&\leq \frac{1}{\gamma} h^\sharp(y_1, \mathcal{K}_1(s_1), \nu_x^1) - \frac{\epsilon^2\sigma^2\kappa e^{-2\kappa s_1}}{\gamma|\nu_x^1|} - \epsilon\kappa e^{-\kappa s_2} \quad \text{(from (37) and (46))} \\
&\leq \frac{1}{\gamma} h(y_1, K_r - \rho_1 w) - \frac{\epsilon\kappa(e^{-\kappa s_1} + e^{-\kappa s_2})}{\gamma} \quad \text{(from (43) and (46) again)} \\
&\leq \frac{1}{\gamma(1 - 2\lambda\epsilon)} h(y_2, K_r + \rho_2 w) + \frac{C\epsilon(e^{-\kappa s_1} + e^{-\kappa s_2})}{\gamma(1 - 2\lambda\epsilon)} - \frac{\epsilon\kappa(e^{-\kappa s_1} + e^{-\kappa s_2})}{\gamma}
\end{aligned}$$

using (45) in the last inequality. This is impossible since $h(y_2, K_r + \rho_2 w) \geq 0$ and we have chosen $\gamma \geq 1/(1-2\lambda\epsilon)$ in (34) and $\kappa = C\gamma + 1$ in (23). So we have found a contradiction, and (20) is proved. □

Proof of Theorem 3.1. Since from our assumption $\overline{\mathcal{K}_1}(0) \cap \widehat{\mathcal{K}_2}(0) = \emptyset$, and since $\overline{\mathcal{K}_1}$ and $\widehat{\mathcal{K}_2}$ have a closed graph, one can find $\tau > 0$ such that

$$\forall t \in [0, \tau], \qquad \overline{\mathcal{K}_1}(t) \cap \widehat{\mathcal{K}_2}(0) = \emptyset.$$

Let us now apply (20) to the subsolution $\mathcal{K}_{1,\delta}$ and the supersolution $\mathcal{K}_2$, where

$$\delta \in (0, \tau) \qquad \forall t \geq 0, \qquad \mathcal{K}_{1,\delta}(t) = \overline{\mathcal{K}_1}(t + \delta).$$

Since $\mathcal{K}_{1,\delta}(0) \cap \widehat{\mathcal{K}_2}(0) = \emptyset$, we have, for any $\gamma > 1$,

$$\forall t \geq 0,\ \mathcal{K}_{1,\delta}(t) \cap \widehat{\mathcal{K}_2}(\gamma t) = \emptyset.$$

Applying this with $t - \delta$ (for $t > \delta$) and to $\gamma = t/(t-\delta) > 1$ gives

$$\emptyset = \mathcal{K}_{1,\delta}(t-\delta) \cap \widehat{\mathcal{K}_2}(\gamma(t-\delta)) = \mathcal{K}_1(t) \cap \widehat{\mathcal{K}_2}(t)$$

because $\gamma(t-\delta) = t$. Since we can choose $\delta > 0$ arbitrary small, the proof of Theorem 3.1 is complete. □

4. Existence, uniqueness, and stability of solutions. In this section, we prove the existence of viscosity solutions for the Hele–Shaw problem for power-law fluids. We also state some uniqueness and stability results.

Throughout this section we assume that h is given by (8). However, most results can be easily extended to the general velocity law h.

4.1. Some preliminary estimates. We give here some technical estimates which are necessary in what follows. We first establish some estimates of the growth of the solutions. For this, we recall that, according to Proposition 2.6, there are constants $r_0 > 0$ and $\sigma > 0$ such that

$$\forall r \geq r_0,\ \forall x \in \partial B(0, r), \qquad h(x, B(0, r)) \leq \sigma r.$$

Moreover, the constants r_0 and σ depend only on S, p, $\|f\|_\infty$, and $\|g\|_\infty$.

LEMMA 4.1. *If $\mathcal{K}$ is a subsolution of the front propagation problem, then*

$$\forall t \geq 0, \quad \mathcal{K}(t) \subset B\left(0, \max\{|\mathcal{K}(0)|, r_0\} e^{\sigma t}\right),$$

where $|\mathcal{K}(0)| = \sup_{y \in \mathcal{K}(0)} |y|$.

Proof of Lemma 4.1. From Proposition 2.6, for any $\epsilon > 0$, the tube

$$\mathcal{K}_2^\epsilon(t) = B\left(0, (\max\{|\mathcal{K}(0)|, r_0\} + \epsilon) e^{\sigma t}\right)$$

is a supersolution of the front propagation problem with $\overline{\mathcal{K}}(0) \cap \widehat{\mathcal{K}_2^\epsilon}(0) = \emptyset$. Hence, $\overline{\mathcal{K}}(t) \cap \widehat{\mathcal{K}_2^\epsilon}(t) = \emptyset$ for any $t \geq 0$, which entails the desired result when letting $\epsilon \to 0^+$. □

The following results state that the left lower semicontinuity of a subsolution is somehow "uniform."

LEMMA 4.2. *Let us fix $\epsilon > 0$ and $\rho > 0$ such that $\rho > \epsilon$. Then there is some constant $\eta > 0$ such that, for any subsolution $\mathcal{K}$ of the front propagation problem,*

with $\overline{\mathcal{K}}(0) \subset B(0,\rho)$ *and for any* $x_0 \in \mathbb{R}^N$ *with* $d_{\overline{\mathcal{K}}(0)}(x_0) \geq \epsilon$ *and* $|x_0| \leq \rho$, *we have* $d_{\mathcal{K}}(0,x_0) \geq \eta$.

Moreover, the constant $\eta > 0$ *depends only on* ϵ, ρ *and on the maximum of the velocity* $h(y,K_r)$ *for* $y \in \partial K_r$ *and for* K_r *belonging to the compact family of smooth sets:*

$$\left\{ B(z,R)\backslash B(z,r) \mid \frac{\epsilon}{4} \leq r \leq \frac{\epsilon}{2},\ 2\rho \leq R \leq 3\rho,\ |z| \leq \rho,\ d_S(z) \geq \epsilon \right\}.$$

Remarks.

1. Since the front propagation problem we are considering is invariant with respect to time translations, the above estimate also shows that, for any subsolution $\mathcal{K}$ of the front propagation problem, with $\overline{\mathcal{K}}(t) \subset B(0,\rho)$ and for any $x_0 \in \mathbb{R}^N$ with $d_{\overline{\mathcal{K}}(t)}(x_0) > \epsilon$ and $|x_0| \leq \rho$, we have $d_{\mathcal{K}}(t,x_0) \geq \eta$.
2. The symmetric estimates for a supersolution (i.e., if $\mathcal{K}$ is a supersolution, $d_{\widehat{\mathcal{K}}(0)}(x_0) > \epsilon$ and $|x_0| \leq \rho$ implies that $d_{\widehat{\mathcal{K}}}(0,x_0) \geq \eta$, for some η) clearly hold with $\eta = \epsilon$ because, since $\mathcal{K}$ is nondecreasing, $\widehat{\mathcal{K}}$ is nonincreasing.

Proof of Lemma 4.2. Let us denote by κ the maximum of the velocity $h(y,K_r)$ for $y \in \partial K_r$ and for K_r belonging to the compact family of smooth sets:

$$\left\{ B(z,R)\backslash B(z,r) \mid \frac{\epsilon}{4} \leq r \leq \frac{\epsilon}{2},\ 2\rho \leq R \leq 3\rho,\ |z| \leq \rho,\ d_S(z) \geq \epsilon \right\}.$$

Note that $\kappa < +\infty$ since the above family is compact and the velocity h is continuous (Proposition 2.4). Let us introduce the tube $\mathcal{K}_2$ defined by

$$\mathcal{K}_2(t) = B(x_0, 2\rho + \kappa t)\backslash B\left(x_0, \frac{\epsilon}{2} - \kappa t\right).$$

Then, from the definition of κ, $\mathcal{K}_2$ is a smooth supersolution of the Hele–Shaw problem on the time interval $[0,\tau]$, where $\tau = \min\{\frac{\epsilon}{4\kappa}, \frac{\rho}{\kappa}\}$, because, on this time interval, $2\rho \leq 2\rho + \kappa t \leq 3\rho$ and $\epsilon/4 \leq \epsilon - \kappa t \leq \epsilon/2$.

Let $\mathcal{K}$ be some subsolution of the Hele–Shaw problem, with $\overline{\mathcal{K}}(0) \subset B(0,\rho)$, and let $x_0 \in \mathbb{R}^N$ with $d_{\overline{\mathcal{K}}(0)}(x_0) > \epsilon$ and $|x_0| \leq \rho$. Then we have $\overline{\mathcal{K}}(0) \subset B(x_0,2\rho)\backslash B(x_0,\epsilon)$. Hence, $\overline{\mathcal{K}}(0) \cap \widehat{\mathcal{K}_2}(0) = \emptyset$. Then the inclusion principle (Theorem 3.1) states that

$$\forall t \in [0,\tau],\ \overline{\mathcal{K}}(t) \cap \widehat{\mathcal{K}_2}(t) = \emptyset.$$

Therefore, $d_{\mathcal{K}}(0,x_0) \geq \eta$, where $\eta = \min\{\epsilon/2, \tau\}$, because $B((0,x_0),\eta) \subset \widehat{\mathcal{K}_2}$. ∎

4.2. Existence and uniqueness of solutions. Let us first give an existence result.

THEOREM 4.3. *For any initial position* K_0, *with* $S \subset Int(K_0)$ *and* K_0 *bounded, there is (at least) one solution to the front propagation problem.*

Moreover, there is a largest solution, denoted by $S(K_0)$, *and a smallest solution, denoted by* $s(K_0)$, *to this problem. The largest solution has a closed graph while the smallest solution has an open graph in* $\mathbb{R}^+ \times \mathbb{R}^N$. *The largest solution contains all the subsolutions of the front propagation problem with initial condition* K_0, *while the smallest solution is contained in any supersolution.*

Remarks.

1. From the maximality property of the largest solution and the time invariance of the evolution law, the semigroup property holds for this solution:

$$\forall s \geq 0,\ t \geq 0, \quad S(\,S(K_0)(s)\,)(t) = S(K_0)(s+t).$$

2. For general front propagation problems, one cannot expect the uniqueness of the solutions. Soner pointed out in [23] the existence of a maximal and a minimal solution for geometric flows of mean curvature type. This result has been generalized in [10] for some class of geometric flows with nonlocal terms.

Proof of Theorem 4.3. The proof is based on Perron's method. Since it is exactly the same as the proof of Theorem 4.1 and of Corollary 4.2 of [11], we omit it. □

We say that the solution of our Hele–Shaw problem with initial position K_0 is *unique* if $\widehat{s(K_0)} = S(K_0)$ or if, equivalently, $\widehat{S(K_0)} = \widehat{s(K_0)}$ (note that $\widehat{s(K_0)} = (\mathbb{R}^+ \times \mathbb{R}^N) \backslash s(K_0)$ since $s(K_0)$ has an open graph in $\mathbb{R}^+ \times \mathbb{R}^N$).

We have the following uniqueness result.

THEOREM 4.4. *Assume that K_0 is the closure of an open, connected, and bounded subset of $\mathbb{R}^N$ with a $\mathcal{C}^2$ boundary and such that $S \subset Int(K_0)$. Then there is a unique viscosity solution to the Hele–Shaw problem.*

Remark. Some uniqueness criteria for geometric flows can be found in [23] and [4]. Our proof uses several arguments from these papers.

Proof of Theorem 4.4. Since K_0 is the closure of an open, connected, and bounded subset of $\mathbb{R}^N$ with a $\mathcal{C}^2$ boundary and such that $S \subset Int(K_0)$, the Hopf maximum principle implies that there is a constant $\delta > 0$ such that $h(x, K_0) \geq 2\delta$ for any $x \in \partial K_0$. Let us set, for any $\sigma \in \mathbb{R}$, $K_\sigma = \{x \in K_0 |\ \mathbf{d}(x) \leq \sigma\}$, where $\mathbf{d}$ is the signed distance to the boundary of K_0 (negative in $Int(K_0)$). From the continuity of h (see (11)), there is some $\epsilon > 0$ such that $h(x, K_\sigma) \geq \delta$ for any $x \in \partial K_\sigma$ and for any σ such that $|\sigma| \leq \epsilon$. Hence, the tube $\mathcal{K}(t) = K_{\delta t - \epsilon}$ is a subsolution of the Hele–Shaw problem starting from $K_{-\epsilon}$ on the time interval $[0, 2\epsilon/\delta]$, because it is smooth and has a normal velocity δ on this interval of time. In particular, $\mathcal{K}(t) \subset S(K_{-\epsilon})(t)$ on $[0, 2\epsilon/\delta]$, which proves that $\mathcal{K}(2\epsilon/\delta) = K_\epsilon \subset S(K_{-\epsilon})(2\epsilon/\delta)$.

Since $K_0 \subset Int(K_\epsilon) \subset Int(S(K_{-\epsilon})(2\epsilon/\delta))$, the inclusion principle (Theorem 3.1) combined with the semigroup property gives

$$S(K_0)(t) \subset S(S(K_{-\epsilon})(2\epsilon/\delta))(t) = S(K_{-\epsilon})(2\epsilon/\delta + t) \quad \forall t \geq 0.$$

Moreover, since $K_{-\epsilon} \subset Int(K_0)$, the inclusion principle also states that $S(K_{-\epsilon})(t) \subset s(K_0)(t)$. Accordingly, we have, for all $t \geq 0$, $\underline{S(K_0)}(t) \subset s(K_0)(2\epsilon/\delta + t)$. Letting $\epsilon \to 0^+$ gives the desired inclusion $S(K_0)(t) \subset \overline{s(K_0)}(t)$. □

4.3. Stability of the solutions. We are now investigating the stability of the flow under variations of the initial position and of the data f and g.

For this we first generalize the well-known stability result of viscosity solutions to our framework.

Let us assume that we are given a family of maps $h_n = h_n(x, K)$ which are defined for any set K with a $\mathcal{C}^{1,1}$ boundary and for any $x \in \partial K$, and continuous in the sense of (11). We also assume that h_n converges to a continuous map h; i.e., if a sequence of closed set K_n with a $\mathcal{C}^{1,1}$ boundary converges to a closed set K with a $\mathcal{C}^{1,1}$ boundary for the $\mathcal{C}^{1,1}$ convergence, and if a sequence of points (x_n), with $x_n \in \partial K_n$, converges to some $x \in \partial K$, then $h_n(x_n, K_n)$ converges to $h(x, K)$.

Let us recall that the upper limit of a sequence of sets A_n is the set of all limits of converging subsequences of sequences (x_n) with $x_n \in A_n$.

PROPOSITION 4.5. *If $\mathcal{K}_n$ is a sequence of subsolutions for h_n, locally uniformly bounded w.r.t. t, then $\mathcal{K}^*$, the upper limit of the $\mathcal{K}_n$, is also a subsolution for h.*

In a similar way, if $\mathcal{K}_n$ is a sequence of supersolutions for h_n, locally uniformly bounded w.r.t. t, then $\mathcal{K}_*$, the complementary of the upper limit of $\widehat{\mathcal{K}_n}$, is also a supersolution for h.

Proof of Proposition 4.5. We prove only the statement for the subsolutions, the proof for the supersolutions being similar. Let us first prove that $\mathcal{K}^*$ is a left lower semicontinuous tube. Indeed $\mathcal{K}^*$ is a tube because the $\mathcal{K}_n$ are locally uniformly bounded. In order to show that $\mathcal{K}^*$ is left lower semicontinuous, it is enough to establish that, for any $T \geq 0$ and for any $\epsilon > 0$, there is some $\eta > 0$ such that

$$\forall t \in [0,T],\ \forall x \in \mathbb{R}^N, \quad d_{\mathcal{K}^*(t)}(x) > \epsilon \ \Rightarrow\ d_{\mathcal{K}^*}(t,x) \geq \eta.$$

For this, let us fix $T \geq 0$ and $\epsilon > 0$. Since the h_n converge to h, Lemma 4.2 states that there is some $\eta > 0$ (independent of n and of $t \in [0,T]$) such that

$$\forall n \in \mathbb{N},\ \forall t \in [0,T],\ \forall x \in \mathbb{R}^N, \quad d_{\mathcal{K}_n(t)}(x) > \epsilon/2 \ \Rightarrow\ d_{\mathcal{K}_n}(t,x) \geq \eta.$$

Let us now assume that $d_{\mathcal{K}^*(t)}(x) > \epsilon$ for some $x \in \mathbb{R}^N$ and for some $t \in [0,T]$. Since $\mathcal{K}^*$ is equal to the upper limit of the $\mathcal{K}_n$, we have $d_{\mathcal{K}_n(t)}(x) > \epsilon/2$ for any n large enough, whence $d_{\mathcal{K}_n}(t,x) \geq \eta$. This implies that $d_{\mathcal{K}^*}(t,x) \geq \eta$. So $\mathcal{K}^*$ is a left lower semicontinuous tube.

Let us now check that $\mathcal{K}^*$ is a subsolution. For this, let us fix some smooth tube $\mathcal{K}_r$ which is externally tangent to $\mathcal{K}^*$ at some point (t,x). We denote by $\mathbf{d}$ the signed distance function to $\partial\mathcal{K}_r$. This function is $\mathcal{C}^{1,1}$ in a neighborhood $\mathcal{V} = \{|\mathbf{d}| < \eta\}$ of $\partial\mathcal{K}_r$.

Let us now consider the function $\mathbf{d}_\epsilon(s,y) = \mathbf{d}(s,y) - \epsilon|(s,y)-(t,x)|^2$, for $\epsilon > 0$. Let us underline that $\mathbf{d}_\epsilon$ has a unique maximum on $\mathcal{K}^*$ at the point (t,x). We can choose $\epsilon > 0$ sufficiently small in such a way that the set $\mathcal{K}_r^\epsilon = \{\mathbf{d}_\epsilon \leq 0\}$ has a boundary which is contained in $\mathcal{V}$ and $\nabla\mathbf{d}_\epsilon \neq 0$ on $\mathcal{V}$. Let us now consider a point (t_n,x_n) of maximum of $\mathbf{d}_\epsilon$ onto $\mathcal{K}_n$. By using a standard argument, we can prove that a subsequence of (t_n,x_n) (again denoted (t_n,x_n)) converges to (t,x), because $\mathbf{d}_\epsilon$ has a unique maximum on $\mathcal{K}^*$ at the point (t,x). Hence, the set $\mathcal{K}_r^n = \{\mathbf{d}_\epsilon \leq \mathbf{d}_\epsilon(t_n,x_n)\}$ is a smooth tube for n large enough, since, for n large enough, the boundary of $\mathcal{K}_r^n$ is in $\mathcal{V}$. Since $\mathcal{K}_n$ is a subsolution and since $\mathcal{K}_r^n$ is externally tangent to $\mathcal{K}_n$ at (t_n,x_n), we have

$$V^{\mathcal{K}_r^n}_{(t_n,x_n)} \leq h_n(x_n, \mathcal{K}_r^n(t_n)).$$

The sequence of sets $\mathcal{K}_r^n$ converges to $\mathcal{K}_r^\epsilon$ for the $\mathcal{C}^{1,1}$ topology. So we get at the limit

$$V^{\mathcal{K}_r^\epsilon}_{(t,x)} \leq h(x, \mathcal{K}_r^\epsilon(t))$$

because h_n converges to h. Letting $\epsilon \to 0$ gives the desired result, since $\mathcal{K}_r^\epsilon$ converges to $\mathcal{K}_r$ for the $\mathcal{C}^{1,1}$ topology and h is continuous. □

We finally investigate the stability of solutions with respect to the initial position K_0 and to the functions f and g.

THEOREM 4.6. *Let (f_n,g_n) and (f,g) satisfy* (10) *for any n, with $f>0$ and locally Lipschitz continuous. Let $K_n \in \mathcal{D}$ be a sequence of initial positions and $K_0 \in \mathcal{D}$.*

Let us assume that the f_n are globally bounded and converge to f locally uniformly, that the g_n converge to some $g > 0$ in $\mathcal{C}^{1,\beta}(\partial S)$ for some $\beta \in (0,1)$, and that the K_n converge to K_0, in the sense that the upper limit of the K_n is contained in K_0 and the upper limit of the $\mathbb{R}^N\backslash K_n$ is contained in $\overline{\mathbb{R}^N\backslash K_0}$. Let us also suppose that there is a unique solution, denoted by $S(K_0)$, of the Hele–Shaw problem starting from K_0 with data f and g.

If $\mathcal{K}_n$ is a solution of the Hele–Shaw problem, with data f_n and g_n, starting from K_n, then the $\mathcal{K}_n$ converge to $S(K_0)$ in the following sense: The upper limit of the $\mathcal{K}_n$ is equal to $S(K_0)$, while the upper limit of the $\widehat{\mathcal{K}_n}$ is equal to $\widehat{S(K_0)}$.

Proof of Theorem 4.6. Let $\mathcal{K}^*$ be the upper limit of the $\mathcal{K}_n$ and $\mathcal{K}_*$ be the complementary of the upper limit of the $\widehat{\mathcal{K}_n}$.

Let us first prove that $\mathcal{K}^*$ is a subsolution to the front propagation problem with initial position K_0. According to Proposition 4.5, it is enough to prove that the $\mathcal{K}_n$ are locally uniformly bounded w.r.t. t and the maps h_n, defined for any smooth set $K_r \in \mathcal{D}$ and any $x \in \partial K_r$ by $h_n(x, K_r) = |\nabla u(x)|^{p-1}$, where u is the solution to

$$\begin{cases} -\mathrm{div}(|\nabla u|^{p-1}\nabla u) = f_n & \text{in } K_r, \\ u = g_n & \text{on } \partial S, \\ u = 0 & \text{on } \partial K_r, \end{cases}$$

converge to h defined by (8). The $\mathcal{K}_n$ are locally uniformly bounded thanks to Lemma 4.1, because the f_n and the g_n are uniformly bounded. Moreover, the local uniform convergence of the h_n to h is a straightforward application of the estimates in [21]. Using Lemma 4.2, we can also show that $\mathcal{K}^*(0) \subset K_0$ (the arguments are similar to those developed for proving that $\mathcal{K}^*$ is left lower semicontinuous in Proposition 4.5). Hence, $\mathcal{K}^*$ is a subsolution to the Hele–Shaw problem with initial position K_0. In particular, this implies that $\mathcal{K}^* \subset S(K_0)$, because $S(K_0)$ contains any subsolution.

In the same way, $\mathcal{K}_*$ is a supersolution for h, with $\widehat{\mathcal{K}_*}(0) \subset \overline{\mathbb{R}^N \backslash K_0}$. Hence, $s(K_0) \subset \mathcal{K}_*$. So we have proved that

$$s(K_0) \subset \mathcal{K}_* \subset \mathcal{K}^* \subset S(K_0). \tag{47}$$

From our assumption, the Hele–Shaw problem with initial position K_0 has a unique solution, i.e., $\overline{s(K_0)} = S(K_0)$. Combining this equality with (47) gives $\overline{s(K_0)} = \overline{\mathcal{K}_*} = \mathcal{K}^* = S(K_0)$, since $\mathcal{K}^*$ and $S(K_0)$ have a closed graph.

Taking the complementary in (47) also gives $\widehat{S(K_0)} \subset \widehat{\mathcal{K}^*} \subset \widehat{\mathcal{K}_*} \subset \widehat{s(K_0)}$. Since $\widehat{S(K_0)} = \widehat{s(K_0)}$ from the uniqueness of the solution, we finally have the equality $\widehat{\mathcal{K}_*} = \widehat{S(K_0)}$, which is the desired result since $\widehat{\mathcal{K}_*} = (\mathbb{R}^+ \times \mathbb{R}^N)\backslash\mathcal{K}_*$ is the upper limit of the $\widehat{\mathcal{K}_n}$. □

PERIODIC OSCILLATIONS OF BLOOD CELL POPULATIONS IN CHRONIC MYELOGENOUS LEUKEMIA*

MICHAEL C. MACKEY†, CHUNHUA OU‡, LAURENT PUJO-MENJOUET§, AND JIANHONG WU¶

Abstract. Periodic chronic myelogenous leukemia and cyclical neutropenia are two hematological diseases that display oscillations in circulating cell numbers with a period far in excess of what one might expect based on the stem cell cycle duration. Motivated by this observation and a desire to understand how long period oscillations can arise, we analytically prove the existence and stability of long period oscillations in a G_0 phase cell cycle model described by a nonlinear differential delay equation. This periodic oscillation p_∞ can be analytically constructed when the proliferative control is of a "bang-bang" type (the Hill coefficient involved in the nonlinear feedback is infinite). We further obtain a contractive return map (for the semiflow generated by the functional differential equation) in a closed and convex cone containing p_∞ when the proliferative control is smooth (the Hill coefficient is large but finite). The fixed point of this contractive map gives the long period oscillation previously observed both numerically and experimentally.

1. Introduction.

Periodic hematological diseases have attracted a significant amount of modeling attention from mathematicians, notably the disorders periodic autoimmune hemolytic anemia [3, 17] and cyclical thrombocytopenia [27, 29]. Periodic hematological diseases of this type, in which only a single cell type is typically involved, usually display a periodicity in circulating cell numbers between two and four times the bone marrow production delay. This clinical observation has a clear explanation within a modeling context [10].

Other periodic hematological diseases such as cyclical neutropenia [4, 10, 11, 15, 16, 18] and periodic chronic myelogenous leukemia (PCML) [8] have more than one circulating blood cell type (i.e., white cells, red blood cells, and platelets) that display oscillatory levels. The oscillations in cell numbers in these two diseases have period durations ranging from weeks to months in general and are thought to originate in the pluripotential stem cell compartment [10]. In the particular case of PCML, the period can range from 40 to 80 days. Two lines of evidence indicate that the PCML oscillations originate in the stem cell population based in the bone marrow. The first suggestion that this is the case comes from the presence of the Philadelphia

chromosome in all hematopoietic cells in PCML [5, 7, 9, 12, 30]. Second, in PCML it is observed that white blood cells, erythrocytes, and platelets all oscillate with the same period [8].

"How do 'short' cell cycles give rise to 'long' period oscillations?" This question has arisen from the observation of circulating blood cell oscillations in PCML [8]. There is an enormous difference between the relatively short cell cycle duration, which ranges between 1 and 4 days [13, 18, 19], and the long period oscillations in PCML (between 40 and 80 days) [8]. The link between these relatively short cycle durations and the long periods of peripheral cell oscillations in PCML is unclear and has been neither biologically explained nor understood.

Using a G_0 model of the cell cycle [6, 20, 28], an attempt to answer this question has been made in [1, 25, 24], where the role of various model parameters on the period and amplitude of the cellular oscillations was examined. When cellular reentry from G_0 into the proliferative phase is subject to "bang-bang" control (technically, where the Hill coefficient in the model re-entry rate n is infinite—see below), qualitatively the cell cycle regulation parameters have a major influence on the oscillation amplitude, while the oscillation period is primarily determined by the cell death and differentiation parameters. Under this strong assumption, the cell cycle model is described by a piecewise linear scalar delay differential equation that, after nontrivial but straightforward calculations, has a periodic solution with large period and amplitude and strong stability properties.

Here, we prove analytically that similar conclusions hold in the more biologically realistic case that the re-entry rate is a smooth monotone function. We construct a convex closed cone containing the periodic solution when $n = \infty$ and a contractive return map defined on this cone such that a fixed point of the return map gives a stable periodic solution of the model equation when n is large. This method was first developed by Walther [31, 32] for a scalar delay differential equation with constant linear instantaneous friction and a negative delayed feedback, and was later extended to state-dependent delay differential equations [33, 34] and to delay differential systems [34, 36]. This method was further developed in [23] by incorporating some ideas from classical asymptotic analysis and using matching methods. Applications of this method to the present cell cycle model are nontrivial since both the instantaneous loss and the delayed production of stem cells involve the nonlinearity and there is no analytic formula for the periodic solution in the limiting case ($n = \infty$).

This paper is organized as follows. In section 2 we present the model in detail. Section 3 summarizes previous results from [24] in the case where the Hill coefficient n is infinite. Then, we introduce a more general result for the perturbed delay equation given in section 4, and we present our main results in section 5 including the full asymptotic expansion for the periodic solutions.

2. Description of the model. The G_0 model of the cell cycle (see Figure 2.1 for a depiction) is conceptually based on the work of Lajtha [14] and was first developed by Burns and Tannock [6]. It can be derived from an age structured system of two coupled partial differential equations, along with appropriate boundary and initial conditions [15, 16, 21, 26]. Integrating along characteristics [35] these equations can be transformed into a pair of coupled nonlinear first-order differential delay equations [15, 16, 18]. The resulting model depicted in Figure 2.1 consists of a proliferating phase cellular population $P(t)$ at time t and a G_0 resting phase, with a population of cells $N(t)$. The proliferative phase cells consist of cells in the G_1 phase of the cell cycle, the DNA synthesis (S) phase, G_2, and mitosis M. In this proliferative phase,

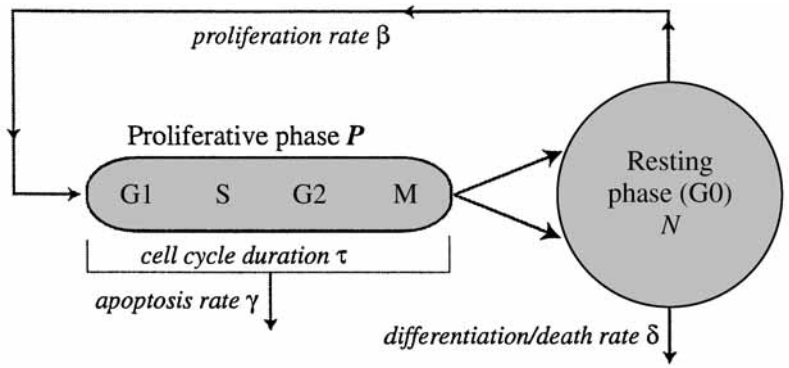

FIG. 2.1. *A schematic representation of the G_0 stem cell model. Proliferating phase cells (P) include those cells in G_1, S (DNA synthesis), G_2, and M (mitosis), while the resting phase (N) cells are in the G_0 phase. δ is the rate of differentiation into all the committed populations arising from the stem cells, and γ represents the apoptotic loss of proliferating phase cells. β is the rate of cell re-entry from G_0 into the proliferative phase, and the cell cycle time τ is the duration of the proliferative phase. See* [15, 16, 18] *for further details.*

cells are committed to undergo cell division a constant time τ after their entry into G_1. The choice of a constant cell cycle time τ simplifies the problem, though some models with a nonconstant value of τ have been examined [2, 4]. The proliferative phase death rate γ is due to apoptosis (programmed cell death). At the point of cytokinesis (cell division), a cell divides into two daughter cells, both of which are assumed to enter the resting (N) phase. In this phase, cells cannot divide but they may have one of three possible fates: differentiate at a constant rate δ, re-enter the proliferative phase at a rate β, or remain in G_0. The re-entry rate β is a nonlinear function of the cellular density and the central focus of this study.

The full model, described by a coupled nonlinear first-order delay equation, takes the form

$$\frac{dP(t)}{dt} = -\gamma P(t) + \beta(N)N - e^{-\gamma\tau}\beta(N_\tau)N_\tau \tag{2.1}$$

and

$$\frac{dN(t)}{dt} = -[\beta(N) + \delta]N + 2e^{-\gamma\tau}\beta(N_\tau)N_\tau, \tag{2.2}$$

where $N_\tau = N(t-\tau)$. The resting (G_0) to proliferative phase feedback rate β is taken to be a monotone Hill function of the form

$$\beta(N) = \frac{\beta_0\theta^n}{\theta^n + N^n}.$$

In (2.2), the first term represents the loss of nonproliferating cells to the proliferative phase (flux $\beta(N)N$) and to differentiation (flux δN). The second term represents the production of G_0 phase cells from the proliferating stem cells. The factor 2 accounts for the amplifying effect of cell division while $e^{-\gamma\tau}$ accounts for the attenuation in the proliferative phase due to apoptosis. Note that we need to study only the dynamics of the G_0 phase resting population (governed by (2.2)) since the proliferating phase dynamics (governed by (2.1)) are driven by the dynamics of the resting cells. This is

strictly a consequence of the fact that we have assumed β to be a function of N alone [21, 22].

Introducing the dimensionless variable $x = N/\theta$, we can rewrite (2.2) as

$$\frac{dx}{dt} = -[\beta(x) + \delta]x + k\beta(x_\tau)x_\tau, \tag{2.3}$$

where

$$\beta(x) = \beta_0 \frac{1}{1 + x^n}, \tag{2.4}$$

and $k = 2e^{-\gamma\tau}$. The steady states x_* of (2.3) are given by the solution of $dx/dt \equiv 0$. Thus we have $x_* \equiv 0$, and

$$x_* = \left(\beta_0 \frac{k-1}{\delta} - 1\right)^{1/n}. \tag{2.5}$$

Here we require

$$\tau < -\frac{1}{\gamma} \ln \frac{\delta + \beta_0}{2\beta_0},$$

so $\beta_0 \frac{k-1}{\delta} > 1$ in (2.5) and the second nontrivial steady state will be positive. Note that when $n \to \infty$, $x_* \to 1$ in (2.5) and $\beta(x)$ tends to a piecewise constant function (the Heaviside step function).

A solution of (2.3) is a continuous function $x : [-\tau, +\infty) \to \mathbf{R}_+$ obeying (2.3) for all $t > 0$. The continuous function $\varphi : [-\tau, 0] \to \mathbf{R}_+, \varphi(t) = x(t)$ for all $t \in [-\tau, 0]$, is called the initial condition for x. Using the method of steps, it is easy to prove that for every $\varphi \in C([-\tau, 0])$, where $C([-\tau, 0])$ is the space of continuous functions on $[-\tau, 0]$, there is a unique solution of (2.3) subject to the initial condition φ.

3. Periodic solutions: Limiting nonlinearity. In this section we study the dynamics of (2.3) when $\beta(x)$ is the step function

$$\beta(x) = \begin{cases} 0, & x \geq 1, \\ \beta_0, & x < 1. \end{cases}$$

By a solution of (2.3) in this case, we mean a continuous function $x(t)$ on the interval $[-\tau, \infty)$ which is piecewise differentiable and satisfies (2.3) for $t \in [0, \infty)$ except at the point t where $x(t)$ or $x(t - \tau)$ is equal to 1. For any initial data $\varphi \in C[-\tau, 0]$, it is not difficult to obtain a unique solution $x(t)$ by using the method of steps. As in [24], we introduce two constants

$$\alpha = \beta_0 + \delta, \quad \Gamma = 2\beta_0 e^{-\gamma\tau} = k\beta_0.$$

Inserting the step function $\beta(x)$ into (2.3), we obtain

$$\frac{dx}{dt} = \begin{cases} -\delta x, & 1 < x, x_\tau, \\ -\alpha x, & 0 < x < 1 < x_\tau, \\ -\alpha x + \Gamma x_\tau, & 0 < x, x_\tau < 1, \\ -\delta x + \Gamma x_\tau, & 0 < x_\tau < 1 < x, \end{cases} \tag{3.1}$$

where $x_\tau = x(t - \tau)$.

For (3.1), we choose the initial function $\varphi(t) \geq 1+\eta$ for $t \in [-\tau, 0)$ and $\varphi(0) = 1+\eta$ where η is a small positive constant specified later. By the continuity of the solution x, we have from (3.1) the existence of t_1 such that $x(t)$ and $x(t-\tau)$ are greater than 1 for $t \in [0, t_1)$ and $x(t_1) = 1$. The solution $x(t)$ then satisfies

$$\frac{dx}{dt} = -\delta x \quad \text{for} \quad t \in [0, t_1]. \tag{3.2}$$

Thus solving the above equation, we have $x(t) = \varphi(0)e^{-\delta t} = (1+\eta)e^{-\delta t}$. It follows that

$$t_1 = \frac{\ln \varphi(0)}{\delta} = \frac{\ln(1+\eta)}{\delta}. \tag{3.3}$$

In the next interval of time, defined by $(t_1, t_1+\tau)$, we have $x(t-\tau) > 1$. From the first two lines in (3.1), the solution is decreasing and thus crosses the level $x = 1$. The dynamics are given by

$$\frac{dx}{dt} = -\alpha x \tag{3.4}$$

as long as $x(t) < 1$. The solution is then given by $x(t) = e^{-\alpha(t-t_1)}$ for $t \in [t_1, t_1+\tau]$ and $x(t_1+\tau) = e^{-\alpha\tau}$ independent of the initial function $\varphi(t)$. Thus, the dynamics eventually destroy all memory of the initial function.

The solution in the next interval will be such that $x, x_\tau < 1$. In order that (3.1) has periodic solutions, we impose an extra condition on Γ and α so that

$$-\alpha x + \Gamma x_\tau > 0. \tag{3.5}$$

Otherwise, if $-\alpha x + \Gamma x_\tau \leq 0$, then the solution may tend to zero as t approaches infinity and thus we cannot expect a periodic solution. In particular, if

$$-\alpha x + \Gamma x_\tau \approx 0,$$

then the solution may stay below the line $x = 1$ so long that the resulting analysis becomes very complicated. Note that for $t \in [t_1+\tau, t_1+2\tau]$, we have $x(t-\tau) = e^{-\alpha(t-t_1-\tau)}$. Then if $x(t) < 1$, from (3.1), we have $\frac{dx}{dt} = -\alpha x + \Gamma x_\tau = -\alpha x + \Gamma e^{-\alpha(t-t_1-\tau)}$ which gives

$$x(t) = e^{-\alpha(t-t_1-\tau)}(e^{-\alpha\tau} + \Gamma(t-t_1-\tau)). \tag{3.6}$$

For the sake of simplicity, we impose an extra condition on Γ:

$$\Gamma > \max\left\{\frac{1}{\tau}(e^{\alpha\tau} - e^{-\alpha\tau}), \alpha e^{\alpha\tau}\right\}. \tag{3.7}$$

Note that condition (3.7) clearly holds if β_0 is large.

Equation (3.6) is only valid if the value of $x(t)$ is less than or equal to 1. However when we directly replace t in (3.6) by $t_1+2\tau$, we have $x(t_1+2\tau) = e^{-\alpha\tau}(e^{-\alpha\tau}+\Gamma\tau) > 1$. Thus we need to use (3.6) to find a point $t_2 \in (t_1+\tau, t_1+2\tau)$ such that $x(t_2) = 1$ and (3.6) is valid for $t \in [t_1+\tau, t_2]$. Assume $t_2 = t_1+\tau+u$, $u \in (0, \tau)$. Then from (3.6) we have

$$e^{\alpha u} = e^{-\alpha\tau} + \Gamma u. \tag{3.8}$$

Equation (3.8) is a transcendental equation and cannot be solved explicitly. However, the existence of a positive solution $u \in (0, \tau)$ is obvious given (3.7). Therefore (3.5) holds for $t \in [t_1 + \tau, t_2]$ (due to the fact that $x(t-\tau) \geq e^{-\alpha\tau}$).

Next for $t \in (t_2, t_2 + \tau)$, we claim that

$$x(t) > 1. \tag{3.9}$$

Indeed, from the above analysis, we know that $e^{-\alpha\tau} < x(t-\tau) < 1$ and at the particular point t_2, $x(t_2 + 0) = \lim_{t \to t_2 + 0} x(t) = 1$, so $x(t_2 - \tau) \geq e^{-\alpha\tau}$. By (2.3) and (3.7) we have

$$x'(t_2 + 0) = -[\beta(x) + \delta]x + k\beta(x_\tau)x_\tau > -\alpha + \Gamma x_\tau > 0.$$

The solution $x(t)$ is differentiable with respect to t as long as $x(t)$ and $x(t-\tau)$ are not equal to 1. To see our claim suppose, by contradiction, that there exists a point $h \in (t_2, t_2 + \tau)$ such that $x(h) = 1$, $x'(h - 0) \leq 0$, and $x(t) > 1$ for $t \in (t_2, h)$. Then using (3.1), we have by (3.7) that

$$x'(h - 0) = -\delta + \Gamma x(h - \tau) \geq -\delta + \Gamma e^{-\alpha\tau} > 0.$$

This is a contradiction, and our claim is true.

Splitting $[t_2, t_2 + \tau]$ into two subintervals $[t_2, t_1 + 2\tau]$ and $[t_1 + 2\tau, t_2 + \tau]$, we can give explicit formulae for the solution $x(t)$ as follows.

For $t \in [t_2, t_1 + 2\tau]$, we know that $x(t-\tau) = e^{-\alpha(t - t_1 - \tau)} < 1$. The dynamics are thus given by

$$\frac{dx}{dt} = -\delta x + \Gamma x_\tau = -\delta x + \Gamma e^{-\alpha(t - t_1 - \tau)},$$

which has the solution

$$x(t) = e^{-\delta\tau(t - t_2)} \left\{ 1 - \frac{\Gamma}{\beta_0} e^{\alpha(t_1 + \tau) - \delta t_2} \left(e^{-\beta_0 t} - e^{-\beta_0 t_2} \right) \right\}. \tag{3.10}$$

Moreover, since the solutions are differentiable provided that $x(t)$ and $x(t-\tau)$ are not equal to 1, and the solutions are continuous everywhere, for $t \in [t_1 + 2\tau, t_2 + \tau]$ we have

$$\begin{aligned} \frac{dx}{dt} &= -\delta x + \Gamma x_\tau \\ &= -\delta x + \Gamma e^{-\alpha(t - t_1 - 2\tau)}(e^{-\alpha\tau} + \Gamma(t - t_1 - 2\tau)), \end{aligned}$$

so

$$x(t) = e^{-\delta(t - t_1 - 2\tau)} \left[x(t_1 + 2\tau) + \Gamma \left(j(t) - j(t_1 + 2\tau) \right) \right],$$

where

$$j(t) = \frac{1}{(\delta - \alpha)} \left(e^{-\alpha\tau} + \Gamma(t - t_1 - 2\tau) - \frac{\Gamma}{\delta - \alpha} \right) e^{(\delta - \alpha)(t - t_1 - 2\tau)}.$$

After the time $t_2 + \tau$, both x_τ and x are greater than 1, and the solution satisfies

$$x' = -\delta x \tag{3.11}$$

as long as $x(t) > 1$ and thus is decreasing. Therefore, there exists a point, say, $t = d$, so that $x(d) = 1$. Note that in the interval $[t_2, d]$, the graph of the solution $x(t)$ is

independent of the initial function $\varphi(t)$. Now we can use (3.9) and (3.11) to choose a small positive constant $\eta < 1$ such that the following hold:

1. We have

$$t_1 = \frac{\log(1+\eta)}{\delta} < \tau; \tag{3.12}$$

2. we have

$$\Gamma > \max\left\{\frac{1}{\tau}(e^{\alpha\tau} - e^{-\alpha\tau}), \alpha(1+\eta)e^{\alpha\tau}\right\}, \tag{3.13}$$

and $x(t)$ reaches $1+\eta$ at a point $t_3 \in (t_2, t_2+\tau)$; and

3. there is a point T_x, $t_3 + \tau < T_x < d$ so that

$$x(T_x) = 1+\eta,\ x(T_x+s) > 1+\eta,\ s \in [-\tau, 0). \tag{3.14}$$

With this choice of η, we have $x(t) > 1+\eta$ for $t \in (t_3, T_x)$ and the solution is strictly increasing for $t \in [t_2, t_3]$ (due to (3.13)). Finally, when we continue to solve (3.1) step by step, we have $x(t) = x(t+T_x)$ for $t \geq 0$. Summarizing the above analysis, we have the following result.

THEOREM 3.1. *Suppose that* Γ *satisfies* (3.7). *Assume that* x *is the solution of* (3.1) *subject to the initial condition* $\phi \geq 1+\eta$ *where* η *is chosen to satisfy* (3.12), (3.13), *and* (3.14). *Then the solution* x *satisfies* $x(t) = x(t+T_x)$ *for* $t \geq 0$.

4. Periodic solutions: General nonlinearity.

4.1. Perturbed delay equation. With the preceding analysis of the G_0 phase cell cycle model when the feedback function β is a Heaviside step function, we turn to a consideration of the general continuous nonlinearity. More precisely, we consider

$$\frac{dy}{dt} = -[\beta(y) + \delta]y + k\beta(y_\tau)y_\tau, \tag{4.1}$$

returning to the original problem with $\beta = \beta_0 \frac{1}{1+y^n}$. Let $\varepsilon = 1/n$. Then we can rewrite the Hill function as

$$\beta_\varepsilon(y) = \beta_0 \frac{1}{1+y^{1/\varepsilon}}.$$

Let the initial function φ be chosen from the closed convex set

$$A_\eta = \{\varphi \in C([-\tau, 0]) : 1+\eta \leq \varphi(t) \quad \text{for} \quad t \in [-\tau, 0], \quad \text{and} \quad \varphi(0) = 1+\eta\},$$

where $\eta < 1$ is a small positive constant as chosen in the previous section. For given φ in A_η, we have a unique solution to (4.1). The relations

$$F_\varepsilon(t, \varphi) = y_t,\ y_t = y(t+s),\ -\tau \leq s \leq 0,\ t \geq 0,$$

define a continuous semiflow $F = F_\varepsilon$ on $C([-\tau, 0])$.

As a technical preparation, we now describe some elementary properties of the Hill function we employ here.

LEMMA 4.1. *Assume* $\varepsilon = \frac{1}{n} < 1$. *The following inequalities hold:*
(a) *If* $y > \left(\frac{1}{\varepsilon}\right)^{\varepsilon/(1-\varepsilon)}$, *then*

$$\beta_\varepsilon(y) < \beta_0\varepsilon, \quad y\beta_\varepsilon(y) < \beta_0\varepsilon$$

and if $0 < y < \varepsilon^\varepsilon$, *then*

$$\beta_0 > \beta_\varepsilon(y) > \beta_0(1-\varepsilon) \quad \textit{and} \quad |y\beta_\varepsilon(y) - \beta_0 y| < \beta_0\epsilon. \tag{4.2}$$

(b) *Also,*

$$\left|\frac{d(y\beta_\varepsilon(y))}{dy}\right| < \beta_0\varepsilon \quad \textit{for } y > \left(\frac{1}{\varepsilon}\right)^{2\varepsilon},$$

and

$$\left|\frac{d(y\beta_\varepsilon(y) - \beta_0 y)}{dy}\right| < \beta_0\varepsilon \quad \textit{for } 0 < y < \left(\frac{\varepsilon^2}{1+\varepsilon}\right)^{\varepsilon}.$$

Proof. (a) If $y > \left(\frac{1}{\varepsilon}\right)^{\varepsilon/(1-\varepsilon)}$, then

$$\beta_\varepsilon(y) = \frac{\beta_0}{1+y^{1/\varepsilon}} < \frac{\beta_0}{y^{1/\varepsilon}} < \frac{\beta_0}{\left(\frac{1}{\varepsilon}\right)^{1/(1-\varepsilon)}} < \beta_0\varepsilon,$$

and

$$y\beta_\varepsilon(y) = \frac{\beta_0 y}{1+y^{1/\varepsilon}} < \frac{\beta_0}{y^{\frac{1}{\varepsilon}-1}} < \beta_0\varepsilon.$$

If $0 < y < \varepsilon^\varepsilon$, then

$$\beta_0 > \beta_\varepsilon(y) = \frac{\beta_0}{1+y^{1/\varepsilon}} > \beta_0(1-y^{1/\varepsilon}) \geq \beta_0(1-\varepsilon),$$

and

$$|y\beta_\varepsilon(y) - \beta_0 y| = \left|\beta_0 \frac{y^{1/\varepsilon+1}}{1+y^{1/\varepsilon}}\right| < \beta_0 y^{1/\varepsilon+1} < \beta_0\varepsilon.$$

(b) If $y > (1/\varepsilon)^{2\varepsilon}$, then

$$\left|\frac{d\,(y\beta_\varepsilon(y))}{dy}\right| = \beta_0 \frac{\left|\left(\frac{1}{\varepsilon}-1\right)y^{1/\varepsilon} - 1\right|}{(1+y^{1/\varepsilon})^2} \leq \beta_0\left(\frac{1}{\varepsilon}-1\right)y^{-1/\varepsilon} < \beta_0\varepsilon.$$

Since

$$f(x) = \frac{\left(1+\frac{1}{\varepsilon}\right)x + \frac{1}{\varepsilon}x^2}{1+x}$$

is strictly increasing for $x \in (0, \frac{\varepsilon^2}{1+\varepsilon})$ and $f(\frac{\varepsilon^2}{1+\varepsilon}) < \varepsilon$, we obtain

$$\left|\frac{d\,(y\beta_\varepsilon(y) - \beta_0 y)}{dy}\right| = \beta_0 \frac{(1+\frac{1}{\varepsilon})y^{1/\varepsilon} + \frac{1}{\varepsilon}y^{2/\varepsilon}}{1+y^{1/\varepsilon}} < \beta_0\varepsilon$$

for $0 < y < (\frac{\varepsilon^2}{1+\varepsilon})^\varepsilon$. ∎

We found that for (3.1), if $\varphi \in A_\eta$, then the solution will return to A_η after finite time. The following lemma shows a similar property for (4.1).

LEMMA 4.2. *Let y be the solution of* (4.1) *with an initial function $\varphi \in A_\eta$. Then there exists a point $T_y > 0$ such that $y(T_y) = 1 + \eta$ and*

$$y(t) \geq 1 + \eta \quad \text{for } t \in [T_y - \tau, T_y]. \tag{4.3}$$

Moreover, there exists a constant $\varepsilon_1, \varepsilon_1 \in (0,1)$, such that for each $\varepsilon \in (0, \varepsilon_1)$, we have

$$T_y = T_x + O(\varepsilon \log \varepsilon) \tag{4.4}$$

and

$$y(t) = x(t) + O(\varepsilon \log \varepsilon), \tag{4.5}$$

uniformly for $t \in [0, T_x]$ and $\varphi \in A_\eta$, where T_x is the period of the periodic solution x to (3.1) *obtained in Theorem* 3.1.

Proof of Lemma 4.2. We first claim that there exist three points η_1, t_1^y, η_2, $0 < \eta_1 < t_1^y < \eta_2$, which are dependent on ε and φ, such that

$$y(\eta_1) = \left(\frac{1}{\varepsilon}\right)^{2\varepsilon} > 1, \;\; y(t_1^y) = 1, \; y(\eta_2) = \left(\frac{\varepsilon^2}{1+\varepsilon}\right)^{\varepsilon} < 1. \tag{4.6}$$

Indeed, if $y(t) > (\frac{1}{\varepsilon})^{2\varepsilon} > \left(\frac{1}{\varepsilon}\right)^{\varepsilon/(1-\varepsilon)} > 1$ and $y(t-\tau) > (\frac{1}{\varepsilon})^{2\varepsilon} > (\frac{1}{\varepsilon})^{\varepsilon/(1-\varepsilon)}$, then we have by Lemma 4.1 that

$$\beta_\varepsilon(y(t))y(t) < \beta_0 \varepsilon, \;\; \beta_\varepsilon(y(t-\tau))y(t-\tau) < \beta_0 \varepsilon$$

and

$$\begin{aligned} \frac{dy(t)}{dt} &= -(\delta + \beta_\varepsilon(y(t)))y(t) + k\beta_\varepsilon(y(t-\tau))y(t-\tau), \\ &= -\delta y(t) + O(\varepsilon) \\ &< -\frac{\delta}{2} \text{ for } \varepsilon \in (0, \sigma_1). \end{aligned} \tag{4.7}$$

Here σ_1 is chosen so that for each $\varepsilon \in (0, \sigma_1)$, we have $-\delta y(t) + O(\varepsilon) < -\frac{\delta}{2}$. This means that y is decreasing as long as $y(t) \geq (\frac{1}{\varepsilon})^{2\varepsilon} > (\frac{1}{\varepsilon})^{\varepsilon/(1-\varepsilon)}$. Therefore there is a point $\eta_1 > 0$ so that $y(\eta_1) = (1/\varepsilon)^{2\varepsilon}$ and $1 + \eta > y(t) > (1/\varepsilon)^{2\varepsilon}$ for $t \in (0, \eta_1)$. Using $\frac{dy}{dt} = -\delta y + O(\varepsilon)$ and $y(0) = 1 + \eta$, we also have

$$\eta_1 = \frac{\log(1+\eta)}{\delta} + O(-\varepsilon \log \varepsilon) = t_1 + O(-\varepsilon \log \varepsilon). \tag{4.8}$$

Here the term $O(-\varepsilon \log \varepsilon)$ holds uniformly for all the initial functions φ in A_η. Next in the interval $(\eta_1, \eta_1 + \tau)$, we have $\beta_\varepsilon(y(t-\tau))y(t-\tau) = O(\varepsilon)$ and

$$\begin{aligned} \frac{dy(t)}{dt} &= -(\delta + \beta_\varepsilon(y(t)))y(t) + k\beta_\varepsilon(y(t-\tau))y(t-\tau) \\ &< -\delta y(t) + k\beta_\varepsilon(y(t-\tau))y(t-\tau) \\ &= -\delta y(t) + O(\varepsilon) \\ &< -\frac{\delta}{2} \text{ for } \varepsilon \in (0, \sigma_2) \end{aligned}$$

as long as $y(t) \geq (\frac{\varepsilon^2}{1+\varepsilon})^{\varepsilon}$. Here σ_2 is chosen so that for each $\varepsilon \in (0, \sigma_2)$, we have

$$-\delta y(t) + O(\varepsilon) < -\delta \left(\frac{\varepsilon^2}{1+\varepsilon}\right)^{\varepsilon} + O(\varepsilon) < -\frac{\delta}{2}.$$

This means that the solution is decreasing and there exist two points t_1^y, η_2, $\eta_1 < t_1^y < \eta_2$, such that

$$y(t_1^y) = 1, \;\; y(\eta_2) = \left(\frac{\varepsilon^2}{1+\varepsilon}\right)^{\varepsilon}.$$

By the mean value theorem, it is easy to show that

$$|y(\eta_1) - y(\eta_2)| \geq \frac{\delta}{2} |\eta_1 - \eta_2|$$

or, equivalently,

$$\eta_2 - \eta_1 \leq \frac{2}{\delta}(y(\eta_1) - y(\eta_2)) = \frac{2}{\delta}\left[\left(\frac{1}{\varepsilon}\right)^{2\varepsilon} - \left(\frac{\varepsilon^2}{1+\varepsilon}\right)^{\varepsilon}\right] = O(-\varepsilon \log \varepsilon).$$

Therefore,

$$0 < t_1^y - \eta_1 < \eta_2 - \eta_1 = O(-\varepsilon \log \varepsilon). \tag{4.9}$$

Now using (4.1) for $t \in [0, \eta_1]$, we have

$$y' = -\delta y + O(\varepsilon), \;\; y(0) = 1 + \eta,$$

which gives

$$y(t) = (1+\eta)e^{-\delta t} + O(\varepsilon).$$

We claim that

$$y(t) = x(t) + O(\varepsilon) \tag{4.10}$$

uniformly for $t \in [0, \xi_1]$ and $\varphi \in A_\eta$, where

$$\xi_1 = \min\{t_1, \eta_1\}.$$

Indeed, this is true, since $x(t) = (1+\eta)e^{-\delta t}$ for $t \in [0, t_1]$.

Next for $t \in [\xi_1, \eta_2]$, using an argument that the length of the interval $[t_1, \eta_1]$ is of order $O(-\varepsilon \log \varepsilon)$, and both $|x'(t)|$ and $|y'(t)|$ are bounded by a constant, say, M, which is independent of ε and η, we conclude from (4.10) that

$$y(t) = x(t) + O(-\varepsilon \log \varepsilon). \tag{4.11}$$

For $t \in [\eta_2, \tau + \xi_1]$, we can show that $y(t-\tau) > (1/\varepsilon)^{2\varepsilon}$. Note that $\eta_2 \leq \xi_1 + \tau$ since $\eta_2 - \xi_1 = O(\varepsilon \log \varepsilon)$ and τ is a constant. Here we have assumed that $\varepsilon \in (0, \sigma_3)$, where σ_3 is small enough so that for each $\varepsilon \in (0, \sigma_3)$, we have $O(\varepsilon \log \varepsilon) < \tau$. By Lemma 4.1, we have

$$y(t-\tau)\beta(y(t-\tau)) = O(\varepsilon).$$

Using (4.1) we know that

$$-\alpha y + O(\varepsilon) \leq y' \leq -\delta y + O(\varepsilon),$$

and thus the solution $y(t) \geq (\varepsilon^2/(1+\varepsilon))^\varepsilon e^{-\alpha\tau} + O(\varepsilon)$ and its derivative

$$y'(t) \leq -\delta(\varepsilon^2/(1+\varepsilon))^\varepsilon e^{-\alpha\tau} + O(\varepsilon) < 0 \text{ for } \varepsilon \in (0, \sigma_4),$$

where σ_4 is chosen so that for each $\varepsilon \in (0, \sigma_4)$, we have $-\delta(\varepsilon^2/(1+\varepsilon))^\varepsilon e^{-\alpha\tau} + O(\varepsilon) < 0$. So $y(t)$ is decreasing for $t \in [\eta_2, \tau + \xi_1]$. Note that $0 < y < y(\eta_2) \leq \varepsilon^\varepsilon$ so that (4.2) in Lemma 4.1 holds. Thus we can derive from (4.1) that

$$y'(t) = -\alpha y(t) + O(\varepsilon) \tag{4.12}$$

for $t \in [\eta_2, \tau + \xi_1]$. Coupling this equation with (3.4) and using (4.11) at the point $t = \eta_2$ give

$$y(t) = x(t) + O(-\varepsilon \log \varepsilon)$$

for $t \in [\eta_2, \tau + \xi_1]$.

For $t \in [\tau + \xi_1, \tau + \eta_2]$, again using the fact that both the derivatives of x and y are bounded and the length of this interval is of order $O(-\varepsilon \log \varepsilon)$, we have

$$y(t) = x(t) + O(-\varepsilon \log \varepsilon).$$

For $t \geq \tau + \eta_2$, the solution y begins to increase since Γ satisfies (3.7). To be precise, we have $\beta_\varepsilon(y(t)) < \beta_0$, $\beta_\varepsilon(y(t-\tau))y(t-\tau) = \beta_0 y(t-\tau) + O(-\varepsilon \log \varepsilon)$ and

$$\begin{aligned} y'(t) &= -(\delta + \beta_\varepsilon(y(t)))y(t) + k\beta_\varepsilon(y(t-\tau))y(t-\tau) \\ &\geq -\alpha y(t) + k\beta_0 y(t-\tau) + O(-\varepsilon \log \varepsilon) \\ &= -\alpha y(t) + \Gamma x(t-\tau) + O(-\varepsilon \log \varepsilon) \\ &\geq -\alpha(1+\eta) + \Gamma e^{-\alpha\tau} + O(-\varepsilon \log \varepsilon) \\ &> 0 \quad \text{for } \varepsilon \in (0, \sigma_5) \end{aligned}$$

as long as $y(t) \leq 1 + \eta$ and $t \leq 2\tau + \eta_2$. Here σ_5 is sufficiently small so that for each $\varepsilon \in (0, \sigma_5)$, we have $-\alpha(1+\eta) + \Gamma e^{-\alpha\tau} + O(-\varepsilon \log \varepsilon) > 0$. Using similar arguments as above, we conclude that there exist three points η_3, t_2^y, η_4, with $\eta_3 < t_2^y < \eta_4$ such that

$$y(\eta_3) = \left(\frac{\varepsilon^2}{1+\varepsilon}\right)^\varepsilon, \quad y(t_2^y) = 1, \quad y(\eta_4) = \left(\frac{1}{\varepsilon}\right)^{2\varepsilon},$$

$$\eta_3 = t_2^y + O(-\varepsilon \log \varepsilon), \quad \eta_4 = t_2^y + O(-\varepsilon \log \varepsilon), \tag{4.13}$$

and

$$t_2^y = t_2 + O(-\varepsilon \log \varepsilon). \tag{4.14}$$

We can continue this process to find that y will satisfy

$$y(t) = x(t) + O(-\varepsilon \log \varepsilon)$$

for $t \in [0, \tau + \xi_2]$, where $\xi_2 = \min\{t_2, \eta_3\}$. From the expression for x, we know from the preceding equation that there exists a point $t_3^y \in (\eta_4, \tau+\xi_2)$ such that $y(t_3^y) = 1+\eta$ and $t_3^y = t_3 + O(-\varepsilon \log \varepsilon)$.

For $t \in [\tau+\xi_2, \tau+\eta_4]$, using the same argument as in the interval $[\tau+\xi_1, \tau+\eta_2]$, we again have

$$y(t) = x(t) + O(-\varepsilon \log \varepsilon). \tag{4.15}$$

Finally for $t \geq \tau+\eta_4$, the solution is decreasing and will reach the value $1+\eta$ at some point T_y. In the whole interval $[0, T_x]$, if we choose $\varepsilon_1 = \min\{\sigma_i, 1 \leq i \leq 5\}$, then we can show as before that for each $\varepsilon \in (0, \varepsilon_1)$, we have

$$y(t) = x(t) + O(-\varepsilon \log \varepsilon),\ x \in [0, T_x], \tag{4.16}$$

and

$$T_y = T_x + O(-\varepsilon \log \varepsilon). \tag{4.17}$$

Furthermore, we also have $y(T_y) = 1 + \eta$ and

$$y(t) \geq 1 + \eta \text{ for } [T_y - \tau, T_y]. \qquad \square \tag{4.18}$$

Remark 4.3. By Lemma 4.2 and (4.1) we have two positive constants M_1 and M_2 which are independent of ε and the initial data φ so that for $t \geq 0$,

$$|y(t)| \leq M_1 \tag{4.19}$$

and

$$\left| \frac{dy(t)}{dt} \right| \leq M_2. \tag{4.20}$$

Now we are ready to define a continuous return map

$$R : A_\eta \ni \varphi \to y_{q(\varphi)} = F_\varepsilon(q(\varphi), \varphi) \in A_\eta,$$

where $q(\varphi) = T_y$. To verify that there exists a unique fixed point in A_η for the map R, we need to show that the map R is contractive, i.e., derive an estimation for the Lipschitz constant and show that the Lipschitz constant is less than 1.

4.2. Lipschitz constant for the map $\mathbb{R}$. The Lipschitz constant of a given map $T : D_T \to Y$, $D_T \subset X$, where X and Y are normed linear spaces, is given by

$$L(T) = \sup_{u \in D_T, v \in D_T, u \neq v} \frac{||T(u) - T(v)||}{||u - v||}.$$

In the case where $D_T = X = Y = \mathbb{R}$, $[u_1, u_2] \subset \mathbb{R}$, and $f = T$, we set

$$L_{[u_1,u_2]}(f) = L(f|[u_1, u_2]).$$

If $f(u) = u\beta_\varepsilon(u)$, $u \in \mathbb{R}$, we define the following four Lipschitz constants:

$$\begin{aligned} L_1^\varepsilon &= L_{[1+\eta, +\infty)}(u\beta_\varepsilon(u)), \\ L_2^\varepsilon &= L_{[(\frac{1}{\varepsilon})^{2\varepsilon}, +\infty)}(u\beta_\varepsilon(u)), \\ L_3^\varepsilon &= L_{(0, +\infty)}(u\beta_\varepsilon(u)), \\ L_4^\varepsilon &= L_{(0, (\frac{\varepsilon^2}{1+\varepsilon})^\varepsilon)}(u\beta_\varepsilon(u)). \end{aligned}$$

Similarly for the function $f(u) = u\beta_\varepsilon(u) - \beta_0 u$, $u \in \mathbb{R}$, we define the following Lipschitz constant for later use:

$$L_5^\varepsilon = L_{(0,(\frac{\varepsilon^2}{1+\varepsilon})^\varepsilon)}(u\beta_\varepsilon(u) - \beta_0 u).$$

When $\varepsilon << 1$, we have

$$L_1^\varepsilon = O\left(\frac{1}{\varepsilon(1+\eta)^{1/\varepsilon}}\right), \quad L_2^\varepsilon = O(\varepsilon), \quad L_3^\varepsilon = O(1/\varepsilon), \quad L_4^\varepsilon = O(1), \quad L_5^\varepsilon = O(\varepsilon). \tag{4.21}$$

THEOREM 4.4. *There exists ε_2, $\varepsilon_2 \in (0, \varepsilon_1)$, such that for each $\varepsilon \in (0, \varepsilon_2)$ the Lipschitz constant L_R^ε of the map R is less than 1. In particular, we have*

$$\lim_{\varepsilon \to 0} L_R^\varepsilon = 0.$$

Proof. Step 1. Take $\phi, \bar{\phi}$ in A_η. Using a similar argument as in the proof of Lemma 4.2, we conclude that there exist η_1, η_2 and $\bar{\eta}_1, \bar{\eta}_2$ such that

$$y^\phi(\eta_1) = \left(\frac{1}{\varepsilon}\right)^{2\varepsilon}, \; y^\phi(\eta_2) = \left(\frac{\varepsilon^2}{1+\varepsilon}\right)^\varepsilon, \; \eta_1 - \eta_2 = O(-\varepsilon \log \varepsilon)$$

and

$$y^{\bar{\phi}}(\bar{\eta}_1) = \left(\frac{1}{\varepsilon}\right)^{2\varepsilon}, \; y^{\bar{\phi}}(\bar{\eta}_2) = \left(\frac{\varepsilon^2}{1+\varepsilon}\right)^\varepsilon, \; \bar{\eta}_1 - \bar{\eta}_2 = O(-\varepsilon \log \varepsilon).$$

Let

$$\eta_{\min} = \min\{\eta_1, \bar{\eta}_1\}$$

and

$$\eta_{\max} = \max\{\eta_2, \bar{\eta}_2\}.$$

Then by (4.8) and (4.9) we have

$$\eta_{\min} = t_1 + O(-\varepsilon \log \varepsilon), \quad \eta_{\max} = t_1 + O(-\varepsilon \log \varepsilon), \quad \text{and} \tag{4.22}$$
$$\eta_{\max} - \eta_{\min} = O(-\varepsilon \log \varepsilon).$$

Since $t_1 = \log(1+\eta)/\delta < \tau$, from (4.22) we have that $\eta_{\min} < \tau$ and $\eta_{\max} < \tau$. Here we have chosen $\sigma_6 > 0$ sufficiently small so that for each $\varepsilon \in (0, \sigma_6)$

$$\eta_{\max} = \log(1+\eta)/\delta + O(-\varepsilon \log \varepsilon) < \tau.$$

For $t \in [0, \eta_{\min}]$, using (4.1) for $y^\phi(t)$ and $y^{\bar{\phi}}(t)$ gives

$$\frac{dy^\phi(t)}{dt} = -[\delta + \beta_\varepsilon(y^\phi(t))]y^\phi(t) + k\beta_\varepsilon(y^\phi(t-\tau))y^\phi(t-\tau) \tag{4.23}$$

and

$$\frac{dy^{\bar{\phi}}(t)}{dt} = -[\delta + \beta_\varepsilon(y^{\bar{\phi}}(t))]y^{\bar{\phi}}(t) + k\beta_\varepsilon(y^{\bar{\phi}}(t-\tau))y^{\bar{\phi}}(t-\tau). \tag{4.24}$$

Now we estimate the difference between $y^{\phi}(t)$ and $y^{\bar{\phi}}(t)$. Subtracting (4.24) from (4.23) yields

$$\begin{aligned}(4.25)\quad (y^{\phi}(t)-y^{\bar{\phi}}(t))' &= -\delta(y^{\phi}(t)-y^{\bar{\phi}}(t))\\ &\quad -[\beta_{\varepsilon}(y^{\phi}(t))y^{\phi}(t)-\beta_{\varepsilon}(y^{\bar{\phi}}(t))y^{\bar{\phi}}(t)]\\ &\quad +k[\beta_{\varepsilon}(y^{\phi}(t-\tau))y^{\phi}(t-\tau)-\beta_{\varepsilon}(y^{\bar{\phi}}(t-\tau))y^{\bar{\phi}}(t-\tau)].\end{aligned}$$

Substituting the inequalities

$$|\beta_{\varepsilon}(y^{\phi}(t))y^{\phi}(t)-\beta_{\varepsilon}(y^{\bar{\phi}}(t))y^{\bar{\phi}}(t)|\le L_2^{\varepsilon}|y^{\phi}(t)-y^{\bar{\phi}}(t)|$$

and

$$|\beta_{\varepsilon}(y^{\phi}(t-\tau))y^{\phi}(t-\tau)-\beta_{\varepsilon}(y^{\bar{\phi}}(t-\tau))y^{\bar{\phi}}(t-\tau)|\le L_1^{\varepsilon}||\phi-\bar{\phi}||$$

into (4.25), we have

$$(4.26)\qquad (y^{\phi}(t)-y^{\bar{\phi}}(t))'\le(\delta+L_2^{\varepsilon})\,|y^{\phi}(t)-y^{\bar{\phi}}(t)|+kL_1^{\varepsilon}||\phi-\bar{\phi}||.$$

Integrating (4.26) from 0 to t gives

$$(y^{\phi}(t)-y^{\bar{\phi}}(t))\le\int_0^t\Big((\delta+L_2^{\varepsilon})\,|y^{\phi}(s)-y^{\bar{\phi}}(s)|+kL_1^{\varepsilon}||\phi-\bar{\phi}||\Big)\,ds.$$

Similarly, we have

$$-(y^{\phi}(t)-y^{\bar{\phi}}(t))\le\int_0^t\Big((\delta+L_2^{\varepsilon})\,|y^{\phi}(s)-y^{\bar{\phi}}(s)|+kL_1^{\varepsilon}||\phi-\bar{\phi}||\Big)\,ds.$$

Thus, we have found that

$$(4.27)\qquad |y^{\phi}(t)-y^{\bar{\phi}}(t)|\le\int_0^t\Big((\delta+L_2^{\varepsilon})\,|y^{\phi}(s)-y^{\bar{\phi}}(s)|+kL_1^{\varepsilon}||\phi-\bar{\phi}||\Big)\,ds.$$

From Gronwall's inequality, we obtain

$$(4.28)\qquad |y^{\phi}(t)-y^{\bar{\phi}}(t)|\le C_1||\phi-\bar{\phi}||,$$

where

$$(4.29)\qquad C_1=\frac{e^{(\delta+L_2^{\varepsilon})\eta_{\min}}-1}{\delta+L_2^{\varepsilon}}kL_1^{\varepsilon}.$$

Step 2. For $t\in[\eta_{\min},\eta_{\max}]$, we have

$$|\beta_{\varepsilon}(y^{\phi}(t))y^{\phi}(t)-\beta_{\varepsilon}(y^{\bar{\phi}}(t))y^{\bar{\phi}}(t)|\le L_3^{\varepsilon}|y^{\phi}(t)-y^{\bar{\phi}}(t)|$$

and

$$|\beta_{\varepsilon}(y^{\phi}(t-\tau))y^{\phi}(t-\tau)-\beta_{\varepsilon}(y^{\bar{\phi}}(t-\tau))y^{\bar{\phi}}(t-\tau)|\le L_1^{\varepsilon}||\phi-\bar{\phi}||.$$

Thus from (4.23) and (4.24) we obtain, as before,

$$|y^{\phi}(t)-y^{\bar{\phi}}(t)|\le\int_{\eta_{\min}}^t\Big((\delta+L_3^{\varepsilon})\,|y^{\phi}(s)-y^{\bar{\phi}}(s)|+kL_1^{\varepsilon}||\phi-\bar{\phi}||\Big)\,ds+C_1||\phi-\bar{\phi}||.$$

Then by Gronwall's inequality, we have

$$|y^{\phi}(t) - y^{\bar{\phi}}(t)| \leq C_2 ||\phi - \bar{\phi}||, \tag{4.30}$$

where

$$C_2 = C_1 e^{(\delta + L_3^{\varepsilon})(\eta_{\max} - \eta_{\min})} + \frac{e^{(\delta + L_3^{\varepsilon})(\eta_{\max} - \eta_{\min})} - 1}{\delta + L_3^{\varepsilon}} k L_1^{\varepsilon} > C_1. \tag{4.31}$$

Remember that $\eta_{\min} \leq \tau$ since $t_1 < \tau$ in (3.14) and $\eta_{\min} = t_1 + O(-\varepsilon \log \varepsilon)$. Moreover $\eta_{\max} \leq \tau$ since $\eta_{\max} = t_1 + O(-\varepsilon \log \varepsilon)$ from (4.22).

Step 3. For $t \in [\eta_{\max}, \tau + \eta_{\min}]$,

$$|\beta_{\varepsilon}(y^{\phi}(\tau))y^{\phi}(t) - \beta_0 y^{\phi}(t) - (\beta_{\varepsilon}(y^{\bar{\phi}}(t))y^{\bar{\phi}}(t) - \beta_0 y^{\bar{\phi}}(t))| \leq L_5^{\varepsilon} |y^{\phi}(t) - y^{\bar{\phi}}(t)|$$

and

$$|\beta_{\varepsilon}(y^{\phi}(t-\tau))y^{\phi}(t-\tau) - \beta_{\varepsilon}(y^{\bar{\phi}}(t-\tau))y^{\bar{\phi}}(t-\tau)| \leq L_2^{\varepsilon} C_2 ||\phi - \bar{\phi}||.$$

It is thus easy to derive

$$|y^{\phi}(t) - y^{\bar{\phi}}(t)| \leq \int_{\eta_{\max}}^{t} \left((\alpha + L_5^{\varepsilon}) |y^{\phi}(s) - y^{\bar{\phi}}(s)| + k L_2^{\varepsilon} C_2 ||\phi - \bar{\phi}|| \right) ds + C_2 ||\phi - \bar{\phi}||$$

and to conclude that (since $\tau + \eta_{\min} - \eta_{\max} < \tau$)

$$|y^{\phi}(t) - y^{\bar{\phi}}(t)| \leq C_3 ||\phi - \bar{\phi}||, \tag{4.32}$$

where

$$C_3 = C_2 e^{\alpha\tau + \tau L_5^{\varepsilon}} + \frac{e^{\alpha\tau + \tau L_5^{\varepsilon}} - 1}{\alpha + L_5^{\varepsilon}} k L_2^{\varepsilon} C_2 > C_2. \tag{4.33}$$

Step 4. When $t \geq \tau + \eta_{\min}$, we have from (4.13) and (4.14) that there exist $\eta_3 < \eta_4$ and $\bar{\eta}_3 < \bar{\eta}_4$ such that

$$y^{\phi}(\eta_3) = \left(\frac{\varepsilon^2}{1+\varepsilon} \right)^{\varepsilon}, \; y^{\phi}(\eta_4) = \left(\frac{1}{\varepsilon} \right)^{2\varepsilon}, \; \eta_4 - \eta_3 = O(-\varepsilon \log \varepsilon)$$

and

$$y^{\bar{\phi}}(\bar{\eta}_3) = \left(\frac{\varepsilon^2}{1+\varepsilon} \right)^{\varepsilon}, \; y^{\bar{\phi}}(\bar{\eta}_4) = \left(\frac{1}{\varepsilon} \right)^{2\varepsilon}, \; \bar{\eta}_4 - \bar{\eta}_3 = O(-\varepsilon \log \varepsilon).$$

Let

$$\eta_{\min}^3 = \min\{\eta_3, \bar{\eta}_3\}, \; \eta_{\max}^4 = \max\{\eta_4, \bar{\eta}_4\}.$$

Then by (4.13) and (4.14) we have

$$\eta_{\min}^3 = t_2 + O(-\varepsilon \log \varepsilon), \; \eta_{\max}^4 = t_2 + O(-\varepsilon \log \varepsilon), \; \eta_{\max}^4 - \eta_{\min}^3 = O(-\varepsilon \log \varepsilon). \tag{4.34}$$

Since $t_2 > t_1 + \tau$, we can choose $\sigma_7 > 0$ sufficiently small so that for each $\varepsilon \in (0, \sigma_7)$ the inequality

$$\tau + \eta_{\max} < \eta_{\min}^3$$

holds. For $t \in [\tau + \eta_{\min}, \eta^3_{\min}]$, we similarly have

$$|y^{\phi}(t) - y^{\bar{\phi}}(t)| \le \int_{\tau+\eta_{\min}}^{t} \left((\alpha + L_5^{\varepsilon})|y^{\phi}(s) - y^{\bar{\phi}}(s)| + kL_3^{\varepsilon} C_3 ||\phi - \bar{\phi}|| \right) ds + C_3 ||\phi - \bar{\phi}||$$

and

$$|y^{\phi} - y^{\bar{\phi}}| \le C_4 ||\phi - \bar{\phi}||, \tag{4.35}$$

where

$$C_4 = C_3 e^{(\alpha + L_5^{\varepsilon})(\eta^3_{\min} - \tau - \eta_{\min})} + \frac{e^{(\alpha + L_5^{\varepsilon})(\eta^3_{\min} - \tau - \eta_{\min})} - 1}{\alpha + L_5^{\varepsilon}} kL_3^{\varepsilon} C_3 > C_3. \tag{4.36}$$

Step 5. For $t \in [\eta^3_{\min}, \eta^4_{\max}]$, from (4.22) and (4.34) it is easy to demonstrate that $\eta_{\max} \le t - \tau \le \eta^3_{\min}$. Thus we have

$$|y^{\phi}(t) - y^{\bar{\phi}}(t)| \le \int_{\eta^3_{\min}}^{t} \left((\delta + L_3^{\varepsilon})|y^{\phi}(s) - y^{\bar{\phi}}(s)| + kL_4^{\varepsilon} C_4 ||\phi - \bar{\phi}|| \right) ds + C_4 ||\phi - \bar{\phi}||.$$

Then it follows that

$$|y^{\phi}(t) - y^{\bar{\phi}}(t)| \le C_5 ||\phi - \bar{\phi}||, \tag{4.37}$$

where

$$C_5 = C_4 \left(e^{(\delta + L_3^{\varepsilon})(\eta^4_{\max} - \eta^3_{\min})} + \frac{e^{(\delta + L_3^{\varepsilon})(\eta^4_{\max} - \eta^3_{\min})} - 1}{\delta + L_3^{\varepsilon}} kL_4^{\varepsilon} \right). \tag{4.38}$$

Step 6. For $t \in [\eta^4_{\max}, \tau + \eta^4_{\max}]$, we claim that $y^{\phi}(t) \ge (1/\varepsilon)^{2\varepsilon}$ and $y^{\bar{\phi}}(t) \ge (1/\varepsilon)^{2\varepsilon}$. We prove this claim only for the function y^{ϕ}, because the proof for the function $y^{\bar{\phi}}$ is similar and hence omitted. Note that $t_3 > \eta^4_{\max} = t_2 + O(-\varepsilon \log \varepsilon)$ for each $\varepsilon \in (0, \sigma_8)$ where σ_8 is chosen so that $t_3 > t_2 + O(-\sigma_8 \log \sigma_8)$. Using $y^{\phi}(t) = x(t) + O(-\varepsilon \log \varepsilon)$, with $y^{\phi}(t - \tau) = x(t - \tau) + O(-\varepsilon \log \varepsilon) \ge e^{-\alpha\tau} + O(-\varepsilon \log \varepsilon)$, and (3.7) and (4.34), we have from (4.1) that $dy^{\phi}(t)/dt > 0$ for $t \in [\eta^4, t_3]$, and thus y^{ϕ} is increasing and satisfies $y^{\phi}(\eta^4_{\max}) \ge y^{\phi}(\eta_4) \ge (1/\varepsilon)^{2\varepsilon}$. For $t \in [t_3, \tau + \eta^4_{\max}]$, $x(t) \ge 1 + \eta$. Then using Lemma 4.2 again we have

$$y^{\phi}(t) = x(t) + O(-\varepsilon \log \varepsilon) > \left(\frac{1}{\varepsilon} \right)^{2\varepsilon}$$

provided $\varepsilon \in (0, \sigma_9)$, where σ_9 is sufficiently small so that the above formula holds for $\varepsilon \in (0, \sigma_9)$. Therefore, we obtain

$$|y^{\phi}(t) - y^{\bar{\phi}}(t)| \le \int_{\eta^4_{\max}}^{t} \left((\delta + L_2^{\varepsilon})|y^{\phi}(s) - y^{\bar{\phi}}(s)| + kL_3^{\varepsilon} C_5 ||\phi - \bar{\phi}|| \right) ds + C_5 ||\phi - \bar{\phi}||$$

and

$$|y^{\phi}(t) - y^{\bar{\phi}}(t)| \le C_6 ||\phi - \bar{\phi}||, \tag{4.39}$$

where

$$C_6 = C_5 \left(e^{(\delta + L_2^{\varepsilon})\tau} + \frac{e^{(\delta + L_2^{\varepsilon})\tau} - 1}{\delta + L_2^{\varepsilon}} kL_3^{\varepsilon} \right). \tag{4.40}$$

Step 7. When $t \geq \tau + \eta_{\max}^4$, both y and $\bar{y}$ are decreasing and will take the value $1+\eta$ after a finite time. Suppose that s and $\bar{s}$ satisfy

$$y^{\phi}(s) = 1+\eta,\ y^{\bar{\phi}}(\bar{s}) = 1+\eta.$$

For the rest of the proof, we consider only the case $s < \bar{s}$, since the case when $s \geq \bar{s}$ can be similarly dealt with and the proof is omitted. By (4.4) and (4.34), we also obtain

$$s - (\tau + \eta_{\max}^4) = T_x - (\tau + t_2) + O(-\varepsilon \log \varepsilon)$$

and

$$\bar{s} - (\tau + \eta_{\max}^4) = T_x - (\tau + t_2) + O(-\varepsilon \log \varepsilon),$$

where T_x is the period of the function x. Because the distance between $\tau + \eta_{\max}^4$ and s may be greater than τ, we need to split the interval $[\tau + \eta_{\max}^4, s]$ into subintervals $[\tau + \eta_{\max}^4, 2\tau + \eta_{\max}^4]$, $[2\tau + \eta_{\max}^4, 3\tau + \eta_{\max}^4], \ldots, [m\tau + \eta_{\max}^4, s]$, where the length of each interval is exactly τ except the last one. Here m is the largest integer less than or equal to $(s - (\tau + \eta_{\max}^4))/\tau$. We can successively estimate $|y^{\phi} - y^{\bar{\phi}}|$ on the above subintervals to obtain

$$|y^{\phi}(t) - y^{\bar{\phi}}(t)| \leq C_7 ||\phi - \bar{\phi}||,\ t \in [\tau + \eta_{\max}^4, s], \tag{4.41}$$

with

$$C_7 = C_6 \left(e^{(\delta + L_2^{\varepsilon})\tau} + \frac{e^{(\delta + L_2^{\varepsilon})\tau} - 1}{\delta + L_2^{\varepsilon}} k L_2^{\varepsilon} \right)^{T_x}. \tag{4.42}$$

For $t \in [s, \bar{s}]$, the function $y^{\bar{\phi}}$ satisfies

$$y^{\bar{\phi}}(\bar{s}) = 1+\eta \text{ and } y^{\bar{\phi}}(t) = 1 + \eta + O(-\varepsilon \log \varepsilon),$$

because the length of the interval $[s, \bar{s}]$ is of order $O(-\varepsilon \log \varepsilon)$ and the derivative of $y^{\bar{\phi}}$ is bounded; c.f. Remark 4.3. On the other hand, since $s = T_x + O(-\varepsilon \log \varepsilon)$, $\bar{s} = T_x + O(-\varepsilon \log \varepsilon)$, $x(t) \geq 1 + \eta$ for $t \in [t_3, T_x]$, and $y^{\bar{\phi}}(t) = x(t) + O(-\varepsilon \log \varepsilon)$ for $t \in [0, T_x]$, we know by (4.20) that for $t \in [s, \bar{s}]$,

$$y^{\bar{\phi}}(t - \tau) \geq \left(\frac{1}{\varepsilon} \right)^{2\varepsilon}$$

and

$$k\beta_{\varepsilon}(y^{\bar{\phi}}(t-\tau)) y^{\bar{\phi}}(t-\tau) = O(-\varepsilon \log \varepsilon).$$

Therefore, from (4.1) we know that for $t \in [s, \bar{s}]$ the function $y^{\bar{\phi}}$ is decreasing and

$$\begin{aligned} \left| \frac{dy^{\bar{\phi}}(t)}{dt} \right| &= \left| -(\delta + \beta_{\varepsilon}(y^{\bar{\phi}}(t))) y^{\bar{\phi}}(t) + k\beta_{\varepsilon}(y^{\bar{\phi}}(t-\tau)) y^{\bar{\phi}}(t-\tau) \right| \\ &\geq |-\delta(1+\eta) + O(-\varepsilon \log \varepsilon)| \\ &\geq \frac{\delta(1+\eta)}{2}. \end{aligned}$$

Here we have assumed that ε is in the interval $(0, \sigma_{10})$, where σ_{10} is chosen so that for each $\varepsilon \in (0, \sigma_{10})$, the inequality

$$-\delta(1+\eta) + O(-\varepsilon \log \varepsilon) < -\frac{\delta(1+\eta)}{2}$$

holds. Applying the mean value theorem to the function $y^{\bar{\phi}}$ yields the existence of $\rho \in [s, \bar{s}]$ such that

$$|y^{\bar{\phi}}(\bar{s}) - y^{\bar{\phi}}(s)| = |(y^{\bar{\phi}})'(\rho)(\bar{s} - s)| \geq \frac{\delta(1+\eta)}{2} |\bar{s} - s|$$

or, by (4.41),

$$\begin{aligned} |\bar{s} - s| &\leq \frac{2}{\delta(1+\eta)} |y^{\bar{\phi}}(\bar{s}) - y^{\bar{\phi}}(s)| = \frac{2}{\delta(1+\eta)} |y^{\phi}(s) - y^{\bar{\phi}}(s)|, \\ &\leq \frac{2C_7}{\delta(1+\eta)} ||\phi - \bar{\phi}||. \end{aligned} \tag{4.43}$$

Our ultimate goal is to derive an estimate of $|y^{\bar{\phi}}_{\bar{s}}(\theta) - y^{\phi}_{s}(\theta)|$ where $\theta \in [-\tau, 0]$. Indeed, we have

$$|y^{\bar{\phi}}_{\bar{s}}(\theta) - y^{\phi}_{s}(\theta)| \leq |y^{\bar{\phi}}_{\bar{s}}(\theta) - y^{\bar{\phi}}_{s}(\theta)| + |y^{\bar{\phi}}_{s}(\theta) - y^{\phi}_{s}(\theta)|. \tag{4.44}$$

The first term of the right-hand side is bounded by

$$\int_{s+\theta}^{\bar{s}+\theta} \frac{dy^{\bar{\phi}}(t)}{dt} dt \leq M_2 |\bar{s} - s|,$$

where M_2 is the maximum value of the derivative of the function $y^{\bar{\phi}}$; c.f. Remark 4.3. The second term of (4.44) is bounded by $C_7 ||\phi - \bar{\phi}||$. Thus from (4.44), we have

$$|y^{\bar{\phi}}_{\bar{s}}(\theta) - y^{\phi}_{s}(\theta)| \leq C_7 \left(1 + \frac{2M_2}{\delta(1+\eta)}\right) ||\phi - \bar{\phi}||. \tag{4.45}$$

Using (4.21), we conclude from (4.29), (4.31), (4.33), (4.36), (4.38), (4.40), and (4.42) that

$$\lim_{\varepsilon \to 0} L^{\varepsilon}_{R} = \lim_{\varepsilon \to 0} C_7 \left(1 + \frac{2M_2}{\delta(1+\eta)}\right) = 0 < 1.$$

Therefore we conclude that there exists $\varepsilon_2 < \min\{\varepsilon_1, \sigma_6, \sigma_7, \sigma_8, \sigma_9, \sigma_{10}\}$ so that for each $\varepsilon \in (0, \varepsilon_2)$, the Lipschitz constant L^{ε}_{R} of the map R is less than 1. This completes our proof. □

For $L^{\varepsilon}_{R} < 1$, the return map R is contractive and there exists a unique fixed point ϕ in A_η. Thus we have demonstrated the existence of a unique slowly oscillating periodic solution for (4.1). The stability and exponential attractivity of this unique periodic orbit can be established using the standard techniques developed in [31, 32, 33, 34, 36].

5. Asymptotic expansions for the periodic solution. In the previous section we used fixed point theory to prove that there exists a unique periodic orbit for (4.1). We now carry out a quantitative analysis of this periodic solution as $\varepsilon < \varepsilon_2$.

Since the map R is contractive and the Lipschitz constant L_R^ε is exponentially decaying as $\varepsilon \to 0$, we are able to give an asymptotic expansion for this particular solution for $t \in [-\tau, 0]$ with error bound beyond all integer orders of ε.

If we take the initial function given by $\phi = 1 + \eta$, then we have a solution $y^{1+\eta}(\cdot)$ which is not periodic. But by Lemma 4.2, we have $y^{1+\eta}(t) = x(t) + O(-\varepsilon \log \varepsilon)$ for $t \in [0, T_x]$, and a $T_{1+\eta} > 0$ such that

$$y^{1+\eta}_{T_{1+\eta}}(0) = 1 + \eta, \quad y^{1+\eta}_{T_{1+\eta}}(\theta) > 1 + \eta, \qquad \theta \in [-\tau, 0).$$

It is obvious that $y^{1+\eta}_{T_{1+\eta}}(\theta) \in A_\eta$.

Assume that y is the periodic solution to (4.1) and satisfies $y(\theta) \in A_\eta$ for $\theta \in [-\tau, 0]$. Suppose also that $y(\theta)$ has the following asymptotic expansion:

$$y(\theta) = \sum_{i=0}^{\infty} \phi_i(\theta), \ \theta \in [-\tau, 0]. \tag{5.1}$$

The function ϕ_0 is given by $y^{1+\eta}_{T_{1+\eta}}$, and $\phi_i, i \geq 1$, with the norm $||\phi|| = \max_{-\tau \leq \theta \leq 0} |\phi(\theta)|$, will be constructed below. Let $y^{\phi_0}_{T_0}$ denote the image of the return map R at ϕ_0, i.e.,

$$y^{\phi_0}_{T_0}(\theta) = R(\phi_0) = F_\varepsilon(T_0, \phi_0), \ \theta \in [-\tau, 0],$$

where $T_0 > 0$ satisfies

$$y^{\phi_0}_{T_0}(0) = 1 + \eta, \ y^{\phi_0}_{T_0}(\theta) > 1 + \eta, \ \theta \in [-\tau, 0).$$

Similarly, by induction, we set

$$\phi_1 = R(\phi_0) - \phi_0 = y^{\phi_0}_{T_0} - \phi_0,$$

$$y^{\phi_1}_{T_1}(\theta) = R(\phi_1) = F_\varepsilon(T_1, \phi_1),$$

$$\phi_n(\theta) = R^n(\phi_0) - R^{n-1}(\phi_0) \text{ for } n \geq 2,$$

$$y^{\phi_n}_{T_n}(\theta) = R(\phi_n) = F_\varepsilon(T_n, \phi_n) \text{ for } n \geq 2,$$

where T_n satisfies

$$y^{\phi_n}_{T_n}(0) = 1 + \eta, \ y^{\phi_n}_{T_n}(\theta) > 1 + \eta, \ \theta \in [-\tau, 0), \ n \geq 1.$$

Thus we have

$$\begin{aligned} |\phi_n(\theta) - \phi_{n-1}(\theta)| &\leq L_R^\varepsilon |\phi_{n-1}(\theta) - \phi_{n-2}(\theta)| \\ &\leq (L_R^\varepsilon)^{n-1} |\phi_1(\theta) - \phi_0(\theta)|. \end{aligned}$$

Therefore, $y(\theta) = \sum_{i=0}^{\infty} \phi_i(\theta)$ is uniformly convergent for $\theta \in [-\tau, 0]$ and it is the fixed point of R.

We now give an asymptotic expansion for the period of the periodic solution y. Using (4.43), we have

$$|T_i - T_{i-1}| \le \frac{2C_7}{\delta(1+\eta)}||\phi_i - \phi_{i-1}||,$$

which means that the series

$$T_0 + \sum_{j=1}^{\infty}(T_j - T_{j-1})$$

is absolutely convergent to some constant, say, T_ε. Since L_R is exponentially decaying as $\varepsilon \to 0$, it is easy to see that the value of T_ε is dominated by T_0 in the sense that $T_\varepsilon - T_0$ is exponentially small as $\varepsilon \to 0$. Likewise the value of $y(\theta)$ in (5.1) is dominated by ϕ_0 with an exponential error bound as $\varepsilon \to 0$. Thus when $t \in [0, T_0]$, we know that the periodic solution $y(t)$ is also dominated by $y^{\phi_0}(t)$. Therefore the estimate of $y^{\phi_0}(t)$ and T_0 becomes significant. From Lemma 4.2 we have the following rough result for $y^{\phi_0}(t)$ and T_0:

$$y^{\phi_0}(t) = x(t) + O(-\varepsilon \log \varepsilon),\ T_0 = T_x + O(-\varepsilon \log \varepsilon).$$

We now give refined estimates for $y^{\phi_0}(t)$ and T_0 using the above information. As in the proof of Lemma 4.2, we split the interval $[0, T_0]$ into subintervals and estimate $y^{\phi_0}(t)$ on each subinterval successively. We demonstrate this process on the first subinterval for the purpose of illustration. Remember that the initial data are taken to be ϕ_0 which is greater than $1+\eta$ when t lies in the interval $[-\tau, 0)$. Let $t_1^{\phi_0}, \eta_1$, and η_2 be the values as defined in the proof of Lemma 4.2. Thus $t_1^{\phi_0}$ satisfy $y^{\phi_0}(t_1^{\phi_0}) = 1$. Integrating (4.1) from 0 to t, $t \in [0, t_1^{\phi_0}]$, gives

$$\begin{aligned} y^{\phi_0}(t) - y^{\phi_0}(0) = &-\delta \int_0^t y^{\phi_0}(s)ds - \int_0^t \beta_\varepsilon(y^{\phi_0}(s))y^{\phi_0}(s)ds \\ &+ k\int_0^t \beta_\varepsilon(y^{\phi_0}(s-\tau))y^{\phi_0}(s-\tau)ds. \end{aligned} \tag{5.2}$$

Since $t_1^{\phi_0} = t_1 + O(-\varepsilon \log \varepsilon)$ and $t_1 < \tau$, it is easy to see that the last term of the right-hand side of (5.2) is small and of $O(\varepsilon)$. Next we claim that

$$\int_0^t \beta_\varepsilon(y^{\phi_0}(s))y^{\phi_0}(s)ds = O(\varepsilon), \quad t \in [0, t_1^{\phi_0}]. \tag{5.3}$$

Indeed when $t \in [0, t_1^{\phi_0}]$, we have $k\beta y^{\phi_0}(t-\tau)y^{\phi_0}(t-\tau) = O(\varepsilon)$. Then from (4.1) we have

$$-\alpha(1+\eta) \le \frac{dy^{\phi_0}(t)}{dt} = -[\beta_\varepsilon(y^{\phi_0}(t)) + \delta]y^{\phi_0}(t) + O(\varepsilon) \le -\delta + O(\varepsilon). \tag{5.4}$$

Thus from (5.4) and the fact that

$$\begin{aligned} \left|\int_0^t \beta_\varepsilon(y^{\phi_0}(s))y^{\phi_0}(s)\frac{dy^{\phi_0}}{ds}ds\right| &\le \left|\int_0^{t_1^{\phi_0}} \beta_\varepsilon(y^{\phi_0}(s))y^{\phi_0}(s)\frac{dy^{\phi_0}}{ds}ds\right| \\ &= \left|\int_{1+\eta}^1 \frac{\beta_0 u}{1+u^{1/\varepsilon}}du\right| \\ &= O(\varepsilon), \end{aligned}$$

we know that $\int_0^t \beta_\varepsilon(y^{\phi_0}(s))y^{\phi_0}(s)ds$ is also of $O(\varepsilon)$ and the claim (5.3) is true. It follows then from (5.2) that for $t \in [0, t_1^{\phi_0}]$,

$$y^{\phi_0}(t) \ = -\delta \int_0^t y^{\phi_0}(t)dt + 1 + \eta + O(\varepsilon).$$

Using Gronwall's inequality, we obtain

$$y^{\phi_0}(t) = (1 + \eta + O(\varepsilon))e^{-\delta t},$$

which implies

$$y^{\phi_0}(t) = x(t) + O(\varepsilon),\ t \in [0, t_1^{\phi_0}]. \tag{5.5}$$

Continuing the above process, we can prove that (5.5) holds in the entire interval $[0, T_0]$. Furthermore, we also have

$$T_0 = T_x + O\left(\varepsilon\right),$$

which completes our refined estimate.

LONG-TIME EXISTENCE OF QUASILINEAR WAVE EQUATIONS EXTERIOR TO STAR-SHAPED OBSTACLES VIA ENERGY METHODS*

JASON METCALFE† AND CHRISTOPHER D. SOGGE‡

Abstract. We establish long-time existence results for quasilinear wave equations in the exterior of star-shaped obstacles. To do so, we prove an analogue of the mixed-norm estimates of Keel, Smith, and Sogge for the perturbed wave equation. The arguments that are presented rely only upon the invariance of the wave operator under translations and spatial rotations.

Key words. systems of nonlinear wave equations, exterior domains, almost global existence, star-shaped

AMS subject classification. 35L70

DOI. 10.1137/050627149

1. Introduction.

The purpose of this article is to establish long-time existence results for quasilinear wave equations in the exterior of a star-shaped obstacle. The proofs that are presented rely upon the classical invariance of the wave operator under translations and spatial rotations. These techniques use only energy methods, and thus we are optimistic about their potential use in other applications. A key step in completing the proof is to establish a weighted $L^2_t L^2_x$-estimate for the perturbed equation that is analogous to the one of Keel, Smith, and Sogge [8] for the free wave equation.

Let us more explicitly describe the initial value boundary value problem that we will study. We begin by fixing an obstacle $\mathcal{K} \subset \mathbb{R}^n$ that is compact, has smooth boundary, and is star-shaped with respect to the origin. The latter condition means that there is a smooth positive function ψ on S^{n-1} so that

$$\mathcal{K} = \{(r,\omega) \,:\, \psi(\omega) - r \geq 0\}.$$

Here, we have expanded x in polar coordinates as $x = r\omega$, $(r,\omega) \in [0,\infty) \times S^{n-1}$.

For such a fixed $\mathcal{K}$, we examine the quasilinear wave equation

$$\begin{cases} \Box u = Q(du, d^2u), \quad (t,x) \in \mathbb{R}_+ \times \mathbb{R}^n \backslash \mathcal{K}, \\ u(t,\,\cdot\,)|_{\partial\mathcal{K}} = 0, \\ u(0,\,\cdot\,) = f, \quad \partial_t u(0,\,\cdot\,) = g. \end{cases} \tag{1.1}$$

Here and throughout, $\Box = (\partial_t^2 - \Delta)$ denotes the standard d'Alembertian.

The nonlinearity $Q(du, d^2u)$ in (1.1) is quadratic in its arguments and is linear in d^2u. We can expand

$$Q(du, d^2u) = B(du) + \sum_{0 \leq \alpha,\beta,\gamma \leq n} B^{\alpha\beta}_{\gamma} \partial_\gamma u \partial_\alpha \partial_\beta u, \tag{1.2}$$

where $B(du)$ is a quadratic form and the $B_\gamma^{\alpha\beta}$ are real constants. We assume the symmetry condition

$$B_\gamma^{\alpha\beta} = B_\gamma^{\beta\alpha}. \tag{1.3}$$

By scaling, we note that it suffices to choose $\mathcal{K} \subset \{|x| < 1\}$, and we will make this assumption throughout.

In order to solve (1.1), the data must be assumed to satisfy the relevant compatibility conditions. Briefly, this means that if we set $J_k u = \{\partial_x^\alpha u : 0 \le |\alpha| \le k\}$ and if u is a formal H^m solution for some fixed m, then we can write $\partial_t^k u(0, \cdot) = \psi_k(J_k f, J_{k-1} g)$, $0 \le k \le m$, for compatibility functions ψ_k which depend on Q, $J_k f$, and $J_{k-1} g$. The compatibility condition for $(f, g) \in H^m \times H^{m-1}$ states that ψ_k must vanish on $\partial\mathcal{K}$ when $0 \le k \le m-1$. Additionally, $(f, g) \in C^\infty$ are said to satisfy the compatibility condition to infinite order if this condition holds for all m. For a more detailed exposition on compatibility conditions, see, e.g., [7].

In describing the main results, we will use the notation $\{\Omega\} = \{x_i\partial_j - x_j\partial_i : 1 \le i < j \le n\}$ to denote the generators of the spatial rotations. We will also use $\{Z\} = \{\partial_k, \Omega : 0 \le k \le n\}$ to denote the generators of translations and spatial rotations.

Our main results are as follows. The first states that small-data solutions to (1.1) exist almost globally if $n = 3$.

THEOREM 1.1. *Assume that the star-shaped obstacle $\mathcal{K} \subset \mathbb{R}^3$ and the nonlinearity $Q(du, d^2u)$ are as above. Suppose that the initial data $(f, g) \in C^\infty(\mathbb{R}^3\backslash\mathcal{K})$ satisfy the compatibility condition to infinite order. Then, there are constants $\kappa, \varepsilon_0 > 0$ and an integer $N > 0$ so that for all $\varepsilon < \varepsilon_0$ and data satisfying*

$$\sum_{|\mu|\le N} \|Z^\mu \nabla_x f\|_{L^2(\mathbb{R}^3\backslash\mathcal{K})} + \sum_{|\mu|\le N} \|Z^\mu g\|_{L^2(\mathbb{R}^3\backslash\mathcal{K})} \le \varepsilon, \tag{1.4}$$

(1.1) *has a unique solution $u \in C^\infty([0, T_\varepsilon] \times \mathbb{R}^3\backslash\mathcal{K})$ with*

$$T_\varepsilon = \exp(\kappa/\varepsilon). \tag{1.5}$$

This bound on the lifespan of solutions in $n = 3$ is sharp, as is illustrated by finite propagation speed and the counterexamples of John [5] and Sideris [21] in the boundaryless case.

The second main result states that small-data solutions exist globally in higher dimensions.

THEOREM 1.2. *Suppose $n \ge 4$. Assume that the star-shaped obstacle $\mathcal{K} \subset \mathbb{R}^n$ and the nonlinearity $Q(du, d^2u)$ are as above. Suppose that the initial data $(f, g) \in C^\infty(\mathbb{R}^n\backslash\mathcal{K})$ satisfy the compatibility condition to infinite order. Then, there are a constant $\varepsilon_0 > 0$ and an integer $N > 0$ so that for all $\varepsilon < \varepsilon_0$ and data satisfying*

$$\sum_{|\mu|\le N} \|Z^\mu \nabla_x f\|_{L^2(\mathbb{R}^n\backslash\mathcal{K})} + \sum_{|\mu|\le N} \|Z^\mu g\|_{L^2(\mathbb{R}^n\backslash\mathcal{K})} \le \varepsilon, \tag{1.6}$$

(1.1) *has a unique solution $u \in C^\infty([0, \infty) \times \mathbb{R}^n\backslash\mathcal{K})$.*

While we have stated only the theorems for scalar wave equations, as the proofs rely only upon energy methods, straightforward modifications would yield the results for multiple speed systems of wave equations. In order not to further complicate the

notation, we will prove only the scalar case. A more detailed exposition concerning the multiple speed case will be available in a forthcoming paper on null-form wave equations.

Theorem 1.1 was first proved by Keel, Smith, and Sogge [9]. It is an analogue of the results concerning boundaryless wave equations of John and Klainerman [6] and Klainerman and Sideris [11]. Theorem 1.2 was previously shown by the authors [17]. This generalizes the work on wave equations in higher dimensions previously completed by Metcalfe [13], Shibata and Tsutsumi [20], and Hayashi [3]. It is also worth pointing out the following works for related problems involving null-form nonlinearities: Keel, Smith, and Sogge [7]; Metcalfe and Sogge [16]; and Metcalfe, Nakamura, and Sogge [14, 15]. The techniques in this paper appear to allow for some simplifications of these proofs, and this will be explored in a subsequent paper. The arguments, however, are more involved as they require the use of the scaling vector field and decay estimates of Klainerman and Sideris [11].

The techniques used to prove Theorem 1.1 represent an improvement over those in [9] in a number of ways. Most importantly, the proofs in this article make no reference to the fundamental solution of the wave equation or to the sharp Huygens' principle. Thus, it is believed that these techniques will be more suitable for other applications. For example, one might compare the methods of Sideris and Tu [24] to those used in Sideris [22, 23]. Additionally, we are not required to use the scaling vector field $L = t\partial_t + r\partial_r$. On a lesser note, we remark that the proofs herein seem to require less regularity of the initial data and less regularity of the boundary of the obstacle. As neither proof takes care to minimize such regularity, there is much possibility for further improvement in this direction. The proof of Theorem 1.2 improves upon the techniques of previous works in similar ways.

It is interesting to note that our arguments never make explicit use of the well-known decay of local energy. See, e.g., Lax, Morawetz, and Phillips [12]. We do, however, rely upon a geometrical condition that is sufficient to ensure such estimates. This condition is used in ways that are reminiscent of those of Morawetz [18] in proving said decay estimates.

A key estimate which is common to many of the previous studies of wave equations in exterior domains was established by Keel, Smith, and Sogge [8] and states that for $n \geq 3$

$$(\log(2+T))^{-1/2}\Big(\|\langle x\rangle^{-1/2}\nabla_{t,x}\phi\|_{L^2_tL^2_x([0,T]\times\mathbb{R}^n)} + \|\langle x\rangle^{-3/2}\phi\|_{L^2_tL^2_x([0,T]\times\mathbb{R}^n)}\Big) \lesssim \|\nabla_{t,x}\phi(0,\,\cdot\,)\|_2 + \int_0^T \|\Box\phi(s,\,\cdot\,)\|_2\,ds. \tag{1.7}$$

The proof is easily modified to yield the second estimate

$$\|\langle x\rangle^{-1/2-}\nabla_{t,x}\phi\|_{L^2_tL^2_x([0,T]\times\mathbb{R}^n)} + \|\langle x\rangle^{-3/2-}\phi\|_{L^2_tL^2_x([0,T]\times\mathbb{R}^n)} \lesssim \|\nabla_{t,x}\phi(0,\,\cdot\,)\|_2 + \int_0^T \|\Box\phi(s,\,\cdot\,)\|_2\,ds. \tag{1.8}$$

Here, we are using the notation $\langle x\rangle = \langle r\rangle = (1+|x|^2)^{1/2}$. We are also using the notation $\langle x\rangle^{-1/2-}$ and $\langle x\rangle^{-3/2-}$ to indicate that (1.8) holds with the weights replaced, respectively, by $\langle x\rangle^{-1/2-\delta}$ and $\langle x\rangle^{-3/2-\delta}$ for any $\delta > 0$. Moreover, we are using $A \lesssim B$ to indicate $A \leq CB$ for some positive, unspecified constant C.

These estimates are related to an earlier one of Strauss [27] and were used by Keel, Smith, and Sogge [8] to give a proof of almost global existence to semilinear

wave equations in exterior domains. Using this estimate, long-time existence was established using the $O(1/|x|)$ decay of the wave equation rather than the more standard $O(1/t)$ decay which is much more difficult to prove when there is a boundary. Metcalfe [13] completed the analogous result for higher dimensions using an estimate of the form (1.8) and arguments that are reminiscent of [8].

It should be noted that estimates similar to (1.7) and (1.8) which hold in all dimensions have been shown by Hidano and Yokoyama [4]. The above estimates should also be compared to the Morawetz identities (see, e.g., [19])

$$\||x|^{-1/2}\not\nabla\phi\|_{L^2_tL^2_x([0,T]\times\mathbb{R}^n)} + \||x|^{-3/2}\phi\|_{L^2_tL^2_x([0,T]\times\mathbb{R}^n)} \lesssim \|\nabla_{t,x}\phi(0,\,\cdot\,)\|_2 + \int_0^T \|\Box\phi(s,\,\cdot\,)\|_2\,ds, \quad n \geq 4,$$

and

$$\||x|^{-1/2}\not\nabla\phi\|_{L^2_tL^2_x([0,T]\times\mathbb{R}^3)} + \|\phi(\,\cdot\,,0)\|_{L^2_t([0,T])} \lesssim \|\nabla_{t,x}\phi(0,\,\cdot\,)\|_2 + \int_0^T \|\Box\phi(s,\,\cdot\,)\|_2\,ds, \quad n = 3,$$

which correspond to choosing $f(r) \equiv 1$ in the proof of Lemma 4.1. Here $\not\nabla$ denotes the angular portion of ∇_x.

The estimates (1.7) and (1.8) are proved by scaling a version of (1.8) where the norms in the left side are taken over $[0,T] \times \{|x| < 1\}$. These local versions are established either, in odd dimensions, by noticing that the backward light cones $s + |x| \in (j-1, j]$, $j = 1, 2, 3, \ldots$, have finite overlap or by an argument using Plancherel's identity (see Smith and Sogge [25]). Then, using techniques that resemble those of [25], one can show that an estimate for the Dirichlet-wave equation follows from those for the free equation.

The estimates (1.7) and (1.8) are, however, insufficient to give a proof of long-time existence for quasilinear equations as there is a loss of regularity in the right side. In order to get around this, previous works have had to rely on pointwise estimates that involve direct estimation of the fundamental solution of the free wave equation.

Recently, Rodnianski [26, Appendix] has given a new proof of an estimate related to (1.8). This new proof relies only upon energy methods. A main topic of this paper is the further study of this argument. In particular, we show that Rodnianski's argument can be used to prove (1.7) and (1.8). Moreover, we show that this argument can be used to directly prove an estimate for the Dirichlet-wave equation if the obstacle is assumed to be star-shaped. Thus, we will not rely on the cutoff methods used previously. Last, this new geometric argument, unlike the previously established proofs, lends itself well to establishing similar weighted estimates for perturbed equations. With such estimates for the perturbed equation, one can prove Theorems 1.1 and 1.2 using the arguments of [8].

The mixed-norm estimates for the perturbed equation in Theorem 5.1 give a partial answer to questions raised in Alinhac [1] concerning the adaptability of the Keel–Smith–Sogge estimates to more general settings. During final preparations of this article, it was learned that Alinhac [2] had independently obtained a Keel–Smith–Sogge-type estimate for the perturbed wave equation using different (although related) techniques. This argument, however, requires assumptions on the perturbation that are less favorable in the current setting. In particular, it is required that the perturbation decay in t. When there is a boundary, such decay is quite difficult to prove, and

we are using the mixed-norm estimates in place of such decay. Thus, it is essential that we require the perturbation terms to have decay only in $|x| = r$.

Before proceeding, we fix some notation. Throughout the paper, we will use the Einstein convention where repeated indices are summed. We will use Greek indices $\alpha, \beta, \gamma, \delta$ when the indices are to run from $0, \dots, n$. We will use Latin indices a, b when the implicit summations run from $1, \dots, n$. We will let $g_{\alpha\beta} = \mathrm{diag}(-1, 1, \dots, 1)$ be the Minkowski metric, and $\langle \cdot, \cdot \rangle$ will occasionally be used to denote the Euclidean inner product on $\mathbb{R}^n$. Unless explicitly stated to the contrary, L^2 norms are taken over $\mathbb{R}^n \backslash \mathcal{K}$. We will let $S_T = [0, T] \times \mathbb{R}^n \backslash \mathcal{K}$ denote a time strip of height T. We will use the notation $t = x_0$, $\partial_t = \partial_0$ interchangeably. And, when convenient, we will use $' = \partial = \nabla_{t,x} = (\partial_t, \nabla_x)$ to denote the full space-time gradient. We will use D to denote the Levi–Civita connection of $g_{\alpha\beta}$, but as this metric is flat, we have the correspondence $D^\alpha = \partial^\alpha$.

This paper is organized as follows. In the next section, we will give the weighted Sobolev inequality from which we easily obtain the required $O(1/|x|^{(n-1)/2})$ decay for solutions to the wave equation. In the third section, we prove the basic energy estimates that will be used in the proofs of long-time existence. In the fourth section, we give the new geometrical proof of the mixed-norm estimates of Keel, Smith, and Sogge. This argument follows that of Rodnianski [26, Appendix] quite closely. In the following section, we show that the energy methods used to prove the mixed-norm estimates are stable under small perturbations. In the final two sections, we give the proofs of Theorems 1.1 and 1.2, respectively.

2. Sobolev estimates. In this section, we give the now standard weighted Sobolev estimate from which one can obtain the necessary $O(1/|x|^{(n-1)/2})$ decay in order to show our long-time existence results. See [10].

LEMMA 2.1. *Suppose that $h \in C^\infty(\mathbb{R}^n)$. Then, for $R \geq 1$,*

$$\|h\|_{L^\infty(R/2<|x|<R)} \lesssim R^{-(n-1)/2} \sum_{|\mu|+|\nu| \leq \frac{n+2}{2}} \|\Omega^\mu \partial_x^\nu h\|_{L^2(R/4<|x|<2R)}. \tag{2.1}$$

3. Energy estimates. In this section, we will collect the energy estimates that we will require. These results are rather standard. We will be concerned with solutions $\phi \in C^\infty(\mathbb{R}_+ \times \mathbb{R}^n \backslash \mathcal{K})$ of the Dirichlet-wave equation

$$\begin{cases} \Box_h \phi = F, \\ \phi|_{\partial\mathcal{K}} = 0, \end{cases} \tag{3.1}$$

where

$$\Box_h \phi = -\partial^\alpha \partial_\alpha \phi + h^{\alpha\beta} \partial_\alpha \partial_\beta \phi = (\partial_t^2 - \Delta)\phi + \sum_{\alpha,\beta=0}^n h^{\alpha\beta}(t,x) \partial_\alpha \partial_\beta \phi.$$

We shall assume that the $h^{\alpha\beta}$ satisfy the symmetry conditions

$$h^{\alpha\beta} = h^{\beta\alpha} \tag{3.2}$$

as well as the size conditions

$$\sum_{\alpha,\beta=0}^n |h^{\alpha\beta}(t,x)| \leq \delta \ll 1. \tag{3.3}$$

We define the energy form associated with $\Box_h$

$$e_0 = e_0(\phi) = (\partial_0\phi)^2 + \frac{1}{2}\partial^\gamma\phi\partial_\gamma\phi - g_{0\gamma}h^{\gamma\delta}\partial_\delta\phi\partial_0\phi - \frac{1}{2}h^{\gamma\delta}\partial_\gamma\phi\partial_\delta\phi. \tag{3.4}$$

Our most basic estimate involves

$$E_M(t) = E_M(\phi)(t) = \int_{\mathbb{R}^n\setminus\mathcal{K}} \sum_{j=0}^{M} e_0(\partial_t^j\phi)(t,x)\,dx.$$

LEMMA 3.1. *Fix $M = 0, 1, 2, \ldots$ and assume that the perturbation terms $h^{\alpha\beta}$ are as above. Suppose also that $\phi \in C^\infty$ solves* (3.1) *and that for every t, $\phi(t,x) = 0$ for large $|x|$. Then,*

$$E_M(T) \lesssim E_M(0) + \sum_{j,k=0}^{M}\int_0^T\int_{\mathbb{R}^n\setminus\mathcal{K}} |(\partial_0\partial_t^k\phi)(\Box_h\partial_t^j\phi)|\,dx\,dt \tag{3.5}$$

$$+ \sum_{j,k=0}^{M}\int_0^T\int_{\mathbb{R}^n\setminus\mathcal{K}} \Big(|(\partial_\alpha h^{\alpha\beta})(\partial_0\partial_t^j\phi)(\partial_\beta\partial_t^k\phi)| + |(\partial_0 h^{\alpha\beta})(\partial_\alpha\partial_t^j\phi)(\partial_\beta\partial_t^k\phi)|\Big)\,dx\,dt.$$

We first note that since $\partial_t^j\phi$ satisfies the Dirichlet boundary conditions for $1 \le j \le M$ it suffices to prove the result for $M = 0$. To proceed with the proof, we must define the other components of the energy-momentum vector. For $k = 1, \ldots, n$, we set

$$e_k = e_k(\phi) = \partial_k\phi\partial_0\phi - g_{k\gamma}h^{\gamma\delta}\partial_\delta\phi\partial_0\phi. \tag{3.6}$$

Calculating the divergence of this energy-momentum vector, we see that

$$D^\alpha e_\alpha = -\partial_0\phi\Box_h\phi - (\partial_\alpha h^{\alpha\delta})\partial_\delta\phi\partial_0\phi + \frac{1}{2}(\partial_0 h^{\gamma\delta})\partial_\gamma\phi\partial_\delta\phi. \tag{3.7}$$

If we integrate in the spatial components and apply the divergence theorem, it follows that

$$\partial_t\int_{\mathbb{R}^n\setminus\mathcal{K}} e_0\,dx + \int_{\partial\mathcal{K}} e_a n^a\,d\sigma = \int_{\mathbb{R}^n\setminus\mathcal{K}} \partial_0\phi\Box_h\phi\,dx \tag{3.8}$$

$$+ \int_{\mathbb{R}^n\setminus\mathcal{K}} \left((\partial_\alpha h^{\alpha\delta})\partial_\delta\phi\partial_0\phi - \frac{1}{2}(\partial_0 h^{\gamma\delta})\partial_\gamma\phi\partial_\delta\phi\right)\,dx,$$

where $\vec{n}$ is the outward unit normal to $\mathcal{K}$ and $d\sigma$ is the surface measure on $\partial\mathcal{K}$.

Since ∂_t preserves the Dirichlet boundary condition, we have that $\partial_t\phi$ vanishes on $\partial\mathcal{K}$ and that the integrand of the second term in the left side of (3.8) vanishes. If we integrate the remaining terms over a time interval $[0,T]$, (3.5) follows easily. □

Next, we will need energy estimates that also involve spatial derivatives.

LEMMA 3.2. *Suppose that the $h^{\alpha\beta}$ are as above with δ chosen sufficiently small. Then, if ϕ solves* (3.1) *and if $N = 0, 1, 2, \dots$ is fixed,*

$$\begin{aligned}\sum_{|\mu|\le N} \|\partial^\mu_{t,x}\phi'(T,\,\cdot\,)\|_2 &\lesssim \sum_{j\le N} \|\partial_t^j \phi'(0,\,\cdot\,)\|_2 \\ &+ \sum_{j,k=0}^N \left(\int_0^T \int_{\mathbb{R}^n\setminus\mathcal{K}} |(\partial_0\partial_t^k\phi)(\Box_h\partial_t^j\phi)|\,dx\,dt\right)^{1/2} \\ &+ \sum_{j,k=0}^N \left[\int_0^T \int_{\mathbb{R}^n\setminus\mathcal{K}} \Big(|(\partial_\alpha h^{\alpha\beta})(\partial_0\partial_t^j\phi)(\partial_\beta\partial_t^k\phi)| + |(\partial_0 h^{\alpha\beta})(\partial_\alpha\partial_t^j\phi)(\partial_\beta\partial_t^k\phi)|\Big)\,dx\,dt\right]^{1/2} \\ &+ \sum_{|\mu|\le N-1} \|\Box\partial^\mu_{t,x}\phi(T,\,\cdot\,)\|_2. \end{aligned} \tag{3.9}$$

Since

$$\frac{1}{2}|\phi'(t,x)|^2 \le e_0(t,x) \le 2|\phi'(t,x)|^2$$

for δ in (3.3) sufficiently small, this follows from (3.9) and a standard elliptic regularity argument. The interested reader can see, e.g., Lemma 2.3 of [16] or Theorem 5.2 of [9]. □

Finally, we will need energy estimates that involve the generators of spatial rotations as well as derivatives.

LEMMA 3.3. *Fix $N = 0, 1, 2, \dots$ and set*

$$Y_N(t) = \sum_{|\mu|\le N} \int e_0(Z^\mu\phi)(t,x)\,dx.$$

Suppose that (3.3) *holds for δ sufficiently small. Then*

$$\begin{aligned}\partial_t Y_N(t) &\lesssim \sum_{|\mu|,|\nu|\le N} \int_{\mathbb{R}^n\setminus\mathcal{K}} |(\partial_0 Z^\mu\phi)(\Box_h Z^\nu\phi)|\,dx \\ &+ \sum_{|\mu|,|\nu|\le N} \int_{\mathbb{R}^n\setminus\mathcal{K}} \Big(|(\partial_\gamma h^{\gamma\delta})(\partial_0 Z^\mu\phi)(\partial_\delta Z^\nu\phi)| + |(\partial_0 h^{\gamma\delta})(\partial_\gamma Z^\mu\phi)(\partial_\delta Z^\nu\phi)|\Big)\,dx \\ &+ \sum_{|\mu|\le N+1} \|\partial^\mu u'(s,\,\cdot\,)\|^2_{L^2(|x|<1)}. \end{aligned} \tag{3.10}$$

In order to prove (3.10), we argue as in the proof of Lemma 3.1 and find that

$$\begin{aligned}\partial_t Y_N &\lesssim \sum_{|\mu|,|\nu|\le N} \int_{\mathbb{R}^n\setminus\mathcal{K}} |(\partial_0 Z^\mu\phi)(\Box_h Z^\nu\phi)|\,dx \\ &+ \sum_{|\mu|,|\nu|\le N} \int_{\mathbb{R}^n\setminus\mathcal{K}} \Big(|(\partial_\gamma h^{\gamma\delta})(\partial_0 Z^\mu\phi)(\partial_\delta Z^\nu\phi)| + |(\partial_0 h^{\gamma\delta})(\partial_\gamma Z^\mu\phi)(\partial_\delta Z^\nu\phi)|\Big)\,dx \\ &+ \int_{\partial\mathcal{K}} |e_k^N n^k|\,d\sigma, \end{aligned}$$

where $\vec{n}$ is the outward normal at a given point of $\partial\mathcal{K}$ and the $e_k^N = \sum_{|\mu|\le N} e_k^N (Z^\mu\phi)(t,x)$ are as in (3.6). Since $\mathcal{K} \subset \{|x|<1\}$ and since

$$\sum_{|\mu|\le N} |Z^\mu\phi(t,x)| \lesssim \sum_{|\mu|\le N} |\partial^\mu\phi(t,x)|, \quad x\in\partial\mathcal{K},$$

we have

$$\int_{\partial\mathcal{K}} |e_k^N n^k|\, d\sigma \lesssim \int_{\{x\in\mathbb{R}^n\setminus\mathcal{K}\,:\,|x|<1\}} \sum_{|\mu|\le N+1} |\partial^\mu\phi'(t,x)|^2\, dx,$$

which completes the proof. □

4. Geometric approach to $L_t^2L_x^2$-estimates. In this section, we show that the estimates (1.7) and (1.8) hold in the exterior of a star-shaped obstacle. In the next section, we will show that these estimates also hold for the perturbed wave equation. For clarity of exposition, we begin here with the proofs for the standard d'Alembertian. These estimates will be shown directly using energy methods and result from straightforward modifications of Rodnianski's argument [26, Appendix].

LEMMA 4.1. *Suppose that $\mathcal{K}$ is as above and $n\ge 3$. Suppose also that $\phi\in C^\infty$ satisfies $\phi|_{\partial\mathcal{K}}=0$ and that ϕ vanishes for large $|x|$ for every t. Then, we have*

$$(\log(2+T))^{-1/2}\Big(\|\langle x\rangle^{-1/2}\phi'\|_{L_t^2L_x^2(S_T)} + \|\langle x\rangle^{-3/2}\phi\|_{L_t^2L_x^2(S_T)}\Big) \lesssim \|\phi'(0,\cdot)\|_2 + \int_0^T \|\Box\phi(s,\cdot)\|_2\, ds \tag{4.1}$$

and

$$\|\langle x\rangle^{-1/2-}\phi'\|_{L_t^2L_x^2(S_T)} + \|\langle x\rangle^{-3/2-}\phi\|_{L_t^2L_x^2(S_T)} \lesssim \|\phi'(0,\cdot)\|_2 + \int_0^T \|\Box\phi(s,\cdot)\|_2\, ds \tag{4.2}$$

for any $T>0$. The implicit constants in (4.1) *and* (4.2) *are independent of $\mathcal{K}$.*

By Duhamel's principle, we shall need only the homogeneous case. So, let ϕ be a solution to

$$\begin{cases} \Box\phi = (\partial_t^2-\Delta)\phi = 0, \\ \phi|_{\partial\mathcal{K}} = 0. \end{cases} \tag{4.3}$$

We let $Q_{\alpha\beta}$ denote its energy-momentum tensor

$$Q_{\alpha\beta}[\phi] = \partial_\alpha\phi\partial_\beta\phi - \frac{1}{2}g_{\alpha\beta}\partial^\gamma\phi\partial_\gamma\phi. \tag{4.4}$$

It is well known that $Q_{\alpha\beta}$ is divergence free. That is,

$$D^\alpha Q_{\alpha\beta}[\phi] = 0.$$

In order to get the weighted estimates, we define the momentum density

$$P_\alpha[\phi, X] = Q_{\alpha\beta}[\phi]X^\beta \tag{4.5}$$

by contracting $Q_{\alpha\beta}[\phi]$ with the radial vector field

$$X = f(r)\partial_r \tag{4.6}$$

(and thus, $X^a = \frac{f(r)}{r}x^a$ for $a = 1, \dots, n$ and $X^0 = 0$). One can check that this satisfies

$$D^\alpha P_\alpha[\phi, X] = \frac{1}{2} Q_{\alpha\beta}[\phi]\pi^{\alpha\beta},$$

where

$$\pi_{\alpha\beta} = D_\alpha X_\beta + D_\beta X_\alpha$$

is the deformation tensor of X.

A direct calculation then yields that

$$D^\alpha P_\alpha[\phi, X] = f'(r)|\partial_r\phi|^2 + \frac{f(r)}{r}|\not\nabla\phi|^2 - \frac{1}{2}\mathrm{tr}\pi\partial^\gamma\phi\partial_\gamma\phi, \tag{4.7}$$

where, as you can check,

$$\mathrm{tr}\pi = f'(r) + (n-1)\frac{f(r)}{r}. \tag{4.8}$$

Here, $\not\nabla\phi$ denotes the angular portion of the spatial gradient $\nabla_x\phi$. At this point, we define the modified momentum density

$$\tilde{P}_\alpha[\phi, X] = P_\alpha[\phi, X] + \frac{1}{2}\mathrm{tr}\pi\phi\partial_\alpha\phi - \frac{1}{4}\partial_\alpha(\mathrm{tr}\pi)|\phi|^2, \tag{4.9}$$

which satisfies

$$D^\alpha \tilde{P}_\alpha[\phi, X] = f'(r)|\partial_r\phi|^2 + \frac{f(r)}{r}|\not\nabla\phi|^2 - \frac{1}{4}\Delta(\mathrm{tr}\pi)|\phi|^2. \tag{4.10}$$

If we integrate this identity over a time strip $[0,T]\times\mathbb{R}^n\backslash\mathcal{K}$ and apply the divergence theorem, we see that

$$\begin{aligned}\int_{\mathbb{R}^n\backslash\mathcal{K}} \tilde{P}_0[\phi, X](0)\,dx - \int_{\mathbb{R}^n\backslash\mathcal{K}} \tilde{P}_0[\phi, X](T)\,dx - \int_0^T\int_{\partial\mathcal{K}} \tilde{P}_a[\phi, X](t)n^a\,d\sigma\,dt \\ = \int_0^T\int_{\mathbb{R}^n\backslash\mathcal{K}} \left(f'(r)|\partial_r\phi|^2 + \frac{f(r)}{r}|\not\nabla\phi|^2 - \frac{1}{4}\Delta(\mathrm{tr}\pi)|\phi|^2\right)\,dx\,dt,\end{aligned} \tag{4.11}$$

where $\vec{n}$ is the outward unit normal to $\mathcal{K}$ and $d\sigma$ is the surface measure on $\partial\mathcal{K}$. Here

$$\int_{\mathbb{R}^n\backslash\mathcal{K}} \tilde{P}_0[\phi, X](0)\,dx = \int_{\mathbb{R}^n\backslash\mathcal{K}} \left(X^a\partial_t\phi(0)\partial_a\phi(0) + \frac{1}{2}\mathrm{tr}\pi\phi(0)\partial_t\phi(0)\right)\,dx.$$

There is an identical expression for the time T piece on the left side of (4.11), since $\mathrm{tr}\pi$ is independent of t. If one chooses $f(r)$ so that $|f(r)| \lesssim 1$ and $|f'(r)| \lesssim \frac{1}{r}$, it follows from (4.8) and the Schwarz inequality that

$$\begin{aligned}\left|\int_{\mathbb{R}^n\backslash\mathcal{K}} \tilde{P}_0[\phi, X](0)\,dx\right| &\lesssim \left(\|r^{-1}\phi(0)\|_2 + \|\nabla_{t,x}\phi(0)\|_2\right)\|\nabla_{t,x}\phi(0)\|_2 \\ &\lesssim \|\nabla_{t,x}\phi(0)\|_2^2.\end{aligned}$$

The last inequality above follows from the Hardy inequality. Analogous estimates hold for the $\tilde{P}_0[\phi, X](T)$ term. Thus, by conservation of energy, this term is also controlled by $\|\nabla_{t,x}\phi(0)\|_2^2$.

Since $\phi|_{\partial\mathcal{K}} = 0$ and since ∂_t preserves the Dirichlet boundary condition, for the remaining boundary term, we have

$$-\int_0^T \int_{\partial\mathcal{K}} \tilde{P}_a[\phi, X](t) \cdot n^a \, d\sigma \, dt = -\int_0^T \int_{\partial\mathcal{K}} \frac{f(r)}{r} \left(\partial_{\vec{n}}\phi \partial_\beta \phi x^\beta - \frac{1}{2}|\nabla\phi|^2 \langle x, \vec{n}\rangle \right) d\sigma \, dt.$$

Here, $\partial_{\vec{n}}\phi = \langle \vec{n}, \nabla_x \rangle \phi$ denotes differentiation with respect to the outward normal to $\mathcal{K}$. Since $\phi = 0$ on $\partial\mathcal{K}$, we have that $\partial_\beta \phi = \partial_{\vec{n}}\phi \, n_\beta$. And, thus, we see that

$$-\int_0^T \int_{\partial\mathcal{K}} \tilde{P}_a[\phi, X](t) \cdot n^a \, d\sigma \, dt = -\frac{1}{2}\int_0^T \int_{\partial\mathcal{K}} \frac{f(r)}{r} (\partial_{\vec{n}}\phi)^2 \langle x, \vec{n}\rangle \, d\sigma \, dt.$$

This term is then easily seen to be negative as $\langle x, \vec{n}\rangle > 0$ for star-shaped $\mathcal{K}$.

Combining (4.11) and these estimates for the boundary terms, we see that

$$\int_0^T \int_{\mathbb{R}^n \setminus \mathcal{K}} \left(f'(r)|\partial_r \phi|^2 + \frac{f(r)}{r}|\not\nabla \phi|^2 - \frac{1}{4}\Delta(\mathrm{tr}\pi)|\phi|^2 \right) dx \, dt \lesssim \|\nabla_{t,x}\phi(0)\|_2^2. \tag{4.12}$$

At this point, we choose the weight function

$$f(r) = \frac{r}{\rho + r} \tag{4.13}$$

for some $\rho > 0$. It is easy to check that

$$\Delta(\mathrm{tr}\pi) = -\frac{1}{r(\rho+r)^4}\Big((n-1)(n-3)r^2 + 2(n^2-2n-2)r\rho + (n+1)(n-1)\rho^2 \Big) < 0 \tag{4.14}$$

for $n \geq 3$. Indeed, each term above is nonpositive. This, therefore, gives the a priori estimate

$$\int_0^T \int_{\mathbb{R}^n \setminus \mathcal{K}} \left(\frac{\rho}{(\rho+r)^2}|\partial_r\phi|^2 + \frac{1}{r+\rho}|\not\nabla\phi|^2 + \frac{\rho}{(\rho+r)^4}|\phi|^2 \right) dx \, dt \lesssim \|\nabla_{t,x}\phi(0)\|_2^2. \tag{4.15}$$

The implicit constant is independent of ρ.

By choosing $\rho = 1$, this yields the estimate

$$\int_0^T \int_{|x|\leq 1} \Big(|\nabla_x \phi|^2 + |\phi|^2 \Big) \, dx \, dt \lesssim \|\nabla_{t,x}\phi(0)\|_2^2. \tag{4.16}$$

Similarly, if we choose $\rho = 2^k$ for an integer $k \geq 0$, we get

$$\int_0^T \int_{2^{k-1}\leq|x|\leq 2^k} \Big(\frac{|\nabla_x\phi|^2}{r} + \frac{|\phi|^2}{r^3} \Big) \, dx \, dt \lesssim \|\nabla_{t,x}\phi(0)\|_2^2. \tag{4.17}$$

If we combine (4.16) and (4.17) and sum over $k \geq 1$, we see immediately that

$$\|\langle r\rangle^{-1/2-}\nabla_x\phi\|_{L_t^2 L_x^2([0,T]\times\mathbb{R}^n\setminus\mathcal{K})} + \|\langle x\rangle^{-3/2-}\phi\|_{L_t^2 L_x^2([0,T]\times\mathbb{R}^n\setminus\mathcal{K})} \lesssim \|\nabla_{t,x}\phi(0)\|_2. \tag{4.18}$$

The same argument also yields

$$(\log(2+T))^{-1/2}\Big(\|\langle r\rangle^{-1/2}\nabla_x\phi\|_{L^2_tL^2_x([0,T]\times\mathbb{R}^n\setminus\mathcal{K})} + \|\langle x\rangle^{-3/2}\phi\|_{L^2_tL^2_x([0,T]\times\mathbb{R}^n\setminus\mathcal{K})}\Big) \lesssim \|\nabla_{t,x}\phi(0)\|_2. \tag{4.19}$$

Indeed, (4.19) follows trivially from the energy inequality and a Hardy inequality if the norms on the left side are taken over $|x| \geq T$. Thus, we need only sum over the $O(\log(2+T))$ choices of k with $2^{k-1} \lesssim T$.

It remains to see that a similar bound holds for $\partial_t\phi$. To do so, we define another modified momentum density

$$\bar{P}_\alpha[\phi, X] = P_\alpha[\phi, X] + \frac{n-1}{2}\frac{f(r)}{r}\phi\partial_\alpha\phi - \frac{n-1}{4}\partial_\alpha\Big(\frac{f(r)}{r}\Big)|\phi|^2. \tag{4.20}$$

Calculating the divergence, we have

$$D^\alpha\bar{P}_\alpha[\phi, X] = f'(r)(\partial_r\phi)^2 + \frac{f(r)}{r}|\not\nabla\phi|^2 - \frac{1}{2}f'(r)\partial^\gamma\phi\partial_\gamma\phi - \frac{n-1}{4}\Delta\Big(\frac{f(r)}{r}\Big)|\phi|^2. \tag{4.21}$$

Thus, if we integrate both sides of (4.21) over a time strip, apply the divergence theorem, and use similar arguments for controlling the boundary terms, it follows that

$$\int_0^T\int_{\mathbb{R}^n\setminus\mathcal{K}} f'(r)(\partial_r\phi)^2 + \frac{f(r)}{r}|\not\nabla\phi|^2 - \frac{1}{2}f'(r)\partial^\gamma\phi\partial_\gamma\phi - \frac{n-1}{4}\Delta\left(\frac{f(r)}{r}\right)|\phi|^2 \lesssim \|\nabla_x\phi(0)\|_2^2. \tag{4.22}$$

For f as in (4.13), we have $f'(r) < f(r)/r$ and

$$\Delta\left(\frac{f(r)}{r}\right) = \frac{-(n-3)r - (n-1)\rho}{r(r+\rho)^3} < 0 \tag{4.23}$$

for $n \geq 3$. Since $\partial^\gamma\phi\partial_\gamma\phi = -(\partial_t\phi)^2 + (\partial_r\phi)^2 + |\not\nabla\phi|^2$, we see from (4.22) that

$$\int_0^T\int_{\mathbb{R}^n\setminus\mathcal{K}} \frac{\rho}{(r+\rho)^2}(\partial_t\phi)^2\,dx\,dt \lesssim \|\nabla_{t,x}\phi(0)\|_2^2.$$

By choosing $\rho = 1$ and $\rho = 2^k$ for $k \geq 1$, we get the estimates analogous to (4.16) and (4.17) for $\partial_t\phi$. Summing over k as above and combining this with (4.18) and (4.19) immediately yield (4.1) and (4.2). □

It is worth noting that the proof shows that there is additional decay for certain derivatives of the solution ϕ, namely, for $\not\nabla\phi$. Indeed, from (4.15), one can see that the $\log(2+T)$ factor in (4.1) is not necessary for the angular derivatives. This extra decay is something that has been exploited in other estimates and applications. See, e.g., Alinhac [1].

5. $L^2_tL^2_x$-estimate for the perturbed equation. The goal of this section is to show that the methods of the previous section can be adapted to give similar bounds for perturbed wave equations. This is the main new estimate of this article.

THEOREM 5.1. *Suppose $\mathcal{K}$ is as above and that $n \geq 3$. Let $\phi \in C^\infty(\mathbb{R}_+ \times \mathbb{R}^n \backslash \mathcal{K})$ be a solution of (3.1). Suppose that $h^{\alpha\beta}$ satisfies (3.2) and (3.3) for a small choice of δ. Then, if $\Box_h \phi = F$, we have*

$$\begin{aligned}(5.1)\quad &\|\langle x\rangle^{-1/2-}\phi'\|_{L^2_t L^2_x(S_T)} + (\log(2+T))^{-1/2}\|\langle x\rangle^{-1/2}\phi'\|_{L^2_t L^2_x(S_T)} \\ &\quad + \|\langle x\rangle^{-3/2-}\phi\|_{L^2_t L^2_x(S_T)} + (\log(2+T))^{-1/2}\|\langle x\rangle^{-3/2}\phi\|_{L^2_t L^2_x(S_T)} \\ &\quad \lesssim \|\phi'(0,\cdot)\|_2 + \left(\int_0^T \int_{\mathbb{R}^n\backslash\mathcal{K}} \left(|\nabla_{t,x}\phi| + \frac{|\phi|}{r}\right)|F|\, dx\, dt\right)^{1/2} \\ &\quad\quad + \left[\int_0^T \int_{\mathbb{R}^n\backslash\mathcal{K}} \left(|\partial h| + \frac{|h|}{r}\right)|\nabla_{t,x}\phi|\left(|\nabla_{t,x}\phi| + \frac{|\phi|}{r}\right) dx\, dt\right]^{1/2}\end{aligned}$$

for any $T \geq 0$.

Here, in an abuse of notation, we are setting

$$|h| = \sum_{\alpha,\beta=0}^n |h^{\alpha\beta}(t,x)|, \quad |\partial h| = \sum_{\alpha,\beta,\gamma=0}^n |\partial_\gamma h^{\alpha\beta}(t,x)|.$$

Although we shall not use this, we point out that this estimate holds when the regularity of the boundary of $\mathcal{K}$ is merely C^1. Also, the implicit constants in (5.1) are independent of the choice of star-shaped obstacle $\mathcal{K}$.

To prove (5.1), we set

$$(5.2)\qquad Q_{\alpha\beta}[\phi] = \partial_\alpha\phi\partial_\beta\phi - \frac{1}{2}g_{\alpha\beta}\partial^\gamma\phi\partial_\gamma\phi - g_{\alpha\gamma}h^{\gamma\delta}\partial_\delta\phi\partial_\beta\phi + \frac{1}{2}g_{\alpha\beta}h^{\gamma\delta}\partial_\gamma\phi\partial_\delta\phi.$$

Then it is straightforward to check that

$$D^\alpha Q_{\alpha\beta}[\phi] = -(\partial_\beta\phi)F - (\partial_\gamma h^{\gamma\delta})\partial_\delta\phi\partial_\beta\phi + \frac{1}{2}(\partial_\beta h^{\gamma\delta})\partial_\gamma\phi\partial_\delta\phi.$$

As above, we contract this with a radial vector field $X = f(r)\partial_r$, define $P_\alpha[\phi, X] = Q_{\alpha\beta}[\phi]X^\beta$, and compute that

$$\begin{aligned}D^\alpha P_\alpha[\phi,X] &= f'(r)(\partial_r\phi)^2 + \frac{f(r)}{r}|\not\nabla\phi|^2 - \frac{1}{2}\mathrm{tr}\pi\partial^\gamma\phi\partial_\gamma\phi - F(\partial_r\phi)f(r) \\ &\quad - (\partial_\gamma h^{\gamma\delta})\partial_\delta\phi\partial_r\phi f(r) + \frac{1}{2}(\partial_r h^{\gamma\delta})\partial_\gamma\phi\partial_\delta\phi f(r) - x_a h^{a\delta}\partial_\delta\phi\partial_r\phi\frac{f'(r)}{r} \\ &\quad\quad + x_a h^{a\delta}\partial_\delta\phi\partial_r\phi\frac{f(r)}{r^2} - h^{a\delta}\partial_\delta\phi\partial_a\phi\frac{f(r)}{r} + \frac{1}{2}(\mathrm{tr}\pi)h^{\gamma\delta}\partial_\gamma\phi\partial_\delta\phi,\end{aligned}$$

where $\mathrm{tr}\pi$ is given as in (4.8).

By modifying this momentum density as in (4.20) and setting

$$\begin{aligned}(5.3)\quad \bar{P}_\alpha[\phi,X] &= P_\alpha[\phi,X] + \frac{n-1}{2}\Big(\frac{f(r)}{r}\Big)\phi\partial_\alpha\phi \\ &\quad - \frac{n-1}{4}\partial_\alpha\left(\frac{f(r)}{r}\right)|\phi|^2 - \frac{n-1}{2}\left(\frac{f(r)}{r}\right)g_{\alpha\gamma}h^{\gamma\beta}\phi\partial_\beta\phi,\end{aligned}$$

it follows that

$$
\begin{aligned}
(5.4)\qquad D^\alpha \bar P_\alpha[\phi, X] &= f'(r)(\partial_r\phi)^2 + \frac{f(r)}{r}|\nabla\!\!\!/\phi|^2 - \frac{1}{2}f'(r)\partial^\gamma\phi\partial_\gamma\phi \\
&\quad - \frac{n-1}{4}\Delta\left(\frac{f(r)}{r}\right)|\phi|^2 - F(\partial_r\phi)f(r) - \frac{n-1}{2}F\frac{\phi}{r}f(r) \\
&\quad - (\partial_\gamma h^{\gamma\delta})\partial_\delta\phi\left(\partial_r\phi + \frac{n-1}{2}\frac{\phi}{r}\right)f(r) + \frac{1}{2}(\partial_r h^{\gamma\delta})\partial_\gamma\phi\partial_\delta\phi f(r) \\
&\quad - x_a h^{a\delta}\partial_\delta\phi\left(\partial_r\phi + \frac{n-1}{2}\frac{\phi}{r}\right)\frac{f'(r)}{r} \\
&\quad + x_a h^{a\delta}\partial_\delta\phi\left(\partial_r\phi + \frac{n-1}{2}\frac{\phi}{r}\right)\frac{f(r)}{r^2} \\
&\quad - h^{a\delta}\partial_\delta\phi\partial_a\phi\frac{f(r)}{r} + \frac{1}{2}f'(r)h^{\gamma\delta}\partial_\gamma\phi\partial_\delta\phi.
\end{aligned}
$$

Integrating both sides of (5.4) in a time strip S_T yields

$$
\begin{aligned}
(5.5)\qquad \int_{\mathbb{R}^n\setminus\mathcal{K}} \bar P_0[\phi, X](0)\,dx - \int_{\mathbb{R}^n\setminus\mathcal{K}} \bar P_0[\phi, X](T)\,dx - \int_0^T\int_{\partial\mathcal{K}} \bar P_a[\phi, X]n^a\,d\sigma\,dt \\
= \int_0^T\int_{\mathbb{R}^n\setminus\mathcal{K}} D^\alpha \bar P_\alpha[\phi, X]\,dx\,dt.
\end{aligned}
$$

For f as given by (4.13), we have $|f(r)| \lesssim 1$ and $|f'(r)| \lesssim \frac{1}{r}$. Thus, we see that

$$
\begin{aligned}
\left|\int_{\mathbb{R}^n\setminus\mathcal{K}} \bar P_0[\phi, X](0)\,dx\right| &= \left|\int_{\mathbb{R}^n\setminus\mathcal{K}}\Big(\partial_t\phi(0)\partial_r\phi(0)f(r) - g_{0\gamma}h^{\gamma\delta}(0)\partial_\delta\phi(0)\partial_r\phi(0)f(r)\right. \\
&\qquad \left. + \frac{n-1}{2}\frac{f(r)}{r}\phi(0)\partial_t\phi(0) - \frac{n-1}{2}\frac{f(r)}{r}g_{0\gamma}h^{\gamma\beta}\phi(0)\partial_\beta\phi(0)\Big)\,dx\right| \\
&\lesssim \|\nabla_{t,x}\phi(0)\|_2^2.
\end{aligned}
$$

For the last inequality, we are, as above, using the Schwarz inequality and the Hardy inequality. We are also using the bound (3.3).

A similar estimate holds for the $\bar P_0[\phi, X](T)$ term. And, thus, by the energy inequality (3.5),

$$
\begin{aligned}
\left|\int_{\mathbb{R}^n\setminus\mathcal{K}} \bar P_0[\phi, X](T)\,dx\right| &\lesssim \|\nabla_{t,x}\phi(T)\|_2^2 \\
&\lesssim \|\nabla_{t,x}\phi(0)\|_2^2 + \int_0^T\int_{\mathbb{R}^n\setminus\mathcal{K}} |\partial_t\phi||F|\,dx\,dt \\
&\quad + \int_0^T\int_{\mathbb{R}^n\setminus\mathcal{K}}\Big(|(\partial_\alpha h^{\alpha\beta})\partial_t\phi\partial_\beta\phi| + |(\partial_t h^{\alpha\beta})\partial_\alpha\phi\partial_\beta\phi|\Big)\,dx\,dt.
\end{aligned}
$$

For the remaining boundary terms, we use the fact that the Dirichlet boundary conditions permit us to write $\partial_a\phi = \partial_{\vec n}\phi\, n_a$ on $\partial\mathcal{K}$. Thus, if δ in (3.3) is small enough,

we have

$$
\begin{aligned}
-\int_0^T \int_{\partial\mathcal{K}} \bar{P}_a[\phi, X] n^a \, d\sigma \, dt \\
&= -\frac{1}{2}\int_0^T \int_{\partial\mathcal{K}} \frac{f(r)}{r}\Big((\partial_{\vec{n}}\phi)^2\langle x,\vec{n}\rangle - (\partial_{\vec{n}}\phi)^2(h^{ab}n_a n_b)\langle x,\vec{n}\rangle\Big)\, d\sigma \, dt \\
&\le -\frac{1}{4}\int_0^T \int_{\partial\mathcal{K}} \frac{f(r)}{r}(\partial_{\vec{n}}\phi)^2\langle x,\vec{n}\rangle \, d\sigma \, dt \le 0.
\end{aligned}
$$

For the first inequality, we are using (3.3). For the second inequality, we use the fact that $\langle x, \vec{n}\rangle > 0$ for star-shaped $\mathcal{K}$.

Using these bounds in (5.5), fixing f as in (4.13), and applying (5.4), it follows that

$$
\begin{aligned}
\int_0^T \int_{\mathbb{R}^n\setminus\mathcal{K}} & f'(r)(\partial_r\phi)^2 + \frac{f(r)}{r}|\not\nabla\phi|^2 - \frac{1}{2}f'(r)\partial^\gamma\phi\partial_\gamma\phi - \frac{n-1}{4}\Delta\left(\frac{f(r)}{r}\right)|\phi|^2 \\
&- (\partial_\gamma h^{\gamma\delta})\partial_\delta\phi\left(\partial_r\phi + \frac{n-1}{2}\frac{\phi}{r}\right)f(r) + \frac{1}{2}(\partial_r h^{\gamma\delta})\partial_\gamma\phi\partial_\delta\phi f(r) \\
&- x_a h^{a\delta}\partial_\delta\phi\left(\partial_r\phi + \frac{n-1}{2}\frac{\phi}{r}\right)\frac{f'(r)}{r} + x_a h^{a\delta}\partial_\delta\phi\left(\partial_r\phi + \frac{n-1}{2}\frac{\phi}{r}\right)\frac{f(r)}{r^2} \\
&- h^{a\delta}\partial_\delta\phi\partial_a\phi\frac{f(r)}{r} + \frac{1}{2}f'(r)h^{\gamma\delta}\partial_\gamma\phi\partial_\delta\phi \, dx \, dt \\
&\lesssim \|\nabla_{t,x}\phi(0)\|_2^2 + \int_0^T\int_{\mathbb{R}^n\setminus\mathcal{K}}\left(|\nabla_{t,x}\phi| + \frac{|\phi|}{r}\right)|F| \, dx \, dt \\
&\quad + \int_0^T\int_{\mathbb{R}^n\setminus\mathcal{K}}\Big(|(\partial_\alpha h^{\alpha\beta})\partial_t\phi\partial_\beta\phi| + |(\partial_t h^{\alpha\beta})\partial_\alpha\phi\partial_\beta\phi|\Big)\, dx \, dt.
\end{aligned}
$$

Using (4.23), this yields

$$
\begin{aligned}
\int_0^T \int_{\mathbb{R}^n\setminus\mathcal{K}} & \frac{\rho}{(r+\rho)^2}(\partial_r\phi)^2 + \frac{1}{r+\rho}|\not\nabla\phi|^2 + \frac{\rho}{(r+\rho)^2}(\partial_t\phi)^2 \\
&+ \frac{\rho}{r(r+\rho)^3}|\phi|^2 \, dx \, dt \\
&\lesssim \|\nabla_{t,x}\phi(0)\|_2^2 + \int_0^T\int_{\mathbb{R}^n\setminus\mathcal{K}}\Big(|\nabla_{t,x}\phi| + \frac{|\phi|}{r}\Big)|F| \, dx \, dt \\
&\quad + \int_0^T\int_{\mathbb{R}^n\setminus\mathcal{K}}\Big(|\partial h| + \frac{|h|}{r}\Big)|\nabla_{t,x}\phi|\Big(|\nabla_{t,x}\phi| + \frac{|\phi|}{r}\Big)\, dx \, dt,
\end{aligned} \tag{5.6}
$$

since $f'(r) < f(r)/r$. Thus, it follows that

$$
\begin{aligned}
\int_0^T \int_{|x|\le 1} & \Big(|\nabla_x\phi|^2 + |\partial_t\phi|^2 + |\phi|^2\Big)\, dx \, dt \\
&\lesssim \|\nabla_{t,x}\phi(0)\|_2^2 + \int_0^T\int_{\mathbb{R}^n\setminus\mathcal{K}}\left(|\nabla_{t,x}\phi| + \frac{|\phi|}{r}\right)|F| \, dx \, dt \\
&\quad + \int_0^T\int_{\mathbb{R}^n\setminus\mathcal{K}}\left(|\partial h| + \frac{|h|}{r}\right)|\nabla_{t,x}\phi|\left(|\nabla_{t,x}\phi| + \frac{|\phi|}{r}\right)\, dx \, dt
\end{aligned} \tag{5.7}
$$

for the choice $\rho = 1$ (since $0 \in \mathcal{K}$ and thus $1/r$ is bounded on the complement of $\mathcal{K}$) and

$$\begin{aligned}(5.8)\quad \int_0^T \int_{2^{k-1}\le|x|\le 2^k} \left(\frac{|\nabla_x \phi|^2}{r} + \frac{|\partial_t \phi|^2}{r} + \frac{|\phi|^2}{r^3}\right) dx\, dt \\ \lesssim \|\nabla_{t,x}\phi(0)\|_2^2 + \int_0^T \int_{\mathbb{R}^n\setminus\mathcal{K}} \left(|\nabla_{t,x}\phi| + \frac{|\phi|}{r}\right)|F|\, dx\, dt \\ + \int_0^T \int_{\mathbb{R}^n\setminus\mathcal{K}} \left(|\partial h| + \frac{|h|}{r}\right)|\nabla_{t,x}\phi| \left(|\nabla_{t,x}\phi| + \frac{|\phi|}{r}\right) dx\, dt\end{aligned}$$

for $\rho = 2^k$. If we sum over $k \ge 1$ as above, (5.1) follows, which completes the proof. □

If we use an elliptic regularity argument as above, the following lemma holds.

LEMMA 5.2. *Suppose that $\mathcal{K}$ is as above and $n \ge 3$. Let $\phi \in C^\infty(\mathbb{R}_+ \times \mathbb{R}^n\setminus\mathcal{K})$ be a solution of* (3.1). *Suppose that $h^{\alpha\beta}$ satisfies* (3.2) *and* (3.3) *for a small choice of δ. Then, we have*

$$\begin{aligned}(5.9)\quad (\log(2+T))^{-1/2} \sum_{|\mu|\le N} \|\langle x\rangle^{-1/2}\partial^\mu_{t,x}\phi'\|_{L^2_t L^2_x(S_T)} \\ + \sum_{|\mu|\le N} \|\langle x\rangle^{-1/2-}\partial^\mu_{t,x}\phi'\|_{L^2_t L^2_x(S_T)} \\ \lesssim \sum_{j\le N} \|\partial_t^j \phi'(0,\cdot)\|_2 + \sum_{j,k\le N} \left(\int_0^T \int_{\mathbb{R}^n\setminus\mathcal{K}} \left(|\nabla_{t,x}\partial_t^j\phi| + \frac{|\partial_t^j\phi|}{r}\right)|\Box_h \partial_t^k \phi|\, dx\, dt\right)^{1/2} \\ + \sum_{j,k\le N} \left[\int_0^T \int_{\mathbb{R}^n\setminus\mathcal{K}} \left(|\partial h| + \frac{|h|}{r}\right)|\nabla_{t,x}\partial_t^j\phi| \left(|\nabla_{t,x}\partial_t^k\phi| + \frac{|\partial_t^k\phi|}{r}\right) dx\, dt\right]^{1/2} \\ + \sum_{|\mu|\le N-1} \|\Box \partial^\mu_{t,x}\phi\|_{L^2_t L^2_x(S_T)}\end{aligned}$$

for any $T > 0$ and $N = 0, 1, 2, \ldots$.

Indeed, in order to obtain (5.9), we argue inductively where (5.1) is the base case ($N = 0$). We then notice that

$$\begin{aligned}(5.10)\quad \sum_{|\mu|\le N} \|\langle x\rangle^{-1/2-}\partial^\mu_{t,x}\phi'\|_{L^2_t L^2_x(S_T)} \le \sum_{|\mu|\le N-1} \|\langle x\rangle^{-1/2-}\partial^\mu_{t,x}\partial_x^2\phi\|_{L^2_t L^2_x(S_T)} \\ + \sum_{|\mu|\le N-1} \|\langle x\rangle^{-1/2-}\partial^\mu_{t,x}(\partial_t\phi)'\|_{L^2_t L^2_x(S_T)} + \|\langle x\rangle^{-1/2-}\phi'\|_{L^2_t L^2_x(S_T)}.\end{aligned}$$

The estimate for the last term on the right follows trivially from (5.1). Since ∂_t preserves the Dirichlet boundary condition, we can use the inductive hypothesis to bound the second term on the right.

In order to bound the first term on the right side of (5.10), we will use elliptic regularity. To see this, we fix a smooth cutoff function β with $\beta \equiv 1$ for $1/2 < |x| < 1$ and $\beta \equiv 0$ outside of $1/4 \le |x| \le 2$. Applying elliptic regularity to $\beta(x/R)\phi(t,x)$,

we see that

$$\sum_{|\mu|\le N-1} \|\partial_{t,x}^{\mu}\partial_x^2\phi(t,\cdot)\|_{L_x^2(\{|x|\in[R/2,R]\})} \lesssim \sum_{|\mu|\le N-1} \|\partial_{t,x}^{\mu}\Delta\phi(t,\cdot)\|_{L_x^2(\{|x|\in[R/4,2R]\})} + \sum_{|\mu|\le N-1} \|\partial_{t,x}^{\mu}\phi'(t,\cdot)\|_{L_x^2(\{|x|\in[R/4,2R]\})} + \|\langle x\rangle^{-1}\phi(t,\cdot)\|_{L_x^2(\{|x|\in[R/4,2R]\})} \tag{5.11}$$

for $R \ge 2$. Similarly

$$\sum_{|\mu|\le N-1} \|\partial_{t,x}^{\mu}\partial_x^2\phi(t,\cdot)\|_{L_x^2(\{|x|\le 1\})} \lesssim \sum_{|\mu|\le N-1} \|\partial_{t,x}^{\mu}\Delta\phi(t,\cdot)\|_{L_x^2(\{|x|\le 2\})} + \sum_{|\mu|\le N-1} \|\partial_{t,x}^{\mu}\phi'(t,\cdot)\|_{L_x^2(\{|x|\le 2\})},$$

where we have used the fact that the Dirichlet boundary conditions allow us to control ϕ locally by ϕ'. By multiplying both sides of (5.11) by $R^{-1/2-}$, summing over $R = 2^k$, $k = 1, 2, \ldots$, and integrating in time, we see that

$$\sum_{|\mu|\le N-1} \|\langle x\rangle^{-1/2-}\partial_{t,x}^{\mu}\partial_x^2\phi\|_{L_t^2L_x^2(S_T)} \lesssim \sum_{|\mu|\le N-1} \|\langle x\rangle^{-1/2-}\partial_{t,x}^{\mu}\Delta\phi\|_{L_t^2L_x^2(S_T)} + \sum_{|\mu|\le N-1} \|\langle x\rangle^{-1/2-}\partial_{t,x}^{\mu}\phi'\|_{L_t^2L_x^2(S_T)} + \|\langle x\rangle^{-3/2-}\phi\|_{L_t^2L_x^2(S_T)}. \tag{5.12}$$

The estimates for the last two terms can, again, be obtained by the inductive hypothesis and (5.1), respectively.

For the first term in the right side of (5.12), we simply notice that

$$\sum_{|\mu|\le N-1} \|\langle x\rangle^{-1/2-}\partial_{t,x}^{\mu}\Delta\phi\|_{L_t^2L_x^2(S_T)} \lesssim \sum_{|\mu|\le N-1} \|\langle x\rangle^{-1/2-}\partial_{t,x}^{\mu}\partial_t^2\phi\|_{L_t^2L_x^2(S_T)} + \sum_{|\mu|\le N-1} \|\partial_{t,x}^{\mu}\Box\phi\|_{L_t^2L_x^2(S_T)}.$$

As ∂_t preserves the boundary condition, we may use the inductive hypothesis to see that the first term on the right is bounded by the right side of (5.9). As a similar argument may be used to obtain the estimate for the first term on the left of (5.9), the proof of Lemma 5.2 is complete. □

Similarly, if as above (Lemma 3.3), we repeat the argument with ϕ replaced by $Z^{\mu}\phi$ for some multi-index μ, we see that the following holds.

LEMMA 5.3. *Suppose that $\mathcal{K}$ is as above and $n \geq 3$. Let $\phi \in C^\infty(\mathbb{R}_+ \times \mathbb{R}^n \backslash \mathcal{K})$ be a solution of (3.1). Suppose that $h^{\alpha\beta}$ satisfies (3.2) and (3.3) for a small choice of δ. Then, we have*

$$
\begin{aligned}
(5.13)\qquad & (\log(2+T))^{-1/2} \sum_{|\mu|\leq N} \|\langle x\rangle^{-1/2} Z^\mu \phi'\|_{L^2_t L^2_x(S_T)} \\
& \qquad + \sum_{|\mu|\leq N} \|\langle x\rangle^{-1/2-} Z^\mu \phi'\|_{L^2_t L^2_x(S_T)} \\
\lesssim & \sum_{|\mu|\leq N} \|Z^\mu \phi'(0,\,\cdot\,)\|_2 + \sum_{|\mu|,|\nu|\leq N} \left(\int_0^T \int_{\mathbb{R}^n\backslash\mathcal{K}} \left(|\nabla_{t,x} Z^\mu \phi| + \frac{|Z^\mu \phi|}{r} \right) |\Box_h Z^\nu \phi| \, dx\, dt \right)^{1/2} \\
& + \sum_{|\mu|,|\nu|\leq N} \left[\int_0^T \int_{\mathbb{R}^n\backslash\mathcal{K}} \left(|\partial h| + \frac{|h|}{r} \right) |\nabla_{t,x} Z^\mu \phi| \left(|\nabla_{t,x} Z^\nu \phi| + \frac{|Z^\nu \phi|}{r} \right) dx\, dt \right]^{1/2} \\
& \qquad + \sum_{|\mu|\leq N+1} \|\partial_x^\mu \phi'\|_{L^2_t L^2_x([0,T]\times\{|x|<1\})}
\end{aligned}
$$

for any $T > 0$ and $N = 0, 1, 2, \ldots$.

In particular, notice that the last term of (5.13) can be controlled using (5.9). The same is true for the boundary term of (3.10).

6. Almost global existence for $n = 3$. In this section, we shall prove Theorem 1.1. Since (5.9) and (5.13) have been established, this proof will resemble that of the semilinear case [8], which is much easier than the subsequent proofs for the quasilinear case. We shall use an iteration argument to solve (1.1) and to show that the solution satisfies

$$
\begin{aligned}
(6.1)\qquad & \sum_{|\mu|\leq 15} \Big(\|\partial^\mu u'(t,\,\cdot\,)\|_2 + (\log(2+t))^{-1/2} \|\langle x\rangle^{-1/2} \partial^\mu u'\|_{L^2_t L^2_x(S_t)} \Big) \\
& \qquad + \sum_{|\mu|\leq 14} \Big(\|Z^\mu u'(t,\,\cdot\,)\|_2 + (\log(2+t))^{-1/2} \|\langle x\rangle^{-1/2} Z^\mu u'\|_{L^2_t L^2_x(S_t)} \Big) \leq C\varepsilon
\end{aligned}
$$

for $0 \leq t \leq T_\varepsilon$ and for uniform constant C.

Here, we let $u_{-1} \equiv 0$ and then recursively define u_k, $k = 0, 1, 2, \ldots$, to solve

$$
(6.2)\qquad \begin{cases} \Box u_k(t,x) = Q(du_{k-1}, d^2 u_k), \quad (t,x) \in [0,T] \times \mathbb{R}^3 \backslash \mathcal{K}, \\ u_k|_{\partial\mathcal{K}} = 0, \\ u_k(0,\,\cdot\,) = f, \quad \partial_t u_k(0,\,\cdot\,) = g. \end{cases}
$$

We set

$$
\begin{aligned}
(6.3)\qquad M_k(T) = \sup_{0\leq t\leq T} & \left[\sum_{|\mu|\leq 15} \Big(\|\partial^\mu u_k'(t,\,\cdot\,)\|_2 + (\log(2+t))^{-1/2} \|\langle x\rangle^{-1/2} \partial^\mu u_k'\|_{L^2_t L^2_x(S_t)} \Big) \right. \\
& \left. + \sum_{|\mu|\leq 14} \Big(\|Z^\mu u_k'(t,\,\cdot\,)\|_2 + (\log(2+t))^{-1/2} \|\langle x\rangle^{-1/2} Z^\mu u_k'\|_{L^2_t L^2_x(S_t)} \Big) \right].
\end{aligned}
$$

Clearly, by (1.3), the standard energy inequality, and (5.9) and (5.13) (with $h^{\alpha\beta} \equiv 0$), there is a uniform constant C_0 so that

$$M_0(T) \le C_0\varepsilon$$

for any T. Here, C_0 can be chosen to be larger than the implicit constants of (3.9), (3.10), (5.9), and (5.13). For $\varepsilon < \varepsilon_0$ sufficiently small and for κ in (1.5) small, we will show inductively that for $k = 1, 2, 3, \dots$

$$M_k(T_\varepsilon) \le 10C_0\varepsilon. \tag{6.4}$$

By (1.4), (3.9), (3.10), (5.9), and (5.13), we have

(6.5)

$$\begin{aligned}
M_k(T_\varepsilon) \le 4C_0\varepsilon &+ \sum_{|\mu|,|\nu|\le 15} \Big(\int_0^{T_\varepsilon}\int_{\mathbb{R}^3\setminus\mathcal{K}} \Big(|\nabla_{t,x}\partial^\mu u_k| + \frac{|\partial^\mu u_k|}{r}\Big)|\partial^\nu \Box_h u_k|\,dx\,dt\Big)^{1/2} \\
&+ \sum_{|\mu|,|\nu|\le 15} \Big(\int_0^{T_\varepsilon}\int_{\mathbb{R}^3\setminus\mathcal{K}} \Big(|\nabla_{t,x}\partial^\mu u_k| + \frac{|\partial^\mu u_k|}{r}\Big)|[\partial^\nu, \Box_h]u_k|\,dx\,dt\Big)^{1/2} \\
&+ \sum_{|\mu|,|\nu|\le 15} \Big[\int_0^{T_\varepsilon}\int_{\mathbb{R}^3\setminus\mathcal{K}} \Big(|\partial h| + \frac{|h|}{r}\Big)|\nabla_{t,x}\partial^\mu u_k|\Big(|\nabla_{t,x}\partial^\nu u_k| + \frac{|\partial^\nu u_k|}{r}\Big)\,dx\,dt\Big]^{1/2} \\
&+ \sum_{|\mu|,|\nu|\le 14} \Big(\int_0^{T_\varepsilon}\int_{\mathbb{R}^3\setminus\mathcal{K}} \Big(|\nabla_{t,x}Z^\mu u_k| + \frac{|Z^\mu u_k|}{r}\Big)|Z^\nu \Box_h u_k|\,dx\,dt\Big)^{1/2} \\
&+ \sum_{|\mu|,|\nu|\le 14} \Big(\int_0^{T_\varepsilon}\int_{\mathbb{R}^3\setminus\mathcal{K}} \Big(|\nabla_{t,x}Z^\mu u_k| + \frac{|Z^\mu u_k|}{r}\Big)|[Z^\nu, \Box_h]u_k|\,dx\,dt\Big)^{1/2} \\
&+ \sum_{|\mu|,|\nu|\le 14} \Big[\int_0^{T_\varepsilon}\int_{\mathbb{R}^3\setminus\mathcal{K}} \Big(|\partial h| + \frac{|h|}{r}\Big)|\nabla_{t,x}Z^\mu u_k|\Big(|\nabla_{t,x}Z^\mu u_k| + \frac{|Z^\mu u_k|}{r}\Big)\,dx\,dt\Big]^{1/2} \\
&+ \sup_{0\le t\le T_\varepsilon}\Big[\sum_{|\mu|\le 14}\|\partial^\mu_{t,x}\Box u_k(t,\cdot)\|_2\Big] + \sum_{|\mu|\le 14}\|\partial^\mu_{t,x}\Box u_k\|_{L^2_tL^2_x(S_{T_\varepsilon})}.
\end{aligned}$$

Here, we set $h^{\gamma\delta} = -\sum_{0\le\beta\le 3} B^{\gamma\delta}_\beta \partial_\beta u_{k-1}$. We note that

$$\begin{aligned}
&\sum_{|\mu|\le 15}\Big(|\partial^\mu \Box_h u_k| + \sum_{|\mu|\le 15}|[\partial^\mu, \Box_h]u_k|\Big) \\
&\qquad \lesssim \sum_{|\mu|\le 7}|\partial^\mu u'_{k-1}| \sum_{|\nu|\le 15}|\partial^\nu u'_k| + \sum_{|\mu|\le 8}|\partial^\mu u'_k| \sum_{|\nu|\le 15}|\partial^\nu u'_{k-1}| \\
&\qquad\qquad + \sum_{|\mu|\le 7}|\partial^\mu u'_{k-1}| \sum_{|\nu|\le 15}|\partial^\nu u'_{k-1}|.
\end{aligned}$$

Similarly,

$$\sum_{|\mu|\le 14}\Big(|Z^\mu \Box_h u_k| + \sum_{|\mu|\le 14}|[Z^\mu,\Box_h]u_k|\Big)$$

$$\lesssim \sum_{|\mu|\le 7}|Z^\mu u'_{k-1}|\sum_{|\nu|\le 14}|Z^\nu u'_k| + \sum_{|\mu|\le 8}|Z^\mu u'_k|\sum_{|\nu|\le 14}|Z^\nu u'_{k-1}|$$

$$+\sum_{|\mu|\le 7}|Z^\mu u'_{k-1}|\sum_{|\nu|\le 14}|Z^\nu u'_{k-1}|.$$

If we use this, (2.1), the Schwarz inequality, and a Hardy inequality, it follows that the second, third, and fourth terms in (6.5) are controlled by

$$\sum_{|\mu|\le 9}\|\langle x\rangle^{-1/2}Z^\mu u'_{k-1}\|^{1/2}_{L^2_tL^2_x(S_{T_\varepsilon})}\sum_{|\mu|\le 15}\|\langle x\rangle^{-1/2}\partial^\mu u'_k\|^{1/2}_{L^2_tL^2_x(S_{T_\varepsilon})}$$

$$\times \sup_{0\le t\le T_\varepsilon}\sum_{|\mu|\le 15}\|\partial^\mu u'_k(t,\,\cdot\,)\|_2^{1/2}$$

$$+\left(\sum_{|\mu|\le 10}\|\langle x\rangle^{-1/2}Z^\mu u'_k\|^{1/2}_{L^2_tL^2_x(S_{T_\varepsilon})}+\sum_{|\mu|\le 9}\|\langle x\rangle^{-1/2}Z^\mu u'_{k-1}\|^{1/2}_{L^2_tL^2_x(S_{T_\varepsilon})}\right)$$

$$\times\sum_{|\mu|\le 15}\|\langle x\rangle^{-1/2}\partial^\mu u'_{k-1}\|^{1/2}_{L^2_tL^2_x(S_{T_\varepsilon})}\left(\sup_{0\le t\le T_\varepsilon}\sum_{|\mu|\le 15}\|\partial^\mu u'_k(t,\,\cdot\,)\|_2^{1/2}\right). \tag{6.6}$$

In particular, for the fourth term in (6.5), notice that for the given choice of h, we have

$$\left(|\partial h|+\frac{|h|}{r}\right)\lesssim\sum_{|\mu|\le 1}|\partial^\mu u'_{k-1}|.$$

Here, we use that $\frac{1}{r}$ is bounded on $\mathbb{R}^3\backslash\mathcal{K}$ since $0\in\mathcal{K}$. Thus, by (2.1) and the Schwarz inequality, we have

$$\sum_{|\mu|,|\nu|\le 15}\int_{2^{j-1}}^{2^j}\left(|\partial h|+\frac{|h|}{r}\right)|\nabla_{t,x}\partial^\mu u_k(t,x)|\left(|\nabla_{t,x}\partial^\nu u_k(t,x)|+\frac{|\partial^\nu u_k(t,x)|}{r}\right)\,dx$$

$$\lesssim\sum_{|\mu|\le 3}\|\langle x\rangle^{-1/2}Z^\mu u'_{k-1}(t,\,\cdot\,)\|_{L^2(2^{j-2}\le|x|\le 2^{j+1})}\sum_{|\mu|\le 15}\|\langle x\rangle^{-1/2}\partial^\mu u'_k(t,\,\cdot\,)\|_{L^2(2^{j-1}\le|x|\le 2^j)}$$

$$\times\left(\sum_{|\mu|\le 15}\|\partial^\nu u'_k(t,\,\cdot\,)\|_2+\left\|\frac{1}{r}u_k(t,\,\cdot\,)\right\|_2\right).$$

A similar bound holds over $|x|\in[0,1]$. If we sum over j and integrate in t, it follows that the fourth term in (6.5) is indeed controlled by the first term in (6.6). Here, we use a Hardy inequality to gain the control $\|(1/r)u_k(t,\,\cdot\,)\|_2\lesssim\|u'_k(t,\,\cdot\,)\|_2$. Similar arguments yield the given bounds for the second and third terms in (6.5).

By the inductive hypothesis, we see that (6.6) is controlled by

$$C_1\varepsilon^{1/2}(\log(2+T_\varepsilon))^{1/2}M_k(T_\varepsilon)+C_1\varepsilon^{3/2}. \tag{6.7}$$

This provides the necessary bound for the second, third, and fourth terms in (6.5).

Similarly, the fifth, sixth, and seventh terms in (6.5) are bounded by

$$\begin{aligned}\sum_{|\mu|\le 9}\|\langle x\rangle^{-1/2}Z^\mu u'_{k-1}\|^{1/2}_{L^2_tL^2_x(S_{T_\varepsilon})}&\sum_{|\mu|\le 14}\|\langle x\rangle^{-1/2}Z^\mu u'_k\|^{1/2}_{L^2_tL^2_x(S_{T_\varepsilon})}\\ &\times\sup_{0\le t\le T_\varepsilon}\sum_{|\mu|\le 14}\|Z^\mu u'_k(t,\,\cdot\,)\|_2^{1/2}\\ +\left(\sum_{|\mu|\le 10}\|\langle x\rangle^{-1/2}Z^\mu u'_k\|^{1/2}_{L^2_tL^2_x(S_{T_\varepsilon})}+\sum_{|\mu|\le 9}\|\langle x\rangle^{-1/2}Z^\mu u'_{k-1}\|^{1/2}_{L^2_tL^2_x(S_{T_\varepsilon})}\right)&\\ \times\sum_{|\mu|\le 14}\|\langle x\rangle^{-1/2}Z^\mu u'_{k-1}\|^{1/2}_{L^2_tL^2_x(S_{T_\varepsilon})}&\left(\sup_{0\le t\le T_\varepsilon}\sum_{|\mu|\le 14}\|Z^\mu u'_k(t,\,\cdot\,)\|_2^{1/2}\right),\end{aligned}$$

which as above is controlled by

$$C_2\varepsilon^{1/2}(\log(2+T_\varepsilon))^{1/2}M_k(T_\varepsilon)+C_2\varepsilon^{3/2}. \tag{6.8}$$

By similar arguments, it follows that the last two terms of (6.5) are controlled by

$$C_3\Big(\varepsilon M_k(T_\varepsilon)+\varepsilon^2+\varepsilon(\log(2+T_\varepsilon))^{1/2}M_k(T_\varepsilon)+\varepsilon^2(\log(2+T_\varepsilon))^{1/2}\Big). \tag{6.9}$$

If we have

$$(C_1+C_2+C_3)\varepsilon^{1/2}(\log(2+T_\varepsilon))^{1/2}\le\frac{1}{2},$$

which indeed is the case if κ is chosen to be smaller than $\frac{1}{2(C_1+C_2+C_3)^2}$, we can bootstrap the terms in (6.7), (6.8), and (6.9) involving $M_k(T_\varepsilon)$. Thus, we see that

$$M_k(T_\varepsilon)\le 2[4C_0\varepsilon+(C_1+C_2+C_3\kappa^{1/2}(\log 2)^{1/2})\varepsilon^{3/2}].$$

Thus, if ε is small enough, we obtain (6.4) as desired.

If we define

$$\begin{aligned}A_k(T)=\sup_{0\le t\le T}\Bigg[&\sum_{|\mu|\le 14}\Big(\|\partial^\mu(u'_k-u'_{k-1})(t,\,\cdot\,)\|_2\\ &+(\log(2+t))^{-1/2}\|\langle x\rangle^{-1/2}\partial^\mu(u'_k-u'_{k-1})\|_{L^2_tL^2_x(S_t)}\Big)\\ &+\sum_{|\mu|\le 13}\Big(\|Z^\mu(u'_k-u'_{k-1})(t,\,\cdot\,)\|_2\\ &+(\log(2+t))^{-1/2}\|\langle x\rangle^{-1/2}Z^\mu(u'_k-u'_{k-1})\|_{L^2_tL^2_x(S_t)}\Big)\Bigg],\end{aligned}$$

similar arguments can be used to show that

$$A_k(T_\varepsilon)\le\frac{1}{2}A_{k-1}(T_\varepsilon).$$

Thus, we have that u_k converges to a solution of (1.1) satisfying (6.1), which completes the proof.

7. Global existence in higher dimensions. In this last section, we provide a few remarks that explain how to modify the proof in the previous section in order to obtain a proof of Theorem 1.2. Indeed, it is possible to show via iteration that a solution exists and satisfies

$$\sum_{|\mu|\le n+10}\Big(\|\partial^\mu u'(t,\,\cdot\,)\|_2+\|\langle x\rangle^{-(n-1)/4}\partial^\mu u'\|_{L^2_tL^2_x(S_t)}\Big)+\sum_{|\mu|\le n+9}\Big(\|Z^\mu u'(t,\,\cdot\,)\|_2+\|\langle x\rangle^{-(n-1)/4}Z^\mu u'\|_{L^2_tL^2_x(S_t)}\Big)\le C\varepsilon \tag{7.1}$$

for any $T>0$. Here, we argue as in the previous section. When we apply the weighted Sobolev estimate, we get weights $\langle x\rangle^{-(n-1)/4}$. When $n\ge 4$, we have $(n-1)/4>1/2$, and thus, we may apply the bound for the first term in the left side of (5.1) rather than that for the second term. Since the first term in the left side of (5.1) does not require the loss of a $\log(2+T)^{1/2}$, we see immediately that we have no restriction on T_ε, which proves the desired global existence result.

Acknowledgments. It is a pleasure to thank J. Sterbenz for pointing out the work of Rodnianski. The authors are also grateful to the anonymous referees for their thorough reading of this manuscript and for their helpful suggestions.

NAVIER–STOKES EQUATIONS WITH NAVIER BOUNDARY CONDITIONS FOR A BOUNDED DOMAIN IN THE PLANE*

JAMES P. KELLIHER†

Abstract. We consider solutions to the Navier–Stokes equations with Navier boundary conditions in a bounded domain Ω in $\mathbb{R}^2$ with a C^2-boundary Γ. Navier boundary conditions can be expressed in the form $\omega(v) = (2\kappa - \alpha)v \cdot \boldsymbol{\tau}$ and $v \cdot \mathbf{n} = 0$ on Γ, where v is the velocity, $\omega(v)$ the vorticity, $\mathbf{n}$ a unit normal vector, $\boldsymbol{\tau}$ a unit tangent vector, and α is in $L^\infty(\Gamma)$. These boundary conditions were studied in the special case where $\alpha = 2\kappa$ by J.-L. Lions and P.-L. Lions. We establish the existence, uniqueness, and regularity of such solutions, extending the work of Clopeau, Mikelić, and Robert and of Lopes Filho, Nussenzveig Lopes, and Planas, which was restricted to simply connected domains and nonnegative α.

Assuming a particular bound on the growth of the L^p-norms of the initial vorticity with p (*Yudovich vorticity*), and also assuming additional smoothness on Γ and α, we obtain a uniform-in-time bound on the rate of convergence in $L^2(\Omega)$ of solutions to the Navier–Stokes equations with Navier boundary conditions to the solution to the Euler equations in the vanishing viscosity limit. We also show that for smoother initial velocities, the solutions to the Navier–Stokes equations with Navier boundary conditions converge uniformly in time in $L^2(\Omega)$, and L^2 in time in $H^1(\Omega)$, to the solution to the Navier–Stokes equations with the usual no-slip boundary conditions as we let α grow large uniformly on the boundary.

Key words. Navier–Stokes equations, vanishing viscosity limit

1. Introduction.

Let Ω be a bounded domain in $\mathbb{R}^2$ with a C^2-boundary Γ consisting of a finite number of connected components, and let $\mathbf{n}$ and $\boldsymbol{\tau}$ be unit normal and tangent vectors, respectively, to Γ. We follow the convention that $\mathbf{n}$ is an outward normal vector and that the ordered pair $(\mathbf{n}, \boldsymbol{\tau})$ gives the standard orientation to $\mathbb{R}^2$. Define the rate-of-strain tensor,

$$D(v) = \frac{1}{2}\left[\nabla v + (\nabla v)^T\right].$$

We consider the existence, uniqueness, and regularity of solutions to the Navier–Stokes equations with *Navier boundary conditions*. These boundary conditions, introduced by Navier in [19] and derived by Maxwell in [18] from the kinetic theory of gases (see [12]), assume that the tangential "slip" velocity, rather than being zero, is proportional to the tangential stress. With a factor of proportionality a in $L^\infty(\Gamma)$, we can express Navier boundary conditions for a sufficiently regular vector field v as

$$v \cdot \mathbf{n} = 0 \text{ and } 2\nu(\mathbf{n} \cdot D(v)) \cdot \boldsymbol{\tau} + av \cdot \boldsymbol{\tau} = 0 \text{ on } \Gamma. \tag{1.1}$$

We will find it more convenient, however, to let $\alpha = a/\nu$, and write these boundary conditions in the form

$$v \cdot \mathbf{n} = 0 \text{ and } 2(\mathbf{n} \cdot D(v)) \cdot \boldsymbol{\tau} + \alpha v \cdot \boldsymbol{\tau} = 0 \text{ on } \Gamma. \tag{1.2}$$

(We give an equivalent form of Navier boundary conditions in Corollary 4.2.)

The reason for preferring the second form for the boundary conditions is that, in the vanishing viscosity limit, we will hold α fixed as we let ν approach zero, and we will show that the solution to the Navier–Stokes equations with Navier boundary conditions converges to a solution to the Euler equations. (See, however, the comment at the end of section 8.)

J.-L. Lions in [15, pp. 87–98] and P.-L. Lions in [16, pp. 129–131] consider the following boundary conditions, which we call *Lions* boundary conditions:

$$v \cdot \mathbf{n} = 0 \text{ and } \omega(v) = 0 \text{ on } \Gamma,$$

where $\omega(v) = \partial_1 v^2 - \partial_2 v^1$ is the vorticity of v. Lions boundary conditions are the special case of Navier boundary conditions in which $\alpha = 2\kappa$, as we show in Corollary 4.3.

J.-L. Lions, in Theorem 6.10 on page 88 of [15], proves existence and uniqueness of a solution to the Navier–Stokes equations in the special case of Lions boundary conditions but includes the assumption that the initial vorticity is bounded. With the same assumption of bounded initial vorticity, the existence and uniqueness are established in Theorem 4.1 of [5] for Navier boundary conditions, under the restriction that α is nonnegative (and in $C^2(\Gamma)$). This is the usual restriction, which is imposed to ensure the conservation of energy. Mathematically, negative values of α present no real difficulty, so we do not make that restriction (except in section 9). The only clear gain from removing the restriction, however, is that it allows us to view Lions boundary conditions as a special case of Navier boundary conditions for more than just convex domains (nonnegative curvature).

P.-L. Lions establishes an energy inequality on page 130 of [16] that can be used in place of the usual one for no-slip boundary conditions. He argues that existence and uniqueness can then be established for initial velocity in $L^2(\Omega)$—and no additional assumption on the initial vorticity—exactly as was done for no-slip boundary conditions in the earlier sections of his text. As we will show, P.-L. Lions's energy inequality applies to Navier boundary conditions in general, which gives us the same existence and uniqueness theorem as for no-slip boundary conditions. (P.-L. Lions's comment on the regularity of $\partial_t u$ does not follow as in [16], though, because (4.18) of [16] is not valid for general Navier boundary conditions.) We include a proof of existence and uniqueness in section 6 that closely parallels the classical proofs due to Leray as they appear in [15] and [22]. In section 7, we extend the existence, uniqueness, regularity, and convergence results of [5] and [17] to multiply connected domains.

It is shown in [17] that if the initial vorticity is in $L^p(\Omega)$ for some $p > 2$, then after extracting a subsequence, solutions to the Navier–Stokes equations with Navier boundary conditions converge in $L^\infty([0,T]; L^2(\Omega))$ to a solution to the Euler equations (with the usual boundary condition of tangential velocity on the boundary) as $\nu \to 0$. This extends a result in [5] for initial vorticity in $L^\infty(\Omega)$, and because the solution to the Euler equations is unique in this case, it follows that the convergence is strong in $L^\infty([0,T]; L^2(\Omega))$—that is, does not require the extraction of a subsequence.

The convergence in [17] also generalizes the similar convergence established for the special case of Lions boundary conditions on page 131 of [16] (though not including the case $p = 2$). The main difficulty faced in making this generalization is establishing a bound on the L^p-norms of the vorticity, a task that is much easier for Lions boundary conditions (see pages 91–92 of [15] or page 131 of [16]). In contrast, nearly all of [5] and [17], including the structure of the existence proofs, is directed toward establishing an analogous bound.

The methods of proof in [5] and [17] do not yield a bound on the rate of convergence. With the assumptions in [17], such a bound is probably not possible. We can, however, make an assumption that is weaker than that of [5] but stronger than that of [17] and achieve a bound on the rate of convergence. Specifically, we assume, as in [14], that the L^p-norms of the initial vorticity grow sufficiently slowly with p (Definition 8.2) and establish the bound given in Theorem 8.4. To achieve this result, we also assume additional regularity on α and Γ.

The bound on the convergence rate in $L^\infty([0,T];L^2(\Omega))$ in Theorem 8.4 is the same as that obtained for $\Omega = \mathbb{R}^2$ in [14]. In particular, when α is nonnegative, it gives a bound on the rate of convergence for initial vorticity in $L^\infty(\Omega)$ that is proportional to

$$(\nu t)^{\frac{1}{2}} \exp\bigl(-C\|\omega^0\|_{L^2\cap L^\infty} t\bigr),$$

where C is a constant depending on Ω and α, and ω^0 is the initial vorticity. This is essentially the same bound on the convergence rate as that for $\Omega = \mathbb{R}^2$ appearing in [3].

Another interesting question is whether solutions to the Navier–Stokes equations with Navier boundary conditions converge to a solution to the Navier–Stokes equations with the usual no-slip boundary conditions if we let the function α grow large. We show in section 9 that such convergence does take place for initial velocity in $H^3(\Omega)$ and Γ in C^3 when we let α approach $+\infty$ uniformly on Γ. This type of convergence is, in a sense, an inverse of the derivation of the Navier boundary conditions from no-slip boundary conditions for rough boundaries discussed in [10] and [11].

In [13], Kato gives necessary and sufficient conditions for the vanishing viscosity limit of solutions to the Navier–Stokes equations with no-slip boundary conditions to converge to a strong solution to the Euler equations. In particular, he shows that the vanishing viscosity limit holds if and only if the L^2-norm of the gradient of the velocity in a boundary layer of width proportional to the viscosity vanishes sufficiently rapidly as the viscosity goes to zero. For Navier boundary conditions, it is easy to show that this norm on the boundary layer converges sufficiently rapidly, and because we have established the vanishing viscosity limit, it follows that Kato's conditions all hold, thus completing, in a sense, Kato's program for Navier boundary conditions. We describe this in more detail in section 10.

We follow the convention that C is always an unspecified constant that may vary from expression to expression, even across an inequality (but not across an equality). When we wish to emphasize that a constant depends, at least in part, upon the parameters $x_1, \dots, x_n$, we write $C(x_1, \dots, x_n)$. To distinguish between unspecified constants, we use C and C'.

For vectors u and v in $\mathbb{R}^2$, by $u \cdot \nabla v$ we mean the vector whose jth component is $u^i \partial_i v^j$. For 2×2 matrices A and B we define $A \cdot B = A^{ij} B^{ij}$, so $\nabla u \cdot \nabla v = \partial_j u^i \partial_j v^i$. Here, as everywhere in this paper, we follow the common convention that repeated indices are summed—whether or not one is a superscript and one is a subscript.

For the vector u and the scalar function ψ we define

$$u^\perp = (-u^2, u^1), \qquad \nabla^\perp \psi = (-\partial_2 \psi, \partial_1 \psi), \qquad \omega(u) = \partial_1 u^2 - \partial_2 u^1.$$

If X is a function space and k a positive integer, we define $(X)^k$ to be

$$\{(f_1, \dots, f_k) : f_1 \in X, \dots, f_k \in X\}.$$

For instance, $(H^1(\Omega))^2$ is the set of all vector fields, each of whose components lies in $H^1(\Omega)$. To avoid excess notation, however, we always suppress the superscript k when it is clear from the context whether we are dealing with scalar-, vector-, or matrix-valued functions.

We will make use of the following generalization of Gronwall's lemma. The succinct form of the proof is due to Tehranchi [21].

LEMMA 1.1 (Osgood's lemma). *Let L be a measurable nonnegative function and γ a nonnegative locally integrable function, each defined on the domain $[t_0, t_1]$. Let $\mu\colon [0,\infty) \to [0,\infty)$ be a continuous nondecreasing function, with $\mu(0) = 0$. Let $a \geq 0$, and assume that for all t in $[t_0, t_1]$,*

$$L(t) \leq a + \int_{t_0}^{t} \gamma(s)\mu(L(s))\, ds. \tag{1.3}$$

If $a > 0$, then

$$\int_a^{L(t)} \frac{ds}{\mu(s)} \leq \int_{t_0}^{t} \gamma(s)\, ds.$$

If $a = 0$ and $\int_0^\infty ds/\mu(s) = \infty$, then $L \equiv 0$.

Proof. We have

$$\begin{aligned}\int_a^{L(t)} \frac{dx}{\mu(x)} &\leq \int_a^{a+\int_{t_0}^t \gamma(u)\mu(L(u))\,du} \frac{dx}{\mu(x)} \\ &\leq \int_{t_0}^{t} \frac{\gamma(s)\mu(L(s))\,ds}{\mu(a+\int_{t_0}^s \gamma(u)\mu(L(u))\,du)} \leq \int_{t_0}^{t} \gamma(s)\,ds.\end{aligned}$$

The last inequality follows from (1.3), since μ is nondecreasing. ∎

We have stated Lemma 1.1 in the form that it appears on page 92 of [4]. This lemma is equivalent to a theorem of Bihari [2], though with an assumption only of measurability of μ rather than continuity; see, for example, Theorem 5.1 on pages 40–41 of [1].[1] An early form of the inequality appears in the work of Osgood [20], who assumes that $a = 0$, $\gamma \equiv 1$, and the bound is on $|L(t)|$ in (1.3); because of this, Lemma 1.1 is often referred to as Osgood's lemma. See also the historical discussion in section 2.14 of [6].

2. Function spaces. Let

$$E(\Omega) = \left\{ v \in (L^2(\Omega))^2 : \operatorname{div} v \in L^2(\Omega) \right\}, \tag{2.1}$$

as in [22], with the inner product

$$(u, v)_{E(\Omega)} = (u, v) + (\operatorname{div} u, \operatorname{div} v).$$

We will use the following theorem, which is Theorem 1.2 on page 7 of [22], several times.

LEMMA 2.1. *There exists a continuous linear operator $\gamma_{\mathbf{n}}$ mapping $E(\Omega)$ into $H^{-1/2}(\Gamma)$ such that*

$$\gamma_{\mathbf{n}} v = \text{ the restriction of } v \cdot \mathbf{n} \text{ to } \Gamma \text{ for every } v \text{ in } (\mathcal{D}(\overline{\Omega}))^2.$$

[1] The inequality in equation (5.2) of Theorem 5.1 of [1] should be $\leq$ instead of $\geq$.

Also, the following form of the divergence theorem holds for all vector fields v in $E(\Omega)$ and scalar functions h in $H^1(\Omega)$:

$$\int_\Omega v \cdot \nabla h + \int_\Omega (\operatorname{div} v) h = \int_\Gamma \gamma_{\mathbf{n}} v \cdot \gamma_0 h.$$

We always suppress the trace function γ_0 in our expressions, and we write $v \cdot \mathbf{n}$ in place of $\gamma_{\mathbf{n}} v$.

Define the following function spaces as in [5]:

$$\begin{aligned} H &= \left\{ v \in (L^2(\Omega))^2 : \operatorname{div} v = 0 \text{ in } \Omega \text{ and } v \cdot \mathbf{n} = 0 \text{ on } \Gamma \right\}, \\ V &= \left\{ v \in (H^1(\Omega))^2 : \operatorname{div} v = 0 \text{ in } \Omega \text{ and } v \cdot \mathbf{n} = 0 \text{ on } \Gamma \right\}, \\ \mathcal{W} &= \left\{ v \in V \cap H^2(\Omega) : v \text{ satisfies (1.2)} \right\}. \end{aligned} \tag{2.2}$$

We give $\mathcal{W}$ the H^2-norm, H the L^2-inner product and norm, which we symbolize by $(\cdot, \cdot)$ and $\|\cdot\|_{L^2(\Omega)}$, and V the H^1-inner product,

$$(u, v)_V = \sum_i (\partial_i u, \partial_i v),$$

and associated norm. This norm is equivalent to the H^1-norm, because Poincaré's inequality,

$$\|v\|_{L^p(\Omega)} \leq C(\Omega, p) \|\nabla v\|_{L^p(\Omega)} \tag{2.3}$$

for all p in $[1, \infty]$, holds for all v in V.

Ladyzhenskaya's inequality,

$$\|v\|_{L^4(\Omega)} \leq C(\Omega) \|v\|^{1/2}_{L^2(\Omega)} \|\nabla v\|^{1/2}_{L^2(\Omega)}, \tag{2.4}$$

also holds for all v in V, though the constant in the inequality is domain dependent, unlike the constant for the classical version of the space V.

We will also frequently use the following inequality, which follows from the standard trace theorem, Sobolev interpolation, and Poincaré's inequality:

$$\|v\|_{L^2(\Gamma)} \leq C(\Omega) \|v\|^{1/2}_{L^2(\Omega)} \|\nabla v\|^{1/2}_{L^2(\Omega)} \leq C(\Omega) \|v\|_V \tag{2.5}$$

for all v in V.

3. Hodge decomposition of H. Only simply connected domains are considered in [5] and [17]. To handle multiply connected domains we will need a portion of the Hodge decomposition of $L^2(\Omega)$. We briefly summarize the pertinent facts, drawing mostly from Appendix I of [22].

We assume that Ω is connected, for if it has multiple components we perform the decomposition separately on each component. Let $\Gamma_1, \ldots, \Gamma_{N+1}$ be the components of the boundary Γ with Γ_{N+1} bounding the unbounded component of Ω^C. Let $\Sigma_1, \ldots, \Sigma_N$ be one-manifolds with boundary that generate $H_1(\Omega, \Gamma; \mathbb{R})$, the one-dimensional real homology class of Ω relative to its boundary Γ.

We can decompose the space H into two subspaces, $H = H_0 \oplus H_c$, where

$$\begin{aligned} H_0 &= \{ v \in H : \text{all internal fluxes are zero} \}, \\ H_c &= \{ v \in H : \omega(v) = 0 \}. \end{aligned}$$

An internal flux is a value of $\int_{\Sigma_i} v \cdot \mathbf{n}$. Then $H_0 = H_c^\perp$.

Define ψ_i, $i = 1, \ldots, N$, to be the solution to $\Delta\psi_i = 0$ on Ω, $\psi_i = C_i$ on Γ_i, and $\psi_i = 0$ on all other components of Γ, where C_i is a nonzero constant. By elliptic regularity, ψ_i is in $H^2(\Omega)$ (apply, for instance, Theorem 8.12 on page 176 of [8]). Thus, $h_i := \nabla^\perp \psi_i$ is in $H^1(\Omega)$ and is divergence-free since $\operatorname{div} \nabla^\perp = 0$, and $h_i \cdot \mathbf{n} = 0$ since ψ_i is locally constant along Γ; that is, h_i is in V. The vectors $(h_1, \ldots, h_N)$ form an orthogonal basis for $H_c \subseteq V$, which we can assume is orthonormal by choosing (C_i) appropriately.

If v is in V then v is also in H so there exist a unique u in H_0 and h in H_c such that $v = u + h$; also, $(u, h)_H = 0$. But h is in V; hence, u also lies in V. This shows that $V = (V \cap H_0) \oplus H_c$, though this is not an orthogonal decomposition of V.

Given v in H we construct an associated stream function ψ in $H^1(\Omega)$ as follows. Fix a point a on $\partial\Omega$. For any x in $\overline{\Omega}$, and let γ be a smooth curve in $\overline{\Omega}$ from a to x. Along the curve γ let $\boldsymbol{\tau}$ be a unit tangent vector in the direction of γ and $\mathbf{n}$ be the unit normal vector for which $(\mathbf{n}, \boldsymbol{\tau})$ gives the standard orientation to $\mathbb{R}^2$. Then one can show that the function ψ defined by

$$\psi(x) = -\int_\gamma v \cdot \mathbf{n}\, ds \tag{3.1}$$

is independent of the choice of γ and of the set of generators, and that $v = \nabla^\perp \psi$. (The salient fact is that $v \cdot \mathbf{n}$ integrates to zero along any generator of the first (nonrelative) homology because $v \cdot \mathbf{n} = 0$ along $\partial\Omega$.)

On the boundary component containing a, ψ is zero, because $v \cdot \mathbf{n} = 0$ on Γ. On the other boundary components, ψ is constant, because the internal fluxes are independent of the path. In the special case where v is in H_0, all the internal fluxes are zero, so ψ is zero on all of Γ. From the way that we defined the basis (h_k) for H_c, it is clear that the projection into H_c of a vector lying in H is uniquely determined by the value of its stream function on the boundary.

The following is due to Yudovich.

LEMMA 3.1. *For any p in $[2, \infty)$ and any v in H_0 with $\omega(v)$ in $L^p(\Omega)$,*

$$\|\nabla v\|_{L^p(\Omega)} \le C(\Omega) p \, \|\omega(v)\|_{L^p(\Omega)} .$$

Proof. Let v be in H_0 with $\omega(v)$ in $L^p(\Omega)$. Then, as noted above, the associated stream function ψ vanishes on Γ. Applying Corollary 1 of [24] with the operator $L = \Delta$ and $r = 0$ gives

$$\|\nabla v\|_{L^p(\Omega)} \le \|\psi\|_{H^{2,p}(\Omega)} \le C(\Omega) p \, \|\Delta\psi\|_{L^p(\Omega)} = C(\Omega) p \, \|\omega(v)\|_{L^p(\Omega)} . \qquad \square$$

For Ω simply connected, $H = H_0$, and Lemma 3.1 applies to all of H. The critical feature of Lemma 3.1 is that the dependence of the inequality on p is made explicit, a fact we will exploit in the proof of Theorem 8.4.

With the assumption of additional regularity on Γ, we have the following result for velocity fields in H.

COROLLARY 3.2. *Assume that Γ is $C^{2,\epsilon}$ for some $\epsilon > 0$. Then for any p in $[2, \infty)$ and any v in H with $\omega(v)$ in $L^p(\Omega)$,*

$$\|\nabla v\|_{L^p(\Omega)} \le C(\Omega) p \, \|\omega(v)\|_{L^p(\Omega)} + C'(\Omega) \, \|v\|_{L^2(\Omega)} ,$$

the constants $C(\Omega)$ and $C'(\Omega)$ being independent of p.

Proof. Because Γ is $C^{2,\epsilon}$, it follows from elliptic regularity theory that each ψ_i is in $C^{2,\epsilon}(\overline{\Omega})$ (apply, for instance, Theorem 6.14 on page 101 of [8]). Thus, each basis element $h_i = \nabla^\perp \psi_i$ for H_c is in $C^{1,\epsilon}(\overline{\Omega})$ and so ∇h_i is in $L^\infty(\Omega)$.

Let v be in H with $\omega(v)$ in $L^p(\Omega)$, and let $v = u + h$, where u is in H_0 and h is in H_c. Let $h = \sum_{i=1}^N c_i h_i$ and $r = \|h\|_{L^2(\Omega)} = (\sum_i c_i^2)^{1/2}$. Then

$$\begin{aligned}\|\nabla h\|_{L^p(\Omega)} &\le \sum_{i=1}^N |c_i| \, \|\nabla h_i\|_{L^p(\Omega)} \le \sum_{i=1}^N r|\Omega|^{1/p} \, \|\nabla h_i\|_{L^\infty(\Omega)} \\ &\le r \max\left\{1, |\Omega|^{1/2}\right\} \sum_{i=1}^N \|\nabla h_i\|_{L^\infty(\Omega)} \le C \, \|h\|_{L^2(\Omega)} \, .\end{aligned}$$

But $H_0 = H_c^\perp$, so $\|v\|^2_{L^2(\Omega)} = \|u\|^2_{L^2(\Omega)} + \|h\|^2_{L^2(\Omega)}$, and thus $\|h\|_{L^2(\Omega)} \le \|v\|_{L^2(\Omega)}$. Therefore,

$$\begin{aligned}\|\nabla v\|_{L^p(\Omega)} &\le \|\nabla u\|_{L^p(\Omega)} + \|\nabla h\|_{L^p(\Omega)} \\ &\le C(\Omega) p \, \|\omega(v)\|_{L^p(\Omega)} + C'(\Omega) \, \|v\|_{L^2(\Omega)}\end{aligned}$$

by virtue of Lemma 3.1. ∎

4. Vorticity on the boundary. Let κ be the curvature of Γ. Then κ is continuous because Γ is C^2, and if we parameterize each component of Γ by arc length, s, it follows that

$$\frac{\partial \mathbf{n}}{\partial \boldsymbol{\tau}} := \frac{d\mathbf{n}}{ds} = \kappa \boldsymbol{\tau}.$$

LEMMA 4.1. *If u and v are in $(H^2(\Omega))^2$ with $u \cdot \mathbf{n} = v \cdot \mathbf{n} = 0$ on Γ, then*

$$(v \cdot \nabla u) \cdot \mathbf{n} = -\kappa u \cdot v, \tag{4.1}$$

$$(\mathbf{n} \cdot \nabla v) \cdot \boldsymbol{\tau} = \omega(v) + (\boldsymbol{\tau} \cdot \nabla v) \cdot \mathbf{n} = \omega(v) - \kappa v \cdot \boldsymbol{\tau}, \tag{4.2}$$

$$(\mathbf{n} \cdot D(v)) \cdot \boldsymbol{\tau} = \frac{1}{2}\omega(v) - \kappa v \cdot \boldsymbol{\tau}. \tag{4.3}$$

Proof. Because $u \cdot \mathbf{n}$ has a constant value (of zero) along Γ,

$$0 = \frac{\partial}{\partial \boldsymbol{\tau}}(u \cdot \mathbf{n}) = \frac{\partial u}{\partial \boldsymbol{\tau}} \cdot \mathbf{n} + u \cdot \frac{\partial \mathbf{n}}{\partial \boldsymbol{\tau}} = (\boldsymbol{\tau} \cdot \nabla u) \cdot \mathbf{n} + \kappa u \cdot \boldsymbol{\tau},$$

so $(\boldsymbol{\tau} \cdot \nabla u) \cdot \mathbf{n} = -\kappa u \cdot \boldsymbol{\tau}$. But v is parallel to $\boldsymbol{\tau}$, so (4.1) follows by linearity. The identity in (4.3) is Lemma 2.1 of [5], and (4.2) is established similarly. ∎

COROLLARY 4.2. *A vector v in $V \cap H^2(\Omega)$ satisfies Navier boundary conditions (that is, lies in $\mathcal{W}$) if and only if*

$$\omega(v) = (2\kappa - \alpha) v \cdot \boldsymbol{\tau} \text{ and } v \cdot \mathbf{n} = 0 \text{ on } \Gamma. \tag{4.4}$$

Also, for all v in $\mathcal{W}$ and u in V,

$$(\mathbf{n} \cdot \nabla v) \cdot u = (\kappa - \alpha) v \cdot u \text{ on } \Gamma. \tag{4.5}$$

Proof. Let v be in $V \cap H^2(\Omega)$. Then from (4.3),

$$2(\mathbf{n} \cdot D(v)) \cdot \boldsymbol{\tau} + 2\kappa(v \cdot \boldsymbol{\tau}) = \omega(v). \tag{4.6}$$

If v satisfies Navier boundary conditions, then (4.4) follows by subtracting $2(\mathbf{n}\cdot D(v))\cdot \boldsymbol{\tau} + \alpha v \cdot \boldsymbol{\tau} = 0$ from (4.6). Conversely, substituting the expression for $\omega(v)$ in (4.4) into (4.6) gives $2(\mathbf{n} \cdot D(v)) \cdot \boldsymbol{\tau} + \alpha v \cdot \boldsymbol{\tau} = 0$.

If v is in $\mathcal{W}$, then from (4.2),

$$(\mathbf{n} \cdot \nabla v) \cdot \boldsymbol{\tau} = \omega(v) - \kappa v \cdot \boldsymbol{\tau} = (2\kappa - \alpha)v \cdot \boldsymbol{\tau} - \kappa v \cdot \boldsymbol{\tau} = (\kappa - \alpha)v \cdot \boldsymbol{\tau},$$

and (4.5) follows from this, since u is parallel to τ on Γ. ∎

COROLLARY 4.3. *For initial velocity in $H^2(\Omega)$, Lions boundary conditions are the special case of Navier boundary conditions in which*

$$\alpha = 2\kappa.$$

That is, any solution of (NS) with Navier boundary conditions where $\alpha = 2\kappa$ is also a solution to (NS) with Lions boundary conditions.

5. Weak formulations. We give two equivalent formulations of a weak solution to the Navier–Stokes equations with Navier boundary conditions, in analogy with Problems 3.1 and 3.2 on pages 190–191 of [22].

For all u in $\mathcal{W}$ and v in V,

$$\begin{aligned} \int_\Omega \Delta u \cdot v &= \int_\Omega (\operatorname{div} \nabla u^i) v^i = \int_\Gamma (\nabla u^i \cdot \mathbf{n}) v^i - \int_\Omega \nabla u^i \cdot \nabla v^i \\ &= \int_\Gamma (\mathbf{n} \cdot \nabla u) \cdot v - \int_\Omega \nabla u \cdot \nabla v = \int_\Gamma (\kappa - \alpha) u \cdot v - \int_\Omega \nabla u \cdot \nabla v, \end{aligned} \tag{5.1}$$

where we used (4.5) of Corollary 4.2. This motivates our first formulation of a weak solution.

DEFINITION 5.1. *Given viscosity $\nu > 0$ and initial velocity u^0 in H, u in $L^2([0,T];V)$ is a weak solution to the Navier–Stokes equations (without forcing) if $u(0) = u^0$ and*

$$(NS) \qquad \frac{d}{dt}\int_\Omega u \cdot v + \int_\Omega (u \cdot \nabla u) \cdot v + \nu \int_\Omega \nabla u \cdot \nabla v - \nu \int_\Gamma (\kappa - \alpha) u \cdot v = 0$$

for all v in V. (We make sense of the initial condition $u(0) = u^0$ as in [22].*)*

This formulation of a weak solution is equivalent to that in (2.11) and (2.12) of [5]. This follows from the identity

$$2\int_\Omega D(u) \cdot D(v) = \int_\Omega \nabla u \cdot \nabla v - \int_\Gamma \kappa u \cdot v,$$

which holds for all u and v in V. To establish this identity, let u and v be in $V \cap H^2(\Omega)$ and observe that $2D(u) \cdot D(v) = \nabla u \cdot \nabla v + \nabla u \cdot (\nabla v)^T$. Also, because u is divergence-free, $\nabla u \cdot (\nabla v)^T = \partial_i u^j \partial_j v^i = \partial_j(\partial_i u^j v^i) = \operatorname{div}(v \cdot \nabla u)$. Then, using (4.1), the identity follows from

$$\int_\Omega \nabla u \cdot (\nabla v)^T = \int_\Omega \operatorname{div}(v \cdot \nabla u) = \int_\Gamma (v \cdot \nabla u) \cdot \mathbf{n} = -\int_\Gamma \kappa u \cdot v$$

and the density of $H^2(\Omega) \cap V$ in V.

Our second formulation of a weak solution will be identical to that of Problem 3.2 on page 191 of [22], except that the operator A of [22] will also include the boundary integral of (5.1). Accordingly, we define the operators A and B by

$$(Au, v)_{V,V'} = \int_\Omega \nabla u \cdot \nabla v - \int_\Gamma (\kappa - \alpha) u \cdot v,$$
$$(Bu, v)_{V,V'} = \int_\Omega (u \cdot \nabla u) \cdot v$$

for all u and v in V.

By (2.5),

$$|(Au, v)_{V,V'}| \leq \|u\|_V \|v\|_V + C \|u\|_{L^2(\Gamma)} \|v\|_{L^2(\Gamma)} \leq C \|u\|_V \|v\|_V . \tag{5.2}$$

Thus, $A : L^2([0,T]; V) \to L^2([0,T]; V')$, and, as it does for the classical version of the space V (for which vectors are zero on Γ), $B : L^2([0,T]; V) \to L^1([0,T]; V')$. Thus, if u is a solution as in Definition 5.1, then $-\nu Au - Bu$ lies in $L^1([0,T]; V')$ and

$$\frac{d}{dt} \langle u, v \rangle = (-\nu Au - Bu, v)_{V,V'}$$

for all v in V. It follows from Lemma 1.1 on page 169 of [22] that u is in $C([0,T]; H)$. This not only makes sense of the initial condition $u(0) = u^0$ but also shows that the following formulation of a weak solution is equivalent to that of Definition 5.1.

DEFINITION 5.2. *Given viscosity $\nu > 0$ and initial velocity u^0 in H, u in $L^2([0,T]; V)$ is a weak solution to the Navier–Stokes equations if $u(0) = u^0$ and*

$$\begin{cases} u' \in L^1([0,T]; V'), \\ u' + \nu Au + Bu = 0 \text{ on } (0,T), \\ u(0) = u^0, \end{cases}$$

where $u' := \partial_t u$.

From here on we will refer to either of the formulations in Definitions 5.1 and 5.2 as (NS).

6. Existence and uniqueness. We can obtain existence and uniqueness of a solution to (NS) assuming only that the initial velocity is in H.

THEOREM 6.1. *Assume that Γ is C^2 and α is in $L^\infty(\Gamma)$. Let u^0 be in H and let $T > 0$. Then there exists a solution u to (NS). Moreover, u is in $L^2([0,T]; V) \cap C([0,T]; H)$, u' is in $L^2([0,T]; V')$, and we have the energy inequality*

$$\|u(t)\|_{L^2(\Omega)} \leq e^{C(\alpha)\nu t} \|u^0\|_{L^2(\Omega)}. \tag{6.1}$$

The constant $C(\alpha)$ is zero if α is nonnegative on Γ.

Sketch of proof. Existence of a solution to (NS) proceeds as in the first proof of existence in [15, pp. 75–77], though using the analogue of the energy inequality on page 130 of [16]. Using (4.5), we have, formally,

$$\frac{1}{2} \frac{d}{dt} \|u\|^2_{L^2(\Omega)} + \nu \|\nabla u\|^2_{L^2(\Omega)} = \nu \int_\Omega (\mathbf{n} \cdot \nabla u) \cdot u \leq C\nu \|u\|^2_{L^2(\Gamma)} , \tag{6.2}$$

where $C = \sup_\Gamma |\kappa - \alpha|$. Arguing exactly as in [16], it follows that

$$\frac{d}{dt}\|u\|^2_{L^2(\Omega)} + \nu\|\nabla u\|^2_{L^2(\Omega)} \le C\nu\|u\|^2_{L^2(\Omega)}.$$

Integrating over time gives

$$\begin{aligned}\|u(t)\|^2_{L^2(\Omega)} + \nu\int_0^t \|\nabla u(s)\|^2_{L^2(\Omega)}\,ds \\ \le \|u^0\|^2_{L^2(\Omega)} + C\nu\int_0^t \|u(s)\|^2_{L^2(\Omega)}\,ds.\end{aligned} \tag{6.3}$$

The energy bound, (6.1), then follows from Gronwall's lemma. (If α is nonnegative, then, in fact, energy is nonincreasing—in the absence of forcing—so $C(\alpha) = 0$. This follows from the equation preceding (2.16) of [5].)

The proofs of regularity in time and space and of uniqueness proceed exactly as in the proof of Theorem 3.2 on page 199 of [22], though in the proof of uniqueness we must account for the presence of the boundary integral in (NS). ∎

7. Additional regularity. If we assume extra regularity on the initial velocity, that regularity will be maintained for all time. This is crucial for establishing the vanishing viscosity limit in section 8, where we must impose stronger regularity on the initial velocity to obtain existence of a solution to the Euler equations.

THEOREM 7.1. *Assume that* Γ *is* $C^{2,1/2+\epsilon}$ *and that* α *is in* $H^{1/2+\epsilon}(\Gamma)+C^{1/2+\epsilon}(\Gamma)$ *for some* $\epsilon > 0$. *Let* u^0 *be in* $\mathcal{W}$ *with initial vorticity* ω^0, *and let* u *be the unique solution to* (NS) *given by Theorem* 6.1 *with corresponding vorticity* ω. *Let* $T > 0$. *Then*

$$u' \in L^2([0,T];V) \cap C([0,T];H).$$

If, in addition, ω^0 *is in* $L^\infty(\Omega)$ *(so* u^0 *is compatible), then*

$$u \in C([0,T];H^2(\Omega)),\ \omega \in C([0,T];H^1(\Omega)) \cap L^\infty([0,T]\times\Omega).$$

Proof. Regularity of u'. We prove that u' lies in $L^2([0,T];V) \cap L^\infty([0,T];H)$ in three steps as in the proof of Theorem 3.5 on pages 202–204 of [22]. In this proof, Temam uses a Galerkin approximation sequence (u_m) to the solution u. We employ the same sequence, though using the basis of Corollary A.3 rather than that of [22]; this is the only change to step (i).

No change to step (ii) of Temam's proof is required, because the bound on $\|u_m'(0)\|^2_{L^2}$ in (3.88) of [22], which does not involve boundary integrals, still holds.

In step (iii), an additional term of

$$\nu\int_\Gamma (\kappa - \alpha)|u_m'|^2$$

appears on the right side of (3.94) of Temam's proof, which we bound by

$$C\nu\|u_m'\|_{L^2(\Omega)}\|\nabla u_m'\|_{L^2(\Omega)} \le \frac{\nu}{2}\|\nabla u_m'\|^2_{L^2(\Omega)} + C\nu\|u_m'\|^2_{L^2(\Omega)}.$$

Then (3.95) of Temam's proof becomes

$$\frac{d}{dt}\|u_m'(t)\|^2_{L^2(\Omega)} \le \phi_m(t)\|u_m'(t)\|^2_{L^2(\Omega)},$$

where

$$\phi_m(t) = \left(\frac{2}{\nu} + C\nu\right) \|u_m(t)\|^2_{L^2(\Omega)},$$

and the proof that u' lies in $L^2([0,T];V) \cap L^\infty([0,T];H)$ is completed as in [22].

Regularity of u and ω. To establish the regularity of u and ω we follow the bootstrap argument in the second half of the proof of Theorem 2.3 in [5]. For completeness, we give a full account of this argument here, adapting it to multiply connected domains.

Because u' is in $L^2([0,T];V)$ we can argue as in the paragraph preceding Definition 5.2, with u' playing the role of u, that u' is in $C([0,T];H)$. The membership of u' in $L^2([0,T];V)$ also gives u in $H^1([0,T];V)$; by one-dimensional Sobolev embedding, u is then in $C^{1/2}([0,T];V)$ and hence in $C([0,T];V)$. It follows that $u \cdot \nabla u$ is in $C([0,T];L^q(\Omega))$ for all q in $[1,2)$ (see, for instance, Theorem 1.4.4.2 on page 28 of [9]).

Now let $\beta > 0$ and let $\Phi := -u \cdot \nabla u - u' + \beta u$. Then Φ is in $C([0,T];L^q(\Omega))$ for all q in $[1,2)$ by our observations above. Because of the additional regularity we have imposed on Γ and on α over that assumed in Theorem 6.1, $g := (2\kappa - \alpha)u \cdot \boldsymbol{\tau}$ lies in $C([0,T];H^{1/2}(\Gamma))$ (see, for instance, Theorem 1.4.1.1 on page 21 and Theorem 1.4.4.2 on page 28 of [9]).

Let $a : V \times V \to \mathbb{R}$ be defined by $a(u,v) = (Au + \beta u, v)_{V,V'}$ and require that $\beta > 0$ be sufficiently large that $a(v,v) \geq \|v\|^2_V$ for all v in V. This is possible because α is in $L^\infty(\Gamma) \subseteq H^{1/2+\epsilon}(\Gamma) + C^{1/2+\epsilon}(\Gamma)$ by one-dimensional Sobolev embedding. Also by (5.2) we see that $|a(u,v)| \leq C \|u\|_V \|v\|_V$. Applying the Lax–Millgram lemma, we find that there exists a unique w in V such that $a(w,v) = \Phi$ for all v in V. By Definition 5.2, $w = u(t)$ for all t in $[0,T]$. By Definition 5.1, $u(t)$ is also the unique variational solution at time t in $[0,T]$ to Stokes's problem,

$$\begin{cases} -\nu\Delta u + \nabla p + \beta u = \Phi & \text{in } \Omega, \\ \operatorname{div} u = 0 & \text{in } \Omega, \\ \omega(u) = g & \text{on } \Gamma. \end{cases}$$

Formally, the vorticity formulation of the above system is

$$\begin{cases} -\nu\Delta\omega + \beta\omega = \omega(\Phi) & \text{in } \Omega, \\ \omega = g & \text{on } \Gamma. \end{cases}$$

Because $\omega(\Phi)$ is in $C([0,T];H^{-1,q}(\Omega))$, standard elliptic theory gives a unique solution ω in $C([0,T];H^{1,q}(\Omega))$. Because u is in $C([0,T];H)$, there exists an associated stream function φ in $C([0,T] \times \Omega)$ that is constant on each component of Γ at time t in $[0,T]$; this follows directly from (3.1). Letting ψ be the unique solution to

$$\begin{cases} \Delta\psi = \omega & \text{in } \Omega, \\ \psi = \varphi & \text{on } \Gamma, \end{cases}$$

it follows that $u = \nabla^\perp\psi$, because u and $\nabla^\perp\psi$ have the same vorticity ($\operatorname{curl}\nabla^\perp = \Delta$) and their stream functions (namely, φ and ψ) share the same value on Γ.

By Theorem 2.5.1.1 on page 128 of [9], ψ is in $C([0,T];H^{3,q}(\Omega))$; u, then, is in $C([0,T];H^{2,q}(\Omega))$ and hence in $C([0,T] \times \Omega)$ by Sobolev embedding. But u is in $C([0,T];V)$, so $u \cdot \nabla u$ and also Φ are in $C([0,T];L^2(\Omega))$. Passing through the same argument again, this time with $q = 2$, gives u in $C([0,T];(H^2(\Omega))^2)$. □

With Theorem 7.1, we have a replacement for Theorem 2.3 of [5] that applies regardless of the sign of α. Since the nonnegativity of α is used nowhere else in [5] and [17], all the results of both of those papers apply to simply connected domains as well regardless of the sign of α—with the regularity we have assumed on Γ and α.

To remove the restriction on the domain being simply connected, it remains only to show that Lemmas 2 and 3 of [17] remain valid for multiply connected domains. We show this for Lemma 2 of [17] in Theorem A.2. Because, however, for multiply connected domains there is no longer a unique vector field in $\mathcal{W}$ with a given vorticity, we must define a *vector field* to be compatible, rather than its *vorticity*, as was done in [17].

DEFINITION 7.2. *A vector field v in $\mathcal{W}$ is called compatible if $\omega(v)$ is in $L^\infty(\Omega)$.*

As for Lemma 3 of [17], we need only use Corollary 3.2 to replace the term $\|\omega(\cdot,t)\|_{L^p(\Omega)}^{1-\theta}$ with $(\|\omega(\cdot,t)\|_{L^p(\Omega)}+\|u(\cdot,t)\|_{L^2(\Omega)})^{1-\theta}$ in the proof of Lemma 3 in [17]. Lemma 3 of [17] then follows with no other changes in the proof—only the value of the constant C changes.

We thus have the following theorem, which is only a slight modification of Proposition 1 of [17], and which applies to multiply connected domains and unsigned α.

THEOREM 7.3. *Assume that Γ and α are as in Theorem 7.1. Let q be in $(2,\infty]$, and assume that u^0 is in V with initial vorticity ω^0 in $L^p(\Omega)$ for some p in $[q,\infty]$. Let $T>0$. Then there exists a unique solution u to (NS) with corresponding vorticity ω, and for all p in $[q,\infty]$,*

$$\|\omega(t)\|_{L^p} \le \|\omega^0\|_{L^p} + C_0 \tag{7.1}$$

a.e. in $[0,T]$. The constant C_0, which is independent of p, is given by

$$C_0 = C(T,\alpha,\kappa,q)e^{C(\alpha)\nu T}\max\{|\Omega|^{1/2},1\}\left(\|u^0\|_{L^2(\Omega)}+\|\omega^0\|_{L^q(\Omega)}\right).$$

Also, u is in $L^\infty([0,T];C(\overline{\Omega}))\cap L^\infty([0,T];V)$, the norm of u in this space being bounded over any finite range of viscosity ν.

Proof. Approximate u^0 by a sequence of compatible vector fields via Theorem A.2, and let u_n be the corresponding solutions to (NS) given by Theorem 7.1. The argument in the proof of Lemma 3 of [17] can be used to bound $\Lambda = \|(2\kappa-\alpha)u_n\cdot\boldsymbol{\tau}\|_{L^\infty(\Omega)}$ in terms of $\|\omega^0\|_{L^q(\Omega)}$, and this in turn gives the bound $\|\omega_n(t)\|_{L^p}\le\|\omega^0\|_{L^p}+C_0$. This bound holds for the solution u in the limit, as in the proof of Proposition 1 in [17]. (The constant $C(T,\alpha,\kappa,q)$ approaches infinity as q approaches 2, so it is not possible to extend this result to $p=2$.)

Finally, using Sobolev interpolation, (2.3), and Corollary 3.2,

$$\begin{aligned}\|u(t)\|_{C(\overline{\Omega})} &\le C\,\|u(t)\|_{L^2(\Omega)}^{\theta}\,\|u(t)\|_{H^{1,q}(\Omega)}^{1-\theta}\\ &\le C\,\|u(t)\|_{L^2(\Omega)}^{\theta}\,(\|\omega(t)\|_{L^q(\Omega)}+\|u(t)\|_{L^2(\Omega)})^{1-\theta},\end{aligned} \tag{7.2}$$

where $\theta=(q-2)/(2q-2)$. This norm is finite by (6.1), so u is also in $L^\infty([0,T];C(\overline{\Omega}))$ and its norm is uniformly bounded over any finite range of viscosity, as is its norm in $L^\infty([0,T];V)$. Explicitly,

$$\begin{aligned}\|u\|_{L^\infty([0,T];V)} &= \|\nabla u\|_{L^\infty([0,T];L^2(\Omega))} \le C\,\|\nabla u\|_{L^\infty([0,T];L^q(\Omega))}\\ &\le C(\|\omega\|_{L^\infty([0,T];L^q(\Omega))}+\|u\|_{L^\infty([0,T];L^2(\Omega))})\\ &\le C(T,\alpha,\kappa)e^{C(\alpha)\nu T},\end{aligned} \tag{7.3}$$

a bound we will use in section 8. In the second inequality above we used Corollary 3.2. ∎

8. Vanishing viscosity. In this section we bound the rate of convergence in $L^\infty([0,T];L^2(\mathbb{R}^2))$ of solutions to (NS) to the unique solution to the Euler equations for the class of (bounded or unbounded) *Yudovich vorticities*. To describe Yudovich vorticity, we need the following definition.

DEFINITION 8.1. *Let $\theta : [p_0,\infty) \to \mathbb{R}$ for some $p_0 > 1$. We say that θ is admissible if the function $\beta : (0,\infty) \to [0,\infty)$, defined for some $M > 0$ by*[2]

$$\beta(x) := \beta_M(x) := x \inf\left\{(M^\epsilon x^{-\epsilon}/\epsilon)\theta(1/\epsilon) : \epsilon \text{ in } (0, 1/p_0]\right\}, \tag{8.1}$$

satisfies

$$\int_0^1 \frac{dx}{\beta(x)} = \infty. \tag{8.2}$$

Because $\beta_M(x) = M\beta_1(x/M)$, this definition is independent of the value of M, though the presence of M in the definition will turn out to be convenient. Also, β is a monotonically increasing continuous function, with $\lim_{x\to 0^+}\beta(x) = 0$.

Yudovich proves in [26] that for a bounded domain in $\mathbb{R}^n$, if $\|\omega^0\|_{L^p} \le \theta(p)$ for some admissible function θ, then at most one solution to the Euler equations exists. Because of this, we call the class of all such vorticities *Yudovich vorticity*.

DEFINITION 8.2. *We say that a vector field v has Yudovich vorticity if $p \mapsto \|\omega(v)\|_{L^p(\Omega)}$ is an admissible function.*

Examples of admissible bounds on vorticity are

$$\theta_0(p) = 1, \theta_1(p) = \log p, \dots, \theta_m(p) = \log p \cdot \log\log p \cdots \log^m p, \tag{8.3}$$

where $\log^m$ is log composed with itself m times. These admissible bounds are described in [26] (see also [14].) Roughly speaking, the L^p-norm of a Yudovich vorticity can grow in p only slightly faster than $\log p$ and still be admissible. Such growth in the L^p-norm arises, for example, from a point singularity of the type $\log\log(1/|x|)$.

DEFINITION 8.3. *Given an initial velocity u^0 in V, $\overline{u}$ in $L^2([0,T];V)$ is a weak solution to the Euler equations if $\overline{u}(0) = u^0$ and*

$$\frac{d}{dt}\int_\Omega \overline{u}\cdot v + \int_\Omega (\overline{u}\cdot\nabla\overline{u})\cdot v = 0$$

for all v in V.

The existence of a weak solution to the Euler equations under the assumption that the initial vorticity ω^0 is in $L^p(\Omega)$ for some $p > 1$ (a weaker assumption than that of Definition 8.3 when $1 < p < 2$) was proved in [25]. By the result in [26] mentioned above, the solutions are unique in the class of all such solutions $\overline{u}$ for which $\omega(\overline{u})$ and $\overline{u}'$ lie in $L^\infty_{loc}(\mathbb{R};L^p(\Omega))$ for all p in an interval $[p_0,\infty)$.

THEOREM 8.4. *Assume that Γ and α are as in Theorem 7.1. Fix $T > 0$, let u^0 be in V, and assume that ω^0 is in $L^p(\mathbb{R}^2)$ for all p in $[2,\infty)$, with $\|\omega^0\|_{L^p} \le \theta(p)$ for some admissible function θ. Let u be the solution to (NS) for $\nu > 0$ given by Theorem 7.3 and $\overline{u}$ be the unique weak solution to the Euler equations for which $\omega(\overline{u})$ and $\overline{u}'$ are in $L^\infty_{loc}(\mathbb{R};L^p(\Omega))$ for all p in $[2,\infty)$, $\overline{u}$ and u both having initial velocity u^0. Then*

$$u(t) \to \overline{u}(t) \text{ in } L^\infty([0,T];L^2(\Omega)\cap L^2(\Gamma)) \text{ as } \nu \to 0.$$

[2] The definition of β in (8.1) differs from that in [14] in that it directly incorporates the factor of p that appears in the Calderón–Zygmund inequality; in [14] this factor is included in the equivalent of (8.2).

Also, there exists a constant $R = C(T, \alpha, \kappa)$, such that if we define the function $f : [0, \infty) \to [0, \infty)$ by

$$\int_{R\nu}^{f(\nu)} \frac{dr}{\beta(r)} = CT,$$

where β is defined as in (8.1)*, then*

$$\begin{aligned} &\|u - \overline{u}\|_{L^\infty([0,T];L^2(\Omega))} \le f(\nu)^{1/2} \text{ and} \\ &\|u - \overline{u}\|_{L^\infty([0,T];L^2(\Gamma))} \le C'(T, \alpha, \kappa) f(\nu)^{1/4} \end{aligned} \tag{8.4}$$

for all ν in $(0, 1]$.

Proof. We let $w = u - \overline{u}$. It is possible to show that integral identity in Definition 5.1 extends to any v in $L^2([0, T]; V)$ in the form

$$\int_\Omega \partial_t u \cdot v + \int_\Omega (u \cdot \nabla u) \cdot v + \nu \int_\Omega \nabla u \cdot \nabla v - \nu \int_\Gamma (\kappa - \alpha) u \cdot v = 0$$

with a similar extension for the identity in Definition 8.3. Applying these identities with $v = w$ and subtracting give

$$\begin{aligned} &\int_\Omega w \cdot \partial_t w + \int_\Omega w \cdot (u \cdot \nabla w) + \int_\Omega w \cdot (w \cdot \nabla \overline{u}) \\ &\quad = \nu \int_\Gamma (\kappa - \alpha) u \cdot w - \nu \int_\Omega \nabla u \cdot \nabla w. \end{aligned} \tag{8.5}$$

Both $\partial_t u$ and $\partial_t \overline{u}$ are in $L^2([0, T]; V')$, so (see, for instance, Lemma 1.2 on page 176 of [22])

$$\int_\Omega w \cdot \partial_t w = \frac{1}{2} \frac{d}{dt} \|w\|^2_{L^2(\Omega)}.$$

Applying Lemma 2.1,

$$\begin{aligned} &\int_\Omega w \cdot (u \cdot \nabla w) \\ &\quad = \int_\Omega w^i u^j \partial_j w^i = \frac{1}{2} \int_\Omega u^j \partial_j \sum_i (w^i)^2 = \frac{1}{2} \int_\Omega u \cdot \nabla |w|^2 \\ &\quad = \frac{1}{2} \int_\Gamma (u \cdot \mathbf{n}) |w|^2 - \frac{1}{2} \int_\Omega (\operatorname{div} u) |w|^2 = 0, \end{aligned}$$

since $u \cdot \mathbf{n} = 0$ on Γ and $\operatorname{div} u = 0$ in Ω. Thus, integrating (8.5) over time,

$$\|w(t)\|^2_{L^2(\Omega)} \le K + 2 \int_0^t \int_\Omega |w|^2 |\nabla \overline{u}|, \tag{8.6}$$

where

$$\begin{aligned} K &= 2\nu \int_0^t \left[\int_\Gamma (\kappa - \alpha) u \cdot w - \int_\Omega \nabla u \cdot \nabla w \right] \\ &\le 2\nu \int_0^t \left[\int_\Gamma (\kappa - \alpha) u \cdot w + \int_\Omega \nabla u \cdot \nabla \overline{u} \right]. \end{aligned}$$

Applying (2.5) and then using (7.3) and its equivalent for solutions to the Euler equations (where the constant does not increase with time), we have

$$\begin{aligned}\left|\int_\Gamma (\kappa-\alpha)u\cdot w\right| &\le \|\kappa-\alpha\|_{L^\infty(\Gamma)}\,\|u\|_{L^2(\Gamma)}\,\|w\|_{L^2(\Gamma)}\\ &\le C\,\|u\|_V\,\|w\|_V \le C(T,\alpha,\kappa)e^{C(\alpha)\nu T}.\end{aligned}\tag{8.7}$$

By (7.3) we also have

$$\left|\int_\Omega \nabla u\cdot\nabla\overline{u}\right| \le \|\nabla u\|_{L^2(\Omega)}\,\|\nabla\overline{u}\|_{L^2(\Omega)} \le C(T,\alpha,\kappa)e^{C(\alpha)\nu T},\tag{8.8}$$

so

$$K \le C(T,\alpha,\kappa)e^{C(\alpha)\nu T}\nu \le R\nu\tag{8.9}$$

for all ν in $(0,1]$ for some constant R.

By (7.2), $\|u\|_{L^\infty([0,T]\times\Omega)} \le C$ for all ν in $(0,1]$. It is also true that $\overline{u}$ is in $L^\infty([0,T]\times\Omega)$ (arguing, for instance, exactly as in (7.2)). Thus,

$$M = \sup_{\nu\in(0,1]} \||w|^2\|_{L^\infty([0,T]\times\Omega)}$$

is finite.

Also, because the L^p-norms of vorticity are conserved for $\overline{u}$, we have, by Corollary 3.2,

$$2\,\|\nabla\overline{u}(t)\|_{L^p(\Omega)} \le Cp\|\omega^0\|_{L^p(\Omega)} + C\|u^0\|_{L^2(\Omega)} \le Cp(\theta(p)+1/p)\tag{8.10}$$

for all $p\ge 2$. Because θ is admissible, so is $p\mapsto C[\theta(p)+1/p]$, and its associated β function—call it $\overline{\beta}$—is bounded by a constant multiple of that associated to θ; that is, $\overline{\beta}\le C\beta$.

We now proceed as in [14]. Let s be in $[0,T]$, and let

$$A = |w(s,x)|^2, \quad B = |\nabla\overline{u}(s,x)|, \quad L(s) = \|w(s)\|_{L^2}^2\,.$$

Then

$$\begin{aligned}\int_{\mathbb{R}^2} |w(s,x)|^2|\nabla\overline{u}(s,x)|\,dx &= \int_{\mathbb{R}^2} AB = \int_{\mathbb{R}^2} A^\epsilon A^{1-\epsilon}B \le M^\epsilon\int_{\mathbb{R}^2} A^{1-\epsilon}B\\ &\le M^\epsilon\|A^{1-\epsilon}\|_{L^{1/(1-\epsilon)}}\|B\|_{L^{1/\epsilon}} = M^\epsilon\|A\|_{L^1}^{1-\epsilon}\|B\|_{L^{1/\epsilon}}\\ &= M^\epsilon L(s)^{1-\epsilon}\|\nabla\overline{u}(s)\|_{L^{1/\epsilon}} \le CM^\epsilon L(s)^{1-\epsilon}\frac{1}{\epsilon}(\theta(1/\epsilon)+\epsilon).\end{aligned}$$

Since this is true for all ϵ in $[1/p_0,\infty)$, it follows that

$$2\int_{\mathbb{R}^2} |\nabla\overline{u}(s,x)||w(s,x)|^2\,dx \le C\overline{\beta}(L(s)) \le C\beta(L(s)).$$

From (8.6) and (8.9), then, we have

$$L(t) \le R\nu + C\int_0^t \beta(L(r))\,dr.$$

By Lemma 1.1,

$$\int_{R\nu}^{L(t)} \frac{ds}{C\beta(s)} = \left(-\int_{L(t)}^{1} + \int_{R\nu}^{1} \right) \frac{ds}{C\beta(s)} \leq \int_0^t ds = t. \tag{8.11}$$

It follows that for all t in $(0, T]$,

$$\int_{R\nu}^{1} \frac{ds}{\beta(s)} \leq CT + \int_{L(t)}^{1} \frac{ds}{\beta(s)}. \tag{8.12}$$

As $\nu \to 0^+$, the left side of (8.12) becomes infinite because of (8.2); hence, so must the right side. But this implies that $L(t) \to 0$ as $\nu \to 0^+$ and that the convergence is uniform over $[0, T]$. It also follows from (8.11) that

$$\int_{R\nu}^{L(t)} \frac{dr}{\beta(r)} \leq Ct \tag{8.13}$$

and that, as $\nu \to 0$, $L(t) \to 0$ uniformly over any finite time interval. The rate of convergence given in $L^\infty([0, T]; L^2(\Omega))$ in (8.4) can be derived from (8.13) precisely as in [14].

By (2.5),

$$\begin{aligned} \|u - \overline{u}\|_{L^2(\Gamma)} = \|w\|_{L^2(\Gamma)} &\leq C \|\nabla w\|_{L^2(\Omega)}^{1/2} \|w\|_{L^2(\Omega)}^{1/2} \\ &\leq C(T, \alpha, \kappa) e^{C(\alpha)\nu T} L(t)^{1/4}, \end{aligned}$$

from which the convergence rate for $L^\infty([0, T]; L^2(\Gamma))$ in (8.4) follows. □

The convergence rate in $L^\infty([0, T]; L^2(\Omega))$ established in Theorem 8.4 is the same as that established for the entire plane in [14], except for the presence of the constant C and the value of the constant R, which now increases with time (linearly, when α is nonnegative).

In the important special cased of bounded initial vorticity, one obtains the bound

$$\|u - \overline{u}\|_{L^\infty([0,T];L^2(\mathbb{R}^2))} \leq M^{1/2} \left(\frac{R\nu}{M} \right)^{\frac{1}{2} e^{-\epsilon T}} \tag{8.14}$$

for all t in $[0, T]$ for which $\nu < (M/R)e^{-2}$. Here, the R and M are defined as in the proof of Theorem 8.4, and $\epsilon = C\|\omega^0\|_{L^2 \cap L^\infty}$. When α is nonnegative, R is proportional to t, and (8.14) is essentially the same bound obtained by Chemin in [3] working in all of $\mathbb{R}^2$.

One can also calculate explicit bounds for the sequence of admissible vorticities in (8.3), obtaining bounds similar to that of (8.14), but with iterated exponentials. In general, it is not possible to obtain an explicit bound. The important point, however, is that, as described in section 5 of [14], it is possible to obtain an arbitrarily poor bound on the convergence rate for properly chosen initial vorticity. This is because the function f, which was defined implicitly in terms of β, can, conversely, be used to define β, and we can choose f so that it approaches zero arbitrarily slowly. (It is an open and difficult question whether initial vorticities actually exist that achieve arbitrarily slow convergence.)

In Theorem 8.4, we held α constant in (1.2) and let $\nu \to 0$, which is equivalent to letting $a \to 0$ linearly with ν in (1.1). One could modify the proof of Theorem 8.4 in

an attempt to obtain the vanishing viscosity limit with slower than linear convergence of a to 0 by being explicit about the value of the constant C_0 in Theorem 7.3. This constant controls the bounds on both K and M in the proof of Theorem 8.4, which, along with the L^p-norms of the initial vorticity, ultimately determine the convergence rate. But C_0 increases to infinity with $\|\alpha\|_{L^\infty(\Gamma)}$, and the bounds on K and M each increase to infinity with C_0. The conclusion is that $\|\alpha\|_{L^\infty(\Gamma)}$ must be bounded over sufficiently small values of ν for the approach in the proof of Theorem 8.4 to remain valid. Thus, using our approach, we cannot significantly improve over the assumption that α remains fixed as $\nu \to 0$ in the vanishing viscosity limit.

9. No-slip boundary conditions. As long as α is nonvanishing, we can let $\gamma = 1/\alpha$ and re-express the Navier boundary conditions in (1.2) as

$$v \cdot \mathbf{n} = 0 \text{ and } 2\gamma(\mathbf{n} \cdot D(v)) \cdot \boldsymbol{\tau} + v \cdot \boldsymbol{\tau} = 0 \text{ on } \Gamma. \tag{9.1}$$

When γ is identically zero, we have the usual no-slip boundary conditions. An obvious question to ask is whether it is possible to arrange for γ to approach zero in such a manner that the corresponding solutions to the Navier–Stokes equations with Navier boundary conditions approach the solution to the Navier–Stokes equations with the usual no-slip boundary conditions in $L^\infty([0,T];L^2(\Omega))$.

Let u^0 be an initial velocity in V, and assume that $\gamma > 0$ lies in $L^\infty(\Gamma)$. Fix a $\nu > 0$ and let

$$\begin{aligned} u &= \text{the unique solution to the Navier–Stokes equations} \\ &\quad \text{with Navier boundary conditions for } \alpha = 1/\gamma \text{ and} \\ \widetilde{u} &= \text{the unique solution to the Navier–Stokes equations} \\ &\quad \text{with no-slip boundary conditions,} \end{aligned}$$

in each case with the same initial velocity u^0.

If we let γ approach 0 uniformly on the boundary, we automatically have some control over u on the boundary.

LEMMA 9.1. *For sufficiently small* $\|\gamma\|_{L^\infty(\Gamma)}$,

$$\|u\|_{L^2([0,T];L^2(\Gamma))} \leq \frac{\|u^0\|_{L^2(\Omega)}}{\sqrt{\nu}} \|\gamma\|^{1/2}_{L^\infty(\Gamma)}. \tag{9.2}$$

Proof. Assume that $\|\gamma\|_{L^\infty(\Gamma)}$ is sufficiently small that $\alpha > \kappa$ on Γ. Then, as in the proof of Theorem 6.1, we have

$$\frac{1}{2}\frac{d}{dt}\|u(t)\|^2_{L^2(\Omega)} + \nu \|\nabla u(t)\|^2_{L^2(\Omega)} = \nu \int_\Gamma (\kappa - \alpha) u \cdot u,$$

so

$$\|u(t)\|^2_{L^2(\Omega)} \leq \|u^0\|^2_{L^2(\Omega)} + 2\nu \int_0^t \int_\Gamma (\kappa - \alpha) u \cdot u.$$

But

$$\int_\Gamma (\kappa - \alpha) u \cdot u \leq -\inf_\Gamma \{\alpha - \kappa\} \|u(t)\|^2_{L^2(\Gamma)},$$

so

$$\|u(t)\|^2_{L^2(\Omega)} \leq \|u^0\|^2_{L^2(\Omega)} - 2\nu \inf_\Gamma \{\alpha - \kappa\} \|u\|^2_{L^2([0,t];L^2(\Gamma))}$$

and

$$\|u\|^2_{L^2([0,t];L^2(\Gamma))} \le \|u^0\|^2_{L^2(\Omega)}/(2\nu \inf_\Gamma \{\alpha - \kappa\}).$$

Then (9.2) follows because $\|\gamma\|_{L^\infty(\Gamma)} \inf_\Gamma \{\alpha - \kappa\} \to 1$ as $\|\gamma\|_{L^\infty(\Gamma)} \to 0$. ∎

If we assume enough smoothness of the initial data and of Γ, we can use (9.2) to establish convergence of u to $\widetilde{u}$ as $\|\gamma\|_{L^\infty(\Gamma)} \to 0$.

THEOREM 9.2. *Fix $T > 0$, assume that u^0 is in $V \cap H^3(\Omega)$ with $u^0 = 0$ on Γ, and assume that Γ is C^3. Then for any fixed $\nu > 0$,*

$$u \to \widetilde{u} \text{ in } L^\infty([0,T];L^2(\Omega)) \cap L^2([0,T];\dot{H}^1(\Omega)) \cap L^2([0,T];L^2(\Gamma)) \tag{9.3}$$

as $\gamma \to 0$ in $L^\infty(\Gamma)$. Here, $\dot{H}^1(\Omega)$ is the homogeneous Sobolev space.

Proof. First, u exists and is unique by Theorem 6.1; the existence and uniqueness of $\widetilde{u}$ are classical results. Because u^0 is in $H^3(\Omega)$ and Γ is C^3, $\widetilde{u}$ is in $L^\infty([0,T];H^3(\Omega))$ by the argument on page 205 of [22] following the proof of Theorem 3.6 of [22]. Hence, $\nabla\widetilde{u}$ is in $L^\infty([0,T];H^2(\Omega))$ and so in $L^\infty([0,T];C(\overline{\Omega}))$.

Arguing as in the proof of Theorem 8.4 with $w = u - \widetilde{u}$, we have

$$\int_\Omega \partial_t w \cdot w + \int_\Omega w \cdot (u \cdot \nabla w) + \int_\Omega w \cdot (w \cdot \nabla \widetilde{u}) + \nu \int_\Omega \nabla w \cdot \nabla w - \nu \int_\Gamma (\kappa - \alpha) u \cdot w + \nu \int_\Gamma (\mathbf{n} \cdot \nabla \widetilde{u}) \cdot w = 0.$$

(Even though w is not a valid test function for $\widetilde{u}$, we are working with sufficiently smooth solutions that this integration is still valid. Since w is divergence-free and tangential to the boundary, the pressure term for each equation integrates to zero.) But $\widetilde{u} = 0$ on Γ, so $w = u$ on Γ, and

$$\int_\Omega \partial_t w \cdot w + \int_\Omega w \cdot (w \cdot \nabla \widetilde{u}) + \nu \int_\Omega |\nabla w|^2 + \nu \int_\Gamma (\alpha - \kappa)|u|^2 + \nu \int_\Gamma (\mathbf{n} \cdot \nabla \widetilde{u}) \cdot u = 0.$$

For $\|\gamma\|_{L^\infty(\Gamma)}$ sufficiently small that $\alpha = 1/\gamma > \kappa$ on Γ, integrating over time gives

$$\|w(t)\|^2_{L^2(\Omega)} + \nu \int_0^t \|\nabla w\|^2_{L^2(\Omega)} \le K + 2 \int_0^t \int_\Omega |w|^2 |\nabla \widetilde{u}|, \tag{9.4}$$

where

$$K = -2\nu \int_0^t \int_\Gamma (\mathbf{n} \cdot \nabla \widetilde{u}) \cdot u \le 2\nu \int_0^t \|\nabla \widetilde{u}\|_{L^2(\Gamma)} \|u\|_{L^2(\Gamma)}$$
$$\le C\nu \int_0^t \|\widetilde{u}\|_{H^2(\Omega)} \|u\|_{L^2(\Gamma)} \le C\nu \|\widetilde{u}\|_{L^2([0,T];H^2(\Omega))} \|u\|_{L^2([0,T];L^2(\Gamma))}.$$

By Theorem 3.10 on page 213 of [22], $\|\widetilde{u}\|_{L^2([0,T];H^2(\Omega))}$ is finite (though the bound on it in [22] increases to infinity as ν goes to 0), so by Lemma 9.1,

$$K \le C_1(\nu) \|\gamma\|^{1/2}_{L^\infty(\Gamma)}. \tag{9.5}$$

Because $\nabla \widetilde{u}$ is in $L^\infty([0,T];C(\overline{\Omega}))$,

$$\int_0^t \int_\Omega |w|^2 |\nabla \widetilde{u}| \leq C_2(\nu) \int_0^t \|w(s)\|^2_{L^2(\Omega)}\, ds,$$

where $C_2(\nu) = \|\nabla \widetilde{u}\|_{L^\infty([0,T]\times\Omega)}$, and (9.4) becomes

$$\|w(t)\|^2_{L^2(\Omega)} + \nu \int_0^t \|\nabla w\|^2_{L^2(\Omega)} \leq C_1(\nu) \|\gamma\|^{1/2}_{L^\infty(\Gamma)} + C_2(\nu) \int_0^t \|w(s)\|^2_{L^2(\Omega)}\, ds.$$

By Gronwall's lemma,

$$\|w(t)\|^2_{L^2(\Omega)} \leq C_1(\nu) \|\gamma\|^{1/2}_{L^\infty(\Gamma)} e^{C_2(\nu)t},$$

and the convergence in $L^\infty([0,T];L^2(\Omega))$ and thus also in $L^2([0,T];\dot{H}^1(\Omega))$ follow immediately. Convergence in $L^2([0,T];L^2(\Gamma))$ then follows directly from Lemma 9.1, since $\widetilde{u} = 0$ on Γ. □

10. The boundary layer. In [13], Kato investigates the vanishing viscosity limit of solutions of the Navier–Stokes equations with no-slip boundary conditions to a solution of the Euler equations for a bounded domain in $\mathbb{R}^d$, $d \geq 2$. What Kato shows is the following: Let u be the weak solution to the Navier–Stokes equations with no-slip boundary conditions and with $u(0)$ in H, and let $\overline{u}$ be the solution to the Euler equations, where sufficient smoothness is assumed for $\overline{u}(0)$ that $\nabla \overline{u}$ is bounded on $[0,T]\times\Omega$. Assume also that $u(0) \to \overline{u}(0)$ in H as $\nu \to 0$. Then the following are equivalent:

(i) $u(t) \to \overline{u}(t)$ in $L^2(\Omega)$ as $\nu \to 0$ uniformly over t in $[0,T]$;
(ii) $u(t) \to \overline{u}(t)$ in $L^2(\Omega)$ as $\nu \to 0$ weakly for all t in $[0,T]$;
(iii) $\nu \int_0^T \|\nabla u\|^2_{L^2(\Omega)}\, dt \to 0$ as $\nu \to 0$;
(iii′) $\nu \int_0^T \|\nabla u\|^2_{L^2(\Gamma_{c\nu})}\, dt \to 0$ as $\nu \to 0$.

Here, $\Gamma_{c\nu}$ is the boundary strip of width $c\nu$ with $c > 0$ fixed but arbitrary.

Let us return to the setting of Theorem 8.4 and compare the situation to that of [13]. We now have zero forcing and the same initial conditions for both (NS) and (E), which simplifies the analysis in [13] slightly, but we have different boundary conditions on (NS) and we have insufficient smoothness of u^0 for Kato's conditions to apply. However, we have already proven that condition (i) holds and hence also (ii), and since conditions (iii) and (iii') follow immediately from (7.1), no further work is required to show the equivalence of Kato's four conditions.

(It is also possible to directly adapt Kato's argument to our setting, thereby establishing the vanishing viscosity limit in the spirit of Kato. This requires, however, all of the results developed to prove the vanishing viscosity limit in Theorem 8.4 and considerably more effort besides.)

We can bound the rate at which the convergence in condition (iii′) occurs, giving us some idea of what is happening in the boundary layer.

THEOREM 10.1. *With the assumptions in Theorem* 8.4*,*

$$\nu \int_0^T \|\nabla u\|^2_{L^2(\Gamma_{c\nu})}\, dt \leq C(p,T,\alpha,\kappa,u^0) T (2c)^{1-2/p} \nu^{2-2/p}$$

for all p *in* $(2,\infty)$ *and* t *in* $[0,T]$.

Proof. We have, using (7.1) and Corollary 3.2,

$$\begin{aligned}\|\nabla u\|_{L^2(\Gamma_{\delta/2})} &\le \|z\nabla u\|_{L^2(\Gamma_\delta)} \le \|z\|_{L^{p'}(\Gamma_\delta)} \|\nabla u\|_{L^p(\Omega)} \\ &\le \|z\|_{L^{p'}(\Gamma_\delta)} \left(Cp\,\|\omega\|_{L^p(\Omega)} + C'\,\|u\|_{L^2(\Omega)}\right) \\ &\le \|z\|_{L^{p'}(\Gamma_\delta)} \left(Cp\left(\|\omega^0\|_{L^p} + C_0\right) + C'\,\|u\|_{L^2(\Omega)}\right),\end{aligned}$$

where $1/p' + 1/p = 1/2$. But

$$\|z\|_{L^{p'}} \le C\delta^{1/p'} = C\delta^{1/2-1/p}.$$

Substituting this into the earlier inequality, squaring the result, setting $\delta = 2c\nu$, and integrating over time conclude the proof. ∎

The proof of Theorem 10.1 shows that the square of the gradient of the velocity for a solution to (NS) with Navier boundary conditions vanishes in the L^2-norm nearly linearly with the width of the boundary layer. We could obtain linear convergence for appropriate smoother initial velocities if we could show that $\|\nabla u\|_{L^\infty(\Omega)}$ is bounded uniformly over small ν. It is not at all clear, however, whether such a result is obtainable. In any case, the behavior of the boundary layer for Navier boundary conditions is principally derived from the boundary conditions themselves and is not highly dependent upon the smoothness of the initial velocity.

This is in contrast to no-slip boundary conditions, where for smooth data probably the strongest general statement that can be made was made by Kato in [13] with his equivalent conditions for the vanishing viscosity limit. (See also the incremental improvement in [23] and [27].) For the less regular initial velocities that we assume in Theorem 8.4, it is quite possible that a condition stronger than Kato's condition (iii′) is required to imply convergence in the vanishing viscosity limit. This is because there is no known bound on $\|u\|_{L^2([0,T];L^\infty(\Omega))}$ uniform over small ν, which is required to achieve the vanishing viscosity limit using Osgood's lemma as in section 8. In fact, obtaining such a bound would almost certainly require obtaining a uniform bound on the L^p-norm of the vorticity for some $p > 2$, which is tantamount to establishing the vanishing viscosity limit to begin with, at least for smooth initial data.

Appendix. Compatible sequences. For p in $(1,\infty)$, define the spaces

$$X_0^p = H_0 \cap H^{1,p}(\Omega) \text{ and } X^p = H \cap H^{1,p}(\Omega) = X_0^p \oplus H_c, \tag{A.1}$$

each with the $H^{1,p}(\Omega)$-norm.

LEMMA A.1. *Let p be in $(1,\infty]$. For $p < 2$ let $\widehat{p} = p/(2-p)$, for $p > 2$ let $\widehat{p} = \infty$, and for $p = 2$ let $\widehat{p}$ be any value in $[2,\infty]$. Then for any v in X_0^p,*

$$\|v\|_{L^{\widehat{p}}(\Gamma)} \le C(p)\,\|\omega(v)\|_{L^p(\Omega)}.$$

Proof. For $p < 2$ and any v in X_0^p, we have

$$\begin{aligned}\|v\|_{L^{\widehat{p}}(\Gamma)} &\le C(p)\,\|v\|_{L^p(\Omega)}^{1-\lambda}\,\|\nabla v\|_{L^p(\Omega)}^{\lambda} \le C(p)\,\|\nabla v\|_{L^p(\Omega)} \\ &\le C(p)\,\|\omega(v)\|_{L^p(\Omega)},\end{aligned}$$

where $\lambda = 2(\widehat{p}-p)/(p(\widehat{p}-1)) = 1$ if $p < 2$ and $\lambda = 2/p$ if $p \ge 2$. The first inequality follows from Theorem 3.1 on page 43 of [7], the second follows from (2.3), and the third from Lemma 3.1. ∎

Given a vorticity ω in $L^p(\Omega)$ with p in $(1,\infty)$, the Biot–Savart law gives a vector field v in H whose vorticity is ω. (That v is in $L^2(\Omega)$ follows as in the proof of Lemma A.1, Ω being bounded.) Let $v = u + h$, where u is in H_0 and h is in H_c. Then $\omega(u) = \omega$ as well, so we can define a function $K_\Omega\colon\ L^p(\Omega) \to H_0$ by $\omega \mapsto u$ having the property that $\omega(K_\Omega[\omega]) = \omega$. By (2.3) and Lemma 3.1, u is also in $H^{1,p}(\Omega)$, so, in fact, $K_\Omega\colon\ L^p(\Omega) \to X_0^p$ and is the inverse of the function ω. It is continuous by the same two lemmas. We can write the inequality in Lemma A.1, then, as $\|K_\Omega[\omega]\|_{L^{\widehat{p}}(\Gamma)} \le C(p)\,\|\omega\|_{L^p(\Omega)}$.

THEOREM A.2. *Assume that Γ is C^2 and α is in $L^\infty(\Gamma)$. Let v be in X^p for some p in $(1,\infty)$ and have vorticity ω. Then there exists a sequence (v_n) of compatible vector fields (Definition 7.2) whose vorticities converge strongly to ω in $L^p(\Omega)$. The vector fields (v_n) converge strongly to v in X^p and, if $p \ge 2$, also in V.*

Proof. Our proof is a minor adaptation of that of Lemma 2 of [17], which we first summarize. Let N_n be a tubular neighborhood of Γ of width $2/n$ (for n sufficiently large) and let $U_n = N_n \cap \Omega$. Define $d\colon U_n \to \mathbb{R}^+$ by $d(x) = \operatorname{dist}(x,\Gamma)$ and $r\colon U_n \to \Gamma$ by letting $r(x)$ be the nearest point to x on Γ. Define a cutoff function ζ_n in $C^\infty(\Omega)$ taking values in $[0,1]$ so that $\zeta_n \equiv 0$ on U_{n+1} and $\zeta_n \equiv 1$ on $\Omega \setminus U_n$, and let the sequence (η_k) be an approximation of the identity.

It is shown in [17] that β is a continuous extension operator from $L^{\widehat{p}}(\Gamma)$ into $L^p(\Omega)$, where

$$\beta(G)(x) := \zeta_n(x)(\eta_n * \omega)(x) + (1 - \zeta_n(x))e^{-nd(x)}G(r(x))$$

and where $\widehat{p}$ is defined as in Lemma A.1. In calculating $\eta_n * \omega$, we extend ω by zero to all of $\mathbb{R}^2$. Defining $\Psi\colon L^{\widehat{p}}(\Gamma) \to L^{\widehat{p}}(\Gamma)$ by

$$\Psi(G) = (2\kappa - \alpha)K_\Omega[\beta_n(G)] \cdot \boldsymbol{\tau},$$

it is shown that Ψ is a contraction mapping for sufficiently large n and so has a unique fixed point, G^n. Finally, defining $\omega_n = \beta(G^n)$, the authors show that ω_n converges to ω in $L^p(\Omega)$ (this argument uses Lemma A.1). Key to this last step is demonstrating that $\|G^n\|_{L^{\widehat{p}}(\Gamma)}$ is bounded over n.

Since the authors of [17] are working in a simply connected domain, they can deal exclusively with vorticity. To adapt their proof to multiply connected domains, where we must recover the velocity with the proper harmonic component, requires only one change to their construction. We suppose that $v = u + h$ with $u \in X_0^p$ and h in H_c and define

$$\Psi(G) = (2\kappa - \alpha)(K_\Omega[\beta(G)] + h) \cdot \boldsymbol{\tau}.$$

In forming the difference $\Psi(G_1) - \Psi(G_2)$ the term $(2\kappa - \alpha)h \cdot \boldsymbol{\tau}$ cancels, and the existence of a unique fixed point G^n follows precisely as in [17].

We can now define

$$\omega_n = \beta(G_n),\ v_n = K_\Omega[\omega_n] + h,$$

and observe that *on* Γ,

$$\begin{aligned}\omega(v_n) = \omega_n = \beta(G^n) = G^n = \Psi(G^n) &= (2\kappa - \alpha)(K_\Omega[\beta(G^n)] + h) \cdot \boldsymbol{\tau} \\ &= (2\kappa - \alpha)(K_\Omega[\omega_n] + h) \cdot \boldsymbol{\tau} = (2\kappa - \alpha)v_n \cdot \boldsymbol{\tau},\end{aligned}$$

so v_n satisfies the Navier boundary conditions. (Note that we had to include the harmonic component h of the velocity in the definition of Ψ; we could not simply apply Lemma 2 of [17] to u and add h to the resulting vector field, because such a vector field would not, in general, satisfy the Navier boundary conditions.)

The convergence of ω_n to ω in $L^p(\Omega)$ is argued as in [17], except that now, to show that $\|G^n\|_{L^{\hat{p}}(\Gamma)}$ is bounded over n, we have

$$\begin{aligned}\|G^n\|_{L^{\hat{p}}(\Gamma)} &\le \|2\kappa-\alpha\|_{L^\infty}\,\|K_\Omega[\omega_n]+h\|_{L^{\hat{p}}(\Gamma)}\\ &\le C(\|K_\Omega[\omega_n]\|_{L^{\hat{p}}(\Gamma)}+\|h\|_{L^{\hat{p}}(\Gamma)})\\ &\le C\left(\|\omega\|_{L^p(\Omega)}+\frac{1}{2}\,\|G^n\|_{L^{\hat{p}}(\Gamma)}+\|\nabla h\|_{L^p(\Omega)}\right)\end{aligned}$$

for n sufficiently large. Here, the bound on $\|K_\Omega[\omega_n]\|_{L^{\hat{p}}(\Gamma)}$ is as in [17] and the bound on $\|h\|_{L^{\hat{p}}(\Gamma)}$ follows from Theorem 3.1 on page 43 of [7] and (2.3) as in the proof of Lemma A.1. It follows that $\|G^n\|_{L^{\hat{p}}(\Gamma)} \le C\,\|v\|_{X_p}$ for sufficiently small n, which is what is required to complete the proof of the convergence of ω_n to ω in $L^p(\Omega)$ as in [17].

To prove the convergence of v_n to v in X^p, we observe that

$$\begin{aligned}\|\nabla v-\nabla v_n\|_{L^p(\Omega)} &= \|\nabla u+\nabla h-(\nabla K_\Omega[\omega_n]+\nabla h)\|_{L^p(\Omega)}\\ &= \|\nabla(u-K_\Omega[\omega_n])\|_{L^p(\Omega)} \le Cp\,\|\omega(u-K_\Omega[\omega_n])\|_{L^p(\Omega)}\\ &= Cp\,\|\omega-\omega_n\|_{L^p(\Omega)}\,,\end{aligned}$$

where we used Lemma 3.1. Then by (2.3), v_n converges strongly to v in X^p as well. Convergence in V for $p \ge 2$ follows since Ω is bounded. □

Our only use of Theorem A.2 is in the proofs of Theorem 7.3 and Corollary A.3. In both of these instances we need only the case $p \ge 2$. We include all the cases, however, for the same reason as in [17]: we hope that if the vorticity bound in Lemma 3 of [17] can be extended to p in $(1,2)$, then the convergence in Proposition 1 of [17] can also be extended (for multiply connected Ω).

COROLLARY A.3. *Assume that Γ is C^2, and α is in $L^\infty(\Gamma)$. Then there exists a basis for V lying in $\mathcal{W}$ that is also a basis for H.*

Proof. The space $V = (V \cap H_0) \oplus H_c$ is separable because $V \cap H_0$ is the image under the continuous function K_Ω of the separable space $L^2(\Omega)$ and H_c is finite-dimensional. Let $\{v_i\}_{i=1}^\infty$ be a dense subset of V. Applying Theorem A.2 to each v_i and unioning all the sequences, we obtain a countable subset $\{u_i\}_{i=1}^\infty$ of $\mathcal{W}$ that is dense in V. Selecting a maximal independent set gives us a basis for V and for H as well, since V is dense in H. □

Acknowledgments. The author wishes to thank Josef Málek for suggesting that he explore the vanishing viscosity limit with Navier boundary conditions, and Misha Vishik for many useful discussions.

UNIQUENESS AND ASYMPTOTICS OF TRAVELING WAVES OF MONOSTABLE DYNAMICS ON LATTICES*

XINFU CHEN†, SHENG-CHEN FU‡, AND JONG-SHENQ GUO§

Abstract. Established here is the uniquenes of solutions for the traveling wave problem $cU'(x) = U(x+1)+U(x-1)-2U(x)+f(U(x))$, $x \in \mathbb{R}$, under the monostable nonlinearity: $f \in C^1([0,1])$, $f(0) = f(1) = 0 < f(s)\ \forall\, s \in (0,1)$. Asymptotic expansions for $U(x)$ as $x \to \pm\infty$, accurate enough to capture the translation differences, are also derived and rigorously verified. These results complement earlier existence and partial uniqueness/stability results in the literature. New tools are also developed to deal with the degenerate case $f'(0)f'(1) = 0$, about which is the main concern of this article.

Key words. traveling wave, monostable, degenerate, lattice dynamics

1. Introduction.

Consider a system of countably many ordinary differential equations, for $\{u_n(\cdot)\}_{n\in\mathbb{Z}}$,

$$\dot{u}_n(t) = u_{n+1}(t) - 2u_n(t) + u_{n-1}(t) + f(u_n(t)), \qquad n \in \mathbb{Z}, t > 0, \tag{1.1}$$

where f is a nonlinear forcing term satisfying $f(0) = f(1) = 0$. This system can be embedded into a larger one, for an unknown $\{u(x,\cdot)\}_{x\in\mathbb{R}}$,

$$u_t(x,t) = u(x+1,t) - 2u(x,t) + u(x-1,t) + f(u(x,t)), \qquad x \in \mathbb{R},\ t > 0. \tag{1.2}$$

A solution of (1.2) or (1.1) is called a *traveling wave with speed* c if there exists a function U defined on $\mathbb{R}$ such that $u(x,t) = U(x+ct)$ or $u_n(t) = U(n+ct)$. Here U is referred to as the *wave profile*. Of interest are solutions taking values in $[0,1]$, specifically, traveling waves connecting the steady states $\mathbf{0}$ and $\mathbf{1}$, i.e., traveling wave solutions $(c,U) \in \mathbb{R}\times C^1(\mathbb{R})$ of the traveling wave problem

$$\begin{cases} cU'(\cdot) = U(\cdot+1) + U(\cdot-1) - 2U(\cdot) + f(U(\cdot)) & \text{on } \mathbb{R}, \\ U(-\infty) = 0, \qquad U(\infty) = 1, \qquad 0 \leqslant U \leqslant 1 & \text{on } \mathbb{R}. \end{cases} \tag{1.3}$$

Equation (1.1) can be found in many biological models (e.g., [9, 20, 22]). Also, it can be regarded as a spatial-discrete version of the parabolic partial differential equation

$$u_t = u_{xx} + f(u). \tag{1.4}$$

The existence, uniqueness, and stability of traveling waves of (1.1) have been extensively studied recently under various assumptions on f; see, for example, [1, 5, 6, 7, 10, 12, 24, 25, 26, 27]. The commonly used assumption includes the condition of nondegeneracy $f'(0)f'(1) \neq 0$. For bistable dynamics, i.e., $f'(0) < 0$ and $f'(1) < 0$, the results on traveling waves are quite complete; see, for example, [1, 7, 25, 26] and the references therein. This paper concerns only the monostable dynamics, i.e., f satisfies

$$f \in C^1([0,1]), \quad f(0) = f(1) = 0 < f(s) \quad \forall\, s \in (0,1). \tag{A}$$

Under the nondegeneracy and the condition that $f(s) \leqslant f'(0)s$ for all $s \in [0,1]$, Zinner, Harris, and Hudson established the existence of traveling waves [27]; see also the later developments of Fu, Guo, and Shieh [10] and Chen and Guo [5]. The uniqueness issue was not satisfactorily resolved until a recent paper of Chen and Guo [6]. For easy reference, we quote here the following existence and uniqueness result from [6].

PROPOSITION 1. *Assume* (A).

(i) *There exists* $c_{\min} > 0$ *such that* (1.3) *admits a solution if and only if* $c \geqslant c_{\min}$.

(ii) *Given* $c \geqslant c_{\min}$, *there is a speed* c *wave profile satisfying* $U' > 0$ *on* $\mathbb{R}$.

(iii) *Given* $c > 0$, (1.3) *admits a solution if there is a supersolution of speed* c.

(iv) *When* $f'(0)f'(1) \neq 0$, *wave profiles are unique up to a translation. In addition,*

$$\lim_{x\to-\infty} \frac{U'(x)}{U(x)} = \lambda, \qquad \lim_{x\to\infty} \frac{U'(x)}{U(x)-1} = \mu, \tag{1.5}$$

where λ *is a positive real root of the characteristic equation*

$$c\,\lambda = e^{\lambda} + e^{-\lambda} - 2 + f'(0) \tag{1.6}$$

and μ *is the negative real root of the characteristic equation*

$$c\,\mu = e^{\mu} + e^{-\mu} - 2 + f'(1). \tag{1.7}$$

In addition, when $c > c_{\min}$, λ *is the smaller real root of the characteristic equation* (1.6).

Here by a *supersolution of wave speed* c it means a nonconstant Lipschitz continuous function Φ from $\mathbb{R}$ to $[0,1]$ satisfying

$$c\,\Phi'(x) \geqslant \Phi(x+1) + \Phi(x-1) - 2\Phi(x) + f(\Phi(x)) \quad \text{a.e.} \quad x \in \mathbb{R}.$$

Note that for any real numbers m and k, the function $z \in \mathbb{R} \to e^z + e^{-z} + mz + k$ is strictly convex, so the characteristic equation has at most two real roots. Since $f'(1) \leqslant 0$ and $c > 0$, there is a unique nonpositive real root μ to $c\,\mu = e^{\mu} + e^{-\mu} - 2 + f'(1)$. For the characteristic equation at 0, we define

$$c_* = \min_{z>0} \frac{e^z + e^{-z} - 2 + f'(0)}{z} \begin{cases} > 0 & \text{if } f'(0) > 0, \\ = 0 & \text{if } f'(0) = 0. \end{cases} \tag{1.8}$$

Suppose $f'(0) > 0$. There are two real roots to $c\lambda = e^{\lambda} + e^{-\lambda} - 2 + f'(0)$ when $c > c_*$; both are positive. When $c = c_*$, there is a unique real root, positive and of multiplicity two. When $c < c_*$, there are no real roots, so the assertion of Proposition 1 implicitly implies that $c_{\min} \geqslant c_*$. In addition, suppose $f(s) \leqslant f'(0)s$ for all $s \in [0,1]$.

Then it is easy to verify that $\Phi(x) := \min\{e^{\lambda x}, 1\}$ is a supersolution of speed c if $c\lambda = e^{\lambda} + e^{-\lambda} - 2 + f'(0)$. This implies that $c_{\min} = c_*$. When $f'(0) = 0$, we see that $c_* = 0$ and $\lambda = 0$ is a root to the characteristic equation at 0. Nevertheless, since $c_{\min} > 0$, we see an example that $c_{\min} > c_*$.

It is important to observe that a (monotonic) wave profile $U^{\min}$ of the minimum speed is a supersolution of any wave speed $c > c_{\min}$. Since among all wave profiles of all admissible speeds $U^{\min}$ decays with the largest exponential rate as $x \to -\infty$, it is not always true that near $-\infty$ a supersolution is bigger than a true solution under a certain translation. Thus, Proposition 1(iii) is highly nontrivial; its proof in [6] was based on an original idea of the authors of [27], with a simplification that avoids the use of degree theory.

The purpose of this paper is to remove the nondegeneracy condition $f'(0)f'(1) \neq 0$ made in Proposition 1(iv); that is, we are mainly concerned with the degenerate case $f'(0)f'(1) = 0$. We shall also introduce a number of new techniques. In terms of the differential equation (1.4), existence, uniqueness, and asymptotic stability of traveling waves have been established (cf. [13, 14, 17, 21]). Here we would like to extend the analogous result for (1.4) to (1.1). We summarize our results for the traveling wave problem (1.3) as follows.

THEOREM 1. *Assume* (A). *Wave profiles of a given speed are unique up to a translation.*

THEOREM 2. *Assume* (A). *Any wave profile is monotonic; i.e.,* $U' > 0$ *on* $\mathbb{R}$.

THEOREM 3. *Assume* (A). *Any solution* (c, U) *of* (1.3) *satisfies* (1.5) *and*

$$\lim_{x\to-\infty} \frac{U''(x)}{U'(x)} = \lambda, \qquad \lim_{x\to-\infty} \frac{f(U(x))}{U'(x)} = \begin{cases} c & \text{if } \lambda = 0, \\ f'(0)/\lambda & \text{otherwise,} \end{cases}$$

$$\lim_{x\to\infty} \frac{U''(x)}{U'(x)} = \mu, \qquad \lim_{x\to\infty} \frac{f(U(x))}{U'(x)} = \begin{cases} c & \text{if } \mu = 0, \\ f'(1)/\mu & \text{otherwise,} \end{cases}$$

where λ *is a nonnegative real root of the characteristic equation* (1.6) *and* μ *is the nonpositive real root of* (1.7).

In addition, λ *is the smaller root when* $c > c_{\min}$ *and the larger root when* $c = c_{\min}$.

Note that the root $\mu \leqslant 0$ to (1.7) is unique. In particular, $\mu = 0$ when $f'(1) = 0$. Also, $\lambda = 0$ when $f'(0) = 0$ and $c > c_{\min}$; otherwise, $\lambda > 0$. Note also that when $c_{\min} > c_*$, the characteristic equation (1.6) always has two positive real roots. To our knowledge, it is new in the literature that, as a principle, λ is the larger root of the characteristic equation (1.6) when $c = c_{\min} > c_*$, where c_* is as in (1.8).

In [6], the following general system is considered

$$u_t(x,t) = g(u(x+1,t)) - 2g(u(x,t)) + g(u(x-1,t)) + f(u(x,t)),$$

where $g(\cdot)$ is increasing. Under a variable change $v = [g(u) - g(0)]/[g(1) - g(0)]$, the system can be rewritten as

$$h(v(x,t))v_t(x,t) = v(x+1,t) + v(x-1,t) - 2v(x,t) + \tilde{f}(v(x,t)).$$

Under assumptions that $h \in C^1$ and $h > 0$ on $[0,1]$, all the analysis and results presented in this paper apply to such an extended version.

In one of his celebrated pioneer works in 1982, Weinberger [23] studied the long time (as $n \to \infty$) behavior and the existence of planar traveling waves for fully discrete Fisher's-type models of the form, for $\mathbf{u}^n := \{u_j^n\}_{j\in H}$,

$$\mathbf{u}^{n+1} - \mathbf{u}^n = Q[\mathbf{u}^n], \qquad n = 0, 1, 2, \ldots,$$

where Q is a translation invariant (e.g., autonomous) nonlinear operator and typical examples of H are $H = \mathbb{R}^m$ and $H = \mathbb{Z}^m$ ($m \geqslant 1$). In particular, for each unit vector ξ there exists a constant $c^*(\xi)$ (the minimal wave speed) such that $c^*(\xi)$ is the asymptotic propagation speed for arbitrarily initial disturbance. After deriving a lower and an upper bound for $c^*(\xi)$, the author established the existence of planar traveling wave with speed c for any $c \geq c^*(\xi)$, and nonexistence for $c < c^*(\xi)$. While Weinberger established striking results for an extremely general fully discrete monostable dynamics, here by contrast, we focus our attention only on a one-dimensional semidiscrete (i.e., continuous in time) version (1.1) or (1.2). Our main concerns in this paper are (1) the uniqueness and asymptotic behavior (as $x \to \infty$) of the traveling waves, and (2) the highly nontrivial extension of the current knowledge on nondegenerate monostable dynamics to its degenerate case, i.e., to the case $f'(0)f'(1) = 0$. That is to say, our work extends that of Weingerber's pioneer systematic analysis in two directions: firstly from the fully discrete version to semidiscrete version and, secondly, from nondegenerate steady states to general degenerate and/or nondegenerate steady states.

In the higher space dimensional case, the dynamics

$$u_t(x,t) = \sum_{i,j=1}^{m} a_{ij} \frac{\partial^2 u(x,t)}{\partial x_i \partial x_j} + f(u(x,t)), \qquad x \in \mathbb{R}^m, t > 0,$$

where $(a_{ij})_{m\times m}$ is a positive definite matrix, exhibits a variety of interesting wave phenomena; see, for example, Hamel and Nadirashvili [11], Berestycki and Larrouturou [3], and the references therein. A two-dimensional analogue of (1.1) takes the form

$$\dot{u}_{ij} = a[u_{i+1,j} + u_{i-1,j}] + b[u_{i,j+1} + u_{i,j-1}] + F(u_{ij}), \qquad i, j \in \mathbb{Z},$$

where a, b are positive constants. Here a planar traveling wave refers to a solution of the form $u_{ij}(t) = U(i\cos\theta + j\sin\theta + ct)$ for all $i, j \in \mathbb{Z}$ and $t \in \mathbb{R}$, where $(\cos\theta, \sin\theta)$ is the wave direction and $c = c(\theta)$ is the wave speed. Note that $U \in C^1(\mathbb{R})$ satisfies

$$cU'(\xi) = a[U(\xi + \cos\theta) + U(\xi - \cos\theta)] + b[U(\xi + \sin\theta) + U(\xi - \sin\theta)] + F(U(\xi)).$$

In this direction, we refer the reader to Chen [4], Chow, Mallet-Paret and Shen [7, 8] and Mallet-Paret [15, 16] for the bistable case and Shen [18, 19] for the bistable time almost periodic case. Clearly, our traveling wave problem is only the special case of $|\theta| = \frac{\pi}{4}$. We expect that our results and methods can be extended in a great extent to this new problem.

We remark that limit, as $a \searrow 0$, of the bistable nonlinearity $f(u) = u(1-u)(u-a)$ is the degenerate monostable nonlinearity $f(u) = u^2(1-u)$. The limiting process is continuous in the sense that the unique (modulo the translation invariance) traveling wave for the bistable nonlinearity approaches the unique minimum wave speed traveling wave for the degenerate monostable nonlinearity. The limiting process is not continuous in the sense that for the bistable case there is only one traveling wave, whereas for the monostable case, there are infinitely many traveling waves. We would like to point out that many tools that work for the bistable case do not work here for the monostable case; for example, in general the tools used for the construction of supersolutions in the bistable case do not work for the monostable case. Exaggerating a little bit, one may say that the bistable dynamics and monostable dynamics are different, and so are many of the mathematical tools to study them.

Now we briefly discuss our analysis towards our main results. The proof of uniqueness (Theorem 1) relies on the monotonicity (Theorem 2) and the detailed asymptotic behavior (Theorem 3) of wave profiles. Two new techniques are specifically developed here to study the uniqueness of traveling waves of monostable dynamics. One of them, which we call *magnification* and is originated from [6], is to magnify appropriately the difference between two wave profiles U and V by (for the purpose of demonstration only, considering the case $c > c_{\min}$)

$$W(\xi, x) = \int_{V(x)}^{U(x+\xi)} \frac{ds}{f(s)}.$$

Such a magnification has a special property $\lim_{x\to-\infty} W_x(\xi, x) = 0$ for any $\xi \in \mathbb{R}$ and a general property $\inf_{(\xi,x)\in\mathbb{R}^2} W_\xi(\xi, x) > 0$. From a basic comparison (for monotonic profiles) which says that if $U > V$ on $[a-1, a)\cup(b, b+1]$, then $U > V$ on $[a, b]$, these two properties prohibit W from any oscillations with nonvanishing magnitude as $x \to -\infty$; namely, there exists $\lim_{x\to-\infty} W(\xi, x)$ (which may be infinite). Consequently, any two wave profiles are ordered near $-\infty$; see section 4 for more details. An additional advantage of this magnification is that $\lim_{x\to-\infty} W(\xi, x)$ exists even if V is merely a sub- or a supersolution. This fact will be used in section 5 to find asymptotic expansions of wave profiles.

The other technique, which we call compression, is developed to include the treatment of the degenerate case $f'(1) = 0$. Traditionally near ∞ one uses $\min\{U + \varepsilon, 1\}$ as a supersolution which works for both monostable and bistable dynamics but needs the assumption that $f' \leqslant 0$ on $[1-\delta, 1]$ for some $\delta > 0$. To deal with the general case, we use the following compression to obtain (local) supersolutions:

$$Z(\ell, x) = U([1 + \ell]x), \qquad x \gg 1, \ell \in (0, 1].$$

The asymptotic behavior of wave profiles implies that Z approaches 1 as $x \to \infty$ at a rate faster than any wave profile. With a limiting $\ell \searrow 0$ process, we can show that near ∞, one wave profile is always bigger than a certain translation of any other wave profile.

The asymptotic behavior (1.5) follows from an analysis similar to that in [6]. After a thorough reinvestigation of the method used in [6], we found that the method in [6] can be rephrased into the following quite fundamental theory.

THEOREM 4. *Let $c > 0$ be a constant and $B(\cdot)$ be a continuous function having finite $B(\pm\infty) := \lim_{x\to\pm\infty} B(x)$. Let $z(\cdot)$ be a measurable function satisfying*

$$c\, z(x) = e^{\int_x^{x+1} z(s)ds} + e^{-\int_{x-1}^{x} z(s)ds} + B(x) \quad \forall\, x \in \mathbb{R}. \tag{1.9}$$

Then z is uniformly continuous and bounded. In addition, $\omega^\pm = \lim_{x\to\pm\infty} z(x)$ exist and are real roots of the characteristic equation $c\,\omega = e^\omega + e^{-\omega} + B(\pm\infty)$.

Note that each of $z = U'/U, U'/(U-1)$ and U''/U' satisfies an equation of the form (1.9). This theory provides a powerful tool to study the asymptotic behavior, as $x \to \pm\infty$, of positive solutions of a variety of semilinear finite difference-differential equations. In particular, once the monotonicity $U' > 0$ is shown, $z = U''/U'$ is then well defined and all the limits stated in Theorem 3 follow immediately from the theory.

Now the focus is shifted to show the monotonicity of U. In the nondegenerate case, $\mu < 0 < \lambda$, so that (1.5) and a comparison between $U(x + h)$ and $U(x)$ on a compact interval imply that $U' > 0$ on $\mathbb{R}$. In the degenerate case, $\lambda\mu = 0$, so (1.5) is not sufficient for such an argument. We shall develop a *blow-up* technique, showing

that $U' > 0$ on a sequence of intervals $\{[\xi_i - 1, \xi_i + 1]\}$ of two-unit length, where $\lim_{i\to\pm\infty} \xi_i = \pm\infty$. Then we develop a *modified sliding method* which enables us to compare $U(x + h)$ and $U(x)$ on any finite interval $[\xi_i - 1, \xi_j + 1]$ $(i < j)$ to prove the monotonicity result.

For a solution of (1.2) or (1.4) with initial value $u(x, 0)$, its long time behavior (e.g. approaching a traveling wave) depends on the asymptotic behavior of $u(x, 0)$ as $x \to -\infty$, i.e., tails of which wave profile $U(x)$ that $u(\cdot, 0)$ resembles; see, for example, [2, 5] and the references therein. For this purpose, we shall also provide asymptotic expansions, accurate enough to capture the translation difference of wave profiles near $\pm\infty$. In particular, under the condition that $f(u) = f'(0)u + O(u^{1+\alpha})$ for some $\alpha > 0$ and all small u, we show the following:

(i) If $c = c_{\min}$ and the larger root λ of (1.6) is not a double root, then for some $x_0 \in \mathbb{R}$,

$$\lim_{x\to-\infty} e^{-\lambda x} U(x + x_0) = 1. \tag{1.10}$$

(ii) If $c = c_{\min}$ and λ is a double root, then for some $x_0 \in \mathbb{R}$,

$$\text{either} \quad \lim_{x\to-\infty} \frac{U(x + x_0)}{|x|e^{\lambda x}} = 1 \quad \text{or} \quad \lim_{x\to-\infty} \frac{U(x + x_0)}{e^{\lambda x}} = 1. \tag{1.11}$$

(iii) If $c > c_{\min}$ and $f'(0) > 0$, then (1.10) holds for some $x_0 \in \mathbb{R}$ with λ the smaller root of (1.6).

Note that $\lambda > 0$ in all these cases, so, as we expected from (1.5), $U(x)$ decays to zero exponentially fast as $x \to -\infty$. Earlier results (e.g., [5, 10, 12, 27]) on this matter depend on the construction of global sub- and supersolution pairs that sandwich a wave profile. Such a construction is possible for all large wave speeds for general f and for all nonminimum wave speeds when $f(s) \leqslant f'(0)s$ for all $s \in [0, 1]$. We remark that the stability (which implies uniqueness) result in [5] was established under the assumption (1.10). By proving (1.10), the result in [5] then implies that any solution of (1.2) approaches, as $t \to \infty$, a traveling wave of speed c $(> c_{\min})$ if $u(\cdot, 0)$ takes values on $[0, 1]$ and

$$\lim_{x\to-\infty} e^{-\lambda x} u(x, 0) = 1, \qquad \liminf_{x\to\infty} u(x, 0) > 0.$$

On the other hand, $\lambda = 0$ when $f'(0) = 0$ and $c > c_{\min}$, so from (1.5), an exponential decay is impossible and an algebraic decay is to be expected (cf. [13, 14, 17, 21] for (1.4)). Indeed, under certain additional assumptions (cf. (B1) in section 5) we show the following:

If $c > c_{\min}$ and $f'(0) = 0$, then for some $x_0 \in \mathbb{R}$,

$$\lim_{x\to-\infty} \left\{ \int_{1/2}^{U(x)} \frac{ds}{f(s)[1 + f'(s)/c^2]} - \frac{x + x_0}{c} \right\} = 0. \tag{1.12}$$

For example, when $f(u) = \kappa u^2(1 - u)^p$ $(\kappa > 0,\ p \geq 1)$, the above limit yields

$$U(x) = \frac{c}{\kappa[|x| - x_0 + o(1)] + (pc - 2\kappa/c) \ln |x|} \quad \text{as } x \to -\infty.$$

The asymptotic expansion of $U(x)$ as $x \to \infty$ can be treated similarly. Indeed,

$$\lim_{x\to\infty} \left\{ \int_{1/2}^{U(x)} \frac{ds}{f(s)[1 + f'(s)/c^2]} - \frac{x + x_0}{\nu} \right\} = 0,$$

for some $x_0 \in \mathbb{R}$, where $\nu = c$ if $f'(1) = 0$ and $\nu = f'(1)/\mu$ if $f'(1) < 0$. Since this limiting behavior has nothing to do with the condition needed on the initial data for the long time behavior of solutions of (1.2), we choose to omit the details here.

This paper is organized as follows. In section 2, we derive the asymptotic behavior of wave profiles near $\pm\infty$ and prove Theorem 3. We prove the monotonicity of wave profiles (Theorem 2) in section 3, by using the method of sliding and a new blow-up technique. In section 4, the uniqueness of traveling waves is established. Finally in section 5, we construct suitable local super/subsolutions to verify our asymptotic expansions of wave profiles near $x = \pm\infty$.

2. Asymptotic behavior of wave profiles near $x = \pm\infty$. In the following, the assumption (A) is always assumed.

2.1. The idea in [6]. The most important technique developed in [6] can be presented as follows. Suppose that the following quantities

$$\rho(x) := \frac{U'(x)}{U(x)}, \quad \sigma(x) := \frac{U'(x)}{U(x)-1}, \quad \chi(x) := \frac{U''(x)}{U'(x)}$$

are well defined. This is the case, if $U > 0$, $U < 1$, and $U' > 0$ for ρ, σ, and χ, respectively. Then each of them satisfies an equation of the form (1.9), where $B(\cdot)$ is a continuous function having $\lim_{x\to\pm\infty} B(x) =: B(\pm\infty)$. For any positive constant m, we set

$$v(x) = e^{mx+\int_0^x z(s)ds}.$$

Then

$$c\,v'(x) = [cm + B(x)]v(x) + e^{-m}v(x+1) + e^{m}v(x-1).$$

Assume that $c > 0$. We take a specific $m = \|B(x)\|_{L^\infty(\mathbb{R})}/c$. Then $v'(x) \geq 0$. Consequently,

$$c\,v(x) - c\,v(x-1/2) > \int_{x-1/2}^{x} e^{-m}v(s+1)ds > \frac{1}{2}v(x+1/2)e^{-m}.$$

This implies that $v(x) > v(x+1/2)/(2ce^m) > v(x+1)/(2ce^m)^2$. Therefore,

$$e^{\int_x^{x+1} z(s)ds} = \frac{v(x+1)e^{-m}}{v(x)} \leqslant 4c^2e^m, \qquad e^{-\int_{x-1}^{x} z(s)ds} = \frac{e^m v(x-1)}{v(x)} \leqslant e^m,$$

and so

$$-m < z(x) < m + 4ce^m + e^m/c \quad \forall\, x \in \mathbb{R}, \quad m := \|B\|_{L^\infty(\mathbb{R})}/c. \tag{2.1}$$

The uniform boundedness of z implies that z is uniformly continuous. Hence, for any unbounded sequence $\{x_i\}$, $\{z(x_i+\cdot)\}$ is a bounded and equicontinuous family. Along a subsequence, it converges to a limit r, uniformly in any compact subset of $\mathbb{R}$. In addition, r satisfies the *fundamental equation*

$$c\,r(x) = e^{\int_x^{x+1} r(s)\,ds} + e^{\int_x^{x-1} r(s)\,ds} + b \quad \forall\, x \in \mathbb{R}, \tag{2.2}$$

where $b = B(\infty)$ if $\lim_{i\to\infty} x_i = \infty$ and $b = B(-\infty)$ if $\lim_{i\to\infty} x_i = -\infty$. For the fundamental equation, Chen and Guo established in [6] the following key result.

PROPOSITION 2. *Let $c > 0$, $b \in \mathbb{R}$ and $P(\omega) = c\omega - e^{\omega} - e^{-\omega} - b$. Consider* (2.2).

(i) *When $P(\omega) = 0$ has no real root, there is no solution.*

(ii) *When $P(\omega) = 0$ has only one real root λ, $r \equiv \lambda$ is the only solution.*

(iii) *When $P(\omega) = 0$ has two real roots $\{\lambda, \Lambda\}$ $(\lambda < \Lambda)$, every solution can be written as*

$$r(x) = \frac{u'(x)}{u(x)}, \quad u(x) = \theta e^{\lambda x} + (1-\theta)e^{\Lambda x}, \quad \theta \in [0,1].$$

In particular, any nonconstant solution satisfies $r' > 0$, $r(-\infty) = \lambda$, and $r(\infty) = \Lambda$.

Proof of Theorem 4. We need consider only the case when the characteristic equation has two real roots. For this, let λ and Λ be the roots where $\lambda < \Lambda$. Suppose $\lim_{x\to-\infty} z(x)$ does not exist. Then there exist $\omega \notin \{\lambda, \Lambda\}$ and a sequence $\{x_i\}$ satisfying $\lim_{i\to-\infty} x_i = -\infty$, $z(x_i) = \omega$ and $z'(x_i) \leqslant 0$ for all i. Since $\{z(x_i + \cdot)\}$ is uniformly bounded and equi-continuous, a subsequence converges to a limit r which solves (2.2) with $b = B(-\infty)$. In addition, by the definition of r, we have $r(0) = \omega$ and $r'(0) \leqslant 0$. But from Proposition 2, there are no such kind of solutions. Hence, $\lim_{x\to-\infty} z(x)$ exists and is one of the two roots to the characteristic equation. Similarly, one can show that $\lim_{x\to\infty} z(x)$ exists. □

Remark 1.

(i) By working on the function $\hat{z}(x) := -z(-x)$ the assertion of the theorem remains unchanged when $c < 0$.

(ii) Theorem 4 extends to a more general equation

$$z(x) = a_1(x)e^{\int_x^{x+1} z(s)ds} + a_2(x)e^{-\int_{x-1}^{x} z(s)ds} + B(x),$$

where a_1 and a_2 are continuous positive functions having limits

$$a^{\pm} := \lim_{x\to\pm\infty} a_1(x) = \lim_{x\to\pm\infty} a_2(x) > 0.$$

(iii) Theorem 4 also extends to the case when z is a continuous function defined on $[-1, \infty)$ (or $(-\infty, 1]$) and satisfies (1.9) on $[0, \infty)$ (or $(-\infty, 0]$). The conclusion is that $\lim_{x\to\infty} z(x)$ (or $\lim_{x\to-\infty} z(x)$) exists and is the root of the characteristic equation.

2.2. The asymptotic behavior. Now we establish the limits stated in Theorem 3.

We begin with the limits in (1.5). First we show that $U > 0$. Suppose on the contrary there exists $y \in \mathbb{R}$ such that $U(y) = 0$. Then it is a global minimum so that $U'(y) = 0$ and from the equation in (1.3), $U(y+1) + U(y-1) = 0$ which implies that $U(y \pm 1) = 0$. An induction gives $U(y+k) = 0$ for all $k \in \mathbb{Z}$, contradicting $U(\infty) = 1$. Thus, $U > 0$. Similarly, $U < 1$. Once we know $0 < U < 1$, we can define

$$\rho(x) := \frac{U'(x)}{U(x)} \quad \Rightarrow \quad \int_x^{x+1} \rho(z)dz = \ln\frac{U(x+1)}{U(x)},$$
$$\sigma(x) := \frac{U'(x)}{U(x)-1} \quad \Rightarrow \quad \int_x^{x+1} \sigma(z)dz = \ln\frac{U(x+1)-1}{U(x)-1}.$$

Dividing the ode in (1.3) by U and $U-1$, respectively, we obtain

$$c\rho(x) = e^{\int_x^{x+1}\rho(z)dz} + e^{\int_x^{x-1}\rho(z)dz} - 2 + B_1(x),$$
$$c\sigma(x) = e^{\int_x^{x+1}\sigma(s)\,ds} + e^{\int_x^{x-1}\sigma(s)\,ds} - 2 + B_2(x),$$

where $B_1(x) = f(U(x))/U(x)$ and $B_2(x) = f(U(x))/[U(x)-1]$. Since $U(-\infty) = 0$ and $U(\infty) = 1$, we see that $B_1(-\infty) = f'(0)$, $B_1(\infty) = 0$, $B_2(-\infty) = 0$, and $B_2(\infty) = f'(1)$. The limits in (1.5) thus follow from Theorem 4.

Next, we establish the remaining limits stated in Theorem 3. Here we shall use the fact $U' > 0$, to be proven in the next section. Differentiating the ode in (1.3) with respect to x we have

$$c\,U''(x) = U'(x+1) + U'(x-1) + [f'(U(x)) - 2]U'(x).$$

Define

$$\chi(x) := \frac{U''(x)}{U'(x)} \quad \Rightarrow \quad \int_x^{x+1} \chi(z)dz = \ln \frac{U'(x+1)}{U'(x)}.$$

Then

$$c\,\chi(x) = e^{\int_x^{x+1}\chi(z)dz} + e^{-\int_{x-1}^{x}\chi(z)dz} + f'(U(x)) - 2 \quad \forall\, x \in \mathbb{R}.$$

The stated limits for χ in Theorem 3 thus follow from Theorem 4 and l'Hôpital's rule.

Finally, the limits of $f(U(x))/U'(x)$ as $x \to \pm\infty$ are obtained by using the limits of χ and the identity

$$\begin{aligned}\frac{f(U(x))}{U'(x)} &= c - \frac{[U(x+1) - U(x)] - [U(x) - U(x-1)]}{U'(x)} \\ &= c - \int_0^1 \Big\{ e^{\int_x^{x+z}\chi(s)ds} - e^{-\int_{x-z}^{x}\chi(s)ds} \Big\} dz.\end{aligned}$$

In the next two subsections, we show the additional part of Theorem 3; namely, we show that λ is the smaller real root to the characteristic equation (1.6) when $c > c_{\min}$ and the larger root when $c = c_{\min}$.

2.3. The characteristic values of nonminimum speed waves.

LEMMA 2.1. *If (c, U) is a traveling wave of speed $c > c_{\min}$, then the characteristic equation $c\lambda = e^{\lambda} + e^{-\lambda} - 2 + f'(0)$ has two different real roots and $\lambda := \lim_{x\to-\infty} U'(x)/U(x)$ is the smaller root. In the particular instance when $f'(0) = 0$, $\lim_{x\to-\infty} U'(x)/U(x) = 0$.*

Proof. Recall from Theorem 2 of [6] that $c_{\min} \geqslant c_*$, where

$$c_* := \min_{z>0} \frac{e^z + e^{-z} - 2 + f'(0)}{z}.$$

Hence $c_{\min} z = e^z + e^{-z} - 2 + f'(0)$ always has a root. This implies that $c\,z = e^z + e^{-z} - 2 + f'(0)$ has exactly two roots, which we denote by $\lambda(c)$ and $\Lambda(c)$ with $\lambda(c) < \Lambda(c)$, for $c > c_{\min}$.

Suppose on the contrary that $\lim_{x\to-\infty} U'(x)/U(x) = \Lambda(c)$. Let $\hat{c} \in (c_{\min}, c)$ and $(\hat{c}, \hat{U})$ be a traveling wave of speed $\hat{c}$. By (1.5), $\lim_{x\to-\infty} \hat{U}'(x)/\hat{U}(x) \leqslant \Lambda(\hat{c})$. Then

$$\lim_{x\to-\infty} \frac{d}{dx}\Big(\ln \frac{\hat{U}(x)}{U(x)} \Big) = \lim_{x\to-\infty} \Big\{ \frac{\hat{U}'(x)}{\hat{U}(x)} - \frac{U'(x)}{U(x)} \Big\} \leqslant \Lambda(\hat{c}) - \Lambda(c) < 0$$

by the strictly monotonicity of $\Lambda(c)$ in c. Thus, $\lim_{x\to-\infty}\ln[\hat{U}(x)/U(x)]=\infty$ and there exists $M>0$ such that $\hat{U}(x)>U(x)$ for all $x\leqslant -M$. Similarly,

$$\lim_{x\to\infty}\frac{d}{dx}\left\{\int_{U(x)}^{\hat{U}(x)}\frac{ds}{f(s)}\right\}=\lim_{x\to\infty}\left\{\frac{\hat{U}'(x)}{f(\hat{U}(x))}-\frac{U'(x)}{f(U(x))}\right\}$$
$$=\begin{cases}1/\hat{c}-1/c & \text{if } f'(1)=0,\\ [\mu(\hat{c})-\mu(c)]/f'(1) & \text{if } f'(1)<0.\end{cases}$$

This quantity is positive when $f'(1)=0$; so is the case when $f'(1)<0$ since the negative root $\mu=\mu(c)$ of $c\mu=e^{\mu}+e^{-\mu}-2+f'(1)$ satisfies $\mu(\hat{c})<\mu(c)$. Thus there exists $M_1>0$ such that $\hat{U}(x)>U(x)$ for all $x\geqslant M_1$. In conclusion, $\hat{U}(\cdot+M_1)>U(\cdot-M)$.

Now both $u_1(x,t):=\hat{U}(x+M_1+\hat{c}t)$ and $u_2(x,t):=U(x-M+ct)$ are solutions of (1.2). Since $u_1(\cdot,0)\geqslant u_2(\cdot,0)$, the comparison principle for (1.2) implies $u_1(\cdot,t)\geqslant u_2(\cdot,t)$ for all $t>0$, which is impossible since $c>\hat{c}$. Thus, $\lim_{x\to-\infty}U'(x)/U(x)=\lambda(c)$. □

The asymptotic behavior of U stated in Theorem 3 immediately gives the following corollary.

COROLLARY 2.2. *Suppose (c_1,U_1) and (c_2,U_2) are two traveling waves where $c_1<c_2$. Then there exist $a,b\in\mathbb{R}$ such that*

$$U_1<U_2 \quad in \quad (-\infty,a), \qquad U_1>U_2 \quad in \quad (b,\infty).$$

We remark that in the case of the differential equation $cU'=U''+f(U)$ one can take $a=b$ to conclude that a smaller speed wave profile is steeper than a larger speed wave profile; namely, on the phase plane (U,U'), if one writes $U'=P(c,U)$, then $P(c_1,s)>P(c_2,s)$ for all $s\in(0,1)$ and $c_2>c_1\geqslant c_{\min}$. For (1.3), we believe that this should also be the case.

2.4. The characteristic value of minimum speed waves.

LEMMA 2.3. *If $(c_{\min},U)$ is a wave of minimum speed, then $\Lambda:=\lim_{x\to-\infty}U'(x)/U(x)$ is the larger root (if there are two) of the characteristic equation $c_{\min}z=e^z+e^{-z}-2+f'(0)$.*

Proof. Notice that when $c_{\min}=c_*$ (defined in (1.8)), the characteristic equation has only one real root, so there is nothing to prove in this case. Hence we consider the case when $c_{\min}>c_*$. We denote the smaller real root by λ and the larger root by Λ. We use a contradiction argument by assuming that $\lim_{x\to-\infty}U'(x)/U(x)=\lambda$. As we shall see, this will allow us to construct a supersolution Φ of wave speed c for some $c<c_{\min}$ by joining an exponential function ψ defined on $(-\infty,0]$ and another function ϕ defined on $[0,\infty)$ obtained from the wave profile U of speed $c_{\min}$. We divide this construction into the following steps.

First, set $\omega=(\lambda+\Lambda)/2$ and $\delta:=c_{\min}\,\omega-e^{\omega}-e^{-\omega}+2-f'(0)$. Then $\delta>0$ since the function $P(z):=c_{\min}\,z-e^z-e^{-z}+2-f'(0)$ is concave and vanishes at λ and Λ. Also by translation, we can assume that $U(0)$ is so small that

$$\sup_{0<s\leqslant U(0)e^{\omega}}\left|\frac{f(s)}{s}-f'(0)\right|<\frac{\delta}{2},\qquad \sup_{x\leqslant 1}\frac{U'(x)}{U(x)}<\omega\ .$$

Set $\psi(x)=U(0)e^{\omega x}$. For every $c\in[c_{\min}-\delta/(2\omega),c_{\min}]$,

$$\mathcal{L}\psi(x):=c\,\psi'(x)-\psi(x+1)-\psi(x-1)+2\psi(x)-f(\psi(x))$$
$$=\psi(x)\left\{c\,\omega-e^{\omega}-e^{-\omega}+2-\frac{f(\psi(x))}{\psi(x)}\right\}>0\quad\forall\ x\leq 1.$$

Next, we construct $\phi(c,\cdot)$, to be used as the supersolution defined on $[0,\infty)$. For each $c \in (0, c_{\min}]$, consider the equation $\phi = \mathbf{T}^c\phi$ on $\mathbb{R}$, where

$$\mathbf{T}^c\phi := \begin{cases} e^{-mx/c}\{U(0) + c\int_0^x e^{mz/c} W[m,\phi](z)dz\} & \text{if } x \geqslant 0, \\ U(x) & \text{if } x < 0, \end{cases}$$
$$W[m,\phi](z) := \phi(z+1) + \phi(z-1) + [m-2]\phi(z) + f(\phi(z)).$$

Following [6], a solution can be obtained as follows. Define $\{\phi_n\}_{n=0}^{\infty}$ by

$$\phi_0(c,\cdot) \equiv \mathbf{1}, \qquad \phi_{n+1}(c,\cdot) := \mathbf{T}^c\phi_n(c,\cdot) \quad \forall\, n \in \mathbb{N}.$$

Note that $\mathbf{T}^c$ is a monotonic operator: $\psi_1 \leqslant \psi_2 \Rightarrow \mathbf{T}^c\psi_1 \leqslant \mathbf{T}^c\psi_2$. It follows that $\phi_{n+1} \leqslant \phi_n \leqslant \mathbf{1}$. In addition, since

$$c\,(e^{mx/c}U)' - e^{mx/c}W[m,U] = (c - c_{\min})U'e^{\mu x/c} \leqslant 0,$$

integrating this inequality over $[0,x]$ gives $U \leqslant \mathbf{T}^cU$. This implies that $\phi_n \geqslant U$ for all n. Consequently, $\phi(c,\cdot) := \lim_{n\to\infty}\phi_n$ exists and is a solution to $\phi = \mathbf{T}^c\phi$. It is easy to see that $U \leqslant \phi < \mathbf{1}$ on $[0,\infty)$, $\phi(c,0) = U(0)$, and

$$c\,\phi'(c,x) = \phi(c,x+1) + \phi(c,x-1) - 2\phi(c,x) + f(\phi(c,x)) \quad \forall\, x > 0.$$

This equation implies, for $0 < c_1 < c_2 \leqslant c_{\min}$, that $\phi(c_2,\cdot) \leqslant \mathbf{T}^{c_1}\phi(c_2,\cdot)$, so that $\phi_n(c_1,\cdot) \geqslant \phi(c_2,\cdot)$ for all n and $\phi(c_1,\cdot) > \phi(c_2,\cdot)$ on $(0,\infty)$. Following an idea in [6] or the technique for the uniqueness of U presented in this paper (section 4), one can further show that $\phi(c,\cdot)$ is unique. The uniqueness implies that $\phi(c,\cdot)$ is continuous in c and $\phi(c_{\min},\cdot) \equiv U$. Therefore, $\lim_{c\to c_{\min}}\phi(c,\cdot) = U$ in $C^1([0,\infty))$. This further implies that

$$\lim_{c\to c_{\min}} \frac{\phi'(c,x)}{\phi(c,x)} = \frac{U'(x)}{U(x)} \quad \text{uniformly for } \ x \in [0,1].$$

Finally, let $c \in [c_{\min} - \delta/(2\omega), c_{\min})$ be such that

$$\max_{x\in[0,1]} \frac{\phi'(c,x)}{\phi(c,x)} < \omega.$$

We define

$$\Phi(x) = \begin{cases} \psi(x) & \text{if } \ x \leqslant 0, \\ \phi(c,x) & \text{if } \ x > 0. \end{cases}$$

Since $\psi(0) = U(0) = \phi(c,0)$ and

$$\frac{\psi'(x)}{\psi(x)} = \omega > \frac{\phi'(c,x)}{\phi(c,x)} \quad \forall x \in (-\infty,0)\cup(0,1],$$

$\phi < \psi$ in $(0,1]$ and $\psi < \phi \equiv U$ in $(-\infty,0)$. That is,

$$\Phi = \min\{\phi\ ,\ \psi\} \qquad \text{on } \ (-\infty,1].$$

Consequently, considering separately $x \in (-\infty,0)$, $(0,1]$ and $(1,\infty)$, we see that

$$c\,\Phi'(x) \geqslant \Phi(x+1) + \Phi(x-1) - 2\Phi(x) + f(\Phi(x)) \quad \forall\ x \in (-\infty,0)\cup(0,\infty);$$

that is, Φ is a supersolution of wave speed c.

Thus, by Proposition 1(iii), there is a traveling wave of speed c for some $c < c_{\min}$, contradicting the minimality of $c_{\min}$. This proves the lemma. □

Remark 2. If $f'(\cdot) \leqslant 0$ on $[1-\delta, 1]$ for some $\delta > 0$, then a constructive proof of Lemma 2.3 can be obtained by taking

$$\Phi(x) = [U(0) + \epsilon]e^{\omega x} \quad \forall\, x \leqslant 0, \qquad \Phi(x) = U(x + \varepsilon - \varepsilon e^{-kx}) + \epsilon \quad \forall\, x > 0,$$

where $0 < \epsilon \ll \varepsilon \ll U(0) \ll 1 \ll k$. We leave the verification to the interested reader.

3. Monotonicity of wave profiles. This section is dedicated to the proof of the monotonicity of any wave profile U. We point out here that the limits in (1.5) are established without the knowledge of the monotonicity of U so that we can use them here.

3.1. The method of sliding. This traditional method is to compare $U(\cdot + \tau)$ and $U(\cdot)$ by decreasing τ continuously from a large value down to zero, namely, to show that

$$\inf \{\tau > 0 \mid U(\cdot + \tau) > U(\cdot) \quad \text{on} \mathbb{R}\} = 0. \tag{3.1}$$

This implies $U' \geqslant 0$, and from an integral equation, $U' > 0$ on $\mathbb{R}$. If we know $U' > 0$ near $x = \pm\infty$ (e.g., by (1.5) for the case $\mu < 0 < \lambda$), then (3.1) follows easily from a comparison principle (cf. [6]). When $f'(0) = 0$, it is very difficult to show directly that $U' > 0$ in a vicinity of $x = -\infty$. Similar difficulty occurs near $x = \infty$ when $f'(1) = 0$. To overcome this difficulty, we use a modification of the method, stated in the third part of the following lemma.

LEMMA 3.1.

(i) *If* $[a, b]$ *is an interval on which* $U' \leqslant 0$, *then* $b - a < 1$.

(ii) *If* $U' > 0$ *on* $[\xi, \xi + 1]$, *then* $U(\xi) < U(x)$ *for all* $x > \xi$.

(iii) *If* $U' > 0$ *on* $[\xi - 1, \xi + 1] \cup [\eta - 1, \eta + 1]$, *where* $\xi < \eta$, *then* $U' > 0$ *on* $[\xi, \eta]$.

Proof.

(i) Let $[a, b]$ be an interval on which $U' \leqslant 0$. We want to show that $b - a < 1$. Suppose otherwise $b - a \geqslant 1$. Let $\hat{x} \in [b, \infty)$ be a point such that $U(\hat{x}) \leqslant U(x)$ for all $x \geqslant b$. Then $\hat{x}$ is a global minimum of U restricted on $[a, \infty)$, since $U' \leqslant 0$ on $[a, b]$. This leads to the following contradiction:

$$0 = c\,U'(\hat{x}) = U(\hat{x} + 1) + U(\hat{x} - 1) - 2U(\hat{x}) + f(U(\hat{x})) \geqslant f(U(\hat{x})) > 0.$$

(ii) Assume that $U' > 0$ on $[\xi, \xi + 1]$. Let $\hat{x} \geqslant \xi + 1$ be a point such that $U(\hat{x}) \leqslant U(x)$ for all $x \geqslant \xi + 1$. Then $U(\xi) < U(\hat{x})$ since otherwise $\hat{x} \geqslant \xi + 1$ is a point of global minimum of U on $[\xi, \infty)$ and the same contradiction as above arises. Thus $U(\xi) < U(x)$ for all $x > \xi$.

(iii) Assume that $U' > 0$ on $[\xi - 1, \xi + 1] \cup [\eta - 1, \eta + 1]$, where $\xi < \eta$. By the second assertion, $U(\eta) > U(\xi)$ so that we can define

$$\tau^* := \inf \{\, \tau \in (0, \eta - \xi] \mid U(\cdot) < U(\cdot + \tau) \quad \text{on} [\xi, \eta - \tau]\}.$$

Clearly, $\tau^* \in [0, \eta - \xi)$. We claim that $\tau^* = 0$. Suppose on the contrary that $\tau^* > 0$. Then there exists $\hat{x} \in [\xi, \eta - \tau^*]$ such that

$$U(\hat{x} + \tau^*) - U(\hat{x}) = 0 \leqslant U(x + \tau^*) - U(x) \quad \forall\, x \in [\xi, \eta - \tau^*].$$

For $x \in [\xi-1,\xi]$: (1) if $x+\tau^* \le \xi$, then $U(x+\tau^*)-U(x)>0$ since $U'>0$ on $[\xi-1,\xi]$; (2) if $x+\tau^*>\xi$, by the second assertion, $U(x+\tau^*)>U(\xi)\ge U(x)$. Thus $U(x+\tau^*)>U(x)$ for all $x\in[\xi-1,\xi]$. Similarly, $U(x+\tau^*)>U(x)$ for all $x\in[\eta-\tau^*,\eta-\tau^*+1]$. Hence,

$$U(\hat{x}+\tau^*)-U(\hat{x})=0\leqslant U(x+\tau^*)-U(x)\quad \forall\, x\in[\xi-1,\eta-\tau^*+1].$$

Consequently, $U'(\hat{x}+\tau^*)=U'(\hat{x})$. Using the equation for U, we conclude that

$$U(\hat{x}+\tau^*+1)+U(\hat{x}+\tau^*-1)=U(\hat{x}+1)+U(\hat{x}-1).$$

Since $U(\cdot+\tau^*)\geqslant U(\cdot)$ on $[\xi-1,\eta-\tau^*+1]$, we see that $U(\hat{x}+\tau^*\pm1)=U(\hat{x}\pm1)$. By induction, $U(\hat{x}+\tau^*+k)=U(\hat{x}+k)$ for all integer k satisfying $\hat{x}+k\in[\xi-1,\eta-\tau^*+1]$. But this is impossible since $U(x+\tau^*)>U(x)$ for all $x\in[\xi-1,\xi]$. Thus, $\tau^*=0$.

That $\tau^*=0$ implies $U(\cdot+\tau)>U(\cdot)$ on $[\xi,\eta-\tau]$ along a sequence $\tau\searrow 0$. In particular, $U'(x)\geqslant 0$ on $[\xi,\eta]$. Finally, for $m=\max_{0\leqslant s\leqslant 1}|2-f'(s)|$ and every $x\in[\xi,\eta]$,

$$cU''(x)=U'(x+1)+U'(x-1)+[f'(U)-2]U'(x)\geqslant -mU'(x).$$

It follows that $(U'(x)e^{mx/c})'\geqslant 0$ or $U'(x)e^{mx/c}\geqslant U'(\xi)e^{m\xi/c}>0$ for all $x\in[\xi,\eta]$. □

3.2. A linear equation from blow-up. To show that $U'>0$ on $\mathbb{R}$, we use Lemma 3.1(iii). For this, we need only to find a sequence $\{[\xi_j-1,\xi_j+1]\}$ of intervals on which $U'>0$. To do this, we shall use a blow-up technique for the functions $\rho=U'/U$ and $\sigma=U'/(U-1)$, leading to the following two linear problems:

$$\begin{cases} cR'(x)=R(x+1)+R(x-1)-2R(x) & \forall\, x\le 1,\\ |R|\le 1 \quad \text{on} \quad (-\infty,2], \qquad |R(0)|=1; \end{cases} \tag{3.2}$$

$$\begin{cases} cR'(x)=R(x+1)+R(x-1)-2R(x) & \forall\, x\ge -1,\\ |R|\le 1 \quad \text{on}[-2,\infty), \qquad |R(0)|=1. \end{cases} \tag{3.3}$$

LEMMA 3.2.

(i) *If R solves* (3.2)*, then $|R|>1/2$ on $[A-1,A+1]$ for some $A>0$.*

(ii) *Any solution of* (3.3) *satisfies $|R|>1/2$ on $[A-1,A+1]$ for some $A>0$.*

Proof.

(i) Suppose R solves (3.2). Then $|R'|\leqslant 4/c$ on $(-\infty,1]$. Set $z(x):=R'(x)/[R(x)+2]$. Dividing the ode in (3.2) by $R(x)+2$ we obtain

$$c\,z(x)=e^{\int_x^{x+1}z(t)dt}+e^{-\int_{x-1}^{x}z(t)dt}-2, \qquad |z(x)|\le 4/c \quad \forall\, x\le 1.$$

Following the argument used in the previous section, we conclude that $\lim_{x\to-\infty}z(x)$ exists. Since R is bounded, $\liminf_{x\to-\infty}|R'(x)|=0$. Thus, $\lim_{x\to-\infty}z(x)=0$, which implies that $\lim_{x\to-\infty}R'(x)=0$.

As $R(0)$ is a global extremum of R restricted on $(-\infty,1]$, $R(j)=R(0)$ for all integer $j\le 1$. Upon using $\lim_{x\to-\infty}R'(x)=0$, we derive that $\lim_{x\to-\infty}R(x)=R(0)$. Since $|R(0)|=1$, there exists $A>0$ such that $|R(\cdot)|>1/2$ on $[A-1,A+1]$. This proves the first assertion (i).

(ii) The proof of the second assertion (ii) is analogous to the case (i) and therefore is omitted. □

3.3. The monotonicity of wave profile. That $U' > 0$ follows from Lemma 3.1(iii) and the following lemma.

LEMMA 3.3. *There exists a sequence* $\{\xi_i\}_{i\in\mathbb{Z}}$ *such that* $U' > 0$ *on* $[\xi_i - 1, \xi_i + 1]$ *for each* $i \in \mathbb{Z}$ *and* $\lim_{i\to\pm\infty} \xi_i = \pm\infty$.

Proof. The sequence $\{\xi_i\}_{i\leqslant 0}$: Here we construct the sequence such that $U' > 0$ on $\cup_{i\leqslant 0}[\xi_i - 1, \xi_i + 1]$ and $\lim_{i\to\infty} \xi_i = -\infty$.

When $f'(0) > 0$, $\lim_{x\to-\infty} U'(x)/U(x) = \lambda > 0$ so $U'(x) > 0$ for all $x \ll -1$. Hence, we need consider only the case $f'(0) = 0$ and $\lim_{x\to-\infty} \rho(x) = 0$, where $\rho(x) = U'(x)/U(x)$. Define

$$\varepsilon_j = \max_{x\leq j} |\rho(x)| \ \forall\ j < 0, \qquad \theta = \limsup_{j\to-\infty} \frac{\varepsilon_{j-3}}{\varepsilon_j} \in [0, 1].$$

We claim that $\theta = 1$. Suppose not. Then, for $\hat\theta = (1 + \theta)/2$, there exists $J < 0$ such that $\varepsilon_{j-3} \leq \hat\theta\varepsilon_j$ for all $j \leq J$. Hence, $\varepsilon_{J-3k} \leq \varepsilon_J\hat\theta^k$ for every integer $k \geq 0$. Consequently, $|\rho(x)| \leq \varepsilon_J\hat\theta^{(J-x)/3-1}$ for all $x \leq J$. For $y < J$,

$$\ln\frac{U(J)}{U(y)} = \int_y^J \rho(x)dx \leqslant \int_y^J \varepsilon_J\hat\theta^{(J-x)/3-1}dx \leqslant \frac{3\varepsilon_J}{|\hat\theta\ln\hat\theta|}.$$

Sending $y \to -\infty$ we obtain a contradiction. Hence $\theta = 1$.

Let $\{j_k\}_{k=1}^\infty$ be a sequence such that $\lim_{k\to\infty} j_k = -\infty$ and $\lim_{k\to\infty} \varepsilon_{j_k-3}/\varepsilon_{j_k} = 1$. Let $x_k \leqslant j_k-3$ be a point such that $|\rho(x_k)| = \varepsilon_{j_k-3}$. Define $\rho_k(x) := \rho(x_k+x)/|\rho(x_k)|$. Then $\max_{x\leq 3} |\rho_k(x)| \leq \varepsilon_{j_k}/\varepsilon_{j_k-3}$, $|\rho_k(0)| = 1$, and

$$\begin{aligned} c\,\rho_k'(x) = {}& [\rho_k(x+1) - \rho_k(x)]e^{\rho(x_k)\int_x^{x+1}\rho_k(z)dz} \\ & + [\rho_k(x-1) - \rho_k(x)]e^{-\rho(x_k)\int_{x-1}^{x}\rho_k(z)dz} + \rho_k(x)f_1(U(x_k + x)), \end{aligned}$$

where $f_1(s) = f'(s) - f(s)/s \to 0$ as $s \searrow 0$. This equation implies that $\{\rho_k\}_{k=1}^\infty$ is a family of bounded and equicontinuous functions on $(-\infty, 2]$. Hence, a subsequence which we still denote by $\{\rho_k\}$ converges to a limit R, uniformly in any compact subset of $(-\infty, 2]$. Clearly, R satisfies (3.2).

By Lemma 3.2(i), there exists a constant $A < 0$ such that either $R \geqslant 1/2$ on $[A - 1, A + 1]$ or $R \leqslant -1/2$ on $[A - 1, A + 1]$. As $\lim_{k\to\infty} \rho_k \to R$ on $[A - 1, A + 1]$, there exists an integer $K > 0$ such that for every integer $k \geqslant K$, either $\rho_k > 0$ on $[A - 1, A + 1]$ or $\rho_k < 0$ on $[A - 1, A + 1]$. By Lemma 3.1(i), the latter case is impossible. Thus $\rho_k > 0$ on $[A - 1, A + 1]$, i.e., $U' > 0$ on $[x_k + A - 1, x_k + A + 1]$. Define $\xi_i = A + x_{K+|i|}$ for all integer $i \leq 0$. Then $\lim_{i\to-\infty} \xi_i = -\infty$ and $U' > 0$ on $[\xi_i - 1, \xi_i + 1]$ for every integer $i \leq 0$.

The sequence $\{\xi_i\}_{i\geqslant 1}$: When $f'(1) < 0$, we have $\lim_{x\to\infty} U'(x)/[1 - U(x)] > 0$ so $U'(x) > 0$ for all $x \gg 1$. It remains to consider the case $f'(1) = 0$. Define

$$\sigma(x) = \frac{U'(x)}{U(x) - 1}, \quad \delta_j = \max_{x\in[j,\infty)} |\sigma(x)|, \quad \theta = \limsup_{j\to\infty} \frac{\delta_{j+3}}{\delta_j} \ \in [0, 1].$$

With an analogous argument as before, we can show that $\theta = 1$. Take a sequence $\{j_k\}_{k=1}^\infty$ satisfying $\lim_{k\to\infty} j_k = \infty$ and $\lim_{k\to\infty} \delta_{j_k+3}/\delta_{j_k} = 1$. Let $x_k \geq j_k + 3$ be a point such that $\delta_{j_k+3} = |\sigma(x_k)|$. Set $\sigma_k(x) = \sigma(x+x_k)/|\sigma(x_k)|$. Then $|\sigma_k| \leq \delta_{j_k}/\delta_{j_k+3}$ in $[-3, \infty)$. Same as before, a subsequence of $\{\sigma_k\}_{k=0}^\infty$ converges to a limit R satisfying (3.3). The rest of the proof follows from an analogous argument as before. This completes the proof of Lemma 3.3 and also the proof of Theorems 2 and 3. ∎

4. Uniqueness of traveling waves. In this section we prove Theorem 1. In the following, U and V are two traveling waves with the same speed c. We want to show that $U(\cdot) \equiv V(\cdot - \xi)$ for some $\xi \in \mathbb{R}$.

4.1. A comparison principle. The sliding method applies on compact intervals.

LEMMA 4.1. *If $V \leqslant U$ on $[a-1,a)\cup(b,b+1]$ where $a \leqslant b$, then $V \leqslant U$ on $[a,b]$.*

Proof. Let ξ be the number such that $\min_{[a-1,b+1]}\{U(\cdot) - V(\cdot - \xi)\} = 0$ and let $y \in [a-1, b+1]$ be the maximum value satisfying $U(y) - V(y-\xi) = 0$. Then $y \notin [a,b]$ since, otherwise, $U'(y) = V'(y-\xi)$ and the equations for $U(\cdot)$ and $V(\cdot - \xi)$ evaluated at y would imply $U(y \pm 1) = V(y - \xi \pm 1)$, contradicting the maximality of y. Thus, $y \in [a-1, a) \cup (b, b+1]$, and by the assumption, $V(y) \leqslant U(y) = V(y-\xi)$. Thus $\xi \leqslant 0$. We conclude that $U(\cdot) \geqslant V(\cdot - \xi) \geqslant V(\cdot)$ on $[a-1, b+1]$. ∎

The success of such a simple translation technique relies on (1) the existence of a minimal translation ξ and (2) the existence of a maximum y, both of which attribute to the fact that a continuous function on a compact set attains its global extremes. When the domain of interest is unbounded, neither ξ nor y may exist, and therefore different techniques are needed.

4.2. Comparison near $x = \infty$. We shall compare traveling waves on the unbounded domain $[0, \infty)$. Since simple translation technique does not work, we shall instead construct a family of supersolutions for which translation technique works. If one is willing to make the assumption $f' \leqslant 0$ on $[1-\delta, 1]$ for some $\delta > 0$, then for every $\varepsilon > 0$,

$$\min\{U + \varepsilon, 1\} \quad \text{on} \quad [-1, \infty)$$

is a supersolution on $[0,\infty)$ provided that $U(-1) \geqslant 1 - \delta$. In this manner, no asymptotic behavior of U near $x = \infty$ is needed.

When only the assumption (A) is made, we construct a different family of supersolutions obtained from the detailed asymptotic behavior of wave profiles and compression:

$$Z(\ell, x) := U([1+\ell]x) \quad \forall\, x \in [-1, \infty), \ell \in (0, 1].$$

The idea here is that the rate of Z approaching 1 as $x \to \infty$ is faster than that of any wave profile, and therefore is strictly bigger than any wave profile for sufficiently large x.

Since $\lim_{x\to\infty} U''(x)/U'(x) = \mu \leqslant 0 < c$ and $U'(x+h)/U'(x) = e^{\int_x^{x+h} U''(s)/U'(s)ds}$, by translation, we may assume that

$$\sup_{x \geqslant 0,\ |h| \leqslant 2} \frac{U''(x+h)}{U'(x)} < c. \tag{4.1}$$

For $\ell \in (0,1]$ and $x \geqslant 0$, writing $y = (1+\ell)x$ and $Z(\ell, x) = Z(x)$, we calculate

$$\begin{aligned}
\mathcal{L}Z(x) &:= c\,Z'(x) - Z(x+1) - Z(x-1) + 2Z(x) - f(Z(x)) \\
&= c[1+\ell]\,U'(y) - U(y+1+\ell) - U(y-1-\ell) + 2U(y) - f(U(y)) \\
&= c\,\ell\,U'(y) + U(y+1) + U(y-1) - U(y+1+\ell) - U(y-1-\ell) \\
&= \ell\,U'(y)\left\{c - \int_0^1 \int_{-1-\ell z}^{1+\ell z} \frac{U''(y+h)}{U'(y)} dh dz\right\} > 0.
\end{aligned}$$

This shows that for each $\ell \in (0,1]$, $Z(\ell, \cdot)$ is a (strict) supersolution on $[0,\infty)$.

LEMMA 4.2. *Assume* (4.1). *Suppose* $V \leqslant U$ *on* $[0,1]$. *Then* $V \leqslant U$ *on* $[0,\infty)$.

Proof. Consider the function, for $x \geqslant 0, \xi \in \mathbb{R}$, and $\ell > 0$,

$$\Psi(\xi,\ell,x) := \int_{V(x-\xi)}^{U([1+\ell]x)} \frac{ds}{f(s)}.$$

Note that

$$\lim_{x\to\infty} \frac{\partial\Psi(\xi,\ell,x)}{\partial x} = \lim_{x\to\infty} \left(\frac{(1+\ell)U'}{f(U)} - \frac{V'}{f(V)} \right) > 0 \quad \forall\, \ell > 0, \xi \in \mathbb{R};$$
$$\inf_{x\geq 0,\xi\in\mathbb{R},\ell\in[0,1]} \frac{\partial\Psi}{\partial\xi} = \inf_{y\in\mathbb{R}} \frac{V'(y)}{f(V(y))} > 0.$$

Thus $\lim_{x\to\infty} \Psi(\xi,\ell,x) = \infty$. For each fixed $\ell \in (0,1]$, there exists at least one ξ such that $\Psi(\xi,\ell,\cdot) \geqslant 0$ on $[0,\infty)$. Let $\xi(\ell)$ be the infimum of such numbers.

We claim that $\xi(\ell) \leqslant 0$. Suppose otherwise. Since $\lim_{x\to\infty} \Psi(\xi(\ell),\ell,x) = \infty$, there exists $y \in [0,\infty)$ such that $\Psi(\xi(\ell),\ell,y) = 0$. We must have $y > 1$, since $V(\cdot - \xi(\ell)) < V(\cdot) \leqslant U(\cdot) \leqslant U([1+\ell]\cdot)$ on $[0,1]$. Thus, for $Z(x) = U([1+\ell]x)$,

$$Z(y) = V(y - \xi(\ell)), \qquad V(\cdot - \xi(\ell)) \leqslant Z(\cdot) \quad \text{on} \quad [0,\infty).$$

This implies $V'(y - \xi(\ell)) = Z'(y)$ and a contradiction

$$0 = \mathcal{L}V\,\big|_{y-\xi(\ell)} \geq \mathcal{L}Z\big|_y > 0.$$

This contradiction shows that $\xi(\ell) \leqslant 0$, so that $V(\cdot) \leqslant V(\cdot - \xi(\ell)) \leqslant U([1+\ell]\cdot)$ on $[0,\infty)$. Sending $\ell \searrow 0$, we obtain that $V(\cdot) \leqslant U(\cdot)$ on $[0,\infty)$. □

4.3. Comparison near $x = -\infty$. In general, on the unbounded interval $(-\infty, 0]$, it is very hard to construct a family of supersolutions that can be used for the translation argument such as that in the previous two subsections; this is due to the fact that the constant state **0** is unstable. Hence we compare directly two traveling waves. We shall show that wave profiles are ordered (i.e., one is bigger than the other) near $x = -\infty$, by magnifying differences between any two wave profiles.

For every $\xi \in \mathbb{R}$ and $x \in \mathbb{R}$, we define

$$W(\xi,x) = \begin{cases} \displaystyle\int_{V(x-\xi)}^{U(x)} \frac{ds}{f(s)} & \text{if } \ c > c_{\min}, \\ \ln U(x) - \ln V(x-\xi) & \text{if } \ c = c_{\min}. \end{cases}$$

Note that $W(\xi,x)$ magnifies the differences between U and V. When $c > c_{\min}$,

$$W_x(\xi,x) := \frac{\partial W(\xi,x)}{\partial x} = \frac{U'}{f(U)} - \frac{V'}{f(V)} \longrightarrow 0 \text{ as } \ x \to \pm\infty.$$

This limit shows that the magnified difference between wave profiles changes slowly. The conclusion for $c = c_{\min}$ is analogous.

LEMMA 4.3. *There exist* $\nu > 0$ *and* $A \in [-\infty,\infty]$ *such that*

$$\lim_{x\to-\infty} W(\xi,x) = A + \nu\xi \quad \forall\, \xi \in \mathbb{R}. \tag{4.2}$$

Consequently, near $x = -\infty$, $U < V(\cdot - \xi)$ *if* $A + \nu\xi < 0$ *and* $U > V(\cdot - \xi)$ *if* $A + \nu\xi > 0$.

Proof. First, we consider the case $c > c_{\min}$. Note that

$$\lim_{x\to-\infty}\Big\{W(\xi,x)-W(0,x)\Big\}=\lim_{x\to-\infty}\int_{x-\xi}^{x}\frac{V'(y)dy}{f(V(y))}=\nu\xi,$$

where $\nu = 1/c$ when $f'(0) = 0$ and $\nu = \lambda/f'(0)$ otherwise. Suppose $\lim_{x\to-\infty} W(\xi,x)$ does not exist. Then $A := \limsup_{x\to-\infty} W(\xi,x) > B := \liminf_{x\to-\infty} W(\xi,x)$. Taking an appropriate ξ, we can assume without loss of generality that $A > 0 > B$. Let α,β be finite numbers satisfying $B < \beta < 0 < \alpha < A$. Then there exist sequences $\{x_i\}$ and $\{y_i\}$ satisfying

$$W(\xi,x_i)=\alpha,\quad W(\xi,y_i)=\beta,\quad x_{i+1}<y_i<x_i,\quad \lim_{i\to\infty}x_i=-\infty.$$

Since $\lim_{x\to-\infty} W_x(\xi,x) = 0$, there exists a large integer i such that $W(\xi,\cdot) > 0$ in $[x_{i+1}-1,x_{i+1}]\cup[x_i,x_i+1]$ and $W(\xi,y_i) < 0$. This implies that $V(\cdot-\xi) < U(\cdot)$ on $[x_{i+1}-1,x_{i+1}]\cup[x_i,x_i+1]$ and $V(y_i-\xi) > U(y_i)$ which is impossible by Lemma 4.1. Thus $A = B$.

The case $c = c_{\min}$ is analogous. ∎

4.4. Proof of Theorem 1. Let U and V be two traveling wave profiles with the same speed c. By translation, we can assume that $V(0) = U(0)$ and that U and V satisfy (4.1). By exchanging the roles of U and V if necessary we can use Lemma 4.3 to conclude that (4.2) holds with $A \in [0,\infty]$.

Let $\eta \geqslant 0$ be the unique value such that

$$\min_{x\in[0,1]}\{U(x)-V(x-\eta)\}=0.$$

By Lemma 4.2, $V(\cdot-\eta)\leqslant U(\cdot)$ on $[0,\infty)$. We claim that $V(\cdot-\eta)\leqslant U(\cdot)$ on $(-\infty,0]$. Suppose not. Then $\inf_{x\in\mathbb{R}} W(\eta,x) < 0$. Since $W_\xi > 0$ and $W(\eta,\pm\infty)\geqslant 0$, there is a unique value $\xi > \eta$ such that $\min_{\mathbb{R}} W(\xi,\cdot) = 0$. This implies that there exists $y\in\mathbb{R}$ such that $W(\xi,y) = 0 = \min_{\mathbb{R}} W(\xi,\cdot)$. It further implies that $V(\cdot-\xi)\leqslant U(\cdot)$ and $V(y-\xi) = U(y)$. A comparison principle shows that this is impossible. Hence, $V(\cdot-\eta)\leqslant U(\cdot)$ on $\mathbb{R}$. Since $\min_{[0,1]}\{U(\cdot-\eta)-V(\cdot)\} = 0$, we must have $\eta = 0$ and $U\equiv V$. ∎

5. Asymptotic expansions. Finally, we derive and verify asymptotic expansions for traveling wave profiles near $x = -\infty$, accurate enough to distinguish the translation differences. The idea is to construct, on $(-\infty,1]$, sub/supersolutions having special tails near $x = -\infty$ and slopes on the interval $[0,1]$. The comparison between a wave profile and a sub/super solution near $x = -\infty$ will be made by a result similar to (4.2) in Lemma 4.3. The comparison on $[0,1]$ will be made in a manner similar to that in the last step of the proof of Lemma 2.3.

5.1. Super/subsolutions. In the following, a Lipschitz continuous function defined on $[a-1,b+1]$ is called a super/subsolution (of speed c) on $[a,b]$ if

$$\pm\,\mathcal{L}\,[\phi](x)\geqslant 0\quad \text{a.e. } x\in(a,b),$$

where $\mathcal{L}\,[\phi](x) := c\,\phi'(x)-\phi(x+1)-\phi(x-1)+2\phi(x)-f(\phi(x))$.

LEMMA 5.1. *Suppose ϕ is a subsolution (or supersolution) on $[a,b]$ and $\phi < U$ (or $\phi > U$) on $[a-1,a)\cup(b,b+1]$. Then $\phi < U$ (or $\phi > U$) on $[a,b]$.*

The proof is similar to that for Lemma 4.1 and is omitted.

Our asymptotic expansion for a wave profile is expressed in terms of a constructed function ϕ such that, for some $x_0 \in \mathbb{R}$,

$$U(x+x_0) = \phi(x+o(1)) \ \ \forall\, x \leqslant 0 \quad \text{where} \quad \lim_{x\to-\infty} o(1) = 0. \tag{5.1}$$

For this, we shall use the same idea as that of Lemma 4.3. Consider the case $\lambda \neq 0$. Suppose ϕ is either a subsolution or a supersolution on $(-\infty, 0]$ and

$$\lim_{x\to-\infty} \frac{\phi'(x)}{\phi(x)} = \lim_{x\to-\infty} \frac{U'(x)}{U(x)} = \lambda > 0. \tag{5.2}$$

Consider the function, for $\xi \in \mathbb{R}$ and $x \leqslant 0$,

$$W(\xi, x) = \int_{\phi(x)}^{U(x+\xi)} \frac{ds}{s} = \ln \frac{U(x+\xi)}{\phi(x)}. \tag{5.3}$$

LEMMA 5.2. *Suppose ϕ satisfies* (5.2) *and is either a supersolution or a subsolution on $(-\infty, 0]$. Let W be defined as in* (5.3). *Then* (4.2) *holds for some $A \in [-\infty, \infty]$.*

The proof is similar to that for Lemma 4.3 and therefore is omitted.

Suppose A is shown to be finite. Then for $x_0 := -A/\nu$, every $\varepsilon > 0$, and all $x \ll -1$, $W(x_0 - \varepsilon, x) < 0 < W(x_0 + \varepsilon, x)$; that is, $\phi(x-\varepsilon) < U(x+x_0) < \phi(x+\varepsilon)$ for every $\varepsilon > 0$ and all $x \ll -1$. Hence (5.1) holds. To construct sub/supersolutions and to show that A is finite, we shall assume that

(B) $|f(u) - f'(0)u| \leq Mu^{1+\alpha}$ for all $u \in [0, 1]$ and some positive constants M and α.

In most cases, we shall construct sub/supersolutions via linear combinations of exponential functions. Note that for $\phi = ae^{\omega x}$, $\mathcal{L}\phi = P(\omega)\phi + [f'(0)\phi - f(\phi)]$, where

$$P(\omega) := c\,\omega - e^{\omega} - e^{-\omega} + 2 - f'(0).$$

Observe that $P(\cdot)$ is concave, positive between its two roots, and negative outside of these two roots. Denote by λ and Λ, where $0 \leqslant \lambda \leqslant \Lambda$, the two roots of $P(\cdot) = 0$. Among all possibilities, we divide them into four cases:

(i) $c = c_{\min}$ and (1.6) has two real roots;
(ii) $c = c_{\min}$ and (1.6) has only one real root;
(iii) $c > c_{\min}$ and $f'(0) > 0$;
(iv) $c > c_{\min}$ and $f'(0) = 0$.

Note that $\lim_{x\to-\infty}\{U'(x)/U(x)\} > 0$ in the cases (i)–(iii). For the last case (iv), $\lambda = 0$ so that sub/supersolutions have to be constructed by nonexponential functions. For this, we need extra assumptions on f.

5.2. The case $c = c_{\min}$ and (1.6) has two real roots. Assume that $c = c_{\min}$ is the minimum wave speed and that the characteristic equation $c_{\min} z = e^z + e^{-z} - 2 + f'(0)$ has two real roots. Let λ be the smaller real root and Λ be the large real root. Then $\lambda < \Lambda$ and

$$\lim_{x\to-\infty} \frac{U'(x)}{U(x)} = \Lambda > 0 \implies \frac{U(x)}{U(0)} = e^{\int_0^x U'/U} = e^{\Lambda x + o(x)}.$$

Choose ω_1 and ω_2 satisfying

$$\lambda < \omega_1 < \Lambda < \omega_2, \qquad \omega_2 < (1+\alpha)\Lambda.$$

Then $P(\omega_1) > 0 = P(\Lambda) > P(\omega_2)$. Consider, for $\varepsilon \in [0,1]$ and small $\delta > 0$,

$$\phi^{\pm}(\varepsilon,\delta,x) := \delta\Big\{e^{\Lambda x} \pm \varepsilon(e^{\omega_1 x} - e^{\Lambda x}) \pm \delta^{\alpha/2}(e^{\Lambda x} - e^{\omega_2 x})\Big\}.$$

Note that when $\varepsilon > 0$ and $x \ll -1$, $\phi^+ \gg U$ and $\phi^- < 0$. Also, for all $x \leqslant 0$,

$$\mathcal{L}\,[\phi^+] = \delta\Big\{\varepsilon P(\omega_1)e^{\omega_1 x} - P(\omega_2)\delta^{\alpha/2}e^{\omega_2 x} + O(1)\delta^{\alpha}\left[\varepsilon^{1+\alpha}e^{(1+\alpha)\omega_1 x} + e^{(1+\alpha)\Lambda x}\right]\Big\} > 0$$

if $\varepsilon \in [0,1]$ and $\delta \in (0,\delta_0]$ for some $\delta_0 > 0$. Similarly, for every $\varepsilon \in [0,1]$ and $\delta \in (0,\delta_0]$, $\max\{0,\phi^-(\varepsilon,\delta,\cdot)\}$ is a subsolution on $(-\infty,0]$. Taking δ_0 small enough we can assume that $\phi_x^{\pm} > 0$ for all $x \in [0,1]$, $\varepsilon \in [0,1]$ and $\delta \in [0,\delta_0]$.

Take ξ negatively large such that $\delta := U(\xi) < \delta_0$. Comparing $U(\cdot + \xi - 1)$ with $\phi^+(\varepsilon,\delta,\cdot)$ on $(-\infty,0]$ for every $\varepsilon \in (0,1]$, we see that $U(x+\xi-1) \leq \phi^+(\varepsilon,\delta,x)$ for all $x \leq 0$. Here the positivity of ε guarantees that $\phi^+ > U$ near $x = -\infty$. Now sending $\varepsilon \searrow 0$ we conclude that $U(x+\xi-1) \leq \delta[1+\delta^{\alpha/2}]e^{\Lambda x}$ for all $x \leqslant 0$. Similarly, $U(x+\xi+1) > \delta[1-\delta^{\alpha/2}]e^{\Lambda x}$ for all $x \leqslant 0$.

Now applying Lemma 5.2 to $\phi = \phi^+(0,\delta_0,x)$, we see that there is the limit

$$A = \lim_{x\to-\infty}\Big\{\ln U(x) - \ln\phi^+(0,\delta_0,x)\Big\} = \lim_{x\to-\infty}\Big\{\ln U(x) - \Lambda x\Big\} - \ln\left[\delta_0\left(1+\delta_0^{\alpha/2}\right)\right].$$

From the estimate in the previous paragraph, A must be finite. Hence we proved the following theorem.

THEOREM 5.1. *Assume* (A) *and* (B). *Let* $(c_{\min}, U)$ *be a traveling wave of the minimum speed where the characteristic equation has two roots* λ, Λ, $\lambda < \Lambda$. *Then, for some* $x_0 \in \mathbb{R}$,

$$U(x) = e^{\Lambda[x+x_0+o(1)]} \quad \forall x \leqslant -1, \quad \textit{where} \quad \lim_{x\to-\infty} o(1) = 0.$$

5.3. The case $c = c_{\min}$ and (1.6) has only one real root. Let $P(z) = c_{\min}z - [e^z + e^{-z} - 2 + f'(0)]$ be the characteristic function at 0. That $P(\cdot) = 0$ has only one real root, denoted by λ, implies that $P(\lambda) = P'(\lambda) = 0$; that is,

$$c_{\min} = e^{\lambda} - e^{-\lambda}, \qquad f'(0) = \lambda(e^{\lambda} - e^{-\lambda}) + (2 - e^{\lambda} - e^{-\lambda}). \tag{5.4}$$

Take $\omega \in (\lambda, [1+\alpha]\lambda)$ and consider the function, for small $\delta > 0$,

$$\phi^*(\delta,x) = \delta[-xe^{\lambda x} - \delta^{\alpha/2}(e^{\lambda x} - e^{\omega x})]. \tag{5.5}$$

Note that $\phi^* > 0$ in $(-\infty,0)$ and $\phi^* < 0$ in $(0,\infty)$. Since $P(\omega) < 0$, for $x \leq 0$,

$$\mathcal{L}\phi^* = \delta\Big\{\delta^{\alpha/2}P(\omega)e^{\omega x} + O(1)\delta^{\alpha}[|x|+1]^{1+\alpha}e^{(1+\alpha)\lambda x}\Big\} < 0.$$

It follows that $\phi^- := \max\{\phi^*, 0\}$ is a subsolution for every $\delta \in (0,\delta_0]$, where $\delta_0 > 0$.

From Lemma 5.2, there exists the limit

$$A = \lim_{x\to-\infty}\Big\{\ln U(x) - \lambda\, x - \ln|x|\Big\}. \tag{5.6}$$

We claim that $A < \infty$. Suppose $A = \infty$. Then for each fixed $\xi \in \mathbb{R}$, $U(x+\xi) > \phi^-(\delta,x)$ for all $x \ll -1$. Since $\phi^- = 0$ on $[0,\infty)$ and ϕ^- is a subsolution, a comparison

gives $U(x+\xi) > \phi^-(\delta, x)$ for all $x \in \mathbb{R}$. This is impossible for every $\xi \in \mathbb{R}$. Thus $A < \infty$.

We now consider the lower bound of A. Since $P(\cdot)$ is a concave function, that λ is a double root to $P(\cdot) = 0$ implies that $P(\omega) < 0$ for every $\omega \neq \lambda$. It is then very hard to construct supersolutions. As the existence of a supersolution implies the existence of a traveling wave, the construction of a supersolution is equivalent to find $c_{\min}$ which is not totally determined by the local behavior of $f(s)$ near $s = 0$. That $c_{\min}$ is the solution of (5.4) which is uniquely determined by $f'(0)$ requires special properties on the nonlinearity on f. The whole nonlinear structure of f on $[0, 1]$ determines whether A is bounded from below. As will be seen in a moment, the answer to whether A is bounded is all we need to determine uniquely the asymptotic behavior of U as $x \to -\infty$, i.e., the alternatives in (1.11).

Case 1. $A > -\infty$. Then A is finite, so from (5.6), the first alternative in (1.11) holds.

Case 2. $A = -\infty$. Fix $\omega \in (\lambda, (1+\alpha)\lambda)$. Consider, for $\varepsilon \in [0, 1]$ and small $\delta > 0$,

$$\phi^+(\varepsilon, \delta, x) = \delta \left\{ [1 - \varepsilon x] e^{\lambda x} - \delta^{\alpha/2} e^{\omega x} \right\}.$$

Direct calculation shows that ϕ^+ is a supersolution on $(-\infty, 0]$ for every $\varepsilon \in [0, 1]$ and $\delta \in (0, \delta_0]$. Fix a translation such that $U(1) \leq \delta_0/2$. For every $\varepsilon \in (0, 1]$ we compare $U(\cdot)$ and $\phi^+(\varepsilon, \delta_0, \cdot)$ on $(-\infty, 0]$. When $x \in [0, 1]$, $U(x) \leq U(1) < \delta_0/2 < \phi(\varepsilon, \delta_0, x)$. Since $A = -\infty$, we see that $U < \phi$ for all $x \ll -1$. It then follows that $U(\cdot) < \phi(\varepsilon, \delta_0, \cdot)$ on $(-\infty, 1]$. Sending $\varepsilon \searrow 0$ we obtain $U(x) \leq \delta_0 e^{\lambda x}$ for all $x \in (-\infty, 0]$.

Also, by Lemma 5.2, there exists the limit

$$\tilde{A} := \lim_{x \to -\infty} \left\{ \ln U(x) - \ln \phi^+(0, \delta_0, x) \right\} = \lim_{x \to -\infty} \left\{ \ln U(x) - \lambda x \right\} - \ln \delta_0.$$

In addition, since $U(x) \leq \delta_0 e^{\lambda x}$ for all $x \in (-\infty, 0]$, $\tilde{A} \leq 0$.

Next we show that $\tilde{A} > -\infty$. To do this, for every $\omega_1 \in [\lambda, \omega]$, consider the function $\phi^-(\omega_1, \delta, x) := \delta[e^{\omega_1 x} + e^{\omega x}]$. It is easy to show that ϕ^- is a subsolution on $(-\infty, 0]$ for every $\omega_1 \in [\lambda, \omega]$ and every $\delta \in (0, \delta_0]$.

Fix a translation such that $U(-1) > 2\delta_0$. For every $\omega_1 \in (\lambda, \omega]$, by comparing U and $\phi^-(\omega_1, \delta_0, x)$, we see that $U > \phi^-(\omega_1, \delta_0, x)$, since $\omega_1 > \lambda$ implies $U > \phi^-$ for all $x \ll -1$. Now sending $\omega_1 \searrow \lambda$ we see that $U(x) \geq \delta_0 e^{\lambda x}$ for all $x \leq 0$. Thus $\tilde{A}$ is finite; namely, the second alternative in (1.11) holds.

Finally, we provide two examples showing that both alternatives in (1.11) can happen.

Example 1. This example provides the second alternative in (1.11). We define

$$U(x) = \frac{e^x}{1 + e^x}, \quad \lambda = 1, \quad c = e - \frac{1}{e},$$
$$f(u) = \frac{u(1-u)(e-1)[2(1-u)^2 + 2eu^2 + (e^2+1)(e+1)u(1-u)/e]}{e(1-u)^2 + eu^2 + u(1-u)(e^2+1)}.$$

Using $e^x = U(x)/[1 - U(x)]$, one can verify that (c, U) is a traveling wave. Since $f'(0) = 2 - 2/e$, $\lambda = 1$ is a double root of the characteristic equation $c\omega = e^\omega + e^{-\omega} - 2 + f'(0)$. Consequently, $c_{\min} = e - 1/e$.

Example 2. We show that the first alternative in (1.11) holds if

$$f \in C^{1+\alpha}([0, 1]), \quad f(0) = f(1) = 0 < f(u) \leqslant f'(0)u \quad \forall\, u \in (0, 1). \tag{5.7}$$

First of all, defining $(c_{\min}, \lambda)$ as in (5.4), one can show that $\min\{1, e^{\lambda x}\}$ is a supersolution with $c = c_{\min}$ so that there is a traveling wave of speed $c_{\min}$. Consequently, the minimum wave speed is given by the solution of (5.4); see, for example, [5, 6, 27].

Also, there is a supersolution given by

$$\phi^+(x) = [1 - \tfrac{\lambda}{1+\lambda}\, x]e^{\lambda x} \quad \forall\, x < 0, \qquad \phi^+(x) = 1 \quad \text{for} \quad x \geqslant 0.$$

Note that, for a large constant M, $\phi^+(x + M) > \phi^*(\delta_0, x)$ on $\mathbb{R}$, where ϕ^* is as in (5.5). Following the existence proof of [5], $(\max\{\phi^*, 0\}, \phi^+)$ sandwiches a solution which satisfies the first alternative in (1.11).

We conclude the following theorem.

THEOREM 5.2. *Assume* (A) *and* (B). *Suppose* $c = c_{\min}$ *and the characteristic equation has a root* λ *of multiplicity 2, i.e.,* (5.4) *holds. Then there is the alternative* (1.11). *In addition, under* (5.7)*, only the first alternative in* (1.11) *holds.*

5.4. The case $c > c_{\min}$ and $f'(0) > 0$. Let λ and Λ, $\lambda < \Lambda$, be two roots of the characteristic equation $P(\cdot) = 0$, where $P(z) = c\, z - [e^z + e^{-z} - 2 + f'(0)]$. Pick ω such that $\lambda < \omega < \min\{\Lambda, (1 + \alpha)\lambda\}$. Then $P(\omega) > 0$. For each $\varepsilon \in (0, e^{-\omega}]$ and small δ, consider functions

$$\phi^{\pm}(\varepsilon, \delta, x) := \delta\left([1 \mp \varepsilon]e^{\lambda x} \pm \varepsilon e^{\omega x}\right), \qquad x \leqslant 1.$$

Note that

$$\min_{0 \leqslant x \leqslant 1} \frac{\phi^+_x(\varepsilon, \delta, x)}{\phi^+(\varepsilon, \delta, x)} = \lambda + \varepsilon(\omega - \lambda), \qquad \max_{0 \leqslant x \leqslant 1} \frac{\phi^-_x(\varepsilon, \delta, x)}{\phi^-(\varepsilon, \delta, x)} = \lambda - \varepsilon(\omega - \lambda).$$

In addition, for all $x \leqslant 0$, $\varepsilon \in (0, 1]$, and $\delta \in (0, 1]$, using $|f(u) - f'(0)u| \leq Mu^{1+\alpha}$ and $0 < \phi^{\pm} \leq 2\delta e^{\lambda x}$ we obtain

$$\begin{aligned} \pm\,\mathcal{L}\,[\phi^{\pm}\delta] &= \delta\varepsilon P(\omega)e^{\omega x} \pm [f(\phi^{\pm}\delta) - f'(0)\phi^{\pm}\delta] \\ &\geqslant \delta e^{\omega x}\left\{\varepsilon\, P(\omega) - 2^{1+\alpha} M\delta^{\alpha} e^{[(1+\alpha)\lambda - \omega]x}\right\}. \end{aligned}$$

Hence, we have the following:

(i) For every $\varepsilon \in (0, e^{-\omega}]$, there exists $x_\varepsilon \leqslant 0$ such that $\phi^{\pm}(\varepsilon, 1, \cdot)$ is a super/subsolution on $(-\infty, x_\varepsilon]$.

(ii) For every $\varepsilon \in (0, e^{-\omega}]$, there exists $\delta_\varepsilon > 0$ such that for every $\delta \in (0, \delta_\varepsilon]$, $\phi^{\pm}(\varepsilon, \delta, \cdot)$ is a super/subsolution on $(-\infty, 0]$.

Indeed, we need only take

$$x_\varepsilon := \min\left\{0, \frac{\ln[\varepsilon P(\omega)] - \ln[2^{1+\alpha}M]}{(1+\alpha)\lambda - \omega}\right\}, \qquad \delta_\varepsilon = \min\left\{1, \left(\frac{\varepsilon P(\omega)}{2^{1+\alpha}M}\right)^{1/\alpha}\right\}.$$

THEOREM 5.3. *Assume* (A), (B), *and* $f'(0) > 0$. *Let* (c, U) *be a traveling wave with speed* $c > c_{\min}$. *Then* $U(x) = e^{\lambda(x + x_0 + o(1))}$ *for some* $x_0 \in \mathbb{R}$, *where* $\lim_{x \to -\infty} o(1) = 0$.

Proof. First of all, note that (4.2) holds for W defined as in (5.3) with $\phi = \phi^+(\varepsilon, 1, x)$.

We show that $A > -\infty$. Suppose $A = -\infty$. Fix $\varepsilon = e^{-\omega}$. Since

$$\lim_{x \to \infty} U'(x)/U(x) = \lambda,$$

there exists $\xi < 0$ such that $U'(x)/U(x) < \lambda + \varepsilon(\omega - \lambda)$ for all $x < \xi + 2$. Now we compare $U(\cdot + \xi)$ with $\phi := \phi^+(\varepsilon, U(\xi), \cdot)$ on $(-\infty, 0]$. By taking negatively large ξ, we may assume that $U(\xi) < \delta_\varepsilon$ so that ϕ is a supersolution on $(-\infty, 0]$.

Note that $\phi(0) = U(0 + \xi)$ and

$$\frac{\phi'(x)}{\phi(x)} > \lambda + \varepsilon(\omega - \lambda) > \frac{U'(x+\xi)}{U(x+\xi)} \quad \forall\, x \in [0, 1]$$

so that $U(\cdot + \xi) < \phi(\cdot)$ on $(0, 1]$. Also, $\lim_{x\to-\infty}[\ln \phi(x) - \ln U(x + \xi)] = \infty$. It follows by comparison that $\phi(\cdot) > U(\cdot + \xi)$ on $(-\infty, 0]$, contradicting $\phi(0) = U(0 + \xi)$. Thus $A > -\infty$.

Similarly, by using the subsolution ϕ^-, one can show that $A < \infty$. Thus $A = \lim_{x\to-\infty}\{\ln U(x) - \lambda x\}$ exists and is finite. This completes the proof. □

5.5. The case $c > c_{\min}$ and $f'(0) = 0$. When $c > c_{\min}$, $\lambda := \lim_{x\to-\infty} U'(x)/U(x)$ is the smaller root to the characteristic equation $cz = e^z + e^{-z} - 2 + f'(0)$. When $f'(0) = 0$, we have $\lambda = 0$. Thus as $x \to -\infty$, $U(x)$ does not decay to 0 exponentially fast. To find the precise rate of decay, we shall assume the following:

(B1) $0 \leqslant ff'' \leqslant Mf'^2$ on $(0, \epsilon]$ for some $\epsilon > 0$ and $M > 0$; $\int_0^\epsilon f'^2(s)/f(s)ds < \infty$.

Simple examples of such functions are

$$f(u) = \kappa u^{1+q}(1-u)^p, \qquad f(u) = \kappa e^{-1/u}(1-u)^p \qquad (\kappa > 0, q > 0, p \geqslant 1).$$

THEOREM 5.4. *Assume* (A), (B1), *and* $f'(0) = 0$. *Let* (c, U) *be a traveling wave with nonminimum speed* c. *Then* (1.12) *holds for some* $x_0 \in \mathbb{R}$.

Proof.

The idea. The proof is based on the following formal calculation. When $f'(0) = 0$ and $c > c_{\min}$, it follows from Theorem 3 that $cU' \approx f(U)$. Then at least formally we should have $c^2U'' \approx cf'(U)U' \approx f(U)f'(U)$. Since by the mean value theorem $U(x+1) + U(x-1) - 2U(x) = U''(y) \approx U''(x)$, we obtain

$$cU' \approx U'' + f(U) \approx f(U)f'(U)/c^2 + f(U) = f(U)[1 + f'(U)/c^2].$$

This suggests that sub/super solutions can be obtained from solutions of ODEs of the form $c\,\phi' = f(\phi)[1 + f'(\phi)/c^2] \pm o(1)$, where $o(1)$ is a small positive term large enough to offset the error of the approximation $U(x+1)+U(x-1)-2U(x) = U''(y) \approx U''(x)$.

Construction of super/subsolutions. Let δ_0 be a small enough constant and be fixed. For every $\delta \in (0, \delta_0]$ and $K \in [1, 1/(4f'^2(\delta))]$, let ϕ be the solution of

$$c\,\phi' = f(\phi)\,\{\,1 + f'(\phi)/c^2 \pm Kf'^2(\phi)\,\} \quad \text{on} \quad (-\infty, 1], \qquad \phi(0) = \delta. \tag{5.8}$$

The solution is given implicitly by

$$\int_\delta^{\phi(x)} \frac{ds}{f(s)[1 + f'(s)/c^2 \pm Kf'^2(s)]} = \frac{x}{c} \quad \forall\, x \leqslant 1.$$

When δ_0 is small, we have $\phi \leq \delta[1 + o(1)]$ and $c\phi' = f(\phi)[1 + o(1)]$ on $(-\infty, 1]$. In the following, $O(1)$ is a quantity bounded by a constant independent of K and δ.

Write (5.8) as $c\,\phi' = (1 + g(\phi))f(\phi)$, where $g := f'/c^2 \pm Kf'^2$. In the following, the arguments of f, f', f'', and g are evaluated at $\phi(x)$, if not specified. Since $f'' \geqslant 0$ and $ff'' = O(1)f'^2$ on the interval of interest, we see that

$$|g| + |g'f/f'| = O(f') + O(f'^2)K.$$

Consequently,

$$c^2\phi''(x) = \{(1+g)f' + fg'\}(1+g)f = ff'\{1 + O(f') + O(f'^2)K\}.$$

Also by the mean value theorem,

$$\phi(x+1) + \phi(x-1) - 2\phi(x) = \phi''(y) \quad \text{for some } \ y \in [x-1, x+1],$$

$$\frac{f'(\phi(y))}{f'(\phi(x))} = \exp\left(\int_x^y \frac{(1+g)ff''}{cf'}\right) = \exp\left(\int_x^y O(f'(\phi(z))dz\right).$$

This implies that

$$f'(\phi(y)) = [1 + O(f'(\phi(x)))]f'(\phi(x)).$$

Similarly,

$$f(\phi(y)) = [1 + O(f'(\phi(x)))]f(\phi(x)).$$

This follows that

$$c^2\phi''(y) = f'f\{1 + O(f') + O(f'^2)K\}\Big|_{\phi(x)}.$$

Hence, for all $x \leqslant 1$,

$$\begin{aligned}\mathcal{L}[\phi](x) &= c\phi' - f - f'f\Big\{c^{-2} + O(f') + O(f'^2)K\Big\} \\ &= ff'^2\Big\{\pm K + O(1) + O(f')K\Big\}.\end{aligned}$$

Thus we have the following lemma.

LEMMA 5.3. *There exist a small positive constant δ_0 and a large constant K_0 such that for every $\delta \in (0, \delta_0]$ and every $K \in [K_0, 1/(4f'^2(\delta))]$, the solution $\phi^{\pm}(\delta, x) := \phi(x)$ of* (5.8) *is a super/subsolution on $(-\infty, 0]$.*

The comparison. Consider the function

$$W^{\pm}(\xi, x) = \int_{\phi^{\pm}(\delta,x)}^{U(x+\xi)} \frac{ds}{f(s)[1 + f'(s)/c^2]} \qquad x \leq 1, \xi \in \mathbb{R}.$$

Following a proof similar to that for Lemma 4.3, we can show that (4.2) holds with $W = W^{\pm}$, $A = A^{\pm} \in [-\infty, \infty]$ and $\nu = 1/c$. Note that

$$\begin{aligned}W^+ - W^- = &\int_{\phi^+}^{\delta} \left\{\frac{1}{f[1 + f'/c^2]} - \frac{1}{f[1 + f'/c^2 + Kf'^2]}\right\} ds \\ &- \int_{\phi^-}^{\delta} \left\{\frac{1}{f[1 + f'/c^2]} - \frac{1}{f[1 + f'/c^2 - Kf'^2]}\right\} ds,\end{aligned}$$

since the two integrals involving K cancel each other. Sending $x \to -\infty$ and using $\phi^{\pm}(-\infty) = 0$ and $\int_0^{\epsilon} f'^2(s)/f(s)ds < \infty$, we then obtain

$$\lim_{x\to-\infty}\{W^+(\xi, x) - W^-(\xi, x)\} = \int_0^{\delta} \frac{2Kf'^2}{f\{[1 + f'/c^2]^2 - [Kf'^2]^2\}}\, ds < \infty.$$

We now show that $A^+ > -\infty$. Suppose on the contrary that $A^+ = -\infty$. For each $\delta \in (0, \delta_0]$, taking $K = 1/(4f'(\delta)^2)$ we see that

$$\frac{\phi^{+\prime}(x)}{f(\phi^+(x))} = \frac{1}{c} - \frac{f'(\phi^+)}{c^3} + \frac{f'^2(\phi^+)}{4cf'^2(\delta)} \geqslant \frac{1}{c} + \frac{1}{8c} \quad \forall\, x \in [0,1]$$

if δ_0 is small enough. As we know that $\lim_{x\to-\infty} U'/f(U) = 1/c$, there exits $\xi < 0$ such that $U'/f(U) < 1/c + 1/(8c)$ for all $x \leq \xi + 1$. Now set $\delta = U(\xi)$ and compare $U(\xi + \cdot)$ and $\phi^+(\delta, \cdot)$ on $(-\infty, 0]$.

As $\phi^{+\prime}/f(\phi^+) > U'/f(U)$ on $[0,1]$ and $\phi(0) = U(\xi + 0)$, we have $\phi^+(\cdot) > U(\xi + \cdot)$ on $(0,1]$. Also, $A^+ = -\infty$ implies that $\phi^+(x) > U(\xi + x)$ for all $x \ll -1$. By comparison, $\phi^+ > U$ on $(-\infty, 0]$, contradicting $\phi^+(0) = U(\xi + 0)$. Thus $A^+ > -\infty$. Similarly, using ϕ^-, we can show that $A^- < \infty$. Hence $A^\pm$ are finite.

Finally, we observe that

$$\lim_{x\to-\infty} W^+(0,x) = \lim_{x\to-\infty} \left\{ \int_\delta^{U(x)} \frac{ds}{f(s)[1 + f'(s)/c^2]} - \frac{x}{c} \right\} - \int_0^\delta \left\{ \frac{1}{1 + f'(s)/c^2} - \frac{1}{1 + f'(s)/c^2 + Kf'^2(s)} \right\} \frac{ds}{f(s)},$$

the assertion of the theorem, i.e., (1.12) thus follows. □

As an illustration, we consider the case when

$$f(u) = \kappa u^2(1-u)^p \qquad (\kappa > 0,\ p \geqslant 1).$$

Then for some integral constant a

$$\int_{1/2}^u \frac{ds}{f(s)[1 + f'(s)/c^2]} = -\frac{1}{\kappa u} + \left(\frac{p}{\kappa} - \frac{2}{c^2}\right) \ln u + a + O(u) \quad \text{as } u \to 0.$$

After translation, we see that, as $x \to -\infty$,

$$-\frac{1}{\kappa U(x)} + \left(\frac{p}{\kappa} - \frac{2}{c^2}\right) \ln U(x) = \frac{x}{c} + o(1).$$

This implies that, as $x \to -\infty$,

$$\frac{1}{U(x)} = \frac{\kappa|x|}{c} + O(\ln|x|) = \frac{\kappa|x|}{c}\Big(1 + o(1)\Big), \qquad \ln U(x) = \ln \frac{c}{\kappa|x|} + o(1).$$

Thus, after another translation,

$$\begin{aligned} U(x) &= \frac{c}{\kappa[|x| - x_0 + o(1)] + (p\,c - 2\kappa/c)\ln|x|} \\ &= \frac{c}{\kappa|x|} - \frac{(pc^2 - 2\kappa)\ln|x|}{\kappa^2 x^2} - \frac{cx_0 + o(1)}{\kappa x^2} \quad \text{as } \ x \to -\infty. \end{aligned}$$

Note that the translation is distinguished by the third term in the Taylor's expansion.

Finally, observe that

$$\int_{1/2}^u \frac{ds}{f(s)[1 + f'(s)/c^2]} = \int_{1/2}^u \frac{ds}{f(s)} - \frac{\ln f(u)}{c^2} + a + o(1) \quad \text{as } u \to 0.$$

In particular, if $f(u) = \kappa u^{1+q}[1 + o(1)]$ for some $q > 0$, then $U \propto |x|^{-1/q}$ so that $\ln f(U) \approx -b \ln |x| + B + o(1)$ for some $b > 0$ and $B \in \mathbb{R}$. Therefore, it is generic that for some constants $b > 0$ and $x_0 \in \mathbb{R}$,

$$\int_{1/2}^{U(x)} \frac{ds}{f(s)} = \frac{c[x + x_0 + o(1)] - b \ln |x|}{c^2}.$$

In a similar manner, we can establish an asymptotic expansion near ∞. We omit the details.

Acknowledgments. We are grateful to the anonymous referees for many helpful comments.

DEAD CORES AND BURSTS FOR QUASILINEAR SINGULAR ELLIPTIC EQUATIONS*

PATRIZIA PUCCI† AND JAMES SERRIN‡

Abstract. We consider divergence structure quasilinear singular elliptic partial differential equations on domains of $\mathbb{R}^n$ and show that there exist solutions with dead cores and, furthermore, solutions which involve both a dead core and *bursts* within the core. The results are obtained under appropriate monotonicity conditions on both the nonlinearity and the elliptic operator. Important special cases treated here are the p-Laplace and the mean curvature operators.

We also study related problems for p-Laplace equations with weights, which include the Matukuma equation as a prototype.

While it is usually thought that dead cores arise due to loss of smoothness of the underlying equation, we show by examples that they can occur equally for analytic p-Laplace equations.

Key words. quasilinear singular elliptic equations, dead cores

1. Introduction.

We consider quasilinear elliptic partial differential equations having the canonical divergence structure

$$\operatorname{div}\{A(|Du|)Du\} = f(u) \quad \text{in } \Omega. \tag{1.1}$$

Here Ω is a domain (connected open set) in $\mathbb{R}^n$, $n \geq 1$, and Du denotes the vector gradient of the given function $u = u(x)$, $x \in \Omega$. *Unless otherwise stated explicitly, we assume throughout the paper the following conditions on the operator $A = A(\varrho)$ and the nonlinearity $f = f(u)$:*

(A1) $A \in C(\mathbb{R}^+)$, $\mathbb{R}^+ := (0, \infty)$;

(A2) $\varrho \mapsto \varrho A(\varrho)$ is strictly increasing in $\mathbb{R}^+$ and $\varrho A(\varrho) \to 0$ as $\varrho \to 0$;

(F1) $f \in C(\mathbb{R})$; and

(F2) $f(0) = 0$, f is nondecreasing on $\mathbb{R}$, and $f(u) > 0$ for $u > 0$.

Condition (A2) is a minimal requirement for ellipticity of (1.1). Furthermore, it allows both singular and degenerate behavior of the operator A at $\varrho = 0$, that is, at critical points of u. We emphasize that no assumptions of differentiability are made on either A or f.

We also study the related elliptic equation

$$\operatorname{div}(g(|x|)|Du|^{p-2}Du) = h(|x|)f(u) \quad \text{in } \Omega, \quad p > 1, \tag{1.2}$$

where $g,\ h : \mathbb{R}^+ \to \mathbb{R}^+$ are radial functions of class $C^1(\mathbb{R}^+)$ and where the general elliptic operator A is replaced by the p-Laplacian function $A(\varrho) = \varrho^{p-2}$. The celebrated Matukuma equation is a prototype for (1.2).

By a *classical solution* (or a classical distribution solution) of (1.1) or (1.2) in Ω we mean a function $u \in C^1(\Omega)$ which satisfies (1.1) or (1.2) in the distribution sense.

With the notation $\Phi(\varrho) = \varrho A(\varrho)$ when $\varrho > 0$, and $\Phi(0) = 0$, we introduce the function

$$H(\varrho) = \varrho\Phi(\varrho) - \int_0^\varrho \Phi(s)ds, \qquad \varrho \geq 0.$$

This function is easily seen to be strictly increasing, as follows from the inequality

$$\varrho_1\Phi(\varrho_1) - \varrho_0\Phi(\varrho_0) > (\varrho_1 - \varrho_0)\Phi(\varrho_1) > \int_{\varrho_0}^{\varrho_1} \Phi(s)ds$$

when $\varrho_1 > \varrho_0 \geq 0$. Alternatively, monotonicity follows from the representation

$$H(\varrho) = \int_0^{\Phi(\varrho)} \Phi^{-1}(s)ds, \qquad \varrho \geq 0,$$

this being a consequence of the Stieltjes formula $H(\varrho) = \int_0^\varrho s\, d\Phi(s)$.

For the Laplace operator, that is, when (1.1) takes the classical form

$$\Delta u = f(u),$$

we have $A(\varrho) \equiv 1$ and $H(\varrho) = \frac{1}{2}\varrho^2$. Similarly, for the degenerate p-Laplace operator, here denoted by Δ_p, $p > 1$, we have $A(\varrho) = \varrho^{p-2}$ and $H(\varrho) = \varrho^p/p'$, while for the mean curvature operator, one has $A(\varrho) = 1/\sqrt{1+\varrho^2}$ and $H(\varrho) = 1 - 1/\sqrt{1+\varrho^2}$. In the last example, note the anomalous behavior $\Phi(\infty) = H(\infty) = 1$, a possibility which requires extra care and will be treated and discussed separately.

It is also worth observing that (1.1) is precisely the Euler–Lagrange equation for the variational integral

$$I[u] = \int_\Omega \{\mathcal{G}(|Du|) + F(u)\}dx, \qquad F(u) = \int_0^u f(s)ds,$$

where $\mathcal{G}$ and A are related by $A(\varrho) = \mathcal{G}'(\varrho)/\varrho$, $\varrho > 0$. In this case $H(\varrho) = \varrho\mathcal{G}'(\varrho) - \mathcal{G}(\varrho)$, the pre-Legendre transform of $\mathcal{G}$. Similarly, the variational integral for (1.2) is given by

$$I[u] = \int_\Omega \left\{ g(|x|)\frac{|Du|^p}{p} + h(|x|)F(u) \right\} dx,$$

where now $H(\varrho) = \varrho^p/p'$ and p' is the Hőlder conjugate of p.

An elliptic equation or inequality is said to have a *dead core solution* u in some domain $\Omega \subset \mathbb{R}^n$ provided that there exists an open subset Ω_1 with compact closure in Ω, called the *dead core* of u, such that

$$u \equiv 0 \quad \text{in } \Omega_1, \qquad u > 0 \quad \text{in } \Omega \setminus \overline{\Omega_1}.$$

The condition $u > 0$ could be replaced by $u \neq 0$, but for definiteness (and physical reality) we prefer the condition as stated. By the strong maximum principle (see Theorem 1.1 of [7, 8]) a nonnegative solution of (1.1) or (1.2) can have a dead core only if

$$\int_{0+} \frac{ds}{H^{-1}(F(s))} < \infty, \tag{1.3}$$

where H^{-1} is the inverse of H. *We assume that condition* (1.3) *holds throughout the sequel, except for Theorems* 1.2, 1.3, 6.2, *and* 6.3.

The equation $\Delta u = u^q$, for example, allows dead cores only if $0 < q < 1$. Actually condition (1.3) is not only necessary but also sufficient for the existence of solutions with dead cores. More specifically, we have the following main result for (1.1).

THEOREM 1.1. *Suppose* $\Phi(\infty) = H(\infty) = \infty$. *Assume the dead core condition* (1.3) *holds and let* u *be a solution of* (1.1), *with* $0 \le u(x) \le m$ *on* $\partial\Omega$ *for some positive constant* m. *Then the following properties are valid:*

(a) $0 \le u < m$ *in* Ω.

(b) *Assume that*

$$C = \int_0^\infty \frac{ds}{H^{-1}(F(s)/n)} < \infty, \tag{1.4}$$

and let B_R *be a ball with radius* $R \ge C$, *compactly contained in* Ω. *Then* u *has a dead core in* Ω *for all* $m > 0$.

(c) *If* B *is any ball compactly contained in* Ω, *then* $u \equiv 0$ *in* B *provided that* $m > 0$ *is suitably small.*

Equation (1.2) allows a corresponding dead core result, which however we defer until section 6.

A more refined version of Theorem 1.1 can be obtained when $\Omega = B_R$, where B_R is any open ball in $\mathbb{R}^n$, $n \ge 1$, of radius $R > 0$. Until explicitly noted in section 9, we continue to assume that $\Phi(\infty) = H(\infty) = \infty$.

THEOREM 1.2. *The problem*

$$\begin{cases} \operatorname{div}\{A(|Du|)Du\} = f(u) & \text{in } B_R, \\ u = m > 0 \quad \text{on } \partial B_R, & u \in C(\overline{B_R}), \end{cases} \tag{1.5}$$

admits a unique classical (distribution) solution u, *necessarily radial. Moreover* $u = u(r) = u(r, m)$ *is of class* $C^1[0, R]$ *and satisfies* $u \ge 0$, $u' \ge 0$ *in* $[0, R]$ *and* $u'(0) = 0$, *where* $' = d/dr$.

Finally, at any $r > 0$ *where* $u(r, m) > 0$ *we have also* $u'(r, m) > 0$.

It follows from Theorem 1.2 that the solution $u(\cdot\,, m)$ must be one of the following three types:

1. $u > 0$ in B_R.
2. $u(0, m) = 0$ and $u'(r, m) > 0$ when $r > 0$.
3. There exists $S \in (0, R)$ such that $u \equiv 0$ in B_S and $u'(r, m) > 0$ when $r > S$.

That is, in case 3 the solution u of (1.5) has a dead core B_S. The solution $u = u(\cdot\,, m)$ of (1.5) has further properties of interest, given in the next result.

THEOREM 1.3. *The function* $u = u(\cdot\,, m)$ *is continuous and nondecreasing in the variable* $m\,(> 0)$, *and* $u < m$ *in* B_R.

The following theorem gives an important relation between the value m and dead cores solutions of (1.5).

THEOREM 1.4. *Let* $u(\cdot\,, m)$ *be the unique solution of* (1.5). *Then either* $u(\cdot\,, m)$ *has a dead core for all* $m > 0$, *or there is a unique (finite) number*

$$m = m_0 = m_0(R) > 0$$

for which a solution $u_0 = u_0(r) = u_0(r\,, m_0)$ *of* (1.5) *in* B_R *exists, with the properties that*

(i) $u_0(0) = 0$;

(ii) $u(0\,,m) > 0$ *for every* $m > m_0$*; and*
(iii) $u(\cdot\,,m)$ *has a dead core for every* $0 < m < m_0$.

For convenience we define $m_0 = m_0(R)$ to be ∞ when $u(0\,,m) = 0$ for all $m > 0$. The examples

$$\Delta u = (\operatorname{sign} u)\sqrt{|u|}, \tag{1.6}$$

$$\Delta_4 u = u \tag{1.7}$$

are particularly interesting as illustrations of the main theorems above. Indeed, both of these are included in the canonical case

$$\Delta_p u = u|u|^{q-1}, \qquad p > 1, \qquad q > 0,$$

for which $F(u) = |u|^{q+1}/(q+1)$. Here the dead core condition (1.3) reduces exactly to

$$0 < q < p - 1.$$

For these special cases, we search for u_0 in the form $c\,r^k$, c, $k > 0$. Then from (1.5) one finds

$$k = \frac{p}{p-1-q}, \qquad c = k^{-k/p'}(n + kq)^{-k/p}, \qquad m_0 = c\,R^k. \tag{1.8}$$

For the case (1.6) we have $p = 2$, $q = 1/2$, $k = 4$, so that

$$m_0 = \frac{1}{(n+2)^2}\left(\frac{R}{2}\right)^4,$$

while $p = 4$, $q = 1$, $k = 2$ for (1.7), and, in turn,

$$m_0 = \frac{R^2}{2\sqrt{2(n+2)}},$$

which reduces exactly to $m_0 = R^4/400$ and $m_0 = R^2/2\sqrt{10}$ when $n = 3$. In particular for the unit radius $R = 1$ we obtain, respectively, the unexpectedly small numbers $m_0 = 0.00125$ and $m_0 \cong 0.158$.

Equation (1.7), when written in full for $n = 2$, has the form

$$|Du|^2\Delta u + 2u_x^2 u_{xx} + 4u_x u_y u_{xy} + 2u_y^2 u_{yy} = u,$$

which is analytic in all its variables. Thus dead core behavior is not due simply to a lack of smoothness in the basic equation. In fact (1.7) is an analytic partial differential equation, elliptic except at the singular point $Du = 0$, which has a nonanalytic solution.

As a final example, consider the equation

$$\Delta u = (\operatorname{sign} u)\sqrt{|u|} + u|u|^2.$$

Here $A(\varrho) \equiv 1$, $H^{-1}(\varrho) = \sqrt{2\varrho}$, and $F(u) = \frac{2}{3}|u|^{3/2} + \frac{1}{4}|u|^4$. Then

$$C = \sqrt{\frac{n}{2}}\int_0^\infty \frac{ds}{\sqrt{(2/3)s^{3/2} + s^4/4}} < \infty.$$

By numerical calculation $C \cong 6.4334$ if $n = 2$. Therefore, by the results of section 4 we have $m_0 = \infty$ whenever $R \geq 7$. In particular, for the problem

$$\begin{cases} \Delta u = (\operatorname{sign} u)\sqrt{|u|} + u|u|^2 & \text{in } B_7 \subset \mathbb{R}^2, \\ u = m > 0 & \text{on } \partial B_7, \end{cases}$$

a dead core occurs for all $m > 0$. This result also follows without recourse to numerical calculation, since one can write, when $n = 2$,

$$C = \left(\frac{9}{2}\right)^{1/5} \int_0^\infty \frac{dt}{\sqrt{t^{3/2} + t^4}} < \left(\frac{9}{2}\right)^{1/5} \left\{ \int_0^1 \frac{dt}{\sqrt{t^{3/2}}} + \int_1^\infty \frac{dt}{\sqrt{t^4}} \right\} = 5(4.5)^{1/5} \cong 6.75.$$

The case $n = 3$ can be treated in the same way, with $C \cong 7.879$, but here the radius $R = 7$ should be replaced by $R = 8$.

In a related paper [1] Bandle and Vernier-Piro also studied the dead core problem for the weighted equation (1.2). Because of the different assumptions on the weights g and h made there it is hard to compare the two papers. A further dead core theorem concerning p-regular equations (see section 11 of [7, 8]) was given by Diaz and Veron [3]. Again the assumptions are different enough to make it difficult to compare the results.

Sperb [10] considers similar dead core problems for the particular special case of the Laplace equation without weights, that is, $A \equiv 1$, $g \equiv 1$, and $h \equiv 1$. He estimates the critical value m_0 for more general domains than balls, but only for the homogeneous case $f(u) = \text{Const}\, u|u|^{q-1}$, $0 < q < 1$. For balls B_R his estimate is weaker than our exact result (1.8). Similarly his estimates for the size of dead cores apply to more general domains than balls, but again are weaker than ours in the latter case.

Theorems 1.4 for the general equation (1.1) and 7.2 for the weighted p-Laplace equation (1.2) seem to capture and extend many of the ideas of these earlier papers.

2. Proof of Theorem 1.2. *Existence of a radial solution u of* (1.5)*, with $u \geq 0$, $u' \geq 0$, and $u'(0) = 0$.* For the purpose of this proof only, we shall redefine f so that $f(v) = f(m)$ for all $v \geq m$, and $f(v) = 0$ when $v \leq 0$. This will not affect the conclusion of the theorem, since clearly any ultimate solution u of (1.5), with $u \geq 0$, $u' \geq 0$ in $[0, R]$, satisfies $0 \leq u \leq m$.

We shall make use of the Leray–Schauder fixed point theorem, as in Proposition 4.1 of [7, 8]. Denote by X the Banach space $X = C[0, R]$, endowed with the usual norm $\|\cdot\|_\infty$, and let $\mathcal{T}$ be the mapping from X to X defined pointwise for all $w \in X$ by

$$\mathcal{T}[w](r) = m - \int_r^R \Phi^{-1}\left(s^{1-n} \int_0^s t^{n-1} f(w(t))dt\right) ds, \qquad r \in [0, R]. \tag{2.1}$$

Clearly $\mathcal{T}[w](R) = m$. Also

$$\mathcal{T}[w]'(r) = \Phi^{-1}\left(r^{1-n} \int_0^r t^{n-1} f(w(t))dt\right), \qquad r \in (0, R]. \tag{2.2}$$

Obviously $\mathcal{T}[w]'$ is continuous and nonnegative in $(0, R]$, since $0 \leq f(w) \leq f(m)$ for all $w \in X$. Moreover $r^{1-n} \int_0^r t^{n-1} f(w(t))dt$ tends to zero as $r \to 0^+$. Therefore $\mathcal{T}[w]'(r)$ approaches 0 as $r \to 0^+$, since $\Phi(0) = 0$, and in turn $\mathcal{T}[w] \in C^1[0, R]$ with $\mathcal{T}[w]'(0) = 0$.

We claim that if w is a fixed point of $\mathcal{T}$ in X, then $w(0) \geq 0$. Otherwise $w(0) < 0$ and $w(R) = m > 0$. Thus there exists a first point $r_0 \in (0, R)$ such that $w(r) < 0$ in $[0, r_0)$ and $w(r_0) = 0$. Consequently $f(w(r)) = 0$ in $[0, r_0]$ and so $w' \equiv 0$ for $r \in [0, r_0]$ by (2.2). Hence $w(r_0) = w(0) < 0$, which is impossible, proving the claim.

Define the homotopy $\mathcal{H} : X \times [0, 1] \to X$ by

$$\mathcal{H}[w, \sigma](r) = \sigma m - \int_r^R \Phi^{-1}\left(\sigma s^{1-n} \int_0^s t^{n-1} f(w(t))dt\right) ds. \tag{2.3}$$

By the above argument, any fixed point $w_\sigma = \mathcal{H}[w_\sigma, \sigma]$ is of class $C^1[0, R]$ and has the properties $w_\sigma \geq 0$, $w'_\sigma \geq 0$ in $[0, R]$, and $w_\sigma(R) = \sigma m$. Additionally, by (2.2) we find that $\Phi(w'_\sigma) \in C^1[0, R]$, and then from (2.1) that w_σ is a classical (distribution) solution of the problem

$$\begin{cases} [r^{n-1}\Phi(w'_\sigma(r))]' - \sigma r^{n-1} f(w_\sigma(r)) = 0 \quad \text{in } (0, R], \\ w'_\sigma(0) = 0, \quad w_\sigma(R) = \sigma m. \end{cases} \tag{2.4}$$

In turn, it is evident that any function w_1 which is a fixed point of $\mathcal{H}[w, 1]$ (that is $w_1 = \mathcal{H}[w_1, 1]$) is a nonnegative radial distribution solution of problem (1.5), in $B_R \setminus \{0\}$, with $w'(0) = 0$ and $w' \geq 0$ in $[0, R]$.

Since $f > 0$ for $u > 0$ it follows equally from (2.4) that the final statement of the theorem is valid.

We assert that such a fixed point $w = w_1$ exists. We shall use Browder's version of the Leray–Schauder theorem for this purpose (see Theorem 11.6 of [5]).

To begin with, obviously $\mathcal{H}[w, 0] \equiv 0$ for all $w \in X$; that is, $\mathcal{H}[w, 0]$ maps X into the single point $w_0 = 0$ in X. (This is the first hypothesis required in the application of the Leray–Schauder theorem.)

We show next that $\mathcal{H}$ is compact from $X \times [0, 1]$ into X. First, $\mathcal{H}$ is continuous on $X \times [0, 1]$. Indeed, let $w_j \to w$, $\sigma_j \to \sigma$, $(w_j, \sigma_j) \in X \times [0, 1]$. Then in (2.3) clearly $\sigma_j f(w_j) \to \sigma f(w)$, since the modified function f is continuous on $\mathbb{R}$. Hence $\mathcal{H}[w_j, \sigma_j] \to \mathcal{H}[w, \sigma]$, as required.

Next let $(w_k, \sigma_k)_k$ be a bounded sequence in $X \times [0, 1]$. It is clear from (2.2) that

$$\|\mathcal{H}[w_k, \sigma_k]'\|_\infty \leq \Phi^{-1}\left(Rf(m)/n\right). \tag{2.5}$$

As an immediate consequence of the Ascoli–Arzelà theorem $\mathcal{H}$ then maps bounded sequences into relatively compact sequences in X, so $\mathcal{H}$ is compact.

To apply the Leray–Schauder theorem it is now enough to show that there is a constant $M > 0$ such that

$$\|w\|_\infty \leq M \quad \text{for all } (w, \sigma) \in X \times [0, 1], \quad \text{with } \mathcal{H}[w, \sigma] = w. \tag{2.6}$$

Let (w, σ) be a pair of type (2.6). But, as observed above, one has $w \geq 0$, $w' \geq 0$, so that $\|w\|_\infty = w(R) \leq \sigma m \leq m$. Thus we can take $M = m$ in (2.6).

The Leray–Schauder theorem therefore implies that the mapping $\mathcal{T}[w] = \mathcal{H}[w, 1]$ has a fixed point $w \in X$ as asserted, which is the required solution of (1.5) in $B_R \setminus \{0\}$. *The fixed point $u = w$ is a C^1 distribution solution of* (1.5) *in* B_R. The proof is standard. Let $\varphi \in C_c^1(B_R)$. We have to show that

$$\int_{B_R} A(|Du|)Du \cdot D\varphi \, dx = -\int_{B_R} f(u)\varphi \, dx.$$

To this end let $\psi = \varphi k_\varepsilon$, $0 < 2\varepsilon < R$, where

$$k_\varepsilon(x) = \begin{cases} 0 & \text{for} \quad |x| \le \varepsilon, \\ 1 & \text{for} \quad |x| \ge 2\varepsilon, \end{cases}$$

and such that $k_\varepsilon \in C^1(\mathbb{R}^n)$, $0 \le k_\varepsilon \le 1$ in $\mathbb{R}^n$, $|Dk_\varepsilon(x)| \le 2/\varepsilon$ for all x with $\varepsilon \le |x| \le 2\varepsilon$. Consequently, using ψ as a test function in $B_R \setminus \{0\}$, we get

$$\begin{aligned} &\int_{B_R \setminus B_{2\varepsilon}} A(|Du|)Du \cdot D\varphi \, dx + \int_{B_{2\varepsilon} \setminus B_\varepsilon} A(|Du|)Du \cdot (k_\varepsilon D\varphi + \varphi Dk_\varepsilon) dx \\ &\quad = -\int_{B_R \setminus B_{2\varepsilon}} f(u)\varphi dx - \int_{B_{2\varepsilon} \setminus B_\varepsilon} f(u)k_\varepsilon \varphi dx. \end{aligned}$$

Now

$$\begin{aligned} \left| \int_{B_{2\varepsilon} \setminus B_\varepsilon} A(|Du|)Du \cdot (k_\varepsilon D\varphi + \varphi Dk_\varepsilon) dx \right| &\le \sup_{B_{2\varepsilon}} \left\{ \Phi(|Du|) \cdot \left[|D\varphi| + \frac{2}{\varepsilon} |\varphi| \right] \right\} \cdot |B_{2\varepsilon}| \\ &= o(\varepsilon^{n-1}) \end{aligned}$$

since $Du(0) = \mathbf{0}$, and Φ is continuous at $\varrho = 0$ by (A2). Moreover

$$\left| \int_{B_{2\varepsilon} \setminus B_\varepsilon} f(u)k_\varepsilon \varphi \, dx \right| \le \text{ Const } \varepsilon^n.$$

Letting $\varepsilon \to 0$ we get the required conclusion.

Uniqueness of C^1 distribution solutions of (1.5). This is an immediate consequence of the weak comparison principle given in Theorem 5.4 of [7, 8].

THEOREM 2.1 (weak comparison principle [7, 8]). *Assume* (A1), (A2), (F1), *and* (F2) *are satisfied. Let u and v be, respectively, classical solutions of*

$$\operatorname{div}\{A(|Du|)Du\} - f(u) \ge 0 \quad \textit{and} \quad \operatorname{div}\{A(|Dv|)Dv\} - f(v) \le 0$$

in a bounded domain Ω; that is, u is a subsolution and v is a supersolution of (1.1). *Suppose also that u and v are continuous in $\overline{\Omega}$, with $u \le v$ on $\partial\Omega$. Then $u \le v$ in Ω.*

3. Proof of Theorem 1.3. *Monotonicity.* This follows from the weak comparison principle, as above.

Continuity. Let $0 < m_1 < m_2$ and write $u_1(r) = u(r, m_1)$ and $u_2(r) = u(r, m_2)$. We show that

$$0 \le u_2(r) - u_1(r) \le m_2 - m_1, \qquad r \in [0, R]. \tag{3.1}$$

By (2.1), for all $r \in [0, R]$,

$$\begin{aligned} u_2(r) &= m_2 - \int_r^R \Phi^{-1}\left(s^{1-n} \int_0^s t^{n-1} f(u_2(t)) dt \right) ds, \\ u_1(r) &= m_1 - \int_r^R \Phi^{-1}\left(s^{1-n} \int_0^s t^{n-1} f(u_1(t)) dt \right) ds. \end{aligned}$$

Then by subtraction

$$\begin{aligned} u_2(r) - u_1(r) &= m_2 - m_1 \\ &\quad - \int_r^R \left[\Phi^{-1}\left(s^{1-n} \int_0^s t^{n-1} f(u_2(t)) dt \right) - \Phi^{-1}\left(s^{1-n} \int_0^s t^{n-1} f(u_1(t)) dt \right) \right] ds. \end{aligned}$$

The function Φ^{-1} is strictly increasing by (A2) and f is nondecreasing by (F2). Therefore, since $u_1 \le u_2$ in $[0,R]$ by monotonicity, one sees that the quantity in square brackets above is nonnegative, and (3.1) is proved.

Proof that $u < m$ in B_R. By (2.1) it is enough to show that

$$I = \int_r^R \Phi^{-1}\left(s^{1-n}\int_0^s t^{n-1}f(u(t))dt\right)ds > 0 \quad \text{for } r \in [0,R).$$

Clearly $u > 0$ in some interval $(r_0, R]$ with $r_0 \ge 0$, and in turn $f(u(s)) > 0$ in $(r_0, R]$ by (F2). Therefore

$$I \ge \int_{\max\{r_0,\, r\}}^R \Phi^{-1}\left(s^{1-n}\int_{r_0}^s t^{n-1}f(u(t))dt\right)ds > 0,$$

as required. □

4. The critical value m_0. We begin with a preliminary result, of interest in itself.

THEOREM 4.1. *If $u_1 = u(\cdot, m_1)$ has a dead core B_{S_1}, then $u_2 = u(\cdot, m_2)$, where $m_2 < m_1$, has a dead core B_{S_2}, with $S_2 > S_1$. Similarly, if either $u_1(0) > 0$ or $u_1(0) = 0$ and $u_1(r) > 0$ for $r \in (0,R]$, then $u_2 > u_1$ in B_R when $m_2 > m_1$.*

Proof. To prove the first part of the lemma, assume for contradiction that $m_2 < m_1$, and either $u_2(r) > 0$ in $(0,R]$, or $0 < S_2 \le S_1$. In the first of these cases the solutions u_1 and u_2 must cross at some point $r_0 \in (S_1, R)$. Then applying Theorem 2.1 we find that $u_1 \equiv u_2$ in $[0, r_0]$, which is an obvious contradiction since $u_2(r) > 0$ on $(0, r_0]$, while $u_2 \equiv u_1 \equiv 0$ in $[0, S_1]$. The next case $0 < S_2 < S_1$ leads to a contradiction in the same way.

The remaining case, when $S = S_2 = S_1 > 0$, needs more care. For $\varepsilon \in (0,R)$ define

$$u_\varepsilon(r) = \begin{cases} 0, & r \in [0,\varepsilon], \\ u_1(r-\varepsilon), & r \in (\varepsilon, R]. \end{cases}$$

If $\varepsilon > 0$ is suitably small then one has $m_1 > u_\varepsilon(R) > m_2 = u_2(R)$, while at the same time

$$u_2(S+\varepsilon) > 0 = u_1(S) = u_\varepsilon(S+\varepsilon). \tag{4.1}$$

Thus there is a point $r_0 \in (S+\varepsilon, R)$ where u_ε and u_2 cross.

We assert that u_ε is a supersolution of (1.1) in the annulus $B_R \setminus \overline{B_\varepsilon}$. Indeed in this set we have

$$\begin{aligned} \operatorname{div}\{A(|Du_\varepsilon|)Du_\varepsilon\} - f(u_\varepsilon) &= \{A(|u_\varepsilon'|)u_\varepsilon'\}' + \frac{n-1}{r}A(|u_\varepsilon'|)u_\varepsilon' - f(u_\varepsilon) \\ &= \left(\frac{n-1}{r} - \frac{n-1}{r-\varepsilon}\right)\Phi(u_1'(r-\varepsilon)) \\ &= -\varepsilon\,\frac{n-1}{r(r-\varepsilon)}\Phi(u_1'(r-\varepsilon)) \le 0. \end{aligned} \tag{4.2}$$

Observing that $u_2(0) = u_\varepsilon(0) = 0$, we can then apply the comparison principle, Theorem 2.1, in B_{r_0}. Therefore $u_2 \le u_\varepsilon$ in $[0, r_0]$, which contradicts (4.1) at the point $r = S + \varepsilon$ and completes the first part of the proof.

To obtain the second part of the theorem, assume for contradiction that $u_2(0) = u_1(0)$ when $m_2 > m_1$. Of course by Theorem 1.2 we have $u_1'(r) > 0$ for $r \in (0, R]$. Define

$$\tilde{u}_\varepsilon(r) = \begin{cases} u_2(0), & r \in [0, \varepsilon], \\ u_2(r - \varepsilon), & r \in (\varepsilon, R], \end{cases}$$

where ε is chosen so small that $m_2 > \tilde{u}_\varepsilon(R) > m_1 = u_1(R)$. On the other hand $u_1(\varepsilon) > \tilde{u}_\varepsilon(\varepsilon) = 0$. Hence there is a crossing point $r_0 \in (\varepsilon, R)$ where $u_1(r_0) = \tilde{u}_\varepsilon(r_0)$. As before u_ε is a supersolution of (1.1) in B_R so that $u_1 \le \tilde{u}_\varepsilon$ in B_{r_0} by Theorem 2.1. Therefore, $u_1 \equiv \tilde{u}_\varepsilon \equiv 0$ in $[0, \varepsilon]$, which is impossible, since $u_1(r) > 0$ for all $r \in (0, R]$.

That $u_2 > u_1$ in all B_R now follows at once, since otherwise u_2 and u_1 would cross at some value $r = r_0$ in which case comparison would lead to the absurd result $u_2 \equiv u_1$ in B_{r_0}. □

Proof of Theorem 1.4. For the purpose of this proof, we suppose that there is some $m > 0$ for which $u(0\,, m) > 0$.

Existence of u_0. Define

$$m_0 = \inf\{m > 0 \ : \ u(0, m) > 0\}. \tag{4.3}$$

We assert first that $m_0 > 0$. Let $\bar{m} > 0$ be so small that

$$C_{\bar{m}} = \int_0^{\bar{m}} \frac{ds}{H^{-1}(F(s)/n)} < R, \tag{4.4}$$

which of course is possible by assumption (1.3); see Lemma 3.2 of [7, 8]. Define $v(r) = w(r - S)$, $r \in [S, R]$, $S = R - C_{\bar{m}}$, where w is the function constructed in the dead core Lemma 7.1 of [7, 8], with $\sigma = 1/n$ and $C = C_{\bar{m}}$. We assert that v is a supersolution of (1.1) in the set $B_R \setminus \overline{B}_S$. In fact

$$\operatorname{div}\{A(|Dv|)Dv\} = [\Phi(v')]' + \frac{n-1}{r}\Phi(v') \le \left\{1 + \frac{n-1}{r}(r - S)\right\} \sigma f(v)$$

by (iii) and (iv) of Lemma 7.1 of [7, 8]. Thus

$$\operatorname{div}\{A(|Dv|)Dv\} \le \left\{1 - \frac{n-1}{nr}S\right\} f(v) \le f(v),$$

as required. Then, since $v(S) = v'(S) = 0$ and $v(R) = \bar{m}$, by defining v to be zero on B_S, the extended function v is a supersolution of (1.1) in B_R. By the comparison principle, Theorem 2.1, we find that $u(\cdot\,, \bar{m}) \equiv 0$ in B_S. Therefore $m_0 \ge \bar{m} > 0$ by (4.3) and the claim is proved.

Next, if (i) would be false, then $u_0(0) > 0$ and by Theorem 1.3 also $u(0\,, m) > 0$ for all $m > 0$ sufficiently near m_0, which would contradict (4.3). Property (ii) is again a direct consequence of the definition (4.3) of m_0 and Theorem 1.3. Finally if there is $m \in (0, m_0)$ such that the corresponding solution $u(\cdot\,, m)$ of (1.5) has no dead core, then $u(0\,, m) \ge 0$ and $u(r\,, m) > 0$ for $r \in (0, R]$. Thus by Theorem 4.1, with $m_1 = m$ and $m_2 = m_0$, we get $u_0(0) > u(0, m) \ge 0$, contradicting (i) and proving (iii).

Uniqueness of u_0. Suppose both m_0 and $\bar{m}_0$ have the properties (i)–(iii) of the theorem. Then $u_0(0) = u_0(0\,, m_0) = 0$ by (i), while $u(0\,, m) > 0$ when $m > \bar{m}_0$ by (ii). Hence $m_0 \le \bar{m}_0$. Similarly $\bar{m}_0 \le m_0$. Therefore $\bar{m}_0 = m_0$, as desired.

The case $m_0 = \infty$. If every solution of (1.5) is such that $u(0\,,m) = 0$ for all $m > 0$, then $u(\cdot\,,m)$ has a dead core for all $m > 0$. Otherwise there would be $\bar m > 0$ for which $u(0\,,\bar m) = 0$ and $u(r\,,\bar m) > 0$ for $r \in (0, R]$. Hence $u(0\,,m) > 0$ for $m > \bar m$ by Theorem 4.1, contradicting the assumption. This also justifies the earlier agreement that $m_0 = \infty$ in this case. □

Remark. In summary, if m_0 is finite and $m > m_0$, then the solution $u = u(\cdot\,,m)$ of (1.5) is positive; namely, $u(r\,,m) > 0$ for all $r \in [0, R]$. On the other hand, if $m < m_0 \le \infty$ then the solution $u = u(\cdot\,,m)$ of (1.5) has a dead core $B_S \subset B_R$, $0 < S < R$.

5. The size of a dead core and proof of Theorem 1.1. Recall the assumption that $\Phi(\infty) = H(\infty) = \infty$, and let

$$C = \int_0^\infty \frac{ds}{H^{-1}(F(s)/n)}. \tag{5.1}$$

Clearly $0 < C \le \infty$ since the integral is convergent at 0 by (1.3) and by Lemma 3.2 of [7, 8] with $\sigma = 1/n$. Of course the integral can possibly diverge at ∞.

THEOREM 5.1. *We have*

$$m_0 = \infty \qquad \textit{if} \quad C < \infty \quad \textit{and} \quad R \ge C, \tag{5.2}$$

while

$$m_0 \ge \bar m \qquad \textit{if} \quad R < C, \tag{5.3}$$

where $\bar m$ *is defined by the relation*

$$R = \int_0^{\bar m} \frac{ds}{H^{-1}(F(s)/n)}.$$

Proof. The proof of (5.2) is essentially the same as the proof of the first part of Theorem 1.4, the only exception being that $C_{\bar m}$ given by (4.4) is replaced by C.

To obtain (5.3), we define $v(r) = w(r)$ as in the proof of Theorem 1.4, with $S = 0$, $\sigma = 1/n$, and $C = R$. Then by Lemma 7.1 of [7, 8] we have $v(0) = v'(0) = 0$, $v(R) = w(R) = \bar m$, while v is a supersolution of (1.1) in B_R. It follows by comparison that $0 \le u(r, \bar m) \le v(r)$. Hence $u(0\,,\bar m) = v(0) = 0$, and in turn from the definition (4.3) of m_0 we get $m_0 \ge \bar m$, as required in (5.3). □

THEOREM 5.2. *Let* $m < m_0$, *so that a dead core exists by Theorem* 1.4, (iii). *In particular the solution* $u = u(\cdot\,,m)$ *satisfies*

$$u \equiv 0 \qquad \textit{in } B_S \subset B_R,$$

where

$$R - \int_0^m \frac{ds}{H^{-1}(F(s)/n)} < S < R.$$

If $R \ge C$, *then for all* $m > 0$ *one has*

$$R - C < S < R.$$

Proof. The proof is the same as the first part of the proof of Theorem 1.4. □

Remark. For any $\varepsilon > 0$, if m is suitably small (depending on ε) we have $R - \varepsilon < S < R$.

Proof of Theorem 1.1. (a) That $u \geq 0$ follows from Theorem 2.1 by comparing the given solution u with the trivial solution 0.

The constant function m is a supersolution of (1.1), so that again by Theorem 2.1 we have $u \leq m$ in Ω. In fact $u < m$ in Ω. To see this, let y be any point of Ω and B a ball in Ω centered at y. Let $v(\cdot\,, m)$ be the radial solution of (1.1) in B constructed in Theorem 1.2, with $v(|x-y|\,, m) = m$ for $x \in \partial B$. Therefore $u(x) \leq m = v(|x-y|\,, m)$ for $x \in \partial B$, and in turn $u(x) \leq v(|x-y|\,, m) < m$ for $x \in B$ by the final part of Theorem 1.3.

(b) This is a direct consequence of Theorem 5.1.

(c) Clearly there exists $R > 0$ such that $\overline{B} \subset B_R \subset\subset \Omega$, with B and B_R centered at the same point of Ω. By (a) we know that $u < m$ on ∂B_R. Denote by $R - \varepsilon$ the radius of B; then by comparison, together with the remark after Theorem 5.2, we have $u \equiv 0$ in B when $m > 0$ is suitably small. □

6. The equation $\mathbf{div}\{g(|x|)|Du|^{p-2}Du\} = h(|x|)f(u)$. Consider the quasilinear singular elliptic equation

$$\mathrm{div}(g(|x|)|Du|^{p-2}Du) = h(|x|)f(u) \qquad \text{in } \Omega, \qquad p > 1, \tag{6.1}$$

where $g,\ h : \mathbb{R}^+ \to \mathbb{R}^+$ are radial functions of class $C^1(\mathbb{R}^+)$, and Ω is a domain of $\mathbb{R}^n$, $n \geq 1$, containing the origin. Prototypes of (6.1), with nontrivial functions g, h, are given, for example, by equations of Matukuma type and equations of Batt–Faltenbacher–Horst type. More precisely, the Matukuma-type equation is given by

$$\Delta_p u = \frac{f(u)}{1 + r^\sigma}, \qquad r = |x|, \qquad \sigma > 0, \tag{6.2}$$

where Δ_p denotes the p-Laplace operator, $p > 1$, and where also $g(|x|) \equiv 1$, $h(|x|) = 1/(1 + r^\sigma)$. A second example is the equation

$$\Delta_p u = \frac{r^\sigma}{(1 + r^{p'})^{\sigma/p'}} \cdot \frac{f(u)}{r^{p'}}, \qquad \sigma > 0, \tag{6.3}$$

where now $g(|x|) \equiv 1$, $h(|x|) = r^{\sigma - p'}/(1 + r^{p'})^{\sigma/p'}$.

All these equations are discussed in detail in section 4 of [6], as special cases of the main example[1]

$$\mathrm{div}(r^k|Du|^{p-2}Du) = r^\ell \left(\frac{r^s}{1 + r^s}\right)^{\sigma/s} f(u), \tag{6.4}$$
$$k \in \mathbb{R}, \qquad \ell \in \mathbb{R}, \qquad s > 0, \qquad \sigma > 0.$$

In particular, in [6] conditions on the exponents were found so that, under appropriate behavior of the nonlinearity f, radial ground states for (6.2)–(6.4) are unique.

We shall also be interested in the radial version of (6.1), when Ω is a ball B_R *centered at* 0 with radius $R > 0$, namely,

$$[a(r)|u'|^{p-2}u']' = b(r)f(u) \qquad \text{in } (0, R), \tag{6.5}$$

[1] In [6] the equation (6.1) was written in the form

$$\mathrm{div}(g(|x|)|Du|^{p-2}Du) + h(|x|)f(u) = 0.$$

The two versions are reconciled by replacing f by $-f$.

where, with obvious notation,

$$a(r) = r^{n-1}g(r), \quad b(r) = r^{n-1}h(r). \tag{6.6}$$

Motivated by the case $a(r) = b(r) = r^{n-1}$ in [6], the functions a and b are assumed to be such that (6.5) *can be transformed* by the change of variables $r \mapsto t(r)$,

$$t(r) = \int_0^r [b(s)/a(s)]^{1/p}\, ds, \qquad r \geq 0, \tag{6.7}$$

$t : \mathbb{R}_0^+ \to \mathbb{R}_0^+$, $t(0) = 0$, to the form

$$[q(t)|v_t|^{p-2}v_t]_t = q(t)f(v), \tag{6.8}$$

where

$$q(t) = [a(r(t))]^{1/p}[b(r(t))]^{1/p'}, \qquad t > 0. \tag{6.9}$$

This requires, in particular, the following conditions on the coefficients:

$$a,\ b > 0, \qquad a,\ b \in C^1(\mathbb{R}^+), \qquad (b/a)^{1/p} \in L^1[0, R]. \tag{A3}$$

We shall ask as well that the transformed equation (6.8) be compatible with the structure:

$$q \in C^1(\mathbb{R}^+), \quad q > 0 \quad \text{in} \ \ \mathbb{R}^+; \tag{Q1}$$

$$\text{there is} \quad \delta > 0 \quad \text{such that} \quad q_t > 0 \quad \text{in} \ \ (0, \delta). \tag{Q2}$$

By (Q2) the weight $q(t)$ has a finite limit as $t \to 0^+$ and in turn also $\bar{q}(r) = q(t(r))$ is bounded as $r \to 0^+$ by (6.7). Hence $b = (b/a)^{1/p}\bar{q} = O((b/a)^{1/p})$ as $r \to 0^+$ by (6.9), and so by (A3)

$$b \in L^1[0, R] \quad \text{and} \quad h \in L^1_{\text{loc}}(B_R). \tag{6.10}$$

Definition. A classical solution of (6.1) is a nonnegative function u of class $C(\Omega) \cap C^1(\Omega \setminus \{0\})$, which is a distribution solution of (6.1) in Ω, of course also with

$$g|Du|^{p-1} \in L^1_{\text{loc}}(\Omega). \tag{6.11}$$

THEOREM 6.1 (weak comparison principle). *Let u and $\tilde{u}$ be, respectively, classical super- and subsolutions of* (6.1) *in a bounded domain Ω. Suppose also that u and $\tilde{u}$ are continuous in $\overline{\Omega}$, with $u \geq \tilde{u}$ on $\partial\Omega$. Then $u \geq \tilde{u}$ in Ω.*

Proof. We follow the proof of Theorem 5.4 of [7, 8].

Let $w = u - \tilde{u}$ in $\overline{\Omega}$. If the conclusion fails, then there exists a point $x_1 \in \Omega$ such that $w(x_1) < 0$. Fix $\varepsilon > 0$ so small that $w(x_1) + \varepsilon < 0$. Consequently, since $w \geq 0$ on $\partial\Omega$ it follows that the function $w_\varepsilon = \min\{w + \varepsilon,\ 0\}$ is nonpositive and has compact support in Ω. By the distribution meaning of solutions, taking the Lipschitz continuous function w_ε as a test function, we get

$$\int_\Omega g(|x|)\{|Du|^{p-2}Du - |D\tilde{u}|^{p-2}D\tilde{u}\}Dw_\varepsilon \leq \int_\Omega h(|x|)\{f(\tilde{u}) - f(u)\}w_\varepsilon. \tag{6.12}$$

The left-hand side of (6.12) is positive since $p > 1$ and $g(|x|) > 0$ for $x \in \Omega \setminus \{0\}$ and $Dw_\varepsilon \equiv Dw = Du - D\tilde{u} \not\equiv \mathbf{0}$ when $w + \varepsilon < 0$, while otherwise $Dw_\varepsilon = \mathbf{0}$ (a.e.).

Moreover, when $w + \varepsilon < 0$ there holds $0 \le u < \tilde{u} - \varepsilon$; hence $f(\tilde{u}) - f(u) \ge 0$ since f is nondecreasing by (F2). Thus the right-hand side of (6.12) is nonpositive, since $h(|x|) > 0$ for $x \in \Omega \setminus \{0\}$, which is a contradiction. □

In the rest of this section we continue to denote by B_R the open ball *centered at* 0 with radius $R > 0$, that is, $B_R = B(0, R)$. Our first result is the analogue of Theorem 1.2, where now we use $A(\varrho) = \varrho^{p-2}$, $\Phi(\varrho) = \varrho^{p-1}$, consistent with section 1. In this case of course $\Phi(\infty) = H(\infty) = \infty$ and $\Phi^{-1}(\tau) = \tau^{1/(p-1)}$.

THEOREM 6.2. *The problem*

$$\begin{cases} \operatorname{div}\{g(|x|)|Du|^{p-2}Du\} = h(|x|)f(u) & \text{in } B_R, \\ u = m > 0 \quad \text{on } \partial B_R, \quad u \in C(\overline{B_R}), \end{cases} \tag{6.13}$$

admits a unique classical solution u, necessarily radial.

Moreover $u = u(r) = u(r, m)$ is of class $C^1[0, R]$ and satisfies $u \ge 0$, $u' \ge 0$ in $[0, R]$ and $u'(0) = 0$, where $' = d/dr$. Finally, at any $r > 0$ where $u(r, m) > 0$ we have also $u'(r, m) > 0$.

It follows from Theorem 6.2 that the solution $u(\cdot, m)$ must be one of the following three types:

1. $u > 0$ in B_R.
2. $u(0, m) = 0$ and $u'(r, m) > 0$ when $r > 0$.
3. There exists $S \in (0, R)$ such that $u \equiv 0$ in B_S and $u'(r, m) > 0$ when $r > S$.

That is, in case 3 the solution u of (1.5) has a dead core B_S.

Proof. Existence of a radial solution u of (6.13)*, with $u \ge 0$, $u' \ge 0$, and $u'(0) = 0$.* This will be accomplished by first showing that (6.8) has a solution $v = v(t)$ on $[0, T]$, $T = t(R)$, with $v \ge 0$, $v_t \ge 0$, and $v_t(0) = 0$, where $t = t(r)$ is given by (6.7).

Indeed, by following the proof of Theorem 1.2 almost word for word, including the redefinition of f, but with the exception that r^{n-1} is replaced by $q(t)$, one obtains[2] an appropriate fixed point $w = w(t) \in X = C[0, T]$ satisfying

$$w(t) = m - \int_t^T \left(\frac{1}{q(s)} \int_0^s q(\tau) f(w(\tau)) d\tau \right)^{1/(p-1)} ds, \qquad t \in [0, T]. \tag{6.14}$$

Clearly $w(T) = m$ and

$$w_t(t) = \left(\frac{1}{q(t)} \int_0^t q(\tau) f(w(\tau)) d\tau \right)^{1/(p-1)}, \qquad t \in (0, T]. \tag{6.15}$$

Obviously w_t is continuous and nonnegative in $(0, T]$, since $0 \le f(w) \le f(m)$ for all $w \in X$. Moreover by (Q2)

$$0 < \frac{1}{q(t)} \int_0^t q(\tau) f(w(\tau)) d\tau \le t f(m) \to 0 \qquad \text{as} \quad t \to 0^+.$$

[2] In view of (Q2), the bound $Rf(m)/n$ in (2.5), holding for the standard weight r^{n-1}, should be replaced by

$$L = \begin{cases} Rf(m) & \text{if } 0 < R \le \delta, \\ R \dfrac{\max_{t \in [\delta, R]} q(t)}{\min_{t \in [\delta, R]} q(t)} f(m) & \text{if } \delta < R. \end{cases}$$

Therefore $w_t(t)$ approaches 0 as $t \to 0^+$ by (6.15). In turn we have $w \in C^1[0,T]$ with $w_t(0) = 0$.

We claim moreover that $w(0) \geq 0$. Otherwise $w(0) < 0$ and $w(T) = m > 0$. Thus there exists a first point $t_0 \in (0,T)$ such that $w(t) < 0$ in $[0,t_0)$ and $w(t_0) = 0$. Consequently $f(w(t)) = 0$ in $[0,t_0]$ and so $w_t \equiv 0$ for $t \in [0,t_0]$ by (6.15). Hence $w(t_0) = w(0) < 0$, which is impossible, proving the claim.

The function $v = w$ is the desired solution of (6.8) in $[0,T]$, and in turn $u(r) = v(t(r))$ is a C^1 solution of (6.5) on $(0,R]$.

The function $u(|x|) = v(t(|x|))$ is a C^1 distribution solution of (6.13) *in B_R.* First we show (6.11) for $\Omega = B_R$. Recall that $v \in C^1[0,T]$ and $v_t(0) = 0$, while also, as shown above, q is bounded as $t \to 0^+$. Then using the change of variables (6.7) we get

$$a(r)|u'(r)|^{p-1} = q(t)|v_t(t)|^{p-1} \to 0 \qquad \text{as} \quad r,\ t \to 0^+.$$

Therefore, recalling (6.6), it follows that (6.11) holds in B_R for $u(|x|) = v(t(|x|))$. The rest of the proof is standard, as in the last part of the proof of Theorem 1.2. Thus u is a C^1 distribution solution of (6.13) in B_R.

Uniqueness of C^1 distribution solutions of (6.13). This is an immediate consequence of the weak comparison principle given in Theorem 6.1. □

The solution $u = u(\cdot\,, m)$ of (6.13) has further properties of interest, given in the next result.

THEOREM 6.3. *The function $u = u(\cdot\,, m)$ is continuous and nondecreasing in the variable m, and $u < m$ in B_R.*

Proof. Monotonicity. This follows from the weak comparison principle Theorem 6.1.

Continuity. Using the notation of the proof of Theorem 1.3, we show that if $0 < m_1 < m_2$, then

$$0 \leq v_2(t) - v_1(t) \leq m_2 - m_1 \qquad \text{on } [0,T]. \tag{6.16}$$

By (6.14) we have for all $t \in [0,T]$

$$v_2(t) - v_1(t) = m_2 - m_1 - \int_t^T \left[\left(\frac{1}{q(s)} \int_0^s q(\tau) f(v_2(\tau)) d\tau \right)^{1/(p-1)} - \left(\frac{1}{q(s)} \int_0^s q(\tau) f(v_1(\tau)) d\tau \right)^{1/(p-1)} \right] ds,$$

and (6.16) now follows exactly as in the proof of Theorem 1.3. Consequently

$$0 \leq u_2(r) - u_1(r) = v_2(t(r)) - v_1(t(r)) \leq m_2 - m_1 \qquad \text{for } r \in [0,R],$$

as required.

Proof that $u < m$ in B_R. It is equivalent to show the same property for the corresponding fixed point solution v of (6.9). By (6.14) it is enough to prove that

$$I = \int_t^T \left(\frac{1}{q(s)} \int_0^s q(\tau) f(v(\tau)) d\tau \right)^{1/(p-1)} ds > 0 \quad \text{for } t \in [0,T).$$

Clearly $v > 0$ in some interval $(t_0, T]$ with $t_0 \geq 0$, and in turn $f(v(t)) > 0$ in $(t_0, T]$ by (F2). Therefore

$$I \geq \int_{\max\{t_0,\, t\}}^T \left(\frac{1}{q(s)} \int_{t_0}^s q(\tau) f(v(\tau)) d\tau \right)^{1/(p-1)} ds > 0,$$

as required. □

7. The critical value m_0 for (6.1). We now turn to the dead core theorem for (6.1), analogous to Theorem 1.4 for (1.1). In the present case we have $H^{-1}(\tau) = (p'\tau)^{1/p}$ and the dead core condition (1.3) becomes

$$\int_{0+} \frac{ds}{[F(s)]^{1/p}} < \infty. \tag{7.1}$$

In what follows we assume also that

$$\frac{q_t}{q} \quad \text{is nonincreasing on } \mathbb{R}^+; \tag{Q3}$$

$$\limsup_{t\to 0^+} \frac{tq_t(t)}{q(t)} < \infty. \tag{Q4}$$

THEOREM 7.1. *If $u_1 = u(\cdot\,, m_1)$ has a dead core B_{S_1}, then $u_2 = u(\cdot\,, m_2)$, $m_2 < m_1$, has a dead core B_{S_2}, with $S_2 > S_1$. On the other hand, if either $u_1(0) > 0$ or $u_1(0) = 0$ and $u_1(r) > 0$ for $r \in (0, R]$, then $u_2 > u_1$ in B_R when $m_2 > m_1$.*

Proof. It is equivalent to show the same result with u_1 and u_2 replaced by $v_1 = v_1(t) = u_1(r(t))$ and $v_2 = v_2(t) = u_2(r(t))$, $t \in [0, T]$, respectively. To do this we can repeat the proof of Theorem 4.1 almost word for word, of course with u_1 and u_2 replaced by v_1 and v_2, and also with the following necessary changes: (i) replace (4.2) by

$$\begin{aligned}\frac{1}{q(t)}\{[q(t)|v_{\varepsilon,t}|^{p-2}v_{\varepsilon,t}]_t - q(t)f(v_\varepsilon)\} &= [|v_{\varepsilon,t}|^{p-2}v_{\varepsilon,t}]_t + \frac{q_t(t)}{q(t)}|v_{\varepsilon,t}|^{p-2}v_{\varepsilon,t} - f(v_\varepsilon)\\ &= \left[\frac{q_t(t)}{q(t)} - \frac{q_t(t-\varepsilon)}{q(t-\varepsilon)}\right][v_{1,t}(t-\varepsilon)]^{p-1},\end{aligned}$$

which is nonpositive in view of (Q3) and the fact that $v_{1,t} \geq 0$, that is,

$$[q(t)|v_{\varepsilon,t}|^{p-2}v_{\varepsilon,t}]_t - q(t)f(v_\varepsilon) \leq 0;$$

and (ii) replace the use of Theorem 2.1 in B_{r_0} by the use of the radial analogue of Theorem 6.1 in $[0, r_0)$. □

The following theorem gives an important relation between the value m and dead core solutions of (6.13).

THEOREM 7.2. *Let $u(\cdot\,, m)$ be the unique solution of (6.13). Then either $u(\cdot\,, m)$ has a dead core for all $m > 0$, or there is a unique (finite) number*

$$m = m_0 = m_0(R) > 0$$

for which a solution $u_0 = u_0(r) = u_0(r\,, m_0)$ of (6.13) in B_R exists, with the properties that

(i) *$u_0(0) = 0$;*
(ii) *$u(0\,, m) > 0$ for every $m > m_0$;*
(iii) *$u(\cdot\,, m)$ has a dead core for every $0 < m < m_0$.*

For convenience we define $m_0 = m_0(R)$ to be ∞ when all solutions of (6.13) are such that $u(0\,, m) = 0$ for all $m > 0$.

Before proving Theorem 7.2, it is useful to give a preliminary lemma. For this and later purposes we introduce the constant $M \geq 1$ by

$$\sup_{0<t<T} \frac{tq_t(t)}{q(t)} = M - 1, \tag{7.2}$$

which is well defined by (Q1), (Q2), and (Q4).

LEMMA 7.3. *Any nonnegative solution u of (6.1) in B_R which is suitably small on ∂B_R has a dead core.*

Proof. Let $\bar{m} > 0$ be so small that

$$D_{\bar{m}} = \int_0^{\bar{m}} \frac{ds}{[F(s)/M]^{1/p}} = M^{1/p} \int_0^{\bar{m}} \frac{ds}{[F(s)]^{1/p}} < T, \qquad T = t(R), \tag{7.3}$$

which of course is possible by assumption (7.1), where $T = t(R)$ and t is given in (6.7). Define $\tilde{v}(t) = w(t - \tilde{S})$, $t \in [\tilde{S}, T]$, $\tilde{S} = T - D_{\bar{m}}$, where w is the function constructed in the dead core Lemma 7.1 of [7, 8], with $\sigma = 1/M$. By analogy with (7.4) of [7, 8] the function $\tilde{v}$ is a supersolution of (6.8) in the interval $[\tilde{S}, T]$; that is, for $t \in (\tilde{S}, T)$

$$\begin{aligned} \{(\tilde{v}_t(t))^{p-1}\}_t + \frac{q_t(t)}{q(t)}(\tilde{v}_t(t))^{p-1} - f(\tilde{v}(t)) &\le \left\{ \sigma \left[1 + (M-1)\frac{t - \tilde{S}}{t} \right] - 1 \right\} f(\tilde{v}(t)) \\ &\le (\sigma M - 1) f(\tilde{v}(t)) = 0, \end{aligned} \tag{7.4}$$

where we have used (iii) and (iv) of the dead core Lemma 7.1 of [7, 8]. Of course also $\tilde{v}(\tilde{S}) = \tilde{v}_t(\tilde{S}) = 0$ and $\tilde{v}(T) = \bar{m}$. Let $\tilde{u}(x) = \tilde{v}(t(|x|))$, $x \in B_R \setminus \overline{B_S}$, where $\tilde{S} = t(S)$. Then

$$\operatorname{div}(g(|x|)|D\tilde{u}|^{p-2} D\tilde{u}) - h(|x|) f(\tilde{u}) \le 0 \quad \text{in } B_R \setminus \overline{B_S}.$$

Moreover defining $\tilde{u}$ to be zero on B_S, the extended function $\tilde{u}$ is a supersolution in B_R of (6.1). Let the given solution u of (6.1) in B_R have nonnegative boundary values less than or equal to m. By the weak comparison Theorem 6.1 we get $u \le \tilde{u}$ whenever $m \le \bar{m}$. Therefore $u \equiv 0$ in B_S. This completes the proof. □

Proof of Theorem 7.2. Existence of u_0. Suppose that there is some $m > 0$ for which $u(0\,, m) > 0$ and define as before

$$m_0 = \inf\{m > 0 \ : \ u(0, m) > 0\}, \tag{7.5}$$

so that $m_0 > 0$ by Lemma 7.3.

The rest of the proof is exactly the same as the proof of Theorem 1.4, with the exception that Theorems 1.3 and 4.1 are replaced by the corresponding Theorems 6.3 and 7.1.

Uniqueness of u_0. The proof is exactly as for the corresponding result in Theorem 1.4.

The case $m_0 = \infty$. If every solution of (6.1) in B_R is such that $u(0\,, m) = 0$ for all $m > 0$, then $u(\cdot\,, m)$ has a dead core for all $m > 0$. Otherwise there would be $\bar{m} > 0$ for which $u(0\,, \bar{m}) = 0$ and $u(r\,, \bar{m}) > 0$ for $r \in (0, R]$. Hence $u(0\,, m) > 0$ for $m > \bar{m}$ by Theorem 7.1, contradicting the assumption. This also justifies the earlier agreement that $m_0 = \infty$ in this case. □

Remark. In summary, if m_0 is finite and $m > m_0$, then the solution $u = u(\cdot\,, m)$ of (6.13) is positive; namely, $u(r\,, m) > 0$ for all $r \in [0, R]$. On the other hand, if $m < m_0 \le \infty$ then the solution $u = u(\cdot\,, m)$ of (6.13) has a dead core $B_S \subset B_R$, $0 < S < R$.

8. The size of a dead core and the case of general domains for (6.1). Recall the assumption that $\Phi(\infty) = H(\infty) = \infty$, and let

$$D = \int_0^{\infty} \frac{ds}{[F(s)/M]^{1/p}}, \tag{8.1}$$

where $M \geq 1$ is the number given in (7.2). Clearly $0 < D \leq \infty$ since the integral is convergent at 0 by (7.1) and by Lemma 3.2 of [7, 8] with $\sigma = 1/M \leq 1$, but possibly divergent at ∞. The next two results are the analogues of Theorems 5.1 and 5.2.

THEOREM 8.1. *We have*

$$m_0 = \infty \quad \text{if} \quad D < \infty \quad \text{and} \quad R \geq r(D), \tag{8.2}$$

where r is the inverse function of change of variable t given in (6.7)*, while*

$$m_0 \geq \bar{m} \qquad \text{if } R < r(D), \tag{8.3}$$

where $\bar{m}$ is given by the relation $R = r(D_{\bar{m}})$.

Proof. The proof of (8.2) is essentially the same as that of Lemma 7.3, the only exception being that $D_{\bar{m}}$ is replaced by D, and R by $T = t(R)$.

To obtain (8.3) one again follows the outline of the proof of Lemma 7.3. Now, however, in addition to replacing $D_{\bar{m}}$ by D, we take $\tilde{S} = S = 0$. One thus obtains (7.4) for $\tilde{v}$, with $\tilde{v}(0) = \tilde{v}_t(0) = 0$ and $\tilde{v}(T) = \bar{m}$. Hence $\tilde{u}(0) = \tilde{u}'(0) = 0$ and $\tilde{u}(R) = \bar{m}$, where $\tilde{u}(r) = \tilde{v}(t(r))$. The conclusion is that $0 \leq \tilde{u}(r\,, \bar{m}) \leq u(r\,, \bar{m})$, by virtue of the weak comparison Theorem 6.1. Hence $\tilde{u}(0\,, \bar{m}) = u(0\,, \bar{m}) = 0$, and in turn from the definition (7.5) of m_0 we get $m_0 \geq \bar{m}$, as required in (8.3). ∎

Remark. It is interesting to calculate the function $t \mapsto r(t)$ for the classical Matukuma equation, in which $g \equiv 1$ and $h(r) = 1/(1 + r^2)$, $p = 2$. One finds from (6.7) that $t(r) = \operatorname{arcsinh} r$, so that $r(t) = \sinh t$. Thus in this case (8.2) becomes

$$m_0 = \infty \quad \text{if } D < \infty \quad \text{and} \quad R \geq \sinh D,$$

with a similar relation for (8.3).

THEOREM 8.2. *Let $m < m_0$, so that a dead core exists in B_R by Theorem* 7.2*. In particular*

$$u \equiv 0 \qquad \text{in } B_S \subset B_R,$$

where $T = t(R)$, $\tilde{S} = t(S)$, and

$$T - \int_0^m \frac{ds}{[F(s)/M]^{1/p}} < \tilde{S} < T. \tag{8.4}$$

If $R \geq r(D)$, then for all $m > 0$ one has

$$R - r(D) < S < R.$$

Proof. This is the same as the proof of (8.2). ∎

Remark. Let $\varepsilon > 0$. Then if m is suitably small (depending on ε) we have $T - \varepsilon < \tilde{S} < T$ by (8.4).

The next result is the analogue for (6.1) of Theorem 1.1 for (1.1) and for general domains Ω. Let $0 \in \Omega$. As before we denote by B_R the open ball *centered at* 0 with radius $R > 0$, and we let

$$\overline{R} = \sup\{R > 0 \ : \ B_R \subset \Omega\}.$$

THEOREM 8.3. *Assume the dead core condition* (7.1) *holds and let u be a solution of* (6.1)*, with $0 \leq u(x) \leq m$ on $\partial\Omega$ for some positive constant m. Then the following properties are valid:*

(a) $0 \le u \le m$ *in* Ω *and* $0 \le u < m$ *in* $B_{\overline{R}}$.
(b) *If* $\overline{R} \ge r(D)$, *with* D *given in* (8.1), *then* u *has a dead core in* Ω *for all* $m > 0$.
(c) *Let* B_R *be compactly contained in* Ω. *Then* $u \equiv 0$ *in* B_R *provided that* $m > 0$ *is suitably small.*

Proof of Theorem 8.3. (a) That $u \ge 0$ follows by comparison (Theorem 6.1) of the given solution u with the trivial solution 0. Also the constant function m is a supersolution of (6.1), so that again by comparison $u \le m$ in Ω.

Moreover $u < m$ in $B_{\overline{R}}$. To see this, let $\overline{u}(\cdot\,, m)$ be the radial solution of (6.1) in $B_{\overline{R}}$ constructed in Theorem 6.2. Clearly $u(x) \le m = \overline{u}(|x|, m)$ for $x \in \partial B_{\overline{R}}$, and in turn $u(x) \le \overline{u}(|x|, m) < m$ for $x \in B_{\overline{R}}$ by the final part of Theorem 6.2.

(b) This is a direct consequence of Theorem 8.1.

(c) Let $\varepsilon > 0$ be so small that $B_R \subset B_{R+\varepsilon} \subset \Omega$. In analogy with part (a), let $\overline{u}(\cdot\,, m)$ be the solution of (6.13) with B_R replaced by $B_{R+\varepsilon}$. Then $u(x) \le \overline{u}(|x|\,, m) = m$ for $x \in \partial B_{R+\varepsilon}$. By the remark after Theorem 8.2 we have $\overline{u} \equiv 0$ in B_R when $m > 0$ is suitably small, and in turn $u \equiv 0$ in B_R by the weak comparison Theorem 6.1. □

9. The case $\Phi(\infty) < \infty$. This is the case, for example, for the mean curvature operator noted in the introduction, in which $\Phi(\infty) = H(\infty) = 1$. Here the proof of the critical Theorem 1.2 requires the modification that the parameter m in (1.5) should be restricted so that

$$f(m) + \Phi(m) < \left(\frac{R}{R+1}\right)^{n-1} \Phi(\infty) \qquad \text{and} \qquad F(m) \le nH(\infty); \tag{9.1}$$

see Proposition 4.1 of [7, 8]. Denote by m_∞ the supremum of all $m > 0$ satisfying (9.1).

Then the main results stated in the introduction remain true provided that the condition $m < m_\infty$ is assumed in all the statements. For instance we have the following analogue of Theorem 1.1.

THEOREM 9.1. *Assume the dead core condition* (1.3) *holds and let* u *be a solution of* (1.1), *with* $0 \le u(x) \le m$ *on* $\partial\Omega$ *for some positive constant* $m < m_\infty$. *Then the following properties are valid:*

(a) $0 \le u < m$ *in* Ω.
(b) *Assume that* $C = \int_0^{m_\infty} \frac{ds}{H^{-1}(F(s)/n)} < \infty$, *and let* B_R *be a ball with radius* $R \ge C$, *compactly contained in* Ω. *Then* u *has a dead core in* Ω *for all* $m \in (0, m_\infty)$.
(c) *If* B *is any ball compactly contained in* Ω, *then* $u \equiv 0$ *in* B *provided that* $m > 0$ *is suitably small.*

It is not hard to show that if $\Phi(\infty) = \infty$ then necessarily $H(\infty) = \infty$, but it is possible to have $\Phi(\infty) < \infty$ and $H(\infty) = \infty$, as shown by $A(\varrho) = 1/(1 + \sqrt{1+\varrho^2})$, with corresponding

$$H(\varrho) = \frac{1}{2}\left[\frac{\varrho^2}{1+\sqrt{1+\varrho^2}} - \log\frac{1+\sqrt{1+\varrho^2}}{2}\right].$$

In this example $\Phi(\infty) = 1$, while $H(\infty) = \infty$.

The case $H(\infty) < \infty$ for unrestricted $m > 0$ was treated by Siegel in [9].

10. Bursts. Here we assume (F1) and apply the previous theory to problems with nonlinearities f with (F2) replaced by the following:

(F3) f is nondecreasing in $(0,\delta)$, $F(u)>0$ on $(0,\beta)$, with $F(\beta)=0$, and there is $\gamma\in(\beta,\infty]$ such that the following conditions hold:
- (i) $f(u)<0$ on $[\beta,\gamma)$, $\quad f(\gamma)=0$ if $\gamma<\infty$;
- (ii) $\max_{[0,\beta]} F(u)+|F(\gamma)|<H(\infty)$ if $H(\infty)<\infty$;
- (iii) $\liminf_{u\to\infty}\frac{H^{-1}(|F(u)|)}{u}=0$ if $H(\infty)=|F(\gamma)|=\infty$ and $\Phi(\infty)<\infty$;
- (iv) $\liminf_{u\to\infty}\frac{H^{-1}(|F(u)|)}{u}<\infty$ if $H(\infty)=\Phi(\infty)=|F(\gamma)|=\infty$.

In (F3) for the case $\gamma=\infty$ we define $F(\gamma)=\lim_{u\to\infty}F(u)$, which certainly exists though possibly being $-\infty$. Clearly $F(\gamma)=-\infty$ can occur only if $\gamma=\infty$. As noted above, $H(\infty)=\infty$ whenever $\Phi(\infty)=\infty$.

For such functions f Franchi, Lanconelli, and Serrin proved in Theorem A of [4] that (1.1) *admits a nonnegative radial ground state $u=u(r)$, with central value $u(0)=\alpha\in(\beta,\gamma]$ if $\gamma<\infty$, or $u(0)=\alpha\in(\beta,\infty)$ if $\gamma=\infty$; moreover $u'(r)\le 0$ for all $r\ge 0$. Furthermore, since the dead core condition* (1.3) *is assumed to hold, then the solution is compactly supported.*

Remarks. Clearly, if $F(\gamma)>-\infty$ and $H(\infty)=\infty$ then only condition (i) is needed. For the Laplacian operator and the p-Laplacian degenerate operator $H(\infty)=\infty$ and $\Phi(\infty)=\infty$, so conditions (ii), (iii), and (iv) are not needed if $\gamma<\infty$, though (iv) must be used when $|F(\gamma)|=\infty$. On the other hand, for the mean curvature operator $H(\infty)=1$, and so in consequence of (ii), the function F must be quite restrictive to apply Theorem A of [4] in order to get existence of radially symmetric ground states for (1.1).

Consider next the Dirichlet problem

$$\begin{cases}\operatorname{div}\{A(|Du|)Du\}=f(u) & \text{in } B_R\subset\mathbb{R}^n,\quad n\ge 2,\\ u=\delta & \text{on } \partial B_R,\end{cases}\tag{10.1}$$

under the dead core condition (1.3) for functions f satisfying (F1) and (F3). If $H(\infty)=\infty$, define

$$C'=\int_0^{\delta}\frac{ds}{H^{-1}(F(s)/n)}<\infty,$$

by (1.3) and (F1). Then there exists, according to Theorems 1.2 and 5.2, a solution of (10.1) which has a dead core B_S, with $R-S<C'$. In other words the main equation (1.1) has two nonnegative solutions—the compact support *burst* shown above by Theorem A of [4], and the dead core solution just derived by Theorem 1.2.

These two solutions can clearly be superposed, even if problem (10.1) is nonlinear, to obtain another combined solution of (10.1), with a dead core $B_S\setminus B_T$, $T<S<R$, and a symmetrical *burst* at its center.

In particular, the Dirichlet problem (10.1), with the *loop* nonlinearity f verifying (F1) and (F3), neither has a *unique* solution nor obeys the ordinary maximum principle.

Since (1.1) in problem (10.1) is translation invariant, it is evident that the *burst* need not be centered in the ball B_R. Even more, if R is made many times larger, one can place multiple bursts into original dead cores.

The main open problem arising in the study of dead cores is the question of stability, particularly in dynamic situations for parabolic time dependent problems of the type, e.g.,

$$u_t=\operatorname{div}\{A(|Du|)Du\}-f(u),\qquad u=u(t,x),\qquad (t,x)\in\mathbb{R}^+\times\Omega.$$

Acknowledgments. The paper is based on a minicourse given by P. Pucci in September 2002, in Grado, Italy, at the workshop Stationary and Evolution Problems, supported by the *GNAMPA* of the Istituto Nazionale di Alta Matematica "F. Severi," and on the lecture of J. Serrin given in June 2003 in the series Lezioni Leonardesche, organized by the Mathematics departments of the two universities in Milan and of the Politechnic of Milan.

ON SYMMETRIC FUNCTIONALS OF THE GRADIENT HAVING SYMMETRIC EQUIDISTRIBUTED MINIMIZERS*

ANDREA CIANCHI† AND ADELE FERONE‡

Abstract. Within a general family of functionals, not necessarily of integral type, depending on the modulus of the gradient, we characterize those possessing only spherically symmetric minimizers in classes of Sobolev functions with level sets of prescribed Lebesgue measures.

Key words. symmetrizations, constrained minimum problems, Sobolev spaces

1. Introduction and main results. In a fundamental paper in the theory of rearrangements [BZ], Brothers and Ziemer elucidated minimal conditions ensuring that functionals that depend on the modulus of the gradient admit only spherically symmetric minimizers in classes of Sobolev functions whose level sets have prescribed Lebesgue measures. The functionals considered in [BZ] have the form

$$J_A(|\nabla u|), \tag{1.1}$$

where J_A is defined at a real-valued measurable function f in $\mathbb{R}^n$ as

$$J_A(f) = \int_{\mathbb{R}^n} A(|f(x)|)\,dx, \tag{1.2}$$

and A is a Young function, namely a convex function from $[0,\infty)$ into $[0,\infty]$ vanishing at 0. It has been long known under the name of the Pólya–Szegö principle that, if a function u belongs to $W^1_+(\mathbb{R}^n)$, the space of nonnegative functions from $W^{1,1}(\mathbb{R}^n)$ satisfying $\mathcal{L}^n(\{u>0\}) < +\infty$, then also its *spherically symmetric rearrangement* $u^\bigstar$ is in $W^1_+(\mathbb{R}^n)$, and

$$J_A(|\nabla u^\bigstar|) \le J_A(|\nabla u|). \tag{1.3}$$

Here, $\mathcal{L}^n$ denotes the Lebesgue measure. The contribution of [BZ] amounts to showing that if A satisfies a slightly stronger condition than just convexity, then any function $u \in W^1_+(\mathbb{R}^n)$, attaining equality in (1.3), necessarily equals $u^\bigstar$ $\mathcal{L}^n$-a.e. (up to translations), provided that

$$\mathcal{L}^n(\{\nabla u = 0\} \cap \{0 < u < \operatorname{ess\,sup} u\}) = 0. \tag{1.4}$$

An exhaustive discussion of the necessity of assumption (1.4) can be found in [BZ]. The condition on A appearing in that paper has a somewhat technical nature, but

was later realized that strict convexity of A is sufficient (and necessary) for the conclusion to be true (see, e.g., [B], [CF1]; see also [FV2], where a more elementary proof of Brothers and Ziemer's theorem is offered, and [CF2], dealing with asymmetry estimates for u in the case where condition (1.4) and the strict convexity of A are dropped).

Apart from its own interest, this symmetry result is relevant in view of applications to the uniqueness of minimizers of variational problems. For instance, as recently observed in [CNV] and in [M], it can be used to prove that the only extremals in the Sobolev inequality with best constant are those exhibited in [Ta]. On the other hand, Brothers and Ziemer's theorem does not apply to certain functionals $\Phi(|\nabla u|)$, not in integral form, on which, nevertheless, Schwarz symmetrization is known to act monotonically. Functionals enjoying this property are, for example, when $\Phi(\,\cdot\,) = \|\,\cdot\,\|_A$, the Luxemburg norm, or $\Phi(\,\cdot\,) = \|\,\cdot\,\|_{(A)}$, the Orlicz norm, in the Orlicz space $L^A(\mathbb{R}^n)$ associated with a Young function A. Recall that these (equivalent) norms are defined at a measurable function f in $\mathbb{R}^n$ as

$$\|f\|_A = \inf\left\{\lambda > 0\colon \int_{\mathbb{R}^n} A\left(\frac{|f(x)|}{\lambda}\right) dx \le 1\right\} \tag{1.5}$$

and

$$\|f\|_{(A)} = \sup\left\{\int_{\mathbb{R}^n} |f(x)g(x)|\, dx\colon \int_{\mathbb{R}^n} \widetilde{A}(|g(x)|)dx \le 1\right\}, \tag{1.6}$$

respectively, where $\widetilde{A}(s) = \sup\{rs - A(r) : r \ge 0\}$, the Young conjugate of A.

Other functionals of the gradient not included in [BZ], but yet satisfying a Pólya–Szegö principle, arise from the definition of the Lorentz spaces $L^{p,q}(\mathbb{R}^n)$ (see, e.g., [A]). Given $p, q \in (0, +\infty]$, the relevant functionals are defined at a measurable function f in $\mathbb{R}^n$ by

$$\|f\|_{p,q} = \|s^{\frac{1}{p}-\frac{1}{q}} f^*(s)\|_{L^q(0,\infty)}, \tag{1.7}$$

where f^* is the *decreasing rearrangement* of f, and

$$\|f\|_{(p,q)} = \|s^{\frac{1}{p}-\frac{1}{q}} f^{**}(s)\|_{L^q(0,\infty)}, \tag{1.8}$$

where

$$f^{**}(s) = \frac{1}{s}\int_0^s f^*(r)dr \qquad \text{for } s > 0.$$

Notice that, if $1 < p \le \infty$ and $0 < q \le \infty$, the quantities $\|\ \|_{p,q}$ and $\|\ \|_{(p,q)}$ are equivalent (up to multiplicative constants)—see, e.g., [BS, Chapter 4, Lemma 4.5].

The fact that, when evaluated at $|\nabla u|$, functionals (1.5), (1.6), (1.8), and also (1.7) for suitable values of p and q do not increase under Schwarz symmetrization of u is a consequence of an extended version of the Pólya–Szegö principle stated in Theorem 1.2 below. This theorem deals with general functionals of the form $\Phi(|\nabla u|)$, with Φ defined in

$$L^1_+(\mathbb{R}^n) = \{f \in L^1(\mathbb{R}^n)\colon f \ge 0 \text{ and } \mathcal{L}^n(\{f > 0\}) < +\infty\}.$$

The key property of Φ in order for the functional $\Phi(|\nabla u|)$ to support a Pólya–Szegö principle is the $**$-monotonicity defined as follows.

DEFINITION 1.1. *A functional* $\Phi : L^1_+(\mathbb{R}^n) \to [0,\infty]$ *is called* $**$-increasing *if*

$$\Phi(f) \le \Phi(g) \qquad \textit{whenever} \qquad f^{**}(s) \le g^{**}(s) \quad \textit{for } s > 0.$$

Besides those considered above, other examples of $**$-increasing functionals are provided by all rearrangement invariant norms in the sense of Luxemburg, namely norms in Banach function spaces depending only on the decreasing rearrangement—see Proposition 5.2, section 5. However, rearrangement invariant norms do not exhaust the class of $**$-increasing functionals, as the case where $\Phi(\cdot) = \|\cdot\|_{(p,q)}$, with $0 < q < 1$, demonstrates. Relations between $**$-monotonicity and other notions of monotonicity, convexity, and semicontinuity will be examined in sections 2 and 5.

THEOREM 1.2. *Let* $\Phi : L^1_+(\mathbb{R}^n) \to [0,\infty]$ *be a* $**$*-increasing functional. Then*

$$\Phi(|\nabla u^\bigstar|) \le \Phi(|\nabla u|) \tag{1.9}$$

for every $u \in W^1_+(\mathbb{R}^n)$.

Theorem 1.2 is essentially known in literature as a consequence of the fact that every $u \in W^1_+(\mathbb{R}^n)$ satisfies

$$|\nabla u^\bigstar|^{**}(s) \le |\nabla u|^{**}(s) \qquad \text{for } s > 0 \tag{1.10}$$

(see, e.g., [CP], [F], [K]). Here, we shall present a proof of Theorem 1.2 where an intermediate step is enucleated, showing that a third quantity, involving $|\nabla u|$, always lies between the left-hand side and the right-hand side of (1.9) (see also [RT] and [FV1] for contributions in this direction). This is crucial in preparation for our main results concerning the equality case in (1.9).

Indeed, the purpose of the present paper is to complement the result of [BZ] and to characterize the class of those $**$-increasing functionals Φ for which the equation

$$\Phi(|\nabla u^\bigstar|) = \Phi(|\nabla u|) < +\infty, \tag{1.11}$$

coupled with condition (1.4), necessarily implies $u = u^\bigstar$ (up to translations). According to the terminology of [BZ], we shall call any $u \in W^1_+(\mathbb{R}^n)$ satisfying (1.11) a *minimal rearrangement* of Φ.

In fact, we give a more detailed picture of the situation at hand. In order to grasp the spirit of our discussion, recall that the proof of the symmetry result for extremals in the standard inequality (1.3), where $\Phi = J_A$, consists of two steps. First, (1.11) is used to deduce that

$$\text{the level sets } \{u > t\} \text{ are (equivalent to) balls} \quad \text{for } \mathcal{L}^1\text{-a.e. } t > 0, \tag{1.12}$$

and that

$$|\nabla u| \text{ is constant } \mathcal{H}^{n-1}\text{-a.e. on } \{u = t\} \quad \text{for } \mathcal{L}^1\text{-a.e. } t > 0, \tag{1.13}$$

where $\mathcal{H}^{n-1}$ denotes the $(n-1)$-dimensional Hausdorff measure. Combining (1.12) and (1.13) with (1.4) then entails that the balls $\{u > t\}$ must be concentric, and hence that u is symmetric. In particular, we stress that (1.11) plays a role in the derivation only of (1.12) and (1.13). In view of these facts, the problem arises of characterizing all $**$-increasing functionals having the property that every minimal rearrangement u necessarily fulfills (1.12) or (1.13). Let us emphasize that the issue is not immaterial, since not every $**$-increasing functional enjoys this property. A typical example in

this connection is provided by the L^∞-norm, since functions u can be easily exhibited which fulfill (1.11) with $\Phi(\,\cdot\,) = \|\cdot\|_{L^\infty}$, but not (1.12) (nor, a *fortiori*, (1.13)—see the comment following Theorem 1.6 below). Our first main result tells us that failure of (1.12) can occur only for minimal rearrangements of $**$-increasing functionals, which, like $\|\ \|_{L^\infty}$, are not strictly monotone in a sense specified in the next definition.

DEFINITION 1.3. *A $**$-increasing functional $\Phi : L^1_+(\mathbb{R}^n) \to [0,\infty]$ is said to be* $*$-strictly increasing *if*

$$f^*(s) \le g^*(s) \text{ for } s \ge 0 \quad \text{and} \quad \Phi(f) = \Phi(g) < +\infty \text{ imply that } f^* \equiv g^*.$$

Actually, the following theorem holds.

THEOREM 1.4. *Let $\Phi : L^1_+(\mathbb{R}^n) \to [0,\infty]$ be a $**$-increasing functional. Then every minimal rearrangement u of Φ necessarily fulfills* (1.12) *if and only if Φ is $*$-strictly increasing.*

Theorem 1.4 settles the question concerning the validity of (1.12) for minimal rearrangements u. The parallel issue for (1.13) turns out to be related to a stronger assumption on Φ, which, loosely speaking, amounts to a proper weak notion of strict convexity. The necessity of an assumption of this kind is suggested by another simple instance corresponding to the choice $\Phi(\,\cdot\,) = \|\cdot\|_{L^1}$. Since such a functional is clearly $*$-strictly increasing, by Theorem 1.4 every minimal rearrangement u satisfies (1.12); however, such a u does not necessarily fulfill (1.13), since the balls $\{u > t\}$ at different levels t need not be concentric. This assertion can be verified via the coarea formula, and remains true even for any other functional given by (1.2) with a nonstrictly convex A.

A sharp assumption on Φ guaranteeing property (1.13) for every minimal rearrangement u is introduced in the next definition.

DEFINITION 1.5. *A $**$-increasing functional $\Phi : L^1_+(\mathbb{R}^n) \to [0,\infty]$ is said to be* $**$-strictly increasing *if*

$$f^{**}(s) \le g^{**}(s) \text{ for } s > 0 \quad \text{and} \quad \Phi(f) = \Phi(g) < +\infty \text{ imply that } f^* \equiv g^*.$$

Connections among $**$-strict monotonicity, classical strict convexity, and other related notions will be discussed in Proposition 5.3 of section 5.

We are now in position to state our second main result.

THEOREM 1.6. *Let $\Phi : L^1_+(\mathbb{R}^n) \to [0,\infty]$ be a $**$-increasing functional. Then every minimal rearrangement u of Φ necessarily fulfills* (1.13) *if and only if Φ is $**$-strictly increasing.*

Notice that, since every $**$-strictly increasing functional is also $*$-strictly increasing, Theorems 1.4 and 1.6 ensure, in particular, that (1.12) is fulfilled by every minimal rearrangement u of Φ whenever (1.13) is.

Thanks to Theorems 1.4 and 1.6, any minimal rearrangement u of a $**$-strictly increasing functional Φ has to satisfy (1.12)–(1.13), and hence, if also (1.4) is in force, it must be spherically symmetric. Thus, the following general version of Brothers and Ziemer's theorem holds.

THEOREM 1.7. *Let $\Phi : L^1_+(\mathbb{R}^n) \to [0,\infty]$ be a $**$-strictly increasing functional. Let u be any minimal rearrangement u of Φ satisfying* (1.4). *Then $u \equiv u^\bigstar$ $\mathcal{L}^n$-a.e in $\mathbb{R}^n$ (up to translations).*

Let us mention that an extension of the theorem of [BZ] in the special case where $\Phi(\,\cdot\,) = \|\cdot\|_{(p,q)}$ can also be found in [Ra].

Theorems 1.2, 1.4, and 1.6 are established in sections 2, 3, and 4, respectively. Applications of these theorems to functionals (1.1) and (1.5)–(1.8) are presented in

section 5; let us just anticipate here that some of the conclusions are somewhat surprising (to us at least). For instance, as a consequence of Theorem 1.4 and Proposition 5.7, strictly convex Young functions A exist, like $A(t) = e^{t^\alpha} - 1$ with $\alpha > 1$, such that

$$\| \, |\nabla u^\bigstar| \, \|_A = \| \, |\nabla u| \, \|_A$$

for some $u \in W^1_+(\mathbb{R}^n)$ fulfilling (1.4), which is not symmetric and does not even satisfy (1.12).

2. The Pólya–Szegö inequality for $**$-increasing functionals. In this section we provide a proof of Theorem 1.2. After recalling a few basic definitions about rearrangements, our first concern will be, however, to clarify the connections between the notion of $**$-monotonicity of functionals, upon which Theorem 1.2 relies, and other definitions of monotonicity which play a role in what follows.

Given any function $f \in L^1_+(\mathbb{R}^n)$, the function $\mu_f : [0, +\infty) \to [0, +\infty)$, defined by

$$\mu_f(t) = \mathcal{L}^n(\{x \in \mathbb{R}^n : f(x) > t\}) \qquad \text{for } t \geq 0,$$

is called the *distribution function* of f. The *decreasing rearrangement* of f is the function $f^* : [0, +\infty) \to [0, +\infty)$ obeying

$$f^*(s) = \sup\{t \geq 0 : \mu_f(t) > s\} \qquad \text{for } s \geq 0.$$

The *spherically symmetric rearrangement* $f^\bigstar : \mathbb{R}^n \to [0, +\infty)$ of f is defined as

$$f^\bigstar(x) = f^*(\omega_n |x|^n) \qquad \text{for } x \in \mathbb{R}^n, \tag{2.1}$$

where ω_n denotes the measure of the unit ball in $\mathbb{R}^n$. Functions having the same distribution function will be called *equidistributed* or *equimeasurable*. Clearly, f, f^*, and $f^\bigstar$ are equidistributed.

A basic property of rearrangements tells us that, if f is as above, then

$$\sup\left\{\int_E f(x)dx : \mathcal{L}^n(E) = s\right\} = \int_0^s f^*(r)dr \qquad \text{for every } s > 0 \tag{2.2}$$

and

$$\int_{\mathbb{R}^n} f(x)dx = \int_0^{+\infty} f^*(r)dr.$$

In what follows, given f and g in $L^1_+(\mathbb{R}^n)$, we write $f \prec g$ to denote that

$$f^{**}(s) \leq g^{**}(s) \quad \text{ for } s > 0 \quad \text{ and } \qquad \int_{\mathbb{R}^n} f(x)dx = \int_{\mathbb{R}^n} g(x)dx.$$

DEFINITION 2.1. *Let Φ be a functional from $L^1_+(\mathbb{R}^n)$ into $[0, \infty]$.*

(i) *Φ is called* pointwise increasing *if*

$$\Phi(f) \leq \Phi(g) \quad \textit{whenever} \quad f(x) \leq g(x) \quad \textit{for } \mathcal{L}^n\textit{-a.e. } x \in \mathbb{R}^n;$$

Φ is called strictly pointwise increasing *if, in addition,*

$$f(x) \leq g(x) \textit{ for } \mathcal{L}^n\textit{ -a.e. } x \in \mathbb{R}^n \quad \textit{and} \quad \Phi(f) = \Phi(g) < +\infty \textit{ imply } f = g \textit{ for } \mathcal{L}^n\textit{ -a.e. } x \in \mathbb{R}^n.$$

(ii) Φ *is called* $*$-increasing *if*

$$\Phi(f) \le \Phi(g) \quad \textit{whenever} \quad f^*(s) \le g^*(s) \quad \textit{for} \ \ s > 0;$$

Φ *is called* $*$-strictly increasing *if, in addition,*

$$f^*(s) \le g^*(s) \quad \textit{for } \mathcal{L}^1\textit{-a.e. } s > 0 \ \ \textit{and} \ \ \Phi(f) = \Phi(g) < +\infty \ \textit{imply } f^* \equiv g^*.$$

(iii) Φ *is called* $\prec$-increasing *if*

$$\Phi(f) \le \Phi(g) \quad \textit{whenever} \quad f \prec g;$$

Φ *is called* $\prec$-strictly increasing *if, in addition,*

$$f \prec g \quad \textit{and} \quad \Phi(f) = \Phi(g) < +\infty \ \ \textit{imply} \ \ f^* \equiv g^*.$$

We give one more definition involving functionals on $L^1_+(\mathbb{R}^n)$.

DEFINITION 2.2. *A functional* $\Phi : L^1_+(\mathbb{R}^n) \to [0, \infty]$ *is called* rearrangement invariant *if*

$$\Phi(f) = \Phi(g) \quad \textit{whenever} \quad f^* \equiv g^*.$$

Relations among the above notions of monotonicity are established in the next proposition.

PROPOSITION 2.3. *Let* Φ *be a functional from* $L^1_+(\mathbb{R}^n)$ *into* $[0, \infty]$. *Then*

(i) Φ *is* $*$*-increasing [respectively* $*$*-strictly increasing] if and only if* Φ *is pointwise increasing [strictly pointwise increasing] and rearrangement invariant.*

(ii) Φ *is* $**$*-increasing [*$**$*-strictly increasing] if and only if* Φ *is* $*$*-increasing [*$*$*-strictly increasing] and* $\prec$*-increasing [*$\prec$*-strictly increasing].*

Proof. (i) If Φ is $*$-increasing, it is obviously rearrangement invariant. It is also pointwise increasing, since if $f, g \in L^1_+(\mathbb{R}^n)$ and $f(x) \le g(x)$ for $\mathcal{L}^n$-a.e. $x \in \mathbb{R}^n$, then $f^*(s) \le g^*(s)$ for $s > 0$, and hence $\Phi(f) \le \Phi(g)$.

Conversely, assume that Φ is pointwise increasing and rearrangement invariant. Let f and g be functions from $L^1_+(\mathbb{R}^n)$ such that $f^*(s) \le g^*(s)$ for $s > 0$. Consequently,

$$\Phi(f) = \Phi(f^\bigstar) \le \Phi(g^\bigstar) = \Phi(g),$$

where the equalities hold because Φ is rearrangement invariant, and the inequality is due to the fact that Φ is pointwise increasing. Thus, Φ is $*$-increasing.

As for the assertions about strict monotonicity, if Φ is $*$-strictly increasing, then it must be also strictly pointwise increasing. Otherwise, there would exist $f, g \in L^1_+(\mathbb{R}^n)$, satisfying $f(x) \le g(x)$ for $\mathcal{L}^n$-a.e. $x \in \mathbb{R}^n$, $f(x) < g(x)$ for x in a set of positive Lebesgue measure, and $\Phi(f) = \Phi(g)$. The first two conditions entail that $f^*(s) \le g^*(s)$ for $s > 0$ and that $f^*(s) < g^*(s)$ for s in a set of positive measure, and these facts, combined with the equality $\Phi(f) = \Phi(g)$, contradict the $*$-strict monotonicity of Φ.

Suppose now that Φ is strictly pointwise increasing and rearrangement invariant, but not $*$-strictly increasing. Then there exist $f, g \in L^1_+(\mathbb{R}^n)$ fulfilling $f^*(s) \le g^*(s)$ for $s > 0$, $f^*(s) < g^*(s)$ for s in a set of positive measure, and $\Phi(f) = \Phi(g)$. The same argument as above shows that the functions $f^\bigstar$ and $g^\bigstar$ violate the strict pointwise monotonicity of Φ.

(ii) The fact that any $**$-increasing functional is both $*$-increasing and $\prec$-increasing is trivial. To prove the converse, choose any $f, g \in L^1_+(\mathbb{R}^n)$ such that

$$f^{**}(s) \leq g^{**}(s) \qquad \text{for } s > 0. \tag{2.3}$$

If $\int_{\mathbb{R}^n} f(x)dx = \int_{\mathbb{R}^n} g(x)dx$, then $f \prec g$, whence $\Phi(f) \leq \Phi(g)$ by the $\prec$-monotonicity of Φ. Suppose, instead, that $\int_{\mathbb{R}^n} f(x)dx < \int_{\mathbb{R}^n} g(x)dx$. Then, there exists $s_0 > 0$ such that

$$\int_{\mathbb{R}^n} f(x)dx = \int_0^{s_0} g^*(s)ds. \tag{2.4}$$

Set $h(x) = g^\bigstar(x)\chi_{[0,s_0]}(\omega_n|x|^n)$, where χ_E denotes the characteristic function of a set E. Clearly, $h^*(s) = g^*(s)\chi_{[0,s_0]}(s) \leq g^*(s)$ for $s > 0$. Thus, since Φ is $*$-increasing,

$$\Phi(h) \leq \Phi(g). \tag{2.5}$$

On the other hand, by (2.3) and (2.4), $f \prec h$, whence, by the $\prec$-monotonicity of Φ,

$$\Phi(f) \leq \Phi(h). \tag{2.6}$$

Combining (2.5) and (2.6) yields the $**$-monotonicity of Φ.

As far as strict monotonicity properties are concerned, it is again clear that any $**$-strictly increasing functional is also $*$-strictly increasing and $\prec$-strictly increasing. Conversely, if Φ is both $*$-strictly increasing and $\prec$-strictly increasing, and if $f, g \in L^1_+(\mathbb{R}^n)$ satisfy (2.3) and $\Phi(f) = \Phi(g)$, then equality holds in (2.5) and (2.6). The $*$-strict monotonicity and the $\prec$-strict monotonicity then imply that $g^* \equiv h^* \equiv f^*$. Hence, Φ is $**$-strictly increasing. □

We now come to the proof of Theorem 1.2. Basic tools are the isoperimetric inequality in $\mathbb{R}^n$ and the coarea formula for Sobolev functions. De Giorgi's isoperimetric theorem in $\mathbb{R}^n$ states that

$$\mathcal{H}^{n-1}(\partial^* E) \geq n\omega_n^{1/n}\mathcal{L}^n(E)^{1-1/n} \tag{2.7}$$

for every measurable subset E of $\mathbb{R}^n$ having finite measure, and that equality holds in (2.7) if and only if E is equivalent to a ball. Here, $\partial^* E$ denotes the reduced boundary of E.

The coarea formula entails that if $u \in W^1_+(\mathbb{R}^n)$ and $f : \mathbb{R}^n \to [0, \infty)$ is a Borel function, then

$$\int_{\mathbb{R}^n} |\nabla u|(x) f(x)dx = \int_0^\infty dt \int_{\partial^*\{u>t\}} f(x)d\mathcal{H}^{n-1}(x) \tag{2.8}$$

(see, e.g., [AFP], [Z]). Notice that, if a suitable precise representative of u is chosen, a choice that will be always tacitly made throughout, then $\partial^*\{u > t\}$ and $\{u = t\}$ agree, up to a set of zero $\mathcal{H}^{n-1}$-measure, for $\mathcal{L}^1$-a.e. $t > 0$, and hence (2.8) reads

$$\int_{\mathbb{R}^n} |\nabla u|(x) f(x)dx = \int_0^\infty dt \int_{\{u=t\}} f(x)d\mathcal{H}^{n-1}(x). \tag{2.9}$$

Another ingredient in our proof of Theorem 1.2 is the following lemma (see [AT], [FV2]).

LEMMA 2.4. *Let $u \in W^1_+(\mathbb{R}^n)$. Then the function given by*

$$s \mapsto \int_{u>u^*(s)} |\nabla u(x)|dx \qquad \text{for } s \geq 0$$

is absolutely continuous in $[0,\infty)$. Moreover, on setting

$$|\nabla u|_{*u}(s) = \frac{d}{ds}\int_{u>u^*(s)} |\nabla u|(x)dx \qquad \text{for } s \geq 0$$

and

$$|\nabla u|_{\bigstar u}(x) = |\nabla u|_{*u}(\omega_n |x|^n) \qquad \text{for } x \in \mathbb{R}^n$$

we have

$$|\nabla u|_{\bigstar u} \prec |\nabla u|. \tag{2.10}$$

Proof of Theorem 1.2. By the coarea formula (2.8),

$$|\nabla u|_{*u}(s) = -\frac{du^*}{ds}(s)\mathcal{H}^{n-1}(\partial^*\{u > u^*(s)\}) \qquad \text{for } \mathcal{L}^1\text{-a.e. } s > 0. \tag{2.11}$$

Denote by $\{t_i\}_{i\in P}$, with $P \subseteq \mathbb{N}$, the (possibly empty) family of all levels $t > 0$ satisfying

$$\mathcal{L}^n(\{u = t_i\}) = \mathcal{L}^1(\{u^* = t_i\}) > 0 \qquad \text{for } i \in P,$$

and by $\{I_i\}_{i\in P}$ the corresponding family of intervals in $[0, \mathcal{L}^n(\{u > 0\})]$ such that $(u^*)_{|I_i} = t_i$ for $i \in P$. Then,

$$\mathcal{L}^n(\{u > u^*(s)\}) = s \quad \text{for every} \quad s \in [0, \mathcal{L}^n(\{u > 0\})] \setminus \left(\cup_{i\in P} I_i\right) \tag{2.12}$$

and

$$\frac{du^*}{ds}(s) = 0 \qquad \text{for } \mathcal{L}^1\text{-a.e. } s \in \cup_{i\in P} I_i.$$

Thus, from (2.11) and from the isoperimetric inequality (2.7), we deduce that

$$n\omega_n^{1/n} s^{1-1/n}\left(-\frac{du^*}{ds}(s)\right) \leq |\nabla u|_{*u}(s) \qquad \text{for } \mathcal{L}^1\text{-a.e. } s > 0. \tag{2.13}$$

Hence, owing to (2.1),

$$|\nabla u^\bigstar(x)| \leq |\nabla u|_{\bigstar u}(x) \qquad \text{for } \mathcal{L}^n\text{-a.e. } x \in \mathbb{R}^n. \tag{2.14}$$

Combining (2.14) and (2.10) yields

$$\Phi(|\nabla u^\bigstar|) \leq \Phi(|\nabla u|_{\bigstar u}) \leq \Phi(|\nabla u|), \tag{2.15}$$

where the first inequality holds because Φ is, in particular, pointwise increasing, and the second one because Φ is also $\prec$-increasing (see Proposition 2.3). □

3. Extremals of $*$-strictly increasing functionals. This section is devoted to Theorem 1.4. Its proof, as well as the proof of Theorem 1.6 contained in the next section, makes use of measure preserving maps. Recall that, given subsets Ω of $\mathbb{R}^n$ and G of $\mathbb{R}^m$ having finite Lebesgue measure, a function $\gamma : G \to \Omega$ is called a *measure preserving* (briefly *m.p.*) *map* if

$$\mathcal{L}^m(\gamma^{-1}(E)) = \mathcal{L}^n(E)$$

for every measurable subset E of Ω. Notice that, on modifying, if necessary, γ on a set of Lebesgue measure zero, we may assume without loss of generality that γ is a Borel function.

Since any measurable function $f : \Omega \to [0, +\infty)$ is equidistributed with the function $f \circ \gamma : G \to [0, +\infty)$, we have

$$\int_G f(\gamma(y))dy = \int_\Omega f(x)dx. \tag{3.1}$$

If $\sigma : \Omega \to [0, \mathcal{L}^n(\Omega)]$ is a bijective m.p. map, then $\sigma^{-1} : [0, \mathcal{L}^n(\Omega)] \to \Omega$ is also an m.p. map, and hence (3.1) yields

$$\int_0^{\mathcal{L}^n(\Omega)} f(\sigma^{-1}(s))ds = \int_\Omega f(x)dx. \tag{3.2}$$

In what follows, we shall repeatedly exploit the fact that if $\sigma : \Omega \to [0, \mathcal{L}^n(\Omega)]$ is any m.p. map, $\phi : [0, \mathcal{L}^n(\Omega)] \to [0, \infty)$ is nondecreasing and right-continuous, and $u : \mathbb{R}^n \to [0, \infty)$ is given by

$$u(x) = \begin{cases} \phi \circ \sigma(x) & \text{if } x \in \Omega, \\ 0 & \text{otherwise,} \end{cases} \tag{3.3}$$

then, by the equimeasurability of u and ϕ,

$$u^*(s) = \begin{cases} \phi(s) & \text{if } s \in [0, \mathcal{L}^n(\Omega)), \\ 0 & \text{otherwise.} \end{cases} \tag{3.4}$$

Proof of Theorem 1.4. Assume that Φ is $*$-strictly increasing. Let u be any minimal rearrangement of Φ. Since u satisfies (1.11), equality holds in the first inequality in (2.15). Inasmuch as Φ is $*$-strictly increasing, by Proposition 2.3 it is also pointwise strictly increasing. An inspection of the proof of Theorem 1.2 then reveals that equality must hold in (2.14) for $\mathcal{L}^n$-a.e. $x \in \mathbb{R}^n$, and hence in (2.13) for $\mathcal{L}^1$-a.e. $s > 0$. In conclusion, owing to (2.11), one has that

$$\mathcal{H}^{n-1}\left(\partial^*\{u > u^*(s)\}\right) = n\omega_n^{1/n} s^{1-1/n} \tag{3.5}$$

for $\mathcal{L}^1$-a.e. $s > 0$ such that $\frac{du^*}{ds}(s)$ exists and is different from zero. Set

$$D_1 = \{s > 0 : u^* \text{ is not differentiable at } s\}$$

and

$$D_2 = \left\{ s > 0 : \frac{du^*}{ds}(s) = 0 \right\},$$

and observe that the intervals $\{I_i\}_{i\in P}$ introduced in the proof of Theorem 1.2 satisfy $\cup_{i\in P} I_i \subseteq D_1 \cup D_2$. Thus, owing to (2.12), equation (3.5) reads

$$\mathcal{H}^{n-1}\left(\partial^*\{u > u^*(s)\}\right) = n\omega_n^{1/n}\mathcal{L}^n\left(\{u > u^*(s)\}\right)^{1-1/n} \tag{3.6}$$

for $\mathcal{L}^1$-a.e. $s \notin D_1 \bigcup D_2$. Since u^* is locally absolutely continuous on $(0,\infty)$, then $\mathcal{L}^1(D_1) = 0$, and since absolutely continuous functions map sets of measure zero into sets of measure zero, $\mathcal{L}^1(u^*(D_1)) = 0$ as well. We also have $\mathcal{L}^1(u^*(D_2)) = 0$ (see, e.g., [CF1, Lemma 2.4]). Consequently, one can infer from (3.6) that

$$\mathcal{H}^{n-1}\left(\partial^*\{u^* > t\}\right) = n\omega_n^{1/n}\mathcal{L}^n\left(\{u > t\}\right)^{1-1/n} \qquad \text{for } \mathcal{L}^1\text{-a.e. } t \in (0, \operatorname{ess\,sup} u).$$

In other words, equality holds in the isoperimetric inequality (2.7) with $E = \{u > t\}$ for $\mathcal{L}^1$-a.e. $t \in (0, \operatorname{ess\,sup} u)$. Hence, (1.12) follows.

Conversely, assume that every function satisfying (1.11) necessarily fulfills (1.12), and suppose, by contradiction, that Φ is not $*$-strictly increasing. Then there exist $f, g \in L^1_+(\mathbb{R}^n)$ and $s_0 > 0$ satisfying

$$f^*(s) \le g^*(s) \qquad \text{for every } s > 0, \tag{3.7}$$

$$\Phi(f) = \Phi(g) < +\infty, \tag{3.8}$$

and

$$0 < f^*(s_0) < g^*(s_0).$$

This information will enable us to exhibit a function $u \in W^1_+(\mathbb{R}^n)$, in the form (3.3), fulfilling (1.11) but not (1.12). First, choose $\Omega = \{x : \omega_N|x|^n \le \mathcal{L}^n(\{g > 0\})\}$ and define $\phi : [0, \mathcal{L}^n(\Omega)] \to [0, +\infty)$ as

$$\phi(s) = \int_s^{\mathcal{L}^n(\Omega)} \frac{f^*(r)}{n\omega_n^{1/n} r^{1-1/n}}\, dr \qquad \text{for } s \in [0, \mathcal{L}^n(\Omega)]. \tag{3.9}$$

Next, we construct σ. Consider any family $\mathcal{D} = \{D(s)\}_{s\in[0,\mathcal{L}^n(\Omega)]}$ of measurable subsets of Ω satisfying

$$D(s_1) \subseteq D(s_2) \qquad \text{if} \quad 0 \le s_1 \le s_2 \le \mathcal{L}^n(\Omega) \tag{3.10}$$

and

$$\mathcal{L}^n(D(s)) = s \qquad \text{for } s \in [0, \mathcal{L}^n(\Omega)]. \tag{3.11}$$

If σ is given by

$$\sigma(x) = \inf\{s > 0 : x \in D(s)\} \qquad \text{for } x \in \Omega, \tag{3.12}$$

then

$$\sigma^{-1}\left((0, s)\right) = D(s) \qquad \text{for } s \in [0, \mathcal{L}^n(\Omega)].$$

Hence, σ is an m.p. map, and its level sets belong to the family $\mathcal{D}$. The point is now to choose the sets $D(s)$ in such a way that the function u given by (3.3), with ϕ as

in (3.9), enjoys the desired properties. To this purpose, suppose for a moment that $D(s) = \{x \in \mathbb{R}^n : \omega_n |x|^n < s\}$ for $s > 0$, and observe that, in this case, $\sigma(x) = \omega_n |x|^n$, $u \equiv u^\bigstar$, and hence, in particular, (1.11) certainly holds. The idea is then to slightly perturb the balls $\{x \in \mathbb{R}^n : \omega_n |x|^n < s\}$ for s close to s_0, and exploit (3.8) to deduce that the function u, associated with this perturbed function σ, still fulfills (1.11). In order to make this idea precise, note that, since f^* and g^* are right continuous, there exist positive numbers ϵ and δ such that

$$f^*(s)(1+\delta) < g^*(s) \qquad \text{for every } s \in [s_0, s_0+\epsilon]. \tag{3.13}$$

Then we define

$$D(s) = \begin{cases} \{x \in \mathbb{R}^n : \omega_n |x|^n < s\} & \text{if } s \notin [s_0, s_0+\epsilon], \\ \left\{ x \in \mathbb{R}^n : \omega_n \left[\dfrac{x_1^2}{a^2(s)} + \displaystyle\sum_{i=2}^n \dfrac{x_i^2}{b^2(s)} \right]^{n/2} < s \right\} & \text{if } s \in [s_0, s_0+\epsilon], \end{cases} \tag{3.14}$$

where the functions a and b are sufficiently smooth, nonconstant in $[s_0, s_0+\epsilon]$, and satisfy the following properties:

$$a(s) b^{n-1}(s) = 1 \quad \text{for} \quad s \in [s_0, s_0+\epsilon], \tag{3.15}$$

$$a(s_0) = a(s_0+\epsilon) = 1, \tag{3.16}$$

$$\min\left\{ \left(a(s)s^{1/n}\right)', \left(b(s)s^{1/n}\right)' \right\} \left(\frac{s_0}{s_0+\epsilon} \right)^{1/n} \geq \frac{s^{-1+1/n}}{n(1+\delta)} \qquad \text{for } s \in [s_0, s_0+\epsilon]. \tag{3.17}$$

Here, prime stands for differentiation. In particular, by (3.17), the functions $s \mapsto a(s)s^{1/n}$ and $s \mapsto b(s)s^{1/n}$ are increasing in $[s_0, s_0+\epsilon]$. A possible choice is, for instance,

$$a(s) = \left[\frac{(s_0+\epsilon)^{1/n} - s_0^{1/n}}{\epsilon} (s - s_0) + s_0^{1/n} \right] s^{-1/n}$$

and

$$b(s) = a(s)^{-1/(n-1)},$$

provided that ϵ is sufficiently small. Notice that (3.16) along with the monotonicity of $a(s)s^{1/n}$ and $b(s)s^{1/n}$ ensure that (3.10) is fulfilled, whereas (3.15) implies (3.11). Condition (3.17), combined with (3.13), will be used to show that

$$\Phi(|\nabla u^\bigstar|) = \Phi(|\nabla u|). \tag{3.18}$$

Clearly, this yields the announced contradiction, since the level sets of u whose measure lies between s_0 and $s_0+\epsilon$ are not balls.

To verify (3.18), observe that, by (3.3) and (3.9),

$$|\nabla u(x)| = \frac{f^*(\sigma(x))}{n\omega_n^{1/n} \sigma(x)^{1-1/n}} |\nabla \sigma(x)| \qquad \text{for } \mathcal{L}^n\text{-a.e. } x \in \Omega. \tag{3.19}$$

Such an equation holds since σ is Lipschitz continuous. The Lipschitz continuity of σ is, in turn, a consequence of the fact that, by (3.12) and (3.14), $\sigma(x)$ equals $\omega_n|x|^n$ when $\omega_n|x|^n \notin [s_0, s_0+\epsilon]$, and that it is implicitly defined by the equation

$$K(x, \sigma(x)) = 1 \tag{3.20}$$

otherwise, where $K : \mathbb{R}^n \times (0,\infty) \to \mathbb{R}$ is given by

$$K(x,s) = \Big(\frac{\omega_n}{s}\Big)^{2/n} \frac{x_1^2}{a(s)^2} + \Big(\frac{\omega_n}{s}\Big)^{2/n} \frac{1}{b(s)^2} \sum_{i=2}^n x_i^2 \qquad \text{for } (x,s) \in \mathbb{R}^n \times (0,\infty).$$

Now we have

$$|\nabla \sigma(x)| = \left[\frac{\left[\left(\frac{\omega_n^{1/n}}{s^{1/n} a(s)} \right)^4 x_1^2 + \left(\frac{\omega_n^{1/n}}{s^{1/n} b(s)} \right)^4 \sum_{i=2}^n x_i^2 \right]^{1/2}}{\left(\frac{\omega_n^{1/n}}{s^{1/n} a(s)} \right)^2 x_1^2 \frac{\big(s^{1/n} a(s)\big)'}{s^{1/n} a(s)} + \left(\frac{\omega_n^{1/n}}{s^{1/n} b(s)} \right)^2 \frac{\big(s^{1/n} b(s)\big)'}{s^{1/n} b(s)} \sum_{i=2}^n x_i^2} \right]_{s=\sigma(x)} \tag{3.21}$$

if $s_0 \le \omega_n|x|^n \le s_0+\epsilon$, by the implicit function theorem, and

$$|\nabla \sigma(x)| = n \omega_n^{1/n} \sigma(x)^{1-1/n} \qquad \text{if} \quad \omega_n|x|^n \notin [s_0, s_0+\epsilon]. \tag{3.22}$$

From (3.21), via the monotonicity of $a(s)s^{1/n}$ and $b(s)s^{1/n}$, and due to (3.16), (3.17), and (3.20), one can easily deduce that

$$|\nabla \sigma(x)| \le n \omega_n^{1/n} \sigma(x)^{1-1/n} (1+\delta) \qquad \text{if } s_0 \le \omega_n|x|^n \le s_0+\epsilon. \tag{3.23}$$

Thus (3.19), (3.22), and (3.23) yield

$$|\nabla u(x)| \le h(x) \qquad \text{for } \mathcal{L}^n\text{-a.e. } x \in \Omega, \tag{3.24}$$

where

$$h(x) = \begin{cases} f^*(\sigma(x))(1+\delta) & \text{if } s_0 \le \omega_n|x|^n \le s_0+\epsilon, \\ f^*(\sigma(x)) & \text{otherwise.} \end{cases}$$

By (3.7) and (3.13),

$$h(x) \le g^*(\sigma(x)) \qquad \text{for } \mathcal{L}^n\text{-a.e. } x \in \Omega. \tag{3.25}$$

Combining (3.24) and (3.25), and exploiting the fact that σ is an m.p. map tell us that

$$|\nabla u|^*(s) \le g^*(s) \qquad \text{for } s > 0. \tag{3.26}$$

On the other hand,

$$f^{**}(s) = |\nabla u^\bigstar|^{**}(s) \le |\nabla u|^{**}(s) \le g^{**}(s) \qquad \text{for } s > 0,$$

where the equality is due to (2.1) and to (3.4) and (3.9), the first inequality to (1.10), and the last inequality to (3.26). Hence, owing to (3.8), equation (3.18) follows. □

4. Extremals of $**$-strictly increasing functionals. The proof of Theorem 1.6, which will be accomplished in this section, requires some preliminary results. The first one appears in [ALT, Theorem 2.3] and deals with weak limits in L^1 of equidistributed sequences of functions.

LEMMA 4.1. *Let Ω be a measurable subset of $\mathbb{R}^n$ having finite measure, and let $f \in L^1(\Omega)$. Let $\{f_k\}_{k\in\mathbb{N}}$ be any sequence of functions in $L^1(\Omega)$ such that*

$$f_k \rightharpoonup f \quad \text{weakly in } L^1(\Omega) \quad \text{and} \quad f_k^* \equiv f^* \qquad \text{for every } k \in \mathbb{N}.$$

Then

$$f_k \to f \quad \text{strongly in } L^1(\Omega).$$

The convergence in L^1 of the composition of a fixed function with a convergent sequence of m.p. maps is the object of the following lemma.

LEMMA 4.2. *Let Ω be a measurable subset of $\mathbb{R}^n$ having finite measure, and let σ and $\{\sigma_k\}_{k\in\mathbb{N}}$ be, respectively, an m.p. map and a sequence of m.p. maps from Ω into $[0, \mathcal{L}^n(\Omega)]$ such that*

$$\lim_{k\to+\infty} \sigma_k(x) = \sigma(x) \qquad \text{for } \mathcal{L}^n\text{-a.e. } x \in \Omega.$$

Let ϕ be any function from $L^1(0, \mathcal{L}^n(\Omega))$. Then

$$\phi \circ \sigma_k \to \phi \circ \sigma \qquad \text{strongly in } L^1(\Omega). \tag{4.1}$$

Proof. When ϕ is continuous, $\lim_{k\to+\infty} \phi(\sigma_k(x)) = \phi(\sigma(x))$ for $\mathcal{L}^n$-a.e. $x \in \Omega$. Moreover, since the functions $\phi\circ\sigma_k$, $\phi\circ\sigma$, and ϕ are equimeasurable for every $k \in \mathbb{N}$, $\| \phi\circ\sigma_k \|_{L^1(\Omega)} = \| \phi\circ\sigma \|_{L^1(\Omega)} = \| \phi \|_{L^1(0,\mathcal{L}^n(\Omega))}$ for every $k \in \mathbb{N}$. Hence (4.1) follows (see, e.g., [AFP, Proposition 1.33]). In the general case, where $\phi \in L^1(0, \ln(\Omega))$, fix any $\epsilon > 0$, and choose a continuous function $\tilde\phi : [0, \mathcal{L}^n(\Omega)] \to \mathbb{R}$ such that $\| \phi - \tilde\phi \|_{L^1(0,\mathcal{L}^n(\Omega))} < \epsilon$. Hence,

$$\begin{aligned}\int_\Omega |\phi(\sigma_k(x)) - \phi(\sigma(x))|dx &\le \int_\Omega |\phi(\sigma_k(x)) - \tilde\phi(\sigma_k(x))|dx \\ &+ \int_\Omega |\tilde\phi(\sigma_k(x)) - \tilde\phi(\sigma(x))|dx + \int_\Omega |\tilde\phi(\sigma(x)) - \phi(\sigma(x))|dx \\ &= 2 \| \phi - \tilde\phi \|_{L^1(0,\mathcal{L}^n(\Omega))} + \| \tilde\phi\circ\sigma_k - \tilde\phi\circ\sigma \|_{L^1(\Omega)} \le 2\epsilon + \| \tilde\phi\circ\sigma_k - \tilde\phi\circ\sigma \|_{L^1(\Omega)}.\end{aligned}$$

Notice that the equality holds by property (3.1). Owing to the arbitrariness of ϵ, (4.1) for ϕ is now a consequence of (4.1) applied to $\tilde\phi$. □

The next lemma provides us with a weak approximation $|\nabla u|_{*u}$ involving a sequence of m.p. maps related to the level sets of u.

LEMMA 4.3. *Let $u \in W^1_+(\mathbb{R}^n)$. Let σ and $\{\sigma_k\}_{k\in\mathbb{N}}$ be an m.p. map and a sequence of bijective m.p. maps, respectively, from $\{u > 0\}$ into $[0, \mathcal{L}^n(\{u > 0\})]$, such that*

$$u(x) = u^*(\sigma(x)) \qquad \text{for } \mathcal{L}^n\text{-a.e. } x \in \{u > 0\} \tag{4.2}$$

and

$$\lim_{k\to+\infty} \sigma_k(x) = \sigma(x) \qquad \text{for } \mathcal{L}^n\text{-a.e. } x \in \{u > 0\}. \tag{4.3}$$

Then

$$|\nabla u| \circ \sigma_k^{-1} \rightharpoonup |\nabla u|_{*u} \qquad \text{weakly in } L^1(0, \mathcal{L}^n(\{u > 0\})).$$

Remark 4.4. Let us notice that σ and $\{\sigma_k\}$, as in the statement of Lemma 5.1, certainly exist owing to [FV1].

Proof. Set $V = \mathcal{L}^n(\{u > 0\})$. We begin by showing that

$$\lim_{k\to+\infty} \int_0^V |\nabla u|(\sigma_k^{-1}(t))\varphi(t)dt = \int_0^V |\nabla u|_{*u}(t)\varphi(t)dt \tag{4.4}$$

for every $\varphi \in C^0(0, V)$. In order to prove (4.4), observe first that

$$\begin{aligned} \lim_{k\to+\infty} \int_0^V |\nabla u|(\sigma_k^{-1}(t))\varphi(t)dt &= \lim_{k\to+\infty} \int_{\{u>0\}} |\nabla u|(x)\varphi(\sigma_k(x))dx \\ &= \int_{\{u>0\}} |\nabla u|(x)\varphi(\sigma(x))dx, \end{aligned} \tag{4.5}$$

where the former equality is due to (3.2) and the latter follows from (4.3) via the dominated convergence theorem for integrals. Now, let $\{t_i\}_{i\in P}$ and $\{I_i\}_{i\in P}$ be the families of levels and intervals, respectively, introduced in the proof of Theorem 1.2. It is easily seen that

$$u^{*-1}(\{t\}) = \mu(t) \qquad \text{if } t \neq t_i \text{ for every } i \in P \tag{4.6}$$

and (see, e.g., [BZ, proof of Lemma 2.4])

$$\mu(u^*(s)) = s \qquad \text{if } s \notin \cup_{i\in P} I_i. \tag{4.7}$$

By the coarea formula (2.9),

$$\int_{\{u>0\}} |\nabla u|(x)\varphi(\sigma(x))dx = \int_0^\infty dt \int_{\{u=t\}} \varphi(\sigma(x))d\mathcal{H}^{n-1}(x). \tag{4.8}$$

Furthermore, by (4.2) and (4.6),

$$\{u = t\} = \{\sigma = \mu(t)\} \qquad \text{if } t \neq t_i \text{ for every } i \in P. \tag{4.9}$$

Consequently, (4.8) reads

$$\int_{\{u>0\}} |\nabla u|(x)\varphi(\sigma(x))dx = \int_0^\infty \varphi(\mu(t))\mathcal{H}^{n-1}(\{u = t\})dt. \tag{4.10}$$

The change of variable $t = u^*(s)$ in the last integral and (4.7) entail that

$$\int_0^\infty \varphi(\mu(t))\mathcal{H}^{n-1}(\{u = t\})dt = \int_0^V \varphi(s)\mathcal{H}^{n-1}(\{u = u^*(s)\}) \left(-\frac{du^*}{ds}(s)\right) ds. \tag{4.11}$$

Thanks to the coarea formula (2.9) again,

$$|\nabla u|_{*u}(s) = \left(-\frac{du^*}{ds}(s)\right) \mathcal{H}^{n-1}(\{u = u^*(s)\}) \qquad \text{for } \mathcal{L}^1\text{-a.e. } s > 0. \tag{4.12}$$

Combining (4.5), (4.8), (4.10), (4.11), and (4.12) yields (4.4).

In order to conclude, we need to extend (4.4) to every $\varphi \in L^\infty(0,V)$. Fixing any such φ and any $\epsilon > 0$, by Lusin's theorem there exists $\tilde{\varphi} \in C^0(0,V)$ such that

$$\mathcal{L}^1(\{t : \varphi(t) \neq \tilde{\varphi}(t)\}) < \epsilon \tag{4.13}$$

and

$$\|\tilde{\varphi}\|_{L^\infty(0,V)} \leq \|\varphi\|_{L^\infty(0,V)}. \tag{4.14}$$

By (4.14),

(4.15)
$$\begin{aligned}
&\left| \int_0^V \big(|\nabla u|(\sigma_k^{-1}(t)) - |\nabla u|_{*u}(t)\big)\varphi(t)dt \right| \leq \left| \int_0^V \big(|\nabla u|(\sigma_k^{-1}(t)) - |\nabla u|_{*u}(t)\big)\tilde{\varphi}(t)dt \right| \\
&\qquad + \left| \int_{\{\varphi \neq \tilde{\varphi}\}} \big(|\nabla u|(\sigma_k^{-1}(t)) - |\nabla u|_{*u}(t)\big)\big(\varphi(t) - \tilde{\varphi}(t)\big)dt \right| \\
&\leq \left| \int_0^V \big(|\nabla u|(\sigma_k^{-1}(t)) - |\nabla u|_{*u}(t)\big)\tilde{\varphi}(t)dt \right| \\
&\qquad + 2\|\varphi\|_{L^\infty(0,V)} \int_{\{\varphi \neq \tilde{\varphi}\}} \big(|\nabla u|(\sigma_k^{-1}(t)) + |\nabla u|_{*u}(t)\big)\, dt.
\end{aligned}$$

Equations (3.2) and (2.10) yield

$$\int_{\{\varphi \neq \tilde{\varphi}\}} |\nabla u|_{*u}(t)dt \leq \int_0^{\mathcal{L}^1(\{\varphi \neq \tilde{\varphi}\})} (|\nabla u|_{*u})^*(s)ds \leq \int_0^{\mathcal{L}^1(\{\varphi \neq \tilde{\varphi}\})} |\nabla u|^*(s)ds. \tag{4.16}$$

Moreover, since σ_k is a bijective m.p. map, $(|\nabla u| \circ \sigma_k^{-1})^* \equiv |\nabla u|^*$ for every $k \in \mathbb{N}$. Hence, by (3.2) and (4.13),

$$\int_{\{\varphi \neq \tilde{\varphi}\}} |\nabla u|(\sigma_k^{-1}(t))dt \leq \int_0^{\mathcal{L}^1(\{\varphi \neq \tilde{\varphi}\})} \big(|\nabla u| \circ \sigma_k^{-1}\big)^*(s)ds \leq \int_0^{\epsilon} |\nabla u|^*(s)ds. \tag{4.17}$$

From (4.15), (4.16), (4.17), and (4.13) one infers that

$$\begin{aligned}
&\left| \int_0^V \big(|\nabla u|(\sigma_k^{-1}(t)) - |\nabla u|_{*u}(t)\big)\varphi(t)dt \right| \\
&\qquad \leq \left| \int_0^V \big(|\nabla u|(\sigma_k^{-1}(t)) - |\nabla u|_{*u}(t)\big)\tilde{\varphi}(t)dt \right| + 4\|\varphi\|_{L^\infty(0,V)} \int_0^{\epsilon} |\nabla u|^*(s)ds.
\end{aligned}$$

Owing to the arbitrariness of ϵ, equation (4.4) follows from the same equation applied with φ replaced by $\tilde{\varphi}$. □

A technical, but crucial, result in preparation for Theorem 1.6 is the following perturbation lemma.

LEMMA 4.5. *Let f and g be any functions in $L^1_+(\mathbb{R}^n)$ satisfying*

$$f \prec g \tag{4.18}$$

and

$$f^* \not\equiv g^*. \tag{4.19}$$

Then there exist numbers $\bar{s} > 0$, $\epsilon > 0$, *and* $\delta \in (0, \frac{1}{2})$ *having the following property. Fix any point* $x_0 \in \mathbb{R}^n$ *such that* $|x_0| < \epsilon$, *and set*

$$\Omega_{\bar{s},\epsilon} = \{x : \omega_n |x - x_0|^n \geq \bar{s} \ \textit{and} \ \omega_n |x|^n \leq \bar{s} + \epsilon\}.$$

If

$$\sigma : \Omega_{\bar{s},\epsilon} \to [\bar{s}, \bar{s} + \epsilon]$$

is an m.p. map and h *is a function from* $L^1_+(\mathbb{R}^n)$ *fulfilling*

$$\int_{\mathbb{R}^n} h(x)dx = \int_{\mathbb{R}^n} f(x)dx, \tag{4.20}$$

$$h(x) = \begin{cases} f^\bigstar(x - x_0) & \textit{if } \omega_n |x - x_0|^n < \bar{s}, \\ f^\bigstar(x) & \textit{if } \omega_n |x|^n > \bar{s} + \epsilon, \end{cases} \tag{4.21}$$

and

$$f^*(\sigma(x))(1 - \delta) \leq h(x) \leq f^*(\sigma(x))(1 + \delta) \qquad \textit{for } \mathcal{L}^n\textit{-a.e.} \quad x \in \Omega_{\bar{s},\epsilon}, \tag{4.22}$$

then

$$h \prec g. \tag{4.23}$$

Proof. By (4.18) and (4.19), there exists $\hat{s} > 0$ such that $\int_0^{\hat{s}} f^*(r)dr < \int_0^{\hat{s}} g^*(r)dr$. Let $[\hat{a}, \hat{b}]$ be the maximal interval in $[0, +\infty)$ containing $\hat{s}$ and having the property that

$$\int_0^s f^*(r)dr < \int_0^s g^*(r)dr \qquad \text{for } s \in (\hat{a}, \hat{b}).$$

Then,

$$\int_0^{\hat{a}} f^*(r)dr = \int_0^{\hat{a}} g^*(r)dr, \qquad \int_0^{\hat{b}} f^*(r)dr = \int_0^{\hat{b}} g^*(r)dr,$$

and

$$f^*(\hat{a}) \leq g^*(\hat{a}), \qquad f^*(\hat{b}^-) \geq g^*(\hat{b}^-).$$

Here, $f^*(\hat{b}^-)$ and $g^*(\hat{b}^-)$ stand for the limits of f^* and g^* at $\hat{b}$ from the left. It is not difficult to see that a subinterval $[a, b]$ of $[\hat{a}, \hat{b}]$ can be found such that

$$\int_0^s f^*(r)dr < \int_0^s g^*(r)dr \qquad \text{for } s \in [a, b],$$

and

$$f^*(a) < g^*(a), \qquad f^*(b) > g^*(b).$$

Fix any $\eta > 0$ fulfilling

$$f^*(a)(1+\eta) < g^*(a), \qquad f^*(b)(1-\eta) > g^*(b). \tag{4.24}$$

We shall prove that the conclusion holds with

$$\bar{s} = b \tag{4.25}$$

$$\delta = \min\left\{\frac{\eta}{2}, \frac{1}{4}, \frac{1}{f^*(b)} \min_{s\in[a,b]} \int_0^s (g^*(r) - f^*(r))\, dr\right\} \tag{4.26}$$

and any $\epsilon \in (0,1)$ satisfying

$$\frac{f^*(b+\epsilon)}{f^*(b)} > \frac{(1-2\delta)}{(1-\delta)}. \tag{4.27}$$

Notice that, since $\delta < \frac{1}{2}$, such an ϵ certainly exists, due to the continuity of f^* from the right. Let h be any function as in the statement. By (4.18) and (4.20),

$$\int_{\mathbb{R}^n} h(x)dx = \int_{\mathbb{R}^n} g(x)dx.$$

Thus, by (2.2), equation (4.23) will follow if we show that

$$\int_E h(x)dx \le \int_0^{\mathcal{L}^n(E)} g^*(s)ds \tag{4.28}$$

for every measurable subset E of $\mathbb{R}^n$. Given any such E, define

$$E_1 = E \cap G_1, \qquad E_2 = E \cap G_2, \qquad E_3 = E \cap G_3,$$

where

$$G_1 = \{x \in \mathbb{R}^n : \omega_n |x - x_0|^n < b\}, \qquad G_2 = \Omega_{b,\epsilon}, \qquad G_3 = \{x \in \mathbb{R}^n : \omega_n |x|^n > b + \epsilon\},$$

and decompose $\int_E h(x)dx$ as

$$\int_E h(x)dx = \int_{E_1} h(x)dx + \int_{E_2} h(x)dx + \int_{E_3} h(x)dx. \tag{4.29}$$

The first and the third integral on the right-hand of (4.29) can be easily estimated in terms of f^* via (4.21). Indeed,

$$\int_{E_1} h(x)dx = \int_{E_1} f^\bigstar(x - x_0)dx \le \int_0^{\mathcal{L}^n(E_1)} f^*(s)ds \tag{4.30}$$

and

$$\int_{E_3} h(x)dx = \int_{E_3} f^\bigstar(x)dx \le \int_{b+\epsilon}^{b+\epsilon+\mathcal{L}^n(E_3)} f^*(s)ds. \tag{4.31}$$

We now accomplish the proof of (4.28) on distinguishing the following three cases.

Case I. $\mathcal{L}^n(E) \le a$. Since σ is an m.p. map and $\sigma(x) \in [b, b+\epsilon]$ for $\mathcal{L}^n$-a.e. $x \in G_2$, by (4.22)

$$\int_{E_2} h(x)dx \le (1+\delta)\int_{E_2} f^*(\sigma(x))dx \le (1+\delta)\int_b^{b+\mathcal{L}^n(E_2)} f^*(s)ds. \tag{4.32}$$

Furthermore,

$$\begin{aligned}(1+\delta)\int_b^{b+\mathcal{L}^n(E_2)} f^*(s)ds &\le (1+\delta)f^*(a)\mathcal{L}^n(E_2) \le g^*(a)\mathcal{L}^n(E_2)\\ &\le \int_{a-\mathcal{L}^n(E_2)}^{a} g^*(s)ds,\end{aligned} \tag{4.33}$$

where the first and the third inequalities lean on the monotonicity of f^* and g^*, respectively, and the second inequality is a consequence of (4.24) and (4.26). The monotonicity of g^* again and the assumption $\mathcal{L}^n(E) \le a$ entail that

$$\int_{a-\mathcal{L}^n(E_2)}^{a} g^*(s)ds \le \int_{\mathcal{L}^n(E)-\mathcal{L}^n(E_2)}^{\mathcal{L}^n(E)} g^*(s)ds = \int_{\mathcal{L}^n(E_1)+\mathcal{L}^n(E_3)}^{\mathcal{L}^n(E)} g^*(s)ds. \tag{4.34}$$

Combining inequalities (4.29)–(4.34) yields

$$\int_E h(x)dx \le \int_0^{\mathcal{L}^n(E_1)} f^*(s)ds + \int_{b+\epsilon}^{b+\epsilon+\mathcal{L}^n(E_3)} f^*(s)ds + \int_{\mathcal{L}^n(E_1)+\mathcal{L}^n(E_3)}^{\mathcal{L}^n(E)} g^*(s)ds. \tag{4.35}$$

On the other hand,

$$\begin{aligned}\int_0^{\mathcal{L}^n(E_1)} f^*(s)ds + \int_{b+\epsilon}^{b+\epsilon+\mathcal{L}^n(E_3)} f^*(s)ds &\le \int_0^{\mathcal{L}^n(E_1)+\mathcal{L}^n(E_3)} f^*(s)ds\\ &\le \int_0^{\mathcal{L}^n(E_1)+\mathcal{L}^n(E_3)} g^*(s)ds,\end{aligned} \tag{4.36}$$

where the last inequality holds because of (4.18). Inequality (4.28) follows from (4.35) and (4.36).

Case II. $a < \mathcal{L}^n(E) \le b$. We have

$$\begin{aligned}&\int_{E_2} h(x)dx \le (1+\delta)\int_b^{\mathcal{L}^n(E_2)+b} f^*(s)ds \le \int_b^{b+\mathcal{L}^n(E_2)} f^*(s)ds + \delta\mathcal{L}^n(E_2)f^*(b)\\ &\quad\le \int_b^{b+\mathcal{L}^n(E_2)} f^*(s)ds + \delta f^*(b) \le \int_b^{b+\mathcal{L}^n(E_2)} f^*(s)ds + \min_{s\in[a,b]}\int_0^s (g^*(r)-f^*(r))\,dr,\end{aligned} \tag{4.37}$$

where the first inequality is due to (4.32), the second one holds thanks to the monotonicity of f^*, the third one is a consequence of the fact that $\mathcal{L}^n(E_2) \le \epsilon < 1$, and the last one follows from (4.26). Since we are assuming that $a < \mathcal{L}^n(E) \le b$, combining (4.29), (4.30), (4.31), and (4.37) ensures that

$$\begin{aligned}\int_E h(x)dx \le &\int_0^{\mathcal{L}^n(E_1)} f^*(s)ds + \int_{b+\epsilon}^{b+\epsilon+\mathcal{L}^n(E_3)} f^*(s)ds\\ &+ \int_b^{b+\mathcal{L}^n(E_3)} f^*(s)ds + \int_0^{\mathcal{L}^n(E)} (g^*(s)-f^*(s))\,ds.\end{aligned} \tag{4.38}$$

Since the first three integrals on the right-hand side of (4.38) are extended over disjoint intervals whose total measure is $\mathcal{L}^n(E)$, their sum does not exceed $\int_0^{\mathcal{L}^n(E)} f^*(s)ds$. Hence, (4.28) follows.

Case III. $\mathcal{L}^n(E) > b$. Assumptions (4.20) and (4.21) and the choice (4.25) ensure that

$$\begin{aligned}\int_{G_2} h(x)dx &= \int_{\mathbb{R}^n} f(x)dx - \int_{G_1} f^\bigstar(x-x_0)dx - \int_{G_3} f^\bigstar(x)dx \\ &= \int_0^{+\infty} f^*(s)ds - \int_0^b f^*(s)ds - \int_{b+\epsilon}^{+\infty} f^*(s)ds = \int_b^{b+\epsilon} f^*(s)ds. \end{aligned} \tag{4.39}$$

Now,

$$\begin{aligned}\int_{G_2\setminus E_2} h(x)dx &\geq (1-\delta)\int_{G_2\setminus E_2} f^\bigstar(\sigma(x))dx \\ &\geq (1-\delta)\int_{b+\epsilon-\mathcal{L}^n(G_2\setminus E_2)}^{b+\epsilon} f^*(s)ds = (1-\delta)\int_{b+\mathcal{L}^n(E_2)}^{b+\epsilon} f^*(s)ds,\end{aligned} \tag{4.40}$$

where the first inequality is a consequence of (4.22), and the second one holds since $\sigma(x) \in [b, b+\epsilon]$ for $\mathcal{L}^n$-a.e. $x \in G_2$. By (4.27), (4.24), and (4.26),

$$\begin{aligned}(1-\delta)\int_{b+\mathcal{L}^n(E_2)}^{b+\epsilon} f^*(s)ds &\geq (1-\delta) f^*(b+\epsilon)\,(\epsilon - \mathcal{L}^n(E_2)) \\ &\geq g^*(b)\,(\epsilon - \mathcal{L}^n(E_2)) \quad \geq \quad \int_b^{b+\epsilon+\mathcal{L}^n(E_2)} g^*(s)ds.\end{aligned} \tag{4.41}$$

From (4.39)–(4.41), and from the assumption $\mathcal{L}^n(E) > b$, one gets

$$\begin{aligned}\int_{E_2} h(x)dx &\leq \int_b^{b+\epsilon} f^*(s)ds - \int_b^{b+\epsilon+\mathcal{L}^n(E_2)} g^*(s)ds \\ &\leq \int_b^{b+\epsilon} f^*(s)ds - \int_{\mathcal{L}^n(E)}^{\epsilon+\mathcal{L}^n(E)-\mathcal{L}^n(E_2)} g^*(s)ds \\ &= \int_b^{b+\epsilon} f^*(s)ds - \int_{\mathcal{L}^n(E)}^{\epsilon+\mathcal{L}^n(E_1)+\mathcal{L}^n(E_3)} g^*(s)ds.\end{aligned} \tag{4.42}$$

Combining (4.29)–(4.31) and (4.42) yields

$$\int_E h(x)dx \leq \int_0^{\mathcal{L}^n(E_1)} f^*(s)ds + \int_b^{b+\epsilon+\mathcal{L}^n(E_3)} f^*(s)ds - \int_{\mathcal{L}^n(E)}^{\epsilon+\mathcal{L}^n(E_1)+\mathcal{L}^n(E_3)} g^*(s)ds. \tag{4.43}$$

Since $\mathcal{L}^n(E_1) \leq b$ and f^* is nonincreasing,

$$\int_b^{b+\epsilon+\mathcal{L}^n(E_3)} f^*(s)ds \leq \int_{\mathcal{L}^n(E_1)}^{\epsilon+\mathcal{L}^n(E_1)+\mathcal{L}^n(E_3)} f^*(s)ds. \tag{4.44}$$

Inequalities (4.43) and (4.44) and assumption (4.18) enable us to conclude that

$$\int_E h(x)dx \leq \int_0^{\epsilon+\mathcal{L}^n(E_1)+\mathcal{L}^n(E_3)} g^*(s)ds - \int_{\mathcal{L}^n(E)}^{\epsilon+\mathcal{L}^n(E_1)+\mathcal{L}^n(E_3)} g^*(s)ds = \int_0^{\mathcal{L}^n(E)} g^*(s)ds.$$

Hence, (4.28) holds also in this case. □

We are now in position to prove Theorem 1.6.

Proof of Theorem 1.6. Assume that Φ is $**$-strictly increasing. By Proposition 2.3, Φ is, in particular, $\prec$-strictly increasing. If u is a minimal rearrangement, i.e., satisfies (1.11), then, thanks to the second of inequalities (2.15),

$$\Phi\left(|\nabla u|_{\bigstar u}\right) = \Phi\left(|\nabla u|\right) < +\infty. \tag{4.45}$$

From (4.45), (2.10), and the $\prec$-strict monotonicity of Φ, one deduces that

$$\left(|\nabla u|_{\bigstar u}\right)^* \equiv |\nabla u|^*. \tag{4.46}$$

Let $\{\sigma_k\}_{k\in\mathbb{N}}$ and σ be as in Lemma 4.3. Since σ_k is an m.p. map for every $k \in \mathbb{N}$, $\left(|\nabla u| \circ \sigma_k^{-1}\right)^* \equiv |\nabla u|^*$ for every $k \in \mathbb{N}$. Hence, inasmuch as $\left(|\nabla u|_{\bigstar u}\right)^* \equiv \left(|\nabla u|_{*u}\right)^*$, equation (4.46) entails that

$$\left(|\nabla u| \circ \sigma_k^{-1}\right)^* \equiv \left(|\nabla u|_{*u}\right)^* \qquad \text{for every } k \in \mathbb{N}. \tag{4.47}$$

From Lemma 4.3, (4.47), and Lemma 4.1, we infer that

$$\lim_{k\to+\infty} \| |\nabla u| \circ \sigma_k^{-1} - |\nabla u|_{*u}\|_{L^1(0,\mathcal{L}^n(\{u>0\}))} = 0,$$

whence, by (3.2),

$$\lim_{k\to+\infty} \| |\nabla u| - |\nabla u|_{*u} \circ \sigma_k\|_{L^1(\{u>0\})} = 0. \tag{4.48}$$

On the other hand, by Lemma 4.2,

$$\lim_{k\to+\infty} \| |\nabla u| - |\nabla u|_{*u} \circ \sigma_k\|_{L^1(\{u>0\})} = \| |\nabla u| - |\nabla u|_{*u} \circ \sigma\|_{L^1(\{u>0\})}. \tag{4.49}$$

Equations (4.48) and (4.49) tell us that

$$|\nabla u(x)| = |\nabla u|_{*u}(\sigma(x)) \qquad \text{for } \mathcal{L}^n\text{-a.e. } x \in \{u > 0\}. \tag{4.50}$$

Denote by N the set of those points in $\{u > 0\}$ where (4.50) does not hold. Thus $\mathcal{L}^n(N) = 0$. Since both $|\nabla u|$ and $|\nabla u|_{*u} \circ \sigma$ are Borel functions, N is a Borel set. Hence, an application of the coarea formula (2.9) with $f = \chi_N$ entails that

$$\mathcal{H}^{n-1}\left(\{u = t\} \cap N\right) = 0 \qquad \text{for } \mathcal{L}^1\text{-a.e. } t > 0. \tag{4.51}$$

Now, let $\{t_i\}_{i\in P}$ be the family of levels introduced in the proof of Theorem 1.2. Then, by (4.6), we again deduce (4.9). Equations (4.50), (4.51), and (4.9) ensure that, for $\mathcal{L}^1$-a.e. $t > 0$,

$$|\nabla u(x)| = |\nabla u|_{*u}(\mu(t)) \qquad \text{for } \mathcal{H}^{n-1}\text{-a.e. } x \in \{u = t\}.$$

Hence, (1.13) follows.

Conversely, suppose that any minimal rearrangement of Φ necessarily fulfills (1.13). We shall prove that Φ is $**$-strictly increasing. By Proposition 2.3, this is equivalent to showing that Φ is simultaneously $*$-strictly increasing and $\prec$-strictly increasing.

The functional Φ has to be $*$-strictly increasing, since otherwise the same function u constructed in the proof of Theorem 1.4 would satisfy (1.11) but not (1.13).

In order to show that Φ is also $\prec$-strictly increasing, we argue by contradiction, and suppose that $f, g \in L^1_+(\mathbb{R}^n)$ exist such that $f \prec g$ and

$$\Phi(f) = \Phi(g) < +\infty, \tag{4.52}$$

but $f^* \not\equiv g^*$. Our aim is to exhibit a function $u \in W^1_+(\mathbb{R}^n)$ satisfying

$$|\nabla u^\bigstar| \equiv f^\bigstar \tag{4.53}$$

and

$$|\nabla u| \prec g \tag{4.54}$$

but not (1.13). This will lead to a contradiction, since, by (2.15), (4.52)–(4.54), and the $**$-monotonicity of Φ, such a function u is a minimal rearrangement of Φ. As in the proof of Theorem 1.4, we look for a function u in the form (3.3), where

$$\phi(s) = \int_s^{\mathcal{L}^n(\Omega)} \frac{f^*(r)}{n\omega_n^{1/n} r^{1-1/n}} dr \qquad \text{for } s \in [0, \mathcal{L}^n(\Omega)] \tag{4.55}$$

and $\Omega = \{x : \omega_n |x|^n \le \mathcal{L}^n(\{g > 0\})\}$. Owing to (3.4) and (4.55), any such function satisfies (4.53). Thus, our task is to construct σ in such a way that (4.54) holds. The idea is again to obtain u as a perturbation of $u^\bigstar$, namely, to define $\sigma(x)$ by a slight modification of $\omega_n |x|^n$. It is at this stage that Lemma 4.5 comes into play. Actually, the functions f and g satisfy the assumptions of this lemma. Let $\bar{s}$, ϵ, and δ be the numbers appearing in its statement. Consider any $\lambda > 0$ and any sufficiently smooth function

$$p : [\bar{s}, \bar{s} + \epsilon] \to [0, \lambda]$$

enjoying the following properties: p is strictly decreasing,

$$p(\bar{s}) = \lambda, \quad p(\bar{s} + \epsilon) = 0, \tag{4.56}$$

and

$$p'(s) \ge -\frac{\delta}{n(1+\delta)} \frac{s^{-1+1/n}}{\omega_n^{1/n}} \qquad \text{for } s \in [\bar{s}, \bar{s} + \epsilon]. \tag{4.57}$$

In particular, by (4.57), the function $s \mapsto p(s) + (\frac{s}{\omega_n})^{1/n}$ is strictly increasing in $[\bar{s}, \bar{s} + \epsilon]$. For instance, the choice

$$\lambda = \frac{\delta}{1+\delta} \frac{(\bar{s} + \epsilon)^{1/n} - \bar{s}^{1/n}}{\omega_n^{1/n}} \qquad \text{and} \qquad p(s) = \frac{\delta}{1+\delta} \frac{(\bar{s} + \epsilon)^{1/n} - s^{1/n}}{\omega_n^{1/n}}$$

is admissible. Now, define $x_0 \equiv (\lambda, \dots, 0) \in \mathbb{R}^n$ and $P(s) \equiv (p(s), 0, \dots, 0) \in \mathbb{R}^n$ for $s \in [\bar{s}, \bar{s} + \epsilon]$, and set

$$D(s) = \begin{cases} \{x \in \mathbb{R}^n : \omega_n |x - x_0|^n < s\} & \text{if } s < \bar{s}, \\ \{x \in \mathbb{R}^n : \omega_n |x - P(s)|^n < s\} & \text{if } \bar{s} \le s \le \bar{s} + \epsilon, \\ \{x \in \mathbb{R}^n : \omega_n |x|^n < s\} & \text{if } s > \bar{s} + \epsilon. \end{cases}$$

The m.p. map σ associated with the family of balls $\mathcal{D} = \{D(s)\}_{s\in[0,\mathcal{L}^n(\Omega)]}$ as in (3.12) obeys

$$\sigma(x) = \begin{cases} \omega_n|x-x_0|^n & \text{if } \omega_n|x-x_0|^n < \bar{s}, \\ \omega_n|x|^n & \text{if } \omega_n|x|^n > \bar{s}+\epsilon, \end{cases} \tag{4.58}$$

and it is otherwise implicitly defined by the equation

$$H(x,\sigma(x)) = 1,$$

where $H : \mathbb{R}^n \times (0,\infty) \to \mathbb{R}$ is given by

$$H(x,s) = \Big(\frac{\omega_n}{s}\Big)^{2/n} \left[(x_1 - p(s))^2 + \sum_{i=2}^n x_i^2\right] \qquad \text{for} \quad (x,s) \in \mathbb{R}^n \times (0,\infty).$$

Such a function σ is clearly Lipschitz continuous. Moreover, one can easily verify from (4.58) that

$$|\nabla\sigma(x)| = n\omega_n^{1/n}\sigma(x)^{1-1/n} \qquad \text{for} \quad \mathcal{L}^n\text{-a.e. } x \text{ such that } \ \sigma(x) \notin [\bar{s},\bar{s}+\epsilon], \tag{4.59}$$

and that, by the implicit function theorem,

$$|\nabla\sigma(x)| = \left[\left(\frac{1}{n}\frac{s^{2/n-1}}{\omega_n^{2/n}} + (x_1 - p(s))p'(s)\right)^{-1}\left(\frac{s}{\omega_n}\right)^{1/n}\right]_{s=\sigma(x)} \tag{4.60}$$

for $\mathcal{L}^n$-a.e. x such that $\sigma(x) \in [\bar{s},\bar{s}+\epsilon]$. We claim that

$$1-\delta \le \frac{|\nabla\sigma(x)|}{n\omega_n^{1/n}\sigma(x)^{1-1/n}} \le 1+\delta \tag{4.61}$$

for $\mathcal{L}^n$-a.e. x such that $\sigma(x) \in [\bar{s},\bar{s}+\epsilon]$. Indeed, since $|x_1 - p(s)| \le \big(\frac{s}{\omega_n}\big)^{1/n}$ if $s \in [\bar{s},\bar{s}+\epsilon]$, by (4.56) and (4.57) we have

$$\frac{1}{1+\delta}\,\frac{s^{2/n-1}}{n\omega_n^{2/n}} \le \frac{s^{2/n-1}}{n\omega_n^{2/n}} + (x_1 - p(s))p'(s) \le \frac{1+2\delta}{1+\delta}\,\frac{s^{2/n-1}}{n\omega_n^{2/n}}. \tag{4.62}$$

Inequality (4.61) follows via (4.60) and (4.62). From (3.19) and (4.61) we deduce that

$$(1-\delta)f^*(\sigma(x)) \le |\nabla u(x)| \le (1+\delta)f^*(\sigma(x)) \tag{4.63}$$

for $\mathcal{L}^n$-a.e. x such that $\sigma(x) \in [\bar{s},\bar{s}+\epsilon]$. On the other hand, by (4.59) and (3.19),

$$|\nabla u(x)| = \begin{cases} f^\bigstar(x-x_0) & \text{if } \omega_n|x-x_0|^n < \bar{s}, \\ f^\bigstar(x) & \text{if } \omega_n|x|^n > \bar{s}+\epsilon. \end{cases} \tag{4.64}$$

Finally, by the coarea formula (2.8),

$$\begin{aligned} \int_{\mathbb{R}^n} |\nabla u(x)|dx &= \int_{\mathbb{R}^n} \frac{f^*(\sigma(x))}{n\omega_n^{1/n}\sigma(x)^{1-1/n}}|\nabla\sigma(x)|dx \\ &= \int_0^\infty \frac{f^*(t)}{n\omega_n^{1/n}t^{1-1/n}}\mathcal{H}^{n-1}(\partial^*\{\sigma > t\})dt = \int_0^\infty f^*(t)dt = \int_{\mathbb{R}^n} f(x)dx. \end{aligned} \tag{4.65}$$

Notice that in the third equality we have made use of the fact that $\{\sigma > t\}$ is a ball of measure t for every $t > 0$. Equation (4.54) follows from (4.63)–(4.65), via Lemma 4.5 applied with $h = |\nabla u|$. The proof is complete. □

5. Examples. We conclude by discussing the monotonicity and strict monotonicity properties involved in Theorems 1.2, 1.4, and 1.6 for the functionals considered in section 1.

We preliminarily present a few general propositions linking $**$-monotonicity and strict monotonicity to customary notions appearing in the literature. The first one provides sufficient conditions for a functional Φ to be $**$-increasing in terms of convexity and lower-semicontinuity.

PROPOSITION 5.1. *Assume that the functional $\Phi : L^1_+(\mathbb{R}^n) \to [0,\infty]$ is convex, weakly lower-semicontinuous in L^1, and $*$-increasing. Then Φ is $**$-increasing.*

Proof. By [CR, Chapter VI, Lemma 20.2], our assumptions on Φ ensure that a family $\{h_j\}_{j\in J}$, with $J \subseteq \mathbb{N}$, of nonnegative functions $h_j \in L^\infty(\mathbb{R}^n)$ and a family $\{r_j\}_{j\in J}$ of real numbers r_j exist such that

$$\Phi(f) = \sup_{j\in J}\left\{\int_0^\infty f^*(s)h_j^*(s)ds + r_j\right\} \qquad \text{for every } f \in L^1_+(\mathbb{R}^n). \tag{5.1}$$

On the other hand, Hardy's lemma [BS, Chapter 2, Proposition 3.6] entails that if $f^{**}(s) \le g^{**}(s)$ for $s > 0$, then

$$\int_0^\infty f^*(s)\phi(s)ds \le \int_0^\infty g^*(s)\phi(s)ds \tag{5.2}$$

for every nonincreasing function $\phi : [0,\infty) \to [0,\infty)$. Combining (5.1) and (5.2) tells us that Φ is $**$-increasing. □

The next result can be found, e.g., in [BS, Chapter 2, Corollary 4.7] (see also [CR]) and concerns the $**$-monotonicity of rearrangement invariant (r.i.) norms, namely norms in Banach function spaces which are r.i. according to Definition 3.2.

PROPOSITION 5.2. *Any r.i. norm is a $**$-increasing functional.*

The last general property that will be established yields a sufficient condition for the $**$-strict monotonicity of a functional Φ in terms of standard strict convexity and, more generally, of rotundity. Recall that a functional $\Phi : L^1_+(\mathbb{R}^n) \to [0,+\infty]$ is called rotund if

$$\Phi(f) = \Phi(g) = \Phi\left(\frac{f+g}{2}\right) < +\infty \quad \text{implies that} \quad f = g \quad \mathcal{L}^n\text{-a.e. in } \mathbb{R}^n.$$

Clearly, any strictly convex functional Φ is rotund.

PROPOSITION 5.3. *Any rotund and $**$-increasing functional $\Phi : L^1_+(\mathbb{R}^n) \to [0,+\infty]$ is $**$-strictly increasing. In particular, Φ is $**$-strictly increasing, provided that it is $**$-increasing and strictly convex.*

Proof. Let f and g be functions in $L^1_+(\mathbb{R}^n)$ such that

$$f^{**}(s) \le g^{**}(s) \qquad \text{for } s > 0 \tag{5.3}$$

and

$$\Phi(f) = \Phi(g) < +\infty. \tag{5.4}$$

By (5.3),

$$f^{**}(s) \le \frac{f^{**}(s) + g^{**}(s)}{2} \le g^{**}(s) \qquad \text{for } s > 0. \tag{5.5}$$

Moreover,

$$\frac{f^{**}(s)+g^{**}(s)}{2}=\left[\frac{f^{\bigstar}+g^{\bigstar}}{2}\right]^{**}(s)\qquad\text{for } s>0. \tag{5.6}$$

Since Φ is $*$-increasing, and hence rearrangement invariant, equations (5.4)–(5.6) imply that

$$\Phi(f^{\bigstar})=\Phi(f)=\Phi\left(\frac{f^{\bigstar}+g^{\bigstar}}{2}\right)=\Phi(g)=\Phi(g^{\bigstar}).$$

The rotundity of Φ then forces $f^{\bigstar}$ to agree with $g^{\bigstar}$, whence $f^*\equiv g^*$. □

We now examine the concrete examples provided by $\|\ \|_{(p,q)}$, $\|\ \|_{p,q}$, J_A, $\|\ \|_A$, and $\|\ \|_{(A)}$. In order to avoid technical complications, we are not going to consider the most general possible choices of the exponents p, q and of the Young function A. However, the cases discussed below cover most situations arising in applications and interestingly show that even equivalent functionals may enjoy different monotonicity properties.

The following two propositions deal with $\|\ \|_{(p,q)}$ and $\|\ \|_{p,q}$, respectively, for $p, q \in [1,\infty]$.

PROPOSITION 5.4. *Let $1\le p,q\le+\infty$. Then*

(i) $\|\ \|_{(p,q)}$ *is $**$-increasing;*

(ii) $\|\ \|_{(p,q)}$ *is $*$-strictly increasing if and only if $q<+\infty$;*

(iii) $\|\ \|_{(p,q)}$ *is $**$-strictly increasing if and only if $q<+\infty$.*

Proof. The facts that $\|\ \|_{(p,q)}$ is $**$-increasing and that, if $q<+\infty$, it is also $**$-strictly increasing (and hence $*$-strictly increasing) are obvious consequences of the definitions.

To verify that $\|\ \|_{(p,q)}$ is not $*$-strictly increasing (and hence also not $**$-strictly increasing) when $q=+\infty$ and $1\le p\le+\infty$, choose any functions $f, g\in L^1_+(\mathbb{R}^n)$ such that

$$f^*(s)=\begin{cases}s^{-1/p} & \text{if } s\in(0,1),\\ 0 & \text{otherwise,}\end{cases}\qquad g^*(s)=\begin{cases}s^{-1/p} & \text{if } s\in(0,1),\\ 1 & \text{if } s\in[1,2),\\ 0 & \text{otherwise.}\end{cases}$$

(Here, we agree that $s^{-1/p}\equiv 1$ if $p=+\infty$.) Obviously, $f^*(s)\le g^*(s)$ for $s>0$, and $f^*\not\equiv g^*$, but nevertheless, $\|f\|_{L^{p,\infty}}=\|g\|_{L^{p,\infty}}$. □

PROPOSITION 5.5. *Let $1\le p,q\le+\infty$. Then*

(i) $\|\ \|_{p,q}$ *is $**$-increasing if and only if $q\le p$;*

(ii) $\|\ \|_{p,q}$ *is $*$-strictly increasing if and only if $q\le p$ and $q<+\infty$;*

(iii) $\|\ \|_{p,q}$ *is $**$-strictly increasing if and only if $q\le p$, $q<+\infty$, and $p>1$.*

Proof. (i) If $q\le p$, then the function $s^{\frac{q}{p}-1}$ is nonincreasing. Thus, by Hardy's lemma [BS, Chapter 2, Proposition 3.6],

$$\int_0^\infty f^*(s)^q s^{\frac{q}{p}-1}ds\le\int_0^\infty g^*(s)^q s^{\frac{q}{p}-1}ds$$

whenever $f^{**}(s)\le g^{**}(s)$. Hence, $\|\ \|_{p,q}$ is $**$-increasing. Assume now that $q>p$. Fix $\alpha\in(0,1)$, and choose any $f, g\in L^1_+(\mathbb{R}^n)$ such that

$$g^*(s)=\begin{cases}s^{-\alpha} & \text{if } s\in(0,1),\\ 0 & \text{otherwise,}\end{cases}\qquad\text{and}\qquad f^*(s)=\begin{cases}\frac{1}{1-\alpha} & \text{if } s\in(0,1),\\ 0 & \text{otherwise.}\end{cases}$$

Then $f \prec g$, but $\| f \|_{p,q} > \| g \|_{p,q}$ if α is sufficiently small. This shows that $\| \quad \|_{p,q}$ is not $**$-increasing.

(ii) When $q \le p$ and $q < +\infty$, the functional $\| \quad \|_{p,q}$ is obviously $*$-strictly increasing. If $p = q = +\infty$, then $\| \quad \|_{\infty,\infty} = \| \quad \|_{(\infty,\infty)} = \| \quad \|_{L^\infty}$, and Proposition 5.4 tells us that it is not $*$-strictly increasing.

(iii) Assume that $q \le p$, $q < \infty$, $p > 1$. Let $f, g \in L^1_+(\mathbb{R}^n) \cap L^{p,q}(\mathbb{R}^n)$. Suppose that

$$f^{**}(s) \le g^{**}(s) \tag{5.7}$$

and

$$\| f \|_{p,q} = \| g \|_{p,q}. \tag{5.8}$$

Inequality (5.7) and [ALT, Proposition 2.1] entail that

$$\int_0^s f^*(t)^q dt \le \int_0^s g^*(t)^q dt \qquad \text{for } s > 0. \tag{5.9}$$

Integration by parts in the integral defining $\| \quad \|_{p,q}$ tells us that (5.8) is equivalent to

$$\int_0^\infty s^{\frac{q}{p}-2} \int_0^s f^*(t)^q dt ds = \int_0^\infty s^{\frac{q}{p}-2} \int_0^s g^*(t)^q dt ds. \tag{5.10}$$

From (5.9) and (5.10) we infer that equality holds in (5.9) for every $s > 0$, and hence that $f^*(s) = g^*(s)$ for $s > 0$. Thus, $\| \quad \|_{p,q}$ is $**$-strictly increasing.

If $p = q = +\infty$, then $\| \quad \|_{\infty,\infty}$ is not $**$-strictly increasing by (ii).

Finally, if $p = 1$, then also $q = 1$. Therefore, $\| \quad \|_{1,1} = \| \quad \|_{L^1}$, and the latter is not $**$-strictly increasing as demonstrated by any couple of functions $f, g \in L^1_+(\mathbb{R}^n)$ satisfying $\int_0^s f^*(t)dt < \int_0^s g^*(t)dt$ for $s \ge 0$ and $\int_0^\infty f^*(t)dt = \int_0^\infty g^*(t)dt$. □

The conclusions of Propositions 5.4–5.5 are summarized in the following table.

$1 \le p, q \le \infty$	$**$-INCREASING	$*$-STRICTLY INCREASING	$**$-STRICTLY INCREASING
$\| \quad \|_{(p,q)}$	any p, q	$q < \infty$	$q < \infty$
$\| \quad \|_{p,q}$	$q \le p$	$q \le p$ and $q < \infty$	$q \le p$, $p > 1$ and $q < \infty$

The functional J_A and the norms $\| \quad \|_A$ and $\| \quad \|_{(A)}$ are the object of the next propositions. Henceforth, we take into account finite-valued Young functions A, which are strictly positive in $(0, +\infty)$ and satisfy

$$\lim_{t \to 0} \frac{A(t)}{t} = 0 \quad \text{and} \quad \lim_{t \to +\infty} \frac{A(t)}{t} = +\infty.$$

According to usage, Young functions fulfilling these mild additional assumptions will be called N-functions.

PROPOSITION 5.6. *Let A be an N-function. Then*

(i) *J_A is $**$-increasing;*

(ii) *J_A is $*$-strictly increasing;*

(iii) *J_A is $**$-strictly increasing if and only if A is strictly convex.*

Proof. (i) The fact that J_A is $**$-increasing for every Young function A is proved, e.g., in [ALT, Corollary 2.1].

(ii) The $*$-strict monotonicity of J_A is a straightforward consequence of the equation

$$J_A(f) = \int_0^\infty A(f^*(s))ds \qquad \text{for every } f \in L^1_+(\mathbb{R}^n)$$

and of the strict monotonicity of A.

(iii) If A is strictly convex, then J_A is strictly convex, and its $**$-strict monotonicity follows from Proposition 5.3.

Conversely, assume that A is not strictly convex. Then there exists an interval $(t_0, t_1) \subset (0, \infty)$ and numbers $a > 0$ and $b \leq 0$ such that

$$A(t) = at + b \qquad \text{if } t_0 < t < t_1. \tag{5.11}$$

Fixing any $C \in (t_0, t_1)$ and any $\epsilon > 0$ such that $(C - \epsilon, C + \epsilon) \subset (t_0, t_1)$, choose any disjoint measurable subsets E_1 and E_2 of $\mathbb{R}^n$ satisfying $\mathcal{L}^n(E_1) = \mathcal{L}^n(E_2) < +\infty$. Define $f, g : \mathbb{R}^n \to [0, +\infty)$ as

$$f(x) = \begin{cases} C & \text{if } x \in E_1 \bigcup E_2, \\ 0 & \text{otherwise,} \end{cases} \quad \text{and} \quad g(x) = \begin{cases} C + \epsilon & \text{if } x \in E_1, \\ C - \epsilon & \text{if } x \in E_2, \\ 0 & \text{otherwise.} \end{cases}$$

It is easily verified that $f \prec g$. Moreover,

$$J_A(f) = 2aC\mathcal{L}^n(E_1) + b = a(C + \epsilon)\mathcal{L}^n(E_1) + a(C - \epsilon)\mathcal{L}^n(E_2) + b = J_A(g).$$

Since $f^* \not\equiv g^*$, J_A is not $**$-strictly monotone. □

The notion of Δ_2-condition near infinity plays a role in the characterization of the monotonicity properties of the Luxemburg norm $\| \quad \|_A$. Recall that a Young function A is said to satisfy the Δ_2 condition near infinity if there exist positive constants K and s_0 such that

$$A(2s) \leq KA(s) \qquad \text{for every } s \geq s_0.$$

We shall also write "$A \in \Delta_2$ near infinity" to denote that A satisfies the Δ_2-condition near infinity. Notice that, as a consequence of [RR, Chapter VII, Theorem 4], $A \in \Delta_2$ near infinity if and only if

$$\int_{\mathbb{R}^n} A\left(\frac{f(x)}{\| f \|_A}\right) dx = 1 \quad \text{for every } f \in L^1_+(\mathbb{R}^n) \cap L^A(\mathbb{R}^n) \setminus \{0\}. \tag{5.12}$$

Clearly, any power t^p, with $p \geq 1$, satisfies the Δ_2 condition near infinity. Functions $A(t)$ behaving like $t^p \log^\alpha(1 + t)$ for large t are in Δ_2 near infinity as well. On the other hand, if $A(t)$ has an exponential growth at infinity of type e^{t^α} for some $\alpha > 0$, then $A \notin \Delta_2$ near infinity. Other instances of Young functions which are not in Δ_2 near infinity are those "oscillating" between different powers.

PROPOSITION 5.7. *Let A be an N-function. Then*

(i) $\| \quad \|_A$ *is $**$-increasing;*

(ii) $\| \quad \|_A$ *is $*$-strictly increasing if and only if $A \in \Delta_2$ near infinity;*

(iii) $\| \quad \|_A$ *is $**$-strictly increasing if and only if $A \in \Delta_2$ near infinity and A is strictly convex.*

Proof. (i) $\|\quad\|_A$ is an r.i. norm. Thus, by Proposition 5.2, it is $**$-increasing.

(ii) Assume that $A \in \Delta_2$ near infinity. Suppose, by contradiction, that $\|\quad\|_A$ is not $*$-strictly monotone. Then there exist two functions f and g in $L^1_+(\mathbb{R}^n) \cap L^A(\mathbb{R}^n)$ and a measurable set $E \subset (0,\infty)$ with $\mathcal{L}^1(E) > 0$ such that

$$f^*(s) \le g^*(s) \qquad \text{for } s \ge 0, \qquad f^*(s) < g^*(s) \qquad \text{for } s \in E, \tag{5.13}$$

and

$$\|f\|_A = \|g\|_A. \tag{5.14}$$

We have

$$\begin{aligned} 1 \ge \int_{\mathbb{R}^n} A\left(\frac{g(x)}{\|g\|_A}\right) dx &= \int_0^\infty A\left(\frac{g^*(s)}{\|g\|_A}\right) ds > \int_0^\infty A\left(\frac{f^*(s)}{\|g\|_A}\right) ds \\ &= \int_0^\infty A\left(\frac{f^*(s)}{\|f\|_A}\right) = \int_{\mathbb{R}^n} A\left(\frac{f(x)}{\|f\|_A}\right) dx = 1, \end{aligned} \tag{5.15}$$

a contradiction. Notice that the second inequality in (5.15) is due to (5.13) and to the strict monotonicity of A, the second equality to (5.14), and the last equality to (5.12).

Conversely, suppose that $\|\quad\|_A$ is $*$-strictly increasing. By (5.12) again, if $A \notin \Delta_2$ near infinity, then there exists $f \in L^1_+(\mathbb{R}^n) \cap L^A(\mathbb{R}^n)$ such that

$$\int_{\mathbb{R}^n} A\left(\frac{f(x)}{\|f\|_A}\right) dx < 1. \tag{5.16}$$

Given three positive numbers s_0, ϵ, and δ, consider the function $g \in L^1_+(\mathbb{R}^n)$ defined by

$$g(x) = \begin{cases} f^\bigstar(x) & \text{if } \omega_n|x|^n \notin [s_0, s_0+\delta], \\ f^*(s_0) + \epsilon & \text{if } \omega_n|x|^n \in [s_0, s_0+\delta]. \end{cases}$$

Clearly, $f^*(s) \le g^*(s)$ for $s > 0$, and $f^*(s) < g^*(s)$ if $s \in [s_0, s_0+\delta]$. Consequently,

$$\|f\|_A < \|g\|_A. \tag{5.17}$$

On the other hand,

$$\begin{aligned} \int_{\mathbb{R}^n} A\left(\frac{g(x)}{\|f\|_A}\right) dx &= \int_{\{x:\omega_n|x|^n \notin [s_0, s_0+\delta]\}} A\left(\frac{f^\bigstar(x)}{\|f\|_A}\right) dx \\ &\quad + \int_{\{x:\omega_n|x|^n \in [s_0, s_0+\delta]\}} A\left(\frac{f^*(s_0)+\epsilon}{\|f\|_A}\right) dx \\ &\le \int_{\mathbb{R}^n} A\left(\frac{f(x)}{\|f\|_A}\right) dx + \delta A\left(\frac{f^*(s_0)+\epsilon}{\|f\|_A}\right). \end{aligned} \tag{5.18}$$

Owing to (5.16) and (5.18), we may choose $\delta > 0$ so small that $\int_{\mathbb{R}^n} A\left(\frac{g(x)}{\|f\|_A}\right) dx \le 1$. Hence, $\|g\|_A \le \|f\|_A$, thus contradicting (5.17).

(iii) Suppose that A is strictly convex and satisfies the Δ_2-condition near infinity. In order to prove that $\|\quad\|_A$ is $**$-strictly increasing, observe that if functions $f, g \in L^1_+(\mathbb{R}^n) \cap L^A(\mathbb{R}^n)$ existed such that

$$f^{**}(s) \le g^{**}(s) \quad \text{for } s > 0, \quad f^* \not\equiv g^*, \quad \text{and } \|f\|_A = \|g\|_A,$$

then we would have the contradiction

$$1 = \int_{\mathbb{R}^n} A\left(\frac{g(x)}{\|g\|_A}\right) dx = \int_{\mathbb{R}^n} A\left(\frac{g(x)}{\|f\|_A}\right) dx > \int_{\mathbb{R}^n} A\left(\frac{f(x)}{\|f\|_A}\right) dx = 1,$$

where the first and the last equality hold thanks to (5.12), and the inequality is due to the fact that, by Proposition 5.6, the functional J_A is $**$-strictly increasing.

Conversely, if $\|\quad\|_A$ is $**$-strictly increasing, then it is, in particular, $*$-strictly increasing, and hence, by (ii), $A \in \Delta_2$ near infinity. We have to show that A is also strictly convex. Assume, by contradiction, that this is not the case. Then there exist $s_0, t_1 \in (0, +\infty)$, $a > 0$, and $b \leq 0$ such that (5.11) holds. Choose C, ϵ, E_1, and E_2 satisfying the same properties as in the proof of Proposition 5.6, and, in addition,

$$2aC\mathcal{L}^n(E_1) + b = 1.$$

Let f and g be defined as in the proof of Proposition 5.6. Then,

$$\int_{\mathbb{R}^n} A(f(x))dx = aC\mathcal{L}^n(E_1) + aC\mathcal{L}^n(E_2) + b = 2aC\mathcal{L}^n(E_1) + b = 1$$

and

$$\int_{\mathbb{R}^n} A\left(\frac{f(x)}{\lambda}\right) dx > 1 \qquad \text{if } \lambda < 1,$$

whence $\|f\|_A = 1$. On the other hand,

$$\int_{\mathbb{R}^n} A(g(x))dx = a\left((C+\epsilon)\mathcal{L}^n(E_1) + (C-\epsilon)\mathcal{L}^n(E_2)\right) + b = 1,$$

and consequently, $\|g\|_A \leq 1$. Since $f \prec g$, $\|f\|_A = \|g\|_A$, and since $f^* \not\equiv g^*$, this contradicts the $**$-strict monotonicity of $\|\quad\|_A$. □

The Orlicz norm $\|\quad\|_{(A)}$ is considered in Proposition 5.8 below. Its proof requires a characterization of $\|\quad\|_{(A)}$, which tells us that, if A is an N-function, then

$$\|f\|_{(A)} = \min\left\{\frac{1}{k}\left(1 + \int_{\mathbb{R}^n} A\left(kf(x)\right) dx\right) : k > 0\right\} \tag{5.19}$$

for every $f \in L^1_+(\mathbb{R}^n) \cap L^A(\mathbb{R}^n)$ (see [RR, Chapter III, Theorem 13]).

PROPOSITION 5.8. *Let A be an N-function. Then*

(i) $\|\quad\|_{(A)}$ *is $**$-increasing;*
(ii) $\|\quad\|_{(A)}$ *is $*$-strictly increasing;*
(iii) $\|\quad\|_{(A)}$ *is $**$-strictly increasing if and only if A is strictly convex.*

Proof. (i) $\|\quad\|_{(A)}$ is an r.i. norm, and hence, by Proposition 5.2, it is $**$-increasing.

(ii) Let $f, g \in L^1_+(\mathbb{R}^n) \cap L^A(\mathbb{R}^n)$ be such that

(5.20)

$$f^*(s) \leq g^*(s) \quad \text{for } s > 0 \quad \text{and } f^*(s) < g^*(s) \text{ for } s \text{ in a set of positive measure.}$$

By (5.19) applied to g, a positive number k_g exists such that

$$\|g\|_{(A)} = \frac{1}{k_g}\left(1 + \int_{\mathbb{R}^n} A(k_g g(x))dx\right). \tag{5.21}$$

We have

$$\|g\|_{(A)} = \frac{1}{k_g}\left(1+\int_{\mathbb{R}^n} A(k_g g(x))dx\right) = \frac{1}{k_g}\left(1+\int_0^\infty A(k_g g^*(s))ds\right) \tag{5.22}$$
$$> \frac{1}{k_g}\left(1+\int_0^\infty A(k_g f^*(s))ds\right) = \frac{1}{k_g}\left(1+\int_{\mathbb{R}^n} A(k_g f(x))dx\right) \geq \|f\|_{(A)},$$

where the first inequality holds thanks to (5.20), and the last inequality is a consequence of (5.19). The $*$-strict monotonicity of $\|\quad\|_{(A)}$ follows.

(iii) Assume that A is strictly convex. By Proposition 5.6, the functional J_A is $**$-strictly increasing. Thus, if $f, g \in L^1_+(\mathbb{R}^n) \cap L^A(\mathbb{R}^n)$ are such that $f^{**}(s) \leq g^{**}(s)$ for $s > 0$ but $f^* \not\equiv g^*$, then

$$\int_{\mathbb{R}^n} A(k_g g(x))dx > \int_{\mathbb{R}^n} A(k_g f(x))dx,$$

where k_g is the number appearing in (5.21). The same chain as in (5.22) tells us that $\|f\|_{(A)} < \|g\|_{(A)}$, and the $**$-strict monotonicity of $\|\quad\|_{(A)}$ follows.

Finally, assume that $\|\quad\|_{(A)}$ is $**$-strictly increasing, and suppose, by contradiction, that A is not strictly convex. Then there exist an interval $(t_0, t_1) \subset (0, +\infty)$ and $a > 0$, $b \leq 0$ such that (5.11) holds. Let f be any function in $L^1_+(\mathbb{R}^n) \bigcap L^A(\mathbb{R}^n)$ such that f^* is continuous and strictly decreasing in $(0, +\infty)$ and $\lim_{s\to 0^+} f^*(s) = +\infty$. Let k_f be a positive number such that

$$\|f\|_{(A)} = \frac{1}{k_f}\left(1+\int_{\mathbb{R}^n} A(k_f f(x))dx\right). \tag{5.23}$$

Since f^* is continuous and $f^*(0, +\infty) = [0, +\infty)$, there exist $\bar{s} > 0$ and $\delta > 0$ satisfying

$$t_0 < k_f f^*(s) < t_1 \qquad \text{if } \ \bar{s} - \delta \leq s \leq \bar{s} + \delta.$$

Let g be the function in $L^1_+(\mathbb{R}^n)$ obeying

$$g^*(s) = \begin{cases} f^*(s) & \text{if } s \notin (\bar{s}-\delta, \bar{s}+\delta), \\ f^*(\bar{s}-\delta) & \text{if } \bar{s}-\delta < s < s_0, \\ f^*(\bar{s}+\delta) & \text{if } s_0 \leq s < \bar{s}+\delta, \end{cases}$$

where s_0 is chosen in $(\bar{s}-\delta, \bar{s}+\delta)$ in such a way that

$$\int_{\bar{s}-\delta}^{\bar{s}+\delta} f^*(s)ds = \int_{\bar{s}-\delta}^{\bar{s}+\delta} g^*(s)ds. \tag{5.24}$$

Thus,

$$f \prec g \qquad \text{and} \qquad f^* \not\equiv g^*. \tag{5.25}$$

On the other hand, by (5.23) and (5.24),

$$\|f\|_{(A)} = \frac{1}{k_f}\left(1+\int_{[0,\infty)\setminus(\bar{s}-\delta,\bar{s}+\delta)} A(k_f f^*(s))ds + \int_{\bar{s}-\delta}^{\bar{s}+\delta}(ak_f f^*(s)+b)ds\right) \tag{5.26}$$
$$= \frac{1}{k_f}\left(1+\int_{[0,\infty)\setminus(\bar{s}-\delta,\bar{s}+\delta)} A(k_f g^*(s))ds + \int_{\bar{s}-\delta}^{\bar{s}+\delta}(ak_f g^*(s)+b)ds\right)$$
$$= \frac{1}{k_f}\left(1+\int_{\mathbb{R}^n} A(k_f g(x))dx\right) \geq \|g\|_{(A)}.$$

Equations (5.25) and (5.26) contradict the $**$-strict monotonicity of $\| \quad \|_{(A)}$. □

For ease of comparison, the results of Propositions 5.6–5.8 are collected in the following table.

A N-FUNCTION	$**$-INCREASING	$*$-STRICTLY INCREASING	$**$-STRICTLY INCREASING
J_A	any A	any A	A strictly convex
$\| \quad \|_A$	any A	$A \in \Delta_2$ near infinity	$A \in \Delta_2$ near infinity and A strictly convex
$\| \quad \|_{(A)}$	any A	any A	A strictly convex

CONTRACTING LORENZ ATTRACTORS THROUGH RESONANT DOUBLE HOMOCLINIC LOOPS*

C. A. MORALES†, M. J. PACIFICO†, AND B. SAN MARTIN‡

Abstract. A *contracting Lorenz attractor* of a three-dimensional vector field is an attractor with a unique singularity whose eigenvalues are real and satisfy the eigenvalue conditions $\lambda_{ss} < \lambda_s < 0 < \lambda_u$ and $\lambda_s + \lambda_u < 0$. The study of contracting Lorenz attractors started in [A. Rovella, *Bol. Soc. Brasil. Mat. (N.S.),* 24 (1993), pp. 233–259]. In this paper we show that certain resonant double homoclinic loops in dimension three generate contracting Lorenz attractors in a positive Lebesgue subset of the parameter space. This gives a positive answer to a question posed in [C. Robinson, *SIAM J. Math. Anal.*, 32 (2000), pp. 119–141].

Key words. contracting Lorenz attractors, resonant double homoclinic loops

DOI. 10.1137/S0036141004443907

1. Introduction.

Inspired by the dynamical features of Lorenz and Henon-like attractors, Rovella [Rov] studied attractors with a *unique* singularity exhibiting real eigenvalues $\lambda_{ss}, \lambda_s, \lambda_u$ satisfying the eigenvalue conditions

$$\lambda_{ss} < \lambda_s < 0 < \lambda_u \quad \text{and} \quad \lambda_s + \lambda_u < 0.$$

Today these kinds of attractors are denominated *contracting Lorenz attractors*, as opposed to *expanding Lorenz attractors* [GW] in which the second eigenvalue condition is replaced by $\lambda_s + \lambda_u > 0$. The result obtained by Rovella was that there are contracting Lorenz attractors which are measure-theoretical persistent in parametrized families of codimension two. In the meantime Robinson [Rob1], [Rob2] developed a theory of expanding Lorenz attractors appearing in the unfolding of resonant double homoclinic loops in dimension three. These works are the motivation for our investigation. Indeed, we prove that positive Lebesgue measure sets of vector fields exhibiting contracting Lorenz attractors also appear in the unfolding of certain resonant double homoclinic loops. This gives a positive answer for a question posed by Robinson in [Rob1, Remark 5.1].

Let us state our main result in a precise way. Hereafter M will be a closed 3-manifold whose space of C^r-vector fields is denoted by $\mathcal{X}^r(M)$, $r \geq 1$. If $X \in \mathcal{X}^r(M)$, we denote by X^t the flow it generates. An invariant set Λ of X is *transitive* if $\Lambda = \omega_X(q)$ for some $q \in \Lambda$, where

$$\omega_X(q) = \left\{ x \in M : \lim_{n\to\infty} X^{t_n}(q) \text{ for some sequence } t_n \to \infty \right\}$$

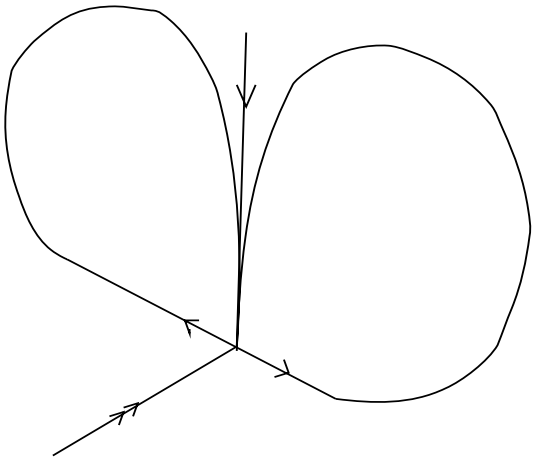

FIG. 1.1. *A butterfly loop for* X_{η_0}.

is the omega-limit set of q. An *attracting set* of X is a compact invariant set Λ such that

$$\Lambda = \bigcap_{t>0} X^t(U)$$

for some compact neighborhood U of Λ. We note that U above can be chosen *positively invariant*, i.e., $X^t(U) \subset \mathrm{Int}(U)$ for all $t > 0$. An *attractor* is a transitive attracting set.

Let Q be a singularity of $X \in \mathcal{X}^r(M)$ with real eigenvalues $\lambda_u, \lambda_{ss}, \lambda_s$ satisfying

$$\lambda_{ss} < \lambda_s < 0 < \lambda_u.$$

Then Q is hyperbolic, and so there are stable and unstable C^r manifolds $W^u(Q,X)$ and $W^s(Q,X)$ tangent to the eigenvectors associated to the eigenvalues λ_u and $\{\lambda_{ss}, \lambda_s\}$, respectively [HPS]. In particular, $W^u(Q,X)$ is one-dimensional and so $W^u(Q,X) \setminus \{Q\}$ consists of two regular orbits Γ^+, Γ^-. There are also a strong stable manifold $W^{ss}(Q,X)$ tangent to the eigenvector associated to λ_{ss} and a central unstable manifold $W^{cu}(Q,X)$ tangent to the eigendirection associated to λ_s, λ_u. The latter one is C^1, is nonunique, and contains $W^u(Q,X)$. Although $W^{cu}(Q,X)$ is not unique in general we can define the plane field $P = \{P(q) : q \in W^u(Q,X)\}$ by

$$P(q) = T_q W^{cu}(Q,X) \quad \text{for} \quad q \in W^u(Q,X).$$

We note that the plane field P defined above is continuous if $W^{cu}(Q,X)$ is transverse to $W^s(Q,X)$ along $W^u(Q,X)$.

We say that X has a *double homoclinic loop at* Q if

$$W^u(Q,X) \subset W^s(Q,X)$$

(equivalently, $\Gamma^+ \cup \Gamma^- \subset W^s(Q,X)$). The double homoclinic loop is said to be either *figure-eight* or *butterfly* depending on whether the regular orbits Γ^+, Γ^- are contained in the same connected component of $W^s(Q,X) \setminus W^{ss}(Q,X)$ or not. (See Figure 1.1.) All double homoclinic loops considered in this paper will satisfy the generic assumption

$$W^u(Q,X) \cap W^{ss}(Q,X) = \{Q\}.$$

Now suppose that X has a double homoclinic loop at Q. If X is C^r with $r \geq 3$, and the eigenvalue condition

$$\lambda_{ss} < 2\lambda_s$$

holds, then $W^{cu}(Q, X)$ is C^2. This permits us to define a constant $C^+(X)$ by taking a parametrization $q^+(t)$ of Γ^+ and defining

$$C^+(X) = \exp\left(\int_{-\infty}^{\infty} Div_2(q^+(t))dt\right),$$

where $Div_2(q^+(t))$ is the Jacobian of X at t restricted to $T_{\Gamma^+}W^{cu}(Q, X)$. Analogously we define the constant $C^-(X)$ just replacing + by − in the above expression. These constants represent the change in area within the planes $P(q)$ along the whole length of $\Gamma^{\pm}$. It happens that $C^+(X), C^-(X)$ are finite and positive when Q is *resonant*, i.e.,

$$\lambda_u + \lambda_s = 0.$$

Then, in the resonant case, we can define the constant $B(X)$ by

$$B(X) = \frac{C^+(X) + C^-(X)}{C^+(X)C^-(X)}.$$

DEFINITION 1.1. *Define $\mathcal{N}$ as the set of vector fields $X \in \mathcal{X}^r(M)$ satisfying the following six properties:*

(A1) *X has a singularity Q whose eigenvalues $\{\lambda_u, \lambda_s, \lambda_{ss}\}$ are real and satisfy*

$$\lambda_{ss} < \lambda_s < 0 < \lambda_u.$$

(A2) *X exhibits a* butterfly *double homoclinic loop at Q.*
(A3) *$W^{cu}(Q, X)$ is transverse to $W^s(Q, X)$ along $W^u(Q, X)$.*
(A4) *$\lambda_{ss} - \lambda_s + 2\lambda_u < 0$ and $\lambda_{ss} < 2\lambda_s$.*
(A5) *$B(X) < 1$.*
(A6) *$\lambda_u + \lambda_s = 0$.*

The implicit function theorem in Banach spaces implies that $\mathcal{N}$ is a codimension three submanifold of $\mathcal{X}^r(M)$ for all $r \geq 1$. Given a set A we denote its closure by $\mathrm{Cl}(A)$. Our main result is the following.

THEOREM 1.2. *Let $\{X_\eta\}$ be a C^k three-parametrized family of C^r-vector fields transverse to $\mathcal{N}$ at X_{η_0}, $k, r \geq 3$. Then, there is a positive Lebesgue measure set $\mathcal{L}$ in the parameter space with $\eta_0 \in \mathrm{Cl}(\mathcal{L})$ such that X_η has a contracting Lorenz attractor for all $\eta \in \mathcal{L}$.*

The proof of this theorem will be reduced to Theorem 2.2 in section 2 where one-parameter families of discontinuous maps are studied.

The present paper, together with [MPS], gives a full description of the bifurcation scenario in the case when the constant $B \neq 1$: The family generates expanding or contracting Lorenz attractors depending on whether $B > 1$ or $B < 1$. Viana posed the question of what bifurcation scenario can appear in the case $B = 1$. Another problem is to exhibit a polynomial vector field with a contracting Lorenz attractor. To find such a polynomial we expect to find a parametrized polynomial vector field family satisfying the hypotheses of Theorem 1.2.

2. One-dimensional reduction. In this section we deduce Theorem 1.2 from Theorem 2.2 stated below. Hereafter we let X_η be a one-parameter family satisfying

the hypotheses of Theorem 1.2. In particular, the parameter η_0 satisfies $X_{\eta_0} \in \mathcal{N}$ and then the corresponding vector field X_{η_0} satisfies assumptions (A1)–(A6).

Throughout the paper we fix the notation

$$C^+ = C^+(X_{\eta_0}), \quad C^- = C^-(X_{\eta_0}), \quad \text{and} \quad B = B(X_{\eta_0}).$$

Let P be the plane field used in the introduction to define the constants $C^{\pm}$. Consider the regular orbits Γ^+, Γ^- forming $W^u(Q_{\eta_0}, X_{\eta_0}) \setminus \{Q_{\eta_0}\}$.

Define $\nu^+ = 1$ (if P is orientable in $\Gamma^+ \cup \{Q_{\eta_0}\}$) and $\nu^+ = -1$ (otherwise). Analogously we define $\nu^- = 1$ (if P is orientable in $\Gamma^- \cup \{Q_{\eta_0}\}$) and $\nu^- = -1$ (otherwise).

By assumption (A2) we can fix a cross-section Σ of X_{η_0} with the following properties: Σ is close to Q_{η_0}, Σ is transversal to $W^s(Q_{\eta_0})$, and Σ intersects both Γ^+ and Γ^-. There is a neighborhood V of $\Sigma \cap W^s(Q_{\eta_0})$ in Σ such that the positive orbit of every point at $V \setminus W^s(Q_{\eta_0})$ intersects Σ for every parameter η near enough η_0. This defines a Poincaré map from $V \setminus W^s(Q_{\eta_0})$ to Σ.

As in [MPS] (see also [Rob2]) we can use (A1)–(A4) and the standard stable manifold theory [HPS], [Sh] to show the existence of a stable foliation in a small neighborhood of $W^s(Q_\eta)$ varying C^2 with the parameter. For convenience, we assume this neighborhood to be equal to V. Hence we can reduce the problem to a one-dimensional Poincaré map

$$f_\eta : V' \setminus \{c_\eta\} \subset [-1,1] \to [-1,1],$$

where c_η is the projection of $W^s(Q_{\eta_0}) \cap V$ onto V'. We assume $c_\eta = 0$ for every η. We shall use the notation

$$a_\eta^{\pm} = f_\eta(0\pm) = \lim_{\tau \to \pm 0} f_\eta(\tau).$$

As in [MPS] or [Rob2] we have the following.

LEMMA 2.1. *There is an interval J, $0 \in J$, such that for every η sufficiently near to η_0, the map $f_\eta : J \subset [-1,1] \to [-1,1]$ has the following form:*

$$f_\eta(\tau) = \begin{cases} a_\eta^+ + \nu^+ C_\eta^+ |\tau|^{\alpha(\eta)} + O_{\eta,1}(|\tau|^{\alpha(\eta)}) & \text{if} \quad \tau > 0, \\ a_\eta^- - \nu^- C_\eta^- |\tau|^{\alpha(\eta)} + O_{\eta,2}(|\tau|^{\alpha(\eta)}) & \text{if} \quad \tau < 0, \end{cases}$$

where $\alpha(\eta) = -\frac{\lambda_s(\eta)}{\lambda_u(\eta)}$, $O_{\eta,i}$ and $C_\eta^{\pm}$ are C^2, varying C^2 with respect to η, and $\lim_{x \to 0} \frac{O_{\eta,i}(x)}{x} = 0$ uniformly on η.

The proof of Theorem 1.2 is a direct consequence of the result below. We denote by $\mathrm{Int}(A)$ the interior and by $\mathrm{Cl}(A)$ the closure of a subset A.

THEOREM 2.2. *Let $\{X_\eta\}$ be a C^k three-parametrized family of C^r-vector fields transverse to $\mathcal{N}$ at X_{η_0}, $k, r \geq 3$. Let f_η be the corresponding three-parametrized family of one-dimensional maps as in Lemma 2.1. For all neighborhoods $\mathcal{V}$ of η_0 in the parameter space there is a positive Lebesgue measure set $\mathcal{L}' \subset \mathcal{V}$ with $\eta_0 \in \mathrm{Cl}(\mathcal{L}')$ such that for every $\eta \in \mathcal{L}'$ one has $\alpha(\eta) > 1$ and further there is a closed nontrivial interval Θ_η with the following properties:*

1. $0 \in \mathrm{Int}(\Theta_\eta)$.
2. *There is a compact interval $W \subset J$ with $\Theta_\eta \subset \mathrm{Int}(W)$ such that $\mathrm{Cl}(f_\eta(W \setminus \{0\})) \subset \mathrm{Int}(W)$ and $f_\eta^2(W \setminus \{0\}) \subset \Theta_\eta$.*
3. *$f_\eta/_{\Theta_\eta \setminus \{0\}}$ is transitive.*

Proof of Theorem 1.2. Let $\{X_\eta\}$ be a C^k three-parametrized family of C^r-vector fields transverse to $\mathcal{N}$ at X_{η_0}, $k, r \geq 3$. We have to prove that there is a positive Lebesgue measure set $\mathcal{L}$ in the parameter space with $\eta_0 \in \mathrm{Cl}(\mathcal{L})$ such that X_η has a contracting Lorenz attractor for all $\eta \in \mathcal{L}$. For this we proceed as follows.

As hypothesis (A1) is an open condition we can fix a neighborhood $\mathcal{V}$ of η_0 in the parameter space such that

$$\lambda_{ss}(\eta) < \lambda_s(\eta) < 0 < \lambda_u(\eta) \qquad \forall\, \eta \in \mathcal{V}. \tag{2.1}$$

Since Q_{η_0} in (A1) is hyperbolic we can consider the analytic continuation Q_η of Q_{η_0} which we assume to be defined for all $\eta \in \mathcal{V}$.

Now, let f_η be the three-parameter family of one-dimensional maps associated to X_η as in Lemma 2.1. Let $\mathcal{L}'$ be the positive Lebesgue measure set in Theorem 2.2 for the fixed neighborhood $\mathcal{V}$ of η_0. Define $\mathcal{L} = \mathcal{L}'$. We shall prove that $\mathcal{L}$ works. First we observe that $\eta_0 \in \mathrm{Cl}(\mathcal{L})$ by Theorem 2.2.

Next we claim that if $\eta \in \mathcal{L}$, then X_η has a contracting Lorenz attractor. Indeed, let π_η be the projection along the invariant stable foliation defining f_η. Define

$$\Sigma_\eta = \pi_\eta^{-1}(\Theta_\eta).$$

It follows that $\Sigma_\eta \subset \Sigma$ is a cross-section of X. We note that the set

$$\bigcup_{t>0} X_\eta^t(\Sigma_\eta)$$

is positively invariant but not closed since there exists a compact part W_η of $W^u(Q_\eta, X_\eta)$ which is not contained in it. However, by item 2 of Theorem 2.2, we can choose a small tubular neighborhood $\mathcal{U}_\eta$ of W_η in a way that

$$U_\eta = \mathcal{U}_\eta \cup \left(\bigcup_{t>0} X_\eta^t(\Sigma_\eta) \right)$$

is now compact and positively invariant. Moreover, by a suitable modification of U_η via the long tubular flow-box theorem [dMP], we can even assume that ∂U_η is smooth and the vector field X_η points inward to U_η in ∂U_η.

Now define

$$\Lambda_\eta = \bigcap_{t>0} X_\eta^t(U_\eta).$$

Item 3 of Theorem 2.2 implies that Λ_η is a transitive set of X_η because the foliation which defines π_η is contracting; see also the proof of Theorem 11.3 in [Rob3]. In particular, Λ_η is compact invariant. On the other hand, $\Lambda \subset \mathrm{Int}(U_\eta)$ because X_η points inward to U_η in ∂U_η. It follows that U_η is a compact neighborhood of Λ_η, and so Λ_η is an attractor.

To finish we prove that Λ is a contracting Lorenz attractor. By item 1 of Theorem 2.2 we have

$$Q_\eta \in \Lambda_\eta,$$

where Q_η is the continuation of Q_{η_0}. As $\eta \in \mathcal{L} \subset \mathcal{V}$ we obtain (2.1). Recalling that $\alpha(\eta) = -\frac{\lambda_s(\eta)}{\lambda_u(\eta)}$ in Lemma 2.1 we have $\lambda_s(\eta) + \lambda_u(\eta) < 0$ because $\alpha(\eta) > 1$ in Theorem 2.2. As $Q_\eta \in \Lambda_\eta$ we conclude that Λ_η is a contracting Lorenz attractor. This finishes the proof. □

The rest of the paper is devoted to the proof of Theorem 2.2. It is done in sections 3–8. In section 3 we restate Lemma 2.2 of [MPS] for $\alpha > 1$ because $B < 1$ in the present case. In section 4 we define new parameters $(\mu(\alpha), \nu(\alpha))$ and study their limits as $\alpha \to 1^+$. These limits will be preperiodic for the piecewise linear map g defined in Lemma 4.2. In section 5 we introduce the rescaling map g_α (see (5.3)). We prove in Lemma 5.7 the convergence g_α (in the C^0, C^1, and C^2 topologies) to a piecewise linear map. We finish section 5 by proving in Theorem 5.8 the existence of invariant intervals for $g_\alpha(\mu, \nu, \cdot)$ for almost all $\alpha \to 1^+$. In section 6 we define the Rovella map and state the Rovella theorem which asserts that a one-parameter unfolding of a Rovella map displays a full density set of parameters exhibiting transitive invariant closed intervals. We refer the reader to the proof of Rovella's theorem in the original paper [Rov]. In section 7 we define the map h_α and prove that it is a Rovella map (Theorem 7.1). In addition, in Theorem 7.3, we use g_α to define a one-parameter family of maps φ_t unfolding h_α and satisfying the hypothesis of Rovella's theorem. As a corollary we obtain that the invariant interval of $g_\alpha(\mu, \nu, \cdot)$ found in section 5 *contains* a transitive invariant interval for a positive Lebesgue measure set of parameters (μ, ν) (Corollary 7.4). We use this interval in section 8 to define the interval Θ_η required in Theorem 2.2. This complete the proof.

3. Preliminary properties of f_η. These are summarized in Lemma 3.1 below. From now on we assume that $\eta \in \mathbb{R}^3$ belongs to a neighborhood of η_0 and X_η satisfies the hypothesis of Theorem 1.2. In particular, $X = X_{\eta_0}$ satisfies (A1)–(A7) in Definition 1.1. By the transversal hypothesis (A7) we have that the map $\eta \mapsto (\alpha_\eta, a^+_\eta, a^-_\eta)$ is a diffeomorphism from a neighborhood of η_0 onto a neighborhood of $(1, 0, 0)$. This allows us to consider the inverse

$$\eta = \eta(\alpha, a^+, a^-) \tag{3.1}$$

of this diffeomorphism. In particular,

$$\eta_0 = \eta(1, 0, 0)$$

and also

$$\alpha(\eta(\alpha, a^+, a^-)) = \alpha, \quad a^+_{\eta(\alpha, a^+, a^-)} = a^+, \quad a^-_{\eta(\alpha, a^+, a^-)} = a^-. \tag{3.2}$$

The next lemma is analogous to Lemma 2.2 in [MPS]. The difference here is that in [MPS] we found $O \subset (0, 1)$ and here we found $O \subset (1, 1 + \Lambda)$ for some $\Lambda > 0$. The proof follows as in [MPS] except, for instance, in the case where $\nu^+ = \nu^- = 1$, when the system of equations $f_\eta(p(\alpha)) = p(\alpha)$, $f_\eta(q(\alpha)) = q(\alpha)$, $f_\eta(0+) = p(\alpha)$, $f_\eta(0-) = q(\alpha)$ can be solved only for $\alpha > 1$ and not for $\alpha < 1$ as in [MPS] because $B < 1$ here and $B > 1$ there.

LEMMA 3.1. *There are $\Lambda > 0$, an open full Lebesgue measure set $O \subset (1, 1 + \Lambda)$, and C^1 maps*

$$a^+(\cdot), a^-(\cdot), p(\cdot), q(\cdot) : O \to \mathbb{R}$$

with $p(\alpha) < 0 < q(\alpha)$ such that if

$$\eta = \eta(\alpha, a^+(\alpha), a^-(\alpha)),$$

then the following hold:

(a) *If $\nu^+ = 1$ and $\nu^- = 1$, then $f_\eta(p(\alpha)) = p(\alpha)$, $f_\eta(q(\alpha)) = q(\alpha)$, $f_\eta(0+) = p(\alpha)$, and $f_\eta(0-) = q(\alpha)$.*

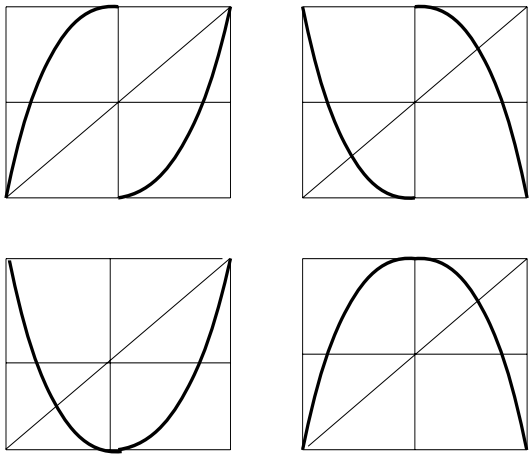

FIG. 3.1. *Possible dynamics for f_η in a neighborhood of* 0.

(b) *If $\nu^+ = 1$ and $\nu^- = -1$, then $f_\eta(p(\alpha)) = q(\alpha)$, $f_\eta(q(\alpha)) = q(\alpha)$, and $f_\eta(0+) = f_\eta(0-) = p(\alpha)$.*
(c) *If $\nu^+ = -1$ and $\nu^- = 1$, then $f_\eta(p(\alpha)) = p(\alpha)$, $f_\eta(q(\alpha)) = p(\alpha)$, and $f_\eta(0+) = f_\eta(0-) = q(\alpha)$.*
(d) *If $\nu^+ = -1$ and $\nu^- = -1$, then $f_\eta(p(\alpha)) = q(\alpha)$, $f_\eta(q(\alpha)) = p(\alpha)$, $f_\eta(0+) = q(\alpha)$, and $f_\eta(0-) = p(\alpha)$.*

In any case,

$$\lim_{\alpha\to 1^+} \frac{p(\alpha)}{q(\alpha)} = -\frac{C^+}{C^-},$$

$$\lim_{\alpha\to 1^+} q(\alpha) = 0 = \lim_{\alpha\to 1^+} p(\alpha), \text{ and } \lim_{\alpha\to 1^+} q(\alpha)^{\alpha-1} = \lim_{\alpha\to 1^+} |p(\alpha)|^{\alpha-1} = B.$$

(*See Figure* 3.1.)

4. Parameters $(\mu(\alpha), \nu(\alpha))$. Consider a parametrized family $\{X_\eta\}$ satisfying the hypotheses of Theorem 1.2. Let O be the set found in Lemma 3.1. Given $\alpha \in O$ let $a^-(\alpha)$, $a^+(\alpha)$, $p(\alpha)$, and $q(\alpha)$ be the maps in Lemma 3.1. Define

$$(\mu(\alpha), \nu(\alpha)) = \left(\frac{a^+(\alpha)}{q(\alpha)}, \frac{a^-(\alpha)}{q(\alpha)}\right). \tag{4.1}$$

The proofs of the next two lemmas follow from direct calculations and are left to the reader.

LEMMA 4.1. *The limits*

$$\mu(1) = \lim_{\alpha\to 1^+} \mu(\alpha) \quad \text{and} \quad \nu(1) = \lim_{\alpha\to 1^+} \nu(\alpha)$$

exist and satisfy the following properties:

1. *If $\nu^+ = 1$ and $\nu^- = 1$, then $\mu(1) = -\frac{C^+}{C^-}$ and $\nu(1) = 1$.*
2. *If $\nu^+ = 1$ and $\nu^- = -1$, then $\mu(1) = -\frac{C^+}{C^-}$ and $\nu(1) = -\frac{C^+}{C^-}$.*
3. *If $\nu^+ = -1$ and $\nu^- = 1$, then $\mu(1) = 1$ and $\nu(1) = 1$.*
4. *If $\nu^+ = -1$ and $\nu^- = -1$, then $\mu(1) = 1$ and $\nu(1) = -\frac{C^+}{C^-}$.*

LEMMA 4.2. *Let $\mu(1), \nu(1)$ be the limits in Lemma 4.1. Let $g : \mathbb{R} \setminus \{0\} \to \mathbb{R}$ be defined by*

$$g(x) = \begin{cases} \mu(1) + \nu^+ C^+ Bx & \text{if} \quad x > 0, \\ \nu(1) + \nu^- C^- Bx & \text{if} \quad x < 0. \end{cases}$$

Then, the following properties hold:

1. *If $\nu^+ = 1$ and $\nu^- = 1$, then $g(\mu(1)) = \mu(1)$ and $g(\nu(1)) = \nu(1)$.*
2. *If $\nu^+ = 1$ and $\nu^- = -1$, then $g(\mu(1)) = 1$ and $g(\nu(1)) = 1$.*
3. *If $\nu^+ = -1$ and $\nu^- = 1$, then $g(\mu(1)) = -\frac{C^+}{C^-}$ and $g(\nu(1)) = -\frac{C^+}{C^-}$.*
4. *If $\nu^+ = -1$ and $\nu^- = -1$ $g(\mu(1)) = \nu(1)$, then and $g(\nu(1)) = \mu(1)$.*

5. The rescaling map g_α. Let $(\mu(\alpha), \nu(\alpha))$ be defined as in (4.1). Let $a^\pm(\cdot)$ be the maps in Lemma 3.1. Define in a neighborhood of $(a^+(\alpha), a^-(\alpha))$ onto a neighborhood of $(\mu(\alpha), \nu(\alpha))$ the map T_α by

$$T_\alpha(a^+, a^-) = \left(\frac{a^+}{q(\alpha)}, \frac{a^-}{q(\alpha)} \right). \tag{5.1}$$

Define the *new parameters* (μ, ν) by

$$(\mu, \nu) = T_\alpha(a^+, a^-) \tag{5.2}$$

and

$$g_\alpha(\mu, \nu, x) = \frac{1}{q(\alpha)} f_{\eta(\alpha, q(\alpha)\mu, q(\alpha)\nu)}(q(\alpha)x). \tag{5.3}$$

For the next lemma we consider $p(\alpha)$ and $q(\alpha)$ as in Lemma 3.1. For all $\alpha \in O$ we define

$$x(\alpha) = \frac{p(\alpha)}{q(\alpha)} \quad \text{and} \quad y(\alpha) = 1. \tag{5.4}$$

Combining Lemmas 3.1 and 4.1 we get the following lemma.

LEMMA 5.1. *The limits*

$$x(1) = \lim_{\alpha \to 1^+} x(\alpha) \quad \textit{and} \quad y(1) = \lim_{\alpha \to 1^+} y(\alpha)$$

exist and satisfy

$$x(1) = -\frac{C^+}{C^-} \quad \textit{and} \quad y(1) = 1.$$

In particular, we have the following:

1. *If $\nu^+ = 1$ and $\nu^- = 1$, then $\mu(1) = x(1)$ and $\nu(1) = y(1)$.*
2. *If $\nu^+ = 1$ and $\nu^- = -1$, then $\mu(1) = x(1)$ and $\nu(1) = x(1)$.*
3. *If $\nu^+ = -1$ and $\nu^- = 1$, then $\mu(1) = y(1)$ and $\nu(1) = y(1)$.*
4. *If $\nu^+ = -1$ and $\nu^- = -1$, then $\mu(1) = y(1)$ and $\nu(1) = x(1)$.*

Replacing (5.4) in (5.3) and using Lemma 3.1 for the respective cases, one gets the following lemma.

LEMMA 5.2. *For all $\alpha \in O$ consider $x(\alpha)$ and $y(\alpha)$ as in (5.4). Then the following cases hold:*

1. *If $\nu^+ = 1$ and $\nu^- = 1$, then*

$$g_\alpha(\mu(\alpha), \nu(\alpha), x(\alpha)) = x(\alpha) \quad \textit{and} \quad g_\alpha(\mu(\alpha), \nu(\alpha), y(\alpha)) = y(\alpha).$$

2. *If* $\nu^+ = 1$ *and* $\nu^- = -1$, *then*

$$g_\alpha(\mu(\alpha), \nu(\alpha), x(\alpha)) = y(\alpha) \quad \text{and} \quad g_\alpha(\mu(\alpha), \nu(\alpha), y(\alpha)) = y(\alpha).$$

3. *If* $\nu^+ = -1$ *and* $\nu^- = 1$, *then*

$$g_\alpha(\mu(\alpha), \nu(\alpha), x(\alpha)) = x(\alpha) \quad \text{and} \quad g_\alpha(\mu(\alpha), \nu(\alpha), y(\alpha)) = x(\alpha).$$

4. *If* $\nu^+ = -1$ *and* $\nu^- = -1$, *then*

$$g_\alpha(\mu(\alpha), \nu(\alpha), x(\alpha)) = y(\alpha) \quad \text{and} \quad g_\alpha(\mu(\alpha), \nu(\alpha), y(\alpha)) = x(\alpha).$$

The proof of the next lemma is straightforward.

LEMMA 5.3. *For all* $\alpha \in O$ *consider* $x(\alpha)$ *and* $y(\alpha)$ *as in* (5.4). *Then the following cases hold:*

1. *If* $\nu^+ = 1$ *and* $\nu^- = 1$, *then* $\mu(\alpha) = x(\alpha)$ *and* $\nu(\alpha) = y(\alpha)$.
2. *If* $\nu^+ = 1$ *and* $\nu^- = -1$, *then* $\mu(\alpha) = x(\alpha)$ *and* $\nu(\alpha) = x(\alpha)$.
3. *If* $\nu^+ = -1$ *and* $\nu^- = 1$, *then* $\mu(\alpha) = y(\alpha)$ *and* $\nu(\alpha) = y(\alpha)$.
4. *If* $\nu^+ = -1$ *and* $\nu^- = -1$, *then* $\mu(\alpha) = y(\alpha)$ *and* $\nu(\alpha) = x(\alpha)$.

The next definitions are the same as in [MPS] except that the differentiability is up to order C^2.

DEFINITION 5.4. *Let* $g : \mathbb{R}^2 \times (\mathbb{R} \setminus \{0\}) \to \mathbb{R}$. *We say that* $g_\alpha \to g$ *in the* C^0 *topology in compact sets of* $\mathbb{R}^3$ *as* $\alpha \to 1^+$ *if*

(a) $Dom(g_\alpha) \to \mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$ *as* $\alpha \to 1^+$, *that is, for all* $R > 0$ *there is* $\delta_0 > 0$ *such that if* $1 < \alpha < 1 + \delta_0$, *then* $B_R(0) \cap (\mathbb{R}^2 \times (\mathbb{R} \setminus \{0\}) \subset Dom(g_\alpha)$, *where* $B_R(0)$ *is the ball of radius* R *centered at* $(0, 0, 0)$.

(b) *for every compact set* $K \subset \mathbb{R}^3$ *and every* $\varepsilon > 0$ *there is* $\delta_0 > 0$ *such that if* $1 < \alpha < 1 + \delta_0$, *then*

$$\sup_{y \in K \cap (\mathbb{R}^2 \times (\mathbb{R} \setminus \{0\}))} |g_\alpha(y) - g(y)| < \varepsilon.$$

DEFINITION 5.5. *Let* $g : \mathbb{R}^2 \times (\mathbb{R} \setminus \{0\}) \to \mathbb{R}$. *We say that* $g_\alpha \to g$ *in the* C^1 *topology in compact sets of* $\mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$ *if*

(a) $Dom(g_\alpha) \to \mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$ *as* $\alpha \to 1^+$, *and*

(b) *for every compact set* $K \subset \mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$ *and every* $\varepsilon > 0$ *there is* $\delta_0 > 0$ *such that if* $1 < \alpha < 1 + \delta_0$, *then*

$$\sup_{i \in \{0,1\}, y \in K} \left| D^i g_\alpha(y) - D^i g(y) \right| < \varepsilon.$$

DEFINITION 5.6. *We say that* $g_\alpha \to g$ *in the* C^2 *topology in x-compact sets of* $\mathbb{R} \setminus \{0\}$ *uniformly in compact sets of* $\mathbb{R}^2$ *if*

(a) $Dom(g_\alpha) \to \mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$ *as* $\alpha \to 1^+$, *and*

(b) *for every compact* $K \subset \mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$ *and every* $\varepsilon > 0$ *there is* $\delta_0 > 0$ *such that if* $1 < \alpha < 1 + \delta_0$, *then*

$$\sup_{i \in \{0,1,2\}, (\rho, x) \in K} \left| \partial_x^i g_\alpha(\rho, x) - \partial_x^i g(\rho, x) \right| < \varepsilon.$$

The following lemma corresponds to Lemma 3.3 in [MPS]. The difference is that in [MPS] we care about C^1 convergence and here we care about C^2 convergence.

LEMMA 5.7. *Let* g_α *be as in* (5.3). *Define*

$$g(\mu, \nu, x) = \begin{cases} \mu + \nu^+ C^+ B x & \text{if} \quad x > 0, \\ \nu + \nu^- C^- B x & \text{if} \quad x < 0. \end{cases}$$

Then the following hold:

(i) $g_\alpha \to g$ *in the* C^0 *topology in compact sets of* $\mathbb{R}^3$ *as* $\alpha \to 1^+$, $\alpha \in O$.
(ii) $g_\alpha \to g$ *in the* C^1 *topology in compact sets of* $\mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$ *as* $\alpha \to 1^+$, $\alpha \in O$.
(iii) $g_\alpha \to g$ *in the* C^2 *topology in compact sets of* $\mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$ *as* $\alpha \to 1^+$, $\alpha \in O$.

Moreover, for any $c > \max\{1, C^+/C^-\}$, *there are constants* $\alpha_0 > 1$, $0 < K_1 < K_2$ *such that for* $\alpha \in O \cap (1, \alpha_0)$ *we have the following:*

(a) $[-c, c]^2 \times ([-c, c] \setminus \{0\}) \subset Dom(g_\alpha)$.
(b) *If* $(\mu, \nu, x) \in [-c, c]^2 \times ([-c, c] \setminus \{0\})$, *then*

$$K_1 \mid x \mid^{\alpha-1} \leq \left| \frac{\partial}{\partial x} g_\alpha(\mu, \nu; x) \right| \leq K_2 \mid x \mid^{\alpha-1} . \tag{5.5}$$

(c) *If* $(\mu, \nu, x) \in [-c, c]^2 \times ([-c, c] \setminus \{0\})$, *then*

$$K_1 \mid x \mid^{\alpha-2} \leq \left| \frac{\partial^2}{\partial x^2} g_\alpha(\mu, \nu; x) \right| \leq K_2 \mid x \mid^{\alpha-2} . \tag{5.6}$$

Proof. The proofs of (i), (ii), (a), and (b) are similar to the proofs in [MPS, Lemma 3.3]. To prove (iii), put $k = q(\alpha)$, where $q(\alpha)$ is given by Lemma 3.1. Recall $k \to 0$ as $\alpha \to 1^+$. Now note that

$$\partial_x^2 g_\alpha(\mu, \nu, x) = \begin{cases} \nu^+ C_\eta^+ \alpha(\alpha-1) k^{\alpha-1} |x|^{\alpha-2} + O''_{\eta,1}(|kx|^\alpha) \alpha^2 k^{2\alpha} |x|^{2(\alpha-1)} \\ \qquad + O'_{\eta,1}(|kx|^\alpha) \alpha(\alpha-1) |kx|^{\alpha-2} k \quad \text{for} \quad x > 0, \\ -\nu^- C_\alpha^- \alpha(\alpha-1) k^{\alpha-1} |x|^{\alpha-2} - O''_{\eta,2}(|kx|^\alpha) \alpha^2 k |kx|^{2(\alpha-1)} \\ \qquad - O'_{\eta,2}(|kx|^\alpha) \alpha(\alpha-1) |kx|^{\alpha-2} k \quad \text{for} \quad x < 0. \end{cases}$$

By Lemma 2.1 $\mathcal{O}_{\eta,i}$ is C^2 and so $\mathcal{O}_{\eta,i}(|kx|^\alpha)$ is uniformly bounded in K. By Lemma 3.1 we have that $k^{2\alpha} \to 0$ and $k^{\alpha-1} \to B$ as $\alpha \to 1^+$. Since $|x|^{2\alpha-1}$ is uniformly bounded in K we finally obtain that $\partial_x^2 g_\alpha(\mu, \nu, x) \to 0$ as $\alpha \to 1^+$ in compact sets of $\mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$. Now note that the expression above for $\partial_x^2 g_\alpha(\mu, \nu, x)$ together with the bounds for k, $k^{2\alpha}$, $k^{\alpha-1}$ imply (c). All together conclude the proof of Lemma 5.7. □

Now we prove the existence of trapping regions for the maps $g_\alpha(\mu, \nu, \cdot)$. A *trapping region* for $g_\alpha(\mu, \nu, .)$ is a closed interval J such that $g_\alpha(\mu, \nu, J) \subset \mathrm{Int}(J)$. The following theorem corresponds to Theorem 4.1 in [MPS] with a similar proof.

Given $(\mu_0, \nu_0) \in \mathbb{R}^2$, $r > 0$ and angles $0 \leq \theta_1 < \theta_2 \leq 2\pi$ we define the cone $C_r(\mu_0, \nu_0; \theta_1, \theta_2) = \{(\mu, \nu) \in \mathbb{R}^2 : || (\mu_0, \nu_0) - (\mu, \nu) || < r; \mathrm{Arg}((\mu_0, \nu_0) - (\mu, \nu)) \in [\theta_1, \theta_2]\}$.

THEOREM 5.8. *Let* O *be the open set given in Lemma* 3.1 *and let* $(\mu(1), \nu(1))$ *be as in Lemma* 4.1. *For every neighborhood* V *of* $(\mu(1), \nu(1))$ *there is an open set* $\mathcal{O} \subset \mathbb{R}^3$ *and* $\alpha_1 > 1$ *such that if* $\alpha \in O \cap (1, \alpha_1)$, *then the set* $\mathcal{O}_\alpha$ *defined by*

$$\mathcal{O}_\alpha = \{(\mu, \nu) : (\alpha, \mu, \nu) \in \mathcal{O}\}$$

is contained in V. *In addition, for every* $\alpha \in O \cap (1, \alpha_1)$, *there is a cone field* $C_r(\mu(\alpha), \nu(\alpha); \theta_1, \theta_2) \subset \mathcal{O}_\alpha$ *such that if* $(\mu, \alpha) \in C_r(\mu(\alpha), \nu(\alpha); \theta_1, \theta_2)$, *then there exists a closed interval*

$$I_{(\alpha,\mu,\nu)} \subset [x(\alpha) - 1, y(\alpha) + 1]$$

with $0 \in \mathrm{Int}(I_{(\alpha,\mu,\nu)})$ *such that*

$$g_\alpha(\mu,\nu,x) \subset \mathrm{Int}(I_{(\alpha,\mu,\nu)}) \qquad \forall\, x \in I_{(\alpha,\mu,\nu)} \setminus \{0\}.$$

Proof. Let $(\mu(1),\nu(1))$ be as in Lemma 4.1. Fix a neighborhood V of $(\mu(1),\nu(1))$. We break the proof into four cases depending on the values of ν^+,ν^-. We work only with the case $\nu^+ = 1$, $\nu^- = 1$ since the remaining cases are similar.

Fix $\alpha \in O$. Let $x(\alpha)$ and $y(\alpha)$ be as in Lemma 5.2. By item 1 of Lemma 5.1 we have that the limits

$$x(1) = \lim_{\alpha\to 1^+} x(\alpha) \quad \text{and} \quad y(1) = \lim_{\alpha\to 1^+} y(\alpha)$$

exist and satisfy $\mu(1) = x(1)$ and $\nu(1) = y(1)$. Then, by item 1 of Lemma 4.2, $x(1)$ and $y(1)$ are fixed points of the map g defined in Lemma 4.2. We have that these fixed points are hyperbolic because $C^{\pm}B > 1$. Then, as $g_\alpha \to g$ in the C^1 topology by Lemma 5.7(ii), there are $\delta_1 > 0$ and a neighborhood $V' \subset V$ of $(\mu(1),\nu(1))$ such that the continuations $x(\alpha,\mu,\nu)$ and $y(\alpha,\mu,\nu)$ of $x(1)$ and $y(1)$ are defined for all (α,μ,ν) in the product neighborhood $(1-\delta_1, 1+\delta_1)\times V'$ with $\alpha \in O$.

Now define

$$\begin{cases} \mathcal{O} = (1-\delta_1, 1+\delta_1)\times V', \\ \alpha_1 = 1+\delta_1. \end{cases}$$

As $V' \subset V$ one has

$$\mathcal{O}_\alpha \subset V$$

for all $\alpha \in O \cap (1,\alpha_1)$.

We claim that

$$x(\alpha) = x(\alpha,\mu(\alpha),\nu(\alpha)) \quad \text{and} \quad y(\alpha) = y(\alpha,\mu(\alpha),\nu(\alpha))$$

for all $\alpha \in O \cap (1,\alpha_1)$. Indeed, by item 1 of Lemma 5.2 $x(\alpha)$ and $y(\alpha)$ are fixed points of the one-dimensional map $g_\alpha(\mu(\alpha),\nu(\alpha),\cdot)$. But $x(1) = \lim_{\alpha\to 1^+} x(\alpha)$ and $y(1) = \lim_{\alpha\to 1^+} y(\alpha)$. So, $x(\alpha) = x(\alpha,\mu(\alpha),\nu(\alpha))$ and $y(\alpha) = y(\alpha,\mu(\alpha),\nu(\alpha))$ since the continuation is unique. The claim is proved.

For all $\alpha \in O \cap (1,\alpha_1)$ we define the C^1 map $F_\alpha : V' \to \mathbb{R}^2$ by

$$F_\alpha(\mu,\nu) = (\mu - x(\alpha,\mu,\nu), \nu - y(\alpha,\mu,\nu)).$$

It follows from Lemmas 5.2 and 5.3 that $F_\alpha(\mu(\alpha),\nu(\alpha)) = (0,0)$.

Shrinking α_1 if necessary we can repeat the proof of Theorem 4.2 in [MPS] to obtain

$$\det DF_\alpha(\mu(\alpha),\nu(\alpha)) \neq 0$$

for all $\alpha \in O \cap (1,\alpha_1)$. The proof uses the above claim, the limits in Lemma 3.1, and $\alpha \to 0^+$ instead of $\alpha \to 0^-$. From this we obtain that F_α is a diffeomorphism in a neighborhood V_α of $(\mu(\alpha),\nu(\alpha))$ onto a neighborhood of $F_\alpha(\mu(\alpha),\nu(\alpha)) = (0,0)$.

Fix $\alpha \in O \cap (1,\alpha_1)$. Define $W_\alpha = F_\alpha(V_\alpha) \cap \{(x,y), x > 0, y < 0\}$. As $\{(x,y), x > 0, y < 0\}$ is a cone and F_α/V_α is a diffeomorphism there are $r > 0$ and angles $0 \le \theta_1 < \theta_2 \le 2\pi$ such that

$$C_r(\mu(\alpha),\nu(\alpha);\theta_1,\theta_2) \subset F_\alpha^{-1}(W_\alpha).$$

But $F_\alpha^{-1}(W_\alpha) \subset V_\alpha \subset V'$. Then, $C_r(\mu(\alpha), \nu(\alpha); \theta_1, \theta_2) \subset V'$ and so

$$C_r(\mu(\alpha), \nu(\alpha); \theta_1, \theta_2) \subset \mathcal{O}_\alpha$$

by the definition of $\mathcal{O}$. This proves the first part of the theorem.

Choose $\alpha \in O \cap (1, \alpha_1)$ and $(\mu, \nu) \in C_r(\mu(\alpha), \nu(\alpha); \theta_1, \theta_2)$. Repeating the argument of the proof of Theorem 4.1-(2) in [MPS] we can find the closed interval $I_{(\alpha,\mu,\nu)} \subset [x(\alpha) - 1, y(\alpha) + 1]$ with $0 \in \mathrm{Int}(I_{(\alpha,\mu,\nu)})$ required in the second part. This finishes the proof. □

COROLLARY 5.9. *Let $(\mu(1), \nu(1))$, V, $\mathcal{O}$, and α_1 be as in Theorem 5.8. Let $\alpha \in O \cap (1, \alpha_1)$ and $C_r(\mu(\alpha), \nu(\alpha); \theta_1, \theta_2)$ be as in the same theorem. Define $\mathcal{I}_\alpha = [\theta_1, \theta_2]$. For each $\theta \in \mathcal{I}_\alpha$ consider the straight line $L_{\alpha,\theta}$ in the (μ, ν)-plane given by*

$$L_{\alpha,\theta} = \{(\mu, \nu) \,:\, \nu = \theta(\mu - \mu(\alpha)) + \nu(\alpha)\}.$$

Then, there is an open segment $\mathcal{I}_{\alpha,\theta} \subset L_{\alpha,\theta} \cap \mathcal{O}_\alpha$ such that

$$\mathcal{I}_{\alpha,\theta} \subset C_r(\mu(\alpha), \nu(\alpha); \theta_1, \theta_2) \quad \textit{and} \quad (\mu(\alpha), \nu(\alpha)) \in \partial \mathcal{I}_{\alpha,\theta}.$$

6. Rovella's theorem. The following definition is similar to Definition 5.6.

DEFINITION 6.1. *Given $a < 0 < b$ let $\varphi : [a, b] \setminus \{0\} \to [a, b]$ be a C^r map, $r \geq 0$. A one-parameter family $\varphi_t : [a, b] \setminus \{0\} \to [a, b]$ of C^r maps converges to φ in the C^r topology as $t \to 0^+$ if for every $\eta > 0$ and $\epsilon > 0$ there is $\delta > 0$ such that*

$$\sup_{i \in \{0,1,\ldots,r\}, x \in [a,b] \setminus (-\eta, \eta)} \left| \varphi_t^{(i)}(x) - \varphi^{(i)}(x) \right| < \epsilon \quad \forall\, 0 < t < \delta.$$

Let φ be a map with domain $Dom(\varphi) \subset \mathbb{R}$. A point $p \in Dom(\varphi)$ is *fixed*, *prefixed*, or *periodic with period* 2 depending on whether $\varphi(p) = p$ or $\varphi(p) \in Dom(\varphi)$ and $\varphi(\varphi(p)) = \varphi(p)$ or $\varphi(p) \in Dom(\varphi)$ and $\varphi(\varphi(p)) = p$.

Now we define a *Rovella map*.

DEFINITION 6.2. *Let $a < 0 < b$ be fixed. A C^1 map $\varphi : [a, b] \setminus \{0\} \to [a, b]$ is a* Rovella map *if it satisfies the following properties.*

1. *φ is monotone in each connected component of $[a, b] \setminus \{0\}$.*
2. *The lateral limits*

$$\varphi(0+) = \lim_{x \to 0^+} \varphi(x), \qquad \varphi(0-) = \lim_{x \to 0^-} \varphi(x)$$

   exist.
3. *The points a and b are fixed, prefixed, or periodic with period 2 and*

$$\varphi(0+), \varphi(0-) \in \{a, b\}.$$

4. *There is $\lambda > 1$ such that for every $\epsilon > 0$ there is $c > 0$ such that if $x \in [a, b]$, $n \in \mathbb{N}$, and $|\varphi^j(x)| \geq \epsilon$ for all integers $0 \leq j \leq n - 1$, then*

$$|(\varphi^n)'(x)| \geq c\lambda^n.$$

As usual we denote $\omega_\varphi(x)$ the omega-limit of the point x with respect to a map φ. The name "Rovella map" above comes from the following result [Rov]. We use the notation

$$CH\{x, y, z, t\}$$

for the convex hull of $x, y, z, t \in \mathbb{R}$.

THEOREM 6.3 (Rovella's theorem). *Let a, a_0, b_0, b be real numbers such that*

$$a < a_0 < 0 < b_0 < b.$$

Let $\varphi : [a, b] \setminus \{0\} \to \mathbb{R}$ be a C^2 map such that $\varphi([a_0, b_0] \setminus \{0\}) \subset [a_0, b_0]$ and $\varphi/_{[a_0,b_0]}$ is a Rovella map. Let $\varphi_t : [a, b] \setminus \{0\} \to \mathbb{R}$, $t \in (0, d]$, be a one-parameter family of C^2 maps satisfying the properties below:

1. *$\varphi_t \to \varphi$ in the C^2 topology as $t \to 0^+$.*
2. *The lateral limits*

$$\varphi_t(0+) = \lim_{x \to 0^+} \varphi_t(x), \qquad \varphi_t(0-) = \lim_{x \to 0^-} \varphi_t(x)$$

exist and satisfy

$$\frac{\partial \varphi_t(0+)}{\partial t}(0) \neq 0, \qquad \frac{\partial \varphi_t(0-)}{\partial t}(0) \neq 0,$$

and

$$\omega_{\varphi_t}(\varphi_t(0+)) \cup \omega_{\varphi_t}(\varphi_t(0-)) \subset [a, b].$$

3. *There are $\alpha > 1$, $t_0 > 0$, and $0 < K_1 < K_2$ such that the following hold:*
   (a) *If $x \in [a, b] \setminus \{0\}$ and $t \in (0, t_0]$, then*

$$K_1 \mid x \mid^{\alpha-1} \leq \left| \frac{\partial}{\partial x} \varphi_t(x) \right| \leq K_2 \mid x \mid^{\alpha-1} . \tag{6.1}$$

   (b) *If $x \in [a, b] \setminus \{0\}$ and $t \in (0, t_0]$, then*

$$K_1 \mid x \mid^{\alpha-2} \leq \left| \frac{\partial^2}{\partial x^2} \varphi_t(x) \right| \leq K_2 \mid x \mid^{\alpha-2} . \tag{6.2}$$

Then

$$\lim_{\delta \to 0^+} \frac{m(C \cap (0, \delta])}{\delta} = 1,$$

where C is the set of $t \in (0, d]$ such that the interval

$$I_t = CH\{\varphi_t(0+), \varphi_t(0-), \varphi_t(\varphi_t(0+)), \varphi_t(\varphi_t(0-))\}$$

contains 0 in its interior and is φ_t-invariant and the map $\varphi_t/_{I_t}$ is transitive. Moreover there is a compact interval W_t with $I_t \subset \mathrm{Int}(W_t)$ such that $\mathrm{Cl}(\varphi_t(W_t \setminus \{0\})) \subset \mathrm{Int}(W_t)$ and $\varphi_t^2(W_t \setminus \{0\}) \subset I_t$.

7. The map h_α. Let $\Lambda > 0$ and $O \subset (1, 1 + \Lambda)$ be as in Lemma 3.1. Let $p(\alpha)$ and $q(\alpha)$ be as in Lemma 3.1. If $\alpha \in O$, we consider $x(\alpha)$ and $y(\alpha)$ as in (5.4), namely,

$$x(\alpha) = \frac{p(\alpha)}{q(\alpha)} \quad \text{and} \quad y(\alpha) = 1.$$

Since $p < 0 < q$ by Lemma 3.1 we have $x(\alpha) < 0 < y(\alpha)$. Let $x(1)$ and $y(1)$ be the limits in Lemma 5.1. Define

$$c_1 = 1 + \max\{-x(1), y(1)\}.$$

By Lemma 5.1 one has

$$c_1 > \max\{1, C^+/C^-\}.$$

Then, by Lemma 5.7, we can fix $\alpha_0 > 1$, $0 < K_1 < K_2$ such that the conclusions (a)–(c) of that lemma hold (with $c = c_1$).

Given $\alpha \in O \cap (1, \alpha_0)$ let $(\mu(\alpha), \nu(\alpha))$ and $g_\alpha(\mu, \nu, x)$ be as in (4.1) and (5.3), respectively.

Define

$$h_\alpha(x) = g_\alpha(\mu(\alpha), \nu(\alpha), x).$$

The first result of this section is the following.

THEOREM 7.1. *There is $\alpha_* > 1$ such that if $1 < \alpha < \alpha_*$, then*

1. *$h_\alpha([x(\alpha), y(\alpha)] \setminus \{0\}) \subset [x(\alpha), y(\alpha)]$, and*
2. *$h_\alpha/_{[x(\alpha), y(\alpha)]\setminus\{0\}}$ is a Rovella map.*

Proof. We shall work only with the cases $\nu^+ = 1$ and $\nu^- = 1$; the remaining cases are similar.

Recall the definition of $x(\alpha)$ and $y(\alpha) = 1$ in the beginning of this section. Let $1 < \alpha < \alpha_0$ and $\delta > 0$ be small (less than $1/2 \cdot \min\{-x(1), 1\}$, say). Define the numbers

$$M_\delta^+(\alpha) = \sup\left\{\left|\frac{\partial}{\partial x} g_\alpha(\mu(\alpha), \nu(\alpha), x)\right| : |x - y(\alpha)| \le \delta\right\},$$

$$m_\delta^+(\alpha) = \inf\left\{\left|\frac{\partial}{\partial x} g_\alpha(\mu(\alpha), \nu(\alpha), x)\right| : |x - y(\alpha)| \le \delta\right\},$$

$$M_\delta^-(\alpha) = \sup\left\{\left|\frac{\partial}{\partial x} g_\alpha(\mu(\alpha), \nu(\alpha), x)\right| : |x - x(\alpha)| \le \delta\right\},$$

and

$$m_\delta^-(\alpha) = \inf\left\{\left|\frac{\partial}{\partial x} g_\alpha(\mu(\alpha), \nu(\alpha), x)\right| : |x - x(\alpha)| \le \delta\right\}.$$

Let g be as in Lemma 5.7. Hence g is piecewise linear with slope C^-B (for $x < 0$) and C^+B (for $x > 0$). By Lemma 5.7(ii) we have that $g_\alpha \to g$ in the C^1 topology in compact sets of $\mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$ as $\alpha \to 1$, $\alpha \in O$. This implies

$$\lim_{(\alpha,\delta)\to(1^+,0)} M_\delta^-(\alpha) = \lim_{(\alpha,\delta)\to(1^+,0)} m_\delta^-(\alpha) = C^-B$$

and

$$\lim_{(\alpha,\delta)\to(1^+,0)} M_\delta^+(\alpha) = \lim_{(\alpha,\delta)\to(1^+,0)} m_\delta^+(\alpha) = C^+B$$

because of the above-mentioned slopes of g. These limits imply

$$\lim_{(\alpha,\delta)\to(1^+,0)} \frac{m_\delta^-(\alpha)}{\left(M_\delta^-(\alpha)\right)^{\frac{\alpha-1}{\alpha}}} = C^-B$$

and

$$\lim_{(\alpha,\delta)\to(1^+,0)} \frac{m_\delta^+(\alpha)}{\left(M_\delta^+(\alpha)\right)^{\frac{\alpha-1}{\alpha}}} = C^+B$$

because $C^\pm B > 0$.

Define

$$\lambda_0 = \min\{C^+B, C^-B\}.$$

The definition of $B = B(X_{\eta_0})$ implies $\lambda_0 > 1$. Then we can fix $1 < \lambda_1 < \lambda_0$. The last limits imply that there are $\delta_1 > 0$ and $1 < \alpha_1 < \alpha_0$ such that

$$\min\left\{\frac{m_\delta^-(\alpha)}{\left(M_\delta^-(\alpha)\right)^{\frac{\alpha-1}{\alpha}}}, \frac{m_\delta^+(\alpha)}{\left(M_\delta^+(\alpha)\right)^{\frac{\alpha-1}{\alpha}}}\right\} > \lambda_1 \tag{7.1}$$

for all $0 < \delta < \delta_1$ and $1 < \alpha < \alpha_1$.

For fixed $\epsilon > 0$, $\delta_0 > 0$, and $\alpha > 1$ we define

$$l_\epsilon^-(x,\alpha) = \min\{l \geq 1 : |h_\alpha^l(x) - x(\alpha)| \geq \delta_0,\, x \in (0,\epsilon)\}$$

and

$$l_\epsilon^+(x,\alpha) = \min\{l \geq 1 : |h_\alpha^l(x) - y(\alpha)| \geq \delta_0,\, x \in (0,\epsilon)\}.$$

Because $h_\alpha(0+) = x(\alpha)$, $h_\alpha(0-) = y(\alpha)$, $h_\alpha(x(\alpha)) = x(\alpha)$, and $h_\alpha(y(\alpha)) = y(\alpha)$ one gets

$$\lim_{(\epsilon,\alpha)\to(0^+,1^+)} \inf_{x\in(0,\epsilon]} \{l_\epsilon^-(x,\alpha)\} = \infty \quad \text{and} \quad \lim_{(\epsilon,\alpha)\to(0^-,1^+)} \inf_{x\in[-\epsilon,0)} \{l_\epsilon^+(x,\alpha)\} = \infty.$$

Fix $1 < \lambda_2 < \lambda_1$ and define

$$N = \frac{\log(\frac{K_1}{\lambda_1}) + \left(\frac{\alpha-1}{\alpha}\right)\cdot\log\left(\frac{\alpha\cdot\delta_0}{K_2}\right)}{-\log\lambda_2}.$$

By the above limits we can fix $\epsilon_0 > 0$ and $1 < \alpha_2 < \alpha_1$ such that

$$l_\epsilon^-(x,\alpha) > N \quad \forall\,(\epsilon,x,\alpha) \in (0,\epsilon_0]\times(0,\epsilon]\times(1,\alpha_2] \tag{7.2}$$

and

$$l_\epsilon^+(x,\alpha) > N \quad \forall\,(\epsilon,x,\alpha) \in (0,\epsilon_0]\times[-\epsilon,0)\times(1,\alpha_2]. \tag{7.3}$$

Hereafter we fix $0 < \delta_0 < \delta_1$ and use the notation

$$m^\pm = m_{\delta_0}^\pm(\alpha), \quad M^\pm = M_{\delta_0}^\pm(\alpha), \quad l^\pm(x) = l_\epsilon^\pm(x,\alpha)$$

for the sake of simplicity.

By Lemma 5.7(ii) we have that $g_\alpha \to g$ in the C^1 topology as $\alpha \to 1^+$. More precisely, the following property holds (see Definition 5.5): For every compact set

$K \subset \mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$ and every $\varepsilon > 0$ there is $1 < \alpha_3 < \alpha_2$ such that if $1 < \alpha < \alpha_3$, then

$$\sup_{i\in\{0,1\},y\in K} \left|D^i g_\alpha(y) - D^i g(y)\right| < \varepsilon.$$

Applying this property to $\varepsilon = \epsilon_0$ and $K = [-c_1, c_1]^2 \times ([-c_1, c_1] \setminus (-\epsilon_0, \epsilon_0))$ we obtain

$$\left|\frac{\partial}{\partial x} g_\alpha(\mu(\alpha), \nu(\alpha), x)\right| \geq \lambda_1 \quad \forall |x| \geq \epsilon_0. \tag{7.4}$$

(For this we use $(\mu(\alpha), \nu(\alpha), x) \in K$ (as $\alpha \to 1^+$), $\lambda_1 < \lambda_0$, and λ_0 is about the slope of the piecewise linear maps $x \to g(\mu(\alpha), \nu(\alpha), x)$.)

Define

$$\lambda = \frac{\lambda_1}{\lambda_2}.$$

Then, $\lambda > 1$. We use λ in the following lemma.

LEMMA 7.2. *Let $0 < \epsilon < \epsilon_0$ and $1 < \alpha < \alpha_3$ be fixed. If $\epsilon \leq x < \epsilon_0$, then*

$$|(h_\alpha^{l^-(x)})'(x)| \geq \lambda^{l^-(x)}$$

and if $-\epsilon_0 < x \leq -\epsilon$, then

$$|(h_\alpha^{l^+(x)})'(x)| \geq \lambda^{l^+(x)}.$$

Proof. We prove only the first inequality since the second one is analogous. Fix $0 < \epsilon < \epsilon_0$, $1 < \alpha < \alpha_3$, and $\epsilon \leq x < \epsilon_0$. The chain rule and the definitions of m^- and h_α imply

$$|(h_\alpha^{l^-(x)-1})'(h_\alpha(x))| = \Pi_{i=1}^{l^-(x)-1} \left|\frac{\partial}{\partial x} g_\alpha(\mu(\alpha), \nu(\alpha), h_\alpha^i(x))\right| \geq (m^-)^{l^-(x)-1}.$$

As above we have $(\mu(\alpha), \nu(\alpha), x) \in [-c_1, c_1]^2 \times ([-c_1, c_1] \setminus \{0\})$ because $\alpha \to 1^+$. The chain rule, (5.5) in Lemma 5.7(b), and the definitions of m^- and $l^-(x)$ imply

$$|(h_\alpha^{l^-(x)})'(x)| = |h_\alpha'(x)| \cdot |(h_\alpha^{l^-(x)-1})'(h_\alpha(x))| \geq K_1 \cdot |x|^{\alpha-1} \cdot (m^-)^{l^-(x)-1}. \tag{7.5}$$

On the other hand, Lemma 3.1(a) and the definition of g_α imply

$$h_\alpha(x(\alpha)) = g_\alpha(\mu(\alpha), \nu(\alpha), x(\alpha)) = x(\alpha).$$

So, $|h_\alpha^{l^-(x)-1}(x(\alpha)) - h_\alpha^{l^-(x)-1}(h_\alpha(x))| = |x(\alpha) - h_\alpha^{l^-(x)}(x)|$. Then, the definition of $l^-(x)$ implies

$$|h_\alpha^{l^-(x)-1}(x(\alpha)) - h_\alpha^{l^-(x)-1}(h_\alpha(x))| \geq \delta_0.$$

Consequently, for some intermediate point ξ in between $x(\alpha)$ and $h_\alpha(x)$ we obtain

$$\begin{aligned} |x(\alpha) - h_\alpha^{l^-(x)}(x)| &= |h_\alpha^{l^-(x)-1}(x(\alpha)) - h_\alpha^{l^-(x)-1}(h_\alpha(x))| \\ &= |(h_\alpha^{l^-(x)-1})'(\xi)| \cdot |x(\alpha) - h_\alpha(x)|. \end{aligned}$$

However, $|(h_\alpha^{l^-(x)-1})'(\xi)| \le (M^-)^{l^-(x)-1}$ because $|x(\alpha)-\xi| \le |x(\alpha)-h_\alpha(x)|$ and so

$$|x(\alpha)-h_\alpha^i(\xi)| \le |x(\alpha)-h_\alpha^{i+1}(x)| \le \delta_0$$

for all $0 \le i \le l^-(x)-2$ because h_α is monotone in $[x(\alpha),0)$. Then,

$$|(h_\alpha^{l^-(x)-1})'(\xi)| \cdot |x(\alpha)-h_\alpha(x)| \le (M^-)^{l^-(x)-1} \cdot |x(\alpha)-h_\alpha(x)|$$

and so

$$|x(\alpha)-h_\alpha^{l^-(x)}(x)| \le (M^-)^{l^-(x)-1} \cdot |x(\alpha)-h_\alpha(x)|.$$

As $|x(\alpha)-h_\alpha^{l^-(x)}(x)| \ge \delta_0$ by the definition of $l^-(x)$ we obtain

$$|x(\alpha)-h_\alpha(x)| \cdot (M^-)^{l^-(x)-1} \ge \delta_0$$

and so

$$|x(\alpha)-h_\alpha(x)| \ge (M^-)^{1-l^-(x)} \cdot \delta_0.$$

On the other hand,

$$|h_\alpha(x)-x(\alpha)| = \left|\int_0^x h'_\alpha(\tau)d\tau\right| \le \int_0^x K_2 \cdot \tau^{\alpha-1}d\tau = \frac{K_2}{\alpha}|x|^\alpha,$$

where K_2 comes from inequality (5.5) in Lemma 5.7(b). With this we obtain

$$|x|^{\alpha-1} \ge \left(\frac{\alpha\cdot\delta_0}{K_2}\cdot(M^-)^{1-l^-(x)}\right)^{\frac{\alpha-1}{\alpha}}. \tag{7.6}$$

Combining (7.5) and (7.6) we obtain

$$|(h_\alpha^{l^-(x)})'(x)| \ge K_1 \cdot \left(\frac{\alpha\cdot\delta_0}{K_2}\right)^{\frac{\alpha-1}{\alpha}} \cdot \left(\frac{m^-}{(M^-)^{\frac{\alpha-1}{\alpha}}}\right)^{l^-(x)-1} \ge K_1 \cdot \left(\frac{\alpha\cdot\delta_0}{K_2}\right)^{\frac{\alpha-1}{\alpha}} \cdot \lambda_1^{l^-(x)-1}$$

because $x \in (0,\epsilon_0)$ and inequality (7.1) holds. Finally using inequality (7.2) we obtain

$$|(h_\alpha^{l^-(x)})'(x)| \ge \lambda^{l^-(x)}.$$

The proof follows. □

Choose $\alpha_3 > 1$ as in Lemma 7.2 and define

$$\alpha_* = \alpha_3.$$

We shall prove that α_* satisfies 1 and 2 of Theorem 7.1. For this we fix $1 < \alpha < \alpha_*$.

Proof of item 1 *of Theorem* 7.1. By item 1 of Lemma 5.2 we have

$$h_\alpha(x(\alpha)) = x(\alpha) \quad \text{and} \quad h_\alpha(y(\alpha)) = y(\alpha).$$

By (5.3) we have

$$h_\alpha(0+) = g_\alpha(\mu(\alpha),\nu(\alpha),0+) = \frac{f_\eta(0+)}{q(\alpha)} = \frac{a^+(\alpha)}{q(\alpha)} = \mu(\alpha)$$

and analogously $h_\alpha(0-) = \nu(\alpha)$. Moreover, h_α is monotone in $[x(\alpha), 0)$ and $(0, y(\alpha)]$ by Lemma 2.1 and the definition of $g_\alpha(\mu, \nu, x)$. Then the result follows.

Proof of item 2 *of Theorem* 7.1. Items 1 and 2 of Definition 6.2 follow from the previous calculations. Item 3 of Definition 6.2 follows from item 1 of Lemma 5.2 and item 1 of Lemma 5.3.

Now we prove item 4 of Definition 6.2. Recall $\lambda = \frac{\lambda_1}{\lambda_2}$ (thus $\lambda > 1$) and $1 < \alpha < \alpha_*$. Fix $\epsilon > 0$. We have to find $c > 0$ such that if for all $x \in [x(\alpha), y(\alpha)]$, $n \in \mathbb{N}$ and $|h_\alpha^j(x)| \geq \epsilon$ for all integers $0 \leq j \leq n-1$, then

$$|(h_\alpha^n)'(x)| \geq c\lambda^n. \tag{7.7}$$

If $\epsilon \geq \epsilon_0$, then (7.7) holds by inequality (7.4) choosing $c = 1$. Then, we can assume

$$0 < \epsilon < \epsilon_0.$$

For simplicity we write h instead of h_α.

Define

$$c = \inf_{|y| \geq \epsilon} \{|h'(y)|\}.$$

Then, $c > 0$ because of the choice of K_1.

Next we break the orbit $\{x, h(x), \ldots, h^{n-1}(x)\}$ of x in the following way:

$$0 \leq r_0 < r_1 < \cdots < r_s \leq n-1,$$

such that

$$\epsilon \leq |h^{r_i}(x)| < \epsilon_0$$

for all $0 \leq i \leq s$. For all i we define the integers

$$l_i = l^*(h^{r_i}(x)),$$

where $*$ is $+$ or $-$ depending on the signal of $h^{r_i}(x)$. The chain rule implies

$$|(h^n)'(x)| = |(h^{r_0})'(x)| \cdot (\Pi_{i=1}^s |(h^{r_i})'(h^{r_{i-1}}(x))|) \cdot |(h^{n-r_s})'(h^{r_s}(x))|. \tag{7.8}$$

This product consists of three terms to be bounded in what follows. The first one is bounded by

$$|(h^{r_0})'(x)| > \lambda^{r_0} \tag{7.9}$$

because of (7.4) since $|h^j(x)| \geq \epsilon_0$ for $0 \leq j < r_0$. The last one is bounded by

$$|(h^{n-r_s})'(h^{r_s}(x))| \geq c \cdot \lambda^{n-r_s-1} \tag{7.10}$$

by the definition of c because $|h^{r_s}(x)| \geq \epsilon$ and $|h^j(x)| \geq \epsilon_0$ for $r_s + 1 \leq j < n$.

Next we bound the middle term $\Pi_{i=1}^s |(h^{r_i})'(h^{r_{i-1}}(x))|$. For all $1 \leq i \leq s$ we have that

$$|(h^{r_i})'(h^{r_{i-1}}(x))| = |(h^{l_{i-1}})'(h^{r_{i-1}}(x))| \cdot |(h^{r_i - l_{i-1}})'(h^{r_i + l_i}(x))|.$$

On the other hand

$$|(h^{l_{i-1}})'(h^{r_{i-1}}(x))| \geq \lambda^{l_{i-1}}$$

by Lemma 7.2 applied to $h^{r_{i-1}}(x)$ (instead of x). And also

$$|(h^{r_i-l_{i-1}})'(h^{r_i+l_i}(x))| \geq \lambda^{r_i+l_{i-1}}$$

by inequality (7.2) because $|h^j(x)| \geq \epsilon_0$ for all $r_{i-1}+1 \leq j < r_i$. All together yield

$$|(h^{r_i})'(h^{r_{i-1}}(x))| \geq \lambda^{l_{i-1}} \cdot \lambda^{r_i+l_{i-1}} = \lambda^{r_i}. \tag{7.11}$$

Replacing (7.11), (7.10), and (7.9) in (7.8) we obtain (7.7). This finishes the proof of Theorem 7.1. □

The second result of this section is the following.

THEOREM 7.3. *Let $(\mu(1),\nu(1))$, V, $\mathcal{O}$, α_1, and O be as in Corollary 5.9. Fix $\alpha \in O \cap (1,\alpha_1)$ and consider $\mathcal{I}_\alpha$ as in that corollary. For each $\theta \in \mathcal{I}_\alpha$ consider the open segment $\mathcal{I}_{\alpha,\theta} \subset L_{\alpha,\theta} \cap \mathcal{O}_\alpha$ as in that corollary. Let $s : [0, d_{\alpha,\theta}] \subset \mathbb{R} \to \mathcal{I}_{\alpha,\theta}$ be the parametrization of $\mathcal{I}_{\alpha,\theta}$ given by*

$$s(t) = t \cdot v_\theta + (\mu(\alpha),\nu(\alpha)),$$

where $v_\theta = (\cos(\theta),\sin(\theta))$ is the unitary vector with argument θ. Define the numbers

$$a = -3\max\{1, C^+/C^-\}, \qquad b = 3\max\{1, C^+/C^-\},$$

and the map $\varphi : [a,b] \setminus \{0\} \to \mathbb{R}$ by

$$\varphi(x) = g_\alpha(\mu(\alpha),\nu(\alpha),x).$$

There is $\alpha_{**} > 1$ such that if $1 < \alpha < \alpha_{**}$ and $\theta \in \mathcal{I}_\alpha \setminus \{0,\pi/2,\pi,3\pi/2,2\pi\}$, then φ and the family $\varphi_t : [a,b] \setminus \{0\} \to \mathbb{R}$, $t \in (0, d_{\alpha,\theta}]$ defined by

$$\varphi_t(x) = g_\alpha(s(t),x)$$

satisfy the hypotheses (1)–(3) of Rovella's theorem (Theorem 6.3).

Proof. Let $x(\alpha)$ and $y(\alpha)$ be as in (5.4), let $\alpha_* > 1$ be as in Theorem 7.1, and define

$$a_0 = x(\alpha) \quad \text{and} \quad b_0 = y(\alpha).$$

The definition of $x(\alpha), y(\alpha)$ and Lemma 5.1 imply

$$\lim_{\alpha\to 1^+} x(\alpha) = -C^+/C^-,$$

and obviously

$$\lim_{\alpha\to 1^+} y(\alpha) = 1.$$

So, there is $1 < \alpha_{**} < \alpha_*$ close to 1 such that if $1 < \alpha < \alpha_{**}$, then

$$a < x(\alpha) - 1 < a_0 < 0 < b_0 < y(\alpha) + 1 < b. \tag{7.12}$$

Let us prove that such an α_{**} works. Hereafter we fix

$$1 < \alpha < \alpha_{**} \quad \text{and} \quad \theta \in \mathcal{I}_\alpha \setminus \{0,\pi/2,\pi,3\pi/2,2\pi\}.$$

By Theorem 7.1 we have $\varphi([a_0,b_0] \setminus \{0\}) \subset [a_0,b_0]$ and $\varphi/_{[a_0,b_0]}$ is a Rovella map.

Let us verify hypothesis 1 of Rovella's theorem. By (5.3) one has

$$\varphi_t(x) = g_\alpha(s(t), x) = \frac{1}{q(\alpha)} \cdot f_{\eta(\alpha, q(\alpha)\cdot s(t))}(q(\alpha)\cdot x).$$

As $t \to 0^+$ we have

$$\varphi_t(x) \to \frac{1}{q(\alpha)} \cdot f_{\eta(\alpha, q(\alpha)\cdot s(0))}(q(\alpha)\cdot x) = \varphi(x)$$

because of (5.3) and the definition of φ. The C^2 convergence $\varphi_t \to \varphi$ required in hypothesis 1 follows from the C^2 variation mentioned in Lemma 2.1.

Next we verify hypothesis 2 of Rovella's theorem. Recalling the definition of v_θ we have

$$s(t) = (\mu_t(\alpha), \nu_t(\alpha)),$$

where

$$\begin{cases} \mu_t(\alpha) = t\cdot\cos\theta + \mu(\alpha), \\ \nu_t(\alpha) = t\cdot\sin\theta + \mu(\alpha). \end{cases}$$

By Lemma 2.1 we have

$$f_\eta(0+) = a_\eta^+ \quad \text{and} \quad f_\eta(0-) = a_\eta^-$$

for all η, where $a_\eta^\pm$ are the leading terms in the Taylor expansion of f_η in Lemma 2.1. Then,

$$f_{\eta(\alpha, q(\alpha)\cdot s(t))}(0+) = a^+_{\eta(\alpha, q(\alpha)\cdot s(t))} = q(\alpha)\cdot\mu_t(\alpha)$$

by (3.2) applied to $a^+ = q(\alpha)\cdot\mu_t(\alpha)$ and $a^- = q(\alpha)\cdot\nu_t(\alpha)$. Analogously

$$f_{\eta(\alpha, q(\alpha)\cdot s(t))}(0-) = q(\alpha)\cdot\nu_t(\alpha).$$

Thus,

$$\begin{aligned} \lim_{x\to 0^+} \varphi_t(x) &= \lim_{x\to 0^+} g_\alpha(s(t), x) = \lim_{x\to 0^+} \frac{1}{q(\alpha)} \cdot f_{\eta(\alpha, q(\alpha)\cdot s(t))}(q(\alpha)\cdot x) \\ &= \frac{1}{q(\alpha)} \cdot f_{\eta(\alpha, q(\alpha)\cdot s(t))}(0+) = \frac{1}{q(\alpha)} \cdot q(\alpha)\cdot\mu_t(\alpha) = \mu_t(\alpha), \end{aligned}$$

and so,

$$\varphi_t(0+) = \mu_t(\alpha).$$

Analogously

$$\varphi_t(0-) = \nu_t(\alpha).$$

This proves the existence of the lateral limits in hypothesis 2. These equalities also imply

$$\frac{\partial\varphi_t(0+)}{\partial t}(0) = \frac{\partial\mu_t(\alpha)}{\partial t}(0) = \frac{\partial(t\cdot\cos\theta + \mu(\alpha))}{\partial t}(0) = \cos\theta \neq 0$$

because $\theta \neq \pi/2, 3\pi/2$. Analogously

$$\frac{\partial \varphi_t(0+)}{\partial t}(0) \neq 0$$

since $\theta \neq 0, \pi$ (for in such cases $\sin\theta \neq 0$). These facts together imply

$$\frac{\partial \varphi_t(0+)}{\partial t}(0) \neq 0, \qquad \frac{\partial \varphi_t(0-)}{\partial t}(0) \neq 0.$$

To see

$$\omega_{\varphi_t}(\varphi_t(0+)) \cup \omega_{\varphi_t}(\varphi_t(0-)) \subset [a, b]$$

we proceed as follows. By Corollary 5.9 we have $\mathcal{I}_{\alpha,\theta} \subset C_r(s(t); \theta_1, \theta_2)$. In particular, $s(t) \in C_r(s(t); \theta_1, \theta_2)$ for all $t \in (0, d_{\alpha,\theta}]$, and so, by the second part of Theorem 5.8, there is a closed interval $I_{(\alpha,s(t))} \subset [x(\alpha)-1, y(\alpha)+1]$ with $0 \in \mathrm{Int}(I_{(\alpha,s(t))})$ such that

$$\varphi_t(x) = g_\alpha(s(t), x) \subset \mathrm{Int}(I_{(\alpha,s(t))}) \quad \forall\, x \in I_{(\alpha,s(t))}.$$

This already implies $\omega_{\varphi_t}(\varphi_t(0+)) \cup \omega_{\varphi_t}(\varphi_t(0-)) \subset I_{(\alpha,s(t))}$ and then we are done because (7.12) implies $[x(\alpha) - 1, y(\alpha) + 1] \subset [a, b]$.

To finish we prove hypothesis 3 of Rovella's theorem. Shrinking α_{**} if necessary we can assume $1 < \alpha_{**} < \alpha_0$, where α_0 comes from Lemma 5.7. Choosing $c = -a$ (or b) we have $c > \max\{1, C^+/C^-\}$. Then, the result follows from (a), inequality (5.5) in (b), and inequality (5.6) in (c) of Lemma 5.7. □

We finish this section with the following corollary. Recall that $CH\{x, y, z, t\}$ denote the convex hull of $x, y, z, t \in \mathbb{R}$.

COROLLARY 7.4. *Let O be as in Lemma* 3.1 *and $(\mu(1), \nu(1))$ be the limit in Lemma* 4.1. *Let V be a neighborhood of $(\mu(1), \nu(1))$. Let $(\mu(\alpha), \nu(\alpha))$ be as in* (4.1). *There is $\alpha_{***} > 1$ such that for all $\alpha \in O \cap (1, \alpha_{***})$ there is a positive Lebesgue measure subset $\tilde{E}_\alpha \subset V$ with $(\mu(\alpha), \nu(\alpha)) \in \mathrm{Cl}(\tilde{E}_\alpha)$ such that the following property holds: If $(\mu, \nu) \in \tilde{E}_\alpha$, then the interval*

$$I = CH\{g_\alpha(\mu, \nu, 0+), g_\alpha(\mu, \nu, 0-), g_\alpha(\mu, \nu, g_\alpha(\mu, \nu, 0+)), g_\alpha(\mu, \nu, g_\alpha(\mu, \nu, 0-))\}$$

contains 0 in its interior and is $g_\alpha(\mu, \nu, \cdot)$-invariant and the map $g_\alpha(\mu, \nu, \cdot)/_I$ is transitive. Moreover there is a compact interval W with $\mathrm{Int}(W) \supset I$ such that $\mathrm{Cl}(g_\alpha(W \setminus \{0\})) \subset W$ and $g_\alpha^2(W \setminus \{0\}) \subset I$.

Proof. Let $\mathcal{O}$ as in Theorem 5.8 and $\alpha_{**} > 1$ be as in Theorem 7.3.

We claim that $\alpha_{***} = \alpha_{**}$ works. Indeed, by Theorem 7.3, for each $\theta \in \mathcal{I}_\alpha \setminus \{o, \pi/2, \pi, 3\pi/2, 2\pi\}$ the family $\varphi_t : [a, b] \setminus \{0\} \to \mathbb{R}$, $t \in (0, d_{\alpha,\theta}]$, defined by

$$\varphi_t(x) = g_\alpha(s(t), x)$$

satisfies (1)–(3) of Rovella's theorem. So, for those θ's we have

$$\lim_{\delta \to 0^+} \frac{m(C(\alpha, \theta) \cap [0, \delta])}{\delta} = 1, \tag{7.13}$$

where $C(\alpha, \theta)$ is the set of $t \in (0, d_{\alpha,\theta}]$ such that the interval

$$I_t = CH\{\varphi_t(0+), \varphi_t(0-), \varphi_t(\varphi_t(0+)), \varphi_t(\varphi_t(0-))\}$$

contains 0 in its interior and is φ_t-invariant and the map $\varphi_t/_{I_t}$ is transitive. Moreover there is a compact interval W_t with $I_t \subset \mathrm{Int}(W_t)$ such that $\mathrm{Cl}(\varphi_t(W_t \setminus \{0\})) \subset \mathrm{Int}(W_t)$ and $\varphi_t^2(W_t \setminus \{0\}) \subset I_t$. Observe that $0 \in \mathrm{Cl}(C(\alpha,\theta))$ because of (7.13). Again by (7.13) we have that $C(\alpha,\theta)$ has positive Lebesgue measure in $\mathbb{R}$.

Define

$$\tilde{E}_{\alpha,\theta} = s(C(\alpha,\theta)).$$

Then, $\tilde{E}_{\alpha,\theta}$ has positive Lebesgue measure in $\mathcal{I}_{\alpha,\theta}$.

Let us prove $\tilde{E}_{\alpha,\theta} \subset V$. Indeed, Corollary 5.9 implies $\mathcal{I}_{\alpha,\theta} \subset C_r(\mu(\alpha),\nu(\alpha);\theta_1,\theta_2)$ where the last cone comes from Theorem 5.8. By the first part of this theorem we have $C_r(\mu(\alpha),\nu(\alpha);\theta_1,\theta_2) \subset \mathcal{O}_\alpha$ which in turn is contained in V. This proves the result.

Now define

$$\tilde{E}_\alpha = \bigcup_{\theta \in \mathcal{I}_\alpha \setminus \{0,\pi/2,\pi,3\pi/2,2\pi\}} \tilde{E}_{\alpha,\theta}.$$

As $\tilde{E}_{\alpha,\theta} \subset V$ for all α,θ we have

$$\tilde{E}_\alpha \subset V.$$

We also have that $\tilde{E}_\alpha$ has positive Lebesgue measure in $\mathbb{R}^2$ by Fubini's theorem since $\tilde{E}_{\alpha,\theta}$ has positive Lebesgue measure in $\mathbb{R}$. We have $(\mu(\alpha),\nu(\alpha)) \in \mathrm{Cl}(\tilde{E}_{\alpha,\theta})$ because of $0 \in \mathrm{Cl}(C(\alpha,\theta))$. Now, the proof follows from the definition of φ_t. □

8. Proof of Theorem 2.2. Let $\{X_\eta\}$ be a C^k three-parametrized family of C^r-vector fields transverse at X_{η_0} to the submanifold $\mathcal{N}$ given in Definition 1.1, $k, r \geq 3$. Hence X_{η_0} satisfies (A1)–(A6) in that definition. Let $f_\eta : J \subset [-1,1] \to [-1,1]$ be the corresponding three-parametrized family of one-dimensional maps as in Lemma 2.1. Fix a neighborhood $\mathcal{V}$ of η_0 in the parameter space. We have to prove that there is a positive Lebesgue measure set $\mathcal{L}' \subset \mathcal{V}$ with $\eta_0 \in \mathrm{Cl}(\mathcal{L}')$ such that for every $\eta \in \mathcal{L}'$ one has $\alpha(\eta) > 1$ and further there is a closed nontrivial interval Θ_η with the following properties:

1. $0 \in \mathrm{Int}(\Theta_\eta)$.
2. There is a compact interval $W \subset J$ with $\Theta_\eta \subset \mathrm{Int}(W)$ such that $\mathrm{Cl}(f_\eta(W \setminus \{0\})) \subset \mathrm{Int}(W)$ and $f_\eta^2(W \setminus \{0\}) \subset \Theta_\eta$.
3. $f_\eta/_{\Theta_\eta \setminus \{0\}}$ is transitive.

We proceed as follows. Let η be the diffeomorphism in (3.1). Fix $\Lambda > 0$ and $O \subset (1, 1+\Lambda)$ as in Lemma 3.1. Let $(\mu(1),\nu(1))$ be the limits in Lemma 4.1. Let T_α be as in (5.1). Then, the inverse of T_α is given by

$$T_\alpha^{-1}(\mu,\nu) = q(\alpha) \cdot (\mu,\nu). \tag{8.1}$$

For all neighborhoods V of $(\mu(1),\nu(1))$ and $\beta > 1$ we define

$$\tilde{V}(\beta) = \bigcup_{\alpha \in O \cap (1,\beta)} \{\alpha\} \times T_\alpha^{-1}(V).$$

Lemma 3.1 implies $\lim_{\alpha \to 1^+} q(\alpha) = 0$. Thus, there are V and $\beta > 1$ such that

$$\eta(\tilde{V}(\beta)) \subset \mathcal{V}.$$

In what follows we fix such V and β.

Let $\alpha_{***} > 1$ be as in Corollary 7.4 for such a V. Shrinking α_{***} if necessary we can assume

$$1 < \alpha_{***} < \beta.$$

For all $\alpha \in O \cap (1, \alpha_{***})$ we define

$$E_\alpha = (T_\alpha)^{-1}(\tilde{E}_\alpha),$$

where $\tilde{E}_\alpha \subset V$ comes from Corollary 7.4. It follows that

$$E_\alpha \subset T_\alpha^{-1}(V).$$

Since T_α is linear (and $\tilde{E}_\alpha$ has positive Lebesgue measure by Corollary 7.4) we have that E_α has positive Lebesgue measure for all $\alpha \in O \cap (1, \alpha_{***})$.

Define

$$\mathcal{L}' = \{\eta(\alpha, a^+, a^-) : \alpha \in O \cap (1, \alpha_{***}), (a^+, a^-) \in E_\alpha\}.$$

As $E_\alpha \subset T_\alpha^{-1}(V)$, the definition of $\tilde{V}(\beta)$ implies $\mathcal{L}' \subset \eta(\tilde{V}(\beta))$, and so,

$$\mathcal{L}' \subset \mathcal{V}.$$

We have that $\mathcal{L}'$ has positive Lebesgue measure because E_α has positive Lebesgue measure (for all $\alpha \in O \cap (1, \alpha_{***})$) and O has full Lebesgue measure in $(1, 1 + \Lambda)$.

LEMMA 8.1. *If η_0 is the parameter in Theorem* 1.2*, then $\eta_0 \in \mathrm{Cl}(\mathcal{L})$.*

Proof. Note that $\eta_0 = \eta(1, 0, 0)$, where η is the map given in (3.1). Pick a sequence $\alpha_n \in O$ converging to 1^+. It follows that $\alpha_n \in O \cap (1, \alpha_{***})$ for n large.

We have $E_{\alpha_n} = T_{\alpha_n}^{-1}(\tilde{E}_{\alpha_n})$ by definition.

Recalling (8.1) and (4.1) we get

$$(\mu(\alpha), \nu(\alpha)) = \left(\frac{a^+(\alpha)}{q(\alpha)}, \frac{a^-(\alpha)}{q(\alpha)}\right);$$

see Lemma 3.1. Then, because $(\mu(\alpha_n), \nu(\alpha_n)) \in \mathrm{Cl}(\tilde{E}_{\alpha_n})$ by Corollary 7.4 we have

$$(a^+(\alpha_n), a^-(\alpha_n)) \in \mathrm{Cl}(E_{\alpha_n})$$

by the definition of E_α. Then, there is a sequence $(a_n^+, a_n^-) \in E_{\alpha_n}$ arbitrarily close to $(a^+(\alpha_n), a^-(\alpha_n))$.

On the other hand,

$$(a^+(\alpha_n), a^-(\alpha_n)) \to (0, 0)$$

as $n \to \infty$ because $q(\alpha_n) \to 0$ (see Lemma 3.1) and (8.1) (note that the limit $(\mu(\alpha_n), \nu(\alpha_n)) \to (\mu(1), \nu(1))$ by Lemma 4.1). Then,

$$(a_n^+, a_n^-) \to (0, 0)$$

and so

$$\eta(\alpha_n, a_n^+, a_n^-) \to \eta(1, 0, 0) = \eta_0.$$

Then the result follows since $\eta(\alpha_n, a_n^+, a_n^-) \in \mathcal{L}$ because $(a_n^+, a_n^-) \in E_{\alpha_n}$. This proves the lemma. □

Define

$$\Theta_\eta = CH\{f_\eta(a^+), f_\eta(a^-), a^+, a^-\}.$$

Recalling (5.3) one has

$$g_\alpha(\mu, \nu, x) = \frac{1}{q(\alpha)} f_\eta(q(\alpha)x).$$

Then, the properties (1)–(3) in Theorem 2.2 follow from the conclusion of Corollary 7.4. The proof follows. □

AN OPTIMAL EXAMPLE FOR THE BALIAN–LOW UNCERTAINTY PRINCIPLE*

JOHN J. BENEDETTO†, WOJCIECH CZAJA‡, AND ALEXANDER M. POWELL§

Abstract. We analyze the time-frequency concentration of the Gabor orthonormal basis $\mathcal{G}(f,1,1)$ constructed by Høholdt, Jensen, and Justesen. We prove that their window function f has near optimal time and frequency localization with respect to a nonsymmetric version of the Balian–Low theorem. In particular, we show that if $(p,q) = (3/2,3)$, then $\int |t|^{p-\epsilon}|f(t)|^2dt < \infty$ and $\int |\gamma|^{q-\epsilon}|\widehat{f}(\gamma)|^2d\gamma < \infty$, for $0 < \epsilon \leq 3/2$, but that both integrals are infinite if $\epsilon = 0$.

Key words. Gabor analysis, Balian–Low theorem, time-frequency analysis

1. Introduction.

Given a square integrable function $g \in L^2(\mathbb{R})$ and constants $a, b > 0$, the associated *Gabor system*, $\mathcal{G}(g,a,b) = \{g_{m,n}\}_{m,n\in\mathbb{Z}}$, is defined by

$$g_{m,n}(t) = e^{2\pi iamt}g(t-bn).$$

Gabor systems are of considerable interest for their ability to give frame decompositions for many function spaces [18], [13], [14], [4]. A collection $\{e_n\}_{n\in\mathbb{Z}} \subseteq L^2(\mathbb{R})$ is a *frame* for $L^2(\mathbb{R})$ if there exist constants $0 < A \leq B < \infty$ such that

$$\forall f \in L^2(\mathbb{R}), \quad A||f||^2_{L^2(\mathbb{R})} \leq \sum_{n\in\mathbb{Z}} |\langle f, e_n\rangle|^2 \leq B||f||^2_{L^2(\mathbb{R})}.$$

If $\mathcal{G}(g,a,b)$ is a frame for $L^2(\mathbb{R})$, we shall refer to it as a *Gabor frame* for $L^2(\mathbb{R})$; if it is an orthonormal basis for $L^2(\mathbb{R})$, we refer to it as a *Gabor orthonormal basis* for $L^2(\mathbb{R})$.

A key property of Gabor systems is the fact that one can construct Gabor frames, $\mathcal{G}(g,a,b)$, for $L^2(\mathbb{R})$ such that the *window function* g has excellent time and frequency localization. For example, if $0 < ab < 1$ and $g(t) = e^{-t^2}$, then $\mathcal{G}(g,a,b)$ is an oversampled Gabor frame for $L^2(\mathbb{R})$; see, e.g., [18, Chapter 7]. Overcompleteness is a very important part of such well-localized constructions and can provide robustness and numerical stability in applied settings. On the other hand, if $g \in L^2(\mathbb{R})$, and $\mathcal{G}(g,a,b)$ is an orthonormal basis for $L^2(\mathbb{R})$, then one must have $ab = 1$; see, e.g., [18, Corollary 7.5.2]. If one wishes to construct Gabor orthonormal bases, i.e., nonredundant frames,

then there are severe restrictions on the window function's time and frequency localization. The Balian–Low theorem makes this precise. We use the Fourier transform defined by $\widehat{g}(\gamma) = \int g(t)e^{-2\pi i\gamma t}dt$, where our convention is that the integral without specific limits denotes the integral over $\mathbb{R}$.

THEOREM 1.1 (Balian–Low). *Let $g \in L^2(\mathbb{R})$. If*

$$\int |t|^2|g(t)|^2dt < \infty \quad \textit{and} \quad \int |\gamma|^2|\widehat{g}(\gamma)|^2d\gamma < \infty,$$

then $\mathcal{G}(g,1,1)$ is not an orthonormal basis for $L^2(\mathbb{R})$.

The Balian–Low theorem has undergone numerous extensions and generalizations since the early references [2], [23], [3], [8]. For example, it holds in higher dimensions for rather general time-frequency lattices, and also holds if one replaces "orthonormal basis" with "Riesz basis." For recent work related to the Balian–Low theorem, see [1], [5], [6], [7], [9], [10], [16], [19], [11]. The issue of sharpness or optimality in the Balian–Low theorem was investigated in [6]. There, it was shown that the following result holds true.

THEOREM 1.2. *If $\frac{1}{p} + \frac{1}{q} = 1$, where $1 < p, q < \infty$, and $d > 2$, then there exists a function $g \in L^2(\mathbb{R})$ such that $\mathcal{G}(g,1,1)$ is an orthonormal basis for $L^2(\mathbb{R})$ and*

$$\int \frac{1+|t|^p}{\log^d(2+|t|)}|g(t)|^2dt < \infty \quad \textit{and} \quad \int \frac{1+|\gamma|^q}{\log^d(2+|\gamma|)}|\widehat{g}(\gamma)|^2d\gamma < \infty.$$

Letting $(p,q) = (2,2)$ in Theorem 1.2 shows how to construct Gabor orthonormal bases which are essentially optimally localized with respect to the Balian–Low theorem. In particular, the bases constructed come within a logarithmic factor of satisfying the forbidden localization hypotheses of the Balian–Low theorem.

Since Theorem 1.2 also constructs Gabor orthonormal bases for values of (p,q) other than $(2,2)$, it is natural to ask whether there are versions of the Balian–Low theorem for the weights (t^p, γ^q). The best that is known is the following.

THEOREM 1.3. *Suppose $\frac{1}{p} + \frac{1}{q} = 1$ with $1 < p < \infty$ and let $\epsilon > 0$. If*

$$\int |t|^{(p+\epsilon)}|g(t)|^2dt < \infty \quad \textit{and} \quad \int |\gamma|^{(q+\epsilon)}|\widehat{g}(\gamma)|^2d\gamma < \infty,$$

then $\mathcal{G}(g,1,1)$ is not an orthonormal basis for $L^2(\mathbb{R})$.

The above theorem follows by combining Theorem 4.4 of [12] and Theorem 1 of [17]. By the Balian–Low theorem, one may set $\epsilon = 0$ if $(p,q) = (2,2)$. A version of the Balian–Low theorem for the case $(p,q) = (1,\infty)$ is given in [7].

2. Overview. Theorem 1.2 constructively produces Gabor orthonormal bases which are almost optimally localized with respect to the Balian–Low theorem and Theorem 1.3. However, these bases do not have simple expressions. The main aim of this paper is to study the elegant Gabor orthonormal basis constructed by Høholdt, Jensen, and Justesen in [22] and to show that it is almost optimally localized with respect to Theorem 1.3 for a certain choice of (p,q). Their basis has a simpler, more explicit form than those in [6] and gives insight into other components needed for constructing well-localized Gabor bases. The key ingredients in the constructions in [22] and [6] are functions which possess unimodular Zak transforms with small singular supports. For perspective, we remark that [21] provides several examples of functions with Zak transforms with few zeros which are used to construct tight Gabor

frames. These examples could provide further insight into the study of optimality in the Balian–Low theorem and merit future investigation.

The remainder of the paper is organized as follows. In section 3, we recall the basis of Høholdt, Jensen, and Justesen, and we state our main result, Theorem 3.3. In section 4 we prove the time localization estimates for the basis, and in section 5 we prove the frequency localization estimates. We conclude with some relevant remarks in section 6.

3. The Gabor basis of Høholdt, Jensen, and Justesen. The Zak transform is an important tool in the analysis and construction of Gabor systems; see, e.g., [18, Chapter 8]. Given $g \in L^2(\mathbb{R})$, the *Zak transform* is formally defined by

$$\forall (t,\gamma) \in \mathbb{R}\times\mathbb{R}, \quad Zg(t,\gamma) = \sum_{n\in\mathbb{Z}} g(t-n)e^{2\pi i n\gamma}.$$

With the above definition, the Zak transform satisfies the *quasi-periodicity relations*

$$\forall k \in \mathbb{Z}, \quad Zf(x,\gamma+k) = Zf(x,\gamma)$$

and

$$\forall k \in \mathbb{Z}, \quad Zf(x+k,\gamma) = Zf(x,\gamma)\; e^{2\pi i k\gamma};$$

see, e.g., [18, section 8.2]. Thus, the Zak transform Zf of a function $f \in L^2(\mathbb{R})$ is a locally square integrable function defined on all of $\mathbb{R}^2$ and is uniquely determined by its values on $Q \equiv [0,1)^2$. Therefore, Z defines a unitary operator from $L^2(\mathbb{R})$ to $L^2(Q)$, and its inverse $Z^{-1} : L^2(Q) \to L^2(\mathbb{R})$ is formally given by

$$\forall t \in \mathbb{R}, \quad (Z^{-1}F)(t) = \int_0^1 F(t,\gamma)d\gamma.$$

The utility of the Zak transform for constructing Gabor bases stems from the following result (see, e.g., [18, Corollary 8.3.2]), which forms the foundation for the constructions in both [6] and [22]; cf. [21].

THEOREM 3.1. *Let $g \in L^2(\mathbb{R})$. Then $\mathcal{G}(g,1,1)$ is an orthonormal basis for $L^2(\mathbb{R})$ if and only if $|Zg(t,\gamma)| = 1$ for a.e. $(t,\gamma) \in Q$.*

This shows that constructing Gabor orthonormal bases is equivalent to constructing unimodular functions on $L^2(Q)$. Høholdt, Jensen, and Justesen consider the function $F \in L^2(Q)$ defined by

$$\forall (t,\gamma) \in Q, \quad F(t,\gamma) = \frac{1+\alpha(t)e^{2\pi i\gamma}}{1+\alpha(t)e^{-2\pi i\gamma}}, \tag{3.1}$$

where $\alpha : [0,1] \to [0,1]$ is a measurable function. In [22], the function α was chosen as $\alpha(t) = \sin(\frac{\pi}{2}t)$, since this was shown to minimize $\int |\gamma|^2 |\widehat{(Z^{-1}F)}(\gamma)|^2 d\gamma$.

DEFINITION 3.2. *Let $f \in L^2(\mathbb{R})$ be the function defined by* (3.1)*, where*

$$f = Z^{-1}F \quad \text{and} \quad \alpha(t) = \sin\left(\frac{\pi}{2}t\right). \tag{3.2}$$

It was proven in [22] *that $f \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$ and that f (see Figure* 3*) is explicitly defined by*

$$f(t) = \begin{cases} 0 & \text{if } t \in (-\infty,-1], \\ \sin(\frac{\pi}{2}(t+1)) & \text{if } t \in (-1,0], \\ (-1)^n \cos^2(\frac{\pi}{2}(t-n)) \sin^n(\frac{\pi}{2}(t-n)) & \text{if } t \in (n,n+1], n = 0,1,2,\ldots. \end{cases}$$

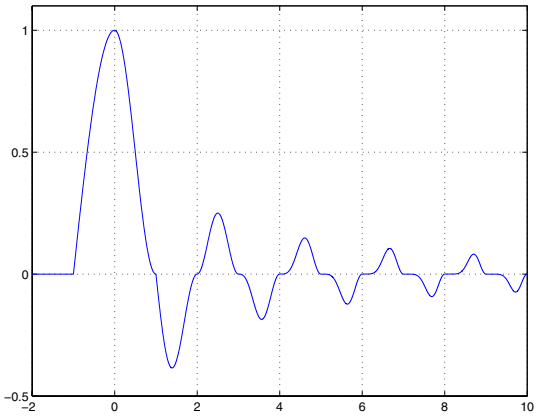

FIG. 3.1. *Graph of the function f.*

It is easy to verify that $|Zf(t,\gamma)| = |F(t,\gamma)| = 1$ for a.e. $(t,\gamma) \in Q$, and hence $\mathcal{G}(f,1,1)$ is an orthonormal basis for $L^2(\mathbb{R})$. We may now state our main result as follows.

THEOREM 3.3. *Let $f \in L^2(\mathbb{R})$ be the window function defined by Definition* 3.2. *For every $0 < \epsilon \leq 3/2$, f satisfies*

$$\int |t|^{3/2-\epsilon}|f(t)|^2 dt < \infty \quad \text{and} \quad \int |\gamma|^{3-\epsilon}|\widehat{f}(\gamma)|^2 d\gamma < \infty. \tag{3.3}$$

Moreover,

$$\int |t|^{3/2}|f(t)|^2 dt = \infty \quad \text{and} \quad \int |\gamma|^{3}|\widehat{f}(\gamma)|^2 d\gamma = \infty. \tag{3.4}$$

In particular, the Gabor orthonormal basis $\mathcal{G}(f,1,1)$ is almost optimally localized with respect to Theorem 1.3 with $(p,q) = (3/2,3)$.

4. Time localization estimates. In this section we derive the time localization estimates in Theorem 3.3.

THEOREM 4.1. *Let $f \in L^2(\mathbb{R})$ be the function defined in Definition* 3.2 *and let $a > 0$. Then*

$$\int |t|^a |f(t)|^2 dt < \infty \quad \text{if and only if} \quad a < 3/2.$$

Proof. A direct calculation shows that for $n = 0, 1, 2, \ldots$

$$\begin{aligned} \int_n^{n+1} |f(t)|^2 dt &= \int_0^1 \cos^4\left(\frac{\pi}{2}t\right) \sin^{2n}\left(\frac{\pi}{2}t\right) dt \\ &= \frac{2}{\pi}\left(\frac{3}{4n^2+12n+8}\right) \int_0^{\pi/2} \sin^{2n} u \, du. \end{aligned} \tag{4.1}$$

One can also calculate that

$$\frac{2}{\pi}\int_0^{\pi/2} \sin^{2n} u \, du = \frac{(1)(3)(5)(7)\cdots(2n-1)}{(2)(4)(6)(8)\cdots(2n)} \equiv P_n. \tag{4.2}$$

By taking the natural log of P_n and using Taylor approximations for $\ln(1-x)$ near $x=0$ to estimate the resulting sum, it is straightforward to show that

$$P_n \sim \frac{1}{\sqrt{n}}. \tag{4.3}$$

Equivalently, we could use Stirling's formula for the Gamma function to show (4.3). Here and subsequently $A \sim B$ means that $A \lesssim B \lesssim A$, where $A \lesssim B$, in turn, means that there exists an absolute constant C such that $A \leq CB$. When necessary, we shall point out any dependence of the implicit constants on other parameters. Therefore,

$$\begin{aligned}\int_1^\infty |t|^a |f(t)|^2 dt &\geq \sum_{n=1}^\infty n^a \int_n^{n+1} |f(t)|^2 dt \\ &= \sum_{n=1}^\infty n^a \left(\frac{3}{4n^2+12n+8}\right) P_n \gtrsim \sum_{n=1}^\infty n^{a-5/2}.\end{aligned}$$

In particular,

$$a \geq 3/2 \Longrightarrow \int |t|^a |f(t)|^2 dt = \infty.$$

Also, using (4.1), (4.2), and (4.3), we obtain the estimate

$$\int_1^\infty |t|^a |f(t)|^2 dt \lesssim \sum_{n=1}^\infty \frac{(n+1)^a}{n^{5/2}}.$$

Since f is bounded on $[-1,1]$, and $f=0$ on $(-\infty,-1)$, it follows that

$$0 < a < 3/2 \Longrightarrow \int |t|^a |f(t)|^2 dt < \infty. \qquad \square$$

5. Frequency localization estimates. In this section we derive the frequency localization estimates in Theorem 3.3.

THEOREM 5.1. *Let $f \in L^2(\mathbb{R})$ be the function defined in Definition* 3.2 *and let $0 < a$. Then*

$$\int |\gamma|^a |\widehat{f}(\gamma)|^2 d\gamma < \infty \quad \text{if and only if} \quad a < 3.$$

It will be convenient to view Theorem 5.1 in terms of Sobolev spaces. Given $s > 0$, the *homogeneous Sobolev space* of order s, denoted by $\dot{H}^s(\mathbb{R})$, consists of all $g \in L^2(\mathbb{R})$ such that $||g||^2_{\dot{H}^s(\mathbb{R})} \equiv \int |\gamma|^{2s} |\widehat{g}(\gamma)|^2 d\gamma < \infty$. For later convenience, we also define $\langle f, g\rangle_{\dot{H}^s(\mathbb{R})} = \int |\gamma|^{2s} \widehat{f}(\gamma)\overline{\widehat{g}(\gamma)} d\gamma$. Theorem 5.1 now says that $0 < s < 3/2$ implies $f \in \dot{H}^s(\mathbb{R})$, and that $s \geq 3/2$ implies $f \notin \dot{H}^s(\mathbb{R})$. The following result (see, e.g., [24, Chapter 8]) gives a useful alternate characterization of $\dot{H}^s(\mathbb{R})$. It is used in the proof of Lemma 5.6.

LEMMA 5.2. *If $0 < s < 2$ and $f \in \dot{H}^s(\mathbb{R})$, then there exists $C_s > 0$ such that*

$$||f||^2_{\dot{H}^s(\mathbb{R})} = C_s \int\int \frac{|f(x+t) + f(x-t) - 2f(x)|^2}{|t|^{1+2s}} dx dt.$$

Lemma 5.2 can be proven by applying Parseval's theorem to the inner integral. A similar calculation gives the following result used in the proof of Lemma 5.8.

LEMMA 5.3. *If $0 < s < 2$ and $f, g \in \dot{H}^s(\mathbb{R})$, then there exists $C_s > 0$ such that*

$$\langle f, g\rangle_{\dot{H}^s(\mathbb{R})} = C_s \iint \frac{(f(x+t)+f(x-t)-2f(x))\overline{(g(x+t)+g(x-t)-2g(x))}}{|t|^{2s+1}} dxdt.$$

We shall use the following lemma directly in Theorem 5.1.

LEMMA 5.4. *If $3 \le a$, then $f \notin \dot{H}^{a/2}(\mathbb{R})$.*

Proof. If $3 \le a < 4$, then for $0 < \eta$ small

$$||f||^2_{\dot{H}^{a/2}(\mathbb{R})} \sim \iint \frac{|f(x+t)+f(x-t)-2f(x)|^2}{|t|^{1+a}} dxdt \ge \int_0^\eta \int_{-t}^0 \frac{\sin^2(\frac{\pi}{2}(x+t))}{|t|^{1+a}} dxdt$$
$$\gtrsim \int_0^\eta \int_{-t}^0 \frac{(x+t)^2}{|t|^{1+a}} dxdt \gtrsim \int_0^\eta \frac{t^3}{|t|^{1+a}} dt = \infty.$$

Since $f \in L^1(\mathbb{R})$, it now also follows that $f \notin \dot{H}^{a/2}(\mathbb{R})$ for all $3 \le a$. ∎

We now prove that $0 < a < 3$ implies $f \in \dot{H}^{a/2}$. Since this is more involved than our prior estimates, we split it up into several lemmas (Lemmas 5.9 and 5.10). Lemma 5.5 is used in Lemma 5.6, which, in turn, is used in the proof of Lemma 5.7. Lemmas 5.7 and 5.8 allow us to prove Lemma 5.9.

LEMMA 5.5. *For $n \ge 3$, let $f_n(t) = \mathbf{1}_{(n,n+1]}(t) f(t)$, where $\mathbf{1}_S(t)$ denotes the characteristic function of a set $S \subseteq \mathbb{R}$. The functions f_n have the following properties:*

1. *f_n is continuous and differentiable on $\mathbb{R}$.*
2. *$f_n''(t)$ exists for all $t \in \mathbb{R}\backslash\{n+1\}$.*
3. *$||f_n||^2_{L^2(\mathbb{R})} \lesssim 1/n^{5/2}$ and $||f_n||^{1/2}_{L^{1/2}(\mathbb{R})} \lesssim 1/n$.*
4. *If $0 < \delta < 3/2$, then $||f_n||^{1/2+\delta}_{L^{1/2+\delta}(\mathbb{R})} \lesssim 1/n^{1+\delta}$.*
5. *For all $t \in \mathbb{R}\backslash\{n+1\}$, $|f_n''(t)| \lesssim 1$.*

The implicit constants in (3) *and* (4) *are independent of n, and the implicit constant in* (5) *is independent of t and n.*

Proof. The first two items can be verified by direct calculations. The estimate for $||f_n||^2_{L^2(\mathbb{R})}$ in (3) has already been done in the proof of Theorem 4.1. In fact,

$$||f_n||^2_{L^2(\mathbb{R})} = \left(\frac{3}{4n^2+12n+8}\right) P_n \lesssim \frac{1}{n^{2.5}}.$$

The estimate for $||f_n||^{1/2}_{L^{1/2}(\mathbb{R})}$ in (3) holds since

$$||f_n||^{1/2}_{L^{1/2}(\mathbb{R})} = \int_n^{n+1} \cos\left(\frac{\pi}{2}(t-n)\right) \sin^{\frac{n}{2}}\left(\frac{\pi}{2}(t-n)\right) dt = \frac{4}{\pi(n+2)}.$$

The fourth item follows from (3) and the following standard interpolation formula (see, e.g., [15, Proposition 6.10]):

$$||f||_{L^q(\mathbb{R})} \le ||f||^\lambda_{L^p(\mathbb{R})} ||f||^{1-\lambda}_{L^r(\mathbb{R})},$$

where

$$0 < p < q < r \le \infty \quad \text{and} \quad \lambda = \frac{1/q - 1/r}{1/p - 1/r}.$$

To prove (5) first note that, for $n < t < n+1$,

$$f_n''(t-n) = (-1)^n \left(-(5n+2)\frac{\pi^2}{4} \sin^n\left(\frac{\pi}{2}t\right)\cos^2\left(\frac{\pi}{2}t\right) + 2\frac{\pi^2}{4}\sin^{n+2}\left(\frac{\pi}{2}t\right) + \frac{\pi^2}{4}n(n-1)\cos^4\left(\frac{\pi}{2}t\right)\sin^{n-2}\left(\frac{\pi}{2}t\right)\right).$$

Therefore, $f_n''(t-n) = (-1)^n h_n(u)$, where $u = \sin^2(\frac{\pi}{2}(t-n))$, and

$$h_n(u) = \frac{\pi^2}{4} u^{n/2-1}\left[2u^2 - (5n+2)u(1-u) + n(n-1)(1-u)^2\right].$$

Straightforward, but tedious, calculations show that $|h_n(t)| \le C$ on $(n, n+1)$ for some constant C independent of t and n. Since $f_n''(t) = 0$ on $\mathbb{R}\backslash(n, n+1]$, we conclude that $|f_n''(t)| \lesssim 1$ on $\mathbb{R}\backslash\{n+1\}$. □

LEMMA 5.6. *Assume $0 < a < 3$, and let $\epsilon = 3 - a$. Then*

$$\forall n \ge 3, \quad ||f_n||^2_{\dot{H}^{a/2}(\mathbb{R})} \lesssim \frac{1}{n^{1+\epsilon/4}}.$$

The implicit constant is independent of n.

Proof. We shall estimate $||f_n||^2_{\dot{H}^{a/2}(\mathbb{R})}$ by using the double integral in Lemma 5.2. Let $B = \{t \in \mathbb{R} : |t| < 1\}$, and note that

$$\int_{\mathbb{R}\backslash B}\int_{\mathbb{R}} \frac{|f_n(x+t) + f_n(x-t) - 2f_n(x)|^2}{|t|^{a+1}} dxdt \lesssim ||f_n||^2_{L^2(\mathbb{R})} \int_{\mathbb{R}\backslash B} \frac{1}{|t|^{a+1}} dt \lesssim \frac{1}{n^{5/2}}.$$

It remains for us to estimate

$$\int_B \int_{\mathbb{R}} \frac{|f_n(x+t) + f_n(x-t) - 2f_n(x)|^2}{|t|^{a+1}} dxdt.$$

We write this as the sum of two integrals, over $[0,1]\times\mathbb{R}$ and $[-1,0]\times\mathbb{R}$, respectively. Since the estimates for both integrals are similar, it suffices to consider the first, which, in turn, is estimated by breaking it up into the following four integrals:

$$I_1 = \int_0^1 \int_{-\infty}^{n-t}, \quad I_2 = \int_0^1 \int_{n-t}^{n+1-t}, \quad I_3 = \int_0^1 \int_{n+1-t}^{n+1+t}, \quad I_4 = \int_0^1 \int_{n+1+t}^{\infty}.$$

First, note that the support properties of f_n imply that $I_1 = 0$ and $I_4 = 0$.

Next note that if $x+t, x-t, x$ are all less than $n+1$, then Lemma 5.5 and the mean value theorem imply

$$|f_n(x+t) + f_n(x-t) - 2f_n(x)| \lesssim |t|^2, \tag{5.1}$$

where the implicit constant is independent of x, t, and n. To estimate I_2 note that, by (5.1) and Lemma 5.5,

$$\begin{aligned} W_2(t) &\equiv \int_{n-t}^{n+1-t} |f_n(x+t) + f_n(x-t) - 2f_n(x)|^2 dx \\ &\lesssim |t|^{3-\epsilon/2} \int_{n-t}^{n+1-t} |f_n(x+t) + f_n(x-t) - 2f_n(x)|^{1/2+\epsilon/4} dx \\ &\lesssim |t|^{3-\epsilon/2}\, ||f_n||^{1/2+\epsilon/4}_{L^{1/2+\epsilon/4}(\mathbb{R})} \lesssim \frac{|t|^{3-\epsilon/2}}{n^{1+\epsilon/4}}. \end{aligned}$$

It now follows that

$$I_2 = \int_0^1 \frac{W_2(t)}{|t|^{a+1}}dt = \int_0^1 \frac{W_2(t)}{|t|^{4-\epsilon}}dt \lesssim 1/n^{1+\epsilon/4}\int_0^1 \frac{1}{|t|^{1-\epsilon/2}}dt \lesssim 1/n^{1+\epsilon/4}.$$

To estimate I_3, define

$$W_3(t) = \int_{n+1-t}^{n+1+t} |f_n(x+t) + f_n(x-t) - 2f_n(x)|^2 dx.$$

Note that by the definition of f_n and its support properties,

$$\begin{aligned} W_3(t) &= \int_{n+1-t}^{n+1+t} |f_n(x-t) - 2f_n(x)|^2 dx \lesssim \int_{n+1-2t}^{n+1} |f_n(x)|^2 dx \\ &\lesssim \int_{n+1-2t}^{n+1} \cos^4\left(\frac{\pi}{2}(x-n)\right) dx \lesssim |t|^5. \end{aligned}$$

Moreover, we also have

$$W_3(t) \lesssim ||f_n||^2_{L^2(\mathbb{R})} \lesssim \frac{1}{n^{5/2}}.$$

Thus, in order to estimate W_3 we may use the fact that for $x, y > 0$ and $\alpha \in [0,1]$, $\min\{x,y\} \le x^\alpha y^{1-\alpha}$. When $\alpha = (6-\epsilon)/10$, we obtain

$$W_3(t) \lesssim \frac{|t|^{3-\epsilon/2}}{n^{1+\epsilon/4}}.$$

Thus

$$I_3 = \int_0^1 \frac{W_3(t)}{|t|^{a+1}}dt = \int_0^1 \frac{W_3(t)}{|t|^{4-\epsilon}}dt \lesssim 1/n^{1+\epsilon/4}. \qquad \square$$

LEMMA 5.7. *Assume $0 < a < 3$ and let $\epsilon = 3 - a$. If $3 \le m, n$, and $|m-n| = 1$, then*

$$|\langle f_n, f_m\rangle_{\dot{H}^{a/2}(\mathbb{R})}| \lesssim \frac{1}{n^{1+\epsilon/4}}.$$

The implicit constant is independent of n and m.

Proof. Without loss of generality assume $m = n+1$. It follows from Lemma 5.6 that

$$\begin{aligned} |\langle f_n, f_m\rangle_{\dot{H}^{a/2}(\mathbb{R})}| &\le ||f_n||_{\dot{H}^{a/2}(\mathbb{R})}||f_m||_{\dot{H}^{a/2}(\mathbb{R})} \\ &\lesssim \left(\frac{1}{n^{1+\epsilon/4}}\right)^{\frac{1}{2}}\left(\frac{1}{m^{1+\epsilon/4}}\right)^{\frac{1}{2}} \le \frac{1}{n^{1+\epsilon/4}}. \qquad \square \end{aligned}$$

LEMMA 5.8. *Let $0 < a$. If $3 \le m, n$ and $1 < |m-n|$, then*

$$|\langle f_n, f_m\rangle_{\dot{H}^{a/2}(\mathbb{R})}| \lesssim \frac{1}{|m-n|^a |n|^{5/4}|m|^{5/4}}.$$

The implicit constant is independent of m and n.

Proof. Without loss of generality assume $0 < n < m - 1$. Let $S_{m,n} = \{t \in \mathbb{R} : |t| > (m - n - 1)/2\}$ and let

$$F_m(x,t) = f_m(x+t) + f_m(x-t) - 2f_m(x).$$

Note that

$$t \notin S_{m,n} \Longrightarrow F_m(x,t)F_n(x,t) = 0.$$

Also,

$$\int |F_m(x,t)F_n(x,t)|dx \lesssim ||f_n||_{L^2(\mathbb{R})}||f_m||_{L^2(\mathbb{R})}.$$

Therefore, by Lemma 5.3,

$$\begin{aligned}|\langle f_n, f_m\rangle_{\dot{H}^{a/2}(\mathbb{R})}| &\leq \int_{S_{m,n}}\int_{\mathbb{R}} \frac{|F_m(x,t)F_n(x,t)|}{|t|^{a+1}}dxdt \\ &\lesssim ||f_n||_{L^2(\mathbb{R})}||f_m||_{L^2(\mathbb{R})}\int_{S_{m,n}} \frac{1}{|t|^{a+1}}dt \\ &\lesssim \frac{||f_n||_{L^2(\mathbb{R})}||f_m||_{L^2(\mathbb{R})}}{|m-n|^a} \lesssim \frac{1}{n^{5/4}m^{5/4}|m-n|^a}. \qquad \square\end{aligned}$$

To estimate the norm $||f||_{\dot{H}^{a/2}(\mathbb{R})}$ we first break f up into the two parts $F_1(t) = f(t)\mathbf{1}_{(-1,3]}(t)$ and $F_2(t) = f(t)\mathbf{1}_{(3,\infty)}(t)$. Since $f = 0$ on $(-\infty, -1]$ we have $f = F_1 + F_2$. We have the following estimate for F_2.

LEMMA 5.9. *If $0 < a < 3$, then $||F_2||^2_{\dot{H}^{a/2}(\mathbb{R})} < \infty$.*

Proof. Let $\epsilon = 3 - a$, and note that $F_2 = \sum_{n=3}^{\infty} f_n$. Define

$$S_1 = \{(m,n) \in \mathbb{Z}^2 : m, n \geq 3 \text{ and } |m-n| = 1\}$$

and

$$S_2 = \{(m,n) \in \mathbb{Z}^2 : m, n \geq 3 \text{ and } |m-n| > 1\}.$$

By Lemmas 5.6, 5.7, and 5.8 we have

$$\begin{aligned}||F_2||^2_{\dot{H}^{a/2}(\mathbb{R})} &= \left|\left|\sum_{n=3}^{\infty} f_n\right|\right|^2_{\dot{H}^{a/2}(\mathbb{R})} \leq \sum_{m=3}^{\infty}\sum_{n=3}^{\infty} |\langle f_m, f_n\rangle_{\dot{H}^{a/2}(\mathbb{R})}| \\ &= \sum_{n=3}^{\infty} ||f_n||^2_{\dot{H}^{a/2}(\mathbb{R})} + \sum_{(m,n)\in S_1} |\langle f_n, f_m\rangle_{\dot{H}^{a/2}(\mathbb{R})}| + \sum_{(m,n)\in S_2} |\langle f_n, f_m\rangle_{\dot{H}^{a/2}(\mathbb{R})}| \\ &\lesssim \sum_{n=1}^{\infty} \frac{1}{n^{1+\epsilon/4}} + \sum_{n=1}^{\infty} \frac{1}{n^{1+\epsilon/4}} + \sum_{(m,n)\in S_2} \frac{1}{n^{5/4}m^{5/4}|m-n|^{2a}} < \infty. \qquad \square\end{aligned}$$

In view of Lemma 5.9, and since

$$||f||_{\dot{H}^{a/2}(\mathbb{R})} \leq ||F_1||_{\dot{H}^{a/2}(\mathbb{R})} + ||F_2||_{\dot{H}^{a/2}(\mathbb{R})},$$

it remains only to estimate $||F_1||_{\dot{H}^{a/2}(\mathbb{R})}$. Note that by the definition of f, F_1 is compactly supported, continuous on $\mathbb{R}$, and infinitely differentiable away from $x_1 =$

$-1, x_2 = 0, x_3 = 1, x_4 = 2$, and $x_5 = 3$. Moreover the first derivative of F_1 also exists at x_2, x_3, x_5. However, the second derivative of F_1 does not exist at any of the points x_1, x_2, x_3, x_4, x_5.

It therefore suffices to estimate $||\varphi_j F_1||_{\dot{H}^{a/2}(\mathbb{R})}$ for $j = 1, 2, 3, 4, 5$, where φ_j is an infinitely differentiable function satisfying

$$\varphi_j(x) = 1 \text{ for } |x - x_j| < 2\nu \quad \text{and} \quad \varphi_j(x) = 0 \text{ for } |x - x_j| > 4\nu,$$

with $0 < \nu$ sufficiently small.

We present a proof that is analogous to our previous estimates and uses Lemma 5.2. Alternately, one can proceed more directly and use an argument involving integration by parts.

LEMMA 5.10. *Let $0 < a < 3$ and let $\varphi_j F_1$ be as above for $j = 1, 2, 3, 4, 5$. Then*

$$||\varphi_j F_1||_{\dot{H}^{a/2}(\mathbb{R})} < \infty, \quad j = 1, 2, 3, 4, 5.$$

Consequently, $||F_1||_{\dot{H}^{a/2}(\mathbb{R})} < \infty$.

Proof. We shall show the estimate for $||\varphi_3 F_1||_{\dot{H}^{a/2}(\mathbb{R})}$ only, since the other four estimates proceed along similar lines.

Let $h(t) = (\varphi_3 F_1)(t - 1)$. We need to estimate the double integral

$$||\varphi_3 F_1||^2_{\dot{H}^{a/2}(\mathbb{R})} = ||h||^2_{\dot{H}^{a/2}(\mathbb{R})} \sim \int\int \frac{|h(x+t) + h(x-t) - 2h(x)|^2}{|t|^{1+a}} dxdt.$$

Let ν be as in the definition of φ_3 above, and note that if $B_\nu = \{t \in \mathbb{R} : |t| < \nu\}$, then

$$\int_{\mathbb{R}\setminus B_\nu} \int_{\mathbb{R}} \frac{|h(x+t) + h(x-t) - 2h(x)|^2}{|t|^{1+a}} dxdt \lesssim ||h||^2_{L^2(\mathbb{R})} \int_{\mathbb{R}\setminus B_\nu} \frac{1}{|t|^{1+a}} dt < \infty.$$

Next note that $h(t)$ is infinitely differentiable away from $t = 0$ and has bounded first and second derivatives on $\mathbb{R}\setminus\{0\}$. Therefore, if $x + t, x - t$ and x are all positive, or all negative, then it follows from the mean value theorem that

$$|h(x+t) + h(x-t) - 2h(x)| \lesssim |t|^2. \tag{5.2}$$

Likewise, if $x + t$ and x are both positive or both negative, then

$$|h(x+t) - h(x)| \lesssim |t|. \tag{5.3}$$

The implicit constants in (5.2) and (5.3) are independent of x and t.

To estimate the remaining integral

$$\int_{-\nu}^{\nu} \int_{\mathbb{R}} \frac{|h(x+t) + h(x-t) - 2h(x)|^2}{|t|^{1+a}} dxdt,$$

we break this integral up over the domains $[\nu, 0] \times \mathbb{R}$ and $[-\nu, 0] \times \mathbb{R}$. Since both integrals are similar we show estimates for the first only, which, in turn, we estimate by considering the integrals

$$J_1 = \int_0^\nu \int_t^\infty, \quad J_2 = \int_0^\nu \int_0^t, \quad J_3 = \int_0^\nu \int_{-t}^0, \quad J_4 = \int_0^\nu \int_{-\infty}^{-t}.$$

It follows from (5.2) and the compact support of h that

$$\begin{aligned} J_1 &= \int_0^\nu \int_t^\infty \frac{|h(x+t)+h(x-t)-2h(x)|^2}{|t|^{1+a}}dxdt \\ &= \int_0^\nu \int_t^{5\nu} \frac{|h(x+t)+h(x-t)-2h(x)|^2}{|t|^{1+a}}dxdt \lesssim \int_0^\nu \frac{|t|^4}{|t|^{1+a}}dt < \infty. \end{aligned}$$

The estimate for $J_4 < \infty$ is similar.

To estimate J_2, note that $J_2 \lesssim J_{2,1} + J_{2,2}$ where

$$J_{2,1} = \int_0^\nu \int_0^t \frac{|h(x+t)-h(x)|^2}{|t|^{a+1}}dxdt \quad \text{and} \quad J_{2,2} = \int_0^\nu \int_0^t \frac{|h(x-t)-h(x)|^2}{|t|^{a+1}}dxdt.$$

It follows from (5.3) that

$$J_{2,1}(t) \lesssim \int_0^\nu \int_0^t \frac{|t|^2}{|t|^{1+a}}dxdt = \int_0^\nu \frac{|t|^3}{|t|^{a+1}}dt < \infty.$$

Next, define

$$\begin{aligned} H(x,t) &= \cos^2\left(\frac{\pi}{2}(x-t-1)\right) + \cos^2\left(\frac{\pi}{2}x\right)\sin\left(\frac{\pi}{2}x\right) \\ &= \sin^2\left(\frac{\pi}{2}(x-t)\right) + \cos^2\left(\frac{\pi}{2}x\right)\sin\left(\frac{\pi}{2}x\right), \end{aligned}$$

and note that

$$\int_0^t |H(x,t)|^2 dx \lesssim \int_0^t |(x-t)^2|^2 dx + \int_0^t |x|^2 dx \lesssim |t|^3.$$

It now follows that

$$J_{2,2} = \int_0^\nu \int_0^t \frac{|H(x,t)|^2}{|t|^{a+1}}dxdt \lesssim \int_0^\nu \frac{|t|^3}{|t|^{a+1}}dt < \infty.$$

Therefore,

$$J_2 \lesssim J_{2,1} + J_{2,2} < \infty.$$

By using calculations similar to those used to deal with J_2, one can also show that $J_3 < \infty$. We can now conclude that $||\varphi_3 F_1||_{\dot{H}^{a/2}(\mathbb{R})} = ||h||_{\dot{H}^{a/2}(\mathbb{R})} < \infty$.

The estimates for $||\varphi_j F_2||_{\dot{H}^{a/2}(\mathbb{R})}$, $j = 1, 2, 4, 5$, proceed along similar lines to those above. □

Proof of Theorem 5.1. Combining Lemmas 5.9 and 5.10 shows that if $0 < a < 3$, then

$$\left(\int |\gamma|^a |\widehat{f}(\gamma)|^2 d\gamma\right)^{1/2} = ||f||_{\dot{H}^{a/2}(\mathbb{R})} \leq ||F_1||_{\dot{H}^{a/2}(\mathbb{R})} + ||F_2||_{\dot{H}^{a/2}(\mathbb{R})} < \infty.$$

Together with Lemma 5.4 this completes the proof of Theorem 5.1. □

Our main result, Theorem 3.3, now follows by combining Theorems 4.1 and 5.1.

6. Concluding remarks. 1. Throughout this remark we shall assume that Zak transforms have been quasi-periodically extended to $L^2_{\text{loc}}(\mathbb{R}^2)$. A key idea in the construction of [6] was to choose the Gabor window function g so that $|Zg| = 1$ almost everywhere and such that Zg has minimal singular support. In fact, the function Zg used in [6] was locally C^∞ on $\mathbb{R}^2$ except at one point in each square $S_{j,k} = (j, j+1] \times (k, k+1], j, k \in \mathbb{Z}$.

By comparison, one can show that the quasi-periodic extension of Høholdt, Jensen, and Justesen's function $F = Zf$ defined in (3.1) is continuous on $\mathbb{R}^2$ except at the set $\{(j, k+1/2) : j, k \in \mathbb{Z}\}$. However, F is nondifferentiable on the set $\{(t, j) : t \in \mathbb{R}, j \in \mathbb{Z}\}$. In this regard, the construction in [6] provides a Gabor orthonormal basis $\mathcal{G}(g, 1, 1)$ such that Zg has more smoothness than $F = Zf$ in (3.1).

2. We have shown that the basis of Høholdt, Jensen, and Justesen is almost optimally localized with respect to the (p, q) Balian–Low result in Theorem 1.3 when $(p, q) = (3/2, 3)$. It would be interesting to see whether Høholdt, Jensen, and Justesen's method of construction can be extended to provide optimality for other values of (p, q). With respect to further potentially optimal examples, Janssen in [20] and [21] provides several other families of functions which have the Zak transforms with minimal singular support. These include Gaussians, hyperbolic secants, and two-sided exponentials. The operation $Z^{-1}(Zg/|Zg|)$ applied to these functions yields examples of Gabor orthonormal bases for $L^2(\mathbb{R})$. The examples of Janssen are analogous in nature to the examples in [22] and [6], but they possess more symmetry in their decay properties. At the present, [6] provides the only construction which has been proven to be optimal for general values of the time and frequency localization parameters (p,q).

Acknowledgments. The authors thank Jacob Sterbenz for valuable discussions related to the material. They also thank the referees for many valuable suggestions, and in particular for pointing out the relevance of the work [21]. A portion of this work was done while the third author was a Junior Research Fellow at the Erwin Schrödinger Institute (ESI) in Vienna. He is grateful to ESI for their hospitality and financial support, and to Hans Feichtinger for having helped to arrange this visit.

THE STRUCTURE OF C^1 SPLINE SPACES ON FREUDENTHAL PARTITIONS*

G. HECKLIN†, G. NÜRNBERGER†, AND F. ZEILFELDER†

Abstract. We analyze the structure of trivariate C^1 splines on uniform tetrahedral partitions Δ. The Freudenthal partitions Δ are obtained from uniform cube partitions by using three planes with a common line to subdivide every cube into six tetrahedra. This is a natural three-dimensional generalization of the well-known three-directional mesh in the plane. By using Bernstein–Bézier techniques, we construct minimal determining sets for C^1 spline spaces on Δ of arbitrary degree and give explicit formulae for the dimension of the spaces.

Key words. trivariate splines, Freudenthal partitions, C^1 smoothness conditions, minimal determining sets, Bernstein–Bézier techniques, dimension of spline spaces

1. Introduction.

Spline spaces play a fundamental role in approximation theory and computer aided geometric design. In particular, this concerns *multivariate splines* (see Chui [12], and the references therein), i.e., splines in more than one variable which are defined on appropriate partitions of a multidimensional domain. In contrast to the univariate case (cf. Nürnberger [24], Schumaker [34]), only few results on the structure of these spaces are known. Even the most basic problems such as determining the *dimension* (i.e., the number of degrees of freedom) of the spaces and *constructing interpolation sets* are often difficult to solve. Recently, there has been some progress in developing efficient interpolation and approximation methods for bivariate splines (cf. Alfeld and Schumaker [4, 5], Davydov and Zeilfelder [13], Lai and Schumaker [19, 20], Nürnberger, Rayevskaya, Schumaker and Zeilfelder [25], Nürnberger, Schumaker and Zeilfelder [27], Nürnberger and Zeilfelder [29, 30], Zeilfelder [42], and the references therein) which are useful for many applications. On the other hand, much less is known for *trivariate splines*, i.e., splines defined on *tetrahedral partitions*. One reason for this is that the smoothness conditions imply complex relations between the coefficients of the splines. For example, it has been observed (cf. Alfeld, Schumaker and Sirvent [6, Example 25], Alfeld, Schumaker and Whiteley [7, Remark 66]) that even for tetrahedral partitions of certain conic domains an analysis of these conditions would require the knowledge of the structure of bivariate spline spaces of any degree on general triangulations. It is known that even for *uniform (type) three-dimensional partitions* it is a complex task to analyze this structure since all the smoothness conditions in space directions have to be taken into account. In this paper, we investigate C^1 spline spaces of any polynomial degree defined on uniform tetrahedral partitions.

Different types of splines in three variables have been suggested in the literature (see the comparison and discussion in Remark 6.2). For trivariate splines as we consider here, there are basically two approaches. For the case of arbitrary tetrahedral partitions, there exist methods for *super spline spaces* (i.e., subspaces with a higher smoothness on lower-dimensional faces) with a relatively high degree (cf. Ženišek [43]).

†University of Mannheim, Institute for Mathematics, D-68131 Mannheim, Germany (hecklin@rumms.uni-mannheim.de, nuern@rumms.uni-mannheim.de, zeilfeld@rumms.uni-mannheim.de).

A C^1 quintic super spline construction, where all the tetrahedra are split into four *subtetrahedra*, was given by Alfeld [2], while the C^1 cubic and quadratic spline methods of Worsey and Farin [40] and Worsey and Piper [41] (see also Sorokina and Worsey [38]) are based on splitting all the tetrahedra into 12 and 24 subtetrahedra, respectively. In the second approach, classes of tetrahedral partitions are investigated, where no splits are used. Smooth quintic super spline constructions on such partitions were recently developed by Lai and Le Méhauté [18] and Schumaker and Sorokina [35]. One special class of tetrahedral partitions is obtained from a cube partition, where each cube is uniformly split into 24 tetrahedra. These partitions are sometimes called *type-6 tetrahedral partitions* and are natural three-dimensional generalizations of the well-known *four-direction mesh* in the plane. For these partitions, independently, Schumaker and Sorokina [36] constructed a generalization of the element of Fraejis de Veubeke and Sander (see the survey of Zeilfelder [42], for instance) by using C^1 trivariate super splines of degree six, while Hangelbroek, Nürnberger, Rössl, Seidel and Zeilfelder [16] determined the dimension of C^1 spline spaces (with no super smoothness) of arbitrary degree. Based on the latter results on the structure of spline spaces, Nürnberger, Rössl, Seidel and Zeilfelder [26, 31, 32] (see also Schlosser, Hesser, Zeilfelder, Rössl, Männer, Nürnberger, and Seidel [33]) developed methods for the *approximation and visualization of volumetric data* by using quadratic and cubic trivariate splines with appropriate smoothness properties. This shows that a structural analysis of the spline spaces is sometimes the first step to develop approaches useful for the applications, where volumetric models with advantageous properties such as high-quality visualization have to be reconstructed from discrete data. The numerical tests in [26, 31, 32, 33] indicate the potential of trivariate splines to approximate huge volumetric (gridded and scattered) data sets with up to millions of data points with a high efficiency.

In this paper, we determine the dimension of trivariate C^1 splines of arbitrary degree on a natural class of uniform type tetrahedral partitions Δ, where no tetrahedron is split. These partitions Δ generalize the well-known *three-direction mesh* in the plane and are called *Freudenthal partitions*. The Freudenthal partitions Δ are obtained from a uniform cube partition of a domain Ω in $\mathbb{R}^3$, where each cube is subdivided into six tetrahedra (see Figure 1). Hence the number of tetrahedra within each cube is smaller than for the above-mentioned type-6 tetrahedral partitions. We investigate the structure of the *spaces of trivariate C^1 polynomial splines on* Δ, i.e., the spaces defined by

$$\mathcal{S}_q^1(\Delta) = \{s \in C^1(\Omega) : s_{|_T} \in \mathcal{P}_q \text{ for all tetrahedra } T \in \Delta\}, \tag{1.1}$$

where

$$\mathcal{P}_q = \text{ span}\{x^i y^j z^k : \ i,j,k \geq 0, \ i+j+k \leq q\}$$

denotes the space of *trivariate polynomials of total degree* q. The main result of this paper (Theorem 3.1) is an explicit formula for the dimension of the spline spaces in (1.1). Its proof is complex. We construct a so-called *minimal determining set* (cf. Alfeld, Piper and Schumaker [3], Schumaker and Sorokina [35, 36]) for $\mathcal{S}_q^1(\Delta)$ based on the piecewise *Bernstein–Bézier representation* of the splines. Our inductive construction is based on two steps. In the first step, we construct minimal determining sets for C^1 splines defined on a tetrahedral partition of a single cube. Then, in the second step, we construct a minimal determining set for the whole C^1 spline space (Theorem 5.1), where in each step, we determine the remaining degrees of freedom. To do this, we pass through the cubes in an appropriate order. The cardinality of the minimal determining set gives the dimension of the spline spaces. As a main tool

for proving our results, we use a well-known *characterization of the C^1 smoothness* of two neighboring polynomial pieces in its Bernstein–Bézier representation (cf. de Boor [8], Farin [14]). We note that, although the results presented here are of independent interest, this paper can be understood as a basis for our recent local data interpolation methods (cf. Hecklin, Nürnberger, Schumaker and Zeilfelder [17]) for *cubic C^1* splines on *partially subdivided* Freudenthal partitions, which yield optimal approximation order of smooth functions. A first paper (cf. Nürnberger, Schumaker and Zeilfelder [28]) dealing with the difficult problem of constructing local Lagrange interpolation sets for smooth trivariate splines has recently appeared.

The paper is organized as follows. In section 2, we describe trivariate splines on Freudenthal partitions Δ, their piecewise Bernstein–Bézier representation and C^1 smoothness conditions. Section 3 contains our main result on the dimension of the spline spaces $\mathcal{S}_q^1(\Delta)$, and the definition of minimal determining sets. In section 4, we construct such sets for C^1 splines on a partition of a cube and give an explicit formula for the dimension of the corresponding spline spaces. These results are used in section 5, where we construct minimal determining sets for the whole space of C^1 splines and prove our main results. We close the paper with some remarks.

2. Splines on Freudenthal partitions and C^1 smoothness conditions. Let $\diamondsuit$ be the uniform cube partition of the domain $\Omega = [0,n] \times [0,n] \times [0,n] \subseteq \mathbb{R}^3$ which is obtained by intersecting Ω with $n+1$ parallel planes in each of the three space dimensions, i.e.,

$$\diamondsuit = \{Q_{(i,j,k)} : \ Q_{(i,j,k)} = [i-1,i] \times [j-1,j] \times [k-1,k],\ i,j,k = 1,\dots,n\}.$$

We cut each of the n^3 cubes $Q_{(i,j,k)},\ i,j,k = 1,\dots,n$, in $\diamondsuit$ with the three planes in $\mathbb{R}^3$ defined by

$$L_1 : \ x - y = i - j, \quad L_2 : \ x - z = i - k, \quad \text{and} \quad L_3 : \ y - z = j - k. \tag{2.1}$$

This leads to a natural, uniform tetrahedral partition Δ of Ω, where in correspondence to the six possible orderings of the variables x, y, and z each cube $Q \in \diamondsuit$ is split into six tetrahedra (see Figure 1, left and middle). More precisely, the construction is as follows. First, we subdivide each cube by slicing with L_1. Then, the two resulting prisms are further subdivided by slicing each of them with L_2 and L_3. Note that the planes L_1, L_2, and L_3 coincide along the main diagonal of $Q_{i,j,k}$, which connects the points $(i-1, j-1, k-1)$ and (i,j,k). It can be observed that the six tetrahedra

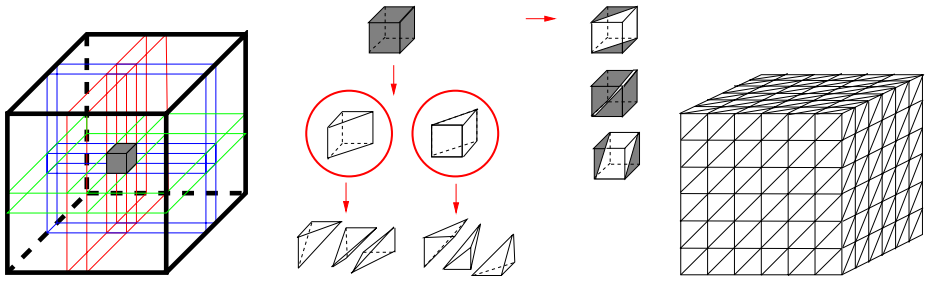

FIG. 1. *Freudenthal partitions Δ are obtained by splitting each cube of a uniform cube partition $\diamondsuit$ (left) into six tetrahedra by using three planes: first each cube is split into two prisms, then both prisms are further subdivided into three tetrahedra (middle). Each cutting plane of these partitions is a three-direction mesh known from bivariate spline theory (right).*

within each cube Q join the main diagonal of Q as a common edge. Moreover, the six tetrahedra can be obtained by taking the main diagonal of the cube as one edge, where the opposite edge is one of the six edges of the cube which are disjoint to the main diagonal. It is easy to see that the intersection of Δ with any plane parallel to the $xy-, xz-$, and $yz-$plane as well as with L_1, L_2, and L_3 is a three-direction mesh known from the bivariate setting (see Figure 1, right). Therefore, the tetrahedral partitions Δ are natural three-dimensional generalizations of these uniform triangulations. According to our knowledge, the partitions Δ were first considered by Freudenthal [15]; therefore we follow Carr, Möller and Snoeyink [11] and call them *Freudenthal (tetrahedral) partitions*.

Counting the number of tetrahedra N_Δ, triangular faces F_Δ, edges E_Δ, and vertices V_Δ of a Freudenthal partition Δ, respectively, it is easy to see that

$$N_\Delta = 6\ n^3, \quad F_\Delta = 12\ n^3 + 6n^2, \quad E_\Delta = 7\ n^3 + 9\ n^2 + 3\ n,$$
$$\text{and} \quad V_\Delta = n^3 + 3\ n^2 + 3\ n + 1. \tag{2.2}$$

In the following, we consider trivariate C^1 splines of arbitrary degree with respect to Δ . This means that we investigate the spaces $\mathcal{S}_q^1(\Delta)$ defined in (1.1). Since this is the trivial space of linear polynomials for $q = 1$, we are obviously interested in the choice $q \geq 2$. In order to analyze the structure of these spaces, the *smoothness conditions* across the interior triangular faces of Δ have to be taken into account. To do this, we use the piecewise Bernstein–Bézier representation of the splines from $\mathcal{S}_q^1(\Delta)$, which allows us to describe these conditions in a convenient form.

Given a (nondegenerate) tetrahedron $T = [v_0, v_1, v_2, v_3] \in \Delta$ with vertices v_0, v_1, v_2, and v_3, the linear polynomials $\Phi_\nu \in \mathcal{P}_1,\ \nu = 0, \ldots, 3$, with the interpolation property $\Phi_\nu(v_\mu) = \delta_{\nu,\mu},\ \mu = 0, \ldots, 3$, are called the *barycentric coordinates w.r.t. T*. Every polynomial piece $p = s_{|T} \in \mathcal{P}_q$ of a continuous spline s on Δ can be written in its *Bernstein–Bézier representation*

$$s_{|T}(z) = \sum_{\omega+\rho+\sigma+\tau=q} b_{\omega,\rho,\sigma,\tau}\ B^{q,T}_{\omega,\rho,\sigma,\tau}(z), \qquad z \in T, \tag{2.3}$$

where $B^{q,T}_{\omega,\rho,\sigma,\tau} = q!/(\omega!\rho!\sigma!\tau!)\ \Phi_0^\omega \Phi_1^\rho \Phi_2^\sigma \Phi_3^\tau \in \mathcal{P}_q,\ \omega+\rho+\sigma+\tau = q$, are the *Bernstein polynomials of degree q w.r.t. T* and $b_{\omega,\rho,\sigma,\tau} \in \mathbb{R},\ \omega+\rho+\sigma+\tau = q$, are the *Bernstein–Bézier coefficients* of p. It is well known (cf. Alfeld, Piper and Schumaker [3], Alfeld, Schumaker and Whiteley [7]) that each coefficient $b_{\omega,\rho,\sigma,\tau}$ in the Bernstein–Bézier representation (2.3) of $s_{|T}$ can be uniquely associated with the *domain point* $\xi_{\omega,\rho,\sigma,\tau} = (\omega\ v_0 + \rho\ v_1 + \sigma\ v_2 + \tau\ v_3)/q$, i.e., we define $b_{\omega,\rho,\sigma,\tau}(s) := b_{\omega,\rho,\sigma,\tau}(s_{|T}) = b_{\omega,\rho,\sigma,\tau},\ \omega + \rho + \sigma + \tau = q$. We note that the coefficients associated with the domain points on common triangular faces of the tetrahedra coincide, since the splines are continuous. Moreover, we set $\mathcal{D}_q(\Delta)$ as the union of all sets of domain points $\mathcal{D}_{q,T}$ w.r.t. the tetrahedra T of Δ.

Due to the special structure of Freudenthal partitions Δ the domain points can be described in terms of Euclidian coordinates. In the following, we set

$$\xi^{Q_{(i,j,k)}}_{\alpha,\beta,\gamma} = (i - 1 + \alpha/q, j - 1 + \beta/q, k - 1 + \gamma/q), \qquad \alpha, \beta, \gamma = 0, \ldots, q,$$

for the domain points $\mathcal{D}_{q,Q_{(i,j,k)}}$ within the cube $Q_{(i,j,k)}$ and indicate for $i, j, k \in \{1, \ldots, n\}$,

$$b_\xi(s) = b_\xi, \quad \xi = \xi^{Q_{(i,j,k)}}_{\alpha,\beta,\gamma}, \quad \alpha, \beta, \gamma = 0, \ldots, q.$$

We use this natural notation to keep the proofs in the subsequent sections short.

It is known that for any tetrahedral partition, the number of domain points coincides with the dimension of continuous spline spaces of arbitrary degree. For Freudenthal partitions Δ, a straightforward computation shows that this number is equal to $(q+1+(n-1)\ q)^3 = (n\ q+1)^3 = q^3\ n^3 + 3q^2\ n^2 + 3q\ n + 1$, since the continuity of a spline s on Δ is equivalent to $b_\xi(s) = b_\xi = b_{\xi'} = b_{\xi'}(s)$ for all ξ, ξ', where

$$\left(\xi = \xi^{Q_{(i,j,k)}}_{q,\alpha,\beta} \text{ and } \xi' = \xi^{Q_{(i+1,j,k)}}_{0,\alpha,\beta}\right), \qquad \left(\xi = \xi^{Q_{(j,i,k)}}_{\alpha,q,\beta} \text{ and } \xi' = \xi^{Q_{(j,i+1,k)}}_{\alpha,0,\beta}\right),$$
$$\left(\xi = \xi^{Q_{(j,k,i)}}_{\alpha,\beta,q} \text{ and } \xi' = \xi^{Q_{(j,k,i+1)}}_{\alpha,\beta,0}\right), \qquad \alpha,\beta = 0,\dots,q,$$

and $i,j,k = 1,\dots,n,\ i \neq n$. The situation is much more complex if we consider differentiable splines s on Δ, i.e., $s \in \mathcal{S}^1_q(\Delta)$, where $\mathcal{S}^1_q(\Delta)$ is the space defined in (1.1). As noted above, in this case, it is necessary to describe the *smoothness conditions* of the polynomial pieces of the splines on *neighboring tetrahedra* of Δ (i.e., tetrahedra with a common triangular face) in a convenient form. It is well known that this can be done by using the next result of Farin [14] (see also de Boor [8], and Chui [12]) which characterizes smoothness conditions for splines on two neighboring tetrahedra in terms of the coefficients of its piecewise Bernstein–Bézier representation.

THEOREM 2.1. *Let two neighboring tetrahedra $T = [v_0, v_1, v_2, v_3]$, $\tilde{T} = [v_0, v_1, v_2, \tilde{v}_3]$, and a continuous spline s on $T \cup \tilde{T}$ with*

$$s_{|_T} = p = \sum_{\omega+\rho+\sigma+\tau=q} b_{\omega,\rho,\sigma,\tau}\ B^{q,T}_{\omega,\rho,\sigma,\tau} \quad \text{and} \quad s_{|_{\tilde{T}}} = \tilde{p} = \sum_{\omega+\rho+\sigma+\tau=q} \tilde{b}_{\omega,\rho,\sigma,\tau}\ B^{q,\tilde{T}}_{\omega,\rho,\sigma,\tau}$$

be given. Then, s is differentiable across the common triangular face $T \cap \tilde{T} = [v_0, v_1, v_2]$, i.e., $s \in C^1(T \cup \tilde{T})$ if and only if for all $\omega+\rho+\sigma = q-1$,

$$\begin{aligned}\tilde{b}_{\omega,\rho,\sigma,1} = {} & b_{\omega+1,\rho,\sigma,0}\ \Phi_0(\tilde{v}_3) + b_{\omega,\rho+1,\sigma,0}\ \Phi_1(\tilde{v}_3) \\ & + b_{\omega,\rho,\sigma+1,0}\ \Phi_2(\tilde{v}_3) + b_{\omega,\rho,\sigma,1}\ \Phi_3(\tilde{v}_3),\end{aligned} \tag{2.4}$$

where $\Phi_\nu(\tilde{v}_3),\ \nu = 0,\dots,3$, are the barycentric coordinates with respect to T, evaluated at the point $\tilde{v}_3$.

The relations in (2.4) show that in order to guarantee the C^1 smoothness across $T \cap \tilde{T}$ exactly $q(q+1)/2$ conditions have to be satisfied. In particular, the relations imply that if coefficients of the form $b_{\omega,\rho,\sigma,\ell},\ \omega+\rho+\sigma = q-\ell,\ \ell = 0,1$, are determined, then the coefficients $\tilde{b}_{\omega,\rho,\sigma,1},\ \omega+\rho+\sigma = q-1$ (i.e., the coefficients *in distance one to* $T \cap \tilde{T}$) are uniquely determined. In general, there are five coefficients involved in each of these conditions (see Figure 2, left). Analogous to the univariate and bivariate case, each of these conditions has the geometric interpretation that there are five corresponding points in $\mathbb{R}^4$ which lie in the same (three-dimensional) hyperplane. The fourth component of these points is a Bernstein–Bézier coefficient which appears in (2.4) while the first three components are the associated domain points. If one or even two of the barycentric coordinates at the point $\tilde{v}_3$ vanish, then the number of involved coefficients is four and three, respectively (see Figure 2, middle and right). In these cases, the smoothness conditions degenerate to lower dimensional conditions which are similar as in the bivariate and univariate setting, i.e., four points of the above form lie in a plane and three points lie on a line, respectively. Therefore, these cases are sometimes called *degenerate cases*.

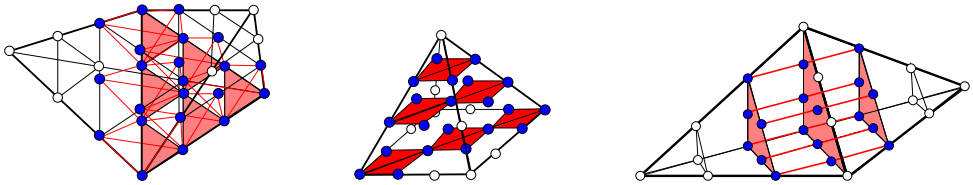

FIG. 2. *Illustration of C^1 smoothness conditions across the common triangular face of two neighboring tetrahedra (in the case $q = 3$). The domain points associated with coefficients involved are shown as dark dots. In general, there are five coefficients involved in every condition (left). In the special case when three of the five vertices of the neighboring tetrahedra lie on one line, the smoothness conditions degenerate to conditions of univariate type, which means that only three points are affected by every condition (right). For Freudenthal partitions Δ only four coefficients are relevant for each C^1 smoothness condition (middle), since for every pair of neighboring tetrahedra in Δ four of the five vertices lie in a plane.*

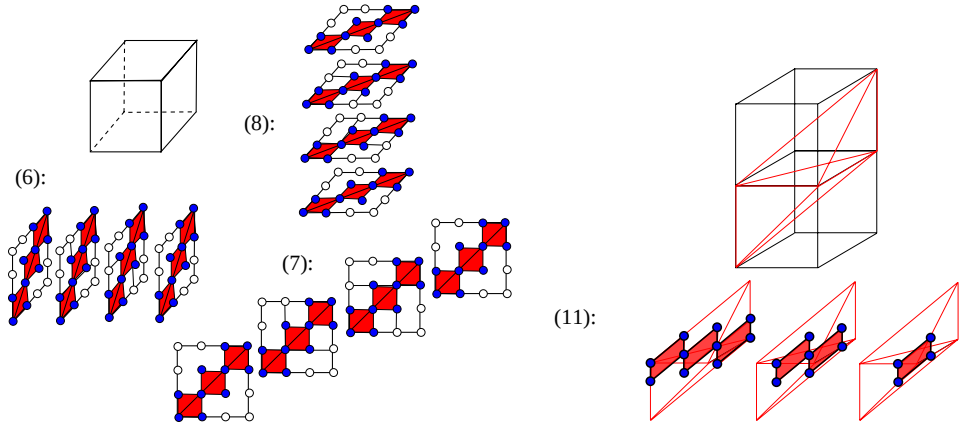

FIG. 3. *Each smoothness condition satisfied by the C^1 splines on Freudenthal partitions Δ degenerates to a C^1 condition of bivariate type. The example shows the case $q = 3$, where the domain points associated with the four coefficients involved in each smoothness condition are shown as dark dots. Conditions on neighboring tetrahedra inside a cube of $\diamondsuit$ (i.e., the conditions in* (6)–(8)*) are illustrated on the left, while an example illustrating the smoothness conditions on two neighboring tetrahedra from different cubes (i.e., the conditions in* (11)*) is shown on the right.*

While on general tetrahedral partitions these three types of smoothness conditions can appear, we observe that *all* the conditions on neighboring tetrahedra satisfied by the splines from $\mathcal{S}_q^1(\Delta)$, where Δ is a Freudenthal partition, are of the *same type*. More precisely, for every pair of neighboring tetrahedra in Δ exactly four Bernstein–Bézier coefficients are involved in each C^1 condition and hence only degenerate smoothness conditions of bivariate type appear for these splines. The following lemma shows that the smoothness conditions satisfied by these splines can easily be described by one single formula. However, the arguments given in the subsequent sections indicate that even for Δ the analysis of the overall smooth spline spaces is a complex task since the conditions have to be satisfied simultaneously across all the interior triangular faces of Δ. Figure 3 further illustrates the lemma.

LEMMA 2.2. *Let s be a continuous spline on a Freudenthal partition Δ with BB-coefficients $b_\xi(s) = b_\xi$, $\xi \in \mathcal{D}_q(\Delta)$ in its piecewise Bernstein–Bézier representation*

(2.3). *Then, $s \in \mathcal{S}_q^1(\Delta)$ if and only if $b_\xi + b_{\xi'} = b_{\xi^*} + b_{\xi''}$ for all ξ, ξ', ξ^*, ξ'', where*

$$\left(\xi = \xi^{Q_{(i,j,k)}}_{\beta,\alpha,\alpha},\ \xi' = \xi^{Q_{(i,j,k)}}_{\beta,\alpha+1,\alpha+1},\ \xi^* = \xi^{Q_{(i,j,k)}}_{\beta,\alpha+1,\alpha},\ \textit{and}\ \ \xi'' = \xi^{Q_{(i,j,k)}}_{\beta,\alpha,\alpha+1}\right), \tag{2.5}$$

$$\left(\xi = \xi^{Q_{(i,j,k)}}_{\alpha,\beta,\alpha},\ \xi' = \xi^{Q_{(i,j,k)}}_{\alpha+1,\beta,\alpha+1},\ \xi^* = \xi^{Q_{(i,j,k)}}_{\alpha+1,\beta,\alpha},\ \textit{and}\ \ \xi'' = \xi^{Q_{(i,j,k)}}_{\alpha,\beta,\alpha+1}\right), \tag{2.6}$$

$$\left(\xi = \xi^{Q_{(i,j,k)}}_{\alpha,\alpha,\beta},\ \xi' = \xi^{Q_{(i,j,k)}}_{\alpha+1,\alpha+1,\beta},\ \xi^* = \xi^{Q_{(i,j,k)}}_{\alpha+1,\alpha,\beta},\ \textit{and}\ \ \xi'' = \xi^{Q_{(i,j,k)}}_{\alpha,\alpha+1,\beta}\right), \tag{2.7}$$
$$\alpha, \beta = 0, \dots, q,\ \alpha \neq q,\ i, j, k = 1, \dots, n,$$

and

$$\left(\xi = \xi^{Q_{(i,j,k)}}_{q,\alpha,\beta},\ \xi' = \xi^{Q_{(i,j,k)}}_{q,\alpha+1,\beta+1},\ \xi^* = \xi^{Q_{(i,j,k)}}_{q-1,\alpha,\beta},\ \textit{and}\ \ \xi'' = \xi^{Q_{(i+1,j,k)}}_{1,\alpha+1,\beta+1}\right), \tag{2.8}$$

$$\left(\xi = \xi^{Q_{(j,i,k)}}_{\alpha,q,\beta},\ \xi' = \xi^{Q_{(j,i,k)}}_{\alpha+1,q,\beta+1},\ \xi^* = \xi^{Q_{(j,i,k)}}_{\alpha,q-1,\beta},\ \textit{and}\ \ \xi'' = \xi^{Q_{(j,i+1,k)}}_{\alpha+1,1,\beta+1}\right), \tag{2.9}$$

$$\left(\xi = \xi^{Q_{(j,k,i)}}_{\alpha,\beta,q},\ \xi' = \xi^{Q_{(j,k,i)}}_{\alpha+1,\beta+1,q},\ \xi^* = \xi^{Q_{(j,k,i)}}_{\alpha,\beta,q-1},\ \textit{and}\ \ \xi'' = \xi^{Q_{(j,k,i+1)}}_{\alpha+1,\beta+1,1}\right), \tag{2.10}$$
$$\alpha, \beta = 0, \dots, q-1,\ i, j, k = 1, \dots, n,\ i \neq n.$$

Proof of Lemma 2.2. Let $T = [v_0, v_1, v_2, v_3]$ and $\tilde{T} = [v_0, v_1, v_2, \tilde{v}_3]$ be two tetrahedra from Δ with a common triangular face $F = T \cap \tilde{T} = [v_0, v_1, v_2]$, where $v_3 \neq \tilde{v}_3$. It follows from the special structure of Δ that in all cases the vertices v_0, v_1, and v_2 of F can be arranged such that v_0, v_1, v_3, and $\tilde{v}_3$ lie in the same plane and form a parallelogram P with diagonal $[v_0, v_1]$. If T and $\tilde{T}$ are contained in two different cubes, then P lies within a plane of the form (2.1). Otherwise, P lies in a plane parallel to one of the three coordinate planes. In both cases, we compute

$$\Phi_0(\tilde{v}_3) = 1, \quad \Phi_1(\tilde{v}_3) = 1, \quad \Phi_2(\tilde{v}_3) = 0, \quad \text{and} \quad \Phi_3(\tilde{v}_3) = -1,$$

where $\Phi_\nu,\ \nu = 0, \dots, 3$, denote the barycentric coordinates w.r.t. T. Therefore, the assertion follows from Theorem 2.1. This proves the lemma. □

Remark 2.3. Combining the conditions in (2.5)–(2.7) which involve the coefficients along the main diagonal of the cube $Q_{(i,j,k)}$, we observe that for any C^1 spline on Δ the hidden conditions $b_\xi + 2\, b_{\xi'} = b_{\xi''} + b_{\xi^*} + b_{\tilde{\xi}}$ are satisfied, where

$$\begin{aligned}&\left(\xi = \xi^{Q_{(i,j,k)}}_{\alpha+1,\alpha+1,\alpha+1},\ \xi' = \xi^{Q_{(i,j,k)}}_{\alpha,\alpha,\alpha},\ \xi'' = \xi^{Q_{(i,j,k)}}_{\alpha+1,\alpha,\alpha},\ \xi^* = \xi^{Q_{(i,j,k)}}_{\alpha,\alpha+1,\alpha},\right.\\ &\left.\text{and}\ \ \tilde{\xi} = \xi^{Q_{(i,j,k)}}_{\alpha,\alpha,\alpha+1}\right), \qquad \alpha = 0, \dots, q-1, \quad i, j, k = 1, \dots, n.\end{aligned} \tag{2.11}$$

3. Minimal determining sets and main result. An analysis of the structure of smooth multivariate splines is frequently done by constructing minimal determining sets for the spaces. Following Alfeld, Piper and Schumaker [3] (see also Schumaker and Sorokina [35, 36]), we call $\mathcal{M} \subseteq \mathcal{D}_q(\Delta)$ a *determining set (DS) for* $\mathcal{S}_q^1(\Delta)$, if setting the coefficients $b_\xi(s),\ \xi \in \mathcal{M}$, of a spline $s \in \mathcal{S}_q^1(\Delta)$ to zero, implies that $s = 0$. A determining set $\mathcal{M}$ is called a *minimal determining set (MDS) for* $\mathcal{S}_q^1(\Delta)$ if no determining set for $\mathcal{S}_q^1(\Delta)$ with fewer elements than in $\mathcal{M}$ exists. Hence, it is obvious that $\mathcal{M}$ is an MDS for $\mathcal{S}_q^1(\Delta)$, if setting the coefficients $b_\xi(s),\ \xi \in \mathcal{M}$, of a spline $s \in \mathcal{S}_q^1(\Delta)$ to arbitrary real values, all its coefficients $b_\xi(s),\ \xi \in \mathcal{D}_q(\Delta)$, are uniquely determined (whereby all smoothness conditions described in (2.5)–(2.10) are satisfied). The cardinality of an MDS for $\mathcal{S}_q^1(\Delta)$ coincides with the dimension (i.e., the

TABLE 1
Dimensions of C^1 and C^0 splines on Freudenthal partitions Δ.

q	Dimension of $\mathcal{S}_q^1(\Delta)$	$n=1$	Dimension of $\mathcal{S}_q^0(\Delta)$	$n=1$

number of degrees of freedom) of the spline space. Moreover, we note that it is well known in multivariate spline theory that the explicit construction of MDS gives insight on the structure of spline spaces. In section 5, we construct an MDS for C^1 splines of any degree on Freudenthal partitions Δ. From this construction (see Theorem 5.1), we obtain the following theorem, which we state here as our main result.

THEOREM 3.1. *Let Δ be a Freudenthal partition. Then the dimension of $\mathcal{S}_q^1(\Delta)$ is given by*

$$(q-3)(q-2)(q-1)\,n^3+6\,(q-2)(q-1)\,n^2+9\,(q-1)\,n+4. \tag{3.1}$$

Table 1 lists the dimension of $\mathcal{S}_q^1(\Delta)$ for low degrees, i.e., $q\in\{1,\dots,9\}$, for arbitrary n and $n=1$ (i.e., the case of one cube), and compares them with the asymptotic number of degrees of freedom as well as with the case $n=1$ for the continuous spline spaces on Δ of the same degree.

In the next corollary, we give some alternative formulae for the dimension of $\mathcal{S}_q^1(\Delta)$. Recall that for Freudenthal partitions Δ the quantities $N_\Delta, F_\Delta, E_\Delta$, and V_Δ are given as in (2.2). In addition, let V_I be the number of interior vertices of Δ, V_B the number of boundary vertices of Δ, F_I the number of interior triangular faces of Δ, and E_I the number of interior edges of Δ. An elementary computation shows that we have

$$V_I=n^3-3\,n^2+3\,n-1,\quad V_B=6\,n^2+2,\quad F_I=12\,n^3-6\,n^2,$$

and

$$E_I=7\,n^3-9\,n^2+3\,n.$$

Since Δ can be completely constructed by starting with an appropriate tetrahedron and adding successively tetrahedra which intersect the union of the tetrahedra considered before along one, two or three triangular faces, the *Euler-type formulae*

$$V_B\;=\;2\,N_\Delta-F_I+2,\qquad N_\Delta\;=\;V_I-E_I+F_I+1,$$

are satisfied (see the discussion on *shellable tetrahedral partitions* in Lai and Schumaker [21]). By using these relations, the formula in (3.1), and some elementary computations, we obtain the following result.

COROLLARY 3.2. *Let Δ be a Freudenthal partition. Then, the dimension of $\mathcal{S}_q^1(\Delta)$ is given by*

$$\begin{aligned}
&\tfrac{1}{6}\,\Big(24\;V_\Delta + 6\;(3\;q-7)\;E_\Delta + 3\;(2\;q^2-15\;q+21)\;F_\Delta \\
&\qquad + (q^3-18\;q^2+80\;q-87)\;N_\Delta\Big) \\
&= \tfrac{1}{6}\,\Big(18\;(q-1)\;V_I + 3\;(2\;q^2-3\;q+1)\;V_B + (q^3-6\;q^2+8\;q-3)\;N_\Delta \\
&\qquad - 12\;(q^2-3\;q)\Big) \\
&= \tfrac{1}{6}\,\Big((q^3+6\;q^2+8\;q-15)\;V_I - (q^3+6\;q^2-10\;q+3)\;E_I + \\
&\qquad (q^3-q)\;F_I + (q^3+6\;q^2+8\;q+9)\Big).
\end{aligned}$$

4. MDS for C^1 splines on a tetrahedrized cube. In this section, we deal with C^1 splines of arbitrary degree on the Freudenthal partition Δ_Q which is obtained by subdividing the single cube $Q = Q_{(1,1,1)}$ into six tetrahedra, i.e., the case $n = 1$. This can be considered as the starting point of our inductive construction of an MDS for $\mathcal{S}_q^1(\Delta)$, which is given in the next section. In the following, we construct two different MDSs for the spaces $\mathcal{S}_q^1(\Delta_Q)$, which we denote by $\widetilde{\mathcal{M}}_Q$ and $\mathcal{M}_Q$, respectively. We first use the set $\widetilde{\mathcal{M}}_Q$ to determine the number of degrees of freedom of the smooth splines on Δ_Q. For defining this set, we consider the tetrahedra T_i of Δ_Q and choose appropriate subsets of $\mathcal{D}_{q,T_i},\ i = 1,\dots,6$. The definition of the second set $\mathcal{M}_Q$ requires the notation introduced in section 2 since its points are not chosen tetrahedron by tetrahedron. (We want to keep the number of symbols as small as possible, and therefore we describe both sets by using the above notation.) The set $\mathcal{M}_Q$ is more complex than $\widetilde{\mathcal{M}}_Q$, but at that point we only have to show that $\mathcal{M}_Q$ is a DS, since the cardinalities of $\mathcal{M}_Q$ and $\widetilde{\mathcal{M}}_Q$ coincide. Note that the construction of $\mathcal{M}_Q$ is the key of the proof of our main result (see section 5).

In the following, we set $\xi_{\alpha,\beta,\gamma} = \xi^Q_{\alpha,\beta,\gamma},\ \alpha,\beta,\gamma = 0,\dots,q$, and define $\widetilde{\mathcal{M}}_Q \subseteq \mathcal{D}_q(\Delta_Q)$. To do this, we consider six auxiliarly sets $\widetilde{\mathcal{M}}_i,\ i = 1,\dots,6$, which are given as follows:

$$\begin{aligned}
\widetilde{\mathcal{M}}_1 &= \{\xi_{\alpha,\beta,\gamma} :\ \gamma \le \beta \le \alpha\},\\
\widetilde{\mathcal{M}}_2 &= \{\xi_{\alpha,\beta,\gamma} :\ \beta+2 \le \gamma \le \alpha\},\\
\widetilde{\mathcal{M}}_3 &= \{\xi_{\alpha,\beta,\gamma} :\ \beta \le \alpha \le \gamma-2\},\\
\widetilde{\mathcal{M}}_4 &= \{\xi_{\alpha,\beta,\gamma} :\ \gamma \le \alpha \le \beta-2\},\\
\widetilde{\mathcal{M}}_5 &= \{\xi_{\alpha,\beta,\gamma} :\ \alpha+2 \le \gamma < \beta\} \cup \{\xi_{\alpha,\beta,\beta} :\ \alpha+3 \le \beta\},\\
\widetilde{\mathcal{M}}_6 &= \{\xi_{\alpha,\beta,\gamma} :\ \alpha+2 \le \beta \le \gamma-2\}\ .
\end{aligned}$$

In these definitions as well as in what follows, the indices which are not further specified run over all possible choices from $\{0,\dots,q\}$. It is easy to see that $\widetilde{\mathcal{M}}_1$ is equal to $\mathcal{D}_{q,T_1}$, where T_1 is the tetrahedron of Δ_Q with the vertices $(0,0,0)$, $(1,0,0)$, $(1,1,0)$, and $(1,1,1)$. The set $\widetilde{\mathcal{M}}_2$ is obtained from $\mathcal{D}_{q,T_2} = \{\xi_{\alpha,\beta,\gamma} :\ \beta \le \gamma \le \alpha\}$, where T_2 is the tetrahedron of Δ_Q with the vertices $(0,0,0)$, $(1,0,0)$, $(1,0,1)$, and $(1,1,1)$, by removing the domain points in $\mathcal{D}_{q,T_2}$ on the common triangular face of T_2 and T_1 as well as the points in $\mathcal{D}_{q,T_2}$ associated with coefficients in distance one to

this face. The set $\widetilde{\mathcal{M}}_4$ is similar to $\widetilde{\mathcal{M}}_2$: here we remove the analogous points from $\mathcal{D}_{q,T_4} = \{\xi_{\alpha,\beta,\gamma} : \gamma \le \alpha \le \beta\}$, where T_4 is the tetrahedron of Δ_Q with vertex $(0,1,0)$, which has the triangular face with vertices $(0,0,0)$, $(1,1,0)$, and $(1,1,1)$ in common with T_1. Similarly, the set $\widetilde{\mathcal{M}}_3$ is obtained from $\mathcal{D}_{q,T_3} = \{\xi_{\alpha,\beta,\gamma} : \beta \le \alpha \le \gamma\}$, where T_3 is the tetrahedron of Δ_Q with the vertices $(0,0,0)$, $(0,0,1)$, $(1,0,1)$, and $(1,1,1)$, by removing the domain points in T_3 on the common triangular face of T_3 and T_2 as well as the points in T_3 associated with coefficients in distance one to this face. The sets $\widetilde{\mathcal{M}}_5$ and $\widetilde{\mathcal{M}}_6$ are subsets of $\mathcal{D}_{q,T_5} = \{\xi_{\alpha,\beta,\gamma} : \alpha \le \gamma \le \beta\}$ and $\mathcal{D}_{q,T_6} = \{\xi_{\alpha,\beta,\gamma} : \alpha \le \beta \le \gamma\}$, where T_5 is the tetrahedron of Δ_Q with the vertices $(0,0,0)$, $(0,1,0)$, $(0,1,1)$, and $(1,1,1)$, and T_6 is the tetrahedron of Δ_Q with the vertices $(0,0,0)$, $(0,0,1)$, $(0,1,1)$, and $(1,1,1)$, respectively: here, we remove similar points as above, and some additional points on their common triangular face with vertices $(0,0,0)$, $(0,1,1)$, and $(1,1,1)$, i.e., the points in distance two to the main diagonal in Q.

We set

$$\widetilde{\mathcal{M}}_Q \;=\; \bigcup_{i=1}^{6} \widetilde{\mathcal{M}}_i.$$

LEMMA 4.1. *Let Δ_Q be the Freudenthal partition of $Q = Q_{(1,1,1)}$. Then, $\widetilde{\mathcal{M}}_Q$ is an MDS for $\mathcal{S}_q^1(\Delta_Q)$ and the dimension of $\mathcal{S}_q^1(\Delta_Q)$ is given by $q^3 + 2\,q + 1$.*

Proof. Let arbitrary coefficients $b_\xi = b_\xi(s),\ \xi \in \widetilde{\mathcal{M}}_Q$ of a spline $s \in \mathcal{S}_q^1(\Delta_Q)$ be given. We have to show that the remaining coefficients of s, i.e., the coefficients b_ξ, where $\xi \in \mathcal{D}_q(\Delta_Q) \setminus \widetilde{\mathcal{M}}_Q$, are uniquely determined, while the C^1 smoothness conditions involving the coefficients associated with each choice of four points in (2.5)–(2.7) are satisfied. In the following, we use the above notation for the tetrahedra $T_1, \ldots, T_6$ in Δ_Q. First, it is obvious that the choice of $\widetilde{\mathcal{M}}_1 \subseteq \widetilde{\mathcal{M}}_Q$ implies that the polynomial piece $s_{|_{T_1}}$ is uniquely determined. In particular, the coefficients b_ξ, where $\xi = \xi_{\beta,\alpha,\alpha} \in T_1,\ \alpha \le \beta$, and $\xi = \xi_{\beta,\alpha+1,\alpha} \in T_1,\ \alpha + 1 \le \beta$, are uniquely determined. In view of (2.5), it follows that the coefficients b_ξ, where $\xi = \xi_{\beta,\alpha,\alpha+1} \in T_2,\ \alpha + 1 \le \beta$, are uniquely determined. The choice of $\widetilde{\mathcal{M}}_2$ therefore implies that $s_{|_{T_2}}$ is uniquely determined. Similarly, the smoothness conditions in (2.6) for the neighboring polynomial pieces on T_2 and T_3 determine the coefficients b_ξ, where $\xi = \xi_{\alpha,\beta,\alpha+1} \in T_3,\ \beta \le \alpha$, and it follows that the choice of $\widetilde{\mathcal{M}}_3$ uniquely determines $s_{|_{T_3}}$. Independently, the smoothness conditions in (2.7) for the neighboring polynomial pieces on T_1 and T_4 determine the coefficients b_ξ, where $\xi = \xi_{\alpha,\alpha+1,\beta} \in T_4,\ \beta \le \alpha$, and hence, the choice of $\widetilde{\mathcal{M}}_4$ shows that $s_{|_{T_4}}$ is uniquely determined. Moreover, the remaining smoothness conditions in (2.6) for the neighboring polynomial pieces on T_4 and T_5 determine the coefficients b_ξ, where $\xi = \xi_{\alpha,\beta,\alpha+1} \in T_5,\ \alpha + 1 \le \beta$, and the remaining smoothness conditions in (2.7) for the neighboring polynomial pieces of T_3 and T_6 determine the coefficients b_ξ, where $\xi = \xi_{\alpha,\alpha+1,\beta} \in T_6,\ \alpha + 1 \le \beta$. Now, we consider the remaining smoothness conditions in (2.5) for the neighboring polynomial pieces on T_5 and T_6 in the case $\alpha = \beta + 1$, i.e.,

$$b_{\xi_{\beta,\beta+2,\beta+2}} = b_{\xi_{\beta,\beta+2,\beta+1}} + b_{\xi_{\beta,\beta+1,\beta+2}} - b_{\xi_{\beta,\beta+1,\beta+1}}\ .$$

It follows from above that the coefficients on the right of this equation are already uniquely determined, and hence $b_{\xi_{\beta,\beta+2,\beta+2}}$ is uniquely determined. The choice of $\widetilde{\mathcal{M}}_5$ now uniquely determines $s_{|_{T_5}}$. Finally, we get that the remaining smoothness

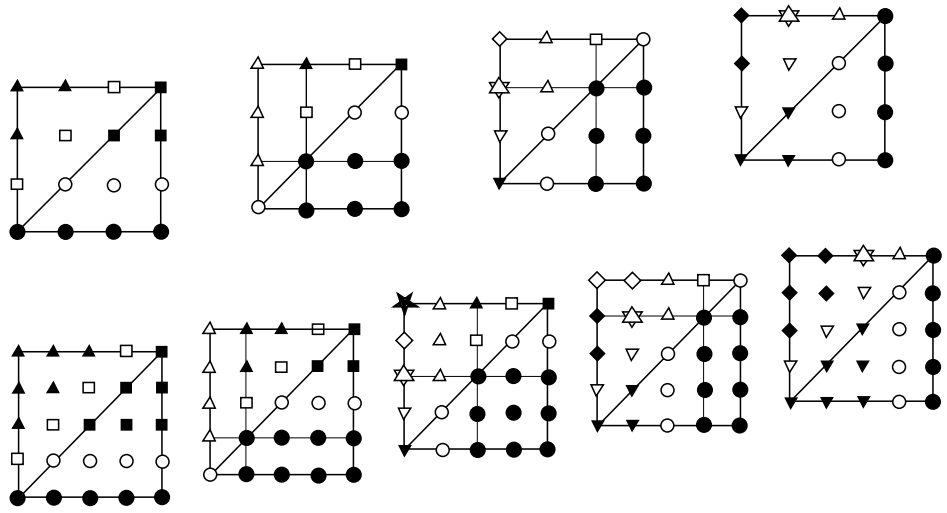

FIG. 4. *Illustration of the MDS $\widetilde{\mathcal{M}}_Q$ for $\mathcal{S}_q^1(\Delta_Q)$ in the cases $q = 3$ (top) and $q = 4$ (bottom). The points of $\widetilde{\mathcal{M}}_Q$ are marked by black symbols, while the white symbols indicate the order of determining the remaining coefficients in the proof of Lemma* 4.1.

conditions in (2.5) for the neighboring polynomial pieces on T_5 and T_6 and the choice of $\widetilde{\mathcal{M}}_6$ imply that $s_{|_{T_6}}$ is uniquely determined, and therefore all the coefficients b_ξ of s are uniquely determined. It is easy to see that the number of points $\widetilde{\mathcal{M}}_i$ is equal to $\binom{q+3}{3} = (q^3 + 6q^2 + 11q + 6)/6$ if $i = 1$, $\binom{q+1}{3} = (q^3 - q)/6$ if $i \in \{2, 3, 4\}$, $\binom{q+1}{3} - (q-1) = (q^3 - 7q + 6)/6$ if $i = 5$, and $\binom{q-1}{3} = (q^3 - 6q^2 + 11q - 6)/6$ if $i = 6$. (Note that we set here and in the following $\binom{j}{k} := 0$ whenever $j < k$.) Therefore, it follows from some elementary computations that the number of points in $\widetilde{\mathcal{M}}_Q$ is equal to $q^3 + 2\,q + 1$. This completes the proof of the lemma. ∎

Example 4.2. In Figure 4, we show the MDS $\widetilde{\mathcal{M}}_Q$ in the cases $q = 3$ (top) and $q = 4$ (bottom). The figure illustrates the different layers of domain points within the cube Q in a front to back manner, where the thin lines indicate the intersections with triangular faces in the interior of Q. In these examples the set $\widetilde{\mathcal{M}}_Q$ contains 34 and 73 points, respectively, which we illustrate by black symbols, i.e., we mark the points from the sets $\widetilde{\mathcal{M}}_i$, $i = 1, \ldots, 6$, by ●, ■, ▲, ▼, ♦ and ★. In the proof of Lemma 4.1, the coefficients associated with the remaining domain points are determined in the order of the white symbols, i.e., ○, □, △, ▽, ⯐ , and ◇. Note that the coefficients indicated by ⯐ are determined from △ and ▽ by using conditions described in (2.5).

We proceed by defining a subset $\mathcal{M}_Q$ of $\mathcal{D}_q(\Delta_Q)$ different from $\widetilde{\mathcal{M}}_Q$ which is also an MDS for $\mathcal{S}_q^1(\Delta_Q)$, but more symmetric. Again, we use the above abbreviations and consider three auxiliary sets $\mathcal{M}_i$, $i = 1, \ldots, 3$, which are defined as follows:

$$\begin{aligned}
\mathcal{M}_1 &= \{\xi_{0,0,0}\} \cup \{\xi_{0,\alpha,\beta},\ \xi_{\alpha,0,\beta},\ \xi_{\alpha,\beta,0} :\ \alpha \neq \beta\},\\
\mathcal{M}_2 &= \{\xi_{\alpha,\beta,\gamma},\ \xi_{\beta,\alpha,\gamma},\ \xi_{\beta,\gamma,\alpha} :\ 1 \leq \alpha \leq q-3,\ \alpha+1 \leq \beta, \gamma \leq q-1,\ \beta \neq \gamma\},\\
\mathcal{M}_3 &= \{\xi_{q,\alpha,\beta},\ \xi_{\alpha,q,\beta},\ \xi_{\alpha,\beta,q} :\ 1 \leq \alpha, \beta \leq q-1,\ \alpha \neq \beta\}.
\end{aligned}$$

The set $\mathcal{M}_1$ consists of all domain points contained in the left, front, and bottom face of Q except for those which differ from $\xi_{0,0,0}$ and lie on a diagonal of such a face. The set $\mathcal{M}_2$ represents a symmetric constellation of points in the interior of Q. Moreover,

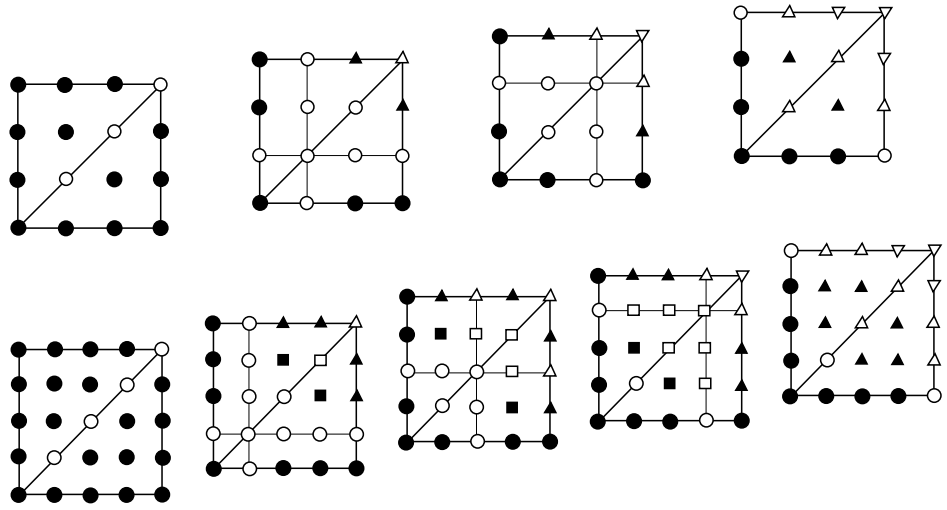

FIG. 5. *Illustration of the MDS $\mathcal{M}_Q$ for $\mathcal{S}_q^1(\Delta_Q)$ in the cases $q = 3$ (top) and $q = 4$ (bottom). The points from $\mathcal{M}_Q$ are marked by black symbols, while the white symbols indicate the order of determining the remaining coefficients in the proof of Theorem* 4.3.

$\mathcal{M}_3$ includes certain domain points contained in the right, back, and top face of Q. This choice of points is illustrated in Figure 5 for the cases $q = 3$ (top) and $q = 4$ (bottom). Here, we use the symbols ●, ■, and ▲ for the points in $\mathcal{M}_1$, $\mathcal{M}_2$, and $\mathcal{M}_3$, respectively. The next theorem shows that

$$\mathcal{M}_Q \;=\; \bigcup_{i=1}^{3} \mathcal{M}_i$$

is an MDS for $\mathcal{S}_q^1(\Delta_Q)$. We note that the construction of $\mathcal{M}_Q$ is the key for showing our main result (see next section). By using Lemma 4.1 its proof is essentially simplified, since it now suffices to show that $\mathcal{M}_Q$ contains the right number of points and is a determining set. Following the proof of the next theorem, it can be seen that the coefficients of the splines associated with the remaining domain points indicated as white symbols in Figure 5 are determined in the order ○, □, △, and ▽.

THEOREM 4.3. *Let Δ_Q be the Freudenthal partition of $Q = Q_{(1,1,1)}$. Then, $\mathcal{M}_Q$ is an MDS for $\mathcal{S}_q^1(\Delta_Q)$.*

Proof. The number of points in $\mathcal{M}_1, \mathcal{M}_2$, and $\mathcal{M}_3$ is equal to $3q^2 + 1$, $q^3 - 6q^2 + 11q - 6$, and $3(q^2 - 3q + 2)$, respectively. Hence, some elementary computations show that the number of points in $\mathcal{M}_Q$ is equal to $q^3 + 2\ q + 1$. Therefore, in view of Lemma 4.1, it suffices to show that $\mathcal{M}_Q$ is a DS. We may assume that $q \geq 2$ and have to show that for any spline $s \in \mathcal{S}_q^1(\Delta_Q)$, with coefficients $b_\xi = b_\xi(s) = 0$, where $\xi \in \mathcal{M}_Q$, the remaining coefficients $b_\xi(s)$, $\xi \in \mathcal{D}_q(\Delta_Q) \setminus \mathcal{M}_Q$, are also zero, i.e., $s = 0$.

First, we note that it follows from an inductive argument involving the smoothness conditions in (2.5) for the case $\beta = 0$ that $b_\xi = 0$, where $\xi = \xi_{0,\alpha,\alpha},\ \alpha = 1, \ldots, q$. Analogously, we get $b_\xi = 0$, where $\xi = \xi_{\alpha,0,\alpha}$ and $\xi = \xi_{\alpha,\alpha,0},\ \alpha = 1, \ldots, q$, by using (2.6) and (2.7), respectively. The choice of $\mathcal{M}_1$ therefore implies that $b_\xi = 0$, where $\xi = \xi_{0,\alpha,\beta},\ \xi = \xi_{\alpha,0,\beta}$, and $\xi = \xi_{\alpha,\beta,0},\ \alpha, \beta = 0, \ldots, q$. We now show inductively that for any $m \in \{1, \ldots, q-1\}$, we have $b_\xi = 0$, where $\xi = \xi_{m,\alpha,\beta}, \xi = \xi_{\alpha,m,\beta}$, and $\xi = \xi_{\alpha,\beta,m},\ \alpha, \beta = m, \ldots, q-1$. Let us assume that this has already been shown

for $m-1 \le q-2$. Then, it follows from induction hypothesis that $b_\xi = 0$, where $\xi = \xi_{\alpha,\beta,\gamma}$ and $\alpha = m-1$ or $\beta = m-1$ or $\gamma = m-1$. The smoothness conditions in (2.5) for the cases $\alpha = m-1$ and $\beta = m, \ldots, q-1$, now read as follows:

$$b_{\xi_{\beta,m,m}} = b_{\xi_{\beta,m,m-1}} + b_{\xi_{\beta,m-1,m}} - b_{\xi_{\beta,m-1,m-1}},$$

and we therefore get $b_\xi = 0$, where $\xi = \xi_{\beta,m,m},\ \beta = m, \ldots, q-1$. Analogously, we get $b_\xi = 0$, where $\xi = \xi_{m,\beta,m}$ and $\xi = \xi_{m,m,\beta},\ \beta = m+1, \ldots, q-1$, by using (2.6) and (2.7), respectively. In particular, $b_\xi = 0$, where $\xi = \xi_{m,m,m}$, $\xi = \xi_{m,m+1,m}$, and $\xi = \xi_{m,m,m+1}$. Thus, (2.5) in the case $\alpha = m+1$ and $\beta = m$ gives $b_\xi = 0$, where $\xi = \xi_{m,m+1,m+1}$. Similarly, $b_\xi = 0$, where $\xi = \xi_{m+1,m,m+1}$ and $\xi = \xi_{m+1,m+1,m}$. The points $\xi_{m,\alpha,\alpha+1}$ and $\xi_{m,\alpha+1,\alpha},\ \alpha = m+1, \ldots, q-2$, are contained in $\mathcal{M}_2$, and therefore a similar inductive argument as above involving the smoothness conditions in (2.5) for the case $\beta = m$ now shows that $b_\xi = 0$, where $\xi = \xi_{m,\alpha,\alpha},\ \alpha = m+2, \ldots, q-1$. Similarly, $b_\xi = 0$, where $\xi = \xi_{\alpha,m,\alpha}$ and $\xi = \xi_{\alpha,\alpha,m},\ \alpha = m+2, \ldots, q-1$. The choice of the remaining points in $\mathcal{M}_2$ now shows that the assertion holds true for m.

We conclude that $b_\xi = 0$ for all domain points ξ which lie in the interior of Q.

It remains to consider the coefficients associated with points on the right, back, and top face of Q. By using the conditions in (2.5)–(2.7) in the case $\alpha = 0$ and $\beta = q$, we can see that $b_\xi = 0$, where $\xi = \xi_{q,1,1},\ \xi = \xi_{1,q,1}$, and $\xi = \xi_{1,1,q}$. The points $\xi_{q,\alpha,\alpha+1}$ and $\xi_{q,\alpha+1,\alpha},\ \alpha = 1, \ldots, q-2$, are contained in $\mathcal{M}_3$, and therefore a similar inductive argument as above involving the smoothness conditions in (2.5) for the case $\beta = q$ now shows that $b_\xi = 0$, where $\xi = \xi_{q,\alpha,\alpha},\ \alpha = 1, \ldots, q-1$. Similarly, $b_\xi = 0$, where $\xi = \xi_{\alpha,q,\alpha}$ and $\xi = \xi_{\alpha,\alpha,q},\ \alpha = 1, \ldots, q-1$. Now, we consider (2.5) in the cases $\alpha = q-1$ and $\beta = 1, \ldots, q-1$, i.e.,

$$b_{\xi_{\beta,q,q}} = b_{\xi_{\beta,q,q-1}} + b_{\xi_{\beta,q-1,q}} - b_{\xi_{\beta,q-1,q-1}}.$$

As one can see from the above, the coefficients on the right of this equation are zero, and hence we have $b_\xi = 0$, where $\xi = \xi_{\beta,q,q},\ \beta = 1, \ldots, q-1$. Similarly, $b_\xi = 0$, where $\xi = \xi_{q,\beta,q}$ and $\xi = \xi_{q,q,\beta},\ \beta = 1, \ldots, q-1$. Finally, (2.11) gives

$$b_{\xi_{q,q,q}} = b_{\xi_{q,q-1,q-1}} + b_{\xi_{q-1,q,q-1}} + b_{\xi_{q-1,q-1,q}} - 2\, b_{\xi_{q-1,q-1,q-1}} = 0,$$

and we conclude that $s = 0$. This proves the theorem. □

We close this section with an explicit example.

Example 4.4. The space $\mathcal{S}_2^1(\Delta_Q)$ is 13-dimensional. In Figure 6 we show the MDS $\mathcal{M}_Q$ with coefficients $a_i,\ i = 0, \ldots, 12$. The remaining coefficients $b_i,\ i = 0, \ldots, 13$, are uniquely determined as follows:

$$\begin{aligned}
b_0 &= -a_0 + a_1 + a_5, & b_1 &= a_0 - a_1 - a_5 + a_7 + a_8,\\
b_2 &= -a_0 + a_3 + a_5, & b_3 &= a_0 - a_3 - a_5 + a_9 + a_{10},\\
b_4 &= -a_0 + a_1 + a_3, & b_5 &= a_0 - a_1 - a_3 + a_{11} + a_{12},\\
b_6 &= -2a_0 + a_1 + a_3 + a_5, & b_7 &= -a_2 + a_7 + a_{11},\\
b_8 &= -a_4 + a_{10} + a_{12}, & b_9 &= -a_6 + a_8 + a_9,\\
b_{10} &= 2a_0 - a_1 - a_2 - a_3 - a_4 - a_5 + a_7 + a_{10} + a_{11} + a_{12},\\
b_{11} &= 2a_0 - a_1 - a_3 - a_4 - a_5 - a_6 + a_8 + a_9 + a_{10} + a_{12},\\
b_{12} &= 2a_0 - a_1 - a_2 - a_3 - a_5 - a_6 + a_7 + a_8 + a_9 + a_{11},\\
b_{13} &= 4a_0 - 2a_1 - a_2 - 2a_3 - a_4 - 2a_5 - a_6 + a_7 + a_8 + a_9 + a_{10} + a_{11} + a_{12}.
\end{aligned}$$

5. An MDS for $\mathcal{S}_q^1(\Delta)$ and proof of main result. We construct an MDS $\mathcal{M}$ for $\mathcal{S}_q^1(\Delta)$, where Δ is a Freudenthal partition obtained from n^3 cubes $Q_{(i,j,k)},\ i,j,k =$

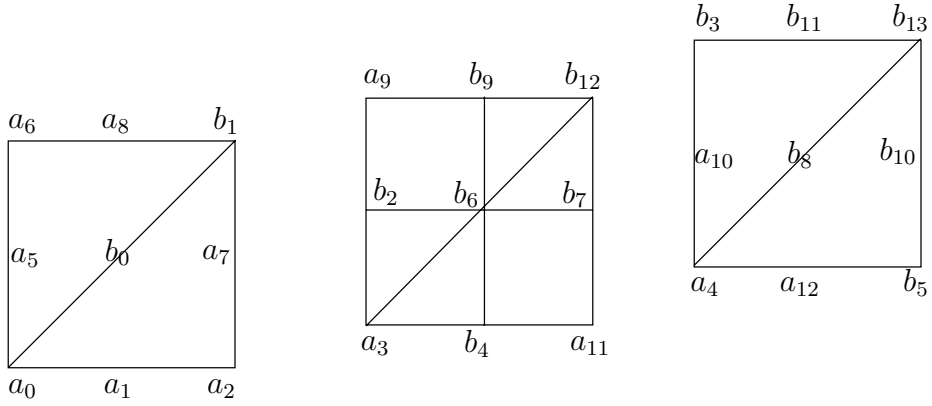

FIG. 6. *Illustration of the case of quadratic C^1 splines on Δ_Q. The points associated with the coefficients a_i, $i = 0, \ldots, 12$, are an MDS for this space.*

$1, \ldots, n$, (see section 2). To do this, we use the results from the previous section. In particular, we use Theorem 4.3 dealing with the case $n = 1$, which shows that $\mathcal{M}_Q$ is an MDS for $\mathcal{S}_q^1(\Delta_Q)$, where $Q = Q_{(1,1,1)}$. In the following, we define $\mathcal{M}$. To do this, we need three auxiliary sets $\mathcal{A}_{(i,j,k)}$, $\mathcal{B}_{(i,j,k)}$, $\mathcal{C}_{(i,j,k)}$, which are based on the construction of $\mathcal{M}_Q$. For $i, j, k = 1, \ldots, n$, we let

$$\mathcal{M}_{(i,j,k)} \;=\; \{\xi \in \mathcal{D}_{q,Q_{(i,j,k)}} : \xi - (i-1, j-1, k-1) \in \mathcal{M}_Q\} \tag{5.1}$$

be the "shifted versions" of the set $\mathcal{M}_Q$. Then, we let

$$\begin{aligned}
\mathcal{A}_{(i,j,k)} &= \{\xi_{\alpha,\beta,\gamma} \in \mathcal{M}_{(i,j,k)} :\ \alpha \geq 2\},\\
\mathcal{B}_{(i,j,k)} &= \{\xi_{\alpha,\beta,\gamma} \in \mathcal{M}_{(i,j,k)} :\ \beta \geq 2\},\\
\mathcal{C}_{(i,j,k)} &= \{\xi_{\alpha,\beta,\gamma} \in \mathcal{M}_{(i,j,k)} :\ \gamma \geq 2\},
\end{aligned}$$

for all $i, j, k = 1, \ldots, n$, where here and in the following for simplicity, we set

$$\xi_{\alpha,\beta,\gamma} := \xi_{\alpha,\beta,\gamma}^{Q_{(i,j,k)}} \in \mathcal{D}_{q,Q_{(i,j,k)}}, \qquad \alpha, \beta, \gamma = 0, \ldots, q.$$

Roughly speaking, $\mathcal{A}_{(i,j,k)}$ consists of all domain points in $Q_{(i,j,k)}$, which are not contained or in distance one to the two triangles which form the left square face of $Q_{(i,j,k)}$. Similarly, $\mathcal{B}_{(i,j,k)}$ and $\mathcal{C}_{(i,j,k)}$ consist of all points in $\mathcal{D}_{q,Q_{(i,j,k)}}$, which are not contained or in distance one to the two triangles which form the front and bottom square face of $Q_{(i,j,k)}$, respectively. Now, we define

$$\begin{aligned}
\mathcal{M} = \mathcal{M}_{(1,1,1)} &\cup \bigcup_{i=2}^{n} \Big[\mathcal{A}_{(i,1,1)} \cup \mathcal{B}_{(1,i,1)} \cup \mathcal{C}_{(1,1,i)}\Big]\\
&\cup \bigcup_{i,j=2}^{n} \Big[\big(\mathcal{A}_{(i,j,1)} \cap \mathcal{B}_{(i,j,1)}\big) \cup \big(\mathcal{A}_{(i,1,j)} \cap \mathcal{C}_{(i,1,j)}\big) \cup \big(\mathcal{B}_{(1,i,j)} \cap \mathcal{C}_{(1,i,j)}\big)\Big]\\
&\cup \bigcup_{i,j,k=2}^{n} \Big[\mathcal{A}_{(i,j,k)} \cap \mathcal{B}_{(i,j,k)} \cap \mathcal{C}_{(i,j,k)}\Big].
\end{aligned}$$

The next theorem particuarly shows that Theorem 3.1 holds true.

THEOREM 5.1. *Let Δ be a Freudenthal partition. Then, $\mathcal{M}$ is an MDS for $\mathcal{S}_q^1(\Delta)$ and the cardinality of $\mathcal{M}$ coincides with the number in* (3.1).

Proof. Let $q \geq 2$ and arbitrary coefficients $b_\xi = b_\xi(s),\ \xi \in \mathcal{M}$, of a spline $s \in \mathcal{S}_q^1(\Delta)$, be given. We first have to show that the remaining coefficients of s, i.e., the coefficients in $\mathcal{D}_q(\Delta) \setminus \mathcal{M}$, are uniquely determined, while all C^1 smoothness conditions described in Lemma 2.2 are satisfied.

Our method of proof is to show inductively that the coefficients $b_\xi,\ \xi \in \mathcal{D}_{q,Q_{(i,j,k)}}$, are uniquely determined for $i,j,k = 1,\dots,n$, where we use Theorem 4.3 and pass through the cubes $Q_{(i,j,k)}$ in an appropriate order. This natural order is as follows. First, we consider $(i,1,1),\ i = 1,\dots,n$. Then, we consider $(1,i,1)$ and $(1,1,i),\ i = 2,\dots,n$. Here, we have to take the C^1 continuity across exactly one square face of the cubes into account. We proceed by considering $(i,j,1)$, $(i,1,j)$, and $(1,i,j),\ i,j = 2,\dots,n$. Now, we have to take the C^1 continuity across exactly two square faces of the cube (which have a common edge) into account. Finally, we consider $(i,j,k),\ i,j,k = 2,\dots,n$. This is the most difficult situation, where we have to take the C^1 continuity across exactly three square faces of the cubes (which have a common point) into account.

Since $\mathcal{M}_{(1,1,1)} = \mathcal{M}_Q \subseteq \mathcal{M}$, it follows from Theorem 4.3 that all the coefficients b_ξ, where $\xi \in \mathcal{D}_{q,Q_{(1,1,1)}}$, are uniquely determined. Now, we consider the cube $Q_{(2,1,1)}$. This cube has exactly one square face in common with $Q_{(1,1,1)}$. This square face contains two triangular faces. Obviously, the coefficients associated with domain points within these triangular faces are uniquely determined. Moreover, since the coefficients b_ξ, where $\xi \in \{\xi_{q-1,\alpha,\beta},\ \xi_{q,\alpha,\beta},\ \xi_{q,\alpha+1,\beta+1}\} \subseteq \mathcal{D}_{q,Q_{(1,1,1)}}$, are uniquely determined, it follows from the smoothness conditions in (2.8) that the coefficients b_ξ, where $\xi = \xi_{1,\alpha+1,\beta+1} \in \mathcal{D}_{q,Q_{(2,1,1)}},\ \alpha,\beta = 0,\dots,q-1$, are determined. Note that an elementary computation shows that the conditions (2.5) for $\beta = 1$ and $\alpha = 1,\dots,q-1$ (w.r.t. $Q_{(2,1,1)}$) are automatically satisfied, and therefore the above coefficients are also uniquely determined. In particular, the coefficients b_ξ, where $\xi = \xi_{1,\beta,1}$ and $\xi = \xi_{1,1,\beta},\ \beta = 1,\dots,q$, are uniquely determined. The smoothness conditions (2.6) and (2.7) for $\alpha = 0$ (w.r.t. $Q_{(2,1,1)}$) now imply that the coefficients b_ξ, where $\xi = \xi_{1,\beta,0}$ and $\xi = \xi_{1,0,\beta},\ \beta = 1,\dots,q$, respectively, are uniquely determined. Finally, we use some elementary computations to show that an application of the smoothness condition (2.5) for $\alpha = 0$ and $\beta = 1$, as well as the smoothness conditions (2.6) and (2.7) for $\alpha = 0$ and $\beta = 0$, respectively, give the same value for the coefficient $b_{\xi_{1,0,0}}$, which is therefore uniquely determined. The choice of $\mathcal{A}_{(2,1,1)} \subseteq \mathcal{M}$ and an argumentation along the lines of the proof of Theorem 4.3 now show that all the coefficients b_ξ, where $\xi \in \mathcal{D}_{q,Q_{(2,1,1)}}$ are uniquely determined, while the smoothness conditions (2.8) for $i = 1,\ j = 1,\ k = 1$, and (2.5)–(2.7) for $i = 2,\ j = 1,\ k = 1$, are satisfied. It now follows from induction, the choice of points in $\mathcal{A}_{(i,1,1)} \cup \mathcal{B}_{(1,i,1)} \cup \mathcal{C}_{(1,1,i)} \subseteq \mathcal{M}$, and the same arguments that b_ξ is uniquely determined if $\xi \in \mathcal{D}_{q,Q_{(i,1,1)}} \cup \mathcal{D}_{q,Q_{(1,i,1)}} \cup \mathcal{D}_{q,Q_{(1,1,i)}}$, where $i = 2,\dots,n$.

Next, we consider the cube $Q_{(2,2,1)}$. According to the above ordering, this cube has exactly two square faces in common with some of the cubes considered before, namely, the cubes $Q_{(1,2,1)}$ and $Q_{(2,1,1)}$. It follows from the above that the coefficients associated with domain points in the triangular faces within these squares are uniquely determined. Moreover, since the coefficients b_ξ, where $\xi \in \{\xi_{q-1,\alpha,\beta},\ \xi_{q,\alpha,\beta},\ \xi_{q,\alpha+1,\beta+1}\} \subseteq \mathcal{D}_{q,Q_{(1,2,1)}}$ and $\xi \in \{\xi_{\alpha,q-1,\beta},\ \xi_{\alpha,q,\beta},\ \xi_{\alpha+1,q,\beta+1}\} \subseteq \mathcal{D}_{q,Q_{(2,1,1)}}$, are uniquely determined, it follows from the smoothness conditions in (2.8) and (2.9) that the coefficients b_ξ, where $\xi \in \{\xi_{1,\alpha+1,\beta+1},\ \xi_{\alpha+1,1,\beta+1}\} \subseteq \mathcal{D}_{q,Q_{(2,2,1)}},\ \alpha,\beta = 0,\dots,q-1$, are uniquely determined. In particular, the smoothness conditions (2.5) and (2.6) for

$\beta = 1$ and $\alpha = 0, \ldots, q-1$ (w.r.t. $Q_{(2,2,1)}$) are automatically satisfied, which can be seen by performing some elementary computations. Moreover, we note that the coefficients of the form b_ξ, where $\xi = \xi_{1,1,\beta},\ \beta = 0, \ldots, q$, are uniquely determined, since the spline s and its (three) first partial derivatives are already uniquely determined along the common edge of $Q_{(1,2,1)}$ and $Q_{(2,1,1)}$. An argument as above shows that the coefficients b_ξ, where $\xi = \xi_{1,\beta,0}$ and $\xi = \xi_{\beta,1,0},\ \beta = 1, \ldots, q$, respectively, are uniquely determined. The choice of $\mathcal{A}_{(2,2,1)} \cap \mathcal{B}_{(2,2,1)} \subseteq \mathcal{M}$ and an argumentation along the lines of the proof of Theorem 4.3 now show that all the coefficients b_ξ, where $\xi \in \mathcal{D}_{q,Q_{(2,2,1)}}$, are uniquely determined, while the smoothness conditions (2.8) for $i = 1,\ j = 2,\ k = 1$, (2.9) for $i = 2,\ j = 1,\ k = 1$, and (2.5)–(2.7) for $i = 2,\ j = 2,\ k = 1$ are satisfied. It now follows from induction, the choice of points in $\big(\mathcal{A}_{(i,j,1)} \cap \mathcal{B}_{(i,j,1)}\big) \cup \big(\mathcal{A}_{(i,1,j)} \cap \mathcal{C}_{(i,1,j)}\big) \cup \big(\mathcal{B}_{(1,i,j)} \cap \mathcal{C}_{(1,i,j)}\big) \subseteq \mathcal{M}$, and the same arguments that b_ξ is uniquely determined if $\xi \in \mathcal{D}_{q,Q_{(i,j,1)}} \cup \mathcal{D}_{q,Q_{(i,1,j)}} \cup \mathcal{D}_{q,Q_{(1,i,j)}}$, where $i, j = 2, \ldots, n$.

Finally, we consider the cube $Q_{(2,2,2)}$. According to the above ordering, this cube has exactly three square faces in common with cubes already considered, namely, the common faces with the cubes $Q_{(1,2,2)},\ Q_{(2,1,2)}$, and $Q_{(2,2,1)}$. It follows from the above that the coefficients associated with domain points in the triangular faces within these squares are uniquely determined. Moreover, since the coefficients b_ξ, where $\xi \in \{\xi_{q-1,\alpha,\beta},\ \xi_{q,\alpha,\beta},\ \xi_{q,\alpha+1,\beta+1}\} \subseteq \mathcal{D}_{q,Q_{(1,2,2)}}$, $\xi \in \{\xi_{\alpha,q-1,\beta},\ \xi_{\alpha,q,\beta},\ \xi_{\alpha+1,q,\beta+1}\} \subseteq \mathcal{D}_{q,Q_{(2,1,2)}}$, and $\xi \in \{\xi_{\alpha,\beta,q-1},\ \xi_{\alpha,\beta,q},\ \xi_{\alpha+1,\beta+1,q}\} \subseteq \mathcal{D}_{q,Q_{(2,2,1)}}$, are uniquely determined, it follows from the smoothness conditions in (2.8)–(2.10) that the coefficients b_ξ, where $\xi \in \{\xi_{1,\alpha+1,\beta+1},\ \xi_{\alpha+1,1,\beta+1},\ \xi_{\alpha+1,1,\beta+1}\} \subseteq \mathcal{D}_{q,Q_{(2,2,2)}}$, $\alpha, \beta = 0, \ldots, q-1$, are uniquely determined. In particular, the smoothness conditions (2.5)–(2.7) for $\beta = 1$ and $\alpha = 0, \ldots, q-1$ (w.r.t. $Q_{(2,2,2)}$) are automatically satisfied, which can be seen by performing some elementary computations. Moreover, we note that the coefficients of the form b_ξ, where $\xi \in \{\xi_{1,1,\beta},\ \xi_{1,\beta,1},\ \xi_{\beta,1,1}\},\ \beta = 0, \ldots, q$, are uniquely determined, since the spline s and its (three) first partial derivatives are already uniquely determined along the common edge of each pair of the cubes $Q_{(1,2,2)},\ Q_{(2,1,2)}$ and $Q_{(2,2,1)}$. The choice of $\mathcal{A}_{(2,2,2)} \cap \mathcal{B}_{(2,2,2)} \cap \mathcal{C}_{(2,2,2)} \subseteq \mathcal{M}$ and an argumentation along the lines of the proof of Theorem 4.3 now show that all the coefficients b_ξ, where $\xi \in \mathcal{D}_{q,Q_{(2,2,2)}}$, are uniquely determined, while the smoothness conditions (2.8) for $i = 1,\ j = 2,\ k = 2$, (2.9) for $i = 2,\ j = 1,\ k = 2$, (2.10) for $i = 2,\ j = 2,\ k = 1$, and (2.5)–(2.7) for $i = 2,\ j = 2,\ k = 2$ are satisfied. It now follows from induction, the choice of points in $\mathcal{A}_{(i,j,k)} \cap \mathcal{B}_{(i,j,k)} \cap \mathcal{B}_{(i,j,k)} \subseteq \mathcal{M}$ and the same arguments that b_ξ is uniquely determined if $\xi \in \mathcal{D}_{q,Q_{(i,j,k)}}$, where $i, j, k = 2, \ldots, n$.

This shows that all the coefficients of s are uniquely determined, while all the C^1 smoothness conditions described in Lemma 2.2 are satisfied. To complete the proof, we have to count the number of points in $\mathcal{M}$ and have to show that the cardinality of this set coincides with the number in (3.1).

Lemma 4.1 and Theorem 4.3 show that the set $\mathcal{M}_{(1,1,1)} = \mathcal{M}_Q$ contains $q^3+2\,q+1$ domain points, and it is obvious that this is also the number of points in every set $\mathcal{M}_{(i,j,k)}$ defined in (5.1), where $i, j, k = 1, \ldots, n$. Since the cardinality of $\mathcal{M}_{(2,1,1)} \setminus \mathcal{A}_{(2,1,1)}$ is $2\,q^2+2$, it follows that $\mathcal{A}_{(2,1,1)}$ contains $q^3-2\,q^2+2\,q-1$ domain points. The same number of points are contained in each of the sets $\mathcal{A}_{(i,1,1)},\ \mathcal{B}_{(1,i,1)}$, and $\mathcal{C}_{(1,1,i)},\ i = 2, \ldots, n$. The cardinality of $\mathcal{M}_{(2,2,1)} \setminus (\mathcal{A}_{(2,2,1)} \cap \mathcal{B}_{(2,2,1)})$ is $4\,q^2-3\,q+3$, and therefore $q^3-4\,q^2+5\,q-2$ domain points are contained in $\mathcal{A}_{(2,1,1)} \cap \mathcal{B}_{(2,2,1)}$. The same number of points are contained in each of the sets $\mathcal{A}_{(i,j,1)} \cap \mathcal{B}_{(i,j,1)},\ \mathcal{A}_{(i,1,j)} \cap \mathcal{C}_{(i,1,j)}$, and $\mathcal{B}_{(1,i,j)} \cap \mathcal{C}_{(1,i,j)},\ i, j = 2, \ldots, n$. Since the cardinality of $\mathcal{M}_{(2,2,2)} \setminus (\mathcal{A}_{(2,2,2)} \cap$

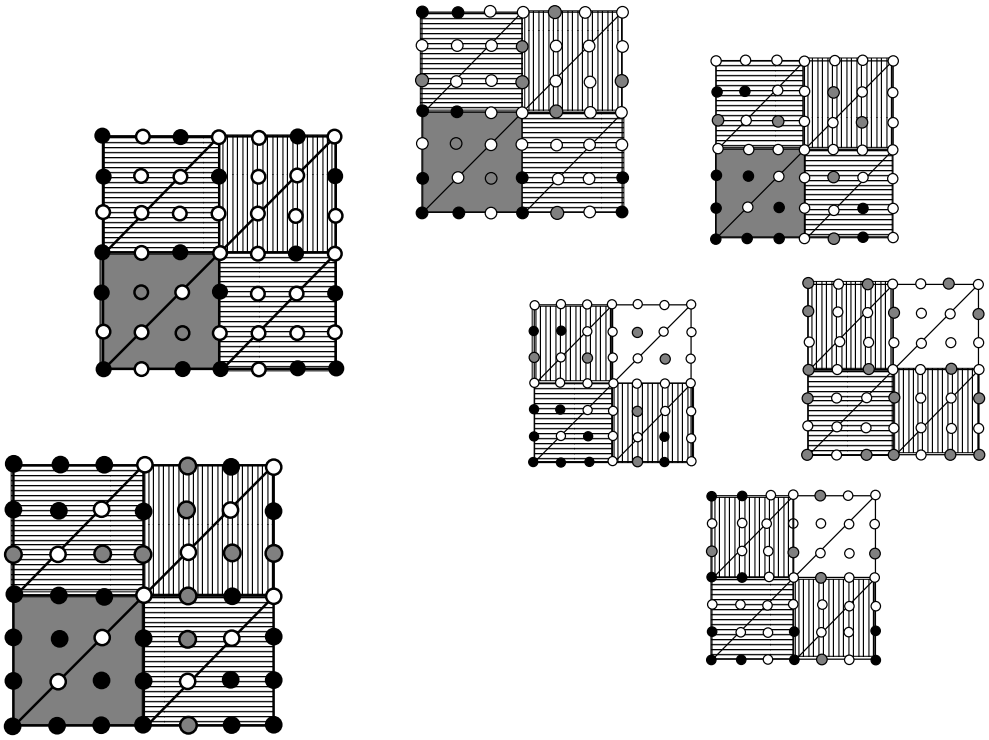

FIG. 7. *The MDS $\mathcal{M}$ for $n = 2$ in the case $q = 3$.*

$\mathcal{B}_{(2,2,2)} \cap \mathcal{C}_{(2,2,2)}$) is $6\ q^2 - 9\ q + 7$, it follows that $\mathcal{A}_{(2,2,2)} \cap \mathcal{B}_{(2,2,2)} \cap \mathcal{C}_{(2,2,2)}$ contains $q^3 - 6\ q^2 + 11\ q - 6$ domain points. The same number of points are contained in each of the sets $\mathcal{A}_{(i,j,k)} \cap \mathcal{B}_{(i,j,k)} \cap \mathcal{C}_{(i,j,k)},\ i, j, k = 2, \ldots, n$. We conclude that the total number of points in $\mathcal{M}$ is equal to

$$(q^3 + 2\ q + 1) + 3\ (n-1)\ (q^3 - 2\ q^2 + 2\ q - 1)$$
$$+3\ (n-1)^2\ (q^3 - 4\ q^2 + 5\ q - 2) + (n-1)^3\ (q^3 - 6\ q^2 + 11\ q - 6).$$

Some elementary computations now show that this is the number in (3.1). The proof is complete. □

Example 5.2. Figures 7 and 8 show examples for the MDS $\mathcal{M}$ for $n = 2$ in the cases $q = 3$ and $q = 4$, respectively. The figures show the different layers of domain points in a front to back manner, i.e., inside the planes $y = \ell/q,\ \ell = 0, \ldots, 2q$, organized in a spiral, where the different sizes of the layers indicate the distances to the front. The points from the set $\mathcal{M}$ are marked by black dots, the domain points associated with coefficients which are removed from $\mathcal{M}_{(i,j,k)}$ are marked by grey dots, while the remaining domain points determined by the various smoothness conditions are marked by white dots. The dimension of the spline spaces $\mathcal{S}_3^1(\Delta)$ and $\mathcal{S}_4^1(\Delta)$ in these examples are 88 and 250, respectively. In the proof of Theorem 5.1, the different cubes are considered in the order illustrated by the different symbols: grey, horizontally stripped, vertically stripped, and white.

6. Remarks. We close the paper with some remarks on possible extensions of our approach and discuss the differences to other spline spaces.

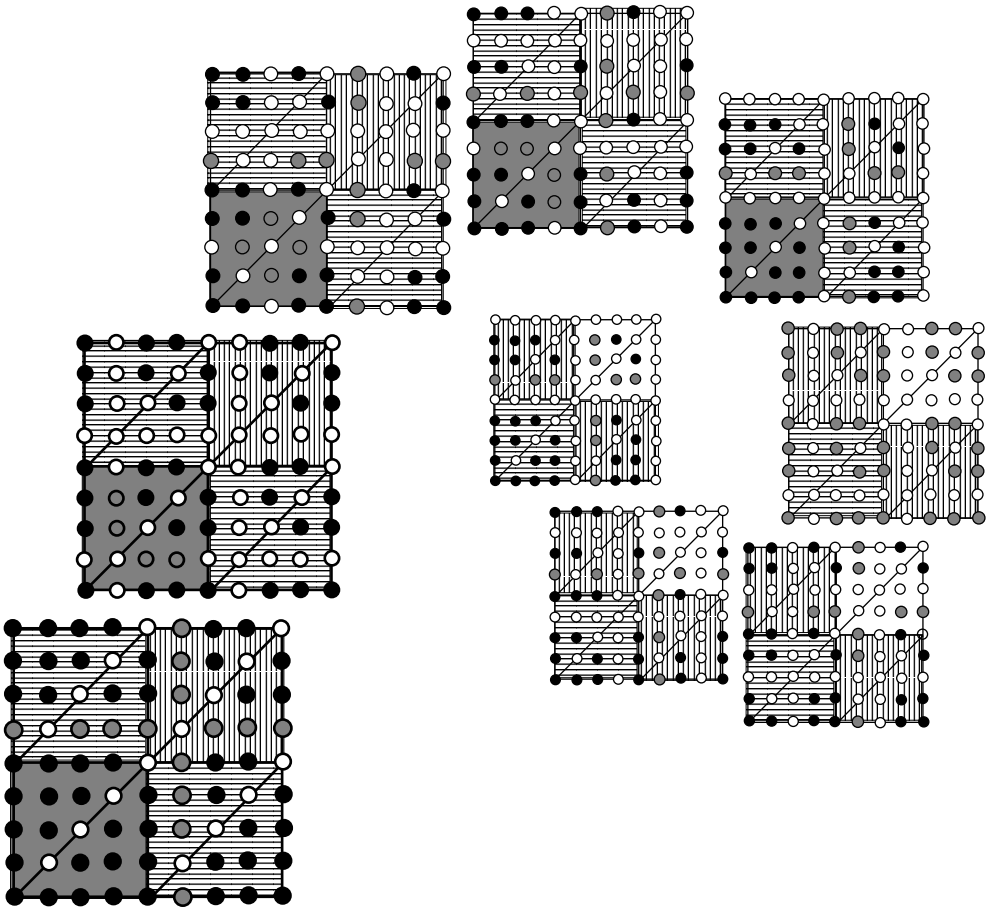

FIG. 8. *The MDS $\mathcal{M}$ for $n = 2$ in the case $q = 4$.*

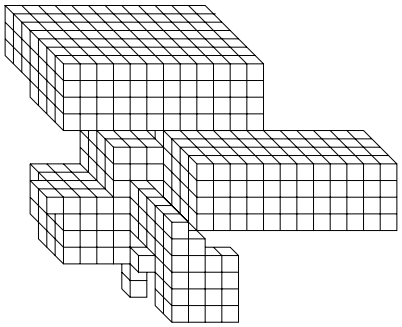

FIG. 9. *A more general domain Ω, where the inductive arguments of the proof of Theorem* 5.1 *can be applied.*

Remark 6.1. Our main results, Theorem 3.1 and Theorem 5.1, can be extended to more general partitions on different domains. An example for such a uniform cube partition is shown in Figure 9. Other examples of such domains are obtained from rectangular cube partitions, where there are n_j cubes with edge lengths 1 in the jth space direction, $j = 1, 2, 3$. In this case, the total number of cubes is equal to $n_1 n_2 n_3$

and the dimension of the corresponding C^1 spline space is given by

$$6\binom{q-1}{3} n_1n_2n_3 + 4\binom{q-1}{2}(n_1n_2 + n_1n_3 + n_2n_3) + 3\binom{q-1}{1}(n_1 + n_2 + n_3) + 4.$$

Moreover, we observe that the spacing in each direction does not need to be uniform, i.e., our arguments still hold when we start from a partition $\diamondsuit$, where $Q_{(i,j,k)} = [x_{i-1}, x_i] \times [y_{j-1}, y_j] \times [z_{k-1}, z_k]$, with $x_{i-1} < x_i,\ i = 1, \ldots, n_1,\ y_{j-1} < y_j,\ j = 1, \ldots, n_2, z_{k-1} < z_k,\ k = 1, \ldots, n_3$. However, in this case, the smoothness conditions of the spaces can no longer be described by one single formula as in Lemma 2.2. More precisely, one has to distinguish two cases: smoothness conditions across triangular faces for tetrahedra in different boxes involve different weights (barycentric coordinates evaluated at $\tilde{v}_3$), while smoothness conditions across triangular faces inside a box remain the same. In both cases, the smoothness conditions are still all of bivariate type, and our arguments hold for these more general partitions. However, in order to avoid complicated notations, we consider the uniform case, only. Moreover, we observe that C^r splines, $r \geq 2$, on Freudenthal partitions lead to more complex spline spaces, since the smoothness conditions are much more involved.

Remark 6.2. Since the trivariate splines we consider here are defined on a tetrahedral partition of a uniform grid, it is possible to compare them with different spline methods, which require the same grid, namely, approaches based on *tensor-product splines* and *box-splines*. First, we observe that the dimension of the trivariate splines is much larger than that of the tensor-product splines of the same total degree. For instance, tensor-product C^1 splines of lowest possible total degree are quadratic tensor-product splines (sometimes called triquadratic splines) and form a n^3+12n^2+6n+8-dimensional subspace of $\mathcal{S}_6^1(\Delta)$. Hence, using the full space $\mathcal{S}_6^1(\Delta)$ instead provides some additional flexibility, since its complete number of degrees of freedom is according to our result $60n^3 + 120n^2 + 45n + 4$. More generally, if tensor-product spline spaces exist, i.e., q is divisible by three, then we can understand these spaces as simple subspaces of $\mathcal{S}_q^1(\Delta)$ possessing a huge number of (unnecessary) supersmoothness conditions. This has also consequences for the approximation order, which for these subspaces is known to be not higher than $q/3 + 1 << q + 1$. A different approach is based on box-splines (see de Boor, Höllig and Riemenschneider [10]). These are piecewise polynomial functions of a certain degree and smoothness on uniform partitions with a local support which are usually defined as in Chui [12]. Most of the papers on these splines deal with the bivariate setting (see, for instance, de Boor and Höllig [9]), and it is known that box-splines may form a subspace or even a linearly dependent set of spline functions (see, for instance, Nürnberger [24]). For (slightly) more nonuniform partitions as described in the previous remark, the box-spline constructions would have to be—at least—adjusted. Moreover, we are not aware of any work on trivariate box-splines which yields explicit results on the dimension of the *full trivariate* spline space as we develop them here. For instance, Shi and Wang [37] focused on the existence of a trivariate box-spline and particularly showed this for $\mathcal{S}_q^1(\Delta)$ iff $q \geq 4$. On the other hand, for defining approximation operators as in Hecklin, Nürnberger, Schumaker and Zeilfelder [17] and Nürnberger, Rössl, Seidel and Zeilfelder [26, 32] (see also Schlosser, Hesser, Zeilfelder, Rössl, Männer, Nürnberger, and Seidel [33]) with advantageous properties for the applications, it is often necessary to know the precise structure of the trivariate spline spaces. We are not aware of a method or a practical test based on the usage of trivariate box-splines which has a comparable algorithmic behavior as it is reported in these trivariate spline methods. Also note that the implementation of the above-mentioned operators does not require an intermediate step of constructing explicitly a basis or a set of locally sup-

ported functions (see also the discussion in [39])—taking advantage of the piecewise Bernstein–Bézier form the methods can be directly applied to the given data and the methods from computer aided geometric design can be used for the effective further treatment of the reconstructed objects. Finally concerning the development of the above-mentioned operators, our approaches using low-degree trivariate splines provide the flexibility to subdivide (some of) the tetrahedra, and can therefore often be applied to deformed grids and more general tetrahedral partitions, too.

Remark 6.3. Bivariate and trivariate C^1 splines of lowest possible degree are extremely complex spaces. For instance, it is known that the dimension of quadratic C^1 bivariate splines on the three-directional mesh essentially coincides with the degrees of freedom of univariate splines, and we particularly showed here that this property is inherited by $\mathcal{S}_2^1(\Delta)$. On the other hand, it is still possible to work with quadratic C^1 splines. We note that the special structure of the Freudenthal partitions Δ *allows* to satisfy the necessary *geometric constraints* described in Worsey and Piper [41] (see also Sorokina and Worsey [38]) to apply the *Worsey–Piper split* to each tetrahedron of Δ.

VANISHING VISCOSITY LIMIT TO RAREFACTION WAVES FOR THE NAVIER–STOKES EQUATIONS OF ONE-DIMENSIONAL COMPRESSIBLE HEAT-CONDUCTING FLUIDS*

SONG JIANG†, GUOXI NI†, AND WENJUN SUN†

Dedicated to Professor Rolf Leis on the occasion of his 75th birthday

Abstract. We prove the solution of the Navier–Stokes equations for one-dimensional compressible heat-conducting fluids with centered rarefaction data of small strength exists globally in time, and moreover, as the viscosity and heat-conductivity coefficients tend to zero, the global solution converges to the centered rarefaction wave solution of the corresponding Euler equations uniformly away from the initial discontinuity.

Key words. compressible Navier–Stokes equations, vanishing viscosity limit, rarefaction waves, Euler equations

1. Introduction and the main result.

We study the asymptotic behavior, as the viscosity and heat-conductivity go to zero, of solutions to the Cauchy problem for the Navier–Stokes equations for a one-dimensional (1-d) compressible heat-conducting fluid (in Lagrangian coordinates):

$$\begin{cases} v_t - u_x = 0, \\ u_t + p_x = \epsilon\Big(\dfrac{u_x}{v}\Big)_x, \\ \Big(e + \dfrac{u^2}{2}\Big)_t + (up)_x = \Big(\kappa\dfrac{\theta_x}{v} + \epsilon\dfrac{uu_x}{v}\Big)_x \end{cases} \tag{1.1}$$

with (discontinuous) initial data

$$(u, v, e)(x, 0) = (u_0, v_0, e_0)(x), \qquad x \in \mathbb{R}, \tag{1.2}$$

where $v, u, \theta, p = p(e, v)$ and e denote the specific volume, the velocity, the temperature, the pressure, and the internal energy, respectively, and ϵ, κ are the viscosity and heat-conductivity coefficients, respectively. At infinity, the initial data u_0, v_0, e_0 are assumed to satisfy

$$\lim_{x\to\pm\infty}(u_0, v_0, e_0)(x) = (u_\pm, v_\pm, e_\pm), \tag{1.3}$$

where $u_\pm$,$v_\pm$ and $e_\pm$ are given constant states.

The system (1.1), describing the motion of the fluid, are the conservation laws of mass, momentum, and energy.

The asymptotic behavior of viscous flows, as the viscosity vanishes, is one of the important topics in the theory of compressible flows. It is expected that a general weak entropy solution to the Euler equations should be a (strong) limit of solutions to the corresponding Navier–Stokes equations with the same initial data as the viscosity and heat-conductivity tend to zero.

For the 1-d compressible isentropic Navier–Stokes equations

$$\begin{cases} v_t - u_x = 0, \\ u_t + p(v)_x = \epsilon\Big(\dfrac{u_x}{v}\Big)_x, \end{cases} \tag{1.4}$$

and the corresponding inviscid p-system

$$\begin{cases} v_t - u_x = 0, \\ u_t + p(v)_x = 0, \end{cases} \tag{1.5}$$

the vanishing viscosity limit for the Cauchy problem has been studied by several researchers. In [7] DiPerna uses the method of compensated compactness and establishes a.e. convergence of admissible solutions (u^ϵ, v^ϵ) of (1.4) to an admissible solution of (1.5), provided that (u^ϵ, v^ϵ) is uniformly L^∞ bounded and v^ϵ is uniform bounded away from zero. However, this uniform boundedness is difficult to verify in general, and the abstract analysis in [7] gets little information on the qualitative nature of the viscous solutions. In [14] Hoff and Liu investigate the inviscid limit problem for (1.4) in the case that the underlying inviscid flow is a single weak shockwave, and they show that solutions of the compressible Navier–Stokes equations with shock data exist and converge to the inviscid shocks, as viscosity vanishes, uniformly away from the shocks. Based on [9, 14], Xin in [30] shows that the solution to the Cauchy problem for the system (1.4) with weak centered rarefaction wave data exists for all time and converges to the weak centered rarefaction wave solution of the corresponding Euler equations, as the viscosity tends to zero, uniformly away from the initial discontinuity. Moreover, for a given centered rarefaction wave to the Euler equations with finite strength, he constructs a viscous solution to the compressible Navier–Stokes system with initial data depending on the viscosity, such that the viscous solution approaches the centered rarefaction wave as the viscosity goes to zero at the rate $|\ln\epsilon|\epsilon^{1/4}$ uniformly for all time away from $t = 0$. In the vanishing viscosity limit, the Prandtl boundary layers (characteristic boundaries) are studied for the multidimensional linearized compressible Navier–Stokes equations by using asymptotic analysis in [31, 32, 29], while the boundary layer stability in the case of noncharacteristic boundaries and one spatial dimension is discussed in [26, 23]. We mention that there is extensive literature on the vanishing artificial viscosity limit for hyperbolic systems of conservation laws; see, for example, [7, 8, 6, 9, 18, 17, 33, 10, 25, 3, 11, 12, 1], also cf. the monographs [2, 5, 24] and the references therein. We also mention that the convergence of the 1-d Broadwell model and the relaxation limit of a rate-type viscoelastic system to the isentropic Euler equations with centered rarefaction wave initial data are studied in [28, 15], respectively.

Our aim in this paper is to study the relation between the solution $(u^\epsilon, v^\epsilon, e^\epsilon)(x,t)$ of the Navier–Stokes equations for a compressible heat-conducting fluid (1.1) and the solution $(u, v, e)(x,t)$ of the corresponding inviscid Euler equations:

$$\begin{cases} v_t - u_x = 0, \\ u_t + p_x = 0, \\ \Big(e + \dfrac{u^2}{2}\Big)_t + (up)_x = 0 \end{cases} \tag{1.6}$$

with the initial data

$$(u,v,e)(x,0)=(\tilde{u}_0,\tilde{v}_0,\tilde{e}_0)(x),\qquad x\in\mathbb{R}, \tag{1.7}$$

satisfying

$$\lim_{x\to\pm\infty}(\tilde{u}_0,\tilde{v}_0,\tilde{e}_0)(x)=(u_\pm,v_\pm,e_\pm) \tag{1.8}$$

with the same constant states $(u_\pm,v_\pm,e_\pm)$ as in (1.3).

It is convenient to work with the equations for the entropy s and the absolute temperature θ. The second law of thermodynamics asserts that

$$\theta ds=de+pdv.$$

We assume, as is customary in thermodynamics, that given any two of the thermodynamics variables ρ,e,θ,s, and p, we can obtain the remaining three variables. If we choose (v,θ) as independent variables and write $(p,e,s)=(p,e,s)(v,\theta)$, we deduce that

$$s_v(v,\theta)=p_\theta(v,\theta),\quad s_\theta(v,\theta)=\frac{e_\theta(v,\theta)}{\theta},\quad e_v(v,\theta)=\theta p_\theta(v,\theta)-p(v,\theta).$$

Then, a straightforward calculation gives

$$s_t=\kappa\Big(\frac{\theta_x}{v\theta}\Big)_x+\kappa\frac{\theta_x^2}{v\theta^2}+\epsilon\frac{u_x^2}{v\theta}, \tag{1.9}$$

$$\theta_t+\frac{\theta p_\theta(v,\theta)}{e_\theta(v,\theta)}u_x=\frac{\kappa}{e_\theta(v,\theta)}\Big(\frac{\theta_x}{v}\Big)_x+\frac{\epsilon}{e_\theta(v,\theta)}\frac{u_x^2}{v}. \tag{1.10}$$

We may also choose (v,s) as independent variables and write

$$p=p(v,s),\quad \theta=\theta(v,s).$$

Thus, instead of (1.1), we shall study the system $(1.1)_1$, $(1.1)_2$, and (1.9), or $(1.1)_1$, $(1.1)_2$, and (1.10). Namely, we shall consider

$$\begin{cases} v_t-u_x=0,\\ u_t+p(v,s)_x=\epsilon\Big(\dfrac{u_x}{v}\Big)_x,\\ s_t=\kappa\Big(\dfrac{\theta_x}{v\theta}\Big)_x+\kappa\dfrac{\theta_x^2}{v\theta^2}+\epsilon\dfrac{u_x^2}{v\theta}, \end{cases} \tag{1.11}$$

with initial data

$$(u,v,s)(x,0)=(u_0,v_0,s_0)(x)=\begin{cases}(u_-,v_-,s_-), & x<0,\\ (u_+,v_+,s_+), & x>0,\end{cases} \tag{1.12}$$

where $u_\pm,v_\pm$ and $s_\pm$ are the constant states. The corresponding inviscid Euler equations read as

$$\begin{cases} v_t-u_x=0,\\ u_t+p(v,s)_x=0,\\ s_t=0. \end{cases} \tag{1.13}$$

We assume in this paper that the pressure p is a smooth function of its arguments satisfying

$$p_v(v,s) < 0 < p_{vv}(v,s) \quad \text{for} \quad v > 0. \tag{1.14}$$

Notice that the condition (1.14) assures that the system (1.13) has characteristic speeds

$$\lambda_1 = -\sqrt{-p_v}, \quad \lambda_2 = 0, \quad \lambda_3 = \sqrt{-p_v},$$

and there are two families of rarefaction waves for the Euler equations (1.13). For illustration, we describe only the 1-rarefaction waves, and thus assume $s^+ = s_- \equiv \overline{s}$. The case for the 3-rarefaction waves can be dealt with similarly.

Suppose the end states $(u_\pm, v_\pm, \overline{s})$ can be connected by 1-rarefaction waves. The centered 1-rarefaction wave connecting $(u_-, v_-, \overline{s})$ to $(u_+, v_+, \overline{s})$ is the self-similar solution $(u,v,s)(x,t) = (u^r, v^r, s^r)(x/t)$ of (1.13) defined by (see, e.g., [27, 4])

$$\begin{cases} s^r(\xi) = \overline{s}, \\ u^r(\xi) = u_- + \displaystyle\int_{v_-}^{v^r(\xi)} \lambda_1(z,\overline{s})dz, \\ \lambda_1(v^r,\overline{s})(x,t) \text{ increasing in } x, \ \ \lambda_1(v^r,\overline{s})(x,t) = -\sqrt{-p_v(v^r(x/t),\overline{s})}, \end{cases} \tag{1.15}$$

which is uniquely determined by the system (1.13) and the rarefaction wave initial data

$$(u,v,s)|_{t=0} \equiv (u_0^r, v_0^r, s_0^r)(x) = \begin{cases} (u_-, v_-, \overline{s}), & x < 0, \\ (u_+, v_+, \overline{s}), & x > 0. \end{cases} \tag{1.16}$$

For the internal energy $e(v,\theta)$ and the viscosity and heat-conductivity coefficients ϵ, κ, we assume that for some constant $C > 0$,

$$\begin{cases} e_\theta(v,\theta) > 0 \quad \text{for } v,\ \theta > 0, \\ \kappa = O(\epsilon) \text{ as } \epsilon \to 0, \quad \kappa(\epsilon)/\epsilon \geq C > 0 \quad \forall \epsilon > 0. \end{cases} \tag{1.17}$$

From the kinetic theory, the viscosity and heat-conductivity should be in the same order. In this sense, the assumption $\kappa = O(\epsilon)$ in (1.17) is reasonable.

For the sake of convenience, throughout this paper we denote

$$\alpha = |u_+ - u_-| + |v_+ - v_-|.$$

In this paper, we prove that the solution of system (1.11) with the centered rarefaction wave initial data (1.16) of small strength α exists for all time and converges to the centered rarefaction wave of the Euler equation (1.13) as $\epsilon \to 0$ uniformly away from the initial discontinuity. More precisely, the main result of this paper is stated in the following theorem.

THEOREM 1.1. *Let the constant states $(u_\pm, v_\pm, \overline{s})$ be connected by a centered 1-rarefaction wave $(u^r(\frac{x}{t}), v^r(\frac{x}{t}), s^r(\frac{x}{t}))$ defined by* (1.15). *Assume that* (1.14) *and* (1.17) *hold. Then, for α small enough, the compressible Navier–Stokes equations* (1.11) *with the rarefaction wave initial data* (1.16) *have a global piecewise smooth*

solution $(u^\epsilon(x,t), v^\epsilon(x,t), s^\epsilon(x,t))$*, such that the following hold:*

(i) $u^\epsilon, \theta^\epsilon$ *are continuous for* $t > 0$*,* v^ϵ *and* $u^\epsilon_x, v^\epsilon_x, \theta^\epsilon_x$ *are uniformly Hölder continuous in the set* $x < 0,\ t \geq \tau$ *and* $x > 0,\ t \geq \tau$ *for any* $\tau > 0$*;* $u^\epsilon_t, u^\epsilon_{xx}, v^\epsilon_{xt}, \theta^\epsilon_t, \theta^\epsilon_{xx}$ *are Hölder continuous on compact set* (x,t)*,* $x \neq 0, t > 0$*. Moreover, the jumps in* v^ϵ *at* $x = 0$ *satisfy*

$$|[v^\epsilon(0,t)]| \leq C_1 \exp\left(-C_2 t/\epsilon\right),$$

and so the other jumps, where C_1, C_2 *are positive constants independent of* t *and* ϵ*, and* $[\,\cdot\,]$ *denotes jumps in what follows.*

(ii) *The solution* $(u^\epsilon, v^\epsilon, s^\epsilon)$ *converges to the centered rarefaction wave* (u^r, v^r, s^r) *as* $\epsilon \to 0$ *uniformly away from* $t = 0$*; i.e., for any positive* h*, we have*

$$\lim_{\epsilon \to 0} \sup_{x \in \mathbb{R}, t > h} \left| (u^\epsilon(x,t), v^\epsilon(x,t), s^\epsilon(x,t)) - \left(u^r\left(\frac{x}{t}\right), v^r\left(\frac{x}{t}\right), s^r\left(\frac{x}{t}\right)\right) \right| = 0.$$

(iii) *For any fixed viscosity* $\epsilon > 0$*, the solution* $(u^\epsilon, v^\epsilon, s^\epsilon)$ *approaches the centered rarefaction wave* (u^r, v^r, s^r) *uniformly as time goes to infinity; i.e.,*

$$\lim_{t \to \infty} \sup_{x \in \mathbb{R}^1} \left| (u^\epsilon(x,t), v^\epsilon(x,t), s^\epsilon(x,t)) - \left(u^r\left(\frac{x}{t}\right), v^r\left(\frac{x}{t}\right), s^r\left(\frac{x}{t}\right)\right) \right| = 0.$$

Remark 1.1. (i) The exponential decay with respect to t of the jumps in v^ϵ also remains valid for $[u^\epsilon_x]$ and $[\theta^\epsilon_x]$.

(ii) The smallness of α is needed in (2.11) in section 2 to make $\|\varphi_{0y}\|_\pm$ small (cf. Remark 2.1).

To prove Theorem 1.1 and to overcome the difficulties induced by nonisentropy of the flow, we shall adapt and modify the arguments in [30, 13, 22]. Namely, we first use a natural scaling argument to reduce the proof to the nonlinear time-asymptotic stability analysis of rarefaction waves for the compressible Navier–Stokes equation (1.11) under nonsmooth initial perturbations. Then, observing that the approximation of the smooth rarefaction waves to the rarefaction wave of Euler equation depends on both the strength and the initial perturbation, we exploit the smoothing property induced by the parabolic parts in (1.12) and the smallness of α, and employ delicate energy estimates and carefully control jumps to obtain the theorem.

We point out here that in view of Theorem 1.1, an initial jump discontinuity at $x = 0$ can be allowed in (1.2). The evolution of this jump discontinuity is an important aspect in our analysis. It has been shown in [13] that the discontinuity evolution follows a curve $\dot{x} = -[u]/[v]$ in the x-t plane, and the jump discontinuity in v, u_x and θ_x decays exponentially in time, while the discontinuity in u and θ is smoothed out at positive time; see [13] for details. We shall exploit this fact in the proof of Theorem 1.1.

In section 2 we reformulate the problem and give the proof of Theorem 1.1, while section 3 is dedicated to the derivation of a priori estimates used in section 2.

Throughout this paper, we use the following notation:

$$\mathbb{R}^- := (-\infty, 0),\ \ \mathbb{R}^+ := (0, \infty), \quad \|\cdot\| \equiv \|\cdot\|_{L^2(\mathbb{R})},\ \ \|\cdot\|_{L^p} \equiv \|\cdot\|_{L^p(\mathbb{R})},$$
$$\|\cdot\|^2_\pm \equiv \|\cdot\|^2_{L^2(\mathbb{R}^-)} + \|\cdot\|^2_{L^2(\mathbb{R}^+)}, \quad \int_\pm \cdot dy \equiv \int_{-\infty}^0 \cdot dy + \int_0^\infty \cdot dy.$$

2. Reformulation and the proof of Theorem 1.1. In this section, we will reduce the proof of Theorem 1.1 to the nonlinear time-asymptotic stability analysis of rarefaction waves for the system (1.11) under nonsmooth perturbations.

First, we derive some necessary estimates on the rarefaction waves of the Euler equations (1.13) based on the inviscid Burgers equation, in particular, we construct an explicit smooth 1-rarefaction wave which well approximates a given centered 1-rarefaction wave. We start with the Riemann problem for the Burgers equation:

$$\begin{cases} w_t + \left(\frac{w^2}{2}\right)_x = 0, \\ w(x,0) = w_0^r(x), \end{cases} \tag{2.1}$$

where $w_0^r(x)$ is given by

$$w_0^r(x) = \begin{cases} w_-, & x < 0, \\ w_+, & x > 0. \end{cases}$$

If $w_- < w_+$, then the problem (2.1) has the centered rarefaction wave solution $w^r(x,t) = w^r(x/t)$ given by

$$w^r(x,t) = \begin{cases} w_-, & x/t \le w_-, \\ x/t, & w_- \le x/t \le w_+, \\ w_+, & x/t \ge w_+. \end{cases}$$

To construct a smooth rarefaction wave solution of the Burgers equation which approximates the centered rarefaction wave, we set for $\delta > 0$,

$$w_\delta(x) = w(\delta x) = \frac{w_+ + w_-}{2} + \frac{(w_+ - w_-)}{2}\tanh(\delta x)$$

and for each $\delta > 0$, we solve the following initial value problem:

$$\begin{cases} w_t + \left(\frac{w^2}{2}\right)_x = 0, \\ w(x,0) = w_\delta(x). \end{cases} \tag{2.2}$$

Next, we state certain properties that will be used later (see [30, 22] for a proof).

LEMMA 2.1. *For each $\delta > 0$, the problem* (2.2) *has a unique global smooth solution $w_\delta^r(x,t)$, such that the following hold:*

(i) $w_- < w_\delta^r(x,t) < w_+$, $\partial_x w_\delta^r(x,t) > 0$ *for* $x \in \mathbb{R}$, $t \ge 0$, $\delta > 0$.

(ii) *For any $1 \le p \le \infty$, there is a constant $C(p)$ depending only on p, such that*

$$\|\partial_x w_\delta^r(\cdot,t)\|_{L^p} \le C(p)\min\{(w_+ - w_-)\delta^{1-1/p}, (w_+ - w_-)^{1/p} t^{-1+1/p}\},$$
$$\|\partial_x^2 w_\delta^r(\cdot,t)\|_{L^p} \le C(p)\min\left\{(w_+ - w_-)\delta^{2-1/p}, \delta^{1-1/p}\frac{1}{t}\right\},$$
$$\|\partial_x^3 w_\delta^r(\cdot,t)\|_{L^p} \le C(p)\min\left\{(w_+ - w_-)\delta^{3-1/p}, \delta^{2-1/p}\frac{1}{t}\right\}.$$

(iii)

$$\lim_{t\to+\infty}\sup_{x\in\mathbb{R}}|w_\delta^r(x,t) - w^r(x,t)| = 0.$$

Now, set $w_\pm = \lambda_1(v_\pm, \overline{s})$, and we define $V(x,t), U(x,t), S(x,t), \Theta(x,t)$, the smooth approximation of $(v^r, u^r, s^r, \theta^r)$, by

$$\lambda_1(V(x,t),\overline{s}) = w_\delta^r(x,t), \quad U(x,t) = u_\pm + \int_{v_\pm}^{V(x,t)} \sqrt{-p_v(z,\overline{s})}dz,$$
$$S(x,t) = \overline{s}, \quad \Theta(x,t) = \theta(V(x,t),\overline{s}).$$

Then, it is not difficult to see that $V(x,t), U(x,t), S(x,t), \Theta(x,t)$ satisfy

$$\begin{cases} V_t - U_x = 0, \\ U_t + p(V,\Theta)_x = 0, \\ S_t(V,\Theta) = 0, \\ \Theta_t + \dfrac{\Theta p_\theta(V,\Theta)}{e_\theta} U_x = 0, \end{cases} \tag{2.3}$$

and due to Lemma 2.1, the following lemma holds for V, U, S, Θ.

LEMMA 2.2. *The functions $V(x,t), U(x,t), S(x,t)$, and $\Theta(x,t)$ constructed above satisfy the following:*

(i) *$V_t = U_x > 0$ for all $x \in \mathbb{R}$, $t \geq 0$.*

(ii) *For any $1 \leq p \leq \infty$, there is a positive constant $C(p)$ depending only on p, such that*

$$\|(V_x, U_x, \Theta_x)(\cdot,t)\|_{L^p} \leq C(p)\min\{\alpha\delta^{1-1/p}, \alpha^{1/p}t^{-1+1/p}\},$$
$$\|(V_{xx}, U_{xx}, \Theta_{xx})(\cdot,t)\|_{L^p} \leq C(p)\min\{\alpha\delta^{2-1/p},\ \delta^{1-1/p}t^{-1}\},$$
$$\|(V_{xxx}, U_{xxx}, \Theta_{xxx})(\cdot,t)\|_{L^p} \leq C(p)\min\{\alpha\delta^{3-1/p},\ \delta^{2-1/p}t^{-1}\}.$$

(iii)

$$\lim_{t\to\infty}\sup_{x\in\mathbb{R}} |(V,U,S,\Theta)(t,x) - (v^r, u^r, s^r, \theta^r)(t,x)| = 0.$$

(iv)

$$|(V_t, U_t, \Theta_t)(x,t)| \leq C|(V_x, U_x, \Theta_x)(x,t)|.$$

Consequently, from Lemmas 2.1 and 2.2, it follows that $(U,V,\Theta)(x,t)$ converges to $(u^r, v^r, \theta^r)(x,t)$ as $t \to \infty$.

Now, we reformulate the problem by a natural scaling. Due to the scale invariance of the Riemann problem (1.13), (1.16), we rescale the Cauchy problem $(1.1)_1, (1.1)_2$ and (1.10) by

$$y = x/\epsilon, \quad \tau = t/\epsilon, \qquad \epsilon > 0$$

to obtain

$$\begin{cases} v_\tau - u_y = 0, \\ u_\tau + p_y(v,\theta) = \Big(\dfrac{u_y}{v}\Big)_y, \\ \theta_\tau + \dfrac{\theta p_\theta(v,\theta)}{e_\theta(v,\theta)} u_y = \dfrac{\mu}{e_\theta(v,\theta)}\Big(\dfrac{\theta_y}{v}\Big)_y + \dfrac{1}{e_\theta(v,\theta)}\dfrac{u_y^2}{v} \end{cases} \tag{2.4}$$

with initial data

$$(u,v,\theta)(y,0)=(u_0,v_0,\theta_0)(y),\quad y\in\mathbb{R}, \tag{2.5}$$

where $\mu=\kappa/\epsilon$ and by virtue of the assumptions (1.17),

$$\underline{\mu}\le\mu\le\overline{\mu}\quad\text{uniformly in }\epsilon>0\ \text{ for some positive constants }\underline{\mu},\ \overline{\mu}.$$

And in the case of the rarefaction wave initial data (1.16), the initial data (2.5) are

$$(u_0,v_0,\theta_0)(y)=\begin{cases}(u_-,v_-,\theta_-), & x<0,\\ (u_+,v_+,\theta_+), & x>0.\end{cases} \tag{2.6}$$

If there exists a unique global solution $(u,v,\theta)(y,\tau)$ to the problem (2.4), (2.5) with the same regularity as stated in Theorem 1.1, then the solution $(u^\epsilon,v^\epsilon,\theta^\epsilon)(x,t)$ to the problem $(1.1)_1,(1.1)_2$, (1.10), and (1.12) is given by

$$(u^\epsilon,v^\epsilon,\theta^\epsilon)(x,t)=(u,v,\theta)(x/\epsilon,t/\epsilon). \tag{2.7}$$

Hence, it follows that Theorem 1.1 can be proved if one can show

$$\lim_{\tau\to\infty}\sup_{y\in\mathbb{R}}\left|(u,v,\theta)(y,\tau)-(u^r,v^r,\theta^r)\left(\frac{y}{\tau}\right)\right|=0, \tag{2.8}$$

where $(u^r,v^r,\theta^r)(y/\tau)=(u^r,v^r,\theta^r)(x/t)$ is the centered 1-rarefaction wave solution defined by (1.15). Thus, the proof of Theorem 1.1 is reduced to showing that the centered rarefaction wave is a time-asymptotic state for the solution of (2.4) with discontinuous initial data (2.6); this will be a consequence of the following (more general) stability theorem.

THEOREM 2.3. *Let $(u^r,v^r,\theta^r)(y/\tau)$ be the centered 1-rarefaction wave as in Theorem* 1.1. *Consider the Cauchy problem for* (2.4), (2.5), *where (u_0,v_0,θ_0) and its derivatives are sufficiently smooth away from $y=0$, but up to $y=0$ with a simple jump discontinuity at $y=0$. Assume that*

$$(u_0-u_\pm,v_0-v_\pm,\theta_0-\theta_\pm)\in L^2(\mathbb{R}^\pm),\quad v_{0y}\in L^2(\mathbb{R}^-)\cap L^2(\mathbb{R}^+).$$

Then, there is a positive constant η_0, such that if

$$\|(u_0-u_\pm,v_0-v_\pm,\theta_0-\theta_\pm)\|_{L^2(\mathbb{R}^\pm)}+\|v_{0y}\|_\pm+\alpha\le\eta_0,$$

then the Cauchy problem (2.4), (2.5) *has a unique global solution $(u,v,\theta)(y,\tau)$ in the same function class as in Theorem* 1.1. *Moreover,*

$$\lim_{\tau\to\infty}\sup_{y\in\mathbb{R}}\left|(u,v,\theta)(y,\tau)-(u^r,v^r,\theta^r)\left(\frac{y}{\tau}\right)\right|=0.$$

Theorem 2.3 looks like nonlinear stability of centered rarefaction waves for the compressible Navier–Stokes equations; see, e.g., [16, 20, 21, 19, 22]. The main difference is that for the nonlinear stability of centered rarefaction waves, initial perturbation is smooth, while here one has to deal with initial perturbation with discontinuities, the time evolution of which has to be controlled properly. But, some ideas from the study of nonlinear stability can be borrowed here.

The proof of Theorem 2.3 is broken up into several steps. We start with the observation that by making use of the smooth rarefaction wave $(U, V, \Theta)(y, \tau)$ constructed above (e.g., one may take $\delta = 1$), one can decompose the solution $(u, v, \theta)(y, \tau)$ of (2.4), (2.5) into

$$(\varphi, \psi, \phi)(y, \tau) = (v - V, u - U, \theta - \Theta)(y, \tau), \quad \xi(y, \tau) = s(y, \tau) - \overline{s}.$$

Substituting the above decomposition into (2.4), (2.5), we obtain the system for the functions φ, ψ, ϕ, ξ:

$$\begin{cases} \varphi_\tau - \psi_y = 0, \\ \psi_\tau + \Big(p(v, \theta) - p(V, \Theta)\Big)_y = \Big(\dfrac{u_y}{v}\Big)_y, \\ \phi_\tau + \dfrac{\theta p_\theta(v, \theta)}{e_\theta(v, \theta)}\psi_y + \left(\dfrac{\theta p_\theta(v, \theta)}{e_\theta(v, \theta)} - \dfrac{\Theta p_\theta(V, \Theta)}{e_\theta(V, \Theta)}\right) U_y = \dfrac{1}{e_\theta(v, \theta)}\left(\mu\left(\dfrac{\theta_y}{v}\right)_y + \dfrac{u_y^2}{v}\right), \\ \xi_\tau = \mu\left(\dfrac{\theta_y}{v\theta}\right)_y + \mu\dfrac{\theta_y^2}{v\theta^2} + \dfrac{u_y^2}{v\theta} \end{cases} \tag{2.9}$$

with initial data

$$(\varphi, \psi, \phi, \xi)(y, 0) = (\varphi_0, \psi_0, \phi_0, \xi_0) \equiv (v_0 - V_0, u_0 - U_0, \theta_0 - \Theta_0, s_0 - \overline{s}), \tag{2.10}$$

where $(\varphi_0, \psi_0, \phi_0, \xi_0)$ and its derivatives are sufficiently smooth away from $y = 0$ but up to $y = 0$, and $(\varphi_0, \psi_0, \phi_0, \xi_0) \in L^2(\mathbb{R})$, $\varphi_{0y} \in L^2(\mathbb{R}^-) \cap L^2(\mathbb{R}^+)$.

We shall show that the Cauchy problem (2.9), (2.10) possesses a unique global solution $(\varphi, \psi, \phi, \xi)(y, \tau)$ in the same function class as for $(u^\epsilon, v^\epsilon, \theta^\epsilon)$ in Theorem 1.1. Moreover, (φ, ψ, ϕ) goes to zero uniformly as $\tau \to \infty$. This convergence then yields Theorem 2.3 due to Lemmas 2.1 and 2.2.

PROPOSITION 2.4. *There exists a positive constant η_0, such that if*

$$N^2(0) := \|(\varphi_0, \psi_0, \phi_0)\|^2 + \|\varphi_{0y}\|_\pm^2 + \alpha \le \eta_0, \tag{2.11}$$

then the Cauchy problem (2.9), (2.10) *has a unique global solution $(\varphi, \psi, \phi)(y, \tau)$ in the same function class as for $(u^\epsilon, v^\epsilon, \theta^\epsilon)(x, t)$ in Theorem* 1.1*, satisfying the following:*

(i)

$$\sup_{\tau \ge 0}(\|(\varphi, \psi, \phi)(\tau)\|^2 + \|\varphi_y(\tau)\|_\pm^2) + \int_0^\infty \|(\varphi_y, \psi_y, \phi_y)(\tau)\|_\pm^2 d\tau \le C\{N^2(0) + \delta^{1/4}\}.$$

(ii) *For any $\tau_0 > 0$, there is a constant $C(\tau_0) > 0$, such that*

$$\sup_{\tau \ge \tau_0}(\|(\psi_y, \phi_y)(\tau)\|_\pm^2 + \|(\psi_{yy}, \phi_{yy})(\tau)\|_\pm^2) + \int_{\tau_0}^\infty \|(\psi_{yy}, \psi_{y\tau}, \phi_{yy}, \phi_{y\tau})(\tau)\|_\pm^2 d\tau \le C(\tau_0)\{N^2(0) + \delta^{1/4}\}.$$

(iii) *The jump discontinuity of $\varphi(y, \tau)$ at $y = 0$ is bounded from above by*

$$\big|[\varphi](\tau)\big| \le C_1 \exp\{-C_2\tau\} \qquad \forall\, \tau \in (0, \infty).$$

Here C, C_1, C_2 are positive constants independent of τ.

Remark 2.1. It is not difficult to see that for the rarefaction wave initial data (1.16), the smallness of $\|(\varphi_0, \psi_0, \phi_0)\|$ in the condition (2.11) is satisfied provided that δ is appropriately large but without smallness of α, while the smallness of $\|\varphi_{0y}\|_\pm$ holds provided that for fixed δ, α is small enough.

Proof. To show Proposition 2.4, we combine the local existence and regularity result in [13] with an a priori energy estimate based on the nature of the underlying rarefaction wave. First, we state the following local existence, the proof of which can be found in [13].

LEMMA 2.5 (see Hoff [13]). *Suppose that $N(0)$ is suitably small so that there exist two positive constants $\underline{v}$ and $\overline{v}$ with $\underline{v} \le v_0^1(y) \le \overline{v}$ for all $y \in \mathbb{R}$. Then, there is a constant $T > 0$, such that the Cauchy problem* (2.9), (2.10) *has a solution (φ, ψ, ϕ) on $\mathbb{R} \times [0, T]$ in the same function class as for $(u^\epsilon, v^\epsilon, \theta^\epsilon)$ in Theorem* 1.1. *Moreover, φ, ψ, ϕ satisfies the following:*

(i) *There exists a positive constant C, such that*

$$\sup_{\tau \ge 0}(\|(\varphi, \psi, \phi)(\tau)\|^2 + \|\varphi_y(\tau)\|_\pm^2) + \int_0^T \|(\varphi_y, \psi_y, \phi_y)(\tau)\|_\pm^2 d\tau \le C\{N^2(0) + \delta^{1/4}\}.$$

(ii) *There is a positive constant C, such that*

$$\sup_{0 \le \tau \le T}(\|(\psi_y, \phi_y)(\tau)\|_\pm^2 + \|(\psi_{yy}, \phi_{yy})(\tau)\|_\pm^2) + \int_{\tau_0}^T \|(\psi_{yy}, \psi_{y\tau}, \phi_{yy}, \phi_{y\tau})(\tau)\|_\pm^2 d\tau \le C\{N^2(0) + \delta^{1/4}\}.$$

(iii) *There are constants $C_1, C_2 > 0$ independent of T, such that*

$$|[p(v, e)]| = \left|\left[\frac{u_y}{v}\right]\right| \le C_1 \exp\{-C_2 \tau\}.$$

By virtue of Lemma 2.5 and the continuation in time of the local solution, we see that to complete the proof of Proposition 2.4, it suffices to prove the following a priori estimate, the proof of which will be postponed to the next section.

PROPOSITION 2.6 (a priori estimate). *Let the assumptions in Lemma* 2.5 *be satisfied. Assume that the Cauchy problem* (2.9), (2.10) *has a solution $(\varphi, \psi, \phi)(y, \tau)$ on $\mathbb{R} \times [0, \tau]$ for some $\tau > 0$ in the same function class as in Lemma* 2.5. *Denote*

$$N^2(\tau_0, \tau) := \sup_{\tau_0 \le s \le \tau} \{\|(\varphi, \psi, \phi)(\tau)\|^2 + \|\varphi_y(\tau)\|_\pm^2\}, \quad 0 \le \tau_0 \le \tau.$$

Then, there are positive constants η_1 and C independent of τ_1, such that for each fixed τ_0, if

$$N^2(\tau_0, \tau_1) \le \eta_1,$$

then the following estimates hold:

$$N^2(\tau_0, \tau_1) + \int_{\tau_0}^{\tau_1} \|(\varphi_y, \psi_y, \phi_y)(\tau)\|_\pm^2 d\tau \le C\{\|(\varphi, \psi, \phi)(\tau_0)\|^2 + \|\varphi_y(\tau_0)\|_\pm^2 + \delta^{1/4}\},$$

$$\sup_{0 \le \tau \le T} \|(\psi_y, \phi_y)(\tau)\|_\pm^2 + \int_{\tau_0}^{\tau_1} \|(\psi_{yy}, \phi_{yy})\|_\pm^2 d\tau \le C\{\|(\varphi, \psi, \phi)(\tau_0)\|_\pm^2 + \|(\varphi_y, \psi_y, \phi_y)(\tau_0)\|_\pm^2 + \delta^{1/4}\}.$$

Proof of Theorem 2.3. By the systems (2.3) and (2.9), Lemma 2.2, and the Cauchy–Schwarz and Sobolev inequalities, we easily find that

$$\int_0^\infty \|(\varphi_t,\psi_t,\phi_t)(\tau)\|_{L^\infty}^2 d\tau<\infty,$$

which together with Proposition 2.4 yields $\lim_{\tau\to\infty}\sup_y|(\varphi(y,\tau),\psi(y,\tau),\phi(y,\tau))|\to 0$. Hence, in view of Lemma 2.2, we have proved Theorem 2.3. □

3. Uniform a priori estimates. In this section we derive the key a priori estimates given in Proposition 2.6. First, we introduce the normalized entropy $\eta(v,u,s,V,U,S)$ around (V,U,S):

$$\begin{aligned}\eta(v,u,s,V,U,S):=&\Big(e(v,\theta)+\frac{u^2}{2}\Big)-\Big(e(V,\Theta)+\frac{U^2}{2}\Big)\\&-\{-p(V,\Theta)(v-V)+U(u-U)+\Theta(s-S)\},\end{aligned}$$

where we have used the fact that $e_v(v,s)=-p(v,\theta),\ e_s(v,s)=0$.

An easy computation implies that η satisfies the following equation:

$$\begin{aligned}&\eta_\tau(v,u,s,V,U,S)+\{(p(v,\theta)-p(V,\Theta)\psi)\}_y+\Big(\Theta\frac{\psi_y^2}{v\theta}+\mu\Theta\frac{\phi_y^2}{v\theta^2}\Big)\\&\quad+\{p(v,s)-p(V,\overline{s})-p_v(V,\overline{s})\psi-p_s(V,\overline{s})\xi\}U_y\\&\quad=\Big(\frac{\psi\psi_y}{v}+\mu\frac{\phi\phi_y}{v\theta}\Big)_y+\Big(-\frac{U_y\psi\phi_y}{v^2}+2\frac{U_y\phi\psi_y}{v\theta}-\mu\frac{\Theta\phi\varphi_y}{v^2\theta}+\mu\frac{\Theta_y\phi\phi_y}{v\theta^2}\Big)\\&\quad+\Big(\frac{U_xx\psi}{v}+\mu\frac{\Theta_{yy}\phi}{v\theta}\Big)+\Big(-\frac{V_yU_y\psi}{v^2}+\frac{U_y^2\phi}{v\theta}-\mu\frac{V_y\Theta_y\phi}{v^2\theta}\Big).\end{aligned}\tag{3.1}$$

Employing (3.1), one has the following lemma.

LEMMA 3.1. *Suppose that the assumptions of Proposition* 2.6 *hold. Then,*

$$\begin{aligned}&\|(\varphi,\psi,\phi)(\tau)\|^2+\int_{\tau_0}^\tau(\|\sqrt{V_\tau}(\varphi,\phi)(\hat\tau)\|^2+\|(\psi_y,\phi_y)(\hat\tau)\|_\pm^2)d\hat\tau\\&\quad\le C\Big\{\|(\varphi,\psi,\phi)(\tau_0)\|^2+\delta^{1/4}+N(\tau_0,\tau)^{2/3}\int_{\tau_0}^\tau\|\varphi_y(\hat\tau)\|_\pm^2d\hat\tau\Big\}.\end{aligned}\tag{3.2}$$

Proof. Integrating (3.1) with respect to τ and y, we get

$$\|(\varphi,\psi,\phi)(\tau)\|^2+\int_{\tau_0}^\tau(\|\sqrt{V_\tau}(\varphi,\phi)\|^2+\|(\psi_y,\phi_y)\|_\pm^2)(\hat\tau)d\hat\tau\le C\Big\{\|(\varphi,\psi,\phi)(\tau_0)\|^2+\sum_{j=1}^{j=4}R_j\Big\},\tag{3.3}$$

where

$$\begin{aligned}R_1&=\int_{\tau_0}^\tau\int_\pm\Big\{-(p(v,\theta)-p(V,\Theta)\psi)_y+\Big(\frac{\psi\psi_y}{v}+\mu\frac{\phi\phi_y}{v\theta}\Big)_y\Big\}(y,\hat\tau)dyd\hat\tau,\\R_2&=\int_{\tau_0}^\tau\int_\pm(|\psi U_{yy}|+|\phi\Theta_{yy}|)(y,\hat\tau)dyd\hat\tau,\\R_3&=\int_{\tau_0}^\tau\int_\pm(|U_y\psi\varphi_y|+|U_y\psi_y\phi|+|\Theta_y\varphi_y\phi|+|\phi\phi_y\Theta_y|)(y,\hat\tau)dyd\hat\tau,\\R_4&=\int_{\tau_0}^\tau\int_\pm(|V_yU_y\psi|+|U_y^2\phi|+|\phi\Theta_yV_y|)(y,\hat\tau)dyd\hat\tau.\end{aligned}$$

Here we have used the assumption (1.17), the smallness of $N(\tau_0,\tau)$ such that $\underline{v}\le v\le\overline{v}$ and $\underline{\theta}\le\theta\le\overline{\theta}$ for some positive constants $\underline{v},\overline{v},\underline{\theta},\overline{\theta}$, the convexity of $p(v,s)$ with respect to v and s, and the equivalence of $|(\varphi,\psi,\xi)|^2$ to $|(\varphi,\psi,\phi)|^2$.

Recalling the definition of $N(\tau,\tau_0)$ and applying Lemma 2.2, for given α, R_j can be estimated as follows:

$$
\begin{aligned}
R_1 &= \int_{\tau_0}^{\tau}\Big\{\Big[-p(v,\theta)+p(V,\Theta)+\frac{\psi_y}{v}\Big]\psi+\Big[\frac{\phi\phi_y}{v\theta}\Big]\Big\}(\hat\tau)d\hat\tau=0,\\
R_2 &\le C\int_{\tau_0}^{\tau}\|(\psi,\phi)(\hat\tau)\|^{1/2}\|(\psi_y,\phi_y)(\hat\tau)\|^{1/2}\|U_{yy}(\hat\tau)\|_{L^1}d\hat\tau\\
&\le C\int_{\tau_0}^{\tau}\Big\{N(\tau_0,\tau)\|(\phi_y,\psi_y)(\hat\tau)\|^2+\|U_{yy}(\hat\tau)\|_{L^1}^{4/3}\Big\}d\hat\tau\\
&\le C\Big\{N(\tau_0,\tau)\int_{\tau_0}^{\tau}\|(\phi_y,\psi_y)(\hat\tau)\|^2d\hat\tau+\delta^{1/4}\Big\},
\end{aligned}
$$

$$
\begin{aligned}
R_4 &\le C\int_{\tau_0}^{\tau}\|(\psi,\phi)(\hat\tau)\|^{1/2}\|(\psi_y,\phi_y)(\hat\tau)\|^{1/2}\|U_y(\hat\tau)\|^2d\hat\tau\\
&\le C\int_{\tau_0}^{\tau}\Big\{N(\tau_0,\tau)\|(\phi_y,\psi_y)(\hat\tau)\|^2+\|U_y(\hat\tau)\|^{8/3}\Big\}d\hat\tau\\
&\le C\Big\{N(\tau_0,\tau)\int_{\tau_0}^{\tau}\|(\phi_y,\psi_y)(\hat\tau)\|^2d\hat\tau+\delta^{1/4}\Big\},
\end{aligned}
$$

and

$$
\begin{aligned}
R_3 &\le C\int_{\tau_0}^{\tau}\|(\psi,\phi,\varphi)(\hat\tau)\|^{1/2}\|(\psi_y,\phi_y,\varphi_y)(\hat\tau)\|^{3/2}\|U_y(\hat\tau)\|d\hat\tau\\
&\le C\int_{\tau_0}^{\tau}\Big\{N(\tau_0,\tau)^{2/3}\|(\phi_y,\psi_y,\varphi_y)(\hat\tau)\|^2+\|U_y(\hat\tau)\|^4\Big\}d\hat\tau\\
&\le C\Big\{N(\tau_0,\tau)^{2/3}\int_{\tau_0}^{\tau}\|(\phi_y,\psi_y)(\hat\tau)\|^2d\hat\tau+\delta^{1/4}\Big\},
\end{aligned}
$$

where we have used the Sobolev inequality and the following inequality:

$$
\begin{aligned}
\int_{\tau_0}^{\tau}\|\partial_x^iU(\hat\tau)\|_{L^p}^{a+b}d\hat\tau &\le \sup_{r\in[\tau_0,\tau]}\|\partial_x^iU(\hat\tau)\|_{L^p}^{a}\int_{\tau_0}^{\tau}\|\partial_x^iU(\hat\tau)\|_{L^p}^{b}d\hat\tau\\
&\le C\delta^{(i-1/p)a}\int_{\tau_0}^{\tau}\|\partial_x^iU(\hat\tau)\|_{L^p}^{b}d\hat\tau.
\end{aligned}
$$

Substituting the above estimates for R_j $(j=1,\dots,4)$ into (3.3), we obtain (3.2). This completes the proof. □

We now proceed to derive bounds for the term $\int_{\tau_0}^{\tau}\|\varphi_x(\hat\tau)\|_{\pm}^2d\hat\tau$, and we have the following lemma.

LEMMA 3.2. *Suppose that the assumptions of Proposition* 2.6 *hold. Then,*

$$
\begin{aligned}
\|\varphi_y(\tau)\|_{\pm}^2+\int_{\tau_0}^{\tau}\|\varphi_y(\hat\tau)\|_{\pm}^2d\hat\tau &\le C\Big\{\|(\varphi_y,\psi)(\tau_0)\|^2+\|\psi(\tau)\|_{\pm}^2\\
&\quad+\int_{\tau_0}^{\tau}\Big(\|(\psi_y,\phi_y)(\hat\tau)\|_{\pm}^2+\|\sqrt{V_\tau(\hat\tau)}(\varphi,\phi)(\hat\tau)\|_{\pm}^2\Big)d\hat\tau+\delta\Big\}.
\end{aligned}
\tag{3.4}
$$

Proof. By (2.9), we easily find that

$$\begin{aligned}\Big(\frac{1}{2}\Big(\frac{\varphi_y}{v}\Big)^2-\frac{\varphi_y}{v}\psi\Big)_\tau-p_v(v,\theta)\frac{\varphi_y^2}{v}-\Big(\frac{\psi_y^2}{v}+\frac{p_\theta\varphi_y\phi_y}{v}\Big)+\Big(\frac{\psi\psi_y}{v}\Big)_y\\ =\Big\{V_y(p_v(v,\theta)-p_v(V,\Theta))\frac{\varphi_y}{v}+\Theta_y(p_\theta(v,\theta)-p_\theta(V,\Theta))\frac{\varphi_y}{v}\\ +\frac{U_y\psi\varphi_y}{v^2-V_y\psi\psi_y/v^2}\Big\}+\frac{V_y\psi_y\varphi_y}{v^3}-\frac{U_{yy}\varphi_y}{v^2}+\frac{V_yU_y\varphi_y}{v^3}.\end{aligned}\tag{3.5}$$

Integrating (3.5) with respect to y,τ over $(\tau_0,\tau)\times\mathbb{R}$, we infer

$$\begin{aligned}\|\varphi_y(\tau)\|_\pm^2+\int_{\tau_0}^\tau\|\varphi_y(\hat\tau)\|_\pm^2d\hat\tau\le C\Big\{\|(\varphi_y,\psi)(\tau_0)\|^2+\|\psi(\tau)\|^2\\ +\int_{\tau_0}^\tau\Big(\|(\psi_y,\phi_y)\|_\pm^2+\|\sqrt{V_t}(\varphi,\phi)\|_\pm^2\Big)(\hat\tau)d\hat\tau+\sum_{j=5}^{j=7}R_j\Big\},\end{aligned}\tag{3.6}$$

with

$$\begin{aligned}&R_5=-\int_{\tau_0}^\tau\int_\pm\Big(\frac{\psi\psi_y}{v}\Big)_yd\hat\tau,\quad R_6=\int_{\tau_0}^\tau\int_\pm(|\psi U_y\varphi_y|+|V_y\psi\psi_y|)(y,\hat\tau)dyd\hat\tau,\\ &R_7=\int_{\tau_0}^\tau\int_\pm(|\psi_yV_y\varphi_y|+|U_{yy}\varphi_y|+|U_yV_y\varphi_y|)(y,\hat\tau)dyd\hat\tau,\end{aligned}$$

where R_5,R_6,R_7 can be bounded as follows, using Sobolev's imbedding theorem and Lemma 2.5(iii):

$$\begin{aligned}R_5&=\int_{\tau_0}^\tau\Big[\frac{\psi\psi_y}{v}\Big]d\hat\tau=\int_{\tau_0}^\tau\psi\Big[\frac{\psi_y}{v}\Big]d\hat\tau\le\int_{\tau_0}^\tau\|\psi\|^{1/2}\|\psi_y\|_\pm^{1/2}\Big[\frac{u_y}{v}\Big]d\hat\tau\\ &\le\frac{1}{4}\int_{\tau_0}^\tau\|\psi_y\|_\pm^2d\hat\tau+C\sup_{\tau_0\le s\le\tau}\|\psi(s)\|^{2/3}\Big|[\varphi(\tau_0)]\Big|^{4/3}\int_{\tau_0}^\tau\exp\Big(-\frac{4}{3}C_3(\hat\tau-\tau_0)\Big)d\hat\tau\\ &\le\frac{1}{4}\int_{\tau_0}^\tau\|\psi_y\|_\pm^2d\hat\tau+\frac{1}{3}\sup_{\tau_0\le s\le\tau}\|\psi(s)\|^2+C\{\|(\varphi(\tau_0)\|^2+\|\varphi_y(\tau_0)\|^2)\},\end{aligned}$$

$$\begin{aligned}R_6&\le C\int_{\tau_0}^\tau\|\psi(\hat\tau)\|^{1/2}\|\psi_y(\hat\tau)\|^{1/2}\|U_y(\hat\tau)\|\,\|(\varphi_y,\psi_y)(\hat\tau)\|d\hat\tau\\ &\le C\Big\{N(\tau_0,\tau)^{2/3}\int_{\tau_0}^\tau\|(\varphi_y,\psi_y)(\hat\tau)\|^2d\hat\tau+\int_{\tau_0}^\tau\|U_y(\hat\tau)\|^4d\hat\tau\Big\}\\ &\le C\Big\{N(\tau_0,\tau)^{2/3}\int_{\tau_0}^\tau\|(\varphi_y,\psi_y)(\hat\tau)\|^2d\hat\tau+\delta^{1/4}\Big\},\end{aligned}$$

$$\begin{aligned}R_7&\le C\alpha\int_{\tau_0}^\tau\|\varphi_y\|_\pm\|\psi_y\|_\pm d\hat\tau+\int_{\tau_0}^\tau(\|U_{yy}\|\,\|\varphi_y\|_\pm+\|V_y\|_{L^4}\|U_y\|_{L^4}\|\varphi_y\|_\pm)d\hat\tau\\ &\le\frac{1}{2}\int_{\tau_0}^\tau\|\varphi_y(\hat\tau)\|_\pm^2d\hat\tau+C\int_{\tau_0}^\tau(\|\psi_y\|_\pm^2+\|U_y\|_{L^4}^4+\|V_y\|_{L^4}^4+\|U_{yy}\|^2)d\hat\tau\\ &\le\frac{1}{2}\int_{\tau_0}^\tau\|\varphi_y(\hat\tau)\|^2d\hat\tau+C\Big\{\int_{\tau_0}^\tau\|\psi_y(\hat\tau)\|^2d\hat\tau+\delta^{1/4}\Big\}.\end{aligned}$$

Inserting the estimates for R_j $(j = 5, 6, 7)$ into (3.6), we arrive at

$$\begin{aligned}\|\varphi_y(\tau)\|_\pm^2 + \int_{\tau_0}^{\tau} \|\varphi_y(\hat\tau)\|_\pm^2 d\hat\tau \le C\Big\{ &\|(\varphi_y,\psi)(\tau_0)\|_\pm^2 + \|\psi(\tau)\|^2 \\ &+ \int_{\tau_0}^{\tau} (\|(\psi_y,\phi_y)(\hat\tau)\|_\pm^2 + \|\sqrt{V_\tau}(\varphi,\phi)(\hat\tau)\|^2) d\hat\tau + \delta^{1/4}\Big\}. \end{aligned} \tag{3.7}$$

Finally, combining Lemma 3.1 with Lemma 3.2, we conclude that

$$\begin{aligned}\|(\varphi,\psi,\phi,\varphi_y)(\tau)\|^2 + \int_{\tau_0}^{\tau} \Big(\|\sqrt{V_\tau(\hat\tau)}(\varphi,\phi)(\hat\tau)\|^2 + \|(\varphi_y,\psi_y,\phi_y)(\hat\tau)\|_\pm^2\Big) d\hat\tau \\ \le C(\|(\varphi,\psi,\phi)(\tau_0)\|^2 + \|\varphi_y(\tau_0)\|_\pm^2 + \delta^{1/4}). \end{aligned} \tag{3.8}$$

Comparing with the standard energy estimate for the compressible Navier–Stokes equations, we refer (3.8) to the basic energy estimate. □

Next, we proceed to estimate higher order derivatives of ψ, ϕ in the space $L^\infty(\tau_0, \tau; L^2(\mathbb{R}^\pm))$.

LEMMA 3.3. *Suppose that the assumptions of Proposition* 2.6 *hold. Then,*

$$\|\psi_y(\tau)\|_\pm^2 + \int_{\tau_0}^{\tau} \|\psi_{yy}(\tau)\|_\pm^2 d\tau \le C(\|\psi_y(\tau_0)\|_\pm + \|(\varphi,\psi,\phi)(\tau_0)\|^2 + \delta^{1/4}). \tag{3.9}$$

Proof. Multiplying the second equation of (2.9) by $-\psi_{yy}$, one obtains

$$\begin{aligned}\Big(\frac{\psi_y^2}{2}\Big)_\tau + \frac{\psi_{yy}^2}{v} - (\psi_\tau\psi_y)_y &= (p_v(v,\theta)\varphi_y + p_\theta(v,\theta)\phi_y)\psi_{yy} + \frac{\varphi_y\psi_y\psi_{yy}}{v^2} \\ &+ V_y\{p_v(v,\theta) - p_v(V,\Theta)\}\psi_{yy} + \Theta_y\{p_\theta(v,\theta) - p_\theta(V,\Theta)\}\psi_{xx} \\ &+ \frac{V_y\psi_y\psi_{yy}}{v^2} + \frac{U_y\varphi_y\psi_{yy}}{v^2} - \frac{U_{yy}\psi_{yy}}{v} + \frac{V_yU_y\psi_{yy}}{v^2}, \end{aligned} \tag{3.10}$$

which, by integrating with respect to y and τ, leads to

$$\begin{aligned}\|\psi_y(\tau)\|_\pm^2 + \int_{\tau_0}^{\tau} \|\psi_{yy}(\hat\tau)\|_\pm^2 d\hat\tau &\le \|\psi_y(\tau_0)\|_\pm^2 + \int_{\tau_0}^{\tau}\int_\pm (\psi_\tau\psi_y)_y dy d\hat\tau \\ &+ C\Big\{ \int_{\tau_0}^{\tau} \Big(\|(\varphi_y,\psi_y,\phi_y)(\hat\tau)\|_\pm^2 + \|\sqrt{V_t}(\varphi,\phi)(\hat\tau)\|^2\Big) d\hat\tau \\ &+ \int_{\tau_0}^{\tau}\int_\pm \Big(|\varphi_y\psi_y\psi_{yy}| + |V_y\psi_y\psi_{yy}| + |U_y\varphi_y\psi_{yy}| \\ &+ |\psi_{yy}|(|U_{yy}| + |U_y^2|)\Big) dy d\hat\tau\Big\}. \end{aligned} \tag{3.11}$$

The terms on the right-hand side of (3.11) can be bounded as follows:

$$\begin{aligned}\int_{\tau_0}^{\tau}\int_\pm (\psi_\tau\psi_y)_y dy d\hat\tau &= [\psi\psi_y]|_{\tau_0}^{\tau} - \int_{\tau_0}^{\tau} \psi[\psi_y]_\tau d\hat\tau = \psi[\psi_y]|_{\tau_0}^{\tau} - \int_{\tau_0}^{\tau} \psi[\psi_y]_\tau d\hat\tau \\ &\le \frac{1}{8}\int_{\tau_0}^{\tau} \|\psi_{yy}(\hat\tau)\|_\pm^2 d\hat\tau + C\int_{\tau_0}^{\tau} (\|\varphi\|^2 + \|\psi\|^2 + \|\psi_y\|_\pm^2)(\hat\tau) d\hat\tau, \end{aligned}$$

where we have used the fact that the jump $[u_y]$ decays exponentially in τ (cf. the estimate of R_5 in the proof of Lemma 3.2); and

$$\begin{aligned}\int_{\tau_0}^{\tau}\int_\pm |(\varphi_y\psi_y\psi_{yy})(y,\hat\tau)| dx d\hat\tau &\le C\int_{\tau_0}^{\tau} \|\varphi_y(\hat\tau)\|_\pm \|\psi_y(\hat\tau)\|_\pm^{1/2} \|\psi_{yy}(\cdot,\hat\tau)\|_\pm^{3/2} d\hat\tau \\ &\le \frac{1}{8}\int_{\tau_0}^{\tau} \|\psi_{yy}(\hat\tau)\|_\pm^2 d\hat\tau + CN(\tau_0,\tau)\int_{\tau_0}^{\tau} \|\psi_y(\hat\tau)\|_\pm^2 d\hat\tau; \end{aligned}$$

$$\int_{\tau_0}^{\tau}\int_{\pm}|\psi_{yy}(y,\hat\tau)|(|V_y\psi_y|+|U_y\varphi_y|)(y,\hat\tau)dyd\hat\tau$$
$$\le\frac{1}{8}\int_{\tau_0}^{\tau}\|\psi_{yy}(\hat\tau)\|_{\pm}^2d\hat\tau+C\delta\int_{\tau_0}^{\tau}\|(\varphi_y,\psi_y)(\hat\tau)\|_{\pm}d\hat\tau;$$

and

$$\int_{\tau_0}^{\tau}\int_{\pm}|(\psi_{yy}(y,\tau))|(|U_{yy}|+|U_y|^2)(y,\tau)dyd\tau$$
$$\le\frac{1}{8}\int_{\tau_0}^{\tau}\|\psi_{yy}(\hat\tau)\|_{\pm}^2d\hat\tau+C\int_{\tau_0}^{\tau}(\|U_{yy}\|^2+\|U_y\|_{L^4}^4)(\hat\tau)d\hat\tau$$
$$\le\frac{1}{8}\int_{\tau_0}^{\tau}\|\psi_{yy}(\hat\tau)\|_{\pm}^2d\hat\tau+C\delta^{1/4}.$$

Substituting the above estimates into (3.10), we obtain (3.9). □

Similarly, we can bound the derivatives of ϕ as follows.

LEMMA 3.4. *Assume that the assumptions of Proposition* 2.6 *hold. Then,*

$$\|\phi_y(\tau)\|_{\pm}^2+\int_{\tau_0}^{\tau}\|\phi_{yy}(\hat\tau)\|_{\pm}^2d\hat\tau\le C(\|(\varphi,\psi,\phi)(\tau_0)\|^2+||\phi_y(\tau_0)\|_{\pm}^2+\delta^{1/4}).\tag{3.12}$$

Proof. Multiplying the third equation of (2.9) by $-\phi_{yy}$, then integrating with respect to y and τ, and utilizing (3.7) and (3.8), we deduce that

$$\begin{aligned}&\|\phi_y(\tau)\|^2+\int_{\tau_0}^{\tau}\|\phi_{yy}(\hat\tau)\|^2d\hat\tau\le\|\phi_y(\tau_0)\|^2+\int_{\tau_0}^{\tau}\|\psi_y(\hat\tau)\|^2d\hat\tau\\&+\int_{\tau_0}^{\tau}\int_{\pm}(\phi_\tau\phi_y)_yd\hat\tau\quad+C\Big\{\int_{\tau_0}^{\tau}\int_{\pm}\Big(|\phi_{yy}|(|\varphi_y\phi_y|+|\psi_y^2|)\\&+|U_y\phi_{yy}|(|\phi|+|\varphi|)+|\phi_{yy}|(|V_y\phi_y|+|\Theta_y\varphi_y|\\&\quad+|U_y\psi_x|)+|\phi_{yy}|(|U_{yy}|+|U_y^2|)\Big)(y,\hat\tau)dyd\hat\tau\Big\},\end{aligned}\tag{3.13}$$

where the right-hand side can be estimated as follows:

$$\int_{\tau_0}^{\tau}\int_{\pm}(\phi_\tau\phi_y)_ydyd\hat\tau=[\phi\phi_y]\Big|_{\tau_0}^{\tau}-\int_{\tau_0}^{\tau}\phi[\phi_y]_\tau=\phi[\phi_y]\Big|_{\tau_0}^{\tau}-\int_{\tau_0}^{\tau}\phi[\phi_y]_\tau$$
$$\le\frac{1}{16}\int_{\tau_0}^{\tau}\|\phi_{yy}(\hat\tau)\|_{\pm}^2d\hat\tau+C\int_{\tau_0}^{\tau}(\|\psi\|^2+\|\phi\|^2+||\phi_y\|_{\pm}^2)(\hat\tau)d\hat\tau;$$

$$\int_{\tau_0}^{\tau}\int_{\pm}|(\varphi_y\phi_y\phi_{yy})(y,\hat\tau)|dyd\hat\tau\le C\int_{\tau_0}^{\tau}\|\varphi_y(\hat\tau)\|_{\pm}\|\phi_y(\hat\tau)\|_{\pm}^{1/2}\|\phi_{yy}(\hat\tau)\|_{\pm}^{3/2}d\hat\tau$$
$$\le\frac{1}{16}\int_{\tau_0}^{\tau}\|\phi_{yy}(\hat\tau)\|_{\pm}^2d\hat\tau+CN(\tau_0,\tau)\int_{\tau_0}^{\tau}\|\phi_y(\hat\tau)\|_{\pm}^2d\hat\tau;$$

$$\int_{\tau_0}^{\tau}\int_{\pm}|(\psi_y^2\phi_{yy})(y,\hat\tau)|dyd\hat\tau\le C\int_{\tau_0}^{\tau}\|\psi_y(\hat\tau)\|_{\pm}^{3/2}\|\psi_{yy}(\hat\tau)\|_{\pm}^{1/2}\|\phi_{yy}(\hat\tau)\|_{\pm}d\hat\tau$$
$$\le\frac{1}{16}\int_{\tau_0}^{\tau}\|\phi_{yy}(\hat\tau)\|_{\pm}^2d\hat\tau+CN(\tau_0,\tau)\int_{\tau_0}^{\tau}(\|\psi_{yy}(\hat\tau)\|_{\pm}^2+\|\psi_y(\hat\tau)\|_{\pm}^2)d\hat\tau;$$

$$\int_{\tau_0}^{\tau}\int_{\pm}|U_y\phi_{yy}|(|\varphi|+|\phi|)(y,\hat{\tau})dyd\hat{\tau}$$
$$\leq \frac{1}{16}\int_{\tau_0}^{\tau}\|\phi_{yy}(\hat{\tau})\|_{\pm}^2 d\hat{\tau}+C\delta\int_{\tau_0}^{\tau}\|\sqrt{V_\tau}(\varphi,\phi)(\hat{\tau})\|d\hat{\tau};$$

$$\int_{\tau_0}^{\tau}\int_{\pm}|\phi_{yy}|(|V_y\phi_y|+|\Theta_y\varphi_y|+|U_y\psi_y|)(y,\hat{\tau})dyd\hat{\tau}$$
$$\leq \frac{1}{16}\int_{\tau_0}^{\tau}\|\phi_{yy}(\hat{\tau})\|_{\pm}^2 d\hat{\tau}+C\delta\int_{\tau_0}^{\tau}\|(\varphi_y,\psi_y,\phi_y)(\hat{\tau})\|_{\pm}d\hat{\tau}$$

and

$$\int_{\tau_0}^{\tau}\int_{\pm}|\phi_{yy}|(|U_{yy}|+|U_y^2|)(y,\hat{\tau})dyd\hat{\tau}\leq\frac{1}{16}\int_{\tau_0}^{\tau}\|\phi_{yy}(\hat{\tau})\|_{\pm}^2 d\hat{\tau}$$
$$+C\int_{\tau_0}^{\tau}(\|U_{yy}\|^2+\|U_y\|_{L^4}^4)(\hat{\tau})d\hat{\tau}\leq\frac{1}{16}\int_{\tau_0}^{\tau}\|\phi_{yy}(\hat{\tau})\|_{\pm}^2 d\hat{\tau}+C\delta^{1/4}.$$

Substitution of the above estimates into (3.13) gives Lemma 3.4 immediately. □

Now, combining Lemmas 3.1–3.4, we obtain Proposition 2.6.

Acknowledgment. The authors would like to thank the referees for their suggestions which improved the presentation of the present paper.

CONCENTRATION OF GINZBURG–LANDAU ENERGIES WITH SUPERCRITICAL GROWTH*

N. DESENZANI† AND I. FRAGALÀ‡

Abstract. We study the asymptotic behavior of energies of Ginzburg–Landau type, for maps from $\mathbb{R}^{n+k}$ into $\mathbb{R}^k$, and when the growth exponent p is strictly larger than k. We prove a compactness and Γ-convergence result, with respect to a suitable topology on the Jacobians, seen as n-dimensional currents. The limit energy is defined on the class of n-integral boundaries M, and its density involves a family of optimal profile constants depending locally on the multiplicity of M.

Key words. Γ-convergence, Ginzburg–Landau functionals, currents, Jacobians, degree

1. Introduction.

The investigation of phase transition and concentration phenomena from a variational point of view involves functionals of the kind

$$E_\varepsilon(u) := \int_\Omega |\nabla u|^p + \frac{1}{\varepsilon^p} W(u), \qquad u \in W^{1,p}(\Omega;\mathbb{R}^k), \tag{1.1}$$

where $n \geq 0$ and $k \geq 1$ are given integers, Ω is a bounded regular domain in $\mathbb{R}^{n+k}$, $p > 1$ is a real exponent, and W is a nonnegative continuous potential on $\mathbb{R}^k$, vanishing only on the unit sphere S^{k-1}. A rigorous mathematical analysis of the asymptotic behavior of E_ε as the positive parameter ε tends to zero began in the 1970s with the celebrated paper by Modica and Mortola [30]. They proved that, taking $p = 2$, $n \geq 0$, and $k = 1$ (so that W is null at -1 and $+1$), the minima of E_ε on the class of functions with prescribed mean converge to a constant times the area of a minimal surface of dimension n. The multiplicative constant is determined by an "optimal profile problem," which selects the 1-dimensional transition of lowest cost between the two wells of the potential. The basic physical motivation was the Cahn–Hilliard model for phase transition of immiscible fluids [8], and the technique adopted to attack the problem was the Γ-convergence introduced by De Giorgi and Franzoni in [10]. For an outline of the proof of the Modica–Mortola theorem close in spirit to the aims of the present work, and for the numerous later extensions by different authors, we refer the reader to the survey paper [1] and enclosed references. Therein the reader may also find a quick introduction to Γ-convergence, whose general theory and applications are developed in [6, 9].

The analogous problem in the vector-valued case involves in its simplest form the Ginzburg–Landau energies obtained by taking $n = 0$ and $k = p = 2$ in (1.1) (so that W is null on S^1). In this case, the physical background is related to phase transition models for superconductors [17] or superfluids [18]. A detailed study of the asymptotic behavior of minimizers of Ginzburg–Landau energies on the class of

functions with prescribed boundary datum $g \in C^\infty(\partial\Omega; S^1)$ has been carried out by Bethuel, Brezis, and Hélein; see the monograph [5]. Roughly, when the degree of g is nonzero, energy concentration occurs near a finite number of isolated points—the so-called Ginzburg–Landau vortices. Moreover, all singularities have degree 1, and they tend to repel each other. These results have been obtained essentially through PDE methods for the Euler–Lagrange equation of E_ε, combined with some complex analysis devices.

A more variational approach allows one to deal with energies of the type (1.1) in any space dimensions $n \geq 0$ and $k \geq 2$, and taking $p = k$. The asymptotic behavior as $\varepsilon \to 0$ of such functionals E_ε has been studied in a recent paper by Alberti, Baldo, and Orlandi [3], and independently (for $k = 2$) by Jerrard and Soner [26]. When the boundary datum has a topological singularity, the energy of minimizers turns out to be of order $|\log \varepsilon|$ and concentrates near a surface of dimension n in Ω. A good topology which allows for the detection of energy concentration is a suitable *flat norm* $\mathbb{F}_\Omega$ for the Jacobians Ju_ε of u_ε; indeed, using a suitable Hodge-type operator between k-covectors and n-vectors, the k-forms Ju_ε may be identified with generalized oriented n-surfaces, or more precisely, with n-dimensional *integral boundaries* $\star Ju_\varepsilon$ in the sense of currents. So, within the general setting of currents theory, the behavior of u_ε can be described in a rigorous way by means of a compactness and Γ-convergence result [3, Theorem 1.1]: with a suitable Dirichlet condition, the minima of E_ε converge to a dimensional constant times the area measure of a minimizing n-current. We also refer the reader to [4, 7, 15, 19, 20, 22, 24, 27, 28, 29, 31] and the references therein for related concentration, compactness, and lower bound results.

In this paper, we study the variational convergence of the functionals E_ε in (1.1) still for arbitrary $n \geq 0$ and $k \geq 2$, but now for p *strictly larger* than k. We stress that, while in the scalar case $k = 1$ the choice of p is essentially not relevant for the problem, in the vector case $k \geq 2$ the choice $p = k$ is in some sense "critical." Indeed, for every $p > 1$, the Γ-limit of E_ε in L^1 is equal to $\int_\Omega |\nabla u|^p$ for $u \in W^{1,p}(\Omega, S^{k-1})$, and $+\infty$ otherwise. Now, the trace operator maps $W^{1,p}(\Omega, S^{k-1})$ onto $W^{1-\frac{1}{p},p}(\partial\Omega, S^{k-1})$ if and only if $p < k$ (see, e.g., [21]). Thus, for $p < k$, imposing any Dirichlet boundary datum does not produce energy concentration (i.e., the energy of minimizers remains bounded). On the other hand, in the supercritical case $p > k$, for suitable boundary data the energy of minimizers turns out to be of order ε^{k-p}. In particular, the appropriate sequence of rescaled functionals to be considered in order to determine a meaningful Γ-limit is obtained by multiplying the functionals E_ε in (1.1) by ε^{p-k}. In this paper, the Γ-limit of $\varepsilon^{p-k}E_\varepsilon$ is determined in the absence of boundary conditions; however, by suitable modifications, our main result (cf. Theorem 1.1 below) can be extended in order to include Dirichlet boundary data; see [11].

Though it seems to have no particular physical interpretation, from a purely mathematical point of view the problem in the case $p > k$ reveals some interesting features, different from the case $p = k$. The main new difficulties concern the influence of the potential W on energy concentration, and the consequent effects on the form of the Γ-limit. This phenomenon can be observed by looking at the behavior of a so-called *recovery sequence*, namely, a sequence $\{u_\varepsilon\}$ which satisfies condition (ii) in Theorem 1.1 below when $p > k$ (respectively, the analogous condition (ii) in Theorem 1.1 of [3] when $p = k$). Indeed, when $p = k$ we see that a zone carrying a vanishing energy is located between the limit integral boundary M and the set where $E_\varepsilon(u_\varepsilon)$ are of order $|\log \varepsilon|$; therefore, the shape of the potential does not modify the Γ-limit. On the contrary, when $p > k$, there is a whole neighborhood of M where $E_\varepsilon(u_\varepsilon)$ are of

order ε^{k-p}. As a consequence, the amount of energy concentration is governed by an auxiliary variational problem, which involves the potential and depends locally on the integer multiplicity of M; so we have to deal with a whole family of "optimal profile constants" τ_d for d varying in $\mathbb{Z}$. Their role is in some respect analogous to the one played by the constant τ which appears in the Γ-limit of E_ε in the scalar case: in terms of the unscaled energy $\int_{\mathbb{R}^n} |\nabla u|^p + W(u)$, when $k = 1$, τ represents the minimal cost for a transition between the two wells of the potential, whereas when $k \geq 2$, τ_d represents the minimal cost for a singularity of degree d. However, though the situation reveals a close resemblance to the scalar case, it is considerably more complicated, not only because τ_d varies with d, but also because, for fixed d, it is quite delicate to determine the class of admissible functions in the variational problem which defines τ_d. Actually, in order to obtain the Γ-lim sup inequality, all the competitors should have the same "trace at infinity," whereas, in order to prove the Γ-lim inf inequality, they should satisfy the strictly weaker condition of having just the same "degree at infinity." Fortunately this dichotomy, which is one of the most intriguing aspects of the problem, is only apparent: in fact the two involved variational problems turn out to have the same infimum, so that no gap occurs between the Γ-limsup and the Γ-liminf.

Our main result reads as follows. For the definition of the constants τ_d, $d \in \mathbb{Z}$, we refer the reader to section 4; moreover, we denote by α_k the Lebesgue measure of the unit ball in $\mathbb{R}^k$.

THEOREM 1.1. *Let $n \geq 0$, $k \geq 2$, and $p > k$. For $\varepsilon > 0$, let $F_\varepsilon := \varepsilon^{p-k} E_\varepsilon$, E_ε being the functionals defined in* (1.1). *Assume that the positive continuous potential W vanishes only on S^{k-1} and satisfies the growth conditions*

$$\liminf_{|y|\to 1} \frac{W(y)}{(1-|y|)^{p/(p-k+1)}} > 0 \quad \text{and} \quad \liminf_{|y|\to+\infty} \frac{W(y)}{|y|^p} > 0. \tag{1.2}$$

Then the following statements hold:

(i) *Compactness and Γ-lim inf inequality. Whenever $\sup_\varepsilon F_\varepsilon(u_\varepsilon) < +\infty$, up to subsequences we have $\mathbb{F}_\Omega(\star J u_\varepsilon - \alpha_k M) \to 0$, where M is an n-dimensional integral boundary in Ω with multiplicity σ, and*

$$\liminf_\varepsilon F_\varepsilon(u_\varepsilon) \geq \int_M \tau_{\sigma(x)}\, d\mathcal{H}^n(x). \tag{1.3}$$

(ii) Γ-lim sup *inequality. For every n-dimensional integral boundary M in Ω with multiplicity σ, there exists a sequence $\{u_\varepsilon\} \subset W^{1,p}(\Omega;\mathbb{R}^k)$ such that $\mathbb{F}_\Omega(\star J u_\varepsilon - \alpha_k M) \to 0$ and*

$$\limsup_\varepsilon F_\varepsilon(u_\varepsilon) \leq \int_M \tau_{\sigma(x)}\, d\mathcal{H}^n(x). \tag{1.4}$$

We point out that a deeper understanding of the infimum problems which define the constants τ_d might allow us to clarify whether the dependence of τ_d on d is linear, and hence to establish whether the Γ-limit given by Theorem 1.1 is a multiple of the area. However, we feel that this is a challenging task. Indeed, while the admissible fields in the variational problems defining τ_d satisfy just a *global* degree condition, to understand the way the infima τ_d depend on d one should obtain some information on the *local* degree of minimizing sequences. (Actually, one should know how concentrated or spread out the subsets of $\mathbb{R}^k$ where the global degree is attained are.) An adequate technique to derive this local information from a global degree seems to be

somehow missing. Still for $n = 0$, one may also try to locate the singularities: it could be of some interest to determine whether their behavior differs in some aspect from that of Ginzburg–Landau vortices for $p = k$.

Let us briefly describe how the contents are organized. Section 2 is conceived so as to make the paper self-contained: we summarize the basic notation and preliminaries, omitting all proofs and details, for which we indicate suitable references. In section 3, we give a proof of the compactness statement in Theorem 1.1 (i), which turns out to be simpler than the corresponding result in [3]; essentially, we use the deformation theorem and the uniform boundedness in mass for a suitably defined notion of projected modified Jacobians. Section 4 is entirely devoted to the study of the optimal profile constants τ_d. In particular, we give "weak" and "strong" definitions of τ_d, a priori different from each other, and we show that they coincide. In section 5, we prove the Γ-liminf inequality, first for $n = 0$, by exploiting the weak definition of τ_d, and then for $n > 0$, by means of a slicing technique. Finally, in section 6, we prove the Γ-limsup inequality, using as a key tool an existence result for maps with prescribed singularities given in [2], combined with the strong definition of τ_d.

2. Preliminaries.

2.1. Notation. Throughout the paper, sets and functions are assumed to be Borel measurable, and, when no ambiguity may arise, we omit the indication of the measure in integrals. We adopt the letters K and C for constants that are, respectively, universal (i.e., depend only on the parameters p, k, and n and possibly on the potential W) and not universal. In general, we do not use indices, so that K and C may take different values even within the same line. Moreover, we adopt the following list of standard symbols.

B^d_r	the open ball in $\mathbb{R}^d$ with center the origin and radius r
S^{d-1}	the unit sphere in $\mathbb{R}^d$
$\mathcal{L}^d$	the Lebesgue measure on $\mathbb{R}^d$
$\mathcal{H}^d$	the d-dimensional Hausdorff measure
$\delta(P)$	the Dirac mass at the point P
$\mu \llcorner A$	the restriction of the measure μ to the set A
α_d	the Lebesgue measure of B^d_1
$A \subset\subset B$	the set A is compactly contained into the set B
χ_A	the characteristic function of the set A
$\mathrm{dist}(x, A)$	the distance of the point x from the set A
$\sharp A$	the cardinality of the finite set A
$\cdot$	the Euclidean scalar product
$\lvert\ \rvert$	the Euclidean norm
$f \ll g$	$\lim(\lvert f\rvert/\lvert g\rvert)$ vanishes
$\mathrm{osc}(f, E)$	the oscillation of $f \in C^0(A; B)$ in the set $E \subseteq A$
$\mathrm{Lip}_{(\mathrm{loc})}(A; B)$	the space of (locally) Lipschitz functions $f : A \to B$
$\mathrm{Lip} f$	the Lipschitz constant of $f \in \mathrm{Lip}(A; B)$
$\big(L^p_{(\mathrm{loc})}(A; B), \|\ \|_{p,A}\big)$	the space of (locally) Lebesgue functions $f : A \to B$
$\big(W^{1,p}_{(\mathrm{loc})}(A; B), \|\ \|_{1,p,A}\big)$	the space of (locally) Sobolev functions $f : A \to B$

From now on, we always assume that $p > k \geq 2$ (while $n \geq 0$) and that Ω is an open bounded domain in $\mathbb{R}^{n+k}$ with a Lipschitz boundary. Given $A \subset \Omega$ and $u \in W^{1,p}(A; \mathbb{R}^k)$, we set

$$F_\varepsilon(u, A) := \int_A e_\varepsilon(u), \qquad e_\varepsilon(u) := \varepsilon^{p-k}|\nabla u|^p + \frac{1}{\varepsilon^k} W(u).$$

Finally, for convenience we fix a positive function ψ on $[0,+\infty)$ which vanishes only at 1 and satisfies $\psi(|y|) \le W(y)$ for every $y \in \mathbb{R}^k$.

2.2. Currents. For every integer $h \in \{0,\dots,n+k\}$, we denote by $\Lambda_h(\mathbb{R}^{n+k})$ and $\Lambda^h(\mathbb{R}^{n+k})$, respectively, the spaces of *h-vectors* and *h-covectors* in $\mathbb{R}^{n+k}$, endowed with the standard notion of duality product $\cdot$, wedge product $\wedge$, and Euclidean norm $|\ |$. An h-vector or covector is called *simple* if it can be represented as the wedge product of h-vectors. Recalling that an *h-form* on Ω is a map from Ω into $\Lambda^h(\mathbb{R}^{n+k})$, we set $\mathcal{D}^h(\Omega)$ as the class of all smooth h-forms with compact support in Ω. By the pairing between vectors and covectors, the dual of $\mathcal{D}^h(\Omega)$ may be identified with the space $\mathcal{D}_h(\Omega)$ of *h-currents* over Ω, namely, distributions with values into $\Lambda_h(\mathbb{R}^{n+k})$. In particular, when a current T is a (locally) finite measure with values into $\Lambda_h(\mathbb{R}^{n+k})$, we say that it has (*locally*) *finite mass*. In this case, we denote by $|T|$ the variation of the measure T, by $\|T\| := |T|(\Omega)$ the total variation of T, and by $\|T\|_A = |T|(A)$ the mass of T in the open set $A \subset \Omega$; furthermore, we call sptT the support of the measure T.

Let us draw our attention to some special classes of currents with locally finite mass. When $M \subseteq \Omega$ is an oriented h-dimensional manifold at least of class C^1, we denote by $[\![M]\!]$ the h-current which applied to an h-form ω gives its integral over M in the classical sense of differential geometry. More generally, when $M \subseteq \Omega$ is an h-rectifiable set (namely, it can be covered by countably many h-surfaces of class C^1 up to an $\mathcal{H}^h$-negligible set) endowed with an orientation ξ (namely, a mapping which associates with $\mathcal{H}^h$-a.e. $x \in M$ a simple unitary h-vector spanning the approximate tangent space to M at x) and a multiplicity σ (namely, a real function locally integrable with respect to $\mathcal{H}^h \llcorner M$), we set (M,ξ,σ) to be the current defined by

$$(M,\xi,\sigma)(\omega) := \int_M \sigma(\omega\cdot\xi)\, d\mathcal{H}^h \qquad \forall \omega \in \mathcal{D}^h(\Omega). \tag{2.1}$$

With some abuse of notation, when dealing with a current (M,ξ,σ), we often denote it just by M. If a current can be represented as in (2.1) for some integer-valued multiplicity σ, we call it an *h-rectifiable current*. A current (M,ξ,σ) is said to be a *real polyhedral current* if M is a sum of finitely many h-simplexes, with ξ and σ constant on each of them; in case σ is also integer-valued, M is called an *integral polyhedral current*.

For $h \ge 1$, the *boundary* of an h-current T is the $(h-1)$-current defined by the identity $\partial T(\omega) := T(d\omega)$, $d\omega$ being the differential of the $(h-1)$-form ω. In particular, by the Stokes theorem, $\partial[\![M]\!] = [\![\partial M]\!]$; notice also that, if T is a boundary, namely, it is the boundary of some current, then $\partial T = 0$. A current T is called a *normal current* if both T and ∂T have locally finite mass and an *integral current* if both T and ∂T are rectifiable.

We also need to introduce the push forward and the flat norm of currents. Given a linear map $L : \mathbb{R}^{n+k} \to \mathbb{R}^m$, the *pull back* of an h-covector $w \in \Lambda^h(\mathbb{R}^m)$ by L is the h-covector $L^\sharp w \in \Lambda^h(\mathbb{R}^{n+k})$ defined by $L^\sharp w \cdot (v_1 \wedge \cdots \wedge v_h) := w \cdot (Lv_1 \wedge \cdots \wedge Lv_h)$ for every $v_1,\dots,v_h \in \mathbb{R}^{n+k}$. Accordingly, if Ω' is an open set of $\mathbb{R}^m$, given a smooth map $f : \Omega \to \Omega'$, the pull back of an h-form $\omega \in \mathcal{D}^h(\Omega')$ is the h-form $f^\sharp\omega \in \mathcal{D}^h(\Omega)$ defined by $f^\sharp\omega(x) := (Df(x))^\sharp \omega(f(x))$. The *push forward* of an h-current $T \in \mathcal{D}_h(\Omega)$ is the h-current $f_\sharp T \in \mathcal{D}_h(\Omega')$ defined through the duality $f_\sharp T(\omega) = T(f^\sharp\omega)$ for every $\omega \in \mathcal{D}^h(\Omega')$. Whenever T has compact support, the push forward and the boundary operator commute; that is, $\partial(f_\sharp T) = f_\sharp(\partial T)$. If in addition T has locally finite mass,

the variation measures of T and $f_\sharp T$ are related by the inequality

$$|f_\sharp T|(A) \le (\mathrm{Lip} f)^h\, |T|(f^{-1}(A)) \qquad \forall A \text{ open } \subset \Omega. \tag{2.2}$$

Given $T \in \mathcal{D}_h(\Omega)$, we shall denote by $\mathbb{F}_\Omega(T)$ the following *flat norm* (see [3]):

$$\mathbb{F}_\Omega(T) := \begin{cases} \inf\{\|S\| : S \in \mathcal{D}_{h+1}(\Omega),\ T = \partial S\} & \text{if } T \text{ is a boundary,} \\ +\infty & \text{otherwise.} \end{cases}$$

We point out that $\mathbb{F}_\Omega$ is strictly related to the usual flat norm $\mathcal{F}_\Omega$ for integral currents, as defined in [13, section 4.1.24]. In particular, if $S_i \to S$ in the flat norm $\mathcal{F}_\Omega$, we have $\mathbb{F}_\Omega(\partial S_i - \partial S) \to 0$, which in turn implies $\partial S_i \to \partial S$ in the dual of forms of class C^1_0; see [3] for more details.

For a broader description of the elements of currents theory sketched above, we refer the reader to [13, 16, 30].

2.3. Jacobians. Given a smooth map $u : \Omega \to \mathbb{R}^k$, its Jacobian is the k-form defined on Ω by

$$Ju := u^\sharp(dy) = du^1 \wedge \cdots \wedge du^k, \tag{2.3}$$

where $dy = dy_1 \wedge \cdots \wedge dy_k$ is the standard volume form on $\mathbb{R}^k$, and the 1-form du^i is the differential of the ith component of u. As long as u is of class $W^{1,k}(\Omega;\mathbb{R}^k)$, (2.3) makes sense and defines a continuous operator $u \mapsto Ju$ from $W^{1,k}(\Omega;\mathbb{R}^k)$ into $L^1(\Omega;\Lambda^k(\mathbb{R}^{n+k}))$. Moreover, Ju may be represented as $\sum_\alpha \det \nabla_\alpha u(x) dx_\alpha$, where the sum is extended over all k-multi-indices $\alpha = (i_1, \dots, i_k)$ with $1 \le i_1 < \cdots < i_k \le n+k$, $\nabla_\alpha u$ is the $(k \times k)$-matrix with columns $\nabla_{i_1} u, \dots, \nabla_{i_k} u$, and dx_α is the k-covector $dx_{i_1} \wedge \cdots \wedge dx_{i_k}$.

For a more geometric interpretation of the Jacobian, it is convenient to consider, instead of the k-form Ju, the n-current $\star Ju$, obtained via the following identification $\star$ of k-vectors and n-covectors. Given a multi-index α of order k, $\star dx_\alpha$ is the n-vector $\mathrm{sgn}(\hat\alpha, \alpha) e_{\hat\alpha}$, where $\hat\alpha = (j_1, \dots, j_n)$ is the set of indices not contained in α, $e_{\hat\alpha}$ is the n-vector $e_{j_1} \wedge \cdots \wedge e_{j_n}$, and $\mathrm{sgn}(\hat\alpha, \alpha)$ is the sign of the permutation $(\hat\alpha, \alpha)$. Then $\star$ extends in a natural way to an operator bringing k-forms into n-currents. Such an operator transforms differentials into boundaries, as one can check that, for every $\omega \in \mathcal{D}^k(\Omega)$, there holds $\star(d\omega) = (-1)^n \partial(\star\omega)$. Now observe that

$$Ju = \frac{1}{k} d(u^\sharp \omega_0), \tag{2.4}$$

where, denoting by $\widehat{dy_i}$ the wedge product of all dy_j with $j \ne i$, ω_0 is the k-form

$$\omega_0(y) := \sum_i (-1)^{i-1} y_i \widehat{dy_i}. \tag{2.5}$$

In view of (2.4), Ju is always a differential, which implies that $\star Ju$ is always a boundary. Further, by (2.4) and the definition of flat norm $\mathbb{F}_\Omega$ given in section 2.2, we deduce that

$$\mathbb{F}_\Omega(\star Ju) \le \|u\|_{\infty,\Omega} \|\nabla u\|^{k-1}_{k-1,\Omega}. \tag{2.6}$$

Finally, let us stress that (2.4) makes sense (differently from (2.3)) even for functions $u : \Omega \to \mathbb{R}^k$ of class $L^\infty_{\mathrm{loc}} \cap W^{1,k-1}_{\mathrm{loc}}$, provided the right-hand side is interpreted as a distribution. Mappings u for which such a distribution turns out to be a measure have been called functions with *bounded k-variation* and were investigated in [25], to which we refer for a more detailed account of the Jacobians theory.

2.4. Degree. Let u be a continuous map between two oriented h-manifolds M and N in $\mathbb{R}^{n+k}$, with $h = 1, \dots, n+k$, M compact, and $\partial N = \emptyset$. Given $y \in N \setminus u(\partial M)$, we denote by $\deg(u, M, N, y)$ the Brouwer degree of u at y. For its general definition and main properties, we refer the reader to [14, 22]. Let us just recall that, if u is of class C^1 and y is a regular value for u, then $\deg(u, M, N, y)$ is the algebraic sum of the number of inverse images $x \in u^{-1}(y)$, each one counted with a plus or minus sign according to whether the linear operator $\nabla u(x)$ is orientation-preserving or orientation-reversing. When $\partial M = \emptyset$ and N is connected, $\deg(u, M, N, y)$ turns out to be independent of y; in this case, it will be denoted by $\deg(u, M, N)$, or by $\deg(u, M)$ if $h = k-1$ and $N = S^{k-1}$.

We shall heavily exploit the behavior of the degree under continuous homotopy: by Hopf's theorem [22, Chapter 5, Theorem 1.10], two functions u and v from a $(k-1)$-dimensional compact manifold M without boundary with values into S^{k-1} are in the same homotopy class if and only if $\deg(u, M) = \deg(v, M)$. Also, we shall use the following remark, whose proof is elementary and may be found, e.g., in [2, section 2.10]: if a function u from an open subset M of $\mathbb{R}^k$ into $\mathbb{R}^k$ maps ∂M into S^{k-1}, then $\deg(u, M, \mathbb{R}^k, y)$ equals $\deg(u, \partial M)$ for $y \in B_1^k$ and 0 for $y \in \mathbb{R}^k \setminus \overline{B_1^k}$.

2.5. Area and coarea formulae. For completeness, we recall the following simple versions of the area and coarea formulae which will be often used in the paper. Let $E \subset \mathbb{R}^k$, and $f : \mathbb{R}^k \to \mathbb{R}$. For every function $u \in W^{1,p}(E; \mathbb{R}^k)$ $(p > k)$ and every Lipschitz function $g : \mathbb{R}^k \to \mathbb{R}$, we have (see, respectively, [16, section 3.1.5] and [12, section 3.4])

$$\int_E f(u)|Ju(x)| = \int_{\mathbb{R}^k} f(y)\, \sharp\{u^{-1}(y) \cap E\}\, d\mathcal{L}^k, \tag{2.7}$$

$$\int_E f(x)|\nabla g(x)| = \int_{\mathbb{R}} dt \int_{g^{-1}(t)\cap E} f\, d\mathcal{H}^{k-1}. \tag{2.8}$$

3. Compactness. The starting point in proving the compactness statement in Theorem 1.1 (i) is the following key inequality:

$$F_\varepsilon(u, A) \geq K \int_A W(u)^{1-k/p}|Ju|. \tag{3.1}$$

It is obtained simply by applying first Young's inequality $a + b \geq K a^\lambda b^{1-\lambda}$ (with $a = \varepsilon^{p-k}|\nabla u|^p$, $b = \varepsilon^{-k} W(u)$, and $\lambda = k/p$) and then the algebraic inequality $|\nabla u|^k \geq |Ju|$. Thanks to (3.1), we can gain compactness without using the lower bound proved by Jerrard in [24], which instead is fundamental in the case $p = k$. Actually, given a sequence of functions $\{u_\varepsilon\}$ with equibounded energies, by applying (3.1) we can deduce a uniform bound in mass not for the very Jacobians of u_ε but for suitably defined "modified Jacobians." Let us introduce them, together with some additional tools and notation.

3.1. Modified Jacobians, grids, and projection maps. Let $\rho : [0, +\infty) \to [0, +\infty)$ be a smooth kernel such that $\rho(t) = 0$ for $t \geq 1/3$ and $\int_{B^k_{1/3}} \rho(|y|) = \alpha_k$. For every smooth function $u : \Omega \to \mathbb{R}^k$, we call *the modified Jacobian of* u the current $J'u := u^\sharp(\rho(|y|)\, dy) = \rho(|u|)Ju$. Thus, the basic distinguishing feature of $J'u$ with respect to Ju is that the support of $J'u$ does not intersect the set of points $x \in \Omega$ where $|u(x)| \geq 1/2$.

Given $l > 0$ and $x_0 \in \mathbb{R}^{n+k}$, we call *the grid of step* l *and center* x_0 the union $\mathcal{G} = \mathcal{G}^l(x_0)$ of all closed cubes of the form $x_0 + lz + [0, l]^{n+k}$ for z varying in $\mathbb{Z}^n$.

(We often omit the center or even the step, and we simply write $\mathcal{G}^l$ or $\mathcal{G}$.) For $h = 1, \dots, n+k$, we call h-cells of $\mathcal{G}$ the h-dimensional faces of the cubes of $\mathcal{G}$, and h-skeleton of $\mathcal{G}$ their union, which we denote by R_h. In particular, by saying that an open set A is delimited by $\mathcal{G}$, we mean that $\partial A \subset R_{n+k-1}$. We indicate by $\mathcal{G}'$ the dual grid of $\mathcal{G} = \mathcal{G}^l(x_0)$, namely, $\mathcal{G}' := \mathcal{G}^l\big(x_0 + (l/2, \dots, l/2)\big)$, and by R'_h the h-skeleton of $\mathcal{G}'$. For every h-cell Q of $\mathcal{G}$, we denote by Q' the unique $(n+k-h)$-cell of $\mathcal{G}'$ which intersects $\mathcal{G}$. When dealing with a sequence of grids $\mathcal{G}_\varepsilon$, $R_{\varepsilon,h}$ will denote the corresponding h-skeletons.

Let a grid of step l and a bounded open set V in $\mathbb{R}^{n+k}$ be given. We denote by V_d the closed d-neighborhood of V, with $d := 2\sqrt{n+k}\, l$ being twice the diameter of the cubes in $\mathcal{G}$. Then a suitable version [3, Lemma 3.8] of the Federer–Fleming deformation theorem [32, section 29] ensures the existence of a locally Lipschitz *projection map* $\Phi : \mathbb{R}^{n+k} \setminus R_{k-1} \to R'_n$ such that the following retraction property holds: for any n-current T in $\mathbb{R}^{n+k}$ with finite mass, such that

$$\mathrm{spt}T \subset \mathbb{R}^k \setminus R_{k-1} \quad \text{and} \quad (\mathrm{spt}\partial T) \cap V_d = \emptyset, \tag{3.2}$$

the push forward $\Phi_\sharp T$ is a well-defined current in $\mathbb{R}^{n+k}$ satisfying

$$\mathrm{spt}\Phi_\sharp T \subset R'_n \quad \text{and} \quad \mathrm{spt}\partial(\Phi_\sharp T) \cap V = \emptyset, \tag{3.3}$$

$$\|\Phi_\sharp T\| \le K\|T\|, \tag{3.4}$$

$$\mathbb{F}_V(T - \Phi_\sharp T) \le K l^{n+1} \int_{V_d} \frac{d|T|(x)}{[\mathrm{dist}(x, R_{k-1})]^n}. \tag{3.5}$$

If in addition $T = [\![M]\!]$ is the current associated with a smooth n-surface M, then for every k-cell Q of $\mathcal{G}$ such that M is transversal to Q and Q' intersects V, the multiplicity of $\Phi_\sharp T$ on Q' is a constant integer. It agrees, up to a sign depending on the orientations of Q and Q', with the intersection number of M and Q (see [22, section 5.2]).

Observe now that, if u is a function smooth in a neighborhood W of V_d, with $|u| \ge 1/2$ on $R_{k-1} \cap W$, then the current T obtained by extending $\star J' u$ to zero out of W fulfills both assumptions in (3.2). Therefore, its push forward $\Phi_\sharp T$ satisfies conditions (3.3), (3.4), and (3.5); in particular, it agrees in V with a real polyhedral boundary. Moreover, applying first the above-mentioned statement on the multiplicity of $\Phi_\sharp [\![M]\!]$ to the currents associated with the level sets of u and then the coarea formula, one may compute the multiplicity of $\Phi_\sharp(\star J' u)$ on an n-cell Q' of $\mathcal{G}'$ which intersects V. It equals up to a sign $\alpha_k \deg(u/|u|, \partial Q)$ (where α_k come out from the integral constraint satisfied by the kernel ρ; see [3, Lemma 3.9] for a complete proof).

PROPOSITION 3.1. *Let a sequence of smooth maps $\{u_\varepsilon\}$ with $\sup_\varepsilon F_\varepsilon(u_\varepsilon) < +\infty$, and open sets U, V, and W with $U \subset\subset V \subset\subset W \subset\subset \Omega$ be given. Then the following statements hold:*

(i) *Boundedness of modified Jacobians. We have $\sup_\varepsilon \| \star J' u_\varepsilon\|_\Omega < +\infty$.*

(ii) *Compactness of projected modified Jacobians. We can find a sequence of grids $\mathcal{G}_\varepsilon$ of infinitesimal step $l(\varepsilon) \gg \varepsilon$, such that $|u_\varepsilon|$ converge uniformly to 1 on $R_{\varepsilon,k-1} \cap W$; moreover, if Φ_ε are the retraction maps associated with $\mathcal{G}_\varepsilon$ as above, we have $\sup_\varepsilon \|(\Phi_\varepsilon)_\sharp(\star J' u_\varepsilon)\|_V < +\infty$, and we can extract a subsequence such that $\mathbb{F}_U[(\Phi_\varepsilon)_\sharp(\star J' u_\varepsilon) - \alpha_k M] \to 0$, where M is a n-dimensional integral boundary with finite mass in U.*

(iii) *Flat asymptotical equivalence. The sequences of currents $\{\star J u_\varepsilon\}$, $\{\star J' u_\varepsilon\}$, and $\{(\Phi_\varepsilon)_\sharp(\star J' u_\varepsilon)\}$ is asymptotically equivalent in the flat norm over U.*

From the previous proposition, it is easy to deduce the following.

Proof of the compactness statement in Theorem 1.1 (i). First, we take an open set $\Omega' \supset\supset \Omega$, and we extend u_ε to $\tilde{u}_\varepsilon$ on Ω' so that the energies remain equibounded, i.e., $\sup_\varepsilon F_\varepsilon(\tilde{u}_\varepsilon, \Omega') < +\infty$. This can be made by reflection around $\partial\Omega$; cf. Remark 8.2 of [3]. Next we observe that, by density, it is not restrictive to assume that u_ε are smooth. Then, it is enough to apply Proposition 3.1, with Ω replaced by Ω' and U replaced by Ω: by (ii), up to subsequences there exists an n-dimensional integral boundary M with finite mass in Ω, such that $\mathbb{F}_\Omega[(\Phi_\varepsilon)_\sharp(\star J' u_\varepsilon) - \alpha_k M] \to 0$; by (iii), we have also $\mathbb{F}_\Omega(\star J u_\varepsilon - \alpha_k M) \to 0$. □

The remainder of this section is devoted to the proof of Proposition 3.1. We need two preliminary lemmas, which will be repeatedly used in later sections as well. They are quite close to some technical results presented in [3, section 8].

LEMMA 3.2. *Given a nonnegative function $v \in L^1(\Omega)$, a positive finite measure μ in Ω, and a positive parameter l, we can position a grid $\mathcal{G}$ of step l so that both the following inequalities are satisfied;*

$$l^{n+1} \int_{R_{k-1}\cap\Omega} v \le K \int_\Omega v, \tag{3.6}$$

$$l^n \int_\Omega \frac{d\mu(x)}{[\mathrm{dist}(x, R_{k-1})]^n} \le K\mu(\Omega). \tag{3.7}$$

Proof. If the grid $\mathcal{G}^l$ is centered at x_0, the left-hand sides of (3.6) and (3.7) are functions of x_0, say, respectively, $f_1(x_0)$ and $f_2(x_0)$. Let us compute the integral means of $f_i(x_0)$ over $Q_l := [0, l]^{n+k}$ for $i = 1, 2$.

We denote by $\mathcal{I}$ the family of all subsets I of $\{1, \dots, n+k\}$ with $\sharp I = k-1$. For $I \in \mathcal{I}$, $I = \{i_1, \dots, i_{k-1}\}$, we let $R_{k-1}(I)$ be the union of the $(k-1)$-cells of $\mathcal{G}^l(x_0)$ which are parallel to the space spanned by the subset $\{e_{i_1}, \dots, e_{i_{k-1}}\}$ of the canonical basis $\{e_1, \dots, e_{n+k}\}$ of $\mathbb{R}^{n+k}$; also, we let $Q_l(I)$ be the set of points $x_0 \in Q_l$ whose coordinates $x_{0i_1}, \dots, x_{0i_{k-1}}$ equal zero. We have

$$\begin{aligned} \fint_{Q_l} f_1(x_0) &= \sum_{I\in\mathcal{I}} \fint_{Q_l} l^{n+1} \int_{R_{k-1}(I)\cap\Omega} v = \sum_{I\in\mathcal{I}} \fint_{Q_l(I)} l^{n+1} \int_{R_{k-1}(I)\cap\Omega} v \\ &= \sum_{I\in\mathcal{I}} \int_{Q_l(I)} \int_{R_{k-1}(I)\cap\Omega} v = \binom{n+k}{k-1} \int_\Omega v =: K_1 \int_\Omega v. \end{aligned}$$

Here the second equality holds since, for $I = \{i_1, \dots, i_{k-1}\}$, the set $R_{k-1}(I) \cap \Omega$ does not depend on the coordinates $x_{0i_1}, \dots, x_{0i_{k-1}}$ of x_0, while the fourth equality follows from Fubini's theorem and the computation of $\sharp\mathcal{I}$.

Denoting by R the $(k-1)$-skeleton of the grid with step 1 centered at the origin, we have

$$\begin{aligned} \fint_{Q_l} f_2(x_0) &= \fint_{Q_l} l^n \int_\Omega \frac{d\mu(x)}{[l\,\mathrm{dist}(l^{-1}(x - x_0), R)]^n}\, d\mathcal{L}^{n+k}(x_0) \\ &= \int_\Omega \fint_{Q_l} \frac{d\mathcal{L}^{n+k}(x_0)}{[\mathrm{dist}(l^{-1}(x - x_0), R)]^n} d\mu(x) \\ &= \left[\fint_{Q_1} \frac{d\mathcal{L}^{n+k}(y)}{[\mathrm{dist}(y, R)]^n} \right] \mu(\Omega) =: K_2 \mu(\Omega), \end{aligned}$$

where in the last line K_2 is a universal constant because the integral between square brackets is finite (see, e.g., [3, Lemma 8.3]).

Now, fix $K > K_1 + K_2$, and set $E_1 := \{x_0 \in Q_l : f_1(x_0) > K \int_\Omega v\}$, $E_2 := \{x_0 \in Q_l : f_2(x_0) > K\mu(\Omega)\}$. Using the above computations, we infer that $\mathcal{L}^{n+k}(E_i) \le (K_i/K)l^{n+k}$ for $i = 1, 2$. So $\mathcal{L}^{n+k}(E_1 \cup E_2) < l^{n+k}$; hence the complement of $E_1 \cup E_2$ in Q_l is nonempty. □

LEMMA 3.3. *Let $u \in W^{1,p}(\Omega; \mathbb{R}^k)$, and let $Q \subset \Omega$ be a $(k-1)$-cell of a grid of step l. If ψ is defined as in the end of section* 2.1*, for every $\varepsilon > 0$ there holds*

$$\fint_Q \psi(|u|) \le K\varepsilon^k l^{-k-n}\left\{l^{n+1}\int_Q e_\varepsilon(u)\right\}. \tag{3.8}$$

Moreover, if we fix $\lambda > (k-1)/p$, and Ψ is a primitive of $\psi^{(1-\lambda)/\lambda p}$, we have

$$\operatorname{osc}(\Psi(|u|), Q)^{\lambda p} \le K\varepsilon^{k-\lambda p} l^{\lambda p-k-n}\left\{l^{n+1}\int_Q e_\varepsilon(u)\right\}. \tag{3.9}$$

Proof. Inequality (3.8) is straightforward by taking into account that $\psi(|u|) \le \varepsilon^k e_\varepsilon(u)$. To prove (3.9), since $\lambda p > k-1$, we may apply the Morrey–Sobolev embedding theorem to obtain

$$\operatorname{osc}(\Psi(|u|), Q)^{\lambda p} \le K l^{\lambda p[1-(k-1)/\lambda p]} \int_Q |\nabla(\Psi(|u|))|^{\lambda p}. \tag{3.10}$$

By Young's inequality and the definition of Ψ, we also have

$$\varepsilon^{k-\lambda p}\int_Q e_\varepsilon(u) \ge K\int_Q |\nabla u|^{\lambda p}\psi(|u|)^{1-\lambda} \ge K\int_Q |\nabla(\Psi(|u|))|^{\lambda p}. \tag{3.11}$$

Combining (3.10) and (3.11), we obtain (3.9). □

We are now in a position to give the following proof.

Proof of Proposition 3.1. (i) Let $K > 0$ be chosen so that $\psi(t)^{1-k/p} \ge K\rho(t)$ for all $t \in [0, +\infty)$. Then (3.1) yields $F_\varepsilon(u_\varepsilon) \ge K\| \star J'u_\varepsilon\|_\Omega$, and the statement follows from the assumption $\sup_\varepsilon F_\varepsilon(u_\varepsilon) < +\infty$.

(ii) Let us define $l(\varepsilon) := \varepsilon^\alpha$, with $0 < \alpha < 1/(n+1)$. By Lemma 3.2, the assumption $\sup_\varepsilon F_\varepsilon(u_\varepsilon) < +\infty$, and assertion (i) is already proved. For every fixed ε we may position a grid $\mathcal{G}_\varepsilon$ of step $l(\varepsilon)$ so that both conditions below hold:

$$\sup_\varepsilon \left\{l(\varepsilon)^{n+1}\int_{R_{\varepsilon,k-1}\cap\Omega} e_\varepsilon(u_\varepsilon)\right\} < +\infty, \tag{3.12}$$

$$\sup_\varepsilon \left\{l(\varepsilon)^n \int_\Omega \frac{d\,|\star J'u_\varepsilon|(x)}{[\operatorname{dist}(x, R_{\varepsilon,k-1})]^n}\right\} < +\infty. \tag{3.13}$$

We claim that $|u_\varepsilon| \to 1$ uniformly on $R_{\varepsilon,k-1} \cap W$. To prove such a claim, we choose λ and Ψ as in the statement of Lemma 3.3, and we denote by Q a generic $(k-1)$-cell of $R_{\varepsilon,k-1}$ entirely contained in Ω. Since ψ vanishes only at 1 and Ψ is continuous and strictly increasing, it is enough to show that

$$\fint_Q \psi(|u_\varepsilon|) \to 0 \quad \text{and} \quad \operatorname{osc}(\Psi(|u_\varepsilon|), Q) \to 0 \quad \text{uniformly in } Q. \tag{3.14}$$

By Lemma 3.3, (3.12), and the choice of $l(\varepsilon)$, we have

$$\fint_Q \psi(|u_\varepsilon|) \le C\varepsilon^k l(\varepsilon)^{-k-n} = C\varepsilon^{k-\alpha(k+n)},$$
$$\operatorname{osc}(\Psi(|u_\varepsilon|), Q)^{\lambda p} \le C\varepsilon^{k-\lambda p} l(\varepsilon)^{\lambda p-k-n} = C\varepsilon^{k-\lambda p+\alpha(\lambda p-k-n)}.$$

Therefore, the first condition in (3.14) is fulfilled, because $\alpha < k/(k+n)$. As for the second condition in (3.14), it is satisfied provided $\lambda < (k+\alpha(\alpha-1)^{-1}n)/p$. This latter inequality turns out to be compatible (thanks to the choice α) with the one already imposed on λ (namely, $\lambda > (k-1)/p$). Thus (3.14) is proved.

Now, since the functions u_ε are smooth on W with $|u_\varepsilon| \to 1$ on $R_{\varepsilon,k-1} \cap W$, for ε small enough the currents obtained by extending to zero $\star J' u_\varepsilon$ out of W satisfy both conditions in (3.2) (indeed, for ε small enough, $|u_\varepsilon| \geq 1/2$ on $R_{\varepsilon,k-1} \cap W$ and, if $d = 2\sqrt{n+k}\, l(\varepsilon)$, V_d is compactly contained in W). Therefore, using (3.3), (3.4), and assertion (i) (already proved), we deduce that $\{(\Phi_\varepsilon)_\sharp(\star J' u_\varepsilon)\}$ is a sequence of polyhedral boundaries in V, with uniformly bounded masses and multiplicities in $\alpha_k\mathbb{Z}$ (cf. section 3.1). As $U \subset\subset V$, by an adaptation of the Federer–Fleming closure theorem (see [3, Proposition 2.8]), we can extract a subsequence such that $\mathbb{F}_U[(\Phi_\varepsilon)_\sharp(\star J' u_\varepsilon) - \alpha_k M] \to 0$, where M is an n-dimensional integral boundary with finite mass in U.

(iii) The asymptotical equivalence between $\{\star J u_\varepsilon\}$ and $\{\star J' u_\varepsilon\}$ follows from the assumption $\sup_\varepsilon F_\varepsilon(u_\varepsilon) < +\infty$, together with the following estimate, holding for all functions u smooth on U:

$$\mathbb{F}_U(\star J u - \star J' u) \leq K\varepsilon F_\varepsilon(u, U). \tag{3.15}$$

To show (3.15), observe first that $k\rho(|y|)\, dy$ is the differential of the $(k-1)$-form $\omega' := \sigma(|y|)\omega_0(y)$, where $\sigma(t) := kt^{-k}\int_0^t \rho(s)s^{k-1}\, ds$ and ω_0 is the $(k-1)$-form defined in (2.5). So there holds

$$\star J u - \star J' u = (-1)^n \frac{1}{k}\partial[\star u^\sharp(\omega_0 - \omega')]. \tag{3.16}$$

Moreover, the difference between the forms ω_0 and ω' satisfies the estimate

$$|\omega_0(y) - \omega'(y)| \leq K|1 - \sigma(|y|)|\, |y| \leq K||y| - 1| \leq KW(y)^{(p-k+1)/p}, \tag{3.17}$$

where the second inequality follows from the identity $\sigma(t) = t^{-k}$ for $t \geq 1/3$, and the third inequality holds due to the growth assumptions (1.2) on W.

Now, using the definition of flat norm together with (3.16), estimate (3.17), and Hölder's inequality, we infer

$$\begin{aligned}
\mathbb{F}_U(\star J u - \star J' u) &\leq K\| \star u^\sharp(\omega_0 - \omega')\|_U \leq K\int_U |\omega_0(u) - \omega'(u)||\nabla u|^{k-1} \\
&\leq K\int_U W(u)^{(p-k+1)/p}|\nabla u|^{k-1} \\
&\leq K\left\{\int_U W(u)\right\}^{(p-k+1)/p}\left\{\int_U |\nabla u|^p\right\}^{(k-1)/p} \\
&\leq K\left\{\varepsilon^k F_\varepsilon(u,U)\right\}^{(p-k+1)/p}\left\{\varepsilon^{k-p}F_\varepsilon(u,U)\right\}^{(k-1)/p} \\
&= K\varepsilon F_\varepsilon(u,U).
\end{aligned}$$

Thus (3.15) is proved, and it remains to show the asymptotical equivalence between $\{\star J' u_\varepsilon\}$ and $\{(\Phi_\varepsilon)_\sharp(\star J' u_\varepsilon)\}$. Since the currents obtained by extending to zero $\star J' u_\varepsilon$ out of W satisfy (3.5), and the grids $\mathcal{G}_\varepsilon$ verify (3.13), we have

$$\mathbb{F}_U\big(\star J' u_\varepsilon - (\Phi_\varepsilon)_\sharp(\star J' u_\varepsilon)\big) \leq Kl(\varepsilon)\left\{l(\varepsilon)^n \int_\Omega \frac{d\,|\star J' u_\varepsilon|(x)}{[\mathrm{dist}(x, R_{\varepsilon,k-1})]^n}\right\} \to 0. \qquad \square$$

4. Optimal profile constants. Throughout this section, we assume that $n = 0$ (so, in particular, all functions in $W^{1,p}(\Omega, \mathbb{R}^k)$ are continuous by the Sobolev embedding theorem). Our goal is to introduce the family of constants τ_d which intervene in Theorem 1.1, and to state their main properties. We proceed according to the following plan. First, we give the strong definition of τ_d, prescribing the trace at infinity (cf. Definition 4.1), and we prove that τ_d is strictly positive for all $d \neq 0$. Next, we show that all functions u with finite energy on $\mathbb{R}^k$ admit a suitably defined notion of degree at infinity, and we introduce the corresponding relaxed definition of optimal profile constant $\overline{\tau}_d$ (cf. Definition 4.8). Finally, we prove that τ_d and $\overline{\tau}_d$ coincide and, as a consequence, that τ_d is a subadditive function of d.

DEFINITION 4.1. *For every $d \in \mathbb{Z}$, let ϕ_d be a fixed Lipschitz map from the sphere S^{k-1} into itself of degree d. We say that a function $u \in W^{1,p}_{\mathrm{loc}}(\mathbb{R}^k; \mathbb{R}^k)$ has* trace ϕ_d at infinity, *and we write* $\mathrm{tr}(u, \infty) = \phi_d$ *if there exists $\overline{r} > 0$ such that $u(x) = \phi_d(x/|x|)$ for all x with $|x| \geq \overline{r}$. Then we set*

$$\tau_d := \inf \left\{ F_1(u, \mathbb{R}^k) \ : \ u \in W^{1,p}_{\mathrm{loc}}(\mathbb{R}^k; \mathbb{R}^k) \text{ such that } \mathrm{tr}(u, \infty) = \phi_d \right\}. \tag{4.1}$$

Remark 4.2. It is straightforward to check that the energy $F_1(u, \mathbb{R}^k)$ is finite for all functions $u \in W^{1,p}_{\mathrm{loc}}(\mathbb{R}^k; \mathbb{R}^k)$ having trace ϕ_d at infinity.

PROPOSITION 4.3. *There exists a positive constant c, independent of d, such that $\tau_d \geq c|d|$ for every $d \in \mathbb{Z}$.*

Proof. Let $u \in W^{1,p}_{\mathrm{loc}}(\mathbb{R}^k; \mathbb{R}^k)$ with $u(x) = \phi_d(x/|x|)$ for $|x| \geq \overline{r}$. Using (3.1) and the area formula (2.7), we get

$$\begin{aligned} F_1(u, \mathbb{R}^k) &\geq K \int_{\mathbb{R}^k} W(u)^{1-k/p} |Ju| \geq K \int_{B^k_{\overline{r}}} W(u)^{1-k/p} |Ju| \\ &= K \int_{\mathbb{R}^k} W(y)^{1-k/p} \sharp \{u^{-1}(y) \cap B^k_{\overline{r}}\} \\ &\geq K \int_{\mathbb{R}^k} W(y)^{1-k/p} |\deg(u, B^k_{\overline{r}}, \mathbb{R}^k, y)| = K|d| \int_{B^k_1} W(y)^{1-k/p}, \end{aligned}$$

where the last equality holds because $u(\partial B^k_{\overline{r}}) \subseteq S^{k-1}$ (cf. section 2.4). ∎

DEFINITION 4.4. *Let a function $u \in C^0(\mathbb{R}^k; \mathbb{R}^k)$ be given. We say that a value $y \in \mathbb{R}^k$ is* not attained by u at infinity *if there exists $\overline{r} = \overline{r}(y) > 0$ such that $y \notin u(\mathbb{R}^k \setminus B^k_{\overline{r}})$. In this case, we can set*

$$\deg(u, \infty, y) := \deg\left(\frac{u - y}{|u - y|}, \partial B^k_r \right) \quad \forall r \geq \overline{r}(y),$$

since the right-hand side of the above definition does not depend on $r \geq \overline{r}(y)$.

LEMMA 4.5. *Let $F_1(u, \mathbb{R}^k) < +\infty$. Then the following hold:*

(i) *For all $\alpha > 0$, B^k_α contains some value not attained by u at infinity.*

(ii) *There exists a sequence of radii $\{r_n\}$, with $\lim_n r_n = +\infty$, such that*

$$\lim_n \left\{ r_n \int_{\partial B^k_{r_n}} e_1(u) \right\} = 0 \quad \text{and} \quad \lim_n \left\{ \sup_{\partial B^k_{r_n}} ||u| - 1| \right\} = 0. \tag{4.2}$$

(iii) *For any two values $y_1, y_2 \in B^k_1$ not attained by u at infinity, there holds $\deg(u, \infty, y_1) = \deg(u, \infty, y_2)$.*

Before proving the above lemma, we add a related definition and remark which will be useful in what follows.

DEFINITION 4.6. *Let $F_1(u,\mathbb{R}^k) < +\infty$. Then, we call the* degree at infinity of *u—and denote it by* $\deg(u,\infty)$*—the quantity* $\deg(u,\infty,y)$ *for* any *value $y \in B_1^k$ not attained by u at infinity. Indeed, such a value exists in view of Lemma* 4.5 (i)*, and it does not depend on the choice of $y \in B_1^k$ in view of Lemma* 4.5 (iii).

Remark 4.7. (i) Let $F_1(u,\mathbb{R}^k) < +\infty$. For every $\delta > 0$, we may find a radius R (arbitrarily large) such that

$$R\int_{\partial B_R^k} e_1(u) < \delta\ , \quad \big||u|-1\big| < \delta \quad \text{on } \partial B_R^k\ , \quad \deg\left(\frac{u}{|u|},\partial B_R^k\right) = \deg(u,\infty). \tag{4.3}$$

Indeed, by Lemma 4.5 we can select a value $y \in B_{1-2\delta}^k$ and an arbitrarily large radius R such that $y \notin u(\mathbb{R}^k \setminus B_R)$ and the first two conditions in (4.3) are satisfied. Then also the third one is fulfilled, as

$$\deg\left(\frac{u}{|u|},\partial B_R^k\right) = \deg\left(\frac{u-y}{|u-y|},\partial B_R^k\right) = \deg(u,\infty,y) = \deg(u,\infty).$$

(ii) Let $F_1(u,\mathbb{R}^k) < +\infty$, and assume in addition that $|u| \geq 1/2$ on ∂Q_n for a sequence of cubes Q_n centered at the origin, whose sides diverge as $n \to +\infty$. Then, by arguing in a similar way as in the item (i) above, one obtains that $\deg(u,\infty) = \deg(u/|u|,\partial Q_n)$ for n large enough.

Proof of Lemma 4.5. (i) Let $\alpha > 0$. By the assumption $F_1(u,\mathbb{R}^k) < +\infty$ and (3.1), we may choose $r = r(\alpha)$ large enough so that

$$\int_{\mathbb{R}^k\setminus B_r^k} W(u)^{1-k/p}|Ju| < \int_{B_\alpha^k} W(y)^{1-k/p}. \tag{4.4}$$

Since by the area formula (2.7) the left-hand side of (4.4) is larger than or equal to $\int_{B_\alpha^k}[W(y)^{1-k/p}\sharp\{u^{-1}(y)\cap(\mathbb{R}^k\setminus B_r^k)\}]$, we deduce that $\sharp\{u^{-1}(y)\cap(\mathbb{R}^k\setminus B_r^k)\}$ cannot be strictly positive for all $y \in B_\alpha^k$.

(ii) By the assumption $F_1(u,\mathbb{R}^k) < +\infty$, a contradiction argument readily yields the existence of a sequence of radii $\{r_n\}$, with $\lim_n r_n = +\infty$, satisfying the first equality in (4.2). Let us show that this sequence also fulfills the second condition in (4.2). Choose λ and Ψ as in Lemma 3.4, and notice that such a lemma still holds (with the very same proof) when u belongs to $W^{1,p}_{\mathrm{loc}}(\mathbb{R}^k;\mathbb{R}^k)$ and the $(k-1)$-cell Q of size l is replaced by ∂B_l^k. Then inequalities (3.8) and (3.9), applied with $n = 0$ and $\varepsilon = 1$, give

$$\fint_{\partial B_{r_n}^k}\psi(|u|) \leq K\, r_n^{-k}\left\{r_n\int_{\partial B_{r_n}^k} e_1(u)\right\},$$
$$\mathrm{osc}(\Psi(|u|),\partial B_{r_n}^k)^{\lambda p} \leq K\, r_n^{\lambda p-k}\left\{r_n\int_{\partial B_{r_n}^k} e_1(u)\right\}.$$

We conclude by taking $\lambda \leq k/p$ and arguing as in the proof of Proposition 3.1.

(iii) Let $y_1, y_2 \in B_1^k$ be two values not attained by u at infinity, and let r_1, r_2 be the corresponding radii such that $y_i \notin u(\mathbb{R}^k \setminus B_{r_i}^k)$ for $i = 1,2$. Since $|y_i| < 1$, by assertion (ii) (already proved), we may find a radius $\overline{r} > \max\{r_1, r_2\}$ such that

$|u(x)| > \max\{|y_1|, |y_2|\}$ for all $x \in \partial B^k_{\overline{r}}$. Therefore,

$$\begin{aligned}\deg(u, \infty, y_1) &= \deg\left(\frac{u(x)-y_1}{|u(x)-y_1|}, \partial B^k_{\overline{r}}\right) = \deg\left(\frac{u(x)-y_2}{|u(x)-y_2|}, \partial B^k_{\overline{r}}\right)\\ &= \deg(u, \infty, y_2). \qquad \square\end{aligned}$$

DEFINITION 4.8. *For every $d \in \mathbb{Z}$, we set*

$$\overline{\tau}_d := \inf\big\{F_1(u, \mathbb{R}^k) \ : \ u \in W^{1,p}_{\mathrm{loc}}(\mathbb{R}^k; \mathbb{R}^k) \ \text{ such that } \ \deg(u, \infty) = d\big\}. \tag{4.5}$$

PROPOSITION 4.9. *For every $d \in \mathbb{Z}$, the constants τ_d and $\overline{\tau}_d$ defined, respectively, by* (4.1) *and* (4.5) *coincide. In particular, τ_d equals τ_{-d}, and it is independent of the choice of ϕ_d.*

Proof. We introduce an auxiliary quantity τ'_d defined by

$$\begin{aligned}\tau'_d := \inf\big\{&F_1(u, \mathbb{R}^k) \ : \ u \in W^{1,p}_{\mathrm{loc}}(\mathbb{R}^k; \mathbb{R}^k) \text{ such that } \exists\, \overline{r} > 0 \text{ with}\\ &|u(x)| = 1 \text{ on } \mathbb{R}^k \setminus B^k_r \ \text{ and } \deg(u, \partial B^k_r) = d \ \ \forall r \geq \overline{r}\big\}.\end{aligned} \tag{4.6}$$

Denoting, respectively, by $\mathcal{A}_d$, $\mathcal{A}'_d$, and $\overline{\mathcal{A}}_d$ the classes of admissible functions in the right-hand sides of (4.1), (4.6), and (4.5), there holds $\mathcal{A}_d \subset \mathcal{A}'_d \subset \overline{\mathcal{A}}_d$. Therefore, $\tau_d \geq \tau'_d \geq \overline{\tau}_d$. We can then achieve the proof in two steps by showing first that $\tau_d \leq \tau'_d$ and then that $\tau'_d \leq \overline{\tau}_d$.

Step 1. To prove that $\tau_d \leq \tau'_d$, let us show that, for any given $u \in \mathcal{A}'_d$ with $F_1(u, \mathbb{R}^k) < +\infty$ and for any $\varepsilon > 0$, there exists $v \in \mathcal{A}_d$ such that

$$F_1(v, \mathbb{R}^k) \leq F_1(u, \mathbb{R}^k) + \varepsilon. \tag{4.7}$$

Let $\overline{r} > 0$ be such that $|u(x)| = 1$ on $\mathbb{R}^k \setminus B^k_r$ and $\deg(u, \partial B^k_r) = d$ for all $r \geq \overline{r}$. For any $r_1 \geq \overline{r}$, the continuous mapping $g_{r_1} : S^{k-1} \to S^{k-1}$ defined by $g_{r_1}(y) := u(r_1 y)$ has degree d. Therefore, we may find a Lipschitz homotopy $\varphi : S^{k-1} \times [0,1] \to S^{k-1}$ such that $\varphi(\cdot, 0) = g_{r_1}(\cdot)$ and $\varphi(\cdot, 1) = \phi_d(\cdot)$. For $r_2 > r_1$, let $\lambda : [r_1, r_2] \to [0,1]$ be an affine function with $\lambda(r_1) = 0$ and $\lambda(r_2) = 1$. We set

$$v(x) := \begin{cases} u(x) & \text{if } |x| \leq r_1,\\ \varphi\big(\frac{x}{|x|}, \lambda(|x|)\big) & \text{if } r_1 \leq |x| \leq r_2,\\ \phi_d\big(\frac{x}{|x|}\big) & \text{if } |x| \geq r_2.\end{cases}$$

Clearly, $v \in \mathcal{A}_d$, and we claim that (4.7) is fulfilled provided r_1 and r_2 are suitably chosen. Indeed, we have

$$F_1(v, \mathbb{R}^k) - F_1(u, \mathbb{R}^k) = \underbrace{F_1(v, \mathbb{R}^k \setminus B^k_{r_2})}_{\mathrm{I}} + \underbrace{F_1(v, B^k_{r_2} \setminus B^k_{r_1})}_{\mathrm{II}} - \underbrace{F_1(u, \mathbb{R}^k \setminus B^k_{r_1})}_{\mathrm{III}}.$$

Term I is infinitesimal when $r_2 \to +\infty$, as $F_1(v, \mathbb{R}^k) < +\infty$ (cf. Remark 4.2). Similarly, term III is infinitesimal when $r_1 \to +\infty$ by the assumption $F_1(u, \mathbb{R}^k) < +\infty$. As for term II, we have $\mathrm{II} = \int_{B^k_{r_2} \setminus B^k_{r_1}} |\nabla v|^p$, and

$$|\nabla v(x)| \leq \Big\{\sup_{S^{k-1} \times [0,1]} |\nabla \varphi|\Big\}\left\{\frac{(k-1)^{1/2}}{|x|} + \frac{1}{r_2 - r_1}\right\} \qquad \forall x \in B^k_{r_2} \setminus B^k_{r_1}.$$

Then, if we choose $r_2 = r_1(1 + r_1^{-\alpha})$, with $0 < \alpha < (p-k)/(p-1)$, term II turns out to be infinitesimal when $r_1 \to +\infty$, because

$$\int_{B^k_{r_2}\setminus B^k_{r_1}} \frac{1}{|x|^p} = K r_1^{k-p}\big[1 - (1 + r_1^{-\alpha})^{k-p}\big] \sim r_1^{k-p-\alpha},$$
$$\int_{B^k_{r_2}\setminus B^k_{r_1}} \frac{1}{(r_2 - r_1)^p} = K r_1^{k+(\alpha-1)p}\big[(1 + r_1^{-\alpha})^k - 1\big] \sim r_1^{k-p+\alpha(p-1)}.$$

Step 2. To prove that $\tau'_d \le \overline{\tau}_d$, let us show that, for any given $u \in \overline{\mathcal{A}}_d$ with $F_1(u, \mathbb{R}^k) < +\infty$, and for any $\varepsilon > 0$, there exists $v \in \mathcal{A}'_d$ such that (4.7) holds. For a fixed $\delta > 0$, we can choose $R > 0$ arbitrarily large such that conditions (4.3) in Remark 4.7 (i) hold. Let $\alpha : S^{k-1} \times [R, +\infty) \to \mathbb{R}$ be defined by

$$\alpha(y,t) := \begin{cases} 1 + (t-R)\mathrm{sgn}\big(1 - |u(Ry)|\big) & \text{if } 0 \le t - R \le \big||u(Ry)|^{-1} - 1\big|, \\ |u(Ry)|^{-1} & \text{if } t - R \ge \big||u(Ry)|^{-1} - 1\big|, \end{cases}$$

and set

$$v(x) := \begin{cases} u(x) & \text{if } |x| \le R, \\ \alpha\big(\frac{x}{|x|}, |x|\big)\, u\big(R\frac{x}{|x|}\big) & \text{if } |x| \ge R. \end{cases}$$

Notice that $v(x) = |u(Rx/|x|)|^{-1} u(Rx/|x|)$ for all x with $|x| \ge R' := R + \sup_{y \in S^{k-1}} \big||u(Ry)|^{-1} - 1\big|$, and hence $v \in \mathcal{A}'_d$. We claim that v fulfills (4.7) provided δ and R are chosen, respectively, sufficiently small and sufficiently large. Indeed, we have

$$F_1(v, \mathbb{R}^k) - F_1(u, \mathbb{R}^k) = \underbrace{\int_{\mathbb{R}^k \setminus B^k_R} |\nabla v|^p}_{\mathrm{I}} + \underbrace{\int_{B^k_{R'} \setminus B^k_R} W(v)}_{\mathrm{II}} - \underbrace{F_1(u, \mathbb{R}^k \setminus B^k_R)}_{\mathrm{III}}.$$

Term III is infinitesimal as $R \to +\infty$ since $F_1(u, \mathbb{R}^k) < +\infty$. Term II is infinitesimal as $\delta \to 0$. Indeed, by the second condition in (4.3) the difference $(R' - R)$ becomes arbitrarily small as $\delta \to 0$, so that the measure of the integration domain in II is infinitesimal with δ (and clearly the integrand remains bounded, because $|v(x)| \le (1 + R' - R)(1 + \delta)$ for all $x \in B^k_{R'} \setminus B^k_R$). Concerning term I, for $|x| \ge R$ we have

$$|\nabla v(x)| \le K\bigg\{|\alpha|\,|\nabla u|\frac{R}{|x|} + |u|\,|\alpha_y|\frac{1}{|x|} + |u|\,|\alpha_t|\bigg\}; \tag{4.8}$$

here and below, α and its derivatives are computed at $(x/|x|, |x|)$, while u and its gradient are computed at $Rx/|x|$. Now, for a suitable constant C_δ which depends on δ but remains bounded as $\delta \to 0$, there holds

$$|\alpha| \le C_\delta, \qquad |u| \le C_\delta, \qquad |\alpha_y| \le C_\delta R|\nabla u|. \tag{4.9}$$

From (4.8) and (4.9), we infer that

$$|\nabla v| \le C_\delta\bigg\{|\nabla u|\frac{R}{|x|} + |\alpha_t|\bigg\}.$$

Taking into account that $\alpha_t(y,t)$ vanishes for $t \ge R'$, and that, by the first condition in (4.3),

$$\int_{\mathbb{R}^k \setminus B^k_R} \bigg|\nabla u\Big(R\frac{x}{|x|}\Big)\bigg|^p \frac{R^p}{|x|^p} = KR\int_{\partial B^k_R} |\nabla u|^p \le K\delta,$$

we deduce that term I is infinitesimal as $\delta \to 0$.

Finally, the last assertion in the statement follows immediately from the definition of $\bar\tau_d$. ∎

PROPOSITION 4.10. *The function $\mathbb{Z} \ni d \mapsto \tau_d \in [0, +\infty)$ is subadditive.*

Proof. By Proposition 4.9, it is enough to prove that, for fixed integers d_1 and d_2, $\overline\tau_{d_1+d_2} \le \tau_{d_1} + \tau_{d_2}$. Moreover, by the same proposition we know that τ_{d_i} are independent of the choice of the trace functions ϕ_{d_i}. Hence, we may assume with no loss of generality that there exists a fixed vector $y_0 \in S^{k-1}$ such that $\phi_{d_1}(y) = y_0$ for y in the hemisphere $S^{k-1} \cap \{y_k \ge 0\}$ and $\phi_{d_2}(y) = y_0$ for y in the hemisphere $S^{k-1} \cap \{y_k \le 0\}$ (here and in the remainder of the proof, we denote by y_k the kth component of a vector $y \in \mathbb{R}^k$). Then, if $\mathcal{A}_d$ and $\overline{\mathcal{A}}_d$ denote, respectively, the classes of admissible functions in (4.1) and (4.5), it suffices to construct, for any given pair $(u_1, u_2) \in \mathcal{A}_{d_1} \times \mathcal{A}_{d_2}$ with $F_1(u_i, \mathbb{R}^k) < +\infty$, a function $v \in \overline{\mathcal{A}}_{d_1+d_2}$ such that $F_1(v, \mathbb{R}^k) = F_1(u_1, \mathbb{R}^k) + F_1(u_2, \mathbb{R}^k)$. Choose $r > \max\{r_1, r_2\}$, with r_i satisfying $u_i(x) = \phi_{d_i}(x/|x|)$ when $|x| \ge r_i$. Then set $P_r := (0, \dots, 0, r)$, and define v by

$$v(x) := \begin{cases} u_1(x + P_r) & \text{if } x_k \le 0, \\ u_2(x - P_r) & \text{if } x_k > 0. \end{cases}$$

Since $u_1(x) = y_0$ on $\{x_k \ge r\}$ and $u_2(x) = y_0$ on $\{x_k \le -r\}$, it is straightforward that $F_1(v, \mathbb{R}^k) = F_1(u_1, \mathbb{R}^k) + F_1(u_2, \mathbb{R}^k)$. It remains to check that $v \in \overline{\mathcal{A}}_{d_1+d_2}$. By construction, there holds

$$v(x) = \begin{cases} \phi_{d_1}\left(\frac{x+P_r}{|x+P_r|}\right) & \text{on } \{|x + P_r| \ge r_1\} \cap \{x_k \le 0\}, \\ \phi_{d_2}\left(\frac{x-P_r}{|x-P_r|}\right) & \text{on } \{|x - P_r| \ge r_2\} \cap \{x_k > 0\} \end{cases}$$

(in particular, $v(x) = y_0$ on $\{|x + P_r| \ge r_1\} \cap \{|x - P_r| \ge r_2\} \cap \{|x_k| \le r\}$). So, if we consider a cube Q centered at the origin, with sides larger than $4r$, we have $|v| = 1$ on ∂Q and $\deg(v, \partial Q) = d_1 + d_2$. In view of Remark 4.7 (ii), we conclude that $\deg(v, \infty) = d_1 + d_2$. ∎

5. Γ-lim inf inequality.

5.1. Case $n = 0$. The reason why we first deal with such a case relies basically on the following *scaling property*, enjoyed by the functionals F_ε for $n = 0$, as it is easily checked by a change of variables:

$$F_1\left(u(\varepsilon x), \frac{A}{\varepsilon}\right) = F_\varepsilon(u(x), A). \tag{5.1}$$

Thanks to (5.1), we can exploit the family of optimal profile constants introduced in section 4 in order to prove the following version of the Γ-lim inf inequality in Theorem 1.1 (i). Until otherwise specified, we keep the assumption $n = 0$ without any further mention.

THEOREM 5.1. *Let $\{u_\varepsilon\} \subset W^{1,p}(\Omega; \mathbb{R}^k)$ be a sequence such that $\mathbb{F}_\Omega(\star J u_\varepsilon - \alpha_k M) \to 0$ as $\varepsilon \to 0$, where $M = \sum_{i=1}^m \sigma^i \delta(x^i)$ is a 0-dimensional integral boundary (with $\sigma^i \in \mathbb{Z}$ and $x^i \in \Omega$). Then $\liminf_\varepsilon F_\varepsilon(u_\varepsilon) \ge \sum_{i=1}^m \tau_{\sigma^i}$.*

The proof of Theorem 5.1 given below may be outlined as follows. We consider the sequence of grids $\mathcal{G}_\varepsilon$ of step $l(\varepsilon) \gg \varepsilon$ constructed in Proposition 3.1, and we use (5.1) in order to scale the functionals F_ε over those cubes of the grids where the degree is located. Then, since the size of the scaled cubes diverges as $\varepsilon \to 0$, we need as a

fundamental ingredient the following estimate for the energy F_1 over enlarging cubes, whose proof is postponed.

PROPOSITION 5.2. *Let $Q_r := [-r,r]^k$, and let $u_r \in W^{1,p}(Q_r;\mathbb{R}^k)$ satisfy the following assumptions:*

$$\sup_r F_1(u_r,\, Q_r) < +\infty, \tag{5.2}$$

$$\sup_r \left\{ r \int_{\partial Q_r} e_1(u_r) \right\} < +\infty, \tag{5.3}$$

$$|u_r| \geq 1/2 \text{ on } \partial Q_r, \tag{5.4}$$

$$\deg\left(\frac{u_r}{|u_r|}, \partial Q_r\right) = d. \tag{5.5}$$

Then $\liminf_{r\to+\infty} F_1(u_r, Q_r) \geq \tau_d$.

Proof of Theorem 5.1. We may assume with no loss of generality that u_ε are smooth and that $\liminf_\varepsilon F_\varepsilon(u_\varepsilon) = \lim_\varepsilon F_\varepsilon(u_\varepsilon) < +\infty$. Given open sets U, V, and W, with $U \subset\subset V \subset\subset W \subset\subset \Omega$, we take a sequence of grids $\mathcal{G}_\varepsilon$ as in Proposition 3.1, and we denote by Q_ε^j for $j = 1,\dots,N(\varepsilon)$ those cubes of $\mathcal{G}_\varepsilon$ whose centers x_ε^j belong to U; for ε small enough, such cubes are entirely contained in Ω. If we equip Q_ε^j with the canonical orientation inherited by $\mathbb{R}^k$, the restrictions of the currents $(\Phi_\varepsilon)_\sharp(\star J' u_\varepsilon)$ to U may be written in the form

$$(\Phi_\varepsilon)_\sharp(\star J' u_\varepsilon) \llcorner U = \alpha_k \sum_{j=1}^{N(\varepsilon)} \sigma_\varepsilon^j \delta(x_\varepsilon^j), \tag{5.6}$$

where $\sigma_\varepsilon^j = \deg(u_\varepsilon/|u_\varepsilon|, \partial Q_\varepsilon^j)$. Since the currents $(\Phi_\varepsilon)_\sharp(\star J' u_\varepsilon)$ are uniformly bounded in mass over U, and the coefficients σ_ε^j are integers, we deduce that the sum in (5.6) can be actually extended over $j \in \{1,\dots,N\}$ for some N independent of ε; moreover, up to subsequences there exist integers $\sigma_0^1,\dots,\sigma_0^N$ such that $\sigma_\varepsilon^j \equiv \sigma_0^j$ for ε small enough. Using (5.1), we have

$$\liminf_\varepsilon F_\varepsilon(u_\varepsilon) \geq \sum_{j=1}^N \liminf_\varepsilon F_1\left(u_\varepsilon(\varepsilon x + x_\varepsilon^j), \frac{Q_\varepsilon^j}{\varepsilon} - x_\varepsilon^j\right). \tag{5.7}$$

Set $r = r(\varepsilon) := l(\varepsilon)/\varepsilon$ (so that $\{r(\varepsilon)\}$ diverges as $\varepsilon \to 0$ because $l(\varepsilon) \gg \varepsilon$), and fix an index $j \in \{1,\dots,N\}$. We have $(Q_\varepsilon^j/\varepsilon) - x_\varepsilon^j = [-r,r]^k$, and we claim that the sequence $u_r(x) := u_\varepsilon(\varepsilon x + x_\varepsilon^j)$ satisfies all the hypotheses of Proposition 5.2. Indeed, (5.2) holds by (5.7) and the assumption $\lim_\varepsilon F_\varepsilon(u_\varepsilon) < +\infty$. By the initial choice of the grid, (5.3) is satisfied (due to (3.12) in the proof of Proposition 3.1), and (5.4) holds for r large enough. Moreover, still for r large enough, we know that $\deg(u_r/|u_r|, \partial Q_r) = \sigma_0^j$. Thus, we may invoke Proposition 5.2 to obtain

$$\sum_{j=1}^N \liminf_\varepsilon F_1\left(u_\varepsilon(\varepsilon x + x_\varepsilon^j), \frac{Q_\varepsilon^j}{\varepsilon} - x_\varepsilon^j\right) \geq \sum_{j=1}^N \tau_{\sigma_0^j}. \tag{5.8}$$

Now observe that, since $\overline{U}$ is compact, up to subsequences there exist points $x_0^1,\dots,x_0^N \in \overline{U}$ such that $\lim_\varepsilon x_\varepsilon^j = x_0^j$ for $j = 1,\dots,N$. Let $\{x^1,\dots,x^h\} := \{x^1,\dots,x^m\} \cap \overline{U}$ (with $h \leq m$). Since by Proposition 3.1 (iii) $\mathbb{F}_U((\Phi_\varepsilon)_\sharp(\star J' u_\varepsilon) - \alpha_k M) \to 0$, we necessarily have $x_0^j \in \{x^1,\dots,x^h\}$ for all $j = 1,\dots,N$, and, setting $\mathcal{J}_i := \{j \in \{1,\dots,N\} :$

$x_0^j = x^i\}$, there holds $\sum_{j\in\mathcal{J}_i}\sigma_0^j = \sigma^i$ for all $i = 1,\dots,h$. Then Proposition 4.10 yields

$$\sum_{j=1}^{N}\tau_{\sigma_0^j} = \sum_{i=1}^{h}\sum_{j\in\mathcal{J}_i}\tau_{\sigma_0^j} \geq \sum_{i=1}^{h}\tau_{\sum_{j\in\mathcal{J}_i}\sigma_0^j} = \sum_{i=1}^{h}\tau_{\sigma^i}. \tag{5.9}$$

The thesis follows from (5.7), (5.8), and (5.9) by taking into account the arbitrariness of U. □

We now turn to the proof of Proposition 5.2. What makes it delicate is the lack of compactness of condition (5.5), as the boundary of Q_r, where the degree is prescribed, is moving to infinity. To overcome this difficulty, we first need to suitably extend u_r on a cube Q_η larger than Q_r (for technical reasons which will be clear in the proof of Proposition 5.2); then, we build a sequence of grids, of fixed step ρ independent of r, such that the functions u_r remain in modulus sufficiently far from zero on their $(k-1)$-skeletons; see Lemma 5.3 below. These grids play a crucial role in the proof of Proposition 5.2, since they allow one to individuate for every r a finite number of cubes which carry the degree. Such cubes can be gathered into some separate "clusters," which possibly go to infinity with r but move away from each other. The scope is "catching" such clusters one by one, in order to recover a condition of prescribed degree at infinity. The concluding argument will be again the subadditivity of τ_d proved in section 4.

LEMMA 5.3. *Let $Q_r = [-r,r]^k$, and let $u_r \in W^{1,p}(Q_r;\mathbb{R}^k)$ satisfy assumptions* (5.2), (5.3), *and* (5.4). *For every r, choose $\eta = \eta(r)$ so that $\eta(r) > r$, and $\eta(r)/r \to 1$ as $r \to +\infty$. Then we may construct extensions u_η of u_r to $Q_\eta = [-\eta,\eta]^k$ with the following properties:*

$$|u_\eta| \geq \frac{1}{2} \quad \text{on } \partial Q_\eta, \tag{5.10}$$

$$\lim_{r\to+\infty} F_1(u_\eta, Q_\eta \setminus Q_r) = 0. \tag{5.11}$$

Further, if $\rho > 0$ is sufficiently large, we may position a sequence of grids $\mathcal{G}_r^\rho$ of fixed step ρ (independent of r) such that

$$|u_\eta| \geq 1/2 \text{ on } R_{r,k-1}\cap Q_\eta, \tag{5.12}$$

$$\deg\left(\frac{u_\eta}{|u_\eta|}, \partial(Q_r^i \cap (Q_\eta \setminus Q_r))\right) = 0 \quad \text{for } r \text{ large enough}, \tag{5.13}$$

$$\sup_r \sum_i \left|\deg\left(\frac{u_\eta}{|u_\eta|}, \partial(Q_r^i \cap Q_\eta)\right)\right| < +\infty, \tag{5.14}$$

where in (5.12) *$R_{r,k-1}$ denotes the $(k-1)$-skeleton of $\mathcal{G}_r^\rho$, in* (5.13) *Q_r^i is any cube of $\mathcal{G}_r^\rho$ which intersects $Q_\eta \setminus Q_r$, and in* (5.14) *the sum is extended over all the cubes Q_r^i of $\mathcal{G}_r^\rho$ which intersect Q_η.*

Proof. Thanks to assumptions (5.3) and (5.4) and to the hypothesis on the asymptotic behavior of $\eta(r)$ for $r \to +\infty$, extensions u_η of u_r to Q_η satisfying (5.10) and (5.11) can be constructed essentially by projection on ∂Q_r (we omit the explicit computations which are tedious but not difficult).

If u_r satisfy in addition assumption (5.2), due to property (5.11) we also have $\sup_r F_1(u_\eta, Q_\eta) < +\infty$. Then, by inequality (3.6) in Lemma 3.2 (applied with $n = 0$), for any $\rho > 0$ we may position a sequence of grids $\mathcal{G}_r^\rho$ of step ρ so that $\rho\int_{R_{r,k-1}\cap Q_\eta} e_1(u_\eta) \leq C$, where C is a positive constant independent of r and ρ. We claim that if ρ is

large enough, such a sequence of grids fulfills (5.12), (5.13), and (5.14). To obtain (5.12) it is enough to show that, for λ and Ψ as in Lemma 3.3, and denoting by Q a generic $(k-1)$-cell of $R_{r,k-1}$, the functions u_η satisfy

$$\lim_{\rho\to+\infty} \fint_{Q\cap Q_\eta} \psi(|u_\eta|) = 0 \quad \text{and} \quad \lim_{\rho\to+\infty} \operatorname{osc}(\Psi(|u_\eta|), Q\cap Q_\eta) = 0$$

(uniformly in r and Q).

These equalities can be verified (provided $\lambda < k/p$), in a similar way as already done in Proposition 3.1 and Lemma 4.5. So we avoid repeating the proof, and we pass to show (5.13) and (5.14). Since $\lim_r F_1(u_\eta, Q_\eta \setminus Q_r) = 0$ and $\sup_r F_1(u_\eta, Q_\eta) < +\infty$, it suffices to prove that

$$\sum_i \left| \deg\left(\frac{u_\eta}{|u_\eta|}, \partial(Q_r^i \cap (Q_\eta \setminus Q_r))\right)\right| \le K F_1(u_\eta, Q_\eta \setminus Q_r), \tag{5.15}$$

$$\sum_i \left| \deg\left(\frac{u_\eta}{|u_\eta|}, \partial(Q_r^i \cap Q_\eta)\right)\right| \le K F_1(u_\eta, Q_\eta), \tag{5.16}$$

where the sums are extended, respectively, over the indices i such that Q_r^i intersects $Q_\eta \setminus Q_r$ and Q_η. (We stress that the degrees in the left-hand sides of (5.15) and (5.16) are well defined by (5.4), (5.10), and (5.12).) We prove only (5.15), omitting the proof of (5.16) which runs in the exact same way. Set for brevity $P_r^i := Q_r^i \cap (Q_\eta \setminus Q_r)$ whenever such a set is nonempty. Using (3.1) and the area formula (2.7), we get

$$\begin{aligned}
\int_{Q_\eta\setminus Q_r} e_1(u_\eta) &\ge K \int_{Q_\eta\setminus Q_r} W^{1-k/p}(u_\eta)|Ju_\eta| \\
&= K \sum_i \int_{P_r^i} W^{1-k/p}(u_\eta)|Ju_\eta| \\
&= K \sum_i \int_{\mathbb{R}^k} W^{1-k/p}(y)\, \sharp\{u_\eta^{-1}(y)\cap P_r^i\} \\
&\ge K \sum_i \int_{B^k_{1/2}} W^{1-k/p}(y)\, |\deg(u_\eta, P_r^i, \mathbb{R}^k, y)|.
\end{aligned} \tag{5.17}$$

For every i, since $u_\eta \in C^0(\overline{P}_r^i; \mathbb{R}^k)$ and $|u_\eta| \ge 1/2$ on ∂P_r^i, we may find a continuous homotopy $\varphi(x,t) : \overline{P}_r^i \times [0,1] \to \mathbb{R}^k$ such that $\varphi(\cdot,0) = u_\eta(\cdot)$, $\varphi(\cdot,1) = w_\eta(\cdot)$ with $w_\eta = u_\eta/|u_\eta|$ on ∂P_r^i, and $\varphi(\cdot,t) \ge 1/2$ on ∂P_r^i for all $t \in [0,1]$. Therefore, for all $y \in B^k_{1/2}$, we have

$$\deg(u_\eta, P_r^i, \mathbb{R}^k, y) = \deg(w_\eta, P_r^i, \mathbb{R}^k, y) = \deg(w_\eta, \partial P_r^i) = \deg(u_\eta/|u_\eta|, \partial P_r^i),$$

where the first equality is due to the homotopy invariance of the degree (cf. [14, Theorem 2.3]) and the second equality holds because $w_\eta(\partial P_r^i) \subseteq S^{k-1}$ (cf. section 2.4). Replacing the above identity in the last line of (5.17), we get (5.15). ∎

Proof of Proposition 5.2. Let $\eta = \eta(r)$ satisfy the assumptions of Lemma 5.3 and the additional condition $\lim_{r\to+\infty} \big(\eta(r) - r\big) = +\infty$. For such $\eta(r)$, let u_η and $\mathcal{G}_r^\rho$ be, respectively, extensions of u_r to Q_η and grids of step ρ as in the statement of Lemma 5.3. By (5.11), it is enough to show that $\liminf F_1(u_\eta, Q_\eta) \ge \tau_d$.

For any cube Q_r^i of $\mathcal{G}_r^\rho$ which intersects Q_η, we set $d_r^i := \deg(u_\eta/|u_\eta|, \partial(Q_r^i \cap Q_\eta))$. By (5.14), there exists a finite number N (independent of r) of cubes Q_r^i such that $d_r^i \neq 0$, and we have $\sup_r \sum_{i=1}^N |d_r^i| < +\infty$. Hence, up to subsequences, $d_r^i \equiv d^i$, with d^i independent of r for $i = 1, \dots, N$.

By (5.13), for all $i = 1, \dots, N$ and r large enough, it must be $Q_r^i \cap Q_r \neq \emptyset$, $Q_r^i \subset Q_\eta$, and $d^i = \deg(u_r/|u_r|, \partial(Q_r^i \cap Q_r))$. Then, by (5.5), we have $\sum_{i=1}^N d^i = d$.

Now, in order to "follow" the location of the cubes Q_r^i as $r \to +\infty$, let us introduce an equivalence relation on the set of indices $\{1, \dots, N\}$. For $i = 1, \dots, N$, let x_r^i denote the center of Q_r^i. We say that i is equivalent to j if $\sup_r |x_r^i - x_r^j| < +\infty$. Possibly passing to subsequences, we may assume that, whenever i and j are *not* equivalent, there holds $\lim_r |x_r^i - x_r^j| = +\infty$. Then, we can associate to each equivalence class $[i]$ a sequence of sets $E_r^{[i]}$, each one contained in Q_η and delimited by $\mathcal{G}_r^\rho$, enjoying the following properties:

$$\text{for every } r,\ E_r^{[i]} \cap E_r^{[j]} = \emptyset \text{ whenever } [i] \neq [j]; \tag{5.18}$$

$$\text{for every } r,\ E_r^{[i]} \text{ contains } Q_r^j \text{ if and only if } j \in [i]; \tag{5.19}$$

$$\text{for any } j \in [i],\ \text{there holds } \bigcup_r (E_r^{[i]} - x_r^j) = \mathbb{R}^k. \tag{5.20}$$

Notice in particular that it is possible to satisfy (5.20) thanks to the assumption $\lim_{r\to+\infty} (\eta(r) - r) = +\infty$, which ensures that $\lim_{r\to+\infty} \operatorname{dist}(x_r^j, \partial Q_\eta) = +\infty$.

Notice also that if $d_r^{[i]}$ denotes the degree of $u_\eta/|u_\eta|$ on $\partial E_r^{[i]}$, by (5.19) $d_r^{[i]}$ is just the sum of all the d^j such that $j \in [i]$. In particular, $d_r^{[i]} =: d^{[i]}$ is independent of r, and we have

$$\sum_{[i]} d^{[i]} = \sum_{[i]} \Big(\sum_{j\in[i]} d^j \Big) = \sum_{j=1}^N d^j = d. \tag{5.21}$$

We can now begin to estimate the energy of u_η on Q_η. By (5.18), we have

$$\liminf_r F_1(u_\eta, Q_\eta) \geq \sum_{[i]} \liminf_r F_1(u_\eta, E_r^{[i]}) = \sum_{[i]} \liminf_r F_1\big(u_\eta(x + x_r^i), E_r^{[i]} - x_r^i\big),$$

where for every class $[i]$ we have chosen a representative i, which will stay fixed in the remainder of the proof. Taking (5.20) into account, we infer that, up to subsequences, there exist functions $u^i \in W^{1,p}_{\mathrm{loc}}(\mathbb{R}^k; \mathbb{R}^k)$ such that $u_\eta(x + x_r^i) \to u^i(x)$ weakly in $W^{1,p}_{\mathrm{loc}}(\mathbb{R}^k; \mathbb{R}^k)$, and strongly in $L^\infty_{\mathrm{loc}}(\mathbb{R}^k, \mathbb{R}^k)$. Since, for any open set A, $F_1(\cdot, A)$ is weakly lower semicontinuous on $W^{1,p}(A; \mathbb{R}^k)$, we have

$$\liminf_r F_1\big(u_\eta(x + x_r^i), E_r^{[i]} - x_r^i\big) \geq \sup_{A\subset\subset\mathbb{R}^k} \liminf_r F_1\big(u_\eta(x + x_r^i), A\big) \geq F_1(u^i, \mathbb{R}^k).$$

Hence, $\liminf_r F_1(u_\eta, Q_\eta) \geq \sum_{[i]} F_1(u^i, \mathbb{R}^k)$. Suppose for a moment that we know that $\deg(u^i, \infty) = d^{[i]}$. Then, using Definition 4.8, Propositions 4.9 and 4.10, and (5.21), we get

$$\sum_{[i]} F_1(u^i, \mathbb{R}^k) \geq \sum_{[i]} \overline{\tau}_{d^{[i]}} = \sum_{[i]} \tau_{d^{[i]}} \geq \tau_{\sum_{[i]} d^{[i]}} = \tau_d,$$

and Proposition 5.2 is proved.

In order to compute $\deg(u^i,\infty)$, we first observe that $\mathcal{G}^\rho_r - x^i_r$ is a grid independent of r that we may denote by $\mathcal{G}^\rho$ (indeed, it has fixed step ρ and it is centered at the origin). In view of (5.19), we may find a fixed cube $Q^{[i]}$, *independent of* r, centered at the origin and delimited by $\mathcal{G}^\rho$, with the following crucial property: for every r, $Q^{[i]}$ contains $(Q^j_r - x^i_r)$ if and only if $j \in [i]$. Then, we take a sequence of cubes $Q^{[i]}_n$, whose sides diverge as $n \to +\infty$, all centered at the origin, delimited by $\mathcal{G}^\rho$, and containing $Q^{[i]}$. For fixed n and r large enough, we have $Q^{[i]}_n \subseteq E^{[i]}_r - x^i_r$; hence $Q^{[i]}_n$ contains $(Q^j_r - x^i_r)$ if and only if $j \in [i]$, which implies $\deg\big(u_\eta(x+x^i_r)/|u_\eta(x+x^i_r)|,\, \partial Q^{[i]}_n\big) = d^{[i]}$. Passing to the limit as $r \to +\infty$ gives $\deg(u^i, \partial Q^{[i]}_n) = d^{[i]}$. Finally, letting $n \to +\infty$ and recalling Remark 4.7 (ii), we obtain $\deg(u^i,\infty) = d^{[i]}$ as required. ∎

5.2. Case $n > 0$. In order to obtain the proof of the Γ-lim inf inequality in Theorem 1.1 (i) when $n > 0$, we may exploit Theorem 5.1 by using a slicing technique. For this purpose, we need to recall some basic facts about the slices of currents by projections: they are collected in section 5.3 below. For more details on these topics and their proofs, we refer the reader to [13, sections 4.3.1 and 4.3.2] or [16, section 2.2.5].

5.3. Slicing currents by projections. Fix an arbitrary orthonormal basis $\{e_1,\dots,e_n,e_{n+1},\dots,e_{n+k}\}$ for $\mathbb{R}^{n+k}$. We set $\mathbb{R}^n_y := \mathrm{span}\{e_1,\dots,e_n\}$ and $\mathbb{R}^k_z := \mathrm{span}\{e_{n+1},\dots,e_{n+k}\}$. Given any point $x \in \mathbb{R}^{n+k}$, we identify it with a pair $(y,z) \in \mathbb{R}^n_y \times \mathbb{R}^k_z$, by writing $y_i = x\cdot e_i$ for $1 \le i \le n$ and $z_i = x \cdot e_i$ for $n+1 \le i \le n+k$. We let $dy = dy_1 \wedge \dots dy_n$ be the standard volume form on $\mathbb{R}^n_y$, and we denote by $P^\sharp(dy)$ its pull back by the orthogonal projection $P : \mathbb{R}^{n+k} \to \mathbb{R}^n_y$.

If T is a normal m-current on $\mathbb{R}^{n+k}$, with $m \ge n$, we denote by $T \llcorner P^\sharp(dy)$ the $(m-n)$-current defined by the identity $T \llcorner P^\sharp(dy)(\omega) := T\big(P^\sharp(dy) \wedge \omega\big)$ for all $\omega \in \mathcal{D}^{m-n}(\mathbb{R}^{n+k})$. Then, for $y \in \mathbb{R}^n_y$, the *slices* of T by P in y are $(m-n)$-currents $\{\langle T,P,y\rangle\}_y$ characterized by the following integral representation identity:

$$T \llcorner P^\sharp(dy)(\omega) = \int_{\mathbb{R}^n_y} \langle T,P,y\rangle(\omega)\, d\mathcal{H}^n(y) \qquad \forall \omega \in \mathcal{D}^{m-n}(\mathbb{R}^{n+k}). \tag{5.22}$$

In case T is rectifiable with integer multiplicity, the same holds for $\langle T,P,y\rangle$ for $\mathcal{H}^n$-a.e. $y \in \mathbb{R}^n_y$. Moreover, the support, the boundary, and the mass of $\langle T,P,y\rangle$ satisfy, respectively,

$$\mathrm{spt}\langle T,P,y\rangle \subset P^{-1}(y) \cap \mathrm{spt}\mathrm{T}, \tag{5.23}$$

$$\partial\langle T,P,y\rangle = (-1)^n \langle \partial T,P,y\rangle \qquad (\text{if } m > n), \tag{5.24}$$

$$\int_{\mathbb{R}^n_y} \|\langle T,P,y\rangle\|\, d\mathcal{H}^n(y) \le \|T\|. \tag{5.25}$$

Finally let us stress that, in the case $m = n$ with which we shall be mainly concerned, $T \llcorner P^\sharp(dy)$ is just a signed measure. In particular, the slices $\{\langle T,P,y\rangle\}_y$ may be seen through (5.22) as the disintegration of the measure $T \llcorner P^\sharp(dy)$ with respect to $\mathcal{H}^n \llcorner \mathbb{R}^n_y$ (see, e.g., [16, section 1.1.5]).

We can now proceed to establish some features about the behavior under the slicing of the Jacobians and of the flat norm. In the next two lemmas, we keep the notation adopted above, decomposing $\mathbb{R}^{n+k}$ as $\mathbb{R}^n_y \times \mathbb{R}^k_z$, and indicating by P the projector from $\mathbb{R}^{n+k}$ onto $\mathbb{R}^n_y$.

LEMMA 5.4. *Let a cube $Q = Q' \times Q'' \subset \mathbb{R}^n_y \times \mathbb{R}^k_z$ and a smooth function $u : Q \to \mathbb{R}^k$ be given. For $y \in Q'$, define $u^y : Q'' \to \mathbb{R}^k$ by $u^y(z) := u(y,z)$. Then, for every test function $\omega \in \mathcal{D}(Q)$, there holds*

$$\langle \star Ju, P, y\rangle(\omega) = \star Ju^y(\omega(y,\cdot)) \qquad \text{for } \mathcal{H}^n\text{-a.e. } y \in Q'. \tag{5.26}$$

Proof. Recall that, by definition, $\star Ju^y$ is the absolutely continuous measure on Q'' with density $\det \nabla_z u(y,z)$, where ∇_z denotes partial differentiation with respect to the components $z_{n+1}, \dots, z_{n+k}$ of x. On the other hand, we have $\star Ju = \sum_\alpha \det \nabla_\alpha u(x) \star dx_\alpha$, where the sum is extended over all k-multi-indices $\alpha = (i_1, \dots, i_k)$ with $1 \le i_1 < \cdots < i_k \le n+k$, $\nabla_\alpha u$ is the $(k \times k)$-matrix with columns $\nabla_{i_1} u, \dots, \nabla_{i_k} u$, and dx_α is the k-covector $dx_{i_1} \wedge \cdots \wedge dx_{i_k}$. In particular, we observe that $\star dx_\alpha \cdot P^\sharp(dy)$ equals 1 if $\alpha = (n+1, \dots, n+k)$, and 0 otherwise. Therefore, for every test function $\omega \in \mathcal{D}(Q)$, we have

$$\begin{aligned}(\star Ju \llcorner P^\sharp(dy))(\omega) = \star Ju(\omega P^\sharp(dy)) &= \sum_\alpha \int_Q \omega(x) \det \nabla_\alpha u(x) \star dx_\alpha \cdot P^\sharp(dy) \\ &= \int_Q \omega(y,z) \det \nabla_z u(y,z) = \int_{Q'} \star Ju^y(\omega(y,\cdot))\, d\mathcal{H}^n(y),\end{aligned}$$

where in the last equality we have applied Fubini's theorem. Hence, recalling the disintegration identity (5.22), we deduce the validity of (5.26). ∎

LEMMA 5.5. *Let $\{T_\varepsilon\}$ be a sequence of boundaries in $\mathcal{D}_n(\Omega)$, with $\mathbb{F}_\Omega(T_\varepsilon) \to 0$. Then, possibly passing to a subsequence, there holds*

$$\mathbb{F}_{P^{-1}(y)\cap\Omega}(\langle T_\varepsilon, P, y\rangle) \to 0 \qquad \text{for } \mathcal{H}^n\text{-a.e. } y.$$

Proof. By the definition of flat norm, there exists a sequence of currents $\{S_\varepsilon\} \subset \mathcal{D}_{n+1}(\Omega)$ such that $T_\varepsilon = \partial S_\varepsilon$, and $\|S_\varepsilon\| \le \mathbb{F}_\Omega(T_\varepsilon) + \varepsilon$. By (5.24), it holds that $\partial\langle S_\varepsilon, P, y\rangle = (-1)^n \langle T_\varepsilon, P, y\rangle$ for $\mathcal{H}^n$-a.e. y. Recalling (5.23) and applying again the definition of a flat norm, we infer that

$$\mathbb{F}_{P^{-1}(y)\cap\Omega}(\langle T_\varepsilon, P, y\rangle) \le \|\langle S_\varepsilon, P, y\rangle\| \qquad \text{for } \mathcal{H}^n\text{-a.e. } y.$$

Since $\|S_\varepsilon\| \to 0$, by (5.25) we can pass to a subsequence (not relabeled) such that $\|\langle S_\varepsilon, P, y\rangle\| \to 0$ for $\mathcal{H}^n$-a.e. y, and the statement follows. ∎

Given an n-dimensional integral current $M = (M, \xi, \sigma)$, let $\widehat{M}$ be the current obtained by just changing the multiplicity of M from $\sigma(x)$ into $\tau_{\sigma(x)}$, namely,

$$M = (M, \xi, \sigma) \;\Rightarrow\; \widehat{M} := (M, \xi, \tau_\sigma). \tag{5.27}$$

We are ready to give the following proof.

Proof of the Γ-lim inf *inequality in Theorem* 1.1 (i). Let $\{u_\varepsilon\}$ and $M = (M, \xi, \sigma)$ be as in the assumptions; it is not restrictive to suppose in addition that u_ε are smooth. With the notation introduced at the beginning of this section, decompose $\mathbb{R}^{n+k}$ as $\mathbb{R}^n_y \times \mathbb{R}^k_z$, and let P denote the orthogonal projection from $\mathbb{R}^{n+k}$ onto $\mathbb{R}^n_y$. Then, for the n-current $\widehat{M}$ defined according to (5.27), consider the signed measure $\widehat{M} \llcorner P^\sharp(dy)$. Also, let Q be a closed cube contained into Ω. We claim that the following inequality holds true and implies (1.3):

$$\liminf_\varepsilon F_\varepsilon(u_\varepsilon, Q) \ge |\widehat{M} \llcorner P^\sharp(dy)|(Q). \tag{5.28}$$

Let us first show how (1.3) follows from (5.28) and then turn back to the proof of (5.28). Assume that (5.28) is satisfied. Then, it continues to hold if the cube Q is replaced by an arbitrary open set $A \subset\subset \Omega$. Indeed, by the Vitali covering theorem, we can find a collection $\{Q_i\}$ of pairwise disjoint closed cubes which cover A up to a $|\widehat{M} \llcorner P^\sharp(dy)|$-negligible set. We then have

$$\liminf_\varepsilon F_\varepsilon(u_\varepsilon, A) \geq \sum_i \liminf_\varepsilon F_\varepsilon(u_\varepsilon, Q_i) \geq \sum_i |\widehat{M} \llcorner P^\sharp(dy)|(Q_i) = |\widehat{M} \llcorner P^\sharp(dy)|(A).$$

Recalling that the basis $\{e_1, \dots, e_{n+k}\}$ chosen at the beginning of this section was arbitrary, we infer that, for any simple unit $w \in \Lambda^n(\mathbb{R}^{n+k})$, there holds

$$\liminf_\varepsilon F_\varepsilon(u_\varepsilon, A) \geq \int_{A \cap M} \tau_{\sigma(x)} w \cdot \xi(x)\, d\mathcal{H}^n(x). \tag{5.29}$$

Applying (5.29) to finitely many pairwise disjoint open sets $A_i \subset\subset \Omega$ and simple unit n-covectors w_i, and then summing over i, we get

$$\liminf_\varepsilon F_\varepsilon(u_\varepsilon) \geq \sum_i \int_{A_i \cap M} \tau_{\sigma(x)} w_i \cdot \xi(x)\, d\mathcal{H}^n(x). \tag{5.30}$$

Finally, the supremum of the right-hand side of (5.30) over all possible choices of A_i and w_i furnishes the total mass of the variation measure $|\widehat{M}|$, that is, $\int_M \tau_{\sigma(x)}\, d\mathcal{H}^n(x)$. We have thus obtained (1.3). It remains to prove (5.28).

We write Q as $Q' \times Q'' \subset \mathbb{R}^n_y \times \mathbb{R}^k_z$. For $y \in Q'$, similarly as in Lemma 5.4, we define u_ε^y on Q'' by $u_\varepsilon^y(z) := u_\varepsilon(y, z)$. We pass to a subsequence (not relabeled) such that $\liminf_\varepsilon F_\varepsilon(u_\varepsilon, Q) = \lim_\varepsilon F_\varepsilon(u_\varepsilon, Q)$ and, using Lemma 5.5,

$$\mathbb{F}_{P^{-1}(y) \cap \Omega}(\langle \star J u_\varepsilon, P, y\rangle - \langle M, P, y\rangle) \to 0 \qquad \text{for } \mathcal{H}^n\text{-a.e. } y. \tag{5.31}$$

For the sake of clarity, in the remainder of the proof we denote by G_ε the functionals F_ε when $n = 0$. We have

$$\lim_\varepsilon F_\varepsilon(u_\varepsilon, Q) \geq \liminf_\varepsilon \int_{Q'} G_\varepsilon(u_\varepsilon^y, Q'')\, d\mathcal{H}^n \geq \int_{Q'} \liminf_\varepsilon G_\varepsilon(u_\varepsilon^y, Q'')\, d\mathcal{H}^n, \tag{5.32}$$

where the first inequality holds since $|\nabla u_\varepsilon^y(z)| \leq |\nabla u_\varepsilon(y, z)|$, and the second one is just the Fatou lemma. Now, we want to apply Theorem 5.1 in order to estimate from below the last integral in (5.32). For $\mathcal{H}^n$-a.e. $y \in Q'$, we may identify $\star J u_\varepsilon^y$ with $\langle \star J u_\varepsilon, P, y\rangle$ according to (5.26) in Lemma 5.4. Hence, writing the slices $\langle M, P, y\rangle$ under the form $\sum_i \sigma(y, z_i)\delta(y, z_i)$, we deduce from (5.31) that $\mathbb{F}_{Q''}\big(\star J u_\varepsilon^y - \sum_i \sigma(y, z_i)\delta(y, z_i)\big) \to 0$ (for a finite collection of points $z_i = z_i(y) \in Q''$). Then Theorem 5.1 yields

$$\liminf_\varepsilon G_\varepsilon(u_\varepsilon^y, Q'') \geq \sum_i \tau_{\sigma(y, z_i)} = \langle \widehat{M}, P, y\rangle(Q'') \qquad \text{for } \mathcal{H}^n\text{-a.e. } y \in Q'. \tag{5.33}$$

Integrating (5.33) over Q', it follows from (5.32) that

$$\lim_\varepsilon F_\varepsilon(u_\varepsilon, Q) \geq \int_{Q'} \langle \widehat{M}, P, y\rangle(Q'')\, d\mathcal{H}^n(y) = |\widehat{M} \llcorner P^\sharp(dy)|(Q). \qquad \square$$

6. Γ-lim sup inequality. The proof of the Γ-lim sup inequality in Theorem 1.1 will be achieved in two steps. The first one consists in reducing our attention to proving the statement when the limit boundary M is polyhedral. This goal is obtained by means of the ad hoc density result stated in Proposition 6.1 below (which is an adaptation of Proposition 8.6 in [3]), combined with a standard diagonal argument. For convenience, given an n-dimensional integral current $M = (M, \xi, \sigma)$, and an $\mathcal{H}^n$-measurable set A in $\mathbb{R}^{n+k}$, we consider the modified current $\widehat{M}$ defined by (5.27), and we introduce the energy $\mathcal{E}(M, A)$ given by

$$\mathcal{E}(M, A) := |\widehat{M}|(A) = \int_{M\cap A} \tau_{\sigma(x)}\, d\mathcal{H}^n(x).$$

PROPOSITION 6.1. *For every n-dimensional integral boundary M in Ω, there exists a sequence $\{M_i\}$ of n-dimensional polyhedral boundaries in Ω such that $|M_i|(\partial\Omega) = 0$, $\mathbb{F}_\Omega(M_i - M) \to 0$, and $\mathcal{E}(M_i, \Omega) \to \mathcal{E}(M, \Omega)$.*

Proof. First, we remark that M agrees in Ω with the boundary of an integral $(n+1)$-current N, with compact support K, such that $|\partial N|(\partial\Omega) = 0$; see Proposition 8.6 (i) in [3]. This implies, in particular, that $\mathcal{E}(M, \partial\Omega) = 0$ (indeed, by Proposition 4.10, $\mathcal{E}(M, A)$ is controlled by the total variation of M over A; namely, there exists a positive constant C, independent of M and A, such that $\mathcal{E}(M, A) \le C\,|M|(A)$). By the strong approximation theorem (see, e.g., [13, sections 4.2.20 and 4.2.21]), for every $\varepsilon > 0$, there exist an integral polyhedral current P and a diffeomorphism $f : \mathbb{R}^{n+k} \to \mathbb{R}^{n+k}$ such that

$$|f(x) - x| < \varepsilon \quad \forall x \in \mathbb{R}^{n+k}, \quad \mathrm{Lip}(f) < 1 + \varepsilon, \quad \mathrm{Lip}(f^{-1}) < 1 + \varepsilon, \tag{6.1}$$

$$\|P - f_\sharp N\| + \|\partial P - \partial f_\sharp N\| < \varepsilon, \tag{6.2}$$

$$\mathcal{F}_K(P - N) < o(1), \tag{6.3}$$

where $\mathcal{F}_K$ is the usual flat norm for integral currents over the compact set K [32, section 31], and $o(1)$ denotes an infinitesimal as $\varepsilon \to 0$. We deduce that

$$\mathcal{E}(\partial P - f_\sharp M, \Omega) \le C\,|\partial P - f_\sharp M|(\Omega) < \varepsilon, \tag{6.4}$$

where the first inequality follows from the definition of $\mathcal{E}$ using Proposition 4.10, while the second one is a consequence of (6.2). On the other hand, if Ω_ε denotes the ε-neighborhood of Ω, we have

$$\mathcal{E}(f_\sharp M, \Omega) \le (\mathrm{Lip} f)^n \mathcal{E}(M, f^{-1}(\Omega)) \le (1+\varepsilon)^n\, \mathcal{E}(M, \Omega_\varepsilon) = \mathcal{E}(M, \Omega) + o(1), \tag{6.5}$$

where the first inequality follows from (2.2) and the identity $\widehat{f_\sharp M} = f_\sharp \widehat{M}$; in the second inequality we have used (6.1), while the third equality is consequence of the null energy condition on the boundary $\mathcal{E}(M, \partial\Omega) = 0$. In a similar way, one has

$$\mathcal{E}(M, \Omega) \le \mathcal{E}(f_\sharp M, \Omega) + o(1). \tag{6.6}$$

By (6.3), (6.4), (6.5), and (6.6), we may find a sequence $\{P_i\}$ of integral polyhedral currents such that $\mathbb{F}_\Omega(\partial P_i - M) \to 0$ and $\mathcal{E}(\partial P_i, \Omega) \to \mathcal{E}(M, \Omega)$. The proof is then achieved by setting $M_i = \partial P_i$, after possibly translating the currents P_i so that they also satisfy the additional condition $|\partial P_i|(\partial\Omega) = 0$ (which can always be done thanks to Fubini's theorem). ∎

Let us turn to the second and main step in the proof of the Γ-lim sup inequality. We assume from now on that M agrees in Ω with the boundary of a polyhedral

$(n+1)$-current N, with $|\partial N|(\partial\Omega) = 0$. Our goal is to exhibit a recovery sequence $\{u_\varepsilon\}$ satisfying (1.4). We denote by S the union of all $(n-1)$-simplexes of N. Moreover, given an n-face F of ∂N, we identify the n-plane spanned by F with $\mathbb{R}^n$, and we write $x \in \mathbb{R}^{n+k}$ as $x = (y, z) \in \mathbb{R}^n \times \mathbb{R}^k$; then, for $\delta, \gamma > 0$, we set

$$U(F, \delta, \gamma) := \big\{x = (y, z) \ : \ y \in F \text{ and } |z| < \min\{\delta, \gamma \operatorname{dist}(y, \partial F)\}\big\}.$$

A crucial ingredient in the construction of the sequence $\{u_\varepsilon\}$ is the following existence result for S^{k-1}-valued functions with prescribed singularities proved in [2]: one can construct a map $u \in W^{1,k-1}_{\mathrm{loc}}(\mathbb{R}^{n+k}; S^{k-1}) \cap \mathrm{Lip}_{\mathrm{loc}}(\mathbb{R}^{n+k} \setminus (M \cup S); \mathbb{R}^k)$ such that $\star Ju = \alpha_k M$, and

$$|\nabla u(x)| \le \frac{C}{\operatorname{dist}(x, M \cup S)}. \tag{6.7}$$

Moreover, one can ask that, for every n-face F of ∂N, and for some $\delta, \gamma > 0$,

$$u(x) = \phi_\sigma\left(\frac{z}{|z|}\right) \qquad \forall x = (y, z) \in U(F, \delta, \gamma), \tag{6.8}$$

where σ is the multiplicity of ∂N on F, and $\phi_\sigma : S^{k-1} \to S^{k-1}$ is a prescribed map of degree σ. Condition (6.8) leads in a natural way to Definition 4.1 of the constant τ_σ. So, we fix $h \in \mathbb{N}$ and, according to (4.1), we consider for every $\sigma \in \mathbb{Z}$ a function $\psi_\sigma \in W^{1,p}_{\mathrm{loc}}(\mathbb{R}^k; \mathbb{R}^k)$ with

$$\operatorname{tr}(\psi_\sigma, \infty) = \phi_\sigma \qquad \text{and} \qquad F_1(\psi_\sigma, \mathbb{R}^k) < \tau_\sigma + \frac{1}{h}. \tag{6.9}$$

The idea is to glue together the trace conditions in (6.8) and (6.9), and to this aim we need a careful choice of some parameters. Precisely, we take $\delta = \delta(\varepsilon)$ and a fixed $\gamma > 0$ such that (6.8) holds and $\varepsilon \ll \delta(\varepsilon) \ll \varepsilon^{k/(k+1)}$. Moreover, we put $r = r(\varepsilon) := \delta(\varepsilon)\sqrt{1 + \gamma^{-2}}$. Then we set $S_\varepsilon := \big\{x \in \mathbb{R}^{n+k} \ : \ \operatorname{dist}(x, S) < r(\varepsilon)\big\}$, and $U_\varepsilon := \bigcup_i U(F_i, \delta, \gamma)$, where the union is extended over all the n-faces F_i of ∂N (with the convention that, whenever $i \neq j$, $F_i \cap F_j$ is either empty or a common face between F_i and F_j).

We are now ready to construct a recovery sequence $\{u_\varepsilon\}$, whose energy concentrates in a transition zone near M, precisely in $\Omega \cap (U_\varepsilon \setminus S_\varepsilon)$. This kind of qualitative behavior is shared with the scalar case $p > k = 1$, and it is in contrast with the Ginzburg–Landau case $p = k > 1$, when the set of energy concentration around M has a "circular crown" shaped section (compare the proof of Proposition 6.2 below, respectively, with section 3.5 in [1] and with Lemma 4.2 in [3]).

PROPOSITION 6.2. *Assume that M is the restriction to Ω of a polyhedral boundary ∂N, with $|\partial N|(\partial\Omega) = 0$, and adopt the notation fixed above. Set*

$$v_\varepsilon(x) = \begin{cases} u(x) & \text{if } x \notin U_\varepsilon, \\ \psi_{\sigma_i}\Big(\frac{\delta z}{\varepsilon g_i(y)}\Big) & \text{if } x = (y, z) \in U(F_i, \delta, \gamma), \end{cases}$$

where σ_i is the multiplicity of ∂N on F_i, and $g_i(y) := \min\{\delta, \gamma \operatorname{dist}(y, \partial F_i)\}$.

Then, if $u_\varepsilon(x) := \min\big\{\operatorname{dist}(x, S)/r, 1\big\}\, v_\varepsilon(x)$, we have $\mathbb{F}_\Omega(\star Ju_\varepsilon - \alpha_k M) \to 0$, and the Γ-lim sup inequality (1.4) is satisfied.

Proof. First we observe that, by (6.8), (6.9), and the assumption $\varepsilon \ll \delta(\varepsilon)$, for ε small enough both $u(x)$ and $\psi_{\sigma_i}\big(\delta z/\varepsilon g_i(y)\big)$ equal $\phi_{\sigma_i}(z/|z|)$ for $x = (y, z) \in$

$\partial U(F_i,\delta,\gamma)$. Notice also that u_ε are equibounded in $L^\infty(\Omega;\mathbb{R}^k)$; therefore, by the choice of u and inequality (2.6), we have $\mathbb{F}_\Omega(\star J u_\varepsilon - \alpha_k M) \to 0$ provided $\int_\Omega |\nabla u_\varepsilon - \nabla u|^{k-1} \to 0$. Let us introduce the following subdomains of Ω:

$$V_\varepsilon^1 = \Omega \cap (U_\varepsilon \setminus S_\varepsilon), \qquad V_\varepsilon^2 = \Omega \setminus (S_\varepsilon \cup U_\varepsilon),$$
$$V_\varepsilon^3 = \Omega \cap (S_\varepsilon \setminus U_\varepsilon), \qquad V_\varepsilon^4 = \Omega \cap S_\varepsilon \cap U_\varepsilon.$$

For $i = 1,\dots,4$, we are going to estimate separately on each V_ε^i the energy amount of u_ε and their $W^{1,k-1}$-convergence.

- On V_ε^1, $u_\varepsilon(x)$ equals $\psi_{\sigma_i}(z/\varepsilon)$ for all $x = (y,z) \in U(F_i,\delta,\gamma)$. Moreover, the projection of $V_\varepsilon^1 \cap U(F_i,\delta,\gamma)$ on the affine plane spanned by F_i is contained into $F_i \cap \Omega_\delta$, Ω_δ being the closed δ-neighborhood of Ω. Below, for the sake of clarity, we indicate by G_ε (respectively, G_1) the functionals F_ε (respectively, F_1) when $n = 0$.

Energy estimate. Using (5.1) and (6.9), we get

$$\begin{aligned} F_\varepsilon(u_\varepsilon, V_\varepsilon^1) &= \sum_i F_\varepsilon\left(\psi_{\sigma_i}\left(\frac{z}{\varepsilon}\right),\, \Omega \cap (U(F_i,\delta,\gamma) \setminus S_\varepsilon)\right) \\ &\le \sum_i \mathcal{H}^n(F_i \cap \Omega_\delta)\, G_\varepsilon\left(\psi_{\sigma_i}\left(\frac{z}{\varepsilon}\right),\, |z| < \delta\right) \\ &= \sum_i \mathcal{H}^n(F_i \cap \Omega_\delta)\, G_1\left(\psi_{\sigma_i}(z),\, |z| < \frac{\delta}{\varepsilon}\right) \\ &\le \sum_i \mathcal{H}^n(F_i \cap \Omega_\delta)(\tau_{\sigma_i} + 1/h). \end{aligned}$$

$W^{1,k-1}$-convergence. By the Hölder inequality and the assumption $\delta(\varepsilon) \ll \varepsilon^{k/(k+1)}$, we have

$$\begin{aligned} \int_{V_\varepsilon^1} |\nabla u_\varepsilon|^{k-1} &\le \sum_i \mathcal{H}^n(F_i \cap \Omega_\delta) \int_{|z|<\delta} \varepsilon^{-k+1} \left|\nabla \psi_{\sigma_i}\left(\frac{z}{\varepsilon}\right)\right|^{k-1} d\mathcal{H}^k(z) \\ &= \sum_i \mathcal{H}^n(F_i \cap \Omega_\delta) \int_{|z|<\delta/\varepsilon} \varepsilon |\nabla \psi_{\sigma_i}(z)|^{k-1}\, d\mathcal{H}^k(z) \\ &\le C\varepsilon \left(\frac{\delta}{\varepsilon}\right)^{k\left(1-\frac{k-1}{p}\right)} \ll C\varepsilon^{1-\frac{k(p-k+1)}{(k+1)p}} \to 0. \end{aligned}$$

- On V_ε^2, $u_\varepsilon(x) = u(x)$. We remark that there exists some positive constant C independent of ε such that outside U_ε (so in particular for $x \in V_\varepsilon^2$), there holds

$$\operatorname{dist}(x, M \cup S) \ge C \operatorname{dist}(x,S). \tag{6.10}$$

Energy estimate. Recalling that u takes values into S^{k-1}, and using (6.7), (6.10), the coarea formula (2.8) (with $D := \sup\{\operatorname{dist}(x,S) : x \in \Omega\}$), and the assumption $r(\varepsilon) \sim \delta(\varepsilon) \gg \varepsilon$, we get

$$\begin{aligned} F_\varepsilon(u_\varepsilon, V_\varepsilon^2) &= \varepsilon^{p-k} \int_{V_\varepsilon^2} |\nabla u|^p \le C\varepsilon^{p-k} \int_{\Omega \setminus S_\varepsilon} \frac{1}{\operatorname{dist}(x,S)^p} \\ &\le C\varepsilon^{p-k} \int_r^D \frac{1}{t^p} \mathcal{H}^{n+k-1}\big(\{x \in \mathbb{R}^{n+k} : \operatorname{dist}(x,S) = t\}\big)\, dt \\ &\le C\varepsilon^{p-k}\big(D^{-p+k+1} - r^{-p+k+1}\big) \to 0. \end{aligned}$$

$W^{1,k-1}$-convergence. We trivially have $\int_{V_\varepsilon^2} |\nabla u_\varepsilon - \nabla u|^{k-1} \equiv 0$.

- On V_ε^3, $u_\varepsilon(x) = r^{-1}\,\mathrm{dist}(x,S)u(x)$. Then, since (6.10) holds on V_ε^3, we have

$$|\nabla u_\varepsilon(x)| \le Cr^{-1} \qquad \forall x \in V_\varepsilon^3. \tag{6.11}$$

Energy estimate. We have $F_\varepsilon(u_\varepsilon, V_\varepsilon^3) = \mathrm{I} + \mathrm{II}$, where, using inequality (6.11) and the assumption $r(\varepsilon) \sim \delta(\varepsilon)$, with $\varepsilon \ll \delta(\varepsilon) \ll \varepsilon^{k/k+1}$,

$$\mathrm{I} = \varepsilon^{p-k} \int_{V_\varepsilon^3} |\nabla u_\varepsilon|^p \le C\varepsilon^{p-k} r^{-p+k+1} \to 0,$$
$$\mathrm{II} = \varepsilon^{-k} \int_{V_\varepsilon^3} W\big(r^{-1}\mathrm{dist}(x,S)u\big) \le C\varepsilon^{-k} r^{k+1} \to 0.$$

$W^{1,k-1}$-convergence. Again by (6.11), we obtain $\int_{V_\varepsilon^3} |\nabla u_\varepsilon|^{k-1} \le Cr^2 \to 0$.

- On $V_\varepsilon^4, u_\varepsilon(x) = r^{-1}\mathrm{dist}(x,S)\psi_{\sigma_i}\big(\delta z/\varepsilon g_i(y)\big)$ for all $x = (y,z) \in U(F_i,\delta,\gamma)$.

For $x = (y,z) \in V_\varepsilon^4$, one can check that $\mathrm{dist}(x,S) \le C\mathrm{dist}(y,S)$, and

$$\left|\nabla\left(\psi_{\sigma_i}\left(\frac{\delta z}{\varepsilon g_i(y)}\right)\right)\right| \le \frac{C\delta}{\varepsilon g_i(y)}\left|\nabla\psi_{\sigma_i}\left(\frac{\delta z}{\varepsilon g_i(y)}\right)\right| \qquad \text{if } x = (y,z) \in U(F_i,\delta,\gamma).$$

It follows that, on $V_\varepsilon^4 \cap U(F_i,\delta,\gamma)$, $|\nabla u_\varepsilon|$ satisfy the inequality

$$|\nabla u_\varepsilon(x)| \le C\left\{\frac{1}{r} + \frac{\mathrm{dist}(y,S)}{r}\frac{\delta}{\varepsilon g_i(y)}\left|\nabla\psi_{\sigma_i}\left(\frac{\delta z}{\varepsilon g_i(y)}\right)\right|\right\}. \tag{6.12}$$

Energy estimate. Using (6.12), we have $F_\varepsilon(u_\varepsilon, V_\varepsilon^4) \le C(\mathrm{I}+\mathrm{II}) + \mathrm{III}$, with

$$\mathrm{I} = \int_{V_\varepsilon^4} \varepsilon^{p-k} r^{-p} \le C\varepsilon^{p-k} r^{-p+k+1} \to 0,$$
$$\begin{aligned}\mathrm{II} &= \sum_i \int_{U(F_i,\delta,\gamma)\cap S_\varepsilon\cap\Omega} \varepsilon^{p-k} r^{-p}\mathrm{dist}(y,S)^p \left(\frac{\delta}{\varepsilon g_i(y)}\right)^p \left|\nabla\psi_{\sigma_i}\left(\frac{\delta z}{\varepsilon g_i(y)}\right)\right|^p \\ &\le \sum_i \left\{\int_{\mathbb{R}^k} |\nabla\psi_{\sigma_i}|^p\right\} \int_{F_i\cap S_\varepsilon\cap\Omega_\delta} \varepsilon^{p-k} r^{-p}\,\mathrm{dist}(y,S)^p \left(\frac{\delta}{\varepsilon g_i(y)}\right)^{p-k} d\mathcal{H}^n(y) \\ &\le C\sum_i \int_{F_i\cap S_\varepsilon\cap\Omega_\delta} \frac{\mathrm{dist}(y,S)^p\delta^{-k}}{g_i(y)^{p-k}}\, d\mathcal{H}^n(y) \le C\sum_i \mathcal{H}^n(F_i\cap S_\varepsilon\cap\Omega_\delta) \to 0,\end{aligned}$$
$$\mathrm{III} = \int_{V_\varepsilon^4} \varepsilon^{-k} W(u_\varepsilon) \le C\varepsilon^{-k} r^{k+1} \to 0.$$

$W^{1,k-1}$-convergence. Using again (6.12), we have $\int_{V_\varepsilon^4} |\nabla u_\varepsilon|^{k-1} \le C(\mathrm{I}+\mathrm{II})$, with

$$\mathrm{I} = \int_{V_\varepsilon^4} r^{-k+1} \le Cr^2 \to 0,$$
$$\begin{aligned}\mathrm{II} &= \sum_i \int_{U(F_i,\delta,\gamma)\cap S_\varepsilon\cap\Omega} r^{-k+1}\,\mathrm{dist}(y,S)^{k-1} \left(\frac{\delta}{\varepsilon g_i(y)}\right)^{k-1} \left|\nabla\psi_{\sigma_i}\left(\frac{\delta z}{\varepsilon g_i(y)}\right)\right|^{k-1} \\ &\le C\sum_i \left\{\int_{|z|<\delta/\varepsilon} |\nabla\psi_{\sigma_i}|^{k-1}\right\} \int_{F_i\cap S_\varepsilon\cap\Omega_\delta} r^{-k+1}\,\mathrm{dist}(y,S)^{k-1} \frac{\varepsilon g_i(y)}{\delta}\, d\mathcal{H}^n(y) \\ &\le C\varepsilon\Big(\frac{\delta}{\varepsilon}\Big)^{k(1-\frac{k-1}{p})} \sum_i \mathcal{H}^n(F_i\cap S_\varepsilon\cap\Omega_\delta) \ll C\varepsilon^{1-\frac{k(p-k+1)}{(k+1)p}} \to 0.\end{aligned}$$

By the estimates obtained on V_ε^i for $i = 1, \dots, 4$, one has $\int_\Omega |\nabla u_\varepsilon - \nabla u|^{k-1} \to 0$, and

$$\begin{aligned}\limsup_\varepsilon F_\varepsilon(u_\varepsilon) &\le \limsup_\varepsilon \sum_i \mathcal{H}^n(F_i \cap \Omega_\delta)(\tau_{\sigma_i} + 1/h) \\ &= \limsup_\varepsilon \left\{ \int_{\partial N \cap \Omega_\delta} \tau_{\sigma(x)}\, d\mathcal{H}^n(x) + (1/h)\mathcal{H}^n(\partial N \cap \Omega_\delta) \right\} \\ &= \int_{M \cap \overline{\Omega}} \tau_{\sigma(x)}\, d\mathcal{H}^n(x) + C/h,\end{aligned}$$

The statement follows from the assumption $|M|(\partial\Omega) = 0$, and letting $h \to +\infty$. ∎

Acknowledgments. The origins of this research are traceable to the work by Alberti, Baldo, and Orlandi; see Remark (iv) after Corollary 1.2 in [3]. In particular, we warmly thank Giovanni Alberti for the stimulating discussions shared on these topics.

THE Γ-CONVERGENCE OF A SHARP INTERFACE THIN FILM MODEL WITH NONCONVEX ELASTIC ENERGY*

PAVEL BĚLÍK† AND MITCHELL LUSKIN‡

Abstract. We give results for the Γ-limit of a scaled elastic energy of a film as the thickness $h > 0$ converges to zero. The elastic energy density models materials with multiple phases or variants and is thus nonconvex. The model includes an interfacial energy that allows sharp interfaces between the phases and variants and is proportional to the total variation of the deformation gradient.

Key words. thin film, Γ-convergence, surface energy, bounded variation, martensite

DOI. 10.1137/050622596

1. Introduction.

Thin films of martensitic crystals are the subject of increasing scientific and technological interest [6, 14, 20]. Dimensionally reduced models that replace the three-dimensional (3-D) bulk energy with a two-dimensional (2-D) thin film energy can make the design of applications more tractable and the computation of the deformation more efficient. New challenges arise in the derivation of thin film energies for martensitic crystals since the presence of multiple phases and variants requires that the elastic energy density be nonconvex [4, 23, 27] and since an interfacial energy that allows sharp interfaces is often useful for accurate modeling [10, 11, 12]. Related work on the general problem of rigorously deriving dimensionally reduced energy functionals has been given in [1, 3, 6, 15, 17, 25, 28].

We present results for the Γ-limit [7, 24] of the scaled elastic energy of a thin film with deformation $\tilde{u} : \Omega_h \to \mathbb{R}^3$ defined on a reference domain of thickness $h > 0$ given by $\Omega_h = S \times (-h/2,\, h/2)$ for $S \subset \mathbb{R}^2$ and subject to boundary conditions

$$\tilde{u}(x_1, x_2, x_3) = y_0(x_1, x_2) + b_0(x_1, x_2)x_3 \quad \text{for } (x_1, x_2, x_3) \in \gamma \times (-h/2,\, h/2) \tag{1.1}$$

so the film adheres on a part of its lateral boundary given by

$$\gamma \times (-h/2,\, h/2) \subset \partial S \times (-h/2,\, h/2).$$

The elastic energy of the film is given by

$$\mathcal{E}_h(\tilde{u}) = \kappa \int_{\Omega_h} |D(\nabla \tilde{u})| + \int_{\Omega_h} \phi(\nabla \tilde{u}(x), x)\, dx, \tag{1.2}$$

where the term $\kappa \int_{\Omega_h} |D(\nabla \tilde{u})|$ for $\kappa > 0$ models the interfacial energy between phases and variants (the total variation of the deformation gradient is precisely defined in section 2), and the term $\int_{\Omega_h} \phi(\nabla \tilde{u}(x), x)\, dx$ models the elastic energy of the film.

Since we are interested in modeling and computing the deformation of thin films that undergo structural phase transformation, the energy density, $\phi(F,x)$, is generally a nonconvex function of the deformation gradient, $F \in \mathbb{R}^{3\times 3}$. The explicit dependence of the energy density, $\phi(F,x)$, on $x \in \Omega_h$ allows the modeling of alloys with compositional fluctuation [11, 12, 14, 19]. We rescale the deformations $\tilde{u} : \Omega_h \to \mathbb{R}^3$ to deformations on a fixed domain of thickness one, $u : \Omega_1 \to \mathbb{R}^3$, by

$$u(z_1, z_2, z_3) = \tilde{u}(z_1, z_2, hz_3) \quad \text{for } z = (z_1, z_2, z_3) \in \Omega_1,$$

and we determine and analyze the Γ-limit of the rescaled energy

$$\mathcal{E}_1^{(h)}(u) = \frac{1}{h}\,\mathcal{E}_h(\tilde{u})$$

subject to rescaled boundary conditions

$$u(z_1, z_2, z_3) = y_0(z_1, z_2) + b_0(z_1, z_2)hz_3 \quad \text{for } (z_1, z_2, z_3) \in \gamma \times (-1/2,\, 1/2). \tag{1.3}$$

We analyze the Γ-limit of $\mathcal{E}_1^{(h)}(u)$ with respect to two related definitions of convergence for deformations. For the first definition, we prove that the Γ-limit of $\mathcal{E}_1^{(h)}(u)$ is given by

$$\mathcal{E}^{(0)}(y,b) = \kappa\left[\int_S |D(\nabla y|\sqrt{2}\,b)| + \sqrt{2}\int_\gamma |b - b_0|\right] + \int_S \phi(\nabla y(\hat{z})|b(\hat{z}), \hat{z}, 0)\,d\hat{z} \tag{1.4}$$

for $y : S \to \mathbb{R}^3$ such that $y = y_0$ on $\gamma \subset \partial S$ and $b : S \to \mathbb{R}^3$. The matrix-valued function $(\nabla y|b) : S \to \mathbb{R}^{3\times 3}$ in the thin film limit (1.4) models the thin film deformation gradient. We also identify $(\hat{z}, 0) \in \mathbb{R}^3$ with $\hat{z} \in S$. For the second definition, we prove that the Γ-limit of $\mathcal{E}_1^{(h)}(u)$ is given by

$$\mathcal{E}_1^{(0)}(u) = \begin{cases} \min\limits_b \mathcal{E}^{(0)}(u_M, b) & \text{if } u_{,3} = 0 \text{ a.e. in } \Omega_1, \\ +\infty & \text{otherwise,} \end{cases}$$

where u_M is the deformation of the midplane, $u_M(z_1, z_2) = u(z_1, z_2, 0)$. For both definitions of convergence of deformations, we give compactness results and show that the uniform coerciveness of the energy functionals $\mathcal{E}_1^{(h)}(u)$ allows us to prove that subsequences of energy-minimizing deformations of $\mathcal{E}_1^{(h)}(u)$ converge to minimizers of the Γ-limit as $h \to 0$.

We have used the thin film energy (1.4) to compute the quasi-static evolution of a martensitic thin film subject to a varying temperature field [8, 9]. In these computations, we use continuation methods for which the film need only be in a local minimum. We think that the results in this paper, especially the Γ-convergence described in Theorem 5.3, justify the use of the thin film energy (1.4) in this context because the result (5.10) guarantees that any admissible (y, b) defined on S can be used to construct an admissible $\tilde{u}_h$ defined on Ω_h that is a "smoothed" version of the deformation

$$y(x_1, x_2) + b(x_1, x_2)x_3 \quad \text{for } (x_1, x_2, x_3) \in \Omega_h,$$

such that $\mathcal{E}^{(0)}(y, b)$ is approximated by $\frac{1}{h}\mathcal{E}_h(\tilde{u}_h)$.

The energy density, $\phi(F,x)$, in models for crystals which undergo a structural phase transformation is not quasi-convex [4, 5, 21, 22, 23, 26, 27]. The Γ-limit with

respect to weak $W^{1,p}$ convergence of a scaled elastic energy that does not include interfacial energy will generally thus involve the quasi-convexification of the elastic energy density [7, 15]. However, the interfacial energy $\kappa \int_{\Omega_h} |D(\nabla \tilde{u})|$ in our model allows us to obtain sequences of deformations with gradients that converge strongly and use the strong continuity of the scaled elastic energy $h^{-1} \int_{\Omega_h} \phi(\nabla \tilde{u}(x), x)\, dx$. A related result has been obtained in [6] for a diffuse interfacial energy $\kappa \int_{\Omega_h} |\nabla^2 \tilde{u}|^2\, dx$.

The loading of a martensitic thin film can be computed by using the Γ-limit of the energy

$$\begin{aligned} \hat{\mathcal{E}}_h(\tilde{u}) &= \kappa \int_{\Omega_h} |D(\nabla \tilde{u})| + \int_{\Omega_h} \phi(\nabla \tilde{u}(x), x)\, dx - \int_{\partial \Omega_h} (Tn) \cdot \tilde{u} \\ &= \kappa \int_{\Omega_h} |D(\nabla \tilde{u})| + \int_{\Omega_h} \phi(\nabla \tilde{u}(x), x)\, dx - \int_{\Omega_h} T \cdot \nabla \tilde{u}, \end{aligned} \tag{1.5}$$

where the dead load is Tn for a constant $T \in \mathbb{R}^{3\times 3}$ at points on the boundary $\partial\Omega_h$ with unit exterior normal vector n. The Γ-limit is shown in this paper to be

$$\hat{\mathcal{E}}_1^{(0)}(u) = \begin{cases} \min\limits_b \hat{\mathcal{E}}^{(0)}(u_M, b) & \text{if } u_{,3} = 0 \text{ a.e. in } \Omega_1, \\ +\infty & \text{otherwise,} \end{cases}$$

with

$$\hat{\mathcal{E}}^{(0)}(y, b) = \kappa \int_S |D(\nabla y |\sqrt{2}\, b)| + \int_S \phi(\nabla y(\hat{z}) | b(\hat{z}), \hat{z}, 0)\, d\hat{z} - \int_S T \cdot (\nabla y | b).$$

In section 2, we recall the total variation of functions of bounded variation and give a few needed properties. In section 3, we describe the assumed properties of the elastic energy density, and in section 4 we recall the definition of Γ-convergence. The main results and analysis for the Γ-limit of the film model with Dirichlet boundary conditions are given in section 5, and the main results and analysis for the Γ-limit of the film model with loading boundary conditions are given in section 6.

Our results in this paper extend the analysis given in [10] by proving the Γ-convergence of the scaled energy functional for the adhering boundary condition (1.1). We also extend the class of energy densities, $\phi(F, x)$, to allow compositional variation, and we extend the class of boundary conditions that can be analyzed by giving results for the Γ-limit of the scaled energy functional with dead loads (1.5).

2. Functions of bounded variation. We will assume that $S \subset \mathbb{R}^2$ is a bounded domain with a Lipschitz continuous boundary, ∂S, and denote the reference undistorted configuration of the thin film of the martensitic material by Ω_h, $0 < h \leq 1$, where

$$\Omega_h = S \times (-h/2,\, h/2).$$

The deformations of the thin film are given by functions $\tilde{u} : \Omega_h \to \mathbb{R}^3$ with gradient $\nabla \tilde{u} : \Omega_h \to \mathbb{R}^{3\times 3}$. We use the notation $\tilde{u}_{i,j} = \partial \tilde{u}_i / \partial x_j$, and we denote the columns of $\nabla \tilde{u}$ by $\tilde{u}_{,i}$, $i = 1, 2, 3$. The "planar" gradient of $\tilde{u}$, denoted by $\nabla_P \tilde{u} : \Omega_h \to \mathbb{R}^{3\times 2}$, has columns given by $\tilde{u}_{,1}$ and $\tilde{u}_{,2}$.

Given an open set $\Omega \subset \mathbb{R}^3$ and a function $v \in L^1(\Omega; \mathbb{R})$, we define the total

variation of v [16, 18] by

$$\int_\Omega |Dv| = \sup\Big\{ \int_\Omega \sum_{k=1,2,3} v(x)\psi_{k,k}(x)\,dx : \psi \in \mathcal{C}_0^\infty(\Omega;\mathbb{R}^3),\ |\psi(x)| \le 1 \ \text{ for all } x \in \Omega \Big\}$$

and say $v \in BV(\Omega)$ if $\int_\Omega |Dv| < +\infty$. We recall that $\mathcal{C}_0^\infty(\Omega;\mathbb{R}^3)$ denotes the space of infinitely differentiable functions compactly supported in Ω, whose range is $\mathbb{R}^3$, and we note that $|\psi(x)|$ denotes the usual Euclidean norm, that is, the square root of the sum of the squares of all the components of $\psi(x)$.

For a matrix-valued function $v \in L^1(\Omega;\mathbb{R}^{m\times p})$, we define

$$\int_\Omega |Dv| = \sup\Big\{ \sum_{\substack{i=1,\dots,m\\ j=1,\dots,p\\ k=1,2,3}} \int_\Omega v_{ij}(x)\psi_{ijk,k}(x)\,dx : \psi \in \mathcal{C}_0^\infty(\Omega;\mathbb{R}^{m\times p\times 3}),\ |\psi(x)| \le 1 \text{ for all } x \in \Omega \Big\} \tag{2.1}$$

and say $v \in BV(\Omega)$ if $\int_\Omega |Dv| < +\infty$. We again assume that $|\psi(x)|$ denotes the square root of the sum of the squares of all the components of $\psi(x)$, which is often called the Frobenius norm. Finally, we define the "planar" variation

$$\int_\Omega |D_P v| = \sup\Big\{ \sum_{\substack{i=1,\dots,m\\ j=1,\dots,p\\ k=1,2}} \int_\Omega v_{ij}(x)\psi_{ijk,k}(x)\,dx : \psi \in \mathcal{C}_0^\infty(\Omega;\mathbb{R}^{m\times p\times 2}),\ |\psi(x)| \le 1 \text{ for all } x \in \Omega \Big\}.$$

For a matrix-valued function $v \in L^1(S;\mathbb{R}^{m\times p})$ we similarly define

$$\int_S |Dv| = \sup\Big\{ \sum_{\substack{i=1,\dots,m\\ j=1,\dots,p\\ k=1,2}} \int_S v_{ij}(x)\psi_{ijk,k}(x)\,dx : \psi \in \mathcal{C}_0^\infty(S;\mathbb{R}^{m\times p\times 2}),\ |\psi(x)| \le 1 \text{ for all } x \in S \Big\}.$$

We remark that if $v \in BV(\Omega_1)$ is independent of z_3, then, abusing the notation slightly, we have

$$\int_{\Omega_1} |Dv| = \int_{\Omega_1} |D_P v| = \int_S |Dv|.$$

The notation $BV_q(\Omega)$ will denote the space $BV(\Omega) \cap L^q(\Omega)$.

For $A \in \mathbb{R}^{m\times p}$ and $B \in \mathbb{R}^{m\times q}$, we denote by $(A|B) \in \mathbb{R}^{m\times(p+q)}$ the matrix whose first p columns are those of A and whose last q columns are those of B. For

$v \in L^1(\Omega_1;\mathbb{R}^{m\times p})$ and $b \in L^1(\Omega_1;\mathbb{R}^m)$, we will use the identity

$$\int_{\Omega_1} |D(v|\sqrt{2}b)| = \int_{\Omega_1} |D(v|b|b)|. \tag{2.2}$$

We will use the following extension of the classical result on the lower semicontinuity of the BV seminorm [16, 18] to functions with fixed trace [10].

THEOREM 2.1. *If $w_j, b_j \in BV(\Omega_1)$ for $j \in \mathbb{N}$ and $w, b \in BV(\Omega_1)$ satisfy*

$$\lim_{j\to\infty} \|w_j - w\|_{L^1(\Omega_1)} = 0 \quad \text{and} \quad \lim_{j\to\infty} \|b_j - b\|_{L^1(\Omega_1)} = 0,$$

and $b_j = b_0$ on $\Gamma_1 = \gamma \times (-\frac{1}{2}, \frac{1}{2})$ for fixed $b_0 \in BV(\Omega_1)$, then

$$\int_{\Omega_1} |D_P(w|\sqrt{2}\, b)| + \sqrt{2}\int_{\Gamma_1} |b - b_0| \le \liminf_{j\to\infty} \int_{\Omega_1} |D_P(w_j|\sqrt{2}\, b_j)|.$$

We will also use the following extension of the classical result on the approximation by smooth functions in the BV seminorm [16, 18] to functions with fixed trace [10].

THEOREM 2.2. *Let $1 \le q < +\infty$, let $b_0 \in W^{1,q}(S)$ be such that $\nabla b_0 \in BV(S)$, let $b \in BV_q(S)$, and let $w \in BV(S)$. Then there exists a family $\{b_\varepsilon : \varepsilon > 0\} \subset W^{1,q}(S)$ with $\nabla b_\varepsilon \in BV(S)$ such that $b_\varepsilon = b_0$ on γ for every $\varepsilon > 0$, and*

$$\lim_{\varepsilon\to 0} \|b_\varepsilon - b\|_{L^q(S)} = 0,$$

$$\lim_{\varepsilon\to 0} \int_S |D(w|\sqrt{2}\, b_\varepsilon)| = \int_S |D(w|\sqrt{2}\, b)| + \sqrt{2}\int_\gamma |b - b_0|.$$

3. The elastic energy density ϕ. We will assume that the energy density $\phi : \mathbb{R}^{3\times 3} \times \Omega_1 \to \mathbb{R}$ satisfies the Carathéodory condition [24]:

1. $\phi(F, \hat{z}, z_3)$ is continuous in $(F, z_3) \in \mathbb{R}^{3\times 3} \times (-1/2, 1/2)$ for almost every $\hat{z} \in S$,
2. $\phi(F, \hat{z}, z_3)$ is measurable in $\hat{z} \in S$ for every $(F, z_3) \in \mathbb{R}^{3\times 3} \times (-1/2, 1/2)$,

and satisfies the growth condition

$$c_1|F|^p - c_2 \le \phi(F, z) \le c_3(|F|^p + 1) \quad \text{for all } F \in \mathbb{R}^{3\times 3} \text{ and } z \in \Omega_1, \tag{3.1}$$

where c_1, c_2, and c_3 are fixed positive constants and $3 < p < +\infty$.

We can obtain this energy density ϕ from a free energy density $\hat{\phi}(F, \theta, c)$, where $\theta(z)$ is a given temperature and $c(z)$ is a given order parameter such as alloy composition, by $\phi(F, z) = \hat{\phi}(F, \theta(z), c(z))$. In what follows, we will usually not denote the explicit dependence of ϕ on z. Notice that ϕ is bounded below and its absolute value satisfies the growth property

$$|\phi(F, z)| \le c_3|F|^p + \max\{c_2, c_3\} \quad \text{for all } F \in \mathbb{R}^{3\times 3} \text{ and } z \in \Omega_1.$$

4. The Γ-limit. We now give a definition of Γ-convergence [3, 7, 24] that allows the domain $\tilde{\mathcal{A}}$ of the approximating functionals $\mathcal{F}_h$ to be different than the domain $\mathcal{A}$ of the Γ-limit $\mathcal{F}$.

DEFINITION 4.1. *Let $\mathcal{A}$ and $\tilde{A}$ be spaces such that the convergence of elements of $\tilde{\mathcal{A}}$ to an element of $\mathcal{A}$ is defined. We say that the family of functionals $\{\mathcal{F}_h : \tilde{\mathcal{A}} \to \mathbb{R} \cup \{+\infty\}$ for $h > 0\}$ Γ-converges to $\mathcal{F} : \mathcal{A} \to \mathbb{R} \cup \{+\infty\}$ as $h \to 0$ if the following*

two conditions are satisfied:

Lower bound: *given any* $u \in \mathcal{A}$ *and any family* $\{u_h \in \tilde{\mathcal{A}} : \ h > 0\}$ *such that* $u_h \to u$ *as* $h \to 0$*, we have*

$$\mathcal{F}(u) \le \liminf_{h\to 0} \mathcal{F}_h(u_h);$$

Upper bound: *given any* $u \in \mathcal{A}$*, there exists a family* $\{u_h \in \tilde{\mathcal{A}} : \ h > 0\}$ *such that* $u_h \to u$ *as* $h \to 0$ *and*

$$\mathcal{F}(u) \ge \limsup_{h\to 0} \mathcal{F}_h(u_h),$$

or equivalently, in view of the lower bound above,

$$\mathcal{F}(u) = \lim_{h\to 0} \mathcal{F}_h(u_h).$$

We note that the first condition above (Lower bound) guarantees that $\mathcal{F}$ is below the Γ-limit (if it exists), and the second condition (Upper bound) guarantees that $\mathcal{F}$ is above the Γ-limit (if it exists). If $\mathcal{F}$ satisfies both conditions, then $\mathcal{F}$ is the Γ-limit.

5. Γ-limit of the film model with Dirichlet boundary conditions. In this section, we assume that the film adheres to a rigid material on its lateral surface

$$\Gamma_h = \gamma \times (-h/2,\, h/2),$$

where we assume that $\gamma \neq \emptyset$ is a finite union of connected $\mathcal{C}^{1,1}$ open subsets of ∂S. Let $y_0, b_0 \in W^{1,p}(S;\mathbb{R}^3)$ be such that $\nabla y_0, \nabla b_0 \in BV(S)$ and define the boundary condition

$$\tilde{u}_0(x_1,x_2,x_3) = y_0(x_1,x_2) + b_0(x_1,x_2)x_3 \quad \text{for } (x_1,x_2,x_3) \in \Omega_h. \tag{5.1}$$

We then define the space $\mathcal{A}_h$ of admissible deformations of the domain Ω_h by

$$\mathcal{A}_h = \left\{\tilde{u} \in W^{1,p}(\Omega_h;\mathbb{R}^3) : \ \nabla\tilde{u} \in BV(\Omega_h),\ \tilde{u} = \tilde{u}_0 \text{ on } \Gamma_h\right\}.$$

We note that due to the growth condition (3.1), we have that

$$\mathcal{A}_h = \left\{\tilde{u} : \Omega_h \to \mathbb{R}^3 : \ \mathcal{E}_h(\tilde{u}) < +\infty,\ \tilde{u} = \tilde{u}_0 \text{ on } \Gamma_h\right\}.$$

Also, since $p > 3$, it follows from the Sobolev embedding theorem [2] that $\mathcal{A}_h \subset \mathcal{C}(\bar{\Omega}_h)$. This ensures that there is no tear in the deformed configurations $\tilde{u}(\Omega_h)$ for $\tilde{u} \in \mathcal{A}_h$.

We are interested in studying the thin film limit of the energies

$$\mathcal{E}_h(\tilde{u}) = \kappa \int_{\Omega_h} |D(\nabla\tilde{u})| + \int_{\Omega_h} \phi(\nabla\tilde{u}(x),x)\,dx, \qquad \tilde{u} \in \mathcal{A}_h, \tag{5.2}$$

where the constant $\kappa > 0$ is a measure of interfacial energy per unit area. We rescale the deformations $\tilde{u} : \Omega_h \to \mathbb{R}^3$ to deformations on a fixed domain of thickness one, $u : \Omega_1 \to \mathbb{R}^3$, via

$$u(z_1,z_2,z_3) = \tilde{u}(z_1,z_2,hz_3) \quad \text{for } z = (z_1,z_2,z_3) \in \Omega_1, \tag{5.3}$$

and we then study the Γ-convergence as $h \to 0$ of the rescaled energy

$$\mathcal{E}_1^{(h)}(u) = \frac{1}{h}\,\mathcal{E}_h(\tilde{u}) \tag{5.4}$$

for u defined in the space of admissible deformations

$$\mathcal{A}_1 = \left\{ u \in W^{1,p}(\Omega_1;\mathbb{R}^3) :\ \nabla u \in BV(\Omega_1),\ u = u_0 \text{ on } \Gamma_1 \right\},$$

where u_0 is defined by (5.1) and (5.3) to be

$$u_0(z_1,z_2,z_3) = y_0(z_1,z_2) + b_0(z_1,z_2)hz_3 \quad \text{for } (z_1,z_2,z_3) \in \Omega_1.$$

We will first define a topology for the convergence of $u_h \in \mathcal{A}_1$ to $(y,b) \in \mathcal{A}_0$, where

$$\mathcal{A}_0 = \{(y,b) \in W^{1,p}(S;\mathbb{R}^3) \times L^p(S;\mathbb{R}^3) :\ \nabla y, b \in BV(S),\ y = y_0 \text{ on } \gamma\}, \tag{5.5}$$

and we will then show that the Γ-limit of $\mathcal{E}_1^{(h)}$ is given by $\mathcal{E}^{(0)}$, where

$$\mathcal{E}^{(0)}(y,b) = \kappa \left[\int_S |D(\nabla y|\sqrt{2}\, b)| + \sqrt{2} \int_\gamma |b - b_0| \right] + \int_S \phi(\nabla y(\hat{z})|b(\hat{z}),\hat{z},0)\, d\hat{z}. \tag{5.6}$$

Here we use Definition 4.1 with $\mathcal{A} = \mathcal{A}_1$ and $\tilde{\mathcal{A}} = \mathcal{A}_0$. We note that above and in what follows we will often use the notation

$$\int_S \phi(\nabla y|b) = \int_S \phi(\nabla y(\hat{z})|b(\hat{z}),\hat{z},0)\, d\hat{z}.$$

In a second approach, we will set $\mathcal{A} = \tilde{\mathcal{A}} = \mathcal{A}_1$ with the topology on the space $\mathcal{A}_1$ given by weak $W^{1,p}$ convergence, and we will prove that a related functional $\mathcal{E}_1^{(0)}$ is the Γ-limit of $\mathcal{E}_1^{(h)}$ as $h \to 0$. The relation between $\mathcal{E}^{(0)}$ and $\mathcal{E}_1^{(0)}$ will become clear.

We now consider the Γ-convergence of $\mathcal{E}_1^{(h)}$ to $\mathcal{E}^{(0)}$ as $h \to 0$. We start by introducing a notion of the convergence of 3-D deformations $\{u_h\} \subset \mathcal{A}_1$ to a 2-D deformation $(y,b) \in \mathcal{A}_0$ as $h \to 0$.

DEFINITION 5.1. *We shall say that a family* $\{u_h \in \mathcal{A}_1 :\ h > 0\}$ *converges to* $(y,b) \in \mathcal{A}_0$ *if the following conditions are satisfied for* $\hat{y}(z_1,z_2,z_3) = y(z_1,z_2)$ *and* $\hat{b}(z_1,z_2,z_3) = b(z_1,z_2)$*:*

$$\left.\begin{array}{llllll} u_h \rightharpoonup \hat{y} & \text{in } W^{1,p}(\Omega_1;\mathbb{R}^3) & \text{and} & h^{-1}u_{h,3} \rightharpoonup \hat{b} & \text{in } L^p(\Omega_1;\mathbb{R}^3) \\ u_h \to \hat{y} & \text{in } W^{1,1}(\Omega_1;\mathbb{R}^3) & \text{and} & h^{-1}u_{h,3} \to \hat{b} & \text{in } L^1(\Omega_1;\mathbb{R}^3) \end{array}\right\} \quad \text{as } h \to 0.$$

We shall use this definition of convergence when proving the Γ-convergence of the functionals $\mathcal{E}_1^{(h)}$ to $\mathcal{E}^{(0)}$ since it allows the compactness property of Lemma 5.2 for sequences of deformations

$$\{u_{h_n} \in \mathcal{A}_1 : n = 1,\dots, \text{ and } h_n \to 0 \text{ as } n \to \infty\}$$

with uniformly bounded energy $\mathcal{E}_1^{(h_n)}(u_{h_n}) \le C$ for all $n \ge 1$. This compactness property can then be used with the Γ-convergence of the functionals $\mathcal{E}_1^{(h)}$ to $\mathcal{E}^{(0)}$ to give a proof of the convergence of minimizers of $\mathcal{E}_1^{(h)}$ to minimizers of the Γ-limit $\mathcal{E}^{(0)}$ (see Corollary 5.4 following the proof of Theorem 5.3). We will see from the proof of Theorem 5.3 that $\mathcal{E}^{(0)}$ is also the Γ-limit of $\mathcal{E}_1^{(h)}$ if we use the strong convergence

$$u_h \to \hat{y} \quad \text{in } W^{1,p}(\Omega_1;\mathbb{R}^3) \qquad \text{and} \qquad h^{-1}u_{h,3} \to \hat{b} \quad \text{in } L^p(\Omega_1;\mathbb{R}^3)$$

in Definition 5.1, but we do not have a compactness property for this topology since $BV(\Omega_1)$ is not compactly embedded in $L^p(\Omega_1)$ if $p \geq \frac{3}{2}$ [18].

LEMMA 5.2. *Suppose that* $\{u_{h_n} \in \mathcal{A}_1 : n = 1, \dots$ *and* $h_n \to 0$ *as* $n \to \infty\}$ *is a sequence of deformations with uniformly bounded energy* $\mathcal{E}_1^{(h_n)}(u_{h_n}) \leq C$ *for all* $n \geq 1$. *Then there exists a further subsequence, also denoted by* $\{u_{h_n} \in \mathcal{A}_1 : n = 1, \dots\}$, *and* $(y, b) \in \mathcal{A}_0$ *such that* $\{u_{h_n} \in \mathcal{A}_1 : n = 1, \dots\}$ *converges to* $(y, b) \in \mathcal{A}_0$ *in the sense of Definition* 5.1. *We may take a further subsequence such that the convergence is also almost everywhere in* Ω_1.

Proof. We have from the definition of the total variation for matrix valued functions (2.1) that

$$\begin{aligned}
&\frac{1}{h_n}\int_{\Omega_{h_n}} |D(\nabla \tilde{u}_{h_n})| \\
&\quad = \sup\Bigg\{ \sum_{\substack{i=1,2,3\\ j,k=1,2}} \int_{\Omega_1} (u_{h_n})_{i,j}\psi_{ijk,k} + \sum_{\substack{i=1,2,3\\ j=1,2}} \int_{\Omega_1} {h_n}^{-1}(u_{h_n})_{i,j}\psi_{ij3,3} \\
&\qquad + \sum_{\substack{i=1,2,3\\ k=1,2}} \int_{\Omega_1} {h_n}^{-1}(u_{h_n})_{i,3}\psi_{i3k,k} + \sum_{i=1,2,3} \int_{\Omega_1} {h_n}^{-2}(u_{h_n})_{i,3}\psi_{i33,3} : \\
&\qquad\qquad \psi \in \mathcal{C}_0^\infty(\Omega_1),\ |\psi(z)| \leq 1 \ \text{ for all } z \in \Omega_1 \Bigg\}.
\end{aligned} \tag{5.7}$$

Since $\mathcal{E}_1^{(h_n)}(u_{h_n}) \leq C$ for all $n \geq 1$, we have by the growth condition (3.1) that

$$\|u_{h_n}\|_{W^{1,p}(\Omega_1;\mathbb{R}^3)} \leq C, \qquad \|h_n^{-1}u_{h_n,3}\|_{L^p(\Omega_1;\mathbb{R}^3)} \leq C, \tag{5.8}$$

and we have by (5.7) that

$$\begin{aligned}
&\int_{\Omega_1} |D(\nabla u_{h_n})| \leq C, \qquad \int_{\Omega_1} |D(h_n^{-1}u_{h_n,3})| \leq C, \\
&\sup\Bigg\{ \sum_{i=1,2,3} \int_{\Omega_1} h_n^{-2}(u_{h_n})_{i,3}\psi_{i33,3} : \\
&\qquad \psi \in \mathcal{C}_0^\infty(\Omega_1),\ |\psi(z)| \leq 1 \ \text{ for all } z \in \Omega_1 \Bigg\} \leq C
\end{aligned} \tag{5.9}$$

for all $n \geq 1$. It then follows from the compactness of the BV spaces [18] and the trace theorem [2] that there exists $\hat{u} \in W^{1,p}(\Omega_1;\mathbb{R}^3)$ such that $\nabla\hat{u} \in BV(\Omega_1)$ and $\hat{u} = y_0$ on $\gamma \times (-\frac{1}{2}, \frac{1}{2})$ and that there exists $\hat{b} \in BV_p(\Omega_1)$ such that for a further subsequence of $\{u_{h_n}\}$, not relabeled, we have that

$$\left.\begin{array}{llll} u_{h_n} \rightharpoonup \hat{u} & \text{in } W^{1,p}(\Omega_1;\mathbb{R}^3) & \text{and} & h_n^{-1}u_{h_n,3} \rightharpoonup \hat{b} \quad \text{in } L^p(\Omega_1;\mathbb{R}^3) \\ u_{h_n} \to \hat{u} & \text{in } W^{1,1}(\Omega_1;\mathbb{R}^3) & \text{and} & h_n^{-1}u_{h_n,3} \to \hat{b} \quad \text{in } L^1(\Omega_1;\mathbb{R}^3) \end{array}\right\} \ \text{as } n \to \infty,$$

and the convergence is also almost everywhere in Ω_1. In addition, from (5.8) and (5.9) it follows that $\hat{u}$ and $\hat{b}$ are independent of z_3, so we can set $y(z_1, z_2) = \hat{u}(z_1, z_2, z_3)$ and $b(z_1, z_2) = \hat{b}(z_1, z_2, z_3)$ to prove the lemma. ∎

We have the following Γ-convergence theorem.

THEOREM 5.3. *The functional* $\mathcal{E}^{(0)} : \mathcal{A}_0 \to \mathbb{R}$ *is the* Γ*-limit of the functionals* $\mathcal{E}_1^{(h)} : \mathcal{A}_1 \to \mathbb{R}$ *with respect to the convergence from Definition* 5.1*; that is,*

Lower bound: *given any* $(y, b) \in \mathcal{A}_0$ *and any family* $\{u_h \in \mathcal{A}_1 : \ h > 0\}$ *that converges to* (y, b)*, we have*

$$\mathcal{E}^{(0)}(y, b) \le \liminf_{h\to 0} \mathcal{E}_1^{(h)}(u_h);$$

Upper bound: *given any* $(y, b) \in \mathcal{A}_0$*, there exists a family* $\{u_h \in \mathcal{A}_1 : \ h > 0\}$ *that converges to* (y, b) *such that*

$$\mathcal{E}^{(0)}(y, b) \ge \limsup_{h\to 0} \mathcal{E}_1^{(h)}(u_h),$$

or equivalently, in view of the lower bound above,

$$\mathcal{E}^{(0)}(y, b) = \lim_{h\to 0} \mathcal{E}_1^{(h)}(u_h). \tag{5.10}$$

Proof (lower bound). To prove the lower bound, let $(y, b) \in \mathcal{A}_0$ and let $\{u_h \in \mathcal{A}_1 : \ h > 0\}$ converge to (y, b) in the sense of Definition 5.1. Consider a subsequence $\{u_{h_n}\}_{n=1}^{\infty}$ such that

$$\lim_{n\to\infty} \mathcal{E}_1^{(h_n)}(u_{h_n}) = \liminf_{h\to 0} \mathcal{E}_1^{(h)}(u_h)$$

and such that $\nabla_P u_{h_n} \to \nabla_P \hat{y}$ and $h_n^{-1} u_{h_n,3} \to \hat{b}$ almost everywhere in Ω_1 as $n \to \infty$. It follows from the identity (2.2) and

$$\int_\Omega v_{i,j}\psi_{ij3,3} = \int_\Omega v_{i,3}\psi_{ij3,j} \qquad \text{for all } v \in W^{1,1}(\Omega; \mathbb{R}^3) \text{ and } \psi_{ij3} \in \mathcal{C}_0^\infty(\Omega)$$

that

$$\begin{aligned}
&\int_{\Omega_1} |D_P(\nabla_P u_{h_n} | \sqrt{2}\, h_n^{-1} u_{h_n,3})| \\
&\quad = \int_{\Omega_1} |D_P(\nabla_P u_{h_n} | h_n^{-1} u_{h_n,3} | h_n^{-1} u_{h_n,3})| \\
&\quad = \sup \Bigg\{ \sum_{\substack{i=1,2,3\\ j,k=1,2}} \int_{\Omega_1} (u_{h_n})_{i,j} \psi_{ijk,k} + \sum_{\substack{i=1,2,3\\ j=1,2}} \int_{\Omega_1} {h_n}^{-1} (u_{h_n})_{i,3} \psi_{ij3,j} \\
&\qquad + \sum_{\substack{i=1,2,3\\ k=1,2}} \int_{\Omega_1} {h_n}^{-1} (u_{h_n})_{i,3} \psi_{i3k,k} : \\
&\qquad\qquad \psi \in \mathcal{C}_0^\infty(\Omega_1), \ |\psi(z)| \le 1 \ \text{ for all } z \in \Omega_1 \Bigg\} \\
&\quad \le \sup \Bigg\{ \sum_{\substack{i=1,2,3\\ j,k=1,2}} \int_{\Omega_1} (u_{h_n})_{i,j} \psi_{ijk,k} + \sum_{\substack{i=1,2,3\\ j=1,2}} \int_{\Omega_1} {h_n}^{-1} (u_{h_n})_{i,j} \psi_{ij3,3}
\end{aligned}$$

$$+\sum_{\substack{i=1,2,3\\k=1,2}}\int_{\Omega_1} {h_n}^{-1}(u_{h_n})_{i,3}\psi_{i3k,k}+\sum_{i=1,2,3}\int_{\Omega_1} {h_n}^{-2}(u_{h_n})_{i,3}\psi_{i33,3}:$$

$$\psi\in\mathcal{C}_0^\infty(\Omega_1),\ |\psi(z)|\le 1\ \text{ for all } z\in\Omega_1\Big\} \tag{5.11}$$

$$=\frac{1}{h_n}\int_{\Omega_{h_n}}|D(\nabla\tilde{u}_{h_n})|.$$

So, by using Theorem 2.1 on (5.11) and Fatou's lemma to control the ϕ term, we obtain that

$$\begin{aligned}\mathcal{E}^{(0)}(y,b)&=\kappa\left[\int_{\Omega_1}\left|D_P(\nabla_P\hat{y}|\sqrt{2}\,\hat{b})\right|+\sqrt{2}\int_{\Gamma_1}|\hat{b}-b_0|\right]+\int_{\Omega_1}\phi(\nabla_P\hat{y}|\hat{b},\hat{z},0)\,dz\\&\le\liminf_{n\to\infty}\mathcal{E}_1^{(h_n)}(u_{h_n})\\&=\lim_{n\to\infty}\mathcal{E}_1^{(h_n)}(u_{h_n})\\&=\liminf_{h\to0}\mathcal{E}_1^{(h)}(u_h),\end{aligned}$$

and this establishes the first part of the theorem. We note that above and in what follows we use the convention $z=(\hat{z},z_3)$ for $\hat{z}\in S$ and $z_3\in(-1/2,1/2)$.

Upper bound. To prove the upper bound, we would like to consider deformations of the form $y(z_1,z_2)+hz_3b(z_1,z_2)$; however, such deformations do not belong to $\mathcal{A}_1$ because b does not belong to $W^{1,p}(S;\mathbb{R}^3)$ and ∇b does not belong to $BV(S)$. We can overcome this problem by using Theorem 2.2: since $b_0\in W^{1,p}(S;\mathbb{R}^3)$ and $\nabla b_0\in BV(S)$, there exists a family of functions $b_\varepsilon\in W^{1,p}(S;\mathbb{R}^3)$ with $\nabla b_\varepsilon\in BV(S)$ such that $b_\varepsilon=b_0$ on γ for every $\varepsilon>0$, $b_\varepsilon\to b$ almost everywhere in S and in $L^p(S)$ as $\varepsilon\to0$, and

$$\lim_{\varepsilon\to0}\int_S|D(\nabla y|\sqrt{2}\,b_\varepsilon)|=\int_S|D(\nabla y|\sqrt{2}\,b)|+\sqrt{2}\int_\gamma|b-b_0|. \tag{5.12}$$

We construct the functions

$$u_h^\varepsilon(z_1,z_2,z_3)=y(z_1,z_2)+hz_3b_\varepsilon(z_1,z_2)\in\mathcal{A}_1\quad\text{ for } 0<h\le1.$$

Now $\nabla_Pu_h^\varepsilon=\nabla_Py+hz_3\nabla_Pb_\varepsilon\to\nabla_Py$ in $L^p(\Omega_1)$ and almost everywhere in Ω_1 as $h\to0$, so we can obtain by using the growth condition (3.1) for ϕ, the Carathéodory property of ϕ given in section 3, and the dominated convergence theorem that

$$\begin{aligned}\frac{1}{h}\int_{\Omega_h}\phi(\nabla\tilde{u}_h^\varepsilon(x),x)\,dx&=\int_{\Omega_1}\phi(\nabla_Pu_h^\varepsilon|h^{-1}u_{h,3}^\varepsilon,\hat{z},hz_3)\,dz\\&=\int_{\Omega_1}\phi(\nabla_Pu_h^\varepsilon|b_\varepsilon,\hat{z},hz_3)\,dz\to\int_{\Omega_1}\phi(\nabla_Py|b_\varepsilon,\hat{z},0)\,dz\end{aligned}$$

as $h\to0$. By the same argument,

$$\int_{\Omega_1}\phi(\nabla_Py|b_\varepsilon,\hat{z},0)\,dz=\int_S\phi(\nabla y|b_\varepsilon)\to\int_S\phi(\nabla y|b)\quad\text{ as }\varepsilon\to0,$$

so

$$\lim_{\varepsilon\to0}\lim_{h\to0}\frac{1}{h}\int_{\Omega_h}\phi(\nabla\tilde{u}_h^\varepsilon(x),x)\,dx=\int_S\phi(\nabla y|b). \tag{5.13}$$

We now have since b_ε is independent of z_3 that

$$\begin{aligned}
&\frac{1}{h}\int_{\Omega_h} |D(\tilde{u}_h^\varepsilon)| \\
&\quad = \sup\Bigg\{ \sum_{\substack{i=1,2,3\\ j,k=1,2}} \int_{\Omega_1} (u_h^\varepsilon)_{i,j}\psi_{ijk,k} + \sum_{\substack{i=1,2,3\\ j=1,2}} \int_{\Omega_1} h^{-1}(u_h^\varepsilon)_{i,3}\psi_{ij3,j} \\
&\qquad + \sum_{\substack{i=1,2,3\\ k=1,2}} \int_{\Omega_1} h^{-1}(u_h^\varepsilon)_{i,3}\psi_{i3k,k} + \sum_{i=1,2,3} \int_{\Omega_1} h^{-2}(u_h^\varepsilon)_{i,3}\psi_{i33,3} : \\
&\qquad\qquad \psi \in \mathcal{C}_0^\infty(\Omega),\ |\psi(z)| \le 1 \ \text{ for all } z \in \Omega_1 \Bigg\} \qquad (5.14)\\
&\quad = \sup\Bigg\{ \sum_{\substack{i=1,2,3\\ j,k=1,2}} \int_{\Omega_1} (u_h^\varepsilon)_{i,j}\psi_{ijk,k} + \sum_{\substack{i=1,2,3\\ j=1,2}} \int_{\Omega_1} b_\varepsilon\psi_{ij3,j} \\
&\qquad + \sum_{\substack{i=1,2,3\\ k=1,2}} \int_{\Omega_1} b_\varepsilon\psi_{i3k,k} : \psi \in \mathcal{C}_0^\infty(\Omega_1),\ |\psi(z)| \le 1 \ \text{ for all } z \in \Omega_1 \Bigg\} \\
&\quad = \int_{\Omega_1} \left| D_P(\nabla_P u_h^\varepsilon | \sqrt{2}\, b_\varepsilon) \right|.
\end{aligned}$$

Since $\nabla b_\varepsilon \in BV(S)$ and y and b_ε are independent of z_3, we have that

$$\begin{aligned}
&\lim_{h\to 0} \int_{\Omega_1} \left| D_P(\nabla_P u_h^\varepsilon | \sqrt{2}\, b_\varepsilon) \right| \\
&\qquad = \lim_{h\to 0} \int_{\Omega_1} |D_P(\nabla_P(y + hz_3 b_\varepsilon)|\sqrt{2}\, b_\varepsilon)| = \int_S |D(\nabla y|\sqrt{2}\, b_\varepsilon)|. \qquad (5.15)
\end{aligned}$$

It then follows from (5.14), (5.15), and (5.12) that

$$\begin{aligned}
\lim_{\varepsilon\to 0}\lim_{h\to 0} \frac{1}{h}\int_{\Omega_h} |D(\tilde{u}_h^\varepsilon)| &= \lim_{\varepsilon\to 0}\lim_{h\to 0} \int_{\Omega_1} |D_P(\nabla_P u_h^\varepsilon|\sqrt{2} b_\varepsilon)| \\
&= \int_S |D(\nabla y|\sqrt{2}\, b)| + \sqrt{2}\int_\gamma |b - b_0|. \qquad (5.16)
\end{aligned}$$

We can then conclude from (5.13) and (5.16) that

$$\lim_{\varepsilon\to 0}\lim_{h\to 0} \mathcal{E}_1^{(h)}(u_h^\varepsilon) = \mathcal{E}^{(0)}(y, b). \qquad (5.17)$$

We note that in view of (5.17), it is clear that for any $\eta > 0$ there exists $\varepsilon > 0$ and $h_0 > 0$ such that

$$|\mathcal{E}_1^{(h)}(u_h^\varepsilon) - \mathcal{E}^{(0)}(y, b)| < \eta \quad \text{ for all } 0 < h \le h_0. \qquad \square$$

COROLLARY 5.4. *For every sequence $\{u_h \in \mathcal{A}_1 : h \to 0\}$ of minimizers of $\mathcal{E}_1^{(h)}$, there exists a subsequence $\{u_{h_n} \in \mathcal{A}_1 : n = 1, \dots$ and $h_n \to 0$ as $n \to \infty\}$ and a minimizer $(y, b) \in \mathcal{A}_0$ of $\mathcal{E}^{(0)}$ such that $\{u_{h_n} \in \mathcal{A}_1 : n = 1, \dots\}$ converges to $(y, b) \in \mathcal{A}_0$ in the sense of Definition* 5.1.

Proof. We first note that $\mathcal{E}_1^{(h)}(u_0)$ is bounded independent of $h > 0$. We can thus prove the existence of minimizers, $u_h \in \mathcal{A}_1$, of the functional $\mathcal{E}_1^{(h)}$ for fixed $h > 0$ by using the bounds (5.8) and (5.9), the compactness and lower-semicontinuity of the BV spaces [18], and Fatou's lemma.

Since $\mathcal{E}_1^{(h)}(u_0)$ is bounded independent of $h > 0$, we have the uniform bound

$$\mathcal{E}_1^{(h)}(u_h) \le \mathcal{E}_1^{(h)}(u_0) \le C.$$

We let $\{u_{h_n} \in \mathcal{A}_1 : n = 1, \dots \text{ and } h_n \to 0 \text{ as } n \to \infty\}$ be a subsequence such that

$$\lim_{n\to\infty} \mathcal{E}_1^{(h_n)}(u_{h_n}) = \liminf_{h\to 0} \mathcal{E}_1^{(h)}(u_h).$$

We can conclude from Lemma 5.2 that there exists a further subsequence (not relabeled), $\{u_{h_n} \in \mathcal{A}_1 : n = 1, \dots \text{ and } h_n \to 0 \text{ as } n \to \infty\}$, and $(y, b) \in \mathcal{A}_0$ such that $\{u_{h_n} \in \mathcal{A}_1 : n = 1, \dots\}$ converges to $(y, b) \in \mathcal{A}_0$ in the sense of Definition 5.1. It follows from the lower bound in Theorem 5.3 that

$$\mathcal{E}^{(0)}(y, b) \le \lim_{n\to\infty} \mathcal{E}_1^{(h_n)}(u_{h_n}) = \liminf_{h\to 0} \mathcal{E}_1^{(h)}(u_h).$$

Since $u_h \in \mathcal{A}_1$ are minimizers of $\mathcal{E}_1^{(h)}$, we can conclude from the upper bound in Theorem 5.3 that $\limsup_{h\to 0} \mathcal{E}_1^{(h)}(u_h) \le \mathcal{E}^{(0)}(y, b)$, so $\lim_{h\to 0} \mathcal{E}_1^{(h)}(u_h)$ exists and

$$\mathcal{E}^{(0)}(y, b) = \lim_{h\to 0} \mathcal{E}_1^{(h)}(u_h).$$

We can now conclude from the upper bound in Theorem 5.3 that $(y, b) \in \mathcal{A}_0$ is a minimizer of $\mathcal{E}^{(0)}$. ∎

We next address the question of Γ-convergence of $\mathcal{E}_1^{(h)}$ with respect to the weak convergence in $\mathcal{A}_1$. We start by considering the problem of minimizing $\mathcal{E}^{(0)}(y, b)$ with respect to b.

LEMMA 5.5. *Let $y \in W^{1,p}(S; \mathbb{R}^3)$ be such that $\nabla y \in BV(S)$ and $y = y_0$ on γ. Then*

$$\inf_{b\in BV_p(S;\mathbb{R}^3)} \mathcal{E}^{(0)}(y, b) = \inf_{\substack{b\in BV_p(S;\mathbb{R}^3)\\ b=b_0 \text{ on } \gamma}} \mathcal{E}^{(0)}(y, b). \tag{5.18}$$

Proof. It is clear that the left-hand side is less than or equal to the right-hand side since the infimum is taken over a larger space.

To show the opposite inequality, it is enough to show that for any $b \in BV_p(S; \mathbb{R}^3)$ the energy $\mathcal{E}^{(0)}(y, b)$ can be arbitrarily closely approximated by energies $\mathcal{E}^{(0)}(y, b)$ with $b \in BV_p(S; \mathbb{R}^3)$ such that $b = b_0$ on γ. However, this follows by applying Theorem 2.2 with $q = p$ and showing that the elastic energy term $\int_S \phi(\nabla y|b_\varepsilon)$ again converges to $\int_S \phi(\nabla y|b)$ as in the proof of the second part of Theorem 5.3. ∎

We next have that the infimum on the left-hand side of (5.18) in Lemma 5.5 is attained for any y.

LEMMA 5.6. *Let $y \in W^{1,p}(S; \mathbb{R}^3)$ be such that $\nabla y \in BV(S)$ and $y = y_0$ on γ. Then there exists a function $\tilde{b} \in BV_p(S; \mathbb{R}^3)$ such that*

$$\mathcal{E}^{(0)}(y, \tilde{b}) = \inf_{b\in BV_p(S;\mathbb{R}^3)} \mathcal{E}^{(0)}(y, b).$$

Proof. Since $\mathcal{E}^{(0)}$ is bounded below, we can consider a minimizing sequence $\{b_j\}_{j=1}^{\infty} \subset BV_p(S;\mathbb{R}^3)$; in view of Lemma 5.5, we can also assume that $b_j = b_0$ on γ for all $j \in \mathbb{N}$. Since the variations of the b_j and their L^p-norms (and thus also the L^1-norms) lie in a compact subset of $\mathbb{R}$, we can use the compactness of $BV(S;\mathbb{R}^3)$ [18] and retrieve a subsequence, not relabeled, which converges to a function $\tilde{b} \in BV_p(S;\mathbb{R}^3)$ strongly in $L^1(S;\mathbb{R}^3)$, weakly in $L^p(S;\mathbb{R}^3)$, and almost everywhere in S. In addition, by applying Theorem 2.1, we have

$$\int_S |D(\nabla y|\sqrt{2}\,\tilde{b})| + \sqrt{2}\int_\gamma |\tilde{b} - b_0| \le \liminf_{j\to\infty} \int_S |D(\nabla y|\sqrt{2}\,b_j)|.$$

Similarly, applying Fatou's lemma to $\phi(\nabla y|b_j)$ gives

$$\int_S \phi(\nabla y|\tilde{b}) \le \liminf_{j\to\infty} \int_S \phi(\nabla y|b_j),$$

and therefore

$$\begin{aligned}\mathcal{E}^{(0)}(y,\tilde{b}) &\le \liminf_{j\to\infty} \mathcal{E}^{(0)}(y,b_j)\\ &= \inf_{b\in BV_p(S;\mathbb{R}^3)} \mathcal{E}^{(0)}(y,b). \qquad \square\end{aligned}$$

We are now in the position to find the Γ-limit of the functionals $\mathcal{E}_1^{(h)} = \frac{1}{h}\,\mathcal{E}_h(\tilde{u})$. Given a continuous $u \in \mathcal{A}_1$, we can define the deformation of the midplane

$$u_M(z_1,z_2) = u(z_1,z_2,0)$$

and a functional

$$\mathcal{E}_1^{(0)}(u) = \begin{cases} \min\limits_{b\in BV_p(S;\mathbb{R}^3)} \mathcal{E}^{(0)}(u_M,b) & \text{if } u_{,3} = 0 \text{ a.e. in } \Omega_1,\\ +\infty & \text{otherwise.}\end{cases}$$

In what follows, C will denote a generic positive constant independent of h, which can change from line to line.

THEOREM 5.7. *The functional $\mathcal{E}_1^{(0)} : \mathcal{A}_1 \to \mathbb{R}\cup\{+\infty\}$ is the Γ-limit of the functionals $\mathcal{E}_1^{(h)} : \mathcal{A}_1 \to \mathbb{R}$ as $h \to 0$ with respect to the weak $W^{1,p}(\Omega_1;\mathbb{R}^3)$ convergence in $\mathcal{A}_1$; that is,*

Lower bound: *given any $u \in \mathcal{A}_1$ and any family $\{u_h \in \mathcal{A}_1 : h > 0\}$ such that $u_h \rightharpoonup u$ in $W^{1,p}(\Omega_1;\mathbb{R}^3)$ as $h \to 0$, we have*

$$\mathcal{E}_1^{(0)}(u) \le \liminf_{h\to 0} \mathcal{E}_1^{(h)}(u_h);$$

Upper bound: *given any $u \in \mathcal{A}_1$, there exists a family $\{u_h \in \mathcal{A}_1 : h > 0\}$ such that $u_h \rightharpoonup u$ in $W^{1,p}(\Omega_1;\mathbb{R}^3)$ as $h \to 0$ and*

$$\mathcal{E}_1^{(0)}(u) \ge \limsup_{h\to 0} \mathcal{E}_1^{(h)}(u_h),$$

or equivalently, in view of the lower bound above,

$$\mathcal{E}_1^{(0)}(u) = \lim_{h\to 0} \mathcal{E}_1^{(h)}(u_h).$$

Proof (lower bound). Let $u \in \mathcal{A}_1$ and let $\{u_h : h > 0\} \subset \mathcal{A}_1$ be such that $u_h \rightharpoonup u$ in $W^{1,p}(\Omega_1)$ as $h \to 0$. If $\liminf_{h\to 0} \mathcal{E}_1^{(h)}(u_h) = +\infty$, then

$$\mathcal{E}_1^{(0)}(u) \le \liminf_{h\to 0} \mathcal{E}_1^{(h)}(u_h)$$

is trivially satisfied.

On the other hand, if $\liminf_{h\to 0} \mathcal{E}_1^{(h)}(u_h) < +\infty$, then we can first consider a subsequence $\{u_{h_n}\}_{n=1}^{\infty}$ such that

$$\lim_{n\to\infty} \mathcal{E}_1^{(h_n)}(u_{h_n}) = \liminf_{h\to 0} \mathcal{E}_1^{(h)}(u_h).$$

Since then $\mathcal{E}_1^{(h_n)}(u_{h_n}) \le C$ for all $n \ge 1$, we have by Lemma 5.2 that there exists $b \in BV_p(\Omega_1;\mathbb{R}^3)$ such that for a further subsequence of $\{u_{h_n}\}$, not relabeled, we have that

$$\left.\begin{array}{llllll} u_{h_n} \rightharpoonup u & \text{in } W^{1,p}(\Omega_1;\mathbb{R}^3) & \text{and} & h_n^{-1}u_{h_n,3} \rightharpoonup b & \text{in } L^p(\Omega_1;\mathbb{R}^3) \\ u_{h_n} \to u & \text{in } W^{1,1}(\Omega_1;\mathbb{R}^3) & \text{and} & h_n^{-1}u_{h_n,3} \to b & \text{in } L^1(\Omega_1;\mathbb{R}^3) \end{array}\right\} \quad \text{as } n \to \infty,$$

and the convergence is also almost everywhere in Ω_1. It also follows from Lemma 5.2 that u and b are independent of z_3. Therefore, by the definition of $\mathcal{E}_1^{(0)}(u)$, we have for $u_M(z_1,z_2) = u(z_1,z_2,0)$ and $b_M(z_1,z_2) = b(z_1,z_2,0)$ that

$$\mathcal{E}_1^{(0)}(u) \le \mathcal{E}^{(0)}(u_M, b_M). \tag{5.19}$$

Using (5.11), Theorem 2.1, and Fatou's lemma to control the ϕ term, we have that

$$\begin{aligned} \mathcal{E}^{(0)}(u_M,b_M) &= \kappa\left[\int_{\Omega_1} |D_P(\nabla_P u|\sqrt{2}\,b)| + \sqrt{2}\int_{\Gamma_1} |b-b_0|\right] + \int_{\Omega_1} \phi(\nabla_P u|b,\hat{z},0)\,d\hat{z} \\ &\le \liminf_{n\to\infty} \mathcal{E}_1^{(h_n)}(u_{h_n}) \\ &= \lim_{n\to\infty} \mathcal{E}_1^{(h_n)}(u_{h_n}) \\ &= \liminf_{h\to 0} \mathcal{E}_1^{(h)}(u_h). \end{aligned}$$

Combining the above result with (5.19) completes the first part of the proof.

Upper bound. If $u \in \mathcal{A}_1$ is not independent of z_3, then $\mathcal{E}_1^{(0)}(u) = +\infty$ and

$$\mathcal{E}_1^{(0)}(u) \ge \limsup_{h\to 0} \mathcal{E}_1^{(h)}(u_h)$$

holds for any family $\{u_h \in \mathcal{A}_1 : h > 0\}$ such that $u_h \rightharpoonup u$ in $W^{1,p}(\Omega_1)$ as $h \to 0$.

On the other hand, if $u_{,3} = 0$ a.e. in Ω_1, then by Lemma 5.6 there exists $\tilde{b} \in BV_p(S;\mathbb{R}^3)$ such that $\mathcal{E}_1^{(0)}(u) = \mathcal{E}^{(0)}(u_M,\tilde{b})$. Using the upper bound of Theorem 5.3, there exists a family $\{u_h \in \mathcal{A}_1 : h > 0\}$ such that

$$u_h \rightharpoonup u \quad \text{in } W^{1,p}(\Omega_1) \text{ as } h \to 0$$

and

$$\begin{aligned} \lim_{h\to 0} \mathcal{E}_1^{(h)}(u_h) &= \mathcal{E}^{(0)}(u_M,\tilde{b}) \\ &= \mathcal{E}_1^{(0)}(u). \qquad \square \end{aligned}$$

We note that the family $\{u_h \in \mathcal{A}_1 : \ h > 0\}$ constructed for the upper bound in Theorem 5.7 actually converges strongly; that is, $u_h \to u$ in $W^{1,p}(\Omega_1)$ as $h \to 0$. We thus have that the functional $\mathcal{E}_1^{(0)} : \mathcal{A}_1 \to \mathbb{R} \cup \{+\infty\}$ is also the Γ-limit of the functionals $\mathcal{E}_1^{(h)} : \mathcal{A}_1 \to \mathbb{R}$ as $h \to 0$ with respect to the strong $W^{1,p}(\Omega_1;\mathbb{R}^3)$ convergence in $\mathcal{A}_1$.

We can obtain the following result on the convergence of minimizers of $\mathcal{E}_1^{(h)}$ to minimizers of $\mathcal{E}_1^{(0)}$ by an argument analogous to that of Corollary 5.4.

COROLLARY 5.8. *For every sequence $\{u_h \in \mathcal{A}_1 : h \to 0\}$ of minimizers of $\mathcal{E}_1^{(h)}$, there exists a subsequence $\{u_{h_n} \in \mathcal{A}_1 : n = 1, \dots$ and $h_n \to 0$ as $n \to \infty\}$ and a minimizer $u \in \mathcal{A}_1$ of $\mathcal{E}_1^{(0)}$ such that $\{u_{h_n} \in \mathcal{A}_1 : n = 1, \dots\}$ converges to $u \in \mathcal{A}_1$ with respect to weak $W^{1,p}(\Omega_1;\mathbb{R}^3)$ convergence in $\mathcal{A}_1$.*

6. Γ-limit of the dead-loaded film model. We now assume that the film is subject to a dead load Tn on its boundary, $\partial\Omega_h$, with unit exterior normal n, where $T \in \mathbb{R}^{3\times 3}$ is independent of $x \in \Omega_h$. In this case, the energy of the three-dimensional thin film is given by

$$\begin{aligned}\hat{\mathcal{E}}_h(\tilde{u}) &= \kappa \int_{\Omega_h} |D(\nabla \tilde{u})| + \int_{\Omega_h} \phi(\nabla \tilde{u}(x), x)\, dx - \int_{\partial\Omega_h} (Tn)\cdot \tilde{u} \\ &= \kappa \int_{\Omega_h} |D(\nabla \tilde{u})| + \int_{\Omega_h} \phi(\nabla \tilde{u}(x), x)\, dx - \int_{\Omega_h} T \cdot \nabla \tilde{u}.\end{aligned}$$

If the elastic energy density ϕ satisfies the growth condition (3.1), then we can define

$$\hat{\phi}(F, x) = \phi(F, x) - T \cdot F$$

and $\hat{\phi}$ still satisfies (3.1) for some different positive constants, which we still denote by c_1, c_2, and c_3.

In this case, we define the space $\hat{\mathcal{A}}_h$ of admissible deformations of the domain Ω_h by

$$\hat{\mathcal{A}}_h = \left\{ \tilde{u} \in W^{1,p}(\Omega_h;\mathbb{R}^3) : \ \nabla \tilde{u} \in BV(\Omega_h), \ \int_{\Omega_h} \tilde{u} = 0 \right\}.$$

The energies of the deformations $\tilde{u} \in \hat{\mathcal{A}}_h$ of films are again given by (5.2) with $\phi(F)$ replaced by $\phi(F) - T \cdot F$. As before, due to the growth condition (3.1), we have

$$\hat{\mathcal{A}}_h = \left\{ \tilde{u} : \Omega_h \to \mathbb{R}^3 : \ \hat{\mathcal{E}}_h(\tilde{u}) < +\infty, \ \int_{\Omega_h} \tilde{u} = 0 \right\} \subset \mathcal{C}(\hat{\Omega}_h).$$

The proof of the convergence to a Γ-limit for the problem of the dead-loaded film is similar to the proof for the film constrained on part of the boundary. We start with the rescaled energy $\hat{\mathcal{E}}_1^{(h)} : \hat{\mathcal{A}}_1 \to \mathbb{R}$ (defined by (5.2)–(5.4)), where the space of admissible deformations, $\hat{\mathcal{A}}_1$, is defined by

$$\hat{\mathcal{A}}_1 = \left\{ u \in W^{1,p}(\Omega_1;\mathbb{R}^3) : \ \nabla u \in BV(\Omega_1), \int_{\Omega_1} u = 0 \right\}.$$

We then show that the Γ-limit of $\hat{\mathcal{E}}_1^{(h)} : \hat{\mathcal{A}}_1 \to \mathbb{R}$ is given by

$$\hat{\mathcal{E}}^{(0)}(y, b) = \kappa \int_S |D(\nabla y|\sqrt{2}\, b)| + \int_S \phi(\nabla y(\hat{z})|b(\hat{z}), \hat{z}, 0)\, d\hat{z} - \int_S T \cdot (\nabla y|b) \quad \text{for } (y, b) \in \hat{\mathcal{A}}_0,$$

where the space of admissible deformations is given by

$$\hat{\mathcal{A}}_0 = \left\{ (y,b) \in W^{1,p}(S;\mathbb{R}^3) \times L^p(S;\mathbb{R}^3) : \ \nabla y, b \in BV(S), \ \int_S y = 0 \right\}.$$

The proof of the following compactness result for sequences

$$\{u_{h_n} \in \hat{\mathcal{A}}_1 : n = 1, \dots \text{ and } h_n \to 0 \text{ as } n \to \infty\}$$

is analogous to that of Lemma 5.2.

LEMMA 6.1. *Suppose that* $\{u_{h_n} \in \hat{\mathcal{A}}_1 : n = 1, \dots$ *and* $h_n \to 0$ *as* $n \to \infty\}$ *is a sequence of deformations with uniformly bounded energy* $\hat{\mathcal{E}}_1^{(h_n)}(u_{h_n}) \le C$ *for all* $n \ge 1$. *Then there exists a further subsequence, also denoted by* $\{u_{h_n} \in \hat{\mathcal{A}}_1 : n = 1, \dots\}$, *and* $(y,b) \in \hat{\mathcal{A}}_0$ *such that* $\{u_{h_n} \in \hat{\mathcal{A}}_1 : n = 1, \dots\}$ *converges to* $(y,b) \in \hat{\mathcal{A}}_0$ *in the sense of Definition* 5.1 *(with the spaces* $\mathcal{A}_1$ *and* $\mathcal{A}_0$ *replaced by* $\hat{\mathcal{A}}_1$ *and* $\hat{\mathcal{A}}_0$, *respectively). We may take a further subsequence such that the convergence is also almost everywhere in* Ω_1.

We have the following Γ-convergence theorem.

THEOREM 6.2. *The functional* $\hat{\mathcal{E}}^{(0)} : \hat{\mathcal{A}}_0 \to \mathbb{R}$ *is the* Γ*-limit of the functionals* $\hat{\mathcal{E}}_1^{(h)} : \hat{\mathcal{A}}_1 \to \mathbb{R}$ *with respect to the convergence from Definition* 5.1.

Proof (lower bound). Let $(y,b) \in \hat{\mathcal{A}}_0$ and let $\{u_h \in \hat{\mathcal{A}}_1 : \ h > 0\}$ converge to (y,b) in the sense of Definition 5.1. Consider a subsequence $\{u_{h_n}\}_{n=1}^{\infty}$ such that

$$\lim_{n\to\infty} \hat{\mathcal{E}}_1^{(h_n)}(u_{h_n}) = \liminf_{h\to 0} \hat{\mathcal{E}}_1^{(h)}(u_h)$$

and such that $\nabla_P u_{h_n} \to \nabla_P \hat{y}$ and $h_n^{-1} u_{h_n,3} \to \hat{b}$ almost everywhere in Ω_1 as $n \to \infty$. Using (5.11), the lower semicontinuity of the total variation, and Fatou's lemma to control the ϕ term, we have that

$$\begin{aligned}
\hat{\mathcal{E}}^{(0)}(y,b) &= \kappa \int_{\Omega_1} |D_P(\nabla_P \hat{y} | \sqrt{2}\, \hat{b})| + \int_{\Omega_1} \phi(\nabla_P \hat{y} | \hat{b}, \hat{z}, 0)\, dz - \int_S T \cdot (\nabla_P \hat{y} | \hat{b}) \\
&\le \liminf_{n\to\infty} \hat{\mathcal{E}}_1^{(h_n)}(u_{h_n}) \\
&= \lim_{n\to\infty} \hat{\mathcal{E}}_1^{(h_n)}(u_{h_n}) \\
&= \liminf_{h\to 0} \hat{\mathcal{E}}_1^{(h)}(u_h),
\end{aligned}$$

which establishes the first part of the theorem.

Upper bound. To prove the upper bound, one should again consider deformations of the form $y(z_1,z_2) + hz_3 b(z_1,z_2)$; as before, such deformations do not belong to $\hat{\mathcal{A}}_1$, because b does not belong to $W^{1,p}(S;\mathbb{R}^3)$. However, we can find a family of functions $b_\varepsilon \in \mathcal{C}^\infty(\hat{S};\mathbb{R}^3) \subset W^{1,p}(S;\mathbb{R}^3)$ such that $b_\varepsilon \to b$ almost everywhere in S and in $L^p(S)$ as $\varepsilon \to 0$ [13], and

$$\lim_{\varepsilon\to 0} \int_S |D(\nabla y | \sqrt{2}\, b_\varepsilon)| = \int_S |D(\nabla y | \sqrt{2}\, b)|. \tag{6.1}$$

Consider now the functions

$$w_h^\varepsilon(z_1,z_2,z_3) = y(z_1,z_2) + hz_3 b_\varepsilon(z_1,z_2) hz_3 \in \mathcal{A}_1 \quad \text{for } 0 < h \le 1,$$

and their mean-zero translations

$$u_h^\varepsilon = w_h^\varepsilon - \frac{1}{|\Omega_1|}\int_{\Omega_1} w_h^\varepsilon \, dz \in \hat{\mathcal{A}}_1.$$

We can now apply the same argument as in the proof of the upper bound in Theorem 5.3 to conclude that

$$\lim_{\varepsilon\to 0}\lim_{h\to 0} \hat{\mathcal{E}}_1^{(h)}(u_h^\varepsilon) = \hat{\mathcal{E}}^{(0)}(y,b),$$

from which it is clear that for any $\eta > 0$ there exist $\varepsilon > 0$ and $h_0 > 0$ such that

$$|\hat{\mathcal{E}}_1^{(h)}(u_h^\varepsilon) - \hat{\mathcal{E}}^{(0)}(y,b)| < \eta \quad \text{for all } 0 < h \le h_0. \qquad \square$$

We can obtain a result on the convergence of minimizers of $\mathcal{E}_1^{(h)}(u)$ to minimizers of $\mathcal{E}^{(0)}(y,b)$ by an argument analogous to that of Corollary 5.8.

The Γ-limit of $\hat{\mathcal{E}}_1^{(h)} : \hat{\mathcal{A}}_1 \to \mathbb{R}$ can again be obtained by minimizing out b in the energy $\hat{\mathcal{E}}^{(0)}(y,b)$. The existence of a minimizing $\tilde{b}$ can be shown by using the direct method of the calculus of variations as in Lemma 5.6.

LEMMA 6.3. *Let $y \in W^{1,p}(S;\mathbb{R}^3)$ be such that $\nabla y \in BV(S)$ and $\int_S y = 0$. Then there exists a function $\tilde{b} \in BV_p(S;\mathbb{R}^3)$ such that*

$$\hat{\mathcal{E}}^{(0)}(y,\tilde{b}) = \inf_{b\in BV_p(S;\mathbb{R}^3)} \hat{\mathcal{E}}^{(0)}(y,b).$$

Proof. Since $\hat{\mathcal{E}}^{(0)}$ is bounded below, we can consider a minimizing sequence $\{b_j\}_{j=1}^\infty \subset BV_p(S;\mathbb{R}^3)$. Since the variations of the b_j and their L^p-norms (and thus also the L^1-norms) lie in a compact subset of $\mathbb{R}$, we can use the compactness of $BV(S;\mathbb{R}^3)$ and retrieve a subsequence, not relabeled, which converges to a function $\tilde{b} \in BV_p(S;\mathbb{R}^3)$ strongly in $L^1(S;\mathbb{R}^3)$, weakly in $L^p(S;\mathbb{R}^3)$, and almost everywhere in S. From the lower semicontinuity of the total variation, we have

$$\int_S |D(\nabla y|\sqrt{2}\,\tilde{b}| \le \liminf_{j\to\infty} \int_S |D(\nabla y|\sqrt{2}\,b_j|.$$

Similarly, applying Fatou's lemma to $\phi(\nabla y|b_j)$ gives

$$\int_S \left[\phi(\nabla y|\tilde{b}) - T\cdot(\nabla y|\tilde{b})\right] \le \liminf_{j\to\infty} \int_S \left[\phi(\nabla y|b_j) - T\cdot(\nabla y|b_j)\right],$$

and therefore

$$\begin{aligned}\hat{\mathcal{E}}^{(0)}(y,\tilde{b}) &\le \liminf_{j\to\infty} \hat{\mathcal{E}}^{(0)}(y,b_j)\\ &= \inf_{b\in BV_p(S;\mathbb{R}^3)} \hat{\mathcal{E}}^{(0)}(y,\tilde{b}). \qquad \square\end{aligned}$$

Next, we define a functional

$$\hat{\mathcal{E}}_1^{(0)}(u) = \begin{cases} \min\limits_{b\in BV_p(S;\mathbb{R}^3)} \hat{\mathcal{E}}^{(0)}(u_M,b) & \text{if } u_{,3} = 0 \text{ a.e. in } \Omega_1,\\ +\infty & \text{otherwise.}\end{cases}$$

THEOREM 6.4. *The functional* $\hat{\mathcal{E}}_1^{(0)} : \hat{\mathcal{A}}_1 \to \mathbb{R} \cup \{+\infty\}$ *is the* Γ*-limit of the functionals* $\hat{\mathcal{E}}_1^{(h)} : \hat{\mathcal{A}}_1 \to \mathbb{R}$ *as* $h \to 0$ *with respect to the weak* $W^{1,p}(\Omega_1;\mathbb{R}^3)$ *convergence in* $\hat{\mathcal{A}}_1$.

Proof (lower bound). The proof is similar to the proof of Theorem 5.7. Let $u \in \hat{\mathcal{A}}_1$ and let $\{u_h : h > 0\} \subset \hat{\mathcal{A}}_1$ be such that $u_h \rightharpoonup u$ in $W^{1,p}(\Omega_1)$ as $h \to 0$. If $\liminf_{h\to 0} \hat{\mathcal{E}}_1^{(h)}(u_h) = +\infty$, then

$$\hat{\mathcal{E}}_1^{(0)}(u) \le \liminf_{h\to 0} \hat{\mathcal{E}}_1^{(h)}(u_h)$$

is trivially satisfied.

On the other hand, if $\liminf_{h\to 0} \hat{\mathcal{E}}_1^{(h)}(u_h) < +\infty$, then we can first consider a subsequence $\{u_{h_n}\}_{n=1}^{\infty} \subset \hat{\mathcal{A}}_1$ such that

$$\lim_{n\to\infty} \hat{\mathcal{E}}_1^{(h_n)}(u_{h_n}) = \liminf_{h\to 0} \hat{\mathcal{E}}_1^{(h)}(u_h).$$

Since then $\hat{\mathcal{E}}_1^{(h_n)}(u_{h_n}) \le C$ for all $n \ge 1$, we have by Lemma 6.1 that there exists $b \in BV_p(\Omega_1;\mathbb{R}^3)$ such that for a further subsequence of $\{u_{h_n}\}$, not relabeled, we have that

$$\left.\begin{array}{llllll} u_{h_n} \rightharpoonup u & \text{in } W^{1,p}(\Omega_1;\mathbb{R}^3) & \text{and} & h_n^{-1}u_{h_n,3} \rightharpoonup b & \text{in } L^p(\Omega_1;\mathbb{R}^3) \\ u_{h_n} \to u & \text{in } W^{1,1}(\Omega_1;\mathbb{R}^3) & \text{and} & h_n^{-1}u_{h_n,3} \to b & \text{in } L^1(\Omega_1;\mathbb{R}^3) \end{array}\right\} \quad \text{as } n \to \infty,$$

and the convergence is also almost everywhere in Ω_1. It also follows from Lemma 6.1 that u and b are independent of z_3. Therefore, we have for $u_M(z_1,z_2) = u(z_1,z_2,0)$ and $b_M(z_1,z_2) = b(z_1,z_2,0)$ that

$$\hat{\mathcal{E}}_1^{(0)}(u) \le \hat{\mathcal{E}}^{(0)}(u_M, b_M). \tag{6.2}$$

Using (5.11), the lower semicontinuity of the total variation, and Fatou's lemma to control the ϕ term, we have that

$$\begin{aligned} \hat{\mathcal{E}}^{(0)}(u_M,b_M) &= \kappa \int_{\Omega_1} |D_P(\nabla_P u|\sqrt{2}\, b)| + \int_{\Omega_1} \phi(\nabla_P u|b,\hat{z},0)\,dz - \int_{\Omega_1} T\cdot(\nabla_P u|b) \\ &\le \liminf_{n\to\infty} \hat{\mathcal{E}}_1^{(h_n)}(u_{h_n}) \\ &= \lim_{n\to\infty} \hat{\mathcal{E}}_1^{(h_n)}(u_{h_n}) \\ &= \liminf_{h\to 0} \hat{\mathcal{E}}_1^{(h)}(u_h). \end{aligned}$$

Combining the above result with (6.2) completes the first part of the proof.

Upper bound. If $u \in \hat{\mathcal{A}}_1$ is not independent of z_3, then $\hat{\mathcal{E}}_1^{(0)}(u) = +\infty$; taking $u_h = u$ for all $h > 0$ produces a family in $\hat{\mathcal{A}}_1$ such that $\lim_{h\to 0} \hat{\mathcal{E}}_1^{(h)}(u_h) = \hat{\mathcal{E}}_1^{(0)}(u) = +\infty$.

On the other hand, if $u_{,3} = 0$ almost everywhere in Ω_1, then by Lemma 6.3 there exists $\tilde{b} \in BV_p(S;\mathbb{R}^3)$ such that $\hat{\mathcal{E}}_1^{(0)}(u) = \hat{\mathcal{E}}^{(0)}(u_M,\tilde{b})$. Using the upper bound of Theorem 6.2, there exists a family $\{u_h \in \hat{\mathcal{A}}_1 : h > 0\}$ such that

$$u_h \rightharpoonup u \quad \text{in } W^{1,p}(\Omega_1) \text{ as } h \to 0$$

and

$$\lim_{h\to 0} \hat{\mathcal{E}}_1^{(h)}(u_h) = \hat{\mathcal{E}}^{(0)}(u_M, \tilde{b}) = \hat{\mathcal{E}}_1^{(0)}(u). \qquad \square$$

We note that we can obtain a result on the convergence of minimizers of $\mathcal{E}_1^{(h)}$ to minimizers of $\mathcal{E}_1^{(0)}$ by an argument analogous to that of Corollary 5.8.

STABLE DETERMINATION OF THE SURFACE IMPEDANCE OF AN OBSTACLE BY FAR FIELD MEASUREMENTS*

E. SINCICH†

Abstract. We deal with the inverse scattering problem of determining the surface impedance of a partially coated obstacle. We prove a stability estimate of logarithmic type for the impedance term by the far field measurements.

Key words. inverse scattering problem, impedance boundary condition, stability

1. Introduction.

We consider the scattering of an acoustic incident time-harmonic plane wave, at a given wave number $k > 0$ and at a given incident direction $\omega \in \mathbb{S}^2$, by an obstacle $D \subset \mathbb{R}^3$ partially coated by a material with surface impedance λ. Such a problem is modeled by the following mixed boundary value problem for the Helmholtz equation:

$$\begin{cases} \Delta u + k^2 u = 0 & \text{in } \mathbb{R}^3 \setminus \overline{D}, \\ u = 0 & \text{on } \Gamma_D, \\ \dfrac{\partial u}{\partial \nu} + i\lambda(x) u = 0 & \text{on } \Gamma_I, \end{cases} \tag{1.1}$$

where $u = u^s + \exp(ikx \cdot \omega)$ is the total field, which is given as the sum of the scattered wave u^s and the incident plane waves $\exp(ikx \cdot \omega)$, and where $\Gamma_I,\ \Gamma_D$ are two open and connected portions of the boundary ∂D such that $\partial D = \overline{\Gamma_I \cup \Gamma_D}$.

Moreover, the scattered field u^s is required to satisfy the so-called *Sommerfeld radiation condition*

$$\lim_{r \to \infty} r \left(\frac{\partial u^s}{\partial r} - iku^s \right) = 0, \quad r = \|x\|. \tag{1.2}$$

It is well known that the scattered field u^s has the following asymptotic behavior:

$$u^s(x) = \frac{\exp(ikr)}{r} \left\{ u_\infty(\hat{x}) + O\left(\frac{1}{r}\right) \right\} \tag{1.3}$$

as r tends to ∞, uniformly with respect to $\hat{x} = \frac{x}{\|x\|}$ and where u_∞ is the so-called far field pattern of the scattered wave (see, for instance, [11]).

The *inverse scattering problem* that we examine here consists in the determination of the surface impedance $\lambda(x)$ by the knowledge of the far field pattern, provided some suitable a priori assumptions on the impedance are made.

Such a problem, in two dimensions, has been recently studied by Cakoni and Colton in [7]. The authors have provided a variational method for the determination of the essential supremum of the surface impedance when the far field data are available.

In this paper, we shall deal with the stability issue; namely, we will prove a stability estimate of logarithmic type for the surface impedance by the far field measurements under some a priori mild assumptions on the impedance itself.

Let us point out that a stability result for this type of problem has been proved in [15] by Labreuche under the assumption of an analytic boundary. The new feature of the present paper consists in a reduced assumption on the regularity of the boundary; namely, we shall assume that Γ_I is a $C^{1,1}$ portion of ∂D. Thus it turns out that the argument of analytic extension used in [15] cannot be applied.

The stable recovering of the surface impedance needs some a priori mild assumptions on the impedance itself. The additional a priori information that we require on the unknown surface impedance λ is an a priori bound on its Lipschitz continuity; that is, we assume that for a given positive constant Λ, the following holds:

$$\|\lambda\|_{C^{0,1}(\Gamma_I)} \leqslant \Lambda. \tag{1.4}$$

Moreover, we prescribe the following uniform lower bound:

$$\lambda(x) \geqslant \lambda_0 \quad \text{for every } x \in \Gamma_I, \tag{1.5}$$

where λ_0 is a given positive constant.

In order to treat the inverse scattering problem we first need to analyze the *direct* one. In section 3, indeed, following the arguments of potential theory developed in [8], we observe that the direct scattering problem is well posed (see Lemma 3.1). The proof relies on the fact that the mixed boundary value problem (1.1) can be reformulated as a system of boundary integral equations. Moreover, we prove (see Theorem 3.2) that the solution and its first order derivatives are Hölder continuous in a neighborhood of the portion Γ_I, where the impedance takes place. The proof is based on Moser's iteration technique. Finally in Corollary 3.3, we obtain a uniform lower bound for the total field u on sets away from the obstacle.

In section 4, we deal with the inverse scattering problem. The underlying ideas and the main tools that lead to the stability result can be outlined as follows:

(i) As the first step we evaluate how much the error on the far field can affect the values of the field near the scatterer.

(ii) In the second step we are concerned with a stability estimate of the field at the boundary in terms of the near field.

(iii) Finally, as the last step, we obtain a stability result for the impedance λ by the estimate of the field at the boundary.

Let us start the analysis of section 4 by illustrating the arguments introduced in step (iii) of the above list.

By the impedance condition in (1.1) we can formally compute λ as

$$\lambda(x) = \frac{i}{u(x)} \frac{\partial u(x)}{\partial \nu(x)}. \tag{1.6}$$

Since u may vanish in some points of Γ_I, it follows that the quotient in (1.6) may be undetermined. In this respect, we found it necessary to evaluate the local vanishing rate of the solution on the boundary. To establish such a control we shall make use of quantitative estimates of unique continuation. We first obtain, in Lemma 4.5, a *volume doubling inequality* at the boundary, namely

$$\int_{\Gamma_{I,2\rho}(x_0)} |u|^2 \leqslant \text{const.} \int_{\Gamma_{I,\rho}(x_0)} |u|^2, \tag{1.7}$$

where $\Gamma_{I,\rho}(x_0)$ and $\Gamma_{I,2\rho}(x_0)$ are the portions of the balls centered at the boundary point x_0 of radius ρ and 2ρ, respectively, contained in $\mathbb{R}^3 \setminus \overline{D}$ (see (2.10) for a precise definition).

In order to obtain the formula in (1.7), we have adapted the arguments developed in [2] for the more general setting of complex valued solutions which is required by the boundary value problem (1.1).

A further difficulty in dealing with such arguments is due to the fact that the techniques used in [2] apply to a homogeneous Neumann boundary condition. We overcome such a difficulty by performing a suitable change of the independent variable (see Proposition 4.3) that fits our problem under the assumptions required in [2]. Moreover, well-known stability estimates for the Cauchy problem [18] allow us to reformulate the *volume* doubling inequality at the boundary, deriving in Theorem 4.6 a new one on the boundary, that is, a *surface doubling inequality*

$$\int_{\Delta_{I,2\rho}(x_0)} |u|^2 \leqslant \text{const.} \int_{\Delta_{I,\rho}(x_0)} |u|^2, \tag{1.8}$$

where $\Delta_{I,\rho}(x_0)$ and $\Delta_{I,2\rho}(x_0)$ are the portions of the boundary of $\Gamma_{I,\rho}(x_0)$ and $\Gamma_{I,2\rho}(x_0)$, respectively, which have nonempty intersection with ∂D (see (2.11) for a precise definition).

The surface doubling inequality allows us to apply the theory of *Muckenhoupt weights* [9], which, in particular, implies the existence of some exponent $p > 1$ such that $|u|^{-\frac{2}{p-1}}$ is integrable on an inner portion of Γ_I; see Corollary 4.7. This integrability property, as well as the Hölder continuity of the normal derivative, justifies the computation made in (1.6) in the $L^{\frac{2}{p-1}}$ sense.

Let us carry over our analysis by discussing the evaluation introduced in step (i). Such an evaluation, introduced by Isakov [13, 14] and then developed by Bushuyev [6], concerns a stability estimate for the *near field* in terms of the measurements of the *far field* (see Lemma 4.1). It means that if u_1 and u_2 are two acoustic fields corresponding to impedances λ_1 and λ_2 such that their scattering amplitudes, $u_{1,\infty}$ and $u_{2,\infty}$, respectively, are close, i.e.,

$$\|u_{1,\infty} - u_{2,\infty}\|_{L^2(\partial B_1(0))} \leqslant \varepsilon, \tag{1.9}$$

then u_1 and u_2 satisfy

$$\|u_1 - u_2\|_{L^2(B_{R_1+1}(0)\setminus B_{R_1}(0))} \leqslant \text{const. } \varepsilon^{\alpha(\varepsilon)}, \tag{1.10}$$

where $R_1 > 0$ is a suitable radius such that $B_{R_1}(0) \supset \overline{D}$ and $\alpha(\varepsilon)$ is the function introduced in (4.2).

As the last step of this treatment we provide the stability estimate introduced in (ii). The proof is based on arguments of quantitative unique continuation, as the *three spheres inequality*, and leads to the following estimate:

$$\|u_1 - u_2\|_{C^1(\Gamma_I^\rho)} \leqslant \text{const.} |\log (\|u_1 - u_2\|^{-1}_{L^2(B_{R_1+1}(0)\setminus B_{R_1}(0))})|^{-2\theta}, \tag{1.11}$$

where $\theta > 0$ and Γ_I^ρ is a given inner portion of Γ_I (see (2.9) for a precise definition).

By combining the stability estimates listed in (i) and (ii), we obtain a stability result for the total field at the boundary in terms of the measurements of the far field (see Theorem 4.2).

Finally, as a consequence of Theorem 4.2 and Corollary 4.7, let us formulate the main result of the present paper, which consists in a stability estimate of the surface impedance by the far field measurements (see Theorem 2.1). Assuming that (1.9) holds, we have shown that the impedances λ_1, λ_2 agree up to an error

$$\big|\log(\varepsilon)\big|^{-\theta}. \tag{1.12}$$

2. Main assumptions and results.

2.1. Main hypothesis and notation. Assumptions on the domain. We shall assume throughout that D is a bounded domain in $\mathbb{R}^3$, such that $\mathrm{diam} D \leqslant d$, with Lipschitz boundary ∂D with constants r_0, M. More precisely, for every $x_0 \in \partial D$, there exists a rigid transformation of coordinates under which

$$D \cap B_{r_0}(x_0) = \{(x', x_3) : x_3 > \gamma(x')\}, \tag{2.1}$$

where $x \in \mathbb{R}^3$, and $x = (x', x_3)$, with $x' \in \mathbb{R}^2$, $x_3 \in \mathbb{R}$, and

$$\gamma : B'_{r_0}(x_0) \subset \mathbb{R}^2 \to \mathbb{R}$$

satisfying $\gamma(0) = 0$ and

$$\|\gamma\|_{C^{0,1}(B'_{r_0}(x_0))} \leqslant M r_0,$$

where for every integer $k \geqslant 1$ and for every multi-index $0 \leqslant |\beta| \leqslant k$ we denote

$$\begin{aligned} \|\gamma\|_{C^{k,1}(B'_{r_0}(z_0))} = \sum_{j=0}^{k} {r_0}^j \sum_{|\beta|=j} \|D^\beta \gamma\|_{L^\infty(B'_{r_0}(z_0))} \\ + {r_0}^{k+1} \sum_{|\beta|=k} \sup_{\substack{x,y \in B'_{r_0}(z_0) \\ x \neq y}} \frac{|D^\beta \gamma(x) - D^\beta \gamma(y)|}{|x-y|} \end{aligned} \tag{2.2}$$

and $B'_{r_0}(x_0)$ denotes a ball in $\mathbb{R}^2$. Moreover, we assume that the portion of the boundary Γ_I is contained in a surface S_I, which is $C^{1,1}$ smooth with constants r_0, M. More precisely, for any $x_0 \in S_I$, we have that up to a rigid change of coordinates,

$$S_I \cap B_{r_0}(x_0) = \{(x', x_3) : x_3 = \varphi_I(x')\}, \tag{2.3}$$

where

$$\varphi_I : B'_{r_0}(z_0) \subset \mathbb{R}^2 \to \mathbb{R} \tag{2.4}$$

is a $C^{1,1}$ function satisfying $\varphi_I(0) = |\nabla \varphi_I(0)| = 0$ and

$$\|\varphi_I\|_{C^{1,1}(B'_{r_0}(z_0))} \leqslant M r_0. \tag{2.5}$$

For the sake of simplicity we shall assume that $0 \in D$.

Fixing $R > d$, $\rho \in (0, r_0)$, and $x_0 \in \Gamma_I$, let us define the following sets:

$$D^+ = \mathbb{R}^3 \setminus \overline{D}, \tag{2.6}$$

$$D_R^+ = B_R(0) \cap D^+, \tag{2.7}$$

$$D_{R,\rho}^+ = \{x \in \overline{D_R^+} \ : \mathrm{dist}(x, \Gamma_D) > \rho\}, \tag{2.8}$$

$$\Gamma_I^\rho = \partial D_{R,\rho}^+ \cap \Gamma_I, \tag{2.9}$$

$$\Gamma_{I,\rho}(x_0) = B_\rho(x_0) \setminus \overline{D}, \tag{2.10}$$

$$\Delta_{I,\rho}(x_0) = \overline{\Gamma_{I,\rho}(x_0)} \cap \partial D. \tag{2.11}$$

A priori information on the impedance term. We assume that the impedance coefficient λ belongs to $C^{0,1}(\Gamma_I, \mathbb{R})$ and is such that (1.5) and (1.4) hold for given positive constants λ_0, Λ.

From now on we shall refer to the *a priori data* as the following set of quantities: $d, r_0, M, \lambda_0, \Lambda, k, \omega$.

In what follows we shall denote with $\eta(t)$ a positive increasing function defined on $(0, +\infty)$, which satisfies

$$\eta(t) \leqslant C|\log(t)|^{-\theta} \quad \text{for every} \quad 0 < t < 1, \tag{2.12}$$

where $C > 0$, $\theta > 0$ are constants depending on the a priori data only.

2.2. The main result.

THEOREM 2.1 (stability for λ). *Let u_i, $i = 1, 2$, be the weak solutions to the problem (1.1) with $\lambda = \lambda_i$ and $u_\infty = u_{i,\infty}$, respectively. There exists a constant $\varepsilon_0 > 0$ depending on the a priori data only, such that if for some ε, $0 < \varepsilon < \varepsilon_0$, we have*

$$\|u_{1,\infty} - u_{2,\infty}\|_{L^2(\partial B_1(0))} \leqslant \varepsilon, \tag{2.13}$$

then

$$\|\lambda_1 - \lambda_2\|_{L^\infty(\Gamma_I^{r_0})} \leqslant \eta(\varepsilon). \tag{2.14}$$

3. The direct scattering problem. Let us introduce the space

$$H^1_{\mathrm{loc}}(D^+) = \{v \in D^*(D^+) : \, v|_{D_R^+} \in H^1(D_R^+) \quad \text{for every } R > 0 \text{ such that } \overline{D} \subset B_R(0)\},$$

where $D^*(D^+)$ is the space of distribution on D^+.

A weak solution to the problem (1.1) is a function $u = \exp(ik\omega \cdot x) + u^s$, where $u^s \in H^1_{\mathrm{loc}}(D^+)$ is a weak solution to the problem

$$\begin{cases} \Delta u^s + k^2 u^s = 0 & \text{in } D^+, \\ u^s = -\exp(ik\omega \cdot x) & \text{on } \Gamma_D, \\ \dfrac{\partial u^s}{\partial \nu} + i\lambda(x) u^s = -\dfrac{\partial}{\partial \nu} \exp(ik\omega \cdot x) - i\lambda(x) \exp(ik\omega \cdot x) & \text{on } \Gamma_I, \\ \lim\limits_{r \to \infty^r} \left(\dfrac{\partial u^s}{\partial r}(r\hat{x}) - iku^s(r\hat{x}) \right) = 0 & \text{uniformly in } \hat{x}, \end{cases} \tag{3.1}$$

where ν is the inward unit normal to D.

LEMMA 3.1 (well-posedness). *The problem (3.1) has one and only one weak solution u^s. Moreover, for every $R > d$, there exists a constant $C_R > 0$ depending on the a priori data and R only, such that the following holds:*

$$\|u^s\|_{H^1(D_R^+)} \leqslant C_R. \tag{3.2}$$

Proof. For the proof we refer to [8, Theorem 2.5], in which the authors show, among various results, that the exterior mixed boundary value problem (3.1) can be reformulated as a 2×2 system of boundary integral equations. In [8], Theorem 2.5 has been proved in two dimensions for a constant λ; however, it can be verified that the same techniques can be carried over in three dimensions (see, for instance, [10]) and with $\lambda = \lambda(x) \in C^{0,1}(\Gamma_I)$. □

THEOREM 3.2 ($C^{1,\alpha}$ regularity at the boundary). *Let u be the weak solution to* (1.1)*; then there exists a constant $\alpha,\ 0 < \alpha < 1$, such that for every $R > d$ and $\rho \in (0, r_0)$, $u \in C^{1,\alpha}(D^+_{R,\rho})$. Moreover, there exists a constant $C_{R,\rho} > 0$ depending on the a priori data, R, and ρ only, such that*

$$\|u\|_{C^{1,\alpha}(D^+_{R,\rho})} \leqslant C_{R,\rho}. \tag{3.3}$$

Proof. The proof mainly relies on the standard iteration techniques due to Moser (see, for instance, [12]) as well as well-known regularity bounds for the Neumann problem (see, for instance, [3, p. 667]). For the details of the proof we refer the reader to [17]. □

COROLLARY 3.3 (lower bound). *Let u be the weak solution to* (1.1)*; then there exists a radius $R_0 > 0$ depending on the a priori data only, such that*

$$|u(x)| > \frac{1}{2} \quad \textit{for every } x,\ |x| > R_0. \tag{3.4}$$

Proof. Let us choose $R = 4d + 4r_0$. By Theorem 3.2 it follows that there exists a constant $C > 0$ depending on the a priori data only, such that

$$\|u\|_{C^{1,\alpha}\left(D^+_{2R,\frac{r_0}{2}}\right)} \leqslant C. \tag{3.5}$$

By Green's formula for the scattered wave u^s (see, for instance, [11, p. 18]), we have that

$$u^s(x) = \int_{\partial B_R(0)} \left(u^s(y) \frac{\partial \phi(x,y)}{\partial \nu(y)} - \frac{\partial u^s(y)}{\partial \nu(y)} \phi(x,y) \right) \mathrm{d}s(y), \qquad |x| > R, \tag{3.6}$$

where

$$\phi(x,y) = \frac{1}{4\pi} \frac{\exp\left(ik|x-y|\right)}{|x-y|}, \quad x \neq y,$$

is the fundamental solution to the Helmholtz equation in $\mathbb{R}^3$.

Thus, by (3.6) and by (3.5) it follows that

$$|u^s| < \frac{1}{2} \quad \text{for every } x,\ |x| > R_0, \tag{3.7}$$

with $R_0 = (k+1)8R^3C + 2R$. The thesis follows, observing that $|u| \geqslant 1 - |u^s|$. □

4. The inverse scattering problem.

LEMMA 4.1 (from the far field to the near field). *Let $u_i, u_{i,\infty},\ i = 1, 2$, be as in Theorem* 2.1*. Suppose that for some $\varepsilon,\ 0 < \varepsilon < 1$,* (2.13) *holds; then there exist a radius $R_1 > 0$ and a constant $C > 0$, depending on the a priori data only, such that*

$$\|u_1 - u_2\|_{L^2(B_{R_1+1}(0) \setminus B_{R_1}(0))} \leqslant C\varepsilon^{\alpha(\varepsilon)}, \tag{4.1}$$

where $\alpha(\varepsilon)$ is defined as

$$\alpha(\varepsilon) = \frac{1}{1 + \log(\log(\varepsilon^{-1}) + e)}. \tag{4.2}$$

Proof. Let us choose $R = 4d + 4r_0$ and let us denote by $u^s_i,\ i = 1, 2$, the scattered wave of the problem (1.1) with $\lambda = \lambda_i$, respectively. By (3.5) it follows that

$$\|u^s_1 - u^s_2\|_{L^2(\partial B_R(0))} \leqslant C, \tag{4.3}$$

where $C > 0$ is a constant depending on the a priori data only.

Hence choosing $R_1 = 16d + 16r_0$, the thesis follows by the argument in [14] (see also [6]). □

THEOREM 4.2 (stability at the boundary). *Let $u_i, u_{i,\infty},\ i = 1, 2$, be as in Theorem 2.1. We have that there exists $\varepsilon_0 > 0$ depending on the a priori data only, such that if for some $\varepsilon,\ 0 < \varepsilon < \varepsilon_0$, (2.13) holds, then for every $\rho \in (0, r_0)$ we have*

$$\|u_1 - u_2\|_{C^1(\Gamma_I^\rho)} \leqslant \eta(\varepsilon), \tag{4.4}$$

where η is given by (2.12), with a constant $C > 0$ depending on the a priori data and ρ only.

Proof. By the Lipschitz regularity of the boundary ∂D, it follows that for every point $Q \in \partial D$, there exists a rigid transformation of coordinates under which we have $Q = 0$ and the finite cone

$$\mathcal{C} = \left\{ x : |x| < r_0,\ \frac{x \cdot \xi}{|x|} > \cos\theta \right\}$$

with axis in the direction ξ and width 2θ, where $\theta = \arctan \frac{1}{M}$, is such that $\mathcal{C} \subset D^+$.

Let Q be a point such that $Q \in \Gamma_I^{r_0}$ and let Q_0 be a point lying on the axis ξ of the cone with vertex in $Q = 0$ such that $d_0 = \operatorname{dist}(Q_0, 0) < \frac{r_0}{2}$.

Let us define $R_2 = 2R_1 + 2$, where R_1 is the radius introduced in the statement of Lemma 4.1. Proceeding as in Lieberman [16], we consider a regularized distance $\tilde{d}$ from the boundary of ∂D such that $\tilde{d} \in C^2(D^+_{R_2}) \cap C^{0,1}(\overline{D^+_{R_2}})$ (see also [4, Lemma 5.2]).

Let us define for every $\rho > 0$

$$D^\rho = \{x \in D^+_{R_2} : \operatorname{dist}(x, \partial D) > \rho\}, \tag{4.5}$$

$$\tilde{D}^\rho = \{x \in D^+_{R_2} : \tilde{d}(x) > \rho\}. \tag{4.6}$$

It follows that there exists a, $0 < a \leqslant 1$, depending on M only such that for every ρ, $0 < \rho \leqslant a r_0$, $\tilde{D}^\rho$ is connected with boundary of class C^1 and

$$\tilde{c}_1 \rho \leqslant \operatorname{dist}(x, \partial D) \leqslant \tilde{c}_2 \rho \quad \text{for every } \ x \in \partial \tilde{D}^\rho, \tag{4.7}$$

where $\tilde{c}_1, \tilde{c}_2$ are positive constants depending on M only. By (4.7) we deduce that

$$D^{\tilde{c}_2 \rho} \subset \tilde{D}^\rho \subset D^{\tilde{c}_1 \rho}.$$

Let us now define $\rho_0 = \min\{\frac{1}{16}, \frac{r_0}{4}\sin\theta\}$ and let P be a point in the annulus $B_{R_1+1}(0) \setminus B_{R_1}(0)$, such that $B_{4\rho_0}(P) \subset B_{R_1+1}(0) \setminus B_{R_1}(0)$. Furthermore, let γ be a path in $\tilde{D}^{\frac{\rho_0}{\tilde{c}_1}}$ joining P to Q_0 and let us define $\{y_i\}$, $i = 0, \dots, s$, as follows: $y_0 = Q_0$, $y_{i+1} = \gamma(t_i)$, where $t_i = \max\{t \text{ such that } |\gamma(t) - y_i| = 2\rho_0\}$ if $|P - y_i| > 2\rho_0$; otherwise let $i = s$ and stop the process.

Let us introduce the function $U \in H^1_{\mathrm{loc}}(D^+)$ defined as

$$U(x) = u_1(x) - u_2(x). \tag{4.8}$$

Thus, by the three spheres inequality for elliptic systems with Laplacian principal part (see [5, Theorem 3.1]), we infer that

$$\int_{B_{3\rho_0}(y_0)} |U|^2 \leqslant C \left(\int_{B_{\rho_0}(y_0)} |U|^2 \right)^\tau \cdot \left(\int_{B_{4\rho_0}(y_0)} |U|^2 \right)^{1-\tau}, \tag{4.9}$$

where $C > 0, 0 < \tau < 1$ are constants depending on the a priori data only.

Let us observe that $B_{4\rho_0}(y_0) \subset D^+_{R_2}$ and $B_{\rho_0}(y_0) \subset B_{3\rho_0}(y_1)$. Thus by (4.9) and by Lemma 3.1 we deduce that

$$\int_{B_{\rho_0}(y_0)} |U|^2 \leqslant C \left(\int_{B_{3\rho_0}(y_1)} |U|^2 \right)^{\tau} \cdot C^{1-\tau}.$$

An iterated application of the three spheres inequality leads to

$$\int_{B_{\rho_0}(y_0)} |U|^2 \leqslant \left(\int_{B_{\rho_0}(y_s)} |U|^2 \right)^{\tau^s} \cdot C^{1-\tau^s}.$$

Finally, since $B_\rho(y_s) \subset B_{R_1+1}(0) \setminus B_{R_1}(0)$, by (4.1) we obtain that

$$\int_{B_{\rho_0}(y_0)} |U|^2 \leqslant C\big\{\varepsilon^{\alpha(\varepsilon)}\big\}^{\tau^s}.$$

We shall construct a chain of balls $B_{\rho_k}(Q_k)$ centered on the axis of the cone, pairwise tangent to one another and all contained in the cone

$$\mathcal{C}' = \left\{ x : |x| < r_0,\ \frac{x \cdot \xi}{|x|} > \cos\theta' \right\},$$

where $\theta' = \arcsin\left(\frac{\rho_0}{d_0}\right)$. Let $B_{\rho_0}(Q_0)$ be the first of them; the rest are defined by induction such that

$$\begin{aligned} Q_{k+1} &= Q_k - (1+\mu)\rho_k \xi, \\ \rho_{k+1} &= \mu \rho_k, \\ d_{k+1} &= \mu d_k, \\ \mu &= \frac{1-\sin\theta'}{1+\sin\theta'}. \end{aligned}$$

Hence, with this choice, we have $\rho_k = \mu^k \rho_0$ and $B_{\rho_{k+1}}(Q_{k+1}) \subset B_{3\rho_k}(Q_k)$.

Considering the following estimate obtained by a repeated application of the three spheres inequality, we have that

$$\begin{aligned} \|U\|_{L^2(B_{\rho_k}(Q_k))} &\leqslant \|U\|^{\tau}_{L^2(B_{\rho_{k-1}}(Q_{k-1}))} \|U\|^{1-\tau}_{L^2(B_{4\rho_{l-1}}(Q_{k-1}))} \\ &\leqslant C\|U\|^{\tau^k}_{L^2(B_{\rho_0}(Q_0))} \leqslant C\Big\{ \big[\varepsilon^{\alpha(\varepsilon)}\big]^{\tau^s} \Big\}^{\tau^k}. \end{aligned} \tag{4.10}$$

For every r, $0 < r < d_0$, let $k(r)$ be the smallest positive integer such that $d_k \leqslant r$; then, since $d_k = \mu^k d_0$, it follows that

$$\frac{|\log(\frac{r}{d_0})|}{\log\mu} \leqslant k(r) \leqslant \frac{|\log(\frac{r}{d_0})|}{\log\mu} + 1, \tag{4.11}$$

and by (4.10) we deduce that

$$\|U\|_{L^2(B_{\rho_{k(r)}}(Q_k(r)))} \leqslant C\Big\{ \big[\varepsilon^{\alpha(\varepsilon)}\big]^{\tau^s} \Big\}^{\tau^{k(r)}}. \tag{4.12}$$

Let $\bar{x} \in \Gamma_I^{\frac{\rho}{2}}$ with $\rho \in (0, r_0)$ and let $x \in B_{\frac{\rho_{k(r)-1}}{2}}(Q_{k(r)-1})$. By Theorem 3.2 it follows that

$$|U(\bar{x})| \leqslant |U(x)| + C_\rho |x - \bar{x}|^\alpha \leqslant |U(x)| + C_\rho \left(\frac{2}{\mu} r\right)^\alpha,$$

where $C_\rho > 0$ is a constant depending on the a priori data and ρ only.

Integrating this inequality over $B_{\frac{\rho_{k(r)-1}}{2}}(Q_{k(r)-1})$, we have that

$$|U(\bar{x})|^2 \leqslant \frac{2}{\omega_3 \left(\frac{\rho_{k-1}}{2}\right)^3} \int_{B_{\frac{\rho_{k(r)-1}}{2}}\left(Q_{k(r)-1}\right)} |U(x)|^2 \mathrm{d}x + 2C_\rho^2 \left(\frac{4r^2}{\mu^2}\right)^\alpha. \tag{4.13}$$

Since $k(r)$ is the smallest integer such that $d_k \leqslant r$, then $d_{k-1} > r$ and thus (4.13) yields

$$|U(\bar{x})|^2 \leqslant \frac{C}{\left(r \sin \theta'\right)^3} \int_{B_{\rho_{k(r)-1}}(Q_{k(r)-1})} |U(x)|^2 \mathrm{d}x + C_\rho r^{2\alpha}.$$

By (4.12) we deduce that

$$|U(\bar{x})|^2 \leqslant \frac{C}{r^3} \left\{ \left[\varepsilon^{\alpha(\varepsilon)}\right]^{\tau^s} \right\}^{\tau^{k(r)-1}} + C_\rho r^{2\alpha}. \tag{4.14}$$

Moreover, Theorem 3.2 also provides that

$$\left|\frac{\partial U(\bar{x})}{\partial \nu}\right| \leqslant \left|\frac{\partial U(x)}{\partial \nu}\right| + C_\rho \left(\frac{2}{\mu} r\right)^\alpha.$$

The Caccioppoli inequality and the same arguments that lead to (4.14) yield

$$\left|\frac{\partial U(\bar{x})}{\partial \nu}\right|^2 \leqslant \frac{C}{r^5} \left\{ \left[\varepsilon^{\alpha(\varepsilon)}\right]^{\tau^s} \right\}^{\tau^{k(r)-1}} + C_\rho r^{2\alpha}. \tag{4.15}$$

The choice in (4.11) guarantees that

$$\tau^{k(r)-1} \geqslant \left(\frac{r}{d_0}\right)^\nu, \tag{4.16}$$

where $\nu = -\log\left(\frac{1}{\mu}\right) \log \tau$. Hence inserting (4.16) into (4.14) and (4.15) and minimizing their right-hand sides with respect to r, we deduce that

$$\|U(\bar{x})\|_{L^\infty(\Gamma_I^{\frac{\rho}{2}})} \leqslant C_\rho \left(\log\left(\varepsilon^{-\alpha(\varepsilon)}\right)\right)^{-\frac{2\alpha}{\nu+2}}, \tag{4.17}$$

$$\left\|\frac{\partial U(\bar{x})}{\partial \nu}\right\|_{L^\infty(\Gamma_I^{\frac{\rho}{2}})} \leqslant C_\rho \left(\log\left(\varepsilon^{-\alpha(\varepsilon)}\right)\right)^{-\frac{2\alpha}{\nu+2}}, \tag{4.18}$$

where $C_\rho > 0$ is a constant depending on the a priori data and ρ only.

By an interpolation inequality and (3.2) we have

$$\|\nabla_t(U)\|_{L^\infty(\Gamma_{1,\rho})} \leqslant c_\rho \|U\|^\beta_{L^\infty(\Gamma_{1,\frac{\rho}{2}})} C_\rho^{\,1-\beta},$$

where $\beta = \frac{\alpha}{\alpha+1}$ and $c_\rho > 0$ depends on the a priori data and ρ only. After straightforward calculations and by a possible replacing of ε_0 with a smaller one depending on the a priori data only, we have that

$$\|u_1 - u_2\|_{C^1(\Gamma_{1,\rho})} \leq C_\rho |\log(\varepsilon)|^{-\frac{2\alpha\beta}{\nu+2}} \quad \text{for every } \varepsilon,\ 0 < \varepsilon < \varepsilon_0. \tag{4.19}$$

Thus the thesis follows, replacing in (2.12) C with C_ρ and θ with $\frac{2\alpha\beta}{\nu+2}$. □

PROPOSITION 4.3. *There exists a radius $r_1 > 0$ depending on the a priori data only, such that for every $x_0 \in \Gamma_I^{r_0}$, the problem*

$$\begin{cases} \Delta\psi + k^2\psi = 0 & \text{in } \Gamma_{I,r_1}(x_0), \\ \dfrac{\partial\psi}{\partial\nu} + i\lambda(x)\psi = 0 & \text{on } \Delta_{I,r_1}(x_0) \end{cases} \tag{4.20}$$

admits a solution $\psi \in H^1(\Gamma_{I,r_1}(x_0))$ satisfying

$$|\psi(x)| \geqslant 1 \text{ for every } x \in \Gamma_{I,r_1}(x_0). \tag{4.21}$$

Moreover, there exists a constant $\bar{\psi} > 0$ depending on the a priori data only, such that for every $x_0 \in \Gamma_I^{r_0}$,

$$\|\psi\|_{C^1(\Gamma_{I,r_1}(x_0))} \leqslant \bar{\psi}. \tag{4.22}$$

Proof. Let us consider a point $x_0 \in \Gamma_I^{r_0}$. After a translation we may assume that $x_0 = 0$ and, fixing local coordinates, we can represent the boundary as a graph of a $C^{1,1}$ function. Namely, we have that

$$D^+ \cap B_{r_0}(0) = \{(x', x_3) \in B_{r_0}(0) : x_3 < \varphi_I(x')\}, \tag{4.23}$$

where φ_I is the $C^{1,1}$ function satisfying (2.4) and (2.5).

Let $\Phi \in C^{1,1}(B_{\frac{r_0}{4M}}, \mathbb{R}^3)$ be the map defined as

$$\Phi(y', y_3) = (y', y_3 + \varphi_I(y')). \tag{4.24}$$

We have that there exist θ_1, θ_2, $\theta_1 > 1 > \theta_2 > 0$, constants depending on M and r_0 only, such that for every $r \in (0, \frac{r_0}{4M})$, it follows that

$$\Gamma_{I,\theta_2 r}(0) \subset \Phi(B_r^-(0)) \subset \Gamma_{I,\theta_1 r}(0), \tag{4.25}$$

where $B_r^-(0) = \{y \in \mathbb{R}^3 : |y| < r,\ y_3 < 0\}$, and furthermore we have

$$|\det D\Phi| = 1. \tag{4.26}$$

The inverse map $\Phi^{-1} \in C^{1,1}(\Gamma_{I,r_0}(0), \mathbb{R}^3)$ and is defined by

$$\Phi^{-1}(x', x_3) = (x', x_3 - \varphi_I(x')). \tag{4.27}$$

Denoting

$$\sigma(y) = (\sigma_{i,j}(y))_{i,j=1}^3 = (D\Phi^{-1})(\Phi(y)) \cdot (D\Phi^{-1})^T(\Phi(y)), \tag{4.28}$$

$$\lambda'(y) = \lambda(\Phi(y)), \tag{4.29}$$

$$\lambda_0{}' = \lambda'(0), \tag{4.30}$$

where λ is the function introduced in (1.5), we have that

$$\sigma(0) = \mathrm{I}, \tag{4.31}$$

$$\|\sigma_{i,j}\|_{C^{0,1}(\Gamma_{I,r_0})} \leqslant \Sigma \quad \text{for} \quad i,j = 1,2,3, \tag{4.32}$$

$$\frac{1}{2}|\xi|^2 \leqslant \sigma(y)\xi\cdot\xi \leqslant C_1|\xi|^2 \text{ for every } y \in B^-_{(\frac{r_0}{4M})}(0) \text{ and every } \xi \in \mathbb{R}^3, \tag{4.33}$$

$$\|\lambda'\|_{C^{0,1}(B'_{\frac{r_0}{4M}}(0))} \leqslant \Lambda', \tag{4.34}$$

where $\Sigma > 0, C_1 > 0$, and $\Lambda' > 0$ are constants depending on M, r_0, and Λ only.

Claim 4.4. *There exist a radius r_2, $0 < r_2 < \frac{r_0}{4M}$, and a solution $\psi' \in H^1(B^-_{r_2}(0))$ to the problem*

$$\begin{cases} \operatorname{div}(\sigma\nabla\psi') + k^2\psi' = 0 & \text{in} \quad B^-_{r_2}(0), \\ \sigma\nabla\psi'\cdot\nu' + i\lambda'\psi' = 0 & \text{on} \quad B'_{r_2}(0), \end{cases} \tag{4.35}$$

where $\nu' = (0,0,1)$ such that $|\psi'| \geqslant 1$ in $B^-_{r_2}(0)$.

Proof of Claim 4.4. We look for a radius $r_2 > 0$ and for a solution of the form $\psi' = \psi_0 - s$ such that $\psi_0 \in H^1(B^-_{r_2}(0))$ is a weak solution to the problem

$$\begin{cases} \Delta\psi_0 + k^2\psi_0 = 0 & \text{in} \quad B^-_{r_2}(0), \\ \dfrac{\partial\psi_0}{\partial\nu} + i\lambda_0{}'\psi_0 = 0 & \text{on} \quad B'_{r_2}(0), \end{cases} \tag{4.36}$$

satisfying $|\psi_0| \geqslant 2$ in $B^-_{r_2}(0)$.

Furthermore, $s \in H^1(B^-_{r_2}(0))$ is a weak solution to the problem

$$\begin{cases} \operatorname{div}(\sigma\nabla s) + k^2 s = \operatorname{div}((\sigma - I)\nabla\psi_0) & \text{in} \quad B^-_{r_2}(0), \\ \sigma\nabla s\cdot\nu + i\lambda' s = (\sigma - I)\nabla\psi_0\cdot\nu + i(\lambda' - \lambda_0{}')\psi_0 & \text{on} \quad B'_{r_2}(0), \\ s = 0 & \text{on} \quad |y| = r_2, \end{cases} \tag{4.37}$$

such that $s(y) = O(|y|^2)$ near the origin.

We can construct ψ_0 explicitly as follows:

$$\psi_0(y_1,y_2,y_3) = 8\cosh\left(|\lambda_0{}'^2 - k^2|^{\frac{1}{2}}y_1\right)\left[\sin\left(\lambda_0{}'y_3\right) + i\cos\left(\lambda_0{}'y_3\right)\right] \text{ if } k^2 < \lambda_0{}'^2,$$
$$\psi_0(y_1,y_2,y_3) = 8\cos\left(|k^2 - \lambda_0{}'^2|^{\frac{1}{2}}y_1\right)\left[\sin\left(\lambda_0{}'y_3\right) + i\cos\left(\lambda_0{}'y_3\right)\right] \text{ if } k^2 > \lambda_0{}'^2,$$
$$\psi_0(y_1,y_2,y_3) = 8\sin\left(\lambda_0{}'y_3\right) + i8\cos\left(\lambda_0{}'y_3\right) \text{ if } k^2 = \lambda_0{}'^2.$$

Denoting $\tilde{r} = \frac{\pi}{4}\min\{|k^2 - \lambda_0{}'^2|^{-\frac{1}{2}}, (\lambda_0{}')^{-1}\}$, it follows, by straightforward calculations, that $\psi_0 \in H^1(B^-_{\tilde{r}}(0))$ is a weak solution of (4.36) with $r_2 = \tilde{r}$ and $|\psi_0| \geqslant 2$ in $B^-_{\tilde{r}}(0)$.

Let us now look for a solution s to the problem (4.37).

Fixing $r \in (0, \frac{r_0}{8M})$, let us define the space

$$H^1_{0^-}(B^-_r(0)) = \{\eta \in H^1(B^-_r(0)) \text{ such that } \eta(y) = 0 \text{ on } |y| = r\}, \tag{4.38}$$

endowed with the usual $\|\cdot\|_{H^1_0(B_r^-(0))}$ norm. Let us introduce the bilinear form

$$A : H^1_{0-}(B_r^-(0)) \times H^1_{0-}(B_r^-(0)) \to \mathbb{C} \tag{4.39}$$

such that

$$A(\eta_1,\eta_2) = \int_{B_r^-(0)} \sigma \nabla\eta_1 \cdot \nabla\bar{\eta_2} - \int_{B_r^-(0)} k^2 \eta_1 \bar{\eta_2} - \int_{B_r'(0)} i\lambda' \eta_1 \bar{\eta_2} \tag{4.40}$$

and the functional

$$F : H^1_{0-}(B_r^-(0)) \to \mathbb{C} \tag{4.41}$$

such that

$$F(\eta) = \int_{B_r^-(0)} (\sigma - I)\nabla\psi_0 \cdot \nabla\bar{\eta} + i\int_{B_r'(0)} (\lambda' - {\lambda_0}')\psi_0\bar{\eta}\ . \tag{4.42}$$

It immediately follows that A and F are continuous on $H^1_{0-}(B_r^-(0))$ as a bilinear form and a functional, respectively.

Moreover, by standard arguments we can infer that there exists a radius $r_3 > 0$, depending on the a priori data only, such that for every $r \in (0, r_3)$, the bilinear form A is coercive on $H^1_{0-}(B_r^-(0))$. Hence by the Lax–Milgram theorem we deduce that for every $r \in (0, r_3)$, there exists a unique solution $s \in H^1_{0-}(B_r^-(0))$ to the problem (4.37).

By the coercitivity of A, we have that

$$\frac{1}{4}\int_{B_r^-(0)} |\nabla s|^2 \leqslant \left|\int_{B_r^-(0)} (\sigma - I)\nabla\psi_0 \cdot \nabla\bar{s}\right| + \left|\int_{B_r'(0)} (\lambda' - {\lambda_0}')\psi_0\bar{s}\right|. \tag{4.43}$$

By the Schwartz inequality, (4.31), and (4.32), we have that

$$\left|\int_{B_r^-(0)} (\sigma - I)\nabla\psi_0 \cdot \nabla\bar{s}\right| \leqslant 16\Sigma r^2 \int_{B_r^-(0)} |\nabla\psi_0|^2 + \frac{1}{16}\int_{B_r^-(0)} |\nabla s|^2. \tag{4.44}$$

By (4.30), (4.34), and a trace inequality it follows that

$$\left|\int_{B_r'(0)} (\lambda' - {\lambda_0}')\psi_0\bar{s}\right| \leqslant c_2^2 r^4 16\Lambda' \int_{B_r^-(0)} |\nabla\psi_0|^2 + \frac{1}{16} r \int_{B_r^-(0)} |\nabla s|^2. \tag{4.45}$$

Hence inserting (4.44) and (4.45) into (4.43) we obtain that

$$\frac{1}{8}\int_{B_r^-(0)} |\nabla s|^2 \leqslant (16\Sigma + c_2^2 16\Lambda')r^2 \int_{B_r^-(0)} |\nabla\psi_0|^2. \tag{4.46}$$

We have that

$$\frac{1}{8}\int_{B_r^-(0)} |\nabla s|^2 \leqslant \frac{4}{3}\pi(16\Sigma + c_1^2 16\Lambda')r^5 Q, \tag{4.47}$$

where $Q = \sup_{B^-_{\frac{r_0}{8M}}(0)} |\nabla\psi_0|^2$. By standard estimates for solutions of elliptic equations (see, for instance, [12, Chap. 8]) and observing that $Q > 0$ depends on the a priori data only, we can infer that for every $r \in (0, \frac{r_3}{2})$

$$\|s\|_{L^\infty(B_r^-(0))} \leqslant c_4 r^2,$$

where $c_4 > 0$ is a constant depending on the a priori data only.

Hence the claim follows, choosing $r_2 = \min\{\tilde{r}, \frac{r_3}{2}, \frac{1}{\sqrt{c_4}}\}$. □

Let us notice that choosing $r_1 = \theta_2 r_2$ and $\psi(x', x_3) = \psi'(\Phi^{-1}(x', x_3))$, we have that $\psi \in H^1(\Gamma_{I,r_1}(0))$ is a weak solution to the problem (4.20) and is such that $|\psi| \geqslant 1$ in $\Gamma_{I,r_1}(0)$. We conclude the proof observing that (4.22) follows with the same argument as in Theorem 3.2. □

LEMMA 4.5 (volume doubling inequality). *Let u be the solution to the problem (1.1); then there exists a radius $\bar{r} > 0$, such that for every $x_0 \in \Gamma_I^{r_0}$ the following holds:*

$$\int_{\Gamma_{I,\beta r}} |u|^2 \leqslant C\beta^K \int_{\Gamma_{I,r}} |u|^2 \tag{4.48}$$

for every r, β such that $\beta > 1$ and $0 < \beta r < \bar{r}$, where $C > 0, K > 0$ are constants depending on the a priori data only.

Proof. Let $x_0 \in \Gamma_I^{r_0}$ and let r_1 and ψ be, respectively, the radius and the function, introduced in Proposition 4.3. Denoting

$$z = \frac{u}{\psi}, \tag{4.49}$$

it follows that $z \in H^1(\Gamma_{I,r_1}(x_0))$ is a weak solution to the problem

$$\begin{cases} \Delta z + 2\dfrac{\nabla\psi}{\psi} \cdot \nabla z = 0 & \text{in } \Gamma_{I,r_1}(x_0), \\ \dfrac{\partial z}{\partial \nu} = 0 & \text{on } \Delta_{I,r_1}(x_0). \end{cases} \tag{4.50}$$

Proceeding as in Proposition 4.3, we may assume that, up to a rigid transformation of coordinates, $x_0 = 0$ and, by local coordinates, we can locally represent the boundary as a graph of a $C^{1,1}$ function as in (4.23).

Following [2, Theorem 0.8] (see also [4, Proposition 3.5]), we have that there exists a map $\Psi \in C^{1,1}(B_{\rho_2}(0), \mathbb{R}^3)$ such that

$$\Psi(B_{\rho_2}(0)) \subset B_{\rho_1}(0), \tag{4.51}$$

$$\Psi(y', 0) = (y', \varphi_I(y')) \qquad \text{for every } y' \in B'_{\rho_2}(0), \tag{4.52}$$

$$\Gamma_{I,\frac{\rho}{2}} \subset \Psi(B_\rho^-(0)) \subset \Gamma_{I,c_1\rho} \quad \text{for every } \rho \in (0, \rho_2), \tag{4.53}$$

$$\frac{1}{8} \leqslant |\det D\Psi| \leqslant c_2, \tag{4.54}$$

where $\rho_1, 0 < \rho_1 < r_0, \rho_2 > 0, c_1 > 0$, and $c_2 > 0$ are constants depending on r_0, M, and Λ only. Denoting

$$A(y) = |\det D\Psi(y)|(D\Psi^{-1})(\Psi(y))(D\Psi^{-1})^T(\Psi(y)), \tag{4.55}$$

$$B(y) = 2|\det D\Psi(y)|(D\Psi^{-1})(\Psi(y))\frac{\nabla\psi(\Psi(y))}{\psi(\Psi(y))}, \tag{4.56}$$

it follows that $v(y) = z(\Psi(y)) \in H^1(B^-_{\rho_2}(0))$ is a weak solution to the problem

$$\begin{cases} \operatorname{div}(A\nabla v) + B\nabla v = 0 & \text{in } B^-_{\rho_2}(0), \\ A(y',0)\nabla v \cdot \nu' = 0 & \text{on } B'_{\rho_2}(0). \end{cases} \tag{4.57}$$

Hence we are under the assumptions of Theorem 1.3 in [2] and thus we can infer that there exists a radius $\rho_3, 0 < \rho_3 < \rho_2$, depending on the a priori data only, such that

$$\int_{B^-_{\beta\rho}(0)} |v|^2 \leqslant c\beta^K \int_{B^-_{\rho}(0)} |v|^2 \tag{4.58}$$

for every ρ, β such that $\beta > 1$ and $0 < \beta\rho \leqslant \rho_3$, where $c > 0$ is constant depending on the a priori data only, and $K > 0$ depends on the a priori data and increasingly on

$$N(\rho_3) = \frac{\int_{B^-_{\rho_3}(0)} \rho_3^2 |\nabla v|^2 + |v|^2}{\int_{B^-_{\rho_3}(0)} |v|^2}. \tag{4.59}$$

By (4.53) and (4.58), it follows that for every r and $\beta > 1$ such that $0 < r < \beta r < \frac{\rho_3}{2}$,

$$\int_{\Gamma_{I,\beta r}} |z|^2 \leqslant C(2\beta c_1)^K \int_{\Gamma_{I,r}(0)} |z|^2. \tag{4.60}$$

Finally the last inequality, (4.21), and (4.22) imply that

$$\int_{\Gamma_{I,\beta r}} |u|^2 \leqslant C(\beta)^K \int_{\Gamma_{I,r}(0)} |u|^2, \tag{4.61}$$

where $C > 0, K > 0$ are constants depending on a priori data and on $N(\rho_3)$ only. Thus the lemma follows with

$$\bar{r} = \frac{\rho_3}{2}. \tag{4.62}$$

It remains only to majorize the quantity (4.59) by a constant depending on the a priori data only. Let us observe that by (4.53), (4.21), (4.22), and (3.3), we have

$$\int_{B^-_{\rho_3}(0)} |\nabla v|^2 + |v|^2 \leqslant C, \tag{4.63}$$

where $C > 0$ is a constant depending on a priori data only.

On the other hand, we have that, choosing $P_0 = \frac{M}{8\sqrt{1+M^2}\rho_3}\nu$ and $\rho_4 = \frac{1}{32}\frac{M}{\sqrt{1+M^2}}\rho_3$, where ν is the outer unit normal to D at 0, it follows that $B_{\rho_4}(P_0) \subset \Gamma_{I,\frac{\rho_3}{2}}(0)$.

Thus, by (4.53) and (4.22) it follows that

$$\int_{B^-_{\rho_3}(0)} |v|^2 \geqslant C \int_{\Gamma_{I,\frac{\rho_3}{2}}(0)} |u|^2 \geqslant C \int_{B_{\rho_4}(P_0)} |u|^2, \tag{4.64}$$

where $C > 0$ is a constant depending on the a priori data only.

Let us consider a point $Q \in \mathbb{R}^3 \setminus D^+_{2R_0}$ such that

$$B_{4\rho_4}(Q) \subset \mathbb{R}^3 \setminus \overline{D}^+_{2R_0}, \tag{4.65}$$

where R_0 is the radius introduced in Corollary 3.3. Proceeding as in the proof of Theorem 4.2, we cover a path joining P_0 to Q by a chain of balls of radius ρ_4 pairwise tangent to each other. Hence, by an iterated use of the three spheres inequality, we have that the following holds:

$$\|u\|_{L^2(B_{\rho_4(P_0)})} \geqslant C, \tag{4.66}$$

where $C > 0$ is a constant depending on a priori data only. Hence, by (4.63) and (4.66), we can majorize $N(\rho_3)$ by a constant depending on the a priori data only and thus the lemma follows. □

THEOREM 4.6 (surface doubling inequality). *Let u be the solution to the problem (1.1); then there exists a constant $C > 0$ depending on the a priori data only, such that for every $x_0 \in \Gamma_I^{r_0}$ and for every $r \in (0, \frac{\bar{r}}{4})$, the following holds:*

$$\int_{\Delta_{I,2r}(x_0)} |u|^2 \, d\sigma \leqslant C \int_{\Delta_{I,r}(x_0)} |u|^2 \, d\sigma. \tag{4.67}$$

Proof. Let $x_0 \in \Gamma_I^{r_0}$ and let $z \in H^1(\Gamma_{I,r_1}(x_0))$ and $\bar{r}$ be, respectively, the solution to the problem (4.50) defined by (4.49) and the radius introduced in (4.62). By a regularity estimate at the boundary (see, for instance, [4, p. 777]), we have that, for any $r \in (0, \frac{\bar{r}}{4})$, the following holds:

$$\int_{\Delta_{I,r}(x_0)} |\nabla_t z|^2 \leqslant C \left(\frac{1}{r} \int_{\Gamma_{I,2r}(x_0)} |\nabla z|^2 \right)^{1-\gamma} \left(\frac{1}{r^2} \int_{\Delta_{I,r}(x_0)} |z|^2 \right)^{\gamma}, \tag{4.68}$$

where $C > 0$ and $0 < \gamma < 1$ are constants depending on the a priori data only and $\nabla_t z$ represents the tangential gradient.

Moreover, by a well-known estimate of stability for the Cauchy problem (see, for instance, [18]), we have that

$$\begin{aligned} \int_{\Gamma_{I,\frac{r}{2}}(x_0)} |z|^2 \leqslant Cr & \left(\int_{\Delta_{I,r}(x_0)} |z|^2 + r^2 \int_{\Delta_{I,r}(x_0)} |\nabla_t z|^2 \right)^{1-\delta} \\ & \cdot \left(\int_{\Delta_{I,r}(x_0)} |z|^2 + r^2 \int_{\Delta_{I,r}(x_0)} |\nabla_t z|^2 + r \int_{\Gamma_{I,r}(x_0)} |\nabla z|^2 \right)^{\delta}, \end{aligned} \tag{4.69}$$

where $C > 0$ and $0 < \delta < 1$ are constants depending on the a priori data only.

Hence by the Young inequality, (4.68), and (4.69), we obtain

$$\int_{\Gamma_{I,\frac{r}{2}}(x_0)} |z|^2 \leqslant \frac{Cr}{\varepsilon^{\frac{\gamma^2+1-\gamma}{\gamma(1-\gamma)}}} \int_{\Delta_{I,r}(x_0)} |z|^2 + C\varepsilon r^2 \int_{\Gamma_{I,2r}(x_0)} |\nabla z|^2,$$

where $C > 0$ is a constant depending on the a priori data only. By the Caccioppoli inequality, (4.21), and (4.22) we can infer that

$$\int_{\Gamma_{I,\frac{r}{2}}(x_0)} |u|^2 \leqslant \frac{Cr}{\varepsilon^{\frac{\gamma^2+1-\gamma}{\gamma(1-\gamma)}}} \int_{\Delta_{I,2r}(x_0)} |u|^2 + C\varepsilon \int_{\Gamma_{I,8r}(x_0)} |u|^2,$$

where $C > 0$ is a constant depending on the a priori data only.

By (4.48) it follows that

$$\int_{\Gamma_{I,\frac{r}{2}}(x_0)} |u|^2 \leqslant \frac{Cr}{\varepsilon^{\frac{\gamma^2+1-\gamma}{\gamma(1-\gamma)}}} \int_{\Delta_{I,r}(x_0)} |u|^2 + C(8)^K \varepsilon \int_{\Gamma_{I,\frac{r}{2}}(x_0)} |u|^2, \tag{4.70}$$

where $C > 0$ is a constant depending on the a priori data only.

Hence, choosing ε in (4.70) such that $\varepsilon = \frac{1}{2C(8)^K}$ and applying again (4.48) on the left-hand side of (4.70), we obtain that

$$\int_{\Gamma_{I,2r}(x_0)} |u|^2 \leqslant Cr \int_{\Delta_{I,r}(x_0)} |u|^2, \tag{4.71}$$

where $C > 0$ is a constant depending on the a priori data only.

Moreover, by a standard Dirichlet trace inequality, we have that

$$\int_{\Delta_{I,2r}(x_0)} |u|^2 \leqslant C \int_{\Delta_{I,r}(x_0)} |u|^2, \tag{4.72}$$

where $C > 0$ is a constant depending on the a priori data only. □

Corollary 4.7 (A_p property on the boundary). *Let u be the solution to the problem (1.1); then there exist constants $p > 1, A > 0$ depending on the a priori data only, such that for every $x_0 \in \Gamma_I^{r_0}$ and every $r \in (0, \frac{\bar{r}}{4})$, the following holds:*

$$\left(\frac{1}{|\Delta_{I,r}(x_0)|} \int_{\Delta_{I,r}(x_0)} |u|^2 d\sigma\right) \left(\frac{1}{|\Delta_{I,r}(x_0)|} \int_{\Delta_{I,r}(x_0)} |u|^{-\frac{2}{p-1}} d\sigma\right)^{p-1} \leqslant A. \tag{4.73}$$

Proof. Let $x_0 \in \Gamma_I^{r_0}$ and let $r \in (0, \frac{\bar{r}}{4})$; then by a trace inequality (see, for instance, [1, Chap. 5]), it follows that

$$\|u\|_{L^4(\Delta_{I,r}(x_0))} \leqslant C \|u\|_{H^1(\Gamma_{I,r}(x_0))}, \tag{4.74}$$

where $C > 0$ is a constant depending on the a priori data only. By the Caccioppoli inequality and the doubling inequality (4.48) we deduce that

$$\|u\|_{L^4(\Delta_{I,r}(x_0))} \leqslant \frac{C}{r} \|u\|_{L^2(\Gamma_{I,r}(x_0))}, \tag{4.75}$$

where $C > 0$ is a constant depending on the a priori data only. Combining (4.71) and (4.75) we have that

$$\|u\|_{L^4(\Delta_{I,r}(x_0))} \leqslant \frac{C}{\sqrt{r}} \|u\|_{L^2(\Delta_{I,2r}(x_0))}, \tag{4.76}$$

where $C > 0$ is a constant depending on the a priori data only. Thus by the doubling inequality (4.67) we have that

$$\|u\|_{L^4(\Delta_{I,r}(x_0))} \leqslant \frac{C}{\sqrt{r}} \|u\|_{L^2(\Delta_{I,r}(x_0))}. \tag{4.77}$$

Hence, we infer that for every $r \in (0, \frac{\bar{r}}{4})$ and every $x_0 \in \Gamma_I^{r_0}$, the following holds:

$$\left(\frac{1}{r^2} \int_{\Delta_{I,r}} |u|^4\right)^{\frac{1}{4}} \leqslant \left(\frac{C}{r^2} \int_{\Delta_{I,r}} |u|^2\right)^{\frac{1}{2}},$$

obtaining a reverse Hölder inequality.

The result in [9] assures the existence of some $p > 1$ and $A > 0$ depending on the a priori data only such that (4.73) holds. □

Proof of Theorem 2.1. Let x_0 be a point in $\Gamma_I^{r_0}$. Let us pick $r = \frac{\bar r}{8}$, where $\bar r$ is the radius introduced in (4.62). Thus by (4.71) with $u = u_2$ it follows that

$$\int_{\Delta_{I,\frac{\bar r}{8}}(x_0)} |u_2|^2 \mathrm{d}\sigma \geqslant C \int_{\Gamma_{I,\frac{\bar r}{16}}(x_0)} |u_2|^2 \mathrm{d}x, \tag{4.78}$$

where $C > 0$ is a constant depending on the a priori data only.

Let P_0 and $\rho_4 > 0$ be, respectively a point and a radius, such that $B_{\rho_4}(P_0) \subset \Gamma_{I,\frac{\bar r}{16}(x_0)}$. By rephrasing the argument leading to (4.66) we deduce by (4.78) that

$$\int_{\Delta_{I,\frac{\bar r}{8}}(x_0)} |u_2|^2 \mathrm{d}\sigma \geqslant C, \tag{4.79}$$

where $C > 0$ is a constant depending on the a priori data only.

Combining (4.73) and (4.79), we have that for every $x_0 \in \Gamma_I^{r_0}$ the following holds:

$$\left(\int_{\Delta_{I,\frac{\bar r}{8}}(x_0)} |u_2|^{-\frac{2}{p-1}} \mathrm{d}\sigma \right)^{p-1} \leqslant C, \tag{4.80}$$

where $C > 0$ is a constant depending on the a priori data only.

Let us now consider $x \in \Delta_{I,\frac{\bar r}{8}}(x_0)$; then by Theorem 4.2 and (1.4) we have that if $0 < \varepsilon < \varepsilon_0$, the following holds:

$$|\lambda_1(x) - \lambda_2(x)| \leqslant (\Lambda + 1)\eta(\varepsilon) \frac{1}{|u_2(x)|}. \tag{4.81}$$

Hence denoting $\delta = \frac{2}{p-1}$ and combining (4.81) and (4.80), we deduce that

$$\left(\int_{\Delta_{I,\frac{\bar r}{8}(x_0)}} |\lambda_1(x) - \lambda_2(x)|^\delta \right)^{\frac{1}{\delta}} \leqslant \eta(\varepsilon). \tag{4.82}$$

By the a priori bound (1.4), we can infer that

$$\|\lambda_1(x) - \lambda_2(x)\|_{L^2(\Delta_{I,\frac{\bar r}{8}(x_0)})} \leqslant (2\Lambda)^{1-\frac{\delta}{2}} \left(\int_{\Delta_{I,\frac{\bar r}{8}}(x_0)} |\lambda_1(x) - \lambda_2(x)|^\delta \right)^{\frac{1}{2}}. \tag{4.83}$$

Hence, by a possible further replacement of the constants C, θ in (2.12), we can infer that the last inequality and (4.82) yield

$$\|\lambda_1(x) - \lambda_2(x)\|_{L^2(\Delta_{I,\frac{\bar r}{8}}(x_0))} \leqslant \eta(\varepsilon). \tag{4.84}$$

By an interpolation inequality (see, for instance, [4, p. 777]), we have that

$$\|\lambda_1 - \lambda_2\|_{L^\infty(\Delta_{I,\frac{\bar r}{8}(x_0)})} \leqslant C \|\lambda_1 - \lambda_2\|^{\frac{1}{2}}_{L^2(\Delta_{I,\frac{\bar r}{8}}(x_0))} \|\lambda_1 - \lambda_2\|^{\frac{1}{2}}_{C^{0,1}(\Delta_{I,\frac{\bar r}{8}}(x_0))}, \tag{4.85}$$

where $C > 0$ is a constant depending on the a priori data only. Hence by (1.4) and combining (4.84) with (4.85), we obtain, by a possible further replacement of the constants C, θ in (2.12), that

$$\|\lambda_1 - \lambda_2\|_{L^\infty(\Delta_{I,\frac{\bar r}{8}}(x_0))} \leqslant \eta(\varepsilon). \tag{4.86}$$

Let us cover $\Gamma_I^{r_0}$ with the sets $\Delta_{I,\frac{\bar{r}}{8}}(x_j),\ j=1,\dots,J$, with $x_j \in \Gamma_I^{r_0}$.
Let i be an index such that

$$\|\lambda_1-\lambda_2\|_{L^\infty(\Delta_{I,\frac{\bar{r}}{8}}(x_i))} = \|\lambda_1-\lambda_2\|_{L^\infty(\Gamma_I^{r_0})}. \tag{4.87}$$

Thus, by a further possible replacement of the constant C,θ in (2.12), we deduce (2.14) from (4.87) and (4.86) with $x_0 = x_i$. □

A UNIQUENESS CRITERION FOR THE SIGNORINI PROBLEM WITH COULOMB FRICTION*

YVES RENARD†

Abstract. The purpose of this paper is to study the solutions to the Signorini problem with Coulomb friction (the so-called Coulomb problem). Some optimal a priori estimates are given, and a uniqueness criterion is exhibited. Recently, nonuniqueness examples have been presented in the continuous framework. It is proved, here, that if a solution satisfies a certain hypothesis on the tangential displacement and if the friction coefficient is small enough, it is the unique solution to the problem. In particular, this result can be useful for the search of multisolutions to the Coulomb problem because it eliminates a lot of uniqueness situations.

Key words. unilateral contact, Coulomb friction, uniqueness of solution

AMS subject classifications. 35J85, 74M10

DOI. 10.1137/050635936

Introduction. The so-called Signorini problem with Coulomb friction (or simply the Coulomb problem) has been introduced by Duvaut and Lions [4]. It does not exactly represent the equilibrium of a solid which encounters an obstacle because when the equilibrium is reached (or any steady state solution) the friction condition is no longer an irregular law. The aim of this problem is in fact to be very close to a time semidiscretization of an evolutionary problem by an implicit scheme. The fact that several solutions could coexist in an implicit scheme (independently of the size of the time step) may be an indication that the evolutionary problem has a dynamical bifurcation.

The first existence results for this problem were obtained by Nečas, Jarušek, and Haslinger in [15] for a two-dimensional elastic strip, assuming that the coefficient of friction is small enough and using a shifting technique previously introduced by Fichera and later applied to more general domains by Jarušek [11]. Eck and Jarušek [5] give a different proof using a penalization method. We emphasize that most results on existence for frictional problems involve a condition of smallness for the friction coefficient (and a compact support on Γ_C).

Recently, examples of nonunique solutions have been given by Hild in [7] and [8] for a large friction coefficient. As far as we know, for a fixed geometry, it is still an open question whether or not there is uniqueness of the solution for a sufficiently small friction coefficient. In the finite element approximation framework, the presence of bifurcation has been studied in [9].

The present paper gives the first (partial) result of uniqueness of a solution to the Coulomb problem. The summary is the following. Section 1 introduces strong and weak formulations of the Coulomb problem. Section 2 gives optimal estimates on the solutions. In particular, a comparison is made with the solution to the frictionless contact problem. Section 3 gives an additional estimate for the Tresca problem, i.e., the problem with a given friction threshold. And finally, section 4 gives the partial

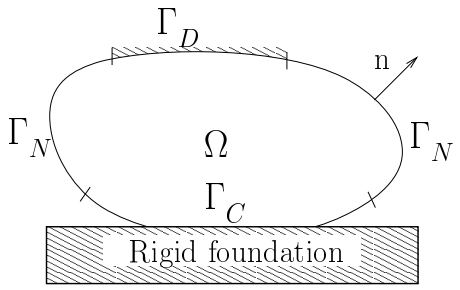

FIG. 1. *Elastic body Ω in frictional contact.*

uniqueness result. It is proved in Proposition 5 for bidimensional problems and a friction coefficient less than one that there is no multisolution with one of the solutions having a tangential displacement with a constant sign. The major result is given by Proposition 6 using the notion of a multiplier in a pair of Sobolev spaces.

1. The Signorini problem with Coulomb friction. Let $\Omega \subset \mathbb{R}^d$ ($d = 2$ or 3) be a bounded Lipschitz domain representing the reference configuration of a linearly elastic body.

It is assumed that this body is submitted to a Neumann condition on a part of its boundary $\Gamma_{_N}$, to a Dirichlet condition on another part $\Gamma_{_D}$, and to a unilateral contact with static Coulomb friction condition on the rest of the boundary $\Gamma_{_C}$ between the body and a flat rigid foundation (see Figure 1). This latter part $\Gamma_{_C}$ is supposed to be of nonzero interior in the boundary $\partial\Omega$ of Ω. The problem consists in finding the displacement field $u(t,x)$ satisfying

$$-\operatorname{div}\sigma(u) = f \quad \text{in} \quad \Omega, \tag{1}$$

$$\sigma(u) = \mathcal{A}\varepsilon(u) \quad \text{in } \Omega, \tag{2}$$

$$\sigma(u)\mathrm{n} = F \quad \text{on } \Gamma_{_N}, \tag{3}$$

$$u = 0 \quad \text{on } \Gamma_{_D}, \tag{4}$$

where $\sigma(u)$ is the stress tensor, $\varepsilon(u)$ is the linearized strain tensor, n is the outward unit normal to Ω on $\partial\Omega$, F and f are the given external loads, and $\mathcal{A}$ is the elastic coefficient tensor which satisfies classical conditions of symmetry and ellipticity.

On $\Gamma_{_C}$, it is usual to decompose the displacement and the stress vector in normal and tangential components as follows:

$$u_{_N} = u\cdot\mathrm{n}, \quad u_{_T} = u - u_{_N}\mathrm{n},$$

$$\sigma_{_N}(u) = (\sigma(u)\mathrm{n})\cdot\mathrm{n}, \quad \sigma_{_T}(u) = \sigma(u)\mathrm{n} - \sigma_{_N}(u)\mathrm{n}.$$

To give a clear sense to this decomposition, we assume $\Gamma_{_C}$ to have the $\mathcal{C}^1$ regularity. The unilateral contact condition is expressed by the following complementary condition:

$$u_{_N} \le g, \quad \sigma_{_N}(u) \le 0, \quad (u_{_N} - g)\sigma_{_N}(u) = 0, \tag{5}$$

where g is the normal gap between the elastic solid and the rigid foundation in reference configuration (see Figure 2).

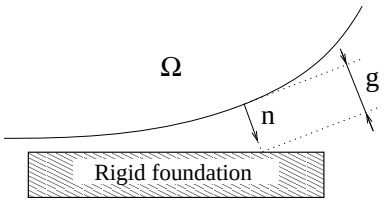

FIG. 2. *Normal gap between the elastic solid* Ω *and the rigid foundation.*

Denoting by $\mathcal{F} \geq 0$ the friction coefficient, the *static Coulomb friction* condition reads as follows:

$$\text{if } u_T = 0, \text{ then } |\sigma_T(u)| \leq -\mathcal{F}\sigma_N(u), \tag{6}$$

$$\text{if } u_T \neq 0, \text{ then } \sigma_T(u) = \mathcal{F}\sigma_N(u)\frac{u_T}{|u_T|}. \tag{7}$$

The friction force satisfies the so-called maximum dissipation principle

$$-\sigma_T(u)\cdot u_T = \sup_{\substack{\mu_T \in \mathbb{R}^{d-1} \\ |\mu_T| \leq -\mathcal{F}\sigma_N(u)}} (-\mu_T \cdot u_T). \tag{8}$$

1.1. Classical weak formulation. We present here the classical weak formulation proposed by Duvaut [3] and Duvaut and Lions [4]. Let us introduce the Hilbert spaces

$$V = \{v \in H^1(\Omega;\mathbb{R}^d), v = 0 \text{ on } \Gamma_D\},$$

$$X = \{v|_{\Gamma_C} : v \in V\} \subset H^{1/2}(\Gamma_C;\mathbb{R}^d),$$

$$X_N = \{v_N|_{\Gamma_C} : v \in V\}, \quad X_T = \{v_T|_{\Gamma_C} : v \in V\},$$

and their topological dual spaces V', X', X'_N, and X'_T. It is assumed that Γ_C is sufficiently smooth such that $X_N \subset H^{1/2}(\Gamma_C)$, $X_T \subset H^{1/2}(\Gamma_C;\mathbb{R}^{d-1})$, $X'_N \subset H^{-1/2}(\Gamma_C)$, and $X'_T \subset H^{-1/2}(\Gamma_C;\mathbb{R}^{d-1})$.

Classically, $H^{1/2}(\Gamma_C)$ is the space of the restriction on Γ_C of traces on $\partial\Omega$ of functions of $H^1(\Omega)$, and $H^{-1/2}(\Gamma_C)$ is the dual space of $H^{1/2}_{00}(\Gamma_C)$, which is the space of the restrictions on Γ_C of functions of $H^{1/2}(\partial\Omega)$ vanishing outside Γ_C. We refer to [1] and [12] for a detailed presentation of trace operators.

Now, the set of admissible displacements is defined as

$$K = \{v \in V, v_N \leq g \quad \text{a.e. on } \Gamma_C\}. \tag{9}$$

The maps

$$a(u,v) = \int_\Omega \mathcal{A}\varepsilon(u) : \varepsilon(v)dx,$$

$$l(v) = \int_\Omega f\cdot v dx + \int_{\Gamma_N} F\cdot v d\Gamma,$$

$$j(\mathcal{F}\lambda_N, v_T) = -\langle \mathcal{F}\lambda_N, |v_T| \rangle_{X'_N, X_N}$$

represent the virtual work of elastic forces, the external load, and the "virtual work" of friction forces, respectively. Standard hypotheses are as follows:

(10) $a(\cdot,\cdot)$ is a bilinear symmetric V-elliptic and continuous form on $V \times V$:
$\exists\ \alpha > 0,\ \exists\ M > 0,\ a(u,u) \geq \alpha \|u\|_V^2,\ a(u,v) \leq M\|u\|_V \|v\|_V\ \forall u, v \in V,$

(11) $l(\cdot)$ is a linear continuous form on V; i.e., $\exists\ L > 0, |l(v)| \leq L\|v\|_V\ \forall v \in V,$

(12) $g \in X_N$,

(13) $\mathcal{F} \in MX_N$ is a nonnegative multiplier in X_N.

The latter condition ensures that $j(\mathcal{F}\lambda_N, v_T)$ is linear continuous on λ_N and convex lower semicontinuous on v_T when λ_N is a nonpositive element of X_N' (see, for instance, [2]). To satisfy condition (10), it is necessary that Γ_D is of nonzero interior in the boundary of Ω and that the elastic coefficient tensor is uniformly elliptic (see [4]).

We refer to Maz'ya and Shaposhnikova [14] for the theory of multipliers. The set MX_N denotes the space of multipliers from X_N into X_N, i.e., the space of function $f : \Gamma_C \longrightarrow \mathbb{R}$ of finite norm

$$\|f\|_{MX_N} = \sup_{\substack{v_N \in X_N \\ v_N \neq 0}} \frac{\|fv_N\|_{X_N}}{\|v_N\|_{X_N}}.$$

This is the norm of the linear mapping $X_N \ni v \longmapsto (fv) \in X_N$. Of course, if $\mathcal{F}$ is a constant on Γ_C, one has $\|\mathcal{F}\|_{MX_N} = \mathcal{F}$. From the fact that Ω is supposed to be a bounded Lipschitz domain and Γ_C is supposed to have the $\mathcal{C}^1$ regularity, it is possible to deduce that for $d = 2$ the space $H^{1/2+\varepsilon}(\Gamma_C)$ is continuously included in MX_N for any $\varepsilon > 0$, and for $d = 3$ the space $H^1(\Gamma_C) \cap L^\infty(\Gamma_C)$ is included in MX_N, continuously for the norm $\|f\|_{H^1(\Gamma_C)} + \|f\|_{L^\infty(\Gamma_C)}$ (see [14]). In particular, the space of Lipschitz continuous functions is continuously included in MX_N.

Condition (10) implies in particular that $a(\cdot,\cdot)$ is a scalar product on V and that the associated norm

$$\|v\|_a = (a(v,v))^{1/2}$$

is equivalent to the usual norm of V:

$$\sqrt{\alpha}\|v\|_V \leq \|v\|_a \leq \sqrt{M}\|v\|_V \quad \forall v \in V.$$

The continuity constant of $l(\cdot)$ can also be given with respect to: $\|\cdot\|_a$:

$$\exists\ L_a > 0, |l(v)| \leq L_a\|v\|_a\ \forall v \in V.$$

Constants L and L_a can be chosen such that

$$\sqrt{\alpha}L_a \leq L \leq \sqrt{M}L_a.$$

The classical weak formulation of problem (1)–(7) is given by

(14)
$$\begin{cases} \text{Find } u \in K \text{ satisfying} \\ \\ a(u, v-u) + j(\mathcal{F}\sigma_N(u), v_T) - j(\mathcal{F}\sigma_N(u), u_T) \geq l(v-u)\ \ \forall\ v \in K. \end{cases}$$

The major difficulty about (14) is due to the coupling between the friction threshold and the contact pressure $\sigma_N(u)$. The consequence is that this problem does not represent a variational inequality, in the sense that it cannot be derived from an optimization problem.

1.2. Neumann to Dirichlet operator. In this section, the Neumann to Dirichlet operator on Γ_C is introduced together with its basic properties. This will allow to restrict the contact and friction problem to Γ_C and obtain useful estimates.

Let $\lambda = (\lambda_N, \lambda_T) \in X'$; then, under hypotheses (10) and (11), the solution u to

$$\left\{ \begin{array}{l} \text{Find } u \in V \text{ satisfying} \\ \\ a(u,v) = l(v) + \langle \lambda, v \rangle_{X',X} \quad \forall\ v \in V \end{array} \right. \tag{15}$$

is unique (see [4]). So it is possible to define the operator

$$\begin{array}{rcl} \mathbb{E} : X' & \longrightarrow & X \\ \lambda & \longmapsto & u_{|\Gamma_C}. \end{array}$$

This operator is affine and continuous. Moreover, it is invertible and its inverse is continuous. It is possible to express $\mathbb{E}^{-1}$ as follows: For $w \in X$, let u be the solution to the Dirichlet problem

$$\left\{ \begin{array}{l} \text{Find } u \in V \text{ satisfying } u_{|\Gamma_C} = w \text{ and} \\ \\ a(u,v) = l(v) \quad \forall\ v \in V,\ v_{|\Gamma_C} = 0; \end{array} \right. \tag{16}$$

then $\mathbb{E}^{-1}(w)$ is equal to $\lambda \in X'$ defined by

$$\langle \lambda, v \rangle_{X',X} = a(u,v) - l(v) \quad \forall\ v \in V.$$

In a weak sense, one has the relation $\mathbb{E}^{-1}(u) = \sigma(u)\mathrm{n}$ on Γ_C. Now, under hypotheses (10) and (11) one has

$$\|\mathbb{E}(\lambda^1) - \mathbb{E}(\lambda^2)\|_X \leq \frac{C_1^2}{\alpha} \|\lambda^1 - \lambda^2\|_{X'}, \tag{17}$$

where C_1 is the continuity constant of the trace operator on Γ_C and α is the coercivity constant of the bilinear form $a(\cdot,\cdot)$. One can verify it as follows. Let λ^1 and λ^2 be given in X'_T and let u^1, u^2 be the corresponding solutions to (15); then

$$\begin{array}{rcl} \alpha \|u^1 - u^2\|_V^2 & \leq & a(u^1 - u^2, u^1 - u^2) \ = \ \langle \lambda^1 - \lambda^2, u^1 - u^2 \rangle_{X',X} \\ & \leq & C_1 \|\lambda^1 - \lambda^2\|_{X'} \|u^1 - u^2\|_V \end{array} \tag{18}$$

and, consequently,

$$\|u^1 - u^2\|_V \leq \frac{C_1}{\alpha} \|\lambda^1 - \lambda^2\|_{X'}. \tag{19}$$

Conversely, one has

$$\|\mathbb{E}^{-1}(u^1) - \mathbb{E}^{-1}(u^2)\|_{X'} \leq M C_2^2 \|u^1 - u^2\|_X, \tag{20}$$

where M is the continuity constant of $a(\cdot,\cdot)$ and $C_2 > 0$ is the continuity constant of the homogeneous Dirichlet problem corresponding to (16) (i.e., with $l(v) \equiv 0$ and

$C_2 = \sup_{\substack{v\in X\\ v\neq 0}} \frac{\|w\|_V}{\|v\|_X}$, where $w_{|\Gamma_C} = v$ and $a(w,z) = 0 \ \ \forall z \in V$). This latter estimate can be performed as follows:

$$\begin{aligned}\|\mathbb{E}^{-1}(u^1) - \mathbb{E}^{-1}(u^2)\|_{X'} &= \sup_{\substack{v\in X\\ v\neq 0}} \frac{\langle \mathbb{E}^{-1}(u^1) - \mathbb{E}^{-1}(u^2), v\rangle_{X',X}}{\|v\|_X} \\ &= \sup_{\substack{v\in X\\ v\neq 0}} \left(\inf_{\{w\in V : w_{|\Gamma_C} = v\}} \frac{a(u^1-u^2, w)}{\|v\|_X} \right) \\ &\leq M\gamma \|u^1 - u^2\|_V, \end{aligned} \tag{21}$$

where $\gamma = \sup_{\substack{v\in X\\ v\neq 0}} \ \inf_{\{w\in V : w_{|\Gamma_C} = v\}} \frac{\|w\|_V}{\|v\|_X}$ is the continuity constant of the homogeneous Poisson problem with respect to a Dirichlet condition on Γ_C. Using $\gamma \leq C_2$, this gives (20).

It is also possible to define the following norms on Γ_C relative to $a(\cdot,\cdot)$:

$$\|v\|_{a,\Gamma_C} = \inf_{w\in V,\ w_{|\Gamma_C} = v} \|w\|_a,$$

$$\|\lambda\|_{-a,\Gamma_C} = \sup_{\substack{v\in X\\ v\neq 0}} \frac{\langle \lambda, v\rangle_{X',X}}{\|v\|_{a,\Gamma_C}} = \sup_{\substack{v\in V\\ v\neq 0}} \frac{\langle \lambda, v\rangle_{X',X}}{\|v\|_a}.$$

These are equivalent, respectively, to the norms in X and X':

$$\frac{\sqrt{\alpha}}{C_1}\|v\|_X \leq \|v\|_{a,\Gamma_C} \leq \sqrt{M}\gamma\|v\|_X,$$

$$\frac{1}{\sqrt{M}\gamma}\|\lambda\|_{X'} \leq \|\lambda\|_{-a,\Gamma_C} \leq \frac{C_1}{\sqrt{\alpha}}\|\lambda\|_{X'}.$$

With these norms, the estimates are straightforward since the following lemma holds.

LEMMA 1. *Let λ^1 and λ^2 be two elements of X' and let $u^1 = \mathbb{E}(\lambda^1)$, $u^2 = \mathbb{E}(\lambda^2)$; then under hypotheses* (10) *and* (11) *one has*

$$\|u^1 - u^2\|_{a,\Gamma_C} = \|u^1 - u^2\|_a = \|\lambda^1 - \lambda^2\|_{-a,\Gamma_C}.$$

Proof. On the one hand, one has

$$\|u^1 - u^2\|^2_{a,\Gamma_C} = \inf_{\substack{w\in V\\ w_{|\Gamma_c} = u^1 - u^2}} \|w\|_a^2 = \|u^1 - u^2\|_a^2,$$

because $u^1 - u^2$ is the minimum of $\frac{1}{2}\|w\|_a^2$ under the constraint $w_{|\Gamma_C} = u^1 - u^2$. This implies

$$\begin{aligned}\|u^1 - u^2\|^2_{a,\Gamma_C} &= a(u^1 - u^2, u^1 - u^2) = \langle \lambda^1 - \lambda^2, u^1 - u^2\rangle_{X',X} \\ &\leq \|\lambda^1 - \lambda^2\|_{-a,\Gamma_C}\|u^1 - u^2\|_{a,\Gamma_C},\end{aligned}$$

and finally

$$\|u^1 - u^2\|_{a,\Gamma_C} \leq \|\lambda^1 - \lambda^2\|_{-a,\Gamma_C}.$$

On the other hand, one has

$$\|\lambda^1-\lambda^2\|_{-a,\Gamma_C} = \sup_{\substack{v\in X\\ v\neq 0}} \frac{\langle \lambda^1-\lambda^2, v\rangle_{X',X}}{\|v\|_{a,\Gamma_C}} = \sup_{\substack{v\in X\\ v\neq 0}} \inf_{\substack{w\in V\\ w\big|_{\Gamma_C}=v}} \frac{a(u^1-u^2,w)}{\|v\|_{a,\Gamma_C}},$$

$$\leq \sup_{\substack{v\in X\\ v\neq 0}} \inf_{\substack{w\in V\\ w\big|_{\Gamma_C}=v}} \frac{\|u^1-u^2\|_a\|w\|_a}{\|v\|_{a,\Gamma_C}} = \|u^1-u^2\|_a = \|u^1-u^2\|_{a,\Gamma_C},$$

which ends the proof of the lemma. □

1.3. Direct weak inclusion formulation. Let

$$K_N = \{v_N \in X_N : v_N \leq 0 \text{ a.e. on } \Gamma_C\}$$

be the (translated) set of admissible normal displacements on Γ_C. The normal cone in X'_N to K_N at $v_N \in X_N$ is defined as

$$N_{K_N}(v_N) = \{\mu_N \in X'_N : \langle \mu_N, w_N - v_N\rangle_{X'_N,X_N} \leq 0 \ \forall w_N \in K_N\}.$$

In particular, $N_{K_N}(v_N) = \emptyset$ if $v_N \notin K_N$. The subgradient of $j(\mathcal{F}\lambda_N, u_T)$ with respect to the second variable is given by

$$\partial_2 j(\mathcal{F}\lambda_N, u_T) = \{\mu_T \in X'_T : j(\mathcal{F}\lambda_N, v_T) \geq j(\mathcal{F}\lambda_N, u_T) + \langle \mu_T, v_T - u_T\rangle_{X'_T,X_T} \ \forall v_T \in X_T\}.$$

With this notation, problem (14) is equivalent to the following problem:

$$\text{(22)} \qquad \begin{cases} \text{Find } u \in V,\ \lambda_N \in X'_N, \text{ and } \lambda_T \in X'_T \text{ satisfying} \\ (u_N, u_T) = \mathbb{E}(\lambda_N, \lambda_T), \\ -\lambda_N \in N_{K_N}(u_N - g) \quad \text{in } X'_N, \\ -\lambda_T \in \partial_2 j(\mathcal{F}\lambda_N, u_T) \quad \text{in } X'_T. \end{cases}$$

More details on this equivalence can be found in [13].

Remark 1. Inclusion $-\lambda_N \in N_{K_N}(u_N - g)$ is equivalent to the complementarity relations

$$u_N \leq g, \quad \langle \lambda_N, v_N\rangle_{X'_N,X_N} \geq 0 \ \ \forall v_N \in K_N, \quad \langle \lambda_N, u_N - g\rangle_{X'_N,X_N} = 0,$$

which is the weak formulation of the strong complementarity relations (5) for the contact conditions. Similarly, the second inclusion $-\lambda_T \in \partial_2 j(\mathcal{F}\lambda_N, u_T)$ represents the friction condition.

1.4. Hybrid weak inclusion formulation. We will now consider the sets of admissible stresses. The set of admissible normal stresses on Γ_C can be defined as

$$\Lambda_N = \{\lambda_N \in X'_N : \langle \lambda_N, v_N\rangle_{X'_N,X_N} \geq 0 \ \ \forall v_N \in K_N\}.$$

This is the opposite of K_N^*, the polar cone to K_N. The set of admissible tangential stresses on Γ_C can be defined as

$$\Lambda_T(\mathcal{F}\lambda_N) = \{\lambda_T \in X_T' : -\langle \lambda_T, w_T\rangle_{X_T', X_T} + \langle \mathcal{F}\lambda_N, |w_T|\rangle_{X_N', X_N} \leq 0 \ \ \forall w_T \in X_T\}.$$

With this, problem (14) is equivalent to the following problem:

$$\text{(23)} \qquad \begin{cases} \text{Find } u \in V,\ \lambda_N \in X_N',\ \text{and } \lambda_T \in X_T' \text{ satisfying} \\ (u_N, u_T) = \mathbb{E}(\lambda_N, \lambda_T), \\ -(u_N - g) \in N_{\Lambda_N}(\lambda_N) \quad \text{in } X_N, \\ -u_T \in N_{\Lambda_T(\mathcal{F}\lambda_N)}(\lambda_T) \quad \text{in } X_T, \end{cases}$$

where the two inclusions can be replaced by inequalities as follows:

$$\text{(24)} \qquad \begin{cases} \text{Find } u \in V,\ \lambda_N \in X_N',\ \text{and } \lambda_T \in X_T' \text{ satisfying} \\ (u_N, u_T) = \mathbb{E}(\lambda_N, \lambda_T), \\ \lambda_N \in \Lambda_N, \ \ \langle \mu_N - \lambda_N, u_N - g\rangle_{X_N', X_N} \geq 0 \ \ \forall \mu_N \in \Lambda_N, \\ \lambda_T \in \Lambda_T(\mathcal{F}\lambda_N), \ \ \langle \mu_T - \lambda_T, u_T\rangle_{X_T', X_T} \geq 0 \ \ \forall \mu_T \in \Lambda_T(\mathcal{F}\lambda_N). \end{cases}$$

Remark 2. The inclusion $-u_T \in N_{\Lambda_T(\mathcal{F}\lambda_N)}(\lambda_T)$ implies the complementarity relation

$$\langle \lambda_T, u_T\rangle_{X_T', X_T} = \langle \mathcal{F}\lambda_N, |u_T|\rangle_{X_N', X_N}$$

and the weak maximum dissipation principle

$$-\langle \lambda_T, u_T\rangle_{X_T', X_T} = \sup_{\mu_T \in \Lambda_T(\mathcal{F}\lambda_N)} \langle -\mu_T, u_T\rangle_{X_T', X_T},$$

which is the weak formulation of (8).

2. Optimal a priori estimates on the solutions to the Coulomb problem. For the sake of simplicity, a vanishing contact gap ($g \equiv 0$) will be considered in the following.

Remark 3. In the case of a nonvanishing gap, it is possible to find $u_g \in V$ such that $u_{g|_{\Gamma_C}} = g\mathrm{n}$, and then $w = u - u_g$ is solution to the problem

$$\text{(25)} \qquad \begin{cases} \text{Find } w \in V,\ \lambda_N \in X_N',\ \text{and } \lambda_T \in X_T' \text{ satisfying} \\ a(w, v) = l(v) - a(u_g, v) + \langle \lambda_N, w_N\rangle_{X_N', X_N} + \langle \lambda_T, w_T\rangle_{X_T', X_T}, \\ -w_N \in N_{\Lambda_N}(\lambda_N) \quad \text{in } X_N, \\ -w_T \in N_{\Lambda_T(\mathcal{F}\lambda_N)}(\lambda_T) \quad \text{in } X_T, \end{cases}$$

i.e., a contact problem without gap but with a modified source term.

Following Remarks 1 and 2, a solution (u, λ) to problem (22) (i.e., a solution u to problem (14)) satisfies the complementarity relations

$$\langle \lambda_N, u_N \rangle_{X'_N, X_N} = 0,$$

$$\langle \lambda_T, u_T \rangle_{X'_T, X_T} = \langle \mathcal{F}\lambda_N, |u_T| \rangle_{X'_N, X_N}.$$

This implies

$$\langle \lambda, u \rangle_{X', X} \leq 0,$$

which expresses the dissipativity of contact and friction conditions. The first consequence of this is that solutions to problem (14) can be bounded independently of the friction coefficient.

PROPOSITION 1. *Assuming hypotheses* (10), (11), *and* (13) *are satisfied and* $g \equiv 0$, *let* (u, λ) *be a solution to problem* (22), *which means that* u *is a solution to problem* (14); *then*

$$\|u\|_a \leq L_a, \quad \|\lambda\|_{-a,\Gamma_C} \leq L_a,$$

$$\|u\|_V \leq \frac{L}{\alpha}, \quad \|\lambda\|_{X'} \leq L\gamma\sqrt{\frac{M}{\alpha}}.$$

Proof. One has

$$\|u\|_a^2 = a(u,u) = l(u) + \langle \lambda, u \rangle_{X',X} \leq L_a \|u\|_a,$$

which states the first estimates. The estimate on $\|\lambda\|_{-a,\Gamma_C}$ can be performed using the intermediary solution $u^{\mathcal{N}}$ to the following problem with a homogeneous Neumann condition on Γ_C:

$$a(u^{\mathcal{N}}, v) = l(v) \quad \forall v \in V. \tag{26}$$

Since $\|u^{\mathcal{N}}\|_a \leq L_a$ for the same reason as for u, and using Lemma 1, one has

$$\|\lambda - 0\|_{-a,\Gamma_C}^2 = a(u - u^{\mathcal{N}}, u - u^{\mathcal{N}}) = \langle \lambda, u - u^{\mathcal{N}} \rangle_{X',X} \leq -\langle \lambda, u^{\mathcal{N}} \rangle_{X',X} \leq L_a \|\lambda\|_{-a,\Gamma_C}.$$

The two last estimates can be stated thanks to equivalence of norms introduced in section 1.1. ∎

It is possible to compare $\|u\|_a$ to the corresponding norm of the solution u^c to the Signorini problem without friction defined as follows:

$$\begin{cases} \text{Find } u^c \in K \text{ satisfying} \\ \\ a(u^c, v - u^c) \geq l(v - u^c) \quad \forall\ v \in K. \end{cases} \tag{27}$$

It is well known that under hypotheses (10) and (11), this problem has a unique solution (see [12]).

PROPOSITION 2. *Assuming hypotheses* (10), (11), *and* (13) *are satisfied and* $g \equiv 0$, *let* u *be a solution to problem* (14), *let* u^c *be the unique solution to problem* (27), *and let* $u^{\mathcal{N}}$ *be the solution to problem* (26); *then*

$$\|u\|_a \leq \|u^c\|_a \leq \|u^{\mathcal{N}}\|_a.$$

Proof. One has

$$a(u^{\mathcal{N}}, u^{\mathcal{N}}) = l(u^{\mathcal{N}}), \quad a(u^c, u^c) = l(u^c), \quad a(u,u) = l(u) + \langle \lambda_{_T}, u_{_T} \rangle_{X'_{_T}, X_{_T}}.$$

Since u^c is the solution to the Signorini problem without friction, it minimizes over K the energy functional $\frac{1}{2}a(v,v) - l(v)$. The solution $u^{\mathcal{N}}$ minimizes this energy functional over V. Thus, since $u \in K$, one has

$$\frac{1}{2}a(u^{\mathcal{N}}, u^{\mathcal{N}}) - l(u^{\mathcal{N}}) \leq \frac{1}{2}a(u^c, u^c) - l(u^c) \leq \frac{1}{2}a(u,u) - l(u),$$

and the following relations allow one to conclude that

$$a(u^c, u^c) - a(u^{\mathcal{N}}, u^{\mathcal{N}}) = l(u^c - u^{\mathcal{N}}),$$

$$a(u,u) - a(u^c, u^c) = l(u - u^c) + \langle \lambda_{_T}, u_{_T} \rangle_{X'_{_T}, X_{_T}}$$

because then

$$\frac{1}{2}a(u^c, u^c) - \frac{1}{2}a(u^{\mathcal{N}}, u^{\mathcal{N}}) \leq 0,$$

$$\frac{1}{2}a(u,u) \leq \frac{1}{2}a(u^c, u^c) + \langle \mathcal{F}\lambda_{_N}, |u_{_T}| \rangle_{X'_{_N}, X_{_N}} \leq \frac{1}{2}a(u^c, u^c). \qquad \square$$

It is also possible to estimate how far from u^c is a solution u to problem (14). Let us introduce the following norms on $\Gamma_{_C}$. For $v \in X$ let us define

$$\|v_{_T}\|_{a,\Gamma_{_C}} = \inf_{\substack{w \in V \\ w_{_T} = v_{_T}}} \|w\|_a = \inf_{\substack{z \in X \\ z_{_T} = v_{_T}}} \|z\|_{a,\Gamma_{_C}},$$

$$\|v_{_N}\|_{a,\Gamma_{_C}} = \inf_{\substack{w \in V \\ w_{_N} = v_{_N}}} \|w\|_a = \inf_{\substack{z \in X \\ z_{_N} = v_{_N}}} \|v\|_{a,\Gamma_{_C}}.$$

One has

$$\|v_{_T}\|_{a,\Gamma_{_C}} \leq \|v\|_{a,\Gamma_{_C}}, \quad \|v_{_N}\|_{a,\Gamma_{_C}} \leq \|v\|_{a,\Gamma_{_C}}.$$

Now, for $\lambda \in X'$, let us define

$$\|\lambda_{_T}\|_{-a,\Gamma_{_C}} = \sup_{\substack{v_{_T} \in X_{_T} \\ v_{_T} \neq 0}} \frac{\langle \lambda_{_T}, v_{_T} \rangle_{X'_{_T}, X_{_T}}}{\|v_{_T}\|_{a,\Gamma_{_C}}} = \sup_{\substack{v \in X \\ v \neq 0}} \frac{\langle \lambda_{_T}, v_{_T} \rangle_{X'_{_T}, X_{_T}}}{\|v\|_{a,\Gamma_{_C}}},$$

$$\|\lambda_{_N}\|_{-a,\Gamma_{_C}} = \sup_{\substack{v_{_N} \in X_{_N} \\ v_{_N} \neq 0}} \frac{\langle \lambda_{_N}, v_{_N} \rangle_{X'_{_N}, X_{_N}}}{\|v_{_N}\|_{a,\Gamma_{_C}}} = \sup_{\substack{v \in X \\ v \neq 0}} \frac{\langle \lambda_{_N}, v_{_N} \rangle_{X'_{_N}, X_{_N}}}{\|v\|_{a,\Gamma_{_C}}}.$$

Then, the following equivalences of norms are immediate:

$$\frac{\sqrt{\alpha}}{C_1}\|v_{_N}\|_{_{X_N}} \leq \|v_{_N}\|_{a,\Gamma_{_C}} \leq \gamma\sqrt{M}\|v_{_N}\|_{_{X_N}},$$

$$\frac{\sqrt{\alpha}}{C_1}\|v_{_T}\|_{_{X_T}} \leq \|v_{_T}\|_{a,\Gamma_{_C}} \leq \gamma\sqrt{M}\|v_{_T}\|_{_{X_T}},$$

$$\frac{1}{\gamma\sqrt{M}}\|\lambda_N\|_{X'_N} \leq \|\lambda_N\|_{-a,\Gamma_C} \leq \frac{C_1}{\sqrt{\alpha}}\|\lambda_N\|_{X'_N},$$

$$\frac{1}{\gamma\sqrt{M}}\|\lambda_T\|_{X'_T} \leq \|\lambda_T\|_{-a,\Gamma_C} \leq \frac{C_1}{\sqrt{\alpha}}\|\lambda_T\|_{X'_T}.$$

And the following result can be easily deduced.

LEMMA 2. *There exists $C_3 > 0$ such that for all $\lambda \in X'$*

$$\|\lambda_T\|_{-a,\Gamma_C} \leq C_3\|\lambda\|_{-a,\Gamma_C}, \quad \|\lambda_N\|_{-a,\Gamma_C} \leq C_3\|\lambda\|_{-a,\Gamma_C}.$$

This also allows us to define an equivalent norm on MX_N given for $\mathcal{F} \in MX_N$ by

$$\|\mathcal{F}\|_a = \sup_{\substack{v_N \in X_N \\ v_N \neq 0}} \frac{\|\mathcal{F}v_N\|_{a,\Gamma_C}}{\|v_N\|_{a,\Gamma_C}},$$

which satisfies

$$\frac{\sqrt{\alpha}}{C_1\gamma\sqrt{M}}\|\mathcal{F}\|_a \leq \|\mathcal{F}\|_{MX_N} \leq \frac{C_1\gamma\sqrt{M}}{\sqrt{\alpha}}\|\mathcal{F}\|_a.$$

With these definitions, the following result holds.

LEMMA 3. *There exists $C_4 > 0$ such that*

$$\|\mathcal{F}|v_T|\,\|_{a,\Gamma_C} \leq C_4\|\mathcal{F}\|_a\|v_T\|_{a,\Gamma_C} \quad \forall v_T \in X_T.$$

Proof. One has

$$\|\mathcal{F}|v_T|\,\|_{a,\Gamma_C} \leq \|\mathcal{F}\|_a\|\,|v_T|\,\|_{a,\Gamma_C}.$$

Moreover, it is known (see [1]) that the norm $\|\cdot\|_{X_N}$ is equivalent to the norm

$$\|v_N\|^2_{1/2,\Gamma_C} = \|v_N\|^2_{L^2(\Gamma_C)} + \int_{\Gamma_C}\int_{\Gamma_C} \frac{|v_N(x) - v_N(y)|^2}{|x-y|^d}dxdy,$$

and it is easy to verify that $\|\,|v_T|\,\|_{1/2,\Gamma_C} \leq \|v_T\|_{1/2,\Gamma_C}$ for any $v_T \in X_T$. Thus, the result can be deduced from the previously presented equivalences of norms. ∎

Of course the tangential stress on Γ_C corresponding to u^c is vanishing. The tangential stress corresponding to u can be estimated as follows. As $\lambda_T \in \Lambda_T(\mathcal{F}\lambda_N)$, one has

$$\|\lambda_T\|_{-a,\Gamma_C} = \sup_{\substack{v_T \in X_T \\ v_T \neq 0}} \frac{\langle \lambda_T, v_T\rangle_{X'_T,X_T}}{\|v_T\|_{a,\Gamma_C}} \leq \sup_{\substack{v_T \in X_T \\ v_T \neq 0}} \frac{-\langle \mathcal{F}\lambda_N, |v_T|\rangle_{X'_N,X_N}}{\|v_T\|_{a,\Gamma_C}}$$
$$\leq C_4\|\mathcal{F}\|_a\|\lambda_N\|_{-a,\Gamma_C}.$$

Now, with the result of Proposition 1 this means that

$$\|\lambda_T\|_{-a,\Gamma_C} \leq L_a C_3 C_4\|\mathcal{F}\|_a, \tag{28}$$

and the following result holds.

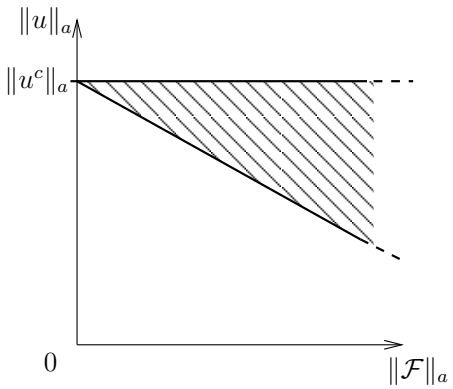

FIG. 3. *Admissibility zone for* $\|u\|_a$.

PROPOSITION 3. *Assuming hypotheses* (10), (11), *and* (13) *are satisfied and* $g \equiv 0$, *let* u *be a solution to problem* (14) *and let* u^c *be the solution to problem* (27); *then*

$$\|u^c - u\|_a \leq L_a C_3 C_4 \|\mathcal{F}\|_a,$$
$$\|u^c - u\|_V \leq \frac{L C_3 C_4}{\alpha} \|\mathcal{F}\|_a.$$

Proof. With $\lambda \in X'$ and $\lambda^c \in X'$ the corresponding stresses on Γ_C, because $-\lambda_N^c \in N_{K_N}(u_N^c)$ and $-\lambda_N \in N_{K_N}(u_N - g)$ and because of the fact that N_{K_N} is a monotone set-valued map, one has

$$\langle \lambda_N^c - \lambda_N, u_N^c - u_N \rangle_{X'_N, X_N} \leq 0.$$

Now, $\|u^c - u\|_a$ can be estimated as follows:

$$\|u^c - u\|_a^2 = a(u^c - u, u^c - u) = \langle \lambda^c - \lambda, u^c - u \rangle_{X',X} \leq \|\lambda_T\|_{-a,\Gamma_C} \|u^c - u\|_a,$$

which gives the result taking into account (28). □

The latter result implies that if problem (14) has several solutions, then they are in a ball of radius $L_a C_3 C_4 \|\mathcal{F}\|_a$ centered around u^c. In particular, if u^1 and u^2 are two solutions to problem (14), one has $\|u^1 - u^2\|_a \leq 2 L_a C_3 C_4 \|\mathcal{F}\|_a$. This is illustrated by Figure 3.

Remark 4. For a friction coefficient $\mathcal{F}$ constant on Γ_C, the graph in Figure 3 can be more precise for $\mathcal{F} = \|\mathcal{F}\|_a$ small, since, from the proof of Proposition 2 and the continuity result given by the latter proposition, one can deduce $\|u\|_a^2 \leq \|u^c\|_a^2 + \mathcal{F}\langle \lambda_N^c, |u_T^c| \rangle_{X'_N, X_N}$ at least if $\langle \lambda_N^c, |u_T^c| \rangle_{X'_N, X_N} < 0$. Of course, if $\langle \lambda_N^c, |u_T^c| \rangle_{X'_N, X_N} = 0$, the solution u^c to the Signorini problem without friction is also a solution to the Coulomb problem for any friction coefficient.

3. Elementary estimates on the Tresca problem. What is usually called the Tresca problem is the friction problem with a given friction threshold. Let $\theta \in X'_N$ be given. Then it can be formulated as follows:

$$\text{(29)} \qquad \begin{cases} \text{Find } u \in K \text{ satisfying} \\ \\ a(u, v-u) + j(\theta, v_T) - j(\theta, u_T) \geq l(v-u) \quad \forall\, v \in K. \end{cases}$$

It is well known that under standard hypotheses (10), (11), and (13), this problem has a unique solution (see [12]) which minimizes the functional $\frac{1}{2}a(u,u)+j(\theta,u)-l(u)$.

In fact, it is not difficult to verify that all the estimates given in the previous section for the solutions to the Coulomb problem are still valid for the solution to the Tresca problem. Moreover, the solution to the Tresca problem continuously depends on the friction threshold θ. This result is stated in the following lemma.

LEMMA 4. *Assuming hypotheses* (10), (11), *and* (13) *are satisfied, if* u^1, u^2 *are the solutions to problem* (29) *for a friction threshold* $\theta^1 \in \Lambda_N$ *and* $\theta^2 \in \Lambda_N$, *respectively, then there exists a constant* $C_5 > 0$ *independent of* θ^1 *and* θ^2 *such that the following estimate holds:*

$$\|u^1 - u^2\|_a^2 \leq C_5 \|\theta^1 - \theta^2\|_{-a,\Gamma_C}.$$

Proof. One has

$$a(u^1, u^2 - u^1) - l(u^2 - u^1) + j(\theta^1, u^2) - j(\theta^1, u^1) \geq 0,$$

$$a(u^2, u^1 - u^2) - l(u^1 - u^2) + j(\theta^2, u^1) - j(\theta^2, u^2) \geq 0,$$

which implies

$$\|u^1 - u^2\|_a^2 \quad \leq \quad \langle \theta^1 - \theta^2, |u_T^1| - |u_T^2| \rangle_{X'_N, X_N},$$

which gives the estimate using Proposition 1 (in fact, $C_5 \leq 2C_4 L_a$). ∎

Remark 5. It does not seem possible to establish a Lipschitz continuity with respect to the friction threshold θ. Such a result would automatically imply the uniqueness of the solution to the Coulomb problem for a sufficiently small friction coefficient.

4. A uniqueness criterion. Hild in [7, 8] exhibits some multisolutions for the Coulomb problem on triangular domains. These solutions have been obtained for a large friction coefficient ($\mathcal{F} > 1$) and for a tangential displacement having a constant sign. For the moment, it seems that no multisolution has been exhibited for an arbitrary small friction coefficient in the continuous case, although such a result exists for finite element approximation in [6], albeit for a variable geometry. As far as we know, no uniqueness result has been proved even for a sufficiently small friction coefficient. The result presented here is a partial uniqueness result, which determines some cases where it is possible to say that a particular solution of the Coulomb problem is in fact the unique solution. A contrario, this result can be used to search multisolutions for an arbitrary small friction coefficient, by the fact that it eliminates a lot of situations. The partial uniqueness results we present in this section are deduced from the estimate given by the following lemma.

LEMMA 5. *Assuming hypotheses* (10), (11), *and* (13) *are satisfied and* $g \equiv 0$, *if* u^1 *and* u^2 *are two solutions to problem* (14) *and* λ^1 *and* λ^2 *are the corresponding contact stresses on* Γ_C, *then one has the following estimate:*

$$\|u^1 - u^2\|_a^2 = \|\lambda^1 - \lambda^2\|_{-a,\Gamma_C}^2 \leq \quad \langle \zeta - \lambda_T^2, u_T^1 - u_T^2 \rangle_{X'_T, X_T} \qquad \forall \zeta \in -\partial_2 j(\mathcal{F}\lambda_N^1, u_T^2).$$

Proof. One has

$$\|u^1 - u^2\|_a^2 = \|\lambda^1 - \lambda^2\|_{-a,\Gamma_C}^2 = \langle \lambda_N^1 - \lambda_N^2, u_N^1 - u_N^2 \rangle_{X'_N, X_N} + \langle \lambda_T^1 - \lambda_T^2, u_T^1 - u_T^2 \rangle_{X'_T, X_T}.$$

Because N_{K_N} is a monotone set-valued map, one has $\langle \lambda_N^1 - \lambda_N^2, u_N^1 - u_N^2 \rangle_{X'_N, X_N} \leq 0$. Thus

$$\|u^1 - u^2\|_a^2 \leq \langle (\lambda_T^1 - \zeta) + (\zeta - \lambda_T^2), u_T^1 - u_T^2 \rangle_{X'_T, X_T} \qquad \forall \zeta \in -\partial_2 j(\mathcal{F}\lambda_N^1, u_T^2).$$

But $\partial_2 j(\mathcal{F}\lambda_N, u_T)$ is also a monotone set-valued map with respect to its second variable, which implies the result (and also the fact that $\|u^1 - u^2\|_a^2 \leq \inf_{\zeta \in -\partial_2 j(\mathcal{F}\lambda_N^1, u_T^2)} \|\zeta - \lambda_T^2\|_{-a,\Gamma_C}$). ∎

An immediate consequence of this lemma is the following result for a vanishing tangential displacement.

PROPOSITION 4. *Assuming hypotheses* (10), (11), *and* (13) *are satisfied and* $g \equiv 0$, *if* u *is a solution to problem* (14) *such that* $u_T = 0$ *a.e. on* Γ_C *and if* $C_3 C_4 \|\mathcal{F}\|_a < 1$, *then* u *is the unique solution to problem* (14).

Proof. Let us assume that $\overline{u}$ is another solution to problem (14). Then from Lemma 5 one has

$$\|u - \overline{u}\|_a^2 \leq \langle \zeta - \overline{\lambda}_T, u_T - \overline{u}_T \rangle_{X'_T, X_T} \qquad \forall \zeta \in -\partial_2 j(\mathcal{F}\lambda_N, \overline{u}_T),$$

but, because $u_T = 0$ and due to the complementarity relations $\langle \overline{\lambda}_T, \overline{u}_T \rangle_{X'_T, X_T} = \langle \mathcal{F}\overline{\lambda}_N, |\overline{u}_T| \rangle_{X'_N, X_N}$ and $\langle \zeta, \overline{u}_T \rangle_{X'_T, X_T} = \langle \mathcal{F}\lambda_N, |\overline{u}_T| \rangle_{X'_N, X_N}$, it implies using Lemma 3 that

$$\begin{aligned} \|u - \overline{u}\|_a^2 &\leq \langle \mathcal{F}(\overline{\lambda}_N - \lambda_N), |\overline{u}_T| \rangle_{X'_N, X_N} \leq C_3 C_4 \|\mathcal{F}\|_a \|\lambda - \overline{\lambda}\|_{-a,\Gamma_C} \|u_T - \overline{u}_T\|_{a,\Gamma_C}^2 \\ &\leq C_3 C_4 \|\mathcal{F}\|_a \|u - \overline{u}\|_a^2, \end{aligned}$$

which concludes the proof. ∎

In the case $d = 2$, it is possible to give a result to a solution having a tangential displacement with a constant sign on Γ_C. We will say that a tangential displacement $u_T \in X_T$ is strictly positive if $\langle \mu_T, u_T \rangle_{X'_T, X_T} > 0$ for all $\mu_T \in X'_T$ such that $\mu_T \geq 0$ (i.e., $\langle \mu_T, v_T \rangle_{X'_T, X_T} \geq 0$ for all $v_T \in X_T$, $v_T \geq 0$, a.e. on Γ_C) and $\mu_T \neq 0$.

PROPOSITION 5. *Assuming hypotheses* (10), (11), *and* (13) *are satisfied,* $g \equiv 0$, *and* $d = 2$, *if* u *is a solution to problem* (14) *such that* $u_T > 0$ *and* $C_3 \|\mathcal{F}\|_a < 1$, *then* u *is the unique solution to problem* (14) *(when* $\mathcal{F}$ *is constant over* Γ_C, *the condition reduces to* $C_3 \mathcal{F} < 1$*).*

Proof. Let us assume that $\overline{u}$ is another solution to problem (14), with $\overline{\lambda}_N$ and $\overline{\lambda}_T$ the corresponding contact stresses on Γ_C. Then from Lemma 5 one has

$$\|\overline{u} - u\|_a^2 \leq \langle \zeta - \lambda_T, \overline{u}_T - u_T \rangle_{X'_T, X_T} \qquad \forall \zeta \in -\partial_2 j(\mathcal{F}\overline{\lambda}_N, u_T).$$

Because $u_T > 0$, one has $\lambda_T = \mathcal{F}\lambda_N$ and $-\partial_2 j(\mathcal{F}\overline{\lambda}_N, u_T)$ contains $\mathcal{F}\overline{\lambda}_N$. Thus, taking $\zeta = \mathcal{F}\overline{\lambda}_N$, one obtains

$$\|\overline{u} - u\|_a^2 \leq \langle \mathcal{F}(\overline{\lambda}_N - \lambda_N), \overline{u}_T - u_T \rangle_{X'_T, X_T} \leq \|\overline{\lambda} - \lambda\|_{-a,\Gamma_C} \|\mathcal{F}(\overline{u} - u)\|_a \leq \|\mathcal{F}\|_a \|\overline{u} - u\|_a^2,$$

which implies $\overline{u} = u$ when $\|\mathcal{F}\|_a < 1$. ∎

Of course, the same reasoning is valid for $u_T < 0$.

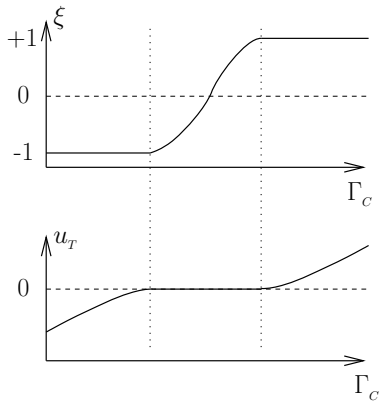

FIG. 4. *Example of tangential displacement u_T and a possible corresponding multiplier ξ for $d = 2$.*

Let us now define the space of multipliers $M(X_T \to X_N)$ of the functions $\xi : \Gamma_C \to \mathbb{R}^d$ such that $\xi \cdot \mathrm{n} = 0$ a.e. on Γ_C and such that the following two equivalent norms are finite:

$$\|\xi\|_{M(X_T \to X_N)} = \sup_{\substack{v_T \in X_T \\ v_T \neq 0}} \frac{\|\xi \cdot v_T\|_{X_N}}{\|v_T\|_{X_T}} \quad \text{and} \quad \|\xi\|_a = \sup_{\substack{v_T \in X_T \\ v_T \neq 0}} \frac{\|\xi \cdot v_T\|_{a,\Gamma_C}}{\|v_T\|_{a,\Gamma_C}}.$$

Because Γ_C is assumed to have the $\mathcal{C}^1$ regularity, $M(X_T \to X_N)$ is isomorphic to $(MX_N)^{d-1}$.

It is possible to give a more general result assuming that $\lambda_T = \mathcal{F}\lambda_N\xi$, with $\xi \in M(X_T \to X_N)$. It is easy to see that this implies that $|\xi| \leq 1$ a.e. on the support of λ_N and, more precisely, that $\xi \in \mathrm{Dir}_T(u_T)$ a.e. on the support of λ_N, where $\mathrm{Dir}_T(.)$ is the subderivative of the convex map $\mathbb{R}^d \ni x \longmapsto |x_T|$. This means that it is reasonable to assume that $\xi \in \mathrm{Dir}_T(u_T)$ a.e. on Γ_C.

PROPOSITION 6. *Assuming hypotheses* (10), (11), *and* (13) *are satisfied and $g \equiv 0$, if u is a solution to problem* (14) *such that $\lambda_T = \mathcal{F}\lambda_N\xi$, with $\xi \in M(X_T \to X_N)$, $\xi \in \mathrm{Dir}_T(u_T)$ a.e. on Γ_C, and $C_3\|\mathcal{F}\|_a\|\xi\|_a < 1$, then u is the unique solution to problem* (14).

Proof. Let us assume that $\overline{u}$ is another solution to problem (14), with $\overline{\lambda}_N$ and $\overline{\lambda}_T$ the corresponding contact stresses on Γ_C. Then from Lemma 5 one has

$$\|\overline{u} - u\|_a^2 \leq \langle \zeta - \lambda_T, \overline{u}_T - u_T \rangle_{X_T', X_T} \qquad \forall \zeta \in -\partial_2 j(\mathcal{F}\overline{\lambda}_N, u_T).$$

Then, a possible choice is $\zeta = \mathcal{F}\overline{\lambda}_N\xi$, which, together with the fact that $\|\mathcal{F}\xi\|_a \leq \|\mathcal{F}\|_a\|\xi\|_a$, gives

$$\begin{aligned}\|\overline{u} - u\|_a^2 \leq \langle \mathcal{F}\xi(\overline{\lambda}_N - \lambda_N), \overline{u}_T - u_T \rangle_{X_T', X_T} &\leq C_3\|\mathcal{F}\|_a\|\xi\|_a\|\overline{\lambda} - \lambda\|_{-a,\Gamma_C}\|\overline{u} - u\|_a \\ &\leq C_3\|\mathcal{F}\|_a\|\xi\|_a\|\overline{u} - u\|_a^2,\end{aligned}$$

which implies $\overline{u} = u$ when $C_3\|\mathcal{F}\|_a\|\xi\|_a < 1$. ∎

Remark 6. Using equivalences of norms, one can deduce that a more restrictive condition than $C_3\|\mathcal{F}\|_a\|\xi\|_a < 1$ is the condition $\|\mathcal{F}\|_{MX_N}\|\xi\|_{M(X_T \to X_N)} < \frac{\sqrt{\alpha}}{C_1C_3\gamma\sqrt{M}}$.

As illustrated in Figure 4, for $d = 2$, the multiplier ξ has to vary from -1 to $+1$ each time the sign of the tangential displacement changes from negative to positive.

The set $M(X_T \to X_N)$ does not contain any multiplier having a discontinuity of the first kind. This implies that in order to satisfy the assumptions of Proposition 6 the tangential displacement of the solution u cannot pass from a negative value to a positive value, being zero on only a single point of Γ_C.

Perspectives. As far as we know, the result given by Propositions 4, 5, and 6 are the first results dealing with the uniqueness of the solution to the Coulomb problem without considering a regularization of the contact or the friction law. In the future, it may be interesting to investigate the following open problems.

Is it possible to prove that, for a sufficiently regular domain and a sufficiently regular loading, a solution of the Coulomb problem is necessarily such that $\lambda_T = \mathcal{F}\lambda_N\xi$ with $\xi \in M(X_T \to X_N)$? This could be a way to prove a uniqueness result for a sufficiently small friction coefficient and regular loadings.

The more the tangential displacement u_T oscillates around 0 (i.e., the more u_T changes its sign for $d = 2$), the more the multiplier ξ varies and thus the greater $\|\xi\|_{M(X_T \to X_N)}$ is. Does it mean that a multisolution for an arbitrary small friction coefficient and a fixed geometry has to be searched with very oscillating tangential displacement (necessarily for all the solutions)?

Finally, the convergence of finite element methods in the uniqueness framework given by Proposition 6 will be presented in [10].

SCALING OF THE ENERGY FOR THIN MARTENSITIC FILMS*

NIRMALENDU CHAUDHURI† AND STEFAN MÜLLER‡

Abstract. We study the scaling behavior of thin martensitic films. Specifically we consider an elastic energy with two $SO(3)$ invariant wells which are strongly incompatible in the sense of Matos and Šverák, but whose two-dimensional projections may be compatible. We show that in a thin film of thickness h the energy per unit height scales like h. This scaling lies in between the classical membrane theory (where the energy per unit height is of order 1) and the Kirchhoff bending theory, which corresponds to a scaling of h^2.

Key words. thin films, martensitic phase transitions, variational methods for solids

1. Introduction.

1.1. Main result. We study the scaling of the elastic energy for a thin film made of a multiphase material. Specifically we consider the cylindrical domain

$$\Omega_h := S \times \left(-\frac{h}{2}\,,\,\frac{h}{2}\right) \subset \mathbb{R}^3, \tag{1}$$

an elastic deformation

$$v : \Omega_h \to \mathbb{R}^3, \tag{2}$$

and its energy (per unit height)

$$E^h(v) := \frac{1}{h}\int_{\Omega_h} W(\nabla v(x))dx. \tag{3}$$

We suppose that the stored energy density W, which is defined on the space $\mathbb{M}^{3\times 3}$ of 3×3 matrices, is nonnegative and vanishes exactly on the set

$$K := SO(3) \cup SO(3)\,H, \quad \det H > 0, \tag{4}$$

which consists of two copies of the group $SO(3) = \{F \in \mathbb{M}^{3\times 3} : F^TF = Id_3, \det F = 1\}$ of rotations, corresponding to two preferred crystalline configurations or phases (see (7)–(9) and (10) below for the full list of assumptions on W). We are interested in low-energy deformations, and these are characterized by the fact that ∇v is close to K, except possibly on a set of small measure.

Bhattacharya and James [5] made the crucial observation that for a number of interesting materials the low-energy states are very different in three-dimensional

(bulk) samples and in the thin film limit. If Id_3 represents the austenite (high-temperature) phase and H represents one of the martensitic phases, then these are usually incompatible in bulk; in particular, there are no nontrivial zero energy states. By contrast, the limiting thin film membrane energy

$$I_{\text{membrane}} := \int_S W_{\text{membrane}}(\nabla' v)\, dx', \quad \text{where } x' = (x_1, x_2), \quad \nabla' := (\partial_1, \partial_2), \tag{5}$$

which, roughly speaking, is the Γ-limit of E^h (see section 1.2 for a more detailed discussion), admits many nontrivial zero energy states, including lamellar arrangements of the two phases, as well as more complicated, e.g., tent-like, structures; see [5]. This drastic difference in the behavior stems from the fact that the three-dimensional compatibility requires the existence of an invariant plane (i.e., Id_3 and RH have to agree on a plane, for some $R \in SO(3)$), while two-dimensional compatibility requires only an invariant line (in the film plane), i.e., one needs a vector v in the film plane such that $v = RHv$. Suppose such a vector v exists. Then in a film of small, but finite, thickness h the juxtaposition of the deformation gradients Id_3 and RH (along a line in direction v) leads to a mismatch of the deformations of order h. Separating the two regions by a strip of width proportional to h, one sees easily that there exist three-dimensional deformations $v^{(h)}$ which have a nontrivial thin film limit and whose energy is bounded from above by Ch.

Our main result that this scaling is optimal. To state the result precisely it is convenient to introduce the rescaling $y(x) := v(x_1, x_2, hx_3)$ and the notation $\Omega := \Omega_1 = S \times (-1/2, 1/2)$. Then $y : \Omega \to \mathbb{R}^3$. As above, we write $\nabla' y = (y_{,1}, y_{,2}) = y_{,1} \otimes e_1 + y_{,2} \otimes e_2$ for the gradient in the plane, where $\otimes$ denotes the tensor product, and $\nabla_h y = (y_{,1}, y_{,2}, \frac{1}{h} y_{,3})$. Thus the elastic energy per unit height is given by

$$I^h(y) := E^h(v) = \int_\Omega W(\nabla_h y) dx\,. \tag{6}$$

We assume that W is Borel measurable and satisfies

$$W \text{ is } C^2 \text{ in a neighborhood of } K = SO(3) \cup SO(3)\, H, \tag{7}$$

$$W \text{ is frame indifferent: } W(F) = W(RF) \text{ for all } R \in K\,, \tag{8}$$

$$W(F) \geq C\text{dist}^2(F\,, K),\ C > 0, \text{ and } W(F) = 0 \text{ if } F \in K\,. \tag{9}$$

We suppose that the two wells are strongly incompatible in the sense of Matos [21] and Šverák [30]. By polar decomposition we may suppose that H is symmetric. Hence H is diagonal in an orthonormal basis (v_1, v_2, v_3), with eigenvalues $\lambda_1, \lambda_2, \lambda_3$. From now on we suppose that the film has been cut so that v_3 is the film normal. Thus, after a suitable rotation, we may suppose that H is diagonal in the standard basis (e_1, e_2, e_3). The strong incompatibility condition reads

$$\sum_{i=1}^{3} (1 - \lambda_i) \left(1 - \frac{\det H}{\lambda_i}\right) > 0. \tag{10}$$

The above Matos–Šverák [30] condition is stronger than the usual rank-one incompatibility condition. By $O(2,3)$ we denote the set of linear isometries from $\mathbb{R}^2$ to $\mathbb{R}^3$,

i.e., the set of all 3×2 matrices F with $F^T F = Id_2$. It is easy to see that the convex hull conv $O(2,3)$ of $O(2,3)$ is given by matrices with $F^T F \leq Id_2$ (in the sense of symmetric matrices), i.e., by all linear maps with Lipschitz constant less than or equal to 1. Let $\tilde{H} := \mathrm{diag}(\lambda_1, \lambda_2)$ be the two-dimensional projection of H. Then $\tilde{H}$ is compatible with the identity if one eigenvalue is bigger than (or equal to) 1 and the other eigenvalue is less than (or equal to) 1. An example for two-dimensional compatibility and three-dimensional strong incompatibility is given by the choice $H = (\lambda, \mu, \mu)$ with $\lambda < 1 < \mu$ and $(\lambda - 1)(3\mu + 1) + 2(\mu - 1) > 0$.

THEOREM 1. *Suppose that W satisfies the conditions* (7)–(9) *and* (10). *Consider a sequence $y^{(h)}$ which satisfies*

$$\frac{1}{h} I^h(y^{(h)}) \leq C \quad \text{for all } 0 < h < h_0. \tag{11}$$

Then, as $h \to 0$, there exists a subsequence (not relabeled) such that $y^{(h)} \rightharpoonup y$ $W^{1,2}(\Omega, \mathbb{R}^3)$ (weakly) and y is independent of x_3.

Moreover, $\nabla' y \in$ conv $O(2,3)$ or $\nabla' y \, \tilde{H}^{-1} \in$ conv $O(2,3)$ a.e. in S. In other words, $\mathcal{L}^2(S \setminus E_1 \cup E_2) = 0$, where

$$E_1 := \{x' \in S : (\nabla' y(x'))^T (\nabla' y(x')) \leq Id_2\},$$
$$E_2 := \{x' \in S : \tilde{H}^{-T} (\nabla' y(x'))^T (\nabla' y(x')) \tilde{H}^{-1} \leq Id_2\}.$$

In addition we have

$$\liminf_{h \to 0} \frac{1}{h} I^h(y^{(h)}) \geq C \inf\{\mathcal{H}^1(S \cap \partial^* E) : E \text{ has finite perimeter } E \subset E_1, S \setminus E \subset E_2\}. \tag{12}$$

Remarks 1. Note that the sets E_1 and E_2 need not be disjoint.

2. The situation is complicated by the fact that in the thin film limit microstructure (i.e., fine scale oscillation of the deformation gradient) can arise from two different sources: phase mixtures and loss of compactness in thin films due to the crumbling under compression, which already occurs in single phase materials (see (17) below). It is due to the crumbling that one can only assure that the limiting deformation gradient is in the *convex hull* of $O(2,3)$ (or $O(2,3)H$) rather than $O(2,3)$ itself. Even for single phase materials crumbling can only be excluded if one has the much stronger energy bound $I^h(y^{(h)}) \leq Ch^2$ (see [12, section 5]).

3. Estimate (12) assures that the scaling proportional to h is optimal if the limit involves a nontrivial *phase* mixture. Indeed if $(1/h) I^h(y^{(h)}) \to 0$, then one can choose either $E_1 = S$ or $E_2 = S$ (up to a nullset); i.e., the corresponding limiting y can already be reached by a single phase material (see next subsection).

4. If the two-dimensional projections of the wells are incompatible, then either $\lambda_1 < 1$ and $\lambda_2 < 1$ or $\lambda_1 > 1$ and $\lambda_2 > 1$. It suffices to consider the former case. Then $E_1 \supset E_2$. Thus we have $\nabla' y \in \mathrm{conv}\, O(2,3)$ a.e., whenever (11) holds. Conversely, if $\nabla' y \in \mathrm{conv}\, O(2,3)$, then by a recent result of Conti and Maggi [9] there exist maps $y^{(h)} \rightharpoonup y$ in $W^{1,2}$ such that $h^{-1} I^h(y^{(h)}) \to 0$; see the next subsection. Thus for two-dimensional incompatible wells the admissible limiting deformations can always be reached by using a single well and crumbling.

5. The scaling $I^h \sim h$ is an unconventional one in terms of classical membrane and plate theories; it lies in between the scaling for membranes ($I^h \sim 1$) and Kirchhoff plates ($I^h \sim h^2$); see the next subsection for details.

6. The Γ-limit of the scaled functionals $(1/h)I^h$ is not known. One difficulty is that, in contrast to many other situations, one cannot expect the Γ-limit to be independent of the boundary conditions. Thus many of the usual cut-and-paste arguments do not apply; see the next subsection for further comments. For rods the corresponding Γ-limit is known; see [22].

1.2. Mathematical context. To put the result above in context, we very briefly review the theory of thin film limits for a single phase material, i.e., for energy functions W which satisfy the coercivity condition

$$W(F) \geq C \operatorname{dist}^2(F, SO(3)), \quad C > 0, \tag{13}$$

instead of (9) (for a more extended review with further references, see [14]).

The derivation of lower dimensional theories of elasticity from the three-dimensional theory has a very long and distinguished history which dates back to the beginning of elasticity theory. Rigorous results, starting from *nonlinear* elasticity, however, have only been obtained since the early 90s, beginning with the work of LeDret and Raoult [18, 19]. They showed, under an additional growth hypothesis on W from above, that the Γ-limit (with respect to strong L^2 convergence in $W^{1,2}(\Omega, \mathbb{R}^3)$) of the functionals I^h exists and is given by

$$I_{\text{membrane}} := \begin{cases} \int_S W_{\text{membrane}}(\nabla' v)\, dx' & \text{if } v_{,3} = 0, \\ \infty & \text{else.} \end{cases} \tag{14}$$

The membrane energy can be computed in two steps. First one minimizes out the derivatives in the third component (corresponding to the third column of F) and defines the energy W_2 on 3×2 matrices by

$$W_2(G) = \min\{W(G + b \otimes e_3) : b \in \mathbb{R}^3\}. \tag{15}$$

Then W_{membrane} is given as the quasi-convex hull of W_2, i.e., by minimizing out over all possible fine-scale oscillations:

$$W_{\text{membrane}}(G) := \inf \left\{ \int_{(0,1)^2} W_2(G + \nabla' \varphi)\, dx' : \varphi \in C_0^\infty((0,1)^2; \mathbb{R}^3) \right\}. \tag{16}$$

For a single well material (i.e., if W vanishes on $SO(3)$ and satisfies (13)) the reduced energy W_2 vanishes on $O(2,3)$ and

$$W_{\text{membrane}}(G) = 0 \quad \Leftrightarrow \quad G \in \operatorname{conv} O(2,3) \tag{17}$$

(the convex, quasi-convex, and rank-one convex hull of $O(2,3)$ agree). Thus the membrane energy is fully degenerate for compressions, which agrees with the physical intuition that a membrane can withstand only tension but not compression. Based on this intuition a so-called tension field theory for membranes has been used in the engineering literature for a long time [32, 28]. Pipkin [25, 26] has shown that tension-field theory arises naturally as a consequence of relaxation and quasi-convexification.

We leave for a moment the case of single phase materials to mention that the limit considered by Bhattacharya and James [5] is slightly different from that studied by LeDret and Raoult. Bhattacharya and James added a regularizing higher gradient perturbation $\kappa^2 |\nabla^2 v|^2$ to the integrand in (3) and (after the usual rescaling

$y(x_1, x_2, x_3) = v(x_1, x_2, hx_3))$ pass to the limit $h \to 0$ for fixed $\kappa > 0$. They thus obtain a limiting two-dimensional energy which involves $W_2(\nabla' y)$ (plus a higher gradient contribution involving κ) rather than $W_{\text{membrane}}(\nabla' y)$. If one takes the limit $\kappa \to 0$ in the Bhattacharya–James limiting energy, then one recovers (14). Shu [29] has shown that one also obtains (14) if one considers a $\kappa(h)$ with $\lim_{h\to 0} \kappa(h) = 0$; in fact, he gives a detailed analysis of a variety of multiparameter limits related to the scale of material heterogeneities in the tangential and normal directions (corresponding, e.g., to polycrystals or multilayers).

Let us now return to single phase materials, i.e., those for which W vanishes on $SO(3)$ and satisfies (13). For those materials it has recently become possible to study also the Γ-limit of the rescaled functionals $h^{-\beta} I^h$ and to derive a full hierarchy of plate theories. For $\beta = 2$ one obtains Kirchhoff's geometrically nonlinear bending theory [11, 12, 23, 24]. This theory imposes the isometry constraint $\nabla' y \in O(2,3)$, and the energy is given by a quadratic expression in the curvature, more precisely in the second fundamental form $A = -(\nabla')^2 y \cdot \nu$, where $\nu := y_{,1} \wedge y_{,2}$ is the normal to the deformed surface. For $\beta = 4$ one obtains the von Kármán plate theory [13]; in fact, the full range of exponents $\beta \geq 2$ is now understood [14].

In contrast, relatively little is known in the range $0 < \beta < 2$. Conti [8] has recently shown that for $0 < \beta < 1$ the Γ-limit of

$$\frac{1}{h^\beta}\left[I^h(y) - \int_\Omega h^\beta f(x') \cdot y(x)\, dx\right] \tag{18}$$

is given by

$$J(y) = \begin{cases} -\int_S f \cdot y\, dx' & \text{if } y_{,3} = 0, \quad \nabla' y \in \operatorname{conv} O(2,3), \\ \infty & \text{else.} \end{cases} \tag{19}$$

The range $1 \leq \beta < 2$ is largely unexplored in terms of rigorous analysis. In the context of delamination and blistering of thin films [15] one is lead to the study of compressive *Dirichlet* boundary conditions such as $y^{(h)}(x', x_3) = (\lambda x', h x_3)$ on $\partial S \times I$, with $0 \leq \lambda < 1$. If this boundary condition is imposed, one can show that $ch \leq \inf I^h(y^{(h)}) \leq Ch$, with $c > 0$; see [4] (as well as [17, 3] for related work). For the extension to anisotropic boundary compression, see [8]. The Γ-limit of $h^{-1} I^h$ is not known.

If instead of Dirichlet boundary conditions we assume only that $y^{(h)} \rightharpoonup (\lambda x', 0)$ in $W^{1,2}$, then much less is known. Venkataramani has constructed maps with periodic boundary conditions whose energy scales like $h^{5/3}$ [31]. His construction shows that for $\lambda = 0$ one can achieve an energy bound $Ch^{5/3}$. Conti and Maggi [9] have generalized this construction to a much larger class of limit maps. They have also shown that every short map (i.e., every map satisfying $(\nabla' y)^T \nabla' y \leq Id_2$) can be approximated in L^∞ (and weakly in $W^{1,2}$) by maps y_h with energy bounded by $Ch^{5/3-\varepsilon}$. The scaling exponent $h^{5/3}$ has been suggested in the physics literature on crumbling as a natural exponent based on a formal scaling argument and an assumed equipartition of bending and stretching energy [20, 10] (see also [2, 6]; for complex folding patterns at free boundaries and their potential relevance for certain growth models in biology, see as well [27, 1]). For a single ridge with well-defined boundary conditions Venkataramini recently showed that the energy scales indeed like $h^{5/3}$ [31].

2. Proof of the lower bound. The key ingredient in the proof is the following rigidity result.

THEOREM 2 (see [7, Theorem 2]). *Let $\Omega \subset \mathbb{R}^n$ be a bounded Lipschitz domain, $n \geq 2$ and $K := SO(n) \cup SO(n)\, H$, where $H = \mathrm{diag}(\lambda_1, \cdots \lambda_n)$, $\lambda_i > 0$, such that $\sum_{i=1}^{n} (1 - \lambda_i)\,(1 - \det H/\lambda_i) > 0$. There exists a positive constant $C(\Omega, H)$ with the following property. For each $u \in W^{1,2}(\Omega, \mathbb{R}^n)$ there is an associated $R := R(u, \Omega) \in K$ such that*

$$\|\nabla u - R\|_{L^2(\Omega)} \leq C(\Omega, H)\, \|\mathrm{dist}(\nabla u\,, K\,)\|_{L^2(\Omega)}\,. \tag{20}$$

The above rigidity estimate is proved in [7], but for the convenience of the readers we give a brief outline of the proof. Suppose $\|\mathrm{dist}(\nabla u\,, K\,)\|_{L^2(\Omega)}$ is small. Consider a smooth uniformly convex function F on $\mathbb{M}^{3\times 3}$ with quadratic growth whose gradient ∇F is the cofactor map when restricted to the set K (such a function exists; see [21]). We then decompose a given Sobolev function u into a part w which satisfies the nonlinear elliptic system of PDEs $\mathrm{div}\, \nabla F(\nabla w) = 0$ with $w = u$ on the boundary $\partial\Omega$. Then w satisfies the standard $W^{2,2}_{\mathrm{loc}}$ estimate. Exploiting that $\nabla(F - \det) = 0$ on K and the uniform monotonicity of ∇F, one can easily prove that the $W^{1,2}$ norm of the remainder $u - w$ is small. By a separation lemma (Lemma 2.4, [7]) and a careful covering argument we prove that ∇w cannot oscillate too much between the wells $SO(n)$ and $SO(n)H$. This shows that ∇w is L^2-close to a single well. Finally the rigidity estimate for a single well energy [12] yields (20).

We note that the inequality (20) is invariant under uniform scaling and translation of the domain; i.e., the same value of C serves for $\lambda\Omega + c$, and the rescaled function $\lambda v((x - c)/\lambda)$ may be associated with the same choice of $R \in K$.

Proof of Theorem 1. Suppose first that $S = (0, 1)^2$ and $h = 1/N$, $N \in \mathbb{N}$. Divide S into squares $S_{a,h}$ of side h with center at $a.$, i.e.,

$$S_{a,h} := a + \left(-\frac{h}{2}, \frac{h}{2}\right)^2, \quad a \in \mathbb{Z}^2_h, \qquad \mathbb{Z}_h := \left\{\frac{h}{2}, \frac{3h}{2}, \ldots, 1 - \frac{h}{2}\right\}. \tag{21}$$

Then $S = \cup S_{a,h}$, up to a set of measure zero. Let us define, $v^{(h)} : \Omega_h \to \mathbb{R}^3$ by $v^{(h)}(x_1, x_2, hx_3) := y^{(h)}(x_1, x_2, x_3)$ for all $x = (x_1, x_2, x_3) \in \Omega := \Omega_1$. Now we apply the rigidity Theorem 3 for $v^{(h)}$ for the domain $S_{a,h} \times \left(-\frac{h}{2}, \frac{h}{2}\right)$ to obtain a constant $C > 0$ (independent of a and h), and $R^h_a \in K = SO(3) \cup SO(3)\, H$, such that

$$\int_{S_{a,h}\times\left(-\frac{h}{2}, \frac{h}{2}\right)} |\nabla v^{(h)}(z) - R^h_a|^2 dz \leq C \int_{S_{a,h}\times\left(-\frac{h}{2}, \frac{h}{2}\right)} \mathrm{dist}^2(\nabla v^{(h)}(z), K) dz. \tag{22}$$

This yields

$$\int_{S_{a,h}\times\left(-\frac{1}{2}, \frac{1}{2}\right)} |\nabla_h y^{(h)}(x) - R^h_a|^2 dx \leq C \int_{S_{a,h}\times\left(-\frac{1}{2}, \frac{1}{2}\right)} \mathrm{dist}^2(\nabla_h y^{(h)}, K) dx, \tag{23}$$

where, as before, $\nabla_h y^{(h)} := \left(\nabla' y^{(h)}, \frac{1}{h} y_{,3}\right)$.

Define the piecewise constant map $R^h : S \to K$ by $R^h := R^h_a$ in $S_{a,h}$. Summing (23) over all $S_{a,h}$ and using (9) and (11), we obtain

$$\begin{aligned} \int_{S\times\left(-\frac{1}{2}, \frac{1}{2}\right)} |\nabla_h y^{(h)}(x) - R^h(x')|^2 dx &\leq C \int_{S\times\left(-\frac{1}{2}, \frac{1}{2}\right)} \mathrm{dist}^2(\nabla_h y^{(h)}(x), K) dx \\ &\leq C\, h\,. \end{aligned} \tag{24}$$

Thus

$$\text{(25)}\qquad \begin{cases} \nabla_h y^{(h)} - R^h \to 0 \quad \text{strongly in } L^2(\Omega, \mathbb{M}^{3\times 3}), \\ \nabla_h y^{(h)} \rightharpoonup (\nabla' y, b) \quad \text{weakly in } L^2(\Omega, \mathbb{M}^{3\times 3}), \\ R^h \rightharpoonup \overline{R} \quad \text{weakly in } L^2(S, \mathbb{M}^{3\times 3}). \end{cases}$$

From (25) we have $\overline{R} = (\nabla' y, b)$, and hence y is independent of x_3.

Let $\epsilon > 0$ be sufficiently small. We divide the family of squares $S_{a,h}$ into three different groups $\mathcal{A}_i$, $i = 0,\ 1,\ 2$, in the following manner:

$$\text{(26)}\qquad a \in \mathcal{A}_0 \quad \text{if and only if } \int_{S_{a,h}\times I} W(\nabla_h y^{(h)}(x))dx \geq \epsilon\, h^2,$$

where $I := \left(-\frac{1}{2}, \frac{1}{2}\right)$. If $a \notin \mathcal{A}_0$, Theorem 2 yields

$$\text{(27)}\qquad \frac{1}{h^2}\int_{S_{a,h}\times I} |\nabla_h y^{(h)}(x) - R^h_a|^2 dx \leq \frac{C}{h^2}\int_{S_{a,h}\times I} W(\nabla_h y^{(h)}(x))dx \leq C\epsilon\,.$$

Now define

$$\text{(28)}\qquad a \in \mathcal{A}_1 \quad \text{if and only if (27) holds for } R^h_a \in SO(3)\,,$$

$$\text{(29)}\qquad a \in \mathcal{A}_2 \quad \text{if and only if (27) holds for } R^h_a \in SO(3)\,H\,.$$

Clearly $\mathcal{A}_1 \cap \mathcal{A}_2 = \emptyset$. Thus the sets

$$\text{(30)}\qquad \Omega^h_i := \mathrm{int} ft(\cup_{a\in\mathcal{A}_i}\ \bar{S}_{a,h}),$$

$i = 0,\ 1,\ 2$, are disjoint and cover S.

Note also that the area of the set Ω^h_0 is bounded by Ch in view of (11). We now would like to estimate the length of the boundary $\partial\Omega^h_1$. Clearly this boundary consists of a union of vertical and horizontal segments of lengths h. The main observation is that each such boundary segment must also be in the boundary of one of the squares in Ω^h_0 (see Lemma 3 below). Then a simple counting argument yields that the length of $\partial\Omega^h_1$ is bounded by a constant independent of h.

To state the argument precisely we introduce the following notation. Let $e_\pm := (0, \pm 1)$ and $\tilde{e}_\pm = (\pm 1, 0)$. Then the boundary $\partial S_{a,h}$ of the square $S_{a,h}$ consists of four segments, namely the top and bottom boundaries $\partial^{e_\pm} S_{a,h} := a + \left(-\frac{h}{2}, \frac{h}{2}\right) \times \left\{\pm\frac{h}{2}\right\}$ and the left and right boundaries $\partial^{\tilde{e}_\pm} S_{a,h} := a + \left\{\pm\frac{h}{2}\right\} \times \left(-\frac{h}{2}, \frac{h}{2}\right)$. Let us denote the line segment of the boundary of $\partial S_{a,h}$ in the direction of the vector $e \in \{(\pm 1, 0),\ (0, \pm 1)\}$ by $\partial^e S_{a,h}$. Thus the boundary of Ω^h_1 is the union of the line segments $\partial^e S_{a,h} \subset \partial S_{a,h}$ for $S_{a,h} \subset \Omega^h_1$ such that $\partial^e S_{a,h} \cap \Omega^h_1 = \emptyset$. In other words,

$$\text{(31)}\qquad \partial\Omega^h_1 = \bigcup_{\substack{a\in\mathcal{A}_1 \\ \partial^e S_{a,h}\cap\Omega^h_1 = \emptyset}} \partial^e S_{a,h}\,.$$

LEMMA 3. *Let $a \in \mathcal{A}_1$ and $\partial^e S_{a,h} \subset \partial\Omega^h_1 \setminus \partial S$ for some $e \in \{(\pm 1, 0),\ (0, \pm 1)\}$. Then $S_{b,h} \subset \Omega^h_0$ for $b := a + h\,e$.*

Proof of Lemma 3. Since $\partial^e S_{a,h} \subset \partial\Omega^h_1 \setminus \partial S$, the square $S_{b,h}$ belongs to S. Suppose $b \notin \mathcal{A}_0$ and apply Theorem 2 to the domain $(S_{a,h} \cup S_{b,h}) \times \left(-\frac{h}{2}, \frac{h}{2}\right)$ to

obtain a constant $C > 0$ (independent of h, a, and b) and a matrix R^h_{ab} such that

$$\frac{1}{h^2}\int_{(S_{a,h}\cup S_{b,h})\times\left(-\frac{1}{2},\frac{1}{2}\right)} |\nabla_h y^{(h)} - R^h_{ab}|^2 dx \le \frac{C}{h^2}\int_{(S_{a,h}\cup S_{b,h})\times\left(-\frac{1}{2},\frac{1}{2}\right)} W(\nabla_h y^{(h)})\,dx \le 2C\,\epsilon\,. \tag{32}$$

Since $S_{a,h} \subset \Omega^h_1$, there exists $R^h_a \in SO(3)$ such that

$$\frac{1}{h^2}\int_{S_{a,h}\times\left(-\frac{1}{2},\frac{1}{2}\right)} |\nabla_h y^{(h)} - R^h_a|^2 dx \le C\,\epsilon\,. \tag{33}$$

Therefore (32) and (33) yield $|R^h_{ab} - R^h_a| \le 4C\epsilon$. Similarly there exist $R^h_b \in SO(3)H$ such that $|R^h_{ab} - R^h_b| \le 4C\epsilon$. We thus obtain a contradiction if ϵ is chosen sufficiently small, and the proof of the lemma is finished. □

Proof of Theorem 1 *(continued).* Let $a \in \mathcal{A}_1$, and $\partial^e S_{a,h} \subset \partial\Omega^h_1 \setminus \partial S$, for some e. Then by Lemma 3, the square adjacent to the side $\partial^e S_{a,h}$ is in Ω^h_0. There can be at most four edges $\partial^e S_{a,h} \subset \partial\Omega^h_1 \setminus \partial S$, touching a single square in Ω^h_0. Thus from (31), (26), and (11) we obtain

$$\begin{aligned}\mathcal{H}^1(\partial\Omega^h_1 \setminus \partial S) &= \sum_{\substack{a\in\mathcal{A}_1\\ \partial^e S_{a,h}\subset\partial\Omega^h_1\setminus\partial S}} \mathcal{H}^1(\partial^e S_{a,h})\\ &= h\,\mathrm{card}\left\{a \in \mathcal{A}_1 \,:\, \partial^e S_{a,h} \subset \partial\Omega^h_1 \setminus \partial S\right\}\\ &\le 4h\,\mathrm{card}\mathcal{A}_0\\ &\le 4h\,\frac{1}{h^2\epsilon}\,I^h(y^{(h)})\\ &\le C\,, \end{aligned} \tag{34}$$

where "card" stands for the cardinality of a set. Hence $\chi_{\Omega^h_1}$ is bounded in $BV(S)$, functions of bounded variation on S (see Example 1.4 in [16]), and passing to a subsequence, we get $\chi_{\Omega^h_1} \overset{*}{\rightharpoonup} \chi_E$ in $BV(S)$. Therefore by the lower semicontinuity and compactness theorems for BV functions (Theorems 1.9 and 1.19, respectively, in [16]) we obtain

$$\mathrm{Per}(E) = \int_S |\nabla\chi_E| \le \liminf_{h\to 0}\int_S |\nabla\chi_{\Omega^h_1}| = \liminf_{h\to 0}\mathcal{H}^1(\partial\Omega^h_1\setminus\partial S) \le C\,\liminf_{h\to 0}\frac{1}{h}I^h(y^{(h)})\,,$$

and $\chi_{\Omega^h_1} \to \chi_E$ strongly in $L^1(S)$.

Furthermore, it follows from (9) that $\mathrm{dist}^2(F, SO(3)) \le C(W(F)+1)$. Using (11), we deduce that

$$\int_{N_h} \mathrm{dist}^2(\nabla_h y^{(h)}, SO(3))\,dx \to 0 \quad \text{whenever } \mathcal{L}^3(N_h) \to 0. \tag{35}$$

Since the map $X \mapsto \mathrm{dist}(X, M)$ is convex, whenever M is a convex set, standard

convexity and lower semicontinuity arguments yield (with $I := (-1/2, 1/2)$)

$$\begin{aligned}
\int_\Omega \chi_{E\times I}\,\mathrm{dist}^2(\nabla' y, \mathrm{conv}\,O(2,3))dx &\le \liminf_{h\to 0}\int_\Omega \chi_{E\times I}\,\mathrm{dist}^2(\nabla' y^{(h)}, \mathrm{conv}\,O(2,3))dx\\
&\le \liminf_{h\to 0}\int_\Omega \chi_{E\times I}\,\mathrm{dist}^2(\nabla_h y^{(h)}, SO(3))dx\\
&\le \liminf_{h\to 0}\int_\Omega \chi_{\Omega_1^h\times I}\,\mathrm{dist}^2(\nabla_h y^{(h)}, SO(3))dx\\
&\le \liminf_{h\to 0}\sum_{a\in\mathcal{A}_1}\int_{S_{a,h}\times I}|\nabla_h y^{(h)} - R_a^h|^2 dx\\
&\le C\,\liminf_{h\to 0}\sum_{a\in\mathcal{A}_1}\int_{S_{a,h}\times I} W(\nabla_h y^{(h)})dx\\
&\le C\,\liminf_{h\to 0} I^h(y^{(h)})\\
&= 0, \qquad (36)
\end{aligned}$$

where we used (35) to obtain the third inequality. Hence $\nabla' y \in \mathrm{conv}\,O(2,3)$ a.e. in E. Since $\mathcal{L}^2(\Omega_0^h) = h^2\,\mathrm{card}\mathcal{A}_0 \le \frac{1}{\epsilon}\,I^h(y^{(h)}) \to 0$ as $h \to 0$ we have

$$\chi_{\Omega_2^h} = 1 - \chi_{\Omega_0^h} - \chi_{\Omega_1^h} \to (1 - \chi_E) \text{ strongly in } L^1(S)\,.$$

Applying the above arguments with $\nabla' y$ replaced by $(\nabla' y)\tilde{H}^{-1}$ and $\chi_{E\times I}$ replaced by $1 - \chi_{E\times I}$, we conclude similarly that $(\nabla' y)\tilde{H}^{-1} \in \mathrm{conv}\,O(2,3)$ a.e. in $S \setminus E$. Thus $E \subset E_1$, $S \setminus E \subset E_2$, and

$$\mathrm{Per}(E) \le C \liminf \frac{1}{h} I^h(y^{(h)})\,.$$

This finishes the proof for S being the unit square and $1/h \in \mathbb{N}$. For a general bounded open set S the assertion follows similarly by first considering the subset S^h which consists of the union of all squares $S_{a,h}$ that are contained in S. ∎

A GENERALIZED DYNAMICAL APPROACH TO THE LARGE TIME BEHAVIOR OF SOLUTIONS OF HAMILTON–JACOBI EQUATIONS*

ANDREA DAVINI† AND ANTONIO SICONOLFI‡

Abstract. We consider the Hamilton–Jacobi equation

$$\partial_t u + H(x, Du) = 0 \qquad \text{in } (0, +\infty) \times \mathbb{T}^N,$$

where $\mathbb{T}^N$ is the flat N-dimensional torus, and the Hamiltonian $H(x, p)$ is assumed continuous in x and strictly convex and coercive in p. We study the large time behavior of solutions, and we identify the limit through a Lax-type formula. Some convergence results are also given for H solely convex. Our qualitative method is based on the analysis of the dynamical properties of the Aubry set, performed in the spirit of [A. Fathi and A. Siconolfi, *Calc. Var. Partial Differential Equations*, 22 (2005), pp. 185–228]. This can be viewed as a generalization of the techniques used in [A. Fathi, *C. R. Acad. Sci. Paris Ser. I Math.*, 327 (1998), pp. 267–270] and [J. M. Roquejoffre, *J. Math. Pures Appl.* (9), 80 (2001), pp. 85–104]. Analogous results have been obtained in [G. Barles and P. E. Souganidis, *SIAM J. Math. Anal.*, 31 (2000), pp. 925–939] using PDE methods.

1. Introduction.

This paper is about the large time behavior of the equation

$$\partial_t u + H(x, Du) = 0$$

in the flat torus $\mathbb{T}^N$. Here and in what follows, (sub-, super-) solutions are meant in the viscosity sense (see [2, 3, 14]).

The subject has been extensively investigated, first in [16], and subsequently in [11], [4], [18]. It is therefore well understood that, under suitable assumptions on H,

$$u(t, x) + ct$$

converges uniformly, for t diverging positively, to a solution v of the stationary equation

$$H(x, D\phi) = c \qquad \text{in } \mathbb{T}^N,$$

where c is the so-called critical value of the Hamiltonian, i.e., given by

$$c = \min\{a \,:\, H(x, D\phi) = a \text{ has a subsolution}\}.$$

This is also the unique value of a for which $H(x, D\phi) = a$ admits a solution on the whole torus; see [15], [13]. Any (sub) solution of the previous equation with $a = c$ will be called critical in what follows.

This problem has been attacked, in the quoted literature, either by means of dynamical techniques or by using viscosity solutions methods.

The dynamical approach, which can be found in [11], [18] (see also [8], [12] for a general introduction on the subject), requires strong regularity assumptions on the Hamiltonian (C^2-regularity, strict convexity, and superlinearity at infinity in the second variable), since it is based on the analysis of the associated Hamiltonian flow. The latter is related to the solution u through the Lax–Oleinik formula. As first pointed out in [11], a crucial role is played by the Aubry set, which consists of accumulation points of the flow and is invariant.

The weakening of the conditions on H has a theoretical relevance and is also an important issue for the applications, since, for instance, the Hamiltonians appearing in control theory are not smooth.

A significant step in this direction has been performed in [4] by means of pure PDE methods. The authors were able to prove the convergence, assuming that H is only continuous and satisfies a coercivity condition. Moreover, they require the Hamiltonian to fulfill a convexity-type inequality, which includes also some nonconvex functions, but not all strictly convex Hamiltonians.

The main contribution of the present paper is to employ generalized dynamical methods to achieve the above convergence result in the presence of weak regularity of H, which is taken continuous, strictly convex, and coercive.

Our procedure yields, even in the continuous case, deeper insight into the convergence phenomenon as well as remarkably simple proofs which avoid any technicality.

The core of our argument is the discovery of some distinguished curves on the torus along which the difference between u and any critical subsolution ϕ enjoys a monotonicity property. This is a generalization of something already proved in [18] for curves of the Hamiltonian flow lying on the Aubry set. The crux is that, of course, no Hamiltonian flow can be generally defined in our setting.

We overcome this difficulty following the ideas of [13], where some aspects of the Aubry–Mather theory are extended to continuous quasi-convex Hamiltonians. Using a nonsymmetric semidistance, denoted by S, suitably related to the c-sublevel set of the Hamiltonian, it is possible to define a generalized (projected) Aubry set, say $\mathcal{A}$, and some relevant properties, holding for the classical Aubry set when H is C^2, are recovered.

Under the additional assumption that H is Lipschitz continuous with respect to x, it is proved in [13], for instance, that a multivalued dynamics can be defined on $\mathcal{A}$. We take a further step here by showing that, even for continuous H, some dynamical properties are encoded in the structure of the Aubry set. We prove indeed that through any point of $\mathcal{A}$ there passes a curve η defined on $\mathbb{R}$ and satisfying

$$S(\eta(t_1),\eta(t_2)) = \int_{t_1}^{t_2} (L(\eta,\dot\eta)+c)\ \mathrm{d}s = -S(\eta(t_2),\eta(t_1)) \quad \text{for any } t_1,t_2\in\mathbb{R},$$

where L is the Lagrangian function related to H. These are precisely the curves, called critical, satisfying the monotonicity property previously mentioned.

Beside this, we get the convergence result by exploiting, as in [18], the relaxed semilimits theory and a generalization of the fact, proved in [13], that all critical subsolutions are differentiable on $\mathcal{A}$ and have the same gradient.

An advantage of our method is that we can single out the point where the strict convexity condition on H—or, to be more precise, the C^1-regularity of L, which is an equivalent condition—is employed (see Lemma 5.2). More precisely, such a property allows us to estimate how the line integral of the Lagrangian on a critical curve varies under suitable perturbation of the parametrization; see also Remark 5.8. This is a crucial step since it is well known, as shown in an example in [4], that the simple convexity of H does not ensure, in general, the convergence phenomenon.

However, we can prove that the mere convexity is actually enough when the equilibrium points form a uniqueness set for the critical equation. This accounts for the fact that a small perturbation, in a convex Hamiltonian, can produce a passage from a convergence to a nonconvergence situation; see Example 5.10. This generalizes the results of [16], where the Hamiltonian is taken only convex, as well.

We are furthermore able to identify the limit function v through a representation formula, which involves $u(0,\cdot)$, the Aubry set, and the semidistance S. It is the critical solution coinciding on $\mathcal{A}$ with the maximal critical subsolution not exceeding $u(0,\cdot)$. This should be compared to the formula given in [11] for Hamiltonians of class C^2 using the Peierls barrier. Our formula has been exploited in [19] to perform a numerical approximation of the Aubry set.

The paper is organized as follows. In section 2 some preliminary material is collected, including definitions of the semidistance S and the generalized Aubry set, as well as some properties of the critical solutions and of the Lax–Oleinik semigroup. In section 3 we introduce, through a representation formula, a distinguished critical solution, which will be proved to be the limit of $u(t,x)+ct$ for $t \to +\infty$. Section 4 is devoted to studying the dynamical properties of the Aubry set and singling out a class of special curves covering $\mathcal{A}$. The main results are finally proved in section 5. In the appendix we show that the usual integral representation formula for the Lax–Oleinik semigroup holds also in the case when H is coercive, but not necessarily superlinear at infinity, and so the Lagrangian L is possibly infinite valued at some points of $\mathbb{T}^N \times \mathbb{R}^N$.

2. Assumptions and preliminary results. We write below a list of symbols used throughout this paper.

N	an integer number.
$B_R(x_0)$	the closed ball in $\mathbb{R}^N$ centered at x_0 of radius R.
B_R	the closed ball in $\mathbb{R}^N$ centered at 0 of radius R.
$\langle \cdot\,, \cdot \rangle$	the scalar product in $\mathbb{R}^N$.
$\lvert \cdot \rvert$	the Euclidean norm in $\mathbb{R}^N$.
$\mathbb{R}_+$	the set of nonnegative real numbers.
$\mathbb{T}^N$	the N-dimensional flat torus.
$\mathrm{C}(\mathbb{T}^N)$	the space of real-valued continuous functions on $\mathbb{T}^N$.
$\mathrm{Lip}(\mathbb{T}^N)$	the space of real-valued Lipschitz-continuous functions on $\mathbb{T}^N$.

A subset of $\mathbb{R}^k$ is called *negligible* if its k-dimensional Lebesgue measure is equal to zero. We say that a property holds *almost everywhere* (*a.e.*) on $\mathbb{R}^k$ if it holds up to a negligible subset of $\mathbb{R}^k$. Given a measurable function $\varphi : \mathbb{T}^N \to \mathbb{R}$, its L^∞-norm on $\mathbb{T}^N$ will be denoted by $\|\varphi\|_\infty$. We will write $\varphi_n \rightrightarrows \varphi$ on $\mathbb{T}^N$ to mean that the sequence of functions $(\varphi_n)_n$ uniformly converges to φ on $\mathbb{T}^N$.

By *modulus* we mean a nondecreasing function from $\mathbb{R}_+$ to $\mathbb{R}_+$, vanishing and continuous at 0. Given a closed convex subset Z of $\mathbb{R}^k$, and $p_0 \in Z$, we define the normal cone of Z at p_0, in symbols $N_Z(p_0)$, as the set $\{q \in \mathbb{R}^N : \langle q, p_0\rangle = \max_{p\in Z}\langle q,p\rangle\}$.

We endow the flat torus $\mathbb{T}^N$ with the Riemannian metric induced by the Euclidean metric on $\mathbb{R}^N$. We recall that $\mathbb{T}^N$ can be viewed as the quotient space $\mathbb{R}^N/\mathbb{Z}^N$, obtained by identifying all points $x, y \in \mathbb{R}^N$ such that $x - y \in \mathbb{Z}^N$.

With the term *curve*, without any further specification, we refer to a Lipschitz-continuous function from some given interval $[a, b]$ to $\mathbb{T}^N$. The space of all such curves is denoted by $\mathrm{Lip}([a, b], \mathbb{T}^N)$, while $\mathrm{Lip}_{x,y}([a, b], \mathbb{T}^N)$ stands for the family of curves γ joining x to y, i.e., such that $\gamma(a) = x$ and $\gamma(b) = y$, for any fixed x, y in $\mathbb{T}^N$. We denote by $W^{1,1}([a, b], \mathbb{T}^N)$ the space of absolutely continuous curves defined in $[a, b]$. Given a curve γ defined on some interval $[a, b]$, a curve γ' defined on $[a', b']$ will be called a *reparametrization of* γ if there exists an order preserving Lipschitz-continuous map $f : [a', b'] \to [a, b]$ surjective and such that $\gamma' = \gamma \circ f$. The Euclidean length of a curve γ is denoted by $\ell(\gamma)$.

Unless otherwise specified, the term (sub-, super-) solution of some PDE is understood in the viscosity sense. Given a continuous function g defined in $\mathbb{R}^k$ and $x_0 \in \mathbb{R}^k$, we denote by $D^+g(x_0)$ (resp., $D^-g(x_0)$) the superdifferential (resp., the subdifferential) of g at x_0, i.e., the (possibly empty) set made up of the differentials of the viscosity test functions from above (resp., from below) to g at x_0. Note that, in the case when g is convex, D^-g coincides with the usual subdifferential of convex analysis. When g is defined on $\mathbb{R}^m \times \mathbb{R}^k$ and $(x_0, p_0) \in \mathbb{R}^m \times \mathbb{R}^k$, we will denote by $D_p^- g(x_0, p_0)$ the subdifferential of the function $g(x_0, \cdot)$ at p_0. For a function $g : \mathbb{R}^k \to (-\infty, +\infty]$, we denote by $\mathrm{dom}(g)$ its effective domain, i.e., the subset of $\mathbb{R}^k$ where g is finite valued.

We deal with a Hamiltonian H, defined on the cotangent bundle $T^*\mathbb{T}^N$, identified with $\mathbb{T}^N \times \mathbb{R}^N$, and satisfying the following set of assumptions:

(H1) $H : \mathbb{T}^N \times \mathbb{R}^N \to \mathbb{R}$ is continuous;

(H2) $p \mapsto H(x, p)$ is convex on $\mathbb{R}^N$ for any $x \in \mathbb{T}^N$;

(H3) $\lim_{|p|\to+\infty}(\inf_{x\in\mathbb{T}^N} H(x, p)) = +\infty$;

(H4) the set of minimizers of $p \mapsto H(x, p)$ has empty interior for any $x \in \mathbb{T}^N$.

To obtain our general convergence result (see in particular Proposition 5.3, which will constitute a crucial step for that), we will, moreover, assume the following:

(H2)′ $p \mapsto H(x, p)$ is strictly convex on $\mathbb{R}^N$ for any $x \in \mathbb{T}^N$.

Notice that condition (H4) is certainly satisfied when (H2)′ holds true, since, in this case, the set of minimizers of $H(x, \cdot)$ reduces to a point for any $x \in \mathbb{T}^N$.

Remark 2.1. Exploiting the subdifferentiability properties of the function $p \mapsto H(x, p)$, for any fixed x, we see that the Lipschitz constant of such a function in B_R, for any $R > 0$, can be estimated, uniformly with respect to x, in terms of R and of $\max\{H(x, p) : (x, p) \in \mathbb{T}^N \times B_{2R}\}$; see, e.g., [17, Proposition 2.2.6].

Remark 2.2. The problem we are dealing with can be equivalently formulated in $\mathbb{R}^N$, instead of $\mathbb{T}^N$, with $\mathbb{Z}^N$-periodicity conditions.

We consider the family of Hamilton–Jacobi equations

$$H(x, D\phi) = a \qquad \text{on } \mathbb{T}^N, \tag{1}$$

with a real parameter, and set

$$c := \inf\{a \in \mathbb{R} : (1) \text{ has a subsolution}\}.$$

This is called the *critical value* of the Hamiltonian H and is characterized by the property of being the unique value for a such that (1) admits (at least) one solution (see, e.g., [15], [13]). A solution (resp., supersolution, subsolution) of

$$H(x, D\phi) = c \qquad \text{in } \mathbb{T}^N \tag{2}$$

will be called critical in what follows. Thanks to hypothesis (H3), all subsolutions of (1) are Lipschitz continuous. Moreover, by the convexity assumption, there is complete equivalence between the notions of (viscosity) subsolution and a.e. subsolution (see [2]).

Following [13], we carry out the study of properties of subsolutions to (1) by means of the semidistances S_a defined on $\mathbb{T}^N \times \mathbb{T}^N$, for $a \geq c$, as follows:

$$S_a(x,y) = \inf \left\{ \int_0^1 \sigma_a(\gamma(s), \dot\gamma(s))\, \mathrm{d}s \,:\, \gamma \in \mathrm{Lip}_{x,y}([0,1], \mathbb{T}^N) \right\}, \tag{3}$$

where $\sigma_a(x,q)$ is the support function of the a-sublevel of H, namely

$$\sigma_a(x,q) := \sup \{ \langle q, p \rangle \,:\, H(x,p) \leq a \}. \tag{4}$$

The function $\sigma_a(x,q)$ is convex in q and upper semicontinuous in x (and even continuous in all points x, where the set $\{p \in \mathbb{R}^N \,:\, H(x,p) \leq a\}$ has a nonempty interior or reduces to a point), while S_a satisfies the following properties:

$$\begin{aligned} &S_a(x,y) \leq S_a(x,z) + S_a(z,y), \\ &S_a(x,y) \leq b_a |x-y| \end{aligned}$$

for all $x, y, z \in \mathbb{T}^N$ and for some positive constant b_a. The following properties hold (see [13]).

PROPOSITION 2.3. *Given $a \geq c$, we have that*

(i) *for any $y \in \mathbb{T}^N$, the functions $S_a(y,\cdot)$ and $-S_a(\cdot,y)$ are both subsolutions of* (1);

(ii) *a function ϕ is a subsolution of* (1) *if and only if*

$$\phi(x) - \phi(y) \leq S_a(y,x) \qquad \textit{for all } x, y \in \mathbb{T}^N.$$

To ease notation, in what follows we will write S, σ in place of S_c, σ_c, respectively.

In the analysis of the behavior of critical subsolutions, a special role is played by a set $\mathcal{A}$, which has been called in [13] the *(projected) Aubry set*, defined as the collection of points $y \in \mathbb{T}^N$ such that

$$\inf \left\{ \int_0^1 \sigma(\gamma, \dot\gamma)\, \mathrm{d}s \,:\, \gamma \in \mathrm{Lip}_{y,y}([0,1], \mathbb{T}^N),\, \ell(\gamma) \geq \delta \right\} = 0 \quad \text{for some } \delta > 0,$$

or, equivalently (cf. [13, Lemma 5.1]),

$$\inf \left\{ \int_0^1 \sigma(\gamma, \dot\gamma)\, \mathrm{d}s \,:\, \gamma \in \mathrm{Lip}_{y,y}([0,1], \mathbb{T}^N),\, \ell(\gamma) \geq \delta \right\} = 0 \quad \text{for any } \delta > 0.$$

The set $\mathcal{A}$ is closed and nonempty (cf. [13, Corollaries 5.7 and 5.9]). In the next theorem we outline the main properties linking $\mathcal{A}$ to (2) (see [13]).

THEOREM 2.4.

(i) *If ϕ and w are a subsolution and a supersolution of* (2)*, respectively, and $\phi \leq w$ on $\mathcal{A}$, then $\phi \leq w$ on $\mathbb{T}^N$. In particular, if two solutions of* (2) *coincide on $\mathcal{A}$, then they coincide on $\mathbb{T}^N$.*

(ii) *If w_0 is a function defined on $C \subset \mathcal{A}$ such that*

$$w_0(x) - w_0(y) \leq S(y,x) \quad \textit{for every } x, y \in C,$$

then the function

$$w(x) := \min_{y\in C} \big(w_0(y) + S(y,x)\big) \tag{5}$$

is the maximal critical subsolution of (2) *equaling* w_0 *on* C*, and a critical solution as well.*

(iii) *If we furthermore set* $C = \mathcal{A}$ *in* (5)*, then* w *is the unique critical solution equaling* w_0 *on* $\mathcal{A}$*.*

We call $y \in \mathbb{T}^N$ an *equilibrium point* if $\min_p H(y,p) = c$. The collection of all such points will be denoted by $\mathcal{E}$. The set $\mathcal{E}$ is a (possibly empty) closed subset of $\mathcal{A}$ (cf. [13, Lemma 5.2]). This property depends on the fact that the c-sublevel $\{p : H(y,p) \le c\}$ is nonvoid and has an empty interior when $y \in \mathcal{E}$ (the latter is a consequence of (H4), and this is actually the unique point where such a condition is used). It is apparent that $c \ge \max_{x\in\mathbb{T}^N} \min_{p\in\mathbb{R}^N} H(x,p)$; we point out that $\mathcal{E}$ is nonempty if and only if the previous formula holds with an equality. In this case, $\mathcal{E}$ is made up of the points x where the maximum is attained.

Let us now focus our attention on the Cauchy problem

$$\begin{cases} \partial_t u + H(x,Du) = 0 & \text{in } (0,+\infty)\times\mathbb{T}^N, \\ u(0,x) = u_0(x) & \text{on } \mathbb{T}^N, \end{cases} \tag{6}$$

where u_0 is a continuous initial datum. The following result holds (see, e.g., [6]).

THEOREM 2.5. *Assume* H *satisfies assumptions* (H1), (H2), (H3), (H4). *Then the Cauchy problem* (6) *admits a unique uniformly continuous solution* $u(t,x)$ *on* $\mathbb{R}_+ \times \mathbb{T}^N$*, for any* $u_0 \in \mathrm{C}(\mathbb{T}^N)$*. If, moreover, the initial datum* $u_0 \in \mathrm{Lip}(\mathbb{T}^N)$*, then* $u(t,x)$ *is Lipschitz continuous on* $\mathbb{R}_+ \times \mathbb{T}^N$ *and satisfies*

$$\|Du\|_\infty \le M, \quad \|\partial_t u\|_\infty \le \operatorname{ess\,sup}\{|H| : |p| \le M\}$$

for any positive constant M *such that*

$$M > \|Du_0\|_\infty, \quad \inf\{H : |p| > M\} > \sup\{|H| : |p| \le \|Du_0\|_\infty\}. \tag{7}$$

In view of the previous theorem, we can define, for any $t > 0$, a nonlinear operator $\mathcal{S}(t)$ on $\mathrm{C}(\mathbb{T}^N)$ by setting $\mathcal{S}(t)\phi := u(t,\cdot)$ for every $\phi \in \mathrm{C}(\mathbb{T}^N)$, where $u(t,x)$ denotes the unique solution of the Cauchy problem (6) with $u_0 = \phi$. The family of operators $\big(\mathcal{S}(t)\big)_{t>0}$ forms a semigroup, whose main properties are summarized below.

PROPOSITION 2.6.

(i) (Semigroup property.) *For any* $t, s > 0$ *we have* $\mathcal{S}(t+s) = \mathcal{S}(t)\circ\mathcal{S}(s)$.

(ii) (Monotonicity property.) *For every* $\phi, \psi \in \mathrm{C}(\mathbb{T}^N)$ *and each* $t > 0$ *we have*

$$\phi \le \psi \;\Rightarrow\; \mathcal{S}(t)\phi \le \mathcal{S}(t)\psi.$$

(iii) *For any* $a \in \mathbb{R}$ *and* $\phi \in \mathrm{C}(\mathbb{T}^N)$*, we have* $\mathcal{S}(t)(\phi + a) = \mathcal{S}(t)\phi + a$.

(iv) (Nonexpansiveness.) *For each* $t > 0$*, the map* $\mathcal{S}(t)$ *is nonexpansive, i.e.,*

$$\|\mathcal{S}(t)\phi - \mathcal{S}(t)\psi\|_\infty \le \|\phi - \psi\|_\infty \quad \textit{for every } \phi, \psi \in \mathrm{C}(\mathbb{T}^N).$$

(v) *For every* $\phi \in \mathrm{C}(\mathbb{T}^N)$*, we have* $\lim_{t\to 0} \mathcal{S}(t)\phi = \phi$.

We define the *Fenchel transform* $L : \mathbb{T}^N \times \mathbb{R}^N \to (-\infty, +\infty]$ of H via

$$L(x,q) := \sup_{p\in\mathbb{R}^N} \{\langle p, q\rangle - H(x,p)\}. \tag{8}$$

The function L is called the Lagrangian related to the Hamiltonian H. We record for later use the following properties.

PROPOSITION 2.7. *Let H satisfy assumptions* (H1), (H2), (H3). *Then the following properties hold for the Lagrangian L:*

(i) *$L(x,q)$ is lower semicontinuous on $\mathbb{T}^N \times \mathbb{R}^N$, and convex in q for any fixed $x \in \mathbb{T}^N$.*

(ii) *L is continuous on $\mathrm{int}(\mathrm{dom}L) =: \Omega$.*

If, in addition, H satisfies (H2)$'$ *then*

(iii) *for every $(x,q) \in \Omega$, L is differentiable with respect to q, and $(x,q) \mapsto D_q L(x,q)$ is continuous on Ω.*

(iv) *if (x,q) is such that the supremum in the definition of $L(x,q)$ is a maximum, then (x,q) belongs to Ω.*

We refer to the appendix for the proof.

Each operator $\mathcal{S}(t)$ can be represented through the integral formula

$$\big(\mathcal{S}(t)\phi\big)(x) = \inf\left\{\phi(\gamma(0)) + \int_0^t L(\gamma(s),\dot\gamma(s))\,\mathrm{d}s \ : \ \gamma \in W^{1,1}([0,t],\mathbb{T}^N),\ \gamma(t) = x\right\} \tag{9}$$

for any $\phi \in \mathrm{C}(\mathbb{T}^N)$. The family of operators $\big(\mathcal{S}(t)\big)_{t>0}$ is called the Lax–Oleinik semigroup.

Remark 2.8. When $\phi \in \mathrm{Lip}(\mathbb{T}^N)$ and L is finite valued, the validity of (9) can be seen, for instance, by combining [10, Theorem 1.1] with Theorem 2.5. This is the case when H is uniformly superlinear in p. The infimum in (9) is then a minimum by classical results of the calculus of variations (see, e.g., [5]), and all minimizers are Lipschitz continuous (cf. [1] for some results on this topic).

We present in the appendix a proof of (9) for $\phi \in \mathrm{C}(\mathbb{T}^N)$ and general L, possibly infinite valued in some subset of $\mathbb{T}^N \times \mathbb{R}^N$, and we show the existence of minimizers in this case too.

We will use the following Tonelli-type semicontinuity theorem (see, e.g., [5, Theorem 3.6]) in the proof of Propositions 4.12 and A.6.

THEOREM 2.9. *Let J be a bounded interval of $\mathbb{R}$, and let $F : \mathbb{R}^N \times \mathbb{R}^N \to (-\infty, +\infty]$ be a function satisfying the following conditions:*

(i) *F is lower semicontinuous;*

(ii) *$F(x,\cdot)$ is convex on $\mathbb{R}^N$ for every $x \in \mathbb{R}^N$;*

(iii) *F is bounded from below by a constant.*

Then the functional

$$\mathcal{F}(\gamma) := \int_J F(\gamma(s),\dot\gamma(s))\,\mathrm{d}s$$

is sequentially weakly lower semicontinuous in $W^{1,1}(J,\mathbb{R}^N)$; i.e., if $(\gamma_k)_k$ converges weakly in $W^{1,1}(J,\mathbb{R}^N)$ to γ, then

$$\mathcal{F}(\gamma) \le \liminf_{k\to+\infty} \mathcal{F}(\gamma_k). \tag{10}$$

Equivalently, we can say that (10) *holds if $(\gamma_k)_k$ converges uniformly to γ and the measures $\nu_k(E) := \int_E |\dot\gamma_k|\,\mathrm{d}s$ are equiabsolutely continuous on J with respect to the Lebesgue measure.*

3. A distinguished critical solution. Before attacking the convergence problem, we try to guess what the asymptotic limit of $\mathcal{S}(t)u_0 + ct$ should be. We start by providing a Lax-type formula which involves the initial datum u_0, the Aubry set, and the semidistance S, and we show that this defines a critical solution, more precisely, the solution whose trace on $\mathcal{A}$ coincides with that of the maximal critical subsolution not exceeding u_0. This formula furthermore generalizes the formula given in (5).

THEOREM 3.1. *Let $w_0 : \mathbb{T}^N \to \mathbb{R}$ be any function bounded from below. Set*

$$v(x) := \inf_{y\in\mathcal{A}} \left(S(y,x) + \inf_{z\in\mathbb{T}^N} (w_0(z) + S(z,y)) \right) \quad \text{for every } x \in \mathbb{T}^N. \tag{11}$$

Then

(i) $\inf_{y\in\mathbb{T}^N} (S(y,\cdot) + w_0(y)) =: v_0$ *is the maximal critical subsolution not exceeding w_0 on $\mathbb{T}^N$.*

(ii) *the function v is the critical solution equaling v_0 on $\mathcal{A}$.*

(iii) *if the inequality $w_0(y) - w_0(x) \le S(x,y)$ holds for all x, $y \in \mathbb{T}^N$, then $v = \min_{y\in\mathcal{A}}(w_0(y) + S(y,\cdot))$ on $\mathbb{T}^N$, and $v_0 = w_0$ on $\mathcal{A}$.*

We show separately, in the next lemma, the relevant fact on which the proof of Theorem 3.1 relies.

LEMMA 3.2. *Let C be a subset of $\mathbb{T}^N$ and $w_0 : C \to \mathbb{R}$ be any function bounded from below. Then*

$$w(x) := \inf_{z\in C} \big(w_0(z) + S(z,x)\big)$$

is the maximal subsolution of (2) not exceeding w_0 on C. The function w is, moreover, a critical solution in $\mathbb{T}^N \setminus \overline{C}$ and in the whole $\mathbb{T}^N$ whenever $C \subset \mathcal{A}$.

Proof. It is easy to check, exploiting the very definition of w, that $w \le w_0$ on C and $w(x) - w(y) \le S(y,x)$ for every $x, y \in \mathbb{T}^N$. The latter inequality implies that w is a critical subsolution by Proposition 2.3. If ϕ is any critical subsolution with $\phi \le w_0$ on C then, taking into account that $\phi(x) - \phi(y) \le S(y,x)$ for every $x, y \in \mathbb{T}^N$, we get

$$\phi(x) \le \min_{z\in C} \big(\phi(z) + S(z,x)\big) \le w(x) \qquad \text{for every } x \in \mathbb{T}^N,$$

which gives the maximality of w. Such a property also implies that w is a supersolution of (2) in $\mathbb{T}^N \setminus \overline{C}$ through a standard argument (see, e.g., the proof of Proposition 3.2 in [13]). If furthermore $C \subset \mathcal{A}$, then by Theorem 2.4(ii) $w = \min_{z\in C} \big(w(z) + S(z,x)\big)$, and so it is a critical solution in $\mathbb{T}^N$. □

Proof of Theorem 3.1. Item (i) comes directly from Lemma 3.2 with $C = \mathbb{T}^N$; (ii) is therefore a consequence of Theorem 2.4(iii). Item (iii) can be finally deduced from Theorem 2.4(ii). □

The proof that the function given in formula (11), with $w_0 = u_0$, actually coincides with the asymptotic limit of $\mathcal{S}(t)u_0 + ct$ is, of course, the main goal of our analysis, and will be attained in the subsequent sections. The remainder of the present one is devoted, instead, to some preliminary remarks which give support to our guess and cast some light on our further analysis.

We start by noticing that, given a solution w of (2) and a general initial datum $u_0 \in \mathrm{C}(\mathbb{T}^N)$, there exist, since $\mathbb{T}^N$ is compact, some constants α, β such that

$$w + \alpha \le u_0 \le w + \beta \quad \text{on } \mathbb{T}^N.$$

This implies, in view of the relation $\mathcal{S}(t)w = w - ct$, which holds for every $t > 0$, and the monotonicity property of the semigroup $\big(\mathcal{S}(t)\big)_{t>0}$,

$$w + \alpha - ct \le \mathcal{S}(t)u_0 \le w + \beta - ct \quad \text{on } T^N$$

for any $t > 0$, or, in other words,

$$w + \alpha \leq \mathcal{S}(t)u_0 + ct \leq w + \beta \quad \text{on } \mathbb{T}^N. \tag{12}$$

Since the family of functions $\left(\mathcal{S}(t)u_0 + ct\right)_{t>0}$ is equicontinuous (in view of Theorem 2.5), and equibounded thanks to (12), we can define the relaxed semilimits,

$$\underline{u}(x) = \limsup_{t\to+\infty}{}^{*} \left(\mathcal{S}(t)u_0\right)(x) + ct := \sup\left\{\limsup_{n\to+\infty} \left(\mathcal{S}(t_n)u_0\right)(x_n) + ct_n\right\}, \tag{13}$$

$$\overline{u}(x) = \liminf_{t\to+\infty}{}_{*} \left(\mathcal{S}(t)u_0\right)(x) + ct := \inf\left\{\liminf_{n\to+\infty} \left(\mathcal{S}(t_n)u_0\right)(x_n) + ct_n\right\}, \tag{14}$$

where the supremum and the infimum in (13) and (14), respectively, are taken for all sequences $(x_n)_n$ converging to x and all diverging sequences $(t_n)_n$. Moreover, thanks to the uniform continuity of the function $\left(\mathcal{S}(t)u_0\right)(x)$ on $\mathbb{R}_+ \times \mathbb{T}^N$ (cf. Theorem 2.5), the sequences $(x_n)_n$ may be chosen identically equal to x, so that the following identities hold true:

$$\underline{u}(x) = \sup\left\{\psi(x) \,:\, \psi \in \omega_{\mathcal{S}}(u_0)\right\},$$
$$\overline{u}(x) = \inf\left\{\psi(x) \,:\, \psi \in \omega_{\mathcal{S}}(u_0)\right\},$$

where

$$\omega_{\mathcal{S}}(u_0) := \left\{\psi \in \mathrm{C}(\mathbb{T}^N) \,:\, \psi = \lim_{n\to+\infty} \mathcal{S}(t_n)u_0 + ct_n \text{ for some diverging sequence } (t_n)_n\right\}.$$

We have the following theorem (cf. proof of Theorem 1 in [16]).

THEOREM 3.3. *The functions $\underline{u}$ and $\overline{u}$ defined by* (13) *and* (14) *are a subsolution and a supersolution of* (2)*, respectively.*

We proceed to establish the asymptotic convergence of $\mathcal{S}(t)u_0 + ct$ to the function v given in (11) with $w_0 = u_0$, provided u_0 is a critical sub- or supersolution.

THEOREM 3.4. *Let $u_0 \in \mathrm{C}(\mathbb{T}^N)$ be either a subsolution or a supersolution of* (2)*. Then $\mathcal{S}(t)u_0 + ct$ uniformly converges, as t goes to $+\infty$, to the critical solution v defined by* (11) *with $w_0 = u_0$.*

Proof. Let us first assume u_0 to be a subsolution of (2). By Theorem 3.1(iii), v is the maximal critical subsolution satisfying $v = u_0$ on $\mathcal{A}$, and hence $v \geq u_0$ on $\mathbb{T}^N$. As $u_0 - ct$ and $v - ct$ are a subsolution and a supersolution of (2), respectively, the comparison principle yields

$$u_0 - ct \leq \mathcal{S}(t)u_0 \leq v - ct \qquad \text{on } \mathbb{T}^N,$$

and consequently, since $v = u_0$ on $\mathcal{A}$, we get

$$u_0 = S(t)u_0 + ct = v \qquad \text{on } \mathcal{A}$$

for every $t > 0$. It follows that $v = \underline{u} = \overline{u}$ on $\mathcal{A}$, and we finally deduce from Theorem 2.4(i) that $v = \underline{u} = \overline{u}$ on $\mathbb{T}^N$. This proves the assertion when u_0 is a critical subsolution.

Let us now assume u_0 to be a supersolution of (2). Let v_0 be the maximal critical subsolution not exceeding u_0 on $\mathbb{T}^N$, i.e.,

$$v_0 = \min_{y\in\mathbb{T}^N} \left(S(y,\cdot) + u_0(y)\right).$$

The maximality of v_0, combined with the fact that u_0 is a critical supersolution, implies that v_0 is a critical solution as well, so that the identity $v = v_0$ on $\mathbb{T}^N$ holds true. Arguing as in the first part of the proof, we therefore obtain

$$v \le \mathcal{S}(t)u_0 + ct \le u_0 \qquad \text{on } \mathbb{T}^N$$

for every $t > 0$. This entails $v \le \overline{u} \le \underline{u} \le u_0$ on $\mathbb{T}^N$. From the fact that $\underline{u}$ is a critical subsolution, and from the maximality property of $v_0 = v$, we get $\underline{u} \le v$, and so $v = \overline{u} = \underline{u}$ on $\mathbb{T}^N$. ∎

We deduce the following from Theorem 3.4.

PROPOSITION 3.5. *Assume $u_0 \in \mathrm{C}(\mathbb{T}^N)$, and let v be the function defined by* (11) *with $w_0 = u_0$. Then the relaxed semilimits $\underline{u}$ and $\overline{u}$, defined by* (13) *and* (14)*, respectively, satisfy*

$$v(x) \le \overline{u}(x) \le \underline{u}(x) \qquad \textit{for every } x \in \mathbb{T}^N. \tag{15}$$

Proof. Set $v_0 = \min_{y\in\mathbb{T}^N}(S(y,\cdot) + u_0(y))$. It is apparent that $v_0 \le u_0$ on $\mathbb{T}^N$, and hence, by the monotonicity property of the semigroup $(\mathcal{S}(t))_{t>0}$, we obtain $\mathcal{S}(t)v_0 + ct \le \mathcal{S}(t)u_0 + ct$ on $\mathbb{T}^N$, and (15) follows in view of Theorems 3.4 and 3.1. ∎

Proposition 3.5, Theorem 2.4, and the facts that v is a critical solution and $\underline{u}$ a critical subsolution imply that the convergence result we aim at is proved as soon as the equality $v = \underline{u}$ is obtained on $\mathcal{A}$. This suggests, in the end, that what really matters in our analysis is the asymptotic behavior of $\mathcal{S}(t)u_0 + ct$ on $\mathcal{A}$.

4. Dynamical properties of the projected Aubry set. Here we define a family of curves, called critical, fully covering the Aubry set, which will play an important role in the convergence result of the next section. We will furthermore investigate the behavior of critical subsolutions on such curves. Throughout the section, conditions (H1), (H2), (H3), (H4) are assumed.

DEFINITION 4.1. *A curve γ defined on an interval J is called* critical *if*

$$S(\gamma(t_1),\gamma(t_2)) = \int_{t_1}^{t_2} (L(\gamma,\dot\gamma) + c)\,\mathrm{d}s = -S(\gamma(t_2),\gamma(t_1))$$

for every t_1, t_2 in J with $t_2 \ge t_1$.

LEMMA 4.2. *Any critical curve is contained in the Aubry set.*

Proof. Let γ be a critical curve, which we first assume to be nonconstant, defined in some interval J. Given t_1, t_2 in J with $t_2 \ge t_1$ and $\gamma(t_1) \ne \gamma(t_2)$, we can find two sequences of curves $\gamma_n^1 \in \mathrm{Lip}_{\gamma(t_1),\gamma(t_2)}([0,1],\mathbb{T}^N)$ and $\gamma_n^2 \in \mathrm{Lip}_{\gamma(t_2),\gamma(t_1)}([0,1],\mathbb{T}^N)$, which approximate the semidistance S of their end points up to $1/n$, for any n. The cycles γ_n, obtained by juxtaposition of γ_n^1 and γ_n^2 and change of parametrization to $[0,1]$, are of length $\ell(\gamma_n) \ge 2|\gamma(t_2) - \gamma(t_1)|$ and satisfy, by Definition 4.1,

$$\lim_n \int_0^1 \sigma(\gamma_n(s),\dot\gamma_n(s))\,\mathrm{d}s = 0,$$

which shows that $\gamma(t_1)$, $\gamma(t_2)$ are in $\mathcal{A}$. If, on the contrary, the support of γ is reduced to a point, say x_0, we find

$$\int_J (L(x_0,0) + c)\,\mathrm{d}s = 0,$$

which implies $x_0 \in \mathcal{E} \subset \mathcal{A}$. ∎

A further step in the analysis is carried out by picking up a special parametrization for curves on the torus. To do this, we use the Lagrangian function related to H.

DEFINITION 4.3. *A curve γ defined on an interval J is said to have a* Lagrangian parametrization *if*

$$L(\gamma(t),\dot\gamma(t))+c=\sigma(\gamma(t),\dot\gamma(t)) \qquad \text{for a.e. } t\in J. \tag{16}$$

The definition of the semidistance S and the inequality $L(x,q)\geq\sigma(x,q)-c$, which holds for every x and q, imply the following.

PROPOSITION 4.4. *Any critical curve has a Lagrangian parametrization.*

More generally, the following reparametrization proposition holds.

PROPOSITION 4.5. *Any curve of finite length and with closure of the support disjoint from $\mathcal{E}$ admits a Lagrangian reparametrization defined on some compact interval $[0,T]$.*

Proof. The first step is to show the existence of an upper semicontinuous (resp., lower semicontinuous) function $\overline\lambda(x,q)$ (resp., $\underline\lambda(x,q)$) defined in $(\mathbb{T}^N\setminus\mathcal{E})\times(\mathbb{R}^N\setminus\{0\})$ such that the equality

$$L(x,\overline\lambda(x,q)q)=\overline\lambda(x,q)\sigma(x,q)-c \tag{17}$$

and the similar one obtained by replacing $\overline\lambda(\cdot,\cdot)$ by $\underline\lambda(\cdot,\cdot)$ hold true.

Given $(x,q)\in(\mathbb{T}^N\setminus\mathcal{E})\times(\mathbb{R}^N\setminus\{0\})$, and denoting $\{p\,:\,H(x,p)\leq c\}$ by Z, we have that $q\in N_Z(p_0)$ for some p_0 with $H(x,p_0)=c$, and therefore

$$\lambda q\in D_p^-H(x,p_0)\quad\text{for some }\lambda>0 \tag{18}$$

in view of Theorem 23.7 of [17]. Consequently the set of nonnegative λ satisfying (17) in place of $\overline\lambda(x,q)$, denoted by $F(x,q)$, is nonempty; see Theorem A.2. It is, moreover, a compact subset of $(0,+\infty)$. We see, in fact, that, for λ large, relation (18) is impossible, when $H(x,p_0)=c$, since Z is compact and $H(x,\cdot)$ is locally Lipschitz continuous. This shows that $F(x,q)$ is bounded from above. It is also closed thanks to the continuity of $\sigma(x,\cdot)$ and $L(x,\cdot)$, and to the inequality

$$L(x,\lambda q)\geq\sigma(x,\lambda q)-c\quad\text{for every }\lambda\geq0.$$

Moreover, $0\notin F(x,q)$ because $x\notin\mathcal{E}$, and consequently $L(x,0)=-\min_pH(x,p)<-c$. We then define

$$\overline\lambda(x,q)=\max_{F(x,q)}\lambda,\quad \underline\lambda(x,q)=\min_{F(x,q)}\lambda,$$

and we see that these functions, for (x,q) varying in $(\mathbb{T}^N\setminus\mathcal{E})\times(\mathbb{R}^N\setminus\{0\})$, are upper semicontinuous and lower semicontinuous, respectively. In particular,

$$0<\inf_{(x,q)\in C}\underline\lambda(x,q)\leq\sup_{(x,q)\in C}\overline\lambda(x,q)<+\infty \tag{19}$$

for every compact set C contained in $(\mathbb{T}^N\setminus\mathcal{E})\times(\mathbb{R}^N\setminus\{0\})$.

The assertion is now obtained, arguing as in [13, Proposition 7.4]. We give the proof for the reader's convenience. Let γ be a curve as in the statement. We may

assume that it is parametrized by arc-length on $[0, \ell(\gamma)]$, with $\ell(\gamma) > 0$. Set

$$\lambda(\varsigma) := \underline{\lambda}(\gamma(\varsigma), \dot\gamma(\varsigma)) \qquad \text{for a.e. } \varsigma \in (0, \ell(\gamma))$$

and

$$T := \int_0^{\ell(\gamma)} \frac{1}{\lambda(\varsigma)}\, \mathrm{d}\varsigma.$$

Such a quantity is finite and positive, thanks to the measurable character of $\lambda(\cdot)$ and to (19) with $C := \gamma\big([0, \ell(\gamma)]\big) \times \{p : |p| = 1\}$. We will now prove the existence of a curve $\overline\gamma$, in $[0, T]$, which is a Lagrangian reparametrization of γ. To this aim, let us define

$$f(s) := \int_0^s \frac{1}{\lambda(\varsigma)}\, \mathrm{d}\varsigma \qquad \text{for any } s \in [0, \ell(\gamma)],$$

and set $\varphi := (f)^{-1}$ on $[0, T]$. As

$$\dot\varphi(\tau) = \lambda(\varphi(\tau)) \qquad \text{for a.e. } \tau \in [0, T],$$

we immediately derive that φ is an order preserving bi-Lipschitz diffeomorphism. Letting $\overline\gamma := \gamma \circ \varphi$, we get

$$\dot{\overline\gamma}(\cdot) := \lambda(\varphi(\cdot))\ \dot\gamma(\varphi(\cdot)) \qquad \text{a.e. on } [0, T],$$

and the conclusion follows at once by the definition of $\lambda(\cdot)$. □

Remark 4.6. A notion of Lagrangian parametrization can be given at any level $a > c$ by replacing in (16) c and σ with a and σ_a, respectively. Proposition 4.5 can be accordingly generalized, providing Lagrangian reparametrizations for any curve, without the requirement of an empty intersection with $\mathcal{E}$. Such a restriction comes, in fact, from the necessity of avoiding that a p_0 satisfying $H(x_0, p_0) = c$, for some x_0, be a minimizer of $p \mapsto H(x_0, p)$. This possibility is actually ruled out for a p_0 with $H(x_0, p_0) = a$ when $a > c$.

Exploiting the previous remark, we can provide, in a sense, a generalization of Proposition 4.5. This result will be used in the proof of Proposition 5.5.

LEMMA 4.7. *Let $\gamma \in \mathrm{Lip}([0,1], \mathbb{T}^N)$. For any $T > 0$ we set*

$$[\gamma]_T := \{\, \xi \in \mathrm{Lip}([0, T], \mathbb{T}^N) \,:\, \xi \text{ is a reparametrization of } \gamma \,\}.$$

Then

$$\int_0^1 \sigma(\gamma, \dot\gamma)\, \mathrm{d}s = \inf \left\{ \int_0^T \Big(L(\xi, \dot\xi) + c \Big)\, \mathrm{d}s \;:\; \xi \in [\gamma]_T,\ T > 0 \right\}. \tag{20}$$

Proof. It is apparent that the left-hand term of (20) is not greater than the right-hand term. To prove the converse inequality, we select a decreasing sequence $(\delta_n)_n$ with $\delta_n \downarrow 0$. Since $\sigma(x, q) = \inf_n \sigma_{c+\delta_n}(x, q)$ for every $(x, q) \in \mathbb{T}^N \times \mathbb{R}^N$, by the monotone convergence theorem we get

$$\int_0^1 \sigma(\gamma, \dot\gamma)\, \mathrm{d}s = \inf_n \int_0^1 \sigma_{c+\delta_n}(\gamma, \dot\gamma)\, \mathrm{d}s. \tag{21}$$

Taking into account Remark 4.6, we have a Lagrangian reparametrization γ_n of γ at level $a = c + \delta_n$, for any n, defined in some interval $[0, T_n]$, with $T_n > 0$, such that

$$\int_0^1 \sigma_{c+\delta_n}(\gamma, \dot\gamma)\,\mathrm{d}s = \int_0^{T_n} \sigma_{c+\delta_n}(\gamma_n, \dot\gamma_n)\,\mathrm{d}s = \int_0^{T_n} (L(\gamma_n, \dot\gamma_n) + c + \delta_n)\ \mathrm{d}s$$
$$\geq \int_0^{T_n} (L(\gamma_n, \dot\gamma_n) + c)\ \mathrm{d}s.$$

The assertion therefore follows from (21). □

The main result we aim at, in this section, is the following.

THEOREM 4.8. *Through any point of $\mathcal{A}$ there passes a critical curve defined on the whole $\mathbb{R}$.*

We start with a lemma, then prove a local version of Theorem 4.8, and thereafter get the full result by using Zorn's lemma.

LEMMA 4.9. *There exists a real number $R > 0$ such that*

$$\{q \in \mathbb{R}^N : L(x, q) + c = \sigma(x, q) \text{ for some } x \in \mathbb{T}^N\} \subseteq B_R.$$

Proof. We can take R as the Lipschitz constant of the function $p \mapsto H(x, p)$ for $x \in \mathbb{T}^N$ and p satisfying $H(x, p) = c$. To see that this quantity is actually well defined, note that the condition on (x, p) singles out a compact set in $\mathbb{T}^N \times \mathbb{R}^N$ in view of the coercivity assumption (H3), and take into account Remark 2.1.

If $q \in \mathbb{R}^N$, $x_0 \in \mathbb{T}^N$ are such that $L(x_0, q) + c = \sigma(x_0, q)$, then $q \in D_p^- H(x_0, p_0)$ for some p_0 with $H(x_0, p_0) = c$, and so $|q| \leq R$. □

LEMMA 4.10. *For any $y \in \mathcal{A}$, there exists $\delta \in (0, +\infty]$ and a critical curve η which is defined in $(-\delta, \delta)$ and satisfies $\eta(0) = y$.*

Proof. If $y \in \mathcal{E}$, we simply set $\eta(t) = y$ for every $t \in \mathbb{R}$. By the definition of equilibrium point, we have

$$L(y, 0) + c = \max_{p \in \mathbb{R}^N} -H(x, p) + c = 0 \tag{22}$$

for every $t \in \mathbb{R}$, which shows that η is indeed a critical curve. If $y \in \mathcal{A} \setminus \mathcal{E}$, we exploit Lemma 9.4 of [13] to see that there exists a curve γ contained in $\mathcal{A}$, and defined in some neighborhood J of $t = 0$, such that $\gamma(0) = y$ and

$$S(\gamma(t_1), \gamma(t_2)) = \int_{t_1}^{t_2} \sigma(\gamma, \dot\gamma)\,\mathrm{d}s = -S(\gamma(t_2), \gamma(t_1))$$

for every t_1, $t_2 \in J$ with $t_2 > t_1$. Note that this result does not require the Lipschitz continuity of H in x, which was assumed in that paper, and therefore holds also in our present setting.

Because of the local character of the construction, we can assume that γ stays away from $\mathcal{E}$. We thus consider a Lagrangian reparametrization of γ, which does exist in view of Proposition 4.5, to get the required curve. □

PROPOSITION 4.11. *Let $y \in \mathcal{A}$. Then there exists a critical curve η defined on $\mathbb{R}$ with $\eta(0) = y$.*

Proof. In view of Lemma 4.10, we may assume that $y \in \mathcal{A} \setminus \mathcal{E}$. We denote by $\mathcal{C}$ the set of pairs (T, η), where $T \in (0, +\infty]$, and η is a critical curve defined on $(-T, T)$ and equaling y at 0. We give an order relation in $\mathcal{C}$ by defining

$$(T, \eta) \preceq (T', \eta') \quad \text{if} \quad T \leq T' \ \text{ and } \ \eta'_{|(-T,T)} = \eta.$$

The set $\mathcal{C}$ is nonempty by Lemma 4.10. To prove that $\mathcal{C}$ is inductively ordered, we take a nonempty chain $\{(T_i, \eta_i)\}$, with i in some set of indices I, and observe that an upper bound $(\hat{T}, \hat{\eta}) \in \mathcal{C}$ can be defined through

$$\hat{T} := \sup_i T_i \quad \text{and} \quad \hat{\eta}(t) := \eta_i(t) \quad \text{if} \quad t \in (-T_i, T_i) \text{ for every } i \in I.$$

Zorn's lemma provides the existence of a maximal element (T_y, η_y) in $\mathcal{C}$. We claim that $T_y = +\infty$. If, in fact, this were not the case, and $T_y < +\infty$, then the curve η_y would have a limit (belonging to $\mathcal{A}$) for t going to $\pm T_y$, in view of Lemma 4.9. It would then be possible to extend η_y to some interval $(-T_y - \delta, T_y + \delta)$ for a suitable $\delta > 0$ by applying Lemma 4.10 to these limit points. This would violate the maximality of (T_y, η_y). □

We denote by $\mathcal{K}$ the family of all maximal critical curves, and by $\mathcal{K}(y)$ the subset of $\mathcal{K}$ made up of those equaling y at $t = 0$, for each $y \in \mathcal{A}$.

We proceed to prove a compactness property for $\mathcal{K}$.

PROPOSITION 4.12. *$\mathcal{K}$ is a compact metric space with respect to the local uniform convergence on $\mathbb{R}$.*

Proof. Let $(\eta_k)_k$ be a sequence in $\mathcal{K}$. The curves η_k are uniformly bounded by the compactness of $\mathbb{T}^N$, and equi-Lipschitz continuous by Lemma 4.9, and hence we can apply the Ascoli–Arzelà theorem to infer the existence of a subsequence (not relabeled) which converges locally uniformly to some curve η defined on $\mathbb{R}$. The limit curve η is contained in $\mathcal{A}$, as the Aubry set is closed, and clearly satisfies

$$S(\eta(t_1), \eta(t_2)) = -S(\eta(t_2), \eta(t_1)) \tag{23}$$

for every t_1, t_2 in $\mathbb{R}$. If, in addition, $t_2 > t_1$, we have

$$S(\eta_k(t_1), \eta_k(t_2)) = \int_{t_1}^{t_2} (L(\eta_k(s), \dot{\eta}_k(s)) + c)\, \mathrm{d}s$$

for every k, and we therefore deduce, thanks to Theorem 2.9,

$$S(\eta(t_1), \eta(t_2)) = \lim_{k \to +\infty} \int_{t_1}^{t_2} (L(\eta_k(s), \dot{\eta}_k(s)) + c)\, \mathrm{d}s \geq \int_{t_1}^{t_2} (L(\eta(s), \dot{\eta}(s)) + c)\, \mathrm{d}s.$$

Since the converse inequality is apparent, we get in the end

$$S(\eta(t_1), \eta(t_2)) = \int_{t_1}^{t_2} (L(\eta(s), \dot{\eta}(s)) + c)\, \mathrm{d}s. \tag{24}$$

Relations (23), (24) show that $\eta \in \mathcal{K}$. □

Given $\eta \in \mathcal{K}$, we denote by $\omega(\eta)$ the set of its ω-limits, i.e., of the points x_0 satisfying

$$x_0 = \lim_k \eta(s_k) \quad \text{with } s_k \to +\infty \text{ as } k \to +\infty. \tag{25}$$

We deduce from Proposition 4.12 that through any point x_0 of $\omega(\eta)$ there passes a critical curve entirely lying in $\omega(\eta)$. If, in fact, (25) holds, then $\{\eta(s_k + \cdot)\}_k$ converges locally uniformly, up to a subsequence, to a curve γ, which equals x_0 at 0, and is contained in $\omega(\eta)$.

Remark 4.13. We can describe more precisely $\omega(\eta)$ if the sequence s_k, appearing in (25), is increasing and such that $s_{k+1} - s_k$ converges to a finite limit, necessarily nonnegative, say T, and $\{\eta(s_k + \cdot)\}_k$ converges locally uniformly to a curve γ.

In this case, $\omega(\eta)$ coincides with the support of γ, which is a cycle of period T because of the relations

$$\gamma(t+T) = \lim_k \eta(s_k + T + t) = \lim_k \eta(s_{k+1} + t) = \gamma(t),$$

which hold for any t. If, in fact, $y_0 := \lim_n \eta(t_n)$ belongs to $\omega(\eta)$, with $(t_n)_n$ a diverging sequence, then we can select, for any n, an index $k_n \in \mathbb{N}$ satisfying $s_{k_n} \leq t_n < s_{k_n+1}$. The sequence $t_n - s_{k_n}$ is therefore bounded and thus convergent, up to a subsequence, to some $t_0 \in [0, T]$. It then follows that $y_0 = \gamma(t_0)$.

If in particular $T = 0$, then γ reduces to a point, which must be the support of a critical curve, and consequently belongs to $\mathcal{E}$.

We know from [13] that, if H is Lipschitz continuous in x, all critical subsolutions are strictly differentiable at any point of the Aubry set and have the same derivative. This implies that they coincide, up to an additive constant, on every rectifiable subset of $\mathcal{A}$. These results are based upon some semiconcavity estimates which, in turn, depend essentially on the Lipschitz character of the Hamiltonian in x that we do not have here. We can nevertheless find something similar in our setting by looking at the behavior of the critical subsolutions on curves of $\mathcal{K}$.

THEOREM 4.14. *Let $\eta \in \mathcal{K}$. Then all critical subsolutions coincide on $\eta(\mathbb{R})$, up to an additive constant. There exists, in addition, a negligible set $\Sigma \subset \mathbb{R}$ such that, for any critical subsolution ϕ, the map $\phi \circ \eta$ is differentiable on $\mathbb{R} \setminus \Sigma$ and satisfies*

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\phi \circ \eta\right)(t_0) = \sigma(\eta(t_0), \dot\eta(t_0)) \qquad \text{whenever } t_0 \in \mathbb{R} \setminus \Sigma. \tag{26}$$

We show first an auxiliary lemma, on which the proof of Theorem 4.14 is based.

PROPOSITION 4.15. *Let $\eta \in \mathcal{K}$. Then there exists a negligible set $\Sigma \subset \mathbb{R}$ such that the functions $\eta(\cdot)$, $S(\eta(t_0), \eta(\cdot))$ and $-S(\eta(\cdot), \eta(t_0))$ are differentiable at any t_0 in $\mathbb{R} \setminus \Sigma$, and*

$$\frac{\mathrm{d}}{\mathrm{d}t} S(\eta(t_0), \eta(t))\Big|_{t=t_0} = -\frac{\mathrm{d}}{\mathrm{d}t} S(\eta(t), \eta(t_0))\Big|_{t=t_0} = \sigma(\eta(t_0), \dot\eta(t_0)). \tag{27}$$

Proof. Let Σ be a negligible subset of $\mathbb{R}$ such that every $t_0 \in \mathbb{R} \setminus \Sigma$ is a differentiability point for $\eta(\cdot)$ and a Lebesgue point for the function $\sigma(\eta(\cdot), \dot\eta(\cdot))$. The existence of such a set is guaranteed by Rademacher and Lebesgue differentiability theorems. As the curve η is critical, we have

$$\frac{S(\eta(t_0), \eta(t))}{t - t_0} = \frac{1}{t - t_0} \int_{t_0}^{t} \sigma(\eta(s), \dot\eta(s))\, \mathrm{d}s \qquad \text{for every } t > t_0.$$

Since t_0 is a Lebesgue point of $\sigma(\eta(\cdot), \dot\eta(\cdot))$, we derive

$$\lim_{t \to t_0^+} \frac{S(\eta(t_0), \eta(t))}{t - t_0} = \sigma(\eta(t_0), \dot\eta(t_0))$$

for every $t_0 \in \mathbb{R} \setminus \Sigma$. A similar limit relation for $t \to t_0^-$ can be deduced analogously. ∎

Proof of Theorem 4.14. Let Σ and ϕ be the subset of $\mathbb{R}$ given by Proposition 4.15 and a critical subsolution, respectively. By Proposition 2.3, we have

$$-S(\eta(t),\eta(t_0)) \le \phi(\eta(t)) - \phi(\eta(t_0)) \le S(\eta(t_0),\eta(t)) \qquad \text{for every } t, t_0 \in \mathbb{R},$$

and hence we get (26), for $t_0 \in \mathbb{R} \setminus \Sigma$, in view of Proposition 4.15. This fully proves the assertion. ∎

We point out two consequences of the previous theorem that we use in the next section and judge to be of independent interest as well.

PROPOSITION 4.16. *Two critical subsolutions coinciding on* $\mathcal{M} := \bigcup_{\eta\in\mathcal{K}} \omega(\eta)$ *must also coincide on* $\mathcal{A}$.

Proof. Let ϕ_1, ϕ_2 be two critical subsolutions coinciding on $\mathcal{M}$. Take y and η in $\mathcal{A}$ and in $\mathcal{K}(y)$, respectively. Let $(t_n)_n$ be a diverging sequence such that $\lim_n \eta(t_n) = x \in \mathcal{M}$. As $S(y,\cdot)$ is a critical subsolution (cf. Proposition 2.3), Theorem 4.14 yields

$$\phi_i(y) = \phi_i(\eta(0)) - S(y,\eta(0)) = \phi_i(\eta(t_n)) - S(y,\eta(t_n))$$

for every $n \in \mathbb{N}$, $i \in \{1,2\}$. Sending n to $+\infty$, we get

$$\begin{aligned}\phi_1(y) &= \lim_{n\to+\infty} \phi_1(\eta(t_n)) - S(y,\eta(t_n)) = \phi_1(x) - S(y,x) = \phi_2(x) - S(y,x)\\ &= \lim_{n\to+\infty} \phi_2(\eta(t_n)) - S(y,\eta(t_n)) = \phi_2(y),\end{aligned}$$

whence we get the assertion since y is an arbitrary point of $\mathcal{A}$. ∎

Remark 4.17. As the curve $\eta(t) := y$, for every $t \in \mathbb{R}$, is critical whenever $y \in \mathcal{E}$, it is apparent from the definitions that the set $\mathcal{E}$ is always contained in $\mathcal{M}$.

PROPOSITION 4.18. *The set* $\mathcal{M}$ *is a uniqueness set for* (2); *i.e., two solutions of* (2) *coinciding on* $\mathcal{M}$ *coincide on the whole torus too.*

Proof. The assertion comes from the previous proposition and from the property that $\mathcal{A}$ is a uniqueness set for (2), as established in Theorem 2.4. ∎

5. Convergence to steady states. We are now ready to prove our main convergence result. Throughout this section we will assume, without loss of generality, $c = 0$. We also assume that H satisfies conditions (H1), (H2)′, (H3). We recall that $u_0 \in C(\mathbb{T}^N)$ is the initial datum of the Cauchy problem (6) and that $\omega_{\mathcal{S}}(u_0)$ denotes the family of the uniform limits of $\mathcal{S}(t_n)u_0$ for some diverging sequence $(t_n)_n$. We start by establishing some monotonicity properties for the function $\mathcal{S}(t)\psi - \phi$ on the curves of $\mathcal{K}$, where ψ is any continuous function and ϕ any critical subsolution. The next result is analogous to Lemma 3.1 in [18].

PROPOSITION 5.1. *Let* $\eta \in \mathcal{K}$. *Then the map* $t \mapsto \big(\mathcal{S}(t)\psi\big)(\eta(t)) - \phi(\eta(t))$ *is nonincreasing on* $\mathbb{R}_+$ *for any* $\psi \in C(\mathbb{T}^N)$ *and any critical subsolution* ϕ.

Proof. Let t_1, t_2 in $\mathbb{R}_+$ with $t_2 \ge t_1$. Taking into account Theorem 4.14 and the integral representation formula for the Lax–Oleinik semigroup, we get

$$\big(\mathcal{S}(t_2)\psi\big)(\eta(t_2)) - \big(\mathcal{S}(t_1)\psi\big)(\eta(t_1)) \le \int_{t_1}^{t_2} L(\eta(s),\dot\eta(s))\,\mathrm{d}s = \phi(\eta(t_2)) - \phi(\eta(t_1)),$$

which proves the assertion. ∎

We proceed to prove that a strict monotonicity property actually holds on the critical curves under appropriate assumptions. This result relies on a lemma, which we demonstrate first and which estimates the modification of the line integral of the Lagrangian on a critical curve when the Lagrangian parametrization is suitably

perturbed. As already pointed out in the introduction, we emphasize that, for this, we essentially use the differentiability of L in q and the continuity of $D_qL(x,q)$ in $\mathrm{int}(\mathrm{dom}L)$, a property that is equivalent, for a continuous Hamiltonian, to the strict convexity of H in the second variable (cf. [7]). These results are key tools for the forthcoming convergence theorem.

LEMMA 5.2. *There is a modulus $\omega(\cdot)$ such that, if η is any curve in $\mathcal{K}$ and λ is suitably close to* 1, *we have*

$$\int_{t_1}^{t_2} L(\eta_\lambda, \dot\eta_\lambda)\,\mathrm{d}s \le S(\eta_\lambda(t_1), \eta_\lambda(t_2)) + |\lambda-1|\,\omega(|\lambda-1|)(t_2-t_1)$$

for every t_1, t_2 with $t_2 > t_1$, where $\eta_\lambda(t) := \eta(\lambda t)$ for all $t \in \mathbb{R}$.

Proof. We claim that $K := \{(x,q) \in \mathcal{A}\times\mathbb{R}^N : L(x,q) = \sigma(x,q)\}$ is a compact subset of $\mathrm{int}(\mathrm{dom}L)$. It is in fact closed by the lower and upper semicontinuity of L and σ, respectively, bounded by Lemma 4.9, and contained in $\mathrm{int}(\mathrm{dom}L)$ thanks to Proposition 2.7(iv). There thus exists $\delta > 0$ such that the set $K_\delta := \{(x,\lambda q) : (x,q) \in K,\ |\lambda-1| \le \delta\}$ is compactly contained in $\mathrm{int}(\mathrm{dom}L)$.

Let us now fix λ in $(1-\delta, 1+\delta)$ and denote by θ a continuity modulus for the function $(x,q) \mapsto D_qL(x,q)$ in K_δ. For a.e. $s \in \mathbb{R}$ we have

$$(\eta(\lambda s), \dot\eta(\lambda s)) \in K, \tag{28}$$

$$\langle D_q\, L(\eta(\lambda s), \dot\eta(\lambda s)), \dot\eta(\lambda s)\rangle = \sigma(\eta(\lambda s), \dot\eta(\lambda s)), \tag{29}$$

where the first relation comes from the very definition of critical curve, and the second one holds in view of Theorem A.2. Let s be such that (28) and (29) hold. The application of the mean value theorem to the function $\mu \mapsto L(\eta(\lambda s), \mu\eta(\lambda s))$ in the interval with end points 1 and λ yields

$$L(\eta(\lambda s), \lambda\,\dot\eta(\lambda s)) - L(\eta(\lambda s), \dot\eta(\lambda s)) = (\lambda-1)\langle D_q\, L(\eta(\lambda s), \mu_0\,\dot\eta(\lambda s)), \dot\eta(\lambda s)\rangle,$$

where μ_0 is a suitable constant between λ and 1. By using (28), (29), and the definition of $\theta(\cdot)$, we derive from this identity

$$L(\eta(\lambda s), \lambda\,\dot\eta(\lambda s)) \le \lambda\,\sigma(\eta(\lambda s), \dot\eta(\lambda s)) + R|\lambda-1|\,\theta(|\lambda-1|R),$$

where R is the positive constant provided by Lemma 4.9. We now exploit the previous estimate and the fact that η is a critical curve to get for any t_1, t_2 in $\mathbb{R}$ with $t_2 > t_1$

$$\begin{aligned}\int_{t_1}^{t_2} L(\eta_\lambda, \dot\eta_\lambda)\,\mathrm{d}s &= \int_{t_1}^{t_2} L(\eta(\lambda s), \lambda\dot\eta(\lambda s))\,\mathrm{d}s\\ &\le \int_{t_1}^{t_2} \lambda\,\sigma(\eta(\lambda s), \dot\eta(\lambda s))\,\mathrm{d}s + (t_2-t_1)|\lambda-1|\,R\;\theta(R\,|\lambda-1|)\\ &= S(\eta_\lambda(t_1), \eta_\lambda(t_2)) + (t_2-t_1)|\lambda-1|\,R\;\theta(R\,|\lambda-1|).\end{aligned}$$

The proof is complete. □

PROPOSITION 5.3. *Let $\eta \in \mathcal{K}$, $\psi \in C(\mathbb{T}^N)$, and ϕ be a critical subsolution. Let us assume $D^+\big((\psi-\phi)\circ\eta\big)(0)\setminus\{0\} \neq \emptyset$ (recall that D^+ indicates the superdifferential); then*

$$(\mathcal{S}(t)\psi)(\eta(t)) - \phi(\eta(t)) < \psi(\eta(0)) - \phi(\eta(0)) \qquad \textit{for every } t > 0. \tag{30}$$

Proof. We fix $t > 0$. Inequality (30) will be proved for $\phi := -S(\cdot, \eta(t))$, which is enough to get the full result, in view of Theorem 4.14. We also assume, without loss of generality in view of Proposition 2.6(iii), that $\psi(\eta(0)) - \phi(\eta(0)) = 0$. We are thus lead to show that the left-hand term of (30) is strictly negative. To this aim, we take into account the integral formula for the Lax–Oleinik semigroup, given in section 2, to get, for λ close to 1 and η_λ defined as in Lemma 5.2,

$$(\mathcal{S}(t)\psi)(\eta(t)) - \phi(\eta(t)) = (\mathcal{S}(t)\psi)(\eta(t)) \leq \int_{(1/\lambda-1)t}^{t/\lambda} L(\eta_\lambda, \dot\eta_\lambda)\,\mathrm{d}s + \psi\big(\eta((1-\lambda)t)\big),$$

whence, by Lemma 5.2,

$$(\mathcal{S}(t)\psi)(\eta(t)) - \phi(\eta(t)) \leq \psi\big(\eta((1-\lambda)t)\big) - \phi\big(\eta((1-\lambda)t)\big) + t|\lambda-1|\,\omega(|\lambda-1|).$$

If $m \neq 0$ is an element of $D^+\big((\psi-\phi)\circ\eta\big)(0)$, we therefore have

$$(\mathcal{S}(t)\psi)(\eta(t)) - \phi(\eta(t)) \leq m\big((1-\lambda)t\big) + o\big((1-\lambda)t\big) + t|\lambda-1|\,\omega(|\lambda-1|),$$

where $o(\cdot)$ satisfies $\lim_{\lambda\to 1} \frac{o((1-\lambda)t)}{1-\lambda} = 0$. A suitable choice of λ close to 1 makes the left-hand term of the previous formula strictly negative, and consequently proves the assertion, for the arbitrariness of t. □

We combine the information gathered in Propositions 5.1 and 5.3 with some properties of the Lax–Oleinik semigroup to get the following.

PROPOSITION 5.4. *Let ϕ be a critical subsolution, and let $\psi \in \omega_{\mathcal{S}}(u_0)$. For any $x_0 \in \mathcal{M}$ there exists a curve $\gamma \in \mathcal{K}(x_0)$ such that the function $t \mapsto \psi(\gamma(t)) - \phi(\gamma(t))$ is constant on $\mathbb{R}$.*

Proof. Let $(s_k)_k$ and $(t_k)_k$ be two diverging sequences, η a curve of $\mathcal{K}$ such that $x_0 = \lim_k \eta(s_k)$, and ψ the uniform limit of $\mathcal{S}(t_k)u_0$ in $\mathbb{T}^N$. We can assume that the curve γ, defined by $\gamma(t) = \lim_k \eta(t+s_k)$, for any t, is the local uniform limit of the sequence $\eta(s_k+\cdot)$ in $\mathbb{R}$, and so $\gamma \in \mathcal{K}$. We assume, in addition, that $t_k - s_k \to +\infty$, as $k \to +\infty$, and that $\mathcal{S}(t_k - s_k)u_0$ uniformly converges to some $\psi_1 \in \omega_{\mathcal{S}}(u_0)$. The nonexpansiveness of the Lax–Oleinik semigroup implies

$$\|\mathcal{S}(t_k)u_0 - \mathcal{S}(s_k)\psi_1\|_\infty = \|\mathcal{S}(s_k+t_k-s_k)u_0 - \mathcal{S}(s_k)\psi_1\|_\infty \leq \|\mathcal{S}(t_k-s_k)u_0 - \psi_1\|_\infty,$$

which entails $\mathcal{S}(s_k)\psi_1 \rightrightarrows \psi$ in $\mathbb{T}^N$. We know from Proposition 5.1 that the function

$$s \mapsto (\mathcal{S}(s)\psi_1)(\eta(s)) - \phi(\eta(s))$$

is nonincreasing in $\mathbb{R}_+$, and hence it admits a limit, denoted by l, as $s \to +\infty$. Such a limit is furthermore finite, since it is greater than or equal to $-\|\overline{u} - \phi\|_\infty$. Given $t > 0$, we have

$$l = \lim_{k\to+\infty} (\mathcal{S}(s_k+t)\psi_1)(\eta(s_k+t)) - \phi(\eta(s_k+t)) = (\mathcal{S}(t)\psi)(\gamma(t)) - \phi(\gamma(t)).$$

The function $t \mapsto (\mathcal{S}(t)\psi)(\gamma(t)) - \phi(\gamma(t))$ is therefore constant on $\mathbb{R}_+$. From this we deduce, by applying Proposition 5.3 to the curve $\gamma(s+\cdot) \in \mathcal{K}$, for any fixed s, that $D^+\big((\psi-\phi)\circ\gamma\big)(s) \setminus \{0\} = \emptyset$ for any $s \in \mathbb{R}$. This implies that $\psi - \phi$ is constant on γ. □

The previous proposition shows that any function ψ in $\omega_{\mathcal{S}}(u_0)$ coincides, on any given critical curve γ lying in $\mathcal{M}$, with some critical subsolution ϕ. Such a critical subsolution may a priori depend on the curve γ and on ψ. We proceed to show that, on the contrary, ϕ is uniquely determined and coincides with the function v defined by (11), putting u_0 in place of w_0. In force of Proposition 5.4, it will be enough to prove the following fact.

PROPOSITION 5.5. *Given $\eta \in \mathcal{K}$, $\psi \in \omega_{\mathcal{S}}(u_0)$, $\varepsilon > 0$, there exists $\tau \in \mathbb{R}$ such that*

$$|v(\eta(\tau)) - \psi(\eta(\tau))| < \varepsilon,$$

where v is the critical solution defined by (11) *with $w_0 = u_0$.*

Proof. Since the curve η is contained in $\mathcal{A}$, and in view of Theorem 3.1(ii), we have

$$v(\eta(0)) = \min_{z \in \mathbb{T}^N} \Big(u_0(z) + S(z, \eta(0)) \Big),$$

and hence $v(\eta(0)) = u_0(z_0) + S(z_0, \eta(0))$, for some $z_0 \in \mathbb{T}^N$. We choose a curve $\gamma \in \mathrm{Lip}_{z_0,\eta(0)}([0,1], \mathbb{T}^N)$ such that

$$v(\eta(0)) + \varepsilon/2 = u_0(z_0) + S(z_0, \eta(0)) + \varepsilon/2 > u_0(z_0) + \int_0^1 \sigma(\gamma, \dot\gamma)\, \mathrm{d}s.$$

We thereafter take into account Lemma 4.7 and the integral representation formula for the Lax–Oleinik semigroup to get

$$v(\eta(0)) + \varepsilon/2 > u_0(z_0) + \int_0^T L(\gamma_T, \dot\gamma_T)\, \mathrm{d}s \geq \big(\mathcal{S}(T)u_0\big)(\eta(0)),$$

where γ_T is a suitable reparametrization of γ on $[0,T]$, for some $T > 0$. Now letting $(\tau_n)_n$ be a diverging sequence with $\mathcal{S}(\tau_n)u_0 \rightrightarrows \psi$, we have

$$\|\mathcal{S}(\tau_n)u_0 - \psi\|_\infty < \varepsilon/2 \qquad \text{and} \qquad \tau_n - T > 0 \qquad \text{for } n \text{ sufficiently large.}$$

Pick such an n and set $\tau = \tau_n - T$, and then use the above inequalities and Theorem 4.14 to obtain

$$\begin{aligned} \psi(\eta(\tau)) - \varepsilon/2 &< \big(\mathcal{S}(\tau_n)u_0\big)(\eta(\tau)) = \big(\mathcal{S}(\tau)\mathcal{S}(T)u_0\big)(\eta(\tau)) \\ &\leq \big(\mathcal{S}(T)u_0\big)(\eta(0)) + \int_0^\tau L(\eta, \dot\eta)\, \mathrm{d}s \\ &< \varepsilon/2 + v(\eta(0)) + \int_0^\tau L(\eta, \dot\eta)\, \mathrm{d}s = \varepsilon/2 + v(\eta(\tau)). \end{aligned}$$

This gives the assertion since $\psi(\eta(\tau)) - v(\eta(\tau)) \geq 0$ by Proposition 3.5. ∎

We directly derive the following theorem from Propositions 5.4 and 5.5.

THEOREM 5.6. *Any function in $\omega_{\mathcal{S}}(u_0)$ coincides with v on $\mathcal{M}$, where v is the critical subsolution defined by* (11)*, with u_0 in place of w_0.*

We finally prove our main result.

THEOREM 5.7. *Let H satisfy conditions* (H1), (H2)′, (H3) *and $u_0 \in \mathrm{C}(\mathbb{T}^N)$. Then $\mathcal{S}(t)u_0$ uniformly converges to v on $\mathbb{T}^N$ as t goes to $+\infty$, where v is the critical solution given by formula* (11) *with $w_0 = u_0$.*

Proof. Theorem 5.6 implies that v and $\underline{u}$ coincide on $\mathcal{M}$; therefore they coincide on $\mathcal{A}$ thanks to Proposition 4.16. The comparison principle given in Theorem 2.4 hence tells us that $\underline{u} \leq v$ on the whole torus, since $\underline{u}$ is a critical subsolution and v is a critical solution. The assertion is at last obtained thanks to Proposition 3.5. ∎

Remark 5.8. We stress that the only place in the present section (actually, in the whole paper) where the strict convexity assumption is directly employed is Lemma 5.2. More precisely, it uses the global continuity of $D_q L(x,q)$ in $\mathrm{int}(\mathrm{dom} L)$, a property that is equivalent to the strict convexity of H in p, as previously noted. As a matter of fact, we do not exploit such a condition in its full strength. The existence of a continuity modulus for $D_q L(x,q)$ in a neighborhood of the image of the map $t \mapsto (\eta, \dot{\eta})$, for each $\eta \in \mathcal{K}$, might be sufficient.

Since the stationary curve $\gamma(\cdot) = y$ belongs to $\mathcal{K}$ whenever $y \in \mathcal{E}$, Proposition 5.5—which has been proved without exploiting the strict convexity assumption (H2)′—directly implies that any function of $\omega_{\mathcal{S}}(u_0)$ coincides with v on $\mathcal{E}$. Hence, whenever $\mathcal{E}$ is a uniqueness set for the critical equation (2), the argument of Theorem 5.7 gives the convergence result, bypassing Proposition 5.4, which instead relies on Lemma 5.2. This happens, for instance, when $\mathcal{M} = \mathcal{E}$. We can therefore state the following.

THEOREM 5.9. *Let H satisfy conditions* (H1), (H2), (H3), (H4) *and $u_0 \in \mathrm{C}(\mathbb{T}^N)$. Then any function in $\omega_{\mathcal{S}}(u_0)$ coincides with v on $\mathcal{E}$, where v is the critical subsolution defined by* (11), *with u_0 in place of w_0. In particular, $\mathcal{S}(t)u_0$ uniformly converges to v on $\mathbb{T}^N$, as t goes to $+\infty$, when $\mathcal{M} = \mathcal{E}$, and, more generally, whenever $\mathcal{E}$ is a uniqueness set for the critical equation* (2).

Note that the previous theorem includes the results of [16], where the Hamiltonian under investigation was assumed only convex and with the Aubry set consisting of equilibria.

The next one-dimensional example deals with a family of Hamiltonians, depending on a parameter $\alpha \in \mathbb{R}$, which satisfy assumptions (H1), (H2), (H3), (H4). It is shown that a suitable initial datum for the time-dependent equation can be selected in such a way that the convergence to a steady state does not take place whenever the Hamiltonian under consideration does not satisfy the assumptions of Theorem 5.9. It can be viewed as a development of the example given in [4, section 5].

Example 5.10. Consider the $\mathbb{Z}$-periodic Hamiltonian

$$H(x,p) = |p| - f(x)$$

defined in $\mathbb{R}$ (cf. Remark 2.2), where f is a continuous periodic potential with $f \not\equiv 0$, $f \geq 0$, and $\min_{\mathbb{R}} f = 0$. The effective Hamiltonian $\overline{H}(\alpha)$, i.e., the critical value of $H(x, p+\alpha)$, is given, for any $\alpha \in \mathbb{R}$, by

$$\overline{H}(\alpha) = \max\left\{0, |\alpha| - \int_0^1 f \,\mathrm{d}s\right\};$$

see [15]. It is not difficult to check that, for $\alpha \in \overline{H}^{-1}(0)$, the set of equilibria $\mathcal{E}(\alpha)$, relative to $H(x, p+\alpha)$, coincides with $f^{-1}(0)$ and is a uniqueness set for the corresponding critical equation, while $\mathcal{A}(\alpha) = \mathcal{M}(\alpha) = \mathbb{R}$ and $\mathcal{E}(\alpha) = \emptyset$ as soon as α lies outside the flat part.

Given $\alpha \notin \overline{H}^{-1}(0)$, we define in $[0, +\infty) \times \mathbb{R}$ the function

$$w(t,x) = u_0(x - \mathrm{sgn}\,\alpha\; t) + \mathrm{sgn}\,\alpha \int_0^x f \,\mathrm{d}s - \left(\mathrm{sgn}\,\alpha \int_0^1 f \,\mathrm{d}s\right) x,$$

where sgn indicates the sign function, and u_0 is a C^1 nonconstant periodic function satisfying

$$\operatorname{sgn}\left\{u_0'(x)+\operatorname{sgn}\alpha\,\left(|\alpha|-\int_0^1 f\,\mathrm{d}s\right)\right\}=\operatorname{sgn}\alpha\qquad\text{for all } x\in\mathbb{R}. \tag{31}$$

Note that relation (31) implies

$$\operatorname{sgn}\left(u_0'(x)+\operatorname{sgn}\alpha\, f(y)-\operatorname{sgn}\alpha\,\int_0^1 f\,\mathrm{d}s+\alpha\right)=\operatorname{sgn}\alpha\qquad\text{for all } x,y\in\mathbb{R}, \tag{32}$$

as f is nonnegative. The function $w(t,\cdot)$ is periodic in $\mathbb{R}$ for any t, as easily seen. By taking into account (32), a direct calculation shows that

$$\partial_t w(t,x)+|\partial_x w(t,x)+\alpha|-f(x)-|\alpha|+\int_0^1 f\,\mathrm{d}s=0$$

for every $(t,x)\in(0,+\infty)\times\mathbb{R}$. Hence, w is a periodic C^1-solution of the time-dependent equation

$$\partial_t u+H(x,\partial_x u+\alpha)-\overline{H}(\alpha)=0\qquad\text{in } (0,+\infty)\times\mathbb{R},$$

but it does not converge to any steady state for $t\to+\infty$. Note that H is not strictly convex in the second argument and that $\mathcal{E}(\alpha)=\emptyset$.

Such a construction is clearly not possible when $\alpha\in\overline{H}^{\,-1}(0)$, or, in other words, when $|\alpha|\le\int_0^1 f\,\mathrm{d}s$, because condition (31) implies, in this case, that u_0' does not change sign on $\mathbb{R}$, in contrast with u_0 being nonconstant and periodic.

Appendix. We consider a Hamiltonian $H:\mathbb{T}^N\times\mathbb{R}^N\to\mathbb{R}$ satisfying conditions (H1), (H2), (H3), and we denote by $L:\mathbb{T}^N\times\mathbb{R}^N\to(-\infty,+\infty]$ the corresponding Lagrangian defined through the Fenchel transform (8). As H is assumed coercive but not superlinear, the Lagrangian L is not finite valued in general. Our aim is to give first a proof of Proposition 2.7, and afterward to show the validity of the integral representation formula (9) for the Lax–Oleinik semigroup. We start by recalling some basic facts of convex analysis, and by giving a characterization of the interior of $\mathrm{dom}(L)$, where $\mathrm{dom}(L):=\{(x,q)\in\mathbb{T}^N\times\mathbb{R}^N:\,L(x,q)<+\infty\}$.

THEOREM A.1. *Let $f:\mathbb{R}^N\to(-\infty,+\infty]$ be a convex function with $f\not\equiv+\infty$. Then $D^-f(q)$ is a nonempty bounded set if and only if $q\in\mathrm{int}(\mathrm{dom}f)$, and it is empty for $q\notin\mathrm{dom}f$.*

We refer to [17, Theorem 23.4] for a proof. Note that $L(x,\cdot)$ turns out to be convex and lower semicontinuous on $\mathbb{R}^N$, as supremum of continuous convex functions, for any $x\in\mathbb{T}^N$. Moreover, $L(x,\cdot)\not\equiv+\infty$ (cf. [17, Theorem 12.2]). We have (cf. [17, Theorem 23.5]) the following.

THEOREM A.2. *Let $x\in\mathbb{T}^N$ and $p,q\in\mathbb{R}^N$. The following conditions are equivalent:*

(a) $H(x,p)+L(x,q)\le\langle p,q\rangle$;
(b) $H(x,p)+L(x,q)=\langle p,q\rangle$;
(c) $q\in D_p^-H(x,p)$;
(d) *the function* $\langle\,\cdot\,,q\rangle-L(x,\cdot)$ *achieves its maximum at* p;
(e) $p\in D_q^-L(x,q)$;
(f) *the function* $\langle p,\,\cdot\,\rangle-L(x,\cdot)$ *achieves its maximum at* q.

THEOREM A.3.

(i) *For any* $x \in \mathbb{T}^N$, $\mathrm{dom}(L(x,\cdot))$ *has a nonempty interior.*

(ii) $\mathrm{int}(\mathrm{dom}L) = \bigcup_{x\in\mathbb{T}^N}\{x\} \times \mathrm{int}(\mathrm{dom}L(x,\cdot))$.

Proof. According to Corollary 13.4.2 in [17], the assertion in (i) holds true if and only if there are no lines along which $H(x,\cdot)$ is (finite and) affine. Such a condition is actually a consequence of the coercivity assumption (H3).

To ease notation, let us temporarily denote by $\widetilde{\Omega}$ the set on the right-hand side of the equality in item (ii). It is apparent that $\mathrm{int}(\mathrm{dom}L) \subset \widetilde{\Omega}$.

To prove the converse inclusion, we assume by contradiction the existence of $(x_0,q_0) \in \widetilde{\Omega} \setminus \mathrm{int}(\mathrm{dom}L)$. According to Theorem A.1, this implies that $D_q^- L(x_0,q_0)$ is nonempty and bounded, and, moreover, that there is a sequence $((x_n,q_n))_n$ converging to (x_0,q_0), with $D_q^- L(x_n,q_n)$ either empty or unbounded. In any case, we may find a sequence $(p_n)_n$ such that $|p_n| \to +\infty$ and

$$\langle p_0, q_n\rangle - H(x_n,p_0) \le \langle p_n,q_n\rangle - H(x_n,p_n), \tag{33}$$

where p_0 is any fixed element of $D_q^- L(x_0,q_0)$. Since the function $p \mapsto \langle p,q_n\rangle - H(x_n,q_n)$ is concave for any $n \in \mathbb{N}$, we see that (33) is still satisfied by putting any convex combination of p_n and p_0 in place of p_n; in particular it holds for some sequence $(\overline{p}_n)_n$ with $|\overline{p}_n - p_0| = r$, where r is an arbitrarily chosen positive constant. Up to subsequences, we can assume that $(\overline{p}_n)_n$ converges to some $\overline{p}$. Sending n to $+\infty$, we obtain

$$L(x_0,q_0) = \langle p_0,q_0\rangle - H(x_0,p_0) \le \langle \overline{p},q_0\rangle - H(x_0,\overline{p}),$$

which implies that $\overline{p} \in D_q^- L(x_0,q_0)$ by Theorem A.2. This is in contrast to $D_q^- L(x_0,q_0)$ being bounded because $|\overline{p} - p_0| = r$ and r is arbitrarily large. □

The argument used for the proof of item (ii) in the previous theorem also gives the following corollary (cf. Remark 2.1).

COROLLARY A.4. *The set-valued map* $(x,q) \mapsto D_q^- L(x,q)$ *is locally uniformly bounded in* $\mathrm{int}(\mathrm{dom}L)$.

Proof of Proposition 2.7. (i) The lower semicontinuous and convex character of L has already been pointed out at the beginning of the appendix.

(ii) By item (i), we need only show that L is upper semicontinuous in Ω. Hence, let $(x_0,q_0) \in \Omega$ be the limit of some sequence $((x_n,q_n))_n$ contained in Ω. Given $p_n \in D_q^- L(x_n,q_n)$, we have that $(p_n)_n$ is bounded by Corollary A.4, and so convergent, up to a subsequence, to some p_0. Thanks to Theorem A.2 we know that

$$L(x_n,q_n) = \langle p_n,q_n\rangle - H(x_n,p_n),$$

and by sending n to infinity we get

$$\limsup_{n\to+\infty} L(x_n,q_n) = \lim_{n\to+\infty} \langle p_n,q_n\rangle - H(x_n,p_n) = \langle p_0,q_0\rangle - H(x_0,\ p_0) \le L(x_0,q_0),$$

which proves the claim.

(iii) Fix $x \in \mathbb{T}^N$. The C^1-regularity of the function $L(x,\cdot)$ in $\mathrm{int}(\mathrm{dom}L(x,\cdot))$ is equivalent to the strict convexity of $H(x,\cdot)$ on $\mathbb{R}^N$ (cf. [7]). In particular,

$$L(x,q) = \langle D_qL(x,q),q\rangle - H(x,D_qL(x,q)) \qquad \text{for all } (x,q) \in \Omega,$$

and $p = D_qL(x,q)$ is the unique maximizer of the function $\langle\cdot\ ,q\rangle - H(x,\cdot)$. To prove the continuity of $D_pL(x,q)$ in Ω, it suffices to show, by Corollary A.4, that

$(x_n, q_n) \to (x_0, q_0)$ in Ω and $D_q L(x_n, q_n) \to \overline{p}$ in $\mathbb{R}^N$ imply $\overline{p} = D_q L(x_0, q_0)$. This actually follows from the continuity of L in Ω, since we can pass to the limit in the equality $L(x_n, q_n) = \langle D_q L(x_n, q_n), q_n\rangle - H(x_n, D_q L(x_n, q_n))$ to obtain $L(x_0, q_0) = \langle \overline{p}, q_0\rangle - H(x_0, \overline{p})$, which gives $\overline{p} = D_p L(x_0, q_0)$ by our previous remarks.

(iv) If the set of maximizers of $p \mapsto \langle p, q\rangle - H(x, p)$ is nonempty, then it reduces to a singleton by the strict convexity of H with respect to p. The assertion thus follows from Theorems A.1 and A.3(ii). □

Let us now define, for each $n \in \mathbb{N}$,

$$H_n(x, p) := H(x, p) + \max\{|p|^2 - n^2, 0\} \qquad \text{for every } (x, p) \in \mathbb{T}^N \times \mathbb{R}^N,$$

and denote by L_n the Fenchel transform of H_n. Note that $(H_n)_n$ is a decreasing sequence of superlinear Hamiltonians, satisfying assumptions (H1), (H2), (H3), uniformly converging to H on compact subsets of $\mathbb{T}^N \times \mathbb{R}^N$. This, in turn, implies that $(L_n)_n$ is an increasing sequence of Lagrangians, defined and continuous on $\mathbb{T}^N \times \mathbb{R}^N$, converging pointwise to L on $\mathbb{T}^N \times \mathbb{R}^N$, and uniformly superlinear at infinity in q, as well (see, e.g., [7]).

THEOREM A.5. *The representation formula* (9) *holds for every* $\phi \in \mathrm{C}(\mathbb{T}^N)$, $t > 0$.

The proof of the theorem is based on a Γ-convergence result (cf. [9]) that we show first. For this, we employ a classical sequential weak compactness criterion in $W^{1,1}$ (see, for instance, Theorem 2.13 of [5]), which is in turn a consequence of the Dunford–Pettis theorem (cf. Theorem 2.11 in [5]).

PROPOSITION A.6. *For any fixed* $x \in T^N$ *and* $t > 0$, *denote by* $X_t(x)$ *the space*

$$\{\gamma \in W^{1,1}([0, t], \mathbb{T}^N),\ \gamma(t) = x\}$$

endowed with the strong topology of $L^1([0, t], \mathbb{T}^N)$. *For any* $\phi \in \mathrm{C}(\mathbb{T}^N)$, *let us set*

$$\mathbb{L}^t(\gamma) := \phi(\gamma(0)) + \int_0^t L(\gamma(s), \dot\gamma(s))\,\mathrm{d}s,$$
$$\mathbb{L}^t_n(\gamma) := \phi(\gamma(0)) + \int_0^t L_n(\gamma(s), \dot\gamma(s))\,\mathrm{d}s.$$

Then the functionals $\mathbb{L}^t_n$ Γ-*converge to* $\mathbb{L}^t$ *on* $X_t(x)$. *Moreover,*

$$\min_{\gamma \in X_t(x)} \mathbb{L}^t(\gamma) = \lim_{n \to +\infty} \min_{\gamma \in X_t(x)} \mathbb{L}^t_n(\gamma).$$

Proof. We first set

$$\Theta(t) := \inf_{x \in \mathbb{T}^N} \left(\inf_{|q| \geq t} L_1(x, q) \right) \qquad \text{for every } t \geq 0$$

and observe that

$$\lim_{t \to +\infty} \frac{\Theta(t)}{t} = +\infty, \qquad \Theta(|q|) \leq L_n(x, q) \leq L(x, q) \tag{34}$$

for any $n \in \mathbb{N}$ and $(x, q) \in \mathbb{T}^N \times \mathbb{R}^N$. We claim that the functionals $\mathbb{L}^t_n$ and $\mathbb{L}^t$ are lower semicontinuous on $X_t(x)$. In fact, any sequence $(\gamma_n)_n$ in $X_t(x)$ with $\lim_n \mathbb{L}^t(\gamma_n) < +\infty$ also satisfies $\sup_n \int_0^t \Theta(\dot\gamma_n)\,\mathrm{d}s < +\infty$ by (34), and this in turn implies that $(\gamma_n)_n$ is weakly convergent in $W^{1,1}([0, t], \mathbb{T}^N)$, up to subsequences (cf. Theorem 2.13 of [5]).

This shows the sequential lower semicontinuity of $\mathbb{L}^t$ in $X_t(x)$, in view of Theorem 2.9; the lower semicontinuity follows as $X_t(x)$ is a metric space. The same argument gives the claim for each $\mathbb{L}^t_n$.

The Γ-convergence result is then assured by [9, Proposition 5.4], since $(\mathbb{L}^t_n)_n$ is, in addition, an increasing sequence of functionals converging pointwise to $\mathbb{L}^t$ on $X_t(x)$. To prove the asserted convergence of the minima, we remark that the set

$$K_t(x) := \left\{ \gamma \in X_t(x) \,:\, \int_0^t \Theta(|\dot\gamma|)\,\mathrm{d}s \le \|\phi\|_\infty + \Bbbk\, t \right\},$$

with $\Bbbk := \sup_{y\in\mathbb{T}^N} L(y,0)$, is sequentially weakly compact in $W^{1,1}([0,t],\mathbb{T}^N)$, and hence compact in $X_t(x)$ because the weak convergence implies the uniform convergence (cf. [5, Theorem 2.13]). Notice also that

$$\int_0^t \Theta(|\dot\gamma_x|)\,\mathrm{d}s \le \mathbb{L}^t_n(\gamma_x) \le \mathbb{L}^t(\gamma_x) \le \|\phi\|_\infty + \Bbbk\, t$$

for any n, where γ_x denotes the curve in $X_t(x)$ constantly equal to x. Consequently $K_t(x)$ is nonempty and

$$\inf\{\, \mathbb{L}^t_n(\gamma) \,:\, \gamma \in X_t(x)\,\} = \min\{\, \mathbb{L}^t_n(\gamma) \,:\, \gamma \in K_t(x)\}$$

for each n, so the assertion follows in view of [9, Theorem 7.4]. □

Proof of Theorem A.5. We first notice that it is enough to show the assertion for $\phi \in \mathrm{Lip}(\mathbb{T}^N)$. The general case of a continuous initial datum may in fact be recovered by density, thanks to the nonexpansiveness property of the Lax–Oleinik semigroup.

We denote by $\mathcal{S}_n(t)$ the semigroup associated with the Cauchy problem (6), with H_n in place of H. Since $\phi \in \mathrm{Lip}(\mathbb{T}^N)$, we have by Theorem 2.5

$$\mathcal{S}(t)\phi = \mathcal{S}_n(t)\phi \tag{35}$$

for n sufficiently large. By Remark 2.8 each $\mathcal{S}_n(t)\phi$ admits an integral representation of the form (9), with L_n in place of L. This fact can be equivalently expressed, using the symbols introduced in Proposition A.6, by

$$\big(\mathcal{S}_n(t)\phi\big)(x) = \min_{\gamma\in X_t(x)} \mathbb{L}^t_n(\gamma)$$

for every $x \in \mathbb{T}^N$ and $t > 0$. In view of Proposition A.6, the assertion follows by sending n to $+\infty$ in (35). □

COARSENING RATES FOR A DROPLET MODEL: RIGOROUS UPPER BOUNDS*

FELIX OTTO†, TOBIAS RUMP†, AND DEJAN SLEPČEV‡

Abstract. Certain liquids on solid substrates form a configuration of droplets connected by a precursor layer. This configuration coarsens: The average droplet size grows while the number of droplets decreases and the characteristic distance between them increases. We study this type of coarsening behavior in a model given by an evolution equation for the film height on an n-dimensional substrate. Heuristic arguments based on the asymptotic analysis of Glasner and Witelski [*Phys. Rev. E,* 67 (2003), p. 016302, *Phys. D.,* 209 (2005), pp. 80–104] and numerical simulations suggest a statistically self-similar behavior characterized by a single exponent which determines the coarsening rate. In this paper, we establish rigorously an upper bound on the coarsening rate in a time-averaged sense. We use the fact that the evolution is a gradient flow, i.e., a steepest descent in an energy landscape. Coarse information on the geometry of the energy landscape serves to obtain coarse information on the dynamics. This robust method was proposed in [R. V. Kohn and F. Otto, *Comm. Math. Phys.,* 229 (2002), pp. 375–395]. Our main analytical contribution is an interpolation inequality involving the Wasserstein distance, which characterizes the coarse shape of the energy landscape. The upper bound we obtain is in agreement with heuristic arguments and numerical simulations.

Key words. thin film equation, Wasserstein distance, coarsening

AMS subject classifications. 76A20, 35K55, 35Q35

DOI. 10.1137/050630192

1. Introduction.

1.1. Statement of the result.

Thin layers of viscous liquid are well described by the lubrication approximation, which capitalizes on the separation of horizontal and vertical length scales. It yields a single equation for the time-dependent film height $h = h(x,t) > 0$, [20]. We now introduce this equation in its nondimensionalized form.

Let $Q \subset \mathbb{R}^n$ parametrize the substrate. We consider smooth solutions $h : (0,\infty) \times Q \to [0,\infty)$ of

$$\partial_t h - \nabla \cdot \left(M(h) \nabla \left(\frac{\partial E}{\partial h} \right) \right) = 0 \quad \text{in } (0,\infty) \times Q. \tag{1.1}$$

Here, $\frac{\partial E}{\partial h}$ denotes the L^2-gradient of the energy functional with respect to h. The total energy E is given by

$$E(h) = \int \frac{1}{2} |\nabla h|^2 + \mathcal{U}(h)\, dx, \tag{1.2}$$

where the gradient term describes the linearized contribution of the liquid-air surface energy, while $\mathcal{U}$ models the intermolecular forces between the substrate and the film; see section 1.3. We shall always write $\int$ for $\int_Q$.

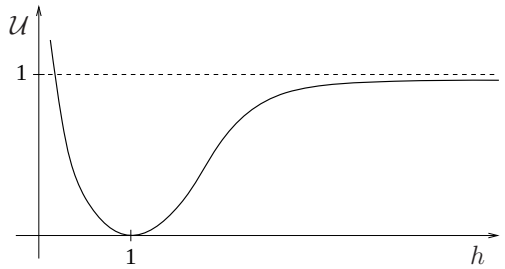

FIG. 1. *The intermolecular potential $\mathcal{U}$ combines repulsive and attractive forces.*

Qualitatively, the potential $\mathcal{U}$ is of the form sketched in Figure 1. We normalize $\mathcal{U}$ so that $\mathcal{U}(\infty) - \min \mathcal{U} = 1$ and $\operatorname{argmin} \mathcal{U} = 1$. The well-known Lennard–Jones potential [9] corresponds to $\mathcal{U}(h) = \frac{1}{3}h^{-8} - \frac{4}{3}h^{-2} + 1$, but other potentials are also physically relevant [24]. In fact, the exact expression for the potential is often not essential; as in [2, 6, 7], our results hold for a large class of potentials.

Bertozzi, Grün, and Witelski [2] studied (1.1) for potentials of the form $\mathcal{U}(h) = h^{-q} - h^{-p}$, $0 < p < q$ on a bounded one-dimensional substrate. If $q \geq 2$—that is, if the potential blew up at zero fast enough—boundedness of the energy was used to show that solutions with positive initial data stay positive for all time. That implied that the equation has unique, classical solutions for given initial data.

In our model (1.1), we consider the linear mobility function

$$M(h) = h. \tag{1.3}$$

Let us clearly state that the appropriate mobility function for a liquid film governed by the Stokes equations with no-slip boundary condition at the substrate would be $M(h) = h^3$. In case of boundary conditions which allow a finite slip (Navier condition), the mobility would be $M(h) = h^2$ provided that film heights are small compared to the slip length; see [16, 17, 20]. The mobility function (1.3) is appropriate for a liquid film governed by the Darcy equation, as in a porous medium ($n = 2$) or a Hele–Shaw cell ($n = 1$). From the applied point of view, $M(h) = h$ is thus a rather artificial choice. It is motivated both by a technical and a conceptual consideration: The technical consideration is that only for $M(h) = h$ is the induced distance in the gradient flow structure (see Appendix B) known explicitly. The conceptual consideration is that for other mobilities the coarse-grained slope of the energy landscape (see section 2) overestimates the heuristically derived coarsening rates: The "collision pathways" (see section 1.3) in the energy landscape are shortcuts not taken by the actual dynamics. Hence the straightforward application of our method would yield suboptimal results for mobilities other than (1.3), even though we believe that the coarsening rate for $M(h) = h^3$ is the same as for $M(h) = h$.

In view of (1.2) and (1.3), (1.1) turns into

$$\partial_t h + \nabla \cdot (h \nabla (\Delta h - \mathcal{U}'(h))) \;=\; 0 \quad \text{in } (0,\infty) \times Q. \tag{1.4a}$$

As suitable boundary conditions, we take equilibrium and no-flux boundary conditions:

$$\nu \cdot \nabla h = \nu \cdot \nabla \left(\frac{\partial E}{\partial h} \right) \;=\; 0 \quad \text{on } (0,\infty) \times \partial Q. \tag{1.4b}$$

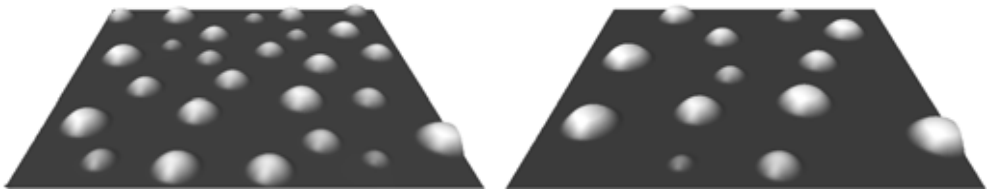

FIG. 2. *Plots of numerically computed height of the liquid on a two-dimensional substrate at two different times.*

These boundary conditions ensure that the total mass $\int h\ dx$ is conserved and that the total energy $E(h)$ decreases over time:

$$\frac{d}{dt}\int h\ dx\ =\ 0,$$

$$\frac{d}{dt}E\ =\ -\int h\Big|\nabla\left(\frac{\partial E}{\partial h}\right)\Big|^2\ dx\ \leq\ 0.$$

A glance at the energy functional E, and $\mathcal{U}$ in particular, reveals that there is a characteristic scale for x and h, both normalized to order one. We are interested in very large systems, i.e.,

$$Q=(0,\Lambda)^n \quad \text{with} \quad \Lambda\gg 1.$$

We focus on initial data which are within the unstable range,

$$h\ \approx\ \text{const} \quad \text{with} \quad \mathcal{U}''(h)<0,$$

and whose height is of the order of the precursor layer, i.e.,

$$h\ \sim\ 1.$$

Our numerical simulations reveal the generic behavior of the evolution. After an initial stage, a configuration of well-defined droplets connected by a precursor layer of height $h\approx 1=\operatorname{argmin}\mathcal{U}$ emerges. From then onward, the large droplets grow at the expense of the small ones via mass exchange through the precursor layer. Eventually, the smaller droplets disappear. Figure 2 shows a typical evolution of the film height. In a sufficiently large system, this coarsening process seems statistically self-similar. It is driven by the reduction of total energy E. Our main result gives a lower bound on the rate by which the energy decreases.

We shall see that E not only is a Lyapunov functional for (1.4), but that (1.4) can, in fact, be interpreted as a gradient flow of (1.2); see Appendix B. For our analysis, we need a measure of the distance in the configuration space, i.e., a way to express how far two droplet configurations h_0, h_1 are. It is natural to take the distance which is given by the gradient flow structure. As motivated in Appendix B, that distance is the Wasserstein distance $\mathcal{W}(h_0,h_1)$:

(1.5)
$$\mathcal{W}(h_0,h_1)^2\ :=\ \inf\left\{\iint|x-y|^2d\pi(x,y)\ \Big|\ \int\ d\pi(\cdot,y)=h_0,\ \int\ d\pi(x,\cdot)=h_1\right\}.$$

The so-called transportation plan, π, is a measure on the product space $Q \times Q$. It is admissible if its projections to first and second coordinates are measures with densities h_0 and h_1, respectively. The transportation cost is measured by the squared Euclidean distance $|x-y|^2$. For properties of $\mathcal{W}$, see section 7.1 in [32].

We are now in a position to formulate our result.

THEOREM 1. *Let $\mathcal{U}$ satisfy*

$$\begin{aligned} &\mathcal{U}(h) \geq 0 \quad \text{on } (0,\infty), \\ &\mathcal{U}(h) \geq 1 \quad \text{on } (2,\infty). \end{aligned} \tag{1.6}$$

Let h be a smooth solution of (1.4)*, which has the same total volume as a constant layer of thickness* 3*:*

$$\int h\,dx \;=\; \int h^*\,dx, \quad h^* \equiv 3. \tag{1.7}$$

Then for $\sigma \in (1, \frac{3n+2}{n})$,

$$\int_0^T \left(\Lambda^{-n} E(h(t))\right)^\sigma \,dt \quad \gtrsim \quad \int_0^T (t^{-\frac{n}{3n+2}})^\sigma \,dt, \tag{1.8}$$

provided $T \gg (\Lambda^{-\frac{n}{2}} \mathcal{W}(h^*, h(0)))^{\frac{3n+2}{n+1}}$ and $\Lambda^{-n} E(h(0)) \ll 1$.

For the precise meaning of the notation "$\gg$" and "$\gtrsim$" we refer to Remark 1 in section 2. The result states that the energy per volume cannot decrease faster than $t^{-\frac{n}{3n+2}}$. For further interpretation of the result in terms of the droplet configuration we refer to section 1.4. The assumption $\Lambda^{-n} E(h(0)) \ll 1$ of small energy densities encodes that $h(0)$ energetically behaves as a configuration of droplets connected by a precursor layer of height $\operatorname{argmin} \mathcal{U} = 1$; see Figure 2. This means that we "start the clock" once the system has entered such a regime. The assumption $T \gg \left(\Lambda^{-\frac{n}{2}} \mathcal{W}(h^*, h(0))\right)^{\frac{3n+2}{n+1}}$, on the other hand, ensures that the initial data $h(0)$ are not too far from a constant film thickness. The values 1, 2, and 3 in (1.6) and (1.7) are set purely for convenience. In particular, given a potential satisfying (1.6), any constant layer of thickness above 2 is admissible. However, the constants in the estimates would depend on the thickness.

The framework for proving lower bounds on energy decay was introduced by Kohn and Otto [10] for the constant-mobility and the degenerate-mobility Cahn–Hilliard equation. The basic idea is to use the gradient flow structure of (1.4). A gradient flow structure is determined by the energy functional E and a (Riemannian) geometry of the state space (the space of all droplet configurations h). The metric tensor encodes the relevant dissipation mechanism, see Appendix B. Following [10], we use coarse information on the geometry of the energy landscape to derive coarse information on the gradient flow dynamics. The coarse information on geometry is the rate at which E can decrease as a function of the distance to a reference configuration h^*, where the function is given by a power law with the "geometric exponent" α; see Figure 3. On the other hand, the coarse information on dynamics limits how fast E can decrease as a function of time, where the function is given by a power law with the "dynamic exponent" γ. Proposition 1 in section 2 relates the dynamic exponent γ to the geometric exponent α.

Let us point out that studying *lower* bounds on the coarsening rate is a more complicated question. In fact, there are solutions which do not coarsen at all; for

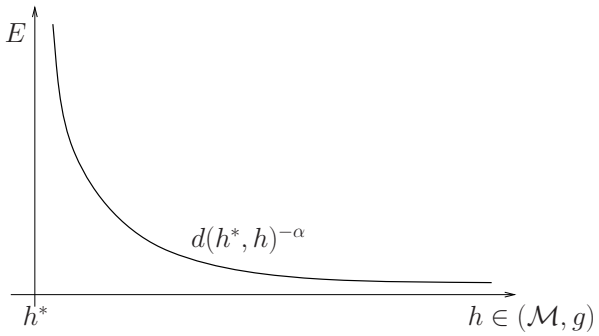

FIG. 3. *The energy $E(h)$ is bounded below by the distance between h and the reference state h^*.*

example, the unstable, periodic steady states. Hence a lower bound can hold only in some generic sense—a statement for all trajectories cannot hold. We do not address this issue.

Other applications of the method proposed in [10] can be found in the literature. In [3], coarsening in off-critical mixtures within the Mullins–Sekerka evolution is studied. The authors of [4] and [5] study the coarsening behavior in mean-field models of phase transitions and in a phase-field model that deals with both temperature and phase fields. In [11] and [12], rigorous bounds on coarsening rates are proven for an epitaxial growth model and for models of multicomponent phase separation.

1.2. Outline. The following subsections provide background information: In section 1.3, we describe the underlying physical processes. Heuristics, which further interpret the result in Theorem 1, are presented in section 1.4. Formal asymptotics, e.g., done for the one-dimensional case in [6], are briefly reviewed in section 1.5. In section 1.6, we present our numerical experiments which support that the power law bounds we obtain are optimal for $n = 1$ and $n = 2$. The proof of Theorem 1 does not depend on the results presented in these subsections.

In section 2, we review the abstract framework, which exploits the gradient flow structure to obtain a bound on the energy, proposed in [10], and give modified proofs of the main results. Our main contribution is the interpolation inequality, which is essential for the framework. From the mathematical point of view, it is an extension of the one established in [3]. We rigorously state and prove the inequality in section 3. Section 4 provides the proof of the main result. Appendix A contains the analysis of stationary droplets, while Appendix B explains the gradient flow structure of the thin-film equation. The Wasserstein metric, as the induced distance, is introduced heuristically.

1.3. Physics. The statics are determined by capillarity (the surface tension between liquid and vapor) and the short range forces between the film and the solid substrate. These intermolecular forces are the combination of a very short-range repulsive (Born-type) force and a moderately short-range attractive (van der Waals) force. Their competition stabilizes a precursor layer of well-defined height, which covers the entire substrate. In particular, our choice of $\mathcal{U}$ with $\operatorname{argmin} \mathcal{U} = 1$ yields a precursor layer of height ≈ 1. On a more mesoscopic level, the liquid is partially wetting: It allows for equilibrium droplets of a well-defined apparent (i.e., mesoscopic) contact angle. The apparent nonzero contact angle arises from the competition between the short range forces and capillarity.

Intermolecular forces of the form discussed above are relevant for a range of liquids: polymers [1, 26, 27, 28, 29, 33], liquid crystal films and liquid metals [8, 31], evaporating films [19], and others.

The dynamics is driven by the reduction of total energy (capillary and intermolecular). The reduction of energy is limited by viscous friction. This dissipation mechanism is rather pronounced in the thin liquid film. This means that inertial effects are negligible and the dynamics is determined by a quasi-stationary balance of thermodynamic driving and viscous frictional forces. Notice that the presence of the precursor layer removes the singularity of the moving contact line which arises from the no-slip boundary condition.

We think of the initial condition as a flat film of height sufficiently large with respect to the equilibrium height of the precursor layer. More precisely, we think of a perturbation of this configuration; due to the intermolecular forces, sufficiently long-wavelength perturbations grow. In analogy with spinodal decomposition of binary mixtures (as described by the Cahn–Hilliard equation) this process is often referred to as spinodal dewetting. The liquid film almost ruptures and holes (with film thickness of the precursor layer) surrounded by a network of ridges form. This initial process may have various morphologies [1, 30]. As time passes, the ridges break up and relax into droplets sitting on the precursor layer. In this paper, we are not concerned with this initial stage of droplet formation.

We are interested in the late-stage *coarsening* behavior. A configuration of well-separated droplets connected by a precursor layer coarsens in time; see Figure 2. We have in mind a scenario with clearly separated time scales: The time scale of the coarsening process is slow compared to the scale on which the droplets relax into equilibrium shape. Hence the configuration is essentially described by the radius and the position of the center of mass of the individual droplets. These quantities evolve slowly. This is sometimes called quasi-static evolution or quasi-stationary motion.

The coarsening process can be mediated by two mechanisms: collapse or collision. Collapse relies on mass exchange between the droplets through the precursor layer. In this scenario, the large droplets grow at the expense of the small ones which eventually collapse. This is a particular instance of Ostwald ripening. The basic difference with respect to the traditional Ostwald ripening for binary mixtures (as described by the late stages of the Cahn–Hilliard equation with strongly off-critical initial data; see for instance [18] for the two-dimensional case) lies in the mixed dimensionality: Ripening of droplets on an n-dimensional substrate is $(n+1)$-dimensional with respect to mass and energy, but n-dimensional when it comes to the kinetics.

We now address collision: As do the particles in traditional Ostwald ripening, the droplets drift. The difference with respect to traditional Ostwald ripening lies in the fact that droplets are much more mobile than particles (since the mobility strongly depends on height). In [6], it has been argued that on a one-dimensional substrate, this effect may lead to collision and thus to "accidental" coarsening.

Unlike for the initial instability and subsequent dewetting, there are few experimental studies of coarsening in liquid films. The only long-time results we are aware of are studies of coarsening for certain polymers [14, 15].

1.4. Dynamical scaling: Heuristics. Numerical simulations suggest that the coarsening, although rather complex in detail, has a simple statistical behavior (see section 1.6). In particular, the time-dependence of averaged quantities, like the average distance L between droplets, in sufficiently large systems appears to be a power

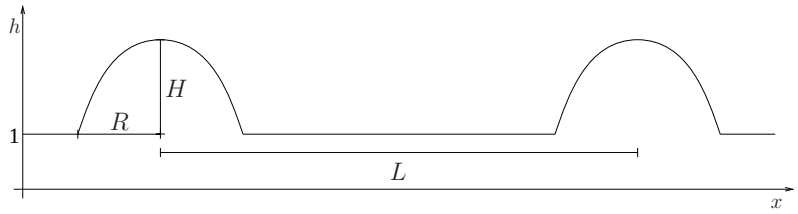

FIG. 4. *Droplet configuration on one-dimensional substrate. The typical length scales H, R, and L are not independent; cf.* (1.10) *and* (1.11).

law:

$$L \sim t^{\beta}.$$

We are interested in understanding the mechanisms which determine the characteristic exponent β. In order to discern what information about β is contained in the energy bound (1.8), we first analyze and relate the length scales present in the problem. We consider configurations of well-separated, equilibrium-shaped droplets with fixed average height greater than the height of the precursor layer. The typical averaged length scales are the typical distance L, the height H, and radius R of a droplet. Figure 4 sketches a typical droplet configuration we have in mind.

From this point of view, we infer the following scaling relations:

(i) On a mesoscopic level, the potential $\mathcal{U}$ acts as the characteristic function of $\{h > 1\}$. Thus the individual droplets are governed by the mesoscopic energy

$$\overline{E}(h) = \int \tfrac{1}{2}|\nabla h|^2 \, dx + \text{ vol}\,(\{h > 1\}),$$

which enforces an apparent equilibrium contact angle of

$$\tfrac{1}{2}|\nabla h|^2 = 1 \quad \text{ on } \partial\{h > 1\}; \tag{1.9}$$

see Appendix A. Notice that (1.9) implies that the average height H and the average radius R of the droplets scale the same:

$$H \sim R. \tag{1.10}$$

(ii) We infer from mass conservation, i.e.,

$$\Lambda^{-n} \int h \, dx \sim 1,$$

and

$$\begin{aligned} \Lambda^{-n} \int h \, dx &\sim \begin{pmatrix} \text{number density} \\ \text{of droplets} \end{pmatrix} \times \begin{pmatrix} \text{volume of} \\ \text{individual droplet} \end{pmatrix} \\ &\sim L^{-n} \times HR^n \\ &\overset{(1.10)}{\sim} L^{-n} \times R^{n+1}, \end{aligned}$$

that R and L are related by

$$L \sim R^{\frac{n+1}{n}}. \tag{1.11}$$

Now let us explain why a lower bound on the energy heuristically yields an upper bound on the average droplet distance L. Indeed, the energy density (i.e., the energy per system volume) is related to L via

$$\begin{aligned}\Lambda^{-n}E &\sim \left(\begin{array}{c}\text{number density}\\ \text{of droplets}\end{array}\right)\times\left(\begin{array}{c}\text{energy of}\\ \text{individual droplet}\end{array}\right)\\ &\overset{(1.10)}{\sim} L^{-n}\times R^n\\ &\overset{(1.11)}{\sim} L^{-\frac{n}{n+1}}.\end{aligned}\tag{1.12}$$

Thus a lower bound on E heuristically yields an upper bound on L. The energy bound (that we show in a time-averaged form in Theorem 1)

$$\Lambda^{-n}E \gtrsim t^{-\frac{n}{3n+2}}$$

in view of (1.12) heuristically amounts to the upper bound

$$\beta \le \frac{n+1}{3n+2} = \begin{cases}\frac{2}{5} & \text{for } n=1,\\ \frac{3}{8} & \text{for } n=2.\end{cases}\tag{1.13}$$

Based on numerical and heuristic predictions (which are solid for $n=1$ and somewhat less so for $n=2$) this bound is optimal (up to logarithmic correction in two dimensions). In the nonphysical case of $n\ge 3$, we do not expect the bound to be optimal.

1.5. Formal asymptotics. The coarsening process on one-dimensional substrates was analytically studied by Glasner and Witelski [6, 7] for physically relevant mobility h^3. Based on the quasi-static assumption, they derive a system of coupled ODEs for droplet pressures $\{P_i\}$ (which are in one-to-one correspondence to their radius) and droplet positions $\{X_i\}$. Using the scale separation $H\sim R\ll L$ they argue heuristically that

$$L \sim t^{\frac{2}{5}}.$$

Their numerical experiments confirm this scaling. Furthermore, Glasner and Witelski show that in certain regimes both collapse and collision of droplets are possible mechanisms of coarsening.

We verified that their heuristics extends to our mobility $M(h)=h$ and yields the same scaling. It is a particularity of the mobility $M(h)=h^3$ that both processes, collapse and collision, yield the same exponent (modulo a logarithm). For $M(h)=h$, however, collapse is eventually the faster process.

A back-of-the-envelope argument for two-dimensional substrates based on the collapse scenario suggests that

$$L \sim t^{\frac{3}{8}}$$

(modulo a logarithm specific to the fundamental solution of a Laplace equation in two dimensions; see [18]). The importance of collisions, as it depends on $M(h)$, is not yet well understood, in our opinion, despite the investigation of droplet mobility in [25].

Our analysis does not rely on a derivation of a reduced model based on a quasi-static assumption. Likewise, it does not presuppose that coarsening is simple on a statistical level.

1.6. Numerics. To gain some understanding of the coarsening dynamics we carried out several numerical experiments. Let us first address the discretization of the thin-film equation (1.4). To solve (1.4) in one and two dimensions we use a modification of the discretization of a Cahn–Hilliard-type equation proposed in [21]. This discretization approach is guided by two features of the model (1.4):

(i) The total mass $\int h$ is preserved due to the continuity equation

$$\partial_t h + \nabla \cdot J \;=\; 0, \tag{1.14}$$

where $J = -h\nabla\left(\frac{\partial E}{\partial h}\right)$.

(ii) The energy E is a Lyapunov functional:

$$\frac{d}{dt}E \;=\; -\int \frac{1}{h}|J|^2 \;\le\; 0.$$

We use a semi-implicit time discretization (explicit in the mobility). Since the time-discrete equation is nonlinear we apply a single Newton step:

$$h^{k+1} - h^k - \tau\nabla\cdot\left[h^k\nabla\left(\frac{\partial^2 E}{\partial h^2}(h^k)(h^{k+1}-h^k) + \frac{\partial E}{\partial h}(h^k)\right)\right] \;=\; 0.$$

By introducing the flux J,

$$h^{k+1} \;=\; h^k - \tau\nabla\cdot J^{k+1},$$

we obtain a symmetric problem

$$\left[\frac{1}{h^k}\mathrm{id} - \tau\nabla\left(\frac{\partial^2 E}{\partial h^2}(h^k)\right)\nabla\cdot\right] J^{k+1} = -\nabla\left(\frac{\partial E}{\partial h}(h^k)\right).$$

We use a finite difference scheme for the fourth-order problem and solve the linear system by the conjugate gradient method, preconditioned by the constant coefficient operator $\mathrm{id} - \tau\nabla(\frac{\partial^2 E}{\partial h^2}(1))\nabla\cdot$, which we invert by FFT.

Now we turn to the numerical experiments. We use the potential

$$\mathcal{U}(h) = 2h^{-3} - 3h^{-2} + 1,$$

which was used in [6, 19], and take as initial data

$$h(t=0) = h^* + \text{perturbation},$$

where we choose $h^* \equiv 2$, which is in the concave part of $\mathcal{U}$ but still of the order of the precursor layer thickness. System sizes are chosen $\Lambda = 10000$ for $n = 1$ and $\Lambda = 1000$ for $n = 2$.

Figure 5 shows a logarithmic plot of the energy density of the configurations versus time both in one and two dimension. Furthermore, we measure the droplets; see Figure 6. Note that the data is averaged over ten runs.

Our numerical experiments reveal the scaling exponent $\beta = \frac{2}{5}$ for $n = 1$ (see Figure 6, left), since the number density $\Lambda^{-n}N$ scales like L^{-n}. This exponent is equal to the upper bound we obtained in (1.13). Experiments for $n = 2$ (see Figure 6, right) suggest a faster decrease of the number density than for $n = 1$, as predicted. The coarsening exponent is in agreement with the bound (1.13) but appears to be

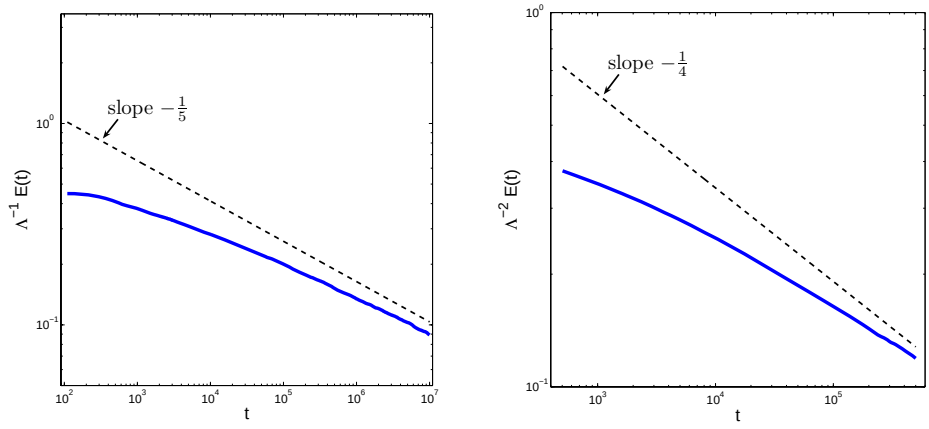

FIG. 5. *Energy density of droplet configuration for $n = 1$ (left) and for $n = 2$ (right) versus time.*

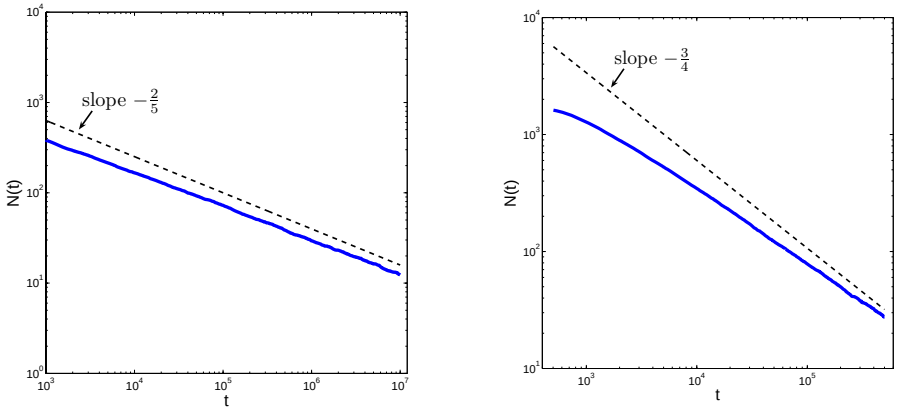

FIG. 6. *Number of droplets for $n = 1$ (left) and for $n = 2$ (right) versus time.*

slightly different than the bound itself. Let us comment on this apparent discrepancy. The heuristics in section 1.4 are based on the assumption that

$$\begin{aligned}\Lambda^{-n}E &\overset{(1.12)}{\sim} L^{-\frac{n}{n+1}}\\ &\sim \left(\Lambda^{-n}N\right)^{\frac{1}{n+1}}.\end{aligned}$$

We therefore monitor the system averaged quantity

$$\Lambda^{-n}E\left(\Lambda^{-n}N\right)^{-\frac{1}{n+1}}$$

over time. For an infinite system this number should reach an asymptotic value if coarsening is statistically self-similar. Figure 7 shows that for $n = 2$ the numerical simulations have barely reached an asymptotic state. Hence for $n = 2$ a numerical confirmation of the optimality of our result would require much larger time horizons and thus much larger system sizes.

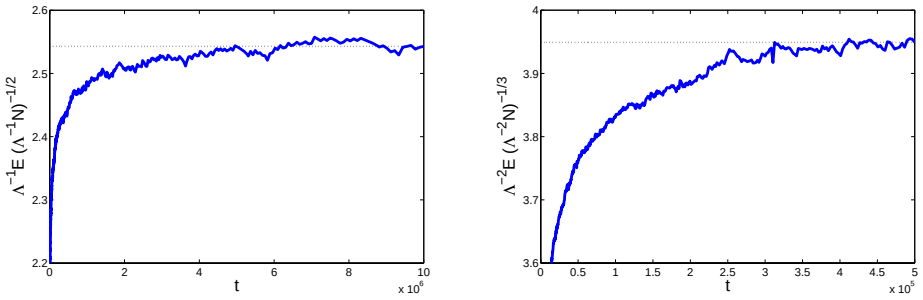

FIG. 7. *The system averaged quantity* $\Lambda^{-n}E\left(\Lambda^{-n}N\right)^{-\frac{1}{n+1}}$ *for* $n=1$ *(left) and for* $n=2$ *(right) versus time.*

2. Abstract framework: From geometry to dynamics. In this section we show how coarse information on the *geometry* of the energy landscape (see Figure 3) leads to coarse information on the gradient flow *dynamics*. Proposition 1 relates the dynamic exponent γ to the geometric exponent α:

$$\gamma \;=\; \frac{\alpha}{\alpha+2}.$$

This insight is essentially from [10]. We give a somewhat different presentation here and include the modified proofs for the convenience of the reader. For the clarity of presentation, we adopt an abstract framework: Let $\mathcal{M}$ be a manifold endowed with a metric tensor g and a function E. We denote by d the induced distance on the Riemannian manifold $(\mathcal{M}, g)$.

PROPOSITION 1 (see [10]). *Let* $h^* \in \mathcal{M}$. *Let* $h : \mathbb{R}_+ \to \mathcal{M}$ *be a solution of*

$$\partial_t h \;=\; -\mathrm{grad}E(h), \tag{2.1}$$

and $h(0) = h_0$.

Assume that for some $\alpha > 0$ *the interpolation inequality*

$$E(h)d(h,h^*)^\alpha \geq 1 \quad \textit{for all } h \in \mathcal{M} \textit{ with } E(h) \leq 1 \tag{2.2}$$

holds. Then for $\sigma \in (1, 1+\frac{2}{\alpha})$

$$\int_0^T E(h(t))^\sigma \, dt \gtrsim \int_0^T (t^{-\frac{\alpha}{\alpha+2}})^\sigma \, dt \tag{2.3}$$

provided $T \gg d(h_0,h^*)^{\alpha+2}$ *and* $E(h(0)) \leq 1$.

Remark 1. The notation $\gtrsim$ and $\gg$ stands for the following.

For all $\sigma \in (1, 1+\frac{2}{\alpha})$ there exists a constant $C = C(\alpha,\sigma)$ such that for all $\delta > 0$ $\exists C_\delta = C(\alpha,\sigma,\delta)$,

$$\int_0^T E(h(t))^\sigma \, dt \geq (1-\delta)C \int_0^T (t^{-\frac{\alpha}{\alpha+2}})^\sigma \, dt \tag{2.4}$$

provided $T \geq C_\delta d(h_0,h^*)^{\alpha+2}$.

Remark 2. It is not true that (2.1) and (2.2) imply the pointwise estimate

$$E(t) \;\gtrsim\; t^{-\frac{\alpha}{\alpha+2}}. \tag{2.5}$$

Indeed, let $\mathcal{M} = \mathbb{R}_+$, $h^* = 0$, and $h(0) = 1$. For a given $b \gg 1$ let E_b be equal to $h^{-\alpha}$ outside the interval $(1, b)$ and let it be linear on $[1, b]$ so that E_b is continuous:

$$E_b(h) := \begin{cases} 1 + \frac{b^{-\alpha}-1}{b-1}(h-1) & \text{on } [1,b], \\ h^{-\alpha} & \text{otherwise.} \end{cases}$$

Then

$$\partial_t h \;=\; -\frac{dE_b}{dh}(h(t)) = -\frac{b^{-\alpha}-1}{b-1}$$

as long as $h(t) \le b$. Hence

$$h(t) = 1 - \frac{b^{-\alpha}-1}{b-1}t$$

and thus $h(t_b) = b$ for $t_b := \frac{(b-1)^2}{1-b^{-\alpha}}$. Therefore

$$\frac{E_b(h(t_b))}{t_b^{-\frac{\alpha}{\alpha+2}}} \;=\; \frac{(b-1)^{\frac{2\alpha}{\alpha+2}}}{b^\alpha (1-b^{-\alpha})^{\frac{\alpha}{\alpha+2}}} \;\le\; 2b^{-\frac{\alpha^2}{\alpha+2}} \to 0$$

as $b \to \infty$.

Remark 3. The range for $1 < \sigma < 1 + \frac{2}{\alpha}$ is (almost) optimal.

The example above can be used to show that for $0 < \sigma < 1$ the statement cannot hold. An elementary (but lengthy) calculation shows that for $T = b^{2+\alpha-\eta}$, with $0 < \eta < \alpha(1-\sigma)$,

$$\int_0^T (E_b(h(t)))^\sigma dt \sim b^{2+\alpha(1-\sigma)-\eta},$$
$$\int_0^T t^{-\frac{\alpha\sigma}{\alpha+2}} dt \sim b^{2+\alpha(1-\sigma)-\eta+\frac{\alpha\sigma\eta}{\alpha+2}}.$$

Thus inequality (2.3) cannot hold when $0 < \sigma < 1$. The case $\sigma = 1$ remains open. The proof we present for $\sigma > 1$ does not extend to $\sigma = 1$ since the constant C in (2.4) vanishes as σ approaches 1; see (2.12).

For $\sigma = 1 + \frac{2}{\alpha}$ the statement would hold if the lower bound 0 in the integrals was replaced by 1. This follows from the continuity of the functionals with respect to σ and from the fact that constant C is bounded away from 0 as σ approaches $1 + \frac{2}{\alpha}$; see (2.12). The range $\sigma > 1 + \frac{2}{\alpha}$ is not of interest, since the integral from 1 to infinity of the right-hand side is finite, and hence the inequality (2.3) would contain no information on the decay rate of E.

We now consider an arbitrary but fixed trajectory $h(t)$ of (2.1). The following lemma restricts the rate at which the distance $d(h, h^*)$ between $h(t)$ and any fixed $h^* \in \mathcal{M}$ can change. We set for convenience

$$E(t) := E(h(t)),$$
$$D(t) := d(h(t), h^*).$$

LEMMA 1. *Let h be a solution of* (2.1) *and $h^* \in \mathcal{M}$.*
Then

$$\left|\tfrac{d}{dt} D(t)\right|^2 \;\le\; -\tfrac{d}{dt} E(t). \tag{2.6}$$

Proof of Lemma 1. The triangle inequality and the definition of d imply for any $\delta \in \mathbb{R}$

$$\begin{aligned}\left|\frac{1}{\delta}(D(t+\delta)-D(t))\right| &\le \frac{1}{\delta} d(h(t+\delta),h(t)) \\ &\le \frac{1}{\delta}\int_0^1 \sqrt{g_{h(t+s\delta)}(\partial_t h(t+s\delta)\delta, \partial_t h(t+s\delta)\delta)}\, ds \\ &= \int_0^1 \sqrt{g_{h(t+s\delta)}(\partial_t h(t+s\delta), \partial_t h(t+s\delta))}\, ds.\end{aligned}$$

Hence we obtain in the limit $\delta \to 0$

$$\left|\frac{d}{dt}D(t)\right| \;\le\; \sqrt{g_{h(t)}(\partial_t h(t), \partial_t h(t))}.$$

Furthermore

$$\tfrac{d}{dt}E(t) = g_{h(t)}(\mathrm{grad}E(t), \partial_t h(t)) \overset{(2.1)}{=} -g_{h(t)}(\partial_t h(t), \partial_t h(t)),$$

so that we conclude

$$\left|\tfrac{d}{dt}D(t)\right|^2 \;\le\; -\tfrac{d}{dt}E(t). \qquad \square$$

Proof of Proposition 1. Since E is a monotone function of time, $D(t)$ can be viewed as a function of $E(t)$. To distinguish the argument of this function from the actual value of the energy we write $D = D(e)$. Hence (2.6) turns into

$$1 \;\ge\; \left(\frac{dD}{de}\right)^2 |\dot{E}|. \tag{2.7}$$

Multiplying (2.7) by $E(t)^\sigma$ and integrating in t yield

$$\int_0^T E(t)^\sigma \, dt \ge \int_0^T E(t)^\sigma \left(\frac{dD}{de}\right)^2 |\dot{E}| \, dt = \int_{E_T}^{E_0} e^\sigma \left(\frac{dD}{de}\right)^2 \, de, \tag{2.8}$$

where we have set $E_0 = E(0)$ and $E_T = E(T)$.

From the Cauchy–Schwarz inequality we obtain

$$\left(\int_{E_T}^{E_0} e^\sigma \left(\frac{dD}{de}\right)^2 \, de \int_{E_T}^{E_0} e^{-\sigma} \, de\right)^{\frac{1}{2}} \;\ge\; \left|\int_{E_T}^{E_0} \frac{dD}{de} \, de\right| \;=\; |D_0 - D_T|,$$

where we define $D_0 = D(0)$ and $D_T = D(T)$. Substituting in (2.8) and integrating $\int_{E_T}^{E_0} e^{-\sigma} \, de = (\sigma-1)^{-1}\left(E_T^{1-\sigma} - E_0^{1-\sigma}\right)$ implies

$$\begin{aligned}\int_0^T E(t)^\sigma \, dt &\ge (\sigma-1)\left(E_T^{1-\sigma} - E_0^{1-\sigma}\right)^{-1} (D_0 - D_T)^2 \\ &\ge (\sigma-1) E_T^{\sigma-1} (D_0 - D_T)^2. \end{aligned} \tag{2.9}$$

Here we have used the assumption $\sigma > 1$. We rewrite the right-hand side of (2.9) as

$$(\sigma-1) E_T^{\sigma-1-\frac{2}{\alpha}} (E_T D_T^\alpha)^{\frac{2}{\alpha}} (1 - \tfrac{D_0}{D_T})^2$$

and apply the interpolation inequality (2.2), so that

$$\int_0^T E(t)^\sigma \, dt \geq (\sigma-1) E_T^{\sigma-1-\frac{2}{\alpha}} (1-\tfrac{D_0}{D_T})^2. \tag{2.10}$$

Set for abbreviation

$$f(T) := \int_0^T E(t)^\sigma \, dt.$$

Then (2.10) turns into

$$\begin{aligned} f(T) &\geq (\sigma-1) f'(T)^{(\sigma-1-\frac{2}{\alpha})/\sigma} (1-\tfrac{D_0}{D_T})^2 \\ &= (\sigma-1) f'(T)^{\frac{\sigma\alpha-\alpha-2}{\sigma\alpha}} (1-\tfrac{D_0}{D_T})^2, \end{aligned}$$

or equivalently,

$$f(T)^{\frac{\sigma\alpha}{\alpha+2-\sigma\alpha}} f'(T) \geq \Big((\sigma-1)(1-\tfrac{D_0}{D_T})^2 \Big)^{\frac{\sigma\alpha}{\alpha+2-\sigma\alpha}}$$

provided $\sigma < 1+\frac{2}{\alpha}$. Note that

$$f(T)^{\frac{\sigma\alpha}{\alpha+2-\sigma\alpha}} f'(T) = \frac{d}{dt} \left(\frac{f(T)^{\frac{\sigma\alpha}{\alpha+2-\sigma\alpha}+1}}{\frac{\sigma\alpha}{\alpha+2-\sigma\alpha}+1} \right) = \frac{d}{dt} \left(\frac{f(T)^{\frac{\alpha+2}{\alpha+2-\sigma\alpha}}}{\frac{\alpha+2}{\alpha+2-\sigma\alpha}} \right).$$

Then we get by integration in time

$$f(T) \geq (\sigma-1)^{\frac{\sigma\alpha}{\alpha+2}} \left(\tfrac{\alpha+2}{\alpha+2-\sigma\alpha} \right)^{1-\sigma\frac{\alpha}{\alpha+2}} \, (1-\tfrac{D_0}{D_T})^{2\frac{\sigma\alpha}{\alpha+2}} \, T^{1-\sigma\frac{\alpha}{\alpha+2}}. \tag{2.11}$$

When T is such that $\frac{D_0}{D_T} \leq 1-(1-\delta)^{\frac{\alpha+2}{2\sigma\alpha}} =: \varepsilon(\delta)$, (2.11) yields

$$f(T) \geq C(\alpha,\sigma)(1-\delta) \, T^{1-\sigma\frac{\alpha}{\alpha+2}}$$

with

$$C(\alpha,\sigma) := (\sigma-1)^{\frac{\sigma\alpha}{\alpha+2}} \left(\tfrac{\alpha+2}{\alpha+2-\sigma\alpha} \right)^{1-\sigma\frac{\alpha}{\alpha+2}}. \tag{2.12}$$

For the case $\frac{D_0}{D_T} > \varepsilon(\delta)$ the interpolation inequality yields

$$E_T^\sigma > \varepsilon(\delta)^{\sigma\alpha} D_0^{-\sigma\alpha}.$$

Since the energy decreases in time this inequality holds for all $t \leq T$, so that

$$\int_0^T E(t)^\sigma \, dt \geq \varepsilon(\delta)^{\sigma\alpha} D_0^{-\sigma\alpha} T = \varepsilon(\delta)^{\sigma\alpha} D_0^{-\sigma\alpha} T^{\sigma\frac{\alpha}{\alpha+2}} \, T^{1-\sigma\frac{\alpha}{\alpha+2}}.$$

Hence

$$f(T) \;\geq\; (1-\delta) C(\alpha,\sigma) \, T^{1-\sigma\frac{\alpha}{\alpha+2}}$$

provided $T \geq C(\alpha,\sigma)^{\frac{\alpha+2}{\sigma\alpha}} \varepsilon(\delta)^{-\alpha-2} \, D_0^{\alpha+2}$, which proves (2.4). □

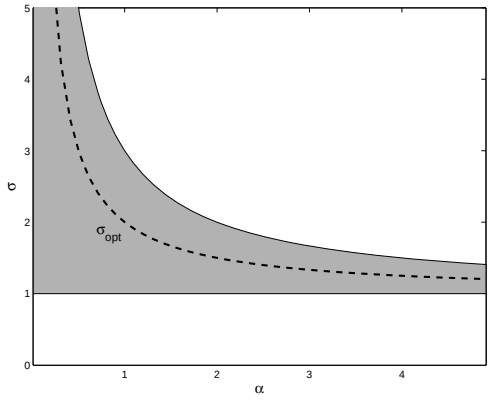

FIG. 8. *Permitted values of σ (grey region) as a function of α. The dotted line $\sigma_{opt} := 1 + \frac{1}{\alpha}$ indicates the values of σ for which the coefficient in* (2.3) *is optimal.*

Remark 4. The coefficient C is optimal for $\sigma = 1 + \frac{1}{\alpha}$; see Figure 8.

To see that the coefficient is optimal for $\sigma = 1 + \frac{1}{\alpha}$, consider in one dimension the energy $E(h) := h^{-\alpha}$. Obviously this energy obeys the interpolation inequality (2.2) for $h^* = 0$. The gradient flow of E with $h_0 = 0$ is given by

$$h(t) = (\alpha(\alpha+2)t)^{\frac{1}{\alpha+2}}.$$

Hence

$$E(h(t)) = h(t)^{-\alpha} = (\alpha(\alpha+2)t)^{-\frac{\alpha}{\alpha+2}}$$

and furthermore

$$\int_0^T E(t)^\sigma \, dt = (\alpha(\alpha+2))^{-\sigma\frac{\alpha}{\alpha+2}} \frac{\alpha+2}{\alpha+2-\sigma\alpha} \, T^{1-\sigma\frac{\alpha}{\alpha+2}}.$$

The coefficient coincides with the coefficient in (2.11) provided $\sigma = 1 + \frac{1}{\alpha}$.

3. An interpolation inequality. From section 2 and Appendix B we learn that relating the energy (1.2) and the induced distance (1.5) by an interpolation inequality of the form (1.12) provides a main ingredient for the proof of a lower bound on the energy. In view of Proposition 1, the geometric exponent α determines the dynamic exponent γ. As mentioned before, we fix $h^* \equiv 3$ to focus on ideas. Proposition 2 shows that the geometric exponent is $\alpha = \frac{n}{n+1}$.

PROPOSITION 2. *There exists a constant $C > 0$ depending only on n such that*

$$\Lambda^{-n} E(h) \, \left(\Lambda^{-\frac{n}{2}} \mathcal{W}(h,3)\right)^{\frac{n}{n+1}} \geq \tfrac{1}{C} \qquad \textit{provided} \quad E(h) \leq \tfrac{1}{C}, \; \Lambda \geq C.$$

Before giving the rigorous proof, let us motivate the result. The exponent $\alpha = \frac{n}{n+1}$ can be heuristically inferred from the following argument:

(i) From (1.12) we have

$$\Lambda^{-n} E \; \sim \; L^{-\frac{n}{n+1}}.$$

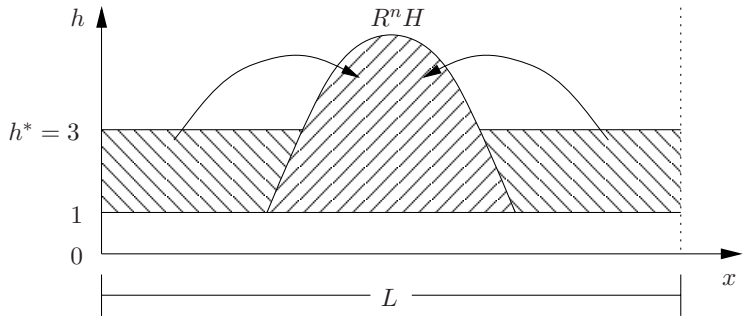

FIG. 9. *Scaling of* $\mathcal{W}(h,3)$.

(ii) From the definition (1.5) of the Wasserstein distance $\mathcal{W}$ we obtain the scaling

$$\begin{aligned}\Lambda^{-n}\mathcal{W}(h,3)^2 &\sim \Lambda^{-n}\iint |x-y|^2\,d\pi(x,y)\\ &\sim \Lambda^{-n}\times L^2\iint d\pi(x,y)\\ &\sim \Lambda^{-n}\times L^2\times\int 3\,dx\\ &\sim L^2,\end{aligned}$$

(see Figure 9); that is,

$$\Lambda^{-\frac{n}{2}}\mathcal{W}(h,3)\ \sim\ L. \tag{3.1}$$

These two scaling relations yield

$$\Lambda^{-n}E\ \left(\Lambda^{-\frac{n}{2}}\mathcal{W}(h,3)\right)^{\frac{n}{n+1}}\ \sim\ L^{-\frac{n}{n+1}}\times L^{\frac{n}{n+1}}\ \sim\ 1.$$

We turn to the rigorous proof of Proposition 2. Set

$$R := (\Lambda^{-n}E(h))^{-1}\qquad\text{and}\qquad \widetilde{h} := (h-2)_+. \tag{3.2}$$

Note that the definition of R is motivated by the scaling (1.11) and (1.12). The proof is done in several lemmas.

(i) Lemma 2 shows that the average droplet height H scales like the average droplet radius in accordance with (1.10). The radius is expressed in terms of the energy; cf. (3.2).

(ii) Lemma 3, applied to $\widetilde{h}$, shows that most of the droplet mass lies in a "small" set in the sense that the volume of the thickened set is controlled.

(iii) Lemmas 2 and 3 imply Lemma 4, which shows that the typical droplet distance L scales like $R^{\frac{n+1}{n}}$, as suggested by the heuristic arguments in (1.11).

(iv) Finally, Lemma 5 reveals that for sufficiently distant droplets the volume-averaged Wasserstein distance between h and the average height scales like L in accordance with (3.1).

LEMMA 2.

(i) *The typical droplet height H is at least of order R in the sense that*

$$\int_{\{\widetilde{h}>H\}}\widetilde{h}\,dx \ge \tfrac{1}{2}\int\widetilde{h}\,dx\qquad \textit{for } H=\tfrac{R}{2}. \tag{3.3}$$

(ii) *The typical droplet radius is at least of the order R in the sense that*

$$R \int |\nabla \widetilde{h}| \, dx \le \int \widetilde{h} \, dx. \tag{3.4}$$

Proof. We first notice that $h \le \widetilde{h} + 2$ implies

$$\int h \, dx \le \int \widetilde{h} \, dx + \tfrac{2}{3} \int 3 \, dx \overset{(1.7)}{=} \int \widetilde{h} \, dx + \tfrac{2}{3} \int h \, dx,$$

so that

$$\int \widetilde{h} \, dx \ge \tfrac{1}{3} \int h \, dx. \tag{3.5}$$

Next we notice that

$$\Lambda^{-n} E(h) \overset{(1.7)}{=} \tfrac{3}{\int h \, dx} \int \tfrac{1}{2} |\nabla h|^2 + \mathcal{U}(h) \, dx \overset{(1.6)}{\ge} \tfrac{3}{\int h \, dx} \operatorname{vol}(\{h > 2\}),$$

so that by (3.2)

$$\operatorname{vol}(\{h > 2\}) \le \tfrac{1}{3R} \int h \, dx. \tag{3.6}$$

This implies

$$\begin{aligned} \int_{\{\widetilde{h} \le H\}} \widetilde{h} \, dx &= \int_{\{2 < h \le H+2\}} (h-2) \, dx \\ &\le H \operatorname{vol}(\{h > 2\}) \\ &\overset{(3.6)}{\le} \tfrac{H}{3R} \int h \, dx \\ &\overset{(3.5)}{\le} \tfrac{H}{R} \int \widetilde{h} \, dx. \end{aligned}$$

Hence we obtain (3.3):

$$\int_{\{\widetilde{h} > H\}} \widetilde{h} \, dx = \int \widetilde{h} \, dx - \int_{\{\widetilde{h} \le H\}} \widetilde{h} \, dx \ge \left(1 - \tfrac{H}{R}\right) \int \widetilde{h} \, dx.$$

This motivates the choice of H.

Now we turn to (3.4):

$$\begin{aligned} \int |\nabla \widetilde{h}| \, dx &= \int_{\{h > 2\}} |\nabla h| \, dx \\ &\overset{(1.6)}{\le} \int |\nabla h| \sqrt{\mathcal{U}(h)} \, dx \\ &\le \int \tfrac{1}{2} |\nabla h|^2 + \mathcal{U}(h) \, dx \\ &\overset{(1.7)}{=} \tfrac{\int h \, dx}{3\Lambda^n} \int \tfrac{1}{2} |\nabla h|^2 + \mathcal{U}(h) \, dx \\ &\overset{(3.5)}{\le} \Lambda^{-n} E(h) \int \widetilde{h} \, dx. \end{aligned}$$

According to (3.2) this turns into

$$R\int|\nabla\widetilde{h}|\,dx\le\int\widetilde{h}\,dx.\qquad\square$$

The next lemma is strongly inspired by [3, Lemma 2.1].

LEMMA 3. *Let $R\le\Lambda$. Assume $g:(0,\Lambda)^n\to[0,\infty)$*

(i) *has height H in the sense that*

$$\int_{\{g\ge H\}}g\,dx\ge\tfrac{1}{2}\int g\,dx \tag{3.7}$$

(ii) *and radius R in the sense that*

$$R\int|\nabla g|\,dx\le\int g\,dx. \tag{3.8}$$

Then there exists a set $A_R\subset\{g\ge H\}$

(i) *which contains substantial mass in the sense that*

$$\int_{A_R}g\,dx\ge\tfrac{1}{4}\int g\,dx$$

(ii) *and is small in the sense that the volume of the thickened sets*

$$A_R^d:=\{x\in(0,\Lambda)^n\mid dist(x,A_R)<d\}$$

is controlled by

$$vol(A_R^d)\le 3^n2^{n+1}\left(1+4\tfrac{d}{R}\right)^n\tfrac{1}{H}\int g\,dx\qquad\text{for all } d>0.$$

Proof. Extend $g:[0,\Lambda]^n\to\mathbb{R}$ to $\overline{g}:\mathbb{R}^n\to\mathbb{R}$ such that

(i) $[0,\Lambda]^n\rightsquigarrow[-\Lambda,\Lambda]^n$ by even reflection and

(ii) $[-\Lambda,\Lambda]^n\rightsquigarrow\mathbb{R}^n$ by periodic continuation.

Set for convenience $\overline{A}:=\{\overline{g}\ge H\}$. Define

$$\overline{A}_R:=\left\{x\in\overline{A}\;\middle|\;\int_{B(x,\frac{R}{8})}\overline{g}\,dy\ge\tfrac{H}{2}\,\mathrm{vol}\left(B\left(x,\frac{R}{8}\right)\right)\right\}. \tag{3.9}$$

With the help of the convolution of $\overline{g}$,

$$\overline{g}_R(x):=\frac{1}{\mathrm{vol}\,(B(x,\frac{R}{8}))}\int_{B(x,\frac{R}{8})}\overline{g}\,dy,$$

$\overline{A}_R$ can be written as $\overline{A}_R=\{x\in\overline{A}\mid\overline{g}_R(x)\ge\frac{H}{2}\}$.

We use the standard estimate

$$\int_{(-\Lambda,\Lambda)^n}|\overline{g}-\overline{g}_R|\,dx\le\tfrac{R}{8}\int_{(-\Lambda,\Lambda)^n}|\nabla\overline{g}|\,dx\overset{(3.8)}{\le}\tfrac{1}{8}\int_{(-\Lambda,\Lambda)^n}\overline{g}\,dx.$$

Since the integrands are even functions this yields

$$\int|g-\overline{g}_R|\,dx\le\tfrac{1}{8}\int g\,dx. \tag{3.10}$$

We now define $A := \overline{A} \cap (0,\Lambda)^n$ and $A_R := \overline{A}_R \cap (0,\Lambda)^n$. Then we have

$$g \geq H \geq 2\overline{g}_R \quad \text{on } A - A_R$$

and thus

$$g \leq 2(g - \overline{g}_R) \quad \text{on } A - A_R.$$

Therefore

$$\int_{A-A_R} g\,dx \leq 2\int_{A-A_R} (g-\overline{g}_R)\,dx \leq 2\int |g-\overline{g}_R|\,dx \overset{(3.10)}{\leq} \tfrac{1}{4}\int g\,dx. \tag{3.11}$$

Notice that by assumption (3.7), $\int_A g\,dx \geq \frac{1}{2}\int g\,dx$. Hence

$$\begin{aligned}\int g\,dx &\leq 2\int_A g\,dx \\ &\leq 2\left(\int_{A_R} g\,dx + \int_{A-A_R} g\,dx\right) \\ &\overset{(3.11)}{\leq} 2\int_{A_R} g\,dx + \tfrac{1}{2}\int g\,dx,\end{aligned}$$

which yields the first assertion.

Let $J \subset A_R$ be maximal with the property

$$\left\{B(x,\tfrac{R}{8})\right\}_{x\in J} \text{ are disjoint.} \tag{3.12}$$

Then necessarily

$$A_R \subset \bigcup_{x\in J} B(x,\tfrac{R}{4}). \tag{3.13}$$

Thus

$$\begin{aligned}\#J\ \mathrm{vol}\,(B(0,\tfrac{R}{8})) &= \sum_{x\in J} \mathrm{vol}\,(B(x,\tfrac{R}{8})) \\ &\overset{(3.9)}{\leq} \tfrac{2}{H}\sum_{x\in J}\int_{B(x,\frac{R}{8})} \overline{g}\,dx \\ &\overset{(3.12)}{\leq} \tfrac{2}{H}\int_{(-\Lambda,2\Lambda)^n} \overline{g}\,dx \\ &= 3^n\tfrac{2}{H}\int g\,dx. \qquad (3.14)\end{aligned}$$

Here we used the assumption $R \leq \Lambda$.

Now (3.13) implies $A_R^d \subset \bigcup_{x\in J} B(x,\frac{R}{4}+d)$, so that

$$\begin{aligned}\mathrm{vol}\,(A_R^d) &\leq \#J\ \mathrm{vol}\,(B(0,\tfrac{R}{4}+d)) \\ &= \frac{\mathrm{vol}\,(B(0,\frac{R}{4}+d))}{\mathrm{vol}\,(B(0,\frac{R}{8}))}\,\#J\ \mathrm{vol}\,(B(0,\tfrac{R}{8})) \\ &\overset{(3.14)}{\leq} 3^n(\tfrac{8}{R}(\tfrac{R}{4}+d))^n\tfrac{2}{H}\int g\,dx \\ &= 3^n 2^{n+1}(1+4\tfrac{d}{R})^n\tfrac{1}{H}\int g\,dx,\end{aligned}$$

which proves the second assertion. ∎

LEMMA 4. *Let $\Lambda \geq R \geq 3^n 2^{8n}$. Then the typical droplet distance L is at least of the order $R^{\frac{n+1}{n}}$ in the following sense: There exists a set $A_R \subset \mathbb{R}^n$ such that*

(i)

$$\int_{A_R} h\,dx \geq \tfrac{1}{12} \int h\,dx \tag{3.15}$$

and

(ii)

$$3\ vol(A_R^L) \leq \tfrac{3}{4} \int_{A_R} h\,dx \quad \text{for } L = 3^{-1}2^{-10}R^{\frac{n+1}{n}}. \tag{3.16}$$

Proof. According to Lemma 3 there exists a set A_R such that

$$\int_{A_R} \widetilde{h}\,dx \geq \tfrac{1}{4} \int \widetilde{h}\,dx, \tag{3.17}$$

which by (3.5) turns into (3.15), and

$$\mathrm{vol}\,(A_R^L) \leq 3^n 2^{n+1} \left(1 + 4\tfrac{L}{R}\right)^n \tfrac{1}{H} \int \widetilde{h}\,dx. \tag{3.18}$$

By the definition of H and R in Lemma 2, (3.18) gives rise to

$$\begin{aligned} \mathrm{vol}\,(A_R^L) &\leq 3^n 2^{n+2} \left(1 + 4\tfrac{L}{R}\right)^n \tfrac{1}{R} \int \widetilde{h}\,dx \\ &\overset{(3.17)}{\leq} 3^n 2^{n+4} \left(1 + 4\tfrac{L}{R}\right)^n \tfrac{1}{R} \int_{A_R} \widetilde{h}\,dx \\ &\leq 3^n 2^{n+4} \left(1 + 4\tfrac{L}{R}\right)^n \tfrac{1}{R} \int_{A_R} h\,dx. \end{aligned}$$

Now L in (3.16) is defined such that

$$3^n 2^{n+4} \left(1 + 4\tfrac{L}{R}\right)^n \tfrac{1}{R} \leq \tfrac{1}{4}$$

provided $R \geq 3^n 2^{8n}$. Hence the inequality turns into

$$3\ \mathrm{vol}\,(A_R^L) \leq \tfrac{3}{4} \int_{A_R} h\,dx. \qquad \square$$

LEMMA 5. *Let $h : Q \to [0, \infty)$ with $h^* := \Lambda^{-n} \int h(x)\,dx$ and let$A \subset \mathbb{R}^n$ and $L > 0$ be given with*

$$h^*\ vol(\{dist(\cdot, A) < L\}) \leq \tfrac{3}{4} \int_A h(x)\,dx. \tag{3.19}$$

Then

$$\mathcal{W}(h, h^*)^2 \geq \tfrac{1}{4} L^2 \int_A h(x)\,dx.$$

Proof. Set for abbreviation $A^L := \{\mathrm{dist}(.,A) < L\}$. Let π be any admissible transportation plan in the definition of $\mathcal{W}$. We conclude that

$$\begin{aligned}\int_{\mathbb{R}^n\times\mathbb{R}^n} |x-y|^2\,d\pi(x,y) &\geq \int_{A\times(\mathbb{R}^n-A^L)} |x-y|^2\,d\pi(x,y)\\ &\geq L^2\pi(A\times(\mathbb{R}^n-A^L))\\ &\geq L^2(\pi(A\times\mathbb{R}^n)-\pi(\mathbb{R}^n\times A^L))\\ &= L^2\left(\int_A h\,dx-\int_{A^L} h^*\,dx\right)\\ &= L^2\left(\int_A h\,dx-h^*\,\mathrm{vol}\,(A^L)\right)\\ &\overset{(3.19)}{\geq} \tfrac{1}{4}L^2\int_A h\,dx. \qquad \square\end{aligned}$$

Proof of Proposition 2. According to Lemma 5 (applied to $h^*=3$ and $A=A_R$) it follows from Lemma 4 for the L defined in (3.16) that

$$\mathcal{W}(h,3)^2 \geq \tfrac{1}{4}L^2\int_{A_R} h\,dx \overset{(3.15)}{\geq} \tfrac{1}{48}L^2\int h\,dx.$$

In view of (1.7), this turns into

$$\Lambda^{-n}\mathcal{W}(h,3)^2 \geq 2^{-4}L^2.$$

In view of the definition (3.2) of R and the definition (3.16) of L this yields

$$\begin{aligned}\Lambda^{-n}E(h)\ \left(\Lambda^{-\frac{n}{2}}\mathcal{W}(h,3)\right)^{\frac{n}{n+1}} &\geq R^{-1}(2^{-4}L^2)^{\frac{n}{2(n+1)}}\\ &= R^{-1}(3^{-2}2^{-24}R^{2\frac{n+1}{n}})^{\frac{n}{2(n+1)}}\\ &= 3^{-\frac{n}{n+1}}2^{-\frac{12n}{n+1}}. \qquad \square\end{aligned}$$

4. Proof of Theorem 1. We cannot apply Proposition 1 right away since the argument for the (infinite-dimensional) gradient flow structure introduced in Appendix B is formal. An inspection of the proof of Proposition 1 reveals that it is only necessary to find a substitute for Lemma 1. In fact, one can directly prove the equivalent of Lemma 1 for the Wasserstein metric as defined in (1.5) and a smooth solution of (1.4).

LEMMA 6. *Let h be a smooth solution of* (1.4). *Then*

$$\left|\frac{d}{dt}\mathcal{W}(3,h(t))\right|^2 \leq \left(-\frac{d}{dt}E(t)\right). \tag{4.1}$$

Proof. We follow [22].

Note that

$$\frac{d}{dt}E(t) = -\int h\left|\nabla\frac{\partial E}{\partial h}\right|^2 dx.$$

It thus is sufficient to establish the inequality

$$\left|\frac{d}{dt}\mathcal{W}(3,h(t))\right|^2 \leq \int h|u|^2\,dx \tag{4.2}$$

for the transport equation

$$\partial_t h + \nabla \cdot (hu) \;=\; 0. \tag{4.3}$$

Due to the triangle inequality we only need to show

$$\lim_{\delta \to 0} \frac{1}{\delta} \mathcal{W}(h_t, h_{t+\delta}) \;\leq\; \sqrt{\int h_t |u_t|^2 \, dx}. \tag{4.4}$$

Here, the indices t and $t+\delta$ denote the time argument of h and u.

First we show that $h_{t+\delta}$ is the push-forward of h_t under the flow map Φ_δ generated by $u_{t+\delta}$, i.e.,

$$\partial_\delta \Phi_\delta = u_{t+\delta} \circ \Phi_\delta, \qquad \Phi_0 = \mathrm{id}. \tag{4.5}$$

Note that by the push-forward one understands that

$$\int \zeta \; h_{t+\delta} \, dx \;=\; \int (\zeta \circ \Phi_\delta) \; h_t \, dx \qquad \text{for all } \zeta \in C_0^0(\mathbb{R}^n). \tag{4.6}$$

For given ζ define $\zeta_\delta := \zeta \circ \Phi_\delta^{-1}$; ζ_δ satisfies

$$\partial_\delta \zeta_\delta + u_{t+\delta} \cdot \nabla \zeta_\delta \;=\; 0.$$

Furthermore, recall that $h_{t+\delta}$ solves the transport equation

$$\partial_\delta h_{t+\delta} + \nabla \cdot (h_{t+\delta} u_{t+\delta}) \;=\; 0.$$

Hence we obtain

$$\frac{d}{d\delta} \int \zeta_\delta \, h_{t+\delta} \, d\delta \;=\; \int (\partial_\delta \zeta_\delta \, h_{t+\delta} + \partial_\delta h_{t+\delta} \, \zeta_\delta) \, dx \;=\; 0,$$

which proves (4.6).

Next we define a product measure π_δ by

$$d\pi_\delta(x,y) \;=\; dh_t(x) \, \delta[y = \Phi_\delta(x)].$$

According to (4.6), π_δ defines an admissible transportation plan in the sense of the definition of $\mathcal{W}$. Thus we get by definition

$$\frac{1}{\delta} \mathcal{W}(h_t, h_{t+\delta}) \leq \sqrt{\int \frac{1}{\delta^2} |x - \Phi_\delta(x)|^2 h_t(x) \, dx}.$$

We obtain from the definition (4.5) of the flow map that $\frac{1}{\delta^2}|x - \Phi_\delta(x)|^2$ converges pointwise to $|u_t|^2$. The dominated convergence theorem yields

$$\lim_{\delta \to 0} \int \frac{1}{\delta^2} |x - \Phi_\delta(x)|^2 h_t(x) \, dx \;=\; \int h_t |u_t|^2 \, dx,$$

which establishes (4.4). ∎

Appendix A. Stationary droplet shape.

In this section, we analyze the shape of a stationary droplet. For this purpose we consider a single droplet with prescribed mass $V > 0$ on top of the precursor layer of equilibrium thickness $h \equiv 1$ on an n-dimensional substrate. We are interested in the stationary droplet shape on a mesoscopic scale. Hence we focus on the mesoscopic energy

$$\overline{E} = \int \tfrac{1}{2}|\nabla h|^2 \, dx + \text{ vol}\,(\{h > 1\}) \tag{A.1}$$

(see section 1.4) for all h, which fulfill the mass constraint

$$\int (h-1)_+ \, dx = V. \tag{A.2}$$

Since the precursor layer of height $h \equiv 1$ has no contribution to the energy $\overline{E}$, we shift h by -1 and consider the problem

$$\text{minimize } \int \tfrac{1}{2}|\nabla h|^2 \, dx + \text{ vol}\,(\{h > 0\}) \text{ subject to } \int h \, dx = V. \tag{A.3}$$

For convenience, we keep the notation h for the shifted film height.

PROPOSITION 3. *Let $V \geq 0$. Then there exists a constant $H > 0$ depending on V such that*

$$\bar{h}(x) \;=\; -\tfrac{1}{2H}|x|^2 + H \qquad \text{on } B(0, \sqrt{2}H) \tag{A.4}$$

is the unique (up to translations) minimizer of problem (A.3).

Proof. We proceed in three steps.

(i) Any minimizer $\bar{h}$ of (A.3) is radially symmetric and monotonically decreasing.

(ii) Any minimizer $\bar{h}$ satisfies

$$-\Delta \bar{h} \;=\; \text{const} \qquad \text{in } \{\bar{h} > 0\}. \tag{A.5}$$

(iii) A unique (up to translations) minimizer $\bar{h}$ exists and satisfies

$$\tfrac{1}{2}|\nabla \bar{h}|^2 \;=\; 1 \qquad \text{on } \partial\{\bar{h} > 0\}. \tag{A.6}$$

Argument for (i)*:* The proof is based on the symmetric decreasing rearrangement $h^{\#}$ of the function h. It is well-known [13, Lemma 7.17] that

$$\int |\nabla h^{\#}|^2 \, dx \;\leq\; \int |\nabla h|^2 \, dx$$

with equality if and only if h is radially symmetric and monotone decreasing. Furthermore, the second contribution to the energy is conserved:

$$\text{vol}\,(\{h^{\#} > 0\}) \;=\; \text{vol}\,(\{h > 0\}).$$

Argument for (ii)*:* The first variation of $\overline{E}$ yields

$$\int (-\Delta h)\, \delta h \, dx \;=\; 0$$

for all variation δh with

$$\int \delta h \, dx = 0 \quad \text{and} \quad \operatorname{supp} \delta h \subset \{h > 0\}.$$

Hence we obtain (A.5).

Argument for (iii)*:* From (1) and (2), we deduce that any minimizer centered at the origin must be of the form

$$h(x) = -A|x|^2 + H \qquad \text{on } B(0, \sqrt{H/A}). \tag{A.7}$$

Note that the family of candidates is invariant under the volume-conserving homothetic variation:

$$h_\lambda(x) \; = \; \lambda^{-n} h\left(\frac{x}{\lambda}\right).$$

Then the first variation of $\overline{E}$ in λ at $\lambda = 1$ yields that at a critical point $\bar{h}$

$$(n+2) \int \tfrac{1}{2} |\nabla \bar{h}|^2 \, dx \; = \; n \; \operatorname{vol}(\{\bar{h} > 0\}). \tag{A.8}$$

Note that the critical point is in fact a minimum since the function

$$\lambda \; \mapsto \; E(h_\lambda) = \lambda^{-(n+2)} \int \tfrac{1}{2} |\nabla \bar{h}|^2 \, dx + \lambda^n \operatorname{vol}(\{\bar{h} > 0\})$$

is convex. We compute

$$\int_{\{\bar{h}>0\}} \tfrac{1}{2} |\nabla \bar{h}|^2 \, dx = \tfrac{2}{n+2} \omega_n A^2 (\sqrt{H/A})^{n+2}$$

and

$$\operatorname{vol}(\{\bar{h} > 0\}) \; = \; \tfrac{1}{n} \omega_n (\sqrt{H/A})^n,$$

where ω_n denotes the $(n-1)$-dimensional measure of $\mathbb{S}^{n-1}$. Thus we obtain from (A.8) that for the minimizer $\bar{h}$ A is determined by

$$2AH = 1. \tag{A.9}$$

Hence at $\partial\{\bar{h} > 0\}$, where $|x|^2 = H/A$,

$$|\nabla \bar{h}|^2 \; = \; 2,$$

which proves (3). Furthermore, we obtain from (A.7) and (A.9) that

$$\bar{h}(x) \; = \; -\tfrac{1}{2H}|x|^2 + H \qquad \text{on } B(0, \sqrt{2}H). \qquad \square$$

Remark 5. Proposition 3 reveals the scaling (1.10)

$$H \; \sim \; R,$$

since the radius of the droplet is given by $\sqrt{2}H$.

Appendix B. The gradient flow structure.

In this section, we specify in which sense the evolution (1.4) is a gradient flow of E defined in (1.2). This heuristic section serves purely as a motivation which guides our analysis. The rigorous result is independent of this section.

The mathematical structure required for a gradient flow,

$$\partial_t h \;=\; -\mathrm{grad} E(h), \tag{B.1}$$

is determined by a smooth function $\mathcal{M} \ni h \mapsto E(h)$ on a Riemannian manifold $(\mathcal{M}, g)$. A trajectory $[0,\infty) \ni t \mapsto h(t) \in \mathcal{M}$ of (B.1) is characterized by the fact that for any tangent vector field $[0,\infty) \ni t \mapsto \delta h(t) \in T_{h(t)}\mathcal{M}$, one has

$$g_{h(t)}\left(\partial_t h(t), \delta h(t)\right) + \left\langle \mathrm{diffE}_{h(t)}, \delta h(t) \right\rangle \;=\; 0 \quad \text{for all } t \geqslant 0. \tag{B.2}$$

In our case $\mathcal{M}$ corresponds to the space of all possible film heights which take the overall mass constraint into account:

$$\mathcal{M} \;= \left\{ h \geq 0 \;\middle|\; \int h(x)\, dx = \int 3\, dx \right\}.$$

The metric tensor encodes the limiting dissipation mechanism by (viscous) friction. Given the continuity equation $\partial_t h + \nabla \cdot (h\, u) = 0$ for the film height $h \geq 0$ by a (vertically averaged horizontal) velocity field $u \in \mathbb{R}^n$, the rate of energy dissipation by friction is given by $\int h\, |u|^2\, dx$ in the case of Darcy-type friction. (It would be $\int \frac{1}{h} |u|^2\, dx$ for Stokes friction with no-slip boundary conditions.) The (quadratic part of) the metric tensor is given by

$$g_h(\delta h, \delta h) \;=\; \inf_u \left\{ \int h|u|^2\, dx \;\middle|\; \delta h + \nabla \cdot (hu) = 0 \right\}. \tag{B.3}$$

For the sake of simplicity, we do not state the boundary conditions such as $\nu \cdot u = 0$ on ∂Q. The squared size, $g_h(\delta h, \delta h)$, of an infinitesimal perturbation δh is the minimal rate of energy dissipation by friction which is necessary to generate δh.

Writing down the Euler–Lagrange equation for (B.3) yields the following representation in terms of the velocity potential φ:

$$g_h(\delta h, \delta h) = \int h|\nabla\varphi|^2\, dx, \qquad \text{where} \quad \delta h + \nabla \cdot (h \nabla \varphi) = 0.$$

By polarization, this yields

$$g_h(\delta h_1, \delta h_2) \;=\; \int h\, \nabla\varphi_1 \cdot \nabla\varphi_2\, dx, \tag{B.4}$$

where the functions φ_i are defined by

$$\delta h_i + \nabla \cdot (h \nabla \varphi_i) = 0.$$

It is easy to check that indeed (1.4) is the gradient flow of (1.2) in the sense of (B.2) with respect to the metric tensor (B.4) defined on $\mathcal{M}$.

Any Riemannian manifold $(\mathcal{M}, g)$ is endowed with a natural distance function d between two points h_0 and h_1 by means of minimizing the action of curves from h_0 to h_1. In view of the definition of the metric tensor (B.3), d turns into

$$d(h_0, h_1)^2 \;=\; \inf_{(h,u)} \left\{ \int_0^1 \int h|u|^2\, dx ds \;\middle|\; \partial_s h + \nabla \cdot (hu) = 0, \left\{ \begin{array}{l} h(0,\cdot) = h_0 \\ h(1,\cdot) = h_1 \end{array} \right\} \right\}.$$

It is shown in [23] that d, in fact, coincides with the Wasserstein distance $\mathcal{W}$ defined in (1.5).

Acknowledgments. The authors thank Patrick Penzler and Maria Reznikoff for fruitful discussions. Dejan Slepčev would also like to thank the University of Bonn for hospitality and Sonderforschungsbereich 611 for supporting his visits.

WAVELETS WITH SHORT SUPPORT*

BIN HAN† AND ZUOWEI SHEN‡

Abstract. This paper is to construct Riesz wavelets with short support. Riesz wavelets with short support are the objective of interest in both theory and application. In theory, it is known that a B-spline of order m has the shortest support among all compactly supported refinable functions with the same regularity. However, it remained open whether a Riesz wavelet with the shortest support and m vanishing moments can be constructed from the multiresolution analysis generated by the B-spline of order m. In various applications, a Riesz wavelet with a short support, a high order of regularity, and vanishing moments is often desirable in signal and image processing, since they have a good time frequency localization and approximation property, as well as fast algorithms. This paper presents a theory for the construction of Riesz wavelets with short support and gives various examples. In particular, from the multiresolution analysis whose underlying refinable function is the B-spline of order m, we are able to construct the shortest supported Riesz wavelet with m vanishing moments. The support of the wavelet functions can be made even shorter by reducing their orders of vanishing moments. The study here also provides a new insight into the structures of the spline tight frame systems constructed in [A. Ron and Z. Shen, *J. Funct. Anal.*, 148 (1997), pp. 408–447, I. Daubechies, B. Han, A. Ron, and Z. Shen, *Appl. Comput. Harmon. Anal.*, 14 (2003), pp. 1–46, B. Han and Q. Mo, *Proc. Amer. Math. Soc.*, 132 (2004), pp. 77–86] and bi-frame systems in [I. Daubechies, B. Han, A. Ron, and Z. Shen, *Appl. Comput. Harmon. Anal.*, 14 (2003), pp. 1–46, I. Daubechies and B. Han, *Constr. Approx.*, 20 (2004), pp. 325–352].

1. Introduction.

The objective of this paper is to design Riesz wavelets with short support from a multiresolution analysis. We start with some basic notions and definitions. A function ϕ is *refinable* if it satisfies the refinement equation

$$\phi = 2\sum_{k\in\mathbb{Z}} a(k)\phi(2\cdot -k), \tag{1.1}$$

where $a : \mathbb{Z} \mapsto \mathbb{C}$ is a sequence on $\mathbb{Z}$, called the *refinement mask* for ϕ.

By $\ell_2(\mathbb{Z})$ we denote the set of all sequences $u : \mathbb{Z} \mapsto \mathbb{C}$ such that

$$\|u\|_{\ell_2(\mathbb{Z})} := \left(\sum_{k\in\mathbb{Z}} |u(k)|^2\right)^{1/2} < \infty.$$

The *Fourier series* $\hat{u}$ of a sequence u in $\ell_2(\mathbb{Z})$ is defined as

$$\hat{u}(\xi) := \sum_{k\in\mathbb{Z}} u(k)e^{-ik\xi}, \qquad \xi \in \mathbb{R}, \tag{1.2}$$

where i is the imaginary unit such that $i^2 = -1$. Similarly, the Fourier transform of a function $f \in L_1(\mathbb{R})$ is defined as

$$\hat{f}(\xi) := \int_{\mathbb{R}} f(t) e^{-i\xi t}\, dt, \qquad \xi \in \mathbb{R},$$

which can be extended naturally to functions in $L_2(\mathbb{R})$ and tempered distributions. Now, refinement equation (1.1) can be rewritten, in terms of the Fourier transform, as

$$\hat{\phi}(\xi) = \hat{a}(\xi/2)\hat{\phi}(\xi/2), \qquad \text{a.e. } \xi \in \mathbb{R}.$$

Using the above definition, one extends the concept of refinable functions to that of refinable distributions. Throughout the paper we assume that $\hat{\phi}(0) \neq 0$ and $\hat{a}(0) = 1$. We also call $\hat{a}$ a refinement mask for convenience.

For a given compactly supported refinable function $\phi \in L_2(\mathbb{R})$, define V_0 to be the smallest closed subspace of $L_2(\mathbb{R})$ generated by $\phi(\cdot - k)$, $k \in \mathbb{Z}$. Then V_0 is a shift (integer translate) invariant subspace of $L_2(\mathbb{R})$. Let $V_j := \{f(2^j \cdot) : f \in V_0\}$, for $j \in \mathbb{Z}$. Then the sequence of subspaces V_j, $j \in \mathbb{Z}$, forms a multiresolution analysis (MRA) in $L_2(\mathbb{R})$, which is generated by ϕ, i.e., (i) $V_j \subset V_{j+1}$, $j \in \mathbb{Z}$; (ii) $\overline{\cup_{j\in\mathbb{Z}} V_j} = L_2(\mathbb{R})$ and $\cap_{j\in\mathbb{Z}} V_j = \{0\}$ (see, e.g., [1] and [15]). In this paper, a function $\psi \in V_1$ (or more precisely, $\psi \in V_1 \backslash V_0$) is called an MRA-based wavelet function, or simply a wavelet, derived from the MRA $\{V_j\}_{j\in\mathbb{Z}}$.

In this paper, we are interested in finding a function ψ such that the wavelet system

$$X(\psi) := \{\psi_{j,k} := 2^{j/2}\psi(2^j \cdot -k) \ : \ j, k \in \mathbb{Z}\}$$

forms a Riesz basis for $L_2(\mathbb{R})$. The set $X(\psi)$ is called the wavelet system generated by ψ. Recall that the system $X(\psi)$ is a *Riesz basis* of $L_2(\mathbb{R})$ if the linear span of $X(\psi)$ is dense in $L_2(\mathbb{R})$ and $X(\psi)$ is a Riesz sequence; that is, there exist two positive constants C_1 and C_2 such that

$$C_1\|\{c_{j,k}\}\|_{\ell_2(\mathbb{Z}^2)} \leqslant \left\|\sum_{j\in\mathbb{Z}}\sum_{k\in\mathbb{Z}} c_{j,k}\psi_{j,k}\right\|_{L_2(\mathbb{R})} \leqslant C_2\|\{c_{j,k}\}\|_{\ell_2(\mathbb{Z}^2)} \qquad \forall\ \{c_{j,k}\}_{j,k\in\mathbb{Z}} \in \ell_2(\mathbb{Z}^2). \tag{1.3}$$

If $X(\psi)$ is a Riesz basis of $L_2(\mathbb{R})$, then ψ is called a *Riesz wavelet*. To construct a compactly supported MRA-based Riesz wavelet ψ, one starts with a compactly supported refinable function ϕ with stable shifts. Recall that the shifts of a function ϕ are *stable* if $\{\phi(\cdot - k) \ : \ k \in \mathbb{Z}\}$ is a Riesz sequence; that is, there exist two positive constants C_1 and C_2 such that $C_1\|\{c_k\}\|_{\ell_2(\mathbb{Z})} \leqslant \|\sum_{k\in\mathbb{Z}} c_k\phi(\cdot - k)\|_{L_2(\mathbb{R})} \leqslant C_2\|\{c_k\}\|_{\ell_2(\mathbb{Z})}$ for all $\{c_k\}_{k\in\mathbb{Z}} \in \ell_2(\mathbb{Z})$. Then a compactly supported Riesz wavelet ψ is obtained by selecting some desirable finitely supported sequence b that is called a *wavelet mask* or a high-pass filter in the language of engineering. With the wavelet mask b, the wavelet function ψ is obtained from b and the refinable function ϕ via

$$\psi = 2\sum_{k\in\mathbb{Z}} b(k)\phi(2\cdot -k), \quad \text{or equivalently,} \quad \hat{\psi}(\xi) = \hat{b}(\xi/2)\hat{\phi}(\xi/2). \tag{1.4}$$

When $\{\phi(\cdot-k) : k\in\mathbb{Z}\}$ forms an orthonormal system, a natural choice of b is

$$b(k)=(-1)^{k-1}\overline{a(1-k)}, \qquad k\in\mathbb{Z}.$$

Its Fourier series can be written as

$$\hat{b}(\xi)=e^{-i\xi}\overline{\hat{a}(\xi+\pi)}. \tag{1.5}$$

Then it is well known that the wavelet system $X(\psi)$ forms an orthonormal basis of $L_2(\mathbb{R})$. The wavelet function ψ has the same length of support as that of the corresponding refinable function ϕ. Thus, once a compactly supported refinable function ϕ whose shifts form an orthonormal system is given, the corresponding orthonormal wavelet ψ can be obtained easily. Hence, the major task and difficulty in constructing compactly supported dyadic orthonormal wavelets in dimension one are to design refinement masks whose corresponding refinable functions have the required smoothness order and whose shifts form an orthonormal system. This was discussed in detail in [6].

On the other hand, compactly supported refinable functions whose shifts form a Riesz sequence are much easier to get. One such class of refinable functions are B-splines.

The B-spline function of order m ($m\in\mathbb{N}$), denoted by B_m, can be obtained via the following recursive formula: $B_1=\chi_{[0,1]}$, the characteristic function of the interval $[0,1]$, and

$$B_m(x):=\int_0^1 B_{m-1}(x-t)\,dt, \qquad x\in\mathbb{R},\ m\in\mathbb{N}. \tag{1.6}$$

The B-spline function $B_m\in C^{m-2}(\mathbb{R})$ is a function of piecewise polynomials of degree less than m, vanishes outside the interval $[0,m]$ and is symmetric about the point $m/2$, that is, $B_m(m-x)=B_m(x)$ for all $x\in\mathbb{R}$. It is well known that the B-spline function B_m is a refinable function satisfying the refinement equation

$$\widehat{B_m}(2\xi)=\Big(\frac{1+e^{-i\xi}}{2}\Big)^m\widehat{B_m}(\xi), \qquad \xi\in\mathbb{R}. \tag{1.7}$$

When $m=1$, the shifts of B_1 form an orthonormal basis of the shift invariant space V_0 generated by B_1. The shifts of B_m, $m>1$, form a Riesz, but not an orthonormal, basis of the shift invariant space V_0 generated by B_m. When m is even, $B_m(\cdot-m/2)$ is symmetric about the origin with the refinement mask

$$\hat{a}(\xi)=\cos^{2m}(\xi/2).$$

While compactly supported refinable functions with stable shifts are easier to obtain, the construction of compactly supported Riesz wavelets from an MRA generated by a B-spline of order m is not straightforward. A compactly supported Riesz wavelet ψ from the MRA generated by B_m was first constructed in [3]. While $X(\psi)$ forms a Riesz basis of $L_2(\mathbb{R})$ and the system keeps the orthogonality between different dilation levels, the support of the prewavelet ψ in [3] is $[0,2m-1]$ (therefore, almost two times that of B_m) and ψ has m vanishing moments. Recently, [16] derived a Riesz wavelet ψ from B_m such that the Riesz wavelet system $X(\psi)$ forms a Riesz basis of $L_2(\mathbb{R})$. When ψ is required to have m vanishing moments, the construction of [16] gives the prewavelet of [3] and hence its support is $[0,2m-1]$; efforts are made in [16] to shorten

the support of the Riesz wavelets at the cost of a reduced order of vanishing moments of the Riesz wavelets. For example, the support of the Riesz wavelet ψ can be reduced to $[0, m]$ when m is odd (or $[0, m+1]$ when m is even) with 1 or 2 vanishing moments. It is a bit surprising to us that there are no discussions in the literature whether the natural choice of a function,

$$\psi := 2\sum_{k\in\mathbb{Z}} b(k)B_m(2\cdot -k) \tag{1.8}$$

with

$$b(k) = (-1)^{k-1}\overline{a(1-k)}, \qquad k \in \mathbb{Z}, \tag{1.9}$$

where $\hat{a}(\xi) = 2^{-m}(1+e^{-i\xi})^m$ is the refinement mask of B_m, is a Riesz wavelet. There are several other motivations that lead to the discussions here. First, the mask defined in (1.9) works for the case $m = 1$. It is clear that when $m = 1$, the corresponding wavelet function ψ is the Haar wavelet. Hence, $X(\psi)$ is an orthonormal basis of $L_2(\mathbb{R})$. In fact, it works for an arbitrary compactly supported refinable function whose shifts form an orthonormal system. It is natural to ask whether the function ψ in (1.8) with the wavelet mask defined in (1.9) is a Riesz wavelet. Second, ψ in (1.8) has the same length of support as that of B_m. Further, as will be shown in section 2, in some sense, ψ is the shortest supported Riesz wavelet of regularity $m - 1/2$ with m vanishing moments. Recall that a function ψ has *m vanishing moments* if

$$\hat{\psi}^{(j)}(0) = 0 \qquad \forall\, j = 0, \dots, m-1,$$

where $\hat{\psi}^{(j)}$ denotes the jth derivative of $\hat{\psi}$. This means that it has good time frequency localization and can lead to efficient algorithms in applications. One of the main objectives of this paper is to prove that the system $X(\psi)$, where ψ is defined in (1.8), forms a Riesz basis of $L_2(\mathbb{R})$, which will be established in section 2. The spline-based Riesz wavelets in this paper with short support and high vanishing moments may be of interest in wavelet-based numerical algorithms, since the wavelet functions are piecewise polynomials, while it is well known that most other wavelets do not have explicit analytic forms.

In many applications, it is not only important to have Riesz wavelets with short support, but also desirable to have short supported Riesz wavelets with a small condition number, namely, a small ratio of the upper and lower Riesz bounds in (1.3). The condition number of the spline Riesz wavelet suggested here cannot be smaller than that of the system $\{B_m(\cdot - k) : k \in \mathbb{Z}\}$. However, it is well known that the condition number of the system $\{B_m(\cdot - k) : k \in \mathbb{Z}\}$ increases as m goes to ∞. In this regard, it is of interest to construct Riesz wavelets with short support, which are as close as possible to some orthonormal wavelets or tight frame wavelets, for a given order of regularity or vanishing moments. Such wavelet systems will then have small condition numbers. This is of interest and importance in various applications, although it is not a topic addressed in this paper.

The general theory needed for this paper is given in section 3. The theory also provides a new insight into the systematic constructions of the tight frame systems from the B-spline of order m by using the unitary extension principle of [20] and the oblique extension principle of [9]. In those constructions, for a given B_m, a set $\Psi := \{\psi^1, \dots, \psi^L\}$ of functions is obtained so that the system

$$X(\Psi) := \{\psi^\ell_{j,k} := 2^{j/2}\psi^\ell(2^j\cdot -k) \ : \ \ell = 1, \dots, L \ \text{ and } \ j, k \in \mathbb{Z}\}$$

forms a tight frame for $L_2(\mathbb{R})$. That is,

$$f = \sum_{\ell=1}^{L} \sum_{j\in\mathbb{Z}} \sum_{k\in\mathbb{Z}} \langle f, \psi_{j,k}^{\ell}\rangle \psi_{j,k}^{\ell} \qquad \forall\, f \in L_2(\mathbb{R}).$$

The system $X(\Psi)$ is a redundant system. However, we discover from the study here that in all spline constructions, there exists a function $\psi \in \Psi$ such that $X(\psi)$ (in some cases $X(\psi(\cdot - 1/2))$ forms a Riesz basis for $L_2(\mathbb{R})$. This finding roughly says that one of the functions in the set Ψ already can generate a Riesz basis for $L_2(\mathbb{R})$, while the other functions in Ψ are there just to either improve the condition number determined by the upper and lower frame bounds or provide a better dual system.

More generally, a system $X(\psi)$ is *Bessel* in $L_2(\mathbb{R})$ if there exists a positive constant C such that

$$\sum_{j\in\mathbb{Z}} \sum_{k\in\mathbb{Z}} |\langle f, \psi_{j,k}\rangle|^2 \leqslant C\|f\|^2 \qquad \forall\, f \in L_2(\mathbb{R}). \tag{1.10}$$

A system $X(\psi)$ is Bessel if both functions $\sum_{k\in\mathbb{Z}} |\hat{\psi}(\cdot + 2\pi k)|$ and $\sum_{j\in\mathbb{Z}} |\hat{\psi}(2^j\cdot)|$ are in $L_\infty(\mathbb{R})$ (see [22, Corollary 15]). This will hold whenever ψ has a sufficient smoothness order. For example, it is known [11, Propositions 2.6 and 3.5] that if, for some $\varepsilon > 0$, there exists a positive constant C such that $|\hat{\psi}(\xi)| \leqslant C(1+|\xi|)^{-1/2-\varepsilon}$ and $|\hat{\psi}(\xi)| \leqslant C|\xi|^{\varepsilon}$ for all $\xi \in \mathbb{R}$, then the corresponding system $X(\psi)$ is Bessel in $L_2(\mathbb{R})$. It is clear that for a finite set Ψ, $X(\Psi)$ is Bessel if and only if $X(\psi)$ is Bessel for each $\psi \in \Psi$.

A system $X(\Psi)$ with $\Psi = \{\psi^1, \dots, \psi^L\}$ is a *frame* for $L_2(\mathbb{R})$ if there exist positive constants C_1 and C_2 such that

$$C_1\|f\|^2 \leqslant \sum_{\ell=1}^{L} \sum_{j\in\mathbb{Z}} \sum_{k\in\mathbb{Z}} |\langle f, \psi_{j,k}^{\ell}\rangle|^2 \leqslant C_2\|f\|^2 \qquad \forall\, f \in L_2(\mathbb{R}). \tag{1.11}$$

Let $\Psi := \{\psi^1, \dots, \psi^L\}$ and $\tilde{\Psi} := \{\tilde{\psi}^1, \dots, \tilde{\psi}^L\}$ be two sets of functions in $L_2(\mathbb{R})$. We say that $(X(\Psi), X(\tilde{\Psi}))$ is a pair of *bi-frames* in $L_2(\mathbb{R})$ if each of $X(\Psi)$ and $X(\tilde{\Psi})$ is Bessel in $L_2(\mathbb{R})$, and if $X(\Psi)$ and $X(\tilde{\Psi})$ satisfy

$$\langle f, g\rangle = \sum_{\ell=1}^{L} \sum_{j\in\mathbb{Z}} \sum_{k\in\mathbb{Z}} \langle f, \tilde{\psi}_{j,k}^{\ell}\rangle \langle \psi_{j,k}^{\ell}, g\rangle \qquad \forall\, f, g \in L_2(\mathbb{R}), \tag{1.12}$$

where $\langle f, g\rangle := \int_{\mathbb{R}} f(t)\overline{g(t)}\, dt$. If (1.12) holds with $\tilde{\psi}^{\ell} = \psi^{\ell}$ for all $\ell = 1, \dots, L$, then $X(\Psi)$ is a tight wavelet frame in $L_2(\mathbb{R})$.

A similar phenomenon also can be found for pairs of bi-frames constructed from B-splines in [9, 8]. All of these phenomena will be discussed in detail in section 4. More examples of Riesz wavelets with short support will be given in the last section. Some of our examples are even from nonspline refinable functions.

2. Riesz spline wavelet bases with short support. In order to show that the system $X(\psi)$ with ψ defined in (1.8) forms a Riesz basis for $L_2(\mathbb{R})$, we need the following lemma that is a special case of Corollary 3.3.

LEMMA 2.1. *Let a be a finitely supported refinement mask for a compactly supported refinable function $\phi \in L_2(\mathbb{R})$ with $\hat{a}(0) = 1$ and $\hat{a}(\pi) = 0$ such that $\hat{\phi}(0) \neq 0$ and $\hat{a}$ can be factorized into the form*

$$\hat{a}(\xi) = \Big(\frac{1 + e^{-i\xi}}{2}\Big)^m \hat{A}(\xi),$$

where $\hat{A}$ is the Fourier series of a finitely supported sequence A with $\hat{A}(\pi) \neq 0$. Suppose that

$$|\hat{a}(\xi)|^2 + |\hat{a}(\xi + \pi)|^2 \neq 0 \quad \forall \quad \xi \in \mathbb{R}.$$

Define

$$\hat{\psi}(2\xi) := e^{-i\xi}\overline{\hat{a}(\xi + \pi)}\hat{\phi}(\xi)$$

and

$$\hat{\tilde{A}}(\xi) := \frac{\hat{A}(\xi)}{|\hat{a}(\xi)|^2 + |\hat{a}(\xi + \pi)|^2}.$$

Assume that

$$\rho_A := \inf_{n\in\mathbb{N}} \|\widehat{A_n}\|^{1/n}_{L_\infty(\mathbb{R})} < 2^{m-1/2} \qquad \text{and} \qquad \rho_{\tilde{A}} := \inf_{n\in\mathbb{N}} \|\widehat{\tilde{A}_n}\|^{1/n}_{L_\infty(\mathbb{R})} < 2^{m-1/2},$$

where $\widehat{A_n}(\xi) := \hat{A}(2^{n-1}\xi)\cdots\hat{A}(2\xi)\hat{A}(\xi)$ and $\widehat{\tilde{A}_n}(\xi) := \hat{\tilde{A}}(2^{n-1}\xi)\cdots\hat{\tilde{A}}(2\xi)\hat{\tilde{A}}(\xi)$. Then $X(\psi)$ is a Riesz basis for $L_2(\mathbb{R})$.

Recall that a function f is in the Sobolev space $W^\beta(\mathbb{R})$ if

$$\int |\hat{f}(\xi)|^2(1 + |\xi|^2)^\beta d\xi < \infty.$$

We say that f has the *regularity* α if $f \in W^\beta(\mathbb{R})$ for all $\beta < \alpha$. It is well known that the B-spline B_m of order m has the regularity $m - 1/2$. A compactly supported function ϕ satisfies the Strang–Fix condition of order m if

$$\hat{\phi}(0) \neq 0 \quad \text{and} \qquad \hat{\phi}^{(j)}(2\pi k) = 0 \qquad \forall\, j = 0, 1, \ldots, m-1, \quad k \in \mathbb{Z}\backslash\{0\}.$$

Applying Lemma 2.1 to the B-spline functions, we obtain the following result.

THEOREM 2.2. *Let B_m be the B-spline function of order m with the refinement mask*

$$\hat{a}(\xi) = 2^{-m}(1 + e^{-i\xi})^m.$$

Define

$$\hat{\psi}(2\xi) = 2^{-m}e^{-i\xi}(1 - e^{i\xi})^m\widehat{B_m}(\xi). \tag{2.1}$$

Then the following hold:

(i) *The function ψ has the regularity $m - 1/2$ and has m vanishing moments. It is either symmetric or antisymmetric satisfying $\psi = (-1)^m\psi(1 - \cdot)$ and it is supported on the interval $[1/2 - m/2, 1/2 + m/2]$.*

(ii) *$X(\psi)$ forms a Riesz basis for $L_2(\mathbb{R})$.*

(iii) *Among all wavelets (redundant or nonredundant) which have m vanishing moments and are based on an MRA whose underlying refinable function has the regularity $m-1/2$, the Riesz wavelet ψ has the shortest support.*

Proof. Conclusion (i) follows directly from the properties of B-splines and the definition of ψ.

For (ii), we apply Lemma 2.1. First, it is easy to check that $|\hat{a}(\xi)|^2+|\hat{a}(\xi+\pi)|^2 \neq 0$ for all $\xi \in \mathbb{R}$. Since $\hat{A}$ in Lemma 2.1 is 1, clearly, $\rho_A = 1 < 2^{m-1/2}$ for all $m \in \mathbb{N}$. The corresponding $\hat{\tilde{A}}$ in Lemma 2.1 is

$$\hat{\tilde{A}}(\xi) = \frac{1}{|\hat{a}(\xi)|^2 + |\hat{a}(\xi+\pi)|^2} = \frac{1}{\cos^{2m}(\xi/2) + \sin^{2m}(\xi/2)}.$$

To prove that $\rho_{\tilde{A}} < 2^{m-1/2}$, we observe that the function $f_m(x) := x^m + (1-x)^m$ decreases on $[0,1/2]$ and increases on $[1/2,1]$ by $f_m'(x) = m[x^{m-1} - (1-x)^{m-1}]$. Consequently, we have $f_m(x) \geqslant f(1/2) = 2^{1-m}$ for all $x \in [0,1]$ and $m \in \mathbb{N}$. Since $\hat{\tilde{A}}(\xi) = [f(\cos^2(\xi/2))]^{-1}$, we conclude that $\rho_{\tilde{A}} \leqslant \|\hat{\tilde{A}}\|_{L_\infty(\mathbb{R})} \leqslant [f(1/2)]^{-1} = 2^{m-1} < 2^{m-1/2}$. By Lemma 2.1, $X(\psi)$ is a Riesz wavelet basis for $L_2(\mathbb{R})$.

For (iii), since the corresponding refinable function ϕ has the regularity $m-1/2$, ϕ must satisfy the Strang–Fix condition of order m (see [19, 14]). Hence, ϕ must be the convolution of B_m with some function/distribution (see [18, Theorem 3.7]). Hence, B_m has the shortest support among all refinable functions of the regularity $m-1/2$.

For any given MRA-based wavelet with m vanishing moments, since the refinable function ϕ satisfies $\hat{\phi}(0) \neq 0$, the wavelet mask must have the factor

$$\Big(\frac{1-e^{i\xi}}{2}\Big)^m.$$

This says that in order to have m vanishing moments, the wavelet mask cannot be shorter than $(\frac{1-e^{i\xi}}{2})^m$. Altogether, we conclude that ψ defined in (2.1) has the shortest support among all wavelets (redundant or nonredundant) which have m vanishing moments and are based on an MRA whose underlying refinable function has the regularity $m-1/2$. □

Since it is rare to be able to derive a wavelet of regularity $m-1/2$ from a multiresolution whose underlying refinable function has the regularity smaller than $m-1/2$, (iii) in the above theorem essentially says that ψ defined in (2.1) is the shortest supported MRA-based wavelet having the regularity $m-1/2$ and m vanishing moments.

Example 2.3. Let $m=2$. Then by (2.1), $\psi = \frac{1}{2}B_2(2\cdot-1) - B_2(2\cdot) + \frac{1}{2}B_2(2\cdot+1)$. By Theorem 2.2, $X(\psi)$ is a Riesz basis for $L_2(\mathbb{R})$. The Riesz wavelet ψ has 2 vanishing moments and the regularity 3/2. See Figure 1 for the graphs of the functions B_2 and ψ.

Example 2.4. Let $m=3$. Then by (2.1), $\psi = \frac{1}{4}B_3(2\cdot-1) - \frac{3}{4}B_3(2\cdot) + \frac{3}{4}B_3(2\cdot+1) - \frac{1}{4}B_3(2\cdot+2)$. By Theorem 2.2, $X(\psi)$ is a Riesz basis for $L_2(\mathbb{R})$. The Riesz wavelet ψ has 3 vanishing moments and the regularity 5/2. See Figure 2 for the graphs of the functions B_3 and ψ.

3. Biorthogonal wavelets with infinite masks. In this section, we give a general form of Lemma 2.1. This not only leads to a proof of Lemma 2.1, but also leads to a result in a more general setting. This further allows us to connect the

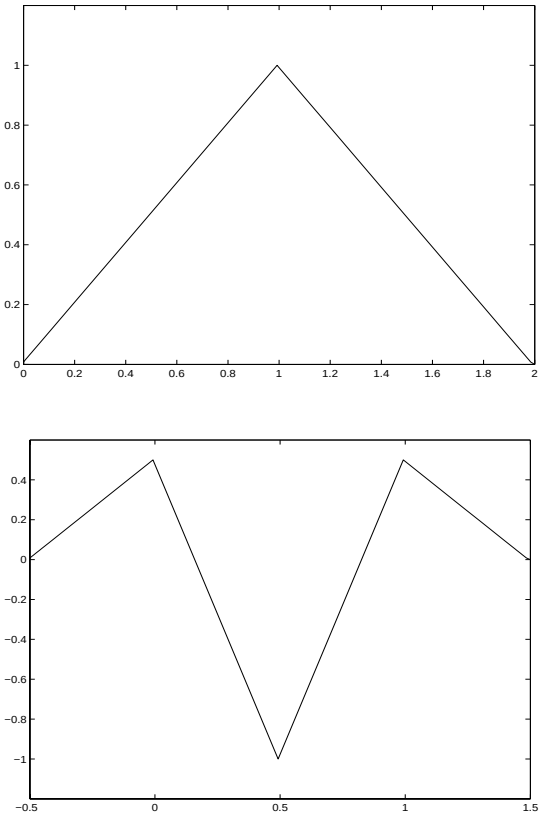

FIG. 1. *The graph of the B-spline B_2 (top) and the graph of the wavelet function ψ (bottom) in Example* 2.3. *The Riesz wavelet ψ has* 2 *vanishing moments and the regularity* 3/2. *The wavelet system $X(\psi)$ is a Riesz basis for $L_2(\mathbb{R})$.*

discussions here to the spline tight frame wavelet systems given in [20, 9, 12] and bi-frame systems in [9, 8], as we will discuss in section 4.

We start with some basic notions. Recall that a function f on $\mathbb{R}$ has *polynomial decay* if

$$(1 + |\cdot|)^j f \in L_\infty(\mathbb{R}) \qquad \forall\, j \in \mathbb{N}$$

and has *exponential decay* if there exists a positive number β such that

$$e^{\beta|\cdot|} f \in L_\infty(\mathbb{R}).$$

If a function f has polynomial decay or exponential decay, then clearly $f \in L_p(\mathbb{R})$ for all $1 \leqslant p \leqslant \infty$.

Similarly, a sequence a on $\mathbb{Z}$ has polynomial decay if

$$\sum_{k\in\mathbb{Z}} (1 + |k|)^j |a(k)| < \infty \qquad \forall\, j \in \mathbb{N},$$

or equivalently, $\sup_{k\in\mathbb{Z}}(1 + |k|)^j |a(k)| < \infty$ for all $j \in \mathbb{N}$. It is easy to see that a sequence a has polynomial decay if and only if $\hat{a} \in C^\infty(\mathbb{R})$.

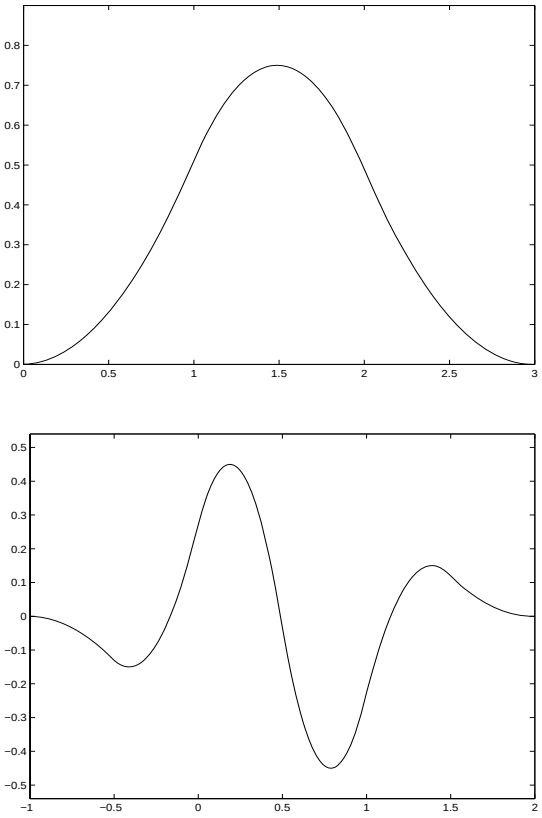

FIG. 2. *The graph of the B-spline B_3 (top) and the graph of the function ψ (bottom) in Example* 2.4. *The function ψ has* 3 *vanishing moments and the regularity* 5/2. *The wavelet system $X(\psi)$ is a Riesz basis for $L_2(\mathbb{R})$.*

For a sequence u on $\mathbb{Z}$ and a function f on $\mathbb{R}$, we define

$$\nabla u := u - u(\cdot - 1) \quad \text{and} \quad \nabla f := f - f(\cdot - 1). \tag{3.1}$$

In general, $\nabla^m u = \sum_{k=0}^m (-1)^k \frac{m!}{k!(m-k)!} u(\cdot - k)$.

The following lemma is similar to [10, Theorem 3.6] and will be needed later.

LEMMA 3.1. *Let $f \in L_2(\mathbb{R})$ be a function with polynomial decay and let m be an arbitrary given positive integer. Then the following statements are equivalent:*

(i) $\hat{f}^{(j)}(2\pi k) = 0$ *for all* $k \in \mathbb{Z}$ *and* $j = 0, \ldots, m-1$.

(ii) *The identity* $f = \nabla^m h$ *holds where*

$$h := \sum_{k=0}^{\infty} \frac{(k+m-1)!}{k!(m-1)!} f(\cdot - k) \tag{3.2}$$

has polynomial decay. In particular, h is in $L_2(\mathbb{R})$.

Proof. Assume that (i) holds. It is easy to see that (i) is equivalent to $\sum_{k\in\mathbb{Z}} k^j f(\cdot - k) = 0$ for all $j = 0, \ldots, m-1$. Let h be the function as given in (3.2). Since f has

polynomial decay, it is easy to see that h is well defined on $\mathbb{R}$. Note that

$$\begin{aligned}\nabla h &= h - h(\cdot - 1)\\ &= \sum_{k=0}^{\infty} \frac{(k+m-1)!}{k!(m-1)!} f(\cdot - k) - \sum_{k=1}^{\infty} \frac{(k+m-2)!}{(k-1)!(m-1)!} f(\cdot - k)\\ &= f + \sum_{k=1}^{\infty} \left[\frac{(k+m-1)!}{k!(m-1)!} - \frac{(k+m-2)!}{(k-1)!(m-1)!} \right] f(\cdot - k)\\ &= f + \sum_{k=1}^{\infty} \frac{(k+m-2)!}{k!(m-2)!} f(\cdot - k)\\ &= \sum_{k=0}^{\infty} \frac{(k+m-2)!}{k!(m-2)!} f(\cdot - k).\end{aligned}$$

Hence, $\nabla^m h = f$ by induction on m. Next, we show that h has polynomial decay. Since f has polynomial decay, there exist positive constants $C_\ell, \ell \in \mathbb{N}$, such that

$$|f(t)| \leqslant C_\ell (1 + |t|)^{-\ell} \qquad \forall\, t \in \mathbb{R}.$$

Let $t \leqslant 0$ and $j \in \mathbb{N}$. Then

$$\begin{aligned}(1+|t|)^j |h(t)| &\leqslant \sum_{k=0}^{\infty} \left| \frac{(k+m-1)\cdots(k+1)}{(m-1)!} \right| |f(t-k)|(1+|t|)^j\\ &\leqslant C_\ell \sum_{k=0}^{\infty} \frac{(k+m-1)^m}{(m-1)!} (1+|t-k|)^{-\ell} (1+|t|)^j\\ &\leqslant C_\ell \sum_{k=0}^{\infty} \frac{m^m (k+1)^m}{(m-1)!} (1+|t|+k)^{-\ell} (1+|t|)^j\\ &\leqslant C_\ell \frac{m^m}{(m-1)!} \sum_{k=0}^{\infty} (1+|t|+k)^{m+j-\ell}\\ &\leqslant C_\ell \frac{m^m}{(m-1)!} \sum_{k=0}^{\infty} (1+k)^{m+j-\ell},\end{aligned}$$

which is finite whenever $\ell > m + j + 1$. (Note here that one always can choose such an ℓ by the definition of the polynomial decay of f.) For $t > 0$, we first note that

$$\frac{(k+m-1)!}{k!} = (k+m-1)\cdots(k+1)$$

(when $m = 1$, by convention it takes value 1) is a polynomial of degree $m-1$ for the variable k. Then (i) asserts that

$$0 = \sum_{k=-\infty}^{-1} \frac{(k+m-1)\cdots(k+1)}{(m-1)!} f(\cdot - k) + \sum_{k=0}^{\infty} \frac{(k+m-1)\cdots(k+1)}{(m-1)!} f(\cdot - k).$$

Hence,

$$h = -\sum_{k=-\infty}^{-1} \frac{(k+m-1)\cdots(k+1)}{(m-1)!} f(\cdot - k).$$

By a similar argument applying to the above identity, we conclude that h must have polynomial decay for $t > 0$.

Assume that (ii) holds. This implies that $\hat{f}(\xi) = (1-e^{-i\xi})^m \hat{h}(\xi)$, which gives (i). This completes the proof. □

By δ we denote the *Dirac sequence* on $\mathbb{Z}$ such that $\delta(0) = 1$ and $\delta(k) = 0$ for all $k \in \mathbb{Z}\backslash\{0\}$. The *bracket product* of two functions f and g in $L_2(\mathbb{R})$ is defined to be (see [13])

$$[f,g](\xi) := \sum_{k\in\mathbb{Z}} f(\xi+2\pi k)\overline{g(\xi+2\pi k)}, \qquad \xi \in \mathbb{R}. \tag{3.3}$$

It is well known that $\langle f(\cdot-k), g\rangle = \delta(k)$ for all $k \in \mathbb{Z}$ if and only if $[\hat{f}, \hat{g}] = 1$.

Assume that $(X(\Psi), X(\tilde{\Psi}))$ is a pair of bi-frames. If the system $(X(\Psi), X(\tilde{\Psi}))$ further satisfies $\langle \psi^\ell_{j,k}, \psi^{\ell'}_{j',k'}\rangle = \delta(\ell-\ell')\delta(j-j')\delta(k-k')$ for all $\ell, \ell' = 1, \ldots, L$ and $j, j', k, k' \in \mathbb{Z}$, then $(X(\Psi), X(\tilde{\Psi}))$ forms a pair of *biorthogonal wavelet bases* in $L_2(\mathbb{R})$. Clearly, if $(X(\Psi), X(\tilde{\Psi}))$ forms a pair of biorthogonal wavelet bases in $L_2(\mathbb{R})$, then both systems $X(\Psi)$ and $X(\tilde{\Psi})$ form a Riesz wavelet basis in $L_2(\mathbb{R})$ (see, e.g., [21]).

With Lemma 3.1, we prove the following result on biorthogonal wavelets with infinite masks.

THEOREM 3.2. *Let a and b be two sequences on $\mathbb{Z}$ satisfying the following two conditions:*

(i) *There are positive integers m and $\tilde{m}$ such that $\hat{a}(\xi) = (\frac{1+e^{-i\xi}}{2})^m \hat{A}(\xi)$ and $\hat{b}(\xi) = (\frac{1-e^{i\xi}}{2})^{\tilde{m}} \hat{B}(\xi)$, where A and B are sequences on $\mathbb{Z}$ with polynomial decay satisfying $\hat{A}(0) = 1$ and $\hat{B}(\pi) \neq 0$.*

(ii) *The function $\hat{d}(\xi) := \hat{a}(\xi)\hat{b}(\xi+\pi) - \hat{a}(\xi+\pi)\hat{b}(\xi)$ does not vanish for all $\xi \in \mathbb{R}$.*

Let

$$\begin{aligned} &\hat{\tilde{a}}(\xi) := \left(\frac{1+e^{-i\xi}}{2}\right)^{\tilde{m}} \hat{\tilde{A}}(\xi), \quad \textit{where} \quad \hat{\tilde{A}}(\xi) := \frac{\overline{\hat{B}(\xi+\pi)}}{\overline{\hat{d}(\xi)}}, \quad \textit{and} \\ &\hat{\tilde{b}}(\xi) := -\frac{\overline{\hat{a}(\xi+\pi)}}{\overline{\hat{d}(\xi)}}. \end{aligned} \tag{3.4}$$

Define

$$\begin{aligned} &\hat{\phi}(\xi) := \prod_{j=1}^{\infty} \hat{a}(2^{-j}\xi) \quad \textit{and} \quad \hat{\tilde{\phi}}(\xi) := \prod_{j=1}^{\infty} \hat{\tilde{a}}(2^{-j}\xi), \\ &\hat{\psi}(\xi) := \hat{b}(\xi/2)\hat{\phi}(\xi/2) \quad \textit{and} \quad \hat{\tilde{\psi}}(\xi) := \hat{\tilde{b}}(\xi/2)\hat{\tilde{\phi}}(\xi/2). \end{aligned}$$

Assume that

$$\limsup_{n\to\infty} \|A_n\|^{1/n}_{\ell_2(\mathbb{Z})} < 2^{m-1/2} \quad \textit{and} \quad \limsup_{n\to\infty} \|\tilde{A}_n\|^{1/n}_{\ell_2(\mathbb{Z})} < 2^{\tilde{m}-1/2}, \tag{3.5}$$

where

$$\widehat{A_n}(\xi) := \hat{A}(2^{n-1}\xi)\cdots\hat{A}(2\xi)\hat{A}(\xi) \quad \textit{and} \quad \widehat{\tilde{A}_n}(\xi) := \hat{\tilde{A}}(2^{n-1}\xi)\cdots\hat{\tilde{A}}(2\xi)\hat{\tilde{A}}(\xi). \tag{3.6}$$

Then all the functions $\phi, \tilde{\phi}, \psi, \tilde{\psi}$ belong to $L_2(\mathbb{R})$ satisfying

$$\begin{aligned} &\langle \phi, \tilde{\phi}(\cdot-k)\rangle = \langle \psi, \tilde{\psi}(\cdot-k)\rangle = \delta(k), \\ &\langle \phi, \tilde{\psi}(\cdot-k)\rangle = \langle \psi, \tilde{\phi}(\cdot-k)\rangle = 0 \qquad \forall\, k \in \mathbb{Z}. \end{aligned} \tag{3.7}$$

If we further assume that

(iii) $[\hat{\phi}, \hat{\phi}] \in L_\infty(\mathbb{R})$ *and* $[\hat{\tilde{\phi}}, \hat{\tilde{\phi}}] \in L_\infty(\mathbb{R})$,

(iv) $X(\psi)$ *and* $X(\tilde{\psi})$ *are Bessel in* $L_2(\mathbb{R})$,

then $(X(\psi), X(\tilde{\psi}))$ *forms a pair of biorthogonal wavelet bases in* $L_2(\mathbb{R})$. *In particular,* $X(\psi)$ *is a Riesz basis of* $L_2(\mathbb{R})$.

Proof. The essential part of the proof is to show that the corresponding cascade algorithms to obtain ϕ and $\tilde{\phi}$ as defined below converge in $L_2(\mathbb{R})$. We shall use some ideas here from the proof of [10, Theorem 4.3], which deals with convergence of vector cascade algorithms in Sobolev spaces. We use the compactly supported orthonormal refinable function η that has a support $[0, 2\max(m, \tilde{m}) + 1]$ (see [7]) satisfying

$$\hat{\eta}(0) = 1,\ \hat{\eta}^{(j)}(2\pi k) = 0 \quad \forall\, k \in \mathbb{Z}\backslash\{0\} \quad \text{and} \quad j = 0, \dots, \max(m, \tilde{m}) \tag{3.8}$$

to obtain the initial seed in the cascade algorithm. Since η and its shifts form an orthonormal system, $[\hat{\eta}, \hat{\eta}] = 1$, it can be easily verified that $(\hat{\eta}\overline{\hat{\eta}})^{(j)}(0) = \delta(j)$ for all $j = 0, \dots, 2\max(m, \tilde{m})$. Since $\hat{\tilde{a}}(0) = \hat{\eta}(0) = 1$, by [10, Lemmas 2.2 and 3.4], there exists a finitely supported sequence c on $\mathbb{Z}$ such that

$$\hat{c}(0) = 1, \qquad 2^{-j}(\hat{\tilde{a}}\hat{c}\hat{\eta})^{(j)}(0) = (\hat{c}\hat{\eta})^{(j)}(0) \qquad \forall\, j = 0, \dots, \max(m, \tilde{m}) \tag{3.9}$$

and $\hat{c}(\xi) \neq 0$ for all $\xi \in \mathbb{R}$. In fact, as shown in [10, Lemmas 2.2 and 3.4], the values $\hat{c}^{(j)}(0), j = 1, \dots, \max(m, \tilde{m})$ are uniquely determined by the system of linear equations given in (3.9).

Now, pick the initial seeds ϕ_0 and $\tilde{\phi}_0$ by $\widehat{\phi_0}(\xi) := \hat{\eta}(\xi)/\overline{\hat{c}(\xi)}$ and $\widehat{\tilde{\phi}_0}(\xi) := \hat{c}(\xi)\hat{\eta}(\xi)$. Since the sequence c is finitely supported and $\hat{c}(\xi) \neq 0$ for all $\xi \in \mathbb{R}$, we see that $\phi_0, \tilde{\phi}_0 \in L_2(\mathbb{R})$ have exponential decay. Moreover, it is easy to check that $[\widehat{\phi_0}, \widehat{\tilde{\phi}_0}] = [\hat{\eta}/\bar{\hat{c}}, \hat{\eta}\hat{c}] = [\hat{\eta}, \hat{\eta}] = 1$. The corresponding cascade operators Q_a and $Q_{\tilde{a}}$ defined by a and $\tilde{a}$ are

$$Q_a f := 2\sum_{k\in\mathbb{Z}} a(k) f(2\cdot - k) \quad \text{and} \quad Q_{\tilde{a}} f := 2\sum_{k\in\mathbb{Z}} \tilde{a}(k) f(2\cdot - k), \qquad f \in L_2(\mathbb{R}). \tag{3.10}$$

Let $g := Q_a\phi_0 - \phi_0$ and $\tilde{g} = Q_{\tilde{a}}\tilde{\phi}_0 - \tilde{\phi}_0$. Then

$$\hat{g}(\xi) = \hat{a}(\xi/2)\widehat{\phi_0}(\xi/2) - \widehat{\phi_0}(\xi) = \hat{a}(\xi/2)\hat{\eta}(\xi/2)/\overline{\hat{c}(\xi/2)} - \hat{\eta}(\xi)/\overline{\hat{c}(\xi)} \tag{3.11}$$

and

$$\hat{\tilde{g}}(\xi) = \hat{\tilde{a}}(\xi/2)\widehat{\tilde{\phi}_0}(\xi/2) - \widehat{\tilde{\phi}_0}(\xi) = \hat{\tilde{a}}(\xi/2)\hat{c}(\xi/2)\hat{\eta}(\xi/2) - \hat{c}(\xi)\hat{\eta}(\xi). \tag{3.12}$$

Since a and $\tilde{a}$ have polynomial decay, by the fact that the function η is compactly supported, it follows from (3.11) and (3.12) that both g and $\tilde{g}$ have polynomial decay.

Next, we prove that

$$\hat{g}^{(j)}(2\pi k) = 0 \quad \forall\, j = 0, \dots, m-1 \quad \text{and} \quad k \in \mathbb{Z} \tag{3.13}$$

and

$$\hat{\tilde{g}}^{(j)}(2\pi k) = 0 \quad \forall\, j = 0, \dots, \tilde{m}-1 \quad \text{and} \quad k \in \mathbb{Z}. \tag{3.14}$$

First, when $k \in 2\mathbb{Z}\backslash\{0\}$, applying (3.8), we obtain $\hat{g}^{(j)}(2\pi k) = \hat{\tilde{g}}^{(j)}(2\pi k) = 0$ for all $j = 0, \ldots, \max(m, \tilde{m})$. Second, when $k \in 2\mathbb{Z}+1$, since $\hat{a}(\xi) = 2^{-m}(1+e^{-i\xi})^m \hat{A}(\xi)$ and $\hat{\tilde{a}}(\xi) = 2^{-\tilde{m}}(1+e^{-i\xi})^{\tilde{m}} \hat{\tilde{A}}(\xi)$, it is easy to see that $\hat{g}^{(j)}(2\pi k) = 0$ for all $j = 0, \ldots, m-1$ and $\hat{\tilde{g}}^{(j)}(2\pi k) = 0$ for all $j = 0, \ldots, \tilde{m} - 1$.

Hence, in order to prove (3.13) and (3.14), it suffices to prove the case $k = 0$. For (3.14), applying (3.9), one obtains that

$$\begin{aligned} \hat{\tilde{g}}^{(j)}(0) &= [\hat{\tilde{a}}(\cdot/2)\hat{c}(\cdot/2)\hat{\eta}(\cdot/2) - \hat{c}\hat{\eta}]^{(j)}(0) \\ &= 2^{-j}[\hat{\tilde{a}}\hat{c}\hat{\eta}]^{(j)}(0) - [\hat{c}\hat{\eta}]^{(j)}(0) = 0 \qquad \forall\, j = 0, \ldots, \max(m, \tilde{m}). \end{aligned} \tag{3.15}$$

This gives (3.14).

Next, we prove (3.13). It follows from the definition of $\tilde{a}$ that

$$\overline{\hat{a}(\xi)}\hat{\tilde{a}}(\xi) + \overline{\hat{a}(\xi+\pi)}\hat{\tilde{a}}(\xi+\pi) = 1.$$

This, together with

$$\hat{a}(\xi) = 2^{-m}(1+e^{-i\xi})^m \hat{A}(\xi), \quad \text{and} \quad \hat{\tilde{a}}(\xi) = 2^{-\tilde{m}}(1+e^{-i\xi})^{\tilde{m}} \hat{\tilde{A}}(\xi),$$

leads to

$$\overline{\hat{a}(\xi)}\hat{\tilde{a}}(\xi) = 1 + O(|\xi|^{m+\tilde{m}-1}) \quad \text{as} \quad \xi \to 0$$

and

$$\hat{a}(\xi) = (\overline{\hat{\tilde{a}}(\xi)})^{-1} + O(|\xi|^{m+\tilde{m}-1}).$$

Hence, as $\xi \to 0$,

$$\begin{aligned} \hat{g}(\xi) &= \hat{a}(\xi/2)\hat{\eta}(\xi/2)/\overline{\hat{c}(\xi/2)} - \hat{\eta}(\xi)/\overline{\hat{c}(\xi)} \\ &= \hat{\eta}(\xi/2)\overline{\hat{\eta}(\xi/2)}\,(\overline{\hat{\tilde{a}}(\xi/2)\hat{\eta}(\xi/2)\hat{c}(\xi/2)})^{-1} - \hat{\eta}(\xi)\overline{\hat{\eta}(\xi)}\,(\overline{\hat{c}(\xi)\hat{\eta}(\xi)})^{-1} + O(|\xi|^{m+\tilde{m}-1}) \\ &= (\overline{\hat{\tilde{a}}(\xi/2)\hat{\eta}(\xi/2)\hat{c}(\xi/2)})^{-1} - (\overline{\hat{c}(\xi)\hat{\eta}(\xi)})^{-1} + O(|\xi|^{\max(m,\tilde{m})}) \\ &= (\overline{\hat{\tilde{a}}(\xi/2)\hat{\eta}(\xi/2)\hat{c}(\xi/2)})^{-1}(\overline{\hat{c}(\xi)\hat{\eta}(\xi)})^{-1}\overline{\Big[\hat{c}(\xi)\hat{\eta}(\xi) - \hat{\tilde{a}}(\xi/2)\hat{c}(\xi/2)\hat{\eta}(\xi/2)\Big]} \\ &\qquad + O(|\xi|^{\max(m,\tilde{m})}) \\ &= (\overline{\hat{\tilde{a}}(\xi/2)\hat{\eta}(\xi/2)\hat{c}(\xi/2)})^{-1}(\overline{\hat{c}(\xi)\hat{\eta}(\xi)})^{-1}\overline{\hat{\tilde{g}}(\xi)} + O(|\xi|^{\max(m,\tilde{m})}) \\ &= O(|\xi|^{\max(m,\tilde{m})}). \end{aligned}$$

The third equality follows from $|\hat{\eta}(\xi)|^2 = 1 + O(|\xi|^{\max(m,\tilde{m})})$, and the last equality holds by (3.15). Therefore, (3.13) holds.

With (3.13) and (3.14), Lemma 3.1 says that there exist two functions $h, \tilde{h} \in L_2(\mathbb{R})$ with polynomial decay such that $g = \nabla^m h$ and $\tilde{g} = \nabla^{\tilde{m}} \tilde{h}$.

Let $f_n := Q_a^n \phi_0$ and $\tilde{f}_n := Q_{\tilde{a}}^n \tilde{\phi}_0$. Then their Fourier transforms are

$$\widehat{f_n}(\xi) = \widehat{\phi_0}(2^{-n}\xi) \prod_{j=1}^{n} \hat{a}(2^{-j}\xi) \quad \text{and} \quad \widehat{\tilde{f}_n}(\xi) = \widehat{\tilde{\phi}_0}(2^{-n}\xi) \prod_{j=1}^{n} \hat{\tilde{a}}(2^{-j}\xi).$$

One can prove inductively that

(3.16)
$$f_{n+1} - f_n = Q_a^n g = 2^n \sum_{k\in\mathbb{Z}} a_n(k)[\nabla^m h](2^n\cdot - k) = 2^n \sum_{k\in\mathbb{Z}} [\nabla^m a_n](k) h(2^n\cdot - k)$$

and

(3.17)
$$\tilde{f}_{n+1} - \tilde{f}_n = Q_{\tilde{a}}^n \tilde{g} = 2^n \sum_{k\in\mathbb{Z}} \tilde{a}_n(k)[\nabla^{\tilde{m}} \tilde{h}](2^n\cdot - k) = 2^n \sum_{k\in\mathbb{Z}} [\nabla^{\tilde{m}} \tilde{a}_n](k) \tilde{h}(2^n\cdot - k),$$

where $\widehat{a_n}(\xi) := \hat{a}(2^{n-1}\xi)\cdots\hat{a}(2\xi)\hat{a}(\xi)$ and $\widehat{\tilde{a}_n}(\xi) := \hat{\tilde{a}}(2^{n-1}\xi)\cdots\hat{\tilde{a}}(2\xi)\hat{\tilde{a}}(\xi)$.

Since both h and $\tilde{h}$ are $L_2(\mathbb{R})$ functions with polynomial decay, we conclude that both $[\hat{h}, \hat{h}]$ and $[\hat{\tilde{h}}, \hat{\tilde{h}}]$ are in $L_\infty(\mathbb{R})$. Hence, identities (3.16) and (3.17) imply that there exists a positive constant C such that, for all $n \in \mathbb{N}$,

$$\begin{aligned} &\|f_{n+1} - f_n\|_{L_2(\mathbb{R})} \leqslant C 2^{n/2} \|\nabla^m a_n\|_{\ell_2(\mathbb{Z})} \quad \text{and} \\ &\|\tilde{f}_{n+1} - \tilde{f}_n\|_{L_2(\mathbb{R})} \leqslant C 2^{n/2} \|\nabla^{\tilde{m}} \tilde{a}_n\|_{\ell_2(\mathbb{Z})}. \end{aligned} \tag{3.18}$$

Since

$$\widehat{\nabla^m a_n}(\xi) = (1 - e^{-i\xi})^m \widehat{a_n}(\xi) = 2^{-mn}(1 - e^{-i2^n\xi})^m \widehat{A_n}(\xi)$$

and

$$\widehat{\nabla^{\tilde{m}} \tilde{a}_n}(\xi) = (1 - e^{-i\xi})^{\tilde{m}} \widehat{\tilde{a}_n}(\xi) = 2^{-\tilde{m}n}(1 - e^{-i2^n\xi})^{\tilde{m}} \widehat{\tilde{A}_n}(\xi),$$

we have

$$\|\nabla^m a_n\|_{\ell_2(\mathbb{Z})} \leqslant 2^{m-mn} \|A_n\|_{\ell_2(\mathbb{Z})}, \quad \text{and} \quad \|\nabla^{\tilde{m}} \tilde{a}_n\|_{\ell_2(\mathbb{Z})} \leqslant 2^{\tilde{m}-\tilde{m}n} \|\tilde{A}_n\|_{\ell_2(\mathbb{Z})}.$$

However, (3.5) says that there exist two positive constants ρ with $0 < \rho < 1$ and C_1 such that

$$\|A_n\|_{\ell_2(\mathbb{Z})} \leqslant C_1 \rho^n 2^{(m-1/2)n} \quad \text{and} \quad \|\tilde{A}_n\|_{\ell_2(\mathbb{Z})} \leqslant C_1 \rho^n 2^{(\tilde{m}-1/2)n} \qquad \forall\, n \in \mathbb{N}. \tag{3.19}$$

Therefore, we deduce from (3.18) that

$$\|f_{n+1} - f_n\|_{L_2(\mathbb{R})} \leqslant 2^m C C_1 \rho^n \quad \text{and} \quad \|\tilde{f}_{n+1} - \tilde{f}_n\|_{L_2(\mathbb{R})} \leqslant 2^{\tilde{m}} C C_1 \rho^n \qquad \forall\, n \in \mathbb{N}.$$

Since $0 < \rho < 1$, both $\{f_n\}_{n\in\mathbb{N}}$ and $\{\tilde{f}_n\}_{n\in\mathbb{N}}$ are Cauchy sequences in $L_2(\mathbb{R})$.

Since $\hat{a}(0) = 1$ and $\hat{b}(\pi) \neq 0$, we have $\hat{\tilde{a}}(0) = 1$. Hence, $\lim_{n\to\infty} \widehat{f_n}(\xi) = \hat{\phi}(\xi)$ and $\lim_{n\to\infty} \widehat{\tilde{f}_n}(\xi) = \hat{\tilde{\phi}}(\xi)$ for $\xi \in \mathbb{R}$. This leads to $\lim_{n\to\infty} \|f_n - \phi\|_{L_2(\mathbb{R})} = 0$ and $\lim_{n\to\infty} \|\tilde{f}_n - \tilde{\phi}\|_{L_2(\mathbb{R})} = 0$, since both $\{f_n\}_{n\in\mathbb{N}}$ and $\{\tilde{f}_n\}_{n\in\mathbb{N}}$ are Cauchy sequences in $L_2(\mathbb{R})$.

Next, we prove that $[\hat{\phi}, \hat{\tilde{\phi}}] = 1$. It is clear that $[\widehat{f_0}, \widehat{\tilde{f}_0}] = [\widehat{\phi_0}, \widehat{\tilde{\phi}_0}] = 1$. Using $\overline{\hat{a}(\xi)}\hat{\tilde{a}}(\xi) + \overline{\hat{a}(\xi+\pi)}\hat{\tilde{a}}(\xi+\pi) = 1$, one can prove inductively that $[\widehat{f_n}, \widehat{\tilde{f}_n}] = 1$ for all $n \in \mathbb{N}$. Finally, since $\lim_{n\to\infty} \|f_n - \phi\|_{L_2(\mathbb{R})} = 0$ and $\lim_{n\to\infty} \|\tilde{f}_n - \tilde{\phi}\|_{L_2(\mathbb{R})} = 0$, we must have $[\hat{\phi}, \hat{\tilde{\phi}}] = 1$. Therefore, $(\phi, \tilde{\phi})$ is a pair of refinable functions whose shifts form a pair of biorthogonal systems.

We further note that by the definition of $\tilde{a}$ and $\tilde{b}$, it is easy to verify that

$$\begin{bmatrix} \hat{a}(\xi) & \hat{a}(\xi+\pi) \\ \hat{b}(\xi) & \hat{b}(\xi+\pi) \end{bmatrix} \overline{\begin{bmatrix} \hat{\tilde{a}}(\xi) & \hat{\tilde{a}}(\xi+\pi) \\ \hat{\tilde{b}}(\xi) & \hat{\tilde{b}}(\xi+\pi) \end{bmatrix}}^T = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}. \tag{3.20}$$

With all these relations, (3.7) and the rest of the conclusions of this theorem follow directly from a standard argument in wavelet analysis on biorthogonal wavelets (see [5, 7, 21]. □

In the above proof, the assumption that both the sequences A and B have polynomial decay is used only to apply Lemma 3.1 and to show that $[\hat{h}, \hat{h}] \in L_\infty(\mathbb{R})$ and $[\hat{\tilde{h}}, \hat{\tilde{h}}] \in L_\infty(\mathbb{R})$. Checking the proof of Lemma 3.1, we see that such polynomial decay condition on both A and B can be further weakened.

As a direct consequence of Theorem 3.2, we have the following result.

COROLLARY 3.3. *Let sequences a and b be given in Theorem* 3.2*, and sequences $\tilde{a}, \tilde{b}, A$, and $\tilde{A}$ and functions $\phi, \tilde{\phi}, \psi, \tilde{\psi}$ be defined as in Theorem* 3.2*. Define*

$$\rho_A := \inf_{n\in\mathbb{N}} \|\widehat{A_n}\|^{1/n}_{L_\infty(\mathbb{R})} \quad \text{and} \quad \rho_{\tilde{A}} := \inf_{n\in\mathbb{N}} \|\widehat{\tilde{A}_n}\|^{1/n}_{L_\infty(\mathbb{R})}, \tag{3.21}$$

where A_n and $\tilde{A}_n$ are defined in (3.6)*. Then for any $\varepsilon > 0$, there exists a positive constant C such that*

$$\max(|\hat{\phi}(\xi)|, |\hat{\psi}(\xi)|) \leqslant C(1+|\xi|)^{-m+\varepsilon+\log_2 \rho_A} \qquad \forall\, \xi \in \mathbb{R} \tag{3.22}$$

and

$$\max(|\hat{\tilde{\phi}}(\xi)|, |\hat{\tilde{\psi}}(\xi)|) \leqslant C(1+|\xi|)^{-\tilde{m}+\varepsilon+\log_2 \rho_{\tilde{A}}} \qquad \forall\, \xi \in \mathbb{R}. \tag{3.23}$$

Consequently, if $\rho_A < 2^{m-1/2}$ and $\rho_{\tilde{A}} < 2^{\tilde{m}-1/2}$, then $(X(\psi), X(\tilde{\psi}))$ forms a pair of biorthogonal wavelet bases in $L_2(\mathbb{R})$. In particular, $X(\psi)$ is a Riesz basis of $L_2(\mathbb{R})$.

Proof. The proof of (3.22) and (3.23) follows from the proof of [7, Lemmas 7.1.1 and 7.1.2]. Note that

$$\limsup_{n\to\infty} \|A_n\|^{1/n}_{\ell_2(\mathbb{Z})} \leqslant \limsup_{n\to\infty} \|\widehat{A_n}\|^{1/n}_{L_\infty(\mathbb{R})} = \inf_{n\in\mathbb{N}} \|\widehat{A_n}\|^{1/n}_{L_\infty(\mathbb{R})}$$

by $\|A_n\|_{\ell_2(\mathbb{Z})} \leqslant \|\widehat{A_n}\|_{L_\infty(\mathbb{R})}$. Therefore, if $\rho_A < 2^{m-1/2}$ and $\rho_{\tilde{A}} < 2^{\tilde{m}-1/2}$, then it follows from (3.22) and (3.23) that there exist $\varepsilon > 0$ and $C > 0$ such that

$$\max(|\hat{\phi}(\xi)|, |\hat{\psi}(\xi)|, |\hat{\tilde{\phi}}(\xi)|, |\hat{\tilde{\psi}}(\xi)|) \leqslant C(1+|\xi|)^{-1/2-\varepsilon}$$

and $\max(|\hat{\psi}(\xi)|, |\hat{\tilde{\psi}}(\xi)|) \leqslant C|\xi|^\varepsilon$ for all $\xi \in \mathbb{R}$. Therefore, by [11, Propositions 2.6 and 3.5], both $X(\psi)$ and $X(\tilde{\psi})$ are Bessel. Moreover, it is evident that $[\hat{\phi}, \hat{\phi}] \in L_\infty(\mathbb{R})$ and $[\hat{\tilde{\phi}}, \hat{\tilde{\phi}}] \in L_\infty(\mathbb{R})$. The proof is completed by Theorem 3.2. □

For a refinement mask a, define b as

$$\hat{b}(\xi) = e^{-i\xi}\overline{\hat{a}(\xi+\pi)}.$$

Then

$$\hat{d}(\xi) := \hat{a}(\xi)\hat{b}(\xi+\pi) - \hat{a}(\xi+\pi)\hat{b}(\xi) = e^{-i(\xi+\pi)}(|\hat{a}(\xi)|^2 + |\hat{a}(\xi+\pi)|^2). \tag{3.24}$$

Further, the masks $\tilde{a}$ and $\tilde{b}$ defined in (3.4) take the following form:

$$\hat{\tilde{a}}(\xi) = \frac{\hat{a}(\xi)}{|\hat{a}(\xi)|^2 + |\hat{a}(\xi+\pi)|^2} \quad \text{and} \quad \hat{\tilde{b}}(\xi) = \frac{e^{-i\xi}\overline{\hat{a}(\xi+\pi)}}{|\hat{a}(\xi)|^2 + |\hat{a}(\xi+\pi)|^2}. \tag{3.25}$$

Now, it is clear that Lemma 2.1 becomes a special case of Corollary 3.3. The mask for the B-spline of order m is $\hat{a}(\xi) = 2^{-m}(1+e^{-i\xi})^m$. It follows from (3.24) that $\hat{d}(\xi) = e^{-i(\xi+\pi)}[\cos^{2m}(\xi/2) + \sin^{2m}(\xi/2)] \neq 0$ for all $\xi \in \mathbb{R}$.

The following result is a direct consequence and a slight modification of Theorem 3.2.

COROLLARY 3.4. *Under the same notations and conditions as in Theorem* 3.2, *for any finitely supported sequence* c *on* $\mathbb{Z}$ *such that* $\hat{c}(\xi) \neq 0$ *for all* $\xi \in \mathbb{R}$, *we redefine the functions* ψ *and* $\tilde{\psi}$ *in Theorem* 3.2 *by*

$$\hat{\psi}(\xi) := \hat{c}(\xi)\hat{b}(\xi/2)\hat{\phi}(\xi/2) \quad \textit{and} \quad \hat{\tilde{\psi}}(\xi) := \hat{\tilde{b}}(\xi/2)\hat{\tilde{\phi}}(\xi/2)/\overline{\hat{c}(\xi)}.$$

Then all the claims in Theorem 3.2 *hold.*

Proof. Denote $\hat{b}^{new} := \hat{c}(2\cdot)\hat{b}$ and $\hat{\tilde{b}}^{new} = \hat{\tilde{b}}/\overline{\hat{c}(2\cdot)}$. To apply Theorem 3.2, one observes that

$$\begin{aligned}\hat{d}^{new}(\xi) &:= \hat{a}(\xi)\hat{b}^{new}(\xi+\pi) - \hat{a}(\xi+\pi)\hat{b}^{new}(\xi)\\ &= \hat{c}(2\xi)[\hat{a}(\xi)\hat{b}(\xi+\pi) - \hat{a}(\xi+\pi)\hat{b}(\xi)] \neq 0 \qquad \forall\, \xi \in \mathbb{R}.\end{aligned}$$

It is easy to see that (3.20) holds with $\hat{b}$ and $\hat{\tilde{b}}$ being replaced by $\hat{b}^{new}$ and $\hat{\tilde{b}}^{new}$, respectively. The rest of the proof follows directly from Theorem 3.2. □

Remark. As shown in section 2, Riesz spline wavelets ψ, constructed using Theorem 3.2 and its corollaries, have, in some sense, the shortest support for a given order of smoothness and vanishing moments. However, its dual wavelet systems normally are not compactly supported and have low smoothness orders. Hence, Riesz wavelets constructed here may be used only in applications where either the reconstruction algorithm or the decomposition algorithm is not required. For example, it only needs the decomposition algorithm in some applications of signal analysis and classification. On the other hand, in other applications such as image compression, while the decomposition can be done offline, reconstruction has to be done online. The short supported reconstruction filter is essential, for example, in computer graphics and numerical algorithms. Furthermore, a fast reconstruction algorithm can be derived by adding a system $X(\psi(\cdot - 1/2))$ to $X(\psi)$ to generate a frame system and by using a compactly supported smooth dual wavelet system of the frame system $X(\psi) \cup X(\psi(\cdot - 1/2))$. The detailed discussion is given at the end of the next section.

4. Connections of Riesz wavelets to spline frame systems. The study here on Riesz wavelets also provides a better understanding of the structure of spline tight frame wavelet systems in [20] and [9, 12] by using the *unitary extension principle* of [20] and the *oblique extension principle* of [9] as we shall discuss in this section.

We first briefly describe the constructions of MRA-based tight frames by using the oblique extension principle in [9], where details can be found. For a given refinable function ϕ, with a refinement mask a, one first chooses a 2π-periodic trigonometric polynomial Θ with $\Theta(0) = 1$, called a fundamental function of the tight frame system, according to the approximation order of the refinable function ϕ and the required approximation order of the tight frame expansion (this is directly related to the order

of the vanishing moments of frame wavelets). Suppose that a fundamental function Θ can be chosen so that it satisfies (i) $\Theta(\xi) \geqslant 0$ for all $\xi \in \mathbb{R}$, and (ii)

$$H(\xi) := \Theta(\xi) - \Theta(2\xi)[|\hat{a}(\xi)|^2 + |\hat{a}(\xi+\pi)|^2] \geqslant 0 \qquad \forall\, \xi \in \mathbb{R}. \tag{4.1}$$

The three wavelet masks are then

$$\widehat{b^1}(\xi) := e^{i\xi}\theta(2\xi)\overline{\hat{a}(\xi+\pi)}, \qquad \widehat{b^2}(\xi) := \frac{\sqrt{2}}{2}h(\xi), \quad \text{and} \quad \widehat{b^3}(\xi) := \frac{\sqrt{2}}{2}e^{i\xi}h(\xi),$$

where θ and h are the square roots of Θ and H, respectively; that is, $\theta(\xi)\overline{\theta(\xi)} = \Theta(\xi)$ and $h(\xi)\overline{h(\xi)} = H(\xi)$.

Define the frame wavelet set $\Psi := \{\psi^1, \psi^2, \psi^3\}$ by

$$\widehat{\psi^\ell}(\xi) := \widehat{b^\ell}(\xi/2)\hat{\phi}(\xi/2), \qquad \ell = 1, 2, 3. \tag{4.2}$$

Then it was proven in [9] that the system $X(\Psi)$ forms a tight frame system of $L_2(\mathbb{R})$ by using the oblique extension principle (see [9, Proposition 1.11]).

One can reduce the number of frame wavelets to two by defining

$$\widehat{b^1}(\xi) := e^{i\xi}\theta(2\xi)\overline{\hat{a}(\xi+\pi)}, \quad \widehat{b^2}(\xi) := \hat{a}(\xi)\, h(2\xi).$$

Then it was proven in [9] that the $X(\Psi)$ with $\Psi := \{\psi^1, \psi^2\}$ defined by

$$\widehat{\psi^\ell}(\xi) = \widehat{b^\ell}(\xi/2)\hat{\phi}(\xi/2), \qquad \ell = 1, 2 \tag{4.3}$$

is again a tight frame wavelet system in $L_2(\mathbb{R})$. Note that ψ^1 in (4.2) is the same function as ψ^1 in (4.3).

The construction of spline tight frame systems given in [9] starts with the MRA generated by a B-spline B_m with refinement mask $\hat{a}(\xi) = 2^{-m}(1 + e^{-i\xi})^m$. The fundamental function Θ can be chosen according to the needs of the approximation order of the truncated wavelet system; it satisfies $\Theta(\xi) > 0$ for all $\xi \in \mathbb{R}$, and (4.1). An explicit form of Θ is given in [9, Lemma 3.4]. With Θ, $\hat{a}$, and H, it is easy to obtain the functions defined in (4.2) and (4.3), whose corresponding wavelet systems form spline tight frame systems of $L_2(\mathbb{R})$. In this case, setting $\hat{c}(\xi) = e^{i\xi}\theta(\xi)$ in Corollary 3.4 and applying Theorem 2.2, one can show easily that $X(\psi^1)$ is a Riesz basis for $L_2(\mathbb{R})$, where ψ^1 is defined in either (4.2) or (4.3).

In both spline function sets defined in (4.2) and (4.3), the first function ψ^1 is already able to generate a Riesz basis of $L_2(\mathbb{R})$, i.e., $X(\psi^1)$ is a Riesz basis of $L_2(\mathbb{R})$, which is an even stronger statement than that $X(\psi^1)$ is a frame of $L_2(\mathbb{R})$. The first role of $X(\psi^2)$ and $X(\psi^3)$ in (4.2) and $X(\psi^2)$ in (4.3) is to reduce the condition number determined by the upper and lower frame bounds of $X(\Psi)$ to be one, so that the whole system $X(\Psi)$ becomes a tight frame. The second role of other functions in both (4.2) and (4.3) is to give better dual systems. As we remarked before, the (unique) function corresponding to the biorthogonal dual of the system $X(\psi^1)$ normally has low order of smoothness with infinite support. With the help of ψ^2 and ψ^3 in system (4.2) and ψ^2 in the system (4.3), the whole system $X(\Psi)$ in both cases becomes a tight frame that is a self-dual system. All these are obtained at the cost of changing a nonredundant system $X(\psi^1)$ to a redundant system $X(\Psi)$.

We further note that since the wavelet mask b^2 in (4.3) vanishes at both 0 and π, therefore $[\widehat{\psi^2}, \widehat{\psi^2}](0) = 0$. Since ψ^2 in (4.3) is compactly supported, ψ^2 and its shifts cannot form a Riesz system. This concludes that $X(\psi^2)$ is not a Riesz basis of $L_2(\mathbb{R})$.

The spline tight frame systems constructed above may not be symmetric since the square root of Θ may not be symmetric. This weak point was overcome in [12] by an elegant and careful choice of a symmetric θ such that $\theta^2 = \Theta$ is the required fundamental function satisfying (4.1). Let h be a square root of H and set

$$\begin{aligned}\widehat{b^1}(\xi) &:= e^{-i\xi}\theta(2\xi)\overline{\hat{a}(\xi+\pi)},\\ \widehat{b^2}(\xi) &:= \hat{a}(\xi)[h(2\xi) + \overline{h(2\xi)}]/2,\\ \widehat{b^3}(\xi) &:= \hat{a}(\xi)[h(2\xi) - \overline{h(2\xi)}]/2.\end{aligned}$$

Define

$$\widehat{\psi^\ell}(\xi) := \widehat{b^\ell}(\xi/2)\hat{\phi}(\xi/2), \qquad \ell = 1, 2, 3. \tag{4.4}$$

Then $X(\Psi)$ with $\Psi := \{\psi^1, \psi^2, \psi^3\}$ being defined in (4.4) forms a tight frame system in $L_2(\mathbb{R})$ and all the functions ψ^1, ψ^2, ψ^3 are either symmetric or antisymmetric (see [12] for details). Similarly, $X(\psi^1)$ is a Riesz basis for $L_2(\mathbb{R})$, but both $X(\psi^2)$ and $X(\psi^3)$ cannot be a Riesz basis of $L_2(\mathbb{R})$.

Next, we discuss the spline wavelet system given in [20] via the unitary extension principle of [20]. We discuss the construction from B-splines with an even order. The other case can be discussed similarly. Let ϕ be the centered B-spline of order $2m$. Then its refinement mask is $\hat{a}(\xi) := \cos^{2m}(\xi/2)$. We define $2m$ wavelet masks by

$$\widehat{b^\ell}(\xi) := i^{2m+\ell}\sqrt{\frac{(2m)!}{\ell!(2m-\ell)!}}\sin^\ell(\xi/2)\cos^{2m-\ell}(\xi/2), \quad \ell = 1, \dots, 2m.$$

Then it was shown in [20] that the $2m$ functions, $\Psi = \{\psi^1, \dots, \psi^{2m}\}$, defined by

$$\widehat{\psi^\ell}(\xi) := \widehat{b^\ell}(\xi/2)\hat{\phi}(\xi/2), \qquad \ell = 1, \dots, 2m, \tag{4.5}$$

form a tight frame system of $L_2(\mathbb{R})$ by using the unitary extension principle ([20, Corollary 6.7]).

Consider the function $\psi := \psi^{2m}(\cdot - 1/2)$. Then ψ is the function derived from an MRA generated by the centered B-spline ϕ with the refinement mask $\hat{a}(\xi) := \cos^{2m}(\xi/2)$. The corresponding wavelet mask of ψ is

$$\hat{b}(\xi) = e^{-i\xi}\sin^{2m}(\xi/2) = e^{-i\xi}\overline{\hat{a}(\xi+\pi)}.$$

Hence, $X(\psi)$ forms a Riesz basis of $L_2(\mathbb{R})$ by Theorem 2.2. Since all the other masks $\widehat{b^\ell}$, $1 \leqslant \ell < 2m$, vanish at both 0 and π, a similar discussion as above shows that $X(\psi^\ell)$, $1 \leqslant \ell < 2m$, cannot be a Riesz basis of $L_2(\mathbb{R})$.

Here are some remarks on the two extension principles mentioned above; the interested reader can find more details in [20, 9, 2]. Both the unitary extension principle of [20] and the oblique extension principle of [9] are derived from the characterization of MRA-based frames given in [20] (also see [11]). The unitary extension principle leads to the first set of the examples of compactly supported spline tight frames defined in (4.5). As pointed out in [9], the approximation order (see [9] for definitions) of the truncated tight frame expansion of $X(\Psi)$, where Ψ is defined in (4.5), cannot be over 2. The attempt to derive spline tight frame systems whose truncated expansions have a better approximation order leads to the oblique extension principle of [9], which is a generalization of the unitary extension principle. This leads to a systematic

construction of spline tight wavelet frame systems whose truncated expansion has an arbitrary preassigned approximation order. Functions defined in (4.2) and (4.3) are examples of constructions given in [9]. In a similar fashion, [2] obtained the oblique extension principle independently by an attempt to improve the vanishing moments of the functions obtained from the unitary extension principle of [20].

In the rest of this section, we discuss some relations between Riesz wavelet bases constructed in this paper and bi-frames constructed in [8, 9]. In order to do so, let us recall a result from [8, Corollary 3.4] (also see [9]). Let ϕ be a compactly supported refinable function in $L_2(\mathbb{R})$ with a finitely supported mask a and $\hat{\phi}(0) \neq 0$. For any finitely supported sequence b on $\mathbb{Z}$ such that

$$\hat{b}(0) = 0 \quad \text{and} \quad \lim_{\xi \to \pi} \frac{\hat{a}(\xi)}{\hat{b}(\xi)} = 0, \tag{4.6}$$

define $\hat{\psi}(2\xi) = \hat{b}(\xi)\hat{\phi}(\xi)$; then $X(\{\psi, \psi(\cdot - 1/2)\})$ forms a wavelet frame in $L_2(\mathbb{R})$. Moreover, there exists $\{\tilde{\psi}^1, \tilde{\psi}^2\}$ of compactly supported functions, which are derived via the mixed oblique extension principle (see [9]) from an MRA generated by an arbitrarily chosen compactly supported refinable function $\tilde{\phi} \in L_2(\mathbb{R})$ whose mask contains the factor $(1 + e^{-i\xi})^\ell$, where ℓ is the smallest integer that is greater than the multiplicity of zeros of $\hat{b}(\xi)$ at $\xi = 0$ such that $(X(\{\psi, \psi(\cdot - 1/2)\}), X(\{\tilde{\psi}^1, \tilde{\psi}^2\}))$ is a pair of bi-frames in $L_2(\mathbb{R})$. Since such a pair of bi-frames is MRA-based and all the wavelet masks are finitely supported, a fast frame transform (see [9]) associated with the bi-frames for both decomposition and reconstruction of functions is available.

Now let us discuss some relations between Riesz wavelet bases and bi-frames. Let $\phi \in L_2(\mathbb{R})$ be a compactly supported refinable function with $\hat{\phi}(0) \neq 0$ and a finitely supported mask a such that $\hat{a}(0) = 1$ and $\hat{a}(\pi) = 0$. Let b be a finitely supported sequence on $\mathbb{Z}$ such that $X(\psi)$ is a Riesz basis for $L_2(\mathbb{R})$, where ψ is defined to be $\hat{\psi}(2\xi) = \hat{b}(\xi)\hat{\phi}(\xi)$. For example, such a wavelet mask b and a function ψ may be chosen as in Theorem 3.2. In particular, when ϕ is a B-spline of order m, the wavelet mask b can be chosen to be

$$e^{-i\xi}\Big(\frac{1 - e^{i\xi}}{2}\Big)^m.$$

Since $X(\psi)$ is a Riesz basis for $L_2(\mathbb{R})$, the compactly supported function ψ must satisfy $\hat{\psi}(0) = 0$ and $[\hat{\psi}, \hat{\psi}](0) \neq 0$. Since $\hat{\phi}(0) \neq 0$ and $\hat{\psi}(0) = 0$, it follows from the definition $\hat{\psi}(\xi) = \hat{b}(\xi/2)\hat{\phi}(\xi/2)$ that $\hat{b}(0) = 0$. On the other hand, we must have $\hat{b}(\pi) \neq 0$ since otherwise $\hat{b}(0) = \hat{b}(\pi) = 0$ implies $[\hat{\psi}, \hat{\psi}](0) = 0$, which is a contradiction. Now by $\hat{a}(\pi) = 0$, it is evident that the wavelet mask b must satisfy the conditions in (4.6). It follows from our discussion above (see [8, Corollary 3.4]) that $X(\{\psi, \psi(\cdot - 1/2)\})$ is a wavelet frame. Note that $X(\{\psi, \psi(\cdot - 1/2)\}) = X(\psi) \cup X(\psi(\cdot - 1/2))$ with $X(\psi)$ being a Riesz basis. Moreover, there exists a set $\{\tilde{\psi}^1, \tilde{\psi}^2\}$ of compactly supported smooth L_2 functions which are derived via the mixed oblique extension principle (see [9]) from an MRA generated by an arbitrarily chosen smooth refinable function such that $(X(\{\psi, \psi(\cdot - 1/2)\}), X(\{\tilde{\psi}^1, \tilde{\psi}^2\}))$ forms a pair of bi-frames. For this MRA based bi-frame pair, one can derive fast decomposition and reconstruction algorithms as given in [9].

On the other hand, since $X(\psi)$ is a Riesz basis, it has a unique Riesz dual basis, say $X(\tilde{\psi})$. But the unique Riesz dual wavelet $\tilde{\psi}$, as indicated by Theorem 3.2, is not compactly supported and has a low order of smoothness. This indicates that $X(\psi)$,

being a Riesz basis, does not imply that the decomposition (analysis) operator must have an inverse in a function space other than the space $L_2(\mathbb{R})$ that is of interest to us in this paper, since its dual wavelet may have lower smoothness. Furthermore, though the decomposition operator may have an inverse in the function space, it may not have a fast reconstruction algorithm due to the slow decay of the dual masks with infinite support. However, the above discussions show that by introducing redundancy into a Riesz wavelet basis $X(\psi)$, one can obtain a compactly supported dual frame system which has the same smoothness (in some case, it can be extended to a tight frame wavelet system). Hence, the frame decomposition operator can be invertible in various function spaces, and a fast decomposition and reconstruction algorithm can be obtained based on the compactly supported dual frame.

The following example illustrates some of the above discussions. The reader is referred to [8, 9] for more details on bi-frames.

Example 4.1. Let B_3 be the B-spline function of order 3. The refinement mask for the refinable function B_3 is $\hat{a}(\xi) = 2^{-3}(1+e^{-i\xi})^3$. Define $\psi = \frac{1}{4}B_3(2\cdot -1) - \frac{3}{4}B_3(2\cdot) + \frac{3}{4}B_3(2\cdot +1) - \frac{1}{4}B_3(2\cdot +2)$, that is, $\hat{\psi}(2\xi) = 2^{-3}e^{-i\xi}(1-e^{i\xi})^3\widehat{B_3}(\xi)$. By Theorem 2.2, $X(\psi)$ is a Riesz basis for $L_2(\mathbb{R})$. The function ψ has 3 vanishing moments and the regularity 5/2. By Theorem 2.2, its unique Riesz dual basis $X(\tilde{\psi})$ must have a noncompactly supported generator $\tilde{\psi}$. However, the frame system $X(\psi)\cup X(\psi(\cdot - 1/2))$ can have a compactly supported smooth dual frame as defined below. We choose $\tilde{\phi} = B_3$. Let $\tilde{b}^1$ and $\tilde{b}^2$ be two finitely supported sequences on $\mathbb{Z}$ given by

$$\widehat{b^1}(\xi) := \frac{(z-1)^3}{1920}\Big[13\,(z^{-6}+z^2) + 78\,(z^{-5}+z) + 356\,(z^{-4}+1) + 1226\,(z^{-3}+z^{-1}) + 2334\,z^{-2}\Big],$$

$$\widehat{b^2}(\xi) := \frac{(z-1)^3}{960}\Big[39\,(z^{-4}+z^2) + 234\,(z^{-3}+z) + 613\,(z^{-2}+1) + 948z^{-1}\Big],$$

where $z := e^{-i\xi}$. Define the dual wavelet functions $\tilde{\psi}^1$ and $\tilde{\psi}^2$ by

$$\widehat{\tilde{\psi}^1}(\xi) = \widehat{\tilde{b}^1}(\xi/2)\widehat{B_3}(\xi/2), \qquad \widehat{\tilde{\psi}^2}(\xi) = \widehat{\tilde{b}^2}(\xi/2)\widehat{B_3}(\xi/2).$$

Then it has been proved in [8, 9] that $(X(\{\psi, \psi(\cdot - 1/2)\}), X(\{\tilde{\psi}^1, \tilde{\psi}^2\}))$ is a pair of bi-frames in $L_2(\mathbb{R})$. Note that both $\tilde{\psi}^1$ and $\tilde{\psi}^2$ are compactly supported and antisymmetric. Moreover, they have the regularity 5/2 and 3 vanishing moments. See Figure 3 for the graphs of all the functions ψ, $\tilde{\psi}^1$ and $\tilde{\psi}^2$.

5. Other examples of Riesz wavelets with short support. In this section, we first show that one can further greatly shorten the support of the Riesz spline wavelets with the same order of smoothness given in section 2 by reducing the order of vanishing moments of the wavelets. The second part gives examples which are derived from interpolatory refinable functions.

THEOREM 5.1. *Let B_m be the B-spline function of order m. For any integer $\tilde{m}$ such that $\tilde{m} \geqslant m\log_6(8/3)$ (note that $\log_6(8/3) \approx 0.5474$) and $\tilde{m}+m$ is an even integer, define $\hat{\psi}(2\xi) := e^{i\xi(m-\tilde{m}-2)/2}(\frac{1-e^{i\xi}}{2})^{\tilde{m}}\widehat{B_m}(\xi)$. Then $X(\psi)$ is a Riesz wavelet basis in $L_2(\mathbb{R})$.*

Proof. We use Corollary 3.3. For this, we first note that the refinement mask of the spline B_m is $\hat{a}(\xi) = (\frac{1+e^{-i\xi}}{2})^m\hat{A}(\xi)$ with $\hat{A}(\xi) = 1$. Let $\hat{b}(\xi) := e^{i\xi(m-\tilde{m}-2)/2}(\frac{1-e^{i\xi}}{2})^{\tilde{m}}$

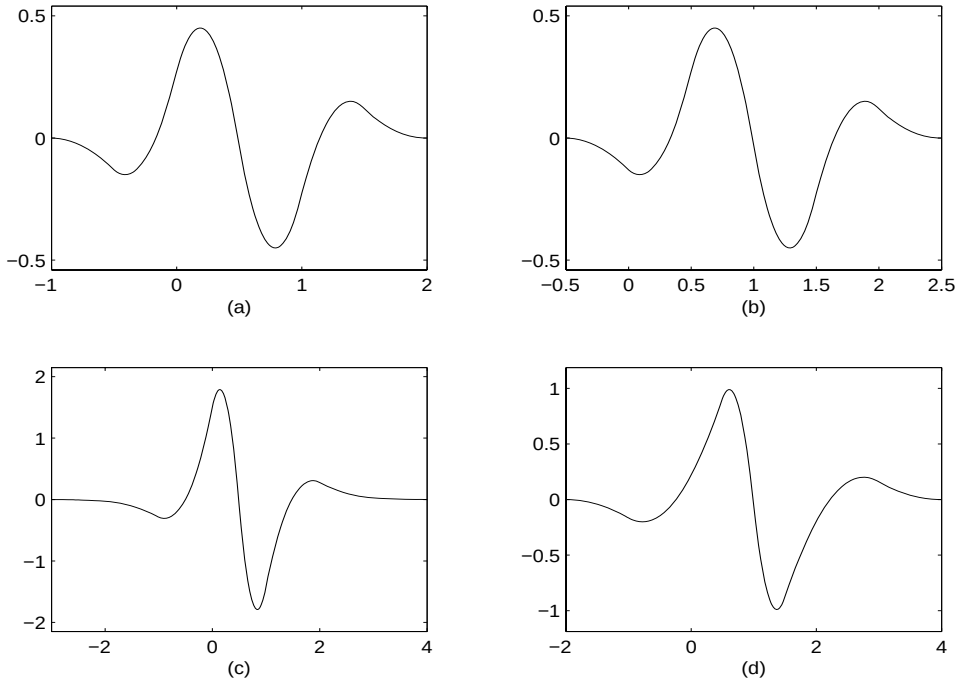

FIG. 3. *The graphs of the functions ψ and $\psi(\cdot - 1/2)$ (top row) and the graphs of the dual functions $\tilde{\psi}^1$ and $\tilde{\psi}^2$ (bottom row) in Example* 4.1. *All the functions ψ, $\psi(\cdot - 1/2)$, $\tilde{\psi}^1$ and $\tilde{\psi}^2$ have* 3 *vanishing moments and the regularity* 5/2. *The system $X(\psi)$ is a Riesz basis for $L_2(\mathbb{R})$ and $(X(\{\psi, \psi(\cdot - 1/2)\}), X(\{\tilde{\psi}^1, \tilde{\psi}^2\}))$ is a pair of bi-frames derived from the B-spline function B_3 of order* 3.

and define $\hat{\psi}(2\xi) = \hat{b}(\xi)\widehat{B_m}(\xi)$. Then

$$\begin{aligned} \hat{d}(\xi) &:= \hat{a}(\xi)\hat{b}(\xi + \pi) - \hat{a}(\xi + \pi)\hat{b}(\xi) \\ &= e^{-i\xi}(-1)^{(m-\tilde{m}-2)/2}[\cos^{m+\tilde{m}}(\xi/2) + \sin^{m+\tilde{m}}(\xi/2)] \neq 0. \end{aligned} \tag{5.1}$$

The mask $\hat{\tilde{a}}$ in Theorem 3.2 is

$$\hat{\tilde{a}}(\xi) = \left(\frac{1 + e^{-i\xi}}{2}\right)^{\tilde{m}} \hat{\tilde{A}}(\xi) \quad \text{with} \quad \hat{\tilde{A}}(\xi) := \frac{e^{-i\xi(m-\tilde{m})/2}}{\cos^{m+\tilde{m}}(\xi/2) + \sin^{m+\tilde{m}}(\xi/2)}.$$

Consider $f_n(x) := x^n + (1-x)^n, 0 \leqslant x \leqslant 1$, and $n \in \mathbb{N}$. Since $f_n'(x) = n[x^{n-1} - (1-x)^{n-1}]$, f_n decreases on $[0, 1/2]$ and increases on $[1/2, 1]$. Therefore, $f_n(x) \geqslant f_n(1/2)$ for all $x \in [0, 1]$.

Since f_n decreases on $[0, 1/4]$, we have

$$f_n((2x-1)^2)f_n(x) \geqslant f_n(1/2)f_n(x) \geqslant f_n(1/2)f_n(1/4) \qquad \forall\, x \in [0, 1/4].$$

On the other hand, since the map $x \mapsto (2x-1)^2$ maps the interval $[1/4, 1/2]$ onto the interval $[0, 1/4]$, we have

$$f_n((2x-1)^2)f_n(x) \geqslant f_n(1/4)f_n(x) \geqslant f_n(1/2)f_n(1/4) \qquad \forall\, x \in [1/4, 1/2].$$

By the symmetry of f_n on $[0,1]$, we conclude that

$$f_n((2x-1)^2)f_n(x) \geqslant f_n(1/2)f_n(1/4) = 2^{1-n}(4^{-n}+3^n4^{-n}) > 2^{1-3n}3^n \qquad \forall\, x\in[0,1], n\in\mathbb{N}.$$

Now, since $m+\tilde{m}$ is an even integer, we observe that for all $\xi\in\mathbb{R}$,

$$|\hat{\tilde{A}}(2\xi)\hat{\tilde{A}}(\xi)| = \left[f_{(m+\tilde{m})/2}((2\cos^2(\xi)-1)^2)f_{(m+\tilde{m})/2}(\cos^2(\xi/2))\right]^{-1} < 2^{3(m+\tilde{m})/2-1}3^{-(m+\tilde{m})/2}.$$

Since $2^{3(m+\tilde{m})/2-1}3^{-(m+\tilde{m})/2} \leqslant 2^{2\tilde{m}-1}$ for all $\tilde{m} \geqslant m\log_6(8/3)$, we conclude that $\rho_{\tilde{A}} < 2^{\tilde{m}-1/2}$ for all $\tilde{m}\geqslant m\log_6(8/3)$. It is clear that $\rho_A = 1 < 2^{m-1/2}$. Hence, $X(\psi)$ is a Riesz basis for $L_2(\mathbb{R})$ by Corollary 3.3. □

The assumption that $m+\tilde{m}$ is an even integer in Theorem 5.1 is used only to guarantee that (5.1) holds. A more refined analysis can be employed in Theorem 5.1 to show that $\rho_{\tilde{A}} \leqslant (4/3)^{(m+\tilde{m})/2}$ by estimating $\hat{\tilde{A}}_3$. Therefore, $\tilde{m} > m\log_3(4/3)+\log_3 2$ is enough and $\log_3(4/3)\approx 0.26186$.

Example 5.2. Let $m=4$ and $\tilde{m}=2$. Define $\hat{b}(\xi) = (1-e^{i\xi})^2/4$ and $\hat{\psi}(2\xi) = \hat{b}(\xi)\widehat{B_4}(\xi)$. Since $m+\tilde{m}=6$ is an even number and $\tilde{m} > m\log_3(4/3)+\log_3 2 \approx 1.6784$, $X(\psi)$ is a Riesz basis for $L_2(\mathbb{R})$. The function ψ has 2 vanishing moments and the regularity 7/2. See Figure 4 for the graphs of the functions B_4 and ψ.

In the following, we consider a continuous refinable function ϕ that satisfies the condition $\phi(k)=\delta(k)$, $k\in\mathbb{Z}$. Such a refinable function is called an *interpolatory refinable function*. Clearly, the centered piecewise linear B-spline B_2 is interpolatory. However, the higher order B-splines are not interpolatory. Smooth interpolatory refinable functions can be obtained by a convolution of a B-spline with a distribution. More precisely, for any positive integer m, the mask a given by

$$\hat{a}(\xi) = \cos^{2m}(\xi/2)P_m(\sin^2(\xi/2)), \tag{5.2}$$

where

$$P_m(x) := \sum_{j=0}^{m-1}\frac{(m-1+j)!}{j!(m-1)!}x^j, \qquad x\in\mathbb{R}, \tag{5.3}$$

defines an interpolatory refinable function ϕ with the refinement mask a in (5.2).

This set of masks for interpolatory refinable functions was provided in [6]. Each of them is the autocorrelation of a refinement mask of some refinable function whose shifts form an orthonormal system. Interpolatory masks were constructed first, then the masks of the compactly supported orthonormal refinable functions were obtained as a square root of $\hat{a}$ in [6]. More details about this construction can be found in [6, 7].

THEOREM 5.3. *Let m be a positive integer. Let ϕ be the interpolatory refinable function with the mask a defined in* (5.2). *Define $\hat{\psi}(2\xi) = e^{-i\xi}\overline{\hat{a}(\xi+\pi)}\hat{\phi}(\xi)$. Then $X(\psi)$ is a Riesz basis in $L_2(\mathbb{R})$.*

Proof. To apply Lemma 2.1, we first note that

$$\hat{a}(\xi) = 2^{-2m}(1+e^{-i\xi})^{2m}\hat{A}(\xi) \quad \text{with} \quad \hat{A}(\xi) := e^{im\xi}P_m(\sin^2(\xi/2)),$$

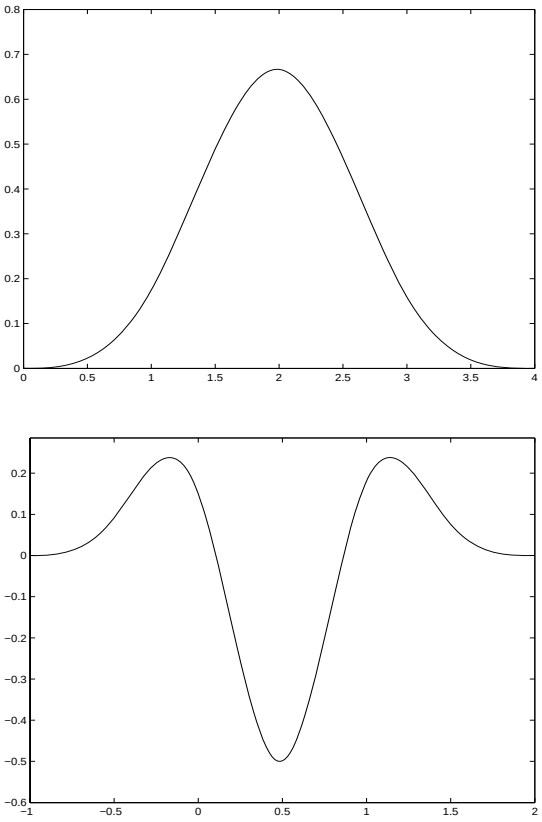

FIG. 4. *The graph of the spline B_4 (top) and the graph of the function ψ (bottom) in Example* 5.2. *The function ψ has* 2 *vanishing moments and the regularity* 7/2. *The system $X(\psi)$ is a Riesz basis for $L_2(\mathbb{R})$.*

and

$$\hat{\tilde{A}}(\xi) = \frac{\hat{A}(\xi)}{|\hat{a}(\xi)|^2 + |\hat{a}(\xi+\pi)|^2}.$$

Then [7, Lemmas 7.1.7 and 7.1.8] say that $\rho_A \leqslant P_m(3/4) \leqslant 3^{m-1}$ for all $m \in \mathbb{N}$ (see [7, p. 226]). Therefore, $\rho_A \leqslant 3^{m-1} < 2^{2m-1/2}$ for all $m \in \mathbb{N}$.

Since the mask of any interpolatory refinable function must satisfy

$$\hat{a}(\xi) + \hat{a}(\xi+\pi) = 1, \qquad \xi \in \mathbb{R},$$

we have $|\hat{a}(\xi)|^2 + |\hat{a}(\xi+\pi)|^2 \geqslant 1/2$ for all $\xi \in \mathbb{R}$. Thus, $|\hat{\tilde{A}}| \leqslant 2|\hat{A}|$. This leads to

$$\rho_{\tilde{A}} \leqslant 2\rho_A \leqslant 2 \times 3^{m-1} < 2^{2m-1/2} \qquad \forall\, m \in \mathbb{N}.$$

Hence, $X(\psi)$ is a Riesz basis for $L_2(\mathbb{R})$ by Lemma 2.1. □

Example 5.4. Let ϕ be the interpolatory refinable function with the mask $\hat{a}(\xi) = \frac{1}{2} + \frac{9}{16}\cos(\xi) - \frac{1}{16}\cos(3\xi)$, that is, the mask a is given in (5.2) with $m = 2$. Define $\hat{b}(\xi) = e^{-i\xi}\overline{\hat{a}(\xi+\pi)}$ and $\hat{\psi}(2\xi) = \hat{b}(\xi)\hat{\phi}(\xi)$. By Theorem 5.3, $X(\psi)$ is a Riesz wavelet basis for $L_2(\mathbb{R})$. The function ψ has 4 vanishing moments and the regularity 2.44077. See Figure 5 for graphs of the interpolatory refinable function ϕ and the function ψ.

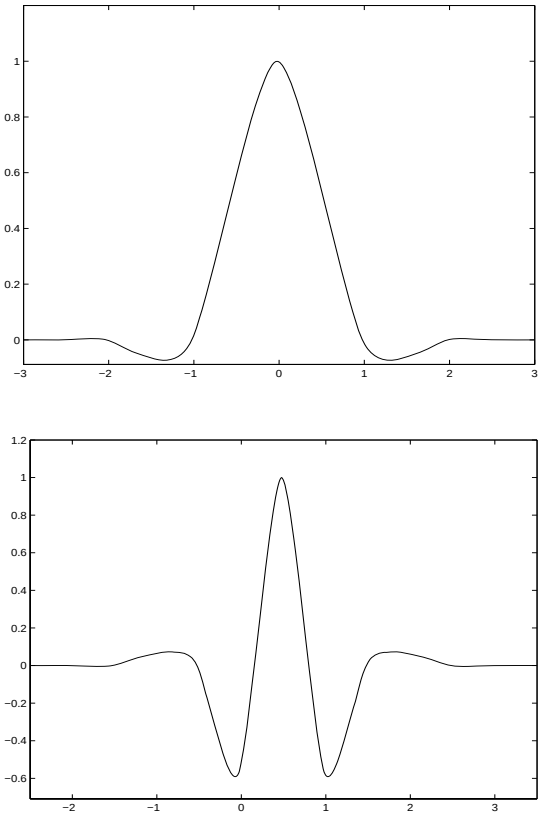

FIG. 5. *The graph of the interpolatory refinable function ϕ (top) and the graph of the function ψ (bottom) in Example* 5.4. *The function ψ has* 4 *vanishing moments and the regularity* 2.44077. *The system $X(\psi)$ is a Riesz basis for $L_2(\mathbb{R})$.*

The support of the function in Theorem 5.3 can be further shortened by reducing the order of vanishing moments as shown in the next result.

THEOREM 5.5. *Let m be a positive integer. Let ϕ be the interpolatory refinable function with the mask a given in* (5.2). *Define $\hat{\psi}(2\xi) = (\frac{1-e^{i\xi}}{2})^2\hat{\phi}(\xi)$. Then $X(\psi)$ is a Riesz basis for $L_2(\mathbb{R})$.*

Proof. We apply Corollary 3.3. For this, we note that

$$\hat{a}(\xi) = 2^{-2m}(1+e^{-i\xi})^{2m}\hat{A}(\xi) \quad \text{with} \quad \hat{A}(\xi) := e^{im\xi}P_m(\sin^2(\xi/2)),$$
$$\hat{b}(\xi) := (1-e^{i\xi})^2/4,$$

and

$$\hat{d}(\xi) = e^{i\xi}[\cos^{2m+2}(\xi/2)P_m(\sin^2(\xi/2)) + \sin^{2m+2}(\xi/2)P_m(\cos^2(\xi/2))] \neq 0 \qquad \forall\, \xi \in \mathbb{R}.$$

Then $\hat{\tilde{a}}(\xi) = 2^{-2}(1+e^{-i\xi})^2\hat{\tilde{A}}(\xi)$ with

$$\hat{\tilde{A}}(\xi) := \frac{e^{i\xi}}{\cos^{2m+2}(\xi/2)P_m(\sin^2(\xi/2)) + \sin^{2m+2}(\xi/2)P_m(\cos^2(\xi/2))}.$$

To apply Corollary 3.3, it remains to estimate $\hat{\tilde{A}}$. We note that for positive numbers a_1, a_2, a_3, a_4, it is easy to verify that $\frac{a_1}{a_2} \leqslant \frac{a_3}{a_4}$ implies $\frac{a_1}{a_2} \leqslant \frac{a_1+a_3}{a_2+a_4} \leqslant \frac{a_3}{a_4}$.

Since $P_m(x) = \sum_{j=0}^{m-1} c_j x^j$, where $c_j := \frac{(m-1+j)!}{j!(m-1)!} > 0$, it follows from

$$\frac{c_0}{c_0} \leqslant \frac{c_1(1-x)}{c_1 x} \leqslant \cdots \leqslant \frac{c_{m-1}(1-x)^{m-1}}{c_{m-1}x^{m-1}} = \frac{(1-x)^{m-1}}{x^{m-1}}, \qquad x \in (0, 1/2],$$

that

$$\frac{P_m(1-x)}{P_m(x)} \leqslant \frac{(1-x)^{m-1}}{x^{m-1}} \leqslant \frac{(1-x)^m}{x^m} \qquad \forall\, x \in (0, 1/2].$$

In other words, we have $x^m P_m(1-x) \leqslant (1-x)^m P_m(x)$ for all $x \in [0, 1/2]$. Thus, we deduce that

$$(1-x-x)x^m P_m(1-x) \leqslant (1-x-x)(1-x)^m P_m(x) \qquad \forall\, x \in [0, 1/2],$$

which is equivalent to

$$(1-x)x^m P_m(1-x) - x^{m+1} P_m(1-x) \leqslant (1-x)^{m+1} P_m(x) - x(1-x)^m P_m(x) \qquad \forall\, x \in [0, 1/2].$$

Hence,

$$(1-x)x^m P_m(1-x) + x(1-x)^m P_m(x) \leqslant x^{m+1} P_m(1-x) + (1-x)^{m+1} P_m(x) \qquad \forall\, x \in [0, 1/2].$$

Note that $x^m P_m(1-x) + (1-x)^m P_m(x) = 1$ for all $x \in [0, 1/2]$. For any $x \in [0, 1/2]$, we have

$$\begin{aligned} 1 &= (1-x+x)[x^m P_m(1-x) + (1-x)^m P_m(x)] \\ &= [(1-x)x^m P_m(1-x) + x(1-x)^m P_m(x)] + [x^{m+1} P_m(1-x) + (1-x)^{m+1} P_m(x)] \\ &\leqslant 2[x^{m+1} P_m(1-x) + (1-x)^{m+1} P_m(x)]. \end{aligned}$$

Consequently, by symmetry, we deduce that

$$x^{m+1} P_m(1-x) + (1-x)^{m+1} P_m(x) \geqslant 1/2 \qquad \forall\, x \in [0, 1].$$

Using the above inequality and taking $x = \cos^2(\xi/2)$, we have

$$|\hat{\tilde{A}}(\xi)| = [x^{m+1} P_m(1-x) + (1-x)^{m+1} P_m(x)]^{-1} \leqslant 2 \qquad \forall\, \xi \in \mathbb{R}.$$

It follows from the definition of $\rho_{\tilde{A}}$ that $\rho_{\tilde{A}} \leqslant 2 < 2^{2-1/2}$. Hence, $X(\psi)$ must be a Riesz basis for $L_2(\mathbb{R})$ by Corollary 3.3. □

Example 5.6. Let ϕ be the interpolatory refinable function with the mask $\hat{a}(\xi) = \frac{1}{2} + \frac{9}{16}\cos(\xi) - \frac{1}{16}\cos(3\xi)$, that is, the mask a is given in (5.2) with $m = 2$. Define $\hat{b}(\xi) = (1 - e^{i\xi})^2/4$ and $\hat{\psi}(2\xi) = \hat{b}(\xi)\hat{\phi}(\xi)$. By Theorem 5.5, $X(\psi)$ is a Riesz wavelet basis for $L_2(\mathbb{R})$. The function ψ has 2 vanishing moments and the regularity 2.44077. See Figure 6 for graphs of the interpolatory refinable function ϕ and the function ψ.

NEUMANN PROBLEMS FOR QUASI-LINEAR PARABOLIC SYSTEMS MODELING POLYDISPERSE SUSPENSIONS*

STEFAN BERRES†, RAIMUND BÜRGER‡, AND HERMANO FRID§

Abstract. We discuss the well-posedness of a class of Neumann problems for $n \times n$ quasi-linear parabolic systems arising from models of sedimentation of polydisperse suspensions in engineering applications. This class of initial-boundary value problems includes the standard (zero-flux) Neumann condition in the limit as a positive perturbation parameter θ goes to 0. We call, in general, the problem associated with $\theta \geq 0$ the θ-flux Neumann problem. The Neumann boundary conditions, although natural and usually convenient for integration by parts, are nonlinear and couple the different components of the system. An important aspect of our analysis is a time stepping procedure that considers linear boundary conditions for each time step in order to circumvent the difficulties arising from the nonlinear coupling in the original boundary conditions. We prove the well-posedness of the θ-flux Neumann problems for $\theta > 0$ and obtain a solution of the standard (zero-flux) Neumann problem as the limit for $\theta \to 0$ of solutions of the θ-flux Neumann problems. Concerning applications, the analysis developed here supports a new model for the settling of polydisperse suspensions forming compressible sediments.

1. Introduction.

We consider the initial-boundary value problem for certain quasi-linear parabolic systems of the (upper triangular) form

$$\partial_t u_i + \partial_x f_i(u) = \sum_{j=i}^{n} \partial_x \big(B_{ij}(u) \partial_x u_j \big), \quad i = 1, \ldots, n, \tag{1.1}$$

where $u = (u_1, \ldots, u_n)^{\mathrm{T}}$ and $(x,t) \in Q := (-1,1) \times (0,T)$. We consider the initial condition

$$u(x,0) = u_0(x), \quad x \in \Omega := (-1,1), \tag{1.2}$$

where $u_0 = (u_{01}, \ldots, u_{0n})^{\mathrm{T}}$ is a function on Ω for which regularity assumptions are made below. The so-called θ-flux Neumann boundary conditions are given by

$$f_i(u) - \sum_{j=i}^{n} B_{ij}(u) \big(\partial_x u_j \pm \theta (u_j - u_j^{\pm}(t)) \big) = 0, \quad x = \pm 1, \quad i = 1, \ldots, n. \tag{1.3}$$

Here, $\theta > 0$ and $u^{\pm} = (u_1^{\pm}, \dots, u_n^{\pm})^{\mathrm{T}}$ are functions on $(0,T)$ for which regularity assumptions are also stated below. In matrix form, (1.1) and (1.3) read

$$\partial_t u + \partial_x f(u) = \partial_x\big(B(u)\partial_x u\big), \quad (x,t) \in Q, \tag{1.4}$$

$$f(u) - B(u)\big(\partial_x u \pm \theta(u - u^{\pm}(t))\big) = 0, \quad x = \pm 1, \quad 0 < t < T, \tag{1.5}$$

where we denote $f(u) = (f_1(u), \dots, f_n(u))^{\mathrm{T}}$ and $B(u) = (B_{ij}(u))_{i,j=1}^n$. We impose the parabolicity condition

$$B_{ii}(u) \geq \nu > 0, \quad u \in \Delta, \quad i = 1, \dots, n, \tag{1.6}$$

and assume that the matrix $B(u)$ is upper triangular, i.e.,

$$B_{ij}(u) \equiv 0 \quad \text{if } i > j. \tag{1.7}$$

When $\theta \to 0$, condition (1.3) reduces to the standard (zero-flux) Neumann boundary condition given by

$$f_i(u) - \sum_{j=i}^{n} B_{ij}(u)\partial_x u_j = 0, \quad x = \pm 1, \quad t \in (0,T), \quad i = 1, \dots, n. \tag{1.8}$$

We assume that the functions $f_i(u)$ and $B_{ij}(u)$ are smooth on the set

$$\Delta := \big\{u \in \mathbb{R}^n \,:\, u_1 \geq 0, \dots, u_n \geq 0,\ u_1 + \cdots + u_n \leq 1\big\} \tag{1.9}$$

and that

$$u_0(x) \in \Delta,\ u^{\pm}(t) \in \Delta \quad \text{for all } x \in \Omega,\ t \in (0,T). \tag{1.10}$$

More precisely, we assume

$$f_i,\ \frac{\partial f_i}{\partial u_j},\ B_{ij},\ \frac{\partial B_{ij}}{\partial u_k},\ \frac{\partial^2 B_{ij}}{\partial u_k \partial u_l} \in H^{\beta}(\Delta),\ \beta \in (0,1), \tag{1.11}$$

where $H^{\beta}(\Delta)$ is the space of Hölder continuous functions (with Hölder exponent β) defined on Δ.

Our interest in problem (1.1), (1.2), (1.8) comes from a mathematical model for the sedimentation of polydisperse suspensions in engineering applications. This model will be further analyzed in this paper. Guided by this model, we assume the following conditions, which are relevant for the invariance of Δ:

$$f_i|_{u_i=0} = 0, \quad i = 1, \dots, n; \quad (f_1 + \cdots + f_n)\big|_{u_1+\cdots+u_n=1} = 0, \tag{1.12}$$

$$\begin{cases} \{B_{ij}\big|_{u_i=0} = \mu_i\, \delta_{ij}, \quad i,j = 1, \dots, n, \\ B_{11}\big|_{u_1+\cdots+u_n=1} = (B_{12} + B_{22})\big|_{u_1+\cdots+u_n=1} \\ \quad = \cdots = \sum_{j=1}^{n} B_{jn}\big|_{u_1+\cdots+u_n=1}, \end{cases} \tag{1.13}$$

where $\delta_{ij} = 0$ for $i \neq j$, $\delta_{ii} = 1$, and the μ_i are positive functions defined over the hyperplanes $u_i = 0$.

We denote by $H^{k+\beta}([a,b])$ the space of the functions on the closed interval $[a,b]$ whose derivatives up to kth order are Hölder continuous with exponent β. By

$H^{\alpha,\alpha/2}(\bar{Q})$ we denote the space of Hölder continuous functions on $\bar{Q}$ associated with the norm

$$|u|_Q^{(\alpha)} := \sup_{\bar{Q}} |u(x,t)| + \sup_{x_1,x_2\in\overline{\Omega},\ t\in[0,T]} \frac{|u(x_1,t)-u(x_2,t)|}{|x_1-x_2|^\alpha} + \sup_{x\in\overline{\Omega},\ t_1,t_2\in[0,T]} \frac{|u(x,t_1)-u(x,t_2)|}{|t_1-t_2|^{\alpha/2}}.$$

Let $H^{2+\alpha,1+\alpha/2}(Q)$ be the space of the functions on Q whose first and second x-derivatives and the t-derivative belong to $H^{\alpha,\alpha/2}(K)$ for any compact set $K \subseteq Q$. For simplicity, we also write, e.g., $v \in H^{\alpha,\alpha/2}(K)$ for a vector function $v = (v_1,\dots,v_n)^{\mathrm{T}}$ if all components of v belong to $H^{\alpha,\alpha/2}$.

The following theorem states our main result concerning the θ-flux Neumann problem (1.1)–(1.3).

THEOREM 1.1. *Let $\theta > 0$ be fixed. Assume that*

$$u_0 \in H^{2+\beta}([-1,1]), \quad u^\pm \in H^{1+\beta}([0,T]), \tag{1.14}$$

and that the compatibility conditions

$$f_i\big(u_0(\pm1)\big) - \sum_{j=i}^n B_{ij}\big(u_0(\pm1)\big)\big(\partial_x u_{0j}(\pm1) \pm \theta(u_{0j}(\pm1) - u_j^\pm(0))\big) = 0, \quad i = 1,\dots,n, \tag{1.15}$$

are satisfied. Furthermore, suppose that $f(u), B(u), u_0, u^\pm$ satisfy (1.6), (1.7), *and* (1.10)–(1.13). *Then, problem* (1.1)–(1.3) *has a unique classical solution u such that $u \in H^{2+\beta,1+\beta/2}(Q)$ and* (1.1) *is satisfied on Q, $u, u_x \in H^{\alpha,\alpha/2}(\bar{Q})$ for some $0 < \alpha \le \beta$, and conditions* (1.2), (1.5) *are satisfied in the usual sense of continuous functions. Moreover, $u(x,t) \in \Delta$ for $(x,t) \in \bar{Q}$.*

We also state here our main result for the limit problem (1.1), (1.2), (1.8).

THEOREM 1.2. *Let $f(u)$ and $B(u)$ be as in Theorem* 1.1. *Assume $u_0 \in L^2(\Omega)$. Then problem* (1.1), (1.2), (1.8) *has a solution $u(x,t)$ in the sense that u satisfies* (1.1) *in the classical sense in Q, u satisfies* (1.2) *in the sense that $u(\cdot,t) \to u_0(\cdot)$ in $L^2(\Omega)$ as $t \to 0$, and the boundary condition* (1.8) *is satisfied in the sense that*

$$\lim_{h\to0} \frac{1}{h} \int_{\Omega_{h\pm}} \int_0^T \big(B(u)u_x - f(u)\big)\chi(t)\,dt\,dx = 0 \quad \text{for all } \chi \in L^2(0,T), \tag{1.16}$$

where $\Omega_{h+} := (1-h,1)$ and $\Omega_{h-} := (-1,-1+h)$. Moreover, $u(x,t) \in \Delta$ for $(x,t) \in \bar{Q}$.

1.1. Brief outline of the proofs of Theorems 1.1 and 1.2. We briefly outline the proofs of Theorems 1.1 and 1.2. Concerning Theorem 1.1, we first consider the approximate problems for $\varepsilon > 0$,

$$\partial_t u_i + \partial_x f_i(u) = \sum_{j=i}^n \partial_x\big(B_{ij}(u)\partial_x u_j\big) + \varepsilon\left(\frac{1}{n} - u_i\right), \quad i = 1,\dots,n, \tag{1.17}$$

$$u(x,0) = u_{0\varepsilon}(x) := (1-\varepsilon)u_0(x) + \frac{\varepsilon}{2n}e, \quad x \in \Omega, \quad e := (1,\dots,1)^{\mathrm{T}}, \tag{1.18}$$

$$f_i(u) - \sum_{j=i}^n B_{ij}(u)\big(\partial_x u_j \pm \theta(u_j - u_{\varepsilon j}^\pm(t))\big) = 0, \quad x = \pm1, \quad i = 1,\dots,n, \tag{1.19}$$

where we define

$$u_\varepsilon^\pm := (1-\varepsilon)u^\pm + \frac{\varepsilon}{2n}e.$$

The importance of introducing the perturbed problem (1.17)–(1.19) is related to the verification of the positive invariance of the region Δ. Indeed, the latter will follow from conditions (1.12) and (1.13) by proceeding as in [6] and [10]. The new point here is the argument on the boundary, which, as in [10], evaluates the sign of the space derivative given by the boundary condition (1.19) by using (1.12) and (1.13). Once we prove the invariance of Δ, for the subsequent analysis in the time stepping procedure we may assume $f(u)$ and $B(u)$ to be defined conveniently outside Δ in order to guarantee the a priori uniform boundedness of the solutions of the step problems; e.g., we may assume $f(u) = 0$ and $B(u) = \nu\,\mathrm{Id}$ outside a bounded open set containing Δ, where Id is the identity matrix.

Because of the nonlinear coupling in the boundary condition (1.19), the proof of Theorem 1.1 requires a *time stepping procedure*. This consists of linearizing the boundary condition in each step and thus obtaining the solution for each of the resulting problems. The initial-boundary value problem in the kth step with initial time $t = k\Delta t$, for $k \geq 1$, is given by (1.17) plus the value of the solution of the $(k-1)$th step as initial condition, i.e.,

$$u(x, k\Delta t) = u^{[k-1]}(x, k\Delta t - 0), \qquad x \in \Omega, \tag{1.20}$$

and the boundary condition

$$\partial_x u \pm \theta\big(u - u_\varepsilon^\pm(t)\big) = B\big(u^{[k-1]}\big)^{-1} f\big(u^{[k-1]}\big)\big|_{x=\pm 1,\ t=k\Delta t-0},\ t > k\Delta t, \tag{1.21}$$

where by $u^{[k]}$ we denote the solution of the kth step problem. Let us call the problem just described the kth step problem (1.17), (1.20), (1.21). For $k = 0$, we may define the 0th step problem (1.17), (1.20), (1.21) as above, agreeing to define $u^{[-1]}(x, 0) = u_0(x)$. Since the initial condition (1.20) and the boundary condition (1.21) may not satisfy the appropriate compatibility conditions, it is not possible to guarantee the well-posedness of (1.17), (1.20), (1.21). Nevertheless, a solution can always be obtained as the limit of solutions of well-posed problems obtained through a small regularization of those initial and boundary conditions enforcing the compatibility conditions. The well-posedness of the regularized kth step problem (1.17), (1.20), (1.21) is proved exactly in the same way as that of the similar problem in [10]. We recall that [10] follows the basic strategy of [13], whose main point is the application of the Leray–Schauder fixed point theorem, combined with bottom to top recursive a priori estimates similar to the procedure in [1]. Actually, the most important point in [10] is related to the regularity at the boundary. In general, in order to prove such regularity (see, e.g., [13]), we need to assume a certain smoothness of the coefficients of the second order terms with respect to one of the independent variables, x, t, which is not possible when dealing with system (1.17) since, although we assume that $B(u)$ is upper triangular, we *do not* assume that the B_{ij} depend only on u_k for $k \geq i$; rather, they can depend on all components of u. To surmount this difficulty, we use the idea introduced in [10], which is to use the good sign of the boundary term resulting from integration by parts in the crucial estimates.

We then define $u^\Delta(x, t)$ in Q by assuming $T = N\Delta t$ and setting $u^\Delta(x, t) := u^{[k]}(x, t)$ for $(x, t) \in \Omega \times [k\Delta t, (k+1)\Delta t)$, $k = 0, 1, \ldots, N$. Looking carefully at

the a priori estimates obtained for the kth step problem (1.17), (1.20), (1.21), $k = 0, 1, \ldots, N$, we show that it is possible to combine the first three, which imply that $u^\Delta \in H^{\beta,\beta/2}(\bar{Q})$ for some $\beta \in (0,1)$ with the Hölder norm bounded by a constant independent of ε and Δt, and that for some $c > 0$, also independent of ε and Δt,

$$\int_Q \left(\left| u^\Delta_{xx} \right|^2 + \left| u^\Delta_x \right|^4 + \left| u^\Delta_t \right|^2 \right) dx\, dt \leq c. \tag{1.22}$$

The uniform boundedness of the Hölder norm of u^Δ in $H^{\beta,\beta/2}(\bar{Q})$ provides the compactness of the sequence $\{u^\Delta\}$ in $H^{\alpha,\alpha/2}(\bar{Q})$ for any $0 < \alpha < \beta$, and so we may make $\Delta t \to 0$ and extract a subsequence $u^{\Delta'}$ converging to a certain u^ε in $H^{\alpha,\alpha/2}(\bar{Q})$ for each $\varepsilon > 0$. The limit u^ε will then satisfy an integral identity which is a weak formulation for problem (1.17)–(1.19). Using this integral identity and the estimate obtained from (1.22) we show that u^ε is in fact the unique smooth solution of (1.17)–(1.19).

Finally, we make $\varepsilon \to 0$ using the relative compactness guaranteed by the regularity of u^ε, which is uniform with respect to ε. It then follows that any vector function which is the limit of a converging subsequence of solutions of problem (1.17)–(1.19) is a classical solution of problem (1.1)–(1.3). Uniqueness follows in a standard way by taking the difference of the equations for any two solutions, multiplying each equation resulting from the difference of the corresponding components by the difference of these components, integrating over Ω, using integration by parts, and making estimates in a bottom-to-top iterative way.

As for Theorem 1.2, we obtain its proof by compactness, taking the limit as $\theta \to 0$ of a subsequence of solutions of (1.1)–(1.3) and proving that the limit function verifies the required properties. As for the uniqueness, no method for proving it is yet known for the class of regularity to which the solution obtained in this limit process belongs, in which we miss boundedness of the first space derivative up to the boundary.

Correlated works besides [9, 10] include the following. In the above mentioned book [13], the theory developed for linear and quasi-linear equations is applied to quasi-linear systems of type (1.1) (in the multidimensional case) where the nonlinear diffusion matrix is a scalar multiple of the identity matrix. We also mention the results of Amann [1] which require $f_i = f_i(u_i, \ldots, u_n)$ and $B_{ij} = B_{ij}(u_i, \ldots, u_n)$, $1 \leq i \leq j \leq n$, besides (1.6) and the upper-triangularity of $B(u)$, and which assume uniform boundedness of a certain Hölder norm of the local solution in order to extend the local solution to all times $t > 0$.

1.2. Brief description of the contents. This paper is organized as follows. In section 2, we prove positive invariance of Δ for problem (1.17)–(1.19). In section 3, we describe our time stepping procedure and obtain a priori estimates in the space of Hölder continuous functions for the solution of each time step problem. The Leray–Schauder fixed point theorem is applied in section 4 in order to prove existence of solutions for the time step problems. We also discuss the independence of some crucial estimates with respect to the time step Δt and the parameter enforcing the compatibility conditions at each time step. In section 5, we conclude the proof of Theorem 1.1 and also give the proof of Theorem 1.2. Finally, in section 6, we derive a model for polydisperse suspensions that improves an earlier model considered in [3], which can be cast, by a change of dependent variables, into a form which satisfies, after the addition of artificial viscosity, the assumptions of Theorem 1.1.

2. Invariance of the physical domain Δ. In this section we prove the positive invariance of Δ under the flow of the solution operator for problem (1.17)–(1.19). More precisely, we have the following result.

LEMMA 2.1. *Let the hypotheses of Theorem* 1.1 *hold. Then, if* $u(x,t)$ *is a classical solution of problem* (1.17)–(1.19) *in* $\bar{Q}$, *we have* $u(x,t) \in \Delta$ *for all* $(x,t) \in \bar{Q}$.

Proof. We argue by contradiction. Thus, assume that there is $(x,t) \in \bar{Q}$ such that $u(x,t) \notin \Delta$. Let

$$t_0 := \inf\{\, t \in [0,T] \,:\, u(x,t) \notin \Delta\}.$$

Since $u_0 \in \operatorname{int}\Delta$, we have $t_0 > 0$. Let $x_0 \in [-1,1]$ be such that $u(x_0,t_0) \in \partial\Delta$. Hence, we have $u_i(x_0,t_0) = 0$, for some $i = 1,\dots,n+1$, where we define $u_{n+1} := 1 - u_1 - \cdots - u_n$. We discuss separately two different cases: (i) $x_0 \in (-1,1)$; (ii) $x_0 = \pm 1$. Let us consider first case (i). In this case, for some $i \in \{1,\dots,n+1\}$, u_i assumes its minimum value in the region $[-1,1] \times [0,t_0]$ at (x_0,t_0), and so we must have

$$u_{it}(x_0,t_0) \le 0, \qquad u_{ix}(x_0,t_0) = 0, \qquad u_{ixx}(x_0,t_0) \ge 0. \tag{2.1}$$

Now, in light of (1.12) and (1.13) we may easily verify that at (x_0,t_0), the ith equation from (1.17) reduces to

$$u_{it} + \lambda_i u_{ix} = (\mu_i u_{ix})_x + \varepsilon l_i(u_i), \tag{2.2}$$

where λ_i and μ_i are scalar functions of u, $\mu_i > 0$ by (1.6), $l_i(u_i) := (\frac{1}{n} - u_i)$ if $i \in \{1,\dots,n\}$, $l_{n+1}(u_{n+1}) = u_{n+1}$, and the equation for u_{n+1} is obtained from the n equations of (1.17) in an obvious manner by summation. Hence, by (2.1) we arrive at a contradiction since the left-hand side of (2.2) is nonpositive, while the right-hand side is positive. We now consider case (ii) and assume without loss of generality that $x_0 = -1$. Let $i \in \{1,\dots,n+1\}$ be such that $u_i(-1,t_0) = 0$. Applying (1.12) and (1.13) to (1.19), we obtain that

$$u_{ix}(-1,t_0) < 0, \tag{2.3}$$

where, again, the equation for $i = n+1$ is obtained from (1.19) in an obvious manner. Now, (2.3) gives a contradiction since $u_i(x,t_0) \ge 0$ for all $x \in [-1,1]$. For $x_0 = 1$ we obtain a contradiction in a similar way. ∎

In view of the above result, we may assume $f_i(u)$ and $B_{ij}(u)$ to be defined as smooth functions for all $u \in \mathbb{R}^n$ in such a way that $f_i(u) \equiv 0$ and $B_{ij}(u) = \nu I$ for $u \notin U$, where $U \subseteq \mathbb{R}^n$ is a bounded open cube with faces parallel to the coordinate axes satisfying $\Delta \subseteq U$. This extension will be needed in what follows, since the invariance of Δ will not hold, in general, for the approximate solutions constructed by our time stepping procedure.

3. A time stepping approximation.

3.1. Initial-boundary value problem on short time intervals. In this section we construct approximate solutions of (1.17)–(1.19), defining them in a recursive way for time intervals $[k\Delta t,(k+1)\Delta t)$, $k = 0,\dots,N-1$, with $T = N\Delta t$. Our one-parameter approximate solution $u^{\Delta}(x,t)$ is a solution of the initial-boundary value problems, which are defined recursively for $(x,t) \in Q_k := [-1,1] \times [k\Delta t,(k+1)\Delta t)$

and consist of (1.17) with initial and boundary conditions given by

$$u^{\Delta}(x,k\Delta t)=u^{\Delta}(x,k\Delta t-0),\quad x\in\Omega, \tag{3.1}$$

$$\partial_x u\pm\theta\big(u-u_{\varepsilon}^{\pm}(t)\big)=\big[B(u^{\Delta}(k\Delta t-0))^{-1}f(u^{\Delta}(k\Delta t-0))\big]_{x=\pm1},\quad t>k\Delta t, \tag{3.2}$$

for $k=1,\dots,N-1$, while, for $k=0$, we set

$$u^{\Delta}(x,0)=u_{0\varepsilon}(x),\quad x\in\Omega, \tag{3.3}$$

$$\partial_x u\pm\theta\big(u-u_{\varepsilon}^{\pm}(t)\big)=B(u_{0\varepsilon}(\pm1))^{-1}f(u_{0\varepsilon}(\pm1)),\quad t>0. \tag{3.4}$$

We remark that the solutions of (1.17), (3.1), (3.2) will in general not be smooth at the corner points $(\pm1,k\Delta t)$, $k=1,\dots,N-1$, since the initial and boundary conditions at each time step, for $t=k\Delta t$, may not be compatible. Nevertheless, we will show that they can be defined in such a way that they are Hölder continuous in $\bar{Q}$, smooth in $\bar{Q}\setminus\{(\pm1,k\Delta t)\,:\,k=1,\dots,N-1\}$, and that (1.1) is satisfied in the classical sense in the interior of Q, while (3.1) and (3.2) are satisfied pointwise except at those corner points. The corresponding problem for $k=0$, that is, (1.17), (3.3), (3.4), is well-posed since here the compatibility conditions at the points $(\pm1,0)$ hold by assumption.

3.2. The kth step problem. Here we discuss the solution of the kth step problem (1.17), (3.1), (3.2), $k\geq1$. The case $k=0$ is treated similarly but does not require regularization of the initial data to enforce compatibility, since this already holds by assumption. As already mentioned, the solution of (1.17), (3.1), (3.2) is obtained as a limit of solutions of regularized problems given by (1.17) with the same boundary condition (3.2) and an initial condition obtained through a regularization of (3.1) in such a way that the new initial condition is compatible with (3.2) at the corners $(\pm1,k\Delta t)$. Thus, let $\zeta_\delta\in C_0(\Omega)$ be such that ζ_δ is even, $\zeta_\delta(x)=1$ for $-1+\delta\leq x\leq1-\delta$, $\zeta_\delta(x)=0$ for $1-\frac{\delta}{3}<|x|\leq1$, and ζ_δ is nonincreasing in $[0,1]$ with $|\zeta_\delta'(x)|\leq2\delta^{-1}$. We may define regularized initial data by

$$u_{\delta}^{\Delta}(x,k\Delta t)=\zeta_\delta(x)u^{\Delta}(x,k\Delta t-0)+\big(1-\zeta_\delta(x)\big)\big(\gamma_{k,\delta}^{-}\,\chi_{[-1,0)}(x)+\gamma_{k,\delta}^{+}\,\chi_{[0,1]}(x)\big), \tag{3.5}$$

where, as usual, χ_A denotes the indicator function of the set A and

$$\gamma_{k,\delta}^{\pm}=u_{\varepsilon}^{\pm}(k\Delta t)\pm\frac{1}{\theta}\big[B\big(u^{\Delta}(x,k\Delta t-0)\big)^{-1}f\big(u^{\Delta}(x,k\Delta t-0)\big)\big]_{x=\pm1}. \tag{3.6}$$

The well-posedness of the regularized kth problem (1.17), (3.2), (3.5) is proved in [10] for the case when $n=2$. The same result for general n is a straightforward consequence for the case when $n=2$. From the results in [10], we easily deduce that the solution of (1.17), (3.2), (3.5) is bounded in $H^{2+\beta,1+\beta/2}(K)$, where K is any compact set contained in $\bar{Q}_k\setminus\{(-1,k\Delta t),(1,k\Delta t)\}$ and $Q_k:=\Omega\times(k\Delta t,k\Delta t+T)$, with $\beta\in(0,1)$ and the corresponding bound depending, in general, on f,B,T, and K, but independent of δ, for δ sufficiently small. The latter is clear since the regularization in (3.5) is visible only for points in a small neighborhood of the corner points $(\pm1,k\Delta t)$ which will not intersect K if δ is small enough.

Using well-known compactness properties of spaces of Hölder continuous functions we easily obtain a solution of (1.17), (3.1), (3.2) as the limit of a subsequence of the solutions to (1.17), (3.2), (3.5). The solution of (1.17), (3.1), (3.2) obtained in this way is not known to belong to a class of well-posedness with respect to this problem

since we do not know whether its space derivative is bounded in the whole domain Q_k. On closer inspection we choose one such solution, and call it $u^{[k]}$.

The following estimate for the solution of the kth step problem (1.17), (3.1), (3.2) is an immediate consequence of the assumptions on f and B stated in section 2.

LEMMA 3.1. *The estimate*

$$\left\|u^{[k]}\right\|_{L^\infty(Q_k)} \le c \tag{3.7}$$

holds for some constant $c = c(\theta) > 0$, depending on θ but independent of ε, Δt, and k.

Proof. By assumption we have $f(u) = 0$ and $B(u) = \nu I$ if $u \notin U$, where U is a bounded open cube centered at the origin and containing Δ. Let $\tilde{U} \supset U$ be another bounded open cube with faces parallel to the coordinate and such that

$$\inf_{\substack{u\in\tilde{F}\\ t\in(0,T)}} |u - u^{\pm}(t)| > \frac{1}{\theta} \sup_{u\in U} |B(u)^{-1} f(u)| \tag{3.8}$$

for any face $\tilde{F}$ of $\tilde{U}$. The solution of the k-regularized problem (1.17), (3.2), (3.5) satisfies (3.7) by reasoning similar to that of the proof of Lemma 2.1, with a constant c determined only by $\tilde{U}$, and so depending on θ, because of (3.8), but independent of ε,Δt, k, and δ. Hence, (3.7) also holds for $u^{[k]}$ since it is a pointwise limit of solutions to (1.17), (3.2), (3.5) as $\delta \to 0$. ∎

We collect in the following lemma the a priori integral estimates for the solution of (1.17), (3.1), (3.2) whose bounds may be taken independent of ε, Δt, and k.

LEMMA 3.2. *The solution of* (1.17), (3.1), (3.2), *$u^{[k]}$ satisfies*

$$\int_\Omega \left|u^{[k]}(t)\right|^2 dx \le c, \qquad \int_{k\Delta t}^{k\Delta t+\tau} \int_\Omega \left|u_x^{[k]}\right|^2 dx\, dt \le c\tau, \quad 0 < \tau \le T. \tag{3.9}$$

Moreover, there exists $\beta \in (0,1)$, independent of ε, Δt, and k, such that $u^{[k]} \in H^{\beta,\beta/2}(\bar{Q}_k)$, with $Q_k = \Omega \times (k\Delta t, k\Delta t + T)$, and

$$\begin{aligned}\int_\Omega \left|u_x^{[k]}(k\Delta t+\tau)\right|^2 dx + c\int_{k\Delta t}^{k\Delta t+\tau} \int_\Omega \left(\left|u_{xx}^{[k]}\right|^2 + \left|u_x^{[k]}\right|^4 + \left|u_t^{[k]}\right|^2\right) dx\, dt \\ \le c'\left(\tau + \int_{k\Delta t}^{k\Delta t+\tau} \int_\Omega \left|u_x^{[k]}\right|^2 dx\, dt\right) + \int_\Omega \left|u_x^{[k]}(k\Delta t)\right|^2 dx.\end{aligned} \tag{3.10}$$

The constants c and c' above are independent of $\varepsilon, \Delta t, k$.

Proof. It suffices to consider the case when $n = 2$. In this case, the lemma follows from Lemmas 2.2, 2.3, 2.4, and 2.5 of [10]. ∎

As mentioned above, we define the approximate solution for the problem (1.17)–(1.19), $u^\Delta(x,t)$, by setting

$$\begin{aligned}&u^\Delta(x,t) = u^{[k]}(x,t)\\ &\text{for } (x,t) \in [-1,1] \times [k\Delta t, (k+1)\Delta t), \quad k = 0, 1, \ldots, N-1.\end{aligned} \tag{3.11}$$

As a corollary of Lemmas 3.1 and 3.2 we immediately obtain the following lemma.

LEMMA 3.3. *The following estimates hold for a constant $c > 0$ independent of ε and Δt:*

$$\|u^\Delta\|_{L^\infty(Q)} \le c, \tag{3.12}$$

$$\|u^\Delta\|_{H^{\beta,\beta/2}(\bar{Q})} \le c, \tag{3.13}$$

$$\int_Q \left|u_x^\Delta\right|^2 dx\, dt \le c, \tag{3.14}$$

$$\int_Q \left(\left|u_{xx}^\Delta\right|^2 + \left|u_x^\Delta\right|^4 + \left|u_t^\Delta\right|^2\right) dx\, dt \le c. \tag{3.15}$$

Moreover, for all $\varphi \in C_0(\mathbb{R} \times (-\infty, T))$ we have

$$\begin{aligned} &\int_Q \left(u^\Delta \varphi_t + f(u^\Delta)\varphi_x - B(u^\Delta)u_x^\Delta \varphi_x\right) dx\, dt + \int_\Omega u_{0\varepsilon}(x)\varphi(x,0)\, dx \\ &= \pm \int_{\{\pm 1\}\times(0,T)} \Big(\left(f(u^\Delta([t/\Delta t]\,\Delta t)) - f(u^\Delta)\right) \\ &\qquad\qquad - \left(B(u^\Delta([t/\Delta t]\,\Delta t)) - B(u^\Delta)\right) u_x^\Delta \Big) \varphi(\pm 1, t)\, dt \\ &\quad \pm \theta \int_{\{\pm 1\}\times(0,T)} B(u^\Delta)(u^\Delta - u_\varepsilon^\pm(t))\varphi(\pm 1, t)\, dt. \end{aligned} \tag{3.16}$$

Proof. The first two estimates follow directly from Lemmas 3.1 and 3.2, while the last two also follow from these lemmas by summing up from $k = 0$ to $k = N - 1$ the inequalities (3.9) and (3.10), respectively, with $\tau = \Delta t$. As for (3.16), we first observe that u^Δ satisfies (1.17) in Q, the boundary condition (3.2), for $t \in [k\Delta t, (k+1)\Delta t)$, $k = 0, 1, \ldots, N-1$, and the initial condition (3.4), for $t = 0$. Hence, (3.16) follows by multiplying (1.17) by φ, integrating over Q, and using integration by parts. ∎

4. Convergence of the approximate solutions. In this section we discuss the convergence of the approximate solutions $u^\Delta(x,t)$. From (3.13) in Lemma 3.3 we see that the family $\{u^\Delta\}$ is compact in $H^{\alpha,\alpha/2}(\bar{Q})$ for any $0 < \alpha < \beta$. Hence, we may extract a subsequence $u^{\Delta'}$ converging to some u^ε in $H^{\alpha,\alpha/2}(\bar{Q})$ as $\Delta t \to 0$. Also from Lemma 3.3 we deduce that u^ε satisfies

$$\|u^\varepsilon\|_{L^\infty(Q)} \le c, \tag{4.1}$$

$$\|u^\varepsilon\|_{H^{\beta,\beta/2}(\bar{Q})} \le c, \tag{4.2}$$

$$\int_Q |u_x^\varepsilon|^2\, dx\, dt \le c, \tag{4.3}$$

$$\int_Q \left(|u_{xx}^\varepsilon|^2 + |u_x^\varepsilon|^4 + |u_t^\varepsilon|^2\right) dx\, dt \le c, \tag{4.4}$$

and, for any $\varphi \in C_0(\mathbb{R} \times (-\infty, T))$,

$$\begin{aligned} &\int_Q \left(u^\varepsilon \varphi_t + f(u^\varepsilon)\varphi_x - B(u^\varepsilon)u_x^\varepsilon \varphi_x\right) dx\, dt + \int_\Omega u_{0\varepsilon}(x)\varphi(x,0)\, dx \\ &= \pm\theta \int_{\{\pm 1\}\times(0,T)} B(u^\varepsilon)(u^\varepsilon - u_\varepsilon^\pm(t))\varphi(\pm 1, t)\, dt. \end{aligned} \tag{4.5}$$

5. Conclusion of the proofs of Theorems 1.1 and 1.2.

Conclusion of the proof of Theorem 1.1. Estimates (4.1)–(4.5) allow for the application of Lemmas 2.7, 2.8, and 2.9 of [10] (these lemmas are stated for $n = 2$, but they are obviously also valid for general n) to conclude that

$$u_x^\varepsilon \in H^{\alpha,\alpha/2}(\bar{Q}) \quad \text{and} \quad |u_x^\varepsilon|^{(\alpha)} \le c \tag{5.1}$$

for some $\alpha \in (0,1)$ and $c > 0$ independent of ε. Hence, u^ε is a classical solution of (1.17)–(1.19), and by Lemma 2.1,

$$u^\varepsilon(x,t) \in \Delta \quad \text{for all } (x,t) \in \bar{Q}. \tag{5.2}$$

Making $\varepsilon \to 0$, using well-known compactness arguments in spaces of Hölder continuous functions, we may extract a subsequence $u^{\varepsilon'}$ converging in $H^{\gamma,\gamma/2}(\bar{Q})$, $0 < \gamma < \alpha$, to some u satisfying $u, u_x \in H^{\alpha,\alpha/2}(\bar{Q})$ and $u(x,t) \in \bar{Q}$ for all $(x,t) \in \bar{Q}$, which is a classical solution of (1.1), (1.2), (1.3). Clearly, we have

$$u(x,t) \in \Delta \quad \text{for all } (x,t) \in \bar{Q}. \tag{5.3}$$

Uniqueness of u in the class of such solutions is proved by the standard arguments already mentioned in section 1. □

Conclusion of the proof of Theorem 1.2. Let u^θ denote the solution of (1.1), (1.2), (1.3) obtained above. Given any compact subset $K \subseteq Q$ we have

$$u^\theta \in H^{2+\alpha,1+\alpha/2}(K) \quad \text{and} \quad \|u^\theta\|_{H^{2+\alpha,1+\alpha/2}(K)} \le c \tag{5.4}$$

for some $\alpha \in (0,1)$ and $c = c(K) > 0$ independent of θ. Moreover, we also have that u^θ satisfies (5.3) and

$$\|u_x^\theta\|_{L^2(Q)} \le c \tag{5.5}$$

for some $c > 0$ also independent of θ. Hence, we may make $\theta \to 0$ and extract a subsequence $u^{\theta'}$ converging in $L^1(Q)$ to a certain function $u \in H^{2+\alpha,1+\alpha/2}(Q)$, which satisfies (1.1) in Q. By (5.5) we may choose $u^{\theta'}$ so that $u_x^{\theta'} \rightharpoonup u_x$ in the weak topology of $L^2(Q)$. It satisfies

$$\int_Q \big(u\varphi_t + f(u)\varphi_x - B(u)u_x\varphi_x\big)\,dx\,dt + \int_\Omega u_0(x)\varphi(x,0)\,dx = 0 \tag{5.6}$$

for all $\varphi \in C_0^\infty(\mathbb{R} \times (-\infty, T))$, which follows from (4.5) by making first $\varepsilon \to 0$ and then $\theta \to 0$, and using the above mentioned convergences. Now, (1.16) follows easily from (5.6) by choosing $\varphi = \chi(t)\zeta_h(x)$, with $\chi \in C_0^1((0,T))$, $0 < h < 1/2$, and $\zeta_h(x) = 1$ for $x \in [-1+h, 1-h]$, $\zeta_h(x) = h^{-1}(1+x)$ for $x \in [-1, -1+h)$, and $\zeta_h(x) = h^{-1}(1-x)$ for $x \in (1-h, 1]$, and making $h \to 0$. Finally, it also satisfies (1.2) in the sense that

$$\lim_{t\to 0} \int_\Omega \big|u(x,t) - u_0(x)\big|^2\,dx = 0. \tag{5.7}$$

Indeed, from (5.6) we easily deduce

$$\lim_{t\to 0} \int_\Omega \big(u(x,t) - u_0(x)\big)\zeta(x)\,dx = 0 \tag{5.8}$$

for all $\zeta \in C_0^1(\mathbb{R})$. On the other hand, also from (5.6) we deduce the energy estimate in a standard way (see, e.g., [13, Chapter III, section 2]),

$$\int_\Omega |u(x,t)|^2\,dx + \frac{\nu}{2}\int_0^t\int_\Omega |u_x(x,s)|^2\,dx\,ds \le \int_\Omega |u_0(x)|^2 + c\int_0^t\int_\Omega |u(x,s)|^2\,dx\,ds,$$

from which it follows that

$$\limsup_{t\to 0}\int_\Omega |u(x,t)|^2\,dx \le \int_\Omega |u_0(x)|^2\,dx. \tag{5.9}$$

On the other hand, from (5.8) and convexity (see, e.g., [17]), we deduce

$$\liminf_{t\to 0}\int_\Omega |u(x,t)|^2\,dx \ge \int_\Omega |u_0(x)|^2\,dx. \tag{5.10}$$

Now, (5.8), (5.9), and (5.10) imply, as expected, (5.7). ∎

6. Sedimentation of polydisperse suspensions.

6.1. Balance equations and model assumptions. Our interest in the initial-boundary value problem (1.1), (1.2), (1.8) is motivated by a model of gravity sedimentation of polydisperse suspensions that form compressible sediments. After a change of variables, which ensures an upper triangular form, this model provides the coefficient functions $f_1(u),\dots,f_n(u)$ and $(B_{ij}(u))_{i,j=1,\dots,n}$. It is a variant of the model introduced in [3] and will be briefly derived here.

We consider small solid particles belonging to n different species having sizes $d_1 \ge d_2 \ge \cdots \ge d_n$ and densities $\varrho_1,\dots,\varrho_n$, where $d_i \ne d_j$ or $\varrho_i \ne \varrho_j$ for $i \ne j$, $1 \le i,j \le n$, which are dispersed in a viscous fluid of density $\varrho_{\rm f}$ and viscosity $\mu_{\rm f}$. We consider the solids and the fluid as $n+1$ superimposed continuous phases, and start from the multidimensional mass and linear momentum balances

$$\partial_t\phi_i + \nabla\cdot(\phi_i\mathbf{v}_i) = 0, \quad i=1,\dots,n; \quad \partial_t\phi - \nabla\cdot\big((1-\phi)\mathbf{v}_{\rm f}\big) = 0, \tag{6.1}$$

where $\Phi := (\phi_1,\dots,\phi_n)$ is the vector of the local volume fractions of the solid phases, $\phi := \phi_1 + \cdots + \phi_n$ is the total solids volume fraction, and $\mathbf{v}_1,\dots,\mathbf{v}_n$ and $\mathbf{v}_{\rm f}$ are the solids and fluid phase velocities, respectively. Summation over all mass balances implies $\nabla\cdot\mathbf{q} = 0$, where $\mathbf{q} := \phi_1\mathbf{v}_1 + \cdots + \phi_n\mathbf{v}_n + (1-\phi)\mathbf{v}_{\rm f}$ is the volume average mixture velocity. Introducing the relative velocities (or slip velocities) $\mathbf{u}_i := \mathbf{v}_i - \mathbf{v}_{\rm f}$ for $i=1,\dots,n$, we obtain $\mathbf{q} = \phi_1\mathbf{u}_1 + \cdots + \phi_n\mathbf{u}_n + \mathbf{v}_{\rm f}$ and

$$\mathbf{v}_i = \mathbf{u}_i + \mathbf{v}_{\rm f} = \mathbf{u}_i + \mathbf{q} - (\phi_1\mathbf{u}_1 + \cdots + \phi_n\mathbf{u}_n), \quad i=1,\dots,n.$$

The momentum balance equations for the n solid species and the fluid are

$$\varrho_i\phi_i(\partial_t\mathbf{v}_i + (\mathbf{v}_i\cdot\nabla)\mathbf{v}_i) = \nabla\cdot\mathbf{T}_i - \varrho_i\phi_i g\mathbf{k} + \mathbf{m}_i, \quad i=1,\dots,n, \tag{6.2}$$

$$\varrho_{\rm f}(1-\phi)(\partial_t\mathbf{v}_{\rm f} + (\mathbf{v}_{\rm f}\cdot\nabla)\mathbf{v}_{\rm f}) = \nabla\cdot\mathbf{T}_{\rm f} - \varrho_{\rm f}(1-\phi)g\mathbf{k} + \mathbf{m}_{\rm f}, \tag{6.3}$$

where $\mathbf{m}_i$ is the interaction force per unit volume between solid species i and the fluid and $\mathbf{m}_{\rm f} = -(\mathbf{m}_1+\cdots+\mathbf{m}_n)$. Interaction forces due to solid-solid contacts are assumed to be negligible compared with the solid-fluid transfer of momentum [5]. Moreover, $\mathbf{T}_i$ denotes the stress tensor of solids phase i, $i=1,\dots,n$, $\mathbf{T}_{\rm f}$ that of the fluid, g is the acceleration of gravity, and $\mathbf{k}$ is the upwards directed unit vector.

We assume that the stress tensors of the solid and fluid phases take the respective forms $\mathbf{T}_i = -p_i\mathbf{I} + \mathbf{T}_i^{\mathrm{E}}$, $i = 1, \ldots, n$, and $\mathbf{T}_{\mathrm{f}} = -p_{\mathrm{f}}\mathbf{I} + \mathbf{T}_{\mathrm{f}}^{\mathrm{E}}$, where p_i denotes the phase pressure of particle species i, p_{f} that of the fluid, $\mathbf{I}$ denotes the identity tensor, and $\mathbf{T}_i^{\mathrm{E}}$ and $\mathbf{T}_{\mathrm{f}}^{\mathrm{E}}$ are the extra (or viscous) stress tensors of particle species i and the fluid, respectively. Since viscous effects due to the motion of the mixture are not considered to be dominant for our analysis, we neglect the viscous stress tensors.

The theoretical phase pressures $p_1, \ldots, p_n$ and p_{f} are now expressed in terms of the pore pressure p and the effective solids stress σ_{e}, which can be measured. As in [3], we assume that σ_{e} is a known material-specific function of ϕ, which satisfies

$$\sigma_{\mathrm{e}}(\phi) \begin{cases} = 0 & \text{for } \phi \le \phi_{\mathrm{c}}, \\ > 0 & \text{for } \phi > \phi_{\mathrm{c}}, \end{cases} \qquad \sigma_{\mathrm{e}}'(\phi) := \frac{d\sigma_{\mathrm{e}}(\phi)}{d\phi} \begin{cases} = 0 & \text{for } \phi \le \phi_{\mathrm{c}}, \\ > 0 & \text{for } \phi > \phi_{\mathrm{c}}, \end{cases} \tag{6.4}$$

where ϕ_{c} is the critical concentration at which the solid particles touch each other.

In this paper, the relationship between the theoretical pressures $p_1, \ldots, p_n$ and p_{f} and the experimental variables p and $\sigma_{\mathrm{e}}(\phi)$ slightly differs from the one given in [3]. In that paper, it is argued that the portions of the total pressure $p_1 + \cdots + p_n + p_{\mathrm{f}} = \phi p + \sigma_{\mathrm{e}}(\phi)$ can be assigned to species i and to the fluid by

$$p_i = \phi_i\big(p + \sigma_{\mathrm{e}}(\phi)/\phi\big), \quad i = 1, \ldots, n; \quad p_{\mathrm{f}} = (1-\phi)p. \tag{6.5}$$

In this work, we do not fix $p_1, \ldots, p_n$ and p_{f} as volume quantities, as expressed by (6.5); rather, the gradient of the pressure of each phase is specified as a surface quantity. Thus, the gradients of the solid and fluid phase pressures introduced by the stress tensors in (6.2) and (6.3) are replaced by the respective expressions

$$\nabla p_i = \phi_i\big(\nabla p + \nabla\sigma_{\mathrm{e}}(\phi)/\phi\big) \quad \text{and} \quad \nabla p_{\mathrm{f}} = (1-\phi)\nabla p. \tag{6.6}$$

Our preference for (6.6) (instead of (6.5)) is in part motivated by the discussion of sediment diffusivity in section 7.5 of [3], where (6.5) is used. In fact, the numerical examples of [3] (see also [2]) show a strong differential relative movement of solid species within the sediment, which is driven by a diffusive term involving the gradient $\nabla(\phi_i/\phi)$. In particular, as is shown in [3], this term leads to a—probably unrealistic—equidistribution of the solid species within the sediment at steady state. The model analyzed herein is nearly the same as that of [3], but it does not include that particular term, and is expected to predict more realistic results.

We emphasize herein that a polydisperse sedimentation model based on (6.6) is supported by mathematical analysis, while a detailed quantitative (numerical) comparison with the predictions generated by using (6.5) is not within the scope of this paper. From an experimental point of view, both alternatives (6.5) and (6.6) are discussed in the literature. Both variants have been scrutinized [21] and considered in parallel [15], and (6.6) is postulated a priori, for example, in [16]. This ambiguity is still an unresolved issue, as is emphasized in [18].

Our analysis is valid only for the case of (6.6). In fact, based on (6.5), the final solid momentum balances would include the additional term $\nabla((\phi_i/\phi)\sigma_{\mathrm{e}}(\phi))$, which in turn later appears in the "Darcy-type law" expression for the slip velocity (6.10) as $-(\sigma_{\mathrm{e}}(\phi)/\phi_i)\nabla(\phi_i/\phi)$. Even in the diffusive flux term, the gradient of ϕ_i remains and precludes recasting the diffusion matrix into an upper-triangular matrix by a change of variables. This particular form is, however, essential for our treatment. The introduction of $\phi = \phi_1 + \cdots + \phi_n$ as a new variable requires an extra equation for ϕ, which can be generated by summing the equations for $\phi_1, \ldots, \phi_n$. If (6.5) is used,

then the resulting equation will involve all variables $\phi_1, \dots, \phi_n, \phi$, while starting from (6.6), the resulting equation depends on ϕ only.

Under the present assumptions, and in particular neglecting the viscous stress tensors, the momentum balances for the solid and fluid phases become

$$\begin{aligned} \phi_i \varrho_i \big(\partial_t \mathbf{v}_i + (\mathbf{v}_i \cdot \nabla)\mathbf{v}_i\big) &= \mathbf{m}_i - \varrho_i \phi_i g \mathbf{k} - \phi_i \nabla p - \frac{\phi_i}{\phi} \nabla \sigma_{\mathrm{e}}(\phi), \\ (1-\phi)\varrho_{\mathrm{f}} \big(\partial_t \mathbf{v}_{\mathrm{f}} + (\mathbf{v}_{\mathrm{f}} \cdot \nabla)\mathbf{v}_{\mathrm{f}}\big) &= \mathbf{m}_{\mathrm{f}} - \varrho_{\mathrm{f}}(1-\phi) g \mathbf{k} - (1-\phi)\nabla p. \end{aligned} \tag{6.7}$$

As a result of a dimensional analysis [3, 5] and due to the reduction to one space dimension, the left-hand sides in (6.7) can be neglected. After applying this simplification, summation of all equations in (6.7) yields the momentum balance of the suspension

$$0 = -\varrho(\Phi) g \mathbf{k} - \nabla p - \nabla \sigma_{\mathrm{e}}(\phi), \tag{6.8}$$

where $\varrho(\Phi) := \phi_1 \varrho_1 + \cdots + \phi_n \varrho_n + (1-\phi)\varrho_{\mathrm{f}}$ is the local density of the mixture. Next, we insert ∇p of the suspension momentum balance (6.8) into a solids momentum balance and assume the proportionality $\mathbf{m}_i = (\lambda_i(\Phi))^{-1}\mathbf{u}_i$ for $i = 1, \dots, n$, where the mobilities $\lambda_1(\Phi), \dots, \lambda_n(\Phi)$ are given by [3]

$$\lambda_i(\Phi) = \frac{d_i^2 \tilde{V}(\phi)}{18 \mu_{\mathrm{f}} \phi_i}, \quad i = 1, \dots, n, \tag{6.9}$$

where μ_{f} is the dynamic viscosity of the pure fluid and $\tilde{V}(\phi)$ is a hindered settling factor. This yields the Darcy-type law

$$\mathbf{u}_i = \lambda_i(\Phi)\phi_i \left(\big(\varrho_i - \varrho(\Phi)\big) g \mathbf{k} - \frac{1-\phi}{\phi} \sigma_{\mathrm{e}}'(\phi) \nabla \phi \right) \tag{6.10}$$

for $i = 1, \dots, n$. Wherever $\phi \le \phi_{\mathrm{c}}$, the solid effective stress $\sigma_{\mathrm{e}}'(\phi)$ vanishes, and (6.10) may be viewed as a generalization of Stokes' law, while for $\phi > \phi_{\mathrm{c}}$, it represents a version of Darcy's law. The hindered settling factor $\tilde{V}(\phi)$ is assumed to satisfy $\tilde{V}(0) = 1$ and $\tilde{V}(1) = 0$ and can, e.g., be chosen as [14] $\tilde{V}(\phi) = (1-\phi)^{N-2}$ for $0 < \phi \le 1$ with $N > 2$, and $\tilde{V}(\phi) = 0$ otherwise.

In one space dimension, the volume average velocity q vanishes for batch settling in a closed vessel. Then, the only equations that actually need to be solved are the continuity equations $\partial_t \phi_i + (\phi_i v_i)_x = 0$, $i = 1, \dots, n$, which now assume the form

$$\partial_t \phi_i + \partial_x \tilde{f}_i(\Phi) = \sum_{j=1}^{n} \partial_x \big(\tilde{B}_{ij}(\Phi) \partial_x \phi_j \big), \quad i = 1, \dots, n, \tag{6.11}$$

with the functions

$$\tilde{f}_i(\Phi) = \phi_i \big(d_i^2 \big(\varrho_i - \varrho(\Phi)\big) - \tilde{S}(\Phi) \big) V(\phi), \quad i = 1, \dots, n, \tag{6.12}$$

where, for convenience, we define

$$V(\phi) := \frac{\tilde{V}(\phi)}{18\mu_{\mathrm{f}}}, \quad \tilde{S}(\Phi) := \sum_{k=1}^{n} \phi_k d_k^2 \big(\varrho_k - \varrho(\Phi)\big)$$

and use the regularized diffusion matrix

$$\tilde{B}_{ij} := \delta_{ij}\nu + \hat{B}_i(\Phi), \quad i,j = 1,\dots,n, \tag{6.13}$$

where $\nu > 0$ is a viscous regularization parameter, and we define

$$\hat{B}_i(\Phi) := \phi_i \left(d_i^2 - \sum_{k=1}^{N} \phi_k d_k^2 \right) \left(\frac{1-\phi}{\phi} \sigma_{\mathrm{e}}'(\phi) \right) V(\phi), \quad i = 1,\dots,n. \tag{6.14}$$

Finally, we mention that a very similar model for polydisperse sedimentation, which equally gives rise to a parabolic system of type (6.11), was proposed and solved numerically in a recent paper by Watson, Barker, and Robins [20]. Summarizing the approaches of [3, 8, 20], one may view the initial-boundary value problem studied herein as a generic model for polydisperse sedimentation.

Remark. The diffusion constant $\nu > 0$ represents the hydrodynamic diffusion of the solids phases. This phenomenon is based on the observation that in reality, solid particles at a given concentration vector Φ do not settle at precisely the same velocity. A detailed account of this variability is given in section 7.4 of [3], but its main effect (as compared to nondiffusive models, e.g., those studied in [3, 4, 5]) is a blurring of otherwise sharp concentration discontinuities. This effect can be most easily modeled by the simple diffusion constant introduced here. In fact, Esipov [8] proposes a similar diffusive model that is approximated by constant diffusivities. The identification of nonlinear but positive diffusion functions accounting for hydrodynamic diffusion is, however, a topic of current research; see, e.g., [5, 7, 11, 12, 19] and the references cited in these papers.

6.2. Initial and boundary conditions. We consider batch settling of a suspension with a given initial composition $\Phi^0(x)$ in a closed cylindrical vessel, where the height of the suspension column has been normalized to 2 and $x \in [-1,1]$ is the corresponding downwards-decreasing depth variable. Thus, we prescribe the initial condition

$$\Phi(x,0) = \Phi^0(x) = \big(\phi_1^0(x),\dots,\phi_n^0(x)\big)^{\mathrm{T}} \in \tilde{\Delta}, \quad x \in [-1,1], \tag{6.15}$$

where

$$\tilde{\Delta} := \big\{ \Phi \in \mathbb{R}^n \,:\, \phi_1 \geq 0,\dots,\phi_n \geq 0,\ \phi_1 + \cdots + \phi_n \leq 1 \big\} \tag{6.16}$$

is the phase space of the original variables. At $x = -1$, the suspension surface is located and at $x = 1$ the vessel bottom is located. Both levels give rise to zero-flux boundary conditions, which means that all solids fluxes through $x = -1$ and $x = 1$ vanish:

$$(\phi_i v_i)|_{x=-1} = (\phi_i v_i)|_{x=1} = 0, \quad i = 1,\dots,n. \tag{6.17}$$

Equations (6.11) represent the solids continuity equations; therefore

$$\phi_i v_i = \tilde{f}_i(\Phi) - \sum_{m=1}^{n} \tilde{B}_{im}(\Phi)\partial_x \phi_m, \quad i = 1,\dots,n, \tag{6.18}$$

and the boundary conditions (6.17) can be written as the zero-flux or Neumann boundary conditions

$$\left(\tilde{f}_i(\Phi) - \sum_{m=1}^{n} \tilde{B}_{im}(\Phi)\partial_x \phi_m \right) \Big|_{x=\pm 1} = 0. \tag{6.19}$$

Thus, (6.11), (6.15), (6.19) is the relevant initial-boundary value problem in our application.

6.3. Transformation to upper-triangular form. The analysis of sections 1–5 applies to our model if we change variables such that the resulting diffusion matrix becomes upper triangular. To this end, we rewrite the model in terms of the new variables $u = (u_1, \dots, u_n)^{\mathrm{T}}$ defined by

$$u_1 := \phi_1, \dots, u_{n-1} := \phi_{n-1}, \quad u_n := 1 - \phi = 1 - (\phi_1 + \cdots + \phi_n). \tag{6.20}$$

The phase space Δ is then as defined in (1.9). With a slight abuse of notation, let us define

$$\varrho(u) = \varrho(\Phi) := u_1(\varrho_1 - \varrho_n) + \cdots + u_{n-1}(\varrho_{n-1} - \varrho_n) + (1 - u_n)\varrho_n + u_n\varrho_{\mathrm{f}}$$

and $S(u) = \tilde{S}(\Phi)$. Noting that the quantity $1 - \phi$ satisfies the equation

$$\begin{aligned} \partial_t(1-\phi) - \partial_x\left(\sum_{i=1}^n \tilde{f}_i(\Phi)\right) &= -\partial_x\left\{\nu\sum_{i=1}^n \partial_x\phi_i + \sum_{i=1}^n \hat{B}_i(\Phi)\left(\sum_{m=1}^n \partial_x\phi_m\right)\right\} \\ &= \nu\partial_x^2(1-\phi) + \partial_x\left(\left[\sum_{i=1}^n \hat{B}_i(\Phi)\right]\partial_x(1-\phi)\right), \end{aligned} \tag{6.21}$$

we then obtain, after the change of variables (6.20),

$$\begin{aligned} f_i(u) &= u_i\big(d_i^2(\varrho_i - \varrho(u)) - S(u)\big)V(1-u_n), \quad i = 1, \dots, n-1, \\ f_n(u) &= -u_n S(u) V(1-u_n), \end{aligned} \tag{6.22}$$

where

$$S(u) := \sum_{i=1}^{n-1} u_i d_i^2\big(\varrho_i - \varrho(u)\big) + \big(1 - (u_1 + \cdots + u_n)\big)d_n^2(\varrho_n - \varrho(u)\big).$$

We easily see that (1.12) is satisfied. Defining

$$d^2(u) := \sum_{i=1}^n \phi_i d_i^2 = \big(1 - (u_1 + \cdots + u_n)\big)d_n^2 + \sum_{i=1}^{n-1} u_i d_i^2,$$

in view of (6.21) and

$$\partial_t\phi_i + \partial_x\tilde{f}_i(\Phi) = \partial_x\left(\nu\partial_x\phi_i - \hat{B}_{in}(\Phi)\partial_x(1-\phi)\right), \quad i = 1, \dots, n-1, \tag{6.23}$$

we see that the new diffusion matrix $(B_{ij})_{1\le i,j\le n}$ is given by

$$\begin{aligned} B_{ii} &= \nu, \quad i = 1, \dots, n-1, \\ B_{in} &= -u_i(d_i^2 - d^2(u))\frac{u_n}{1-u_n}\sigma_{\mathrm{e}}'(1-u_n)V(1-u_n), \quad i = 1, \dots, n-1, \\ B_{nn} &= \nu + d^2(u)\frac{u_n^2}{1-u_n}\sigma_{\mathrm{e}}'(1-u_n)V(1-u_n), \end{aligned} \tag{6.24}$$

and $B_{ij} = 0$ otherwise. Note that the matrix has nonzero entries on its diagonal and in its last column only (as a special case of a triangular matrix). Satisfaction of conditions (1.13) can easily be verified.

The original problem is recast in the new variables, which means that we refer to system (1.1) with the flux vector f and the matrix B given by (6.22) and (6.24), respectively, and use the initial datum

$$u(x,0) = u^0(x) := \left(\phi_1^0(x), \dots, \phi_{n-1}^0(x), 1 - (\phi_1^0(x) + \cdots + \phi_n^0(x))\right)^{\mathrm{T}} \in \Delta, \quad x \in \overline{\Omega},$$

where $\phi_1^0(x), \dots, \phi_n^0(x)$ are the initial solids concentrations. Finally, it is easy to check from (6.19) and (6.21) that for the variables $u_1, \dots, u_n$, the boundary conditions are again the Neumann (zero-flux) conditions

$$\left(f_i(u) - \sum_{m=1}^{n} B_{im}(u) \partial_x u_m \right) \Bigg|_{x=\pm 1} = 0. \tag{6.25}$$

LOCALIZED TIGHT FRAMES ON SPHERES*

F. J. NARCOWICH†, P. PETRUSHEV‡, AND J. D. WARD†

Abstract. In this paper we wish to present a new class of tight frames on the sphere. These frames have excellent pointwise localization and approximation properties. These properties are based on pointwise localization of kernels arising in the spectral calculus for certain self-adjoint operators, and on a positive-weight quadrature formula for the sphere that the authors have recently developed. Improved bounds on the weights in this formula are another by-product of our analysis.

Key words. tight frames, n-sphere, localization

1. Introduction.

Frames were introduced in the 1950s by Duffin and Schaeffer [4] to represent functions via over-complete sets. Let $\mathcal{H}$ be a Hilbert space with norm $\|\cdot\|$ and inner product $\langle\cdot,\cdot\rangle$. In that case, a set $\{\psi_j\}_{j\in\mathcal{J}}$ is a *frame* if there are constants $c, C > 0$ such that for all $f \in \mathcal{H}$

$$c\|f\|^2 \le \sum_{j\in\mathcal{J}} |\langle f, \psi_j\rangle|^2 \le C\|f\|^2.$$

The smallest C and largest c are called upper and lower *frame bounds*. If $C = c$, we say the frame is *tight*. If $C = c = 1$, then the frame is *normalized*, and if in addition $\|\psi_j\| = 1$ for all j, then the frame is an orthonormal basis.

Frames, including tight ones, arise naturally in wavelet analysis on $\mathbb{R}^n$ when continuous wavelet transforms are discretized. They provide a redundancy that helps reduce the effect of noise in data, and they have been constructed, studied, and employed extensively in both theoretical and applied problems [1, 2, 6, 7, 10, 12].

Tight frames are similar in many respects to orthonormal wavelet bases; decomposing and synthesizing a signal or image from known data are tasks carried out with the same set of functions, the ones in the frame or in the basis. A feature that makes one frame preferable to another is simultaneous localization of the frame functions in both space and frequency. Frames with this feature have been successfully developed in $\mathbb{R}^n$ [1, 2].

On $\mathbb{S}^n$, the n-dimensional unit sphere in $\mathbb{R}^{n+1}$, various types of both wavelets and frames have been constructed and used; see [8, 13, 16, 21] for references and more discussion. Tight, well-localized frames are another matter.

The purpose of this paper is to construct and study a class of well-localized, computationally implementable, tight frames on $\mathbb{S}^n$. Central to this construction is a key result of this paper, Theorem 3.5. This result concerns pointwise localization for a

family of kernels for certain operators on $\mathbb{S}^n$; the family depends on a parameter and localization increases as the parameter becomes small. The frame functions, which are compactly supported in the frequency domain, are constructed from such kernels. This construction has an interesting connection to wavelet masks, which we will point out below. Another application of our localization result, one that is essential to turning the frame functions into a tight frame—that is, a hierarchical, multiresolution setting—is an improved positive-weight quadrature formula for $\mathbb{S}^n$, where the weights have known bounds. This quadrature formula is used for discretization purposes. In addition to Theorem 3.5, the main results of this paper are Proposition 5.1, Theorem 5.2, and Corollary 5.3. The first of these concerns the approximation power of the frames, the second shows that the frames are tight, and the third shows that the frame functions have excellent spatial localization.

The frame functions and quadrature formula are of interest in their own right. In particular, they can be used in the construction and characterization of many of the classical Banach spaces, including $L^p(\mathbb{S}^n)$, Besov spaces, and Triebel–Lizorkin spaces [18]. We mention also that the operator-theoretic approach that we use here may provide a foundation for extending our results to other Riemannian manifolds.

Strategy. The best way to view our method for constructing frames is to take an operator-theoretic approach. Let E_λ be the (right-continuous) spectral family for an unbounded, nonnegative, self-adjoint operator L defined on a Hilbert space $\mathcal{H}$. Thus, $\mathsf{L} = \int_{0^-}^{\infty} \lambda d\mathsf{E}_\lambda$. On the sphere $\mathbb{S}^n$, this will be related to the square root of the Laplace–Beltrami operator shifted by a constant. For now, that connection isn't required.

We wish to decompose the spectral family in a way reminiscent of the decomposition of frequency space used by Meyer [10, 12] in connection with the construction of his wavelets. For this, we need a function $a \in C(\mathbb{R})$, with support in $[\frac{1}{2}, 2]$, and satisfying $|a(t)|^2 + |a(2t)|^2 \equiv 1$ on $[\frac{1}{2}, 1]$. Such a function can be easily constructed out of an *orthogonal wavelet mask* m_0 [2, section 8.3]. In fact, if $m_0(\xi) \in C^{k+1}$, then $a(t) := m_0(\pi \log_2(t))$ on $[\frac{1}{2}, 2]$, and 0 otherwise, is a C^k function that satisfies the appropriate criteria.

Define $b \in C(\mathbb{R})$ by

$$b(t) := \begin{cases} 1, & t \le 1, \\ a(t)\overline{\tilde{a}(t)}, & t > 1. \end{cases} \tag{1}$$

Using the properties of a we see that $\sum_{j=-\infty}^{J} |a(t/2^j)|^2 = b(t/2^J)$ if $t > 0$ and is 0 if $t \le 0$. Integrating both sides above with respect to $d\mathsf{E}_\lambda$ and using the spectral calculus for L, we obtain $\sum_{j=-\infty}^{J} a(\mathsf{L}/2^j)a(\mathsf{L}/2^j)^* = b(\mathsf{L}/2^J) - \mathsf{E}_0$. Define the operators,

$$\mathsf{A}_j = a(\mathsf{L}/2^j), \tag{2}$$

$$\mathsf{B}_J := b(\mathsf{L}/2^J), \tag{3}$$

and note that the relationship derived above becomes $\sum_{j=-\infty}^{J} \mathsf{A}_j\mathsf{A}_j^* = \mathsf{B}_J - \mathsf{E}_0$. Finally, it is easy to show that the strong limit of B_J as $J \to \infty$ is I, the identity. Taking limits above then yields $\sum_{j=-\infty}^{\infty} \mathsf{A}_j\mathsf{A}_j^* = \mathsf{I} - \mathsf{E}_0$.

We now can use this identity to define *decomposition* and *reconstruction* operators for $f \in \mathcal{H}$, which are, respectively,

$$f \to w_j = \mathsf{A}_j^* f \text{ and } f = \mathsf{E}_0 f + \sum_{j=-\infty}^{\infty} \mathsf{A}_j w_j.$$

PROPOSITION 1.1. *For any $a \in C(\mathbb{R})$ satisfying the conditions above, the operator frame that we have constructed is tight in the sense that*

$$\|f\|^2 = \|\mathsf{E}_0 f\|^2 + \sum_{j=-\infty}^{\infty} \|\mathsf{A}_j^* f\|^2.$$

In addition, we have that $\langle w_j, w_{j'} \rangle = 0$ for $|j - j'| \geq 2$, where $w_j = \mathsf{A}_j^* f$.

Proof. This follows immediately from the decomposition and reconstruction formulas above, the properties of a and of the spectral family. ∎

Note that the decomposition arrived at above is *nearly* orthogonal. The level j decomposition w_j is *not* orthogonal to $w_{j\pm1}$, but it *is* orthogonal to the decomposition at all other levels.

As we pointed out above, when we deal with the sphere $\mathbb{S}^n$, we will take L proportional to $L_n := \sqrt{\lambda_n^2 - \Delta_{\mathbb{S}^n}}$, where $\lambda_n := \frac{n-1}{2}$. Notation and background pertinent to this operator, spherical harmonics, and related topics can be found in section 2.1.

In section 2.2, we show that with this choice of L the decomposition operator A_j^* is given in terms of a kernel $\overline{A_j}(\xi \cdot \eta)$, $\xi, \eta \in \mathbb{S}^n$, which is a polynomial in $\xi \cdot \eta$. Using the addition theorem for spherical harmonics, one can see that the level j decomposition $w_j(\eta) = \langle f(\xi), A_j(\xi \cdot \eta) \rangle_{\mathbb{S}^n}$ is a finite sum of spherical harmonics.

In the reconstruction phase, we need to find $\mathsf{A}_j w_j(\omega) = \langle w_j(\eta), \overline{A_j}(\omega \cdot \eta) \rangle_{\mathbb{S}^n}$. The integrand in this inner product is also a finite sum of spherical harmonics. At this point, the order of the spherical harmonics is such that we can compute the integral exactly using a quadrature formula introduced in [14, 15] and, in section 4, developed into the tool we need here. The point is that the frame functions have the form $\psi_{j,\xi}(\eta) = \sqrt{c_{j,\xi}} A_j(\eta \cdot \xi)$, where the $c_{j,\xi}$ and $\xi \in X_j$ are weights and nodes for the quadrature formula appropriate to level j. The details are given in section 5.

What makes these frame functions special is that they have excellent pointwise localization properties. These properties follow from the results on pointwise localization of certain kernels, given in section 3.

2. Near-orthogonal spectral decomposition for $\mathbb{S}^n$.

2.1. Background and notation for $\mathbb{S}^n$.

Centers and decompositions of $\mathbb{S}^n$. Let X be a finite set of distinct points in $\mathbb{S}^n$; we will call these the *centers*. There are several important quantities associated with this set: the *mesh norm*, $h_X = \sup_{y \in \mathbb{S}^n} \inf_{\xi \in X} d(\xi, y)$, where $d(\cdot, \cdot)$ is the geodesic distance between points on the sphere; the *separation radius*, $q_X = \frac{1}{2} \min_{\xi \neq \xi'} d(\xi, \xi')$; and the *mesh ratio*, $\rho_X := h_X / q_X \geq 1$.

For $\rho \geq 1$, let $\mathcal{F}_\rho = \mathcal{F}_\rho(\mathbb{S}^n)$ be the family of all sets of centers X with $\rho_X \leq \rho$; we will say that the family $\mathcal{F}_\rho$ is *ρ-uniform*. Unless confusion would arise, we will not indicate $\mathbb{S}^n$, and just use $\mathcal{F}_\rho$ to designate a family. The specific sphere $\mathbb{S}^n$ will be clear from the context. We will also say that a set of centers X is ρ-uniform if $X \in \mathcal{F}_\rho$. It is possible to show that for every $\rho \geq 2$ there exist nonempty ρ-uniform families for any $\mathbb{S}^n$ and that they contain sets of centers X for which h_X becomes arbitrarily small. The result is stated below. For a proof of the facts mentioned here as well as further discussion, see [19, section 2].

PROPOSITION 2.1 (see [19, Proposition 2.1]). *Let $\rho \geq 2$ and let $\mathcal{F}_\rho$ be the corresponding ρ-uniform family. Then, there exists a sequence of sets $X_k \in \mathcal{F}_\rho$, $k = 0, 1, \ldots$, such that the sequence is nested, $X_k \subset X_{k+1}$, and such that at each step the mesh norms satisfy $\frac{1}{4} h_{X_k} < h_{X_{k+1}} \leq \frac{1}{2} h_{X_k}$.*

We will need to consider a decomposition of $\mathbb{S}^n$ into a finite number of nonoverlapping, connected regions R_ξ, each containing an interior point ξ that will serve for function evaluations as well as labeling. For example, if $\mathcal{X}$ is the Voronoi tessellation for a set of centers X, then we may take R_ξ to be the region associated with $\xi \in X$. In any case, we will let X be the set of the ξ's used for labels and $\mathcal{X} = \{R_\xi \subset \mathbb{S}^n \,|\, \xi \in X\}$. In addition, let $\|\mathcal{X}\| = \max_{\xi\in X}\{\mathrm{diam}(R_\xi)\}$. Du, Gunzburger, and Ju [3] construct a very interesting Voronoi tessellation in which $\xi \in X$ is the centroid of $R_\xi \in \mathcal{X}$.

Spherical harmonics. We turn to the situation in which the underlying Hilbert space is $\mathcal{H} = L^2(\mathbb{S}^n)$, with $d\mu$ being the usual measure on the n-sphere. Throughout the paper, we will let $\lambda_n := \frac{n-1}{2}$ and $\{Y_{\ell,m} : \ell = 0, 1, \ldots, m = 1 \ldots d_\ell^n\}$ be the usual orthonormal set of spherical harmonics [17, 24] associated with $\mathbb{S}^n$, where for $n \geq 2$,

$$d_\ell^n = \frac{\ell+\lambda_n}{\lambda_n}\binom{\ell+n-2}{\ell} \overset{\ell\to\infty}{\sim} \frac{\ell^{n-1}}{\lambda_n(n-2)!}. \tag{4}$$

Denote by $\mathcal{H}_\ell$ the span of the spherical harmonics with fixed order ℓ, and let $\Pi_L = \bigoplus_{\ell=0}^L \mathcal{H}_\ell$ be the span of all spherical harmonics of order at most L. The orthogonal projection P_ℓ onto $\mathcal{H}_\ell$ is given by

$$\mathsf{P}_\ell f = \sum_{m=1}^{d_\ell^n} \langle f, Y_{\ell,m}\rangle Y_{\ell,m}. \tag{5}$$

Using the addition formula for spherical harmonics, one can write the kernel for this projection as

$$P_\ell(\xi,\eta) = \sum_{m=1}^{d_\ell^n} Y_{\ell,m}(\xi)\overline{Y_{\ell,m}(\eta)} = \frac{\ell+\lambda_n}{\lambda_n\omega_n} P_\ell^{(\lambda_n)}(\xi\cdot\eta), \tag{6}$$

where $\lambda_n = \frac{n-1}{2}$ and $P_\ell^{(\lambda_n)}$ is the ultraspherical polynomial of order λ_n and degree ℓ. We regard $\mathbb{S}^n$ as being the unit sphere in $\mathbb{R}^{n+1}$, and we let the quantity $\xi\cdot\eta$ denote the usual "dot" product for $\mathbb{R}^{n+1}$.

On the sphere, an operator K with a kernel of the form $K(\xi\cdot\eta)$ can be written as a convolution on $\mathbb{S}^n$; that is, $\mathsf{K}f = K * f$, where

$$K * f(\xi) = \int_{\mathbb{S}^n} K(\xi\cdot\eta) f(\eta) d\mu(\eta).$$

Because of the form of the convolution, these operators commute with rotations. Depending on the properties of the kernel, one may (and will!) apply these operators to spaces other than $L^2(\mathbb{S}^n)$.

The spherical harmonic $Y_{\ell,m}$ is an eigenfunction corresponding to the eigenvalue $-\ell(\ell+n-1) = \lambda_n^2 - (\ell+\lambda_n)^2$ for Laplace–Beltrami operator $\Delta_{\mathbb{S}^n}$ on $\mathbb{S}^n$. It follows that $\ell+\lambda_n$ is an eigenvalue corresponding to the eigenfunctions $Y_{\ell,m}\,, m = 1\ldots d_\ell^n$, of the pseudodifferential operator

$$\mathsf{L}_n := \sqrt{\lambda_n^2 - \Delta_{\mathbb{S}^n}} = \sum_{\ell=0}^\infty (\ell+\lambda_n)\mathsf{P}_\ell. \tag{7}$$

2.2. Operator frames and their kernels on $\mathbb{S}^n$. We now turn to the operators A_j defined in (2), when the underlying Hilbert space is $\mathcal{H} = L^2(\mathbb{S}^n)$ and L is proportional to the self-adjoint operator L_n given by (7). It is convenient to normalize

the L_n's when $n \geq 2$ so that the lowest eigenvalue in the spectrum is in the interval $[1, 2)$. To do that, let $j_n = \log_2\lfloor\lambda_n\rfloor$ for $n \geq 2$ and let $j_1 = 0$. We will work with $\mathsf{L} \to 2^{-j_n}\mathsf{L}_n$. Thus, $\mathsf{A}_j = a(2^{-j-j_n}\mathsf{L}_n)$, where the properties of $a \in C(\mathbb{R})$ are discussed in section 1. The spectral measure for $2^{-j_n}\mathsf{L}_n$ is $d\mathsf{E}_\lambda = \sum_{\ell=0}^\infty \mathsf{P}_\ell \delta\big(\lambda - 2^{-j_n}(\ell+\lambda_n)\big)$, where the P_ℓ's are the projections defined in (5) and have kernels given in (6). We can write the A_j's in kernel form:

$$A_j(\xi\cdot\eta) = \begin{cases} \frac{1}{\pi}\sum_{\ell=1}^\infty a(2^{-j}\ell)\cos(\ell\theta), & n = 1,\ \xi\cdot\eta = \cos\theta, \\ \sum_{\ell=0}^\infty a\left(\frac{\ell+\lambda_n}{2^{j+j_n}}\right)\frac{\ell+\lambda_n}{\lambda_n\omega_n}P_\ell^{(\lambda_n)}(\xi\cdot\eta), & n \geq 2,\ j_n = \lfloor\log_2(\lambda_n)\rfloor. \end{cases} \tag{8}$$

The operator $\mathsf{B}_J = b(2^{-J-j_n}\mathsf{L}_n)$, with b defined in (1), has the kernel

$$B_J(\xi\cdot\eta) = \begin{cases} \frac{1}{2\pi}b(0) + \frac{1}{\pi}\sum_{\ell=1}^\infty b(2^{-J}\ell)\cos(\ell\theta), & n = 1,\ \xi\cdot\eta = \cos\theta \\ \sum_{\ell=0}^\infty b\left(\frac{\ell+\lambda_n}{2^{J+j_n}}\right)\frac{\ell+\lambda_n}{\lambda_n\omega_n}P_\ell^{(\lambda_n)}(\xi\cdot\eta), & n \geq 2,\ j_n = \lfloor\log_2(\lambda_n)\rfloor. \end{cases} \tag{9}$$

Taking into account the support of a, when $n \geq 2$ in these operators it is easy to see that $\mathsf{B}_J = \sum_{j=0}^J \mathsf{A}_j\mathsf{A}_j^*$. For $n = 1$, the projection P_0 enters and $\mathsf{B}_J = \mathsf{P}_0 + \sum_{j=0}^J \mathsf{A}_j\mathsf{A}_j^*$.

We will study and establish various properties of operator kernels similar to these in section 3. In section 5 we will discuss how these give rise to tight frames on $\mathbb{S}^n$ and discuss approximation properties of these frames.

3. Localization of kernels on $\mathbb{S}^n$. We want to study the localization properties of operator kernels related to the Laplace–Beltrami operator $\Delta_{\mathbb{S}^n}$ on the sphere. As we did earlier, let $\mathsf{L}_n := \sqrt{\lambda_n^2 - \Delta_{\mathbb{S}^n}}$ and let $\kappa(t) \in C^k(\mathbb{R})$, with $k \geq \max\{2, n-1\}$, be even and satisfy

$$|\kappa^{(r)}(t)| \leq C_\kappa(1+|t|)^{r-\alpha} \text{ for all } t \in \mathbb{R},\ r = 0, \ldots, k, \tag{10}$$

where $\alpha > n + k$ and $C_\kappa > 0$ are fixed constants. We remark that all compactly supported, even C^k functions satisfy (10), as do even functions in the Schwartz class $\mathcal{S}$. Even functions in $\mathcal{S}$ satisfy (10) for arbitrarily large k and α. Define the family of operators

$$\mathsf{K}_{\varepsilon,n} := \kappa(\varepsilon\mathsf{L}_n) = \sum_{\ell=0}^\infty \kappa(\varepsilon(\ell+\lambda_n))\mathsf{P}_\ell, \quad 0 < \varepsilon \leq 1,$$

along with the associated family of kernels

$$K_{\varepsilon,n}(\underbrace{\xi\cdot\eta}_{\cos\theta}) := \begin{cases} \frac{1}{2\pi}\kappa(0) + \frac{1}{\pi}\sum_{\ell=1}^\infty \kappa(\varepsilon\ell)\cos\ell\theta, & n = 1, \\ \sum_{\ell=0}^\infty \kappa(\varepsilon(\ell+\lambda_n))\frac{\ell+\lambda_n}{\lambda_n\omega_n}P_\ell^{(\lambda_n)}(\cos\theta), & n \geq 2, \end{cases} \tag{11}$$

where $\cos\theta = \xi\cdot\eta$ and $0 < \varepsilon \leq 1$.

Our aim in this section is to obtain uniform bounds on the kernel $K_\varepsilon(\xi\cdot\eta)$ for small ε, with the bounds being explicitly dependent on ε.

The simple estimates given below in section 3.1 on the terms in the series used to define the kernels $K_{\varepsilon,n}$ confirm that, under mild conditions, these series are uniformly convergent. Let $n \geq 2$. Consider the ultraspherical identity [25, (4.7.14)] with $\lambda = \lambda_n$, $\frac{d}{dx}P_\ell^{(\lambda_n)}(x) = 2\lambda_n P_{\ell-1}^{(\lambda_n+1)}(x)$. Since $\lambda_n + 1 = \lambda_{n+2}$ and $\omega_n = \lambda_{n+2}\omega_{n+2}/\pi$, we have, for $\ell \geq 1$,

$$\frac{d}{dx}\left\{\left(\frac{\ell+\lambda_n}{\lambda_n\omega_n}\right)P_\ell^{(\lambda_n)}(x)\right\} = 2\pi\left(\frac{\ell-1+\lambda_{n+2}}{\lambda_{n+2}\omega_{n+2}}\right)P_{\ell-1}^{(\lambda_{n+2})}(x).$$

Multiply both sides by $\kappa(\varepsilon(\ell+\lambda_n))$ and sum on ℓ from 1 to ∞. Adjust the summation index on the right side and on the left use $\frac{d}{dx}P_0^{(\lambda_n)}(x) = 0$ to arrive at the identity below, which holds even when $n = 1$:

$$\frac{d}{dx}K_{\varepsilon,n}(x) = 2\pi K_{\varepsilon,n+2}(x). \tag{12}$$

3.1. Convergence issues and an L^∞ estimate on $K_{\varepsilon,n}$. The series defining the kernels are uniformly and absolutely convergent, by the M-test. This is easy to see for $n = 1$. For $n \geq 2$, start with the bound [25, (4.7.3) and (7.33.1)]

$$|P_\ell^{(\lambda_n)}(\cos\theta)| \leq \binom{\ell+n-2}{\ell} = P_\ell^{(\lambda_n)}(1), \tag{13}$$

and note that

$$\frac{\ell+\lambda_n}{\lambda_n}\binom{\ell+n-2}{\ell} \leq 2\binom{\ell+n-1}{\ell} \leq 2(1+\ell)^{n-1}.$$

From this and the assumptions on $\kappa(t)$, the terms in the series satisfy the bound

$$|\kappa(\varepsilon(\ell+\lambda_n))|\frac{\ell+\lambda_n}{\lambda_n\omega_n}\big|P_\ell^{(\lambda_n)}(\cos\theta)\big| \leq \frac{2\,C_\kappa(1+\ell)^{n-1}}{\omega_n(1+\varepsilon(\ell+\lambda_n))^\alpha} \leq \frac{2\,C_\kappa\varepsilon^{-(n-1)}}{\omega_n(1+\varepsilon\ell)^{\alpha-n+1}},$$

which suffices for the M-test, since $\alpha > n+k \geq n+2$ implies the series on the right above is convergent. Note that the estimate holds even when $n = 1$, provided the terms on the right are properly adjusted.

It is easy to take this a step further and obtain an estimate on $\|K_{\varepsilon,n}\|_\infty$, which we will need later on anyway.

PROPOSITION 3.1. *If κ satisfies* (10)*, then*

$$\|K_{\varepsilon,n}\|_\infty \leq \frac{3\,C_\kappa}{\omega_n}\varepsilon^{-n}. \tag{14}$$

Proof. From the series definition of the kernel and the estimate on each term, we get this chain of inequalities:

$$\begin{aligned}\|K_{\varepsilon,n}\|_\infty &\leq \sum_{\ell=0}^{\infty}\frac{2\,C_\kappa\varepsilon^{-(n-1)}}{\omega_n(1+\varepsilon\ell)^{\alpha-n+1}}\\ &\leq \frac{2\,C_\kappa\varepsilon^{-(n-1)}}{\omega_n} + \int_0^\infty \frac{2\,C_\kappa\varepsilon^{-(n-1)}du}{\omega_n(1+\varepsilon u)^{\alpha-n+1}}\\ &\leq \frac{2\,C_\kappa\varepsilon^{-n}}{\omega_n}\left(\varepsilon + \frac{1}{\alpha-n}\right)\end{aligned}$$

Using $\varepsilon \leq 1$ and $\alpha - n > k \geq 2$ in the previous inequality and simplifying, we obtain (14). ∎

3.2. Integral representations. We now wish to obtain integral representations for the kernels $K_\varepsilon(\cos\theta)$. We begin with the Dirichlet–Mehler integral representation for the Gegenbauer polynomials [5, p. 177],

$$P_\ell^{(\lambda)}(\cos\theta) = \frac{2^\lambda\Gamma(\lambda+\frac{1}{2})\Gamma(\ell+2\lambda)}{\sqrt{\pi}\ell!\Gamma(\lambda)\Gamma(2\lambda)(\sin\theta)^{2\lambda-1}}\int_\theta^\pi \frac{\cos\big((\ell+\lambda)\varphi - \lambda\pi\big)}{(\cos\theta-\cos\varphi)^{1-\lambda}}d\varphi,$$

which holds for any real $\lambda > 0$. We will take $\lambda = \lambda_n = \frac{n-1}{2}$, with $n \geq 2$ throughout this section. Multiply both sides of the previous equation by $\frac{\ell+\lambda_n}{\lambda_n \omega_n}$ and then simplify to get

$$\frac{\ell+\lambda_n}{\lambda_n\omega_n} P_\ell^{(\lambda_n)}(\cos\theta) = \frac{\gamma_n(\ell+\lambda_n)(\ell+n-2)!}{\ell!(\sin\theta)^{n-2}} \int_\theta^\pi \frac{\cos\big((\ell+\lambda_n)\varphi - \lambda_n\pi\big)}{(\cos\theta-\cos\varphi)^{1-\lambda_n}} d\varphi, \tag{15}$$

where

$$\gamma_n := \frac{2^{\lambda_n}\Gamma(\lambda_n+\frac{1}{2})}{\sqrt{\pi}\lambda_n\omega_n\Gamma(\lambda_n)\Gamma(2\lambda_n)}. \tag{16}$$

Using the expression on the right in (15) in the series definition of $K_{\varepsilon,n}$, we get this representation:

$$K_{\varepsilon,n}(\cos\theta) = \frac{\gamma_n}{(\sin\theta)^{n-2}} \int_\theta^\pi \frac{C_{\varepsilon,n}(\varphi)}{(\cos\theta-\cos\varphi)^{1-\lambda_n}} d\varphi, \tag{17}$$

where $C_{\varepsilon,n}$ is given by the series

$$\begin{aligned} &C_{\varepsilon,n}(\varphi) \\ &:= \sum_{\ell=0}^\infty \kappa(\varepsilon(\ell+\lambda_n)) \frac{(\ell+\lambda_n)(\ell+n-2)!}{\ell!} \begin{cases} \sin(\lambda_n\pi)\sin(\ell+\lambda_n)\varphi, & n \text{ even}, \\ \cos(\lambda_n\pi)\cos(\ell+\lambda_n)\varphi, & n \text{ odd}. \end{cases} \end{aligned} \tag{18}$$

We want to put this series in a more convenient form. To begin, the factor $\frac{(\ell+\lambda_n)(\ell+n-2)!}{\ell!}$ is the product $(\ell+\lambda_n)(\ell+n-2)(\ell+n-3)\cdots(\ell+1)$, which can be rewritten as

$$\frac{(\ell+\lambda_n)(\ell+n-2)!}{\ell!} = \prod_{r=1}^{\lfloor\frac{n-1}{2}\rfloor} \big((\ell+\lambda_n)^2 - (\lambda_n-r)^2\big) \times \begin{cases} \ell+\lambda_n, & \text{even}, \\ 1, & \text{odd}. \end{cases}$$

From this, we see that if we define the degree $n-1$ polynomial

$$Q_{n-1}(z) := \prod_{r=1}^{\lfloor\frac{n-1}{2}\rfloor} \big(z^2 - (\lambda_n-r)^2\big) \times \begin{cases} z\sin(\lambda_n\pi), & n \text{ even}, \\ \cos(\lambda_n\pi), & n \text{ odd}, \end{cases} \tag{19}$$

then we have that

$$C_{\varepsilon,n}(\varphi) = \sum_{\ell=0}^\infty \kappa(\varepsilon(\ell+\lambda_n)) Q_{n-1}(\ell+\lambda_n) \begin{cases} \sin(\ell+\lambda_n)\varphi, & n \text{ even}, \\ \cos(\ell+\lambda_n)\varphi, & n \text{ odd}. \end{cases} \tag{20}$$

We want to make a few observations about the polynomial Q_{n-1}. First, by direct calculation we have that $Q_{n-1}(-z) = (-1)^{n-1}Q_{n-1}(z)$, so that Q_{n-1} is an even function for odd n and an odd function for even n. Second, the zeros of Q_{n-1} are located at $\pm(\lambda_n - r)$ for $r = 1, \ldots, \lfloor\frac{n-1}{2}\rfloor$. This means that the function

$$g(t) := \kappa(\varepsilon t) Q_{n-1}(t) \begin{cases} \sin(t\varphi), & n \text{ even}, \\ \cos(t\varphi), & n \text{ odd}, \end{cases}$$

is even in t and has its zeros at $t = \pm(\lambda_n - r)$ for $r = 1\ldots, \lfloor\lambda_n\rfloor$. In addition, we have defined g above so that from (20) we have $C_{\varepsilon,n}(\varphi) = \sum_{\ell=0}^\infty g(\ell+\lambda_n)$.

We want to apply the Poisson summation formula (PSF),

$$\sum_{\mu\in\mathbb{Z}} f(\mu) = \sum_{\nu\in\mathbb{Z}} \hat{f}(2\pi\nu), \quad \hat{f}(\omega) = \int_{\mathbb{R}} f(t)e^{-i\omega t}dt,$$

which holds for "nice" f, to $f(t) = g(t+\lambda_n)$. Using the evenness of g and what we said about its zeros, we see that the left side of the PSF becomes

$$\sum_{\mu\in\mathbb{Z}} g(\mu+\lambda_n) = 2\sum_{\ell=0}^{\infty} g(\ell+\lambda_n) = 2C_{\varepsilon,n}(\varphi).$$

Employing elementary properties of the Fourier transform, we can show that

$$\hat{f}(\omega) = e^{i\lambda_n\omega}\hat{g}(\omega) = \varepsilon^{-1}e^{i\lambda_n\omega}Q_{n-1}(i\tfrac{d}{d\omega})\hat{\kappa}(\tfrac{\varphi+\omega}{\varepsilon}),$$

and so the right side of the PSF is

$$\begin{aligned}\sum_{\nu\in\mathbb{Z}} \hat{f}(2\pi\nu) &= \varepsilon^{-1}\sum_{\nu\in\mathbb{Z}} e^{2\pi\nu i\lambda_n}Q_{n-1}(i\tfrac{d}{d\omega})\hat{\kappa}(\tfrac{\varphi+\omega}{\varepsilon})|_{\omega=2\pi\nu}\\ &= \varepsilon^{-1}\sum_{\nu\in\mathbb{Z}}(-1)^{(n-1)\nu}Q_{n-1}(i\tfrac{d}{d\varphi})\hat{\kappa}(\tfrac{\varphi+2\pi\nu}{\varepsilon}).\end{aligned}$$

Equating the two sides of the PSF and dividing by 2, we arrive at the following result.

PROPOSITION 3.2. *If κ satisfies* (10)*, then for $n \geq 2$* (17) *holds with $C_{\varepsilon,n}$ given by*

$$C_{\varepsilon,n}(\varphi) = (2\varepsilon)^{-1}\sum_{\nu\in\mathbb{Z}}(-1)^{(n-1)\nu}Q_{n-1}(i\tfrac{d}{d\varphi})\hat{\kappa}(\tfrac{\varphi+2\pi\nu}{\varepsilon}). \tag{21}$$

In addition, for the $n = 1$ case we have

$$K_{\varepsilon,1}(\cos\theta) = (2\pi\varepsilon)^{-1}\sum_{\nu\in\mathbb{Z}}\hat{\kappa}(\tfrac{\theta+2\pi\nu}{\varepsilon}). \tag{22}$$

3.3. Estimates on $C_{\varepsilon,n}$. We need to obtain bounds on the kernels $C_{\varepsilon,n}$ from the previous section. The key to obtaining these bounds is this result.

LEMMA 3.3. *Let κ satisfy* (10)*. If $0 \leq j \leq n-1$ and $0 \leq r \leq k$ are integers, then $\frac{d^r}{dt^r}\{t^j\kappa\} \in L^1$ and $|\omega|^r|\hat{\kappa}^{(j)}(\omega)| \leq \|\frac{d^r}{dt^r}\{t^j\kappa\}\|_{L^1}$.*

Proof. Since $\kappa \in C^k$, the derivative $\frac{d^r}{dt^r}\{t^j\kappa\}$ is a linear combination of terms of the form $t^p\kappa^{(q)}$, each of which is bounded by a multiple of $(1+|t|)^{p+q-\alpha}$. This is in L^1 because $\alpha - p - q > \alpha - (n-1) - k > 1$. This allows us to apply standard properties of the Fourier transform to obtain the formula $(-i)^{r+j}\omega^r\hat{\kappa}^{(j)}(\omega) = \widehat{\frac{d^r}{dt^r}\{t^j\kappa\}}$, which immediately implies the inequality. ∎

Consider the function $\left(\frac{\varphi+\omega}{\varepsilon}\right)^r Q_{n-1}(i\frac{d}{d\varphi})\hat{\kappa}(\frac{\varphi+\omega}{\varepsilon}) = \sum_{j=0}^{n-1}\varepsilon^{-j}q_{j,n}\left(\frac{\varphi+\omega}{\varepsilon}\right)^r\hat{\kappa}^{(j)}(\frac{\varphi+\omega}{\varepsilon})$, where $Q_{n-1}(z) = \sum_{j=0}^{n-1} q_{j,n}z^j$ is defined in (19). From Lemma 3.3, we have that

$$\begin{aligned}\left|\left(\tfrac{\varphi+\omega}{\varepsilon}\right)^r Q_{n-1}(i\tfrac{d}{d\varphi})\hat{\kappa}(\tfrac{\varphi+\omega}{\varepsilon})\right| &\leq \textstyle\sum_{j=0}^{n-1}\varepsilon^{-j}|q_{j,n}|\,\|\frac{d^r}{dt^r}\{t^j\kappa\}\|_{L^1}\\ &\leq B_{n,k,\kappa}\varepsilon^{-(n-1)},\end{aligned}$$

where

$$B_{n,k,\kappa} := \left(\sum_{j=0}^{n-1} |q_{n,j}|\right) \max_{j<n,\, r\le k} \| \tfrac{d^r}{dt^r} \left\{ t^j \kappa \right\} \|_{L^1}. \tag{23}$$

Adding the inequalities for $r = 0$ and $r = k$ and manipulating the result, we get that

$$\left| Q_{n-1}(i\tfrac{d}{d\varphi}) \hat{\kappa}(\tfrac{\varphi+\omega}{\varepsilon}) \right| \le \frac{2B_{n,k,\kappa}\varepsilon^{-(n-1)}}{1 + \left|\frac{\varphi+\omega}{\varepsilon}\right|^k}.$$

We can use this inequality in conjunction with the series for $C_{\varepsilon,n}$ in (21) to arrive at the bound

$$|C_{\varepsilon,n}(\varphi)| \le (2\varepsilon)^{-1} \sum_{\nu\in\mathbb{Z}} \frac{2B_{n,k,\kappa}\varepsilon^{-(n-1)}}{1 + \left|\frac{\varphi+2\pi\nu}{\varepsilon}\right|^k} = \sum_{\nu\in\mathbb{Z}} \frac{B_{n,k,\kappa}\varepsilon^{-n}}{1 + \left|\frac{\varphi+2\pi\nu}{\varepsilon}\right|^k}, \tag{24}$$

which holds for all $\varphi \in \mathbb{R}$ and $0 < \varepsilon \le 1$. If we restrict φ to be in the interval $[0, \pi]$, then the dominant term in the series on the right comes from $\nu = 0$. The other terms are each bounded above by $B_{n,k,\kappa}\varepsilon^{k-n}((2|\nu| - 1)\pi)^{-k}$. Summing them and then estimating the resulting series by an integral gives us

$$\sum_{\nu\in\mathbb{Z},\nu\neq 0} \frac{B_{n,k,\kappa}\varepsilon^{-n}}{1 + \left|\frac{\varphi+2\pi\nu}{\varepsilon}\right|^k} \le B_{n,k,\kappa}\varepsilon^{k-n}\pi^{-k}\frac{2k-1}{k-1}.$$

Multiply top and bottom on the left above by $1 + \left(\frac{\varphi}{\varepsilon}\right)^k$ and use $0 \le \varphi \le \pi$ and $k \ge 2$ to get

$$\sum_{\nu\in\mathbb{Z},\nu\neq 0} \frac{B_{n,k,\kappa}\varepsilon^{-n}}{1 + \left|\frac{\varphi+2\pi\nu}{\varepsilon}\right|^k} \le \frac{6B_{n,k,\kappa}\varepsilon^{-n}}{1 + \left(\frac{\varphi}{\varepsilon}\right)^k}.$$

Combining this bound with that from (24) yields the result below.

PROPOSITION 3.4. *Let κ satisfy* (10)*, with $k \ge 2$ and $n \ge 2$. If $0 \le \varphi \le \pi$, then the kernel $C_{\varepsilon,n}$ defined in* (18) *satisfies the bound*

$$|C_{\varepsilon,n}(\varphi)| \le \frac{7B_{n,k,\kappa}\varepsilon^{-n}}{1 + \left(\frac{\varphi}{\varepsilon}\right)^k}. \tag{25}$$

In addition, for the case $n = 1$, we have

$$|K_{\varepsilon,1}(\cos\theta)| \le \frac{7B_{1,k,\kappa}\varepsilon^{-1}}{1 + \left(\frac{\theta}{\varepsilon}\right)^k}. \tag{26}$$

Proof. Only the second inequality requires comment. The proof we gave works for the $n = 1$ case because it has the form given in (22), which is essentially the same as that for the $C_{\varepsilon,n}$'s. ∎

3.4. Estimates on $K_{\varepsilon,n}$. We now turn to obtaining explicit bounds on the ΨDO kernels $K_{\varepsilon,n}$ similar to the bound on $K_{\varepsilon,1}$ in (26). From the integral representation in (17) and the bound on $C_{\varepsilon,n}$, we have that

$$|K_{\varepsilon,n}(\cos\theta)| \le \frac{7B_{n,k,\kappa}\gamma_n\varepsilon^{-n}}{(\sin\theta)^{n-2}} \int_\theta^\pi \frac{(\cos\theta - \cos\varphi)^{\frac{n-3}{2}} d\varphi}{1 + \left(\frac{\varphi}{\varepsilon}\right)^k}. \tag{27}$$

The two values of θ that present difficulties are $\theta = 0$ and $\theta = \pi$. The form of the inequality above is adequate for the $\theta = 0$ case, but needs to be reformulated for the $\theta = \pi$ case. To do that, we begin by denoting the angle supplementary to an angle α by $\tilde{\alpha}$, so throughout this section we will let $\tilde{\theta} = \pi - \theta$ and $\tilde{\varphi} = \pi - \varphi$. Changing variables in the integral on the right above and using $\sin\tilde{\alpha} = \sin\alpha$ and $\cos\tilde{\alpha} = -\cos\alpha$, we have the following reformulation of (27):

$$|K_{\varepsilon,n}(\cos\theta)| \le \frac{7B_{n,k,\kappa}\gamma_n\varepsilon^{-n}}{(\sin\tilde{\theta})^{n-2}} \int_0^{\tilde{\theta}} \frac{(\cos\tilde{\varphi} - \cos\tilde{\theta})^{\frac{n-3}{2}} d\tilde{\varphi}}{1 + \left(\frac{\pi-\tilde{\varphi}}{\varepsilon}\right)^k}. \tag{28}$$

The next step is to bound both of these integrals. Recall the sum-to-product identity, $\cos\alpha - \cos\beta \equiv 2\sin\frac{\alpha+\beta}{2}\sin\frac{\beta-\alpha}{2}$, which holds for all α and β. Assuming that $\pi \ge \beta > \alpha \ge \pi/2$ and using the fact that $\frac{\sin t}{t}$ is decreasing for $0 \le t \le \pi$, we have that

$$6 < 8\frac{\sin(3\pi/4)}{3\pi/4}\frac{\sin(\pi/4)}{\pi/4} \le \frac{\cos\alpha - \cos\beta}{\beta^2 - \alpha^2} = 8\frac{\sin\frac{\alpha+\beta}{2}}{\frac{\alpha+\beta}{2}}\frac{\sin\frac{\beta-\alpha}{2}}{\frac{\beta-\alpha}{2}} \le 8,$$

and so

$$\left(\frac{\cos\alpha - \cos\beta}{\beta^2 - \alpha^2}\right)^{\frac{n-3}{2}} \le 2^{\frac{3(n-3)}{2}} \times \begin{cases} \frac{2}{\sqrt{3}}, & n = 2, \\ 1, & n \ge 3 \end{cases} \le 2 \cdot 2^{\frac{3(n-3)}{2}}. \tag{29}$$

Assume that $\varepsilon \le \theta \le \pi/2$, and apply (29) to (27) to get the following chain of inequalities:

$$\begin{aligned} |K_{\varepsilon,n}(\cos\theta)| &\le \frac{14 \cdot 2^{\frac{3(n-3)}{2}} B_{n,k,\kappa}\gamma_n\varepsilon^{-n}}{(\sin\theta)^{n-2}} \int_\theta^\pi \frac{(\theta^2 - \varphi^2)^{\frac{n-3}{2}} d\varphi}{1 + \left(\frac{\varphi}{\varepsilon}\right)^k} \\ &\le 14 \cdot 2^{\frac{3(n-3)}{2}} B_{n,k,\kappa}\gamma_n\varepsilon^{-n} \left(\frac{\theta}{\sin\theta}\right)^{n-2} \int_1^{\pi/\theta} \frac{(t^2-1)^{\frac{n-3}{2}} dt}{1 + (\theta/\varepsilon)^k t^k} \\ &\le \frac{14 \cdot 2^{\frac{3(n-3)}{2}} B_{n,k,\kappa}\gamma_n\varepsilon^{-n}(\pi/2)^{n-2}}{(\frac{\theta}{\varepsilon})^k} \int_1^\infty \frac{(t^2-1)^{\frac{n-3}{2}} dt}{t^k}. \end{aligned}$$

Use $2(\theta/\varepsilon)^k \ge 1 + (\theta/\varepsilon)^k$, change variables of integration from $t \to 1/t$, and note that because $k \ge \max\{2, n-1\} \ge n-1$, the resulting integral on the right is bounded above by $\int_0^1 (1-t^2)^{\frac{n-3}{2}} dt = 2^{n-3}\Gamma(\lambda_n)^2/\Gamma(2\lambda_n)$ [26, p. 255]. After simplifying, we arrive at this estimate:

$$|K_{\varepsilon,n}(\cos\theta)| \le \frac{14 \cdot 2^{\frac{3(n-3)}{2}} \pi^{n-2} B_{n,k,\kappa}\gamma_n\Gamma(\lambda_n)^2/\Gamma(2\lambda_n)}{1 + (\frac{\theta}{\varepsilon})^k} \varepsilon^{-n}.$$

The messy quantity in the numerator can be simplified considerably. This requires employing the definition of γ_n in (16), the formula for ω_n, the familiar properties of the Γ-function, along with the less familiar duplication formula [26, p. 240], $\sqrt{\pi}\Gamma(2z) = 2^{2z-1}\Gamma(z)\Gamma(z+\frac{1}{2})$, and manipulating the expressions involved. The result is that

$$2^{\frac{3(n-3)}{2}} \pi^{n-2}\gamma_n\Gamma(\lambda_n)^2/\Gamma(2\lambda_n) = \frac{\omega_{n-1}}{4\sqrt{\pi}}, \ \omega_{n-1} = \frac{2\pi^{\frac{n}{2}}}{\Gamma(\frac{n}{2})}.$$

Thus we can rewrite the previous inequality, which holds for $\varepsilon \le \theta \le \pi/2$, as

$$|K_{\varepsilon,n}(\cos\theta)| \le \frac{7\omega_{n-1}B_{n,k,\kappa}}{2\sqrt{\pi}(1+(\frac{\theta}{\varepsilon})^k)}\varepsilon^{-n}.$$

If we now apply (29) to (28), with $0 \le \tilde{\theta} \le \pi/2$ (or, equivalently, $\pi/2 \le \theta \le \pi$), then

$$\begin{aligned}|K_{\varepsilon,n}(\cos\theta)| &\le \frac{7B_{n,k,\kappa}\gamma_n\varepsilon^{-n}}{(\sin\tilde{\theta})^{n-2}}\int_0^{\tilde{\theta}}\frac{(\tilde{\theta}^2-\tilde{\varphi}^2)^{\frac{n-3}{2}}d\tilde{\varphi}}{1+\left(\frac{\pi-\tilde{\varphi}}{\varepsilon}\right)^k}\\ &\le \frac{14\cdot 2^{\frac{3(n-3)}{2}}B_{n,k,\kappa}\gamma_n\varepsilon^{-n}}{(1+\left(\frac{\theta}{\varepsilon}\right)^k)(\sin\tilde{\theta})^{n-2}}\int_0^{\tilde{\theta}}(\tilde{\theta}^2-\tilde{\varphi}^2)^{\frac{n-3}{2}}d\tilde{\varphi}.\end{aligned}$$

Carrying out manipulations analogous to those for the previous case, we obtain

$$|K_{\varepsilon,n}(\cos\theta)| \le \frac{7\omega_{n-1}B_{n,k,\kappa}}{4\sqrt{\pi}(1+(\frac{\theta}{\varepsilon})^k)}\varepsilon^{-n}.$$

The final case concerns $0 \le \theta \le \varepsilon$. For such θ, we have, from the L^∞ bound in (14), that

$$|K_{\varepsilon,n}(\cos\theta)| \le \frac{3\,C_\kappa}{\omega_n}\varepsilon^{-n} \le \frac{3\,C_\kappa}{\omega_n}\left(\frac{1+(\frac{\theta}{\varepsilon})^k}{1+(\frac{\theta}{\varepsilon})^k}\right)\varepsilon^{-n} \le \frac{6\,C_\kappa}{\omega_n(1+(\frac{\theta}{\varepsilon})^k)}\varepsilon^{-n},$$

which, when combined with (22) for $n=1$, gives us the main result of this section.

THEOREM 3.5. *Let κ satisfy* (10)*, with $k \ge \max\{2, n-1\}$. If $0 \le \theta \le \pi$, then the kernel $K_{\varepsilon,n}$ satisfies the bound*

$$|K_{\varepsilon,n}(\cos\theta)| \le \frac{\beta_{n,k,\kappa}}{1+(\frac{\theta}{\varepsilon})^k}\varepsilon^{-n}, \tag{30}$$

where

$$\beta_{n,k,\kappa} := \begin{cases} 7B_{1,k,\kappa} & \text{if } n=1,\\ \max\left\{\frac{6\,C_\kappa}{\omega_n}, \frac{7\omega_{n-1}B_{n,k,\kappa}}{2\sqrt{\pi}}\right\} & \text{if } n \ge 2.\end{cases} \tag{31}$$

We conclude this section with an application of this theorem to obtaining a bound on the L^1 norm of $K_{\varepsilon,n}(\xi\cdot\eta)$, with η fixed. By the Funk–Hecke formula [17, Theorem 6], this norm is given by

$$\int_{\mathbb{S}^n}|K_{\varepsilon,n}(\xi\cdot\eta)|d\mu(\xi) = \omega_{n-1}\int_0^\pi |K_{\varepsilon,n}(\cos\theta)|\sin^{n-1}\theta\,d\theta,$$

which is of course independent of η. For that reason we will drop any reference to η and denote the norm by $\|K_{\varepsilon,n}\|_1$. Here is the bound we want.

COROLLARY 3.6. *Let $n \ge 1$. If κ satisfies* (10)*, with $k > \max\{2, n\}$, then*

$$\|K_{\varepsilon,n}\|_1 \le 2\omega_{n-1}\beta_{n,k,\kappa}.$$

Proof. By Theorem 3.5 and the remarks above, we have

$$\|K_{\varepsilon,n}\|_1 \le \omega_{n-1}\int_0^\pi |K_{\varepsilon,n}(\cos\theta)|\sin^{n-1}\theta\,d\theta \le \beta_{n,k,\kappa}\omega_{n-1}\varepsilon^{-n}\int_0^\pi \frac{\sin^{n-1}\theta\,d\theta}{1+(\frac{\theta}{\varepsilon})^k}.$$

The integral on the right side above can be estimated this way:

$$\begin{aligned}\int_0^\pi \frac{\sin^{n-1}\theta\,d\theta}{1+(\frac{\theta}{\varepsilon})^k} &< \varepsilon^n\int_0^{\pi/\varepsilon}\frac{t^{n-1}dt}{1+t^k}\\ &< \varepsilon^n\left\{\int_0^1 t^{n-1}dt + \int_1^\infty \frac{dt}{t^{k+1-n}}\right\} < 2\varepsilon^n.\end{aligned}$$

The corollary then follows immediately from the estimate. ∎

3.5. Operator properties of $\mathsf{K}_{\varepsilon,n}$. We now turn to the operator properties of $\mathsf{K}_{\varepsilon,n}$. Our first result is calculating the norm of the map of $\mathsf{K}_{\varepsilon,n} : L^p \to L^q$. After that we will prove a lemma showing that for certain κ the operator $\mathsf{K}_{\varepsilon,n}$ will be a reproducing kernel on Π_L. We will close the section with a result showing that for such κ and $\varepsilon \le (L+\lambda_n)^{-1}$ the norm of $f - \mathsf{K}_{\varepsilon,n}f$ is comparable to the distance from f to Π_L in appropriate norms.

THEOREM 3.7. *If κ satisfies* (10)*, with $k > \max\{2,n\}$, then, for all $1 \le p \le \infty$ and $1 \le q \le \infty$, the operator $\mathsf{K}_{\varepsilon,n}\colon L^p(\mathbb{S}^n) \to L^q(\mathbb{S}^n)$ is bounded and its norm satisfies*

$$\|\mathsf{K}_{\varepsilon,n}\|_{p,q} \le 2\omega_{n-1}\beta_{n,k,\kappa}(4\omega_{n-1}\varepsilon^n)^{-(\frac{1}{p}-\frac{1}{q})_+},$$

where $\beta_{n,k,\kappa}$ is defined in (31) *and $(x)_+ = x$ for $x > 0$ and $(x)_+ = 0$ otherwise.*

Proof. The operators are all of the form $K_{\varepsilon,n} * f$ and so, for the (p,q) pairs $(1,1)$, (∞,∞), $(\infty,1)$, all satisfy $\|K_{\varepsilon,n} * f\|_q \le \|K_{\varepsilon,n}\|_1\|f\|_p$. By the Riesz–Thorin theorem [28, p. 95] and Corollary 3.6, we then have for $1 \le q \le p \le \infty$

$$\|\mathsf{K}_{\varepsilon,n}\|_{p,q} \le \|K_{\varepsilon,n}\|_1 \le 2\omega_{n-1}\beta_{n,k,\kappa}.$$

For the pair $(1,\infty)$, we have $\|K_{\varepsilon,n} * f\|_\infty \le \|K_{\varepsilon,n}\|_\infty\|f\|_1$. By (14) and (31), we have $\|K_{\varepsilon,n}\|_\infty \le \frac{1}{2}\beta_{n,k,\kappa}\varepsilon^{-n}$, and so $\|K_{\varepsilon,n} * f\|_\infty \le \frac{1}{2}\beta_{n,k,\kappa}\varepsilon^{-n}\|f\|_1$. Apply the Riesz–Thorin theorem to the pairs (p,q), where $\frac{1}{p} = (1-t)\alpha + t$ and $\frac{1}{q} = (1-t)\alpha$, where $0 < t < 1$ and $0 < \alpha < 1$, $(\frac{1}{\alpha},\frac{1}{\alpha})$ and $(1,\infty)$ to get

$$\|\mathsf{K}_{\varepsilon,n}\|_{p,q} \le (2\beta_{n,k,\kappa}\omega_{n-1})^{1-t}\left(\frac{1}{2}\beta_{n,k,\kappa}\varepsilon^{-n}\right)^t = 2\omega_{n-1}\beta_{n,k,\kappa}(4\omega_{n-1}\varepsilon^n)^{-t}.$$

Since $\frac{1}{p} = (1-t)\alpha + t = \frac{1}{q} + t$, $t = \frac{1}{p} - \frac{1}{q}$. Thus, for $q > p$, we have

$$\|\mathsf{K}_{\varepsilon,n}\|_{p,q} \le 2\omega_{n-1}\beta_{n,k,\kappa}(4\omega_{n-1}\varepsilon^n)^{-(\frac{1}{p}-\frac{1}{q})}.$$

Putting the last inequality together with that for $q \le p$ yields the result. ∎

The following lemma is obvious.

LEMMA 3.8. *Let $L > 0$ be an integer and let $0 < \varepsilon \le (L+\lambda_n)^{-1}$. If κ satisfies* (10)*, with $k \ge \max\{2,n-1\}$, and if $\kappa(t) \equiv 1$ on $[0,1]$, then $K_{\varepsilon,n}(\xi\cdot\eta)$ is a reproducing kernel on Π_L, the space of spherical harmonics having degree at most L.*

Remark 3.9. Let $L > 0$ be an integer. If we choose ε so that $L = \lfloor \varepsilon^{-1} - \lambda_n \rfloor$, then by combining the previous theorem and lemma we get a familiar result about harmonic polynomials: *If $S \in \Pi_L$, then $\|S\|_q \le C_n L^{n(\frac{1}{p}-\frac{1}{q})_+}\|S\|_p$.*

We let $E_L(f)_p$ denote the distance of $f \in L^p(\mathbb{S}^n)$ to Π_L, i.e.,

$$E_L(f)_p := \inf_{S \in \Pi_L} \|f - S\|_p. \tag{32}$$

COROLLARY 3.10. *Let κ satisfy (10), with $k > \max\{2, n\}$, and in addition suppose $\kappa(t) \equiv 1$ on $[0, 1]$. If $f \in L^p(\mathbb{S}^n)$, $1 \le p \le \infty$, and $\varepsilon \le (L + \lambda_n)^{-1}$, then*

$$\|f - K_{\varepsilon,n} * f\|_p \le (1 + 2\omega_{n-1}\beta_{n,k,\kappa}) E_L(f)_p. \tag{33}$$

Also, for $1 \le p < \infty$ or, if $p = \infty$, for $f \in C(\mathbb{S}^n)$, we have $\lim_{\varepsilon \downarrow 0} K_{\varepsilon,n} * f = f$.

Proof. By Lemma 3.8, then $K_{\varepsilon,n} * S = S$ if $S \in \Pi_L$. It follows that $f - K_{\varepsilon,n} * f = (I + \mathsf{K}_\varepsilon)(f - S)$. From this and Theorem 3.7, we have that $\|f - K_{\varepsilon,n} * f\|_p \le (1 + 2\omega_{n-1}\beta_{n,k,\kappa})\|f - S\|_p$. Taking the infimum over all $S \in \Pi_L$ yields (33). That $\lim_{\varepsilon \downarrow 0} K_{\varepsilon,n} * f = f$ follows from (33) together with the fact that the spherical harmonics are dense in L^p for $1 \le p < \infty$ and in $C(\mathbb{S}^n)$ in the usual L^∞ norm [24, section IV.2]. ∎

The estimate in (33) is useful for obtaining rates of approximation, simply because rates of approximation by spherical harmonics are well known for many classes of functions; see, for example, Rustamov [23]. For further discussion, see the remarks following Proposition 5.1.

4. Quadrature on $\mathbb{S}^n$. To do the discretizations required to construct tight spherical frames in section 5, we need a strengthened version of the quadrature formula given in [14, 15]. There are two reasons for this. First, the earlier quadrature formula applies to a partition of $\mathbb{S}^n$ that is restricted. Second, it utilizes a set of centers that is not a general set of scattered points, but rather a set that has been "culled" from one. Our aim is to use the results obtained in section 3 to produce an improved positive-weight quadrature formula that avoids these restrictions. Indeed, out of this will also come strengthened versions of the inequalities derived in [14].

4.1. Marcinkiewicz–Zygmund inequalities. In this section we wish to give Marcinkiewicz–Zygmund type inequalities. These inequalities provide equivalences between norms defined through integrals and discrete norms stemming from sampled points and certain weights. Here, instead of polynomials, we will work with functions of the form $K_{\varepsilon,n} * f$ for $f \in L^1(\mathbb{S}^n)$.

The place to start is with a decomposition of the sphere into a finite number of nonoverlapping, connected regions R_ξ, each containing an interior point ξ that will serve for function evaluations as well as labeling. For example, given a set of centers X, one can form the corresponding Voronoi tessellation, and then take R_ξ to be the region associated with $\xi \in X$. In any case, we will let X be the set of the ξ's used for labels and $\mathcal{X} = \{R_\xi \subset \mathbb{S}^n \,|\, \xi \in X\}$. In addition, let $\|\mathcal{X}\| = \max_{\xi \in X}\{\mathrm{diam}(R_\xi)\}$.

The quantity that we wish to estimate first is the magnitude of the difference between the continuous and discrete norms for $g = K_{\varepsilon,n} * f$,

$$E_{\mathcal{X}} := \big|\|g\|_1 - \sum_{\xi \in X} |g(\xi)|\mu(R_\xi)\big|,$$

where we assume that $f \in L^1(\mathbb{S}^n)$. It is straightforward to show that

$$E_{\mathcal{X}} \le \sum_{\xi \in X} \int_{R_\xi} |g(\eta) - g(\xi)| d\mu(\eta) \le \sup_{\zeta \in \mathbb{S}^n} F_{\varepsilon,\mathcal{X}}(\zeta) \|f\|_1 ,$$

where $F_{\varepsilon,\mathcal{X}}(\zeta) := \sum_{\xi\in X}\int_{R_\xi}\big|K_{\varepsilon,n}(\eta\cdot\zeta)-K_{\varepsilon,n}(\xi\cdot\zeta)\big|d\mu(\eta)$, which is the quantity we need to estimate.

Choose ζ to be the north pole of $\mathbb{S}^n$ and let θ be the colatitude in spherical coordinates; set $\theta_\eta = \cos^{-1}(\eta\cdot\zeta)$ and $\theta_\xi = \cos^{-1}(\xi\cdot\zeta)$. Denote by θ_ξ^+ and θ_ξ^-, respectively, the high and low values for θ over R_ξ. Using (12) for the derivative of $K_{\varepsilon,n}$, we can write $F_{\varepsilon,\mathcal{X}}(\zeta)$ as

$$\begin{aligned}F_{\varepsilon,\mathcal{X}}(\zeta) &= 2\pi\sum_{\xi\in X}\int_{R_\xi}\left|\int_{\theta_\zeta}^{\theta_\eta}K_{\varepsilon,n+2}(\cos t)\sin t dt\right|d\mu(\eta)\\ &\le 2\pi\sum_{\xi\in X}\mu(R_\xi)\int_{\theta_\xi^-}^{\theta_\xi^+}|K_{\varepsilon,n+2}(\cos t)|\sin t\,dt.\end{aligned}$$

Divide $\mathbb{S}^n$ into $M = \lfloor\pi/\|\mathcal{X}\|\rfloor$ equal bands in which $(m-1)\pi/M\le\theta\le m\pi/M$, $m=1,\dots,M$. To avoid trivial situations and simplify later inequalities, we will assume that $M\ge 3$. Call these bands $B_1,\dots,B_M$. Each R_ξ can have nontrivial intersection with at most two adjacent bands, because $\operatorname{diam}(R_\xi)\le\|\mathcal{X}\|\le\pi/M$. So if $R_\xi\subset B_m\cup B_{m+1}$, then $(m-1)\pi/M\le\theta_\xi^-\le\theta_\xi^+\le(m+1)\pi/M$. In addition, the sum of the contributions from all $R_\xi\subset B_m\cup B_{m+1}$ is bounded above by the quantity

$$I_m := 2\pi\mu(B_m\cup B_{m+1})\int_{\frac{m-1}{M}\pi}^{\frac{m+1}{M}\pi}|K_{\varepsilon,n+2}(\cos t)|\sin t\,dt,$$

where $\mu(B_m\cup B_{m+1}) = \omega_{n-1}\int_{\frac{m-1}{M}\pi}^{\frac{m+1}{M}\pi}\sin^{n-1}t\,dt$. It follows that $F_{\varepsilon,\mathcal{X}}(\zeta)\le\sum_{m=1}^{M-1}I_m$. From Theorem 3.5, if we assume $k\ge n+2>\max\{2,n+1\}$ and if we use various linear approximations to the sine, we have

$$I_m \le 2\pi\omega_{n-1}\beta_{n+2,k,\kappa}\varepsilon^{-n-2}\int_{\frac{m-1}{M}\pi}^{\frac{m+1}{M}\pi}t^{n-1}dt\int_{\frac{m-1}{M}\pi}^{\frac{m+1}{M}\pi}\frac{t}{1+(\frac{t}{\varepsilon})^k}dt. \tag{34}$$

For $2\le m\le M-1$, we can bound the first integral by $\frac{2\pi}{M}\left(\frac{m+1}{M}\pi\right)^{n-1}$. In the second integral, we divide and multiply the integrand by t^{n-1}, and replace the t^{n-1} in the denominator by its lowest value. The result is that

$$\int_{\frac{m-1}{M}\pi}^{\frac{m+1}{M}\pi}\frac{t}{1+(\frac{t}{\varepsilon})^k}dt\le\left(\frac{M}{(m-1)\pi}\right)^{n-1}\int_{\frac{m-1}{M}\pi}^{\frac{m+1}{M}\pi}\frac{t^n}{1+(\frac{t}{\varepsilon})^k}dt.$$

Putting these two bounds together yields

$$I_m\le\frac{4\pi^2}{M}\omega_{n-1}\beta_{n+2,k,\kappa}\varepsilon^{-n-2}\underbrace{\left(\frac{m+1}{m-1}\right)^{n-1}}_{\le 3^{n-1}}\int_{\frac{m-1}{M}\pi}^{\frac{m+1}{M}\pi}\frac{t^n}{1+(\frac{t}{\varepsilon})^k}dt.$$

Summing both sides from $m=2$ to $M-1$, taking account of intervals appearing twice in the sum, and doing some obvious manipulations, we obtain

$$\begin{aligned}\sum_{m=2}^{M-1}I_m &< \frac{8\pi^2 3^{n-1}\omega_{n-1}}{M\varepsilon}\beta_{n+2,k,\kappa}\int_{\frac{\pi}{M\varepsilon}}^{\frac{\pi}{\varepsilon}}\frac{t^n}{1+t^k}dt\\ &< \frac{8\pi^2 3^{n-1}\omega_{n-1}}{M\varepsilon}\beta_{n+2,k,\kappa}\underbrace{\int_0^\infty\frac{t^n}{1+t^k}dt}_{\le 3/2} < \frac{4\pi^2 3^n\omega_{n-1}}{M\varepsilon}\beta_{n+2,k,\kappa}.\end{aligned}$$

We now need to estimate I_1. From (34) we have

$$I_1 \le n^{-1}\omega_{n-1}(2\pi/M)^n \int_0^{\frac{2\pi}{M}} \frac{\beta_{n+2,k,\kappa}\varepsilon^{-n-2}}{1+(\frac{t}{\varepsilon})^k} t dt < \frac{\omega_{n-1}}{2n}\left(\frac{2\pi}{M\varepsilon}\right)^{n+2}\beta_{n+2,k,\kappa}.$$

We arrive at the estimate

$$F_{\varepsilon,\mathcal{X}}(\zeta) \le 2\pi\omega_{n-1}\beta_{n+2,k,\kappa}\frac{2\pi}{M\varepsilon}\left\{\frac{1}{2n}\left(\frac{2\pi}{M\varepsilon}\right)^{n+1} + 3^n\right\}.$$

To finish up, we want to put our inequalities in terms of the ratio $\|\mathcal{X}\|/\varepsilon$. Since we have assumed that $M \ge 3$, we have that $\pi/M \le \frac{4}{3}\|\mathcal{X}\|$. Using this in the previous inequality and simplifying, we arrive at

$$F_{\varepsilon,\mathcal{X}}(\zeta) < 16\pi\cdot 3^{n-1}\omega_{n-1}\beta_{n+2,k,\kappa}\frac{\|\mathcal{X}\|}{\varepsilon}\left\{1+\frac{3}{2n}\left(\frac{8\|\mathcal{X}\|}{9\varepsilon}\right)^{n+1}\right\}.$$

We remark that if $\|\mathcal{X}\| \le \varepsilon \le 1$, then the assumption that $M \ge 3$ is automatically fulfilled. In addition, the right side of the inequality above is independent of ζ, so it holds for the left replaced by $\sup_{\zeta\in\mathbb{S}^n} F_{\varepsilon,\mathcal{X}}(\zeta)$. Finally, the inequality itself simplifies considerably. We collect all these observations in the result below.

PROPOSITION 4.1. *Let κ satisfy (10) with $k \ge n+2$, and for $f \in L^1(\mathbb{S}^n)$ let $g = K_{\varepsilon,n} * f$. If $\mathcal{X}$ is the decomposition of $\mathbb{S}^n$ described above and if $\|\mathcal{X}\| \le \varepsilon \le 1$, then*

$$\left|\|g\|_1 - \sum_{\xi\in X}|g(\xi)|\mu(R_\xi)\right| \le 16\pi\cdot 3^n\omega_{n-1}\beta_{n+2,k,\kappa}\frac{\|\mathcal{X}\|}{\varepsilon}\|f\|_1. \tag{35}$$

This result leads immediately to a version of the Marcinkiewicz–Zygmund inequalities for $\mathbb{S}^n$. This result extends an earlier result proved in [14, Theorem 3.1]. As we noted at the start of the section, the earlier result held only for restricted classes of decompositions.

THEOREM 4.2. *Let $L > 0$ be an integer and let $\delta \in (0,1)$. If $\mathcal{X}$ is the decomposition of $\mathbb{S}^n$ described above and $S \in \Pi_L$, then there exists a constant $s_n \ge 1$, which depends only on n, such that*

$$(1-\delta)\|S\|_1 \le \sum_{\xi\in X}|S(\xi)|\mu(R_\xi) \le (1+\delta)\|S\|_1 \tag{36}$$

holds whenever $\|\mathcal{X}\| \le \delta s_n^{-1}(L+\lambda_n)^{-1}$.

Proof. Let κ satisfy (10), with $k \ge n+2$. In addition, require $\kappa(t) \equiv 1$ for $t \in [0,1]$. Choose $\varepsilon = (L+\lambda_n)^{-1}$. By Lemma 3.8, $S = K_{\varepsilon,n} * S$, and so if we take $f = S$ and $\|\mathcal{X}\| \le \varepsilon = (L+\lambda_n)^{-1} \le 1$ in Proposition 4.1, then $g = K_{\varepsilon,n} * S = S$ there. Manipulating the resulting expression in (35) then gives us

$$\tilde{s}_n := \sup \frac{\left|\|S\|_1 - \sum_{\xi\in X}|S(\xi)|\mu(R_\xi)\right|}{(L+\lambda_n)\|\mathcal{X}\|\|S\|_1} \le 16\pi\cdot 3^n\omega_{n-1}\beta_{n+2,k,\kappa}\,,$$

where the supremum is over all $\mathcal{X}$ and $L > 0$ such that $\|\mathcal{X}\| \le (L+\lambda_n)^{-1}$ and clearly depends *only* on n. Now, let

$$s_n := \max\{1, \tilde{s}_n\} \le \max\{1, 16\pi\cdot 3^n\omega_{n-1}\beta_{n+2,k,\kappa}\}. \tag{37}$$

If we further restrict $\|\mathcal{X}\|$ so that $\|\mathcal{X}\| \le \delta s_n^{-1}(L+\lambda_n)^{-1}$, then (36) follows. ∎

4.2. Positive-weight quadrature for $\mathbb{S}^n$. Our aim is to extend the quadrature formula in [14, Theorem 4.1] to more general sets of centers and decompositions than the restricted class covered there. Even more important for us here is obtaining upper and *lower* bounds on the positive weights. For the restricted case covered in [14], upper bounds were given in [15], but nothing was said about lower bounds, which we need for constructing tight-frames on $\mathbb{S}^n$.

There is an important map associated with Π_L and the decomposition $\mathcal{X}$ and the corresponding finite set X. Let $|X|$ be the cardinality of X. We define the sampling map, $T_X : \Pi_L \to \mathbb{R}^{|X|}$, by $T_X S := (S(\xi))_{\xi\in X}$. From Theorem 4.2, it follows that if $\|\mathcal{X}\| \le \delta s_n^{-1}(L+\lambda_n)^{-1}$ holds and if $T_X S = 0$, we have that $\|S\|_1 = 0$ and, hence, $S \equiv 0$. The sampling map, which is linear, is therefore injective. Moreover, if we let the subspace $V_L = T_X\Pi_L \subset \mathbb{R}^{|X|}$, then the inverse map $T_X^{-1} : V_L \to \Pi_L$ is of course linear. Also, we will let $S_X = (S(\xi))_{\xi\in X}$.

Since our interest here is in weights for quadrature, we start with the linear functional $\Phi : \Pi_L \to \mathbb{R}$ given by

$$\Phi(S) := \int_{\mathbb{S}^n} S(\eta)d\mu(\eta),\ S \in \Pi_L.$$

Let $\Phi_X(S_X) = \Phi(T_X^{-1}(S_X)) = \Phi(S)$. If $S_X \ge 0$, then $|S(\xi)| = S(\xi)$ for $\xi \in X$, and so from (36) we have that

$$\big|\Phi(S) - \sum_{\xi\in X} S(\xi)\mu(R_\xi)\big| \le \big|\|S\|_1 - \sum_{\xi\in X} S(\xi)\mu(R_\xi)\big| \le \frac{\delta}{1-\delta}\sum_{\xi\in X} S(\xi)\mu(R_\xi),$$

provided only that $\|\mathcal{X}\| \le \delta s_n^{-1}(L+\lambda_n)^{-1}$. For any $\delta < \frac{1}{2}$, this implies that

$$\frac{1-2\delta}{1-\delta}\sum_{\xi\in X} S(\xi)\mu(R_\xi) \le \Phi(S) \le \frac{1}{1-\delta}\sum_{\xi\in X} S(\xi)\mu(R_\xi).$$

From this, we see that the linear functional

$$\Psi_X(S_X) := \Phi_X(S_X) - \frac{1-2\delta}{1-\delta}\sum_{\xi\in X} S(\xi)\mu(R_\xi) \tag{38}$$

is positive on the cone $0 \le S_X \in V_L$, which itself is contained in the positive cone of $\mathbb{R}^{|X|}$.

There are two facts we will take account of. The first is that the positive cone of V_L is contained in the positive cone of $\mathbb{R}^{|X|}$. The second is that the vector $(1)_{\xi\in X}$, which is in both cones, is an interior point of the positive cone of $\mathbb{R}^{|X|}$. By the Krein–Rutman theorem [9], there exists a positive linear functional $\widetilde{\Psi}_X$ that extends Ψ_X to all $\mathbb{R}^{|X|}$. Consequently, there exist weights $\alpha_\xi \ge 0$ such that $\widetilde{\Psi}_X(x) = \sum_{\xi\in X}\alpha_\xi x_\xi$. Using this and $\Phi_X(S_X) = \Phi(S)$ in (38), we obtain

$$\Phi(S) = \sum_{\xi\in X} c_\xi S(\xi), \quad c_\xi := a_\xi + \frac{1-2\delta}{1-\delta}\mu(R_\xi),\ a_\xi \ge 0. \tag{39}$$

This is of course a positive-weight quadrature formula on $\mathbb{S}^n$, with weights bounded below by $\frac{1-2\delta}{1-\delta}\mu(R_\xi)$.

We want to get upper bounds as well. To do that, we let $L' = \lfloor \frac{L}{2} \rfloor$ and fix $\xi_0 \in X$. If $S \in \Pi_{L'}$, then S^2 is in Π_L. The quadrature formula (39) then implies that

$$\|S\|_2^2 = \Phi(S^2) = \sum_{\xi \in X} c_\xi (S(\xi))^2 \geq c_{\xi_0} (S(\xi_0))^2.$$

Choose $S(\eta) = \sum_{\ell=0}^{L'} \sum_{m=1}^{d_\ell^n} Y_{\ell,m}(\eta) \overline{Y_{\ell,m}(\xi_0)} = \sum_{\ell=0}^{L'} \frac{\ell+\lambda_n}{\omega_n \lambda_n} P_\ell^{(\lambda_n)}(\xi_0 \cdot \eta)$, which is real valued. Using the orthogonality of the $Y_{\ell,m}$'s, one can show that $\|S\|_2^2 = S(\xi_0) = \sum_{\ell=0}^{L'} \frac{\ell+\lambda_n}{\omega_n \lambda_n} \binom{\ell+n-2}{\ell}$. From the previous inequality, (13) and (4), and the fact that $\dim \Pi_{L'} = d_{L'}^{n+1}$ [17, p. 4], we get $c_{\xi_0} \leq \omega_n / d_{L'}^{n+1}$, where $L' := \lfloor L/2 \rfloor$. We summarize these results below.

THEOREM 4.3. *Adopt the notation of Theorem* 4.2. *In particular,* s_n *is given by* (37) *and depends only on* n. *For any* $0 < \delta < \frac{1}{2}$ *and any integer* $L > 0$, *if* $\|\mathcal{X}\| \leq \delta s_n^{-1} (L + \lambda_n)^{-1}$, *then there exist positive weights* c_ξ, $\xi \in X$, *such that the quadrature formula*

$$\int_{\mathbb{S}^n} f(\eta) d\mu(\eta) \doteq \sum_{\xi \in X} c_\xi f(\xi) \tag{40}$$

is exact for spherical harmonics in Π_L. *Also, the weights satisfy the bounds*

$$\frac{1-2\delta}{1-\delta} \mu(R_\xi) \leq c_\xi \leq \frac{\omega_n}{d_{L'}^{n+1}}, \ L' = \lfloor L/2 \rfloor. \tag{41}$$

The theorem just proved starts with L and puts conditions on the decomposition $\mathcal{X}$. The centers in X play a secondary role, serving as labels for regions in $\mathcal{X}$ and as evaluation points in the quadrature formula.

It's useful to turn this around and have the centers X play the primary role. To do that, we need to make the assumption that we are considering only ρ-uniform X; that is, for some fixed ρ we assume that the mesh ratio $h_X/q_X = \rho_X \leq \rho$. We will take the $\mathcal{X} = \mathcal{X}_V$ to be the Voronoi decomposition associated with X. For this decomposition, we have $h_X \leq \|\mathcal{X}_V\|$. Also, since the smallest distance between two points in X is $2q_X$, every $R_\xi \in \mathcal{X}_V$ contains a spherical cap with center ξ and radius $q_X \geq h_X/\rho$; hence, $\mu(R_\xi) \geq \omega_{n-1}(2/\pi)^{n-1} \rho^{-n} h_X^n / n$. Applying Theorem 4.3, we arrive at this result.

COROLLARY 4.4. *Adopt the notation of Theorem* 4.3 *and let* X *be a* ρ*-uniform set of centers. If* $h_X \leq \delta s_n^{-1} (L + \lambda_n)^{-1}$, *then the quadrature formula* (40) *holds with weights satisfying*

$$\omega_{n-1}(2/\pi)^{n-1} \left(\frac{1-2\delta}{1-\delta} \right) \rho^{-n} h_X^n \leq c_\xi \leq \frac{\omega_n}{d_{L'}^{n+1}}, \qquad L' = \lfloor L/2 \rfloor. \tag{42}$$

Set $\delta = 1/4$. To get a better idea of how the weights are bounded in terms of $h = h_X$ or L, note that by (4) we have $d_{L'}^{n+1} \sim \frac{(L/2)^n}{\lambda_{n+1}(n-1)!}$. In addition, if we take L as large as possible, but still consistent with the condition that $h_X \leq \delta s_n^{-1} (L + \lambda_n)^{-1}$, then $L \sim h^{-1}$. In that case, we see that

$$c_\xi = \mathcal{O}\{h^n\} = \mathcal{O}\{L^{-n}\}, \tag{43}$$

where the constants hidden by $\mathcal{O}$ are dependent only on the dimension n.

So far we have only addressed the *existence* of positive weights, along with bounds on them. In fact, the existence of such weights implies the *feasibility* of solving a quadratic programming problem that produces weights minimizing $\sum_{\xi\in X} c_\xi^2$, subject to constraints. Thus it is possible to numerically compute the weights. For more details, see [14, section 4.3].

5. Tight frames on $\mathbb{S}^n$. In this section, we discuss three important features of the operator frames on $\mathbb{S}^n$ introduced earlier in section 2.2. The first is the approximation power of these frames in various spaces. The second is how to turn them into *tight* frames for $\mathbb{S}^n$. This requires discretizing them using the quadrature results from the previous section. The third and final feature is their excellent localization properties.

We will turn to discussing the approximation power of these operator frames, after a brief word about notation. Throughout this section, the operators A_j and B_J are their kernels A_j and B_J, which are defined in section 2.2. The function $b(t)$ is defined in (1). We assume that the function $a(t)$, whose properties are discussed in section 1, is in $C^k(\mathbb{R})$.

PROPOSITION 5.1. *Let $k > \max\{n, 2\}$, and let b be defined by* (1)*, with $a \in C^k(\mathbb{R})$. If $f \in L^p(\mathbb{S}^n)$, $1 \le p \le \infty$, and if $L > 0$ is an integer such that $2^{-J-j_n} \le (L+\lambda_n)^{-1}$, then*

$$\|f - \mathsf{B}_J f\|_p \le C_{b,k,n} E_L(f)_p, \qquad E_L(f)_p := \operatorname{dist}_{L^p}(f, \Pi_L). \tag{44}$$

Also, for $1 \le p < \infty$ or, if $p = \infty$, for $f \in C(\mathbb{S}^n)$, we have $\lim_{J\to\infty} \mathsf{B}_J f = f$.

Proof. Apply Corollary 3.10 with $\kappa = b$, k as above, and $\varepsilon = 2^{-J-j_n}$. ∎

The proposition implies that $\mathsf{B}_J f$ approximates f to within an error comparable to $E_L(f)_p$, which is that for the best approximation to f from Π_L in L^p. Much work [11, 20, 22, 23, 27] has been done on estimating this error for various smoothness classes and spaces. This work allows us to obtain rates of approximation when f has additional smoothness requirements. A typical result [11] is this: If $f \in L^p(\mathbb{S}^n)$, with $\|f\|_p = 1$, belongs to a smoothness class $W_p^\alpha(\mathbb{S}^n)$, which is analogous to a Sobolev space, then $E_L(f)_p \sim L^{-\alpha}$. Choosing f similarly and taking $L \sim 2^J$, we get a corresponding result for our case: $\|f - \mathsf{B}_J f\|_p \sim 2^{-\alpha J}$.

We now turn to constructing tight frames on $\mathbb{S}^n$. The quadrature formulas from section 4.2 will play a pivotal role in their construction; we will also require a sequence of sets of centers to use in conjunction with them. Let $\rho \ge 2$ be fixed. By Proposition 2.1, we can find a sequence of sets of centers $\{X_j \in \mathcal{F}_\rho\}_{j=0}^\infty$ such that X_j is nested and such that the mesh norm $h_j := h_{X_j}$ halves going from j to $j+1$; that is, $h_{j+1} \le h_j/2$. In what follows, assume that the X_j's form such a sequence.

Recall that on $\mathbb{S}^n$, the frame transform $f \to w_j = \widetilde{\mathsf{A}}_j^* f$ takes the form $w_j(\eta) = \mathsf{A}_j^* f(\eta) = \langle f(\zeta), A_j(\zeta\cdot\eta)\rangle_{L^2(\mathbb{S}^n)}$. Because $A_j(\zeta\cdot\eta)$ is a spherical polynomial with degree less than 2^{j+j_n+1}, the function $w_j(\eta)$ is a spherical polynomial of degree less than 2^{j+j_n+1}. In the reconstruction formula this then contributes the term

$$\mathsf{A}_j w_j(\omega) = \int_{\mathbb{S}^n} A_j(\omega\cdot\eta) w_j(\eta)\, d\mu(\eta).$$

The product $A_j(\omega\cdot\eta)w_j(\eta)$ is a spherical polynomial having degree less than $2^{j+j_n+1} + 2^{j+j_n+1} = 2^{j+j_n+2}$.

We can integrate this *exactly* using the quadrature formula (40), with $L = 2^{j+j_n+2}$. First of all, the condition on the mesh norm h in both Theorem 4.3

and Corollary 4.4 is that $h \le \delta s_n^{-1}(L+\lambda_n)^{-1}$, where $\delta \in (0,1/2)$ is arbitrary. Choose $\delta = 1/4$ to be definite. For $n = 1$ (the circle), we have $\lambda_1 = 0$ and $j_1 = 0$, and the condition is $h \le \delta s_1^{-1} 2^{-j-2} = s_1^{-1} 2^{-j-4}$. For $n \ge 2$, note that $2^{j+j_n+2} + \lambda_n \le 2^{j+2}\lfloor \lambda_n \rfloor + \lambda_n < 2^{j+3}\lambda_n$. The condition for $n \ge 2$ is then fulfilled if $h \le \delta(\lambda_n s_n)^{-1} 2^{-j-3} = (\lambda_n s_n)^{-1} 2^{-j-5}$. It is clear that these conditions can be met by using the sets X_j.

Let the quadrature weight corresponding to the center $\xi \in X_j$ be denoted by $c_{j,\xi}$, so that

$$\mathsf{A}_j w_j(\omega) = \sum_{\xi \in X_j} c_{j,\xi} A_j(\xi \cdot \omega) w_j(\omega) = \sum_{\xi \in X_j} \langle f, \psi_{j,\xi} \rangle \psi_{j,\xi}, \tag{45}$$

where

$$\psi_{j,\xi}(\eta) := \sqrt{c_{j,\xi}}\, A_j(\eta \cdot \xi),\ \xi \in X_j, \tag{46}$$

is the analysis frame function at level j. The frame function $\psi_{j,\xi}$ is computable: A_j is known and, as we noted at the end of section 4.2, the weights can be found numerically. We can now prove this result.

THEOREM 5.2. *Let $k > \max\{n, 2\}$, and let A_j be the kernel in (8), with $a \in C^k(\mathbb{R})$. If $f \in C(\mathbb{S}^n)$ or, for $1 \le p < \infty$, if $f \in L^p(\mathbb{S}^n)$, then*

$$f = \sum_{j=0}^{\infty} \sum_{\xi \in X_j} \langle f, \psi_{j,\xi} \rangle \psi_{j,\xi},$$

with convergence being in the appropriate space. In addition, if $f \in L^2(\mathbb{S}^n)$, the frame $\{\psi_{j,\xi}\}_{j \in \mathbb{Z}_+, \xi \in X_j}$ is tight:

$$\|f\|^2 = \begin{cases} \frac{1}{2\pi} |\langle f, 1 \rangle|^2 + \sum_{j=0}^{\infty} \sum_{\xi \in X_j} |\langle f, \psi_{j,\xi} \rangle|^2, & n = 1, \\ \sum_{j=0}^{\infty} \sum_{\xi \in X_j} |\langle f, \psi_{j,\xi} \rangle|^2, & n \ge 2. \end{cases}$$

Finally, the frame functions have vanishing moments that increase with j, and are orthogonal on nonadjacent levels.

Proof. From (9) and (45), for $n \ge 2$ we get $\mathsf{B}_J f = \sum_{j=0}^{J} \sum_{\xi \in X_j} \langle f, \psi_{j,\xi} \rangle \psi_{j,\xi}$. By Proposition 5.1 this converges to f in all of the spaces mentioned. To prove that the frame is tight, just observe that for $f \in L^2(\mathbb{S}^n)$, we have $\langle \mathsf{B}_J f, f \rangle = \sum_{j=0}^{J} \sum_{\xi \in X_j} \left| \langle f, \psi_{j,\xi} \rangle \right|^2$. Taking the limit as $J \to \infty$ then yields the equation for $\|f\|^2$. The statement concerning vanishing moments follows from the structure of the A_j's, and the orthogonality between nonadjacent levels is proved in Proposition 1.1. The $n = 1$ case has a projection P_0 in B_J, where P_0 projects onto the constants. The effect of this is to add a term to the series for $\|f\|^2$. ∎

Our last result concerns the localization properties of the frame function defined by (46).

COROLLARY 5.3. *Let $k > \max\{n, 2\}$ and let $\psi_{j,\xi}$ be given by (46). If $\theta := \cos^{-1}(\eta \cdot \xi)$, then for all $\theta \in [0, \pi]$ there are constants C and C', which depend on k, n, and a, such that these hold:*

$$|\psi_{j,\xi}(\eta)| \le \frac{2^{n(j+j_n)/2}\, C}{1 + (2^{j+j_n}\theta)^k} \text{ and } |B_J(\eta \cdot \xi)| \le \frac{2^{n(J+j_n)}\, C'}{1 + (2^{J+j_n}\theta)^k}.$$

Proof. Use Theorem 3.5, with $\kappa = b$ and $\varepsilon = 2^{-J-j_n}$, to bound $B_J(\xi \cdot \eta)$, and again, with $\kappa = a$ and $\varepsilon = 2^{-j-j_n}$, to bound $A_j(\eta \cdot \xi)$. Next, use $L = 2^{j+j_n+2}$ in (43) to see that $c_\xi = \mathcal{O}\{2^{-(j+j_n)n}\}$, where the constants depend only on n. To bound $\psi_{j,\xi}$, use the bounds on A_j and c_ξ in (46). □

COUPLING CONDITIONS FOR A CLASS OF SECOND-ORDER MODELS FOR TRAFFIC FLOW*

M. HERTY† AND M. RASCLE‡

Abstract. This paper deals with a model for traffic flow based on a system of conservation laws [A. Aw and M. Rascle, *SIAM J. Appl. Math.*, 60 (2000), pp. 916–938]. We construct a solution of the Riemann problem at an arbitrary junction of a road network. Our construction provides a solution of the full system. In particular, all moments are conserved.

Key words. hyperbolic systems of conservation laws, traffic flow, road networks, homogenization

AMS subject classifications. 35LXX, 35L6

1. Introduction.

Macroscopic modeling of vehicular traffic started with the work of Lighthill and Whitham (LWR) [25]. Since then there has been intense discussion and research; see [26, 10, 2, 19, 21, 22, 6, 24] and the references therein. Today, fluid dynamic models for traffic flow are appropriate for describing traffic phenomena such as congestion and stop-and-go waves [18, 14, 20]. The case of road networks based on the LWR model has been considered in particular in [17, 5, 16]. Recently in [12], Garavello and Piccoli considered a road network based on the Aw–Rascle (AR) model [2] of traffic flow. Here, in contrast to [12], we propose a modeling of the junctions conserving the mass *and* the pseudo-"momentum" $\rho v\, w$. We will discuss below further differences between the two modelings.

We consider a finite directed graph as a model for a road network with unidirectional flow. Each road $i = 1, \dots, \mathcal{I}$ is modeled by an interval $I_i := [a_i, b_i] \subset \mathbb{R}$ possibly with $a_i = -\infty$ or $b_i = \infty$. Each vertex of the graph corresponds to a junction. For a fixed junction k the set δ_k^- contains all road indices i which are incoming roads, so that $\forall i \in \delta_k^- : b_i = k$. Similarly, δ_k^+ denotes the indices of outgoing roads: $\forall j \in \delta_k^+ : a_j = k$. We skip the index k whenever the situation is clear.

The evolution of $\rho_i(x,t)$ and $v_i(x,t)$ on each road i is given by the AR model [2]

$$\partial_t \rho_i + \partial_x(\rho_i v_i) = 0, \tag{1.1a}$$

$$\partial_t(\rho_i w_i) + \partial_x(\rho_i v_i w_i) = 0, \tag{1.1b}$$

$$w_i = v_i + p_i(\rho_i), \tag{1.1c}$$

where for each i, $\rho \mapsto p_i(\rho)$ is a known function ("traffic pressure") with the following properties:

$$\forall \rho : \rho p_i''(\rho) + 2p_i'(\rho) > 0 \text{ and } p_i(\rho) \sim \rho^\gamma \text{ near } \rho = 0 \tag{1.2}$$

and where $\gamma > 0$. The conservative form of (1.1) is

$$\partial_t \begin{pmatrix} \rho_i \\ y_i \end{pmatrix} + \partial_x \begin{pmatrix} y_i - \rho_i p_i(\rho_i) \\ (y_i - \rho_i p_i(\rho_i)) y_i/\rho_i \end{pmatrix} = 0,$$

where $y_i = \rho_i w_i = \rho(v_i + p_i(\rho_i))$. Since w_i and v_i are related by (1.1), we choose to describe solutions in terms of ρ_i and $\rho_i v_i$. For a motivation and a complete discussion of these equations we refer to section 2 and [2], respectively.

We consider weak solutions of the network problem as in [17]: Let a set $i = 1, \dots, \mathcal{I}$ of smooth functions $\phi_i : [0, +\infty] \times I_i \to \mathbb{R}^2$ having compact support in $I_i = [a_i, b_i]$, which are "smooth" across each junction k, be given, i.e.,

$$\phi_i(b_i) = \phi_j(a_j) \quad \forall i \in \delta_k^-, \quad \forall j \in \delta_k^+. \tag{1.3}$$

Then a set of functions

$$U_i = (\rho_i, \rho_i v_i), \quad i = 1, \dots, \mathcal{I}, \tag{1.4}$$

is called a weak solution of (1.1) if and only if equations (1.5) hold for all families of test functions $\{\phi_i\}_{i \in \mathcal{I}}$ with the property (1.3).

$$\sum_{i=1}^{\mathcal{I}} \int_0^\infty \int_{a_i}^{b_i} \begin{pmatrix} \rho_i \\ \rho_i w_i \end{pmatrix} \cdot \partial_t \phi_i + \begin{pmatrix} \rho_i v_i \\ \rho_i v_i w_i \end{pmatrix} \cdot \partial_x \phi_i dx dt$$

$$- \int_{a_i}^{b_i} \begin{pmatrix} \rho_{i,0} \\ \rho_{i,0} w_{i,0} \end{pmatrix} \cdot \phi_i(x, 0) dx = 0, \tag{1.5a}$$

$$w_i(x,t) = v_i(x,t) + p_i^\dagger(\rho_i(x,t)). \tag{1.5b}$$

Here, $U_{i,0}(x) = (\rho_{i,0}(x), (\rho_{i,0} v_{i,0})(x))$ are the initial data. *The functions $p_i^\dagger(\cdot)$ are initially unknown.* The explicit form of each $p_i^\dagger$ depends on the initial data and the type of junction. Near any junction k the function $p_i^\dagger$ is equal to p_i for all incoming roads. The same is true for all outgoing roads of the junction if there is only *one* incoming road. This is discussed in sections 3 and 4. In section 6 we discuss the case where $p_i^\dagger \neq p_i$ and give arguments for the necessity of introducing $p_i^\dagger$. At this point let us just note that in the general case $p_i^\dagger$ depends on a mixture of the incoming flows.

In the case of a single junction we derive from (1.5a), (1.5b) the Rankine–Hugoniot conditions for piecewise smooth solutions:

$$\sum_{i \in \delta^-} (\rho_i v_i)(b_i^-, t) = \sum_{i \in \delta^+} (\rho_i v_i)(a_i^+, t), \tag{1.6a}$$

$$\sum_{i \in \delta^-} (\rho_i v_i w_i)(b_i^-, t) = \sum_{i \in \delta^+} (\rho_i v_i w_i)(a_i^+, t). \tag{1.6b}$$

Properties (1.6a) and (1.6b) correspond to conservation of mass and of (pseudo-) "momentum." We remark that the solution constructed in [12] does *not* conserve the (pseudo-)"momentum" (see Proposition 2.3 in [12]) and therefore is *not* a weak solution in the sense of (1.5a), (1.6a), and (1.6b).

In the next section we discuss the construction of weak solutions in the sense of (1.5) for initial data constant on each road:

$$(\rho_{i,0}, \rho_{i,0} v_{i,0}) = U_{i,0} = \text{const}_i. \tag{1.7}$$

We consider a single junction. We look for solutions to Riemann problems on each road i as if the road were extended to $]-\infty, \infty[$:

$$\partial_t \begin{pmatrix} \rho_i \\ \rho_i w_i \end{pmatrix} + \partial_x \begin{pmatrix} \rho_i v_i \\ \rho_i v_i w_i \end{pmatrix} = 0, \qquad U_i(x,0) = \begin{pmatrix} U^- & x < x_0 \\ U^+ & x > x_0 \end{pmatrix}. \tag{1.8}$$

Depending on the road, only one of the Riemann data is defined for $t = 0$:

$$\text{If } i \in \delta^- : U^- = U_{i,0}\,,\ x_0 = b_i \ \text{ and if } i \in \delta^+ : U^+ = U_{i,0}\,,\ x_0 = a_i. \tag{1.9}$$

We construct an (entropy) solution to (1.5) such that all generated waves have nonpositive ($i \in \delta^-$) or nonnegative ($i \in \delta^+$) speed. Moreover, the solutions satisfy conditions (1.6a) and (1.6b).

We have to impose additional conditions [12] to obtain a unique solution. First, the flux ρv is nonnegative. Next, it has to be distributed according to a priori given ratios; see sections 3 to 7 for further details. Finally, we require that the *total flux be maximized* subject to the other conditions.

The paper is organized as follows. In section 2 we discuss the general properties of the Riemann problem for (1.1). First, we construct the demand and supply functions, which are necessary to determine the flux at the junction. Refer to [23, 8, 9] for the presentation of supply and demand functions for first-order models. Next, we define admissible states on each road at the junction and finally we construct all intermediate states in the solution of (1.1).

In section 3 we consider the easiest possible situation, namely, two roads connected by a junction. In section 4 we extend the results to a junction with one incoming and two outgoing roads. For the results on two incoming and one outgoing road we need a description of the mixture of flows on the outgoing road. Therefore we briefly revisit the main results of [1] and [3] in section 5. In section 6 we solve the case of two incoming and two outgoing roads and define homogenized flow. In section 7 we consider the general case of an intersection with an arbitrary number of incoming and outgoing roads.

2. Preliminary discussion. The conservative variables are ρ_i and $y_i := \rho_i w_i$. We assume $\forall i : 0 \le \rho_i \le \rho_{\max} = 1$ and $\forall i : 0 \le v_i \le v_{\max} = 1$. Furthermore, we set

$$U_i := (\rho_i, \rho_i v_i),\ U := (\rho, \rho v) \tag{2.1}$$

and we skip the subindex i at ρ_i and v_i whenever the intention is clear. The system (1.1) is strictly hyperbolic if $\rho_i > 0$ for all i. The eigenvalues are

$$\lambda_{1,i}(U) = v - \rho p_i'(\rho) \quad \text{ and } \quad \lambda_{2,i}(U) = v. \tag{2.2}$$

The right eigenvectors corresponding to $\lambda_{1,i}$ and $\lambda_{2,i}$ are

$$\mathbf{r}_{1,i} = \begin{pmatrix} 1 \\ -p_i'(\rho) \end{pmatrix} \quad \text{ and } \quad \mathbf{r}_{2,i} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}.$$

Let ∇ denote the gradient with respect to (ρ, v). We recall that k is called a genuinely nonlinear characteristic family if $\nabla \lambda_{k,i}(\rho, v) \cdot \mathbf{r}_{k,i}(\rho, v) \neq 0\ \forall (\rho, v)$. Depending on

the initial data, the associated waves are rarefaction or shock waves. If $\nabla\lambda_{k,i}(\rho, v) \cdot \mathbf{r}_{k,i}(\rho, v) = 0\ \forall(\rho, v)$, then k is called a linearly degenerated characteristic family and the associated waves are contact discontinuities. We refer to Definitions 7.2.1 and 7.5.1 in [7] for more details.

Here, $k = 1$ is a genuinely nonlinear and $k = 2$ is a linearly degenerated characteristic family for all roads i. Moreover, the 1-shock and 1-rarefaction curves coincide and we have a 2-contact discontinuity; see [2]. For each road i the Riemann invariants are

$$w_i(U) = v + p_i(\rho) \quad \text{and} \quad v_i(U) = v. \tag{2.3}$$

Let us be more specific about the physical interpretation of w and $p(\cdot)$. Other descriptions than (2.3) could be envisioned. In particular, the *additive* role of $p_i(\cdot)$ in w_i (as in the Payne–Whitham model [26]) is not essential. It was introduced in [2] for "historical" reasons, but it has a drawback: The associated individual fundamental diagram (see Figure 1 below) implies a zero speed at a maximal (jam) traffic density which is *different* for each category of car-driver pairs, i.e., each pairing (w_i, p_i). We keep the above expression (2.3) throughout the paper for the sake of simplicity. As noted in [3], the only crucial property of w_i is that it is a *Lagrangian* marker. As an example assume that on each road i, the (pseudo-)pressure is $p_i(\rho) := v_{max} - V_i(\rho)$, where, e.g., v_{max} is the maximal speed on all roads and $V_i(\rho)$ is an *equilibrium* speed on road i. Therefore, the *function* $U := (\rho, v) \to w_i(U) = v + p_i(\rho)$ describes the *distance to equilibrium*. The "momentum" equation tells us that each value w is a Lagrangian property, such as a label or a color. Hence, when passing from road i to another road j, each driver will preserve its "color." In other words, he will keep the *same value* w, which will now satisfy

$$w_j(U) = w = w_i(U).$$

This simple observation will be essential in what follows. In particular, it will lead to a very natural homogenization problem in section 6.

The classical description by *first*-order models is just a *particular case* of our second-order model. It corresponds to setting all the w's equal to the same constant. So our description can be drastically simplified when no sophisticated information is needed.

We return to the mathematical description. Usually, we draw the level curves of the Riemann invariants (in short the Riemann invariants) in the $(\rho, \rho v)$ plane. An example of the curves is depicted in Figure 1. There is a one-to-one correspondence to the (ρ, y) plane; see [2].

For an arbitrary fixed i we discuss the shape of the Riemann invariants in the $(\rho, \rho v)$ plane and characterize important points.

The Riemann invariant $\{v_i(U) = c\}$ is a straight line with slope c passing through the origin. Consider the curve $\{w(U) := w_i(U) = c\}$, where $c \in \mathbb{R}$ denotes a constant. By assumption (1.2) on $p := p_i$ this curve is strictly concave and passes through the origin. Furthermore, if $c > 0$, then the curve $\{w(U) = c\}$ lies in the first quadrant of the $(\rho, \rho v)$ plane for ρ between 0 and a maximal value $\bar{\rho} \in]0, 1]$. The maximal value $\bar{\rho}$ depends on c and $p(\cdot)$. Due to the strict concavity there exists a unique point (i.e., the "sonic point") $\sigma(w, c)$ with $0 < \sigma(w, c) \leq 1$, depending on c and the function $p(\cdot)$. The point $\sigma(w, c)$ maximizes the flux ρv on $\{w(U) = c\}$.

The total flux has to be conserved through an intersection. Therefore, we introduce the functions $r(\rho; w, c)$ and $u(\rho; w, c)$ below. Assume $c > 0$. Then for all

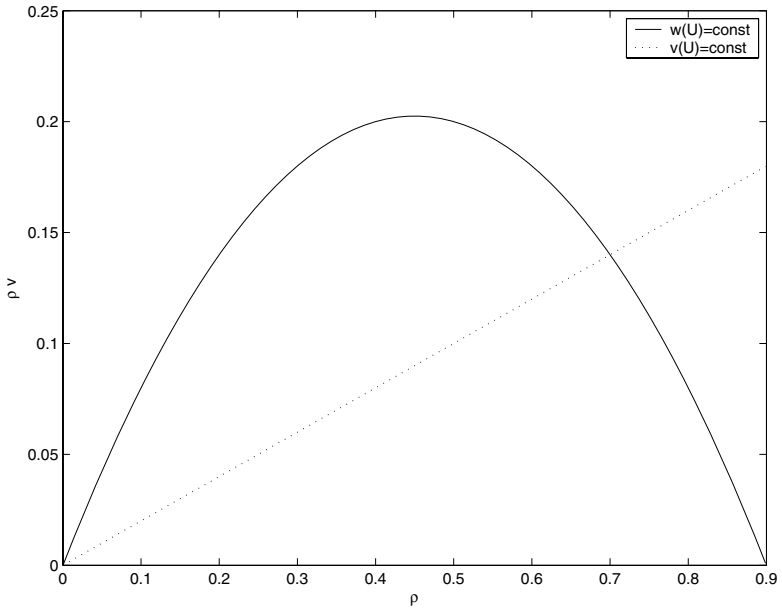

FIG. 1. *Riemann invariants in the* $(\rho, \rho v)$ *plane.*

$\rho \in [0, \bar{\rho}]$ there exists a unique v such that $w((\rho, \rho v)) = c$. Moreover, there exists a unique pair (r, u) such that

$$w(r, r\ u) = w(\rho, \rho\ v), \tag{2.4a}$$

$$r\ u = \rho\ v, \tag{2.4b}$$

$$r \neq \rho \text{ except for } \rho = \sigma(w, c). \tag{2.4c}$$

In other words (ρ, v) and (r, u) correspond to the same flux and the same level curve of w; see Figure 2 for an example. Hence, for each curve $\{w(U) = c\}$ with $c > 0$ there exist two unique functions $\rho \to r(\rho; w, c)$ and $\rho \to u(\rho; w, c)$ satisfying (2.4) for all $\rho \in [0, \bar{\rho}]$.

Next, we describe the construction of the demand and supply functions for a given curve $\{w(U) = c\}$, $c \geq 0$. As in the case of first-order models, e.g., [23], in the $(\rho, \rho v)$ plane, the demand function $d(\rho; w, c)$ is an extension of the *nondecreasing* part of the curve $\{w(U) = c\}$ for $\rho \geq 0$, whereas the supply function $s(\rho; w, c)$ is an extension of the *nonincreasing* part of the curve $\{w(U) = c\}$ and $\rho \geq 0$; see Figures 2 and 3 for examples.

Now we consider the Riemann problem (1.8) for a given *incoming* road $i \in \delta^-$. Hence, only the initial datum $U^- = U_{i,0}$ is given. We want to determine all "admissible" states U^+: A state U^+ is called "admissible" if and only if either the waves of the solution to (1.8) with initial data (U^-, U^+) have negative speed or the solution is constant $(U^+ = U^-)$. As in [17] we neglect waves of zero speed (stationary waves). Later on U^+ will be an intermediate state in the solution $U_i(\cdot, \cdot)$ on the incoming road i for the full Riemann problem at the junction, i.e., $U_i(x_0-, t) = U^+$.

PROPOSITION 2.1. *Let* $U^- = (\rho^-, \rho^- v^-) \neq (0, 0)$ *be the initial value on an incoming road* i. *Let the* 1*-curve through* U^- *be* $w_i(U) = v + p_i(\rho) = w^-$ *with* $w^- := w_i(U^-)$. *Then the "admissible" states* $U^+ = (\rho^+, \rho^+ v^+)$ *for the Riemann problem*

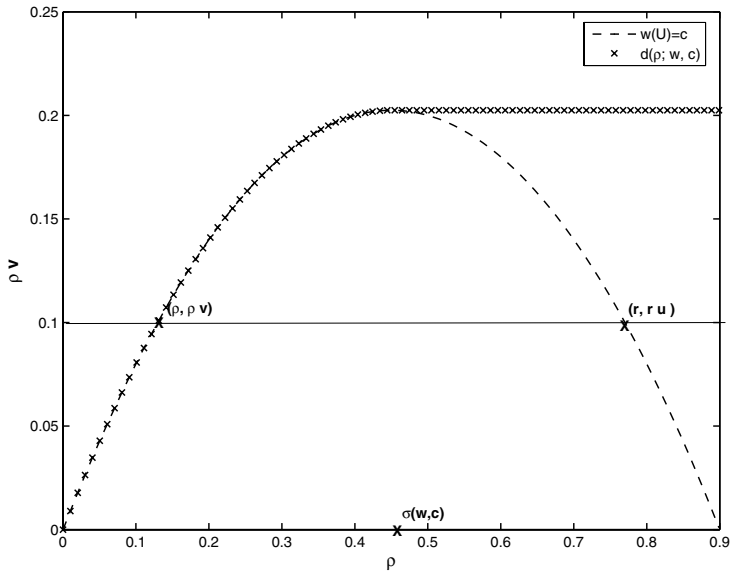

FIG. 2. *Demand function for given* $w(U) = v + p(\rho) = \text{const}$. *Additionally,* $\sigma(w, c)$ *and the position of a sample point* $(\rho, \rho\, v)$ *and the corresponding* $(r, r\, u)$ *are shown.*

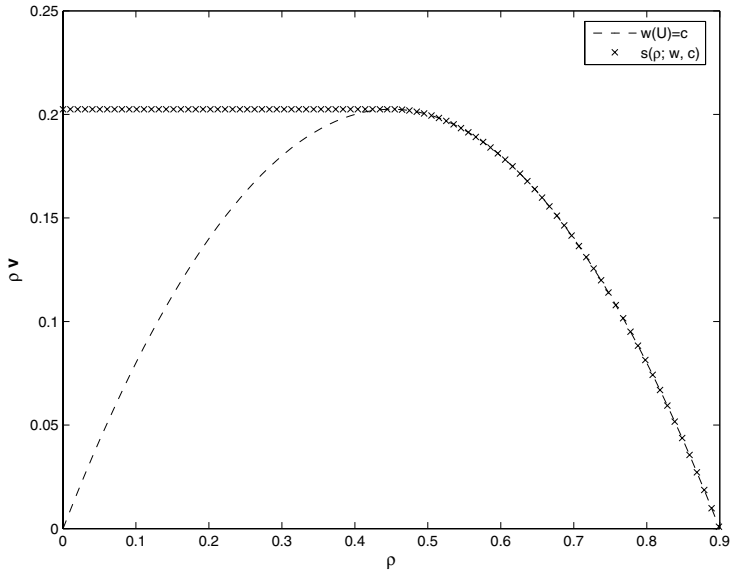

FIG. 3. *Supply function for a given* $w(U) = v + p(\rho) = \text{const}$.

must belong to that curve; i.e., $w_i(U^+) = w^-$ *and* $\rho^+ v^+ \geq 0$. *Depending on* U^- *we distinguish two cases:*

1. $\rho^- < \sigma(w_i, w^-)$: U^+ *is admissible if and only if* $\rho^+ > r(\rho^-; w_i, w^-)$ *or if* $U^+ \equiv U^-$.
2. $\rho^- \geq \sigma(w_i, w^-)$: U^+ *is admissible if and only if* $\sigma(w_i, w^-) \leq \rho^+ \leq 1$.

If $U^- = (0, 0)$, *then the admissible state is* $U^+ \equiv U^-$.

In all cases the maximal possible flux associated with any admissible state U^+ is $d(\rho^-; w, w^-)$ with $w = w_i$.

Proof. For $U^- \neq (0,0)$ the 2-contact discontinuities are waves with speed $v^- > 0$. Hence, we only have to discuss 1-shock or 1-rarefaction waves. Following [2], a left state U^- can be connected to a right state U^+ by a 1-shock if and only if $\rho^+ > \rho^-$. The shock speed is then given by the slope of the chord U^-U^+. A left state U^- can be connected to a right state U^+ by a 1-rarefaction wave if and only if $\rho^+ < \rho^-$. Note that in the $(\rho, \rho v)$ plane the slope of the tangent to the curve $\{w_i(U) = c\}$ at a point U is the characteristic speed $\lambda_1(U)$.

By the discussion in the previous section there exists a state U^* with $\rho^* = r(\rho^-; w_i, w^-)$ and $v^* = u(\rho^-; w_i, w^-)$, such that $w_i(U^*) = w^-$. Furthermore, the chord U^-U^* has a zero slope. Hence, we have a 1-rarefaction wave for all states U^+ with $\sigma(w_i, w^-) \leq \rho^+ \leq \rho^-$, and a 1-shock for $\rho^+ \geq \rho^-$.

In both cases the associated flux is not greater than the demand $d(\rho^-; w, w^-)$.

Finally, if $\rho^+ > 0$, then $U^- = (0,0)$ can be connected to U^+ by a 2-contact discontinuity, which has either positive speed or zero speed; cf. Case 5 in [2]. Hence, only $U^+ \equiv (0,0)$ is admissible. □

Next, we consider the Riemann problem (1.8) for a given *outgoing* road $i \in \delta^+$, a function $w(U) := v + p_i(\rho)$, and a nonnegative constant c. Later on, c will of course depend on the initial states on the incoming roads (!); see sections 3 to 7. We look for "admissible" states U^-, i.e., all the states such that the waves of the solution have a positive speed or such that the solution is a constant. Again, we exclude the case of stationary waves. As in the previous case, U^- will be an intermediate state in the solution on the outgoing road i for the full Riemann problem at the junction. Now $U_i(x_0+, t) = U^-$ will hold.

PROPOSITION 2.2. *Consider a state $U^+ \neq (0,0)$ and the level curve of the first Riemann invariant $\{w(U) = c\}$ with an arbitrary nonnegative constant c.*

Let $U^\dagger = (\rho^\dagger, \rho^\dagger v^\dagger)$ be the point of intersection, if it exists, of the two Riemann invariants $\{v(U) = v^+\}$ and $\{w(U) = c\}$ with $\rho > 0$ and $v > 0$.

Then the "admissible" states U^- for the Riemann problem satisfying $w(U^-) = c$ and $\rho^- v^- \geq 0$ are given by two cases:

1. *$\rho^\dagger \leq \sigma(w, c)$: U^- is admissible if and only if $0 \leq \rho^- \leq \sigma(w, c)$.*
2. *$\rho^\dagger > \sigma(w, c)$: U^- is admissible if and only if $0 \leq \rho^- < r(\rho^\dagger; w, c)$ or if $U^- \equiv U^\dagger$.*

Note that the set of admissible states U^- depends on the existence of the point $U^\dagger$. Now assume that either $U^+ = (0,0)$ or there is no such point $U^\dagger$ with $\rho^\dagger, v^\dagger > 0$. Then we set $U^\dagger = (0,0)$ and as in Case 1, U^- is admissible if and only if $0 \leq \rho^- \leq \sigma(w, c)$.

In all cases the maximal possible flux associated with any "admissible" state U^- is $s(\rho^\dagger; w, c)$.

Proof. Due to the range of the eigenvalues we can connect a left state U^- to an intermediate state $U^\dagger$ by a 1-shock or a 1-rarefaction wave of positive speed. Then $U^\dagger$ can be connected to U^+ by a 2-contact discontinuity.

If $U^\dagger$ exists, it is well defined, since the curves $\{w(U) = c\}$ and $\{v(U) = v^+\}$ have a unique intersection point such that $\rho > 0, \rho v > 0$. If there is no point $U^\dagger$ with $\rho, v > 0$, then the curves have a unique intersection point at $(0,0)$.

Using the same kind of argument as in Proposition 2.1, we see that either the 1-shock or the 1-rarefaction waves connecting U^- and $U^\dagger$ have a positive speed or the solution is constant.

Next, if $\rho^+ = 0$, we set $U^\dagger = U^+$ and can connect to U^- by waves of the first family only; cf. Case 4 in [2]. □

Combining these two results, we obtain the following proposition.

PROPOSITION 2.3. *Consider an incoming (resp., outgoing) road i, an initial datum $U^- := U_{i,0}$ (resp., $U^+ := U_{i,0}$), and an arbitrary flux $q_0 \geq 0$. Let $w(U) := v + p_i(\rho)$ and $c := w(U_{i,0})$. Assume*

$$q_0 \leq d(\rho_{i,0}; w, c) \ (resp., \ q_0 \leq s(\rho_{i,0}; w, c)).$$

By Propositions 2.1 *and* 2.2*, there exists a unique state U^+ (resp., U^-), such that the corresponding Riemann problem* (1.8) *admits a solution such that $w(U^+) = c$ and $\rho^+ v^+ = q_0$ (resp., $w(U^+) = c$ and $\rho^+ v^+ = q_0$)* and *either all the waves have negative (resp., positive) speed, or the solution is a constant on the corresponding road.*

The reader is advised to pay attention to the notation. In the *full* solution to the Riemann problem at a junction we will have

$$\text{for } i \in \delta^- : \ U_i^+ = U_i(x_0-, t) \quad \text{and} \quad \text{for } i \in \delta^+ : \ U_i^- = U_i(x_0+, t). \tag{2.5}$$

Unfortunately, it seems hard to avoid this possibly misleading notation. Moreover, the state referred to here as U^+ will itself be an intermediate state called $U^\dagger$, defined as in Proposition 2.2.

To summarize, Proposition 2.3 describes the set of "admissible" states for the Riemann data on incoming and outgoing roads. We will refer to Proposition 2.3 regarding these states, which will be intermediate states in the solution of the full problem, satisfying (1.6a) *and* (1.6b). We now turn to the study of the first case.

3. One incoming and one outgoing road. The simplest possible network contains two roads connected by a junction, i.e., one road with two different road conditions.

PROPOSITION 3.1. *Consider two roads $i = 1, 2$ with $a_1 = -\infty$, $b_1 = a_2$, and $b_2 = \infty$ and initial data $U_{i,0} = (\rho_{i,0}, \rho_{i,0} v_{i,0})$, $i = 1, 2$ constant.*

Then there exists a unique solution $U_i(x, t)$ of the Riemann problem at the junction (1.8) *and* (1.9) *with the properties* (1) *and* (2)*. We refer to equation* (3.2) *and to the end of the proof for a description of the structure of this solution.*

(1) *$U_i(x, t)$ is a weak solution of the network problem* (1.5a)–(1.5b)*, where $p_i^\dagger \equiv p_i$, $i = 1, 2$, as given in* (1.1)*. Furthermore* (1.6a)–(1.6b) *are satisfied, and $\rho_i(x, t) v_i(x, t) \geq 0$, $i = 1, 2$.*

(2) *The flux $(\rho_1 v_1)(b_1^-, t)$ is maximal at the interface, subject to the above conditions.*

Proof. Let $U_1^- := U_{1,0}$, $U_2^+ := U_{2,0}$, and $w_i(U) = v + p_i(\rho)$ for $i = 1, 2$. As described in section 2 we construct the *demand* function for the incoming road

$$d(\rho) := d(\rho; w_1, w_1(U_1^-)),$$

and the *supply* function for the outgoing road

$$s(\rho) := s(\rho; w_2, w_1(U_1^-)). \tag{3.1}$$

Note that the supply function is an extension of the nonincreasing part of the curve $\{w_2(U) = w_1(U_1^-)\}$. The expression (3.1) of the supply function $s(\cdot)$ involves the *function* w_2 and the *value* $w_1(U_1^-)$, since the cars which are initially on road 1 and have moved onto road 2 have kept their Lagrangian "color" $w_1(U_1^-)$.

By Proposition 2.2 we obtain $U_2^\dagger$ either as the intersection of the curves $\{v_2(U) = v_2^+\}$ and $\{w_2(U) = w_1(U_1^-)\}$ or by $U_2^\dagger = (0,0)$. Then we solve the maximization problem

$$\begin{aligned} &\max q_1 \text{ subject to} \\ &0 \le q_1 \le d(\rho_1^-), \\ &0 \le q_1 \le s(\rho_2^\dagger). \end{aligned}$$

Denote by $\tilde{q}$ the point where the maximum is attained. Of course the above is equivalent to $\tilde{q} = \min\{d(\rho_1^-), s(\rho_2^\dagger)\}$, but we will need the general form later.

Now, as in Proposition 2.3 there exist U_1^+ and U_2^- such that $\rho_1^+ v_1^+ = \rho_2^- v_2^- = \tilde{q}$.

Knowing the states U_1^+ and U_2^-, we solve the two Riemann problems to obtain weak entropy solutions $U_1(x,t)$ and $U_2(x,t)$:

$$i = 1,2 : \partial_t \begin{bmatrix} \rho_i \\ v_i \end{bmatrix} + \partial_x \begin{bmatrix} \rho_i v_i \\ \rho_i v_i w_i \end{bmatrix} = 0, \tag{3.2a}$$

$$i = 1 : U_1(x,0) = \begin{bmatrix} U_1^- \equiv U_{1,0} & x < b_1 \\ U_1^+ & x \ge b_1 \end{bmatrix}, \tag{3.2b}$$

$$i = 2 : U_2(x,0) = \begin{bmatrix} U_2^- & x \le a_2 \\ U_2^+ \equiv U_{2,0} & x > a_2 \end{bmatrix}. \tag{3.2c}$$

Each solution consists of at most two waves: a 1-rarefaction or a 1-shock wave associated with the first eigenvalue, followed by a 2-contact discontinuity associated with the second eigenvalue.

The conditions (1.6a)–(1.6b) are satisfied since

$$\tilde{q} = \rho_1^+ v_1^+ = \rho_2^- v_2^-$$

and

$$w_1(U_1^+) = w_1(U_1^-) = w_2(U_2^-) = w_2(U_2^\dagger). \qquad \square$$

An example of a solution in the (x,t) plane is depicted in Figure 4.

4. One incoming and two outgoing roads. We now consider the case of one incoming and two outgoing roads. We cannot expect to obtain a unique solution without imposing additional assumptions on the distribution of the flux among the outgoing roads. One could impose an optimization criterion, such as maximizing the total flux at the interface [17, 5].

Here, we impose the proportions (α and $(1-\alpha)$) of cars which go from road 1 to roads 2 and 3. This condition was first introduced in [5] for the first-order LWR model and in [12] for the AR model. In the case of first-order models, the car distribution at junctions has also been studied in [23, 8] and many other works.

PROPOSITION 4.1. *Consider three roads $i = 1,2,3$ with $a_1 = -\infty$, $b_1 = a_2 = a_3$, and $b_2 = b_3 = \infty$ and constant initial data $U_{i,0} = (\rho_{i,0}, \rho_{i,0} v_{i,0})$, $i = 1,2,3$. Let $0 \le \alpha \le 1$ be given.*

Then there exists a unique solution $U_i(x,t)$, $i = 1,2,3$, of the Riemann problem at the junction (1.8) *and* (1.9) *with the following properties* (1) *and* (2). *A description of its structure can be found at the end of the proof.*

(1) *$U_i(x,t)$ is a weak solution of the network problem* (1.5a)–(1.5b), *wherein $p_i^\dagger \equiv p_i$ for all $i = 1,2,3$.*

Furthermore (1.6a)–(1.6b) *are satisfied, and $\rho_i(x,t) v_i(x,t) \ge 0$, $i = 1,2,3$.*

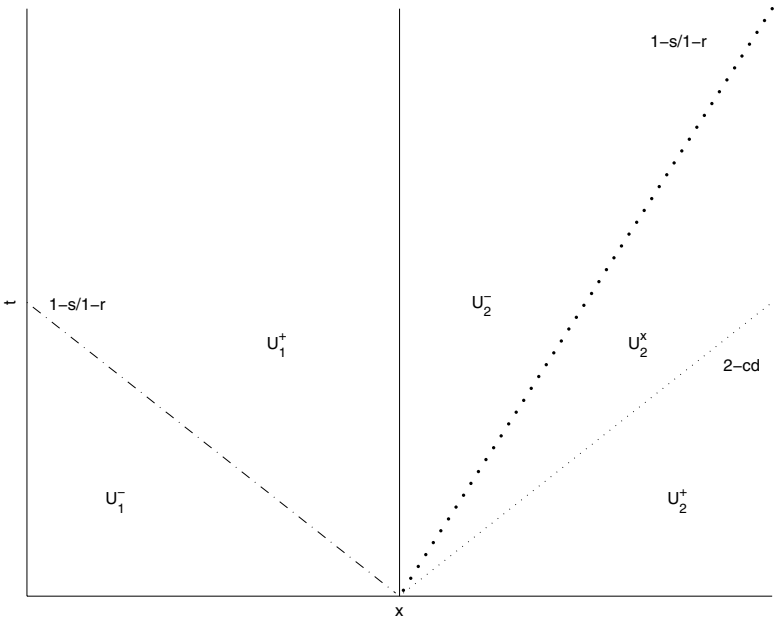

FIG. 4. *Possible solution to the Riemann problems of road* 1 (*left*) *and road* 2 (*right*). $1-s/1-r$ *stands for the* 1*-shock or* 1*-rarefaction wave connecting the left and right states. Similarly,* 2*-cd denotes the* 2*-contact discontinuity.*

(2) *For all* $t > 0$ *the flux is distributed in proportions* α *and* $1-\alpha$ *between roads* 2 *and* 3*:*

$$\alpha(\rho_1 v_1)(b_1^-, t) = (\rho_2 v_2)(a_2^+, t), \tag{4.1a}$$

$$(1-\alpha)(\rho_1 v_1)(b_1^-, t) = (\rho_3 v_3)(a_3^+, t). \tag{4.1b}$$

(3) *The flux* $(\rho_1 v_1)(b_1^-, t)$ *is maximal at the interface, subject to the above conditions.*

Proof. Let $U_1^- = U_{1,0}$, $U_i^+ = U_{i,0}$, $i = 2, 3$, and for $i = 1, 2, 3$ let $w_i(U) := v + p_i(\rho)$. As in section 2 we construct the demand function

$$d(\rho) := d(\rho; w_1, w_1(U_1^-))$$

and the two supply functions

$$s_2(\rho) := s(\rho; w_2, w_1(U_1^-)), \qquad s_3(\rho) := s(\rho; w_3, w_1(U_1^-)).$$

For $i = 2, 3$ we obtain the points $U_i^\dagger$ as the intersection of $\{v(U) = v_i^+\}$ with $\{w_i(U) = w_1(U_1^-)\}$ or as $U_i^\dagger = (0, 0)$; cf. Proposition 2.2. We solve the maximization problem

$$\max q_1 \text{ subject to} \tag{4.2a}$$

$$0 \le q_1 \le d(\rho_1^-), \tag{4.2b}$$

$$0 \le \alpha q_1 \le s_2(\rho_2^\dagger), \tag{4.2c}$$

$$0 \le (1-\alpha) q_1 \le s_3(\rho_3^\dagger). \tag{4.2d}$$

Denote by $\tilde{q}$ the point where the maximum is attained. Of course the above is equivalent to $\tilde{q} = \min\{d(\rho_1^-), s_2(\rho_2^\dagger)/\alpha, s_3(\rho_3^\dagger)/(1-\alpha)\}$. By Proposition 2.3 we conclude that

$$\exists U_1^+ \text{ such that } \rho_1^+ v_1^+ = \tilde{q},\ w_1(U_1^+) = w_1(U_1^-), \tag{4.3a}$$

$$\exists U_2^- \text{ such that } \rho_2^- v_2^- = \alpha\tilde{q},\ w_2(U_2^-) = w_1(U_1^-), \tag{4.3b}$$

$$\text{and } \exists U_3^- \text{such that } \rho_3^- v_3^- = (1-\alpha)\tilde{q},\ w_3(U_3^-) = w_1(U_1^-). \tag{4.3c}$$

Clearly, the conditions (1.6a)–(1.6b) and (4.1a)–(4.1b) are satisfied by (4.3). Again, each solution $U_i(x,t)$ consists of a juxtaposition of rarefaction or shock waves associated with the first eigenvalue and a contact discontinuity associated with the second eigenvalue of (1.1). The construction is similar to (3.2) in Proposition (3.1). In the limit cases $\alpha = 0$ or $\alpha = 1$ we are exactly in the setting of Proposition 3.1. ∎

Before studying the more surprising case of two incoming and one outgoing roads in section 6, we must recall a few basic facts on the Lagrangian version of the model and the corresponding homogenized system.

The reader is advised to take a look at the first part of section 5 and then move to section 6. The second part of section 5 deals with details on the homogenization and can be read after section 6.

5. The Lagrangian model and its homogenized version. The Lagrangian formulation is introduced in [1]. A formal derivation is given in [28] and a mathematical study in [13]. The homogenization of this system is studied in [3]. Proofs of statements below can be found in the above references.

Consider a single road with $p_i := p$. Then it turns out that the weak entropy solutions of

$$\rho_t + (\rho v)_x = 0, \qquad (\rho w)_t + (\rho v w)_x = 0, \qquad w = v + p(\rho)$$

correspond to the weak entropy solutions of the equivalent system in (mass) Lagrangian coordinates (X,t):

$$\tau_t - v_X = 0, \qquad w_t = 0, \qquad w = v + P(\tau), \tag{5.1}$$

with $\tau := 1/\rho, P(\tau) := p(\rho)$. Here, X is the Lagrangian (mass) coordinate, defined by $\partial_x X = \rho$ and $\partial_t X = -\rho\, v$. The existence of $X(\cdot,\cdot)$ follows from the mass conservation equation. For some unspecified t_0, $X(x,t_0) := \int_0^x \rho(y,t_0)\, dy$, where we implicitly define ρ as the dimensionless density, i.e., the *fraction of space* occupied by the cars; see [1]. Therefore X is the position of each car if all cars are parked "nose to tail."

As in [1] consider two different approximations of the system (5.1):

(i) the fully discrete solution of (5.1) constructed with the Godunov scheme, with space and time steps ΔX and Δt;

(ii) the semidiscrete approximation, namely the (infinite) system of ODEs

$$\partial_t \begin{bmatrix} \tau_j \\ w_j \end{bmatrix} - \begin{bmatrix} \frac{v_{j+1}-v_j}{\Delta X} \\ 0 \end{bmatrix} = 0,$$

where ΔX is the length of a car (fixed for simplicity). It is easy to see that this system can be rewritten in the form

$$\dot{x_j} = v_j,\ \dot{w_j} = 0 \text{ with } \tau_j = (x_{j+1} - x_j)/\Delta X,\ w_j = v_j + P(\tau_j). \tag{5.2}$$

In other words, the *semi*discretization of (5.1) is *exactly* the "follow-the-leader model" [15].

The *rigorous* results of convergence in [1, 13] are as follows:

(a) When ΔX and Δt tend to zero with a fixed ratio and satisfy the CFL stability condition, a subsequence of the fully discrete (Godunov) solution converges to a weak entropy solution of (5.1). This limit is viewed as a coarse graining limit, i.e., a "zooming" with the same ratio in X and t ("hyperbolic scaling").

(b) Next, when Δt tends to zero, with ΔX fixed, the Godunov solution converges to the unique solution of the microscopic follow-the-leader model (FLM) system.

(c) Finally, when ΔX tends to zero, this microscopic FLM solution converges to a weak entropy solution to (5.1).

These results were essentially based on uniform a priori BV-estimates (estimates on the total variation) for the Godunov solution. Indeed, this Lagrangian scheme preserves the total variation of the two Riemann invariants if the initial data are BV-functions.

The case of initial data with large oscillations in w, i.e., oscillations in the characteristics of car-driver pairs, is studied in [3]. Oscillations in w also generate oscillations in τ. Note that oscillations in v would be unrealistic (and dangerous!) and would be immediately cancelled by the genuinely nonlinear eigenvalue λ_1.

In the above mentioned (hyperbolic) "zooming," the oscillations in w are wilder and wilder as the zoom parameter goes to 0. Therefore, the corresponding sequence of functions converges only *weakly* to some limit. The above results can be extended, and uniqueness can be proved in this more general setting. The modification involves a homogenized relation between v, w, and τ, which uses the language of Young measures; see [27, 4, 11].

Let us briefly recall a few basic facts on Young measures, adapted to our context. The reader is advised to take a look at the practical example given in section 6.

We introduce a (Lagrangian) grid (X_j) and define $U_j = (\tau_j, w_j)$ and $U_{\Delta X}(X,t) := \sum_j U_j(t)\chi_j(X)$, where χ_j is the characteristic function on $I_j := (X_{j-1/2}, X_{j+1/2})$. For any $\Delta X > 0$, let $U_j^0 = (\tau_j^0, w_j^0)$ be uniformly bounded for all j, and let $U_{\Delta X}^0(X) := \sum_j U_j^0 \chi_j(X)$ be the corresponding sequence of piecewise constant initial data. Of course, this sequence is uniformly bounded in L^∞ when $\Delta X \to 0$.

Therefore [27, 4], there exist a subsequence, still denoted by $U_{\Delta X}^0(\cdot)$, and a family of probability measures $\nu_{X,t}$ in the (v,w) plane, depending on X, such that the weak-$*$ limit of *any* continuous function $F(v_{\Delta X}^0,\, w_{\Delta X}^0)$ is equal a.e. to

$$\langle \nu_{X,t},\, F(v,\, w)\rangle \;:=\; \int F(v,w)\, d\nu_{X,t}(v,\, w). \tag{5.3}$$

Since the sequence $(v_{\Delta X})$ does *not* oscillate, the same subsequence converges pointwise to some strong limit $v^*(X,t)$. Hence, (5.3) can be rewritten as

$$\langle \nu_{X,t},\, F(v,\, w)\rangle \;=\; \langle \mu_X,\, F(v^*(X,t),\, w)\rangle \;:=\; \int F(v^*(X,t),w)\, d\mu_X(w),$$

where the probability measures μ_X describe the weak limit of all functions in the single variable w. Therefore μ depends on X but not on t.

The main result in [3] can be stated as follows.

PROPOSITION 5.1. (i) *Under the above assumptions, the (sub)sequence of weak entropy solutions corresponding to the above (sub)sequence converges in L^∞ weak-$*$*

to the unique weak "entropy" solution $U^* = (\tau^*, w^*)$ *of the* homogenized *problem*

$$\partial_t \tau^* - \partial_X v^* = 0,\ \partial_t w^* = 0. \tag{5.4}$$

(ii) *Furthermore,* $(v_{\Delta X})$ *converges almost everywhere, and the limit state can be characterized as*

$$\tau^*(X,t) = \int P^{-1}(w - v^*(X,t))d\mu_X(w), \tag{5.5a}$$

$$w^*(X,t) = w^*(X,0) = \int w d\mu_X(w), \tag{5.5b}$$

where μ_X *is the Young measure associated with the sequence* $(w_{\Delta X})$.

Moreover, there is a similar result of homogenization for a *multiclass* FLM, similar to (5.2), with *oscillating* data w_j. We again refer to [3] for more details. Proposition 6.1 in the next section deals with a practical example of the above result.

6. Two incoming and one outgoing road. As in section 4, we need an additional assumption to obtain a unique solution at the junction. We introduce a "mixture rule," which describes how cars of the incoming road mix when they enter the outgoing road. One of the most natural assumptions is an equal priority rule: *The cars of both incoming roads enter the outgoing road alternately.*

Note that other assumptions on the mixture of cars are also possible. The discussion below remains valid with obvious changes according to different mixture rules.

PROPOSITION 6.1. *Consider three roads* $i = 1,2,3$ *with* $a_1 = a_2 = -\infty$, $b_1 = b_2 = a_3$, *and* $b_3 = \infty$ *and constant initial data* $U_{i,0} = (\rho_{i,0}\rho_{i,0}v_{i,0})$, $i = 1,2,3$.

Then there exists a unique solution $U_i(x,t)$, $i = 1,2,3$, *of the Riemann problem at the junction* (1.8) *and* (1.9) *with the following properties.*

(1) $U_i(x,t)$ *is a weak solution of the network problem* (1.5a)–(1.5b), *where* $p_i^\dagger \equiv p_i$ *for the incoming roads* $i = 1,2$.
For the outgoing road $i = 3$, *we obtain two different expressions for* $p_3^\dagger$, *depending on the position* (x,t)*:*
   (a) *In the triangle* $\{(x,t) : a_3 \le x \le a_3 + v_{3,0}t\}$ *of the* $x-t$ *plane, we consider the* homogenized solution *described below. Therefore,* $p_i^\dagger(\cdot) := p_i^*(\cdot)$ *is given by* (6.3)–(6.6). *This solution depends on the applied mixture principle, the initial data on* $U_{1,0}, U_{2,0}$, *and the road conditions* p_3. *The triangle is bounded at any fixed time* $t > 0$ *by* $x = a_3$ *and* $x = a_3 + tv_{3,0}$.
   (b) *In the remaining part of the outgoing road we have* $p_3^\dagger \equiv p_3$.

(2) *The equations* (1.6a)–(1.6b) *are satisfied, with* $\rho_i(x,t)v_i(x,t) \ge 0$, $1 \le i \le 3$. *In particular* $U_3(a_3^+, t)$ *satisfies*

$$w_3^\dagger(U_3(a_3^+,t)) := w_3^*(U_3(a_3^+,t)) := v_3(a_3^+,t) + p_3^*(\rho_3(a_3^+,t)) = \bar{w},$$

where $\bar{w}$ *is the* homogenized value*:*

$$\bar{w} := \frac{1}{2}\left(w_1(U_{1,0}) + w_2(U_{2,0})\right). \tag{6.1}$$

(3) *The two incoming fluxes are equal (equal priority rule), and the total flux* $2(\rho_1 v_1)(b_1^-, t) = 2(\rho_2 v_2)(b_2^-, t) = (\rho_3 v_3)(a_3^+, t)$ *is maximal subject to the other conditions.*

Before giving the proof of this result, let us motivate the definition of (6.1) and the necessity of dealing with a function p_3^*. Consider the discrete FLM (5.2), with oscillating $w_j = v_j + P(\tau_j)$:

$$\partial_t \begin{bmatrix} \tau_j \\ w_j \end{bmatrix} - \begin{bmatrix} \frac{v_{j+1}-v_j}{\Delta X} \\ 0 \end{bmatrix} = 0.$$

More precisely, consider a microscopic situation on the outgoing road 3. As in the introduction of this section, assume that the cars coming from each incoming road pass the junction in an alternating way.

Although w was *constant* on each of the roads 1 and 2, the outgoing flow is obviously oscillating. In fact, in *Lagrangian* coordinates,

$$w_j^0 = \begin{bmatrix} w_1 & j \text{ even} \\ w_2 & j \text{ odd} \end{bmatrix},$$

where the constants w_1 and w_2 are given by the two *incoming* flows. The corresponding function P on the outgoing road is the function $P_3(\tau) := p_3(1/\tau)$. Then the piecewise constant approximation $w_{\Delta X}$ alternately takes the two values w_1 and w_2. Consequently, for any continuous function F,

$$F(w_{\Delta X}) \rightharpoonup^* (F(w))^* := \frac{1}{2}(F(w_1) + F(w_2)) = \int F(w) d\mu_X(w),$$

$$\text{where } \mu_X := \frac{1}{2}\left(\delta_{w_1} + \delta_{w_2}\right). \tag{6.2}$$

The value of w has to be given by (6.1), since one car out of two comes from each road 1 or 2 (think of black and white cars producing a grey homogenized flow) *and* since any Lagrangian interval of length ΔX contains one car. Recall that we assumed that all cars have the same length. This assumption could be relaxed, and the formulas would be modified in an obvious way.

Therefore, in the limit $\Delta X \to 0$, the cars passing through the junction have the average property associated with the Young measure μ_X in (6.2). By section 5, the corresponding homogenized solution is the unique weak entropy solution of (5.4), where τ^* is given by (5.5a), i.e., here by

$$\tau^*(X,t) = \frac{1}{2}\left(P_3^{-1}(w_1 - v^*(X,t)) + P_3^{-1}(w_2 - v^*(X,t))\right), \tag{6.3}$$

which (by monotonicity of P_3) defines a one-to-one relation between $v := v^*(X,t)$ and $\tau := \tau^*(X,t)$.

We *choose* to rewrite (6.3) in the form

$$v = w - P_3^*(\tau),\ w := \bar{w}, \tag{6.4}$$

where $\bar{w}$ is given by (6.1). In other words, we *define* P_3^* so that, for each $\tau = \tau^*$, the value $v = v^*$ defined by (6.4) is the *unique* solution of (6.3) to the unknown v. This (convenient) notation could be misleading for an *arbitrary* value w. Indeed, the homogenized relation between v and τ depends on μ_X; see (5.5a). Therefore, it depends on the local proportions of cars coming from each incoming road. In other words, (6.4) would be *wrong* for any value $w \neq \bar{w}$. However, as we see below, on the relevant portion of road 3, the homogenized w *only* takes the value $\bar{w}$.

Now, three questions arise:

(i) How do we express this in Eulerian coordinates?

(ii) In Eulerian coordinates, what is the portion of road 3 concerned with this homogenized flow?

(iii) Does this solution respect the Rankine–Hugoniot relations (1.6a), (1.6b) at the interface $x = b_1 = b_2 = a_3$, and how is it connected with the downstream flow on road 3?

(i) First (see [1]), we can rewrite (5.4), (6.3) in Eulerian coordinates to get the equivalent system (even for weak entropy solutions):

$$\partial_t \rho + \partial_x(\rho v) = 0, \tag{6.5a}$$

$$\partial_t(\rho w) + \partial_x(\rho v w) = 0, \tag{6.5b}$$

$$w(U) \equiv w^*(U) = v + p_3^*(\rho), \tag{6.5c}$$

with $w(U) \equiv \bar{w}$ and

$$p_3^*(\rho) := P_3^*(\rho^{-1}) \tag{6.6}$$

defined by (6.4). Again, for *arbitrary* values of w, we would not recover the correct homogenized solution.

(ii) In the (x,t) plane, at time $t > 0$, the portion of road 3 concerned with this self-similar, homogenized flow is a triangle bounded by $x = b_1 = b_2 = a_3$ and by $x = a_3 + t\, v_{3,0}$. Here, $v_{3,0}$ is the initial datum on road 3.

(iii) On the above portion of road 3, our solution satisfies (6.5), (6.6) and the value of w is *a constant* and is equal to the corresponding average value given by (6.1).

The boundary data specified below preserve the conservation of mass at the intersection and satisfy the equal priority rule on the mixture of the cars:

$$\rho_3\, v_3 = \rho_1\, v_1 + \rho_2\, v_2 = 2\,\rho_1\, v_1.$$

Therefore, combining with (6.1), we see that $\rho_3\, v_3\, w_3 = \rho_1\, v_1\, w_1 + \rho_2\, v_2\, w_2$; i.e., we recover (1.6b): Our solution *also* satisfies the conservation of $y = \rho\, w$ at the junction. Roughly speaking, the total number of white cars is also preserved at the intersections!

Now we can give the proof of Proposition 6.1.

Proof. Let $U_i^- = U_{i,0}$ for $i = 1, 2$ and let $U_3^+ = U_{3,0}$. Denote by $w_i(U) = v + p_i(\rho)$. Let the demand functions d_1 and d_2 be defined by

$$d_1(\rho) := d(\rho; w_1, w_1(U_1^-)), \qquad d_2(\rho) := d(\rho; w_2, w_2(U_2^-)).$$

With all the previous remarks in mind and again with $w_3^\dagger(U) = v + p_3^\dagger(U)$ and $p_3^\dagger(\cdot) := p_3^*(\cdot)$, we consider the following supply function:

$$s_3(\rho) := s_3^\dagger(\rho) := s(\rho; w_3^\dagger, \bar{w}),\ \bar{w} = \frac{1}{2}\left(w_1(U_1^-) + w_2(U_2^-)\right).$$

As in Proposition 2.2 we obtain the intermediate state $U_3^\dagger = (\rho_3^\dagger, \rho_3^\dagger v_3^\dagger)$ as the intersection of $\{v_3(U) = v_3^+\}$ and $\{w_3^\dagger(U) = \bar{w}\}$, or as $U_3^\dagger = (0,0)$. Then we solve for

q_1, q_2:

$$\begin{aligned} &\max q_1 + q_2 \text{ subject to} \\ 0 \le \quad & q_i \quad \le d_i(\rho_i^-), \qquad i = 1, 2, \\ 0 \le \quad & q_1 + q_2 \quad \le s_3(\rho_3^\dagger), \\ & q_1 = q_2. \end{aligned}$$

Clearly, $\tilde{q} = q_1 = q_2 = \min\{s_3(\rho_3^\dagger)/2, d_1(\rho_1^-), d_2(\rho_2^-)\}$ is the unique solution. As in Proposition (2.3) we conclude that

$$\begin{aligned} \exists U_i^+ \text{ such that } \rho_i^+ v_i^+ = \tilde{q}, \quad w_i(U_i^+) = w_i(U_i^-),\ i = 1, 2, \\ \exists U_3^- \text{ such that } \rho_3^- v_3^- = 2\tilde{q}, \quad w_3^\dagger(U_3^-) = \bar{w}. \end{aligned}$$

We recall that $U_i(b_i-, t) = U_i^+$ for $i = 1, 2$ and $U_3(a_3+, t) = U_3^-$.

Then the conditions (1.6a)–(1.6b) are satisfied. Using the considerations above, the function $p_3^\dagger$ is defined in the triangle $\{(x, t) : a_3 \le x \le a_3 + tv_{3,0}\}$ of the $x - t$ plane.

Each solution $U_i(x, t)$ is a juxtaposition of either a rarefaction or a shock wave and a contact discontinuity.

In particular, on the outgoing road $i = 3$, the states U_3^- and $U_3^\dagger$ are connected by a rarefaction or a shock wave associated with the first eigenvalue of system (1.1), with $p_i = p_3^\dagger = p_3^*$. Then $U_3^\dagger$ is connected to $U_3^+ = U_{3,0}$ by a contact discontinuity associated with the second eigenvalue $\lambda_2 = v_{3,0}$, which is *independent* of p_i. Hence, out of the above mentioned triangle, $U_3(x, t) \equiv U_{3,0}$. ∎

An example of a solution is depicted in Figures 5 and 6.

7. Arbitrary number of incoming and outgoing roads. We combine the results of sections 4 to 6 to treat the general case. We consider a fixed junction with m incoming roads $\delta^- = \{1, \dots, m\}$ and n outgoing roads $\delta^+ = \{m + 1, \dots, m + n\}$. We assume constant initial data $U_{i,0}$ for all i and we look for solutions to the Riemann problem (1.8) and (1.9).

In sections 4 to 6 we imposed additional conditions to obtain a unique solution. Here, as in section 6 we introduce a mixture principle for the outgoing traffic which is an extension of the equal priority rule; cf. assumption (H4) below. However, the stated results can be adapted to other mixture rules.

For a set of functions $U_i(x, t) = (\rho_i(x, t), \rho_i(x, t)v_i(x, t))\,,\ i \in \delta^- \cup \delta^+$, we introduce the following abbreviations:

$$\mathbf{q}_i := \rho_i(b_i^-, t)v_i(b_i^-, t)\ \forall i \in \delta^-, \tag{7.1a}$$

$$\mathbf{q}_j := \rho_j(a_j^+, t)v_j(a_j^+, t)\ \forall j \in \delta^+. \tag{7.1b}$$

Next, we introduce real numbers $q_{ji} \in \mathbb{R}$ for $j \in \delta^+$ and $i \in \delta^-$ corresponding to the (a priori unknown) *actual fluxes* of cars coming from road i and going to road j. Since the number of cars entering and leaving the junction is the same,

$$\mathbf{q}_i = \sum_{j \in \delta^+} q_{ji}, \qquad \mathbf{q}_j = \sum_{i \in \delta^-} q_{ji}. \tag{7.2}$$

We look for a solution $U_k(x, t)$ which satisfies the following assumptions and constraints.

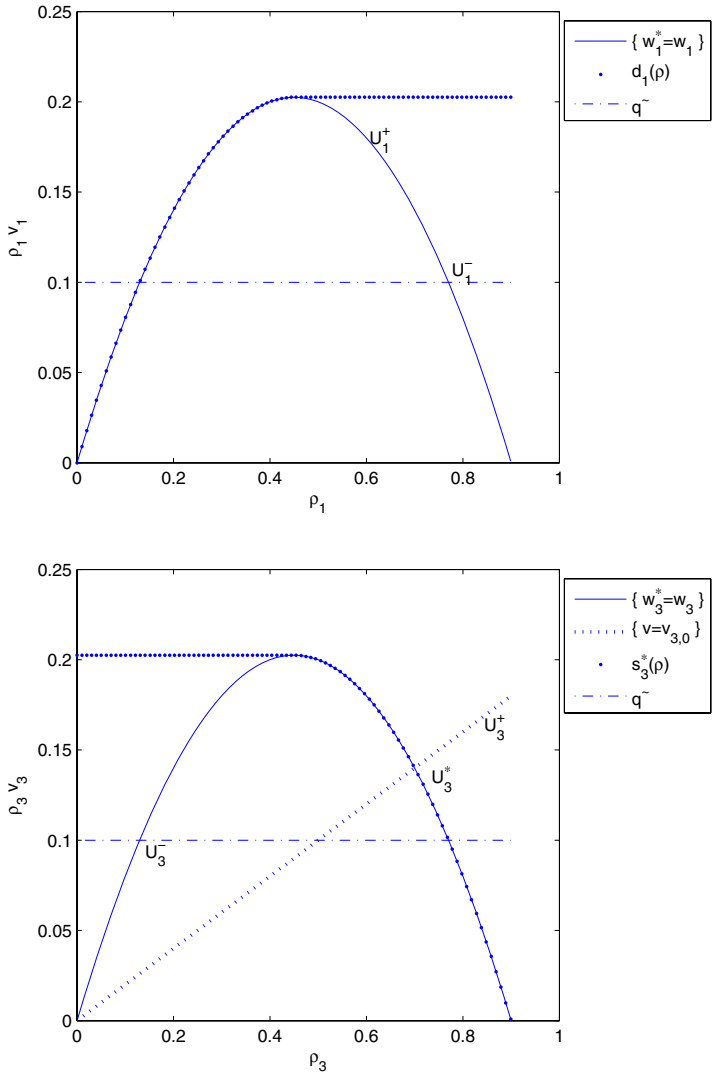

FIG. 5. *An example of intermediate states on road* 1 (*top*) *and road* 3 (*bottom*) *in the case where* $\tilde{q} = d_2(\rho_{2,0}; w_2, w_2(U_{2,0}))$, *i.e.,* $\tilde{q} < d_1(\cdot)$ *and* $\tilde{q} < s_3^\dagger(\cdot)$, *respectively. In this case the solution* U_2 *on road* 2 *is a constant* $U_2(x,t) = U_{2,0} \equiv U_2^-$ *and therefore is omitted from the plots. In the drawings* U_3^*, s_3^*, w_3^*, *and* w_1^* *stand for* $U_3^\dagger, s_3^\dagger, w_3^\dagger$, *and* $w_1^\dagger$, *respectively.*

(H1) Preferred choice of the drivers:
As in [12] we are given a matrix A,

$$A = (\alpha_{ji})_{j\in\delta^+, i\in\delta^-} \in \mathbb{R}^{n\times m}, \tag{7.3}$$

such that $0 \le \alpha_{ji} \le 1$ and $\sum_{j\in\delta^+} \alpha_{ji} = 1 \; \forall i \in \delta^-$.
We introduce $\mathbf{a}_j := \sum_{i\in\delta^-} \alpha_{ji}$ for notational convenience. We impose the constraint

$$q_{ji} = \alpha_{ji}\mathbf{q}_i \qquad \forall j \in \delta^+, \; i \in \delta^-. \tag{7.4}$$

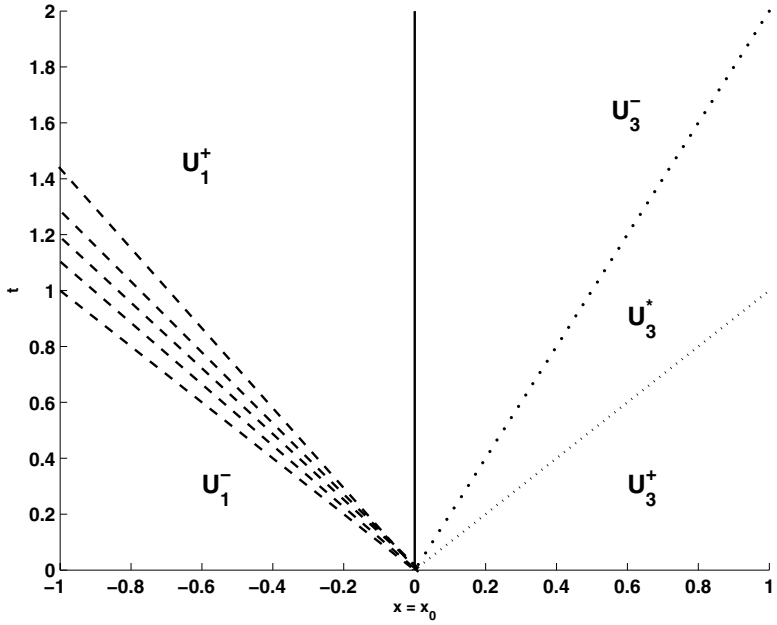

FIG. 6. *Plot of the solution U_1 and U_3 in the $x-t$ plane with data as in Figure 5. Left of the interface, $U_1^- \equiv U_{1,0}$ is connected by a 1-rarefaction to U_1^+. Right of the interface, U_3^- is connected by a 2–shock to $U_3^* \equiv U_3^\dagger$, and this state in turn is connected to $U_3^+ \equiv U_{3,0}$ by a 2–contact discontinuity. We omit the solution U_2 since it is constant.*

(H2) Relation for $w_j^\dagger$ (on the outgoing roads):

$$\forall j \in \delta^+ : w_j^\dagger(U_j(a_j^+,t)) = \sum_{i\in\delta^-} \frac{q_{ji}}{\mathbf{q}_j} w_i(U_i(b_i^-,t)). \tag{7.5}$$

As in the previous sections $w_i(U_i(b_i-,t)) = w_i(U_{i,0})\ \forall i \in \delta^-$ and $\forall j \in \delta^+$:

$$w_j^\dagger(U_j(a_j^+,t)) := v_j(a_j^+,t) + p_j^\dagger(\rho_j(a_j^+,t)) = \bar{w}_j.$$

The functions $p_j^\dagger$ and the homogenized values $\bar{w}_j$ have to be specified later.

(H3) Bounds on the actual fluxes:

$$0 \le \mathbf{q}_i \le d_i(\rho_{i,0})\ \forall i \in \delta^-, \tag{7.6a}$$

$$0 \le \mathbf{q}_j \le s_j(\rho_j^\dagger)\ \forall j \in \delta^+. \tag{7.6b}$$

Here d_i denotes the demand function on road i, i.e., $d_i := d_i(\rho; w_i, w_i(U_{i,0}))$, where $w_i(U) = v + p_i(\rho)$, and $s_j := s_j(\rho; w_j^\dagger, \bar{w}_j)$ is the supply function on road j. The functions $w_j^\dagger$ and the homogenized values $\bar{w}_j$ are specified later and depend on the applied mixture rule. Finally, $(\rho_j^\dagger, \rho_j^\dagger v_j^\dagger)$ is the intermediate state on road j, i.e., the unique intersection of the curves $\{v_j(U) = v_{j,0}\}$ and $\{w_j^\dagger(U) = \bar{w}_j\}$.

In order to define a unique solution, we have to impose a further constraint, i.e., a maximization criterion as in [17, 12]. Here, as in section 6, we choose to impose the following rule.

(H4) The mixture rule:
The *actual* incoming fluxes $(\mathbf{q}_i)_{i\in\delta^-}$ are proportional to a *given* nonnegative vector $(\tilde{q}_i)_{i\in\delta^-}$. The equal priority rule introduced in section 6 is a particular subcase, with $(\tilde{q}_i)_{i\in\delta^-} = (1,\dots,1)$. So we impose in general

$$\mathbf{q}_i = \tilde{q}\,\tilde{q}_i \geq 0, \tag{7.7}$$

where $\tilde{q} > 0$ is *a priori unknown*, but $(\tilde{q}_i)_{i\in\delta^-}$ is given.

THEOREM 7.1. *Consider a junction with m incoming and n outgoing roads, with constant initial data $U_{i,0} = (\rho_{i,0}, \rho_{i,0}v_{i,0})$ $\forall i \in \delta^- \cup \delta^+$ under the assumptions* (H1)–(H4).

Then there exists a unique solution $\{U_i(x,t)\}_{i\in\delta^-\cup\delta^+}$ to the Riemann problems (1.8)–(1.9) *which is described below, and which satisfies the following properties.*

(1) *$\{U_i(x,t)\}_{i\in\delta^-\cup\delta^+}$ is a weak entropy solution of the network problem* (1.5a)–(1.5b) *and for $i \in \delta^- : p_i^\dagger \equiv p_i$.*

For the outgoing roads $j \in \delta^+$ we obtain two different expressions for $p_j^\dagger$, depending on the region. In the $x-t$ plane in a triangle near the junction, we consider the homogenized solution and hence $p_j^\dagger(\cdot) = p_j^*(\cdot)$ defined below in (7.14). *This triangle is defined by $\{(x,t) : a_j \leq x \leq tv_{j,0}\}$ for any fixed time $t > 0$. Beyond this triangle we have $p_j^\dagger(\cdot) \equiv p_j(\cdot)$.*

(2) *The constraints* (7.4)–(7.6) *are satisfied, and the homogenized values $\bar{w}_j$ are given by*

$$\bar{w}_j := \sum_{i\in\delta^-} \frac{q_{ji}}{\mathbf{q}_j} w_i(U_{i,0})\ \forall j \in \delta^+. \tag{7.8}$$

The ratios $q_{ji}/\mathbf{q}_j$ are defined below in (7.15).

(3) *Moreover, the incoming fluxes satisfy* (7.7) *and are maximal subject to the other conditions.*

For simplicity we restrict ourselves the case of the equal priority rule. Obviously the proof can be extended to the general case (7.7). Note that the matrix A plays the same role as in [12], but we do *not* need the same restrictions on A.

Proof. With the discussion in section 6 in mind we consider the following supply functions for $j \in \delta^+$:

$$s_j(\rho) := s(\rho; w_j^\dagger; \bar{w}_j), \tag{7.9}$$

$$\bar{w}_j := \sum_{i\in\delta^-} \frac{q_{ji}}{\mathbf{q}_j} w_i(U_{i,0}), \tag{7.10}$$

where $w_i(U) = v + p_i(U)$ $\forall i \in \delta^-$ and where $w_j^\dagger(U) = v + p_j^\dagger(U)$ and $p_j^\dagger(\cdot) := p_j^*(\cdot)$ $\forall j \in \delta^+$. For each $j \in \delta^+$, $p_j^*(\cdot)$ is defined as in section 6. Namely, we first define the function

$$P_j(\tau) := p_j(1/\tau). \tag{7.11}$$

Then we set

$$v \to \tau := \sum_{i\in\delta^-} \frac{q_{ji}}{\mathbf{q}_j} P_j^{-1}(w_i(U_{i,0}) - v). \tag{7.12}$$

Next, we *choose* to define a new invertible function P_j^* by rewriting the relation (7.12) under the form

$$\tau := (P_j^*)^{-1}(\bar{w}_j - v), \tag{7.13}$$

which we use *only* with the particular value $\bar{w}_j$ defined in (7.8). Finally, we set

$$p_j^\dagger(\rho) := p_j^*(\rho) := P_j^*(1/\rho). \tag{7.14}$$

Of course this construction assumes that the proportions $q_{ji}/\mathbf{q}_j$ are known. Here, thanks to the crucial assumption (H4), we can determine them:

$$\frac{q_{ji}}{\mathbf{q}_j} = \frac{\alpha_{ji}\mathbf{q}_i}{\sum_{i\in\delta^-} q_{ji}} = \frac{\alpha_{ji}\tilde{q}_i}{\sum_{i\in\delta^-}\alpha_{ji}\tilde{q}_i}\ \forall i\in\delta^-,\ \forall j\in\delta^+. \tag{7.15}$$

In particular in the case of the equal priority rule, $\tilde{q}_i = 1\ \forall i\in\delta^-$ holds true. Therefore, $\mathbf{q}_i = \tilde{q}$, $\mathbf{q}_j = \mathbf{a}_j\tilde{q}$, and $q_{ji}/\mathbf{q}_j = \alpha_{ji}/\mathbf{a}_j$ for $i\in\delta^-$, $j\in\delta^+$ and for some unknown $\tilde{q}\in\mathbb{R}$.

Before we turn to the determination of $\tilde{q}$ we define $U_j^\dagger$. As in Proposition 2.2 we obtain for each j the intermediate state $U_j^\dagger$ as the intersection of $\{v_j(U) = v_{j,0}\}$ and $\{w_j^\dagger(U) = \bar{w}_j\}$.

Now, we obtain $\tilde{q}$ as the unique solution to the following maximization problem:

$$\max_{q\in\mathbb{R}} q \ \text{ subject to} \tag{7.16a}$$

$$0 \le \mathbf{q}_i = q \le d_i(\rho_{i,0}; w_i; w_i(U_{i,0}))\ \forall i\in\delta^-, \tag{7.16b}$$

$$0 \le \mathbf{q}_j = \mathbf{a}_j q \le s_j(\rho_j^\dagger; w_j^\dagger; \bar{w}_j)\ \forall j\in\delta^+, \tag{7.16c}$$

where the functions $s_j(\cdot), w_j^\dagger(\cdot)$ and the values $\bar{w}_j$ are well defined since the proportions $q_{ji}/\mathbf{q}_j$ are known.

We conclude as before that

$$\begin{aligned}
&\exists U_i^+ \text{ such that } \rho_i^+ v_i^+ = \tilde{q},\quad w_i(U_i^+) = w_i(U_{i,0})\ \forall i\in\delta^+,\\
&\exists U_j^- \text{ such that } \rho_j^- v_j^- = \mathbf{a}_j\tilde{q},\quad w_j^\dagger(U_j^-) = \bar{w}_j\ \forall j\in\delta^+.
\end{aligned}$$

The conditions (1.6a)–(1.6b) are satisfied. Also (7.5) and (7.6) are fulfilled.

Again, each $U_i(x,t)$ consists of a juxtaposition of rarefaction or shock waves associated with the first eigenvalue and, for $i\in\delta^+$, an additional contact discontinuity associated with the second eigenvalue. Furthermore, the solution satisfies on the incoming roads $i\in\delta^- : U_i^+ = U_i(b_i-,t)$ and on the outgoing roads $j\in\delta^+ : U_j^- = U_i(a_j+,t)$.

For general $\tilde{q}_i$, (7.16b) and (7.16c), respectively, become

$$\begin{aligned}
&0 \le \mathbf{q}_i = \tilde{q}_i\, q \le d_i(\rho_{i,0}; w_i, w_i(U_{i,0}))\ \ \forall i\in\delta^-,\\
&\text{and } 0 \le \mathbf{q}_j = \left(\sum_{i\in\delta^-}\alpha_{ji}\tilde{q}_i\right) q \le s_j^\dagger(\rho_{j,0}; w_j^\dagger, \bar{w}_j)\ \ \forall j\in\delta^+. \qquad \square
\end{aligned}$$

8. Conclusion. In this paper, we have introduced coupling conditions for the AR traffic flow model. Contrary to [12] the total "momentum" (e.g., the total number of white cars) is conserved at each junction. We have presented the full solution to Riemann problems for different cases and have given a microscopic motivation and validation of the approach. Last, we have discussed the general case of arbitrary numbers of incoming and outgoing roads. The most striking fact is the role of the homogenized flow on some part of the outgoing roads. It is worth noting that, even with Riemann data and with the *same* function $p_j \equiv p$ on *all* the roads, after some time, due to the mixture of cars at each junction, the flow is associated with a *new homogenized* pseudopressure $p_j^\dagger$, which depends on the proportions of the mixture.

As we already said in section 2, the model presented is too sophisticated for real life applications. But it contains as a particular case the classical first-order models.

HIGH FREQUENCY ANALYSIS OF HELMHOLTZ EQUATIONS: CASE OF TWO POINT SOURCES*

ELISE FOUASSIER†

Abstract. We derive the high frequency limit of the Helmholtz equation with source term when the source is the sum of two point sources. We study it in terms of Wigner measures (quadratic observables). We prove that the Wigner measure associated with the solution satisfies a Liouville equation with, as source term, the sum of the source terms that would be created by each of the two point sources taken separately. The first step, and main difficulty, in our study is to obtain uniform estimates on the solution. Then, from these bounds, we derive the source term in the Liouville equation together with the radiation condition at infinity satisfied by the Wigner measure.

Key words. Wigner measures, high frequencies, energy propagation

1. Introduction.

In this article, we are interested in the analysis of the high frequency limit of the Helmholtz equation

$$-i\frac{\alpha_\varepsilon}{\varepsilon}u^\varepsilon + \Delta u^\varepsilon + \frac{n(x)^2}{\varepsilon^2}u^\varepsilon = S^\varepsilon(x), \qquad x \in \mathbb{R}^3, \tag{1.1}$$

with

$$S^\varepsilon(x) = S_0^\varepsilon(x) + S_1^\varepsilon(x) = \frac{1}{\varepsilon^3}S_0\Big(\frac{x}{\varepsilon}\Big) + \frac{1}{\varepsilon^3}S_1\Big(\frac{x-q_1}{\varepsilon}\Big),$$

where q_1 is a point in $\mathbb{R}^3$ different from the origin.

In what follows, we assume that the refraction index n is constant, $n(x) \equiv 1$.

Equation (1.1) models the propagation of a source wave in a medium with refraction index $n(x)$. There, the small positive parameter ε is related to the frequency $\omega = \frac{1}{2\pi\varepsilon}$ of u^ε. In this paper, we study the high frequency limit, i.e., the asymptotics $\varepsilon \to 0$. We assume that the regularizing parameter α_ε is positive, with $\alpha_\varepsilon \to 0$ as $\varepsilon \to 0$. The positivity of α_ε ensures the existence and uniqueness of a solution u^ε to the Helmholtz equation (1.1) in $L^2(\mathbb{R}^3)$ for any $\varepsilon > 0$.

The source term S^ε models a source signal that is the sum of two source signals concentrating, respectively, close to the origin and close to the point q_1 at the scale ε. The concentration profiles S_0 and S_1 are given functions. Since ε is also the scale of the oscillations dictated by the Helmholtz operator $\Delta + \frac{1}{\varepsilon^2}$, resonant interactions can occur between these oscillations and the oscillations due to the sources S_0^ε and S_1^ε. On the other hand, since the two sources are concentrating close to two different points in $\mathbb{R}^3$, one can guess that they do not interact when $\varepsilon \to 0$. These are the phenomena that the present paper aims at studying quantitatively. We refer to section 3 for the precise assumptions we need on the sources.

In some sense, the sign of the term $-i\alpha_\varepsilon u^\varepsilon/\varepsilon$ prescribes a radiation condition at infinity for u^ε, i.e., the oscillations of the solution at infinity (as $e^{-in|x|}$). One of the key difficulties in our problem is following this condition in the limiting process $\varepsilon \to 0$. We refer to section 3 for more details.

We study the high frequency limit in terms of Wigner measures (or semiclassical measures). This is a means of describing the propagation of quadratic quantities, like the local energy density $|u^\varepsilon(x)|^2$, as $\varepsilon \to 0$. The Wigner measure $\mu(x,\xi)$ is the energy carried by rays at the point x with frequency ξ. These measures were introduced by Wigner [14] and mathematically developed by Gérard [6] and Lions and Paul [9] (see also the surveys [3] and [7]). They are relevant when a typical length ε is prescribed. They have already proven to be an efficient tool in the study of high frequencies; see, for instance, [2], [4] for Helmholtz equations, Gérard et al. [7] for periodic media, Papanicolaou and Ryzhik [11] for a formal analysis of general wave equations, Erdös and Yau [5] for an approach linked to statistical physics, and Miller [10] for a study in the case with sharp interface.

The high frequency limit of Helmholtz equations has been studied in Benamou et al. [2] and Castella, Perthame, and Runborg [4]. In [2], the authors considered the case of one point source and a general index of refraction, whereas in [4] they treated the case of a source concentrating close to a general manifold with a constant refraction index. In the present paper, we borrow the methods used in both articles.

In the case of one point source, for instance, S_0^ε only, with a constant index of refraction, it is proved in [2] that the corresponding Wigner measure μ_0 is the solution to the Liouville equation

$$0^+\mu_0(x,\xi) + \xi\cdot\nabla_x\mu_0(x,\xi) = Q_0(x,\xi) = \frac{1}{(4\pi)^2}\delta(x)\delta(|\xi|^2-1)|\widehat{S_0}(\xi)|^2,$$

the term 0^+ meaning that μ is the outgoing solution given by

$$\mu_0(x,\xi) = \int_{-\infty}^0 Q_0(x+t\xi,\xi)dt.$$

In particular, the energy source created by S_0^ε is supported at $x=0$. Similarly, the energy source created by the source S_1^ε is supported at $x=q_1$. Thinking of the orthogonality property on Wigner measures, one can guess that the energy source generated by the sum $S_0^\varepsilon + S_1^\varepsilon$ is the sum of the two energy sources created asymptotically by S_0^ε and S_1^ε.

Indeed, we prove in this paper that the Wigner measure μ associated with the sequence (u^ε) satisfies

$$0^+\mu(x,\xi) + \xi\cdot\nabla_x\mu(x,\xi) = Q_0 + Q_1, \tag{1.2}$$

where Q_0 and Q_1 are the source terms obtained in [2] in the case of one point source. However, our proof does not rest on the mere orthogonality property.

Let us now give some details about our proof. Our strategy is borrowed from [2]. First, we prove uniform estimates on the sequence of solutions (u^ε). It turns out that we also need to study the limiting behavior of (and to estimate) the rescaled solutions $\varepsilon u^\varepsilon(\varepsilon x)$ and $\varepsilon u^\varepsilon(q_1+\varepsilon x)$. The latter point is the key difficulty in our paper. It relies on the study of the sequence (a^ε) such that

$$-i\alpha_\varepsilon\varepsilon a^\varepsilon + \Delta a^\varepsilon + a^\varepsilon = S_1\Big(x - \frac{q_1}{\varepsilon}\Big).$$

Using the explicit formula for the Fourier transform of a^ε, we prove that a^ε is uniformly bounded in a suitable space and that $a^\varepsilon \to 0$ as $\varepsilon \to 0$ weakly. We would like to point out that our analysis, based on a study in Fourier space, strongly rests on the assumption of a constant index of refraction.

Second, our results on the Wigner measure then follow from the properties proved in [2]. They are essentially consequences of the uniform bounds on (u^ε): we write the equation satisfied by the Wigner transform associated with (u^ε) and pass to the limit $\varepsilon \to 0$ in the various terms that appear in this equation. The only difficult (and new) term to handle is the source term.

Third, we prove an improved version of the radiation condition of [2]. Our argument relies on the observation that μ is localized on the energy set $\{|\xi|^2 = 1\}$, a property that was not exploited in [2].

The paper is organized as follows. In section 2, we recall some definitions and state our assumptions. Section 3 is devoted to the proof of uniform bounds on the sequence of solutions (u^ε) and of the convergence of the rescaled solutions. Then, in section 4, we establish the transport equation satisfied by the Wigner measure μ together with the radiation condition at infinity.

2. Notation and assumptions. In this section, we recall the definitions of Wigner transforms and of the B, B^* norms introduced by Agmon and Hörmander [1] for the study of Helmholtz equations. Then, we give our assumptions.

2.1. Wigner transform and Wigner measures. We use the following definition for the Fourier transform:

$$\hat{u}(\xi) = (\mathcal{F}_{x\to\xi}u)(\xi) = \frac{1}{(2\pi)^3}\int_{\mathbb{R}^d} e^{-ix\cdot\xi}u(x)dx.$$

For $u, v \in \mathcal{S}(\mathbb{R}^3)$ and $\varepsilon > 0$, we define the Wigner transform

$$W^\varepsilon(u,v)(x,\xi) = (\mathcal{F}_{y\to\xi})\left(u\left(x+\frac{\varepsilon}{2}y\right)\bar{v}\left(x-\frac{\varepsilon}{2}y\right)\right),$$
$$W^\varepsilon(u) = W^\varepsilon(u,u).$$

In what follows, we denote $W^\varepsilon = W^\varepsilon(u^\varepsilon)$.

If (u^ε) is a bounded sequence in $L^2(\mathbb{R}^d)$ (or in some weighted-L^2 space, as we will see later on), it turns out that (see [6], [9]), up to extracting a subsequence, the sequence $(W^\varepsilon(u^\varepsilon))$ converges weakly to a positive Radon measure μ on the phase space $T^*\mathbb{R}^3 = \mathbb{R}^3_x \times \mathbb{R}^3_\xi$ called the Wigner measure (or semiclassical measure) associated with (u^ε):

$$\forall \varphi \in \mathcal{C}_c^\infty(\mathbb{R}^6),\ \lim_{\varepsilon\to 0}\langle W^\varepsilon(u^\varepsilon),\varphi\rangle = \int \varphi(x,\xi)d\mu. \tag{2.1}$$

We recall that these measures can be obtained using pseudodifferential operators. The Weyl semiclassical operator $a^W(x,\varepsilon D_x)$ (or $Op_\varepsilon^W(a)$) is the continuous operator from $\mathcal{S}(\mathbb{R}^d)$ to $\mathcal{S}'(\mathbb{R}^d)$ associated with the symbol $a \in \mathcal{S}'(T^*\mathbb{R}^d)$ by Weyl quantization rule

$$(a^W(x,\varepsilon D_x)u)(x) = \frac{1}{(2\pi)^d}\int_{\mathbb{R}^d_\xi}\int_{\mathbb{R}^d_y} a\left(\frac{x+y}{2},\varepsilon\xi\right)f(y)e^{i(x-y)\cdot\xi}d\xi dy. \tag{2.2}$$

We have the following formula: for $u, v \in \mathcal{S}'(\mathbb{R}^d)$ and $a \in \mathcal{S}(\mathbb{R}^d \times \mathbb{R}^d)$,

$$\langle W^\varepsilon(u,v), a\rangle_{\mathcal{S}',\mathcal{S}} = \langle \bar{v}, a^W(x,\varepsilon D_x)\bar{u}\rangle_{\mathcal{S}',\mathcal{S}}, \tag{2.3}$$

where the duality brackets $\langle .,. \rangle$ are semilinear with respect to the second argument. This formula is also valid for u, v lying in other spaces, as we will see in section 3.

2.2. Besov-like norms. In order to get uniform (in ε) bounds on the sequence (u^ε), we shall use the following Besov-like norms, introduced by Agmon and Hörmander [1]: for $u, f \in L^2_{loc}(\mathbb{R}^3)$, we denote

$$\|u\|_{B^*} = \sup_{j \geq -1} \left(2^{-j} \int_{C(j)} |u|^2 dx \right)^{1/2},$$
$$\|f\|_B = \sum_{j \geq -1} \left(2^{j+1} \int_{C(j)} |f|^2 dx \right)^{1/2},$$

where $C(j)$ denotes the ring $\{x \in \mathbb{R}^3 / 2^j \leq |x| < 2^{j+1}\}$ for $j \geq 0$ and $C(-1)$ is the unit ball.

These norms are adapted to the study of Helmholtz operators. Indeed, Agmon and Hörmander [1] proved that if v is the solution to

$$-i\alpha v + \Delta v + v = f,$$

where $\alpha > 0$, then there exists a constant C independent of α such that

$$\|v\|_{B^*} \leq C \|f\|_B.$$

Perthame and Vega [12] generalized this result to Helmholtz equations with general indices of refraction.

We denote, for $x \in \mathbb{R}^3$, $|x| = \sqrt{\sum_{j=1}^3 x_j^2}$ and $\langle x \rangle = (1 + |x|^2)^{1/2}$. For all $\delta > \frac{1}{2}$, we have

$$\|u\|_{L^2_{-\delta}} := \|\langle x \rangle^{-\delta} u\|_{L^2} \leq C(\delta) \|u\|_{B^*}, \tag{2.4}$$

and

$$\|f\|_B \leq C(\delta) \|f\|_{L^2_\delta}. \tag{2.5}$$

We end this section by stating two properties of these spaces that will be useful for our purpose (the reader can find the proofs in [1]). The first proposition states that, in some sense, we can define the trace of a function in B on a linear manifold of codimension 1.

PROPOSITION 2.1. *There exists a constant C such that for all $f \in B$, we have*

$$\int_{\mathbb{R}} \|f(x_1, .)\|_{L^2(\mathbb{R}^2)} dx_1 \leq C \|f\|_B.$$

The second property gives the stability of the space B by change of variables in Fourier space.

PROPOSITION 2.2. *Let Ω_1, Ω_2 be two open sets in $\mathbb{R}^3$, $\psi : \Omega_1 \to \Omega_2$ a $\mathcal{C}^2$ diffeomorphism, $\chi \in \mathcal{C}^1_c(\mathbb{R}^3)$. For all $u \in B$, we denote*

$$Tu = \mathcal{F}^{-1}\big(\chi(\hat{u} \circ \psi)\big).$$

Then

$$\|Tu\|_B \leq C \|\chi\|_{\mathcal{C}^1_b} \|\psi\|_{\mathcal{C}^2_b} \|u\|_B.$$

2.3. Assumptions. We are now ready to state our assumptions. Our first assumption, borrowed from [2], concerns the regularizing parameter $\alpha_\varepsilon > 0$.

(H1) $\alpha_\varepsilon \geq \varepsilon^\gamma$ for some $\gamma > 0$.

This assumption is technical and is used to get a radiation condition at infinity in the limit $\varepsilon \to 0$. Next, in order to compute the limit of the energy source, we shall need the following assumption.

(H2) $\langle x\rangle^N S_0 \in L^2(\mathbb{R}^3)$ and $\langle x\rangle^N S_1 \in L^2(\mathbb{R}^3)$ for some $N > \frac{1}{2} + \frac{3\gamma}{\gamma+1}$.

Note that (H2) implies that the source terms S_0 and S_1 belong to the natural Besov space that is needed to actually solve the Helmholtz equation (1.1):

$$\|S_0\|_B, \|S_1\|_B < \infty.$$

3. Bounds on solutions to Helmholtz equations. In this section, we first establish uniform bounds on the sequence (u^ε) that will imply estimates on the sequence of Wigner transforms (W^ε). It turns out that we shall also need to compute the limit of the rescaled solutions w_0^ε and w_1^ε defined below in order to obtain the energy source in the equation satisfied by the Wigner measure μ.

Before stating our two results, let us define these rescaled solutions. Following [2] and [4], we denote

$$\left\{ \begin{array}{l} w_0^\varepsilon(x) = \varepsilon u^\varepsilon(\varepsilon x), \\ w_1^\varepsilon(x) = \varepsilon u^\varepsilon(q_1 + \varepsilon x). \end{array} \right. \tag{3.1}$$

They, respectively, satisfy

$$\left\{ \begin{array}{l} -i\alpha_\varepsilon \varepsilon w_0^\varepsilon + \Delta w_0^\varepsilon + w_0^\varepsilon = S_0(x) + S_1\left(x - \dfrac{q_1}{\varepsilon}\right), \\ -i\alpha_\varepsilon \varepsilon w_1^\varepsilon + \Delta w_1^\varepsilon + w_1^\varepsilon = S_0\left(x + \dfrac{q_1}{\varepsilon}\right) + S_1(x). \end{array} \right.$$

We are ready to state our results on u^ε, w_0^ε, and w_1^ε.

PROPOSITION 3.1. *Assume S_0, $S_1 \in B$. Then*

(i) *the solution u^ε to the Helmholtz equation* (1.1) *satisfies the bound*

$$\|u^\varepsilon\|_{B^*} \leq C(\|S_0\|_B + \|S_1\|_B);$$

(ii) *the rescaled solutions (w_0^ε) and (w_1^ε) are uniformly bounded in B^*:*

$$\|w_0^\varepsilon\|_{B^*} + \|w_1^\varepsilon\|_{B^*} \leq C(\|S_0\|_B + \|S_1\|_B).$$

(In both points, C denotes a constant independent of ε.)

PROPOSITION 3.2. *The sequences of rescaled solutions (w_0^ε) and (w_1^ε) converge weakly-$*$ in B^* to the outgoing solutions w_0 and w_1 to the Helmholtz equations*

$$\left\{ \begin{array}{l} \Delta w_0 + w_0 = S_0, \\ \Delta w_1 + w_1 = S_1, \end{array} \right.$$

i.e., w_0 and w_1 are given in Fourier space by

$$\widehat{w_j}(\xi) = \frac{-\widehat{S_j}(\xi)}{|\xi|^2 - 1 + i0} = -\left(p.v.\left(\frac{1}{|\xi|^2 - 1}\right) + i\pi\delta(|\xi|^2 - 1)\right)\widehat{S_j}(\xi), \quad j = 0, 1.$$

Remark. The Helmholtz equation $\Delta w + w = S$ does not uniquely specify the solution w. An extra condition is necessary, for instance, the Sommerfeld radiation condition. When the refraction index is constant equal to 1, this condition reads

$$\lim_{r\to\infty} \frac{1}{r} \int_{S_r} \left| \frac{\partial w}{\partial r} + iw \right|^2 d\sigma = 0. \tag{3.2}$$

Such a solution is called an outgoing solution.

Alternatively, still assuming that the refraction index is constant, the outgoing solution to the Helmholtz equation may be defined as the weak limit, as $\delta \to 0$, w of the sequence (w^δ) such that

$$-i\delta w^\delta + \Delta w^\delta + w^\delta = S(x).$$

We point out that the two points of view are equivalent in the case of a constant index of refraction (which is not true for a general index of refraction).

We prove the two propositions in the following two sections. As we will see in the proofs, our main difficulties are linked to the rays that are emitted by the source at 0 towards the point q_1 (and conversely). Hopefully, the interaction between those rays is "destructive" and not constructive.

3.1. Proof of Proposition 3.1. In what follows, C will denote any constant independent of ε.

Proof of point (i). Since u^ε is a solution to the Helmholtz equation (1.1), and *since the refraction index is constant*, we may write $u^\varepsilon(x) = u_0^\varepsilon(x) + u_1^\varepsilon(x - q_1)$, where u_0^ε and u_1^ε satisfy

$$\begin{cases} -i\dfrac{\alpha_\varepsilon}{\varepsilon} u_0^\varepsilon + \Delta u_0^\varepsilon + \dfrac{1}{\varepsilon^2} u_0^\varepsilon = \dfrac{1}{\varepsilon^3} S_0\left(\dfrac{x}{\varepsilon}\right), \\ -i\dfrac{\alpha_\varepsilon}{\varepsilon} u_1^\varepsilon + \Delta u_1^\varepsilon + \dfrac{1}{\varepsilon^2} u_1^\varepsilon = \dfrac{1}{\varepsilon^3} S_1\left(\dfrac{x}{\varepsilon}\right). \end{cases}$$

If we denote, for $j = 0, 1$, $\widetilde{w_j^\varepsilon}(x) = \varepsilon u_j^\varepsilon(\varepsilon x)$, then

$$\begin{cases} -i\alpha_\varepsilon \varepsilon \widetilde{w_0^\varepsilon} + \Delta \widetilde{w_0^\varepsilon} + \widetilde{w_0^\varepsilon} = S_0(x), \\ -i\alpha_\varepsilon \varepsilon \widetilde{w_1^\varepsilon} + \Delta \widetilde{w_1^\varepsilon} + \widetilde{w_1^\varepsilon} = S_1(x). \end{cases}$$

Moreover, the bound $\|\widetilde{w_j^\varepsilon}\|_{B^*} \le C\|S_j\|_B$ is established in Agmon and Hörmander [1] (see also Perthame and Vega [12]). Hence, using the scaling invariance

$$\|u_j^\varepsilon\|_{B^*} \le \|\widetilde{w_j^\varepsilon}\|_{B^*},$$

we get

$$\|u_j^\varepsilon\|_{B^*} \le C\|S_j\|_B.$$

Finally, we obtain the uniform estimate on u^ε by noting that, since q_1 is a fixed point, we have

$$\|u_1^\varepsilon(. - q_1)\|_{B^*} \le C(q_1)\|u_1^\varepsilon\|_{B^*},$$

which implies

$$\|u^\varepsilon\|_{B^*} \le \|u_0^\varepsilon\|_{B^*} + C(q_1)\|u_1^\varepsilon\|_{B^*} \le C(q_1)\left(\|S_0\|_B + \|S_1\|_B\right).$$

Proof of point (ii). Unfortunately, to get the bound on the rescaled sequences w_0^ε and w_1^ε, we cannot use a method similar to the one used in the proof of point (i) (roughly, because of the translation q_1/ε and not q_1). We instead use the explicit formula for w_j^ε that is available. In what follows, we prove the result for w_0^ε; the estimate on w_1^ε can be obtained similarly.

Since w_0^ε is a solution to

$$-i\alpha_\varepsilon \varepsilon w_0^\varepsilon + \Delta w_0^\varepsilon + w_0^\varepsilon = S_0(x) + S_1\left(x - \frac{q_1}{\varepsilon}\right)$$

we may decompose $w_0^\varepsilon = \widetilde{w_0^\varepsilon} + a^\varepsilon$, where $\widetilde{w_0^\varepsilon}$ is defined above and a^ε satisfy

$$-i\alpha_\varepsilon \varepsilon a^\varepsilon + \Delta a^\varepsilon + a^\varepsilon = S_1\left(x - \frac{q_1}{\varepsilon}\right).$$

Since $\|\widetilde{w_0^\varepsilon}\|_{B^*} \leq C\|S_0\|_B$, the proof of point (ii) reduces to the proof of the following lemma.

LEMMA 3.3. *If a^ε is the solution to*

$$-i\alpha_\varepsilon \varepsilon a^\varepsilon + \Delta a^\varepsilon + a^\varepsilon = S_1\left(x - \frac{q_1}{\varepsilon}\right),$$

then a^ε is uniformly (in ε) bounded in $B^\star$:

$$\|a^\varepsilon\|_{B^*} \leq C\|S_1\|_B.$$

Proof. We want to prove that

$$\forall v \in B, \quad |\langle a^\varepsilon, v\rangle| \leq C\|S_1\|_B\|v\|_B.$$

Using Parseval's equality, we write

$$\langle a^\varepsilon, v\rangle = \int_{\mathbb{R}^3} \frac{e^{-i\frac{q_1\cdot\xi}{\varepsilon}}\widehat{S_1}(\xi)\bar{\hat{v}}(\xi)}{-|\xi|^2 + 1 - i\varepsilon\alpha_\varepsilon} d\xi. \tag{3.3}$$

To estimate this integral, we shall distinguish the values of ξ close to or far from two critical sets: the sphere $\{|\xi|^2 = 1\}$ (the set where the denominator in (3.3) vanishes when $\varepsilon \to 0$) and the line $\{\xi$ collinear to $q_1\}$ (the set where we cannot apply directly the stationary phase theorem to (3.3)).

More precisely, we first take a small parameter $\delta \in]0,1[$, and we distinguish in the integral (3.3) the contributions due to the values of ξ such that $|\xi^2 - 1| \geq \delta$ or $|\xi^2 - 1| \leq \delta$. Let $\chi \in \mathcal{C}_c^\infty(\mathbb{R})$ be a truncation function such that $\chi(\lambda) = 0$ for $|\lambda| \geq 1$. We denote $\chi_\delta(\xi) = \chi\big(\frac{|\xi|^2-1}{\delta}\big)$. We accordingly decompose

$$\begin{aligned}\langle a^\varepsilon, v\rangle &= \int_{\mathbb{R}^3} \frac{e^{-i\frac{q_1}{\varepsilon}\cdot\xi}\widehat{S_1}(\xi)\bar{\hat{v}}(\xi)\chi_\delta(\xi)}{-|\xi|^2 + 1 - i\varepsilon\alpha_\varepsilon} d\xi + \int_{\mathbb{R}^3} \frac{e^{-i\frac{q_1}{\varepsilon}\cdot\xi}\widehat{S_1}(\xi)\bar{\hat{v}}(\xi)(1-\chi_\delta(\xi))}{-|\xi|^2 + 1 - i\varepsilon\alpha_\varepsilon} d\xi \\ &= I^\varepsilon + II^\varepsilon.\end{aligned}$$

First, since the denominator is not singular on the support of χ_δ, we easily bound the first part with the L^2 norms,

$$|I^\varepsilon| \leq \frac{\|\chi\|_{L^\infty}}{\delta}\|\widehat{S_1}\|_{L^2}\|\hat{v}\|_{L^2},$$

and using $B \hookrightarrow L^2$, we obtain the desired bound:

$$|I^\varepsilon| \leq C\|S_1\|_B\|v\|_B. \tag{3.4}$$

Let us now study the second part, II^ε, where the denominator is singular. Up to a rotation, we may assume $q_1 = |q_1|e_1$, where e_1 is the first vector of the canonical base. We make the polar change of variables,

$$\xi = \begin{cases} r\sin\theta\cos\varphi, \\ r\sin\theta\sin\varphi, \\ r\cos\theta. \end{cases}$$

Hence, $q_1 \cdot \xi = |q_1| r\sin\theta\cos\varphi$, and we get

$$II^\varepsilon = \int \frac{e^{-i\frac{|q_1|}{\varepsilon}r\sin\theta\cos\varphi}}{-r^2+1-i\varepsilon\alpha_\varepsilon}\big(\widehat{S_1\bar{v}}(1-\chi_\delta)\big)(\xi(r,\theta,\varphi))r^2\sin\theta dr d\theta d\varphi.$$

Now, we distinguish the contributions to the integral $d\theta d\phi$ linked to the values close to or far from the critical direction $\{\theta = \frac{\pi}{2},\ \varphi = 0,\ \text{or } \varphi = \pi\}$ (which corresponds to the case $\{\xi \text{ collinear to } q_1\}$). To that purpose, let $\eta > 0$ be a small parameter and denote

$$\Omega_0 = \left\{(r,\theta,\varphi) \;\middle|\; \left(1-\chi\left(\frac{r^2-1}{\delta}\right)\right) \neq 0, \chi\left(\frac{\theta-\frac{\pi}{2}}{\eta}\right) \neq 0, \chi\left(\frac{\varphi}{\eta}\right) \neq 0\right\},$$
$$\Omega_\pi = \left\{(r,\theta,\varphi) \;\middle|\; \left(1-\chi\left(\frac{r^2-1}{\delta}\right)\right) \neq 0, \chi\left(\frac{\theta-\frac{\pi}{2}}{\eta}\right) \neq 0, \chi\left(\frac{\varphi-\pi}{\eta}\right) \neq 0\right\}.$$

Let $k_0,\ k_\pi \in \mathcal{C}_c^\infty$ be such that $(1-\chi_\delta)k_0(\theta,\varphi)$ is a localization function on Ω_0 and $(1-\chi_\delta)k_\pi(\theta,\varphi)$ is a localization function on Ω_π. We denote $k = k_0 + k_\pi$. We write

$$\begin{aligned} II^\varepsilon = &\int \frac{e^{-i\frac{|q_1|}{\varepsilon}r\sin\theta\cos\varphi}}{-r^2+1-i\varepsilon\alpha_\varepsilon}(\widehat{S_1\bar{v}})(\xi(r,\theta,\varphi))(1-\chi_\delta(r))k_0(\theta,\varphi)r^2\sin\theta dr d\theta d\varphi \\ &+ \int \frac{e^{-i\frac{|q_1|}{\varepsilon}r\sin\theta\cos\varphi}}{-r^2+1-i\varepsilon\alpha_\varepsilon}(\widehat{S_1\bar{v}})(\xi(r,\theta,\varphi))(1-\chi_\delta(r))k_\pi(\theta,\varphi)r^2\sin\theta dr d\theta d\varphi \\ &+ \int \frac{e^{-i\frac{|q_1|}{\varepsilon}r\sin\theta\cos\varphi}}{-r^2+1-i\varepsilon\alpha_\varepsilon}(\widehat{S_1\bar{v}})(\xi(r,\theta,\varphi))(1-\chi_\delta(r))(1-k(\theta,\varphi))r^2\sin\theta dr d\theta d\varphi, \end{aligned}$$

$$II^\varepsilon = III_0^\varepsilon + III_\pi^\varepsilon + IV^\varepsilon.$$

The two parts III_0^ε and III_π^ε being similar, we write only how to estimate III_0^ε. In order to translate the stationary point in $(0,0)$, we consider the new variable $\alpha = \theta - \frac{\pi}{2}$. The phase function is $rg(\alpha,\varphi) = r\cos\alpha\cos\varphi$, so

$$\frac{\partial g}{\partial \alpha} = -\sin\alpha\cos\varphi = 0 \ \text{ at } (\alpha,\varphi) = (0,0),$$
$$\frac{\partial g}{\partial \varphi} = -\cos\alpha\sin\varphi = 0 \ \text{ at } (\alpha,\varphi) = (0,0),$$

and the Hessian at the point $(0,0)$ is

$$D^2 g(0,0) = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}.$$

We apply the Morse lemma: upon choosing $\eta > 0$ small enough, there exists a $\mathcal{C}^\infty$ change of variables on Ω_0, $(\alpha, \varphi) \mapsto (\alpha', \varphi')$, such that

$$g(\alpha, \varphi) = 1 - \frac{\alpha'^2}{2} - \frac{\varphi'^2}{2}.$$

Then, we make the change of variables $\alpha'' = \sqrt{\frac{r}{2}}\alpha'$, $\varphi'' = \sqrt{\frac{r}{2}}\varphi'$. Finally, we decompose $(1-\chi_\delta)k_0 = \chi^1\chi^2$, with $\chi^1,\ \chi^2 \in \mathcal{C}_c^\infty$. Thus, we obtain, for the contribution III_0^ε, the formula

$$III_0^\varepsilon = \int \frac{e^{i\frac{q_1}{\varepsilon}(-r+\alpha''^2+\varphi''^2)}}{-r+1+i\varepsilon\alpha_\varepsilon} \widehat{T^1 S_1}(r,\alpha'',\varphi'')\overline{\widehat{T^2 v}}(r,\alpha'',\varphi'')drd\alpha''d\varphi'', \tag{3.5}$$

where

$$\begin{aligned} T^1 S_1 &:= \mathcal{F}^{-1}\Big((\chi^1\widehat{S_1}) \circ \xi(r,\alpha(\alpha'',\varphi''),\varphi(\alpha'',\varphi''))\Big), \\ T^2 v &:= \mathcal{F}^{-1}\Bigg(\frac{-r+1+i\varepsilon\alpha_\varepsilon}{-r^2+1-i\varepsilon\alpha_\varepsilon}(\chi^2\hat{v}) \circ \xi(r,\alpha(\alpha'',\varphi''),\varphi(\alpha'',\varphi'')) \\ &\qquad \times \frac{2}{r}\Big|\frac{\mathrm{d}\xi}{\mathrm{d}(r,\alpha,\varphi)}\Big|\Big|\frac{\mathrm{d}(\alpha,\varphi)}{\mathrm{d}(\alpha',\varphi')}\Big|\Bigg). \end{aligned}$$

As a first step, using Proposition 2.2, we directly get $T^1 S_1 \in B$ with

$$\|T^1 S_1\|_B \leq C\|S_1\|_B.$$

As a second step, we study $T^2 v$. Since for r close to 1,

$$\Big|\frac{-r+1+i\varepsilon\alpha_\varepsilon}{-r^2+1-i\varepsilon\alpha_\varepsilon}\Big| \leq 1,$$

we recover, from Proposition 2.2,

$$T^2 v \in B \qquad \text{and} \qquad \|T^2 v\|_B \leq C\|v\|_B.$$

Now, we apply Parseval's equality with respect to the r variable in the formula (3.5)

$$\begin{aligned} III_0^\varepsilon &= \int \frac{e^{i\frac{|q_1|}{\varepsilon}(\alpha''^2+\varphi''^2)}}{-r+1+i\varepsilon\alpha_\varepsilon} T^1 S_1\left(\widehat{. - \frac{|q_1|}{\varepsilon}, ., .}\right)\overline{\widehat{T^2 v}}drd\alpha''d\varphi'' \\ &= \int e^{i\frac{|q_1|}{\varepsilon}(\alpha''^2+\varphi''^2)}\mathbf{1}_{\{t>0\}}e^{-(\varepsilon\alpha_\varepsilon - i)t}\mathcal{F}_{r\to\rho}\left(T^1 S_1\left(\widehat{. - \frac{|q_1|}{\varepsilon}, ., .}\right)\right)(\rho - t, \alpha'', \varphi'') \\ &\qquad \times \mathcal{F}_{r\to\rho}(\overline{\widehat{T^2 v}})(\rho,\alpha'',\varphi'')dtd\rho d\alpha''d\varphi'', \end{aligned}$$

where $\mathbf{1}_{\{t>0\}}$ denotes the characteristic function of the set $\{t > 0\}$. Hence, we obtain

$$\begin{aligned} |III_0^\varepsilon| &\leq \left(\int \left\|\mathcal{F}_{r\to\rho}\left(T^1 S_1\left(\widehat{. - \frac{|q_1|}{\varepsilon}, ., .}\right)\right)(\rho)\right\|_{L^2} d\rho\right) \\ &\qquad \times \left(\int \|\mathcal{F}_{r\to\rho}(\widehat{T^2 v})(\rho)\|_{L^2} d\rho\right), \\ |III^\varepsilon| &\leq \left(\int \left\|T^1 S_1\left(\rho - \frac{|q_1|}{\varepsilon}\right)\right\|_{L^2} d\rho\right)\left(\int \|T^2 v(\rho)\|_{L^2} d\rho\right), \\ |III^\varepsilon| &\leq \sum_{j=1}^n \left(\int \|T^1 S_1(\rho)\|_{L^2} d\rho\right)\left(\int \|T^2 v(\rho)\|_{L^2} d\rho\right). \end{aligned}$$

Now, using Proposition 2.1, we get

$$|III_0^\varepsilon| \le C\|T^1 S_1\|_B \|T^2 v\|_B,$$
$$|III_0^\varepsilon| \le C\|S_1\|_B \|v\|_B,$$

which is the desired estimate.

We are left with the part IV^ε, which corresponds to the directions ξ that are not collinear to q_1. We denote by K' the support of $(1-\chi_\delta)(1-k)$, which is a compact set. If we denote

$$\eta_1 = |\xi|^2 - 1, \quad \eta_2 = -q_1 \cdot \xi, \tag{3.6}$$

then

$$\frac{\mathrm{d}(\eta_1,\eta_2)}{\mathrm{d}\xi} = \begin{pmatrix} 2\xi \\ -q_1 \end{pmatrix}$$

is of maximal rank 2 for $\xi \in K'$. Hence, there exists a finite covering $(\Omega_j)_{j=1,m}$ ($m \in \mathbb{N}$) of K' such that in Ω_j, we can make the change of variables $\xi \mapsto \eta$, where η_1, η_2 are given by (3.6) and η_3 is one of the components of ξ (depending on Ω_j). We denote by $\chi_j = \chi_j^3 \chi_j^4$ some localization functions on Ω_j such that $(1-\chi_\delta)(1-k) = \sum_{j=1}^m \chi_j$. Thus, for $j = 1, \dots, m$,

$$\int \frac{e^{-i\frac{q_1}{\varepsilon}\cdot\xi}}{-|\xi|^2 + 1 + i\varepsilon\alpha_\varepsilon} \widehat{S_1 \bar{\hat{v}}} \chi_j d\xi = \int \frac{e^{i\frac{\eta_2}{\varepsilon}}}{-\eta_1 + i\varepsilon\alpha_\varepsilon} (\widehat{S_1 \bar{\hat{v}}} \chi_j)(\xi(\eta)) \left|\frac{\mathrm{d}\xi}{\mathrm{d}\eta}\right| d\eta.$$

If we denote

$$T_j^3 S_1 := \mathcal{F}^{-1}((\chi_j^3 \widehat{S_1}) \circ \xi),$$
$$T_j^4 v := \mathcal{F}^{-1}((\chi_j^4 \hat{v}) \circ \xi) \left|\frac{\mathrm{d}\xi}{\mathrm{d}\eta}\right|,$$

and if $\mathcal{F}_1$ denotes the Fourier transform with respect to the η_1 variable, Parseval's equality with respect to η_1 gives

$$\begin{aligned}\left| \int \frac{e^{-i\frac{q_1}{\varepsilon}\cdot\xi}}{-|\xi|^2 + 1 + i\varepsilon\alpha_\varepsilon} \widehat{S_1 \bar{\hat{v}}} \chi_j d\xi \right| &= (2\pi)^d \Bigg| \int \chi_{\{t>0\}} e^{-\varepsilon\alpha_\varepsilon t} (\mathcal{F}_1^{-1}(\widehat{T_j^3 S_1}))(x_1 - t) \\ &\qquad \times (\mathcal{F}_1^{-1}(\overline{\widehat{T_j^4 v}}))(x_1) e^{i\eta_2/\varepsilon} dt dx_1 d\eta_2 d\eta_3 \Bigg| \\ &\le C\|S_1\|_B \|v\|_B,\end{aligned}$$

using Proposition 2.1 again. Summing over j, we obtain

$$|IV^\varepsilon| \le C\|S_1\|_B \|v\|_B,$$

which ends the proof of the bound

$$|\langle a^\varepsilon, v\rangle| \le C\|S_1\|_B \|v\|_B. \qquad \square$$

3.2. Proof of Proposition 3.2. As before, we prove the result for the sequence (w_0^ε) only. As we did in the proof of Proposition 3.1, we write $w_0^\varepsilon = \widetilde{w_0^\varepsilon} + a^\varepsilon$. Since $\widetilde{w_0^\varepsilon}$ is the solution to a Helmholtz equation with constant index of refraction and fixed source, it converges weakly-$*$ to the outgoing solution w_0 to $\Delta w + w = S_0$. Hence, it suffices to show the following result.

LEMMA 3.4. *If $a^\varepsilon \in B^\star$ is the solution to*

$$-i\alpha_\varepsilon \varepsilon a^\varepsilon + \Delta a^\varepsilon + a^\varepsilon = S_1\left(x - \frac{q_1}{\varepsilon}\right),$$

then $a^\varepsilon \to 0$ in $B^\star$.

Proof. The proof of this result requires two steps (using a density argument):

1. For $v \in B$, we have the bound $\left|\langle a^\varepsilon, v\rangle\right| \leq C\|S_1\|_B\|v\|_B$.
2. If S_1 and v are smooth, then $\langle a^\varepsilon, v\rangle \to 0$.

The first point is exactly the result in Lemma 3.3. It remains to prove the convergence in the smooth case (the second point above). We write

$$\langle a^\varepsilon, v\rangle = \int_{\mathbb{R}^3} \frac{e^{-i\frac{q_1}{\varepsilon}\cdot\xi}\widehat{S_1}(\xi)\bar{\hat{v}}(\xi)}{-|\xi|^2 + 1 - i\varepsilon\alpha_\varepsilon} d\xi.$$

We are thus left with the study of

$$R_\varepsilon(\psi) = \int_{\mathbb{R}^3} \frac{e^{-i\frac{q_1}{\varepsilon}\cdot\xi}\psi(\xi)}{-|\xi|^2 + 1 - i\varepsilon\alpha_\varepsilon} d\xi, \tag{3.7}$$

where $\psi = \widehat{S_1}\widehat{\bar{v}}$ belongs to $\mathcal{S}(\mathbb{R}^3)$.

As in the proof of Lemma 3.3, we distinguish the contributions of various values of ξ. We shall use exactly the same partition, according to the values of ξ close to or far from the sphere $|\xi| = 1$ and collinear or not to q_1. We shall use the same notation for the various truncation functions.

We first separate the contributions of ξ such that $|\xi^2 - 1| \leq \delta$ and $|\xi^2 - 1| \geq \delta$ using the truncation function χ_δ:

$$\begin{aligned} R_\varepsilon(\psi) &= \int_{\mathbb{R}^3} \frac{e^{-i\frac{q_1}{\varepsilon}\cdot\xi}\psi(\xi)\chi_\delta(\xi)}{-|\xi|^2 + 1 - i\varepsilon\alpha_\varepsilon} d\xi + \int_{\mathbb{R}^3} \frac{e^{-i\frac{q_1}{\varepsilon}\cdot\xi}\psi(\xi)(1-\chi_\delta(\xi))}{-|\xi|^2 + 1 - i\varepsilon\alpha_\varepsilon} d\xi \\ &= I^\varepsilon + II^\varepsilon. \end{aligned}$$

In the support of χ_δ, since the denominator is not singular, we can apply the nonstationary phase method. Since $q_1 \neq 0$, we may assume $q_1^1 \neq 0$, and we have

$$\begin{aligned} I^\varepsilon &= \frac{\varepsilon}{iq_1^1}\int_{\mathbb{R}^3} e^{-i\frac{q_1}{\varepsilon}\cdot\xi}\partial_{\xi_1}\left(\frac{\psi(\xi)\chi_\delta(\xi)}{-|\xi|^2 + 1 - i\varepsilon\alpha_\varepsilon}\right)d\xi \\ &= \frac{\varepsilon}{iq_1^1}\int_{\mathbb{R}^3} e^{-i\frac{q_1}{\varepsilon}\cdot\xi}\left(\frac{\partial_{\xi_1}(\psi(\xi)\chi_\delta(\xi))}{-|\xi|^2 + 1 - i\varepsilon\alpha_\varepsilon} - \frac{2\psi(\xi)\chi_\delta(\xi)\xi_1}{(-|\xi|^2 + 1 - i\varepsilon\alpha_\varepsilon)^2}\right). \end{aligned}$$

Hence, we obtain the bound

$$|I^\varepsilon| \leq \frac{\varepsilon}{|q_1^1|}\int_{\mathbb{R}^3}\left(\frac{1}{\delta}|\partial_{\xi_1}(\chi\psi)| + \frac{2}{\delta^2}|\xi_1\chi\psi|\right)d\xi.$$

Since $\partial_{\xi_1}(\chi\psi)$ and $\xi_1\chi\psi$ belongs to $\mathcal{S}$, we have, as $\varepsilon \to 0$,

$$I^\varepsilon \to 0.$$

Let us now study the second term, II^ε. As in section 3.1, we first decompose II^ε into the sum $III_0^\varepsilon + III_\pi^\varepsilon + IV^\varepsilon$. We then use the same changes of variables. It leads to the following formula for III_0^ε:

$$III_0^\varepsilon = \int \frac{e^{-i\frac{q_1}{\varepsilon}(r-\alpha''^2-\varphi''^2)}}{-r+1+i\varepsilon\alpha_\varepsilon}\widetilde{\chi}(r,\alpha'',\varphi'')\widetilde{\psi}(r,\alpha'',\varphi'')drd\alpha''d\varphi'',$$

where

$$\begin{aligned}\widetilde{\chi}(r,\alpha'',\varphi'') &= ((1-\chi_\delta)k_0)\circ\xi(r,\alpha(\alpha'',\varphi''),\varphi(\alpha'',\varphi''))\\ &\qquad\times\frac{2(-r+1+i\varepsilon\alpha_\varepsilon)}{r(-r^2+1-i\varepsilon\alpha_\varepsilon)}\left|\frac{\mathrm{d}(\alpha,\varphi)}{\mathrm{d}(\alpha',\varphi')}\right|,\\ \widetilde{\psi}(r,\alpha'',\varphi'') &= \psi\circ\xi(r,\alpha(\alpha'',\varphi''),\varphi(\alpha'',\varphi''))\end{aligned}$$

are still smooth functions that are bounded independently from ε.

Using Parseval's inequality with respect to the variables (α'',φ''), we obtain the bound

$$|III_0^\varepsilon| \le C\varepsilon\left|\int\frac{e^{-i\frac{|q_1|}{\varepsilon}r}e^{-i\varepsilon(\lambda^2+\mu^2)}}{-r+1+i\varepsilon\alpha_\varepsilon}\mathcal{F}_{\lambda,\mu}(\widetilde{\chi}\widetilde{\psi})drd\lambda d\mu\right|.$$

To obtain the convergence of III_0^ε, it remains to study an integral of the type

$$\int_{|r-1|\le\delta}\frac{e^{-i\frac{|q_1|}{\varepsilon}r}w(r)}{-r+1+i\varepsilon\alpha_\varepsilon}dr,\ \text{where } w\in\mathcal{S}.$$

This is done in the following lemma.

LEMMA 3.5. *For all $w\in\mathcal{S}$ and all $\theta\in(0,1)$, we have*

$$\int_{|r|\le\delta}\frac{e^{-i\frac{|q_1|}{\varepsilon}r}w(r)}{-r+i\varepsilon\alpha_\varepsilon}dr = -i\pi w(0)+O_{\varepsilon\to0}(\varepsilon^{-\theta}).$$

Using this lemma, we readily get the estimate

$$|III^\varepsilon| \le C\varepsilon^{1-\theta}\quad\forall\theta\in(0,1), \tag{3.8}$$

which proves that $III^\varepsilon\to0$ as $\varepsilon\to0$.

Remark. In order to make the calculations easier, we write this paper in dimension equal to 3, but the proof would be similar in any dimension $d\ge2$. For a general dimension $d\ge2$, we will obtain an estimate in $O(\varepsilon^{(d-1)/2-\theta})$ instead of $O(\varepsilon^{1-\theta})$ above. The result fails in dimension $d=1$.

It remains to give the following proof.

Proof of Lemma 3.5. We write

$$\begin{aligned}\int_{-\delta}^{\delta}\frac{e^{-i\frac{|q_1|}{\varepsilon}r}w(r)}{-r+i\varepsilon\alpha_\varepsilon}dr &= \int_{-\delta}^{\delta}\frac{e^{-i\frac{|q_1|}{\varepsilon}r}w(r)}{r^2+(\varepsilon\alpha_\varepsilon)^2}(r-i\varepsilon\alpha_\varepsilon)dr\\ &= -i\varepsilon\alpha_\varepsilon\int_{-\delta}^{\delta}\frac{e^{-i\frac{|q_1|}{\varepsilon}r}w(r)}{r^2+(\varepsilon\alpha_\varepsilon)^2}dr+\int_{-\delta}^{\delta}e^{-i\frac{|q_1|}{\varepsilon}r}\frac{rw(r)}{r^2+(\varepsilon\alpha_\varepsilon)^2}dr\\ &= I+II.\end{aligned}$$

We have

$$I = -i \int_{-\frac{\delta}{\varepsilon\alpha_\varepsilon}}^{\frac{\delta}{\varepsilon\alpha_\varepsilon}} \frac{e^{-i|q_1|\alpha_\varepsilon y} w(\varepsilon\alpha_\varepsilon y)}{y^2+1} dy \to -i\pi w(0)$$

and

$$II = \int_{-\delta}^{\delta} \big(e^{-i\frac{|q_1|}{\varepsilon}r} w(r) - w(0)\big) \frac{r}{r^2 + (\varepsilon\alpha_\varepsilon)^2} dr + \int_{-\delta}^{\delta} w(0) \frac{r}{r^2+(\varepsilon\alpha_\varepsilon)^2} dr \ .$$

The last term vanishes because the integrand is odd. Moreover, using the smoothness of w, we easily obtain that for all $\theta \in (0,1)$,

$$\big|e^{-i\frac{|q_1|}{\varepsilon}r} w(r) - w(0)\big| \le C_\theta \Big(\frac{r}{\varepsilon}\Big)^\theta .$$

Thus,

$$\left| \int_{-\delta}^{\delta} \big(e^{-i\frac{|q_1|}{\varepsilon}r} w(r) - w(0)\big) \frac{r}{r^2+(\varepsilon\alpha_\varepsilon)^2} dr \right| \le \frac{C}{\varepsilon^\theta} \int_{-\delta}^{\delta} |r|^{\theta-1} dr$$

and the result is proved. □

We are left with the study of IV^ε. We use the same change of variables as in section 3.1:

$$\begin{aligned} IV^\varepsilon &= \sum_{j=1}^m \int \frac{e^{-i\frac{q_1}{\varepsilon}\cdot\xi}}{-|\xi|^2 + 1 + i\varepsilon\alpha_\varepsilon} \psi(\xi)\chi_j(\xi) d\xi \\ &= \sum_{j=1}^m \int \frac{e^{i\frac{\eta_2}{\varepsilon}}}{-\eta_1 + i\varepsilon\alpha_\varepsilon} (\psi\chi_j)(\xi(\eta)) \Big|\frac{\mathrm{d}\xi}{\mathrm{d}\eta}\Big| d\eta \\ &= i\varepsilon \sum_{j=1}^m \int \frac{e^{i\frac{\eta_2}{\varepsilon}}}{-\eta_1 + i\varepsilon\alpha_\varepsilon} \partial_{\eta_2}\Big((\psi\chi_j)(\xi(\eta)) \Big|\frac{\mathrm{d}\xi}{\mathrm{d}\eta}\Big|\Big) d\eta. \end{aligned}$$

The integral obviously converges with respect to all the variables except η_1. It remains to prove the convergence with respect to the η_1 variable, i.e., the convergence of

$$\int \frac{\phi(\eta)}{-\eta_1 + i\varepsilon\alpha_\varepsilon} d\eta_1,$$

where

$$\phi = \partial_{\eta_2}\Big((\psi\chi_j)(\xi(\eta)) \Big|\frac{\mathrm{d}\xi}{\mathrm{d}\eta}\Big|\Big)$$

is smooth and compactly supported with respect to η. It is a consequence of the fact that the distribution $(x+i0)^{-1}$ is well defined on $\mathbb{R}$ by

$$\frac{1}{x+i0} = p.v.\left(\frac{1}{x}\right) - i\pi\delta(x).$$

We conclude that $IV^\varepsilon \to 0$ and $\langle a^\varepsilon, v\rangle \to 0$ as $\varepsilon \to 0$. □

4. Transport equation and radiation condition on μ. In this section, we state and prove our results on the Wigner measure associated with (u^ε). Since we established the uniform bounds on (u^ε) and the convergence of (w_0^ε), (w_1^ε), these results now essentially follow from the results proved in [2]. We first prove bounds on the sequence of Wigner transforms (W^ε) that allow us to define a Wigner measure μ associated to (u^ε). Then, we get the transport equation satisfied by μ together with the radiation condition at infinity, which uniquely determines μ.

4.1. Results.

THEOREM 4.1. *Let $S_0,\ S_1 \in B$ and $\lambda > 0$. The sequence (W^ε) is bounded in the Banach space $X_\lambda^\star$, and up to extracting a subsequence, it converges weakly-$*$ to a positive and locally bounded measure μ such that*

$$\sup_{R>0} \frac{1}{R} \int_{|x|<R} \int_{\xi\in\mathbb{R}^3} \mu(x,\xi)\, dxd\xi \leq C(\|S_0\|_B + \|S_1\|_B)^2. \tag{4.1}$$

The Banach space X_λ^* is defined as the dual space of the set X_λ of functions $\hat\varphi(x,\xi)$ such that $\varphi(x,y) := \mathcal{F}_{\xi\to y}(\hat\varphi(x,\xi))$ satisfies

$$\int_{\mathbb{R}^3} \sup_{x\in\mathbb{R}^3} (1+|x|+|y|)^{1+\lambda} |\varphi(x,y)| dy < \infty. \tag{4.2}$$

THEOREM 4.2. *Assume* (H1), (H2). *Then the Wigner measure μ associated with (u^ε) satisfies the transport equation*

$$\xi\cdot\nabla_x\mu = \frac{1}{(4\pi)^2}\Big(\delta(x)|\widehat{S_0}(\xi)|^2 + \delta(x-q_1)|\widehat{S_1}(\xi)|^2\Big)\delta(|\xi|^2-1) := Q(x). \tag{4.3}$$

Moreover, μ is the outgoing solution to (4.3) *in the following sense: for all test functions $R \in \mathcal{C}_c^\infty(\mathbb{R}^6)$, if we denote $g(x,\xi) = \int_0^\infty R(x-\xi t,\xi)dt$, then*

$$\int_{\mathbb{R}^6} R(x,\xi) d\mu(x,\xi) = -\int_{\mathbb{R}^6} Q(x,\xi) g(x,\xi) dxd\xi. \tag{4.4}$$

Remark. Here the support of the test function R contains 0, contrary to [2].

4.2. Proof of Theorem 4.1. This theorem, which is proved in [2], is a consequence of the uniform estimate on the sequence (u^ε) in the space B^* obtained in Proposition 3.1. We observe that for any $\lambda > 0$,

$$\|\langle x\rangle^{-\frac12-\lambda} u^\varepsilon(x)\|_{L^2} \leq C\|u^\varepsilon\|_{B^*} \leq C\left(\|S_0\|_B + (\|S_1\|_B\right); \tag{4.5}$$

hence, for any function φ satisfying (4.2), we have

$$\begin{aligned}
&|\langle W^\varepsilon(u^\varepsilon), \hat\varphi\rangle| \\
&\leq \int_{\mathbb{R}^6} \frac{|u^\varepsilon|(x+\frac{\varepsilon}{2}y)|\overline{u^\varepsilon}|(x-\frac{\varepsilon}{2}y)}{\left\langle x+\frac{\varepsilon}{2}y\right\rangle^{\frac12+0}\left\langle x-\frac{\varepsilon}{2}y\right\rangle^{\frac12+0}} \left\langle x+\frac{\varepsilon}{2}y\right\rangle^{\frac12+0}\left\langle x-\frac{\varepsilon}{2}y\right\rangle^{\frac12+0} |\varphi|(x,y)dxdy \\
&\leq C\left(\|S_0\|_B + \|S_1\|_B\right)^2 \int_{\mathbb{R}^3} \sup_{x\in\mathbb{R}^3} \langle|x|+|y|\rangle^{1+0} |\varphi(x,y)| dy.
\end{aligned}$$

So $(W^\varepsilon(u^\varepsilon))$ is bounded in X_λ^*, $\lambda > 0$. We deduce that, up to extracting a subsequence, $(W^\varepsilon(u^\varepsilon))$ converges weakly-$*$ to a nonnegative measure μ satisfying

$$|\langle\mu,\hat\varphi\rangle| \leq C\left(\|S_0\|_B + \|S_1\|_B\right)^2 \int_{\mathbb{R}^3} \sup_{x\in\mathbb{R}^3} \langle|x|+|y|\rangle^{1+0} |\varphi(x,y)| dy. \tag{4.6}$$

We refer, for instance, to Lions and Paul [9] for the proof of the nonnegativity of μ.

The bound (4.1) is obtained using the family of functions

$$\varphi_\delta^R(x,y) = \frac{1}{\delta^{3/2}} e^{-|y|^2/\delta} \frac{1}{R} \chi(\langle x \rangle \leq R)$$

and letting $\delta \to 0$, $R \to \infty$. □

4.3. Proof of the transport equation (4.3). This section is devoted to the proof of the transport equation satisfied by μ. We first write the transport equation satisfied by W^ε in a dual form. Then we study the convergence of the source term (the convergence of the other terms is obvious). Finally, choosing an appropriate test function in the limiting process, we get the radiation condition at infinity satisfied by μ. Proving first a localization property, we improve the radiation condition proved in [2].

4.3.1. Transport equation satisfied by W^ε. W^ε satisfies the equation

$$\alpha_\varepsilon W^\varepsilon + \xi \cdot \nabla_x W^\varepsilon = Q^\varepsilon, \tag{4.7}$$

where, for $\psi \in \mathcal{S}(T^*\mathbb{R}^d)$, if $\varphi(x,y) = \mathcal{F}^{-1}_{y \to \xi}(\psi(x,\xi))$,

$$\begin{aligned}
\langle Q^\varepsilon, \psi \rangle &= \frac{i\varepsilon}{2} \mathcal{I}m \, \langle W^\varepsilon(S^\varepsilon, u^\varepsilon), \psi \rangle \\
&= \frac{i}{2} \mathcal{I}m \left(\int_{\mathbb{R}^6} \overline{w_0^\varepsilon}(x+y) S_0^\varepsilon(y) \varphi \left(\varepsilon \left(x + \frac{y}{2} \right), y \right) dxdy \right) \\
&+ \frac{i}{2} \mathcal{I}m \left(\int_{\mathbb{R}^6} \overline{w_1^\varepsilon}(x+y) S_1^\varepsilon(y) \varphi \left(q_1 + \varepsilon \left(x + \frac{y}{2} \right), y \right) dxdy \right).
\end{aligned}$$

This equation can be obtained writing first the equation satisfied by

$$v^\varepsilon(x,y) = u^\varepsilon \left(x + \frac{\varepsilon}{2} y \right) \overline{u^\varepsilon} \left(x - \frac{\varepsilon}{2} y \right).$$

From the equality

$$\nabla_y \cdot \nabla_x v^\varepsilon = \frac{\varepsilon}{2} \left[\Delta u^\varepsilon \left(x + \frac{\varepsilon}{2} y \right) \overline{u^\varepsilon} \left(x - \frac{\varepsilon}{2} y \right) - \Delta \overline{u^\varepsilon} \left(x - \frac{\varepsilon}{2} y \right) u^\varepsilon \left(x + \frac{\varepsilon}{2} y \right) \right],$$

we deduce

$$\alpha_\varepsilon v^\varepsilon + i \nabla_y \cdot \nabla_x v^\varepsilon + \frac{i}{2\varepsilon} \left[n^2 \left(x + \frac{\varepsilon}{2} y \right) - n^2 \left(x - \frac{\varepsilon}{2} y \right) \right] v^\varepsilon = \sigma_\varepsilon(x,y),$$

where

$$\sigma_\varepsilon(x,y) := \frac{i\varepsilon}{2} \left[S^\varepsilon \left(x + \frac{\varepsilon}{2} y \right) \overline{u^\varepsilon} \left(x - \frac{\varepsilon}{2} y \right) - \overline{S^\varepsilon} \left(x - \frac{\varepsilon}{2} y \right) u^\varepsilon \left(x + \frac{\varepsilon}{2} y \right) \right].$$

After a Fourier transform, we obtain (4.7).

Then we write the dual form of this equation. Letting $\psi \in \mathcal{S}(\mathbb{R}^6)$, we have

$$\alpha_\varepsilon \langle W^\varepsilon, \psi \rangle - \langle W^\varepsilon, \xi \cdot \nabla_x \psi \rangle = \langle Q^\varepsilon, \psi \rangle. \tag{4.8}$$

By the definition of the Wigner measure μ, we get

$$\alpha_\varepsilon \langle W^\varepsilon, \psi \rangle \to 0 \qquad \text{and} \qquad \langle W^\varepsilon, \xi \cdot \nabla_x \psi \rangle \to \langle \mu, \xi \cdot \nabla_x \psi \rangle.$$

Hence we are left with the study of the source term $\langle Q^\varepsilon, \psi \rangle$.

4.3.2. Convergence of the source term. In order to compute the limit of the source term in (4.7), we develop

$$\langle Q^\varepsilon,\psi\rangle = \frac{i\varepsilon}{2}\mathcal{I}m\Big(\langle W^\varepsilon(S_0^\varepsilon,u^\varepsilon),\psi\rangle + \langle W^\varepsilon(S_1^\varepsilon,u^\varepsilon),\psi\rangle\Big).$$

Thus, the result is contained in the following proposition.

PROPOSITION 4.3. *The sequences* $\big(\varepsilon W^\varepsilon(S_0^\varepsilon,u^\varepsilon)\big)$ *and* $\big(\varepsilon W^\varepsilon(S_1^\varepsilon,u^\varepsilon)\big)$ *are bounded in* $\mathcal{S}'(\mathbb{R}^6)$*, and for all real-valued* $\psi\in\mathcal{S}(\mathbb{R}^6)$*, we have*

$$\lim_{\varepsilon\to0}\varepsilon\langle W^\varepsilon(S_0^\varepsilon,u^\varepsilon),\psi\rangle_{\mathcal{S}',\mathcal{S}} = \frac{1}{(2\pi)^3}\int_{\mathbb{R}^3}\overline{\widehat{w_0}}(\xi)\widehat{S_0}(\xi)\psi(0,\xi)d\xi, \tag{4.9}$$

$$\lim_{\varepsilon\to0}\varepsilon\langle W^\varepsilon(S_1^\varepsilon,u^\varepsilon),\psi\rangle_{\mathcal{S}',\mathcal{S}} = \frac{1}{(2\pi)^3}\int_{\mathbb{R}^3}\overline{\widehat{w_1}}(\xi)\widehat{S_1}(\xi)\psi(q_1,\xi)d\xi, \tag{4.10}$$

where w_0 *and* w_1 *are defined in Proposition* 3.2.

Using Proposition 4.3, we readily get, for any real-valued test function ψ,

$$\begin{aligned}\lim_{\varepsilon\to0}\langle Q^\varepsilon,\psi\rangle &= \frac{i}{2(2\pi)^3}\mathcal{I}m\left(\int_{\mathbb{R}^3}\overline{\widehat{w_0}}(\xi)\widehat{S_0}(\xi)\psi(0,\xi)d\xi+\int_{\mathbb{R}^3}\overline{\widehat{w_1}}(\xi)\widehat{S_1}(\xi)\psi(q_1,\xi)d\xi\right)\\ &= \frac{1}{(4\pi)^2}\bigg(\int_{\mathbb{R}^3}|\widehat{S_0}(\xi)|^2\delta(\xi^2-1)\psi(0,\xi)d\xi\\ &\qquad\qquad+\int_{\mathbb{R}^3}|\widehat{S_1}(\xi)|^2\delta(\xi^2-1)\psi(q_1,\xi)d\xi\bigg),\end{aligned}$$

which is the result in Theorem 4.2. ∎

Let us now prove Proposition 4.3.

Proof of Proposition 4.3. The two terms to study being of the same type, we consider only the first one in our proof. Let $\psi\in\mathcal{S}(T^*\mathbb{R}^d)$ and $\varphi(x,y)=\mathcal{F}^{-1}_{y\to\xi}(\psi(x,\xi))$. Then we have

$$\begin{aligned}\varepsilon\langle W^\varepsilon(S_0^\varepsilon,u^\varepsilon),\psi\rangle_{\mathcal{S}',\mathcal{S}} &= \varepsilon\int S_0^\varepsilon\left(x+\frac{\varepsilon}{2}y\right)\overline{u^\varepsilon}\left(x-\frac{\varepsilon}{2}y\right)\varphi(x,y)dxdy\\ &= \int S_0(x)\overline{w_0^\varepsilon}(x+y)\varphi\left(\varepsilon\left(x+\frac{y}{2}\right),y\right)dxdy.\end{aligned}$$

As a first step, let us prove that $\varepsilon\langle W^\varepsilon(S_0^\varepsilon,u^\varepsilon),\psi\rangle_{\mathcal{S}',\mathcal{S}}$ is bounded. Using the fact that $\psi\in\mathcal{S}(\mathbb{R}^{2d})$, we get

$$\begin{aligned}\big|\varepsilon\langle W^\varepsilon(S_0^\varepsilon,u^\varepsilon),\psi\rangle_{\mathcal{S}',\mathcal{S}}\big| &\le C\int\langle x\rangle^N|S_0(x)|\frac{|w_0^\varepsilon(x+y)|}{\langle x+y\rangle^\beta}\frac{\langle x+y\rangle^\beta}{\langle x\rangle^N\langle y\rangle^k}dxdy\\ &\le C\|\langle x\rangle^N S_0\|_{L^2}\|w_0^\varepsilon\|_{B^*}\int_{\mathbb{R}^3_y}\sup_{x\in\mathbb{R}^3}\frac{\langle x+y\rangle^\beta}{\langle x\rangle^N\langle y\rangle^k}dy\end{aligned}$$

for any $k\ge0$ and $\frac12<\beta<N$, upon using the Cauchy–Schwarz inequality in x. Then we distinguish the cases $|x|\le|y|$ and $|x|\ge|y|$: the term stemming from the first case gives a contribution which is bounded by $C\int\frac{dy}{\langle y\rangle^{k-\beta}}$, and the second contribution is bounded by $C\int\frac{dy}{\langle y\rangle^k}$. Hence, upon choosing k large enough, we obtain

$$|\varepsilon\langle W^\varepsilon(S_0^\varepsilon,u^\varepsilon),\psi\rangle_{\mathcal{S}',\mathcal{S}}|\le C\|\langle x\rangle^N S_0\|_{L^2}\|w^\varepsilon\|_{B^*}.$$

As a second step, we compute the limit (4.9). We write

$$\begin{aligned}\varepsilon\langle W^\varepsilon(S_0^\varepsilon,u^\varepsilon),\psi\rangle &= \int S_0(x)\overline{w_0^\varepsilon}(x+y)\Big(\varphi\Big(\varepsilon\Big(x+\frac{y}{2}\Big),y\Big)-\varphi(0,y)\Big)dxdy\\ &\quad+\int \overline{w_0^\varepsilon}(x)S_0(x-y)\varphi(0,y)dxdy\\ &= I_\varepsilon + II_\varepsilon.\end{aligned}$$

Reasoning as above, we readily get that $\lim_{\varepsilon\to 0} I_\varepsilon = 0$. Indeed, since $\varphi\in\mathcal{S}(\mathbb{R}^{2d})$, we have, for all $k\in\mathbb{N}$ and $x,\ y\in\mathbb{R}^d$,

$$\Big|\varphi\Big(\varepsilon\Big(x+\frac{y}{2}\Big),y\Big)-\varphi(0,y)\Big| \le C\varepsilon\frac{|x|+|y|}{\langle y\rangle^k} \le C\varepsilon\frac{\langle|x|+|y|\rangle}{\langle y\rangle^k}.$$

Hence,

$$\begin{aligned}|I^\varepsilon| &\le C\varepsilon\int\langle x\rangle^N|S_0(x)|\frac{|w_0^\varepsilon(x+y)|}{\langle x+y\rangle^\beta}\frac{\langle|x|+|y|\rangle^{\beta+1}}{\langle x\rangle^N\langle y\rangle^k}dxdy\\ &\le C\varepsilon\|\langle x\rangle^N S_0\|_{L^2}\|w_0^\varepsilon\|_{B^*}\int_{\mathbb{R}^3_y}\sup_{x\in\mathbb{R}^3}\frac{\langle|x|+|y|\rangle^{\beta+1}}{\langle x\rangle^N\langle y\rangle^k}dy\end{aligned}$$

for any $k\ge 0$ and $1/2<\beta<N-1$. As above, the previous integral converges for k large enough. Therefore, $I^\varepsilon\to 0$.

We end the proof by proving that the second term, II^ε, converges to $\int S_0(x)\overline{w_0}(x+y)\widehat{\psi}(0,y)dxdy$. We have

$$II_\varepsilon = \int \overline{w_0^\varepsilon}(x)\big(S_0*\varphi(0,.)\big)(x)dx.$$

Hence, since w_0^ε converges weakly-$*$ in B^*, it suffices to prove that $S_0*\varphi(0,.)$ belongs to B. We denote $\phi=\varphi(0,.)$. Then, $\phi\in\mathcal{S}(\mathbb{R}^3)$. Let $1/2<\beta<N$. We have, using (2.5),

$$\|S_0*\phi\|_B^2 \le C\|S_0*\phi\|_{L^2_\beta}^2 = C\int\langle x\rangle^{2\beta}|S_0*\phi(x)|^2dx.$$

Moreover, upon using the Cauchy–Schwarz inequality, we get, for all $x\in\mathbb{R}^3$,

$$\begin{aligned}|S_0*\phi(x)|^2 &\le \left(\int_{\mathbb{R}^d_y}|S_0(x-y)||\phi(y)|dy\right)^2\\ &\le \left(\int_{\mathbb{R}^d_y}|S_0(x-y)|^2|\phi(y)|dy\right)\left(\int_{\mathbb{R}^d_y}|\phi(y)|dy\right)\\ &= \|\phi\|_{L^1}|S_0|^2*|\phi|(x).\end{aligned}$$

Therefore, we obtain

$$\begin{aligned}\|S_0*\phi\|_B^2 &\le C\|\phi\|_{L^1}\int\langle x\rangle^{2\beta}|S_0(x-y)|^2|\phi(y)|dydx\\ &\le C\|\langle x\rangle^N S_0\|_{L^2}^2\int_{\mathbb{R}^3_y}\sup_{x\in\mathbb{R}^3}\frac{\langle x+y\rangle^{2\beta}}{\langle x\rangle^{2N}\langle y\rangle^k}dy\end{aligned}$$

for any k. As before, this integral converges. Thus, we have established that $S_0 * \widehat{\psi}(0,.)$ belongs to B, which implies that

$$II_\varepsilon \to \int S_0(x)\overline{w_0}(x+y)\widehat{\psi}(0,y)dxdy. \qquad \square$$

4.4. Proof of the radiation condition (4.4). It remains to prove that μ satisfies the weak radiation condition (4.4).

4.4.1. Support of μ. In order to prove the radiation condition without restriction on the test function R (as assumed in [2]), we first prove a localization property on the Wigner measure μ. This property is well known when u^ε satisfies a Helmholtz equation without source term. It is still valid here thanks to the scaling of S^ε.

PROPOSITION 4.4. *Under hypotheses* (H1), (H2)*, the Wigner measure μ satisfies*

$$\mathrm{supp}(\mu) \subset \{(x,\xi) \in \mathbb{R}^6 / \ |\xi|^2 = 1\}.$$

Proof. Let $\phi \in \mathcal{C}_c^\infty(\mathbb{R}^6)$ and $\phi^\varepsilon = \phi^W(x, \varepsilon D_x)$. Let us denote $H^\varepsilon = -\varepsilon^2\Delta - 1$. Since u^ε satisfies the Helmholtz equation (1.1), we have

$$i\alpha_\varepsilon \varepsilon u^\varepsilon + H^\varepsilon u^\varepsilon = \varepsilon^2 S^\varepsilon. \tag{4.11}$$

Moreover, H^ε is a pseudodifferential operator with symbol $|\xi|^2 - 1$. By pseudodifferential calculus, $\phi^\varepsilon H^\varepsilon = Op_\varepsilon^W(\phi(x,\xi)(|\xi|^2-1)) + O(\varepsilon)$; thus, using the definition of the measure μ, we get that

$$\begin{aligned}\lim_{\varepsilon\to 0}(\phi^\varepsilon H^\varepsilon u^\varepsilon, u^\varepsilon) &= \lim_{\varepsilon\to 0}(Op_\varepsilon^W(\phi(x,\xi)(|\xi|^2-1))u^\varepsilon, u^\varepsilon) \\ &= \int \phi(x,\xi)(|\xi|^2-1)d\mu.\end{aligned}$$

Using (4.11), we write

$$(\phi^\varepsilon H^\varepsilon u^\varepsilon, u^\varepsilon) = \varepsilon^2(\phi^\varepsilon S^\varepsilon, u^\varepsilon) - i\alpha_\varepsilon\varepsilon(\phi^\varepsilon u^\varepsilon, u^\varepsilon) = \varepsilon^2(W^\varepsilon(S^\varepsilon, u^\varepsilon), \phi) - i\alpha_\varepsilon\varepsilon(\phi^\varepsilon u^\varepsilon, u^\varepsilon).$$

On the one hand, Proposition 4.3 gives that $\lim_{\varepsilon\to 0}\varepsilon^2(W^\varepsilon(S^\varepsilon,u^\varepsilon),\phi) = 0$. On the other hand, $(\phi^\varepsilon u^\varepsilon, u^\varepsilon)$ is bounded, so $\lim_{\varepsilon\to 0}\alpha_\varepsilon\varepsilon(\phi^\varepsilon u^\varepsilon, u^\varepsilon) = 0$. Therefore, for any $\phi \in \mathcal{C}_c^\infty(\mathbb{R}^6)$, we have $\int \phi(|\xi|^2-1)d\mu = 0$, so $\mathrm{supp}(\mu) \subset \{|\xi|^2 = 1\}$. $\square$

4.4.2. Proof of the condition (4.4). Using the previous localization property, in order to prove the radiation condition (4.4), one may only use test functions $R \in \mathcal{C}_c^\infty(\mathbb{R}^6)$ such that $\mathrm{supp}(R) \subset \mathbb{R}^6 \backslash \{\xi = 0\}$.

Let R be such a test function. We associate with R the solution g^ε to

$$-\alpha_\varepsilon g^\varepsilon + \xi \cdot \nabla_x g^\varepsilon = R(x,\xi).$$

By duality, we have

$$\langle Q^\varepsilon, g^\varepsilon\rangle = \langle W^\varepsilon, R\rangle,$$

so that it suffices to establish the following two convergences:

$$\lim_{\varepsilon\to 0}\langle Q^\varepsilon, g^\varepsilon\rangle = \langle Q, g\rangle, \tag{4.12}$$

$$\lim_{\varepsilon\to 0}\langle W^\varepsilon, R\rangle = \langle f, R\rangle, \tag{4.13}$$

where Q and g are defined in Theorem 4.2.

As before, since $R \in X_\lambda$ for any $\lambda > 0$, the limit (4.13) follows from the weak-$*$ convergence of W^ε in $X_\lambda^\star$.

On the other hand,

$$\langle Q^\varepsilon, g^\varepsilon \rangle = \mathcal{I}m \int_{\mathbb{R}^6} \overline{S_0}(x) w_0^\varepsilon(x+y) \widehat{g^\varepsilon}\left(\varepsilon\left[x+\frac{y}{2}\right], y\right) dxdy + \mathcal{I}m \int_{\mathbb{R}^6} \overline{S_1}(x) w_1^\varepsilon(x+y) \widehat{g^\varepsilon}\left(q_1 + \varepsilon\left[x+\frac{y}{2}\right], y\right) dxdy, \tag{4.14}$$

so $\langle Q^\varepsilon, g^\varepsilon \rangle$ is the sum of two terms of the same type. Such a term has been studied in [2], where the following result is proved.

PROPOSITION 4.5. *Assume that (w^ε) is bounded in B^* and that (w^ε) converges weakly-$*$ in B^* to w_0. Assume that S_0 satisfy* (H2). *Let $R \in \mathcal{C}_c^\infty(\mathbb{R}^6)$ be such that* $\mathrm{supp}(R) \subset \mathbb{R}^6 \backslash \{\xi = 0\}$. *Let g^ε be the solution to*

$$-\alpha_\varepsilon g^\varepsilon + \xi \cdot \nabla_x g^\varepsilon = R(x,\xi)$$

and $g(x,\xi) = \int_0^\infty R(x+t\xi,\xi)dt$. Then we have

$$\lim_{\varepsilon\to 0} \int_{\mathbb{R}^6} \overline{S_0}(x) w_0^\varepsilon(x+y) \widehat{g^\varepsilon}\left(\varepsilon\left[x+\frac{y}{2}\right], y\right) dxdy = \frac{1}{(2\pi)^3} \int_{\mathbb{R}^3} \overline{\widehat{S_0}}(\xi)\widehat{w_0}(\xi) g(0,\xi) d\xi.$$

Using the proposition above together with Proposition 3.2, we get that

$$\begin{aligned}
&\lim_{\varepsilon\to 0} \langle Q^\varepsilon, g^\varepsilon \rangle \\
&= \mathcal{I}m\left(\frac{1}{(2\pi)^3} \int_{\mathbb{R}^3} \overline{\widehat{S_0}}(\xi)\widehat{w_0}(\xi) g(0,\xi) d\xi + \frac{1}{(2\pi)^3} \int_{\mathbb{R}^3} \overline{\widehat{S_1}}(\xi)\widehat{w_1}(\xi) g(q_1,\xi) d\xi \right) \\
&= \frac{1}{(4\pi)^2} \left(\int_{\mathbb{R}^3} |\widehat{S_0}(\xi)|^2 \delta(\xi^2 - 1) g(0,\xi) d\xi + \int_{\mathbb{R}^3} |\widehat{S_1}(\xi)|^2 \delta(\xi^2-1) g(q_1,\xi) d\xi \right).
\end{aligned}$$

Thus, the radiation condition (4.4) is proved.

Acknowledgments. I would like to thank my advisor François Castella for having guided this work. I would also like to thank the referee for having suggested the short proof of the estimate of u^ε. Finally, I would like to thank Patrick Gérard for having pointed out to me that the measures μ_0 and μ_1 are mutually singular, using a dimension argument which is analogous to that of our proof so that the result follows from the orthogonality property.

WEAK SHOCKS FOR A ONE-DIMENSIONAL BGK KINETIC MODEL FOR CONSERVATION LAWS*

C. M. CUESTA† AND C. SCHMEISER‡

Abstract. For one-dimensional kinetic BGK models, regarded as relaxation models for scalar conservation laws with genuinely nonlinear fluxes, existence of small amplitude traveling waves is proven. Dynamic stability of these kinetic shock profiles is shown by extending a classical energy method for viscous regularizations of conservation laws.

Key words. weak shocks, kinetic BGK model, micro-macro decomposition, scalar conservation laws

1. Introduction.

In this paper we study small amplitude traveling wave solutions of the following one-dimensional Bhatnagar–Gross–Krook (BGK) type equation:

$$\partial_t f + v\partial_x f = M(\rho_f, v) - f\,, \quad \text{with } t > 0\,,\ x \in \mathbb{R}\,,\ v \in \Omega\,. \tag{1.1}$$

Here $f(t,x,v)$ can be interpreted (in analogy with the Boltzmann equation) as a time-dependent phase space density of particles with time t, position x, and velocity v. We shall assume that $\Omega \subset \mathbb{R}$ is the support of a measure $d\mu(v)$. In particular, both continuous velocity distributions as well as discrete velocity models, where (1.1) is a hyperbolic system, are included in our assumptions.

The function $\rho_f(t,x)$ in (1.1) is the macroscopic density corresponding to the distribution f, i.e., the zeroth order velocity moment

$$\rho_f(t,x) = \int f(t,x,v)d\mu(v)\,. \tag{1.2}$$

Here and in the following we refrain from writing Ω under the integral sign in integrals with respect to the measure $d\mu(v)$. Note that in the case of a discrete velocity model, Ω is a discrete set, and the integral above is a sum. The "Maxwellian" $M(\rho,v)$ is an equilibrium distribution satisfying the moment conditions

$$\int M(\rho,v)d\mu(v) = \rho \quad \text{and} \quad \int v\, M(\rho,v)d\mu(v) = a(\rho) \tag{1.3}$$

for a macroscopic flux function $a(\rho)$ that will be assumed smooth and genuinely nonlinear, actually (without loss of generality) concave: $a''(\rho) < 0$. The properties (1.3) ensure, at least formally, that the macroscopic limit equation (scaling with $(t,x) \to (t/\varepsilon, x/\varepsilon)$ and taking $\varepsilon \to 0$) of (1.1) is the scalar conservation law

$$\partial_t \rho + \partial_x a(\rho) = 0\,. \tag{1.4}$$

It is well known that initial value problems for (1.4) do not possess smooth solutions in general, and that weak solutions are not unique. Uniqueness can be obtained by considering (1.4) as the limit of an appropriately regularized problem. Classically this is done by introducing an artificial viscosity and carrying out the limit $\nu \to 0^+$ in

$$\partial_t \rho + \partial_x a(\rho) = \nu \partial_x^2 \rho \,; \tag{1.5}$$

see, e.g., [10]. In this work, instead of (1.5), the kinetic regularization (1.1) is studied.

Typical weak solutions of (1.4) are shock waves of the form

$$\rho(t,x) = \begin{cases} \rho_- & \text{if } x - st < x_0 \,, \\ \rho_+ & \text{if } x - st > x_0 \,, \end{cases}$$

where the constants $\rho_\pm$ and the wave speed s are related by the Rankine–Hugoniot condition

$$s = \frac{a(\rho_+) - a(\rho_-)}{\rho_+ - \rho_-} \,. \tag{1.6}$$

The admissibility condition

$$\frac{a(\rho) - a(\rho_-)}{\rho - \rho_-} - s > 0 \quad \text{for all } \rho \in (\min(\rho_+, \rho_-), \max(\rho_+, \rho_-)) \tag{1.7}$$

can be derived by constructing viscous profiles, i.e., traveling wave solutions of (1.5). In this framework, (1.7) gives a necessary and sufficient condition for existence of traveling wave solutions connecting the values $\rho_\pm$ at $x - st = \pm\infty$. For the concave flux functions $a(\rho)$ considered here, (1.7) reduces to the condition $\rho_- < \rho_+$. This is called an *entropy condition* since it can also be obtained from the (distributional) entropy inequality

$$\partial_t \phi(\rho) + \partial_x \psi(\rho) \le 0 \,,$$

which can be derived for every convex entropy density $\phi(\rho)$ and corresponding entropy flux $\psi(\rho)$ (satisfying $\psi' = \phi' a$) in the limit $\nu \to 0$ from (1.5).

An entropy inequality can also be derived for solutions of the kinetic equation (1.1) under an additional structure condition on the equilibrium distribution. We shall assume that the Maxwellian is a smooth and strictly increasing function of ρ:

$$\partial_\rho M(\rho, v) > 0 \,. \tag{1.8}$$

Then there exists a function $\theta(f,v)$ such that $f = M(\rho,v)$ is equivalent to $\rho = \theta(f,v)$. With the primitive $\Theta(f,v)$ ($\partial_f \Theta = \theta$), solutions of (1.1) formally satisfy the entropy inequality

$$\begin{aligned} &\partial_t \int \Theta(f,v) d\mu(v) + \partial_x \int v\, \Theta(f,v)\, d\mu(v) \\ &= \int (M(\rho_f, v) - f)(\theta(f,v) - \rho_f)\, d\mu(v) \le 0 \,. \end{aligned}$$

In the context of relaxation systems, condition (1.8) can be seen as a subcharacteristic condition. It can be used for proving stability results such as a total variation

diminishing property corresponding to that for entropy solutions of the macroscopic equation (1.4); see [1], [5]. A class of examples of Maxwellians $M(\rho, v)$ satisfying the moment conditions (1.3) as well as (1.8) has been given by the authors in [3]:

$$M(\rho, v) = \int_0^\rho m(v - a'(r))dr\,,$$

where $m(v) > 0$ for $v \in \mathbb{R}$ is an even function satisfying $\int_{-\infty}^{\infty} m(v)d\mu(v) = 1$ ($\Omega = \mathbb{R}$, $d\mu(v) = dv$).

It is our aim to study small amplitude kinetic shock profiles as traveling wave solutions of kinetic models of the form (1.1). Assuming (1.8), we shall prove their existence under the same entropy condition as required for the viscous regularization in section 3. This is no surprise considering that our constructive existence proof shows asymptotic closeness of viscous and kinetic profiles for small shocks. A main ingredient of the proof is a fluid-kinetic (or micro-macro) decomposition in the spirit of the one introduced by Caflisch and Nicolaenko [2] for the gas dynamics Boltzmann equation.

A well-known kinetic model for scalar conservation laws is the Perthame–Tadmor model [9]. There the Maxwellian is a discontinuous function. This lack of smoothness is an obstacle for the study of small waves by perturbation arguments as carried out here. Existence of big traveling waves has been studied by compactness arguments in [4]. The same approach has been carried out for (1.1) by the authors of this work [3]. In this parallel, the results of the present study are reviewed, and the existence result is extended to large amplitude waves. As opposed to the results here, the existence proof for large waves is nonconstructive, and their stability is still open.

In section 4, local dynamic stability of the constructed traveling waves is proven. Again, a micro-macro decomposition (now in the spirit of Liu and Yu [7]) is at the heart of the argument. A classical energy method for proving stability on the macroscopic level is combined with entropy estimates for the kinetic perturbations.

In the remainder of this section, we present the formal asymptotics for the construction of small amplitude waves as well as the energy method for proving stability of viscous profiles.

Formal construction of kinetic shock profiles. We look for solutions of (1.1), whose dependence on x and t is only through the traveling wave variable $\xi = x - st$, with s being the wave speed:

$$(v - s)\partial_\xi f = M(\rho_f, v) - f\,, \qquad \xi \in \mathbb{R},\ v \in \Omega\,, \tag{1.9}$$

subject to the far-field conditions

$$f(\pm\infty, v) = M(\rho^\pm, v)\,, \qquad v \in \Omega\,. \tag{1.10}$$

We are interested in small amplitude waves and assume

$$\rho^+ - \rho^- = \varepsilon \qquad \text{with } 0 < \varepsilon \ll 1\,. \tag{1.11}$$

The positivity of ε reflects the entropy condition (1.7). It turns out that it is appropriate to rescale the traveling wave variable by $\xi \to \xi/\varepsilon$, to get

$$\varepsilon(v - s)\partial_\xi f = M(\rho_f, v) - f, \qquad \xi \in \mathbb{R},\ v \in \Omega\,. \tag{1.12}$$

The Rankine–Hugoniot condition (1.6) is derived as a necessary condition for existence by integrating (1.12) with respect to v and by (1.3).

The formal asymptotics below is a variant of the Chapman–Enskog expansion procedure. We start by introducing the decomposition

$$f = M(\rho_f, v) + \varepsilon^2 f^\perp, \quad \text{with} \int f^\perp d\mu(v) = 0\,, \tag{1.13}$$

of the solution into an equilibrium part and a remainder (or into a macroscopic and a microscopic contribution, or into a fluid and a kinetic part). As a next step, the traveling wave equation (1.12) is integrated with respect to v and ξ:

$$\int v f \, d\mu(v) - s\rho_f = a(\rho_-) - s\rho_-\,. \tag{1.14}$$

Essentially, this equation is considered as an equation for the macroscopic density ρ_f, and the full kinetic equation (1.12) should determine $f^\perp$. The smallness of the wave is reflected in the fact that the macroscopic density is everywhere close to its far-field value at $\xi = -\infty$ and that the wave speed is close to the characteristic speed there:

$$\rho_f = \rho_- + \varepsilon u, \quad s = a'(\rho_-) + \varepsilon\sigma\,. \tag{1.15}$$

Substitution of this and (1.13) into (1.12) and (1.14) give the leading order ($O(\varepsilon^2)$) term equation

$$f^\perp = -(v - a'(\rho_-))\partial_\rho M(\rho_-, v)\partial_\xi u\,, \tag{1.16}$$

$$-\int v f^\perp d\mu(v) = \frac{a''(\rho_-)}{2} u^2 - \sigma u\,. \tag{1.17}$$

The limiting version of the Rankine–Hugoniot condition (1.6) is given by $\sigma = a''(\rho_-)/2 < 0$. After elimination of $f^\perp$, this becomes the traveling wave equation of the viscous Burgers equation

$$D_0\,\partial_\xi u = -\sigma u(1-u)\,, \tag{1.18}$$

with the diffusivity

$$D_0 = \int (v - a'(\rho_-))^2\,\partial_\rho M(\rho_-, v)\, d\mu(v) > 0\,, \tag{1.19}$$

by $\partial_\rho M > 0$. Obviously, solutions of (1.18) connecting $u = 0$ at $\xi = -\infty$ to $u = 1$ at $\xi = +\infty$ exist. The lack of uniqueness due to the translation invariance of the traveling wave problem will be an issue below.

It is far from obvious how to make this argument rigorous, since (1.16) for $f^\perp$ is a singular limit and, even worse, its solution is a differentiation problem. In the existence proof in section 3 we adapt an idea from Caflisch and Nicolaenko [2], where existence of weak shock profiles for the Boltzmann equation of gas dynamics has been proven. It is based on a slight modification of the micro-macro decomposition such that the fluid and the kinetic terms satisfy a system of equations with separated derivatives.

Stability of viscous shock profiles. In section 4 we prove local dynamic stability of small amplitude traveling waves. The idea is to decouple the equation into a macroscopic part and a small microscopic part. Then we use L^2-type energy (actually entropy) methods for the macroscopic equation, which can be extended to also control the microscopic part. Similar techniques have been used by Liu and Yu [7] for the Boltzmann equation. For the Broadwell model, a discrete velocity model for the Boltzmann equation, energy estimates have also been used in [6].

We expand briefly on the ideas behind the L^2-estimates at the macroscopic level. If ϕ is a traveling wave solution of the diffusive regularization (1.5), then the perturbation $\tilde{\rho} = \rho - \phi$ satisfies

$$\partial_t \tilde{\rho} - s\partial_\xi \tilde{\rho} + \partial_\xi (a(\phi + \tilde{\rho}) - a(\phi)) = \nu \partial_\xi^2 \tilde{\rho}.$$

Linearizing this equation and testing it with $\tilde{\rho}$ produces a term with the wrong sign, which is not possible to control. The usual trick (see, e.g., [8]) for overcoming this problem is to introduce the new macroscopic unknown

$$W(\xi, t) = \int_{-\infty}^{\xi} \tilde{\rho}(x, t)\, dx \tag{1.20}$$

after choosing the shift in ϕ such that $\int_{\mathbb{R}} (\rho - \phi) d\xi = 0$. Testing the integrated perturbation equation

$$\partial_t W - s\partial_\xi W + a(\phi + \tilde{\rho}) - a(\phi) = \nu \partial_\xi^2 W\,,$$

with W, gives in particular the term

$$\int_{\mathbb{R}} (a(\phi + \tilde{\rho}) - a(\phi)) W \; d\xi = -\frac{1}{2} \int_{\mathbb{R}} \partial_\xi (a'(\phi)) W^2 \, d\xi + n.l.t.$$

(*n.l.t.* stands for *nonlinear terms*). By the monotonicity of the wave profile the term on the right-hand side is positive, indicating decay of the L^2-norm of W if the nonlinear terms can be controlled.

The idea now consists of combining the energy estimates for W and for $\tilde{\rho} = \partial_\xi W$ to get an estimate on the H^1-norm of W. Clearly in both cases the contribution of the diffusion term has the good sign. This way we can also control the term with the wrong sign for $\tilde{\rho}$ by the term coming from diffusion for W. The basic estimate reads

$$\frac{1}{2} \frac{d}{dt} \int_{\mathbb{R}} \left(W^2 + \gamma (\partial_\xi W)^2 \right) \, d\xi \leq - \left(\nu - C_0 \sup |W| - \gamma C_1 \right) \int_{\mathbb{R}} (\partial_\xi W)^2 \, d\xi \tag{1.21}$$

for some arbitrary $\gamma > 0$. Here C_0 and C_1 are positive constants depending on pointwise bounds for the density ρ which are a consequence of the maximum principle. The supremum norm of W is controlled by the H^1-norm in one dimension. Hence, starting with initial data such that $\sup |W(t = 0)|$ is small enough, and choosing γ small enough, the right-hand side of (1.21) is negative initially and remains so. This implies global existence for $W \in H^1(\mathbb{R})$, as well as stability of macroscopic traveling waves. To achieve an analogous result for the kinetic equation, the argument will be similar, but one has to take care of the contribution of the microscopic part, which shall, however, be small by assumption (1.11). Additional difficulties will rise from the absence of a maximum principle requiring estimates for $\tilde{\rho}$ in H^1 (W in H^2) for pointwise control of $\tilde{\rho}$, as well as from the fact that the monotonicity of the macroscopic density of the kinetic traveling wave is not obvious.

2. Notation and assumptions. Since we shall linearize around the state $M(\rho_-, v)$, we introduce the notation $F(v) := \partial_\rho M(\rho_-, v)$ for simplicity. We shall sometimes skip the dependence on v in the function M, and write $M'(\rho)$ instead of $\partial_\rho M(\rho, v)$ (i.e., $F = M'(\rho_-)$).

We shall work in the weighted Hilbert space L^2_v of functions of the velocity, defined by the scalar product

$$\langle f, g\rangle_v = \int \frac{fg}{F} d\mu(v)\,,$$

where $\|\cdot\|_v$ denotes the induced norm. We also consider the L^2- and H^k-norms for functions of ξ. We write these spaces as L^2_ξ and H^k_ξ, and their norms as $\|\cdot\|_\xi$ and $\|\cdot\|_{H^k}$, respectively.

The Hilbert space $L^2_{\xi,v}$ is then naturally defined by the scalar product

$$\langle f, g\rangle_{\xi,v} = \int_{\mathbb{R}} \langle f, g\rangle_v d\xi\,,$$

with the induced norm $\|\cdot\|_{\xi,v}$. Similarly, we shall denote by $H^k_\xi(L^2_v)$ the space of functions with derivatives with respect to ξ up to order k in L^2_v, and the corresponding norm

$$\|f\|_{H^k_\xi(L^2_v)} = \left(\|f\|^2_{\xi,v} + \cdots + \|\partial^k_\xi f\|^2_{\xi,v}\right)^{1/2}\,. \tag{2.1}$$

The linearization of the collision operator on the right-hand side of (1.1) around $M(\rho_-, v)$ is given by

$$\mathcal{L}f := F\rho_f - f\,. \tag{2.2}$$

It is symmetric and negative semidefinite in L^2_v. These properties are easily seen from the identity

$$\langle \mathcal{L}f_1, f_2\rangle_v = -\frac{1}{2}\iint FF'\left(\frac{f_1}{F} - \frac{f_1'}{F'}\right)\left(\frac{f_2}{F} - \frac{f_2'}{F'}\right) d\mu(v)\, d\mu(v')\,,$$

where $'$ denotes evaluation at v'. The entropy inequality $\langle \mathcal{L}f, f\rangle_v \le 0$ is a straightforward consequence.

Apart from the essential requirements (1.3) and (1.8), our existence and stability proofs rely on additional technical assumptions on M. For fixed $v \in \Omega$, we assume that $M(\rho, v)$ is a C^3-function of ρ. Moreover, for a given ρ, up to fourth order moments of the derivatives exist, i.e.,

$$\int \left|v^m \partial^k_\rho M(\rho, v)\right| d\mu(v) < \infty \qquad \text{for } k \le 3,\ m \le 4\,. \tag{2.3}$$

For the second and third order derivatives of M with respect to ρ we require that for given ρ_1 and ρ_2,

$$\int |v|^m \frac{(\partial^k_\rho M(\rho_1, v))^2}{\partial_\rho M(\rho_2, v)}\, d\mu(v) < \infty \qquad \text{for } k \le 3,\ m \le 4\,. \tag{2.4}$$

As a consequence of (2.3), up to second order moments of velocity distributions can be bound by their L^2_v-norm:

$$\left|\int (v-s)^m f\, d\mu(v)\right| \le \left(\int |v-s|^{2m} F\, d\mu(v)\right)^{1/2} \|f\|_v \qquad \text{for } m \le 2\,. \tag{2.5}$$

This will be used repeatedly in the following. For simplicity we also adopt the notation

$$\hat{D} := \int (v-s)^2 F \, d\mu(v) \,. \tag{2.6}$$

Finally, we assume that for fixed ρ, $\partial_\rho M(\rho, v)$ is a continuous function of $v \in \Omega$.

3. Existence of small amplitude traveling waves.

3.1. An approximate solution. In this section we prove existence of solutions of (1.12) subject to (1.10) for $\varepsilon \ll 1$. We start by returning to the problem of constructing a formal approximation. Instead of formally passing to the limit as in section 1, we avoid expansion errors wherever possible and produce a residual whose v-integral vanishes. We start with the ansatz

$$f_{as} := M(\rho, v) + \varepsilon^2 f^\perp \,, \tag{3.1}$$

formally resembling (1.13). The residual is then given by

$$\varepsilon^3 h := M(\rho_{as}) - f_{as} - \varepsilon(v-s)\partial_\xi f_{as} \,, \qquad \text{with } \rho_{as} = \rho + \varepsilon^2 \rho^\perp \,. \tag{3.2}$$

Recalling (1.16), we eliminate two terms in the right-hand side by the choice

$$f^\perp := -\frac{1}{\varepsilon}(v-s)\partial_\xi M(\rho, v) \,. \tag{3.3}$$

Finally, the requirement that the v-integral of h vanish and that f_{as} satisfy the far-field conditions (1.10) leads to an ordinary differential equation (ODE) for ρ:

$$\frac{a(\rho) - a(\rho_-) - s(\rho - \rho_-)}{\varepsilon^2} = \frac{1}{\varepsilon}\left(\int (v-s)^2 M'(\rho, v) d\mu(v) \right) \partial_\xi \rho \tag{3.4}$$

subject to

$$\rho(-\infty) = \rho_- \quad \text{and} \quad \rho(+\infty) = \rho_+ \,. \tag{3.5}$$

With $\rho = \rho_- + \varepsilon u$ the problem for u formally tends to (1.18) in the limit $\varepsilon \to 0$. Actually, since the diffusivity $D(\rho) := \int (v-s)^2 M'(\rho, v)\, d\mu(v)$ is obviously positive, (3.4) has the same qualitative properties as (1.18), and a solution of (3.4), (3.5) exists, which is determined uniquely by the condition

$$\rho(0) = \frac{\rho_- + \rho_+}{2} \,. \tag{3.6}$$

It is easily shown that u and $\partial_\xi u$ are uniformly bounded as $\varepsilon \to 0$ and for $\xi \in \mathbb{R}$, and, therefore, the same holds for ρ and $\partial_\xi \rho/\varepsilon$. As a consequence, $D(\rho)$ is uniformly bounded away from zero. Division of (3.4) by $D(\rho)$ and differentiation shows that also $\partial_\xi^k \rho/\varepsilon$ is uniformly bounded for $k = 2, 3$ (here assumption (2.3) is used). Furthermore, the convergence of all these terms as $\xi \to \pm\infty$ is exponential. Recalling $s = a'(\rho_-) + O(\varepsilon)$,

$$\rho^\perp = -\frac{1}{\varepsilon}(a'(\rho) - s)\partial_\xi \rho = O(\varepsilon)$$

holds uniformly for $\xi \in \mathbb{R}$. This shows that the scaling of the residual in (3.2) has been chosen correctly in terms of the sup-norm:

$$h = \frac{M(\rho + \varepsilon^2 \rho^\perp) - M(\rho)}{\varepsilon^3} - (v-s)\partial_\xi f^\perp \tag{3.7}$$

is uniformly bounded in ε and ξ and decays exponentially as $\xi \to \pm\infty$. However, we shall need the following result also in other norms.

LEMMA 3.1. *Let the assumptions* (2.3) *and* (2.4) *be satisfied and let* f_{as} *be determined by* (3.1) *and* (3.3)–(3.5). *Then* f_{as} *satisfies the far-field conditions* (1.10), *and the traveling wave equation* (1.12) *up to the residual* $\varepsilon^3 h$, *where* h *is in* $H^1_\xi(L^2_v)$ *uniformly in* ε, *and* $\int h\, d\mu(v) = 0$.

Proof. The far-field conditions and the last statement are a direct consequence of the construction of f_{as}.

The boundedness of the first term on the right-hand side of (3.7) in $H^1_\xi(L^2_v)$ is a consequence of our observations above and of (2.4) ($m = 0$, $k = 2$). For the second term (2.4) is used with $m = 4$, $k = 2$. Of course the exponential decay of all terms suffices for integrability with respect to ξ. ∎

3.2. The micro-macro decomposition of the correction term. In terms of the correction term $\varepsilon^2 g = f - f_{as}$, the traveling wave problem reads

$$\begin{aligned} &\varepsilon(v-s)\partial_\xi g - \mathcal{L}g \\ &= (M'(\rho_{as}) - F)\rho_g + \frac{M(\rho_{as}+\varepsilon^2\rho_g) - M(\rho_{as}) - \varepsilon^2 M'(\rho_{as})\rho_g}{\varepsilon^2} + \varepsilon h \end{aligned} \tag{3.8}$$

subject to

$$g(\pm\infty, v) = 0 \quad \text{for all } v \in \Omega\,. \tag{3.9}$$

The left-hand side of (3.8) is the linearization of the traveling wave equation (1.12) around $M(\rho_-)$ with the linearized collision operator $\mathcal{L}$ defined in (2.2). The right-hand side contains an $O(\varepsilon)$ linear correction (since we should actually linearize around $M(\rho_{as})$), an $O(\varepsilon^2\rho_g^2)$ nonlinear term, and the residual. The homogeneous far-field conditions and Lemma 3.1 imply, after integration of (3.8) with respect to ξ, that the flux of g vanishes:

$$\int (v-s) g\, d\mu(v) = 0\,. \tag{3.10}$$

The problem (3.8), (3.9) will be solved in several steps. First, we introduce a splitting of g into a macroscopic part and a microscopic part. Then, in the following two subsections, we solve the linear equations associated to the decomposition of g, and finally solve the nonlinear problem.

In the first step, two ideas from the work by Caflisch and Nicolaenko [2] on the Boltzmann equation will be adapted to the present situation. The first one is a special micro-macro decomposition defined by

$$g(\xi, v) = z(\xi)\Phi(v) + \varepsilon w(\xi, v)\,, \tag{3.11}$$

where $\Phi := F\big(1 + \varepsilon\frac{\sigma}{\hat{D}}(v-s)\big)$, and the orthogonality condition $\langle (v-s)\Phi, w\rangle_v = 0$ holds.

The choice of the coefficient $\sigma/\hat{D}$ (see (1.15) and (2.6) for the definition of the constants) in front of the correction term in Φ guarantees that Φ shares the property (3.10) with g:

$$\int (v-s)\Phi\, d\mu(v) = 0\,. \tag{3.12}$$

This and the definition of the decomposition imply several properties of z and w.

LEMMA 3.2. *If g satisfies* (3.8), (3.9), *then*

$$w(\pm\infty, v) \equiv 0, \ z(\pm\infty) = 0\,, \tag{3.13}$$

and

$$\int (v-s)w(\xi,v)\,d\mu(v) = 0, \qquad \int (v-s)^2 w(\xi,v)\,d\mu(v) = 0 \quad \textit{for all } \xi \in \mathbb{R}\,. \tag{3.14}$$

Substitution of (3.11) into (3.8) and division by ε gives

$$(v-s)\Phi\,\partial_\xi z + \varepsilon(v-s)\partial_\xi w - \mathcal{L}w - \Lambda z = \varepsilon\Gamma\rho_w + \varepsilon R(\rho_g) + h\,, \tag{3.15}$$

where again the right-hand side contains a linear correction, the nonlinearity, and the residual, with

$$\Lambda := \frac{M'(\rho_{as})\rho_\Phi - \Phi}{\varepsilon}\,, \qquad \Gamma := \frac{M'(\rho_{as}) - F}{\varepsilon}\,,$$
$$R(\rho_g) := \frac{1}{\varepsilon^4}[M(\rho_{as} + \varepsilon^2\rho_g) - M(\rho_{as}) - \varepsilon^2 M'(\rho_{as})\rho_g]\,.$$

These terms are formally $O(1)$ such that the ε-powers in (3.15) reflect the expected orders of magnitude.

Observe that, in terms of z and w, the nonlinearity should be written as $R(\rho_g) = R(z\rho_\Phi + \varepsilon\rho_w)$ with $\rho_\Phi = 1 - \varepsilon^2\sigma^2/\hat{D}$ (a constant). The identities $\int \Lambda\,d\mu(v) = \int \Gamma\,d\mu(v) = \int R(\rho_g)\,d\mu(v) = 0$ hold.

In order to get an equation for z (the macroscopic equation), we apply an approximation of the macroscopic projection to (3.15), i.e., we multiply (3.15) by $(v-s)$ and integrate with respect to v:

$$\tilde{D}\,\partial_\xi z - r(\xi)z = \varepsilon\frac{a'(\rho_{as}) - s}{\varepsilon}\rho_w + \varepsilon\int (v-s)R(\rho_g)\,d\mu(v) + \int (v-s)h\,d\mu(v)\,, \tag{3.16}$$

with

$$\tilde{D} := \int (v-s)^2\Phi\,d\mu(v) = D_0 + O(\varepsilon) > 0\,, \tag{3.17}$$

$$r(\xi) := \int (v-s)\Lambda(\xi,v)\,d\mu(v) = \frac{a'(\rho_{as}(\xi)) - s}{\varepsilon}\rho_\Phi\,. \tag{3.18}$$

Here we have used (3.12) and Lemma 3.2. This equation already reveals the magic of the micro-macro decomposition (3.11). It does not contain derivatives of w, and actually becomes independent of w as $\varepsilon \to 0$. The formal limit is the linearization of the viscous Burgers traveling wave equation (1.18). In particular, $r(\xi) = \sigma(2u-1) + O(\varepsilon)$ and, consequently, there exist $\gamma, \bar{\xi} > 0$ such that

$$r(\xi) \le -\gamma \quad \text{for } \xi \ge \bar{\xi}\,, \qquad r(\xi) \ge \gamma \quad \text{for } \xi \le -\bar{\xi}\,. \tag{3.19}$$

Now an equation for w (the microscopic equation) is derived by substituting (3.16) into (3.15), which actually amounts to applying the projection

$$Pf := f - \frac{(v-s)\Phi}{\tilde{D}}\int (v-s)f\,d\mu(v) \tag{3.20}$$

to (3.15):

$$\varepsilon(v-s)\partial_\xi w - \mathcal{L}w - P\Lambda z = \varepsilon\tilde{\Gamma}\rho_w + \varepsilon PR(\rho_g) + Ph\,, \tag{3.21}$$

with

$$\tilde{\Gamma} = P\Gamma - \frac{(v-s)\Phi}{\tilde{D}}\int (v-s)F\,d\mu(v) = \Gamma - \frac{(v-s)\Phi}{\tilde{D}}(a'(\rho_{as}) - s)\,.$$

We make one more manipulation to get a final equation for w. This corresponds to the second idea from [2]. As we observed in section 2 the operator $\mathcal{L}$ is symmetric negative semidefinite, but not strictly negative. We introduce a new operator $\mathcal{M}$, which is strictly negative and coincides with $\mathcal{L}$ on the set of functions w satisfying the property (3.14):

$$\mathcal{M}w := \mathcal{L}w - (v-s)^2 F\int (v-s)^2 w\,d\mu(v)\,.$$

LEMMA 3.3. *The operator $\mathcal{M}$ is symmetric and negative definite in L^2_v, i.e., there exists a $\kappa > 0$ such that*

$$-\langle \mathcal{M}w, w\rangle_v > \kappa\|w\|_v^2 \qquad \textit{for all } w \in L^2_v\,.$$

Proof. The symmetry follows from the symmetry of $\mathcal{L}$ and from

$$\langle \mathcal{M}w_1, w_2\rangle_v = \langle \mathcal{L}w_1, w_2\rangle_v - \int (v-s)^2 w_1\,d\mu(v)\int (v-s)^2 w_2\,d\mu(v)\,.$$

To prove that $\mathcal{M}$ is negative definite, we write $w = F\rho_w + w^\perp$ and observe that $\mathcal{L}w = -w^\perp$:

$$\begin{aligned}
-\langle \mathcal{M}w, w\rangle_v &= \|w^\perp\|_v^2 + \left(D_0\,\rho_w + \int (v-s)^2 w^\perp d\mu(v)\right)^2 \\
&= \|w^\perp\|_v^2 + \gamma D_0^2\,\rho_w^2 + (1-\gamma)D_0^2\,\rho_w^2 \\
&\quad + 2D_0\,\rho_w\int (v-s)^2 w^\perp\,d\mu(v) + \left(\int (v-s)^2 w^\perp\,d\mu(v)\right)^2
\end{aligned}$$

for $\gamma \in (0,1)$. Hence

$$\begin{aligned}
-\langle \mathcal{M}w, w\rangle_v &= \|w^\perp\|_v^2 + \gamma D_0^2\rho_w^2 \\
&\quad + (1-\gamma)\left[D_0\,\rho_w + \frac{1}{1-\gamma}\int (v-s)^2 w^\perp\,d\mu(v)\right]^2 - \frac{\gamma}{1-\gamma}\left(\int (v-s)^2 w^\perp\,d\mu(v)\right)^2 \\
&\geq \gamma D_0^2\,\rho_w^2 + \|w^\perp\|_v^2\left(1 - \frac{\gamma}{1-\gamma}\|(v-s)^2 F\|_v^2\right) \geq \kappa(\rho_w^2 + \|w^\perp\|_v^2) = \kappa\|w\|_v^2\,,
\end{aligned}$$

with $\kappa > 0$ for γ small enough. Here we have used (2.5) with $m = 2$. ∎

We shall prove existence of solutions of equations (3.16) and

$$\varepsilon(v-s)\partial_\xi w - \mathcal{M}w - zP\Lambda = \varepsilon\tilde{\Gamma}\rho_w + \varepsilon PR(\rho_g) + Ph \tag{3.22}$$

subject to (3.13). The relation to the original problem (3.8), (3.9) is not obvious.

LEMMA 3.4. *The function* $g = z\Phi + \varepsilon w$ *is a solution of* (3.8), (3.9) *iff* z *and* w *solve* (3.16), (3.22) *subject to* (3.13).

Proof. The problem (3.16), (3.22), (3.13) has been derived from (3.8), (3.9) using the property (3.14) of solutions of the latter. The proof relies on showing that (3.14) also holds for solutions of (3.16), (3.22), (3.13) without requiring it as a side condition.

The properties of Φ imply that for an $f(v)$ satisfying $\int f\,d\mu(v) = 0$, also $\int Pf\,d\mu(v) = 0$ and $\int (v-s)Pf\,d\mu(v) = 0$ hold. Since the v-integrals of Λ, Γ, $R(\rho_g)$, and h vanish, these terms do note contribute when we integrate (3.22) and its product with $v - s$ with respect to v:

$$\varepsilon\partial_\xi \int (v-s)w\,d\mu(v) = -D_0 \int (v-s)^2 w\,d\mu(v)\,,$$
$$\varepsilon\partial_\xi \int (v-s)^2 w\,d\mu(v) = -\int (v-s)w\,d\mu(v) - \int (v-s)^3 F\,d\mu(v) \int (v-s)^2 w\,d\mu(v)\,.$$

This is a system of linear ODEs with constant coefficients for the unknowns $\int (v-s)w\,d\mu(v)$ and $\int (v-s)^2 w\,d\mu(v)$. The decay of w at $\xi = \pm\infty$ implies homogeneous far-field conditions for these quantities and, thus, $\int (v-s)w\,d\mu(v) \equiv \int (v-s)^2 w\,d\mu(v) \equiv 0$. ∎

3.3. The linear problem. In this section we prove solvability of (3.16) and (3.22) regarding the right-hand sides as given inhomogeneities. In particular, we look for solutions of

$$\varepsilon(v-s)\partial_\xi w - \mathcal{M}w = h_w \qquad \text{with } h_w \in H^1_\xi(L^2_v) \tag{3.23}$$

and

$$\partial_\xi z - r(\xi)z = h_z \qquad \text{with } h_z \in L^2_\xi\,. \tag{3.24}$$

We shall look for solutions in the same spaces as the inhomogeneities. This will replace homogeneous far-field conditions in the following. Whereas this requirement provides uniqueness for the solution of (3.23), it permits a one-parameter set of solutions of (3.24). This reflects the arbitrary shift in traveling wave solutions. Uniqueness will be guaranteed by the additional requirement

$$z(0) = z_0\,, \tag{3.25}$$

where $z_0 \in \mathbb{R}$ parametrizes the set of solutions.

LEMMA 3.5. *Let* z *be the solution of* (3.24), (3.25) *with* r *bounded and satisfying* (3.19). *Then there exists a positive constant* C, *such that*

$$\|z\|_{H^1_\xi} \le C(|z_0| + \|h_z\|_\xi)\,.$$

Proof. The solution of (3.24), (3.25) is given by

$$z(\xi) = E(\xi,0)z_0 + \int_0^\xi E(\xi,y)h_z(y)dy \qquad \text{with} \quad E(\xi,y) = \exp\left(\int_y^\xi r(\eta)d\eta\right).$$

For $|\xi| < \bar{\xi}$, $E(\xi,y)$ is bounded and thus, obviously,

$$\|z\|_{L^2_\xi(-\bar{\xi},\bar{\xi})} \le C\|h_z\|_{L^2_\xi(-\bar{\xi},\bar{\xi})}\,.$$

For $\xi > \bar{\xi}$, by (3.19), we have

$$|z(\xi)| \le E(\bar{\xi},0)e^{\gamma(\bar{\xi}-\xi)}|z_0| + \int_0^{\bar{\xi}} E(\bar{\xi},y)e^{\gamma(\bar{\xi}-\xi)}|h_z(y)|dy + \int_{\bar{\xi}}^{\xi} e^{\gamma(y-\xi)}|h_z(y)|dy$$
$$\le Ce^{-\gamma\xi}(|z_0| + \|h_z\|_{L^2_\xi(0,\bar{\xi})}) + z_1(\xi)\,,$$

where z_1 solves $\partial_\xi z_1 = -\gamma z_1 + |h_z|$, with $z_1(\bar{\xi}) = 0$. Multiplying by z_1 and integrating over $(\bar{\xi},\infty)$ gives $\|z_1\|_{L^2_\xi(\bar{\xi},\infty)} \le \frac{1}{\gamma}\|h_z\|_{L^2_\xi(\bar{\xi},\infty)}$, and hence

$$\|z\|_{L^2_\xi(\bar{\xi},\infty)} \le C(|z_0| + \|h_z\|_{L^2_\xi(0,\infty)})\,.$$

The interval $(-\infty,-\bar{\xi})$ is treated analogously, completing the estimation of $\|z\|_\xi$.

The estimate on $\|\partial_\xi z\|_\xi$ is an obvious consequence of the differential equation and the boundedness of r. ∎

THEOREM 3.6. *There exists a unique solution $w \in H^1_\xi(L^2_v)$ of (3.23). Moreover w satisfies*

$$\|\partial^k_\xi w\|_{\xi,v} \le \frac{1}{\kappa}\|\partial^k_\xi h_w\|_{\xi,v} \quad \textit{for } k = 0,1\,,$$

with κ as in Lemma 3.3.

Proof. We introduce an approximation by discrete velocity models. We choose an increasing sequence $\{\Omega^N\}$ of bounded measurable subsets of the support of the velocity measure exhausting it:

$$\Omega^N \subset \Omega^{N+1}\,, \qquad \bigcup_{N=1}^{\infty} \Omega^N = \Omega\,.$$

Each of the Ω^N is written as a finite disjoint union $\Omega^N = \bigcup_{j=1}^N \Omega^N_j$ of connected measurable subsets Ω^N_j, and the discrete velocities are chosen from these subsets: $v^N_j \in \Omega^N_j$ such that

$$\frac{1}{F(v^N_j)} = \frac{1}{\mu(\Omega^N_j)}\int_{\Omega^N_j} \frac{d\mu(v)}{F(v)}\,,$$

which is possible by the continuity of F. A quadrature formula for v-integrals is then defined by

$$\int f(v)\,d\mu(v) \approx \sum_{j=1}^N f(v^N_j)\mu(\Omega^N_j)\,.$$

These choices imply that for functions f and g, whose support is a subset of Ω^N and which are piecewise constant, i.e., constant on each Ω^N_j, the quadrature formula is exact both for the scalar product $\langle f,g\rangle_v$ and for the integrals $\int f\,d\mu(v)$ and $\int g\,d\mu(v)$. Finally, we make the decomposition of Ω^N fine enough such that

$$\lim_{N\to\infty}\sup_{1\le j\le N}\left|(v^N_j - s)^2 - \frac{1}{\mu(\Omega^N_j)}\int_{\Omega^N_j}(v-s)^2 d\mu(v)\right| = 0\,. \tag{3.26}$$

Now we approximate (3.23) by the discrete velocity model

(3.27)
$$\varepsilon(v_j^N - s)\partial_\xi w_j^N - (\mathcal{M}^N w^N)_j = h_{wj}^N := \frac{F(v_j^N)}{\mu(\Omega_j^N)} \int_{\Omega_j^N} \frac{h_w(v)}{F(v)} d\mu(v)\,, \quad j = 1, \dots, N\,,$$

where w^N denotes both the vector $(w_1^N, \dots, w_N^N)$ and the piecewise constant function in L_v^2 defined by

$$w^N(v) = \begin{cases} w_j^N & \text{for } v \in \Omega_j^N\,, \\ 0 & \text{for } v \in \Omega \setminus \Omega^N\,. \end{cases}$$

Note that by the construction of the quadrature we have

$$\langle f^N, g^N \rangle_N := \sum_{j=1}^N \frac{f_j^N g_j^N}{F(v_j^N)} \mu(\Omega_j^N) = \langle f^N, g^N \rangle_v\,.$$

The matrix $\mathcal{M}^N$ is defined by

(3.28)
$$(\mathcal{M}^N w^N)_j := F(v_j^N) \sum_{l=1}^N w_l^N \mu(\Omega_l^N) - w_j^N - (v_j^N - s)^2 F(v_j^N) \sum_{l=1}^N (v_l^N - s)^2 w_l^N \mu(\Omega_l^N)\,.$$

Equations (3.27) are a system of linear constant coefficient ODEs. A proof analogous to that of Lemma 3.3 shows that $\mathcal{M}^N$ is symmetric and negative definite with respect to $\langle \cdot, \cdot \rangle_N$ and, as a consequence, the generalized eigenvalue problem

$$(\mathcal{M}^N - \lambda(\mathcal{V}^N - s\mathrm{Id}^N))\phi = 0\,, \qquad \text{with } \mathcal{V}^N = \mathrm{diag}(v_1^N, \dots, v_N^N)\,,$$

corresponding to the left-hand side of (3.27) has only real eigenvalues away from zero. Thus, a unique bounded solution exists which converges to zero as $\xi \to \pm\infty$. Computing the scalar product of the resulting equation with w^N and integration with respect to ξ gives

$$-\int_{-\infty}^{\infty} \langle \mathcal{M}^N w^N, w^N \rangle_N \, d\xi = \int_{-\infty}^{\infty} \langle h_w^N, w^N \rangle_N \, d\xi\,.$$

With the definiteness of $\mathcal{M}^N$ and the properties of the quadrature, this implies

$$\|w^N\|_{\xi,v} \le \frac{1}{\kappa} \|h_w\|_{\xi,v}\,.$$

The uniform boundedness of w^N in $L_{\xi,v}^2$ implies its weak convergence (for a subsequence) to $w \in L_{\xi,v}^2$. We can also pass to the limit in (3.27). Here we use (3.26) for proving convergence of the last term in (3.28). The above estimate carries over to the limit w. Then the estimate for $\partial_\xi w$ is obtained by differentiating equation (3.23). Uniqueness is an obvious consequence. ∎

3.4. The nonlinear problem. In this section we prove existence and uniqueness of solutions of the nonlinear problem (3.16), (3.22) subject to $z(0) = z_0$ and to the requirement that the solution is square integrable with respect to ξ, replacing homogeneous far-field conditions.

After the preparations in the previous subsections, the proof is a straightforward contraction argument. We need, however, estimates for the right-hand sides of (3.16) and (3.22). In the following, C denotes (possibly different) ε-independent constants.

LEMMA 3.7.

(i) *The coefficients* Λ *and* Γ *satisfy*

$$\|\Lambda\|_{C^1_\xi(L^2_v)} + \|\Gamma\|_{C^1_\xi(L^2_v)} \le C\,.$$

(ii) *The nonlinear term* $R(\rho)$ *is quadratic in* ρ*: Let* $\rho_1, \rho_2 \in H^1_\xi$ *satisfy* $|\rho_1|, |\rho_2| \le C\varepsilon^{-2}$*. Then*

$$\|R(\rho_1) - R(\rho_2)\|_{H^1_\xi(L^2_v)} \le C\left(\|\rho_1\|_{H^1_\xi} + \|\rho_2\|_{H^1_\xi}\right)\|\rho_1 - \rho_2\|_{H^1_\xi}\,.$$

Proof. The proofs of the statements are straightforward. All that is needed is the boundedness in L^2_v of the derivatives $\partial^k_\rho M(\rho_{as} + \varepsilon^2\tilde\rho)$ for $k \le 3$ with $\tilde\rho$ between values of ρ_1 and ρ_2, as well as the continuous embedding $L^\infty_\xi \to H^1_\xi$. ∎

LEMMA 3.8. *The projection* $P : L^2_v \to L^2_v$*, defined by* (3.20)*, is a bounded operator.*

Proof. The proof is a straightforward consequence of (2.3)–(2.5). ∎

Before stating the existence and uniqueness result for traveling waves we recall the micro-macro decomposition $g(\xi, v) = z(\xi)\Phi(v) + \varepsilon w(\xi, v)$ of functions $g \in H^1_\xi(L^2_v)$, made unique by the requirement $\langle (v-s)\Phi, w\rangle_v = 0$, since

$$\langle (v-s)\Phi, \Phi\rangle_v = \frac{\varepsilon\sigma\tilde D}{\hat D} \ne 0\,.$$

We define a norm on $H^1_\xi(L^2_v)$ by

$$\|g\| := \|z\|_{H^1_\xi} + \varepsilon\|w\|_{H^1_\xi(L^2_v)}\,. \tag{3.29}$$

We also note that in terms of the original unknown $f = f_{as} + \varepsilon^2 g$, the condition $z(0) = z_0$ reads

$$\langle (v-s)\Phi, f - f_{as}\rangle_v(\xi = 0) = \frac{\varepsilon^3\sigma\tilde D}{\hat D} z_0\,. \tag{3.30}$$

THEOREM 3.9. *Let the assumptions stated in section* 2 *be satisfied. Then for every* $z_0 \in \mathbb{R}$ *and for* ε *small enough, there exists a solution* f *of* (1.12) *satisfying* (3.30)*, unique in a ball in* $(H^1_\xi(L^2_v), \|\ \|)$ *with center* f_{as} *and an* $O(\varepsilon)$ *radius. It satisfies*

$$\|f - M(\rho)\|_{H^1_\xi(L^2_v)} = O(\varepsilon^2)\,,$$

where ρ *is the solution of* (3.4)–(3.6)*, or, more precisely,*

$$f = M(\rho) - \varepsilon(v-s)\partial_\xi M(\rho) + \varepsilon^2 z\Phi + \varepsilon^3 w\,,$$

where $\|z\|_{H^1_\xi}$ *and* $\|w\|_{H^1_\xi(L^2_v)}$ *are uniformly bounded as* $\varepsilon \to 0$.

Proof. As a consequence of Lemmas 3.7 and 3.8 we have

$$\left\| \frac{a'(\rho_{as}) - s}{\varepsilon} \rho_w \right\|_{H^1_\xi} \le C \|w\|_{H^1_\xi(L^2_v)} ,$$
$$\|P\Lambda z\|_{H^1_\xi(L^2_v)} \le C\|z\|_{H^1_\xi} , \qquad \|\tilde{\Gamma}\rho_w\|_{H^1_\xi(L^2_v)} \le C\|w\|_{H^1_\xi(L^2_v)} .$$

This implies that for ε small enough, the results from Lemmas 3.5 and 3.6 can be extended to the linear system

$$\tilde{D}\,\partial_\xi z - r(\xi) z = \varepsilon \frac{a'(\rho_{as}) - s}{\varepsilon} \rho_w + h_z ,$$
$$\varepsilon(v - s)\partial_\xi w - \mathcal{M} w - zP\Lambda = \varepsilon \tilde{\Gamma} \rho_w + h_w ,$$

with inhomogeneities h_z, h_w and $z_0 = z(0)$. Applying the solution operator for this system to (3.16), (3.22), we obtain a fixed point problem of the form

$$z = \varepsilon R_z(z\rho_\Phi + \varepsilon\rho_w) + \tilde{h}_z , \tag{3.31}$$
$$w = \varepsilon R_w(z\rho_\Phi + \varepsilon\rho_w) + \tilde{h}_w , \tag{3.32}$$

with R_z and R_w sharing the properties of R given in Lemma 3.7, and $\tilde{h}_z$ and $\tilde{h}_w$ are given and bounded. Using $\|z\rho_\Phi + \varepsilon\rho_w\|_{H^1_\xi} \le \|(z, w)\|$ (see (3.29)), the estimate

$$\|(\varepsilon R_z(z\rho_\Phi + \varepsilon\rho_w) + \tilde{h}_z, \varepsilon R_w(z\rho_\Phi + \varepsilon\rho_w) + \tilde{h}_w)\| \le c(1 + \varepsilon\|(z, w)\|^2)$$

follows. Here we have identified $g = z\Phi + \varepsilon w$ with the pair (z, w). The estimate implies that for ε small enough both the ball with radius $2c$ and the ball with radius $1/(2\varepsilon c)$ are mapped into themselves by the right-hand side of (3.31), (3.32). Also, with the property of the nonlinearity from Lemma 3.7, the fixed point operator is a contraction on a ball with an $O(\varepsilon^{-1})$ radius. We conclude that for ε small enough, (3.31), (3.32) has a solution with $\|(z, w)\| \le 2c$ which is unique in a ball with an $O(\varepsilon^{-1})$ radius. Knowing this and returning to (3.32), the boundedness of $\|w\|_{H^1_\xi(L^2_v)}$ follows. ∎

By its construction the approximating density ρ is strictly monotone. It will be important for the stability proof below to extend this property to the exact density ρ_f.

LEMMA 3.10. *Let the assumptions of Theorem* 3.9 *hold and let f be the solution of* (1.12), (3.30). *Then the macroscopic density $\rho_f(\xi)$ is strictly monotone.*

Proof. The previous proof is easily extended to show that the dependence of z and w on z_0 is Lipschitz continuous with ε-independent Lipschitz constant. Actually, the difference of two solutions (z, w) and $(\hat{z}, \hat{w})$ with different z_0-values z_0 and $\hat{z}_0$, respectively, satisfies a system similar to (3.31), (3.31) with inhomogeneities proportional to $z_0 - \hat{z}_0$. With the properties of the nonlinearities from Lemma 3.7 it is straightforward that

$$\|z - \hat{z}\|_{H^1_\xi}, \ \|w - \hat{w}\|_{H^1_\xi(L^2_v)} \le C|z_0 - \hat{z}_0| . \tag{3.33}$$

For the corresponding solutions f and $\hat{f}$ of (1.12), (3.30),

$$\rho_f(0) - \rho_{\hat{f}}(0) = \varepsilon^2(z_0 - \hat{z}_0)\rho_\Phi + \varepsilon^3(\rho_w(0) - \rho_{\hat{w}}(0))$$

holds. The continuous embedding of $C(\mathbb{R})$ in H^1_ξ and (3.33) imply

$$|\rho_w(0) - \rho_{\hat{w}}(0)| \le C|z_0 - \hat{z}_0|\,,$$

and, thus, strict monotonicity (and therefore invertibility) of the map $z_0 \mapsto \rho_f(0)$ for ε small enough. This in turn implies that the traveling wave can also be made locally unique by prescribing the value of $\rho_f(0)$ instead of z_0. This argument can of course be repeated with $\rho_f(\xi_0)$ for every $\xi_0 \in \mathbb{R}$ instead of the origin.

Now assume that ρ_f is not strictly monotone. Then there are two ξ-values ξ_0 and $\xi_0 + \delta$ with arbitrarily small positive δ such that $\rho_f(\xi_0) = \rho_f(\xi_0 + \delta)$. Now $\tilde{f}(\xi, v) = f(\xi + \delta, v)$ is a traveling wave with $\rho_{\tilde{f}}(\xi_0) = \rho_f(\xi_0)$ and $\tilde{f}$ arbitrarily close to f by making δ small. By the uniqueness result $\tilde{f} \equiv f$, and, consequently, f is periodic, which is a contradiction to the far-field boundary conditions. ∎

4. Local stability of small amplitude traveling waves. In this section we prove dynamic stability of the small amplitude traveling waves constructed above. As mentioned in the introduction, the techniques we employ are commonly used for conservation laws regularized with diffusion terms. This motivates the following scaling: we write (1.1) in the traveling wave variable $\xi = (x - st)\varepsilon$, and introduce the *parabolic* scaling $t \to t/\varepsilon^2$, where ε is the amplitude of the wave. Then (1.1) reads

$$\varepsilon^2 \partial_t f + \varepsilon(v - s)\partial_\xi f = M(\rho_f) - f\,, \tag{4.1}$$

and we pose the same far-field boundary conditions as for the traveling wave:

$$f(t, \xi = \pm\infty, v) = M(\rho_\pm, v)\,.$$

Let us denote by ϕ a traveling wave solution as constructed in Theorem 3.9. By Lemma 3.10 its macroscopic profile is monotone, implying

$$\partial_\xi(a'(\rho_\phi)) \le 0\,. \tag{4.2}$$

Observe that formally the integral of $\rho_f - \rho_\phi$ is constant in t. This allows us to choose ϕ, by shifting in the ξ-direction if necessary, such that

$$\int_{\mathbb{R}} (\rho_f - \rho_\phi)\, d\xi = 0\,. \tag{4.3}$$

Condition (4.3) fixes the shift in ξ; we expect the solution f to approach this particular ϕ as $t \to \infty$.

Let us denote by G the deviation of f from ϕ, namely,

$$\varepsilon G = f - \phi\,. \tag{4.4}$$

Then G satisfies the equation

$$\varepsilon\partial_t G + (v - s)\partial_\xi G = \frac{1}{\varepsilon^2}\left[M(\rho_\phi + \varepsilon\rho_G) - M(\rho_\phi)\right] - \frac{1}{\varepsilon}G\,. \tag{4.5}$$

We recall that condition (4.3) allows us to deal with the *macroscopic* unknown $W = \int_{-\infty}^{\xi} \rho_G\, d\xi$; see (1.20).

We decompose G into a macroscopic part and into a microscopic part by simply using the natural *macroscopic* projection $f \to F\rho_f$; thus we write

$$G = \rho F + \varepsilon g, \quad \text{i.e.,} \quad \rho := \rho_G\,.$$

Analogously, we split (4.5) into its microscopic and macroscopic parts, i.e., we apply the macroscopic projection, and its complementary *microscopic* projection, which is in fact the operator $-\mathcal{L}$. Application of the macroscopic projection and division by F gives the equation

$$\partial_t \rho + \frac{1}{\varepsilon}(a'(\rho_-) - s)\partial_\xi \rho + \partial_\xi \int (v-s) g \, d\mu(v) = 0\,, \tag{4.6}$$

and application of $-\mathcal{L}$ gives

$$\varepsilon^2 \partial_t g + (v - a'(\rho_-))F\partial_\xi \rho - \varepsilon \partial_\xi \mathcal{L}((v-s)g) = R_2[\rho] - g\,, \tag{4.7}$$

with

$$R_2[\rho](t,\xi,v) = \frac{1}{\varepsilon^2}\left[M(\rho_\phi(\xi) + \varepsilon\rho(t,\xi), v) - M(\rho_\phi(\xi), v) - \varepsilon\rho(t,\xi)F(v)\right]\,. \tag{4.8}$$

Integrating (4.6) with respect to ξ gives, in terms of $W = \int_{-\infty}^{\xi} \rho(t,y)\,dy$,

$$\partial_t W - \sigma \partial_\xi W + \int (v-s) g \, d\mu(v) = 0\,. \tag{4.9}$$

Using (4.7) we compute

$$\begin{aligned}\int (v-s) g \, d\mu(v) = \int (v-s) R_2[\rho] \, d\mu(v) - \varepsilon^2 \int (v-s)\partial_t g \, d\mu(v) \\ + \varepsilon\, \partial_\xi \int (v-s)\mathcal{L}((v-s)g) d\mu(v) - D_0 \partial_\xi \rho\,.\end{aligned} \tag{4.10}$$

Substituting (4.10) into (4.9) and setting

$$r_2[\rho](t,\xi) := \int (v-s) R_2[\rho](t,\xi,v)\, d\mu(v)\,, \tag{4.11}$$

we arrive at the integrated *macroscopic* equation

$$\partial_t W - \sigma \partial_\xi W + r_2[\rho] - D_0 \partial_\xi^2 W = \varepsilon S[g]\,, \tag{4.12}$$

with

$$S[g] = \partial_\xi \int (v-s)\left(\varepsilon \partial_t g - \mathcal{L}((v-s)\partial_\xi g)\right)\, d\mu(v)\,. \tag{4.13}$$

Observe that (4.12) has the form of the perturbation equation for viscous shock profiles with a microscopic perturbation on the right-hand side and the nonlinearity

$$r_2[\rho] = \frac{1}{\varepsilon^2}(a(\rho_\phi + \varepsilon\rho) - a(\rho_\phi) - \varepsilon\rho a'(\rho_-))\,. \tag{4.14}$$

For controlling the nonlinear terms, a uniform (in ε) bound on the L^∞-norm of the density ρ is needed. For the macroscopic equation without the microscopic perturbation on the right-hand side, this is a consequence of the maximum principle. Here we shall employ bounds in H^1_ξ for the same purpose.

Assuming such a bound, we write $R_2[\rho]$ as

$$R_2[\rho] = \rho \int_0^1 \frac{M'(\rho_\phi + \varepsilon\rho\eta) - M'(\rho_-)}{\varepsilon}\, d\eta\,.$$

Then by differentiation with respect to ξ and by assumption (2.4),

$$\|R_2[\rho]\|_{H^k_\xi(L^2_v)} \le C\|\rho\|_{H^k_\xi} \quad \text{for } k=0,1,2\,, \tag{4.15}$$

and, consequently, by (2.5),

$$\|r_2[\rho]\|_{H^k_\xi} \le C\|\rho\|_{H^k_\xi} \quad \text{for } k=0,1,2\,, \tag{4.16}$$

where here and in the following the symbols C as well as C_j with various j denote constants depending on $\|\rho\|_{L^\infty_\xi}$ but independent of ε.

As the next step we derive integral estimates as one would do for the purely macroscopic case.

LEMMA 4.1. *Let W be a solution of* (4.12) *(for given g) and $\rho=\partial_\xi W$. Then the following estimates hold:*

$$\frac{1}{2}\frac{d}{dt}\|W\|^2_\xi + (D_0 - C_0\|W\|_{L^\infty_\xi})\|\partial_\xi W\|^2_\xi \le \varepsilon\int_{-\infty}^{\infty} W\,S[g]d\xi\,, \tag{4.17}$$

$$\frac{1}{2}\frac{d}{dt}\|\partial^k_\xi W\|^2_\xi + \frac{D_0}{2}\|\partial^{k+1}_\xi W\|^2_\xi - C_k\|\rho\|^2_{H^{k-1}_\xi} \le \varepsilon\int_{-\infty}^{\infty}\partial^k_\xi W\,S[\partial^k_\xi g]d\xi \tag{4.18}$$

for $k=1,2$. The constants C_0, C_1, C_2 depend on $\|\rho\|_{L^\infty_\xi}$.

Proof. For proving (4.17), we test (4.12) with W. Let us look at the term containing $r_2[\rho]$ by writing

$$r_2[\rho] = \frac{1}{\varepsilon}\left(a'(\rho_\phi) - a'(\rho_-)\right)\rho + \frac{1}{2}a''(\tilde\rho)\rho^2\,,$$

with $\tilde\rho$ between ρ_ϕ and $\rho_\phi+\varepsilon\rho$. Then we get

$$\begin{aligned}\int_{\mathbb{R}} r_2[\rho]\,W d\xi &= \frac{1}{2\varepsilon}\int_{\mathbb{R}}(a'(\rho_\phi)-a'(\rho_-))\partial_\xi(W^2)\,d\xi + \frac{1}{2}\int_{\mathbb{R}} a''(\tilde\rho)(\partial_\xi W)^2 W\,d\xi\\ &\ge -\frac{1}{2\varepsilon}\int_{\mathbb{R}}\partial_\xi(a'(\rho_\phi))W^2 d\xi - C_0\|W\|_{L^\infty_\xi}\|\partial_\xi W\|^2_\xi\,.\end{aligned} \tag{4.19}$$

The first term on the right-hand side of (4.19) is positive by (4.2), completing the proof of (4.17).

For $k=1,2$, the corresponding ξ-derivatives of (4.12) are tested with $\partial^k_\xi W$. As already mentioned in the introduction, no positive term can be expected to arise from the nonlinearity. Therefore we just estimate the corresponding terms using (4.16):

$$\left|\int_{\mathbb{R}}\partial^k_\xi\, r_2[\rho]\,\partial^k_\xi W d\xi\right| \le \int_{\mathbb{R}}|\partial^{k-1}_\xi r_2[\rho]\,\partial^{k+1}_\xi W|d\xi \le C_k\|\rho\|^2_{H^{k-1}_\xi} + \frac{D_0}{2}\|\partial^{k+1}_\xi W\|^2_\xi\,, \tag{4.20}$$

completing the proof of (4.18). ∎

Before deriving estimates for the microscopic contributions, we have to deal with the difficulty that the operator $S[g]$ describing the microscopic perturbation of the macroscopic equation contains the time derivative $\partial_t g$.

LEMMA 4.2. *Let W and g satisfy* (4.9)*, and let the operator S be defined by* (4.13)*. Then for $k=0,1,2$ the following holds:*

$$\begin{aligned}&\int_{-\infty}^{\infty}\partial^k_\xi W\,S[\partial^k_\xi g]d\xi\\ &\le \varepsilon\frac{d}{dt}\int_{-\infty}^{\infty}\langle F\partial^k_\xi W, (v-s)\partial^k_\xi g\rangle_{\xi,v} + C(\|\partial^{k+1}_\xi W\|^2_\xi + \|\partial^k_\xi g\|^2_{\xi,v})\,.\end{aligned} \tag{4.21}$$

Proof. A straightforward computation, using the kth order derivative of (4.9), gives

$$\int_{-\infty}^{\infty} \partial_\xi^k W\, S[\partial_\xi^k g] d\xi = \varepsilon \frac{d}{dt} \int_{-\infty}^{\infty} \partial_\xi^k W \int (v-s) \partial_\xi^k g d\mu(v)\, d\xi$$
$$- \varepsilon\sigma \int_{-\infty}^{\infty} \partial_\xi^{k+1} W \int (v-s)\partial_\xi^k g\, d\mu(v)\, d\xi + \int_{-\infty}^{\infty} \left(\int (v-s)\partial_\xi^k g\, d\mu(v) \right)^2 d\xi$$
$$+ \int_{-\infty}^{\infty} \partial_\xi^{k+1} W \int (v-s)\mathcal{L}((v-s)\partial_\xi^k g) d\mu(v)\, d\xi\,.$$

To estimate the last three terms, we use the Cauchy–Schwarz inequality and (2.5). ∎

To get control of the microscopic part, we derive entropy estimates from the full kinetic perturbation equation (4.5).

LEMMA 4.3. *Let $G = \rho F + \varepsilon g$ be a solution of* (4.5). *Then, for $k = 0, 1, 2$,*

$$\frac{d}{dt} \left(\|\partial_\xi^k \rho\|_\xi^2 + \varepsilon^2 \|\partial_\xi^k g\|_{\xi,v}^2 \right) + \|\partial_\xi^k g\|_{\xi,v}^2 \le C \|\rho\|_{H_\xi^k}^2\,. \tag{4.22}$$

Proof. Writing the right-hand side of (4.5) as $R_2[\rho] - g$ and taking the scalar product of its kth derivative with $\partial_\xi^k G = \partial_\xi^k \rho F + \partial_\xi^k g$, we get

$$\frac{1}{2}\frac{d}{dt} \|\partial_\xi^k G\|_{\xi,v}^2 + \|\partial_\xi^k g\|_{\xi,v}^2 = \langle \partial_\xi^k R_2[\rho], \partial_\xi^k g \rangle_{\xi,v}\,.$$

The result is a consequence of using $\|\partial_\xi^k G\|_{\xi,v}^2 = \|\partial_\xi^k \rho\|_\xi^2 + \varepsilon^2 \|\partial_\xi^k g\|_{\xi,v}^2$, and then applying the Cauchy–Schwarz inequality, the Young inequality, and (4.15) to the right-hand side. ∎

Now we are prepared for proving our stability result for small kinetic shock profiles.
