$$Q(R) = Q(0, R), \quad Q = Q(1).$$

In local analysis, the most reasonable object to study is so-called suitable weak solutions, introduced by Caffarelli, Kohn, and Nirenberg in their celebrated paper [1]. We are going to use the slightly simpler definition of Lin in [10].

Definition 1.1. *The pair v and p is called a suitable weak solution to the Navier–Stokes equations in Q if the following conditions are satisfied:*

$$v \in L_{2,\infty}(Q) \cap W_2^{1,0}(Q), \qquad p \in L_{\frac{3}{2}}(Q),$$

where $W_2^{1,0}(Q) = \{v \in L_2(Q) \parallel \nabla v \in L_2(Q)\}$;

v and p satisfy the Navier–Stokes equations in the sense of distributions;

for a.a. $t \in]-1, 0[$, the local energy inequality

$$\int_{\mathcal{C}} \varphi(x,t)|v(x,t)|^2 dx + 2\int_{-1}^{t}\int_{\mathcal{C}} \varphi|\nabla v|^2 dxdt'$$
$$\leq \int_{-1}^{t}\int_{\mathcal{C}} \Big\{|v|^2(\Delta\varphi + \partial_t\varphi) + v\cdot\nabla\varphi(|v|^2 + 2p)\Big\} dxdt'$$

holds for all nonnegative cut-off functions $\varphi \in C_0^\infty(\mathbb{R}^3 \times \mathbb{R})$ vanishing in a neighborhood of the parabolic boundary of Q.

For discussions of the above definition, we refer the reader to [8] and [17].

The following is our main result.

Theorem 1.2. *Let v and p be an axially symmetric suitable weak solution to the Navier–Stokes equations in Q. Assume that*

$$\mathcal{A}_0 = \operatorname{ess}\sup_{-1 \leq t \leq 0} \int_{\mathcal{C}} \frac{1}{\varrho}|v(x,t)|^2 dx < +\infty. \tag{1.3}$$

Then the point $(x,t)=(0,0)$ is a regular point of v; i.e., there exists $r\in\,]0,1]$ such that v is Hölder continuous in the closure of the cylinder $Q(r)$.

By c, we shall denote all generic constants that may vary from one bound to others.

Our paper is organized as follows. In the second section, we discuss known inequalities of the local regularity theory and prove some useful facts about suitable weak solutions. The proof of the main result is started in the third section with scaling and blowup of our solution at a singular point. We also discuss properties of the blowup velocity and the blowup pressure in this section. In the fourth section, we prove some additional differential properties of axially symmetric suitable weak solutions. They are needed to establish a decay of the blowup velocity at infinity. Finally, we end up with the proof of the main theorem in the fifth section. Here, with the help of backward uniqueness results for the heat operator with variable lower order terms, we show that in fact our blowup velocity is trivial.

2. Preliminaries. In what follows, we are going to make use of the following scaling invariant functionals:

$$A(z_0,r;v)=\mathrm{ess}\sup_{t_0-r^2<t<t_0}\frac{1}{r}\int_{\mathcal{C}(x_0,r)}|v(x,t)|^2dx,\quad C(z_0,r;v)=\frac{1}{r^2}\int_{Q(z_0,r)}|v|^3dz,$$

$$E(z_0,r;v)=\frac{1}{r}\int_{Q(z_0,r)}|\nabla v|^2dz,\qquad D(z_0,r;p)=\frac{1}{r^2}\int_{Q(z_0,r)}|p|^{\frac{3}{2}}dz.$$

First, let us recall that, by the Navier–Stokes equations scaling,

$$v^\lambda(x,t)=\lambda v(\lambda x,\lambda^2t),\qquad p^\lambda(x,t)=\lambda^2p(\lambda x,\lambda^2t),$$

we may define suitable weak solutions to the Navier–Stokes equations in $Q(z_0,R)$. So, if v and p form a suitable weak solution to the Navier–Stokes equations in $Q(z_0,R)$, then, for appropriate choice of the cut-off function in the local energy inequality, we can reduce it to the following invariant form:

$$\begin{aligned}A(z_0,R/2;v)+E(z_0,R/2;v)\le c\Big(&C^{\frac{2}{3}}(z_0,R;v)\\&+C(z_0,R;v)+D(z_0,R;p)\Big).\end{aligned}\tag{2.1}$$

We also need the so-called decay estimate for pressure,

$$D(z_0,r;p)\le c\Big[\frac{r}{r_1}D(z_0,r_1;p)+\Big(\frac{r_1}{r}\Big)^2C(z_0,r_1;v)\Big],\tag{2.2}$$

which is valid for all $0<r\le r_1\le R$. The proof of the latter estimate is given in [14]. Repeating the arguments of Lemma 1.8 in [18], we can prove the following.

LEMMA 2.1. *Let v and p be a suitable weak solution to the Navier–Stokes equations in Q and let*

$$A_0=\sup_{0<r<1}A(0,r;v)<+\infty.\tag{2.3}$$

Then, for any $r\in]0,1/2[$, we have

$$\begin{aligned}C^{\frac{4}{3}}(0,r;v)+D(0,r;p)+E(0,r;v)\le c\Big(&(A_0+1)r^{\frac{1}{2}}(D(0,1;p)\\&+E(0,1;v))+A_0^4+A_0^2+A_0\Big).\end{aligned}\tag{2.4}$$

Lemma 2.1, together with the invariance of our functionals under the Navier–Stokes equations scaling and under the shift in the direction of x_3, gives us the following.

Lemma 2.2. *Under the conditions of Theorem* 1.2*, we have*

$$A(z_0,r;v)+C(z_0,r;v)+D(z_0,r;p)+E(z_0,r;v)\leq \mathcal{A}<+\infty \tag{2.5}$$

for all $z_0=(x_0,0)$, $x_0=(0,b)$, $|b|\leq 1/4$, and for all $0<r\leq 1/4$, where a bound $\mathcal{A}$ depends only on quantities $D(0,1;p)$ and $E(0,1;v)$ and the number $\mathcal{A}_0$, defined in Theorem 1.2.

We say that the pair v and p is a suitable weak solution to the Navier–Stokes equations in the space-time cylinder $\Omega\times]T_1,T_2[$ if, for any $z_0=(x_0,t_0)$ with $x_0\in\Omega$ and $T_1<t\leq T_2$, the pair v and p is a suitable weak solution to the Navier–Stokes equations in $Q(z_0,R)$ for some $R>0$.

Next, let us introduce the family of sets

$$\mathcal{P}(R_1,R_2;a)=\{x\in\mathbb{R}^3\parallel R_1<|x'|<R_2,\,|x_3|<a\}.$$

Now, we would like to formulate and prove the following statement.

Lemma 2.3. *Let v and p be a suitable weak solution to the Navier–Stokes equations in the set $\widehat{Q}=\mathcal{P}(3/4,9/4;3/2)\times]-(3/2)^2,0[$. Assume that*

$$\int_{\widehat{Q}}|v(z)|^6dz\leq m<+\infty. \tag{2.6}$$

Then there exists a function $\Phi_0:\mathbb{R}_+\times\mathbb{R}_+\to\mathbb{R}_+$, nondecreasing in each variables, such that

$$|v(z)|+|\nabla v(z)|\leq \Phi_0(m,\mathcal{A}_*)<+\infty \tag{2.7}$$

for any $z\in\mathcal{P}(1,2;1)\times]-1,0[$. Here,

$$\mathcal{A}_*=\int_{\widehat{Q}}|p(z)|^{\frac32}dz=\int_{-(3/2)^2}^0dt\int_{\mathcal{P}(3/4,9/4;3/2)}|p|^{\frac32}dx.$$

Proof. First, we remark that $Q(z_0,1/4)\subset\widehat{Q}$ for any $z_0\in\mathcal{P}(1,2;1)\times]-1,0[$. It follows from (2.2), Hölder's inequality, and (2.6) that

$$D(z_0,r;p)\leq c\Big[\frac{r}{r_1}D(z_0,r_1;p)+\Big(\frac{r_1}{r}\Big)^2m^{\frac12}r_1^{\frac12}\Big], \tag{2.8}$$

which is valid for all $0<r\leq r_1\leq 1/4$. For $\tau\in]0,1[$, let us take $r=\tau^{k+1}/4$ and $r_1=\tau^k/4$ in (2.8) and find

$$D(z_0,\tau^{k+1}/4;p)\leq c\tau\Big[D(z_0,\tau^k/4;p)+m^{\frac12}\tau^{-3}\tau^{\frac{k}{2}}\Big]$$

for all nonnegative integer numbers k. We can choose $\tau\in]0,1[$ so small to provide

$$c\tau^{\frac34}\leq 1$$

and conclude

$$D(z_0,\tau^{k+1}/4;p)\leq \tau^{\frac14}\Big[D(z_0,\tau^k/4;p)+m^{\frac12}\tau^{-3}\tau^{\frac{k}{2}}\Big]$$

for all nonnegative integer numbers k. The latter inequality may be easily iterated. As a result, we have

$$D(z_0,\tau^{k+1}/4;p)\le \tau^{\frac{k+1}{4}}\Big[D(z_0,1/4;p)+m^{\frac12}\tau^{-3}\sum_{i=0}^{k}\tau^{\frac{i}{4}}\Big]$$

for all nonnegative integer numbers k. So,

$$\begin{aligned}C(z_0,\tau^{k+1}/4;v)+D(z_0,\tau^{k+1}/4;p)&\le cm^{\frac12}\tau^{\frac{k+1}{2}}\\ &\quad+\tau^{\frac{k+1}{4}}\Big[D(z_0,1/4;p)+m^{\frac12}\tau^{-3}(1-\tau^{\frac14})^{-1}\Big]\\ &\le c\Big[m^{\frac12}\tau^{\frac{k+1}{2}}+\tau^{\frac{k+1}{4}}\Big(\mathcal{A}_*+m^{\frac12}\tau^{-3}(1-\tau^{\frac14})^{-1}\Big)\Big]\end{aligned}$$

for all nonnegative integer numbers k. Given $\varepsilon>0$, we can find an integer number k_0 so that

$$c\Big[m^{\frac12}\tau^{\frac{k_0+1}{2}}+\tau^{\frac{k_0+1}{4}}\Big(\mathcal{A}_*+m^{\frac12}\tau^{-3}(1-\tau^{\frac14})^{-1}\Big)\Big]\le\varepsilon.$$

But according to the so-called ε-regularity theory (see, for example, [8], [4], and [17]), the latter implies two bounds,

$$|v(z_0)|\le\frac{c}{r_0}\quad\text{and}\quad|\nabla v(z_0)|\le\frac{c}{r_0^2},$$

where $r_0=\tau^{(k_0+1)}/4$. Lemma 2.3 is proved. $\square$

The last preliminary statement is as follows.

LEMMA 2.4. *Assume that all conditions of Theorem* 1.2 *hold. Then*

$$\int_{\mathcal{C}}\frac{1}{\varrho}|v(x,t)|^2dx\le\mathcal{A}_0 \tag{2.9}$$

for all $t\in\,]-1,0[$.

Proof. It is easy to derive the estimate

$$\int_Q\partial_t v\cdot w dz\le\mathcal{A}_1\Big(\int_Q|\nabla w|^3dz\Big)^{\frac13}$$

for any $C_0^\infty(Q)$. Here, a constant $\mathcal{A}_1$ depends on $C(0,1;v)$, $E(0,1;v)$, and $D(0,1;p)$ only. So, v has the first derivative in t in the space

$$L_{\frac32}(-1,0;W^{-1}_{\frac32}(\mathcal{C})).$$

In turn, the latter, together with boundedness of the energy, implies weak continuity in time in the following sense: the function

$$t\to\int_{\mathcal{C}}v(x,t)\cdot w(x)dx$$

is continuous on $[-1,0]$ for any $w\in L_2(\mathcal{C})$. Now, the statement of the lemma follows from the weak lower semicontinuity of the functional

$$w\in L_2(\mathcal{C})\to\int_{\mathcal{C}}\frac{1}{\varrho}|w(x)|^2dx.$$

Lemma 2.4 is proved. $\square$

3. Scaling and blowup. Here, we begin the proof of Theorem 1.2. Assume that the statement of this theorem is false. Then, according to the local regularity theory for the Navier–Stokes equations, there exist an absolute positive constant ε and a sequence $\{R_k\}_{k=1}^{\infty}$ such that $R_k \to 0$ as $k \to +\infty$ and

$$\frac{1}{R_k^2}\int_{Q(R_k)} |v|^3 dz \geq \varepsilon > 0 \tag{3.1}$$

for all $k \in \mathbb{N}$; see [15, Lemma 3.3] for a similar situation or [17, Proposition 5.7].

Next, we scale v and p in the following way:

$$u^k(y,s) = R_k v(R_k y, R_k^2 s), \quad q^k(y,s) = R_k^2 p(R_k y, R_k^2 s),$$

where $e = (y,s) \in Q(1/R_k)$. Functions u^k and q^k are extended by zero to the whole space-time $\mathbb{R}^3 \times \mathbb{R}$.

Now let us fix numbers a and b in $\mathbb{R}$ so that $a > 0$. Let

$$x_k^b = (0, bR_k), \quad y^b = (0,b), \quad z_k^b = (x_k^b, 0), \quad e^b = (y^b, 0).$$

Obviously, for sufficiently large k,

$$|b|R_k < 1/4, \qquad aR_k < 1/4;$$

by Lemma 2.2, the following estimates are valid:

$$C(z_k^b, aR_k; v) = C(e^b, a; u^k) \leq \mathcal{A},$$

$$E(z_k^b, aR_k; v) = E(e^b, a; u^k) \leq \mathcal{A},$$

$$A(z_k^b, aR_k; v) = A(e^b, a; u^k) \leq \mathcal{A}, \tag{3.2}$$

$$D(z_k^b, aR_k; p) = D(e^b, a; q^k) \leq \mathcal{A}$$

for all $k \geq k_0(a,b)$.

First, let b be equal to zero. In this particular case, we can produce three estimates. The first of them is well known in the Navier–Stokes theory and is but a consequence of multiplicative inequalities:

$$\frac{1}{a^{\frac{5}{2}}}\int_{Q(a)} |u^k|^{\frac{10}{3}} de \leq c(\mathcal{A}). \tag{3.3}$$

The second estimate follows from the Navier–Stokes equations, written for u^k and q^k in the weak form, and from (3.2):

$$\int_{Q(a)} \partial_t u^k \cdot w de \leq c(a,\mathcal{A})\Big(\int_{Q(a)} |\nabla w|^3 de\Big)^{\frac{1}{3}}$$

for all $w \in C_0^\infty(Q(a))$. Hence,

$$\partial_t u^k \text{ is bounded in } L_{\frac{3}{2}}(-a^2, 0; W^{-1}_{\frac{3}{2}}(\mathcal{C}(a))). \tag{3.4}$$

The third estimate comes from our main condition (1.3) and has the form

$$\text{ess}\sup_{-(aR_k)^2\le t\le 0}\int_{\mathcal{C}(aR_k)}\frac{|v(x,t)|^2}{|x'|}dx=\text{ess}\sup_{-a^2\le s\le 0}\int_{\mathcal{C}(a)}\frac{|u^k(y,t)|^2}{|y'|}dy\le\mathcal{A}_0. \tag{3.5}$$

Now, making use of the diagonal process for extending space-time cylinders $Q(a)$ and known compactness arguments, we can select subsequences (still denoted by u^k and q^k) such that, for each $a>0$,

$$\begin{aligned} u^k &\rightharpoonup u \qquad \text{in } W^{1,0}_2(Q(a)),\\ u^k &\overset{\star}{\rightharpoonup} u \qquad \text{in } L_{2,\infty}(Q(a)),\\ u^k &\to u \qquad \text{in } L_3(Q(a)),\\ q^k &\rightharpoonup q \qquad \text{in } L_{\frac{3}{2}}(Q(a)). \end{aligned} \tag{3.6}$$

The aim of our further considerations is to describe properties of limit functions u and q called the blowup velocity and blowup pressure, respectively. They are defined on $\mathbb{R}^3\times\mathbb{R}_-$, where $\mathbb{R}_-=\{s\in\mathbb{R}\,\|\,s\le 0\}$. For each $a>0$, the pair u and q is a suitable weak solution to the Navier–Stokes equations in $Q(a)$. From (3.2) and (3.6), it follows that the limit functions obey the inequalities

$$\begin{aligned} C(e^b,a;u)&\le\mathcal{A},\\ A(e^b,a;u)&\le\mathcal{A},\\ E(e^b,a;u)&\le\mathcal{A},\\ D(e^b,a;q)&\le\mathcal{A} \end{aligned} \tag{3.7}$$

for all $b\in\mathbb{R}$ and for all $0<a\in\mathbb{R}$. Moreover, we can derive from (3.6), (3.5), and (3.1) two additional estimates:

$$\text{ess}\sup_{-\infty<s\le 0}\int_{\mathbb{R}^3}\frac{|u(y,t)|^2}{|y'|}dy\le\mathcal{A}_0 \tag{3.8}$$

and

$$\frac{1}{R_k^2}\int_{Q(R_k)}|v|^3dz=\int_Q|u^k|^3de\to\int_Q|u|^3de\ge\varepsilon. \tag{3.9}$$

According to (3.9), the blowup velocity u is a nontrivial solution to the Navier–Stokes equations in $\mathbb{R}^3\times\mathbb{R}_-$. But we are going to show that in fact $u\equiv 0$. This would contradict (3.9) and prove Theorem 1.2.

Obviously, the blowup velocity field u is axially symmetric and, by Caffarelli–Kohn–Nirenberg-type results, all points $y'\ne 0$ are regular, which make it possible to conclude that all spatial derivatives of u are Hölder continuous in a vicinity of each point with $y'\neq 0$.

We can also make use of the local regularity theory for the Stokes system; see [16] and [17]. According to it and by known multiplicative inequality, we have

$$\|\partial_t u^k\|_{L_{\frac98,\frac32}(Q(a/2))}+\|\nabla^2 u^k\|_{L_{\frac98,\frac32}(Q(a/2))}+\|\nabla q^k\|_{L_{\frac98,\frac32}(Q(a/2))}$$

$$\leq c(a)\Big[\|u^k\cdot\nabla u^k\|_{L_{\frac98,\frac32}(Q(a))}+\|u^k\|_{W^{1,0}_2(Q(a))}+\|q^k\|_{L_{\frac32}(Q(a))}\Big]$$

$$\leq c(a)\Big[\|u^k\|^{\frac23}_{L_{2,\infty}(Q(a))}\|u^k\|^{\frac13}_{W^{1,0}_2(Q(a))}+\cdots\Big]\leq c(a,\mathcal{A}).$$

The latter estimate shows that we can select a subsequence (still denoted by u^k) such that, for any $a>1$,

$$u^k\to u \qquad \text{in } C([-1,0];L_{\frac98}(\mathcal{C}(a))). \tag{3.10}$$

We can exploit (3.10) in the following way. For any fixed positive numbers r_1, r_2, and h, we have

$$\Big(\int_{\mathcal{P}(r_1,r_2;h)}|u(y,0)|^{\frac98}dy\Big)^{\frac89}\leq\Big(\int_{\mathcal{P}(r_1,r_2;h)}|u^k(y,0)-u(y,0)|^{\frac98}dy\Big)^{\frac89}$$
$$+\Big(\int_{\mathcal{P}(r_1,r_2;h)}|u^k(y,0)|^{\frac98}dy\Big)^{\frac89}=\alpha_k+\beta_k.$$

By (3.10),

$$\alpha_k\to 0$$

as $k\to+\infty$. To evaluate β_k, we make use of inverse scaling and Hölder's inequality:

$$\beta_k=\Big(R_k^{-\frac{15}{8}}\int_{\mathcal{P}(R_kr_1,R_kr_2;R_kh)}|v(x,0)|^{\frac98}dx\Big)^{\frac89}$$
$$\leq c(r_1,r_2,h)\Big(\frac{1}{R_k}\int_{\mathcal{P}(R_kr_1,R_kr_2;R_kh)}|v(x,0)|^2dx\Big)^{\frac12}$$
$$\leq c(r_1,r_2,h)\Big(\int_{\mathcal{P}(R_kr_1,R_kr_2;R_kh)}\frac{|v(x,0)|^2}{|x'|}dx\Big)^{\frac12}.$$

Now, it remains to apply Lemma 2.4 at $t=0$ and absolute continuity of Lebesgue's integral and conclude that

$$\beta_k\to 0$$

as $k\to+\infty$. This implies the identity

$$\int_{\mathcal{P}(r_1,r_2;h)}|u(y,0)|^{\frac98}dy=0$$

for all positive numbers r_1, r_2, and h. So, we can state that

$$u(\cdot,0)=0 \qquad \text{in}\quad \mathbb{R}^3. \tag{3.11}$$

4. Estimates of axially symmetric solutions. The main result of this section is going to be as follows.

PROPOSITION 4.1. *Let V and P be a sufficiently smooth axially symmetric solution to the Navier–Stokes equations in $\widetilde{Q} = \widetilde{\mathcal{P}} \times \,]-2^2, 0[$, where $\widetilde{\mathcal{P}} = \mathcal{P}(1/4, 3; 2)$. Then there exists a nondecreasing function $\Phi : \mathbb{R}_+ \to \mathbb{R}_+$ such that*

$$\sup_{z\in\mathcal{P}(1,2;1)\times]-1,0[} \Big(|V(z)| + |\nabla V(z)|\Big) \leq \Phi(\mathcal{A}_2), \tag{4.1}$$

where

$$\mathcal{A}_2 = \sup_{-2^2<t<0} \int_{\widetilde{\mathcal{P}}} |V(x,t)|^2 dx + \int_{\widetilde{Q}} \Big(|\nabla V|^2 + |V|^3 + |P|^{\frac{3}{2}}\Big) dz.$$

To prove the above proposition, we need the following.

LEMMA 4.2. *Under assumptions of Proposition 4.1, there exists a function $\Phi_1 : \mathbb{R}_+ \times \mathbb{R}_+ \to \mathbb{R}_+$, nondecreasing in each variable, such that*

$$\sup_{-(7/4)^2<t<0} \int_{\widetilde{\mathcal{P}}_1} |V^a(x,t)|^q dx \leq \Phi_1(q, \mathcal{A}_2), \qquad 1 \leq q < +\infty. \tag{4.2}$$

Here, $V^a = (V_\varrho, V_3)$, $|V^a| = \sqrt{|V_\varrho|^2 + |V_3|^2}$, $\widetilde{\mathcal{P}}_1 = \mathcal{P}(5/16, 11/4; 7/4)$, and $\widetilde{Q}_1 = \widetilde{\mathcal{P}}_1 \times \,]-(7/4)^2, 0[$.

Proof. Let us denote by ω the vorticity of V, i.e., $\omega = \nabla \wedge V$. For $\chi = \omega_\varphi$, V_ϱ, and V_3, we have the following identities:

$$V_{\varrho,\varrho} + V_{3,3} = -\frac{1}{\varrho} V_\varrho, \tag{4.3}$$

$$V_{\varrho,3} - V_{3,\varrho} = \chi, \tag{4.4}$$

$$\partial_t \chi + V_\varrho \chi_{,\varrho} + V_3 \chi_{,3} - \frac{1}{\varrho}\chi V_\varrho - \Big(\chi_{,\varrho\varrho} + \chi_{,33} + \frac{1}{\varrho}\chi_{,\varrho} - \frac{1}{\varrho^2}\chi\Big) = \frac{2}{\varrho} V_\varphi V_{\varphi,3}, \tag{4.5}$$

where we have used the notation

$$f_{,\varrho} = \frac{\partial f}{\partial \varrho}, \qquad f_{,3} = \frac{\partial f}{\partial x_3}.$$

Next, we let $\widetilde{\chi} = \chi\psi$, $\widetilde{V} = V^a\psi$, $\widetilde{V}_\varrho = V_\varrho\psi$, and $\widetilde{V}_3 = V_3\psi$, where a nonnegative smooth and axially symmetric cut-off function ψ vanishes in a neighborhood of the parabolic boundary of $\widetilde{Q}$ and is equal to 1 in $\widetilde{Q}_1$. For $\widetilde{\chi}$, $\widetilde{V}_\varrho$, and $\widetilde{V}_3$, we have

$$\widetilde{V}_{\varrho,\varrho} + \widetilde{V}_{3,3} = -\frac{1}{\varrho}\widetilde{V}_\varrho + V_\varrho \psi_{,\varrho} + V_3 \psi_{,3}, \tag{4.6}$$

$$\widetilde{V}_{\varrho,3} - \widetilde{V}_{3,\varrho} = \widetilde{\chi} + V_\varrho \psi_{,3} - V_3 \psi_{,\varrho}, \tag{4.7}$$

$$\partial_t \widetilde{\chi} + V_\varrho \widetilde{\chi}_{,\varrho} + V_3 \widetilde{\chi}_{,3} - \frac{1}{\varrho} V_\varrho \widetilde{\chi} - \Big(\widetilde{\chi}_{,\varrho\varrho} + \widetilde{\chi}_{,33} + \frac{1}{\varrho}\widetilde{\chi}_{,\varrho} - \frac{1}{\varrho^2}\widetilde{\chi}\Big) = J_1 + J_2 + J_3, \tag{4.8}$$

where

$$J_1=\frac{2}{\varrho}V_\varphi V_{\varphi,3}\psi,$$

$$J_2=\chi\Big(\partial_t\psi-\psi_{,\varrho\varrho}-\psi_{,33}-\frac{1}{\varrho}\psi_{,\varrho}\Big)-2\Big(\chi_{,\varrho}\psi_{,\varrho}+\chi_{,3}\psi_{,3}\Big),$$

$$J_3=\chi\Big(V_\varrho\psi_{,\varrho}+V_3\psi_{,3}\Big).$$

Now, we multiply (4.8) by $\widetilde{\chi}\varrho^{-2}$ and integrate the product by parts over $\widetilde{\mathcal{P}}$:

$$\begin{aligned}&\frac{1}{2}\partial_t\int\limits_{\widetilde{\mathcal{P}}}\Big|\frac{\widetilde{\chi}}{\varrho}\Big|^2dx+\int\limits_{\widetilde{\mathcal{P}}}\Big(\Big|\Big(\frac{\widetilde{\chi}}{\varrho}\Big)_{,\varrho}\Big|^2+\Big|\Big(\frac{\widetilde{\chi}}{\varrho}\Big)_{,3}\Big|^2\Big)dx\\ &=\int\limits_{\widetilde{\mathcal{P}}}J_1\frac{\widetilde{\chi}}{\varrho^2}dx+\int\limits_{\widetilde{\mathcal{P}}}J_2\frac{\widetilde{\chi}}{\varrho^2}dx+\int\limits_{\widetilde{\mathcal{P}}}J_3\frac{\widetilde{\chi}}{\varrho^2}dx.\end{aligned}\tag{4.9}$$

Our aim is to evaluate the right-hand side of (4.9). We start with the first term there:

$$\begin{aligned}\int\limits_{\widetilde{\mathcal{P}}}J_1\frac{\widetilde{\chi}}{\varrho^2}dx&=-\int\limits_{\widetilde{\mathcal{P}}}\frac{V_\varphi^2}{\varrho^2}\Big(\frac{\widetilde{\chi}}{\varrho}\Big)_{,3}\psi dx-\int\limits_{\widetilde{\mathcal{P}}}\frac{V_\varphi^2}{\varrho^2}\frac{\widetilde{\chi}}{\varrho}\psi_{,3}dx\\ &\le c\Big(\int\limits_{\widetilde{\mathcal{P}}}\frac{|V_\varphi|^4}{\varrho^4}dx\Big)^{\frac12}\Big(\int\limits_{\widetilde{\mathcal{P}}}\Big|\Big(\frac{\widetilde{\chi}}{\varrho}\Big)_{,3}\Big|^2dx+\int\limits_{\widetilde{\mathcal{P}}}\Big|\frac{\widetilde{\chi}}{\varrho}\Big|^2dx\Big)^{\frac12}.\end{aligned}$$

To estimate the first multiplier of the right-hand side of the latter inequality, we are going to exploit a two-dimensional feature of our axially symmetric problem in the following way. So, by Ladyzhenskaya's inequality,

$$\begin{aligned}\int\limits_{\widetilde{\mathcal{P}}}|V_\varphi|^4dx&\le c\int\limits_{-2}^{2}\int\limits_{1/4}^{3}|V_\varphi|^4d\varrho dx_3\\ &\le c\int\limits_{-2}^{2}\int\limits_{1/4}^{3}|V_\varphi|^2d\varrho dx_3\int\limits_{-2}^{2}\int\limits_{1/4}^{3}\Big(|V_\varphi|^2+|\nabla_aV_\varphi|^2\Big)d\varrho dx_3\\ &\le c\int\limits_{\widetilde{\mathcal{P}}}|V|^2dx\int\limits_{\widetilde{\mathcal{P}}}\Big(|V|^2+|\nabla V|^2\Big)dx\le c\mathcal{A}_2\int\limits_{\widetilde{\mathcal{P}}}\Big(|V|^2+|\nabla V|^2\Big)dx,\end{aligned}$$

where the notation $\nabla_af=(f_{,\varrho},f_{,3})$ has been used. Thus, we find the first estimate:

$$\begin{aligned}\int\limits_{\widetilde{\mathcal{P}}}J_1\frac{\widetilde{\chi}}{\varrho^2}dx&\le c\mathcal{A}_2^{\frac12}\Big(\int\limits_{\widetilde{\mathcal{P}}}\Big(|V|^2+|\nabla V|^2\Big)dx\Big)^{\frac12}\\ &\times\Big(\int\limits_{\widetilde{\mathcal{P}}}\Big|\nabla_a\Big(\frac{\widetilde{\chi}}{\varrho}\Big)\Big|^2dx+\int\limits_{\widetilde{\mathcal{P}}}\Big|\frac{\widetilde{\chi}}{\varrho}\Big|^2dx\Big)^{\frac12}.\end{aligned}\tag{4.10}$$

For the second term, we have

$$\int\limits_{\widetilde{\mathcal{P}}}J_2\frac{\widetilde{\chi}}{\varrho^2}dx\le c\int\limits_{\widetilde{\mathcal{P}}}|\chi|^2dx.\tag{4.11}$$

The third term is estimated in a slightly different way:

$$\begin{aligned}\int_{\widetilde{\mathcal{P}}} J_3\frac{\widetilde{\chi}}{\varrho^2}dx &= \int_{\widetilde{\mathcal{P}}}\frac{\chi\widetilde{\chi}}{\varrho^2}\Big(V_\varrho\psi_{,\varrho}+V_3\psi_{,3}\Big)dx\\ &\le c\Big(\int_{\widetilde{\mathcal{P}}}|\chi|^2dx\Big)^{\frac12}\Big(\int_{\widetilde{\mathcal{P}}}|V^a\cdot\nabla_a\psi|^2\Big|\frac{\widetilde{\chi}}{\varrho}\Big|^2dx\Big)^{\frac12}\\ &\le c\int_{\widetilde{\mathcal{P}}}|\chi|^2dx+c\Big(\int_{\widetilde{\mathcal{P}}}|V^a\cdot\nabla_a\psi|^4dx\Big)^{\frac12}\Big(\int_{\widetilde{\mathcal{P}}}\Big|\frac{\widetilde{\chi}}{\varrho}\Big|^4dx\Big)^{\frac12},\end{aligned}$$

where we let $V^a\cdot\nabla_a\psi=V_\varrho\psi_{,\varrho}+V_3\psi_{,3}$. To estimate the last term on the right-hand side of the latter relation, we exploit Ladyzhenskaya's inequality once more. So, we have

$$\begin{aligned}\int_{\widetilde{\mathcal{P}}}\Big|\frac{\widetilde{\chi}}{\varrho}\Big|^4dx &\le c\int_{-2}^{2}\int_{1/4}^{3}\Big|\frac{\widetilde{\chi}}{\varrho}\Big|^4d\varrho dx_3\\ &\le c\int_{-2}^{2}\int_{1/4}^{3}\Big|\nabla_a\Big(\frac{\widetilde{\chi}}{\varrho}\Big)\Big|^2d\varrho dx_3\int_{-2}^{2}\int_{1/4}^{3}\Big|\frac{\widetilde{\chi}}{\varrho}\Big|^2d\varrho dx_3\\ &\le c\int_{\widetilde{\mathcal{P}}}\Big|\nabla_a\Big(\frac{\widetilde{\chi}}{\varrho}\Big)\Big|^2dx\int_{\widetilde{\mathcal{P}}}\Big|\frac{\widetilde{\chi}}{\varrho}\Big|^2dx\end{aligned}$$

and, in the same way,

$$\int_{\widetilde{\mathcal{P}}}|V^a\cdot\nabla_a\psi|^4dx\le c\int_{\widetilde{\mathcal{P}}}\Big|\nabla_a\Big(V^a\cdot\nabla_a\psi\Big)\Big|^2dx\int_{\widetilde{\mathcal{P}}}|V^a\cdot\nabla_a\psi|^2dx.$$

As a result, we find

$$\begin{aligned}\int_{\widetilde{\mathcal{P}}} J_3\frac{\widetilde{\chi}}{\varrho^2}dx &\le c\int_{\widetilde{\mathcal{P}}}|\chi|^2dx+c\Big(\int_{\widetilde{\mathcal{P}}}|V_a|^2dx+\int_{\widetilde{\mathcal{P}}}|\nabla_aV^a|^2dx\Big)^{\frac12}\\ &\quad\times\Big(\int_{\widetilde{\mathcal{P}}}|V_a|^2dx\Big)^{\frac12}\Big(\int_{\widetilde{\mathcal{P}}}\Big|\nabla_a\Big(\frac{\widetilde{\chi}}{\varrho}\Big)\Big|^2dx\Big)^{\frac12}\Big(\int_{\widetilde{\mathcal{P}}}\Big|\frac{\widetilde{\chi}}{\varrho}\Big|^2dx\Big)^{\frac12}\\ &\le c\int_{\widetilde{\mathcal{P}}}|\nabla V|^2dx+c\Big(\mathcal{A}_2+\mathcal{A}_2^{\frac12}\Big(\int_{\widetilde{\mathcal{P}}}|\nabla V|^2dx\Big)^{\frac12}\Big)\\ &\quad\times\Big(\int_{\widetilde{\mathcal{P}}}\Big|\nabla_a\Big(\frac{\widetilde{\chi}}{\varrho}\Big)\Big|^2dx\Big)^{\frac12}\Big(\int_{\widetilde{\mathcal{P}}}\Big|\frac{\widetilde{\chi}}{\varrho}\Big|^2dx\Big)^{\frac12}.\end{aligned}\tag{4.12}$$

Combining estimates (4.9)–(4.12) and applying Young's inequality, we arrive at the final inequality:

$$\begin{aligned}\partial_t\int_{\widetilde{\mathcal{P}}}\Big|\frac{\widetilde{\chi}}{\varrho}\Big|^2dx+\int_{\widetilde{\mathcal{P}}}\Big|\nabla_a\Big(\frac{\widetilde{\chi}}{\varrho}\Big)\Big|^2dx &\le c\int_{\widetilde{\mathcal{P}}}|\nabla V|^2dx\\ &\quad+\Big(\mathcal{A}_2^2+\mathcal{A}_2\int_{\widetilde{\mathcal{P}}}|\nabla V|^2dx\Big)\Big(\int_{\widetilde{\mathcal{P}}}\Big|\frac{\widetilde{\chi}}{\varrho}\Big|^2dx+1\Big).\end{aligned}\tag{4.13}$$

Estimate (4.13) implies

$$\|\widetilde{\chi}\|_{L_{2,\infty}(\widetilde{Q})}\le\Phi_3(\mathcal{A}_2).$$

According to (4.6) and (4.7), one may conclude

$$\int_{-2}^{2}\int_{1/4}^{3}\Big|\nabla_a\widetilde{V}\Big|^2d\varrho dx_3\le c\int_{-2}^{2}\int_{1/4}^{3}\Big(|\widetilde{\chi}|^2+|V^a|^2\Big)d\varrho dx_3\le\Phi_3(\mathcal{A}_2)$$

and thus

$$\int_{-2}^{2}\int_{1/4}^{3}\left|\widetilde{V}(x,t)\right|^{q}d\varrho dx_3 \leq \Phi_4(q,\mathcal{A}_2)$$

for all $t\in\,]-2^2,0[$. Now, (4.2) immediately follows from the latter inequality. Lemma 4.2 is proved. $\square$

The second counterpart of the proof of Proposition 4.1 is the following statement.

LEMMA 4.3. *Under the assumptions of Proposition* 4.1*, there exists a nondecreasing function* $\Phi_5:\mathbb{R}_+\to\mathbb{R}_+$ *such that*

$$\int_{\widetilde{Q}_2}|V_\varphi|^6dz \leq \Phi_5(\mathcal{A}_2), \tag{4.14}$$

where $\widetilde{Q}_2=\widetilde{\mathcal{P}}_2\times\,]-(3/2)^2,0[$ *and* $\widetilde{\mathcal{P}}_2=\mathcal{P}(3/8,5/2;3/2)$.

Proof. We know that V_φ satisfies the equation

$$\partial_t V_\varphi + V_\varrho V_{\varphi,\varrho} + V_3V_{\varphi,3} + \frac{1}{\varrho}V_\varrho V_\varphi - \Big(V_{\varphi,\varrho\varrho} + V_{\varphi,33} + \frac{1}{\varrho}V_{\varphi,\varrho} - \frac{1}{\varrho^2}V_\varphi\Big) = 0. \tag{4.15}$$

We fix a nonnegative smooth and axially symmetric cut-off function ψ vanishing in a neighborhood of the parabolic boundary of $\widetilde{Q}_1$ and being equal to 1 in $\widetilde{Q}_2$. Then, for $\widetilde{\alpha}=V_\varphi\psi\varrho$, we have the following identity:

$$\begin{aligned}&\partial_t\widetilde{\alpha} + V_\varrho\widetilde{\alpha}_{,\varrho} + V_3\widetilde{\alpha}_{,3} - \Big(\widetilde{\alpha}_{,\varrho\varrho} + \widetilde{\alpha}_{,33} + \frac{1}{\varrho}\widetilde{\alpha}_{,\varrho}\Big) + \frac{2}{\varrho}\widetilde{\alpha}_{,\varrho}\\ &= \alpha\Big(\partial_t\psi + V_\varrho\psi_{,\varrho} + V_3\psi_{,3}\Big) - \Big(2\alpha_{,\varrho}\psi_{,\varrho} + 2\alpha_{,3}\psi_{,3} + \alpha\psi_{,\varrho\varrho} + \alpha\psi_{,33}\Big) + \frac{1}{\varrho}\alpha\psi_{,\varrho},\end{aligned}$$

where $\alpha=V_\varphi\varrho$.

Then we multiply the latter identity by $\widetilde{\alpha}|\widetilde{\alpha}|^2$ and integrate the product by parts over $\widetilde{\mathcal{P}}_1$,

$$\frac{1}{4}\partial_t\int_{\widetilde{\mathcal{P}}_1}|\widetilde{\alpha}|^4dx + \frac{3}{4}\int_{\widetilde{\mathcal{P}}_1}|\nabla_a(|\widetilde{\alpha}|^2)|^2dx = J_1 + J_2, \tag{4.16}$$

where

$$J_1 = \int_{\widetilde{\mathcal{P}}_1}\alpha\widetilde{\alpha}|\widetilde{\alpha}|^2\Big(V_\varrho\psi_{,\varrho} + V_3\psi_{,3}\Big)dx$$

and

$$J_2 = \int_{\widetilde{\mathcal{P}}_1}\widetilde{\alpha}|\widetilde{\alpha}|^2\Big(\alpha\partial_t\psi - 2\alpha_{,\varrho}\psi_{,\varrho} - 2\alpha_{,3}\psi_{,3} - \alpha\psi_{,\varrho\varrho} - \alpha\psi_{,33} + \frac{1}{\varrho}\alpha\psi_{,\varrho}\Big)dx.$$

We let $\beta=|\widetilde{\alpha}|^2$, then $|\beta|^{\frac{10}{3}}=|\widetilde{\alpha}|^{\frac{20}{3}}$ and

$$\int_{\widetilde{\mathcal{P}}_1}|\beta|^{\frac{10}{3}}dx \leq c\Big(\int_{\widetilde{\mathcal{P}}_1}|\beta|^2dx\Big)^{\frac{2}{3}}\int_{\widetilde{\mathcal{P}}_1}|\nabla\beta|^2dx. \tag{4.17}$$

We start with J_1, setting $\mathcal{A}_3 = \|V^a\|_{L_{4,\infty}(\widetilde{Q}_1)}$. By Hölder's inequality and by multiplicative inequality (4.17),

$$\begin{aligned}
J_1 &\le c\Big(\int_{\widetilde{\mathcal{P}}_1} |\widetilde{\alpha}|^{\frac{20}{3}}\,dx\Big)^{\frac{9}{20}}\Big(\int_{\widetilde{\mathcal{P}}_1} |\alpha|^{\frac{20}{11}}|V^a|^{\frac{20}{11}}\,dx\Big)^{\frac{11}{20}}\\
&\le c\Big(\int_{\widetilde{\mathcal{P}}_1} |\beta|^{\frac{10}{3}}\,dx\Big)^{\frac{9}{20}}\Big(\int_{\widetilde{\mathcal{P}}_1} |\alpha|^{\frac{10}{3}}\,dx\Big)^{\frac{3}{10}}\Big(\int_{\widetilde{\mathcal{P}}_1} |V^a|^4 dx\Big)^{\frac{1}{4}}\\
&\le c\Big(\int_{\widetilde{\mathcal{P}}_1} |\beta|^{\frac{10}{3}}\,dx\Big)^{\frac{9}{20}}\Big(\int_{\widetilde{\mathcal{P}}_1} |V|^2 dx\Big)^{\frac{1}{5}}\Big(\int_{\widetilde{\mathcal{P}}_1} |V|^2 dx+\int_{\widetilde{\mathcal{P}}_1} |\nabla V|^2 dx\Big)^{\frac{3}{10}}\mathcal{A}_3\\
&\le c\Big(\int_{\widetilde{\mathcal{P}}_1} |\beta|^{\frac{10}{3}}\,dx\Big)^{\frac{9}{20}}\mathcal{A}_2^{\frac{1}{5}}\Big(\int_{\widetilde{\mathcal{P}}_1} |\nabla V|^2 dx+\mathcal{A}_2\Big)^{\frac{3}{10}}\mathcal{A}_3\\
&\le c\Big(\int_{\widetilde{\mathcal{P}}_1} |\beta|^2 dx\Big)^{\frac{3}{10}}\Big(\int_{\widetilde{\mathcal{P}}_1} |\nabla\beta|^2 dx\Big)^{\frac{9}{20}}\mathcal{A}_2^{\frac{1}{5}}\Big(\int_{\widetilde{\mathcal{P}}_1} |\nabla V|^2 dx+\mathcal{A}_2\Big)^{\frac{3}{10}}\mathcal{A}_3.
\end{aligned}$$

Term J_2 is estimated in the same way:

$$\begin{aligned}
J_2 &\le c\Big(\int_{\widetilde{\mathcal{P}}_1} |\widetilde{\alpha}|^{\frac{20}{3}}\,dx\Big)^{\frac{9}{20}}\Big(\int_{\widetilde{\mathcal{P}}_1} (|\alpha|+|\alpha_{,\varrho}|+|\alpha_{,3}|)^{\frac{20}{11}}\,dx\Big)^{\frac{11}{20}}\\
&\le c\Big(\int_{\widetilde{\mathcal{P}}_1} |\beta|^2 dx\Big)^{\frac{3}{10}}\Big(\int_{\widetilde{\mathcal{P}}_1} |\nabla\beta|^2 dx\Big)^{\frac{9}{20}}\Big(\int_{\widetilde{\mathcal{P}}_1} |\nabla V|^2 dx+\mathcal{A}_2\Big)^{\frac{1}{2}}.
\end{aligned}$$

Now, making use of Young's inequality, we derive from (4.17) and from the two latter estimates the main inequality:

$$\begin{aligned}
&\partial_t\int_{\widetilde{\mathcal{P}}_1} |\widetilde{\alpha}|^4 dx+\int_{\widetilde{\mathcal{P}}_1} |\nabla_a(|\widetilde{\alpha}|^2)|^2 dx\\
&\le c\Big(\int_{\widetilde{\mathcal{P}}_1} |\beta|^2 dx\Big)^{\frac{6}{11}}\mathcal{A}_2^{\frac{4}{11}}\Big(\int_{\widetilde{\mathcal{P}}_1} |\nabla V|^2 dx+\mathcal{A}_2\Big)^{\frac{6}{11}}\mathcal{A}_3^{\frac{20}{11}}\\
&\quad+c\Big(\int_{\widetilde{\mathcal{P}}_1} |\beta|^2 dx\Big)^{\frac{6}{11}}\Big(\int_{\widetilde{\mathcal{P}}_1} |\nabla V|^2 dx+\mathcal{A}_2\Big)^{\frac{10}{11}}\\
&\le c\int_{\widetilde{\mathcal{P}}_1} |\beta|^2 dx\Big(\int_{\widetilde{\mathcal{P}}_1} |\nabla V|^2 dx+\mathcal{A}_2\Big)+c(\mathcal{A}_2\mathcal{A}_3^5)^{\frac{4}{5}}+c\Big(\int_{\widetilde{\mathcal{P}}_1} |\nabla V|^2 dx+\mathcal{A}_2\Big)^{\frac{4}{5}}.
\end{aligned}$$

This, together with the statement of Lemma 4.2 at $q = 4$, implies

$$\sup_{-(7/4)^2\le t\le 0}\int_{\widetilde{\mathcal{P}}_1} |\beta(x,t)|^2 dx+\int_{\widetilde{Q}_1} |\nabla\beta|^2 dz\le\Phi_5(\mathcal{A}_2). \tag{4.18}$$

So, (4.14) follows from (4.17) and (4.18). Lemma 4.3 is proved. □

From Lemmas 4.2 and 4.3, we find the following.

COROLLARY 4.4. *Under the assumptions of Proposition* 4.1*, there exists a non-decreasing function* $\Phi_6 : \mathbb{R}_+ \to \mathbb{R}_+$ *such that*

$$\int_{\widetilde{Q}_2} |V|^6 dz\le\Phi_6(\mathcal{A}_2). \tag{4.19}$$

Proof of Proposition 4.1. Applying Corollary 4.4 and Lemma 2.3, we end up with the proof of Proposition 4.1. □

5. Proof of Theorem 1.2. Given $R > 1$, let us consider the space-time cylinder

$$\widetilde{Q}^b_R = \widetilde{\mathcal{P}}^b_R \times]-(2R)^2, 0[,$$

where $b \in \mathbb{R}$ and

$$\widetilde{\mathcal{P}}^b_R = \widetilde{\mathcal{P}}_R + be_3, \qquad \widetilde{\mathcal{P}}_R = \mathcal{P}(R/4, 3R; 2R).$$

Now, we scale our blowup functions u and q in the following way:

$$u^R(x,t) = Ru(Rx + be_3, R^2t), \qquad q^R(x,t) = R^2 q(Rx + be_3, R^2t)$$

for $z = (x,t) \in \widetilde{Q}$.

Functions u^R and q^R are axially symmetric and, as was explained before, sufficiently smooth to apply Proposition 4.1. According to that, we have

$$\sup_{z \in \widetilde{Q}_0} \Big\{ |u^R(z)| + |\nabla u^R(z)| \Big\} \le \Phi(\mathcal{A}_2),$$

where $\widetilde{Q}_0 = \mathcal{P}(1,2;1) \times]-1,0[$ and

$$\mathcal{A}_2 = \sup_{-2^2 \le t \le 0} \int_{\widetilde{\mathcal{P}}} |u^R(x,t)|^2 dx + \int_{\widetilde{Q}} \Big(|\nabla u^R|^2 + |u^R|^3 + |q^R|^{\frac{3}{2}} \Big) dz.$$

Then we make the inverse change of variables. As a result, we find

$$\sup_{(y,s) \in Q^b_R} \Big\{ R|u(y,s)| + R^2 |\nabla u(y,s)| \Big\} \le \Phi(\widetilde{\mathcal{A}}_{2R}),$$

where $Q^b_R = \widetilde{\mathcal{P}}^b_{0R} \times]-R^2, 0[$, $\widetilde{\mathcal{P}}^b_{0R} = be_3 + \mathcal{P}_{0R}$, $\mathcal{P}_{0R} = \mathcal{P}(R, 2R; R)$, and

$$\begin{aligned}
\widetilde{\mathcal{A}}_{2R} = & \sup_{-(2R)^2 \le s \le 0} \frac{1}{R} \int_{-2R+b}^{2R+b} dy_3 \int_{R/4 < |y'| < 3R} |u(y,s)|^2 dy' \\
& + \frac{1}{R} \int_{-(2R)^2}^0 ds \int_{-2R+b}^{2R+b} dy_3 \int_{R/4 < |y'| < 3R} |\nabla u(y,s)|^2 dy' \\
& + \frac{1}{R^2} \int_{-(2R)^2}^0 ds \int_{-2R+b}^{2R+b} dy_3 \int_{R/4 < |y'| < 3R} \Big(|u(y,s)|^3 + |q(y,s)|^{\frac{3}{2}} \Big) dy' \\
\le & \; c\Big(A(e^b, 3R; u) + E(e^b, 3R; u) + C(e^b, 3R; u) + D(e^b, 3R; q) \Big) \le c\mathcal{A},
\end{aligned}$$

$e^b = (y^b, 0)$ and $y^b = (0, b)$. So, assuming that $|y'| > 20$, we can derive from the latter estimates

$$|y'||u(y', b, s)| + |y'|^2 |\nabla u(y', b, s)| \le \Phi(c\mathcal{A}) \tag{5.1}$$

for any $b \in \mathbb{R}$, for any $|y'| > 20$, and for any $s \in [-20, 0]$. It follows directly from (5.1) that

$$|u(y,s)| + |\nabla u(y,s)| \le c\Phi(c\mathcal{A}) = c(\mathcal{A}) \tag{5.2}$$

for any y such that $|y'| > 20$ and for any $s \in [-20, 0]$.

Now, we consider the vorticity $\omega(u) = \nabla \wedge u$. It satisfies the vorticity equation

$$\partial_t \omega - \Delta\omega = \omega \cdot \nabla u - u \cdot \nabla \omega,$$

which, together with (5.2), implies

$$|\partial_t \omega - \Delta \omega| \leq c(\mathcal{A})(|\omega| + |\nabla \omega|) \tag{5.3}$$

for any y such that $|y'| > 20$ and for any $s \in [-20, 0]$. Moreover, by (3.11),

$$\omega(\cdot, 0) = 0 \qquad \text{in} \quad \mathbb{R}^3. \tag{5.4}$$

By the backward uniqueness results for the heat operator with variable lower order terms in a half-space (see [3], [4], and [15]) and by (5.3) and (5.4), we state

$$\omega(y, s) = 0 \tag{5.5}$$

for any y such that $|y'| > 20$ and for any $s \in [-20, 0]$.

Since our solution is sufficiently smooth in $\mathbb{R}^3 \setminus \{y' = 0\} \times [-10, 0]$, one can make use of the unique continuation through spatial boundaries and conclude that

$$\nabla \wedge u \equiv 0 \qquad \text{in} \quad \mathbb{R}^3 \setminus \{y' = 0\} \times [-8, 0]. \tag{5.6}$$

On the other hand, from (3.8), it follows that

$$\mathcal{A}_0 \geq \operatorname{ess} \sup_{-20 \leq s \leq 0} \int_{|y'| \leq 40} \frac{|u(y,s)|^2}{|y'|} dy.$$

So, we observe that, for any $s \in S$,

$$\int_{-\infty}^{+\infty} dy_3 \int_{|y'| \leq 40} \frac{|u(y,s)|^2}{|y'|} dy' \leq \mathcal{A}_0 < +\infty, \tag{5.7}$$

where $S \subset [-20, 0]$ and $|S| = 20$.

Now, we wish to show

$$\nabla \wedge u(\cdot, s) \equiv 0 \qquad \text{in} \quad \mathbb{R}^3 \tag{5.8}$$

for any $s \in S$. To this end, we proceed as follows. Let $\varphi \in C_0^\infty(B')$ be a nonnegative cut-off function being equal to 1 in $B'(1/2)$. Here, B' and $B'(1/2)$ are two-dimensional balls centered at the origin with radii 1 and 1/2, respectively. Next, let ψ be an arbitrary smooth, compactly supported in $\mathbb{R}^3$, vector-valued function. Then, by (5.6), for any $s \in [-8, 0]$,

$$\begin{aligned}
&\int_{\mathbb{R}^3} u(y,s) \cdot \nabla \wedge \Big(\psi(y)(1 - \varphi(y'/R))\Big) dy = 0 \\
&= \int_{\mathbb{R}^3} u(y,s) \cdot \nabla \wedge \psi(y) dy - \int_{\mathbb{R}^3} u(y,s) \cdot \nabla \wedge \Big(\psi(y)\varphi(y'/R)\Big) dy = J_1(s) + J_2(s).
\end{aligned}$$

For J_2, we have the estimate

$$\begin{aligned}
|J_2(s)| &\leq c\Big(1 + \frac{1}{R}\Big) \int_{\operatorname{spt}\psi \cap \{|y'| < R\}} |u(y,s)| dy \\
&= c\Big(1 + \frac{1}{R}\Big) \int_{\operatorname{spt}\psi \cap \{|y'| < R\}} \frac{|u(y,s)|}{|y'|^{\frac12}} |y'|^{\frac12} dy \\
&\leq c\Big(1 + \frac{1}{R}\Big) \Big(\int_{\operatorname{spt}\psi \cap \{|y'| < R\}} \frac{|u(y,s)|^2}{|y'|} dy\Big)^{\frac12} \Big(\int_{\operatorname{spt}\psi \cap \{|y'| < R\}} |y'| dy\Big)^{\frac12} \\
&\leq c(\psi)\Big(1 + \frac{1}{R}\Big) R^{\frac32} \Big(\int_{-\infty}^{+\infty} dy_3 \int_{|y'| < 40} \frac{|u(y,s)|^2}{|y'|} dy'\Big)^{\frac12}.
\end{aligned}$$

By (5.7), the right-hand side of the latter inequality goes to zero as $R \to 0$ for any $s \in S$. Hence, $J_1(s) = 0$ for any $s \in S \cap [-8, 0]$, which is but a weak form of (5.8). By the fact that u is divergence-free, we then show

$$\Delta u(\cdot, s) = 0 \qquad \text{in} \quad \mathbb{R}^3$$

for any $s \in S \cap [-8, 0]$.

Now, let $B(y_0, R)$ be a ball of radius R with the center at point y_0. For any $y_0 \in \{|y'| \leq 30,\, y_3 \in \mathbb{R}\}$,

$$B(y_0, 1) \subset \{|y'| \leq 40,\, y_3 \in \mathbb{R}\}$$

and, since u is harmonic,

$$|u(y_0, s)| \leq c\Big(\int_{B(y_0,1)} |u(y,s)|^2 dy\Big)^{\frac{1}{2}} \leq c\Big(\int_{|y'|\leq 40} |u(y,s)|^2 dy\Big)^{\frac{1}{2}} \leq c\sqrt{40\mathcal{A}_0}$$

for any $s \in S \cap [-8, 0]$. So, according to (5.2), the function $u(\cdot, s)$ is bounded in $\mathbb{R}^3$ for any $s \in S \cap [-8, 0]$. However, by (5.1), in fact, $u(\cdot, s) = 0$ in $\mathbb{R}^3$ for any $s \in S \cap [-8, 0]$. This contradicts (3.9). Theorem 1.2 is proved. $\square$

EFFECTIVE TRANSMISSION CONDITIONS FOR REACTION-DIFFUSION PROCESSES IN DOMAINS SEPARATED BY AN INTERFACE*

MARIA NEUSS-RADU† AND WILLI JÄGER‡

Abstract. In this paper, we develop multiscale methods appropriate for the homogenization of processes in domains containing thin heterogeneous layers. Our model problem consists of a nonlinear reaction-diffusion system defined in such a domain, and properly scaled in the layer region. Both the period of the heterogeneities and the thickness of the layer are of order ε. By performing an asymptotic analysis with respect to the scale parameter ε we derive an effective model which consists of the reaction-diffusion equations on two domains separated by an interface together with appropriate transmission conditions across this interface. These conditions are determined by solving local problems on the standard periodicity cell in the layer. Our asymptotic analysis is based on weak and strong two-scale convergence results for sequences of functions defined on thin heterogeneous layers. For the derivation of the transmission conditions, we develop a new method based on test functions of boundary layer type.

Key words. nonlinear reaction-diffusion systems, thin heterogeneous layer, homogenization, two-scale convergence, transmission conditions

1. Introduction.

In this paper, we will be concerned with a nonlinear system of reaction-diffusion equations in a domain containing a thin heterogeneous layer. Such problems often occur in applications like, e.g., transdermal diffusion of drugs, diffusion of substances through the epithelial monolayer, and transport of ions through membranes.

We start from a microscopic model defined on a domain containing a thin layer of thickness ε. The processes are modeled by a system of reaction-diffusion equations properly scaled inside the layer. Our aim is to study the behavior of the solutions of the microscopic equations when the thickness ε tends to zero.

In the limit $\varepsilon \to 0$ the thin layer reduces to an interface between the two bulk regions. We derive an effective model which consists of a system of reaction-diffusion equations on both sides of this interface together with appropriate transmission conditions for the limit concentrations across the interface.

For the derivation of the limit equations in the bulk regions we use standard compactness results based on classical a priori estimates. However, the thin heterogeneous layer poses additional problems. We have to adapt the concepts of weak and strong two-scale convergences to functions on thin domains with oscillatory and (for simplicity) periodic structure. Due to the arising nonlinearities, it is necessary to prove strong two-scale convergence of the solutions to the ε-problems in the thin layer. To this end, we introduce macroscopic and microscopic coordinates and analyze the regularity of the solutions with respect to this pair of coordinates. Whereas the gradients

with respect to the microvariable and the time can be controlled in L^2 in a standard way, the control of the dependence on the macrovariable demands a new approach. Using the partial differential equation in the layer and the strong compactness of the traces of the microscopic concentrations on the interfaces between the bulk regions and the thin layer, we are able to derive L^2-equicontinuity also with respect to the macrovariable. When these results are combined, a Kolmogorov criterion for strong two-scale convergence in the thin layer is satisfied.

For the derivation of the transmission conditions we introduce a new method which is based on testing the microscopic equations with test functions of boundary layer type. The effective transmission conditions consist of relations for the jump of the concentrations and the normal fluxes across the interface. They are calculated by solving local problems on the standard periodicity cell in the layer. These local problems are coupled with the effective equations in the bulk regions through the boundary values on the upper and lower boundaries of the standard cell.

Our paper is organized as follows: We start with the precise description of the geometry and of the microscopic equations and the formulation of the main results (section 2). Then we show a priori estimates (section 3). In section 4, we present the convergence concepts needed to pass to the limit in the thin layer. Section 5 gives the proofs for the convergence (up to subsequences) of the microscopic solutions in the bulk and in the layer. Here, the most challenging part is to show strong two-scale convergence of the concentration inside the layer. In section 6, we derive the effective model including the macroscopic equations in the bulk regions, the local problem in the layer, and the transmission conditions across the interface separating the bulk regions. In the last section, we show uniqueness for the homogenized solution and thus the convergence of the whole sequence.

Reducing the computational work is one of the main purposes of the homogenization limit. The algorithms for solving the derived transmission problem numerically will be considered in a forthcoming paper.

The limiting methods developed in this paper are crucial in treating the ion transport through membrane channels modeled by the Nernst–Planck equations. This system couples the transport of ions and the electric field in a domain separated by a thin membrane with periodically distributed channels. In the channels, partially fixed charges control the permeability of the membrane. Here again, the derivation of the transmission conditions is the crucial topic. A formulation of the results and a sketch of the steps necessary in the analysis are given in [14], and the full mathematical derivation is presented in the forthcoming paper [15].

2. Statement of the problem and the results.

2.1. Setting of the problem. Let $\varepsilon > 0$ be a sequence of strictly positive numbers tending to zero, with the property that $\frac{1}{\varepsilon} \in \mathbb{N}$, and let $H > 0$ be a fixed real number.

We consider a bounded domain $\Omega =]0,1[^{n-1} \times]-H,H[\subset \mathbb{R}^n,\ n \geq 2$, consisting of three subdomains: the bulk regions Ω_ε^+, Ω_ε^- and the thin heterogeneous layer Ω_ε^M, separated by the interfaces S_ε^+ and S_ε^-; see Figure 2.1. Thus we have

$$\Omega = \Omega_\varepsilon^+ \cup \Omega_\varepsilon^- \cup \Omega_\varepsilon^M \cup S_\varepsilon^+ \cup S_\varepsilon^-,$$

where $\Omega_\varepsilon^+ =]0,1[^{n-1} \times]\varepsilon, H[$, $\Omega_\varepsilon^- =]0,1[^{n-1} \times]-H,-\varepsilon[$, $\Omega_\varepsilon^M =]0,1[^{n-1} \times]-\varepsilon,\varepsilon[$, $S_\varepsilon^+ =]0,1[^{n-1} \times \{\varepsilon\}$, $S_\varepsilon^- =]0,1[^{n-1} \times \{-\varepsilon\}$. We denote

$$\Sigma =]0,1[^{n-1} \times \{0\}.$$

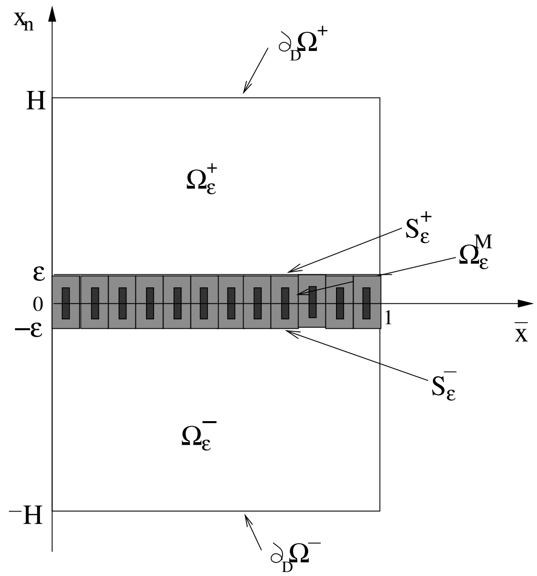

FIG. 2.1. *The domain Ω including the thin heterogeneous layer Ω_ε^M.*

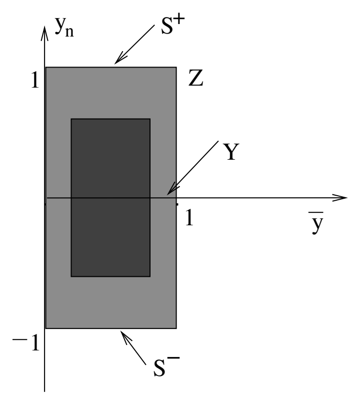

FIG. 2.2. *The standard cell $Z = Y \times [-1,1] = [0,1]^{n-1} \times [-1,1]$.*

The microscopic structure of the layer Ω_ε^M is obtained by the periodic repetition of the standard cell Z (see Figure 2.2), scaled with ε. Here

$$Z = Y \times [-1,1] = [0,1]^{n-1} \times [-1,1],$$

and we denote by

$$S^\pm = \{y \in \mathbb{R}^n : \bar{y} \in Y, y_n = \pm 1\}$$

the upper and lower boundaries of Z. The outer unit normal at the boundaries of the domains Ω and Ω_ε^M is denoted by ν. The restrictions of functions defined on Ω to the subdomains Ω_ε^+, Ω_ε^-, and Ω_ε^M are denoted by the superscripts $+$, $-$, and M, respectively.

In the domain Ω we consider the following system of reaction-diffusion equations for the unknown vector $u_\varepsilon = (u_{1\varepsilon}, \ldots, u_{m\varepsilon}) : (0,T) \times \Omega \to \mathbb{R}^m$,

$$
\begin{aligned}
\partial_t u^+_{j\varepsilon} - D^+_j \Delta u^+_{j\varepsilon} &= f_j(x, u^+_\varepsilon) \qquad \text{in } (0,T)\times\Omega^+_\varepsilon,\\
\partial_t u^-_{j\varepsilon} - D^-_j \Delta u^-_{j\varepsilon} &= f_j(x, u^-_\varepsilon) \qquad \text{in } (0,T)\times\Omega^-_\varepsilon,\\
\frac{1}{\varepsilon}\partial_t u^M_{j\varepsilon} - \nabla\cdot\left(\varepsilon D^M_j\left(\frac{x}{\varepsilon}\right)\nabla u^M_{j\varepsilon}\right) &= \frac{1}{\varepsilon}\, g_j\left(\frac{x}{\varepsilon}, u^M_\varepsilon\right) \text{ in } (0,T)\times\Omega^M_\varepsilon,
\end{aligned}
\tag{2.1}
$$

subjected to the boundary conditions

$$
\begin{aligned}
u^\pm_\varepsilon &= u^\pm_D \quad \text{on } \partial_D\Omega^\pm,\\
\nabla u_{j\varepsilon}\cdot\nu &= 0 \quad\ \ \text{on } \partial_N\Omega
\end{aligned}
\tag{2.2}
$$

and initial conditions

$$
u_\varepsilon(0,x) = \begin{cases} U_0(x), & x\in\Omega^+_\varepsilon,\\ U^M_0\left(\bar{x}, \frac{x_n}{\varepsilon}\right), & x\in\Omega^M_\varepsilon,\\ U_0(x), & x\in\Omega^-_\varepsilon. \end{cases}
\tag{2.3}
$$

Here the boundaries $\partial_D\Omega^\pm$, respectively, $\partial_N\Omega$, are defined as follows:

$$
\begin{aligned}
\partial_D\Omega^\pm &= \partial\Omega \cap \{x\in\mathbb{R}^n, x_n = \pm H\},\\
\partial_N\Omega &= \partial\Omega \setminus \{\partial_D\Omega^+ \cup \partial_D\Omega^-\}.
\end{aligned}
$$

On the interfaces S^+_ε and S^-_ε we require the natural transmission conditions, i.e., the continuity of the solutions and of the normal fluxes:

$$
\begin{aligned}
u^\pm_\varepsilon &= u^M_\varepsilon \qquad\qquad\qquad\quad \text{on } S^\pm_\varepsilon,\\
D^\pm_j \nabla u^\pm_{j\varepsilon}\cdot\nu &= \varepsilon D^M_j\left(\frac{x}{\varepsilon}\right)\nabla u^M_{j\varepsilon}\cdot\nu \quad \text{on } S^\pm_\varepsilon.
\end{aligned}
\tag{2.4}
$$

Assumptions on the data. For the diffusion coefficients $D_j : \Omega \to \mathbb{R}$, $j = 1, \ldots, m$, given by

$$
D_j(x) = \begin{cases} D^+_j, & x\in\Omega^+_\varepsilon,\\ D^M_j\left(\frac{x}{\varepsilon}\right), & x\in\Omega^M_\varepsilon,\\ D^-_j, & x\in\Omega^-_\varepsilon, \end{cases}
$$

we assume the following:

- $D^+_j > 0, D^-_j > 0,\ j = 1, \ldots, m$.
- D^M_j is defined on the standard cell Z and belongs to $C^1_{per}([0,1]^{n-1}, C^1([-1,1]))$. We also assume that it is strictly positive.

Concerning the reaction terms we suppose the following:

- $f = f(x,z) : \bar{\Omega}\times\mathbb{R}^m \to \mathbb{R}^m$ is continuous and Lipschitz continuous with respect to z, with a Lipschitz constant independent of x.
- $g = g(\bar{y}, y_n, z) : [0,1]^{n-1}\times[-1,1]\times\mathbb{R}^m \to \mathbb{R}^m$ is continuous, Lipschitz continuous in z, and periodic in $\bar{y} = (y_1, \ldots, y_{n-1})$.

The assumptions on the reaction terms imply that there exist positive constants c_1 and c_2 such that for $j = 1, \ldots, m$

$$
|f_j(x,z)| \le c_1(1+|z|) \quad \text{for all } z\in\mathbb{R}^m, x\in\bar{\Omega},
\tag{2.5}
$$

$$
|g_j(y,z)| \le c_2(1+|z|) \quad \text{for all } z\in\mathbb{R}^m, y\in Z.
\tag{2.6}
$$

Additionally, we have to impose on f and g structural conditions which guarantee L^∞-estimates of the solutions u_ε. A possible choice of such conditions is given in the following.

Let $M_j \in \mathbb{R}, M_j > 0$, $j = 1, \dots, m$, be given. We consider

$$f_j(\cdot, z) \le A_j z_j \quad \text{for } z_j \ge M_j, \tag{2.7}$$

$$g_j(\cdot, z) \le A_j z_j \quad \text{for } z_j \ge M_j, \tag{2.8}$$

where $A_j \in \mathbb{R}$, $A_j \ge 0, j = 1, \dots, m$. We also require that

$$\sum_{j=1}^m f_j(\cdot, z)(z_j)_- \le C \sum_{j=1}^m |(z_j)_-|^2, \tag{2.9}$$

$$\sum_{j=1}^m g_j(\cdot, z)(z_j)_- \le C \sum_{j=1}^m |(z_j)_-|^2, \tag{2.10}$$

where $(z_j)_- = \min\{z_j, 0\}$. For the initial functions we assume that $U_0 \in H^2(\Omega^+, \mathbb{R}^m) \cap H^2(\Omega^-, \mathbb{R}^m)$, $U_0^M \in H^2(\Sigma \times]-1, 1[, \mathbb{R}^m)$, such that

$$\frac{1}{\sqrt{\varepsilon}} \left\| U_0^M \left(\cdot, \frac{\cdot}{\varepsilon}\right) \right\|_{L^2(\Omega_\varepsilon^M, \mathbb{R}^m)} + \sqrt{\varepsilon} \left\| \nabla U_0^M \left(\cdot, \frac{\cdot}{\varepsilon}\right) \right\|_{L^2(\Omega_\varepsilon^M, \mathbb{R}^m)} \le C, \tag{2.11}$$

and that they satisfy the compatibility conditions

$$\begin{aligned} U_0(x) &= U_0^M \left(\bar{x}, \frac{x_n}{\varepsilon}\right) && \text{on } S_\varepsilon^\pm, \\ D_j^\pm \nabla U_{j0} \cdot \overrightarrow{\nu} &= \varepsilon D_j^M \left(\frac{x}{\varepsilon}\right) \nabla U_{j0}^M \cdot \overrightarrow{\nu} && \text{on } S_\varepsilon^\pm, \\ U_0(x) &= u_D(0, x) && \text{on } \partial_D \Omega^\pm. \end{aligned} \tag{2.12}$$

For the Dirichlet boundary data we require

$$u_D \in L^2((0,T), H^2(\Omega, \mathbb{R}^m)), \ \operatorname{supp}(u_D) \cap \Omega_\varepsilon^M = \emptyset, \tag{2.13}$$

$$\partial_t u_D^\pm \in L^2((0,T), H^1(\Omega, \mathbb{R}^m)) \cap L^\infty((0,T) \times \Omega, \mathbb{R}^m). \tag{2.14}$$

In order to obtain the L^∞-estimates for the solution u_ε, we have to assume that the initial and boundary functions also satisfy corresponding bounds. For the example of reaction terms given above, we assume that

$$0 \le U_{j0} \le M_j, \ 0 \le U_{j0}^M \le M_j, \ 0 \le u_{jD} \le M_j, \quad j = 1, \dots, m. \tag{2.15}$$

Variational formulation of the microscopic problem. We denote by X the function space

$$X = \{u \in H^1(\Omega, \mathbb{R}^m) : u = 0 \text{ on } \partial_D \Omega^+ \cup \partial_D \Omega^-\}.$$

The variational formulation of problem (2.1)–(2.4) is given as follows: Find $u_\varepsilon : (0,T) \times \Omega \to \mathbb{R}^m$, such that $u_\varepsilon - u_D \in L^2((0,T), X)$, $\partial_t(u_\varepsilon - u_D) \in L^2((0,T), L^2(\Omega))$, and for all $\varphi \in L^2((0,T), X)$ and a.e. $t \in (0,T)$ we have

$$\begin{aligned} &\int_{\Omega_\varepsilon^+} \partial_t u_{j\varepsilon}^+ \varphi_j \, dx + \int_{\Omega_\varepsilon^-} \partial_t u_{j\varepsilon}^- \varphi_j \, dx + \frac{1}{\varepsilon} \int_{\Omega_\varepsilon^M} \partial_t u_{j\varepsilon}^M \varphi_j \, dx \\ &+ D_j^+ \int_{\Omega_\varepsilon^+} \nabla u_{j\varepsilon}^+ \nabla \varphi_j \, dx + D_j^- \int_{\Omega_\varepsilon^-} \nabla u_{j\varepsilon}^- \nabla \varphi_j \, dx + \int_{\Omega_\varepsilon^M} \varepsilon D_j^M \nabla u_{j\varepsilon}^M \nabla \varphi_j \, dx \\ &= \int_{\Omega_\varepsilon^+} f_j(x, u_\varepsilon^+) \varphi_j \, dx + \int_{\Omega_\varepsilon^-} f_j(x, u_\varepsilon^-) \varphi_j \, dx + \frac{1}{\varepsilon} \int_{\Omega_\varepsilon^M} g_j \left(\frac{x}{\varepsilon}, u_\varepsilon^M\right) \varphi_j \, dx \end{aligned} \tag{2.16}$$

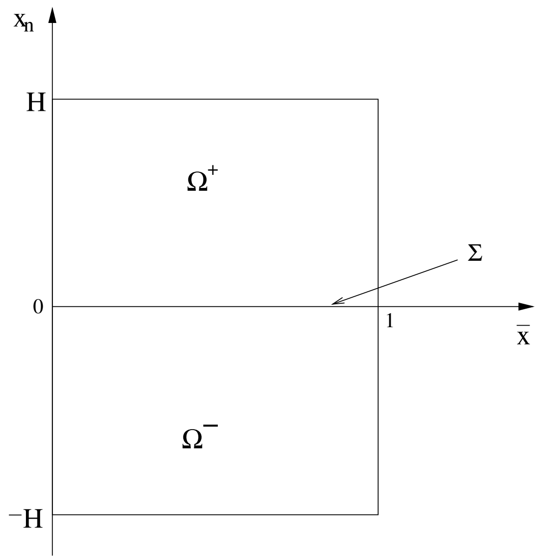

FIG. 2.3. *The structure of the domain* Ω *in the limit* $\varepsilon = 0$.

and

$$u_\varepsilon(0,x) = \begin{cases} U_0(x), & x \in \Omega_\varepsilon^+, \\ U_0^M\left(\bar{x}, \frac{x_n}{\varepsilon}\right), & x \in \Omega_\varepsilon^M, \\ U_0(x), & x \in \Omega_\varepsilon^-. \end{cases}$$

The existence and uniqueness of weak solutions for the problem (2.1)–(2.4) for every fixed $\varepsilon > 0$ is standard, e.g., by using the Galerkin method based on estimates similar to those in section 3.

Our aim is now to study the behavior of the solutions u_ε for small values of the parameter ε. We will do this by studying the asymptotic behavior of the sequence u_ε for $\varepsilon \to 0$.

When ε tends to zero, the thin layer Ω_ε^M approaches the interface Σ. The domains Ω_ε^+ and Ω_ε^- tend to the domains Ω^+ and Ω^-, respectively, defined below:

$$\Omega^+ =]0,1[^{n-1} \times]0,H[, \tag{2.17}$$

$$\Omega^- =]0,1[^{n-1} \times]-H,0[. \tag{2.18}$$

Thus the macroscopic limit of the sequence u_ε (if it exists) will be defined on the domain Ω consisting of (see Figure 2.3)

$$\Omega = \Omega^+ \cup \Omega^- \cup \Sigma.$$

2.2. Main results. From the a priori estimates (given in section 3), it is obvious that different convergence concepts have to be used for studying the asymptotic behavior of the solutions u_ε in the bulk and thin layer regions. Whereas in $\Omega_\varepsilon^\pm$ classical compactness results can be used, in Ω_ε^M compactness needs to be considered with respect to the weak and strong two-scale convergences adapted to the thin layer. The concepts of multiscale convergence in the weak and strong sense, also for thin and periodic structures, are crucial for formulating and proving the main results of this paper. For the definition and properties of two-scale convergence for thin heterogeneous layers, see section 4.

In the following two propositions, we state the convergence results in the bulk and thin layer regions as well as the convergence of the traces on the interfaces $S_\varepsilon^\pm$. For the layer region, we obtain in a first step weak two-scale convergence.

PROPOSITION 2.1. *There exists a subsequence denoted again u_ε and limit functions $u_0^\pm \in L^2((0,T), H^1(\Omega^\pm, \mathbb{R}^m))$, with $\partial_t u_0^\pm \in L^2((0,T), L^2(\Omega^\pm, \mathbb{R}^m))$, and $u_0^M \in L^2((0,T)\times\Sigma, H^1_{per}(Y, H^1(]-1,1[))^m$, with $\partial_t u_0^M \in L^2((0,T)\times\Sigma, L^2(Z))^m$, such that*

1. $\chi_{\Omega_\varepsilon^\pm} u_{j\varepsilon} \to u_{j0}^\pm$ *strongly in* $L^2((0,T), L^2(\Omega^\pm))$;
2. $\chi_{\Omega_\varepsilon^\pm} \nabla u_{j\varepsilon} \to \nabla u_{j0}^\pm$ *weakly in* $L^2((0,T), L^2(\Omega^\pm))$;
3. $\chi_{\Omega_\varepsilon^\pm} \partial_t u_{j\varepsilon} \to \partial_t u_{j0}^\pm$ *weakly in* $L^2((0,T), L^2(\Omega^\pm))$;
4. $u_{j\varepsilon}^M \overset{t.s.}{\to} u_{j0}^M(t,\bar{x},y)$ *weakly in the two-scale sense*;
5. $\varepsilon\,\nabla u_{j\varepsilon}^M \overset{t.s.}{\to} \nabla_y u_{j0}^M(t,\bar{x},y)$ *weakly in the two-scale sense*;
6. $\partial_t u_{j\varepsilon}^M \overset{t.s.}{\to} \partial_t u_{j0}^M(t,\bar{x},y)$ *weakly in the two-scale sense.*

Furthermore, we have

$$u_0^M(t,\bar{x},\bar{y},\pm 1) = u_0^\pm(t,\bar{x},0) \quad a.e.\ (t,\bar{x}) \in (0,T)\times\Sigma,\ \bar{y}\in Y. \tag{2.19}$$

PROPOSITION 2.2. *There exists a subsequence denoted again by $u_\varepsilon^\pm$, such that*

$$\tilde{u}_{j\varepsilon}^\pm \to u_{j0}^\pm \ \textit{strongly in}\, L^2((0,T)\times\Sigma), \tag{2.20}$$

$$\lim_{\varepsilon\to 0}\int_0^T \int_{S_\varepsilon^\pm} u_{j\varepsilon}^\pm(t,x)\varphi_j\left(t,\bar{x},\frac{x}{\varepsilon}\right)dxdt = \int_0^T\int_\Sigma\int_Y u_{j0}^\pm(t,\bar{x},0)\varphi_j(t,\bar{x},\bar{y},\pm 1)\,d\bar{y}\,d\bar{x}dt \tag{2.21}$$

for all $\varphi_j \in C^\infty([0,T]\times\Sigma, C^\infty_{per}(Y, C^\infty([-1,1])))$, where $u_0^\pm$ are the limit functions given in Proposition 2.1*, and the scaled functions $\tilde{u}_{j\varepsilon}^\pm$ are defined in* (5.2).

A central contribution of this paper is formulated in Theorem 2.3 below, where a strong two-scale convergence of the solutions u_ε in the layer Ω_ε^M is obtained. This strong two-scale convergence is not based on extension properties but uses the reaction-diffusion equations in the layer and the compactness of the traces on $S_\varepsilon^\pm$.

THEOREM 2.3. *The extension $\hat{u}_\varepsilon^M$ of u_ε^M to $\hat{\Omega}_\varepsilon^M$ defined in section* 5.4 *can be estimated in terms of its boundary values on $\hat{S}_\varepsilon^\pm$ and its initial values $\hat{U}_0^M$ in the following way: Fix $h \in \left(0,\frac{1}{4}\right)$ and assume $l \in \mathbb{Z}^{n-1}$ such that $|l\varepsilon| < h$. Then there exists a constant C independent of ε and l, such that*

$$\begin{aligned}
&\frac{1}{\sqrt{\varepsilon}}||\hat{u}_\varepsilon^M(t,x+(l,0)\varepsilon) - \hat{u}_\varepsilon^M(t,x)||_{L^2((0,T)\times\Omega_\varepsilon^M,\mathbb{R}^m)}\\
&\le C\Bigg(||\hat{u}_\varepsilon^+(t,x+(l,0)\varepsilon) - \hat{u}_\varepsilon^+(t,x)||_{L^2((0,T)\times\hat{S}_\varepsilon^+,\mathbb{R}^m)}\\
&\quad + ||\hat{u}_\varepsilon^-(t,x+(l,0)\varepsilon) - \hat{u}_\varepsilon^-(t,x)||_{L^2((0,T)\times\hat{S}_\varepsilon^-,\mathbb{R}^m)}\\
&\quad + \frac{1}{\sqrt{\varepsilon}}\left\|\hat{U}_0^M\left(\bar{x}+l\varepsilon,\frac{x_n}{\varepsilon}\right) - \hat{U}_0^M\left(\bar{x},\frac{x_n}{\varepsilon}\right)\right\|_{L^2(\hat{\Omega}_\varepsilon^M,\mathbb{R}^m)}\Bigg)\\
&\quad + C\frac{\varepsilon}{h} + Ch^{\frac{1}{2}}.
\end{aligned} \tag{2.22}$$

Thus, up to subsequence, u_ε^M converges also strongly in the two-scale sense to the limit function u_0^M.

The limit functions satisfy the macroscopic problem formulated in the following theorem.

THEOREM 2.4. *The limit functions $u_0^\pm$ given in Proposition 2.1 satisfy in a distributional sense the initial boundary value problem on Ω^+ and Ω^-, respectively,*

$$\partial_t u_{j0}^+ - D_j^+ \Delta u_{j0}^+ = f_j(x, u_0^+), \qquad (t,x) \in (0,T) \times \Omega^+, \tag{2.23}$$

$$\partial_t u_{j0}^- - D_j^- \Delta u_{j0}^- = f_j(x, u_0^-), \qquad (t,x) \in (0,T) \times \Omega^-, \tag{2.24}$$

$$u_0^\pm(t,x) = u_D^\pm, \qquad (t,x) \in (0,T) \times \partial_D\Omega^\pm, \tag{2.25}$$

$$\frac{\partial u_0^\pm}{\partial \nu} = 0, \qquad (t,x) \in (0,T) \times \partial_N\Omega^\pm, \tag{2.26}$$

$$u_0^\pm(0,x) = U_0(x), \qquad x \in \Omega^\pm, \tag{2.27}$$

together with the effective transmission conditions on the interface Σ,

$$\begin{aligned} [u_{j0}]_\Sigma(t,\bar{x}) = &\int_Z (g_j(y, u_0^M(t,\bar{x},y)) - \partial_t u_{j0}^M(t,\bar{x},y))\eta_j(y)\, dy \\ &+ D_j^+ \eta_j^+ \partial_n u_{j0}^+(t,\bar{x},0) - D_j^- \eta_j^- \partial_n u_{j0}^-(t,\bar{x},0), \end{aligned} \tag{2.28}$$

$$\begin{aligned} &(D_j^+ \partial_n u_{j0}^+ - D_j^- \partial_n u_{j0}^-)(t,\bar{x},0) \\ &\qquad = \int_Z (\partial_t u_{j0}^M(t,\bar{x},y) - g_j(y, u_0^M(t,\bar{x},y)))\, dy. \end{aligned} \tag{2.29}$$

The limit function u_0^M, which enters the transmission conditions, is the weak solution of the local problem

$$\begin{aligned} &\partial_t u_{j0}^M(t,\bar{x},y) - \nabla_y(D_j^M(y)\nabla_y u_{j0}^M(t,\bar{x},y)) \\ &\qquad = g_j(y, u_0^M(t,\bar{x},y)) \text{ in } (0,T)\times Z, \end{aligned} \tag{2.30}$$

$$u_0^M(t,\bar{x},y) = u_0^\pm(t,\bar{x},0) \text{ on } (0,T) \times S^\pm, \tag{2.31}$$

$$u_0^M \text{ is periodic in } Y, \tag{2.32}$$

$$u_0^M(0,\bar{x},y) = U_0^M(\bar{x}, y_n) \text{ in } Z \tag{2.33}$$

for a.e. $\bar{x} \in \Sigma$. The constants $\eta^\pm = (\eta_1^\pm, \dots, \eta_m^\pm)$ are the constant boundary values on $S^\pm$ of the solution $\eta = (\eta_1, \dots, \eta_m)$ to the following boundary value problem on the standard cell: Find

$$\eta = (\eta_1, \dots, \eta_m) \in V := \{\varphi \in H^1(Z, \mathbb{R}^m), \varphi \text{ periodic in } Y, \varphi \equiv \text{const on } S^+ \cup S^-\}$$

such that $\frac{1}{|Z|}\int_Z \eta(y)\, dy = 0$ and, for all $\varphi \in V$,

$$\int_Z D_j^M(y)\nabla\eta_j(y)\nabla\varphi_j(y)\, dy = \int_{S^+} \varphi_j(y)\, ds - \int_{S^-} \varphi_j(y)\, ds. \tag{2.34}$$

In the final step, we prove uniqueness for the macroscopic problem, and therefore we obtain that the sequence of solutions to the microscopic problems converges to the solution of the macroscopic problem in the corresponding topology on every subdomain.

THEOREM 2.5. *The solution (u_0^+, u_0^-, u_0^M) of the macroscopic system* (2.23)–(2.33) *is unique.*

3. A priori estimates for the microscopic model. In order to get some information about the compactness properties of the sequence u_ε, we have to control the dependence of the solutions on the scale parameter ε.

LEMMA 3.1. *For the solutions of problem* (2.1)–(2.4)*, the following estimates hold, with a generic constant C independent of ε:*

$$||u_{j\varepsilon}^{\pm}||_{L^\infty((0,T),H^1(\Omega_\varepsilon^{\pm}))} \le C, \tag{3.1}$$

$$\frac{1}{\sqrt{\varepsilon}}||u_{j\varepsilon}^{M}||_{L^\infty((0,T),L^2(\Omega_\varepsilon^{M}))} + \sqrt{\varepsilon}||\nabla u_{j\varepsilon}^{M}||_{L^\infty((0,T),L^2(\Omega_\varepsilon^{M}))} \le C, \tag{3.2}$$

$$||\partial_t\, u_{j\varepsilon}^{\pm}||_{L^2((0,T),L^2(\Omega_\varepsilon^{\pm}))} \le C, \quad \frac{1}{\sqrt{\varepsilon}}||\partial_t u_{j\varepsilon}^{M}||_{L^2((0,T),L^2(\Omega_\varepsilon^{M}))} \le C. \tag{3.3}$$

In the case that the reaction terms satisfy the additional structural conditions (2.7)–(2.9)*, we obtain the following pointwise bounds for the solution:*

$$0 \le u_{j\varepsilon} \le M_j e^{A_j t} \quad \textit{for a.e.}\,(t,x) \in (0,T)\times\Omega. \tag{3.4}$$

Proof. Let us first set

$$U_\varepsilon = u_\varepsilon - u_D = \begin{cases} u_\varepsilon^{\pm} - u_D, & x \in \Omega_\varepsilon^{\pm}, \\ u_\varepsilon^{M}, & x \in \Omega_\varepsilon^{M}, \end{cases}$$

and use it as a test function in (2.16). We obtain

$$\begin{aligned}
&\int_{\Omega_\varepsilon^{\pm}} \partial_t U_{j\varepsilon}^{\pm}(t) U_{j\varepsilon}^{\pm}(t)\,dx \;+\; \int_{\Omega_\varepsilon^{\pm}} \partial_t u_{jD}(t) U_{j\varepsilon}^{\pm}(t)\,dx \\
&+ D_j^{\pm}\int_{\Omega_\varepsilon^{\pm}} \nabla U_{j\varepsilon}^{\pm}(t)\nabla U_{j\varepsilon}^{\pm}(t)\,dx \;+\; D_j^{\pm}\int_{\Omega_\varepsilon^{\pm}} \nabla u_{jD}(t)\nabla U_{j\varepsilon}^{\pm}(t)\,dx \\
&+ \frac{1}{\varepsilon}\int_{\Omega_\varepsilon^{M}} \partial_t u_{j\varepsilon}^{M}(t) u_{j\varepsilon}^{M}(t)\,dx + \varepsilon\int_{\Omega_\varepsilon^{M}} D_j^{M}\left(\frac{x}{\varepsilon}\right)\nabla u_{j\varepsilon}^{M}(t)\nabla u_{j\varepsilon}^{M}(t)\,dx \\
&= \int_{\Omega_\varepsilon^{\pm}} f_j(x, u_\varepsilon^{\pm}(t,x)) U_{j\varepsilon}^{\pm}(t)dx \;+\; \frac{1}{\varepsilon}\int_{\Omega_\varepsilon^{M}} g_j\left(\frac{x}{\varepsilon}, u_\varepsilon^{M}(t,x)\right) u_{j\varepsilon}^{M}(t)dx \\
&\le C_1\int_{\Omega_\varepsilon^{\pm}} (1+|u_\varepsilon^{\pm}|)\,|U_{j\varepsilon}^{\pm}(t)|\,dx + \frac{C_2}{\varepsilon}\int_{\Omega_\varepsilon^{M}} (1+|u_\varepsilon^{M}|)\,|u_{j\varepsilon}^{M}(t)|\,dx
\end{aligned} \tag{3.5}$$

a.e. in $(0,T)$. Here the integrals over $\Omega_\varepsilon^{\pm}$ stand for the sum of the integrals over Ω_ε^{+} and Ω_ε^{-}. For the last inequality we used the growth conditions (2.5) and (2.6) on the reaction terms. Adding up the estimates in (3.5) for $j = 1, \dots, m$ and integrating with respect to time yields

$$\begin{aligned}
&\frac{1}{2}||U_\varepsilon^{\pm}(t)||^2_{L^2(\Omega_\varepsilon^{\pm},\mathbb{R}^m)} + \frac{1}{2\varepsilon}||u_\varepsilon^{M}(t)||^2_{L^2(\Omega_\varepsilon^{M},\mathbb{R}^m)} \\
&+ \int_0^t\int_{\Omega_\varepsilon^{\pm}} |\nabla U_\varepsilon^{\pm}|^2 dxdt + \varepsilon\int_0^t\int_{\Omega_\varepsilon^{M}} |\nabla u_\varepsilon^{M}(t)|^2 dxdt \\
&\le C\left(\int_0^t\int_{\Omega_\varepsilon^{\pm}} |\partial_t u_D(t) U_\varepsilon^{\pm}| dxdt + \int_0^t\int_{\Omega_\varepsilon^{\pm}} |\nabla u_D \nabla U_\varepsilon^{\pm}|\,dxdt\right) \\
&\quad + C\left(1 + \int_0^t\int_{\Omega_\varepsilon^{\pm}} |U_\varepsilon^{\pm}|^2 dxdt + \frac{1}{\varepsilon}\int_0^t\int_{\Omega_\varepsilon^{M}} |u_\varepsilon^{M}|^2 dxdt\right) \\
&\quad + \frac{1}{2}||U_\varepsilon^{\pm}(0)||^2_{L^2(\Omega_\varepsilon^{\pm},\mathbb{R}^m)} + \frac{1}{2\varepsilon}||u_\varepsilon^{M}(0)||^2_{L^2(\Omega_\varepsilon^{M},\mathbb{R}^m)}.
\end{aligned} \tag{3.6}$$

Here we also used the regularity properties (2.14) of the boundary data u_D. To estimate the second term on the right-hand side, we make use of the inequality

$$2ab \leq \delta a^2 + \frac{1}{\delta} b^2$$

to get

$$\int_0^t \int_{\Omega_\varepsilon^\pm} |\nabla u_D \nabla U_\varepsilon^\pm| \, dx dt \leq C \left(\frac{1}{\delta} + \delta ||\nabla U_\varepsilon^\pm||^2_{L^2((0,T)\times\Omega_\varepsilon^\pm, \mathbb{R}^m)} \right).$$

If δ is small enough, the term involving $\nabla U_\varepsilon^\pm$ can be absorbed on the left-hand side. Now, using Gronwall's lemma and the assumptions (2.11) on the initial conditions, we obtain

$$||U_\varepsilon^\pm||_{L^\infty((0,T),L^2(\Omega_\varepsilon^\pm,\mathbb{R}^m))} + \frac{1}{\sqrt{\varepsilon}} ||u_\varepsilon^M||_{L^\infty((0,T),L^2(\Omega_\varepsilon^M,\mathbb{R}^m))} \leq C$$

and

$$||\nabla U_\varepsilon^\pm(t)||_{L^2((0,T),L^2(\Omega_\varepsilon^\pm,\mathbb{R}^m))} + \sqrt{\varepsilon} ||\nabla u_\varepsilon^M(t)||_{L^2((0,T),L^2(\Omega_\varepsilon^M,\mathbb{R}^m))} \leq C.$$

To obtain the L^∞-estimates with respect to time for the gradients and the estimates for the time derivatives, we take $\varphi = \partial_t U_\varepsilon$ as a test function in (2.16). It yields

$$\begin{aligned} &\int_{\Omega_\varepsilon^\pm} \partial_t U_{j\varepsilon}^\pm(t) \partial_t U_{j\varepsilon}^\pm(t) \, dx \; + \int_{\Omega_\varepsilon^\pm} \partial_t u_{jD}(t) \partial_t U_{j\varepsilon}^\pm(t) \, dx \\ &+ D_j^\pm \int_{\Omega_\varepsilon^\pm} \nabla U_{j\varepsilon}^\pm(t) \nabla \partial_t U_{j\varepsilon}^\pm(t) dx + D_j^\pm \int_{\Omega_\varepsilon^\pm} \nabla u_{jD}(t) \nabla \partial_t U_{j\varepsilon}^\pm(t) \, dx \\ &+ \frac{1}{\varepsilon} \int_{\Omega_\varepsilon^M} \partial_t u_{j\varepsilon}^M(t) \partial_t u_{j\varepsilon}^M(t) \, dx + \varepsilon \int_{\Omega_\varepsilon^M} D_j^M \left(\frac{x}{\varepsilon}\right) \nabla u_{j\varepsilon}^M(t) \nabla \partial_t u_{j\varepsilon}^M(t) \, dx \\ &= \int_{\Omega_\varepsilon^\pm} f_j(x, u_\varepsilon^\pm) \partial_t U_{j\varepsilon}^\pm(t) dx \; + \frac{1}{\varepsilon} \int_{\Omega_\varepsilon^M} g_j \left(\frac{x}{\varepsilon}, u_\varepsilon^M\right) \partial_t u_{j\varepsilon}^M(t) dx \end{aligned}$$

a.e. on $(0,T)$. First, we have to transform the energy integral on Ω_ε^M as follows:

$$\begin{aligned} \varepsilon \int_{\Omega_\varepsilon^M} D_j^M \left(\frac{x}{\varepsilon}\right) \nabla u_{j\varepsilon}^M(t) \nabla \partial_t u_{j\varepsilon}^M(t) \, dx &= \frac{d}{dt} \int_{\Omega_\varepsilon^M} \varepsilon D_j^M \left(\frac{x}{\varepsilon}\right) \nabla u_{j\varepsilon}^M(t) \nabla u_{j\varepsilon}^M(t) \, dx \\ - \varepsilon \int_{\Omega_\varepsilon^M} D_j^M \left(\frac{x}{\varepsilon}\right) \nabla \partial_t u_{j\varepsilon}^M(t) \nabla u_{j\varepsilon}^M(t) \, dx. \end{aligned}$$

Thus,

(3.7)
$$\varepsilon \int_{\Omega_\varepsilon^M} D_j^M \left(\frac{x}{\varepsilon}\right) \nabla u_{j\varepsilon}^M(t) \nabla \partial_t u_{j\varepsilon}^M(t) \, dx = \frac{1}{2} \frac{d}{dt} \int_{\Omega_\varepsilon^M} \varepsilon D_j^M \left(\frac{x}{\varepsilon}\right) \nabla u_{j\varepsilon}^M(t) \nabla u_{j\varepsilon}^M(t) \, dx.$$

Adding up the equations for $j = 1, \ldots, m$, taking into account (3.7) and the growth conditions (2.5), (2.6), and integrating with respect to time, we obtain

$$\begin{aligned} &||\partial_t U_\varepsilon^\pm||^2_{L^2((0,T),L^2(\Omega_\varepsilon^\pm,\mathbb{R}^m))} + \frac{1}{\varepsilon} ||\partial_t u_\varepsilon^M||^2_{L^2((0,T),L^2(\Omega_\varepsilon^M,\mathbb{R}^m))} \\ &+ ||\nabla U_\varepsilon^\pm(t)||^2_{L^2(\Omega_\varepsilon^\pm,\mathbb{R}^m)} + \varepsilon ||\nabla u_\varepsilon^M(t)||^2_{L^2(\Omega_\varepsilon^M,\mathbb{R}^m)} \\ &\leq C \left(1 + ||U_\varepsilon^\pm||^2_{L^2((0,T),L^2(\Omega_\varepsilon^\pm,\mathbb{R}^m))} + \frac{1}{\varepsilon} ||u_\varepsilon^M||^2_{L^2((0,T),L^2(\Omega_\varepsilon^M,\mathbb{R}^m))} \right) \\ &+ C ||\nabla U_\varepsilon^\pm||^2_{L^2((0,T),L^2(\Omega_\varepsilon^\pm,\mathbb{R}^m))}. \end{aligned} \tag{3.8}$$

Using the estimates obtained in the first part of the proof, it follows that the right-hand side of (3.8) is bounded independently of ε. Thus estimates (3.1)–(3.3) are proved.

Now, it remains to show the L^∞-bounds for the solution under the hypothesis (2.7)–(2.10) on the reaction terms. We first show positivity of the solutions. Let us test our system (2.16) with the test function φ given by

$$\varphi_j = (u_{j\varepsilon})_- = \min\{u_{j\varepsilon}, 0\} \quad \text{a.e. on } [0,T]\times\Omega.$$

Due to the the assumptions (2.15), our test function has zero boundary values on the parabolic boundary. Thus we obtain

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\Omega_\varepsilon^+} |(u_{j\varepsilon}^+)_-|^2\,dx + \frac{1}{2}\frac{d}{dt}\int_{\Omega_\varepsilon^-} |(u_{j\varepsilon}^-)_-|^2\,dx + \frac{1}{2\varepsilon}\frac{d}{dt}\int_{\Omega_\varepsilon^M} |(u_{j\varepsilon}^M)_+|^2\,dx \\
&+ D_j^+\int_{\Omega_\varepsilon^+} |\nabla(u_{j\varepsilon}^+)_-|^2\,dx + D_j^-\int_{\Omega_\varepsilon^-} |\nabla(u_{j\varepsilon}^-)_-|^2\,dx + \int_{\Omega_\varepsilon^M} \varepsilon D_j^M |\nabla(u_{j\varepsilon}^M)_-|^2\,dx \\
&= \int_{\Omega_\varepsilon^+} f_j(x,u_\varepsilon^+)(u_{j\varepsilon}^+)_- + \int_{\Omega_\varepsilon^-} f_j(x,u_\varepsilon^-)(u_{j\varepsilon}^-)_- + \frac{1}{\varepsilon}\int_{\Omega_\varepsilon^M} g_j\left(\frac{x}{\varepsilon}, u_\varepsilon^M\right)(u_{j\varepsilon}^M)_-.
\end{aligned}$$

Integrating with respect to time, adding up the equations for $j = 1,\dots,m$, and using the assumptions (2.9), (2.10) on the reaction terms leads to

$$\begin{aligned}
&\int_{\Omega_\varepsilon^+}\sum_{j=1}^m |(u_{j\varepsilon}^+)_-(t)|^2 dx + \int_{\Omega_\varepsilon^-}\sum_{j=1}^m |(u_{j\varepsilon}^-)_-(t)|^2 dx + \frac{1}{\varepsilon}\int_{\Omega_\varepsilon^M}\sum_{j=1}^m |(u_{j\varepsilon}^M)_-(t)|^2 dx \\
&\le C\int_0^t \left\{ \int_{\Omega_\varepsilon^+}\sum_{j=1}^m |(u_{j\varepsilon}^+)_-|^2 dx + \int_{\Omega_\varepsilon^-}\sum_{j=1}^m |(u_{j\varepsilon}^-)_-|^2 dx + \frac{1}{\varepsilon}\int_{\Omega_\varepsilon^M}\sum_{j=1}^m |(u_{j\varepsilon}^M)_-|^2 dx \right\} dt.
\end{aligned}$$

Now, Gronwall's inequality implies that $(u_{j\varepsilon})_- = 0$. Thus the positivity of the solution is proved. To obtain the upper bound, we first test (2.16) with the test function

$$\varphi_j(t,x) = e^{-A_j t}\psi_j(t,x),$$

where $\psi \in L^2((0,T),H^1(\Omega))$ and has zero boundary values on the parabolic boundary. We obtain

$$\begin{aligned}
&\int_{\Omega_\varepsilon^+} \partial_t u_{j\varepsilon}^+ e^{-A_j t}\psi_j dx + \int_{\Omega_\varepsilon^-} \partial_t u_{j\varepsilon}^- e^{-A_j t}\psi_j dx + \frac{1}{\varepsilon}\int_{\Omega_\varepsilon^M} \partial_t u_{j\varepsilon}^M e^{-A_j t}\psi_j dx \\
&+ D_j^+\int_{\Omega_\varepsilon^+} e^{-A_j t}\nabla u_{j\varepsilon}^+ \nabla\psi_j dx + D_j^-\int_{\Omega_\varepsilon^-} e^{-A_j t}\nabla u_{j\varepsilon}^- \nabla\psi_j dx \\
&+ \int_{\Omega_\varepsilon^M} \varepsilon D_j^M e^{-A_j t}\nabla u_{j\varepsilon}^M \nabla\psi_j dx = \int_{\Omega_\varepsilon^+} f_j(x,u_\varepsilon^+) e^{-A_j t}\psi_j dx \\
&+ \int_{\Omega_\varepsilon^-} f_j(x,u_\varepsilon^-) e^{-A_j t}\psi_j dx + \frac{1}{\varepsilon}\int_{\Omega_\varepsilon^M} g_j\left(\frac{x}{\varepsilon}, u_\varepsilon^M\right) e^{-A_j t}\psi_j dx.
\end{aligned}$$

Now we intend to set

$$\psi_j = (e^{-A_j t}u_{j\varepsilon} - M_j)_+ = \max\{e^{-A_j t}u_{j\varepsilon} - M_j, 0\} \quad \text{a.e. on } [0,T]\times\Omega.$$

Therefore, we write the terms containing the time derivative as

$$\int_{\Omega_\varepsilon^+} \partial_t u_{j\varepsilon}^+ e^{-A_j t}\psi_j dx = \int_{\Omega_\varepsilon^+} \partial_t(e^{-A_j t}u_{j\varepsilon}^+ - M_j)\psi_j dx + \int_{\Omega_\varepsilon^+} A_j e^{-A_j t}u_{j\varepsilon}^+\psi_j dx,$$

and analogously the terms on Ω_ε^- and Ω_ε^M. We obtain

$$
\begin{aligned}
(3.9)\quad & \frac{1}{2}\frac{d}{dt}\int_{\Omega_\varepsilon^+} |(e^{-A_jt}u_{j\varepsilon}^+ - M_j)_+|^2\,dx + \frac{1}{2}\frac{d}{dt}\int_{\Omega_\varepsilon^-} |(e^{-A_jt}u_{j\varepsilon}^- - M_j)_+|^2\,dx \\
& + \frac{1}{2\varepsilon}\frac{d}{dt}\int_{\Omega_\varepsilon^M} |(e^{-A_jt}u_{j\varepsilon}^M - M_j)_+|^2\,dx + \int_{\Omega_\varepsilon^+} A_j e^{-A_jt}u_{j\varepsilon}^+(e^{-A_jt}u_{j\varepsilon}^+ - M_j)_+ dx \\
& + \int_{\Omega_\varepsilon^-} A_j e^{-A_jt}u_{j\varepsilon}^-(e^{-A_jt}u_{j\varepsilon}^- - M_j)_+ dx + \frac{1}{\varepsilon}\int_{\Omega_\varepsilon^M} A_j e^{-A_jt}u_{j\varepsilon}^M(e^{-A_jt}u_{j\varepsilon}^M - M_j)_+ dx \\
\le & \int_{\Omega_\varepsilon^+} f_j(x,u_\varepsilon^+)e^{-A_jt}(e^{-A_jt}u_{j\varepsilon}^+ - M_j)_+ dx + \int_{\Omega_\varepsilon^-} f_j(x,u_\varepsilon^-)e^{-A_jt}(e^{-A_jt}u_{j\varepsilon}^- - M_j)_+ dx \\
& + \frac{1}{\varepsilon}\int_{\Omega_\varepsilon^M} g_j\left(\frac{x}{\varepsilon},u_\varepsilon^M\right)e^{-A_jt}(e^{-A_jt}u_{j\varepsilon}^M - M_j)_+ dx.
\end{aligned}
$$

Now, due to assumptions (2.7), (2.8) on the reaction terms, the right-hand side in the above inequality can be estimated from above by

$$
\begin{aligned}
& \int_{\Omega_\varepsilon^+} A_j u_{j\varepsilon}^+ e^{-A_jt}(e^{-A_jt}u_{j\varepsilon}^+ - M_j)_+ dx + \int_{\Omega_\varepsilon^-} A_j u_{j\varepsilon}^- e^{-A_jt}(e^{-A_jt}u_{j\varepsilon}^- - M_j)_+ dx \\
+ & \frac{1}{\varepsilon}\int_{\Omega_\varepsilon^M} A_j u_{j\varepsilon}^M e^{-A_jt}(e^{-A_jt}u_{j\varepsilon}^M - M_j)_+ dx.
\end{aligned}
$$

However, these terms cancel with the corresponding terms on the left-hand side in (3.9), and thus, after integration with respect to time, we get

$$
\begin{aligned}
& \int_{\Omega_\varepsilon^+} |(e^{-A_jt}u_{j\varepsilon}^+ - M_j)_+|^2\,dx + \int_{\Omega_\varepsilon^-} |(e^{-A_jt}u_{j\varepsilon}^- - M_j)_+|^2\,dx \\
+ & \frac{1}{\varepsilon}\int_{\Omega_\varepsilon^M} |(e^{-A_jt}u_{j\varepsilon}^M - M_j)_+|^2\,dx \le 0.
\end{aligned}
$$

Finally, we have

$$e^{-A_jt}u_{j\varepsilon} - M_j \le 0 \quad \text{a.e. on } [0,T]\times\Omega.$$

This completes the proof. □

4. Two-scale convergence for thin heterogeneous layers. From the a priori estimates in Lemma 3.1, we see that on the subdomain Ω_ε^M we cannot use the classic compactness results for passing to the limit when $\varepsilon \to 0$. Here, we have to consider special convergence concepts which are adapted to sequences of functions varying on different scales.

The so-called two-scale convergence was introduced in [1] and [12] in order to handle two-scale phenomena with periodic structure in all space dimensions. Then it was extended to multiple scales [2]; periodic surfaces [13] and measures [17], [4]; thin domains [11]; and stochastic media [6]. For our problem, we need to generalize the concept of two-scale convergence to thin heterogeneous domains. Thus let $G \subset \mathbb{R}^{n-1}$ be a bounded domain and let $Y = [0,1]^{n-1}$ be the closed unit cube in $\mathbb{R}^{n-1}$. Let G_ε be a thin domain defined by

$$G_\varepsilon = G \times]-\varepsilon, \varepsilon[.$$

Let Σ be the interface

$$\Sigma = G \times \{0\}$$

and, as before, let us denote by Z the standard cell

$$Z = Y \times [-1, 1].$$

Let $C_{per}(Y)$ be the space of continuous functions in $\mathbb{R}^{n-1}$ which are periodic of period Y. Let $L^2_{per}(Y)$ (respectively, $H^1_{per}(Y)$) be the completion of $C_{per}(Y)$ in the norm of $L^2(Y)$ (respectively, $H^1(Y)$).

DEFINITION 4.1. *A sequence of functions $u_\varepsilon \in L^2((0,T)\times G_\varepsilon)$ is said to two-scale converge weakly to $u_0(t,\bar{x},y)$ belonging to $L^2((0,T)\times\Sigma\times Z)$ if, for any*

$$\psi(t,\bar{x},\bar{y},y_n) \in C\left([0,T]\times\bar{\Sigma}, C_{per}([0,1]^{n-1}, C([-1,1]))\right),$$

we have

$$\lim_{\varepsilon\to 0}\frac{1}{\varepsilon}\int_0^T\int_{G_\varepsilon} u_\varepsilon(t,x)\psi\left(t,\bar{x},\frac{x}{\varepsilon}\right)dx\,dt = \int_0^T\int_\Sigma\int_Z u_0(t,\bar{x},y)\psi(t,\bar{x},y)dy\,d\bar{x}\,dt. \tag{4.1}$$

A sequence $u_\varepsilon \in L^2((0,T)\times G_\varepsilon)$ which converges weakly to $u_0 \in L^2((0,T)\times\Sigma\times Z)$ is said to converge strongly in the two-scale sense to the limit u_0 if

$$\lim_{\varepsilon\to 0}\frac{1}{\sqrt{\varepsilon}}||u_\varepsilon||_{L^2((0,T)\times G_\varepsilon)} = ||u_0||_{L^2((0,T)\times\Sigma\times Z)}. \tag{4.2}$$

REMARK 1. *If u_0 in* (4.2) *has the property that $u_0(\cdot,\cdot,\frac{\cdot}{\varepsilon}) \in L^2((0,T)\times G_\varepsilon)$, then the relation* (4.2) *is equivalent to*

$$\lim_{\varepsilon\to 0}\frac{1}{\sqrt{\varepsilon}}\left\|u_\varepsilon(t,x) - u_0\left(t,\bar{x},\frac{x}{\varepsilon}\right)\right\|_{L^2((0,T)\times G_\varepsilon)} = 0.$$

A sufficient condition for $u_0(\cdot,\cdot,\frac{\cdot}{\varepsilon})$ to be in $L^2((0,T)\times G_\varepsilon)$ is, e.g., that $u_0 \in L^2((0,T)\times\Sigma, C_{per}(Y, C([-1,1])))$. For more details concerning this topic, see [1, Remark 1.10].

The main compactness result obtained for standard two-scale convergence in [12] and [1] can be generalized for the case of sequences defined on thin domains with microstructure.

PROPOSITION 4.2. *Let u_ε be a sequence in $L^2((0,T)\times G_\varepsilon)$, such that*

$$\frac{1}{\sqrt{\varepsilon}}||u_\varepsilon||_{L^2((0,T)\times G_\varepsilon)} \le C$$

with a positive constant C, independent of ε. Then there exists a subsequence (which we still denote by ε) and a limit function $u_0 \in L^2((0,T)\times\Sigma\times Z)$, such that

$$\lim_{\varepsilon\to 0}\frac{1}{\varepsilon}\int_0^T\int_{G_\varepsilon} u_\varepsilon(t,x)\varphi\left(t,\bar{x},\frac{x}{\varepsilon}\right)dx\,dt = \int_0^T\int_\Sigma\int_Z u_0(t,\bar{x},y)\varphi(t,\bar{x},y)dy\,d\bar{x}\,dt \tag{4.3}$$

for every test function $\varphi \in C([0,T]\times\bar{\Sigma}, C_{per}([0,1]^{n-1}, C([-1,1])))$.

Proof. Using Lemma 4.3 below, this result can be proved analogously to Theorem 1.2 in [1]. However, we have to take into account new aspects like time dependence and domains shrinking to a hypersurface.

Let us first consider functions u_ε, which do not vary with respect to time. Let $\varphi \in C\left(\bar{\Sigma}, C_{per}(Y, C([-1,1]))\right)$ and define

$$\mu_\varepsilon(\varphi) := \frac{1}{\varepsilon}\int_{G_\varepsilon} u_\varepsilon(x)\varphi\left(\bar{x}, \frac{x}{\varepsilon}\right) dx.$$

Since

$$|\mu_\varepsilon(\varphi)| \leq \frac{1}{\sqrt{\varepsilon}}||u_\varepsilon||_{L^2(G_\varepsilon)} \cdot \left\{\frac{1}{\varepsilon}\int_{G_\varepsilon}\left|\varphi\left(\bar{x}, \frac{x}{\varepsilon}\right)\right|^2 dx\right\}^{\frac{1}{2}} \leq C||\varphi||_B,$$

μ_ε is a bounded sequence of functionals on $B = C(\bar{\Sigma}, C_{per}(Y, C([-1,1])))$. Since this space is a separable Banach space, one can extract a subsequence of μ_ε (denoted μ_ε again) which weak*-converges to a limit functional $\mu_0 \in B$. Using now the boundedness of u_ε and Lemma 4.3, we obtain for every $\varphi \in B$

$$|\mu_0(\varphi)|^2 = \lim_{\varepsilon\to 0}|\mu_\varepsilon(\varphi)|^2 \leq C\lim_{\varepsilon\to 0}\frac{1}{\varepsilon}\int_{G_\varepsilon}\left|\varphi\left(\bar{x}, \frac{x}{\varepsilon}\right)\right|^2 dx = C||\varphi||^2_{L^2(\Sigma\times Z)}.$$

From the density of B in $L^2(\Sigma\times Z)$, it follows that μ_0 is a bounded functional on the Hilbert space $L^2(\Sigma\times Z)$. Thus the Riesz representation theorem implies the existence of a function $u_0 \in L^2(\Sigma\times Z)$ such that (4.3) is satisfied.

The proof of the theorem for the case of time-dependent functions can be reduced to the previous one by considering functions defined on the spatial domain with values in the separable Banach space $L^2((0,T))$. $\square$

Lemma 4.3. *Let*

$$B = C\left([0,T]\times\bar{\Sigma}, C_{per}(Y, C([-1,1]))\right)$$

be the space of continuous functions on $[0,T]\times\bar{\Sigma}$ *with values in the space* $C_{per}(Y, C([-1,1]))$ *of continuous functions on* Z *and* Y *periodic.* B *is a separable Banach space, which is dense in* $L^p((0,T)\times\Sigma\times Z)$ *for* $1 \leq p < \infty$, *and for every* $\varphi \in B$ *the following assertions hold:*

$$\frac{1}{\varepsilon}\int_0^T\int_{G_\varepsilon}\left|\varphi\left(t,\bar{x},\frac{x}{\varepsilon}\right)\right|^p dx\,dt \leq C||\varphi||^p_B \tag{4.4}$$

and

$$\lim_{\varepsilon\to 0}\frac{1}{\varepsilon}\int_0^T\int_{G_\varepsilon}\left|\varphi\left(t,\bar{x},\frac{x}{\varepsilon}\right)\right|^p dx\,dt = \int_0^T\int_\Sigma\int_Z|\varphi(t,\bar{x},y)|^p\ dy\,d\bar{x}\,dt. \tag{4.5}$$

The proof of (4.4) is obvious. To prove (4.5), we consider a paving of Σ with ε-cells and approximate φ by step functions with respect to the variable $\bar{x}\in\Sigma$. Using then the periodicity of φ with respect to the variable $\bar{y}\in Y$ and taking the limit for $\varepsilon\to 0$, the assertion follows.

Next we investigate the situation where we also have bounds on the gradients.

Proposition 4.4.

(i) *Let* u_ε *be a sequence of functions in* $L^2((0,T),H^1(G_\varepsilon))$, *such that*

$$\frac{1}{\sqrt{\varepsilon}}||u_\varepsilon||_{L^2((0,T)\times G_\varepsilon)} + \frac{1}{\sqrt{\varepsilon}}||\nabla u_\varepsilon||_{L^2((0,T)\times G_\varepsilon)} \leq C.$$

Then there exist functions $u_0 \in L^2((0,T), H^1(\Sigma))$ *and* $u_1 \in L^2((0,T) \times \Sigma, H^1_{per}(Y, H^1[-1,1])/\mathbb{R})$*, such that*

$$u_\varepsilon \xrightarrow{t.s.} u_0(t,\bar{x}) \text{ weakly in the two-scale sense,}$$
$$\nabla u_\varepsilon \xrightarrow{t.s.} \nabla_{\bar{x}} u_0(t,\bar{x}) + \nabla_y u_1(t,\bar{x},y) \text{ weakly in the two-scale sense.}$$

(ii) *Let* u_ε *be a sequence in* $L^2((0,T), H^1(G_\varepsilon))$*, such that*

$$\frac{1}{\sqrt{\varepsilon}}||u_\varepsilon||_{L^2((0,T)\times G_\varepsilon)} + \sqrt{\varepsilon}||\nabla u_\varepsilon||_{L^2((0,T)\times G_\varepsilon)} \leq C.$$

Then there exists $u_0 \in L^2((0,T) \times \Sigma, H^1_{per}(Y, H^1[-1,1]))$ *such that*

$$u_\varepsilon \xrightarrow{t.s.} u_0(t,\bar{x},y) \text{ weakly in the two-scale sense,}$$
$$\varepsilon\nabla u_\varepsilon \xrightarrow{t.s.} \nabla_y u_0(t,\bar{x},y) \text{ weakly in the two-scale sense.}$$

The proof of this theorem is given by using Theorem 4.2 and arguments similar to the ones in Proposition 1.14 in [1].

Equivalent formulation. When we are dealing with nonlinear problems, the weak two-scale convergence is no longer sufficient for passing to the limit in the nonlinear terms. Here one needs strongly two-scale convergent sequences. However, it is very difficult to show directly the strong two-scale convergence for sequences defined on varying domains, e.g., thin heterogeneous layers. In such cases we use an equivalent characterization of the two-scale convergence described below. This reformulation has the strong advantage that sequences of functions defined on varying domains are transformed to sequences on fixed domains.

Contributions to the development of this method are given in [3], [5], [8], and [9]. In our paper we adapt this method to the case of thin heterogeneous layers and nonlinear problems. Recently, in [16], a proof for the "thick" Neumann sieve was given using multiscale techniques based on [9].

For each $\varepsilon > 0$, let us consider the lattice

$$\mathcal{A}_\varepsilon = \{\bar{x} = \varepsilon i, i \in \mathbb{Z}^{n-1}\} = \varepsilon\mathbb{Z}^{n-1}.$$

To every $\bar{x} \in \Sigma$ we can associate a unique lattice point $c_\varepsilon(\bar{x}) := \varepsilon\left[\frac{\bar{x}}{\varepsilon}\right] \in \mathcal{A}_\varepsilon$, such that $\bar{x} \in c_\varepsilon(\bar{x}) + \varepsilon Y$. For simplicity, from now on we consider domains G_ε of the form $G_\varepsilon =]0,1[^{n-1} \times]-\varepsilon,\varepsilon[$.

Definition 4.5. *We define the operator* L_ε*, mapping measurable functions* u_ε *on* $(0,T) \times G_\varepsilon$ *to measurable functions* $L_\varepsilon u_\varepsilon$ *on* $(0,T) \times \Sigma \times Z$*, with*

$$(L_\varepsilon u_\varepsilon)(t,\bar{x},y) = u_\varepsilon(t,(c_\varepsilon(\bar{x}),0) + \varepsilon y) \tag{4.6}$$

for a.e. $\bar{x} \in c_\varepsilon(\bar{x}) + \varepsilon Y,\ (t,y) \in (0,T) \times Z$.

The following properties of the operator L_ε can be proved in analogy to Lemma 2 in [3].

Lemma 4.6. *For* $u_\varepsilon, v_\varepsilon \in L^2((0,T) \times G_\varepsilon)$*, we have*

$$(L_\varepsilon u_\varepsilon, L_\varepsilon v_\varepsilon)_{L^2((0,T)\times\Sigma\times Z)} = \frac{1}{\varepsilon}(u_\varepsilon, v_\varepsilon)_{L^2((0,T)\times G_\varepsilon)},$$
$$||L_\varepsilon u_\varepsilon||_{L^2((0,T)\times\Sigma\times Z)} = \frac{1}{\sqrt{\varepsilon}}||u_\varepsilon||_{L^2((0,T)\times G_\varepsilon)},$$
$$\nabla_y L_\varepsilon u_\varepsilon = \varepsilon L_\varepsilon(\nabla_x u_\varepsilon) \quad \text{a.e. in } (0,T)\times\Sigma\times Z.$$

The next proposition shows that weak (strong) two-scale convergence for a sequence $u_\varepsilon \in L^2((0,T)\times G_\varepsilon)$ is equivalent to weak (strong) convergence for the sequence $L_\varepsilon u_\varepsilon$ in $L^2((0,T)\times\Sigma\times Z)$.

PROPOSITION 4.7. *Let $u_\varepsilon \in L^2((0,T)\times G_\varepsilon)$ be a sequence, such that*

$$\frac{1}{\sqrt{\varepsilon}}||u_\varepsilon||_{L^2((0,T)\times G_\varepsilon)} \leq C.$$

Then there exists a subsequence (again denoted by u_ε) and a limit function $u_0 \in L^2((0,T)\times\Sigma\times Z)$, such that the following statements are equivalent:

(i) $u_\varepsilon \xrightarrow{t.s.} u_0$ *weakly (strongly) in the two-scale sense.*
(ii) $L_\varepsilon u_\varepsilon \longrightarrow u_0$ *weakly (strongly) in* $L^2((0,T)\times\Sigma\times Z)$.

Proof. Since by Lemma 4.6

$$||L_\varepsilon u_\varepsilon||_{L^2((0,T)\times\Sigma\times Z)} = \frac{1}{\sqrt{\varepsilon}}||u_\varepsilon||_{L^2((0,T)\times G_\varepsilon)} \leq C$$

it follows that there exists a subsequence of u_ε (again denoted by u_ε), and there exist $u_0, u_* \in L^2((0,T)\times\Sigma\times Z)$, such that

$$\begin{aligned} u_\varepsilon &\xrightarrow{\text{t.s.}} u_0 \quad \text{weakly in the two-scale sense,}\\ L_\varepsilon u_\varepsilon &\longrightarrow u_* \quad \text{weakly in } L^2((0,T)\times\Sigma\times Z). \end{aligned}$$

Then a proof analogous to that of Proposition 4.6 in [5] shows that $u_0 \equiv u_*$. To prove the equivalence of statements (i) and (ii) with respect to the strong convergences let us remark that

$$\begin{aligned} ||L_\varepsilon u_\varepsilon - u_0||^2_{L^2((0,T)\times\Sigma\times Z)} &= \int_0^T\int_\Sigma\int_Z |L_\varepsilon u_\varepsilon - u_0|^2\, dy\, d\bar{x}\, dt\\ = ||L_\varepsilon u_\varepsilon||^2_{L^2((0,T)\times\Sigma\times Z)} &- 2\int_0^T\int_\Sigma\int_Z (L_\varepsilon u_\varepsilon)u_0\, dy\, d\bar{x}\, dt + ||u_0||^2_{L^2((0,T)\times\Sigma\times Z)}\\ = \frac{1}{\varepsilon}||u_\varepsilon||^2_{L^2((0,T)\times G_\varepsilon)} &- 2\int_0^T\int_\Sigma\int_Z (L_\varepsilon u_\varepsilon)u_0\, dy\, d\bar{x}\, dt + ||u_0||^2_{L^2((0,T)\times\Sigma\times Z)}. \end{aligned}$$

Taking now the limits $\varepsilon \to 0$ on both sides of this equality, the equivalence of (i) and (ii) is proved. □

5. Proofs for the convergence results stated in Propositions 2.1 and 2.2 and Theorem 2.3. From the a priori estimates we see that we have different compactness properties for the solutions u_ε on the subdomains $\Omega^\pm_\varepsilon$ and Ω^M_ε. Thus we have to study the convergence of the sequences $u^\pm_\varepsilon$ and u^M_ε separately.

5.1. Convergence in the bulk. In this subsection, we give the proof of the first three convergence results from Proposition 2.1.

Proof. Let us consider the transformations

$$\Omega^\pm \mapsto \Omega^\pm_\varepsilon, \quad (\bar{x}, \tilde{x}_n) \mapsto (\bar{x}, x_n) = \left(\bar{x}, \frac{H-\varepsilon}{H}\tilde{x}_n \pm \varepsilon\right) \tag{5.1}$$

and define

$$\tilde{u}_\varepsilon^\pm : [0,T] \times \Omega^\pm \to \mathbb{R}^m, \quad \tilde{u}_\varepsilon^\pm(t,\bar{x},\tilde{x}_n) = u_\varepsilon^\pm\left(t,\bar{x},\frac{H-\varepsilon}{H}\tilde{x}_n \pm \varepsilon\right). \tag{5.2}$$

Using the transformation formula for integrals, we can easily show the estimates for the functions $\tilde{u}_\varepsilon^\pm$,

$$||\tilde{u}_{j\varepsilon}^\pm||_{L^2(0,T;H^1(\Omega^\pm))} \le C\,||u_{j\varepsilon}^\pm||_{L^2((0,T),H^1(\Omega_\varepsilon^\pm))}, \tag{5.3}$$

$$||\partial_t\tilde{u}_{j\varepsilon}^\pm||_{L^2((0,T),L^2(\Omega^\pm))} \le C\,||\partial_t u_{j\varepsilon}^\pm||_{L^2((0,T),L^2(\Omega_\varepsilon^\pm))}, \tag{5.4}$$

with a constant C independent of ε. Now, since the functions $\tilde{u}_\varepsilon^\pm$ are defined on fixed domains $\Omega^\pm$, standard compactness results together with the estimates (5.3) and (5.4) imply that there exist $u_0^\pm \in L^2((0,T),H^1(\Omega^\pm,\mathbb{R}^m))$ with $\partial_t u_0^\pm \in L^2((0,T),L^2(\Omega^\pm,\mathbb{R}^m))$, such that up to a subsequence

$$\begin{aligned}
&\tilde{u}_{j\varepsilon}^\pm \to u_{j0}^\pm \quad \text{weakly in } L^2((0,T),H^1(\Omega^\pm)),\\
&\partial_t\tilde{u}j_\varepsilon{}^\pm \to \partial_t u_{j0}^\pm \quad \text{weakly in } L^2((0,T),L^2(\Omega^\pm)),\\
&\tilde{u}_{j\varepsilon}^\pm \to u_{j0}^\pm \quad \text{strongly in } L^2((0,T),L^2(\Omega^\pm)).
\end{aligned}$$

The strong convergence follows from the estimate

$$||\tilde{u}_{j\varepsilon}^\pm||_{L^2(0,T;H^1(\Omega^\pm))} + ||\partial_t\tilde{u}_{j\varepsilon}^\pm||_{L^2(0,T;L^2(\Omega^\pm))} \le C$$

and a compactness theorem of Lions; see [10, Theorem 1, p. 58].

Now let $\varphi \in C_0^\infty([0,T]\times\Omega^\pm,\mathbb{R}^m)$. Using the transformations (5.1), (5.2), we have

$$\begin{aligned}
&\int_0^T\int_{\Omega^\pm}(\chi_{\Omega_\varepsilon^\pm}u_{j\varepsilon})(t,x)\varphi_j(t,x)\,dx\,dt = \int_0^T\int_{\Omega_\varepsilon^\pm}u_{j\varepsilon}^\pm(t,\bar{x},x_3)\varphi_j(t,\bar{x},x_3)d\bar{x}\,dx_3\,dt\\
&= \int_0^T\int_{\Omega^\pm}u_{j\varepsilon}^\pm\left(t,\bar{x},\frac{H-\varepsilon}{H}\tilde{x}_3\pm\varepsilon\right)\varphi_j\left(t,\bar{x},\frac{H-\varepsilon}{H}\tilde{x}_3\pm\varepsilon\right)\frac{H-\varepsilon}{H}d\bar{x}\,d\tilde{x}_3\,dt\\
&= \frac{H-\varepsilon}{H}\int_0^T\int_{\Omega^\pm}\tilde{u}_{j\varepsilon}^\pm(t,\bar{x},\tilde{x}_3)\varphi_j(t,\bar{x},\tilde{x}_3)d\bar{x}\,d\tilde{x}_3\,dt\\
&\quad+\frac{H-\varepsilon}{H}\int_0^T\int_{\Omega^\pm}\tilde{u}_{j\varepsilon}^\pm(t,\bar{x},\tilde{x}_3)\left[\varphi_j\left(t,\bar{x},\frac{H-\varepsilon}{H}\tilde{x}_3\pm\varepsilon\right)-\varphi_j(t,\bar{x},\tilde{x}_3)\right]d\bar{x}\,d\tilde{x}_3\,dt\\
&\to \int_0^T\int_{\Omega^\pm}u_{j0}^\pm(t,\bar{x},\tilde{x})\varphi_j(t,\bar{x},\tilde{x})\,d\bar{x}\,d\tilde{x}\,dt
\end{aligned}$$

due to the convergence properties of $\tilde{u}_\varepsilon^\pm$ and the smoothness of φ. Thus

$$\chi_{\Omega_\varepsilon^\pm}u_{j\varepsilon} \to u_{j0}^\pm \quad \text{weakly in } L^2((0,T),L^2(\Omega^\pm)).$$

Additionally, we have that

$$||\chi_{\Omega_\varepsilon^\pm}u_{j\varepsilon}||_{L^2((0,T),L^2(\Omega^\pm))} = \sqrt{1-\varepsilon/H}||\tilde{u}_{j\varepsilon}^\pm||_{L^2(0,T;L^2(\Omega^\pm))} \to ||u_{j0}^\pm||_{L^2(0,T;L^2(\Omega^\pm))},$$

since $\tilde{u}_\varepsilon^\pm$ converges to $u_0^\pm$ strongly in $L^2((0,T)\times\Omega^\pm,\mathbb{R}^m)$. Thus, statement 1 of Proposition 2.1 is proved. The proofs of statements 2 and 3 follow along the same line. $\square$

5.2. Convergence for the traces on the interfaces bulk/layer. The compactness of the traces of u_ε on $S_\varepsilon^\pm$ is crucial for the control of the solutions in the layer. In the following, we give the proof of Proposition 2.2.

Proof. Since

$$||\tilde{u}_{j\varepsilon}^\pm||_{L^2((0,T),H^1(\Omega^\pm))} + ||\partial_t \tilde{u}_{j\varepsilon}^\pm||_{L^2((0,T),L^2(\Omega^\pm))} \le C$$

and the embedding

$$H^1(\Omega^\pm) \hookrightarrow H^\beta(\Omega^\pm)$$

is compact for every $\frac{1}{2} < \beta < 1$, it follows from Lions compactness theorem [10, Theorem 1, p. 58] that there exists a subsequence such that

$$\tilde{u}_{j\varepsilon}^\pm \to u_{j0}^\pm \quad \text{strongly in } L^2((0,T), H^\beta(\Omega^\pm)).$$

Due to the continuity of the embedding

$$H^\beta(\Omega^\pm) \hookrightarrow L^2(\partial\Omega^\pm) \quad \text{for } \frac{1}{2} < \beta < 1,$$

it follows that

$$||\tilde{u}_{j\varepsilon}^\pm - u_{j0}^\pm||_{L^2((0,T)\times\Sigma)} \le C||\tilde{u}_{j\varepsilon}^\pm - u_{j0}^\pm||_{L^2((0,T),H^\beta(\Omega^\pm))} \to 0 \quad \text{for } \varepsilon \to 0.$$

Thus the first assertion is proved. To prove the second one, we notice that, since $\tilde{u}_\varepsilon|_\Sigma$ is strongly convergent in $L^2((0,T)\times\Sigma, \mathbb{R}^m)$, it is also weakly two-scale convergent to the same limit; see [1]. Then, using again (5.1) and (5.2), we obtain for $\varepsilon \to 0$

$$\begin{aligned}\int_0^T \int_{S_\varepsilon^\pm} u_{j\varepsilon}^\pm(t,x)\varphi_j\left(t,\bar{x},\frac{x}{\varepsilon}\right) dxdt &= \frac{H-\varepsilon}{H}\int_0^T \int_\Sigma \tilde{u}_{j\varepsilon}^\pm(t,\bar{x},0)\varphi_j\left(t,\bar{x},\frac{\bar{x}}{\varepsilon},\pm 1\right) d\bar{x}dt \\ &\to \int_0^T \int_\Sigma \int_Y u_{j0}^\pm(t,\bar{x},0)\varphi_j\left(t,\bar{x},\bar{y},\pm 1\right) d\bar{y}d\bar{x}dt. \qquad \square\end{aligned}$$

5.3. Weak two-scale convergence in the layer. The compactness results with respect to the weak two-scale convergence of u_ε^M in the layer stated in statements 4–6 of Proposition 2.1 follow directly from Proposition 4.4 and the a priori estimates for u_ε^M. It remains to prove the coupling condition between the effective solutions in the bulk regions and the local solution in the layer given in (2.19).

Proof. Let us start from the identity

$$\lim_{\varepsilon\to 0}\frac{1}{\varepsilon}\int_0^T\int_{\Omega_\varepsilon^M}\varepsilon\nabla u_{j\varepsilon}^M(t,x)\varphi_j\left(t,\bar{x},\frac{x}{\varepsilon}\right)dx\,dt = \int_0^T\int_\Sigma\int_Z \nabla_y u_{j0}^M(t,\bar{x},y)\varphi_j(t,\bar{x},y)\,dy\,d\bar{x}\,dt$$

for any $\varphi_j \in C^\infty([0,T]\times\Sigma\times Z, \mathbb{R}^n)$ periodic in $Y = [0,1]^{n-1}$ and with compact support with respect to $\bar{x} \in \Sigma$. Integrating by parts on the left-hand side and using the continuity of the solution u_ε on S_ε^+, respectively, S_ε^-, and Proposition 2.2, we obtain

$$\lim_{\varepsilon\to 0}\left\{-\frac{1}{\varepsilon}\int_0^T\int_{\Omega_\varepsilon^M} u_{j\varepsilon}^M(t,x)\left(\varepsilon\nabla_{\bar{x}}\,\varphi_j\left(t,\bar{x},\frac{x}{\varepsilon}\right)+\nabla_y\,\varphi_j\left(t,\bar{x},\frac{x}{\varepsilon}\right)\right)dx\,dt\right.$$
$$\left.+\int_0^T\int_{S_\varepsilon^+} u_{j\varepsilon}^+(t,x)\varphi_j\left(t,\bar{x},\frac{x}{\varepsilon}\right)\cdot\nu\,dx\,dt+\int_0^T\int_{S_\varepsilon^-} u_{j\varepsilon}^-(t,x)\varphi_j\left(t,\bar{x},\frac{x}{\varepsilon}\right)\cdot\nu\,dx\,dt\right\}$$
$$=-\int_0^T\int_\Sigma\int_Z u_{j0}^M(t,\bar{x},y)\nabla_y\,\varphi_j(t,\bar{x},y)\,dy\,d\bar{x}\,dt$$
$$+\int_0^T\int_\Sigma\int_Y u_{j0}^+(t,\bar{x},0)\varphi_j(t,\bar{x},\bar{y},1)\cdot n\,dy\,d\bar{x}\,dt$$
$$-\int_0^T\int_\Sigma\int_Y u_{j0}^-(t,\bar{x},0)\varphi_j(t,\bar{x},\bar{y},-1)\cdot n\,dy\,d\bar{x}\,dt.$$

Here $n=(0,\dots,0,1)$. By equality between the two limits, we obtain statement (2.19) of the theorem. ∎

5.4. Strong two-scale convergence in the layer. In the following, we prove strong two-scale convergence for the sequence u_ε^M. The method to be used is of general interest. Here, we are in the situation that the standard estimates of the solutions u_ε^M imply only weak two-scale convergence, and due to the scaling in the diffusion coefficients we cannot use the method of bounded extensions to get strong convergence for u_ε^M in L^2. The best compactness result we get for u_ε^M is strong two-scale convergence. To prove this, we show the strong convergence of the transformed solution $L_\varepsilon u_\varepsilon^M$ in $L^2((0,T)\times\Sigma\times Z)$ (see Proposition 4.7). The control of the dependence of $L_\varepsilon u_\varepsilon^M$ on y and t is standard since we can use the differential equations in the cells. However, the dependence on x poses more serious problems since the functions $L_\varepsilon u_\varepsilon^M$ are only step functions with respect to x. To get equicontinuity in L^2 also with respect to shifts in x, we mainly have to compare solutions of the differential equations in different cells. A similar argument, although in a quite different situation, can be found in [7], which deals with the Neumann problem for rapidly oscillatory boundaries.

Verifying the compactness criteria requires the extension of u_ε^M into a neighborhood of Ω_ε^M. We construct the extension

$$\hat{u}_\varepsilon^M:(0,T)\times\mathbb{R}^{n-1}\times\,]-\varepsilon,\varepsilon[\,\to\mathbb{R}^m$$

as follows.

First, we extend u_ε^M by reflection with respect to the plane $\{(x_1,x_2,\dots,x_n):x_1=0\}$ to

$$\hat{u}_\varepsilon^M(t,x)=\begin{cases} u_\varepsilon^M(t,x), & (t,x)\in(0,T)\times\Omega_\varepsilon^M,\\ u_\varepsilon^M(t,-x_1,x_2,\dots,x_{n-1},x_n), & (t,-x_1,x_2,\dots,x_{n-1},x_n)\in(0,T)\times\Omega_\varepsilon^M.\end{cases}$$

Then we repeat this extension procedure with respect to the planes $\{(x_1,x_2,\dots,x_n):x_2=0\},\dots,\{(x_1,x_2,\dots,x_n):x_{n-1}=0\}$ and obtain the extension $\hat{u}_\varepsilon^M$ on the domain

$$(0,T)\times\hat{\Omega}_\varepsilon^M=(0,T)\times\,]-1,1[^{n-1}\times\,]-\varepsilon,\varepsilon[.$$

Now, we further extend $\hat{u}_\varepsilon^M$ by periodicity to $(0,T)\times\mathbb{R}^{n-1}\times\,]-\varepsilon,\varepsilon[$. Due to our extension procedure, we have that

$$\hat{u}_\varepsilon^M\in L^2((0,T),H^1_{per}(]-1,1[^{n-1},H^1(]-\varepsilon,\varepsilon[,\mathbb{R}^m)))$$

and

$$\|\hat{u}_\varepsilon^M\|_{L^2((0,T),H^1(\hat{\Omega}_\varepsilon^M,\mathbb{R}^m))} \le C\|u_\varepsilon^M\|_{L^2((0,T),H^1(\Omega_\varepsilon^M,\mathbb{R}^m))}.$$

In an analogous way, we extend $u_\varepsilon^\pm$ to $\hat{u}_\varepsilon^\pm$, satisfying

$$\hat{u}_\varepsilon^+ \in L^2((0,T), H^1_{per}(]-1,1[^{n-1}, H^1(]\varepsilon, H[,\mathbb{R}^m))),$$

$$\hat{u}_\varepsilon^- \in L^2((0,T), H^1_{per}(]-1,1[^{n-1}, H^1(]-H,-\varepsilon[,\mathbb{R}^m))).$$

We also define

$$\hat{S}_\varepsilon^\pm = \{x = (\bar{x}, x_n) : \bar{x} \in \,]-1,1[^{n-1}, x_n = \pm\varepsilon\}$$

and remark that the traces $\hat{u}_\varepsilon^\pm|_{\hat{S}_\varepsilon^\pm}$ are periodic with respect to $\bar{x}$ with period $]-1,1[^{n-1}$, and the continuity condition

$$\hat{u}_\varepsilon^M|_{\hat{S}_\varepsilon^\pm} = \hat{u}_\varepsilon^\pm|_{\hat{S}_\varepsilon^\pm}$$

holds. Let us now give the proof of Theorem 2.3.

Proof. We denote

$$\begin{aligned}
\delta\hat{u}_\varepsilon^M(t,x) &= \hat{u}_\varepsilon^M(t, x+(l,0)\varepsilon) - \hat{u}_\varepsilon^M(t,x),\\
\delta\hat{u}_\varepsilon^\pm(t,x) &= \hat{u}_\varepsilon^\pm(t, x+(l,0)\varepsilon) - \hat{u}_\varepsilon^\pm(t,x),\\
\delta g(t,x) &= g\left(\frac{x}{\varepsilon}, u_\varepsilon^M(t, x+(l,0)\varepsilon)\right) - g\left(\frac{x}{\varepsilon}, u_\varepsilon^M(t,x)\right)\\
\delta U_0^M(x) &= U_0^M\left(\bar{x}+l\varepsilon, \frac{x_n}{\varepsilon}\right) - U_0^M\left(\bar{x}, \frac{x_n}{\varepsilon}\right).
\end{aligned}$$

Now let $\delta v_\varepsilon = (\delta v_{1\varepsilon}, \dots, \delta v_{m\varepsilon})$ be the solution to the following problem:

$$\begin{aligned}
\frac{1}{\varepsilon}\partial_t(\delta v_{j\varepsilon})(t,x) - \varepsilon\nabla\left(D_j^M\left(\frac{x}{\varepsilon}\right)\nabla(\delta v_{j\varepsilon})(t,x)\right) &= 0 \quad \text{in } (0,T)\times\hat{\Omega}_\varepsilon^M,\\
\delta v_\varepsilon(t,x) &= \delta\hat{u}_\varepsilon^\pm(t,x) \quad \text{on } (0,T)\times\hat{S}_\varepsilon^\pm,\\
\delta v_\varepsilon(0,x) &= 0 \quad \text{in } \hat{\Omega}_\varepsilon^M\\
\delta v_\varepsilon \text{ is periodic with period } \ ]-1,1[^{n-1}.&
\end{aligned}$$

The following estimates hold:

$$\text{(5.5)}\quad \frac{1}{\sqrt{\varepsilon}}||\delta v_\varepsilon||_{L^\infty((0,T),L^2(\hat{\Omega}_\varepsilon^M,\mathbb{R}^m))} + \sqrt{\varepsilon}||\nabla(\delta v_\varepsilon)||_{L^2((0,T)\times\hat{\Omega}_\varepsilon^M,\mathbb{R}^m)} \le C,$$

$$\text{(5.6)}\quad \frac{1}{\sqrt{\varepsilon}}||\delta v_\varepsilon||_{L^2((0,T)\times\hat{\Omega}_\varepsilon^M,\mathbb{R}^m)} \le C(||\delta\hat{u}_\varepsilon^+||_{L^2((0,T)\times\hat{S}_\varepsilon^+,\mathbb{R}^m)} + ||\delta\hat{u}_\varepsilon^-||_{L^2((0,T)\times\hat{S}_\varepsilon^-,\mathbb{R}^m)}).$$

To prove (5.5), we test the equation for δv_ε with $\delta v_\varepsilon - \delta\hat{u}_\varepsilon^M$ and use the same techniques as in the first part the proof of Lemma 3.1, together with the a priori estimates for u_ε^M. For the proof of (5.6), we use the solution $h = (h_1, \dots, h_m)$ to the adjoint problem

$$\begin{aligned}
-\frac{1}{\varepsilon}\partial_t h_j(t,x) - \varepsilon\nabla(D_j^M(\frac{x}{\varepsilon})\nabla h_j(t,x)) &= \frac{1}{\varepsilon}\delta v_{j\varepsilon}(t,x) \quad \text{in } (0,T)\times\hat{\Omega}_\varepsilon^M,\\
h(t,x) &= 0 \quad \text{on } (0,T)\times\hat{S}_\varepsilon^\pm,\\
h(T,x) &= 0 \quad \text{in } \hat{\Omega}_\varepsilon^M,\\
h \text{ is periodic with period } \ ]-1,1[^{n-1}.&
\end{aligned}$$

Regularity theory for parabolic systems together with a scaling argument implies that $h \in L^2((0,T), H^2(\hat{\Omega}_\varepsilon^M, \mathbb{R}^m))$ and we have

$$
(5.7)\quad \frac{1}{\sqrt{\varepsilon}}||h_j||_{L^2((0,T)\times\hat{\Omega}_\varepsilon^M)} + \sqrt{\varepsilon}||\nabla h_j||_{L^2((0,T)\times\hat{\Omega}_\varepsilon^M,\mathbb{R}^n)} + \varepsilon\sqrt{\varepsilon}||\nabla^2 h_j||_{L^2((0,T)\times\hat{\Omega}_\varepsilon^M,\mathbb{R}^{n^2})} \leq \frac{C}{\sqrt{\varepsilon}}||\delta v_{j\varepsilon}||_{L^2((0,T)\times\hat{\Omega}_\varepsilon^M,\mathbb{R}^m)}.
$$

Let us now multiply the equation for h by $\delta v_{j\varepsilon}$ and integrate. We obtain

$$
\begin{aligned}
&\frac{1}{\varepsilon}\int_0^T\int_{\hat{\Omega}_\varepsilon^M}|\delta v_{j\varepsilon}|^2 dxdt \\
&= \int_0^T\int_{\hat{\Omega}_\varepsilon^M}\left(-\frac{1}{\varepsilon}\partial_t h_j - \varepsilon\nabla\left(D_j^M\left(\frac{x}{\varepsilon}\right)\nabla h_j\right)(\delta v_{j\varepsilon})\right)dxdt \\
&= \int_0^T\int_{\hat{\Omega}_\varepsilon^M}\frac{1}{\varepsilon}h_j\partial_t(\delta v_{j\varepsilon}) + \varepsilon D_j^M\left(\frac{x}{\varepsilon}\right)\nabla h_j\nabla(\delta v_{j\varepsilon})dxdt \\
&\quad - \varepsilon\int_0^T\int_{\hat{S}_\varepsilon^+}D_j^M\left(\frac{x}{\varepsilon}\right)\delta v_{j\varepsilon}\nabla h_j\cdot\nu dxdt - \varepsilon\int_0^T\int_{\hat{S}_\varepsilon^-}D_j^M\left(\frac{x}{\varepsilon}\right)\delta v_{j\varepsilon}\nabla h_j\cdot\nu dxdt.
\end{aligned}
$$

Now, using the problem for δv_ε and the fact that h is equal to zero on $(0,T)\times\hat{S}_\varepsilon^\pm$, we obtain

$$
\begin{aligned}
&\frac{1}{\varepsilon}||\delta v_{j\varepsilon}||^2_{L^2((0,T)\times\hat{\Omega}_\varepsilon^M)} \leq C\varepsilon||\delta v_{j\varepsilon}||_{L^2((0,T)\times\hat{S}_\varepsilon^+)}||\nabla h_j\cdot\nu||_{L^2((0,T)\times\hat{S}_\varepsilon^+)} \\
&\quad + C\varepsilon||\delta v_{j\varepsilon}||_{L^2((0,T)\times\hat{S}_\varepsilon^-)}||\nabla h_j\cdot\nu||_{L^2((0,T)\times\hat{S}_\varepsilon^-)} \\
&\leq C\varepsilon\left(\frac{1}{\sqrt{\varepsilon}}||\nabla h_j\cdot\nu||_{L^2((0,T)\times\hat{\Omega}_\varepsilon^M,\mathbb{R}^n)} + \sqrt{\varepsilon}||\nabla(\nabla h_j\cdot\nu)||_{L^2((0,T)\times\hat{\Omega}_\varepsilon^M,\mathbb{R}^{n^2})}\right) \\
&\quad \times(||\delta v_{j\varepsilon}||_{L^2((0,T)\times\hat{S}_\varepsilon^+)} + ||\delta v_{j\varepsilon}||_{L^2((0,T)\times\hat{S}_\varepsilon^-)}).
\end{aligned}
$$

For the last inequality, we used the trace estimate for the thin domain $\hat{\Omega}_\varepsilon^M$ given in Lemma 5.1. The estimate (5.7) and the boundary condition for δv_ε on $\hat{S}_\varepsilon^\pm$ imply the assertion (5.6).

Let us now consider the function $\delta w_\varepsilon = (\delta w_{1\varepsilon}, \dots, \delta w_{m\varepsilon})$ defined by

$$
\delta w_\varepsilon(t,x) = \delta\hat{u}_\varepsilon^M(t,x) - \delta v_\varepsilon(t,x).
$$

In order to avoid the boundary values of δw_ε on the lateral boundary of Ω_ε^M, we will cut off this part of the boundary and estimate $\frac{1}{\sqrt{\varepsilon}}||\delta w_\varepsilon||_{L^2((0,T)\times\Omega_{2h}^M,\mathbb{R}^m)}$, where

$$
(5.8)\qquad \Omega_{2h}^M = \{x\in\Omega_\varepsilon^M : 2h < x_i < 1-2h,\ i = 1,\dots,n-1\}.
$$

Defining Ω_h^M and $S_h^\pm$ analogously to (5.8), we have that δw_ε satisfies

$$
\begin{aligned}
\frac{1}{\varepsilon}\partial_t(\delta w_{j\varepsilon})(t,x) - \varepsilon\nabla\left(D_j^M\left(\frac{x}{\varepsilon}\right)\nabla(\delta w_{j\varepsilon})(t,x)\right) &= \frac{1}{\varepsilon}\delta g_j(t,x) && \text{in } (0,T)\times\Omega_h^M, \\
(\delta w_\varepsilon)(t,x) &= 0 && \text{on } (0,T)\times S_h^\pm, \\
(\delta w_\varepsilon)(0,x) &= \delta U_0^M(x) && \text{in } \Omega_h^M.
\end{aligned}
$$

Now, we test the equation for δw_ε with a function which vanishes on the lateral boundary of Ω_ε^M. We consider the following cut-off function $\varphi \in C_0^\infty((h, 1-h)^{n-1}, C^\infty(]-\varepsilon, \varepsilon[, [0,1]))$ with the properties

$$\varphi \equiv 1 \quad \text{in } \Omega_{2h}^M, \quad ||\nabla\varphi||_{L^\infty(\Omega_h^M)} \leq \frac{C}{h}.$$

Multiplying the equation for $\delta w_{j\varepsilon}$ by $\delta w_{j\varepsilon}\varphi^2$ and integrating over Ω_h^M, we obtain

$$\frac{1}{\varepsilon}\int_{\Omega_h^M} \partial_t(\delta w_{j\varepsilon})\delta w_{j\varepsilon}\varphi^2 + \varepsilon\int_{\Omega_h^M} D_j^M\left(\frac{x}{\varepsilon}\right)\nabla(\delta w_{j\varepsilon})\nabla(\delta w_{j\varepsilon})\varphi^2 \tag{5.9}$$

$$+\,\varepsilon\int_{\Omega_h^M} D_j^M\left(\frac{x}{\varepsilon}\right)\nabla(\delta w_{j\varepsilon})\delta w_{j\varepsilon}2\varphi\nabla\varphi = \frac{1}{\varepsilon}\int_{\Omega_h^M}\delta g_j\delta w_{j\varepsilon}\varphi^2. \tag{5.10}$$

Integration with respect to time and the Lipschitz continuity of g in the second argument imply

$$\begin{aligned}
&\frac{1}{\varepsilon}\int_{\Omega_h^M}|\delta w_{j\varepsilon}(t)|^2\varphi^2 + \varepsilon\int_0^t\int_{\Omega_h^M}|\nabla(\delta w_{j\varepsilon})|^2\varphi^2 \\
&\leq \frac{C}{\varepsilon}\left(\int_0^t\int_{\Omega_h^M}|\delta u_{j\varepsilon}^M||\delta w_{j\varepsilon}|\varphi^2 + \int_{\Omega_h^M}|\delta U_{j0}^M|^2\varphi^2\right) \\
&+ C\left(\eta\varepsilon\int_0^t\int_{\Omega_h^M}|\nabla(\delta w_{j\varepsilon})\varphi|^2 + \frac{1}{\eta}\varepsilon\int_0^t\int_{\Omega_h^M}|\delta w_{j\varepsilon}|^2|\nabla\varphi|^2\right).
\end{aligned}\tag{5.11}$$

Let us now estimate the last term on the right-hand side of (5.11). Since $\varphi \equiv 1$ in Ω_{2h}^M, the support of $\nabla\varphi$ is contained in the domain

$$T_h^M := \Omega_h^M \setminus \Omega_{2h}^M.$$

Using the estimate for $\nabla\varphi$ and Poincaré's inequality (since $\delta w_\varepsilon|_{S_\varepsilon^\pm} = 0$), we have

$$\begin{aligned}
&\varepsilon\int_0^t\int_{T_h^M}|\delta w_{j\varepsilon}|^2|\nabla\varphi|^2 \leq \frac{C\varepsilon}{h^2}\int_0^t\int_{T_h^M}|\delta w_{j\varepsilon}|^2 \\
&\leq \frac{C\varepsilon^3}{h^2}\int_0^t\int_{T_h^M}|\nabla(\delta w_{j\varepsilon})|^2 \leq \frac{C\varepsilon^3}{h^2}\int_0^t\int_{T_h^M}|\nabla(\delta\hat{u}_{j\varepsilon}^M)|^2 + |\nabla(\delta v_{j\varepsilon})|^2) \\
&\leq \frac{C\varepsilon^2}{h^2}.
\end{aligned}\tag{5.12}$$

For the last inequality, we used the a priori estimates for u_ε^M and the estimate (5.5) for δv_ε.

Going back to relation (5.11), taking η small enough, and using the estimate (5.12) and the fact that $\delta u_\varepsilon^M = \delta v_\varepsilon + \delta w_\varepsilon$, we get

$$\begin{aligned}
&\frac{1}{\varepsilon}\int_{\Omega_h^M}|\delta w_{j\varepsilon}(t)|^2\varphi^2 + \varepsilon\int_0^t\int_{\Omega_h^M}|\nabla(\delta w_{j\varepsilon})|^2\varphi^2 \\
&\leq \frac{C}{\varepsilon}\left(\int_0^t\int_{\Omega_h^M}(|\delta u_{j\varepsilon}^M|^2 + |\delta w_{j\varepsilon}|^2)\varphi^2 + \int_{\Omega_h^M}|\delta U_{j0}^M|^2\varphi^2\right) + \frac{C\varepsilon^2}{h^2} \\
&\leq \frac{C}{\varepsilon}\left(\int_0^t\int_{\Omega_h^M}(|\delta v_{j\varepsilon}|^2 + |\delta w_{j\varepsilon}|^2)\varphi^2 + \int_{\Omega_h^M}|\delta U_{j0}^M|^2\varphi^2\right) + \frac{C\varepsilon^2}{h^2}.
\end{aligned}\tag{5.13}$$

Finally, Gronwall's lemma implies the estimate

$$\frac{1}{\varepsilon}||\delta w_{j\varepsilon}\varphi||^2_{L^2((0,T)\times\Omega_h^M)} \leq \frac{C}{\varepsilon}||\delta v_{j\varepsilon}\varphi||^2_{L^2((0,T)\times\Omega_h^M)} + \frac{C}{\varepsilon}||\delta U_{j0}^M\varphi||^2_{L^2(\Omega_h^M)} + \frac{C\varepsilon^2}{h^2}. \tag{5.14}$$

Now, it remains to estimate $\frac{1}{\sqrt{\varepsilon}}||\delta u_\varepsilon^M||_{L^2((0,T)\times(\Omega_\varepsilon^M\setminus\Omega_{2h}^M),\mathbb{R}^m)}$. For this estimate, we will exploit the fact that the domain $\Omega_\varepsilon^M\setminus\Omega_{2h}^M$ can be decomposed in subdomains which have thickness $O(h)$ at least in one space direction. Using the L^∞-estimate (3.4), we obtain

$$\frac{1}{\sqrt{\varepsilon}}\left\{\int_0^T\int_{\Omega_\varepsilon^M\setminus\Omega_{2h}^M}|u_{j\varepsilon}^M|^2\right\}^{\frac{1}{2}} \leq \frac{M_j e^{A_j T}}{\sqrt{\varepsilon}}\left\{\int_0^T\int_{\Omega_\varepsilon^M\setminus\Omega_{2h}^M}dxdt\right\}^{\frac{1}{2}} \leq Ch^{\frac{1}{2}}. \tag{5.15}$$

The estimates (5.6), (5.14), and (5.15) imply the estimate (2.22) from the first part of the theorem.

To prove the strong two-scale convergence for u_ε^M, we will show that

$$L_\varepsilon u_\varepsilon^M \to u_0^M \quad \text{strongly in} \quad L^2((0,T)\times\Sigma\times Z,\mathbb{R}^m).$$

We first show that for all $\rho > 0$, there exists $\delta > 0$, such that for all $\varepsilon \leq \varepsilon_0$

$$||L_\varepsilon\hat{u}_\varepsilon^M(t,\bar{x}+\bar{\xi},y) - L_\varepsilon\hat{u}_\varepsilon^M(t,\bar{x},y)||^2_{L^2((0,T)\times\Sigma\times Z,\mathbb{R}^m)} < \rho \tag{5.16}$$

for all $\bar{\xi}\in\mathbb{R}^{n-1}, |\bar{\xi}| < \delta$.

Let $I \subset \mathbb{Z}^{n-1}$, such that

$$\Sigma = \sum_{i\in I}\varepsilon(Y+i) =: \sum_{i\in I}\varepsilon Y_i.$$

Obviously, for $\bar{x}\in\varepsilon Y_i$ we have that $\left[\frac{\bar{x}}{\varepsilon}\right] = i$. For every $i \in I$ we divide the cell εY_i into subsets εY_i^k with $k\in\{0,1\}^{n-1}$, defined as follows:

$$\varepsilon Y_i^k = \left\{\bar{x}\in\varepsilon Y_i, \left[\frac{\bar{x}+\left\{\frac{\bar{\xi}}{\varepsilon}\right\}\varepsilon}{\varepsilon}\right]\varepsilon = \varepsilon(i+k)\right\}.$$

Then $\varepsilon Y_i = \bigcup_{k\in\{0,1\}^{n-1}}\varepsilon Y_i^k$. In Figure 5.1, we sketch the subsets εY_i^k of εY_i in the case $n = 3$, $Y = [0,1]^2$ and the translation $\bar{\xi}$ is of the form $\bar{\xi} = (\xi_1, 0),\ \xi_1 > 0$.

Now, let us calculate

$$\begin{aligned}
&||L_\varepsilon\hat{u}_{j\varepsilon}^M(t,\bar{x}+\bar{\xi},y) - L_\varepsilon\hat{u}_{j\varepsilon}^M(t,\bar{x},y)||^2_{L^2((0,T)\times\Sigma\times Z)}\\
&= \sum_{i\in I}\int_0^T\int_{\varepsilon Y_i}\int_Z\left|\hat{u}_{j\varepsilon}^M\left(t,\varepsilon\left(\left[\frac{\bar{x}+\bar{\xi}}{\varepsilon}\right],0\right)+\varepsilon y\right) - \hat{u}_{j\varepsilon}^M\left(t,\varepsilon\left(\left[\frac{\bar{x}}{\varepsilon}\right],0\right)+\varepsilon y\right)\right|^2 dyd\bar{x}dt\\
&= \sum_{i\in I}\sum_{k\in\{0,1\}^{n-1}}\int_0^T\int_{\varepsilon Y_i^k}\int_Z\left|\hat{u}_{j\varepsilon}^M\left(t,\varepsilon\left(i+\left[\frac{\bar{\xi}}{\varepsilon}\right]+k,0\right)+\varepsilon y\right) - \hat{u}_{j\varepsilon}^M\left(t,\varepsilon(i,0)+\varepsilon y\right)\right|^2 dyd\bar{x}dt\\
&\leq \sum_{i\in I}\sum_{k\in\{0,1\}^{n-1}}\int_0^T\int_{\varepsilon Y_i}\int_Z\left|\hat{u}_{j\varepsilon}^M\left(t,\varepsilon\left(i+\left[\frac{\bar{\xi}}{\varepsilon}\right]+k,0\right)+\varepsilon y\right) - \hat{u}_{j\varepsilon}^M\left(t,\varepsilon(i,0)+\varepsilon y\right)\right|^2 dyd\bar{x}dt\\
&= \sum_{k\in\{0,1\}^{n-1}}\frac{1}{\varepsilon}\int_0^T\int_{\Omega_\varepsilon^M}\left|\hat{u}_{j\varepsilon}^M\left(t,x+\varepsilon\left(\left[\frac{\bar{\xi}}{\varepsilon}\right]+k,0\right)\right) - \hat{u}_{j\varepsilon}^M(t,x)\right|^2 dxdt.
\end{aligned}$$

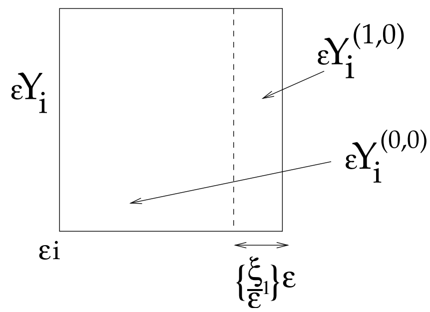

FIG. 5.1. *The subsets* εY_i^k *for* $\bar{\xi} = (\xi_1, 0)$, $\xi_1 > 0$.

Let us fix $h \in \left(0, \min\left\{\frac{1}{4}, \frac{\rho}{3}\frac{1}{2^{(n-1)}C}\right\}\right)$, where C is the constant in the estimate (2.22). Let δ_1 and ε_1 be such that for $|\bar{\xi}| < \delta_1$ and $\varepsilon < \varepsilon_1$ we have

$$\left| \left[\frac{\bar{\xi}}{\varepsilon}\right] \varepsilon + k\varepsilon \right| < h.$$

Then we can apply the first part of the theorem to estimate

$$\begin{aligned}
&\sum_{k\in\{0,1\}^{n-1}} \frac{1}{\varepsilon}\int_0^T \int_{\Omega_\varepsilon^M} \left| \hat{u}_{j\varepsilon}^M \left(t, x + \varepsilon\left(\left[\frac{\bar{\xi}}{\varepsilon}\right] + k, 0\right)\right) - \hat{u}_{j\varepsilon}^M(t,x)\right|^2 dxdt \\
\leq \quad & \sum_{k\in\{0,1\}^{n-1}} C \left\| \hat{u}_\varepsilon^+ \left(t, x + \varepsilon\left(\left[\frac{\bar{\xi}}{\varepsilon}\right] + k, 0\right)\right) - \hat{u}_\varepsilon^+(t,x)\right\|^2_{L^2((0,T)\times \hat{S}_\varepsilon^+, \mathbb{R}^m)} \\
+ & \sum_{k\in\{0,1\}^{n-1}} C \left\| \hat{u}_\varepsilon^- \left(t, x + \varepsilon\left(\left[\frac{\bar{\xi}}{\varepsilon}\right] + k, 0\right)\right) - \hat{u}_\varepsilon^-(t,x)\right\|^2_{L^2((0,T)\times \hat{S}_\varepsilon^-, \mathbb{R}^m)} \\
+ & \sum_{k\in\{0,1\}^{n-1}} \frac{C}{\varepsilon} \left\| \hat{U}_0^M \left(\bar{x} + \varepsilon\left(\left[\frac{\bar{\xi}}{\varepsilon}\right] + k\right), \frac{x_n}{\varepsilon}\right) - \hat{U}_0^M\left(\bar{x}, \frac{x_n}{\varepsilon}\right)\right\|^2_{L^2(\hat{\Omega}_\varepsilon^M, \mathbb{R}^m)} \\
+ & \sum_{k\in\{0,1\}^{n-1}} C\left\{\frac{\varepsilon^2}{h^2} + h\right\}.
\end{aligned} \tag{5.17}$$

The properties of the initial concentration U_0^M ensure that $\hat{U}_0^M$ is a function in H^1 on the rescaled domain obtained from $\hat{\Omega}_\varepsilon^M$, and thus it satisfies the Kolmogorov criterion. This fact and the strong convergence of the traces of $u_\varepsilon^\pm$ on $S_\varepsilon^\pm$ from Proposition 2.2 imply that there exists $\delta^* > 0$, such that the sum over the differences of the boundary values and of the initial values in (5.17) is smaller than $\frac{\rho}{3}$ for

$$\left| \left[\frac{\bar{\xi}}{\varepsilon}\right] \varepsilon + k\varepsilon \right| < \delta^*.$$

This condition is fulfilled for all $\bar{\xi} = (\xi_1, \dots, \xi_{n-1}) \in \mathbb{R}^{n-1}$, such that $|\xi_i| < \frac{\delta^*}{2\sqrt{n-1}}$ for $i = 1, \dots, n-1$ and all $\varepsilon < \frac{\delta^*}{2\sqrt{n-1}}$.

Now, we set $\delta_2 = \min\{\delta_1, \frac{\delta^*}{2\sqrt{n-1}}\}$. Then, for all $\bar{\xi}$ with $|\bar{\xi}| < \delta_2$ and all $\varepsilon < \varepsilon_2 = \min\{\varepsilon_0, \varepsilon_1, \frac{\delta^*}{2\sqrt{n-1}}, \sqrt{\frac{\rho}{3C\cdot 2^{n-1}}}h\}$, we have that

$$||L_\varepsilon \hat{u}_\varepsilon^M(t, \bar{x} + \bar{\xi}, y) - L_\varepsilon \hat{u}_\varepsilon^M(t, \bar{x}, y)||_{L^2((0,T)\times\Sigma\times Z, \mathbb{R}^m)} < \rho. \tag{5.18}$$

For $\varepsilon \in (\varepsilon_2, \varepsilon_0)$, the estimate (5.16) holds for every ε if $|\bar{\xi}| < \delta(\varepsilon)$ due to the continuity in the mean of L^2-functions. Since we consider sequences ε of the form $\varepsilon_k = \frac{1}{k}$, $k \in \mathbb{N}$, there are finitely many elements ε_k in the interval $(\varepsilon_2, \varepsilon_0)$. Thus choosing

$$\delta = \min\left\{\delta_2, \delta(\varepsilon_k), \varepsilon_k \in (\varepsilon_2, \varepsilon_0)\right\},$$

the property (5.16) is proved.

In addition, for $L_\varepsilon u_\varepsilon^M$ the following conditions are satisfied:

$$||\nabla_y L_\varepsilon u_\varepsilon^M||_{L_2((0,T)\times\Sigma\times Z,\mathbb{R}^m)} = \sqrt{\varepsilon}||\nabla u_\varepsilon^M||_{L_2((0,T)\times\Omega_\varepsilon^M,\mathbb{R}^m)} \leq C, \tag{5.19}$$

$$||\partial_t L_\varepsilon u_\varepsilon^M||_{L_2((0,T)\times\Sigma\times Z,\mathbb{R}^m)} = \frac{1}{\sqrt{\varepsilon}}||\partial_t u_\varepsilon^M||_{L_2(0,T)\times\Omega_\varepsilon^M,\mathbb{R}^m)} \leq C. \tag{5.20}$$

The conditions (5.16), (5.19), and (5.20) imply that the Kolmogorov criterion for $L_\varepsilon u_\varepsilon^M$ holds true in $L_2((0,T)\times\Sigma\times Z,\mathbb{R}^m)$. This concludes the proof of our theorem. $\square$

LEMMA 5.1. *For $u_\varepsilon \in H^1(\Omega_\varepsilon^M)$, the following trace estimate holds:*

$$||u_\varepsilon||_{L^2(S_\varepsilon^+\cup S_\varepsilon^-)} \leq C\left(\frac{1}{\sqrt{\varepsilon}}||u_\varepsilon||_{L^2(\Omega_\varepsilon^M)} + \sqrt{\varepsilon}||\nabla u_\varepsilon||_{L^2(\Omega_\varepsilon^M)}\right). \tag{5.21}$$

Proof. The proof follows by a scaling argument and by the standard trace estimate for H^1-functions. $\square$

6. Derivation of the macroscopic model. Using the convergence results proved in section 5, we are able to pass to the limit in the weak formulation of the microscopic problem.

6.1. Derivation of the equations in the bulk. First, we derive the macroscopic problem satisfied by the limit functions $u_0^\pm$.

Proof. Let us consider test functions $\varphi^\pm \in C_0^\infty((0,T)\times\Omega,\mathbb{R}^m)$ with

$$\operatorname{supp}\varphi^\pm \subset (0,T)\times\Omega^\pm.$$

Choose ε_0 such that

$$\min\left\{\operatorname{dist}\{\Sigma, \operatorname{supp}\varphi^+\},\ \operatorname{dist}\{\Sigma, \operatorname{supp}\varphi^-\}\right\} \geq \varepsilon_0. \tag{6.1}$$

Then for every $\varepsilon < \varepsilon_0$ we have

$$\operatorname{supp}\varphi^\pm \cap \Omega_\varepsilon^M = \emptyset.$$

Testing now (2.16) with φ^+ and φ^-, we obtain

$$\begin{aligned}&\int_0^T\int_{\Omega_\varepsilon^\pm}\partial_t u_{j\varepsilon}^\pm(t,x)\varphi_j^\pm(t,x)dx\,dt + D_j^\pm\int_0^T\int_{\Omega_\varepsilon^\pm}\nabla u_{j\varepsilon}^\pm(t,x)\nabla\varphi_j^\pm(t,x)dx\,dt\\ &= \int_0^T\int_{\Omega_\varepsilon^\pm} f_j(x,u_\varepsilon^\pm(t,x))\varphi_j^\pm(t,x)dx\,dt.\end{aligned} \tag{6.2}$$

For $\varepsilon \to 0$ the terms on the left-hand side converge due to the weak compactness results from Proposition 2.1. The convergence of the right-hand side follows due to the following argument: By Proposition 2.1

$$\chi_{\Omega_\varepsilon^\pm} u_{j\varepsilon} \to u_{j0}^\pm \quad \text{strongly in } L^2((0,T), L^2(\Omega^\pm)),$$

and there exists a subsequence, again denoted by $u_\varepsilon^\pm$, such that

$$\chi_{\Omega_\varepsilon^\pm} u_{j\varepsilon} \to u_{j0}^\pm \quad \text{a.e. in } (0,T) \times \Omega^\pm.$$

Then the continuity of f implies

$$f(\cdot, \chi_{\Omega_\varepsilon^\pm} u_\varepsilon(\cdot,\cdot)) \to f(\cdot, u_0^\pm(\cdot,\cdot)) \quad \text{a.e. in } (0,T) \times \Omega^\pm.$$

On the other hand, from the growth conditions (2.5) and the a priori estimates on $u_\varepsilon^\pm$, we have

$$\begin{aligned} &||f_j(\cdot, \chi_{\Omega_\varepsilon^\pm} u_\varepsilon(\cdot,\cdot))||^2_{L^2((0,T)\times\Omega^\pm)} = \int_0^T \int_{\Omega^\pm} |f_j(x, \chi_{\Omega_\varepsilon^\pm} u_\varepsilon(t,x))|^2 dx\, dt \\ &\leq \int_0^T \int_{\Omega^\pm} C(1 + |\chi_{\Omega_\varepsilon^\pm} u_\varepsilon(t,x)|^2) dx\, dt \leq C. \end{aligned}$$

Thus,

$$f_j(\cdot, \chi_{\Omega_\varepsilon^\pm} u_\varepsilon(\cdot,\cdot)) \to f_j(\cdot, u_0^\pm(\cdot,\cdot)) \quad \text{weakly in } L^2((0,T)\times\Omega^\pm).$$

Now, taking the limit $\varepsilon \to 0$ in (6.2), we obtain

$$\begin{aligned} &\int_0^T \int_{\Omega^\pm} \partial_t u_{j0}^\pm(t,x) \varphi_j^\pm(t,x) dx\, dt + D_j^\pm \int_0^T \int_{\Omega^\pm} \nabla u_{j0}^\pm(t,x) \nabla \varphi_j^\pm(t,x) dx\, dt \\ &= \int_0^T \int_{\Omega^\pm} f_j(x, u_0^\pm(t,x)) \varphi_j^\pm(t,x) dx\, dt, \end{aligned}$$

which is exactly the variational formulation for equations (2.23) and (2.24). The Dirichlet boundary condition can be deduced very easily, since $u_\varepsilon^\pm|_{\partial_D\Omega^\pm} = u_D^\pm|_{\partial_D\Omega^\pm}$. The Neumann boundary conditions are obtained by testing (2.16) with test functions $\varphi^\pm \in C_0^\infty((0,T), C^\infty(\Omega, \mathbb{R}^m))$ with $\operatorname{supp} \varphi^\pm \subset (0,T) \times \{\Omega^\pm \cup \partial_N \Omega^\pm\}$ and by repeating the arguments from the first part of the proof.

It remains to derive the initial conditions for $u_0^\pm$. Thus, let us consider $\varphi^\pm \in C_0^\infty(\Omega^\pm, \mathbb{R}^m)$ and again choose $\varepsilon_0 > 0$ as in (6.1). Then let $\xi \in C^\infty([0,T])$, such that $\xi(T) = 0$. Then for every $\varepsilon < \varepsilon_0$ we have

$$\begin{aligned} \int_0^T \int_{\Omega_\varepsilon^\pm} \partial_t u_{j\varepsilon}^\pm(t,x) \varphi_j^\pm(x) \xi(t)\, dx\, dt = &- \int_{\Omega_\varepsilon^\pm} U_{j0}(x) \varphi_j^\pm(x) \xi(0)\, dx \\ &- \int_0^T \int_{\Omega_\varepsilon^\pm} u_{j\varepsilon}^\pm(t,x) \varphi_j^\pm(x) \partial_t \xi(t)\, dx\, dt. \end{aligned}$$

Proposition 2.1 and the choice of our test function allow us to pass to the limit for $\varepsilon \to 0$ and to obtain

$$\begin{aligned} \int_0^T \int_{\Omega^\pm} \partial_t u_{j0}^\pm \varphi_j^\pm(x) \xi(t)\, dx\, dt = &- \int_{\Omega^\pm} U_{j0}(x) \varphi_j^\pm(x) \xi(0)\, dx \\ &- \int_0^T \int_{\Omega^\pm} u_{j0}^\pm(t,x) \varphi_j^\pm(x) \partial_t \xi(t)\, dx\, dt, \end{aligned}$$

which is equivalent to the initial conditions (2.27). $\square$

6.2. Derivation of the local equations in the layer. We now derive the local problem for the limit function u_0^M which enters the transmission conditions.

Proof. We start from the weak formulation (2.16) and use as test function

$$\varphi^\varepsilon(t,x) = \begin{cases} 0, \ (t,x) \in (0,T) \times (\Omega_\varepsilon^+ \cup \Omega_\varepsilon^-), \\ \varphi(t,\bar{x},\frac{x}{\varepsilon}), \ (t,x) \in (0,T) \times \Omega_\varepsilon^M, \end{cases}$$

where $\varphi \in \left\{ C_0^\infty((0,T)\times\Sigma, C_{per}^\infty(Y, C_0^\infty(]-1,1[))) \right\}^m$. Thus, we obtain

$$\begin{aligned} &\frac{1}{\varepsilon}\int_0^T \int_{\Omega_\varepsilon^M} \partial_t u_{j\varepsilon}^M \, \varphi_j\left(t,\bar{x},\frac{x}{\varepsilon}\right) dx\,dt \\ &+\frac{1}{\varepsilon}\int_0^T \int_{\Omega_\varepsilon^M} D_j^M\left(\frac{x}{\varepsilon}\right) \varepsilon \nabla u_{j\varepsilon}^M \left(\varepsilon \nabla_{\bar{x}}\varphi_j\left(t,\bar{x},\frac{x}{\varepsilon}\right) + \nabla_y \varphi_j\left(t,\bar{x},\frac{x}{\varepsilon}\right)\right) dx\,dt \\ &= \frac{1}{\varepsilon}\int_0^T \int_{\Omega_\varepsilon^M} g_j\left(\frac{x}{\varepsilon}, u_\varepsilon^M\right)\varphi_j\left(t,\bar{x},\frac{x}{\varepsilon}\right) dx\,dt. \end{aligned} \tag{6.3}$$

Using the weak two-scale convergence properties from Proposition 2.1, we can pass to the limit for $\varepsilon \to 0$ on the left-hand side of the equation above. In order to pass to the limit in the nonlinear term on the right-hand side, we have to use the strong two-scale convergence given in Theorem 2.3 to show that

$$g_j\left(\frac{\cdot}{\varepsilon}, u_\varepsilon^M\right) \overset{t.s.}{\to} g_j(y, u_0^M) \quad \text{weakly in the two-scale sense.}$$

Thus, let us consider

$$\begin{aligned} L_\varepsilon\left[g_j\left(\frac{\cdot}{\varepsilon}, u_\varepsilon^M\right)\right](t,\bar{x},y) &= g_j\left(\frac{(c_\varepsilon(\bar{x})+\varepsilon\bar{y},\varepsilon y_n)}{\varepsilon}, u_\varepsilon^M(t,(c_\varepsilon(\bar{x})+\varepsilon\bar{y},\varepsilon y_n))\right) \\ &= g_j(y, L_\varepsilon u_\varepsilon^M(t,\bar{x},y)). \end{aligned}$$

Since g is continuous and $L_\varepsilon u_\varepsilon^M$ converges strongly to u_0^M in $L^2((0,T)\times\Sigma\times Z,\mathbb{R}^m)$, we have that

$$g_j(\cdot, L_\varepsilon u_\varepsilon^M) \longrightarrow g_j(\cdot, u_0^M) \quad \text{a.e. in } (0,T)\times\Sigma\times Z.$$

From the growth conditions (2.6) and the a priori estimates on u_ε^M we obtain

$$\begin{aligned} ||g_j(\cdot, L_\varepsilon u_\varepsilon^M)||_{L^2((0,T)\times\Sigma\times Z)} &= \int_0^T \int_\Sigma \int_Z |g_j(y, u_\varepsilon^M(t,(c_\varepsilon(\bar{x})+\varepsilon\bar{y},\varepsilon y_n)))|^2 dy d\bar{x} dt \\ &\le C \int_0^T \int_\Sigma \int_Z 1 + |u_\varepsilon^M(t,(c_\varepsilon(\bar{x})+\varepsilon\bar{y},\varepsilon y_n))|^2 dy d\bar{x} dt \\ &\le C_1 + \frac{C_2}{\varepsilon}||u_\varepsilon^M||^2_{L^2((0,T)\times\Omega_\varepsilon^M,\mathbb{R}^m)} \le C. \end{aligned} \tag{6.4}$$

Thus,

$$g_j(\cdot, L_\varepsilon u_\varepsilon^M) \longrightarrow g_j(\cdot, u_0^M) \quad \text{weakly in } L^2((0,T)\times\Sigma\times Z).$$

This now implies that

$$L_\varepsilon\left[g_j\left(\frac{\cdot}{\varepsilon}, u_\varepsilon^M\right)\right] \to g_j(\cdot, u_0^M) \quad \text{weakly in } L^2((0,T)\times\Sigma\times Z),$$

and by Theorem 4.7 it follows that

$$g_j\left(\frac{\cdot}{\varepsilon}, u_\varepsilon^M\right) \stackrel{t.s.}{\to} g_j(y, u_0^M) \quad \text{weakly in the two-scale sense.}$$

Thus, we can pass to the limit in (6.3) and obtain

$$\begin{aligned} \int_0^T \int_\Sigma \int_Z \partial_t u_{j0}^M(t,\bar{x},y)\varphi_j(t,\bar{x},y)\,dy\,d\bar{x}\,dt \\ + \int_0^T \int_\Sigma \int_Z D_j^M(y)\nabla_y u_{j0}^M(t,\bar{x},y)\nabla_y\varphi_j(t,\bar{x},y)\,dy\,d\bar{x}\,dt \\ = \int_0^T \int_\Sigma \int_Z g_j(y, u_0^M(t,\bar{x},y))\varphi_j(t,\bar{x},y)\,dy\,d\bar{x}\,dt. \end{aligned} \tag{6.5}$$

This is just the weak formulation of (2.30). The boundary conditions have already been proved in Proposition 2.1; see (2.19). It remains to prove the initial condition for u_0^M. We will proceed as in section 6.1.

Let $\varphi \in \{C_0^\infty(\Sigma, C_{per}(Y, C_0^\infty(]-1,1[)))\}^m$ and $\xi \in C^\infty([0,T])$ such that $\xi(T) = 0$. Then the following relation holds:

$$\begin{aligned} \frac{1}{\varepsilon}\int_0^T \int_{\Omega_\varepsilon^M} \partial_t u_{j\varepsilon}^M(t,x)\varphi_j\left(\bar{x},\frac{x}{\varepsilon}\right)\xi(t)\,dx\,dt = -\frac{1}{\varepsilon}\int_{\Omega_\varepsilon^M} U_{j0}^M\left(\bar{x},\frac{x_n}{\varepsilon}\right)\varphi_j\left(\bar{x},\frac{x}{\varepsilon}\right)\xi(0)\,dx \\ -\frac{1}{\varepsilon}\int_0^T \int_{\Omega_\varepsilon^M} u_{j\varepsilon}^M(t,x)\varphi_j\left(\bar{x},\frac{x}{\varepsilon}\right)\partial_t\xi(t)\,dx\,dt. \end{aligned}$$

Using the convergence results from Proposition 2.1 together with Lemma 4.3, we can pass to the limit for $\varepsilon \to 0$ and obtain

$$\begin{aligned} \int_0^T \int_\Sigma \int_Z \partial_t u_{j0}^M(t,\bar{x},y)\varphi(\bar{x},y)\xi(t)\,dy\,d\bar{x}\,dt = -\int_\Sigma \int_Z U_{j0}^M(\bar{x},y_n)\varphi_j(\bar{x},y)\xi(0)\,dy\,d\bar{x} \\ -\int_0^T \int_\Sigma \int_Z u_{j0}^M(t,\bar{x},y)\varphi_j(\bar{x},y)\partial_t\xi(t)\,dy\,d\bar{x}\,dt, \end{aligned}$$

which immediately implies the initial conditions (2.33) for the local problem. ∎

6.3. Derivation of the transmission conditions across Σ. Measurements and experiments indicate jumps of the concentrations and their normal derivatives across the interface Σ. We derive formulas for these jumps which involve the solutions of the local cell problems. Thus, the jumps become computable.

DEFINITION 6.1. *For $u \in L^2((0,T)\times\Omega,\mathbb{R}^m)$ with $u^\pm \in L^2((0,T), H^1(\Omega^\pm,\mathbb{R}^m))$, the jump of u across Σ is defined as*

$$[u]_\Sigma(t,\bar{x}) = u^+(t,\bar{x},0) - u^-(t,\bar{x},0), \quad (t,\bar{x}) \in (0,T)\times\Sigma.$$

To find a relation for the jump in the concentrations, we use the boundary layer function constructed below.

Consider the Hilbert space

$$V = \{\varphi \in H^1(Z,\mathbb{R}^m), \varphi \text{ periodic in } Y, \varphi \equiv \text{ const on } S^+ \cup S^-\}.$$

Find $\eta \in V$ such that

$$\frac{1}{|Z|}\int_Z \eta(y)\,dy = 0 \tag{6.6}$$

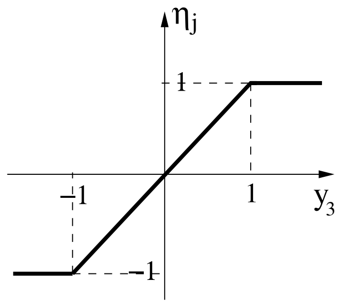

FIG. 6.1. *The boundary layer $\eta_j(y)$ for $D_j(y) \equiv 1$.*

and, for all $\varphi \in V$,

$$\int_Z D_j^M(y)\nabla\eta_j(y)\nabla\varphi_j(y)\,dy = \int_{S^+}\varphi_j(y)\,ds - \int_{S^-}\varphi_j(y)\,ds. \tag{6.7}$$

Since the right-hand side of (6.7) defines a linear, continuous functional on V, the Lax–Milgram lemma implies the existence of a unique solution $\eta \in V$ to problem (6.7) with (6.6). The strong formulation for the problem for η is given as follows: Find $\eta \in V$ with $\frac{1}{|Z|}\int_Z \eta(y)\,dy = 0$ such that

$$\nabla_y(D_j^M(y)\nabla_y\eta_j(y)) = 0, \quad y \in Z, \tag{6.8}$$

$$\int_{S^+} D_j^M(y)\partial_n\eta_j(y)\,dy = 1, \tag{6.9}$$

$$-\int_{S^-} D_j^M(y)\partial_n\eta_j(y)\,dy = -1. \tag{6.10}$$

In the case $D_j^M(y) \equiv 1$, the function η is given by (see Figure 6.1)

$$\eta_j(y) = y_n, \quad j = 1, \dots, m.$$

We denote

$$\eta^\pm \in \mathbb{R}^m \text{ the constant values of } \eta \text{ on } S^\pm. \tag{6.11}$$

The derivation of the transmission condition is now possible by using a test function of boundary layer type as shown below.

Proof. Consider the function

$$\eta_\varepsilon(x) = \begin{cases} \eta^+, & x \in \Omega_\varepsilon^+, \\ \eta\left(\frac{x}{\varepsilon}\right), & x \in \Omega_\varepsilon^M, \\ \eta^-, & x \in \Omega_\varepsilon^-, \end{cases} \tag{6.12}$$

and let $\xi(t, \bar{x})$ be a smooth function, $\xi \in C_0^\infty((0,T) \times \Sigma, \mathbb{R}^m)$. To get the jump condition for u_{j0} across Σ, we evaluate the integral

$$I_\varepsilon = \int_0^T \int_{\Omega_\varepsilon^M} \varepsilon D_j^M\left(\frac{x}{\varepsilon}\right)\nabla\eta_{j\varepsilon}(x)\nabla(u_{j\varepsilon}^M(t,x)\xi_j(t,\bar{x}))dx\,dt \tag{6.13}$$

in two different ways and then pass to the limit for $\varepsilon \to 0$. First, integrating by parts and taking into account (6.8) and the continuity of u_ε across S_ε^+ and S_ε^-, we obtain

$$\begin{aligned} I_\varepsilon = & \int_0^T \int_{S_\varepsilon^+} \varepsilon D_j^M \left(\frac{x}{\varepsilon}\right) \frac{1}{\varepsilon} \nabla_y \eta_j \left(\frac{x}{\varepsilon}\right) \cdot \vec{\nu}(x)\, u_{j\varepsilon}^+(t,x) \xi_j(t,\bar{x}) dx\, dt \\ & + \int_0^T \int_{S_\varepsilon^-} \varepsilon D_j^M \left(\frac{x}{\varepsilon}\right) \frac{1}{\varepsilon} \nabla_y \eta_j \left(\frac{x}{\varepsilon}\right) \cdot \vec{\nu}(x)\, u_{j\varepsilon}^-(t,x) \xi_j(t,\bar{x}) dx\, dt. \end{aligned}$$

Now, Proposition 2.2 allows us to pass to the limit for $\varepsilon \to 0$ and to obtain

$$\begin{aligned} \lim_{\varepsilon \to 0} I_\varepsilon &= \int_0^T \int_\Sigma \int_Y u_{j0}^+(t,\bar{x},0) \xi_j(t,\bar{x}) D_j^M(\bar{y},1) \partial_n \eta_j(\bar{y},1) d\bar{y}\, d\bar{x}\, dt \\ & \quad - \int_0^T \int_\Sigma \int_Y u_{j0}^-(t,\bar{x},0) \xi_j(t,\bar{x}) D_j^M(\bar{y},-1) \partial_n \eta_j(\bar{y},-1) d\bar{y}\, d\bar{x}\, dt \\ &= \int_0^T \int_\Sigma (u_{j0}^+(t,\bar{x},0) - u_{j0}^-(t,\bar{x},0)) \xi_j(t,\bar{x}) d\bar{x}\, dt, \end{aligned}$$

where the last equality follows from the boundary conditions (6.9) and (6.10) for η.

Second, by differentiation in the second gradient, we have

$$\begin{aligned} I_\varepsilon &= \int_0^T \int_{\Omega_\varepsilon^M} \varepsilon D_j^M \left(\frac{x}{\varepsilon}\right) \nabla \eta_{j\varepsilon}(x) \nabla \xi_j(t,\bar{x}) u_{j\varepsilon}^M(t,x) dx\, dt \\ & \quad + \int_0^T \int_{\Omega_\varepsilon^M} \varepsilon D_j^M \left(\frac{x}{\varepsilon}\right) \nabla(\eta_{j\varepsilon}(x) \xi_j(t,\bar{x})) \nabla u_{j\varepsilon}^M(t,x) dx\, dt \\ & \quad - \int_0^T \int_{\Omega_\varepsilon^M} \varepsilon D_j^M \left(\frac{x}{\varepsilon}\right) \eta_{j\varepsilon}(x) \nabla \xi_j(t,\bar{x}) \nabla u_{j\varepsilon}^M(t,x) dx\, dt \\ &= I_\varepsilon^1 + I_\varepsilon^2 + I_\varepsilon^3. \end{aligned}$$

Since u_ε^M and $\varepsilon \nabla u_\varepsilon^M$ converge weakly in the two-scale sense (see Proposition 2.1), the integrals I_ε^1 and I_ε^3 converge to zero for $\varepsilon \to 0$. To calculate $\lim_{\varepsilon \to 0} I_\varepsilon^2$, we start from the weak formulation (2.16) where we insert as test function

$$\varphi(t,x) = \eta_\varepsilon(x) \xi(t,\bar{x}) \psi(x_n) \tag{6.14}$$

with $\psi \in C_0^\infty((-H,H),\mathbb{R})$, such that $\psi(x_n) \equiv 1$ for $|x_n| < \frac{H}{2}$. Thus, we have

$$\begin{aligned} \lim_{\varepsilon \to 0} I_\varepsilon^2 = & \lim_{\varepsilon \to 0} \int_0^T \int_{\Omega_\varepsilon^+} (f_j(x,u_\varepsilon^+) - \partial_t u_{j\varepsilon}^+) \eta_j^+ \xi_j(t,\bar{x}) \psi(x_n) dx\, dt \\ & + \lim_{\varepsilon \to 0} \int_0^T \int_{\Omega_\varepsilon^-} (f_j(x,u_\varepsilon^-) - \partial_t u_{j\varepsilon}^-) \eta_j^- \xi_j(t,\bar{x}) \psi(x_n) dx\, dt \\ & + \lim_{\varepsilon \to 0} \frac{1}{\varepsilon} \int_0^T \int_{\Omega_\varepsilon^M} \left(g_j\left(\frac{x}{\varepsilon}, u_\varepsilon^M\right) - \partial_t u_{j\varepsilon}^M\right) \eta_j \left(\frac{x}{\varepsilon}\right) \xi_j(t,\bar{x}) dx\, dt \\ & - \lim_{\varepsilon \to 0} \int_0^T \int_{\Omega_\varepsilon^+} D_j^+ \eta_j^+ \nabla u_{j\varepsilon}^+ \nabla(\xi_j(t,\bar{x}) \psi(x_n)) dx\, dt \\ & - \lim_{\varepsilon \to 0} \int_0^T \int_{\Omega_\varepsilon^-} D_j^- \eta_j^- \nabla u_{j\varepsilon}^- \nabla(\xi_j(t,\bar{x}) \psi(x_n)) dx\, dt. \end{aligned}$$

Using the convergence properties from Proposition 2.1, Theorem 2.3, and the macroscopic problem for the limit functions u_0^+ and u_0^-, we obtain

$$\lim_{\varepsilon\to 0} I_\varepsilon^2 = \int_0^T \int_\Sigma \int_Z (g_j(y, u_0^M(t,\bar{x},y)) - \partial_t u_{j0}^M(t,\bar{x},y))\eta_j(y)\,dy\,\xi_j(t,\bar{x})\,d\bar{x}\,dt$$
$$+ \int_0^T \int_\Sigma (D_j^+\eta_j^+\partial_n u_{j0}^+(t,\bar{x},0) - D_j^-\eta_j^-\partial_n u_{j0}^-(t,\bar{x},0))\xi_j(t,\bar{x})\,d\bar{x}\,dt.$$

Thus, the first transmission condition is proved. It remains to derive a transmission condition for the fluxes. We start again from the weak formulation (2.16) and use as test function

$$\varphi(t,x) = \xi(t,\bar{x})\psi(x_n),$$

with ξ and ψ as in (6.14). For $\varepsilon \to 0$ we obtain

$$\int_0^T \int_{\Omega^+} \partial_t u_{j0}^+ \xi_j\psi_j dx\,dt + \int_0^T \int_{\Omega^+} D_j^+\nabla u_{j0}^+ \nabla(\xi_j\psi_j) dx\,dt - \int_0^T \int_{\Omega^+} f_j(x,u_0^+)\xi_j\psi_j dx\,dt$$
$$+ \int_0^T \int_{\Omega^-} \partial_t u_{j0}^- \xi_j\psi_j dx\,dt + \int_0^T \int_{\Omega^-} D_j^-\nabla u_{j0}^- \nabla(\xi_j\psi_j) dx\,dt - \int_0^T \int_{\Omega^-} f_j(x,u_0^-)\xi_j\psi_j dx\,dt$$
$$+ \int_0^T \int_\Sigma \int_Z (\partial_t u_{j0}^M(t,\bar{x},y) - g_j(y,u_0^M(t,\bar{x},y)))\,dy\,\xi_j(t,\bar{x})\,d\bar{x}\,dt = 0.$$

Using again the macroscopic equations for u_0^+ and u_0^-, we get the following transmission condition:

$$\int_0^T \int_\Sigma (D_j^+\partial_n u_{j0}^+(t,\bar{x},0) - D_j^-\partial_n u_{j0}^-(t,\bar{x},0))\xi_j(t,\bar{x})$$
$$= \int_0^T \int_\Sigma \int_Z (\partial_t u_{j0}^M(t,\bar{x},y) - g_j(y,u_0^M(t,\bar{x},y)))\,dy\,\xi_j(t,\bar{x})\,d\bar{x}\,dt. \qquad \square$$

7. Uniqueness for the macroscopic model. In this section, we want to show uniqueness of the solutions (u_0^+, u_0^-, u_0^M) to the effective model presented in Theorem 2.4. To this end, let us first formulate a corollary which gives an equivalent formulation of the transmission conditions (2.28), (2.29).

COROLLARY 7.1. *The transmission conditions* (2.28), (2.29) *are equivalent to*

$$D_j^+\partial_n u_{j0}^+(t,\bar{x},0) = \int_{S^+} D_j^M(y)\partial_n u_{j0}^M(t,\bar{x},y)dy, \tag{7.1}$$

$$D_j^-\partial_n u_{j0}^-(t,\bar{x},0) = \int_{S^-} D_j^M(y)\partial_n u_{j0}^M(t,\bar{x},y)dy. \tag{7.2}$$

These equivalent transmission conditions hold in a distributional sense with respect to t and $\bar{x}$.

REMARK 2. *The physical interpretation of* (7.1) *and* (7.2) *is obvious; it states that the macroscopic flux is given by the microscopic flux averaged over the corresponding part of the cell surface.*

Proof. Using the properties (6.8), (6.9), and (6.10) of the boundary layer η and the boundary conditions

$$u_0^M(t,\bar{x},y) = u_0^\pm(t,\bar{x},0) \quad \text{on } (0,T)\times\Sigma\times S^\pm,$$

we obtain

$$
\begin{aligned}
[u_{j0}]|_\Sigma(t,\bar{x}) &= u_{j0}^+(t,\bar{x},0) - u_{j0}^-(t,\bar{x},0) \\
&= \int_{S^+} u_{j0}^M(t,\bar{x},y)dy - \int_{S^-} u_{j0}^M(t,\bar{x},y)dy \\
&= \int_Z D_j^M(y)\nabla\eta_j(y)\nabla u_{j0}^M(t,\bar{x},y)dy.
\end{aligned}
$$

Equation (2.30) for u_0^M and the fact that η is constant on S^+ and S^- with constants defined in (6.11) yield

$$
\begin{aligned}
[u_{j0}]_\Sigma(t,\bar{x}) = &\int_Z (g_j(y,u_0^M(t,\bar{x},y)) - \partial_t u_{j0}^M(t,\bar{x},y))\eta_j(y)\,dy \\
&+ \int_{S^+} D_j^M(y)\partial_n u_{j0}^M(t,\bar{x},y)\eta_j^+ dy - \int_{S^-} D_j^M(y)\partial_n u_{j0}^M(t,\bar{x},y)\eta_j^- dy.
\end{aligned} \tag{7.3}
$$

From (2.28) and (7.3), we then obtain

$$
\begin{aligned}
&D_j^+\partial_n u_{j0}^+(t,\bar{x},0)\eta_j^+ - D_j^-\partial_n u_{j0}^-(t,\bar{x},0)\eta_j^- \\
&= \int_{S^+} D_j^M(y)\partial_n u_{j0}^M(t,\bar{x},y)\eta_j^+ dy - \int_{S^-} D_j^M(y)\partial_n u_{j0}^M(t,\bar{x},y)\eta_j^- dy.
\end{aligned} \tag{7.4}
$$

On the other hand, using (2.30) for u_0^M, the transmission condition (2.29) transforms to

$$
\begin{aligned}
&D_j^+\partial_n u_{j0}^+(t,\bar{x},0) - D_j^-\partial_n u_{j0}^-(t,\bar{x},0) \\
&= \int_{S^+} D_j^M(y)\partial_n u_{j0}^M(t,\bar{x},y)dy - \int_{S^-} D_j^M(y)\partial_n u_{j0}^M(t,\bar{x},y)dy.
\end{aligned} \tag{7.5}
$$

Relations (7.4) and (7.5) are equivalent with the transmission conditions (7.1) and (7.2) since $\eta_j^+ - \eta_j^- \neq 0$. This follows from the relations

$$\eta_j^+ > 0 \ \text{ and } \ \eta_j^- < 0 \quad \text{for } j = 1, \dots n,$$

which hold by the maximum principle for elliptic equations. ∎

In the following, we prove uniqueness for the macroscopic system by using the equivalent transmission conditions (7.1) and (7.2).

Proof. Assume that (u_i^+, u_i^-, u_i^M), $i = 1, 2$, are solutions of the macroscopic system with the same data. Let δu^+, δu^-, δu^M denote the differences. Now, we consider a test function $\varphi \in V$, where

$$V = \{(C_0^\infty((0,T), C^\infty(\overline{\Omega^+})))^m \cap (C_0^\infty((0,T), C^\infty(\overline{\Omega^-})))^m, \varphi = 0 \,\text{on}\, \partial_D\Omega^+ \cup \partial_D\Omega^-\}.$$

We multiply (2.23) and (2.24) by φ and integrate, obtaining

$$
\begin{aligned}
&\int_{\Omega^+} \partial_t u_{j0}^+ \varphi_j^+ \,dx + \int_{\Omega^-} \partial_t u_{j0}^- \varphi_j^- \,dx + D_j^+ \int_{\Omega^+} \nabla u_{j0}^+ \nabla \varphi_j^+ \,dx \\
&+ D_j^- \int_{\Omega^-} \nabla u_{j0}^- \nabla \varphi_j^- \,dx + \int_\Sigma D_j^+ \partial_n u_{j0}^+ \varphi_j^+ d_\Sigma(x) - \int_\Sigma D_j^- \partial_n u_{j0}^- \varphi_j^- d_\Sigma(x) \\
&= \int_{\Omega^+} f_j(x, u_0^+)\varphi_j^+ \,dx + \int_{\Omega^-} f_j(x, u_0^-)\varphi_j \,dx.
\end{aligned} \tag{7.6}
$$

From (7.6) and the transmission conditions (7.1) and (7.2), we obtain the following equation for the differences $\delta u^+, \delta u^-$:

$$\begin{aligned} &\int_{\Omega^+} \partial_t(\delta u_j^+)\varphi_j^+\,dx + \int_{\Omega^-} \partial_t(\delta u_j^-)\varphi_j^-\,dx + D_j^+ \int_{\Omega^+} \nabla(\delta u_j^+)\nabla\varphi_j^+\,dx \\ &+ D_j^- \int_{\Omega^-} \nabla(\delta u_j^-)\nabla\varphi_j^-\,dx + \int_\Sigma \int_{S^+} D_j^M(y)\partial_n(\delta u_j^M)dy\,\varphi_j^+\,d_\Sigma(x) \\ &- \int_\Sigma \int_{S^-} D_j^M \partial_n(\delta u_j^M)dy\,\varphi_j^-\,d_\Sigma(x) = \int_{\Omega^+} \delta f_j^+ \varphi_j^+\,dx + \int_{\Omega^-} \delta f_j^- \varphi_j\,dx, \end{aligned} \tag{7.7}$$

where we denoted

$$\delta f_j^+ = f_j(x, u_1^+) - f_j(x, u_2^+), \quad \delta f_j^- = f_j(x, u_1^-) - f_j(x, u_2^-).$$

Now, we insert $\varphi^+ = \delta u^+$ and $\varphi^- = \delta u^-$ as test functions. Using the boundary conditions (2.31), we get for the terms on Σ

$$\begin{aligned} &\int_\Sigma \int_{S^+} D_j^M(y)\partial_n(\delta u_j^M)dy\,\delta u_j^+ d_\Sigma - \int_\Sigma \int_{S^-} D_j^M \partial_n(\delta u_j^M)dy\,\delta u_j^- d_\Sigma \\ &= \int_\Sigma \int_{S^+} D_j^M(y)\partial_n(\delta u_j^M)\delta u_j^M dy d_\Sigma - \int_\Sigma \int_{S^-} D_j^M \partial_n(\delta u_j^M)\,\delta u_j^M dy d_\Sigma \\ &= \int_\Sigma \int_Z D_j^M(y)\nabla(\delta u_j^M)\nabla(\delta u_j^M)dy d_\Sigma + \int_\Sigma \int_Z \partial_t(\delta u_j^M)\delta u_j^M dy d_\Sigma \\ &\quad - \int_\Sigma \int_Z \delta g_j \delta u_j^M dy d_\Sigma. \end{aligned} \tag{7.8}$$

Here, we used the notation $\delta g_j = g_j(y, u_1^M) - g_j(y, u_2^M)$. Inserting (7.8) in (7.7), summing up for $j = 1, \ldots, m$, and integrating with respect to t, we obtain

$$\begin{aligned} &\frac{1}{2}||\delta u^+(t)||^2_{L^2(\Omega^+)} + \frac{1}{2}||\delta u^-(t)||^2_{L^2(\Omega^-)} + \frac{1}{2}||\delta u^M(t)||^2_{L^2(\Sigma\times Z)} \\ &+ D_j^+ \int_0^t \int_{\Omega^+} |\nabla(\delta u^+)|^2\,dxdt + D_j^- \int_0^t \int_{\Omega^-} |\nabla(\delta u^-)|^2\,dxdt \\ &+ \int_0^t \int_\Sigma \int_Z D^M(y)|\nabla(\delta u^M)|^2 dy d_\Sigma dt = \int_0^t \int_\Sigma \int_Z \delta g \delta u^M dy d_\Sigma dt \\ &+ \int_0^t \int_{\Omega^+} \delta f^+ \delta u^+\,dxdt + \int_0^t \int_{\Omega^-} \delta f^- \delta u^-\,dxdt. \end{aligned} \tag{7.9}$$

Using the Lipschitz continuity of the reaction terms, the right-hand side in (7.9) can be estimated by

$$C\left(||\delta u^M||^2_{L^2((0,t)\times\Sigma\times Z)} + ||\delta u^+||^2_{L^2((0,t)\times\Omega^+)} + ||\delta u^-||^2_{L^2((0,t)\times\Omega^-)}\right).$$

Then Gronwall's inequality yields

$$\delta u^+ = \delta u^- = \delta u^M = 0$$

and the theorem is proved. ∎

COROLLARY 7.2. *The entire sequence* $(u_\varepsilon^+, u_\varepsilon^-, u_\varepsilon^M)$ *converges to the limit* (u_0^+, u_0^-, u_0^M)*, solving the macroscopic system.*

REMARK 3. *An important aim of our homogenization procedure is to reduce the computational complexity. The algorithms for solving the derived transmission problem numerically will be considered in a forthcoming paper.*

Acknowledgment. The authors appreciate the comments and suggestions of the referees and tried to include them as much as possible.

UNIQUENESS THEOREMS FOR STABLE ANISOTROPIC CAPILLARY SURFACES*

MIYUKI KOISO† AND BENNETT PALMER‡

Abstract. We consider capillary surfaces for certain rotationally invariant elliptic parametric functionals supported on two hydrophobically wetted horizontal plates separated by a fixed distance. It is shown that each such stable capillary surface is uniquely determined by the volume interior to the surface.

Key words. anisotropic, capillary surface, uniqueness, stability

AMS subject classifications. 49Q10, 53C42, 76D45

DOI. 10.1137/060657297

1. Introduction.

When the temperature of a fluid is gradually lowered, it undergoes a process of crystallization in which its constituent atoms, molecules, or ions will align themselves in a regular repeating pattern. It is rare that a single crystal will form, and instead many crystals will form a polycrystal. This is the state in which, for example, most metals occur.

As the fluid cools, the usual isotropic surface energy (surface tension) will no longer be appropriate to model the shape of the interface of the fluid with its environment. Because of the internal structure of the material, the isotropic surface energy must be replaced by an anisotropic one, i.e., an energy that depends on the direction of the surface at each point. In this paper, we will treat a class of capillary problems for the simplest type of anisotropic surface energy: a constant coefficient, elliptic parametric functional.

Particularly, we consider a variational problem whose solution is a mathematical model of a drop of a cooled liquid trapped between two horizontal plates. The plates are hydrophobically wetted and are made of the same material. It is natural to consider the volume of the drop, the distance between the plates, and the wetting constant ω which couples the energy of the fluid-plate interface to the free surface energy as "initial data" and then ask if the shape of the drop is uniquely determined. In our previous paper [6], we obtained a geometric characterization of such drops. In this paper, we show (Theorem 2.1) that under certain assumptions on the energy functional the uniqueness follows if the additional natural condition of stability is imposed. Not only do we have uniqueness but we are able to determine the shape of the drop (Theorem 2.3) to the extent that a parameterization can be easily obtained from our previous work [4].

We wish to emphasize that we have restricted ourselves to the cases of hydrophobic wetting and equal contact angle. This is not to suggest that the other cases are of lesser importance. At present we also ignore gravitational and other external forces.

This paper should be considered as part of a program in which these more general problems will be considered.

Our assumptions imposed on the energy functional are satisfied by the usual area functional. In this important special case, solutions are constant mean curvature (CMC) surfaces which meet each of the supporting planes with constant angle. In the CMC case without wetting, the uniqueness and characterization of stable solutions follow from the results in Athanassenas [1] and Vogel [7]. For hydrophobic wetting, they follow from the results in Vogel [8] and Finn and Vogel [3]. The lower bound for the volume of a stable spanning drop of height h was shown by Finn and Vogel in [3] to be h^3/π, giving an affirmation of Carter's conjecture. We will generalize this result to the anisotropic case with hydrophobic wetting (Theorem 2.4).

The paper is organized as follows. Section 2 contains precise statements of our main results. Sections 3 and 4 will be devoted to proofs of the results stated in section 2. In section 5, we will give a strict examination of the uniqueness for the case without wetting energy. Section 6 contains a summary of results concerning anisotropic Delaunay surfaces (rotationally symmetric surfaces with constant anisotropic mean curvature). These surfaces were introduced in detail in [4] and play a fundamental role in our stability and uniqueness analysis.

2. Statements of results. Let F be a smooth, positive function on S^2. To an immersion $X : \Sigma \to \mathbf{R}^3$ from a two-dimensional oriented, connected, compact, smooth manifold Σ (possibly with boundary $\partial\Sigma$) to the three-dimensional Euclidean space $\mathbf{R}^3$, we assign the free anisotropic energy

$$\mathcal{F}[X] := \int_\Sigma F(\nu)\, d\Sigma\,, \tag{1}$$

where $\nu = (\nu_1, \nu_2, \nu_3) : \Sigma \to S^2$ is the Gauss map of X, and $d\Sigma$ is the area form of the induced metric. We will assume that F satisfies a "convexity condition" in the following sense: Denote by DF and D^2F the gradient and Hessian of F on S^2. We assume that at each point in S^2 the matrix $D^2F + FI$ is positive definite, where I is the identity endomorphism field on TS^2. Such an energy functional $\mathcal{F}$ is then referred to as a constant coefficient elliptic parametric functional.

It is known that the energy $\mathcal{F}$ possesses a canonical critical point which minimizes $\mathcal{F}$ among closed surfaces enclosing a specific three-dimensional volume (see [2]), and it is known as the *Wulff shape* (for $\mathcal{F}$), which we will denote by W. W is a uniformly convex smooth surface and given by the immersion $\chi : S^2 \to \mathbf{R}^3$ defined by $\chi(\nu) = DF(\nu) + F(\nu)\cdot\nu$. In the special case where $F \equiv 1$, $\mathcal{F}$ is the area functional and W is the round sphere of radius 1 with center at the origin.

The property that X is a critical point of $\mathcal{F}$ for all compactly supported volume-preserving variations is characterized by the property that the anisotropic mean curvature Λ of X is constant, where Λ is given by

$$\Lambda := 2HF - \mathrm{div}_\Sigma DF = -\mathrm{trace}_\Sigma(D^2F + FI)\circ d\nu$$

(cf. [4]). Here H is the mean curvature of X. This definition is a generalization of the idea of constant mean curvature which arises from the area functional. Since $D^2F + FI$ is positive definite, the equation $\Lambda =$ constant is absolutely elliptic, and hence a maximum principle analogous to that for CMC surfaces holds for surfaces of constant anisotropic mean curvature.

In this paper, we consider connected, compact surfaces X with nonempty boundary embedded in a region $\Omega := \{z_0 \le z \le z_1\}$ whose interiors are included in the interior of Ω, whose boundary components are restricted to lie on the two supporting (horizontal) planes $\Pi_i := \{z = z_i\}$, $i = 0, 1$, and which are constrained to enclose a fixed volume V in Ω. These considerations require that the surface bounds a connected volume so that we preclude some physically important configurations like a "string of spheres." Also, for simplicity, we are assuming that each boundary component of the considered surface is homeomorphic to a circle. We will call such a surface an *anisotropic capillary surface* if it is in equilibrium for a functional

$$\mathcal{E}[X] := \mathcal{F}[X] + \omega_0 \mathcal{A}_0[X] + \omega_1 \mathcal{A}_1[X]\,. \tag{2}$$

Here $\mathcal{A}_i[X]$ is the area in the plane Π_i which is bounded by the boundary components of X in Π_i (physically, the area which is wetted by the material inside the surface) and the ω_i's are coupling constants. In practice the ω_i's are determined by the materials involved. Throughout this paper we use the term "capillary surface" to mean anisotropic capillary surface. We will use the adjective isotropic when it is needed to denote the special case when the free energy is the surface area.

For an embedding $X : (\Sigma, \partial\Sigma) \to (\Omega, \Pi_0 \cup \Pi_1)$ with outward pointing unit normal ν, the contact angle of X with Π_i at $X(\zeta) \in \Pi_i$ ($\zeta \in \partial\Sigma$) is defined as the angle $\vartheta \in [0, \pi]$, between $\nu(\zeta)$ and $(-1)^i(0, 0, 1)$. The surface X is a capillary surface if and only if the anisotropic mean curvature Λ of X is constant, and the contact angle ϑ of X with each Π_i is a constant $\vartheta(\omega_i)$ (see [6, Propositions 3.1 and 3.2]). The precise value $\vartheta(\omega_i)$ will be given below. Now, by the maximum principle and the Alexandrov reflection methods, X is a surface of revolution with vertical rotation axis, and its genus is zero (see [6, Corollary 3.2]).

A capillary surface is said to be stable if the second variation of the energy functional $\mathcal{E}$ is nonnegative for all volume-preserving variations satisfying the boundary condition.

A natural question to ask is whether one can uniquely determine the shape of the (stable) capillary surface from the "initial data" $\mathcal{F}$, V, $h := z_1 - z_0$, ω_0, and ω_1. We will show that this is possible under certain conditions.

We will first impose conditions on the functional $\mathcal{F}$ which will be described via the corresponding Wulff shape W. We will assume the following:

- (W1) W is a uniformly convex surface of revolution with vertical rotation axis.
- (W2) W is symmetric with respect to reflection through the horizontal plane $z = 0$.
- (W3) The generating curve of W has nondecreasing curvature (with respect to the inward pointing normal) as a function of arc length on $\{z \geq 0\}$ as one moves in an upward direction.

In addition, it will be assumed that $\omega_0 = \omega_1 =: \omega \geq 0$ holds in (2). In the isotropic (liquid) case, the condition $\omega_i > 0$ is known as *hydrophobic wetting* since the material inside the surface will tend to avoid the supporting planes when minimizing energy. The case of the ω_i's being equal would occur (physically) if both supporting planes were made from the same material.

The Wulff shape W can be represented as

$$(x_1, x_2, x_3) = (u(\sigma)\cos\theta, u(\sigma)\sin\theta, v(\sigma)),$$

where σ is the arc length of the generating curve

$$\Gamma_W : (u(\sigma), v(\sigma))$$

of W. Denote by $\bar{\omega}$ the maximum height on W, that is, $\bar{\omega} = \max_\sigma v(\sigma)$. At times we will also represent the generating curve of W as a graph $(u(v), v)$, $-\bar{\omega} \leq v \leq \bar{\omega}$.

For $\omega \in (-\bar{\omega}, \bar{\omega})$, denote by $\vartheta(\omega)$ the contact angle between the region $W \cap \{x_3 \leq \omega\}$ of W and the plane $\{x_3 = \omega\}$. Also we define $\vartheta(-\bar{\omega}) := 0$, $\vartheta(\bar{\omega}) := \pi$. Then $\vartheta(\omega)$ is a continuous strictly increasing function of ω on $[0, \pi]$ with $\vartheta(0) = \pi/2$. An embedding X is a capillary surface for

$$\mathcal{E} := \mathcal{E}_\omega := \mathcal{F} + \omega\mathcal{A}_0 + \omega\mathcal{A}_1 \tag{3}$$

if and only if the anisotropic mean curvature of X is constant, and the contact angle between X and each bounding plane Π_i is constant $\vartheta(\omega)$ along the boundary (see [6, Propositions 3.1 and 3.2]).

We will call an anisotropic capillary surface *spanning* if its intersection with both supporting planes is a circle of positive radius. We denote by $V_0(h, \omega)$ the infimum of the volumes of stable spanning anisotropic capillary surfaces having height h and contact angle $\vartheta(\omega)$.

In keeping with the classical terminology, we will refer to a compact anisotropic capillary surface having nonempty boundary components only on the plane $z = z_0$ (resp., $z = z_1$) as a *sessile drop* (resp., *pendent drop*). Such a surface is necessarily rotationally invariant, and therefore homothetic to a part of the Wulff shape (see [6]).

If $|\omega| > \bar{\omega}$, then there is no capillary surface for the energy $\mathcal{E}_\omega$ (see [6, Corollary 3.1]). For $0 \leq \omega \leq \bar{\omega}$, we will show the following uniqueness theorem.

Theorem 2.1. *We assume* (W1) *through* (W3) *stated above.*

I. *Assume $0 \leq \omega < \bar{\omega}$. Then $V_0(h, \omega) > 0$ holds and*
   (i) *for volume $V < V_0$, any stable capillary surface for the energy $\mathcal{E}_\omega$ with volume V and height h is a sessile or pendent drop;*
   (ii) *for volumes $V \geq V_0$, there exists a unique stable spanning capillary surface for the energy $\mathcal{E}_\omega$ with volume V and height h.*

II. *Assume $\omega = \bar{\omega}$. Then any capillary surface for the energy $\mathcal{E}_\omega$ is tangent to the supporting planes $\Pi_0 \cup \Pi_1$. $V_0(h, \omega) > 0$ holds, and it coincides with the volume of the closed surface homothetic to the Wulff shape which is tangent to both Π_0 and Π_1. Also,*
   (i) *for volume $V \leq V_0$, there is no stable capillary surface for the energy $\mathcal{E}_\omega$ with volume V and height h;*
   (ii) *for volumes $V > V_0$, there exists a unique stable capillary surface for the energy $\mathcal{E}_\omega$ with volume V and height h. Moreover, this surface is spanning.*

Actually, we will later give analytic and geometric characterizations of each of the unique solutions for $V \geq V_0$ in Theorem 2.1. In order to do this, we first recall the classification of surfaces of revolution with constant anisotropic mean curvature (see section 6). Such surfaces were studied in detail by the authors in [4] and are called *anisotropic Delaunay surfaces*. They are classified into six classes: horizontal plane, anisotropic catenoid, Wulff shape (up to translation and homothety), cylinder, anisotropic unduloid, and anisotropic nodoid. Each surface in each of these classes has similar properties to the corresponding Delaunay surface.

We let μ_i, $i = 1, 2$, denote the principal curvatures of the Wulff shape W with respect to the inward pointing normal. Here we let μ_1 denote the curvature of the generating curve of W.

The following characterization of stable anisotropic capillary surfaces was obtained in our previous papers [5], [6].

Theorem 2.2. *Let X be a capillary surface with free boundary on two horizontal planes for the functional* (3) *with $\omega \geq 0$ and with the Wulff shape for the functional satisfying conditions* (W1) *through* (W3) *stated above.*

(i) *If* $\omega = 0$*, then* X *is stable if and only if the surface is either homothetic to a half of the Wulff shape or a cylinder which is perpendicular to* $\Pi_0 \cup \Pi_1$ *and whose height* h *and radius* R *satisfy*

$$\frac{\mu_1(0)}{\mu_2(0)}(1/R^2) \leq (\pi/h)^2 \,,$$

where $\mu_i(0)$*,* $i = 1, 2$*, is the value of* μ_i *along the equator of* W*.*

(ii) *If* $\omega > 0$ *holds, then* X *is stable if and only if* X *is a portion of an anisotropic Delaunay surface whose generating curve has no inflection points in its interior.*

Define

$$V_1 := V_1(h, \omega) := \pi h^3 \frac{\int_{-\omega}^{\omega} u^2 \, dv}{\left(\int_{-\omega}^{\omega} \, dv\right)^3} \,.$$

V_1 is the volume of the capillary surface which is homothetic to the part of the Wulff shape with contact angle $\vartheta(\omega)$ on the plane Π_i, $i = 0, 1$.

$$V_2 := V_2(h, \omega) := \pi h^3 \frac{\int_{-\omega}^{\bar{\omega}} u^2 \, dv}{\left(\int_{-\omega}^{\bar{\omega}} \, dv\right)^3} \,.$$

V_2 is the volume of the surface which is homothetic to the part of the Wulff shape which is tangent to the plane Π_1 and with contact angle $\vartheta(\omega)$ on the plane Π_0.

THEOREM 2.3. *We assume* (W1) *through* (W3) *stated above.*

I. *Assume* $0 < \omega < \bar{\omega}$*. Then the following hold:*

(i) *For volumes* $V_0 \leq V < V_1$*, there exists a unique stable spanning capillary surface with volume* V*, height* h*, and contact angle* $\vartheta(\omega)$*, and the surface is an anisotropic unduloid. For* $V = V_0$*, this surface has inflection points on the boundary, while, for* $V_0 < V < V_1$*, it does not have inflection points.*

(ii) *For* $V = V_1$*, there exists a unique stable capillary surface with volume* V*, height* h*, and contact angle* $\vartheta(\omega)$*, and the surface is homothetic to a part of the Wulff shape.*

(iii) *For* $V_1 < V$*, there exists a unique stable capillary surface with volume* V*, height* h*, and contact angle* $\vartheta(\omega)$*, and the surface is an anisotropic nodoid.*

II. *Assume* $\omega = \bar{\omega}$*. Then, for* $V_0 < V$*, there exists a unique stable capillary surface with volume* V*, height* h*, and contact angle* $\vartheta(\omega)$*, and the surface is an anisotropic nodoid.*

Figure 1 shows the generating curves of examples of Theorem 2.3 (I) (i), (ii), and (iii) for the isotropic case, while Figure 2 shows examples for the anisotropic case.

For a fixed volume V, height h, and $\bar{\omega} \geq \omega > 0$, we let $U(V, h, \omega)$ (resp., $N(V, h, \omega)$) denote the stable anisotropic unduloid (resp., nodoid) with volume V, height $h := z_1 - z_0$, and contact angle $\vartheta(\omega)$ which we obtained in Theorem 2.3.

Remark 2.1. In the theorems above "unique" means "unique up to horizontal translation."

Remark 2.2. Even in the isotropic case, there is no uniqueness without the stability assumption. Figure 3 shows the plots of the volumes of two families of

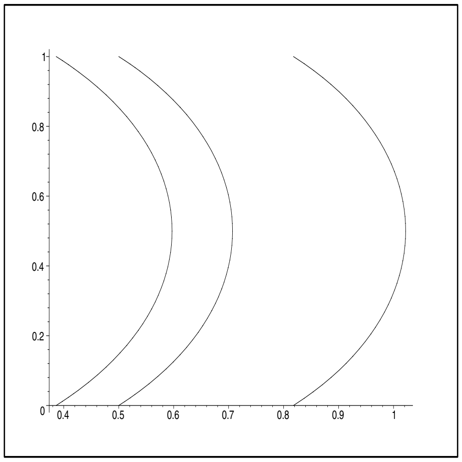

FIG. 1. *The innermost curve generates an (isotropic) unduloid, the middle curve is a sphere, and the outer curve is a nodoid. The height is* 1 *and the contact angle is* $\pi/4$*. The values of* a *are* 0.25*,* 0*, and* -1*.*

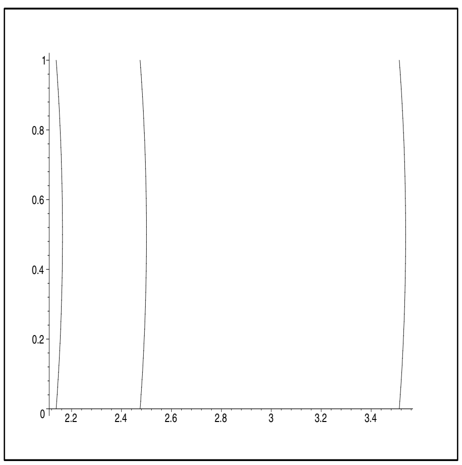

FIG. 2. *The innermost curve generates an anisotropic unduloid, the middle curve is a part of the Wulff shape* $u^2 + v^4 = 1$*, and the outer curve is an anisotropic nodoid. The height is* 1 *and the contact angle is* $\omega = \pi/4$*. The values of* a *are* 0.25*,* 0*, and* -1*.*

capillary surfaces for the area functional. The top curve represents the volumes of stable capillary unduloids with height 1 and contact angle $\pi/4$ with two planes. The bottom curve shows the volumes of unstable capillary unduloids with the same height and contact angles. The generating curves of these surfaces have exactly one interior inflection point, which makes them unstable by Theorem 2.2. This shows that volume does not uniquely determine the surface without the stability assumption.

Also, there is no positive lower bound for the volume without the assumption of stability. For any functional satisfying the conditions above, any vertical round cylinder is a capillary surface for the case $\omega = 0$. However, the volume of the cylinder can be made arbitrarily small. Also, for $0 < \omega < \bar{\omega}$, there is an unstable unduloid with contact angle $\vartheta(\omega)$ and an arbitrarily small volume.

Remark 2.3. For $V \geq V_2$, the capillary surface is unique. If $V_0 < V_2$, then, for

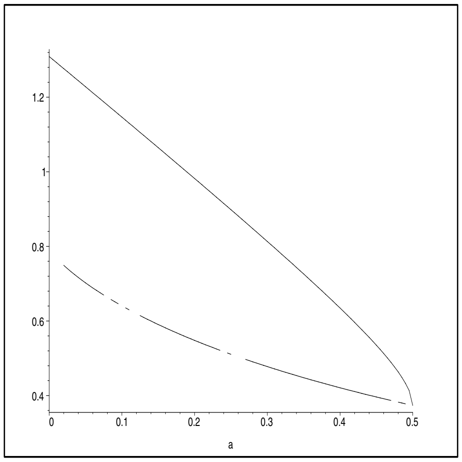

FIG. 3. *Plot of the volumes of stable (upper) and unstable (lower) unduloids as a function of* a*. The height is* 1 *and the contact angle is* $\pi/4$*. The generating curves of the unstable unduloids have exactly one inflection point.*

$V_0 \le V < V_2$, there exist exactly two stable capillary surfaces (up to translation) with volume V, height h, and contact angle $\vartheta(\omega)$. One of them is a sessile or pendent drop, while the other has two boundary components. In the isotropic case, these results follow from Chapter 6 of [10]. It would be interesting to know whether $V_0 \le V < V_2$ holds in general. This inequality is proved in the case $\omega = 0$ in section 5.

The next result yields a numerical lower bound on the volume of a stable, spanning capillary surface.

THEOREM 2.4. *Assume that the Wulff shape satisfies conditions* (W1) *through* (W3)*. If* $0 < \omega \le \bar{\omega}$*, then*

$$V_0(h,\omega) > \frac{h^3}{\pi}\left(\frac{2u(\omega)(u(0)-u(\omega))}{\omega^2-(u(0)-u(\omega))^2}\right) > 0 \tag{4}$$

holds. If $\omega = 0$*, then*

$$V_0(h,0) \ge \frac{h^3}{\pi}\left(\frac{\mu_1(0)}{\mu_2(0)}\right) \tag{5}$$

holds, and this inequality is sharp in the sense that there is a stable cylinder which satisfies the equality in (5)*.*

Remark 2.4. For the CMC case, Theorem 2.4 implies that if the contact angle $\vartheta = \vartheta(\omega)$ satisfies $\pi/2 \le \vartheta \le \pi$, then

$$V_0(h,\omega) \ge \frac{h^3}{\pi}$$

holds and the equality holds only for the most slender stable cylinder. This is exactly the result proved by Finn and Vogel in [3] for $0 < \vartheta \le \pi$. Zhou [9] proved this for the general case where the contact angle on the lower and upper planes may be different.

Finally, we will show the following.

THEOREM 2.5. *Assume* $0 \le \omega \le \bar{\omega}$ *and that the Wulff shape satisfies conditions* (W1) *through* (W3)*. For* $V \ge V_0$*, let* $\Sigma(V) = \Sigma(V,h,\omega)$ *denote the unique stable* *capillary surface with volume V, height h, and contact angles $\vartheta(\omega)$ with two boundary components. Here, we let $\Sigma(V_0, h, \bar{\omega})$ be the homothety of the Wulff shape with height h which touches both Π_0 and Π_1. Then the family of surfaces $\Sigma(V)$, $V > V_0$, foliate the open region of space which lies exterior to the surface $\Sigma(V_0)$ and lies between the planes $z = z_i$, $i = 0, 1$.*

3. Preliminary results. We introduce the auxiliary quantity

$$V^* := V^*(h, \omega) := \pi h^3 \left(\int_{-\omega}^{\omega} \frac{1}{\sqrt{u^2 - u^2(\omega)}} \, dv \right)^{-2}, \tag{6}$$

which will be used to obtain the lower bound for the volume in Theorem 2.4. The main result of this section is the following technical lemma.

LEMMA 3.1. *Assume $0 < \omega \leq \bar{\omega}$ and that the Wulff shape satisfies conditions* (W1) *through* (W3). *Let $\hat{R}$ denote the radius of the circle through the points $(u(\omega), \pm\omega), (u(0), 0)$. Define*

$$A(\omega) = \left[\frac{u(\omega) + (\hat{R} - u(0))}{u(\omega)} \right]^{1/2}. \tag{7}$$

Then there holds

$$\int_{-\omega}^{\omega} \frac{dv}{\sqrt{u^2(v) - u^2(\omega)}} < \pi A(\omega), \tag{8}$$

and consequently

$$V^*(h, \omega) > \frac{h^3}{\pi} \left(\frac{2u(\omega)(u(0) - u(\omega))}{\omega^2 - (u(0) - u(\omega))^2} \right) > 0 \tag{9}$$

holds.

The generating curve Γ_W^+ of the Wulff shape is represented as

$$\begin{aligned} &(u(\sigma), v(\sigma)), \qquad -L \leq \sigma \leq L, \\ u_0 &:= \max u = u(0) \geq u(\sigma) \geq 0 = u(-L) = u(L) \qquad \forall \sigma \in [-L, L], \\ \bar{\omega} &:= \max v = v(L) \geq v(\sigma) \geq -\bar{\omega} = v(-L) \qquad \forall \sigma \in [-L, L], \end{aligned}$$

where σ is the arc length of (u, v) and $2L$ is the length of Γ_W^+.

$$(u(\sigma), v(\sigma)), \qquad -2L \leq \sigma \leq 2L,$$

gives a convex closed curve Γ_W, which is the section of W by the (x_1, x_3)-plane. For simplicity, we set

$$\kappa := \mu_1,$$

which is the curvature of $(u(\sigma), v(\sigma))$ with respect to the inward pointing normal.

LEMMA 3.2.

$$f(\sigma) := u^2(\sigma) + v^2(\sigma)$$

is a nondecreasing function of σ in $0 \leq \sigma \leq L$.

In order to prove Lemma 3.2, we need the following.

LEMMA 3.3. *Consider the eigenvalue problem*

$$\varphi'' + \kappa^2\varphi = -\lambda\varphi \quad in\ 0 \le \sigma \le L, \qquad \varphi(0) = \varphi(L) = 0. \tag{10}$$

Then the first eigenvalue $\lambda_1[0, L]$ of problem (10) *is nonnegative.*

Proof. Set $\eta := v'$. Let ϕ be a function on $[0, L]$ which satisfies $\phi(0) = \phi(L) = 0$. Since

$$\eta > 0 \quad \text{in } 0 < \sigma < L, \quad \eta(L) = 0, \quad \eta'(L) \neq 0,$$

the function

$$\zeta := \phi/\eta$$

is well-defined on $0 \le \sigma \le L$. Elementary calculations show

$$\eta'' + \kappa^2\eta = \kappa' u'.$$

Using this, we obtain

$$\phi'' + \kappa^2\phi = \zeta''\eta + 2\zeta'\eta' + \zeta\kappa' u'.$$

Therefore,

$$\begin{aligned}
-\int_0^L \phi(\phi'' + \kappa^2\phi)\, d\sigma &= -\int_o^L \zeta\eta(\zeta''\eta + 2\zeta'\eta' + \zeta\kappa' u')\, d\sigma \\
&= -\int_0^L \Big\{(\zeta\zeta'\eta^2)' - (\zeta')^2\eta^2 + \kappa'\zeta^2\eta u'\Big\}\, d\sigma \\
&= -[\zeta'\eta\phi]_0^L + \int_0^L \Big\{(\zeta')^2\eta^2 - \kappa'\zeta^2 u'v'\Big\}\, d\sigma \\
&= \int_0^L \Big\{(\zeta')^2\eta^2 - \kappa'\zeta^2 u'v'\Big\}\, d\sigma \ge 0,
\end{aligned}$$

which implies that $\lambda_1[0, L] \ge 0$. □

Proof of Lemma 3.2. We will prove $f' \ge 0$. Note that $\kappa' = 0$ on interval $[0, L]$ is equivalent to $f =$ constant and so $f' = 0$ on $[0, L]$. Denote by q the support function of the curve (u, v). Then $q = uv' - u'v > 0$. By elementary calculations, we obtain

$$f''' + \kappa^2 f' = -2\kappa' q \le 0.$$

Note that $f'(0) = f'(L) = 0$ holds. Now assume $f'(\sigma) < 0$ at some $\sigma \in (0, L)$. Then there exist some $\sigma_1,\ \sigma_2 \in [0, L]$ such that $0 \le \sigma_1 < \sigma_2 \le L$ and

$$f'(\sigma) < 0 \quad \forall\sigma \in (\sigma_1, \sigma_2), \qquad f'(\sigma_1) = f'(\sigma_2) = 0$$

holds. If $[\sigma_1, \sigma_2] = [0, L]$, then

$$-\int_0^L f'(f''' + \kappa^2 f')\, d\sigma = 2\int_0^L \kappa' q f'\, d\sigma < 0.$$

Therefore, $\lambda_1[0, L] < 0$ holds. This contradicts Lemma 3.3. If $[\sigma_1, \sigma_2] \neq [0, L]$, then

$$-\int_{\sigma_1}^{\sigma_2} f'(f''' + \kappa^2 f')\, d\sigma = 2\int_{\sigma_1}^{\sigma_2} \kappa' q f'\, d\sigma \le 0. \tag{11}$$

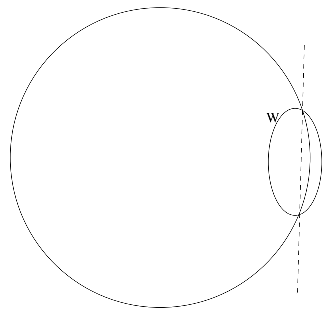

FIG. 4.

Since the eigenvalues of problem (10) have monotonicity with respect to the region, (11) implies that $\lambda_1[0, L] < \lambda_1[\sigma_1, \sigma_2] \le 0$. Again this contradicts Lemma 3.3. $\square$

We assume $0 < \omega \le \bar{\omega}$. Γ_W can be regarded as the graph $(u(v), v)$, $-\bar{\omega} \le v \le \bar{\omega}$, of a function $u(v)$ of v.

The line segment ℓ through the points $(u(\omega), \pm\omega)$ is the limit as $R \to \infty$ of a family of arcs α_R through $(u(\omega), \pm\omega)$ of circles C_R of radius R having centers $(-z_R, 0)$ on the real axis. Let Γ denote the arc of Γ_W with $u > 0$ and $-\omega < v < \omega$. It is clear that for $R \gg 0$, α_R lies strictly between ℓ and Γ. From now on we will consider only these values of R. Thus, if α_R is given by $(U_R(v), v)$ with $-\omega < v < \omega$, then $0 \le U_R(v) \le u(v)$ holds. It is also clear that $0 \le u(\omega) \le U_R$ holds and so $U_R^2 - u^2(\omega) \ge 0$ holds. (See Figure 4.) It follows that

$$\int_{-\omega}^{\omega} \frac{1}{\sqrt{u^2 - u^2(\omega)}}\, dv < \int_{-\omega}^{\omega} \frac{1}{\sqrt{U_R^2 - u^2(\omega)}}\, dv\,. \tag{12}$$

We will try to obtain a lower bound of $U_R^2 - u^2(\omega)$.

The equation of C_R is

$$(U + z_R)^2 + v^2 = R^2\,, \tag{13}$$

and so

$$(u(\omega) + z_R)^2 + \omega^2 = R^2\,. \tag{14}$$

Subtracting these equations and performing elementary manipulations leads to

$$(U_R - u(\omega))(U_R + u(\omega) + 2z_R) = (\omega^2 - v^2)\,.$$

Letting $\hat{z}_R = \max(0, z_R)$, we have

$$U_R^2 - u^2(\omega) \ge \left[\frac{U_R + u(\omega)}{U_R + u(\omega) + 2\hat{z}_R}\right](\omega^2 - v^2)\,.$$

Since the function on the right is a nondecreasing function of U_R ($\ge u(\omega)$), we have

$$U_R^2 - u^2(\omega) \ge \left[\frac{2u(\omega)}{2u(\omega) + 2\hat{z}_R}\right](\omega^2 - v^2)\,. \tag{15}$$

In order to obtain a lower bound of $U_R^2 - u^2(\omega)$ from (15), we will need a lower bound on $\hat{z}_R$.

LEMMA 3.4. *We consider circles*

$$C_+(a,r) : (U-a)^2 + V^2 = r^2, \qquad U \geq a.$$

If a circle $C_+(a,r)$ touches the right half

$$\Gamma_W^+ := \{(u(\sigma), v(\sigma)) \mid u(\sigma) \geq 0\}$$

of Γ_W at a point (u_0, v_0) $(v_0 \neq 0)$ from the left-hand side, then Γ_W is a circle.

Proof. We denote by $\kappa(v) > 0$ the curvature of Γ_W at (u, v). Then $\kappa(v)$ is an even function and

$$\kappa'(v) \geq 0, \qquad 0 \leq \forall v \leq \bar{\omega}. \tag{16}$$

Set

$$\Gamma := \{(u,v) \in \Gamma_W^+ \mid -|v_0| \leq v \leq |v_0|\},$$
$$C := \{(U,V) \in C_+(a,r) \mid -|v_0| \leq V \leq |v_0|\}.$$

Because of symmetry, C touches Γ on the boundary from the left-hand side.

About the curvatures of these two curves at the point (u_0, v_0), it holds that

$$1/r \geq \kappa(v_0).$$

Therefore, by assumption (W3),

$$1/r \geq \kappa(v), \qquad -v_0 \leq \forall v \leq v_0, \tag{17}$$

holds.

We now move Γ in the negative direction of the u axis so that it does not intersect C. Then we move Γ toward the positive direction of the u axis until it intersects C for the first time, and we denote by $\tilde{\Gamma}$ the translated curve at this time. $\tilde{\Gamma}$ is tangent to C at an interior point $(\tilde{u}, \tilde{v})$. Because of the symmetry of $\tilde{\Gamma}$ and C with respect to the v axis, we may assume that $0 < \tilde{v} \leq v_0$. Since $\tilde{\Gamma}$ lies in the negative side of C with respect to u,

$$1/r \leq \kappa(\tilde{v}) \tag{18}$$

holds. It holds from (16), (17), and (18) that

$$1/r = \kappa(v) \qquad \forall v \in [-v_0, -\tilde{v}] \cup [\tilde{v}, v_0].$$

Therefore, $\tilde{\Gamma}$ is tangent to C at the point (u_0, v_0) and lies on the negative side of C with respect to u. On the other hand, since both $\tilde{\Gamma}$ and Γ are tangent to C at point (u_0, v_0), $\tilde{\Gamma}$ coincides with Γ. Recall that Γ lies on the positive side of C with respect to u. Therefore, Γ coincides with C. Again by assumption (W3), Γ_W is a circle. ∎

LEMMA 3.5. *If we decrease the radius of the circle C_R, then the inequalities*

$$u(\omega) \leq U_R \leq u$$

are satisfied until a value $R = \hat{R}$ is reached, at which the curve $(U_{\hat{R}}(v), v)$ is tangent to the curve (u, v) at the point $(u(0), 0)$. Moreover, $\hat{R} \geq u(0)$ holds. Here, the equality holds if and only if Γ_W is a circle.

Proof. If the Wulff shape W is a sphere, then the statement clearly holds. Hence we assume that W is not a sphere.

Now, assume that the circle $(U_R(v), v)$ is tangent to the curve (u, v) at a point $(u(v_0), v_0)$ $(0 < v_0 \le \omega)$ and

$$u(\omega) \le U_R(v) \le u(v), \qquad -\omega \le \forall v \le \omega,$$

holds. Then, by Lemma 3.4, W must be a sphere, which is a contradiction. Therefore, we have proved the first statement.

Next, we prove $\hat{R} \ge u(0)$. We consider circles $C(r)$ with center at the origin. If $r > 0$ is small, then $C(r)$ is contained in the domain bounded by Γ_W. If we increase r, then, at a certain r_1, $C(r)$ touches Γ_W for the first time from the inside of Γ_W. Because of Lemma 3.4, $C(r)$ touches Γ_W at $(\pm u(0), v(0))$. This implies $\hat{R} \ge u(0)$.

If $\hat{R} = u(0)$, then $C(u(0)) = C_{\hat{R}}$, and this circle touches Γ_W at $(u(\omega), \pm\omega)$. Therefore, by Lemma 3.4, Γ_W is a circle. ∎

Proof of Lemma 3.1. Lemma 3.5 supplies a lower bound for z_R which we denote by $\hat{z}(\omega)$; that is, if $\hat{R}$ is the radius of the circle passing the three points $(u(\omega), \pm\omega), (u(0), 0)$, then

$$\hat{z}(\omega) = \hat{R} - u(0).$$

Therefore,

$$A(\omega) := \left[\frac{u(\omega) + \hat{R} - u(0)}{u(\omega)}\right]^{1/2} = \left[\frac{u(\omega) + \hat{z}(\omega)}{u(\omega)}\right]^{1/2} . \tag{19}$$

We obtain from (12) and (15),

$$\int_{-\omega}^{\omega} \frac{1}{\sqrt{u^2 - u^2(\omega)}}\, dv < A(\omega) \int_{-\omega}^{\omega} \frac{1}{\sqrt{\omega^2 - v^2}}\, dv = A(\omega)\pi . \tag{20}$$

This implies (8). Since the points $(u(\omega), \pm\omega), (u(0), 0)$ lie on the circle given by (13) with center $(-\hat{z}(\omega), 0)$ and radius $\hat{R}$, we have

$$(u(\omega) + \hat{z}(\omega))^2 + \omega^2 = \hat{R}^2 = (u(0) + \hat{z}(\omega))^2 .$$

This leads to

$$\hat{z}(\omega) = \frac{u^2(\omega) + \omega^2 - u^2(0)}{2(u(0) - u(\omega))} > 0 . \tag{21}$$

The last inequality is because the numerator above is nonnegative by Lemma 3.2. By substituting (21) into (19), we obtain

$$A(\omega) = \left[\frac{\omega^2 - (u(0) - u(\omega))^2}{2u(\omega)(u(0) - u(\omega))}\right]^{1/2} . \tag{22}$$

The first inequality in (9) follows from (6), (8), and (22). ∎

4. Proofs of Theorems 2.1, 2.3, 2.4, and 2.5. First, we give a lemma.

LEMMA 4.1. *$V_1 > V_2$ holds.*

Proof.

$$V_1 = \pi h^3 \frac{\int_{-\omega}^{\omega} u^2\, dv}{(2\omega)^3} , \tag{23}$$

$$V_2 = \pi h^3 \frac{\int_{-\omega}^{\bar{\omega}} u^2\, dv}{(\bar{\omega}+\omega)^3} = \pi h^3 \frac{1}{2\omega(\bar{\omega}+\omega)^2} \int_{\frac{-2\omega^2}{\bar{\omega}+\omega}}^{\frac{2\omega\bar{\omega}}{\bar{\omega}+\omega}} u^2(v(\eta))\, d\eta\,, \quad \eta := \frac{2\omega}{\bar{\omega}+\omega} v\,. \tag{24}$$

Since

$$v(\eta) = \frac{\bar{\omega}+\omega}{2\omega}\eta, \qquad \frac{\bar{\omega}+\omega}{2\omega} > 1$$

holds,

$$u(v(\eta)) < u(\eta)$$

holds. Hence,

$$\int_{\frac{-2\omega^2}{\bar{\omega}+\omega}}^{\omega} u^2(v(\eta))\, d\eta < \int_{\frac{-2\omega^2}{\bar{\omega}+\omega}}^{\omega} u^2(v)\, dv \tag{25}$$

holds. Set

$$A := \int_{\omega}^{\frac{2\omega\bar{\omega}}{\bar{\omega}+\omega}} u^2(v(\eta))\, d\eta, \qquad B := \int_{-\omega}^{\frac{-2\omega^2}{\bar{\omega}+\omega}} u^2(v)\, dv.$$

We will show $A < B$. By the symmetry of $u(v)$ with respect to v, we have

$$B = \int_{\frac{2\omega^2}{\bar{\omega}+\omega}}^{\omega} u^2(v)\, dv.$$

Set

$$\xi(\eta) := \eta - \frac{\omega(\bar{\omega}-\omega)}{\bar{\omega}+\omega}.$$

Then

$$v(\eta) = \frac{\bar{\omega}+\omega}{2\omega}\xi + \frac{\bar{\omega}-\omega}{2} > \xi.$$

Therefore, we have

$$A = \int_{\frac{2\omega^2}{\bar{\omega}+\omega}}^{\omega} u^2(v(\eta(\xi)))\, d\xi < \int_{\frac{2\omega^2}{\bar{\omega}+\omega}}^{\omega} u^2(\xi)\, d\xi = B. \tag{26}$$

Formulas (23)–(26) imply that $V_2 < V_1$ holds. ∎

Proof of Theorems 2.1, 2.3, *and* 2.4. First note that, for $V > V_2$, there is no sessile or pendent drop. Especially, by Lemma 4.1, for $V \geq V_1$, there is no sessile or pendent drop.

Assume $0 < \omega \leq \bar{\omega}$. Let $X(s, \theta) = (x(s)e^{i\theta}, z(s))$ be a stable spanning capillary surface. Then, by Theorem 2.2 (ii), X is a convex part of an anisotropic Delaunay surface. From the representation formula (Theorem 6.2) for anisotropic Delaunay surfaces and Remark 6.1, it follows that for stable capillary surfaces, the height h and volume V are given as follows: First note that

$$dz = \frac{z_s}{x_s} dx = \frac{v_\sigma}{u_\sigma} dx = x_u dv$$

holds. Therefore,

$$h = \int_{v=-\omega}^{v=\omega} dz = \int_{-\omega}^{\omega} x_u \, dv = \frac{1}{-\Lambda} \int_{-\omega}^{\omega} 1 + \frac{u}{\sqrt{u^2 + \Lambda c}} \, dv, \tag{27}$$

$$V = \pi \int_{v=-\omega}^{v=\omega} x^2 \, dz = \pi(-\Lambda)^{-3} \int_{-\omega}^{\omega} \frac{(u + \sqrt{u^2 + \Lambda c})^3}{\sqrt{u^2 + \Lambda c}} \, dv,$$

where $\Lambda \leq 0$ is the anisotropic mean curvature of X and c is the flux parameter for X.

We consider the scale invariant quantity,

$$a := -\Lambda c.$$

Then

$$h = \frac{1}{-\Lambda} \int_{-\omega}^{\omega} 1 + \frac{u}{\sqrt{u^2 - a}} \, dv, \tag{28}$$

$$V = \pi(-\Lambda)^{-3} \int_{-\omega}^{\omega} \frac{(u + \sqrt{u^2 - a})^3}{\sqrt{u^2 - a}} \, dv, \tag{29}$$

and we obtain

$$V = \pi h^3 \left(\int_{-\omega}^{\omega} 1 + \frac{u}{\sqrt{u^2 - a}} \, dv \right)^{-3} \int_{-\omega}^{\omega} \frac{(u + \sqrt{u^2 - a})^3}{\sqrt{u^2 - a}} \, dv \,. \tag{30}$$

By applying Hölder's inequality for the measure $dv/\sqrt{u^2 - 1}$ to the formula for h, we obtain

$$h \leq \frac{1}{-\Lambda} \left(\int_{-\omega}^{\omega} \frac{(u + \sqrt{u^2 - a})^3}{\sqrt{u^2 - a}} \, dv \right)^{1/3} \left(\int_{-\omega}^{\omega} \frac{1}{\sqrt{u^2 - a}} \, dv \right)^{2/3}.$$

It then follows that

$$V/h^3 \geq \pi \left(\int_{-\omega}^{\omega} \frac{1}{\sqrt{u^2 - a}} \, dv \right)^{-2} \geq \pi \left(\int_{-\omega}^{\omega} \frac{1}{\sqrt{u^2 - u^2(\omega)}} \, dv \right)^{-2}. \tag{31}$$

If $V_0(h, \omega)$ is defined as the infimum of the volume of all stable capillary surfaces with the given height and ω having *nonempty* boundary components on both planes, (31) shows that $V_0(h, \omega) \geq V^*(h, \omega)$ holds. The first half of Theorem 2.4 then follows from this inequality and Lemma 3.1. The second half of Theorem 2.4 follows easily from Theorem 2.2 (i).

Now we prove Theorems 2.1 and 2.3. Define

$$\Gamma(a, \omega) := \pi \left(\int_{-\omega}^{\omega} 1 + \frac{u}{\sqrt{u^2 - a}} \, dv \right)^{-3} \int_{-\omega}^{\omega} \frac{(u + \sqrt{u^2 - a})^3}{\sqrt{u^2 - a}} \, dv \,. \tag{32}$$

It follows from (28) and (29) that a necessary and sufficient condition for there to exist a spanning, stable capillary surface with prescribed h and V is that $V/h^3 = \Gamma(a, \omega)$ for some real value a.

Note that

$$a = -\Lambda c \le u^2(\omega) \quad \text{for } 0 < \omega \le \bar{\omega},$$

$$0 = u(\bar{\omega}) < u(\omega) < u(0) \quad \text{for } 0 < \omega < \bar{\omega}$$

hold. Also note (see section 6) that for $a > 0$ the capillary surfaces are anisotropic unduloids, for $a = 0$ they are part of the Wulff shape (up to translation and homothety), while for $a < 0$ they are anisotropic nodoids. The result will then follow by showing that with the height h fixed, the volume is a strictly decreasing function of a for $a \le u^2(\omega)$.

First assume $a < u^2(\omega)$. Differentiating (30) with respect to a, we have

$$\begin{aligned} &-2(\pi h^3)^{-1} V_a \left(\int_{-\omega}^{\omega} 1 + \frac{u}{\sqrt{u^2 - a}}\, dv \right)^4 \\ &= 3 \int_{-\omega}^{\omega} \frac{u}{(u^2 - a)^{3/2}}\, dv \int_{-\omega}^{\omega} \frac{(u + \sqrt{u^2 - a})^3}{\sqrt{u^2 - a}}\, dv \\ &- \int_{-\omega}^{\omega} \frac{u + \sqrt{u^2 - a}}{\sqrt{u^2 - a}}\, dv \int_{-\omega}^{\omega} \frac{(u + \sqrt{u^2 - a})^2 (u - 2\sqrt{u^2 - a})}{(u^2 - a)^{3/2}}\, dv. \end{aligned} \tag{33}$$

We will show that the right-hand side of (33) is positive. If

$$u - 2\sqrt{u^2 - a} \le 0$$

holds for all u for $-\omega \le v \le \omega$, then it is done. Assume now that

$$u - 2\sqrt{u^2 - a} > 0 \tag{34}$$

holds for some u. In particular, a must be positive. Note that

$$\begin{aligned} &-2(\pi h^3)^{-1} V_a \left(\int_{-\omega}^{\omega} 1 + \frac{u}{\sqrt{u^2 - a}}\, dv \right)^4 \\ &= \frac{1}{a} \left(3 \int_{-\omega}^{\omega} \frac{au}{(u^2 - a)^{3/2}}\, dv \int_{-\omega}^{\omega} \frac{(u + \sqrt{u^2 - a})^3}{\sqrt{u^2 - a}}\, dv \right. \\ &\left. - \int_{-\omega}^{\omega} \frac{a(u + \sqrt{u^2 - a})}{\sqrt{u^2 - a}}\, dv \int_{-\omega}^{\omega} \frac{(u + \sqrt{u^2 - a})^2 (u - 2\sqrt{u^2 - a})}{(u^2 - a)^{3/2}}\, dv \right). \end{aligned} \tag{35}$$

We will prove that

$$(u + \sqrt{u^2 - a})^3 > a(u + \sqrt{u^2 - a}), \tag{36}$$

$$au > (u + \sqrt{u^2 - a})^2 (u - 2\sqrt{u^2 - a}) \tag{37}$$

holds for any u satisfying (34). Because $a < u^2$ holds, (36) clearly holds. Inequality (34) is equivalent to

$$a < u^2 < \frac{4}{3} a. \tag{38}$$

Set

$$f(u) := au - (u + \sqrt{u^2 - a})^2(u - 2\sqrt{u^2 - a}).$$

Then

$$f(u) = 2(u + \sqrt{u^2 - a})(u^2 - a) > 0$$

holds. This proves (37). Combining (35) with (36) and (37) gives

$$V_a < 0.$$

This implies that V is a strictly decreasing function of a.

It remains to show that the monotonicity extends to the point $a = u^2(\omega)$. This will follow if we can show that, again with the height fixed, V has an extension to $u^2(\omega)$ which is continuous from below.

Both integrals in (32) are of the form

$$\int_{-\omega}^{\omega} \frac{(u + \sqrt{u^2 - a})^p}{\sqrt{u^2 - a}}\, dv$$

with $p = 1, 3$. Also, both integrands are bounded by constant $\cdot\, (\sqrt{u^2 - a})^{-1} \leq$ constant $\cdot\, (\sqrt{u^2 - u^2(\omega)})^{-1}$. Therefore, the continuity of V from below follows by the dominated convergence theorem since it follows from Lemma 3.1 that the integral

$$I := \int_{-\omega}^{\omega} \frac{1}{\sqrt{u^2 - u^2(\omega)}}\, dv$$

is convergent. □

Proof of Theorem 2.5. In the case where $\omega = 0$, because of Theorem 2.2 (i), the statement clearly holds. So, we will assume $0 < \omega \leq \bar{\omega}$. For convenience we will assume that the height is 1. We may assume $z_0 = -1/2$ and $z_1 = 1/2$. For $-\omega \leq v \leq \omega$, we write the generating curve of the Wulff shape as $(u(v), v)$. By using Theorem 6.2 and (28), we can express the coordinates of each capillary surface as $v \mapsto (x(a, v), z(a, v))$, with

$$x(a, v) = \frac{u(v) + \sqrt{u^2(v) - a}}{\int_{-\omega}^{\omega} 1 + u(v)/\sqrt{u^2(v) - a}\, dv}\,.$$

Then for $a < u^2(\omega)$,

$$\begin{aligned}(\partial_a x)(a, v) = &-(1/2)\left(\sqrt{u^2(v) - a}\int_{-\omega}^{\omega} 1 + u(v)/\sqrt{u^2(v) - a}\, dv\right)^{-1}\\ &-(1/2)(u(v) + \sqrt{u^2(v) - a})\left(\int_{-\omega}^{\omega} u(v)(u^2(v) - a)^{-3/2}\, dv\right)\\ &\times\left(\int_{-\omega}^{\omega} (1 + u(v)/\sqrt{u^2(v) - a})\, dv\right)^{-2}\\ &< 0\,.\end{aligned}$$

Thus, for v fixed, $x(a, v)$ is strictly decreasing as a function of a for $a < u^2(\omega)$. Note that the generating curve of each capillary surface can also be represented as a graph $x = \underline{x}(a, z)$, $-1/2 \leq z \leq 1/2$.

We now assume that two generating curves $(x(a,v),z(a,v))$, $(x(b,v),z(b,v))$, $a<b<u^2(\omega)$, intersect. By the above, it is clear that $x(b,0)<x(a,0)$ and equivalently $\underline{x}(b,0)<\underline{x}(a,0)$. Similarly, $x(b,\pm\omega)<x(a,\pm\omega)$ holds, and so equivalently $\underline{x}(b,\pm 1/2)<\underline{x}(a,\pm 1/2)$.

Note that these two curves cannot have any nontransversal intersections for $-1/2<z<1/2$. If they did, then at the point of intersection, the values of v (which depends only on the tangent at each point) for both curves must agree, contradicting the fact that $x(A,v)$ is strictly decreasing in A for $A<u^2(\omega)$.

It follows from the inequalities given above that the two curves have at least two transversal intersections at heights $0<z=\zeta_1<\zeta_2<z_1$. We will assume that ζ_1 is the height of the "first" such intersection and that ζ_2 is the next such intersection.

Since $\underline{x}(b,0)<\underline{x}(a,0)$ holds, we must have

$$\partial_z\underline{x}(a,\zeta_1)\le\partial_z\underline{x}(b,\zeta_1)<0\,,$$

$$\partial_z\underline{x}(b,\zeta_2)\le\partial_z\underline{x}(a,\zeta_2)<0\,.$$

By the intermediate value theorem, $\partial_z\underline{x}(a,\zeta^*)=\partial_z\underline{x}(b,\zeta^*)$ must hold for some $\zeta^*\in[\zeta_1,\zeta_2]$. Note that for $z\in(\zeta_1,\zeta_2)$, $\underline{x}(a,z)<\underline{x}(b,z)$ holds. A contradiction is reached because at the points $(\underline{x}(a,\zeta^*),\zeta^*)$ and $(\underline{x}(b,\zeta^*),\zeta^*)$, the tangent vectors agree and hence the values of v at both points agree. Thus $\underline{x}(a,\zeta^*)>\underline{x}(b,\zeta^*)$ must hold by monotonicity of $x(A,v)$ with respect to A. This shows that distinct generating curves do not intersect.

By (28), it follows that $-\Lambda\to 2\omega$ as $a\to-\infty$. It then follows from the formula for $x(a,v)$ that

$$x(a,0)\to\infty,\quad x(a,\pm\omega)\to\infty,\quad \text{as}\quad a\to-\infty\,.$$

It then follows that since the deformation of the generating curves depends continuously on a, the family of surfaces $\Sigma(V)$ fill out the region exterior to $\Sigma(V_0)$. □

5. Deflating a cylinder. Theorem 2.1 (I) asserts that for each $\omega\in[0,\bar{\omega})$ there is a least volume, stable capillary surface having two boundary components on the planes $z=z_i$, $i=0,1$. One may ask what will occur if the volume of this surface is decreased. It is expected that one or both boundary components will detach from the supporting planes and that the surface of the drop forms into one or more sessile or pendent drops or rescaled Wulff shapes.

In order for the drop to remain, it must be the case that the sessile drop with contact angle $\vartheta(\omega)$ or the entire rescaled Wulff shape with height z_1-z_0 has volume at least as large as V_0. We consider here only the case $\omega=0$. Since, for the fixed height, the entire rescaled Wulff shape contains one-fourth the volume of half of the Wulff shape, we consider the first possibility.

We assume for convenience that $z_1-z_0=1$. Theorem 2.2 (i) implies that the radius R of the least volume stable capillary cylinder satisfies

$$R=\big(\mu_1(0)/\mu_2(0)\big)^{1/2}\pi^{-1}.$$

Therefore, the minimum volume is

$$V_0(\omega=0)=\frac{\mu_1(0)}{\pi\mu_2(0)}\,.$$

Representing, the generating curve of the Wulff shape as $u = u(v)$, we have $\mu_1(0) = -u_{vv}(0)$, $\mu_2(0) = 1/u(0)$, and hence

$$V_0(\omega = 0) = \frac{u(0)|u_{vv}(0)|}{\pi} \,. \tag{39}$$

Proposition 5.1. *Assume* (W1)–(W3). *Then there holds*

$$V_2(\omega = 0) > V_0(\omega = 0) \,.$$

Proof. Let $u = u(v)$ be the generating curve of W. We claim that

$$u(t\bar{\omega}) \geq (1-t)u(0) - (u_{vv}(0)/2)\bar{\omega}^2 t(1-t) \tag{40}$$

holds. Assume this for now.

Using the inequality $(a+b)^2 \geq 4ab$ for all $a, b \geq 0$, we obtain

$$u^2(t\bar{\omega}) \geq 2u(0)|u_{vv}(0)|\bar{\omega}^2 t(1-t)^2 \,.$$

Therefore,

$$\begin{aligned}\int_0^{\bar{\omega}} u^2 \, dv &= \bar{\omega} \int_0^1 u^2(t\bar{\omega}) \, dt \\ &\geq 2u(0)|u_{vv}(0)|\bar{\omega}^3 \int_0^1 t(1-t)^2 \, dt \\ &= (1/6)u(0)|u_{vv}(0)|\bar{\omega}^3 \,.\end{aligned}$$

It follows that

$$\begin{aligned}V_2(\omega = 0) = (\pi/\bar{\omega}^3) \int_0^{\bar{\omega}} u^2 \, dv &\geq (\pi/6)u(0)|u_{vv}(0)| \\ &> (1/\pi)u(0)|u_{vv}(0)| = V_0(\omega = 0) \,.\end{aligned}$$

We now show (40). Let $H(t) = u(t\bar{\omega}) - (1-t)u(0) + (u_{vv}(0)/2)\bar{\omega}^2 t(1-t)$. Note that $H(0) = H(1) = 0$. If (40) doesn't hold, then H attains a negative minimum at some point in $(0,1)$ where $H'' \geq 0$ holds. A simple calculation shows that $H''(t) = \bar{\omega}^2(u_{vv}(t\bar{\omega}) - u_{vv}(0))$, which is negative since $-u_{vv} > -u_{vv}(1+u_v^2)^{-3/2} \geq -u_{vv}(0)$ holds on $(0, \bar{\omega})$ by assumption (W3) on the curvature of the Wulff shape. ☐

6. Appendix. Anisotropic Delaunay surfaces. We summarize important results about surfaces of revolution with constant anisotropic mean curvature for a rotationally symmetric energy functional (anisotropic Delaunay surfaces). Such surfaces were studied in detail by the authors in [4] (see also [5] and [6]).

Let

$$\chi(\sigma, \theta) = (u(\sigma)e^{i\theta}, v(\sigma))$$

be a parametrization of the Wulff shape W, where $(u(\sigma), v(\sigma))$ is the arc length parametrization of the generating curve. We have identified $\mathbf{R}^3$ with $\mathbf{C} \times \mathbf{R}$ in the formula above. We may extend $(u(\sigma), v(\sigma))$ so that it is defined for all real numbers σ. In this case, $(u(\sigma), v(\sigma))$ represents the section of W by (x_1, x_3)-plane.

Consider an anisotropic Delaunay surface Σ parameterized by

$$X(s,\theta) = (x(s)e^{i\theta}, z(s))\,,$$

where $(x(s), z(s))$ is the arc length parameterization of the generating curve, and $x(s) \geq 0$ holds for all s. The Gauss map of the surface X is given by

$$\nu = (z'(s)e^{i\theta}, -x'(s)).$$

We choose the orientation of the generating curve so that ν points "outward" from the surface. There is a natural map from the surface to the Wulff shape W defined by the requirement that the oriented tangent planes to both surfaces agree at corresponding points. Thus, at corresponding points the outward pointing unit normals must agree and we have

$$x' = u_\sigma\,, \qquad z' = v_\sigma. \tag{41}$$

In [4], we showed that the profile curve (x, z) satisfies the equation

$$2{\mu_2}^{-1}xz' + \Lambda x^2 = c\,, \tag{42}$$

where Λ is the anisotropic mean curvature and c is a real constant called the flux parameter. Also, $-\mu_2$ is the principal curvature of the Wulff shape in the θ direction. Since W is a surface of revolution, we have $\mu_2 = \mu_2(\nu_3) = \mu_2(-u_\sigma) = \mu_2(-x')$ by (41). Computing the principal curvature $-\mu_2 = -v_\sigma/u$, (42) can be expressed as

$$2ux + \Lambda x^2 = c\,. \tag{43}$$

The orientation of an anisotropic Delaunay surface may be chosen so that $\Lambda \leq 0$ holds and then the anisotropic Delaunay surfaces fall into six cases as follows:

(I-1) $\Lambda = 0$ and $c = 0$: *horizontal plane.*
(I-2) $\Lambda = 0$ and $c \neq 0$: *anisotropic catenoid.*
(II-1) $\Lambda < 0$ and $c = 0$: *Wulff shape (up to vertical translation and homothety).*
(II-2) $\Lambda < 0$ and $c = ((\mu_2|_{\nu_3=0})^2|\Lambda|)^{-1}$: *cylinder of radius* $(\mu_2|_{\nu_3=0}|\Lambda|)^{-1}$.
(II-3) $\Lambda < 0$ and $((\mu_2|_{\nu_3=0})^2|\Lambda|)^{-1} > c > 0$: *anisotropic unduloid.*
(II-4) $\Lambda < 0$ and $c < 0$: *anisotropic nodoid.*

Any surface in each case above is complete, and it has similar properties to the corresponding CMC surface in the sense of the following theorem.

THEOREM 6.1 (see [4], [5], [6]).

(i) *The generating curve $C : (x(s), z(s))$ of an anisotropic catenoid is a graph over the whole z axis, and $z'(s) \neq 0$ for all s. C is perpendicular to the horizontal line at a unique point.*
(ii) *Let $(x(s), z(s))$, $x \geq 0$, be the generating curve of an anisotropic unduloid or an anisotropic nodoid. Then there is a unique local maximum B and a unique local minimum $N > 0$ of x, which we will call a bulge and a neck, respectively.*
(iii) *The generating curve $C : (x(s), z(s))$ of an anisotropic unduloid is a graph over the z axis, and $z'(s) > 0$ for all s. C is a periodic curve with respect to the vertical translation, and the region from one neck to the next neck (and/or one bulge to the next bulge) gives one period. Therefore, C has a unique inflection point (x, z) between each neck and the next bulge, which satisfies $x = \sqrt{c/(-\Lambda)}$.*

(iv) *The curvature of the generating curve C of an anisotropic nodoid has a definite sign. C is a nonembedding periodic curve with respect to the vertical translation. The region from one neck to the next neck (and/or one bulge to the next bulge) gives one period.*

In the previous sections, we needed a representation formula for the profile curves, which is summarized in the following result from [4].

THEOREM 6.2 (see [4]). *Let W be the Wulff shape of a rotationally symmetric anisotropic surface energy $\mathcal{F}$. Let*

$$\sigma \mapsto (u(\sigma), v(\sigma)), \quad \sigma \in (-\infty, \infty),$$

be the profile curve of W, where σ is the arc length. Then

$$\mu_2^{-1} v_\sigma - u = 0$$

holds. Let $X(s,\theta) = (x(s)e^{i\theta}, z(s))$ be a surface with constant anisotropic mean curvature $\Lambda \leq 0$, and let the Gauss map of X coincide with that of W at $s = s(\sigma)$. Then X is given as follows.

(i) *When X is an anisotropic catenoid,*

$$x = c/(2u)$$

for some nonzero constant c.

(ii) *When X is an anisotropic unduloid,*

$$x = \frac{u \pm \sqrt{u^2 + \Lambda c}}{-\Lambda}$$

for some constants $c > 0$ and $\Lambda < 0$, where $x = x(u(\sigma))$ is defined in $\{\sigma | u \geq \sqrt{-\Lambda c}\}$.

(iii) *When X is an anisotropic nodoid,*

$$x = \frac{u + \sqrt{u^2 + \Lambda c}}{-\Lambda}$$

for some constants $c < 0$ and $\Lambda < 0$, where $x = x(u(\sigma))$ is defined in $\{-\infty < \sigma < \infty\}$.

In all cases above, z is given by

$$z = \int^u v_u x_u \, du. \tag{44}$$

Conversely, for a Wulff shape W defined as above, define x and z as in (i)–(iii) *and* (44). *Then $X(s,\theta) = (x(s)e^{i\theta}, z(s))$ is an anisotropic Delaunay surface which satisfies*

$$2\mu_2^{-1} z_s x + \Lambda x^2 = c,$$

where s is the arc length of (x, z), and Λ is supposed to be zero for case (i). *Moreover, X has the same regularity as that of W.*

Remark 6.1. In (ii) of Theorem 6.2, $x = (-\Lambda)^{-1}(u + \sqrt{u^2 + \Lambda c})$ gives the part of the anisotropic unduloid whose Gaussian curvature is positive (i.e., the convex part), while $x = (-\Lambda)^{-1}(u - \sqrt{u^2 + \Lambda c})$ gives the part of the anisotropic unduloid whose Gaussian curvature is negative.

Remark 6.2. In (iii) of Theorem 6.2, $u > 0$ corresponds to the part of the anisotropic nodoid whose Gaussian curvature is positive (i.e., the convex part), while $u < 0$ gives the part of the anisotropic nodoid whose Gaussian curvature is negative.

Acknowledgment. We would like to convey our sincere thanks to the referees for calling the references [3], [9], and [10] to our attention and suggesting various improvements to our paper.

NAVIER–STOKES EQUATIONS INTERACTING WITH A NONLINEAR ELASTIC BIOFLUID SHELL*

C. H. ARTHUR CHENG†, DANIEL COUTAND†, AND STEVE SHKOLLER‡

Abstract. We study a moving boundary value problem consisting of a viscous incompressible fluid moving and interacting with a nonlinear elastic fluid shell. The fluid motion is governed by the Navier–Stokes equations, while the fluid shell is modeled by a bending energy which extremizes the Willmore functional and a membrane energy with density given by a convex function of the local area ratio. The fluid flow and shell deformation are coupled together by continuity of displacements and tractions (stresses) along the moving surface defining the shell. We prove the existence and uniqueness of solutions in Sobolev spaces for a short time.

Key words. Navier–Stokes equations, free boundary problems, shell theory, biofluids, Willmore energy

1. Introduction.

1.1. The problem statement and background. We are concerned with establishing the existence and uniqueness of solutions to the time-dependent incompressible Navier–Stokes equations interacting with a nonlinear elastic fluid shell (biomembrane) for a short time. Recently, there have been many experimental and analytic studies on the configurations and deformations of elastic biomembranes (see, for example, [3], [11], [13], [16], [17], [18], [19], and [21]), but the basic analysis of the coupled fluid-structure interaction remains open. The fundamental difficulties arise from the degenerate elliptic operators that arise as the shell tractions. As we detail below, the bending energy of the shell is the well-known Willmore function, the integral over the moving surface of the square of the mean curvature. The degenerate elliptic operator arising from the first variation of this functional is a fourth order nonlinear operator that smoothes only in the direction which is normal to the moving domain. Our analysis will provide a well-posedness theorem and explain the interesting interaction between the shape of the shell and the flow of the fluid.

Fluid-structure interaction problems involving moving material interfaces have been the focus of active research since the 1990s. The first problem solved in this area was for the case of a rigid body moving in a viscous fluid (see [9], [14], and the early works of [22] and [20] for a rigid body moving in a Stokes flow in the full space). The case of an elastic body moving in a viscous fluid was considerably more challenging because of some apparent regularity incompatibilities between the parabolic fluid phase and the hyperbolic solid phase. The first existence results in this area were for regularized elasticity laws, such as in [10] for a *finite* number of

elastic modes, or in [1], [4], and [2] for hyperviscous elasticity laws, or in [15] in which a phase-field regularization "fattens" the sharp interface via a diffuse-interface model.

The treatment of classical elasticity laws for the solid phase, without any regularizing term, was considered only recently in [7] for the three-dimensional linear St. Venant–Kirchhoff constitutive law and in [8] for quasi-linear elastodynamics coupled to the Navier–Stokes equations. Some of the basic new ideas introduced in those works concerned a functional framework that scales in a hyperbolic fashion (and is therefore driven by the solid phase), the introduction of approximate problems either penalized with respect to the divergence-free constraint in the moving fluid domain or smoothed by an appropriate parabolic artificial viscosity in the solid phase (chosen in an asymptotically convergent and consistent fashion), and the tracking of the motion of the interface by difference quotient techniques.

In our companion paper [5], we study the interaction of the Navier–Stokes equations with an elastic solid shell. Herein, we treat the case of a fluid shell or biomembrane. This is a moving boundary problem that models the motion of a viscous incompressible Newtonian fluid inside of a deformable elastic fluid structure.

Let $\Omega \subset \mathbb{R}^3$ denote an open bounded domain with boundary $\Gamma := \partial\Omega$. For each $t \in (0,T]$, we wish to find the domain $\Omega(t)$, a divergence-free velocity field $u(t,\cdot)$, a pressure function $p(t,\cdot)$ on $\Omega(t)$, and a volume-preserving transformation $\eta(t,\cdot) : \Omega \to \mathbb{R}^3$ such that

$$\Omega(t) = \eta(t,\Omega), \tag{1.1a}$$
$$\eta_t(t,x) = u(t,\eta(t,x)), \tag{1.1b}$$
$$u_t + \nabla_u u - \nu\Delta u = -\nabla p + f \quad \text{in } \Omega(t), \tag{1.1c}$$
$$\operatorname{div} u = 0 \quad \text{in } \Omega(t), \tag{1.1d}$$
$$(\nu \operatorname{Def} u - p \operatorname{Id})n = \mathfrak{t}_{shell} \quad \text{on } \Gamma(t), \tag{1.1e}$$
$$u(0,x) = u_0(x) \quad \forall\, x \in \Omega, \tag{1.1f}$$
$$\eta(0,x) = x \quad \forall\, x \in \Omega, \tag{1.1g}$$

where ν is the kinematic viscosity, $n(t,\cdot)$ is the outward pointing unit normal to $\Gamma(t)$, $\Gamma(t) := \partial\Omega(t)$ denotes the boundary of $\Omega(t)$, $\operatorname{Def} u$ is twice the rate of deformation tensor of u, given in coordinates by $u^i_{,j} + u^j_{,i}$, and $\mathfrak{t}_{shell}$ is the traction imparted onto the fluid by the elastic shell, which we describe next.

We shall consider a thin elastic shell modeled by the nonlinear Saint Venant–Kirchhoff constitutive law. With ε denoting the thickness of the shell, the hyperelastic stored energy function has the asymptotic expansion

$$E_{shell} = \varepsilon E_{mem} + \varepsilon^3 E_{ben} + \mathcal{O}(\varepsilon^4).$$

The membrane energy satisfies

$$E_{mem} = \int_\Gamma \mathcal{P}(\mathcal{J})dS, \tag{1.2}$$

where $\mathcal{J}$ is the local area ratio and $\mathcal{P}$ is a convex function attaining its minimum at $\mathcal{J} = 1$, while the bending energy E_{ben} is given by

$$E_{ben} = \int_{\Gamma(t)} (\sigma H^2 - \sigma_1 K)dS, \tag{1.3}$$

where H and K denote the mean and Gauss curvatures on $\Gamma(t)$, respectively, and where σ and σ_1 are positive constants. The traction vector

$$\mathfrak{t}_{shell} = \varepsilon \mathfrak{t}_{mem} + \varepsilon^3 \mathfrak{t}_{ben} + \mathcal{O}(\varepsilon^4)$$

is computed from the first variation of the energy function E_{shell}; the traction vector associated with the membrane energy is

$$\mathfrak{t}_{\text{mem}} = \Big[\mathcal{J}\mathcal{P}''(\mathcal{J}) + 2\mathcal{P}'(\mathcal{J})\Big]\mathcal{J}_{,\beta} g^{\alpha\beta}\eta_{,\alpha} + \Big[\mathcal{J}\mathcal{P}'(\mathcal{J}) + \mathcal{P}(\mathcal{J})\Big]Hn, \tag{1.4}$$

while the traction associated with the bending energy has a simple intrinsic characterization given by

$$\mathfrak{t}_{ben} = \sigma(\Delta_g H - 2HK + 2H^3)n, \tag{1.5}$$

where Δ_g denotes the Laplacian with respect to the induced metric g on $\Gamma(t)$:

$$\Delta_g f = \frac{1}{\sqrt{\det(g)}} \frac{\partial}{\partial x^\alpha}\left(\sqrt{\det(g)} g^{\alpha\beta} \frac{\partial f}{\partial x^\beta}\right).$$

In this paper, we ignore the inertia of the shell and focus our analysis on the difficulties associated with the degenerate elliptic operators in $\mathfrak{t}_{shell}$.

1.2. Outline of the paper. In section 2, in addition to the use of Lagrangian variables, we introduce a new coordinate system near the boundary (shell) and three new maps, η^ν, η^τ, and h, which facilitate the computation of the membrane and bending tractions $\mathfrak{t}_{\text{mem}}$ and $\mathfrak{t}_{\text{ben}}$. A key observation is the symmetry relation (2.7) which reduces the derivative count on the tangential reparameterization map η^τ.

The space of solutions (to the problem $\mathfrak{t}_{mem} = 0$) is introduced in section 3, and the main theorem is stated in section 4. Section 5 defines our notation, and section 6 provides some useful lemmas.

In section 7, we introduce the linearized and regularized problems. The regularization requires smoothing certain variables as well as the introduction of a certain artificial viscosity term on the boundary of the fluid domain. Weak solutions of this linear problem are established via a penalization scheme which approximates the incompressibility of the fluid.

In section 8, we establish a regularity theory for our weak solution using energy estimates for the mollified problem with constants that depend on the mollification parameters. In section 9, we improve these estimates so that the constants are independent of the artificial viscosity as well as other regularization parameters. This requires an elliptic estimate, arising from the boundary condition (1.1e), which provides additional regularity for the shape of the boundary.

In section 10, the Tychonoff fixed-point theorem is used to prove the existence of solutions to the original nonlinear problem (1.1). Uniqueness, following required compatibility conditions, is established in sections 4 and 10.

In section 11, we consider the inclusion of the lower order membrane traction into the problem formulation so that the full problem is solved.

The inclusion of the inertial term $\epsilon_1\eta_{tt}$ into the membrane traction $\mathfrak{t}_{\text{mem}}$ will be studied in a future publication.

2. Lagrangian formulation.

2.1. A new coordinate system near the shell. Consider the isometric immersion $\eta_0 : (\Gamma, g_0) \to (\mathbb{R}^3, \text{Id})$. Let $\mathcal{B} = \Gamma \times (-\epsilon_1, \epsilon_1)$, where ϵ_1 is chosen sufficiently small so that the map

$$B : \mathcal{B} \to \mathbb{R}^3 : (y, z) \mapsto y + zN(y)$$

is itself an immersion, defining a tubular neighborhood of Γ in $\mathbb{R}^3$. We can choose a coordinate system $\frac{\partial}{\partial y^\alpha}$, $\alpha = 1, 2$, and $\frac{\partial}{\partial z}$ on $\mathcal{B}$, where $\frac{\partial}{\partial y^\alpha}$ denotes the tangential derivative and $\frac{\partial}{\partial z}$ denotes the normal derivative.

Let $G = B^*(\mathrm{Id})$ denote the induced metric on $\mathcal{B}$ from $\mathbb{R}^3$ so that

$$G(y, z) = G_z(y) + dz \otimes dz,$$

where G_z is the metric on the surface $\Gamma \times \{z\}$; note that $G_0 = g_0$.

REMARK 1. *By assumption,* $g_{0\alpha\beta} = \frac{\partial}{\partial y^\alpha} \cdot \frac{\partial}{\partial y^\beta}$, *where* $\cdot$ *denotes the usual Cartesian inner product on* $\mathbb{R}^n$. *Let* $C_{\alpha\beta}$ *denote the covariant components of the second fundamental form of the base manifold* Γ *so that* $C_{\alpha\beta} = -N_{,\alpha} \cdot \frac{\partial}{\partial y^\beta}$. *Then* G_z *is given by*

$$(G_z)_{\alpha\beta} = (g_0)_{\alpha\beta} - 2zC_{\alpha\beta} + z^2 g_0^{\gamma\delta} C_{\alpha\gamma} C_{\beta\delta}.$$

Let $h : \Gamma \to (-\epsilon_1, \epsilon_1)$ be a smooth height function and consider the graph of h in $\mathcal{B}$, parameterized by $\phi : \Gamma \to \mathcal{B} : y \mapsto (y, h(y))$. The tangent space to graph(h), considered as a submanifold of $\mathcal{B}$, is spanned at a point $\phi(x)$ by the vectors

$$\phi_* \left(\frac{\partial}{\partial y^\alpha} \right) = \frac{\partial \phi}{\partial y^\alpha} = \frac{\partial}{\partial y^\alpha} + \frac{\partial h}{\partial y^\alpha} \frac{\partial}{\partial z},$$

and the normal to graph(h) is given by

$$n(y) = J_h^{-1}(y) \left(-G_{h(y)}^{\alpha\beta} \frac{\partial h}{\partial y^\alpha} \frac{\partial}{\partial y^\beta} + \frac{\partial}{\partial z} \right), \tag{2.1}$$

where $J_h = (1 + h_{,\alpha} G_{h(y)}^{\alpha\beta} h_{,\beta})^{1/2}$. The mean curvature H of graph(h) is defined to be the trace of ∇n, where

$$(\nabla n)_{ij} = G\left(\nabla^{\mathcal{B}}_{\frac{\partial}{\partial w^i}} n, \frac{\partial}{\partial w^j} \right) \quad \text{for } i, j = 1, 2, 3,$$

where $\frac{\partial}{\partial w^\alpha} = \frac{\partial}{\partial y^\alpha}$ for $\alpha = 1, 2$ and $\frac{\partial}{\partial w^3} = \frac{\partial}{\partial z}$, and $\nabla^{\mathcal{B}}$ denotes the covariant derivative. Using (2.1),

$$\begin{aligned}
(\nabla n)_{\alpha\beta} &= G\left(\nabla^{\mathcal{B}}_{\frac{\partial}{\partial y^\alpha}} \left[-J_h^{-1} G_h^{\gamma\delta} h_{,\gamma} \frac{\partial}{\partial y^\delta} + J_h^{-1} \frac{\partial}{\partial z} \right], \frac{\partial}{\partial y^\beta} \right) \\
&= -(G_h)_{\delta\beta} \Big[(J_h^{-1} G_h^{\gamma\delta} h_{,\gamma})_{,\alpha} + J_h^{-1} (-G_h^{\gamma\sigma} h_{,\gamma} \Gamma^\delta_{\alpha\sigma} + \Gamma^\delta_{\alpha 3}) \Big]; \\
(\nabla n)_{33} &= G\left(\nabla^{\mathcal{B}}_{\frac{\partial}{\partial z}} \left[-J_h^{-1} G_h^{\gamma\delta} h_{,\gamma} \frac{\partial}{\partial y^\delta} + J_h^{-1} \frac{\partial}{\partial z} \right], \frac{\partial}{\partial z} \right) \\
&= J_h^{-1} (-G_h^{\gamma\delta} h_{,\gamma} \Gamma^3_{3\delta} + \Gamma^3_{33}),
\end{aligned}$$

where Γ^k_{ij} denotes the Christoffel symbols with respect to the metric G. It follows that the curvature of graph(h) (in the divergence form) is

$$H = -(J_h^{-1} G_h^{\gamma\delta} h_{,\gamma})_{,\delta} + J_h^{-1} (-G_h^{\gamma\delta} h_{,\gamma} \Gamma^j_{j\delta} + \Gamma^j_{j3}), \tag{2.2}$$

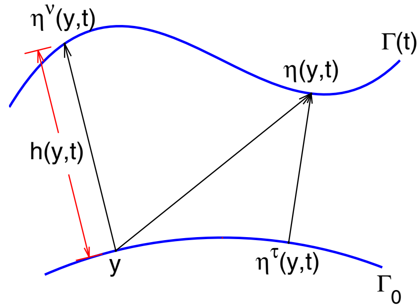

FIG. 1. *The maps η^τ and η^ν.*

or (in the quasi-linear form)

$$H = -J_h^{-1} G_h^{\alpha\beta} \Big[\delta_{\beta\gamma} - J_h^{-2} G_h^{\gamma\delta} h_{,\beta} h_{,\delta} \Big] h_{,\alpha\gamma} + G_h^{\alpha\beta} F_{\alpha\beta}(y, h, \nabla h), \tag{2.3}$$

where $F_{\alpha\beta}$ denotes a smooth generic function of y, h, and ∇h.

REMARK 2. *Note that G_h denotes the metric $G_{z=h(y)}$ and not the metric on the submanifold graph(h).*

REMARK 3. *If the initial height function is zero, i.e., $h(0) = 0$, then $H(0) = \Gamma^j_{j3}(0)$ which is the mean curvature of the base manifold Γ as required.*

2.2. Tangential reparameterization symmetry. Let $\mathcal{N}$ denote the normal bundle to Γ so that for each $y \in \Gamma$ we have the Whitney sum $\mathbb{R}^3 = T_y\Gamma \oplus \mathcal{N}_y$.

Given a signed height function $h : \Gamma \times [0, T) \to \mathbb{R}$, for each $t \in [0, T)$, define the *normal* map (see Figure 1)

$$\eta^\nu : \Gamma \times [0, T) \to \Gamma(t), \quad (y, t) \mapsto y + h(y, t)N(y), \quad N(y) \in \mathcal{N}_y.$$

Then there exists a unique *tangential* map $\eta^\tau : \Gamma \times [0, T) \to \Gamma$ (a diffeomorphism as long as h remains a graph) such that the diffeomorphism $\eta(t)$ has the decomposition

$$\eta(\cdot, t) = \eta^\nu(\cdot, t) \circ \eta^\tau(\cdot, t), \quad \eta(y, t) = \eta^\tau(y, t) + h(\eta^\tau(y, t), t)N(\eta^\tau(y, t)).$$

The tangent vector $\eta_{,\alpha}$ to $\Gamma(t)$ can be decomposed with respect to the Whitney sum as $\eta_{,\alpha}(y, t) = \eta^\kappa_{,\alpha}(y, t)\frac{\partial}{\partial y^\kappa} + h_{,\kappa}(\eta^\tau(y, t), t)\eta^\kappa_{,\alpha}\frac{\partial}{\partial z}$, and hence the induced metric $g_{\alpha\beta} = \eta_{,\alpha} \cdot \eta_{,\beta}$ may be expressed as

$$g_{\alpha\beta} = \Big[\Big((G_h)_{\kappa\sigma} + h_{,\kappa} h_{,\sigma} \Big) \circ \eta^\tau \Big] \eta^\kappa_{,\alpha} \eta^\sigma_{,\beta} := \Big[\mathcal{G}_{\kappa\sigma} \circ \eta^\tau \Big] \eta^\kappa_{,\alpha} \eta^\sigma_{,\beta}. \tag{2.4}$$

Note that $\mathcal{G}_{\kappa\sigma}$ is the induced metric with respect to the *normal* map η^ν. Furthermore, we have the following useful relationship between the determinant of the two induced metrics:

$$\det(g) = \det(\nabla_0 \eta^\tau)^2 \Big[\det(G_h) J_h^2 \Big] \circ \eta^\tau = \det(\nabla_0 \eta^\tau)^2 \Big[\det(\mathcal{G}) \Big] \circ \eta^\tau, \tag{2.5}$$

where ∇_0 denotes the surface gradient.

REMARK 4. *The identity* (2.4) *can also be read as $(\eta^\tau)^* g = \mathcal{G}$.*

Let y and $\tilde{y} = \varphi(y)$ denote two different coordinate systems on Γ with associated metrics

$$g_{\alpha\beta} = \frac{\partial \eta^i}{\partial y^\alpha}\frac{\partial \eta^i}{\partial y^\beta}, \qquad \tilde{g}_{\alpha\beta} = \frac{\partial \eta^i}{\partial \tilde{y}^\alpha}\frac{\partial \eta^i}{\partial \tilde{y}^\beta}.$$

It follows that $\varphi^*\tilde{g} = g$. Let H, $\tilde{H}$, K, $\tilde{K}$, n, and $\tilde{n}$ denote the mean curvature, Gauss curvature, and the unit normal vector computed with respect to y and $\tilde{y}$, respectively. Since H, K, and n depend only on the shape of $\Gamma(t)$, these geometric quantities are invariant to tangential reparameterization; thus, we have the identity

$$\tilde{H} = H \circ \varphi, \quad \tilde{K} = K \circ \varphi, \quad \tilde{n} = n \circ \varphi. \tag{2.6}$$

Similarly, computing the first variation of $\int_{\Gamma(t)} H^2 dS$ in our two coordinate systems yields

$$\Big[\Big(\Delta_g H + H(H^2 - K)\Big)n\Big](y) = \Big[\Big(\Delta_{\tilde{g}}\tilde{H} + \tilde{H}(\tilde{H}^2 - \tilde{K})\Big)\tilde{n}\Big](\tilde{y}) \qquad \forall\ \tilde{y} = \varphi(y).$$

By (2.6), we have the following important identity:

$$\Big[\Delta_{\varphi^*\tilde{g}} H\Big](y) = \Big[\Delta_{\tilde{g}}(H \circ \varphi)\Big](\tilde{y}) \qquad \forall\ \tilde{y} = \varphi(y), \tag{2.7}$$

and hence

$$[\Delta_{\mathcal{G}}(H \circ \eta^{-\tau})] \circ \eta^\tau = \Delta_g H, \tag{2.8}$$

where by (2.3),

$$H \circ \eta^{-\tau} = -J_h^{-1} G_h^{\alpha\beta}\Big[\delta_{\beta\gamma} - J_h^{-2} G_h^{\gamma\delta} h_{,\beta} h_{,\delta}\Big] h_{,\alpha\gamma} + G_h^{\alpha\beta} F_{\alpha\beta}(y, h, \nabla h). \tag{2.9}$$

2.3. Bounds on $\boldsymbol{\eta^\tau}$. Let u^τ denote the tangential velocity defined by $\eta^\tau_t = u^\tau \circ \eta^\tau$. Time differentiating the relation $\eta = \eta^\nu \circ \eta^\tau$ and using the definition of η^ν, we find that

$$u^\tau = (\nabla_0 \eta^\nu)^{-1}\Big[u \circ \eta^\nu - h_t \frac{\partial}{\partial z}\Big]. \tag{2.10}$$

From the trace theorem, it follows that

$$\|u^\tau\|_{H^{2.5}(\Gamma)} \le C\mathcal{P}(\|h\|_{H^{3.5}(\Gamma)}, \|\eta\|_{H^3(\Omega)})\Big[\|v\|_{H^3(\Omega)} + \|h_t\|_{H^{2.5}(\Gamma)}\Big] \tag{2.11}$$

for some polynomial $\mathcal{P}$. Since $\eta^\tau(y,t) = y + \int_0^t (u^\tau \circ \eta^\tau)(y,s)ds$, it follows that

$$\|\nabla_0 \eta^\tau(y,t)\|_{H^{1.5}(\Gamma)} \le C\Big[1 + \int_0^t \|u^\tau\|_{H^{2.5}(\Gamma)}\Big(1 + \|\nabla_0\eta^\tau\|_{H^{1.5}(\Gamma)}\Big)^4 ds\Big],$$

and hence by Gronwall's inequality,

$$\|\nabla_0 \eta^\tau(y,t)\|_{H^{1.5}(\Gamma)} \le C\Big[1 + \int_0^t \|u^\tau\|_{H^{2.5}(\Gamma)} ds\Big] \tag{2.12}$$

for $t \in [0,T]$ sufficiently small. Furthermore, we also have

$$\|\eta^\tau_t(y,t)\|_{H^{2.5}(\Gamma)} \le C\|u^\tau\|_{H^{2.5}(\Gamma)}\Big[1 + \|\nabla_0\eta^\tau\|_{H^{1.5}(\Gamma)}\Big]^4. \tag{2.13}$$

2.4. An expression for $\mathbf{t}_{\mathbf{ben}}$ in terms of h and η^τ. Now we can compute $\mathbf{t}_{ben}$ in terms of h and η^τ: the highest order term of $\Delta_g H$ is

$$\left\{\frac{1}{\sqrt{\det(\mathcal{G})}}\frac{\partial}{\partial y^\gamma}\left[\sqrt{\det(\mathcal{G})}\mathcal{G}^{\gamma\delta}\frac{\partial}{\partial y^\delta}\Big(J_h^{-1}(G_h^{\alpha\beta}-J_h^{-2}G_h^{\alpha\kappa}G_h^{\beta\sigma}h_{,\kappa}h_{,\sigma})h_{,\alpha\beta}\Big)\right]\right\}\circ\eta^\tau.$$

Since $\mathcal{G}_{\alpha\beta}=(G_h)_{\alpha\beta}+h_{,\alpha}h_{,\beta}$, the inverse of $\mathcal{G}_{\gamma\delta}$ is

$$\frac{1}{\det(\mathcal{G})}\begin{bmatrix}(G_h)_{22}+h_{,2}^2 & -(G_h)_{12}-h_{,1}h_{,2}\\ -(G_h)_{12}-h_{,1}h_{,2} & (G_h)_{11}+h_{,1}^2\end{bmatrix},$$

which can also be written as

$$\mathcal{G}^{\alpha\beta}=J_h^{-2}\Big[G_h^{\alpha\beta}-(-1)^{\kappa+\sigma}\det(G_h)^{-1}(1-\delta_{\alpha\kappa})(1-\delta_{\beta\sigma})h_{,\kappa}h_{,\sigma}\Big].$$

Therefore, the highest order term of $\Delta_g H$ can be written as

$$\frac{1}{\sqrt{\det(g_0)}}\Big[\sqrt{\det(g_0)}A^{\alpha\beta\gamma\delta}h_{,\alpha\beta}\Big]_{,\gamma\delta}\circ\eta^\tau,$$

where

$$\begin{aligned}A^{\alpha\beta\gamma\delta}=J_h^{-3}&\Big[G_h^{\alpha\gamma}-(-1)^{\kappa+\sigma}\det(G_h)^{-1}(1-\delta_{\alpha\kappa})(1-\delta_{\gamma\sigma})h_{,\kappa}h_{,\sigma}\Big]\\ &\times(G_h^{\beta\delta}-J_h^{-2}G_h^{\beta\kappa}G_h^{\delta\sigma}h_{,\kappa}h_{,\sigma})\end{aligned}\tag{2.14}$$

is a fourth-rank tensor.

2.5. Lagrangian formulation of the problem. Let $\eta(t,x)=x+\int_0^t u(s,x)ds$ denote the Lagrangian particle placement field, a volume-preserving embedding of Ω onto $\Omega(t)\subset\mathbb{R}^3$, and denote the cofactor matrix of $\nabla\eta(x,t)$ by

$$a(x,t)=[\nabla\eta(x,t)]^{-1}.\tag{2.15}$$

Let $v=u\circ\eta$ denote the Lagrangian or material velocity field, $q=p\circ\eta$ the Lagrangian pressure function, and $F=f\circ\eta$ the forcing function in the material frame. In the following discussion, we also set $\varepsilon=1$. Then the system (1.1) can be reformulated as

$$\eta_t=v \quad \text{in } (0,T)\times\Omega,\tag{2.16a}$$

$$v_t^i-\nu(a_\ell^j D_\eta(v)_\ell^i)_{,j}=-(a_i^k q)_{,k}+F^i \quad \text{in } (0,T)\times\Omega,\tag{2.16b}$$

$$a_i^k v_{,k}^i=0 \quad \text{in } (0,T)\times\Omega,\tag{2.16c}$$

$$(\nu D_\eta(v)_\ell^i-q\delta_\ell^i)a_\ell^j N_j=\sigma\Theta\Big[L(h)B_*(-G_h^{\alpha\beta}h_{,\alpha},1)\Big]\circ\eta^\tau \quad \text{on } (0,T)\times\Gamma,\tag{2.16d}$$

$$h_t=B_*((-G_h^{\alpha\beta}h_{,\alpha},1))\cdot(v\circ\eta^{-\tau}) \quad \text{on } (0,T)\times\Gamma,\tag{2.16e}$$

$$v=u_0 \quad \text{on } \{t=0\}\times\Omega,\tag{2.16f}$$

$$h=0 \quad \text{on } \{t=0\}\times\Gamma,\tag{2.16g}$$

$$\eta=\mathrm{Id} \quad \text{on } \{t=0\}\times\Omega,\tag{2.16h}$$

where $D_\eta(v)_\ell^i:=(a_\ell^k v_{,k}^i+a_i^k v_{,k}^\ell)$, N denotes the outward-pointing unit normal to Γ, Θ is defined in Remark 5, and B_* is the pushforward of B defined as

$$B_*(\gamma'(0))=(B\circ\gamma)'(0)\qquad\forall\ \gamma(t)\subset\Gamma.$$

$L(h)$ is the representation of $\mathfrak{t}_{shell} \cdot n$ using the height function h. It is defined as follows:

$$L(h) = \frac{1}{\sqrt{\det(g_0)}} \Big[\sqrt{\det(g_0)} A^{\alpha\beta\gamma\delta} h_{,\alpha\beta} \Big]_{,\gamma\delta} + L_1^{\alpha\beta\gamma}(y, h, Dh, D^2 h) h_{,\alpha\beta\gamma} \\ + L_2(y, h, Dh, D^2 h),$$

where L_1 and L_2 are polynomials of their variables with $L_1(y, 0) = 0$, and g_0 is the metric tensor on Γ. Note that $\mathfrak{t}_{mem}$ is included in L_2, since it is a second order operator of h.

REMARK 5. *For a point $\eta(y,t) \in \Gamma(t)$, there are two ways of defining the unit normal n to $\Gamma(t)$:*

1. *Let $n = \sqrt{g}^{-1} a^T N$, where N is the unit normal to Γ.*
2. *Let $n = [J_h^{-1}(-G_h^{\alpha\beta} h_{,\alpha} \frac{\partial}{\partial y^\beta} + \frac{\partial}{\partial z})] \circ \eta^\tau$ (denoted by $[J_h^{-1}(-\nabla_0 h, 1)] \circ \eta^\tau$).*

The function Θ is defined by

$$\Theta(-\nabla_0 h \circ \eta^\tau, 1) = a^T N.$$

Equating the modulus of both sides, by (2.5) *we must have*

$$\Theta = \sqrt{\det(g)} [(J_h^{-1}) \circ \eta^\tau] = \det(\nabla_0 \eta^\tau) \sqrt{\det(G_h) \circ \eta^\tau}.$$

REMARK 6. *An equivalent form of* (2.16e) *is given by*

$$h_t = -h_{,\alpha} (v \circ \eta^{-\tau})_\alpha + (v \circ \eta^{-\tau})_z.$$

This equation states that the shape of the boundary moves with the normal velocity of the fluid.

REMARK 7. *For many of the nonlinear estimates that appear later, it is important that $L(h)$ is linear in the third derivative $h_{,\alpha\beta\gamma}$.*

REMARK 8. *Without using the symmetry* (2.8), *we can still compute $\Delta_g H$ in terms of h and η^τ by using* (2.4) *and* (2.5); *however, L_1 would then depend on $\nabla_0^2 \eta^\tau$ and thus lose one derivative of regularity, preventing the closure of our energy estimate.*

3. Notation and conventions. For $T > 0$, we set

$$\mathcal{V}^1(T) = \Big\{ v \in L^2(0,T; H^1(\Omega)) \;\Big|\; v_t \in L^2(0,T; H^1(\Omega)') \Big\};$$
$$\mathcal{V}^2(T) = \Big\{ v \in L^2(0,T; H^2(\Omega)) \;\Big|\; v_t \in L^2(0,T; L^2(\Omega)) \Big\};$$
$$\mathcal{V}^k(T) = \Big\{ v \in L^2(0,T; H^k(\Omega)) \;\Big|\; v_t \in L^2(0,T; H^{k-2}(\Omega)) \Big\} \quad \text{for } k \geq 3;$$
$$\mathcal{H}(T) = \Big\{ h \in L^2(0,T; H^{5.5}(\Gamma)) \;\Big|\; h_t \in L^2(0,T; H^{2.5}(\Gamma)),\, h_{tt} \in L^2(0,T; H^{0.5}(\Gamma)) \Big\}$$

with norms

$$\|v\|^2_{\mathcal{V}^1(T)} = \|v\|^2_{L^2(0,T;H^1(\Omega))} + \|v_t\|^2_{L^2(0,T;H^1(\Omega)')};$$
$$\|v\|^2_{\mathcal{V}^2(T)} = \|v\|^2_{L^2(0,T;H^2(\Omega))} + \|v_t\|^2_{L^2(0,T;L^2(\Omega))};$$
$$\|v\|^2_{\mathcal{V}^k(T)} = \|v\|^2_{L^2(0,T;H^k(\Omega))} + \|v_t\|^2_{L^2(0,T;H^{k-2}(\Omega))} \quad \text{for } k \geq 3;$$
$$\|h\|^2_{\mathcal{H}(T)} = \|h\|^2_{L^2(0,T;H^{5.5}(\Gamma))} + \|h_t\|^2_{L^2(0,T;H^{2.5}(\Gamma))} + \|h_{tt}\|^2_{L^2(0,T;H^{0.5}(\Gamma))}.$$

We then introduce the space (of "divergence-free" vector fields)

$$\mathcal{V}_v = \Big\{ w \in H^1(\Omega) \,\Big|\, a_i^j(t) w^i_{,j} = 0 \ \forall\, t \in [0,T] \Big\}$$

and

$$\mathcal{V}_v(T) = \Big\{ w \in L^2(0,T;H^1(\Omega)) \,\Big|\, a_i^j(t) w^i_{,j} = 0 \ \forall\, t \in [0,T] \Big\},$$

where the cofactor matrix a is defined by (2.15). We use X_T to denote the space $\mathcal{V}^3(T) \times \mathcal{H}(T)$ with norm

$$\|(v,h)\|^2_{X_T} = \|v\|^2_{\mathcal{V}^3(T)} + \|h\|^2_{\mathcal{H}(T)}$$

and use Y_T, a subspace of X_T, to denote the space

$$Y_T = \Big\{ (v,h) \in \mathcal{V}^3(T) \times \mathcal{H}(T) \,\Big|\, h_t \in L^\infty(0,T;H^2(\Gamma)) \Big\}$$

with norm

$$\begin{aligned}\|(v,h)\|^2_{Y_T} = \|(v,h)\|^2_{X_T} &+ \|v\|^2_{L^\infty(0,T;H^2(\Omega))} + \|h\|^2_{L^\infty(0,T;H^4(\Gamma))} \\ &+ \|h_t\|^2_{L^\infty(0,T;H^2(\Gamma))}.\end{aligned}$$

We will solve (2.16) by a fixed-point method in an appropriate subset of Y_T.

4. The main theorem. Before stating the main theorem, we define the following quantities. Let q_0 be defined by

$$\Delta q_0 = -\nabla u_0 : (\nabla u_0)^T + \nu [a^k_\ell D_\eta(u_0)^i_\ell]_{,ki}(0) + \operatorname{div} F(0) \quad \text{in} \quad \Omega, \tag{4.1a}$$

$$q_0 = \nu(\operatorname{Def} u_0 \cdot N)\cdot N - \sigma L(0) \quad \text{on} \quad \Gamma \tag{4.1b}$$

and

$$u_1 = \nu \Delta u_0 - \nabla q_0 + F(0). \tag{4.2}$$

We also define the projection operator $\mathcal{P}_{ij}(x) : \mathbb{R}^3 \to T_{\eta(x,t)}\Gamma(t)$ by

$$\mathcal{P}_{ij}(x) = [\delta_{ij} - (J_h^{-2} \circ \eta^\tau) a^k_i a^\ell_j N_k(x) N_\ell(x)] = \left[\delta_{ij} - \frac{a^k_i N_k(x)}{|a^k_i N_k(x)|} \frac{a^\ell_j N_\ell(x)}{|a^\ell_j N_\ell(x)|} \right].$$

Theorem 4.1. *Let $\nu > 0$, $\sigma > 0$ be given, and*

$$F \in L^2(0,T;H^2(\Omega)), \quad F_t \in L^2(0,T;L^2(\Omega)), \quad F(0) \in H^1(\Omega).$$

Suppose that the shell traction satisfies the compatibility condition

$$[\operatorname{Def} u_0 \cdot N]_{tan} = 0. \tag{4.3}$$

There exists $T > 0$ depending on u_0 and F such that there exists a solution $(v,h) \in Y_T$ of problem (2.16). Moreover, if $u_0 \in H^{5.5}(\Omega) \cap H^{7.5}(\Gamma)$ and the associated u_1, q_0 also satisfy the compatibility condition

$$\begin{aligned} CP := &\Big[g_0^{ki} u^j_{0,k} N_j N_\ell + g_0^{k\ell} u^j_{0,k} N_j N_i\Big]\Big[\nu (\operatorname{Def} u_0)^j_i - q_0 \delta^j_i\Big] N_j \\ &+ \nu(\delta_{i\ell} - N_i N_\ell)\Big[(\operatorname{Def} u_1)^j_i - \Big((\nabla u_0 \nabla u_0) + (\nabla u_0 \nabla u_0)^T\Big)^j_i\Big] N_j \\ &- (\delta_{i\ell} - N_i N_\ell)\Big[\nu(\operatorname{Def} u_0)^j_i - q_0 \delta^j_i\Big] u^k_{0,j} N_k = 0, \end{aligned} \tag{4.4}$$

then the solution $(v,h) \in Y_T$ is unique.

5. A bounded convex closed set of Y_T.

DEFINITION 5.1. *Given $M > 0$, let $C_T(M)$ denote the subset of Y_T consisting of elements of (v,h) in Y_T such that*

$$\|(v,h)\|^2_{Y_T} \le M \tag{5.1}$$

and such that $v(0) = u_0$, $h(0) = 0$, and $h_t(0) = (B_0)_*((0,1)) \cdot u_0$.

REMARK 9. *For $(v,h) \in C_T(M)$, define u^τ by (2.10) and let η^τ be the associated flow map. Also define v^τ as $u^\tau \circ \eta^\tau$. By (2.12) and (2.13), we have*

$$\sup_{t\in[0,T]} \|\nabla_0 \eta^\tau(t)\|_{H^{1.5}(\Gamma)} + \|v^\tau\|^2_{L^2(0,T;H^{2.5}(\Gamma))} \le C(M) \tag{5.2}$$

for some constant $C(M)$.

We will make use of the following lemmas (proved in [7]).

LEMMA 5.2. *There exists $T_0 \in (0,T)$ such that for all $T \in (0,T_0)$ and for all $v \in C_T(M)$, the matrix a is well defined (by (2.15)) with the estimate (independent of $v \in C_T(M)$)*

$$\begin{aligned} &\|a\|_{L^\infty(0,T;H^2(\Omega))} + \|a_t\|_{L^\infty(0,T;H^1(\Omega))} + \|a_t\|_{L^2(0,T;H^2(\Omega))} \\ &+ \|a_{tt}\|_{L^\infty(0,T;L^2(\Omega))} + \|a_{tt}\|_{L^2(0,T;H^1(\Omega))} \le C(M). \end{aligned} \tag{5.3}$$

LEMMA 5.3. *There exist $T_1 \in (0,T)$ and a constant C (independent of M) such that for all $T \in (0,T_1)$ and $v \in C_T(M)$, for all $\phi \in H^1(\Omega)$ and $t \in [0,T]$*

$$C\|\phi\|^2_{H^1(\Omega)} \le \int_\Omega \Big[|v|^2 + |D_\eta(v)|^2\Big] dx, \tag{5.4}$$

where

$$|D_\eta(v)|^2 := D_\eta(v)^i_j D_\eta(v)^i_j = (a^k_j v^i_{,k} + a^k_j v^i_{,k})(a^\ell_j v^i_{,\ell} + a^\ell_i v^j_{,\ell}).$$

In the remainder of the paper, we will assume that

$$0 < T < \min\{T_0, T_1, \bar{T}\}$$

for some fixed $\bar{T}$ where the forcing F is defined on the time interval $[0,\bar{T}]$.

6. Preliminary results.

6.1. Pressure as a Lagrange multiplier. In the following discussion, we use $H^{1;2}(\Omega;\Gamma)$ to denote the space $H^1(\Omega) \cap H^2(\Gamma)$ with norm

$$\|u\|^2_{H^{1;2}(\Omega;\Gamma)} = \|u\|^2_{H^1(\Omega)} + \|u\|^2_{H^2(\Gamma)}$$

and $\bar{\mathcal{V}}_{\bar{v}}$ ($\bar{\mathcal{V}}_{\bar{v}}(T)$) to denote the space

$$\Big\{ v \in \mathcal{V}_{\bar{v}} \;\Big|\; v \in H^2(\Gamma) \Big\} \Big(\Big\{ v \in \mathcal{V}_{\bar{v}}(T) \;\Big|\; v \in L^2(0,T;H^2(\Gamma)) \Big\} \Big).$$

LEMMA 6.1. *For all $p \in L^2(\Omega)$, $t \in [0,T]$, there exist a constant $C > 0$ and $\phi \in H^{1;2}(\Omega;\Gamma)$ such that $a^j_i(t)\phi^i_{,j} = p$ and*

$$\|\phi\|_{H^{1;2}(\Omega;\Gamma)} \le C\|p\|_{L^2(\Omega)}. \tag{6.1}$$

Proof. We solve the following problem on the time-dependent domain $\Omega(t)$:

$$\operatorname{div}(\phi \circ \eta(t)^{-1}) = p \circ \eta(t)^{-1} \quad \text{in } \eta(t,\Omega) := \Omega(t).$$

The solution to this problem can be written as the sum of the solutions to the following two problems:

$$\operatorname{div}(\phi \circ \eta(t)^{-1}) = p \circ \eta(t)^{-1} - \bar{p}(t) \qquad \text{in} \quad \eta(t,\Omega), \tag{6.2}$$

$$\operatorname{div}(\phi \circ \eta(t)^{-1}) = \bar{p}(t) \qquad \text{in} \quad \eta(t,\Omega), \tag{6.3}$$

where $\bar{p}(t) = \frac{1}{|\Omega|}\int_\Omega p(t,x)dx$. The existence of the solution to problem (6.2) with zero boundary condition is standard (see, for example, [12, Chapter 3]), and the solution to problem (6.3) can be chosen as a linear function (linear in x), for example, $\bar{p}(t)x_1$. The estimate (6.1) follows from the estimates of the solutions to (6.2). ☐

Define the linear functional on $H^{1;2}(\Omega;\Gamma)$ by $(p, a_i^j(t)\varphi^i_{,j})_{L^2(\Omega)}$, where $\varphi \in H^{1;2}(\Omega;\Gamma)$. By the Riesz representation theorem, there is a bounded linear operator $Q(t) : L^2(\Omega) \to H^{1;2}(\Omega;\Gamma)$ such that for all $\varphi \in H^{1;2}(\Omega;\Gamma)$,

$$(p, a_i^j(t)\varphi^i_{,j})_{L^2(\Omega)} = (Q(t)p, \varphi)_{H^{1;2}(\Omega;\Gamma)} := (Q(t)p,\varphi)_{H^1(\Omega)} + (Q(t)p,\varphi)_{H^2(\Gamma)}.$$

Letting $\varphi = Q(t)p$ shows that

$$\|Q(t)p\|_{H^{1;2}(\Omega;\Gamma)} \le C\|p\|_{L^2(\Omega)}$$

for some constant $C > 0$. By Lemma 6.1,

$$\|p\|^2_{L^2(\Omega)} \le \|Q(t)p\|_{H^{1;2}(\Omega;\Gamma)}\|\varphi\|_{H^{1;2}(\Omega;\Gamma)} \le C\|Q(t)p\|_{H^{1;2}(\Omega;\Gamma)}\|p\|_{L^2(\Omega)},$$

which shows that $R(Q(t))$ is closed in $H^{1;2}(\Omega;\Gamma)$. Since $\bar{\mathcal{V}}_v(t) \subset R(Q(t))^\perp$ and $R(Q(t))^\perp \subset \bar{\mathcal{V}}_v(t)$, it follows that

$$H^{1;2}(\Omega;\Gamma)(t) = R(Q(t)) \oplus_{H^{1;2}(\Omega;\Gamma)} \bar{\mathcal{V}}_v(t). \tag{6.4}$$

We can now introduce our Lagrange multiplier.

LEMMA 6.2. *Let $\mathcal{L}(t) \in H^{1;2}(\Omega;\Gamma)'$ be such that $\mathcal{L}(t)\varphi = 0$ for any $\varphi \in \bar{\mathcal{V}}_v(t)$. Then there exists a unique $q(t) \in L^2(\Omega)$, which is termed the pressure function, satisfying*

$$\forall\ \varphi \in H^{1;2}(\Omega;\Gamma), \qquad \mathcal{L}(t)(\varphi) = (q(t), a_i^j(t)\varphi^i_{,j})_{L^2(\Omega)}.$$

Moreover, there is a $C > 0$ (which does not depend on $t \in [0,T]$ and ϵ_1 and on the choice of $v \in C_T(M)$) such that

$$\|q(t)\|_{L^2(\Omega)} \le C\|\mathcal{L}(t)\|_{H^{1;2}(\Omega;\Gamma)'}.$$

Proof. By the decomposition (6.4), for given $\tilde{a}$, let $\varphi = v_1 + v_2$, where $v_1 \in \mathcal{V}_v(t)$ and $v_2 \in R(Q(t)$. It follows that

$$\mathcal{L}(t)(\varphi) = \mathcal{L}(t)(v_2) = (\psi(t), v_2)_{H^{1;2}(\Omega;\Gamma)} = (\psi(t),\varphi)_{H^{1;2}(\Omega;\Gamma)}$$

for a unique $\psi(t) \in R(Q(t))$.

From the definition of $Q(t)$ we then get the existence of a unique $q(t) \in L^2(\Omega)$ such that

$$\forall\ \varphi \in H^{1;2}(\Omega;\Gamma), \qquad \mathcal{L}(t)(\varphi) = (q(t), a_i^j(t)\varphi^i_{,j})_{L^2(\Omega)}.$$

The estimate stated in the lemma is then a simple consequence of (6.1). ☐

6.2. Estimates for a and h. We make use of near-identity transformations. The following lemmas can be found in [7].

LEMMA 6.3. *There exist $K > 0$ and $T_0 > 0$ such that if $0 < t \leq T_0$, then, for any $(\tilde{v}, \tilde{h}) \in C_{T_0}(M)$,*

$$\|\tilde{a}^T - Id\|_{L^\infty(0,T;\mathcal{C}^0(\overline{\Omega}_0))} \leq K\sqrt{t}, \tag{6.5a}$$

$$\|\tilde{a} - Id\|_{L^\infty(0,T;H^2(\Omega))} \leq K\sqrt{t}, \tag{6.5b}$$

$$\|\tilde{a}_t - \tilde{a}_t(0)\|_{L^\infty(0,T;H^1(\Omega))} \leq C(M)t, \tag{6.5c}$$

$$\|\tilde{a}_t\|_{L^\infty(0,T;H^1(\Omega))} \leq K. \tag{6.5d}$$

We also need the following lemma.

LEMMA 6.4. *For any $(\tilde{v}, \tilde{h}) \in C_{T_0}(M)$,*

$$\|\tilde{h}\|_{H^{3.5}(\Gamma)} \leq CMt^{1/4} \tag{6.6}$$

for all $0 < t \leq T_0$.

Proof. For $(\tilde{v}, \tilde{h}) \in C_T(M)$, $\|\tilde{h}\|^2_{H^4(\Gamma)} + \|\tilde{h}_t\|^2_{H^2(\Gamma)} \leq M$. By $\tilde{h}(0) = 0$,

$$\|\tilde{h}(t)\|_{H^2(\Gamma)} \leq \int_0^t \|\tilde{h}_t\|_{H^2(\Gamma)} ds \leq \sqrt{M}t.$$

Finally, the interpolation inequality

$$\|\nabla_0^2 f(t)\|_{H^{1.5}(\Gamma)} \leq C\|\nabla_0^4 f\|^{3/4}_{L^2(\Gamma)} \|\nabla_0^2 f\|^{1/4}_{L^2(\Gamma)} \tag{6.7}$$

implies

$$\|\tilde{h}\|_{H^{3.5}(\Gamma)} \leq C\|\tilde{h}\|^{3/4}_{H^4(\Gamma)} \|\tilde{h}\|^{1/4}_{H^2(\Gamma)} \leq CMt^{1/4}. \qquad \square$$

COROLLARY 6.5. *$\|L_1(t)\|_{H^{1.5}(\Gamma)}$ and $\|L_2(t)\|_{H^{1.5}(\Gamma)}$ converge to zero as $t \to 0$, uniformly in $(v, h) \in C_{T_0}(M)$. Furthermore, for $t \leq 1$,*

$$\|L_1(t)\|_{H^{1.5}(\Gamma)} + \|L_2(t)\|_{H^{1.5}(\Gamma)} \leq C(M)t^{1/4}.$$

By the fact that $\|\tilde{h}_t\|^2_{H^2(\Gamma)} \leq M$ and $\|\tilde{h}_{tt}\|^2_{L^2(0,T;H^{0.5}(\Gamma))} \leq M$ if $(\tilde{v}, \tilde{h}) \in C_T(M)$, similar computations lead to the following lemma.

LEMMA 6.6. *For all $(\tilde{v}, \tilde{h}) \in C_T(M)$,*

$$\|\tilde{h}_t(t)\|_{H^{1.5}(\Gamma)} \leq CMt^{1/8} \tag{6.8}$$

for all $0 < t \leq T$.

7. The linearized problem. Suppose that $(\tilde{v}, \tilde{h}) \in C_T(M)$ is given. Let $\tilde{\eta}(t) = \text{Id} + \int_0^t \tilde{v}(s)ds$ and $\tilde{a} = (\nabla\tilde{\eta})^{-1}$. We are concerned with the following time-dependent linear problem, whose fixed point $v = \tilde{v}$ provides a solution to (2.16):

$$v^i_t - \nu[\tilde{a}^k_\ell D_{\tilde{\eta}}(v)^i_\ell]_{,k} = -(\tilde{a}^k_i q)_{,k} + F^i \quad \text{in } (0,T)\times\Omega, \tag{7.1a}$$

$$\tilde{a}^j_i v^i_{,j} = 0 \quad \text{in } (0,T)\times\Omega, \tag{7.1b}$$

$$\begin{aligned}[\nu D_{\tilde{\eta}}(v)^j_i - q\delta^j_i]\tilde{a}^\ell_j N_\ell = {} & \sigma\tilde{\Theta}\Big[\mathcal{L}_{\tilde{h}}(h)(-\nabla_0\tilde{h}, 1)\Big]\circ\tilde{\eta}^\tau \\ & + \sigma\tilde{\Theta}\Big[[\mathcal{M}(\tilde{h})(-\nabla_0\tilde{h}, 1)]\circ\tilde{\eta}^\tau\Big]\end{aligned} \quad \text{on } (0,T)\times\Gamma, \tag{7.1c}$$

$$h_t\circ\tilde{\eta}^\tau = [\tilde{h}_{,\alpha}\circ\tilde{\eta}^\tau]v_\alpha - v_z \quad \text{on } (0,T)\times\Gamma, \tag{7.1d}$$

$$v = u_0 \quad \text{on } \{t=0\}\times\Omega, \tag{7.1e}$$

$$h = 0 \quad \text{on } \{t=0\}\times\Gamma, \tag{7.1f}$$

where $D_{\tilde\eta}(v)^j_i = \tilde a^k_i v^j_{,k} + \tilde a^k_j v^i_{,k}$, $\tilde\Theta = \det(\nabla_0 \tilde\eta^\tau)$, and

$$\mathcal{L}_{\tilde h}(h) = \frac{1}{\sqrt{\det(g_0)}} \Big[\sqrt{\det(g_0)} \tilde A^{\alpha\beta\gamma\delta} h_{,\alpha\beta} \Big]_{,\gamma\delta}$$

with

$$\begin{aligned} \tilde A^{\alpha\beta\gamma\delta} &= J^{-3}_{\tilde h} \sqrt{\det(G_{\tilde h})} \Big[G^{\alpha\gamma}_{\tilde h} - (-1)^{\kappa+\sigma} \det(G_{\tilde h})^{-1} (1-\delta_{\alpha\kappa})(1-\delta_{\gamma\sigma}) \tilde h_{,\kappa} \tilde h_{,\sigma} \Big] \\ &\quad \times (G^{\beta\delta}_{\tilde h} - J^{-2}_{\tilde h} G^{\beta\mu}_{\tilde h} G^{\delta\nu}_{\tilde h} \tilde h_{,\mu} \tilde h_{,\nu}) \end{aligned}$$

and

$$\mathcal{M}(\tilde h) = \sqrt{\det(G_{\tilde h}) \circ \tilde\eta^\tau} \Big[L_1^{\alpha\beta\gamma}(y, \tilde h, D\tilde h, D^2 \tilde h) \tilde h_{,\alpha\beta\gamma} + L_2(y, \tilde h, D\tilde h, D^2\tilde h) \Big].$$

Here the thickness ϵ_1 is assumed to be 1.

We will also use $L_{\tilde h}(h)$ to denote $\mathcal{L}_{\tilde h}(h) + \mathcal{M}(\tilde h)$.

Remark 10. *$\mathcal{L}_{\tilde h}$ is a coercive fourth order operator for small $\tilde h \le \delta$. Actually, it is easy to see that $\mathcal{L}_{\tilde h}$ is coercive at time $t = 0$, and the coercivity of $\mathcal{L}_{\tilde h}$ for $t > 0$ (but sufficiently small) follows from the continuity of $\tilde h$ in time into the space $H^2(\Gamma)$. Moreover, by Lemma* 6.4*, we have the following corollary.*

Corollary 7.1. *There exist $\nu_1 > 0$ and $0 < T \le T_0$ such that for all $0 < t \le T$,*

$$\nu_1 \|\nabla_0^2 f(t)\|^2_{L^2(\Gamma)} \le \int_\Gamma \tilde A^{\alpha\beta\gamma\delta} f_{,\alpha\beta}(t) f_{,\gamma\delta}(t) dS$$

for all $0 < t \le T$. Later we will denote the right-hand side quantity of this inequality by $E_{\bar h}(f)$, where the subscript $\bar h$ indicates that $\bar A$ is a function of $\bar h$.

Remark 11. *Given $(\tilde v, \tilde h) \in \mathcal{V}^3(T) \times \mathcal{H}(T)$, for the corresponding $\tilde\eta^\tau$, we have*

$$\|\tilde\eta^\tau\|^2_{L^\infty(0,T;H^{2.5}(\Omega))} + \|\tilde\eta^\tau_t\|^2_{L^2(0,T;H^{2.5}(\Gamma))} \le C(M),$$

where (2.13) *and* (2.12) *are used to obtain this estimate.*

The solution of (7.1) is found as a weak limit of a sequence of regularized problems.

Definition 7.2 (mollifiers on Γ). *For $\epsilon_1 > 0$, let*

$$K^p_{\epsilon_1} := (1 - \epsilon_1 \Delta_0)^{-\frac{p}{2}} : H^s(\Gamma) \to H^{s+p}(\Gamma)$$

denote the usual self-adjoint Friedrich mollifier on the compact manifold Γ, where Δ_0 is the surface Laplacian defined on Γ.

By the Sobolev extension theorem, there exist bounded extension operators

$$E_s : H^s(\Omega) \to H^s(\mathbb{R}^n), \qquad s \ge 1.$$

For fixed (but small) ϵ_1 and $\epsilon_{11} > 0$, let ρ_{ϵ_1} be a (positive) smooth mollifier on $\mathbb{R}^n$. Set $\bar v = \rho_{\epsilon_1} * E_1(\tilde v)$, $\tilde F = \rho_{\epsilon_1} * E_2(F)$, $\tilde u_0 = \rho_{\epsilon_1} * E_3(u_0)$, where $*$ denotes the convolution in space, and $\bar h = K^m_{\epsilon_1}(\tilde h)$ for large enough m. Define $\bar\eta$ and $\bar a$ in the same fashion as $\tilde\eta$ and $\tilde a$. Note that $\bar v \to \tilde v \in V(T)$, $\tilde F \to F$ in $\mathcal{V}^2(T)$, $\tilde{u_0} \to u_0$ in $H^{2.5}(\Omega)$, and $\bar h \to \tilde h$ in $\mathcal{H}(T)$ as $\epsilon_1 \to 0$.

The regularized problem takes the form

$$v_t^i - \nu[\bar{a}_\ell^k D_{\bar{\eta}}(v)_\ell^i]_{,k} = -(\bar{a}_i^k q)_{,k} + \tilde{F}^i \quad \text{in } (0,T)\times\Omega, \tag{7.2a}$$

$$\bar{a}_i^j v^i_{,j} = 0 \quad \text{in } (0,T)\times\Omega, \tag{7.2b}$$

$$\begin{aligned}[\nu D_{\bar{\eta}}(v)_i^j - q\delta_i^j]\bar{a}_j^\ell N_\ell &= \sigma\mathcal{L}_{\bar{h}}^{\epsilon_2}(h^{\epsilon_2})(-\nabla_0\bar{h}\circ\bar{\eta}^\tau, 1)\\ &\quad + \sigma\mathcal{M}_{\bar{h}}^{\epsilon_2}(-\nabla_0\bar{h}\circ\bar{\eta}^\tau, 1) + \kappa\Delta_0^2 v \quad \text{on } (0,T)\times\Gamma,\end{aligned} \tag{7.2c}$$

$$h_t\circ\bar{\eta}^\tau = [(\bar{h}_{,\alpha})\circ\bar{\eta}^\tau]v_\alpha - v_z \quad \text{on } (0,T)\times\Gamma, \tag{7.2d}$$

$$v = \tilde{u}_0 \quad \text{on } \{t=0\}\times\Omega, \tag{7.2e}$$

$$h = 0 \quad \text{on } \{t=0\}\times\Gamma, \tag{7.2f}$$

where

$$\begin{aligned}\bar{\mathcal{L}}_{\bar{h}}^{\epsilon_2}(f) &= \frac{\bar{\Theta}}{\sqrt{\det(g_0)}}\Big[\Big(\sqrt{\det(g_0)}\bar{A}^{\alpha\beta\gamma\delta}f_{,\alpha\beta}\Big)_{,\gamma\delta}\Big]^{\epsilon_2}\circ\bar{\eta}^\tau,\\ \bar{\mathcal{M}}_{\bar{h}}^{\epsilon_2} &= \bar{\Theta}\Big[\Big(L_1^{\alpha\beta\gamma}(\cdot,\bar{h},D\bar{h},D^2\bar{h})\bar{h}_{,\alpha\beta\gamma} + L_2(\cdot,\bar{h},D\bar{h})\Big)^{\epsilon_2}\Big]^{\epsilon_2}\circ\bar{\eta}^\tau(y,t).\end{aligned}$$

Note that $\bar{\mathcal{L}}_{\bar{h}}^{\epsilon_2}(f) + \bar{\mathcal{M}}_{\bar{h}}^{\epsilon_2} = \bar{\Theta}\big[L_{\bar{h}}(f)\big]^{\epsilon_2}\circ\bar{\eta}^\tau$.

7.1. Weak solutions.

DEFINITION 7.3. *A vector $v\in\bar{\mathcal{V}}_{\bar{v}}(T)$ with $v_t\in\bar{\mathcal{V}}_{\bar{v}}(T)'$ for almost all (a.a.) $t\in(0,T)$ is a weak solution of* (7.2)*, provided that*

$$\begin{aligned}&\text{(i) } \langle v_t,\varphi\rangle + \frac{\nu}{2}\int_\Omega D_{\bar{\eta}}v : D_{\bar{\eta}}\varphi dx + \sigma\int_\Gamma \bar{A}^{\alpha\beta\gamma\delta}h^{\epsilon_2}_{,\alpha\beta}\Big[-\bar{h}_{,\sigma}(\varphi^\sigma\circ\bar{\eta}^{-\tau})\\ &\qquad + (\varphi^z\circ\bar{\eta}^{-\tau})\Big]^{\epsilon_2}_{,\gamma\delta}dS + \kappa\int_\Gamma \Delta_0 v\cdot\Delta_0\varphi dS = \langle\tilde{F},\varphi\rangle - \sigma\langle\mathcal{M}_{\bar{h}}^{\epsilon_2},\varphi\rangle_\Gamma,\end{aligned} \tag{7.3a}$$

$$\text{(ii) } v(0,\cdot) = \tilde{u}_0 \tag{7.3b}$$

for a.a. $t\in[0,T]$, where $\langle\cdot,\cdot\rangle$ denotes the duality product between $\bar{\mathcal{V}}_v(t)$ and its dual $\bar{\mathcal{V}}_v(t)'$, and h is given by the evolution equation (7.2d) *and the initial condition* (7.2f)*:*

$$h(y,t) = \int_0^t \Big[-\bar{h}_{,\alpha}(y,s)v^\alpha(\bar{\eta}^{-\tau}(y,s),0,s) + v^z(\bar{\eta}^{-\tau}(y,s),0,s)\Big]ds. \tag{7.4}$$

7.2. Penalized problems. Letting $\theta>0$ denote the penalized parameter, we define w_θ (also with ϵ_1 and ϵ_{11} dependence in mind) to be the "unique" solution of the problem (whose existence can be obtained via a modified Galerkin method which will be presented in the following sections):

$$\begin{aligned}&\text{(i)}\quad \langle w_{\theta t},\varphi\rangle + \frac{\nu}{2}\int_\Omega D_{\bar{\eta}}w_\theta : D_{\bar{\eta}}\varphi dx + \sigma\int_\Gamma \bar{A}^{\alpha\beta\gamma\delta}h^{\epsilon_2}_{,\alpha\beta}\Big[-\bar{h}_{,\sigma}(\varphi^\sigma\circ\bar{\eta}^{-\tau})\\ &\qquad + (\varphi^z\circ\bar{\eta}^{-\tau})\Big]^{\epsilon_2}_{,\gamma\delta}dS + \kappa\int_\Gamma\Delta_0 v\cdot\Delta_0\varphi dS + \left(\frac{1}{\theta}\bar{a}_i^j v^i_{,j}, \bar{a}_k^\ell\varphi^k_{,\ell}\right)_{L^2(\Omega)}\\ &\quad = \langle\tilde{F},\varphi\rangle - \sigma\langle\bar{\mathcal{M}}_{\bar{h}}^{\epsilon_2}(-\nabla_0\bar{h}\circ\bar{\eta}^\tau,1),\varphi\rangle_\Gamma,\end{aligned} \tag{7.5a}$$

$$\text{(ii) } v(0,\cdot) = \tilde{u}_0, \tag{7.5b}$$

where $\langle\cdot,\cdot\rangle$ denotes the pairing between $H^1(\Omega)$ and its dual, and h in (7.5a) satisfies (7.4) with v replaced by w_θ.

7.3. Weak solutions for the penalized problem. The goal of this section is to establish the existence of v to the problem (7.2) (or the weak formulation (7.3)), as well as the energy inequality satisfied by v and v_t. Before proceeding, we introduce variables $\tilde{q}_0$ and $\tilde{w}_1$ as follows: let $\tilde{q}_0$ be the solution of the Laplace equation

$$\Delta\tilde{q}_0 = \nabla\tilde{u}_0 : (\nabla\tilde{u}_0)^t - \operatorname{div}\tilde{F}(0) \qquad \text{in } \Omega, \tag{7.6a}$$

$$\tilde{q}_0 = \nu(\operatorname{Def}\tilde{u}_0)^j_i N_i N_j - \sigma\mathcal{M}_0^{\epsilon_2}(0) + \kappa\Delta_0^2\tilde{u}_0\cdot N \qquad \text{on } \Gamma \tag{7.6b}$$

and $\tilde{w}_1$ be defined by

$$\tilde{w}_1 = \nu\Delta\tilde{u}_0 - \nabla\tilde{q}_0 + \tilde{F}(0). \tag{7.7}$$

By elliptic regularity,

$$\begin{aligned}\|\tilde{q}_0\|^2_{H^1(\Omega)} &\leq C\Big[\|\tilde{u}_0\|^2_{H^2(\Omega)} + \|\tilde{F}(0)\|^2_{L^2(\Omega)} + \|\mathcal{M}_0^{\epsilon_2}(0)\|^2_{H^{0.5}(\Gamma)} + \|\Delta_0^2\tilde{u}_0\|^2_{H^{0.5}(\Gamma)}\Big]\\ &\leq C(M)\Big[\|\tilde{u}_0\|^2_{H^2(\Omega)} + \|\tilde{u}_0\|^2_{H^{4.5}(\Gamma)} + \|\tilde{F}(0)\|^2_{L^2(\Omega)} + 1\Big],\end{aligned}$$

and hence

$$\|\tilde{w}_1\|^2_{L^2(\Omega)} \leq C(M)\Big[\|\tilde{u}_0\|^2_{H^2(\Omega)} + \|\tilde{u}_0\|^2_{H^{4.5}(\Gamma)} + \|\tilde{F}(0)\|^2_{L^2(\Omega)} + 1\Big].$$

REMARK 12. *By* (6.6)*, the constant $C(M)$ in the estimates above can also be refined as a constant independent of M if T is chosen small enough.*

By introducing a (smooth) basis $(e_\ell)_{\ell=1}^\infty$ of $H^{1;2}(\Omega;\Gamma)$, taking the approximation at rank $m \geq 2$ under the form $w_\ell(t,x) = \sum_{k=1}^{\ell} d_k(t)e_k(x)$ with

$$h_\ell(y,t) = \int_0^t \Big[-\bar{h}_{,\alpha}(y,s)w_\ell^\alpha(\bar{\eta}^{-\tau}(y,s),0,s) + w_\ell^z(\bar{\eta}^{-\tau}(y,s),0,s)\Big]ds, \tag{7.8}$$

and satisfying on $[0,T]$,

(7.9a)

$$\begin{aligned}&\text{(i)}\quad (w_{\ell tt},\varphi)_{L^2(\Omega)} + \nu(\bar{a}^j_i w_{\ell t,j}, \bar{a}^k_i\varphi_{,k})_{L^2(\Omega)} + \nu((\bar{a}^j_i\bar{a}^k_i)_t w_\ell,\varphi_{,k})_{L^2(\Omega)}\\ &+ \nu\int_\Omega \Big[\bar{a}^j_r\bar{a}^k_i w^i_{\ell t,j} + (\bar{a}^j_r\bar{a}^k_i)_t w^i_{\ell,j}\Big]\varphi^r_{,k}dx + \kappa\int_\Gamma \Delta_0 w_{\ell t}\cdot\Delta_0\varphi dS - ((\bar{a}^j_i q_\ell)_t,\varphi^i_{,j})_{L^2(\Omega)}\\ &+ \sigma\int_\Gamma \bar{A}^{\alpha\beta\gamma\delta}[-\bar{h}_{,\sigma}(w_\ell^\sigma\circ\bar{\eta}^{-\tau}) + w_\ell^z\circ\bar{\eta}^{-\tau}]^{\epsilon_2}_{,\alpha\beta}[-\bar{h}_{,\sigma}(\varphi^\sigma\circ\bar{\eta}^{-\tau}) + \varphi^z\circ\bar{\eta}^{-\tau}]^{\epsilon_2}_{,\gamma\delta}dS\\ &+ \sigma\int_\Gamma (\bar{A}^{\alpha\beta\gamma\delta})_t h^{\epsilon_2}_{\ell,\alpha\beta}[-\bar{h}_{,\sigma}(\varphi^\sigma\circ\bar{\eta}^{-\tau}) + \varphi^z\circ\bar{\eta}^{-\tau}]^{\epsilon_2}_{,\gamma\delta}dS\\ &+ \sigma\int_\Gamma \bar{A}^{\alpha\beta\gamma\delta}h^{\epsilon_2}_{\ell,\alpha\beta}[-\bar{h}_{t,\sigma}(\varphi^\sigma\circ\bar{\eta}^{-\tau}) + \bar{h}_{,\sigma}\bar{v}^\kappa(\varphi^\sigma_{,\kappa}\circ\bar{\eta}^{-\tau}) + \bar{v}^\kappa(\varphi^z_{,\kappa}\circ\bar{\eta}^{-\tau})]^{\epsilon_2}_{,\gamma\delta}dS\\ &= \langle\tilde{F}_t,\varphi\rangle - \sigma\int_\Gamma \Big[L_1^{\alpha\beta\gamma}\bar{h}_{,\alpha\beta\gamma} + L_2\Big]^{\epsilon_2}_t\Big[\bar{h}_{,\sigma}(\varphi^\sigma\circ\bar{\eta}^{-\tau}) - \varphi^z\circ\bar{\eta}^{-\tau}\Big]^{\epsilon_2}dS\\ &- \sigma\int_\Gamma \Big[L_1^{\alpha\beta\gamma}\bar{h}_{,\alpha\beta\gamma} + L_2\Big]^{\epsilon_2}\Big[\bar{h}_{t,\sigma}(\varphi^\sigma\circ\bar{\eta}^{-\tau}) - \bar{h}_{,\sigma}\bar{v}^\kappa(\varphi^\sigma_{,\kappa}\circ\bar{\eta}^{-\tau}) - \bar{v}^\kappa(\varphi^z_{,\kappa}\circ\bar{\eta}^{-\tau})\Big]^{\epsilon_2}dS\\ &\forall\ \varphi\in\operatorname{span}(e_1,\dots,e_\ell),\end{aligned}$$

(7.9b)

$$\text{(ii)}\quad w_{\ell t}(0) = (w_1)_\ell,\ w_\ell(0) = (u_0)_\ell \quad \text{in } \Omega,$$

where $q_\ell = \tilde{q}_0 - \frac{1}{\theta}\bar{a}_i^j w^i_{\ell,j}$, and $(\tilde{u}_0)_\ell$ denotes the respective $H^{1;2}(\Omega;\Gamma)$ projections of u_0 on $\text{span}(e_1, e_2, \dots, e_\ell)$.

REMARK 13. *The existence of w_k follows from the solution of*

$$d_k''(t) + d_\ell'(t)A_{k\ell}(t) + d_\ell(t)B_{k\ell}(t) + \int_0^t d_\ell(s)C_{k\ell}(s,t)ds = F(t)$$

for functions A, B, C, and F; however, the existence of the solution d_k does not immediately follow from the fundamental theorem of ODE due to the presence of the time integral. A straightforward fixed-point argument can be implemented, whose details we leave to the interested reader.

The use of the test function $\varphi = w_{\ell t}$ in this system of ODE gives us, in turn, the energy law

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|w_{\ell t}\|^2_{L^2(\Omega)} + \frac{\nu}{2}\|D_{\bar\eta}(w_{\ell t})\|^2_{L^2(\Omega)} + \frac{\sigma}{2}\frac{d}{dt}E_{\bar h}(h^{\epsilon_2}_{\ell t,\alpha\beta}) + \theta\|q_{\ell t}\|^2_{L^2(\Omega)}\\
&+ \nu((\bar{a}_i^j\bar{a}_i^k)_t w_{\ell,j}, w_{\ell t,k})_{L^2(\Omega)} + \nu\int_\Omega(\bar{a}_r^j\bar{a}_i^k)_t w^i_{\ell,j}w^r_{\ell t,k}dx + \kappa\|\Delta_0 w_{\ell t}\|^2_{L^2(\Gamma)}\\
&+ (q_{\ell t}, \bar{a}^j_{it}w^i_{\ell,j})_{L^2(\Omega)} - (q_\ell, \bar{a}^j_{it}w^i_{\ell t,j})_{L^2(\Omega)} - \frac{\sigma}{2}\int_\Gamma(\bar{A}^{\alpha\beta\gamma\delta})_t h^{\epsilon_2}_{\ell t,\alpha\beta}h^{\epsilon_2}_{\ell t,\gamma\delta}dS\\
&- \sigma\int_\Gamma(\bar{A}^{\alpha\beta\gamma\delta})_t h^{\epsilon_2}_{\ell,\alpha\beta}\Big[h_{\ell tt} + \bar{h}_{t,\sigma}(w^\sigma_{\ell t}\circ\bar\eta^{-\tau})\Big]^{\epsilon_2}_{,\gamma\delta}dS + \sigma\int_\Gamma\bar{A}^{\alpha\beta\gamma\delta}h^{\epsilon_2}_{\ell,\alpha\beta}\\
&\times\Big[-\bar{h}_{t,\sigma}(w^\sigma_{\ell t}\circ\bar\eta^{-\tau}) + \bar{h}_{,\sigma}\bar{v}^\kappa(w^\sigma_{\ell t,\kappa}\circ\bar\eta^{-\tau}) + \bar{v}^\kappa(w^z_{\ell t,\kappa}\circ\bar\eta^{-\tau})\Big]^{\epsilon_2}_{,\gamma\delta}dS\\
=\;&\langle\tilde{F}_t, w_{\ell t}\rangle - \sigma\int_\Gamma\Big[(L_1^{\alpha\beta\gamma}\bar{h}_{,\alpha\beta\gamma} + L_2)(-\nabla_0\bar{h},1)\Big]_t\cdot(w_{\ell t}\circ\bar\eta^{-\tau})dS\\
&- \sigma\int_\Gamma(L_1^{\alpha\beta\gamma}\bar{h}_{,\alpha\beta\gamma} + L_2)\bar{v}^\kappa\Big[-\bar{h}_{,\sigma}(w^\sigma_{\ell t,\kappa}\circ\bar\eta^{-\tau}) + (w^z_{\ell t,\kappa}\circ\bar\eta^{-\tau})\Big]dS.
\end{aligned}\tag{7.10}$$

For the tenth term (the integral with $\frac{\sigma}{2}$ as its coefficient), we have

$$\left|\int_\Gamma(\bar{A}^{\alpha\beta\gamma\delta})_t h^{\epsilon_2}_{\ell t,\alpha\beta}h^{\epsilon_2}_{\ell t,\gamma\delta}dS\right| \le C(M)\|\bar{h}_t\|_{H^{2.5}(\Gamma)}\|\nabla_0^2 h_{\ell t}\|^2_{L^2(\Gamma)}.$$

By ϵ_2-regularization and the identity

$$\begin{aligned}
\int_\Gamma(\bar{A}^{\alpha\beta\gamma\delta})_t h^{\epsilon_2}_{\ell,\alpha\beta}h^{\epsilon_2}_{\ell tt,\gamma\delta}dS &= \int_\Gamma\frac{1}{\sqrt{\det(g_0)}}\Big[\sqrt{\det(g_0)}(\bar{A}^{\alpha\beta\gamma\delta})_t\Big]_{,\gamma\delta}h^{\epsilon_2}_{\ell,\alpha\beta}h^{\epsilon_2}_{\ell tt}dS\\
&+ \int_\Gamma\frac{2}{\sqrt{\det(g_0)}}\Big[\sqrt{\det(g_0)}(\bar{A}^{\alpha\beta\gamma\delta})_t\Big]_{,\gamma}h^{\epsilon_2}_{\ell,\alpha\beta\delta}h^{\epsilon_2}_{\ell tt}dS\\
&+ \int_\Gamma(\bar{A}^{\alpha\beta\gamma\delta})_t h^{\epsilon_2}_{\ell,\alpha\beta\gamma\delta}h^{\epsilon_2}_{\ell tt}dS,
\end{aligned}$$

we find that

$$\begin{aligned}
&\left|\int_\Gamma(\bar{A}^{\alpha\beta\gamma\delta})_t h^{\epsilon_2}_{\ell,\alpha\beta}h^{\epsilon_2}_{\ell tt,\gamma\delta}dS\right|\\
&\le C(\epsilon_2)\Big[1 + \|\bar{h}_t\|_{H^{2.5}(\Gamma)}\Big]\|\nabla_0^2 h_\ell\|_{L^2(\Gamma)}\Big[\|w_\ell\|_{H^1(\Omega)} + \|w_{\ell t}\|_{H^1(\Omega)}\Big].
\end{aligned}$$

Similarly, the second part of the eleventh term and the last term of the left-hand side can be bounded by

$$C(\epsilon_2)\|\bar{h}_t\|_{H^{2.5}(\Gamma)}\|\nabla_0^2 h_\ell\|_{L^2(\Gamma)}\|w_{\ell t}\|_{H^1(\Omega)},$$

where we also use the ϵ_2-regularization to control $\nabla_0^3 w_{\ell t}$. It also follows that the last two terms on the right-hand side can be bounded by

$$C(M)\Big[1+\|\bar{h}_t\|_{H^{2.5}(\Gamma)}\Big]\|w_{\ell t}\|_{H^1(\Omega)}.$$

With positive θ, the fourth term of the left-hand side involving the square of $q_{\ell t}$ acts as a viscous energy term. Integrating (7.10) in time from 0 to t, we then get

(7.11)

$$\begin{aligned}
&\|w_{\ell t}\|^2_{L^2(\Omega)}+\|\nabla_0^2 h_{\ell t}\|^2_{L^2(\Gamma)}+\int_0^t\Big[\|\nabla w_{\ell t}\|^2_{L^2(\Omega)}+\kappa\|w_{\ell t}\|^2_{H^2(\Gamma)}+\theta\|q_{\ell t}\|^2_{L^2(\Omega)}\Big]ds\\
&\le C(M)\Big[\|w_{\ell t}(0)\|^2_{L^2(\Omega)}+\|w_\ell(0)\|^2_{H^1(\Omega)}+\|q_\ell(0)\|^2_{H^{0.5}(\Omega)}\Big]\\
&\quad+C(\epsilon_2)\int_0^t\Big[1+\|\bar{h}_t(s)\|^2_{H^{2.5}(\Gamma)}\Big]\|\nabla_0^2 h_{\ell t}(s)\|^2_{L^2(\Gamma)}ds\\
&\quad+C(\theta)\int_0^t\|\bar{v}(t')\|^2_{H^3(\Omega)}\int_0^{t'}\Big[\|\nabla w_{\ell t}(s)\|^2_{L^2(\Omega)}+\|q_{\ell t}(s)\|^2_{L^2(\Omega)}\Big]ds\,dt',
\end{aligned}$$

where $C(\epsilon_2), C(\theta)\to\infty$ as $\epsilon_2,\theta\to 0$, and we use

$$\|f(t)\|_X\le\|f(0)\|_X+\int_0^t\|f_t(s)\|_X ds\le\|f(0)\|_X+\sqrt{t}\int_0^t\|f_t(s)\|_X^2 ds$$

for $f=w_\ell$, $f=h_\ell$, and $f=g_\ell$ to obtain (7.11).

REMARK 14. *The θ-dependence follows from estimating the terms $(q_{\ell t},\bar{a}^j_{it}w^i_{\ell,j})_{L^2(\Omega)}$:*

$$\begin{aligned}
\Big|(q_{\ell t},\bar{a}^j_{it}w^i_{\ell,j})_{L^2(\Omega)}\Big|&\le\frac{\theta}{2}\|q_{\ell t}\|^2_{L^2(\Omega)}+\frac{1}{2\theta}\|\bar{a}^j_{it}\|^2_{L^\infty(\Omega)}\|w^i_{\ell,j}\|^2_{L^2(\Omega)}\\
&\le\frac{\theta}{2}\|q_{\ell t}\|^2_{L^2(\Omega)}+\frac{C(M)}{\theta}\Big[\|\nabla w_\ell(0)\|^2_{L^2(\Omega)}+t\int_0^t\|\nabla w_{\ell t}\|^2_{L^2(\Omega)}(s)ds\Big].
\end{aligned}$$

By the Gronwall inequality, for $0\le t\le T$,

$$\begin{aligned}
&\|w_{\ell t}(t)\|^2_{L^2(\Omega)}+\|\nabla_0^2 h_{\ell t}(t)\|^2_{L^2(\Gamma)}\\
&+\int_0^t\Big[\|\nabla w_{\ell t}\|^2_{L^2(\Omega)}+\kappa\|w_{\ell t}\|^2_{H^2(\Gamma)}+\theta\|q_{\ell t}\|^2_{L^2(\Omega)}\Big]ds\le C(\epsilon_2,\theta)N_0(u_0,F),
\end{aligned}\tag{7.12}$$

where

$$N_0(u_0,F):=\|u_0\|^2_{H^{2.5}(\Omega)}+\|u_0\|^2_{H^{4.5}(\Gamma)}+\|F_t\|^2_{L^2(0,T;H^1(\Omega)')}+\|F(0)\|^2_{H^{0.5}(\Omega)}+1.$$

We can then infer that w_ℓ is defined on $[0,T]$, and that there is a subsequence, still denoted with the subscript ℓ, satisfying

$$w_\ell\rightharpoonup w_\theta\quad\text{in } L^2(0,T;H^{1;2}(\Omega;\Gamma)),\tag{7.13a}$$

$$w_{\ell t}\rightharpoonup w_{\theta t}\quad\text{in } L^2(0,T;H^{1;2}(\Omega;\Gamma)),\tag{7.13b}$$

$$\nabla_0^2 h_\ell\rightharpoonup\nabla_0^2 h_\theta\quad\text{in } L^2(0,T;L^2(\Gamma)),\tag{7.13c}$$

$$\nabla_0^2 h_{\ell t}\rightharpoonup\nabla_0^2 h_{\theta t}\quad\text{in } L^2(0,T;L^2(\Gamma)),\tag{7.13d}$$

$$q_{\ell t}\rightharpoonup q_{\theta t}\quad\text{in } L^2(0,T;L^2(\Omega)),\tag{7.13e}$$

where

$$q_\theta = \tilde{q}_0 - \frac{1}{\theta}\bar{a}_i^j w^i_{\theta,j}.$$

From the standard procedure for weak solutions, we can now infer from these weak convergences and the definition of w_ℓ that $w_{\ell tt} \in L^2(0,T;H^1(\Omega)')$. In turn, $w_{\ell t} \in \mathcal{C}^0([0,T];H^1(\Omega)')$, $w_\ell \in \mathcal{C}^0([0,T];L^2(\Omega))$ with $w_\theta(0) = u_0$, $w_{\theta t}(0) = w_1$.

Moreover, (7.13) implies that w_θ satisfies

(7.14a)

$$\begin{aligned}
\text{(i)}\quad & \int_0^T \Big[(w_{\theta tt},\varphi)_{L^2(\Omega)} + \nu(\bar{a}_i^j w_{\theta t,j}, \bar{a}_i^k \varphi_{,k})_{L^2(\Omega)} + \nu((\bar{a}_i^j\bar{a}_i^k)_t w_\theta, \varphi_{,k})_{L^2(\Omega)}\Big]dt \\
& + \nu\int_0^T \left[\int_\Omega \bar{a}_r^j\bar{a}_i^k w^i_{\theta t,j}\varphi^r_{,k}dx + \nu\int_\Omega (\bar{a}_r^j\bar{a}_i^k)_t w^i_{\theta,j}\varphi^r_{,k}dx\right]dt + \sigma\int_0^T\int_\Gamma \bar{A}^{\alpha\beta\gamma\delta} \\
& \qquad \times [-\bar{h}_{,\sigma}(w^\sigma_\theta\circ\bar{\eta}^{-\tau}) + w^z_\theta\circ\bar{\eta}^{-\tau}]^{\epsilon_2}_{,\alpha\beta}[-\bar{h}_{,\sigma}(\varphi^\sigma\circ\bar{\eta}^{-\tau}) + \varphi^z\circ\bar{\eta}^{-\tau}]^{\epsilon_2}_{,\gamma\delta}dSdt \\
& + \sigma\int_0^T\int_\Gamma (\bar{A}^{\alpha\beta\gamma\delta})_t h^{\epsilon_2}_{\theta,\alpha\beta}[-\bar{h}_{,\sigma}(\varphi^\sigma\circ\bar{\eta}^{-\tau}) + \varphi^z\circ\bar{\eta}^{-\tau}]^{\epsilon_2}_{,\gamma\delta}dSdt \\
& + \sigma\int_0^T\int_\Gamma \bar{A}^{\alpha\beta\gamma\delta}h^{\epsilon_2}_{\theta,\alpha\beta}[-\bar{h}_{t,\sigma}(\varphi^\sigma\circ\bar{\eta}^{-\tau}) + \bar{h}_{,\sigma}\bar{v}^\kappa(\varphi^\sigma_{,\kappa}\circ\bar{\eta}^{-\tau}) + \bar{v}^\kappa(\varphi^z_{,\kappa}\circ\bar{\eta}^{-\tau})]^{\epsilon_2}_{,\gamma\delta}dSdt \\
& + \kappa\int_0^T\int_\Gamma \Delta_0 w_{\theta t}\cdot\Delta_0\varphi dSdt - \int_0^T ((\bar{a}_i^j q_\theta)_t, \varphi^i_{,j})_{L^2(\Omega)}dt \\
& = \int_0^T \Bigg\{\langle \tilde{F}_t,\varphi\rangle - \sigma\int_\Gamma \Big[L_1^{\alpha\beta\gamma}\bar{h}_{,\alpha\beta\gamma} + L_2\Big]^{\epsilon_2}_t \Big[\bar{h}_{,\sigma}(\varphi^\sigma\circ\bar{\eta}^{-\tau}) - \varphi^z\circ\bar{\eta}^{-\tau}\Big]^{\epsilon_2}dS \\
& \qquad - \sigma\int_\Gamma \Big[L_1^{\alpha\beta\gamma}\bar{h}_{,\alpha\beta\gamma} + L_2\Big]^{\epsilon_2}\Big[\bar{h}_{t,\sigma}(\varphi^\sigma\circ\bar{\eta}^{-\tau}) - \bar{h}_{,\sigma}\bar{v}^\kappa(\varphi^\sigma_{,\kappa}\circ\bar{\eta}^{-\tau}) \\
& \qquad\qquad - \bar{v}^\kappa(\varphi^z_{,\kappa}\circ\bar{\eta}^{-\tau})\Big]^{\epsilon_2}dS\Bigg\}dt,
\end{aligned}$$

(7.14b)

(ii) $w_{\theta t}(0) = \tilde{w}_1$, $w_\theta(0) = \tilde{u}_0$ in Ω

for all $\varphi \in L^2(0,T;H^{1;2}(\Omega;\Gamma))$. Choosing φ to be independent of time, we find that for all $t\in[0,T]$,

$$\begin{aligned}
& (w_{\theta t},\varphi)_{L^2(\Omega)} + \frac{\nu}{2}\int_\Omega D_{\bar{\eta}}(w_\theta) : D_{\bar{\eta}}(\varphi)dx + \kappa\int_\Gamma \Delta_0 w_\theta\cdot\Delta_0\varphi dS \\
& + \sigma\int_\Gamma \bar{A}^{\alpha\beta\gamma\delta}h^{\epsilon_2}_{\theta,\alpha\beta}[-\bar{h}_{,\sigma}(\varphi^\sigma\circ\bar{\eta}^{-\tau}) + \varphi^z\circ\bar{\eta}^{-\tau}]^{\epsilon_2}_{,\gamma\delta}dS - (\bar{a}_i^j q_\theta, \varphi^i_{,j})_{L^2(\Omega)} \\
= {} & \langle\tilde{F},\varphi\rangle + \sigma\int_\Gamma \Big[L_1^{\alpha\beta\gamma\delta}\bar{h}_{,\alpha\beta\gamma} + L_2\Big]^{\epsilon_2}\Big[-\bar{h}_{,\sigma}\varphi^\sigma\circ\bar{\eta}^{-\tau} + \varphi^z\circ\bar{\eta}^{-\tau}\Big]^{\epsilon_2}dS + c(\varphi)
\end{aligned}$$

for all $\varphi\in H^{1;2}(\Omega;\Gamma)$, where $c(\varphi)\in\mathbb{R}$ is given by

$$\begin{aligned}
c(\varphi) = {} & (\tilde{w}_1,\varphi)_{L^2(\Omega)} + \frac{\nu}{2}\int_\Omega \mathrm{Def}(\tilde{u}_0) : \mathrm{Def}\,\varphi dx - \left(\tilde{q}_0 - \frac{1}{\theta}\operatorname{div}\tilde{u}_0, \operatorname{div}\varphi\right)_{L^2(\Omega)} \\
& - (\tilde{F}(0),\varphi)_{L^2(\Omega)} - \sigma(\bar{\mathcal{M}}_0^{\epsilon_2}(0)(0,1),\varphi)_{L^2(\Gamma)} + \kappa(\Delta_0\tilde{u}_0,\Delta_0\varphi)_{L^2(\Gamma)}.
\end{aligned}$$

By compatibility conditions (7.6) and (7.7), $c(\varphi) = 0$. Therefore, the weak limit (w_θ, h_θ) satisfies, for all $t \in [0,T]$,

$$\begin{aligned}(7.15)\qquad &(w_{\theta t},\varphi)_{L^2(\Omega)} + \frac{\nu}{2}\int_\Omega D_{\bar\eta}(w_\theta) : D_{\bar\eta}(\varphi)dx + \kappa\int_\Gamma \Delta_0 w_\theta \cdot \Delta_0\varphi dS \\ &- (\bar a_i^j q_\theta, \varphi^i_{,j})_{L^2(\Omega)} + \sigma\int_\Gamma \bar A^{\alpha\beta\gamma\delta} h^{\epsilon_2}_{\theta,\alpha\beta}[-\bar h_{,\sigma}(\varphi^\sigma\circ\bar\eta^{-\tau}) + \varphi^z\circ\bar\eta^{-\tau}]^{\epsilon_2}_{,\gamma\delta} dS \\ &= \langle \tilde F, \varphi\rangle - \sigma\int_\Gamma \left[L_1^{\alpha\beta\gamma\delta}\bar h_{,\alpha\beta\gamma} + L_2\right]^{\epsilon_2}\left[-\bar h_{,\sigma}\varphi^\sigma\circ\bar\eta^{-\tau} + \varphi^z\circ\bar\eta^{-\tau}\right]^{\epsilon_2} dS\end{aligned}$$

for all $\varphi \in H^{1;2}(\Omega;\Gamma)$.

Since $w_\theta \in L^2(0,T;H^{1;2}(\Omega;\Gamma))$, we can use it as a test function in (7.15) and obtain (after time integration)

$$\begin{aligned}(7.16)\qquad &\frac12\|w_\theta\|^2_{L^2(\Omega)} + \frac{\sigma}{2}E_{\bar h}(h_\theta^{\epsilon_2}) + \int_0^t \left[\frac{\nu}{2}\|D_{\bar\eta}w_\theta\|^2_{L^2(\Omega)} + \kappa\|\Delta_0 w_\theta\|^2_{L^2(\Gamma)}\right. \\ &\left. + \theta\|q_\theta\|^2_{L^2(\Omega)}\right]ds - \theta\int_0^t (q_\theta,\tilde q_0)dt - \frac{\sigma}{2}\int_0^t\int_\Gamma (\bar A^{\alpha\beta\gamma\delta})_t h^{\epsilon_2}_{\theta,\alpha\beta}h^{\epsilon_2}_{\theta,\gamma\delta}dSds \\ &= \frac12\|\tilde u_0\|^2_{L^2(\Omega)} + \int_0^t \langle\tilde F,\varphi\rangle + \sigma\langle \bar{\mathcal M}^{\epsilon_2}_{\bar h}(-\nabla_0\bar h\circ\bar\eta^\tau, 1),\varphi\rangle_\Gamma dt.\end{aligned}$$

Consequently,

$$\begin{aligned}&\left[\|w_\theta(t)\|^2_{L^2(\Omega)} + \|\nabla_0^2 h_\theta^{\epsilon_2}(t)\|^2_{L^2(\Gamma)}\right] + \int_0^t \|\nabla w_\theta\|^2_{L^2(\Omega)}ds + \kappa\int_0^t \|w_\theta\|^2_{H^2(\Gamma)}ds \\ &+ \theta\int_0^t \|q_\theta\|^2_{L^2(\Omega)}ds \\ &\le C(M)\left[\|\tilde u_0\|^2_{L^2(\Omega)} + \theta\|\tilde q_0\|^2_{L^2(\Omega)} + \|\tilde F\|^2_{H^1(\Omega)'} + \|\bar{\mathcal M}^{\epsilon_2}_{\bar h}(-\nabla_0\bar h\circ\bar\eta^\tau,1)\|^2_{L^2(\Gamma)}\right] \\ &+ C(M)\int_0^t \|\bar h_t\|_{H^{2.5}(\Gamma)}\|\nabla_0^2 h_\theta^{\epsilon_2}\|^2_{L^2(\Gamma)}ds \\ &\le C(M)\left[N_1(u_0,F) + \int_0^t \|\bar h_t\|_{H^{2.5}(\Gamma)}\|\nabla_0^2 h_\theta^{\epsilon_2}\|^2_{L^2(\Gamma)}ds\right],\end{aligned}$$

where

$$\begin{aligned}N_1(u_0,F) = {}&\|u_0\|^2_{H^2(\Omega)} + \|u_0\|^2_{H^{4.5}(\Gamma)} + \|F\|^2_{L^2(0,T;H^1(\Omega)')} + \|F_t\|^2_{L^2(0,T;H^1(\Omega)')} \\ &+ \|F(0)\|^2_{H^1(\Omega)} + 1.\end{aligned}$$

By the Gronwall inequality,

$$\begin{aligned}(7.17)\qquad &\sup_{0\le t\le T}\left[\|w_\theta(t)\|^2_{L^2(\Omega)} + \|\nabla_0^2 h_\theta^{\epsilon_2}(t)\|^2_{L^2(\Gamma)}\right] + \int_0^T \left[\|\nabla w_\theta\|^2_{L^2(\Omega)} + \theta\|q_\theta\|^2_{L^2(\Omega)}\right]ds \\ &\le C(M)N_1(u_0,F).\end{aligned}$$

7.4. Improved pressure estimates. By ϵ_2-regularization, we can rewrite (7.15) as, for a.a. $t \in [0,T]$,

$$\begin{aligned}&(w_{\theta t},\varphi)_{L^2(\Omega)} + \frac{\nu}{2}\int_\Omega D_{\bar\eta}(w_\theta) : D_{\bar\eta}(\varphi)dx + \kappa(\Delta_0 w_\theta, \Delta_0\varphi)_{L^2(\Gamma)} - (\bar a_i^j q_\theta, \varphi^i_{,j})_{L^2(\Omega)} \\ &+ \sigma\int_\Gamma \bar{\mathcal L}^{\epsilon_2}_{\bar h}(h_\theta^{\epsilon_2})\left[-\bar h_{,\sigma}\circ\bar\eta^\tau\varphi^\sigma + \varphi^z\right]dS = \langle\tilde F,\varphi\rangle + \sigma\langle\bar{\mathcal M}^{\epsilon_2}_{\bar h}(-\nabla_0\bar h\circ\bar\eta^\tau,1),\varphi\rangle_\Gamma.\end{aligned}$$

Therefore, by the Lagrange multiplier lemma, we conclude that

$$\|q_\theta\|^2_{L^2(\Omega)} \le C(M)\Big[\|w_{\theta t}\|^2_{H^1(\Omega)'} + \|\nabla w_\theta\|^2_{L^2(\Omega)} + \|\tilde F\|^2_{H^1(\Omega)'} + \kappa\|\Delta_0^2 w_\theta\|^2_{H^{-2}(\Gamma)} + \|[\bar{\mathcal{L}}^{\epsilon_2}_{\bar h}(h^{\epsilon_2}_\theta) + \bar{\mathcal{M}}^{\epsilon_2}_{\bar h}](-\nabla_0 \bar h \circ \bar\eta^\tau, 1)\|^2_{H^{-2}(\Gamma)}\Big],$$

and hence

$$\|q_\theta\|^2_{L^2(\Omega)} \le C(M)\Big[\|w_{\theta t}\|^2_{L^2(\Omega)} + \|\nabla w_\theta\|^2_{L^2(\Omega)} + \kappa\|w_\theta\|^2_{H^2(\Gamma)} + \|\nabla_0^2 h_\theta\|^2_{L^2(\Gamma)} + \|F\|^2_{H^1(\Omega)'} + 1\Big]. \tag{7.18}$$

7.5. Weak limits as $\theta \to 0$. Since $w_{\theta t} \in L^2(0,T;H^{1;2}(\Omega;\Gamma))$, we can use it as a test function in (7.14). Similar to the way we obtain (7.11), we find that

$$\begin{aligned}
&\frac12\|w_{\theta t}\|^2_{L^2(\Omega)} + \frac{\nu}{2}\int_0^t \|D_{\bar\eta} w_{\theta t}\|^2_{L^2(\Omega)} ds + \frac{\sigma}{2} E_{\bar h}(h^{\epsilon_2}_{\theta t}) + \kappa\int_0^t \|\Delta_0^2 w_{\theta t}\|^2_{L^2(\Gamma)} ds \\
&\quad + \theta\int_0^t \|q_{\theta t}\|^2_{L^2(\Omega)} ds + \int_0^t (q_{\theta t}, \bar a^j_{it} w^i_{\theta,j})_{L^2(\Omega)} ds - \int_0^t (q_\theta, \bar a^j_i w^i_{\theta t,j}) ds \\
&\le C(M) N_0(u_0,F) + C(M)\int_0^t \|\bar v(t')\|^2_{H^3(\Omega)} \int_0^{t'} \|\nabla w_{\theta t}(s)\|^2_{L^2(\Omega)} ds dt' \\
&\quad + C(\epsilon_2)\int_0^t \Big[1 + \|\bar h_t\|_{H^{2.5}(\Gamma)}\Big] \|\nabla_0^2 h^{\epsilon_2}_{\theta t}\|^2_{L^2(\Gamma)} ds.
\end{aligned}$$

By (7.18),

$$\begin{aligned}
\left|\int_0^t (q_\theta, \bar a^j_i w^i_{\theta t,j}) ds\right| &\le C(M,\delta)\int_0^t \|q_\theta\|^2_{L^2(\Omega)} ds + \delta\int_0^t \|\nabla w_{\theta t}\|^2_{L^2(\Omega)} ds \\
&\le C(M)\Big[N_1(u_0,F) + \int_0^t \Big(\|w_{\theta t}\|^2_{L^2(\Omega)} + \kappa\|w_\theta\|^2_{H^2(\Gamma)} + \|\nabla_0^2 h_\theta\|^2_{L^2(\Gamma)}\Big) ds\Big] \\
&\quad + \delta\int_0^t \|\nabla w_{\theta t}\|^2_{L^2(\Omega)} ds,
\end{aligned} \tag{7.19}$$

where (7.17) is used to bound $\|\nabla w_\theta\|^2_{L^2(0,T;L^2(\Omega))}$.

Integrating by parts,

$$\begin{aligned}
\int_0^t (q_{\theta t}, \bar a^j_{it} w^i_{\theta,j})_{L^2(\Omega)} ds &= (q_\theta, \bar a^j_{it} w^i_{\theta,j})_{L^2(\Omega)}(t) + (\tilde q_0, \tilde u^j_{0,i} \tilde u^i_{0,j})_{L^2(\Omega)} \\
&\quad - \int_0^t (q_\theta, \bar a^j_{itt} w^i_{\theta,j})_{L^2(\Omega)} ds - \int_0^t (q_\theta, \bar a^j_{it} w^i_{\theta t,j})_{L^2(\Omega)} ds.
\end{aligned}$$

By ϵ_1-regularization, the last two terms can be bounded by

$$C(M)\int_0^t \|q_\theta\|_{L^2(\Omega)}\Big[C(\epsilon_1)\|\nabla w_\theta\|_{L^2(\Omega)} + \|\nabla w_{\theta t}\|_{L^2(\Omega)}\Big] ds,$$

and hence

$$\left|\int_0^t (q_\theta, \bar{a}^j_{itt} w^i_{\theta,j})_{L^2(\Omega)} ds\right| + \left|\int_0^t (q_\theta, \bar{a}^j_{it} w^i_{\theta t,j})_{L^2(\Omega)} ds\right|$$

$$\leq C(M,\delta)\int_0^t \|q_\theta\|^2_{L^2(\Omega)} ds + C(\epsilon_1)\int_0^t \|\nabla w_\theta\|^2_{L^2(\Omega)} ds + \delta\int_0^t \|\nabla w_{\theta t}\|^2_{L^2(\Omega)} ds$$

$$\leq C(\epsilon_1,\delta)N_1(u_0,F) + C(M,\delta)\int_0^t \|w_{\theta t}\|^2_{L^2(\Omega)} ds + C(\epsilon_2)\int_0^t \|\nabla_0^2 h_\theta\|^2_{L^2(\Gamma)} ds$$

$$+\,\delta\int_0^t \|\nabla w_{\theta t}\|^2_{L^2(\Omega)} ds. \tag{7.20}$$

For $(q_\theta, \bar{a}^j_{it} w^i_{\theta,j})_{L^2(\Omega)}(t)$, it is easy to see that

$$\left|(q_\theta, \bar{a}^j_{it} w^i_{\theta,j})_{L^2(\Omega)}(t)\right| \leq \delta_1 \|w_{\theta t}\|^2_{L^2(\Omega)} + C(\epsilon_1,\delta_1)\|\nabla w_\theta\|^2_{L^2(\Omega)}$$

$$\leq C(\epsilon_1,\delta_1)\|\nabla w_\theta\|^2_{L^2(\Omega)} + \delta_1 C(\epsilon_2)\|\nabla_0^2 h_\theta\|^2_{L^2(\Gamma)} + \delta_1\Big[\|w_{\theta t}\|^2_{L^2(\Omega)} + \|F\|_{L^2(\Omega)} + 1\Big],$$

while for $(\tilde{q}_0, \tilde{u}^j_{0,i}\tilde{u}^i_{0,j})_{L^2(\Omega)}$, it is bounded by $C(M)N_1(u_0,F)$. Combining (7.19), (7.20), and the estimates above, by choosing $\delta > 0$ and $\delta_1 > 0$ small enough,

$$\|w_{\theta t}\|^2_{L^2(\Omega)} + \|\nabla_0^2 h_{\theta t}\|^2_{L^2(\Gamma)} + \int_0^t \Big[\|\nabla w_{\theta t}\|^2_{L^2(\Omega)} + \kappa\|w_{\theta t}\|^2_{H^2(\Gamma)} + \theta\|q_{\theta t}\|^2_{L^2(\Omega)}\Big] ds$$

$$\leq C(\epsilon_2,\epsilon_1)\Bigg[N_2(u_0,F) + \int_0^t \Bigg(\|w_{\theta t}\|^2_{L^2(\Omega)} + (1+\|\bar{h}_t\|_{H^{2.5}(\Gamma)})\|\nabla_0^2 h_{\theta t}\|^2_{L^2(\Gamma)}$$

$$+\,\|\bar{v}\|^2_{H^3(\Omega)}\int_0^s \|\nabla w_{\theta t}\|^2_{L^2(\Omega)} dt'\Bigg) ds\Bigg] + C_1(\epsilon_2,\epsilon_1)\|\nabla w_\theta\|^2_{L^2(\Omega)},$$

where $N_2(u_0,F) = N_1(u_0,F) + \|F\|^2_{L^\infty(0,T;L^2(\Omega))}$. By the Gronwall inequality,

$$\|w_{\theta t}\|^2_{L^2(\Omega)} + \|\nabla_0^2 h_{\theta t}\|^2_{L^2(\Gamma)} + \int_0^t \Big[\|\nabla w_{\theta t}\|^2_{L^2(\Omega)} + \kappa\|w_{\theta t}\|^2_{H^2(\Gamma)}\Big] ds$$

$$\leq C(\epsilon_2,\epsilon_1)N_2(u_0,F) + C_1(\epsilon_2,\epsilon_1)\|\nabla w_\theta\|^2_{L^2(\Omega)}. \tag{7.21}$$

By using $w_\theta(t) = \tilde{u}_0 + \int_0^t w_{\theta t} ds$, we see that

$$\|w_{\theta t}\|^2_{L^2(\Omega)} + \|\nabla_0^2 h_{\theta t}\|^2_{L^2(\Gamma)} + \int_0^t \Big[\|\nabla w_{\theta t}\|^2_{L^2(\Omega)} + \kappa\|w_{\theta t}\|^2_{H^2(\Gamma)}\Big] ds$$

$$\leq C(\epsilon_2,\epsilon_1)N_2(u_0,F) + C_1(\epsilon_2,\epsilon_1)t\int_0^t \|\nabla w_{\theta t}\|^2_{L^2(\Omega)} ds.$$

Therefore, for any $0 \leq t \leq t_1 = \min\{T, \frac{1}{2C_1}\}$, we have

$$\|w_{\theta t}\|^2_{L^2(\Omega)} + \|\nabla_0^2 h_{\theta t}\|^2_{L^2(\Gamma)} + \frac{1}{2}\int_0^t \Big[\|\nabla w_{\theta t}\|^2_{L^2(\Omega)} + \kappa\|w_{\theta t}\|^2_{H^2(\Gamma)}\Big] ds$$

$$\leq C(\epsilon_2,\epsilon_1)N_2(u_0,F).$$

By $w_\theta(t_1) = \tilde{u}_0 + \int_0^{t_1} w_{\theta t} ds$, we also have

$$\|\nabla w_\theta(t_1)\|^2_{L^2(\Omega)} \leq C(\epsilon_2,\epsilon_1)N_2(u_0,F). \tag{7.22}$$

For $t \geq t_1$, since $w_\theta(t) = w_\theta(t_1) + \int_{t_1}^t w_{\theta t} ds$, we have from (7.21) and (7.22) that

$$\begin{aligned}
&\|w_{\theta t}\|^2_{L^2(\Omega)} + \|\nabla_0^2 h_{\theta t}\|^2_{L^2(\Gamma)} + \int_0^t \left[\|\nabla w_{\theta t}\|^2_{L^2(\Omega)} + \kappa \|w_{\theta t}\|^2_{H^2(\Gamma)}\right] ds \\
&\leq C(\epsilon_2, \epsilon_1) N_2(u_0, F) + C_1(\epsilon_2, \epsilon_1)\left[\|w_\theta(t_1)\|^2_{L^2(\Omega)} + (t - t_1)\int_{t_1}^t \|\nabla_0 w_{\theta t}\|^2_{L^2(\Omega)} ds\right] \\
&\leq C(\epsilon_2, \epsilon_1) N_2(u_0, F) + C_1(\epsilon_2, \epsilon_1)(t - t_1)\int_{t_1}^t \|\nabla_0 w_{\theta t}\|^2_{L^2(\Omega)} ds.
\end{aligned}$$

Therefore, for any $t_1 \leq t \leq 2t_1$, we also have

$$\begin{aligned}
&\|w_{\theta t}\|^2_{L^2(\Omega)} + \|\nabla_0^2 h_{\theta t}\|^2_{L^2(\Gamma)} + \frac{1}{2}\int_0^t \left[\|\nabla w_{\theta t}\|^2_{L^2(\Omega)} + \kappa \|w_{\theta t}\|^2_{H^2(\Gamma)}\right] ds \\
&\leq C(\epsilon_2, \epsilon_1) N_2(u_0, F),
\end{aligned}$$

which with $w_\theta(2t_1) = \tilde{u}_0 + \int_0^{2t_1} w_{\theta t} ds$ gives

$$\|\nabla w_\theta(2t_1)\|^2_{L^2(\Omega)} \leq C(\epsilon_2, \epsilon_1) N_2(u_0, F).$$

By induction, for any $t \in [0, T]$,

$$\begin{aligned}
&\|w_{\theta t}\|^2_{L^2(\Omega)} + \|\nabla_0^2 h_{\theta t}\|^2_{L^2(\Gamma)} + \frac{1}{2}\int_0^t \left[\|\nabla w_{\theta t}\|^2_{L^2(\Omega)} + \kappa \|w_{\theta t}\|^2_{H^2(\Gamma)}\right] ds \\
&\leq C(\epsilon_2, \epsilon_1) N_2(u_0, F).
\end{aligned} \tag{7.23}$$

We also get a θ-independent bound for $\|q_\theta\|^2_{L^2(0,T;L^2(\Omega))}$ by (7.18):

$$\|q_\theta\|^2_{L^2(0,T;L^2(\Omega))} \leq C(\epsilon_2, \epsilon_1) N_2(u_0, F). \tag{7.24}$$

Let $\theta = \frac{1}{m}$. Energy inequalities (7.17), (7.23), and (7.24) show that there exists a subsequence $w_{\frac{1}{m_\ell}}$ such that

$$w_{\frac{1}{m_\ell}} \rightharpoonup \mathfrak{v} \quad \text{in} \quad L^2(0, T; H^{1;2}(\Omega; \Gamma)), \tag{7.25a}$$

$$w_{\frac{1}{m_\ell} t} \rightharpoonup \mathfrak{v}_t \quad \text{in} \quad L^2(0, T; H^{1;2}(\Omega; \Gamma)), \tag{7.25b}$$

$$\nabla_0^2 h_{\frac{1}{m_\ell}} \rightharpoonup \nabla_0^2 \mathfrak{h} \quad \text{in} \quad L^2(0, T; L^2(\Omega)), \tag{7.25c}$$

$$\nabla_0^2 h_{\frac{1}{m_\ell} t} \rightharpoonup \nabla_0^2 \mathfrak{h}_t \quad \text{in} \quad L^2(0, T; L^2(\Omega)), \tag{7.25d}$$

$$q_{\frac{1}{m_\ell}} \rightharpoonup \mathfrak{q} \quad \text{in} \quad L^2(0, T; L^2(\Omega)). \tag{7.25e}$$

Moreover, (7.17) also shows that $\|\bar{a}_i^j w^i_{\frac{1}{m},j}\|_{L^2(0,T;L^2(\Omega))} \to 0$ as $m \to \infty$. Therefore, the weak limit $\mathfrak{v}$ satisfies the "divergence-free" condition (7.2b), i.e.,

$$\mathfrak{v} \in \mathcal{V}_{\bar{v}}(T). \tag{7.26}$$

Since (7.17) is independent of θ and ϵ_2, by the property of lower semicontinuity of norms,

$$\begin{aligned}
&\sup_{0 \leq t \leq T}\left[\|\mathfrak{v}(t)\|^2_{L^2(\Omega)} + \|\nabla_0^2 \mathfrak{h}(t)\|^2_{L^2(\Gamma)}\right] + \|\nabla \mathfrak{v}\|^2_{L^2(0,T;L^2(\Omega))} + \kappa \|\mathfrak{v}\|^2_{H^2(\Gamma)} \\
&\leq C(M) N_1(u_0, F).
\end{aligned} \tag{7.27}$$

By (7.25) and ϵ_2-regularization, the weak limit $(\mathfrak{v}, \mathfrak{h}, \mathfrak{q})$ satisfies, for all $\varphi \in L^2(0,T; H^{1;2}(\Omega;\Gamma))$,

$$\begin{aligned}
&\int_0^T (\mathfrak{v}_t, \varphi)_{L^2(\Omega)}dt + \frac{\nu}{2}\int_0^T\int_\Omega D_{\bar\eta}(\mathfrak{v}) : D_{\bar\eta}(\varphi)dxdt + \kappa\int_0^T\int_\Gamma \Delta_0\mathfrak{v}\cdot\Delta_0\varphi dSdt \\
&-\int_0^T (\bar a_i^j \mathfrak{q}, \varphi^i_{,j})_{L^2(\Omega)}dt + \sigma\int_0^T\int_\Gamma \bar A^{\alpha\beta\gamma\delta}\mathfrak{h}^{\epsilon_2}_{,\alpha\beta}[-\bar h_{,\sigma}(\varphi^\sigma\circ\bar\eta^{-\tau}) + \varphi^z\circ\bar\eta^{-\tau}]^{\epsilon_2}_{,\gamma\delta}dSdt \\
= &\int_0^T \left\{\langle \tilde F, \varphi\rangle - \sigma\int_\Gamma \left[L_1^{\alpha\beta\gamma\delta}\bar h_{,\alpha\beta\gamma} + L_2\right]^{\epsilon_2}\left[-\bar h_{,\sigma}\varphi^\sigma\circ\bar\eta^{-\tau} + \varphi^z\circ\bar\eta^{-\tau}\right]^{\epsilon_2} dS\right\}dt.
\end{aligned}$$

By the density argument, we find that for a.a. $t\in[0,T]$, $\varphi\in H^{1;2}(\Omega;\Gamma)$,

$$\begin{aligned}
&(\mathfrak{v}_t, \varphi)_{L^2(\Omega)} + \frac{\nu}{2}\int_\Omega D_{\bar\eta}(\mathfrak{v}) : D_{\bar\eta}(\varphi)dx + \kappa\int_\Gamma \Delta_0\mathfrak{v}\cdot\Delta_0\varphi dS - (\bar a_i^j\mathfrak{q}, \varphi^i_{,j})_{L^2(\Omega)} \\
&+\sigma\int_\Gamma \bar A^{\alpha\beta\gamma\delta}\mathfrak{h}^{\epsilon_2}_{,\alpha\beta}[-\bar h_{,\sigma}(\varphi^\sigma\circ\bar\eta^{-\tau}) + \varphi^z\circ\bar\eta^{-\tau}]^{\epsilon_2}_{,\gamma\delta}dS \\
&= \langle\tilde F, \varphi\rangle - \sigma\int_\Gamma \left[L_1^{\alpha\beta\gamma\delta}\bar h_{,\alpha\beta\gamma} + L_2\right]^{\epsilon_2}\left[-\bar h_{,\sigma}\varphi^\sigma\circ\bar\eta^{-\tau} + \varphi^z\circ\bar\eta^{-\tau}\right]^{\epsilon_2}dS,
\end{aligned} \tag{7.28}$$

or after a change of variable $y' = \bar\eta^\tau(y,t)$,

$$\begin{aligned}
&(\mathfrak{v}_t, \varphi)_{L^2(\Omega)} + \frac{\nu}{2}(D_{\bar\eta}\mathfrak{v}, D_{\bar\eta}\varphi)_{L^2(\Omega)} + \kappa\int_\Gamma \Delta_0\mathfrak{v}\cdot\Delta_0\varphi dS - (\bar a_i^j\mathfrak{q}, \varphi^i_{,j})_{L^2(\Omega)} \\
&+\sigma\int_\Gamma \mathcal{L}^{\epsilon_2}_{\bar h}(\mathfrak{h})(-\nabla_0\bar h\circ\bar\eta^\tau, 1)\cdot\varphi dS = \langle\tilde F,\varphi\rangle - \sigma\int_\Gamma \bar{\mathcal{M}}^{\epsilon_2}_{\bar h}(-\nabla_0\bar h\circ\bar\eta^\tau, 1)\cdot\varphi dS.
\end{aligned} \tag{7.29}$$

Furthermore, if $\varphi\in\mathcal{V}_{\bar v}$, then

$$\begin{aligned}
&(\mathfrak{v}_t, \varphi)_{L^2(\Omega)} + \frac{\nu}{2}(D_{\bar\eta}\mathfrak{v}, D_{\bar\eta}\varphi)_{L^2(\Omega)} + \kappa\int_\Gamma \Delta_0\mathfrak{v}\cdot\Delta_0\varphi dS \\
&+\sigma\int_\Gamma \mathcal{L}^{\epsilon_2}_{\bar h}(\mathfrak{h})(-\nabla_0\bar h\circ\bar\eta^\tau, 1)\cdot\varphi dS = \langle\tilde F,\varphi\rangle - \sigma\int_\Gamma \bar{\mathcal{M}}^{\epsilon_2}_{\bar h}(-\nabla_0\bar h\circ\bar\eta^\tau, 1)\cdot\varphi^{\epsilon_2} dS
\end{aligned}$$

for a.a. $t\in[0,T]$. In other words, $(\mathfrak{v},\mathfrak{h},\mathfrak{q})$ is a weak solution of (7.2).

8. Estimates independent of ϵ_2.

8.1. Partition of unity. Since Ω is compact, by partition of unity, we can choose two nonnegative smooth functions ζ_0 and ζ_1 so that

$$\begin{aligned}
&\zeta_0 + \zeta_1 = 1 \quad \text{in } \Omega, \\
&\operatorname{supp}(\zeta_0) \subset\subset \Omega, \\
&\operatorname{supp}(\zeta_1) \subset\subset \Gamma\times(-\epsilon_1, \epsilon_1) := \Omega_1.
\end{aligned}$$

We will assume that $\zeta_1 = 1$ inside the region $\Omega_1' \subset \Omega_1$ and $\zeta_0 = 1$ inside the region $\Omega'\subset\Omega$. Note that then $\zeta_1 = 1$, while $\zeta_0 = 0$ on Γ.

8.2. Higher regularity.

8.2.1. ϵ_2-independent bounds for $\mathfrak{q}$. Similar to (7.18), we have

$$\begin{aligned}
\|\mathfrak{q}\|^2_{L^2(\Omega)} \le C(M)\Big[&\|\mathfrak{v}_t\|^2_{L^2(\Omega)} + \|\nabla\mathfrak{v}\|^2_{L^2(\Omega)} + \kappa\|\mathfrak{v}\|^2_{H^2(\Gamma)} + \|\nabla_0^2\mathfrak{h}^{\epsilon_2}\|^2_{L^2(\Gamma)} \\
&+ \|F\|^2_{L^2(\Omega)} + 1\Big].
\end{aligned} \tag{8.1}$$

8.2.2. Interior regularity. Converting the fluid equation (7.2) into Eulerian variables by composing with $\bar{\eta}^{-1}$, we obtain a Stokes problem in the domain $\bar{\eta}(\Omega)$:

$$-\nu\Delta\mathfrak{u} + \nabla\mathfrak{p} = \tilde{F}\circ\bar{\eta}^{-1} - \mathfrak{v}_t\circ\bar{\eta}^{-1} + \nu\bar{a}^j_{\ell,j}\circ\bar{\eta}^{-1}\mathfrak{u}_{,\ell} - \mathfrak{p}\bar{a}^j_{i,j}\circ\bar{\eta}^{-1}, \tag{8.2a}$$

$$\operatorname{div}\mathfrak{u} = 0, \tag{8.2b}$$

where $\mathfrak{u} = \mathfrak{v}\circ\bar{\eta}^{-1}$ and $\mathfrak{p} = \mathfrak{q}\circ\bar{\eta}^{-1}$. By the regularity results for the Stokes problem,

$$\begin{aligned} &\|\mathfrak{u}\|^2_{H^2(\bar{\eta}(\Omega))} + \|\mathfrak{p}\|^2_{H^1(\bar{\eta}(\Omega))} \\ &\le C\Big[\|\tilde{F}\circ\bar{\eta}^{-1}\|^2_{L^2(\bar{\eta}(\Omega))} + \|\mathfrak{v}_t\circ\bar{\eta}^{-1}\|^2_{L^2(\bar{\eta}(\Omega))} + \|\nabla\mathfrak{u}\|^2_{L^2(\bar{\eta}(\Omega))} + \|\mathfrak{p}\|^2_{L^2(\bar{\eta}(\Omega))} \\ &\qquad + \|\mathfrak{u}\|^2_{H^{1.5}(\Gamma)}\Big] \end{aligned}$$

or

$$\begin{aligned} \|\mathfrak{v}\|^2_{H^2(\Omega)} + \|\mathfrak{q}\|^2_{H^1(\Omega)} \le C\Big[\|F\|^2_{L^2(\Omega)} + \|\mathfrak{v}_t\|^2_{L^2(\Omega)} + \|\mathfrak{v}\|^2_{H^{1.5}(\Gamma)}\Big] \\ + C(M)\Big[\|\nabla\mathfrak{v}\|^2_{L^2(\Omega)} + \|\mathfrak{q}\|^2_{L^2(\Omega)}\Big] \end{aligned}$$

for some constant C independent of M and ϵ_1. By (8.1),

$$\begin{aligned} \|\mathfrak{v}\|^2_{H^2(\Omega)} + \|\mathfrak{q}\|^2_{H^1(\Omega)} \le C(M)\Big[\|\mathfrak{v}_t\|^2_{L^2(\Omega)} + \|\nabla\mathfrak{v}\|^2_{L^2(\Omega)} + \|\mathfrak{v}\|^2_{H^2(\Gamma)} \\ + \|\nabla_0^2\mathfrak{h}^{\epsilon_2}\|^2_{L^2(\Gamma)} + \|F\|^2_{L^2(\Omega)} + 1\Big]. \end{aligned} \tag{8.3}$$

Similarly,

$$\begin{aligned} \|\mathfrak{v}\|^2_{H^3(\Omega)} + \|\mathfrak{q}\|^2_{H^2(\Omega)} \le C\Big[\|F\|^2_{H^1(\Omega)} + \|\mathfrak{v}_t\|^2_{H^1(\Omega)} + \|\mathfrak{v}\|^2_{H^{2.5}(\Gamma)}\Big] \\ + C(M)\Big[\|\nabla\mathfrak{v}\|^2_{H^1(\Omega)} + \|\mathfrak{q}\|^2_{H^1(\Omega)}\Big], \end{aligned}$$

and therefore by (8.1) and (8.3),

$$\begin{aligned} \|\mathfrak{v}\|^2_{H^3(\Omega)} + \|\mathfrak{q}\|^2_{H^2(\Omega)} \le C(M)\Big[\|\mathfrak{v}_t\|^2_{H^1(\Omega)} + \|\nabla\mathfrak{v}\|^2_{L^2(\Omega)} + \|\nabla_0^2\mathfrak{v}\|^2_{H^1(\Omega_1)} \\ + \|\nabla_0^2\mathfrak{h}^{\epsilon_2}\|^2_{L^2(\Gamma)} + \|F\|^2_{H^1(\Omega)} + 1\Big]. \end{aligned} \tag{8.4}$$

For the regularized problem, because the ϵ_1-regularization ensures that the forcing and the initial data are smooth, while the ϵ_2-regularization ensures that the right-hand side of (7.2c) is smooth, by the standard difference quotient technique, it is also easy to see that

$$\nabla_0^k\mathfrak{v} \in L^2(0,T;H^1(\Omega_1)\cap H^2(\Gamma)) \quad \text{for } k = 1,2,3,4. \tag{8.5}$$

Since (7.25b) implies that $\mathfrak{v}_t \in L^2(0,T;H^1(\Omega))$, by ϵ_2-regularization and (8.4) we conclude that

$$\mathfrak{v} \in L^2(0,T;H^3(\Omega)), \qquad \mathfrak{q} \in L^2(0,T;H^2(\Omega)). \tag{8.6}$$

8.3. Estimates for $\mathfrak{v}_t(0)$ and $\mathfrak{q}(0)$. By (8.6) and ϵ_2-regularization, $(\mathfrak{v},\mathfrak{h},\mathfrak{q})$ satisfies the strong form (7.2). Taking the "divergence" of (7.2a) and then making use of condition (7.2b), we find that

$$-\bar{a}^k_{it}\mathfrak{v}^i_{,k} - \nu\bar{a}^k_i[\bar{a}^j_\ell D_{\bar{\eta}}(\mathfrak{v})^i_\ell]_{,jk} = -\bar{a}^k_i(\bar{a}^j_i\mathfrak{q})_{,jk} + \bar{a}^k_i\tilde{F}^i_{,k}. \tag{8.7}$$

Let $t=0$; by the identity $\bar{a}^\ell_{kt} = -\bar{a}^i_k\bar{v}^j_{,i}\bar{a}^\ell_j$,

$$\Delta\mathfrak{q}(0) = \nabla\tilde{u}_0 : (\nabla\tilde{u}_0)^T - \operatorname{div}(\tilde{F}(0)) \quad \text{in } \Omega$$

with

$$\mathfrak{q}(0) = \nu(\operatorname{Def}\tilde{u}_0)^j_i N_i N_j - \sigma\mathcal{M}^{\epsilon_2}_0(0) + \kappa\Delta_0^2\tilde{u}_0 \quad \text{on } \Gamma,$$

while (7.2a) gives us

$$\mathfrak{v}_t(0) = \nu\Delta\tilde{u}_0 - \nabla\mathfrak{q}(0) + \tilde{F}(0) \quad \text{in } \Omega.$$

By standard elliptic regularity result,

$$\|\mathfrak{v}_t(0)\|^2_{L^2(\Omega)} + \|\mathfrak{q}(0)\|^2_{H^1(\Omega)} \le CN_0(u_0,F) \tag{8.8}$$

for some constant independent of M, ϵ_1, and ϵ_2.

8.4. $L^2_tL^2_x$-estimates for $\mathfrak{v}_t$. Since $\mathfrak{v}_t \in L^2(0,T;H^1(\Omega))$, we can use it as a test function in (7.29). By (7.26), we find that

$$\begin{aligned}
&\|\mathfrak{v}_t\|^2_{L^2(\Omega)} + \frac{\nu}{4}\frac{d}{dt}\int_\Omega |D_{\bar{\eta}}\mathfrak{v}|^2dx - \frac{\nu}{2}\int_\Omega (D_{\bar{\eta}}\mathfrak{v})^j_i\bar{a}^k_{jt}\mathfrak{v}^i_{,k}dx + \kappa\int_\Gamma \Delta_0\mathfrak{v}\cdot\Delta_0\varphi dS\\
&\quad + \int_\Omega \mathfrak{q}\bar{a}^\ell_{kt}\mathfrak{v}^k_{,\ell}dx + \sigma\int_\Gamma \mathcal{L}^{\epsilon_2}_{\bar{h}}(\mathfrak{h})(-\nabla_0\bar{h}\circ\bar{\eta}^\tau,1)\cdot\mathfrak{v}_t dS\\
&= \langle\tilde{F},\mathfrak{v}_t\rangle - \sigma\int_\Gamma \mathcal{M}^{\epsilon_2}_{\bar{h}}(-\nabla_0\bar{h}\circ\bar{\eta}^\tau,1)\cdot\mathfrak{v}_t dS.
\end{aligned}$$

By (5.3),

$$\int_\Omega (D_{\bar{\eta}}\mathfrak{v})^j_i\bar{a}^k_{jt}\mathfrak{v}^i_{,k}dx \le C(M)C(\delta)\|\nabla\mathfrak{v}\|^2_{L^2(\Omega)} + \delta\|\mathfrak{v}\|^2_{H^2(\Omega)},$$

and by (8.1) and the interpolation inequality,

$$\begin{aligned}
\left|\int_\Omega \mathfrak{q}\bar{a}^\ell_{kt}\mathfrak{v}^k_{,\ell}dx\right| &\le C(M)C(\delta)\Big[\|\nabla\mathfrak{v}\|^2_{L^2(\Omega)} + \|\nabla_0^4\mathfrak{h}^{\epsilon_2}\|^2_{L^2(\Gamma)} + \|F\|^2_{L^2(\Omega)} + 1\Big]\\
&\quad + \delta\|\mathfrak{v}\|^2_{H^2(\Omega)} + \frac{1}{2}\|\mathfrak{v}_t\|^2_{L^2(\Omega)}
\end{aligned}$$

for some $C(\delta)$. Also, the last term on the left-hand side is bounded by

$$\begin{aligned}
&C(M)\Big[\|\nabla_0^4\mathfrak{h}^{\epsilon_2}\|_{L^2(\Gamma)} + 1\Big]\|\mathfrak{v}_t\|_{H^1(\Omega)}\\
&\le C(M)C(\delta_1)\Big[\|\nabla_0^4\mathfrak{h}^{\epsilon_2}\|^2_{L^2(\Gamma)} + 1\Big] + \delta_1\|\mathfrak{v}_t\|^2_{H^1(\Omega)}.
\end{aligned}$$

Combining all the estimates above,

$$\begin{aligned}&\frac{1}{2}\|\mathfrak{v}_t\|^2_{L^2(\Omega)}+\frac{\nu}{4}\frac{d}{dt}\int_\Omega |D_{\bar\eta}\mathfrak{v}|^2dx+\frac{\kappa}{2}\frac{d}{dt}\int_\Gamma |\Delta_0\mathfrak{v}|^2dS\\&\le C\Big[\|\nabla\mathfrak{v}\|^2_{L^2(\Omega)}+\|\nabla_0^4\mathfrak{h}^{\epsilon_2}\|^2_{L^2(\Gamma)}+\|F\|^2_{L^2(\Omega)}+1\Big]+\delta\|\mathfrak{v}\|^2_{H^2(\Omega)}+\delta_1\|\mathfrak{v}_t\|^2_{H^1(\Omega)}\end{aligned}$$

for some constant C depending on M, δ, and δ_1. Therefore, by (7.27),

$$\begin{aligned}&\int_0^t\|\mathfrak{v}_t\|^2_{L^2(\Omega)}ds+\|\nabla\mathfrak{v}(t)\|^2_{L^2(\Omega)}+\kappa\|\mathfrak{v}\|^2_{H^2(\Gamma)}\\&\le C\Big[N_2(u_0,F)+\int_0^t\|\nabla_0^4\mathfrak{h}^{\epsilon_2}\|^2_{L^2(\Gamma)}ds\Big]+\delta\int_0^t\|\mathfrak{v}\|^2_{H^2(\Omega)}ds+\delta_1\int_0^t\|\mathfrak{v}_t\|^2_{H^1(\Omega)}ds.\end{aligned}\tag{8.9}$$

8.5. Energy estimates for $\nabla_0^2 v$ near the boundary. Because of (8.5), $\nabla_0^2(\zeta_1^2\nabla_0^2\mathfrak{v})$ in (7.28) can be used as a test function in (7.29). It follows that

$$\begin{aligned}&\left|\int_\Gamma\Big[\bar{\mathcal{L}}^{\epsilon_2}_{\bar h}(\mathfrak{h}^{\epsilon_2})+\bar{\mathcal{M}}^{\epsilon_2}_{\bar h}\Big](-\nabla_0\bar h\circ\bar\eta^\tau,1)\cdot\nabla_0^4\mathfrak{v}dS\right|\\&\le C(M)\Big[\|\nabla_0^2\mathfrak{h}^{\epsilon_2}\|_{H^2(\Gamma)}+1\Big]\|\mathfrak{v}\|_{H^4(\Gamma)}\\&\le C(M,\delta_3)\Big[1+\|\mathfrak{h}\|^2_{H^4(\Gamma)}\Big]+\delta_3\|\mathfrak{v}\|^2_{H^4(\Gamma)}.\end{aligned}$$

By (7.4), we find that

$$\|\mathfrak{h}\|^2_{H^4(\Gamma)}\le C(\epsilon_1)\Big[\int_0^t\|\bar h\|_{H^5(\Gamma)}\|\mathfrak{v}\|_{H^4(\Gamma)}ds\Big]^2\le C(\epsilon_1)\int_0^t\|\mathfrak{v}\|^2_{H^4(\Gamma)}ds,$$

and hence

$$\begin{aligned}&\left|\int_\Gamma\Big[\bar{\mathcal{L}}^{\epsilon_2}_{\bar h}(\mathfrak{h}^{\epsilon_2})+\bar{\mathcal{M}}^{\epsilon_2}_{\bar h}\Big](-\nabla_0\bar h\circ\bar\eta^\tau,1)\cdot\nabla_0^4\mathfrak{v}dS\right|\\&\le\bar C\Big[1+\int_0^t\|\mathfrak{v}\|^2_{H^4(\Gamma)}\Big]+\delta_3\|\mathfrak{v}\|^2_{H^4(\Gamma)}\end{aligned}$$

for some constant $\bar C$ depending on M, ϵ_1, and δ_3. Since

$$\Delta_0 f=\frac{1}{\sqrt{\det(g_0)}}\frac{\partial}{\partial y^\alpha}\Big[\sqrt{\det(g_0)}g_0^{\alpha\beta}\frac{\partial}{\partial y^\beta}f\Big],$$

by the regularity on Γ (and hence on g_0),

$$\begin{aligned}\int_\Gamma|\Delta_0\nabla_0^2\mathfrak{v}|^2dS&\le\int_\Gamma\Delta_0^2\mathfrak{v}\cdot(\nabla_0^4v)dS+C\|\mathfrak{v}\|_{H^3(\Gamma)}\|\mathfrak{v}\|_{H^4(\Gamma)}\\&\le\int_\Gamma\Delta_0^2v\cdot(\nabla_0^4v)dS+C(\delta)\|\mathfrak{v}\|^2_{H^1(\Omega)}+\delta\|\mathfrak{v}\|^2_{H^4(\Gamma)},\end{aligned}$$

which implies, by choosing $\delta>0$ small enough, that

$$\nu_2\|v\|^2_{H^4(\Gamma)}\le\int_\Gamma\Delta_0^2v\cdot(\nabla_0^4v)dS+C\|v\|^2_{H^1(\Omega)}.$$

By the identity

$$
\begin{aligned}
&(\mathfrak{q}, \bar{a}^\ell_k \nabla_0^2(\zeta_1^2 \nabla_0^2 \mathfrak{v}^k)_{,\ell}) \\
&= (\mathfrak{q}, \nabla_0^2 \bar{a}^\ell_k (\zeta_1^2 \nabla_0^2 \mathfrak{v}^k)_{,\ell}) + 4(\zeta_1 \nabla_0 \mathfrak{q}, \nabla_0 \bar{a}^\ell_k \zeta_{1,\ell} \nabla_0^2 \mathfrak{v}^k) + 2(\nabla_0 \mathfrak{q}, \zeta_1^2 \nabla_0 \bar{a}^\ell_k \nabla_0^2 \mathfrak{v}^k_{,\ell}) \\
&\quad - 2(\zeta_1 \nabla_0 \mathfrak{q}, \nabla_0(\bar{a}^\ell_k \zeta_{1,\ell} \nabla_0^2 \mathfrak{v}^k)) + 2(\mathfrak{q}, \nabla_0(\bar{a}^\ell_k \zeta_{1,\ell} \nabla_0 \zeta_1 \nabla_0^2 \mathfrak{v}^k)) \\
&\quad + (\nabla_0 \mathfrak{q}, \nabla_0(\zeta_1^2 \nabla_0 \bar{a}^\ell_k \nabla_0 \mathfrak{v}^k_{,\ell})),
\end{aligned}
\tag{8.10}
$$

(5.3) and (8.3) imply that

$$
\begin{aligned}
&(\mathfrak{q}, \bar{a}^\ell_k \nabla_0'^2(\zeta_1^2 \nabla_0^2 \mathfrak{v}^k)_{,\ell}) \le C(M) \|\mathfrak{q}\|_{H^1(\Omega)} \|\mathfrak{v}\|_{H^3(\Omega)} \\
&\le C(M)C(\delta)\Big[\|\mathfrak{v}_t\|^2_{L^2(\Omega)} + \|\nabla \mathfrak{v}\|^2_{L^2(\Omega)} + \|\nabla\nabla_0 \mathfrak{v}\|^2_{L^2(\Omega_1)} + \kappa \|\mathfrak{v}\|^2_{H^2(\Gamma)} \\
&\qquad + \|\nabla_0^2 \mathfrak{h}^{\epsilon_2}\|^2_{L^2(\Gamma)} + \|F\|^2_{L^2(\Omega)} + 1\Big] + \delta \|\mathfrak{v}\|^2_{H^3(\Omega)}.
\end{aligned}
$$

For the viscosity term,

$$
\begin{aligned}
&\int_\Omega D_{\bar\eta} \mathfrak{v} : D_{\bar\eta}(\nabla_0^2(\zeta_1^2 \nabla_0^2 \mathfrak{v}))dx \\
&= \|\zeta_1 D_{\bar\eta} \nabla_0^2 \mathfrak{v}\|^2_{L^2(\Omega)} + \frac{1}{2}\int_\Omega \Big[\nabla_0^2(\bar{a}^k_i \bar{a}^\ell_i)\mathfrak{v}^j_{,\ell} + \nabla_0^2(\bar{a}^k_i \bar{a}^\ell_j)\mathfrak{v}^i_{,\ell}\Big](\zeta_1^2 \nabla_0^2 \mathfrak{v}^j)_{,k} dx \\
&\quad + \int_\Omega \Big[\nabla_0(\bar{a}^k_i \bar{a}^\ell_i)\nabla_0 \mathfrak{v}^j_{,\ell} + \nabla_0(\bar{a}^k_i \bar{a}^\ell_j)\nabla_0 \mathfrak{v}^i_{,\ell}\Big](\zeta_1^2 \nabla_0^2 \mathfrak{v}^j)_{,k} dx \\
&\quad + \int_\Omega D_{\bar\eta}(\nabla_0^2 \mathfrak{v})^j_i \bar{a}^k_i \zeta_1 \zeta_{1,k} \nabla_0^2 \mathfrak{v}^j dx,
\end{aligned}
$$

and hence by interpolation

$$
\begin{aligned}
\frac{1}{2}\|\zeta_1 D_{\bar\eta} \nabla_0'^2 \mathfrak{v}\|^2_{L^2(\Omega)} &\le \int_\Omega D_{\bar\eta} \mathfrak{v} : D_{\bar\eta}(\nabla_0^2(\zeta_1^2 \nabla_0^2 \mathfrak{v}))dx \\
&\quad + C(M)C(\delta)\Big[\|\nabla \mathfrak{v}\|^2_{L^2(\Omega)} + \|\nabla\nabla_0 \mathfrak{v}\|^2_{L^2(\Omega_1')}\Big] + \delta \|\mathfrak{v}\|^2_{H^3(\Omega)}.
\end{aligned}
$$

Summing all the estimates, by letting $\delta_3 = \frac{\nu_2 \kappa}{2}$, we conclude that

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|\zeta_1 \nabla_0^2 \mathfrak{v}\|^2_{L^2(\Omega)} + \frac{\nu}{4}\|\zeta_1 D_{\bar\eta} \nabla_0^2 \mathfrak{v}\|^2_{L^2(\Omega)} + \frac{\nu_2 \kappa}{2}\|\mathfrak{v}\|^2_{H^4(\Gamma)} \\
&\le \bar{C}\Big[\|\mathfrak{v}_t\|^2_{L^2(\Omega)} + \|\mathfrak{v}\|^2_{H^1(\Omega)} + \|\nabla\nabla_0 \mathfrak{v}\|^2_{L^2(\Omega_1')} + \|\mathfrak{v}\|^2_{H^2(\Gamma)} + \|\nabla_0^2 \mathfrak{h}^{\epsilon_2}\|^2_{L^2(\Gamma)} \\
&\qquad + \|F\|^2_{H^1(\Omega)} + 1\Big] + \bar{C}\int_0^t \|\mathfrak{v}\|^2_{H^4(\Gamma)} ds + \delta \|\mathfrak{v}\|^2_{H^3(\Omega)}
\end{aligned}
$$

for some constant $\bar{C}$ depending on M, κ, ϵ_1, and δ. Integrating the inequality above in time from 0 to t, by (7.27) we find that

$$
\begin{aligned}
&\|\nabla_0^2 \mathfrak{v}(t)\|^2_{L^2(\Omega_1)} + \int_0^t \Big[\|\nabla\nabla_0^2 \mathfrak{v}\|^2_{L^2(\Omega_1)} + \kappa \|\mathfrak{v}\|^2_{H^4(\Gamma)}\Big] ds \\
&\le \bar{C} N_2(u_0, F) + \bar{C}\int_0^t \Big[\|\mathfrak{v}_t\|^2_{L^2(\Omega)} + \|\nabla\nabla_0 \mathfrak{v}\|^2_{L^2(\Omega_1')} + \|\mathfrak{v}\|^2_{H^2(\Gamma)}\Big] ds \\
&\quad + \bar{C}\int_0^t \int_0^s \|\mathfrak{v}(r)\|^2_{H^4(\Gamma)} dr + \delta \int_0^t \|\mathfrak{v}\|^2_{H^3(\Omega)} ds.
\end{aligned}
\tag{8.11}
$$

By using $\nabla_0(\zeta_1^2\nabla_0\mathfrak{v})$ as a testing function in (7.29), similar computations lead to

$$
\begin{aligned}
&\|\nabla_0\mathfrak{v}(t)\|^2_{L^2(\Omega_1)} + \int_0^t \Big[\|\nabla\nabla_0\mathfrak{v}\|^2_{L^2(\Omega_1)} + \kappa\|\mathfrak{v}\|^2_{H^3(\Gamma)}\Big]ds \\
&\le C(M)N_2(u_0,F) + C(M,\delta)\int_0^t \Big[\|\mathfrak{v}_t\|^2_{L^2(\Omega)} + \kappa\|\mathfrak{v}\|^2_{H^2(\Gamma)}\Big]ds \\
&\quad + C(M)\int_0^t\int_0^s \|\mathfrak{v}(r)\|^2_{H^4(\Gamma)}drds + \delta\int_0^t \|\mathfrak{v}\|^2_{H^3(\Omega)}ds.
\end{aligned}
\tag{8.12}
$$

8.6. Energy estimates for v_t: $L^2_tH^1_x$-estimates. In this section, we time differentiate (7.29) and then use $\mathfrak{v}_t$ as a test function to obtain

$$
\begin{aligned}
&\langle \mathfrak{v}_{tt},\mathfrak{v}_t\rangle + \nu\int_\Omega \Big[\bar a^k_\ell (D_{\bar\eta}\mathfrak{v})^i_{\ell,k}\Big]_t \mathfrak{v}^i_t dx + \sigma\int_\Gamma \Big[\bar{\mathcal{L}}^{\epsilon_2}_{\bar h}(\mathfrak{h}^{\epsilon_2})(-\nabla_0\bar h\circ\bar\eta^\tau,1)\Big]_t\cdot\mathfrak{v}_t dS \\
&+\kappa\int_\Gamma |\Delta_0\mathfrak{v}_t|^2 dS - \int_\Omega (\bar a^\ell_k\mathfrak{q})_t\mathfrak{v}^k_{t,\ell}dx = \langle F_t,\mathfrak{v}_t\rangle - \sigma\int_\Gamma \Big[\bar{\mathcal{M}}^{\epsilon_2}_{\bar h}(-\nabla_0\bar h\circ\bar\eta^\tau,1)\Big]_t\cdot\mathfrak{v}_t dS.
\end{aligned}
$$

By the chain rule,

$$
\begin{aligned}
&\int_\Gamma \Big[(\bar{\mathcal{L}}^{\epsilon_2}_{\bar h}(\mathfrak{h}^{\epsilon_2}) + \bar{\mathcal{M}}^{\epsilon_2}_{\bar h})(-\nabla_0\bar h\circ\bar\eta^\tau,1)\Big]_t\cdot\mathfrak{v}_t dS \\
&= \int_\Gamma \bar\Theta_t\Big[L_{\bar h}(\mathfrak{h}^{\epsilon_2})\Big]^{\epsilon_2}\circ\bar\eta^\tau(-\nabla_0\bar h\circ\bar\eta^\tau,1)\cdot\mathfrak{v}_t dS \\
&\quad + \int_\Gamma \bar\Theta\bar\eta^\tau_t\cdot\Big[\nabla_0[L_{\bar h}(\mathfrak{h}^{\epsilon_2})]^{\epsilon_2}(-\nabla_0\bar h,1)\Big]\circ\bar\eta^\tau\cdot\mathfrak{v}_t dS \\
&\quad + \int_\Gamma \bar\Theta\Big[[L_{\bar h}(\mathfrak{h}^{\epsilon_2})]^{\epsilon_2}(\nabla_0\bar h,-1)\Big]_t\circ\bar\eta^\tau\cdot\mathfrak{v}_t dS.
\end{aligned}
$$

By using the $H^2(\Gamma)$-$H^{-2}(\Gamma)$ duality pairing with ϵ_1-regularization on $\bar\Theta$ and $\bar v$, it follows that

$$
\begin{aligned}
&\left|\int_\Gamma \Big[(\bar{\mathcal{L}}^{\epsilon_2}_{\bar h}(\mathfrak{h}^{\epsilon_2}) + \bar{\mathcal{M}}^{\epsilon_2}_{\bar h})(-\nabla_0\bar h\circ\bar\eta^\tau,1)\Big]_t\cdot\mathfrak{v}_t dS\right| \\
&\le C(\epsilon_1)\Big[\|\nabla_0^3\mathfrak{h}\|_{L^2(\Gamma)} + \|\nabla_0^2\mathfrak{h}_t\|_{L^2(\Gamma)} + 1\Big]\|\mathfrak{v}_t\|_{H^2(\Gamma)} \\
&\le C(\epsilon_1,\delta_3)\left[\int_0^t \|\mathfrak{v}\|^2_{H^4(\Gamma)}ds + \|\mathfrak{v}\|^2_{H^2(\Gamma)} + 1\right] + \delta_3\|\mathfrak{v}_t\|^2_{H^2(\Gamma)} \\
&\le \bar C\left[\int_0^t \|\mathfrak{v}\|^2_{H^4(\Gamma)}ds + \|\mathfrak{v}\|^2_{H^1(\Omega)} + 1\right] + \delta\|\mathfrak{v}\|^2_{H^3(\Omega)} + \delta_3\|\mathfrak{v}_t\|^2_{H^2(\Gamma)}
\end{aligned}
$$

for some constant $\bar C$ depending on M, ϵ_1, δ, and δ_3, where we estimate $\|\mathfrak{v}\|^2_{H^2(\Gamma)}$ by interpolation.

Also by interpolation,

$$
\begin{aligned}
\int_\Omega |D_{\bar\eta}\mathfrak{v}_t|^2 dx &= 2\int_\Omega \Big[\bar a^k_i D_{\bar\eta}(\mathfrak{v})^j_i\Big]_t \mathfrak{v}^j_{t,k}dx - 2\int_\Omega \Big[(\bar a^k_i\bar a^\ell_i)_t\mathfrak{v}^j_{,\ell} + (\bar a^k_i\bar a^\ell_j)_t\mathfrak{v}^i_{,\ell}\Big]\mathfrak{v}^j_{t,k}dx \\
&\le 2\int_\Omega \Big[\bar a^k_i D_{\bar\eta}(\mathfrak{v})^j_i\Big]_t \mathfrak{v}^j_{t,k}dx + C(M)C(\delta,\delta_1)\|\nabla\mathfrak{v}\|^2_{L^2(\Omega)} \\
&\quad - \int_\Omega (\bar a^\ell_k\mathfrak{q})_t\mathfrak{v}^k_{t,\ell}dx + \delta\|\mathfrak{v}\|^2_{H^2(\Omega)} + \delta_1\|\mathfrak{v}_t\|^2_{H^1(\Omega)}.
\end{aligned}
$$

Note that

$$\langle F_t, \mathfrak{v}_t\rangle \le C\|F_t\|_{H^1(\Omega)'}\|\mathfrak{v}_t\|_{H^1(\Omega)} \le C(\delta_1)\|F_t\|^2_{H^1(\Omega)'} + \delta_1\|\mathfrak{v}_t\|^2_{H^1(\Omega)}.$$

Summing all the estimates above,

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|\mathfrak{v}_t\|^2_{L^2(\Omega)} + \frac{\nu}{4}\|\nabla\mathfrak{v}_t\|^2_{L^2(\Omega)} + \kappa\|\Delta_0\mathfrak{v}_t\|^2_{L^2(\Gamma)}\\
&\le \bar{C}\left[\int_0^t \|\mathfrak{v}\|^2_{H^4(\Gamma)}ds + \|\mathfrak{v}\|^2_{H^1(\Omega)} + 1\right] + C(\delta_1)\|F_t\|^2_{H^1(\Omega)'}\\
&\quad + \delta\|\mathfrak{v}\|^2_{H^3(\Omega)} + \delta_1\|\mathfrak{v}_t\|^2_{H^1(\Omega)} + \delta_3\|\mathfrak{v}_t\|^2_{H^2(\Gamma)} + \int_\Omega (\bar{a}^\ell_k\mathfrak{q})_t\mathfrak{v}^k_{t,\ell}dx
\end{aligned} \tag{8.13}$$

for some constant $\bar{C}$ depending on M, κ, δ, and δ_1. As in [7] and [8], the integral involving the pressure q has the following estimate:

$$\begin{aligned}
\int_0^t\int_\Omega (\bar{a}^\ell_k\mathfrak{q})_t\mathfrak{v}^k_{t,\ell}dxds \le C(M)C(\delta,\delta_1)N_3(u_0,F) + \delta\int_0^t \|\mathfrak{v}\|^2_{H^3(\Omega)}ds\\
+ \delta_1\int_0^t \|\mathfrak{v}_t\|^2_{H^1(\Omega)}ds,
\end{aligned}$$

where

$$\begin{aligned}
N_3(u_0,F) := \|u_0\|^2_{H^{2.5}(\Omega)} + \|u_0\|^2_{H^{4.5}(\Gamma)} + \|F\|^2_{L^2(0,T;H^1(\Omega))}\\
+ \|F_t\|^2_{L^2(0,T;H^1(\Omega)')} + \|F(0)\|^2_{H^1(\Omega)} + 1.
\end{aligned}$$

Integrating (8.13) in time from 0 to t and choosing $\delta_1, \delta_3 > 0$ small enough, (7.27) and (8.9) imply that, for all $t \in [0,T]$,

$$\begin{aligned}
&\|\mathfrak{v}_t(t)\|^2_{L^2(\Omega)} + \int_0^t \left[\|\nabla\mathfrak{v}_t\|^2_{L^2(\Omega)} + \kappa\|\mathfrak{v}_t\|^2_{H^2(\Gamma)}\right]ds\\
&\le \bar{C}N_3(u_0,F) + \bar{C}\int_0^t\int_0^s \|\mathfrak{v}(r)\|^2_{H^4(\Gamma)}drds + \delta\int_0^t \|\mathfrak{v}\|^2_{H^3(\Omega)}ds
\end{aligned} \tag{8.14}$$

for some constant $\bar{C}$ depending on M, κ, δ, and δ_2. In (8.14), (8.8) is used to bound $\|v_t(0)\|^2_{L^2(\Omega)}$.

8.7. ϵ_2-independent estimates. Integrating (8.3) in time from 0 to t, (7.27), (8.9), and (8.12) imply that

$$\begin{aligned}
&\int_0^t \left[\|\mathfrak{v}\|^2_{H^2(\Omega)} + \|\mathfrak{q}\|^2_{H^1(\Omega)}\right]ds\\
&\le C(M)N_1(u_0,F) + \int_0^t \left[\|\mathfrak{v}_t\|^2_{L^2(\Omega)} + \|\mathfrak{v}\|^2_{H^2(\Gamma)}\right]ds\\
&\le \bar{C}N_3(u_0,F) + \bar{C}\int_0^t\int_0^s \|\mathfrak{v}(r)\|^2_{H^4(\Gamma)}drds + \delta\int_0^t \|\mathfrak{v}\|^2_{H^3(\Omega)}ds
\end{aligned} \tag{8.15}$$

for some constant $\bar{C}$ depending on M, κ, and δ. Integrating (8.4) in time from 0 to t, making use of (8.11), (8.12), (8.14), and (8.15), and then choosing $\delta > 0$ small enough and T even smaller, we find that

$$\int_0^t \left[\|\mathfrak{v}\|^2_{H^3(\Omega)} + \|\mathfrak{q}\|^2_{H^2(\Omega)}\right]ds \le \bar{C}N_3(u_0,F) + \bar{C}\int_0^t\int_0^s \|\mathfrak{v}(r)\|^2_{H^4(\Gamma)}drds \tag{8.16}$$

for some constant $\bar{C}$ depending on M, κ, and ϵ_1.

Having (8.16), by choosing $\delta_2 > 0$ small enough, the estimates (8.11) can be rewritten as

$$\|\nabla_0^2 \mathfrak{v}(t)\|^2_{L^2(\Omega_1)} + \int_0^t \Big[\|\nabla\nabla_0^2 \mathfrak{v}\|^2_{L^2(\Omega_1)} + \kappa\|\mathfrak{v}\|^2_{H^4(\Gamma)}\Big] ds$$

$$\le \bar{C} N_3(u_0, F) + \bar{C}\int_0^t\int_0^s \|\mathfrak{v}(r)\|^2_{H^4(\Gamma)} dr ds \tag{8.17}$$

for some constant $\bar{C}$ depending on M, κ, and ϵ_1. Therefore,

$$X(t) \le \bar{C}\Big[\int_0^t X(s)ds + N_3(u_0, F)\Big],$$

where

$$X(t) = \int_0^t \|\mathfrak{v}\|^2_{H^4(\Gamma)} ds.$$

By the Gronwall inequality,

$$\int_0^t\int_0^s \|\mathfrak{v}(r)\|^2_{H^4(\Gamma)} dr ds \le \bar{C} N_3(u_0, F) \tag{8.18}$$

for all $t \in [0, T]$ for some constant $\bar{C}$ depending on M, κ, and ϵ_1. Having (8.18), estimates (8.9), (8.14), (8.16), and (8.17) along with the standard embedding theorem lead to

$$\sup_{0\le t\le T}\Big[\|\mathfrak{v}(t)\|^2_{H^2(\Omega)} + \|\mathfrak{v}_t(t)\|^2_{L^2(\Omega)}\Big] + \|\mathfrak{v}\|^2_{\mathcal{V}^3(T)} + \|\mathfrak{q}\|^2_{L^2(0,T;H^2(\Omega))}$$

$$+ \kappa\|\mathfrak{v}\|^2_{L^2(0,T;H^4(\Gamma))} \le \bar{C} N_3(u_0, F) \tag{8.19}$$

for some constant $\bar{C}$ depending on M, κ, and ϵ_1.

8.8. Weak limits as $\epsilon_2 \to 0$. Since the estimate (8.19) is independent of ϵ_2, the weak limit as $\epsilon_2 \to 0$ of the sequence $(\mathfrak{v}, \mathfrak{h}, \mathfrak{q})$ exists. We will denote the weak limit of $(\mathfrak{v}, \mathfrak{h}, \mathfrak{q})$ by $(v_\kappa, h_\kappa, q_\kappa)$. By lower semicontinuity, (8.8) and thus (8.19) hold for the weak limit $(v_\kappa, h_\kappa, q_\kappa)$. Furthermore,

$$\langle v_{\kappa t}, \varphi\rangle + \frac{\nu}{2}\int_\Omega D_{\bar{\eta}} v_\kappa : D_{\bar{\eta}}\varphi dx + \sigma\int_\Gamma \bar{\Theta}\Big[[\mathcal{L}_{\bar{h}}(h_\kappa)(-\nabla_0 \bar{h}, 1)] \circ \bar{\eta}^\tau\Big] \cdot \varphi dS$$

$$+ \kappa\int_\Gamma \Delta_0 v_\kappa \cdot \Delta_0 \varphi dS - (q_\kappa, \bar{a}^\ell_k \varphi^k_{,\ell})_{L^2(\Omega)} \tag{8.20}$$

$$= \langle F, \varphi\rangle - \sigma\int_\Gamma \bar{\Theta}\Big[[\mathcal{M}(\bar{h})(-\nabla_0 \bar{h}, 1)] \circ \bar{\eta}^\tau\Big] \cdot \varphi dS$$

for all $\varphi \in H^{1;2}(\Omega; \Gamma)$ and a.a. $t \in [0, T]$.

9. Estimates independent of κ and ϵ_1.

9.1. Energy estimates which are independent of κ. Although (8.19) does not imply that $h_\kappa \in H^4(\Gamma)$, h_κ is indeed in $H^4(\Gamma)$ by (7.4). Therefore, we have that

$(v_\kappa, h_\kappa, q_\kappa)$ satisfies

$$v_{\kappa}{}_t^i - \nu[\bar{a}_\ell^k D_{\bar\eta}(v_\kappa)_\ell^i]_{,k} = -(\bar{a}_i^k q_\kappa)_{,k} + \tilde{F}^i \quad \text{in } (0,T)\times\Omega, \tag{9.1a}$$

$$\bar{a}_i^j v_{\kappa}{}_{,j}^i = 0 \quad \text{in } (0,T)\times\Omega, \tag{9.1b}$$

$$[\nu D_{\bar\eta}(v_\kappa)_i^j - q_\kappa \delta_i^j]\bar{a}_j^\ell N_\ell = \sigma\bar\Theta[\mathcal{L}_{\bar h}(h_\kappa)(-\nabla_0 \bar h, 1)]\circ\bar\eta^\tau + \sigma\bar\Theta[\mathcal{M}_{\bar h}(-\nabla_0\bar h, 1)]\circ\bar\eta^\tau + \kappa\Delta_0^2 v_\kappa \quad \text{on } (0,T)\times\Gamma, \tag{9.1c}$$

$$h_t\circ\bar\eta^\tau = [(\bar h_{,\alpha})\circ\bar\eta^\tau]v_\alpha - v_z \quad \text{on } (0,T)\times\Gamma, \tag{9.1d}$$

$$v = \tilde{u}_0 \quad \text{on } \{t=0\}\times\Omega, \tag{9.1e}$$

$$h = 0 \quad \text{on } \{t=0\}\times\Gamma. \tag{9.1f}$$

Having (9.1c), (A.7) in Appendix A implies that h_κ is in $H^5(\Gamma)$ for a.a. $t\in[0,T]$ with estimate

$$\int_0^t \|\nabla_0^2 h_\kappa\|_{H^3(\Gamma)}^2 ds \le C(\epsilon_1)\int_0^t \Big[\|\nabla_0^4 h_\kappa\|_{L^2(\Gamma)}^2 + \|v_\kappa\|_{H^3(\Omega)}^2 + \|q_\kappa\|_{H^2(\Omega)}^2 + 1\Big]ds,$$

where the forcing f in (A.7) is given by

$$[\nu D_{\bar\eta}(v_\kappa)_i^j - q_\kappa\delta_i^j]\bar{a}_j^\ell N_\ell - \sigma\bar\Theta[\mathcal{M}_{\bar h}(-\nabla_0\bar h, 1)]\circ\bar\eta^\tau.$$

By the same argument, (7.18) holds with all θ replaced by κ. Therefore, by (8.4) (which follows from (7.18)),

$$\int_0^t \|\nabla_0^2 h_\kappa\|_{H^3(\Gamma)}^2 ds \le C(\epsilon_1)\int_0^t \Big[\|v_{\kappa t}\|_{H^1(\Omega)}^2 + \|\nabla_0^4 h_\kappa\|_{L^2(\Gamma)}^2 + \|\nabla_0^2 v_\kappa\|_{H^1(\Omega_1)}^2\Big]ds + C(\epsilon_1)N_2(u_0,F). \tag{9.2}$$

With this extra regularity of h_κ, the energy estimate (8.19) can be made independent of κ. In section B.2 in Appendix B, we prove that

$$\begin{aligned}\frac{\nu_1}{2}\|\nabla_0^4 h_\kappa(t)\|_{L^2(\Gamma)}^2 &\le \int_0^t\int_\Gamma \bar\Theta\Big[[L_{\bar h}(h_\kappa)(-\nabla_0\bar h,1)]\circ\bar\eta^\tau\Big]\cdot\nabla_0^2(\zeta_1^2\nabla_0^2 v_\kappa)dSds\\ &+ C'\int_0^t\Big[1+\|\tilde v\|_{H^3(\Omega)}^2 + \|\tilde h_t\|_{H^{2.5}(\Gamma)}^2 + \|\tilde h\|_{H^5(\Gamma)}^2\Big]\|\nabla_0^4 h_\kappa\|_{L^2(\Gamma)}^2 ds\\ &+ C'\int_0^t\Big[\|\tilde h\|_{H^5(\Gamma)}^2 + 1\Big]ds + \delta\int_0^t \|v_\kappa\|_{H^3(\Omega)}^2 ds + \delta_1\int_0^t \|\nabla_0^2 h_\kappa\|_{H^3(\Gamma)}^2 ds\end{aligned}$$

for some constant C' depending on M, ϵ_1, δ, and δ_1. By (9.2),

$$\begin{aligned}\frac{\nu_1}{2}\|\nabla_0^4 h_\kappa(t)\|_{L^2(\Gamma)}^2 &\le \int_0^t\int_\Gamma \bar\Theta\Big[[L_{\bar h}(h_\kappa)(-\nabla_0\bar h,1)]\circ\bar\eta^\tau\Big]\cdot\nabla_0^2(\zeta_1^2\nabla_0^2 v_\kappa)dSds\\ &+ C'N_2(u_0,F) + C'\int_0^t\Big[\|\nabla_0^2 v_\kappa\|_{H^1(\Omega_1)}^2 + K(s)\|\nabla_0^4 h_\kappa\|_{L^2(\Gamma)}^2\Big]ds\\ &+ \delta\int_0^t \|v_\kappa\|_{H^3(\Omega)}^2 ds + \delta_1\int_0^t \|v_{\kappa t}\|_{H^1(\Omega)}^2 ds,\end{aligned} \tag{9.3}$$

where

$$K(s) := 1 + \|\tilde v\|_{H^3(\Omega)}^2 + \|\tilde h_t\|_{H^{2.5}(\Gamma)}^2 + \|\tilde h\|_{H^5(\Gamma)}^2.$$

With (9.3), (8.11) now is replaced by

$$
\begin{aligned}
&\Big[\|\nabla_0^2 v_\kappa(t)\|^2_{L^2(\Omega_1)} + \|\nabla_0^4 h_\kappa(t)\|^2_{L^2(\Gamma)}\Big] + \int_0^t \Big[\|\nabla\nabla_0^2 v_\kappa\|^2_{L^2(\Omega_1)} + \kappa\|v_\kappa\|^2_{H^4(\Gamma)}\Big] ds \\
&\le C' N_2(u_0,F) + C'\int_0^t \Big[\|v_{\kappa t}\|^2_{L^2(\Omega)} + \|\nabla_0^2 v_\kappa\|^2_{H^1(\Omega_1)} + K(s)\|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)}\Big] ds \\
&\quad + \delta\int_0^t \|v_\kappa\|^2_{H^3(\Omega)} ds + \delta_1 \int_0^t \|v_{\kappa t}\|^2_{H^1(\Omega)} ds
\end{aligned}
\tag{9.4}
$$

for some C' depending on M, ϵ_1, δ, and δ_1, where (A.5) is applied to bound $\kappa\|v_\kappa\|^2_{H^3(\Gamma)}$ (this is where $\|v_{\kappa t}\|^2_{L^2(\Omega)}$ comes from). Similar computations lead to

$$
\begin{aligned}
&\Big[\|\nabla_0 v_\kappa(t)\|^2_{L^2(\Omega_1)} + \|\nabla_0^3 h_\kappa(t)\|^2_{L^2(\Gamma)}\Big] + \int_0^t \Big[\|\nabla\nabla_0 v_\kappa\|^2_{L^2(\Omega_1)} + \kappa\|v_\kappa\|^2_{H^3(\Gamma)}\Big] ds \\
&\le C N_2(u_0,F) + C\int_0^t \|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)} ds + \delta \int_0^t \|v_\kappa\|^2_{H^3(\Omega)} ds
\end{aligned}
\tag{9.5}
$$

for some constant C depending on M and δ.

In Appendix C, we establish the following κ- and ϵ_1-independent inequality for the time-differentiated problem:

$$
\begin{aligned}
&\int_0^t \|\nabla_0^2 h_{\kappa t}\|^2_{L^2(\Gamma)} ds \le \int_0^t \int_\Gamma \Big[[L_{\bar h}(h_\kappa)(\nabla_0 \bar h, -1)] \circ \bar\eta^\tau\Big]_t \cdot v_{\kappa t} dS \\
&+ C N_3(u_0,F) + C\int_0^t K(s)\Big[\|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)} + \|\nabla_0^2 h_{\kappa t}\|^2_{L^2(\Gamma)}\Big] ds \\
&+ (\delta + C t^{1/2}) \int_0^t \|v_\kappa\|^2_{H^3(\Omega)} ds + (\delta_1 + C t^{1/2}) \int_0^t \|v_{\kappa t}\|^2_{H^1(\Omega)} ds + \delta_2 \|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)}
\end{aligned}
$$

for some constant C depending on M, δ, δ_1, and δ_2. Therefore, (8.14) can be replaced by the following estimate:

$$
\begin{aligned}
&\Big[\|v_{\kappa t}\|^2_{L^2(\Omega)} + \|\nabla_0^2 h_{\kappa t}\|^2_{L^2(\Gamma)}\Big] + \int_0^t \Big[\|\nabla v_{\kappa t}\|^2_{L^2(\Omega)} + \kappa\|\Delta_0 v_{\kappa t}\|^2_{L^2(\Gamma)}\Big] ds \\
&\le C N_3(u_0,F) + C\int_0^t K(s)\Big[\|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)} + \|\nabla_0^2 h_{\kappa t}\|^2_{L^2(\Gamma)}\Big] ds \\
&\quad + (\delta + C t^{1/2}) \int_0^t \|v_\kappa\|^2_{H^3(\Omega)} ds + (\delta_1 + C t^{1/2}) \int_0^t \|v_{\kappa t}\|^2_{H^1(\Omega)} ds + \delta_2 \|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)}.
\end{aligned}
\tag{9.6}
$$

9.2. κ-independent estimates. Just as in section 8.7, we find that

$$
\begin{aligned}
&\int_0^t \Big[\|v_\kappa\|^2_{H^3(\Omega)} + \|q_\kappa\|^2_{H^2(\Omega)}\Big] ds \\
&\le C(M) N_2(u_0,F) + C(M)\int_0^t \Big[\|v_{\kappa t}\|^2_{H^1(\Omega)} + \|\nabla_0^2 v_\kappa\|^2_{H^1(\Omega_1)}\Big] ds.
\end{aligned}
\tag{9.7}
$$

By choosing $\delta = \delta_1 = \delta_2 = 1/8$ and $T > 0$ so that $CT^{1/2} < 1/8$ in (9.6), we find that

$$
\begin{aligned}
&\int_0^t \Big[\|v_\kappa\|^2_{H^3(\Omega)} + \|q_\kappa\|^2_{H^2(\Omega)}\Big] ds \le CN_3(u_0,F) + \frac{1}{8}\|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)} \\
&\quad + C(M)\int_0^t \Big[\|\nabla_0^2 v_\kappa\|^2_{H^1(\Omega_1)} + K(s)\Big(\|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)} + \|\nabla_0^2 h_{\kappa t}\|^2_{L^2(\Gamma)}\Big)\Big] ds.
\end{aligned}
\tag{9.8}
$$

Combining the estimates (7.27), (8.9), (9.4), and (9.5) with (9.6),

$$
\begin{aligned}
&\Big[\|v_\kappa\|^2_{H^1(\Omega)} + \|\nabla_0^2 v_\kappa\|^2_{L^2(\Omega_1)} + \|\nabla_0^2 h_\kappa\|^2_{H^2(\Gamma)} + \|v_{\kappa t}\|^2_{L^2(\Omega)} + \|\nabla_0^2 h_{\kappa t}\|^2_{L^2(\Gamma)}\Big](t) \\
&+ \int_0^t \Big[\|\nabla v_\kappa\|^2_{L^2(\Omega)} + \|\nabla\nabla_0 v_\kappa\|^2_{L^2(\Omega_1)} + \|\nabla\nabla_0^2 v_\kappa\|^2_{L^2(\Omega_1)} + \|v_{\kappa t}\|^2_{H^1(\Omega)}\Big] ds \\
&\le C' N_3(u_0,F) + C'\int_0^t \Big[\|v_{\kappa t}\|^2_{L^2(\Omega)} + K(s)\Big(\|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)} + \|\nabla_0^2 h_{\kappa t}\|^2_{L^2(\Gamma)}\Big)\Big] ds
\end{aligned}
$$

for some constant C' depending on M and ϵ_1. By the Gronwall inequality and (8.4),

$$
\begin{aligned}
&\sup_{0\le t\le T}\Big[\|v_\kappa\|^2_{H^2(\Omega)} + \|v_{\kappa t}\|^2_{L^2(\Omega)} + \|\nabla_0^2 h_{\kappa t}\|^2_{L^2(\Gamma)} + \|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)} \\
&\qquad + \|q_\kappa\|^2_{H^1(\Omega)}\Big](t) + \|v_\kappa\|^2_{\mathcal{V}^3(T)} + \|q_\kappa\|^2_{L^2(0,T;H^2(\Omega))} \le C(\epsilon_1)N_3(u_0,F).
\end{aligned}
$$

9.3. Weak limits as $\boldsymbol{\kappa \to 0}$. Just as in section 8.8, the weak limit $(v_{\epsilon_1}, h_{\epsilon_1}, q_{\epsilon_1})$ of $(v_\kappa, h_\kappa, q_\kappa)$ as $\kappa \to 0$ exists in $V(T) \times L^2(0,T;H^4(\Gamma)) \times L^2(0,T;H^2(\Omega))$ with estimate

$$
\begin{aligned}
&\sup_{0\le t\le T}\Big[\|v_{\epsilon_1}(t)\|^2_{H^2(\Omega)} + \|v_{\epsilon_1 t}(t)\|^2_{L^2(\Omega)} + \|\nabla_0^2 h_{\epsilon_1 t}(t)\|^2_{L^2(\Gamma)} + \|\nabla_0^4 h_{\epsilon_1}(t)\|^2_{L^2(\Gamma)} \\
&\qquad + \|q_{\epsilon_1}(t)\|^2_{H^1(\Omega)}\Big] + \|v_\kappa\|^2_{\mathcal{V}^3(T)} + \|q_{\epsilon_1}\|^2_{L^2(0,T;H^2(\Omega))} \le C(\epsilon_1)N_3(u_0,F).
\end{aligned}
\tag{9.9}
$$

Equation (9.9) implies that for a.a. $t \in [0,T]$,

$$\|v_\kappa(t)\|_{H^{2.5}(\Gamma)} \le \bar{C}(t)$$

for some $\bar{C}(t)$ independent of κ, and therefore for a.a. $t \in [0,T]$,

$$\kappa\int_\Gamma \Delta_0 v_\kappa \cdot \Delta_0\varphi dS \to 0$$

as $\kappa \to 0$. This observation with (8.20) shows that $(v_{\epsilon_1}, h_{\epsilon_1}, q_{\epsilon_1})$ satisfies, for a.a. $t \in [0,T]$,

$$
\begin{aligned}
&(v_{\kappa t},\varphi)_{L^2(\Omega)} + \frac{\nu}{2}\int_\Omega D_{\bar\eta} v_\kappa : D_{\bar\eta}(\varphi) dx + \sigma\int_\Gamma \bar\Theta \mathcal{L}_{\bar h}(h_\kappa)\Big[-\bar h_{,\sigma}\circ\bar\eta^\tau \varphi^\sigma + \varphi^z\Big] dS \\
&- (\bar a_i^j q_\kappa, \varphi^i_{,j})_{L^2(\Omega)} = \langle \tilde F, \varphi\rangle + \sigma\langle \bar\Theta \mathcal{M}_{\bar h}(-\nabla_0 \bar h\circ\bar\eta^\tau, 1), \varphi\rangle_\Gamma
\end{aligned}
\tag{9.10}
$$

for all $\varphi \in H^{1;2}(\Omega;\Gamma)$. Since (9.10) also defines a linear functional on $H^1(\Omega)$, by the density argument, we have that (9.10) holds for all $\varphi \in H^1(\Omega)$. As $(v_{\epsilon_1}, h_{\epsilon_1}, q_{\epsilon_1})$ are smooth enough, we can integrate by parts and find that $(v_{\epsilon_1}, h_{\epsilon_1}, q_{\epsilon_1})$ satisfies (7.2) with (7.2c) replaced by

$$
[\nu D_{\bar\eta}(v_{\epsilon_1})^j_i - q_{\epsilon_1}\delta^j_i]\bar a^\ell_j N_\ell = \sigma\Big[\bar\Theta[(\mathcal{L}_{\bar h}(h_{\epsilon_1}) + \mathcal{M}(\bar h))(\nabla_0 \bar h, -1)]\circ\bar\eta^\tau\Big] \quad \text{on } (0,T)\times\Gamma.
\tag{9.11}
$$

9.4. $H^{5.5}$-regularity of h_κ. By (9.11), we have the following lemma.

LEMMA 9.1. *For a.a. $t \in [0,T]$, $h_{\epsilon_1}(t) \in H^{5.5}(\Gamma)$ with*

$$\|h_{\epsilon_1}\|^2_{H^{5.5}(\Gamma)} \le C(M)\Big[\|v_{\epsilon_1 t}\|^2_{H^1(\Omega)} + \|\nabla v_{\epsilon_1}\|^2_{L^2(\Omega)} + \|\nabla_0^2 v_{\epsilon_1}\|^2_{H^1(\Omega_1)} + \|\nabla_0^4 h_{\epsilon_1}\|^2_{L^2(\Gamma)} + \|F\|^2_{H^1(\Omega)} + 1\Big], \tag{9.12}$$

and hence

$$\|h_{\epsilon_1}\|^2_{L^2(0,T;H^{5.5}(\Gamma))} \le C(M)e^{C(M)+T} N_3(u_0,F). \tag{9.13}$$

Proof. We write the boundary condition (9.11) as

$$\mathcal{L}_{\bar h}(h_{\epsilon_1}) = \frac{1}{\sigma} J_{\bar h}^{-2}(-\nabla_0 \bar h, 1)\cdot \Big\{\bar\Theta^{-1}\Big[[\nu D_{\bar\eta}(v_{\epsilon_1})^j_i - q_{\epsilon_1}\delta^j_i]\bar a^\ell_j N_\ell\Big]\Big\}\circ \bar\eta^{-\tau} - \mathcal{M}(\bar h). \tag{9.14}$$

By Corollary 7.1, $\mathcal{L}_{\bar h}$ is uniformly elliptic with the elliptic constant ν_1 which is independent of M which defines our convex subset $C_T(M)$. Since $\bar h \in \mathcal{H}(T)$, $\mathcal{M}(\bar h) \in L^2(0,T;H^{2.5}(\Gamma)) \cap L^\infty(0,T;H^1(\Gamma))$, and hence by (8.19), the right-hand side of (9.14) is bounded in $H^{1.5}(\Gamma)$. The important point is that these bounds are independent of ϵ_1. Thus, elliptic regularity of $\mathcal{L}_{\bar h}$ proves the estimate

$$\|h_{\epsilon_1}\|^2_{H^{5.5}(\Gamma)} \le C(M)\Big[\|D_{\bar\eta}(v_{\epsilon_1})\|^2_{H^{1.5}(\Gamma)} + \|q_{\epsilon_1}\|^2_{H^{1.5}(\Gamma)} + 1\Big]$$

so that with (8.4), (9.12) is proved. ◻

9.5. Energy estimates which are independent of ϵ_1. Having estimate (9.12), one can follow exactly the same procedure as in section 9.2 to show that the constant C' appearing in (9.9) is independent of ϵ_1, provided that we have an ϵ_1-independent version of (9.4). By section B.2, we indeed have such an estimate:

$$\begin{aligned}\frac{\nu_1}{2}\|\nabla_0^4 h_{\epsilon_1}(t)\|^2_{L^2(\Gamma)} &\le \int_0^t\int_\Gamma \bar\Theta\Big[[L_{\bar h}(h_{\epsilon_1})(-\nabla_0\bar h,1)]\circ\bar\eta^\tau\Big]\cdot\nabla_0^2(\zeta_1^2\nabla_0^2 v_{\epsilon_1})dSds\\ &+ CN_2(u_0,F) + C\int_0^t K(s)\|\nabla_0^4 h_{\epsilon_1}\|^2_{L^2(\Gamma)}ds + (\delta + Ct^{1/2})\int_0^t \|v_{\epsilon_1}\|^2_{H^3(\Omega)}ds\\ &+ (\delta_1 + Ct^{1/2})\int_0^t \|v_{\epsilon_1 t}\|^2_{H^1(\Omega)}ds\end{aligned}$$

for some constant C depending on M, δ, and δ_1. Therefore, we can conclude that

$$\begin{aligned}&\sup_{0\le t\le T}\Big[\|v_{\epsilon_1}\|^2_{H^2(\Omega)} + \|v_{\epsilon_1 t}\|^2_{L^2(\Omega)} + \|\nabla_0^2 h_{\epsilon_1 t}\|^2_{L^2(\Gamma)} + \|\nabla_0^4 h_{\epsilon_1}\|^2_{L^2(\Gamma)}\\ &\quad + \|q_{\epsilon_1}\|^2_{H^1(\Omega)}\Big](t) + \|v_{\epsilon_1}\|^2_{\mathcal{V}^3(T)} + \|q_{\epsilon_1}\|^2_{L^2(0,T;H^2(\Omega))} \le C(M)e^{C(M)+T}N_3(u_0,F).\end{aligned} \tag{9.15}$$

REMARK 15. *Literally speaking, we cannot use $\nabla_0^2(\zeta_1^2\nabla_0^2 v_{\epsilon_1})$ as a test function in* (9.10)*, since it is not a function in $H^1(\Omega)$. However, since $h_{\epsilon_1} \in H^{5.5}(\Gamma)$ for a.a. $t \in [0,T]$,* (9.10) *also holds for all $\varphi \in H^1(\Omega)' \cap H^{-1.5}(\Gamma)$ and $\nabla_0^2(\zeta_1^2\nabla_0^2 v_{\epsilon_1})$ is a function of this kind.*

9.6. Weak limits as $\epsilon_1 \to 0$. The same argument leads to the fact that weak limits of $(v_{\epsilon_1}, h_{\epsilon_1}, q_{\epsilon_1})$ (denoted by (v,h,q)) as $\epsilon_1 \to 0$ exist and (v,h,q) satisfies (7.1).

9.7. Uniqueness. In this section, we show that for a given $(\tilde{v},\tilde{h}) \in Y_T$, the solution to (7.1) is unique in Y_T. Suppose (v_1, h_1) and (v_2, h_2) are two solutions (in Y_T) to (7.3). Let $w = v_1 - v_2$ and $g = h_1 - h_2$; then w and g satisfy

$$\begin{aligned}\langle w_t, \varphi\rangle + \frac{\nu}{2}\int_\Omega D_{\tilde{\eta}} w : D_{\tilde{\eta}}\varphi dx + \sigma\int_\Gamma \tilde{\Theta}\Big[\tilde{L}_{\tilde{h}}\Big(\int_0^t (\tilde{h}_{,\alpha} w_\alpha - w_z)ds\Big)\Big]\circ\tilde{\eta}^\tau \\ \times(-\tilde{h}_{,\alpha}\circ\tilde{\eta}^\tau\varphi^\alpha + \varphi^z)dS = 0\end{aligned} \tag{9.16}$$

for all $\varphi \in \mathcal{V}_v(T)$ with $w(0) = 0$, where $\tilde{L}$ equals L, except $L_1 = L_2 = 0$. Since w is in $\mathcal{V}_v(T)$, letting $w = \varphi$ in (9.16) leads to

$$\begin{aligned}&\Big[\|v\|^2_{H^1(\Omega)} + \|\nabla_0^2 v\|^2_{L^2(\Omega_1)} + \|\nabla_0^4 h\|^2_{L^2(\Gamma)} + \|v_t\|^2_{L^2(\Omega)} + \|\nabla_0^2 h_t\|^2_{L^2(\Gamma)}\Big](t) \\ &\quad + \int_0^t \Big[\|\nabla v\|^2_{L^2(\Omega)} + \|\nabla\nabla_0 v\|^2_{L^2(\Omega_1)} + \|\nabla\nabla_0^2 v\|^2_{L^2(\Omega_1)} + \|v_t\|^2_{H^1(\Omega)}\Big]ds \\ &\leq C(M)\int_0^t K(s)\Big[\|\nabla_0^4 h\|^2_{L^2(\Gamma)} + \|\nabla_0^2 h_t\|^2_{L^2(\Gamma)}\Big]ds.\end{aligned}$$

Therefore, by the Gronwall inequality and the zero initial condition ($w(0) = 0$), we have that w (and hence g) is identical to zero.

10. Fixed-point argument. From previous sections, we establish a map Θ_T from Y_T into Y_T; i.e., given $(\tilde{v},\tilde{h}) \in C_T(M)$, there exists a unique $\Theta_T(\tilde{v},\tilde{h}) = (v, h)$ satisfying (7.1). Theorem 4.1 is then proved if this mapping Θ_T has a fixed point. We shall make use of the Tychonoff fixed-point theorem which states as follows.

THEOREM 10.1. *For a reflexive Banach space X, and $C \subset X$ a closed, convex, bounded subset, if $F : C \to C$ is weakly sequentially continuous into X, then F has at least one fixed point.*

In order to apply the Tychonoff fixed-point theorem, we need to show that $\Theta(\tilde{v},\tilde{h}) \in C_T(M)$, and this is the case if T is small enough. In the following discussion, we will always assume T is smaller than a fixed constant (for example, say $T \leq 1$) so that the right-hand side of (9.15) can be written as $C(M)N_3(u_0, F)$.

REMARK 16. *The space Y_T is not reflexive. We will treat $C_T(M)$ as a convex subset of X_T and apply the Tychonoff fixed-point theorem on the space X_T.*

Before proceeding with the fixed-point proof, we note that Lemma 6.3 implies that for a short time, the constant $C(M)$ in (8.1) and (8.4) can be chosen to be independent of M. To be more precise, for a.a. $0 < t \leq T_1$,

$$\|q\|^2_{L^2(\Omega)} \leq C\Big[\|v_t\|^2_{L^2(\Omega)} + \|\nabla v\|^2_{L^2(\Omega)} + \|\nabla_0^4 h\|^2_{L^2(\Gamma)} + \|F\|^2_{L^2(\Omega)} + 1\Big], \tag{10.1}$$

$$\begin{aligned}\|v\|^2_{H^3(\Omega)} + \|q\|^2_{H^2(\Omega)} \leq C\Big[&\|v_t\|^2_{H^1(\Omega)} + \|\nabla v\|^2_{H^1(\Omega)} + \|\nabla_0 v\|^2_{H^1(\Omega_1)} \\ &+ \|\nabla_0^2 v\|^2_{H^1(\Omega)} + \|F\|^2_{H^1(\Omega)} + 1\Big],\end{aligned} \tag{10.2}$$

and

$$\begin{aligned}\|h\|^2_{H^{5.5}(\Gamma)} \leq C\Big[&\|v_t\|^2_{H^1(\Omega)} + \|\nabla v\|^2_{L^2(\Omega)} + \|\nabla_0^2 v\|^2_{H^1(\Omega_1)} + \|\nabla_0^4 h\|^2_{L^2(\Gamma)} \\ &+ \|F\|^2_{H^1(\Omega)} + 1\Big]\end{aligned} \tag{10.3}$$

for some constant C independent of M.

10.1. Continuity in time of h. By the evolution equation (7.1d) and the fact that $v \in \mathcal{V}^3(T_1)$, $h_t \in L^2(0,T_1;H^{2.5}(\Gamma))$. Since $h \in L^2(0,T_1;H^{5.5}(\Gamma))$, we have that $h \in \mathcal{C}^0([0,T_1];H^4(\Gamma))$ by the standard interpolation theorem. Although there is no uniform rate that h converges to zero in $H^4(\Gamma)$, we have the following lemma.

LEMMA 10.2. *Let $(v,h) = \Theta_{T_1}(\tilde{v},\tilde{h})$. Then $\|h(t)\|_{H^{2.5}(\Gamma)}$ converges to zero as $t \to 0$, uniformly for all $(\tilde{v},\tilde{h}) \in C_{T_1}(M)$.*

Proof. By the evolution equation (7.1d),

$$\|h(t)\|_{H^{2.5}(\Gamma)} \leq \int_0^t \|\tilde{h}_{,\alpha}v_\alpha - v_z\|_{H^{2.5}(\Gamma)}dS \leq C(M)N_3(u_0,F)^{1/2}t^{1/2}.$$

The lemma follows directly from the inequality. ∎

By Lemma 10.2 and the interpolation inequality, we also have the following lemma.

LEMMA 10.3. *$\|\nabla_0^2 h(t)\|_{H^{1.5}(\Gamma)}$ converges to zero as $t \to 0$, uniformly for all $\tilde{h} \in C_{T_1}(M)$ with estimate*

$$\|\nabla_0^2 h(t)\|_{H^{1.5}(\Gamma)} \leq C(M)N_3(u_0,F)t^{1/4} \tag{10.4}$$

for all $0 < t \leq T_1$.

10.2. Improved energy estimates. In order to apply the fixed-point theorem, we have to use the fact that the forcing F is in $\mathcal{V}^2(T)$. We also define a new constant

$$N(u_0,F) := \|u_0\|^2_{H^{2.5}(\Omega)} + \|F\|^2_{\mathcal{V}^2(T_1)} + \|F\|^2_{L^\infty(0,T_1;L^2(\Omega))} + \|F(0)\|^2_{H^1(\Omega)} + 1.$$

Note that $N_3(u_0,F) \leq N(u_0,F)$.

REMARK 17. *For the linearized problem* (7.1), *we need only $F \in \mathcal{V}^1(T)$ to obtain a unique solution $(v,h) \in Y_T$.*

10.2.1. Estimates for $\nabla_0^2 v$ near the boundary. Note that

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\left[\|\zeta_1\nabla_0^2 v\|^2_{L^2(\Omega)} + \sigma\int_\Gamma \tilde{\Theta}B\tilde{A}^{\alpha\beta\gamma\delta}\nabla_0^2 h_{,\alpha\beta}\nabla_0^2 h_{,\gamma\delta}dS\right] + \frac{\nu}{2}\|\zeta_1 D_{\tilde{\eta}}(\nabla_0^2 v)\|^2_{L^2(\Omega)}\\
&= \langle F, \nabla_0^2(\zeta_1^2\nabla_0^2 v)\rangle - \frac{\nu}{4}\int_\Omega\left[\nabla_0^2(\tilde{a}_i^k\tilde{a}_i^\ell)v^j_{,\ell} + \nabla_0^2(\tilde{a}_i^k\tilde{a}_j^\ell)v^i_{,\ell}\right](\zeta_1^2\nabla_0^2 v^j)_{,k}dx\\
&\quad - \frac{\nu}{2}\int_\Omega\left[\nabla_0(\tilde{a}_i^k\tilde{a}_i^\ell)\nabla_0 v^j_{,\ell} + \nabla_0(\tilde{a}_i^k\tilde{a}_j^\ell)\nabla_0 v^i_{,\ell}\right](\zeta_1^2\nabla_0^2 v^j)_{,k}dx\\
&\quad - \frac{\nu}{2}\int_\Omega D_{\tilde{\eta}}(\nabla_0^2 v)^j_i\tilde{a}_i^k\zeta_1\zeta_{1,k}\nabla_0^2 v^j dx + \int_\Omega q\tilde{a}_k^\ell[\nabla_0^2(\zeta_1^2\nabla_0^2 v^k)]_{,\ell}dx - \sigma\left(\sum_{k=1}^3 I_k + \sum_{k=1}^8 J_k\right),
\end{aligned}$$

where I_k's and J_k's are defined in section B.1 (with $\bar{}$ replaced by $\tilde{}$, and no ϵ_1 and ϵ_2).

As in [7] and [8], we study the time integral of the right-hand side of the identity above in order to prove the validity of the requirement of applying the Tychonoff fixed-point theorem. By interpolation and (9.9),

$$\begin{aligned}
&\int_0^t\int_\Omega\left[\nabla_0^2(\tilde{a}_i^k\tilde{a}_i^\ell)v^j_{,\ell} + \nabla_0^2(\tilde{a}_i^k\tilde{a}_j^\ell)v^i_{,\ell}\right](\zeta_1^2\nabla_0^2 v^j)_{,k}dxds\\
&\leq C\int_0^t \|\tilde{a}\tilde{a}\|_{H^2(\Omega)}\|\nabla v\|_{L^\infty(\Omega)}\|v\|_{H^3(\Omega)}ds
\end{aligned}$$

$$
\begin{aligned}
&\leq C(M)C(\delta)\int_0^t \|v\|_{H^3(\Omega)}^{1/2}\|v\|_{H^1(\Omega)}^{1/2}ds+\delta\|v\|^2_{L^2(0,T;H^3(\Omega))}\\
&\leq C(M)C(\delta)N(u_0,F)^{1/2}\int_0^t \|v\|_{H^3(\Omega)}^{1/2}ds+\delta C(M)N(u_0,F)\\
&\leq C(M)N(u_0,F)\Big[C(\delta)t^{3/4}+\delta\Big].
\end{aligned}
$$

Similarly,

$$
\begin{aligned}
&\int_0^t\int_\Omega \Big[\nabla_0(\tilde a_i^k\tilde a_i^\ell)\nabla_0 v^j_{,\ell}+\nabla_0(\tilde a_i^k\tilde a_j^\ell)\nabla_0 v^i_{,\ell}\Big](\zeta_1^2\nabla_0^2 v^j)_{,k}dxds\\
&+\int_0^t\int_\Omega D_{\tilde\eta}(\nabla_0^2 v)_i^j\tilde a_i^k\zeta_1\zeta_{1,k}\nabla_0^2 v^j dxds\leq C(M)N(u_0,F)\Big[t^{1/2}+C(\delta)t+\delta\Big].
\end{aligned}
$$

For the pressure term, by interpolation and (8.10),

$$
\begin{aligned}
&\int_0^t\int_\Omega q\tilde a_k^\ell[\nabla_0^2(\zeta_1^2\nabla_0^2 v^k)]_{,\ell}dxds\\
&\leq C(M)\int_0^t\Big[\|q\|_{L^\infty(\Omega)}+\|q\|_{W^{1,4}(\Omega)}+\|q\|_{H^1(\Omega)}\Big]\|v\|_{H^3(\Omega)}ds\\
&\leq C(M)C(\delta)\int_0^t\|q\|^2_{H^1(\Omega)}ds+\delta\Big[\|v\|^2_{L^2(0,T;H^3(\Omega)}+\|q\|^2_{L^2(0,T;H^2(\Omega))}\Big]\\
&\leq C(M)N(u_0,F)\Big[C(\delta)t^{1/2}+\delta\Big].
\end{aligned}
$$

By the estimates already established in Appendix B, with the help of (6.6), it is also easy to see that

$$
\int_0^t\left(\sum_{k=1}^3 I_k+\sum_{k=1}^8 J_k\right)ds\leq C(M)N(u_0,F)\Big[t^{1/4}+t^{1/2}+C(\delta)t^{2/3}+\delta\Big].
$$

Finally, for the forcing term, by the extra regularity we assume on F,

$$
\begin{aligned}
\int_0^t\langle F,\nabla_0^2(\zeta_1^2\nabla_0^2 v)\rangle ds&\leq\int_0^t\|F\|_{H^2(\Omega)}\|v\|_{H^2(\Omega)}ds\leq N(u_0,F)+\int_0^t\|v\|^2_{H^2(\Omega)}ds\\
&\leq N(u_0,F)+C(M)N(u_0,F)t.
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
&\Big[\|\nabla_0^2 v(t)\|^2_{L^2(\Omega_1)}+\sigma E_{\tilde h}(\nabla_0^2 h)\Big]+\nu\int_0^t\|D_{\tilde\eta}(\nabla_0^2 v)\|^2_{L^2(\Omega_1)}ds\\
&\leq\|u_0\|^2_{H^2(\Omega)}+CN(u_0,F)+C(M)N(u_0,F)\Big[C(\delta)(t^{3/4}+t^{2/3}+t^{1/2}+t)+\delta\Big].
\end{aligned}
$$

By Corollary 7.1,

$$
\begin{aligned}
&\Big[\|\nabla_0^2 v(t)\|^2_{L^2(\Omega_1)}+\|\nabla_0^4 h(t)\|^2_{L^2(\Gamma)}\Big]+\int_0^t\|\nabla_0^2 v\|^2_{H^1(\Omega_1)}ds\\
&\leq CN(u_0,F)+C(M)N(u_0,F)\Big[C(\delta)\mathcal{O}(t)+\delta\Big]\quad\text{as}\quad t\to 0,
\end{aligned}
\tag{10.5}
$$

where C depends on ν, σ, ν_1, and the geometry of Γ.

By similar computations, we can also conclude (the (7.27), (8.9), and (9.5) variants) that

$$\begin{aligned}
&\left[\|v(t)\|^2_{L^2(\Omega)} + \|\nabla_0^2 h(t)\|^2_{L^2(\Gamma)}\right] + \int_0^t \|v\|^2_{H^1(\Omega)} ds \\
&\leq CN(u_0,F) + C(M)N(u_0,F)\mathcal{O}(t) \qquad \text{as} \quad t\to 0; \qquad (10.6)\\
&\left[\|\nabla_0 v(t)\|^2_{L^2(\Omega_1)} + \|\nabla_0^3 h(t)|^2_{L^2(\Gamma)}\right] + \int_0^t \|\nabla_0 v\|^2_{H^1(\Omega_1)} ds \\
&\leq CN(u_0,F) + C(M)N(u_0,F)\mathcal{O}(t) \qquad \text{as} \quad t\to 0; \qquad (10.7)\\
&\|\nabla v(t)\|^2_{L^2(\Omega)} + \int_0^t \|v_t\|^2_{L^2(\Omega)} ds \\
&\leq CN(u_0,F) + C(M)N(u_0,F)\mathcal{O}(t) \qquad \text{as} \quad t\to 0, \qquad (10.8)
\end{aligned}$$

where C depends on ν, σ, ν_1, and the geometry of Γ.

10.2.2. $L^2_t H^1_x$-estimate for v_t. For the time-differentiated problem, we are not able to use estimates such as those in sections 8.6 and 10.2.1, since no ϵ_1-regularization is present; nevertheless, we can obtain estimates at the ϵ_1-regularization level and then pass ϵ_1 to the limit once the estimate is found to be ϵ_1-independent. We have that

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|v_t\|^2_{L^2(\Omega)} + \frac{\nu}{2}\|D_{\bar\eta} v_t\|^2_{L^2(\Omega)} + \frac{\sigma}{2}\frac{d}{dt}\int_\Gamma \bar\Theta \bar A^{\alpha\beta\gamma\delta} h_{t,\alpha\beta} h_{t,\gamma\delta} dS \\
&= \langle F_t, v_t\rangle - \nu \int_\Omega \left[(\bar a^k_i \bar a^\ell_j)_t v^j_{,\ell} + (\bar a^k_i \bar a^\ell_j)_t v^i_{,\ell}\right] v^j_{t,k} dx + \int_\Omega q_t \bar a^\ell_{kt} v^k_{,\ell} dx \\
&\quad + \frac{1}{2}\int_\Gamma (\bar\Theta \bar A^{\alpha\beta\gamma\delta})_t h_{t,\alpha\beta} h_{t,\gamma\delta} dS - \int_\Gamma \frac{\bar\Theta}{\sqrt{\det(g_0)}} \left[\sqrt{\det(g_0)} (\bar A^{\alpha\beta\gamma\delta})_t h_{,\alpha\beta}\right]_{,\gamma\delta} h_{tt} dS \\
&\quad - 2\int_\Gamma \bar\Theta_{,\gamma} \bar A^{\alpha\beta\gamma\delta} h_{t,\alpha\beta} h_{tt,\delta} dS - \int_\Gamma \bar\Theta_{,\gamma\delta} \bar A^{\alpha\beta\gamma\delta} h_{t,\alpha\beta} h_{tt} dS \\
&\quad - \int_\Gamma \bar\Theta \left[L_1^{\alpha\beta\gamma} \bar h_{,\alpha\beta\gamma}\right]_t h_{tt} dS - \int_\Gamma \bar\Theta (L_2)_t h_{tt} dS + K_1 + K_3 + K_4 + K_5 + K_6,
\end{aligned}$$

where K_i's are defined in Appendix C (without ϵ_2).

As in the previous section, the time integral of the right-hand side of the identity above is studied. It is easy to see that

$$\begin{aligned}
&\int_0^t \left[\langle F_t, v_t\rangle - \nu\Big((\bar a^k_i \bar a^\ell_j)_t v^j_{,\ell} + (\bar a^k_i \bar a^\ell_j)_t v^i_{,\ell}\Big) v^j_{t,k} + K_1 + K_5 + K_6\right] ds \\
&\leq C(M)N(u_0,F)\left[t^{1/4} + t^{1/2} + C(\delta)(t^{1/2} + t) + \delta\right],
\end{aligned}$$

and by Appendix C, particularly Remark 22,

$$\begin{aligned}
&\int_0^t \int_\Gamma \left[\frac{1}{2}(\bar\Theta \bar A^{\alpha\beta\gamma\delta})_t h_{t,\alpha\beta} h_{t,\gamma\delta} - \frac{\bar\Theta}{\sqrt{\det(g_0)}}\left[\sqrt{\det(g_0)} (\bar A^{\alpha\beta\gamma\delta})_t h_{,\alpha\beta}\right]_{,\gamma\delta} h_{tt}\right. \\
&\qquad \left. - 2\bar\Theta_{,\gamma} \bar A^{\alpha\beta\gamma\delta} h_{t,\alpha\beta} h_{tt,\delta} - \bar\Theta_{,\gamma\delta} \bar A^{\alpha\beta\gamma\delta} h_{t,\alpha\beta} h_{tt}\right] dS ds \\
&\leq C(M)N(u_0,F) t^{1/2}.
\end{aligned}$$

Special treatment is needed for the rest of the terms, and we break this procedure into several steps.

Step 1. Let $B_1 = \int_0^t \int_\Omega (q\bar{a}_k^\ell)_t v^k_{t,\ell} dxds$. By the "divergence-free" condition (7.2b),

$$B_1 = \int_0^t \int_\Omega \bar{a}^\ell_{kt} q v^k_{t,\ell} dxds - \int_0^t \int_\Omega \bar{a}^\ell_{kt} q_t v^k_{,\ell} dxds.$$

By interpolation and (8.1),

$$\begin{aligned}
&\left| \int_0^t \int_\Omega \bar{a}^\ell_{kt} q v^k_{t,\ell} dxds \right| \\
&\le C(M)C(\delta) \int_0^t \|q\|^2_{L^2(\Omega)} ds + \delta \Big[\|q\|^2_{L^2(0,T;H^1(\Omega))} + \|v_t\|^2_{L^2(0,T;H^1(\Omega))} \Big] \\
&\le C(M)N(u_0,F)\Big[C(\delta)t + \delta\Big].
\end{aligned}$$

For the second integral, we have the following identity:

$$\begin{aligned}
\int_0^t \int_\Omega \bar{a}^\ell_{kt} q_t v^k_{,\ell} dxds = \int_\Omega (\bar{a}^\ell_{kt} q v^k_{,\ell})(t) dx - \int_\Omega \bar{a}^\ell_{kt}(0) q(0) u^k_{0,\ell} dx \\
- \int_0^t \int_\Omega (\bar{a}^\ell_{kt} v^k_{,\ell})_t q dxds.
\end{aligned}$$

By the identity $\bar{a}^\ell_{kt} = -\bar{a}^i_k \bar{v}^j_{,i} \bar{a}^\ell_j$,

$$\begin{aligned}
\left| \int_0^t \int_\Omega (\bar{a}^\ell_{kt} v^k_{,\ell})_t q dxds \right| &\le \int_0^t \int_\Omega \left| \Big[\bar{a}^\ell_{ktt} v^k_{,\ell} + \bar{a}^\ell_{kt} v^k_{t,\ell} \Big] q \right| dxds \\
&\le C(M) \int_0^t (1 + \|\bar{v}_t\|_{H^1(\Omega)}) \|\nabla v\|_{L^4(\Omega)} \|q\|_{L^4(\Omega)} ds.
\end{aligned}$$

Therefore,

$$\begin{aligned}
&\left| \int_0^t \int_\Omega (\bar{a}^\ell_{kt} v^k_{,\ell})_t q dxds \right| \\
&\le C(M)C(\delta)N(u_0,F) \int_0^t \|q\|^{2\alpha}_{H^1(\Omega)} \|q\|^{2(1-\alpha)}_{L^2(\Omega)} ds + \delta \int_0^t (1 + \|\bar{v}_t\|^2_{H^1(\Omega)}) ds \\
&\le C(M)N(u_0,F)^2 \Big[C(\delta)(t + t^{\frac{1-\alpha}{2}}) + \delta \Big],
\end{aligned}$$

where $\alpha = \frac{3}{4}$ if $n = 3$ and $\alpha = \frac{1}{2}$ if $n = 2$.

The second integral equals $\int_\Omega \nabla u_0 : (\nabla u_0)^T q(0) dx$, which is bounded by $CN(u_0,F)$. It remains to estimate the first integral. By adding and subtracting $\int_\Omega \bar{a}^\ell_{kt}(0) q v^k_{,\ell} dx$, we find, by $\bar{a}_t(0) \in H^2(\Omega)$, that

$$\begin{aligned}
\left| \int_\Omega (\bar{a}^\ell_{kt} q v^k_{,\ell})(t) dx \right| &\le \int_\Omega \left| (\bar{a}^\ell_{kt} - \bar{a}^\ell_{kt}(0))(q v^k_{,\ell})(t) \right| dx + \int_\Omega \left| \bar{a}^\ell_{kt}(0) q v^k_{,\ell} \right| dx \\
&\le C \|\bar{a}_t(t) - \bar{a}_t(0)\|_{L^4(\Omega)} \|q\|_{L^2(\Omega)} \|\nabla v\|_{L^4(\Omega)} \\
&\quad + C(\delta_1) \|\nabla v\|^2_{L^2(\Omega)} + \delta_1 \|q\|^2_{L^2(\Omega)}.
\end{aligned}$$

Noting that

$$\|\nabla v\|^2_{L^2(\Omega)} = \left\|\nabla u_0 + \int_0^t \nabla v_t ds\right\|^2_{L^2(\Omega)} \le \left[\|\nabla u_0\|_{L^2(\Omega)} + \int_0^t \|\nabla v_t\|_{L^2(\Omega)} ds\right]^2$$
$$\le 2\Big[\|u_0\|^2_{H^1(\Omega)} + C(M)N(u_0,F)t\Big],$$

(9.9), (6.5c), and (10.1) imply that

$$\left|\int_\Omega \bar{a}^\ell_{kt} q v^k_{,\ell}(t)dx\right| \le C(M)N(u_0,F)t^{1/2} + C(\delta_1)N(u_0,F)$$
$$+ \delta_1\Big[\|v_t\|^2_{L^2(\Omega)} + \|\nabla_0^4 h\|^2_{L^2(\Gamma)}\Big].$$

Summing all the estimates above, we find that

$$|B_1| \le C(\delta_1)N(u_0,F) + C(M)N(u_0,F)^2\Big[C(\delta)(t + t^{\frac{1-\alpha}{2}}) + \delta\Big]$$
$$+ \delta_1\Big[\|v_t\|^2_{L^2(\Omega)} + \|\nabla_0^4 h\|^2_{L^2(\Gamma)}\Big].$$

REMARK 18. *It may be tempting to use an interpolation inequality to show that $q \in \mathcal{C}([0,T];X)$ for some Banach space X by analyzing q_t via Laplace's equation. The problem, however, is that the boundary condition for q_t has low regularity $L^2(0,T;H^{-1.5}(\Gamma))$ (by the fact that $h_t \in L^2(0,T;H^{2.5}(\Gamma))$), and thus standard elliptic estimates do not provide the desired conclusion that $q_t \in L^2(0,T;H^1(\Omega)')$ (and hence by interpolation, $q \in \mathcal{C}([0,T];H^{0.5}(\Omega))$). However, suppose that $q_t \in L^2(0,T;H^1(\Omega)')$; then we can estimate $\int_0^t\int_\Omega \bar{a}^\ell_{kt} q_t v^k_{,\ell} dxds$ by the following method:*

$$\left|\int_0^t\int_\Omega \bar{a}^\ell_{kt} q_t v^k_{,\ell} dxds\right| \le \int_0^t \|\bar{a}^i_k \bar{v}^j_{,i} \bar{a}^\ell_j v^k_{,\ell}\|_{H^1(\Omega)} \|q_t\|_{H^1(\Omega)'} ds$$
$$\le C(M)N(u_0,F)\Big[t + t^{5/8}\Big].$$

Step 2. Let $B_2 = \int_0^t\int_\Gamma \tilde{\Theta}\big[[L_1^{\alpha\beta\gamma}\tilde{h}_{,\alpha\beta\gamma}]_t h_{tt} + (L_2)_t h_{tt}\big]dSds$. It is easy to see that

$$\left|\int_0^t\int_\Gamma \bar{\Theta}(L_2)_t h_{tt} dSds\right| \le C(M)\int_0^t \Big[\|v\|_{L^\infty(\Gamma)} + \|v_t\|_{L^2(\Gamma)}\Big]ds$$
$$\le C(M)N(u_0,F)^{1/2}(t + t^{3/4}).$$

For parts involving L_1, we have

$$\int_0^t\int_\Gamma \tilde{\Theta}\Big[L_1^{\alpha\beta\gamma}\tilde{h}_{,\alpha\beta\gamma}\Big]_t h_{tt} dSds = \int_0^t\int_\Gamma \tilde{\Theta}\Big[L_1^{\alpha\beta\gamma}\Big]_t \bar{h}_{,\alpha\beta\gamma} h_{tt} dSds \quad (\equiv B_2^1)$$
$$+ \int_0^t\int_\Gamma \tilde{\Theta} L_1^{\alpha\beta\gamma} \bar{h}_{t,\alpha\beta\gamma} h_{tt} dSds \quad (\equiv B_2^2).$$

By interpolation,

$$|B_2^1| \le C(M)\int_0^t \|\bar{\Theta}\|_{L^\infty(\Gamma)} \|\tilde{h}\|_{W^{1,4}(\Gamma)} \|h_{tt}\|_{L^4(\Gamma)} dSds$$
$$\le C(M)\int_0^t \Big[\|v\|_{H^2(\Omega)} + \|v_t\|_{H^1(\Omega)}\Big]ds$$
$$\le C(M)N(u_0,F)^{1/2}t^{1/2},$$

while by (6.6) and Corollary 6.5,

$$
\begin{aligned}
|B_2^2| &\le \int_0^t \|\bar\Theta\|_{H^{1.5}(\Gamma)} \|\tilde h_t\|_{H^{2.5}(\Gamma)} \|L_1^{\alpha\beta\gamma}\|_{H^{1.5}(\Gamma)} \|h_{tt}\|_{H^{0.5}(\Gamma)} ds \\
&\le C(M) \|L_1^{\alpha\beta\gamma}\|_{H^{1.5}(\Gamma)} \int_0^t \|\tilde h\|_{H^{2.5}(\Gamma)} \Big[\|v\|_{H^2(\Omega)} + \|v_t\|_{H^1(\Omega)} \Big] ds \\
&\le C(M) N(u_0, F) t^{1/4}.
\end{aligned}
$$

Therefore,

$$
|B_2| \le C(M) N(u_0, F)(t + t^{3/4} + t^{1/4}).
$$

Step 3. Let $B_3 = \int_0^t K_3 ds = \int_0^t \int_\Gamma \bar\Theta [L_{\bar h}(h)]_t [(\bar v \circ \bar\eta^{-\tau}) \cdot (\nabla_0 h_t)] dS ds$. The L_1 and L_2 part of B_3 is bounded by

$$
C(M) \int_0^t \|\bar\Theta\|_{H^{1.5}(\Gamma)} \|\bar v\|_{H^{1.5}(\Gamma)} \|\bar h\|_{H^{3.5}(\Gamma)} \|\bar h_t\|_{H^2(\Gamma)} \|h_t\|_{H^2(\Omega)} ds,
$$

and hence

$$
\left| \int_0^t \bar\Theta \Big[L_1^{\alpha\beta\gamma} \bar h_{,\alpha\beta\gamma} + L_2 \Big]_t [(\bar v \circ \bar\eta^{-\tau}) \cdot (\nabla_0 h_t)] dS ds \right| \le C(M) N(u_0, F) t^{1/4}.
$$

By the integration by parts formula, the highest order part of B_3 can be expressed as

$$
\begin{aligned}
&\int_0^t \int_\Gamma \frac{\bar\Theta(\bar v \circ \bar\eta^{-\tau})}{\sqrt{\det(g_0)}} \Big[\sqrt{\det(g_0)} (\bar A^{\alpha\beta\gamma\delta})_t h_{,\alpha\beta} \Big]_{,\gamma\delta} \nabla_0 h_t dS ds \quad (\equiv B_3^1) \\
&+ \int_0^t \int_\Gamma \bar\Theta(\bar v \circ \bar\eta^{-\tau}) \bar A^{\alpha\beta\gamma\delta} h_{t,\alpha\beta} \nabla_0 h_{t,\gamma\delta} dS ds \quad (\equiv B_3^2) \\
&+ 2 \int_0^t \int_\Gamma [\bar\Theta(\bar v \circ \bar\eta^{-\tau})]_{,\gamma} \bar A^{\alpha\beta\gamma\delta} h_{t,\alpha\beta} \nabla_0 h_{t,\delta} dS ds \quad (\equiv B_3^3) \\
&+ \int_0^t \int_\Gamma [\bar\Theta(\bar v \circ \bar\eta^{-\tau})]_{,\gamma\delta} \bar A^{\alpha\beta\gamma\delta} h_{t,\alpha\beta} \nabla_0 h_t dS ds \quad (\equiv B_3^4).
\end{aligned}
$$

It is easy to see that

$$
\begin{aligned}
|B_3^1| &\le C(M) \int_0^t \|\bar\Theta \bar v \circ \bar\eta^{-\tau}\|_{H^{1.5}(\Gamma)} \|\bar h_t\|_{H^2(\Gamma)} \|h\|_{H^4(\Gamma)} \|h_t\|_{H^2(\Gamma)} dS \\
&\le C(M) N(u_0, F) t
\end{aligned}
$$

and

$$
\begin{aligned}
|B_3^3| &\le C(M) \int_0^t \|\bar\Theta \bar v \circ \bar\eta^{-\tau}\|_{W^{1,4}(\Gamma)} \|\bar A\|_{L^\infty(\Gamma)} \|h_t\|_{H^2(\Gamma)} \|h_t\|_{W^{2,4}(\Gamma)} dS \\
&\le C(M) N(u_0, F) t^{1/2}.
\end{aligned}
$$

For B_3^2, by the integration by parts formula,

$$
\begin{aligned}
B_3^2 &= \frac{1}{2} \int_0^t \int_\Gamma \bar\Theta(\bar v \circ \bar\eta^{-\tau}) \bar A^{\alpha\beta\gamma\delta} \nabla_0 \Big[h_{t,\alpha\beta} h_{t,\gamma\delta} \Big] dS ds \\
&= -\frac{1}{2} \int_0^t \int_\Gamma \frac{1}{\sqrt{\det(g_0)}} \nabla_0 \Big[\sqrt{\det(g_0)} \bar\Theta(\bar v \circ \bar\eta^{-\tau}) \bar A^{\alpha\beta\gamma\delta} \Big] h_{t,\alpha\beta} h_{t,\gamma\delta} dS ds,
\end{aligned}
$$

and hence

$$
\begin{aligned}
|B_3^2| &\leq \int_0^t \Big[\|\nabla_0 \bar{\Theta}\|_{L^4(\Gamma)} \|\bar{v}\bar{A}\|_{L^\infty(\Gamma)} + \|\bar{\Theta}\|_{L^\infty(\Gamma)} \|\bar{v}\bar{A}\|_{W^{1,4}(\Gamma)}\Big] \\
&\qquad \times \|h_t\|_{W^{2,4}(\Gamma)} \|h_t\|_{H^2(\Gamma)} ds \\
&\leq C(M) N(u_0, F)^{1/2} \int_0^t \|v\|_{H^3(\Omega)} ds \\
&\leq C(M) N(u_0, F) t^{1/2}.
\end{aligned}
$$

For B_3^4, noting that

$$
\begin{aligned}
\bar{\Theta}_{,\gamma\delta} &= \det(\nabla_0 \bar{\eta}^\tau)_{,\gamma\delta} \sqrt{\det(G_{\bar{h}}) \circ \bar{\eta}^\tau} + \det(\nabla_0 \bar{\eta}^\tau)_{,\gamma} \sqrt{\det(G_{\bar{h}}) \circ \bar{\eta}^\tau}_{,\delta} \\
&\quad + \det(\nabla_0 \bar{\eta}^\tau)_{,\delta} \sqrt{\det(G_{\bar{h}}) \circ \bar{\eta}^\tau}_{,\gamma} + \det(\nabla_0 \bar{\eta}^\tau) \sqrt{\det(G_{\bar{h}}) \circ \bar{\eta}^\tau}_{,\gamma\delta}
\end{aligned}
$$

and $\|\nabla_0 \det(\nabla_0 \bar{\eta}^\tau)\|_{H^{0.5}(\Gamma)} \leq C(M) t^{1/2}$, we find that

$$
\begin{aligned}
|B_3^4| &\leq C(M) \int_0^t \|\nabla_0 \det(\nabla_0 \bar{\eta}^\tau)\|_{H^{0.5}(\Gamma)} \|\nabla_0^2 h_t\|_{H^{0.5}(\Gamma)} \|\nabla_0 h_t\|_{H^{1.5}(\Gamma)} ds \\
&\quad + C(M) \int_0^t \|\det(\nabla_0 \bar{\eta}^\tau)\|_{L^\infty(\Gamma)} \|\nabla_0 \bar{\eta}^\tau\|^2_{L^\infty(\Gamma)} \|\nabla_0^2 h_t\|_{L^2(\Gamma)} \|\nabla_0 h_t\|_{L^2(\Gamma)} ds \\
&\leq C(M) N(u_0, F) t^{1/2} + C(M) N(u_0, F)^{3/4} \int_0^t \|v\|^{1/2}_{H^3(\Omega)} ds \\
&\leq C(M) N(u_0, F)(t^{1/2} + t^{3/4}).
\end{aligned}
$$

Combining all the estimates, we find that

$$
|B_3| \leq C(M) N(u_0, F)(t + t^{1/2} + t^{3/4}).
$$

Step 4. Let $B_4 = \int_0^t K_4 ds = \int_0^t \int_\Gamma \bar{\Theta}[L_{\bar{h}}(h)]_t [(\nabla_0 \bar{h}, -1)_t \cdot (v \circ \bar{\eta}^{-\tau})] dS ds$. Integrating by parts,

$$
\begin{aligned}
B_4 &= -\int_0^t \int_\Gamma L_{\bar{h}}(h) \Big[\bar{\Theta}_t (\nabla_0 \bar{h}, -1)_t \cdot (v \circ \bar{\eta}^{-\tau}) + \bar{\Theta}(\nabla_0 \bar{h}, -1)_t \cdot (v \circ \bar{\eta}^{-\tau})_t \\
&\quad + \bar{\Theta}(\nabla_0 \bar{h}, -1)_{tt} \cdot (v \circ \bar{\eta}^{-\tau})\Big] dS ds + \int_\Gamma \bar{\Theta} L_{\tilde{h}}(h) [(\nabla_0 \tilde{h}, -1)_t \cdot (v \circ \bar{\eta}^{-\tau})] dS.
\end{aligned}
$$

For the first integral, (6.8) implies that

$$
\begin{aligned}
&\left| \int_\Gamma \bar{\Theta} L_{\tilde{h}}(h) [(\nabla_0 \tilde{h}, -1)_t \cdot (v \circ \bar{\eta}^{-\tau})] dS \right| \\
&\leq \|\bar{\Theta}\|_{L^\infty(\Gamma)} \|L_{\tilde{h}}(h)\|_{L^2(\Gamma)} \|\nabla_0 \tilde{h}_t\|_{L^4(\Gamma)} \|v \circ \bar{\eta}^{-\tau}\|_{L^4(\Gamma)} \\
&\leq C(M) N(u_0, F) \|\tilde{h}_t\|_{H^{1.5}(\Gamma)} \\
&\leq C(M) N(u_0, F) t^{1/8}.
\end{aligned}
$$

It is also easy to see that

$$\begin{aligned}&\left|\int_0^t\int_\Gamma L_{\bar h}(h)\Big[\bar\Theta_t(\nabla_0\bar h,-1)_t\cdot(v\circ\bar\eta^{-\tau})+\bar\Theta(\nabla_0\tilde h,-1)_t\cdot(v\circ\bar\eta^{-\tau})_t\Big]dSds\right|\\&\le C(M)\int_0^t\Big[\|v\|_{L^\infty(\Gamma)}+\|v_t\|_{L^4(\Gamma)}\Big]\|L_{\tilde h}(h)\|_{L^2(\Gamma)}\|\nabla_0\tilde h_t\|_{L^4(\Gamma)}ds\\&\le C(M)N(u_0,F)^{1/2}\int_0^t\Big[\|v\|_{H^3(\Omega)}+\|v_t\|_{H^1(\Omega)}\Big]ds\\&\le C(M)N(u_0,F)t^{1/2}.\end{aligned}$$

For the remaining terms, the $H^{0.5}(\Gamma)$-$H^{-0.5}(\Gamma)$ duality pairing leads to

$$\begin{aligned}&\left|\int_0^t\int_\Gamma\bar\Theta L_{\tilde h}(h)(\nabla_0\tilde h,-1)_{tt}\cdot vdSds\right|\\&\le\int_0^t\|\bar\Theta\|_{H^{1.5}(\Gamma)}\|L_{\tilde h}(h)\|_{H^{0.5}(\Gamma)}\|v\|_{H^{1.5}(\Gamma)}\|\tilde h_{tt}\|_{H^{0.5}(\Gamma)}ds.\end{aligned}$$

By interpolation,

$$\|L_{\tilde h}(h)\|_{H^{0.5}(\Gamma)}\le C(M)\Big[\|h\|^{1/2}_{H^{5.5}(\Gamma)}\|h\|^{1/2}_{H^{3.5}(\Gamma)}+1\Big],$$

and hence

$$\begin{aligned}&\left|\int_0^t\int_\Gamma\tilde\Theta L_{\tilde h}(h)(\nabla_0\tilde h,-1)_{tt}\cdot(v\circ\bar\eta^{-\tau})dSds\right|\\&\le C(M)N(u_0,F)\int_0^t\|\tilde h_{tt}\|_{H^{0.5}(\Gamma)}\Big[\|\nabla_0^5h\|^{1/2}_{L^2(\Gamma)}+1\Big]ds\\&\le C(M)C(\delta)N(u_0,F)\int_0^t\Big[\|\nabla_0^5h\|_{L^2(\Gamma)}+1\Big]ds+\delta C(M)N(u_0,F)\\&\le C(M)N(u_0,F)\Big[C(\delta)(t^{1/2}+t)+\delta\Big].\end{aligned}$$

All the inequalities above give us

$$|B_4|\le C(M)N(u_0,F)\Big[C(\delta)(t^{1/2}+t)+t^{1/8}+\delta\Big].$$

Summing all the estimates above, we find that

$$\begin{aligned}&\Big[\|v_t\|^2_{L^2(\Omega)}+\sigma\int_\Gamma\bar\Theta\bar A^{\alpha\beta\gamma\delta}h_{t,\alpha\beta}h_{t,\gamma\delta}|^2dS\Big](t)+\nu\int_0^t\|D_{\tilde\eta}v_t\|^2_{L^2(\Omega)}ds\\&\le\|v_t(0)\|^2_{L^2(\Omega)}+\sigma\int_\Gamma|G_0^{\alpha\beta}h_{t,\alpha\beta}(0)|^2dS+(C+C(\delta_1))N(u_0,F)\\&\quad+C(M)N(u_0,F)\Big[C(\delta)(t+t^{3/4}+t^{1/2}+t^{1/4}+t^{1/8}+t^{\frac{1-\alpha}{2}})+\delta\Big]\\&\quad+\delta_1\Big[\|v_t\|^2_{L^2(\Omega)}+\|\nabla_0^4h\|^2_{L^2(\Gamma)}\Big],\end{aligned}$$

and by Corollary 7.1,

$$
\begin{aligned}
&\Big[\|v_t(t)\|^2_{L^2(\Omega)} + \|\nabla_0^2 h_t(t)\|^2_{L^2(\Gamma)}\Big] + \int_0^t \|v_t\|^2_{H^1(\Omega)} ds \\
&\le (C + C(\delta_1))N(u_0, F) + C(M)N(u_0, F)\Big[C(\delta)\mathcal{O}(t) + \delta\Big] \\
&\quad + \delta_1 \Big[\|v_t\|^2_{L^2(\Omega)} + \|\nabla_0^4 h\|^2_{L^2(\Gamma)}\Big],
\end{aligned}
\tag{10.9}
$$

where C depends on ν, σ, ν_1, and the geometry of Γ. Since this estimate is independent of ϵ_1, we pass ϵ_1 to zero and conclude that the solution (v, h) to (7.1) also satisfies (10.9).

10.3. Mapping from $C_T(M)$ into $C_T(M)$. In this section, we are going to choose M so that $\Theta(\tilde{v}, \tilde{h}) \in C_T(M)$ if $(\tilde{v}, \tilde{h}) \in C_T(M)$.

Summing (10.5), (10.6), (10.7), (10.8), and (10.9), by (6.5) we find that

$$
\begin{aligned}
&\Big[\|v(t)\|^2_{L^2(\Omega)} + \|\nabla_0 v(t)\|^2_{L^2(\Omega_1)} + \|\nabla_0^2 v(t)\|^2_{L^2(\Omega_1)} + \|v_t(t)\|^2_{L^2(\Omega)} \\
&+ \|\nabla_0^2 h(t)\|^2_{L^2(\Gamma)} + \|\nabla_0^3 h(t)\|^2_{L^2(\Gamma)} + \|\nabla_0^4 h(t)\|^2_{L^2(\Gamma)} + \|\nabla_0^2 h_t(t)\|^2_{L^2(\Gamma)}\Big] \\
&+ \int_0^t \Big[\|v\|^2_{H^1(\Omega)} + \|\nabla_0 v\|^2_{H^1(\Omega_1)} + \|\nabla_0^2 v\|^2_{H^1(\Omega_1)} + \|v_t\|^2_{H^1(\Omega)}\Big] ds \\
&\le (C + C(\delta_1))N(u_0, F) + C(M)N(u_0, F)\Big[C(\delta)\mathcal{O}(t) + \delta\Big] \\
&\quad + \delta_1 \Big[\|v_t\|^2_{L^2(\Omega)} + \|\nabla_0^4 h\|^2_{L^2(\Gamma)}\Big],
\end{aligned}
$$

where C depends on ν, σ, ν_1, and the geometry of Γ. Choosing $\delta_1 = \frac{1}{2}$,

$$
\begin{aligned}
&\Big[\|v(t)\|^2_{L^2(\Omega)} + \|\nabla_0 v(t)\|^2_{L^2(\Omega_1)} + \|\nabla_0^2 v(t)\|^2_{L^2(\Omega_1)} + \|v_t(t)\|^2_{L^2(\Omega)} \\
&+ \|\nabla_0^2 h(t)\|^2_{L^2(\Gamma)} + \|\nabla_0^3 h(t)\|^2_{L^2(\Gamma)} + \|\nabla_0^4 h(t)\|^2_{L^2(\Gamma)} + \|\nabla_0^2 h_t(t)\|^2_{L^2(\Gamma)}\Big] \\
&+ \int_0^t \Big[\|v\|^2_{H^1(\Omega)} + \|\nabla_0 v\|^2_{H^1(\Omega_1)} + \|\nabla_0^2 v\|^2_{H^1(\Omega_1)} + \|v_t\|^2_{H^1(\Omega)}\Big] ds \\
&\le C_1 N(u_0, F) + C(M)N(u_0, F)^2\Big[C(\delta)\mathcal{O}(t) + \delta\Big],
\end{aligned}
$$

where C_1 depends on ν, σ, μ, and the geometry of Γ. Similar to section 8.7, for a.a. $0 < t \le T$,

$$
\begin{aligned}
&\Big[\|v(t)\|^2_{H^2(\Omega)} + \|v_t(t)\|^2_{L^2(\Omega)} + \|\nabla_0^2 h(t)\|^2_{H^2(\Gamma)} + \|\nabla_0^2 h_t(t)\|^2_{L^2(\Gamma)}\Big] \\
&+ \int_0^t \Big[\|v\|^2_{H^3(\Omega)} + \|v_t\|^2_{H^1(\Omega)} + \|q\|^2_{H^2(\Omega)}\Big] ds \\
&\le C_2 N(u_0, F) + C(M)N(u_0, F)^2\Big[C(\delta)\mathcal{O}(t) + \delta\Big]
\end{aligned}
\tag{10.10}
$$

for some constant C_2 depending on C_1.

By (6.6), (6.8), and (7.1d),

$$
\begin{aligned}
\int_0^t \|h_t\|^2_{H^{2.5}(\Gamma)} ds &\le \int_0^t \Big[1 + \|\tilde{h}\|^2_{H^{3.5}(\Gamma)}\Big] \|v\|^2_{H^{2.5}(\Gamma)} ds \\
&\le C(M)N(u_0, F)t^{1/4}
\end{aligned}
\tag{10.11}
$$

and

$$\begin{aligned}\int_0^t \|h_{tt}\|^2_{H^{0.5}(\Gamma)} ds &\le C(M)\int_0^t \Big[\|\tilde{h}_t\|^2_{H^{1.5}(\Gamma)}\|v\|^2_{H^2(\Omega)} + \|\tilde{h}\|^2_{H^{2.5}(\Gamma)}\|v_t\|^2_{H^1(\Omega)}\Big] ds \\ &\le C(M)N(u_0,F)\Big[t^{1/4}+t^{1/2}\Big]. \end{aligned} \tag{10.12}$$

Also, by (10.3) and (10.10),

$$\begin{aligned}\int_0^t \|h\|^2_{H^{5.5}(\Gamma)} ds &\le C\int_0^t \Big[\|v_t\|^2_{H^1(\Omega)} + \|\nabla v\|^2_{L^2(\Omega)} + \|\nabla_0^2 v\|^2_{H^1(\Omega_1)} + \|\nabla_0^4 h\|^2_{L^2(\Gamma)} \\ &\qquad + \|F\|^2_{H^1(\Omega)} + 1\Big] ds \\ &\le C_3 N(u_0,F) + C(M)N(u_0,F)^2\Big[C(\delta)\mathcal{O}(t)+\delta\Big] \end{aligned} \tag{10.13}$$

for some constant C_3 depending on C_2.

Combining (10.10), (10.11), (10.12), and (10.13), we have the following inequality:

$$\begin{aligned}&\Big[\|v(t)\|^2_{H^2(\Omega)} + \|v_t(t)\|^2_{L^2(\Omega)} + \|h(t)\|^2_{H^4(\Gamma)} + \|h_t(t)\|^2_{H^2(\Gamma)}\Big] \\ &+ \int_0^t \Big[\|v\|^2_{H^3(\Omega)} + \|v_t\|^2_{H^1(\Omega)} + \|h\|^2_{H^{5.5}(\Gamma)} + \|h_t\|^2_{H^{2.5}(\Gamma)} + \|h_{tt}\|^2_{H^{0.5}(\Gamma)}\Big] ds \\ &\le (C_2+C_3)N(u_0,F) + C(M)N(u_0,F)^2\Big[C(\delta)\mathcal{O}(t)+\delta\Big].\end{aligned}$$

Let $M = 2(C_2+C_3)N(u_0,F)+1$ (and hence corresponding T_0 and T in Lemma 6.3 and Corollary 7.1 are fixed). Choose $\delta > 0$ small enough (but fixed) so that

$$C(M)N(u_0,F)^2\delta \le \frac{1}{4}$$

and then choose $T > 0$ small enough so that

$$C(M)N(u_0,F)^2 C(\delta) T \le \frac{1}{4}.$$

Then for a.a. $0 < t \le T$,

$$\begin{aligned}&\Big[\|v(t)\|^2_{H^2(\Omega)} + \|v_t(t)\|^2_{L^2(\Omega)} + \|h(t)\|^2_{H^4(\Gamma)} + \|h_t(t)\|^2_{H^2(\Gamma)}\Big] \\ &+ \int_0^t \Big[\|v\|^2_{H^3(\Omega)} + \|v_t\|^2_{H^1(\Omega)} + \|h_t\|^2_{H^{2.5}(\Gamma)} + \|h_{tt}\|^2_{H^{0.5}(\Gamma)}\Big] ds \\ &\le C_2 N(u_0,F) + \frac{1}{2},\end{aligned}$$

and therefore

$$\begin{aligned}&\sup_{0\le t\le T}\Big[\|v(t)\|^2_{H^2(\Omega)} + \|v_t(t)\|^2_{L^2(\Omega)} + \|h(t)\|^2_{H^4(\Gamma)} + \|h_t(t)\|^2_{H^2(\Gamma)}\Big] \\ &+ \|v\|^2_{\mathcal{V}^3(T)} + \|h\|^2_{\mathcal{H}(T)} \le 2C_2 N(u_0,F) + 1,\end{aligned} \tag{10.14}$$

or in other words,

$$\|(v,h)\|^2_{Y(T)} \le 2C_2 N(u_0,F) + 1.$$

REMARK 19. *Equation* (10.14) *implies that for* $(\tilde{v},\tilde{h}) \in C_T(M)$ *(with* M *and* T *chosen as above), the corresponding solution to the linear problem* (7.1) $(v,h) = \Theta_T(\tilde{v},\tilde{h})$ *is also in* $C_T(M)$.

10.4. Weak continuity of the mapping Θ_T.

LEMMA 10.4. *The mapping Θ_T is weakly sequentially continuous from $C_T(M)$ into $C_T(M)$ (endowed with the norm of X_T).*

Proof. Let $(v_p, h_p)_{p\in\mathbb{N}}$ be a given sequence of elements of $C_T(M)$ weakly convergent (in Y_T) toward a given element $(v,h) \in C_T(M)$ (where $C_T(M)$ is sequentially weakly closed as a closed convex set) and let $(v_{\sigma(p)}, h_{\sigma(p)})_{p\in\mathbb{N}}$ be any subsequence of this sequence.

Since $\mathcal{V}^3(T)$ is compactly embedded into $L^2(0,T;H^2(\Omega))$, we deduce the following strong convergence results in $L^2(0,T;L^2(\Omega))$ as $p \to \infty$:

$$(a_\ell^j)_p(a_\ell^k)_p \to a_\ell^j a_\ell^k \quad \text{and} \quad (a_\ell^j)_p(a_k^\ell)_p \to a_\ell^j a_k^\ell, \tag{10.15a}$$

$$[(a_\ell^j)_p(a_\ell^k)_p]_{,j} \to (a_\ell^j a_\ell^k)_{,j} \quad \text{and} \quad [(a_\ell^j)_p(a_k^\ell)_p]_{,j} \to (a_\ell^j a_k^\ell)_{,j}, \tag{10.15b}$$

$$(a_i^k)_p \to a_i^k. \tag{10.15c}$$

Now let $(w_p, g_p) = \Theta_T(v_p, h_p)$ and let q_p be the associated pressure so that $(q_p)_{p\in\mathbb{N}}$ is in a bounded set of $\mathcal{V}^2(T)$. Since X_T is a reflexive Hilbert space, let $(w_{\sigma(p)}, g_{\sigma(p)}, q_{\sigma(p)})_{p\in\mathbb{N}}$ be a subsequence weakly converging in $X_T \times \mathcal{V}^2(T)$ toward an element $(w,g,q) \in X_T \times \mathcal{V}^2(T)$. Since $C_T(M)$ is weakly closed in X_T, we also have $(w,g) \in C_T(M)$.

For each $\phi \in L^2(0,T;H^1(\Omega))$, we deduce from (7.3) (and Remark 6) that

$$\int_0^T \left[(w_t, \phi)_{L^2(\Omega)} + \frac{\mu}{2}\int_\Omega D_\eta w : D_\eta \phi dx + \sigma \int_\Gamma L_h(g)(g_{,\alpha}\phi_\alpha - \phi_z) dS \right.$$
$$\left. + \int_\Omega q a_i^j \phi^i_{,j} dx \right] dt = \int_0^T \langle F, \phi \rangle dt,$$

which with the fact that, from (10.15), for all $t \in [0,T]$, $w \in \mathcal{V}_v$, provides that (w,g) is a solution of (2.16) in $C_T(M)$, i.e., $(w,g) = \Theta_T(v,h)$.

Therefore, we deduce that the whole sequence $(\Theta_T(v_n,h_n))_{n\in\mathbb{N}}$ weakly converges in $C_T(M)$ toward $\Theta_T(v,h)$, which concludes the lemma. ∎

10.5. Uniqueness. For the uniqueness result, we assume that u_0, F, and Γ are smooth enough (e.g., $u_0 \in H^{5.5}(\Omega)$, $F \in \mathcal{V}^4(T)$, Γ is a $H^{8.5}$ surface) so that u_0 and the associated u_1, q_0 satisfy compatibility condition (4.4). Therefore, the solution (v,h,q) is such that $v \in \mathcal{V}^6(T)$, $q \in L^2(0,T;H^5(\Omega))$ and $h \in L^\infty(0,T;H^7(\Gamma)) \cap L^2(0,T;H^{8.5}(\Gamma))$, $h_t \in L^\infty(0,T;H^5(\Gamma)) \cap L^2(0,T;H^{5.5}(\Gamma))$, $h_{tt} \in L^\infty(0,T;H^2(\Gamma)) \cap L^2(0,T;H^{3.5}(\Gamma))$. This implies $a \in L^\infty(0,T;H^5(\Omega))$, and hence by studying the elliptic equation

$$(a_i^\ell a_i^k q_{t,k})_{,\ell} = \left[\nu a_i^\ell (a_p^k a_p^j v^i_{,j})_{,k\ell} + a^\ell_{it} v^i_{,\ell} + a_i^\ell F_{,\ell}\right]_t - [(a_i^\ell a_i^k)_t q_{,k}]_{,\ell} \qquad \text{in} \quad \Omega,$$
$$q_t = J_h^{-2}\left[\left(\sigma L_h(h) N_i - \nu D_\eta(v)_i^\ell a_i^j N_j\right)_t - (a_i^j N_j)_t q\right] a_i^\ell N_\ell \quad \text{on} \quad \Gamma,$$

we find that $q_t \in L^2(0,T;H^2(\Omega))$, and this implies $v_{tt} \in L^2(0,T;H^1(\Omega))$. By the interpolation theorem, we also conclude that $v_t \in \mathcal{C}^0([0,T];H^{2.5}(\Omega))$.

Suppose (v,h,q) and $(\tilde{v},\tilde{h},\tilde{q})$ are two sets of solutions of (1.1). Then

$$(v-\tilde{v})_t - \nu[a_\ell^k D_\eta(v-\tilde{v})^i_\ell]_{,k} = -a_i^k (q-\tilde{q})_{,k} + \delta F, \tag{10.16a}$$

$$a_i^j (v-\tilde{v})^i_{,j} = \delta a, \tag{10.16b}$$

$$\left[\nu[D_\eta(v-\tilde{v})]_i^\ell - (q-\tilde{q})\delta_i^\ell\right] a_\ell^j N_j = \sigma\Theta\left[L_h(h-\tilde{h})(-\nabla_0 h, 1)\right] \circ \eta^\tau + \delta L_1 + \delta L_2 + \delta L_3, \tag{10.16c}$$

$$(h-\tilde h)_t\circ\eta^\tau = [h_{,\alpha}\circ\eta^\tau](v_\alpha-\tilde v_\alpha)-(v_z-\tilde v_z) + \delta h_1+\delta h_2+\delta h_3, \tag{10.16d}$$

$$(v-\tilde v)(0)=0, \tag{10.16e}$$

$$(h-\tilde h)(0)=0, \tag{10.16f}$$

where

$$\delta F = f\circ\eta - f\circ\tilde\eta + \nu[(a^k_\ell a^j_\ell - \tilde a^k_\ell \tilde a^j_\ell)\tilde v^i_{,j}]_{,k} + \nu[(a^k_\ell a^j_i - \tilde a^k_\ell\tilde a^j_i)\tilde v^\ell_{,j}]_{,k} - (a^k_i-\tilde a^k_i)\tilde q_{,k}, \tag{10.17a}$$

$$\delta a = (a^j_i-\tilde a^j_i)\tilde v^i_{,j}, \tag{10.17b}$$

$$\delta L_1 = \sigma\Theta\Big[L_h(\tilde h)(\nabla_0 h-\nabla_0\tilde h,0)\Big]\circ\eta^\tau - \nu(a^k_i a^j_\ell - \tilde a^k_i\tilde a^j_\ell)\tilde v^\ell_{,k}N_j - \nu(a^k_\ell a^j_\ell - \tilde a^k_\ell\tilde a^j_\ell)\tilde v^i_{,k}N_j + (a^j_i-\tilde a^j_i)\tilde q N_j, \tag{10.17c}$$

$$\delta L_2 = \tilde\Theta[L_{\tilde h}(\tilde h)\circ\eta^\tau](\nabla_0\tilde h\circ\eta^\tau-\nabla_0\tilde h\circ\tilde\eta^\tau,0) + \Big[\Theta L_h(\tilde h)\circ\eta^\tau - \tilde\Theta L_h(\tilde h)\circ\tilde\eta^\tau\Big](\nabla_0\tilde h\circ\tilde\eta^\tau,-1), \tag{10.17d}$$

$$\delta L_3 = \Big[[L_h(\tilde h)-L_{\tilde h}(\tilde h)](\nabla_0\tilde h,-1)\Big]\circ\tilde\eta^\tau, \tag{10.17e}$$

$$\delta h_1 = (h_{,\alpha}\circ\eta^\tau - h_{,\alpha}\circ\tilde\eta^\tau)\tilde v_\alpha, \tag{10.17f}$$

$$\delta h_2 = \Big[(h_{,\alpha}-\tilde h_{,\alpha})\circ\tilde\eta^\tau\Big]\tilde v_\alpha, \tag{10.17g}$$

$$\delta h_3 = -(\tilde h_t\circ\eta^\tau - \tilde h_t\circ\tilde\eta^\tau). \tag{10.17h}$$

We will also use δL and δh to denote $\sum_{k=1}^3 L_k$ and $\sum_{k=1}^3\delta h_k$, respectively.

Similar to (11.3) in [8], we also have the following estimates.

LEMMA 10.5. *For $f\in H^2(\Omega)$ and $g\in H^{1.5}(\Gamma)$,*

$$\|f\circ\eta - f\circ\tilde\eta\|_{L^2(\Omega)} \le C\sqrt{t}\|f\|_{H^2(\Omega)}\left[\int_0^t \|v-\tilde v\|^2_{H^1(\Omega)}ds\right]^{1/2}, \tag{10.18}$$

$$\|g\circ\eta^\tau - g\circ\tilde\eta^\tau\|_{L^2(\Gamma)} \le C\sqrt{t}\|g\|_{H^{1.5}(\Gamma)}\left[\int_0^t \|v-\tilde v\|^2_{H^1(\Omega)}ds\right]^{1/2} \tag{10.19}$$

for some constant C.

REMARK 20. *Assuming the regularity of h, h_t, and h_{tt} given in the beginning of this section, we have*

$$\|\delta L_2\|_{H^2(\Gamma)} + \|\delta h_1+\delta h_3\|_{H^{2.5}(\Gamma)} \le C\sqrt{t}\left[\int_0^t \|v-\tilde v\|^2_{H^3(\Omega)}ds\right]^{1/2} \tag{10.20}$$

and

$$\|(\delta L_2)_t\|_{L^2(\Gamma)} + \|(\delta h_1+\delta h_3)_t\|_{H^1(\Gamma)} \le C\left[\|v-\tilde v\|_{H^1(\Omega)} + \sqrt{t}\left(\int_0^t \|v-\tilde v\|^2_{H^2(\Omega)}ds\right)^{1/2}\right] \tag{10.21}$$

and

$$\|\nabla_0^2(\delta h_3)_t\|_{L^2(\Gamma)} \le C\Bigg[\|v-\tilde v\|_{H^1(\Omega)} + \|v-\tilde v\|_{H^3(\Omega)}$$

$$+ \sqrt{t}\|\tilde h_{tt}\|_{H^{3.5}(\Gamma)}\left(\int_0^t \|v-\tilde v\|^2_{H^3(\Omega)}ds\right)^{1/2}\Bigg]. \tag{10.22}$$

By using (10.18) to estimate $\|\delta F\|_{L^2(\Omega)}$, we find that

$$\|\nabla(v-\tilde v)(t)\|^2_{L^2(\Omega)} + \int_0^t \|(v-\tilde v)_t\|^2_{L^2(\Omega)}ds$$
$$\le C(\delta)\int_0^t \left[\|v-\tilde v\|^2_{H^1(\Omega)} + \|h-\tilde h\|^2_{H^4(\Gamma)}\right]ds + (C(\delta)t^2+\delta)\int_0^t \|v-\tilde v\|^2_{H^2(\Omega)}ds$$
$$+\delta\int_0^t \left[\|(v-\tilde v)_t\|^2_{H^1(\Omega)} + \|q-\tilde q\|^2_{H^1(\Omega)}\right]ds. \tag{10.23}$$

For the $L^2_tH^3_x$-estimate for $v-\tilde v$ and the $L^2_tH^1_x$-estimate for $(v-\tilde v)_t$, we have

$$\frac12\frac{d}{dt}\left[\|\zeta_1\nabla_0^2(v-\tilde v)\|^2_{L^2(\Omega)} + 2\sigma E_h(\nabla_0^2(h-\tilde h))\right] + \frac{\nu}{4}\|\zeta_1 D_{\bar\eta}\nabla_0^2(v-\tilde v)\|^2_{L^2(\Omega)}$$
$$\le C\Big[\|\delta F\|^2_{H^1(\Omega)} + \|(v-\tilde v)_t\|^2_{L^2(\Omega)} + \|\nabla(v-\tilde v)\|^2_{L^2(\Omega)} + \|\nabla\nabla_0(v-\tilde v)\|^2_{L^2(\Omega_1')}$$
$$+\|\nabla_0^4(h-\tilde h)\|^2_{L^2(\Gamma)}\Big] + \delta\|v-\tilde v\|^2_{H^3(\Omega)} + D_1 + D_2 + D_3$$

and

$$\frac12\frac{d}{dt}\left[\|(v-\tilde v)_t\|^2_{L^2(\Omega)} + 2\sigma E_h((h-\tilde h)_t)\right] + \frac{\nu}{4}\|\nabla(v-\tilde v)_t\|^2_{L^2(\Omega)}$$
$$\le C\Big[(\|\nabla_0^4(h-\tilde h)\|^2_{L^2(\Gamma)} + \|\nabla_0^2(h-\tilde h)_t\|^2_{L^2(\Gamma)}) + \|\delta F_t\|^2_{H^1(\Omega)'}\Big] + \delta\|v-\tilde v\|^2_{H^3(\Omega)}$$
$$+E_1+E_2+E_3,$$

where

$$D_1 := \int_\Omega \zeta_1^2\nabla_0^2(q-\tilde q)\nabla_0^2\delta a dx, \qquad D_2 := \int_\Gamma \Theta\Big[[L_h(h-\tilde h)]\circ\eta^\tau\Big](\nabla_0^4\delta h)dS,$$
$$D_3 := \int_\Gamma \delta L\cdot\nabla_0^4(v-\tilde v)dS$$

and

$$E_1 := \int_\Omega (q-\tilde q)_t(\delta a)_t dx, \qquad E_2 := \int_\Gamma \Big[\Theta[L_h(h-\tilde h)]\circ\eta^\tau\Big]_t(\delta h)_t dS,$$
$$E_3 := \int_\Gamma (\delta L)_t\cdot(v-\tilde v)_t dS.$$

By using (10.20) to estimate D_i and (10.21), (10.22) to estimate E_i, we obtain

$$\left[\|\nabla_0^2(v-\tilde v)(t)\|^2_{L^2(\Omega_1)} + \|\nabla_0^4(h-\tilde h)(t)\|^2_{L^2(\Gamma)}\right] + \int_0^t \|\nabla\nabla_0^2(v-\tilde v)\|^2_{L^2(\Omega_1)}ds$$
$$\le C(\delta)\int_0^t \left[\|(v-\tilde v)_t\|^2_{L^2(\Omega)} + \|\nabla_0(v-\tilde v)\|^2_{L^2(\Omega)} + \|\nabla_0^4(h-\tilde h)\|^2_{L^4(\Gamma)}\right]ds$$
$$+(C(\delta)t^2+\delta)\int_0^t \|v-\tilde v\|^2_{H^3(\Omega)}ds + \delta\int_0^t \|q-\tilde q\|^2_{H^2(\Omega)}ds \tag{10.24}$$

and

$$
\begin{aligned}
&\Big[\|(v-\tilde v)_t(t)\|^2_{L^2(\Omega)} + \|\nabla_0^2(h-\tilde h)_t\|^2_{L^2(\Gamma)}\Big] + \int_0^t \|\nabla(v-\tilde v)_t\|^2_{L^2(\Omega)}ds \\
&\le C(\delta)\int_0^t \Big[\|v-\tilde v\|^2_{H^1(\Omega)} + \|\nabla_0^4(h-\tilde h)\|^2_{L^2(\Gamma)} + (1+\|\tilde h_{tt}\|^2_{H^{4.5}(\Gamma)}) \\
&\qquad \times \|\nabla_0^2(h-\tilde h)_t\|^2_{L^2(\Gamma)}\Big]ds \\
&\quad + (C(\delta)(t+t^2)+\delta)\int_0^t \|v-\tilde v\|^2_{H^3(\Omega)}ds + \delta\|q-\tilde q\|^2_{L^2(\Omega)} \\
&\quad + \delta\int_0^t \Big[\|(v-\tilde v)_t\|^2_{H^1(\Omega)} + \|q-\tilde q\|^2_{H^2(\Omega)}\Big]ds.
\end{aligned}
\tag{10.25}
$$

Summing (10.23), (10.24), and (10.25), we find that

$$
Y(t) + \int_0^t Z(s)ds \le C(\delta)\int_0^t k(s)Y(s)ds + (C(\delta)(t^2+t)+\delta)\int_0^t Z(s)ds, \tag{10.26}
$$

where

$$
\begin{aligned}
k(t) &= 1+\|\tilde h_{tt}(t)\|^2_{H^{3.5}(\Gamma)}, \\
Y(t) &= \Big[\|v-\tilde v(t)\|^2_{H^1(\Omega)} + \|\nabla_0^2(v-\tilde v)(t)\|^2_{L^2(\Omega_1)} + \|(v-\tilde v)_t(t)\|^2_{L^2(\Omega)} \\
&\quad + \|h-\tilde h\|^2_{H^4(\Gamma)} + \|(h-\tilde h)_t\|^2_{H^2(\Gamma)}\Big], \\
Z(t) &= \|(v-\tilde v)_t(t)\|^2_{H^1(\Omega)} + \|\nabla\nabla_0^2(v-\tilde v)(t)\|^2_{L^2(\Omega_1)}.
\end{aligned}
$$

By letting $\delta = 1/4$ and choosing $T_u \le T$ so that $C(\delta)(T_u^2+T_u) \le 1/4$,

$$
Y(t) + \int_0^t Z(s)ds \le C\int_0^t k(s)Y(s)ds \tag{10.27}
$$

for all $0 < t \le T_u$. Since $Y(0) = 0$, the uniqueness of the solution follows from that $Y(t) = 0$ for all $0 < t \le T_u$.

11. The analysis of the membrane traction.

The analysis of the membrane traction consists of four parts: (1) the modified linearized (and regularized) problem; (2) the κ-independent estimates; (3) the fixed-point argument; and (4) the uniqueness of the solution.

11.1. The modified linearized and regularized problem.

Recall that the membrane traction is

$$
\mathfrak{t}_{\rm mem} = \Big[\mathcal{J}\mathcal{P}''(\mathcal{J}) + 2\mathcal{P}'(\mathcal{J})\Big]\mathcal{J}_{,\beta}g^{\alpha\beta}\eta_{,\alpha} + \Big[\mathcal{J}\mathcal{P}'(\mathcal{J}) + \mathcal{P}(\mathcal{J})\Big]Hn.
$$

For given $\bar v = \rho_{\epsilon_1} * \tilde v$ (and hence $\bar\eta$, $\bar g$, etc.), we define (for fixed but small $\epsilon > 0$)

$$
L^{\epsilon}_{\bar m} = \frac{1}{2}\bar{\mathcal{J}}^{-1}\Big[(\partial_\beta\rho_\epsilon) * \Big(\frac{\bar g}{g_0}\Big)\Big]\Big[\bar{\mathcal{J}}\mathcal{P}''(\bar{\mathcal{J}}) + 2\mathcal{P}'(\bar{\mathcal{J}})\Big]\bar g^{\alpha\beta}\bar\eta_{,\alpha} + \Big[\bar{\mathcal{J}}\mathcal{P}'(\bar{\mathcal{J}}) + \mathcal{P}(\bar{\mathcal{J}})\Big]\bar H\bar n.
$$

For the linearized problem, we change the boundary condition (7.1c) to

$$
\begin{aligned}
[\nu D_{\tilde\eta}(v)^j_i - q\delta^j_i]\tilde a^\ell_j N_\ell = (L^\epsilon_{\bar m})^i + \sigma\tilde\Theta\Big[\mathcal{L}_{\tilde h}(h)(-\nabla_0\tilde h, 1)\Big]\circ\tilde\eta^\tau \quad \text{on} \quad (0,T)\times\Gamma \\
+ \sigma\tilde\Theta\Big[[\mathcal{M}(\tilde h)(-\nabla_0\tilde h, 1)]\circ\tilde\eta^\tau\Big],
\end{aligned}
\tag{11.1}
$$

where we recall that $\bar{\Theta} = \det(\nabla_0 \bar{\eta}^\tau)\sqrt{\det(G_{\bar{h}}) \circ \bar{\eta}^\tau}$. Note that here we treat the membrane traction as a given forcing on the boundary. The regularized problem consists of adding the artificial viscosity, as introduced in (7.2c), in (11.1). Note that here we also mollify $\bar{\mathcal{J}}_{,\beta}$ and use the equality $(\rho_\epsilon * f)_{,\beta} = \rho_{\epsilon,\beta} * f$.

Since $L_{\bar{m}}$ is given as a forcing, all the estimates are essentially the same as those in the previous sections. Therefore, we have a unique solution (v_κ, h_κ) to the regularized problem (with ϵ_1-, ϵ-, and κ-dependent estimates).

11.2. The κ-independent estimates. The introduction of the artificial viscosity is to provide enough regularity for the solution to the linearized problem. As in Appendix A, the κ-independent estimates are obtained by studying the normal component of (A.1). Note that with the help of the mollification operation in (11.1), the corresponding f in (A.1) is also a function in $L^2(0,T;H^{1.5}(\Gamma))$. Therefore, (A.7) is still valid. This κ-independent estimate will enable us to take the limit as $\kappa \to 0$ and obtain the solution $(v_{\epsilon_1}, h_{\epsilon_1})$. Essentially the same proof as in section 9.4 shows that (9.12) still holds, and hence taking the limit as $\epsilon_1 \to 0$, the weak limit (v_ϵ, h_ϵ) solves the linearized problem (7.1), and all the estimates in the previous sections hold with $C(M)$ replaced by $C(M,\epsilon)$.

REMARK 21. *The estimate for (v_ϵ, h_ϵ) still depends on ϵ, where the extra ϵ-regularization is used in the $L^2_t H^3_x$-estimates, which requires estimating the following boundary integral:*

$$\int_\Gamma \frac{1}{2}\bar{\mathcal{J}}^{-1}\left[(\partial_\beta \rho_\epsilon) * \left(\frac{\bar{g}}{g_0}\right)\right]\left[\bar{\mathcal{J}}\mathcal{P}''(\bar{\mathcal{J}}) + 2\mathcal{P}'(\bar{\mathcal{J}})\right]\bar{g}^{\alpha\beta}\bar{\eta}_{,\alpha}\nabla_0^4 v dS.$$

Moreover, even though the estimate for h_{ϵ_1} depends only on the normal component of $L_{\bar{m}}$, in the linearized problem, there are still contributions to the normal direction made by $\bar{g}^{\alpha\beta}\bar{\eta}_{,\alpha}$.

11.3. The fixed-point argument. Similar fixed-point arguments as in section 10 guarantee the existence of a fixed point (which is still denoted by (v_ϵ, h_ϵ)) in the space X_{T_ϵ}; that is, there is a fixed point $(v_\epsilon, h_\epsilon) \in \mathcal{V}^3(T_\epsilon) \times \mathcal{H}(T_\epsilon)$. This fixed point satisfies the boundary condition

$$\begin{aligned}[\nu D_{\eta_\epsilon}(v_\epsilon)^j_i - q_\epsilon \delta^j_i](a_\epsilon)^\ell_j N_\ell = (L^\epsilon_m)^i + \sigma\Theta_\epsilon\Big[\mathcal{L}_{h_\epsilon}(h_\epsilon)(-\nabla_0 h_\epsilon, 1)\Big] \circ {\eta_\epsilon}^\tau \\ + \sigma\Theta_\epsilon\Big[[\mathcal{M}(h_\epsilon)(-\nabla_0 h_\epsilon, 1)] \circ {\eta_\epsilon}^\tau\Big]\end{aligned} \tag{11.2}$$

on $(0,T) \times \Gamma$, where

$$L^\epsilon_m = \frac{1}{2}\mathcal{J}_\epsilon^{-1}\left[\rho_\epsilon * \left(\frac{g_\epsilon}{g_0}\right)\right]_{,\beta}\Big[\mathcal{J}_\epsilon\mathcal{P}''(\mathcal{J}_\epsilon) + 2\mathcal{P}'(\mathcal{J}_\epsilon)\Big]g^{\alpha\beta}_\epsilon \eta_{\epsilon,\alpha} + \Big[\mathcal{J}_\epsilon\mathcal{P}'(\mathcal{J}_\epsilon) + \mathcal{P}(\mathcal{J}_\epsilon)\Big]H_\epsilon n_\epsilon.$$

By studying the tangential component of (11.2), we find that for $\gamma = 1, 2$,

$$\mathcal{J}_\epsilon^{-1}\left[\rho_\epsilon * \left(\frac{g_\epsilon}{g_0}\right)\right]_{,\gamma}\Big[\mathcal{J}_\epsilon\mathcal{P}''(\mathcal{J}_\epsilon) + 2\mathcal{P}'(\mathcal{J}_\epsilon)\Big] = 2[\nu D_{\eta_\epsilon}(v_\epsilon)^j_i - q_\epsilon\delta^j_i](a_\epsilon)^\ell_j N_\ell {\eta_\epsilon}^i_{,\gamma}. \tag{11.3}$$

Take T_ϵ even smaller so that

$$\begin{aligned} &\frac{1}{2} \le \|\Theta_\epsilon\|_{H^{1.5}(\Gamma)} \le \frac{3}{2}, && \frac{1}{2} \le \|a_\epsilon\|_{H^2(\Omega)} \le \frac{3}{2}, \\ &\|v_\epsilon\|_{L^2(0,T_\epsilon;H^3(\Omega))} \le \|u_0\|^2_{H^3(\Omega)} + 1, && \|\eta_\epsilon\|_{H^3(\Omega)} \le |\Omega| + 1. \end{aligned}$$

With these bounds, (11.3) together with the assumptions that $\mathcal{P}$ is strictly convex and $\mathcal{P}$ attains its minimum at $\mathcal{J} = 1$ (that assure that the second bracket of the left-hand side of (11.3) is bounded away from zero) implies that

$$\left\| \nabla_0 \left[\rho_\epsilon * \left(\frac{g_\epsilon}{g_0} \right) \right] \right\|_{H^{1.5}(\Gamma)} \leq C(u_0, \Omega). \tag{11.4}$$

Since (11.4) is independent of the ϵ, we find that

$$\|g_\epsilon\|_{H^{2.5}(\Gamma)} \leq C(u_0, g_0, \Omega). \tag{11.5}$$

Having (11.5), we no longer need ϵ-regularization to estimate the boundary integral in Remark 21 and the study of (A.1), and hence all the estimates in the previous sections are still valid with $C(M)$ replaced by $C(u_0, g_0, \Omega)$. These ϵ-independent estimates allow us to construct a solution (v_ϵ, h_ϵ) in $X(T)$ (where T is independent of ϵ) with the same estimates. The solution of the original problem (1.1) is then the limit of (v_ϵ, h_ϵ) as $\epsilon \to 0$.

11.4. The uniqueness of the solution. The uniqueness of the solution follows from the elliptic estimate

$$\|g - \tilde{g}\|^2_{H^{2.5}(\Gamma)} \leq C\Big[\|v - \tilde{v}\|^2_{H^3(\Omega)} + \|v_t - \tilde{v}_t\|^2_{H^1(\Omega)} \Big],$$

which follows from the equation

$$\left(\frac{g - \tilde{g}}{g_0} \right)_{,\gamma} \mathcal{Q}(\eta) + \left(\frac{\tilde{g}}{g_0} \right)_{,\gamma} \Big[\mathcal{Q}(\eta) - \mathcal{Q}(\tilde{\eta}) \Big] = F(v, q)^\gamma - F(\tilde{v}, \tilde{q})^\gamma,$$

where

$$\mathcal{Q}(\eta) = \mathcal{J}^{-1} \Big[\mathcal{J} \mathcal{P}''(\mathcal{J}) + 2\mathcal{P}'(\mathcal{J}) \Big] \quad \text{and} \quad F(v, q)^\gamma = 2[\nu D_\eta(v)^j_i - q\delta^j_i] a^\ell_j N_\ell \eta^i_{,\gamma}.$$

Appendix A. Elliptic regularity. We establish a κ-independent elliptic estimate for solutions of

$$\frac{\bar{\Theta}}{\sqrt{\det(g_0)}} \Big[\Big(\sqrt{\det(g_0)} \bar{A}^{\alpha\beta\gamma\delta} h_{\kappa,\alpha\beta} \Big)_{,\gamma\delta} (-\nabla_0 \bar{h}, 1) \Big] \circ \bar{\eta}^\tau + \kappa \Delta_0^2 v_\kappa = f, \tag{A.1}$$

where h_κ and v_κ satisfy (7.4) with $h_\kappa \in H^4(\Gamma)$, $v_\kappa \in H^4(\Gamma)$, and $f \in H^{1.5}(\Gamma)$. Letting $w = v_\kappa \circ \bar{\eta}^{-\tau}$, (A.1) is equivalent to

$$\frac{\bar{\Theta}}{\sqrt{\det(g_0)}} \Big[\sqrt{\det(g_0)} \bar{A}^{\alpha\beta\gamma\delta} h_{\kappa,\alpha\beta} \Big]_{,\gamma\delta} (-\nabla_0 \bar{h}, 1) + \kappa \Delta_0^2 w = f \circ \bar{\eta}^\tau, \tag{A.2}$$

which implies that

$$\begin{aligned} &\frac{\bar{\Theta}}{\sqrt{\det(g_0)}} \Big[\sqrt{\det(g_0)} \bar{A}^{\alpha\beta\gamma\delta} h_{\kappa,\alpha\beta} \Big]_{,\gamma\delta} + \kappa J_{\bar{h}}^{-2} \Delta_0^2 w \cdot (-\nabla_0 \bar{h}, 1) \\ &= J_{\bar{h}}^{-2} f \circ \bar{\eta}^\tau \cdot (-\nabla_0 \bar{h}, 1). \end{aligned} \tag{A.3}$$

Recall that $w \cdot (-\nabla_0 \bar{h}, 1) = h_{\kappa t}$.

Let D_h denote the difference quotients (with respect to the surface coordinate system). Taking the inner product of (A.3) with $D_{-h}D_h\nabla_0^4 h_\kappa$, by Corollary 7.1 we find that

$$\nu_1 \int_0^t \|D_h\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)} ds \le C(\epsilon_1)\int_0^t \Big[\|h_\kappa\|^2_{H^2(\Gamma)} + \|f\|^2_{H^1(\Gamma)} + \kappa\|w\|^2_{H^4(\Gamma)}\Big] ds.$$

Since the right-hand side is independent of difference parameter h, it follows that $h_\kappa \in H^5(\Gamma)$ (as it is already a H^4-function) with the estimate

$$\int_0^t \|\nabla_0^5 h_\kappa\|^2_{L^2(\Gamma)} ds \le C(\epsilon_1)\int_0^t \Big[\|h_\kappa\|^2_{H^2(\Gamma)} + \|f\|^2_{H^1(\Gamma)} + \kappa\|w\|^2_{H^4(\Gamma)}\Big] ds. \tag{A.4}$$

Next, we obtain a κ-independent estimate of $\kappa\|w\|^2_{H^4(\Gamma)}$. By taking the inner product of (A.2) with $\nabla_0^2 w$ and $\nabla_0^4 w$, we find that

$$\begin{aligned}&\|\nabla_0^3 h_\kappa(t)\|^2_{L^2(\Gamma)} + \kappa\int_0^t \|w\|^2_{H^3(\Gamma)} ds\\ &\quad\le C(\epsilon_1)\int_0^t \Big[\|\nabla_0^3 h_\kappa\|^2_{L^2(\Gamma)} + \|f\|^2_{L^2(\Gamma)} + \|w\|^2_{H^{2.5}(\Omega)}\Big] ds\end{aligned} \tag{A.5}$$

and

$$\begin{aligned}&\|\nabla_0^4 h_\kappa(t)\|^2_{L^2(\Gamma)} + \kappa\int_0^t \|w\|^2_{H^4(\Gamma)} ds\\ &\le C(\epsilon_1,\delta_1)\int_0^t \Big[\|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)} + \|f\|^2_{H^{1.5}(\Gamma)} + \|w\|^2_{H^3(\Omega)}\Big] ds + \delta_1\int_0^t \|\nabla_0^5 h_\kappa\|^2_{L^2(\Gamma)} dS,\end{aligned} \tag{A.6}$$

where we use (A.5) to estimate $\kappa\int_0^t \|w\|_{H^3(\Gamma)} ds$. Equation (A.6) provides a κ-independent estimate for $\kappa\|w\|^2_{H^4(\Gamma)}$; hence by choosing $\delta_1 > 0$ small enough, (A.4) implies that for all $t \in [0,T]$,

$$\int_0^t \|\nabla_0^2 h_\kappa\|^2_{H^3(\Gamma)} ds \le C'\int_0^t \Big[\|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)} + \|f\|^2_{H^{1.5}(\Gamma)} + \|w\|^2_{H^3(\Omega)}\Big] ds \tag{A.7}$$

for some constant C' depending on ϵ_1.

Appendix B. Inequalities in the estimates for $\nabla_0^2 v$ near the boundary.

B.1. κ-independent estimates. Since $\zeta_1 \equiv 1$ on Γ and

$$\begin{aligned}(-\nabla_0\bar h\circ\bar\eta^\tau,1)\cdot\nabla_0^4 v_\kappa &= \nabla_0^4((-\nabla_0\bar h\circ\bar\eta^\tau,1)\cdot v_\kappa) - \nabla_0^4(-\nabla_0\bar h\circ\bar\eta^\tau,1)\cdot v_\kappa\\ &\quad - 4\nabla_0^3(-\nabla_0\bar h\circ\bar\eta^\tau,1)\cdot\nabla_0 v_\kappa - 6\nabla_0^2(-\nabla_0\bar h\circ\bar\eta^\tau,1)\cdot\nabla_0^2 v_\kappa\\ &\quad - 4\nabla_0(-\nabla_0\bar h\circ\bar\eta^\tau,1)\cdot\nabla_0^3 v_\kappa,\end{aligned}$$

we find that

$$
\begin{aligned}
&\int_\Gamma \bar\Theta\Big[L_{\bar h}(h_\kappa)\circ\bar\eta^\tau\Big]((-\nabla_0\bar h\circ\bar\eta^\tau,1)\cdot\nabla_0^2(\zeta_1^2\nabla_0^2 v_\kappa))dS\\
&= -\int_\Gamma \bar\Theta\Big[L_{\bar h}(h_\kappa)\circ\bar\eta^\tau\Big]\Big[\nabla_0^4(-\nabla_0\bar h\circ\bar\eta^\tau,1)\cdot v_\kappa + 4\nabla_0^3(-\nabla_0\bar h\circ\bar\eta^\tau,1)\cdot\nabla_0 v_\kappa\\
&\qquad\qquad + 6\nabla_0^2(-\nabla_0\bar h\circ\bar\eta^\tau,1)\cdot\nabla_0^2 v_\kappa\Big]dS \qquad (\equiv I_1)\\
&\quad - 4\int_\Gamma \bar\Theta\Big[L_{\bar h}(h_\kappa)\circ\bar\eta^\tau\Big](\nabla_0(-\nabla_0\bar h\circ\bar\eta^\tau,1)\cdot\nabla_0^3 v_\kappa)dS \qquad (\equiv I_2)\\
&\quad + \int_\Gamma \frac{\bar\Theta}{\sqrt{\det(g_0)}}\nabla_0^2\Big[\sqrt{\det(g_0)}\Big(L_1^{\alpha\beta\gamma}\tilde h_{,\alpha\beta\gamma}+L_2\Big)\circ\bar\eta^\tau\Big]\nabla_0^2(h_{\kappa t}\circ\bar\eta^\tau)dS \qquad (\equiv I_3)\\
&\quad + \int_\Gamma \frac{2\nabla_0\bar\Theta}{\sqrt{\det(g_0)}}\nabla_0\Big[\sqrt{\det(g_0)}\Big(L_1^{\alpha\beta\gamma}\tilde h_{,\alpha\beta\gamma}+L_2\Big)\circ\bar\eta^\tau\Big]\nabla_0^2(h_{\kappa t}\circ\bar\eta^\tau)dS \qquad (\equiv I_4)\\
&\quad + \int_\Gamma (\nabla_0^2\bar\Theta)\Big[\Big(L_1^{\alpha\beta\gamma}\tilde h_{,\alpha\beta\gamma}+L_2\Big)\circ\bar\eta^\tau\Big]\nabla_0^2(h_{\kappa t}\circ\bar\eta^\tau)dS \qquad (\equiv I_5)\\
&\quad + \int_\Gamma \frac{\bar\Theta}{\sqrt{\det(g_0)}}\Big[(\sqrt{\det(g_0)}\bar A^{\alpha\beta\gamma\delta}h_{\kappa,\alpha\beta})_{,\gamma\delta}\circ\bar\eta^\tau\Big]\nabla_0^4(h_{\kappa t}\circ\bar\eta^\tau)dS.
\end{aligned}
$$

The last term of the identity above, by a change of coordinates, can be written as

$$
\begin{aligned}
&\int_\Gamma \frac{\bar\Theta}{\sqrt{\det(g_0)}}\Big[(\sqrt{\det(g_0)}\bar A^{\alpha\beta\gamma\delta}h_{\kappa,\alpha\beta})_{,\gamma\delta}\circ\bar\eta^\tau\Big]\nabla_0^4(h_{\kappa t}\circ\bar\eta^\tau)dS\\
&= \int_\Gamma \frac{B}{\sqrt{\det(g_0)}}\nabla_0^2(\sqrt{\det(g_0)}\bar A^{\alpha\beta\gamma\delta}h_{\kappa,\alpha\beta})_{,\gamma\delta}\nabla_0^2 h_{\kappa t}dS + R_1\\
&\quad + 2\int_\Gamma \frac{\nabla_0\bar\Theta}{\sqrt{\det(g_0)}}\nabla_0\Big[(\sqrt{\det(g_0)}\bar A^{\alpha\beta\gamma\delta}h_{\kappa,\alpha\beta})_{,\gamma\delta}\circ\bar\eta^\tau\Big]\nabla_0^2(h_{\kappa t}\circ\bar\eta^\tau)dS \qquad (\equiv J_1)\\
&\quad + \int_\Gamma \frac{\nabla_0^2\bar\Theta}{\sqrt{\det(g_0)}}\Big[(\sqrt{\det(g_0)}\bar A^{\alpha\beta\gamma\delta}h_{\kappa,\alpha\beta})_{,\gamma\delta}\circ\bar\eta^\tau\Big]\nabla_0^2(h_{\kappa t}\circ\bar\eta^\tau)dS \qquad (\equiv J_2)\\
&= \frac12\frac{d}{dt}\int_\Gamma B\bar A^{\alpha\beta\gamma\delta}\nabla_0^2 h_{\kappa,\alpha\beta}\nabla_0^2 h_{\kappa,\gamma\delta}dS + R_1',
\end{aligned}
$$

where $B = b^t\otimes b^t\otimes b^t\otimes b^t$ with $b=\nabla_0\bar\eta^\tau$, and

$$
\begin{aligned}
R_1(t) &= \int_\Gamma b^t\otimes b^t\otimes(\nabla_0 b^t)\otimes(\nabla_0 b^t)\nabla_0(\sqrt{\det(g_0)}\bar A^{\alpha\beta\gamma\delta}h_{\kappa,\alpha\beta})_{,\gamma\delta}\nabla_0 h_{\kappa t}dS \quad (\equiv J_3)\\
&\quad + \int_\Gamma b^t\otimes b^t\otimes b^t\otimes(\nabla_0 b^t)\nabla_0(\sqrt{\det(g_0)}\bar A^{\alpha\beta\gamma\delta}h_{\kappa,\alpha\beta})_{,\gamma\delta}\nabla_0^2 h_{\kappa t}dS \quad (\equiv J_4)\\
&\quad + \int_\Gamma b^t\otimes b^t\otimes b^t\otimes(\nabla_0 b^t)\nabla_0^2(\sqrt{\det(g_0)}\bar A^{\alpha\beta\gamma\delta}h_{\kappa,\alpha\beta})_{,\gamma\delta}\nabla_0 h_{\kappa t}dS \quad (\equiv J_5)
\end{aligned}
$$

and

$$
\begin{aligned}
R_1'(t) &= R_1(t)+J_1(t)+J_2(t)-\frac12\int_\Gamma (B\bar A^{\alpha\beta\gamma\delta})_t\nabla_0^2 h_{\kappa,\alpha\beta}\nabla_0^2 h_{\kappa,\gamma\delta}dS \quad (\equiv J_6)\\
&\quad + 2\int_\Gamma \frac{B}{\sqrt{\det(g_0)}}\nabla_0(\sqrt{\det(g_0)}\bar A^{\alpha\beta\gamma\delta})\nabla_0 h_{\kappa,\alpha\beta}\nabla_0^2 h_{\kappa t,\gamma\delta}dS \quad (\equiv J_7)\\
&\quad + \int_\Gamma \frac{B}{\sqrt{\det(g_0)}}\nabla_0^2(\sqrt{\det(g_0)}\bar A^{\alpha\beta\gamma\delta})h_{\kappa,\alpha\beta}\nabla_0^2 h_{\kappa t,\gamma\delta}dS \quad (\equiv J_8)
\end{aligned}
$$

$$+ 2\int_\Gamma \frac{B_{,\gamma}}{\sqrt{\det(g_0)}} \nabla_0^2(\sqrt{\det(g_0)}\bar{A}^{\alpha\beta\gamma\delta} h_{\kappa,\alpha\beta}) \nabla_0^2 h_{\kappa t,\delta} dS \quad (\equiv J_9)$$
$$+ \int_\Gamma \frac{B_{,\gamma\delta}}{\sqrt{\det(g_0)}} \nabla_0^2(\sqrt{\det(g_0)}\bar{A}^{\alpha\beta\gamma\delta} h_{\kappa,\alpha\beta}) \nabla_0^2 h_{\kappa t} dS \quad (\equiv J_{10}).$$

It follows that

$$|I_1| \le C(\epsilon_1)(1 + \|\nabla_0^4 h_\kappa\|_{L^2(\Gamma)})\|\nabla_0^2 v_\kappa\|_{H^1(\Omega_1')},$$
$$|I_3| + |I_4| + |I_5| \le C(M)(1 + \|\tilde{h}\|_{H^5(\Gamma)})\|\nabla_0^2 v_\kappa\|_{H^1(\Omega_1)}$$

and hence that

$$|I_1| + |I_3| + |I_4| + |I_5| \le C(\epsilon_1)\Big[\|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)} + \|\tilde{h}\|^2_{H^5(\Gamma)} + 1\Big] + \delta\|v_\kappa\|^2_{H^3(\Omega)}.$$

It follows that

$$|J_2| + |J_3| + |J_5| + |J_{10}| \le C(\epsilon_1)\|\nabla_0^4 h_\kappa\|_{L^2(\Gamma)}\|\nabla_0^2 h_{\kappa t}\|_{L^2(\Gamma)},$$
$$|J_6| \le C(M)(\|\tilde{v}\|_{H^3(\Omega)} + \|\tilde{h}_t\|_{H^{2.5}(\Gamma)})\|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)}.$$

We need only obtain κ-independent estimates for the terms I_2, J_1, J_4, J_7, J_8, and J_9. By the $H^{-0.5}(\Gamma)$-$H^{0.5}(\Gamma)$ duality pairing,

$$|I_2| \le C(M)\Big[\|\nabla_0^2 h_\kappa\|_{H^{2.5}(\Gamma)} + 1\Big]\|v_\kappa\|_{H^{2.5}(\Gamma)}.$$

Therefore, by interpolation and Young's inequality,

$$|I_2| \le C\Big[\|h_\kappa\|^2_{H^4(\Gamma)} + 1\Big] + \delta_1\|\nabla_0^2 h_\kappa\|^2_{H^3(\Gamma)} + \delta\|v_\kappa\|^2_{H^3(\Omega)} \tag{B.1}$$

for some C depending on M, δ, and δ_1.

For J_1, J_4, and J_9, we find that

$$|J_1| + |J_4| + |J_9| \le C(\epsilon_1)\|h_\kappa\|_{H^{4.5}(\Gamma)}\|v_\kappa\|_{H^{2.5}(\Gamma)}$$
$$\le C'\Big[\|\nabla_0^2 h_\kappa\|^2_{H^2(\Gamma)} + 1\Big] + \delta_1\|\nabla_0^2 h_\kappa\|^2_{H^3(\Gamma)} + \delta\|v_\kappa\|^2_{H^3(\Omega)}$$

for some constant C' depending on M, ϵ_1, δ, and δ_1.

For J_7 and J_8, by the $H^{-1.5}(\Gamma)$-$H^{1.5}(\Gamma)$ duality pairing,

$$|J_7| + |J_8| \le C(M)\|B\|_{H^{1.5}(\Gamma)}\|\bar{h}\|_{H^{3.5}(\Gamma)}\|h_\kappa\|_{H^{4.5}(\Gamma)}\|v_\kappa\|_{H^{2.5}(\Gamma)}.$$

Similarly to the estimate in (B.1), we find that

$$|J_7| + |J_8| \le C(M)\Big[\|h_\kappa\|^2_{H^4(\Gamma)} + 1\Big] + \delta_1\|\nabla_0^2 h_\kappa\|^2_{H^3(\Gamma)} + \delta\|v_\kappa\|^2_{H^3(\Omega)}.$$

Summing all the estimates and then integrating in time from 0 to t, by Corollary 7.1 and the fact that B is close to 1 in the uniform norm for T small,

$$\frac{\nu_1}{2}\|\nabla_0^4 h_\kappa(t)\|^2_{L^2(\Gamma)} \le \int_0^t\int_\Gamma \bar{\Theta}\Big[[L_{\bar{h}}(h_\kappa)(-\nabla_0\bar{h},1)]\circ\bar{\eta}^\tau\Big]\cdot\nabla_0^2(\zeta_1^2\nabla_0^2 v_\kappa)dSds$$
$$+ C'\int_0^t K(s)\|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)}ds + C'\int_0^t\Big[\|\tilde{h}\|^2_{H^5(\Gamma)} + 1\Big]ds$$
$$+ \delta\int_0^t\|v_\kappa\|^2_{H^3(\Omega)}ds + \delta_1\int_0^t\|\nabla_0^2 h_\kappa\|^2_{H^3(\Gamma)}ds$$

for some constant C' depending on M, ϵ_1, δ, and δ_1, where

$$K(s) := 1 + \|\tilde{v}\|^2_{H^3(\Omega)} + \|\tilde{h}\|^2_{H^5(\Gamma)} + \|\tilde{h}_t\|^2_{H^{2.5}(\Gamma)}.$$

B.2. ϵ_1-independent estimates. We next obtain ϵ_1-independent estimates for the first two terms of I_1, as well as those for I_2, J_1, J_2, J_3, J_4, J_5, J_9, and J_{10} with h_κ replaced by h_{ϵ_1}. Let

$$I_1^1 = -\int_\Gamma \bar\Theta \Big[L_{\tilde h}(h_{\epsilon_1}) \circ \bar\eta^\tau\Big]\Big[\nabla_0^4(-\nabla_0\bar h \circ \bar\eta^\tau, 1) \cdot v_{\epsilon_1}\Big] dS,$$
$$I_1^2 = -4\int_\Gamma \bar\Theta \Big[L_{\tilde h}(h_{\epsilon_1}) \circ \bar\eta^\tau\Big]\Big[\nabla_0^3(-\nabla_0\bar h \circ \bar\eta^\tau, 1) \cdot \nabla_0 v_{\epsilon_1}\Big] dS.$$

By the $H^{-1.5}(\Gamma)$-$H^{1.5}(\Gamma)$ duality pairing,

$$|I_1^1| + |I_1^2| \le C(M)\|L_{\tilde h}(h_{\epsilon_1})\|_{H^{1.5}(\Gamma)}\|v_{\epsilon_1}\|_{H^{2.5}(\Gamma)}\|(\nabla_0\tilde h)\circ\bar\eta^\tau\|_{H^{2.5}(\Gamma)}.$$

Therefore, by (6.6) and (9.12),

$$\text{(B.2)}\quad |I_1^1| + |I_1^2| \le C(M)t^{1/4}\Big[\|h_{\epsilon_1}\|^2_{H^{5.5}(\Gamma)} + 1\Big]\|v_{\epsilon_1}\|_{H^3(\Omega)}$$
$$\le Ct^{1/2}\Big[\|v_{\epsilon_1 t}\|^2_{H^1(\Omega)} + \|\nabla_0^4 h_{\epsilon_1}\|^2_{L^2(\Gamma)} + \|F\|^2_{H^1(\Omega)} + 1\Big] + (\delta + Ct^{1/2})\|v_{\epsilon_1}\|^2_{H^3(\Omega)}$$

for some constant C depending on M and δ.

For J_1, we use an L^4-L^4-L^2-type of Hölder inequality and conclude that

$$|J_1| \le C(M)t^{1/2}\|h_{\epsilon_1}\|_{H^{5.5}(\Gamma)}\|v_{\epsilon_1}\|_{H^{2.5}(\Gamma)},$$

while for the other J terms, we use the $H^{0.5}(\Gamma)$-$H^{-0.5}(\Gamma)$ duality pairing to obtain

$$|J_2| + |J_3| + |J_4| + |J_5| + |J_9| + |J_{10}| \le C(M)t^{1/2}\|h_{\epsilon_1}\|_{H^{5.5}(\Gamma)}\|v_{\epsilon_1}\|_{H^{2.5}(\Gamma)},$$

and hence all the J terms are bounded by the same right-hand side of the inequality in (B.2). Therefore,

$$\frac{\nu_1}{2}\|\nabla_0^4 h_{\epsilon_1}(t)\|^2_{L^2(\Gamma)} \le \int_0^t\int_\Gamma \bar\Theta\Big[[L_{\bar h}(h_{\epsilon_1})(-\nabla_0\bar h, 1)]\circ\bar\eta^\tau\Big]\cdot\nabla_0^2(\zeta_1^2\nabla_0^2 v_{\epsilon_1})dSds$$
$$+ CN_2(u_0, F) + C\int_0^t K(s)\|\nabla_0^4 h_{\epsilon_1}\|^2_{L^2(\Gamma)}ds + (\delta + Ct^{1/2})\int_0^t \|v_{\epsilon_1}\|^2_{H^3(\Omega)}ds$$
$$+ (\delta_1 + Ct^{1/2})\int_0^t \|v_{\epsilon_1 t}\|^2_{H^1(\Omega)}ds$$

for some constant C depending on M, δ, and δ_1.

Appendix C. $L_t^2H_x^1$-estimates for v_t. By the chain rule and integrating by parts,

$$\int_\Gamma \Big[\bar\Theta[L_{\bar h}(h_\kappa)(-\nabla_0\bar h, 1)]\circ\bar\eta^\tau\Big]_t \cdot v_{\kappa t}dS = \int_\Gamma \bar\Theta_t\Big[L_{\bar h}(h_\kappa)\Big]\circ\bar\eta^\tau(-\nabla_0\bar h\circ\bar\eta^\tau, 1)\cdot v_{\kappa t}dS$$
$$+ \int_\Gamma \bar\Theta\bar\eta_t^\tau\cdot\Big[\nabla_0[L_{\bar h}(h_\kappa)](-\nabla_0\bar h, 1)\Big]\circ\bar\eta^\tau\cdot v_{\kappa t}dS \quad (\equiv K_1)$$
$$+ \int_\Gamma \bar\Theta\Big[[L_{\bar h}(h_\kappa)](\nabla_0\bar h, -1)\Big]_t\circ\bar\eta^\tau\cdot v_{\kappa t}dS \quad (\equiv K_2).$$

The first term is bounded by

$$C(M)\|\bar v\|_{H^3(\Omega)}\Big[\|\nabla_0^4 h_\kappa\|_{L^2(\Gamma)} + 1\Big]\|v_{\kappa t}\|_{L^2(\Gamma)}.$$

After integrating by parts, the most difficult term to estimate in K_1 consists of the integral

$$\int_\Gamma \frac{\bar v}{\sqrt{\det(g_0)}}\Big[[\sqrt{\det(g_0)}\bar A^{\alpha\beta\gamma\delta}h_{\kappa,\alpha\beta}]_{,\gamma\delta}(\nabla_0\bar h,-1)\Big]\circ\bar\eta^\tau\nabla_0 v_{\kappa t}dS.$$

Integrating from 0 to t and integrating by parts in time, we find that

$$\begin{aligned}&\int_0^t\int_\Gamma \frac{\bar v}{\sqrt{\det(g_0)}}\Big[[\sqrt{\det(g_0)}\bar A^{\alpha\beta\gamma\delta}h_{\kappa,\alpha\beta}]_{,\gamma\delta}(\nabla_0\bar h,-1)\Big]\circ\bar\eta^\tau\nabla_0 v_{\kappa t}dSds\\ &=-\int_0^t\int_\Gamma \frac{\bar v}{\sqrt{\det(g_0)}}\Big[[\sqrt{\det(g_0)}\bar A^{\alpha\beta\gamma\delta}h_{\kappa,\alpha\beta}]_{t,\gamma\delta}(\nabla_0\bar h,-1)\Big]\circ\bar\eta^\tau\nabla_0 v_{\kappa}dSds+R_3,\end{aligned}$$

where R_3 is bounded by

$$\begin{aligned}C\int_0^t\Big[1+\|\tilde v_t\|^2_{H^1(\Omega)}\Big]\|\nabla_0^4h_\kappa\|^2_{L^2(\Gamma)}ds+\delta_2\|\nabla_0^4h_\kappa\|^2_{L^2(\Gamma)}\\ +\delta\int_0^t\|v_\kappa\|^2_{H^3(\Omega)}ds+(\delta+Ct^{1/2})\int_0^t\|v_{\kappa t}\|^2_{H^1(\Omega)}ds\end{aligned}$$

for some constant C depending on M, δ, and δ_2. Next, using that

$$[(-\nabla_0\bar h,1)\circ\bar\eta^\tau]\cdot\nabla_0 v_\kappa=b^t(\nabla_0h_{\kappa t})\circ\bar\eta^\tau+b^t(\nabla_0^2\bar h\circ\bar\eta^\tau,0)\cdot v_\kappa$$

and integrating by parts, we find that the integral on the right-hand side is identical to

$$\frac12\int_0^t\int_\Gamma\frac{1}{\sqrt{\det(g_0)}}\nabla_0\Big[\sqrt{\det(g_0)}\bar\Theta\bar v b^t\bar A^{\alpha\beta\gamma\delta}\Big]h_{\kappa t,\alpha\beta}h_{\kappa t,\gamma\delta}dSds+R_4,$$

where

$$|R_4|\le C(M)C(\delta)\int_0^t\|\nabla_0^4h_\kappa\|^2_{L^2(\Gamma)}ds+\delta\int_0^t\|v_\kappa\|^2_{H^3(\Omega)}ds.$$

By interpolation, the integral part is bounded by

$$C\Big[N(u_0,F)+\int_0^t\|\nabla_0^4h_\kappa\|^2_{L^2(\Gamma)}ds\Big]+\delta\int_0^t\|v_\kappa\|^2_{H^3(\Omega)}ds+Ct\int_0^t\|v_{\kappa t}\|^2_{H^1(\Omega)}ds$$

for some constant C depending on M and δ. Therefore, K_1 satisfies

(C.1)
$$\begin{aligned}\Big|\int_0^tK_1ds\Big|\le C\int_0^t\Big[K(s)\Big(\|\nabla_0^4h_\kappa\|^2_{L^2(\Gamma)}+\|\nabla_0^2h_{\kappa t}\|^2_{L^2(\Gamma)}\Big)+1\Big]ds+\delta_2\|\nabla_0^4h_\kappa\|^2_{L^2(\Gamma)}\\ +(\delta+Ct^{1/2})\int_0^t\|v_\kappa\|^2_{H^3(\Omega)}ds+(\delta+Ct^{1/2})\int_0^t\|v_{\kappa t}\|^2_{H^1(\Omega)}ds\end{aligned}$$

for some constant C depending on M, δ, and δ_2.

For K_2, by time differentiating the evolution equation, we find that

$$\begin{aligned}(-\nabla_0\bar h\circ\bar\eta^\tau,1)v_{\kappa t}=h_{\kappa tt}\circ\bar\eta^\tau+\bar v^\tau\cdot(\nabla_0h_{\kappa t})\circ\bar\eta^\tau-\bar v^\tau\cdot(\nabla_0^2\bar h\circ\bar\eta^\tau,0)\cdot v_\kappa\\ -(\nabla_0\bar h_t\circ\bar\eta^\tau,0)\cdot v_\kappa,\end{aligned}$$

and hence (after a change of coordinates)

$$\begin{aligned}K_2 = &\int_\Gamma [L_{\bar h}(h_\kappa)]_t h_{\kappa tt} dS + \int_\Gamma [L_{\bar h}(h_\kappa)]_t [(\bar v^\tau \circ \bar\eta^{-\tau}) \cdot (\nabla_0 h_{\kappa t})] dS \quad (\equiv K_3)\\ &- \int_\Gamma [L_{\bar h}(h_\kappa)]_t [(\nabla_0 \bar h_t, 0) \cdot (v_\kappa \circ \bar\eta^{-\tau})] dS \quad (\equiv K_4)\\ &- \int_\Gamma [L_{\bar h}(h_\kappa)]_t [(\bar v^\tau \circ \bar\eta^{-\tau}) \cdot (\nabla_0^2 \bar h, 0)(v_\kappa \circ \bar\eta^{-\tau})] dS \quad (\equiv K_5)\\ &+ \int_\Gamma [L_{\bar h}(h_\kappa)] [(\nabla_0 \bar h_t, 0) \cdot (v_{\kappa t} \circ \bar\eta^{-\tau})] dS \quad (\equiv K_6).\end{aligned}$$

For the first term, we have

$$\begin{aligned}\int_\Gamma [L_{\bar h}(h_\kappa)]_t h_{\kappa tt} dS = &\frac{1}{2}\frac{d}{dt}\int_\Gamma \bar A^{\alpha\beta\gamma\delta} h_{\kappa t,\alpha\beta} h_{\kappa t,\gamma\delta} dS\\ &+ \int_\Gamma \frac{1}{\sqrt{\det(g_0)}}\Big[\sqrt{\det(g_0)}(\bar A^{\alpha\beta\gamma\delta})_t\Big]_{,\gamma\delta} h_{\kappa,\alpha\beta} h_{\kappa tt} dS \quad (\equiv K_7) + R_5,\end{aligned} \tag{C.2}$$

where R_5 is bounded by

$$C\Big[1 + \|\tilde h_t\|^2_{H^{2.5}(\Gamma)}\Big]\Big[1 + \|\nabla_0^2 h_{\kappa t}\|^2_{L^2(\Gamma)}\Big] + \delta\Big[\|v_\kappa\|^2_{H^2(\Omega)} + \|\nabla_0^2 v_\kappa\|^2_{H^1(\Omega_1')}\Big] + \delta_1 \|v_{\kappa t}\|^2_{H^1(\Omega)}$$

for some constant C depending on M, δ, and δ_1. Also, by the inequality $\|h_{\kappa tt}\|_{L^4(\Gamma)} \le C(M)\big[\|v_\kappa\|_{H^2(\Omega)} + \|v_{\kappa t}\|_{H^1(\Omega)}\big]$,

$$\begin{aligned}|K_7| &\le C \|[\sqrt{\det(g_0)}(\bar A^{\alpha\beta\gamma\delta})_t]_{,\gamma\delta}\|_{H^{-0.5}(\Gamma)} \left\|\frac{1}{\sqrt{\det(g_0)}} h_{\kappa,\alpha\beta} h_{\kappa tt}\right\|_{H^{0.5}(\Gamma)}\\ &\le C(M)C(\delta,\delta_1)\|\tilde h_t\|^2_{H^{2.5}(\Gamma)}\|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)} + \delta\|v_\kappa\|^2_{H^2(\Omega)} + \delta_1\|v_{\kappa t}\|^2_{H^1(\Omega)}.\end{aligned}$$

REMARK 22. *The bound for K_7 can be refined even further as*

$$|K_7| \le C(M)C(\delta)\|\tilde h_t\|^2_{H^{1.5}(\Gamma)}\|\nabla_0^2 h_\kappa\|^2_{H^{1.5}(\Gamma)} + \delta\|v_\kappa\|^2_{H^3(\Omega)} + \delta\|v_{\kappa t}\|^2_{H^1(\Omega)};$$

it is this inequality that will be used in the proof of the fixed-point argument.

It remains to estimate K_3 to K_6. By proper use of Hölder's inequality,

$$\begin{aligned}|K_3| + |K_5| + |K_6| \le &C\Big[1 + \|\tilde h_t\|^2_{H^{2.5}(\Gamma)}\Big]\Big[1 + \|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)}\Big]\\ &+ (\delta + Ct^{1/2})\|v_\kappa\|^2_{H^3(\Omega)} + \delta\|v_{\kappa t}\|^2_{H^1(\Omega)}\end{aligned}$$

for some constant C depending on M and δ. For K_4, most of the terms can be estimated in the same fashion, except the term

$$\int_\Gamma \frac{1}{\sqrt{\det(g_0)}}\Big[\sqrt{\det(g_0)}\bar A^{\alpha\beta\gamma\delta} h_{\kappa t,\alpha\beta}\Big][(\nabla_0 \bar h_{t,\gamma\delta}, 0) \cdot (v_\kappa \circ \bar\eta^{-\tau})] dS,$$

which is identical to

$$\int_\Gamma \left\{\frac{1}{\sqrt{\det(g_0)}}\Big[\sqrt{\det(g_0)}\bar A^{\alpha\beta\gamma\delta} h_{\kappa t,\alpha\beta}\Big][(\nabla_0 \bar h_{,\gamma\delta}, 0) \cdot (v_\kappa \circ \bar\eta^{-\tau})]\right\}_t dS \ (\equiv K_8) + R_6,$$

where

$$|R_6| \le C\|\tilde{h}\|^2_{H^{5.5}(\Gamma)}\Big[\|v_\kappa\|^2_{L^2(\Omega)} + \|\nabla_0^2 h_{\kappa t}\|^2_{L^2(\Gamma)}\Big] + \delta\|v_\kappa\|^2_{H^3(\Omega)} + \delta_1\|v_{\kappa t}\|^2_{H^1(\Omega)}$$

for some constant C depending on M, δ, and δ_1. Time integrating K_8 and using the interpolation inequality together with Young's inequality, we find that

$$\begin{aligned}\left|\int_0^t K_8(s)ds\right| &\le C(M)\Big[\|u_0\|^2_{H^{2.5}(\Omega)} + \|\nabla_0^2 h_{\kappa t}\|_{L^2(\Omega)}\|v_\kappa\|_{L^4(\Omega)}\Big]\\ &\le C(M)C(\delta_1,\delta_2)N_3(u_0,F) + \delta_2\|\nabla_0^2 h_{\kappa t}\|^2_{L^2(\Gamma)} + \delta_1\int_0^t \|v_{\kappa t}\|^2_{H^1(\Omega)}ds, \end{aligned}\tag{C.3}$$

where

$$\begin{aligned}N_3(u_0,F) := \|u_0\|^2_{H^{2.5}(\Omega)} &+ \|u_0\|^2_{H^{4.5}(\Gamma)} + \|F\|^2_{L^2(0,T;H^1(\Omega))}\\ &+ \|F_t\|^2_{L^2(0,T;H^1(\Omega)')} + \|F(0)\|^2_{H^1(\Omega)} + 1,\end{aligned}$$

and we use $\|v_\kappa\|^2_{H^1(\Omega)} \le C\big[\int_0^t \|v_{\kappa t}\|^2_{H^1(\Omega)}ds + \|u_0\|^2_{H^1(\Omega)}\big]$ to obtain (C.3), and hence

$$\begin{aligned}\sum_{i=3}^6 |K_i| \le C\Big[1 + \|\tilde{h}\|^2_{H^{5.5}(\Gamma)} + \|\tilde{h}_t\|^2_{H^{2.5}(\Gamma)}\Big]\Big[1 + \|v_\kappa\|^2_{L^2(\Omega)} + \|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)}\Big]\\ + (\delta + Ct^{1/2})\|v_\kappa\|^2_{H^3(\Omega)} + \delta_1\|v_{\kappa t}\|^2_{H^1(\Omega)} + K_8\end{aligned}\tag{C.4}$$

with K_8 satisfying inequality (C.3). Finally, combining all the estimates,

(C.5)

$$\begin{aligned}&\int_0^t \|\nabla_0^2 h_{\kappa t}\|^2_{L^2(\Gamma)}ds \le \int_0^t\int_\Gamma \Big[[L_{\bar{h}}(h_\kappa)(\nabla_0\bar{h},-1)]\circ\bar{\eta}^\tau\Big]_t \cdot v_{\kappa t}dS + CN_3(u_0,F)\\ &+ C\int_0^t K(s)\Big[\|v_\kappa\|^2_{L^2(\Omega)} + \|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)} + \|\nabla_0^2 h_{\kappa t}\|^2_{L^2(\Gamma)}\Big]ds\\ &+ (\delta + Ct^{1/2})\int_0^t \|v_\kappa\|^2_{H^3(\Omega)}ds + (\delta_1 + Ct^{1/2})\int_0^t \|v_{\kappa t}\|^2_{H^1(\Omega)}ds + \delta_2\|\nabla_0^4 h_\kappa\|^2_{L^2(\Gamma)}\end{aligned}$$

for some constant C depending on M, δ, δ_1, and δ_2.

Acknowledgment. We thank the referees for the valuable comments that helped improve the manuscript.

CLASSICAL SOLUTIONS FOR NONELLIPTIC EULER–LAGRANGE EQUATIONS VIA CONTINUATION*

MARKUS LILLI†

Abstract. We consider a higher-gradient model in one-dimensional nonlinear elasticity. Therefore we consider a physically reasonable stored-energy density W such that $W(\nu)$ goes to infinity for $\nu \searrow 0$ and $\nu \nearrow \infty$. We prescribe a parameter-dependent body-forcing. Our main goal is to show under a certain sign condition for the body-force that global solution branches of the singular perturbed problem converge to a global branch of weak solutions of vanishing capillarity. Moreover, the solution satisfies the first and the second Weierstrass–Erdmann corner conditions, and the strain field is uniformly pointwise positive.

Key words. nonlinear elasticity, singular limits, global continuation

1. Introduction. This paper is motivated to a large extent by results presented in [10]. There a two-phase model for an elastic solid in the presence of live body-forcing and interfacial or higher-gradient effects is considered, the latter characterized by a small capillarity coefficient $\varepsilon > 0$. The existence of families of equilibria is proved by continuation methods, and the main goal in [10] is the analysis of those solutions in the limit $\varepsilon \searrow 0$. Assuming that the loading is bounded and everywhere nonnegative, uniform a priori bounds on solutions via maximum-principle arguments are obtained. An important by-product of that analysis is a certain monotonicity property for all solutions. In the end, global weak solutions that satisfy the Maxwell condition are obtained.

In this work we pursue precisely the same question, but we allow the loading to change sign exactly one time in a prescribed manner. The latter makes the application of maximum principles much more delicate. We impose very general, physically reasonable growth conditions on both the stored-energy function and the body-force function. Also, in contrast to [10], we impose the pointwise unilateral constraint introduced in [4], ensuring that all deformations of the bar are injective (with the concomitant infinite growth of the stored energy).

The outline of the work is as follows: In the second section we introduce the model, the variational problem under consideration, and the corresponding Euler–Lagrange equation. Afterwards we give the assumptions on the potentials. The existence of solutions of the singular perturbed Euler–Lagrange equation via a global implicit function theorem is fairly routine, which we summarize in section 3. Uniform a priori bounds on solutions are given in section 4. There we pay careful attention to the injectivity constraint and show that the strains are uniformly (pointwise) positive. Furthermore, we prove the unboundedness of the branch. To prove this for every λ is another main difference compared to [10], where a similar result is obtained via a maximum principle which does not apply to the more general body-force considered

in this work. Our approach also applies in [10]. Hence all the results given there remain valid if one replaces the condition that the body-force is bounded by the more general growth conditions given in Theorem 5. The next section is the core of the paper. We introduce a further assumption on the body-force, namely, that it changes sign exactly once. By a careful application of maximum principles and monotonicity criteria, we prove some properties for all solutions lying on the branch. These properties enable us to obtain a singular limit in a classical function space (in contrast to [21], where, under weaker assumptions on the body-force, the existence of Young-measure solutions was proved). Moreover, we show in section 6 that this limit is a solution of the Euler–Lagrange equation of the unperturbed problem and satisfies the Maxwell conditions, forming a global and unbounded continuum. We remark that the results denoted here, without imposing the pointwise unilateral constraint ensuring that all deformations of the bar are injective, can also be found in [20].

One of the most powerful tools in nonlinear analysis is the Leray–Schauder degree. It was especially used for semilinear elliptic PDEs of second order to prove existence and obtain qualitative properties of classical solutions (see [25], or, for a recent treatment, [17]). Even in quasi-linear equations the degree was used to obtain branches of positive solutions (see, e.g., [19]). In [14], [15], [16] the existence of classical solutions of a nonelliptic Euler–Lagrange equation was proved also by using singular perturbation, which in recent years has become a widely used tool to tackle nonconvex variational problems (see, e.g., [18], [22]).

In three-dimensional elasticity problems, global continuation results were obtained in [9], [11], [12] by employing generalized degree theoretic methods. In this case, the resulting solution continua are characterized not only by the usual two alternatives given in [25], but also by a third concerning the termination of the branch. This phenomenon can happen due to loss of local injectivity, ellipticity, and/or the complementing condition.

2. Formulation. We briefly discuss the physical model behind our analysis. We follow the lines of [13]; see also [8], [21].

We consider a one-dimensional elastic solid placed in a soft loading device. Let $[0,1]$ be the reference configuration in the undeformed state and let $v = v(x)$ be the displacement of the material point occupying position x in the undeformed state. Hence, $u(x) = x + v(x)$ is the placement of the bar, and $u'(x) = 1 + v'(x)$ is the stretch ratio.

We assume the bar to be homogenous, which means that the stored-energy density $W \in C^2(\mathbb{R}^+)$ is independent of the spatial variable and depends only on u'. Furthermore, let $B(\lambda, u, x) : \mathbb{R} \times \mathbb{R}_0^+ \times [0,1] \mapsto \mathbb{R}$ be a potential delivering in general a live body-force

$$-\frac{\partial B}{\partial u}(\lambda, u, x) := b(\lambda, u, x),$$

where $b \in C(\mathbb{R} \times \mathbb{R}_0^+ \times [0,1])$. The left end of the bar is fixed, which assigns the boundary condition $u(0) = 0$. We assume

$$b(0, \cdot, \cdot) \equiv 0. \tag{2.1}$$

We consider a potential $W \geq 0$ and we impose the following assumptions on $W \in C^2(\mathbb{R}^+)$: Because we assume the bar to be stable in the undeformed state, we derive

$$W(1) = \sigma(1) = 0 \text{ and } W''(1) > 0, \tag{2.2}$$

where $\sigma(\nu) := W'(\nu)$ denotes the stress. Moreover,

$$\begin{aligned} &W(\nu) \geq W(1) = 0 \text{ for every } \nu \in \mathbb{R}^+, \\ &\lim_{\nu \searrow 0} W(\nu) = \lim_{\nu \nearrow \infty} W(\nu) = \infty. \end{aligned} \tag{2.3}$$

Condition $(2.3)_2$ reflects the fact that one needs an infinite amount of energy to compress the bar to volume zero and also that an infinite amount of energy is necessary to stretch the bar to infinity.

Furthermore, we assume the existence of ν_1, $\nu_2 \in (1, \infty)$ such that

$$W''(\nu) \begin{cases} < 0 \text{ for } \nu \in (\nu_1, \nu_2), \\ > 0 \text{ otherwise.} \end{cases} \tag{2.4}$$

Let W be a so-called one-well potential, which means

$$\sigma(\nu) \begin{cases} < 0 \text{ for } \nu \in (0, 1), \\ > 0 \text{ for } \nu \in (1, \infty). \end{cases} \tag{2.5}$$

We require the following growth conditions for σ and b:

(i) We assume

$$\lim_{\nu \to \infty} \frac{\sigma(\nu)\nu}{|\nu|^{p+1}} \geq K > 0 \tag{2.6}$$

and

(ii)

$$\sup_{\lambda \in [-\hat{\lambda}, \hat{\lambda}]} |b(\lambda, u, x)| \leq c_3 |u|^r + c_4 \tag{2.7}$$

for some $r < p$, $c_3 = c_3(\hat{\lambda})$, $c_4 = c_4(\hat{\lambda}) \geq 0$. Moreover, we have c_3, $c_4 < \infty$ provided that $\hat{\lambda} < \infty$ and both constants can be chosen independently of x.

The total *potential energy* of the bar is given by

$$\begin{aligned} &J(u) := \int_0^1 [W(u') + B(\lambda, u, x)]\, dx, \\ &u(0) = 0. \end{aligned} \tag{2.8}$$

Here "λ" is a loading parameter. The corresponding Euler–Lagrange equation is

$$\begin{aligned} &\frac{d}{dx} [\sigma(u')] + b(\lambda, u, x) = 0, \\ &u(0) = 0 \quad \text{and} \quad \sigma(u'(1)) = 0. \end{aligned} \tag{2.9}$$

Note that (2.8) has no global minimizer, in general, due to the fact that W is nonconvex. In particular, existence of a solution of (2.9) cannot be guaranteed by the direct methods of the calculus of variations (see [7] for details). For the same reason, the boundary value problem (2.9) is singular, obviating any systematic solution strategy.

Instead we introduce a “relaxed” variational problem by adding an additional strain gradient-term, intended to model interfacial energy:

$$
\begin{aligned}
J_\varepsilon(u) &:= \int_0^1 \Big(\frac{\varepsilon}{2}(u'')^2 + W(u') + B(\lambda, u, x)\Big)\, dx, \\
u(0) &= 0,
\end{aligned}
\tag{2.10}
$$

where $\varepsilon > 0$ is a small parameter. The Euler–Lagrange equation of equilibrium is the fourth-order equation

$$
-\varepsilon u^{(4)} + \frac{d}{dx}\left[\sigma(u')\right] + b(\lambda, u, x) = 0 \tag{2.11}
$$

with boundary conditions

$$
u(0) = u''(0) = u''(1) = 0, \qquad \varepsilon u'''(1) = \sigma(u'(1)). \tag{2.12}
$$

Integration of (2.11) yields the system

$$
\begin{aligned}
u' &= z, \\
-\varepsilon z'' + \sigma(z) &= \int_x^1 b(\lambda, u(\eta), \eta) d\eta, \\
u(0) &= z'(0) = z'(1) = 0.
\end{aligned}
\tag{2.13}
$$

In contrast to (2.8) and (2.9), (2.10) and (2.13) are amenable to existence methods for each $\varepsilon > 0$ (see [3], [7], [10] for details).

3. Global analysis. We just sketch the ideas. The details can be found in [10] and [20]. The only difference is that one has to take care of $(2.3)_2$, which is done by methods introduced in [9].

We define $Y := C^2([0,1])$, we let

$$
Y_0 := \{y \in Y \mid y(0) = 0\}, Y_1 := \left\{y \in Y \mid \int_0^1 y dx = 0\right\},
$$

and, moreover, we define

$$
\mu := \int_0^1 u'(s) ds = \int_0^1 z(s) ds, \quad v := z - \mu.
$$

Finally we define the triple

$$
w := (u, v, \mu) \in \mathcal{W} \equiv Y_0 \times Y_1 \times \mathbb{R},
$$

where $\mathcal{W}$ is endowed with the norm $||w||_{\mathcal{W}} = ||u||_{C^2} + ||v||_{C^2} + |\mu|$ and, in particular, $\mathcal{W}$ is a Banach space. Moreover, let

$$
K := \{(y, \mu) \in Y_1 \times \mathbb{R} \mid y(x) + \mu > 0 \text{ for all } x \in [0,1]\}
$$

and for arbitrary $\delta > 0$

$$
K_\delta := \{(y, \mu) \in K \mid y(x) + \mu > \delta \text{ for all } x \in [0,1]\}.
$$

Obviously $(\lambda, w) := (0, w_0) \in \mathbb{R} \times \mathcal{W}$ is a solution of (2.13), where

$$w_0 := (Id, 0, 1).$$

By an easy calculation one obtains that (2.13) can be written as a compact perturbation of the identity (see [10] for details). Hence the Leray–Schauder degree is well defined, and a well-known argument proved in [25] and generalized in [9], employing the homotopy invariance of the degree and taking the restriction $u' > 0$ into account, yields the following proposition.

Proposition 1. *Let $\mathcal{C}_\varepsilon \subset \mathbb{R} \times \mathcal{W}$ be the connected component of solutions of* (2.13) *containing the trivial solution* $(0, w_0)$. *Then $\mathcal{C}_\varepsilon$ is characterized by at least one of the following alternatives:*

(i) *$\mathcal{C}_\varepsilon$ is unbounded in $\mathbb{R} \times \mathcal{W}$.*
(ii) *$\mathcal{C}_\varepsilon \setminus \{(0, 0)\}$ is connected.*
(iii) *$\mathcal{C}_\varepsilon \setminus \mathbb{R} \times Y_0 \times K_\delta \neq \emptyset$ for every $\delta > 0$.*

Remark 2. Alternative (ii) means that the branch forms a loop. The third alternative means that the branch can terminate and is due to the singularity of W. If (iii) holds, then there exists a sequence $(\lambda_n, u_n, z_n)_{n\in\mathbb{N}} \in \mathcal{C}_\varepsilon$ and $(x_n)_{n\in\mathbb{N}} \in [0, 1]$ with

$$(\lambda_n)_{n\in\mathbb{N}} \text{ is bounded and } z_n(x_n) \searrow 0.$$

4. Properties of the continuum. By a standard phase-plane analysis like the one in [5] it is easy to show that alternative (ii) in Proposition 1 is impossible (see [10] for details).

Furthermore, we have the following theorem.

Theorem 3. *Let σ and b satisfy the growth conditions* (2.6) *and* (2.7). *Fix some arbitrary λ_0 and let $(\lambda, u_\varepsilon^\lambda, v_\varepsilon^\lambda, \mu_\varepsilon^\lambda) \in \mathcal{C}_\varepsilon$ for $\lambda \in [-\lambda_0, \lambda_0]$ and $z_\varepsilon^\lambda := v_\varepsilon^\lambda + \mu_\varepsilon^\lambda$. Then there exists some $\delta > 0$, such that for every $\lambda \in [-\lambda_0, \lambda_0]$ and for every $\varepsilon > 0$ we have*

$$z_\varepsilon^\lambda(x) > \delta$$

for all $x \in [0, 1]$.

We give a sketch of the proof. For a detailed proof we refer to [21].

We prove by contradiction and therefore we assume sequences $(\varepsilon_n)_n$, $(x_n)_n \in [0, 1]$ and $(z_{\varepsilon_n})_n := (z_n)_n$ with

$$\varepsilon_n \searrow 0, \quad z_n(x_n) \searrow 0.$$

Step 1. First we prove by virtue of (2.13), $(2.3)_2$, and (2.7) $||z_n||_{L^{p+1}} \to \infty$.

Step 2. We define

$$A_n := \{x \in [0, 1] \mid z_n(x) > 1\} := \bigcup_{j=1}^{k(n)} (x_1^j(n), x_2^j(n)).$$

Observe that

$$z_n'(x_1^j(n)) \geq 0, \quad z_n'(x_2^j(n)) \leq 0 \tag{4.1}$$

for all j. Multiplying (2.13) by z_n and integrating over A_n yields

$$\int_{A_n} \sigma(x, z_n) z_n dx \leq \int_{A_n} \left[\int_x^1 (b(u_n(\eta), \eta) d\eta + \tau) \, z_n \right] dx \tag{4.2}$$

for every $n \in \mathbb{N}$.

Step 3. From Step 1 we deduce

$$||z_n||_{L^{p+1}(A_n)} \to \infty. \tag{4.3}$$

Multiplying (4.2) by $\frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}}$, we obtain for every $n \in \mathbb{N}$

$$\begin{aligned} &\frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}} \int_{A_n} \sigma(x, z_n) z_n \, dx \\ &\qquad \le \frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}} \int_{A_n} \left(\int_x^1 b(u_n(\eta), \eta) d\eta + \tau \right) z_n dx. \end{aligned} \tag{4.4}$$

One can prove the following:

(a) The right side of (4.4) converges to 0 for $n \to \infty$.

(b) We have

$$\lim_{n\to\infty} \frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}} \int_{A_n} \sigma(x, z_n) z_n \, dx \ge K > 0 \tag{4.5}$$

with K given in (2.6).

By virtue of (4.4) we get

$$\begin{aligned} 0 < K &\le \lim_{n\to\infty} \left(\frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}} \int_{A_n} \sigma(x, z_n) z_n \, dx \right) \\ &\le \lim_{n\to\infty} \left(\frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}} \int_{A_n} \left(\int_x^1 b(u_n(\eta), \eta) d\eta + \tau \right) z_n \, dx \right) = 0, \end{aligned}$$

which is obviously a contradiction.

Remark 4. For fixed λ consider $(u_\varepsilon, v_\varepsilon, \mu_\varepsilon) \in \mathcal{C}_\varepsilon$ with associated z_ε. Then, by Theorem 3 there exists $\delta > 0$ such that $z_\varepsilon > \delta$ for every $\varepsilon > 0$. In particular, Theorem 3 excludes alternative (iii) for every finite λ_0.

Hence the global continuum $\mathcal{C}_\varepsilon$ is unbounded in $\mathbb{R} \times \mathcal{W}$, but one can prove more by the assumed growth conditions on σ and b.

THEOREM 5. *Let σ and b satisfy* (2.6), (2.7) *and let $\varepsilon > 0$. Then the projection of $\mathcal{C}_\varepsilon$ onto the λ-axis is $\mathbb{R}$.*

For the proof we refer to [21]; see also [20].

LEMMA 6. *Let σ and b satisfy the growth conditions as in Theorem* 5 *and let $(z_n)_{n\in\mathbb{N}}$ be a sequence with $z_n \in \mathcal{C}_{\varepsilon_n}$ for all n as $\varepsilon_n \searrow 0$. Then we obtain the following: The sequence $(z_n)_{n\in\mathbb{N}}$ is uniformly bounded in $C^0([0,1])$. Furthermore, there exists a subsequence of $(z_n)_{n\in\mathbb{N}}$, which we again denote by $(z_n)_{n\in\mathbb{N}}$, such that the following holds: We have $\varepsilon_n z_n'' \rightharpoonup^* 0$ in $L^\infty(0,1)$.*

One can find the proof of Lemma 6 in [21]. For the reader's convenience we give a sketch of the proof.

Let $(z_n)_{n\in\mathbb{N}}$ be a sequence as in Lemma 6 and assume the existence of $x_m \in [0,1]$ and n_m such that $z_{n_m}(x_m) > m$ for every $m \in \mathbb{N}$. Without loss of generality, we assume that $x = x_m$ is a maximum of z_{n_m}. By properties (2.5) and (2.6) we deduce

$$\lim_{m\to\infty} \sigma(z_{n_m}(x_m)) = \infty. \tag{4.6}$$

Moreover, we have for every $m \in \mathbb{N}$

$$-\varepsilon_{n_m} z''_{n_m}(x_m) + \sigma(z_{n_m}(x_m)) = \int_{x_m}^1 b(\lambda, u_{n_m}(\eta), \eta) d\eta. \tag{4.7}$$

The growth conditions (2.7) imply that for every $m \in \mathbb{N}$

$$\left| \int_{x_m}^1 b(\lambda, u_{n_m}(\eta), \eta) d\eta \right| \leq c_5,$$

where c_5 is independent of m. Therefore we have by (4.6) and (4.7)

$$z''_{n_m}(x_m) > 0$$

for m sufficiently large. On the other hand, we have $z'_{n_m}(x_m) = 0$ for every $m \in \mathbb{N}$. Hence x_m cannot be a maximum, which contradicts our assumption.

5. Geometric structure of $\mathcal{C}_\varepsilon^+$. In order to obtain a priori estimates for $(z_n)_{n\in\mathbb{N}}$ to establish *strong* convergence in some Sobolev space, we consider a body-force potential b with the following properties.

There exists $x_0 = x_0(\lambda) \in (0, 1)$ such that for every $\lambda \in \mathbb{R}^+$ and $u \in \mathbb{R}_0^+$ we have

(H1) $b(\lambda, u, \cdot)_{|[0,x_0]} \geq 0$,
(H2) $b(\lambda, u, \cdot)_{|[x_0,1]} \leq 0$.
(H3) Furthermore, there exist an open subset $\Omega_2 \subseteq (x_0, 1]$ and $b(\lambda, u, \cdot)_{|\Omega_2} < 0$.
(H4) There exists $\vartheta > 0$ such that $b(\lambda, u, \cdot)_{|(0,\vartheta)} > 0$ for every $\lambda \in \mathbb{R}^+$ and $u \in \mathbb{R}_0^+$.

Example 7. The above assumptions are valid for the following body-force: Let W be some "one-well" potential satisfying the growth conditions with some $p \in \mathbb{N}$, and let $b(\lambda, u, x) := c(\lambda, x)(1 + u^r)$ with $r < p$, $c \in C(\mathbb{R} \times [0, 1], \mathbb{R})$ and c changing sign from + to − at $x_0 = x_0(\lambda)$ for $\lambda > 0$.

Let $\mathcal{C}_\varepsilon^+$ be the unbounded branch obtained by the global implicit function theorem for fixed $\varepsilon > 0$ and $\lambda > 0$, and let $(u, v, \mu) \in \mathcal{C}_\varepsilon^+$, $z := v + \mu$. For our convenience we say $z \in \mathcal{C}_\varepsilon$ if z is constructed as above. Our goal is to show that by virtue of (H1)–(H4) z' changes sign in $(0, 1)$ at most once.

One can find the following definition in [2].

DEFINITION 8. *A function v has exactly k changes of sign in* $[0, 1]$ *provided that the following hold:*

(i) *There are points $s_1 < s_2 < \cdots < s_{k+1} \in [0, 1]$ with $v(s_i)v(s_{i+1}) < 0$ for all $i = 1, \ldots, k$.*
(ii) *We will say that v changes sign at the points $x_1 < \cdots < x_k$ provided $v(x_i) = 0$ and the points in* (i) *can be chosen so that $s_i < x_i < s_{i+1}$ and v does not change sign in $[x_i, x_{i+1}]$.*

Let us further remark that for our forthcoming analysis differentiation of (2.13) turns out to be very useful:

$$\begin{aligned} &h = z', \\ &\varepsilon h'' - \sigma'(z)h = b(\lambda, u, \cdot), \\ &h(0) = h(1) = 0. \end{aligned} \tag{5.1}$$

Remark 9. By the continuation method, (2.4), and $z_{|\{\lambda=0\}} \equiv 1$, there exists λ_0 sufficiently small such that $\sigma'(z_\lambda) > 0$ for every $0 \leq \lambda \leq \lambda_0$.

Hence we derive the following lemma.

LEMMA 10. *Let $z_\lambda \in \mathcal{C}_\varepsilon^+$ and consider λ_0 such that $\sigma'(z_\lambda)_{|\lambda\in[0,\lambda_0]} > 0$. Then z'_λ changes sign at most once for $0 < \lambda \le \lambda_0$.*

Proof. We prove by contradiction and accordingly we assume that z'_λ changes sign at least two times in $[0,1]$. By Definition 8 there exist $s_1, s_2, s_3 \in (0,1)$ with $z'_\lambda(s_i)z'_\lambda(s_{i+1}) < 0$ and $x_1, x_2 \in (0,1)$ such that $s_1 < x_1 < s_2 < x_2 < s_3$ and $z'_\lambda(x_1) = z'_\lambda(x_2) = 0$. By the boundary condition $z'_\lambda(0) = z'_\lambda(1) = 0$ we have three nodal areas of z'_λ in $[0,1]$. On the other hand, we have just one sign change of b, and hence, there exists a nodal area $\Omega' \subseteq [0,1]$ of z'_λ such that

$$\operatorname{sign} b_{|\Omega'} = \operatorname{sign} z'_{\lambda|\Omega'}. \tag{5.2}$$

For every $x \in \Omega'$ we have by (5.1)

$$\begin{aligned} \varepsilon(z'_\lambda)'' - \sigma'(z_\lambda)z'_\lambda &= b, \\ z'_{\lambda|\partial\Omega'} &= 0. \end{aligned} \tag{5.3}$$

By the weak maximum principle we conclude $\operatorname{sign} b_{|\Omega'} \ne \operatorname{sign} z'_{\lambda|\Omega'}$, which contradicts (5.2). ∎

First we give a property of an arbitrary solution of (2.13).

LEMMA 11. *Let z be a solution of* (2.13). *Then there is no negative minimum of z' in $(x_0, 1)$.*

Proof. Suppose there exists $x_1 \in (x_0, 1)$ with

$$z'(x_1) < 0, \quad z''(x_1) = 0, \quad z'''(x_1) \ge 0.$$

With respect to the identity

$$-\sigma'(z(x_1))z'(x_1) = -\varepsilon z'''(x_1) + b(\lambda, u(x_1), x_1) \le 0,$$

we obtain by (2.4)

$$z(x_1) \in [\nu_1, \nu_2] \subseteq (1, \infty). \tag{5.4}$$

On the other hand, we have the identity $\sigma(z(x_1)) = \int_{x_1}^1 b(\lambda, u(\tau), \tau)d\tau \le 0$, which yields $z(x_1) \le 1$ by (2.5), and this contradicts (5.4). ∎

Again maximum principles yield for λ sufficiently small the following lemma.

LEMMA 12. *Let λ_0 be defined by Remark* 9 *and let $z_\lambda \in \mathcal{C}_\varepsilon^+$ for $\lambda < \lambda_0$ and an arbitrary $\varepsilon > 0$. Then there exists no interval $J \subseteq [0, x_0]$ such that $z'_{\lambda|J} \equiv 0$.*

Proof. Suppose there exists an interval $J := [x_\alpha, x_\beta] \subseteq [0, x_0]$ with $z'_{\lambda|J} \equiv 0$. For the remainder of the proof we omit λ. Let $\hat{x} \in (x_\alpha, x_\beta)$ and $z'_{|(0,\hat{x})}$ satisfy the equation

$$\begin{aligned} \varepsilon(z')'' - \sigma'(z)z' &= b \ge 0, \\ z'(0) = z'(\hat{x}) &= z''(\hat{x}) = 0. \end{aligned} \tag{5.5}$$

The weak maximum principle tells us $z'_{|(0,\hat{x})} \le 0$, and the strong maximum principle implies $z'_{|(0,\hat{x})} \equiv 0$ and, in particular, $z'_{|(0,x_\beta)} \equiv 0$. By virtue of (5.5) we have $b_{|(0,x_\beta)} \equiv 0$, contradicting (H4). ∎

LEMMA 13. *Let λ_0 be defined by Remark* 9 *and let $\lambda \in (0, \lambda_0)$ and $z_\lambda \in \mathcal{C}_\varepsilon^+$ for an arbitrary but fixed $\varepsilon > 0$. We assume the existence of an interval $J \subseteq (x_0, 1)$ such* *that* $z'_{\lambda|J} \equiv 0$. *Then we obtain* $z'_\lambda(x) \le 0$ *for every* $x \in [0,1]$. *Moreover, there exists* $\bar{x} \in (x_0, 1]$ *with* $z'_{\lambda|(0,\bar{x})} < 0$ *and* $z'_{\lambda|(\bar{x},1)} \equiv 0$.

Proof. Let $J := [x_\alpha, x_\beta] \subseteq (x_0, 1)$ be an interval with $z'_{\lambda|J} \equiv 0$. Similar to the proof of Lemma 12, one can show that this implies

$$z'_{\lambda|[x_\alpha,1]} \equiv 0.$$

Furthermore (H3) excludes $z'_{\lambda|(x_0,1)} \equiv 0$. Thus there exists an $x \in (x_0, 1)$ such that $z'_\lambda(x) \ne 0$, and we let $\bar{x} \in (x_0, 1)$ such that $z'_\lambda(\bar{x}) = z''_\lambda(\bar{x}) = 0$ and $z'_\lambda(x) \ne 0$ for $x \in (\bar{x} - \delta, \bar{x})$ for some $\delta > 0$. The strong maximum principle applied to (5.1) implies

$$z'_{\lambda|(\bar{x}-\delta,\bar{x})} < 0.$$

The weak maximum principle yields

$$z'_{\lambda|(x_0,1)} \le 0, \quad z'_{\lambda|(x_0,\bar{x})} < 0.$$

By a further application of the maximum principle the proof is done. ∎

By virtue of Lemmas 12 and 13 we can refine our possibilities for z'_λ for λ small.

Corollary 14. *Choose an arbitrary but fixed* $\varepsilon > 0$. *Furthermore, consider* $z_\lambda \in \mathcal{C}^+_\varepsilon$ *for* $\lambda \in (0, \lambda_0)$ *with* λ_0 *such that* $\sigma'(z_\lambda) > 0$. *Then we have the following two possibilities:*

(i) z'_λ *has exactly one sign change, and, moreover,* $z''_\lambda(0) < 0$, $z''_\lambda(1) < 0$, *and the only zero at* $x = x_1$ *of* z'_λ *is nondegenerate with* $z''_\lambda(x_1) > 0$. *In particular, the zero of* z'_λ *in* $(0,1)$ *is unique,* $z'_{\lambda|(0,x_1)} < 0$, $z'_{\lambda|(x_1,1)} > 0$.

(ii) z'_λ *does not change sign, and if there exists an interval* $J \subseteq (0,1)$ *such that* $z'_{\lambda|J} \equiv 0$, *then* $J = (\bar{x}, 1]$ *with* $\bar{x} > x_0$ *and* $z'_{\lambda|(0,\bar{x})} < 0$.

Proof. We let λ_0 be defined as above and we omit λ in the remainder of the proof.

(i) We assume that z' has exactly one sign change at x_1. By virtue of Lemmas 12 and 13 there exists no interval J with $z'_{|J} \equiv 0$, and the weak maximum principle applied to (5.1) implies immediately $z'_{|(0,x_1)} \le 0$ and $z'_{|(x_1,1)} \ge 0$. Hopf's maximum principle yields the assertion.

(ii) This case is identical to Lemmas 12 and 13. ∎

In the remainder of this section we propose a continuation method to obtain the following: The function z'_λ has at most one sign change in $(0,1)$ for every $\lambda \in \mathbb{R}^+$.

Remark 15. Because $\mathcal{C}^+_\varepsilon$ is connected in the C^2-topology by construction of the continuum, we deduce that the corresponding z'_λ are connected in the C^1-topology. A well-known result is the following proposition.

Proposition 16. *There are two (respectively, three) possibilities for creating a new zero on a* C^1*-component:*

1. *There exists* $x_2 \in (0,1)$ *such that* $z'(x_2) = z''(x_2) = 0$ *and, moreover, we have* $\operatorname{sign}(z'(x_2 - \gamma)) = \operatorname{sign}(z'(x_2 + \gamma))$ *for every* $\gamma \in (0, \kappa)$, κ *sufficiently small.*
2. *To create a new zero at the boundary we assume either* $z''(0) = 0$ *or* $z''(1) = 0$.
3. *Another possibility in case* (i) *of Corollary* 14 *is the following: Let* z' *change sign at* $x = x_1$ *with* $z'(x_1) = z''(x_1) = 0$.

In the forthcoming analysis we will often apply the well-known generalized maximum principle to (5.1), where the sign of $\sigma'(z)$ does not matter. In what follows we refer to Hopf's generalized maximum principle by (HGM). For a proof of (HGM) we refer to [24].

Lemma 17. *Let $\lambda_1 \in \mathbb{R}^+$ and let $x = x_1 \in (0,1)$ be the nondegenerate zero of z'_{λ_1} such that $z'_{\lambda_1|(0,x_1)} < 0$ and $z'_{\lambda_1|(x_1,1)} > 0$. Moreover, we assume $z''_{\lambda_1}(0) < 0$ and $z''_{\lambda_1}(1) < 0$. Then we have two possibilities:*

1. *z'_λ has the same properties as z'_{λ_1} for every $\lambda > \lambda_1$.*
2. *We obtain existence of $\lambda_2 > \lambda_1$ with $z'_{\lambda_2} \le 0$. Moreover, we have $z''_{\lambda_2}(0) < 0$, and if there exists an interval $J \subseteq [0,1]$ with $z'_{\lambda_2|J} \equiv 0$, then $J = [x_2, 1]$ for some $x_2 > x_0$.*

Proof. Let x_1 be the nondegenerate zero of z'_{λ_1}, and by assumption we have

$$z'_{\lambda_1|(0,x_1)} < 0 \text{ and } z'_{\lambda_1|(x_1,1)} > 0.$$

Step 1. First we exclude the creation of a new zero if $x_1 \in (x_0, 1)$.

Suppose the existence of $\lambda_2 > \lambda_1$ and $x_2 \in (0, x_0)$ with $z'_{\lambda_2}(x_2) = z''_{\lambda_2}(x_2) = 0$. Moreover, we have $\operatorname{sign}(z'_{\lambda_2}(x_2 - \gamma)) = \operatorname{sign}(z'_{\lambda_2}(x_2 + \gamma))$ for every $\gamma \in (0, \kappa)$, κ sufficiently small. We know by Corollary 14 and the continuation method that $z'_{\lambda_2|(0,x_2)} < 0$, and, furthermore, we have

$$\varepsilon(z')'' - \sigma'(z)z' = b,$$

$$z'(0) = z'(x_2) = 0.$$

(HGM) yields $z'_{\lambda_2|[0,x_2]} \equiv 0$, which is impossible by (H4).

If we assume the existence of $x_3 \in (x_0, x_1)$ with $z'_{\lambda_2}(x_3) = z''_{\lambda_2}(x_3) = 0$, then we have two possibilities:

1. There exists $x' \in (x_3, x_1)$ such that z'_{λ_2} possesses a negative minimum at x', which is impossible by Lemma 11.
2. We have $z'_{\lambda_2|(x_3,1)} \equiv 0$ and we obtain $z'_{\lambda_2} \le 0$.

If we consider $x_4 \in (x_1, 1)$ with $z'_{\lambda_2}(x_4) = z''_{\lambda_2}(x_4) = 0$, then we obtain $z'_{\lambda_2|(x_4,1)} \equiv 0$ and $z'_{\lambda_2} \le 0$ by virtue of (HGM).

We consider the creation of a new zero at the boundary: First we observe that $z''_{\lambda_2}(0) = 0$ for some $\lambda_2 > \lambda_1$ is impossible by (HGM). Moreover, $z''_{\lambda_2}(1) = 0$ predicts again $z'_{\lambda_2} \le 0$.

Step 2. We consider $x_1 \in (0, x_0)$ such that $z'_{\lambda_1|(0,x_1)} < 0$ and $z'_{\lambda_1|(x_1,1)} > 0$.

First we exclude possibility one of Proposition 16: If there exists $x_2 \in (0, x_1)$, respectively, $x_3 \in (x_0, 1)$ with $z'_{\lambda_2}(x_j) = z''_{\lambda_2}(x_j) = 0$ for $j = 2, 3$ and for some $\lambda_2 > \lambda_1$, we obtain again by (HGM)

$$z'_{\lambda_2|(0,x_1)} \equiv 0, \text{ respectively, } z'_{\lambda_2|(x_0,1)} \equiv 0.$$

Both are impossible by virtue of (5.1) and (H3), (H4).

The case $x_4 \in (x_1, x_0)$ with $z'_{\lambda_2}(x_4) = z''_{\lambda_2}(x_4) = 0$ for some $\lambda_2 > \lambda_1$ involves more difficulties because a maximum principle does not apply. First we observe by the continuation method the existence of $\bar{x} \in (x_1, x_4)$ with

$$z'_{\lambda_2}(\bar{x}) > 0, \quad z''_{\lambda_2}(\bar{x}) = 0, \quad z'''_{\lambda_2}(\bar{x}) \le 0.$$

By the identity

$$-\sigma'(z_{\lambda_2}(\bar{x}))z'_{\lambda_2}(\bar{x}) = b(\lambda_2, u(\bar{x}), \bar{x}) - \varepsilon z'''_{\lambda_2}(\bar{x}) \ge 0,$$

we deduce $\sigma'(z_{\lambda_2}(\bar{x})) \le 0$ and therefore

$$z_{\lambda_2}(\bar{x}) \in [\nu_1, \nu_2].$$

Because of $z'_{\lambda_2|(x_1,1)} \geq 0$ we know that $z_{\lambda_2}(1) \geq z_{\lambda_2}(\bar{x}) \geq \nu_1 > 1$, and by virtue of $\sigma(z_{\lambda_2}(1)) = \varepsilon z''_{\lambda_2}(1)$ we get $z''_{\lambda_2}(1) > 0$, which yields

$$z'_{\lambda_2|(1-\varrho,1)} < 0 \quad \text{for } \varrho > 0 \text{ sufficiently small.}$$

But z' does not change sign in $(x_0, 1)$, hence a contradiction.

Next we exclude the creation of new zeros at the boundary: We assume existence of $\lambda_3 > \lambda_1$ with $z''_{\lambda_3}(0) = 0$, respectively, $z''_{\lambda_3}(1) = 0$. Both cases imply by (HGM) $z'_{\lambda_3|(0,x_1)} \equiv 0$, respectively, $z'_{\lambda_3|(x_0,1)} \equiv 0$, which is again impossible by (H3) and (H4).

Excluding possibility 3 of Proposition 16 is obvious. ∎

LEMMA 18. *Let $\lambda_1 \in \mathbb{R}^+$ be such that $z'_{\lambda_1} \leq 0$. Then we have two possibilities:*

1. *For every $\lambda > \lambda_1$ any solution $z_\lambda \in \mathcal{C}_\varepsilon^+$ satisfies the property $z'_\lambda \leq 0$.*
2. *There exists $\lambda_2 > \lambda_1$ such that z'_{λ_2} changes sign exactly once at $x = x_1$, and we have $z'_{\lambda_2|(0,x_1)} < 0$ and $z'_{\lambda_2|(x_1,1)} > 0$. Moreover, all zeros of z'_{λ_2} are nondegenerate.*

Proof. First we treat $z'_{\lambda_1}(x) \leq 0$ for a certain $\lambda_1 \in \mathbb{R}^+$ and for every $x \in [0,1]$. We have to show that z'_λ changes sign at most once for arbitrary $\lambda > \lambda_1$.

Again by (HGM) applied to (5.1) we exclude existence of a solution $z_\lambda \in \mathcal{C}_\varepsilon^+$ satisfying $z''_\lambda(0) = 0$. By the same reason existence of $x_1 \in (0, x_0]$ with $z'_\lambda(x_1) = z''_\lambda(x_1) = 0$ is impossible.

Oscillation of $z'_{\lambda|(x_0,1)}$ cannot occur by virtue of Lemma 11. Moreover, if a change in sign takes place at $x = x_1$, then we obtain by (HGM) $z'_{\lambda|(x_1,1)} > 0$, $z'_{\lambda|(0,x_1)} < 0$ and every zero of z'_λ is nondegenerate. ∎

LEMMA 19. *Let $\lambda_1 \in \mathbb{R}^+$ such that $z'_{\lambda_1} \geq 0$. Then we have two possibilities:*

1. *We have for every $\lambda > \lambda_1$ the property $z'_\lambda \geq 0$.*
2. *There exists $\lambda_2 > \lambda_1$ such that z'_{λ_2} changes sign exactly once. The zeros of z'_{λ_2} are nondegenerate.*

Proof. Let $z'_{\lambda_1|(0,1)} \geq 0$ for a certain $\lambda_1 > 0$. Then we have to show that z'_λ changes sign at most once for every $\lambda > \lambda_1$.

We assume for the remainder of the proof the existence of $\lambda_2 > \lambda_1$ such that z'_{λ_2} changes sign at least twice: Then there exists a local positive maximum at $x := x_\alpha$. Note that $x_\alpha \leq x_0$ holds due to Lemma 11. By virtue of $z'_{\lambda_2}(x_\alpha) > 0$ and $z'''_{\lambda_2}(x_\alpha) \leq 0$, we obtain

$$-\sigma'(z_{\lambda_2}(x_\alpha))z'_{\lambda_2}(x_\alpha) \geq \varepsilon z'''(x_\alpha) - \sigma'(z_{\lambda_2}(x_\alpha))z'_{\lambda_2}(x_\alpha) = b(\lambda_2, u(x_\alpha), x_\alpha) \geq 0.$$

In particular, this implies $z_{\lambda_2}(x_\alpha) \in [\nu_1, \nu_2]$. Hence a necessary condition for the existence of a local positive maximum and a local negative minimum of z'_{λ_2} is the existence of $x \in [0,1]$ such that

$$z_{\lambda_2}(x) \geq \nu_1 > 1.$$

On the other hand, we have

$$0 > \varepsilon z''_{\lambda_1}(1) = \sigma(z_{\lambda_1}(1)), \tag{5.6}$$

and this implies, due to the assumed monotonicity,

$$z_{\lambda_1}(x) < 1 \text{ for every } x \in [0,1].$$

Of course, z_λ is connected with respect to the C^1-topology, and we obtain by virtue of Lemmas 17 and 18 the existence of $\hat{\lambda} \in (\lambda_1, \lambda_2)$ such that $z_{\hat{\lambda}}$ fulfills

$$z'_{\hat{\lambda}_{|(0,1)}} \geq 0 \text{ and there exists } \hat{x} \in [0,1] \text{ with } z_{\hat{\lambda}}(\hat{x}) = 1. \tag{5.7}$$

Due to $z'_{\hat{\lambda}} \geq 0$ we obtain $z''_{\hat{\lambda}}(1) < 0$ by (HGM). As in (5.6) we conclude that $z_{\hat{\lambda}}(1) < 1$, a contradiction to (5.7). ☐

Now we are in a position to state the main result of this section.

THEOREM 20. *Let $\varepsilon > 0$ be arbitrary but fixed and consider an arbitrary $z \in \mathcal{C}^+_\varepsilon$. Then we obtain three possibilities for the shape of z':*

(i) *The function z' has exactly one change in sign at $x = x_1$, and, moreover, we have $z'_{|(0,x_1)} < 0$ and $z'_{|(x_1,1)} > 0$. Furthermore, $z''(0) < 0$, $z''(x_1) > 0$, and $z''(1) < 0$ hold.*

(ii) *We have $z'(x) \leq 0$ for every $x \in [0,1]$, and if there exists an interval $J \subseteq [0,1]$ such that $z'_{|J} \equiv 0$, then $J = [x_\alpha, 1]$ for a certain $x_\alpha > x_0$.*

(iii) *For every $x \in (0,1)$ we obtain $z'(x) > 0$.*

Proof. By virtue of Corollary 14, the continuation method, and Lemmas 17, 18, and 19, we obtain that z'_λ changes sign at most once for every $\lambda \in \mathbb{R}^+_0$, and, moreover, (i) and (ii) of Theorem 20 are valid.

It remains to show (iii) of Theorem 20, and therefore we assume

$$z'(x) \geq 0 \quad \text{for every } x \in [0,1]$$

and, moreover, existence of $\hat{x} \in (0,1)$ such that $z'(\hat{x}) = 0$. (HGM) yields that we have no degenerate zero of z' in $[x_0, 1)$. If we assume $\hat{x} \in (0, x_0)$, we obtain by (H4) and (5.1) that

$$z'_{|(0,\gamma)} \text{ is not identically zero}$$

for some $\gamma > 0$. Hence, by our assumption on z' we get existence of a local maximum $x_2 \in (0, x_1)$ with $z'(x_2) > 0$. In a manner analogous to that in the proof of Lemma 19, we obtain a contradiction, which completes the proof of Theorem 20. ☐

6. Singular limit analysis. Let $z_{\varepsilon_n} \in \mathcal{C}^+_{\varepsilon_n}$ for every $n \in \mathbb{N}$. Our goal here is to pass to the limit for the sequence $(z_{\varepsilon_n})_{n\in\mathbb{N}}$ as $\varepsilon_n \searrow 0$. This is essentially done by Theorem 20 and Helly's theorem. Afterwards we show some qualitative properties of this limit.

LEMMA 21. *Consider for fixed $\lambda \in \mathbb{R}^+$ a sequence $(z_n)_{n\in\mathbb{N}}$ with $z_n \in \mathcal{C}^+_{\varepsilon_n}$ and $\varepsilon_n \searrow 0$. We obtain that $(z_n)_{n\in\mathbb{N}}$ is uniformly bounded in $BV(0,1)$, where $BV(0,1)$ denotes the space of functions with bounded variation defined on $(0,1)$.*

Proof. By Theorem 20, z'_n has at most one sign change, say at $x = x(n)$. Due to the fundamental theorem of calculus we obtain by Lemma 6

$$||z'_n||_{L^1} = \int_0^{x(n)} -z'_n(s)ds + \int_{x(n)}^1 z'_n(s)ds \leq 4\,||z_n||_{C^0} \leq K,$$

where K is independent of n. The same bound obviously holds for $BV(0,1)$. ☐

By Helly's theorem (see [23]) we conclude that the following theorem holds.

THEOREM 22. *For fixed $\lambda \in \mathbb{R}^+$ we consider a sequence $(z_n)_{n\in\mathbb{N}}$ as in Lemma 21. Then there exists a subsequence which we again denote by $(z_n)_{n\in\mathbb{N}}$ and a function $z \in L^\infty(0,1) \cap BV(0,1)$, such that*

$$\lim_{n\to\infty} z_n(x) = z(x) \tag{6.1}$$

for every $x \in [0,1]$. In particular, there exists $\delta > 0$ such that

$$z(x) \geq \delta \text{ for all } x \in [0,1]. \tag{6.2}$$

Moreover, we have for every $x \in [0,1]$

(i)

$$\lim_{n\to\infty} \varepsilon_n z_n''(x) = 0, \tag{6.3}$$

(ii)

$$\lim_{n\to\infty} \sigma(z_n(x)) = \sigma(z(x)) = \int_x^1 b(\lambda, u(\tau), \tau) d\tau, \tag{6.4}$$

where $u = \int_0^x z(s)ds$ is the limit of $(u_n)_{n\in\mathbb{N}}$ in $C^0(0,1)$. In particular, the first Weierstrass–Erdmann corner condition is fulfilled.

Proof. Let $\lambda \in \mathbb{R}^+$ be fixed and consider $(z_n)_{n\in\mathbb{N}}$ as in Lemma 21. Then (6.1) is a consequence of Lemma 21, (6.2) is obvious by Theorem 3, (6.3) is proved by Lemma 6 and (6.1), and (6.4) is obvious by (6.1). $\square$

Hence, the continuation method delivers a stress field

$$\sigma(x, z_n) \to \sigma(x, z) \quad \text{pointwise.}$$

Equation (6.4) expresses force-balance at $x \in [0,1]$. Observe that (6.4) may even be differentiated:

$$\frac{d}{dx}\sigma(x, z(x)) = b(\lambda, u(x), x) \quad \text{in } (0,1).$$

Moreover, z also satisfies the second Weierstrass–Erdmann corner condition. For the proof we refer to [10].

Corollary 23. *Let z be the limit obtained by Theorem 22. Then*

$$x \mapsto W(z(x)) - \sigma(z(x))z(x)$$

is continuous for every $x \in [0,1]$.

The next goal is to show that z jumps at most once in the unit interval. The first step in this direction is the observation that the last two cases in Theorem 20 cannot occur as $\varepsilon \searrow 0$.

Lemma 24. *Let $(z_n)_{n\in\mathbb{N}}$ be as in Lemma 21 for fixed $\lambda > 0$. Then we obtain for n sufficiently large*

$$\operatorname{sign}(z_n') \neq const.$$

Proof. We argue by contradiction: By assumption there exists a sequence $(z_n)_{n\in\mathbb{N}}$ with $\operatorname{sign}(z_n') \equiv const.$ for every $n \in \mathbb{N}$, and we assume without loss of generality $\operatorname{sign}(z_n') \geq 0$. We obtain by Helly's theorem

$$\lim_{n\to\infty} z_n(x) = z(x)$$

for every $x \in [0,1]$, and z is monotonically increasing and satisfies the equation

$$\sigma(z(x)) = \int_x^1 b(\lambda, u(\tau), \tau) d\tau$$

with $u(x) = \int_0^x z(s)ds$. By (H1), $\int_x^1 b(\lambda, u(\tau), \tau)d\tau_{|[0,x_0]}$ is monotonically decreasing, and by (2.4) and the monotonicity of z and b we obtain

$$z_{|[0,x_0]} \in [\nu_1, \nu_2] \subseteq (1, \infty).$$

On the other hand, we have $\sigma(z(x_0)) = \int_{x_0}^1 b(\lambda, u(\tau), \tau)d\tau < 0$ which yields

$$z(x_0) < 1,$$

a contradiction. ∎

In the remainder let $\lambda > 0$ be fixed. We consider a sequence $(\varepsilon_n)_{n\in\mathbb{N}}$ with $\varepsilon_n \searrow 0$ and let $(u_n)_{n\in\mathbb{N}} = ((u_\lambda)_n)_{n\in\mathbb{N}}$ be a sequence of functions on the branch $\mathcal{C}^+_{\varepsilon_n}$ with $u_n \to u$ uniformly in $C^0(0,1)$. Because of (H1) and (H2) on b we define for $\eta > 0$ sufficiently small

$$x_0 := \max\left\{\hat{x} \in [0,1] \mid b(\lambda, u_n(\hat{x}), \hat{x}) = 0 \text{ and } b(\lambda, u_n(x), x)_{|(\hat{x}-\eta,\hat{x})} > 0\right\}. \tag{6.5}$$

Note that by our assumptions x_0 is independent from $n \in \mathbb{N}$ for fixed λ and b changes sign at $x = x_0$.

Furthermore we define $x_s = x_s(n)$ by

$$\begin{aligned} x_s(n) := \Big\{\tilde{x} \in [0,1] \mid &\int_{\tilde{x}}^1 b(\lambda, u_n(\tau), \tau)d\tau = 0 \text{ and} \\ &\int_x^1 b(\lambda, u_n(\tau), \tau)d\tau > 0 \text{ for every } x < \tilde{x}\Big\}. \end{aligned} \tag{6.6}$$

Note that existence of $x_s = x_s(n)$ is by no means guaranteed. But if x_s exists, then $x_s < x_0$ holds. Furthermore we define

$$\tilde{x}_s(n) := \begin{cases} x_s(n) & \text{if } x_s \text{ exists,} \\ 0 & \text{elsewhere.} \end{cases}$$

Due to the obvious fact that $\tilde{x}_s(n) < x_0$, there exists $\varrho(n) > 0$ with $\tilde{x}_s(n) + \varrho(n) = x_0$. We define

$$\varrho_0 := \inf_{n\in\mathbb{N}} \{\varrho_n\}, \tag{6.7}$$

and it is easy to see that $\varrho_0 > 0$.

Lemma 25. *Let $z_\varepsilon \in \mathcal{C}^+_\varepsilon$. We claim the following: For every $\varrho \in (0, \varrho_0)$ there exists $\varepsilon_0 = \varepsilon_0(\varrho)$ such that for all $\varepsilon < \varepsilon_0$*

$$z'_{\varepsilon|(0,x_0-\varrho)} < 0.$$

Proof. We argue by contradiction and we assume the existence of $\varrho_1 \in (0, \varrho_0)$ such that for every $\varepsilon_0 > 0$ there exist $\varepsilon < \varepsilon_0$ and $x_\varepsilon \in (0, x_0 - \varrho_1)$ such that $z'_\varepsilon(x_\varepsilon) \geq 0$. By virtue of Theorem 20 and Lemma 24 we obtain $(z_n)_{n\in\mathbb{N}} \in \mathcal{C}^+_{\varepsilon_n}$ and $x_1 = x_1(n)$ with

$$z'_{n|(0,x_1(n))} < 0 \quad \text{and} \quad z'_{n|(x_1(n),1)} > 0.$$

Due to our assumption we deduce $z'_{n|[x_0-\varrho_1,1]} > 0$ for every $n \in \mathbb{N}$. Helly's theorem yields $z_{n|[x_0-\varrho_1,1]} \to z_{|[x_0-\varrho_1,1]}$ pointwise, and, in particular, $z_{|[x_0-\varrho_1,1]}$ is monotonically increasing. By virtue of (6.6) and (6.7) we obtain for every $x \in [x_0-\varrho_1, x_0]$

$$\sigma(z(x)) = \int_x^1 b(\lambda, u(\tau), \tau)d\tau \leq 0, \tag{6.8}$$

where $u(x) = \int_0^x z(s)ds$, and hence $z_{|[x_0-\varrho_1,x_0]} \leq 1$. Furthermore, $x \mapsto \int_x^1 b(\lambda, u(\tau), \tau)d\tau$ is monotonically decreasing for $x \in (x_0-\varrho_1, x_0)$. This yields either (i)

$$z_{|[x_0-\varrho_1,x_0]} \in (\nu_1, \nu_2)$$

or (ii)

$$z_{|[x_0-\varrho_1,x_0]} \equiv const.$$

Then (i) contradicts $z_{|[x_0-\varrho_1,x_0]} \leq 1$, and (ii) implies $\int_x^1 b(\lambda, u(\tau), \tau)d\tau = const.$ for every $x \in [x_0-\varrho_1, x_0]$, contradicting (6.5). $\square$

Let $(u_n)_{n\in\mathbb{N}} \in (\mathcal{C}^+_{\varepsilon_n})_n$ be a sequence for fixed $\lambda > 0$ with $\varepsilon_n \searrow 0$, and by virtue of Theorem 22 we obtain functions u, z such that $\lim_{n\to\infty} u_n =: u$ and $\lim_{n\to\infty} z_n =: z = u'$.

We define

$$\begin{aligned} \nu_a &:= \min\left\{\nu \in \mathbb{R}^+ \mid \sigma(\nu) = \sigma(\nu_2)\right\}, \\ \nu_b &:= \max\left\{\nu \in \mathbb{R}^+ \mid \sigma(\nu) = \sigma(\nu_1)\right\}, \end{aligned} \tag{6.9}$$

and

$$A := \left\{x \in [0,1] \mid \int_x^1 b(\lambda, u(\tau), \tau)d\tau \in \mathbb{R}\backslash[\sigma(\nu_a), \sigma(\nu_b)]\right\},$$

and due to the identity

$$\sigma(z(x)) = \int_x^1 b(\lambda, u(\tau), \tau)d\tau, \tag{6.10}$$

we have $A = \{x \in [0,1] \mid z(x) \in \mathbb{R}\backslash[\nu_a, \nu_b]\}$. Also by (6.10) we deduce that $z_{|A}$ is continuously differentiable.

Furthermore, we define

$$B := [0,1]\backslash A,$$

and $B \subseteq [0, x_0-\varrho_0)$ is obvious by (6.6), (6.7). We assume the existence of $\lambda \in \mathbb{R}^+$ and u obtained by the limit process such that

$$\int_{x_2}^1 b(\lambda, u(\tau), \tau)d\tau \in B \quad \text{for a certain } x_2 \in [0, x_0].$$

In particular, we have $\int_0^1 b(\lambda, u(\tau), \tau)d\tau > 0$. Thus $x_s(n) \in (0,1)$ defined in (6.6) exists for every $n \in \mathbb{N}$, and by virtue of Lemma 25 we have

$$z'_{n|(0,x_0-\frac{\varrho_0}{2})} < 0$$

for all $n \in \mathbb{N}$. By Helly's theorem we obtain that

$$z_{|B} \text{ is monotonically decreasing,}$$

where z denotes the pointwise limit of $(z_n)_{n\in\mathbb{N}}$. In particular, z has at most finitely many jumps in B. Moreover, we have that

$$\int_x^1 b(\lambda, u(\tau), \tau) d\tau_{|B} = \sigma(z)_{|B} \text{ is monotonically decreasing.}$$

Let $\nu_m, \nu_M \in \mathbb{R}^+$, $\nu_m < \nu_M$, be the Maxwell points associated with W. Then we obtain the following theorem.

THEOREM 26. *Let $(z_n)_{n\in\mathbb{N}}$ be a sequence with $z_n \in \mathcal{C}^+_{\varepsilon_n}$ for every $n \in \mathbb{N}$, $\varepsilon_n \searrow 0$ and for fixed $\lambda > 0$. Let z be the pointwise limit of the sequence. Furthermore, let $u(x) := \int_0^x z(s)ds$. Then z has at most one jump in $(0,1)$ in accordance with the first and the second Weierstrass–Erdmann corner conditions.*

If $\int_0^1 b(\lambda, u(\tau), \tau)d\tau < \sigma(\nu_m)$, then z has no jump, and if $\int_0^1 b(\lambda, u(\tau), \tau)d\tau > \sigma(\nu_1)$, then z suffers exactly one jump discontinuity at $x_J \in (0, x_0)$ satisfying

$$\int_{x_J}^1 b(\lambda, u(\tau), \tau) d\tau = \sigma(\nu_m). \tag{6.11}$$

Moreover, we obtain $z(x_J - 0) = \nu_M$ and $z(x_J + 0) = \nu_m$.

If $\int_0^1 b(\lambda, u(\tau), \tau)d\tau \in [\sigma(\nu_m), \sigma(\nu_1)]$, then z has either no jump or exactly one at $x = x_J$ such that (6.11) holds.

Proof. The proof is obvious due to the fact that z satisfies the first and the second Weierstrass–Erdmann corner conditions and, moreover, z is monotonically decreasing in B. Note that z cannot jump in the region where z is monotonically increasing. ∎

We define for some $q < \infty$ the set

$$\Sigma_0^+ = \Big\{(\lambda, u) \in \mathbb{R} \times W^{1,q}(0,1) \mid (\lambda_n, u_n, v_n, \mu_n) \in \bar{\mathcal{C}}^+_{\varepsilon_n}, \lambda_n \to \lambda, u_n \to u \\ \text{in } W^{1,q}(0,1) \text{ as } \varepsilon_n \searrow 0\Big\}. \tag{6.12}$$

Then one can prove the following theorem in the same way as in [10] using [1].

THEOREM 27. *The set $\Sigma_0^+ \subseteq \mathbb{R} \times W^{1,q}(0,1)$ is a continuum having projection $[0, \infty)$ onto the parameter axis.*

The question of whether the obtained solution of the Euler–Lagrange equation (2.13) is also the global minimizer of the nonconvex variational problem (2.8) is answered only in a very special case: We consider a body-force $b = b(\lambda, x)$ independent of the placement u and let z_* be the jump solution obtained by the singular limit process if $\int_0^1 b(\lambda, \tau)d\tau > \sigma(\nu_m)$, and a continuous differentiable solution otherwise. Then we deduce the following theorem.

THEOREM 28. *Let (λ, z_*) be as described above. Then $J(\lambda, u)$ defined by (2.8) attains its minimum at $u_* := \int_0^x z_*(s)ds$; i.e.,*

$$\min_u \big\{J(\lambda, u) \mid u \in W^{1,p+1}(0,1),\, u(0) = 0\big\} = J(\lambda, u_*).$$

We omit the proof because it is completely analogous to the proof of Theorem 6.4 in [10].

7. Concluding remark. By our continuation method we were not able to prove that a solution of (2.13) lying on the branch is the global minimizer of (2.10). Hence, in general, we cannot prove that the limit u obtained in Theorem 22 is a global minimizer of (2.8). However, our results give some hints in this direction, because u satisfies the first and second Weierstrass–Erdmann corner conditions, and, moreover, u' is strictly bounded away from 0. Note that the existence of a global minimizer of (2.8) in the live load case is entirely unclear, because [6] cannot be applied to this problem.

Acknowledgments. I am indebted to Prof. H. Kielhöfer and Prof. T. Healey for helpful hints and discussions and to the referees for their valuable comments.

OBSTACLE AND BOUNDARY DETERMINATION FROM SCATTERING DATA*

GEN NAKAMURA† AND MOURAD SINI‡

Abstract. In this paper, we are concerned with the identification of complex obstacles from the scattering data for the acoustic problem. The complex obstacle is characterized by its shape and the boundary values of the impedance coefficient. We establish pointwise formulas which can be used to reconstruct the shape of the obstacle and give explicitly the values of the surface impedance as a function of the far field. In addition, these formulas enable us to distinguish and recognize the coated and the noncoated parts of the obstacle.

Key words. inverse scattering, far-field, impedance boundary, singularity analysis, numerics

1. Introduction.

Let D be a bounded domain of $\mathbb{R}^m$, $m \geq 3$, such that $\mathbb{R}^m \setminus \overline{D}$ is connected. In addition, we assume that its boundary ∂D is of class C^2. Precisely, for every point $a \in \partial D$, there exists a rigid transformation of coordinates under which $a = 0$ and a $C^2(B_{m-1}(0,r))$-function f such that

$$f(0) = \frac{\partial f}{\partial x_i}(0) = 0, \quad i = 1, 2, \ldots, m, \tag{1}$$

and

$$D \cap B(0,r) := \{x \in B(0,r); x_m > f(x_1, x_2, \ldots, x_{m-1})\}$$

in terms of the new coordinates where $B_{m-1}(0,r)$ and $B(0,r)$ are the $(m-1)$-dimensional and the m-dimensional balls of centers 0 with some radius $r > 0$.

The propagation of time-harmonic acoustic fields in a homogeneous media is governed by the *Helmholtz equation*

$$\Delta u + \kappa^2 u = 0 \quad \text{in} \quad \mathbb{R}^m \setminus \overline{D}, \tag{2}$$

where κ is the real positive *wave number*. At the boundary of the scatterers we assume that the total field u satisfies the *impedance boundary condition*

$$\frac{\partial u}{\partial \nu} + i\lambda u = 0 \text{ on } \partial D_I \tag{3}$$

with some function λ on ∂D and the *Dirichlet condition*

$$u = 0 \text{ on } \partial D_D, \tag{4}$$

where ∂D_D and ∂D_I are open surfaces in ∂D such that

$$\partial D = \overline{\partial D_I} \cup \overline{\partial D_D} \text{ and } \partial D_I \cap \partial D_D = \emptyset.$$

The unit normal ν on ∂D is directed inside D. We assume that λ is a Hölder continuous function of order $\beta \in (0,1]$ and $\lambda_- < \lambda(x)$ on ∂D_I, where λ_- is a positive constant. The part ∂D_I is referred to by the coated part of ∂D, and ∂D_D is the noncoated part as it is commonly used in the radar detection theory; see [4]. The obstacle D is characterized by its shape, ∂D_D, ∂D_I, and the surface impedance distributed on ∂D_I. We call such obstacles *complex obstacles*.

Given an incident field u^i which satisfies $\Delta u^i + \kappa^2 u^i = 0$ we look for a solution $u := u^i + u^s$ of (2) and (3) where the *scattered field* u^s is assumed to satisfy the Sommerfeld radiation condition

$$\lim_{r\to\infty} r^{\frac{m-1}{2}} \left(\frac{\partial u^s}{\partial r} - i\kappa u^s \right) = 0, \tag{5}$$

where $r = |x|$ and the limit is uniform with respect to all of the directions $\hat{x} := \frac{x}{|x|}$.

The mixed problem (2)–(5) is well posed. More generally, for $f \in H^{\frac{1}{2}}(\partial D_D)$ and $h \in H^{-\frac{1}{2}}(\partial D_I)$, there exists a unique solution $u \in H^1_{loc}(R^m \setminus \overline{D})$ of the mixed problem

$$\begin{cases} (\Delta + \kappa^2)u = 0 \quad \text{in } R^m \setminus \overline{D}, \\ u = f \quad \text{on } \partial D_D, \\ \frac{\partial u}{\partial \nu} + i\lambda u = h \quad \text{on } \partial D_I, \\ \lim_{r\to\infty} r^{\frac{m-1}{2}} (\frac{\partial u}{\partial r} - i\kappa u) = 0, \end{cases} \tag{6}$$

and the solution satisfies

$$\|u\|_{H^1(\Omega_R \cap (R^m \setminus \overline{D}))} \leq C_R(\|f\|_{H^{1/2}(\partial D_D)} + \|h\|_{H^{-\frac{1}{2}}(\partial D_I)}), \tag{7}$$

where Ω_R is a disk of radius R; and C_R is positive constant depending on R, see [4] for more details.

It is well known (see [6]) that this reflected field satisfies the following asymptotic property:

$$u^s(x) = \frac{e^{i\kappa r}}{r^{\frac{m-1}{2}}} u^\infty(\hat{x}) + O(r^{-\frac{m+1}{2}}), \quad r \to \infty, \tag{8}$$

where the function $u^\infty(\cdot)$ defined on the unit sphere $\mathbb{S}^m$ of R^m is called the far field associated to the incident field u^i. Taking particular incident fields given by the plane waves, $u^i(x,d) := e^{i\kappa d\cdot x}$, $d \in \mathbb{S}^m$, we define the far-field pattern $u^\infty(\hat{x}, d)$ for $(\hat{x}, d) \in \mathbb{S}^m \times \mathbb{S}^m$. Analogously, for an incident point source $\Phi(\cdot, z)$, where

$$\Phi(x,y) := \frac{1}{(m-2)\sigma_m} \frac{e^{i\kappa|x-y|}}{|x-y|^{m-2}}, \quad x \neq y, x, y \in \mathbb{R}^m,$$

is the fundamental solution of $\Delta + \kappa^2$ in $\mathbb{R}^m$ and σ_m is the surface of the unit sphere in $\mathbb{R}^m$, we denote the scattered field by $\Phi^s(\cdot, z)$ and its far-field pattern by $\Phi^\infty(\cdot, z)$. The problem we are concerned with is the following.

Complex obstacle reconstruction problem. *Given* $u^\infty(\cdot,\cdot)$ *on* $\mathbb{S}^m \times \mathbb{S}^m$ *for the scattering problem* (2)–(5) *reconstruct the shape of the obstacle* D*, distinguish the coated part* ∂D_D *from* ∂D_I*, and reconstruct the surface impedance* $\lambda(x)$*.*

The uniqueness character of this problem is already known; see [4]. The part of the problem consisting of the effective detection of the shape of the obstacle ∂D can be justified, for instance, via the linear sampling method, the factorization method, or the probing methods (the probe method or, equivalently, the singular sources method); see [16, 17] for a review of these methods. Our goal in this paper is to show that not only the shape but the full complex obstacle can be reconstructed. Many efforts have been made regarding the determination of the surface impedance function $\lambda(x)$. We refer to the paper [11] where an optimization method has been proposed by assuming that the shape of the obstacle is known in advance. A different method is given in [7], where the authors first reduce the far-field data to the near-field data, and then from these near-field data they propose a moment method to reconstruct λ. Another work is [5]; see also [4], where the authors computed the L^∞-norm of λ. As a consequence, if λ is known to be constant $\lambda = \lambda_0$, then they compute λ_0. All of these works use a part of or the total far field. We mention the work [2], where the authors use only one incident wave to detect $\lambda(x)$. Assuming that the whole surface ∂D is coated and known, they first compute the total field and then use the impedance boundary condition to give the values of $\lambda(x)$. By the unique continuation, there is no open subset of ∂D in which the normal derivative of the total field may vanish. However, there can be infinitely many points in ∂D at which the total field vanishes. By avoiding these points, it is possible to reconstruct the value of $\lambda(x)$, and then by $\lambda \in C(\partial D)$, it is possible to know λ on the whole ∂D. Hence this method cannot sample each point x of ∂D to obtain the value $\lambda(x)$. To remedy this difficulty, the authors propose a regularization method.

We want to contribute to this problem by giving pointwise formulas to reconstruct fully the complex obstacle. Indeed, these formulas simultaneously reconstruct the shape of the obstacle, distinguish between the coated and the noncoated parts, and detect $\lambda(x)$ directly from the far-field pattern defined on any small open part of the unit sphere $\mathbb{S}^m$.

To justify our formulas, we need to analyze the asymptotic behavior of the Green's function, of the mixed boundary problem, near ∂D. The impedance function $\lambda(x)$ appears in the asymptotic behavior of the imaginary part of this Green's function with respect to the source parameter z; see the proof of Proposition 3.1. In the 2-dimensional case the imaginary part of the corresponding Green's function is bounded with respect to the source parameter z. This is why we consider the m-dimensional case with $m > 2$. For the 2-dimensional case, we need to use more singular sources to capture the values of the surface impedance. This has been analyzed in [13], and the corresponding formulas have been justified theoretically and tested numerically. We refer to that paper for more details on how the formulas are used numerically.

Regarding the stability issue for detecting the surface impedance, in case we know the shape, we cite the results of [12, 18], where the authors use one incident wave and give interesting and optimal results. Another interesting question is to consider the stability of the complex obstacle. We leave this for future investigations.

The rest of the paper is organized as follows. In section 2, we present the results as Theorem 2.1. In section 3, we give the proof of this theorem by splitting it into two propositions, which we prove in sections 3.1 and 3.2.

2. Presentation of the results. It is well known (see [6]) that the scattered field associated with the Herglotz incident field $v_g^i := v_g$ defined by

$$v_g(x) := \int_{\mathbb{S}^m} e^{i\kappa x\cdot d} g(d)\, ds(d), \quad x \in \mathbb{R}^m, \tag{9}$$

with $g \in L^2(\mathbb{S}^m)$, is given by

$$v_g^s(x) := \int_{\mathbb{S}^m} u^s(x,d) g(d)\, ds(d), \quad x \in \mathbb{R}^m \setminus D, \tag{10}$$

and its far field is given by

$$v_g^\infty(\hat{x}) := \int_{\mathbb{S}^m} u^\infty(\hat{x}, d) g(d)\, ds(d), \quad \hat{x} \in \mathbb{S}^m. \tag{11}$$

We will need the following identity:

$$u^\infty(\hat{x}, d) = -\frac{1}{(m-2)\sigma_m} \int_{\partial D} \left\{ \frac{\partial u^s(y,d)}{\partial \nu} e^{-i\kappa \hat{x}\cdot y} - \frac{\partial e^{-i\kappa\hat{x}\cdot y}}{\partial \nu} u^s(y,d) \right\} ds(y) \tag{12}$$

given by using the Green's formula in $\mathbb{R}^m \setminus \overline{D}$ for $u^s(\cdot, d)$ and $\Phi(\cdot, y)$ and their asymptotic behavior at infinity (see [6, Theorem 2.5]). The representation of the scattered field $\Phi^s(x,z)$ for $x, z \in \mathbb{R}^m \setminus \overline{D}$ is given by the Green's formula

$$\Phi^s(x,z) = -\int_{\partial D} \left\{ \frac{\partial \Phi^s(y,z)}{\partial \nu(y)} \Phi(x,y) - \Phi^s(y,z) \frac{\partial \Phi(x,y)}{\partial \nu(y)} \right\} ds(y), \quad x, z \in \mathbb{R}^3 \setminus \overline{D}. \tag{13}$$

Let $a \in \partial D$ and a sequence of points

$$(z_p)_{p\in\mathbb{N}} \subset \mathbb{R}^m \setminus \overline{D} \tag{14}$$

such that z_p tends to a. We consider the sequence of point sources $\Phi(\cdot, z_p)$. We set D_a^p a C^2-regular open set such that $\overline{D} \subset D_a^p$, $z_p \in \mathbb{R}^n \setminus \overline{D_a^p}$ for every $p \in \mathbb{N}$ and that the Dirichlet interior problem on D_a^p is uniquely solvable. In this case, the Herglotz wave operator H defined from $L^2(\mathbb{S}^m)$ to $L^2(\partial D_a^p)$ by

$$H(g)(x) := v_g(x) = \int_{\mathbb{S}^m} e^{i\kappa x\cdot d} g(d)\, ds(d) \tag{15}$$

is injective, compact with a dense range; see [6]. Hence by the Tikhonov regularization method (see [8, 10]) we can construct a sequence g_n^p in $L^2(\mathbb{S}^m)$ such that for every p fixed

$$\|v_{g_n^p} - \Phi(\cdot, z_p)\|_{L^2(\partial D_a^p)} \to 0, \quad n \to \infty. \tag{16}$$

Since both $v_{g_n^p}$ and $\Phi(\cdot, z_p)$ satisfy the same Helmholtz equation in D_a^p, (16) implies that

$$\|v_{g_n^p} - \Phi(\cdot, z_p)\|_{H^{\frac{1}{2}}(\partial D)} \to 0, \quad n \to \infty.$$

Multiplying (12) by $g_n^p(\hat{x}) g_n^p(d)$ and integrating over $\mathbb{S}^m$, we have

$$\begin{aligned}
&\int_{\mathbb{S}^m}\int_{\mathbb{S}^m} u^\infty(-\hat{x}, d) g_n^p(\hat{x}) g_n^p(d)\, ds(\hat{x}) ds(d) \\
&= -\frac{1}{(m-2)\sigma_m} \int_{\partial D} \left\{ \int_{\mathbb{S}^m} \frac{\partial u^s(y,d)}{\partial \nu} g_n^p(d)\, ds(d) \cdot \int_{\mathbb{S}^m} e^{i\kappa\hat{x}\cdot y} g_n^p(\hat{x})\, ds(\hat{x}) \right. \\
&\quad \left. - \int_{\mathbb{S}^m} \frac{\partial e^{i\kappa\hat{x}\cdot y}}{\partial \nu} g_n^p(\hat{x})\, ds(\hat{x}) \cdot \int_{\mathbb{S}^m} u^s(y,d) g_n^p(d)\, ds(d) \right\} ds(y) \\
&= -\frac{1}{(m-2)\sigma_m} \int_{\partial D} \left\{ \frac{\partial v^s_{g_n^p}}{\partial \nu}(y) v^i_{g_n^p}(y) + \frac{\partial v^i_{g_n^p}}{\partial \nu}(y) v^s_{g_n^p}(y) \right\} ds(y). \qquad (17)
\end{aligned}$$

From (17), we have

$$\lim_{n\to\infty}\int_{\mathbb{S}^m}\int_{\mathbb{S}^m} u^\infty(-\hat{x},d)\; g_n^p(\hat{x})\; g_n^p(d)\; ds(\hat{x})ds(d)$$

$$= -\frac{1}{(m-2)\sigma_m}\int_{\partial D}\frac{\partial(\Phi^s)}{\partial\nu(y)}(y,z_p)\Phi(y,z_p) - \Phi^s(y,z_p)\frac{\partial(\Phi)}{\partial\nu(y)}(y,z_p)\; ds(y) \tag{18}$$

$$= \frac{1}{(m-2)\sigma_m}\Phi^s(z_p,z_p). \tag{19}$$

For a point $a\in\partial D$, we choose the sequence $(z_p)_{p\in\mathbb{N}}$ included in $C_{a,\theta}$, where $C_{a,\theta}$ is the cone with center a, angle $\theta\in[0,\frac{\pi}{2})$, and axis $-\nu(a)$, where $\nu(a)$ is the unit normal of ∂D directed inside D.

Theorem 2.1. *The surface of the obstacle can be localized via the formulas:*

$$\left|32\pi^2\lim_{n\to\infty}\mathrm{Re}\int_{\mathbb{S}^m}\int_{\mathbb{S}^m} u^\infty(-\hat{x},d)g_n^p(\hat{x})g_n^p(d)ds(x)ds(d)\right|$$

$$= \frac{1}{|(z_p-a)\cdot\nu(a)|} + O(|\ln(|z_p-a|)|) \tag{20}$$

for $m=3$ and

$$\left|\frac{(m-2)\sigma_m 2^{2m-2}\pi^{m-1}}{\sigma_{m-1}}\lim_{n\to\infty}\mathrm{Re}\int_{\mathbb{S}^m}\int_{\mathbb{S}^m} u^\infty(-\hat{x},d)g_n^p(\hat{x})g_n^p(d)ds(x)ds(d)\right|$$

$$= \frac{1}{|(z_p-a)\cdot\nu(a)|^{m-2}} + O(|z_p-a|^{3-m}) \tag{21}$$

for $m>3$.

In addition, we have the following formulas for distinguishing the coated part from the noncoated part of the obstacle and for detecting the surface impedance.

I. *The case $m=3$.*

I.1. *If $a\in\partial D_I$, then we have*

$$\lim_{p\to\infty} -8\pi^2\frac{\lim_{n\to\infty}\mathrm{Im}\int_{\mathbb{S}^m}\int_{\mathbb{S}^m} u^\infty(-\hat{x},d)g_n^p(\hat{x})g_n^p(d)\; ds(\hat{x})ds(d)}{|\ln|(z_p-a)\cdot\nu(a)||^s}$$

$$= \begin{cases}\infty \;\; \textit{if } s\in[0,1),\\ \lambda(a) \;\; \textit{if } s=1,\\ 0 \;\; \textit{if } s>1.\end{cases} \tag{22}$$

I.2. *If $a\in\partial D_D$, then for all $s>0$ we have*

$$\lim_{p\to\infty}\frac{\lim_{n\to\infty}\mathrm{Im}\int_{\mathbb{S}^m}\int_{\mathbb{S}^m} u^\infty(-\hat{x},d)g_n^p(\hat{x})g_n^p(d)\; ds(\hat{x})ds(d)}{|\ln|(z_p-a)\cdot\nu(a)||^s} = 0. \tag{23}$$

II. *The case $m>3$.*

II.1. *If $a\in\partial D_I$, then we have*

(24)

$$\lim_{p\to\infty}\frac{(m-2)\sigma_m(2\pi)^{m-1}}{\sigma_{m-1}}(2(z_p-a)\cdot\nu(a))^{m-4+s}$$

$$\lim_{n\to\infty}\mathrm{Im}\int_{\mathbb{S}^m}\int_{\mathbb{S}^m} u^\infty(-\hat{x},d)g_n^p(\hat{x})g_n^p(d)\; ds(\hat{x})ds(d) = \begin{cases}\infty \;\; \textit{if } s\in[0,1),\\ \lambda(a) \;\; \textit{if } s=1,\\ 0 \;\; \textit{if } s>1.\end{cases}$$

II.2. *If $a \in \partial D_D$, then for all $s > 0$ we have*

$$\lim_{p\to\infty}((z_p - a)\cdot\nu(a))^{m-3+s}$$
$$\lim_{n\to\infty}\mathrm{Im}\int_{\mathbb{S}^m}\int_{\mathbb{S}^m} u^\infty(-\hat{x},d)g_n^p(\hat{x})g_n^p(d)\,ds(\hat{x})ds(d) = 0. \tag{25}$$

Remark 2.2. 1. In the case $m = 3$, from (22) and (23), we can localize the coated part of the obstacle by taking any $s \in (0,1)$, then taking $s = 1$ in (22), we obtain the pointwise values of the surface impedance. Similarly, we have the same conclusions for $m \geq 4$.

2. We stated the results by using the full far-field pattern, i.e., $(\theta, d) \in \mathbb{S}^m \times \mathbb{S}^m$. We used this information to approximate the point sources $\Phi(\cdot, z_p)$ by Herglotz functions defined on the whole unit sphere $\mathbb{S}^m$. However, this approximation is also justified if we define the Herglotz functions on any subsurface $\gamma \subset \mathbb{S}^m$, and hence the results of Theorem 2.1 are also valid if we replace $\mathbb{S}^m$ by any subsurface $\gamma \subset \mathbb{S}^m$.

3. Proof of Theorem 2.1. Let $\Gamma_{\lambda(a)}$ be a local Green's function satisfying

$$\begin{cases} \Delta\Gamma_{\lambda(a)} = -\delta(x,z) \text{ in } \mathbb{R}^m_+, \\ \left(\frac{\partial\Gamma_{\lambda(a)}}{\partial\nu} + i\lambda(a)\Gamma_{\lambda(a)}\right)(x_1, x_2, \dots, x_{m-1}, 0) = 0 \end{cases} \tag{26}$$

and Γ_D defined by

$$\Gamma_D(x,z) := \Gamma(x,z) - \Gamma(x^*, z),$$

where $x = (x_1, x_2, \dots, x_m)$, $x^* = (x_1, x_2, \dots, -x_m)$, and $\Gamma(x,z) = \frac{1}{(m-2)\sigma_m|x-z|^{m-2}}$.

It is clear that $\Gamma_D(x,z)$ satisfies

$$\begin{cases} \Delta\Gamma_D = -\delta(x,z) \text{ in } \mathbb{R}^m_+, \\ \Gamma_D(x_1, x_2, \dots, x_{m-1}, 0) = 0. \end{cases} \tag{27}$$

We state the following propositions. Their proofs will be given in sections 3.1 and 3.2, respectively.

Proposition 3.1. *The local Green function $\Gamma_{\lambda(a)}$ is given by*

$$\Gamma_{\lambda(a)}(x,z) := \Gamma(x,z) + \frac{1}{2(2\pi)^{m-1}}\int_{\mathbb{R}^{m-1}} e^{i(x'-z')\cdot\xi'}e^{-(x_m+z_m)|\xi'|}\frac{|\xi'| + i\lambda(a)}{|\xi'|(|\xi'| - i\lambda(a))}d\xi', \tag{28}$$

where $x' = (x_1, x_2, \dots, x_{m-1})$ and $\xi' = (\xi_1, \xi_2, \dots, \xi_{m-1})$.

In addition, we have the following asymptotics for the function $(\Gamma_{\lambda(a)} - \Gamma)(x,z)$:

$$\mathrm{Re}(\Gamma_{\lambda(a)} - \Gamma)(z,z) = \frac{\sigma_{m-1}}{2(2\pi)^{m-1}}\frac{1}{(2z_m)^{m-2}} + O\left(\frac{1}{(z_m)^{m-3}}\right),$$

$$\lim_{z_3\to 0^+} -2\pi\frac{\mathrm{Im}(\Gamma_{\lambda(a)} - \Gamma)(z,z)}{\ln(z_3)} = \lambda(a) \text{ for } m = 3$$

and

$$\lim_{z_m\to 0^+}\frac{(2\pi)^{m-1}}{\sigma_{m-1}}(2z_m)^{m-3}\mathrm{Im}(\Gamma_{\lambda(a)} - \Gamma)(z,z) = \lambda(a) \text{ for } m > 3.$$

Proposition 3.2. *If $a \in \partial D_I$, then there exist $\delta(a) > 0$ and $C > 0$ such that*

$$|\Phi^s(x,z)-(\Gamma_{\lambda(a)}-\Gamma)(x,z)| \le C\begin{cases} |\ln|z-a|| & \text{if } m=3 \\ \frac{1}{|z-a|^{m-3}} & \text{if } m>3 \end{cases} \quad \text{for } (x,z)\in B_+(a,\delta(a))\cap C_{a,\theta}, \tag{29}$$

and

$$|\mathrm{Im}(\Phi^s(x,z)-(\Gamma_{\lambda(a)}-\Gamma)(x,z))| \le \frac{C}{|z-a|^{m-3-\beta}}+C \quad \text{for } m\ge 3 \text{ and } (x,z)\in B_+(a,\delta(a))\cap C_{a,\theta}, \tag{30}$$

where $B_+(a,\delta(a)) := B(a,\delta(a))\cap(\mathbb{R}^3\setminus D)$ and $B(a,\delta(a))$ is the ball of center a and radius $\delta(a)$.

Similarly, if $a\in\partial D_D$, we obtain (29) *and* (30) *by replacing $\Gamma_{\lambda(a)}$ by Γ_D.*

End of the proof of Theorem 2.1.

1. Let $a\in\partial D_I$; i.e., we have the impedance boundary condition around a. By a rigid transformation of coordinates, we can assume that $a=(0,0,0,\dots,0)$. Using (19) and Propositions 3.1 and 3.2 we obtain the formulas (20), (21), (22) and (24).
2. Let $a\in\partial D_D$; i.e., we have the Dirichlet boundary condition around a. Similarly, we can assume that $a=(0,0,0)$. Using (19), Proposition 3.2, and the fact that $\mathrm{Im}\Gamma_D = 0 = \mathrm{Im}\Gamma$ we obtain (23) and (25). ∎

The rest of this section is devoted to proving Propositions 3.1 and 3.2.

3.1. Proof of Proposition 3.1. We set $\Gamma_{\lambda(a)}(x,z) := \Gamma(x,z)+w(x,z)$, and then $w(x,z)$ satisfies

$$\begin{cases} \Delta w(x,z)=0 \text{ in } \mathbb{R}^m_+, \\ (\partial_{x_3}+i\lambda(a))w(x,z) = -(\partial_{x_3}+i\lambda(a))\Gamma(x,z) \text{ on } \partial\mathbb{R}^m_+. \end{cases} \tag{31}$$

The first part of this proposition is to show the following explicit form of $w(x,z)$.

Lemma 3.3.

$$w(x,z)=\frac{1}{2(2\pi)^{m-1}}\int_{\mathbb{R}^{m-1}} e^{i(x'-z')\cdot\xi'}e^{-(x_m+z_m)|\xi'|}\frac{|\xi'|+i\lambda(a)}{|\xi'|(|\xi'|-i\lambda(a))}d\xi'.$$

Proof of Lemma 3.3. We represent $w(x,z)$ using up-going and down-going operators $U_\pm$

$$w(x,z) := (U_\pm(x_m)\phi)(x') := \frac{1}{(2\pi)^{m-1}}\int_{\mathbb{R}^{m-1}} e^{ix'\cdot\xi'\mp x_m|\xi'|}\hat{\phi}_\pm(\xi',z)d\xi', \tag{32}$$

where $\hat{\phi}_\pm$ is the $(m-1)$-dimensional Fourier transform of $\phi_\pm$. The goal is to find $\phi_\pm$ or $\hat{\phi}_\pm$. We start by the corresponding representation of $\Gamma(x,z)$. We write

$$\Gamma(x,z)=\begin{cases} \Gamma_+(x,z) \text{ in } x_m>z_m, \\ \Gamma_-(x,z) \text{ in } x_m<z_m, \end{cases} \tag{33}$$

and then $\Delta\Gamma_\pm = 0$ in $\pm(x_m-z_m)>0$ with the transmission conditions

$$\begin{cases} \Gamma_+|_{x_m=z_m+0} = \Gamma_-|_{x_m=z_m-0}, \\ \partial_{x_m}\Gamma_+|_{x_m=z_m+0} - \partial_{x_m}\Gamma_-|_{x_m=z_m-0} = -\delta(x',z'). \end{cases} \tag{34}$$

Now we look for $\Gamma_\pm$ in the form

$$\Gamma_\pm(x,z) = U_\pm(x_m - z_m)\psi_\pm(x', z')$$

and try to determine the potentials $\psi_\pm$.

Clearly, from the definition of $U_\pm$, we have

$$\Delta\Gamma_\pm = 0 \text{ in } \pm(x_m - z_m) > 0,$$

and from the first equation of (34), we get

$$\psi_+ = \psi_-. \tag{35}$$

Let us now consider the second equation of (34). We set

$$(Bf)(x') := \int_{\mathbb{R}^{m-1}} e^{ix'\cdot\xi'}(-|\xi|)\hat{f}(\xi')\bar{d}\xi',$$

and then we deduce that

$$\partial_{x_m} U_\pm(x_m) = \pm B U_\pm(x_m). \tag{36}$$

The second point of (34) implies that

$$B\psi_+ + B\psi_- = -\delta(x' - z').$$

Taking the Fourier transform, we have

$$-|\xi'|\hat{\psi}_+ - |\xi'|\hat{\psi}_- = -e^{iz'\cdot\xi'}, \tag{37}$$

and by combining (35) with (37), we end up with

$$\hat{\psi}_\pm(\xi', z') = \frac{1}{2}|\xi'|^{-1}e^{-iz'\cdot\xi'}. \tag{38}$$

Now we go back to $w(x,z)$. We set $\phi_\pm := \phi$ in (32), i.e.,

$$w(x,z) = (U_+(x_m)\phi)(x', z),$$

and then from (36) we have

$$(\partial_{x_3} + i\lambda(a))w|_{x_m=0} = B\phi + i\lambda(a)\phi, \tag{39}$$

because $U_+(0)\phi = \phi$. By Fourier transform, the right-hand side of (39) becomes

$$-|\xi'|\hat{\phi}(\xi') + i\lambda(a)\hat{\phi}(\xi'). \tag{40}$$

By similar computations for the fundamental solution $\Gamma(x,z)$, we have

$$\begin{aligned} -(\partial_{x_m}\Gamma_- + i\lambda(a)\Gamma_-)\,|_{x_m=0} &= -(-B\Gamma_- + i\lambda(a)\Gamma_-)\,|_{x_m=0} \\ &= -(-U_-(-z_m)B\psi_- + i\lambda(a)U_-(-z_m)\psi_-)(x') \end{aligned} \tag{41}$$

because

$$BU_\pm = U_\pm B.$$

The Fourier transform of (41) is

$$-e^{-z_m|\xi'|}(|\xi'|+i\lambda(a))\hat{\psi}_-(\xi',z'), \tag{42}$$

and hence by combining (40) with (42), we obtain

$$\hat{\phi}(\xi',z) = \frac{|\xi'|+i\lambda(a)}{|\xi'|-i\lambda(a)} e^{-z_m|\xi'|}\hat{\psi}_-(\xi',z'). \tag{43}$$

Using (35), we have

$$\hat{\phi}(\xi',z) = \frac{1}{2}\frac{|\xi'|+i\lambda(a)}{|\xi'|(|\xi'|-i\lambda(a))} e^{-z_m|\xi'|}e^{-iz'\cdot\xi'}.$$

Finally (32) becomes

$$w(x,z) = \frac{1}{2(2\pi)^{m-1}}\int_{\mathbb{R}^{m-1}} e^{i(x'-z')\cdot\xi'}e^{-(x_m+z_m)|\xi'|}\frac{|\xi'|+i\lambda(a)}{|\xi'|(|\xi'|-i\lambda(a))}d\xi'. \tag{44}$$ ∎

Next we deal with the second part of the proposition. From Lemma 3.3, we have

$$w(z,z) = \frac{1}{(2\pi)^{m-1}}\int_{\mathbb{R}^{m-1}} e^{-(2z_m)|\xi'|}\frac{1}{2}\frac{|\xi'|+i\lambda(a)}{|\xi'|(|\xi'|-i\lambda(a))}d\xi'. \tag{45}$$

We start with the case $m=3$. Using polar coordinates, we write

$$\begin{aligned} w(z,z) &= \frac{1}{4\pi^2}\int_0^{2\pi} d\theta \int_0^\infty e^{-2z_3 r}\frac{1}{2r}\left(1+\frac{2i\lambda(a)}{r-i\lambda(a)}\right) r dr \\ &= \frac{1}{2\pi}\int_0^\infty e^{-2z_3 r}\frac{1}{2r}\left(1+\frac{2i\lambda(a)}{r-i\lambda(a)}\right) r dr. \end{aligned}$$

After some computations, we obtain

$$\mathrm{Re}w(z,z) = \frac{1}{8\pi z_3} + O(1). \tag{46}$$

Similarly we obtain

$$2\pi \mathrm{Im} w(z,z) = \lambda(a)\left[-\ln(\lambda(a)) + \int_0^\infty e^{-2t}\ln(t^2+z_3^2\lambda(a)^2)dt - \ln(z_3)\right]. \tag{47}$$

Hence

$$2\pi\frac{\mathrm{Im}w(z,z)}{\ln(z_3)} = -\lambda(a) + \frac{\lambda(a)(-\ln(\lambda(a)) + \int_0^\infty e^{-2t}\ln(t^2+z_3^2\lambda^2)dt)}{\ln(z_3)},$$

which gives the formula:

$$\lim_{z_3\to 0^+} -2\pi\frac{\mathrm{Im}w(z,z)}{\ln(z_3)} = \lambda(a). \tag{48}$$

For $m>3$, we use also the hyperspherical coordinates and get

$$w(z,z) = \frac{\sigma_{m-1}}{2(2\pi)^{m-1}}\int_0^\infty e^{-2z_m r}\frac{1}{2r}\left(1+\frac{2i\lambda(a)}{r-i\lambda(a)}\right) r^{m-1}dr.$$

Hence

$$\mathrm{Re}w(z,z) = \frac{\sigma_{m-1}}{2(2\pi)^{m-1}} \frac{1}{(2z_m)^{m-2}} + O\left(\frac{1}{(z_m)^{m-3}}\right)$$

and

$$\mathrm{Im}w(z,z) = \frac{\sigma_{m-1}}{(2\pi)^{m-1}} \frac{\lambda(a)}{(2z_m)^{m-3}} + O(1).$$

This ends the proof of Proposition 3.1. ∎

3.2. Proof of Proposition 3.2. We assume that the point a is on ∂D_I. The case where a is on ∂D_D is similar and easier.

Let $\tilde{\Phi}^s$ be the corresponding solution as Φ^s replacing ∂D_I by ∂D (i.e., taking $\partial D_D = \emptyset$). We set $G_\lambda(x,z) := \tilde{\Phi}^s(x,z) + \Phi(x,z)$, the Green's function of the problem (2),(3),(5). We set also $G_{\lambda(a)}(x,z)$ to be the Green's function of (2),(3),(5) when the function $\lambda(x)$ is replaced by the constant function $\lambda(a)$. For both of the Green's functions we assumed $\partial D_D = \emptyset$. Finally, we set $G^0_{\lambda(a)}$ to be the Green's function satisfying

$$\left\{\begin{array}{l} \Delta G^0_\lambda = -\delta \text{ in } \Omega \setminus \overline{D}, \\ \frac{\partial G^0_\lambda}{\partial \nu}(x,z) + i\lambda(a) G^0_\lambda(x,z) = 0 \text{ on } \partial D, \\ G^0_{\lambda(a)}(\cdot, z) = 0 \text{ on } \partial\Omega, \end{array}\right. \tag{49}$$

with an arbitrary fixed C^2-regular domain Ω containing $\overline{D}$.

We have the following lemma.

LEMMA 3.4. *For every $R > 0$, there exists a positive constant $C := C(R)$ such that*

1. $|G_\lambda(x,z)| \leq \frac{C}{|x-z|^{m-2}}$,
2. $|\nabla G_\lambda(x,z)| \leq \frac{C}{|x-z|^{m-1}}$ *for* $(x,z) \in (\mathbb{R}^m \setminus D) \cap B(0,R)$.

Proof of Lemma 3.4. These properties are known for general equations and boundary conditions. We refer to [19, 20], where these results are justified for boundary value problems stated on bounded domains. Since the arguments are local, these estimates are also justified for exterior problems. ∎

The function $\tilde{\Phi}^s - \Phi^s$ satisfies

$$\left\{\begin{array}{l} (\Delta + \kappa^2)(\tilde{\Phi}^s - \Phi^s) = 0 \text{ in } \mathbb{R}^m \setminus \overline{D}, \\ \tilde{\Phi}^s - \Phi^s(x,z) = \tilde{\Phi}^s + \Phi \text{ on } \partial D_D, \\ \frac{\partial(\tilde{\Phi}^s - \Phi^s)}{\partial \nu}(x,z) + i\lambda(x)(\tilde{\Phi}^s - \Phi^s)(x,z) = 0 \text{ on } \partial D_I, \\ (\tilde{\Phi}^s - \Phi^s)(\cdot, z) \text{ satisfies Sommerfeld radiation conditions.} \end{array}\right. \tag{50}$$

For z near a, Lemma 3.4 implies that $(\tilde{\Phi}^s + \Phi)(\cdot, z)$ is bounded in $H^{1/2}(\partial D_D)$. The well-posedness of (50) (see [5]) implies that $(\tilde{\Phi}^s - \Phi^s)(\cdot, z)$ is bounded in $H^1_{loc}(\mathbb{R}^m \setminus \overline{D})$. Introducing a cutoff function around the point a and knowing that $\tilde{\Phi}^s(\cdot, z)$ and $\Phi(\cdot, z)$ and their derivatives are bounded for x near ∂D_D and z near a (which is in ∂D_I), we deduce that $(\tilde{\Phi}^s - \Phi^s)$ is bounded for x and z near a. This implies that we can replace Φ^s by $\tilde{\Phi}^s$ in Proposition 3.2. In addition, by setting

$$\tilde{\Phi}^s - (\Gamma_{\lambda(a)} - \Gamma) = G_\lambda - \Gamma_{\lambda(a)} - (\Phi - \Gamma),$$

and knowing that $(\Phi-\Gamma)(x,z)$ is bounded in $\mathbb{R}^m$, then the proof of Proposition 3.2 is reduced to considering the term $G_\lambda - \Gamma_{\lambda(a)}$. We split the rest of the proof into the following three lemmas.

LEMMA 3.5. *There exist $\delta(a)>0$ and $C(R)>0$ such that $|G_\lambda(x,z)-G_{\lambda(a)}(x,z)|\leq C(R)|z-a|^{3-m+\beta}+C(R)$ for $z\in B(a,\delta(a))\cap C_{a,\theta}$ and $x\in\mathbb{R}^m\setminus D$.*

LEMMA 3.6. *There exists $C>0$ such that $|G_{\lambda(a)}(x,z)-G^0_{\lambda(a)}(x,z)|\leq C|z-a|^{4-m}+C$ for z near D and $x\in\Omega\setminus D$.*

LEMMA 3.7. *There exist $C>0$ and $\delta(a)>0$ such that*

1. $|\mathrm{Im}G^0_{\lambda(a)}(x,z)-\mathrm{Im}\Gamma_{\lambda(a)}(x,z)|\leq C|z-a|^{4-m}+C$ *for* $(x,z)\in B(a,\delta(a))\cap C_{a,\theta}$.
2. $|\mathrm{Re}G^0_{\lambda(a)}(x,z)-\mathrm{Re}\Gamma_{\lambda(a)}(x,z)|\leq C|\ln|z-a||$ *for* $(x,z)\in B(a,\delta(a))\cap C_{a,\theta}$, *if* $m=3$.
3. $|\mathrm{Re}G^0_{\lambda(a)}(x,z)-\mathrm{Re}\Gamma_{\lambda(a)}(x,z)|\leq C|z-a|^{3-m}$ *for* $(x,z)\in B(a,\delta(a))\cap C_{a,\theta}$, *if* $m>3$.

In the proofs of these last lemmas we do not, in general, specify the interdependency of the constants appearing in the estimates. However, we distinguish the constant depending on the angle θ and the ones which do not depend.

Proof of Lemma 3.5. We set $R(x,z):=G_\lambda(x,z)-G_{\lambda(a)}(x,z)$. Then it satisfies

$$
(51)\qquad \begin{cases} (\Delta+\kappa^2)R(x,z)=0 \text{ in } \mathbb{R}^m\setminus\overline{D},\\ \frac{\partial R(x,z)}{\partial\nu}+i\lambda(a)R(x,z)=-i(\lambda-\lambda(a))G_\lambda(x,z) \quad \text{on} \quad \partial D,\\ R(\cdot,z) \text{ satisfies the Sommerfeld radiation condition.}\end{cases}
$$

From (51), we have the representation:

$$
R(x,z)=-\int_{\partial D} i(\lambda(y)-\lambda(a))G_{\lambda(a)}(y,x)G_\lambda(y,z)ds(y) \text{ for } (x,z)\in\mathbb{R}^m\setminus\overline{D}.
$$

Hence letting x tend to ∂D we have

$$
(52)\qquad R(x,z)=-\int_{\partial D} i(\lambda(y)-\lambda(a))G_{\lambda(a)}(y,x)G_\lambda(y,z)ds(y) \text{ for } x\in\partial D \text{ and } z\in\mathbb{R}^m\setminus\overline{D}.
$$

From the assumption on the regularity of the surface impedance $\lambda(x)$, we have

$$
|\lambda(y)-\lambda(a)|\leq C|y-a|^\beta.
$$

It is clear that $|y-a|\leq c(\theta)|y-z|$ for $y\in\partial D_I$ and $z\in C_{a,\theta}\cap B(a,\delta(a))$ with a positive constant $c(\theta)$ depending on the angle θ. This is due to the fact that ∂D_I and $C_{a,\theta}\cap B(a,\delta(a))$ are separated, i.e., $\partial D_I\cap C_{a,\theta}\cap B(a,\delta(a))=\{a\}$. From the inequality

$$
\frac{|\lambda(y)-\lambda(a)|}{|y-z|^{m-2}}\leq\frac{c(\theta)^\beta C}{|y-z|^{m-2-\beta}}
$$

and point 1 of Lemma 3.4, we have

$$
|R(x,z)|\leq\int_{\partial D}\frac{c(\theta)^\beta C}{|y-z|^{m-2-\beta}|y-x|^{m-2}}dy\leq\frac{C}{|x-z|^{m-3-\beta}}+C
$$

and then

$$
\max_{x\in\partial D}|R(x,z)|\leq\frac{C}{|z-a|^{m-3-\beta}}+C \text{ for } z\in C_{a,\theta}\cap B(a,\delta(a)).
$$

Now the solvability of the forward problem

$$\left\{\begin{array}{l}(\Delta+\kappa^2)R(x,z)=0 \text{ in } \mathbb{R}^m\setminus\overline{D},\\ |R(\cdot,z)|\leq \frac{C}{|z-a|^{m-3-\beta}}+C \quad \text{on} \quad \partial D,\\ R(\cdot,z) \text{ satisfies the radiation conditions}\end{array}\right. \tag{53}$$

implies the desired estimate for $R(x,z)$ for $x\in\mathbb{R}^m\setminus D$ and $z\in C_{a,\theta}\cap B(0,R)$. ∎

Proof of Lemma 3.6. We recall that $G^0_{\lambda(a)}$ satisfies

$$\left\{\begin{array}{l}\Delta G^0_\lambda(x,z)=-\delta(x,z) \text{ in } \Omega\setminus\overline{D},\\ \frac{\partial G^0_\lambda}{\partial\nu}(x,z)+i\lambda G^0_\lambda(x,z)=0 \text{ on } \partial D,\\ G^0_\lambda(x,z)=0 \text{ on } \partial\Omega.\end{array}\right. \tag{54}$$

Then $G_{\lambda(a)}-G^0_{\lambda(a)}$ is the solution of the problem

$$\left\{\begin{array}{l}\Delta(G_{\lambda(a)}-G^0_{\lambda(a)})(x,z)=\kappa^2G_{\lambda(a)}(x,z) \text{ in } \Omega\setminus\overline{D},\\ \frac{\partial(G_{\lambda(a)}-G^0_{\lambda(a)})}{\partial\nu}(x,z)+i\lambda(a)(G_{\lambda(a)}-G^0_{\lambda(a)})(x,z)=0 \text{ on } \partial D,\\ (G_{\lambda(a)}-G^0_{\lambda(a)})(x,z)=G_{\lambda(a)}(x,z) \text{ on } \partial\Omega.\end{array}\right. \tag{55}$$

Using integral representation for the solution of (55) and Lemma 3.4 applied for $G_{\lambda(a)}$ and $G^0_{\lambda(a)}$, we have the desired estimate for $(G_{\lambda(a)}-G^0_{\lambda(a)})(x,z)$ for x in $\Omega\setminus D$ and z near ∂D. ∎

Proof of Lemma 3.7. We can assume without loss of generality that $a=(0,0,0,\ldots,0)$ by using a rigid transformation of coordinates. Let $\xi=F(x)$ be the following local change of variables:

$$\left\{\begin{array}{l}\xi'=x',\\ \xi_m=x_m-f(x'),\end{array}\right. \tag{56}$$

where f is the function defined in the introduction. We have the following properties:

$$\left\{\begin{array}{l}c_1|x-z|\leq|F(x)-F(z)|\leq c_2|x-z|,\\ |F(x)-x|\leq c_3|x|^2,\\ |DF(x)-I|\leq c_4|x|,\end{array}\right. \tag{57}$$

for x,z near the point a, where $c_i, i=1,\ldots,4$, are positive constants, which is due to the C^2 regularity of ∂D.

Let x,z be near the point a. We set $\tilde{G}^0_{\lambda(a)}(\xi,\eta):=G^0_{\lambda(a)}(x,y)$, where $\xi=F(x)$ and $\eta:=F(z)$. Then $\tilde{G}^0_{\lambda(a)}(\cdot,\eta)$ satisfies

$$\left\{\begin{array}{l}\nabla\cdot B(\xi)\nabla\tilde{G}^0_{\lambda(a)}=-\delta(\xi-\eta) \text{ near } F(a),\\ |J^{-T}\nu|B\nabla\tilde{G}^0_{\lambda(a)}\cdot\nu+i\lambda(a)\tilde{G}^0_{\lambda(a)}=0 \text{ on } \partial\mathbb{R}^m_+ \text{ near } F(a),\end{array}\right. \tag{58}$$

where $B=JJ^T$ and $J=\frac{\partial\xi}{\partial x}(F^{-1}(\xi))$. From the properties (57), we have

$$|J(\xi)-J(0)|\leq c|\xi|, |B(\xi)-B(0)|\leq c|\xi|,$$

and $J(0)=B(0)=I$.

First step. Using similar notations as in the proof of Lemma 3.5, we write $\tilde{R}(\xi,\eta) = \tilde{G}^0_{\lambda(a)}(\xi,\eta) - \Gamma_{\lambda(a)}(\xi,\eta)$, and hence

(59)
$$\begin{cases} \Delta\tilde{R}(\xi,\eta) = \nabla\cdot(I-B)\nabla\tilde{G}^0_{\lambda(a)} \text{ near } F(a) \\ \nabla\tilde{R}\cdot\tilde{\nu} + i\lambda(a)\tilde{R} = (I-B)\nabla\tilde{G}^0_{\lambda(a)}\cdot\tilde{\nu} + i\lambda(a)(1-|J^{-T}|)\tilde{R} \text{ on } \partial\mathbb{R}^m_+ \text{ near } F(a). \end{cases}$$

Let $B_r^+ := B(F(a),r)\cap[F(D)]^c$ for r small enough; then by (59) and using the local Green's function $\Gamma_{\lambda(a)}$, the solution $\tilde{R}$ has the following representation:

$$-\tilde{R}(\xi,\eta) + \int_{\partial B_r^+}\frac{\partial\tilde{R}(z,\xi)}{\partial\nu}\Gamma_{\lambda(a)}(z,\eta)ds(z) - \int_{\partial B_r^+}\frac{\partial\Gamma_{\lambda(a)}(z,\eta)}{\partial\nu}\tilde{R}(z,\xi)ds(z)$$

$$= -\int_{B_r^+}(I-B)\nabla\tilde{G}^0_{\lambda(a)}(z,\xi)\cdot\nabla\Gamma_{\lambda(a)}(z,\eta)dz + \int_{\partial B_r^+}(I-B)\nabla\tilde{G}^0_{\lambda(a)}(z,\xi)\cdot\nu\Gamma_{\lambda(a)}(z,\eta)ds(z)$$

for ξ and η in B_r^+. We write $\partial B_r^+ = S_r\cup S_r^c$, where $S_r = \partial B_r^+\cap\partial(F(D))$. Using the impedance boundary condition on S_r, the last equation becomes

$$-\tilde{R}(\xi,\eta) - \int_{S_r} i\lambda(a)\tilde{R}(z,\xi)\cdot\Gamma_{\lambda(a)}(z,\eta)ds(z) + \int_{S_r} i\lambda(a)\Gamma_{\lambda(a)}(z,\eta)\tilde{R}(z,\xi)ds(z)$$

$$= -\int_{B_r^+}(I-B)\nabla\tilde{G}^0_{\lambda(a)}(z,\eta)\cdot\nabla\Gamma_{\lambda(a)}(z,y)dz + \int_{\partial B_r^+}(I-B)\nabla\tilde{G}^0_{\lambda(a)}(z,\xi)\cdot\nu\Gamma_{\lambda(a)}(z,\eta)ds(z)$$

$$+\int_{S_r^c}\frac{\partial}{\partial\nu}\tilde{R}(z,\xi)\Gamma_{\lambda(a)}(z,\eta)ds(z) + \int_{S_r^c}\frac{\partial}{\partial\nu}\Gamma_{\lambda(a)}(z,\eta)\tilde{R}(z,\xi)ds(z)$$

$$-\int_{S_r}(I-B)\nabla\tilde{G}^0_{\lambda(a)}(z,\xi)\cdot\nu\Gamma_{\lambda(a)}(z,\eta)ds(z) - i\lambda(a)\int_{S_r}(1-|J^{-T}\nu|)\tilde{R}(z,\eta)\Gamma_{\lambda(a)}(z,\xi)ds(z).$$

After simplification we have

$$\begin{aligned} -\tilde{R}(\xi,\eta) = &-\int_{B_r^+}(I-B)\nabla\tilde{G}^0_{\lambda(a)}(z,\xi)\cdot\nabla\Gamma_{\lambda(a)}(z,\eta)dz \\ &+\int_{S_r^c}(I-B)\frac{\partial\tilde{G}^0_{\lambda(a)}(z,\xi)}{\partial\nu}\Gamma_{\lambda(a)}(z,\eta)ds(z) \\ &+\int_{S_r^c}\frac{\partial\tilde{R}}{\partial\nu}(z,\xi)\Gamma_{\lambda(a)}(z,\eta)ds(z) + \int_{S_r^c}\frac{\partial}{\partial\nu}\Gamma_{\lambda(a)}(z,\eta)\tilde{R}(z,\xi)ds(z) \\ &-i\lambda(a)\int_{S_r}(1-|J^{-T}\nu|)\tilde{R}(z,\eta)\Gamma_{\lambda(a)}(z,\xi)ds(z). \end{aligned} \tag{60}$$

Taking the imaginary part in the last equality, we have

$$
\begin{aligned}
-\mathrm{Im}\tilde{R}(\xi,\eta) = &-\int_{B_r^+}(I-B)\nabla(\mathrm{Im}\tilde{G}^0_{\lambda(a)})(z,\xi)\cdot\nabla(\mathrm{Re}\Gamma_{\lambda(a)})(z,\eta)dz\\
&-\int_{B_r^+}(I-B)\nabla(\mathrm{Re}\tilde{G}^0_{\lambda(a)})(z,\xi)\cdot\nabla(\mathrm{Im}\Gamma_{\lambda(a)})(z,\eta)dz\\
&+\int_{S_r^c}(I-B)\frac{\partial\mathrm{Im}\tilde{G}^0_{\lambda(a)}}{\partial\nu}(z,\xi)\mathrm{Re}\Gamma_{\lambda(a)}(z,\eta)ds(z)\\
&+\int_{S_r^c}(I-B)\frac{\partial\mathrm{Re}\tilde{G}^0_{\lambda(a)}}{\partial\nu}(z,\xi)\mathrm{Im}\Gamma_{\lambda(a)}(z,\eta)ds(z)\\
&+\int_{S_r^c}\frac{\partial\mathrm{Im}\tilde{R}}{\partial\nu}(z,\xi)\mathrm{Re}\Gamma_{\lambda(a)}(z,\eta)ds(z)\\
&+\int_{S_r^c}\frac{\partial\mathrm{Re}\tilde{R}}{\partial\nu}(z,\xi)\mathrm{Im}\Gamma_{\lambda(a)}(z,\eta)ds(z)\\
&+\int_{S_r^c}\frac{\partial}{\partial\nu}\mathrm{Im}\Gamma_{\lambda(a)}(z,\eta)\mathrm{Re}\tilde{R}(z,\xi)ds(z)\\
&+\int_{S_r^c}\frac{\partial}{\partial\nu}\mathrm{Re}\Gamma_{\lambda(a)}(z,\eta)\mathrm{Im}\tilde{R}(z,\xi)ds(z)\\
&-\lambda(a)\int_{S_r}(1-|J^{-T}\nu|)\mathrm{Re}[\tilde{R}(z,\eta)\Gamma_{\lambda(a)}(z,\xi)]ds(z).
\end{aligned}\tag{61}
$$

We have for $\Gamma_{\lambda(a)}$ similar estimates as in Lemma 3.4. In particular, we have

$$|\nabla(\mathrm{Re}\Gamma_{\lambda(a)})(x,z)|\leq c|x-z|^{1-m}.$$

It is of importance to remark that the imaginary parts have fewer singularities. Indeed, we will prove the following lemma.

LEMMA 3.8. *For every $R>0$, there exists $c:=c(R)$ such that*

$$|\nabla(\mathrm{Im}\Gamma_{\lambda(a)})(x,z)|\leq c|x-z|^{2-m+s}d^{-s}(x,\partial B_+)$$

and

$$|\nabla(\mathrm{Im}\tilde{G}^0_{\lambda(a)})(x,z)|\leq c|x-z|^{2-m+s}d^{-s}(x,\partial B_+)$$

for x,z in $B_+(0,R):=B(0,R)\cap\mathbb{R}^m_+$.

Proof of Lemma 3.8. From (26), we deduce that $\mathrm{Im}\Gamma_{\lambda(a)}(\cdot,z)$ satisfies

$$
\begin{cases}\Delta(\mathrm{Im}\Gamma_{\lambda(a)})(\cdot,z)=0 \text{ in } \mathbb{R}^m_+,\\ \frac{\partial}{\partial\nu}\mathrm{Im}\Gamma_{\lambda(a)}(\cdot,z)=-\lambda(a)\mathrm{Re}\Gamma_{\lambda(a)}(\cdot,z) \text{ on } \partial\mathbb{R}^m_+.\end{cases}\tag{62}
$$

Let Ω be a regular domain in $\mathbb{R}^m$ symmetric with respect to the plane $\{x_m=0\}$. We state the problem (62) on $\Omega_+:=\Omega\cap\mathbb{R}^m_+$. Let G_+ be the Neumann Green's function of the Laplace on Ω_+. From (62) we can write

$$\mathrm{Im}\Gamma_{\lambda(a)}(x,z)=\int_{\partial\Omega_+}G_+(x,y)\frac{\partial\mathrm{Im}\Gamma_{\lambda(a)}}{\partial\nu}(z,y)ds(y).\tag{63}$$

The boundary condition in (62) on $\partial\Omega_+\cap\partial\mathbb{R}^m_+$ gives

$$
\begin{aligned}
\mathrm{Im}\Gamma_{\lambda(a)}(x,z)=&-\int_{\partial\Omega_+\cap\partial\mathbb{R}^m_+}\lambda(a)G_+(x,y)\mathrm{Re}\Gamma_{\lambda(a)}(z,y)ds(y)\\
&-\int_{\partial\Omega_+\setminus\partial\mathbb{R}^m_+}G_+(x,y)\frac{\partial\mathrm{Im}\Gamma_{\lambda(a)}}{\partial\nu}(z,y)ds(y).
\end{aligned}
$$

Taking the derivatives, we have

$$\nabla_x(\mathrm{Im}\Gamma_{\lambda(a)})(x,z) = -\int_{\partial\Omega_+\cap\partial\mathbb{R}^m_+} \lambda(a)\nabla_x G_+(x,y)\mathrm{Re}\Gamma_{\lambda(a)}(z,y)ds(y) - \int_{\partial\Omega_+\setminus\partial\mathbb{R}^m_+} \nabla_x G_+(x,y)\frac{\partial \mathrm{Im}\Gamma_{\lambda(a)}}{\partial\nu}(z,y)ds(y). \tag{64}$$

Taking Ω large enough to contain $B_+(0,R)$ and using the estimates of G_+ and $\Gamma_{\lambda(a)}$ given in Lemma 3.4, we deduce that the second term in the right-hand side is bounded for x, z in $B_+(0,R)$ because $\partial\Omega_+ \setminus \partial\mathbb{R}^m_+$ is away from $B_+(0,R)$. The first term can be estimated by

$$\begin{aligned}
&\left|\int_{\partial\Omega_+\cap\partial\mathbb{R}^m_+} \lambda(a)\nabla_x G_+(x,y)\mathrm{Re}\Gamma_{\lambda(a)}(z,y)ds(y)\right| \\
&\quad\le c\int_{\partial\Omega_+\cap\partial\mathbb{R}^m_+} |x-y|^{1-m}|y-z|^{2-m}ds(y) \\
&\quad\le c\int_{\partial\Omega_+\cap\partial\mathbb{R}^m_+} |x-y|^{1-m+s}|y-z|^{2-m}ds(y)d^{-s}(x,\partial\Omega_+) \\
&\quad\le c_s|x-z|^{2-m+s}d^{-s}(x,\partial\Omega_+),
\end{aligned}$$

where c_s is a positive constant behaving as $\frac{1}{1-s}$; see [14] (or [21] for Lipschitz surfaces). Similar arguments can be applied for $\tilde{G}^0_{\lambda(a)}$. □

Using this lemma and the estimates of $\tilde{G}^0_{\lambda(a)}$ in (61), we have

$$\begin{aligned}
|\mathrm{Im}\tilde{R}(\xi,\eta)| \le c\Bigg[&\int_{B_r^+} |z|d^{-s}(z,\partial B_r^+)|z-\xi|^{2-m+s}|z-\eta|^{1-m}dz \\
&+\int_{B_r^+} |z||z-\xi|^{1-m}d^{-s}(z,\partial B_r^+)|z-\eta|^{2-m+s}dz \\
&+\int_{S_r^c} d^{-s}(z,\partial B_r^+)|z-\xi|^{2-m+s}|z-\eta|^{1-m}ds(z) \\
&+\int_{S_r^c} |z-\xi|^{1-m}d^{-s}(z,\partial B_r^+)|z-\eta|^{2-m+s}ds(z) \\
&+\int_{S_r} |z||z-\xi|^{2-m}|z-\eta|^{2-m}ds(z)\Bigg],
\end{aligned} \tag{65}$$

where c is a positive constant independent on ξ and η.

Taking $\eta \in C_{F(a),\theta}$ and ξ on S_r away from S_r^c, from (65) we will show the desired estimate of $\mathrm{Im}\tilde{R}(\xi,\eta)$.

The third and the fourth integrals in (65) are bounded because ξ is away from S_r^c. Let us consider the first integral. For $\eta \in C_{F(a),\theta}$ and ξ on S_r, we have the inequality

$$|\xi| \le c(\theta)|\xi-\eta|, \tag{66}$$

with some positive constant $c(\theta)$. We decompose B_r^+ as $B_r^+ = B_{r_1}^+ \cup B_{r_2}^+$, where $B_{r_1}^+ := B_r^+ \cap C_{F(a),\tilde{\theta}}$, where $\theta < \tilde{\theta} < \frac{\pi}{2}$ and $B_{r_2}^+ := B_r^+ \setminus B_{r_1}^+$.

Let us consider $\int_{B_{r_1}^+} |z|d^{-s}(z,\partial B_r^+)|z-\xi|^{2-m+s}|z-\eta|^{1-m}dz$. For $z \in B_r^+$, we have $|z| \le c(\tilde{\theta})d(z,\partial B_r^+)$ for some positive constant $c(\tilde{\theta})$. Hence we need to consider the integral:

$$\int_{B_{r_1}^+} |z|^{1-s}|z-\xi|^{2-m+s}|z-\eta|^{1-m}dz.$$

At this point, we make use of an argument from [1, pp. 209–210]. We decompose the last integral as the sum of

$$I_1(\xi,\eta) := \int_{\{|z|<4c(\theta)h\}\cap B^+_{r_1}} |z|^{1-s}|z-\xi|^{2-m+s}|z-\eta|^{1-m}dz$$

and

$$I_2(\xi,\eta) := \int_{\{|z|>4c(\theta)h\}\cap B^+_{r_1}} |z|^{1-s}|z-\xi|^{2-m+s}|z-\eta|^{1-m}dz,$$

where $h := |\xi-\eta|$. After the change of variables $t := \frac{z}{h}$, we obtain

$$I_1(\xi,\eta) \leq h^{4-m}4c(\theta)\int_{|t|<4c(\theta)} |t|^{1-s}\left|\frac{\xi}{h}-t\right|^{2-m+s}\left|\frac{\eta}{h}-t\right|^{1-m}dt.$$

Since $|\frac{\xi}{h}-\frac{\eta}{h}| = 1$, then from [14, Chapter 2, section 11], the integral in the left-hand side is bounded. Hence

$$I_1(\xi,\eta) \leq c|\xi-\eta|^{4-m}. \tag{67}$$

Let us now consider the term $I_2(\xi,\eta)$. From the inequality (66), we have

$$|z| \ \leq |z-\xi| + |\xi| \leq |z-\xi| + c(\theta)|h| \leq |z-\xi| + \frac{1}{4}|z|,$$

and hence

$$|z| \leq \frac{4}{3}|z-\xi|. \tag{68}$$

Similarly we get $|z| \leq \frac{4c(\theta)}{3c(\theta)-1}|z-\eta|$. In (66), we can always take $c(\theta) > \frac{1}{3}$. Hence

$$I_2(\xi,\eta) \leq c\int_{r>|z|>4c(\theta)h} |z|^{4-2m}dz \leq C|\xi-\eta|^{4-m} + C. \tag{69}$$

Summing up (67) and (69) implies

$$\int_{B^+_{r_1}} |z|d^{-s}(z,\partial B^+_r)|z-\xi|^{2-m+s}|z-\eta|^{1-m}dz \leq C|\xi-\eta|^{4-m} + C. \tag{70}$$

Now we deal with $\int_{B^+_{r_2}}|z|d^{-s}(z,\partial B^+_r)|z-\xi|^{2-m+s}|z-\eta|^{1-m}dz$. In this case $d(z,\partial B^+_{r_2}) = |z_m|$. Since $\eta \in C_{F(a),\theta}$, then $|z-\eta|^{1-m} > c > 0$, since $C_{F(a),\theta}$ and $B^+_{r_2}$ are separated sets.

Hence, using this information with the fact that $|z| \leq \frac{4}{3}|z-\xi|$, we have

$$\int_{B^+_{r_2}} |z|d^{-s}(z,\partial B^+_r)|z-\xi|^{2-m+s}|z-\xi|^{1-m}dz \leq \int_{B^+_{r_2}} |z|^{3-m+s}|z_m|^{-s}dz.$$

By using the Holder inequality and choosing s small enough we have $\int_{B^+_{r_2}} |z|^{3-m+s}|z_m - \xi|^s dz < \infty$. This means that the first integral of (65) is estimated by $C|\xi-\eta|^{4-m} + C$.

Arguing as before for the first terms of (65), we deduce that the second term has a similar estimate. From the inequality (68), the last integral is bounded by $c\int_{S_r} |z-\xi|^{3-m}|z-\eta|^{2-m}ds(z)$, which is itself bounded by $C|\xi-\eta|^{4-m} + C$. Finally we deduce that the integral in (65) is also bounded by $C|\xi-\eta|^{4-m} + C$.

Second step. We go back to estimate $R(x,z) := G^0_{\lambda(a)}(x,z) - \Gamma_{\lambda(a)}(x,z)$. We have

$$R(x,z) = G^0_{\lambda(a)}(x,z) - \Gamma_{\lambda(a)}(F(x),F(z)) + \Gamma_{\lambda(a)}(F(x),F(z)) - \Gamma_{\lambda(a)}(x,z),$$

which we write as

$$\begin{aligned} R(x,z) = \tilde{R}(F(x),F(z)) &+ (\Gamma_{\lambda(a)}(F(x),F(z)) - \Gamma_{\lambda(a)}(F(x),z)) \\ &+(\Gamma_{\lambda(a)}(F(x),z) - \Gamma_{\lambda(a)}(x,z)). \end{aligned} \tag{71}$$

Let us show that $F(C_{a,\theta} \cap B(0,\delta(a))) \subset C_{F(a),\theta'}$ for some $\theta' \in (0,\pi/2)$ and $\theta \leq \theta'$ with $\delta(a)$ small enough. Recall that $a = (0,0,0)$. We set $M := \max_{(z_1,z_2)\in\overline{B_2}(0,\delta(a))} |f(z_1, z_2)|$ and then $M = |f(z_1^0, z_2^0)|$ for some point (z_1^0, z_2^0). We draw the cone with vertex a, axis $(-\nu(a))$, and having the point (z_1^0, z_2^0, M) on its boundary. We denote by ϕ the angle between this cone and the plane $\{z_3 = 0\}$. Since $|\nabla f(0,0)| = 0$ and $f \in C^1(0,\delta(a))$, $\phi = \phi(\delta(a))$ tends to zero if $\delta(a)$ tends to zero. Hence taking $\delta(a)$ small enough, if necessary, we can assume that $0 \leq \phi < \pi/2 - \theta$. Finally we define the cone with center a, axis $(-\nu(a))$, and angle $\theta' := \phi + \theta$. Then $F(C_{a,\theta}) \subset C_{F(a),\theta'}$.

Let x be near a such that $F(x) \in S_r$ and away from S_r^c and $z \in C_{a,\theta} \cap B(a,\delta(a))$. Then $(F(x),F(z)) \in S_r \times C_{F(a),\theta'}$ and hence

$$\mathrm{Im}\tilde{R}(F(x),F(z)) \leq C|F(x) - F(z)|^{4-m} + C \leq C|x-z|^{4-m} + C$$

as shown in the first step.

In the following we need to estimate the second and the third terms of the right-hand side of (71). We write

$$|\Gamma_{\lambda(a)}(F(x),F(z)) - \Gamma_{\lambda(a)}(F(x),z)| \leq |\nabla_z \mathrm{Im}\Gamma_{\lambda(a)}(F(x),\cdot)|_{L^\infty(V_{z,\epsilon})}|F(z) - z| \tag{72}$$

and

$$|\Gamma_{\lambda(a)}(F(x),z) - \Gamma_{\lambda(a)}(x,z)| \leq |\nabla_x \mathrm{Im}\Gamma_{\lambda(a)}(\cdot,z)|_{L^\infty(V_{x,\epsilon})}|F(x) - x|, \tag{73}$$

where $V_{z,\epsilon}$ is an open set containing z and $F(z)$ such that $F(x) \in V^c_{z,\epsilon}$, and $V_{x,\epsilon}$ is an open set containing x and $F(x)$ such that $z \in V^c_{x,\epsilon}$.

From the representation (64) in the proof of Lemma 3.8, we have

$$|\nabla_z(\mathrm{Im}\Gamma_{\lambda(a)}(F(x),\cdot))|_{L^\infty(V_{z,\epsilon})} < c[d(F(x),\partial V_{z,\epsilon})]^{2-m},$$

and similarly, we have

$$|\nabla_x(\mathrm{Im}\Gamma_{\lambda(a)}(\cdot,z))|_{L^\infty(V_{x,\epsilon})} < c[d(z,\partial V_{x,\epsilon})]^{2-m},$$

where c is independent of $V_{z,\epsilon}$ and $V_{x,\epsilon}$.

Hence (72) and (73) become

$$|\Gamma_{\lambda(a)}(F(x),F(z)) - \Gamma_{\lambda(a)}(F(x),z)| \leq c[d(F(x),\partial V_{z,\epsilon})]^{2-m}|F(z) - z|$$

and

$$|\Gamma_{\lambda(a)}(F(x),z) - \Gamma_{\lambda(a)}(x,z)| \leq c[d(z,\partial V_{x,\epsilon})]^{2-m}|F(x) - x|,$$

respectively. Since $\epsilon > 0$ is arbitrary, we deduce, by shrinking $V_{z,\epsilon}$ to tend to a line joining the points z and $F(z)$ and similarly $V_{x,\epsilon}$ to tend to a line joining the points x and $F(x)$, that there exists $c > 0$ such that

$$(74)\quad \begin{cases} |\Gamma_{\lambda(a)}(F(x), F(z)) - \Gamma_{\lambda(a)}(F(x), z)| \leq c|F(x) - F(z)|^{2-m}|F(z) - z| \\ \text{or} \\ |\Gamma_{\lambda(a)}(F(x), F(z)) - \Gamma_{\lambda(a)}(F(x), z)| \leq c|F(x) - z|^{2-m}|F(z) - z| \end{cases}$$

and

$$(75)\quad \begin{cases} |\Gamma_{\lambda(a)}(F(x), z) - \Gamma_{\lambda(a)}(x, z)| \leq c|x - z|^{2-m}|F(x) - x| \\ \text{or} \\ |\Gamma_{\lambda(a)}(F(x), z) - \Gamma_{\lambda(a)}(x, z)| \leq c|F(x) - z|^{2-m}|F(x) - x|. \end{cases}$$

Recalling that

$$|x| \leq c(\theta)|x - z|$$

for x near a and $z \in C_{a,\theta} \cap B(a, \delta(a))$ and using (57), we have

$$|x - z| \leq |x - F(x)| + |F(x) - z| \leq c|x|^2 + |F(x) - z| \leq c(\theta)|x - z|^2 + |F(x) - z|.$$

Hence

$$|x - z|[1 - c(\theta)|x - z|] \leq |F(x) - z|.$$

Taking $\delta(a)$ small enough so that we have $(1 - c(\theta)|x - z|^2) \geq 1/2$,

$$|x - z| \leq 2|F(x) - z|.$$

From (57), we have

$$(76)\quad |F(x) - x| \leq c|x|^2 \leq c(\theta)|x - z|^2$$

and also

$$(77)\quad |F(z) - z| \leq c|z|^2 \leq c(\theta)|x - z|^2.$$

Since $|x - z| \leq c|F(x) - F(z)|$, using (76) and (77) in (74) and (75), we deduce that the second and the third terms of (71) are estimated by $C|x - z|^{4-m}$.

This means that

$$(78)\quad |\mathrm{Im}R(x, z)| \leq C|x - z|^{4-m} + C$$

for $x \in B(a, \delta(a))$ such that $F(x) \in S_r$ and $z \in C_{a,\theta} \cap B(a, \delta(a))$.

For $z \in C_{a,\theta} \cap B(a, \frac{\delta(a)}{2})$ and $x \in [\partial B(a, \delta(a))] \cap \mathbb{R}^m \setminus \overline{D}$, we have

$$(79)\quad |\mathrm{Im}R(x, z)| \leq C$$

with some positive constant c, because $C_{a,\theta} \cap B(a, \frac{\delta(a)}{2})$ and $\partial B(a, \delta(a)] \cap \mathbb{R}^3 \setminus \overline{D}$ are separated sets. Since in $B(a, \delta(a)) \cap (\mathbb{R}^3 \setminus \overline{D})$ we have $\Delta_x \mathrm{Im}R(x, z) = 0$, using (78) and (79), we have, by the maximum principle,

$$|\mathrm{Im}R(x, z)| \leq c(\theta)|z - a|^{4-m} + C$$

for $x \in [\mathbb{R}^3 \setminus D] \cap B(a, \delta(a))$ and $z \in C_{a,\theta} \cap B(a, \frac{\delta(a)}{2})$.

Considering the real part of $R(x, z)$, by similar arguments as for $\mathrm{Im}R(x, z)$, we prove that

$$|\mathrm{Re}R(x, z)| \leq \begin{cases} c(\theta)|\ln |z-a|| \text{ if } m = 3, \\ c(\theta)\frac{1}{|z-a|^{m-3}} \text{ if } m > 3. \end{cases}$$

This ends the proof of Lemma 3.7. $\square$

ON A CLASS OF NONCONVEX BOLZA PROBLEMS RELATED TO BLATZ–KO ELASTIC MATERIALS*

P. CELADA† AND S. PERROTTA‡

Abstract. We study the existence of solutions to Bolza problems for a special class of one-dimensional, nonconvex integrals. These integrals describe the possibly singular, radial deformations of certain rubberlike materials called Blatz–Ko materials.

Key words. nonconvex variational problems, Bolza problems, existence of minimizers, cavitation, Blatz–Ko materials

1. Introduction.

In this paper we investigate the existence of solutions to Bolza problems for a special class of one-dimensional, nonconvex integrals of the form

$$\int_0^1 r^{N-1}\Phi\left(v'(r)\,,\frac{v(r)}{r}\right)dr+\theta(v(0)), \tag{1.1}$$

where $\Phi\colon \mathbb{R}^2_+ \to [0\,,+\infty)$ and $\theta\colon [0\,,+\infty) \to [0\,,+\infty)$ are smooth functions and the competing functions $v > 0$ satisfy the unilateral constraint $v' > 0$ a.e. and the one-point boundary condition $v(1) = \lambda$ for a given $\lambda > 1$. We emphasize that Φ need not be convex with respect to the derivative v'.

This special class of variational problems arises in mathematical models describing the deformations of some foam rubberlike materials, including the so-called *Blatz–Ko materials*.

The variational elasticity problem that motivates the model can be described as follows. Let the open unit ball B_1 be the reference configuration of a hyperelastic, isotropic material with stored energy density W so that the total energy corresponding to a smooth deformation u with given displacement $u(x) = \lambda x > 1$ at the boundary $|x| = 1$ is given by

$$E_0(u)=\int_{B_1} W(Du(x))\,dx.$$

Physical arguments require that admissible deformations u be orientation preserving, i.e., $\det Du > 0$, and that $W(Du) \to +\infty$ as $\det Du \to +\infty$ and $\det Du \to 0_+$. The first hypothesis means that no interpenetration of matter occurs, and the others mean that infinite energy is required for unbounded expansion of the body or compression to a single point.

We restrict our analysis to the special case of radial deformations, i.e., $u(x) = v(|x|)x/|x|$ with $v(r) > 0$ for $0 < r < 1$ and $v(1) = \lambda > 1$. In this case, the total

energy, by a change of variables, turns out to be

$$E_0(u) = J_0(v) = \omega_N \int_0^1 r^{N-1} \Phi\left(v'(r)\,, \frac{v(r)}{r}\right) dr, \tag{1.2}$$

where ω_N is the $(N-1)$-dimensional measure of the surface of B_1 and Φ is associated with the stored energy density W; see section 2. We look for those radial deformations that minimize the total energy among all radial deformations and we emphasize here that, on the grounds of experimental evidence, we want to include among the feasible functions those v satisfying $v(0) > 0$, i.e., corresponding to deformations u which are singular at the origin. The variational problem thus obtained was considered by Ball in [1], and it is known as the problem of *cavitation*. Indeed, the existence of optimal radial deformations with $v(0) > 0$ for large enough displacement λ at the boundary can be interpreted as the occurrence of a spherical fracture—a *cavity*—inside the body. Ball in [1] extensively studied this problem with different possible boundary conditions—displacement and dead load traction—and for both compressible and incompressible materials. With regard to cavitation, we mention also [31], [19] as well as [21] and [7], which address the full three-dimensional problem. See also [13] for a description of cavitation in the language of currents. Among the results of [1], we are especially interested in those regarding isotropic, compressible materials whose stored energy density $W(Du)$, as a function of the singular values $\lambda_1, \dots, \lambda_N$ of the deformation gradient Du, takes the form

$$W(Du) = \sum_n w_0(\lambda_n) + w(\lambda_1 \cdots \lambda_N). \tag{1.3}$$

In Ball's paper [1], w_0 and w are suitable strictly convex functions with superlinear growth at infinity, and these hypotheses play a crucial role in the analysis. Ball then shows that minimizers in the restricted class of radial deformations exist and, moreover, that cavitation occurs for large enough displacements λ. Since Ball's seminal paper, the problem of cavitation has been extensively investigated, and several other aspects, including stability, have been considered. See [23], [25], [26], [27], [28] and [29], to mention just a few. We refer to [15] and the references therein for a recent survey of theoretical and experimental results about cavitation. Yet, apart from the contribution by Müller and Spector [21] mentioned above and related papers, investigation on cavitation has been carried out so far mostly in the radial case, and little is known in the unrestricted case, in particular, about the symmetry of possible minimizers. As to this question, we mention the uniqueness result by Knops and Stuart [17] and the existence result by Spector [30], which single out two situations where minimizers in the unrestricted case are radially symmetric. None of these results, however, applies to the case considered here.

The hypotheses of [1] do not include the case that w in (1.3) is nonconvex, i.e., that the model can possibly exhibit phase transition, and in particular do not include the case that w is given by

$$w_{BK}(t) = \frac{2\alpha}{t} + (1-\alpha)\left(2t + \frac{1}{t^2}\right), \qquad t > 0, \tag{1.4}$$

with $\alpha = -0.19$. Indeed, $w_{BK}(t) \to +\infty$ as $t \to 0_+$ and $t \to +\infty$ as expected, but w_{BK} is at the same time asymptotically linear and concave as $t \to +\infty$. This special choice of w was proposed by Blatz and Ko in [3] on the grounds of experimental results; see also [18] and [14]. It is supposed to describe the behavior of some foam rubberlike materials, now called Blatz–Ko materials.

The problem of cavitation was studied also by Marcellini in [19]. Marcellini's approach to the problem is based on the idea that, contrary to Ball's approach, the energy corresponding to a singular, radial deformation v featuring cavitation cannot be taken equal to (1.2) but must be defined elastically by lower semicontinuity or relaxation, i.e., choosing the energy of the radial deformation associated to v to be

$$J_V(v) = \inf \left\{ \liminf_{k\to+\infty} J_0(v_k) : \; v_k \to v \right\},$$

where the greatest lower bound is taken among all regular deformations v_k with $v_k(0) = 0$ (no cavitation occurs), and the convergence is in the strong Sobolev sense. Marcellini's main result is the derivation of a representation formula for the resulting relaxed energy J_V which turns out to be

$$J_V(v) = \omega_N \int_0^1 r^{N-1}\Phi\left(v'(r)\,, \frac{v(r)}{r}\right) dr + c\frac{\omega_N}{N}\left[v(0)\right]^N . \tag{1.5}$$

It is important to emphasize here that relaxation is made with respect to strong Sobolev convergence; otherwise the energy density Φ would be replaced by its convex envelope Φ^{**} with respect to v', in contrast with the experimental results of [3] which suggest for Blatz–Ko materials a nonconvex dependence on the determinant of the deformation gradient.

The additional term appearing in the relaxed energy J_V is thus proportional to the N-dimensional measure of the cavity and can be interpreted as the contribution to the total energy of the singular part of the Jacobian determinant of the radial deformation $u(x) = v(|x|)x/|x|$. The coefficient c appearing in (1.5) depends on Φ and, when Φ comes from a stored energy density W as those considered in [1] (see (1.3)), it is given by the recession w^∞ of the convex function w at $t = 1$ (see (2.4)). Clearly, the additional term in the definition of J_V penalizes the occurrence of cavitation, and, moreover, according to this model and contrary to Ball's, singular radial deformations require infinite energy for superlinear w since $w^\infty = +\infty$.

Following Müller and Spector's full three-dimensional model [21], a further radial model is considered in [4], where the energy associated with a radial deformation v is given by

$$J_S(v) = \omega_N \int_0^1 r^{N-1}\Phi\left(v'(r)\,, \frac{v(r)}{r}\right) dr + \omega_N w^\infty \left[v(0)\right]^{N-1} .$$

In this case, the contribution of the cavity to the total energy is proportional to the surface of the cavity as in [21], and we refer to [4] for a detailed discussion of the features of this model and for a comparative analysis with Ball's and Marcellini's models.

All the models considered so far thus lead, in the restricted case of radial deformations, to the problem of minimizing either an energy of the form J_0 defined by (1.2) when W is superlinear with respect to the Jacobian as in Ball's model [1] or an energy of the form (1.1) which we rewrite as

$$J(v) = \omega_N \int_0^1 r^{N-1}\Phi\left(v'(r)\,, \frac{v(r)}{r}\right) dr + \omega_N w^\infty \theta(v(0))$$

when W is linear in the Jacobian as in Marcellini's model [19] and in [4]. In these latter cases, the function $\theta\colon [0\,,+\infty) \to [0\,,+\infty)$ appearing in the definition of J is continuous, increasing, and null at zero, and the coefficient $0 < w^\infty < +\infty$ is given by (2.4). In both cases, minimization is subject to the one-point boundary condition $v(1) = \lambda > 1$.

When the stored energy density W is polyconvex, the resulting Φ is convex with respect to the derivative v' so that J_0 is lower semicontinuous for the natural convergence and the existence of minimizers for J_0 follows from standard arguments as in Ball [1]. If, in addition, the function

$$t \in [0\,,+\infty) \mapsto \frac{t^N}{N} - \theta(t)$$

is increasing, the same argument applies to J (Theorem 3.4). By contrast, when W fails to be polyconvex, Φ need not be convex with respect to v', and minimizers of J and J_0 need not exist. Our aim in this paper is the proof of fairly general attainment results for the minimum problems for J (Theorem 3.3) and J_0 (Theorem 3.5) when Φ is nonconvex with respect to v'. We show in particular (Theorem 2.1) that the result for J (linear growth) applies to the special choice of $w = w_{BK}$ corresponding to Blatz–Ko materials.

Our analysis in this paper mainly deals with the case of nonpolyconvex energy densities W that grow linearly as the Jacobian $\det Du \to +\infty$, and this leads to the one-dimensional integral J which comes from relaxing J_0 as in Marcellini [19]. Yet, the very same arguments and proofs apply unchanged to the superlinear case, which turns out to be even simpler. We thus emphasize that our existence results apply to elastomers which can possibly exhibit phase transition because of the lack of polyconvexity in both cases of "soft" elastomers, i.e., having linear growth in the Jacobian, as well as in the case of "hard" or nearly incompressible elastomers featuring very fast growth in the Jacobian. However, as a disclaimer, we wish to emphasize also that we do not address in this paper the issue of the onset of cavitation, i.e., whether optimal radial deformations for Blatz–Ko materials are singular at the origin or not, and we refer to [4] for a detailed discussion of this problem in the polyconvex case.

The issue of attainment for one-dimensional, nonconvex variational problems has been extensively studied in recent years, and we refer to the references in [20] for a far from exhaustive list of contributions on this subject. See also the references in [5] for more recent years. In particular, for the radial case we mention [6], [8], and [9]. The existence results we prove here are partially based on the ideas developed in [5].

The rest of the paper is organized as follows. In section 2, we briefly introduce the notation, we describe with more details the physical model and the variational problems we end up with, and we state our main result on the existence of optimal, radially symmetric deformations for Blatz–Ko materials (Theorem 2.1). Then, in section 3, we study the associated one-dimensional, nonconvex Bolza problem for J (linear growth) and we state an attainment result for it (Theorem 3.3). In the same section, we consider also the nonconvex variational problem for J_0 (superlinear growth) and we state an attainment result in this case as well (Theorem 3.5). We prove both results in section 4. Finally, in section 5, we prove Theorem 2.1 by showing that the existence result of section 3 applies to the w of Blatz–Ko materials given by (1.4).

2. Notation and description of the problem. We denote the norm of a vector x in $\mathbb{R}^N$ by $|x|$ and the scalar product of x and y by $\langle x, y\rangle$. If A is a subset of $\mathbb{R}^N$, we denote the interior, the closure, and the boundary of A by $\mathrm{int}(A)$, $\overline{A}$, and ∂A, respectively.

As for matrices, let $\mathbb{M}^{N\times N}$ be the set of all $N\times N$ real matrices $A = (A^m_n)_{m,n=1,\dots,N}$ endowed with the euclidean norm denoted by $|A|$. Let $\mathbb{I}_N$ be the identity matrix and let $\mathrm{Adj}\, A$ be the $N\times N$ matrix defined as the transpose of the *cofactors* of A so that Laplace's formula yields

$$\det A = \sum_{1\le n\le N} A^1_n\,(\mathrm{Adj}\, A)^1_n\,.$$

The *singular values* of the matrix A are the eigenvalues $\lambda_1(A),\dots,\lambda_N(A)$ of the positive, symmetric matrix $\sqrt{AA^T}$ so that

$$|A|^2 = \lambda_1^2(A) + \cdots + \lambda_N^2(A) \quad \text{and} \quad |\det A| = \lambda_1(A)\cdots\lambda_N(A).$$

The standard basis of $\mathbb{R}^N$ is denoted by $\{e_1,\dots,e_N\}$, and the *tensor product* of two vectors $a = a^1e_1 + \cdots + a^Ne_N$ and $b = b^1e_1 + \cdots + b^Ne_N$ is the rank-one matrix $a\otimes b$ defined by $(a\otimes b)^m_n = a^mb^n$ for every m and n. Finally, we denote the group of all matrices with positive determinant by $\mathbb{M}^{N\times N}_+$ and its special orthogonal subgroup by $SO(N)$.

With regard to measure and functional theoretic notation, we denote the Lebesgue measure of a measurable subset E in some euclidean space $\mathbb{R}^n$ by $|E|$. We use standard notation for the spaces of continuously differentiable functions as well as for Lebesgue and Sobolev spaces and their norms. In the special case of functions of one variable on a bounded interval I, we let $AC(I)$ and $AC_{\mathrm{loc}}(I)$ be the space of all absolutely continuous functions on I and on all compact subintervals of I, respectively.

In what follows, we shall consider the Jacobian determinant of Sobolev mappings $u\colon \Omega\to\mathbb{R}^N$, $u = (u^1,\dots,u^N)$, where Ω is an open subset of $\mathbb{R}^N$. If $u\in W^{1,p}(\Omega,\mathbb{R}^N)$ for some $p\ge 1$, we denote by $\det Du$ the measurable function defined a.e. as the *pointwise Jacobian determinant* of u which is in $L^1(\Omega)$ for $p\ge N$. If $p<N$, $\det Du$ loses its natural meaning, and for $p\ge N^2/(N+1)$ or when $u\in W^{1,N-1}(\Omega,\mathbb{R}^N)\cap L^\infty(\Omega,\mathbb{R}^N)$, we consider instead the *distributional Jacobian determinant* of u defined as the distributional divergence

$$\mathrm{Det}\, Du = \sum_{1\le n\le N} D_n\left(u^1\,(\mathrm{Adj}\, Du)^1_n\right).$$

In general, $\mathrm{Det}\, Du$ is not a function, and $\mathrm{Det}\, Du \ne \det Du$ in the sense of distribution. However, if u is in $W^{1,p}(\Omega,\mathbb{R}^N)$ with $p\ge N^2/(N+1)$ and $\mathrm{Det}\, Du$ is a Radon measure, then $\det Du$ is the Radon–Nikodym derivative (density) of the absolutely continuous part of $\mathrm{Det}\, Du$ with respect to the Lebesgue measure and we denote the *singular part* of $\mathrm{Det}\, Du$ by $(\mathrm{Det}\, Du)^{\mathrm{s}}$. We refer to [12] for further results on the relation between det and Det and the structure of the distributional Jacobian determinant.

As motivated in the introduction, we are interested in studying the deformations of a hyperelastic, homogeneous, solid body whose reference configuration is the open unit ball B_1 of $\mathbb{R}^N$, the physically interesting case being obviously $N=2$ and $N=3$. We assume that the *stored energy density* of the body is a smooth function $W\in\mathcal{C}^1(\mathbb{M}^{N\times N}_+)$, $W\ge 0$, which can be written as

$$W(A) = W_0(A) + w(\det A), \qquad A\in\mathbb{M}^{N\times N}_+,$$

where the first term $W_0 \in \mathcal{C}^1(\mathbb{M}_+^{N\times N})$, $W_0 \geq 0$, is *frame indifferent* and *isotropic*; i.e.,

$$W_0(QA) = W_0(A) = W_0(AQ), \qquad A \in \mathbb{M}_+^{N\times N}, \quad Q \in SO(N). \tag{2.1}$$

With regard to the behavior of W_0 for large $|A|$, we assume that W_0 has superlinear growth

$$\lim_{|A|\to+\infty} \frac{W_0(A)}{|A|} = +\infty, \tag{2.2}$$

but at the same time, as we are interested in possibly discontinuous deformations, we assume also that W_0 has polynomial growth of order strictly less than N, i.e.,

$$0 \leq W_0(A) \leq C\,(1 + |A|^p)\,, \qquad A \in \mathbb{M}_+^{N\times N}, \tag{2.3}$$

for some $C \geq 0$ and $1 < p < N$. As for the term w depending on the deformation of volume elements, we assume that $w \in \mathcal{C}^1(\mathbb{R}_+)$, $w \geq 0$, is such that

$$\lim_{t\to 0_+} w(t) = +\infty \quad \text{ and } \quad \lim_{t\to+\infty} \frac{w(t)}{t} = w^\infty \in (0\,,+\infty]. \tag{2.4}$$

Hence, linear growth corresponds to $0 < w^\infty < +\infty$ and superlinear growth to $w^\infty = +\infty$. We emphasize again that in both cases w need not be convex and that, for Blatz–Ko materials, (2.4) holds with $w^\infty = w^\infty_{BK} = 2(1-\alpha)$ where $\alpha = -0.19$, i.e., $w^\infty_{BK} = 2.38$.

The properties of frame indifference and isotropy (2.1) of the function W_0 obviously hold for the entire energy W as well, and, as is well known, both W_0 and W can then be written as functions of the singular values $\lambda_1 = \lambda_1(A), \dots, \lambda_N = \lambda_N(A)$ of the gradient matrix A, i.e.,

$$\begin{aligned} W_0(A) &= \Phi_0\,(\lambda_1\,, \dots, \lambda_N)\,, \\ W(A) &= \Phi\,(\lambda_1\,, \dots, \lambda_N) = \Phi_0\,(\lambda_1\,, \dots, \lambda_N) + w\,(\lambda_1 \cdots \lambda_N) \end{aligned} \tag{2.5}$$

for symmetric functions Φ_0, $\Phi\colon \mathbb{R}^N_+ \to [0\,,+\infty)$ satisfying the appropriate growth properties corresponding to (2.2) and (2.3). Moreover, Φ_0 and Φ share the same smoothness with W_0 and W, respectively.

For this energy density W, the total energy associated with a smooth deformation u is given by the integral

$$E_0(u) = \int_{B_1} W(Du(x))\,dx. \tag{2.6}$$

We want to consider bounded deformations which are possibly singular at the origin, i.e., deformations $u\colon B_1 \to \mathbb{R}^N$ corresponding to possibly discontinuous Sobolev functions $u \in L^\infty(B_1, \mathbb{R}^N) \cap W^{1,1}(B_1, \mathbb{R}^N)$ satisfying an appropriate notion of invertibility; see [21] for a general discussion of this issue. For these Sobolev mappings, however, the pointwise Jacobian determinant $\det Du$ loses its natural meaning and has to be replaced by the distributional Jacobian determinant $\mathrm{Det}\, Du$. A general discussion of this question as in Chapter 2 of [13] or [21]—admissible class of deformations and possible definitions of the energy when the pointwise Jacobian determinant is meaningless—goes far beyond the aim of this paper. Indeed, here we shall consider only possibly singular, radial deformations for which invertibility can be stated in elementary terms and for which a reasonable definition of the total energy encompassing the nonregular part of the distributional Jacobian determinant can be easily given. Accordingly, we shall assume that the total energy of a deformation $u \in L^\infty(B_1,\mathbb{R}^N)\cap W^{1,1}(B_1,\mathbb{R}^N)$ such that $\operatorname{Det} Du$ is a nonnegative Radon measure is given by E_0 as in Ball's case when W has superlinear growth with respect to the Jacobian; i.e., the energy depends only on the regular part of the deformation gradient. By contrast, when W is linear with respect to the Jacobian, the energy is the sum of E_0 and a term depending on the total mass of the singular part of $\operatorname{Det} Du$, i.e.,

$$E(u) = E_0(u) + w^\infty \Theta\left((\operatorname{Det} Du)^{\mathrm{s}}(B_1)\right), \tag{2.7}$$

where $\Theta\colon [0\,,+\infty) \to [0\,,+\infty)$ is a continuous, increasing function which vanishes at zero. This special class of deformations is the class of *radial deformations* for which no eversion occurs, i.e., mappings $u \in L^\infty(B_1,\mathbb{R}^N)$ such that

$$u(x) = v(|x|)\frac{x}{|x|} \qquad \text{for a.e. } x \in B_1 \tag{2.8}$$

for some $v \in L^\infty(0\,,1)$ satisfying $v > 0$ a.e. on $(0\,,1)$. It is clear that v is uniquely associated with u up to a null set by (2.8) and vice versa. It is then easy to check (see Lemma 4.1 in [1]) that, whenever the two measurable functions $u\colon B_1 \to \mathbb{R}^N$ and $v\colon (0\,,1] \to [0\,,+\infty)$ are related by (2.8), we have that

$$u \in W^{1,p}(B_1,\mathbb{R}^N) \quad \Longleftrightarrow \quad \begin{cases} v \in AC_{\mathrm{loc}}((0\,,1]) \\ \text{and} \\ \displaystyle\int_0^1 r^{N-1}\left(|v'(r)|^p + \left|\frac{v(r)}{r}\right|^p\right) dr < +\infty \end{cases} \tag{2.9}$$

for every index $1 \le p < +\infty$. In this case, the gradient of u and its singular values are given by

$$Du(x) = \frac{v(|x|)}{|x|}\mathbb{I}_N + \left(v'(|x|) - \frac{v(|x|)}{|x|}\right)\frac{x\otimes x}{|x|^2} \qquad \text{for a.e. } x \in B_1 \tag{2.10}$$

and

$$\begin{cases} \lambda_1(Du(x)) = v'(|x|), \\ \lambda_n(Du(x)) = \dfrac{v(|x|)}{|x|}, \quad n = 2,\dots,N, \end{cases} \qquad \text{for a.e. } x \in B_1. \tag{2.11}$$

It follows from (2.9) that a radial deformation u with a cavity $v(0) > 0$ can be in $W^{1,p}(B_1,\mathbb{R}^N)$ with at most $p < N$.

We shall assume throughout the paper that u defined by (2.8) is such that the corresponding v can be chosen to be strictly increasing. Thus, u is injective and v is actually defined up to a countable set, and we assume also that it is defined by continuity at $r = 0$ and $r = 1$. With this additional assumption, it follows easily that the equivalence (2.9) actually holds with $v \in AC([0\,,1])$, and, moreover, for these mappings u satisfying (2.8) and (2.9) for some $p \ge 1$, the distributional Jacobian determinant is a nonnegative Radon measure whose absolutely continuous part with respect to the Lebesgue measure has density

$$\det Du(x) = v'(|x|)\left(\frac{v(|x|)}{|x|}\right)^{N-1} \qquad \text{for a.e. } x \in B_1 \tag{2.12}$$

and whose singular part is

$$(\operatorname{Det} Du)^{\mathrm{s}} = \frac{\omega_N}{N}[v(0)]^N \delta_0, \tag{2.13}$$

where δ_0 is the Dirac measure at the origin.

For the energies E and E_0 defined by (2.7) and (2.6), respectively, we shall consider the radial displacement boundary value problem in the class of radial deformations, i.e., the variational problem of minimizing E and E_0 among all radial deformations $u \in L^\infty(B_1, \mathbb{R}^N) \cap W^{1,1}(B_1, \mathbb{R}^N)$ satisfying $\det Du > 0$ a.e. on B_1 and the boundary condition $u(x) = \lambda$ for $|x| = 1$ for some $\lambda > 1$. The set of all functions v associated with these radial deformations u by (2.8) is the set

$$\mathcal{A} = \{v \in AC([0\,,1]) :\ v > 0 \text{ on } (0\,,1] \text{ and } v' > 0 \text{ a.e. on } (0\,,1]\}\,, \tag{2.14}$$

and we denote by $\mathcal{A}(\lambda)$ those $v \in \mathcal{A}$ such that $v(1) = \lambda$. Note also that

$$\int_0^1 r^{N-1}\left[v'(r) + \frac{v(r)}{r}\right] dr < +\infty, \qquad v \in \mathcal{A}(\lambda), \tag{2.15}$$

which is the second condition in (2.9). By a change of variables and by (2.5) and (2.11), we have

$$E_0(u) = \omega_N \int_0^1 r^{N-1}\Phi\left(v'(r)\,, \frac{v(r)}{r}\right) dr,$$

where

$$\Phi(\xi\,,\eta) = \Phi_0(\xi\,,\eta) + w(\xi\eta^{N-1}), \qquad \eta\,,\xi > 0,$$

are defined by (2.5) and we have used the shortcuts $\Phi_0(\xi\,,\eta) = \Phi_0(\xi\,,\eta\,,\ldots\,,\eta)$ and $\Phi(\xi\,,\eta) = \Phi(\xi\,,\eta\,,\ldots\,,\eta)$. Similarly, as the singular part of $\operatorname{Det} Du$ for a radial deformation u is a function of $v(0)$ for the corresponding v by (2.13), E defined by (2.7) becomes

$$E(u) = \omega_N \int_0^1 r^{N-1}\Phi\left(v'(r)\,, \frac{v(r)}{r}\right) dr + \omega_N w^\infty \theta\left(v(0)\right),$$

where $\theta\colon [0\,,+\infty) \to [0\,,+\infty)$ is a continuous and increasing function such that $\theta(0) = 0$. Thus, we are led to consider the variational problem

$$\min\left\{J_0(v) :\ v \in \mathcal{A}(\lambda)\right\}, \tag{$\mathcal{P}_0$}$$

where

$$J_0(v) = \omega_N \int_0^1 r^{N-1}\Phi\left(v'(r)\,, \frac{v(r)}{r}\right) dr, \qquad v \in \mathcal{A}(\lambda), \tag{2.16}$$

in the case of superlinear growth and the Bolza problem

$$\min\left\{J(v) :\ v \in \mathcal{A}(\lambda)\right\}, \tag{$\mathcal{P}$}$$

where

$$J(v) = J_0(v) + \omega_N w^\infty \theta\left(v(0)\right), \qquad v \in \mathcal{A}(\lambda), \tag{2.17}$$

in the linear case.

In section 3, we shall prove two general existence results for the Bolza problem $(\mathcal{P})$ (Theorem 3.3) and the variational problem $(\mathcal{P}_0)$ (Theorem 3.5) which apply to stored energy densities Φ which fail to be convex with respect to the derivative v'. As a consequence of Theorem 3.3, we shall prove the following existence result (Theorem 2.1) of optimal, radial solutions for Blatz–Ko materials.

THEOREM 2.1. *Let*

$$W(A) = |A|^2 + w_{BK}(\det A), \qquad A \in \mathbb{M}_+^{N\times N},$$

where $w_{BK}\colon (0\,,+\infty) \to [0\,,+\infty)$ *is given by* (1.4), *and let* $\Theta\colon [0\,,+\infty) \to [0\,,+\infty)$ *be a continuous and increasing function such that*

(a) $\Theta(0) = 0$;

(b) $s \in [0\,,+\infty) \mapsto s - \Theta(s)$ *is increasing.*

Then, the variational integral

$$E(u) = \int_{B_1} W(Du(x))\,dx + w_{BK}^{\infty}\Theta\left((\operatorname{Det} Du)^s(B_1)\right)$$

with $w_{BK}^{\infty} = 2.38$ *has a minimizer among all radial deformations* $u(x) = v(|x|)\frac{x}{|x|}$ *corresponding to* $v \in \mathcal{A}(\lambda)$.

The proof is given in section 5. Here, we point out again that this theorem does not assert that optimal radial deformations for Blatz–Ko materials exhibit cavitation. The issue of the existence of singular radial solutions is more subtle, even for polyconvex energies W, and we refer to [4] for a thorough discussion of this issue in the polyconvex case.

3. The nonconvex, one-dimensional problems. In this section we state two fairly general attainment results for the one-dimensional, one-point boundary value problems $(\mathcal{P}_0)$ and $(\mathcal{P})$ associated with the problem of minimizing, among radial deformations, the energies E_0 and E defined by (2.6) and (2.7), respectively. We shall prove both results in section 4.

We begin by recalling some elementary results from convex analysis. Consider a lower semicontinuous function $\varphi\colon \mathbb{R}_+ \to [0\,,+\infty)$ such that $\varphi(\xi) \to +\infty$ as $\xi \to 0_+$ and $\varphi(\xi)/\xi \to +\infty$ as $\xi \to +\infty$. The *polar function* of φ is the lower semicontinuous, convex function $\varphi^*\colon \mathbb{R} \to \mathbb{R}$ defined by

$$\varphi^*(\xi) = \sup\left\{\xi\zeta - \varphi(\xi) :\ \xi > 0\right\}, \qquad \zeta \in \mathbb{R}$$

(see [11] or [24]), and the *bipolar function* or *convex envelope* of φ is the polar $\varphi^{**}\colon \mathbb{R}_+ \to [0\,,+\infty)$ of φ^*. Thus, φ^{**} is convex, continuous, and such that

(3.1) $\varphi^{**}(\xi) \le \varphi(\xi)$ for every $\xi > 0$;

(3.2) the open set $\{\varphi^{**} < \varphi\}$ has bounded connected components;

(3.3) the closure of each connected component of $\{\varphi^{**} < \varphi\}$ is contained in $\mathbb{R}_+$;

(3.4) φ^{**} is affine on each connected component of $\{\varphi^{**} < \varphi\}$.

Moreover, it is easy to check that whenever $\varphi \in \mathcal{C}^1(\mathbb{R}_+)$, then $\varphi^{**} \in \mathcal{C}^1(\mathbb{R}_+)$ as well and that the values of φ^{**} at $\xi > 0$ and φ^* at $d = (\varphi^{**})'(\xi)$ are related by

$$\varphi^{**}(\xi) + \varphi^*(d) = d\xi \tag{3.5}$$

because of the equality $\varphi^{***} = \varphi^*$ (see [11]). Thus, the convexity inequality

$$\varphi^{**}(\xi) \geq \varphi^{**}(\xi_0) + d(\xi - \xi_0), \qquad \xi\,,\,\xi_0 > 0,$$

where $d = (\varphi^{**})'(\xi_0)$ can be written as

$$\varphi^{**}(\xi) \geq d\xi - \varphi^*(d), \qquad \xi > 0, \tag{3.6}$$

and $-\varphi^*(d)$ yields the value at the origin of the supporting affine function to the graph of φ^{**} at the point ξ. Moreover, because of (3.4), whenever an interval $(\alpha\,,\beta)$ is a connected component of $\{\varphi^{**} < \varphi\}$, (3.6) turns into the equality

$$\varphi^{**}(\xi) = d\xi - \varphi^*(d), \qquad \xi \in (\alpha\,,\beta), \tag{3.7}$$

where $d = (\varphi^{**})'(\xi_0)$ and $\xi_0 \in (\alpha\,,\beta)$.

We can now describe the class of one-dimensional integrands that we shall consider in this section. Recalling the discussion of section 2 on the stored energy W and the formula (2.11) for the singular values of the gradient of radial deformations, we consider a function $\Phi\colon \mathbb{R}^2_+ \to [0\,,+\infty)$ which is the sum of two terms, i.e.,

$$\Phi(\xi\,,\eta) = \Phi_0(\xi\,,\eta) + w(\xi\eta^{N-1}), \qquad \xi\,,\,\eta > 0, \tag{H1}$$

where $\Phi_0\colon \mathbb{R}^2_+ \to [0\,,+\infty)$ and $w\colon \mathbb{R}_+ \to [0\,,+\infty)$. We assume first that both terms are smooth; i.e.,

$$\Phi_0 \in \mathcal{C}^1(\mathbb{R}^2_+) \text{ and } w \in \mathcal{C}^1(\mathbb{R}_+). \tag{H2}$$

Then, recalling the meaning of ξ and η and (2.11), we set

$$\|(\xi\,,\eta)\| = \sqrt{\xi^2 + (N-1)\eta^2}, \qquad \xi\,,\,\eta > 0,$$

for the euclidean norm of the matrix corresponding to the singular values given by $(\xi\,,\eta,\ldots,\eta)$ and, in view of the hypotheses (2.2) and (2.3) on W_0, we assume that

$$\lim_{\|(\xi\,,\eta)\|\to+\infty} \frac{\Phi_0(\xi\,,\eta)}{\|(\xi\,,\eta)\|} = +\infty, \tag{H3}$$

$$0 \leq \Phi_0(\xi\,,\eta) \leq C\,(1 + \|(\xi\,,\eta)\|^p), \qquad \xi,\,\eta > 0, \tag{H4}$$

for some constant $C \geq 0$ and some index $1 < p < N$. Similarly, in view of (2.4), we assume that w is such that either

$$\lim_{t\to 0_+} w(t) = +\infty \text{ and } \lim_{t\to+\infty} \frac{w(t)}{t} = w^\infty \in (0\,,+\infty) \tag{H5$_\mathrm{L}$}$$

(linear case) or

$$\lim_{t\to 0_+} w(t) = +\infty \text{ and } \lim_{t\to+\infty} \frac{w(t)}{t} = w^\infty = +\infty \tag{H5$_\mathrm{S}$}$$

(superlinear case). We remark again that w need not be convex and we note that (H4) and either (H5$_{\mathrm{L}}$) or (H5$_{\mathrm{S}}$) imply that

$$\lim_{\xi\to+\infty}\frac{\Phi(\xi\,,\xi)}{\xi^N}=w^\infty. \tag{3.8}$$

For any such Φ, we consider the variational integrals J_0 and J defined by (2.16) and (2.17), respectively, and the corresponding variational problems $(\mathcal{P}_0)$ and $(\mathcal{P})$ for $\lambda>1$. Moreover, we denote the polar of Φ and the convex envelope of Φ with respect to the first variable ξ by $\Phi^*\colon\mathbb{R}\times\mathbb{R}_+\to\mathbb{R}$ and $\Phi^{**}\colon\mathbb{R}^2_+\to[0\,,+\infty)$, respectively; i.e., $\Phi^*(\xi\,,\eta)$ and $\Phi^{**}(\xi\,,\eta)$ are the polar and the convex envelope of the function $\xi'\to\Phi(\xi'\,,\eta)$ at the point ξ.

In what follows, a special role is played by the *detachment set* $\mathcal{D}$ defined by

$$\mathcal{D}=\{(\xi\,,\eta):\ \Phi^{**}(\xi\,,\eta)<\Phi(\xi\,,\eta)\}\,. \tag{3.9}$$

For every $\xi>0$ and $\eta>0$, its horizontal and vertical sections will be denoted by

$$\mathcal{D}^\eta=\{\xi>0:\ \Phi^{**}(\xi\,,\eta)<\Phi(\xi\,,\eta)\}\quad\text{and}\quad\mathcal{D}_\xi=\{\eta>0:\ \Phi^{**}(\xi\,,\eta)<\Phi(\xi\,,\eta)\}\,,$$

respectively. Also, whenever $(\xi\,,\eta)\in\mathcal{D}$, the connected component of $\mathcal{D}_\xi$ containing η will be denoted by $\mathcal{D}_\xi(\eta)$, and similarly for $\mathcal{D}^\eta(\xi)$. The main properties of the detachment set $\mathcal{D}$ are listed in the following proposition for which we refer to Proposition 3.1 in [5].

PROPOSITION 3.1. *Let $\Phi\colon\mathbb{R}^2_+\to[0\,,+\infty)$ be a continuously differentiable function such that*

$$\lim_{\xi\to+\infty}\frac{\Phi(\xi\,,\eta)}{\xi}=+\infty\ \textit{uniformly with respect to}\ \eta>0; \tag{3.10}$$

$$\lim_{(\xi\,,\eta)\to(\xi_0\,,\eta_0)}\Phi(\xi\,,\eta)=+\infty\ \textit{whenever}\ \xi_0\eta_0=0. \tag{3.11}$$

Then,

(a) *the detachment set $\mathcal{D}$ is open;*

(b) *for every $0<a<b$, the connected components of $\mathcal{D}\cap(\mathbb{R}\times(a\,,b))$ are bounded.*

Moreover, for every $(\xi_0\,,\eta_0)\in\mathcal{D}$, there exist $\delta=\delta(\xi_0\,,\eta_0)>0$ and two functions $d^\pm\colon[\eta_0-\delta\,,\eta_0+\delta]\to\mathbb{R}$ such that

(c) *$d^-(\eta)<\xi_0<d^+(\eta)$ for every $\eta\in[\eta_0-\delta\,,\eta_0+\delta]$;*

(d) *d^+ and d^- are bounded, upper and lower semicontinuous functions, respectively;*

(e) *$\mathcal{D}^\eta(\xi_0)=(d^-(\eta)\,,d^+(\eta))$ for every $\eta\in[\eta_0-\delta\,,\eta_0+\delta]$;*

(f) *$\Phi^{**}(d^\pm(\eta)\,,\eta)=\Phi(d^\pm(\eta)\,,\eta)$ for every $\eta\in[\eta_0-\delta\,,\eta_0+\delta]$.*

Note that this result applies to every Φ satisfying (H1), ..., (H4) and either (H5$_{\mathrm{L}}$) or (H5$_{\mathrm{S}}$). As for the properties of $\mathcal{D}$ listed above, note that, with different words, (b) states that, in the $\xi\eta$ plane, every connected component of every horizontal strip of $\mathcal{D}$ is bounded, and (e) states that, provided that the strip is narrow enough, every such connected component is the plane set contained between the graphs of two functions $d^\pm$ satisfying (d).

In the following proposition, we describe the properties of the convex envelope Φ^{**} of Φ that will be used in what follows. We refer to [2] and [16] for a more detailed discussion of the regularity properties of convex envelopes. We are also indebted to J. Kristensen for pointing us to the proof of (a) in [2].

Proposition 3.2. *Let*

$$\Phi(\xi\,,\eta) = \Phi_0(\xi\,,\eta) + w(\xi\eta^{N-1}), \qquad \xi\,,\,\eta > 0,$$

satisfy (H1), ..., (H4) *and either* ($\mathrm{H5_L}$) *or* ($\mathrm{H5_S}$). *Then,*

(a) Φ^{**} *is continuous;*

(b) $\lim_{\|(\xi\,,\eta)\|\to+\infty} \frac{\Phi^{**}(\xi\,,\eta)}{\|(\xi\,,\eta)\|} = +\infty$*;*

(c) $(w^{**})^\infty = w^\infty$ *and* $\lim_{\xi\to+\infty} \frac{\Phi^{**}(\xi\,,\xi)}{\xi^N} = w^\infty$*;*

(d) *the partial derivative* $m(\xi\,,\eta) = \Phi^{**}_\xi(\xi\,,\eta)$ *exists at every point* $(\xi\,,\eta) \in \mathcal{D}$ *and is continuous on* $\mathcal{D}$*;*

(e) *the function* $q(\xi\,,\eta) = -\Phi^*(m(\xi\,,\eta)\,,\eta)$, $(\xi\,,\eta) \in \mathcal{D}$, *is continuous on* $\mathcal{D}$*;*

(f) *the restrictions* $\xi \in \mathcal{D}^\eta \mapsto m(\xi\,,\eta)$ *and* $\xi \in \mathcal{D}^\eta \mapsto q(\xi\,,\eta)$ *are constant on each connected component of* $\mathcal{D}^\eta$*;*

(g) *if each connected component of* $\mathcal{D}$ *is simply connected, there exists a continuous function* $M\colon \mathcal{D} \to \mathbb{R}$ *such that the partial derivative* M_η *exists in* $\mathcal{D}$ *and*

$$M_\eta(\xi\,,\eta) = m(\xi\,,\eta), \qquad (\xi\,,\eta) \in \mathcal{D}. \tag{3.12}$$

Moreover, $\xi \in \mathcal{D}^\eta \mapsto M(\xi\,,\eta)$ *is locally constant on* $\mathcal{D}^\eta$*.*

It follows from (b), (d), and (e), that m and q are locally constant with respect to ξ on $\mathcal{D}$; i.e., for every $(\xi_0\,,\eta_0) \in \mathcal{D}$ we have

$$\begin{cases} m(\xi\,,\eta) = m(\xi_0\,,\eta), \\ q(\xi\,,\eta) = q(\xi_0\,,\eta), \end{cases} \qquad \xi \in \mathcal{D}^\eta(\xi_0), \quad \eta \in \mathcal{D}_{\xi_0}(\eta_0). \tag{3.13}$$

Moreover, it follows also from (e) and (3.7) that, on the connected component of $\mathcal{D}^\eta$ containing ξ_0, the convex envelope Φ^{**} can be written as an affine function of ξ, i.e.,

$$\Phi^{**}(\xi\,,\eta) = m(\xi_0\,,\eta)\xi + q(\xi_0\,,\eta), \qquad \xi \in \mathcal{D}^\eta(\xi_0), \quad \eta \in \mathcal{D}_{\xi_0}(\eta_0). \tag{3.14}$$

Finally, as for (g), it is clear that, even if $\mathcal{D}$ has multiply connected components, a continuous function M satisfying (3.12) can be locally defined anyway.

Proof of Proposition 3.2. Property (a) is essentially known (see [2] for instance), and (b) follows from (H3). As for (c), the first equality is easy, and hence (H4) and

$$w^{**}(\xi\eta^{N-1}) \le \Phi^{**}(\xi\,,\eta) \le C\,(1 + \|(\xi\,,\eta)\|^p) + w(\xi\eta^{N-1}), \qquad \xi\,,\,\eta > 0,$$

yield the conclusion in both cases of ($\mathrm{H5_L}$) and ($\mathrm{H5_S}$) because $1 < p < N$. The remaining properties (d), (e), and (f) are proved in Proposition 2.1 in [5], and, finally, (g) is obvious. □

After these preliminaries, we can turn to the existence result for the nonconvex Bolza problem ($\mathcal{P}$). To this aim, we consider the relaxed problem

$$\min\left\{J^{**}(v)\colon\ v \in \mathcal{A}(\lambda)\right\}, \tag{$\mathcal{P}^{**}$}$$

where

$$J^{**}(v) = \omega_N \int_0^1 r^{N-1}\Phi^{**}\left(v'(r)\,,\frac{v(r)}{r}\right)dr + \omega_N w^\infty \theta\left(v(0)\right), \qquad v \in \mathcal{A}(\lambda),$$

and, for the sake of simplicity, we state the attainment result for $(\mathcal{P})$ with the following additional hypothesis:

(H6) each connected component of $\mathcal{D}$ is simply connected,

so that (g) of Proposition 3.2 holds. As we shall see at point (c) after Theorem 3.3 below, this additional hypothesis gives a simpler statement but does not affect the scope of application of the existence result.

THEOREM 3.3. *Let*

$$\Phi(\xi,\eta) = \Phi_0(\xi,\eta) + w(\xi\eta^{N-1}), \qquad \xi,\eta > 0,$$

be such that (H1), ..., ($H5_L$) *and* (H6) *hold and let* $\theta\colon [0,+\infty) \to [0,+\infty)$ *be a continuous and increasing function such that* $\theta(0) = 0$. *Set*

$$\psi(\xi,\eta) = -NM(\xi,\eta) + m(\xi,\eta)\eta + q(\xi,\eta), \qquad (\xi,\eta) \in \mathcal{D}, \tag{3.15}$$

and assume also that the following properties of ψ *hold at every point* $(\xi_0,\eta_0) \in \mathcal{D}$:

(3.16) *there exists* $\delta = \delta(\xi_0,\eta_0) > 0$ *such that* $[\eta_0 - \delta, \eta_0 + \delta] \subset \mathcal{D}_{\xi_0}(\eta_0)$ *and such that the section* $\eta \in \mathcal{D}_{\xi_0} \to \psi(\xi_0,\eta)$ *is monotone on both intervals* $[\eta_0 - \delta, \eta_0]$ *and* $[\eta_0, \eta_0 + \delta]$;

(3.17) *if* $\xi_0 = \eta_0$, *then the section* $\eta \in \mathcal{D}_{\xi_0} \to \psi(\xi_0,\eta)$ *has no strict local minima at* $\eta = \eta_0$.

Then, the minimum problem $(\mathcal{P})$ *admits a solution whenever* $(\mathcal{P}^{**})$ *has a solution.*

Before giving sufficient conditions for the existence of solutions to the relaxed problem $(\mathcal{P}^{**})$ (see Theorem 3.4 below), we want to make a few remarks about the hypotheses and the proof of Theorem 3.3.

(a) If the detachment set $\mathcal{D}$ does not meet the line $\xi = \eta$, attainment for the variational problem $(\mathcal{P})$ holds with (3.16) only, which is a mild assumption on the behavior of the convex envelope Φ^{**}. As we shall see in detail in section 5, this is the case of Blatz–Ko materials where $w = w_{BK}$.

(b) By (3.13), ψ is locally constant with respect to ξ; i.e., $\psi(\xi_1,\eta) = \psi(\xi_2,\eta)$ for every $(\xi_i,\eta) \in [\xi_0 - \rho, \xi_0 + \rho] \times [\eta_0 - \delta, \eta_0 + \delta] \subset \mathcal{D}$. Moreover, it follows from (3.12) and (3.14) that in the simplest case when all sections $\mathcal{D}_\xi$ of $\mathcal{D}$ are intervals, (H6) obviously holds and ψ can be explicitly written as

$$\psi(\xi,\eta) = -N\int \Phi^{**}_\xi(\xi,\eta)\,d\eta + \Phi^{**}_\xi(\xi,\eta)(\eta - \xi) + \Phi^{**}(\xi,\eta), \qquad (\xi,\eta) \in \mathcal{D}.$$

(c) Theorem 3.3 remains valid even if $\mathcal{D}$ has multiply connected components. Indeed, in that case, ψ can be defined only locally by (3.15), on every convex open subset of $\mathcal{D}$, for instance, and any two such locally defined functions ψ differ only by a constant on the intersections of their domains. As the other hypotheses (3.16) and (3.17) on ψ have local nature, the theorem remains true with the very same proof even if (H6) fails.

(d) The proof of Theorem 3.3 follows a somewhat standard path for this kind of variational problem. We start with a solution $\overline{v}$ to the relaxed problem $(\mathcal{P}^{**})$ which exists by assumption and we show that $\overline{v}$ can be modified so as to find a new solution v to $(\mathcal{P}^{**})$ satisfying $v(0) = \overline{v}(0)$ and the differential relation

$$\left(v'(r), \frac{v(r)}{r}\right) \notin \mathcal{D} \qquad \text{for a.e. } r \in (0,1). \tag{3.18}$$

Thus, $\Phi^{**}(v'(r)\,,v(r)/r)=\Phi(v'(r)\,,v(r)/r)$ for a.e. $r\in(0\,,1)$, and the minimality of v for J follows staightforwardly from the corresponding property for J^{**} and the convexity inequality $\Phi^{**}\le\Phi$ on $\mathbb{R}^2_+$. As is to be expected, the most technically difficult part of this program is the definition of new solutions v to $(\mathcal{P}^{**})$ satisfying the differential relation (3.18). For this part of the proof, we shall adapt the ideas developed in [5].

We now proceed to give sufficient conditions for attainment for the relaxed problem $(\mathcal{P}^{**})$. The proof of the following result is essentially the same as Marcellini's relaxation result; see Theorem 1 in [19].

THEOREM 3.4. *Let*

$$\Phi(\xi\,,\eta)=\Phi_0(\xi\,,\eta)+w(\xi\eta^{N-1}),\qquad \xi\,,\eta>0,$$

be such that (H1)$,\ldots,$(H5$_\mathrm{L}$) *hold and let* $\theta\colon[0\,,+\infty)\to[0\,,+\infty)$ *be a continuous and increasing function such that*

(a) $\theta(0)=0$*;*

(b) $\Delta(t)=t^N/N-\theta(t)$*,* $t\ge0$*, is increasing.*

Then, the minimum problem $(\mathcal{P}^{**})$ *admits a solution.*

Proof. First, set $v_\lambda(r)=\lambda r$ for every $r\in(0\,,1]$ and note that J^{**} is finite at v_λ. Then, as Φ^{**} is now convex with respect to ξ, attainment for $(\mathcal{P}^{**})$ can be proved by Tonelli's direct method, and the proof follows immediately from the following two claims.

Claim 1. For every minimizing sequence $\{v_k\}_k\subset\mathcal{A}(\lambda)$, there exists $v\in\mathcal{A}(\lambda)$ and a subsequence (not relabeled) $\{v_k\}_k$ such that $v_k\rightharpoonup v$ weakly in $\mathcal{A}(\lambda)$; i.e.,

$$\begin{cases} v_k\to v & \text{pointwise on } (0\,,1];\\ v_k'\rightharpoonup v' & \text{weakly in } L^1(\varepsilon\,,1) \text{ for every } 0<\varepsilon<1.\end{cases}\tag{3.19}$$

Claim 2. Let v_k, $v\in\mathcal{A}(\lambda)$ be such that $v_k\rightharpoonup v$ as in (3.19). Then,

$$J^{**}(v)\le\liminf_{k\to+\infty}J^{**}(v_k).\tag{3.20}$$

Proof of Claim 1. Set

$$J_0^{**}(z)=\omega_N\int_0^1 r^{N-1}\Phi^{**}\left(z'(r)\,,\frac{z(r)}{r}\right)dr,\qquad z\in\mathcal{A}(\lambda).\tag{3.21}$$

As $\{v_k\}_k$ is a minimizing sequence for J^{**} and $\theta\ge0$, we have

$$J_0^{**}(v_k)\le J^{**}(v_k)\le C\tag{3.22}$$

for every k and for some $C>0$. Thus, the growth assumption (b) of Proposition 3.2 implies that the sequence is sequentially weakly compact in $AC([\varepsilon\,,1])$ for every $0<\varepsilon<1$, and the usual diagonal argument yields a subsequence $\{v_h\}_h$ converging to a function $v\in AC_{\mathrm{loc}}((0\,,1])$ in the sense of (3.19). The pointwise convergence implies that $v(1)=\lambda$ and that v is increasing on $[0\,,1]$ because every v_h enjoys the same properties. Hence, $v'\ge0$ a.e. on $(0\,,1)$, and we set $v(0)=\lim_{r\to0_+}v(r)$. To complete the proof of the claim, we only have to check that $v\in\mathcal{A}(\lambda)$, i.e., that (2.14) holds.

To see this, note that the first assertion of ($\mathrm{H5_L}$) implies that Φ^{**} can be extended to a lower semicontinuous function defined on $\mathbb{R}^2$ by setting $\Phi^{**}(\xi\,,\eta)=+\infty$ whenever either $\xi\le 0$ or $\eta\le 0$. Therefore, for every $0<\varepsilon<1$, the integral

$$z\in AC_{\mathrm{loc}}((0\,,1])\mapsto \omega_N\int_\varepsilon^1 r^{N-1}\Phi^{**}\left(z'(r)\,,\frac{z(r)}{r}\right)\,dr$$

is sequentially lower semicontinuous along sequences converging as in (3.19) by classical results (see [10] or [11]) whence

$$\int_\varepsilon^1 r^{N-1}\Phi^{**}\left(v'(r)\,,\frac{v(r)}{r}\right)\,dr\le\liminf_h\int_\varepsilon^1 r^{N-1}\Phi^{**}\left(v_h'(r)\,,\frac{v_h(r)}{r}\right)\,dr$$

follows for every $0<\varepsilon<1$. As $\phi^{**}\ge 0$, the right-hand side of the estimate above is obviously bounded by $\liminf_h J_0^{**}(v_h)$ and hence, letting $\varepsilon\to 0_+$ on the left-hand side, we conclude that

$$J_0^{**}(v)\le\liminf_h J_0^{**}(v_h)\le C, \tag{3.23}$$

where C is as in (3.22). Thus, $v'>0$ a.e. on $(0\,,1)$, and this gives also that $v>0$ on $(0\,,1]$. Thus, $v\in\mathcal{A}(\lambda)$ and the claim is proved.

Proof of Claim 2. First, set

$$J_V^{**}(z)=J_0^{**}(z)+w^\infty\frac{\omega_N}{N}\left[z(0)\right]^N\,,\qquad z\in\mathcal{A}(\lambda),$$

and recall that Theorem 1 in [19] shows that

$$J_V^{**}(v)=\inf\left\{\liminf_k J_0^{**}(v_k):\ v_k\in\mathcal{A}(\lambda),\,v_k(0)=0\text{ and }v_k\rightharpoonup v\right\} \tag{3.24}$$

for every $v\in\mathcal{A}(\lambda)$ and that

$$J_V^{**}(v)\le\liminf_k J_V^{**}(v_k); \tag{3.25}$$

i.e., J_V^{**} is lower semicontinuous along sequences $v_k\rightharpoonup v$ as in (3.19). Moreover,

$$J_0^{**}(v)\le J^{**}(v)\le J_V^{**}(v),\qquad v\in\mathcal{A}(\lambda), \tag{3.26}$$

because of (a) and (b). Then, without loss of generality, we can assume that both sequences $\{J_0^{**}(v_k)\}_k$ and $\{v_k(0)\}_k$ are convergent so that

$$\liminf_k J^{**}(v_k)=\lim_k J_0^{**}(v_k)+\omega_N w^\infty\lim_k\theta(v_k(0)).$$

If there is a subsequence $\{v_h\}_h$ such that $v_h(0)=0$ for every h, then $J^{**}(v_h)=J_0^{**}(v_h)$ and (3.24) and (3.26) yield that

$$\lim_k J^{**}(v_k)=\lim_h J_0^{**}(v_h)\ge J_V^{**}(v)\ge J^{**}(v).$$

Otherwise, we can assume that $v_k(0)>0$ for every k and either $v(0)\le\lim_k v_k(0)$ or $v(0)>\lim_k v_k(0)$. In the former case, the conclusion follows from (3.23) and the monotonicity of θ. Otherwise, we have

$$J^{**}(v_k)=J_V^{**}(v_k)-w^\infty\omega_N\Delta(v_k(0))$$

for every k where Δ is defined in (b), and then (3.25) yields

$$\begin{aligned}\liminf_k J^{**}(v_k) &= \liminf_k J_V^{**}(v_k) - w^\infty \omega_N \lim_k \Delta(v_k(0)) \\ &\geq J_V^{**}(v) - w^\infty \omega_N \lim_k \Delta(v_k(0)) \\ &= J^{**}(v) + w^\infty \omega_N \left[\Delta(v(0)) - \lim_k \Delta(v_k(0))\right].\end{aligned}$$

As $v(0) > \lim_k v_k(0)$ and Δ is increasing by assumption, the conclusion follows. ◻

We conclude this section with the existence result for the nonconvex variational problem $(\mathcal{P}_0)$ corresponding to the case of functions w having superlinear growth at infinity. As already explained, this is the situation of nearly incompressible elastomers which can possibly exhibit phase transition. In this superlinear case, the existence result of Theorem 3.3 turns into the following theorem.

THEOREM 3.5. *Let the hypotheses of Theorem* 3.3 *hold with* ($\mathrm{H5_L}$) *replaced by* ($\mathrm{H5_S}$). *Then, the minimum problem* $(\mathcal{P}_0)$ *admits a solution.*

4. Attainment for the nonconvex, one-dimensional problems. In this section, we prove Theorems 3.3 and 3.5. Our starting point is the following result which is proved as Lemma 3.2 in [5]. It describes a procedure to define local, piecewise linear approximations of absolutely continuous functions subject to the constraint of using only two given values of the derivative.

LEMMA 4.1. *Let* $z \in AC([0,1])$ *be differentiable at some point* $0 < r_0 < 1$ *with* $m = z(r_0)$ *and* $\xi_0 = z'(r_0)$ *and let* $\alpha,\ \beta \in \mathbb{R}$ *be such that*

$$\alpha < \xi_0 < \beta.$$

Then, for every $\delta > 0$, *there exist two families of compact subintervals* $\{H_\varepsilon^\pm\}_\varepsilon$ *of* $(0,1)$ *and two families of functions* $\{z_\varepsilon^\pm\}_\varepsilon$ *in* $AC([0,1])$ *such that, setting*

$$\begin{cases} I_\varepsilon^+ = \left(r_0 - \dfrac{\varepsilon}{\beta - \xi_0}, r_0 + \dfrac{\varepsilon}{\xi_0 - \alpha}\right), \\ I_\varepsilon^- = \left(r_0 - \dfrac{\varepsilon}{\xi_0 - \alpha}, r_0 + \dfrac{\varepsilon}{\beta - \xi_0}\right), \end{cases}$$

the following properties hold for every $\varepsilon > 0$ *small enough:*

(4.1) $\quad I_{\varepsilon/2}^\pm \subset H_\varepsilon^\pm \subset I_{2\varepsilon}^\pm \subset (0,1)$;

(4.2) $\quad z_\varepsilon^\pm = z$ *on* $[0,1] \setminus \operatorname{int}\left(H_\varepsilon^\pm\right)$;

(4.3+) $\quad z(r) < z_\varepsilon^+(r) \leq z(r) + \delta$ *for every* $r \in \operatorname{int}\left(H_\varepsilon^+\right)$;

(4.3−) $\quad z(r) - \delta \leq z_\varepsilon^-(r) < z(r)$ *for every* $r \in \operatorname{int}\left(H_\varepsilon^-\right)$;

(4.4+) $\quad \varepsilon \geq z_\varepsilon^+(r) - [m + \xi_0(r - r_0)] \geq \varepsilon/2$ *for every* $r \in I_{\varepsilon/2}^+$;

(4.4−) $\quad -\varepsilon/2 \geq z_\varepsilon^-(r) - [m + \xi_0(r - r_0)] \geq -\varepsilon$ *for every* $r \in I_{\varepsilon/2}^-$;

(4.5) $\quad \left(z_\varepsilon^\pm(r)\right)' \in \{\alpha, \beta\}$ *for a.e.* $r \in H_\varepsilon^\pm$.

We can then exploit the construction of the previous lemma to find comparison functions that decrease the value of the integral

$$\int_I r^{N-1} f\left(\frac{v(r)}{r}\right) dr$$

when $v \in \mathcal{A}(\lambda)$ and the compact interval $I \subset (0,1)$ have the property that $v(r)/r$ stays on a strict, local maximum point of f on a subset of I of positive measure.

PROPOSITION 4.2. *Let $0 < \delta < m$ and let $f\colon [m-\delta, m+\delta] \to \mathbb{R}$ be a continuous function such that*

(a) *f has a strict, local maximum point at m;*

(b) *f is increasing on the interval $[m-\delta, m]$ and decreasing on $[m, m+\delta]$.*

Assume also that there exist a compact interval $I \subset (0,1)$ and a function $v \in \mathcal{A}(\lambda)$ such that

(c) *$|v(r)/r - m| \le \delta/2$ for every $r \in I$;*

(d) *$|I \cap \{v(r)/r = m\}| > 0$.*

Then, $v' = m$ a.e. on $I \cap \{v(r)/r = m\}$, and there exists $u \in \mathcal{A}(\lambda)$ such that

$$\{u \ne v\} \subset \operatorname{int}(I); \tag{4.6}$$

$$|u(r)/r - m| \le \delta \text{ for every } r \in I; \tag{4.7}$$

$$|u'(r) - m| \le \delta \text{ for a.e. } r \in \{u \ne v\}; \tag{4.8}$$

$$\int_I r^{N-1} f\left(\frac{u(r)}{r}\right) dr < \int_I r^{N-1} f\left(\frac{v(r)}{r}\right) dr. \tag{4.9}$$

Proof. The proof is based on the same idea of Step 3 of Theorem 2.2 in [5]. Set $z(r) = v(r)/r$ for $0 < r \le 1$ and $E = \{z = m\}$. Then, $z \in AC_{\mathrm{loc}}((0,1])$ and $z' = 0$ a.e. on $I \cap E$ for it is a level set of positive measure; i.e., $v' = m$ a.e. on $I \cap E$. We choose a density point $r_0 \in \operatorname{int}(I) \cap E$ where v and z are both differentiable and $z'(r_0) = 0$ so that $v'(r_0) = v(r_0)/r_0 = m$. Then, we apply Lemma 4.1 to the function z choosing $\alpha < 0 < \beta$ such that $\max\{-\alpha, \beta\} < \delta/4$ and with δ replaced by $\delta/4$ in (4.3$-$) and (4.3+). We thus find compact intervals $\{H_\varepsilon^\pm\}_\varepsilon$ of $(0,1)$ and functions $\{z_\varepsilon^\pm\}_\varepsilon$ in $AC_{\mathrm{loc}}((0,1])$ such that (4.1), …, (4.5) hold. Moreover, choosing $0 < \gamma < \min\{-\alpha, \beta\}$, we can assume that

$$H_\varepsilon^\pm \subset I_{2\varepsilon}^\pm \subset [r_0 - 2\varepsilon/\gamma, r_0 - 2\varepsilon/\gamma] \subset \operatorname{int}(I) \tag{4.10}$$

holds for every ε small enough because of (4.1), $z'(r_0) = 0$, and the choice of α and β. Then, set

$$v_\varepsilon^\pm(r) = r z_\varepsilon^\pm(r), \qquad 0 < r \le 1.$$

We shall prove that either $u = v_\varepsilon^+$ or $u = v_\varepsilon^-$ has the required properties for ε small enough.

First, it is clear that $v_\varepsilon^\pm \in AC([0,1])$ and that $\{v_\varepsilon^\pm \ne v\} \subset \operatorname{int}(H_\varepsilon^\pm) \subset \operatorname{int}(I)$ because of (4.2). Moreover, (c) and either (4.3+) or (4.3$-$) with $\delta/4$ yield

$$\left|v_\varepsilon^\pm(r)/r - m\right| \le \left|v_\varepsilon^\pm(r)/r - v(r)/r\right| + |v(r)/r - m| \le \delta/4 + \delta/2 = 3\delta/4 < \delta \tag{4.11}$$

which will be (4.7), and we claim that

$$\left|\left(v_\varepsilon^\pm\right)'(r) - m\right| \le \delta \qquad \text{for a.e. } r \in H_\varepsilon^\pm$$

which will be (4.8). In particular, this implies that $\left(v_\varepsilon^\pm\right)' > 0$ a.e. on $H_\varepsilon^\pm$ and hence that $v_\varepsilon^\pm \in \mathcal{A}(\lambda)$. Indeed, we have $\left(z_\varepsilon^\pm\right)' \in \{\alpha, \beta\}$ a.e. on $H_\varepsilon^\pm$ by (4.5), and hence

$$\left|\left(v_\varepsilon^\pm\right)' - m\right| \le \left|\left(z_\varepsilon^\pm\right)'\right| + \left|v_\varepsilon^\pm(r)/r - m\right| \le \max\{-\alpha, \beta\} + 3\delta/4 < \delta$$

for a.e. $r \in H_\varepsilon^\pm$ by (4.11) and the choice of α and β. At last, we prove that either v_ε^+ or v_ε^- is such that

$$\int_I r^{N-1} f\left(\frac{v_\varepsilon^\pm(r)}{r}\right) dr < \int_I r^{N-1} f\left(\frac{v(r)}{r}\right) dr$$

eventually as $\varepsilon \to 0_+$ so that also (4.9) holds for u chosen accordingly.

To see this, note first that it is enough to compare the integrals over the intervals $H_\varepsilon^\pm$ only because of (4.2). Then, we choose a sequence $\varepsilon_j \to 0_+$ and we set

$$\eta_j = \frac{1}{\varepsilon_j} \sup\left\{|v(r)/r - m| : |r - r_0| \le 2\varepsilon_j/\gamma\right\}.$$

We note that $\eta_j\varepsilon_j \le \delta/2$ by (c) and that $\eta_j \to 0_+$ because $z = v/r$ is differentiable at r_0 with $z(r_0) = m$ and $z'(r_0) = 0$. Then, possibly passing to a subsequence still denoted by ε_j, we can assume that the minimum between $f(m-\eta_j\varepsilon_j)$ and $f(m+\eta_j\varepsilon_j)$ is actually achieved for every j by terms having always the same sign inside, say $f(m + \eta_j\varepsilon_j)$, so that

$$0 < f(m) - f(m + \eta_j\varepsilon_j) = \max\left\{f(m) - f(m \pm \eta_j\varepsilon_j)\right\} \tag{4.12}$$

holds for every j. According to this assumption, we choose the + functions and, to simplify the notation, we set $v_j = v_{\varepsilon_j}^+$ and $H_j = H_{\varepsilon_j}^+$. Finally, set $I_j^1 = I_{\varepsilon_j/2}^+$ and $I_j^2 = I_{2\varepsilon_j}^+$ so that (4.1) turns into

$$I_j^1 \subset H_j \subset I_j^2 \tag{4.13}$$

and set also

$$A_j^1 = \frac{1}{|H_j|}\int_{H_j} r^{N-1}\left[f(m) - f\left(\frac{v_j(r)}{r}\right)\right] dr,$$
$$A_j^2 = \frac{1}{|H_j|}\int_{H_j} r^{N-1}\left[f(m) - f\left(\frac{v(r)}{r}\right)\right] dr.$$

We shall prove that $A_j^1 - A_j^2 > 0$ eventually. In fact, note first that (4.4+) reduces to $\varepsilon_j/2 \le v_j(r)/r - m \le \varepsilon_j$ for every $r \in I_j^1$. Hence, (4.13) and (a) and (b) of Proposition 4.2 yield that

$$\begin{aligned} A_j^1 &\ge \frac{1}{|I_j^2|}\int_{I_j^1} r^{N-1}\left[f(m) - f\left(\frac{v_j(r)}{r}\right)\right] dr \\ &\ge \frac{1}{|I_j^2|}\int_{I_j^1} r^{N-1}\left[f(m) - f\left(m + \frac{\varepsilon_j}{2}\right)\right] dr \ge \frac{c^{N-1}}{4}\left[f(m) - f\left(m + \frac{\varepsilon_j}{2}\right)\right] \end{aligned}$$

because $|I_j^2|/|I_j^1| = 4$ with $c > 0$ such that $c < \inf I_j^1$ for every j. As for A_j^2, we have

$$A_j^2 = \frac{1}{|H_j|}\int_{H_j\setminus E} r^{N-1}\left[f(m) - f\left(\frac{v(r)}{r}\right)\right] dr$$

and $|v(r)/r - m| \le \eta_j\varepsilon_j$ for every $r \in H_j \subset I_j^2$ by (4.13), the definition of η_j, and (4.10). Hence,

$$0 \le f(m) - f(v(r)/r) \le \max\left\{f(m) - f(m \pm \eta_j\varepsilon_j)\right\} = f(m) - f(m + \eta_j\varepsilon_j)$$

for every $r \in H_j$ because of (a) and (b) whence

$$A_j^2 \leq 4 \frac{|I_j^2 \setminus E|}{|I_j^2|} \left[f(m) - f(m + \eta_j \varepsilon_j) \right].$$

Since $\eta_j \to 0_+$ and f is decreasing on the interval $[m\,, m+\delta]$, we conclude that $f(m) - f(m + \varepsilon_j/2) \geq f(m) - f(m + \eta_j \varepsilon_j) > 0$ eventually. Finally, as r_0 is a density point of E by assumption, the ratio $|I_j^2 \setminus E|/|I_j^2|$ goes to zero and the conclusion follows. $\square$

The next step is the construction of a further family of comparison functions which are obtained as solutions to partial differential relations. This construction is an instance of the convex integration of partial differential relations developed in this variational framework by Müller and Šverák in [22]. Again, apart from minor and obvious changes, this construction is similar to the one described in Proposition 3.3 in [5], and we refer to this paper for the proof.

Proposition 4.3. *Let $d^{\pm} \colon [\eta_0 - \delta\,, \eta_0 + \delta] \to \mathbb{R}$ be two bounded, upper and lower semicontinuous functions, respectively, and let $u \in \mathcal{A}(\lambda)$ be such that*

(a) *u is differentiable at $0 < r_0 < 1$;*

(b) *$d^-(\eta) < u'(r_0) < d^+(\eta)$ for every $\eta \in [\eta_0 - \delta\,, \eta_0 + \delta]$, where $\eta_0 = u(r_0)/r_0$.*

Then, there exist $\varepsilon_0 = \varepsilon_0(r_0\,, \delta) > 0$, two families of compact subintervals $\mathcal{K}^{\pm} = \{K_\varepsilon^{\pm}\}_\varepsilon$ of $(0\,,1)$ such that

$$\text{(4.14)} \qquad \textit{each set } K_\varepsilon^{\pm} \textit{ is a neighborhood of } r_0 \textit{ and } |K_\varepsilon^{\pm}| \to 0 \textit{ as } \varepsilon \to 0^+,$$

and two families of functions $\mathcal{U}^{\pm} = \{u_\varepsilon^{\pm}\}_\varepsilon$ in $\mathcal{A}(\lambda)$ such that the following properties hold for every $0 < \varepsilon < \varepsilon_0$:

(4.15) $\quad u_\varepsilon^{\pm} = u$ *on* $(0\,,1] \setminus \operatorname{int}\left(K_\varepsilon^{\pm}\right)$;

(4.16^+) $\quad u(r)/r < u_\varepsilon^+(r)/r \leq u(r)/r + \varepsilon$ *for every* $r \in \operatorname{int}\left(K_\varepsilon^+\right)$;

(4.16^-) $\quad u(r)/r - \varepsilon \leq u_\varepsilon^-(r)/r < u(r)/r$ *for every* $r \in \operatorname{int}\left(K_\varepsilon^-\right)$;

(4.17) $\quad |u_\varepsilon^{\pm}(r)/r - \eta_0| \leq \delta$ *for every* $r \in K_\varepsilon^{\pm}$;

$$\text{(4.18)} \qquad \left(u_\varepsilon^{\pm}\right)'(r) \in \left\{ d^- \left(\frac{u_\varepsilon^{\pm}(r)}{r} \right),\ d^+ \left(\frac{u_\varepsilon^{\pm}(r)}{r} \right) \right\} \textit{ for a.e. } r \in K_\varepsilon^{\pm}.$$

After these technical preliminaries, we can turn to the proof of Theorem 3.3.

Proof of Theorem 3.3. Let $v \in \mathcal{A}(\lambda)$ be a solution to the relaxed Bolza problem $(\mathcal{P}^{**})$ which exists by assumption and set

$$\text{(4.19)} \qquad E(v) = \left\{ r \in (0\,,1) : \ v \text{ is differentiable at } r \text{ and } \left(v'(r)\,, \frac{v(r)}{r} \right) \in \mathcal{D} \right\},$$

where $\mathcal{D}$ is the detachment set defined by (3.9).

We are going to prove the theorem by showing that, among all solutions $v \in \mathcal{A}(\lambda)$ to $(\mathcal{P}^{**})$, there is one such that $|E(v)| = 0$ so that

$$\Phi^{**} \left(v'(r)\,, \frac{v(r)}{r} \right) = \Phi \left(v'(r)\,, \frac{v(r)}{r} \right) \qquad \text{for a.e. } r \in (0\,,1),$$

which implies immediately that v is a solution to $(\mathcal{P})$ as well.

To this aim, note first that by Proposition 3.2, the function $\xi \in \mathcal{D}^\eta \mapsto \psi(\xi\,,\eta)$ defined by (3.15) is constant on each connected component of $\mathcal{D}^\eta$ and hence (3.16) implies the existence of a countable family of subsets $\{m_i\}\times L_i$ such that every open interval L_i is a connected component of $\mathcal{D}^{m_i}$ and, for every $\xi \in L_i$, m_i is a strict, local extremum point of the mapping $\eta \mapsto \psi(\xi\,,\eta)$. Moreover, setting $\mathcal{M} = \cup_i (\{m_i\}\times L_i)$, the set $\mathcal{D}\setminus\mathcal{M}$ is open, and we emphasize that ψ is locally constant with respect to ξ and locally monotone with respect to η on the set $\mathcal{D}\setminus\mathcal{M}$.

Then, when v is a solution to $(\mathcal{P}^{**})$, we write

$$E(v) = E_0(v) \cup \left[\bigcup_i E_i(v)\right],$$

where

$$\begin{aligned} E_0(v) &= \left\{ r \in E(v):\ \left(v'(r)\,, \frac{v(r)}{r}\right) \in \mathcal{D}\setminus\mathcal{M} \right\}, \\ E_i(v) &= \left\{ r \in E(v):\ \frac{v(r)}{r} = m_i \right\}. \end{aligned} \tag{4.20}$$

We shall prove the theorem by proving the following two claims.

Claim 1. There exists a solution $v \in \mathcal{A}(\lambda)$ to $(\mathcal{P}^{**})$ such that $|E_0(v)| = 0$.

Claim 2. For the solution v of Claim 1, we have $|E_i(v)| = 0$ for every i.

Proof of Claim 1. Let $u \in \mathcal{A}(\lambda)$ be a solution to $(\mathcal{P}^{**})$ and assume that the corresponding set $E_0(u)$ defined by (4.20) has positive measure. Choose $r_0 \in E_0(u)$ and set $\eta_0 = u(r_0)/r_0$ and $\xi_0 = u'(r_0)$ so that $(\xi_0\,,\eta_0) \in \mathcal{D}\setminus\mathcal{M}$. Then, we find $\delta > 0$ and two functions $d^\pm$ satisfying (c), (d), (e), and (f) of Proposition 3.1 and we set

$$\mathcal{D}' = \left\{(\xi\,,\eta):\ |\eta-\eta_0| < \delta \text{ and } d^-(\eta) < \xi < d^+(\eta)\right\}$$

so that, recalling (d), (e), and (f) of Proposition 3.2, we can write the convex envelope Φ^{**} (with respect to ξ) of Φ on the set $\mathcal{D}'$ as in (3.14); i.e.,

$$\Phi^{**}(\xi\,,\eta) = m(\eta)\xi + q(\eta), \qquad (\xi\,,\eta) \in \mathcal{D}', \tag{4.21}$$

where the continuous functions $m,\ q\colon [\eta_0-\delta\,,\eta_0+\delta] \to \mathbb{R}$ are defined by $m(\eta) = m(\xi\,,\eta)$ and $q(\eta) = q(\xi\,,\eta)$ for every $(\xi\,,\eta) \in \mathcal{D}'$ as in (3.13). Similarly, relying again on (d), (e), (f), and (g) of the same proposition, we can write

$$\psi(\eta) = \psi(\xi\,,\eta), \qquad (\xi\,,\eta) \in \mathcal{D}', \tag{4.22}$$

and, recalling that $(\xi_0\,,\eta_0) \in \mathcal{D}\setminus\mathcal{M}$ and possibly choosing a smaller value of δ, we can assume also that (3.16) holds for δ; i.e., ψ is monotone on the interval $[\eta_0-\delta\,,\eta_0+\delta]$. Then, going back to the properties of Φ^{**}, we note also that

$$\Phi^{**}(\xi\,,\eta) \geq m(\eta)\xi + q(\eta), \qquad \eta \in [\eta_0-\delta\,,\eta_0+\delta], \quad \xi \in \mathbb{R}, \tag{4.23}$$

holds because of (3.6) and that the equalities

$$\Phi^{**}(d^\pm(\eta)\,,\eta) = \Phi(d^\pm(\eta)\,,\eta), \qquad \eta \in [\eta_0-\delta\,,\eta_0+\delta], \tag{4.24}$$

follow from (f) of Proposition 3.1.

Then, we apply Proposition 4.3 and we let $\mathcal{K}^{\pm}_{r_0} = \{K^{\pm}_{r_0,\varepsilon}\}_\varepsilon$ and $\mathcal{V}^{\pm}_{r_0} = \{u^{\pm}_{r_0,\varepsilon}\}_\varepsilon$ be the corresponding intervals and functions. We assume in addition that $\varepsilon = \varepsilon_0(r_0)$ is small enough so as to have

$$\begin{cases} |u(r)/r - \eta_0| \le \delta, \\ |u^{\pm}_{r_0,\varepsilon}(r)/r - \eta_0| \le \delta, \end{cases} \qquad r \in K^{\pm}_{r_0,\varepsilon}, \quad 0 < \varepsilon \le \varepsilon_0. \tag{4.25}$$

Now, we wish to compare $J^{**}(u^{\pm}_{r_0,\varepsilon})$ and $J^{**}(u)$. Since $u(0) = u^{\pm}_{r_0,\varepsilon}(0)$, we have

$$\begin{aligned} &J^{**}(u^{\pm}_{r_0,\varepsilon}) - J^{**}(u) \\ &\qquad = \omega_N \int_{K^{\pm}_{r_0,\varepsilon}} r^{N-1} \left[\Phi^{**}\left((u^{\pm}_{r_0,\varepsilon})'(r)\, , \frac{u^{\pm}_{r_0,\varepsilon}(r)}{r} \right) - \Phi^{**}\left(u'(r)\, , \frac{u(r)}{r} \right) \right] dr, \end{aligned}$$

and, because of (4.21) and (4.23), the right-hand side is less than or equal to

$$\begin{aligned} \omega_N \int_{K^{\pm}_{r_0,\varepsilon}} r^{N-1} \Bigg\{ &\left[m\left(\frac{u^{\pm}_{r_0,\varepsilon}(r)}{r} \right) (u^{\pm}_{r_0,\varepsilon})'(r) - m\left(\frac{u(r)}{r} \right) u'(r) \right] \\ &\qquad + \left[q\left(\frac{u^{\pm}_{r_0,\varepsilon}(r)}{r} \right) - q\left(\frac{u(r)}{r} \right) \right] \Bigg\}\, dr. \end{aligned}$$

To evaluate this, let $z \in AC([\alpha\, , \beta])$ be any function such that $|z(r)/r - \eta_0| \le \delta$ for $0 < \alpha \le r \le \beta$. Then, recalling the definition of M in (g) of Proposition 3.2 and (H6) and integrating by parts, we obtain that

$$\begin{aligned} \int_\alpha^\beta r^{N-1} m\left(\frac{z(r)}{r} \right) z'(r)\, dr &= \int_\alpha^\beta r^N \left\{ \left[M\left(\frac{z(r)}{r} \right) \right]' + m\left(\frac{z(r)}{r} \right) \frac{z(r)}{r^2} \right\} dr \\ = r^N M\left(\frac{z(r)}{r} \right) \Bigg|_\alpha^\beta &+ \int_\alpha^\beta r^{N-1} \left[-NM\left(\frac{z(r)}{r} \right) + m\left(\frac{z(r)}{r} \right) \frac{z(r)}{r} \right] dr. \end{aligned}$$

We now exploit this equality with both $z = u^{\pm}_{r_0,\varepsilon}$ and $z = u$. Since (4.25) holds and $u^{\pm}_{r_0,\varepsilon}$ and u coincide at the endpoints of the interval $K^{\pm}_{r_0,\varepsilon}$, we finally get

$$J^{**}(u^{\pm}_{r_0,\varepsilon}) - J^{**}(u) \le \omega_N \int_{K^{\pm}_{r_0,\varepsilon}} r^{N-1} \left[\psi\left(\frac{u^{\pm}_{r_0,\varepsilon}(r)}{r} \right) - \psi\left(\frac{u(r)}{r} \right) \right] dr. \tag{4.26}$$

Thus, recalling again (4.25), the fact that ψ is monotone on the interval $[\eta_0 - \delta\, , \eta_0 + \delta]$ by (3.16), and the assumption that $(\xi_0\, , \eta_0) \in \mathcal{D} \setminus \mathcal{M}$, we conclude that, choosing $\sigma = \sigma(r_0)$ to be either $+$ or $-$ according to the monotonicity of ψ on the 2δ long interval centered at η_0, we can make the right-hand side of the previous estimate ≤ 0, thus showing that all modified functions $u^{\sigma}_{r_0,\varepsilon}$ are solutions to $(\mathcal{P}^{**})$ satisfying

$$\Phi^{**}\left(\left(u^{\sigma}_{r_0,\varepsilon}\right)'(r)\, , \frac{u^{\sigma}_{r_0,\varepsilon}(r)}{r} \right) = \Phi\left(\left(u^{\sigma}_{r_0,\varepsilon}\right)'(r)\, , \frac{u^{\sigma}_{r_0,\varepsilon}(r)}{r} \right) \qquad \text{for a.e. } r \in K^{\pm}_{r_0,\varepsilon}$$

because of (4.18) and (4.24).

At last, a new solution $v \in \mathcal{A}(\lambda)$ to $(\mathcal{P}^{**})$ satisfying $|E_0(v)| = 0$ can be easily defined by exploiting a standard covering argument. In fact, Vitali's covering theorem applies because of (4.14) and yields countably many points $r_j \in E_0(u)$, positive numbers ε_j, and symbols $\sigma_j \in \{+\,,-\}$ such that the corresponding sets K_j are pairwise disjoint and cover $E_0(u)$ up to a null set, i.e.,

$$|E_0(u) \setminus (\cup_j K_j)\,| = 0,$$

while the corresponding functions u_j are solutions to $(\mathcal{P}^{**})$ satisfying

$$\Phi^{**}\left(u_j'(r)\,,\,\frac{u_j(r)}{r}\right) = \Phi\left(u_j'(r)\,,\,\frac{u_j(r)}{r}\right) \qquad \text{for a.e. } r \in K_j.$$

It is then easy to check that the series $v = u + \sum_j (u_j - u)$ (there is only one nonvanishing summand at every point r) defines a function in $\mathcal{A}(\lambda)$ as required.

Proof of Claim 2. Let v be the solution to $(\mathcal{P}^{**})$ of Claim 1, assume that $|E_i(v)| > 0$ for some i and, to simplify the notation, write $m = m_i$ and $E = E_i(v)$. As E is a level set of $v(r)/r$ of positive measure, $v'(r) = v(r)/r = m$ for a.e. $r \in E$, and hence we can choose $\delta > 0$ small enough so that the square $Q = [m-\delta\,, m+\delta]\times[m-\delta\,, m+\delta]$ is contained in $\mathcal{D}$ and then, arguing again as in Claim 1, we can assume that the functions $m(\eta) = m(\xi\,,\eta)$, $q(\eta) = q(\xi\,,\eta)$, and $\psi(\eta) = \psi(\xi\,,\eta)$ are well defined and continuous for every $(\xi\,,\eta) \in Q$ and that (4.21) and (4.23) hold for every $(\eta\,,\xi) \in Q$ and $(\eta\,,\xi) \in [m-\delta\,, m+\delta]\times\mathbb{R}$, respectively. Moreover, the very definition of E implies that m is a strict, local maximum point of ψ by (3.17), and, finally, we can assume that δ is small enough to have ψ increasing on the interval $[m-\delta\,, m]$ and decreasing on the interval $[m\,, m+\delta]$ by (3.16). Then, we choose a compact interval $I \subset (0\,,1)$ such that (c) and (d) of Proposition 4.2 hold and we exploit this result with $f = \psi$. We thus find a function $u \in \mathcal{A}(\lambda)$ satisfying (4.6), …, (4.9). Relying on (4.6), (4.7), and (4.8) which says that the derivative of the modified function u' remains in the interval where $\Phi^{**}(\xi\,,\eta)$ is affine with respect to ξ, we can repeat the argument of Claim 1 leading to (4.26) to find that

$$J^{**}(u) - J^{**}(v) \leq \omega_N \int_I r^{N-1}\left[\psi\left(\frac{u(r)}{r}\right) - \psi\left(\frac{v(r)}{r}\right)\right] dr.$$

This gives a contradiction to the minimality of v as the right-hand side is negative by (4.9). Thus, $|E| = 0$, and this completes the proof. ∎

Finally, the very same proof of Theorem 3.3 provides attainment in the superlinear case as well.

Proof of Theorem 3.5. The convexified integral J_0^{**} defined by (3.21) has a minimizer over $\mathcal{A}(\lambda)$, say u, because of Claim 1 of Theorem 3.4 and (3.23). Then, u can be modified to find a solution v to $(\mathcal{P}_0)$ by exploiting the very same arguments of Theorem 3.3. In fact, the proofs of Claims 1 and 2 in that theorem are of local nature so that the behavior of w at infinity is irrelevant and, moreover, the proofs involve only the absolutely continuous part of J^{**} because the modified functions out of which v is constructed in Claim 1 and the comparison functions with which v is compared in Claim 2 share the same value at $r = 0$ with the original u so that comparing J_0^{**} is the same as comparing J^{**}. ∎

5. The special case of Blatz–Ko materials. In this section we prove the existence of optimal radial solutions for Blatz–Ko materials (Theorem 2.1) by showing that the related Lagrangian satisfies all the hypotheses of Theorem 3.3.

Proof of Theorem 2.1. We want to check that the function

$$\Phi(\xi\,,\eta) = \xi^2 + 2\eta^2 + \frac{2\alpha}{\xi\eta^2} + (1-\alpha)\left(2\xi\eta^2 + \frac{1}{\xi^2\eta^4}\right), \qquad \xi,\,\eta > 0,$$

satisfies all the hypotheses of Theorem 3.3. Indeed, the hypotheses (H1), ..., ($\mathrm{H5_L}$), (H6), and (3.16) obviously hold and we shall prove that $\xi < \eta$ for every $(\xi\,,\eta) \in \mathcal{D}$ so that (3.17) is actually empty. In order to draw the graph of the function Φ, we set $\theta = \xi\eta^2$ and consider the new function Ψ defined by

$$\Psi(\theta\,,\eta) = \Phi\left(\frac{\theta}{\eta^2}\,,\eta\right) = \frac{\theta^2}{\eta^4} + 2\eta^2 + \frac{2\alpha}{\theta} + (1-\alpha)\left(2\theta + \frac{1}{\theta^2}\right), \qquad \theta,\,\eta > 0.$$

We want to estimate the set $I_\eta = \{\theta :\ \Psi^{**}(\theta\,,\eta) < \Psi(\theta\,,\eta)\}$ for every η and prove that $\theta < \eta^3$ for every $\theta \in I_\eta$.

To this aim, consider first the second derivative

$$\Psi''_{\theta\theta}(\theta\,,\eta) = \frac{2}{\eta^4} + \frac{4\alpha}{\theta^3} + (1-\alpha)\frac{6}{\theta^4}, \qquad \theta,\,\eta > 0.$$

Then, $\Psi''_{\theta\theta}(\theta\,,\eta) \to +\infty$ as $\theta \to 0_+$ and $\Psi''_{\theta\theta}(\theta\,,\eta) \to 2/\eta^4$ as $\theta \to +\infty$, and, moreover, setting

$$\theta_0 = \frac{\alpha - 1}{\alpha} > 0,$$

we find that the minimum of $\theta \mapsto \Psi''_{\theta\theta}(\theta\,,\eta)$ is achieved at $2\theta_0$ and is given by $2/\eta^4 + (\alpha/8)\theta_0^3$ for every $\eta > 0$. Thus, for $\eta > \eta^* = 2\sqrt[4]{\theta_0^3/(-\alpha)}$, the set I_η is nonempty and the set where $\theta \mapsto \Psi''_{\theta\theta}(\theta\,,\eta)$ is ≤ 0 is an interval, say $[\theta_1(\eta)\,,\theta_2(\eta)]$. Since, for every $\eta > \eta^*$, $\Psi''_{\theta\theta}(2\theta_0\,,\eta) < 0$ and $\Psi''_{\theta\theta}(3\theta_0/2\,,\eta) = 2/\eta^4 > 0$, we conclude that

$$\frac{3}{2}\theta_0 < \theta_1(\eta) < 2\theta_0 < \theta_2(\eta). \tag{5.1}$$

Therefore, the first derivative $\Psi'_\theta(\cdot\,,\eta)$ has a local maximum at $\theta = \theta_1(\eta)$ and a local minimum at $\theta = \theta_2(\eta)$, and goes to $-\infty$ as $\theta \to 0_+$ and to $+\infty$ as $\theta \to +\infty$. Moreover, it is easy to check that $\Psi'_\theta(\theta_2(\eta)\,,\eta) > 0$ for $\eta > \eta^*$, so that $\Psi'_\theta(\theta\,,\eta)$ vanishes at one point only, say $\theta = \theta_3(\eta) < \theta_1(\eta)$.

Finally, the function $\theta \mapsto \Psi(\theta, \eta)$ is decreasing on the interval $(0\,,\theta_3(\eta)]$, increasing on $[\theta_3(\eta)\,,+\infty)$, and convex on $(0\,,\theta_1(\eta)]$ and on $[\theta_2(\eta)\,,+\infty)$. Thus, the set I_η is a bounded, open interval containing $\theta_1(\eta)$ and $\theta_2(\eta)$, say $I_\eta = (\overline{\theta}_1(\eta)\,,\overline{\theta}_2(\eta))$.

In order to estimate $\overline{\theta}_2(\eta)$, we note that the tangent lines to the graph of $\theta \mapsto \Psi(\theta\,,\eta)$ at the points $\overline{\theta}_1$ and $\overline{\theta}_2$ are the same so that the following two equalities hold:

(a) $\Psi'_\theta(\overline{\theta}_1\,,\eta) = \Psi'_\theta(\overline{\theta}_2\,,\eta)$;

(b) $\Psi(\overline{\theta}_1\,,\eta) - \overline{\theta}_1\Psi'_\theta(\overline{\theta}_1\,,\eta) = \Psi(\overline{\theta}_2\,,\eta) - \overline{\theta}_2\Psi'_\theta(\overline{\theta}_2\,,\eta)$.

It follows from (b) that, for every $\eta > \eta^*$, the interval I_η is contained in the complement of the set $\{\overline{\theta} :\ q(\overline{\theta}\,,\eta) \neq q(\theta\,,\eta)$ for every $\theta > 0$ and $\theta \neq \overline{\theta}\}$, where q is the function $q(\theta\,,\eta) = \Psi(\theta\,,\eta) - \theta\Psi'_\theta(\theta\,,\eta)$. It is then easy to check that, for $\eta > \eta^*$, q has the following properties:

(5.2) $q(\theta\,,\eta) \to +\infty$ as $\theta \to 0_+$ and $q(\theta\,,\eta) \to -\infty$ as $\theta \to +\infty$;

(5.3) $\theta \mapsto q(\theta\,,\eta)$ has a local minimum at $\theta = \theta_1(\eta)$ and a local maximum at $\theta = \theta_2(\eta)$;

(5.4) $\theta \mapsto q(\theta\,,\eta)$ is decreasing on the intervals $(0\,,\theta_1(\eta)]$ and $[\theta_2(\eta)\,,+\infty)$ and increasing on the interval $[\theta_1(\eta)\,,\theta_2(\eta)]$.

For $\eta > \eta^*$, the interval I_η is a subset of $[\tilde{\theta}_2(\eta)\,,\tilde{\theta}_1(\eta)]$ where the $\tilde{\theta}_i(\eta)$'s are defined by

$$\tilde{\theta}_2 < \theta_2 \text{ and } q(\tilde{\theta}_2\,,\eta) = q(\theta_2\,,\eta),$$
$$\tilde{\theta}_1 > \theta_1 \text{ and } q(\tilde{\theta}_1\,,\eta) = q(\theta_1\,,\eta).$$

Therefore, if we show that $\tilde{\theta}_1(\eta) < \eta^3$ for every $\eta > \eta^*$, we conclude that $\theta < \eta^3$ for every $\theta \in I_\eta$.

To see this, note that (5.1), (5.3), and (5.4) yield

$$q(\tilde{\theta}_1\,,\eta) = q(\theta_1\,,\eta) = \min_{1\le s\le 2} q(s\theta_0\,,\eta) \ge -\frac{4}{\eta^4}\frac{(1-\alpha)^2}{\alpha^2} + 2\eta^2 - \frac{13}{4}\frac{\alpha^2}{1-\alpha}.$$

Moreover,

$$q\left(\eta^2\theta_0\,,\eta\right) = -\frac{(1-\alpha)^2}{\alpha^2} + 2\eta^2 + \frac{\alpha^2}{1-\alpha}\left(-\frac{4}{\eta^2} + \frac{3}{\eta^4}\right).$$

Thus, for $\eta > \eta^*$, we have

$$q(\tilde{\theta}_1\,,\eta) - q\left(\eta^2\theta_0\,,\eta\right) > -\frac{7}{2}\frac{\alpha^2}{1-\alpha} - \frac{3}{16}\frac{\alpha^6}{(1-\alpha)^4} + \frac{(1-\alpha)^2}{\alpha^2} > 0.$$

Since $\theta \mapsto q(\theta\,,\eta)$ is decreasing on $[\theta_2\,,+\infty)$ and $(\eta^*)^2\theta_0 < (\eta^*)^3$, we conclude that $\tilde{\theta}_1(\eta) < \eta^2\theta_0 < \eta^3$ for every $\eta > \eta^*$. Thus, $\theta < \eta^3$ for every $\theta \in I_\eta$ for $\eta > \eta^*$, and this concludes the proof. $\square$

INCOMPRESSIBLE IONIZED NON-NEWTONIAN FLUID MIXTURES*

TOMÁŠ ROUBÍČEK†

Abstract. The model combining Navier–Stokes equations in a non-Newtonian p-power-law modification for barycentric velocity together with the Nernst–Planck equation for concentrations of particular mutually reacting constituents, the heat equation, and the Poisson equation for a self-induced quasi-static electric field is formulated, existence of its (very) weak solutions is proved for $p > 11/5$, and its thermodynamics is discussed.

Key words. chemically reacting fluids, Eckart–Prigogine concept, Navier–Stokes equation, Nernst–Planck equation, Poisson equation, heat equation

AMS subject classifications. 35Q35, 76T30, 80A20, 92C05

1. Introduction.

Chemically reacting mixtures represent a framework for modeling various complicated processes in biology and chemistry. The research in this area, resulting in a model [36], was initiated by Nečas who, for many years before he passed away, spoke about "living fluids," although he never elaborated on any concept of such fluids. The model proposed in [36] uses an incompressible Newtonian framework with the barycentric impulse balance. This "barycentric" approach is called the Eckart–Prigogine [13, 29] concept, phenomenologically simplifying the description by considering only one temperature and one velocity of the whole mixture and being awarded in the context of nonequilibrium thermodynamics of dissipative structures the Nobel prize in chemistry in 1977; for the compressible case, see also [3, 5, 12, 17]. The incompressibility refers here to each particular constituent and, through a volume-additivity hypothesis (i.e., Amagat's law) as in, e.g., [22, 31, 40], also to the overall mixture. To cover biological applications on a cellular or subcellular level where the intensity of the electric field on cell membranes is very high, the self-induced electrostatic field must be considered; recall that the intracellular electric potential usually ranges between 60 and 100 mV, while the thickness of cell membranes is on the order of 10–100 nm, which results in an intensity of the electric field on the order of 1 MV/m.

In comparison with [33, 34, 36] or [35, sect. 12.6], we consider here a more general model exploiting the non-Newtonian concept with a (possibly temperature-dependent) shear-thickening p-power-law stress tensor and admitting diffusive fluxes with different mobilities, and we prove existence of its solution in a fully coupled and fully nonlinear case. The key mathematical tool is a nonvariational technique for the heat equation based on integrability of temperature gradient observed in [6, 7, 8] combined with a regularization of the Navier–Stokes equation and a sophisticated limit passage. Finally, in section 4, thermodynamics of a specific model is discussed.

2. The model: A general framework. We consider a three-dimensional incompressible flow of a mixture of L mutually reacting chemical ionic constituents, the ℓth constitutent having a specific charge z_ℓ, $\ell = 1, \dots, L$. Our model consists in a system of 4+L+1+1 differential equations combining the *non-Newtonian* modification of the *Navier–Stokes equation* (balancing the barycentric momentum ϱv) with the incompressibility constraint $\mathrm{div}(v) = 0$, the *Nernst–Planck equation* modified for moving media (balancing the mass of particular constituents), the *heat equation* (balancing the heat part $c_\mathrm{v}\theta$ of the internal energy u; cf. (4.17) below), and the quasi-static *Poisson equation* for the electrostatic field (balancing the electric induction $\varepsilon\nabla\phi$):

$$\varrho\frac{\partial v}{\partial t} - \mathrm{div}\big(\tau(\mathrm{D}v, c, \theta) - \varrho v \otimes v\big) + \nabla\pi = -q\nabla\phi, \qquad q = c\cdot z, \tag{2.1a}$$

$$\mathrm{div}(v) = 0, \tag{2.1b}$$

$$\frac{\partial c}{\partial t} - \mathrm{div}\big(\mathfrak{D}(c,\theta)\nabla c + \mathfrak{m}(c,\theta)\otimes\nabla\phi - c\otimes v\big) = r(c,\theta)\,, \tag{2.1c}$$

$$\begin{aligned} c_\mathrm{v}\frac{\partial\theta}{\partial t} - \mathrm{div}\big(\kappa\nabla\theta - c_\mathrm{v} v\,\theta\big) &= \tau(\mathrm{D}v, c, \theta){:}\mathrm{D}v \\ &\quad + \big(\mathfrak{D}(c,\theta)\nabla c + \mathfrak{m}(c,\theta)\otimes\nabla\phi\big) : (z\otimes\nabla\phi) + h(c,\theta), \end{aligned} \tag{2.1d}$$

$$-\,\mathrm{div}(\varepsilon\nabla\phi) = q. \tag{2.1e}$$

The variables v, π, c, θ, and ϕ have the following meanings:

$v = (v_1, v_2, v_3)$: barycenter velocity,
π: pressure,
$c = (c_1, \dots, c_L)$: the vector of concentrations of particular constituents,
ϕ: electrostatic potential,
θ: temperature,

where the concentration vector c is to satisfy the constraint

$$\forall \ell = 1, \dots, L: \quad c_\ell(t,x) \ge 0 \quad \text{and} \quad \sum_{\ell-1}^{L} c_\ell(t,x) = 1 \quad \text{for a.a. } (t,x). \tag{2.2}$$

We will write (2.2) briefly as $c(t,x)\in G_1^+$ for a.a. (t,x), where we denote

$$G_1^+ := \{c\in\mathbb{R}^L; \quad c\cdot\mathbf{1} = 1, \quad \forall\ell = 1,\dots,L{:} \quad c_\ell \ge 0\} \tag{2.3}$$

with $\mathbf{1} \in \mathbb{R}^L$ denoting the "unit" vector $(1, \dots, 1)$; usually G_1^+ is called the *Gibbs simplex*. The meaning of the scalar or tensorial products (denoted by "$\cdot$" and "$\otimes$," respectively) is standard, while "$:$" means $[\tau_{ij}]{:}[e_{ij}] = \sum_{i=1}^n \sum_{j=1}^n \tau_{ij}e_{ij}$; i.e., (2.1a), (2.1b) means

$$\varrho\frac{\partial v_i}{\partial t} - \sum_{j=1}^{3}\frac{\partial}{\partial x_j}\big(\tau_{ij}(\mathrm{Dv}, c, \theta) - \varrho v_i v_j\big) + \frac{\partial\pi}{\partial x_i} = -q\frac{\partial\phi}{\partial x_i}, \quad q = \sum_{\ell=1}^{L} c_\ell z_\ell, \tag{2.4a}$$

$$\sum_{j=1}^{3}\frac{\partial v_j}{\partial x_j} = 0, \tag{2.4b}$$

while (2.1c) means

$$\frac{\partial c_\ell}{\partial t} - \sum_{i=1}^{3}\frac{\partial}{\partial x_i}\left(\sum_{k=1}^{L}\mathfrak{D}_{k\ell}(c,\theta)\frac{\partial c_k}{\partial x_i} + \mathfrak{m}_\ell(c,\theta)\frac{\partial\phi}{\partial x_i} - v_i c_\ell\right) = r_\ell(c,\theta) \tag{2.5}$$

for any $\ell = 1, \ldots, L$, and (2.1d) means

$$c_{\mathrm{v}}\frac{\partial\theta}{\partial t} - \sum_{i=1}^{3}\frac{\partial}{\partial x_i}\Big(\kappa\frac{\partial\theta}{\partial x_i} - c_{\mathrm{v}}v_i\,\theta\Big) = \sum_{i=1}^{3}\sum_{j=1}^{3}\tau_{ij}(\mathrm{D}v,c,\theta)\Big(\frac{1}{2}\frac{\partial v_j}{\partial x_i} + \frac{1}{2}\frac{\partial v_i}{\partial x_j}\Big) + \sum_{\ell=1}^{L}\sum_{i=1}^{3}\left(\sum_{k=1}^{L}\mathfrak{D}_{k\ell}(c,\theta)\frac{\partial c_k}{\partial x_i} + \mathfrak{m}_\ell(c,\theta)\frac{\partial\phi}{\partial x_i}\right)z_\ell\frac{\partial\phi}{\partial x_i} + h(c,\theta). \tag{2.6}$$

We use the following notation:
$\tau = [\tau_{ij}]_{i,j=1}^3$: the stress tensor, depending on $(\mathrm{D}v, c, \theta)$,
$\mathrm{D}v = \frac{1}{2}(\nabla v)^\top + \frac{1}{2}\nabla v$: the symmetrized velocity gradient,
$\varrho > 0$: mass density (assumed to be equal to 1 in what follows),
$z = (z_1, \ldots, z_L)$: the vector of specific charges of particular constituents,
$q = c \cdot z$: the total charge, depending on time t and space x,
$\varepsilon > 0$: permitivity,
$r = (r_1, \ldots, r_L)$: the vector of chemical production rates, depending on (c, θ),
h: the heat production rate due to all chemical reactions, depending on (c, θ),
$\mathfrak{D} = [\mathfrak{D}_{kl}]_{k,l=1}^L$: the matrix of diffusion coefficients, depending on (c, θ),
$\mathfrak{m} = (\mathfrak{m}_1, \ldots, \mathfrak{m}_L)$: the vector of effective mobilities, depending on (c, θ),
$\kappa > 0$: thermal conductivity, and
$c_{\mathrm{v}} > 0$: heat capacity.
The system (2.1) is to be completed by the initial conditions

$$v(0,\cdot) = v_0\,, \qquad c(0,\cdot) = c_0\,, \qquad \theta(0,\cdot) = \theta_0 \tag{2.7}$$

on a bounded C^2-domain under consideration, and by the boundary conditions corresponding, e.g., to a closed container, which, in some simplified version, leads, respectively, to

$$v = 0, \tag{2.8a}$$

$$\big(\mathfrak{D}(c,\theta)\nabla c + \mathfrak{m}(c,\theta)\otimes\nabla\phi\big)\nu = 0, \tag{2.8b}$$

$$\varepsilon\frac{\partial\phi}{\partial\nu} = \alpha(\phi_\Sigma - \phi), \tag{2.8c}$$

$$\kappa\frac{\partial\theta}{\partial\nu} = 0 \tag{2.8d}$$

on $(0, T) \times \partial\Omega$, where ν is the unit outward normal to the boundary $\partial\Omega$, ϕ_Σ is a prescribed external electric potential, and $\alpha > 0$ is a "lumped capacity" of the boundary $\partial\Omega$.

Remark 2.1 (right-hand sides of (2.1)). The right-hand side of (2.1a) represents the *Lorenz force* $q\nabla\phi$ due to Coulomb electrostatic interactions. The particular terms on the right-hand side of (2.1d) represent, respectively, the production rate of the *dissipative heat* due to friction in the fluid $\tau(\mathrm{D}v, c, \theta){:}\mathrm{D}v$, the power $(\mathfrak{D}(c,\theta)\nabla c) : (z \otimes \nabla\phi)$ of the electric current arising by the diffusion flux $z^\top(\mathfrak{D}(c,\theta)\nabla c)$ in the electric field gradient $\nabla\phi$ (so-called *Peltier effect*), the power of the *Joule heat* produced by the electric current $(\mathfrak{m} \otimes \nabla\phi) : (z \otimes \nabla\phi) = (z{\cdot}\mathfrak{m})|\nabla\phi|^2$, and, as already stated, the heat production rate due to all chemical reactions h; see also Remark 4.6 below.

Remark 2.2 (Fourier's, Fick's, Ohm's laws). The model (2.1) involves various phenomenological laws. Certainly, (2.1d) relies on the conventional *Fourier law* in linear isotropic homogenous medium; i.e., the heat flux $-\kappa\nabla\theta$ is proportional to the negative temperature gradient. Further, (2.1c) involves a certain generalization of *Fick's law* stating that diffusive fluxes are proportional to negative concentration gradients; here, however, cross-effects make it more complicated, and a nonconstant diffusivity matrix $\mathfrak{D}$ occurs instead of a single constant; see also (3.8) below. In view of Remark 2.1, the effective *electric conductivity* is $\sigma := z{\cdot}\mathfrak{m}$, and we can identify *Ohm's law* that the electric current $(z{\cdot}\mathfrak{m})\nabla\phi$ is proportional to the gradient $\nabla\phi$ of the electric field just via σ. Naturally, σ now depends through $\mathfrak{m} = \mathfrak{m}(c,\theta)$ on the ion concentrations c.

Remark 2.3 (simplifying assumptions). It should be emphasized that many simplifications are adopted in the presented model. In particular, we have considered small electrical currents (i.e., the magnetic field is neglected), we have adopted the mentioned volume-additivity and incompressibility assumption, we have further assumed mass densities equal for all constituents and diffusion fluxes independent of the temperature gradient (i.e., Soret's effect is neglected), and then, in agreement with Onsager's reciprocity principle, we also have considered the heat flux independent of the concentration gradients (i.e., Dufour's effect is neglected). Detailed identification of simplifying assumptions related to (2.1) in comparison with the rational Truesdell concept [24, 30, 38, 39, 41, 42] was made by Samohýl [40].

3. Analysis of the model: Existence of a solution. We will prove the existence of a very weak solution, defined in section 3.1, in several steps. First, in section 3.2 we treat an auxiliary, so-called *multipolar* regularization of the Navier–Stokes equation and prove existence of its solution by Schauder's fixed point technique in a way similar to how it was done in [33] for the spatial regular case (except that [33] had thus assumed composition/temperature-independent potential stress-tensor τ). Then, in section 3.3 we pass this regularization to zero. This two-step approach allows us to avoid any regularity results for p-power-law non-Newtonian fluids (and thus any qualifications of data related to them) and to admit a temperature-dependent stress tensor and rather low exponent $p > 11/5$; this bound even improves some particular known results; cf. Remark 3.4. The advantage of the smoothing is that it avoids difficult (or even unrealistic) requirements of uniqueness or convexity of the set of solutions of decoupled systems needed for Schauder's or Kakutani's fixed point theorems. It is also particularly important for the multicomponent fluids to have $\frac{\partial}{\partial t}c$ in duality with the negative part of c to get $c \geq 0$; cf. (3.57). As a side effect, it simplifies some other arguments; e.g., it ensures the sum-equals-one property $\sum_{\ell=1}^{L} c_\ell = 1$ in (3.47) for smooth velocity field v, and the unique response (see, e.g., (3.50)) for the fixed-point mapping that is used in Schauder's fixed point theorem.

3.1. Definition of a very weak solution and data qualification. We consider an evolution of (2.1) on a fixed time interval $(0,T)$. We use a standard notation $C^1(\cdot;\mathbb{R}^n)$ of continuously differentiable $\mathbb{R}^n$-valued functions, and $L^p(\cdot;\mathbb{R}^n)$ for Lebesgue L^p-spaces as well as $W^{k,p}(\cdot;\mathbb{R}^n)$ for the Sobolev spaces on the domain indicated. Let us abbreviate $I := (0,T)$, $Q := I\times\Omega$, $\Sigma := I\times\Gamma$, $\Gamma := \partial\Omega$, and let $W^{k,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3)$ denote the space of functions from the zero-trace Sobolev space $W^{k,p}_0(\Omega;\mathbb{R}^3)$ but with zero divergence (in the distributional sense), and later we will also use $L^2_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3)$ to denote the closure of $W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3)$ in $L^2(\Omega;\mathbb{R}^3)$. Usage of such divergence-free test functions has the usual effect that the pressure π disappears from the (very) weak formulation. If $\mathbb{R}^n$ is replaced by a Banach space X, then $L^p(I;X)$ refers to the L^p-Bochner space of Banach-space-valued functions, while $W^{k,p}(I;X)$ is a Sobolev–Bochner space. We also denote standardly

$W^{-k,2}(\Omega) = W_0^{k,2}(\Omega)^*$.

The adjective "very weak" is used to emphasize that, contrary to conventional weak solutions, the very weak solutions have less regularity than possible test functions, which particularly concerns the temperature.

DEFINITION 3.1 (very weak solution). *We will call*

$$v \in L^p(I; W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3)) \cap W^{1,p/(p-1)}(I; W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3)^*), \tag{3.1a}$$

$$c \in L^\infty(I; L^2(\Omega;\mathbb{R}^L)) \cap L^2(I; W^{1,2}(\Omega;\mathbb{R}^L)) \cap W^{1,r/(r-1)}(I; W^{1,r}(\Omega;\mathbb{R}^L)^*), \tag{3.1b}$$

$$\theta \in L^\infty(I; L^1(\Omega)) \cap L^{5/4-\xi}(I; W^{1,5/4-\xi}(\Omega)) \cap W^{1,1}(I; W^{-3,2}(\Omega)), \tag{3.1c}$$

$$\phi \in L^\infty(I; W^{1,2}(\Omega)) \tag{3.1d}$$

with any $\xi > 0$ *and* $r = \max(2, 10p/(7p-6))$ *a very weak solution to the system* (2.1)–(2.2) *with the initial and boundary conditions* (2.7) *and* (2.8) *if*

$$\int_Q \tau(\mathrm{D}v, c, \theta):\mathrm{D}w - (v\otimes v):\nabla w + (z\cdot c)(\nabla\phi\cdot w) - v\frac{\partial w}{\partial t}\,\mathrm{d}x\mathrm{d}t = \int_\Omega v_0(x)\cdot w(0,x)\,\mathrm{d}x \tag{3.2}$$

for any $w \in C^1(Q;\mathbb{R}^3)$ *with* $\operatorname{div} w = 0$, $w|_\Sigma = 0$, *and* $w(T,\cdot) = 0$,

$$\int_Q \big(\mathfrak{D}(c,\theta)\nabla c + \mathfrak{m}(c,\theta)\otimes\nabla\phi - c\otimes v\big):\nabla w + r(c,\theta)w - c\cdot\frac{\partial w}{\partial t}\,\mathrm{d}x\,\mathrm{d}t = \int_\Omega c_0(x)\cdot w(0,x)\,\mathrm{d}x \tag{3.3}$$

with the test-function $w \in C^1(Q;\mathbb{R}^L)$ *arbitrary with* $w(T,\cdot) = 0$,

$$\int_Q \varepsilon\nabla\phi\cdot\nabla w - qw\,\mathrm{d}x\,\mathrm{d}t + \int_\Sigma \phi\alpha w\,\mathrm{d}S\,\mathrm{d}t = \int_\Sigma \alpha\phi_\Sigma w\,\mathrm{d}S\,\mathrm{d}t \tag{3.4}$$

for any $w \in C^1(Q)$, *and*

$$\int_Q \big(\kappa\nabla\theta - c_{\mathrm{v}}v\theta\big)\cdot\nabla w - \Big(\tau(\mathrm{D}v,c,\theta):\mathrm{D}v + \big(\mathfrak{D}(c,\theta)\nabla c + \mathfrak{m}(c,\theta)\otimes\nabla\phi\big) : (z\otimes\nabla\phi) + h\Big)w - c_{\mathrm{v}}\theta\frac{\partial w}{\partial t}\,\mathrm{d}x\,\mathrm{d}t = c_{\mathrm{v}}\int_\Omega \theta_0(x)w(0,x)\,\mathrm{d}x \tag{3.5}$$

for any $w \in C^1(Q)$ *with* $w(T,\cdot) = 0$ *on* Ω. *Finally,* (2.2) *is to be satisfied, too.*

We naturally assume the mass conservation in all chemical reactions, and the volume-additivity constraint holding for the initial conditions c_0, i.e.,

$$r(c,\theta)\cdot\mathbf{1} = 0, \tag{3.6a}$$

$$c_0\cdot\mathbf{1} = 1, \qquad [c_0]_\ell \geq 0 \quad \forall \ell = 1,\dots,L. \tag{3.6b}$$

Other important qualifications concern the diffusion matrix $\mathfrak{D}$ and the effective-mobility vector $\mathfrak{m}$:

(3.7a) $\mathfrak{D}: G_1^+ \times \mathbb{R} \to \mathbb{R}^{L\times L}$, $\mathfrak{m}: G_1^+ \times \mathbb{R} \to \mathbb{R}^L$ continuous and bounded,

(3.7b) $\exists \eta_0 > 0\ \forall c \in G_1^+,\ \theta \in \mathbb{R},\ d \in \mathbb{R}^L: \quad d^\top \mathfrak{D}(c,\theta) d := \sum_{\ell=1}^L \sum_{k=1}^L \mathfrak{D}_{k\ell}(c,\theta) d_k d_\ell \geq \eta_0 |d|^2,$

(3.7c) $\exists \beta \geq 0\ \forall k = 1, \ldots, L: \quad \sum_{\ell=1}^L \mathfrak{D}_{k\ell}(c,\theta) = \beta,$

(3.7d) $\sum_{\ell=1}^L \mathfrak{m}_\ell(c,\theta) = 0,$

where ${G_1}^+$ is from (2.3). Note that, if $\beta = 0$, then (3.7c), (3.7d) means that the sum $\sum_{\ell=1}^L j_\ell$ of the diffusive fluxes

$$j_\ell := \sum_{k=1}^L \mathfrak{D}_{k\ell}(c,\theta) \nabla c_k + \mathfrak{m}_\ell(c,\theta) \nabla \phi \tag{3.8}$$

is identically zero, which is to hold the equality constraint in (2.2). Essentially the same effect is made by (3.7c), (3.7d) also if $\beta > 0$; cf. the arguments around (3.47). In fact, (3.7b) suffices to hold only for d with $\sum_{\ell=1}^L d_\ell = 0$ if later (3.47) is used simultaneously when testing (3.18d) by c in the proof of (3.22e), e.g., in an additional auxiliary Galerkin approximation just for (3.18d) itself. This makes (3.7c) indeed consistent with (3.7b) even for $\beta = 0$.

As for the stress tensor $\tau: \mathbb{R}^{3\times3}_{\rm sym} \times G_1^+ \times \mathbb{R} \to \mathbb{R}^{3\times3}_{\rm sym}$, where $\mathbb{R}^{3\times3}_{\rm sym}$ denotes the set of symmetric 3×3-matrices, we assume that, for some $\eta_1 > 0$, $C \in \mathbb{R}$, it satisfies

(3.9a) $\tau: \mathbb{R}^{3\times3}_{\rm sym} \times G_1^+ \times \mathbb{R} \to \mathbb{R}^{3\times3}_{\rm sym}$ continuously differentiable,

(3.9b) $\forall D_1, D_2 \in \mathbb{R}^{3\times3}_{\rm sym},\ c \in G_1^+,\ \theta \in \mathbb{R}: \quad \big(\tau(D_1,c,\theta) - \tau(D_2,c,\theta)\big):(D_1 - D_2) \geq \eta_1 \big|D_1 - D_2\big|^p,$

(3.9c) $\forall D \in \mathbb{R}^{3\times3}_{\rm sym},\ c \in G_1^+,\ \theta \in \mathbb{R}: \quad |\tau(D,c,\theta)| \leq C\big(1 + |D|^{p-1}\big),$

(3.9d) $\big|\tau'_D(D,c,\theta)\big| \leq C\big(1 + |D|^{p-2}\big),$

(3.9e) $\big|\tau'_{(c,\theta)}(D,c,\theta)\big| \leq C,$

(3.9f) $\tau(0,c,\theta) = 0.$

Note that (3.9b), (3.9f) yields the coercivity $\tau(D,c,\theta) : D \geq \eta_1 |D|^p$. Other important assumptions ensure nonnegativity of concentrations during their evolution, namely by nonnegative production rate and by a natural direction of the flux j_ℓ of the ℓth constituent from (3.8) if the concentration of this particular constituent vanishes:

(3.10a) $\mathfrak{D}_{k\ell}(c_1, \ldots, c_{\ell-1}, 0, c_{\ell+1}, \ldots, c_L, \theta) \begin{cases} \geq 0 & \text{for } k = \ell, \\ = 0 & \text{for } k \neq \ell, \end{cases}$

(3.10b) $\mathfrak{m}_\ell(c_1, \ldots, c_{\ell-1},\ 0,\ c_{\ell+1}, \ldots, c_L, \theta) = 0\,,$

(3.10c) $r_\ell\,(c_1, \ldots, c_{\ell-1},\ 0,\ c_{\ell+1}, \ldots, c_L, \theta) \geq 0$

for each $\ell = 1, \ldots, L$. Eventually, we still assume

$$r_\ell, h: G_1^+ \times \mathbb{R} \to \mathbb{R} \ \text{ continuous and bounded.} \tag{3.11}$$

Remark 3.2 (extension convention). For the purpose of the proof of Proposition 3.9, we consider $\mathfrak{D}$, $\mathfrak{m}$, τ, r_ℓ, and h extended suitably from the Gibbs' simplex G_1^+ defined by (2.3) on the affine manifold

$$G_1 := \left\{ c \in \mathbb{R}^L;\ \sum_{\ell=1}^{L} c_\ell = 1 \right\}. \tag{3.12}$$

We assume continuous and bounded extension so that (3.7b)–(3.7d) and (3.9b)–(3.9e) hold even for $c \in G_1 \setminus G_1^+$. Moreover, (3.10) allows us to consider nonnegative extensions of r_ℓ and zero-extension of $\mathfrak{m}_\ell$ if $c_\ell \le 0$.

Remark 3.3 (data qualification versus reality). The assumption (3.11) represents a rather drastic mathematical simplification contrasting with the usual feature that the rate of chemical reactions r and the corresponding heat production h depend rather exponentially on the temperature θ. In fact, making the estimates in section 3.2 in a still more complicated (and less lucid) way, a certain (although only sublinear) growth of $r(c,\cdot)$ and $h(c,\cdot)$ may be admitted, too; cf. also [36]. The mentioned exponential growth would allow for "explosive" blow-ups which we do not have in mind, especially in the context of usual biological applications. Also, (3.7b) is not directly relevant and contradicts an Einstein law if $\theta \searrow 0$; cf. also the arguments in Remark 4.6. Yet, considering $\mathfrak{D}(c,\theta)$ approaching zero if $\theta \searrow 0$ would inevitably make the analysis of the problem extremely difficult, if possible at all. Anyhow, the model of fluid mixtures loses its validity much earlier than the absolute temperature θ approaches zero because of ultimate phase transition to solid state.

Remark 3.4 (special case: single-component fluids). A subsystem (2.1a), (2.1b), and (2.1d) with $\mathfrak{D}$ and $\mathfrak{m}$ vanishing and with a general heat flux $j_0(\theta, \nabla\theta)$ instead of $\kappa\nabla\theta$ together with a fixed right-hand side instead of $q\nabla\phi$ was considered in [9]. Assuming monotonicity and p_0-polynomial structure of $j_0(\theta,\cdot) : \mathbb{R}^3 \to \mathbb{R}^3$, existence of a weak solution was proved for $p \ge 5/2$ and $p_0 \ge 10p/(5p-1) > 2$. Physically, the heat flux j_0 may depend substantially on θ, but the dependence of $\nabla\theta$ is rather linear, which corresponds to the case $p_0 = 2$ not covered by [9]. Our results cover, in particular, the case $11/5 < p < 5/2$ and enable us to treat the physically more relevant case $p_0 = 2$ for such a subsystem (2.1a), (2.1b), (2.1d). Also, [9] assumed $\tau(\cdot,\theta)$ to have a potential, even with a special structure $\sum_{l=1}^{L} \mu_l(\theta) F_l(|\cdot|)$ (which we do not need at all) but, on the other hand, allowed for a temperature dependence of $c_{\rm v}$ and κ.

3.2. Auxiliary multipolar regularization. We will regularize (2.1a) by a $2k$th-order term $(-1)^k \epsilon \Delta^k v$ with a regularization parameter $\epsilon > 0$ and with an integer $k \ge 5$ specified later (see (3.21) with (3.29)) as follows:

$$\frac{\partial v}{\partial t} - \mathrm{div}\big(\tau(\mathrm{D}v, c, \theta) - v \otimes v\big) + \nabla\pi + (-1)^k \epsilon \Delta^k v = -c{\cdot}z\nabla\phi, \tag{3.13a}$$

$$\mathrm{div}(v) = 0. \tag{3.13b}$$

Such a "multipolar" regularization is even physically motivated; cf. [25]. Let us emphasize that we distinguish ε (the permitivity) from ϵ (the regularizing parameter). The boundary conditions (2.8) are now to be completed by another higher-order condition for the Δ^k-operator. In fact, its choice is not important as this term has only an auxiliary character; let us choose, say, the homogeneous Dirichlet condition

$$\frac{\partial^l v}{\partial \nu^l} = 0, \qquad l = 1, \ldots, k-1. \tag{3.14}$$

We modify Definition 3.1 for a weak solution to the system (2.1c)–(2.1e) and (3.13) with the initial and boundary conditions (2.7) and (2.8) and (3.14).

DEFINITION 3.5 (weak solution to (2.1c)–(2.1e) and (3.13)). *We will call* (v, c, θ, ϕ) *satisfying*

$$v \in L^\infty(I; W^{k,2}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3)) \cap W^{1,2}(I; L^2(\Omega;\mathbb{R}^3)), \tag{3.15a}$$

$$c \in L^2(I; W^{1,2}(\Omega;\mathbb{R}^L)) \cap W^{1,2}(I; W^{1,2}(\Omega;\mathbb{R}^L)^*), \tag{3.15b}$$

$$\theta \in L^\infty(I; W^{1,2}(\Omega)) \cap W^{1,2}(I; L^2(\Omega)), \tag{3.15c}$$

$$\phi \in L^\infty(I; W^{1,2}(\Omega)) \tag{3.15d}$$

a weak solution to the system (2.1c)–(2.1e) *and* (3.13) *with the initial and boundary conditions* (2.7), (2.8), *and* (3.14) *if* (3.3), (3.4), (3.5), *and* (2.2) *hold, while, instead of* (3.2), *we require the following identity to hold for any* $w \in C^1(Q;\mathbb{R}^3)$ *with* $\mathrm{div}(w) = 0$, $\frac{\partial^l}{\partial\nu^l} w|_\Sigma = 0$ *for* $l = 0, \dots, k-1$, *and* $w(T, \cdot) = 0$:

$$\int_Q \tau(\mathrm{D}v, c, \theta) : \mathrm{D}w - (v \otimes v) : \nabla w + z \cdot c \nabla\phi \cdot w + \epsilon \nabla^k v \,\vdots\, \nabla^k w - v \frac{\partial w}{\partial t} \,\mathrm{d}x\,\mathrm{d}t = \int_\Omega v_0(x) \cdot w(0, x) \,\mathrm{d}x, \tag{3.16}$$

where " $\vdots$ *" denotes the scalar product of kth-order tensors; for* $k = 1$ *or* $k = 2$ *we already used "* $\cdot$ *" or "* $:$*," respectively.*

To correct the concentrations that satisfy the constraint $\sum_{\ell=1}^L c_\ell = 1$ but that may possibly be negative, we define a retract $K : G_1 \to G_1^+$ by

$$K_\ell(c) := \frac{c_\ell^+}{\sum_{l=1}^L c_l^+}, \qquad c_\ell^+ := \max(c_\ell, 0), \tag{3.17}$$

where G_1 is from (3.12). Let us note that K is continuous and bounded on G_1 and leaves G_1^+ fixed, and even $K_\ell(c) = 0$ if $c_\ell \le 0$. Further, we consider r, h, $\mathfrak{D}$, and $\mathfrak{m}$ continuously and boundedly extended on G_1. Considering $\gamma = (\gamma_1, \dots, \gamma_L) =$ "old" concentrations and $\vartheta =$ an "old" temperature field, we define the quadruple (v, c, θ, ϕ) as the weak solution to the *decoupled regularized system*:

$$-\,\mathrm{div}(\varepsilon \nabla\phi) = q, \qquad q = z \cdot K(\gamma), \tag{3.18a}$$

$$\frac{\partial v}{\partial t} - \mathrm{div}\big(\tau(\mathrm{D}v, \gamma, \vartheta) - v \otimes v\big) + \nabla\pi + (-1)^k \epsilon \Delta^k v = -q \nabla\phi, \tag{3.18b}$$

$$\mathrm{div}(v) = 0\,, \tag{3.18c}$$

$$\frac{\partial c}{\partial t} - \mathrm{div}\big(\mathfrak{D}(\gamma, \vartheta) \nabla c + \mathfrak{m}(\gamma, \vartheta) \otimes \nabla\phi - c \otimes v\big) = r(\gamma, \vartheta)\,, \tag{3.18d}$$

$$c_\mathrm{v} \frac{\partial\theta}{\partial t} - \mathrm{div}\big(\kappa \nabla\theta - c_\mathrm{v} v\, \theta\big) = \tau(\mathrm{D}v, \gamma, \vartheta) : \mathrm{D}v + \big(\mathfrak{D}(\gamma, \vartheta) \nabla c + \mathfrak{m}(\gamma, \vartheta) \otimes \nabla\phi\big) : (z \otimes \nabla\phi) + h(\gamma, \vartheta), \tag{3.18e}$$

$$c \cdot \mathbf{1} := \sum_{\ell=1}^L c_\ell = 1 \tag{3.18f}$$

with the boundary conditions (2.8) and (3.14) and with the initial conditions

$$v(0, \cdot) = v_{0\epsilon}\,, \qquad c(0, \cdot) = c_0\,, \qquad \theta(0, \cdot) = \theta_{0\epsilon}. \tag{3.19}$$

Obviously, given (γ,ϑ), we are to solve first (3.18a), and after knowing also ϕ we can solve (3.18b), (3.18c) to get v, and then we can solve (3.18d) to obtain c, and finally (3.18e) to obtain also θ. In (3.19), we have made a regularization of the original initial conditions $v_0\in L^2_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3)$ and $\theta_0\in L^1(\Omega)$, respectively, by $v_{0\epsilon}\in W^{k,2}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3)$ and $\theta_{0\epsilon}\in W^{1,2}(\Omega)$ in such a way that

$$\text{(3.20a)}\qquad \big\|v_{0\epsilon}\big\|_{W^{k,2}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3)}\le\frac{C}{\epsilon},\qquad \big\|\theta_{0\epsilon}\big\|_{W^{1,2}(\Omega)}\le\frac{C}{\epsilon},\quad\text{and}$$

$$\text{(3.20b)}\qquad \big\|v_{0\epsilon}\big\|_{L^2(\Omega;\mathbb{R}^3)}\le C,\qquad \big\|\theta_{0\epsilon}\big\|_{L^1(\Omega)}\le C.$$

PROPOSITION 3.6 (a priori estimates for (3.18)). *Let the assumptions* (3.6), (3.7), (3.9), (3.10), (3.11) *hold, let* $v_{0\epsilon}\in W^{k,2}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3)$, $c_0\in L^\infty(\Omega;\mathbb{R}^L)$, $\theta_{0\epsilon}\in W^{1,2}(\Omega)$ *satisfy* (3.20), *let* Ω *be a bounded* C^2*-domain, and let* $p\in\mathbb{R}$ *and* $k\in\mathbb{N}$ *satisfy*

$$\text{(3.21)}\qquad p>\frac{11}{5}\quad\textit{and}\quad k\ge\frac{5p-3}{2}.$$

Further, let $(\gamma,\vartheta)\in L^2(I;W^{1,2}(\Omega))^{L+1}$ *be given such that* $\sum_{\ell=1}^L\gamma_\ell=1$ *a.e. on* Q*. Then,* (3.18) *with the boundary condition* (2.8) *and the initial condition* (3.19) *has a weak solution (which need not satisfy* $c_\ell\ge 0$*, however) which satisfies, for any* $\xi>0$ *and some* $C_0,\dots,C_{11}<+\infty$ *independent of* ϵ*, the following a priori estimates:*

$$\text{(3.22a)}\qquad \big\|\phi\big\|_{L^\infty(I;W^{2,r}(\Omega))}\le C_1\quad\textit{with}\quad r<+\infty,$$

$$\text{(3.22b)}\qquad \big\|v\big\|_{L^\infty(I;L^2(\Omega;\mathbb{R}^3))\,\cap\,L^p(I;W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3))}\le C_2,$$

$$\text{(3.22c)}\qquad \big\|v\big\|_{L^\infty(I;W^{k,2}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3))\,\cap\,W^{1,2}(I;L^2(\Omega;;\mathbb{R}^3))}\le\frac{C_3\mathrm{e}^{C_0/\epsilon^2}}{\epsilon},$$

$$\text{(3.22d)}\qquad \Big\|\frac{\partial v}{\partial t}+(-1)^k\epsilon\Delta^k v\Big\|_{L^{p/(p-1)}(I;W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3)^*)}\le C_4,$$

$$\text{(3.22e)}\qquad \big\|c\big\|_{L^\infty(I;L^2(\Omega;\mathbb{R}^L))\,\cap\,L^2(I;W^{1,2}(\Omega;\mathbb{R}^L))}\le C_5,$$

$$\text{(3.22f)}\qquad \Big\|\frac{\partial c}{\partial t}\Big\|_{L^2(I;W^{1,2}(\Omega;\mathbb{R}^L)^*)}\le\frac{C_6}{\sqrt{\epsilon}},$$

$$\text{(3.22g)}\qquad \Big\|\frac{\partial c}{\partial t}\Big\|_{L^{r/(r-1)}(I;W^{1,r}(\Omega;\mathbb{R}^L)^*)}\le C_7\quad\textit{with}\quad r=\max\Big(2,\frac{10p}{7p-6}\Big),$$

$$\text{(3.22h)}\qquad \big\|\theta\big\|_{L^2(I;W^{1,2}(\Omega))}\le\frac{C_8}{\sqrt{\epsilon}},$$

$$\text{(3.22i)}\qquad \big\|\theta\big\|_{L^\infty(I;W^{1,2}(\Omega))\,\cap\,W^{1,2}(I;L^2(Q))}\le\frac{C_9\mathrm{e}^{C_0/\epsilon^2}}{\epsilon},$$

$$\text{(3.22j)}\qquad \big\|\theta\big\|_{L^\infty(I;L^1(\Omega))\,\cap\,L^{5/4-\xi}(I;W^{1,5/4-\xi}(\Omega))}\le C_{10},$$

$$\text{(3.22k)}\qquad \Big\|\frac{\partial\theta}{\partial t}\Big\|_{L^1(I;W^{-3,2}(\Omega))}\le C_{11}.$$

Moreover, except for C_0*,* C_3*, and* C_9*, the constants* C *are independent of* (γ,ϑ)*, while* C_0*,* C_3*, and* C_9 *depend on* $\|(\nabla\gamma,\nabla\vartheta)\|_{L^2(Q;\mathbb{R}^3))^{L+1}}$ *due to* (3.32) *below. The meaning of* $\frac{\partial v}{\partial t}+(-1)^k\epsilon\Delta^k v$ *in* (3.22d) *as a linear continuous functional on* $L^p(I;W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3))$ *is a continuous extension of the weak form of* $\mathrm{div}(\tau(\mathrm{D}v,\gamma,\vartheta)-v\otimes v)-q\nabla\phi$*, which has a good sense for smooth functions; cf.* (3.26).

Proof. First, we realize that the total charge $z{\cdot}K(\gamma)$ in (3.18a) is always bounded, namely, $\|z{\cdot}K(\gamma)\|_{L^\infty(Q)} \le \max_{\ell=1,\dots,L}|z_\ell|$, and then (3.22a) follows by usual $W^{2,r}$-regularity of the Δ-operator with (2.8) for any $r<+\infty$; cf. [1, 2]. Then also the driving force $q\nabla\phi=(z\cdot K(\gamma))\nabla\phi$ in (3.18b) is bounded in $L^\infty(Q;\mathbb{R}^3)$, and hence certainly in $L^1(I;L^2(\Omega;\mathbb{R}^3))$. Then, by a test of (3.13) by v itself and by using the Korn inequality

$$\exists\eta_2>0\quad \forall v\in W^{1,p}_0(\Omega;\mathbb{R}^3):\qquad \eta_2\big\|v\big\|_{W^{1,p}_0(\Omega;\mathbb{R}^3)}\le\big\|\mathrm{D}v\big\|_{L^p(\Omega;\mathbb{R}^{3\times3})} \tag{3.23}$$

with $\eta_2>0$ depending on the Lipschitz domain Ω, and by using the usual trick that $\int_\Omega\nabla\pi\cdot v\,\mathrm{d}x=-\int_\Omega\pi\,\mathrm{div}(v)\,\mathrm{d}x=0$ as well as $\int_\Omega(v\otimes v){:}\nabla v\,\mathrm{d}x=0$, and by using also (3.9b), we obtain the estimate

$$\begin{aligned}\frac12\frac{\mathrm{d}}{\mathrm{d}t}\big\|v\big\|^2_{L^2(\Omega;\mathbb{R}^3)}&+\eta_1\eta_2^p\big\|v\big\|^p_{W^{1,p}_0(\Omega;\mathbb{R}^3)}+\epsilon\big\|\nabla^m v\big\|^2_{L^2(\Omega;\mathbb{R}^{3^{k+1}})}\\ &\le\int_\Omega\frac{\partial v}{\partial t}\cdot v+\tau(\mathrm{D}v,\gamma,\theta){:}\mathrm{D}v+\epsilon\nabla^m v\,\vdots\,\nabla^m v\ \mathrm{d}x\\ &=-\int_\Omega q\nabla\phi{\cdot}v\ \mathrm{d}x\le\max_{\ell=1,\dots,L}|z_\ell|\ \big\|\nabla\phi\big\|_{L^2(\Omega;\mathbb{R}^3)}\big\|v\big\|_{L^2(\Omega;\mathbb{R}^3)};\end{aligned} \tag{3.24}$$

let us recall the convention pronounced in Remark 3.2 so that $\tau(\mathrm{D}v,\gamma,\theta)$ behaves well even if some γ's are negative. By Young's and Gronwall's inequalities, we obtain (3.22b) and

$$\big\|v\big\|_{L^2(I;W^{k,2}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3))}\le\frac{C_3}{\sqrt{\epsilon}} \tag{3.25}$$

by a test of (3.13) by v itself and using the usual trick that $\int_\Omega\nabla\pi{\cdot}v\,\mathrm{d}x=-\int_\Omega\pi\,\mathrm{div}(v)\,\mathrm{d}x=0$ as well as $\int_\Omega(v\otimes v){:}\nabla v\,\mathrm{d}x=0$. Note that, because of the retract K used in (3.18a), the bounds in (3.22b) and (3.25) are completely independent of γ.

The estimate (3.22d) can be obtained by testing (3.18b) by $w\in L^p(I;W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3))$ as follows:

$$\begin{aligned}&\Big\|\frac{\partial v}{\partial t}+(-1)^k\epsilon\Delta^k v\Big\|_{L^{p/(p-1)}(I;W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3)^*)}\\ &\quad:=\sup_{\|w\|_{L^p(I;W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3))}\le1}\Big\langle\frac{\partial v}{\partial t}+(-1)^k\epsilon\Delta^k v,w\Big\rangle\\ &\quad=\sup_{\|w\|_{L^p(I;W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3))}\le1}\int_Q\tau(\mathrm{D}v,\gamma,\vartheta){:}\mathrm{D}w-(v\otimes v){:}\nabla w+q\,\nabla\phi{\cdot}w\,\mathrm{d}x\,\mathrm{d}t.\end{aligned} \tag{3.26}$$

The boundedness of $\int_Q(v\otimes v){:}\nabla w\ \mathrm{d}x\,\mathrm{d}t$ just requires $p\ge11/5$ because, by interpolation, (3.22b) guarantees v bounded in $L^{11/3}(Q;\mathbb{R}^3)$ so that $(v\otimes v){:}\nabla w\in L^1(Q)$ if $\nabla w\in L^{11/5}(Q;\mathbb{R}^3)$; see also, e.g., [21, Chap. 5, Lemma 2.44(iii)].

To get (3.22e), we test (3.18d) by c. We realize that

$$\int_\Omega c_\ell v{\cdot}\nabla c_\ell\ \mathrm{d}x=\frac12\int_\Omega v{\cdot}\nabla c_\ell^2\ \mathrm{d}x=-\frac12\int_\Omega(\mathrm{div}\,v)c_\ell^2\ \mathrm{d}x=0 \tag{3.27}$$

for each $\ell = 1, \dots, L$; i.e., $\int_\Omega (c\otimes v){:}\nabla c \,\mathrm{d}x = 0$. By (3.27), we obtain

$$\begin{aligned}\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega |c|^2\,\mathrm{d}x + \eta_0\int_\Omega |\nabla c|^2\,\mathrm{d}x &\le \frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega |c|^2\,\mathrm{d}x + \int_\Omega \nabla c^\top \mathfrak{D}(\gamma,\vartheta)\nabla c\,\mathrm{d}x\\ &= \int_\Omega (c\otimes v){:}\nabla c - \big(\mathfrak{m}(\gamma,\vartheta)\otimes\nabla\phi\big){:}\nabla c + r(\gamma,\vartheta)\,\mathrm{d}x\\ &\le \frac{\eta_0}{2}\|\nabla c\|^2_{L^2(\Omega;\mathbb{R}^{3\times L})} + \frac{1}{2\eta_0}\|\mathfrak{m}\|_{L^\infty(\mathbb{R}^2;\mathbb{R}^L)}\|\nabla\phi\|^2_{L^2(\Omega;\mathbb{R}^3)} + \|r\|_{L^1(\mathbb{R}^2;\mathbb{R}^L)}.\end{aligned}$$

Then (3.22e) follows by Young's and Gronwall's inequalities when using also (3.11) and (3.22a). Again, Remark 3.2 applies, of course.

As for (3.22f), let us realize that, by (3.22e), c is bounded in $L^\infty(I;L^2(\Omega;\mathbb{R}^L))$ and, by (3.25), $\sqrt{\epsilon}v$ is bounded in $L^2(I;L^\infty(\Omega;\mathbb{R}^3))$ so that $\sqrt{\epsilon}\,c\otimes v$ is certainly bounded in $L^2(Q;\mathbb{R}^{3\times L})$. Then we obtain (3.22f) by testing (3.18d) by an arbitrary w from $L^2(I;W^{1,2}(\Omega;\mathbb{R}^L))$ when using (3.11) and (3.22a).

The estimate (3.22g) can be obtained in the same way as (3.22d) by testing (3.18d) by arbitrary $w \in L^r(I;W^{1,r}(\Omega;\mathbb{R}^L))$ with a suitable r. The resulting term $\int_Q (c\otimes v){:}\nabla w \,\mathrm{d}x\,\mathrm{d}t$ is now to be estimated as

$$\int_Q (c\otimes v) : \nabla w\,\mathrm{d}x\,\mathrm{d}t \le C\|v\|_{L^{5p/3}(Q;\mathbb{R}^3)}\|c\|_{L^{10/3}(Q;\mathbb{R}^L)}\|\nabla w\|_{L^r(Q;\mathbb{R}^{3\times L})}, \tag{3.28}$$

provided that $r \ge 10p/(7p-6)$. The other resulting term, $\int_Q \nabla w^\top\mathfrak{D}(\gamma,\vartheta)\nabla c\,\mathrm{d}x\,\mathrm{d}t$, requires $r \ge 2$, which eventually gives the restriction (3.22g) on r.

We now want to show boundedness of ∇v in $L^{2p}(Q;\mathbb{R}^{3\times 3})$, which will guarantee the dissipative heat $\tau(\mathrm{D}v,\gamma,\vartheta){:}\mathrm{D}v$ bounded in $L^2(Q)$ to allow for a test of (3.18e) by $\frac{\partial\theta}{\partial t}$. We get it by the Gagliardo–Nirenberg inequality $\|w\|_{W^{1,2p}(\Omega)} \le C\|w\|^\lambda_{W^{k,2}(\Omega)}\|w\|^{1-\lambda}_{L^2(\Omega)}$, which holds for $1/(2p) + \lambda k/3 \ge 5/6$. To also have the interpolation $\|w\|_{L^{2p}(I)} \le C\|w\|^\lambda_{L^2(I)}\|w\|^{1-\lambda}_{L^\infty(I)}$, which holds for $0 \le \lambda \le 1/p$, we put $\lambda = 1/p$. Choosing k large enough, namely, as specified in (3.21), we obtain the desired interpolation

$$\|v\|_{L^{2p}(I;W^{1,2p}(\Omega;\mathbb{R}^3))} \le \|v\|^\lambda_{L^2(I;W^{k,2}(\Omega;\mathbb{R}^3))}\|v\|^{1-\lambda}_{L^\infty(I;L^2(\Omega;\mathbb{R}^3))} = \mathcal{O}\left(\frac{1}{\epsilon^{\frac{\lambda}{2}}}\right) = \mathcal{O}\left(\frac{1}{\epsilon^{\frac{1}{2p}}}\right), \tag{3.29}$$

where the order with respect to the parameter ϵ comes from (3.22b) and (3.25). Thus

$$\|\tau(\mathrm{D}v,\gamma,\vartheta){:}\mathrm{D}v\|_{L^2(Q)} = \mathcal{O}\left(\frac{1}{\sqrt{\epsilon}}\right). \tag{3.30}$$

The other terms on the right-hand side of (3.18e) are bounded in $L^2(Q)$, too; note that $\nabla c_\ell\cdot\nabla\phi \in L^2(Q)$ because $\nabla c_\ell \in L^2(Q;\mathbb{R}^3)$ due to (3.22e), while $\nabla\phi \in L^\infty(Q;\mathbb{R}^3)$ due to (3.22a). Hence the total right-hand side of (3.18e), let us denote it by h_{tot}, is bounded in $L^2(Q)$. Then the test of (3.18e) by θ gives (3.22h) with the order $\mathcal{O}(1/\sqrt{\epsilon})$ coming from (3.30), the constant C_8 being still independent of γ and ϑ.

Now we simultaneously test (3.18b) by $\frac{\partial v}{\partial t}$ and (3.18e) by $\frac{\partial\theta}{\partial t}$. (Rigorously, this step is not legal unless we have L^2-information about $\frac{\partial v}{\partial t}$ and $\frac{\partial\theta}{\partial t}$ which we want just to derive, but one can, for a moment, imagine, e.g., a Galerkin approximation of (3.18b) and (3.18e) to make these tests and a subsequent limit passage.) We sum them to obtain, for a.a. $t \in I$,

$$
\begin{aligned}
(3.31)\quad & \Big\|\frac{\partial v}{\partial t}\Big\|^2_{L^2(\Omega;\mathbb{R}^3)} + c_{\rm v}\Big\|\frac{\partial \theta}{\partial t}\Big\|^2_{L^2(\Omega)} + \frac{\rm d}{{\rm d}t}\Big(\frac{\epsilon}{2}\big\|\nabla^k v\big\|^2_{L^2(\Omega;\mathbb{R}^{3^{k+1}})} + \frac{\kappa}{2}\big\|\nabla\theta\big\|^2_{L^2(\Omega;\mathbb{R}^3)}\Big) \\
&= \int_\Omega {\rm div}\big(\tau({\rm D}v,\gamma,\vartheta)\big)\cdot\frac{\partial v}{\partial t} - (v\cdot\nabla)v\cdot\frac{\partial v}{\partial t} + q\nabla\phi\cdot\frac{\partial v}{\partial t} - c_{\rm v}(v\cdot\nabla)\theta\frac{\partial\theta}{\partial t} + h_{\rm tot}\frac{\partial\theta}{\partial t} \\
&\le 2\big\|{\rm div}\big(\tau({\rm D}v,\gamma,\vartheta)\big)\big\|^2_{L^2(\Omega;\mathbb{R}^3)} + 2\big\|(v\cdot\nabla)v\big\|^2_{L^2(\Omega;\mathbb{R}^3)} \\
&\quad + 2\big\|q\nabla\phi\big\|^2_{L^2(\Omega;\mathbb{R}^3)} + \frac{1}{2}\Big\|\frac{\partial v}{\partial t}\Big\|^2_{L^2(\Omega;\mathbb{R}^3)} \\
&\quad + \frac{1}{c_{\rm v}}\big\|(v\cdot\nabla)\theta\big\|^2_{L^2(\Omega)} + \frac{1}{c_{\rm v}}\big\|h_{\rm tot}\big\|^2_{L^2(\Omega)} + \frac{c_{\rm v}}{2}\Big\|\frac{\partial\theta}{\partial t}\Big\|^2_{L^2(\Omega)}.
\end{aligned}
$$

The particular right-hand side terms can be estimated as follows. The first one allows for the estimate

$$
\begin{aligned}
(3.32)\ & \big\|{\rm div}\big(\tau({\rm D}v,\gamma,\vartheta)\big)\big\|^2_{L^2(\Omega;\mathbb{R}^3)} \le \big\|\tau_D'({\rm D}v,\gamma,\vartheta)\big\|^2_{L^2(\Omega;\mathbb{R}^{3\times3\times3})}\big\|\nabla^2 v\big\|^2_{L^\infty(\Omega;\mathbb{R}^{3^{k+1}})} \\
&\quad + \big\|\tau_\gamma'({\rm D}v,\gamma,\vartheta)\big\|^2_{L^\infty(\Omega;\mathbb{R}^{3\times3})}\big\|\nabla\gamma\big\|^2_{L^2(\Omega;\mathbb{R}^3)} \\
&\quad + \big\|\tau_\theta'({\rm D}v,\gamma,\vartheta)\big\|^2_{L^\infty(\Omega;\mathbb{R}^{3\times3})}\big\|\nabla\vartheta\big\|^2_{L^2(\Omega;\mathbb{R}^3)} \\
&\le \tilde C\Big(1+\big\|\nabla v\big\|^{2p}_{L^{2p}(\Omega;\mathbb{R}^{3\times3})}\Big)\big\|\nabla^k v\big\|^2_{L^2(\Omega;\mathbb{R}^{3^{k+1}})} + \tilde C\big\|\nabla\gamma\big\|^2_{L^2(\Omega;\mathbb{R}^3)} + \tilde C\big\|\nabla\vartheta\big\|^2_{L^2(\Omega;\mathbb{R}^3)},
\end{aligned}
$$

where (3.9e) and the embedding $W^{k,2}(\Omega) \subset W^{2,\infty}(\Omega)$ have been used as well as the growth condition (3.9d) to estimate

$$
\begin{aligned}
\big\|\tau_D'({\rm D}v,\gamma,\vartheta)\big\|^2_{L^2(\Omega;\mathbb{R}^{3\times3\times3})} &\le \int_\Omega C^2\big(1+|\nabla v|^{p-2}\big)^2\,{\rm d}x \\
&\le 2C^2\Big({\rm meas}(\Omega) + \int_\Omega |\nabla v|^{2p-4}\,{\rm d}x\Big) \le \tilde C\Big(1+\int_\Omega |\nabla v|^{2p}\,{\rm d}x\Big)
\end{aligned}
$$

with C from (3.9d). In view of (3.22b), this term can then be handled by Gronwall's inequality because, due to (3.29), $t \mapsto \|\nabla v(t,\cdot)\|^{2p}_{L^{2p}(\Omega;\mathbb{R}^{3\times3})}$ is integrable; note that (3.29) implies that the $L^1(0,T)$-norm of this function is of the order $\mathcal{O}(1/\epsilon)$, which gives the factors ${\rm e}^{C_0/\epsilon}$ in (3.22c), (3.22i). The second term in the right-hand side of (3.31) can be estimated as

$$
\big\|(v\cdot\nabla)v\big\|^2_{L^2(\Omega;\mathbb{R}^3)} \le \big\|v\big\|^2_{L^2(\Omega;\mathbb{R}^3)}\big\|\nabla v\big\|^2_{L^\infty(\Omega;\mathbb{R}^{3\times3})} \le C_2^2N^2\big\|\nabla^k v\big\|^2_{L^2(\Omega;\mathbb{R}^{3^{k+1}})},
$$

where C_2 is from (3.22b) and N is the norm of the embedding $W^{k,2}(\Omega) \subset W^{1,\infty}(\Omega)$, so that this term also can be handled by Gronwall's inequality. The term $q\nabla\phi$ is already estimated in (3.22a). The term $(v\cdot\nabla)\theta$ is to be estimated as

$$
\big\|(v\cdot\nabla)\theta\big\|^2_{L^2(\Omega)} \le \big\|v\big\|^2_{L^\infty(\Omega;\mathbb{R}^3)}\big\|\nabla\theta\big\|^2_{L^2(\Omega;\mathbb{R}^3)} \le N^2\big\|\nabla^k v\big\|^2_{L^2(\Omega;\mathbb{R}^{3^{k+1}})}\big\|\nabla\theta\big\|^2_{L^2(\Omega;\mathbb{R}^3)},
$$

where N is the norm of the embedding $W^{k,2}(\Omega) \subset L^\infty(\Omega)$, and again we can treat it by Gronwall's inequality if (3.25) is taken into account. The boundedness of $h_{\rm tot}$ in $L^2(Q)$ has already been mentioned. Therefore, (3.31) yields both (3.22c) and (3.22i); note that (3.25) gives $\|\nabla^k v\|^2_{L^2(\Omega;\mathbb{R}^{3^{k+1}})} = \mathcal{O}(1/\epsilon)$ and (3.30) gives $\|h_{\rm tot}\|^2_{L^2(\Omega)} = \mathcal{O}(1/\epsilon)$, which (together with the already mentioned factor $\mathrm{e}^{C_0/\epsilon}$) eventually determines the order both in (3.22c) and in (3.22i).

Having ∇v bounded in $L^p(Q;\mathbb{R}^{3\times3})$) (see (3.22b)), $\tau(\mathrm{D}v,\gamma,\vartheta){:}\mathrm{D}v$ is then certainly bounded in $L^1(Q)$ (independently of ϵ) while the other right-hand side terms of (3.18e) are bounded in this space, too, because of (3.22a), (3.22e), and (3.11). This allows us to use fine results about integrability of temperature gradient [6, 7, 8] modified for the initial-boundary-value problem

$$c_\mathrm{v}\frac{\partial\theta}{\partial t}-\mathrm{div}\big(\kappa\nabla\theta-c_\mathrm{v}v\,\theta\big)=h_\mathrm{tot}\ \text{on } Q,\qquad \kappa\frac{\partial\theta}{\partial\nu}=0\ \text{on } \Sigma,\qquad \theta(0,\cdot)=\theta_0\ \text{on } \Omega; \tag{3.33}$$

recall that $h_\mathrm{tot}\in L^1(Q)$ denotes the total right-hand side of (3.18e). First, let us test (3.33) by $\mathrm{sign}(\theta)$ or, more rigorously, by a regularization of it, say $\max(-1,\min(1,n\theta))$, and then make a limit passage with $n\to\infty$, which gives the first part of the estimate (3.22j), i.e., a bound for θ in $L^\infty(I;L^1(\Omega))$; for more details about this rather standard technique, see, e.g., [35, sect. 9.4 with sect. 3.2.3]. The second part of (3.22j) is more involved. Following [7, 8], we test (3.33) by $\psi_n(\theta)$ with $\psi_n:\mathbb{R}\to[-1,1]$ a bounded Lipschitz function defined, for $n\in\mathbb{N}$, by

$$\psi_n(\theta):=\begin{cases}0 & \text{if } |\theta|\le n,\\ \mathrm{sign}(\theta)(|\theta|-n) & \text{if } n\le|\theta|\le n+1,\\ \mathrm{sign}(\theta) & \text{if } |\theta|\ge n+1.\end{cases} \tag{3.34}$$

We use

$$\begin{aligned}\int_\Omega\theta\,v\cdot\nabla\psi_n(\theta)\,\mathrm{d}x&=\int_\Omega\theta\,\psi_n'(\theta)\,v\cdot\nabla\theta\,\mathrm{d}x\\&=\int_\Omega v\cdot\nabla\hat\phi_n(\theta)\,\mathrm{d}x=-\int_\Omega\mathrm{div}(v)\hat\phi_n(\theta)\,\mathrm{d}x=0,\end{aligned} \tag{3.35}$$

where $\hat\phi_n:\mathbb{R}\to\mathbb{R}$ denotes a primitive function of $\phi_n:\theta\mapsto\theta\,\psi_n'(\theta)$. Further, we denote by $\hat\psi_n$ the primitive function of ψ_n such that $\hat\psi_n(0)=0$; note that $0\le\hat\psi_n(\theta)\le|\theta|$. Testing (3.33) by $\psi_n(\theta)$ and denoting $B_n:=\{(t,x)\in Q:\ n\le|\theta(t,x)|\le n{+}1\}$ then gives

$$\begin{aligned}\kappa\int_{B_n}|\nabla\theta|^2\,\mathrm{d}x\,\mathrm{d}t&=\kappa\int_Q\psi_n'(\theta)|\nabla\theta|^2\,\mathrm{d}x\,\mathrm{d}t=\int_Q\kappa\nabla\theta{\cdot}\nabla\psi_n(\theta)\,\mathrm{d}x\,\mathrm{d}t\\&\le\int_Q\kappa\nabla\theta\cdot\nabla\psi_n(\theta)\,\mathrm{d}x\,\mathrm{d}t+\int_\Omega c_\mathrm{v}\hat\psi_n(\theta(T,\cdot))\,\mathrm{d}x\\&=\int_\Omega c_\mathrm{v}\hat\psi_n(\theta_{0\epsilon})\,\mathrm{d}x+\int_Q h_\mathrm{tot}\psi_n(\theta)\,\mathrm{d}x\,\mathrm{d}t\\&\le c_\mathrm{v}\big\|\theta_{0\epsilon}\big\|_{L^1(\Omega)}+\big\|h_\mathrm{tot}\big\|_{L^1(Q)}.\end{aligned} \tag{3.36}$$

For $\mu>0$ fixed, we get

$$\begin{aligned}\int_Q\frac{|\nabla\theta|^2}{(1+\theta)^{1+\mu}}\,\mathrm{d}x\,\mathrm{d}t&=\sum_{n=0}^\infty\int_{B_n}\frac{|\nabla\theta|^2}{(1+\theta)^{1+\mu}}\,\mathrm{d}x\,\mathrm{d}t\\&\le\sum_{n=0}^\infty\frac{1}{(1+n)^{1+\mu}}\int_{B_n}|\nabla\theta|^2\,\mathrm{d}x\,\mathrm{d}t\\&\le\frac{c_\mathrm{v}\big\|\theta_{0\epsilon}\big\|_{L^1(\Omega)}+\big\|h_\mathrm{tot}\big\|_{L^1(Q)}}{\kappa}\sum_{n=0}^\infty\frac{1}{(1+n)^{1+\mu}}\le C_\mu\end{aligned} \tag{3.37}$$

with some C_μ. Further, we simplify [7, 8] which estimate $\nabla\theta$ in an anisotropic space. For our purposes, an estimate of $\nabla\theta$ in an "isotropic" space $L^\zeta(Q;\mathbb{R}^3)$ will suffice. For this, let us take $1 \le \zeta < 2$. By Hölder's inequality,

$$
\begin{aligned}
(3.38)\qquad \int_Q |\nabla\theta|^\zeta \,\mathrm{d}x\,\mathrm{d}t &= \int_Q \frac{|\nabla\theta|^\zeta}{(1+\theta)^{(1+\mu)\zeta/2}}(1+\theta)^{(1+\mu)\zeta/2}\,\mathrm{d}x\,\mathrm{d}t \\
&\le \left(\int_Q \frac{|\nabla\theta|^2}{(1+\theta)^{1+\mu}}\,\mathrm{d}x\,\mathrm{d}t\right)^{\zeta/2}\left(\int_Q (1+\theta)^{(1+\mu)\zeta/(2-\zeta)}\,\mathrm{d}x\,\mathrm{d}t\right)^{(2-\zeta)/2} \\
&\le C_\mu^{\zeta/2}\left(\int_0^T \|1+\theta(t,\cdot)\|_{L^{(1+\mu)\zeta/(2-\zeta)}(\Omega)}^{(1+\mu)\zeta/(2-\zeta)}\,\mathrm{d}t\right)^{(2-\zeta)/2}.
\end{aligned}
$$

The proven first part of (3.22j), i.e., $\|\theta\|_{L^\infty(I;L^1(\Omega))} \le C_{10}$, allows us further to estimate, by using the Gagliardo–Nirenberg inequality,

$$
\begin{aligned}
(3.39)\qquad \|1+\theta(t,\cdot)\|_{L^{(1+\mu)\zeta/(2-\zeta)}(\Omega)} &\le C_{\mathrm{GN}}\|\nabla\theta(t,\cdot)\|_{L^\zeta(\Omega)}^\lambda \|1+\theta(t,\cdot)\|_{L^1(\Omega)}^{1-\lambda} \\
&\le C_{\mathrm{GN}}\big(|\Omega|+C_{10}\big)^{1-\lambda}\|\nabla\theta(t,\cdot)\|_{L^\zeta(\Omega)}^\lambda
\end{aligned}
$$

for some $C_{\mathrm{GN}} \in \mathbb{R}$, provided that

$$
(3.40)\qquad \frac{2-\zeta}{(1+\mu)\zeta} \ge \lambda\left(\frac{1}{\zeta}-\frac{1}{3}\right)+1-\lambda.
$$

We raise (3.39) to the power $(1+\mu)\zeta/(2-\zeta)$, exploit it for (3.38), and choose $\lambda := (2-\zeta)/(1+\mu)$, which yields

$$
\begin{aligned}
(3.41)\qquad &\left(\int_0^T \|1+\theta(t,\cdot)\|_{L^{(1+\mu)\zeta/(2-\zeta)}(\Omega)}^{(1+\mu)\zeta/(2-\zeta)}\,\mathrm{d}t\right)^{(2-\zeta)/2} \\
&\le \left(\int_0^T C_{\mathrm{GN}}^{\frac{(1+\mu)\zeta}{2-\zeta}}\big(|\Omega|+C_{10}\big)^{\frac{(1-\lambda)(1+\mu)\zeta}{2-\zeta}}\|\nabla\theta(t,\cdot)\|_{L^\zeta(\Omega)}^{\frac{\lambda(1+\mu)\zeta}{2-\zeta}}\,\mathrm{d}t\right)^{\frac{2-\zeta}{2}} \\
&\le \left(\int_0^T C_{\mathrm{GN}}^{\frac{(1+\mu)\zeta}{2-\zeta}}\big(|\Omega|+C_{10}\big)^{\frac{(1-\lambda)(1+\mu)\zeta}{2-\zeta}}\|\nabla\theta(t,\cdot)\|_{L^\zeta(\Omega)}^{\zeta}\,\mathrm{d}t\right)^{\frac{2-\zeta}{2}} \\
&= C_{\mathrm{GN}}^{(1+\mu)\zeta/2}\big(|\Omega|+C_{10}\big)^{\zeta(\zeta-1+\mu)/2}\left(\int_Q |\nabla\theta|^\zeta\,\mathrm{d}x\,\mathrm{d}t\right)^{(2-\zeta)/2}.
\end{aligned}
$$

Merging (3.38) with (3.41) gives the estimate

$$
(3.42)\qquad \|\nabla u\|_{L^\zeta(Q;\mathbb{R}^3)}^\zeta \le C_\mu C_{\mathrm{GN}}^{1+\mu}\big(|\Omega|+C_{10}\big)^{\zeta-1+\mu}.
$$

Putting our choice of $\lambda := (2-\zeta)/(1+\mu)$ into (3.40), one obtains, after some algebra, the conditions $\zeta \le (5-3\mu)/4$ so that (3.42) gives just the second part of the estimate (3.22j) with $\xi := \frac{3}{4}\mu$.

To prove (3.22k), we must, in particular, estimate the term $\mathrm{div}(v\theta)$ in the following way:

$$\begin{aligned}(3.43)\qquad \big\|\mathrm{div}(v\theta)\big\|_{L^1(I;W^{-3,2}(\Omega))} &= \sup_{\|w\|_{L^\infty(I;W_0^{3,2}(\Omega))}\le 1} \int_Q v\theta\cdot\nabla w \,\mathrm{d}x\,\mathrm{d}t \\ &\le \sup_{\|w\|_{L^\infty(I;W_0^{3,2}(\Omega))}\le 1} C\big\|v\big\|_{L^{5p/3}(Q;\mathbb{R}^3)}\big\|\theta\big\|_{L^{5/3-\delta}(Q)}\big\|\nabla w\|_{L^\infty(Q;\mathbb{R}^3)} \\ &= C\big\|v\big\|_{L^{5p/3}(Q;\mathbb{R}^3)}\big\|\theta\big\|_{L^{5/3-\delta}(Q)}\end{aligned}$$

with a sufficiently small $\delta > 0$ and with a suitable constant C, where we used the embedding $W^{3,2}(\Omega) \subset W^{1,\infty}(\Omega)$ and, by the Gagliardo–Nirenberg inequality, also the embedding

$$(3.44)\qquad L^p(I;W^{1,p}(\Omega)) \cap L^\infty(I;L^2(\Omega)) \subset L^{5p/3}(Q)$$

(cf. [11, sect. I.3]), and finally also the embedding

$$(3.45)\qquad L^\infty(I;L^1(\Omega)) \,\cap\, L^{5/4-\xi}(I;W^{1,5/4-\xi}(\Omega)) \subset L^{5/3-\delta}(Q),$$

again by the Gagliardo–Nirenberg inequality. Alternatively, we could use here Sobolev embeddings and usual interpolation of Lebesgue spaces; note that (3.43) works even for $p > 3/2$.

Eventually, we prove (3.18f). Let us abbreviate $\sigma := \sum_{\ell=1}^L c_\ell = 1$. By summing (3.18e) for $\ell = 1,\dots,L$ and by (3.6a) and (3.7c,d), one gets

$$\begin{aligned}(3.46)\qquad \frac{\partial\sigma}{\partial t} &= \sum_{\ell=1}^L r_\ell\big(\gamma,\vartheta\big) + \mathrm{div}\left(\sum_{\ell=1}^L\sum_{k=1}^L \mathfrak{D}_{k\ell}(\gamma,\vartheta)\nabla c_k + \mathfrak{m}_\ell(\gamma,\vartheta)\nabla\phi - vc_\ell\right) \\ &= 0 + \mathrm{div}\left(\beta\sum_{k=1}^L\nabla c_k + \left(\sum_{\ell=1}^L \mathfrak{m}_\ell(\gamma,\vartheta)\right)\nabla\phi - v\left(\sum_{\ell=1}^L c_\ell\right)\right) \\ &= \mathrm{div}(\beta\nabla\sigma) - v\cdot\nabla\sigma.\end{aligned}$$

Due to (3.6b) and (2.8b), a solution to the thus obtained initial-boundary-value problem for a parabolic (if $\beta > 0$) or hyperbolic (if $\beta = 0$) equation, i.e.,

$$(3.47)\qquad \frac{\partial\sigma}{\partial t} - \mathrm{div}(\beta\nabla\sigma) + v\cdot\nabla\sigma = 0 \text{ on } Q, \qquad \frac{\partial\sigma}{\partial\nu} = 0 \text{ on } \Sigma, \qquad \sigma(0,\cdot) = 1 \text{ on } \Omega,$$

is $\sigma \equiv 1$. This solution is unique, which can be proved by testing the difference of (3.47) for two solutions σ_1 and σ_2 by $\sigma_1 - \sigma_2$. The important fact is that the resulting term $\int_\Omega (v\cdot\nabla(\sigma_1-\sigma_2))(\sigma_1-\sigma_2)\,\mathrm{d}x$ vanishes as in (3.27); note that our estimates (3.25) and (3.22e) ensure integrability of all integrands occurring in (3.27) with $\sigma_1-\sigma_2$ in place of c_ℓ. ∎

Remark 3.7. The parabolic/hyperbolic equation (3.47) can be found in the literature in this context; cf. [17, sect. 7.3.5].

PROPOSITION 3.8 (continuity). *Let the assumptions of Proposition* 3.6 *hold. Then the weak solution to* (3.18)–(3.19) *with the boundary conditions* (2.8) *and* (3.14) *is determined uniquely, and the mapping*

$$(3.48)\qquad (\gamma,\vartheta) \mapsto \big\{(v,c,\theta,\phi) \textit{ is a weak solution to } (3.18),(3.19),(2.8),(3.14)\big\}$$

with $\sum_{\ell=1}^{L}\gamma_\ell=1$ *is continuous from the weak topology on* $\mathcal{W}^L\times\mathcal{W}$ *with*

$$\mathcal{W}:=L^2(I;W^{1,2}(\Omega))\cap W^{1,2}(I;W^{1,2}(\Omega)^*) \tag{3.49}$$

to the weak topology related to the spaces from the estimates* (3.22a), (3.22c), (3.22f), (3.22i).

Proof. The uniqueness of the solution to (3.18a) follows in a standard way because of linearity and because $\varepsilon>0$ and $\alpha>0$ are assumed. As for (3.18b), (3.18c), the uniqueness is due to the monotonicity (3.9b) of $\tau(\cdot,\gamma,\vartheta)$ and because the term $\mathrm{div}(v\otimes v)$ can be estimated on the right-hand side: indeed, considering two solutions v_1 and v_2, by the difference of the weak formulations of (3.18b), (3.18c) for v_1 and v_2 tested by v_1-v_2 and using Green's formula several times, we obtain

$$\begin{aligned}\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\big\|v_1-v_2\big\|^2_{L^2(\Omega;\mathbb{R}^3)}&+\epsilon\big\|\nabla^k v_1-\nabla^k v_2\big\|^2_{L^2(\Omega;\mathbb{R}^{3^{k+1}})}\\ &\le\int_\Omega\big(v_1\otimes v_1-v_2\otimes v_2\big):\nabla(v_1-v_2)\,\mathrm{d}x\\ &=\int_\Omega\big((v_1\cdot\nabla)v_1-(v_2\cdot\nabla)v_2\big)\cdot(v_1-v_2)\,\mathrm{d}x\\ &=\int_\Omega\big(((v_1-v_2)\cdot\nabla)v_1\big)\cdot(v_1-v_2)\,\mathrm{d}x\le\big\|\nabla v_1\big\|_{L^\infty(\Omega;\mathbb{R}^{3\times3})}\big\|v_1-v_2\big\|^2_{L^2(\Omega;\mathbb{R}^3)}\end{aligned} \tag{3.50}$$

from which $v_1=v_2$ follows by Gronwall's inequality when taking into account also the estimates $\|\nabla v_1\|_{L^\infty(\Omega;\mathbb{R}^{3\times3})}\le N\|\nabla^k v_1\|_{L^2(\Omega;\mathbb{R}^{3^{k+1}})}$ and (3.22c). The uniqueness of solutions to (3.18d), (3.18e) then follows in a standard way because these equations are decoupled and linear and all time derivatives are in duality with the corresponding solutions.

Take a sequence $\{(\gamma_n,\vartheta_n)\}_{n\in\mathbb{N}}$ converging weakly to some (γ,ϑ) in $\mathcal{W}^L\times\mathcal{W}$. Take the corresponding $(v_n,c_n,\theta_n,\phi_n)$ and choose a subsequence converging weakly* in the spaces specified in the estimates (3.22). By the Aubin–Lions compact-embedding theorem [4, 19] (see also, e.g., [35, Lemma 7.7]), the estimates (3.22e) and (3.22f) imply that

$$\gamma_n\to\gamma\ \text{ in }\ L^2(I;L^{6-\xi}(\Omega;\mathbb{R}^L)) \tag{3.51}$$

in the norm topology with any $\xi>0$. This allows us to pass to the limit $K(\gamma_n)\to K(\gamma)$ and also ensures $\nabla\phi_n\to\nabla\phi$ strongly in $L^r(Q;\mathbb{R}^3)$ for any $r<+\infty$ to be exploited for (3.18e). Using again the Aubin–Lions theorem, we obtain $\vartheta_n\to\vartheta$ strongly in $L^2(I;L^{6-\xi}(\Omega))$, which allows us to pass to the limit $h(\gamma_n,\vartheta_n)\to h(\gamma,\vartheta)$ and $r_\ell(\gamma_n,\vartheta_n)\to r_\ell(\gamma,\vartheta)$. Moreover, again by the Aubin–Lions theorem and by interpolation as in (3.29) in the proof of Proposition 3.6,

$$\nabla v_n\to\nabla v\ \text{ in }\ L^{2p}(Q;\mathbb{R}^3) \tag{3.52}$$

in the norm topology; hence

$$\tau(\mathrm{D}v_n,\gamma_n,\vartheta_n){:}\mathrm{D}v_n\to\tau(\mathrm{D}v,\gamma,\vartheta){:}\mathrm{D}v\ \text{ in }\ L^2(Q), \tag{3.53}$$

which is essential for the limit passage in (3.18e) to obtain a weak solution. For the convective term in (3.18e), let us realize that $v_n\to v$ weakly* in $L^\infty(Q;\mathbb{R}^3)$ and, due to (3.22i), $\theta_n\to\theta$ weakly in $W^{1,2}(Q)$ and hence strongly in $L^2(Q)$ just by Rellich's theorem, which easily implies $v_n\theta_n\to v\theta$ weakly in $L^2(Q;\mathbb{R}^3)\subset L^1(Q;\mathbb{R}^3)$.

The limit passage in (3.18) is then routine. The uniqueness already proved above eventually ensures the convergence of the whole sequence. ∎

PROPOSITION 3.9 (existence of a weak solution to (2.1c)–(2.1e) and (3.13)). *Let again the assumptions of Proposition* 3.6 *hold; then the mapping* $\mathcal{F}:(\gamma,\vartheta)\mapsto(c,\theta)$, *where* (c,θ) *is uniquely determined by* (3.18)*, maps the set*

$$\text{(3.54)}\qquad \mathcal{S}:=\bigg\{(c,\theta)\in\mathcal{W}^L\times\mathcal{W}:\ \big\|c\big\|_{\mathcal{W}^L}\le\max\Big(C_5,\frac{C_6}{\sqrt{\epsilon}}\Big),\\ \big\|\theta\big\|_{\mathcal{W}}\le\max\bigg(\frac{C_8}{\sqrt{\epsilon}},\frac{C_9\mathrm{e}^{C_0/\epsilon^2}}{\epsilon}\bigg),\ \ \sum_{\ell=1}^L c_\ell=1\bigg\},$$

where C_0,C_5,C_6,C_8,C_9 *are from* (3.22e), (3.22f), (3.22h), (3.22i) *with* C_0 *and* C_9 *depending on* C_5 *and* C_8*, into itself and has a fixed point* $(c,\theta)\in\mathcal{S}$*. Moreover, every such fixed point also satisfies* $c_\ell\ge 0$ *for each* $\ell=1,\dots,L$*, and, considering the corresponding* ϕ *and* v*, the quadruple* (v,c,θ,ϕ) *is a weak solution to* (2.1c)–(2.1e) *and* (3.13) *with* (2.8), (3.14) and (3.19).

Proof. The fact that $\mathcal{F}:\mathcal{S}\to\mathcal{S}$ follows from Proposition 3.6 because C_5, C_6, and C_8 from (3.22e), (3.22f), (3.22h) do not depend on (γ,ϑ) at all, while C_0 and C_9 from (3.22i) are fixed when C_5 and C_8 are fixed; hence $\mathcal{F}$ indeed maps $\mathcal{S}$ into itself. We use $\mathcal{S}$ equipped with the weak topology $\mathcal{W}^{L+1}$. The continuity of $\mathcal{F}$ in this topology was proved in Proposition 3.8. The fixed point then exists by Schauder's theorem (in Tikhonov's modification).

Although we cannot prove $c_\ell\ge0$ if $c\ne\gamma$, in the fixed point we have $c=\gamma$ and we can prove $c_\ell\ge0$ for each $\ell=1,\dots,L$ by testing (3.18d) by the negative part c^- with $c_\ell^-:=\min(c_\ell,0)$. It is important that c is a conventional weak solution so that $\frac{\partial}{\partial t}c_\ell$ is in duality with c_ℓ and also with $c_\ell^-\in L^2(I;W^{1,2}(\Omega))$. For any $\ell=1,\dots,L$, by (3.10a), we use

$$\text{(3.55)}\qquad \sum_{k=1}^3\mathfrak{D}_{k\ell}(c,\theta)\nabla c_k\cdot\nabla c_\ell^-=\begin{cases}\mathfrak{D}_{\ell\ell}(c,\theta)\nabla c_\ell\cdot\nabla c_\ell^-\ge0 & \text{if } c_\ell(t,x)<0,\\ 0\quad\text{ as just }\ \nabla c_\ell^-=0 & \text{if } c_\ell(t,x)\ge0,\end{cases}$$

which holds for a.a. $(t,x)\in Q$; recall that $\mathfrak{D}$ is considered as extended continuously (cf. Remark 3.2), so that (3.10a) holds for c_ℓ negative, too. For the convective term, we use

$$\text{(3.56)}\quad \int_\Omega c_\ell v\cdot\nabla c_\ell^-\,\mathrm{d}x=\int_\Omega c_\ell^- v\cdot\nabla c_\ell^-\,\mathrm{d}x=\int_\Omega v\cdot\nabla\frac{(c_\ell^-)^2}{2}\,\mathrm{d}x=\int_\Omega(-\mathrm{div}\,v)\frac{(c_\ell^-)^2}{2}\,\mathrm{d}x=0.$$

Recall also (3.10c) which allows us to consider $r_\ell(\cdot,\theta)$ extended continuously and nonnegatively for $c_\ell\le0$ (cf. Remark 3.2), so that $r_\ell(\cdot,\theta)c_\ell^-\le0$. By (3.10b), similar extension can be assumed for $\mathfrak{m}_\ell(\cdot,\theta)$ so that $\mathfrak{m}_\ell(\cdot,\theta)\nabla\phi\cdot\nabla c_\ell^-=0$ a.e. on Q.

Hence the suggested test of the Nernst–Planck equation (3.18d) in the weak formulation by $c^-(t,\cdot)$ yields

$$\text{(3.57)}\qquad \frac12\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega|c_\ell^-|^2\,\mathrm{d}x\le\frac12\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega|c_\ell^-|^2\,\mathrm{d}x+\int_\Omega\sum_{k=1}^L\mathfrak{D}_{k\ell}(c,\theta)\nabla c_k\cdot\nabla c_\ell^-\,\mathrm{d}x\\ +\int_\Omega\mathfrak{m}_\ell(c,\theta)\nabla\phi\cdot\nabla c_\ell^-\,\mathrm{d}x-\int_\Omega c_\ell v\cdot\nabla c_\ell^-\,\mathrm{d}x=\int_\Omega r_\ell(c,\theta)c_\ell^-\,\mathrm{d}x\le0$$

for a.a. $t \in (0,T)$, so that $c_\ell^- = 0$ a.e. on Q provided $c_\ell|_{t=0} \geq 0$ for any $\ell = 1,\ldots,L$, as indeed assumed in (3.6a). Therefore $c = K(c)$ and the retract K occurring in (3.18b) can eventually be "forgotten" in the fixed point. ∎

3.3. Limit passage for $\epsilon \to 0$. In this section we will make a limit passage for $\epsilon \to 0$ in the weak solution to (2.1c)–(2.1e) and (3.13), denoted in this section by $(v_\epsilon, c_\epsilon, \theta_\epsilon, \phi_\epsilon)$, whose existence was proved in Proposition 3.9. This means that $(v_\epsilon, c_\epsilon, \theta_\epsilon, \phi_\epsilon)$ together with some π_ϵ solves (in the weak sense) the system

$$\frac{\partial v_\epsilon}{\partial t} - \operatorname{div}\big(\tau(\mathrm{D}v_\epsilon, c_\epsilon, \theta_\epsilon) - v_\epsilon \otimes v_\epsilon\big) + \nabla\pi_\epsilon + (-1)^k \epsilon \Delta^k v_\epsilon = -c_\epsilon{\cdot}z\nabla\phi_\epsilon, \tag{3.58a}$$

$$\operatorname{div}(v_\epsilon) = 0, \tag{3.58b}$$

$$\frac{\partial c_\epsilon}{\partial t} - \operatorname{div}\big(\mathfrak{D}(c_\epsilon,\theta_\epsilon)\nabla c_\epsilon + \mathfrak{m}(c_\epsilon,\theta_\epsilon) \otimes \nabla\phi_\epsilon - c_\epsilon \otimes v_\epsilon\big) = r(c_\epsilon,\theta_\epsilon)\,, \tag{3.58c}$$

$$\begin{aligned} c_{\rm v}\frac{\partial \theta_\epsilon}{\partial t} - \operatorname{div}\big(\kappa\nabla\theta_\epsilon - c_{\rm v} v_\epsilon\,\theta_\epsilon\big) &= \tau(\mathrm{D}v_\epsilon, c_\epsilon, \theta_\epsilon){:}\mathrm{D}v_\epsilon \\ &\quad + \big(\mathfrak{D}(c_\epsilon,\theta_\epsilon)\nabla c_\epsilon + \mathfrak{m}(c_\epsilon,\theta_\epsilon) \otimes \nabla\phi_\epsilon\big){:}(z \otimes \nabla\phi_\epsilon) + h(c_\epsilon,\theta_\epsilon), \end{aligned} \tag{3.58d}$$

$$-\operatorname{div}(\varepsilon\nabla\phi_\epsilon) = c_\epsilon{\cdot}z\,, \tag{3.58e}$$

$$c_\epsilon \cdot \mathbf{1} := \sum_{\ell=1}^{L} [c_\epsilon]_\ell = 1 \quad \text{ and } \quad [c_\epsilon]_\ell \geq 0 \quad \text{for } \ell = 1,\ldots,L, \tag{3.58f}$$

together with the initial conditions,

$$v_\epsilon(0,\cdot) = v_{0\epsilon}\,, \qquad c_\epsilon(0,\cdot) = c_0\,, \qquad \theta_\epsilon(0,\cdot) = \theta_{0\epsilon}, \tag{3.59}$$

and the boundary conditions on Σ,

$$\frac{\partial^l v_\epsilon}{\partial \nu^l} = 0, \qquad l = 0,\ldots,k{-}1, \tag{3.60a}$$

$$\big(\mathfrak{D}(c_\epsilon,\theta_\epsilon)\nabla c_\epsilon + \mathfrak{m}(c_\epsilon,\theta_\epsilon) \otimes \nabla\phi_\epsilon\big)\nu = 0, \tag{3.60b}$$

$$\varepsilon\frac{\partial \phi_\epsilon}{\partial \nu} = \alpha(\phi_\Sigma{-}\phi_\epsilon), \tag{3.60c}$$

$$\kappa\frac{\partial \theta_\epsilon}{\partial \nu} = 0. \tag{3.60d}$$

Proposition 3.10 (existence of a very weak solution to (2.1)–(2.3)). *Let the assumptions of Proposition* 3.6 *be satisfied, let $v_0 \in L^2_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3)$, $c_0 \in L^\infty(\Omega;\mathbb{R}^L)$, $\theta_0 \in L^1(\Omega)$, and let $v_{0\epsilon} \to v_0$ in $L^2(\Omega;\mathbb{R}^3)$ and $\theta_{0\epsilon} \to \theta_0$ in $L^1(\Omega)$. Then any sequence $\{(v_\epsilon, c_\epsilon, \theta_\epsilon, \phi_\epsilon)\}_{\epsilon>0}$ of weak solutions obtained in Proposition* 3.9 *contains a subsequence converging weakly* in spaces involved in* (3.22a), (3.22b), (3.22d), (3.22e), (3.22g), (3.22j), (3.22k)*; let us denote by (v,c,θ,ϕ) its limit, and every (v,c,θ,ϕ) obtained in this way is a very weak solution due to Definition* 3.1.

Proof. We choose a subsequence that converges weakly* as claimed. Without confusion, let us denote it briefly again by $\{(v_\epsilon, c_\epsilon, \theta_\epsilon, \phi_\epsilon)\}_{\epsilon>0}$.

First, by the Aubin–Lions theorem [4, 19] and by (3.22e), (3.22g) together with the L^∞-information from Proposition 3.9, $c_\epsilon \to c$ in $L^r(Q;\mathbb{R}^L)$ for any $r < +\infty$, and from (3.58e) together with the already used $W^{2,2}$-regularity of Δ-operator, $\phi_\epsilon \to \phi$ strongly in $L^s(I;W^{2,2}(\Omega))$.

Let us prove that the weak* limit v is the very weak solution to (2.1a), (2.1b) that we seek. We use Minty's trick for the term $\operatorname{div}\tau(\mathrm{D}v,c,\theta)$ and compactness for the convective term. The important fact is that we have chosen the subsequence so that, by (3.22d), for some $\dot v \in L^{p/(p-1)}(I; W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3)^*)$, we have at our disposal

$$\frac{\partial v_\epsilon}{\partial t} + (-1)^k \epsilon \Delta^k v_\epsilon \to \dot v \quad \text{weakly in } \ L^{p/(p-1)}(I; W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3)^*). \tag{3.61}$$

For any w smooth with a compact support in Q, it holds that

$$\begin{aligned} \langle \dot v, w\rangle &= \lim_{\epsilon\to 0}\left\langle \frac{\partial v_\epsilon}{\partial t} + (-1)^k\epsilon\Delta^k v_\epsilon, w\right\rangle = \lim_{\epsilon\to 0}\int_Q \frac{\partial v_\epsilon}{\partial t} w + \epsilon\nabla^k v_\epsilon \,\vdots\, \nabla^k w \,\mathrm{d}x\,\mathrm{d}t \\ &= \lim_{\epsilon\to 0}\int_Q -v_\epsilon\frac{\partial w}{\partial t} + \epsilon\nabla^k v_\epsilon \,\vdots\, \nabla^k w \,\mathrm{d}x\,\mathrm{d}t = \int_Q -v\frac{\partial w}{\partial t}\,\mathrm{d}x\,\mathrm{d}t \end{aligned} \tag{3.62}$$

because $v_\epsilon \to v$ weakly in $L^p(I; W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3))$ thanks to (3.22b) and also because $\|\epsilon\nabla^k v_\epsilon\|_{L^2(Q;\mathbb{R}^{3^{k+1}})} = \epsilon\mathcal{O}(1/\sqrt{\epsilon}) = \mathcal{O}(\sqrt{\epsilon}) \to 0$ due to (3.25) so that

$$\lim_{\epsilon\to 0}\int_Q \epsilon\nabla^k v_\epsilon \,\vdots\, \nabla^k w \,\mathrm{d}x\,\mathrm{d}t = 0. \tag{3.63}$$

This shows that $\dot v$ is the distributional derivative of v; let us denote it naturally as $\frac{\partial v}{\partial t}$. In particular, we have shown that

$$\frac{\partial v}{\partial t} = \dot v \in L^{p/(p-1)}(I; W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3)^*). \tag{3.64}$$

Furthermore, for $w \in L^2(I; W^{k,2}_0(\Omega;\mathbb{R}^3)) \cap L^p(I; W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3))$, by monotonicity of $\tau(\cdot, c_\epsilon(t,x), \theta_\epsilon(t,x))$, it holds that

$$\begin{aligned} 0 &\le \int_Q (\tau(\mathrm{D}v_\epsilon, c_\epsilon, \theta_\epsilon) - \tau(\mathrm{D}w, c_\epsilon, \theta_\epsilon)) : \mathrm{D}(v_\epsilon - w)\,\mathrm{d}x\,\mathrm{d}t \\ &= \int_Q z\cdot c_\epsilon\nabla\phi_\epsilon\cdot(v_\epsilon - w) - \frac{\partial v_\epsilon}{\partial t}\cdot(v_\epsilon - w) + (v_\epsilon\otimes v_\epsilon) : \nabla(v_\epsilon - w) \\ &\qquad - \epsilon\nabla^k v_\epsilon \,\vdots\, \nabla^k(v_\epsilon - w) - \tau(\mathrm{D}w, c_\epsilon, \theta_\epsilon) : \mathrm{D}(v_\epsilon - w)\,\mathrm{d}x\,\mathrm{d}t \\ &\le \int_Q z\cdot c_\epsilon\nabla\phi_\epsilon\cdot(v_\epsilon - w) - \frac{\partial v_\epsilon}{\partial t}\cdot(v_\epsilon - w) + (v_\epsilon\otimes v_\epsilon) : \nabla(v_\epsilon - w) \\ &\qquad + \epsilon\nabla^k v_\epsilon \,\vdots\, \nabla^k w - \tau(\mathrm{D}w, c_\epsilon, \theta_\epsilon) : \mathrm{D}(v_\epsilon - w)\,\mathrm{d}x\,\mathrm{d}t. \end{aligned} \tag{3.65}$$

Then we can bound from above the limit superior. The important fact is that $\frac{\partial v}{\partial t} \in L^{p/(p-1)}(I; W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3)^*)$ is in duality to v due to (3.64) and the estimate (3.22b). First, let us realize that (3.61) implies

$$\begin{aligned} v_\epsilon(T) = v_{0\epsilon} + \int_0^T \frac{\partial v_\epsilon}{\partial t}\,\mathrm{d}t = v_{0\epsilon} + \int_0^T \left(\frac{\partial v_\epsilon}{\partial t} + (-1)^k\epsilon\Delta^k v_\epsilon\right)\mathrm{d}t \\ -(-1)^k\int_0^T \epsilon\Delta^k v_\epsilon\,\mathrm{d}t \to v_0 + \int_0^T \frac{\partial v}{\partial t}\,\mathrm{d}t = v(T) \end{aligned} \tag{3.66}$$

weakly in $W^{k,2}(\Omega;\mathbb{R}^3)^*$. Due to the estimate (3.22b), $v_\epsilon(T)$ also converges weakly in $L^2(\Omega;\mathbb{R}^3)$; hence we can conclude that even

$$v_\epsilon(T) \to v(T) \quad \text{weakly in } \ L^2(\Omega;\mathbb{R}^3). \tag{3.67}$$

Thus we can use the usual bound

$$\liminf_{\epsilon\to 0}\int_Q \frac{\partial v_\epsilon}{\partial t}v_\epsilon \,\mathrm{d}x\,\mathrm{d}t = \liminf_{\epsilon\to 0}\frac{1}{2}\big\|v_\epsilon(T)\big\|^2_{L^2(\Omega;\mathbb{R}^3)} - \frac{1}{2}\big\|v_0\big\|^2_{L^2(\Omega;\mathbb{R}^3)} \\ \geq \frac{1}{2}\big\|v(T)\big\|^2_{L^2(\Omega;\mathbb{R}^3)} - \frac{1}{2}\big\|v_0\big\|^2_{L^2(\Omega;\mathbb{R}^3)} = \int_0^T \Big\langle \frac{\partial v}{\partial t}, v\Big\rangle \,\mathrm{d}t. \tag{3.68}$$

We also exploit (3.63) and the strong convergence $\tau(\mathrm{D}w, c_\epsilon, \theta_\epsilon) \to \tau(\mathrm{D}w, c, \theta)$ in $L^p(Q;\mathbb{R}^{3\times 3})$. Thus, from (3.65), we eventually get

$$0 \geq \int_0^T \bigg(\Big\langle \frac{\partial v}{\partial t}, v-w\Big\rangle - \int_\Omega z\cdot c\nabla\phi\cdot(v-w) \\ -(v\otimes v):\nabla(v-w) + \tau(\mathrm{D}w,c,\theta):\mathrm{D}(v-w)\,\mathrm{d}x\bigg)\,\mathrm{d}t. \tag{3.69}$$

Now we can extend this inequality for all $w \in L^p(I;W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3))$ by continuity. Then, substituting $w = v + \delta\tilde{w}$, canceling $\delta > 0$, passing $\delta \to 0$, and choosing $\tilde{w}$ arbitrary, we prove that v satisfies

$$\int_0^T \bigg(\Big\langle \frac{\partial v}{\partial t}, \tilde{w}\Big\rangle + \int_\Omega (v\otimes v):\nabla\tilde{w} + \tau(\mathrm{D}v,c,\theta):\mathrm{D}\tilde{w} - z\cdot c\nabla\phi\cdot\tilde{w}\,\mathrm{d}x\bigg)\,\mathrm{d}t = 0 \tag{3.70}$$

for any $\tilde{w} \in L^p(I;W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3))$. Hence v is a weak solution to (2.1a).

Let us prove the most essential and most difficult fact, namely, the strong convergence of $\mathrm{D}v_\epsilon$ to $\mathrm{D}v$ in $L^p(Q;\mathbb{R}^{3\times 3})$. We will use $\int_0^T \langle \frac{\partial(v_\epsilon - v)}{\partial t}, v_\epsilon - v\rangle \,\mathrm{d}t \geq -\frac{1}{2}\|v_{0\epsilon} - v_0\|^2_{L^2(\Omega;\mathbb{R}^3)}$; here again it is important that $\frac{\partial v}{\partial t}$ belongs to $L^{p/(p-1)}(I;W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3)^*)$ and is thus in duality to v due to (3.64) and the estimate (3.22b), and also that $\frac{\partial v_\epsilon}{\partial t}$ lives in $L^2(Q;\mathbb{R}^3)$ due to (3.22c) so it is certainly in duality with $v_\epsilon - v$. By uniform monotonicity (3.9b) of $\tau(\cdot, c_\epsilon(t,x), \theta_\epsilon(t,x))$, we get

$$\eta_2\big\|\mathrm{D}v_\epsilon - \mathrm{D}v\big\|^p_{L^p(Q;\mathbb{R}^{3\times 3}))} \leq \int_0^T\int_\Omega \big(\tau(\mathrm{D}v_\epsilon, c_\epsilon, \theta_\epsilon) - \tau(\mathrm{D}v, c_\epsilon, \theta_\epsilon)\big):\mathrm{D}(v_\epsilon - v)\,\mathrm{d}x\,\mathrm{d}t \\ \leq \int_0^T \bigg(\Big\langle \frac{\partial(v_\epsilon - v)}{\partial t}, v_\epsilon - v\Big\rangle \\ + \int_\Omega \big(\tau(\mathrm{D}v_\epsilon, c_\epsilon, \theta_\epsilon) - \tau(\mathrm{D}v, c_\epsilon, \theta_\epsilon)\big):\mathrm{D}(v_\epsilon - v)\,\mathrm{d}x\bigg)\,\mathrm{d}t + \frac{1}{2}\big\|v_{0\epsilon} - v_0\big\|^2_{L^2(\Omega;\mathbb{R}^3)} \\ = \int_0^T \bigg(\Big\langle \frac{\partial(v_\epsilon - v)}{\partial t}, v_\epsilon - v\Big\rangle + \int_\Omega \big(\tau(\mathrm{D}v_\epsilon, c_\epsilon, \theta_\epsilon) - \tau(\mathrm{D}v, c, \theta)\big):\mathrm{D}(v_\epsilon - v)\,\mathrm{d}x \\ + \int_\Omega \big(\tau(\mathrm{D}v, c, \theta) - \tau(\mathrm{D}v, c_\epsilon, \theta_\epsilon)\big):\mathrm{D}(v_\epsilon - v)\,\mathrm{d}x\bigg)\,\mathrm{d}t + \frac{1}{2}\big\|v_{0\epsilon} - v_0\big\|^2_{L^2(\Omega;\mathbb{R}^3)} \\ =: I_\epsilon^{(1)} + I_\epsilon^{(2)} + I_\epsilon^{(3)} + I_\epsilon^{(4)}. \tag{3.71}$$

Using (3.70) with $\tilde{w} := v_\epsilon - v$, the integrals $I_\epsilon^{(1)}$ and $I_\epsilon^{(2)}$ can be estimated in its sum as follows:

$$I_\epsilon^{(1)} + I_\epsilon^{(2)} = \int_0^T\int_\Omega \bigg(\frac{\partial v_\epsilon}{\partial t}\cdot v_\epsilon + \tau(\mathrm{D}v_\epsilon, c_\epsilon, \theta_\epsilon):\mathrm{D}v_\epsilon\bigg)\,\mathrm{d}x\,\mathrm{d}t \\ - \int_0^T\int_\Omega \bigg(\frac{\partial v_\epsilon}{\partial t}\cdot v + \tau(\mathrm{D}v_\epsilon, c_\epsilon, \theta_\epsilon):\mathrm{D}v\bigg)\,\mathrm{d}x\,\mathrm{d}t \tag{3.72}$$

$$
\begin{aligned}
&-\int_0^T\Big(\Big\langle\frac{\partial v}{\partial t},v_\epsilon\Big\rangle+\int_\Omega\tau(\mathrm{D}v,c,\theta):\mathrm{D}v_\epsilon\;\mathrm{d}x\Big)\,\mathrm{d}t\\
&+\int_0^T\Big(\Big\langle\frac{\partial v}{\partial t},v\Big\rangle+\int_\Omega\tau(\mathrm{D}v,c,\theta):\mathrm{D}v\;\mathrm{d}x\Big)\,\mathrm{d}t\\
=&\int_Q\Big(-\epsilon|\nabla^k v_\epsilon|^2-z\cdot c_\epsilon\nabla\phi_\epsilon\cdot v_\epsilon+(v_\epsilon\otimes v_\epsilon):\mathrm{D}v_\epsilon\\
&+\epsilon\nabla^k v_\epsilon\,\vdots\,\nabla^k\tilde v+z\cdot c_\epsilon\nabla\phi_\epsilon\cdot\tilde v-(v_\epsilon\otimes v_\epsilon):\mathrm{D}\tilde v\\
&+z\cdot c\nabla\phi\cdot v_\epsilon-(v\otimes v):\mathrm{D}v_\epsilon\\
&-z\cdot c\nabla\phi\cdot v+(v\otimes v):\mathrm{D}v\\
&-\frac{\partial v_\epsilon}{\partial t}\cdot(v-\tilde v)-\tau(\mathrm{D}v_\epsilon,c_\epsilon,\theta_\epsilon):\mathrm{D}(v-\tilde v)\Big)\,\mathrm{d}x\,\mathrm{d}t\\
\le&\int_Q\Big(-z\cdot c_\epsilon\nabla\phi_\epsilon\cdot(v_\epsilon-\tilde v)+(v_\epsilon\otimes v_\epsilon):\mathrm{D}(v_\epsilon-\tilde v)\\
&+\epsilon\nabla^k v_\epsilon\,\vdots\,\nabla^k\tilde v+z\cdot c\nabla\phi\cdot(v_\epsilon-v)-(v\otimes v):\mathrm{D}(v_\epsilon-v)\\
&-\frac{\partial v_\epsilon}{\partial t}\cdot(v-\tilde v)-\tau(\mathrm{D}v_\epsilon,c_\epsilon,\theta_\epsilon):\mathrm{D}(v-\tilde v)\Big)\,\mathrm{d}x\,\mathrm{d}t
\end{aligned}
$$

for any $\tilde v\in L^2(I;W_0^{k,2}(\Omega;\mathbb{R}^3))$. Now we can pass to the limit with $\epsilon\to 0$. The important trick is based on (3.61) with (3.64) and on integration-by-parts in time and on (3.67), which allows for

$$
\begin{aligned}
(3.73)\quad &\lim_{\epsilon\to 0}\int_Q\Big(\frac{\partial v_\epsilon}{\partial t}\cdot(v-\tilde v)+\epsilon\nabla^k v_\epsilon\,\vdots\,\nabla^k\tilde v\Big)\,\mathrm{d}x\,\mathrm{d}t\\
&=\lim_{\epsilon\to 0}\int_0^T\Big(\Big\langle(-1)^{k+1}\epsilon\Delta^k v_\epsilon-\frac{\partial v_\epsilon}{\partial t},\tilde v\Big\rangle-\Big\langle\frac{\partial v}{\partial t},v_\epsilon\Big\rangle\Big)\,\mathrm{d}t\\
&\quad+\int_\Omega\big(v_\epsilon(T)\cdot v(T)-v_{0\epsilon}\cdot v_0\big)\,\mathrm{d}x\\
&=-\int_0^T\Big(\Big\langle\frac{\partial v}{\partial t},\tilde v\Big\rangle+\Big\langle\frac{\partial v}{\partial t},v\Big\rangle\Big)\,\mathrm{d}t+\big\|v(T)\big\|^2_{L^2(\Omega;\mathbb{R}^3)}-\big\|v_0\big\|^2_{L^2(\Omega;\mathbb{R}^3)}\\
&=\int_0^T\Big\langle\frac{\partial v}{\partial t},v-\tilde v\Big\rangle\,\mathrm{d}t.
\end{aligned}
$$

The limit passage in the convective term $(v_\epsilon\otimes v_\epsilon):\mathrm{D}(v_\epsilon-\tilde v)\to(v\otimes v):\mathrm{D}(v-\tilde v)$ in $L^1(Q)$ is standard, using the strong convergence $v_\epsilon\to v$ in $L^{5p/3-\xi}(Q;\mathbb{R}^3)$ which can be proved by interpolating $L^\infty(I;L^2(\Omega))$ and $L^p(I;W^{1-\delta,p}(\Omega))$ by the Gagliardo–Nirenberg inequality (cf. [11, sect. I.3], and by using the Aubin–Lions theorem to have strong convergence in $L^p(I;W^{1-\delta,p}(\Omega))$ for any $\delta>0$; here the restriction $p>11/5$ is originated. As for the next-to-last term in (3.71), we have $\lim_{\epsilon\to 0}I_\epsilon^{(3)}=0$ because $\tau(\mathrm{D}v,c_\epsilon,\theta_\epsilon)\to\tau(\mathrm{D}v,c,\theta)$ strongly in $L^p(Q;\mathbb{R}^{3\times 3})$. By our assumption $v_{0\epsilon}\to v_0$ in $L^2(\Omega;\mathbb{R}^3)$, we also have $\lim_{\epsilon\to 0}I_\epsilon^{(4)}=0$. Now we can pass to the limit superior in

(3.71) with $\epsilon \to 0$ to obtain

$$
\begin{aligned}
(3.74)\qquad &\limsup_{\epsilon\to 0} \eta_2 \big\|\mathrm{D}v_\epsilon - \mathrm{D}v\big\|^p_{L^p(Q;\mathbb{R}^{3\times 3})} \\
&\le \int_0^T \bigg(\Big\langle \frac{\partial v}{\partial t}, v - \tilde v \Big\rangle + \int_\Omega (v\otimes v) : \mathrm{D}(v{-}\tilde v) - z{\cdot}c\nabla\phi{\cdot}(v{-}\tilde v)\,\mathrm{d}x \bigg)\,\mathrm{d}t \\
&\quad + C \limsup_{\epsilon\to 0} \Big(1 + \big\|v_\epsilon\big\|^{p-1}_{L^p(I;W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3))}\Big) \big\|v - \tilde v\big\|_{L^p(I;W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3))}
\end{aligned}
$$

with C being the constant from (3.9c). Using the estimates (3.22b) and (3.22d) and passing with $\tilde v$ to v in the norm topology of $L^p(I;W^{1,p}_{0,\mathrm{DIV}}(\Omega;\mathbb{R}^3))$, we can see that $\limsup_{\epsilon\to 0}\|\mathrm{D}v_\epsilon - \mathrm{D}v\|_{L^p(Q;\mathbb{R}^{3\times 3})} \le 0$; i.e., $\mathrm{D}v_\epsilon \to \mathrm{D}v$ strongly.

Having this strong convergence, we can pass to the limit in the term $\tau(\mathrm{D}v_\epsilon, c_\epsilon, \theta_\epsilon) : \mathrm{D}v_\epsilon \to \tau(\mathrm{D}v, c, \theta) : \mathrm{D}v$ in $L^1(Q)$ in the right-hand side of the heat equation (3.58d). For the limit passage in the convective term in (3.58d) it suffices to prove, in the weak formulation, that $v_\epsilon\theta_\epsilon \to v\theta$ weakly in $L^1(Q)$, which is simple due to the weak convergence $v_\epsilon \to v$ in $L^{5p/3}(Q;\mathbb{R}^3)$ based on (3.22b) with (3.44) and, by the Aubin–Lions theorem with the interpolation based on (3.22j) and (3.22k), the strong convergence $\theta_\epsilon \to \theta$ in $L^{5/3-\delta}(Q)$; thus we get $v_\epsilon\theta_\epsilon \to v\theta$ weakly even in $L^{55/48-\delta}(Q;\mathbb{R}^3)$ (see also (3.43)).

Limit passage in the other terms is routine; e.g., $\mathfrak{D}(c_\epsilon,\theta_\epsilon)\nabla c_\epsilon \cdot \nabla\phi_\epsilon \to \mathfrak{D}(c,\theta)\nabla c \cdot \nabla\phi$ because $(c_\epsilon,\theta_\epsilon) \to (c,\theta)$ strongly in $L^2(Q;\mathbb{R}^L) \times L^{5/3-\delta}(Q)$, $\nabla c_\epsilon \to \nabla c$ weakly in $L^2(Q;\mathbb{R}^{L\times 3})$ and $\nabla\phi_\epsilon \to \nabla\phi$ strongly in $L^\infty(I;L^r(\Omega;\mathbb{R}^3))$ for any $r < +\infty$, and, similarly, $(\mathfrak{m}(c_\epsilon,\theta_\epsilon)\otimes\nabla\phi_\epsilon){:}(z\otimes\nabla\phi_\epsilon) \to (\mathfrak{m}(c,\theta)\otimes\nabla\phi){:}(z\otimes\nabla\phi)$ in $L^1(Q)$. The limit passage in the term $c_\mathrm{v}\frac{\partial\theta_\epsilon}{\partial t}$ is made easy after integration-by-parts based on the estimates (3.22j) and (3.22k); i.e., $\int_Q c_\mathrm{v}\theta_\epsilon\frac{\partial w}{\partial t}\,\mathrm{d}x\,\mathrm{d}t + \int_\Omega c_\mathrm{v}\theta_{0\epsilon}w(0,\cdot)\,\mathrm{d}x$ indeed converges to $\int_Q c_\mathrm{v}\theta\frac{\partial w}{\partial t}\,\mathrm{d}x\,\mathrm{d}t + \int_\Omega c_\mathrm{v}\theta_0 w(0,\cdot)\,\mathrm{d}x$ for any test function $w \in C^1(Q)$ as used in (3.5).

Eventually, the constraints $\sum_{\ell=1}^L c_{\epsilon,\ell} = 1$ and $c_{\epsilon,\ell} \ge 0$ for $\ell = 1,\ldots,L$, which have been proved valid for the approximate solution (see (3.58f)), are inherited by the limit, too. □

Remark 3.11 (weak solutions). For $p \ge 3$, the estimate (3.22g) involves $r = 2$, and then c is the conventional weak solution to the Nernst–Planck equation (2.1c). The weak solution to the whole system (2.1) needs regularity of v. This was proved in [33] for a very narrow interval of p's (of length only about 0.0528), namely $\frac{9}{4} \le p < \frac{1+\sqrt{13}}{2}$, by using deep regularity results from [20] holding, however, only for a stress tensor τ independent of compositon and temperature and having a potential. Let us recall that regularity for the Navier–Stokes equation is generally recognized as an extremely difficult problem which is, at this writing, open and, in particular for $p = 2$ and τ linear, assigned to a $1 million Clay Mathematics Institute award.

4. Discussion of the model and particular cases. The general idea for determining the phenomenological fluxes j_ℓ is a drift/diffusion model like that in Roosbroeck's model of semiconductors [32]; for comparison of semiconductors and electrolytes; see, e.g., [37, p. 20]. In the simplest linear case, the phenomenological fluxes in Roosbroeck's model appear as

$$(4.1)\qquad j_\ell := m z_\ell c_\ell \nabla\phi + d\nabla c_\ell = m c_\ell \nabla\mu_\ell, \qquad \text{where} \quad \mu_\ell := \rho \ln c_\ell + z_\ell\phi,$$

where $m > 0$ is a mobility and $d > 0$ a diffusivity coefficient, and where μ_ℓ is the *electrochemical potential* of the ℓth constituent involving the ratio $\rho = d/m$; any influence of the temperature and its gradient on j_ℓ (in particular Soret's cross-effect) is neglected. In bipolar semiconductors, we have $L = 2$ and $z_1 = -z_2$, but here for multicomponent electrolytes we admit $L > 2$ in general. The form (4.1), however, does not satisfy (3.7d) except in the very trivial case $z_\ell m = 0$. More generally, mobilities in concrete mixtures may vary considerably for various components, especially if the size of molecules of particular constituents varies considerably from constituent to constituent [14], and then it is standardly considered that

$$j_\ell := \sum_{k=1}^{L} \mathbb{M}_{k\ell}(c)\nabla\mu_k, \tag{4.2}$$

where $\mu_\ell := \rho \ln c_\ell + z_\ell\phi$ is again from (4.1) now with $\rho = R\theta_{\rm R}$ with $\theta_{\rm R}$ a reference temperature and R a universal gas constant; let us mention that we consider z_ℓ to involve Faraday's constant.

To satisfy the zero-sum condition for the fluxes, i.e., (3.7c), (3.7d) with $\beta = 0$, the matrix $[\mathbb{M}_{k\ell}(c)]$ should satisfy

$$\forall k = 1, \ldots, L,\ \forall c \in G_1^+ : \qquad \sum_{\ell=1}^{L} \mathbb{M}_{k\ell}(c) = 0 \tag{4.3}$$

because then obviously

$$\sum_{\ell=1}^{L} j_\ell = \sum_{\ell=1}^{L}\sum_{k=1}^{L} \mathbb{M}_{k\ell}(c)\nabla\mu_k = \sum_{k=1}^{L}\ \underbrace{\sum_{\ell=1}^{L} \mathbb{M}_{k\ell}(c)}_{=0}\ \nabla\mu_k = 0. \tag{4.4}$$

Moreover, by the celebrated (Nobel prize winning) Onsager's principle [26, 27], the matrix $[\mathbb{M}_{k\ell}(c)]$ should be symmetric.

Example 4.1 (symmetric models). The zero-sum condition (4.3) for $[\mathbb{M}_{k\ell}(c)]$ has actually been adopted, e.g., in [10, 17, 28] or, in a bit different context of multicomponent alloys, in [15, 16, 23], where essentially the following matrix has been considered:

$$\mathbb{M}_{k\ell}(c) := m_\ell c_\ell \left(\delta_{k\ell} - \frac{m_k c_k}{\sum_{l=1}^{L} m_l c_l} \right) \tag{4.5}$$

with m_ℓ being "actual" mobilities of particular constituents (assumed to be) known from experiments. Such $[\mathbb{M}_{k\ell}]$ is symmetric and satisfies (4.3) because obviously $\sum_{\ell=1}^{L} \mathbb{M}_{k\ell}(c) = m_k c_k - (\sum_{\ell=1}^{L} m_\ell c_\ell) m_k c_k / (\sum_{l=1}^{L} m_l c_l) = 0$. Moreover, (4.5) also makes j_ℓ proportional to c_ℓ, which is a natural property.

Substituting (4.5) into (4.2) gives

$$j_\ell = m_\ell\big(\rho\nabla c_\ell + c_\ell z_\ell \nabla\phi\big) - \frac{m_\ell c_\ell}{\sum_{l=1}^{L} m_l c_l} \left(\sum_{k=1}^{L} m_k \big(\rho\nabla c_k + c_k z_k \nabla\phi\big) \right). \tag{4.6}$$

Comparing it with (3.8), we can see that our diffusion matrix $\mathfrak{D} = [\mathfrak{D}_{k\ell}]_{\ell,k=1}^{L}$ is now

$$\mathfrak{D}_{k\ell} = \mathfrak{D}_{k\ell}(c) = \rho m_\ell \left(\delta_{k\ell} - \frac{m_k c_\ell}{\sum_{l=1}^{L} m_l c_l} \right) \tag{4.7}$$

and our condition (3.10a) is indeed satisfied and also that (3.7c) is satisfied with $\beta = 0$ because $\sum_{\ell=1}^L \mathfrak{D}_{k\ell} = \rho m_k - \rho m_k(\sum_{\ell=1}^L c_\ell m_\ell)/(\sum_{l=1}^L c_l m_l)$=0. Therefore we can see that the coercivity and the monotonicity assumptions (3.7b) would be satisfied if and only if the matrix $[\mathfrak{D}_{k\ell}]$ given by (4.7) is positive definite uniformly with respect to $c \in G_1^+$. In fact, the positive definiteness of $[\mathfrak{D}_{k\ell}]$ in (3.7b) suffices to verify for the symmetric part of $[\mathfrak{D}_{k\ell}]$ only, and it suffices to hold on the manifold $\sum \nabla c_\ell = 0$ and in particular for $[\mathfrak{D}_{k\ell}] + \frac{\beta}{L}(\mathbf{1}\otimes\mathbf{1})$ with some $\beta \geq 0$ so that (3.7c) then holds with this β; see also [17, Chap. 7]. As for the effective mobilities $\mathfrak{m}_\ell$, comparing (4.6) with (3.8) yields

$$\mathfrak{m}_\ell = \mathfrak{m}_\ell(c) = m_\ell z_\ell c_\ell - m_\ell c_\ell \frac{\sum_{k=1}^L m_k c_k z_k}{\sum_{l=1}^L m_l c_l}, \tag{4.8}$$

and we can see that our conditions (3.7d) and (3.10b) are indeed satisfied.

Remark 4.2. The form (4.6) was suggested in [36, Remark 4.4], namely, if $m_\ell \rho \delta_{k\ell}$ and $m_\ell \delta_{k\ell}$ are taken, respectively, for quantities $d_{k\ell}$ and $m_{k\ell}$ in [36].

Remark 4.3 (special case: equal mobilities). As in (4.1), the very special situation with equal mobilities $m := m_1 = \cdots = m_L$, the formula (4.6) gives

$$j_\ell = m z_\ell c_\ell \nabla\phi + m\rho\nabla c_\ell - m c_\ell \left(\rho \sum_{k=1}^L \nabla c_k + \sum_{k=1}^L z_k c_k \nabla\phi\right); \tag{4.9}$$

again (3.7) with $\beta = 0$ holds. In fact, one can even omit $\sum_{k=1}^L \nabla c_k$ in (4.9) because it expectedly vanishes if $\sum_{k=1}^L c_k = 1$; then (3.7c) will be satisfied with $\beta = 1$ and such a j_ℓ is exactly what has been considered in [33, 34, 35, 36]; i.e.,

$$j_\ell = m c_\ell (z_\ell - q)\nabla\phi + m\rho\nabla c_\ell, \qquad \text{where again } q = \sum_{\ell=1} c_\ell z_\ell. \tag{4.10}$$

Example 4.4 (nonsymmetric models). Some other models neglect cross-effects and treat one selected constitutent, say L, in a nonsymmetric way by the formula

$$j_\ell = m_\ell c_\ell \nabla(\mu_\ell - \mu_L) \text{ for } \ell = 1, \ldots, L{-}1 \text{ and } j_L = -\sum_{\ell=1}^{L-1} j_\ell; \tag{4.11}$$

see, e.g., [18, formula (2.26)]. In this case, the symmetric matrix $[\mathbb{M}_{k\ell}(c)]$ satisfying (4.3) is given by

$$\mathbb{M}_{k\ell}(c) := \begin{cases} m_\ell c_\ell \delta_{k\ell} & \text{for } k < L,\ \ell < L, \\ -m_\ell c_\ell & \text{for } k = L,\ \ell < L, \\ -m_k c_k & \text{for } k < L,\ \ell = L, \\ \sum_{l=1}^{L-1} m_l c_l & \text{for } k = L,\ \ell = L. \end{cases} \tag{4.12}$$

Substituting μ_ℓ from (4.1) into (4.11) yields

$$j_\ell = \begin{cases} m_\ell\big(\rho\nabla c_\ell - \rho\frac{c_\ell}{c_L}\nabla c_L + (z_\ell - z_L)c_\ell\nabla\phi\big) & \text{for } \ell < L, \\ \sum_{k=1}^{L-1} m_k\big(\rho\frac{c_k}{c_L}\nabla c_L - \rho\nabla c_k + (z_L - z_k)c_\ell\nabla\phi\big) & \text{for } \ell = L. \end{cases} \tag{4.13}$$

This is sometimes used in electrochemistry either for hydrogen ions as the L-component or, in the case of very diluted water solutions, for water as the L-component.

Remark 4.5 (thermodynamics of the model). It is with a certain internal consistency and beauty that the thermodynamics of the model based on μ_ℓ from (4.1) can be derived from a single thermodynamical potential, namely, the specific *free energy* in the form

$$\psi = \psi(c, \theta, \phi, E) = \rho \sum_{\ell=1}^{L} c_\ell \big(\ln c_\ell - 1\big) - c_\mathrm{v}\,\theta \ln \frac{\theta}{\theta_\mathrm{R}} + \sum_{\ell=1}^{L} c_\ell z_\ell \phi - \frac{\varepsilon}{2} E^2, \tag{4.14}$$

where E plays the role of the *intensity of electric field*. The partial derivatives of ψ define, respectively, the *electrochemical potential* μ_ℓ, the *entropy* s, the *total electric charge* q, and the *electric induction* D, namely,

$$\mu_i = \frac{\partial \psi}{\partial c_i}, \qquad s = -\frac{\partial \psi}{\partial \theta}, \qquad q = \frac{\partial \psi}{\partial \phi}, \qquad D = -\frac{\partial \psi}{\partial E}. \tag{4.15}$$

This indeed yields expected relations, namely,

$$\mu_i = \rho \ln c_i + z_i \phi, \tag{4.16a}$$

$$s = c_\mathrm{v} \left(\ln \frac{\theta}{\theta_\mathrm{R}} + 1 \right), \tag{4.16b}$$

$$q = \sum_{\ell=1}^{L} c_\ell z_\ell, \tag{4.16c}$$

$$D = \varepsilon E. \tag{4.16d}$$

Furthermore, the *internal energy* u is then defined through Gibbs' relation as

$$u = \psi + \theta s = c_\mathrm{v} \theta + \rho \sum_{\ell=1}^{L} c_\ell \big(\ln c_\ell - 1\big) + \sum_{\ell=1}^{L} c_\ell z_\ell \phi - \frac{\varepsilon}{2} E^2. \tag{4.17}$$

It is interesting that $\frac{\varepsilon}{2}E^2$ has a negative sign in (4.17); let us remark that this term $-\frac{\varepsilon}{2}E^2$ can indeed be found in the literature (e.g., in [12, p. 342]).

The energetics of the model (2.1) considered, for simplicity, with $\alpha = 0$ in (2.8), has been derived in [36], resulting in

$$\frac{\mathrm{d}}{\mathrm{d}t} \int_\Omega \Big(\underbrace{\frac{\varrho}{2}|v|^2}_{\substack{\text{kinetic}\\ \text{energy}}} + \underbrace{\frac{\varepsilon}{2}|\nabla\phi|^2}_{\substack{\text{electrostatic}\\ \text{energy}}} + \underbrace{c_\mathrm{v}\theta}_{\substack{\text{heat part}\\ \text{of internal}\\ \text{energy } u}} \Big) \,\mathrm{d}x = \int_\Omega \underbrace{h(c,\theta)}_{\substack{\text{heat production by}\\ \text{chemical reactions}}} \,\mathrm{d}x. \tag{4.18}$$

Under the constitutive relation $E = -\nabla\phi$, we have

$$\begin{aligned} \int_\Omega q\phi - \frac{\varepsilon}{2}E^2 \,\mathrm{d}x &= -\int_\Omega (\varepsilon\Delta\phi)\phi + \frac{\varepsilon}{2}|\nabla\phi|^2 \,\mathrm{d}x \\ &= \int_\Omega \varepsilon\nabla\phi\cdot\nabla\phi - \frac{\varepsilon}{2}|\nabla\phi|^2 \,\mathrm{d}x = \int_\Omega \frac{\varepsilon}{2}|\nabla\phi|^2 \,\mathrm{d}x \end{aligned} \tag{4.19}$$

and we can rewrite the above energy balance (4.18) in terms of u and μ_ℓ as

$$\frac{\mathrm{d}}{\mathrm{d}t} \int_\Omega \left(\frac{\varrho}{2}|v|^2 + u - \sum_{\ell=1}^{L} c_\ell \mu_\ell + q\phi \right) \mathrm{d}x = \int_\Omega h(c,\theta) \,\mathrm{d}x. \tag{4.20}$$

Alternatively, (4.20) can equally be written in terms of u and c_ℓ as

$$\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega\Big(\frac{\varrho}{2}|v|^2+u-\rho\sum_{\ell=1}^L c_\ell \ln c_\ell\Big)\,\mathrm{d}x=\int_\Omega h(c,\theta)\,\mathrm{d}x. \tag{4.21}$$

In addition, ϕ solving (2.1e) is just the critical point of the overall free energy $\Psi:\phi\mapsto\int_\Omega\psi(c,\theta,\phi,-\nabla\phi)\,\mathrm{d}x$; interestingly, as $\Psi(c,\theta,\cdot,\cdot)$ given by (4.14) is concave, this critical point is the global maximum.

The *Clausius–Duhem inequality* (under our zero-flux boundary conditions (2.8), i.e., in the isolated system) reads as

$$\begin{aligned}0&\le\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega s\,\mathrm{d}x=\int_\Omega\frac{c_{\rm v}}{\theta}\frac{\partial\theta}{\partial t}\,\mathrm{d}x\\&=\int_\Omega\frac{1}{\theta}\Big(\mathrm{div}(\kappa\nabla\theta-c_{\rm v}v\theta)+\tau(\mathrm{D}v,c,\theta):\mathrm{D}v+\sum_{\ell=1}^L f_\ell\cdot j_\ell+h\Big)\,\mathrm{d}x\\&=\int_\Omega\Big(\mathrm{div}\Big(\frac{\kappa\nabla\theta}{\theta}\Big)-c_{\rm v}v\nabla\ln\theta+\kappa\frac{|\nabla\theta|^2}{\theta^2}+\frac{\tau(\mathrm{D}v,c,\theta){:}\mathrm{D}v}{\theta}+\sum_{\ell=1}^L\frac{f_\ell{\cdot}j_\ell}{\theta}+\frac{h}{\theta}\Big)\,\mathrm{d}x,\end{aligned}$$

where $f_\ell=-z_\ell c_\ell\nabla\phi$ is the Lorenz force acting on the ℓ-constituent. The first and second terms in the last integral vanish in a thermally isolated system, and the third and fourth terms are always nonnegative (if $\theta>0$), while the nonnegativity of $\int_\Omega(\sum_{\ell=1}^L f_\ell{\cdot}j_\ell+h)/\theta\,\mathrm{d}x$ is a condition on j_ℓ and h.

Remark 4.6 (thermodynamics in the special case of equal mobilities). As already observed in [33, 36], the special case (4.10) gives the heat sources $\sum_{\ell=1}^L f_\ell\cdot j_\ell$ in the form

$$\sum_{\ell=1}^L f_\ell\cdot j_\ell=m\rho\nabla q{\cdot}\nabla\phi+\sum_{\ell=1}^L mc_\ell z_\ell^2|\nabla\phi|^2-mq^2|\nabla\phi|^2. \tag{4.22}$$

The meaning of these terms is the following: The first term $m\rho\nabla q{\cdot}\nabla\phi$ is the power (per unit volume) of the electric current arising by the diffusion flux, which can create local cooling effects; this is related to the *Peltier effect* mentioned already in Remark 2.1. This cooling effect may seemingly violate the entropy production law, but, at least in equilibrium situations (i.e., here spatially isothermal cases when $\theta(t,\cdot)$ is constant), the overall entropy production due to this term on Ω is nonnegative: indeed, by using Green's formula, one gets

$$\int_\Omega\nabla q{\cdot}\nabla\phi\,\mathrm{d}x=-\int_\Omega\varepsilon\nabla(\Delta\phi){\cdot}\nabla\phi\mathrm{d}x=\int_\Omega\varepsilon|\Delta\phi|^2\mathrm{d}x\ge0. \tag{4.23}$$

In the anisothermal case, we would get the nonnegative entropy production if the coefficient m in (4.10) were proportional to the absolute temperature θ, as it is really considered, e.g., in the kinetic theory of gases and known as Einstein's law. Such dependence would, however, make derivation of the a priori estimates (3.22e) difficult because $\inf\theta>0$ would have to be proved. The second term $\sum_{\ell=1}^L mc_\ell z_\ell^2|\nabla\phi|^2$ in (4.22) is the power of hypothetical *Joule's heat* produced by the electric currents j_ℓ in ideally diluted water solutions. The third term $-mq^2|\nabla\phi|^2=-mf_{\rm R}^2$ reduces it and represents the rate of cooling by the force which balances the volume-additivity constraint. Furthermore, the total actual Joule's heat is always nonnegative because the second term in (4.22) always dominates the third one thanks to the algebraic inequality

$$\sum_{\ell=1}^{L} c_\ell z_\ell^2 \geq \left(\sum_{\ell=1}^{L} c_\ell z_\ell\right)^2 \tag{4.24}$$

if (2.2) holds; cf. [36, Remark 2.2].

Acknowledgments. The author is deeply indebted to Petr Kaplický, Josef Málek, František Maršík, Milan Pokorný, and Ivan Samohýl for inspiring and very helpful discussions. Also many thanks go to the anonymous referees for suggesting many improvements and detecting various discrepancies in the original version of this article.

KINETIC FORMULATION FOR A PARABOLIC CONSERVATION LAW. APPLICATION TO HOMOGENIZATION*

ANNE-LAURE DALIBARD†

Abstract. We derive a kinetic formulation for the parabolic scalar conservation law $\partial_t u + \mathrm{div}_y A(y,u) - \Delta_y u = 0$. This allows us to define a weaker notion of solutions in L^1, which is enough to recover the L^1 contraction principle. We also apply this kinetic formulation to a homogenization problem studied in a previous paper; namely, we prove that the kinetic solution u^ε of $\partial_t u^\varepsilon + \mathrm{div}_x A(x/\varepsilon, u^\varepsilon) - \varepsilon \Delta_x u^\varepsilon = 0$ behaves in L^1_{loc} as $v(x/\varepsilon, \bar{u}(t,x))$, where v is the solution of a cell problem and $\bar{u}$ the solution of the homogenized problem.

Key words. scalar conservation law, kinetic formulation, homogenization

1. Introduction.

This paper is devoted to the study of the solution $u \in \mathcal{C}([0,\infty), L^1(Y)) \cap L^2_{\mathrm{loc}}([0,\infty), H^1_{\mathrm{per}}(Y)) \cap L^\infty_{\mathrm{loc}}([0,\infty) \times Y)$ of the equation

$$\begin{cases} \partial_t u(t,y) + \mathrm{div}_y A(y, u(t,y)) - \Delta_y u(t,y) = 0, & t > 0,\ y \in Y, \\ u(t=0,y) = u_0(y), \end{cases} \tag{1.1}$$

where $Y = [0,1]^N$ is the N-dimensional torus; $A = A(y,v) \in \mathbb{R}^N$, $y \in Y$, $v \in \mathbb{R}$, is a given N-dimensional flux, periodic in the space variable y.

In [5], a kinetic formulation was derived for such heterogeneous conservation laws (in fact, that work was achieved for hyperbolic laws, but it can be generalized to parabolic laws with no difficulty), based on the previous papers of Lions, Perthame, and Tadmor concerning hyperbolic homogeneous conservation laws (see [14], [13], [18], [16], and the general presentation in [17]). However, this formulation is not entirely satisfactory: indeed, it is based on the comparison between the solution $u(t,y)$ of the conservation law and the constants via the function $\mathbf{1}_{v<u(t,y)}$, where v is an additional fluctuation variable. But the constants, which happen to be stationary solutions of homogeneous conservation laws, no longer play a special role in the context of heterogeneous conservation laws. Hence, our goal in this article is to derive a kinetic formulation based on the study of the stationary solutions of (1.1). Let us mention a related work of Audusse and Perthame [2], which defines a notion of entropy solution which is not based on Kruzkhov's inequalities, but rather on the comparison with special stationary solutions, and which is sufficient to derive the L^1 contraction principle.

Let us make precise some notation which will be used later on: if $\mathcal{C}^\infty_{\mathrm{per}}(Y)$ denotes the space of Y-periodic functions in $\mathcal{C}^\infty(\mathbb{R}^N)$, then

$$W^{k,p}_{\mathrm{per}}(Y) := \overline{\mathcal{C}^\infty_{\mathrm{per}}(Y)}^{W^{k,p}(Y)},$$
$$W^{1,\infty}_{\mathrm{per,loc}}(Y \times \mathbb{R}) := \{u = u(y,v) \in W^{1,\infty}_{\mathrm{loc}}(\mathbb{R}^{N+1}), u \text{ is } Y\text{-periodic in } y\},$$

†CEREMADE-UMR 7534, Université Paris-Dauphine, Place du maréchal de Lattre de Tassigny, 75775 Paris Cedex 16, France (dalibard@ceremade.dauphine.fr).

$$\mathcal{D}_{\rm per}([0,\infty)\times Y\times\mathbb{R}) := \{u = u(t,y,v)\in \mathcal{C}^\infty([0,\infty)\times\mathbb{R}^{N+1}),$$
$$u \text{ is periodic in } y \text{ and } \exists R>0,\ u(t,y,v)=0 \text{ if } t+|v|\geq R\},$$
$$\langle v\rangle := \frac{1}{|Y|}\int_Y v(y)\,dy \quad \forall v\in L^1(Y).$$

First, let us recall a few results on the stationary solutions of (1.1), which were studied in [3].

Proposition 1.1. *Let $A = A(y,v)\in W^{1,\infty}_{per,loc}(Y\times\mathbb{R})^N$.*

Let $a_i(y,v) := \partial_v A_i(y,v)$, $1\leq i\leq N$, $b(y,v) := \mathrm{div}_y A(y,v) \in L^\infty_{loc}(\mathbb{R}^{N+1})$. Assume that there exist real numbers $C_0>0$, $m\in[0,\infty)$, $n\in[0,\frac{N+2}{N-2})$ when $N\geq 3$, such that for all $(y,p)\in Y\times\mathbb{R}$

$$|a_i(y,p)| \leq C_0\left(1+|p|^m\right) \quad \forall 1\leq i\leq N, \tag{1.2}$$
$$|b(y,p)| \leq C_0\left(1+|p|^n\right). \tag{1.3}$$

Assume as well that the couple (m,n) satisfies at least one of the following conditions:

$$m=0 \tag{1.4}$$

or

$$0\leq n<1 \tag{1.5}$$

or

$$n<\min\left(\frac{N+2}{N},2\right) \quad \text{and} \quad \exists p_0\in\mathbb{R}\ \forall y\in Y \quad b(y,p_0)=0. \tag{1.6}$$

Then for all $p\in\mathbb{R}$, there exists a unique solution $v(\cdot,p)\in H^1_{per}(Y)$ of the equation

$$-\Delta_y v(y,p) + \mathrm{div}_y A(y,v(y,p)) = 0, \quad \langle v(\cdot,p)\rangle = p. \tag{1.7}$$

For all $p\in\mathbb{R}$, $v(\cdot,p)$ belongs to $W^{2,q}_{per}(Y)$ for all $1<q<+\infty$ and satisfies the following a priori estimate: for all $R>0$, there exists a constant $C_R>0$ depending only on N, Y, C_0, m, n, q, p_0, and R, such that

$$||v(\cdot,p)||_{W^{2,q}(Y)} \leq C_R \quad \forall p\in\mathbb{R},\ |p|\leq R. \tag{1.8}$$

Moreover, for all $p\in\mathbb{R}$, $\partial_p v(\cdot,p)\in H^1_{per}(Y)$ and is a solution of

$$-\Delta_y\frac{\partial v}{\partial p} + \mathrm{div}_y\left[a(y,v(y,p))\frac{\partial v}{\partial p}\right] = 0, \quad \left\langle\frac{\partial v}{\partial p}\right\rangle = 1. \tag{1.9}$$

And for all $R>0$, there exists $\alpha>0$ depending only on N, Y, C_0, m, n, q, p_0, and R, such that for all $(y,p)\in Y\times(-R,R)$,

$$\frac{\partial v}{\partial p}(y,p)\geq\alpha>0.$$

Equation (1.7) is also called a "cell problem" on account of its significance in homogenization problems.

Following the idea of Audusse and Perthame (see [2]), we now give a notion of entropy solution for (1.1) based on the comparison with stationary solutions.

Definition 1.2. *Assume the hypotheses of Proposition* 1.1 *are satisfied.*

Let $u \in \mathcal{C}([0,\infty), L^1(Y)) \cap L^2_{loc}([0,\infty), H^1_{per}(Y)) \cap L^\infty_{loc}([0,\infty)\times Y)$ *be a solution of* (1.1). *We say that* u *is an entropy solution of* (1.1) *if* u *satisfies the inequality*

$$\partial_t (u(t,y)-v(y,p))_+ + \mathrm{div}_y \left[\mathbf{1}_{u>v(y,p)} (A(y,u)-A(y,v(y,p)))\right] - \Delta_y (u(t,y)-v(y,p))_+ \le 0 \tag{1.10}$$

for all $p \in \mathbb{R}$ *and in the sense of distributions on* $[0,\infty)\times Y$.

Notice that this notion of entropy solution is different (at least in its formulation) from the one of Kruzkhov, since the latter is based on the comparison with constants. However, inequality (1.10) was known by Kruzkhov, since it can be considered as a particular case of the comparison principle (notice that $v(y,p)$ is a stationary solution of (1.1)). It will be proved in the second section, under suitable regularity assumptions on the flux function A, that all solutions of (1.1) are entropy solutions in the sense of Definition 1.2.

Let us mention here an important application of inequality (1.10) and of the kinetic formulation which follows from (1.10): we give in this paper another proof for a homogenization result proved in [3], which we recall here for the reader's convenience.

Proposition 1.3. *Assume that* $A \in W^{1,\infty}_{per,loc}(\mathbb{R}^{N+1})^N$ *satisfies the assumptions of Proposition* 1.1, *and that* $\partial_{y_j} a_i \in L^1_{loc}(\mathbb{R}^{N+1})$, $\partial_v a_i \in L^1_{loc}(\mathbb{R}^{N+1})$ *for* $1 \le i \le N+1$, $1 \le j \le N$.

For $\varepsilon > 0$, *let* $v^\varepsilon \in L^\infty_{loc}([0,\infty)\times\mathbb{R}^N) \cap \mathcal{C}([0,\infty), L^1_{loc}(\mathbb{R}^N)) \cap L^2_{loc}([0,\infty), H^1_{loc}(\mathbb{R}^N))$ *be a solution of the parabolic scalar conservation law:*

$$\frac{\partial v^\varepsilon}{\partial t}(t,x) + \sum_{i=1}^N \frac{\partial}{\partial x_i} A_i\left(\frac{x}{\varepsilon}, v^\varepsilon(t,x)\right) - \varepsilon \Delta_x v^\varepsilon = 0, \quad t \ge 0,\ x \in \mathbb{R}^N, \tag{1.11}$$

$$v^\varepsilon(t=0) = v_0\left(x, \frac{x}{\varepsilon}\right). \tag{1.12}$$

Let $p \in \mathbb{R}$, *and let* $v = v(y,p)$ *be the unique solution in* $H^1_{per}(Y)$ *of the cell problem* (1.7). *Define*

$$\bar{A}_i(p) := \frac{1}{|Y|}\int_Y A_i(y, v(y,p))\, dy. \tag{1.13}$$

Assume also that v_0 *is "well-prepared," i.e., satisfies*

$$v_0(x,y) = v(y, \bar{v}_0(x)) \tag{1.14}$$

for some $\bar{v}_0 \in L^1 \cap L^\infty(\mathbb{R}^N)$.

Then as ε *goes to* 0,

$$v^\varepsilon(t,x) - v\left(\frac{x}{\varepsilon}, \bar{v}(t,x)\right) \to 0 \quad \text{in } L^2_{loc}([0,\infty)\times\mathbb{R}^N),$$

where $\bar{v} = \bar{v}(t,x) \in \mathcal{C}([0,\infty), L^1(\mathbb{R}^N)) \cap L^\infty([0,\infty)\times\mathbb{R}^N)$ *is the unique entropy solution of the hyperbolic scalar conservation law*

$$\begin{cases} \dfrac{\partial \bar{v}}{\partial t} + \displaystyle\sum_{i=1}^N \frac{\partial \bar{A}_i(\bar{v}(t,x))}{\partial x_i} = 0, \\ \bar{v}(t=0,x) = \bar{v}_0(x) \in L^1 \cap L^\infty(\mathbb{R}^N). \end{cases} \tag{1.15}$$

Actually, the result proved in section 3 is more general than Proposition 1.3 but is much more complicated to state at this stage. In particular, we work in an L^1 rather than L^∞ setting, which appears to us to be entirely new for this kind of equation; this point will be developed a little further in Remark 3.2. We emphasize that inequality (1.10) was already used in [3], but we believe that the proof given here provides better insight into the homogenization process.

Let us mention related results of W. E (see [6], [7]) and W. E and Serre (see [8]), who use two-scale Young measures instead of the kinetic formulation in a hyperbolic context. In fact, the proof of [3] is close to those of these articles, although the viscous term in (1.11) is absent from the problems studied by W. E in [6] and W. E and Serre in [8]. Indeed, the scaling in our problem is chosen so that the viscosity has the same order of magnitude than the size of the oscillations in the flux function, and thus the viscosity has an effect at a microscopic level only. Notice that the (macroscopic) homogenized problem (1.15) is hyperbolic; this justifies the use of hyperbolic tools, such as Young measures or a kinetic formulation, in the study of (1.11).

We also wish to point out that the expression of the homogenized flux in the case studied by W. E and Serre in [8] when $N = 1$ is the same as that in (1.13). However, the corrector v appearing in the expression is not the same in both cases: indeed, in the hyperbolic case studied by W. E and Serre, v is a solution of

$$\partial_y A(y, v(y,p)) = 0.$$

In particular, v is not unique in general, although the homogenized flux is. We refer the interested reader to [8] and [12] for details; the latter uses an equivalent formulation using Hamilton–Jacobi equations.

The organization of this article is as follows: first we derive a kinetic formulation for (1.1). As usual, this allows us to define a weaker notion of solutions of the parabolic conservation law (1.1), called *kinetic solutions*. We also derive formally the L^1 contraction principle for kinetic solutions of (1.1). Then we use this formulation to give another proof of Proposition 1.3 in section 3. Eventually, in section 4 we give a rigorous proof for the derivation of the L^1 contraction principle announced in section 2.

2. Kinetic formulation. This section is devoted to the derivation of a kinetic formulation for (1.1). Throughout the section, we assume that the hypotheses of Proposition 1.1 are satisfied, that is, $A \in W^{1,\infty}_{\text{per,loc}}(Y \times \mathbb{R})$, and A satisfies either (1.4), (1.5), or (1.6). Additionally, we assume that

$$a(y,\cdot) \in \mathcal{C}(\mathbb{R})^N \quad \text{for a.e. } y \in Y. \tag{2.1}$$

Under such hypotheses, the following result is easily deduced from Proposition 1.1.

LEMMA 2.1. *For a.e. $y \in Y$, $p \mapsto v(y,p)$ is a $\mathcal{C}^1$ diffeomorphism from $\mathbb{R}$ to $(\alpha_-(y), \alpha_+(y))$, where $\alpha_\pm(y) = \lim_{p\to\pm\infty} v(y,p)$.*

Its reciprocal application is denoted by $w(y,\cdot)$

$$w(y) : (\alpha_-(y), \alpha_+(y)) \to \mathbb{R}.$$

REMARK 2.1. *Notice that $+\infty$ (resp., $-\infty$) is an admissible value for α_+ (resp., α_-). In fact, it can be checked that*

$$\langle \alpha_\pm \rangle = \pm\infty,$$

and there are cases when

$$\alpha_\pm(y) = \pm\infty \quad \forall y \in Y.$$

Indeed, for all $y \in Y$, the family $(v(y,p) - v(y,0))_{p>0}$ is increasing in p and nonnegative. Moreover,

$$\langle v(\cdot,p) - v(\cdot,0)\rangle = p \quad \forall p \in \mathbb{R}.$$

Hence according to Lebesgue's monotone convergence theorem, $\langle \alpha_+ - v(\cdot,0)\rangle = +\infty$, and thus $\langle \alpha_+\rangle = +\infty$. If we assume additionally that $m = 0$ in hypothesis (1.2) *(i.e., we assume that* (1.4) *is satisfied), then it is proved in* [3, Lemma 6] *that*

$$\lim_{p\to+\infty} \inf_{y\in Y} v(y,p) = +\infty.$$

In that case, $\alpha_+(y) = +\infty$ for all $y \in Y$.

We begin our study of (1.1) with the following lemma.

LEMMA 2.2. *Let $u \in \mathcal{C}([0,\infty); L^1(Y)) \cap L^2_{loc}(0,\infty; H^1_{per}(Y)) \cap L^\infty_{loc}([0,\infty)\times Y)$ be an arbitrary solution of* (1.1). *Assume that the flux $A \in W^{1,\infty}_{per,loc}(Y\times\mathbb{R})$ satisfies* (2.1) *and the hypotheses of Proposition* 1.1.

Then the function u satisfies the following equality in the sense of distributions on $[0,\infty)\times Y\times\mathbb{R}_p$:

(2.2)
$$\partial_t (u - v(y,p))_+ + \mathrm{div}_y \left[\mathbf{1}_{u>v(y,p)}(A(y,u) - A(y,v(y,p)))\right] - \Delta_y (u - v(y,p))_+ = -m,$$

where

$$m(t,y,p) = \frac{1}{\frac{\partial v}{\partial p}(y,p)} \left|\nabla_y (u(t,y) - v(y,p))\right|^2 \delta(p = w(y,u(t,y)))$$

is a nonnegative measure on $(0,\infty)\times Y\times\mathbb{R}$.

Consequently, u is an entropy solution of (1.1) *in the sense of Definition* 1.2.

We postpone the proof of Lemma 2.2 to the end of section 2. Let us stress that (2.2) is to be understood in the sense of distributions in $[0,\infty)\times Y\times\mathbb{R}$. Such an equality would indeed be meaningless were it considered for $p \in \mathbb{R}$ fixed.

Let us now write down the kinetic formulation for (1.1). Let u be an entropy solution of (1.1); differentiating (2.2) with respect to p leads to

(2.3)
$$\frac{\partial}{\partial t}\left(\frac{\partial v(y,p)}{\partial p} f^+\right) + \frac{\partial}{\partial y_i}\left(\frac{\partial v(y,p)}{\partial p} a_i(y,v(y,p)) f^+\right) - \Delta_y \left(\frac{\partial v(y,p)}{\partial p} f^+\right) = \frac{\partial m(t,y,p)}{\partial p},$$

where $f^+(t,y,p) = \mathbf{1}_{u(t,y)>v(y,p)}$.

The same kind of equation holds for $f^- = \mathbf{1}_{u(t,y)<v(y,p)} = 1 - f^+$ (recall (1.9)):

(2.4)
$$\frac{\partial}{\partial t}\left(\frac{\partial v(y,p)}{\partial p} f^-\right) + \frac{\partial}{\partial y_i}\left(\frac{\partial v(y,p)}{\partial p} a_i(y,v(y,p)) f^-\right) - \Delta_y \left(\frac{\partial v(y,p)}{\partial p} f^-\right) = -\frac{\partial m(t,y,p)}{\partial p}.$$

This leads to a notion of kinetic solution.

DEFINITION 2.3. *Assume that the flux A satisfies the hypotheses of Proposition* 1.1 *and* (2.1). *Let $u = u(t,y) \in \mathcal{C}([0,\infty); L^1(Y)) \cap L^2_{loc}(0,\infty; H^1_{per}(Y))$ such that*

$$\alpha_-(y) < u(t,y) < \alpha_+(y) \quad \textit{for a.e. } (t,y) \in [0,\infty)\times Y.$$

We say that u is a kinetic solution of (1.1) *if $f^+ = \mathbf{1}_{u(t,y)>v(y,p)}$ satisfies* (2.3) *in the sense of distributions with the initial data $f^+(t=0,y,p) = \mathbf{1}_{u_0(y)>v(y,p)}$, and if there exists a function $\mu \in L^\infty(\mathbb{R})$ such that $\mu(p) \to 0$ as $|p| \to \infty$, and*

$$\int_0^\infty \int_Y m(t,y,p)\,dy\,dt \le \mu(p) \quad \textit{in } \mathcal{D}'(\mathbb{R}). \tag{2.5}$$

Precisely, u is a kinetic solution of (1.1) *if* (2.5) *holds and if for every test function* $\psi = \psi(t,y,p) \in \mathcal{D}_{per}([0,\infty) \times Y \times \mathbb{R})$, *we have*

$$\int_0^\infty \int_{Y\times\mathbb{R}} f^+(t,y,p) \frac{\partial v(y,p)}{\partial p} \{\partial_t \psi + a_i(y, v(y,p))\partial_{y_i}\psi + \Delta_y \psi\}\, dt\, dy\, dp \tag{2.6}$$
$$= \int_0^\infty \int_{Y\times\mathbb{R}} m(t,y,p)\partial_p \psi(t,y,p)\, dtdydp - \int_{Y\times\mathbb{R}} \mathbf{1}_{u_0(y)>v(y,p)} \frac{\partial v(y,p)}{\partial p} \psi(0,y,p) dydp.$$

Notice that without any loss of generality, we can choose a function μ in (2.5) which is nonincreasing on $(0,\infty)$ and nondecreasing on $(-\infty, 0)$.

It is easily checked that the notions of entropy and kinetic solutions are equivalent as long as u is bounded in some kind of L^∞ norm.

Proposition 2.4. *Assume that A satisfies* (2.1) *and the hypotheses of Proposition* 1.1. *Let $u = u(t,y) \in \mathcal{C}([0,\infty); L^1(Y)) \cap L^2_{loc}(0,\infty; H^1_{per}(Y))$. Assume that there exist real numbers $\beta_1, \beta_2 \in \mathbb{R}$ such that*

$$v(y,\beta_1) \le u(t,y) \le v(y,\beta_2) \quad \text{for a.e. } (t,y) \in (0,\infty) \times Y. \tag{2.7}$$

Then u is an entropy solution of (1.1) *if and only if u is a kinetic solution.*

We are then able to prove the L^1 contraction principle thanks to the kinetic formulation; we wish to emphasize that when u satisfies (2.7), this result is not new by any means, and has been known since the articles of Kruzkhov [10], [11]. However, we present here a different proof (see section 4), using merely regularizations by convolution following [16], [17]. Moreover, we prove that the L^1 contraction principle holds for a larger class of solutions.

Theorem 2.5. *Assume the hypotheses of Proposition* 1.1 *are satisfied, with $a \in W^{1,1}_{per,loc}(Y \times \mathbb{R})^N$, and*

$$\partial_v a \in L^\infty_{loc}(Y\times\mathbb{R})^N, \tag{2.8}$$

(2.9)
$$\forall R>0,\ \exists\, \alpha, C>0,\ \forall (y,y') \in Y^2,\ \forall v \in (-R,R) \quad |a(y,v) - a(y',v)| \le C|y-y'|^\alpha.$$

Let u_1, u_2 be two kinetic solutions of (1.1). *Then*

$$||(u_1(t) - u_2(t))_+||_{L^1(Y)} \le ||(u_1(t=0) - u_2(t=0))_+||_{L^1(Y)}. \tag{2.10}$$

Moreover, if for all $T>0$

$$\int_0^T \int_Y \int_{\mathbb{R}} \frac{\partial v(y,p)}{\partial p} |a(y, v(y,p))|\, \mathbf{1}_{u_2(t,y)<v(y,p)<u_1(t,y)}\, dt\, dy\, dp < +\infty, \tag{2.11}$$

then the following inequality holds in the sense of distributions on $[0,\infty) \times Y$:

$$\frac{\partial}{\partial t}(u_1-u_2)_+ + \frac{\partial}{\partial y_i}\left[\mathbf{1}_{u_1>u_2} \left(A_i(y,u_1) - A_i(y,u_2)\right)\right] - \Delta_y (u_1-u_2)_+ \le 0. \tag{2.12}$$

Remark 2.2. *Hypothesis* (2.11) *is necessary in order to retrieve inequality* (2.12). *However, if the sole purpose is to derive the L^1 contraction inequality* (2.10), *hypothesis* (2.11) *is no longer required. Hypothesis* (2.11) *implies that the function*

$$(t,y) \mapsto \mathbf{1}_{u_1>u_2} \left[A(y,u_1(t,y)) - A(y,u_2(t,y))\right]$$

belongs to $L^1((0,T)\times Y)^N$ for all $T>0$. Notice that such an integrability property is not obvious in general, since we no longer assume that $u\in L^\infty_{loc}$, and thus $A(\cdot,u)$ does not belong to L^∞_{loc} either.

Let us explain formally how inequality (2.12) is derived: let u_1, u_2 be two kinetic solutions of (1.1). We set $f_1=\mathbf{1}_{u_1(t,y)>v(y,p)}$, $f_2=\mathbf{1}_{u_2(t,y)<v(y,p)}$,

$$m_i=|\nabla_y u_i(t,y)-\nabla_y v(y,p)|^2\frac{1}{\frac{\partial v(y,p)}{\partial p}}\delta(p=w(y,u_i(t,y))),\quad i=1,2.$$

Then

$$\frac{\partial}{\partial t}\left(\frac{\partial v}{\partial p}f_1\right)+\frac{\partial}{\partial y_i}\left(\frac{\partial v}{\partial p}a_i(y,v(y,p))f_1\right)-\Delta_y\left(\frac{\partial v}{\partial p}f_1\right)=\frac{\partial m_1}{\partial p},\tag{2.13}$$

$$\frac{\partial}{\partial t}\left(\frac{\partial v}{\partial p}f_2\right)+\frac{\partial}{\partial y_i}\left(\frac{\partial v}{\partial p}a_i(y,v(y,p))f_2\right)-\Delta_y\left(\frac{\partial v}{\partial p}f_2\right)=-\frac{\partial m_2}{\partial p}.\tag{2.14}$$

Multiply (2.13) by f_2, and (2.14) by f_1; recalling (1.9), we add the two equations thus obtained and are led to

$$\begin{aligned}\frac{\partial}{\partial t}\left(\frac{\partial v}{\partial p}f_1f_2\right)+\frac{\partial}{\partial y_i}\left(\frac{\partial v}{\partial p}a_i(y,v(y,p))f_1f_2\right)-\Delta_y\left(\frac{\partial v}{\partial p}f_1f_2\right)&\\ =\frac{\partial m_1}{\partial p}f_2-\frac{\partial m_2}{\partial p}f_1-2\frac{\partial v}{\partial p}\nabla_y f_1\cdot\nabla_y f_2.&\end{aligned}\tag{2.15}$$

Set $\varphi_i(t,y)=w(y,u_i(t,y))$ $(i=1,2)$, i.e., $v(y,\varphi_i(t,y))=u_i(t,y)$. Then

$$\nabla_y\varphi_i(t,y)=\frac{1}{\frac{\partial v}{\partial p}(y,\varphi_i(t,y))}\left[\nabla_y u_i(t,y)-\nabla_y v(y,\varphi_i(t,y))\right].$$

Notice that

$$\begin{aligned}f_1&=\mathbf{1}_{u_1(t,y)>v(y,p)}=\mathbf{1}_{\varphi_1(t,y)>p},\\ f_2&=\mathbf{1}_{u_2(t,y)<v(y,p)}=\mathbf{1}_{\varphi_2(t,y)<p},\end{aligned}$$

and thus, setting $\eta_1=1$ and $\eta_2=-1$,

$$\begin{aligned}\frac{\partial f_i}{\partial p}&=-\eta_i\,\delta(p=\varphi_i(t,y)),\\ \nabla_y f_i&=\eta_i\nabla_y\varphi_i(t,y)\delta(p=\varphi_1(t,y)).\end{aligned}$$

We refer to the proof of Lemma 2.2, at the end of the present section, for a derivation of the above equalities in the sense of distributions on $[0,\infty)\times Y\times\mathbb{R}$.

On the other hand, for any function $G\in W^{1,\infty}_{\rm loc}(\mathbb{R})$,

$$\begin{aligned}\int_{\mathbb{R}}G'(v(y,p))f_1f_2\frac{\partial v(y,p)}{\partial p}\,dp&=\int_{\mathbb{R}}G'(v(y,p))\mathbf{1}_{u_2(t,y)<v(y,p)<u_1(t,y)}\frac{\partial v(y,p)}{\partial p}\,dp\\ &=\mathbf{1}_{u_2(t,y)<u_1(t,y)}\left[G(u_1(t,y))-G(u_2(t,y))\right].\end{aligned}$$

Hence, integrating (2.15) with respect to p on $\mathbb{R}$ yields

$$\begin{aligned}
&\frac{\partial}{\partial t}(u_1-u_2)_+ + \frac{\partial}{\partial y_i}\mathbf{1}_{u_2(t,y)<u_1(t,y)}\left[A_i(y,u_1(t,y))-A_i(y,u_2(t,y))\right]-\Delta_y(u_1-u_2)_+\\
&=\int_{\mathbb{R}} -m_1\partial_p f_2 + m_2\partial_p f_1 - 2\frac{\partial v}{\partial p}\nabla_y f_1\cdot\nabla_y f_2\,dp\\
&=-\int_{\mathbb{R}}|\nabla_y u_1(t,y)-\nabla_y v(y,\varphi_1)|^2\frac{1}{\frac{\partial v(y,p)}{\partial p}}\delta(p=\varphi_1)\delta(p=\varphi_2)dp\\
&\quad-\int_{\mathbb{R}}|\nabla_y u_2(t,y)-\nabla_y v(y,\varphi_2)|^2\frac{1}{\frac{\partial v(y,p)}{\partial p}}\delta(p=\varphi_2)\delta(p=\varphi_1)dp\\
&\quad+2\int_{\mathbb{R}}\frac{\partial v}{\partial p}(y,p)\,\nabla_y\varphi_1(t,y)\cdot\nabla_y\varphi_2(t,y)\delta(p=\varphi_1)\delta(p=\varphi_2)dp\\
&=-\int_{\mathbb{R}}\frac{1}{\frac{\partial v(y,p)}{\partial p}}\delta(p=\varphi_1)\delta(p=\varphi_2)|\nabla_y(u_1-u_2)(t,y)-\nabla_y v(y,\varphi_1)+\nabla_y v(y,\varphi_2)|^2\,dp\\
&\le 0,
\end{aligned}$$

which is exactly the L^1 contraction principle between u_1 and u_2.

However, the calculations above are entirely formal, since the product of Dirac masses is not a well-defined object, and f_1, f_2 do not have enough regularity to perform nonlinear calculations. Thus, regularizations are necessary in order to justify the contraction principle, which is proved in section 4.

Proof of Lemma 2.2. Notice first that since $u(t,y)$ and $v(y,p)$ are both solutions of (1.1), we always have

$$\partial_t\left[u(t,y)-v(y,p)\right]+\mathrm{div}_y\left[A(y,u)-A(y,v(y,p))\right]-\Delta_y\left[u(t,y)-v(y,p)\right]=0.$$

Thanks to the regularizing parabolic (resp., elliptic) term, the regularity of u (resp., v) is sufficient for us to use the chain rule, and thus

$$\begin{aligned}
\mathbf{1}_{u(t,y)>v(y,p)}\partial_t\left[u(t,y)-v(y,p)\right]&=\partial_t\left[u(t,y)-v(y,p)\right]_+,\\
\mathbf{1}_{u(t,y)>v(y,p)}\mathrm{div}_y\left[A(y,u)-A(y,v(y,p))\right]&=\mathrm{div}_y\left[\mathbf{1}_{u(t,y)>v(y,p)}\left(A(y,u)-A(y,v(y,p))\right)\right],\\
\mathbf{1}_{u>v(y,p)}\Delta_y\left[u-v(y,p)\right]&=\Delta_y\left[u-v(y,p)\right]_+-\nabla_y\mathbf{1}_{u>v(y,p)}\cdot\nabla_y\left[u-v(y,p)\right].
\end{aligned}$$

Similar calculations can be found, for instance, in [10], [11] and are in fact at the heart of Kruzkhov's method for proving the L^1 contraction principle.

The major difficulty comes from the term $\nabla_y\mathbf{1}_{u(t,y)>v(y,p)}$. Notice that $\mathbf{1}_{u(t,y)>v(y,p)} = \mathbf{1}_{w(y,u(t,y))>p}$. When $p\in\mathbb{R}$ is considered as a fixed parameter, we have

$$\nabla_y\mathbf{1}_{u>v(y,p)}=\nu\otimes\mathcal{H}^{n-1}_{\partial\omega},$$

where $\omega := \{y\in Y;\ w(y,u(t,y))>p\}$, $\mathcal{H}^{n-1}_{\partial\omega}$ is the $(n-1)$-dimensional Hausdorff measure along $\{w(y,u(t,y))=p\}$, and ν is the unit normal vector field oriented from $\{w(y,u(t,y))<p\}$ to $\{w(y,u(t,y))>p\}$. In general, no simplification occurs. However, when deriving a kinetic formulation for (1.1), we are interested only in the computation of $\nabla_y\mathbf{1}_{u>v(y,p)}$ in the sense of distributions on $[0,\infty)\times Y\times\mathbb{R}_p$ (see, for instance, [14], [13], and [17, section 3.2]). In that case, we can give another expression for the gradient of $\mathbf{1}_{u>v(y,p)}$, namely,

$$\begin{aligned}\nabla_y \mathbf{1}_{u(t,y)>v(y,p)} &= \nabla_y \mathbf{1}_{w(y,u(t,y))>p}\\ &= \nabla_y \left(w(y,u(t,y))\right)\delta(p=w(y,u(t,y)))\\ &= \frac{1}{\frac{\partial v}{\partial p}(y,p)}\nabla_y(u(t,y)-v(y,p))\delta(p=w(y,u(t,y))).\end{aligned}$$

Notice that the above expression, although meaningless if considered for $p\in\mathbb{R}$ fixed, is well-defined in the sense of distributions on $[0,\infty)\times Y\times\mathbb{R}_p$.

Thus (2.2) is proved. Consequently, all solutions of (1.1) satisfy inequality (1.10) in the sense of distributions on $[0,\infty)\times Y\times\mathbb{R}$. And it is then easily checked that if a solution u of (1.1) satisfies (1.10) in the sense of distributions in t,y,p, then u satisfies (1.10) for all p in the sense of distributions in t, y. $\square$

3. An application to homogenization. We provide here a proof for Proposition 1.3. The kinetic formulation derived above allows a better understanding of the homogenization process, and the proof is much more elegant than the original one in [3], which used two-scale Young measures.

We will work in the context of kinetic solutions of (1.11): Let $\varepsilon>0$, and let $u^\varepsilon\in L^\infty_{\text{loc}}([0,\infty);L^1_{\text{loc}}(\mathbb{R}^N))\cap L^2_{\text{loc}}(0,+\infty;H^1_{\text{loc}}(\mathbb{R}^N))$. We assume that

$$f^\varepsilon(t,x,p):=\mathbf{1}_{v\left(\frac{x}{\varepsilon},p\right)<u^\varepsilon(t,x)}$$

is a solution in the sense of distributions of

$$\begin{aligned}&\partial_t\left(v_p\left(\frac{x}{\varepsilon},p\right)f^\varepsilon\right)+\partial_{x_i}\left[a_i\left(\frac{x}{\varepsilon},v\left(\frac{x}{\varepsilon},p\right)\right)v_p\left(\frac{x}{\varepsilon},p\right)f^\varepsilon\right]-\varepsilon\Delta_x\left(v_p\left(\frac{x}{\varepsilon},p\right)f^\varepsilon\right)=\partial_p m^\varepsilon,\\ &f^\varepsilon(t=0)=\mathbf{1}_{v\left(\frac{x}{\varepsilon},p\right)<u_0\left(x,\frac{x}{\varepsilon}\right)},\end{aligned}\tag{3.1}$$

where

$$m^\varepsilon(t,x,p):=\varepsilon\left|\nabla_x u^\varepsilon(t,x)-\nabla_y v\left(\frac{x}{\varepsilon},p\right)\right|^2\frac{1}{v_p\left(\frac{x}{\varepsilon},p\right)}\delta\left(p=w\left(\frac{x}{\varepsilon},u^\varepsilon(t,x)\right)\right).$$

We assume that the hypotheses of Proposition 1.1 are satisfied, together with (2.1), so that $w(y,p)$ is well-defined (see Lemma 2.1). We have used the notation $v_p(y,p)=\partial_p v(y,p)$.

The hypotheses on f^ε are the following:

(H1) $u_0(x,y)=v(y,\bar u_0(x))$ for some $\bar u_0\in L^1(\mathbb{R}^N)$.

(H2) $u_0-v(y,0)\in L^1(\mathbb{R}^N,\mathcal{C}_{\text{per}}(Y))$; this means that

$$\int_{\mathbb{R}^N}\sup_{y\in Y}|v(y,\bar u_0(x))-v(y,0)|\,dx<+\infty,$$

which is slightly stronger than requiring $\bar u_0\in L^1$.

(H3) $f^\varepsilon(t,x,p)\to 0$ (resp., $1-f^\varepsilon\to 0$) as $p\to+\infty$ (resp., as $p\to-\infty$) for a.e. $(t,x)\in[0,\infty)\times\mathbb{R}^N$ and for all $\varepsilon>0$. Equivalently,

$$\alpha_-\left(\frac{x}{\varepsilon}\right)<u^\varepsilon(t,x)<\alpha_+\left(\frac{x}{\varepsilon}\right)\quad\text{for a.e. }(t,x)\in(0,\infty)\times\mathbb{R}^N,$$

where α_- and α_+ were defined in Lemma 2.1.

(H4) For all $\varepsilon > 0$, there exists a function $\mu_\varepsilon \in L^\infty(\mathbb{R})$ such that $\mu_\varepsilon(p) \to 0$ as $|p| \to \infty$ and

$$\int_0^\infty \int_{\mathbb{R}^N} m^\varepsilon(t,x,p)\,dt\,dx \le \mu_\varepsilon(p) \quad \forall p \in \mathbb{R}.$$

(H5) For all $\varepsilon > 0$, the function

$$(t,x,p) \mapsto \frac{\partial v}{\partial p}\left(\frac{x}{\varepsilon}, p\right)\left[\mathbf{1}_{p>0} f^\varepsilon(t,x,p) + \mathbf{1}_{p<0}(1 - f^\varepsilon(t,x,p))\right]$$

belongs to $L^\infty_{\mathrm{loc}}([0,\infty), L^1(\mathbb{R}^{N+1}))$. Equivalently, the function

$$(t,x) \mapsto u^\varepsilon(t,x) - v\left(\frac{x}{\varepsilon}, 0\right)$$

belongs to $L^\infty_{\mathrm{loc}}([0,\infty), L^1(\mathbb{R}^N))$.

A function $u^\varepsilon \in L^\infty_{\mathrm{loc}}([0,\infty); L^1_{\mathrm{loc}}(\mathbb{R}^N)) \cap L^2_{\mathrm{loc}}(0,+\infty; H^1_{\mathrm{loc}}(\mathbb{R}^N))$ such that f^ε is a solution of (3.1) and such that (H3)–(H5) are satisfied is called a *kinetic solution* of the parabolic scalar conservation law (1.11). Notice that we do not assume that (1.11) is satisfied in the sense of distributions.

Let us now state the result we prove in this section.

THEOREM 3.1. *Assume that A satisfies the hypotheses of Proposition* 1.1 *and* (2.1)*. Let $u^\varepsilon \in L^\infty_{loc}([0,\infty); L^1_{loc}(\mathbb{R}^N)) \cap L^2_{loc}(0,+\infty; H^1_{loc}(\mathbb{R}^N))$ be a kinetic solution of* (1.11) *such that hypotheses* (H1)–(H5) *are satisfied. Then*

$$u^\varepsilon(t,x) - v\left(\frac{x}{\varepsilon}, \bar{u}(t,x)\right) \to 0$$

in $L^1_{loc}([0,\infty) \times \mathbb{R}^N)$, where $\bar{u} \in L^\infty([0,\infty), L^1(\mathbb{R}^N))$ is the kinetic solution of (1.15) *with initial data $\bar{u}_0$.*

REMARK 3.1. *When hypothesis* (H1) *on the microscopic profile of the initial data is not satisfied, it is proved in the L^∞ case in* [4] *that there is an initial layer of typical size ε, during which the solution adapts itself to the profile dictated by the microscopic structure. The proof of this result relies on the parabolic structure of the equation, which cannot be used here since the kinetic formulation is essentially a hyperbolic tool.*

REMARK 3.2. *It can be checked that* (H2)–(H5) *are always satisfied when $\bar{u}_0 \in L^\infty \cap L^1(\mathbb{R}^N)$ and $u^\varepsilon \in L^\infty_{loc}$ is an entropy solution. However, we wish to stress that hypothesis* (H3) *does not imply that $u^\varepsilon \in L^\infty_{\mathrm{loc}}([0,\infty) \times \mathbb{R}^N)$ in general. For instance, in the case when hypothesis* (1.4) *is satisfied, we have $\alpha_\pm = \pm\infty$, as explained in Remark* 2.1*. Hence in that case, hypothesis* (H3) *is always satisfied, and the only bound required on u^ε is* (H5)*, which is an L^1 bound. Consequently, we refer to* (H2)–(H5) *as an "L^1 setting," in contrast with the "L^∞ setting" of entropy solutions.*

At last, let us mention that the function μ_ε in hypothesis (H4) *can in fact be derived from* (3.1) *(see Lemma* 3.2 *below) if it is known that* (H4) *holds for some function μ_ε; nonetheless,* (H4) *cannot be avoided and is necessary for Lemma* 3.2 *to hold.*

We will prove the convergence in several steps; first, we introduce the two-scale weak limit $f(t,x,y,p)$ of f^ε. Then the key point in the analysis is to show that $f(t,x,y,p) = \mathbf{1}_{p<\bar{u}(t,x)}$, where $\bar{u}$ is the solution of the homogenized problem. Hence, we first prove that f does not depend on y. Then we derive the macroscopic equation solved by f and prove that $f(t=0) = \mathbf{1}_{p<\bar{u}_0(x)}$; this entails that $f = \mathbf{1}_{p<\bar{u}}$, and $\bar{u}$ can be identified thanks to the equation solved by f. Eventually, we prove the strong convergence in L^1_{loc}.

We begin with a few preliminary bounds on m^ε and f^ε, of which we give only a rough idea of the proof (see, for instance, [17, Proposition 4.1.7 and Lemma 3.1.7] for the derivation of similar inequalities).

LEMMA 3.2. *Assume that* (H1)–(H5) *are satisfied.*

- *There exists a constant $C > 0$ such that for all $\varepsilon > 0$, for a.e. $t > 0$,*

$$\int_{\mathbb{R}^{N+1}} v_p\left(\frac{x}{\varepsilon}, p\right)\left(\mathbf{1}_{p>0} f^\varepsilon(t,x,p) + \mathbf{1}_{p<0}(1-f^\varepsilon)(t,x,p)\right)\, dx\, dp \le C.$$

- *There exists a constant $C > 0$ such that for all $p_0 > 0$, $\varepsilon > 0$,*

$$\int_0^\infty \int_{\mathbb{R}^N} m^\varepsilon(t,x,p_0)\, dx\, dt \le \int_{\mathbb{R}^N} \left(v\left(\frac{x}{\varepsilon}, \bar{u}_0(x)\right) - v\left(\frac{x}{\varepsilon}, p_0\right)\right)_+ dx \le C.$$

The same kind of bound holds for $p_0 < 0$.
Thus $m^\varepsilon((0,+\infty)\times\mathbb{R}^N\times(-R,R))$ is bounded for all $R > 0$ uniformly in ε.

- *For all $t \ge 0$, for all $p_0 > 0$, and for all $\varepsilon > 0$,*

$$\int_{\mathbb{R}^N} \left(u^\varepsilon(t,x) - v\left(\frac{x}{\varepsilon}, p_0\right)\right)_+ dx \le \int_{\mathbb{R}^N} \left(v\left(\frac{x}{\varepsilon}, \bar{u}_0(x)\right) - v\left(\frac{x}{\varepsilon}, p_0\right)\right)_+ dx. \tag{3.2}$$

We deduce from the second bound in the lemma that we can take in (H4)

$$\begin{aligned}\mu_\varepsilon(p) := \mathbf{1}_{p>0} &\int_{\mathbb{R}^N} \left(v\left(\frac{x}{\varepsilon}, \bar{u}_0(x)\right) - v\left(\frac{x}{\varepsilon}, p\right)\right)_+ dx \\ &+ \mathbf{1}_{p<0} \int_{\mathbb{R}^N} \left(v\left(\frac{x}{\varepsilon}, \bar{u}_0(x)\right) - v\left(\frac{x}{\varepsilon}, p\right)\right)_- dx.\end{aligned}$$

Then μ_ε is bounded in L^∞, uniformly in ε. Moreover, it will be proved in the very last step of the proof that for all p, $\mu_\varepsilon(p)$ converges as $\varepsilon \to 0$ toward $\mu_0(p)$ for some function $\mu_0 \in L^\infty(\mathbb{R})$ vanishing at infinity.

Proof. Thanks to the integrability assumptions (H4)–(H5) on f^ε and m^ε, we prove that for any test function $S' \in \mathcal{D}(\mathbb{R})$, for all $t > 0$, we have

$$\begin{aligned}\int_{\mathbb{R}^{N+1}} S'(p) f^\varepsilon(t,x,p) v_p\left(\frac{x}{\varepsilon}, p\right) dx\, dp - \int_{\mathbb{R}^{N+1}} S'(p) f^\varepsilon(t=0,x,p) v_p\left(\frac{x}{\varepsilon}, p\right) dx\, dp \\ = -\int_0^t \int_{\mathbb{R}^{N+1}} m^\varepsilon(t,x,p) S''(p)\, dt\, dx\, dp.\end{aligned}$$

Then, using the fact that μ_ε vanishes at infinity, we prove that the above equality holds for more general functions S. In particular, the choice $S'(p) = \mathbf{1}_{p>0}$ (and thus $S''(p) = \delta(p=0)$) yields the first bound on f^ε, and the choice $S'(p) = \mathbf{1}_{p>p_0}$ for some $p_0 > 0$ gives the one on m^ε. Moreover

$$\begin{aligned}\int_{\mathbb{R}^{N+1}} \mathbf{1}_{p>p_0} f^\varepsilon(t,x,p) v_p\left(\frac{x}{\varepsilon}, p\right) dx\, dp &= \int_{\mathbb{R}^{N+1}} \mathbf{1}_{v\left(\frac{x}{\varepsilon}, p_0\right) < v\left(\frac{x}{\varepsilon}, p\right) < u^\varepsilon(t,x)} v_p\left(\frac{x}{\varepsilon}, p\right) dx\, dp \\ &= \int_{\mathbb{R}^N} \left[u^\varepsilon(t,x) - v\left(\frac{x}{\varepsilon}, p_0\right)\right]_+ dx,\end{aligned}$$

and thus the choice $S'(p) = \mathbf{1}_{p>p_0}$ also yields the bound on u^ε. ∎

We now use the concept of two-scale convergence, defined by Allaire in [1] following an idea of Nguetseng (see [15]), in order to find a two-scale limit for f^ε.

PROPOSITION 3.3. *Let $\{v^\varepsilon\}_{\varepsilon>0}$ be a bounded sequence of $L^2(\Omega)$, where Ω is an open set of $\mathbb{R}^N$. Then as $\varepsilon \to 0$, there exists a subsequence, still denoted by ε, and $v^0 \in L^2(\Omega \times Y)$, such that*

$$\int_\Omega \psi\left(x, \frac{x}{\varepsilon}\right) v^\varepsilon(x)\, dx \to \int_{\Omega\times Y} \psi(x,y) v^0(x,y)\, dx\, dy$$

for all $\psi \in \mathcal{C}_{per}(Y, L^2(\Omega))$.

It is then said that the sequence $\{v^\varepsilon\}_{\varepsilon>0}$ "two-scale" converges to v_0.

This concept is easily generalized to functions in L^∞ (the proof goes along the same lines as the one given in [1]), which allows us to prove the following.

LEMMA 3.4. *There exists a function $f(t,x,y,p) \in L^\infty((0,\infty)\times\mathbb{R}^N \times Y \times \mathbb{R})$ and a subsequence, still denoted by ε, such that f^ε two-scale converges to f.*

It is easily checked that $0 \le f \le 1$ almost everywhere. Since v_p, f, and $1-f$ are nonnegative, Lemma 3.2 entails that there exists a constant C such that

$$\int_{\mathbb{R}^N\times Y\times\mathbb{R}} \{\mathbf{1}_{p>0} f(t,x,y,p) + \mathbf{1}_{p<0}(1-f(t,x,y,p))\}\, v_p(y,p) dx dy dp \le C \quad \text{for a.e. } t>0.$$

The goal is now to identify the equations solved by f in order to prove that f is an indicator function. Hence, we now focus on the microscopic (i.e., in y) and macroscopic (i.e., in t,x) equations solved by f.

First step. Microscopic profile. Multiplying (3.1) by a test function of the form $\varepsilon\varphi(t,x,x/\varepsilon,p)$, with $\varphi \in \mathcal{D}_{\rm per}((0,\infty)\times\mathbb{R}^N\times Y\times\mathbb{R})$, and passing to the limit as $\varepsilon \to 0$ leads to the equation

$$-\Delta_y\left(\frac{\partial v}{\partial p} f\right) + \mathrm{div}_y\left(a(y,v(y,p))\frac{\partial v}{\partial p} f\right) = 0 \tag{3.3}$$

in the sense of distributions on $(0,\infty)\times\mathbb{R}^N\times Y\times\mathbb{R}$. Let us point out that $a(y,v(y,p))$ is an "admissible" test function in the sense of Allaire (see [1]) thanks to the continuity assumption (2.1).

Then we regularize (3.3) in the variables t,x,y,p thanks to a convolution kernel, and pass to the limit as the parameter of the regularization vanishes. We easily deduce that (3.3) in fact holds almost everywhere in t,x,p in the variational sense in y.

Notice that the constant function equal to 1 on Y, denoted by $\bar{1}$, is a positive solution of the dual problem

$$-\Delta_y \bar{1} - a(y,v(y,p))\cdot\nabla_y \bar{1} = 0.$$

Consequently, by the Krein–Rutman theorem, we infer that any solution g of the equation

$$-\Delta_y g + \mathrm{div}_y\left(a(y,v(y,p))g\right) = 0$$

can be written $g(y) = c\frac{\partial v(y,p)}{\partial p}$, where c is a constant in y (recall (1.9)).

Thus $f(t,x,y,p)$ does not depend on y, and $f = f(t,x,p)$.

Second step. Evolution equation. Now, we multiply (3.1) by a test function of the form $\varphi(t,x,p)$, with $\varphi(t,x,p) = 0$ when $|p| \ge R$, $R>0$ arbitrary; thanks to

Lemma 3.2, $m^\varepsilon((0,\infty)\times\mathbb{R}^N\times(-R,R))$ is bounded uniformly in ε, and thus up to the extraction of a subsequence, there exists a measure $\bar m_R$ such that

$$m^\varepsilon \rightharpoonup \bar m_R \quad \text{in } w-M^1((0,\infty)\times\mathbb{R}^N\times(-R,R)).$$

We define, for any $p\in\mathbb{R}$,

$$\bar a(p)=\frac{1}{|Y|}\int_Y a(y,v(y,p))\frac{\partial v}{\partial p}\,dy;$$

recall also that

$$\frac{1}{|Y|}\int_Y \frac{\partial v}{\partial p}\,dy=1.$$

Then f satisfies, in the sense of distributions on $(0,\infty)\times\mathbb{R}^N\times(-R,R)$,

$$\partial_t f+\operatorname{div}_x(\bar a(p)f)=\frac{\partial \bar m_R}{\partial p}. \tag{3.4}$$

We deduce that for any $0<R<R'$, $\bar m_R=\bar m_{R'}$ on $(0,\infty)\times\mathbb{R}^N\times(-R,R)$. Consequently, the measure $\bar m$, defined by $\bar m=\bar m_R$ on $(0,\infty)\times\mathbb{R}^N\times(-R,R)$, is well-defined. Hence (3.4) holds in $(0,\infty)\times\mathbb{R}^{N+1}$ with $\bar m_R$ replaced by $\bar m$, and $\bar m\in\mathcal{C}(\mathbb{R}_p,w-M^1([0,\infty)\times\mathbb{R}^N_x))$. Moreover the measure $\bar m$ inherits the following property from the bounds on m^ε: for almost every $p\in\mathbb{R}$,

$$\int_0^\infty\int_{\mathbb{R}^N\times Y}\bar m(t,x,y,p)\,dt\,dx\,dy\le\mu_0(p), \tag{3.5}$$

and μ_0 belongs to L^∞ and vanishes at infinity, as we shall prove in the fourth step.

Equation (3.4) looks very much like the kinetic formulation for a homogeneous and hyperbolic scalar conservation law (see, for instance, [14], [13], and [17, Chapter 3]). However, we have to work out a few points before coming to a conclusion.

Third step. Identification of f as an indicator function. First, the function which occurs in the kinetic formulation is the function $\chi:\mathbb{R}^2\to\{1,-1,0\}$ defined by

$$\chi(v,u):=\begin{cases}1 & \text{if } 0<v<u,\\ -1 & \text{if } u<v<0,\\ 0 & \text{otherwise.}\end{cases}$$

Here, if $u^\varepsilon(t,x)-v\left(x/\varepsilon,\bar u(t,x)\right)$ converges strongly to 0, as we intend to prove, then $f=\mathbf{1}_{v(y,p)<v(y,\bar u(t,x))}=\mathbf{1}_{p<\bar u(t,x)}$; hence, a good candidate for a function $\chi(v,\bar u(t,x))$ seems to be

$$g(t,x,p)=\mathbf{1}_{p>0}f-\mathbf{1}_{p<0}(1-f)=f-\mathbf{1}_{p<0}.$$

The function g satisfies the same equation as f, and

$$\operatorname{sgn}(p)g=\mathbf{1}_{p>0}f+\mathbf{1}_{p<0}(1-f)=|g|\in[0,1].$$

Moreover,

$$\frac{\partial g}{\partial p}=\delta(p=0)+\partial_p f. \tag{3.6}$$

Recall that

$$\partial_p f^\varepsilon(t,x,p) = -\delta\left(p - w\left(\frac{x}{\varepsilon}, u^\varepsilon(t,x)\right)\right);$$

Hence $-\partial_p f^\varepsilon(t,x,p)$ is a nonnegative measure, uniformly bounded in ε on compact sets of $(0,\infty)\times\mathbb{R}^{N+1}$. Since $\partial_p f^\varepsilon$ weakly converges to $\partial_p f$, we deduce that $\partial_p f$ is a nonpositive locally finite measure.

It remains to check that

$$g(t=0,x,p) = \chi(p,\bar{u}_0(x)); \tag{3.7}$$

this equality is in fact not obvious: if $f^\varepsilon(t=0,x,p) = f_0\left(x, x/\varepsilon, p\right)$, then it is false in general that $f(t=0,x,y,p) = f_0(x,y,p)$. Indeed, there might be initial layers of typical size ε. These are not taken into account when passing to the two-scale limit because the test functions do not select the microscopic information in time. In order to see the possible initial layers, we should have taken test functions of the kind

$$\psi\left(t, \frac{t}{\varepsilon}, x, \frac{x}{\varepsilon}, p\right).$$

Here, it is unnecessary to consider test functions which have microscopic oscillations in time because the initial data is well prepared. Hence, there is no initial layer in this case. In other words, the u^ε are uniformly continuous in time at time $t=0$ (with values in L^1_{loc}). In terms of the kinetic formulation, this result follows directly from the fact that

$$f^\varepsilon(t=0,x,p) = \mathbf{1}_{v\left(\frac{x}{\varepsilon},p\right) < v\left(\frac{x}{\varepsilon},\bar{u}_0(x)\right)} = \mathbf{1}_{p<\bar{u}_0(x)}.$$

Hence $f^\varepsilon(t=0)$ does not depend on ε. Consequently, multiplying (3.1) by a test function $\varphi(t,x,p)\in\mathcal{D}([0,\infty)\times\mathbb{R}^{N+1})$ yields

$$\begin{aligned}&\int_0^\infty\!\!\int_{\mathbb{R}^{N+1}} f^\varepsilon(t,x,p)\frac{\partial v}{\partial p}\left(\frac{x}{\varepsilon},p\right)\left\{\partial_t\varphi + a_i\left(\frac{x}{\varepsilon}, v\left(\frac{x}{\varepsilon},p\right)\right)\partial_{x_i}\varphi + \varepsilon\Delta_x\varphi\right\}\,dt\,dx\,dp\\ &= \int_0^\infty\!\!\int_{\mathbb{R}^{N+1}} m^\varepsilon(t,x,p)\partial_p\varphi(t,x,p)dtdxdp - \int_{\mathbb{R}^{N+1}}\frac{\partial v}{\partial p}\left(\frac{x}{\varepsilon},p\right)\mathbf{1}_{p<\bar{u}_0(x)}\varphi(t=0,x,p)dxdp.\end{aligned}$$

Passing to the limit as $\varepsilon\to 0$ entails that

$$f(t=0,x,p) = \mathbf{1}_{p<\bar{u}_0(x)},$$

and thus

$$g(t=0,x,p) = \chi(p,\bar{u}_0(x)).$$

Gathering (3.4), (3.5), (3.6), (3.7), we infer that g is a generalized kinetic solution (see Definition 4.1.2 in [17]) of the scalar conservation law

$$\frac{\partial u}{\partial t} + \frac{\partial \bar{A}_i(u)}{\partial x_i} = 0,$$

where

$$\bar{A}_i'(p) = \bar{a}_i(p).$$

Now, we can apply Theorem 4.3.1 in [17]: there exists $\bar{u}(t,x) \in L^\infty([0,\infty); L^1(\mathbb{R}^N))$ such that $g(t,x,p) = \chi(p, \bar{u}(t,x))$ almost everywhere, and $\bar{u}$ is a kinetic solution of the above scalar conservation law.

And since

$$\mathbf{1}_{p>0} f - \mathbf{1}_{p<0}(1-f) = \chi(p, \bar{u}(t,x)),$$

we deduce that

$$f(t,x,p) = \mathbf{1}_{p<\bar{u}(t,x)}$$

almost everywhere.

Fourth step. Strong convergence. Let us now prove that this result entails that

$$u^\varepsilon(t,x) - v\left(\frac{x}{\varepsilon}, \bar{u}(t,x)\right) \to 0$$

in L^1_{loc}.

(i) *Convergence of* $u^\varepsilon \wedge v(x/\varepsilon, p_0)$ *for all* $p_0 > 0$: Take an arbitrary cut-off function $\varphi = \varphi(t,x)$ with compact support in $[0,\infty) \times \mathbb{R}^N$, $p_0 > 0$ and set

$$\psi(t,x,y,p) := \mathbf{1}_{\bar{u}(t,x)<p<p_0} \frac{\partial v}{\partial p}(y,p)\, \varphi(t,x).$$

Since $f^\varepsilon(t,x,p) = \mathbf{1}_{v\left(\frac{x}{\varepsilon},p\right)<u^\varepsilon(t,x)}$ two-scale converges to $f = \mathbf{1}_{p<\bar{u}(t,x)}$, we deduce that as $\varepsilon \to 0$

$$\int_0^\infty \int_{\mathbb{R}^{N+1}} \psi\left(t,x,\frac{x}{\varepsilon},p\right) \mathbf{1}_{v\left(\frac{x}{\varepsilon},p\right)<u^\varepsilon(t,x)}\, dp\, dx\, dt \to 0.$$

And the left-hand side can be transformed as follows:

$$\begin{aligned}
&\int_0^\infty \int_{\mathbb{R}^{N+1}} \psi\left(t,x,\frac{x}{\varepsilon},p\right) \mathbf{1}_{v\left(\frac{x}{\varepsilon},p\right)<u^\varepsilon(t,x)}\, dp\, dx\, dt \\
&= \int_0^\infty \int_{\mathbb{R}^{N+1}} \mathbf{1}_{v\left(\frac{x}{\varepsilon},\bar{u}(t,x)\right)<v\left(\frac{x}{\varepsilon},p\right)<u^\varepsilon(t,x)\wedge v\left(\frac{x}{\varepsilon},p_0\right)}\, \varphi(t,x) \frac{\partial v}{\partial p}\left(\frac{x}{\varepsilon},p\right) dp\, dx\, dt \\
&= \int_0^\infty \int_{\mathbb{R}^{N+1}} \mathbf{1}_{v\left(\frac{x}{\varepsilon},\bar{u}(t,x)\right)<v<u^\varepsilon(t,x)\wedge v\left(\frac{x}{\varepsilon},p_0\right)}\, \varphi(t,x) dv\, dx\, dt \\
&= \int_0^\infty \int_{\mathbb{R}^N} \varphi(t,x) \left[u^\varepsilon(t,x) \wedge v\left(\frac{x}{\varepsilon},p_0\right) - v\left(\frac{x}{\varepsilon},\bar{u}(t,x)\right)\right]_+ dx\, dt.
\end{aligned}$$

Take any compact set $K \subset [0,\infty) \times \mathbb{R}^N$ and choose a test function $\varphi \in \mathcal{D}([0,\infty) \times \mathbb{R}^N)$ such that $0 \le \varphi \le 1$, and $\varphi \equiv 1$ on K. Then for all $\varepsilon > 0$,

$$\begin{aligned}
&\left\| \left[u^\varepsilon(t,x) \wedge v\left(\frac{x}{\varepsilon},p_0\right) - v\left(\frac{x}{\varepsilon},\bar{u}(t,x)\right)\right]_+ \right\|_{L^1(K)} \\
&\le \int_0^\infty \int_{\mathbb{R}^N} \varphi(t,x) \left[u^\varepsilon(t,x) \wedge v\left(\frac{x}{\varepsilon},p_0\right) - v\left(\frac{x}{\varepsilon},\bar{u}(t,x)\right)\right]_+ dx\, dt.
\end{aligned}$$

In the inequality above, we have used the fact that $u_+ = \max(u,0)$ is always nonnegative. Thus we deduce that for all $p_0 > 0$

$$\left\| \left[u^\varepsilon(t,x) \wedge v\left(\frac{x}{\varepsilon},p_0\right) - v\left(\frac{x}{\varepsilon},\bar{u}(t,x)\right)\right]_+ \right\|_{L^1_{\text{loc}}([0,\infty)\times\mathbb{R}^N)} \underset{\varepsilon\to 0}{\longrightarrow} 0.$$

The same kind of result holds for $p_0 < 0$.

(ii) *Convergence of* u^ε: Let $T > 0$, $R > 0$, and set $Q := (0,T) \times B_R$. For $p_0 > 0$ arbitrary, we have

$$\begin{aligned}
&\left\| \left[u^\varepsilon(t,x) - v\left(\frac{x}{\varepsilon}, \bar{u}(t,x)\right)\right]_+ \right\|_{L^1(Q)} \\
\le &\left\| \left[u^\varepsilon \wedge v\left(\frac{x}{\varepsilon}, p_0\right) - v\left(\frac{x}{\varepsilon}, \bar{u}(t,x)\right)\right]_+ \right\|_{L^1(Q)} + \left\| \left[u^\varepsilon - u^\varepsilon \wedge v\left(\frac{x}{\varepsilon}, p_0\right)\right]_+ \right\|_{L^1(Q)} \\
\le &\left\| \left[u^\varepsilon \wedge v\left(\frac{x}{\varepsilon}, p_0\right) - v\left(\frac{x}{\varepsilon}, \bar{u}(t,x)\right)\right]_+ \right\|_{L^1(Q)} + \left\| \left[u^\varepsilon - v\left(\frac{x}{\varepsilon}, p_0\right)\right]_+ \right\|_{L^1(Q)} \\
\le &\left\| \left[u^\varepsilon \wedge v\left(\frac{x}{\varepsilon}, p_0\right) - v\left(\frac{x}{\varepsilon}, \bar{u}(t,x)\right)\right]_+ \right\|_{L^1(Q)} + T\int_{\mathbb{R}^N} \left[v\left(\frac{x}{\varepsilon}, \bar{u}_0(x)\right) - v\left(\frac{x}{\varepsilon}, p_0\right)\right]_+ dx
\end{aligned}$$

thanks to inequality (3.2).

According to (H2), we have $[v(y,\bar{u}_0) - v(y,p_0)]_+ \in L^1(\mathbb{R}^N; \mathcal{C}_{\text{per}}(Y))$; thus, using a result of Allaire (see [1]), we deduce

$$\int_{\mathbb{R}^N} \left[v\left(\frac{x}{\varepsilon}, \bar{u}_0(x)\right) - v\left(\frac{x}{\varepsilon}, p_0\right)\right]_+ dx \to \int_{\mathbb{R}^N \times Y} \left[v\left(y, \bar{u}_0(x)\right) - v\left(y, p_0\right)\right]_+ dx\, dy$$

as $\varepsilon \to 0$ for all $p_0 > 0$. Since $||\left(v(y,p) - v(y,p')\right)_+||_{L^1(Y)} = (p-p')_+$ for all $p, p' \in \mathbb{R}$, we derive the bound

$$\begin{aligned}
&\int_0^T \int_{B_R} \left[u^\varepsilon(t,x) - v\left(\frac{x}{\varepsilon}, \bar{u}(t,x)\right)\right]_+ dx\, dt \\
\le &\int_0^T \int_{B_R} \left[u^\varepsilon(t,x) \wedge v\left(\frac{x}{\varepsilon}, p_0\right) - v\left(\frac{x}{\varepsilon}, \bar{u}(t,x)\right)\right]_+ dx\, dt \\
&+ T \left| \int_{\mathbb{R}^N} \left[v\left(\frac{x}{\varepsilon}, \bar{u}_0(x)\right) - v\left(\frac{x}{\varepsilon}, p_0\right)\right]_+ dx - ||(\bar{u}_0 - p_0)_+||_{L^1(\mathbb{R}^N)} \right| \\
&+ T||(\bar{u}_0 - p_0)_+||_{L^1(\mathbb{R}^N)}.
\end{aligned}$$

In the above inequality, take p_0 large enough so that $||(\bar{u}_0 - p_0)_+||_{L^1(\mathbb{R}^N)}$ is small enough, and then for this p_0, take $\varepsilon > 0$ small enough so that the two other terms are small (notice that the first one vanishes thanks to the first step). We deduce that

$$\left[u^\varepsilon(t,x) - v\left(\frac{x}{\varepsilon}, \bar{u}(t,x)\right)\right]_+ \to 0$$

in $L^1_{\text{loc}}([0,\infty) \times \mathbb{R}^N)$, and Theorem 3.1 is proved.

Moreover, we have proved that for all $p > 0$,

$$\begin{aligned}
\lim_{\varepsilon \to 0} \mu_\varepsilon(p) &= \lim_{\varepsilon \to 0} \int_{\mathbb{R}^N} \left[v\left(\frac{x}{\varepsilon}, \bar{u}_0(x)\right) - v\left(\frac{x}{\varepsilon}, p\right)\right]_+ dx \\
&= \int_{\mathbb{R}^N \times Y} \left[v\left(y, \bar{u}_0(x)\right) - v\left(y, p\right)\right]_+ dx\, dy \\
&= ||(\bar{u}_0 - p)_+||_{L^1(\mathbb{R}^N)} =: \mu_0(p).
\end{aligned}$$

Thus μ_0 vanishes at infinity, and the result stated after Lemma 3.2 holds.

4. Rigorous proof of the L^1 contraction principle. This section is devoted to the proof of inequality (2.12) under assumption (2.11) and the hypotheses of Theorem 2.5. The main ideas behind the proof were exposed in the formal calculations of section 2; however, regularizations are necessary in order to justify nonlinear manipulations of the type

$$f_1\partial_t f_2 + f_2\partial_t f_1 = \partial_t(f_1 f_2),$$

as well as the reduction of the right-hand side.

As in [16], [17, Chapter 4], we will merely regularize the equation by convolution; let $\varepsilon > 0$ be a small parameter, $\zeta_1 \in \mathcal{D}(\mathbb{R})$, $\zeta_2 \in \mathcal{D}(\mathbb{R}^N)$, $\zeta_3 \in \mathcal{D}(\mathbb{R})$, such that

$$\zeta_i \geq 0 \quad (i = 1, 2, 3),$$
$$\operatorname{supp} \zeta_1 \subset [-1, 0], \quad \operatorname{supp} \zeta_2 \subset B_1, \quad \operatorname{supp} \zeta_3 \subset [-1, 1], \quad \zeta_1(0) = 0,$$
$$\int_{\mathbb{R}} \zeta_1 = \int_{\mathbb{R}^N} \zeta_2 = \int_{\mathbb{R}} \zeta_3 = 1.$$

We set, for $\varepsilon > 0$, $(t, x, p) \in \mathbb{R}^{N+2}$,

$$\phi_\varepsilon(t, x, p) := \frac{1}{\varepsilon^{N+2}}\zeta_1\left(\frac{t}{\varepsilon}\right)\zeta_2\left(\frac{x}{\varepsilon}\right)\zeta_3\left(\frac{p}{\varepsilon}\right),$$

and for $(t, x, p) \in [0, \infty) \times \mathbb{R}^N \times \mathbb{R}$,

$$f_i^\varepsilon(t, x, p) = \int_{\mathbb{R}^{N+2}} f_i(s, z, q)\phi_\varepsilon(t - s, x - z, p - q)\, ds\, dz\, dq,$$
$$m_i^\varepsilon(t, x, p) = \int_{\mathbb{R}^{N+2}} m_i(s, z, q)\phi_\varepsilon(t - s, x - z, p - q)\, ds\, dz\, dq.$$

(Notice that the convolution in the space variable x is meant in the whole of $\mathbb{R}^N$: f_i is thus considered as a function defined on $[0, \infty) \times \mathbb{R}^N \times \mathbb{R}$, periodic with period Y in its second variable. The function f_i^ε is of course Y-periodic as well.)

We begin with the derivation of the equation solved by f^ε.

LEMMA 4.1. *Set* $\tilde{a}_i(y, p) = a_i(y, v(y, p))\frac{\partial v(y,p)}{\partial p}$ *for* $1 \leq i \leq N$, $y \in Y$, $p \in \mathbb{R}$.

Then for $\varepsilon < 1/2$, f_j^ε $(j = 1, 2)$ *is a classical solution of*

$$\frac{\partial}{\partial t}\left(\frac{\partial v}{\partial p} f_j^\varepsilon\right) + \frac{\partial}{\partial y_i}\left(\tilde{a}_i(y, p) f_j^\varepsilon\right) - \Delta_y\left(\frac{\partial v}{\partial p} f_j^\varepsilon\right) = \eta_j\frac{\partial m_j^\varepsilon}{\partial p} + r_j^\varepsilon, \tag{4.1}$$

where $\eta_1 = 1$, $\eta_2 = -1$, *and the error term* r_j^ε *is equal to*

$$\begin{aligned} r_j^\varepsilon(t, y, p) = {} & \frac{\partial}{\partial t}\left[\frac{\partial v}{\partial p}(y, p) f_j^\varepsilon(t, y, p) - \left(\frac{\partial v}{\partial p} f_j\right) * \phi_\varepsilon(t, y, p)\right] \\ & + \frac{\partial}{\partial y_i}\left[\tilde{a}_i(y, p) f_j^\varepsilon(t, y, p) - (\tilde{a}_i f_j) * \phi_\varepsilon(t, y, p)\right] \\ & - \Delta_y\left[\frac{\partial v}{\partial p}(y, p) f_j^\varepsilon(t, y, p) - \left(\frac{\partial v}{\partial p} f_j\right) * \phi_\varepsilon(t, y, p)\right]. \end{aligned}$$

Moreover, for all $0 < \varepsilon < 1/2$, *for all* $p \in \mathbb{R}$,

$$\int_0^\infty \int_Y m_i^\varepsilon(t, y, p)\, dt\, dy \leq \max(\mu_i(p + 1), \mu_i(p - 1)),$$

where the functions μ_i *were introduced in hypothesis* (2.5) *in Definition* 2.3.

We postpone the proof of Lemma 4.1 until the end of the section.

Now, since f_j^ε is smooth we can multiply (4.1) written for f_1^ε (resp., f_2^ε) by f_2^ε (resp., f_1^ε) and add the two equations thus obtained. Following the calculations in section 2 leads to

$$\begin{aligned}\frac{\partial}{\partial t}\left(\frac{\partial v}{\partial p}f_1^\varepsilon f_2^\varepsilon\right) + \frac{\partial}{\partial y_i}\left(\tilde{a}_i(y,p)f_1^\varepsilon f_2^\varepsilon\right) - \Delta_y\left(\frac{\partial v}{\partial p}f_1^\varepsilon f_2^\varepsilon\right)\\ = \frac{\partial m_1^\varepsilon}{\partial p}f_2^\varepsilon - \frac{\partial m_2^\varepsilon}{\partial p}f_1^\varepsilon - 2\frac{\partial v}{\partial p}\nabla_y f_1^\varepsilon \cdot \nabla_y f_2^\varepsilon + r_1^\varepsilon f_2^\varepsilon + r_2^\varepsilon f_1^\varepsilon.\end{aligned}$$

Let $R>0$ arbitrary, and let $K_R \in \mathcal{D}(\mathbb{R})$ be a cut-off function such that

$$\begin{gathered}0 \le K_R(p) \le 1, \quad |K_R'(p)| \le 2 \quad \forall p \in \mathbb{R},\\ K_R(p) = 1 \quad \forall p \in [-R,R],\\ K_R(p) = 0 \quad \forall p \in (-\infty,-R-1] \cup [R+1,+\infty).\end{gathered}$$

Classically, the following convergence results hold for any test function $\theta = \theta(t,y) \in \mathcal{D}_{\text{per}}([0,\infty)\times Y)$ (recall (2.11)):

$$\lim_{R\to\infty}\lim_{\varepsilon\to 0}\int_0^\infty\int_{Y\times\mathbb{R}}\frac{\partial v}{\partial p}(y,p)f_1^\varepsilon f_2^\varepsilon \theta(t,y)K_R(p)\,dt\,dy\,dp = \int_Y (u_1-u_2)_+\theta(t,y)\,dt\,dy,$$

$$\begin{aligned}\lim_{R\to\infty}\lim_{\varepsilon\to 0}\int_0^\infty\int_{Y\times\mathbb{R}}\tilde{a}_i(y,p)f_1^\varepsilon f_2^\varepsilon \partial_{y_i}\theta(t,y)K_R(p)\,dt\,dy\,dp\\ = \int_0^\infty\int_Y \mathbf{1}_{u_1>u_2}\left[A_i(y,u_1) - A_i(y,u_2)\right]\partial_{y_i}\theta(t,y)\,dt\,dy.\end{aligned}$$

(If one is interested in deriving (2.10), without assumption (2.11), instead of (2.12), one should merely take $\theta \in \mathcal{D}([0,\infty))$, independent of y, at this stage; the left-hand side in the second equality above is zero in that case. The rest of the proof remains unchanged.)

On the other hand, it is easily proved that the first order terms in r_j^ε go to 0 in $L^1_{\text{loc}}((0,\infty)\times\mathbb{R}^{N+1})$ as $\varepsilon \to 0$ thanks to the assumption $a \in W^{1,1}_{\text{loc}}$. Hence, we now focus on the convergence of

$$\frac{\partial m_1^\varepsilon}{\partial p}f_2^\varepsilon - \frac{\partial m_2^\varepsilon}{\partial p}f_1^\varepsilon - 2\frac{\partial v}{\partial p}\nabla_y f_1^\varepsilon \cdot \nabla_y f_2^\varepsilon$$

and the second order terms in r_j^ε, that is,

$$\begin{aligned}-\Delta_y\left[\frac{\partial v}{\partial p}(y,p)f_1^\varepsilon(t,y,p) - \left(\frac{\partial v}{\partial p}f_1\right) * \phi_\varepsilon(t,y,p)\right]f_2^\varepsilon,\\ -\Delta_y\left[\frac{\partial v}{\partial p}(y,p)f_2^\varepsilon(t,y,p) - \left(\frac{\partial v}{\partial p}f_2\right) * \phi_\varepsilon(t,y,p)\right]f_1^\varepsilon.\end{aligned}$$

In the following, we set

$$\varphi_i(t,y) = w(y,u_i(t,y)) \quad \text{(i.e., } v(y,\varphi_i(t,y)) = u_i(t,y)\text{)}, \tag{4.2}$$

$$\gamma_i(t,y) = \frac{1}{\frac{\partial v}{\partial p}(y,\varphi_i(t,y))}\left[\nabla_y u_i(t,y) - (\nabla_y v)(y,\varphi_i(t,y))\right] = \nabla_y \varphi_i(t,y). \tag{4.3}$$

We recall that

$$m_i(t,y,p) = |\nabla_y \varphi_i(t,y)|^2 \frac{\partial v}{\partial p}(y,\varphi_i(t,y))\; \delta(p=\varphi_i(t,y)) \tag{4.4}$$

$$= |\gamma_i|^2(t,y)\frac{\partial v}{\partial p}(y,\varphi_i(t,y))\; \delta(p=\varphi_i(t,y)), \tag{4.5}$$

$$\nabla_y f_i(t,y,p) = \eta_i \nabla_y \varphi_i(t,y)\delta(p=\varphi_i(t,y)) \tag{4.6}$$

$$= \eta_i \gamma_i(t,y)\delta(p=\varphi_i(t,y)), \tag{4.7}$$

$$\partial_p f_i = -\eta_i \delta(p=\varphi_i(t,y)) \tag{4.8}$$

for $i=1,2$, where $\eta_1 = 1$ and $\eta_2=-1$.

First, for any test function $\theta = \theta(t,y) \in \mathcal{D}_{\text{per}}([0,+\infty)\times Y)$ such that $\theta \geq 0$, for $\varepsilon < 1$, $R>1$, we claim that

$$\begin{aligned}
&\int_0^\infty \int_{Y\times\mathbb{R}} \left[\frac{\partial m_1^\varepsilon}{\partial p} f_2^\varepsilon - \frac{\partial m_2^\varepsilon}{\partial p} f_1^\varepsilon - 2\frac{\partial v}{\partial p}\nabla_y f_1^\varepsilon \cdot \nabla_y f_2^\varepsilon\right]\theta(t,y)K_R(p)\,dt\,dy\,dp\\
&\leq \int_0^\infty \int_{\mathbb{R}^{2N+2}} \int_{Y\times\mathbb{R}} \phi^\varepsilon(t-s_1,y-y_1,p-\varphi_1)\phi^\varepsilon(t-s_2,y-y_2,p-\varphi_2)\theta(t,y)K_R(p)\\
&\quad\times 2\left[\gamma_1\cdot\gamma_2\left(\frac{\partial v}{\partial p}(y,p) - \sqrt{\frac{\partial v}{\partial p}(y_1,\varphi_1)\frac{\partial v}{\partial p}(y_2,\varphi_2)}\right)\right]\,dy\,dp\,dy_1\,dy_2\,ds_1\,ds_2\,dt\\
&\quad + 2||\theta||_\infty\left[\mu_1(R-1)+\mu_1(-R+1)+\mu_2(R-1)+\mu_2(-R+1)\right].
\end{aligned} \tag{4.9}$$

In the integral of the right-hand side above, γ_i, φ_i are evaluated at (s_i,y_i) $(i=1,2)$.

The derivation of this inequality is rather technical but straightforward if one follows the formal calculations of section 2. Let us focus on the first term of the left-hand side, namely,

$$\begin{aligned}
I_\varepsilon &:= \int_0^\infty \int_{Y\times\mathbb{R}} \frac{\partial m_1^\varepsilon}{\partial p} f_2^\varepsilon \theta(t,y)K_R(p)\,dt\,dy\,dp\\
&= -\int_0^\infty \int_{Y\times\mathbb{R}} m_1^\varepsilon\;\partial_p f_2^\varepsilon\;\theta(t,y)K_R(p)\,dt\,dy\,dp - \int_0^\infty\int_{Y\times\mathbb{R}} m_1^\varepsilon f_2^\varepsilon\;\theta(t,y)\;K_R'(p)\,dt\,dy\,dp\\
&=: -(I_{\varepsilon,1}+I_{\varepsilon,2}).
\end{aligned}$$

Remembering (4.5) and (4.8), we have

$$m_1^\varepsilon(t,y,p) = \int_{\mathbb{R}^{N+1}} |\gamma_1(s_1,y_1)|^2 \frac{\partial v}{\partial p}(y_1,\varphi_1(s_1,y_1))\phi^\varepsilon(t-s_1,y-y_1,p-\varphi_1(s_1,y_1))\,ds_1\,dy_1,$$

$$\partial_p f_2^\varepsilon = \int_{\mathbb{R}^{N+1}} \phi^\varepsilon(t-s_2,y-y_2,p-\varphi_2(s_2,y_2))\,ds_2\,dy_2,$$

and thus

$$\begin{aligned}
I_{\varepsilon,1} &= \int_0^\infty \int_{\mathbb{R}^{2N+2}} \int_{Y\times\mathbb{R}} \phi^\varepsilon(t-s_1,y-y_1,p-\varphi_1)\phi^\varepsilon(t-s_2,y-y_2,p-\varphi_2)\theta(t,y)K_R(p)\\
&\qquad\times\left[\sqrt{\frac{\partial v}{\partial p}(y_1,\varphi_1(s_1,y_1))}\gamma_1(s_1,y_1)\right]^2\,dy\,dp\,dy_1\,dy_2\,ds_1\,ds_2\,dt.
\end{aligned}$$

On the other hand, according to Lemma 4.1 and the assumptions on K_R,

$$\begin{aligned}|I_{\varepsilon,2}| &\leq \int_0^\infty \int_{Y\times\mathbb{R}} m_1^\varepsilon \theta(t,y)|K_R'(p)|\,dt\,dy\,dp\\ &\leq 2||\theta||_\infty \left[\mu_1(R-1)+\mu_1(-R+1)\right].\end{aligned}$$

The two other terms are treated in a similar way; eventually, we use the inequality $-(|a|^2+|b|^2)\leq -2a\cdot b$ for all $a,b\in\mathbb{R}^N$ with $a=\sqrt{v_p(y_1,\varphi_1)}\,\gamma_1$, $b=\sqrt{v_p(y_2,\varphi_2)}\,\gamma_2$, and γ_i, φ_i are evaluated at $(s_i,y_i)\in[0,\infty)\times\mathbb{R}^N$. This concludes the derivation of (4.9).

Next, we investigate the second order terms in r_j^ε, i.e.,

$$\begin{aligned}\int_0^\infty \int_{\mathbb{R}^{N+1}} -\Bigg\{\Delta_y\left[\frac{\partial v}{\partial p}(y,p)f_1^\varepsilon(t,y,p)-\left(\frac{\partial v}{\partial p}f_1\right)*\phi_\varepsilon(t,y,p)\right]f_2^\varepsilon\\ +\Delta_y\left[\frac{\partial v}{\partial p}(y,p)f_2^\varepsilon(t,y,p)-\left(\frac{\partial v}{\partial p}f_2\right)*\phi_\varepsilon(t,y,p)\right]f_1^\varepsilon\Bigg\}\,\theta(t,y)K_R(p)\,dt\,dy\,dp.\end{aligned}$$

Integrating by parts, we obtain for instance

$$\begin{aligned}&\int_0^\infty \int_{Y\times\mathbb{R}} -\Delta_y\left[\frac{\partial v}{\partial p}f_1^\varepsilon-\left(\frac{\partial v}{\partial p}f_1\right)*\phi_\varepsilon\right]f_2^\varepsilon\ \theta(t,y)K_R(p)\,dt\,dy\,dp\\ =&\int_0^\infty \int_{Y\times\mathbb{R}}\left[\frac{\partial v}{\partial p}\nabla_y f_1^\varepsilon-\left(\frac{\partial v}{\partial p}\left(\nabla_y f_1\right)\right)*\phi_\varepsilon\right]\cdot\nabla_y f_2^\varepsilon\ \theta(t,y)K_R(p)\,dt\,dy\,dp\\ &+\int_0^\infty \int_{Y\times\mathbb{R}}\left[\nabla_y\frac{\partial v}{\partial p}f_1^\varepsilon-\left(\left(\nabla_y\frac{\partial v}{\partial p}\right)f_1\right)*\phi_\varepsilon\right]\cdot\nabla_y f_2^\varepsilon\ \theta(t,y)K_R(p)\,dt\,dy\,dp\\ &-\int_0^\infty \int_{Y\times\mathbb{R}}\left[\frac{\partial v}{\partial p}f_1^\varepsilon-\left(\frac{\partial v}{\partial p}f_1\right)*\phi_\varepsilon\right]\nabla_y f_2^\varepsilon\cdot\nabla\theta(t,y)K_R(p)\,dt\,dy\,dp\\ &-\int_0^\infty \int_{Y\times\mathbb{R}}\left[\frac{\partial v}{\partial p}f_1^\varepsilon-\left(\frac{\partial v}{\partial p}f_1\right)*\phi_\varepsilon\right]f_2^\varepsilon\Delta\theta(t,y)K_R(p)\,dt\,dy\,dp\\ =:&\ J_{\varepsilon,1}+J_{\varepsilon,2}+J_{\varepsilon,3}+J_{\varepsilon,4}.\end{aligned}$$

Notice that hypothesis (2.8) ensures that $\frac{\partial^2 v}{\partial p^2}$ exists and is Hölder continuous in y, with locally uniform bounds in p (see Theorem 8.24 in [9]), and hypothesis (2.9) entails that $\nabla_y\frac{\partial v}{\partial p}$ is Hölder continuous in y, with locally uniform bounds in p (see Theorem 8.32 in [9]).

Hence, $\frac{\partial v}{\partial p}$ belongs to $\mathcal{C}(\mathbb{R},\mathcal{C}^\alpha_{\text{per}}(Y))$ for some $\alpha\in(0,1)$. Moreover, thanks to classical H^1 bounds for elliptic equations, we deduce that $\nabla_y\frac{\partial v}{\partial p}$ belongs to $\mathcal{C}(\mathbb{R},L^2(Y))$. Together with identity (4.7), these regularity results easily entail that for all $R>0$,

$$\lim_{\varepsilon\to0} J_{\varepsilon,i}=0\quad\text{for } i=2,3,4.$$

In the following, we denote by $\omega_R:[0,\infty)\to[0,\infty)$ a function such that $\lim_{0^+}\omega_R=0$ and

$$|J_{\varepsilon,2}|+|J_{\varepsilon,3}|+|J_{\varepsilon,4}|\leq\omega_R(\varepsilon)\quad\forall R>0,\ \forall\varepsilon>0.$$

Without loss of generality, we can also assume that the first order terms in r_j^ε are bounded by $\omega_R(\varepsilon)$.

We now focus on the term $J_{\varepsilon,1}$; thanks to identity (4.7), we have

$$J_{\varepsilon,1} = -\int_0^\infty\int_{\mathbb{R}^{2N+2}}\int_{Y\times\mathbb{R}} \phi_\varepsilon(t-s_1, y-y_1, p-\varphi_1)\phi_\varepsilon(t-s_2, y-y_2, p-\varphi_2) \times \left[\frac{\partial v}{\partial p}(y,p) - \frac{\partial v}{\partial p}(y_1,\varphi_1)\right]\gamma_1\cdot\gamma_2\;\theta(t,y)\;K_R(p)\;dy\;dp\;dy_1\;dy_2\;ds_1\;ds_2\;dt,$$

and γ_i, φ_i are evaluated at t_i, s_i. Gathering all the terms, we infer

$$\begin{aligned}
&\int_0^\infty\int_{Y\times\mathbb{R}}\left[\frac{\partial m_1^\varepsilon}{\partial p}f_2^\varepsilon - \frac{\partial m_2^\varepsilon}{\partial p}f_1^\varepsilon - 2\frac{\partial v}{\partial p}\nabla_y f_1^\varepsilon\cdot\nabla_y f_2^\varepsilon + r_1^\varepsilon f_2^\varepsilon + r_2^\varepsilon f_1^\varepsilon\right]\theta K_R\\
&\le \int \phi_\varepsilon(t-s_1, y-y_1, p-\varphi_1)\phi_\varepsilon(t-s_2, y-y_2, p-\varphi_2)\theta(t,y)K_R(p)\gamma_1\cdot\gamma_2\\
&\quad\times\left(\frac{\partial v}{\partial p}(y_1,\varphi_1) + \frac{\partial v}{\partial p}(y_2,\varphi_2) - 2\sqrt{\frac{\partial v}{\partial p}(y_1,\varphi_1)\frac{\partial v}{\partial p}(y_2,\varphi_2)}\right)dy\;dp\;dy_1\;dy_2\;ds_1\;ds_2\;dt\\
&\quad + 2\|\theta\|_\infty\left[\mu_1(R-1)+\mu_1(-R+1)+\mu_2(R-1)+\mu_2(-R+1)\right] + C\omega_R(\varepsilon)\\
&\le \int_0^\infty\int_{\mathbb{R}^{2N+2}}\int_{Y\times\mathbb{R}}\phi_\varepsilon(t-s_1, y-y_1, p-\varphi_1)\phi_\varepsilon(t-s_2, y-y_2, p-\varphi_2)\theta(t,y)K_R(p)\\
&\quad\times\gamma_1\cdot\gamma_2\left[\sqrt{\frac{\partial v}{\partial p}(y_1,\varphi_1)} - \sqrt{\frac{\partial v}{\partial p}(y_2,\varphi_2)}\right]^2 dy\;dp\;dy_1\;dy_2\;ds_1\;ds_2\;dt\\
&\quad + 2\|\theta\|_\infty\left[\mu_1(R-1)+\mu_1(-R+1)+\mu_2(R-1)+\mu_2(-R+1)\right] + C\omega_R(\varepsilon).
\end{aligned}$$

The function $\frac{\partial v}{\partial p}$ belongs to $W^{1,\infty}_{\mathrm{per,loc}}(Y\times\mathbb{R})$ and is bounded away from zero on bounded subsets of $Y\times\mathbb{R}$. As a consequence, there exists a constant $C_R>0$, depending on R, such that for all $\varepsilon>0$,

$$\left|\sqrt{\frac{\partial v}{\partial p}(y_1,\varphi_1)} - \sqrt{\frac{\partial v}{\partial p}(y_2,\varphi_2)}\right| \le C_R\,\varepsilon$$

whenever $|y_1-y_2|\le 2\varepsilon$, $|\varphi_1-\varphi_2|\le 2\varepsilon$, and $|\varphi_1|,|\varphi_2|\le R$. We set

$$\phi(t,x,p) := \zeta_1(t)\,\zeta_2(x)\,\zeta_3(p).$$

Performing changes of variables in the integral on the right-hand side, we obtain

$$\begin{aligned}
&\int_0^\infty\int_{Y\times\mathbb{R}}\left[\frac{\partial m_1^\varepsilon}{\partial p}f_2^\varepsilon - \frac{\partial m_2^\varepsilon}{\partial p}f_1^\varepsilon - 2\frac{\partial v}{\partial p}\nabla_y f_1^\varepsilon\cdot\nabla_y f_2^\varepsilon + r_1^\varepsilon f_2^\varepsilon + r_2^\varepsilon f_1^\varepsilon\right]\theta K_R\\
&\le C_R\,\varepsilon^2\int_0^\infty\int_{\mathbb{R}^{2N+2}}\int_{Y\times\mathbb{R}}\phi_\varepsilon(t-s_1, y-y_1, p-\varphi_1)\phi_\varepsilon(t-s_2, y-y_2, p-\varphi_2)\\
&\quad\times\theta(t,y)K_R(p)\gamma_1\cdot\gamma_2\;dy\;dp\;dy_1\;dy_2\;ds_1\;ds_2\;dt\\
&\quad + 2\|\theta\|_\infty\left[\mu_1(R-1)+\mu_1(-R+1)+\mu_2(R-1)+\mu_2(-R+1)\right] + C\omega_R(\varepsilon)\\
&\le C_R\,\varepsilon\int_0^\infty\int_{\mathbb{R}^{2N+2}}\int_{Y\times\mathbb{R}}\theta(t,y)K_R(p+\varepsilon\varphi_1(t-\varepsilon s_1, y-\varepsilon y_1))\\
&\quad\times\phi(s_1,y_1,p)\phi\left(s_2,y_2,p+\frac{\varphi_1(t-\varepsilon s_1,y-\varepsilon y_1)-\varphi_2(t-\varepsilon s_2, y-\varepsilon y_2)}{\varepsilon}\right)\\
&\quad\times\gamma_1(t-\varepsilon s_1, y-\varepsilon y_1)\cdot\gamma_2(t-\varepsilon s_2, y-\varepsilon y_2)\;dy\;dp\;dy_1\;dy_2\;ds_1\;ds_2\;dt\\
&\quad + 2\|\theta\|_\infty\left[\mu_1(R-1)+\mu_1(-R+1)+\mu_2(R-1)+\mu_2(-R+1)\right] + C\omega_R(\varepsilon)\\
&\le C_R\,\varepsilon + 2\|\theta\|_\infty\left[\mu_1(R-1)+\mu_1(-R+1)+\mu_2(R-1)+\mu_2(-R+1)\right] + C\omega_R(\varepsilon),
\end{aligned}$$

so that eventually, for all test functions $\theta(t,y)\in\mathcal{D}_{\rm per}([0,\infty)\times\mathbb{R}^N)$ such that $\theta\geq 0$,

(4.10)
$$\limsup_{R\to\infty}\limsup_{\varepsilon\to 0}\int_0^\infty\int_{Y\times\mathbb{R}}\left[\frac{\partial m_1^\varepsilon}{\partial p}f_2^\varepsilon-\frac{\partial m_2^\varepsilon}{\partial p}f_1^\varepsilon-2\frac{\partial v}{\partial p}\nabla_y f_1^\varepsilon\cdot\nabla_y f_2^\varepsilon+r_1^\varepsilon f_2^\varepsilon+r_2^\varepsilon f_1^\varepsilon\right]$$
$$\times\,\theta(t,y)K_R(p)dt\,dy\,dp\leq 0.$$

Consequently, in the limit, we obtain for any test function $\theta(t,y)\in\mathcal{D}_{\rm per}([0,\infty)\times\mathbb{R}^N)$ such that $\theta\geq 0$

$$\int_0^\infty\int_Y (u_1-u_2)_+\partial_t\theta(t,y)+\mathbf{1}_{u_1>u_2}\left[A(y,u_1)-A(y,u_2)\right]\cdot\nabla_y\theta(t,y)\,dtdy$$
$$\geq\int_Y (u_1(t=0,y)-u_2(t=0,y))_+\,\theta(t=0,y)\,dy,$$

which means exactly that

$$\partial_t(u_1-u_2)_+ +\mathrm{div}_y\left[1_{u_1>u_2}\left(A(y,u_1)-A(y,u_2)\right)\right]\leq 0 \tag{4.11}$$

in the sense of distributions.

Integrating this last inequality on $(0,T)\times Y$ for any $T>0$ yields

$$||(u_1(t=T)-u_2(t=T))_+||_{L^1(Y)}\leq ||(u_1(t=0)-u_2(t=0))_+||_{L^1(Y)}. \tag{4.12}$$

Hence the derivation of (2.10) and (2.12) is complete; there remains only to prove Lemma 4.1. The argument goes along the same lines as Lemma 4.2.1 in [17].

Proof of Lemma 4.1. Notice that (4.1) is equivalent to

$$\frac{\partial}{\partial t}\left(\frac{\partial v}{\partial p}f_j\right)*\phi^\varepsilon+\frac{\partial}{\partial y_i}\left(\tilde{a}_i f_j\right)*\phi^\varepsilon-\Delta_y\left(\frac{\partial v}{\partial p}f_j\right)*\phi^\varepsilon=\eta_j\frac{\partial m_j^\varepsilon}{\partial p}. \tag{4.13}$$

Thus we focus on the derivation of (4.13) for f_1; let $(t,y,p)\in[0,\infty)\times Y\times\mathbb{R}$ be arbitrary. Following [17], one is tempted to consider the test function

$$(s,z,q)\mapsto\phi^\varepsilon(t-s,y-z,p-q)=\frac{1}{\varepsilon^{N+2}}\zeta_1\left(\frac{t-s}{\varepsilon}\right)\zeta_2\left(\frac{y-z}{\varepsilon}\right)\zeta_3\left(\frac{p-q}{\varepsilon}\right)$$

in Definition 2.3 of kinetic solutions. However, such a test function is not periodic in z, as required in Definition 2.3; but the support of $z\mapsto\zeta_2\left((y-z)/\varepsilon\right)$ is a subset of $\bar{B}(y,\varepsilon)$, the closed ball centered on y and of radius ε. Thus, for $0<\varepsilon<1/2$,

$$\mathrm{supp}\,\zeta_2\left((y-\cdot)/\varepsilon\right)\subset\bar{B}(y,\varepsilon)\subset\Pi_{i=1}^N\left(y_i-\frac{1}{2},y_i+\frac{1}{2}\right).$$

Hence for $\varepsilon<1/2$, we can extend $\zeta_2\left((y-\cdot)/\varepsilon\right)$ by periodicity on $\mathbb{R}^N$; the function thus obtained is denoted by $\tilde{\zeta}_{y,\varepsilon}$ and belongs to $\mathcal{C}^\infty_{\rm per}(\mathbb{R}^N)$.

Now, for fixed $(t, y, p) \in [0, \infty) \times Y \times \mathbb{R}$, we define the test function

$$\psi : (s, z, q) \mapsto \frac{1}{\varepsilon^{N+2}} \zeta_1 \left(\frac{t-s}{\varepsilon} \right) \tilde{\zeta}_{y,\varepsilon}(z) \zeta_3 \left(\frac{p-q}{\varepsilon} \right).$$

By construction, ψ belongs to $\mathcal{D}_{\rm per}([0, \infty) \times Y \times \mathbb{R})$. Thus ψ is an admissible test function, and according to Definition 2.3,

$$\int_0^\infty \int_{Y \times \mathbb{R}} f_1(s, z, q) \frac{\partial v(z, q)}{\partial q} \left\{ \partial_s \psi + a_i(z, v(z, q)) \partial_{z_i} \psi + \Delta_z \psi \right\} ds\, dz\, dq$$
$$= \int_0^\infty \int_{Y \times \mathbb{R}} m(s, z, q) \partial_q \psi(s, z, q)\ dsdzdq - \int_{Y \times \mathbb{R}} \mathbf{1}_{u_0(z) > v(z,q)} \psi(0, z, q) \frac{\partial v(z, q)}{\partial q} dzdq.$$

First, notice that since $\operatorname{supp} \zeta_1 \subset [-1, 0]$, we have $\psi(0, z, q) = 0$ for all z, q. Moreover, since f_1 and ψ are Y-periodic in their second variable, we have, for instance, setting $Y_y = \Pi_{i=1}^N (y_i - 1/2, y_i + 1/2) = y - e + Y$, where $e := (1/2, \ldots, 1/2) \in \mathbb{R}^N$,

$$\int_0^\infty \int_{Y \times \mathbb{R}} f_1 \frac{\partial v}{\partial q} \partial_s \psi = \int_0^\infty \int_{Y_y \times \mathbb{R}} f_1 \frac{\partial v}{\partial q} \partial_s \psi.$$

And when $z \in Y_y$, $\psi(s, z, q) = \phi^\varepsilon(t-s, y-z, p-q)$ by definition. Thus, using once again the assumption on the support of ζ_2,

$$\begin{aligned}
&\int_0^\infty \int_{Y \times \mathbb{R}} f_1(s, z, q) \frac{\partial v}{\partial q}(z, q) \partial_s \psi(s, z, q) ds\, dz\, dq \\
&= \int_0^\infty \int_{Y_y \times \mathbb{R}} f_1(s, z, q) \frac{\partial v}{\partial q}(z, q) \partial_s \phi^\varepsilon(t-s, y-z, p-q) ds\, dz\, dq \\
&= \int_0^\infty \int_{\mathbb{R}^N \times \mathbb{R}} f_1(s, z, q) \frac{\partial v}{\partial q}(z, q) \partial_s \phi^\varepsilon(t-s, y-z, p-q) ds\, dz\, dq \\
&= -\int_0^\infty \int_{\mathbb{R}^N \times \mathbb{R}} f_1(s, z, q) \frac{\partial v}{\partial q}(z, q) \partial_t \phi^\varepsilon(t-s, y-z, p-q) ds\, dz\, dq \\
&= -\partial_t \left[(f_1 v_p) * \phi^\varepsilon \right](t, y, p).
\end{aligned}$$

The other terms are treated in a similar way; we obtain

$$\int_0^\infty \int_{Y \times \mathbb{R}} f_1(s, z, q) \tilde{a}_i(z, q) \partial_{z_i} \psi(s, z, q)\ ds\, dz\, dq$$
$$= \int_0^\infty \int_{\mathbb{R}^N \times \mathbb{R}} f_1(s, z, q) \tilde{a}_i(z, q) \partial_{z_i} \phi^\varepsilon(t-s, y-z, p-q)\ ds\, dz\, dq = -\partial_{y_i} \left[f_1 \tilde{a}_i \right] * \phi^\varepsilon(t, y, p),$$

$$\int_0^\infty \int_{Y \times \mathbb{R}} f_1(s, z, q) v_q(z, q) \Delta_z \psi(s, z, q) ds\, dz\, dq = \Delta_y \left[(f_1 v_p) * \phi^\varepsilon \right](t, y, p),$$

$$\int_0^\infty \int_{Y \times \mathbb{R}} m(s, z, q) \partial_q \psi(s, z, q)\ ds\, dz\, dq = -\partial_p m_1^\varepsilon(t, y, p).$$

There remains to derive the bound on m_1^ε: by definition,

$$\begin{aligned}
&\int_0^\infty \int_Y m_1^\varepsilon(t,y,p)\,dt\,dy \\
&= \int_0^\infty \int_Y \int_{\mathbb{R}^{N+2}} m_1(s,z,q)\phi^\varepsilon(t-s,y-z,p-q)ds\,dz\,dq\,dt\,dy \\
&= \int_Y \int_{\mathbb{R}^{N+1}} \int_0^\infty \int_0^\infty m_1(s,z,q)\phi^\varepsilon(t-s,y-z,p-q)\,dt\,ds\,dz\,dq\,dy \\
&= \int_Y \int_{\mathbb{R}^{N+1}} \int_0^\infty \int_{-s}^\infty m_1(s,z,q)\phi^\varepsilon(u,y-z,p-q)\,du\,ds\;\,dz\,dq\,dy \\
&\leq \int_Y \int_{\mathbb{R}^{N+1}} \int_0^\infty \int_{\mathbb{R}} m_1(s,z,q)\phi^\varepsilon(u,y-z,p-q)\,du\,ds\;\,dz\,dq\,dy \\
&\leq \frac{1}{\varepsilon^{N+1}} \int_Y \int_{\mathbb{R}^{N+1}} \int_0^\infty m_1(s,z,q)\zeta_2\left(\frac{y-z}{\varepsilon}\right)\zeta_3\left(\frac{p-q}{\varepsilon}\right)\,ds\;\,dz\,dq\,dy.
\end{aligned}$$

Then, with the same notation as earlier,

$$\begin{aligned}
\int_Y \int_{\mathbb{R}^N} m_1(s,z,q)\zeta_2\left(\frac{y-z}{\varepsilon}\right)\,dz\,dy &= \int_Y dy\left(\int_{Y_y} dz\; m_1(s,z,q)\zeta_2\left(\frac{y-z}{\varepsilon}\right)\right) \\
&= \int_{Y\times Y} m_1(s,y+y'-e,q)\zeta_2\left(\frac{-y'+e}{\varepsilon}\right)dy\,dy' \\
&= \int_{Y\times Y} m_1(s,y,q)\zeta_2\left(\frac{-y'+e}{\varepsilon}\right)dy\,dy' \\
&= \left(\int_Y m_1(s,y,q)\,dy\right)\times\left(\int_{\mathbb{R}^N}\zeta_2\left(\frac{-y'}{\varepsilon}\right)\,dy'\right).
\end{aligned}$$

In the penultimate step, we have used the periodicity of m_1.

Thus

$$\begin{aligned}
\int_0^\infty \int_Y m_1^\varepsilon(t,y,p)\,dt\,dy &\leq \frac{1}{\varepsilon}\int_{\mathbb{R}}\int_{z\in Y}\int_0^\infty m_1(s,z,q)\zeta_3\left(\frac{p-q}{\varepsilon}\right)\,ds\;\,dz\,dq \\
&\leq \frac{1}{\varepsilon}\int_{\mathbb{R}} \mu_1(q)\zeta_3\left(\frac{p-q}{\varepsilon}\right)\,dq \\
&\leq \int_{-1}^1 \mu_1(p-\varepsilon q)\zeta_3(q)\,dq.
\end{aligned}$$

The monotonicity of μ_1 yields the desired result.

BOUNDS ON ENERGY AND HELICITY DISSIPATION RATES OF APPROXIMATE DECONVOLUTION MODELS OF TURBULENCE*

WILLIAM LAYTON†

Abstract. We consider a family of high-accuracy, approximate deconvolution models of turbulence. For body force driven turbulence, we prove directly from the model's equations of motion the following bounds on the model's time-averaged energy dissipation rate $\langle \varepsilon_{ADM} \rangle$ and helicity dissipation rate $\langle \gamma_{ADM}(w) \rangle$:

$$\langle \varepsilon_{ADM} \rangle \leq 2\frac{U^3}{L} + \mathrm{Re}^{-1}\frac{U^3}{L}\left(1 + \left(\frac{\delta}{L}\right)^2\right) \quad \text{and}$$

$$|\langle \gamma_{ADM}(w) \rangle| \leq \frac{U^3}{L^2} + \sqrt{2}\,\mathrm{Re}^{-\frac{1}{2}}\left(1 + \frac{\delta^2}{L^2}\right)^{\frac{1}{2}}\frac{U^3}{L^2} + \mathrm{Re}^{-1}\left(1 + \frac{\delta^2}{L^2}\right)\frac{U^3}{L^2},$$

where U, L are global velocity and length scales, respectively, and δ is the large eddy simulation filter radius. We also give a partial result on the helicity dissipation rate of solutions of the Navier–Stokes equations.

Key words. energy dissipation rate, helicity, helicity dissipation rate, large eddy simulation, turbulence, deconvolution

1. Introduction.

Turbulent flows consist of complex, interacting three-dimensional (3d) eddies of various sizes down to the Kolmogorov microscale, $\eta = O(\mathrm{Re}^{-3/4})$ in $3d$. A direct numerical simulation of the persistent eddies in a $3d$ flow thus requires roughly $O(\mathrm{Re}^{+9/4})$ mesh points in space per time step. Therefore, direct numerical simulation of turbulent flows is often not computationally economical or even feasible. On the other hand, the largest structures in the flow (containing most of the flow's energy) are responsible for much of the mixing and most of the flow's momentum transport. One promising approach to predicting a flow's large structures is called *large eddy simulation* (LES). LES seeks to model and predict the evolution of local, spatial averages over a user-selected length scale δ. The correct treatment by an LES model of fundamental flow quantities is critical to predicting correctly a flow's large structures.

The first fundamental integral invariant of the Euler equations is kinetic energy

$$E(u)(t) := \frac{1}{|\Omega|}\int_\Omega \frac{1}{2} u \cdot u dx.$$

Inviscid conservation of kinetic energy leads (by the reasoning of Richardson and Kolmogorov) to the kinetic energy cascade for turbulent flows which has important and universal features. If the LES model does not dissipate enough energy, the statistics of any energy cascade predicted by the model can be wrong, and there can be an accumulation of energy around the smallest resolved scales (i.e., wiggles in the model's

predicted velocity). The energy dissipation rates in various LES models are adjusted in various ways, such as using mixed models (i.e., adding eddy viscosity) and picking the parameters introduced (e.g., Lilly [L67]) to match the energy dissipation rate of homogeneous, isotropic turbulence. On the other hand, parameter-free models have great advantages, and understanding their important statistics, such as their energy dissipation rate, is critical to advancing their reliability.

The second fundamental integral invariant of the $3d$ Euler equations (discovered in 1961 by Moreau [M61]) is helicity or streamwise vorticity

$$H(u)(t) := \frac{1}{|\Omega|}\int_\Omega u\cdot(\nabla\times u)dx.$$

The helicity of a flow vanishes if and only if a flow has a reflectional symmetry and has the interpretation as the degree to which vortex lines are knotted and intertwined (Moffatt [M84], Moffatt and Tsoniber [MT92]). The interaction of helicity and energy is thought to play a key role in organizing flows. However, much less is known about helicity than energy, and its mathematical study is more difficult than that of energy because more derivatives are involved and neither H nor γ has one sign. (The best current result concerning helicity of weak solutions of the Navier–Stokes equations (NSE) appears to be Foias, Hoang, and Nicolenko [FHN06], in which it is proven that if the body force is potential, then $H(u)(T)\to 0$ as $T\to\infty$ for $\nu>0$.) By the same reasoning as energy, a similarity theory of coupled helicity and energy cascades with universal statistics has also been developed by Brissaud et al. [BFL73], Andre and Lesieur [AL77], Chen, Chen, and Eyink [CCE03], and Chen et al. [CCEH03], by Ditlevsen and Giuliani [DG01a], [DG01b] (and observed by Bourne and Orszag [BO97]) in turbulent flows and for the family of approximate deconvolution model (ADM) turbulence models in [LMNR06]. Helical modes where both signs exist are fundamental to the analysis of helicity cascades. In this theory the time-averaged helicity dissipation rate plays a key role analogous to that of the time-averaged energy dissipation rate. In the inertial range (after suitable averaging), the only quantities that distinguish one flow from another in these two cascades are their energy and helicity dissipation rates. Thus, a model prediction of energy and helicity dissipation rates is critical for evaluating a model's physical fidelity.

Herein we consider one family of high-accuracy, parameter-free models, ADMs, and bound the ADM time-averaged energy and helicity dissipation rates. The bounds derived mirror both dissipation rates of the underlying solution of the NSE (in the limit $\delta\to 0$) and the estimates of it derived in [LN07b], [LMNR06] by dimensional analysis.

To begin, consider the NSE in a periodic box in $\mathbb{R}^3$, $\Omega=(0,L_\Omega)^3$:

$$\begin{gathered} u_t+u\cdot\nabla u-\nu\triangle u+\nabla p=f(x) \quad \text{in } \Omega=(0,L_\Omega)^3,\ t>0,\\ \nabla\cdot u=0 \quad \text{in } (0,L_\Omega)^3, \end{gathered} \tag{1.1}$$

subject to periodic (with zero mean) conditions

$$\begin{gathered} u(x+L_\Omega e_j,t)=u(x,t), \quad j=1,2,3, \quad \text{and}\\ \int_\Omega \phi dx=0 \ \text{ for } \ \phi=u,\ u_0,\ f,\ p. \end{gathered} \tag{1.2}$$

We suppose throughout that the data $u_0(x), f(x)$ are smooth and satisfy

$$\nabla\cdot u_0=0 \quad \text{and } \nabla\cdot f=0.$$

Many averaging operators are used in LES; see, e.g., Sagaut [S01], John [J04], and Berselli, Iliescu, and Layton [BIL06]. Herein we consider a *differential filter* (Germano [Ger86]) associated with length scale $\delta > 0$ related to the Yoshida regularization (and sometimes called a *Helmholz filter* in the alpha-model literature, e.g., Cheskidov et al. [CHOT05]) defined as follows. Given $\phi(x)$, $\overline{\phi(x)}$ is the unique L-periodic solution of

$$A\overline{\phi} := -\delta^2 \triangle\overline{\phi} + \overline{\phi} = \phi \text{ in } \Omega.$$

Averaging the NSE (i.e., applying A^{-1} to (1.1)) gives the exact space-filtered NSE for $\overline{u}$

$$\begin{aligned} \overline{u}_t + \overline{u \cdot \nabla u} - \nu\triangle\overline{u} + \nabla\overline{p} = \overline{f}(x) \text{ and} \\ \nabla \cdot \overline{u} = 0. \end{aligned}$$

This is not closed since (noting that $\overline{u \cdot \nabla u} = \nabla \cdot (\overline{uu})$)

$$\overline{u\,u} \;\neq \overline{u}\,\overline{u}.$$

There are many closure models used in LES; see Sagaut [S01], John [J04], Lesieur, Metais, and Comte [LMC05], and Berselli, Iliescu, and Layton [BIL06] for surveys. Approximate deconvolution models, studied herein, are used, with success, in many simulations of turbulent flows, e.g., the works of Adams, Stolz, and Kleiser [AS01], [AS02], [SA99], [SAK01a], [SAK01b], [SAK02]. They are among the most accurate of turbulence models, and one of the few turbulence models for which a mathematical confirmation of their effectiveness is known [LL06b] and [DE06]. Briefly, an approximate deconvolution operator (constructed in section 3) denoted by D_N is an operator satisfying

$$\phi = D_N(\overline{\phi}) + O(\delta^{2N+2}) \quad \text{for smooth } \phi.$$

Since $D_N\overline{u}$ approximates u to accuracy $O(\delta^{2N+2})$ in the smooth flow regions, it is justified to consider the closure approximation:

$$\overline{uu} \simeq \overline{D_N\overline{u}D_N\overline{u}} + O(\delta^{2N+2}). \tag{1.3}$$

Using this closure approximation, the resulting family of ADMs is given by[1]

$$\begin{aligned} w_t + \nabla \cdot (\overline{D_N w\; D_N w}) - \nu\triangle w + \nabla q = \overline{f}(x), \\ \nabla \cdot w = 0, N = 0, 1, 2, \ldots. \end{aligned} \tag{1.4}$$

As a special case, $D_0\overline{u} = \overline{u} + O(\delta^2)$ gives the zeroth order ADM:

$$w_t + \nabla \cdot (\overline{w\; w}) - \nu\triangle w + \nabla q = \overline{f}(x) \text{ and } \nabla \cdot w = 0.$$

We consider two important flow statistics: the *time-averaged energy* and *helicity dissipation rates*. The energy dissipation rate is a fundamental statistic in experimental and theoretical studies of turbulence, e.g., Sreenivasan [S84], [S98], Bourne and Orszag [BO97], Pope [P00], Frisch [Frisch], and Lesieur [Les97]. In the theory of turbulent energy cascades, the time-averaged energy dissipation is the only quantity

[1]In practical computations with ADMs an additional time relaxation term $\chi\,(w - \overline{w})$ has often been added to (1.4). This term can be used as a numerical regularization in any model and is studied in [LN07a], [ELN07], [AS02], [P06], and [Gue04].

that distinguishes the inertial range of one flow from another. In the early 1990s Constantin and Doering [CD92] (see also Doering and Gibbon [DG95]) established a direct link between the phenomenology of energy dissipation and that predicted for shear flows directly from the NSE. This work builds on the work of Busse [B78] and Howard [H72] (and others) and has developed in many important directions, including Childress, Kerswell, and Gilbert [CKG01], Kerswell [K98], and Wang [W97] (shear flows) and Foias [F97], Doering and Foias [DF02], and Cheskidov, Doering, and Petrov [CDP07] (body force driven flows). Because of the greater difficulties of studying helicity directly from the NSE, this connection remains open for helicity dissipation rates; see section 5.1.

Let $\langle\cdot\rangle$ denote long time averaging (defined in section 2). K41 phenomenology (e.g., Frisch [Frisch], Muschinski [Mus97], and Pope [P00]) in [LN07b] suggests the scaling of the energy dissipation rate $\langle\varepsilon_{ADM}\rangle$

$$\langle\varepsilon_{ADM}\rangle \approx \frac{U^3}{L}\left(1+\frac{\delta^2}{L^2}\right).$$

In section 4, we prove directly from the equations of motion (1.4) that the energy dissipation rate of the model satisfies

$$\langle\varepsilon_{ADM}\rangle \leq 2\frac{U^3}{L} + \mathrm{Re}^{-1}\frac{U^3}{L}\left(1+\left(\frac{\delta}{L}\right)^2\right).$$

Here U, L denote natural velocity and length scales, respectively, associated with the largest scales of the model (1.4), defined precisely in section 2.1.

The time-averaged helicity dissipation rate is defined in an analogous way. For the NSE, it is known[2] that the helicity satisfies the balance equation

$$H(u)(T) + \int_0^T \gamma(u)(t)dt = H(u_0) + \int_0^T \frac{1}{|\Omega|}(\nabla\times f, u)dt. \tag{1.5}$$

The term $\gamma(u)$ is thus taken to be the helicity dissipation rate and is given by

$$\gamma(u) := \frac{\nu}{|\Omega|}(\nabla\times u, \nabla\times\nabla\times u). \tag{1.6}$$

The helicity dissipation rate is defined several ways in the literature on the phenomenology of helicity cascades due to possible coupling with energy dissipation rates. Herein we use the above definition for the NSE, which is natural from the point of view of the above helicity balance equation. For the model (1.4), we use the definition of the model helicity dissipation rate $\gamma_{ADM}(w)$ that comes from the model's helicity balance in the same way as above for the NSE. In section 5, we prove that the model's helicity dissipation rate $|\langle\gamma_{ADM}(w)\rangle|$ satisfies

$$|\langle\gamma_{ADM}(w)\rangle| \leq \frac{U^3}{L^2} + \sqrt{2}\,\mathrm{Re}^{-\frac{1}{2}}\left(1+\frac{\delta^2}{L^2}\right)^{\frac{1}{2}}\frac{U^3}{L^2} + \mathrm{Re}^{-1}\left(1+\frac{\delta^2}{L^2}\right)\frac{U^3}{L^2}.$$

This estimate of $|\langle\gamma_{ADM}(w)\rangle|$ is consistent, as $\delta\to 0$, with the dimensional analysis estimate of $\frac{U^3}{L^2}$ for the NSE.

[2] Derived formally by multiplication by the vorticity, integration over the flow domain and integration by parts.

The higher order models give much more accurate predictions of flow quantities. However, the mathematical structures of the zeroth order model and the entire family of ADMs are closely related. Proofs will be given in detail for the zeroth order model and the corresponding proofs (which involve only additional subscripts) for the Nth ADM sketched. Aside from the family of ADMs, we also give a partial result on the helicity dissipation rate for the NSE and delineate why the technique (just) fails to isolate the NSE's helicity dissipation rate. Thus, it seems likely that the techniques used herein can be used to prove parallel estimates of energy and helicity dissipation rates for other models which have more regular solutions than the NSE and known helicity balance equations, such as the alpha model.

2. Notation and preliminaries. The long time average of a function $\phi(t)$ is defined, following [DF02], by

$$\langle \phi \rangle := Lim_{T\to\infty} \frac{1}{T}\int_0^T \phi(t)dt,$$

where Lim denotes a generalized limit. (It can also be defined by a limit superior which lengthens several proofs.)

First consider the zeroth order model. With $|\Omega|$ the volume of the flow domain, the scale of the body force and the large scale velocity are defined, respectively, by

$$F := \left(\frac{1}{|\Omega|}\int_\Omega |f(x)|^2 dx\right)^{\frac{1}{2}} \text{ and}$$
$$U := \left\langle \frac{1}{|\Omega|}\int_\Omega |w(x,t)|^2 dx\right\rangle^{\frac{1}{2}}.$$

Let $||\cdot||, (\cdot,\cdot)$ denote the usual $L^2(\Omega)$ norm and inner product, respectively (other norms are explicitly indicated by a subscript). The global length scale associated with the power input of the large scales, i.e., with $f(x)$, is

$$L := \min\left\{ L_\Omega, \frac{F}{||\nabla f||_{L^\infty(\Omega)}}, \frac{F}{(\frac{1}{|\Omega|}||\nabla f||^2)^{\frac{1}{2}}}, \frac{F}{(\frac{1}{|\Omega|}||\nabla\times f||^2)^{\frac{1}{2}}}, \frac{F^{\frac{1}{2}}}{(\frac{1}{|\Omega|}||\triangle f||^2)^{\frac{1}{4}}}\right\}.$$

It is easy to check that L has units of length and satisfies the inequalities:

$$\begin{aligned} &||\nabla f||_{L^\infty} \le \frac{F}{L},\\ &\frac{1}{|\Omega|}\int_\Omega |\nabla f(x)|^2 dx \le \frac{F^2}{L^2}, \frac{1}{|\Omega|}\int_\Omega |\nabla\times f(x)|^2 dx \le \frac{F^2}{L^2}, \quad \text{and}\\ &\frac{1}{|\Omega|}\int_\Omega |\triangle f(x)|^2 dx \le \frac{F^2}{L^4}. \end{aligned} \tag{2.1}$$

The kinetic viscosity is denoted ν, and the associated global Reynolds number is $\mathrm{Re} := \frac{LU}{\nu}$.

The energy dissipation rate induced by the model depends on the precise form of the model's kinetic energy balance. Let w denote the solution of the zeroth order model. The appropriate definitions (see Proposition 3.1, Remark 4.1, (3.2)–(3.5), as well as [LL03], [LL06a], [LL06b]) for the zeroth order model are

$$\varepsilon_{ADM-0}(w)(t) = \frac{\nu}{L^3}\{||\nabla w(t)||^2 + \delta^2||\triangle w(t)||^2\} \text{ and}$$
$$\langle \varepsilon_{ADM-0}\rangle := \langle \varepsilon_{ADM-0}(w)(t)\rangle.$$

Before introducing the notation for the general case we must first define the van Cittert approximate deconvolution operators.

2.1. Approximate deconvolution operators. The filtering or convolution operator $u \to \overline{u}$ is a bounded map: $L^2(\Omega) \to L^2(\Omega)$. If (as in the case we study) it is smoothing, its inverse cannot be bounded due to small divisor problems. An approximate deconvolution operator D_N is an approximate inverse $\overline{u} \to D_N(\overline{u}) \approx u$, (e.g., [Geu97]) which

- is a bounded operator on $L^2(\Omega)$,
- approximates u in some useful (typically asymptotic) sense, and
- satisfies other conditions necessary for the application at hand.

The deconvolution operator we consider was studied by van Cittert in 1931, e.g., Bertero and Boccacci [BB98], and its use in LES pioneered by Adams, Kleiser, and Stolz [AS01], [SA99], [AS02], [SAK01a], [SAK01b], [SAK02]. The Nth van Cittert approximate deconvolution operator D_N is defined by N steps of Picard iteration [BB98] for the fixed point problem:

$$\text{Given } \overline{u}, \text{ solve } u = u + \{\overline{u} - A^{-1}u\} \text{ for } u.$$

ALGORITHM 2.1 (van Cittert approximate deconvolution operator). *$u_0 = \overline{u}$, for $n = 1, 2, \ldots, N-1$, perform $u_{n+1} = u_n + \{\overline{u} - A^{-1}u_n\}$. Define $D_N\overline{u} := u_N$.*

By eliminating the intermediate steps, the Nth deconvolution operator D_N is given explicitly by

$$D_N\phi := \sum_{n=0}^{N} (I - A^{-1})^n \phi. \tag{2.2}$$

For example, the approximate deconvolution operators corresponding to $N = 0, 1, 2$ are

$$D_0\overline{u} = \overline{u},$$
$$D_1\overline{u} = 2\overline{u} - \overline{\overline{u}},$$
$$D_2\overline{u} = 3\overline{u} - 3\overline{\overline{u}} + \overline{\overline{\overline{u}}}.$$

DEFINITION 2.1. *The deconvolution-weighted inner product and norm $(\cdot,\cdot)_N$ and $||\cdot||_N$ are, respectively,*

$$(u, v)_N := (u, D_N v)\,, \quad ||u||_N := (u, u)_N^{\frac{1}{2}}.$$

LEMMA 2.2. *Consider the approximate deconvolution operator*

$$D_N : L^2(\Omega) \to L^2(\Omega).$$

D_N is a bounded, self-adjoint, positive-definite operator and satisfies

$$||\phi||^2 \le ||\phi||_N^2 \le (N+1)||\phi||^2 \ \forall \phi \in L^2(\Omega).$$

Proof. D_N is a function of the bounded, self-adjoint operator A^{-1} and is thus bounded and self-adjoint. By the spectral mapping theorem we have

$$\lambda(D_N) = \sum_{n=0}^{N} \lambda(I - A^{-1})^n = \sum_{n=0}^{N} (1 - \lambda(A^{-1}))^n, \text{ and}$$
$$0 < \lambda(A^{-1}) \le 1 \text{ by the definition of operator } A.$$

Thus, $1 \le \lambda(D_N) \le N+1$. Since D_N is a self-adjoint operator, this proves positive definiteness and the above equivalence of norms. □%newpage

3. Kinetic energy balance of ADM turbulence models. To see the mathematical key to the estimates of energy and helicity dissipation rates, we first recall from [LL03], [DE06] (see also [LL06a], and [MM06] for the more difficult case of no-slip boundary conditions) the energy equality for the ADM (1.4).

PROPOSITION 3.1. *If w is a weak or strong solution*[3] *of* (1.4), *w satisfies*

$$\frac{1}{2}[||w(T)||_N^2 + \delta^2||\nabla w(T)||_N^2] + \int_0^T \nu||\nabla w(t)||_N^2 + \nu\delta^2||\triangle w(t)||_N^2 dt = \frac{1}{2}[||\overline{u}_0||_N^2 + \delta^2||\nabla \overline{u}_0||_N^2] + \int_0^T (f, w(t))_N \, dt.$$

Proof (*sketch*). Let (w, q) denote a periodic solution of the ADM (1.4). Multiplying (1.4) by $AD_N w$ and integrating over Ω gives

$$\int_\Omega w_t \cdot AD_N w + \nabla \cdot (\overline{D_N w \ D_N w}) \cdot AD_N w - \nu \triangle w \cdot AD_N w + \nabla q \cdot AD_N w d\mathbf{x} = \int_\Omega \overline{f} \cdot AD_N w d\mathbf{x}.$$

The nonlinear term vanishes exactly because

$$\int_\Omega \nabla \cdot (\overline{D_N w \ D_N w}) \cdot AD_N w d\mathbf{x} = \int_\Omega A^{-1}(\nabla \cdot (D_N w \ D_N w)) \cdot AD_N w d\mathbf{x} = \int_\Omega \nabla \cdot (D_N w \ D_N w) \cdot D_N w d\mathbf{x} = 0.$$

Integrating by parts the remaining terms gives

$$\frac{d}{dt}\frac{1}{2}\{||w(t)||_N^2 + \delta^2||\nabla w(t)||_N^2\} + \nu\{||\nabla w(t)||_N^2 + \delta^2||\triangle w(t)||_N^2\} = (f, w(t))_N \,. \tag{3.1}$$

The results follow by integrating this from 0 to t. □

From Proposition 3.1, the ADM kinetic energy $E_{ADM-N}(w)(t)$, energy dissipation rate $\varepsilon_{ADM-N}(w)(t)$, time-averaged dissipation rate $\langle\varepsilon_{ADM-N}\rangle$, and power input $P_{ADM-N}(w)(t)$ are clearly identified.

$$E_{ADM-N}(w)(t) := \frac{1}{2|\Omega|}\{||w(t)||_N^2 + \delta^2||\nabla w(t)||_N^2\}, \tag{3.2}$$

$$\varepsilon_{ADM-N}(w)(t) := \frac{\nu}{|\Omega|}\{||\nabla w(t)||_N^2 + \delta^2||\triangle w(t)||_N^2\}, \tag{3.3}$$

$$\langle\varepsilon_{ADM-N}\rangle := \langle\varepsilon_{ADM-N}(w)(t)\rangle, \tag{3.4}$$

$$P_{ADM-N}(w)(t) := \frac{1}{|\Omega|}(f, w(t))_N. \tag{3.5}$$

[3]Unlike the NSE case, e.g., [Gal95], it is known that weak=strong for the ADM and that both exist and are unique.

Let $||\cdot||_N$ denote the deconvolution-weighted $L^2(\Omega)$ norm (Definition 2.1). The deconvolution weighted scales of the body force and large scale velocity are defined by

$$F_N := \left(\frac{1}{|\Omega|}||f||_N^2\right)^{\frac{1}{2}}, \text{ and } U_N := \left\langle \frac{1}{|\Omega|}||w||_N^2 \right\rangle^{\frac{1}{2}}.$$

Note that these are related to F and U by

$$F \le F_N \le (N+1)^{\frac{1}{2}} F, U \le U_N \le (N+1)^{\frac{1}{2}} U, \text{ and also}$$
$$\langle \varepsilon_{ADM-0}(w)\rangle \le \langle \varepsilon_{ADM-N}(w)\rangle \le (N+1)^{\frac{1}{2}} \langle \varepsilon_{ADM-0}(w)\rangle.$$

For $N = 1, 2, 3, \dots$ the deconvolution-weighted global length scale associated with the power input to the large scales, i.e., with $f(x)$, is defined to be

$$L_N := \min \left\{ L_\Omega, \frac{F_N}{||D_N^{\frac{1}{2}} \nabla f||_{L^\infty(\Omega)}}, \frac{F_N}{(\frac{1}{|\Omega|}||\nabla f||_N^2)^{\frac{1}{2}}}, \frac{F_N}{(\frac{1}{|\Omega|}||\nabla \times f||_N^2)^{\frac{1}{2}}}, \frac{F_N^{\frac{1}{2}}}{(\frac{1}{|\Omega|}||\triangle f||_N^2)^{\frac{1}{4}}} \right\}.$$

It is easy to check that L_N has units of length and satisfies the deconvolution-weighted form of the inequalities (2.1) above.

LEMMA 3.2. *As $\delta \to 0$, for $N = 0, 1, 2, \dots$*

$$E_{ADM-N}(w)(t) \to E(w)(t) = \frac{1}{2|\Omega|}||w(t)||^2,$$
$$\varepsilon_{ADM-N}(w)(t) \to \varepsilon(w)(t) = \frac{\nu}{2|\Omega|}||\nabla w(t)||^2, \textit{ and}$$
$$P_{ADM-N}(w)(t) \to P(w)(t) = \frac{1}{|\Omega|}(f(t), w(t)).$$

Proof. As $\delta \to 0$ all of the δ^2 terms drop out in the definitions above, $D_N \to I$, and $||\phi||_N \to ||\phi||$. ☐

COROLLARY 3.3. *Let $f = f(x) \in L^2(\Omega)$ and w be a solution of the ADM turbulence model* (1.4)*; then*

$$\sup_{t\in(0,\infty)} E_{ADM-N}(w)(t) \le C(data) < \infty,$$
$$\frac{1}{T}\int_0^T \varepsilon_{ADM-N}(w)(t)dt \le C(data) < \infty.$$

Proof. We begin with (3.1) from the proof of Proposition 3.1. Using the Poincaré and Cauchy–Schwarz inequalities we have from (3.1)

$$\frac{d}{dt}E_{ADM-N}(t) + \alpha E_{ADM-N}(t) \le ||f||_N^2$$

for some $\alpha > 0$, which implies $E_{ADM-N}(w)(t)$ is uniformly bounded in time. For boundedness of the time-averaged dissipation rate, divide the energy estimate of the

ADM turbulence model energy equality from Proposition 3.1 by T :

$$\frac{1}{T}E_{ADM-N}(w)(T)+\frac{1}{T}\int_0^T \varepsilon_{ADM-N}(w)(t)dt$$
$$=\frac{1}{T}E_{ADM-N}(w)(0)+\frac{1}{T}\int_0^T (f,w(t))_N dt$$
$$\leq \frac{1}{T}E_{ADM-N}(w)(0)+||f||_N\left[\frac{1}{T}\int_0^T ||w(t)||_N^2 dt\right]^{\frac{1}{2}} \tag{3.6}$$
$$\leq C(data). \qquad \square \tag{3.7}$$

4. Bounds on energy dissipation rates. We prove the following estimate on the model's time-averaged energy dissipation rates. Recall that the body force $f(x)$ is a smooth, divergence-free function. The global velocity and length scales are given in section 3.

THEOREM 4.1. *Let the data $f(x)$ and $u_0(x)$ be smooth, divergence-free functions. For all cases $N=0,1,2,3,\ldots$*

$$\langle\varepsilon_{ADM-N}(w)\rangle \leq 2\frac{U_N^3}{L_N}+\mathrm{Re}^{-1}\frac{U_N^3}{L_N}\left(1+\frac{\delta^2}{L_N^2}\right).$$

The proof in the general case follows the zeroth order case by adding subscripts as appropriate. The mathematics driving the proof in both cases is the precise estimate of the model's energy balance. In the general case, the model's kinetic energy balance satisfies the analog of the zeroth order's energy balance with norms replaced by deconvolution-weighted norms. We shall give the proof in detail for the notationally clearest, $N=0$, case (indicating the notational modifications in the general case).

PROPOSITION 4.2. *Let the data $f(x)$ and $u_0(x)$ be smooth, divergence-free functions. For the case $N=0$,*

$$\langle\varepsilon_{ADM-0}(w)\rangle \leq 2\frac{U^3}{L}+\mathrm{Re}^{-1}\frac{U^3}{L}\left(1+\frac{\delta^2}{L^2}\right).$$

The proof of the proposition and theorem follow next. They combine the energy estimate for the ADM in Proposition 3.1 with the breakthrough arguments of Foias [F97] and Doering and Foias [DF02] from the NSE case.

The case of general $N=0,1,2,\ldots$. The first of two key bounds is obtained by time averaging the energy inequality of Proposition 3.1. Using Corollary 3.3 we have for $N=0,1,2,\ldots$

$$Lim_{T\to\infty}\frac{1}{T}\int_0^T \nu||\nabla w(t)||_N^2+\nu\delta^2||\triangle w(t)||_N^2 dt \leq Lim_{T\to\infty}\frac{1}{T}\int_0^T (f,w(t))_N\, dt.$$

The Cauchy–Schwarz inequality and Corollary 3.3 imply

$$\langle\ \varepsilon_{ADM-N}\rangle \leq F_N U_N, \text{ and thus } \langle\varepsilon_{ADM-0}\rangle \leq FU. \tag{4.1}$$

Time averaging the ADM turbulence model (1.4) gives for $N=0,1,2,\ldots$

$$\langle w\rangle_t+\nabla\cdot(\langle\overline{D_N w\ D_N w}\rangle)-\nu\triangle\langle w\rangle+\nabla\langle q\rangle=\langle\overline{f}\rangle, \tag{4.2}$$
$$\nabla\cdot\langle w\rangle=0.$$

The case $N = 0$. Set $N = 0$ and recall that $D_0 = I$. Take the inner product of the time-averaged model (4.2) with Af. Note that because $f = f(x)$, $\langle \overline{f} \rangle = f(x)$. Further $(\overline{f}, Af) = (A^{-1}f, Af) = ||f||^2$ and analogously for the nonlinear term. Since $\nabla \cdot f = 0$, the pressure term vanishes. This gives

$$\frac{1}{|\Omega|}||f||^2 = \frac{1}{|\Omega|}(Af, \langle w \rangle_t) - \frac{1}{|\Omega|}(\nabla f, \langle D_0 w \ D_0 w \rangle) + \frac{\nu}{|\Omega|}(A \nabla f, \nabla \langle w \rangle).$$

The time derivative term vanishes in the limit as $T \to \infty$ by the Cauchy–Schwarz inequality and Corollary 3.3. The last term on the right-hand side (RHS) is integrated by parts, giving:

$$\frac{1}{|\Omega|}||f||^2 = -\frac{1}{|\Omega|}(\nabla f, \langle D_0 w \ D_0 w \rangle) + \frac{\nu}{|\Omega|}\{(\nabla f, \nabla \langle w \rangle) + \delta^2 (\triangle f, \triangle \langle w \rangle)\}.$$

Thus, using the Cauchy–Schwarz inequality,

$$\frac{1}{|\Omega|}||f||^2 \leq -\frac{1}{|\Omega|}(\nabla f, \langle D_0 w \ D_0 w \rangle) + \varepsilon_{ADM-0}(f)^{\frac{1}{2}} \varepsilon_{ADM-0}(\langle w \rangle)^{\frac{1}{2}}. \tag{4.3}$$

Next, consider the nonlinear term on the above RHS. By the definitions of L, F, U we have (recalling $D_0 w = w$)

$$\frac{1}{|\Omega|}(\nabla f, \langle w \ w \rangle) \leq ||\nabla f||_{L^\infty} \left\langle \frac{1}{|\Omega|}||w||^2 \right\rangle \leq \frac{FU^2}{L}. \tag{4.4}$$

By the triangle inequality we have

$$||\nabla \langle w \rangle||^2 \leq \langle ||\nabla w||^2 \rangle, \text{ and } ||\triangle \langle w \rangle||^2 \leq \langle ||\triangle w||^2 \rangle. \tag{4.5}$$

(This step is not sharp.) This implies, by the definitions of F, L,

$$\begin{gathered} \varepsilon_{ADM-0}(\langle w \rangle)^{\frac{1}{2}} \leq \langle \varepsilon_{ADM-0}(w) \rangle^{\frac{1}{2}}, \\ \frac{\nu}{|\Omega|}||\nabla f||^2 \leq \nu \frac{F^2}{L^2}, \text{ and } \frac{\nu \delta^2}{|\Omega|}||\triangle f||^2 \leq \nu \delta^2 \frac{F^2}{L^4}. \end{gathered} \tag{4.6}$$

Using the bounds (4.4), (4.6), and (4.7) in (4.3) gives

$$F^2 \leq \frac{FU^2}{L} + \left(\frac{\nu F^2}{L^2} + \frac{\nu \delta^2 F^2}{L^4} \right)^{\frac{1}{2}} \langle \varepsilon_{ADM-0}(w) \rangle^{\frac{1}{2}}. \tag{4.7}$$

From the first basic estimate $\langle \varepsilon_{ADM-0}(w) \rangle \leq FU$. Inserting this in the RHS and cancelling the obvious terms gives

$$\langle \varepsilon_{ADM-0}(w) \rangle \leq FU \leq \frac{U^3}{L} + U \left(\frac{\nu}{L^2} + \frac{\nu \delta^2}{L^4} \right)^{\frac{1}{2}} \langle \varepsilon_{ADM-0}(w) \rangle^{\frac{1}{2}}. \tag{4.8}$$

Thus, by Young's inequality

$$\langle \varepsilon_{ADM-0}(w) \rangle \leq 2\frac{U^3}{L} + \frac{\nu U^2}{L^2} \left(1 + \frac{\delta^2}{L^2} \right),$$

and Proposition 4.2 is proven:

$$\langle \varepsilon_{ADM-0}(w) \rangle \leq 2\frac{U^3}{L} + \mathrm{Re}^{-1} \frac{U^3}{L} \left(1 + \frac{\delta^2}{L^2} \right).$$

The case of general $N = 0, 1, 2, \ldots$. For the general case in Theorem 4.1, the claimed estimates hold by the same proof as the $N = 0$ case (above) with norms and inner products replaced by their deconvolution-weighted versions (i.e., by adding subscripts N).

Remark 4.1. *Exactly as in the NSE case, Foias* [F97] *and Doering and Foias* [DF02]*, the estimate can be improved by more careful treatment of the quadratic equation. The result is the elimination of the multiplier* 2 *on the RHS and a slight modification of the second term.*

5. Bounds on helicity dissipation rates. This section considers bounds on the time-averaged helicity dissipation rate for both the NSE and the ADM turbulence models (1.4). We consider the NSE case first and derive a partial result. The expected result predicted by dimensional analysis in the NSE case is recovered if it is known that the helicity of a solution of the NSE is eventually bounded—a property that seems physically obvious but mathematically intractable. Because of the enhanced kinetic energy bound available for the ADM turbulence model, we are able to prove a bound on the ADM helicity, $\langle \gamma_{ADM-N}(w) \rangle$.

5.1. Helicity dissipation for the NSE. Because of the incomplete nature of the final result, we proceed formally. Dividing the helicity balance equation by T gives

$$\frac{1}{T}H(u)(T) + \frac{1}{T}\int_0^T \gamma(u)(t)dt = \frac{1}{T}H(u_0) + \frac{1}{T}\int_0^T \frac{1}{|\Omega|}(\nabla \times f, u)dt.$$

If the initial velocity is smooth, $\frac{1}{T}H(u_0) \to 0$ as $T \to \infty$. Further, if $\nabla \times f$ is square integrable, then, by the Cauchy–Schwarz inequality,

$$Lim_{T\to\infty} \left| \frac{1}{T}\int_0^T \frac{1}{|\Omega|}(\nabla \times f, u)dt \right| \leq \frac{FU}{L}(< \infty). \tag{5.1}$$

Thus, the following generalized limits satisfy

$$Lim_{T\to\infty} \left| \frac{1}{T}H(u)(T) + \frac{1}{T}\int_0^T \gamma(u)(t)dt \right| \leq \frac{FU}{L}(< \infty).$$

In the NSE case, Foias [F97] and Doering and Foias [DF02] prove, as a step to bounds on energy dissipation rates, the following intermediate result on the numerator of the RHS:

$$FU \leq \frac{U^3}{L} + \nu^{\frac{1}{2}}\frac{U}{L}\langle \varepsilon \rangle^{\frac{1}{2}}. \tag{5.2}$$

(For example, formally set $\delta = 0$ in the estimate (4.8).) Using this and the bound on energy dissipation in [F97], [DF02] that $\langle \varepsilon \rangle \leq 2\frac{U^3}{L} + \mathrm{Re}^{-1}\frac{U^3}{L}$, in (5.1) gives

$$Lim_{T\to\infty} \left| \frac{1}{T}H(u)(T) + \frac{1}{T}\int_0^T \gamma(u)(t)dt \right| \leq \frac{U^3}{L^2} + \sqrt{2}\,\mathrm{Re}^{-\frac{1}{2}}\frac{U^3}{L^2} + \mathrm{Re}^{-1}\frac{U^3}{L^2}. \tag{5.3}$$

If $H(T)$ is eventually bounded (as is expected physically but unknown mathematically), this gives the upper bound

$$|\langle \gamma \rangle| \leq \frac{U^3}{L^2} + \sqrt{2}\,\mathrm{Re}^{-\frac{1}{2}}\frac{U^3}{L^2} + \mathrm{Re}^{-1}\frac{U^3}{L^2}. \tag{5.4}$$

Thus, it is clear that obtaining a bound on the helicity dissipation, i.e., completing the step between (5.3) and (5.4), depends on proving boundedness of $H(T)$.

5.2. Helicity dissipation in ADM turbulence models. From the NSE case, it is clear that the key to completing the argument of section 5.1 for the ADM turbulence model will be proving $H_{ADM-N}(w)(T)$ is bounded. We begin by recalling the ADM turbulence model's helicity balance (the essential first ingredient in the analysis) discovered by Rebholz [R07]. Define the ADM helicity which is exactly conserved by the model if $\nu = 0$

$$H_{ADM-N}(w)(t) := \frac{1}{|\Omega|}[(w, \nabla \times w)_N + \delta^2(\nabla \times w, \nabla \times \nabla \times w)_N]. \tag{5.5}$$

For the ADM, it is known [R07] that the ADM helicity satisfies the balance equation

$$H_{ADM-N}(w)(T) + \int_0^T \gamma_{ADM-N}(w)(t)dt = H(w(0)) + \int_0^T \frac{1}{|\Omega|}(\nabla \times f, w)dt, \tag{5.6}$$

where $\gamma_{ADM-N}(w)$ is the model's helicity dissipation rate given by

$$\gamma_{ADM-N}(w) := \frac{\nu}{|\Omega|}[(\nabla \times w, \nabla \times \nabla \times w)_N + \delta^2(\nabla \times \nabla \times w, \nabla \times \nabla \times \nabla \times w)_N]. \tag{5.7}$$

Note that (in the zeroth order model, to simplify notation)

$$H_{ADM}(w) = H(w) + \delta^2 H(\nabla \times w) \text{ and}$$
$$\gamma_{ADM}(w) = \gamma(w) + \delta^2 \gamma(\nabla \times w).$$

5.3. Bounding model helicity. Arguing as in [LN07b], the zeroth order model, (1.4) with $N = 0$, is equivalent to $\nabla \cdot Aw = 0$ and

$$Aw_t + w \cdot \nabla w + \nabla Aq - \nu \triangle Aw = f. \tag{5.8}$$

LEMMA 5.1. *Let the data $f(x)$ and $u_0(x)$ be smooth, divergence-free functions. Suppose $\delta > 0$; then*

$$\sup_{0 \le T < \infty} [||w(T)|| + ||\nabla w(T)|| + ||\triangle w(T)||] \le C(data, \delta) < \infty. \tag{5.9}$$

Proof. First we note that it has been proven that the ADM turbulence model (1.4) has a unique strong solution that is as smooth as the problem data, so formal manipulations of the model are mathematically justified. The bound on w and ∇w follows from the energy inequality for the model in Proposition 3.1. Taking the inner product of (5.8) with Aw gives

$$\frac{1}{2}\frac{d}{dt}||Aw||^2 + \nu||\nabla Aw||^2 = (Af, w) - (w \cdot \nabla w, Aw).$$

Basic inequalities and the bounds on w and ∇w give

$$|(Af, w)| \le C(data),$$
$$|(w \cdot \nabla w, Aw)| \le C||\nabla w||^2||\nabla Aw||^2 \le C(data, \delta) + \frac{\nu}{2}||\nabla Aw||^2.$$

Thus,

$$\frac{1}{2}\frac{d}{dt}||Aw||^2 + \nu||\nabla Aw||^2 \leq C(data,\delta) + \frac{\nu}{2}||\nabla Aw||^2,$$

and the result follows by a Poincaré inequality and using an integrating factor. ∎

COROLLARY 5.2. *Let the data $f(x)$ and $u_0(x)$ be smooth, divergence-free functions and $N = 0$. If $\delta > 0$, then $|H_{ADM-0}(w)(T)|$ is uniformly bounded.*

Proof. There follows

$$|H_{ADM-0}(w)(T)| \leq C(||w||||\nabla w|| + \delta^2||\nabla w||||\triangle w||) \leq C(data,\delta). \qquad \square$$

In the general case, the analogous estimates hold by essentially the same proofs.

COROLLARY 5.3. *Let the data $f(x)$ and $u_0(x)$ be smooth, divergence-free functions. If $\delta > 0$, then, for all cases $N = 0,1,2,\dots$, $|H_{ADM-0}(w)(T)|$ is uniformly bounded.*

Proof (*sketch*). By using weighted norms, we show by the same proof as the above lemma that the estimate holds:

$$\sup_{0\leq T<\infty} [||w(T)||_N + ||\nabla w(T)||_N + ||\triangle w(T)||_N] \leq C(data,\delta,N) < \infty. \tag{5.10}$$

Using this estimate it follows that

$$|H_{ADM-N}(w)(T)| \leq C(||w||_N||\nabla w||_N + \delta^2||\nabla w||_N||\triangle w||_N) \leq C(data,\delta,N). \qquad \square$$

With these bounds, the final step lacking in the argument from section 5.1 in the NSE case can be carried through successfully.

THEOREM 5.4. *Let $f(x), u_0(x)$ be smooth, divergence-free functions and $\delta > 0$. Then for any $N = 0,1,2,\dots$*

$$|\langle\gamma_{ADM-N}(w)\rangle| \leq \frac{U_N^3}{L_N^2} + \sqrt{2}\,\mathrm{Re}^{-\frac{1}{2}}\left(1+\frac{\delta^2}{L_N^2}\right)^{\frac{1}{2}}\frac{U_N^3}{L_N^2} + \mathrm{Re}^{-1}\left(1+\frac{\delta^2}{L_N^2}\right)\frac{U_N^3}{L_N^2}.$$

Proof. We shall give the proof in the case $N = 0$. The proof for general N is the same as the $N = 0$ case with subscripts N added.

Time average the ADM turbulence model's helicity balance relation; both helicity terms drop out by Corollaries 5.2 ($N = 0$ case) and 5.3 ($N > 0$ case). Thus, when $N = 0$ we have

$$Lim_{T\to\infty}\left|\frac{1}{T}\int_0^T \gamma_{ADM-0}(w)(t)dt\right| \leq Lim_{T\to\infty}\left|\frac{1}{T}\int_0^T \frac{1}{|\Omega|}(\nabla\times f,u)dt\right| \leq \frac{FU}{L}.$$

Inserting the bounds on FU and $\langle\varepsilon_{ADM}(w)\rangle$ from section 4 gives

$$\begin{aligned}
|\langle\gamma_{ADM-0}(w)\rangle| &\leq \frac{FU}{L} \leq \frac{U^3}{L^2} + \frac{U}{L}\left(\frac{\nu}{L^2}+\frac{\nu\delta^2}{L^4}\right)^{\frac{1}{2}}\langle\varepsilon_{ADM-0}(w)\rangle^{\frac{1}{2}} \\
&\leq \frac{U^3}{L^2} + \mathrm{Re}^{-\frac{1}{2}}\left(\frac{U}{L}\right)^{\frac{3}{2}}(1+\delta^2)^{\frac{1}{2}}\left[2\frac{U^3}{L} + \mathrm{Re}^{-1}\frac{U^3}{L}\left(1+\frac{\delta^2}{L^2}\right)\right]^{\frac{1}{2}} \\
&\leq \frac{U^3}{L^2} + \sqrt{2}\,\mathrm{Re}^{-\frac{1}{2}}(1+\delta^2)^{\frac{1}{2}}\frac{U^3}{L^2} + \mathrm{Re}^{-1}(1+\delta^2)\frac{U^3}{L^2},
\end{aligned}$$

as claimed. When $N > 0$ the proof is the same with only subscripts N added. ∎

6. Conclusions. Similarity theories of cascades in homogeneous, isotropic turbulence are based on several assumptions which have yet to be verified directly from the NSE. Nevertheless, the predictions of these theories have been observed in many turbulent flows in nature. As analytic understanding advances, many of these predictions have also been proven directly from the Navier–Stokes equations.

The correctness of the predictions of turbulence models, however, can be very unclear, and simulations based on those models can be even more so. We have considered the energy and helicity dissipation rates of general solutions of one promising family of models. These rates are key quantities in physical theories of energy and helicity cascades. Rigorous upper bounds of the model's energy and helicity dissipation rates are derived. These estimates agree with those proven for energy for the NSE and derived by physical theories of homogeneous, isotropic turbulence. This analysis is based on a rigorous understanding of physical integral invariants of flow models and their corresponding dissipation rates. It gives important (even essential) analytic insight into the reliability of models and the predictions coming from them. Approximate deconvolution models have a systematic mathematical derivation which is reflected in their high-accuracy, exact conservation (when $\nu = 0$) of a model energy and helicity and the validity of their predictions of energy and helicity dissipation rates (when $\nu > 0$).

SPATIAL DYNAMICS METHODS FOR SOLITARY GRAVITY-CAPILLARY WATER WAVES WITH AN ARBITRARY DISTRIBUTION OF VORTICITY*

M. D. GROVES† AND E. WAHLÉN‡

Abstract. This paper presents existence theories for several families of small-amplitude solitary-wave solutions to the classical two-dimensional water-wave problem in the presence of surface tension and with an arbitrary distribution of vorticity. Moreover, the established local bifurcation diagram for irrotational solitary waves is shown to remain qualitatively unchanged for any choice of vorticity distribution. The hydrodynamic problem is formulated as an infinite-dimensional Hamiltonian system in which the horizontal spatial direction is the timelike variable. A center-manifold reduction technique is employed to reduce the system to a locally equivalent Hamiltonian system with a finite number of degrees of freedom. Homoclinic solutions to the reduced system, which correspond to solitary water waves, are detected by a variety of dynamical systems methods.

Key words. water waves, vorticity, capillarity, bifurcation theory

1. Introduction. The *gravity-capillary water-wave problem* concerns the flow of a perfect fluid of unit density subject to the forces of gravity and surface tension; the fluid is bounded below by a rigid horizontal bottom $\{y = 0\}$ and above by a free surface $\{y = \eta(x, t)\}$, where η depends upon the horizontal spatial coordinate x and time t. *Traveling waves* are waves which propagate from left to right with constant speed c and without change of shape, so that $\eta(x, t) = \eta(x - ct)$. The two principal classes of traveling waves are *Stokes waves*, which are periodic in a frame of reference moving with the wave, and *solitary waves*, which have the property that $\eta(x - ct) \to 0$ as $x - ct \to \pm\infty$. In this paper we construct rigorous existence theories for solitary waves on flows with an arbitrary distribution of vorticity; the physical setting corresponds to waves originating from a distant storm advancing into a shear current.

Working in a frame of reference moving with the wave, let us describe the velocity field $(u(x, y), v(x, y))$ within the fluid domain $D_\eta = \{(x, y) : x \in \mathbb{R}, 0 < y < \eta(x)\}$ in terms of a stream function $\psi(x, y)$ which satisfies $\psi_x = -v$, $\psi_y = u - c$ and suppose that $u < c$, so that $\psi_y < 0$. The vorticity $\omega(x, y) = v_x(x, y) - u_y(x, y)$ is known under this condition to be a function of the stream function ψ, and we specify its distribution by prescribing a *vorticity function* γ such that $\omega = \gamma(\psi)$. The hydrodynamic problem is to solve the nonlinear elliptic equation

$$\Delta\psi = -\gamma(\psi), \qquad 0 < y < \eta(x), \tag{1}$$

subject to the Dirichlet boundary conditions

$$\psi(x, 0) = 0, \tag{2}$$

$$\psi(x, \eta(x)) = m_0, \tag{3}$$

where $m_0 < 0$ is the constant mass flux, the asymptotic conditions

$$\eta(x) \to d \qquad \text{as } x \to \pm\infty, \tag{4}$$

and the nonlinear boundary condition

$$\frac{1}{2}|\nabla\psi|^2 + g(y-d) - \sigma\left[\frac{\eta_x}{\sqrt{1+\eta_x^2}}\right]_x = \frac{\lambda}{2} \qquad \text{on } y = \eta(x), \tag{5}$$

where g, σ, and d are, respectively, the acceleration due to gravity, the coefficient of surface tension, and the asymptotic depth of the water, and λ is a constant called the Bernoulli constant (e.g., see Constantin and Strauss [11]).

Several existence theories for *irrotational* gravity-capillary solitary waves (where $\gamma = 0$) are available in the literature (see below), and many of them use *spatial dynamics* methods. The phrase "spatial dynamics" refers to an approach where a system of partial differential equations governing a physical problem is formulated as a (typically ill-posed) evolutionary equation

$$u_\xi = L(u) + N(u), \tag{6}$$

in which an unbounded spatial coordinate plays the role of the timelike variable ξ. The water-wave problem has one bounded or semibounded coordinate, namely, the vertical coordinate y; by contrast no restriction is placed upon the behavior of the waves in the horizontal coordinate x, and so this coordinate qualifies as "timelike." One therefore studies the problem using spatial dynamics by formulating it as an evolutionary system of the form (6), where $\xi = x$, in an infinite-dimensional phase space consisting of functions of y. Notice that the hydrodynamic problem is conservative and isotropic in x, and these symmetries manifest themselves in the fact that its spatial dynamics formulation is *Hamiltonian* and *reversible*. In section 2 we derive a formulation of the water-wave problem with an arbitrary choice of $\gamma \in L^2(m_0, 0)$ as a reversible Hamiltonian system and place it in a secure functional-analytic framework.

One particularly useful technique for finding solutions of (6) is known as *center-manifold reduction*. Supposing that L has a finite number of purely imaginary eigenvalues and that certain technical hypotheses are satisfied, one can show that (6) admits an invariant manifold called the *center manifold* which contains all its small, bounded solutions; the dimension of the center manifold is given by the number of purely imaginary eigenvalues. This reduction procedure is explained in detail by Mielke [32] and is shown in section 3.1 to be applicable to our spatial dynamics formulation of the gravity-capillary water-wave problem for fluid of finite depth and with any choice of $\gamma \in H^1(m_0, 0)$ which satisfies

$$\int_0^1 \frac{1}{\sqrt{2\Gamma(s) - 2\Gamma_{\min}}}\,\mathrm{d}s > 1, \qquad \Gamma_{\min} = \min_{s\in[0,1]} \Gamma(s), \tag{7}$$

where

$$\Gamma(s) = \frac{d^2}{m_0}\int_s^1 \gamma(m_0 u)\,\mathrm{d}u.$$

(The additional regularity requirement on γ simplifies the calculation of the spectrum of L.) An important aspect of the center-manifold reduction procedure is that it preserves symmetries of the initial evolutionary equation. This feature can be exploited in existence theories for water waves: Since our spatial dynamics formulation is Hamiltonian and reversible, the reduced system on the center manifold is a reversible Hamiltonian system with finitely many degrees of freedom.

Bifurcation phenomena obtained by varying a parameter can also be captured by the center-manifold reduction procedure. A bifurcation parameter ε may be introduced by perturbing physical parameters present in the problem (in the case of water waves, $\alpha = gd^3/m_0^2$ and $\beta = \sigma d/m_0^2$) around fixed reference values, and the reduction procedure delivers an ε-dependent manifold which captures the small-amplitude dynamics for small values of this parameter; the manifold is a true center manifold at criticality ($\varepsilon = 0$), so that its dimension is the number of purely imaginary eigenvalues of L at $\varepsilon = 0$. The reduction procedure is therefore especially helpful in detecting bifurcations which are associated with a change in the number of purely imaginary eigenvalues. In the case of irrotational waves there are three critical curves C_2, C_3, C_4 in the (β, α) parameter plane at which the number of purely imaginary eigenvalues of L changes (see Figure 1(a)), together with a fourth curve C_1 at which the number of real eigenvalues changes; an explicit parametrization of each of these curves is available (Kirchgässner [29]). Section 3.2 contains spectral theory which shows that this "bifurcation diagram" remains qualitatively unchanged for each choice of vorticity function γ; explicit formulas are, however, available only for $C_3 = \{(\beta, \alpha_\star) : \beta < \beta_\star\}$ and $C_4 = \{(\beta, \alpha_\star) : \beta > \beta_\star\}$, where $\beta_\star$, $\alpha_\star$ are positive constants determined by the choice of γ (the values of $\beta_\star$ and $\alpha_\star$ for $\gamma = 0$ are, respectively, 1/3 and 1).

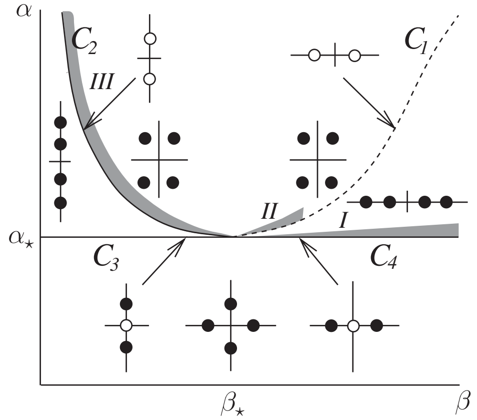
In irrotational water-wave theory the curves C_1, C_2, and C_4 are associated with *homoclinic bifurcation*, where solutions of the reduced Hamiltonian system which are asymptotically zero bifurcate from the trivial solution; these solutions correspond to solitary water waves. Figure 1 illustrates the regions I, II, and III adjacent to, respectively, C_4, C_1, and C_2 in which homoclinic solutions exist for $\gamma = 0$, and in the present paper we show that the same is true for any choice of $\gamma \in H^1(m_0, 0)$ satisfying (7). There are, however, physical differences in the corresponding solitary waves: A small-amplitude irrotational solitary wave is a perturbation of a uniform flow, while a solitary wave with $\gamma \neq 0$ "rides" a laminar flow in which the velocity field is horizontal but depth-dependent.

Irrotational waves in region I were studied by Kirchgässner [29] (see also Amick and Kirchgässner [1], Sachs [33], and Iooss and Kirchgässner [24]). A *Hamiltonian* 0^2*-resonance* takes place at C_4; that is, two imaginary eigenvalues collide at the origin and become real as one crosses the curve from below. Kirchgässner showed that the flow on the two-dimensional center manifold is controlled by the reversible, Hamiltonian equation

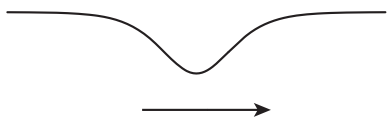
$$u_{xx} = u + \frac{3}{2}u^2 + O(\delta^{1/2}),$$

where $0 < \delta \ll 1$ is the bifurcation parameter $\alpha - \alpha_\star$. This equation admits a homoclinic solution which corresponds to a solitary wave of depression whose tail decays exponentially and monotonically. In section 4.1 we show that Kirchgässner's analysis and conclusions remain valid for an arbitrary choice of $\gamma \neq 0$ and give a geometric interpretation of his method.

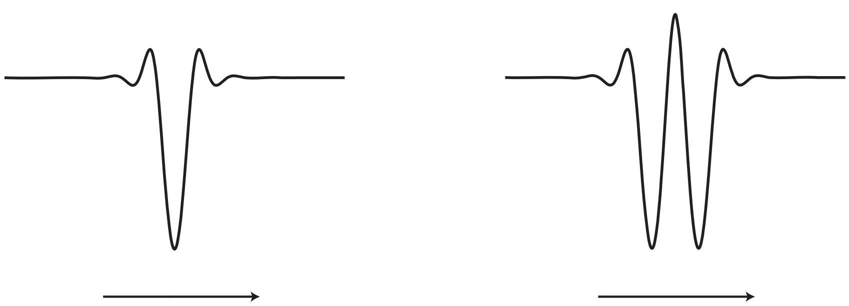
Region II lies on the "complex side" of the curve C_1, at points of which two pairs of small-magnitude real eigenvalues collide and become complex. The center manifold is four-dimensional, and it was shown by Buffoni, Groves, and Toland [8] that for $\gamma = 0$



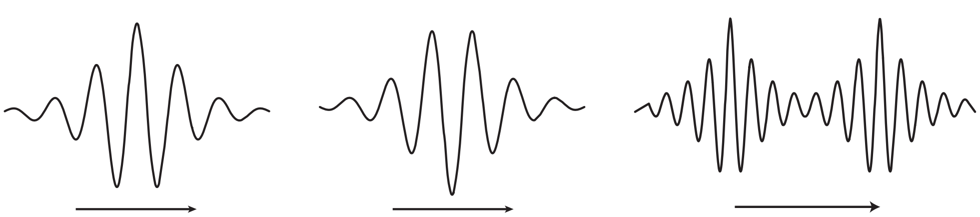
(a) *Bifurcation curves in the* (β, α)*-plane; the shaded regions indicate the parameter regimes in which homoclinic bifurcation is detected.*



(b) *A symmetric solitary wave of depression (left) is found in region* I.



(c) *Region* II *contains an infinite family of multitroughed solitary waves which decay in an oscillatory fashion.*



(d) *Symmetric unipulse modulated solitary waves (left and center) coexist with an infinite family of multipulse modulated solitary waves (right) in region* III.

FIG. 1. *Summary of the solitary waves whose existence is established in the present paper by center-manifold reduction and homoclinic bifurcation theory.*

the flow on the center manifold is controlled by the reversible, Hamiltonian equation

$$u_{xxxx} - 2(1+\delta)u_{xx} + u - u^2 = 0(\mu), \tag{8}$$

where $0 < \mu \ll 1$ measures the distance from the point $(\beta_\star, \alpha_\star)$ and $0 < \delta \ll 1$ is the bifurcation parameter (measuring the distance from C_1). This equation has an infinite family of *multipulse* homoclinic solutions which make several large excursions away from the origin. The corresponding water waves are solitary waves of depression with $2, 3, 4, \ldots$ large troughs separated by $2, 3, \ldots$ small oscillations; their tails are oscillatory and decay exponentially. In section 4.2 we compute the reduced Hamiltonian system for a general choice of γ using a method which is simpler than that employed by Buffoni, Groves, and Toland. We again arrive at (8), so that our hydrodynamic problem also admits a plethora of multipulse solitary waves in this parameter regime.

Region III was first examined by Iooss and Kirchgässner [23], who studied homoclinic bifurcation associated with the *Hamiltonian-Hopf bifurcation* at points of C_2 (two pairs of purely imaginary eigenvalues collide at nonzero points $\pm \mathrm{i}q$ and become complex). The center manifold is four-dimensional at Hamiltonian-Hopf points, and the two-degree-of-freedom reduced Hamiltonian system is conveniently studied using complex coordinates (A, B) and a normal-form transformation. Introducing a bifurcation parameter δ so that positive values of δ correspond to points on the complex side of C_2, one obtains the reduced Hamiltonian system

$$A_x = \frac{\partial H}{\partial \bar{B}}, \qquad B_x = -\frac{\partial H}{\partial \bar{A}},$$

$$H = \mathrm{i}q(A\bar{B} - \bar{A}B) + |B|^2 + H_{\mathrm{NF}}(|A|^2, \mathrm{i}(A\bar{B} - \bar{A}B), \delta) + O(|(A,B)|^2 |(\delta, A, B)|^{n_0}),$$

where H_{NF} is a real polynomial which satisfies $H_{\mathrm{NF}}(0,0,\delta) = 0$; it contains the terms of order $3, \ldots, n_0 + 1$ in the Taylor expansion of H. Supposing that the coefficients of certain terms in H_{NF} have the correct sign, one finds that the "truncated normal form" obtained by neglecting the remainder term admits a circle of homoclinic solutions, two of which persist when the remainder terms are reinstated (see Iooss and Pérouème [26]). The corresponding water waves are symmetric solitary waves which take the form of periodic wave trains modulated by exponentially decaying envelopes. Buffoni and Groves [7] strengthened this result by showing that the above Hamiltonian system in fact has an infinite number of geometrically distinct homoclinic solutions which generically resemble multiple copies of one of the homoclinic solutions found by Iooss and Kirchgässner. The relevant normal-form coefficients were computed for irrotational waves by Buffoni and Groves [7, Appendix B]. Although such explicit formulas are not available, for a general choice of γ it is possible to prove that the coefficients have the correct signs in the local part of region III near $(\beta_\star, \alpha_\star)$; this procedure is carried out in section 4.3.

A different homoclinic bifurcation phenomenon occurs at C_3, where a *Hamiltonian* $0^2\mathrm{i}\omega$ *resonance* takes place; that is, two imaginary eigenvalues collide at the origin and become real as C_3 is crossed from above, while a second pair of eigenvalues remains on the imaginary axis. Lombardi [30] has proved the existence of irrotational *generalized solitary waves* in the region just below C_3; their pulselike profile decays at infinity to a periodic ripple whose amplitude is exponentially small compared to that of the pulse. It is still an open question whether genuine solitary waves exist in this parameter regime, although Sun [34] has recently proved that they do not exist for values of β

close to $\beta_\star$, and there is strong numerical evidence that the same is true for all values of $\beta < \beta_\star$ (Champneys, Vanden-Broeck, and Lord [9]). The corresponding discussion for $\gamma \neq 0$ is beyond the scope of the present paper.

Spatial dynamics techniques are also used in a variety of existence proofs for other types of irrotational gravity-capillary water waves, notably in center-manifold methods for three-dimensional traveling waves (Groves and Mielke [18], Groves [15], Groves and Haragus [16], Groves and Sandstede [19]). On the other hand, center-manifold reduction is not available in other situations, for example, in the existence theories for three-dimensional solitary waves by Groves, Haragus, and Sun [17] and for two-dimensional solitary waves on water of infinite depth by Iooss and Kirrmann [25]; in these cases other methods are used to find solutions of the spatial dynamics formulation of the hydrodynamic problem as an infinite-dimensional evolutionary equation.

The present contribution is one of a series of papers in which established existence theories for irrotational water waves are generalized to flows with arbitrary distributions of vorticity. This program of research began with Constantin and Strauss [11], who generalized Keady and Norbury's [28] proof of the existence of a connected global branch of irrotational symmetric gravity Stokes waves containing waves whose speeds at the crest are arbitrarily small. Wahlén [35] has recently generalized the bifurcation theory for small-amplitude gravity-capillary Stokes waves by Jones [27] (see also Zeidler [36, 37]), while Hur [21] has extended Beale's [2] construction of small-amplitude gravity solitary waves.

2. Formulation as a Hamiltonian system. In this section we formulate the hydrodynamic problem as a reversible Hamiltonian system, the irrotational version of which was outlined by Groves [14] (see also Benjamin [3, Appendix B]). Note that the irrotational version differs from the Hamiltonian system by Groves and Toland [20] which is employed in the center-manifold reduction methods for irrotational water waves described above.

We begin by writing the hydrodynamic problem (1)–(5) in terms of the dimensionless variables

$$(x', y') = \frac{1}{d}(x, y), \quad \eta'(x') = \frac{1}{d}\eta(x), \quad \psi'(x', y') = -\frac{1}{m_0}\psi(x, y)$$

and dimensionless vorticity function

$$\gamma'(\psi') = -\frac{d^2}{m_0}\gamma(\psi).$$

One finds that

$$\Delta\psi = -\gamma(\psi), \qquad 0 < y < \eta(x), \tag{9}$$

$$\psi(x, 0) = 0, \tag{10}$$

$$\psi(x, \eta(x)) = -1, \tag{11}$$

$$\eta(x) \to 1 \qquad \text{as } x \to \pm\infty, \tag{12}$$

and

$$\frac{1}{2}|\nabla\psi|^2 + \alpha(y-1) - \beta\left[\frac{\eta_x}{\sqrt{1+\eta_x^2}}\right]_x = \frac{\mu}{2} \qquad \text{on } y = \eta(x), \tag{13}$$

in which

$$\alpha = \frac{gd^3}{m_0^2}, \quad \beta = \frac{\sigma d}{m_0^2}, \quad \mu = \frac{\lambda d^2}{m_0^2}$$

are dimensionless parameters and the primes have been dropped for notational simplicity. The next step is to map the unknown fluid domain D_η into a fixed strip $\mathbb{R} \times (0,1)$ using a transformation devised by Dubreil-Jacotin [13]. We define $s = -\psi(x,y)$, $h = y$, and treat $(x,s) \in \mathbb{R} \times (0,1)$ as independent variables and $\eta(x)$, $h(x,s)$ as dependent variables. A straightforward calculation shows that (9)–(13) are transformed into

$$\text{(14)} \quad \left[\frac{h_x}{h_s}\right]_x - \left[\frac{1+h_x^2}{2h_s^2}\right]_s + \gamma(-s) = 0, \qquad 0 < s < 1,$$

$$\text{(15)} \quad h(x,0) = 0,$$

$$\text{(16)} \quad h(x,1) = \eta,$$

$$\text{(17)} \quad \eta(x) \to 1 \qquad \text{as } x \to \pm\infty,$$

$$\text{(18)} \quad \frac{1+h_x^2}{2h_s^2} + \alpha(h-1) - \beta\left[\frac{h_x}{\sqrt{1+h_x^2}}\right]_x = \frac{\mu}{2}, \qquad s = 1,$$

and we seek solutions with $h_s > 0$, a condition which is implied by the assumption $\psi_y < 0$ (Constantin and Strauss [11]). The following proposition, which is proved by straightforward arguments from the theory of elliptic boundary-value problems, relates solutions of the transformed equations to those of (9)–(13).

PROPOSITION 2.1. *Define $I = (x_1, x_2)$, $I' = (x_1', x_2')$, with $x_1 < x_1' < x_2' < x_2$, and let $D_{\eta,I} = \{(x,y) : x \in I,\ 0 < y < \eta(x)\}$.*

(i) *Suppose that $\gamma \in L^2(-1,0)$. Any solution $h \in H^2(I \times (0,1)) \cap C^1(I \times [0,1])$ and $\eta = h|_{\{s=1\}} \in C^2(I)$ of (14)–(16), (18) defines a solution $\psi \in H^2(D_{\eta,I'}) \cap C^1(\overline{D_{\eta,I'}})$, $\eta \in C^2(I)$ of (9)–(11), (13).*

(ii) *The additional regularity $\gamma \in C^{k,\alpha}[-1,0]$ and $\eta \in C^{k+2,\alpha}(I)$ for some $\alpha \in (0,1)$ and some nonnegative integer k implies that $\psi \in C^{k+2,\alpha}(\overline{D_{\eta,I'}})$.*

Observe that (14)–(16), (18) follow from the formal variational principle

$$\delta\mathcal{J} = 0,$$

where

$$\text{(19)} \quad \mathcal{J} = \int \left\{ \int_0^1 \left(-\frac{1+h_x^2}{2h_s^2} + \alpha(h-1) - \frac{\mu}{2} - \Gamma(s) \right) h_s \,\mathrm{d}s + \beta\sqrt{1+\eta_x^2} \right\} \mathrm{d}x,$$

$$\Gamma(s) = -\int_s^1 \gamma(-u)\,du, \qquad s \in [0,1],$$

and the variations are taken with respect to $\eta(x)$ and $h(x,s)$ such that $h(x,1) = \eta(x)$ and $h(x,0) = 0$. (The corresponding variational principle for gravity waves was given by Constantin, Sattinger, and Strauss [10].) We exploit this variational principle by regarding $\mathcal{J}$ as an action functional of the form

$$\mathcal{J} = \int J(\eta, h, \eta_x, h_x)\,\mathrm{d}x,$$

in which J is the integrand on the right-hand side of (19), and deriving a Hamiltonian formulation of (14)–(16), (18) by means of the Legendre transform. To this end, let us introduce new variables ω and w by the formulas

$$\omega = \frac{\delta \mathcal{J}}{\delta \eta_x} = \frac{\beta \eta_x}{\sqrt{1+\eta_x^2}}, \qquad w = \frac{\delta \mathcal{J}}{\delta h_x} = -\frac{h_x}{h_s}, \tag{20}$$

in which the variational derivatives are taken in, respectively, $L^2(\mathbb{R})$ and $L^2(\mathbb{R}\times(0,1))$, and define the Hamiltonian function by

$$\begin{aligned} &H(\eta,\omega,h,w) \\ &\quad = \int_0^1 w h_x \,\mathrm{d}s + \omega\eta_x - J(\eta,h,\eta_x,h_x) \\ &\quad = \int_0^1 \left\{ \frac{1}{2}\left(\frac{1}{h_s} - h_s w^2\right) + \Gamma(s) h_s \right\} \mathrm{d}s - \frac{1}{2}\alpha(\eta-1)^2 + \frac{1}{2}\alpha + \frac{\mu}{2}\eta - \sqrt{\beta^2-\omega^2}. \end{aligned} \tag{21}$$

This procedure suggests that the equations

$$\eta_x = \frac{\delta H}{\delta \omega}, \quad \omega_x = -\frac{\delta H}{\delta \eta}, \quad h_x = \frac{\delta H}{\delta w}, \quad w_x = -\frac{\delta H}{\delta h}$$

formally represent Hamilton's equations for a formulation of the hydrodynamic problem (14)–(16), (18) as a Hamiltonian system.

In order to make the above suggestion rigorous, we define the Hilbert spaces

$$\begin{aligned} X &= \{(\eta,\omega,h,w) \in \mathbb{R}\times\mathbb{R}\times H^1(0,1)\times L^2(0,1) : h(0)=0,\ h(1)=\eta\}, \\ Y &= \{(\eta,\omega,h,w) \in \mathbb{R}\times\mathbb{R}\times H^2(0,1)\times H^1(0,1) : h(0)=0,\ h(1)=\eta\} \end{aligned}$$

and consider the symplectic manifold (X,Ω), where Ω is the position-independent 2-form on X given by

$$\Omega|_{(\eta,\omega,h,w)}((\eta_1,\omega_1,h_1,w_1),(\eta_2,\omega_2,h_2,w_2)) = \int_0^1 (w_2 h_1 - w_1 h_2)\,\mathrm{d}s + \omega_2\eta_1 - \omega_1\eta_2$$

(the canonical 2-form with respect to the $\mathbb{R}\times\mathbb{R}\times L^2(0,1)\times L^2(0,1)$-inner product). Choose $\gamma \in L^2(-1,0)$, so that $\Gamma \in H^1(-1,0)$, and observe that the set

$$M = \{(\eta,\omega,h,w) \in Y : |\omega| < \beta,\ \eta > 0,\ h_s(s) > 0 \text{ for each } s \in [0,1]\}$$

is a manifold domain of X and that the function H given by (21) belongs to $C^\infty(M,\mathbb{R})$; a direct calculation shows that

$$\begin{aligned} \mathrm{d}H|_m(v_1|_m) = \int_0^1 \left\{ -\frac{1}{2}\left(w^2 + \frac{1}{h_s^2}\right) + \Gamma(p) \right\} h_{1s}\,\mathrm{d}s - \int_0^1 h_s w w_1 \,\mathrm{d}s \\ - \alpha(\eta-1)\eta_1 + \frac{\mu}{2}\eta_1 + \frac{\omega\omega_1}{\sqrt{\beta^2-\omega^2}} \end{aligned}$$

for $m = (\eta,\omega,h,w) \in M$ and $v_1|_m = (\eta_1,\omega_1,h_1,w_1) \in TM|_m \cong Y$. The triple (X,Ω,H) is therefore a Hamiltonian system.

Recall that the point $m \in M$ belongs to the domain $\mathcal{D}(v_H)$ of the Hamiltonian vector field v_H associated with (X,Ω,H), with $v_H|_m = \bar{v}|_m$, if and only if

$$\Omega_m(\bar{v}|_m, v_1|_m) = \mathrm{d}H|_m(v_1|_m)$$

for all tangent vectors $v_1|_m \in TM|_m \subset TX|_m$. Using this criterion and the above expression for $\mathrm{d}H|_m(v_1|_m)$ and integrating by parts, one finds that

$$\mathcal{D}(v_H) = \left\{ (\eta, \omega, h, w) \in M : \ w(0) = 0, \ h_s(1)w(1) = -\frac{\omega}{\sqrt{\beta^2 - \omega^2}} \right\}$$

and that Hamilton's equations

$$u_x = v_H(u)$$

are given explicitly by

$$\eta_x = \frac{\omega}{\sqrt{\beta^2 - \omega^2}}, \tag{22}$$

$$\omega_x = \frac{1}{2}\left(w^2(1) + \frac{1}{h_s^2(1)} \right) + \alpha(\eta - 1) - \frac{\mu}{2}, \tag{23}$$

$$h_x = -h_s w, \tag{24}$$

$$w_x = -\frac{1}{2}\left(w^2 + \frac{1}{h_s^2} \right)_s + \gamma(-s). \tag{25}$$

Observe that Hamilton's equations are reversible; the reverser $S : X \to X$ is defined by $S(\eta, \omega, h, w) = (\eta, -\omega, h, -w)$.

Proposition 2.2. *Suppose that $(\eta, \omega, h, w) \in C(I, \mathcal{D}(v_H)) \cap C^1(I, X)$, $I = (x_1, x_2)$ solves Hamilton's equations, and let $I' = (x_1', x_2')$, with $x_1 < x_1' < x_2' < x_2$. The functions $\tilde{h}, \tilde{w}$ defined by*

$$\tilde{h}(x, s) = h(x)(s), \qquad \tilde{w}(x, s) = w(x)(s)$$

belong to, respectively, $H^2(D_{\eta,I'}) \cap C^1(\overline{D_{\eta,I'}})$ and $H^1(D_{\eta,I'}) \cap C(\overline{D_{\eta,I'}})$, while η and ω belong to, respectively, $C^2(\overline{I'})$ and $C^1(\overline{I'})$. These functions satisfy $\tilde{h}(x, s) > 0$ in $\overline{D_{\eta,I'}}$, $|\omega| < \beta$ in $\overline{I'}$, the equations

$$\tilde{h}_x = -\tilde{h}_s \tilde{w}, \qquad \tilde{w}_x = -\frac{1}{2}\left(\tilde{w}^2 + \frac{1}{\tilde{h}_s^2} \right)_s + \gamma(-s)$$

in $D_{\eta,I'}$ with boundary conditions

$$\tilde{h}(x, 0) = \tilde{w}(x, 0) = 0, \qquad \tilde{h}(x, 1) = \eta(x), \qquad \tilde{h}_s(x, 1)\tilde{w}(x, 1) = -\frac{\omega}{\sqrt{\beta^2 - \omega^2}},$$

and the equations

$$\eta_x = \frac{\omega}{\sqrt{\beta^2 - \omega^2}},$$

$$\omega_x = \frac{1}{2}\left(\tilde{w}^2 + \frac{1}{\tilde{h}_s^2} \right)\Bigg|_{s=1} + \alpha(\eta - 1) - \frac{\mu}{2}$$

in I'.

The above proposition is proved using the methods given by Groves and Toland [20]. Eliminating ω and $\tilde{w}$ between the above equations, we find that $\tilde{h}$ and η satisfy (14)–(16), (18), and Proposition 2.1 yields a solution of the hydrodynamic problem (9)–(11), (13). Note that the additional regularity $\gamma \in C^{k,\alpha}[0,1]$ and $u \in C^{k+2}(I, \mathcal{D}(v_H)) \cap C^{k+3}(I, X)$ for some $\alpha \in (0,1)$ and some nonnegative integer k

implies that $\psi \in C^{k+2,\alpha}(\overline{D_{\eta,I'}})$. In the remainder of this article we take $\gamma \in H^1(0,1)$ rather than $\gamma \in L^2(0,1)$ in order to simplify the spectral theory presented in section 3.2.

We proceed by seeking solutions $(\eta, \omega, h, w) \in C(\mathbb{R}, \mathcal{D}(v_H)) \cap C^1(\mathbb{R}, X)$ of Hamilton's equations which satisfy $\eta(x) \to 1$ as $x \to \pm\infty$. These solutions take the form of perturbations of equilibrium (that is, x-independent) solutions $(\eta_0, \omega_0, h_0(s), w_0(s))$, where necessarily $\eta_0 = 1$ and $\omega_0 = 0$, $w_0 = 0$ (see (20)); our solitary waves therefore ride a horizontal laminar flow (which is, in general, not uniform). The requirement that the hydrodynamic problem admits a horizontal laminar flow for a given vorticity function fixes the value of the Bernoulli constant μ.

LEMMA 2.3. *Suppose that*

$$\int_0^1 \frac{1}{\sqrt{2\Gamma(s) - 2\Gamma_{\min}}} \, \mathrm{d}s > 1, \tag{26}$$

where

$$\Gamma_{\min} = \min_{s \in [0,1]} \Gamma(s), \qquad \Gamma_{\max} = \max_{s \in [0,1]} \Gamma(s).$$

There exists a unique value $\mu^\star > -2\Gamma_{\min}$ of μ for which Hamilton's equations (22)–(25) *admit a solution of the form*

$$(\eta, \omega, h, w) = (1, 0, \theta(s), 0) \tag{27}$$

for all $\beta, \alpha > 0$. The function $\theta(s)$ is given by the formula

$$\theta(s) = \int_0^s a^{-1}(u) \, \mathrm{d}u, \qquad a(s) = \sqrt{\mu^\star + 2\Gamma(s)}.$$

Proof. Any solution of (22)–(25) of the form (27) satisfies

$$\frac{1}{2}\left(\frac{1}{\theta_s^2}\right)_s = \gamma(-s), \qquad \frac{1}{\theta_s^2(1)} = \mu, \qquad \theta(0) = 0,$$

so that

$$\theta(s) = \int_0^s \frac{1}{\sqrt{\mu + 2\Gamma(u)}} \, \mathrm{d}u,$$

where we have assumed that $\mu > -2\Gamma_{\min}$. It remains to satisfy the boundary condition $h(1) = \eta$; that is, $\theta(1) = 1$. Observe that $\theta(1)$ is a strictly decreasing function of $\mu \in [-2\Gamma_{\min}, \infty)$ which satisfies $\theta(1) \to 0$ as $\mu \to \infty$ and $\theta(1)|_{\mu = -2\Gamma_{\min}} > 1$ under the assumption (26). It follows that there exists a unique value $\mu^\star$ of μ such that $\theta(1) = 1$. $\square$

In accordance with Lemma 2.3 we take $\mu = \mu^\star$ and seek solutions of Hamilton's equations for (X, Ω, H) of the form

$$\eta = 1 + \rho, \qquad h = \theta + \phi,$$

where $\rho > -1$ and $\phi_s(s) > -a^{-1}(s)$ for $s \in [0,1]$. Let us write

$$(\beta, \alpha) = (\beta_0 + \varepsilon_1, \alpha_0 + \varepsilon_2),$$

where (β_0, α_0) is fixed and $(\varepsilon_1, \varepsilon_2)$ lies in a neighborhood Λ of the origin in $\mathbb{R}^2$, and consider solutions (ρ, ω, ϕ, w) which lie in a neighborhood V of the origin in Y; here Λ and V are chosen small enough so that

$$|\varepsilon_1| < \frac{\beta_0}{4}, \quad \rho > -\frac{1}{2} > -1, \quad |\omega| < \frac{\beta_0}{2} < \beta_0 + \varepsilon_1,$$
$$\phi_s(s) > -\frac{1}{2}(\mu^\star + 2\Gamma_{\max})^{-1/2} > -a^{-1}(s)$$

for each $s \in [0,1]$. This change of variable transforms (X, Ω, H) into $(X, \Omega, H^\varepsilon)$, where $H^\varepsilon \in C^\infty(V, \mathbb{R})$ is defined by the formula

$$\begin{aligned} H^\varepsilon(\rho, \omega, \phi, w) = &\int_0^1 \left\{ \frac{1}{2} \left(\frac{1 - (a^{-1}(s) + \phi_s)^2 w^2}{a^{-1}(s) + \phi_s} \right) - \frac{1}{2} a(s) + \Gamma(s)\phi_s \right\} \mathrm{d}s \\ &- \frac{1}{2}(\alpha_0 + \varepsilon_2)\rho^2 + \frac{1}{2}\mu^\star \rho + (\beta_0 + \varepsilon_1) - \sqrt{(\beta_0 + \varepsilon_1)^2 - \omega^2} \end{aligned}$$

(a constant term has also been added to the Hamiltonian to ensure that $H^\varepsilon(0) = 0$). Hamilton's equations (22)–(25) are transformed into

$$\rho_x = \frac{\omega}{\sqrt{(\beta_0 + \varepsilon_1)^2 - \omega^2}}, \tag{28}$$

$$\omega_x = \frac{1}{2} \left(w^2(1) + \frac{a^2(1)}{(1 + a(1)\phi_s(1))^2} \right) + (\alpha_0 + \varepsilon_2)\rho - \frac{\mu^\star}{2}, \tag{29}$$

$$\phi_x = -(a^{-1}(s) + \phi_s)w, \tag{30}$$

$$w_x = -\frac{1}{2} \left(w^2 + \frac{a^2(s)}{(1 + a(s)\phi_s)^2} \right)_s + \gamma(-s), \tag{31}$$

the domain $\mathcal{D}(v_{H^\varepsilon})$ of the Hamiltonian vector field on the right-hand side of this system of equations is the set of elements $(\rho, \omega, \phi, w) \in V$ which satisfy

$$\begin{aligned} w(0) &= 0, \\ (\phi_s(1) + a^{-1}(1))w(1) &= -\frac{\omega}{\sqrt{(\beta + \varepsilon_1)^2 - \omega^2}}, \end{aligned} \tag{32}$$

and the action of the reverser $S : X \to X$ is given by $S(\rho, \omega, \phi, w) = (\rho, -\omega, \phi, -w)$. Our task is to find homoclinic solutions of the above equations, that is, solutions $(\rho, \omega, \phi, w) \in C(\mathbb{R}, \mathcal{D}(v_{H^\varepsilon})) \cap C^1(\mathbb{R}, X)$ which satisfy

$$(\rho(x), \omega(x), \phi(x), w(x)) \to (0, 0, 0, 0)$$

as $x \to \pm\infty$.

3. Center-manifold reduction.

3.1. Application of the reduction theorem. Our strategy in finding solutions to Hamilton's equations (28)–(31) for $(X, \Omega, H^\varepsilon)$ consists in applying a reduction principle which asserts that $(X, \Omega, H^\varepsilon)$ is locally equivalent to a finite-dimensional Hamiltonian system. The key result is the following theorem, which is a parametrized, Hamiltonian version of a reduction principle for quasi-linear evolutionary equations presented by Mielke [31, Theorem 4.1] (see Buffoni, Groves, and Toland [8, Theorem 4.1]).

THEOREM 3.1. *Consider the reversible differential equation*

$$u_x = \mathcal{L}u + \mathcal{N}(u;\lambda), \tag{33}$$

which is Hamilton's equation for the Hamiltonian system $(X, \Omega^\lambda, H^\lambda)$. *Here* u *belongs to a Hilbert space* $\mathcal{X}$, $\lambda \in \mathbb{R}^\ell$ *is a parameter, and* $\mathcal{L} : \mathcal{D}(\mathcal{L}) \subset \mathcal{X} \to \mathcal{X}$ *is a densely defined, closed linear operator. Regarding* $\mathcal{D}(\mathcal{L})$ *as a Hilbert space equipped with the graph norm, suppose that* 0 *is an equilibrium point of* (33) *when* $\lambda = 0$ *and that*

(H1) *the part of the spectrum* $\sigma(\mathcal{L})$ *of* $\mathcal{L}$ *which lies on the imaginary axis consists of a finite number of eigenvalues of finite multiplicity and is separated from the rest of* $\sigma(\mathcal{L})$ *in the sense of Kato, so that* $\mathcal{X}$ *admits the decomposition* $\mathcal{X} = \mathcal{X}_1 \oplus \mathcal{X}_2$, *where* $\mathcal{X}_1 = \mathcal{P}(\mathcal{X})$, $\mathcal{X}_2 = (I - \mathcal{P})(\mathcal{X})$, *and* $\mathcal{P}$ *is the spectral projection corresponding the purely imaginary part of* $\sigma(\mathcal{L})$;

(H2) *the operator* $\mathcal{L}_2 = \mathcal{L}|_{\mathcal{X}_2}$ *satisfies the estimate*

$$\|(\mathcal{L}_2 - \mathrm{i}\xi I)^{-1}\|_{\mathcal{X}_2 \to \mathcal{X}_2} \le \frac{C}{1 + |\xi|}, \qquad \xi \in \mathbb{R}$$

for some constant C *that is independent of* ξ;

(H3) *there exists a natural number* k *and neighborhoods* $\Lambda \subset \mathbb{R}^\ell$ *of* 0 *and* $U \subset \mathcal{D}(\mathcal{L})$ *of* 0 *such that* $\mathcal{N}$ *is* $(k+1)$ *times continuously differentiable on* $U \times \Lambda$, *its derivatives are bounded and uniformly continuous on* $U \times \Lambda$, *and* $\mathcal{N}(0,0) = 0$, $\mathrm{d}_1\mathcal{N}[0,0] = 0$.

Under these hypotheses there exist neighborhoods $\tilde{\Lambda} \subset \Lambda$ *of* 0 *and* $\tilde{U}_1 \subset U \cap \mathcal{X}_1$, $\tilde{U}_2 \subset U \cap \mathcal{X}_2$ *of* 0 *and a reduction function* $r : \tilde{U}_1 \times \tilde{\Lambda} \to \tilde{U}_2$ *with the following properties. The reduction function* r *is* k *times continuously differentiable on* $\tilde{U}_1 \times \tilde{\Lambda}$, *its derivatives are bounded and uniformly continuous on* $\tilde{U}_1 \times \tilde{\Lambda}$, *and* $r(0;0) = 0$, $\mathrm{d}_1 r[0;0] = 0$. *The graph* $\tilde{X}^\lambda = \{u_1 + r(u_1;\lambda) \in \tilde{U}_1 \times \tilde{U}_2 : u_1 \in \tilde{U}_1\}$ *is a Hamiltonian center manifold for* (33), *so that*

(i) $\tilde{X}^\lambda$ *is a locally invariant manifold of* (33): *Through every point in* $\tilde{X}^\lambda$ *there passes a unique solution of* (33) *that remains on* $\tilde{X}^\lambda$ *as long as it remains in* $\tilde{U}_1 \times \tilde{U}_2$;

(ii) *every small bounded solution* $u(x)$, $x \in \mathbb{R}$ *of* (33) *satisfying* $(u_1(x), u_2(x)) \in \tilde{U}_1 \times \tilde{U}_2$ *lies completely in* $\tilde{X}^\lambda$;

(iii) *every solution* $u_1 : (x_1, x_2) \to \tilde{U}_1$ *of the reduced equation*

$$u_{1x} = \mathcal{L}u_1 + \mathcal{P}\mathcal{N}(u_1 + r(u_1;\lambda);\lambda) \tag{34}$$

generates a solution

$$u(x) = u_1(x) + r(u_1(x);\lambda) \tag{35}$$

of the full equation (33);

(iv) $\tilde{X}^\lambda$ *is a symplectic submanifold of* X, *and the flow determined by the Hamiltonian system* $(\tilde{X}^\lambda, \tilde{\Omega}^\lambda, \tilde{H}^\lambda)$, *where the tilde denotes restriction to* $\tilde{X}^\lambda$, *coincides with the flow on* $\tilde{X}^\lambda$ *determined by* $(X, \Omega^\lambda, H^\lambda)$. *The reduced equation* (34) *is reversible and represents Hamilton's equations for* $(\tilde{X}^\lambda, \tilde{\Omega}^\lambda, \tilde{H}^\lambda)$.

The center manifold $\tilde{X}^\lambda$ is equipped with the single coordinate chart $\tilde{U}_1 \subset \mathcal{X}_1$ and coordinate map $\chi : \tilde{X}^\lambda \to \tilde{U}_1$ defined by $\chi^{-1}(u_1) = u_1 + r(u_1;\lambda)$. It is, however, more convenient to use an alternative coordinate map for calculations. According to the parameter-dependent version of Darboux's theorem presented by Buffoni and Groves [7, Theorem 4], there exists a near-identity change of variable

$$\tilde{u}_1 = u_1 + \Theta(u_1;\lambda) \tag{36}$$

of class C^{k-1} which transforms $\tilde{\Omega}^\lambda$ into Ψ, where

$$\Psi(v_1, v_2) = \Omega^0|_0(v_1, v_2).$$

Define the function $\tilde{r} : \tilde{U}_1 \times \tilde{\Lambda} \to \tilde{U}_1 \times \tilde{U}_2$ (which, in general, has components in $\mathcal{X}_1$ and $\mathcal{X}_2$) by the formula

$$\tilde{u}_1 + \tilde{r}(\tilde{u}_1; \lambda) = \mathcal{T}(u_1 + r(u_1; \lambda); \lambda), \qquad \mathcal{T}(u_1, u_2; \lambda) = (u_1 + \Theta(u_1; \lambda), u_2),$$

where $\tilde{r}(0; 0) = 0$, $\mathrm{d}_1\tilde{r}[0; 0] = 0$, and equip $\tilde{X}^\lambda$ with the coordinate map $\tilde{\chi} : \tilde{X}^\lambda \to \tilde{U}_1$ given by $\tilde{\chi}^{-1}(\tilde{u}_1) = \tilde{u}_1 + \tilde{r}(\tilde{u}_1; \lambda)$. One can always choose a basis for $\mathcal{X}_1$ so that Ψ is the canonical symplectic 2-form Υ in this coordinate system (a "symplectic basis"). The choice of $\tilde{\chi}$ as coordinate map therefore yields a finite-dimensional canonical Hamiltonian system.

Theorem 3.1 cannot be applied directly to (28)–(29) because of the nonlinear boundary condition (32). We overcome this difficulty by using the change of variable $(\rho, \zeta, \phi, z) = G^\varepsilon(\rho, \omega, \phi, w)$, where

$$\zeta = -\frac{a(1)\omega}{\sqrt{(\beta + \varepsilon_1)^2 - \omega^2}}, \qquad z(s) = (1 + a(s)\phi_s(s))w(s),$$

which transforms the nonlinear boundary condition into the linear condition $z(1) = \zeta$. The following lemma shows that G^ε defines a valid change of variable.

LEMMA 3.2.

(i) *For each $\varepsilon \in \Lambda$ the mapping G^ε is a smooth diffeomorphism from the neighborhood V of 0 in Y onto itself.*

(ii) *For each $(v, \varepsilon) \in V \times \Lambda$ the operators $\mathrm{d}G^\varepsilon[v]$, $\mathrm{d}((G^\varepsilon)^{-1})[v] : Y \to Y$ extend to mappings $X \to X$ that depend smoothly upon $(v, \varepsilon) \in V \times \Lambda$.*

Proof. These results follow from the explicit formula

$$G^{-1}(\rho, \zeta, \phi, z) = (\rho, \omega, \phi, w),$$

where

$$\omega = -\frac{(\beta_0 + \varepsilon_1)\zeta}{\sqrt{\zeta^2 + a^2(1)}}, \qquad w(s) = \frac{z(s)}{1 + a(s)\phi_s(s)},$$

and

$$\begin{aligned}
&\mathrm{d}G^\varepsilon[\rho, \omega, \phi, w](\rho_1, \omega_1, \phi_1, w_1)\\
&\quad = \left(\rho_1, -\frac{a(1)(\beta_0 + \varepsilon_1)^2\omega_1}{((\beta_0 + \varepsilon_1)^2 - \omega^2)^{3/2}}, \phi_1, (1 + a(s)\phi_s)w_1 + a(s)w\phi_{1s}\right),\\
&\mathrm{d}((G^\varepsilon)^{-1}))[\rho, \zeta, \phi, z](\rho_1, \zeta_1, \phi_1, z_1)\\
&\quad = \left(\rho_1, -\frac{(\beta_0 + \varepsilon_1)a^2(1)\zeta_1}{(a^2(1) + \zeta^2)^{3/2}}, \phi_1, \frac{z_1}{1 + a(s)\phi_s} - \frac{a(s)z\phi_{1s}}{(1 + a(s)\phi_s)^2}\right). \qquad \square
\end{aligned}$$

An explicit calculation shows that the above change of variable transforms (28)–(31) into

$$\rho_x = -a^{-1}(1)\zeta, \tag{37}$$

$$\zeta_x = -\frac{(a^2(1) + \zeta^2)^{3/2}}{a^2(1)(\beta_0 + \varepsilon_1)}\left(\frac{z^2(1) + a^2(1)}{2(1 + a(1)\phi_s(1))^2} + (\alpha_0 + \varepsilon_2)\rho - \frac{\mu^\star}{2}\right), \tag{38}$$

$$\phi_x = -a^{-1}(s)z, \tag{39}$$

$$z_x = -\frac{a(s)z(a^{-1}(s)z)_s}{1 + a(s)\phi_s} - (1 + a(s)\phi_s)\left(\left(\frac{z^2 + a^2(s)}{2(1 + a(s)\phi_s)^2}\right)_s - \gamma(-s)\right); \tag{40}$$

these equations hold in the phase space X, and the domain of the vector field on their right-hand side is a neighborhood of the origin in the linear space

$$Z = \{(\rho, \zeta, \phi, z) \in Y : \ z(0) = 0, \ z(1) = \zeta\}.$$

Notice that the change of variable preserves the reversibility; the action of the reverser $S : X \to X$ is given by $S(\rho, \zeta, \phi, z) = (\rho, -\zeta, \phi, -z)$. Equations (37)–(40) represent Hamilton's equations for the Hamiltonian system $(X, \Phi^\varepsilon, K^\varepsilon)$, where

$$\begin{aligned}\Phi^\varepsilon|_{(\rho,\zeta,\phi,z)}&((\rho_1, \zeta_1, \phi_1, z_1), (\rho_2, \zeta_2, \phi_2, z_2)) \\ &= \int_0^1 \left\{ \frac{z_2\phi_1 - z_1\phi_2}{1 + a(s)\phi_s} - \frac{a(s)z}{(1 + a(s)\phi_s)^2}(\phi_{2s}\phi_1 - \phi_{1s}\phi_2) \right\} \mathrm{d}s \\ &\quad - \frac{(\beta_0 + \varepsilon_1)a^2(1)}{(\zeta^2 + a^2(1))^{3/2}}(\zeta_2\rho_1 - \zeta_1\rho_2)\end{aligned}$$

and $K^\varepsilon \in C^\infty(V, \mathbb{R})$ is defined by the formula

$$\begin{aligned}K^\varepsilon(\rho, \zeta, \phi, z) = \int_0^1 &\left\{ \frac{a(s) - a^{-1}(s)z^2}{2(1 + a(s)\phi_s)} + \Gamma(s)\phi_s - \frac{a(s)}{2} \right\} \mathrm{d}s \\ &- \frac{1}{2}(\alpha_0 + \varepsilon_2)\rho^2 + \frac{1}{2}\mu^\star\rho - \frac{a(1)(\beta_0 + \varepsilon_1)}{\sqrt{a^2(1) + \zeta^2}} + (\beta_0 + \varepsilon_1).\end{aligned}$$

The next step is to verify that (37)–(40) satisfy the hypotheses of Theorem 3.1. We write these equations as

$$u_x = Lu + N^\varepsilon(u), \tag{41}$$

in which the linear operator $L : \mathcal{D}(L) \subset X \to X$, with $\mathcal{D}(L) = Z$, is given by

$$L \begin{pmatrix} \rho \\ \zeta \\ \phi \\ z \end{pmatrix} = \begin{pmatrix} -a^{-1}(1)\zeta \\ a^4(1)\beta_0^{-1}\phi_s(1) - a(1)\alpha_0\beta_0^{-1}\rho \\ -a^{-1}(s)z \\ (a^3(s)\phi_s)_s \end{pmatrix} \tag{42}$$

(the linearization of the Hamiltonian vector field v_{K^ε} at $\varepsilon = 0$). It follows from Proposition 3.3 and Lemma 3.4, the former of which is proved using the elementary theory of ordinary differential equations, that L satisfies hypotheses (H1) and (H2); hypothesis (H3) is clearly satisfied for an arbitrary value of k.

Proposition 3.3. *The spectrum of the operator $L : \mathcal{D}(L) \subset X \to X$ consists of isolated, geometrically simple eigenvalues of finite algebraic multiplicity.*

Lemma 3.4. *There exist real constants C, $\xi_0 > 0$ such that each solution $v \in Y$ of the resolvent equation*

$$(L - \mathrm{i}\xi I)v = f^\star, \tag{43}$$

in which $f^\star$ belongs to X and ξ is a real number with $|\xi| > \xi_0$, satisfies the estimates

$$\|v\|_Y \le C\|f^\star\|_X, \qquad \|v\|_X \le \frac{C}{|\xi|}\|f^\star\|_X.$$

Proof. Let us write the resolvent equation (43) in the form

$$-a^{-1}(1)\zeta - \mathrm{i}\xi\rho = \rho^\star, \tag{44}$$

$$a^4(1)\beta_0^{-1}\phi_s(1) - a(1)\alpha_0\beta_0^{-1}\rho - \mathrm{i}\xi\zeta = \zeta^\star, \tag{45}$$

$$-a^{-1}(s)z - \mathrm{i}\xi\phi = \phi^\star, \tag{46}$$

$$(a^3(s)\phi_s)_s - \mathrm{i}\xi z = z^\star, \tag{47}$$

where $(\rho^\star, \omega^\star, \phi^\star, z^\star) \in X$ and $(\rho, \omega, \phi, z) \in Z$, so that $\phi^\star(0) = 0$, $\phi^\star(1) = \rho^\star$, and $\phi(0) = 0$, $\phi(1) = \rho$, $z(0) = 0$, $z(1) = \zeta$.

The first step is to differentiate (46) and multiply by $a^{3/2}(s)$, and multiply (47) by $a^{-1/2}(s)$, so that

$$\begin{aligned} -a^{3/2}(s)(a^{-1}(s)z)_s - \mathrm{i}\xi a^{3/2}(s)\phi_s &= a^{3/2}(s)\phi_s^\star, \\ a^{-1/2}(s)(a^3(s)\phi_s)_s - \mathrm{i}\xi a^{-1/2}(s)z &= a^{-1/2}(s)z^\star; \end{aligned}$$

squaring and adding these equations, one finds that

$$\begin{aligned} &a^3(s)|(a^{-1}(s)z)_s|^2 + a^{-1}(s)|(a^3(s)\phi_s)_s| + \xi^2(a^3(s)|\phi_s|^2 + a^{-1}(s)|z|^2) \\ &\quad + 2\xi\,\mathrm{Im}\,\{(a^{-1}(s)z)_s a^3(s)\overline{\phi}_s + a^{-1}(s)z(a^3(s)\overline{\phi}_s)_s\} = a^3(s)|\phi_s^\star|^2 + a^{-1}(s)|z^\star|^2. \end{aligned}$$

Let $\|\cdot\|$ and $\|\cdot\|_w$ denote, respectively, the usual $L^2(0,1)$-norm and the $L^2(0,1)$-norm with weight function w. We integrate the above equation over $(0,1)$, so that

$$\begin{aligned} &\|(a^{-1}(s)z)_s\|_{a^3}^2 + \|(a^3(s)\phi_s)_s\|_{a^{-1}}^2 + \xi^2(\|\phi_s\|_{a^3}^2 + \|z\|_{a^{-1}}^2) \\ &\qquad = \|\phi_s^\star\|_{a^3}^2 + \|z^\star\|_{a^{-1}}^2 - 2\xi a^2(1)\mathrm{Im}\,\{z(1)\overline{\phi}_s(1)\}, \end{aligned} \tag{48}$$

and multiplying (45) by $\overline{\phi}_s(1)$ and taking real parts, we find that

$$\begin{aligned} \xi\,\mathrm{Im}\,\{z(1)\overline{\phi}_s(1)\} &= -\frac{a^4(1)}{\beta_0}|\phi_s(1)|^2 + \frac{a(1)\alpha_0}{\beta_0}\mathrm{Re}\,\{\phi(1)\overline{\phi}_s(1)\} + \mathrm{Re}\,\{\zeta^\star\overline{\phi}_s(1)\} \\ &\le C_1(|\phi_s(1)|^2 + |\phi(1)|^2 + |\zeta^\star|^2). \end{aligned} \tag{49}$$

To estimate $|\phi_s(1)|^2$ we multiply (47) by s^n, where n is a positive integer, and integrate over $(0,1)$, so that

$$a^3(1)\phi_s(1) = \int_0^1 a^3(s)\phi_s(s)ns^{n-1}\,\mathrm{d}s + \mathrm{i}\xi\int_0^1 z(s)s^n\,\mathrm{d}s + \int_0^1 z^\star(s)s^n\,\mathrm{d}s,$$

and an application of the Cauchy–Schwarz inequality yields

$$|\phi_s(1)|^2 \le C_2\left(\frac{n^2}{2n-1}\|\phi_s\|_{a^6}^2 + \frac{\xi^2}{2n+1}\|z\|^2 + \frac{1}{2n+1}\|z^\star\|^2\right). \tag{50}$$

A straightforward combination of estimates (48)–(50), the inequality $|\phi(1)|^2 \le \|\phi_s\|^2$, and the fact that $\|\cdot\|$ and $\|\cdot\|_w$ are equivalent norms for any positive $w \in C[0,1]$ shows that

$$\begin{aligned} &\|\phi_{ss}\|^2 + \|\phi_s\|^2 + \|z_s\|^2 + \|z\|^2 + \xi^2(\|\phi_s\|^2 + \|z\|^2) \\ &\qquad \le C_3\left(\frac{n^2}{2n-1}\|\phi_s\|^2 + \frac{\xi^2}{2n+1}\|z\|^2 + \|\phi_s^\star\|^2 + \|z^\star\|^2 + |\zeta^\star|^2\right). \end{aligned}$$

Choosing n large enough so that $C_3/(2n+1) \leq 1/2$, we therefore find that

$$\|\phi_{ss}\|^2 + \|\phi_s\|^2 + \|z_s\|^2 + \|z\|^2 + \frac{\xi^2}{2}(\|\phi_s\|^2 + \|z\|^2) \leq C_3(|\zeta^\star|^2 + \|\phi_s^\star\|^2 + \|z^\star\|^2)$$

and hence that

$$\|\phi\|_{H^2}^2 + \|z\|_{H^1}^2 + \frac{\xi^2}{2}(\|\phi\|_{H^1}^2 + \|z\|^2) \leq C_4(|\zeta^\star|^2 + \|\phi^\star\|_{H^1}^2 + \|z^\star\|^2)$$

for sufficiently large ξ, where we have exploited the fact that $\phi(0)$, $\phi^\star(0)$, and $z(0)$ all vanish.

It follows from (45) that

$$\xi^2|\zeta|^2 \leq C_4(|\zeta^\star|^2 + |\phi(1)|^2 + |\phi_s(1)|^2) \leq C_5(|\zeta^\star|^2 + \|\phi\|_{H^1}^2 + \xi^2\|z\|^2 + \|z^\star\|^2)$$

and clearly $|\rho|^2 = |\phi(1)|^2 \leq \|\phi\|_{H^1}^2$, so that altogether

$$\|\phi\|_{H^2}^2 + \|z\|_{H^1}^2 + \frac{\xi^2}{2}(|\rho|^2 + |\zeta|^2 + \|\phi\|_{H^1}^2 + \|z\|^2) \leq C_6(|\zeta^\star|^2 + \|\phi^\star\|_{H^1}^2 + \|z^\star\|^2). \qquad \square$$

3.2. Eigenvalues of the linearized problem. In this section we examine the spectrum of L in more detail, in particular the qualitative dependence of its eigenvalues upon (β_0, α_0). Eliminating ρ, ζ, and z, we find that the eigenvalue problem $Lu = \kappa u$ is equivalent to

$$-a^{-1}(s)(a^3(s)\phi_s)_s = \kappa^2\phi, \qquad 0 < s < 1, \tag{51}$$

$$-\frac{a^3(1)}{\beta}\phi_s(1) + \frac{\alpha}{\beta}\phi(1) = \kappa^2\phi(1), \tag{52}$$

$$\phi(0) = 0 \tag{53}$$

(for convenience we drop the subscript 0 in this section). The change of variable

$$y = \int_0^s a^{-1}(u)\,\mathrm{d}u, \qquad v(y) = a(s)\phi(s)$$

transforms the above equations into the equivalent non-self-adjoint Sturm–Liouville problem

$$-v_{yy} + Q(y)v = \nu v, \tag{54}$$

$$\frac{v_y(1)}{v(1)} = \hat{\alpha} - \hat{\beta}\nu, \tag{55}$$

$$v(0) = 0, \tag{56}$$

where $\nu = \kappa^2$, $Q(y) = -\gamma'(-s)$, $\hat{\alpha} = a'(1) + a^{-2}(1)\alpha$, and $\hat{\beta} = a^{-2}(1)\beta$; detailed spectral results for problems of this type have been presented by Binding et al. [4].

The Sturm–Liouville problem (54)–(56) has a countable number of geometrically simple eigenvalues which can be listed as $\nu_0, \nu_1, \nu_2, \ldots,$ where $\operatorname{Re}\nu_n \leq \operatorname{Re}\nu_{n+1}$ (entries are repeated according to their algebraic multiplicity); they occur in complex-conjugate pairs and satisfy

$$\nu_n = n^2\pi^2 + \int_0^1 Q(y)\,\mathrm{d}y - \frac{2\hat{\alpha}}{\hat{\beta}} + o\left(\frac{1}{n}\right), \qquad n \in \mathbb{N}_0. \tag{57}$$

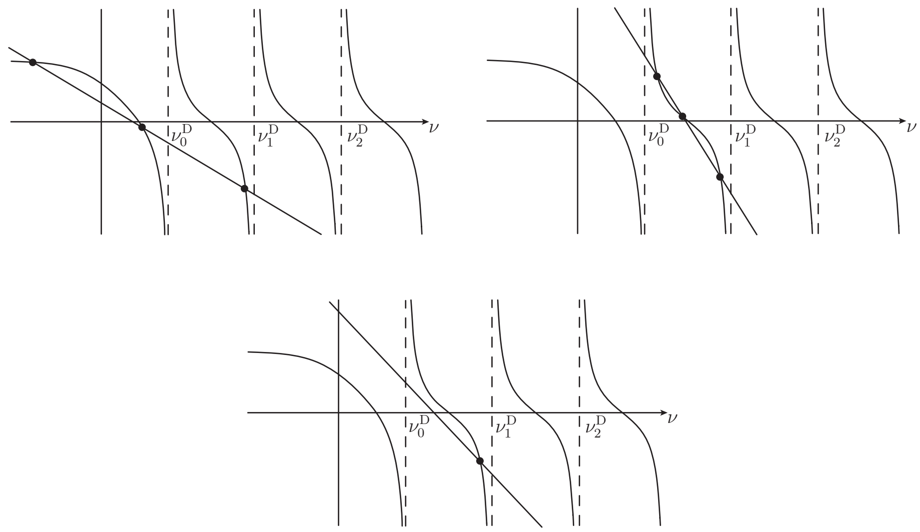


FIG. 2. *Geometric characterization of the eigenvalues ν_n as the points of intersection of the curve $s = B(\nu)$ with the straight line $s = \hat{\alpha} - \hat{\beta}\nu$; one real eigenvalue lies in each interval $(\nu_{n-1}^{\mathrm{D}}, \nu_n^{\mathrm{D}})$, $n \in \mathbb{N}$. Clockwise from top left: two additional real eigenvalues to the left of ν_0^{D}; two additional real eigenvalues in the interval $(\nu_{n-1}^{\mathrm{D}}, \nu_n^{\mathrm{D}})$ for some $n \in \mathbb{N}$; two additional complex eigenvalues.*

Observe that the real eigenvalues of the spectral problem (54)–(56) correspond to the intersections in the (ν, s) plane of the line $s = \hat{\alpha} - \hat{\beta}\nu$ and the curve $s = B(\nu)$, where $B(\nu) = v_y(1;\nu)/v(1;\nu)$ and $v(y;\nu)$ solves the initial-value problem

$$-v_{yy} + Q(y)v = \nu v, \qquad v(0;\nu) = 0;$$

a tangent intersection indicates that the eigenvalue has algebraic multiplicity 2. The function $B(\nu) = v_y(1;\nu)/v(1;\nu)$ has poles exactly at the *Dirichlet eigenvalues* ν_n^{D} (the necessarily real, positive, and algebraically simple eigenvalues of the self-adjoint problem in which (55) is replaced by $v(1) = 0$); it is strictly decreasing from $+\infty$ to $-\infty$ in each interval $(-\infty, \nu_0^{\mathrm{D}})$ and $(\nu_{k-1}^{\mathrm{D}}, \nu_k^{\mathrm{D}})$, $k \in \mathbb{N}$. It follows that (54)–(56) have at least one real eigenvalue in each interval $(\nu_{k-1}^{\mathrm{D}}, \nu_k^{\mathrm{D}})$, $k \in \mathbb{N}$ (see Figure 2).

Further information concerning the distribution of the eigenvalues ν_n is obtained by comparing (57) with the corresponding formula

$$\nu_n^{\mathrm{D}} = (n+1)^2\pi^2 + \int_0^1 Q(y)\,\mathrm{d}y + o\left(\frac{1}{n}\right), \qquad n \in \mathbb{N}_0$$

for the Dirichlet eigenvalues; in particular one finds that

$$\nu_{n-1}^{\mathrm{D}} < \operatorname{Re}\nu_{n+1} < \nu_n^{\mathrm{D}}$$

for sufficiently large n. It follows that for sufficiently large n the eigenvalue ν_{n+1} is real and located in the interval $(\nu_{n-1}^{\mathrm{D}}, \nu_n^{\mathrm{D}})$. Using this observation and the above geometrical characterization of real eigenvalues, one concludes that

(i) each interval $(\nu_{n-1}^{\mathrm{D}}, \nu_n^{\mathrm{D}})$, $n \in \mathbb{N}$ contains a simple real eigenvalue;

(ii) there are precisely two additional eigenvalues (counted according to algebraic multiplicity) which are either

  (a) real and located to the left of ν_0^{D} (Figure 2 (top left)),

  (b) real and located in the interval $(\nu_{n-1}^{\mathrm{D}}, \nu_n^{\mathrm{D}})$ for some $n \in \mathbb{N}$ (Figure 2 (top right)),

(c) a complex-conjugate pair (with a nonvanishing imaginary part) whose real part is smaller than ν_0^{D} (Figure 2 (bottom)),

(d) a complex-conjugate pair (with a nonvanishing imaginary part) whose real part lies in the interval $(\nu_{n-1}^{\mathrm{D}}, \nu_n^{\mathrm{D}})$ for some $n \in \mathbb{N}$ (Figure 2 (bottom)).

The eigenvalues κ of L are recovered from the above analysis by the formula $\nu = \kappa^2$, so that in particular they occur in plus-minus pairs. Clearly L has a real eigenvalue in each interval $((\nu_{n-1}^{\mathrm{D}})^{1/2}, (\nu_n^{\mathrm{D}})^{1/2})$ and $(-(\nu_n^{\mathrm{D}})^{1/2}, -(\nu_{n-1}^{\mathrm{D}})^{1/2})$, $n \in \mathbb{N}$ (see point (i) above), and it follows from point (ii) that there are four additional eigenvalues (counted according to algebraic multiplicity). The four additional eigenvalues could be real with magnitude greater than $(\nu_0^{\mathrm{D}})^{1/2}$ (case (b)) or a plus-minus, complex-conjugate quartet with nonvanishing real and imaginary parts (cases (c) and (d)). Observe that only the remaining case (a) can lead to purely imaginary eigenvalues of L, and we now examine this case in detail.

Case (a) has eight subcases, each of which is illustrated in Figure 3. Clearly a positive eigenvalue ν yields a plus-minus pair of real eigenvalues of L, while a negative eigenvalue ν yields a complex-conjugate pair of purely imaginary eigenvalues of L; an algebraically double positive or negative eigenvalue ν yields a pair of algebraically double real or purely imaginary eigenvalues. A zero eigenvalue of (54)–(56) similarly leads to a zero eigenvalue of L, the algebraic multiplicity of which is readily determined by studying the equation $Lu = 0$ directly. A straightforward calculation shows that zero is an eigenvalue of L if and only if $\alpha = \alpha_\star$; the eigenvalue has algebraic multiplicity 2 when $\beta \neq \beta_\star$ and algebraic multiplicity 4 when $\beta = \beta_\star$, where

$$\alpha_\star = \left(\int_0^1 a^{-3}(s)\,\mathrm{d}s\right)^{-1}, \qquad \beta_\star = \alpha_\star^2 \int_0^1 a(s)\left(\int_0^s a^{-3}(t)\,\mathrm{d}t\right)^2 \mathrm{d}s.$$

The generalized eigenvectors w_j, where $Lw_1 = 0$, $Lw_2 = w_1$, and $Lw_j = w_{j-1}$, $j = 3, 4$, for $\beta = \beta_\star$ are given by

$$w_1 = \begin{pmatrix} \int_0^1 a^{-3}(s)\,\mathrm{d}s \\ 0 \\ \int_0^s a^{-3}(t)\,\mathrm{d}t \\ 0 \end{pmatrix}, \qquad w_2 = \begin{pmatrix} 0 \\ -a(1)\int_0^1 a^{-3}(s)\,\mathrm{d}s \\ 0 \\ -a(s)\int_0^s a^{-3}(t)\,\mathrm{d}t \end{pmatrix}, \tag{58}$$

$$w_3 = \begin{pmatrix} -\int_0^1 a^{-3}(s)\int_0^s a(t)\int_0^t a^{-3}(u)\,\mathrm{d}u\,\mathrm{d}t\,\mathrm{d}s \\ 0 \\ -\int_0^s a^{-3}(t)\int_0^t a(u)\int_0^u a^{-3}(v)\,\mathrm{d}v\,\mathrm{d}u\,\mathrm{d}t \\ 0 \end{pmatrix}, \tag{59}$$

$$w_4 = \begin{pmatrix} 0 \\ a(1)\int_0^1 a^{-3}(s)\int_0^s a(t)\int_0^t a^{-3}(u)\,\mathrm{d}u\,\mathrm{d}t\,\mathrm{d}s \\ 0 \\ a(s)\int_0^s a^{-3}(t)\int_0^t a(u)\int_0^u a^{-3}(v)\,\mathrm{d}v\,\mathrm{d}u\,\mathrm{d}t \end{pmatrix}. \tag{60}$$

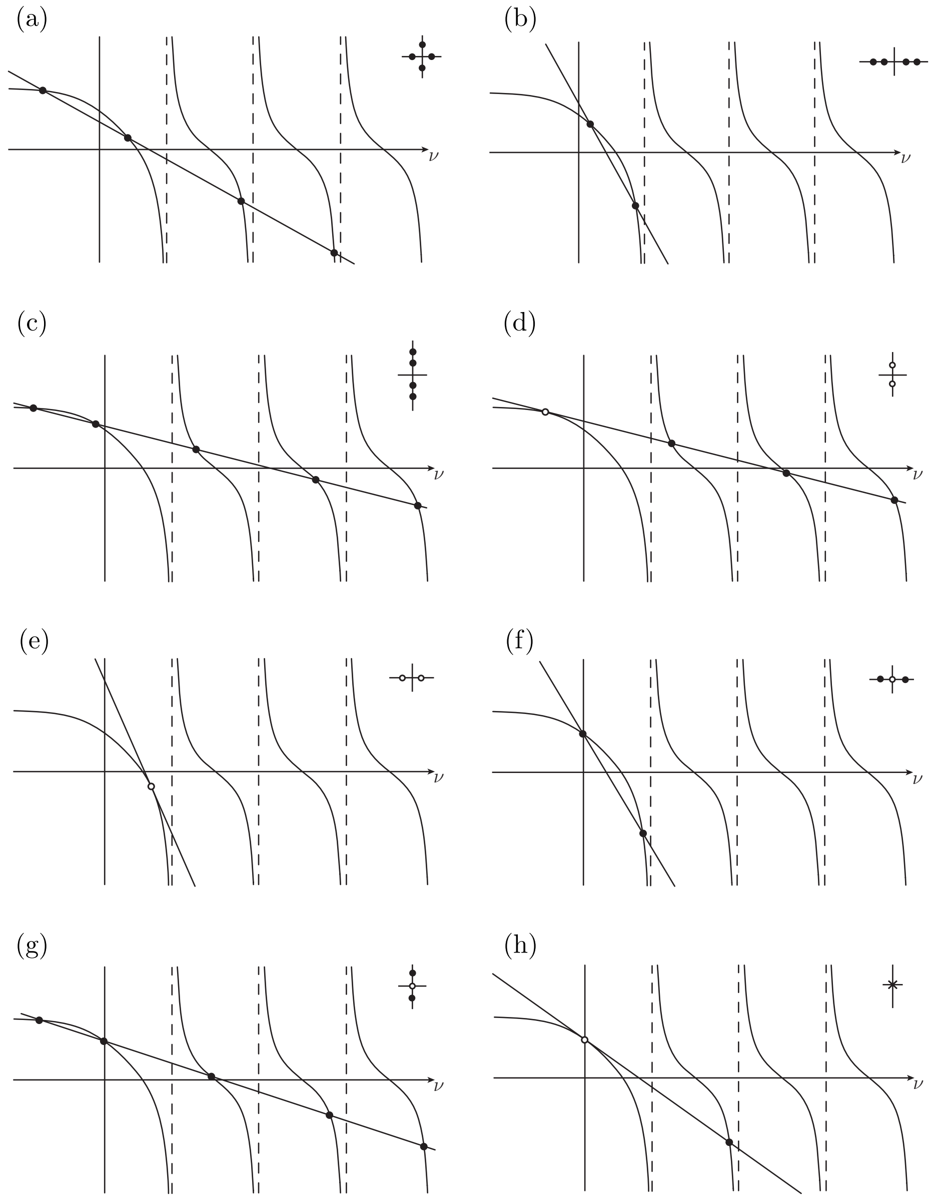

FIG. 3. *The eight cases in which the Sturm–Liouville problem* (54)–(56) *has two real eigenvalues (counted according to algebraic multiplicity) which are less than ν_0^{D}; solid and hollow dots denote, respectively, algebraically simple and algebraically double eigenvalues. The insets show the corresponding eigenvalues of the linear operator L; the cross denotes an eigenvalue of algebraic multiplicity* 4.

Recall that L has four eigenvalues (counted according to algebraic multiplicity) with a real part in the interval $(-(\nu_0^{\mathrm{D}})^{1/2}, (\nu_0^{\mathrm{D}})^{1/2})$. An algebraically simple zero eigenvalue of (54)–(56) (Figure 3(f) or (g)) therefore corresponds to the case $\alpha = \alpha_\star$, $\beta \neq \beta_\star$, while an algebraically double zero eigenvalue (Figure 3(h)) corresponds to the case $\alpha = \alpha_\star$, $\beta = \beta_\star$; it follows that

$$B(0) = a'(1) + a^{-2}(1)\alpha_\star, \qquad B'(0) = -a^{-2}(1)\beta_\star.$$

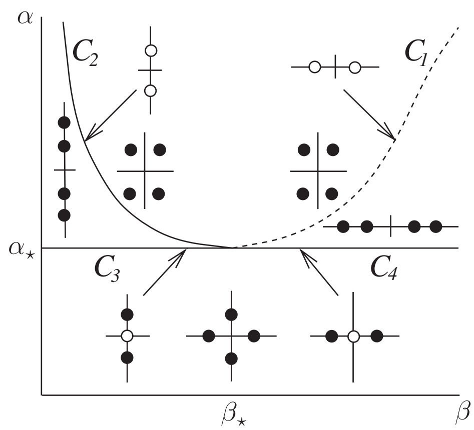

FIG. 4. *Eigenvalues of L whose real parts lie in $(-(\nu_0^{\mathrm{D}})^{1/2}, (\nu_0^{\mathrm{D}})^{1/2})$; solid and hollow dots denote, respectively, algebraically simple and double eigenvalues. The curves C_j, $j = 1, \ldots, 4$, consist of points in (β, α) parameter space at which the qualitative nature of the eigenvalue picture changes; the real parts of the four complex eigenvalues just above $C_1 \cup C_2$ move out of the range $(-(\nu_0^{\mathrm{D}})^{1/2}, (\nu_0^{\mathrm{D}})^{1/2})$ as one moves away from $C_1 \cup C_2$.*

From this observation we conclude that Figure 3(f) corresponds to the case $\alpha = \alpha_\star$, $\beta > \beta_\star$, while Figure 3(g) corresponds to the case $\alpha = \alpha_\star$, $\beta < \beta_\star$; furthermore, Figure 3(a) corresponds to the case $\alpha < \alpha_\star$, Figures 3(b) and (e) arise when $\alpha > \alpha_\star$, $\beta > \beta_\star$, and Figures 3(c) and (d) arise when $\alpha > \alpha_\star$, $\beta < \beta_\star$.

Figure 4 summarizes the behavior of the four eigenvalues of L whose real parts lie in $(-(\nu_0^{\mathrm{D}})^{1/2}, (\nu_0^{\mathrm{D}})^{1/2})$. The values of β and α determine, respectively, the gradient of the straight line in Figure 3 and its point of intersection with the vertical axis: Increasing β makes it steeper, while increasing α moves it upwards. Suppose, for example, that $\alpha < \alpha_\star$ (Figure 3(a)), and we increase the value of α while keeping β fixed; according to whether $\beta < \beta_\star$ or $\beta > \beta_\star$ we pass through the sequence (a), (g), (c), (d) or (a), (f), (b), (e). Figure 4 follows from these observations. Of particular interest are the four bifurcation curves C_j, $j = 1, 4$, at points of which the qualitative nature of the eigenvalue picture changes. In contrast to $C_4 = \{(\beta, \alpha_\star) : \beta > \beta_\star\}$ and $C_3 = \{(\beta, \alpha_\star) : \beta < \beta_\star\}$, explicit parametrizations of C_2 and C_1 are available only in certain special cases, in particular for irrotational flows (Kirchgässner [29]).

Recall that L also has a countably infinite number of eigenvalues whose real parts lie outside the range $(-(\nu_0^{\mathrm{D}})^{1/2}, (\nu_0^{\mathrm{D}})^{1/2})$; these eigenvalues are all real and simple at points in the (β, α) parameter plane below the curve $C_1 \cup C_2$, while all but possibly four of the complete set of eigenvalues are real above $C_1 \cup C_2$. The region above $C_1 \cup C_2$ contains a further countably infinite family of bifurcation curves, points of the nth of which correspond to the transition between Figure 2 (top right) and Figure 2 (bottom): Four real eigenvalues with magnitudes in the interval $((\nu_{n-1}^{\mathrm{D}})^{1/2}, (\nu_n^{\mathrm{D}})^{1/2})$ become complex by colliding in pairs on the real axis. At each point in (β, α) parameter space above $C_1 \cup C_2$ there is therefore an infinite number of real, simple eigenvalues and possibly one pair of algebraically double real eigenvalues or one plus-minus, complex-conjugate quartet of complex eigenvalues.

The spectral theory presented above can also be formulated in terms of self-adjoint operators on Pontryagin spaces (see, e.g., Bognár [5] and Iohvidov, Krein, and Langer [22]). Introduce the π_1-space $P = L^2(0,1) \times \mathbb{R}$ with indefinite inner product

$$[(\phi_1, b_1), (\phi_2, b_2)] = \langle a\phi_1, \phi_2 \rangle_{L^2(0,1)} - \beta b_1 b_2$$

and the linear operator $T : \mathcal{D}(T) \subset P \to P$ defined by

$$T(\phi, b) = (-a^{-1}(s)(a^3(s)\phi_s)_s, -a^3(1)\beta^{-1}\phi_s(1) + \alpha\beta^{-1}\phi(1)),$$

with

$$\mathcal{D}(T) = \{(\phi, b) : \phi \in H^2(0,1),\ \phi(0) = 0,\ \phi(1) = b\}.$$

Observe that T is densely defined (with respect to the topology of $L^2(0,1) \times \mathbb{R}$) and symmetric (with respect to $[\cdot\,,\cdot]$), so that it is a self-adjoint operator on P, and it follows from (51)–(53) that κ is an eigenvalue of L if and only if κ^2 is an eigenvalue of T. This framework, which was used by Wahlén [35] in his study of periodic water waves, yields a convenient method of calculating the local parts of the curves C_1 and C_2 in Figure 4 near the point $(\beta_\star, \alpha_\star)$.

A point $(\beta_\kappa, \alpha_\kappa)$ of C_1 is characterized by the fact that κ^2 is a geometrically simple eigenvalue of $T_\kappa := T|_{(\beta,\alpha)=(\beta_\kappa,\alpha_\kappa)}$ with algebraic multiplicity 2, and since the algebraic multiplicity of this eigenvalue exceeds its geometric multiplicity the corresponding eigenspace E_{κ^2} is neutral; that is, $[\tilde{v}, \tilde{v}]_\kappa := [\tilde{v}, \tilde{v}]_{\beta=\beta_\kappa}$ vanishes for every $\tilde{v} = (v, v(1)) \in E_{\kappa^2}$ (see Wahlén [35, p. 12]). One obtains expressions for v_j, β_j, α_j by inserting the expansions

$$T_\kappa = T_0 + \kappa^2 T_2 + \kappa^4 T_4 + \cdots, \qquad [\cdot\,,\cdot]_\kappa = [\cdot\,,\cdot]_0 + \kappa^2[\cdot\,,\cdot]_2 + \kappa^4[\cdot\,,\cdot]_4 + \cdots$$

and

$$v_\kappa = v_0 + \kappa^2 v_2 + \kappa^4 v_4 + \cdots,$$

$$\beta_\kappa = \beta_\star + \kappa^2\beta_2 + \kappa^4\beta_4 + \cdots, \qquad \alpha_\kappa = \alpha_\star + \kappa^2\alpha_2 + \kappa^4\alpha_4 + \cdots$$

into

$$T_\kappa \tilde{v}_\kappa = \kappa^2 \tilde{v}_\kappa, \qquad [\tilde{v}_\kappa, \tilde{v}_\kappa]_\kappa = 0,$$

and equating coefficients of κ^2. In particular we find that

$$v_0 = \int_0^s a^{-3}(s)\,\mathrm{d}t, \qquad v_2 = -\int_0^s a^{-3}(t)\int_0^t a(u)\int_0^u a^{-3}(v)\,\mathrm{d}v\,\mathrm{d}u\,\mathrm{d}t,$$

$$\beta_2 = \frac{2[\tilde{v}_2, \tilde{v}_0]_0}{v_0^2(1)}, \qquad \alpha_2 = 0, \quad \alpha_4 = \frac{[\tilde{v}_2, \tilde{v}_0]_0}{v_0^2(1)},$$

and hence that

$$\alpha_4 = \alpha_\star^2 d_1, \qquad \beta_2 = 2\alpha_\star^2 d_1, \tag{61}$$

where

$$\begin{aligned} d_1 = &-\alpha_\star \left(\int_0^1 a^{-3}(s)\int_0^s a(t)\int_0^t a^{-3}(u)\,\mathrm{d}u\,\mathrm{d}t\,\mathrm{d}s\right)^2 \\ &+ \int_0^1 a^{-3}(s)\left(\int_0^s a(t)\int_0^t a^{-3}(u)\,\mathrm{d}u\,\mathrm{d}t\right)^2\mathrm{d}s > 0. \end{aligned} \tag{62}$$

A similar calculation shows that the corresponding parametrization of the local part of C_2 near $(\beta_\star, \alpha_\star)$ is

$$\beta_\lambda = \beta_\star - 2\alpha_\star^2 d_1\lambda^2 + O(\lambda^4), \qquad \alpha_\lambda = \alpha_\star + \alpha_\star^2 d_1\lambda^4 + O(\lambda^6)$$

(a point $(\beta_\lambda, \alpha_\lambda)$ of C_2 is characterized by the fact that $-\lambda^2$ is a geometrically simple eigenvalue of $T_\lambda := T|_{(\beta,\alpha)=(\beta_\lambda,\alpha_\lambda)}$ with algebraic multiplicity 2).

4. The reduced Hamiltonian systems. Our existence theory for solitary waves is completed by showing that the reduced Hamiltonian system on the center manifold admits homoclinic solutions. Irrotational solitary waves have been found at points in (β, α) parameter space near C_1, C_2, and C_4 in this fashion, and in this section we examine the corresponding reduced systems in our more general context.

4.1. Homoclinic bifurcation at C_4. A *Hamiltonian* 0^2 *resonance* takes place at points of the curve C_4 in Figure 4: Two real eigenvalues become purely imaginary by colliding at the origin and forming a Jordan chain of length 2. This resonance is associated with the bifurcation of a branch of homoclinic solutions into the region with real eigenvalues (the parameter regime marked I in Figure 1(a)). Let us therefore fix reference values $(\beta_0, \alpha_0) \in C_4$, so that $\beta_0 > \beta_\star$, $\alpha_0 = \alpha_\star$, and introduce a bifurcation parameter by choosing $(\varepsilon_1, \varepsilon_2) = (0, \delta)$, where $0 < \delta \ll 1$.

Formulas for the generalized eigenvectors w_1, w_2, where $Lw_1 = 0$, $Lw_2 = w_1$, are given in (58), and one finds that

$$\Psi(w_1, w_2) = \alpha_\star^{-2}(\beta_0 - \beta_\star),$$

where

$$\begin{aligned}\Psi((\rho_1, \zeta_1, \phi_1, z_1), (\rho_2, \zeta_2, \phi_2, z_2)) &= \Phi^0|_0((\rho_1, \zeta_1, \phi_1, z_1), (\rho_2, \zeta_2, \phi_2, z_2)) \\ &= -\beta_0 a^{-1}(1)(\zeta_2\rho_1 - \zeta_1\rho_2) + \int_0^1 (z_2\phi_1 - z_1\phi_2)\,\mathrm{d}s.\end{aligned}$$

It follows that $\{e, f\}$, where

$$e = \alpha_\star(\beta_0 - \beta_\star)^{-1/2} w_1, \qquad f = \alpha_\star(\beta_0 - \beta_\star)^{-1/2} w_2,$$

is a symplectic basis for the central subspace $X_1 = P(X)$ of X defined by the spectral projection $P : X \to X$ corresponding to the purely imaginary part of L. The coordinates q, p in the e and f directions are canonical coordinates for X_1, and the action of the reverser S on this space is given by

$$S(q, p) = (q, -p).$$

Modeling the center manifold $\tilde{X}^\varepsilon$, $\varepsilon = (0, \delta)$, upon the single coordinate chart $\tilde{U}_1$ and choosing the coordinate map according to the recipe given in the paragraph below Theorem 3.1, we can identify $(\tilde{X}^\varepsilon, \tilde{\Phi}^\varepsilon, \tilde{H}^\varepsilon)$ with the two-dimensional canonical Hamiltonian system $(\mathcal{M}, \Upsilon, \tilde{H}^\varepsilon)$, where $\mathcal{M}$ is a neighborhood of the origin in $\mathbb{R}^2$,

$$\Upsilon((q^1, p^1), (q^2, p^2)) = q^1 p^2 - p^1 q^2$$

and

$$\tilde{H}^\varepsilon(q, p) = K^\varepsilon(\tilde{u}_1 + \tilde{r}(\tilde{u}_1; \varepsilon)), \qquad \tilde{u}_1 = qe + pf.$$

A direct calculation shows that

$$\tilde{H}_2^{0,0}(q, p) = K_2^{0,0}[\tilde{u}_1, \tilde{u}_1] = \frac{1}{2}p^2,$$

where $\varepsilon_1^i \varepsilon_2^j \tilde{H}_k^{i,j}(\tilde{u}_1)$ denotes the part of the Taylor expansion of $\tilde{H}^\varepsilon(\tilde{u}_1)$ which is homogeneous of order i in ε_1, j in ε_2, and k in $\tilde{u}_1 \cong (q, p)$ and $K_k^{i,j}$ denotes the symmetric,

k-linear operator $X_1^k \to \mathbb{R}$ which defines the corresponding coefficient in the Taylor expansion of K^ε. Anticipating the scaling $q \sim \delta Q$, $p \sim \delta^{3/2} P$, we write

$$\tilde{H}^\varepsilon(q,p) = \frac{1}{2}p^2 + c_1\delta q^2 + c_2 q^3 + O(|p||(q,p)||(\delta,q,p)|) + O(|(q,p)|^2|(\delta,q,p)|^2),$$

so that the first three terms on the right-hand side of the above equation are $O(\delta^3)$ and the remainder is of higher order. The coefficients c_1 and c_2 are obtained from the calculations

$$\begin{aligned} c_1 &= K_2^{0,1}[e,e] + 2K_2^{0,0}[e,\tilde{r}_{10}^{0,1}] \\ &= K_2^{0,1}[e,e] + \Psi(Le,\tilde{r}_{10}^{0,1}) \\ &= K_2^{0,1}[e,e] \\ &= -\frac{1}{2}(\beta_0 - \beta_\star)^{-1} \end{aligned}$$

and

$$c_2 = K_3^{0,0}[e,e,e] + 2K_2^{0,0}[e,\tilde{r}_{20}^{0,0}] = -\frac{1}{2}c_0(\beta_0-\beta_\star)^{-3/2}, \qquad c_0 = \alpha_\star^3 \int_0^1 a^{-5}(s)\,\mathrm{d}s,$$

in which $\tilde{r}_{k\ell}^{i,j}$ denotes the coefficient of $\varepsilon_1^i \varepsilon_2^j q^k p^\ell$ in the Taylor expansion of $\tilde{r}$ and we have made use of the identity

$$\Psi(L\tilde{u}_1^1, \tilde{u}_1^2) = 2K_2^{0,0}[\tilde{u}_1^1, \tilde{u}_2^2]. \tag{63}$$

Hamilton's equations for $(\mathcal{M}, \Upsilon, \tilde{H}^\varepsilon)$ are

$$q_x = p + \mathcal{R}_1(q,p,\delta), \tag{64}$$

$$p_x = \delta(\beta_0-\beta_\star)^{-1}q + \frac{3}{2}c_0(\beta_0-\beta_\star)^{-3/2}q^2 + \mathcal{R}_2(q,p,\delta), \tag{65}$$

where $\mathcal{R}_1$, $\mathcal{R}_2$ are, respectively, odd and even in their second arguments and

$$\mathcal{R}_1 = O(|p||(\delta,q,p)|) + O(|(q,p)||(\delta,q,p)|^2), \qquad \mathcal{R}_2 = O(|(q,p)||(\delta,q,p)|).$$

Introducing the scaled variables

$$X = \delta^{1/2}(\beta_0-\beta_\star)^{-1/2}x, \quad q(x) = c_0^{-1}\delta(\beta_0-\beta_\star)^{1/2}Q(X), \quad p(x) = c_0^{-1}\delta^{3/2}P(X),$$

one finds from (64), (65) that

$$Q_X = P + \mathcal{R}_3(Q,P,\delta), \tag{66}$$

$$P_X = Q + \frac{3}{2}Q^2 + \mathcal{R}_4(Q,P,\delta), \tag{67}$$

where the remainder terms $\mathcal{R}_3$ and $\mathcal{R}_4$ are $O(\delta^{1/2})$ and, respectively, odd and even in their second arguments. In the limit $\delta \to 0$, (66), (67) are equivalent to

$$\begin{aligned} Q_X &= P, \\ P_X &= Q + \frac{3}{2}Q^2, \end{aligned}$$

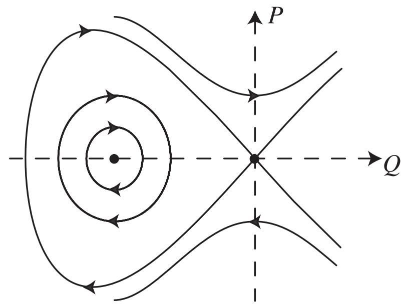

FIG. 5. *Phase portrait of the scaled reduced system of equations.*

whose phase portrait is easily calculated by elementary methods and is depicted in Figure 5. Notice in particular that it has a nonzero equilibrium $(-2/3, 0)$, surrounded by the symmetric homoclinic orbit

$$Q(X) = -\mathrm{sech}^2\left(\frac{X}{2}\right), \qquad P(X) = \mathrm{sech}^2\left(\frac{X}{2}\right)\tanh\left(\frac{X}{2}\right).$$

One can exploit the reversibility of (66), (67) to deduce that it has a symmetric homoclinic orbit for small positive values of δ. For $\delta = 0$ the stable manifold W_{s}^0 of the zero equilibrium is known explicitly (it consists of the points on the homoclinic orbit), and since $TW_{\mathrm{s}}^0|_{(-1,0)} = \{Q = 0\}$ it intersects the symmetric section Fix S $= \{P = 0\}$ transversally in the point $(-1, 0)$. The stable manifold theorem states that W_{s}^δ depends uniformly smoothly upon δ, and because the symmetric section is independent of δ it follows that W_{s}^δ and Fix S intersect transversally in a point near $(-1, 0)$ for sufficiently small positive values of δ. One concludes that the phase portrait of (66), (67) has a reversible homoclinic orbit in the left half-plane for sufficiently small positive values of δ.

Tracing back the various changes of variable, one finds that the surface profile of the water corresponding to the homoclinic orbit detected above is given by

$$\rho(x) = -c_0^{-1}\delta\,\mathrm{sech}^2\left(\frac{\delta^{1/2}x}{2(\beta_0 - \beta_\star)^{1/2}}\right) + O(\delta^{3/2}).$$

We therefore obtain a symmetric solitary wave of depression which decays exponentially and monotonically to a horizontal laminar flow as $x \to \pm\infty$ and is sketched in Figure 1(b).

4.2. Homoclinic bifurcation at C_1. A *Hamiltonian real* $1:1$ *resonance* occurs at points of the curve C_1 in Figure 4: Two pairs of real eigenvalues become complex by colliding at nonzero points on the real axis and forming two Jordan chains of length 2. Of particular interest here is the local part of C_1 near the point $(\beta_\star, \alpha_\star)$, since we can access this curve using the center-manifold reduction technique with reference value $(\beta_0, \alpha_0) = (\beta_\star, \alpha_\star)$. We choose values of the bifurcation parameter $\varepsilon = (\varepsilon_1, \varepsilon_2)$ in a fashion which enables us to access this curve effectively, namely, by writing

$$\varepsilon_1 = \beta_2(1+\delta)\mu^2, \qquad \varepsilon_2 = \alpha_4\mu^4, \tag{68}$$

where β_2, α_4 are the first nonvanishing coefficients in the parametrization

$$\beta_\kappa = \beta_\star + \beta_2\kappa^2 + O(\kappa^4), \qquad \alpha_\kappa = \alpha_\star + \alpha_4\kappa^4 + O(\kappa^6)$$

of the local part of C_1 near $(\beta_\star, \alpha_\star)$; explicit formulas for β_2 and α_4 are given in (61). Notice that μ indicates the distance from the point $(\beta_\star, \alpha_\star)$, while δ plays the role of a bifurcation parameter (varying δ through zero from above we cross the critical curve C_1 in parameter space from above); the parameter regime marked II in Figure 1(a) corresponds to small, positive values of δ and μ.

The point $(\beta_0, \alpha_0) = (\beta_\star, \alpha_\star)$ in parameter space is associated with a *Hamiltonian* 0^4 *resonance* (L has a zero eigenvalue with a Jordan chain of length 4); formulas for the generalized eigenvectors w_j, $j = 1, \ldots 4$, where $Lw_1 = 0$ and $Lw_j = w_{j-1}$, $j = 2, 3, 4$, are given in (58)–(60). One finds that

$$\Psi(w_1, w_4) = -d_1, \quad \Psi(w_2, w_3) = d_1, \quad \Psi(w_3, w_4) = d_2,$$

and the symplectic product of any other combination of these vectors is zero; here $d_1 > 0$ is given by (62) and

$$d_2 = \beta_\star \left(\int_0^1 a^{-3}(s) \int_0^s a(t) \int_0^t a^{-3}(u)\, \mathrm{d}u\, \mathrm{d}t\, \mathrm{d}s \right)^2 - \int_0^1 a(s) \left(\int_0^s a^{-3}(t) \int_0^t a(u) \int_0^u a^{-3}(v)\, \mathrm{d}v\, \mathrm{d}u\, \mathrm{d}t \right)^2 \mathrm{d}s.$$

It follows that $\{e_1, e_2, f_1, f_2\}$, where

$$e_1 = d_1^{-1/2}(w_4 + d_3 w_2), \quad e_2 = d_1^{-1/2} w_2, \qquad f_1 = d_1^{-1/2} w_1, \quad f_2 = d_1^{-1/2} w_3,$$

and $d_3 = d_2/d_1$, is a symplectic basis for the central subspace X_1. The coordinates q_1, q_2, p_1, and p_2 in the e_1, e_2, f_1, and f_2 directions are canonical coordinates for X_1, and the action of the reverser S on this space is given by

$$S(q_1, q_2, p_1, p_2) = (-q_1, -q_2, p_1, p_2).$$

Modeling the center manifold $\tilde{X}^\varepsilon$ upon the single coordinate chart $\tilde{U}_1$ and choosing the coordinate map according to the recipe given in the paragraph below Theorem 3.1, we can identify $(\tilde{X}^\varepsilon, \tilde{\Phi}^\varepsilon, \tilde{H}^\varepsilon)$ with the four-dimensional canonical Hamiltonian system $(\mathcal{M}, \Upsilon, \tilde{H}^\varepsilon)$, where $\mathcal{M}$ is a neighborhood of the origin in $\mathbb{R}^4$,

$$\Upsilon((q_1^1, q_2^1, p_1^1, p_1^1), (q_2^2, q_2^2, p_2^2, p_2^2)) = q_1^1 p_1^2 + q_2^1 p_2^2 - p_1^1 q_1^2 - p_2^1 q_2^2$$

and

$$\tilde{H}^\varepsilon(q_1, q_2, p_1, p_2) = K^\varepsilon(\tilde{u}_1 + \tilde{r}(\tilde{u}_1; \varepsilon)), \qquad \tilde{u}_1 = q_1 e_1 + q_2 e_2 + p_1 f_1 + p_2 f_2.$$

The quadratic part of the reduced Hamiltonian is readily computed; one finds that

$$\tilde{H}_2^{0,0}(q_1, q_2, p_1, p_2) = K_2^{0,0}[\tilde{u}_1, \tilde{u}_1] = -\frac{d_3}{2} q_1^2 - q_1 q_2 + \frac{1}{2} p_2^2,$$

and anticipating the scaling $q_1 \sim \mu^7 Q_1$, $q_2 \sim \mu^5 Q_2$, $p_1 \sim \mu^4 P_1$, $p_2 \sim \mu^6 P_2$ and the parametrization (68), we write

$$\begin{aligned} \tilde{H}^\varepsilon(q_1, q_2, p_1, p_2) &= \frac{1}{2} p_2^2 - q_1 q_2 \\ &+ c_1^{1,0} \varepsilon_1 p_1^2 + c_2^{1,0} \varepsilon_1 p_1 p_2 + c_6^{1,0} \varepsilon_1 q_2^2 + c_1^{0,1} \varepsilon_2 p_1^2 + c_1^{2,0} \varepsilon_1^2 p_1^2 + c p_1^3 + \mathcal{R}(q_1, q_2, p_1, p_2), \end{aligned} \tag{69}$$

so that the third term on the right-hand side of the above equation is $O(\mu^{10})$, the remainder term $\mathcal{R}$ is $O(\mu^{14})$ (note that $\tilde{H}^\varepsilon(-q_1,-q_2,p_1,p_2) = \tilde{H}^\varepsilon(q_1,q_2,p_1,p_2)$ because of the reversibility), and all other terms are $O(\mu^{12})$.

PROPOSITION 4.1. *The Darboux transformation used to construct* $(\mathcal{M},\Upsilon,\tilde{H}^\varepsilon)$ *(see* (36)*) can be chosen so that* $c_2^{1,0}=0$.

Proof. Observe that the change of variable

$$\bar{q}_1 = q_1 - c_2^{1,0}\varepsilon_1 q_2, \quad \bar{q}_2 = q_2, \quad \bar{p}_1 = p_1, \quad \bar{p}_2 = p_2 + c_2^{1,0}\varepsilon_1 p_1 \tag{70}$$

is symplectic and transforms $(\mathcal{M},\Upsilon,\tilde{H}^\varepsilon)$ into $(\mathcal{M},\Upsilon,\bar{H}^\varepsilon)$, where

$$\begin{aligned}\bar{H}^\varepsilon(\bar{q}_1,\bar{q}_2,\bar{p}_1,\bar{p}_2) &= \frac{1}{2}\bar{p}_2^2 - \bar{q}_1\bar{q}_2\\ &\quad + c_1^{1,0}\varepsilon_1\bar{p}_1^2 + \bar{c}_6^{1,0}\varepsilon_1\bar{q}_2^2 + c_1^{0,1}\varepsilon_2\bar{p}_1^2 + \bar{c}_1^{2,0}\varepsilon_1^2\bar{p}_1^2 + c\bar{p}_1^3 + \bar{\mathcal{R}}(\bar{q}_1,\bar{q}_2,\bar{p}_1,\bar{p}_2)\end{aligned}$$

and $\bar{c}_6^{1,0} = c_6^{1,0} - c_2^{1,0}$, $\bar{c}_1^{2,0} = c_1^{2,0} - \frac{1}{2}(c_2^{1,0})^2$ (the remainder term $\bar{\mathcal{R}}$ is $O(\mu^{14})$ in the sense explained above). The result follows by replacing the Darboux transformation used in the construction by its composition with the change of variable (70). ◻

To calculate the remaining coefficients on the right-hand side of (69), we exploit the identity

$$\begin{aligned}&L\tilde{r}(\tilde{u}_1;\varepsilon) - \mathrm{d}_1\tilde{r}[\tilde{u}_1;\varepsilon](L\tilde{u}_1)\\ &\qquad = -N^\varepsilon(\tilde{u}_1 + \tilde{r}(\tilde{u}_1;\varepsilon)) + \mathrm{d}_1\tilde{r}[\tilde{u}_1;\varepsilon](P^\varepsilon(\tilde{u}_1)) + P^\varepsilon(\tilde{u}_1),\end{aligned} \tag{71}$$

in which $P^\varepsilon(\tilde{u}_1)$ is the nonlinear part of the reduced Hamiltonian vector field $v_{\tilde{H}^\varepsilon}$; this identity is derived by substituting $u = \tilde{u}_1 + \tilde{r}(\tilde{u}_1;\varepsilon)$ and $\tilde{u}_{1x} = L\tilde{u}_1 + P^\varepsilon(\tilde{u}_1)$ into (41). Let us write

$$\tilde{H}_2^{1,0}(q_1,q_2,p_1,p_2) = c_1^{1,0}p_1^2 + c_3^{1,0}p_2^2 + c_4^{1,0}q_1^2 + c_5^{1,0}q_1q_2 + c_6^{1,0}q_2^2$$

(the coefficients of the remaining terms vanish because of the reversibility), so that

$$P_1^{1,0}(\tilde{u}_1) = 2c_1^{1,0}p_1e_1 + 2c_3^{1,0}p_2e_2 - (2c_4^{1,0}q_1 + c_5^{1,0}q_2)f_1 - (2c_6^{1,0}q_2 + c_5^{1,0}q_1)f_2,$$

and equating coefficients of $\varepsilon_1\tilde{u}_1$ on both sides of (71), we find that

$$L\tilde{r}_{1000}^{1,0} - \tilde{r}_{0001}^{1,0} - d_3\tilde{r}_{0010}^{1,0} = -N_1^{1,0}[e_1] - 2c_4^{1,0}f_1 - c_5^{1,0}f_2, \tag{72}$$

$$L\tilde{r}_{0100}^{1,0} - \tilde{r}_{0010}^{1,0} = -N_1^{1,0}[e_2] - c_5^{1,0}f_1 - 2c_6^{1,0}f_2, \tag{73}$$

$$L\tilde{r}_{0010}^{1,0} = -N_1^{1,0}[f_1] + 2c_1^{1,0}e_1, \tag{74}$$

$$L\tilde{r}_{0001}^{1,0} - \tilde{r}_{0100}^{1,0} = -N_1^{1,0}[f_2] + 2c_3^{1,0}e_2. \tag{75}$$

Here the notation $N_k^{i,j}$ and $\tilde{r}_k^{i,j}$, $P_k^{i,j}$ is defined analogously to the notation $K_k^{i,j}$ and $\tilde{H}_k^{i,j}$, while $\tilde{r}_{k_1k_2k_3k_4}^{i,j}$ is the coefficient of $\varepsilon_1^i\varepsilon_2^jq_1^{k_1}q_2^{k_2}p_1^{k_3}p_2^{k_4}$ in the Taylor expansion of $\tilde{r}$. Explicit calculations show that $N_1^{1,0}(e_1)$, $N_1^{1,0}(e_2)$, $N_1^{1,0}(f_1)$ vanish while

$$N_1^{1,0}(f_2) = \left(0, d_1^{-1/2}\beta_\star^{-1}\alpha_\star^{-1}a(1), 0, 0\right).$$

It follows by elementary linear algebra that the system of equations (72)–(75) is solvable if and only if

$$c_1^{1,0} = 0, \qquad c_6^{1,0} = -\frac{1}{2d_1\alpha_\star^2},$$

and $\tilde{r}_{0010}^{1,0} = \gamma f_1$ for some $\gamma \in \mathbb{R}$.

The value of the coefficient $c_1^{0,1}$ is obtained from the calculation

$$\begin{aligned} c_1^{0,1} &= K_2^{0,1}[f_1,f_1] + 2K_2^{0,0}[f_1,\tilde{r}_{0010}^{0,1}] \\ &= K_2^{0,1}[f_1,f_1] + \Psi(Lf_1,\tilde{r}_{0010}^{0,1}) \\ &= K_2^{0,1}[f_1,f_1] \\ &= -\frac{1}{2d_1\alpha_\star^2}. \end{aligned}$$

Equating coefficients of $\varepsilon^2 p_1$ on both sides of (71), we find that

$$L\tilde{r}_{0010}^{2,0} = -N_1^{2,0}[f_1] - N_1^{1,0}[\tilde{r}_{0010}^{1,0}] + 2c_1^{2,0}e_1 + c_2^{2,0}e_2, \tag{76}$$

where the notation for the coefficients in $\tilde{H}_1^{0,1}$ is analogous to that used for $\tilde{H}_1^{1,0}$. An explicit calculation shows that

$$N_1^{2,0}[f_1] = 0, \qquad N_1^{1,0}[\tilde{r}_{0010}^{1,0}] = \gamma_1 N_1^{1,0}[f_1] = 0,$$

and it follows from (76) that

$$c_1^{2,0} = \frac{1}{2}\Psi(L\tilde{r}_{0010}^{2,0}, f_1) = -\frac{1}{2}\Psi(\tilde{r}_{0010}^{2,0}, Lf_1) = 0$$

(the "skew orthogonality" of L with respect to Ψ follows from (63)). Similarly, one finds from the p_1^3 component of (71), namely,

$$L\tilde{r}_{0020}^{0,0} = -N_2^{0,0}[f_1,f_1] + 3ce_1,$$

that

$$3c - \Psi(N_2^{0,0}[f_1,f_1],f_1) = \Psi(L\tilde{r}_{2000}^{0,0}, f_1) = -\Psi(\tilde{r}_{2000}^{0,0}, Lf_1) = 0$$

and hence that

$$c = \frac{1}{3}\Psi(N_2^{0,0}[f_1,f_1],f_1) = -\frac{1}{2d_1^{3/2}}\int_0^1 a^{-5}(s)\,\mathrm{d}s.$$

Observe that

$$c_6^{1,0} = -\frac{1}{\beta_2}, \qquad c_1^{0,1} = -\frac{1}{2\alpha_4}.$$

Choosing ε_1, ε_2 according to (68) and introducing the scaled variables $X = \mu x$ and

$$q_1(x) = \mu^7 Q_1(X), \quad q_2(x) = \mu^5 Q_2(X), \quad p_1(x) = \mu^4 P_1(X), \quad p_2(x) = \mu^6 P_2(X),$$

we therefore find that

$$\tilde{H}^\varepsilon(q_1,q_2,p_1,p_2) = \mu^{12}\left[-\frac{1}{2}P_1^2 - (1+\delta)Q_2^2 + \frac{1}{2}P_2^2 - Q_1Q_2 + cP_1^3\right] + O(\mu^{14})$$

and that Hamilton's equations for $(\mathcal{M},\Upsilon,\tilde{H}^\varepsilon)$ are

$$Q_{1X} = -P_1 + 3cP_1^2 + O(\mu), \tag{77}$$

$$Q_{2X} = P_2 + O(\mu), \tag{78}$$

$$P_{1X} = Q_2 + O(\mu), \tag{79}$$

$$P_{2X} = 2(1+\delta)Q_2 + Q_1 + O(\mu). \tag{80}$$

In the limit $\mu \to 0$ this dynamical system is equivalent to the single fourth-order ordinary differential equation

$$\partial_X^4 u - 2(1+\delta)\partial_X^2 u + u - u^2 = 0 \tag{81}$$

for the variable $u = 3c\,P_1$.

It was shown by Buffoni, Champneys, and Toland [6, section 2] that for $\delta = 0$ (81), and hence the system (77)–(80), has a homoclinic solution which corresponds to a transverse intersection (relative to the zero energy surface) of the stable and unstable manifolds of the zero equilibrium. Since transversality is an open condition, it follows that the same is true of the system (77)–(80) for sufficiently small positive values of δ and μ, for which (77)–(80) is a four-dimensional Hamiltonian system whose linearization has a plus-minus, complex-conjugate quartet of complex eigenvalues. The work of Devaney [12] therefore implies that there is a Smale horseshoe in the dynamics within the zero energy surface, and implicit in this construction is the existence of infinitely many homoclinic orbits which pass several times through a neighborhood of the "primary" transverse homoclinic orbit. These "multipulse" homoclinic orbits resemble multiple copies of the primary homoclinic orbit, between which there are distributed smaller local maxima and minima, and have an exponentially decaying oscillatory tail at infinity.

Tracing back the various changes of variable, one finds that the surface profile of the water is given by

$$\rho(x) = d_1^{-1/2}\mu^4 P_1(\mu x) + O(\mu^5).$$

The primary homoclinic orbit $u(x)$ of (81) satisfies $\max_{x\in\mathbb{R}} u(x) > 0$, so that the homoclinic orbits of (77)–(80) correspond to multitroughed solitary waves of depression which decay exponentially to a horizontal laminar flow as $x \to \pm\infty$ (see Figure 1(c)).

4.3. Homoclinic bifurcation at C_2. A *Hamiltonian Hopf bifurcation* takes place at points of the curve C_2 in Figure 4: Two pairs of purely imaginary eigenvalues become complex by colliding at nonzero points $\pm \mathrm{i}q$ on the imaginary axis and forming two Jordan chains of length 2. This resonance is associated with the bifurcation of a branch of homoclinic solutions into the region with complex eigenvalues (the parameter regime marked III in Figure 1(a)). Let us therefore fix reference values $(\beta_0, \alpha_0) \in C_2$ and introduce a bifurcation parameter by choosing $(\varepsilon_1, \varepsilon_2) = (0, \delta)$, where $0 < \delta \ll 1$.

By normalizing e, f and modifying f by the addition of a suitable multiple of e if necessary, we may suppose that the generalized eigenvectors e, f, where

$$Le = \mathrm{i}qe, \quad L\bar{e} = -\mathrm{i}q\bar{e}, \qquad (L - \mathrm{i}qI)f = e, \quad (L + \mathrm{i}qI)\bar{f} = \bar{e}, \tag{82}$$

satisfy $Se = \bar{e}$, $Sf = -\bar{f}$ and $\Psi(e, \bar{f}) = 1$, $\Psi(f, \bar{e}) = -1$, and the symplectic products of all other combinations are zero (note that Ψ acts bilinearly on pairs of complex vectors). It follows that $\{e, f, \bar{e}, \bar{f}\}$ is a symplectic basis for the central subspace X_1 (so that the coordinates A, B, $\bar{A}$, and $\bar{B}$ in the e, f, $\bar{e}$, and $\bar{f}$ directions are canonical coordinates for X_1), and the action of the reverser S on this space is given by

$$S(A, B) = (\bar{A}, -\bar{B}).$$

Modeling the center manifold $\tilde{X}^\varepsilon$, $\varepsilon = (0,\delta)$, upon the single coordinate chart $\tilde{U}_1$ and choosing the coordinate map according to the recipe given in the paragraph below Theorem 3.1, we can identify $(\tilde{X}^\varepsilon, \tilde{\Phi}^\varepsilon, \tilde{H}^\varepsilon)$ with the four-dimensional canonical Hamiltonian system $(\mathcal{M}, \Upsilon, \tilde{H}^\varepsilon)$, where $\mathcal{M}$ is a neighborhood of the origin in $\mathbb{R}^4$,

$$\Upsilon((A^1, B^1, \overline{A^1}, \overline{B^1}), (A^2, B^2, \overline{A^2}, \overline{B^2})) = A^1\overline{B^2} - A^2\overline{B^1} + \overline{A^1}B^2 - \overline{A^2}B^1$$

and

$$\tilde{H}^\varepsilon(A,B) = K^\varepsilon(\tilde{u}_1 + \tilde{r}(\tilde{u}_1;\varepsilon)), \qquad \tilde{u}_1 = Ae + Bf + \bar{A}\bar{e} + \bar{B}\bar{f}.$$

The flow of the above four-dimensional Hamiltonian system can be analyzed using the theory developed by Iooss and Pérouème [26] and Buffoni and Groves [7]. The Birkhoff normal-form theory states that for each $n_0 \geq 2$ there is a near-identity, analytic, symplectic change of coordinates with the property that

$$\begin{aligned}\tilde{H}^\varepsilon(A,B) = {} & \mathrm{i}q(A\bar{B} - \bar{A}B) + |B|^2 \\ & + H_{\mathrm{NF}}(|A|^2, \mathrm{i}(A\bar{B} - \bar{A}B), \delta) + O(|(A,B)|^2|(\delta, A, B)|^{n_0})\end{aligned}$$

in the new coordinates; the function H_{NF} is a real polynomial of order n_0+1 which satisfies

$$H_{\mathrm{NF}}(|A|^2, \mathrm{i}(A\bar{B} - \bar{A}B), \delta) = O(|(A,B)|^2|(\delta, A, B)|),$$

and in these coordinates Hamilton's equations for the reduced system are given by

$$A_x = \mathrm{i}qA + B + \mathrm{i}A\partial_2 H_{\mathrm{NF}}(|A|^2, \mathrm{i}(A\bar{B} - \bar{A}B), \delta) + O(|(A,B)||(\delta, A, B)|^{n_0}), \tag{83}$$

$$\begin{aligned}B_x = {} & \mathrm{i}qB + \mathrm{i}B\partial_2 H_{\mathrm{NF}}(|A|^2, \mathrm{i}(A\bar{B} - \bar{A}B), \delta) \\ & - A\partial_1 H_{\mathrm{NF}}(|A|^2, \mathrm{i}(A\bar{B} - \bar{A}B), \delta) + O(|(A,B)||(\delta, A, B)|^{n_0}).\end{aligned} \tag{84}$$

The theory by Iooss and Pérouème and Buffoni and Groves demands that the coefficients c_1 and c_3 in the expansion

$$\begin{aligned}H_{\mathrm{NF}} = {} & \delta c_1|A|^2 + \delta \mathrm{i}c_2(A\bar{B} - \bar{A}B) + c_3|A|^4 \\ & + \mathrm{i}c_4|A|^2(A\bar{B} - \bar{A}B) - c_5(A\bar{B} - \bar{A}B)^2 + \delta^2 c_6|A|^2 + \delta^2 \mathrm{i}c_7(A\bar{B} - \bar{A}B) + \cdots\end{aligned}$$

are, respectively, negative and positive; the methods explained in section 4.2 show that

$$c_1 = \Psi(N_1^{0,1}[e], \bar{e})$$

and

$$c_3 = \Psi(N_2^{0,0}[e, \tilde{r}_{1010}^{0,0}], \bar{e}) + \Psi(N_2^{0,0}[\bar{e}, \tilde{r}_{2000}^{0,0}], \bar{e}) + \frac{3}{2}\Psi(N_3^{0,0}[e,e,\bar{e}], \bar{e}),$$

where $\tilde{r}_{1010}^{0,0}$ and $\tilde{r}_{2000}^{0,0}$ are the unique solutions of the equations

$$\begin{aligned}L\tilde{r}_{1010}^{0,0} &= -2N_2^{0,0}[e, \bar{e}], \\ (L - 2\mathrm{i}qI)\tilde{r}_{2000}^{0,0} &= -N_2^{0,0}[e,e].\end{aligned}$$

THEOREM 4.2. *Suppose that* $c_1 < 0$ *and* $c_3 > 0$.

(i) *(Iooss and Pérouème) For each sufficiently small, positive value of* δ *the two-degree-of-freedom Hamiltonian system* (83), (84) *has two distinct symmetric homoclinic solutions.*

(ii) *(Buffoni and Groves) For each sufficiently small, positive value of* δ *the two-degree-of-freedom Hamiltonian system* (83), (84) *has an infinite number of geometrically distinct homoclinic solutions which generically resemble multiple copies of one of the homoclinic solutions in part* (i).

The homoclinic solutions identified above correspond to envelope solitary waves of amplitude $O((-c_1\delta)^{1/2})$ *which decay exponentially to a horizontal flow as* $x \to \pm\infty$*; they are sketched in Figure* 1(c).

Explicit formulas for c_1 and c_3 were computed for irrotational waves by Buffoni and Groves [7, Appendix B], and for general vorticity distributions one can prove that $c_1 < 0$, $c_3 > 0$ for values of (β_0, α_0) on the local part of C_2 near $(\beta_\star, \alpha_\star)$. To this end suppose that $(\beta_0, \alpha_0) = (\beta_\mu, \alpha_\mu)$, where

$$\beta_\mu = \beta_\star - 2\alpha_\star^2 d_1 \mu^2 + O(\mu^4), \qquad \alpha_\mu = \alpha_\star + \alpha_\star^2 d_1 \mu^4 + O(\mu^6),$$

so that $q = \mu$. We find that

$$Le_0 = \mathrm{i}\mu e_0, \qquad (L - \mathrm{i}\mu I) f_0 = e_0,$$

where

$$e_0 = \begin{pmatrix} \mathrm{i}\mu\alpha_\star^{-1} + \mathrm{i}\mu^3 \int_0^1 a^{-3}(s) \int_0^s a(t) \int_0^t a^{-3}(u)\,\mathrm{d}u\,\mathrm{d}t\,\mathrm{d}s + O_\mathrm{i}(\mu^5) \\ \mu^2 a(1)\alpha_\star^{-1} + \mu^4 a(1) \int_0^1 a^{-3}(s) \int_0^s a(t) \int_0^t a^{-3}(u)\,\mathrm{d}u\,\mathrm{d}t\,\mathrm{d}s + O_\mathrm{r}(\mu^6) \\ \mathrm{i}\mu \int_0^s a^{-3}(t)\,\mathrm{d}t + \mathrm{i}\mu^3 \int_0^s a^{-3}(t) \int_0^t a(u) \int_0^u a^{-3}(v)\,\mathrm{d}v\,\mathrm{d}u\,\mathrm{d}t + O_\mathrm{i}(\mu^5) \\ \mu^2 a(s) \int_0^s a^{-3}(t)\,\mathrm{d}t + \mu^4 a(s) \int_0^s a^{-3}(t) \int_0^t a(u) \int_0^u a^{-3}(v)\,\mathrm{d}v\,\mathrm{d}u\,\mathrm{d}t + O_\mathrm{r}(\mu^6) \end{pmatrix},$$

$$f_0 = \begin{pmatrix} 2\mu^2 \int_0^1 a^{-3}(s) \int_0^s a(t) \int_0^t a^{-3}(u)\,\mathrm{d}u\,\mathrm{d}t\,\mathrm{d}s + O_\mathrm{r}(\mu^4) \\ -\mathrm{i}\mu a(1)\alpha_\star^{-1} - 3\mathrm{i}\mu^3 a(1) \int_0^1 a^{-3}(s) \int_0^s a(t) \int_0^t a^{-3}(u)\,\mathrm{d}u\,\mathrm{d}t\,\mathrm{d}s + O_\mathrm{i}(\mu^5) \\ 2\mu^2 \int_0^s a^{-3}(t) \int_0^t a(u) \int_0^u a^{-3}(v)\,\mathrm{d}v\,\mathrm{d}u\,\mathrm{d}t + O_\mathrm{r}(\mu^4) \\ -\mathrm{i}\mu a(s) \int_0^s a^{-3}(t)\,\mathrm{d}t - 3\mathrm{i}\mu^3 a(1) \int_0^s a^{-3}(t) \int_0^t a(u) \int_0^u a^{-3}(v)\,\mathrm{d}v\,\mathrm{d}u\,\mathrm{d}t + O_\mathrm{i}(\mu^5) \end{pmatrix},$$

and the symbols $O_\mathrm{r}(\mu^n)$, $O_\mathrm{i}(\mu^n)$ denote quantities of $O(\mu^n)$ which are, respectively, real and purely imaginary. Observe that $e_0 = \mathrm{i}\mu(\phi_\mu(1), -\mathrm{i}\mu a(1)\phi_\mu(1), \phi_\mu, -\mathrm{i}\mu a(s)\phi_\mu)^\mathrm{T}$, where

$$T_\mu \tilde{\phi}_\mu = -\mu^2 \tilde{\phi}_\mu, \qquad [\tilde{\phi}_\mu, \tilde{\phi}_\mu]_\mu = 0.$$

The next step is to normalize the generalized eigenvectors. We have that

$$\Psi(e_0, \overline{f_0}) = -\Psi(f_0, \overline{e_0}) = d_4, \qquad \Psi(f_0, \overline{f_0}) = \mathrm{i}d_5,$$

where

$$d_4 = 4d_1\mu^4 + O_\mathrm{r}(\mu^6), \qquad d_5 = -4d_1\mu^3 + O_\mathrm{r}(\mu^5),$$

and the calculations

$$\Psi(e_0, \overline{e_0}) = 2\mathrm{i}\mu^3 [\tilde{\phi}_\mu, \tilde{\phi}_\mu]_\mu$$

and

$$\mathrm{i}\mu\Psi(e_0,f_0)=\Psi(Le_0,f_0)=-\Psi(e_0,Lf_0)=-\Psi(e_0,\mathrm{i}\mu f_0+e_0)=-\mathrm{i}\mu\Psi(e_0,f_0)$$

imply that $\Psi(e_0,\bar{e}_0)=\Psi(e_0,f_0)=\Psi(\bar{e}_0,\bar{f}_0)=0$. It follows that

$$e=\frac{\mathrm{i}}{d_4^{1/2}}e_0,\qquad f=\frac{\mathrm{i}}{d_4^{1/2}}\left(f_0-\frac{\mathrm{i}d_5}{2d_4}e_0\right)$$

satisfy (82) and the normalization requirements given below it.

Performing a series of lengthy calculations, one finds that

$$c_1=\frac{1}{d_4}\Psi(N_1^{0,1}[e_0],\overline{e_0})=-\frac{1}{4d_1}\alpha_\star^{-2}\mu^{-2}+O_\mathrm{r}(1)<0$$

and

$$\begin{aligned}c_3&=\frac{1}{d_4^2}\Psi(N_2^{0,0}[e_0,\tilde{R}_{1010}^{0,0}],\overline{e_0})+\frac{1}{d_4^2}\Psi(N_2^{0,0}[\overline{e_0},\tilde{R}_{2000}^{0,0}],\overline{e_0})+\frac{3}{2d_4^2}\Psi(N_3^{0,0}[e_0,e_0,\overline{e_0}],\overline{e_0})\\&=\frac{19}{64d_1^3}\left(\int_0^1 a^{-5}(s)\,\mathrm{d}s\right)^2\mu^{-8}+O_\mathrm{r}(\mu^{-6})>0,\end{aligned}$$

where

$$\begin{aligned}\tilde{R}_{1010}^{0,1}&=-2L^{-1}N_2^{0,0}[e_0,\overline{e}_0]\\&=\begin{pmatrix}-3d_1^{-1}\alpha_\star^{-1}\mu^{-2}\int_0^1 a^{-5}(s)\,\mathrm{d}s+O_\mathrm{r}(1)\\0\\-3d_1^{-1}\mu^{-2}\int_0^1 a^{-5}(s)\,\mathrm{d}s\int_0^s a^{-3}(t)\,\mathrm{d}t+O_\mathrm{r}(1)\\0\end{pmatrix},\end{aligned}$$

$$\begin{aligned}\tilde{R}_{2000}^{0,1}&=-(L-2\mathrm{i}\mu I)^{-1}N_2^{0,0}[e_0,e_0]\\&=\begin{pmatrix}\frac{1}{6}d_1^{-1}\alpha_\star^{-1}\mu^{-2}\int_0^1 a^{-5}(s)\,\mathrm{d}s+O_\mathrm{r}(1)\\-\frac{1}{3}\mathrm{i}d_1^{-1}\alpha_\star^{-1}\mu^{-1}a(1)\int_0^1 a^{-5}(s)\,\mathrm{d}s+O_\mathrm{i}(\mu)\\\frac{1}{6}d_1^{-1}\mu^{-2}\int_0^1 a^{-5}(s)\,\mathrm{d}s\int_0^s a^{-3}(t)\,\mathrm{d}s+O_\mathrm{r}(\mu)\\-\frac{1}{3}\mathrm{i}d_1^{-1}\mu^{-1}a(p)\int_0^1 a^{-5}(s)\,\mathrm{d}s\int_0^s a^{-3}(t)\,\mathrm{d}t+O_\mathrm{i}(\mu)\end{pmatrix}.\end{aligned}$$

WELL-POSEDNESS THEORY FOR A NONCONSERVATIVE BURGERS-TYPE SYSTEM ARISING IN DISLOCATION DYNAMICS*

AHMAD EL HAJJ†

Abstract. In this work we study a system of nonconservative Burgers type in one space dimension, arising in modeling the dynamics of dislocation densities in crystals. Starting from physically relevant initial data that are of a special form, namely nondecreasing, periodic plus linear functions, we prove the global existence and uniqueness of a solution in $H^1_{loc}(\mathbb{R} \times [0, +\infty))$ that preserves the nature of the initial data. The approach is made by adding some viscosity to the system, obtaining energy estimates, and passing to the limit for vanishing viscosity. A comparison principle is shown for this system as well as an application in the case of the classical Burgers equation.

Key words. system of Burgers equations, system of nonlinear transport equations, nonlinear hyperbolic system, dynamics of dislocation densities

1. Introduction.

1.1. Physical motivations and presentation of the model. Real crystals comprise certain defects in the organization of their crystalline structure called dislocations. In a particular case where these defects are parallel straight lines in the three-dimensional space, they can be viewed as points in a plan. Under the effect of exterior constraints, dislocations can move in a certain crystallographic direction called the slip direction. This slip direction is given by a vector called the "Burgers vector." The norm of this vector represents the amplitude of the generated deformation. (We refer the reader to [12] for further physical explanation.)

In this work, we are interested in the study of a one-dimensional submodel of a problem introduced by Groma and Balogh [11], initially proposed in the two-dimensional case. In fact, this one-dimensional submodel was defined by El Hajj and Forcadel [8, Lemme 3.1].

This two-dimensional model is characterized by the fact that dislocations propagate in the plane (x_1, x_2) following the two Burgers vectors $\pm\vec{b}$ with $\vec{b} = (1, 0)$. In this one-dimensional submodel we suppose also that dislocation densities depend only on the variable $x = x_1 + x_2$, which transforms the two-dimensional into a one-dimensional model (see El Hajj and Forcadel [8] for more modeling details).

More precisely this one-dimensional model is given by the following coupled

equations of nonconservative Burgers type:

(1)
$$\left\{\begin{array}{rcl} \dfrac{\partial\rho^+}{\partial t}(x,t) & = & -\left(a(t)+(\rho^+-\rho^-)(x,t)+\alpha\displaystyle\int_0^1(\rho^+-\rho^-)(y,t)dy\right)\dfrac{\partial\rho^+}{\partial x}(x,t) \\ & & \text{in } \mathcal{D}'(\mathbb{R}\times(0,T)), \\ \dfrac{\partial\rho^-}{\partial t}(x,t) & = & \left(a(t)+(\rho^+-\rho^-)(x,t)+\alpha\displaystyle\int_0^1(\rho^+-\rho^-)(y,t)dy\right)\dfrac{\partial\rho^-}{\partial x}(x,t) \\ & & \text{in } \mathcal{D}'(\mathbb{R}\times(0,T)). \end{array}\right.$$

The unknowns ρ^+ and ρ^- are scalar-valued functions, which we denote for simplicity by $\rho^\pm$. Their spatial derivatives $\frac{\partial\rho^\pm}{\partial x}$ are the dislocation densities of the Burgers vector $\pm\vec{b}=\pm(1,0)$. The function $a=a(t)$, representing the field of the imposed exterior constraint, is supposed to be independent of x, and the constant α depends on the elastic coefficients and the material size.

We consider the following initial conditions for (1):

$$\rho^\pm(x,t=0)=\rho_0^\pm(x)=\rho_0^{\pm,per}(x)+L_0x, \quad x\in\mathbb{R}, \tag{2}$$

where $\rho_0^{\pm,per}$ are 1-periodic functions. We thus modelize a periodic distribution for the $\pm$ dislocations, with a spatial period of length 1. Note that each type of $\pm$ dislocation has a mean density equal to L_0. In fact, the use of the periodic boundary conditions is a way of regarding what is going on in the interior of the material away from its boundary.

1.2. A brief review of some related literature. From a mathematical point of view, system (1) is related to other similar models such as transport equations based on vector fields with low regularity. Such equations were, for instance, studied by DiPerna and Lions in [7]. They proved the existence and uniqueness of a solution (in the renormalized sense) for vector fields in $L^1((0,+\infty);W^{1,1}_{loc}(\mathbb{R}^N))$ whose divergence is in $L^1((0,+\infty);L^\infty(\mathbb{R}^N))$. This study was generalized by Ambrosio [3], who considered vector fields in $L^1((0,+\infty);BV_{loc}(\mathbb{R}^N))$ with bounded divergence. In the present paper, we work in dimension $N=1$ and prove the existence and uniqueness of solutions of the system (1)–(2) with a vector field (i.e., the velocity) only in $L^\infty((0,+\infty),H^1_{loc}(\mathbb{R}))$.

We also refer the reader to the works of LeFloch [13] and LeFloch and Liu [14], in which they considered the study in the framework of functions of bounded variation for a system of the form

$$\left\{\begin{array}{ll} \dfrac{\partial u}{\partial t}(x,t)+A(u)\dfrac{\partial u}{\partial x}(x,t)=0, & u(x,t)\in U,\ x\in\mathbb{R},\ t\in(0,T), \\ u(x,0)=u_0(x), & x\in\mathbb{R}, \end{array}\right. \tag{3}$$

where the space of states U is an open subset of $\mathbb{R}^p$, and A is a $(p\times p)$ matrix which is of class C^1 on U. Moreover, $A(u)$ have p scalar distinct eigenvalues that we denote by $\lambda_1(u)<\lambda_2(u)<\cdots<\lambda_p(u)$. We remark that this condition on the eigenvalues does not enter into our framework even in the case where $\alpha=a=0$, because we have not sign property on $\rho^+-\rho^-$. LeFloch and Liu proved that if the initial condition u_0 is sufficiently close to a constant state, and if the total variation $TV(u_0)$ is assumed to be small enough, then system (3) admits a unique solution in

$L^\infty(\mathbb{R} \times (0, +\infty)) \cap BV(\mathbb{R} \times (0, +\infty))$, in the sense of weak entropy solutions with respect to admissible function (see LeFloch [13, Definition 3.2]).

When the system is hyperbolic and symmetric, this corresponds to the case $\alpha = a = 0$ in our system (1); it is proved in Serre [17, Thm. 3.6.1] and [18] to be a result of local existence and uniqueness in $C([0,T); H^s(\mathbb{R}^N)) \cap C^1([0,T); H^{s-1}(\mathbb{R}^N))$, with $s > \frac{N}{2} + 1$, this result being only local in time, even in dimension $N = 1$.

The assumptions of increasing initial conditions were also considered in the study of the Euler equation for compressible fluids in dimension one. With regard to these studies, we refer the reader to Chen and Wang [6, Thm. 3.1] for an existence and uniqueness result in $C^1(\mathbb{R} \times [0, +\infty))$ based on the method of characteristic. The result of Chen and Wang shows that the Euler equation of compressible fluids does not create shocks for suitable increasing and $C^1(\mathbb{R})$ initial conditions. In our case, we already knew that solutions of (1) are Lipschitz continuous; see El Hajj and Forcadel [8]. Even if this regularity question is not addressed in the present paper, we may expect some $C^1(\mathbb{R} \times [0, +\infty))$ regularity of the solution for $C^1(\mathbb{R})$ initial data.

1.3. Main result. The main result of this paper is the existence and uniqueness of global in time solutions for the system (1)–(2), modeling the dynamics of dislocation densities. This result ensures the mathematical well-posedness of the Groma–Balogh model [11] in the particular case of our interest.

THEOREM 1.1 (existence and uniqueness). *For all $T, L_0 \geq 0$, $\alpha \in \mathbb{R}$, and $\rho_0^\pm \in H^1_{loc}(\mathbb{R})$, and under the assumptions*

(H1) $\rho_0^\pm(x+1) = \rho_0^\pm(x) + L_0$ *(1-periodic function + linear function),*

(H2) $\dfrac{\partial \rho_0^\pm}{\partial x} \geq 0$ *a.e. in $\mathbb{R}$ ($\rho_0^\pm$ nondecreasing),*

(H3) $a \in L^\infty(0,T)$,

the system (1)–(2) *admits a unique solution $\rho^\pm \in H^1_{loc}(\mathbb{R} \times [0,T))$ such that, for a.e. $t \in (0,T)$, the function $\rho^\pm(.,t) : x \longmapsto \rho^\pm(x,t)$ verifies* (H1) *and* (H2).

The preceding theorem gives a global existence and uniqueness result of the system (1). Its proof is based on the following steps. First, we regularize the system (1); then we show a uniform a priori estimate in $L^\infty((0,T); H^1_{loc}(\mathbb{R}))$ for this regularized system. These estimates lead to a result of existence for long time solution and ensure the passage to the limit by compactness. Finally, the demonstration of uniqueness is done in a direct way.

THEOREM 1.2 (comparison principle for (1) with $\alpha = 0$). *Let $a(\cdot)$ satisfy* (H3) *and $\rho_1^{\pm,}$, $\rho_2^\pm \in H^1_{loc}(\mathbb{R}\times[0,T))$ be two solutions of the system* (1) *with $\alpha = 0$. Moreover, let $\rho_1^\pm(.,t)$, $\rho_2^\pm(.,t)$ verify* (H1) *and* (H2) *for a.e. $t \in (0,T)$. Then, if $\rho_1^\pm(\cdot,0) \leq \rho_2^\pm(\cdot,0)$ in $\mathbb{R}$, we have $\rho_1^\pm \leq \rho_2^\pm$ a.e. in $\mathbb{R} \times (0,T)$.*

This comparison result was crucial in a previous work [8], for the demonstration of existence and uniqueness of a Lipschitz solution to problem (1), in the sense of viscosity solution, for Lipschitz initial conditions. Here the interest of this result is a little bit secondary. Indeed, thanks to this comparison principle, we have been able to obtain indirectly $H^1_{loc}(\mathbb{R} \times [0,T))$ estimates. These estimates in turn lead to a result of existence in $H^1_{loc}(\mathbb{R} \times [0,T))$.

Our work focuses on the study of the dynamics of dislocation densities. In a different direction, let us quote some recent results on the dynamics of dislocation lines, taken individually, that are represented by nonlocal Hamilton–Jacobi equations (see [2, 9] and [1, 4] for local and global in time results, respectively).

Remark 1.3 (existence and uniqueness for the Burgers equation). We remark that these techniques can be applied to the case of the classical Burgers equations in

$W^{1,p}_{loc}(\mathbb{R}\times[0,T))$ for all $1\le p<+\infty$.

Indeed, if we consider for a given function f and initial data u_0 the equation

$$(4)\qquad \begin{cases} \dfrac{\partial u}{\partial t}+\dfrac{\partial}{\partial x}(f(u))=0 & \text{in}\quad \mathcal{D}'(\mathbb{R}\times(0,T)),\\ u(x,0)=u_0(x), & x\in\mathbb{R},\end{cases}$$

then we have the following theorem.

THEOREM 1.4. *Let $p\in[1,+\infty)$ and f be locally Lipschitz and convex; then, for all $T,L_0\ge 0$, and $u_0\in W^{1,p}_{loc}(\mathbb{R})$, they satisfy* (H1) *and* (H2). *Equation* (4) *admits a solution $u\in W^{1,p}_{loc}(\mathbb{R}\times[0,T))$, unique in the class of solutions satisfying* (H1) *and* (H2), *a.e. $t\in(0,T)$.*

1.4. Organization of the paper. In section 2, we regularize the function $a(\cdot)$ and the initial conditions and prove that the system (1)–(2) modified by the term $(\varepsilon\{\frac{\partial^2\rho^\pm}{\partial x^2}\})$ admits local in time solutions (in the "mild" sense). This will be achieved by using an application of a fixed point theorem in the space of functions in $C([0,T);H^1_{loc}(\mathbb{R}))$ and verifying (H1) for all $t\in(0,T)$. In section 3, we prove that the obtained solutions are regular and verify (H2) for all $t\in(0,T)$, with initial conditions verifying (H2). In section 4, we prove some uniform a priori estimates on the regularized solution obtained in section 3. Thanks to these estimates, we also prove the existence of global in time solutions. In section 5, we give the demonstration of Theorem 1.1, and in section 6 we prove a comparison principle result of the system (1) in the case $\alpha=0$. Finally, in section 7 we give an application of the previous results in the case of the classical Burgers equation.

2. Existence of solutions for an approximated system. In this section, we prove a theorem of existence of solutions, local in time, for the system (1) modified by the term $\varepsilon\{\frac{\partial^2\rho^\pm}{\partial x^2}\}$ after the regularization of the function $a(\cdot)$ and the initial conditions. This approximation brings us back to the study, for every $0<\varepsilon<1$, of the following system:

(5)
$$\begin{cases} \dfrac{\partial\rho^{+,\varepsilon}}{\partial t}-\varepsilon\dfrac{\partial^2\rho^{+,\varepsilon}}{\partial x^2}= & -\left(a^\varepsilon(t)+(\rho^{+,\varepsilon}-\rho^{-,\varepsilon})+\alpha\displaystyle\int_0^1(\rho^{+,\varepsilon}-\rho^{-,\varepsilon})(y,t)dy\right)\dfrac{\partial\rho^{+,\varepsilon}}{\partial x}\\ & \text{in }\mathcal{D}'(\mathbb{R}\times(0,T)),\\ \dfrac{\partial\rho^{-,\varepsilon}}{\partial t}-\varepsilon\dfrac{\partial^2\rho^{-,\varepsilon}}{\partial x^2}= & \left(a^\varepsilon(t)+(\rho^{+,\varepsilon}-\rho^{-,\varepsilon})+\alpha\displaystyle\int_0^1(\rho^{+,\varepsilon}-\rho^{-,\varepsilon})(y,t)dy\right)\dfrac{\partial\rho^{-,\varepsilon}}{\partial x}\\ & \text{in }\mathcal{D}'(\mathbb{R}\times(0,T)),\end{cases}$$

where $a^\varepsilon=\tilde a*\eta_\varepsilon$, with $\eta_\varepsilon(\cdot)=\frac{1}{\varepsilon}\eta(\frac{\cdot}{\varepsilon})$, such that $\eta\in C^\infty_c(\mathbb{R})$, η is positive, and $\int_{\mathbb{R}}\eta=1$. The function $\tilde a(\cdot)$ is an extension in $\mathbb{R}$ of the function $a(\cdot)$ by 0.

We also consider the regularized initial conditions of the system (5):

$$(6)\qquad \rho^{\pm,\varepsilon}(x,0)=\rho_0^{\pm,\varepsilon}(x)=\rho_0^{\pm,\varepsilon,per}(x)+L_0x=\rho_0^{\pm,per}*_{\mathbb{T}}\eta_\varepsilon(x)+L_0x.$$

We have the following local in time existence result for the approximated system.

THEOREM 2.1 (short time existence). *Assume* (H1) *and* (H3). *For all $\alpha\in\mathbb{R}$ and $\rho_0^\pm\in H^1_{loc}(\mathbb{R})$ there exists*

$$T^\star(\|\rho_0^{\pm,per}\|_{H^1(\mathbb{T})},\|a\|_{L^\infty(0,T)},L_0,\alpha,\varepsilon)>0$$

such that the system (5)–(6) *admits a solution* $\rho^{\pm,\varepsilon} \in C([0,T^\star); H^1_{loc}(\mathbb{R}))$ *with* $\rho^{\pm,\varepsilon}(.,t)$ *verifying* (H1).

For the proof of this theorem, see subsection 2.3. Before going on, we need to give some notation and preliminary results that will be used throughout the paper.

2.1. Notation. In what follows, we are going to use the following notation:

1. $\rho^\varepsilon = \rho^{+,\varepsilon} - \rho^{-,\varepsilon}$.
2. $\rho^{\pm,\varepsilon,per} = \rho^{\pm,\varepsilon} - L_0 x$.
3. $\mathbb{T} = (\mathbb{R}/\mathbb{Z})$ is the $[0,1)$-periodic interval.
4. Let $f = (f_1, f_2)$ be a vector such that $f_i \in H^1(\mathbb{T})$ for $i \in \{1,2\}$. The norm of f in $\left(H^1(\mathbb{T})\right)^2$ will be defined by $\|f\|_{H^1(\mathbb{T})} = \max(\|f_1\|_{H^1(\mathbb{T})}, \|f_2\|_{H^1(\mathbb{T})})$.
5. Let f be a function from $\mathbb{R} \times (0,T)$ to $\mathbb{R}$. We note by $f(t) = f(.,t) : x \longmapsto f(x,t)$.

Remark 2.2 (periodicity). According to (H1)–(H2), it is clear that ρ^ε, $\rho^{\pm,\varepsilon,per}$, and $\frac{\partial \rho^{\pm,\varepsilon}}{\partial x}$ are 1-periodic in space functions.

Under the notation of section 2.1, we know that the system (5) is equivalent to

$$\frac{\partial \rho^{\pm,\varepsilon,per}}{\partial t} - \varepsilon \frac{\partial^2 \rho^{\pm,\varepsilon,per}}{\partial x^2} = \overbrace{\mp C_\alpha[\rho^\varepsilon(t)] \frac{\partial \rho^{\pm,\varepsilon,per}}{\partial x}}^{\text{bilinear term}} \overbrace{\mp a^\varepsilon(t) \frac{\partial \rho^{\pm,\varepsilon,per}}{\partial x} \mp L_0 C_\alpha[\rho^\varepsilon(t)]}^{\text{linear term}} \mp L_0 a^\varepsilon(t) \quad \text{in } \mathbb{T} \times (0,T), \tag{7}$$

where $C_\alpha[\rho^\varepsilon(t)](x) = (\rho^\varepsilon(x,t) + \alpha \int_0^1 \rho^\varepsilon(y,t)dy)$, with the periodic initial conditions

$$\rho^{\pm,\varepsilon,per}(x,0) = \rho_0^{\pm,\varepsilon,per}(x) \quad \text{in} \quad \mathbb{T}. \tag{8}$$

2.2. Preliminary results.

LEMMA 2.3 (properties of the regularized sequence). *Under hypotheses* (H1) *and* (H3) *and for every* $\rho_0^{\pm} \in H^1_{loc}(\mathbb{R})$*, we have the following:*

1. *The functions* $\rho_0^{\pm,\varepsilon,per} \in C^\infty(\mathbb{T})$ *and verify the following estimate:*
$$\|\rho_0^{\pm,\varepsilon,per}\|_{H^1(\mathbb{T})} \le C \|\rho_0^{\pm,per}\|_{H^1(\mathbb{T})}.$$
2. *The function* $a^\varepsilon(\cdot) \in C^\infty(\mathbb{R}) \cap L^\infty(\mathbb{R})$ *and verifies the following estimate:*
$$\|a^\varepsilon\|_{L^\infty(\mathbb{R})} \le \|a\|_{L^\infty(0,T)}.$$
3. *The sequence* $a^\varepsilon(\cdot)$ *strongly converges to* $a(\cdot)$ *in* $L^2(0,T)$*. The sequences* $\rho_0^{\pm,\varepsilon,per}$ *strongly converge to* $\rho_0^{\pm,per}$ *in* $H^1(\mathbb{T})$.

The proof of this lemma is a classical property of the regularizing sequence $(\eta_\varepsilon)_\varepsilon$.

LEMMA 2.4 (mild solution). *Assume* (H3). *For every* $T \ge 0$*, if* $\rho^{\pm,\varepsilon,per} \in C([0,T); H^1(\mathbb{T}))$ *are solutions of the equation*

$$\begin{aligned} \rho^{\pm,\varepsilon,per}(x,t) &= S_\varepsilon(t)\rho_0^{\pm,\varepsilon,per} \\ &\mp L_0 \int_0^t a^\varepsilon(s)ds \mp \int_0^t S_\varepsilon(t-s)\left(C_\alpha[\rho^\varepsilon(s)] \frac{\partial \rho^{\pm,\varepsilon,per}}{\partial x}(s)\right)ds \\ &\mp \int_0^t S_\varepsilon(t-s)\left(L_0 C_\alpha[\rho^\varepsilon(s)] + a(t)\frac{\partial \rho^{\pm,\varepsilon,per}}{\partial x}(s)\right)ds, \end{aligned} \tag{9}$$

where $S_\varepsilon(t) = e^{\varepsilon t\Delta}$ *is the heat semigroup, then* $\rho^{\pm,\varepsilon,per}$ *is a solution of the system* (7)–(8) *in the sense of distributions.*

For the proof of this lemma, we refer the reader to Pazy [16, Thm. 5.2, p. 146].

LEMMA 2.5 (fixed point). *Let* E *be a Banach space,* B *be a continuous bilinear application from* $E \times E$ *to* E*, and* L *be a continuous linear application from* E *to* E *such that*

$$\|B(x,y)\|_E \leq \lambda \|x\|_E \|y\|_E \quad \textit{for all} \quad x, y \in E,$$

$$\|L(x)\|_E \leq \mu \|x\|_E \quad \textit{for all} \quad x \in E,$$

where $\lambda > 0$ *and* $\mu \in (0,1)$ *are given constants. Then, for all* $x_0 \in E$ *such that*

$$\|x_0\|_E < \frac{1}{4\lambda}(\mu - 1)^2,$$

the equation $x = x_0 + B(x,x) + L(x)$ *admits a solution in* E*.*

For the proof of this lemma we refer the reader to Cannone [5, Lem. 4.2.14].

In order to show the existence of a solution within the framework of Lemma 2.4, we apply Lemma 2.5 in the space $E = \left(L^\infty((0,T); H^1(\mathbb{T}))\right)^2$, where x_0, B, and L are defined, for $u = (u_1, u_2),\ v = (v_1, v_2) \in E$, by

(10)
$$x_0 = S_\varepsilon(t)\rho^\varepsilon_{0,vec} + L_0 \vec{i} \int_0^t a^\varepsilon(s) ds, \quad \text{where} \quad \rho^\varepsilon_{0,vec} = (\rho_0^{+,\varepsilon,per}, \rho_0^{-,\varepsilon,per}),\ \vec{i} = \begin{pmatrix} -1 \\ 1 \end{pmatrix},$$

(11)
$$B(u,v)(t) = \bar{I}_1 \int_0^t S_\varepsilon(t-s) \left(C_\alpha [u_1(s) - u_2(s)] \frac{\partial v}{\partial x}(s) \right) ds, \text{ where } \bar{I}_1 = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix},$$

(12)
$$L(u)(t) = L_0 \vec{i} \int_0^t S_\varepsilon(t-s) C_\alpha [u_1(s) - u_2(s)] ds + \bar{I}_1 \int_0^t S_\varepsilon(t-s) \left(a^\varepsilon(s) \frac{\partial u}{\partial x}(s) \right) ds.$$

LEMMA 2.6 (decreasing estimates). *If* $f \in L^q(\mathbb{T})$ *with* $2 \leq q \leq +\infty$ *and* $g \in L^2(\mathbb{T})$*, then for all* $t > 0$ *we have the following estimates:*

(i)

$$\|S_\varepsilon(t)(fg)\|_{L^\infty(\mathbb{T})} \leq C t^{-\frac{1}{2}} \|f\|_{L^2(\mathbb{T})} \|g\|_{L^2(\mathbb{T})}.$$

(ii)

$$\left\| \frac{\partial}{\partial x}(S_\varepsilon(t) f) \right\|_{L^2(\mathbb{T})} \leq C t^{-\frac{1}{2}} \|S_\varepsilon \left(\frac{t}{2} \right) f\|_{L^2(\mathbb{T})}.$$

(iii)

$$\left\| \frac{\partial}{\partial x} \left(S_\varepsilon(t)(fg) \right) \right\|_{L^2(\mathbb{T})} \leq C t^{-\frac{1}{2}(1+\frac{1}{q})} \|f\|_{L^q(\mathbb{T})} \|g\|_{L^2(\mathbb{T})},$$

where $C = C(\varepsilon)$ is a positive constant depending on ε.

For the proof of this lemma, see Pazy [16, Lem. 1.1.8 and Thm. 6.4.5].

PROPOSITION 2.7 (bilinear operator). *Let $F_T = \left(L^\infty((0,T); H^1(\mathbb{T}))\right)^2$. Then for every $T \geq 0$, $\alpha \in \mathbb{R}$, $u = (u_1, u_2) \in F_T$, and $v = (v_1, v_2) \in F_T$ the bilinear operator B defined in* (11) *is continuous from $F_T \times F_T$ to F_T. Moreover, there exists a positive constant $C = C(\alpha, \varepsilon)$ such that for all $u, v \in F_T$ we have*

$$\|B(u,v)\|_{F_T} \leq CT^{\frac{1}{2}} \|u\|_{F_T} \|v\|_{F_T}.$$

Proof of Proposition 2.7. First, we know that

$$\begin{aligned} \|B(u,v)(t)\|_{H^1(\mathbb{T})} &= \left\| \bar{I}_1 \int_0^t S_\varepsilon(t-s) \left(C_\alpha [u_1(s) - u_2(s)] \frac{\partial v}{\partial x}(s) \right) ds \right\|_{H^1(\mathbb{T})} \\ &\leq \int_0^t \left\| S_\varepsilon(t-s) \left(C_\alpha [u_1(s) - u_2(s)] \frac{\partial v}{\partial x}(s) \right) \right\|_{H^1(\mathbb{T})} ds. \end{aligned}$$

Then, since $L^\infty(\mathbb{T}) \hookrightarrow L^2(\mathbb{T})$, we have

$$\begin{aligned} \|B(u,v)(t)\|_{H^1(\mathbb{T})} &\leq \int_0^t \left\| S_\varepsilon(t-s) \left(C_\alpha [u_1(s) - u_2(s)] \frac{\partial v}{\partial x}(s) \right) \right\|_{L^\infty(\mathbb{T})} ds \\ &+ \int_0^t \left\| \frac{\partial}{\partial x} S_\varepsilon(t-s) \left(C_\alpha [u_1(s) - u_2(s)] \frac{\partial v}{\partial x}(s) \right) \right\|_{L^2(\mathbb{T})} ds. \end{aligned}$$

Using Lemma 2.6(i) for the first term and Lemma 2.6(iii) with $q = \infty$ for the second term, we can conclude that

$$\begin{aligned} \|B(u,v)(t)\|_{H^1(\mathbb{T})} &\leq C \int_0^t \frac{1}{(t-s)^{\frac{1}{2}}} \|C_\alpha [u_1(s) - u_2(s)]\|_{L^\infty(\mathbb{T})} \left\| \frac{\partial v}{\partial x}(s) \right\|_{L^2(\mathbb{T})} ds \\ &\leq C \sup_{0 \leq t < T} (\|u(t)\|_{H^1(\mathbb{T})}) \sup_{0 \leq t < T} (\|v(t)\|_{H^1(\mathbb{T})}) \int_0^t \frac{1}{(t-s)^{\frac{1}{2}}} ds. \end{aligned}$$

Then, for all $t \in (0,T)$, we have

$$\begin{aligned} \|B(u,v)(t)\|_{H^1(\mathbb{T})} &\leq Ct^{\frac{1}{2}} \|u\|_{L^\infty((0,T);H^1(\mathbb{T}))^2} \|v\|_{L^\infty((0,T);H^1(\mathbb{T}))^2} \\ &\leq CT^{\frac{1}{2}} \|u\|_{L^\infty((0,T);H^1(\mathbb{T}))^2} \|v\|_{L^\infty((0,T);H^1(\mathbb{T}))^2}. \end{aligned} \tag{13}$$

□

PROPOSITION 2.8 (linear operator). *Let $F_T = \left(L^\infty((0,T); H^1(\mathbb{T}))\right)^2$ and $a(\cdot)$ satisfy* (H3). *Then for all L_0 $T \geq 0$, and $u = (u_1, u_2) \in F_T$, the linear operator L defined in* (12) *is continuous from F_T to F_T. Moreover, there exists a positive constant $C = C(\alpha, \varepsilon, \|a\|_{L^\infty(0,T)}, L_0)$ such that*

$$\|L(u)\|_{F_T} \leq CT^{\frac{1}{2}} \|u\|_{F_T}.$$

The proof of Proposition 2.8 is similar to the one used in Proposition 2.7.

LEMMA 2.9. *For all L_0, $T \geq 0$, and $a(\cdot)$ satisfying* (H3), *if*

$$X_{a^\varepsilon}(t) = L_0 \vec{i} \int_0^t a^\varepsilon(s) ds, \quad t \in (0,T),$$

then

$$\|X_{a^\varepsilon}\|_{(L^\infty(0,T))^2} \leq L_0 T \|a\|_{L^\infty(0,T)}.$$

The proof of Lemma 2.9 is trivial (from Lemma 2.3(2)).

LEMMA 2.10 (continuity of the semigroup). *For all $f \in W^{2,2}(\mathbb{T})$ and $0 \le \theta < t$, we have the following estimates:*

(i)

$$\|(S_\varepsilon(t-\theta) - Id)f\|_{L^2(\mathbb{T})} \le C(t-\theta) \left\| \frac{\partial^2 f}{\partial x^2} \right\|_{L^2(\mathbb{T})}.$$

(ii)

$$\|(S_\varepsilon(t-\theta) - Id)f\|_{L^2(\mathbb{T})} \le 2\|f\|_{L^2(\mathbb{T})},$$

where $C = C(\varepsilon)$ is a positive constant depending on ε.

We refer the reader to Pazy [16, Lem. 6.2, p. 151] for the proof of this lemma.

LEMMA 2.11 (time continuity). *Assume* (H3). *If $\rho_{0,vec} = (\rho_0^{+,per}, \rho_0^{-,per}) \in (H^1(\mathbb{T}))^2$, then for all $T \ge 0$ and $u = (u_1, u_2) \in \big(L^\infty((0,T); H^1(\mathbb{T}))\big)^2$, we have the following applications:*

(A1) $t \to X_{a^\varepsilon}(t)$;

(A2) $t \to S_\varepsilon(t)\rho^\varepsilon_{0,vec}$, *where* $\rho^\varepsilon_{0,vec} = (\rho_0^{+,\varepsilon,per}, \rho_0^{-,\varepsilon,per})$;

(A3) $t \to B(u,u)(t)$;

(A4) $t \to L(u)(t)$ *are* $\big(C([0,T); H^1(\mathbb{T}))\big)^2$, *where X_{a^ε}, B, and L are defined in Lemma* 2.9, (11), *and* (12), *respectively.*

Proof of Lemma 2.11. The continuity of (A1) is trivial since $a \in L^\infty(0,T)$. From the fact that the semigroup $S_\varepsilon(\cdot)$ is continuous from $[0,T)$ to $(H^1(\mathbb{T}))^2$, we deduce the continuity of (A2).

It remains to prove the continuity of (A3) and (A4). Indeed, the continuity of (A3) at 0 is a consequence of inequality (13). Now we are going to prove the continuity of (A3) for all $\theta \in (0,T)$. For all t, such that $\theta < t \le \min(T, \frac{3\theta}{2})$, we write $t = (1+\gamma)\theta$ and denote $\tau = (1-\gamma)\theta$ (where $0 < \gamma \le \frac{1}{2}$), and we write

$$\begin{aligned} B(u,u)(t) - B(u,u)(\theta) &= \int_0^\tau (S(t-s) - S(\theta-s)) \left(C_\alpha[u_1(s) - u_2(s)] \frac{\partial u}{\partial x}(s) \right) ds \\ &\quad + \int_\tau^\theta (S(t-s) - S(\theta-s)) \left(C_\alpha[u_1(s) - u_2(s)] \frac{\partial u}{\partial x}(s) \right) ds \\ &\quad + \int_\theta^t S(t-s) \left(C_\alpha[u_1(s) - u_2(s)] \frac{\partial u}{\partial x}(s) \right) ds \end{aligned}$$

$$\begin{aligned} = & \overbrace{\int_0^\tau ((S(t-\theta) - Id)S(\theta-s)) \left(C_\alpha[u_1(s) - u_2(s)] \frac{\partial u}{\partial x}(s) \right) ds}^{I_1} \\ & + \overbrace{\int_\tau^\theta ((S(t-\theta) - Id)S(\theta-s)) \left(C_\alpha[u_1(s) - u_2(s)] \frac{\partial u}{\partial x}(s) \right) ds}^{I_2} \\ & + \int_\theta^t S(t-s) \left(C_\alpha[u_1(s) - u_2(s)] \frac{\partial u}{\partial x}(s) \right) ds. \end{aligned}$$

We apply Lemma 2.10(i) and Lemma 2.6(ii) to find an upper bound to I_1. We then apply Lemma 2.10(ii) to find an upper bound to I_2. After that, we follow the same steps of the proof of Proposition 2.7 to conclude that

$$\begin{aligned}\|B(u,u)(t)-B(u,u)(\theta)\|_{H^1}\leq\quad & C(t-\theta)\|u\|^2_{(L^\infty((0,T);H^1(\mathbb{T})))^2}\int_0^\tau\frac{1}{(\theta-s)^{\frac{3}{2}}}ds\\ & +C\|u\|^2_{(L^\infty((0,T);H^1(\mathbb{T})))^2}\int_\tau^\theta\frac{1}{(\theta-s)^{\frac{1}{2}}}ds\\ & +C\|u\|^2_{(L^\infty((0,T);H^1(\mathbb{T})))^2}\int_\theta^t\frac{1}{(t-s)^{\frac{1}{2}}}ds.\end{aligned}$$

After the computation of each integral we deduce that

$$\begin{aligned}\|B(u,u)(t)-B(u,u)(\theta)\|_{H^1}\leq\quad & C(t-\theta)\left(\tfrac{1}{(\theta-\tau)^{\frac{1}{2}}}-\tfrac{1}{\theta^{\frac{1}{2}}}\right)\|u\|^2_{(L^\infty((0,T);H^1(\mathbb{T})))^2}\\ & +C\left((\theta-\tau)^{\frac{1}{2}}+(t-\theta)^{\frac{1}{2}}\right)\|u\|^2_{(L^\infty((0,T);H^1(\mathbb{T})))^2}.\end{aligned}$$

Observing that $t-\theta=\theta-\tau=\gamma\theta$ we finally obtain the following inequality:

$$\|B(u,u)(t)-B(u,u)(\theta)\|_{H^1}\leq C(\theta,\gamma)\left((t-\theta)^{\frac{1}{2}}+(t-\theta)\right)\|u\|^2_{(L^\infty((0,T);H^1(\mathbb{T})))^2},$$

and hence we get the continuity of (A3). In the same way we get the continuity in time of (A4). ∎

2.3. Proof of Theorem 2.1. We rewrite the system (9) in the following vectorial form:

$$\begin{aligned}\rho^\varepsilon_{vec}(\cdot,t)=\quad & S_\varepsilon(t)\rho^\varepsilon_{0,vec}+L_0\vec{i}\int_0^t a^\varepsilon(s)ds+\bar{I}_1\int_0^t S_\varepsilon(t-s)\left(C_\alpha[\rho^\varepsilon(s)]\frac{\partial\rho^\varepsilon_{vec}}{\partial x}(s)\right)ds\\ & +L_0\vec{i}\int_0^t S_\varepsilon(t-s)C_\alpha[\rho^\varepsilon(s)]ds+\bar{I}_1\int_0^t S_\varepsilon(t-s)\left(a^\varepsilon(s)\frac{\partial\rho^\varepsilon_{vec}}{\partial x}(s)\right)ds\end{aligned}$$

such that ρ^ε_{vec} is the vector $(\rho^{+,\varepsilon,per},\rho^{-,\varepsilon,per})$ and $\rho^\varepsilon_{0,vec}$ is the vector $(\rho_0^{+,\varepsilon,per},\rho_0^{-,\varepsilon,per})$. $\vec{i}$ and $\bar{I}_1$ are defined in (10) and (11), respectively.

This altogether leads to the following equation:

$$\rho^\varepsilon_{vec}(\cdot,t)=S_\varepsilon(t)\rho^\varepsilon_{0,vec}+X_{a^\varepsilon}(t)+B(\rho^\varepsilon_{vec},\rho^\varepsilon_{vec})(t)+L(\rho^\varepsilon_{vec})(t),\tag{14}$$

where B is the bilinear application and L is the linear application defined in (11) and (12), respectively, and X_{a^ε} is defined in Lemma 2.9. Moreover, according to Lemmas 2.9 and 2.3 we know that

$$\begin{aligned}\|S(t)\rho^\varepsilon_{0,vec}+X_{a^\varepsilon}(t)\|_{(L^\infty((0,T);H^1(\mathbb{T})))^2}\quad & \leq\|\rho^\varepsilon_{0,vec}\|_{H^1(\mathbb{T})}+L_0T\|a^\varepsilon\|_{L^\infty(\mathbb{R})}\\ & \leq C_0\|\rho_{0,vec}\|_{H^1(\mathbb{T})}+L_0T\|a\|_{L^\infty(0,T)}.\end{aligned}$$

In order to apply Lemma 2.5, we want, for a well-chosen time T, that the following inequality holds:

$$C_0\|\rho^0_{vec}\|_{H^1(\mathbb{T})}+L_0T\|a\|_{L^\infty(0,T)}<\frac{1}{4CT^{\frac{1}{2}}}(CT^{\frac{1}{2}}-1)^2,\quad\text{and } CT^{\frac{1}{2}}<1,\tag{15}$$

where C is the largest constant between the two constants computed in Propositions 2.8 and 2.7. For

$$(T^\star)^{\frac{1}{2}}(\|\rho_{0,vec}\|_{H^1(\mathbb{T})}, \|a\|_{L^\infty(0,T)}, L_0, \varepsilon) = \min\left(1, \frac{1}{2C}, \frac{1}{16C(C_0\|\rho^0_{vec}\|_{H^1(\mathbb{T})} + L_0\|a\|_{L^\infty(0,T)})}\right), \tag{16}$$

we can easily verify that $T^\star$ satisfies the inequality (15). We apply Lemma 2.5 over the space $F_{T^\star} = \left(L^\infty((0,T^\star); H^1(\mathbb{T}))\right)^2$ to prove the existence of a solution for the system (14) in $F_{T^\star}$.

Then, according to Lemma 2.11, we deduce that the obtained solution is $(C([0,T^\star); H^1(\mathbb{T})))^2$.

This proves, by Lemma 2.4, the existence of a solution in the sense of distributions for the system (5)–(6) in $C([0,T^\star); H^1_{loc}(\mathbb{R}))$ that verifies (H1). ∎

3. Properties of the solution to the approximated system. In this section we show that the solutions of system (5)–(6) obtained in the previous section are regular and verify (H2), provided that initial conditions verify (H2).

Lemma 3.1 (regularity of the solution). *Assume* (H1), (H3), *and* $\rho_0^\pm \in H^1_{loc}(\mathbb{R})$; *if* $\rho^{\pm,\varepsilon} \in C([0,T); H^1_{loc}(\mathbb{R}))$ *are solutions of the system* (5)–(6), *then* $\rho^{\pm,\varepsilon} \in C^\infty(\mathbb{R} \times [0,T))$.

Proof of Lemma 3.1. If we denote the second term of the system (7) by

$$f^\pm_{a^\varepsilon,\alpha}[\rho^\varepsilon(t)] = \mp a^\varepsilon(t)\left(L_0 + \frac{\partial \rho^{\pm,\varepsilon,per}}{\partial x}\right) \mp C_\alpha[\rho^\varepsilon(t)]\left(\frac{\partial \rho^{\pm,\varepsilon,per}}{\partial x} + L_0\right),$$

we know that $f^\pm_{a^\varepsilon,\alpha}[\rho^\varepsilon] \in L^2(\mathbb{T}\times(0,T))$. Moreover, we know that the initial conditions $\rho_0^{\pm,\varepsilon,per} \in C^\infty(\mathbb{T})$, which allows us to apply the L^2 regularity of the heat equation over the system (7)–(8) (see Lions and Magenes [15, Thm. 8.2]). Then we deduce by induction that the solution is $C^\infty(\mathbb{T}\times[0,T))$. ∎

Lemma 3.2 (monotonicity of the solution in space). *Assume* (H1), (H2), (H3), *and* $\rho_0^\pm \in H^1_{loc}(\mathbb{R})$; *if* $\rho^{\pm,\varepsilon} \in C^\infty(\mathbb{R}\times[0,T))$ *are solutions of the system* (5)–(6), *then* $\rho^{\pm,\varepsilon}(.,t)$ *verifies* (H2) *for all* $t \in (0,T)$.

Proof of Lemma 3.2. First, we remark that if $\frac{\partial \rho_0^\pm}{\partial x} \geq 0$, then $\frac{\partial \rho_0^{\pm,\varepsilon}}{\partial x} \geq 0$. Indeed, we have

$$\begin{aligned}\frac{\partial \rho_0^{\pm,\varepsilon}}{\partial x} = \frac{\partial \rho_0^{\pm,per}}{\partial x} * \eta_\varepsilon + L_0 \quad &= \left(\frac{\partial \rho_0^{\pm,per}}{\partial x} + L_0\right) * \eta_\varepsilon \\ &= \left(\frac{\partial \rho_0^{\pm}}{\partial x}\right) * \eta_\varepsilon \geq 0, \quad \text{because } \eta \text{ is positive.}\end{aligned}$$

We apply the maximum principle over the derived system of (5)–(6):

$$\begin{cases} \dfrac{\partial \theta^{\pm,\varepsilon}}{\partial t} - \varepsilon \dfrac{\partial^2 \theta^{\pm,\varepsilon}}{\partial x^2} \pm (C_\alpha[\rho^\varepsilon(t)] + a^\varepsilon(t))\dfrac{\partial \theta^{\pm,\varepsilon}}{\partial x} \pm (\theta^{+,\varepsilon} - \theta^{-,\varepsilon})\theta^{\pm,\varepsilon} = 0 \\ \qquad\qquad \text{in} \quad \mathbb{T}\times(0,T), \\ \theta^{\pm,\varepsilon}(x,0) = \dfrac{\partial \rho_0^{\pm,\varepsilon}}{\partial x}, \end{cases}$$

where $\theta^{\pm,\varepsilon} = \frac{\partial \rho^{\pm,\varepsilon}}{\partial x}$ (see Gilbarg and Trudinger [10, Thm. 8.1]). Since $\rho^{\pm,\varepsilon} \in C^\infty(\mathbb{R}\times[0,T))$, we deduce that $\theta^{\pm,\varepsilon} \geq 0$ belongs to $\mathbb{T}\times(0,T)$. $\square$

Corollary 3.3 (short time existence of nondecreasing regular solutions). *For all $\alpha \in \mathbb{R}$ and $\rho_0^\pm \in H^1_{loc}(\mathbb{R})$, under the assumptions* (H1), (H2), *and* (H3), *there exists*

$$T^\star(\|\rho_0^{\pm,per}\|_{H^1(\mathbb{T})}, \|a\|_{L^\infty(0,T)}, L_0, \alpha, \varepsilon) > 0$$

such that the system (5)–(6) *admits a solution $\rho^{\pm,\varepsilon} \in C^\infty(\mathbb{R}\times[0,T^\star))$ with $\rho^{\pm,\varepsilon}(.,t)$ verifying* (H1) *and* (H2).

The proof of Corollary 3.3 is a consequence of Theorem 2.1 and Lemmas 3.1 and 3.2 (with $T = T^\star$).

Remark 3.4. Here we remark that the case of nondecreasing solutions corresponds to a nonshock case in the Burgers equation. On the other hand, the decreasing solutions represent the shock case.

4. A priori estimates and long time existence for the approximated system. In this section, we are going to show some ε-uniform estimates on the solutions of the system (5)–(6). These estimates will be used in section 4 for the passage to the limit as ε tends to zero.

Lemma 4.1 (L^2 estimates over the space derivatives of the solutions). *Assume* (H1), (H2), (H3), *and $\rho_0^\pm \in H^1_{loc}(\mathbb{R})$; if $\rho^{\pm,\varepsilon} \in C^\infty(\mathbb{R}\times[0,T))$ is a solution of the system* (5)–(6) *for all $T \geq 0$, then*

$$\left\|\frac{\partial \rho^{+,\varepsilon}}{\partial x}\right\|^2_{L^\infty((0,T);L^2(\mathbb{T}))} + \left\|\frac{\partial \rho^{-,\varepsilon}}{\partial x}\right\|^2_{L^\infty((0,T);L^2(\mathbb{T}))} \leq CB_0,$$

with $B_0 = (\|\frac{\partial \rho_0^+}{\partial x}\|^2_{L^2(\mathbb{T})} + \|\frac{\partial \rho_0^-}{\partial x}\|^2_{L^2(\mathbb{T})})$.

Proof of Lemma 4.1. If we denote $\rho^\varepsilon = \rho^{+,\varepsilon} - \rho^{-,\varepsilon}$ and $k^\varepsilon = \rho^{+,\varepsilon} + \rho^{-,\varepsilon}$, then, according to (H1), it is clear that ρ^ε, $\frac{\partial \rho^\varepsilon}{\partial x}$, and $\frac{\partial k^\varepsilon}{\partial x}$ are 1-periodic functions. Moreover, by Lemma 3.2, we know that $\frac{\partial k^\varepsilon}{\partial x} \geq 0$.

If we take into consideration the equations of the system (5), we can conclude that ρ^ε and k^ε verify the following system:

$$(17)\quad \begin{cases} \dfrac{\partial \rho^\varepsilon}{\partial t} - \varepsilon \dfrac{\partial^2 \rho^\varepsilon}{\partial x^2} = -\left(\rho^\varepsilon + \alpha \displaystyle\int_0^1 \rho^\varepsilon dx + a^\varepsilon(t)\right)\dfrac{\partial k^\varepsilon}{\partial x} & \text{in} \quad \mathcal{D}'(\mathbb{R}\times(0,T)), \\ \dfrac{\partial k^\varepsilon}{\partial t} - \varepsilon \dfrac{\partial^2 k^\varepsilon}{\partial x^2} = -\left(\rho^\varepsilon + \alpha \displaystyle\int_0^1 \rho^\varepsilon dx + a^\varepsilon(t)\right)\dfrac{\partial \rho^\varepsilon}{\partial x} & \text{in} \quad \mathcal{D}'(\mathbb{R}\times(0,T)). \end{cases}$$

We derive the first equation of the system (17) with respect to x, then we multiply the result by $\frac{\partial \rho^\varepsilon}{\partial x}$, and, finally, we integrate in space. For all $t \in (0,T)$, we then obtain

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}\left\|\frac{\partial \rho^\varepsilon}{\partial x}(t)\right\|^2_{L^2(\mathbb{T})} + \varepsilon\left\|\frac{\partial^2 \rho^\varepsilon}{\partial x^2}(t)\right\|^2_{L^2(\mathbb{T})} = & -\int_0^1 \left(\frac{\partial \rho^\varepsilon}{\partial x}\right)^2 \frac{\partial k^\varepsilon}{\partial x} - \int_0^1 \rho^\varepsilon \frac{\partial \rho^\varepsilon}{\partial x}\frac{\partial^2 k^\varepsilon}{\partial x^2} \\ & -\left(\alpha\int_0^1 \rho^\varepsilon + a^\varepsilon(t)\right)\int_0^1 \frac{\partial^2 k^\varepsilon}{\partial x^2}\frac{\partial \rho^\varepsilon}{\partial x}. \end{aligned}$$

Now we proceed in the same way as for the previous equation, but we multiply the second equation of the system (17) by $\frac{\partial k^\varepsilon}{\partial x}$. For every $t \in (0,T)$, we obtain

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\left\|\frac{\partial k^\varepsilon}{\partial x}(t)\right\|^2_{L^2(\mathbb{T})} + \varepsilon\left\|\frac{\partial^2 k^\varepsilon}{\partial x^2}(t)\right\|^2_{L^2(\mathbb{T})} = \; & -\int_0^1\left(\frac{\partial\rho^\varepsilon}{\partial x}\right)^2\frac{\partial k^\varepsilon}{\partial x} - \int_0^1 \rho^\varepsilon\frac{\partial k^\varepsilon}{\partial x}\frac{\partial^2\rho^\varepsilon}{\partial x^2}\\ & -\left(\alpha\int_0^1\rho^\varepsilon + a^\varepsilon(t)\right)\int_0^1\frac{\partial^2\rho^\varepsilon}{\partial x^2}\frac{\partial k^\varepsilon}{\partial x}.\end{aligned}$$

Adding the two previous equations, thanks to the periodicity of ρ^ε and $\frac{\partial k^\varepsilon}{\partial x}$, we infer that

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\left\|\frac{\partial\rho^\varepsilon}{\partial x}(t)\right\|^2_{L^2(\mathbb{T})} + \frac{1}{2}\frac{d}{dt}\left\|\frac{\partial k^\varepsilon}{\partial x}(t)\right\|^2_{L^2(\mathbb{T})} \le & -\int_0^1\left(\frac{\partial\rho^\varepsilon}{\partial x}\right)^2\frac{\partial k^\varepsilon}{\partial x} - \int_0^1\frac{\partial}{\partial x}\left(\rho^\varepsilon\frac{\partial\rho^\varepsilon}{\partial x}\frac{\partial k^\varepsilon}{\partial x}\right)\\ & -\left(\alpha\int_0^1\rho^\varepsilon + a^\varepsilon(t)\right)\int_0^1\frac{\partial}{\partial x}\left(\frac{\partial\rho^\varepsilon}{\partial x}\frac{\partial k^\varepsilon}{\partial x}\right)\\ \le & -\int_0^1\left(\frac{\partial\rho^\varepsilon}{\partial x}\right)^2\frac{\partial k^\varepsilon}{\partial x} \le 0.\end{aligned}$$

We integrate in time and use the fact that $\rho^{\pm,\varepsilon} \in C^\infty(\mathbb{R}\times[0,T))$ and Lemma 2.3. We obtain, in particular,

$$\begin{aligned}&\sup_{t\in(0,T)}\left\|\frac{\partial\rho^\varepsilon}{\partial x}(t)\right\|^2_{L^2(\mathbb{T})} + \sup_{t\in(0,T)}\left\|\frac{\partial k^\varepsilon}{\partial x}(t)\right\|^2_{L^2(\mathbb{T})}\\ &\quad\le C\left(\left\|\frac{\partial(\rho_0^+ - \rho_0^-)}{\partial x}\right\|^2_{L^2(\mathbb{T})} + \left\|\frac{\partial(\rho_0^+ + \rho_0^-)}{\partial x}\right\|^2_{L^2(\mathbb{T})}\right).\end{aligned}$$

That leads to the desired result. ∎

Lemma 4.2 (L^2 estimates of the solutions). *Assume* (H1), (H2), (H3), *and* $\rho_0^\pm \in H^1_{loc}(\mathbb{R})$; *if* $\rho^{\pm,\varepsilon} \in C^\infty(\mathbb{R}\times[0,T))$ *are solutions of the system* (5)–(6) *for every* $T \ge 0$, *then*

$$\begin{aligned}&\|\rho^{+,\varepsilon}\|^2_{L^\infty((0,T);L^2(0,1))} + \|\rho^{-,\varepsilon}\|^2_{L^\infty((0,T);L^2(0,1))}\\ &\quad\le C\left(M_0 + (B_0 + \|a\|^2_{L^\infty(0,T)})\right)e^{4L_0(1+\alpha^2)T},\end{aligned}$$

where B_0 *is defined in Lemma* 4.1, *and* $M_0 = (\|\rho_0^+\|^2_{L^2(0,1)} + \|\rho_0^-\|^2_{L^2(0,1)})$.

Proof of Lemma 4.2. We will use the same procedure of the proof of Lemma 4.1. We multiply the first equation of the system (17) by ρ^ε; then we integrate in space. For every $t \in (0,T)$, we obtain

$$\frac{1}{2}\frac{d}{dt}\|\rho^\varepsilon(t)\|^2_{L^2(\mathbb{T})} + \varepsilon\left\|\frac{\partial\rho^\varepsilon}{\partial x}(t)\right\|^2_{L^2(\mathbb{T})} = -\int_0^1(\rho^\varepsilon)^2\frac{\partial k^\varepsilon}{\partial x} - \left(\alpha\int_0^1\rho^\varepsilon + a^\varepsilon(t)\right)\int_0^1\rho^\varepsilon\frac{\partial k^\varepsilon}{\partial x}.$$

Similarly, we multiply the second equation of the system (17) by k^ε and integrate in space. For every $t \in (0,T)$, we obtain

$$\frac{1}{2}\frac{d}{dt}\|k^\varepsilon(t)\|^2_{L^2(0,1)} + \varepsilon\left\|\frac{\partial k^\varepsilon}{\partial x}(t)\right\|^2_{L^2(\mathbb{T})} = -\int_0^1\rho^\varepsilon\frac{\partial\rho^\varepsilon}{\partial x}k^\varepsilon - \left(\alpha\int_0^1\rho^\varepsilon + a^\varepsilon(t)\right)\int_0^1 k^\varepsilon\frac{\partial\rho^\varepsilon}{\partial x}.$$

Now we add the two previous equations and get

$$
\begin{aligned}
&\frac{1}{2}\left(\frac{d}{dt}\|\rho^\varepsilon(t)\|^2_{L^2(\mathbb{T})}+\frac{d}{dt}\|k^\varepsilon(t)\|^2_{L^2(0,1)}\right)\\
&\quad\le -\int_0^1\left((\rho^\varepsilon)^2\frac{\partial k^\varepsilon}{\partial x}+\frac{1}{2}k^\varepsilon\frac{\partial(\rho^\varepsilon)^2}{\partial x}\right)\\
&\qquad -\left(\alpha\int_0^1\rho^\varepsilon+a^\varepsilon(t)\right)\left(\int_0^1 k^\varepsilon\frac{\partial\rho^\varepsilon}{\partial x}+\int_0^1\rho^\varepsilon\frac{\partial k^\varepsilon}{\partial x}\right)\\
&\quad\le -\frac{1}{2}\int_0^1(\rho^\varepsilon)^2\frac{\partial k^\varepsilon}{\partial x}-\frac{1}{2}\int_0^1\frac{\partial((\rho^\varepsilon)^2k^\varepsilon)}{\partial x}\\
&\qquad -\left(\alpha\int_0^1\rho^\varepsilon+a^\varepsilon(t)\right)\int_0^1\frac{\partial(k^\varepsilon\rho^\varepsilon)}{\partial x}.
\end{aligned}
$$

Recalling that ρ^ε is periodic and k^ε is nondecreasing, we see that

$$
\frac{1}{2}\left(\frac{d}{dt}\|\rho^\varepsilon(t)\|^2_{L^2(\mathbb{T})}+\frac{d}{dt}\|k^\varepsilon(t)\|^2_{L^2(0,1)}\right)\le -\left(\alpha\int_0^1\rho^\varepsilon+a^\varepsilon(t)\right)\int_0^1\frac{\partial(k^\varepsilon\rho^\varepsilon)}{\partial x}.
$$

But we know from (H1) that ρ^ε and $(k^\varepsilon-2L_0x)$ are 1-periodic functions, which implies that

$$
\int_0^1\frac{\partial(k^\varepsilon\rho^\varepsilon)}{\partial x}=\int_0^1\frac{\partial((k^\varepsilon-2L_0x)\rho^\varepsilon)}{\partial x}+2L_0\int_0^1\frac{\partial(x\rho^\varepsilon)}{\partial x}=2L_0\int_0^1 x\frac{\partial\rho^\varepsilon}{\partial x}+2L_0\int_0^1\rho^\varepsilon.
$$

We use Lemmas 4.1 and 2.3 and the fact that ($ab\le\frac{1}{2}(a^2+b^2)$ and $(a+b)^2\le 2(a^2+b^2)$) to deduce that

$$
\begin{aligned}
&\frac{d}{dt}\left(\|k^\varepsilon(t)\|^2_{L^2(0,1)}+\|\rho^\varepsilon(t)\|^2_{L^2(\mathbb{T})}\right)\\
&\quad\le 4L_0\left(|\alpha|\,\|\rho^\varepsilon(t)\|_{L^2(\mathbb{T})}+\|a\|_{L^\infty(0,T)}\right)\left(\left\|\frac{\partial\rho^\varepsilon}{\partial x}(t)\right\|_{L^2(\mathbb{T})}+\|\rho^\varepsilon(t)\|_{L^2(\mathbb{T})}\right)\\
&\quad\le 4L_0\left(\|a\|^2_{L^\infty(0,T)}+(1+\alpha^2)\|\rho^\varepsilon(t)\|^2_{L^2(\mathbb{T})}+\left\|\frac{\partial\rho^\varepsilon}{\partial x}(t)\right\|^2_{L^2(\mathbb{T})}\right)\\
&\quad\le 4L_0\left(CB_0+\|a\|^2_{L^\infty(0,T)}\right)+4L_0(1+\alpha^2)\left(\|\rho^\varepsilon(t)\|^2_{L^2(\mathbb{T})}+\|k^\varepsilon(t)\|^2_{L^2(0,1)}\right).
\end{aligned}
$$

Using the previous estimate and the fact that $\rho^{\pm,\varepsilon}\in C^\infty(\mathbb{R}\times[0,T))$, we finally obtain

$$
\|\rho^\varepsilon\|^2_{L^\infty((0,T);L^2(\mathbb{T}))}+\|k^\varepsilon\|^2_{L^\infty((0,T)L^2(0,1))}\le C\left(M_0+B_0+\|a\|^2_{L^\infty(0,T)}\right)e^{4L_0(1+\alpha^2)T}.
$$

This leads to the desired result. $\square$

LEMMA 4.3 (L^2 estimate on the time derivatives of the solutions). *Assume* (H1), (H2), (H3), *and* $\rho_0^\pm \in H^1_{loc}(\mathbb{R})$; *if* $\rho^{\pm,\varepsilon} \in C^\infty(\mathbb{R}\times[0,T))$ *is a solution of the system* (5)–(6) *for every* $T \geq 0$, *then there exists a constant* $C\left(T, L_0, \alpha, \|a\|_{L^\infty(0,T)}, M_0, B_0\right)$ *independent of* ε *such that*

$$\left\|\frac{\partial \rho^{\pm,\varepsilon}}{\partial t}\right\|_{L^2(\mathbb{T}\times(0,T))} \leq C.$$

Proof of Lemma 4.3. For the proof of Lemma 4.3, it is sufficient to show that the second term of the system (5),

$$f^\pm_{a^\varepsilon,\alpha}[\rho^\varepsilon(t)] = \mp\left(a^\varepsilon(t) + \rho^\varepsilon + \alpha\int_0^1 \rho^\varepsilon dx\right)\frac{\partial \rho^{\pm,\varepsilon}}{\partial x},$$

is bounded in $L^\infty((0,T);L^2(\mathbb{T}))$ uniformly in ε. Indeed,

$$\begin{aligned}
&\left\|f^\pm_{a^\varepsilon,\alpha}[\rho^\varepsilon]\right\|_{L^\infty((0,T^\star);L^2(\mathbb{T}))}\\
&\quad\leq \left\|\left(a^\varepsilon(\cdot) + \rho^\varepsilon + \alpha\int_0^1 \rho^\varepsilon dx\right)\frac{\partial \rho^{\pm,\varepsilon}}{\partial x}\right\|_{L^\infty((0,T);L^2(\mathbb{T}))}\\
&\quad\leq C\left(\|\rho^\varepsilon\|_{L^\infty(\mathbb{T}\times(0,T))} + \|a\|_{L^\infty(0,T)}\right)\left\|\frac{\partial \rho^{\pm,\varepsilon}}{\partial x}\right\|_{L^\infty((0,T);L^2(\mathbb{T}))}.
\end{aligned}$$

We use Lemmas 4.1 and 4.2 and the Sobolev injections to deduce that there exists a constant $C\left(T, L_0, \alpha, \|a\|_{L^\infty(0,T)}, M_0, B_0\right)$ such that

$$\left\|f^\pm_{a^\varepsilon,\alpha}[\rho^\varepsilon]\right\|_{L^\infty((0,T);L^2(\mathbb{T}))} \leq C.$$

To conclude, we multiply the first and the second equations of the system (5) by $\frac{\partial \rho^{+,\varepsilon}}{\partial t}$ and $\frac{\partial \rho^{-,\varepsilon}}{\partial t}$, respectively, and we integrate in space. We deduce that for every $t \in (0,T)$ we have

$$\left\|\frac{\partial \rho^{\pm,\varepsilon}}{\partial t}(t)\right\|^2_{L^2(\mathbb{T})} + \frac{\varepsilon}{2}\frac{d}{dt}\left\|\frac{\partial \rho^{\pm,\varepsilon}}{\partial x}(t)\right\|^2_{L^2(\mathbb{T})} = \int_0^1 f^\pm_{a^\varepsilon,\alpha}[\rho^\varepsilon(t)]\frac{\partial \rho^{\pm,\varepsilon}}{\partial t}.$$

Integrating in time and using the fact that $\rho^{\pm,\varepsilon} \in C(\mathbb{R}\times[0,T))$ for all $T \geq 0$, we get

$$\begin{aligned}
&\left\|\frac{\partial \rho^{\pm,\varepsilon}}{\partial t}\right\|^2_{L^2(\mathbb{T}\times(0,T))} + \frac{\varepsilon}{2}\left\|\frac{\partial \rho^{\pm,\varepsilon}}{\partial x}(T)\right\|^2_{L^2(\mathbb{T})}\\
&\qquad = \int_0^T\int_0^1 f^\pm_{a^\varepsilon,\alpha}[\rho^\varepsilon(t)]\frac{\partial \rho^{\pm,\varepsilon}}{\partial t} + \frac{\varepsilon}{2}\left\|\frac{\partial {\rho_0}^{\pm,\varepsilon}}{\partial x}\right\|^2_{L^2(\mathbb{T})}.
\end{aligned}$$

We apply Hölder's inequality and the fact that $\varepsilon < 1$ and $ab \leq \frac{1}{2}(a^2+b^2)$ to obtain that

$$\begin{aligned}
&\left\| \frac{\partial \rho^{\pm,\varepsilon}}{\partial t} \right\|^2_{L^2(\mathbb{T}\times(0,T))} \\
&\quad \le \left\| f^{\pm}_{a^\varepsilon,\alpha}[\rho^\varepsilon] \right\|_{L^2(\mathbb{T}\times(0,T))} \left\| \frac{\partial \rho^{\pm,\varepsilon}}{\partial t} \right\|_{L^2(\mathbb{T}\times(0,T))} + \frac{1}{2} \left\| \frac{\partial {\rho_0}^{\pm,\varepsilon}}{\partial x} \right\|^2_{L^2(\mathbb{T})} \\
&\quad \le \frac{C}{2} \left(\left\| f^{\pm}_{a^\varepsilon,\alpha}[\rho^\varepsilon] \right\|^2_{L^2(\mathbb{T}\times(0,T))} + \left\| \frac{\partial \rho^{\pm,\varepsilon}}{\partial t} \right\|^2_{L^2(\mathbb{T}\times(0,T))} + \left\| \frac{\partial {\rho_0}^{\pm}}{\partial x} \right\|^2_{L^2(\mathbb{T})} \right),
\end{aligned}$$

which leads to

$$\begin{aligned}
\left\| \frac{\partial \rho^{\pm,\varepsilon}}{\partial t} \right\|^2_{L^2(\mathbb{T}\times(0,T))} &\le C \left(\left\| f^{\pm}_{a^\varepsilon,\alpha}[\rho^\varepsilon] \right\|^2_{L^2(\mathbb{T}\times(0,T))} + \left\| \frac{\partial {\rho_0}^{\pm}}{\partial x} \right\|^2_{L^2(\mathbb{T})} \right) \\
&\le C \left(T \left\| f^{\pm}_{a^\varepsilon,\alpha}[\rho^\varepsilon] \right\|^2_{L^\infty((0,T);L^2(\mathbb{T}))} + \left\| \frac{\partial {\rho_0}^{\pm}}{\partial x} \right\|^2_{L^2(\mathbb{T})} \right) \le C,
\end{aligned}$$

where $C\left(T, L_0, \alpha, \|a\|_{L^\infty(0,T)}, M_0, B_0\right)$. ∎

Remark 4.4 (the sense of the initial conditions). According to Lemma 4.3, we have $\rho^{\pm,\varepsilon,per} \in C([0,T), L^2(\mathbb{T}))$ uniformly in ε. This will give a sense to the limit of the initial conditions.

THEOREM 4.5 (long time existence). *Assume* (H1), (H2), *and* (H3); *for all* L_0, $T \ge 0$, $\alpha \in \mathbb{R}$, *and* $\rho_0^{\pm} \in H^1_{loc}(\mathbb{R})$, *the system* (5)–(6) *admits the solutions* $\rho^{\pm,\varepsilon} \in C^\infty(\mathbb{R}\times[0,T))$, *with* $\rho^{\pm,\varepsilon}(.,t)$ *verifying* (H1) *and* (H2). *Moreover, there exists a constant* $C\left(T, L_0, \alpha, \|a\|_{L^\infty(0,T)}, M_0, B_0\right)$ *independent of* ε, *with* B_0 *and* M_0 *defined in Lemmas* 4.1 *and* 4.2, *respectively, such that*

$$\left\|\rho^{\pm,\varepsilon,per}\right\|_{L^\infty((0,T);L^2(\mathbb{T}))} + \left\| \frac{\partial \rho^{\pm,\varepsilon}}{\partial x} \right\|_{L^\infty((0,T);L^2(\mathbb{T}))} + \left\| \frac{\partial \rho^{\pm,\varepsilon}}{\partial t} \right\|_{L^2(\mathbb{T}\times(0,T))} \le C, \tag{18}$$

where $\rho^{\pm,\varepsilon,per} = \rho^{\pm,\varepsilon} - L_0 x$.

Proof of Theorem 4.5. We are going to prove that local time solutions obtained by Corollary 3.3 can be extended to global time solutions for the same system.

We argue by contradiction: Assume that there exists a maximum time T_{max} such that we have the existence of solutions of the system (5)–(6) in the function space $C^\infty(\mathbb{R}\times[0,T_{max}))$.

For every $\delta > 0$, we consider the system (5) with the initial conditions

$$\rho^{\pm,\varepsilon}_{\delta,max} = \rho^{\pm,\varepsilon}(x, T_{max} - \delta).$$

We apply for the second time the same technique of Corollary 3.3 to deduce that there exists a time

$$T^\star_{\delta,max}(\|\rho^{\pm,\varepsilon,per}_{\delta,max}\|_{H^1(\mathbb{T})}, \|a\|_{L^\infty(0,T)}, L_0, \alpha, \varepsilon) > 0, \qquad \text{where } \rho^{\pm,\varepsilon,per}_{\delta,max} = \rho^{\pm,\varepsilon}_{\delta,max} - L_0 x,$$

such that the system (5)–(6) admits a solution defined until the time

$$T_0 = (T_{max} - \delta) + T^\star_{\delta,max}.$$

Moreover, according to Lemmas 4.1 and 4.2, we know that $\rho^{\pm,\varepsilon,per}_{\delta,max}$ are δ-uniformly bounded in $H^1(\mathbb{T})$. We use (16) to deduce that there exists a constant $C(\varepsilon, T_{max}, \alpha, \|a\|_{L^\infty(0,T)}, L_0) > 0$ independent of δ such that $T^\star_{\delta,max} \ge C > 0$; then $\lim_{\delta\to 0} T^\star_{\delta,max} \ge C > 0$, which implies that $T_0 > T_{max}$, and so we have a contradiction.

The estimation (18) is a consequence of Lemmas 4.1, 4.2, and 4.3. ∎

5. Existence and uniqueness of the solution of (1)–(2). In this section, we are going to prove that the system (1)–(2) admits a unique solution $\rho^{\pm}$ (in the distribution sense) which is the limit as $\varepsilon \to 0$ of $\rho^{\pm,\varepsilon}$ given by Theorem 4.5. In order to do that, we pass to the limit when ε tends to 0 in the system (7)–(8), and we use (18) in order to ensure the compactness. The proof of the uniqueness uses direct arguments.

Proof of Theorem 1.1. We first prove the existence and then establish the uniqueness.

Step 1 *(existence).* Let $\rho^{\pm,\varepsilon}$ be the solution of the system (5) given by Theorem 4.5. According to (18) we know that $\rho^{\pm,\varepsilon,per}$ are ε-uniformly bounded in $H^1(\mathbb{T}\times(0,T))$; then we can extract a subsequence that converges weakly in $H^1(\mathbb{T}\times(0,T))$. Knowing that $H^1(\mathbb{T}\times(0,T))$ is compact in $L^2(\mathbb{T}\times(0,T))$, this subsequence strongly converges in $L^2(\mathbb{T}\times(0,T))$. If we denote by $\rho^{\pm,per}$ the limit of this subsequence, we have to prove that $\rho^{\pm,per}+L_0x$ is a solution of the system (1)–(2) in the sense of distribution. Indeed, by Lemma 2.3, the term $\mp(L_0a^{\varepsilon})$ of (7) converges strongly to $(\mp L_0a)$ in $L^2(0,T)$.

The linear term

$$\mp\left(L_0C_\alpha[\rho^\varepsilon]+a^\varepsilon(t)\frac{\partial\rho}{\partial x}^{\pm,\varepsilon,per}\right)$$

of (7) weakly converges in $L^1(\mathbb{T}\times(0,T))$, and the reason is, on the one hand, that $\frac{\partial\rho}{\partial x}^{\pm,\varepsilon,per}$ are ε-uniformly bounded in $L^2(\mathbb{T}\times(0,T))$, which gives us the weak convergence in $L^2(\mathbb{T}\times(0,T))$, and, on the other hand, that a^ε strongly converges in $L^2(0,T)$. Then the linear term converges in the sense of distributions (i.e., in $\mathcal{D}'(\mathbb{T}\times(0,T))$). It remains to prove that the bilinear term

$$C_\alpha[\rho^\varepsilon]\frac{\partial\rho}{\partial x}^{\pm,\varepsilon,per}$$

of (7) also converges in the sense of distributions. We have the following:

1. The sequence $C_\alpha[\rho^\varepsilon]$ is compact in $L^2(\mathbb{T}\times(0,T))$.
2. The functions $\frac{\partial\rho}{\partial x}^{\pm,\varepsilon,per}$ are ε-uniformly bounded in $L^2(\mathbb{T}\times(0,T))$.

This gives us a strong convergence in $L^2(\mathbb{T}\times(0,T))$ times a weak convergence in $L^2(\mathbb{T}\times(0,T))$ and hence a weak convergence of the product in $L^1(\mathbb{T}\times(0,T))$. This leads, as a consequence, to the convergence in the distribution sense. This altogether shows that $\rho^{\pm,per}+L_0x$ is a solution in the sense of distribution of the system (1)–(2) and $\rho^{\pm,per}$ verifies estimate (18).

It remains to prove that the initial condition is satisfied by the limit function $\rho^{\pm,per}$. In fact, according to the estimate (18) on $\rho^{\pm,\varepsilon,per}$, $\frac{\partial\rho}{\partial t}^{\pm,\varepsilon}$, and $\frac{\partial\rho}{\partial x}^{\pm,\varepsilon}$, we see that $\rho^{\pm,\varepsilon,per}$ is ε-uniformly bounded in $H^1(\mathbb{T}\times(0,T))$.

From the fact that the injection of $H^1(\mathbb{T}\times(0,T))$ in $C([0,T];L^2(\mathbb{T}))$ is continuous and compact by classical arguments, we see that, for all $v\in L^2(\mathbb{T})$, the application $\gamma: U\longmapsto\int_0^1 U(0)v$ is a continuous linear form for $U\in C([0,T];L^2(\mathbb{T}))$ and hence $\gamma(\rho^{\pm,\varepsilon,per})\to\gamma(\rho^{\pm,per})$ as $\varepsilon\to 0$, because up to a subsequence $\rho^{\pm,\varepsilon,per}$ converges strongly in $C([0,T];L^2(\mathbb{T}))$. This altogether proves that the solution verifies the initial conditions (2).

Step 2 *(uniqueness).* Let $\rho_1^\pm$ and $\rho_2^\pm$ be two solutions of the system (1) such that $\rho_1^\pm(\cdot,0)=\rho_2^\pm(\cdot,0)=\rho_0^\pm$ and $\rho_i^\pm(\cdot,t)$ verify (H1), (H2), and estimate (18) for $i=1,2$, $t\in(0,T)$.

If we denote $\rho_i = \rho_i^+ - \rho_i^-$, $k_i = \rho_i^+ + \rho_i^-$ for $i = 1, 2$, then it is clear that $(\rho_1 - \rho_2)$ and $(k_1 - k_2)$ are 1-periodic functions in space and ρ_i, k_i verify the following system for $i = 1, 2$:

$$\left\{ \begin{aligned} \frac{\partial \rho_i}{\partial t} &= -\left(\rho_i + \alpha \int_0^1 \rho_i dx + a(t)\right) \frac{\partial k_i}{\partial x} \quad \text{in} \quad \mathcal{D}'(\mathbb{R} \times (0,T)), \\ \frac{\partial k_i}{\partial t} &= -\left(\rho_i + \alpha \int_0^1 \rho_i dx + a(t)\right) \frac{\partial \rho_i}{\partial x} \quad \text{in} \quad \mathcal{D}'(\mathbb{R} \times (0,T)). \end{aligned} \right. \tag{19}$$

We substract the two systems to obtain that

$$\left\{ \begin{aligned} \frac{\partial(\rho_1 - \rho_2)}{\partial t} &= -\left(\rho_1 + \alpha \int_0^1 \rho_1 dx\right) \frac{\partial k_1}{\partial x} + \left(\rho_2 + \alpha \int_0^1 \rho_2 dx\right) \frac{\partial k_2}{\partial x} \\ &\quad - a(t) \frac{\partial(k_1 - k_2)}{\partial x}, \\ \frac{\partial(k_1 - k_2)}{\partial t} &= -\left(\rho_1 + \alpha \int_0^1 \rho_1 dx\right) \frac{\partial \rho_1}{\partial x} + \left(\rho_2 + \alpha \int_0^1 \rho_2 dx\right) \frac{\partial \rho_2}{\partial x} \\ &\quad - a(t) \frac{\partial(\rho_1 - \rho_2)}{\partial x}. \end{aligned} \right.$$

The previous system is equivalent to

$$\left\{ \begin{aligned} \frac{\partial(\rho_1 - \rho_2)}{\partial t} &= -\left((\rho_1 - \rho_2) + \alpha \int_0^1 (\rho_1 - \rho_2) dx\right) \frac{\partial k_1}{\partial x} \\ &\quad - \left(\rho_2 + \alpha \int_0^1 \rho_2 dx\right) \frac{\partial(k_1 - k_2)}{\partial x} - a(t) \frac{\partial(k_1 - k_2)}{\partial x}, \\ \frac{\partial(k_1 - k_2)}{\partial t} &= -\left((\rho_1 - \rho_2) + \alpha \int_0^1 (\rho_1 - \rho_2) dx\right) \frac{\partial \rho_1}{\partial x} \\ &\quad - \left(\rho_2 + \alpha \int_0^1 \rho_2 dx\right) \frac{\partial(\rho_1 - \rho_2)}{\partial x} - a(t) \frac{\partial(\rho_1 - \rho_2)}{\partial x}. \end{aligned} \right.$$

We multiply the first equation of this system by $(\rho_1 - \rho_2)$ and integrate in space to obtain, for almost every t, that

$$\begin{aligned} \frac{1}{2} \frac{d}{dt} \|(\rho_1 - \rho_2)(t)\|^2_{L^2(\mathbb{T})} = \; & -\int_0^1 \left((\rho_1 - \rho_2)^2 \frac{\partial k_1}{\partial x}\right) \\ & -\alpha \left(\int_0^1 (\rho_1 - \rho_2)\right) \int_0^1 \left((\rho_1 - \rho_2) \frac{\partial k_1}{\partial x}\right) \\ & -\int_0^1 \left((\rho_1 - \rho_2) \left(\rho_2 + \alpha \int_0^1 \rho_2\right) \frac{\partial(k_1 - k_2)}{\partial x}\right) \\ & -a(t) \int_0^1 \left((\rho_1 - \rho_2) \frac{\partial(k_1 - k_2)}{\partial x}\right). \end{aligned}$$

Similarly, we multiply the second equation by $(k_1 - k_2)$ and integrate in space to get, for almost every time t,

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\|(k_1-k_2)(t)\|^2_{L^2(\mathbb{T})} = \; & -\int_0^1\left((\rho_1-\rho_2)(k_1-k_2)\frac{\partial\rho_1}{\partial x}\right)\\ & -\alpha\left(\int_0^1(\rho_1-\rho_2)\right)\int_0^1(k_1-k_2)\frac{\partial\rho_1}{\partial x}\\ & -\int_0^1\left((k_1-k_2)\left(\rho_2+\alpha\int_0^1\rho_2\right)\frac{\partial(\rho_1-\rho_2)}{\partial x}\right)\\ & -a(t)\int_0^1\left((k_1-k_2)\frac{\partial(\rho_1-\rho_2)}{\partial x}\right).\end{aligned}$$

We add the two previous equations to obtain, for almost every time t,

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\left(\|(\rho_1-\rho_2)(t)\|^2_{L^2(\mathbb{T})}+\|(k_1-k_2)(t)\|^2_{L^2(\mathbb{T})}\right)\\ &\quad=-\int_0^1\left((\rho_1-\rho_2)^2\frac{\partial k_1}{\partial x}\right)-\alpha\left(\int_0^1(\rho_1-\rho_2)\right)\int_0^1\left((\rho_1-\rho_2)\frac{\partial k_1}{\partial x}\right)\\ &\qquad-\alpha\left(\int_0^1(\rho_1-\rho_2)\right)\int_0^1\left((k_1-k_2)\frac{\partial\rho_1}{\partial x}\right)\\ &\qquad-\int_0^1\left(\frac{\partial}{\partial x}\left((\rho_1-\rho_2)(k_1-k_2)\left(\rho_2+\alpha\int_0^1\rho_2\right)\right)\right)\\ &\qquad-\int_0^1\left((\rho_1-\rho_2)(k_1-k_2)\frac{\partial(\rho_1-\rho_2)}{\partial x}\right)-a(t)\int_0^1\left(\frac{\partial}{\partial x}\left((\rho_1-\rho_2)(k_1-k_2)\right)\right).\end{aligned}$$

From the fact that ρ_i, $i=1,2$, and (k_1-k_2) are 1-periodic functions in space, the previous equation becomes

$$\begin{aligned}&=\overbrace{-\int_0^1\left((\rho_1-\rho_2)^2\frac{\partial k_1}{\partial x}\right)}^{I_1}\;\overbrace{-\alpha\left(\int_0^1(\rho_1-\rho_2)\right)\int_0^1\left((\rho_1-\rho_2)\frac{\partial k_1}{\partial x}\right)}^{I_2}\\ &\overbrace{-\alpha\left(\int_0^1(\rho_1-\rho_2)\right)\int_0^1\left((k_1-k_2)\frac{\partial\rho_1}{\partial x}\right)}^{I_3}\;\overbrace{-\int_0^1\left((\rho_1-\rho_2)(k_1-k_2)\frac{\partial(\rho_1-\rho_2)}{\partial x}\right)}^{I_4}.\end{aligned}$$

And since $\frac{\partial k_i}{\partial x}\geq 0$ for $i=1,2$, we know that

$$\begin{aligned}I_1+I_4 &= -\int_0^1\left((\rho_1-\rho_2)^2\frac{\partial k_1}{\partial x}\right)-\frac{1}{2}\int_0^1\left((k_1-k_2)\frac{\partial}{\partial x}\left((\rho_1-\rho_2)^2\right)\right)\\ &= -\int_0^1\left((\rho_1-\rho_2)^2\frac{\partial k_1}{\partial x}\right)+\frac{1}{2}\int_0^1\left((\rho_1-\rho_2)^2\frac{\partial(k_1-k_2)}{\partial x}\right)\\ &= -\frac{1}{2}\int_0^1\left((\rho_1-\rho_2)^2\frac{\partial(k_1+k_2)}{\partial x}\right)\leq 0.\end{aligned}$$

Moreover, from (18), we have, for almost every t,

$$\begin{aligned} I_2 &\leq |\alpha| \|(\rho_1 - \rho_2)(t)\|_{L^2(\mathbb{T})} \|(\rho_1 - \rho_2)(t)\|_{L^2(\mathbb{T})} \left\| \frac{\partial k_1}{\partial x}(t) \right\|_{L^2(\mathbb{T})} \\ &\leq C \|(\rho_1 - \rho_2)(t)\|^2_{L^2(\mathbb{T})}. \end{aligned}$$

Similarly, from (18), we have, for almost every t,

$$\begin{aligned} I_3 &\leq |\alpha| \|(\rho_1 - \rho_2)(t)\|_{L^2(\mathbb{T})} \|(k_1 - k_2)(t)\|_{L^2(\mathbb{T})} \left\| \frac{\partial \rho_1}{\partial x}(t) \right\|_{L^2(\mathbb{T})} \\ &\leq C \left(\|(\rho_1 - \rho_2)(t)\|^2_{L^2(\mathbb{T})} + \|(k_1 - k_2)(t)\|^2_{L^2(\mathbb{T})} \right). \end{aligned}$$

Then

$$\begin{aligned} &\frac{d}{dt} \left(\|(\rho_1 - \rho_2)(t)\|^2_{L^2(\mathbb{T})} + \|(k_1 - k_2)(t)\|^2_{L^2(\mathbb{T})} \right) \\ &\qquad \leq C \left(\|(\rho_1 - \rho_2)(t)\|^2_{L^2(\mathbb{T})} + \|(k_1 - k_2)(t)\|^2_{L^2(\mathbb{T})} \right). \end{aligned}$$

Now we integrate in time and use the fact that $\rho_i,\, k_i \in C([0,T), L^2_{loc}(\mathbb{R}))$, $\rho_1(\cdot,0) = \rho_2(\cdot,0)$, and $k_1(\cdot,0) = k_2(\cdot,0)$ to obtain that

$$\sup_{t\in(0,T)} \|(\rho_1 - \rho_2)(t)\|^2_{L^2(\mathbb{T})} + \sup_{t\in(0,T)} \|(k_1 - k_2)(t)\|^2_{L^2(\mathbb{T})} \leq 0.$$

This achieves the proof of uniqueness. $\square$

Remark 5.1. In Theorem 1.1, we have proved a result of existence and uniqueness in $H^1_{loc}(\mathbb{R}\times[0,T))$ depending on some uniform estimates in this space. These estimates give a sufficient compactness in order to ensure the passage to the limit as ε tends to 0 in the bilinear term. However, the space $W^{1,1}_{loc}(\mathbb{R}\times[0,T))$ does not give enough compactness. On the other hand, the space of functions $L^2_{loc}(\mathbb{R}\times[0,T))$ having their derivatives in $L^\infty((0,T); \left(L^1 \log L^1\right)_{loc}(\mathbb{R}))$ requires the minimal properties to ensure the passage to the limit in the bilinear term. The result of existence in this space will be the core of a paper in preparation.

6. Further properties: Comparison principle with case $\boldsymbol{\alpha = 0}$. In this section, we are going to prove a comparison principle result of the system (1) in the case $\alpha = 0$ (i.e., Theorem 1.2). In order to do this, first we prove in the following subsection the same result for the approximate system (5). Then we give the proof of Theorem 1.2.

6.1. Comparison principle for the regularized system with case $\boldsymbol{\alpha = 0}$.

LEMMA 6.1 (comparison principle). *Let $a(\cdot)$ satisfy* (H3) *and $\rho_1^{\pm,\varepsilon}$, $\rho_2^{\pm,\varepsilon} \in C^\infty(\mathbb{R}\times[0,T))$ be two solutions of the system* (5) *with $\alpha = 0$. Moreover, let $\rho_1^{\pm,\varepsilon}(.,t)$, $\rho_2^{\pm,\varepsilon}(.,t)$ verify* (H1) *and* (H2) *for all $t \in [0,T)$. Then, if $\rho_1^{\pm,\varepsilon}(\cdot,0) \leq \rho_2^{\pm,\varepsilon}(\cdot,0)$ in $\mathbb{R}$, we have $\rho_1^{\pm,\varepsilon} \leq \rho_2^{\pm,\varepsilon}$ on $\mathbb{R}\times[0,T)$.*

Proof of Lemma 6.1. We know that $\rho_1^{\pm,\varepsilon}$ and $\rho_2^{\pm,\varepsilon}$ verify the following systems:

$$\begin{cases} \dfrac{\partial \rho_1^{+,\varepsilon}}{\partial t} - \varepsilon \dfrac{\partial^2 \rho_1^{+,\varepsilon}}{\partial x^2} = & -\left(\rho_1^{+,\varepsilon} - \rho_1^{-,\varepsilon} + a^\varepsilon(t)\right) \dfrac{\partial \rho_1^{+,\varepsilon}}{\partial x} \quad \text{in } \mathcal{D}'(\mathbb{R}\times(0,T)),\\ \dfrac{\partial \rho_1^{-,\varepsilon}}{\partial t} - \varepsilon \dfrac{\partial^2 \rho_1^{-,\varepsilon}}{\partial x^2} = & \left(\rho_1^{+,\varepsilon} - \rho_1^{-,\varepsilon} + a^\varepsilon(t)\right) \dfrac{\partial \rho_1^{-,\varepsilon}}{\partial x} \quad \text{in } \mathcal{D}'(\mathbb{R}\times(0,T)),\end{cases}$$

$$\begin{cases} \dfrac{\partial \rho_2^{+,\varepsilon}}{\partial t} - \varepsilon \dfrac{\partial^2 \rho_2^{+,\varepsilon}}{\partial x^2} = & -\left(\rho_2^{+,\varepsilon} - \rho_2^{-,\varepsilon} + a^\varepsilon(t)\right) \dfrac{\partial \rho_2^{+,\varepsilon}}{\partial x} \quad \text{in } \mathcal{D}'(\mathbb{R}\times(0,T)),\\ \dfrac{\partial \rho_2^{-,\varepsilon}}{\partial t} - \varepsilon \dfrac{\partial^2 \rho_2^{-,\varepsilon}}{\partial x^2} = & \left(\rho_2^{+,\varepsilon} - \rho_2^{-,\varepsilon} + a^\varepsilon(t)\right) \dfrac{\partial \rho_2^{-,\varepsilon}}{\partial x} \quad \text{in } \mathcal{D}'(\mathbb{R}\times(0,T)),\end{cases}$$

respectively.

If we denote $w^{\pm,\varepsilon}$ by $\tilde{\rho}_2^{\pm,\varepsilon} - \tilde{\rho}_1^{\pm,\varepsilon}$, where

$$\tilde{\rho}_2^{\pm,\varepsilon} = \rho_2^{\pm,\varepsilon} e^{-\gamma t} \quad \text{and} \quad \tilde{\rho}_1^{\pm,\varepsilon} = \rho_1^{\pm,\varepsilon} e^{-\gamma t} \quad \text{with} \quad \gamma > 0,$$

we can easily check that $w^{\pm,\varepsilon}$ are solutions of the following system:

$$\begin{cases} \dfrac{\partial w^{+,\varepsilon}}{\partial t} - \varepsilon \dfrac{\partial^2 w^{+,\varepsilon}}{\partial x^2} + \gamma w^{+,\varepsilon} & = -\, e^{\gamma t}\left(w^{+,\varepsilon} - w^{-,\varepsilon}\right) \dfrac{\partial \tilde{\rho}_2^{+,\varepsilon}}{\partial x} \\ & \quad - e^{\gamma t}\left(\tilde{\rho}_1^{+,\varepsilon} - \tilde{\rho}_1^{-,\varepsilon} + e^{-\gamma t} a^\varepsilon(t)\right) \dfrac{\partial w^{+,\varepsilon}}{\partial x}, \\ \dfrac{\partial w^{-,\varepsilon}}{\partial t} - \varepsilon \dfrac{\partial^2 w^{-,\varepsilon}}{\partial x^2} + \gamma w^{-,\varepsilon} & = \quad e^{\gamma t}\left(w^{+,\varepsilon} - w^{-,\varepsilon}\right) \dfrac{\partial \tilde{\rho}_2^{-,\varepsilon}}{\partial x} \\ & \quad + e^{\gamma t}\left(\tilde{\rho}_1^{+,\varepsilon} - \tilde{\rho}_1^{-,\varepsilon} + e^{-\gamma t} a^\varepsilon(t)\right) \dfrac{\partial w^{-,\varepsilon}}{\partial x}. \end{cases} \tag{20}$$

We are interested in the $\min_{(k,x,t)\in\{+,-\}\times\mathbb{T}\times(0,T)}(w^{k,\varepsilon}(x,t))$. Our result follows if we can prove that this minimum is positive. However, this minimum is attained at a point $(k_0, x_0, t_0) \in \{+,-\}\times\mathbb{T}\times[0,T]$ (because $w^{+,\varepsilon}$ and $w^{-,\varepsilon}$ are $C^\infty(\mathbb{T}\times(0,T))$). Two cases may occur:

1. Case $t_0 = 0$. We have

$$\min_{(k,x,t)\in\{+,-\}\times\mathbb{T}\times(0,T)}(w^{k,\varepsilon}(x,t))$$
$$= w^{k_0,\varepsilon}(x_0,t_0) = \left(\rho_2^{k_0,\varepsilon}(x_0,0) - \rho_1^{k_0,\varepsilon}(x_0,0)\right) e^{-\gamma t_0} \geq 0;$$

   and we are done.

2. Case $t_0 \in (0,T]$. We have that (k_0,x_0,t_0) is a minimum point; then

$$\frac{\partial^2 w^{k_0,\varepsilon}}{\partial x^2}(x_0,t_0) \geq 0, \tag{21}$$

$$\frac{\partial w^{k_0,\varepsilon}}{\partial t}(x_0,t_0) \leq 0, \tag{22}$$

$$\frac{\partial w^{k_0,\varepsilon}}{\partial x}(x_0,t_0) = 0. \tag{23}$$

Combining (21), (22), (23) and taking into consideration that $w^{\pm,\varepsilon}$ verifies the system (20), we obtain that

$$\begin{aligned}\gamma w^{k_0,\varepsilon}(x_0,t_0) &\geq e^{\gamma t_0} sign(w^{+,\varepsilon}(x_0,t_0) - w^{-,\varepsilon}(x_0,t_0))(w^{+,\varepsilon}(x_0,t_0) \\ &\quad - w^{-,\varepsilon}(x_0,t_0))\frac{\partial \tilde{\rho}_2^{k_0,\varepsilon}}{\partial x} \\ &\geq e^{\gamma t_0}|w^{+,\varepsilon}(x_0,t_0) - w^{-,\varepsilon}(x_0,t_0)|\frac{\partial \tilde{\rho}_2^{k_0,\varepsilon}}{\partial x} \geq 0.\end{aligned}$$

Then $\tilde{\rho}_1^{\pm,\varepsilon} \leq \tilde{\rho}_2^{\pm,\varepsilon}$ in $\mathbb{R} \times (0,T)$, which gives $\rho_1^{\pm,\varepsilon} \leq \rho_2^{\pm,\varepsilon}$. ◻

We now give the proof of Theorem 1.2.

6.2. Proof of Theorem 1.2. Let

$$\rho_1^{\pm}(x,0) = \rho_{1,0}^{\pm}(x) = \rho_{1,0}^{\pm,per}(x) + L_0 x \quad \text{and} \quad \rho_2^{\pm}(x,0) = \rho_{2,0}^{\pm}(x) = \rho_{2,0}^{\pm,per}(x) + L_0 x.$$

If we denote

$$\rho_{1,0}^{\pm,\varepsilon}(x) = \rho_{1,0}^{\pm,per} * \eta_\varepsilon(x) + L_0 x \quad \text{and} \quad \rho_{2,0}^{\pm,\varepsilon}(x) = \rho_{2,0}^{\pm,per} * \eta_\varepsilon(x) + L_0 x,$$

where η_ε is a regularization sequence, we can easily check that $\rho_{1,0}^{\pm,\varepsilon} \leq \rho_{2,0}^{\pm,\varepsilon}$.

Moreover, according to the uniqueness of the solution, we know that there exist $\rho_1^{\pm,\varepsilon}$, $\rho_2^{\pm,\varepsilon} \in C^\infty(\mathbb{R} \times [0,T))$, verifying (H2) for all $t \in (0,T)$, which are solutions of the system (5), such that

$$\rho_1^{\pm} = \lim_{\varepsilon\to 0} \rho_1^{\pm,\varepsilon}, \quad \rho_2^{\pm} = \lim_{\varepsilon\to 0} \rho_2^{\pm,\varepsilon},$$

$$\rho_1^{\pm,\varepsilon}(x,0) = \rho_{1,0}^{\pm,\varepsilon}(x) \quad \text{and} \quad \rho_2^{\pm,\varepsilon}(x,0) = \rho_{2,0}^{\pm,\varepsilon}(x).$$

We apply Lemma 6.1 to obtain that $\rho_1^{\pm,\varepsilon} \leq \rho_2^{\pm,\varepsilon}$. We pass to the limit as $\varepsilon \to 0$ to deduce that $\rho_1^{\pm} \leq \rho_2^{\pm}$ a.e. in $\mathbb{R} \times (0,T)$. ◻

Remark 6.2. Thanks to this comparison result, we proved in a previous paper [8] the existence and the uniqueness of a solution (in the viscosity sense). Here this comparison result is an indirect explanation of our estimates obtained in Lemmas 4.1, 4.2, and 4.3 that have ensured our principal theorem, Theorem 1.1.

7. Application in the case of the classical Burgers equation. In this paragraph we are going to prove that this technique can be also applied to the classical Burgers equation, even in the frame of functions in $W^{1,p}_{loc}(\mathbb{R} \times (0,T))$ for all $1 \leq p < +\infty$, constituting the proof of Theorem 1.4.

Proof of Theorem 1.4. First, we remark that the existence of solution to the regularized problem can be done thanks to the continuous injection $W^{1,p}(\mathbb{T})$ in $L^\infty(\mathbb{T})$. Now, for the proof of this theorem, it suffices to show an estimation over the space derivatives of the solution (i.e., a result similar to that of Lemma 4.1).

First, we put ourselves in the hypothesis of Lemma 4.1. We derive the equation (4) with respect to x, then we multiply it by $(\frac{\partial u}{\partial x})^{p-1}$, and, finally, we integrate over

$(0,1)$; since u verifies (H2), we obtain that

$$\begin{aligned}\frac{1}{p}\frac{d}{dt}\left\|\frac{\partial u}{\partial x}(t)\right\|^p_{L^p(\mathbb{T})} &= -\int_0^1 f''(u)\frac{\partial u}{\partial x}\left(\frac{\partial u}{\partial x}\right)^p - \int_0^1 f'(u)\frac{\partial^2 u}{\partial x^2}\left(\frac{\partial u}{\partial x}\right)^{p-1}\\ &= -\int_0^1 \frac{\partial (f'(u))}{\partial x}\left(\frac{\partial u}{\partial x}\right)^p - \frac{1}{p}\int_0^1 f'(u)\frac{\partial}{\partial x}\left(\frac{\partial u}{\partial x}\right)^p\\ &= -\frac{1}{p}\int_0^1 \frac{\partial}{\partial x}\left(f'(u)\left(\frac{\partial u}{\partial x}\right)^p\right) - \left(1-\frac{1}{p}\right)\int_0^1 f''(u)\frac{\partial u}{\partial x}\left(\frac{\partial u}{\partial x}\right)^p \le 0,\end{aligned}$$

because f is convex, u verifies (H2), and $p \ge 1$. To terminate the demonstration, we follow the same steps of the proof of Theorem 1.1. We remark that here we do not need the L^2 bound over the solution and also the compactness in the passage to the limit, because (4) is in the conservative form, which was not the case of our study.

Acknowledgments. We would like to thank M. Cannone, R. Monneau, and F. Ribaud for fruitful discussions in the preparation of this paper. We thank also N. Forcadel and H. Ibrahim for the second reading of this paper.

HOMOGENIZATION OF A DOUBLY NONLINEAR STEFAN-TYPE PROBLEM*

AUGUSTO VISINTIN†

Abstract. Temperature and phase evolution in phase transitions are represented here by coupling the energy balance equation with a multivalued constitutive relation between the density of internal energy and the temperature, and with a nonlinear conduction law. This doubly nonlinear problem generalizes the classical Stefan model. Existence of a weak solution is proved via time discretization, a priori estimates, and passage to the limit. A medium exhibiting periodic oscillations in space is then considered; as the oscillation period vanishes, *two-scale convergence* (in the sense of Nguetseng) to a corresponding two-scale homogenized problem is proved. The latter is shown to be equivalent to a coarse-scale model. The cases of Fourier's law with either temperature- or phase-dependent conductivity are also treated.

Key words. phase transitions, Stefan problem, homogenization, two-scale convergence

DOI. 10.1137/060676647

1. Introduction.

This paper deals with the two- and single-scale homogenization of a class of quasi-linear parabolic problems that includes Stefan-type models of phase transitions.

The model. Let us consider a (possibly inhomogeneous and anisotropic) incompressible material capable of attaining two phases, say solid and liquid, that occupies a three-dimensional domain Ω. Let us denote the temperature by u, the density of internal energy (or enthalpy at fixed pressure) by w, the heat flux by $\vec{q}$, and the intensity of a heat source or sink by f.

Let $\varphi : \mathbf{R} \times \Omega \to \mathbf{R} \cup \{+\infty\}$ and $\vec{\alpha} : \mathbf{R}^3 \times \mathbf{R} \times \Omega \times]0, T[\to \mathbf{R}^3$, and assume that φ is convex w.r.t. the first variable and that $\vec{\alpha}(\vec{\xi}, u, x, t)$ is continuous w.r.t. the pair $(\vec{\xi}, u)$ and nondecreasing w.r.t. $\vec{\xi}$. We fix any $T > 0$, set $\Omega_T := \Omega \times]0, T[$, and provide a weak formulation for an initial- and boundary-value problem for the following nonlinear system:

$$\frac{\partial w}{\partial t} + \nabla \cdot \vec{q} = f(u, \nabla u) \qquad \text{in } \mathcal{D}'(\Omega_T)\ (\nabla \cdot := \mathrm{div}), \tag{1.1}$$

$$w \in \partial\varphi(u, x) \qquad \text{a.e. in } \Omega_T, \tag{1.2}$$

$$\vec{q} = \vec{\alpha}(-\nabla u, u, x, t) \qquad \text{a.e. in } \Omega_T \tag{1.3}$$

(by $\partial\varphi(\cdot, x)$ we denote the subdifferential of $\varphi(\cdot, x)$) or, more synthetically,

$$\frac{\partial}{\partial t}\partial\varphi(u, x) + \nabla \cdot \vec{\alpha}(-\nabla u, u, x, t) \ni f(u, \nabla u) \qquad \text{in } \mathcal{D}'(\Omega_T). \tag{1.4}$$

The occurrence of a double nonlinearity in the principal part of the equation may be noticed. An initial condition for w and boundary conditions for either u or the normal

*Received by the editors December 4, 2006; accepted for publication (in revised form) April 13, 2007; published electronically October 19, 2007. This research was partially supported by the project "Free boundary problems, phase transitions and models of hysteresis" of Italian M.U.R.

component of $\vec{q}$ may be appended to this system. Equation (1.1) represents the energy balance, whereas (1.2) and (1.3) are constitutive relations. The explicit dependence on x of the constitutive functions φ and $\vec{\alpha}$ may account for either a mixture of different materials or a single material whose behavior varies in space; in the first case these functions will be discontinuous w.r.t. x, whereas in the latter case they need not be so.

A free boundary problem. The discontinuity of the dependence of w on u may account for a simplified model of phase transitions, e.g., in a solid-liquid system, in which density variations and convection are neglected. For instance let us assume that (1.2) is of the form $w \in \int_0^u C(\xi, x)\, d\xi + L(x)H(u - u_*(x))$ a.e. in Ω_T, with $C = C(u,x)$ being the temperature- and space-dependent specific heat, L the space-dependent density of latent heat of phase transition, H the Heaviside function (i.e., $H(v) = 0$ for $v \le 0$, $H(v) = 1$ for $v > 0$), and u_* the space-dependent temperature of phase equilibrium. Equation (1.1) may then account for the energy balance in a solid-liquid system, and the space-time domains

$$\Omega_T^+ := \{(x,t) \in \Omega_T : u > u_*(x)\}, \qquad \Omega_T^- := \{(x,t) \in \Omega_T : u < u_*(x)\}$$

represent, respectively, the evolution of the liquid and solid phases. The set $\Omega_{T*} := \{(x,t) \in \Omega_T : u(x,t) = u_*(x)\}$ may consist of one or more moving surfaces that represent the space-time interface $\mathcal{S}$ between the phases; but Ω_{T*} may also comprise a component with nonempty interior that would represent a fine mixture of liquid and solid and is known as a *mushy region*.

In general for an inhomogeneous material the interface $\mathcal{S}$ need not be smooth even in the absence of a mushy region. For instance a connected component of $\mathcal{S}_t := \mathcal{S} \cap (\Omega \times \{t\})$ may end at the boundary between two grains of materials that are characterized by different temperatures of phase transition. If $\partial\varphi$ is as above, in the neighborhood U of any regular point $(x,t) \in \mathcal{S}$, (1.1) is equivalent to the following bulk and interface conditions:

$$C(u,x)\frac{\partial u}{\partial t} + \nabla \cdot \vec{q} = f \qquad \text{in } U \setminus \mathcal{S}, \tag{1.5}$$

$$u = u_*(x) \qquad \text{on } U \cap \mathcal{S}, \tag{1.6}$$

$$\vec{q}_1 \cdot \vec{\nu} - \vec{q}_2 \cdot \vec{\nu} = L(x)\vec{v} \cdot \vec{\nu} \qquad \text{on } U \cap \mathcal{S}. \tag{1.7}$$

Here by $\vec{q}_1$ we denote the heat flux contributed by the liquid phase, by $\vec{q}_2$ that absorbed by the solid phase, by $\vec{v}$ the interface velocity, and by $\vec{\nu}$ a normal vector field to $\mathcal{S}_t$.

Equation (1.3) includes the nonlinear Fourier conduction law

(1.8)
$$\vec{q} = -K(u,x) \cdot \nabla u \quad \text{in } \Omega_T \ \Big(\text{i.e., } \ q_i = -\textstyle\sum_{j=1,2,3} K_{ij}(u,x)\partial u/\partial x_j \ \text{ for } i = 1,2,3\Big);$$

here K is a symmetric and positive-definite tensor function and represents the heat conductivity. For an isotropic material $K(u,x) = k(u,x)I$ (I being the identity tensor), and (1.7) is reduced to the classical *Stefan condition*

$$k(u,x)\frac{\partial u_+}{\partial \nu} - k(u,x)\frac{\partial u_-}{\partial \nu} = -L(x)\vec{v} \cdot \vec{\nu} \qquad \text{on } U \cap \mathcal{S}, \tag{1.9}$$

where by $\partial u_\pm/\partial \nu$ we denote the limit of the normal derivative of u taken from the set $\Omega_T^\pm$. The system (1.5)–(1.8) is a (local) strong formulation of the classical two-phase Stefan problem in several space dimensions. This is a *free boundary problem*, for the evolution of the interface between the phases is unknown. Here we shall be concerned with the more general system (1.1)–(1.3). From the physical point of view, the fact that the conduction law (1.3) allows for the dependence of the heat flux on the temperature seems more relevant than the nonlinearity of this equation.

Existence of a solution. We formulate an initial- and boundary-value problem for the system (1.1)–(1.3) in the framework of Sobolev spaces and prove existence of a weak solution via approximation by time discretization, derivation of a priori estimates, and passage to the limit.

Some remarks about this argument are in order. Here the standard estimate procedure based on multiplying the approximate equation by the time derivative of the approximate temperature seems to hardly be applicable, because of the dependence of the conductivity on the temperature. Therefore it is not evident that a uniform L^p-estimate might be derived for the time derivative of the approximating temperature if we exclude the special cases in which the Kirchhoff transformation can be applied (see section 6). However, here we prove the strong convergence of the approximate temperature in $L^2(\Omega_T)$ via *compactness by strict convexity*—namely the property that (freely speaking) weak convergence in L^p_{loc} ($p > 1$) joint with convergence of a strictly convex potential entail strong convergence in L^q_{loc} for any $q < p$; see, e.g., [77], [78, Chap. X]. Along the lines of [4], one might also derive strong L^2-convergence by multiplying the approximate equation by the time increment (rather than the time-incremental ratio) of the approximate temperature.

We deal with a heat conductivity that depends continuously on the temperature and (possibly nonstrictly) monotonically on the temperature gradient. In case of a degenerate parabolic part (e.g., for φ identically constant), we would then miss the strong convergence of the temperature; however, if (1.3) were independent of the temperature, our results might easily be extended to this case, too. Via the classical Kirchhoff transformation we also treat the case of phase-dependent conductivity under a structure hypothesis on the conductivity itself.

Homogenization. The main concern of this work is the homogenization of composite materials in which the constitutive functions φ and $\vec{\alpha}$ are discontinuous functions of the space variable x. By a classical procedure, we assume that φ and $\vec{\alpha}$ depend not only on the coarse-scale variable x but also on a fine-scale variable x/ε (ε being a *small* scalar parameter), and we assume that the latter dependence if periodic. We then let ε vanish and show that the solution of the ε-dependent problem *two-scale converges* (in the sense of Nguetseng [65] and Allaire [2]) to a solution of a two-scale problem in which two further fields $u_\sharp$ and $\vec{q}_\sharp$ occur besides the coarse-scale fields u and $\vec{q}$. Our argument is based on two-scale techniques somehow analogous to those that we used for the existence result. (The analogy between these methods seems to confirm the potentialities of an approach based on two-scale convergence.)

We then retrieve a purely coarse-scale problem of the form (1.1)–(1.3) (so-called *upscaling*) with different constitutive functions φ and $\vec{\alpha}$. These functions are determined via the solution of a family of nonlinear *cell problems*; in the case of the linear Fourier law, we also construct a solution of these problems along the lines of a well-known procedure.

We also show the inverse statement: any solution of the coarse-scale problem may be retrieved from the two-scale model (this procedure might be referred to as *downscaling*). The two- and single-scale formulations are thus equivalent, although the latter provides a somehow more synthetic picture of the phenomenon. This entails that no spurious solution may be introduced by dealing with the coarse-scale model and that inspection of the macroscopic behavior does not allow one to distinguish a composite from a mesoscopically homogeneous material. This part is the main issue of this paper and is based on techniques that are also studied in [83]. The restrictions that are required here are consistent with the Stefan model.

Plan of the paper. In section 2 we state some preliminary results that are used in the remainder of this paper. More specifically we review Nguetseng's notion of two-scale convergence and illustrate some properties of convexity and monotonicity that involve either single- or two-scale convergence, mainly referring to [81]. In section 3 we provide the weak formulation of an initial- and boundary-value problem for the system (1.1)–(1.3) and show existence of a weak solution.

In section 4 we introduce the dependence on the fine-scale variable x/ε, pass to the limit as the space period ε vanishes, and prove convergence to a solution of a two-scale problem. In section 5 we complete the homogenization procedure by upscaling the latter problem to a purely coarse-scale formulation and show that the two problems are equivalent. In section 6 we assume a linear dependence of the heat flux on the temperature gradient and retrieve the homogenized conductivity tensor via the two-scale formulation of a standard procedure; see [2]. (If the function K is scalar and independent of the temperature, we thus retrieve the results of [38].) In this section we also illustrate the use of the classical Kirchhoff transformation.

Literature. The Stefan problem and its various generalizations were studied in an impressive number of works; see, e.g., the monographs [1, 21, 36, 46, 48, 50, 62, 70, 71, 78], the references therein, and the extensive bibliography [75]. Physical and engineering aspects of phase transitions were dealt with, e.g., in [28, 47, 56, 85].

Homogenization, namely the search for effective models representing the macroscopic behavior of mesoscopically inhomogeneous materials, has also been and still is the object of intense research; see, e.g., [3, 7, 9, 11, 19, 33, 37, 39, 55, 61, 63, 72, 74]. In particular the homogenization of integral functionals was studied in [24, 60]; see also [19, 23, 30, 31, 37]. A new approach to periodic homogenization based on two-scale convergence was proposed by Nguetseng [65] and then developed by Allaire [2] and others; see also, e.g., [6, 18, 32]. This notion is receiving increasing attention; see, e.g., [59] for a recent review. Some results of [81, 82, 83] are applied in the present paper.

Apparently so far just a few works have been devoted to the homogenization of models of phase transitions. In [17, 38, 69] this was accomplished assuming the linear Fourier law with a space-oscillating conductivity $\vec{q} = -k(x/\varepsilon)\nabla u$, with k being a positive definite tensor function. In [17] these results were also applied to a univariate magnetic medium that under the eddy-current approximation was represented by a similar model. [17, 38] dealt with the homogenization of the weak formulation of the two-phase Stefan problem, whereas [69] addressed the analogous question for the single-phase problem via a well-known integral transformation due to C. Baiocchi and G. Duvaut, and also proved the convergence of the free boundary. [38] also raised the question of extending the homogenization result to a temperature-dependent conductivity (this is performed in the present work). The homogenization of the phase-field model of phase transition for binary mixtures was also addressed via two-scale convergence in [42, 43, 44]. Recently two-scale convergence was applied to the homogenization of stationary variational inequalities in [29].

Doubly nonlinear parabolic problems were studied in a number of works, e.g., [4, 10, 12, 13, 14, 25, 27, 40, 49, 53, 57, 58, 66, 76, 78]. Equations of this class may model not only phase transitions but also filtration of either gas or liquid through porous media; see, e.g., [4]; their homogenization was addressed, for instance, in [18, 52, 64]. In [64] oscillations w.r.t. the time variable were also accounted for in the elliptic term, and consequently space-time two-scale convergence was used. The uniqueness of the solution for doubly nonlinear elliptic-parabolic equations is less obvious than for the standard Stefan model; however, it was proved in [14, 25, 26, 53] by using the notions of entropy solutions, renormalization, and L^1-contractions. These results cover a fairly general setting that includes the problem addressed in the present work.

Our argument for the existence of a solution for the parabolic problem in the presence of a nonstrictly monotone elliptic part is based on classical techniques; in particular it rests on a result (i.e., Theorem 2.10 below) that, in turn, is based on Lemma 5 of [22, p. 27]; in this respect see also [15, 16, 57].

The methods of this paper may also be applied to other quasi-linear equations that represent different phenomena. For instance, a doubly nonlinear parabolic problem arises as a model of electromagnetic processes under the eddy-current approximation; its homogenization is studied in the parallel paper [84]. That setting differs from the present one under several respects: there the unknown fields are vectors, the energy balance and the Fourier law are replaced by the Maxwell and Ohm equations, the curl and the divergence operators occur in place of the gradient, compensated compactness plays a key role, and so on. Some results of [84] and of the present work were announced in the note [80].

2. Two-scale convergence, convexity, and monotonicity. In this section first we review some basic properties of two-scale convergence, along the lines of the fundamental works [2, 65]. We then state some results concerning convexity, monotonicity, and either single- or two-scale convergence that will be used afterwards; for these arguments we mainly refer to [81], with the exception of Theorem 2.10, which we prove here.

Let us set $Y := [0,1[^3$, denote by $\mathcal{Y}$ the same set equipped with the metric of the three-dimensional unit torus, and identify any Y-periodic function on $\mathbf{R}^3$ with a function on $\mathcal{Y}$. Let us denote by ε a parameter that we assume vanishes along a prescribed sequence. Let $p \in [1,+\infty[$ (resp., $p=\infty$), $\{u_\varepsilon\}$ be any bounded sequence in $L^p(\mathbf{R}^3)$, and $u \in L^p(\mathbf{R}^3 \times \mathcal{Y})$; by a natural extension of Nguetseng's definition of [65], we say that u_ε *weakly* (resp., *weakly star*) *two-scale converges* to u in $L^p(\mathbf{R}^3 \times \mathcal{Y})$, and write $u_\varepsilon \underset{2}{\rightharpoonup} u$ (resp., $u_\varepsilon \underset{2}{\overset{*}{\rightharpoonup}} u$), whenever

$$(2.1)\qquad \int_{\mathbf{R}^3} u_\varepsilon(x)\, v(x, x/\varepsilon)\, dx \to \iint_{\mathbf{R}^3\times\mathcal{Y}} u(x,y)\, v(x,y)\, dxdy \qquad \forall v \in \mathcal{D}(\mathbf{R}^3 \times \mathcal{Y}).$$

If $p \in]1,+\infty[$, following Allaire [2] we say that u_ε *strongly two-scale converges* to u in $L^p(\mathbf{R}^3 \times \mathcal{Y})$, and write $u_\varepsilon \underset{2}{\to} u$, whenever (2.1) holds and $\|u_\varepsilon\|_{L^p(\mathbf{R}^3)} \to \|u\|_{L^p(\mathbf{R}^3\times\mathcal{Y})}$. On the other hand, we denote the standard *(single-scale)* weak (resp., weak star, strong) convergence by $\rightharpoonup$ (resp., $\overset{*}{\rightharpoonup}$, $\to$). These definitions and the next two statements trivially take over to vector functions and also to functions defined on a domain Ω of $\mathbf{R}^3$ just by extending these functions with vanishing value outside Ω.

PROPOSITION 2.1 (see [2, 65]). *For any bounded sequence $\{u_\varepsilon\}$ of $L^p(\mathbf{R}^3)$ ($p \in]1,+\infty]$), there exists $u \in L^p(\mathbf{R}^3 \times \mathcal{Y})$ such that, possibly extracting a subsequence,*

$$(2.2)\qquad u_\varepsilon \underset{2}{\rightharpoonup} u \qquad in\ L^p(\mathbf{R}^3 \times \mathcal{Y}) \quad (u_\varepsilon \underset{2}{\overset{*}{\rightharpoonup}} u \quad if\ \ p=\infty).$$

Proposition 2.2 (see [2]). *If $\{u_\varepsilon\}$ is a sequence of $L^p(\mathbf{R}^3)$ ($p \in [1,+\infty[$) such that $u_\varepsilon \underset{2}{\rightharpoonup} u$ in $L^p(\mathbf{R}^3 \times \mathcal{Y})$, then*

$$u_\varepsilon \rightharpoonup \hat{u} := \int_{\mathcal{Y}} u(\cdot, y)\, dy \qquad \text{in } L^p(\mathbf{R}^3), \tag{2.3}$$

$$\liminf_{\varepsilon\to 0} \|u_\varepsilon\|_{L^p(\mathbf{R}^3)} \geq \|u\|_{L^p(\mathbf{R}^3\times\mathcal{Y})} \geq \|\hat{u}\|_{L^p(\mathbf{R}^3)}. \tag{2.4}$$

If $u_\varepsilon \to \hat{u}$ in $L^p(\mathbf{R}^3)$, then $u = \hat{u}$ (that is, u does not depend on y).

Dealing with functions of (x, y) we shall denote the gradient operator w.r.t. x (resp., y) by ∇_x (resp., ∇_y). For any $v \in L^1_{\text{loc}}(\mathbf{R}^3 \times \mathcal{Y})$ we define the average and fluctuating components:

$$\hat{v}(x) := \int_{\mathcal{Y}} v(x, y)\, dy, \qquad \tilde{v}(x) := v(x, y) - \hat{v}(x) \qquad \text{for a.e. } (x, y) \in \mathbf{R}^3 \times \mathcal{Y}, \tag{2.5}$$

and similarly for vectors. The next two statements deal with the two-scale limit of derivatives.

Proposition 2.3 (see [2, 32, 65]). *Let $p \in]1,+\infty[$, and let a sequence $\{u_\varepsilon\}$ of $W^{1,p}(\mathbf{R}^3)$ be such that $u_\varepsilon \rightharpoonup u$ in $W^{1,p}(\mathbf{R}^3)$. Then there exists $u_\sharp \in L^p\big(\mathbf{R}^3; W^{1,p}(\mathcal{Y})\big)$ such that $\widehat{u_\sharp} = 0$ a.e. in $\mathbf{R}^3$ and, as $\varepsilon \to 0$ along a suitable subsequence,*

$$\nabla u_\varepsilon \underset{2}{\rightharpoonup} \nabla_x u + \nabla_y u_\sharp \qquad \text{in } L^p(\mathbf{R}^3 \times \mathcal{Y})^3. \tag{2.6}$$

Henceforth we confine ourselves to $p = 2$. Let us set $L^2_{\text{div}}(\mathbf{R}^3)^3 := \big\{\vec{v} \in L^2(\mathbf{R}^3)^3 : \nabla \cdot \vec{v} \in L^2(\mathbf{R}^3)\big\}$, which is a Hilbert space equipped with the graph norm, and denote by $\nabla\times$ the curl operator.

Proposition 2.4 (see [79, 82]). *Let $\{\vec{u}_\varepsilon\}$ be a bounded sequence of $L^2_{\text{div}}(\mathbf{R}^3)^3$ such that $\vec{u}_\varepsilon \underset{2}{\rightharpoonup} \vec{u}$ in $L^2(\mathbf{R}^3\times\mathcal{Y})^3$. Then $\hat{\vec{u}} \in L^2_{\text{div}}(\mathbf{R}^3)^3$ and $\nabla_y \cdot \vec{u} = 0$ in $\mathcal{D}'(\mathbf{R}^3\times\mathcal{Y})$. Moreover, there exists $\vec{u}_\sharp \in L^2\big(\mathbf{R}^3; H^1(\mathcal{Y})^3\big)$ such that $\widehat{\vec{u}_\sharp} = \vec{0}$ a.e. in $\mathbf{R}^3$, $\nabla_y \times \vec{u}_\sharp = \vec{0}$ a.e. in $\mathbf{R}^3 \times \mathcal{Y}$, and, as $\varepsilon \to 0$ along a suitable subsequence,*

$$\nabla \cdot \vec{u}_\varepsilon \underset{2}{\rightharpoonup} \nabla_x \cdot \hat{\vec{u}} + \nabla_y \cdot \vec{u}_\sharp \qquad \text{in } L^2(\mathbf{R}^3 \times \mathcal{Y}). \tag{2.7}$$

(An analogous statement holds for the curl operator, with exchanged roles of curl and divergence [79, 82].) The above definitions and results are trivially extended to time-dependent functions, if time is regarded as a parameter, and to functions defined on a subdomain of $\mathbf{R}^3$.

Convexity and two-scale convergence. Here we review some results about convex integral functionals and maximal monotone graphs that will be applied in the next sections. For several statements we provide two versions: the first one is written for a fixed value of the parameter $\varepsilon > 0$, concerns the standard (single-scale) convergence, and stems from classical properties. We then extend it to two-scale convergence as $\varepsilon \to 0$; see [81].

First, we state some known properties of integral functionals. We shall denote by $\mathcal{L}(\Omega)$ (resp., $\mathcal{B}(\Omega)$) the σ-algebra of Lebesgue- (resp., Borel-) measurable subsets of Ω, define $\mathcal{L}(\mathcal{Y})$ and $\mathcal{B}(\mathcal{Y})$ similarly, and denote by $\mathcal{A}_1 \otimes \mathcal{A}_2$ the σ-algebra generated by any pair of σ-algebras $\mathcal{A}_1, \mathcal{A}_2$.

LEMMA 2.5 (see [81]). (i) *Assume that*

$$\begin{aligned}
&\varphi : \mathbf{R} \times \Omega \times \mathcal{Y} \to \mathbf{R} \cup \{+\infty\},\\
&\varphi(v,\cdot,\cdot) \text{ is measurable w.r.t. either } \mathcal{B}(\Omega) \otimes \mathcal{L}(\mathcal{Y}) \text{ or } \mathcal{L}(\Omega) \otimes \mathcal{B}(\mathcal{Y}) \qquad \forall v,\\
&\varphi(\cdot,x,y) \text{ is convex and lower semicontinuous} \qquad \text{for a.e. } (x,y),\\
&\{v \in \mathbf{R} : \varphi(v,x,y) < +\infty\} \text{ has nonempty interior} \qquad \text{for a.e. } (x,y).
\end{aligned} \tag{2.8}$$

Then

$$\begin{aligned}
&x \mapsto \varphi(v(x), x, x/\varepsilon) \text{ is measurable} \qquad \forall v \in L^1_{\mathrm{loc}}(\Omega),\ \forall \varepsilon > 0,\\
&(x,y) \mapsto \varphi(v(x,y), x, y) \text{ is measurable} \qquad \forall v \in L^1_{\mathrm{loc}}(\Omega \times \mathcal{Y}).
\end{aligned} \tag{2.9}$$

(ii) *Moreover, assume that*

$$\exists w \in L^2(\Omega),\ \exists h \in L^1(\Omega) : \quad \varphi(v,x,y) \ge w(x)v + h(x) \qquad \forall v \text{ for a.e. } (x,y), \tag{2.10}$$

and set

$$\begin{aligned}
&\varphi_\varepsilon(v,x) := \varphi(v,x,x/\varepsilon) \qquad \forall (v,x) \in \mathbf{R} \times \Omega,\ \forall \varepsilon > 0,\\
&\Phi_\varepsilon : L^2(\Omega) \to \mathbf{R} \cup \{+\infty\} : v \mapsto \int_\Omega \varphi(v,x,x/\varepsilon)\,dx \qquad \forall \varepsilon > 0,\\
&\Phi : L^2(\Omega \times \mathcal{Y}) \to \mathbf{R} \cup \{+\infty\} : v \mapsto \iint_{\Omega \times \mathcal{Y}} \varphi(v(x,y),x,y)\,dxdy.
\end{aligned} \tag{2.11}$$

The functionals Φ_ε and Φ are then convex and lower semicontinuous.

(iii) *Under the above hypotheses, for any sequence $\{v_\varepsilon\}$ in $L^2(\Omega)$,*

$$v_\varepsilon \underset{2}{\to} v \quad \text{in } L^2(\Omega \times \mathcal{Y}) \quad \Rightarrow \quad \Phi_\varepsilon(v_\varepsilon) \to \Phi(v), \tag{2.12}$$

$$v_\varepsilon \underset{2}{\rightharpoonup} v \quad \text{in } L^2(\Omega \times \mathcal{Y}) \quad \Rightarrow \quad \liminf_{\varepsilon \to 0} \Phi_\varepsilon(v_\varepsilon) \ge \Phi(v). \tag{2.13}$$

We shall denote by φ^* the *convex conjugate function* of φ w.r.t. the first variable; see, e.g., [45, 51, 68]. The convex conjugate functionals Φ^*_ε and Φ^* then coincide with the integral functionals of φ^*_ε and φ^*, respectively; see, e.g., [45, 67].

The next result is based on simple properties of convexity. We shall not display the proof and just refer the reader to the analogous argument of Theorem 2.1 of [81]. The weight function θ is here introduced in view of the application of this result that we shall perform in the next sections.

PROPOSITION 2.6. *Let φ fulfil* (2.8) *and* (2.10)*, fix any $\varepsilon > 0$, and define $\varphi_\varepsilon, \Phi_\varepsilon, \Phi$ as in* (2.11)*. Let θ be any nonnegative function of $\mathcal{D}(\bar{\Omega})$, and let $\{u_m\}$ and $\{w_m\}$ be two sequences of $L^2(\Omega_T)$. If*

$$w_m(x,t) \in \partial\varphi_\varepsilon(u_m(x,t),x) \qquad \text{for a.e. } (x,t) \in \Omega_T\ \forall m, \tag{2.14}$$

$$u_m \rightharpoonup u,\ \ w_m \rightharpoonup w \qquad \text{in } L^2(\Omega_T), \tag{2.15}$$

$$\liminf_{m \to \infty} \iint_{\Omega_T} u_m w_m \theta\,dxdt \le \iint_{\Omega_T} uw\,\theta\,dxdt, \tag{2.16}$$

then, denoting by $\tilde{\Omega}$ the support of θ,

$$w(x,t) \in \partial\varphi_\varepsilon(u(x,t),x) \qquad \textit{for a.e. } (x,t) \in \tilde{\Omega}_T, \tag{2.17}$$

$$\iint_{\Omega_T} \varphi_\varepsilon(u_m,x)\theta \, dxdt \to \iint_{\Omega_T} \varphi_\varepsilon(u,x)\theta \, dxdt, \tag{2.18}$$

$$\iint_{\Omega_T} \varphi^*_\varepsilon(w_m,x)\theta \, dxdt \to \iint_{\Omega_T} \varphi^*_\varepsilon(w,x)\theta \, dxdt, \tag{2.19}$$

$$\iint_{\Omega_T} u_m w_m \theta \, dxdt \to \iint_{\Omega_T} uw \, \theta \, dxdt. \tag{2.20}$$

Next we state an extension to two-scale convergence.

Proposition 2.7 (see [81]). *Let φ fulfil* (2.8) *and* (2.10), *and define $\varphi_\varepsilon, \Phi_\varepsilon, \Phi$ as in* (2.11) *for any $\varepsilon > 0$. Let $\{u_\varepsilon\}$ and $\{w_\varepsilon\}$ be two sequences of $L^2(\Omega_T)$, and let θ be any nonnegative function of $\mathcal{D}(\bar{\Omega})$. If*

$$w_\varepsilon(x,t) \in \partial\varphi_\varepsilon(u_\varepsilon(x,t),x) \qquad \textit{for a.e. } (x,t) \in \Omega_T \ \forall\varepsilon, \tag{2.21}$$

$$u_\varepsilon \underset{2}{\rightharpoonup} u, \ \ w_\varepsilon \underset{2}{\rightharpoonup} w \qquad \textit{in } L^2(\Omega_T \times \mathcal{Y}), \tag{2.22}$$

$$\liminf_{\varepsilon\to 0} \iint_{\Omega_T} u_\varepsilon w_\varepsilon \, \theta \, dxdt \le \iiint_{\Omega_T\times\mathcal{Y}} uw \, \theta \, dxdydt, \tag{2.23}$$

then, denoting by $\tilde{\Omega}$ the support of θ,

$$w(x,y,t) \in \partial\varphi(u(x,y,t),x,y) \qquad \textit{for a.e. } (x,y,t) \in \tilde{\Omega}_T \times \mathcal{Y}, \tag{2.24}$$

$$\iint_{\Omega_T} \varphi_\varepsilon(u_m,x)\theta \, dxdt \to \iiint_{\Omega_T\times\mathcal{Y}} \varphi(u,x,y)\theta \, dxdydt, \tag{2.25}$$

$$\iint_{\Omega_T} \varphi^*_\varepsilon(w_m,x)\theta \, dxdt \to \iiint_{\Omega_T\times\mathcal{Y}} \varphi^*(w,x,y)\theta \, dxdydt, \tag{2.26}$$

$$\iint_{\Omega_T} u_\varepsilon w_\varepsilon \theta \, dxdt \to \iiint_{\Omega_T\times\mathcal{Y}} uw \, \theta \, dxdydt. \tag{2.27}$$

Compactness by strict convexity. The following result will be used in the next section.

Proposition 2.8 (see [77], [78, Chap. X]). *Let φ fulfil* (2.8) *and be such that*

$$\begin{aligned} &\exists c > 0, \ \exists w \in L^2(\Omega), \ \exists h \in L^1(\Omega): \\ &\varphi(v,x,y) \ge w(x)v + cv^2 + h(x) \qquad \forall v \textit{ for a.e. } (x,y), \end{aligned} \tag{2.28}$$

$$v \mapsto \varphi(v,x,y) \textit{ is strictly convex} \qquad \textit{for a.e. } (x,y). \tag{2.29}$$

Let us then fix any $\varepsilon > 0$, and define φ_ε as in $(2.11)_1$. *If $\{u_m\}$ is a sequence of $L^2(\Omega_T)$ such that*

$$u_m \rightharpoonup u \qquad \textit{in } L^2(\Omega_T), \tag{2.30}$$

$$\iint_{\Omega_T} \varphi_\varepsilon(u_m,x) \, dxdt \to \iint_{\Omega_T} \varphi_\varepsilon(u,x) \, dxdt, \tag{2.31}$$

then

$$u_m \to u \qquad \textit{in } L^2(\Omega_T). \tag{2.32}$$

Here is an extension to two-scale convergence.

PROPOSITION 2.9 (see [81]). *Let φ fulfil* (2.8), (2.28), *and* (2.29), *and define φ_ε as in* $(2.11)_1$ *for any $\varepsilon > 0$. If $\{u_\varepsilon\}$ is a sequence of $L^2(\Omega_T)$ such that*

$$u_\varepsilon \underset{2}{\rightharpoonup} u \qquad \text{in } L^2(\Omega_T \times \mathcal{Y}), \tag{2.33}$$

$$\iint_{\Omega_T} \varphi_\varepsilon(u_\varepsilon, x)\, dxdt \to \iiint_{\Omega_T \times \mathcal{Y}} \varphi(u, x, y)\, dxdydt, \tag{2.34}$$

then

$$u_\varepsilon \underset{2}{\to} u \qquad \text{in } L^2(\Omega_T \times \mathcal{Y}). \tag{2.35}$$

Monotonicity and two-scale convergence. After dealing with the subdifferential of convex lower semicontinuous functions, namely maximal cyclically monotone functions, now we extend some of these results to the larger class of maximal monotone functions. Here we confine ourselves to single-valued functions, and in view of the developments of the next sections we also allow for continuous dependence on a further scalar argument. Let us assume that

$$\begin{aligned} &\vec{\alpha} : \mathbf{R}^3 \times \mathbf{R} \times \Omega \times \mathcal{Y} \times]0, T[\to \mathbf{R}^3, \\ &\vec{\alpha}(\cdot, u, x, y, t) \text{ is monotone} \qquad \forall u \text{ and for a.e. } (x, y, t), \\ &\vec{\alpha}(\cdot, \cdot, x, y, t) \text{ is continuous} \qquad \text{for a.e. } (x, y, t), \text{ and} \\ &\vec{\alpha}(\vec{z}, u, \cdot, \cdot, \cdot) \text{ is measurable w.r.t. either } \mathcal{B}(\Omega) \otimes \mathcal{L}(\mathcal{Y}) \otimes \mathcal{L}(]0, T[) \\ &\text{or } \mathcal{L}(\Omega) \otimes \mathcal{B}(\mathcal{Y}) \otimes \mathcal{L}(]0, T[) \qquad \forall (\vec{z}, u), \end{aligned} \tag{2.36}$$

$$\begin{aligned} &\exists L > 0,\, \exists \xi \in L^2(\Omega_T) : \forall (\vec{z}, u) \qquad \text{for a.e. } (x, y, t), \\ &|\vec{\alpha}(\vec{z}, u, x, y, t)| \le L|\vec{z}| + L|u| + \xi(x, t), \end{aligned} \tag{2.37}$$

and set

$$\vec{\alpha}_\varepsilon(\vec{z}, u, x, t) := \vec{\alpha}(\vec{z}, u, x, x/\varepsilon, t) \qquad \forall (\vec{z}, u) \in \mathbf{R}^3 \times \mathbf{R} \text{ for a.e. } (x, t) \in \Omega_T\ \forall \varepsilon > 0. \tag{2.38}$$

This function is measurable w.r.t. x and thus is of Caratheodory class.

The first part of the next statement is a simple extension of a standard result of the theory of maximal monotone graphs; see, e.g., [20]. The second part is based on Lemma 5 of [22, p. 27]; see also [16, 15], [57, p. 183]. (A proof is needed, however, for this statement is not a direct consequence of the known results.)

THEOREM 2.10. *Let $\vec{\alpha}$ fulfil* (2.36) *and* (2.37), *fix any $\varepsilon > 0$, and define $\vec{\alpha}_\varepsilon$ as in* (2.38). *Let $\{\vec{z}_m\}$ (resp., $\{u_m\}$) be a sequence of $L^2(\Omega_T)^3$ (resp., $L^2(\Omega_T)$).*

(i) *If*

$$\vec{r}_m(x, t) := \vec{\alpha}_\varepsilon(\vec{z}_m(x, t), u_m(x, t), x, t) \rightharpoonup \vec{r} \qquad \text{in } L^2(\Omega_T)^3, \tag{2.39}$$

$$\vec{z}_m \rightharpoonup \vec{z} \qquad \text{in } L^2(\Omega_T)^3, \tag{2.40}$$

$$u_m \to u \qquad \text{in } L^2(\Omega_T), \tag{2.41}$$

$$\liminf_{m \to \infty} \iint_{\Omega_T} \vec{r}_m \cdot \vec{z}_m\, dxdt \le \iint_{\Omega_T} \vec{r} \cdot \vec{z}\, dxdt, \tag{2.42}$$

then

$$\vec{r}(x, t) = \vec{\alpha}_\varepsilon(\vec{z}(x, t), u(x, t), x, t) \qquad \text{for a.e. } (x, t) \in \Omega_T. \tag{2.43}$$

(ii) *If, moreover,*

$$
\begin{aligned}
&\text{for a.e. } (x,y) \in \Omega \times \mathcal{Y} \qquad \forall \vec{s} \in \mathbf{R}^3,\ \forall \{\vec{s}_n\} \subset \mathbf{R}^3,\\
&\forall \text{ bounded sequence } \{v_n\} \subset \mathbf{R} \qquad \text{for a.e. } t \in\,]0,T[,\\
&[\vec{\alpha}(\vec{s}, v_n, x, y, t) - \vec{\alpha}(\vec{s}_n, v_n, x, y, t)] \cdot (\vec{s} - \vec{s}_n) \to 0 \quad \Rightarrow \quad \vec{s}_n \to \vec{s},
\end{aligned}
\tag{2.44}
$$

$$
\begin{aligned}
&\exists c_1 \in \mathbf{R},\ \exists c_2 > 0,\ \exists \ell \in L^1(\Omega_T):\\
&\text{for a.e. } (x,y,t) \in \Omega_T \times \mathcal{Y} \qquad \forall (\vec{z}, v) \in \mathbf{R}^3 \times \mathbf{R},\\
&\vec{\alpha}(\vec{z}, v, x, y, t) \cdot \vec{z} + c_1 |v|^2 \geq c_2 |\vec{z}|^2 + \ell(x,t),
\end{aligned}
\tag{2.45}
$$

then

$$
\vec{z}_m \to \vec{z}, \qquad \vec{\alpha}_\varepsilon(\vec{z}_m, u_m, x, t) \to \vec{\alpha}_\varepsilon(\vec{z}, u, x, t) \qquad \text{in } L^2(\Omega_T)^3. \tag{2.46}
$$

The condition (2.44) may be interpreted as an assumption of strict monotonicity of $\vec{w} \mapsto \vec{\alpha}_\varepsilon(\vec{w}, v, x, t)$ uniform w.r.t. v.

Proof. (i) The monotonicity of $\vec{\alpha}_\varepsilon$ w.r.t. its first argument yields

$$
\iint_{\Omega_T} [\vec{r}_m - \vec{\alpha}_\varepsilon(\vec{s}, u_m, x, t)] \cdot (\vec{z}_m - \vec{s})\, dxdt \geq 0 \qquad \forall \vec{s} \in L^2(\Omega_T)^3.
$$

By (2.36), (2.37), and (2.41),

$$
\vec{\alpha}_\varepsilon(\vec{s}, u_m, x, t) \to \vec{\alpha}_\varepsilon(\vec{s}, u, x, t) \qquad \text{in } L^2(\Omega_T)^3\ \forall \vec{s} \in L^2(\Omega_T)^3. \tag{2.47}
$$

By passing to the inferior limit as $m \to \infty$ in the latter inequality, by (2.39)–(2.42) we then get

$$
\iint_{\Omega_T} [\vec{r} - \vec{\alpha}_\varepsilon(\vec{s}, u, x, t)] \cdot (\vec{z} - \vec{s})\, dxdt \geq 0 \qquad \forall \vec{s} \in L^2(\Omega_T)^3.
$$

By the maximal monotonicity of $\vec{\alpha}_\varepsilon$ w.r.t. its first argument, this inequality is equivalent to (2.43).

(ii) Let us now set

$$
P_m(x,t) := [\vec{\alpha}_\varepsilon(\vec{z}_m, u_m, x, t) - \vec{\alpha}_\varepsilon(\vec{z}, u_m, x, t)] \cdot (\vec{z}_m - \vec{z}) \qquad \text{for a.e. } (x,t) \in \Omega_T.
$$

By (2.39), (2.40), (2.42), and (2.47), $\liminf_{m\to\infty} \iint_{\Omega_T} P_m(x,t)\, dxdt \leq 0$. As P_m is nonnegative this means that for a suitable sequence that we label by m':

$$
P_{m'} \to 0 \qquad \text{in } L^1(\Omega_T). \tag{2.48}
$$

Hence there exists a subsequence that we label by m'' such that $P_{m''}(\cdot,\cdot) \to 0$ a.e. in Ω_T. By (2.41), possibly extracting a further subsequence, $u_{m''} \to u$ a.e. in Ω_T. By (2.44) we then get

$$
\vec{z}_{m''} \to \vec{z} \qquad \text{a.e. in } \Omega_T, \tag{2.49}
$$

whence

$$
\vec{\alpha}_\varepsilon(\vec{z}_{m''}, u_{m''}, x, t) \to \vec{\alpha}_\varepsilon(\vec{z}, u, x, t) = \vec{r} \qquad \text{a.e. in } \Omega_T. \tag{2.50}
$$

By (2.37), (2.40), (2.41), and (2.50), we have

$$\iint_{\Omega_T} \vec{\alpha}_\varepsilon(\vec{z}, u_{m''}, x, t) \cdot (\vec{z}_{m''} - z)\, dxdt \to 0. \tag{2.51}$$

By the definition of P_m, (2.40), (2.48), and (2.51), we get

$$\begin{aligned}
&\iint_{\Omega_T} \vec{\alpha}_\varepsilon(\vec{z}_{m''}, u_{m''}, x, t) \cdot \vec{z}_{m''}\, dxdt \\
&= \iint_{\Omega_T} [P_{m''}(x,t) + \vec{\alpha}_\varepsilon(\vec{z}, u_{m''}, x, t) \cdot (\vec{z}_{m''} - z)]\, dxdt \\
&+ \iint_{\Omega_T} \vec{\alpha}_\varepsilon(\vec{z}_{m''}, u_{m''}, x, t) \cdot \vec{z}\, dxdt \to \iint_{\Omega_T} \vec{r} \cdot \vec{z}\, dxdt.
\end{aligned}$$

We claim that this entails that

$$\xi_{m''} := \vec{r}_{m''} \cdot \vec{z}_{m''} \to \vec{r} \cdot \vec{z} =: \xi \qquad \text{in } L^1(\Omega_T)^3. \tag{2.52}$$

In view of proving this statement, first notice that we already know that

$$\xi_{m''} \geq 0, \qquad \xi_{m''} \to \xi \qquad \text{a.e. in } \Omega_T, \qquad \iint_{\Omega_T} \xi_{m''}\, dxdt \to \iint_{\Omega_T} \xi\, dxdt.$$

Moreover, setting $A_{m''} := \{(x,t) \in \Omega_T : \xi_{m''}(x,t) \leq \xi(x,t)\}$,

$$\iint_{\Omega_T} |\xi_{m''} - \xi|\, dxdt = 2 \iint_{A_{m'}} (\xi - \xi_{m''})\, dxdt + \iint_{\Omega_T} (\xi_{m''} - \xi)\, dxdt.$$

The Lebesgue dominated convergence theorem then yields (2.52).

By (2.45) we have

$$c_2 |\vec{z}_{m''}|^2 \leq \vec{r}_{m''} \cdot \vec{z}_{m''} + c_1 u_{m''}^2 - \ell \qquad \text{a.e. in } \Omega;$$

(2.41) and (2.52) then entail that the sequence $\{|\vec{z}_{m''}|^2\}$ is equi-integrable in Ω. By (2.37) the same then applies to $\{|\vec{r}_{m''}|^2\}$, so that by Vitali's convergence theorem we infer that

$$\vec{z}_{m''} \to \vec{z}, \qquad \vec{r}_{m''} = \vec{\alpha}_\varepsilon(\vec{z}_{m''}, u_{m''}, x, t) \to \vec{\alpha}_\varepsilon(\vec{z}, u, x, t) \qquad \text{in } L^2(\Omega_T)^3. \tag{2.53}$$

As both limits are independent of the extracted subsequence, the whole sequence converges; (2.46) is thus established. ☐

Here is an extension to two-scale convergence that rests on a similar argument.

PROPOSITION 2.11 (see [81]). *Let $\vec{\alpha}$ fulfil* (2.36) *and* (2.37), *and define $\vec{\alpha}_\varepsilon$ as in* (2.38) *for any $\varepsilon > 0$. Let $\{\vec{r}_\varepsilon\}$ (resp., $\{u_\varepsilon\}$) be a sequence of $L^2(\Omega_T)^3$ (resp., $L^2(\Omega_T)$).*

(i) *If*

$$\vec{r}_\varepsilon(x,t) = \vec{\alpha}_\varepsilon(\vec{z}_\varepsilon(x,t), u_\varepsilon(x,t), x, t) \qquad \textit{for a.e. } (x,t) \in \Omega_T\ \forall \varepsilon, \tag{2.54}$$

$$\vec{z}_\varepsilon \underset{2}{\rightharpoonup} \vec{z}, \quad \vec{r}_\varepsilon \underset{2}{\rightharpoonup} \vec{r} \qquad \textit{in } L^2(\Omega_T \times \mathcal{Y})^3, \tag{2.55}$$

$$u_\varepsilon \underset{2}{\to} u \qquad \textit{in } L^2(\Omega_T \times \mathcal{Y}), \tag{2.56}$$

$$\liminf_{\varepsilon \to 0} \iint_{\Omega_T} \vec{r}_\varepsilon(x,t) \cdot \vec{z}_\varepsilon(x,t)\, dxdt \leq \iiint_{\Omega_T \times \mathcal{Y}} \vec{r}(x,y,t) \cdot \vec{z}(x,y,t)\, dxdydt, \tag{2.57}$$

then

$$\vec{r}(x,y,t) = \vec{\alpha}(\vec{z}(x,y,t), u(x,y,t), x, y, t) \qquad \textit{for a.e. } (x,y,t) \in \Omega_T \times \mathcal{Y}. \tag{2.58}$$

(ii) *If, moreover,* (2.44) *and* (2.45) *are satisfied, then*

$$\vec{z}_\varepsilon \underset{2}{\to} \vec{z}, \qquad \vec{\alpha}_\varepsilon(\vec{z}_\varepsilon, u_\varepsilon, x, t) \underset{2}{\to} \vec{\alpha}(\vec{z}, u, x, y, t) \qquad \textit{in } L^2(\Omega_T)^3. \tag{2.59}$$

3. A quasi-linear parabolic problem. In this section we deal with an initial- and boundary-value problem for the system (1.1)–(1.3): we provide a weak formulation in Sobolev spaces and prove existence of a solution.

We denote by Ω a domain of $\mathbf{R}^3$, fix any $T > 0$, and set $A_t := A \times]0,t[$ for any set A and any $t > 0$. We fix a partition $\{\Gamma_0, \Gamma_1\}$ of the boundary of Ω and prescribe the evolution of u on Γ_0 and of the normal component of ∇u on Γ_1. We also assume that we are given three constitutive functions

$$\varphi : \mathbf{R} \times \Omega \times \mathcal{Y} \to \mathbf{R} \cup \{+\infty\}, \qquad \vec{\alpha} : \mathbf{R}^3 \times \mathbf{R} \times \Omega \times \mathcal{Y} \times]0,T[\to \mathbf{R}^3,$$
$$\beta : \mathbf{R} \times \mathbf{R}^3 \times \Omega \times \mathcal{Y} \times]0,T[\to \mathbf{R}$$

that satisfy (2.8) and (2.36) and such that

$$\begin{aligned} &\exists c_1, \tilde{c}_1 > 0,\ \exists h_1, \tilde{h}_1 \in L^1(\Omega) : \text{ for a.e. } (x,y),\\ &\forall v \in \mathbf{R},\ \forall w \in \partial\varphi(v,x,y), \qquad c_1|v| + h_1(x) \le |w| \le \tilde{c}_1|v| + \tilde{h}_1(x), \end{aligned} \tag{3.1}$$

$$\begin{aligned} &\exists L > 0,\ \exists \ell_1 \in L^2(\Omega_T) : \forall(\vec{z}, v) \qquad \text{for a.e. } (x,y,t),\\ &|\vec{\alpha}(\vec{z}, v, x, y, t)| \le L|\vec{z}| + L|v| + \ell_1(x,t), \end{aligned} \tag{3.2}$$

$$\begin{aligned} &\text{for a.e. } (x,y,t) \in \Omega_T \times \mathcal{Y} \qquad \forall \vec{s} \in \mathbf{R}^3,\ \forall\{\vec{s}_n\} \subset \mathbf{R}^3,\ \forall\{v_n\} \subset \mathbf{R},\\ &[\vec{\alpha}(\vec{s}, v_n, x, y, t) - \vec{\alpha}(\vec{s}_n, v_n, x, y, t)] \cdot (\vec{s} - \vec{s}_n) \to 0 \quad \Rightarrow \quad \vec{s}_n \to \vec{s}, \end{aligned} \tag{3.3}$$

$$\begin{aligned} &\exists c_2 > 0,\ \exists \ell_2 \in L^1(\Omega_T) : \forall(\vec{z}, v) \qquad \text{for a.e. } (x,y,t),\\ &\vec{\alpha}(\vec{z}, v, x, y, t) \cdot \vec{z} \ge c_2|\vec{z}|^2 + \ell_2(x,t), \end{aligned} \tag{3.4}$$

$$\begin{aligned} &\beta(\cdot,\cdot,x,y,t) \text{ is continuous} \qquad \text{for a.e. } (x,y,t),\\ &\beta(v,\vec{z},\cdot,\cdot,\cdot) \text{ is measurable w.r.t. either } \mathcal{B}(\Omega) \otimes \mathcal{L}(\mathcal{Y}) \otimes \mathcal{L}(]0,T[)\\ &\text{or } \mathcal{L}(\Omega) \otimes \mathcal{B}(\mathcal{Y}) \otimes \mathcal{L}(]0,T[) \qquad \forall v, \vec{z}, \end{aligned} \tag{3.5}$$

$$\begin{aligned} &\exists c_3 > 0,\ \exists \ell_3 \in L^2(\Omega_T) : \forall v \in \mathbf{R},\ \forall \vec{z} \in \mathbf{R}^3,\\ &|\beta(v, \vec{z}, x, y, t)| \le c_3(|v| + |\vec{z}|) + \ell_3(x,t) \qquad \text{for a.e. } (x,y,t). \end{aligned} \tag{3.6}$$

Let us fix any $\varepsilon > 0$, define φ_ε, $\vec{\alpha}_\varepsilon$, and β_ε as in $(2.11)_1$ and (2.38), and set

$$\beta_\varepsilon(v, \vec{z}, x, t) := \beta(v, \vec{z}, x, x/\varepsilon, t) \qquad \forall v \in \mathbf{R},\ \forall \vec{z} \in \mathbf{R}^3 \text{ for a.e. } (x,t) \in \Omega_T\ \forall \varepsilon > 0. \tag{3.7}$$

In view of specifying the functional framework, we assume that the domain Ω is bounded and of Lipschitz class and that Γ_0 is measurable and has positive bidimensional Hausdorff measure. We denote by γ_0 the trace operator and set

$$V := \big\{ v \in H^1(\Omega) : \gamma_0 v = 0 \ \text{ a.e. on } \Gamma_0 \big\}, \qquad \|v\|_V := \|\nabla v\|_{L^2(\Omega)^3}.$$

By the Poincaré inequality, $\|\cdot\|_V$ is equivalent to the usual Sobolev norm, so that V is a closed Banach subspace of $H^1(\Omega)$. Identifying $H := L^2(\Omega)$ with its dual H' and the latter with a closed subspace of the dual space V' of V, we get the Hilbert triplet

$$V \subset H = H' \subset V' \qquad \text{with compact, continuous, and dense injections.}$$

We denote by $\langle \cdot, \cdot \rangle$ the duality pairing between V' and V and define the linear and continuous operator

$$\nabla^* \cdot : L^2(\Omega)^3 \to V', \qquad \langle \nabla^* \cdot \vec{z}, v \rangle := -\int_\Omega \vec{z} \cdot \nabla v \, dx \qquad \forall \vec{z} \in L^2(\Omega)^3, \, \forall v \in V$$

(thus $\nabla^* \cdot \vec{z} = \nabla \cdot \vec{z}$ in $\mathcal{D}'(\Omega)$). Finally, we assume that

$$w^0 \in L^2(\Omega), \qquad z \in H^1(\Omega_T), \qquad g \in L^2(0, T; V'), \tag{3.8}$$

and for any $\varepsilon > 0$ we introduce the weak formulation of an initial- and boundary-value problem for the system (1.1)–(1.3) with φ_ε and $\vec{\alpha}_\varepsilon$ in place of φ and $\vec{\alpha}$.

Problem 3.1_ε. *Find $u_\varepsilon \in L^2(0, T; V) + z$ and $w_\varepsilon \in L^2(\Omega_T)$ such that, setting*

$$\vec{q}_\varepsilon(x, t) = \vec{\alpha}_\varepsilon(-\nabla u_\varepsilon(x, t), u_\varepsilon(x, t), x, t) \qquad \textit{for a.e. } (x, t) \in \Omega_T, \tag{3.9}$$

$$f_\varepsilon(x, t) = \beta_\varepsilon(u_\varepsilon(x, t), \nabla u_\varepsilon(x, t), x, t) \qquad \textit{for a.e. } (x, t) \in \Omega_T, \tag{3.10}$$

one has

$$w_\varepsilon(x, t) \in \partial \varphi_\varepsilon(u_\varepsilon(x, t), x) \qquad \textit{for a.e. } (x, t) \in \Omega_T, \tag{3.11}$$

$$\begin{gathered} \iint_{\Omega_T} \left((w^0 - w_\varepsilon) \frac{\partial v}{\partial t} - \vec{q}_\varepsilon \cdot \nabla v - f_\varepsilon v \right) dxdt = \int_0^T \langle g, v \rangle \, dt \\ \forall v \in H^1(0, T; H) \cap L^2(0, T; V), \, v(\cdot, T) = 0 \qquad \textit{a.e. in } \Omega. \end{gathered} \tag{3.12}$$

Interpretation. Equation (3.12) yields the equation

$$\frac{\partial w_\varepsilon}{\partial t} + \nabla^* \cdot \vec{q}_\varepsilon = f_\varepsilon + g \qquad \text{in } V' \text{ a.e. in }]0, T[. \tag{3.13}$$

By comparing these terms, we see that $w_\varepsilon \in H^1(0, T; V')$. Integrating by parts in time in (3.12) we then get the initial condition

$$w_\varepsilon(\cdot, 0) = w_\varepsilon^0 \qquad \text{in } V'. \tag{3.14}$$

If

$$h \in L^2(\Gamma_{1T}), \qquad \langle g, v \rangle = \int_{\Gamma_1} h \, \gamma_0 v \, d\sigma \qquad \forall v \in V \text{ a.e. in }]0, T[, \tag{3.15}$$

then (3.13) accounts for the energy balance equation

$$\frac{\partial w_\varepsilon}{\partial t} + \nabla \cdot \vec{q}_\varepsilon = f_\varepsilon \qquad \text{in } \mathcal{D}'(\Omega_T), \tag{3.16}$$

coupled with the boundary condition

$$\vec{q}_\varepsilon \cdot \vec{\nu} = -h \qquad \text{on } \Gamma_{1T} \text{ (with } \vec{\nu} = \text{outward-oriented unit normal vector)} \tag{3.17}$$

in weak form.

THEOREM 3.1. *For any fixed $\varepsilon > 0$, let (2.8), (2.36), (3.1)–(3.6), and (3.8) be fulfilled, and define φ_ε, $\vec{\alpha}_\varepsilon$, and β_ε as in $(2.11)_1$, (2.38), and (3.7). Assume also that*

$$v \mapsto \varphi(v,x,y) \text{ is strictly convex} \qquad \text{for a.e. } (x,y). \tag{3.18}$$

Then there exists a solution of Problem 3.1_ε such that $w_\varepsilon \in L^\infty(0,T;H)$.

It is easily seen that, under the hypothesis (2.8), the assumption (3.18) is equivalent to the continuity of $(\partial\varphi)^{-1}(\cdot,x,y) = \partial\varphi^*(\cdot,x,y)$.

Proof. Throughout this argument we drop the index ε, in order to make formulas more readable.

(i) *Approximation.* Let us fix any $m \in \mathbf{N}$, set $k := T/m$, and

$$\left.\begin{aligned} z_m^n &:= \frac{1}{k}\int_{(n-1)k}^{nk} z(\cdot,t)\,dt, & g_m^n &:= \frac{1}{k}\int_{(n-1)k}^{nk} g(\cdot,t)\,dt,\\ \vec{\alpha}_m^n &:= \frac{1}{k}\int_{(n-1)k}^{nk} \vec{\alpha}(\cdot,\cdot,\cdot,t)\,dt, & \beta_m^n &:= \frac{1}{k}\int_{(n-1)k}^{nk} \beta(\cdot,\cdot,\cdot,t)\,dt \end{aligned}\right. \qquad (n = 1,\dots,m).$$

We then introduce an implicit time-discretization scheme of our problem.

PROBLEM 3.1_m. *Find $u_m^n \in V + z_m^n$ and $w_m^n \in L^2(\Omega)$ for $n = 1,\dots,m$ such that, setting $u_m^0 := 0$, $w_m^0 := w^0$, and*

$$\vec{q}_m^{\,n}(x) = \vec{\alpha}_m^n(-\nabla u_m^n(x), u_m^{n-1}(x), x) \qquad \text{for a.e. } x \in \Omega, \tag{3.19}$$

$$f_m^n(x) = \beta_m^n(u_m^{n-1}(x), \nabla u_m^{n-1}(x), x) \qquad \text{for a.e. } x \in \Omega, \tag{3.20}$$

one has

$$w_m^n(x) \in \partial\varphi(u_m^n(x), x) \qquad \text{for a.e. } x \in \Omega, \tag{3.21}$$

$$\frac{w_m^n - w_m^{n-1}}{k} + \nabla^* \cdot \vec{q}_m^{\,n} = f_m^n + g_m^n \qquad \text{in } V'. \tag{3.22}$$

In view of proving the existence of a solution of this problem, let us fix any $n \in \{1,\dots,m\}$, set

$$\mathcal{A}_m^n(v) := \partial\varphi(v,\cdot) + k\nabla^* \cdot \vec{\alpha}_m^n(-\nabla v, u_m^{n-1}, \cdot)\ (\subset V') \qquad \forall v \in H^1(\Omega),$$

and notice that for any n the system (3.21), (3.22) also reads

$$\mathcal{A}_m^n(u_m^n) \ni w_m^{n-1} + kf_m^n + kg_m^n \qquad \text{in } V'. \tag{3.23}$$

At the nth step the right-hand side of this equation is known. The operator $\mathcal{A}_m^n$ is maximal monotone, for it is the sum of two maximal monotone operators, and $v \mapsto \nabla^* \cdot \vec{\alpha}_m^n(-\nabla v, u_m^{n-1}, \cdot)$ is defined on the whole $H^1(\Omega)$. Because of (2.8) and (3.4), $\mathcal{A}_m^n$ is also coercive. Therefore (3.23) has a solution u_m^n, and this determines a solution of Problem 3.1_m.

(ii) *A priori estimates.* Let us now define time-interpolate functions as follows. For any family $\{v_m^n\}_{n=0,\dots,m}$ of numbers let us denote by v_m the piecewise linear time interpolate of $v_m^0 := v^0$, v_m^1, $\dots$, v_m^m a.e. in Ω. Let us denote by $\bar{v}_m$ the corresponding piecewise constant interpolate function; that is, $\bar{v}_m(t) := v_m^n$ if $(n-1)k < t \le nk$

for $n = 1, \dots, m$. Let us also set $\tau_k v := v(\cdot - k)$ for any function v of time. Setting $\bar{u}_m(x,t) := 0$ for any $t < 0$, the system (3.19)–(3.22) then reads

$$\bar{\vec{q}}_m(x,t) = \vec{\alpha}_m(-\nabla \bar{u}_m(x,t), \tau_k \bar{u}_m(x,t), x, t) \qquad \text{for a.e. } (x,t) \in \Omega_T, \tag{3.24}$$

$$\bar{f}_m(x,t) = \beta_m(\tau_k \bar{u}_m(x,t), \tau_k \nabla \bar{u}_m(x,t), x, t) \qquad \text{for a.e. } (x,t) \in \Omega_T, \tag{3.25}$$

$$\bar{w}_m(x,t) \in \partial\varphi(\bar{u}_m(x,t), x) \qquad \text{for a.e. } (x,t) \in \Omega_T, \tag{3.26}$$

$$\frac{\partial w_m}{\partial t} + \nabla^* \cdot \bar{\vec{q}}_m = \bar{f}_m + \bar{g}_m \qquad \text{in } V' \text{ a.e. in }]0,T[. \tag{3.27}$$

Multiplying the latter equation by $\bar{u}_m - \bar{z}_m$ and integrating in time, we get

$$\iint_{\Omega_t} \left(\frac{\partial w_m}{\partial t} \bar{u}_m - \bar{\vec{q}}_m \cdot \nabla(\bar{u}_m - \bar{z}_m) \right) dx d\tau = \iint_{\Omega_t} \frac{\partial w_m}{\partial t} \bar{z}_m \, dx d\tau$$
$$+ \iint_{\Omega_t} \bar{f}_m (\bar{u}_m - \bar{z}_m) \, dx d\tau + \int_0^t \langle \bar{g}_m, \bar{u}_m - \bar{z}_m \rangle \, d\tau \qquad \forall t \in]0,T].$$

By (3.26) $\bar{u}_m(x,t) \in \partial\varphi^*(\bar{w}_m(x,t), x)$ for a.e. $(x,t) \in \Omega_T$, whence

$$\iint_{\Omega_t} \frac{\partial w_m}{\partial t} \bar{u}_m \, dx d\tau \geq \int_\Omega \left[\varphi^*(\bar{w}_m(\cdot,t), x) - \varphi^*(w^0, x) \right] dx.$$

Moreover, denoting by $C_1, C_2, \dots$ suitable constants that may depend on ε but not on m, by (3.1) and (3.6) we have

$$\iint_{\Omega_t} \frac{\partial w_m}{\partial t} \bar{z}_m \, dx d\tau = - \iint_{\Omega_t} (\tau_k \bar{w}_m) \frac{\partial z_m}{\partial t} \, dx d\tau + \int_\Omega [\bar{w}_m(x,t) \bar{z}_m(x,t) - w^0(x) z_m(x,0)] \, dx$$
$$\leq C_1 \big(\|\bar{w}_m\|_{L^2(\Omega_t)} + \|\bar{w}_m(\cdot,t)\|_H + \|w^0\|_H \big) \|z_m\|_{H^1(0,T:H)},$$

$$\int_\Omega \bar{f}_m (\bar{u}_m - \bar{z}_m) \, dx \leq \big(c_3 \|\bar{u}_m\|_{H^1(\Omega)} + \|\ell_3\|_{L^2(\Omega)} \big) \left(\|\bar{u}_m\|_H + \|\bar{z}_m\|_H \right)$$
$$\leq \big(c_3 \|\bar{u}_m\|_{H^1(\Omega)} + \|\ell_3\|_{L^2(\Omega)} \big) \left(\frac{1}{c_1} \|\bar{w}_m\|_H + \frac{1}{c_1} \|h_1\|_H + \|\bar{z}_m\|_H \right) \qquad \text{a.e. in }]0,T[.$$

We thus get

$$\int_\Omega \left[\varphi^*(\bar{w}_m(\cdot,t), x) - \varphi^*(w^0, x) \right] dx - \iint_{\Omega_t} \bar{\vec{q}}_m \cdot \nabla(\bar{u}_m - \bar{z}_m) \, dx d\tau$$
$$\leq C_1 \big(\|\bar{w}_m\|_{L^2(\Omega_t)} + \|\bar{w}_m(\cdot,t)\|_H + \|w^0\|_H \big) \|z_m\|_{H^1(0,T:H)} + \int_0^t \langle \bar{g}_m, \bar{u}_m - \bar{z}_m \rangle \, d\tau$$
$$+ \big(c_3 \|\bar{u}_m\|_{H^1(\Omega)} + \|\ell_3\|_{L^2(\Omega)} \big) \left(\frac{1}{c_1} \|\bar{w}_m\|_H + \frac{1}{c_1} \|h_1\|_H + \|\bar{z}_m\|_H \right) \qquad \forall t \in]0,T]. \tag{3.28}$$

Notice that by (3.1)

$$\frac{c_1}{2} |\bar{w}_m|^2 \leq \varphi(\bar{w}_m, \cdot) + |h_1 \bar{w}_m| \qquad \text{a.e. in } \Omega. \tag{3.29}$$

Recalling (3.4), (3.6), and (3.8) a standard calculation then yields

$$\|w_m\|_{L^\infty(0,T;H)}, \ \|u_m\|_{L^2(0,T;H^1(\Omega))}, \ \|f_m\|_{L^2(\Omega_T)} \leq C_2. \tag{3.30}$$

By applying (3.2) and comparing the terms of (3.27), we also infer that

$$\|\vec{q}_m\|_{L^2(\Omega_T)},\ \|w_m\|_{L^\infty(0,T;H)\cap H^1(0,T;V')} \leq C_3. \tag{3.31}$$

(iii) *Limit procedure.* By these estimates there exist $u, w, \vec{q}, f$ such that, as $m \to \infty$ along a suitable sequence (still omitting the fixed index ε),

$$u_m \rightharpoonup u \qquad \text{in } L^2\big(0,T;H^1(\Omega)\big), \tag{3.32}$$

$$w_m \overset{*}{\rightharpoonup} w \qquad \text{in } L^\infty(0,T;H) \cap H^1(0,T;V'), \tag{3.33}$$

$$\vec{q}_m \rightharpoonup \vec{q} \qquad \text{in } L^2(\Omega_T)^3, \tag{3.34}$$

$$f_m \rightharpoonup f \qquad \text{in } L^2(\Omega_T). \tag{3.35}$$

Passing to the limit in (3.27) we then get (3.13), whence (3.12) follows. Let us now fix any nonnegative function $\theta \in \mathcal{D}(\bar{\Omega})$. By a compactness result of Aubin (see [8, 57, 73]), (3.32) and (3.33) yield

$$\iint_{\Omega_t} \bar{w}_m\, \bar{u}_m\, \theta\, dxd\tau \to \iint_{\Omega_t} w\, u\, \theta\, dxd\tau \qquad \forall t \in\,]0,T]. \tag{3.36}$$

By Proposition 2.6 we then get (3.11) and

$$\iint_{\Omega_t} \varphi(\bar{u}_m(x,\tau),x)\,\theta(x)\, dxd\tau \to \iint_{\Omega_t} \varphi(u(x,\tau),x)\,\theta(x)\, dxd\tau \qquad \forall t \in\,]0,T], \tag{3.37}$$

$$\iint_{\Omega_t} \varphi^*(\bar{w}_m(x,\tau),x)\,\theta(x)\, dxd\tau \to \iint_{\Omega_t} \varphi^*(w(x,\tau),x)\,\theta(x)\, dxd\tau \qquad \forall t \in\,]0,T]. \tag{3.38}$$

Of course this also applies for $\theta \equiv 1$; by (3.29), (3.18), and (3.37), Proposition 2.8 yields

$$u_m \underset{2}{\to} u \qquad \text{in } L^2(\Omega_T), \tag{3.39}$$

whence

$$\iint_{\Omega_t} \bar{u}_m \bar{\vec{q}}_m \cdot \nabla\theta\, dxd\tau \to \iint_{\Omega_t} u\vec{q} \cdot \nabla\theta\, dxd\tau \qquad \forall t \in\,]0,T]. \tag{3.40}$$

In view of proving (3.9), let us now assume that θ is a nonnegative function of $\mathcal{D}(\Omega)$, multiply (3.13) by $u\theta$, and integrate in time. (We still imply the index ε.) By (3.11) $u\theta \in \partial\varphi^*(w)\theta$ a.e. in Ω_T, whence

$$\int_0^t \left\langle \frac{\partial w}{\partial t}, u\theta \right\rangle = \int_\Omega \big[\varphi^*(w(x,t),x) - \varphi^*(w^0(x),x)\big]\theta\, dx \qquad \text{for a.e. } t \in\,]0,T[. \tag{3.41}$$

We then get

$$\begin{aligned} &\int_\Omega \big[\varphi^*(w(x,t),x) - \varphi^*(w^0(x),x)\big]\theta\, dx - \iint_{\Omega_t} \vec{q} \cdot (\nabla u)\,\theta\, dxd\tau \\ &= \iint_{\Omega_t} (u\vec{q} \cdot \nabla\theta + fu\theta)\, dxd\tau + \int_0^t \langle g, u\theta\rangle\, d\tau \qquad \text{for a.e. } t \in\,]0,T[. \end{aligned} \tag{3.42}$$

Similarly, multiplying (3.27) by $\bar{u}_m\theta$ we have

$$\begin{aligned}&\int_\Omega \big(\varphi^*(\bar{w}_m(\cdot,t)) - \varphi^*(w^0)\big)\theta\, dx - \iint_{\Omega_t} \bar{\vec{q}}_m \cdot (\nabla \bar{u}_m)\theta\, dxd\tau \\ &\le \iint_{\Omega_t} (\bar{u}_m\bar{\vec{q}}_m \cdot \nabla\theta + \bar{f}_m\bar{u}_m\theta)\, dxd\tau + \int_0^t \langle \bar{g}_m, \bar{u}_m\theta\rangle\, d\tau \qquad \forall t \in\,]0,T].\end{aligned} \tag{3.43}$$

By (3.38), (3.40), (3.42), and (3.43), after a further integration in time we then obtain

$$\liminf_{m\to\infty} \int_0^T dt \iint_{\Omega_t} \bar{\vec{q}}_m \cdot (-\nabla \bar{u}_m)\theta\, dxd\tau \le \int_0^T dt \iint_{\Omega_t} \vec{q} \cdot (-\nabla u)\theta\, dxd\tau.$$

The constitutive relation (3.9) then follows from Theorem 2.10. Finally, by part (ii) of the same theorem we infer that

$$\nabla u_m \to \nabla u \qquad \text{in } L^2(\Omega_T)^3. \tag{3.44}$$

This and (3.39) yield (3.10). □

Remarks. (i) In view of the developments of the next section, notice that (3.30) and (3.31) yield the following uniform estimates for the solutions of Problem 3.1_ε (here written displaying the index ε):

$$\begin{aligned}&\|w_\varepsilon\|_{L^\infty(0,T;H)\cap H^1(0,T;V')}, \|u_\varepsilon\|_{L^2(0,T;H^1(\Omega))}, \|\vec{q}_\varepsilon\|_{L^2(\Omega_T)^3}, \|f_\varepsilon\|_{L^2(\Omega_T)} \\ &\le \text{Constant (independent of } \varepsilon).\end{aligned} \tag{3.45}$$

(ii) If f_ε is assumed to be independent of ∇u_ε, the assumption (3.3) may be dropped ($\vec{\alpha}$ is thus assumed only to be nondecreasing w.r.t. its first argument). □

4. Two-scale homogenized problem. In this section we show that as ε vanishes the solutions of Problem 3.1_ε converge to a solution of a two-scale homogenized problem.

Two-scale formulation. Let us assume that (2.8), (2.36), and (3.5) are fulfilled and that

$$w_\varepsilon^0 \underset{2}{\to} w^0 \qquad \text{in } L^2(\Omega \times \mathcal{Y}), \qquad z \in H^1(\Omega_T), \qquad g \in L^2(0,T;V'). \tag{4.1}$$

We shall deal with functions that depend on two (vector) space variables x and y and denote the respective gradient operators by ∇_x (resp., ∇_y). We shall use the notation (2.5), set

$$Z := \big\{v \in L^2\big(\Omega; H^1(\mathcal{Y})\big) : \hat{v} \in V\big\}, \tag{4.2}$$

and equip this space with the graph norm. Now we introduce the weak formulation of a two-scale problem that we then retrieve by letting ε vanish in Problem 3.1_ε.

PROBLEM 4.1. *Find*

$$\begin{aligned}&u \in L^2(0,T;V) + z, \qquad w \in L^2(\Omega_T \times \mathcal{Y}), \qquad \vec{q} \in L^2(\Omega_T \times \mathcal{Y})^3, \\ &u_\sharp \in L^2\big(\Omega_T; H^1(\mathcal{Y})\big), \qquad \vec{q}_\sharp \in L^2(\Omega_T \times \mathcal{Y})^3\end{aligned} \tag{4.3}$$

such that $\hat{u}_\sharp \equiv 0$, $\hat{\vec{q}}_\sharp \equiv \vec{0}$ *a.e. in* Ω_T *and, setting*

$$f = \beta(u, \nabla_x u + \nabla_y u_\sharp, x, y, t) \qquad \text{a.e. in } \Omega_T \times \mathcal{Y}, \tag{4.4}$$

one has

$$\vec{q} = \vec{\alpha}(-\nabla_x u - \nabla_y u_\sharp, u, x, y, t) \qquad \text{a.e. in } \Omega_T \times \mathcal{Y}, \tag{4.5}$$

$$w \in \partial\varphi(u, x, y) \qquad \text{a.e. in } \Omega_T \times \mathcal{Y}, \tag{4.6}$$

$$\begin{gathered}\iiint_{\Omega_T \times \mathcal{Y}} \left((w^0 - w)\,\frac{\partial v}{\partial t} - \hat{\vec{q}} \cdot \nabla_x \hat{v} - \vec{q}_\sharp \cdot \nabla_y v - fv \right) dxdydt = \int_0^T \langle g, v\rangle \, dt \\ \forall v \in H^1\big(0,T; L^2(\Omega \times \mathcal{Y})\big) \cap L^2(0,T;Z),\ v(\cdot,\cdot,T) = 0 \qquad \text{a.e. in } \Omega \times \mathcal{Y},\end{gathered} \tag{4.7}$$

$$\int_{\mathcal{Y}} \vec{q} \cdot \nabla_y v \, dy = 0 \qquad \forall v \in H^1(\mathcal{Y}) \text{ a.e. in } \Omega_T. \tag{4.8}$$

(It should be noticed that the function u is independent of y.)

Interpretation. Equation (4.7) yields the two-scale equation

$$\frac{\partial w}{\partial t} + \nabla_x \cdot \hat{\vec{q}} + \nabla_y \cdot \vec{q}_\sharp = f + g \qquad \text{in } Z' \text{ a.e. in }]0,T[\tag{4.9}$$

and the initial condition

$$w(\cdot,\cdot,0) = w^0 \qquad \text{in } Z', \tag{4.10}$$

for by comparing the terms of (4.9) we infer that $w \in H^1(0,T;Z')$. Conversely (4.9) and (4.10) entail (4.7). By selecting v independent of y in (4.7), we get the following system for the coarse-scale fields $\hat{w}, \hat{\vec{q}}$:

$$\begin{aligned}&\frac{\partial \hat{w}}{\partial t} + \nabla_x \cdot \hat{\vec{q}} = \hat{f} + g \qquad \text{in } V' \text{ a.e. in }]0,T[,\\ &\hat{w}(\cdot,0) = \widehat{w^0} \qquad \text{in } V'.\end{aligned} \tag{4.11}$$

Equations (4.9)–(4.11) then yield the fine-scale system

$$\begin{aligned}&\frac{\partial \tilde{w}}{\partial t} + \nabla_y \cdot \vec{q}_\sharp = \tilde{f} \qquad \text{in } L^2\big(\Omega; H^1(\mathcal{Y})'\big) \text{ a.e. in }]0,T[,\\ &\tilde{w}(\cdot,\cdot,0) = \widetilde{w^0} \qquad \text{in } V' \text{ for a.e. } y \in \mathcal{Y}.\end{aligned} \tag{4.12}$$

The two latter systems are coupled via the nonlinear constitutive equations (4.4)–(4.6). Equation (4.8) also reads $\nabla_y \cdot \vec{q} = 0$ in $\mathcal{D}'(\mathcal{Y})$ a.e. in Ω_T.

We now retrieve Problem 4.1 from Problem 3.1_ε by letting ε vanish.

THEOREM 4.1. *For any fixed $\varepsilon > 0$, let* (4.1) *and the hypotheses of Theorem* 3.1 *be satisfied. Let $\{(u_\varepsilon, w_\varepsilon) : \varepsilon > 0\}$ be a family of solutions of Problem 3.1_ε that also fulfils the uniform estimates* (3.45) *(we saw that such a family exists). Then there exist $u, w, \vec{q}, u_\sharp, \vec{q}_\sharp$ such that, as $\varepsilon \to 0$ along a suitable sequence,*

$$u_\varepsilon \rightharpoonup u \qquad \text{in } L^2\big(0,T;H^1(\Omega)\big), \tag{4.13}$$

$$\nabla u_\varepsilon \underset{2}{\rightharpoonup} \nabla_x u + \nabla_y u_\sharp \qquad \text{in } L^2(\Omega_T \times \mathcal{Y})^3, \tag{4.14}$$

$$w_\varepsilon \underset{2}{\overset{*}{\rightharpoonup}} w \qquad \text{in } L^\infty\big(0,T;L^2(\Omega \times \mathcal{Y})\big), \tag{4.15}$$

$$\vec{q}_\varepsilon \underset{2}{\rightharpoonup} \vec{q} \qquad \text{in } L^2(\Omega_T \times \mathcal{Y})^3, \tag{4.16}$$

$$\nabla \cdot \vec{q}_\varepsilon \underset{2}{\rightharpoonup} \nabla_x \cdot \hat{\vec{q}} + \nabla_y \cdot \vec{q}_\sharp \qquad \text{in } L^2(\Omega_T \times \mathcal{Y}). \tag{4.17}$$

This entails that $(u, w, \vec{q}, u_\sharp, \vec{q}_\sharp)$ *is a solution of Problem* 4.1.

Proof. This argument follows the lines of part (iii) of the proof of Theorem 3.1, obviously with two-scale in place of single-scale convergence. By the estimates (3.45) and Propositions 2.1, 2.3, and 2.4 there exist $u, w, \vec{q}, u_\sharp, \vec{q}_\sharp$ such that, as $\varepsilon \to 0$ along a suitable subsequence, (4.8) and (4.13)–(4.17) hold. By passing to the limit in (3.12), we then get (4.7).

In view of deriving the relations (4.4)–(4.6), let us now fix any nonnegative $\theta \in \mathcal{D}(\bar{\Omega})$, and notice that by (3.45), (4.15), and Proposition 2.2

$$w_\varepsilon \overset{*}{\rightharpoonup} \hat{w} \qquad \text{in } L^\infty(0,T;H) \cap H^1(0,T;V').$$

By the aforementioned compactness result of Aubin (see [8, 57, 73]), we then have

$$\begin{aligned}(4.18)\qquad &\iint_{\Omega_T} w_\varepsilon(x,t) u_\varepsilon(x,t)\,\theta(x)\,dxdt \\ &\to \iint_{\Omega_T} \hat{w}(x,t)u(x,t)\,\theta(x)\,dxdt = \iiint_{\Omega_T\times\mathcal{Y}} w(x,y,t)u(x,t)\,\theta(x)\,dxdydt.\end{aligned}$$

By (3.11) and Proposition 2.7, we then get (4.6) and, setting $\bar{\varphi}(v,x) := \int_{\mathcal{Y}} \varphi(v,x,y)\,dy$ for any v and a.e. x,

$$\begin{aligned}(4.19)\qquad &\iint_{\Omega_T} \varphi_\varepsilon(u_\varepsilon(x,t),x)\theta(x)\,dxdt \\ &\to \iiint_{\Omega_T\times\mathcal{Y}} \varphi(u(x,t),x,y)\theta(x)\,dxdydt = \iint_{\Omega_T} \bar{\varphi}(u(x,t),x)\theta(x)\,dxdt,\end{aligned}$$

$$(4.20)\qquad \iint_{\Omega_T} \varphi_\varepsilon^*(w_\varepsilon(x,t),x)\theta(x)\,dxdt \to \iiint_{\Omega_T\times\mathcal{Y}} \varphi^*(w(x,y,t),x,y)\theta(x)\,dxdydt.$$

This also applies for $\theta \equiv 1$. As (3.18) entails that the mapping $v \mapsto \bar{\varphi}(v,x)$ is strictly convex for a.e. x, Proposition 2.9 then yields $u_\varepsilon \underset{2}{\to} u$ in $L^2(\Omega_T \times \mathcal{Y})$; that is, as u is independent of y,

$$(4.21)\qquad u_\varepsilon \to u \qquad \text{in } L^2(\Omega_T).$$

In view of the proof of (4.5) let us now assume that θ is a nonnegative function of $\mathcal{D}(\Omega)$; notice that $\vec{q}_\varepsilon \rightharpoonup \hat{\vec{q}}$ in $L^2(\Omega_T)^3$ and by (4.21)

$$(4.22)\qquad \iint_{\Omega_t} u_\varepsilon \vec{q}_\varepsilon \cdot \nabla_x \theta\,dxd\tau \to \iint_{\Omega_t} u\hat{\vec{q}} \cdot \nabla_x\theta\,dxd\tau \qquad \forall t \in\,]0,T].$$

Let us now select $v = u\theta$ in (4.7) and integrate in time. As by (4.6)

(4.23)

$$\iint_{\mathcal{Y}_t} \left\langle \frac{\partial w}{\partial t}, u\theta \right\rangle dyd\tau = \iint_{\Omega\times\mathcal{Y}} \left[\varphi^*(w(x,y,t),x,y) - \varphi^*(w^0(x,y),x,y)\right]\theta\,dxdy \qquad \text{for a.e. } t \in\,]0,T[,$$

we thus get

(4.24)

$$\begin{aligned}&\iint_{\Omega\times\mathcal{Y}} \left[\varphi^*(w(x,y,t),x,y) - \varphi^*(w^0(x,y),x,y)\right]\theta\,dxdy - \iiint_{\Omega_t\times\mathcal{Y}} \vec{q}\cdot(\nabla_x u)\theta\,dxdyd\tau \\ &= \iint_{\Omega_t} \left(u\hat{\vec{q}}\cdot\nabla_x\theta + fu\theta\right) dxd\tau + \int_0^t \langle g, u\theta\rangle\,d\tau \qquad \text{for a.e. } t \in\,]0,T[.\end{aligned}$$

Let us also rewrite (3.42) displaying the index ε,

$$
\begin{aligned}
&\int_\Omega \big[\varphi^*_\varepsilon(w_\varepsilon(x,t),x) - \varphi^*(w^0_\varepsilon(x),x)\big]\theta(x)\,dx - \iint_{\Omega_t} \vec{q}_\varepsilon \cdot (\nabla u_\varepsilon)\,\theta\,dxd\tau \\
&= \iint_{\Omega_t} (u_\varepsilon \vec{q}_\varepsilon \cdot \nabla\theta + f_\varepsilon u_\varepsilon \theta)\,dxd\tau + \int_0^t \langle g, u_\varepsilon\theta\rangle\,d\tau \qquad \text{for a.e. } t\in\,]0,T[,
\end{aligned}
\tag{4.25}
$$

and notice that by (4.1) $\int_\Omega \varphi^*_\varepsilon(w^0_\varepsilon)\theta\,dx \to \iint_{\Omega\times\mathcal{Y}} \varphi^*(w^0)\theta\,dxdy$. After a further integration in time (4.20)–(4.25) yield

$$
\begin{aligned}
&\int_0^T dt \iint_{\Omega_t} \vec{q}_\varepsilon \cdot (\nabla u_\varepsilon)\theta\,dxd\tau \\
&= \int_0^T dt \int_\Omega \big[\varphi^*(w(x,y,t),x,y) - \varphi^*(w^0(x,y),x,y)\big]\theta(x)\,dxdy \\
&- \int_0^T dt \iint_{\Omega_t} (u_\varepsilon \vec{q}_\varepsilon \cdot \nabla\theta + f_\varepsilon u_\varepsilon\theta)\,dxd\tau - \int_0^T dt \int_0^t \langle g, u_\varepsilon\theta\rangle\,d\tau \\
&\to \int_0^T dt \int_\Omega \big[\varphi^*(w(x,t),x) - \varphi^*(w^0(x),x)\big]\theta(x)\,dx - \int_0^T dt \iint_{\Omega_t} (u\vec{q}\cdot\nabla\theta + fu\theta)\,dxd\tau \\
&- \int_0^T dt \int_0^t \langle g, u\theta\rangle\,d\tau = \int_0^T dt \iiint_{\Omega_t\times\mathcal{Y}} \vec{q}\cdot(\nabla_x u)\theta\,dxdyd\tau;
\end{aligned}
$$

that is, as by (4.8) $\int_{\mathcal{Y}} \vec{q}\cdot\nabla_y u_\sharp\,dy = 0$ a.e. in Ω_T,

$$
\int_0^T dt \iint_{\Omega_t} \vec{q}_\varepsilon \cdot (\nabla u_\varepsilon)\theta\,dxd\tau \to \int_0^T dt \iiint_{\Omega_t\times\mathcal{Y}} \vec{q}\cdot(\nabla_x u + \nabla_y u_\sharp)\theta\,dxdyd\tau.
$$

Proposition 2.11 then yields (4.5). Finally, by part (ii) of Proposition 2.11 we infer that

$$
\nabla u_\varepsilon \underset{2}{\to} \nabla_x u + \nabla_y u\sharp \qquad \text{in } L^2(\Omega_T\times\mathcal{Y})^3. \tag{4.26}
$$

This convergence and (4.21) yield (4.4). $\square$

Remark. Similarly to what we saw for Theorem 3.1, if f_ε were assumed to be independent of ∇u_ε, the assumption (3.3) might be dropped. $\square$

5. Coarse-scale homogenized problem. In this section we reduce the two-scale problem of the last section to an equivalent coarse-scale formulation under some minor restrictions. This will complete the homogenization procedure.

Here we assume that the source term f is independent of u and ∇u and that the maximal monotone function $\vec{\alpha}$ is the subdifferential $\partial\psi(\cdot,v,x,y,t)$ of a function $\psi : \mathbf{R}^3\times\mathbf{R}\times\Omega\times\mathcal{Y}\times\,]0,T[\,\to\mathbf{R}$ such that

(5.1)

$$
\begin{aligned}
&\psi \text{ is measurable w.r.t. either } \mathcal{B}(\Omega)\otimes\mathcal{L}(\mathbf{R}^3\times\mathbf{R}\times\mathcal{Y}_T) \text{ or } \mathcal{L}(\mathbf{R}^3\times\mathbf{R}\times\Omega_T)\otimes\mathcal{B}(\mathcal{Y}),\\
&\psi(\vec{\xi},\cdot,x,y,t) \text{ is continuous} \qquad \forall\vec{\xi} \text{ and for a.e. } (x,y,t),\\
&\psi(\cdot,v,x,y,t) \text{ is lower semicontinuous and convex} \qquad \forall v \text{ and for a.e. } (x,y,t),
\end{aligned}
$$

$$
\begin{aligned}
&\exists L>0,\ \exists \ell_4\in L^2(\Omega_T) : \forall(\vec{\xi},v) \qquad \text{for a.e. } (x,y,t),\\
&\forall\vec{\eta}\in\partial\psi(\vec{\xi},v,x,y,t), \qquad |\vec{\eta}| \le L|\vec{\xi}| + L|v| + \ell_4(x,t),
\end{aligned}
\tag{5.2}
$$

$$\begin{aligned}&\exists c_4 > 0,\, \exists h_4 \in L^1(\Omega_T) : \forall(\vec{\xi}, v) \qquad \text{for a.e. } (x,y,t),\\ &\psi(\vec{\xi}, v, x, y, t) \geq c_4|\vec{\xi}|^2 + h_4(x,t).\end{aligned} \tag{5.3}$$

We define the function φ as in section 3, assume (3.1)–(3.6), and define the homogenized potentials φ_0 and ψ_0:

$$\varphi_0(v,x) := \int_{\mathcal{Y}} \varphi(v,x,y)\,dy \qquad \forall v \in \mathbf{R} \text{ for a.e. } x \in \Omega, \tag{5.4}$$

$$\begin{aligned}\psi_0(\vec{\xi}, v, x, t) := \inf\Bigg\{ &\int_{\mathcal{Y}} \psi(\vec{\xi} + \vec{\xi}_1(y), v, x, y, t)\,dy :\\ &\vec{\xi}_1 \in L^2(\mathcal{Y})^3,\, \hat{\vec{\xi}}_1 = \vec{0},\, \nabla_y \times \vec{\xi}_1 = \vec{0} \text{ in } \mathcal{D}'(\mathcal{Y})^3 \Bigg\}\\ &\forall \vec{\xi} \in \mathbf{R}^3,\, \forall v \in \mathbf{R} \qquad \text{for a.e. } (x,t) \in \Omega_T.\end{aligned} \tag{5.5}$$

This minimization problem is equivalent to the corresponding Euler equation

$$\begin{cases}\theta \in H^1(\mathcal{Y})^3,\\ \nabla_y \cdot \partial\psi(\vec{\xi} + \nabla_y\theta(y), v, x, y, t) \ni 0 \quad \text{in } H^{-1}(\mathcal{Y})^3\end{cases} \qquad \text{for a.e. } (x,t) \in \Omega_T. \tag{5.6}$$

In the case of a quadratic function ψ this family of *cell problems* will be studied in the next section.

Here we assume that

$$w^0 \in L^2(\Omega \times \mathcal{Y}), \qquad z \in H^1(\Omega_T), \qquad f \in L^2(\Omega_T \times \mathcal{Y}), \qquad g \in L^2(0,T;V') \tag{5.7}$$

and introduce a coarse-scale problem using the notation (2.5).

PROBLEM 5.1. *Find $u \in L^2(0,T;V) + z$, $\bar{w} \in L^2(\Omega_T)$, and $\bar{\vec{q}} \in L^2(\Omega_T)^3$ such that*

$$\bar{w}(x,t) \in \partial\varphi_0(u(x,t), x) \qquad \textit{for a.e. } (x,t) \in \Omega_T, \tag{5.8}$$

$$\bar{\vec{q}}(x,t) \in \partial\psi_0(-\nabla u(x,t), u(x,t), x, t) \qquad \textit{for a.e. } (x,t) \in \Omega_T, \tag{5.9}$$

$$\begin{aligned}&\iint_{\Omega_T} \left(\left(\bar{w} - \widehat{w^0}\right) \frac{\partial v}{\partial t} - \bar{\vec{q}} \cdot \nabla v - \hat{f} v \right) dxdt = \int_0^T \langle g, v \rangle\, dt\\ &\forall v \in H^1(0,T;H) \cap L^2(0,T;V),\ v(\cdot,T) = 0 \qquad \textit{a.e. in } \Omega.\end{aligned} \tag{5.10}$$

This formulation may be compared with Problem 3.1_ε. In particular (5.10) yields the energy balance equation in the form

$$\frac{\partial \bar{w}}{\partial t} + \nabla \cdot \bar{\vec{q}} = \hat{f} + g \qquad \text{in } \mathcal{D}'(\Omega_T). \tag{5.11}$$

In view of relating Problems 4.1 and 5.1 to each other, first we review some basic properties of subdifferentials and convex conjugate functions that will be used in what follows.

LEMMA 5.1. *Let B be a real Banach space and $\langle \cdot, \cdot \rangle$ be the duality pairing between B and its dual B'. If $F : B \to \mathbf{R} \cup \{+\infty\}$ is such that $F \not\equiv +\infty$, then for any $u \in B$ and any $w \in B'$,*

$$F(u) + F^*(w) \geq \langle w, u \rangle, \tag{5.12}$$

$$w \in \partial F(u) \quad \Leftrightarrow \quad F(u) + F^*(w) \leq \langle w, u \rangle, \tag{5.13}$$

$$w \in \partial F(u) \quad \Leftrightarrow \quad F(u) + F^*(w) = \langle w, u \rangle. \tag{5.14}$$

The inequality (5.12) directly follows from the definition of the convex conjugate function F^*. The proof of (5.13) may be found, e.g., in [45, 51, 54, 69]. The statement (5.14) is an obvious consequence of (5.12) and (5.13).

The next lemma will allow us to upscale from Problem 4.1 to 5.1 and may be compared with classical results about the homogenization of integral functionals of [24, 60].

LEMMA 5.2. *Let the function* ψ *fulfil* (5.1)–(5.3), *define* ψ_0 *as in* (5.5), *and let* $\nu \in L^2(\Omega_T)$. *If* $\vec{\xi}, \vec{\eta} \in L^2(\Omega_T \times \mathcal{Y})^3$ *are such that*

$$\vec{\eta}(x,y,t) \in \partial\psi(\vec{\xi}(x,y,t), \nu(x,t), x, y, t) \qquad \text{for a.e. } (x,y,t) \in \Omega_T \times \mathcal{Y}, \tag{5.15}$$

$$\nabla_y \times \vec{\xi} = \vec{0} \qquad \text{in } \mathcal{D}'(\Omega_T \times \mathcal{Y})^3, \qquad \nabla_y \cdot \vec{\eta} = 0 \qquad \text{in } \mathcal{D}'(\Omega_T \times \mathcal{Y}), \tag{5.16}$$

then

$$\hat{\vec{\eta}}(x,t) \in \partial\psi_0(\hat{\vec{\xi}}(x,t), \nu(x,t), x, t) \qquad \text{for a.e. } (x,t) \in \Omega_T. \tag{5.17}$$

Proof. As here the independent variables $(x,t) \in \Omega_T$ just occur as parameters, for the sake of simplicity we shall omit them as well as $\nu(x,t)$ throughout this argument. For instance, we thus replace (5.15) by

$$\vec{\eta}(y) \in \partial\psi(\vec{\xi}(y), y) \qquad \text{for a.e. } y \in \mathcal{Y}. \tag{5.18}$$

Using the notation (2.5), let us first set

$$\begin{aligned} W &:= \{\vec{w} \in L^2(\mathcal{Y})^3 : \nabla \cdot \vec{w} = 0 \quad \text{in } \mathcal{D}'(\mathcal{Y})\}, \qquad W_* := \{\vec{v} \in W : \hat{\vec{v}} = \vec{0}\}, \\ Z &:= \{\vec{v} \in L^2(\mathcal{Y})^3 : \nabla \times \vec{v} = \vec{0} \quad \text{in } \mathcal{D}'(\mathcal{Y})^3\}, \qquad Z_* := \{\vec{v} \in Z : \hat{\vec{v}} = \vec{0}\}; \end{aligned}$$

these are Hilbert subspaces of $L^2(\mathcal{Y})^3$. Notice that $Z_* = \nabla H^1_*(\mathcal{Y})$, and this is the orthogonal space of W_* in $L^2(\mathcal{Y})^3$. Hence

$$\begin{aligned} &\int_{\mathcal{Y}} \vec{v}(y) \cdot \vec{w}(y)\, dy - \hat{\vec{v}} \cdot \hat{\vec{w}} = \int_{\mathcal{Y}} [\hat{\vec{v}} \cdot \tilde{\vec{w}}(y) + \tilde{\vec{v}}(y) \cdot \hat{\vec{w}} + \tilde{\vec{v}}(y) \cdot \tilde{\vec{w}}(y)]\, dy \\ &= \hat{\vec{v}} \cdot \int_{\mathcal{Y}} \tilde{\vec{w}}(y)\, dy + \left(\int_{\mathcal{Y}} \tilde{\vec{v}}(y)\, dy\right) \cdot \hat{\vec{w}} + \int_{\mathcal{Y}} \tilde{\vec{v}}(y) \cdot \tilde{\vec{w}}(y)\, dy = 0 \qquad \forall (\vec{v}, \vec{w}) \in Z \times W. \end{aligned} \tag{5.19}$$

By (5.15)

$$\int_{\mathcal{Y}} \vec{\eta}(y) \cdot [\vec{\xi}(y) - \vec{v}(y)]\, dy \geq \int_{\mathcal{Y}} \psi(\vec{\xi}(y), y)\, dy - \int_{\mathcal{Y}} \psi(\vec{v}(y), y)\, dy \qquad \forall \vec{v} \in L^2(\mathcal{Y})^3;$$

hence, applying (5.19) and noticing that $\int_{\mathcal{Y}} \psi(\vec{\xi}(y), y)\, dy \geq \psi_0(\hat{\vec{\xi}})$,

$$\hat{\vec{\eta}} \cdot (\hat{\vec{\xi}} - \hat{\vec{v}}) = \int_{\mathcal{Y}} \vec{\eta}(y) \cdot [\vec{\xi}(y) - \vec{v}(y)]\, dy \geq \psi_0(\hat{\vec{\xi}}) - \int_{\mathcal{Y}} \psi(\vec{v}(y), y)\, dy \qquad \forall \vec{v} \in Z.$$

By the arbitrariness of $\tilde{\vec{v}}$, we then get $\hat{\vec{\eta}} \cdot (\hat{\vec{\xi}} - \hat{\vec{v}}) \geq \psi_0(\hat{\vec{\xi}}) - \psi_0(\hat{\vec{v}})$ for any $\hat{\vec{v}} \in \mathbf{R}^3$, that is, $\hat{\vec{\eta}} \in \partial\psi_0(\hat{\vec{\xi}})$. ∎

The next statement inverts Lemma 5.2 and will be used to downscale from Problem 5.1 to 4.1.

LEMMA 5.3. *Let the function ψ fulfil* (5.1)–(5.3), *define ψ_0 as in* (5.5), *and let $\nu \in L^2(\Omega_T)$. If*

(5.20)
$$\vec r, \vec s \in L^2(\Omega_T)^3, \qquad \vec s(x,t) \in \partial\psi_0(\vec r(x,t), \nu(x,t), x, t) \qquad \textit{for a.e. } (x,t) \in \Omega_T,$$

then there exist $\vec\xi, \vec\eta \in L^2(\Omega_T \times \mathcal{Y})^3$ such that

$$\hat{\vec\xi}(x,t) = \vec r(x,t), \qquad \hat{\vec\eta}(x,t) = \vec s(x,t) \qquad \textit{for a.e. } (x,t) \in \Omega_T,$$
$$\vec\eta(x,y,t) \in \partial\psi(\vec\xi(x,y,t), \nu(x,t), x, y, t) \qquad \textit{for a.e. } (x,y,t) \in \Omega_T \times \mathcal{Y}. \tag{5.21}$$

If, moreover, $\psi(\cdot, v, x, y, t)$ and $\psi^*(\cdot, v, x, y, t)$ are strictly convex for any $v \in \mathbf{R}$ and a.e. $(x,y,t) \in \Omega_T \times \mathcal{Y}$, then the pair $(\vec\xi, \vec\eta)$ is unique.

Proof. Here we imply the dependence on (x,t) and $\nu(x,t)$, as we did in the proof of Lemma 5.2. Let us first set

$$\rho_0(\vec\eta) := \inf\left\{\int_{\mathcal{Y}} \psi^*(\vec\eta + \vec z(y), y)\, dy : \vec z \in Z\right\} \qquad \forall \vec\eta \in \mathbf{R}^3. \tag{5.22}$$

By (5.3) the conjugate function ψ^* also has quadratic growth at infinity, so that

$$\psi(\vec\lambda, y) \to +\infty, \qquad \psi^*(\vec\lambda, y) \to +\infty \qquad \text{as } |\vec\lambda| \to +\infty, \text{ uniformly for } y \in \mathcal{Y}. \tag{5.23}$$

By the convexity and the lower semicontinuity of ψ and ψ^*, the infima $\psi_0(\hat{\vec\xi})$ and $\rho_0(\hat{\vec\eta})$ (cf. (5.4) and (5.22)) are then both attained, that is,

$$\exists \vec\xi \in \mathbf{R}^N + W: \quad \hat{\vec\xi} = r, \qquad \psi_0(\hat{\vec\xi}) = \int_{\mathcal{Y}} \psi(\vec\xi(y), y)\, dy,$$
$$\exists \vec\eta \in \mathbf{R}^N + Z: \quad \hat{\vec\eta} = s, \qquad \rho_0(\hat{\vec\eta}) = \int_{\mathcal{Y}} \psi^*(\vec\eta(y), y)\, dy. \tag{5.24}$$

By (5.13) the inclusion $\vec s \in \partial\psi_0(\vec r)$ is thus equivalent to

$$\hat{\vec\xi} \cdot \hat{\vec\eta} \geq \psi_0(\hat{\vec\xi}) + \psi_0^*(\hat{\vec\eta}). \tag{5.25}$$

The definitions of ψ_0 and ρ_0, respectively, yield $\psi_0 \leq \psi$ and $\rho_0 \leq \psi^*$ in $\mathbf{R}^3 \times \mathcal{Y}$; the former inequality entails that $\psi^* \leq \psi_0^*$. Thus $\rho_0 \leq \psi^* \leq \psi_0^*$, namely, $\rho_0 \leq \psi_0^*$ in $\mathbf{R}^3$. The inequality (5.25) then yields $\hat{\vec\xi} \cdot \hat{\vec\eta} \geq \psi_0(\hat{\vec\xi}) + \rho_0(\hat{\vec\eta})$, which by (5.19) and (5.24) reads

$$\int_{\mathcal{Y}} \vec\xi(y) \cdot \vec\eta(y)\, dy \geq \int_{\mathcal{Y}} [\psi(\vec\xi(y), y) + \psi^*(\vec\eta(y), y)]\, dy.$$

By (5.12), on the other hand, $\vec\xi(y) \cdot \vec\eta(y) \leq \psi(\vec\xi(y), y) + \psi^*(\vec\eta(y), y)$ for a.e. $y \in \mathcal{Y}$. By the two latter inequalities, we infer that

$$\vec\xi(y) \cdot \vec\eta(y) = \psi(\vec\xi(y), y) + \psi^*(\vec\eta(y), y) \qquad \text{for a.e. } y \in \mathcal{Y},$$

and by (5.14) this is tantamount to $\vec\eta(y) \in \partial\psi(\vec\xi(y), y)$ for a.e. $y \in \mathcal{Y}$. The final statement about uniqueness is obvious. ∎

Next by Lemmata 5.2 and 5.3 we show that Problems 4.1 and 5.1 are equivalent.

THEOREM 5.4. *Let φ and $\vec{\alpha} := \partial\psi$ fulfil* (2.8) *and* (2.36). *Let* (3.1)–(3.4), (3.6), (5.1)–(5.5), *and* (5.7) *also be satisfied (with β independent of v and $\vec{z}$). Then we have the following:*

(i) *If $(u, w, \vec{q}, u_\sharp, \vec{q}_\sharp)$ is a solution of Problem* 4.1 *(by Theorem* 4.1 *such a solution exists), then $(u, \hat{w}, \hat{\vec{q}})$ is a solution of Problem* 5.1.

(ii) *Conversely, for any solution $(u, \bar{w}, \bar{\vec{q}})$ of Problem* 5.1 *there exists a solution $(u, w, \vec{q}, u_\sharp, \vec{q}_\sharp)$ of Problem* 4.1 *such that $\hat{w} = \bar{w}$ and $\hat{\vec{q}} = \bar{\vec{q}}$ a.e. in Ω_T.*

Proof. (i) The inclusion (5.9) follows from (4.5) and Lemma 5.2, because of (4.8). Equation (5.8) is an even simpler consequence of (4.6), for u is independent of y. Indeed (4.6) is tantamount to

$$\iiint_{\Omega_T\times\mathcal{Y}} [\varphi(u(x,t),x,y) - u(x,t)w(x,y,t)]\,dxdydt$$
$$\le \iiint_{\Omega_T\times\mathcal{Y}} [\varphi(v(x,y,t),x,y) - v(x,y,t)w(x,y,t)]\,dxdydt \qquad \forall v \in L^2(\Omega_T\times\mathcal{Y});$$

selecting v independent of y we then get

$$\iint_{\Omega_T} [\varphi_0(u(x,t),x) - u\hat{w}]\,dxdt \le \iint_{\Omega_T} [\varphi_0(v(x,t),x) - v\hat{w}]\,dxdt \qquad \forall v \in L^2(\Omega_T),$$

that is, (5.8).

(ii) This part is a direct consequence of Lemma 5.3. ◻

We can now state our single-scale homogenization result.

COROLLARY 5.5. *Under the hypotheses of Theorems* 4.1 *and* 5.4 *there exist $u, \bar{w}, \bar{\vec{q}}$ such that, as $\varepsilon \to 0$ along a suitable sequence,*

$$u_\varepsilon \rightharpoonup u \qquad \text{in } L^2\big(0,T;H^1(\Omega)\big), \tag{5.26}$$

$$w_\varepsilon \overset{*}{\underset{2}{\rightharpoonup}} \bar{w} \qquad \text{in } L^\infty(0,T;H), \tag{5.27}$$

$$\vec{q}_\varepsilon \underset{2}{\rightharpoonup} \bar{\vec{q}} \qquad \text{in } L^2(\Omega_T)^3. \tag{5.28}$$

This entails that $(u, \bar{w}, \bar{\vec{q}})$ is a solution of Problem 5.1.

Proof. By Proposition 2.2, (4.13), (4.15), and (4.16) yield (5.26)–(5.28). It then suffices to apply part (i) of Theorem 5.4. ◻

6. Single nonlinearity, Kirchhoff transformation, and discussion. Obviously the analysis of sections 3, 4, and 5 can be much simplified whenever either of the two constitutive relations (1.2) and (1.3) is linear, for each of Problems 3.1_ε, 4.1, and 5.1 is then reduced to a single variational inequality, so that existence of a solution can be established without using compactness properties. In that case these problems are actually well-posed.

Here we assume that (1.3) is linear w.r.t. ∇u but not w.r.t. u, and we retrieve the homogenized conductivity tensor from the two-scale relation (4.5) via a well-known procedure. Afterwards we show how a class of nonlinear conduction laws may be reduced to linear form via a generalization of the classical Kirchhoff transformation. So let

$$\vec{\alpha}(\vec{z}, v, x, y, t) = K(v, x, y, t)\cdot\vec{z} \qquad \forall(\vec{z}, v) \in \mathbf{R}^3\times\mathbf{R} \text{ for a.e. } (x,y,t) \in \Omega_T\times\mathcal{Y}, \tag{6.1}$$

where K is a (possibly asymmetric) positive-definite 3×3-tensor function with entries k_{ij} that are Caratheodory functions. The relation (4.5) and (4.8) then read, respectively,

$$\vec{q}(x,y,t) = -K(u(x,t),x,y,t) \cdot [\nabla_x u(x,t) + \nabla_y u_\sharp(x,y,t)] \qquad \text{for a.e. } (x,y,t) \in \Omega_T \times \mathcal{Y}, \tag{6.2}$$

$$\nabla_y \cdot \big\{ K(u(x,t),x,y,t) \cdot [\nabla_x u(x,t) + \nabla_y u_\sharp(x,y,t)] \big\} = 0 \qquad \text{in } H^{-1}(\mathcal{Y}) \qquad \text{for a.e. } (x,t) \in \Omega_T. \tag{6.3}$$

We claim that (6.2) and (6.3) entail a homogenized relation of the form

$$\hat{\vec{q}}(x,t) = -K_0(u(x,t),x,t) \cdot \nabla_x u(x,t) \qquad \text{for a.e. } (x,t) \in \Omega_T, \tag{6.4}$$

where the tensor function K_0 is determined as follows. Along the lines of [2] and consistently with a classical approach to the homogenization of linear elliptic and parabolic equations (see, e.g., the works quoted in the introduction), we search for a family of auxiliary scalar functions $w_1(x,y,t), \dots, w_3(x,y,t)$ such that

$$u_\sharp(x,y,t) = \sum_{j=1,2,3} \frac{\partial u}{\partial x_j}(x,t) w_j(x,y,t) \qquad \text{for a.e. } (x,y,t) \in \Omega_T \times \mathcal{Y}.$$

Denoting by $\vec{e}_j$ the unit vector of the axis y_j ($j = 1,2,3$), (6.2) and (6.3) then read, respectively,

$$\begin{aligned} &\vec{q}(x,y,t) = -K(u(x,t),x,y,t) \cdot \sum_{j=1,2,3} \frac{\partial u}{\partial x_j}(x,t)[\vec{e}_j + \nabla_y w_j(x,y,t)] \\ &\qquad\qquad\qquad\qquad \text{for a.e. } (x,y,t) \in \Omega_T \times \mathcal{Y}, \\ &\nabla_y \cdot \left\{ K(u(x,t),x,y,t) \cdot \sum_{j=1,2,3} \frac{\partial u}{\partial x_j}(x,t)[\vec{e}_j + \nabla_y w_j(x,y,t)] \right\} = 0 \\ &\qquad\qquad\qquad\qquad \text{in } H^{-1}(\mathcal{Y}) \qquad \text{for a.e. } (x,t) \in \Omega_T, \end{aligned} \tag{6.5}$$

i.e., $\frac{\partial}{\partial y_\ell}\big\{k_{\ell m} \frac{\partial u}{\partial x_j}(\delta_{jm} + \frac{\partial w_j}{\partial y_m})\big\} = 0$, assuming that repeated indices are summed from 1 to 3 and denoting by $\{\delta_{jm}\}$ the 3×3 identity tensor. This equation is fulfilled whenever $w_1, \dots, w_3$ solve the following three families of *cell problems*:

$$\begin{aligned} &\nabla_y \cdot \big\{ K(u(x,t),x,y,t) \cdot [\vec{e}_j + \nabla_y w_j(x,y,t)] \big\} = 0 \\ &\text{in } H^{-1}(\mathcal{Y}) \qquad \text{for a.e. } (x,t) \in \Omega_T \text{ for } j = 1,2,3, \end{aligned} \tag{6.6}$$

i.e., $\frac{\partial}{\partial y_\ell}\big\{k_{\ell m}(\delta_{jm} + \frac{\partial w_j}{\partial y_m})\big\} = 0$. These linear elliptic problems have one and only one solution $w_1, \dots, w_3 \in L^2\big(\Omega_T; H^1(\mathcal{Y})\big)$ such that $\int_{\mathcal{Y}} w_j(\cdot,\cdot,y)dy = 0$ a.e. in Ω_T for $j = 1,2,3$. By integrating (6.5) over $\mathcal{Y}$, we then see that (6.4) is fulfilled if we define the tensor function K_0 with entries

$$\begin{aligned} k_{0ij}(v,x,t) &:= \int_{\mathcal{Y}} \vec{e}_i \cdot K(v,x,y,t) \cdot [\vec{e}_j + \nabla_y w_j(x,y,t)]\, dy \\ &= \int_{\mathcal{Y}} [\vec{e}_i + \nabla_y w_i(x,y,t)] \cdot K(v,x,y,t) \cdot [\vec{e}_j + \nabla_y w_j(x,y,t)]\, dy \\ &= \int_{\mathcal{Y}} \left[\delta_{i\ell} + \frac{\partial w_i}{\partial y_\ell}(x,y,t)\right] k_{\ell m}(v,x,y,t) \left[\delta_{jm} + \frac{\partial w_j}{\partial y_m}(x,y,t)\right] dy \end{aligned} \tag{6.7}$$

(still with the sum convention) for any $v \in \mathbf{R}$, a.e. $(x,t) \in \Omega_T$, and $i,j = 1,2,3$.

Next let us consider two special cases. If $K(v,x,y,t)$ might be factorized in the form

$$K(v,x,y,t) = K_1(v) \cdot K_2(x,y,t) \qquad \forall v \in \mathbf{R} \text{ for a.e. } (x,y,t) \in \Omega_T \times \mathcal{Y}, \tag{6.8}$$

then the problems (6.6) would be reduced to three families of cell problems that are independent of the function u:

$$\begin{aligned} &\nabla_y \cdot \big\{ K_2(x,y,t) \cdot [\vec{e}_j + \nabla_y w_j(x,y,t)] \big\} = 0 \\ &\text{in } H^{-1}(\mathcal{Y}) \qquad \text{for a.e. } (x,t) \in \Omega_T \text{ for } j = 1,2,3. \end{aligned} \tag{6.9}$$

Finally, if

$$K(v,x,y,t) = K_3(v,x,t) \cdot K_4(y) \qquad \forall v \in \mathbf{R} \text{ for a.e. } (x,y,t) \in \Omega_T \times \mathcal{Y}, \tag{6.10}$$

then the w_j's would be independent of (x,t) and the problems (6.6) would be reduced to three linear problems in the cell $\mathcal{Y}$:

$$\nabla_y \cdot \big\{ K_4(y) \cdot [\vec{e}_j + \nabla_y w_j(y)] \big\} = 0 \qquad \text{in } H^{-1}(\mathcal{Y}) \text{ for } j = 1,2,3. \tag{6.11}$$

The reader will notice that the problems (6.9) and (6.11) are independent of the solution u, at variance with (6.6). Moreover, the three linear problems (6.11) do not contain the parameters (x,t), at variance with (6.9). One may thus solve them once for all and then use the w_j's to construct the homogenized conductivity tensor K_0 via (6.7).

Remarks. (i) The tensor K_0 is symmetric whenever K is; however, the nondiagonal elements of K_0 need not vanish even if K is a diagonal tensor. An anisotropic medium may thus be the outcome of the homogenization of an isotropic one: this is quite natural, for the fine-scale arrangement need not be isotropic.

(ii) The tensor K need not be symmetric; namely, the function $\vec{v} \mapsto K \cdot \vec{v}$ need not be cyclically monotone. Nevertheless, Theorem 5.4 and Corollary 5.5 hold also in this case, with (6.4) and (6.7) in place of (5.9) in Problem 5.1.

(iii) If K is independent of the temperature, then Problem 3.1_ε is reduced to the weak formulation of the multidimensional extension of the Stefan problem. The same applies to the single-scale homogenized Problem 5.1 if (5.9) is replaced by (6.4) and (6.7).

(iv) If $K = k(y)I$ (k being a positive scalar function), we thus retrieve the results of [38].

The Kirchhoff transformation. For an isotropic and homogeneous material in the Fourier law (1.8), we have $K(u,x) = k(u)I$. In this case a simple but powerful tool for handling the heat balance equation is provided by the classical *Kirchhoff transformation*

$$\mathcal{K} : u \mapsto U := \int_0^u k(\xi)\, d\xi \tag{6.12}$$

that reduces (1.8) to a linear relation: $\vec{q} = -\nabla U$. Because of the strict monotonicity of the operator $\mathcal{K}$, (1.2) may be rewritten in the form $w \in \partial\tilde{\varphi}(U,x)$, where $\tilde{\varphi}(\cdot,x)$ is strictly convex whenever $\varphi(\cdot,x)$ is. One might then equivalently formulate the system (1.1)–(1.3) in terms of the triplet $(U,w,\vec{q})$ and thus with a single nonlinearity. However, in this paper we were concerned with an inhomogeneous material and hence with a space-dependent conductivity: $k = k(u, x)$. In this case if both k and $\nabla_x k(\cdot, x)$ were uniformly bounded, then one might still deal with a weak solution via the above transformation. But the boundedness of $\nabla_x k(\cdot, x)$ would exclude composite materials, which were our main concern; this author does not see how the Kirchhoff transformation might be used here without severe restrictions.

This transformation may also be extended to a class of anisotropic materials as follows. If

$$K(u,x) = G(x)h(u), \quad \text{i.e.,} \quad k_{ij}(u,x) = g_{ij}(x)h(u) \qquad \text{for } j = 1,2,3, \tag{6.13}$$

with $G = \{g_{ij}\}$ a positive-definite tensor function and h a positive real function, then

$$\vec{q} = -G(x)h(u) \cdot \nabla u = -G(x) \cdot \nabla V, \quad \text{where} \quad V := \int_0^u h(\xi)\, d\xi. \tag{6.14}$$

Equation (1.1) then reads

$$\frac{\partial w}{\partial t} - \nabla \cdot [G(x) \cdot \nabla V] = f \qquad \text{in } \mathcal{D}'(\Omega_T), \tag{6.15}$$

and V and w are related by a subdifferential condition analogous to (1.2), so that the developments of this paper are easily extended. This latter setting fits the framework that was already addressed in [17, 38].

Phase-dependent conductivity. The latter formulation also applies if the function h is discontinuous. As the phase depends discontinuously on the temperature, this approach may also be used in the physically relevant case in which the heat conductivity of the two phases are different, provided that the temperature u_* of phase equilibrium is independent of x.

More specifically, denoting by $\tilde{\phi}$ the pointwise content of latent heat (that we denoted by $L(x)$), the function $\phi := \tilde{\phi}/L(x)$ characterizes the phase, for

$$\phi = 0 \ \text{ in the solid phase}, \quad 0 < \phi < 1 \ \text{ in the mushy region}, \quad \phi = 1 \ \text{ in the liquid phase}. \tag{6.16}$$

Thus $\phi \in \tilde{H}(u - u_*)$ a.e. in Ω_T, with $\tilde{H}$ being the Heaviside graph:

$$\tilde{H}(v) = \{0\} \qquad \forall v \le 0, \qquad \tilde{H}(0) = [0,1], \qquad \tilde{H}(v) = \{1\} \qquad \forall v > 0. \tag{6.17}$$

If K can be factorized in the form

$$K(u,x) = G(x)h(u,\phi) \qquad \text{a.e. in } \Omega_T, \tag{6.18}$$

then $K(u,x) \in G(x)h(u, \tilde{H}(u - u_*))$ a.e. in Ω_T. Assuming that u_* is differentiable and setting

$$V := \int_0^u h(\xi, \tilde{H}(\xi - u_*))\, d\xi \qquad \forall u \in \mathbf{R}, \tag{6.19}$$

a simple computation yields $\nabla V = [h(u_*, 0) - h(u_*, 1)]\nabla u_* + h(u, \tilde{H}(u - u_*))\nabla u$. The Fourier law (1.8) then reads

$$\vec{q} = -h(u,\phi)G(x) \cdot \nabla u = -G(x) \cdot \nabla V + G(x) \cdot [h(u_*, 0) - h(u_*, 1)]\nabla u_* \qquad \text{a.e. in } \Omega_T. \tag{6.20}$$

The analysis of this work may thus easily be extended to this setting.

On the other hand, if $K(u,x)$ cannot be factorized as in (6.18), it is not clear how existence of a weak solution might be proved. Open questions also include the extension of the downscaling result, i.e., Theorem 5.4, to a noncyclically monotone function $\vec{\alpha}$.

Generalizations. Another class of doubly nonlinear parabolic problems also seems of interest:

$$w + \nabla \cdot \vec{q} = f \qquad \text{in } \mathcal{D}'(\Omega_T), \tag{6.21}$$

$$w \in \beta(\partial u/\partial t, x) \qquad \text{a.e. in } \Omega_T, \tag{6.22}$$

$$\vec{q} = \partial\psi(-\nabla u, u, x) \qquad \text{a.e. in } \Omega_T, \tag{6.23}$$

here with $\beta : \mathbf{R} \times \Omega \to \mathbf{R}$ and $\psi : \mathbf{R}^3 \times \mathbf{R} \times \Omega \to \mathbf{R} \cup \{+\infty\}$. (Notice the exchanged role of the subdifferential and of the maximal monotone function here and in (1.1)–(1.3).) Existence of a solution for associated initial- and boundary-value problems were studied in several works; see, e.g., [5, 34, 35, 78]. The homogenization of this system might be treated via techniques analogous to those of this work.

The developments of this paper might be extended in several directions. For instance, one might insert a relaxation dynamics into the phase evolution equation (1.2) and/or into the nonlinear conduction law (1.3):

$$\frac{\partial w}{\partial t} + w \in \partial\varphi(u, x, t) \qquad \text{a.e. in } \Omega_T, \tag{6.24}$$

$$\frac{\partial \vec{q}}{\partial t} + \vec{q} = \vec{\alpha}(-\nabla u, u, x, t) \qquad \text{a.e. in } \Omega_T. \tag{6.25}$$

The latter is a nonlinear extension of the classical Cattaneo–Fourier law. Existence of a weak solution is known for either case; see, e.g., [78]; the homogenization is less obvious but might be performed via techniques of [83].

It might also be of applicative interest to extend the present analysis to the homogenization of phase transitions in binary mixtures, to account for two time scales, and to homogenize a nonperiodic medium.

ERRATUM: "GLOBAL SOLUTIONS OF NONLINEAR TRANSPORT EQUATIONS FOR CHEMOSENSITIVE MOVEMENT" [SIAM J. MATH. ANAL. 36 (2005), PP. 1177–1199]*

HYUNG JU HWANG†, KYUNGKEUN KANG‡, AND ANGELA STEVENS§

Abstract. The purpose of this erratum is to correct Assumption 4.2 in [H. J. Hwang, K. Kang, and A. Stevens, *SIAM J. Math. Anal.*, 36 (2005), pp. 1177–1199]. We also modify some errors caused by the incorrectly stated assumption.

Key words. chemosensitive movement, drift-diffusion limit, Keller-Segel model

AMS subject classifications. 35K55, 45K05, 82C70, 92C17

DOI. 10.1137/070680813

First we correct Assumption 4.2 ([2], p. 1191, lines 3–4) by adding condition (0.3) given below

$$\phi_\epsilon^S[S] \geq \gamma \left(1 - \epsilon\Lambda(\|\nabla S\|_{W^{1,\infty}(\mathbb{R}^3)})\right) FF', \tag{0.1}$$

$$\int_V \frac{\phi_\epsilon^A[S]^2}{F\phi_\epsilon^S[S]} dv' \leq \epsilon^2 \Lambda\left(\|\nabla S\|_{W^{1,\infty}(\mathbb{R}^3)}\right), \tag{0.2}$$

$$\left\| \frac{(\nabla\phi_\epsilon^S[S])^2}{\phi_\epsilon^S[S]} \right\|_{L^{\frac{q}{2}}(\mathbb{R}^3)} + \left\| \frac{(\nabla\phi_\epsilon^A[S])^2}{\phi_\epsilon^S[S]} \right\|_{L^{\frac{q}{2}}(\mathbb{R}^3)} \leq C\epsilon^2 \|\nabla S\|^2_{W^{2,q}(\mathbb{R}^3)}, \quad 2 \leq q \leq \infty, \tag{0.3}$$

where $\phi_\epsilon^S[S]$ and $\phi_\epsilon^A[S]$ denote the symmetric and antisymmetric parts of the turning kernel, respectively, i.e., $\phi_\epsilon^S := \frac{1}{2}\left(T_\epsilon[S]F' + T_\epsilon^*[S]F\right)$ and $\phi_\epsilon^A := \frac{1}{2}\left(T_\epsilon[S]F' + T_\epsilon^*[S]F\right)$, and $\Lambda \in L^\infty_{\text{loc}}([0,\infty))$ is a nondecreasing function. Here F indicates a bounded velocity distribution satisfying (A0) in [1, p. 128, lines 18–23]. In what follows, we suppose, for simplicity, that the bounded velocity distribution fulfills $F = 1$. These conditions (0.1)–(0.3) hold for the example

$$T_\epsilon[S] = C + h\left(S(x+\epsilon v,t) - S(x-\epsilon v',t)\right) + h\left(\nabla S(x+\epsilon v,t) - \nabla S(x-\epsilon v',t)\right), \tag{0.4}$$

where $C > 0$ and h is a nonnegative and differentiable function satisfying $|h'(x)| \leq M$ and $C_1|x| \leq h(x) \leq C_2|x|$ for some $C_2 > C_1 > 0$ (see the appendix for details).

Our main purpose of this erratum is to fix the error in the proof of Theorem 4.3 in [2], where the estimate of ∇S ([2], p. 1191, line 5 from the bottom) is not correct. Here we consider only the case $\tau = 0, n = 3$, and $\beta = 0$. For the other cases similar arguments work.

Assume for the initial data $f_\epsilon^0, \nabla_x f_\epsilon^0 \in L^q(V \times \mathbb{R}^3)$. Our model equation is

$$\frac{\partial}{\partial t} f_\epsilon + \frac{1}{\epsilon} v \cdot \nabla_x f_\epsilon = -\frac{1}{\epsilon^2}\mathcal{T}[S_\epsilon](f_\epsilon), \tag{0.5}$$

with

$$\mathcal{T}[S_\epsilon](f_\epsilon) = -\int_V \left(T[S_\epsilon]f'_\epsilon - T^*[S_\epsilon]f_\epsilon\right) dv'.$$

Let $q > 3$. Multiplying (0.5) with f_ϵ^{q-1} and integrating over $\mathbb{R}^3 \times V$, we obtain

$$\begin{aligned}
&\frac{1}{q}\frac{d}{dt}\int_{\mathbb{R}^3}\int_V f_\epsilon^q dv dx + \frac{1}{4\epsilon^2}\int_{\mathbb{R}^3}\int_V\int_V \phi_\epsilon^S[S](f_\epsilon - f'_\epsilon)\left(f^{q-1} - (f')^{q-1}\right) dv' dv dx \\
&\quad \le \frac{1}{4\epsilon^2}\int_{\mathbb{R}^3}\int_V\int_V \frac{\phi_\epsilon^A[S]^2}{\phi_\epsilon^S[S]}\frac{(f_\epsilon + f'_\epsilon)^2\left(f_\epsilon\left|f_\epsilon\right|^{q-2} - f'_\epsilon\left|f'_\epsilon\right|^{q-2}\right)}{f_\epsilon - f'_\epsilon} dv' dv dx \\
&\le C_q\Lambda\left(\left\|\nabla S_\epsilon\right\|_{W^{1,\infty}(\mathbb{R}^3)}\right)\int_{\mathbb{R}^3}\int_V f_\epsilon^q dv dx \le C_q\Lambda\left(\left\|\nabla f_\epsilon\right\|_{L^q(V\times\mathbb{R}^3)}\right)\int_{\mathbb{R}^3}\int_V f_\epsilon^q dv dx.
\end{aligned}$$

Here (0.1), (0.2), and Lemma 1 in [1, p. 129] are used, and $\left\|\nabla S_\epsilon\right\|_{W^{1,\infty}(\mathbb{R}^3)} \le C\left\|\nabla\rho_\epsilon\right\|_{L^q(\mathbb{R}^3)} \le C\left\|\nabla f_\epsilon\right\|_{L^q(V\times\mathbb{R}^3)}$. Therefore, we obtain

$$\frac{d}{dt}\left\|f_\epsilon\right\|^q_{L^q(V\times\mathbb{R}^3)} \le C_q\Lambda\left(\left\|\nabla f_\epsilon\right\|_{L^q(V\times\mathbb{R}^3)}\right)\left\|f_\epsilon\right\|^q_{L^q(V\times\mathbb{R}^3)}. \tag{0.6}$$

Now set $g_\epsilon = \partial_{x_j} f_\epsilon$, $j = 1, 2, 3$. Differentiating (0.5) with respect to x_j, we get

$$\frac{\partial}{\partial t}g_\epsilon + \frac{1}{\epsilon}v\cdot\nabla_x g_\epsilon = -\frac{1}{\epsilon^2}\mathcal{T}[S_\epsilon](g_\epsilon) - \frac{1}{\epsilon^2}\left(\partial_{x_j}\mathcal{T}[S_\epsilon]\right)(f_\epsilon),$$

where

$$\left(\partial_{x_j}\mathcal{T}[S_\epsilon]\right)(f_\epsilon) = -\int_V\left[\left(\partial_{x_j}T[S_\epsilon]\right)f'_\epsilon - \left(\partial_{x_j}T^*[S_\epsilon]\right)f_\epsilon\right] dv'.$$

Let $q > 3$. Multiplying with $\left|g_\epsilon\right|^{q-2} g_\epsilon$ and integrating over $\mathbb{R}^3 \times V$, we have

$$\begin{aligned}
\frac{1}{q}\frac{d}{dt}\int_{\mathbb{R}^3}\int_V \left|g_\epsilon\right|^q &= -\frac{1}{\epsilon^2}\int_{\mathbb{R}^3}\int_V \mathcal{T}[S_\epsilon](g_\epsilon)\left|g_\epsilon\right|^{q-2} g_\epsilon - \frac{1}{\epsilon^2}\int_{\mathbb{R}^3}\int_V\left(\partial_{x_j}\mathcal{T}[S_\epsilon]\right)(f_\epsilon)\left|g_\epsilon\right|^{q-2} g_\epsilon \\
&:= \mathrm{I} + \mathrm{II}.
\end{aligned}$$

Using again Lemma 1 in [1, p. 129], we note that I can be written as

$$\begin{aligned}
\mathrm{I} = &-\frac{1}{2\epsilon^2}\int_{\mathbb{R}^3}\int_V\int_V \phi_\epsilon^S[S](g_\epsilon - g'_\epsilon)\left(g_\epsilon\left|g_\epsilon\right|^{q-2} - g'_\epsilon\left|g'_\epsilon\right|^{q-2}\right) dv' dv dx \\
&+ \frac{1}{2\epsilon^2}\int_{\mathbb{R}^3}\int_V\int_V \phi_\epsilon^A[S](g_\epsilon + g'_\epsilon)\left(g_\epsilon\left|g_\epsilon\right|^{q-2} - g'_\epsilon\left|g'_\epsilon\right|^{q-2}\right) dv' dv dx.
\end{aligned}$$

Following a similar procedure as before, we obtain

$$\begin{aligned}
\mathrm{I} \le &-\frac{1}{4\epsilon^2}\int_{\mathbb{R}^3}\int_V\int_V \phi_\epsilon^S[S](g_\epsilon - g'_\epsilon)\left(g_\epsilon\left|g_\epsilon\right|^{q-2} - g'_\epsilon\left|g'_\epsilon\right|^{q-2}\right) dv' dv dx \\
&+ C_q\left\|\nabla f_\epsilon\right\|_{L^q(\mathbb{R}^3\times V)}\int_{\mathbb{R}^3}\int_V \left|g_\epsilon\right|^q dv dx. \qquad (0.7)
\end{aligned}$$

Next we estimate II:

$$\begin{aligned}
\mathrm{II} = &-\frac{1}{2\epsilon^2}\int_{\mathbb{R}^3}\int_V\int_V \left(\partial_{x_j}\phi_\epsilon^S[S]\right)(f_\epsilon - f'_\epsilon)\left(g_\epsilon\,|g_\epsilon|^{q-2} - g'_\epsilon\,|g'_\epsilon|^{q-2}\right) dv'dvdx \\
&+ \frac{1}{2\epsilon^2}\int_{\mathbb{R}^3}\int_V\int_V \left(\partial_{x_j}\phi_\epsilon^A[S]\right)(f_\epsilon + f'_\epsilon)\left(g_\epsilon\,|g_\epsilon|^{q-2} - g'_\epsilon\,|g'_\epsilon|^{q-2}\right) dv'dvdx \\
&\le \frac{1}{8\epsilon^2}\int_{\mathbb{R}^3}\int_V\int_V \phi_\epsilon^S[S](g_\epsilon - g'_\epsilon)\left(g_\epsilon\,|g_\epsilon|^{q-2} - g'_\epsilon\,|g'_\epsilon|^{q-2}\right) dv'dvdx \\
&+ \frac{1}{\epsilon^2}\int_{\mathbb{R}^3}\int_V\int_V \frac{\left(\partial_{x_j}\phi_\epsilon^S[S]\right)^2}{\phi_\epsilon^S[S]}(f_\epsilon - f'_\epsilon)^2\left|\frac{\left(g_\epsilon\,|g_\epsilon|^{q-2} - g'_\epsilon\,|g'_\epsilon|^{q-2}\right)}{g-g'}\right| dv'dvdx \\
&+ \frac{1}{\epsilon^2}\int_{\mathbb{R}^3}\int_V\int_V \frac{\left(\partial_{x_j}\phi_\epsilon^A[S]\right)^2}{\phi_\epsilon^S[S]}(f_\epsilon + f'_\epsilon)^2\left|\frac{\left(g_\epsilon\,|g_\epsilon|^{q-2} - g'_\epsilon\,|g'_\epsilon|^{q-2}\right)}{g-g'}\right| dv'dvdx \\
&\le \frac{1}{8\epsilon^2}\int_{\mathbb{R}^3}\int_V\int_V \phi_\epsilon^S[S](g_\epsilon - g'_\epsilon)\left(g_\epsilon\,|g_\epsilon|^{q-2} - g'_\epsilon\,|g'_\epsilon|^{q-2}\right) dv'dvdx \\
&+ \frac{C_q}{\epsilon^2}\int_{\mathbb{R}^3}\int_V\int_V \left(\frac{\left(\partial_{x_j}\phi_\epsilon^S[S]\right)^2}{\phi_\epsilon^S[S]} + \frac{\left(\partial_{x_j}\phi_\epsilon^A[S]\right)^2}{\phi_\epsilon^S[S]}\right)\left({f_\epsilon}^2 + {f'_\epsilon}^2\right)\left(|g_\epsilon|^{q-2} + |g'_\epsilon|^{q-2}\right) dv'dvdx.
\end{aligned}$$

For the last term, interchanging the order of integration and utilizing (0.3), Hölder's inequality, using the potential estimate for S_ϵ (see, e.g., [2, Lemma 4.1]), and Sobolev's embedding theorem, we can estimate

$$\begin{aligned}
&\frac{1}{\epsilon^2}\int_{\mathbb{R}^3}\int_V\int_V \left(\frac{\left(\partial_{x_j}\phi_\epsilon^S[S]\right)^2}{\phi_\epsilon^S[S]} + \frac{\left(\partial_{x_j}\phi_\epsilon^A[S]\right)^2}{\phi_\epsilon^S[S]}\right)\left(f_\epsilon^2 + {f'_\epsilon}^2\right)\left(|g_\epsilon|^{q-2} + |g'_\epsilon|^{q-2}\right) dv'dvdx \\
&= \frac{1}{\epsilon^2}\int_V\int_V\int_{\mathbb{R}^3} \left(\frac{\left(\partial_{x_j}\phi_\epsilon^S[S]\right)^2}{\phi_\epsilon^S[S]} + \frac{\left(\partial_{x_j}\phi_\epsilon^A[S]\right)^2}{\phi_\epsilon^S[S]}\right)\left({f_\epsilon}^2 + {f'_\epsilon}^2\right)\left(|g_\epsilon|^{q-2} + |g'_\epsilon|^{q-2}\right) dxdv'dv \\
&\quad\le \frac{1}{\epsilon^2}\int_V\int_V \|f_\epsilon + f'_\epsilon\|^2_{L^\infty(\mathbb{R}^3)}\left\|\left(\frac{\left(\partial_{x_j}\phi_\epsilon^S[S]\right)^2}{\phi_\epsilon^S[S]}\right) + \left(\frac{\left(\partial_{x_j}\phi_\epsilon^A[S]\right)^2}{\phi_\epsilon^S[S]}\right)\right\|_{L^{\frac{q}{2}}(\mathbb{R}^3)} \\
&\quad\times \|(|g_\epsilon| + |g'_\epsilon|)\|^{q-2}_{L^q(\mathbb{R}^3)}\,dv'dv \\
&\quad\le C\,\|\nabla S_\epsilon\|^2_{W^{2,q}(\mathbb{R}^3)}\int_V\int_V \|f_\epsilon + f'_\epsilon\|^2_{W^{1,q}(\mathbb{R}^3)}\,\|(|g_\epsilon| + |g'_\epsilon|)\|^{q-2}_{L^q(\mathbb{R}^3)}\,dv'dv \\
&\quad\le C\,\|\nabla\rho_\epsilon\|^2_{L^q(\mathbb{R}^3)}\left(\|f_\epsilon\|^2_{L^q(V\times\mathbb{R}^3)} + \|\nabla f_\epsilon\|^2_{L^q(V\times\mathbb{R}^3)}\right)\|g_\epsilon\|^{q-2}_{L^q(V\times\mathbb{R}^3)} \\
&\quad\le C_q\left(\|f_\epsilon\|^{q+2}_{L^q(V\times\mathbb{R}^3)} + \|\nabla f_\epsilon\|^{q+2}_{L^q(V\times\mathbb{R}^3)}\right).
\end{aligned}$$

Summing up, we obtain

$$\begin{aligned}
\frac{1}{q}\frac{d}{dt}\int_{\mathbb{R}^3}\int_V |g_\epsilon|^q + \frac{1}{8\epsilon^2}\int_{\mathbb{R}^3}\int_V\int_V \phi_\epsilon^S[S](g_\epsilon - g'_\epsilon)\left(g_\epsilon\,|g_\epsilon|^{q-2} - g'_\epsilon\,|g'_\epsilon|^{q-2}\right) dv'dvdx \\
\le C_q\left(\|f_\epsilon\|^{q+2}_{L^q(V\times\mathbb{R}^3)} + \|\nabla f_\epsilon\|^{q+2}_{L^q(V\times\mathbb{R}^3)}\right).
\end{aligned}$$

The second term on the left-hand side of the above inequality is nonnegative, so it can be omitted. Adding up for $j = 1, 2, 3$, we obtain

$$\frac{d}{dt}\|\nabla f_\epsilon\|^q_{L^q(V\times\mathbb{R}^3)} \le C_q\left(\|f_\epsilon\|^{q+2}_{L^q(V\times\mathbb{R}^3)} + \|\nabla f_\epsilon\|^{q+2}_{L^q(V\times\mathbb{R}^3)}\right). \tag{0.8}$$

Let $X(t) := \|f_\epsilon\|^q_{L^q(V\times\mathbb{R}^3)} + \|\nabla f_\epsilon\|^q_{L^q(V\times\mathbb{R}^3)}$. Combining (0.6) and (0.8), we get

$$X'(t) \le C\Lambda\left(X^{\frac{1}{q}}(t)\right)X(t) + X^{\frac{q+2}{q}}(t).$$

Since $\Lambda \in L^\infty_{\text{loc}}([0,\infty))$, the above inequality ensures a short time existence of solutions, independent of ϵ. This completes the correction of the proof of Theorem 4.3.

On p. 1195 of [2] the following assumption has to be added between lines 4 and 5 from the bottom:

$$\left\|\frac{(\nabla\phi^S_\epsilon[S])^2}{\phi^S_\epsilon[S]}\right\|_{L^{\frac{q}{2}}(\mathbb{R}^3)} + \left\|\frac{(\nabla\phi^A_\epsilon[S])^2}{\phi^S_\epsilon[S]}\right\|_{L^{\frac{q}{2}}(\mathbb{R}^3)} \le C\epsilon^2\|\nabla S\|^2_{W^{2,q}(\mathbb{R}^3)}, \quad 2 \le q \le \infty.$$

Appendix. Here we show that the turning kernel (0.4) satisfies (0.1)–(0.3). Conditions (0.1) and (0.2) are straightforward. To show condition (0.3), denote for simplicity

$$\begin{aligned} S_v &:= S(x+\epsilon v) - S(x-\epsilon v'), & S_{v'} &:= S(x+\epsilon v') - S(x-\epsilon v),\\ \nabla S_v &:= \nabla S(x+\epsilon v) - \nabla S(x-\epsilon v'), & \nabla S_{v'} &:= \nabla S(x+\epsilon v') - \nabla S(x-\epsilon v). \end{aligned}$$

The symmetric and antisymmetric parts are given by

$$\begin{aligned} \phi^S_\epsilon[S] &= C + \frac{1}{2}\left(h(S_v) + h(S_{v'}) + h(\nabla S_v) + h(\nabla S_{v'})\right),\\ \phi^A_\epsilon[S] &= \frac{1}{2}\left(h(S_v) - h(S_{v'}) + h(\nabla S_v) - h(\nabla S_{v'})\right). \end{aligned}$$

Taking the derivative with respect to the x-variable, we get

$$\begin{aligned} \nabla\phi^S_\epsilon[S] &= \frac{1}{2}\left(h'(S_v)\nabla S_v + h'(S_{v'})\nabla S_{v'} + h'(\nabla S_v)\nabla^2 S_v + h'(\nabla S_{v'})\nabla^2 S_{V'}\right),\\ \nabla\phi^A_\epsilon[S] &= \frac{1}{2}\left(h'(S_v)\nabla S_v - h'(S_{v'})\nabla S_{v'} + h'(\nabla S_v)\nabla^2 S_v - h'(\nabla S_{v'})\nabla^2 S_{V'}\right). \end{aligned}$$

By means of the mean value theorem, we have

$$\begin{aligned} \nabla S_v &= \epsilon(v-v')\nabla^2 S\left(x+\epsilon\theta_1 v - \epsilon(1-\theta_1)v'\right), & 0 \le \theta_1 \le 1,\\ \nabla S_{v'} &= \epsilon(v'-v)\nabla^2 S\left(x+\epsilon\theta_2 v' - \epsilon(1-\theta_2)v\right), & 0 \le \theta_2 \le 1,\\ \nabla^2 S_v &= \epsilon(v-v')\nabla^3 S\left(x+\epsilon\theta_3 v - \epsilon(1-\theta_3)v'\right), & 0 \le \theta_3 \le 1,\\ \nabla^2 S_v &= \epsilon(v-v')\nabla^3 S\left(x+\epsilon\theta_4 v - \epsilon(1-\theta_4)v'\right), & 0 \le \theta_4 \le 1. \end{aligned}$$

Therefore, since $\|h'\|_{L^\infty} < M$ with a fixed constant M, we obtain

$$\left\|\frac{(\nabla\phi^S_\epsilon[S])^2}{\phi^S_\epsilon[S]}\right\|_{L^{\frac{q}{2}}(\mathbb{R}^3)} \le C\epsilon^2\left(\int_{\mathbb{R}^3}\left|\nabla^2 S\right|^q + \left|\nabla^3 S\right|^q dx\right)^{\frac{2}{q}} \le C\epsilon^2\|\nabla S\|^2_{W^{2,q}(\mathbb{R}^3)}.$$

The estimate for $\nabla\phi^A_\epsilon[S]$ follows by a similar procedure.

STABILITY AND BIFURCATION ANALYSIS OF VOLTERRA FUNCTIONAL EQUATIONS IN THE LIGHT OF SUNS AND STARS*

ODO DIEKMANN†, PHILIPP GETTO‡, AND MATS GYLLENBERG§

Abstract. We show that the perturbation theory for dual semigroups (sun-star-calculus) that has proved useful for analyzing delay-differential equations is equally efficient for dealing with Volterra functional equations. In particular, we obtain both the stability and instability parts of the principle of linearized stability and the Hopf bifurcation theorem. Our results apply to situations in which the instability part has not been proved before. In applications to general physiologically structured populations even the stability part is new.

Key words. delay equations, dual semigroup, sun-star-calculus, Lipschitz perturbations, principle of linearized stability, center manifold, Hopf bifurcation, physiologically structured populations

1. Introduction.

Delay equations are rules for extending (in one direction) a function that is a priori defined on an interval. Usually, as in the books [23, 40], one considers delay *differential* equations of the type

$$\dot{x}(t) = F(x_t), \quad t \geq 0, \tag{1.1}$$

where, for some given $h > 0$,

$$x_t(\theta) := x(t + \theta) \tag{1.2}$$

for $\theta \in [-h, 0]$. Here, in contrast, we consider functional equations of Volterra type, so the extension rule prescribes the value of the function itself, rather than that of its derivative, in terms of the history. We thus study initial value problems of the form

$$x(t) = F(x_t), \quad t > 0, \tag{DE}$$

$$x_0(\theta) = \varphi(\theta), \quad \theta \in [-h, 0], \tag{IC}$$

with φ being a given function on $[-h, 0]$. The formula labels (DE), (IC) stand for delay equation and initial condition, respectively.

In [23], the main tool for analyzing the delay differential equation (1.1) is the perturbation theory for dual semigroups developed in [9, 10, 11, 12, 20], which under appropriate assumptions transforms the Cauchy problem (1.1) and (IC) into an abstract *semilinear* problem. This theory has proved to be equally efficient for treating

age-structured population models; see [9, 11] and various exercises in [23]. The aim of this paper is to show in detail that the same theory applies to functional equations of Volterra type (DE), the only difference being the choice of the underlying function space.

To give a feeling for the problems involved, we make a few formal manipulations. Let

$$u(t,\theta) := x_t(\theta), \quad t \geq 0,\ -h \leq \theta \leq 0. \tag{1.3}$$

The problem (DE), (IC) is equivalent to the following PDE with boundary and initial conditions:

$$\frac{\partial u}{\partial t} - \frac{\partial u}{\partial \theta} = 0, \quad t > 0,\ -h \leq \theta \leq 0, \tag{1.4}$$

$$u(t,0) = F(u(t,\cdot)), \quad t \geq 0, \tag{1.5}$$

$$u(0,\theta) = \varphi(\theta), \quad -h \leq \theta \leq 0. \tag{1.6}$$

If $F = 0$, the problem reduces to an elementary linear problem. Its solution semigroup $T_0 = \{T_0(t)\}_{t\geq 0}$ is simply translation to the left with extension by zero:

$$(T_0(t)\varphi)(\theta) := \begin{cases} \varphi(t+\theta) & \text{for} \quad t+\theta \in [-h,0], \\ 0 & \text{for} \quad t+\theta > 0, \end{cases} \qquad t \geq 0,\ \theta \in [-h,0]. \tag{1.7}$$

Next we have to specify the state space (history space) on which the semigroup T_0 acts. The continuous functions will not do, because as can be seen from (1.7), $C[-h,0]$ is not invariant under T_0. A natural choice is $X = L^1[-h,0]$. With this choice of state space, the generator A_0 of T_0 is differentiation with the zero boundary condition entering into the domain of definition:

$$\mathcal{D}(A_0) = \{\varphi \in X : \varphi \in AC,\ \varphi(0) = 0\}, \tag{1.8}$$

$$A_0\varphi = \varphi', \tag{1.9}$$

where the notation $\varphi \in AC$ means that φ is absolutely continuous [2, p. 11].

The nonlinear problem (1.4)–(1.6) with $F \neq 0$ can now be written as the abstract Cauchy problem

$$\frac{du(t)}{dt} = A(u(t))u(t), \quad t > 0, \tag{1.10}$$

$$u(0) = \varphi \tag{1.11}$$

for $u(t) := u(t,\cdot) = x_t$, where the action of $A(u(t))$ is still differentiation, but the domain depends on the solution itself in a nonlinear way:

$$\mathcal{D}(A(u(t))) = \{\varphi \in X : \varphi \in AC, \varphi(0) = F(u(t))\}. \tag{1.12}$$

So the problem is *quasi-linear* and hence notoriously difficult [49]. A small trick, however, turns the quasi-linear problem into a *semilinear* one, that is, a problem in which the nonlinearity appears as an additive and relatively bounded perturbation of the linear operator A_0. Next we explain how this is done.

The space $L^1[-h,0]$ can be embedded into $\mathrm{NBV}(-h,0]$, the space of functions of bounded variation on $(-h,0]$ normalized to be zero at zero and continuous from the right, by integration $j : L^1[-h,0] \to \mathrm{NBV}(-h,0]$,

$$(j\varphi)(\theta) := -\int_\theta^0 \varphi(\tau)d\tau, \quad \theta \in (-h,0]. \tag{1.13}$$

The image of $L^1[-h,0]$ in $\mathrm{NBV}(-h,0]$ under j consists of all functions absolutely continuous on $[-h,0]$ and vanishing at 0 [46, sections IX. 2–4].

Integrating (1.4) from θ to 0 and taking the boundary condition (1.5) into account, one obtains the semilinear problem

$$\frac{d}{dt} ju(t) = A_0^{\odot *} ju(t) + F(u(t))H, \quad t > 0, \tag{1.14}$$

$$u(0) = \varphi, \tag{1.15}$$

where the operator $A_0^{\odot *}$ is differentiation on $\mathrm{NBV}(-h,0]$ with appropriate domain of definition (the $\odot *$-notation will be explained in section 2) and H is a Heaviside function defined by

$$H(\theta) := \begin{cases} -1 & \text{for} \quad \theta \in (-h,0), \\ 0 & \text{for} \quad \theta = 0. \end{cases} \tag{1.16}$$

The price one has to pay for the transformation of the quasi-linear problem into a semilinear one is that, while the unknown $u(t) = x_t$ belongs to $L^1[-h,0]$, the range of the perturbation lies in the bigger space $\mathrm{NBV}(-h,0]$ and actually outside $j\left(L^1[-h,0]\right)$ (note that $H \in \mathrm{NBV}(-h,0]$, but because of the discontinuity in 0 it is not absolutely continuous). The perturbation theory mentioned above was designed especially to have a general framework for such problems.

A key step is to replace the Cauchy problem (1.14) and (1.15) by an abstract integral equation of the variation-of-constants type, which is obtained from (1.14) and (1.15) by formal integration. The main point is that, in fact, this abstract integral equation is equivalent to the original problem (DE), (IC), while at the same time, it allows us to prove linearized stability and other properties in a standard manner. As these proofs are provided in detail in [23], we can concentrate here on the equivalence. Note, however, that in the present paper we shall always explicitly express the embedding operator j, while in [23] it is often suppressed with the understanding that one can identify X and $X^{\odot\odot}$ once and for all.

The mathematics of age-structured populations mentioned above has been extensively treated, for instance, in the books [17, 56]. Our main motivation comes from the theory of general physiologically structured populations [24, 25, 27, 45]. Individuals are distinguished from one another by their i-state (i for individual), which belongs to a measurable space Ω. The population state (p-state) is a measure m on Ω giving the distribution of i-states. Deterministic structured population models are defined in terms of ingredients prescribing i-state specific survival, reproduction, and i-state development, given the course of the *environmental condition* (or *input*) $I(t)$ and a feedback mechanism, which often is of the form

$$I(t) = \int_\Omega \gamma(\xi) m(t)(d\xi). \tag{1.17}$$

From the basic ingredients one can calculate the quantities $\mathcal{F}_{I_{|[t-a,t]}}(\xi,\omega)$ and $\lambda_{I_{|[t-a,t]}}(\xi,\omega)$ with the following interpretations: Let I be a given function of time, let $\xi \in \Omega$, and let ω be a measurable subset of Ω. Then we have the following.

- $\mathcal{F}_{I_{|[t-a,t]}}(\xi,\omega)$ is the probability that an individual who was born at time $t-a$ with i-state ξ is still alive at time t (when it has age a) and then has i-state in ω.
- $\lambda_{I_{|[t-a,t]}}(\xi,\omega)$ is the rate at which an individual who was born at time $t-a$ with i-state ξ produces offspring with state-at-birth in ω at time t (when it has age a).

The subscripts $I_{|[t-a,t]}$ of $\mathcal{F}$ and λ indicate that the quantities depend on the restriction of I to the interval $[t-a,t]$; that is, they depend only on the values of I during the lifetime of the individual in question.

Let $b(t)(\omega)$ denote the rate at which individuals are born with i-state in ω at time t. Assuming a maximal life span h, bookkeeping gives

$$b(t)(\omega) = \int_0^h \int_\Omega b(t-a)(d\xi)\lambda_{I_{|[t-a,t]}}(\xi,\omega)da, \tag{1.18}$$

$$m(t)(\omega) = \int_0^h \int_\Omega b(t-a)(d\xi)\mathcal{F}_{I_{|[t-a,t]}}(\xi,\omega)da. \tag{1.19}$$

Thus in this generality one has an abstract variant of (DE).

Often there is but one possible state-at-birth. Or, in particular when dealing with several interacting populations, there may be a finite number of possible states-at-birth. In such cases one may limit ω in (1.18) to points chosen from a finite set. If, in addition, $I(t)$ in (1.17) has only finitely many components, we can condense the essential information concerning the population problem into a finite dimensional equation (DE). Indeed, combining (1.18) and (1.19) with the feedback law (1.17), one finds that the value

$$x(t) = \begin{pmatrix} b(t) \\ I(t) \end{pmatrix} \tag{1.20}$$

is a nonlinear function of the history of x on $[t-h,t]$; that is, x satisfies a delay equation of the form (DE), with F being a function from $L^1\big([-h,0],\mathbf{R}^N\big)$ to $\mathbf{R}^N$ for some integer $N \geq 2$.

The population dynamical applications also motivate our choice of $L^1\left([-h,0],\mathbf{R}^N\right)$ as the history space. The components of b are *rates* at which individuals are born with certain i-states. While rates may be unbounded, *numbers* of individuals (integrals of rates) must remain finite.

The idea to use the history of I is new. The fact that in this manner we can use perturbation theory for dual semigroups to treat *general* physiologically structured population models, and not just age-structured models, triggered the writing of this paper. In a companion paper, to be written jointly with J. A. J. Metz, we shall elaborate in detail how the results of the present paper apply to population models.

In the present paper we shall consider only the case of finite delay. The reason is that in this case the semigroup defined by (1.7) has a desirable property called sun-reflexivity, which is lost in the case of infinite delay. However, our results can easily be extended to also encompass the case of infinite delay. In section 6 we briefly indicate how this can be done.

In this paper we follow a top-down approach. We start in section 2 by presenting the abstract perturbation theory for dual semigroups and then we formulate the principle of linearized stability which says that, under appropriate assumptions, local (in)stability of a steady state is completely determined by the spectral properties of the generator of the linearized semigroup. Under the extra assumption of finite dimensional range of the nonlinear perturbation G, we derive a characteristic equation, the roots of which are the spectral values of the generator of the linearized semigroup. We then give results on the stable, unstable, and center manifolds and on Hopf bifurcation. The results of section 2 are either known or slight modifications of known results. In section 3 we then specialize to the system (DE), (IC) and the associated unperturbed semigroup T_0 defined by (1.7) and verify that the assumptions made in section 2 indeed hold true. Models of structured populations often lead to delay equations coupled with delay differential equations. In section 4 we therefore consider such coupled systems. In section 5 we illustrate our theoretical results by two examples from population dynamics. We conclude in section 6 by relating our results to results by other authors and by discussing directions for future work.

2. Lipschitz perturbations in the sun-reflexive case. We start by briefly recalling the basic facts about dual semigroups. The books [4, 42, 47] are good general references, as are Chapter III and Appendix II of [23]. The theory of nonlinear Lipschitz continuous perturbations of generators of dual semigroups was first introduced in [11], where the principle of linearized stability was proved following [19]. The treatment of the stable, unstable, and center manifolds and of Hopf bifurcation follows [23].

2.1. Sun-reflexive dual semigroups. Let X be a real Banach space and $T_0 := \{T_0(t)\}_{t\geq 0}$ be a strongly continuous (i.e., the orbit $t \mapsto T_0(t)\varphi$ is continuous with respect to the norm topology on X for all initial values $\varphi \in X$) semigroup of bounded linear operators on X with infinitesimal generator A_0. Then $T_0^* := \{T_0^*(t)\}_{t\geq 0}$, where $T_0^*(t) : X^* \to X^*$ is the adjoint of $T_0(t)$, is a semigroup on the dual space X^* of X. T_0^* is called the *adjoint* or *dual* semigroup of T_0. If X is not reflexive, then T^* need not be strongly continuous. All one can say in general is that the orbits are continuous with respect to the weak* topology of X. At the level of generators this is reflected in the fact that the adjoint A_0^* of A_0 need not have dense domain and that A_0^* is the weak*-generator of T_0^*.

The maximal invariant subspace of X^* on which T_0^* is strongly continuous is denoted by $X^{\odot}$, that is,

$$X^{\odot} := \left\{ \varphi^* \in X^* : \lim_{t\downarrow 0} \|T_0^*(t)\varphi^* - \varphi^*\| = 0 \right\}. \tag{2.1}$$

Note that this so-called sun-subspace depends on the dynamical system one considers on the original space. It is known that

$$X^{\odot} = \overline{D(A_0^*)}, \tag{2.2}$$

where the bar denotes closure with respect to the norm topology of X^*. The operators $T_0^*(t)$, $t \geq 0$, leave $X^{\odot}$ invariant, and the restriction $T_0^{\odot}(t) := T_0^*(t)|_{X^{\odot}}$ of T_0^* to $X^{\odot}$ is a strongly continuous semigroup and its generator $A_0^{\odot}$ is the part of A_0^* in $X^{\odot}$; that is,

$$\mathcal{D}(A_0^{\odot}) := \{\varphi^{\odot} \in \mathcal{D}(A_0^*) : A_0^*\varphi^{\odot} \in X^{\odot}\}, \tag{2.3}$$

$$A_0^{\odot}\varphi^{\odot} := A_0^*\varphi^{\odot}. \tag{2.4}$$

We now have on $X^\odot$ exactly the same situation as we had on X at the outset. So in self-explanatory notation we obtain $X^{\odot *}$, $T_0^{\odot *}$, $A_0^{\odot *}$ and $X^{\odot\odot}$, $T_0^{\odot\odot}$, $A_0^{\odot\odot}$.

As usual, we denote the duality pairing between a Banach space X and its normed dual X^* by $\langle \cdot, \cdot \rangle$; that is, for $\varphi \in X$, $\varphi^* \in X^*$ we write $\langle \varphi, \varphi^* \rangle$ instead of $\varphi^*(\varphi)$. The formula

$$\langle \varphi^\odot, j\varphi \rangle = \langle \varphi, \varphi^\odot \rangle, \quad \varphi \in X, \ \varphi^\odot \in X^\odot \tag{2.5}$$

defines an embedding j of X into $X^{\odot *}$, the range of which lies in $X^{\odot\odot}$. Moreover, one has $T_0^{\odot *}(t)j = jT_0(t)$ for $t \geq 0$.

Definition 2.1. *A Banach space X is called* sun-reflexive *with respect to the strongly continuous linear semigroup T_0 if*

$$j(X) = X^{\odot\odot}.$$

From now on we shall always assume that X is sun-reflexive with respect to the unperturbed semigroup T_0.

2.2. Lipschitz perturbations and the nonlinear semigroup. Let $G : X \to X^{\odot *}$ be a nonlinear operator. The initial value problem

$$\frac{dju}{dt}(t) = A_0^{\odot *} ju(t) + G(u(t)), \quad t > 0, \tag{2.6}$$

$$u(0) = \varphi, \tag{2.7}$$

where u is an X-valued function, can be formally integrated to yield the abstract integral equation

$$u(t) = T_0(t)\varphi + j^{-1}\left(\int_0^t T_0^{\odot *}(t-s) G(u(s)) ds \right), \tag{AIE}$$

but we have to verify that the integral does indeed belong to $j(X)$.

The integral in (AIE) is to be interpreted in the weak*-sense. More precisely, if Z is a Banach space and $f : [a, b] \to Z^*$ is weakly*-continuous, then $\int_a^b f(t)dt$ is defined as the continuous linear functional on Z which takes $z \in Z$ to $\int_a^b \langle z, f(t) \rangle dt$. Note that $\int_a^b f(t)dt$ is an element of Z^*. For weak* integrals of the form

$$v(t) = \int_0^t T_0^{\odot *}(t-s) f(s) ds,$$

we have the following desirable result.

Proposition 2.2 (see [9, Theorem 3.2]). *If f is weakly*-continuous, then v is weakly*-continuous with values in $X^{\odot *}$. If f is norm continuous, then v is norm continuous as well and takes values in $X^{\odot\odot}$.*

We now consider (AIE). If G is globally Lipschitz continuous, then standard contraction mapping arguments yield existence and uniqueness of a solution $u(\cdot\,; \varphi) : \mathbf{R}_+ \to X$ of (AIE) for every $\varphi \in X$. The formula

$$\Sigma(t)\varphi := u(t; \varphi), \quad t \geq 0, \ \varphi \in X, \tag{2.8}$$

defines a strongly continuous nonlinear semigroup Σ on X. The generator of Σ, which we denote by C, is defined exactly as in the linear case: Its domain $\mathcal{D}(C)$ is the set of all $\varphi \in X$ for which the limit $\lim_{t\downarrow 0}(\Sigma(t)\varphi - \varphi)/t$ exists in the norm topology of X and $C\varphi$ is equal to this limit. The weak* generator $C^\times$ of Σ is defined as follows: $\varphi \in X$ belongs to $\mathcal{D}(C^\times)$ if $(j\Sigma(t)\varphi - j\varphi)/t$ converges to some $\varphi^{\odot *} \in X^{\odot *}$ as $t \downarrow 0$ and in this case $C^\times\varphi = \varphi^{\odot *}$.

THEOREM 2.3 (see [11, Theorems 3.2–3.6]).

(a) *$j\left(\mathcal{D}(C^\times)\right) = \mathcal{D}(A_0^{\odot *})$ and $C^\times\varphi = A_0^{\odot *}j\varphi + G(\varphi)$.*

(b) *C is the part of $C^\times$ in X, that is,*

$$\mathcal{D}(C) = \left\{\varphi \in X : \varphi \in \mathcal{D}(C^\times),\ C^\times\varphi \in j(X)\right\},$$

$$C\varphi = j^{-1}\left(C^\times\varphi\right).$$

(c) *If $\varphi \in \mathcal{D}(C)$ and if G is continuously Fréchet differentiable, then $t \mapsto u(t;\varphi) = \Sigma(t)\varphi$ is continuously differentiable and*

$$\frac{d}{dt}u(t;\varphi) = j^{-1}\left(A_0^{\odot *}ju(t;\varphi) + G(u(t;\varphi))\right).$$

2.3. Linearization around a steady state. In what follows we assume that the nonlinear operator $G : X \to X^{\odot *}$ is continuously Fréchet differentiable.

Assume that $\overline{\varphi} \in X$ is a steady state of the nonlinear dynamical system; that is,

$$\Sigma(t)\overline{\varphi} = \overline{\varphi} \tag{2.9}$$

for all $t \geq 0$. Equivalently, $j\overline{\varphi} \in \mathcal{D}(A_0^{\odot *})$ and

$$A_0^{\odot *}j\overline{\varphi} + G(\overline{\varphi}) = 0; \tag{2.10}$$

cf. Theorem 2.3(c). Because $G : X \to X^{\odot *}$ is Fréchet differentiable at $\overline{\varphi}$, its Fréchet derivative $B := G'(\overline{\varphi})$ is a bounded linear operator from X to $X^{\odot *}$. Formal linearization of (AIE) yields the following linear abstract integral equation:

$$T(t)\varphi = T_0(t)\varphi + j^{-1}\left(\int_0^t T_0^{\odot *}(t-\tau)BT(\tau)\varphi d\tau\right). \tag{LAIE}$$

For such equations the following result is known.

THEOREM 2.4 (see [9]). *The linear abstract integral equation* (LAIE) *uniquely defines a strongly continuous semigroup $T = \{T(t)\}_{t\geq 0}$ of bounded linear operators with generator A given by*

$$\mathcal{D}(A) = \{\varphi \in X : j\varphi \in \mathcal{D}(A_0^{\odot *}), A_0^{\odot *}j\varphi + B\varphi \in j(X)\},$$

$$A\varphi = j^{-1}(A_0^{\odot *}j\varphi + B\varphi).$$

That the formal linearization yields the desired result is the content of the following theorem.

THEOREM 2.5 (see [11]). *Let* (2.9) *hold and assume that the nonlinear operator $G : X \to X^{\odot *}$ is continuously Fréchet differentiable. Then for every $t > 0$ the nonlinear operator $\Sigma(t)$ is Fréchet differentiable at $\overline{\varphi}$. Its Fréchet derivative*

$$T(t) = (D\Sigma(t))(\overline{\varphi}) \tag{2.11}$$

defines a strongly continuous semigroup of bounded linear operators with generator A given by

$$\mathcal{D}(A) = \{\varphi \in X : j\varphi \in \mathcal{D}(A_0^{\odot *}), A_0^{\odot *}j\varphi + G'(\overline{\varphi})\varphi \in j(X)\},$$

$$A\varphi = j^{-1}(A_0^{\odot *}j\varphi + G'(\overline{\varphi})\varphi).$$

Moreover, for every $\varphi \in X$, $T(t)\varphi$ is the unique solution of (LAIE) *with $B = G'(\overline{\varphi})$.*

2.4. Eventual compactness and spectral analysis of the linearized semigroup. In subsection 2.6 we shall deal with criteria for the stability of a steady state. As is well known from the theory of ordinary differential equations (ODEs), *spectral analysis* of the linearized system is a most efficient tool for investigating stability. Therefore we shall in this subsection analyze the spectrum of the generator A of the semigroup T defined by (LAIE).

Our original nonlinear problem is meaningful only for *real* Banach spaces, whereas spectral analysis requires complex scalars. We therefore have to complexify X before doing spectral analysis. In the infinite dimensional case and, in particular, in our sun-star-framework, this is not a trivial task. We shall, however, omit the details because they can all be found in [23, section III.7].

As usual, we denote the resolvent set and the spectrum of a linear operator L by $\varrho(L)$ and $\sigma(L)$, respectively. The point spectrum of L, that is, the set of eigenvalues of L, is denoted by $P\sigma(L)$. The identity operator is denoted by E (to follow the tradition of Hilbert [14, formula (8), p. 5] and to avoid confusion with the input I of (1.17)), and Laplace transformation is denoted by $\widehat{\ }$:

$$\widehat{f}(\lambda) = \int_0^\infty e^{-\lambda t} f(t)dt. \tag{2.12}$$

$R(\lambda, L)$ denotes the *resolvent operator* of L:

$$R(\lambda, L) := (\lambda E - L)^{-1}, \quad \lambda \in \varrho(L). \tag{2.13}$$

Recall that $\lambda \mapsto R(\lambda, L)$ is a holomorphic operator-valued function on $\varrho(L)$. As for complex valued functions, an operator-valued function is *entire* if it is holomorphic in the whole complex plane.

The *growth bound* $\omega_0(T)$ of a semigroup T is defined by

$$\omega_0(T) = \inf\{\omega \in \mathbf{R} : \exists M_\omega \geq 1 \text{ such that } \|T(t)\| \leq M_\omega e^{\omega t} \text{ for all } t \geq 0\},$$

and the *spectral bound* $s(A)$ of its generator A is defined by

$$s(A) = \sup\{\operatorname{Re}\lambda : \lambda \in \sigma(A)\}.$$

One has $\sigma(A) = \sigma(A^*) = \sigma(A^\odot) = \sigma(A^{\odot *})$, $s(A) = s(A^*) = s(A^\odot) = s(A^{\odot *})$, and $\omega_0(T) = \omega_0(T^*) = \omega_0(T^\odot) = \omega_0(T^{\odot *})$ [26, Proposition 2.18, p. 262].

We start by characterizing the part of the point spectrum which belongs to $\varrho(A_0)$.

PROPOSITION 2.6. *Let A be the generator of the semigroup T defined by* (LAIE); *cf. Theorem 2.4. Then $\lambda \in \varrho(A_0)$ is an eigenvalue of A if and only if 1 is an eigenvalue of $j^{-1}R(\lambda, A_0^{\odot *})B$ and the corresponding eigenvectors are the same.*

Proof. Let $\psi \in X$. Using Theorem 2.4 we see that in the following sequence of identities, each implies both the preceding and the next one:

$$j^{-1}R(\lambda, A_0^{\odot *})B\psi = \psi,$$

$$j\psi \in \mathcal{D}(A_0^{\odot *}) \quad \text{and} \quad B\psi = \left(\lambda E - A_0^{\odot *}\right) j\psi,$$

$$j\psi \in \mathcal{D}(A_0^{\odot *}) \quad \text{and} \quad A_0^{\odot *} j\psi + B\psi = \lambda j\psi,$$

$$j\psi \in \mathcal{D}(A_0^{\odot *}) \quad \text{and} \quad j^{-1}\left(A_0^{\odot *} j\psi + B\psi\right) = \lambda\psi,$$

$$\psi \in \mathcal{D}(A) \quad \text{and} \quad A\psi = \lambda\psi. \qquad \square$$

If the semigroup T is *eventually compact*, that is, if the operators $T(t)$ are compact for all t greater than some $t_0 \geq 0$, then spectral analysis becomes as easy as one can possibly expect from an infinite dimensional system.

THEOREM 2.7. *Let A generate an eventually compact C_0-semigroup T on the Banach space X. Then*

$$\sigma(A) = P\sigma(A),$$

$$s(A) = \omega_0(T),$$

and every $\lambda \in \sigma(A)$ is a pole of the resolvent $R(\lambda, A)$ of finite algebraic multiplicity. Every right half-plane $\{\lambda \in \mathbf{C} : \alpha \leq \operatorname{Re}\lambda\}$ $(-\infty < \alpha)$ contains at most finitely many eigenvalues of A.

For a proof of this well-known result, see, e.g., [2, Theorem 2.1, p. 209].

Next we give a criterion for the eventual compactness of the perturbed semigroup which is easy to check and which applies to all our applications.

THEOREM 2.8. *Let T_0 be an eventually compact C_0-semigroup and let $B : X \to X^{\odot *}$ be compact. Then the C_0-semigroup T defined by* (LAIE) *is eventually compact.*

The corresponding result for the case in which B maps X into X is known [26, Proposition 1.14, p. 166], but Theorem 2.8 does not seem to have been stated in the literature yet. We therefore give a complete proof in the appendix.

2.5. Perturbations with finite dimensional range. If, as in the case of the delay problem (DE), (IC), the nonlinear perturbation G has finite dimensional range in $X^{\odot *}$, much of the analysis becomes considerably simpler, in fact, essentially finite dimensional. We therefore have a closer look at this special case. So let $G : X \to X^{\odot *}$ have the form

$$G(\varphi) = \sum_{i=1}^{N} F_i(\varphi) r_i^{\odot *}, \quad \varphi \in X, \tag{2.14}$$

where $F = (F_1, F_2, \ldots, F_N)$ is a mapping from X to $\mathbf{R}^N$ and $\{r_1^{\odot *}, r_2^{\odot *}, \ldots, r_N^{\odot *}\}$ is a linearly independent set in $X^{\odot *}$.

Note. In what follows we shall use the letter j both as a summation index and, as before, to denote the canonical embedding of X into $X^{\odot *}$, sometimes even in the same formula. This should not lead to any misunderstanding.

Clearly G is Fréchet differentiable at $\overline{\varphi}$ if and only if F is Fréchet differentiable at $\overline{\varphi}$, which is the case if and only if all the components F_i are Fréchet differentiable at $\overline{\varphi}$. So when G is Fréchet differentiable at $\overline{\varphi}$, there exist elements $r_1^*, r_2^*, \ldots, r_N^*$ of X^* such that the derivative $G'(\overline{\varphi})$ is the linear operator $B : X \to X^{\odot *}$ given by

$$B\varphi = \sum_{i=1}^{N} \langle \varphi, r_i^* \rangle r_i^{\odot *}, \quad \varphi \in X. \tag{2.15}$$

In order to exploit the finite dimensional structure of the perturbation we define

$$r_i(\lambda) = j^{-1} R(\lambda, A_0^{\odot *}) r_i^{\odot *}, \quad \lambda \in \varrho(A_0), \tag{2.16}$$

$$r_i^{\odot}(\lambda) = R(\lambda, A_0^*) r_i^*, \quad \lambda \in \varrho(A_0), \tag{2.17}$$

and let $M(\lambda)$ be the matrix with entries

$$M_{ij}(\lambda) = \langle r_j(\lambda), r_i^* \rangle, \quad \lambda \in \varrho(A_0). \tag{2.18}$$

Note that the matrix-valued function M is defined in $\varrho(A_0)$ only. When the real part of λ is greater than the growth bound of T_0, we can express $r_i(\lambda)$ and $r_i^{\odot}(\lambda)$ using the Laplace transform representation of the resolvent [26, Theorem 1.10, p. 55]:

$$r_i(\lambda) = j^{-1} \int_0^\infty e^{-\lambda t} T_0^{\odot *}(t) r_i^{\odot *} dt, \quad \operatorname{Re}\lambda > \omega_0(T_0), \tag{2.19}$$

$$r_i^{\odot}(\lambda) = \int_0^\infty e^{-\lambda t} T_0^*(t) r_i^* dt, \quad \operatorname{Re}\lambda > \omega_0(T_0). \tag{2.20}$$

We start with a few lemmas.

LEMMA 2.9. *Let M be the matrix-valued function defined by* (2.18). *Then*

$$M_{ij}(\lambda) = \left\langle r_i^{\odot}(\lambda), r_j^{\odot *} \right\rangle, \quad \lambda \in \varrho(A_0). \tag{2.21}$$

Proof. We first prove the claim for $\operatorname{Re}\lambda > \omega_0(T_0)$ using the representations (2.19) and (2.20). If $r_i^* \in X^{\odot}$, the equality of the right-hand sides of (2.18) and (2.21) is clear from the definition of the weak*-integral. Next we approximate r_i^* by

$$\varphi_s^{\odot} = \frac{1}{s} \int_0^s T_0^*(\tau) r_i^* d\tau, \quad s > 0.$$

It follows from Proposition 2.2 (just interchange the roles of X and $X^{\odot}$) that $\varphi_s^{\odot} \in X^{\odot}$ for all $s > 0$. By the observation made above, one has

$$\left\langle j^{-1} \int_0^\infty e^{-\lambda t} T_0^{\odot *}(t) r_i^{\odot *} dt, \varphi_s^{\odot} \right\rangle = \left\langle \int_0^\infty e^{-\lambda t} T_0^{\odot}(t) \varphi_s^{\odot} dt, r_i^{\odot *} \right\rangle \tag{2.22}$$

for all $s > 0$. A straightforward calculation (see the proof of Lemma 2.17 in [23, p. 61] for a very similar case) shows that the left-hand side of (2.22) converges to (2.18) and that the right-hand side of (2.22) converges to the right-hand side of (2.21). This proves the assertion for the case $\operatorname{Re}\lambda > \omega_0(T_0)$. The general case follows from the resolvent identity. ∎

When B has finite dimensional range we get a more detailed description of the point spectrum of A than we do in Proposition 2.6.

LEMMA 2.10. *Let A be the generator of the semigroup T defined by* (LAIE) *and assume that B has the form* (2.15). *If $\lambda \in \varrho(A_0)$ and $\psi \in X$, then*

$$A\psi = \lambda\psi \tag{2.23}$$

if and only if

$$\psi = \sum_{i=1}^N c_i r_i(\lambda), \tag{2.24}$$

where the coefficients c_i are the components of a vector c satisfying

$$M(\lambda)c = c \tag{2.25}$$

and $M(\lambda)$ *is the matrix defined by* (2.18).

Proof. By Proposition 2.6, $A\psi = \psi$ if and only if

$$j^{-1}R(\lambda, A_0^{\odot *})B\psi = \psi. \tag{2.26}$$

Because the vectors $r_1^{\odot *}, r_2^{\odot *}, \dots, r_N^{\odot *}$ are linearly independent and $j^{-1}R(\lambda, A_0^{\odot *})$ is one-to-one, the definition (2.16) shows that also the vectors $r_1(\lambda), r_2(\lambda), \dots, r_N(\lambda)$ are linearly independent. Equation (2.26) shows that ψ belongs to the subspace spanned by the vectors $r_i(\lambda)$, $i = 1, 2, \dots, N$; that is, ψ is of the form (2.24). Substituting (2.24) into (2.26), one obtains (2.25). ☐

The following dual version of Lemma 2.10 is proved analogously.

LEMMA 2.11. *Let A be the generator of the semigroup T defined by* (LAIE) *and assume that B has the form* (2.15). *If $\lambda \in \varrho(A_0)$ and $\psi^\odot \in X^\odot$, then*

$$A^*\psi^\odot = \lambda\psi^\odot \tag{2.27}$$

if and only if

$$\psi^\odot = \sum_{i=1}^{N} d_i r_i^\odot(\lambda), \tag{2.28}$$

where the coefficients d_i are the components of a row vector d satisfying

$$dM(\lambda) = d \tag{2.29}$$

and $M(\lambda)$ *is the matrix defined by* (2.18).

LEMMA 2.12. *The mapping $\lambda \mapsto \langle r_j(\lambda), r_i^*\rangle$ is holomorphic in $\varrho(A_0)$ and*

$$\frac{d}{d\lambda}\langle r_j(\lambda), r_i^*\rangle = -\left\langle r_j(\lambda), r_i^\odot(\lambda)\right\rangle, \quad \lambda \in \varrho(A_0). \tag{2.30}$$

Proof. Using the resolvent identity, one finds that

$$\begin{aligned}\frac{1}{\lambda-\mu}\left(\langle r_j(\lambda), r_i^*\rangle - \langle r_j(\mu), r_i^*\rangle\right) &= -\left\langle j^{-1}R(\lambda, A_0^{\odot *})R(\mu, A_0^{\odot *})r_j^{\odot *}, r_i^*\right\rangle \\ &= -\left\langle j^{-1}R(\mu, A_0^{\odot *})r_j^{\odot *}, R(\lambda, A_0^*)r_i^*\right\rangle \\ &= -\left\langle r_j(\mu), r_i^\odot(\lambda)\right\rangle,\end{aligned}$$

which proves the assertion. ☐

As a direct consequence of the three preceding lemmas we obtain the following result.

COROLLARY 2.13. *The matrix-valued function $\lambda \mapsto M(\lambda)$ is holomorphic in $\varrho(A_0)$, and if λ is an eigenvalue of A with eigenvector ψ and adjoint eigenvector $\psi^\odot$, then*

$$\left\langle \psi, \psi^\odot\right\rangle = -dM'(\lambda)c, \quad \lambda \in \varrho(A_0), \tag{2.31}$$

where c and d are as described in Lemmas 2.10 *and* 2.11, *respectively.*

Corollary 2.13 provides a convenient criterion for the simplicity of an eigenvalue, which we shall use in the context of the Hopf bifurcation theorem to be treated in subsection 2.8. In the present subsection we shall show that when B has finite dimensional range, there exists a so-called characteristic equation, the roots of which are the eigenvalues of the generator of the perturbed semigroup. It turns out that the order of λ as a root of the characteristic equation equals the algebraic multiplicity of λ as an eigenvalue of A. An easy way to show this is to use the theory of Weinstein–Aronszajn determinants; see [43, section IV.6] for an account of the general theory and [22] for an application to perturbed dual semigroups. Before we can present the Weinstein–Aronszajn formula we have to define the multiplicity functions for closed operators and meromorphic functions.

Let L be a closed operator in a Banach space. For every isolated point λ of $\sigma(L)$ we denote the spectral projection onto the corresponding generalized eigenspace by P_λ. The *multiplicity function* $\widetilde{\nu}(\lambda, L)$ of L is defined as

$$\widetilde{\nu}(\lambda, L) = \begin{cases} 0 & \text{if } \lambda \in \varrho(L), \\ \dim \mathcal{R}(P_\lambda) & \text{if } \lambda \text{ is an isolated point of } \sigma(L), \\ \infty & \text{in all other cases.} \end{cases} \tag{2.32}$$

The multiplicity function of a (numerical) meromorphic function f is defined as

$$\nu(\lambda, f) = \begin{cases} k & \text{if } \lambda \text{ is a zero of order } k \text{ of } f, \\ -k & \text{if } \lambda \text{ is a pole of order } k \text{ of } f, \\ 0 & \text{otherwise.} \end{cases} \tag{2.33}$$

THEOREM 2.14 (Weinstein–Aronszajn formula). *Let A be the generator of the semigroup T defined by* (LAIE), *assume that B has the form* (2.15), *and let $M(\lambda)$ be the matrix-valued function defined in* (2.18). *Then*

$$\widetilde{\nu}(\lambda, A) = \widetilde{\nu}(\lambda, A_0) + \nu\left(\lambda, \det\left(E - M(\lambda)\right)\right). \tag{2.34}$$

Proof. Because B has finite dimensional range one can unambiguously define the so-called Weinstein–Aronszajn determinant $\det\left(E - BR\left(\lambda, A_0^{\odot *}\right)\right)$ as the determinant of the restriction of $E - BR\left(\lambda, A_0^{\odot *}\right)$ to $\mathcal{R}(B)$. The definition of M together with Lemma 2.9 shows that

$$\det\left(E - BR\left(\lambda, A_0^{\odot *}\right)\right) = \det\left(E - M(\lambda)\right).$$

The Weinstein–Aronszajn formula [43, Theorem IV.6.2] now yields

$$\widetilde{\nu}(\lambda, A^{\odot *}) = \widetilde{\nu}(\lambda, A_0^{\odot *}) + \nu\left(\lambda, \det\left(E - M(\lambda)\right)\right). \tag{2.35}$$

But A_0 (resp., A) is the part of $A_0^{\odot *}$ (resp., $A^{\odot *}$) in $j(X)$, and hence it follows from [26, Lemma 1.15, p. 245 and Proposition 2.17, p. 261] that

$$\widetilde{\nu}(\lambda, A_0^{\odot *}) = \widetilde{\nu}(\lambda, A_0),$$

$$\widetilde{\nu}(\lambda, A^{\odot *}) = \widetilde{\nu}(\lambda, A),$$

from which the conclusion (2.34) follows. ∎

We are now ready to prove the following theorem.

THEOREM 2.15. *Let A be the generator of the semigroup T defined by* (LAIE). *Suppose that B has the form* (2.15) *and let M be the corresponding matrix-valued function defined by* (2.18). *Then $\lambda \in \varrho(A_0)$ is in $\sigma(A)$ if and only if*

$$\det(E - M(\lambda)) = 0, \tag{2.36}$$

where E denotes the $N \times N$ identity matrix. Moreover, when this is the case, λ belongs to $P\sigma(A)$ and the algebraic multiplicity of λ equals the order of λ as a root of (2.36).

In particular, if $\sigma(A_0) = \emptyset$, then

$$\sigma(A) = P\sigma(A) = \{\lambda \in \mathbf{C} : \det(E - M(\lambda)) = 0\}. \tag{2.37}$$

Proof. Taking the Laplace transform of (LAIE), one obtains

$$R(\lambda, A) = R(\lambda, A_0) + j^{-1}R(\lambda, A_0^{\odot *})BR(\lambda, A)$$

or

$$\left(E - j^{-1}R(\lambda, A_0^{\odot *})B\right) R(\lambda, A) = R(\lambda, A_0). \tag{2.38}$$

From (2.38) we deduce that if $\lambda \in \varrho(A_0)$, then $\lambda \in \sigma(A)$ if and only if

$$E - j^{-1}R(\lambda, A_0^{\odot *})B$$

is not invertible. But because $j^{-1}R(\lambda, A_0^{\odot *})B$ is a bounded linear operator $X \to X$ with finite dimensional range, this is the case if and only if 1 is an eigenvalue of $j^{-1}R(\lambda, A_0^{\odot *})B$. According to Proposition 2.6, this in turn is equivalent to λ being an eigenvalue of A, which by Lemma 2.10 is equivalent to 1 being an eigenvalue of $M(\lambda)$. This shows that $\lambda \in \sigma(A)$ if and only if λ is a root of (2.36) and that then $\lambda \in P\sigma(A)$.

Since $\widetilde{\nu}(\lambda, A_0)$ is zero, the assertion concerning the multiplicity of λ follows from Theorem 2.14.

The final assertion is obvious, because if $\sigma(A_0)$ is empty, then the basic assumption $\lambda \in \varrho(A_0)$ is automatically satisfied. □

Equation (2.36) is called the *characteristic equation*.

Remark 2.16. It was shown in [9, Lemma 5.1] that there exists a matrix-valued function $k \in L^\infty_{\text{loc}}(\mathbf{R}_+, \mathbf{R}^{N\times N})$ such that

$$\left\langle j^{-1}\left(\int_0^t T_0^{\odot *}(t-\tau)r_j^{\odot *}\eta(\tau)d\tau\right), r_i^*\right\rangle = \int_0^t k_{ij}(t-\tau)\eta(\tau)d\tau$$

for all $\eta \in L^1_{\text{loc}}(\mathbf{R}_+)$. From this it follows easily that

$$\widehat{k}(\lambda) = M(\lambda), \quad \lambda \in \varrho(A_0),$$

where M is the matrix-valued function defined by (2.18). The characteristic equation can thus be rewritten as

$$\det\left(E - \widehat{k}(\lambda)\right) = 0. \tag{2.39}$$

In subsection 3.4 we shall compute the matrix k explicitly in the concrete case connected to (DE).

Using properties of the Laplace transform and holomorphic functions (in particular, the Riemann–Lebesgue lemma and the fact that the zeros of holomorphic functions have no limit points) it is possible to prove directly (in the case $\sigma(A_0) = \emptyset$) that there are only finitely many eigenvalues in each right half-plane. But because we obtain this result from Theorem 2.7 in all our applications, we have refrained from stating it in Theorem 2.15.

As the proof of Theorem 2.15 shows, the existence of a characteristic equation depends on two facts: the analyticity in the whole complex plane of the resolvent of the generator A_0 of the unperturbed semigroup and the finite dimensionality of the range of the perturbation. We shall later encounter applications where $R(\lambda, A_0)$ has a simple pole at the origin. Anticipating this situation, we next show that the corresponding singularity of $R(\lambda, A)$ is removable and that we still get a characteristic equation.

THEOREM 2.17. *Let B be given by* (2.15) *and assume that*

$$R(\lambda, A_0^{\odot *}) = \frac{1}{\lambda} P H_1(\lambda) + (E - P) H_2(\lambda), \tag{2.40}$$

where $P : X^{\odot *} \to X^{\odot *}$ is a projection with finite dimensional range in $j(X)$, H_1 and H_2 are entire functions with values in $\mathcal{L}(X^{\odot *})$, and the range of $H_2(\lambda)$ is in $j(X)$. Then $\sigma(A) = P\sigma(A)$, and there exists an entire matrix-valued function Δ such that $\lambda \in \sigma(A)$ if and only if

$$\det \Delta(\lambda) = 0. \tag{2.41}$$

Proof. The assumption (2.40) implies that

$$j^{-1} R(\lambda, A_0^{\odot *}) B = \left(E - j^{-1} P j + \frac{1}{\lambda} j^{-1} P j \right) K(\lambda) \tag{2.42}$$

for the entire function K defined by

$$K(\lambda)\varphi = \sum_{i=1}^{N} \langle \varphi, r_i^* \rangle \, j^{-1} \left(P H_1(\lambda) + (E - P) H_2(\lambda) \right) r_i^{\odot *}$$

with values in the subspace of finite rank operators of $\mathcal{L}(X)$. It follows (cf. (2.38)) that

$$\begin{aligned} &\left(E - \left(E - j^{-1} P j + \frac{1}{\lambda} j^{-1} P j \right) K(\lambda) \right) R(\lambda, A) \\ &\qquad = j^{-1} \left(\frac{1}{\lambda} P H_1(\lambda) + (E - P) H_2(\lambda) \right) j. \end{aligned} \tag{2.43}$$

If one multiplies (2.43) by $E - j^{-1} P j + \lambda j^{-1} P j$, one obtains

$$(E - j^{-1} P j + \lambda j^{-1} P j - K(\lambda)) R(\lambda, A) = j^{-1} \left(P H_1(\lambda) + (E - P) H_2(\lambda) \right) j. \tag{2.44}$$

Because the right-hand side of (2.44) is entire, $R(\lambda, A)$ is holomorphic everywhere except at the points where $(E - j^{-1} P j + \lambda j^{-1} P j - K(\lambda))$ is not invertible. Because $j^{-1} P j - \lambda j^{-1} P j + K(\lambda)$ has finite dimensional range and is everywhere holomorphic, it follows as in the proof of Theorem 2.15 that there is an entire matrix $\Delta(\lambda)$ such that $(E - j^{-1} P j + \lambda j^{-1} P j - K(\lambda))$ is not invertible if and only if $\Delta(\lambda)$ is not invertible, that is, if and only if (2.41) holds. ∎

2.6. Linearized stability. Recall that a steady state $\overline{\varphi}$ of Σ is (locally) *stable* if for every $\varepsilon > 0$ there exists a $\delta > 0$ such that

$$\|\Sigma(t)\varphi - \overline{\varphi}\| \leq \varepsilon \quad \text{for all } t \geq 0$$

whenever $\|\varphi - \overline{\varphi}\| \leq \delta$. If $\overline{\varphi}$ is not stable, it is *unstable*. It is (locally) *exponentially stable* if there exist numbers $\delta > 0,\ K > 0,\ \alpha > 0$ such that

$$\|\Sigma(t)\varphi - \overline{\varphi}\| \leq Ke^{-\alpha t}, \quad t \geq 0,$$

for all φ with $\|\varphi - \overline{\varphi}\| \leq \delta$.

The next result is called the *principle of linearized stability.* It has two parts. The first states that if the growth bound of the linearized semigroup is negative, then the steady state is exponentially stable. The second part states that if the generator of the linearized semigroup has at least one eigenvalue of finite multiplicity with positive real part, then the steady state is not stable.

Theorem 2.18 (see [19], [11, Theorems 4.2 and 4.3], [23, Corollary 5.12]). *Let Σ be a strongly continuous nonlinear semigroup. Let $\overline{\varphi}$ be a steady state of Σ and assume that for each $t \geq 0$, $\Sigma(t)$ has a (uniform) Fréchet derivative $T(t)$ at $\overline{\varphi}$. Let A be the infinitesimal generator of T. Assume further that X admits a decomposition*

$$X = X_- \oplus X_+$$

into two $T(t)$-invariant subspaces X_- and X_+ such that

(i) *X_+ is finite dimensional,*

(ii) *the restriction of $T(t)$ to X_- converges exponentially to* 0 *as $t \to \infty$.*

Then $\overline{\varphi}$ is

(a) *(locally) exponentially stable if* $\operatorname{Re} \lambda < 0$ *for all $\lambda \in \sigma(A\big|_{X_+})$,*

(b) *unstable if there exists a $\lambda \in \sigma(A\big|_{X_+})$ with* $\operatorname{Re} \lambda > 0$.

Note that if $\omega_0(T) < 0$, then (i) and (ii) are satisfied with X_+ equal to the trivial subspace $\{0\}$, and hence $\overline{\varphi}$ is exponentially stable because $\sigma(A\big|_{X_+})$ is empty.

Theorem 2.5 shows that the differentiability assumption of Theorem 2.18 is indeed satisfied for the semigroup Σ generated by the abstract integral equation (AIE).

When applied to the nonlinear semigroup Σ generated by the abstract integral equation (AIE), Theorem 2.18 becomes particularly simple to apply if T_0 is eventually compact and $G'(\overline{\varphi})$ is compact (in particular if G has finite dimensional range). Indeed, Theorem 2.7 immediately implies the following corollary.

Corollary 2.19. *Assume that $G : X \to X^{\odot *}$ is continuously Fréchet differentiable. Let Σ be the nonlinear semigroup "generated" by* (AIE) *(i.e., defined through* (2.8)*) and let A be the generator of the linearized semigroup T as in Theorem* 2.5. *Let $\overline{\varphi}$ be a steady state of Σ.*

If T_0 is eventually compact and if $G'(\overline{\varphi})$ is compact, then $\overline{\varphi}$ is locally exponentially stable if all $\lambda \in \sigma(A)$ have real part less than zero, whereas if there exists at least one $\lambda \in \sigma(A)$ with positive real part, then $\overline{\varphi}$ is unstable.

Proof. By Theorem 2.8 T is eventually compact, and hence the growth bound equals the spectral bound (Theorem 2.7). Thus, if all $\lambda \in \sigma(A) = P\sigma(A)$ have negative real part, then $\omega_0(T) < 0$ and, as noted after Theorem 2.18, $\overline{\varphi}$ is exponentially stable. If there exists an eigenvalue with positive real part, there exist finitely many eigenvalues with positive real part, and they all have generalized eigenspaces of finite dimension (Theorem 2.7). Therefore there exists a decomposition as in Theorem 2.18

with X_+ finite dimensional and a $\lambda \in \sigma(A\big|_{X_+})$ with $\operatorname{Re}\lambda > 0$. An application of Theorem 2.18 completes the proof. $\square$

We close this section by applying a version of the argument principle [52, Theorem 10.43(a)], also known as Nyquist's theorem, to derive a very convenient criterion for the (in)stability of steady states in the case where the perturbation has finite dimensional range and we have a characteristic equation. Nyquist's theorem states that if the matrix-valued function k belongs to $L^1(\mathbf{R}_+)$ and satisfies $\det\big(E - \widehat{k}(i\omega)\big) \neq 0$ for all $\omega \in \mathbf{R}$, then the number of zeros of $\det\big(E - \widehat{k}(\lambda)\big)$ in the open right half-plane $\operatorname{Re}\lambda > 0$, counted according to their multiplicities, equals the index $\operatorname{Ind}_\Gamma(0)$ of the curve $\Gamma : \omega \mapsto \det\big(E - \widehat{k}(i\omega)\big)$, where ω runs from $+\infty$ to $-\infty$ [29, Theorem 6.3, p. 61]. Recall the geometrical interpretation of the index $\operatorname{Ind}_\Gamma(0)$: it is the number of times the curve Γ winds counterclockwise around the origin as ω runs from $+\infty$ to $-\infty$.

COROLLARY 2.20. *Assume in addition to the hypotheses of Corollary* 2.19 *that* T_0 *is nilpotent and that* G *has finite dimensional range. Let* $M(\lambda) = \widehat{k}(\lambda)$ *be the matrix-valued function as defined by* (2.18) *and Remark* 2.16 *and let* Γ *be the curve defined above. If the characteristic equation* (2.39) *has no roots on the imaginary axis, then* $\overline{\varphi}$ *is exponentially stable if* $\operatorname{Ind}_\Gamma(0) = 0$ *and unstable if* $\operatorname{Ind}_\Gamma(0) > 0$.

Proof. The nilpotency of T_0 implies that k has compact support and hence (being locally L^∞) belongs to $L^1(\mathbf{R}_+)$. The conclusion now follows from Nyquist's theorem. $\square$

The assumption that T_0 is nilpotent is much stronger than is actually needed, but it is a convenient assumption that is satisfied in many applications (including structured populations with a maximum individual life span). The key point is that when we extend the argument principle from integration along closed curves to integration along the imaginary axis, we need to control the behavior of the integrand at infinity. The assumption $k \in L^1$ makes the Riemann–Lebesgue lemma valid and gives an easy estimate of the behavior at infinity.

The stability criterion of Corollary 2.20 is easy to implement numerically and even graphically. By the Riemann–Lebesgue lemma, $\widehat{k}(i\omega)$ tends to 0 as $\omega \to \pm\infty$, and hence $\det\big(E - \widehat{k}(i\omega)\big)$ tends to 1 as $\omega \to \pm\infty$. Choose ω_0 so large that $\det\big(E - \widehat{k}(i\omega_0)\big)$ is close to 1 for $|\omega| > \omega_0$ and plot $\det\big(E - \widehat{k}(i\omega)\big)$ as ω runs from $+i\omega_0$ to $-i\omega_0$. If the plotted curve does not wind around the origin, then $\overline{\varphi}$ is exponentially stable; otherwise it is unstable. If the curve passes through the origin, the test does not give any information.

2.7. The unstable, stable, and center manifolds. It is possible to give a more detailed description of the behavior near an unstable steady state. For the linearized semigroup, one has, provided that the characteristic equation has no roots on the imaginary axis, a direct sum spectral decomposition into a finite dimensional unstable subspace X_+ and an infinite dimensional stable subspace X_-. On X_+ one can go backwards in time. As a matter of fact, X_+ is *characterized* by the property that the orbit through a point in X_+ can be extended in the negative time-direction to $-\infty$ and that the α-limit set equals $\{0\}$. Similarly, X_- consists of precisely those points that have $\{0\}$ as ω-limit set. A general orbit shows saddle-point behavior: It may come close to 0 but will eventually move far away and, if it can be extended in the negative time-direction, it will also move far away in that direction.

One can construct a finite dimensional local unstable manifold $\mathcal{W}_u$ as the graph of a smooth function from X_+ to X_-, shifted to $\overline{\varphi}$. The manifold $\mathcal{W}_u$ is invariant, and the tangent space at $\overline{\varphi}$ is exactly X_+. Moreover, an orbit starting in a sufficiently small ball around $\overline{\varphi}$ can be extended to $t = -\infty$ with α-limit set equal to $\{\overline{\varphi}\}$ if and only if it starts (and hence remains) in $\mathcal{W}_u$. We refer to [23, Chapter VIII] for precise formulations (see in particular Theorems 4.4 and 4.7 and Corollary 4.11). Similarly, one can construct and characterize the local stable manifold $\mathcal{W}_s$ [23, Chapter VIII, Theorem 6.1].

If A does have a spectrum on the imaginary axis, the spectral decomposition involves a third component X_0, which in the setting of Theorem 2.15 or Theorem 2.17 is finite dimensional. The orbits of the linearized semigroup that start in X_0 are characterized by the fact that they grow at most polynomially as $t \to \pm\infty$ (note that in X_0 orbits can be extended to $t = -\infty$). As this characterization is more difficult to work with, the construction of the corresponding center manifold for the nonlinear semigroup (and the proof of its smoothness) is much more involved. Moreover, modification of the nonlinearity outside a small ball around $\overline{\varphi}$ plays a role in the construction and as a consequence the center manifold is not unique (yet it will contain all solutions which are defined for all times and remain inside the small ball for all times). We refer to [23, Chapter IX] for detailed formulations and proofs that apply verbatim to the setting of Theorem 2.15 or Theorem 2.17.

A situation of particular interest is the case that the nonlinear semigroup depends on a parameter and that for a specific value of this parameter, the characteristic equation (2.39) has a pair of simple roots on the imaginary axis (note that since the kernel k takes on real values, $\widehat{k}(-i\omega) = \overline{\widehat{k}(i\omega)}$, and hence complex roots of (2.39) occur in conjugate pairs). Under some further mild genericity conditions one then finds periodic orbits for nearby parameter values. Chapter X of [23] gives a detailed treatment of this so-called Hopf bifurcation in the setting of exactly the abstract integral equation (AIE) that we consider here. We present the main result in the next subsection and at the end of subsection 3.4 we shall briefly indicate how to obtain a corollary for Volterra functional equations.

2.8. Hopf bifurcation. In this subsection we consider Hopf bifurcation under the assumption that the nonlinear perturbation $G : X \to X^{\odot *}$ has finite dimensional range, which does *not* depend on the bifurcation parameter θ. So G is of the form

$$G(\varphi, \theta) = \sum_{i=1}^{N} F_i(\varphi, \theta) r_i^{\odot *}, \tag{2.45}$$

and its derivative with respect to φ at 0 is

$$B(\theta)\varphi = \sum_{i=1}^{N} \langle \varphi, r_i^*(\theta) \rangle \, r_i^{\odot *}. \tag{2.46}$$

Note carefully that now the vector r_i^* depends on the bifurcation parameter θ, as do the vector $r_i^{\odot}(\lambda)$ and the matrix $M(\lambda)$ introduced in (2.17) and (2.18), respectively:

$$M_{ij}(\lambda, \theta) = \langle r_j(\lambda), r_i^*(\theta) \rangle = \left\langle r_i^{\odot}(\lambda, \theta), r_j^{\odot *} \right\rangle. \tag{2.47}$$

In order to have Hopf bifurcation, we need to make sure that a conjugate pair $\pm i\omega_0$ of simple eigenvalues crosses the imaginary axis with positive speed as the bifurcation parameter θ passes some value θ_0. (Note: The real number ω_0 used in this subsection has of course nothing to do with the growth bound of a semigroup. We use the same symbol to denote two unrelated numbers because in both cases the usage conforms with common practice. No confusion is expected to arise.)

The simplicity of the eigenvalues is, by Corollary 2.13 and Theorem 2.15, ensured by the condition

$$\left\langle \psi(\theta_0), \psi^{\odot}(\theta_0) \right\rangle = -d(\theta_0)\frac{\partial M}{\partial \lambda}(i\omega_0, \theta_0)c(\theta_0) \neq 0. \tag{2.48}$$

The condition of crossing the imaginary axis with positive speed means more precisely that

$$\operatorname{Re} \lambda'(\theta_0) \neq 0, \tag{2.49}$$

where $\lambda(\theta)$ is a branch of eigenvalues through $i\omega_0$ at $\theta = \theta_0$. To derive a verifiable form of this condition, let $c(\theta)$ and $d(\theta)$ be the right and left eigenvectors, respectively, of $M(\lambda, \theta)$ normalized by

$$|c(\theta)| = \sum_{i=1}^{N} |c_i(\theta)| = 1, \tag{2.50}$$

$$d(\theta)c(\theta) = 1. \tag{2.51}$$

Differentiating the equation

$$d(\theta)M(\lambda, \theta)c(\theta) = 1$$

implicitly with respect to θ, one obtains

$$\frac{d}{d\theta}\left(d(\theta)c(\theta)\right) + d(\theta)\frac{\partial M}{\partial \theta}c(\theta) + d(\theta)\frac{\partial M}{\partial \lambda}c(\theta)\lambda'(\theta) = 0. \tag{2.52}$$

It now follows from (2.51) and Corollary 2.13 that

$$d(\theta)\frac{\partial M}{\partial \theta}(\lambda(\theta), \theta)c(\theta) = \left\langle \psi(\theta), \psi^{\odot}(\theta) \right\rangle \lambda'(\theta). \tag{2.53}$$

From (2.48) and (2.53) we deduce that (2.49) holds if and only if

$$\operatorname{Re} d(\theta_0)\frac{\partial M}{\partial \theta}(i\omega_0, \theta_0)c(\theta_0) \neq 0. \tag{2.54}$$

We are now ready to formulate the Hopf bifurcation theorem.

THEOREM 2.21 (Hopf bifurcation theorem, [23, Theorem 2.6, p. 290]). *Consider the abstract integral equation*

$$u(t) = T_0(t-s)u(s) + j^{-1}\int_s^t T_0^{\odot *}(t-\tau)G(u(\tau), \theta)d\tau, \quad -\infty < s \leq t < \infty, \tag{AIE}$$

and assume that the following hold:

(H1) $G(\varphi, \theta) = \sum_{i=1}^{N} F_i(\varphi, \theta)r_i^{\odot *}$, $F : X \times \mathbf{R} \to \mathbf{R}^N$ *is* C^k, $k \geq 2$.

(H2) $F(0, \theta) = 0$ *for all* θ.

(H3) $D_1G(0, \theta) = B(\theta)$ *with* $B(\theta)$ *defined by* (2.46). *The corresponding matrix* $M(\lambda, \theta)$ *has for* $\lambda = \pm i\omega_0$, $\theta = \theta_0$, *eigenvalue* 1 *with right eigenvector* $c(\theta_0)$ *and left eigenvector* $d(\theta_0)$ *and* $d(\theta_0)\frac{\partial}{\partial \lambda}M(i\omega_0, \theta_0)c(\theta_0) \neq 0$. *For* $\theta = \theta_0$, *no root of the characteristic equation* $\det(E - M(\lambda)) = 0$ *other than* $\lambda = \pm i\omega_0$ *belongs to* $i\omega_0\mathbf{Z}$.

(H4) $\operatorname{Re} d(\theta_0)\frac{\partial}{\partial\theta}M(i\omega_0,\theta_0)c(\theta_0) \neq 0$.

There exist C^{k-1} functions $\varepsilon \mapsto \widetilde{\theta}(\varepsilon)$, $\varepsilon \mapsto \widetilde{\psi}(\varepsilon)$, and $\varepsilon \mapsto \widetilde{\omega}(\varepsilon)$ with values in $\mathbf{R}$, X, and $\mathbf{R}$, respectively, defined for ε sufficiently small, such that the solution of (AIE) *with $u(0) = \widetilde{\psi}(\varepsilon)$ is $2\pi/\widetilde{\omega}(\varepsilon)$ periodic. Moreover, $\widetilde{\theta}$ and $\widetilde{\omega}$ are even functions, $\widetilde{\theta}(0) = \theta_0$, $\widetilde{\omega}(0) = \omega_0$, $\widetilde{\psi}(-\varepsilon) = \widetilde{\psi}(\varepsilon + \frac{\pi}{\widetilde{\omega}(\varepsilon)})$. If $u(t)$ is any small periodic solution of* (AIE) *for θ close to θ_0 and period close to $2\pi/\omega_0$, then necessarily $\theta = \widetilde{\theta}(\varepsilon)$ for some ε and there exists $\sigma \in [0, 2\pi/\widetilde{\omega}(\varepsilon))$ such that $u(\sigma) = \widetilde{\psi}(\varepsilon)$. If for $\theta = \theta_0$ all roots λ of the characteristic equation*

$$\det(E - M(\lambda, \theta_0)) = 0$$

other than $\pm i\omega_0$ lie in the left half-plane and $\operatorname{Re} d(\theta_0)\frac{\partial}{\partial\theta}M(i\omega_0,\theta_0)c(\theta_0) < 0$, then the periodic solution is, for ε sufficiently small, asymptotically stable with asymptotic phase if $\widetilde{\theta}(\varepsilon) > \theta_0$ and unstable if $\widetilde{\theta}(\varepsilon) < \theta_0$.

Remark 2.22. In order to determine the direction of the bifurcation one has to compute the second derivative of $\widetilde{\theta}$. How this is done is explained in [23, section X.3].

3. Volterra functional equations.

3.1. Unperturbed semigroup for systems of delay equations. We let h denote a positive real number and N a positive integer. $X = L^1\left([-h, 0]; \mathbf{R}^N\right)$ is the space of all (equivalence classes of) $\mathbf{R}^N$-valued measurable functions φ defined and absolutely integrable on $[-h, 0]$ (i.e., each component φ_i, $i = 1, 2, \ldots, N$, is absolutely integrable) with norm

$$\|\varphi\|_1 := \sum_{i=1}^{N} \|\varphi_i\|_1. \tag{3.1}$$

The dual space X^* of $X = L^1\left([-h, 0]; \mathbf{R}^N\right)$ is represented by $L^\infty\left([0, h]; \mathbf{R}^N\right)$, that is, the space of (equivalence classes of) $\mathbf{R}^N$-valued essentially bounded measurable functions g with norm

$$\|g\|_\infty := \max_{1\le i\le N} \|g_i\|_\infty \tag{3.2}$$

via the duality pairing

$$\langle \varphi, g\rangle = \sum_{i=1}^{N} \int_{-h}^{0} \varphi_i(\theta) g_i(-\theta)\, d\theta, \quad \varphi \in X,\ g \in X^*. \tag{3.3}$$

In order to apply the general linear theory summarized in section 2, we take X as above and consider the strongly continuous semigroup T_0 defined by (1.7):

$$(T_0(t)\varphi)(\theta) := \begin{cases} \varphi(t+\theta) & \text{for} \quad t+\theta \in [-h, 0], \\ 0 & \text{for} \quad t+\theta > 0, \end{cases} \quad \varphi \in X,\, t \ge 0,\, \theta \in [-h, 0]. \tag{3.4}$$

Note that T_0 is nilpotent ($T_0(t) = 0$ for $t > h$). In particular, T_0 is eventually compact.

Remark 3.1. The explicit formula (3.4) makes it clear that equivalence classes are mapped to equivalence classes, such that $T_0(t)$ is indeed an operator mapping X into X. In line with common praxis, we will be sloppy when it comes to distinguishing elements of L^1, namely equivalence classes, from their representatives. It is, however, important to note that an equivalence class is by definition absolutely continuous if it contains an absolutely continuous function (that is, a function all the components of which are absolutely continuous). We shall always use this absolutely continuous function to represent an absolutely continuous equivalence class. As in the introduction we shall use the notation $\varphi \in AC$ to indicate that φ is absolutely continuous.

The following characterization of the generator of T_0 is well known, at least in the case of scalar-valued functions [2, p. 11]. As the vector-valued case is not more difficult, we present it without proof.

PROPOSITION 3.2. *The generator A_0 of T_0 is given by*

$$\begin{aligned} \mathcal{D}(A_0) &= \{\varphi \in X : \varphi \in AC,\ \varphi(0) = 0\}, \\ A_0\varphi &= \varphi'. \end{aligned}$$

Our next task is to characterize $X^{\odot *}$ and $T_0^{\odot *}$ and prove sun-reflexivity of X with respect to T_0 so that we can give a precise meaning to the abstract integral equation (AIE) for the specific application we are considering. This is a rather straightforward exercise. In the case of scalar-valued functions it is essentially carried out in [9], the only difference being the way in which the spaces X^*, $X^{\odot}$, $X^{\odot *}$ are represented. Because the smoothness and boundary conditions entering into the domains of definition of the generators are defined componentwise, the vector-valued case does not present any extra difficulties [27, Chapter 3]. We shall therefore give only a brief sketch of the construction of $X^{\odot *}$ and $T_0^{\odot *}$ and a precise formulation of the result that we need.

With the chosen representation of X^*, the adjoint semigroup T_0^* is translation to the left with extension by zero. Translation is clearly *not* continuous in L^∞ (to see this, just consider translation of any discontinuous function). The maximal subspace on which T_0^* is strongly continuous is $X^{\odot} = C_0\left([0,h);\mathbf{R}^N\right)$, the space of all continuous $\mathbf{R}^N$-valued functions vanishing at h. This last condition derives, of course, from the extension by zero of the translated function.

By the Riesz representation theorem, the dual $X^{\odot *}$ can be represented by $\mathrm{NBV}((-h,0];\ \mathbf{R}^N)$, the space of all $\mathbf{R}^N$-valued functions f, all the components of which are of bounded variation, are continuous from the right, and vanish at 0. Note, in particular, that $f \in \mathrm{NBV}\big((-h,0];\mathbf{R}^N\big)$ does *not* have a jump in $-h$ and that this is indicated by the half-open interval $(-h,0]$ of definition of f. The duality pairing between $X^{\odot} = C_0\big([0,h);\mathbf{R}^N\big)$ and $X^{\odot *} = \mathrm{NBV}\big((-h,0];\mathbf{R}^N\big)$ is given by the sum of Riemann–Stieltjes integrals

$$\langle g, f\rangle = \sum_{i=1}^{N} \int_{-h}^{0} g_i(-\theta) f_i(d\theta), \quad g \in X^{\odot},\ f \in X^{\odot *}, \tag{3.5}$$

and the norm on $X^{\odot *}$ by

$$\|f\|_{\mathrm{NBV}} := \sum_{i=1}^{N} \|f_i\|_{\mathrm{NBV}}, \tag{3.6}$$

where on the right-hand side $\|f_i\|_{\mathrm{NBV}}$ denotes the total variation of f_i.

The semigroup $T_0^{\odot *}$ is again translation to the left with extension by zero and it is not strongly continuous on $X^{\odot *}$. It is strongly continuous precisely on $X^{\odot\odot} = \{f \in X^{\odot *} : f \in AC\}$ [4, 9]. By the definition (2.5) of the canonical injection j :

$X \to X^{\odot *}$ and the definitions (3.3) and (3.5) of the pairings between our particular representations of X and $X^{\odot}$ and $X^{\odot}$ and $X^{\odot *}$, one obtains

$$\sum_{i=1}^{N} \int_{-h}^{0} g_i(-\theta)(j\varphi)_i(d\theta) = \langle g, j\varphi \rangle = \langle \varphi, g \rangle = \sum_{i=1}^{N} \int_{-h}^{0} \varphi_i(\theta) g_i(-\theta) d\theta,$$

from which it follows that $(j\varphi)' = \varphi$ or, equivalently,

$$j(\varphi)(\theta) = -\int_{\theta}^{0} \varphi(\tau) d\tau, \quad \theta \in (-h, 0]. \tag{3.7}$$

Now it is well known [52, Theorem 8.18] that a function of bounded variation is absolutely continuous if and only if it is the primitive of an L^1-function. Thus $j\,(X) = X^{\odot\odot}$; that is, X is sun-reflexive. We formulate the main conclusions as the following proposition.

PROPOSITION 3.3. *The space* $X = L^1\left([-h, 0]; \mathbf{R}^N\right)$ *is sun-reflexive with respect to the strongly continuous semigroup* T_0 *of bounded linear operators defined by* (3.4). *For* $\psi \in X^{\odot *} = \mathrm{NBV}((-h, 0]; \mathbf{R}^N)$, $t \geq 0$, *and* $\theta \in [-h, 0]$ *one has*

$$(T_0^{\odot *}(t)\psi)(\theta) = \begin{cases} \psi(t+\theta) & \text{for} \quad t + \theta \in [-h, 0), \\ 0 & \text{for} \quad t + \theta \geq 0. \end{cases} \tag{3.8}$$

The generator $A_0^{\odot *}$ *of* $T_0^{\odot *}$ *is given by*

$$\begin{aligned} \mathcal{D}(A_0^{\odot *}) = \{\varphi \in X^{\odot *} :\ & \varphi(\theta) = \int_{\theta}^{0} \psi(\alpha) d\alpha \text{ for all } \theta \in [-h, 0] \\ & \text{and some } \psi \in X^{\odot *}\}, \end{aligned} \tag{3.9}$$

$$A_0^{\odot *}\varphi = -\psi \tag{3.10}$$

or, in shorthand notation, $A_0^{\odot *}\varphi = \varphi'$.

As a corollary to Proposition 3.3 we get a formula for the resolvent of $A_0^{\odot *}$ which we state for later use.

COROLLARY 3.4. *For* $f \in X^{\odot *} = \mathrm{NBV}((-h, 0]; \mathbf{R}^N)$ *and* $\lambda \in \mathbf{C}$ *we have*

$$\left(j^{-1} R\left(\lambda, A_0^{\odot *}\right) f\right)(\theta) = \int_{\theta}^{0} e^{\lambda(\theta - \tau)} f(d\tau), \quad \theta \in [-h, 0].$$

Proof. By definition, $R\left(\lambda, A_0^{\odot *}\right) f$ is the unique element $\varphi \in \mathcal{D}(A_0^{\odot *})$ which satisfies the equation

$$(\lambda E - A_0^{\odot *})\varphi = f. \tag{3.11}$$

By Proposition 3.3 there exists a $\psi \in X^{\odot *}$ such that

$$\varphi(\theta) = \int_{\theta}^{0} \psi(\alpha) d\alpha, \quad \theta \in [-h, 0], \tag{3.12}$$

and

$$A_0^{\odot *}\varphi = -\psi. \tag{3.13}$$

Equation (3.11) therefore becomes

$$\lambda \int_\theta^0 \psi(\alpha)d\alpha + \psi(\theta) = f(\theta), \quad \theta \in [-h, 0], \tag{3.14}$$

which has the unique solution

$$\psi(\theta) = -\int_\theta^0 e^{\lambda(\theta-\tau)} f(d\tau), \quad \theta \in [-h, 0]. \tag{3.15}$$

The inverse of the canonical injection j defined by (3.7) is clearly differentiation. Therefore

$$j^{-1} R\left(\lambda, A_0^{\odot *}\right) f = j^{-1}\varphi = \varphi' = -\psi. \tag{3.16}$$

The assertion now follows from (3.15) and (3.16). ◻

3.2. The perturbed problem. In this subsection we show that with a specific choice of perturbation $G : X \to X^{\odot *}$, the perturbed problem, which, as we have shown in section 2, amounts to the abstract integral equation (AIE), is equivalent to the originally given delay equation (DE) and initial condition (IC). To this end, we let $F : X \to \mathbf{R}^N$ be a nonlinear mapping and define $G : X \to X^{\odot *}$ by

$$G(\varphi) = \sum_{i=1}^N F_i(\varphi) H_i, \tag{3.17}$$

where F_i denotes the ith component of F for $i = 1, \dots, N$ and H_i is defined by

$$H_i(\theta) := \begin{cases} e_i & \text{for} \quad \theta \in (-h, 0), \\ 0 & \text{for} \quad \theta = 0. \end{cases} \tag{3.18}$$

Here and in what follows $\{e_1, e_2, \dots, e_N\}$ is the standard basis of $\mathbf{R}^N$. Notice that G has finite dimensional range spanned by $\{H_1, H_2, \dots, H_N\}$ in $X^{\odot *}$.

Next we compute the weak* integral in (AIE) when G is defined through (3.17) and (3.18).

LEMMA 3.5. *Let T_0 be the strongly continuous semigroup defined by* (3.4). *Then for every $\eta \in L^1_{\mathrm{loc}}(\mathbf{R}_+)$ and $t \geq 0$ one has*

$$\left(\int_0^t T_0^{\odot *}(t-\tau)\eta(\tau) H_i d\tau\right)(\theta) = -e_i \int_{t+\max\{-t,\theta\}}^t \eta(\sigma)d\sigma, \quad \theta \in (-h, 0].$$

Proof. First notice that for $0 \leq s < h$ one has

$$\left(T_0^{\odot *}(s) H_i\right)(\theta) = \begin{cases} -e_i & \text{for} \quad -h \leq \theta < -s, \\ 0 & \text{for} \quad -s \leq \theta \leq 0. \end{cases} \tag{3.19}$$

The NBV function $T_0^{\odot *}(s) H_i$ thus has a unit jump at $\theta = -s$, and hence

$$\left\langle T_0^{\odot *}(t) H_i, g\right\rangle = \int_{-h}^0 g(-\theta)\left(T_0^{\odot *}(s) H_i\right)(d\theta) = g_i(s) \tag{3.20}$$

for any continuous g. It follows that for $0 \le t \le h$

$$\left\langle \int_0^t T_0^{\odot *}(t-s)\eta(s)H_i ds, g \right\rangle = \int_0^t \eta(s)g_i(t-s)ds$$

$$= \int_{-t}^0 \eta(t+s)g_i(-s)ds = \langle y, g\rangle,$$

where y is the absolutely continuous NBV function defined by

$$y(\theta) = \begin{cases} -\int_{t+\theta}^t \eta(s)ds & \text{for} \quad \theta \le 0 \le 0, \\ -\int_0^t \eta(s)ds & \text{for} \quad -h \le \theta < -t, \end{cases} \tag{3.21}$$

and the conclusion follows. □

Applying this result to $\eta(t) = F_i(u(t))$, we get the following corollary.

COROLLARY 3.6. *Let T_0 be the strongly continuous semigroup defined by* (3.4) *and let $G : X \to X^{\odot *}$ be defined by* (3.17) *and* (3.18). *If $u : [0, t) \to X$ is continuous, then*

$$\left(\int_0^t T_0^{\odot *}(t-s)G(u(s))ds\right)(\theta) = -\int_{t+\max\{-t,\theta\}}^t F(u(s))ds \tag{3.22}$$

for all $\theta \in [-h, 0]$.

Proof. Using Lemma 3.5, one computes

$$\left(\int_0^t T_0^{\odot *}(t-s)G(u(s))ds\right)(\theta) = \sum_{i=1}^N \left(\int_0^t T_0^{\odot *}(t-s)F_i(u(s))H_i ds\right)(\theta)$$

$$= -\sum_{i=1}^N e_i \int_{t+\max\{-t,\theta\}}^t F_i(u(s))ds = -\int_{t+\max\{-t,\theta\}}^t F(u(s))ds. \qquad \square$$

We are now ready to prove equivalence of solutions of the abstract integral equation

$$u(t) = T_0(t)\varphi + j^{-1}\left(\int_0^t T_0^{\odot *}(t-s)G(u(s))ds\right) \tag{AIE}$$

and the delay problem

$$x(t) = F(x_t), \quad t > 0, \tag{DE}$$

$$x_0(\theta) = \varphi(\theta), \quad \theta \in [-h, 0]. \tag{IC}$$

For ease of formulation we consider global solutions, i.e., solutions defined for all future times. It should, however, be evident that one can formulate and prove an analogous result concerning local solutions.

THEOREM 3.7. *Let $\varphi \in X = L^1\left([-h, 0]; \mathbf{R}^N\right)$ be given.*

(a) *Suppose that $x \in L^1_{\text{loc}}\left([-h, \infty); \mathbf{R}^N\right)$ satisfies* (DE) *and* (IC). *Then the function $u : [0, \infty) \to X$ defined by $u(t) := x_t$ is continuous and satisfies* (AIE).

(b) *Suppose that there is a continuous map* $u : [0,\infty) \to X$ *that satisfies* (AIE). *Then the function* x *defined as*

$$x(t) := \begin{cases} \varphi(t) & \text{for} \quad t \in [-h, 0), \\ u(t)(0) & \text{for} \quad t \geq 0 \end{cases} \tag{3.23}$$

is an element of $L^1_{\text{loc}}\left([-h,\infty);\mathbf{R}^N\right)$ *and satisfies* (DE) *and* (IC).

Proof. (a) First, note that the continuity assertion follows from the fact that translation is continuous in L^1. Then, by (DE) and (IC) we get

$$u(t)(\theta) - (T_0(t)\varphi)(\theta) = \begin{cases} 0 & \text{for} \quad t+\theta \in [-h,0), \\ x(t+\theta) & \text{for} \quad t+\theta \geq 0 \end{cases} \tag{3.24}$$

$$= \begin{cases} 0 \\ F(x_{t+\theta}) \end{cases} = \begin{cases} 0 & \text{for} \quad t+\theta \in [-h,0), \\ F(u(t+\theta)) & \text{for} \quad t+\theta \geq 0. \end{cases}$$

On the other hand, by Corollary 3.6 one gets

$$j^{-1}\left(\int_0^t T_0^{\odot *}(t-s)G(u(s))ds\right)(\theta) = \begin{cases} 0 & \text{for} \quad t+\theta \in [-h,0), \\ F(u(t+\theta)) & \text{for} \quad t+\theta \geq 0, \end{cases}$$

which equals (3.24), and therefore (AIE) holds.

(b) Suppose now that u satisfies (AIE). Then by Corollary 3.6 for $t \geq 0$ one has

$$\begin{aligned} x(t) = u(t)(0) &= j^{-1}\left(\int_0^t T_0^{\odot *}(t-s)G(u(s))ds\right)(0) \\ &= -\frac{d}{da}\int_{t+\max\{-t,a\}}^t F(u(s))ds|_{a=0} \qquad (3.25) \\ &= F(u(t)). \end{aligned}$$

Hence it remains to be shown that $u(t) = x_t$. Using (AIE), Corollary 3.6, and (3.25), one computes for $\theta \in [-h, 0]$ that

$$u(t)(\theta) = \begin{cases} \varphi(t+\theta) & \text{for} \quad t+\theta \in [-h,0), \\ j^{-1}\left(\int_0^t T_0^{\odot *}(t-s)G(u(s))ds\right)(\theta) & \text{for} \quad t+\theta \geq 0 \end{cases}$$

$$= \begin{cases} \varphi(t+\theta) & \text{for} \quad t+\theta \in [-h,0), \\ j^{-1}\left(\int_{t+\max\{-t,\cdot\}}^t F(u(s))ds\right)(\theta) & \text{for} \quad t+\theta \geq 0 \end{cases}$$

$$= \begin{cases} \varphi(t+\theta) & \text{for} \quad t+\theta \in [-h,0), \\ F(u(t+\theta)) & \text{for} \quad t+\theta \geq 0. \end{cases}$$

Thus one has $u(t) = x_t$, and (b) is also proved. ∎

As is clear from the results of section 2, the abstract integral equation approach is ideal for deriving results concerning the qualitative behavior of solutions, such as stability and bifurcation. On the other hand, for proving regularity of solutions it is usually easier to attack the problem (DE) and (IC) directly. This is shown in the proof of the next theorem (which is not the sharpest possible result; indeed, the conclusion holds even if F is only locally Lipschitz, but then the proof is a bit more technical).

One of the advantages of the equivalence result of Theorem 3.7 is that we can freely choose between the abstract and the concrete, according to our needs.

THEOREM 3.8. *Let $F : L^1\left([-h,0];\mathbf{R}^N\right) \to \mathbf{R}^N$ be globally Lipschitz continuous. Then the unique solution $x : [-h,\infty) \to \mathbf{R}^N$ of* (DE), (IC) *with $\varphi \in L^1\left([-h,0];\mathbf{R}^N\right)$ is continuous in $[0,\infty)$.*

Proof. Let $\varphi \in L^1\left([-h,0];\mathbf{R}^N\right)$ and $\ell > 0$. Define

$$Z = \left\{ y \in C\left([0,\ell];\mathbf{R}^N\right) : y(0) = F(\varphi) \right\}.$$

Then Z is a closed subset of the Banach space $C\left([0,\ell];\mathbf{R}^N\right)$ and thus a complete metric space. Define for each $y \in Z$ the function $\Phi(y)$ on $[0,\ell]$ by

$$\left(\Phi y\right)(t) = F(z_t^y), \quad 0 \le t \le \ell,$$

where z^y is the function defined by

$$z^y(\tau) = \begin{cases} \varphi(\tau) & \text{for} \quad -h \le \tau < 0, \\ y(\tau) & \text{for} \quad \le \tau \le \ell \end{cases}$$

and z_t^y is the translate of z^y as in (1.2). Clearly z^y belongs to L^1. Because translation is continuous when regarded as a mapping from an interval to L^1 and F is continuous on L^1, it follows that Φy is continuous. Moreover, $\left(\Phi y\right)(0) = F(z_0^y) = F(\varphi)$, and hence Φy belongs to Z. Next we show that Φ is a contraction on Z for ℓ sufficiently small. Because F is globally Lipschitz continuous we have for y_1, $y_2 \in Z$

$$\begin{aligned} \left|\left(\Phi y_1\right)(t) - \left(\Phi y_2\right)(t)\right| &= \left|F\left(z_t^{y_1}\right) - F\left(z_t^{y_2}\right)\right| \\ &\le L \left\|z_t^{y_1} - z_t^{y_2}\right\|_{L^1([-h,0];\mathbf{R}^N)} \\ &\le L \int_0^\ell |y_1(\tau) - y_2(\tau)| \, d\tau. \end{aligned}$$

Hence Φ has, for ℓ sufficiently small, a unique fixed point. The fixed point is obviously a solution of (DE) and (IC). This proves the assertion. ∎

The present way to associate a dynamical system with a Volterra integral equation is dual to the way studied in [21], where, of course, "dual" is precisely defined only in the linear case. The advantage of the present approach is that we also cover autonomous nonlinear problems that are *not* of convolution type, while [21] is restricted to convolution equations (see subsection 3.5 below).

3.3. Steady states. In this subsection we characterize the steady states of the nonlinear semigroup Σ generated by the abstract integral equation (AIE) in terms of constant solutions of (DE) and (IC).

THEOREM 3.9. (a) *Suppose $\overline{\varphi}$ is a steady state of Σ. Then $\overline{\varphi}$ is a constant function*

$$\overline{\varphi}(\theta) = \overline{x}, \quad \theta \in [-h,0], \tag{3.26}$$

and

$$\overline{x} = F\left(\overline{\varphi}\right). \tag{3.27}$$

(b) *Conversely, if the constant function $\overline{\varphi}$ given by* (3.26) *satisfies* (3.27)*, then it is a steady state of Σ.*

Proof. (a) Let $\overline{\varphi}$ be a steady state of Σ, i.e., $\Sigma(t)\overline{\varphi} = \overline{\varphi}$ for all $t \geq 0$. From (AIE) we then get

$$\overline{\varphi} = T_0(t)\overline{\varphi} + j^{-1}\left(\int_0^t T_0^{\odot*}(t-\tau)G(\overline{\varphi})d\tau\right), \quad t \geq 0.$$

Because $T_0(t) = 0$ for $t > h$, it follows that

$$j\overline{\varphi} = \int_0^t T_0^{\odot*}(t-\tau)G(\overline{\varphi})d\tau = \sum_{i=1}^N \int_0^t T_0^{\odot*}(\tau)H_iF_i(\overline{\varphi})d\tau.$$

Using Lemma 3.5 we then deduce that for $t > h$

$$(j\overline{\varphi}) = \sum_{i=1}^N -e_i \int_{t+\theta}^t F_i(\overline{\varphi})d\theta = \sum_{i=1}^N e_i\theta F_i(\overline{\varphi}).$$

But because j is integration, this means precisely that

$$\overline{\varphi}(\theta) = \sum_{i=1}^N e_iF_i(\overline{\varphi}) = F(\overline{\varphi}), \quad \theta \in [-h, 0];$$

that is, $\overline{\varphi}$ is a constant function and (3.27) holds.

The proof of (b) is similar. ∎

From the equivalence of (AIE) and (DE), (IC) (Theorem 3.7) it is clear that a function $\overline{\varphi}$ that takes the constant value $\overline{x} \in \mathbf{R}^N$ on $[-h, 0]$ is a steady state of Σ if and only if the constant function $x(t) = \overline{x},\ t \in [-h, \infty)$ is the solution of (DE), (IC).

Remark 3.10. In what follows we shall abuse notation and denote both the constant function $\overline{\varphi}$ on $[-h, 0]$ and the corresponding constant function on $[-h, \infty)$ by the same symbol as the constant value they take, viz. $\overline{x}$.

Because the constant solutions of (DE), (IC) are steady states of the dynamical system Σ, we have well-defined notions of stability at our disposal. It follows immediately from Theorem 3.8 that the constant solution $\overline{x}$ of (DE), (IC) is (locally) stable if and only if for every $\varepsilon > 0$ there exists a $\delta > 0$ such that

$$\int_{-h}^0 |x(t) - \overline{x}|dt \leq \delta \quad \Rightarrow \quad |x(t) - \overline{x}| \leq \varepsilon \text{ for all } t > 0$$

and (locally) *exponentially stable* if there exist numbers $\delta > 0,\ K > 0,\ \alpha > 0$ such that

$$\int_{-h}^0 |x(t) - \overline{x}|dt \leq \delta \quad \Rightarrow \quad |x(t) - \overline{x}| \leq Ke^{-\alpha t} \text{ for all } t > 0.$$

3.4. The characteristic equation. In section 2.5 we showed that whenever $\sigma(A_0)$ is empty (in particular, when T_0 is nilpotent) and the perturbation has finite dimensional range, the spectrum $\sigma(A)$ of the perturbed generator consists entirely of eigenvalues and there exists a characteristic equation

$$\det(E - M(\lambda)) = 0,$$

the roots of which are exactly the eigenvalues. The characteristic equation contains all the information about asymptotic behavior, Hopf bifurcation, etc. In this section we identify the matrix $M(\lambda)$ for the special case in which the unperturbed semigroup T_0 is given by (3.4) and the perturbation G is of the form (3.17).

If G is differentiable at $\overline{\varphi}$, there exist functions $k_{ij} \in L^\infty([0,h];\mathbf{R})$ such that

$$G'(\overline{\varphi})\varphi = \sum_{i=1}^{N}\left(\sum_{j=1}^{N}\int_{-h}^{0} k_{ij}(-\theta)\varphi_j(\theta)d\theta\right)H_i.$$

$B = G'(\overline{\varphi})$ is thus of the form (2.15), with $r_i^{\odot *} = H_i$ and $r_i^* = k_i = \{k_{ij}\}_{j=1}^N$. Corollary 3.4 now yields

$$\begin{aligned}(r_j(\lambda))(\theta) &= \left(j^{-1}R(\lambda, A_0^{\odot *})H_j\right)(\theta) \\ &= \int_\theta^0 e^{\lambda(\theta-\tau)}H_j(d\tau) = e^{\lambda\theta}e_j, \quad \theta \in [-h,0],\end{aligned} \tag{3.28}$$

and hence

$$M_{ij}(\lambda) = \langle r_j(\lambda), k_i\rangle = \int_{-h}^{0} e^{\lambda\theta}k_{ij}(-\theta)d\theta = \int_0^h e^{-\lambda\theta}k_{ij}(\theta)d\theta = \widehat{k}_{ij}(\lambda).$$

Denoting the matrix with entries k_{ij} by k, the characteristic equation thus takes the form

$$\det\left(E - \widehat{k}(\lambda)\right) = 0. \tag{3.29}$$

The results of subsection 2.6 now tell us that if all the roots of the characteristic equation (3.29) have negative real part, then the steady state is exponentially stable, whereas it is unstable if at least one root has positive real part. Note that the hypotheses of Corollary 2.20 are fulfilled, so Nyquist's criterion for (in)stability is applicable. It is also a straightforward fill-in exercise to translate Theorem 2.21 into a result for delay equations (generalizing Theorem 11.1 in [21] to include equations which are not of convolution type, and being the analogue of Theorem X.2.7 in [23], which applies to delay differential equations).

3.5. Differentiability for three important classes of nonlinearity. In order to apply the general results on stability and bifurcation to the system (DE), (IC) we have to give conditions that ensure that the map $G : X \to X^{\odot *}$ is Fréchet differentiable with $X = L^1\left([-h,0];\mathbf{R}^N\right)$ and G of finite dimensional range given by (3.17) or, more generally, by (2.14). As noted in subsection 2.5, G is differentiable if and only if F is differentiable from $L^1\left([-h,0];\mathbf{R}^N\right)$ to $\mathbf{R}^N$. This leads us to have a closer look at differentiability criteria for functions from $L^1\left([-h,0];\mathbf{R}^N\right)$ to $\mathbf{R}^N$.

There is one obvious class of differentiable mappings from $L^1\left([-h,0];\mathbf{R}^N\right)$ to $\mathbf{R}^N$, consisting of those mappings of the form $\varphi \mapsto (g\circ\Lambda)\varphi$, where $\Lambda : L^1\left([-h,0];\mathbf{R}^N\right) \to \mathbf{R}^N$ is a bounded linear map and g is a smooth function from $\mathbf{R}^N$ to $\mathbf{R}^N$.

A map F that occurs frequently in applications is $F = \Lambda \circ N_g$, where Λ is a bounded linear map from $L^1\left([-h,0];\mathbf{R}^N\right)$ to $\mathbf{R}^N$ and N_g is the Nemytskiĭ operator induced by a smooth function $g : \mathbf{R}^N \to \mathbf{R}^N$ as follows:

$$(N_g(\varphi))(\theta) = g(\varphi(\theta)). \tag{3.30}$$

For instance, the nonlinear Volterra convolution equation

$$x(t) = \int_0^h k(s)g(x(t-s))ds, \quad t > 0, \tag{3.31}$$

$$x(t) = \varphi(t), \quad -h \le t \le 0, \tag{3.32}$$

is of the form (DE), (IC) with $F = \Lambda \circ N_g$ and $\Lambda\varphi = \int_0^h k(\theta)\varphi(-\theta)d\theta$.

It may come as a surprise that the Nemytskiĭ operator from $L^1\left([-h,0];\mathbf{R}^N\right)$ to $L^1\left([-h,0];\mathbf{R}^N\right)$ generated by a differentiable, globally Lipschitz continuous function $g:\mathbf{R}^N \to \mathbf{R}^N$ is *not* Fréchet differentiable unless g is affine (a constant plus a linear operator), but in hindsight this is easy to understand. An indication of the reason is that in the formal Taylor series expansion

$$\begin{aligned}(N_g(\varphi))(\theta) &= g(\varphi(\theta)) \\ &= g(\overline{\varphi}(\theta)) + g'(\overline{\varphi}(\theta))(\overline{\varphi}(\theta)-\varphi(\theta)) + \frac{1}{2}g''(\overline{\varphi}(\theta))(\overline{\varphi}(\theta)-\varphi(\theta))^2 + \cdots\end{aligned} \tag{3.33}$$

around an element $\overline{\varphi} \in L^1$, the higher order terms contain powers of φ which need not belong to L^1. So showing that the higher order terms are small cannot be done in the standard way (and, in fact, cannot be done at all).

The above result may seem disastrous for our theory because it appears as if the important case of the nonlinear Volterra convolution equation (3.31) would not be covered by it. Fortunately, a simple transformation saves our bacon.

Consider the Volterra functional equation

$$x(t) = \Lambda N_g(x_t) \tag{3.34}$$

with initial condition

$$x_0 = \varphi. \tag{3.35}$$

Applying the function g to both sides of (3.34) and (3.35), one obtains

$$(g\circ x)(t) = g\left(\Lambda N_g(x_t)\right) \tag{3.36}$$

and

$$g(x_0) = g(\varphi). \tag{3.37}$$

But

$$(g\circ x)_t(\theta) = g(x(t+\theta)) = g(x_t(\theta)) = (N_g(x_t))(\theta),$$

that is,

$$(g\circ x)_t = N_g(x_t), \tag{3.38}$$

and hence (3.36) and (3.37) take the form

$$y(t) = (g\circ\Lambda)\left(y_t\right), \tag{3.39}$$

$$y_0 = \psi \tag{3.40}$$

with

$$y(t) = (g \circ x)(t), \tag{3.41}$$

$$\psi = g \circ \varphi. \tag{3.42}$$

But $g \circ \Lambda$ is differentiable, and thus our theory applies to the transformed problem (3.39), (3.40): A constant solution $\overline{y}$ of (3.39), (3.40) is exponentially stable if all the roots λ of the characteristic equation

$$\det\left(E - g'(\overline{x})\widehat{k}(\lambda)\right) = 0 \tag{3.43}$$

satisfy $\mathrm{Re}\lambda < 0$ and unstable if there exists at least one root with positive real part.

We recover the solution x of our original problem (3.34), (3.35), because (3.34), (3.41), and (3.38) together show that

$$x(t) = \Lambda y_t. \tag{3.44}$$

It remains to be shown that the stability properties of the transformed problem determine those of the original problem. For this the differentiability of g is irrelevant; we assume only global Lipschitz continuity as this guarantees that the Nemytskiĭ operator N_g maps L^1 into L^1.

THEOREM 3.11. *Let $\Lambda : L^1\left([-h,0];\mathbf{R}^N\right) \to \mathbf{R}^N$ be a bounded linear operator and let $g : \mathbf{R}^N \to \mathbf{R}^N$ be globally Lipschitz continuous with Lipschitz constant L. Let $\overline{x}$ be a constant solution of* (3.34), (3.35) *and let $\overline{y} = g(\overline{x})$ be the corresponding constant solution of* (3.39), (3.40). *Then the following hold:*

(a) *If $\overline{y}$ is [exponentially] stable, then so is $\overline{x}$.*

(b) *If $\overline{y}$ is unstable, then so is $\overline{x}$.*

Proof. The estimate

$$|x(t) - \overline{x}| = |\Lambda y_t - \Lambda g(\overline{x})| \leq \|\Lambda\| \|y_t - \overline{y}\|_1 \tag{3.45}$$

proves (a). Assume now that $\overline{x}$ is stable and let y be the solution of (3.39), (3.40). Define

$$x(t) = \Lambda y_t, \quad t \geq 0. \tag{3.46}$$

We know by Theorem 3.8 that y is continuous for $t \geq 0$; it follows that $x_h \in L^1\left([-h,0];\mathbf{R}^N\right)$. So, for $t \geq h$, y may be regarded as the solution of (3.39) with the initial condition (3.40) replaced by

$$y_h = g \circ x_h. \tag{3.47}$$

Because the mapping that takes ψ to y_t is a strongly continuous (nonlinear) semigroup, $\sup_{0 \leq t \leq h} \|y_t - \overline{y}\|_1$ can be made arbitrarily small by choosing $\|\psi - \overline{y}\|_1$ sufficiently small. Now (3.45) shows that $x_h - \overline{x}$ also can be made arbitrarily small.

Let $\varepsilon > 0$ be arbitrary. Because $\overline{x}$ is stable one can choose $\delta > 0$ such that $\|x_h - \overline{x}\| < \delta$ implies $|x(t) - \overline{x}| < \varepsilon/L$ for all $t > h$. It follows that

$$|y(t) - \overline{y}| = |g(x(t)) - g(\overline{x})| \leq L|x(t) - \overline{x}| < \varepsilon$$

for all $t > 0$ provided that $\|\psi - \overline{y}\|_1$ is sufficiently small, that is, $\overline{y}$ is stable. ∎

Note that if we linearize the nonlinear Volterra integral equation (3.31) in $\mathbf{R}^N$ (as opposed to linearizing $F : L^1 \to \mathbf{R}^N$ in the delay equation), we obtain

$$x(t) = \int_0^t k(s)g'(\overline{x})x(t-s)ds + G(x)(t), \tag{3.48}$$

where $G(x)(t)$ stands for the higher order terms. In the theory of Volterra integral equations [29] one associates the characteristic equation

$$\det\left(E - \widehat{k}(\lambda)g'(\overline{x})\right) = 0 \tag{3.49}$$

with (3.48). Clearly, (3.43) and (3.49) have exactly the same roots.

A third class of differentiable maps from $L^1\left([-h,0];\mathbf{R}^N\right)$ to $\mathbf{R}^N$ is obtained by composing a map from the space $C\left([0,\ell];\mathbf{R}^N\right)$ of continuous functions on some interval $[0,\ell]$ to $\mathbf{R}^N$ with a linear (or affine) map from $L^1\left([-h,0];\mathbf{R}^N\right)$ to $C\left([0,\ell];\mathbf{R}^N\right)$. The reason for this detour via $C\left([0,\ell];\mathbf{R}^N\right)$ is that, roughly speaking, it is much easier for a function to be differentiable if it is defined on $C\left([0,\ell];\mathbf{R}^N\right)$ than if it is defined on L^1. Indeed, the product of two continuous functions which are small in the supremum norm is continuous, and the supremum norm of the product is of quadratic order. In particular, the expansion (3.33) applied to a continuous function φ shows that the Nemytskiĭ operator is differentiable in $C\left([0,\ell];\mathbf{R}^N\right)$ and that

$$N_g'(\overline{\varphi}) = N_{g'}(\overline{\varphi}). \tag{3.50}$$

This observation is important in applications to, for instance, population dynamics. Let us illustrate it by an age-structured model of the type first studied in [30]. Assume that the age-specific per capita death rate depends on the present value $I(t)$ of the (one-dimensional) environmental condition in the following way:

$$\mu(a, I(t)) = \mu_0(a) + \mu_1(a)I(t) \tag{3.51}$$

(where μ_0 and μ_1 are nonnegative functions). Then the probability $\mathcal{F}(a;\varphi)$ that an individual that was born a time units ago is still alive, given the history φ of the environmental condition, is the solution of the ODE initial value problem

$$\frac{d}{d\alpha}\mathcal{F}(\alpha;\varphi) = -\mu(\alpha, \varphi(\alpha - a))\mathcal{F}(\alpha,\varphi), \tag{3.52}$$

$$\mathcal{F}(0) = 1 \tag{3.53}$$

at $\alpha = a$, that is,

$$\mathcal{F}(a;\varphi) = \exp\left(-\int_0^a \left(\mu_0(\alpha) + \mu_1(\alpha)\varphi(\alpha - a)\right)d\alpha\right). \tag{3.54}$$

The theory presented in this paper presupposes a maximum life span h. This is achieved by assuming that μ_0 has a nonintegrable singularity at h:

$$\int_0^h \mu_0(a)da = \infty,$$

because then the survival probability

$$\mathcal{F}_0(a) = \exp\left(-\int_0^a \mu_0(\alpha)d\alpha\right) \tag{3.55}$$

with respect to density-independent effects vanishes at h.

If $\beta(a, I(t))$ is the age-specific fecundity, then the integral equations (1.18), (1.19) combined with the feedback law (1.17) yield

$$b(t) = \int_0^h \beta(a, I(t))\mathcal{F}(a; I_t)b(t-a)da, \tag{3.56}$$

$$I(t) = \int_0^h \gamma(a)\mathcal{F}(a; I_t)b(t-a)da, \tag{3.57}$$

which is a delay equation of the type (DE). More specifically, we have

$$\begin{pmatrix} b(t) \\ I(t) \end{pmatrix} = F\begin{pmatrix} b_t \\ I_t \end{pmatrix} \tag{3.58}$$

with F given by

$$F\begin{pmatrix} \psi \\ \varphi \end{pmatrix} = \begin{pmatrix} \int_0^h \beta\left(a, \int_0^h \gamma(\alpha)\mathcal{F}(\alpha;\varphi)\psi(-\alpha)d\alpha\right)\mathcal{F}(a;\varphi)\psi(-a)da \\ \int_0^h \gamma(a)\mathcal{F}(a;\varphi)\psi(-a)da \end{pmatrix}. \tag{3.59}$$

F is a well-defined mapping from $L^1\left([-h,0];\mathbf{R}^2\right)$ to $\mathbf{R}^2$ if $\gamma\mathcal{F}_0 \in L^\infty[0,h]$ and $\beta(\cdot,\overline{I})\mathcal{F}_0 \in L^\infty[0,h]$ for all $\overline{I} \in \mathbf{R}$, and hence we make this assumption.

We want to show that F is differentiable. First notice that the argument of the exponential function in formula (3.54) is an affine map taking $\varphi \in L^1[-h,0]$ to $C[0,h]$. The mapping $\varphi \mapsto \mathcal{F}(\cdot;\varphi)$ is thus obtained by composing the Nemytskiĭ operator induced in $C[0,h]$ by the exponential function with an affine map. As we already saw, this map is Fréchet differentiable. For fixed ψ, the second component F_2 of F is now obtained by applying a continuous linear mapping to the differentiable map $\varphi \mapsto \mathcal{F}(\cdot;\varphi)$. Hence F_2 is differentiable in φ. Because F_2 is linear in ψ it is also differentiable in ψ. Because $F_2(\psi,\varphi)$ appears as the second argument of β in the expression for F_1, the chain rule implies that F_2 also is differentiable provided that $\beta : \mathbf{R}^2 \to \mathbf{R}$ is differentiable in its second argument.

The derivative of F can be computed explicitly. A straightforward but tedious computation yields F' at a steady state $(\overline{b},\overline{I})$:

$$\left[F'\begin{pmatrix} \overline{b} \\ \overline{I} \end{pmatrix}\right]\begin{pmatrix} \psi \\ \varphi \end{pmatrix} = \int_0^h k(a)\begin{pmatrix} \psi \\ \varphi \end{pmatrix}(-a)da, \tag{3.60}$$

where k is a 2×2 matrix-valued function with entries

$$k_{11}(a) = \left(\gamma(a)\int_0^h \partial_2\beta(\tau,\overline{I})\mathcal{F}(\tau;\overline{I})d\tau\,\overline{b} + \beta(a,\overline{I})\right)\mathcal{F}(a;\overline{I}), \tag{3.61}$$

$$\begin{aligned} k_{12}(a) = {} & \int_0^h \partial_2\beta(\tau,\overline{I})\mathcal{F}(\tau;\overline{I})d\tau\,\overline{b}\,k_{22}(a) \\ & - \int_0^{h-a} \mu_1(\alpha)\beta(\alpha+a,\overline{I})\mathcal{F}(\alpha+a;\overline{I})d\alpha\,\overline{b}, \end{aligned} \tag{3.62}$$

$$k_{21}(a) = \gamma(a)\mathcal{F}(a;\overline{I}), \tag{3.63}$$

$$k_{22}(a) = -\int_0^{h-a} \mu_1(\alpha)\gamma(\alpha+a)\mathcal{F}(\alpha+a;\overline{I})d\alpha\,\overline{b}. \tag{3.64}$$

The characteristic equation is (3.29) with the matrix k defined by (3.61)–(3.64). It is easy to check that the resulting stability criterion is equivalent (as it should be) to the one given in [30] for $\gamma \equiv 1$ and in [32] and [50] for the general case.

The steady environmental condition $\overline{I}$ of a nontrivial equilibrium $(\bar{b}, \overline{I}) \neq (0,0)$ is a solution (there may be many) of the steady state condition

$$1 = \int_0^h \beta(a, \overline{I})\mathcal{F}(a; \overline{I})da. \tag{3.65}$$

Once $\overline{I}$ has been solved from (3.65), the corresponding steady birth rate is obtained from

$$\bar{b} = \frac{\overline{I}}{\int_0^h \gamma(a)\mathcal{F}(a; \overline{I})da}. \tag{3.66}$$

On the other hand, for the population-free, or trivial, steady state $(\bar{b}, \overline{I}) = (0,0)$, the characteristic equation (3.29) reduces to the scalar equation

$$1 = \int_0^h e^{-\lambda a}\beta(a, 0)\mathcal{F}_0(a)da. \tag{3.67}$$

As a consequence, the population-free steady state is exponentially stable if

$$R_0 := \int_0^h \beta(a, 0)\mathcal{F}_0(a)da < 1$$

and unstable if

$$R_0 > 1.$$

In subsection 5.1 we shall elaborate on this a bit more in the context of a model for an age-structured population with cannibalistic behavior.

4. Volterra functional equations coupled with delay differential equations. In applications to structured population dynamics, one encounters models that take the form of a Volterra functional equation coupled with a delay differential equation [31, 32]. In this section we therefore briefly consider systems of the following type:

$$x(t) = F_1(x_t, y_t), \tag{4.1}$$

$$\dot{y}(t) = F_2(x_t, y_t). \tag{4.2}$$

For the component x of the delay equation (4.1), we choose as before $X = L^1\left([-h, 0]; \mathbf{R}^N\right)$ as state space, whereas the natural state space for the component y of the delay differential equation (4.2) is $Y = C\left([-h, 0]; \mathbf{R}^M\right)$ (see [23]). We therefore have to assume that the mappings $F_1 : X \times Y \to \mathbf{R}^N$ and $F_2 : X \times Y \to \mathbf{R}^M$ are at least Lipschitz continuous. Equations (4.1) and (4.2) must, of course, be supplemented by initial conditions

$$x(\theta) = \varphi(\theta), \quad -h \leq \theta \leq 0, \tag{4.3}$$

$$y(\theta) = \psi(\theta), \quad -h \leq \theta \leq 0. \tag{4.4}$$

In section 3 we showed in detail how a Volterra functional equation could be written as a semilinear abstract integral equation. The same program has been carried out for delay differential equations in the book [23] (see also [40]). It is now an easy exercise to combine the two procedures for the coupled system (4.1)–(4.4).

Let T_{10} be the C_0-semigroup defined on X by (3.4) and define the C_0-semigroup T_{20} on Y by

$$(4.5)\quad (T_{20}(t)\psi)(\theta) := \begin{cases} \psi(t+\theta) & \text{for} \quad t+\theta \in [-h,0], \\ \psi(0) & \text{for} \quad t+\theta \geq 0, \end{cases} \quad \psi \in Y,\, t \geq 0,\, \theta \in [-h,0].$$

The two semigroups T_{10} and T_{20} induce in an obvious way a semigroup T_0 on $X \times Y$:

$$(4.6)\qquad T_0(t) = \begin{pmatrix} T_{10}(t) & 0 \\ 0 & T_{20}(t) \end{pmatrix}.$$

It was shown in [23] that $Y^{\odot *}$ has the representation $\mathbf{R}^M \times L^\infty\left([-h,0];\mathbf{R}^M\right)$ and that Y is $\odot$-reflexive with respect to T_{20}. Because X is $\odot$-reflexive with respect to T_{10}, as shown in section 3, it is plain that $X \times Y$ is $\odot$-reflexive with respect to T_0, that $(X \times Y)^{\odot *}$ is (isometrically isomorphic to) $X^{\odot *} \times Y^{\odot *}$, and that $j_{X\times Y}(X \times Y) = j_X(X) \times j_Y(Y)$ (here, of course, j_Z denotes the canonical embedding of Z into $Z^{\odot *}$). Note also that for $t > h$, the range of $T_{20}(t)$ lies in the subspace of Y consisting of the constant functions, which is finite dimensional. In particular, $T_{20}(t)$ is eventually compact. As T_{10} is nilpotent, the semigroup T_0 on $X \times Y$ is eventually compact.

The system (4.1)–(4.4) is equivalent to the abstract integral equation

$$(\text{AIE})\qquad u(t) = T_0(t)\begin{pmatrix} \varphi \\ \psi \end{pmatrix} + j^{-1}\left(\int_0^t T_0^{\odot *}(t-s)G(u(s))ds\right),$$

where $G : X \times Y \to X^{\odot *} \times Y^{\odot *}$ is defined by

$$(4.7)\qquad G(\varphi,\psi) = \sum_{i=1}^{N} F_{1i}(\varphi,\psi)\begin{pmatrix} r_i^{\odot *} \\ 0 \end{pmatrix} + \sum_{i=1}^{M} F_{2i}(\varphi,\psi)\begin{pmatrix} 0 \\ s_i^{\odot *} \end{pmatrix}.$$

Here $r_i^{\odot *} \in X^{\odot *}$ is the Heaviside function (3.18), and $s_i^{\odot *} = (f_i, 0) \in Y^{\odot *}$, where $\{f_1, f_2, \ldots, f_M\}$ is the standard basis of $\mathbf{R}^M$ and 0 is the zero element of $L^\infty\left([-h,0];\mathbf{R}^M\right)$. We are now exactly in the situation described in section 2.5.

The resolvent $R\left(\lambda, A_{10}^{\odot *}\right)$ of $T_{10}^{\odot *}$ was calculated in Corollary 3.4 and the associated vector $r_i(\lambda)$ in (3.28). An analogous computation for $T_{20}^{\odot *}$ shows that $\sigma(A_{20}) = \sigma(A_{20}^{\odot *}) = \{0\}$ and that the resolvent of $A_{20}^{\odot *}$ is given by

$$(4.8)\qquad \left(R\left(\lambda, A_{20}^{\odot *}\right)(\alpha,\psi)\right)(\theta)$$
$$= \frac{1}{\lambda}e^{\lambda\theta}\alpha + \int_\theta^0 e^{\lambda(\theta-\tau)}\psi(\tau)d\tau, \quad (\alpha,\psi) \in Y^{\odot *}, \quad \theta \in [-h,0].$$

In particular,

$$(4.9)\qquad s_i(\lambda) := \left(j^{-1}R\left(\lambda, A_{20}^{\odot *}\right)s_i^{\odot *}\right)(\theta) = \frac{1}{\lambda}e^{\lambda\theta}f_i, \quad \theta \in [-h,0].$$

If F is Fréchet differentiable, its derivative can be represented by the $(N+M) \times (N+M)$ matrix

$$(4.10)\qquad \begin{pmatrix} k_{11} & m_{12} \\ k_{21} & m_{22} \end{pmatrix},$$

where k_{11} and k_{21} are $N \times N$ (resp., $N \times M$) matrices of elements of $L^\infty([0,h]$ and m_{12} and m_{22} are $M \times N$ (resp., $M \times M$) matrices of elements in $NBV[0,h]$. The interpretation of (4.10) is that

$$F'(\overline{\varphi},\overline{\psi})\begin{pmatrix}\varphi\\ \psi\end{pmatrix} = \begin{pmatrix}\int_0^h k_{11}(\theta)\varphi(-\theta)d\theta + \int_0^h m_{12}(d\theta)\psi(-\theta)\\ \int_0^h k_{21}(\theta)\varphi(-\theta)d\theta + \int_0^h m_{22}(d\theta)\psi(-\theta)\end{pmatrix}. \tag{4.11}$$

Using the expressions (3.28) and (4.9) for $r_i(\lambda)$ and $s_i(\lambda)$, respectively, and the definition (2.18) of the matrix $M(\lambda)$, we deduce that

$$M(\lambda) = \begin{pmatrix}\widehat{k}_{11}(\lambda) & \frac{1}{\lambda}\widehat{dm}_{12}(\lambda)\\ \widehat{k}_{21}(\lambda) & \frac{1}{\lambda}\widehat{dm}_{22}(\lambda)\end{pmatrix}, \quad \lambda \neq 0, \tag{4.12}$$

where, as before, $\widehat{k}$ denotes the Laplace transform of k and $\widehat{dm}$ denotes the Laplace–Stieltjes transform of m,

$$\widehat{dm}(\lambda) = \int_0^h e^{-\lambda\theta} m(d\theta). \tag{4.13}$$

It now follows from Theorem 2.15 that $\lambda \neq 0$ is an eigenvalue of the generator of the linearized equation (LAIE) if and only if

$$\det\left(E - M(\lambda)\right) = 0 \tag{4.14}$$

and that the algebraic multiplicity of λ coincides with the order of λ as a root of (4.14). Clearly, for $\lambda \neq 0$, (4.14) is equivalent to

$$\det\left(\begin{pmatrix} E & 0\\ 0 & \lambda E\end{pmatrix} - \begin{pmatrix}\widehat{k}_{11}(\lambda) & \widehat{dm}_{12}(\lambda)\\ \widehat{k}_{21}(\lambda) & \widehat{dm}_{22}(\lambda)\end{pmatrix}\right) = 0. \tag{4.15}$$

As Theorem 2.17 shows that the singularity at $\lambda = 0$ is removable, we conclude that (4.15) is the characteristic equation for the (AIE) with T_0 and G as specified above.

5. Examples.

5.1. Cannibalistic interaction. Even though *size* is the more natural individual state variable used to describe cannibalistic interaction, we shall here use *age* as a substitute, while referring to [25, section 4.1] and [28] for size-structured models. We assume that individuals turn adult and start to reproduce upon reaching age $\overline{a}$. Furthermore, only adults practice cannibalism and their victims are juveniles. The vulnerability for intraspecific predation is defined by a function c of age, the support of which lies in $[0,\overline{a})$.

Let $\mathcal{F}_0(a)$ be the survival probability to at least age a with respect to causes of death other than cannibalism. Let $b(t)$ be the population birth rate at time t and $I_1(t)$ the total number of adults at time t. We assume that "standard" adult food (that is, food other than juveniles of their own kind) is available at a constant density and that an adult produces, from this food, offspring at a rate Z. Let $I_2(t)$ denote the rate at which an adult produces offspring at time t on the basis of the energy provided by its cannibalistic actions. Then, by definition,

$$b(t) = \left(Z + I_2(t)\right) I_1(t), \tag{5.1}$$

$$I_1(t) = \int_{\overline{a}}^\infty b(t-a)\mathcal{F}_0(a)e^{-\int_0^a c(\alpha)I_1(t-a+\alpha)d\alpha}da. \tag{5.2}$$

To these equations we add

$$I_2(t) = \int_0^{\overline{a}} b(t-a)\mathcal{F}_0(a)e^{-\int_0^a c(\alpha)I_1(t-a+\alpha)d\alpha}c(a)E(a)da, \tag{5.3}$$

expressing that the (instantaneous) offspring yield resulting from the consumption of an individual of age a is given by $E(a)$.

The system (5.1)–(5.3) is of the form (3.54)–(3.57) (albeit with two instead of one interaction variable), and thus the arguments provided in section 3.5 establish that the system is a (DE) on L^1 with a C^1-map F. To guarantee that the maximum delay is finite, we assume that $\mathcal{F}_0$ drops to zero at a finite age h (or, equivalently, that the μ_0 of (3.55) has a nonintegrable singularity at h).

By elementary manipulations one can eliminate $\overline{I}_2$ and $\overline{b}$ from the equations for nontrivial steady states to arrive at a single equation

$$Z = \frac{e^{C\overline{I}_1}}{\int_{\overline{a}}^h \mathcal{F}_0(a)da}\left(1 - \overline{I}_1\int_0^{\overline{a}} c(a)E(a)\mathcal{F}_0(a)e^{-\overline{I}_1\int_0^a c(\alpha)d\alpha}da\right) \tag{5.4}$$

for the unknown $\overline{I}_1$. Here

$$C := \int_0^{\overline{a}} c(a)da. \tag{5.5}$$

Next we consider Z (thus, in essence, the density of the standard food) as a bifurcation parameter. The formula (5.4) is an explicit expression for Z as a function of $\overline{I}_1$. If we insert $\overline{I}_1 = 0$ at the right-hand side of (5.4), we obtain the critical value

$$Z_{\text{crit}} = \frac{1}{\int_{\overline{a}}^h \mathcal{F}_0(a)da} \tag{5.6}$$

such that newborn individuals, on average, produce exactly one offspring. In the absence of cannibalism (i.e., for $c \equiv 0$), a nontrivial steady state exists if and only if $Z > Z_{\text{crit}}$. By computing the derivative of Z with respect to $\overline{I}_1$ from (5.4) and evaluating at $\overline{I}_1 = 0$, one concludes that the condition

$$\int_0^{\overline{a}} (E(a)\mathcal{F}_0(a) - 1)\, c(a)da > 0 \tag{5.7}$$

guarantees that the bifurcation from the trivial steady state is subcritical in the sense that $\overline{I}_1$ is positive for values of Z slightly less than Z_{crit}. Thus if (5.7) holds, cannibalism allows the population to persist at levels of the standard food that are, by themselves, insufficient to sustain a consumer population. We refer once more to [25, section 4.1] and [28] for the biological interpretation and further elaborations.

A characteristic equation can now be derived as for the system (3.54)–(3.57) treated in section 3.5. The stability of the trivial steady state is governed by the position of the roots of

$$1 = Z\int_{\overline{a}}^h e^{-\lambda a}\mathcal{F}_0(a)\,da \tag{5.8}$$

in the complex plane. Hence the trivial solution is stable for $Z < Z_{\text{crit}}$ and unstable for $Z > Z_{\text{crit}}$. According to the principle of exchange of stability (see [15, 16, 44] and [3] for an application to population dynamics), the branch of positive steady states described by (5.4) is locally (i.e., for Z near Z_{crit}) stable if the bifurcation is supercritical and unstable if it is subcritical.

For the nontrivial steady states a detailed analysis of the global shape of the curve defined by (5.4) and the changes in the position of the roots of the associated characteristic equation along this curve requires a considerable effort and is beyond the scope of this paper. The point, however, is that the results of this paper allow one to derive conclusions about (in)stability and Hopf bifurcation from the appropriate information about these roots.

5.2. A structured metapopulation model. In this subsection we consider a metapopulation model first introduced in [33] and later modified and analyzed in [34, 35, 36, 37, 39, 41]. The model considers an infinite collection of identical patches that can support local populations. The structuring variable is the size x of a local population. Local populations may go extinct due to a catastrophe, but the vacated patch is immediately recolonized by migrants arriving from other patches. In PDE-formulation, the model is described by

$$\frac{\partial}{\partial t}n(t,x) + \frac{\partial}{\partial x}\left(f(x,D(t))n(t,x)\right) = -\mu(x)n(t,x), \quad t>0,\ x>0, \tag{5.9}$$

$$f(0,D(t))n(t,0) = \int_{\mathbf{R}_+} \mu(x)n(t,x)\,dx, \tag{5.10}$$

$$\frac{d}{dt}D(t) = -(\alpha+\nu)D(t) + \int_{\mathbf{R}_+} \gamma(x)n(t,x)\,dx, \quad t>0, \tag{5.11}$$

supplemented, of course, by appropriate initial conditions.

In (5.9)–(5.11), $n(t,\cdot)$ is the size-distribution of local populations at time t, and $D(t)$ is the density of dispersers at time t. $\gamma(x) = k(x)x$ is the emigration rate ($k(x)$ is the *per capita* emigration rate), α is the rate at which dispersers immigrate into a patch, and ν is the death rate during dispersal. $f(x,D)$ is the growth rate of a local population of size x when the density of dispersers is D. It is given by

$$f(x,D) = g(x) + \alpha D = r(x)x - k(x)x + \alpha D, \tag{5.12}$$

where $r(x)$ is the difference between the per capita birth and death rates when the local population size is x. Finally, $\mu(x)$ is the size-specific catastrophe rate of local populations.

Next we rewrite the equations (5.9)–(5.11) as a coupled system of the form (4.1)–(4.2). By the *age* of the local population of a patch we shall mean the time elapsed since the last catastrophe. Hence a local population of age a at time t had size zero at time $t-a$. The dynamics of such a local population is therefore described by the scalar ODE

$$\frac{d}{d\tau}x(\tau) = g(x(\tau)) + \alpha D_t(\tau - a), \quad 0<\tau\le a, \tag{5.13}$$

$$x(0) = 0. \tag{5.14}$$

For the solution of (5.13)–(5.14) we use the notation

$$x(\tau) = X(\tau, a, D_t), \quad 0\le\tau\le a. \tag{5.15}$$

The probability that a local population survives to age a, given the history of D, is

$$\mathcal{F}(a, D_t) = e^{-\int_0^a \mu(X(\tau,a,D_t))\,d\tau}. \tag{5.16}$$

The results formulated in this paper require a finite maximum life span. In the present model, this could be achieved by assuming that the catastrophe rate has a nonintegrable singularity at some finite local population size. However, in nature it is often the case that large local populations are much less prone to extinction than small ones, which experience a high risk of extinction due to demographic stochasticity. If this is the case, μ should rather be a decreasing function of local population size instead of blowing up. Also, exponentially distributed lifetimes (corresponding to constant catastrophe rates μ) occur frequently in applications. Fortunately, our theory carries over almost *verbatim* to the case of infinite delay (see section 6). In this example we shall therefore not make the assumption of a finite maximum life span. In particular, we shall allow the catastrophe rate μ to be constant.

We can now express the age-distribution

$$m(t, a) = f(X(a, a, D_t), D(t))n(t, X(a, a, D_t)) \tag{5.17}$$

of local populations in terms of the histories of the disperser density D and the birth rate

$$b(t) = f(0, D(t))n(t, 0) \tag{5.18}$$

of local populations as follows:

$$m(t, a) = b(t-a)\mathcal{F}(a, D_t) = b_t(-a)\mathcal{F}(a, D_t), \quad t \geq 0,\ 0 \leq a. \tag{5.19}$$

Equations (5.10) and (5.11) now yield the following system of a delay equation coupled with a delay differential equation:

$$b(t) = \int_0^\infty \mu(X(a, a, D_t))\mathcal{F}(a, D_t)b_t(-a)\,da, \tag{5.20}$$

$$\frac{d}{dt}D(t) = -(\alpha+\nu)D(t) + \int_0^\infty \gamma(X(a, a, D_t))\mathcal{F}(a, D_t)b_t(-a)\,da. \tag{5.21}$$

Here D plays the role of the environmental interaction variable. As we saw in section 4, the state space of b_t should be taken as L^1 and the space of D_t as C.

The steady state equation for (5.20), (5.21) is readily found. For constant functions b and D, (5.20) becomes an identity because

$$\int_0^\infty \mu(X(a, a, \overline{D}))\mathcal{F}(a, \overline{D})da = 1. \tag{5.22}$$

The identity (5.22) reflects the conservation of local populations: After a catastrophe, the patch is immediately recolonized. If we normalize the total amount of patches to 1, then

$$\overline{b} = \frac{1}{\int_0^\infty \mathcal{F}(a, \overline{D})da} \tag{5.23}$$

and the steady state condition becomes

$$\overline{D} = \frac{1}{\alpha+\nu} \cdot \frac{\int_0^\infty \gamma(X(a,a,\overline{D}))\mathcal{F}(a,\overline{D})da}{\int_0^\infty \mathcal{F}(a,\overline{D})da}. \tag{5.24}$$

The numerator on the right-hand side of (5.24) is the expected number of dispersers produced by a local population during its lifetime. When divided by the expected lifetime $\int_0^\infty \mathcal{F}(a,\overline{D})da$, it yields the average rate of dispersers produced by a patch, and when this rate is multiplied by the expected sojourn time $1/(\alpha+\nu)$ in the disperser pool, one gets the local population's contribution to the disperser pool. Equation (5.24) says that at equilibrium this contribution equals the steady disperser density (i.e., dispersers per patch).

In order to derive a characteristic equation and apply our theory, we have to show that the right-hand sides of (5.20) and (5.21) are differentiable in b_t and D_t. As they are linear in b_t, we only have to prove differentiability of $\varphi \mapsto X(\tau,a,\varphi)$ as a mapping on C. The differentiability of $\varphi \mapsto \mathcal{F}(a,\varphi)$ then follows immediately, and to obtain the desired result we only have to assume differentiability of the real functions μ and γ.

Assume that g is differentiable. Differentiating the integrated form of (5.13), (5.14),

$$X(\tau,a,\varphi) = \int_0^\tau g(X(\sigma,a,\varphi))\,d\sigma + \alpha\int_0^\tau \varphi(\sigma-a)\,d\sigma, \tag{5.25}$$

with respect to φ at $\overline{D}$, one obtains the linear equation

$$\frac{\partial}{\partial\varphi}X(\tau,a,\overline{D})\varphi = \int_0^\tau g'(X(\sigma,a,\overline{D}))\frac{\partial}{\partial\varphi}X(\sigma,a,\overline{D})\varphi\,d\sigma + \alpha\int_0^\tau \varphi(\sigma-a)\,d\sigma, \tag{5.26}$$

the solution of which is

$$\frac{\partial}{\partial\varphi}X(\tau,a,\overline{D})\varphi = \alpha\int_0^\tau e^{\int_\sigma^\tau g'(X(s,a,\overline{D}))\,ds}\varphi(\sigma-a)\,d\sigma. \tag{5.27}$$

Let us now assume that the catastrophe rate μ and the per capita emigration rate k are constant. The survival probability then becomes independent of φ: $\mathcal{F}(a) = \exp(-\mu a)$, and the equations (5.20), (5.21) simplify to

$$b(t) = \int_0^\infty \mu e^{-\mu a} b_t(-a)\,da, \tag{5.28}$$

$$\frac{d}{dt}D(t) = -(\alpha+\nu)D(t)$$
$$+\, k\int_0^\infty X(a,a,D_t)e^{-\mu a}b_t(-a)\,da, \tag{5.29}$$

while the steady state condition (5.24) simplifies to

$$\overline{D} = \frac{\mu k}{\alpha+\nu}\int_0^\infty X(a,a,\overline{D})e^{-\mu a}da. \tag{5.30}$$

We take the per capita emigration rate k as a bifurcation parameter. Note that $X(a,a,\overline{D})$, being the solution of $dx/da = r(x)x - kx + \alpha\overline{D}$, $x(0)=0$, depends on k, so in general one cannot solve (5.30) explicitly for k as a function of $\overline{D}$.

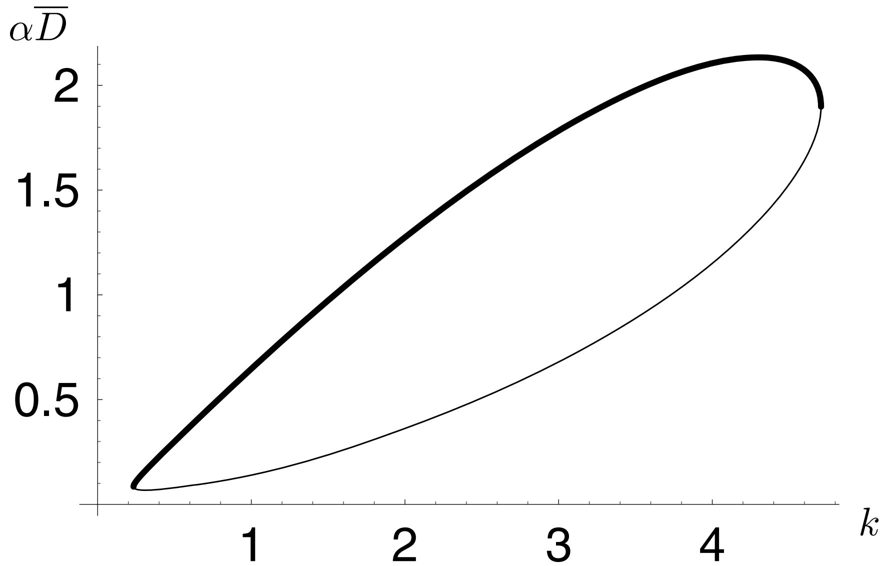

FIG. 1. *Equilibrium values for the immigration rate $\alpha\overline{D}$ in the case of an Allee effect with $f(x, D)$ given by* (5.32). *Parameters: $\alpha = 0.5$, $\mu = 0.2$, $\nu = 0.1$, $H = 1$, $\beta = 18$, $c = 1$, $d = 8$.*

Next we assume that there is an *Allee effect*, that is, that small local populations have a negative intrinsic growth rate [1] and therefore cannot persist without a sufficiently large immigration rate. We model this by assuming that the per capita birth rate depends on the local population size x as

$$\frac{\beta x}{H + x} \tag{5.31}$$

for some positive constants β and H. For a discussion of the rationale for this choice and its biological interpretation we refer to [18, 38]. Furthermore, if we make the standard assumption of density-dependent death rate as in the logistic equation, we end up with

$$f(x, D) = \left(\frac{\beta x}{H + x} - c - dx \right) x - kx + \alpha D \tag{5.32}$$

for some positive constants c and d.

It is clear that with the choice (5.32), the curve defined by (5.30) in the $k\overline{D}$-plane does not touch the axis $\overline{D} = 0$. As a matter of fact, as shown in [39], equation (5.30) defines a closed curve like the one depicted in Figure 1, at least for some choices of parameter values. As seen in Figure 1, there is a saddle-node bifurcation at $k \approx 0.2$ and another one at $k \approx 4.9$. In contrast to the situation with the transcritical bifurcation treated in subsection 5.1, we cannot allude here to the principle of exchange of stability to determine which of the two branches is stable and which is not. That information has to be deduced from the characteristic equation, which we now derive.

The linearized version of (5.28), (5.29) is

$$\psi(t) = \int_0^\infty \mu e^{-\mu a} \psi(t - a)\, da, \tag{5.33}$$

$$\frac{d}{dt}\varphi(t) = -(\alpha+\nu)\varphi(t) + k\int_0^\infty Y(a,\overline{D})\psi(t-a)\,da$$
$$+\,\alpha k\int_0^\infty Z(a,\overline{D})\varphi(t-a)\,da, \tag{5.34}$$

where

$$Y(a,\overline{D}) = X(a,a,\overline{D})e^{-\mu a}, \tag{5.35}$$

$$Z(a,\overline{D}) = \mu\int_a^\infty e^{\int_{\sigma-a}^{\sigma} g'(X(\tau,\sigma,\overline{D}))d\tau} e^{-\mu\sigma}\,d\sigma. \tag{5.36}$$

Taking the Laplace transform of (5.33), (5.34), one obtains

$$\widehat{\psi}(\lambda) = \frac{\mu}{\mu+\lambda}\widehat{\psi}(\lambda), \tag{5.37}$$

$$\lambda\widehat{\varphi}(\lambda) - \varphi(0) = -(\alpha+\nu)\widehat{\varphi}(\lambda) + k\widehat{Y}(\lambda,\overline{D})\widehat{\psi}(\lambda) + \alpha k\widehat{Z}(\lambda,\overline{D})\widehat{\varphi}(\lambda). \tag{5.38}$$

Hence the characteristic equation is

$$\det\begin{pmatrix} 1-\frac{\mu}{\mu+\lambda} & 0 \\ -k\widehat{Y}(\lambda,\overline{D}) & \lambda+\alpha+\nu-\alpha k\widehat{Z}(\lambda,\overline{D}) \end{pmatrix} = 0. \tag{5.39}$$

$\lambda = 0$ is always a root of (5.39). The reason is the indeterminacy of $\overline{b}$ explained above. The situation is analogous to the simple ODE SIS-model of mathematical epidemiology. If one treats the SIS model as a two-dimensional ODE, zero is an eigenvalue, which disappears after the substitution $S = N - I$ (N is the total population). Similarly, in our case the stability of the steady state is determined by the location in the complex plane of the roots of the equation

$$\lambda+\alpha+\nu-\alpha k\widehat{Z}(\lambda,\overline{D}) = 0. \tag{5.40}$$

For $\lambda \neq -(\alpha+\nu)$, (5.40) is equivalent to

$$1-\alpha k\frac{\widehat{Z}(\lambda,\overline{D})}{\lambda+\alpha+\nu} = 0, \tag{5.41}$$

and to this equation we can apply Nyquist's criterion (Corollary 2.20). The (numerical) results show that the upper branch (the thick line in Figure 1) is stable, while the lower branch (thin line) is unstable.

6. Discussion. The principle of linearized stability and the Hopf bifurcation theorem are among the fundamental results of the theory of ODEs. In the past three decades they have been generalized in various ways to infinite dimensional dynamical systems. In this paper we have used perturbation theory of adjoint semigroups (sun-star-calculus) to prove the principle of linearized stability and the Hopf bifurcation theorem for Volterra functional equations. The sun-star-framework made it possible to treat fully nonlinear functional equations as semilinear problems by transforming the original equation into an abstract integral equation of variation-of-constants type.

The transformation of the fully nonlinear problem into a seminlinear problem was made possible by extending the originally given state space. The idea that one should extend the state space when dealing with Hopf bifurcation for delay differential equations was introduced by Chow and Mallet-Paret in 1977 in a pioneering paper [7]. The sun-star-framework provides a functional analytic elaboration of this idea.

The principle of linearized stability consists of two parts. The first part concerns stability and says that if all roots of the so-called characteristic equation associated with a steady state have negative real part, then the steady state is exponentially stable. The second part states that if at least one characteristic root has positive real part, then the steady state is unstable.

The proof of the stability part of the principle of linearized stability is relatively simple as it uses only standard estimates and Gronwall's inequality, and therefore this part can be rather easily generalized from the ODE setting to infinite dimensional systems. In contrast, the proof of the instability part is geometric in nature and is even in the finite dimensional case much more difficult than the proof of the stability part. As a consequence, infinite dimensional generalizations of the instability part are comparatively rare in the literature. In many cases authors hint that the instability part is valid, but without giving a formal proof.

In the important paper [19], Desch and Schappacher proved both the stability and instability parts of the principle of linearized stability for nonlinear perturbations of generators of strongly continuous semigroups. Following their proof, Clément et al. [11] proved both parts within the context of adjoint semigroups and Thieme [53] within the framework of integrated semigroups. In the book [23] sun-star-calculus was systematically used for stability and bifurcation analysis of delay differential equations.

Our main motivation comes from structured population dynamics. In their seminal paper [30], Gurtin and MacCamy proved the stability part of the principle of linearized stability for age-structured populations but passed the instability part with silence. The same applies to most of the papers published in the early 1980s (e.g., [31, 32]). In the first comprehensive book [56] on the mathematical theory of age-structured population dynamics, Webb treated both the stability and instability parts using semigroup methods. Finally, in a somewhat neglected paper [50], Prüß proved both the stability and instability parts in a very general setting of several interacting age-structured populations.

When one moves from age-structured models to general physiologically structured models, even results on stability become rare. Tucker and Zimmermann [55] proved the stability part for a class of models, which, however, did not allow for a finite number of states-at-birth. Calsina and Saldaña [5] considered a size-structured model in which all individuals are born with the same size and gave conditions for the existence of a global attractor. They also gave sufficient conditions for conditional convergence to a steady state. Here conditional convergence means that the size distribution converges to a steady distribution in L^1, given that the total population converges.

There is also a vast literature on the stability of Volterra integral equations

$$x(t) = \int_0^t k(s)x(t-s)ds + G(x)(t); \tag{6.1}$$

see [29] and the references and historical remarks therein. These results are usually based on a classical theorem of Paley and Wiener [48] or generalizations thereof. In its basic form, the Paley–Wiener theorem says that if the kernel k belongs to $L^1(\mathbf{R}_+)$, then its resolvent kernel r is in $L^1(\mathbf{R}_+)$ if the characteristic equation

$$\det\left(E - \widehat{k}(\lambda)\right) = 0 \tag{6.2}$$

has no roots in the closed half-plane $\{\lambda \in \mathbf{C} : \mathrm{Re}\lambda \geq 0\}$. Using the fact that the solution x of (6.1) satisfies

$$x(t) = G(x)(t) + \int_0^t r(t-s)G(x)(s)ds, \tag{6.3}$$

it is easy to show that if $G(x)$ is of higher order, then the zero solution of (6.1) is stable. If (6.2) has no roots in $\{\lambda \in \mathbf{C} : \mathrm{Re}\lambda \geq -\varepsilon\}$ for some $\varepsilon > 0$ (this is the case, for instance, if k has compact support), then 0 is exponentially stable. So the stability part of the principle of linearized stability is well known for Volterra integral equations. On the other hand, a clear statement of the instability part seems to be lacking in the literature (however, see [21]). In section 3.5 we showed that our general theory applies to equations of the type (6.1) (at least if k has compact support), and hence it provides the instability part of the principle of linearized stability for Volterra integral equations.

In some respects the theory presented in this paper is not general enough. It does not, for instance, encompass all population dynamical applications that we want to consider. First of all, we have made the assumption of a finite delay h. In applications to population dynamics this corresponds to the assumption of a maximum individual life span. Although true in nature, it disregards the (mathematically) important case of exponentially distributed lifetimes. However, this is not a serious defect. The assumption was made to have sun-reflexivity, which simplified analysis for the following reason: For a norm continuous function $f : [0, \infty) \to X^{\odot *}$, the weak*- integral

$$\int_0^t T_0^{\odot *}(t-\sigma)f(\sigma)d\sigma \tag{6.4}$$

takes values in $X^{\odot\odot}$ (Proposition 2.2). The key advantage of assuming sun-reflexivity is that then the integral automatically takes values in $j(X)$, so that we can apply j^{-1} to obtain an element of X. If, by lack of compactness, we do not have sun-reflexivity, it may still be the case that this integral takes values in $j(X)$ if we restrict f to take values in a certain subspace of $X^{\odot *}$. For (nonlinear) perturbation operators taking values in such a subspace, the complete machinery retains its strength and all the results carry through. We intend to elaborate on this very useful remark in detail in a separate publication, with two motivating examples: infinite delay and a continuum of birth states.

Secondly, the unknown $x(t)$, which in population dynamical applications is a vector consisting of the components of the birth rate and the environmental interaction variables, is a vector in $\mathbf{R}^N$. There are important applications, for instance, models of size-dependent cannibalism [8], which require an infinite dimensional environmental condition. Prüß [50] treated an age-structured model, and Calsina and Saldaña [6] a size-structured model with an infinite dimensional environmental condition by other means, but it is unclear how the results of the present paper could be extended to cover that situation.

Thirdly, because the Nemytskiĭ operator from $L^1([-h, 0]; \mathbf{R}^N)$ to $L^1([-h, 0]; \mathbf{R}^N)$ generated by a smooth function $g : \mathbf{R}^N \to \mathbf{R}^N$ is Fréchet differentiable if and only if g is affine, we have to assume in applications to population dynamics that, for instance, the death rate is of the form $\mu(\xi, I) = \mu_0(\xi) + \mu_1(\xi)I$, where ξ is the individual state variable and I the interaction variable. Interestingly, this affine form, which corresponds to mass action interaction, is biologically the most relevant. In the future we shall investigate this aspect in detail in collaboration with J. A. J. Metz.

Appendix. Proof of Theorem 2.8. In this appendix we prove that if T_0 is eventually compact and if the perturbation $B : X \to X^{\odot *}$ is a compact operator, then the semigroup T defined by (LAIE) is eventually compact. This does not seem to have been stated in the literature yet. Clément et al. [13] proved the eventual compactness of the perturbed semigroup under the slightly weaker assumption that $R(\lambda, A_0^{\odot *})B$ is compact, but in addition to that they needed the assumption that

$$t \mapsto \int_0^t T_0^{\odot *}(t-\tau)BT(\tau)d\tau$$

is eventually uniformly continuous (that is, continuous from $[t_0, \infty)$ to $\mathcal{L}(X)$ equipped with the uniform operator topology, for some t_0).

The corresponding result for the case in which B maps X into X is known [26, Proposition 1.14, p. 166]. Without the compactness assumption on B the statement is false [26, Example 1.15, p. 166]. Therefore, the task in Exercise 2.5 of [23, p. 57] is impossible.

The proof in [26] is rather opaque, as it is based on statements like "without loss of generality . . . we may . . . assume that [X] is $C[0,1]$" [26, p. 525]. The proof provided here, which also covers the case in which the range of B lies in X, is more straightforward as it depends only on basic properties of semigroups and integrals.

Note. After we had finished this paper, Horst Thieme pointed out to us that Theorem 2.8 is an easy consequence of [54, Theorem 3], which he proved using the theory of integrated semigroups.

PROPOSITION A.1. *Let $B : X \to X^{\odot *}$ be compact. Then $j^{-1} \int_0^t T_0^{\odot *}(\tau)Bd\tau$ is a compact operator from X to X.*

Proof. By Schauder's theorem, $B^* : X^{\odot **} \to X^*$ is compact, and hence so is its "restriction" to $X^\odot$. Because the composition of a compact operator and a bounded operator is compact, it follows that $B^* \int_0^t T_0^\odot(\tau)d\tau : X^\odot \to X^*$ is compact. Using Schauder's theorem once more, we conclude that

$$\left(\left(B^* \int_0^t T_0^\odot(\tau)d\tau\right)^*\right)\Big|_X = j^{-1} \int_0^t T_0^{\odot *}(\tau)Bd\tau$$

is compact, as asserted. $\square$

Let V be a subset of a Banach space. In what follows, $\overline{\mathrm{con}}\, V$ denotes the closed convex hull of V, that is, the smallest closed convex set that contains V. Without any specifications, closedness refers to the norm topology. When other topologies are considered, the topology is indicated by a subscript. For instance, if $V \subset X^*$, then $\overline{\mathrm{con}}_{\sigma(X^*,X)}\, V$ is the smallest weakly* closed convex set that contains V.

The closed ball of radius r with center at x is denoted by $U(x, r)$.

THEOREM A.2. *Let $B : X \to X^{\odot *}$ be compact. Then $j^{-1} \int_0^t T_0^{\odot *}(\tau)BT(t-\tau)d\tau$ is a compact operator from X to X.*

Proof. Because T is a strongly continuous semigroup on X, the function $y : \tau \mapsto T(t-\tau)x$ is continuous from $[0, t]$ to X, and its range belongs to $U(0, M)$ for all $x \in U(0, 1)$ for some $M \geq 1$. Because $j^{-1} \int_0^t T_0^{\odot *}(\tau)Bd\tau$ is compact,

$$j^{-1} \int_0^t T_0^{\odot *}(\tau)Bd\tau(U(0, M))$$

is relatively compact, and hence

$$\overline{\mathrm{con}}\, j^{-1} \int_0^t T_0^{\odot *}(\tau) B d\tau (U(0,M))$$

is compact [51, Theorem 3.25, p. 72]. The proof is therefore completed if we can show that

$$j^{-1} \int_0^t T_0^{\odot *}(\tau) B T(t-\tau) x d\tau \in t\, \overline{\mathrm{con}}\, j^{-1} \int_0^t T_0^{\odot *}(\tau) B d\tau (U(0,M)).$$

This last statement is proved in the next lemmas. ◻

LEMMA A.3. *Let $t \mapsto x^*(t)$ be a weakly* continuous function from $[a,b]$ to X^*. Then*

$$\int_a^b x^*(t) dt \in (b-a)\, \overline{\mathrm{con}}_{\sigma(X^*,X)}\, x^*([a,b]).$$

Proof. First note that by the uniform boundedness principle a weakly* continuous function is norm bounded on compact intervals. By the definition of the weak* integral, one has that $\int_a^b x^*(t)dt$ belongs to the ball

$$U\left(0, (b-a) \sup_{a \le t \le b} \|x^*(t)\|\right),$$

which is weakly* compact by the Banach–Alaoglu theorem. Clearly $x^*([a,b]) \subset U\left(0, \sup_{a\le t\le b} \|x^*(t)\|\right)$, which is convex and weakly* compact. Hence

$$\overline{\mathrm{con}}_{\sigma(X^*,X)}\, x^*([a,b])$$

is weakly* compact. Theorem 3.27 of [51] now implies the assertion. ◻

LEMMA A.4. *Let $y : [0,t] \to X$ be continuous. Then*

$$x_0 := j^{-1} \int_0^t T_0^{\odot *}(\tau) B y(t-\tau) d\tau \in t\, \overline{\mathrm{con}}\, j^{-1} \int_0^t T_0^{\odot *}(\tau) B d\tau\, y([0,t]).$$

Proof. Because $j^{-1} \int_0^t T_0^{\odot *}(\tau) B d\tau$ is a compact operator from X to X (Proposition A.1), the set $V := j^{-1} \int_0^t T_0^{\odot *}(\tau) B d\tau\, y([0,t])$ is relatively compact in X, and hence $t\, \overline{\mathrm{con}}\, V$ is compact [51, Theorem 3.25, p. 72]. It follows that $t\, \overline{\mathrm{con}}\, j(V) = j(t\, \overline{\mathrm{con}}\, V)$ is compact in $X^{\odot *}$. Because $\sigma(X^{\odot *}, X^{\odot})$ is weaker than the norm topology of $X^{\odot *}$, the set $t\, \overline{\mathrm{con}}\, j(V)$ is also $\sigma(X^{\odot *}, X^{\odot})$-compact.

Suppose x_0 does *not* belong to $t\, \overline{\mathrm{con}}\, V$ or, equivalently, $jx_0 \notin t\, \overline{\mathrm{con}}\, j(V)$. A version of the Hahn–Banach theorem [51, Theorem 3.4, p. 58] then implies that there exist $x^{\odot} \in X^{\odot}$ and $\gamma \in \mathbf{R}$ such that

$$\mathrm{Re}\, \langle x^{\odot}, jx_0 \rangle < \gamma < \mathrm{Re}\, \langle x^{\odot}, x^{\odot *} \rangle \quad \text{for all } x^{\odot *} \in t\, \overline{\mathrm{con}}\, j(V).$$

So

$$\left\{ x^{\odot *} \in X^{\odot *} : \mathrm{Re} \langle x^{\odot}, x^{\odot *} - jx_0 \rangle < \gamma \right\}$$

is a $\sigma(X^{\odot *}, X^{\odot})$-neighborhood of jx_0 which does *not* intersect $t\, \overline{\mathrm{con}}\, j(V)$. Hence $jx_0 \notin t\, \overline{\mathrm{con}}_{\sigma(X^{\odot *}, X^{\odot})}\, j(V)$. But this contradicts Lemma A.3. ◻

Theorem 2.8 is now an immediate corollary of Theorem A.2.

Acknowledgments. We are very grateful to Pavol Brunovsky who kindly pointed out to us that the Nemytskiĭ operator from $L^1\left([-h,0];\mathbf{R}^N\right)$ to $L^1\left([-h,0];\mathbf{R}^N\right)$ generated by a smooth function $f:\mathbf{R}^N\to\mathbf{R}^N$ is Fréchet differentiable if and only if f is affine, and that the same necessary and sufficient conditions hold for the operator taking I in $L^1[0,h]$ to the solution $x\in C[0,h]$ of the differential equation $\dot{x}(t)=f(x(t),I(t))$.

During the past years O. D., M. G., and J. A. J. Metz have had the opportunity to meet regularly for a couple of weeks each year thanks to the hospitality of the Volkswagen-Stiftung (Research in Pairs programme at Oberwolfach), the Universities of Utrecht and Helsinki, as well as the International Institute for Applied Systems Analysis (IIASA). In the spring semester of 2006, M. G. held the F. C. Donders Visiting Chair of Mathematics at the University of Utrecht. The present paper is the result of research done at these *rendezvous*.

SPECTRA OF LINEARIZED OPERATORS FOR NLS SOLITARY WAVES*

SHU-MING CHANG†, STEPHEN GUSTAFSON‡, KENJI NAKANISHI§, AND TAI-PENG TSAI‡

Abstract. Nonlinear Schrödinger equations (NLSs) with focusing power nonlinearities have solitary wave solutions. The spectra of the linearized operators around these solitary waves are intimately connected to stability properties of the solitary waves and to the long-time dynamics of solutions of NLSs. We study these spectra in detail, both analytically and numerically.

Key words. spectrum, linearized operator, nonlinear Schrödinger equation, solitary waves, stability

1. Introduction.

Consider the nonlinear Schrödinger equation (NLS) with focusing power nonlinearity,

$$i\partial_t\psi = -\Delta\psi - |\psi|^{p-1}\psi, \tag{1.1}$$

where $\psi(t,x) : \mathbb{R}\times\mathbb{R}^n \to \mathbb{C}$ and $1 < p < \infty$. Such equations arise in many physical settings, including nonlinear optics, water waves, and quantum physics. Mathematically, nonlinear Schrödinger equations with various nonlinearities are studied as basic models of nonlinear dispersive phenomena. In this paper, we stick to the case of a pure power nonlinearity for the sake of simplicity.

For a certain range of the power p (see below), the NLS (1.1) has special solutions of the form $\psi(t,x) = Q(x)\,e^{it}$. These are called *solitary waves.* The aim of this paper is to study the spectra of the *linearized operators* which arise when (1.1) is linearized around solitary waves. The main motivation for this study is that properties of these spectra are intimately related to the problem of the stability (orbital and asymptotic) of these solitary waves and to the long-time dynamics of solutions of NLSs.

Let us begin by recalling some well-known facts about (1.1). Standard references include [5, 33, 34]. Many basic results on the linearized operators we study here were proved by Weinstein [38, 39]. The Cauchy (initial value) problem for (1.1) is locally (in time) well-posed in $H^1(\mathbb{R}^n)$ if $1 < p < p_{\max}$, where

$$p_{\max} := 1 + 4/(n-2) \quad \text{if } n \ge 3; \quad p_{\max} := \infty \quad \text{if } n = 1, 2.$$

Moreover, if $1 < p < p_c$, where

$$p_c := 1 + 4/n,$$

the problem is globally well-posed. For $p \geq p_c$, there exist solutions whose H^1-norms go to ∞ (*blow up*) in finite time. In this paper, the cases $p < p_c$, $p = p_c$, and $p > p_c$ are called *subcritical*, *critical*, and *supercritical*, respectively.

The set of all solutions of (1.1) is invariant under the symmetries of translation, rotation, phase, Galilean transform, and scaling: if $\psi(t,x)$ is a solution, then so is

$$\widetilde{\psi}(t,x) := \lambda^{2/(p-1)}\psi\left(\lambda^2 t,\ \lambda Rx - \lambda^2 tv - x_0\right) \exp\left\{i\left[\frac{\lambda Rx\cdot v}{2} - \frac{\lambda^2 tv^2}{4} + \gamma_0\right]\right\}$$

for any constant $x_0, v \in \mathbb{R}^n$, $\lambda > 0$, $\gamma_0 \in \mathbb{R}$, and $R \in O(n)$. When $p = p_c$, there is an additional symmetry called the "pseudoconformal transform" (see [34, p. 35]).

We are interested here in solutions of (1.1) of the form

$$\psi(t,x) = Q(x)\, e^{it}, \tag{1.2}$$

where $Q(x)$ must therefore satisfy the nonlinear elliptic equation

$$-\Delta Q - |Q|^{p-1}Q = -Q. \tag{1.3}$$

Any such solution generates a family of solutions by the above-mentioned symmetries, called *solitary waves*. Solitary waves are special examples of *nonlinear bound states*, which, roughly speaking, are solutions that are spatially localized for all time. More precisely, one could define nonlinear bound states to be solutions $\psi(t,x)$ which are *nondispersive* in the sense that

$$\sup_{t\in\mathbb{R}} \inf_{x_0\in\mathbb{R}^n} \||x|\psi(t,x-x_0)\|_{L^2_x(\mathbb{R}^n)} < \infty.$$

Testing (1.3) with $\bar{Q}$ and $x.\nabla\bar{Q}$ and taking real parts, one arrives at the *Pohozaev identity* [28]

$$\frac{1}{2}\int |Q|^2 = b\frac{1}{p+1}\int |Q|^{p+1}, \quad \frac{1}{2}\int |\nabla Q|^2 = a\frac{1}{p+1}\int |Q|^{p+1}, \tag{1.4}$$

where

$$a = \frac{n(p-1)}{4}, \quad b = \frac{n+2-(n-2)p}{4}.$$

The coefficients a and b must be positive, and hence a necessary condition for existence of nontrivial solutions is $p \in (1, p_{\max})$.

For $p \in (1, p_{\max})$, and for all space dimensions, there exists at least one nontrivial radial solution $Q(x) = Q(|x|)$ of (1.3) (existence goes back to [28]). This solution, called a *nonlinear ground state*, is smooth, decreases monotonically as a function of $|x|$, decays exponentially at infinity, and can be taken to be positive: $Q(x) > 0$. It is the unique positive solution. (See [34] for references for the various existence and uniqueness results for various nonlinearities.) The ground state can be obtained as the minimizer of several different variational problems. One such result we shall briefly use later is that, for all $n \geq 1$ and $p \in (1, p_{\max})$, the ground state minimizes the Gagliardo–Nirenberg quotient

$$J[u] := \frac{\left(\int |\nabla u|^2\right)^a \left(\int u^2\right)^b}{\int u^{p+1}} \tag{1.5}$$

among nonzero $H^1(\mathbb{R}^n)$ radial functions (see Weinstein [38]).

For $n=1$, the ground state is the unique $H^1(\mathbb{R})$-solution of (1.3) up to translation and phase [5, Theorem 8.1.6, p. 259]. For $n \geq 2$, this is not the case: there are countably infinitely many radial solutions (still real-valued), denoted in this paper by $Q_{0,k,p}(x)$, $k = 0, 1, 2, 3, \ldots$, each with exactly k positive zeros as a function of $|x|$ (Strauss [32]; see also [2, 3]). In this notation, $Q_{0,0,p}$ is the ground state.

There are also nonradial (and complex-valued) solutions, for example, those suggested by Lions [22] with nonzero angular momenta,

$$n = 2, \quad Q = \phi(r)\, e^{im\theta} \quad \text{in polar coordinates } r, \theta;$$

$$n = 3, \quad Q = \phi(r, x_3)\, e^{im\theta} \quad \text{in cylindrical coordinates } r, \theta, x_3;$$

and similar definitions for $n \geq 4$. When $n = 2$, some of these solutions are denoted here by $Q_{m,k,p}$, with $p \in (1, p_{\max})$ and $k = 0, 1, 2, \ldots$ denoting their numbers of positive zeros. See section 4 for more details.

We will refer to all the solitary waves generated by $Q_{0,0,p}$ as *nonlinear ground states* and all others as *nonlinear excited states*. We are not aware of a complete characterization of all solutions of (1.3) or of (1.1). For example, the uniqueness of $Q_{m,k,p}$ with $m, k \geq 1$ is apparently open. Also, we do not know if there are "breather" solutions, analogous to those of the generalized KdV equations. In this paper we will mainly study radial solutions (and in particular the ground state), but we will also briefly consider nonradial solutions numerically in section 4.

To study the stability of a solitary wave solution (1.2), one considers solutions of NLSs of the form

$$\psi(t, x) = [Q(x) + h(t, x)]\, e^{it}. \tag{1.6}$$

For simplicity, let $Q = Q_{0,0,p}$ be the ground state for the remainder of this introduction (see section 4 for the general case). The perturbation $h(t, x)$ satisfies an equation

$$\partial_t h = \mathcal{L}h + (\text{nonlinear terms}), \tag{1.7}$$

where $\mathcal{L}$ is the *linearized operator* around Q:

$$\mathcal{L}h = -i\left\{(-\Delta + 1 - Q^{p-1})h - \tfrac{p-1}{2}\, Q^{p-1}(h + \bar{h})\right\}. \tag{1.8}$$

It is convenient to write $\mathcal{L}$ as a matrix operator acting on $\left[\begin{smallmatrix}\operatorname{Re} h \\ \operatorname{Im} h\end{smallmatrix}\right]$,

$$\mathcal{L} = \begin{bmatrix} 0 & L_- \\ -L_+ & 0 \end{bmatrix}, \tag{1.9}$$

where

$$L_+ = -\Delta + 1 - pQ^{p-1}, \quad L_- = -\Delta + 1 - Q^{p-1}. \tag{1.10}$$

Clearly the operators L_- and L_+ play a central role in the stability theory. They are self-adjoint Schrödinger operators with continuous spectrum $[1, \infty)$ and with finitely many eigenvalues below 1. In fact, when Q is the ground state, it is easy to see that L_- is a nonnegative operator, while L_+ has exactly one negative eigenvalue (these facts follow from Lemma 2.2 below).

Because of its connection to the stability problem, the object of interest to us in this paper is the spectrum of the non-self-adjoint operator $\mathcal{L}$. The simplest properties of this spectrum are the following:

1. For all $p \in (1, p_{\max})$, 0 is an eigenvalue of $\mathcal{L}$.
2. The set $\Sigma_c := \{ir : r \in \mathbb{R}, |r| \geq 1\}$ is the continuous spectrum of $\mathcal{L}$.

(See the next section for the first statement. The second is easily checked.)

It is well known that the exponent $p = p_c$ is critical for stability of the ground state solitary wave (as well as for blow-up of solutions). For $p < p_c$ the ground state is *orbitally stable*, while for $p \geq p_c$ it is unstable (see [40, 14]). These facts have immediate spectral counterparts: for $p \in (1, p_c]$, all eigenvalues of $\mathcal{L}$ are purely imaginary, while for $p \in (p_c, p_{\max})$, $\mathcal{L}$ has at least one eigenvalue with positive real part.

The goal of this paper is to get a more detailed understanding of the spectrum of $\mathcal{L}$ using both analytical and numerical techniques. See [13, 7, 8, 9] for related work. This finer information is essential for understanding the long-time dynamics of solutions of NLSs : (i) To prove asymptotic (rather than simply orbital) stability, one often assumes either the linearized operator $\mathcal{L}$ has no nonzero eigenvalue, or its nonzero eigenvalues are $\pm ri$ with $0.5 < r < 1$. These assumptions need to be verified. (ii) To determine the rate of relaxation to stable solitary waves when there is a unique pair of nonzero eigenvalues $\pm ri$ with $0 < r < 1$, heuristic arguments suggest that $[1/r]$, the smallest integer no larger than $1/r$, may decide the rate. (iii) To construct stable manifolds of unstable solitary waves, one needs to know if there are eigenvalues which are not purely imaginary and to find their locations. These are highly active areas of current research; see, e.g., [15, 18, 30] and the references therein.

Interesting questions with direct relevance to these stability-type problems include the following:

(i) Can one determine (or estimate) the number and locations of the eigenvalues of $\mathcal{L}$ lying on the segment between 0 and i?
(ii) Can $\pm i$, the thresholds of the continuous spectrum Σ_c, be eigenvalues or resonances?
(iii) Can eigenvalues be embedded inside the continuous spectrum?
(iv) Can the linearized operator have eigenvalues with nonzero real *and* imaginary parts (this is already known not to happen for the ground state—see the next section—and so we pose this question with excited states in mind).
(v) Are there bifurcations, as p varies, of pairs of purely imaginary eigenvalues into pairs of eigenvalues with nonzero real part (a stability/instability transition)?

The detailed discussion of the numerical methods is postponed to the appendix. Roughly speaking, we first compute the nonlinear ground state by iteration and renormalization and then compute the spectra of various suitably discretized linear operators.

Let us now summarize the main results and observations of this paper.

1. *Numerics for spectra.* When Q is the ground state, we compute numerically the spectra of $\mathcal{L}$, L_+, and L_- as functions of p; see Figures 1–5. In these figures, the horizontal axis is the logarithm of $p-1$. The vertical axis is comprised of the following: Solid lines are purely imaginary eigenvalues of $\mathcal{L}$ (without i) for $p \in (1, p_c)$; dashed lines are real eigenvalues of $\mathcal{L}$; dotted lines are eigenvalues of L_+; dash-dot lines are eigenvalues of L_-. We have ignored imaginary eigenvalues of the discretized operators with modulus greater than one, which correspond to the continuous spectra of the original operators. Figure 1 is the one-dimensional case. Figures 2 and 3 are the spectra of these operators restricted to radial functions for space dimensions $n = 2$ and 3.

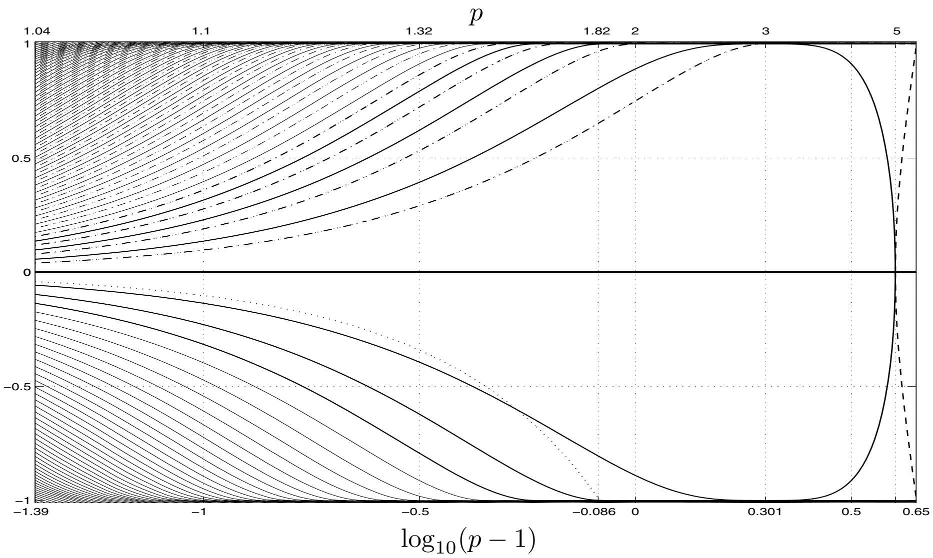

FIG. 1. *Spectra of $\mathcal{L}$, L_+, and L_- for $n = 1$ with logarithmic axis for the values of $p-1$. (Solid line: purely imaginary eigenvalues of $\mathcal{L}$; dashed line: real eigenvalues of $\mathcal{L}$; dotted line: eigenvalues of L_+; dash-dot line: eigenvalues of L_-).*

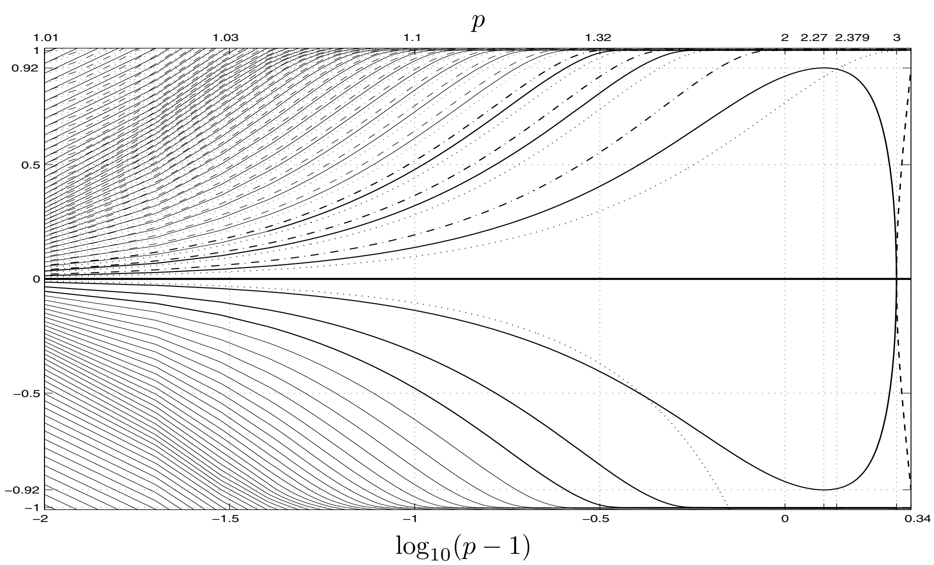

FIG. 2. *Spectra of $\mathcal{L}$, L_+, and L_- restricted to radial functions in the two-dimensional space with logarithmic axis for the values of $p-1$. (Solid line: purely imaginary eigenvalues of $\mathcal{L}$; dashed line: real eigenvalues of $\mathcal{L}$; dotted line: eigenvalues of L_+; dash-dot line: eigenvalues of L_-).*

Figures 4 and 5 are for $n = 2$ and are the spectra restricted to functions of the form $\phi(r)e^{i\theta}$ and $\phi(r)e^{i2\theta}$, respectively. These pictures shed some light on questions (i), (iv), and (v) above and to a certain extent on question (ii). Figures 10–15 are concerned with the spectra of excited states; see the discussion below.

2. *One-dimensional phenomena.* The case $n = 1$ is the easiest case to handle analytically. In section 3, we undertake a detailed study of the one-dimensional

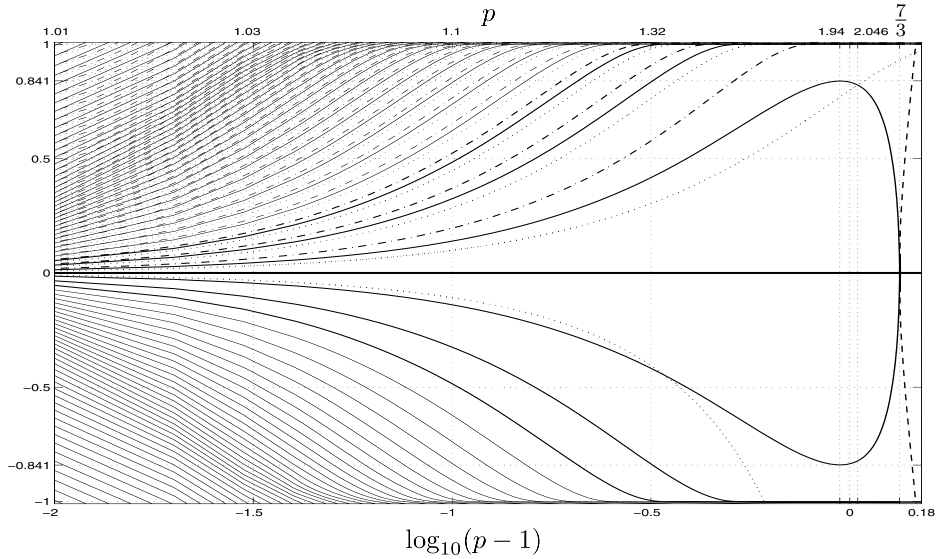

FIG. 3. *Spectra of $\mathcal{L}$, L_+, and L_- restricted to radial functions in the three-dimensional space.*

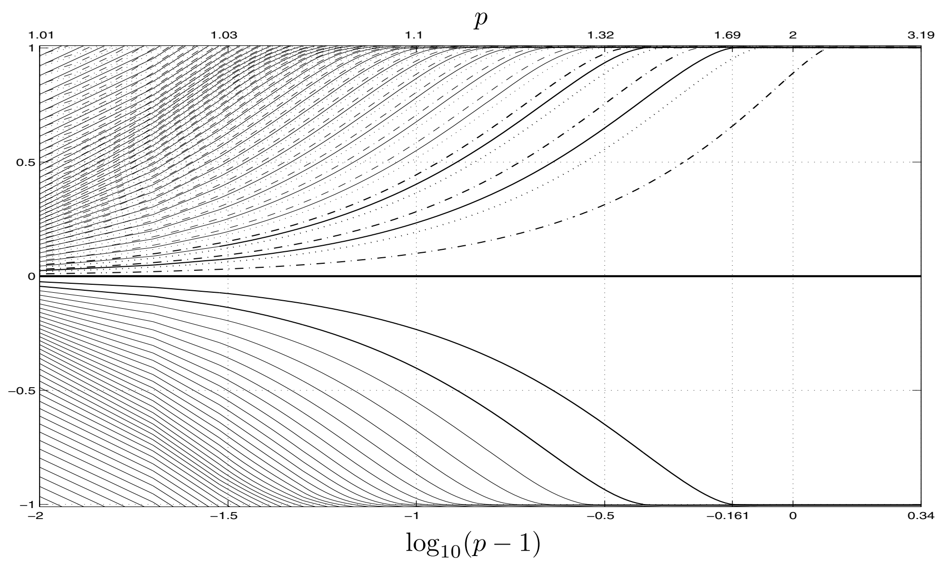

FIG. 4. *Spectra of $\mathcal{L}$, L_+, and L_- restricted to functions of the form $\phi(r)e^{i\theta}$ in the two-dimensional space.*

problem, giving rigorous proofs of a number of phenomena observed in Figure 1. One simple such phenomenon is the (actually classical) fact that the eigenvalues of L_+ and L_- exactly coincide, with the exception of the first (negative) eigenvalue of L_+ (note that this appears to be a strictly one-dimensional phenomenon: the eigenvalues of L_+ and L_- are different for $n \geq 2$, as Figures 2–5 indicate). In fact, we are able to prove sufficiently precise upper and lower bounds on the eigenvalues of $\mathcal{L}$ (lying outside the continuous spectrum) to determine their number, and estimate their positions, as functions of p (see Theorem 3.8). We use two basic techniques: an embedding of L_+ and L_- into a hierarchy of related operators, and a novel

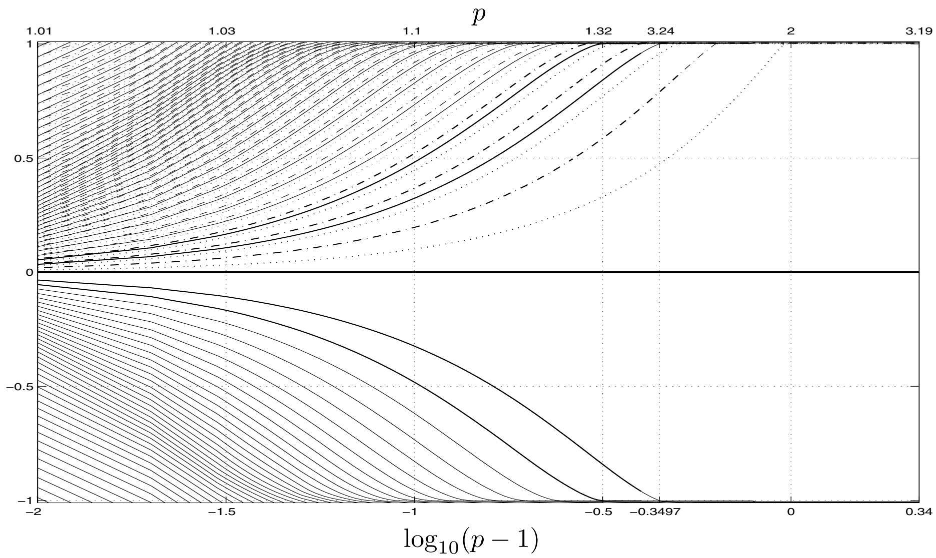

FIG. 5. *Spectra of $\mathcal{L}$, L_+, and L_- restricted to functions of the form $\phi(r)e^{i2\theta}$ in the two-dimensional space.*

variational problem for the eigenvalues, in terms of a fourth-order self-adjoint differential operator (see Theorem 3.6). In this way, we get a fairly complete answer to question (i) above for $n = 1$.

3. *Variational characterization of eigenvalues*. We present self-adjoint variational formulations of the eigenvalue problem for $\mathcal{L}$ in any dimension (see Summary 2.5), including the novel $n = 1$ formulation mentioned above. In principle, these provide a means of counting/estimating the eigenvalues of $\mathcal{L}$ (and hence addressing question (i) above in higher dimensions), though we obtain only such detailed information for $n = 1$.
4. *Bifurcation at $p = p_c$*. In each of Figures 1–3, a pair of purely imaginary eigenvalues for $p < p_c$ appears to collide at 0 at $p = p_c$ and becomes a pair of real eigenvalues for $p > p_c$. This is exactly the stability/instability transition for the ground state. We rigorously verify this picture, determining analytically the spectrum near 0 for p near p_c and making concrete a bifurcation picture suggested by M. I. Weinstein (personal communication); see Theorem 2.6. This gives a partial answer to question (v) above. It is worth pointing out that for $n = 1$, the imaginary part of the (purely imaginary) eigenvalue bifurcating for $p < p_c$ is always larger than the third eigenvalue of L_+ (the first is negative and the second is zero)—this is proved analytically in Theorem 3.8. For $n \geq 2$, however, they intersect at $p \approx 2.379$ for two dimensions and $p \approx 2.046$ for three dimensions, (see Figures 1–3).
5. *Interlacing property.* A numerical observation is that in all the figures, the adjacent eigenvalues of $\mathcal{L}$ each seem to bound an eigenvalue of L_+ and one of L_- (at least for p small enough). We are able to establish this "interlacing" property analytically in dimension one (see Theorem 3.8).
6. *Threshold resonance*. An interesting fact observed numerically (Figure 1) is that, in the one-dimensional case, as $p \to 3$, one eigenvalue curve converges to $\pm i$, the threshold of the continuous spectrum. One might suspect that, at $p = 3$, $\pm i$ corresponds to a resonance or embedded eigenvalue. It is indeed

a resonance: we find an explicit nonspatially-decaying "eigenfunction" and show numerically in section 3.7 that the corresponding eigenfunctions converges, as $p \to 3$, to this function. This observation addresses question (ii) above for $n = 1$.

7. *Excited states.* In section 4 we consider the spectra of linearized operators around excited states with nonzero angular momenta. We observe that, in addition to the bifurcation mentioned above at $p = p_c$, there are complex eigenvalues which are neither real nor purely imaginary (addressing question (iv) above; see Figures 10–15), symmetric w.r.t. both real and purely imaginary axes. These complex eigenvalues also come from bifurcation: as p decreases, a quadruple of complex eigenvalues will collide into the imaginary axis away from 0 and then split into four purely imaginary eigenvalues. It seems that all eigenvalues lie on the imaginary axis for $p \in (1, p_*)$ for some p_* close to 1. In other words, *numerically these excited states are spectrally stable for p close to* 1. It is possible that the numerical error increases enormously as $p \to 1_+$ due to the artificial boundary condition, since the spectrum is approaching the continuous one for $p = 1$. This has to be verified analytically in the future. Even if they are indeed spectrally stable, it is not clear if they are *nonlinearly* stable.

It is worth mentioning some important questions we *cannot* answer:

1. We are so far unable to give precise rigorous estimates on the number and positions of the eigenvalues of $\mathcal{L}$ for $n \geq 2$ (question (i) above).
2. We cannot exclude the possible existence of embedded eigenvalues (question (iii) above).
3. We do not know a nice variational formulation for eigenvalues of $\mathcal{L}$ when Q is an *excited* state (this problem is also linked to question (i) above).
4. We do not have a complete characterization of solitary waves or, more generally, of nonlinear bound states.

We end this introduction by describing some related numerical work. Buslaev and Grikurov [4] and Grikurov [12] study the linearized operators for solitary waves of the following one-dimensional NLS with $p < q$:

$$i\psi_t + \psi_{xx} + |\psi|^p\psi - \alpha|\psi|^q\psi = 0.$$

They draw the bifurcation picture for eigenvalues near zero when the parameter $\alpha > 0$ is near a critical value with the frequency of the solitary wave fixed. This picture is similar to Weinstein's picture, which we study in section 2.3.

Demanet and Schlag [9] consider the same linearization as us and study the supercritical case $n = 3$ and $p \leq 3$ near 3. In this case, it is numerically shown that both L_+ and L_- have no eigenvalues in $(0, 1]$ and no resonance at 1, a condition which implies (see [30]) that $\mathcal{L}$ has no purely imaginary eigenvalues in $[-i, 0) \cup (0, i]$ and no resonance at $\pm i$.

We outline the rest of the paper: in section 2 we consider general results for all dimensions for ground states. In section 3 we consider one-dimensional theory. In section 4 we discuss the spectra for excited states with angular momenta. In the appendix we discuss the numerical methods.

Notation. For an operator A, $N(A) = \{\phi \in L^2 |\ A\phi = 0\}$ denotes the nullspace of A. $N_g(A) = \cup_{k=1}^{\infty} N(A^k)$ denotes the generalized nullspace of A. The L^2-inner product in $\mathbb{R}^n$ is $(f, g) = \int_{\mathbb{R}^n} \bar{f} g \, dx$.

2. Revisiting the general theory for ground states. In this section we review mostly well-known results which are valid for all dimensions and for the ground state $Q(x) = Q_{0,0,p}(x)$, and we give new proofs of some statements.

We begin by recalling some well-known results for the linearized operator $\mathcal{L}$ defined by (1.8). As is well known for linearized Hamiltonian systems (and can be checked directly), if λ is an eigenvalue, then so are $-\lambda$ and $\pm\bar{\lambda}$. Hence if $\lambda \neq 0$ is real or purely imaginary, it comes in a pair. If it is complex with nonzero real and imaginary parts, it comes in a quadruple. It follows from nonlinear stability and instability results [40, 14] that all eigenvalues are purely imaginary if $p \in (1, p_c)$ and that there is at least one eigenvalue with positive real part when $p \in (p_c, p_{\max})$. It is also known (see, e.g., [8]) that the set of isolated and embedded eigenvalues is finite, and the dimensions of the corresponding generalized eigenspaces are finite.

2.1. L_+, L_-, and the generalized nullspace of $\mathcal{L}$. Here we recall the makeup of the generalized nullspace $N_g(\mathcal{L})$ of $\mathcal{L}$. Easy computations give

$$L_+ Q_1 = -2Q, \quad L_- Q = 0, \quad \text{where } Q_1 := \left(\tfrac{2}{p-1} + x \cdot \nabla\right)Q, \tag{2.1}$$

and

$$L_- xQ = -2\nabla Q, \quad L_+ \nabla Q = 0. \tag{2.2}$$

In the critical case $p = p_c$, we also have

$$L_-(|x|^2 Q) = -4Q_1, \quad L_+ \rho = |x|^2 Q \tag{2.3}$$

for some radial function $\rho(x)$ (for which we do not know an explicit formula in terms of Q). Denote

$$\delta^p_{p_c} = \begin{cases} 1, & p = p_c, \\ 0, & p \neq p_c. \end{cases} \tag{2.4}$$

For $1 < p < p_{max}$, the generalized nullspace of $\mathcal{L}$ is given by (see [39])

$$N_g(\mathcal{L}) = \operatorname{span}\left\{ \begin{bmatrix} 0 \\ Q \end{bmatrix}, \begin{bmatrix} 0 \\ xQ \end{bmatrix}, \delta^p_{p_c} \begin{bmatrix} 0 \\ |x|^2 Q \end{bmatrix}, \begin{bmatrix} \nabla Q \\ 0 \end{bmatrix}, \begin{bmatrix} Q_1 \\ 0 \end{bmatrix}, \delta^p_{p_c} \begin{bmatrix} \rho \\ 0 \end{bmatrix} \right\}. \tag{2.5}$$

In particular

$$\dim N_g(\mathcal{L}) = 2n + 2 + 2\delta^p_{p_c}.$$

The fact that the vectors on the right-hand side of (2.5) lie in $N_g(\mathcal{L})$ follows immediately from the computations (2.1)–(2.3). That these vectors span $N_g(\mathcal{L})$ is established in [39, Theorems B.2 and B.3]. These theorems rely on the nondegeneracy of the kernel of L_+.

LEMMA 2.1. *For all $n \geq 1$ and $p \in (1, p_{\max})$,*

$$N(L_+) = \operatorname{span}\{\nabla Q\}.$$

This lemma is proved in [39] for certain n and p ($n = 1$ and $1 < p < \infty$, or $n = 3$ and $1 < p \leq 3$) and is completely proved later by a general result of [19]. We present here a direct proof of this lemma, without referring to [19], relying only on oscillation properties of Sturm–Liouville ODE eigenvalue problems. A similar argument (which in the present case, however, applies only for $p \le 3$) appears in [10, Appendix C]. For completeness, we also include some arguments of [39].

A new proof. We begin with the cases $n \ge 2$. Since the potential in L_+ is radial, any solution of $L_+ v = 0$ can be decomposed as $v = \sum_{k \ge 0} \sum_{\mathbf{j} \in \Sigma_k} v_{k,\mathbf{j}}(r) Y_{k,\mathbf{j}}(\hat{x})$, where $r = |x|$, $\hat{x} = \frac{x}{r}$ is the spherical variable, and $Y_{k,\mathbf{j}}$ denote spherical harmonics: $-\Delta_{S^{n-1}} Y_{k,\mathbf{j}} = \lambda_k Y_{k,\mathbf{j}}$ (a secondary multi-index $\mathbf{j}$, appropriate to the dimension, runs over a finite set Σ_k for each k). Then $L_+ v = 0$ can be written as $A_k v_{k,\mathbf{j}} = 0$, where, for $k = 0, 1, 2, 3, \dots,$

$$A_0 = -\partial_r^2 - \frac{n-1}{r}\partial_r + 1 - pQ^{p-1}(r), \quad A_k = A_0 + \lambda_k r^{-2}, \quad \lambda_k = k(k+n-2).$$

Case 1. $k = 1$. Note that $\nabla Q = Q'(r)\hat{x}$. Since $A_1 Q' = 0$ and $Q'(r) < 0$ (monotonicity of the ground state) for $r \in (0, \infty)$, $Q'(r)$ is the unique ground state of A_1 (up to a factor), and so $A_1 \ge 0$, $A_1|_{\{Q'\}^\perp} > 0$.

Case 2. $k \ge 2$. Since $A_k = A_1 + (\lambda_k - \lambda_1) r^{-2}$ and $\lambda_k > \lambda_1$, we have $A_k > 0$, and hence $A_k v_k = 0$ has no nonzero L^2-solution.

Case 3. $k = 0$. Note that the first eigenvalue of A_0 is negative because $(Q, A_0 Q) = (Q, -(p-1)Q^p) < 0$. The second eigenvalue is nonnegative due to (2.7) and the minimax principle. Hence, if there is a nonzero solution of $A_0 v_0 = 0$, then 0 is the second eigenvalue. By Sturm–Liouville theory, $v_0(r)$ can be taken to have only one positive zero, which we denote by $r_0 > 0$. By (2.1), $A_0 Q = -(p-1)Q^p$ and $A_0 Q_1 = -2Q$. Hence $(Q^p, v_0) = 0 = (Q, v_0)$. Let $\alpha = (Q(r_0))^{p-1}$. Since $Q'(r) < 0$ for $r > 0$, the function $Q^p - \alpha Q = Q(Q^{p-1} - \alpha)$ is positive for $r < r_0$ and negative for $r > r_0$. Thus $v_0(Q^p - \alpha Q)$ does not change sign, contradicting $(v_0, Q^p - \alpha Q) = 0$. Combining all these cases gives Lemma 2.1 for $n \ge 2$.

Finally, consider $n = 1$. Suppose $L_+ v = 0$. Since L_+ preserves oddness and evenness, we may assume v is either odd or even. If it is odd, it vanishes at the origin, and so by linear ODE uniqueness, v is a multiple of Q'. So suppose v is even. As in Case 3 above, since L_+ has precisely one negative eigenvalue and has Q' in its kernel, $v(x)$ can be taken to have two zeros at $x = \pm x_0$, $x_0 \ne 0$. The argument of Case 3 above then applies on $[0, \infty)$ to yield a contradiction. □

We complete this section by summarizing some positivity estimates for the operators L_+ and L_-. These estimates are closely related to the stability/instability of the ground state.

Lemma 2.2.

$$L_- \ge 0, \quad L_-|_{\{Q\}^\perp} > 0 \quad (1 < p < p_{\max}), \tag{2.6}$$

$$(Q, L_+ Q) < 0, \quad L_+|_{\{Q^p\}^\perp} \ge 0 \quad (1 < p < p_{\max}), \tag{2.7}$$

$$L_+|_{\{Q\}^\perp} \ge 0 \quad (1 < p \le p_c), \tag{2.8}$$

$$L_+|_{\{Q, xQ\}^\perp} > 0, \quad L_-|_{\{Q_1\}^\perp} > 0 \quad (1 < p < p_c), \tag{2.9}$$

$$L_+|_{\{Q, xQ, |x|^2 Q\}^\perp} > 0, \quad L_-|_{\{Q_1, \rho\}^\perp} > 0 \quad (p = p_c). \tag{2.10}$$

Proof. Most estimates here are proved in [39] except the second part of (2.7) when $p > p_c$. It can be proved for $p \in (1, p_{\max})$ by modifying the proof of [39, Proposition 2.7] for (2.8) as follows. (It is probably also well known, but we do not know a reference.)

Recall that the ground state Q is obtained by the minimization problem (1.5). If a minimizer $Q(x)$ is rescaled so that

$$\frac{\int |\nabla Q|^2}{2a} = \frac{\int Q^2}{2b} = \frac{\int Q^{p+1}}{p+1} = \text{constant } k > 0,$$

i.e., (1.4) is satisfied, then $Q(x)$ satisfies (1.3). The minimization inequality $\frac{d^2}{d\varepsilon^2}\Big|_{\varepsilon=0} J[Q+\varepsilon\eta] \geq 0$ for all real functions η is equivalent to

$$k(\eta,\, L_+\eta) \geq \frac{1}{a}\left(\int \eta\Delta Q\right)^2 + \frac{1}{b}\left(\int Q\eta\right)^2 - \left(\int Q^p\eta\right)^2. \tag{2.11}$$

Thus $(\eta,\, L_+\eta) \geq 0$ if $\eta \perp Q^p$. Note that, if $\eta \perp Q$, by (1.3) the right-hand side of (2.11) is positive if $a \leq 1$, i.e., $p \leq p_c$. In this way, we recover (2.8). ∎

2.2. Variational formulations of the eigenvalue problem for $\mathcal{L}$. In this subsection we summarize various variational formulations for eigenvalues of $\mathcal{L}$. The generalized nullspace is given by (2.5). Suppose $\lambda \neq 0$ is a (complex) eigenvalue of $\mathcal{L}$ with corresponding eigenfunction $\left[\begin{smallmatrix} u \\ w \end{smallmatrix}\right] \in L^2$:

$$\begin{bmatrix} 0 & L_- \\ -L_+ & 0 \end{bmatrix} \begin{bmatrix} u \\ w \end{bmatrix} = \lambda \begin{bmatrix} u \\ w \end{bmatrix}. \tag{2.12}$$

The functions u and w satisfy

$$L_+ u = -\lambda w, \quad L_- w = \lambda u. \tag{2.13}$$

Therefore

$$L_- L_+ u = \mu u, \quad \mu = -\lambda^2. \tag{2.14}$$

Since $(\mu u, Q) = (L_- L_+ u, Q) = (L_+ u, L_- Q) = 0$ and $\mu \neq 0$, we have $u \perp Q$.

Denote by Π the L^2-orthogonal projection onto $Q^\perp$. We can write $L_+ u = \Pi L_+ u + \alpha Q$. Equation (2.14) implies $L_- \Pi L_+ u = \mu u$, and hence, using $u \perp Q$ and (2.6), $\Pi L_+ u = L_-^{-1} \mu u$. Thus

$$(u, Q) = 0, \quad L_+ u = \mu L_-^{-1} u + \alpha Q. \tag{2.15}$$

Since (2.14) is also implied by (2.15), these two equations are equivalent.

If $Q(x)$ is a general solution of (1.3), then $\mu = -\lambda^2$ may not be real. However, it must be real for the nonlinear ground state $Q = Q_{0,0,p}$. This fact is already known (see [29]). We will give a different proof.

Lemma. For $Q = Q_{0,0,p}$, every eigenvalue μ of (2.14) is real.

A new proof. Multiply (2.13) by $\bar{u}$ and $\bar{w}$, respectively, and integrate. Then we get

$$(u, L_+ u) = -\lambda(u, w), \quad (w, L_- w) = \lambda(w, u) = \lambda\overline{(u, w)}. \tag{2.16}$$

Taking the product, we get

$$(u, L_+ u)(w, L_- w) = -\lambda^2 |(u, w)|^2 = \mu |(u, w)|^2.$$

If $\mu \neq 0$, then w is not a multiple of Q, and so by (2.6), $(w, L_- w) > 0$. Hence $(u, w) \neq 0$ by (2.16). Thus

$$\mu = \frac{(u, L_+ u)(w, L_- w)}{|(u,w)|^2} \in \mathbb{R}. \qquad \square$$

This argument does not work when Q is an excited state, since (u, w) may be zero (see, e.g., [37, equation (2.63)]). The fact that $\mu \in \mathbb{R}$ implies that eigenvalues λ of $\mathcal{L}$ are either real or purely imaginary. Thus $\mathcal{L}$ has no complex eigenvalues with nonzero real and imaginary parts. This is not the case for excited states (see section 4 and [37]).

The proof of reality of μ in [29] uses the following formulation. For the nonlinear ground state Q, L_- is nonnegative and the operator $L_-^{1/2}$ is defined on L^2 and invertible on $Q^\perp$. A nonzero $\mu \in \mathbb{C}$ is an eigenvalue of (2.14) if and only if it is also an eigenvalue of the following problem:

$$L_-^{1/2} L_+ L_-^{1/2} g = \mu g, \tag{2.17}$$

with $g = L_-^{-1/2} u$. The operator $L_-^{1/2} L_+ L_-^{1/2}$ already appeared in [36]. Since it can be realized as a self-adjoint operator, μ must be real.

Furthermore, the eigenvalues of $L_-^{1/2} L_+ L_-^{1/2}$ can be counted using the minimax principle. Note that Q is an eigenfunction with eigenvalue 0. For easy comparison with other formulations, we formulate the principle on $Q^\perp$. Let

$$\mu_j := \inf_{g \perp Q, g_k, k=1,\dots,j-1} \frac{(g, L_-^{1/2} L_+ L_-^{1/2} g)}{(g,g)} \quad (j = 1,2,3,\dots) \tag{2.18}$$

with a suitably normalized minimizer denoted by g_j (if it exists—the definition terminates once a minimizer fails to exist). The corresponding definition for (2.15) is

$$\mu_j := \inf_{u \perp Q,\, (u, L_-^{-1} u_k)=0,\, k=1,\dots,j-1} \frac{(u, L_+ u)}{(u, L_-^{-1} u)} \quad (j = 1,2,3,\dots) \tag{2.19}$$

with a suitably normalized minimizer denoted by u_j (if it exists). In fact, the minimizer u_j satisfies

$$L_+ u_j = \mu_j L_-^{-1} u_j + \alpha_j Q + \beta_1 L_-^{-1} u_1 + \cdots + \beta_{j-1} L_-^{-1} u_{j-1} \tag{2.20}$$

for some Lagrange multipliers $\beta_1, \dots, \beta_{j-1}$. Testing (2.20) with u_k, with $k < j$, we get $(u_k, \beta_k L_-^{-1} u_k) = (u_k, L_+ u_j) = (L_+ u_k, u_j) = 0$ by (2.20) for u_k and the orthogonality conditions. Thus $\beta_k = 0$ and $L_+ u_j = \mu_j L_-^{-1} u_j + \alpha_j Q$, and hence u_j satisfies (2.15).

LEMMA 2.3. *The eigenvalues of* (2.18) *and* (2.19) *are the same, and*

$$\begin{aligned} \textit{if } 1 < p < p_c: &\quad \mu_1 = \cdots = \mu_n = 0, \quad \mu_{n+1} > 0; \\ \textit{if } p = p_c: &\quad \mu_1 = \cdots = \mu_{n+1} = 0, \quad \mu_{n+2} > 0; \\ \textit{if } p_c < p < p_{\max}: &\quad \mu_1 < 0, \quad \mu_2 = \cdots = \mu_{n+1} = 0, \quad \mu_{n+2} > 0. \end{aligned}$$

The 0*-eigenspaces are* span $L_-^{-1/2}\{\nabla Q, \delta_{p_c}^p Q_1\}$ *for* (2.18) *and* span$\{\nabla Q, \delta_{p_c}^p Q_1\}$ *for* (2.19)*, where* $\delta_{p_c}^p$ *is defined in* (2.4).

Proof. The eigenvalues of (2.18) and (2.19) are seen to be the same by taking $g = L_-^{-1/2} u$ up to a factor. By estimate (2.8), $\mu_1 \geq 0$ for $p \in (1, p_c]$. For $p \in (p_c, p_{\max})$, using (1.4), $\Pi Q_1 = Q_1 - \frac{(Q_1,Q)}{(Q,Q)}Q$, and elementary computations (such as (2.22) below), one finds that

$$(\Pi Q_1, L_+\Pi Q_1) = \frac{n^2(p-1)}{4}(p_c - p)\frac{1}{p+1}\int Q^{p+1},$$

which is negative for $p > p_c$. Thus $\mu_1 < 0$. By estimate (2.7), $\mu_2 \geq 0$ for $p \in (1, p_{\max})$.

It is clear that $u = \frac{\partial}{\partial x_j}Q$, $j = 1, \dots, n$, provides n 0-eigenfunctions. For $p = p_c$, another 0-eigenfunction is $u = Q_1$, since $Q_1 \perp Q$ (see again (2.22) below), $L_-^{-1}\nabla Q = -\frac{1}{2}xQ$, and $(Q_1, L_+Q_1) = 0$. It remains to show that $\mu_{n+1} > 0$ for $p \in (1, p_c)$ and $\mu_{n+2} > 0$ for $p \in [p_c, p_{\max})$. If $\mu_{n+2} = 0$ for $p \in (p_c, p_{\max})$, the argument after (2.20) shows the existence of a function $u_{n+2} \neq 0$ satisfying

$$L_+u_{n+2} = \alpha Q \quad \text{for some } \alpha \in \mathbb{R}, \quad u_{n+2} \perp Q,\, L_-^{-1}u_1,\, L_-^{-1}\nabla Q = -\tfrac{1}{2}xQ.$$

By Lemma 2.1, $u_{n+2} + \frac{\alpha}{2}Q_1 = c \cdot \nabla Q$ for some $c \in \mathbb{R}^d$. The orthogonality conditions imply $u_{n+2} = 0$. The cases $p \in (1, p_c]$ are proved similarly. ∎

Remark 2.4. The formulation (2.19) for μ_1 has been used for the stability problem (see, e.g., [34, equation (4.1.9), p. 73]), which can be used to prove that $\mu_1 < 0$ if and only if $p \in (p_c, p_{\max})$ by a different argument. The latter fact also follows from [39, 14] indirectly.

We summarize our previous discussion in the following.

SUMMARY 2.5. *Let $Q(x)$ be the unique positive radial ground state solution of* (1.3)*, and let $\mathcal{L}$, L_+, and L_- be as in* (1.8) *and* (1.10)*. The eigenvalue problems* (2.14), (2.15)*, and* (2.17) *for $\mu \neq 0$ are equivalent, and the eigenvalues μ must be real. These eigenvalues can be counted by either* (2.18) *or* (2.19)*. $\mu_1 < 0$ if and only if $p \in (p_c, p_{\max})$. Furthermore, all eigenvalues of $\mathcal{L}$ are purely imaginary except for an additional real pair when $p \in (p_c, p_{\max})$.*

The last statement follows from the relation $\mu = -\lambda^2$ in (2.14).

2.3. Spectrum near 0 for p near p_c. We now consider eigenvalues of $\mathcal{L}$ near 0 when p is near p_c. It was suggested by Weinstein that as p approaches p_c from below, a pair of purely imaginary eigenvalues will collide at the origin and split into a pair of real eigenvalues for $p > p_c$. In the following theorem and corollary we prove this picture rigorously and identify the leading terms of the eigenvalues and eigenfunctions.

Note that Comech and Pelinovsky [7] consider a different problem, where the equation is fixed and the varying parameter is frequency ω rather than exponent p of the nonlinearity. That problem has only $U(1)$ symmetry and no translation, but its situation is similar to ours, since we consider radial functions only in our proof. It seems one can adapt their approach to give an alternative proof. They use an abstract projection (Riesz projection) onto the discrete spectrum to reduce the problem to a 4×4 matrix problem (and exploit the complex structure), while we are more direct.

THEOREM 2.6. *There are small constants $\mu_* > 0$ and $\varepsilon_* > 0$ so that for every $p \in (p_c - \varepsilon_*, p_c + \varepsilon_*)$, there is a solution of*

$$L_+L_-w = \mu w \tag{2.21}$$

of the form

$$w = w_0 + (p-p_c)^2 g, \quad w_0 = Q + a(p-p_c)|x|^2 Q, \quad g \perp Q,$$

$$\mu = 8a(p - p_c) + (p - p_c)^2\eta, \quad a = a(p) = \frac{n(Q_1, Q^p)}{4(Q_1, x^2 Q)} < 0,$$

with $\|g\|_{L^2}$, $|\eta|$, $|a|$, *and* $1/|a|$ *uniformly bounded in* p. *Moreover, for* $p \neq p_c$, *this is the unique solution of* (2.21) *with* $0 < |\mu| \leq \mu_*$.

Proof. Set $\varepsilon := p - p_c$. Computations yield

$$(Q_1, Q) = \left(\frac{2}{p-1} - \frac{n}{2}\right)(Q, Q) = -\frac{\varepsilon n}{2(p-1)}(Q, Q), \tag{2.22}$$

$$(Q_1, Q^p) = -\frac{1}{p-1}(L_+ Q, Q_1) = -\frac{1}{p-1}(Q, L_+ Q_1) = \frac{2}{p-1}(Q, Q), \tag{2.23}$$

and

$$(Q_1, |x|^2 Q) = \left(\frac{2}{p-1} - \frac{n+2}{2}\right)(Q, |x|^2 Q) = -\left(1 + \frac{\varepsilon n}{2(p-1)}\right)(Q, |x|^2 Q). \tag{2.24}$$

Since by (2.21) with $\mu \neq 0$

$$(Q_1, w) = \mu^{-1}(Q_1, L_+ L_- w) = \mu^{-1}(L_- L_+ Q_1, w) = 0,$$

we require the leading term $(Q_1, w_0) = 0$, which decides the value of a using (2.22) and (2.24). Thus we also need $(Q_1, g) = 0$. That $a < 0$ (at least for ε sufficiently small) follows from (2.23) and (2.24).

Using the computations

$$L_- |x|^2 Q = [L_-, |x|^2] Q = -4x \cdot \nabla Q - 2nQ = -4Q_1 - \frac{2n}{p-1}\varepsilon Q \tag{2.25}$$

and

$$L_+ Q = [L_- - (p-1)Q^{p-1}]Q = -(p-1)Q^p,$$

we find that

$$L_+ L_- w_0 = a\varepsilon L_+ \left[-4Q_1 - \frac{2n}{p-1}\varepsilon Q\right] = a\varepsilon[8Q + 2n\varepsilon Q^p].$$

Thus $\mu = 8a\varepsilon + o(\varepsilon)$ and we need to solve

$$0 = [L_+ L_- - 8a\varepsilon - \varepsilon^2\eta][w_0 + \varepsilon^2 g],$$

which yields our main equation for g and η:

$$L_+ L_- g = 8a^2(|x|^2 Q) - 2an(Q^p) + \eta w_0 + (8a\varepsilon + \varepsilon^2\eta)g. \tag{2.26}$$

Recall that on radial functions (we will work only on radial functions here)

$$\ker[(L_+ L_-)^*] = \ker[L_- L_+] = \operatorname{span}\{Q_1\}.$$

Let P denote the L^2-orthogonal projection onto Q_1 and $\bar{P} := \mathbf{1} - P$. It is necessary that

$$P[8a^2(|x|^2 Q) - 2an(Q^p) + \eta w_0 + (8a\varepsilon + \varepsilon^2\eta)g] = 0$$

for (2.26) to be solvable. This solvability condition holds since $(Q_1, g) = (Q_1, w_0) = 0$, and, using the relations (2.24) and (2.23), $(Q_1, 8a^2(|x|^2 Q) - 2an(Q^p)) = 0$.

Consider the restriction (on radial functions)

$$T = L_+ L_- : \ [\ker L_-]^\perp = Q^\perp \longrightarrow Ran(\bar{P}) = Q_1^\perp.$$

Its inverse $T^{-1} = (L_-)^{-1}(L_+)^{-1}$ is bounded because $(L_+)^{-1} : Q_1^\perp \to Q^\perp$ and $(L_-)^{-1} : Q^\perp \to Q^\perp$ are bounded. So our strategy is to solve (2.26) as

$$g = T^{-1}\bar{P}[8a^2(|x|^2 Q) - 2an(Q^p) + \eta w_0 + (8a\varepsilon + \varepsilon^2\eta)g] \tag{2.27}$$

by a contraction mapping argument, with η chosen so that $(Q_1, g) = 0$. Specifically, we define a sequence $g_0 = 0$, $\eta_0 = 0$, and

$$\begin{aligned} g_{k+1} &= \bar{P}T^{-1}\bar{P}[8a^2(|x|^2 Q) - 2an(Q^p) + \eta_k w_0 + (8a\varepsilon + \varepsilon^2\eta_k)g_k], \\ \eta_{k+1} &= -\frac{1}{(Q_1, T^{-1}w_0)}\,(Q_1, T^{-1}\bar{P}[8a^2(|x|^2 Q) - 2an(Q^p) + (8a\varepsilon + \varepsilon^2\eta_k)g_k]). \end{aligned}$$

We need to check that$(Q_1, T^{-1}w_0)$ is of order one. Since $w_0 = Q + O(\varepsilon)$ and $L_+ Q_1 = -2Q$, we have $(L_+)^{-1}w_0 = -\frac{1}{2}\Pi Q_1 + O(\varepsilon)$, where Π denotes the orthogonal projection onto $Q^\perp$. Thus, using (2.25) and (2.22),

$$\begin{aligned} (Q_1, T^{-1}w_0) &= -\frac{1}{2}(Q_1, (L_-)^{-1}\Pi Q_1) + O(\varepsilon) \\ &= \frac{1}{8}(Q_1, \Pi|x|^2 Q) + O(\varepsilon) = \frac{1}{8}(Q_1, |x|^2 Q) + O(\varepsilon), \end{aligned}$$

which is of order one because of (2.24). One may then check that $N_k := \|g_{k+1} - g_k\|_{L^2} + \varepsilon^{1/2}|\eta_{k+1} - \eta_k|$ satisfies $N_{k+1} \le C\varepsilon^{1/2}N_k$, and hence (g_k, η_k) is indeed a Cauchy sequence.

Finally, the uniqueness follows from the invariance of the total dimension of generalized eigenspaces near 0 under perturbations. □

Remark 2.7. To understand heuristically the leading terms in w and μ, consider the following analogy. Let $A_\varepsilon = \left[\begin{smallmatrix} 0 & 1 \\ 0 & \varepsilon \end{smallmatrix}\right]$, which corresponds to L_+L_-. One has $A_\varepsilon \left[\begin{smallmatrix} 1 \\ 0 \end{smallmatrix}\right] = \left[\begin{smallmatrix} 0 \\ 0 \end{smallmatrix}\right]$, $A_\varepsilon \left[\begin{smallmatrix} 0 \\ 1 \end{smallmatrix}\right] = \left[\begin{smallmatrix} 1 \\ \varepsilon \end{smallmatrix}\right]$, and $A_\varepsilon \left[\begin{smallmatrix} 1 \\ \varepsilon \end{smallmatrix}\right] = \varepsilon \left[\begin{smallmatrix} 1 \\ \varepsilon \end{smallmatrix}\right]$. The vectors $\left[\begin{smallmatrix} 1 \\ 0 \end{smallmatrix}\right]$, $\left[\begin{smallmatrix} 0 \\ 1 \end{smallmatrix}\right]$, and $\left[\begin{smallmatrix} 1 \\ \varepsilon \end{smallmatrix}\right]$ correspond to Q, $|x|^2 Q$, and w, respectively.

The theorem yields an eigenvalue μ with the same sign as $p_c - p$. Since the eigenvalues of $\mathcal{L}$ are given by $\lambda = \pm\sqrt{-\mu}$, we have the following corollary.

COROLLARY 2.8. *With notation as in Theorem* 2.6*, $\mathcal{L}$ has a pair of eigenvalues $\lambda = \pm\sqrt{-\mu} = \pm\sqrt{8|a|(p - p_c) - (p - p_c)^2\eta}$ with corresponding eigenvectors $\left[\begin{smallmatrix} u \\ w \end{smallmatrix}\right]$ solving* (2.12) *and*

$$u = \lambda^{-1}L_- w = \mp\sqrt{2|a|(p - p_c)}\,Q_1 + O((p - p_c)^{3/2}).$$

When $p \in (p_c - \varepsilon_*,\ p_c)$ (stable case), λ and u are purely imaginary.

When $p \in (p_c,\ p_c + \varepsilon_*)$ (unstable case), λ and u are real.

In deriving the leading term of u we have used (2.25). We solved for w before u simply because w is larger than u.

3. One-dimensional theory. In this section we focus on the one-dimensional theory. For $n = 1$, the ground state $Q(x)$ has an explicit formula for all $p \in (1, \infty)$:

$$Q(x) = c_p \cosh^{-\beta}\left(\frac{x}{\beta}\right), \quad c_p := \left(\frac{p+1}{2}\right)^{\frac{1}{p-1}}, \quad \beta := \frac{2}{p-1}. \tag{3.1}$$

The function $Q(x)$ satisfies (1.3) and is the unique $H^1(\mathbb{R})$-solution of (1.3) up to translation and phase [5, Theorem 8.1.6, p. 259].

3.1. Eigenfunctions of L_+ and L_-. We first consider eigenvalues and eigenfunctions of L_+ and L_-. For $n = 1$,

$$L_+ = -\partial_{xx} + 1 - pQ^{p-1}, \quad L_- = -\partial_{xx} + 1 - Q^{p-1}. \tag{3.2}$$

By (3.1), these operators are both of the form

$$-\partial_{xx} + 1 - C\,\mathrm{sech}^2(x/\beta).$$

Such operators have essential spectrum $[1, \infty)$ and finitely many eigenvalues below 1. A lot of information about such operators is available in the classical book [35, p. 103]:

- all eigenvalues are simple and can be computed explicitly as zeros and poles of an explicit meromorphic function;
- all eigenfunctions can be expressed in terms of the hypergeometric function.

We begin by presenting another way to derive the eigenvalues as well as different formulas for the eigenfunctions. We will not prove right here that this set contains all of the eigenvalues/eigenfunctions. This fact is a consequence of the more general theorem, Theorem 3.4, proved later (and see also [35]).

Define

$$\begin{aligned} &\lambda_m := 1 - k_m^2, \quad k_m := \frac{p+1}{2} - \frac{m(p-1)}{2}, \\ &p_m := \frac{m+1}{m-1} \quad \text{for } m > 1, \quad p_1 = \infty. \end{aligned} \tag{3.3}$$

The following theorem agrees with the numerical observation Figure 1.

Theorem 3.1. *For $n = 1$ and $1 < p < \infty$, let $Q(x)$ be defined by (3.1), L_+ and L_- be defined by (3.2), and λ_m, k_m, p_m be defined by (3.3). Suppose for $M \in \mathbb{Z}^+$,*

$$p_{M+1} \le p < p_M. \tag{3.4}$$

Then the operator L_+ has eigenvalues λ_m, $0 \le m \le M$, with eigenfunctions of the form

$$\varphi_{2\ell} = \sum_{j=0}^{\ell} c_{2j}^{2\ell} Q^{k_{2j}}, \quad \varphi_{2\ell-1} = \sum_{j=1}^{\ell} c_{2j-1}^{2\ell-1} (Q^{k_{2j-1}})_x,$$

and the operator L_- has eigenvalues λ_m, $1 \le m \le M$, with eigenfunctions of the form

$$\psi_{2\ell-1} = \sum_{j=1}^{\ell} d_{2j-1}^{2\ell-1} Q^{k_{2j-1}}, \quad \psi_{2\ell} = \sum_{j=1}^{\ell} d_{2j}^{2\ell} (Q^{k_{2j}})_x.$$

In particular, all eigenvalues of L_- are eigenvalues of L_+, and L_+ always has one more eigenvalue ($\lambda_0 < 0$) than L_-.

Proof. It can be proved by induction, using

$$Q^{p-1} = \frac{p+1}{2}\cosh^{-2}\left(\frac{x}{\beta}\right), \quad Q_x = -Q\tanh\left(\frac{x}{\beta}\right), \quad Q_x^2 = Q^2\left(1 - \frac{2}{p+1}Q^{p-1}\right),$$

and

$$Q^{-k}L_+Q^k = \frac{(k+p)\,(2k-p-1)}{p+1}\,Q^{p-1} + (1-k^2), \tag{3.5}$$

$$[(Q^k)_x]^{-1}L_+(Q^k)_x = \frac{(k-1)(2k+3p-1)}{p+1}\,Q^{p-1} + (1-k^2),$$

$$Q^{-k}L_-Q^k = \frac{(k-1)(2k+p+1)}{p+1}\,Q^{p-1} + (1-k^2), \tag{3.6}$$

$$[(Q^k)_x]^{-1}L_-(Q^k)_x = \frac{(k+p)(2k+p-3)}{p+1}\,Q^{p-1} + (1-k^2).$$

The coefficients of Q^{p-1} vanish when $k = \frac{p+1}{2}, 1, 1, \frac{3-p}{2}$, respectively. It is why the highest power of Q is $Q^{\frac{p+1}{2}}$ in $\varphi_{2\ell}$, Q_x in $\phi_{2\ell-1}$, Q in $\psi_{2\ell-1}$, and $(Q^{\frac{3-p}{2}})_x$ in $\psi_{2\ell}$. ◻

3.2. Connection between L_+ and L_- and their factorizations. In light of Theorem 3.1, it is natural to ask *why* all eigenvalues of L_- are also eigenvalues of L_+. Is there a simple connection between their eigenfunctions? In this section we prove this is indeed so.

We first look for an operator U of the form

$$U = \partial_x + R(x) \quad (\text{ so } U^* = -\partial_x + R(x))$$

such that

$$L_-U = UL_+ \quad (\text{ so } U^*L_- = L_+U^*). \tag{3.7}$$

It turns out that there is a unique choice of $R(x)$:

$$R(x) = -\frac{p+1}{2}\frac{Q_x}{Q} = \frac{p+1}{2}\tanh\left(\frac{(p-1)x}{2}\right).$$

In fact, with this choice of $R(x)$,

$$U = \varphi_0\partial_x\varphi_0^{-1} \quad (\text{ so } U^* = -\varphi_0^{-1}\partial_x\varphi_0), \tag{3.8}$$

where $\varphi_0 = Q^{\frac{p+1}{2}}$ is the ground state of L_+ and is considered here as a multiplication operator: $Uf = \varphi_0\partial_x(\varphi_0^{-1}f)$.

Suppose now ψ is an eigenfunction of L_- with eigenvalue λ: $L_-\psi = \lambda\psi$. By (3.7),

$$0 = U^*(L_- - \lambda)\psi = (L_+ - \lambda)U^*\psi.$$

Thus $U^*\psi$ is an eigenfunction of L_+ with the same eigenvalue λ (provided $U^*\psi \in L^2$). Therefore the map

$$\psi \mapsto U^*\psi$$

sends an eigenfunction of L_- to an eigenfunction of L_+ with the same eigenvalue. This map is not onto because U^* is not invertible. Specifically, the ground state φ_0 is not in the range. In fact, $U\varphi_0 = \varphi_0\partial_x\varphi_0^{-1}\varphi_0 = 0$. If $\varphi_0 = U^*\psi$, then $(\varphi_0,\varphi_0) = (\varphi_0, U^*\psi) = (U\varphi_0, \psi) = 0$, a contradiction. We summarize our finding as the following proposition.

PROPOSITION 3.2. *Under the same assumptions and notation as Theorem* 3.1, *the eigenfunctions* φ_m *and* ψ_m *of* L_+ *and* L_- *satisfy*

$$\varphi_m = U^* \psi_m \quad (m = 1, \dots, M)$$

up to constant factors. Note that U^* *sends even functions to odd functions and vice versa.*

Proof. We need only verify that $U^*\psi_m \in L^2$. This is the case, since $U^* = -\partial_x + \frac{p+1}{2}\tanh(x/\beta)$, $\psi_m(x)$ are sums of powers of Q and Q_x and since $\tanh(x/\beta)$, Q_x/Q, and Q_{xx}/Q_x are bounded. ◻

Analogous to the definition of U, we define

$$S := Q\partial_x Q^{-1} = \partial_x - \frac{Q_x}{Q} \quad (\text{ so } S^* = -Q^{-1}\partial_x Q). \tag{3.9}$$

Clearly $SQ = 0$. Recall that λ_0 is the first eigenvalue of L_+ with eigenfunction φ_0. Hence $L_+ - \lambda_0$ is a nonnegative operator. In fact we have the following factorizations.

LEMMA 3.3. *Let* U *and* S *be defined by* (3.8) *and* (3.9), *respectively. One has*

$$L_+ - \lambda_0 = U^*U, \quad L_- - \lambda_0 = UU^*. \tag{3.10}$$

$$L_- = S^*S, \quad SS^* = -\partial_x^2 + 1 + \frac{p-3}{p+1}Q^{p-1}. \tag{3.11}$$

Moreover, $SS^* = L_- + \frac{2(p-1)}{p+1}Q^{p-1} > 0$.

The formula $L_- = S^*S$ was known; see, e.g., [34, equation (4.1.8), p. 73]. It is an example of the Darboux transformations; see, e.g., [23]. Factorization of Schrödinger operators into first-order operators has been known since the times of Darboux (1840s).

3.3. Hierarchy of operators. In this subsection we generalize Theorem 3.1 and Lemma 3.3 to a family of operators containing L_+ and L_-. As a reminder, we have

$$\begin{aligned} &\frac{Q''}{Q} = 1 - Q^{p-1}, \quad \left(\frac{Q'}{Q}\right)^2 = 1 - \frac{2}{p+1}Q^{p-1}, \\ &\left(\frac{Q'}{Q}\right)' = \frac{Q''}{Q} - \left(\frac{Q'}{Q}\right)^2 = -\frac{p-1}{p+1}Q^{p-1}. \end{aligned} \tag{3.12}$$

Let $S(a) := Q^a\partial_x Q^{-a}$. We have

$$\begin{aligned} &S(a) = \partial_x - \frac{aQ'}{Q}, \quad S(a)^* = -\partial_x - \frac{aQ'}{Q}, \\ &S(a)^*S(a) = -\partial_x^2 + a^2 - a\left\{a + \frac{p-1}{2}\right\}\frac{2}{p+1}Q^{p-1}. \end{aligned} \tag{3.13}$$

Define the following hierarchy of operators:

$$\begin{aligned} &S_j := S(k_j), \quad \text{where recall} \quad k_j = 1 - (j-1)\frac{p-1}{2}, \\ &L_j := S_{j-1}S_{j-1}^* + \lambda_{j-1} = S_j^*S_j + \lambda_j, \quad \text{where recall} \quad \lambda_j = 1 - k_j^2. \end{aligned} \tag{3.14}$$

Then we have

$$\begin{aligned} &S_0 = U, \quad S_1 = S, \dots, \\ &L_0 = L_+, \quad L_1 = L_-, \quad L_2 = SS^*, \dots, \\ &S_j L_j = L_{j+1} S_j, \quad L_j S_j^* = S_j^* L_{j+1}. \end{aligned} \tag{3.15}$$

More explicitly,

$$L_j = -\partial_x^2 + 1 - k_{j-1} k_j \frac{2}{p+1} Q^{p-1}. \tag{3.16}$$

Note that j here can be any real number.

Recall the definition $p_j := 1 + 2/(j-1)$ for $j > 1$, and set $p_j = \infty$ for $j \le 1$. Then p_j is a monotone decreasing function of j, $k_j > 0$ for $p < p_j$, $k_j = 0$ for $p = p_j$, and $k_j < 0$ for $p > p_j$. Let

$$\lambda_j' := \begin{cases} \lambda_j & (1 < p \le p_j), \\ 1 & (p_j < p < p_{j-1}), \\ \lambda_{j-1} & (p_{j-1} \le p). \end{cases} \tag{3.17}$$

By the second identity of (3.14), and (3.16) together with the fact $k_{j-1}k_j < 0$ for $p_j < p < p_{j-1}$, we have the lower bound

$$L_j \ge \lambda_j'. \tag{3.18}$$

In fact, this estimate is sharp: for $p \in (1, p_j) \cup (p_{j-1}, \infty)$, the ground state is obvious from the second identity of (3.14):

$$\begin{cases} L_j Q_j = \lambda_j Q_j & (1 < p < p_j), \\ L_j Q_{j-1}^* = \lambda_{j-1} Q_{j-1}^* & (p_{j-1} < p), \end{cases} \tag{3.19}$$

where we denote

$$Q_j := Q^{k_j}, \quad Q_j^* := Q^{-k_j}. \tag{3.20}$$

For $p \in [p_j, p_{j-1}]$, there is no ground state. Thus we have completely determined the ground state of L_j for all $p > 1$. The complete spectrum, together with explicit eigenfunctions, is derived using the third identity of (3.15) as follows.

THEOREM 3.4. *For any $j \in \mathbb{R}$ and $p > 1$, the point spectrum of L_j consists of simple eigenvalues*

$$\begin{aligned} spec_p(L_j) = &\{\lambda_k \mid p < p_k,\ k \in \{j, j+1, j+2, \dots\}\} \\ &\cup \{\lambda_k \mid p > p_k,\ k \in \{j-1, j-2, j-3, \dots\}\}, \end{aligned} \tag{3.21}$$

and the eigenfunction for the eigenvalue λ_k is given uniquely up to constant multiple by

$$\begin{cases} S_j^* \cdots S_{k-1}^* Q_k & (k \in \{j, j+1, \dots\}), \\ S_{j-1} \cdots S_{k+1} Q_k^* & (k \in \{j-1, j-2, \dots\}), \end{cases} \tag{3.22}$$

each of which is a linear combination of

$$\begin{cases} Q_j, Q_{j+2}, \dots Q_k & (k \in \{j, j+2, \dots\}), \\ Q_{j+1}R, Q_{j+3}R, \dots Q_k R & (k \in \{j+1, j+3, \dots\}), \\ Q^*_{j-1}, Q^*_{j-3}, \dots Q^*_k & (k \in \{j-1, j-3, \dots\}), \\ Q^*_{j-2}R, Q^*_{j-4}R, \dots Q^*_k R & (k \in \{j-2, j-4, \dots\}), \end{cases} \tag{3.23}$$

where $R := Q'/Q$.

Proof. The ground states have been determined. The third identity of (3.15) implies that (3.22) belongs to the eigenspace of L_j with eigenvalue λ_k. Moreover, each function is nonzero because S_k^* is injective for $p < p_k$, and so is S_k for $p_k < p$. Since S_j annihilates only the ground state Q_j for $p < p_j$ and S^*_{j-1} annihilates only the ground state Q^*_{j-1} for $p > p_j$, all the excited states of L_j for $p < p_j$ are mapped injectively by S_j to bound states of L_{j+1} and for $p > p_j$ by S^*_{j-1} to those of L_{j-1}. Hence we have (3.21), and all the eigenvalues are simple because so too are the ground states. Equation (3.23) follows from the fact that S_j and S_j^* act on Q^a like $C(a,j)R$, while S_jS_{j-1} and $S^*_{j-1}S^*_j$ act on Q^a like $C_1(a,j) + C_2(a,j)Q^{p-1}$. ∎

3.4. Mirror conjugate identity. The following remarkable identity has application to estimating eigenvalues of $\mathcal{L}$ (see section 3.6):

$$S_j(L_{j-1} - \lambda_j)S_j^* = S_j^*(L_{j+2} - \lambda_j)S_j. \tag{3.24}$$

To prove this, start with the formula

$$\begin{aligned}(\partial_x + R)(\partial_x^2 + V)(\partial_x - R) &= \partial_x^4 + (-3R' - R^2 + V)\partial_x^2 + (-3R' - R^2 + V)'\partial_x \\ &\qquad - R''' - (VR)' - RR'' - R^2V,\end{aligned} \tag{3.25}$$

which implies that $(\partial_x + R)(\partial_x^2 + V_+)(\partial_x - R) = (\partial_x - R)(\partial_x^2 + V_-)(\partial_x + R)$ is equivalent to

$$V_\pm = -R''/R \pm 3R' - R^2 + C/R. \tag{3.26}$$

Now set $R := aQ'/Q$. Plugging the identities

$$\begin{aligned} &R^2 = a^2\left(1 - \frac{2}{p+1}Q^{p-1}\right), \quad R' = -a\frac{p-1}{p+1}Q^{p-1}, \\ &\frac{R''}{R} = -\frac{(p-1)^2}{p+1}Q^{p-1} \end{aligned} \tag{3.27}$$

into (3.26), we get, for $C = 0$,

$$V_\pm = -a^2 + \frac{2}{p+1}(a \pm (p-1))\left(a \pm \frac{(p-1)}{2}\right)Q^{p-1}. \tag{3.28}$$

Hence for $a = k_j$ we have

$$V_\pm = -k_j^2 + \frac{2}{p+1}k_{j\pm2}k_{j\pm1}, \tag{3.29}$$

which gives the desired identity (3.24). The above proof also shows that L_{j-1} and L_{j+2} are the unique choices for the identity to hold with S_j (modulo a constant multiple of Q/Q_x, which is singular).

3.5. Variational formulations for eigenvalues of $\mathcal{L}$. We considered two variational formulations for nonzero eigenvalues of $\mathcal{L}$ in general dimensions in section 2.2. Here we present a new variational formulation for one dimension. Define the self-adjoint operator

$$H := SL_+S^*. \tag{3.30}$$

This is a fourth-order differential operator with essential spectrum $[1, \infty)$. By a direct check, we have

$$HQ = SL_+S^*Q = SL_+(-2Q_x) = 0.$$

Thus Q is an eigenfunction with eigenvalue 0. Since $(Q, S^*f) = (SQ, f) = 0$ for any f, we have

$$\text{Range } S^* \perp Q. \tag{3.31}$$

In particular, since $L_+|_{Q^\perp}$ is nonnegative for $p \le 5$ by Lemma 2.2, so is H.

LEMMA 3.5. *The nullspace of H is*

$$N(H) = \text{span}\left\{Q, \delta^p_{p_c} xQ\right\},$$

where, recall, $\delta^p_{p_c}$ is 0 if $p \neq p_c$ and 1 if $p = p_c$.

Remark. Note that $\dim N(H) = 1+\delta^p_{p_c}$, which is different from $\dim N(L_-^{1/2}L_+L_-^{1/2}) = 2 + \delta^p_{p_c}$. We will show below that H and $L_-^{1/2}L_+L_-^{1/2}$ have the same *nonzero* eigenvalues.

Proof. If $Hf = 0$, then $L_+S^*f = -2cQ$ and $S^*f = cQ_1 + dQ_x$ for some $c, d \in \mathbb{R}$ by Lemma 2.1. We have $Q_1 \perp Q$ if and only if $p = p_c = 5$. Thus, if $p \neq 5$, $c = 0$ by (3.31), and $S^*(f + \frac{d}{2}Q) = 0$. We conclude that $f = -\frac{d}{2}Q$.

When $p = 5$, we have $S^*xQ = -Q^{-1}\partial_x(QxQ) = -2Q_1$. Thus $S^*(f+\frac{c}{2}Q_1+\frac{d}{2}Q) = 0$ and $f = -\frac{c}{2}Q_1 - \frac{d}{2}Q$. $\square$

Define eigenvalues of H as follows:

$$\tilde{\mu}_j := \inf_{f\perp f_k, k<j} \frac{(f, Hf)}{(f, f)}, \qquad (j = 1, 2, 3, \dots) \tag{3.32}$$

with a suitably normalized minimizer denoted by f_j if it exists. By standard variational arguments, if $\tilde{\mu}_j < 1$, then a minimizer f_j exists. By convention, if μ_k is the first of the μ_j's to hit 1 (and so f_k may not be defined), we set $\mu_j := 1$ for all $j > k$.

We can expand Summary 2.5 to the following.

THEOREM 3.6 (equivalence). *Let $n = 1$. Let μ_j be defined as in Summary 2.5 and $\tilde{\mu}_j$ be defined by (3.32). Then $\mu_j = \tilde{\mu}_j$. When $\mu_j \neq 0$ and $\mu_j < 1$, the eigenfunctions of (2.19) and (3.32) can be chosen to satisfy*

$$u_j = S^*f_j, \quad f_j = \frac{1}{\mu_j}SL_+u_j.$$

Proof. First, we establish the equivalence of nonzero eigenvalues. Suppose $f = f_j$ is an eigenfunction of (3.32) with eigenvalue $\tilde{\mu} \neq 0$; then $SL_+S^*f = \tilde{\mu}f$. Let $u := S^*f \neq 0$, and apply S^* on both sides. By $L_- = S^*S$ we get $L_-L_+u = \tilde{\mu}u$. Thus u is an eigenfunction satisfying (2.14) with $\mu = \tilde{\mu}$. On the other hand, suppose u satisfies

$L_-L_+u = \mu u$ with $\mu \neq 0$. Applying SL_+ on both sides and using $L_- = S^*S$, we get $SL_+S^*SL_+u = \mu SL_+u$, i.e., $Hf = \mu f$ for $f = \mu^{-1}SL_+u$.

Now use Lemmas 2.3 and 3.5. If $p \in (1,5)$, then $\mu_1 = \tilde{\mu}_1 = 0$, corresponding to Q_x and Q, and $\mu_2 = \tilde{\mu}_2 > 0$. If $p = 5$, then $\mu_1 = \mu_2 = \tilde{\mu}_1 = \tilde{\mu}_2 = 0$, corresponding to Q_x, Q_1, and Q, xQ, and $\mu_3 = \tilde{\mu}_3 = 1$. If $p \in (5,\infty)$, then $\mu_1 = \tilde{\mu}_1 < 0$, $\mu_2 = \tilde{\mu}_2 = 0$, corresponding to Q_x and Q, and $\mu_3 = \mu_3 = 1$. We have shown that $\tilde{\mu}_j = \mu_j$. $\square$

In the following we will make no distinction between μ_j and $\tilde{\mu}_j$. By the minimax principle, (3.32) has the following equivalent formulations:

$$\mu_j = \inf_{\dim M = j} \sup_{f \in M} \frac{(f,Hf)}{(f,f)} = \sup_{\dim M = j-1} \inf_{f \perp M} \frac{(f,Hf)}{(f,f)}. \tag{3.33}$$

Here M runs over all linear subspaces of $L^2(\mathbb{R})$ with the specified dimension.

3.6. Estimates of eigenvalues of $\mathcal{L}$. In this subsection we prove lower and upper bounds for eigenvalues of $\mathcal{L}$, confirming some aspects of the numerical computations shown in Figures 1 and 6. Recall that, by Lemma 2.3, the first positive μ_j is μ_2 for $p \in (1, p_c)$ and μ_3 for $p \in [p_c, p_{\max})$. The first theorem concerns upper bounds for μ_1 and μ_2.

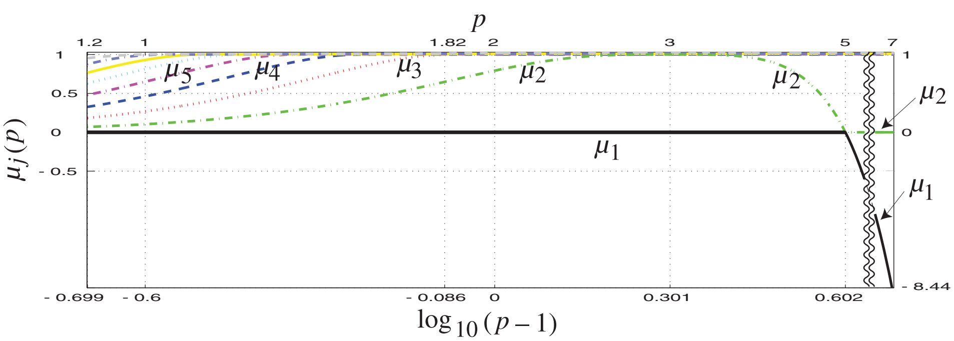

FIG. 6. *p vs. μ_j.*

THEOREM 3.7. *Suppose $n = 1$ and $1 < p < \infty$.*

(a) *If $p \neq 3$, then $\mu_2 \le C_p$ for some explicitly computable $C_p < 1$. In particular, f_2 exists.*

(b) *$\mu_1 < 0$ if and only if $p > 5$. For any $C > 0$, we have $\mu_1(p) \le -Cp^3$ for p sufficiently large.*

Proof. For part (a), we already know $\mu_2 = 0$ for $p \ge 5$. Assume $p \in (1,5)$. Consider test functions of the form $f = SQ^k$ with $k > 0$. f is odd, and hence $f \perp Q$, the 0-eigenfunction of H. Since $H = SL_+S^*$ and $S^*S = L_-$, we have

$$\mu_2 \le \frac{(f,Hf)}{(f,f)} = \frac{(L_-Q^k, L_+L_-Q^k)}{(Q^k, L_-Q^k)}.$$

By formulas (3.5) and (3.6),

$$L_-Q^k = aQ^{k+p-1} + bQ^k, \quad a = \frac{1}{p+1}(k-1)(2k+p+1), \quad b = 1 - k^2,$$

$$L_+Q^{k+p-1} = \sigma Q^{k+2p-2} + dQ^{k+p-1},$$

$$\sigma = \frac{1}{p+1}(k+2p-1)(2k+p-3), \quad d = 1-(k+p-1)^2,$$

$$L_+Q^k = cQ^{k+p-1} + bQ^k, \quad c = \frac{1}{p+1}(k+p)(2k-p-1).$$

Thus

$$\frac{(f,Hf)}{(f,f)} = \frac{a^2\sigma J_3 + a(ad+bc+b\sigma)J_2 + b(ad+ab+bc)J_1 + b^3 J_0}{aJ_1 + bJ_0}, \tag{3.34}$$

where

$$J_m = \int_{\mathbb{R}} Q^{2k+m(p-1)}(x)\,dx \quad (m = 0,1,2,3),$$

which are always positive. If $k \to 0^+$, then J_m converges to $\int_{\mathbb{R}} Q^{m(p-1)}\,dx$ for $m > 0$, and $J_0 = O(k^{-1})$. The above quotient can be written as

$$(3.34) = b^2 + \frac{J}{aJ_1 + bJ_0},$$

where

$$J = a^2\sigma J_3 + a(ad+bc+b\sigma)J_2 + b(ad+bc)J_1.$$

Note that $J_m|_{k=0} = (\frac{p+1}{2})^m \frac{2}{p-1} \int_{\mathbb{R}} \operatorname{sech}^{2m}(y)\,dy$ with $\int_{\mathbb{R}} \operatorname{sech}^{2m}(y)\,dy = 2, \frac{4}{3}, \frac{16}{15}$ for $m = 1,2,3$, respectively. Also, as $k \to 0^+$, $a \to -1$, $b \to 1$, $c \to -p$, $\sigma \to \frac{(2p-1)(p-3)}{p+1}$, and $d \to 1-(p-1)^2$. Direct calculation shows that

$$\lim_{k\to 0^+} J = -\frac{2}{15(p-1)}\,(p+1)^2(p-3)^2.$$

Also note that $b^2 < 1$ for $k > 0$. Thus, if $1 < p < \infty$ and $p \neq 3$, then $J < 0$ and the quotient (3.34) is less than 1 for k sufficiently small. (If $p = 3$, the sign of J is unclear and (3.34) may not be less than 1.) This proves $\mu_2 < 1$ and provides an upper bound less than 1 for μ_2. It also implies the existence of f_2. This establishes statement (a).

For statement (b), the fact that $\mu_1 < 0$ if and only if $p > 5$ is part of Lemma 2.3. We now consider the behavior of μ_1 for p large. Fix $k > 1$ to be chosen later. As $p \to \infty$,

$$J_m = \left(\frac{p+1}{2}\right)^{\frac{2k}{p-1}+m} \cdot \frac{2}{p-1} \cdot \int_{\mathbb{R}} (\operatorname{sech} x)^{\frac{4k}{p-1}+2m}\,dx \sim C_m p^{m-1},$$

with $C_m = 2^{1-m}\int_{\mathbb{R}}(\operatorname{sech} x)^{2m}dx = 2, \frac{2}{3}, \frac{4}{15}$ for $m = 1,2,3$, respectively, and

$$a \sim k-1, \quad b = 1-k^2, \quad c \sim -p, \quad \sigma \sim 2p, \quad d \sim -p^2.$$

Thus, by (3.34),

$$\frac{(f,Hf)}{(f,f)} \sim \frac{a\sigma J_3 + adJ_2}{J_1} \sim \frac{1-k}{15}\,p^3 \quad \text{as } p \to \infty.$$

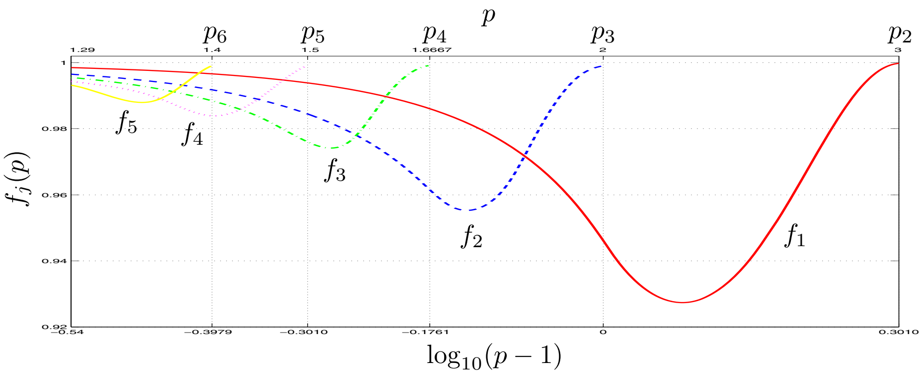

FIG. 7. *p vs. f_j for $j = 1, \ldots, 5$, where $f_j(p) = \frac{\lambda_{j+1}\lambda_{j+2}}{\mu_{j+1}}$ for $1 < p < p_{j+2}$ and $f_j(p) = \frac{\lambda_{j+1}}{\mu_{j+1}}$ for $p_{j+2} \le p < p_{j+1}$.*

By choosing $k > 1$ sufficiently large, we have shown that for any C, $\mu_1 \le -Cp^3$ for p sufficiently large. □

The next theorem bounds eigenvalues of $\mathcal{L}$ by eigenvalues of L_+ and L_-. Recall that p_j and $\lambda_j(p)$ are defined in (3.4) and (3.3).

THEOREM 3.8 (interlacing of eigenvalues). *Fix $k \ge 1$ and $p \in [p_{k+2},\ p_{k+1})$, where, recall, $p_j = \frac{j+1}{j-1}$. Let $\lambda_j(p) = 1 - \frac{1}{4}[(p+1) - j(p-1)]^2$ be as in (3.3), and so $\lambda_{k+1} < 1 \le \lambda_{k+2}$. For the eigenvalues μ_j defined by (3.32), we have*

$$\lambda_{j+1}^2(p) < \mu_{j+1}(p) < \lambda_{j+2}^2(p) \quad (1 \le j < k); \qquad \lambda_{k+1}^2(p) < \mu_{k+1}(p) \le 1. \tag{3.35}$$

In particular, there are K simple eigenvalues $\mu_2, \ldots, \mu_{K+1}$ in $(0, 1)$, where $K = k$ if $\mu_{k+1} < 1$ and $K = k - 1$ if $\mu_{k+1} = 1$. Moreover, K is always 1 when $k = 1$. Finally,

$$\mu_2 \ge \begin{cases} \lambda_2\lambda_3 & (1 < p \le 2), \\ \lambda_2 & (2 < p < 5), \end{cases} \qquad \mu_3 \ge \begin{cases} \lambda_3\lambda_4 & (1 < p \le 5/3), \\ \lambda_3 & (5/3 < p \le 2), \\ 1 & (2 < p < \infty), \end{cases}$$

$$\mu_1 \ge -\frac{1}{16}(p-1)^3(p-5) \quad (5 \le p < \infty).$$

Remark 3.9. In view of the above lower bounds for μ_2 and μ_3, we conjecture that

$$\mu_{j+1} \ge \lambda_{j+1}\lambda_{j+2} \quad (1 < p < p_{j+2}); \qquad \mu_{j+1} \ge \lambda_{j+1} \quad (p_{j+2} \le p < p_{j+1}). \tag{3.36}$$

This is further confirmed numerically for $j = 3, 4, 5$ (see Figure 7). Note that $\lim_{p \to p_{j+1}-} \frac{\lambda_{j+1}}{\mu_{j+1}} = 1$ because both λ_{j+1} and μ_{j+1} converge to 1. It also seems that $\frac{\lambda_{j+1}\lambda_{j+2}}{\mu_{j+1}}$ has a limit as $p \to 1+$, but it is not clear even though we have (3.35) and $\lambda_j = (j-1)(p-1) + O((p-1)^2)$ as $p \to 1+$.

Proof. We first prove the upper bound: For $j < k$, use the test functions

$$S\psi_2,\ S\psi_3, \ldots,\ S\psi_{j+2}$$

(we cannot use $S\psi_1$, since it is zero). Recall $L_-\psi_m = \lambda_m\psi_m$. Let $a = (a_2, \ldots, a_{j+2})$ vary over $\mathbb{C}^{j+1} - \{0\}$. By equivalent definition (3.33), $H = SL_+S^*$, $L_- = S^*S$, and the orthogonality between the ψ_m's, we have

$$\begin{aligned}\mu_{j+1} &\le \sup_a \frac{(\sum_m a_m S\psi_m, H\sum_\ell a_\ell S\psi_\ell)}{(\sum_m a_m S\psi_m, \sum_\ell a_\ell S\psi_\ell)} = \sup_a \frac{(\sum_m a_m\psi_m, L_-L_+L_-\sum_\ell a_\ell\psi_\ell)}{(\sum_m a_m\psi_m, L_-\sum_\ell a_\ell\psi_\ell)} \\ &\le \sup_a \frac{(\sum_m a_m\psi_m, L_-L_-L_-\sum_\ell a_\ell\psi_\ell)}{(\sum_m a_m\psi_m, L_-\sum_\ell a_\ell\psi_\ell)} = \sup_a \frac{\sum_m |a_m|^2\lambda_m^3}{\sum_m |a_m|^2\lambda_m} \\ &\le \max_{m=2,\dots,j+2} \lambda_m^2 = \lambda_{j+2}^2.\end{aligned}$$

Since $\mu_{j+1} \le \lambda_{j+2}^2 < 1$, it is attained at some function for which the second inequality above cannot be replaced by an equality sign. Thus $\mu_{j+1} < \lambda_{j+2}^2$.

For the lower bound of eigenvalues, we use only the special case $j = 1$ of (3.24):

$$H = SL_+S^* = SL_0S^* = S^*L_3S. \tag{3.37}$$

In particular, we have for $1 < p < 3$,

$$H \ge S^*L_2S = S^*SS^*S = L_1^2 = L_-^2, \tag{3.38}$$

which implies that

$$\lambda_{j+1}^2 \le \mu_{j+1} \quad (1 < p < 3) \tag{3.39}$$

(and again, equality is impossible).

For the second eigenvalue μ_2, we can get a more precise estimate by using (3.18) for $L_3 \ge \lambda_3'$ together with

$$L_1|_{Q^\perp} \ge \lambda_2', \tag{3.40}$$

which follows from *spec*(L_1). Combining these estimates, we have for any $f \perp Q$ and $p < 5$,

$$(Hf, f) \ge \lambda_3'(Sf, Sf) \ge \lambda_3'\lambda_2'(f, f), \tag{3.41}$$

which implies that $\mu_2 \ge \lambda_3'\lambda_2'$, i.e.,

$$\mu_2 \ge \begin{cases}\lambda_2\lambda_3 & (1 < p \le 2), \\ \lambda_2 & (2 < p < 5).\end{cases} \tag{3.42}$$

For $p > 3$, we have $L_3 \ge \lambda_2 = -(p-1)(p-5)/4$ and

$$L_3 - L_2 \ge -(p-1)(p-3)/2 =: -a. \tag{3.43}$$

Hence for any $t \in [0, 1]$, we have

$$L_3 \ge tL_2 - at + (1-t)\lambda_2, \tag{3.44}$$

and so for $b > 0$, we have

$$\begin{aligned}(Hf, f) + b(f, f) &\ge (S^*(tL_2 - at + (1-t)\lambda_2)Sf, f) + b(f, f) \\ &= t\|L_1f\|^2 - (at - (1-t)\lambda_2)(L_1f, f) + b\|f\|^2,\end{aligned} \tag{3.45}$$

which is nonnegative if

$$b \geq (at - (1-t)\lambda_2)^2/(4t), \tag{3.46}$$

whose infimum is attained at $t = -\lambda_2/(a+\lambda_2) = (p-5)/(p-1) \in (0,1)$ for $p > 5$. Plugging this back in, we obtain the lower bound

$$\mu_1 \geq \lambda_2(a+\lambda_2) = -\frac{1}{16}(p-1)^3(p-5) \quad (p > 5). \tag{3.47}$$

We have a similar bound on μ_3 by using the even-odd decomposition $L^2(\mathbb{R}) = L^2_{ev}(\mathbb{R}) \oplus L^2_{od}(\mathbb{R})$. Let ψ_j, ξ_j be the eigenfunction of L_1 and L_3 such that

$$L_1\psi_j = \lambda_j\psi_j, \quad L_3\xi_j = \lambda_j\xi_j. \tag{3.48}$$

ψ_j starts from $j = 1$, and ξ_j starts with $j = 3$. They are even for odd j and odd for even j. For any even function $f \perp Q = \psi_1$, Sf is odd, and so we have $f \perp \psi_1 = Q, \psi_2$ and $Sf \perp \xi_3$. Hence by *spec*(L_3) and *spec*(L_1), we have

$$(Hf,f) = (L_3Sf, Sf) \geq \tilde{\lambda}_4(Sf,Sf) = \tilde{\lambda}_4(L_1f,f) \geq \tilde{\lambda}_4\tilde{\lambda}_3(f,f), \tag{3.49}$$

where we denote

$$\tilde{\lambda}_j := \begin{cases} \lambda_j & (1 < p < p_j), \\ 1 & (p_j < p). \end{cases} \tag{3.50}$$

Thus the second eigenvalue of H on L^2_{ev} is $\geq \tilde{\lambda}_4\tilde{\lambda}_3$. Next for any odd function $f \perp \psi_2$, we have $f \perp \psi_1, \psi_2, \psi_3$. Hence we have

$$(Hf,f) = (L_3Sf, Sf) \geq \lambda_3'(Sf,Sf) = \lambda_3'(L_1f,f) \geq \lambda_3'\tilde{\lambda}_4(f,f). \tag{3.51}$$

Similarly, every odd function $f \perp S^*\xi_3$ satisfies $f \perp \psi_1$ and $Sf \perp \xi_3, \xi_4$, and so

$$(Hf,f) \geq \tilde{\lambda}_5\tilde{\lambda}_2(f,f). \tag{3.52}$$

Hence the second eigenfunction on L^2_{od} is $\geq \max(\tilde{\lambda}_4\lambda_3', \tilde{\lambda}_5\tilde{\lambda}_2) \geq \tilde{\lambda}_4\tilde{\lambda}_3$. Therefore we have $\mu_3 \geq \tilde{\lambda}_3\tilde{\lambda}_4$, i.e.,

$$\mu_3 \geq \begin{cases} \lambda_3\lambda_4 & (1 < p < 5/3), \\ \lambda_3 & (5/3 < p < 2), \\ 1 & (2 < p). \end{cases} \tag{3.53}$$

This argument, however, does not yield any useful estimates for the higher μ_j. □

3.7. Resonance for $p = 3$. In the theory of dispersive estimates for the linear Schrödinger evolution, it is important to know whether or not the endpoints of the continuous spectrum of the linear operator are eigenvalues or *resonances*. For our $\mathcal{L}$, the endpoints are $\lambda = \pm i$. Resonance here refers to a function ϕ which satisfies the eigenvalue problem locally in space with eigenvalue i or $-i$ but which does not belong to $L^2(\mathbb{R}^n)$. For dimension $n = 1$, one requires $\phi \in L^\infty(\mathbb{R})$. (Note for comparison's sake that in one dimension, the operator $-d^2/dx^2$ has a resonance—corresponding to the constant function—at the endpoint 0 of its continuous spectrum.)

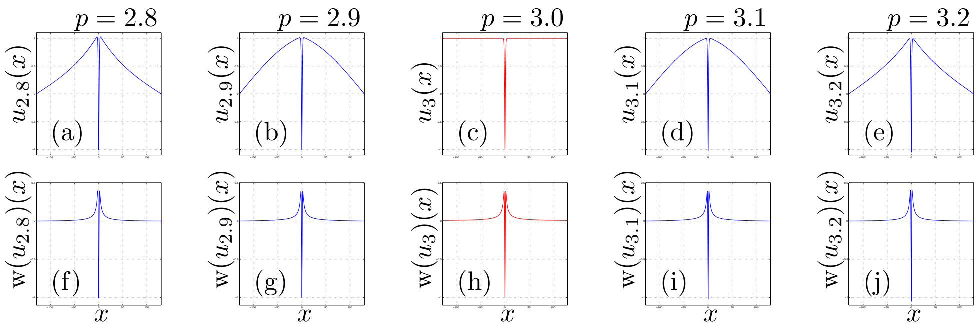

FIG. 8. *$u_p(x)$ and $\mathrm{w}(u_p)(x)$ for $p = 2.8, 2.9, 3, 3.1,$ and* 3.2.

Before we made the numerical calculation, we did not expect to see any resonance. However, from Figure 1, one sees that $\kappa = \sqrt{\mu_2}$ converges to 1 as $p \to 3$. What does the point $\kappa = 1$ at $p = 3$ correspond to? A natural conjecture is that it is a resonance or an eigenvalue, since the $p = 3$ case is well known to be completely integrable and special phenomena may occur.

This is indeed the case, since we have the following solution to the eigenvalue problem (2.12) when $p = 3$:

$$\phi = \begin{bmatrix} 1 - Q^2 \\ i \end{bmatrix}, \quad \lambda = i. \tag{3.54}$$

It is clear that $\phi \in L^\infty(\mathbb{R})$ but $\phi \notin L^q(\mathbb{R})$ for any $q < \infty$.

Let $u_p(x)$ denote the real-valued (and suitably normalized) solution of (2.14) corresponding to $\mu = \mu_2$. It is the first component of the eigenfunction of (2.12). A natural question is: does $u_p(x)$ converge in some sense to $u_3(x) := 1 - Q^2(x)$ as $p \to 3$? Since $u_p - u_3$ is not in $L^q(\mathbb{R})$ for all $q \in [1, \infty)$, it seems natural to measure the convergence in the following weighted norm,

$$\|f\|_{\mathrm{w}} := \int_{\mathbb{R}} \mathrm{w}(f)^2(x)\, dx,$$

where a weighting operator w is defined by $\mathrm{w}(f)(x) := f(x)\frac{1}{\sqrt{1+x^2}}$. This deemphasizes the value of $u_p - u_3$ for x large, and so it should converge to 0 as p goes to 3. This is confirmed numerically as follows.

Let $u_3 := 1 - Q^2$ and $\delta := \|u_3\|_{\mathrm{w}}$. In the appendix we will propose a numerical method to solve for the eigenpair $\{\lambda, [u_p(x),\ w_p(x)]^\top\}$ of (2.12) corresponding to $\mu_2 = -\lambda^2$. Renormalize $u_p(x)$ for $p \neq 3$ so that it is real-valued, $u_p(0) < 0$, and $\|u_p\|_{\mathrm{w}} = \delta$. In Figure 8(c) we plot u_3 in a large interval $|x| < 130$ with $\delta = 1.3588$. According to the numerical method in the appendix, we get $u_{2.8}, u_{2.9}, u_{3.1}$, and $u_{3.2}$ plotted in Figure 8(a), (b), (d), and (e), respectively. The vertical range is roughly $[-1, 1]$. In Figure 8(f)–(j) we plot $\mathrm{w}(u_p)$ for $p = 2.8, 2.9, 3, 3.1$, and 3.2, for $|x| < 130$, and with vertical range $[-1, 0.5]$.

In Figure 9 we plot p vs. $\|u_p - u_3\|_{\mathrm{w}}$ and observe that $u_p(x)$ converge to $u_3(x)$ in the weighted norm $\|\cdot\|_{\mathrm{w}}$ as $p \to 3$. In the numerical calculation for Figure 9, our increment for p is 0.01.

Remark 3.10. For the operators L_+L_- and L_-L_+, and in general fourth-order operators, it seems difficult to exclude the possibility that $\mu = 1$ is an eigenvalue. Consider the following example. Let $\tilde{H} := (L_+)^2$ with $p = \sqrt{8} - 1$. Note that -1 is

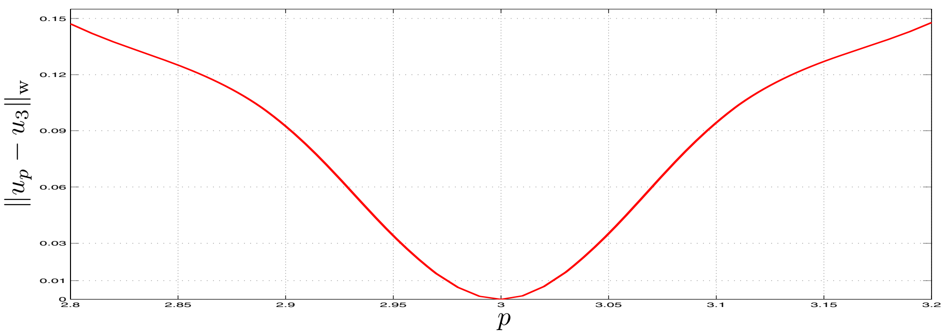

FIG. 9. p *vs.* $\|u_p - u_3\|_{\mathrm{w}}$.

an eigenvalue of L_+ when $p = \sqrt{8} - 1$. Hence 1 is an eigenvalue of $\tilde{H}$ at the endpoint of its continuous spectrum.

It would be interesting to prove the above convergence analytically and characterize the leading-order behavior near $p = 3$ as we did in Theorem 2.6.

4. Excited states with angular momenta. In this section we consider excited states with angular momenta in $\mathbb{R}^n$, $n \geq 2$. Let $k = [n/2]$, the largest integer no larger than $n/2$. For $x = (x_1, \dots, x_n) \in \mathbb{R}^n$, use polar coordinates r_j and θ_j for each pair x_{2j-1} and x_{2j}, $j = 1, \dots, k$. Lions [22] considers solutions of the form

$$Q(x) = \phi(r_1, r_2, \dots r_k, x_n)\, e^{i(m_1\theta_1 + \cdots + m_k\theta_k)}, \quad m_j \in \mathbb{Z}.$$

The dependence of ϕ in x_n is dropped if n is even. He proves the existence of energy minimizing solutions in each such class.

For the simplest case $n = 2$, $Q(x) = \phi(r)\, e^{im\theta}$, and, by (1.3), $\phi = \phi(r)$ satisfies

$$-\phi'' - \frac{1}{r}\phi' + \frac{m^2}{r^2}\phi + \phi - |\phi|^{p-1}\phi = 0 \quad (r > 0). \tag{4.1}$$

The natural boundary conditions are

$$\lim_{r\to 0} r^{-m}\phi(r) = \alpha, \quad \lim_{r\to 0} r^{-m+1}\phi'(r) = m\alpha, \quad \lim_{r\to\infty} \phi(r) = 0 \tag{4.2}$$

for some $\alpha \geq 0$. One can choose $\phi(r)$ real-valued. It is shown by Iaia and Warchall [17] that (4.1)–(4.2) has countably infinite many solutions, denoted by $\phi_{m,k,p}(r)$, each having exactly k positive zeros. They correspond to "m-equivariant" nonlinear bound states of the form

$$Q_{m,k,p} = \phi_{m,k,p}(r)\, e^{im\theta} \quad (k = 0, 1, 2, \dots). \tag{4.3}$$

Note that $Q_{m,k,p}$ are radial if and only if $m = 0$, and the ground state $Q = Q_{0,0,p}$ is considered in the previous sections. The uniqueness question of $\phi_{m,k,p}(r)$ is not addressed in [17]. It is proved for the case $k = 0$ in [24].

Mizumachi [24], [25], [26], and [27] considered the stability problem for these solutions. He showed the following:

1. under m-equivariant perturbations of the form $\varepsilon(r)e^{im\theta}$, $Q_{m,0,p}$ are stable for $1 < p < 3$ and unstable for $p > 3$;
2. under general perturbations, $Q_{m,k,p}$ are unstable for $p > 3$ for any k;

3. linear (spectral) instability implies nonlinear instability (it can also be obtained by extending the results in [31] to higher dimensions using the method of [1]);
4. for fixed $p > 1$, if $m > M(p)$ is sufficiently large, $Q_{m,k,p}$ are linearly unstable and its linearized operator has a positive eigenvalue.

We are most interested in the last result. Intuitively, for $1 < p < \infty$, $Q_{m,k,p}$ should be unstable for all $(m, k) \neq (0, 0)$, since they are excited states. Can this be observed numerically? It turns out to be true for p away from 1 but false for p near 1.

In the following, we first describe our numerical methods for $k = 0$ and then discuss their relations. We will discuss our numerical results in the end. We compute only $m = 1, 2$, but the same methods work for other m.

Remark 4.1. Our numerical methods do not apply when $k > 0$. Indeed, for $m \geq 0$ and $k > 0$, the radial functions $\phi_{m,k,p}(r)$ are sign-changing and cannot be numerically calculated using the method described in the appendix. In fact, it is an open question whether they are unique. Assuming the uniqueness, one needs to develop a new algorithm to compute them before one can compute the spectra of $\mathcal{L}$ for $Q_{m,k,p}$.

4.1. Numerical algorithms. There are two steps in our numerical method: First, compute $\phi_{m,0,p}(r)$. Second, compute the spectra of the discretized linearized operator around $Q_{m,0,p}$. The second step is more involved, and we will present three algorithms.

Step 1. Compute $\phi(r) = \phi_{m,0,p}(r)$. It is energy minimizing among all solutions of (4.1)–(4.2) for fixed m, p, and it is positive for $r > 0$. Since our algorithm in the appendix is applicable to all positive (ground state) solutions, we can use it to calculate the discretized vector of $\phi(r)$ with a small change of the code.

Step 2. Compute the spectra of the discretized linearized operator. The linearized operator $\mathcal{L}$ has a slightly different form than (1.9) because $Q = \phi_{m,0,p}(r)e^{im\theta}$ is no longer real. With the same ansatz (1.6)–(1.7), the linearized operator $\mathcal{L}$ has the form

$$\mathcal{L}h = i\left(\Delta h - h + \frac{p+1}{2}|Q|^{p-1}h + \frac{p-1}{2}|Q|^{p-3}Q^2\bar{h}\right). \tag{4.4}$$

We have developed three algorithms for computing the spectrum of $\mathcal{L}$.

Algorithm 1. Write $Q = \phi(r)\, e^{im\theta} = \phi(r)\cos(m\theta) + i\phi(r)\sin(m\theta)$. In vector form with $\mathcal{L}$ acting on $[\operatorname{Re} h, \operatorname{Im} h]^\top$, we have

$$\mathcal{L} \sim \begin{bmatrix} 0 & -\Delta + 1 \\ \Delta - 1 & 0 \end{bmatrix} + |\phi(r)|^{p-1} \begin{bmatrix} -(p-1)\cos\sin & -\cos^2 - p\sin^2 \\ p\cos^2 + \sin^2 & (p-1)\cos\sin \end{bmatrix}(m\theta). \tag{4.5}$$

It is convenient to use polar coordinates to discretize the operator. We use a two-dimensional mesh:

$$\text{2d mesh:} \quad r = 0 : \delta_r : r_{\max}, \quad \theta = 0 : \delta_\theta : 2\pi. \tag{4.6}$$

The discretized matrix has size NT by NT with $N = r_{\max}/\delta_r$ and $T = 2\pi/\delta_\theta$. We use zero boundary condition with $r_{\max} = 15$, $\delta_r = 0.04$, and $T = 160$.

Although the matrix operator (4.5) is slightly more complicated than (1.9) and the mesh is two-dimensional, the same numerical routine can be applied to compute the spectrum of the discretized matrix of (4.5). The only difference is that the matrix size is much larger.

ALGORITHM 2. By restricting the problem to some invariant subspaces of $\mathcal{L}$, as we did for the computation of Figures 4–5, we will reduce the problem to one dimension.

Observe that functions of the form $a(r)e^{ij\theta}$ with a fixed integer j are not preserved by $\mathcal{L}$ unless $j = m$, but the following L^2-subspaces are invariant under $\mathcal{L}$:

$$X_k = X_k^{(m)} = \left\{h(r,\theta) : h = a(r)e^{i(m+k)\theta} + b(r)e^{i(m-k)\theta}\right\}, \quad 0 \le j \in \mathbb{N}.$$

If $k = 0$, we drop $b(r)$ and $X_0 = \left\{h(r,\theta) : h = a(r)e^{im\theta}\right\}$. We will compute the spectra of $\mathcal{L}$ limited to each subspace X_k. Define

$$V = \frac{p-1}{2}\phi^{p-1}, \quad H_k = -\Delta_r + 1 + \frac{(m+k)^2}{r^2} - \frac{p+1}{2}\phi^{p-1}.$$

For $k = 0$, with $a = a_1 + ia_2$, and $a_1, a_2 \in \mathbb{R}$, we have

$$\mathcal{L}[a(r)e^{im\theta}] = -i\left[H_0 a - V\bar{a}\right]e^{im\theta} = [H_0(a_2 - ia_1) + V(a_2 + ia_1)]e^{im\theta}.$$

Thus, acting on $[a_1, a_2]^\top$, $\mathcal{L}|_{X_0}$ has the matrix form

$$L_{X_0} = \begin{bmatrix} 0 & H_0 + V \\ -H_0 + V & 0 \end{bmatrix}.$$

For $k > 0$, with $a = a_1 + ia_2$, $b = b_1 + ib_2$, and $a_1, a_2, b_1, b_2 \in \mathbb{R}$, we have

$$\begin{aligned} &\mathcal{L}[a(r)e^{i(m+k)\theta} + b(r)e^{i(m-k)\theta}] \\ &= [H_k(a_2 - ia_1) + V(b_2 + ib_1)]e^{i(m+k)\theta} + [H_{-k}(b_2 - ib_1) + V(a_2 + ia_1)]e^{i(m-k)\theta}. \end{aligned}$$

Thus, acting on $[a_1, a_2, b_1, b_2]^\top$, $\mathcal{L}|_{X_k}$ has the matrix form

$$L_{X_k} = \begin{bmatrix} 0 & H_k & 0 & V \\ -H_k & 0 & V & 0 \\ 0 & V & 0 & H_{-k} \\ V & 0 & -H_{-k} & 0 \end{bmatrix}.$$

To discretize the operator, we use the one-dimensional mesh

$$\text{1d mesh:} \quad r = 0 : \delta_r : r_{\max}, \quad N = r_{\max}/\delta_r. \tag{4.7}$$

The matrix corresponding to X_0 has size $2N$ by $2N$. The matrix for X_k with $k > 0$ has size $4N$ by $4N$. We use zero boundary condition with $r_{\max} = 30$ and $\delta_r = 0.01$.

Counting multiplicity, the set of eigenvalues of $\mathcal{L}$ is the union of eigenvalues of $\mathcal{L}|_{X_k}$ with $k = 0, 1, 2, \ldots$.

ALGORITHM 3. Instead of the form (1.6), include the phase $e^{im\theta}$ in the linearization: $\psi = (\phi + h)e^{im\theta + it}$. Then the linearized operator acting on $[\operatorname{Re} h, \operatorname{Im} h]^\top$ is

$$\mathcal{L}' = \begin{bmatrix} -2m/r^2\partial_\theta & -\Delta + 1 + m^2/r^2 - \phi^{p-1} \\ -(-\Delta + 1 + m^2/r^2 - p\phi^{p-1}) & -2m/r^2\partial_\theta \end{bmatrix},$$

which is invariant on subspaces $Z_k = \left\{[a_1(r), a_2(r)]^\top e^{ik\theta}\right\}$ with integers k. We have

$$\mathcal{L}' \begin{bmatrix} a_1(r) \\ a_2(r) \end{bmatrix} e^{ik\theta} = e^{ik\theta} L_{m,k} \begin{bmatrix} a_1(r) \\ a_2(r) \end{bmatrix},$$

where

$$L_{m,k} := \begin{bmatrix} -\frac{2imk}{r^2} & -\Delta_r + 1 + \frac{m^2+k^2}{r^2} - \phi^{p-1} \\ -(-\Delta_r + 1 + \frac{m^2+k^2}{r^2} - p\phi^{p-1}) & -\frac{2imk}{r^2} \end{bmatrix}$$

acting on radial functions. We use the same one-dimensional mesh (4.7) as in Algorithm 2. For every k, the matrix size is $2N$ by $2N$. We then compute the spectra of $L_{m,k}$ for each k.

Counting multiplicity, the set of eigenvalues of $\mathcal{L}$ is the union of eigenvalues of $L_{m,k}$ with $k = 0, \pm 1, \pm 2, \dots$.

4.2. Properties of these algorithms. We now address the relation between these algorithms. First, note that X_k is essentially the sum of Z_k and Z_{-k}. Let us make it more precise, and suppose $k > 0$. The case $k = 0$ is easier. A function $h = (a_1 + ia_2)(r)e^{i(m+k)\theta} + (b_1 + ib_2)(r)e^{i(m-k)\theta}$ in $X_k \subset L^2(\mathbb{R}^2)$ can be identified with $[a_1, a_2, b_1, b_2] \in \tilde{X}_k = L^2_{rad}(\mathbb{R}^2; \mathbb{R}^4)$. The space $\tilde{X}_k$ is a subspace of $L^2_{rad}(\mathbb{R}^2; \mathbb{C}^4)$ on which we compute the spectrum. The function h can be also identified with

$$\begin{bmatrix} a_1(r) \\ a_2(r) \end{bmatrix} e^{ik\theta} + \begin{bmatrix} b_1(r) \\ b_2(r) \end{bmatrix} e^{-ik\theta},$$

the collection of which form a subspace of $Z_k \oplus Z_{-k}$ with real components.

Nullspace of $\mathcal{L}$. The nullspace of $\mathcal{L}$ gives a good test of the correctness of our numerical results. For $k = 0$, the 0-eigenfunction iQ of $\mathcal{L}$ corresponds to $[0, \phi]^\top e^{im\theta}$ in X_0 and $[0, \phi]^\top$ in Z_0. The generalized eigenfunction $Q_1 = \frac{2}{p-1}Q + x \cdot \nabla Q$ corresponds to $[Q_1, 0]^\top e^{im\theta}$ in X_0 and $[\frac{2}{p-1}\phi + r\phi', 0]^\top$ in Z_0. Since $X_0 \subset L^2(\mathbb{R}^2, \mathbb{C})$, they also provide two (generalized) eigenvectors for Algorithm 1.

For $k = \pm 1$, the 0-eigenfunctions

$$2Q_{x_1} = 2(\phi' \cos\theta - i\psi \sin\theta)e^{im\theta} = (\phi' - \psi)e^{i(m+1)\theta} + (\phi' + \psi)e^{i(m-1)\theta},$$

$$2Q_{x_2} = 2(\phi' \sin\theta + i\psi \cos\theta)e^{im\theta} = i(-\phi' + \psi)e^{i(m+1)\theta} + i(\phi' + \psi)e^{i(m-1)\theta},$$

where $\psi = m\phi/r$, belong to X_1, and correspond to 0-eigenvectors $[\phi' - \psi, 0, \phi' + \psi, 0]^\top$ and $[0, -\phi' + \psi, 0, \phi' + \psi]^\top$ of L_{X_1}. For Algorithm 3, they correspond to the following vectors in $Z_1 \oplus Z_{-1}$:

$$2\begin{bmatrix} \phi' \cos\theta \\ -\psi \sin\theta \end{bmatrix} = W_+ e^{i\theta} + W_- e^{-i\theta}, \quad 2\begin{bmatrix} \phi' \sin\theta \\ \psi \cos\theta \end{bmatrix} = -iW_+ e^{i\theta} + iW_- e^{-i\theta},$$

where

$$W_\pm = \begin{bmatrix} \phi' \\ \pm i\psi \end{bmatrix}, \quad L_{m,\pm 1} W_\pm = \begin{bmatrix} 0 \\ 0 \end{bmatrix}.$$

Thus $W_+ e^{i\theta}$ is a 0-eigenvector of $\mathcal{L}'$ in Z_1, and $W_- e^{-i\theta}$ is a 0-eigenvector of $\mathcal{L}'$ in Z_{-1}.

The generalized eigenfunctions

$$\begin{aligned} ix_1 Q &= ir\phi \cos\theta e^{im\theta} = ir\phi e^{i(m+1)\theta} + ir\phi e^{i(m-1)\theta}, \\ ix_2 Q &= ir\phi \sin\theta e^{im\theta} = r\phi e^{i(m+1)\theta} - r\phi e^{i(m-1)\theta} \end{aligned}$$

also lie in X_1 and correspond to generalized 0-eigenvectors $[0, r\phi, 0, r\phi]^\top$ and $[r\phi, 0, -r\phi, 0]^\top$ of L_{X_1}. For Algorithm 3, they correspond to $[0, r\phi\cos\theta]^\top$ and $[0, r\phi\sin\theta]^\top$ in $Z_1 \oplus Z_{-1}$. By the same consideration as for Q_{x_1} and Q_{x_2}, their span over $\mathbb{C}$ is the same as the span of $[0, r\phi]^\top e^{i\theta} \in Z_1$ and $[0, r\phi]^\top e^{-i\theta} \in Z_{-1}$. One can check that

$$L_{m,\pm 1}\begin{bmatrix} 0 \\ r\phi \end{bmatrix} = -2\begin{bmatrix} \phi' \\ \pm i\psi \end{bmatrix}. \tag{4.8}$$

Thus, the multiplicity of 0-eigenvalue in each of X_0, Z_{-1}, Z_0, and Z_1 is at least 2. The multiplicity of 0-eigenvalue on X_1 is at least 4.

Symmetry of spectra. If

$$L_{m,k}\begin{bmatrix} A \\ B \end{bmatrix} = \lambda\begin{bmatrix} A \\ B \end{bmatrix},$$

then

$$L_{m,-k}\begin{bmatrix} \bar{A} \\ \bar{B} \end{bmatrix} = \bar{\lambda}\begin{bmatrix} \bar{A} \\ \bar{B} \end{bmatrix}, \quad L_{m,-k}\begin{bmatrix} A \\ -B \end{bmatrix} = -\lambda\begin{bmatrix} A \\ -B \end{bmatrix}, \quad L_{m,k}\begin{bmatrix} \bar{A} \\ -\bar{B} \end{bmatrix} = -\bar{\lambda}\begin{bmatrix} \bar{A} \\ -\bar{B} \end{bmatrix}.$$

In particular, if $\lambda \in \sigma(L_{m,k})$, then $-\bar{\lambda} \in \sigma(L_{m,k})$, and $\bar{\lambda}, -\lambda \in \sigma(L_{m,-k})$. Thus $\sigma(L_{m,k})$ itself is symmetric w.r.t. the imaginary axis, and $\sigma(L_{m,k})$ and $\sigma(L_{m,-k})$ are symmetric w.r.t. the real axis.

Similarly, one can show that the spectra of L_{X_k} are symmetric w.r.t. both real and imaginary axes.

Equivalence of Algorithms 2 and 3. In Algorithm 2, for $k > 0$, we can write

$$L_{X_k} = \begin{bmatrix} H_k J & VU \\ VU & H_{-k} J \end{bmatrix},$$

where

$$J = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}, \quad U = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \quad I = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}.$$

Let

$$M = \begin{bmatrix} I & -J \\ I & J \end{bmatrix}, \quad M^{-1} = \frac{1}{2}\begin{bmatrix} I & I \\ J & -J \end{bmatrix}, \quad P = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \quad P^{-1} = P.$$

Noting that $JU = -UJ$, we have

$$M^{-1} L_{X_k} M = \begin{bmatrix} \alpha J + cU & -\beta \\ -\beta & \alpha J + cU \end{bmatrix} = \begin{bmatrix} 0 & \alpha + c & \beta & 0 \\ -\alpha + c & 0 & 0 & \beta \\ -\beta & 0 & 0 & \alpha + c \\ 0 & -\beta & -\alpha + c & 0 \end{bmatrix},$$

where

$$\alpha = \frac{1}{2}(H_k + H_{-k}) = H_0 + \frac{k^2}{r^2}, \quad \beta = \frac{1}{2}(H_k - H_{-k}) = \frac{2mk}{r^2}, \quad c = V.$$

Let

$$L' := P^{-1}M^{-1}L_{X_k}MP = \begin{bmatrix} 0 & \beta & \alpha+c & 0 \\ -\beta & 0 & 0 & \alpha+c \\ -\alpha+c & 0 & 0 & \beta \\ 0 & -\alpha+c & -\beta & 0 \end{bmatrix}.$$

In Algorithm 3, $L_{m,k}$ acts on $[A(r), B(r)]^\top$. If we write the enlarged matrix of $L_{m,k}$ acting on $[\operatorname{Re} A, \operatorname{Im} A, \operatorname{Re} B, \operatorname{Im} B]^\top$, the matrix is exactly L'. The matrix for $L_{m,-k}$ will be also L' if it acts on $[\operatorname{Re} A, -\operatorname{Im} A, \operatorname{Re} B, -\operatorname{Im} B]^\top$. This amounts to a choice of assigning J or $-J$ to the complexification of i.

More precisely, if $L_{m,k}u = \lambda u$ with $u = [A, B]^\top$, then $L_{m,k}iu = \lambda iu$. Write $A = A_1 + iA_2$ and $B = B_1 + iB_2$, and suppose $k > 0$. These two equations are equivalent to

$$L' \begin{bmatrix} A_1 \\ A_2 \\ B_1 \\ B_2 \end{bmatrix} = \begin{bmatrix} \operatorname{Re} \lambda A \\ \operatorname{Im} \lambda A \\ \operatorname{Re} \lambda B \\ \operatorname{Im} \lambda B \end{bmatrix}, \quad L' \begin{bmatrix} -A_2 \\ A_1 \\ -B_2 \\ B_1 \end{bmatrix} = \begin{bmatrix} -\operatorname{Im} \lambda A \\ \operatorname{Re} \lambda A \\ -\operatorname{Im} \lambda B \\ \operatorname{Re} \lambda B \end{bmatrix}.$$

Adding the second equation multiplied by $-i$ to the first equation, we get

$$L'w = \lambda w, \quad w = [A, -iA, B, -iB]^\top.$$

Taking conjugation we get $L'\bar{w} = \bar{\lambda}\bar{w}$. Thus λ and $\bar{\lambda}$ are eigenvalues of L' and hence of L_{X_k}. Since $L_{m,k}u = \lambda u$ if and only if $L_{m,-k}\bar{u} = \bar{\lambda}\bar{u}$, eigenvalues of $L_{m,-k}$ also correspond to eigenvalues of L_{X_k}.

Counting eigenvalues. L_{X_k} acts on $L^2_{rad}(\mathbb{R}^2, \mathbb{C}^4)$ and $L_{m,\pm k}$ on $L^2_{rad}(\mathbb{R}^2, \mathbb{C}^2)$. The set of eigenvalues of L_{X_k} is the union of eigenvalues of $L_{m,k}$ and $L_{m,-k}$. For any ball B_R on the complex plane disjoint from the continuous spectrum $\Sigma_c = \{ir : r \in \mathbb{R}, |r| \geq 1\}$,

$$\#(\sigma(L_{X_k}) \cap B_R) = \#(\sigma(L_{m,k}) \cap B_R) + \#(\sigma(L_{m,-k})) \cap B_R,$$

which is equal to $2\#(\sigma(L_{m,k}) \cap B_R)$ if the center of B_R is on the real axis.

Numerical efficiency. Algorithm 1 is two-dimensional and thus more expensive to compute and less accurate. Both Algorithms 2 and 3 are one-dimensional and more accurate.

The benefit of Algorithm 3 rather than Algorithm 2 is that it further decomposes the subspace of $L^2(\mathbb{R}^2, \mathbb{C}^4)$ corresponding to X_k to two subspaces. Although its matrix size is only half that of Algorithm 2, its components are complex and hence require more storage space. Numerically these two algorithms are not very different.

4.3. Numerical results. The results of our numerical computations of the spectra of $\mathcal{L}$ for $m = 1, 2$ and various k and p are shown in Figures 10–15. As before, we focus on eigenvalues in the square $\{a + bi : |a| < 1, |b| < 1\}$. Purely imaginary eigenvalues with modulus greater than 1 correspond to the continuous spectrum of $\mathcal{L}$ and are discrete due to discretization.

Let us first describe some simple observations:

1. The distribution of eigenvalues (see Figures 10–11) is more complicated and interesting than Figures 1–5. There are not only purely imaginary eigenvalues and real eigenvalues but also complex eigenvalues, whose existence implies instability.

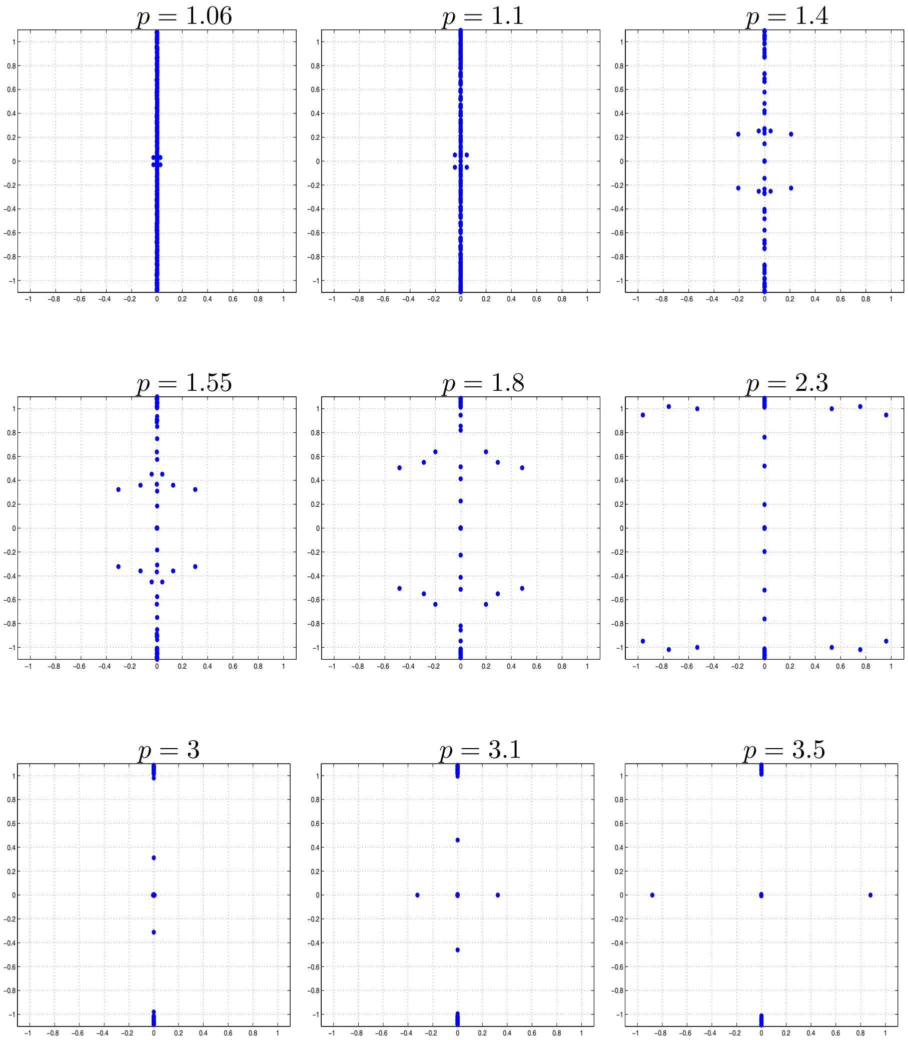

FIG. 10. *Spectra of* $\mathcal{L}$ *in* $\mathbb{R}^2$ *for* $m = 1$ *and* $0 \le k \le 24$ *as* $p = 1.06, 1.1, 1.4, 1.55, 1.8, 2.3, 3, 3.1, 3.5$ *computed by Algorithm* 3.

2. In Figures 12–13, we compare the results obtained from three algorithms. For Algorithms 2 and 3 the parameter k ranges from 0 to 9. Results from these algorithms have a high degree of agreement, except when p is near 3 and eigenvalues are near 0. We will discuss this exceptional case in the end.
3. For Algorithms 2 and 3, the numerical 0-eigenvalue occurs only when $k = 0$ and $k = \pm 1$. It agrees with our discussion in the previous subsection. Their multiplicities also match, and there is no unaccounted eigenvector. In particular, $N_g(\mathcal{L})$ has dimension 6 if $p \neq 3$ and 8 if $p = 3$, the same as the case of ground states. We also numerically verified the nullspace; for example, the discrete version of (4.8) is correct.
4. As p increases, two pairs of purely imaginary eigenvalues may collide away from 0 and then split into a quadruple of complex eigenvalues which are neither real nor purely imaginary. For $m = 1$, this bifurcation phenomenon

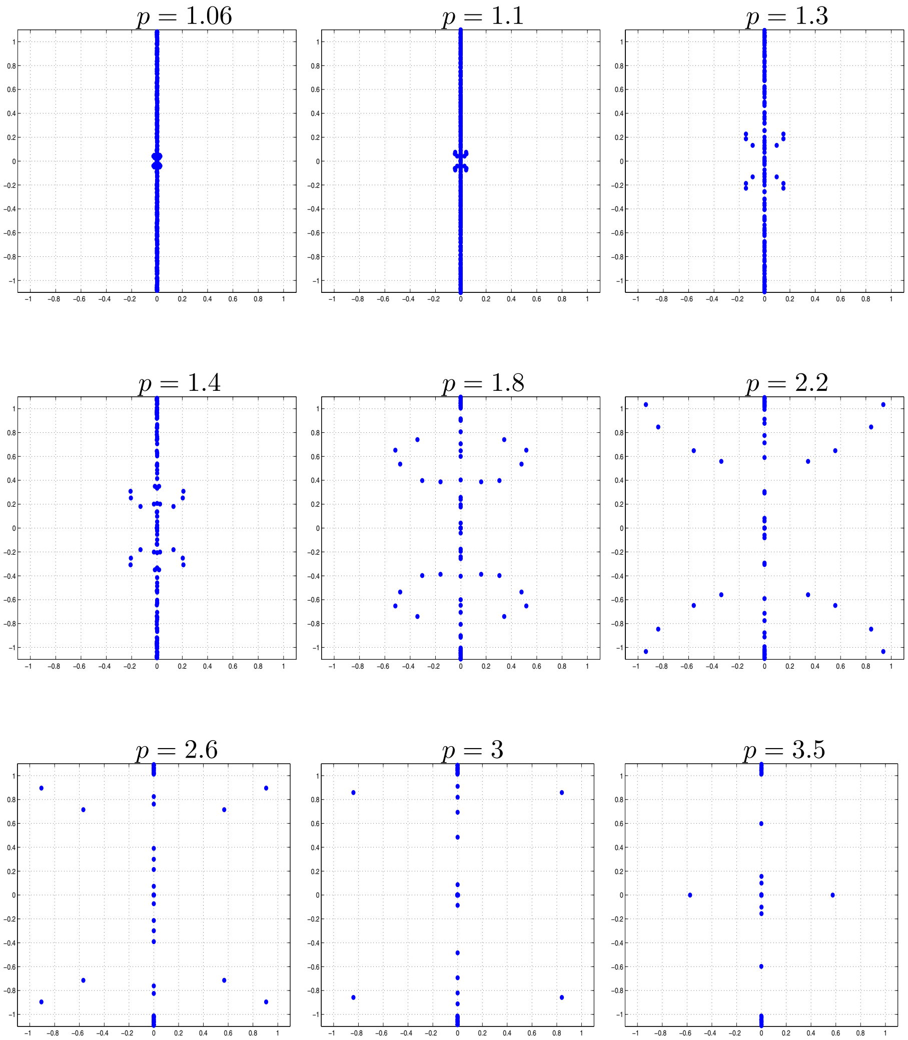

FIG. 11. *Spectra of* $\mathcal{L}$ *in* $\mathbb{R}^2$ *for* $m = 2$ *and* $0 \leq k \leq 28$ *as* $p = 1.06, 1.1, 1.3, 1.4, 1.8, 2.2, 2.6, 3, 3.5$ *computed by Algorithm* 3.

appears three times before $p = 1.55$, and there are three complex quadruples for $p > 1.55$. For $m = 2$, it occurs five times before $p = 1.5$, and there are five quadruples for $p > 1.5$. These complex eigenvalues seem to move away from the imaginary axis as p increases further.

5. As p increases to 3 (by Algorithms 2 and 3), a pair of purely imaginary eigenvalues from the 0th subspace collides at 0 and then splits into a pair of real eigenvalues as p increases further. This is the same picture as in the ground state case in section 3. Indeed, Mizumachi [24] proves that $Q_{m,0,p}$ are stable in the 0th subspace if $p < 3$ and unstable if $p > 3$. Thus $p = 3$ is a bifurcation point. Also note that when $p = 3$ the NLS (1.1) has conformal invariance, and explicit blow-up solutions can be found as in the ground state case.
6. In Figures 14–15 we observe the bifurcation more closely. For $m = 1$, the

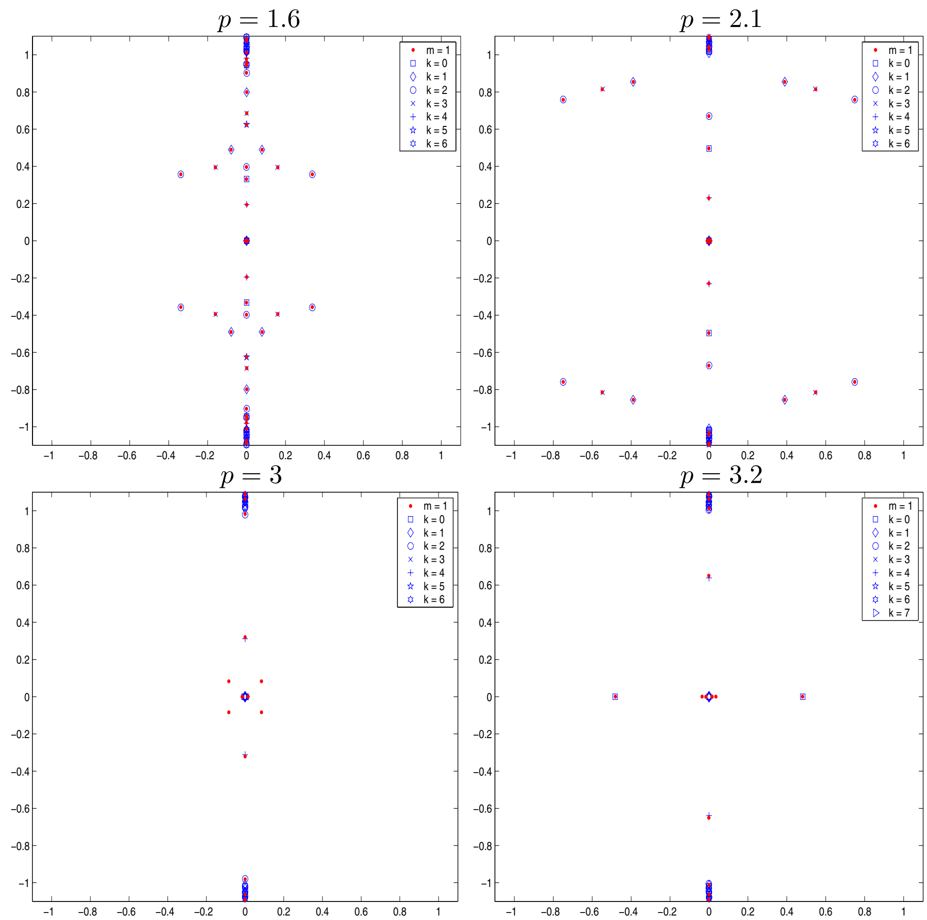

FIG. 12. *Spectra of $\mathcal{L}$ in $\mathbb{R}^2$ for $m = 1$ and various $p = 1.6, 2.1, 3, 3.2$. Point "·" denotes the spectra computed by Algorithm* 1*, and the other symbols denote the spectra computed by Algorithms* 2 *and* 3*.*

bifurcation occurs when (k, p, λ) equal

$$(0, 3, 0), \quad (1, 1.5276, -0.436i), \quad (2, 1.0165, -0.016i), \quad (3, 1.3495, -0.219i).$$

For $m = 2$, the bifurcation occurs when (k, p, λ) equal

$$(0,\ 3,\ 0), \quad (1,\ 1.357,\ -0.180i), \quad (2,\ 1.007,\ -0.027i), \quad (3,\ 1.0245,\ -0.035i)$$

and

$$(4,\ 1.0455,\ -0.045i), \quad (5,\ 1.3955,\ -0.347i).$$

7. Due to the existence of complex eigenvalues for $m = 1, 2$ and $p \geq 1.02$, $Q_{m,0,p}$ is spectrally unstable for these parameters. However, all these complex eigenvalues bifurcate from some discrete eigenvalues $\pm bi$ with $|b| < 1$ and $p > 1.008$. Our computation for both $m = 1, 2$ and

$$p = \ell \cdot 0.001, \quad \ell = 1, 2, 3, \ldots, 8 \quad (\text{up to } 15 \text{ if } m = 1),$$

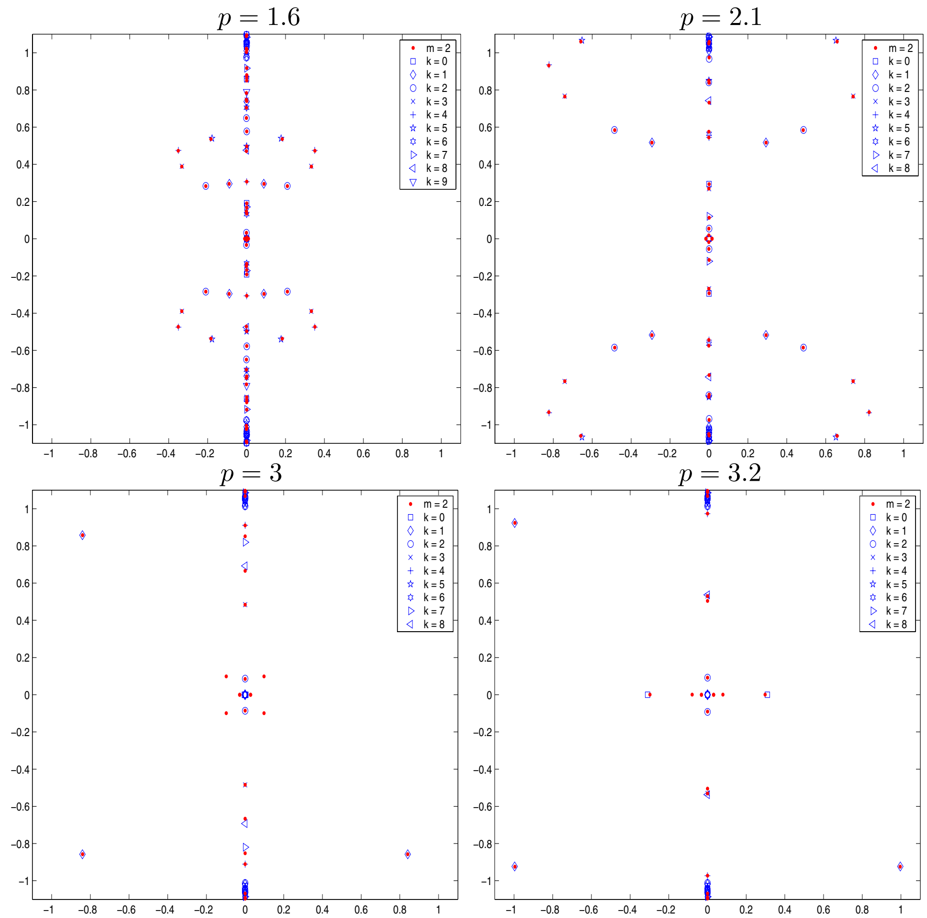

FIG. 13. *Spectra of $\mathcal{L}$ in $\mathbb{R}^2$ for $m = 2$ and various $p = 1.6, 2.1, 3, 3.2$. Point "·" denotes the spectra computed by Algorithm* 1*, and the other symbols denote the spectra computed by Algorithms* 2 *and* 3*.*

does not find any complex eigenvalues. This suggests that the two excited states $\phi_{1,0,p}(r)e^{i\theta}$ and $\phi_{2,0,p}(r)e^{i2\theta}$ are *linearly stable* when p is sufficiently close to 1. It is possible that the numerical error increases enormously as $p \to 1_+$ due to the artificial boundary condition, since the spectrum is approaching the continuous one for $p = 1$. This has to be verified analytically in the future.

We finally discuss the exceptional case when p is near 3 for eigenvalues near 0. In this case Algorithm 1 produces a quadruple of complex eigenvalues $\pm 0.0849 \pm 0.0836i$, and the 0-eigenvalue has multiplicity 4. We expect to see larger errors from Algorithm 1, but the error in this exceptional case is much larger. It is related to the large size of a Jordan block for the 0-eigenvalue. As discussed in the previous subsection, the nullspace is at least six-dimensional. The analysis in section 2.3 suggests that (we do not claim a proof), as p goes to the bifurcation exponent $p_c = 3$ from below, a pair of imaginary eigenvalues merges into the Jordan block containing the eigenfunctions iQ and Q_1, and the Jordan block becomes size 4. As is well known in matrix analysis (see [11, p. 324], [41]), if a matrix contains a Jordan block of size ℓ, the computed

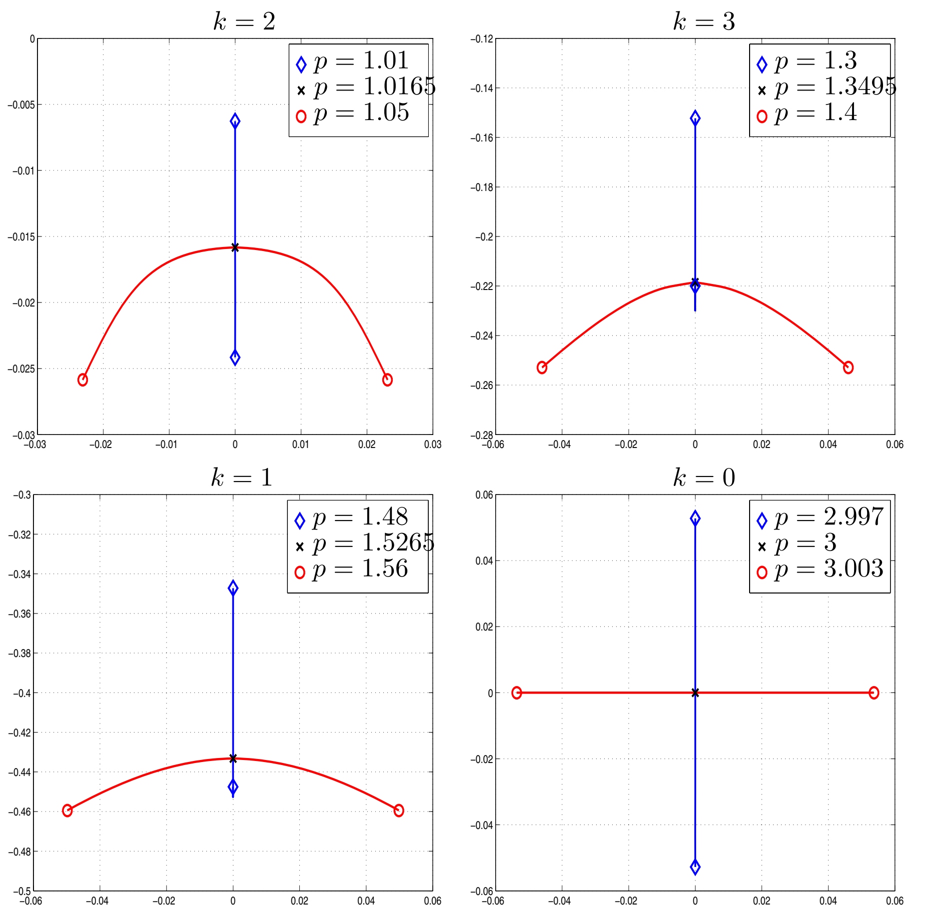

FIG. 14. *Bifurcation diagrams of* $L_{m,k}$ *for* $m = 1$ *and* $0 \leq k \leq 3$.

eigenvalues corresponding to that block have errors of order $\varepsilon^{1/\ell}$, where ε is the sum of the machine zero, the truncation error from discretization, and the perturbation (from varying p). Since $\delta_r = 0.04$ for Algorithm 1 and the truncation error of a central difference scheme for Δ_r has order $O(\delta_r^2)$, the error for the zero eigenvalue near $p = 3$ could be

$$(\delta_r^2)^{1/4} \approx 0.2.$$

In contrast, for other bifurcation points on the imaginary axis, the Jordan block at the bifurcation exponent is of size 2 and the error is of order $(\delta_r^2)^{1/2} = 0.04$. In practice, the error is smaller due to cancellation, and the numerical results by Algorithm 1 do not differ too much from those by Algorithms 2 and 3. Also note that numerically the 0-eigenspace has dimension 4, accounting for Q_{x_j} and ix_jQ. The complex quadruple corresponds to iQ, Q_1, and the joining pair of nonzero eigenvalues.

Appendix: Numerical method. In this appendix we describe a numerical method to compute the spectrum of the linear operator $\mathcal{L}$ defined by (1.8) for $p > 1$ and space dimension $n \geq 1$. There are two main steps in this method. First, we

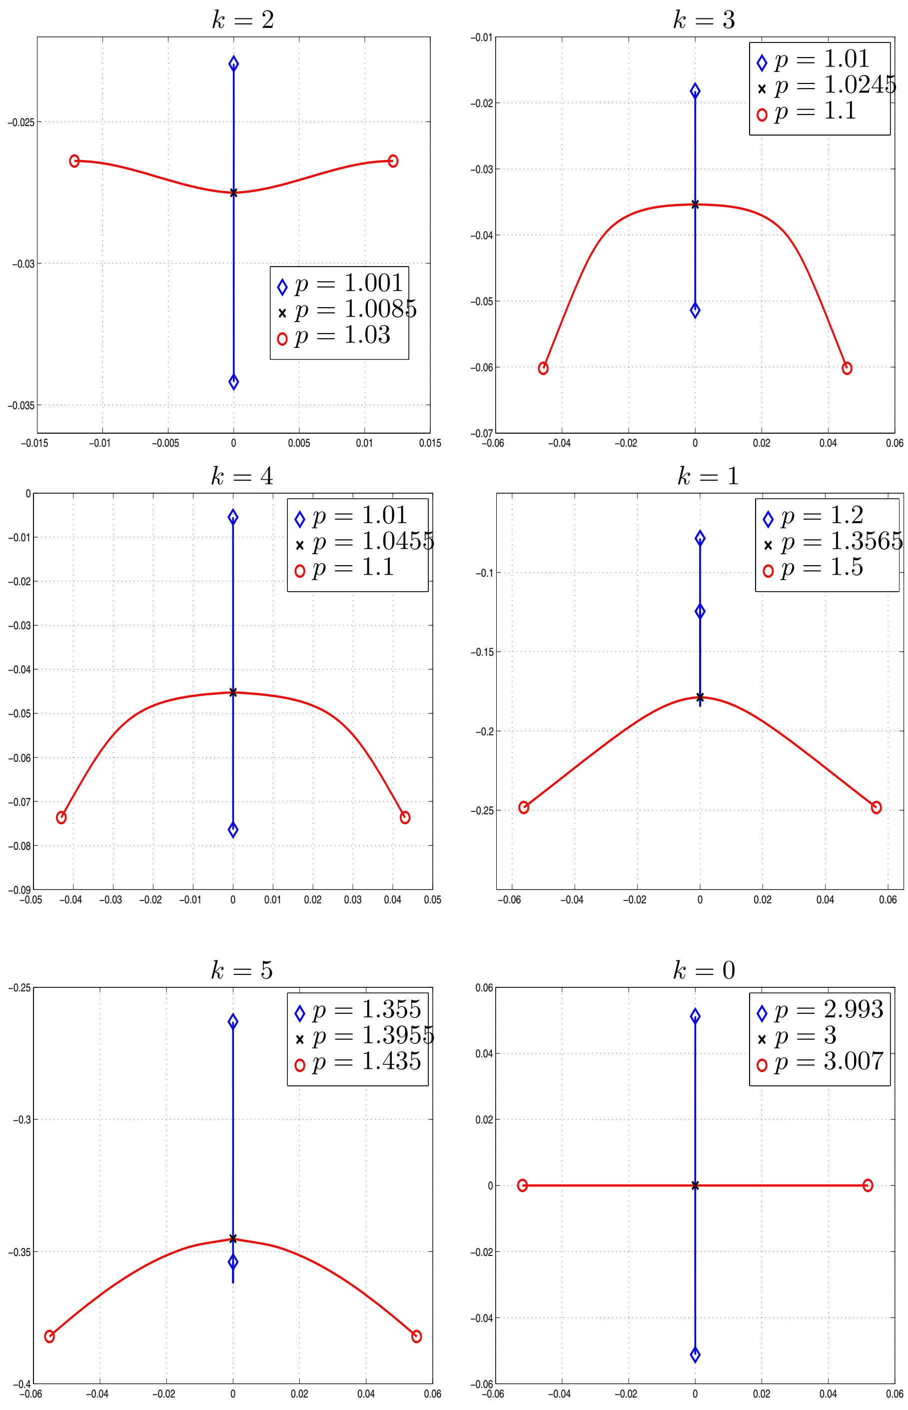

FIG. 15. *Bifurcation diagrams of* $L_{m,k}$ *for* $m = 2$ *and* $0 \le k \le 5$.

will solve the nonlinear problem (1.3) for Q: we will discretize it into a nonlinear algebraic equation and then solve it by an iterative method. Second, we will compute the spectrum of $\mathcal{L}$: we will discretize the operator $\mathcal{L}$ into a large-scale linear algebraic eigenvalue problem and then use implicitly restarted Arnoldi methods to deal with this problem.

Hereafter, we use the boldface letters or symbols to denote a matrix or a vector. For $\mathbf{A} \in \mathbb{R}^{M\times N}$, $\mathbf{q} = (q_1, \ldots, q_N)^\top \in \mathbb{R}^N$, $\mathbf{q}^{ⓟ} = \mathbf{q} \circ \cdots \circ \mathbf{q}$ denotes the p-time Hadamard product of $\mathbf{q}$, and $[\![\mathbf{q}]\!] := \operatorname{diag}(\mathbf{q})$ denotes the diagonal matrix of $\mathbf{q}$.

Step I. We first discretize (1.3) into a nonlinear algebraic equation and consider it on an n-dimensional ball $\Omega = \{x \in \mathbb{R}^n : |x| \le R, R \in \mathbb{R}\}$. We rewrite the Laplace operator $-\Delta$ in the polar coordinate system with a Dirichlet boundary condition. Based on the recently proposed discretization scheme [20], the *standard central finite difference method*, we discretize $-\Delta\mathbf{q}(x)$ into

$$\mathbf{A}\mathbf{q} = \mathbf{A}[q_1, \ldots, q_N]^\top, \ \mathbf{A} \in \mathbb{R}^{N\times N}, \tag{A.1}$$

where $\mathbf{q}$ is an approximation of the function $Q(x)$. The matrix $\mathbf{A}$ is irreducible and diagonally dominant with positive diagonal entries. The discretization of the nonlinear equation (1.3) can now be formulated as the following nonlinear algebraic equation:

$$\mathbf{A}\mathbf{q} + \mathbf{q} - \mathbf{q}^{ⓟ} = 0. \tag{A.2}$$

We introduce an iterative algorithm [16] to solve (A.2):

$$\mathbf{A}\widetilde{\mathbf{q}}_{j+1} + \widetilde{\mathbf{q}}_{j+1} = \mathbf{q}_j^{ⓟ}, \tag{A.3}$$

where $\widetilde{\mathbf{q}}_{j+1}$ and $\mathbf{q}_j$ are the unknown and known discrete values of the function $Q(\mathbf{x})$, respectively. The iterative algorithm is shown below.

Iterative Algorithm for Solving $Q(\mathbf{x})$.

Step 0 Let $j = 0$.
  Choose an initial solution $\widetilde{\mathbf{q}}_0 > 0$, and let $\mathbf{q}_0 = \frac{\widetilde{\mathbf{q}}_0}{\|\widetilde{\mathbf{q}}_0\|_2}$.
Step 1 Solve (A.3); then obtain $\widetilde{\mathbf{q}}_{j+1}$.
Step 2 Let $\alpha_{j+1} = \frac{1}{\|\widetilde{\mathbf{q}}_{j+1}\|_2}$ and normalize $\widetilde{\mathbf{q}}_{j+1}$ to obtain $\mathbf{q}_{j+1} = \alpha_{j+1}\widetilde{\mathbf{q}}_{j+1}$.
Step 3 If (convergent), then
    Output the scaled solution $(\alpha_{j+1})^{\frac{1}{p-1}}\mathbf{q}_{j+1}$. Stop.
  else
    Let $j := j + 1$.
    Goto Step 1.
  end

If the components of $\mathbf{q}_0$ are nonnegative, this property is preserved by each iteration $\mathbf{q}_j$ and hence also by the limit vector if it exists (see [16, Theorem 3.1]). The convergence of a subsequence of this iteration method to a nonzero vector is proved in [16, Theorem 2.1]. Although the convergence of the entire sequence is not proved, it is observed numerically to be very robust. See Chen, Zhou, and Ni [6] for a survey on numerically solving nonlinear elliptic equations.

Step II. Next we discretize the operator $\mathcal{L}$ of (1.10) into a linear algebraic eigenvalue problem:

$$\mathbf{L}\begin{bmatrix}\mathbf{u}\\ \mathbf{w}\end{bmatrix} = \lambda\begin{bmatrix}\mathbf{u}\\ \mathbf{w}\end{bmatrix}, \tag{A.4}$$

where

$$\mathbf{L} = \begin{bmatrix} 0 & \mathbf{A} + \mathrm{I} - [\![\mathbf{q}^{\odot}]\!] \\ -\mathbf{A} - \mathrm{I} + [\![p\,\mathbf{q}^{\odot}]\!] & 0 \end{bmatrix},$$

$\gamma = p - 1$, $\mathbf{u} = (u_1, \ldots, u_N)^\top \in \mathbb{R}^N$, $\mathbf{w} = (w_1, \ldots, w_N)^\top \in \mathbb{R}^N$, and $\mathbf{q}$ is the output of the previous step, and satisfies the equation in (A.2). We use ARPACK [21] in MATLAB version 6.5 to deal with the linear algebraic eigenvalue problem (A.4) and obtain eigenvalues λ of $\mathbf{L}$ near the origin for $p > 1$ and space dimension $n \geq 1$. Furthermore, the eigenvectors of $\mathbf{L}$ can be also produced.

Step II above can in principle be used to compute all eigenfunctions in $L^2(\mathbb{R}^n)$. However, in producing Figures 2–5, we look for eigenfunctions of the form $\phi(r)e^{im\theta}$. These problems can be reformulated as one-dimensional eigenvalue problems for $\phi(r)$, which can be computed using the same algorithm and MATLAB code. This dimensional reduction saves a lot of computation time and memory. Even with this dimensional reduction, and applying an algorithm for sparse matrices, the computation is still very heavy, and we cannot compute all eigenvalues in one step. We can compute only a portion of them each time.

Acknowledgments. Special thanks go to Wen-Wei Lin, whose constant advice and interest were indispensable for this project. We thank V.S. Buslaev, Y. Martel, F. Merle, T. Mizumachi, C. Sulem, and W.C. Wang for fruitful discussions and providing many references to us. We also thank the referees for many valuable suggestions and for pointing out [7] to us. Part of the work was done when Nakanishi was visiting the University of British Columbia, Vancouver, and when Tsai was visiting the National Center for Theoretical Sciences, Hsinchu and Taipei. The hospitality of these institutions is gratefully acknowledged.

EXTREMAL FIRST DIRICHLET EIGENVALUE OF DOUBLY CONNECTED PLANE DOMAINS AND DIHEDRAL SYMMETRY*

AHMAD EL SOUFI† AND ROLA KIWAN†

Abstract. We deal with the following eigenvalue optimization problem: Given a bounded domain $D \subset \mathbf{R}^2$, place an obstacle B of fixed shape within D so as to maximize or minimize the fundamental eigenvalue λ_1 of the Dirichlet Laplacian on $D \setminus B$. This means that we want to extremize the function $\rho \mapsto \lambda_1(D \setminus \rho(B))$, where ρ runs over the set of rigid motions such that $\rho(B) \subset D$. We answer this problem in the case where both D and B are invariant under the action of a dihedral group $\mathbb{D}_n$, $n \geq 2$, and where the distance from the origin to the boundary is monotonous as a function of the argument between two axes of symmetry. The extremal configurations correspond to the cases where the axes of symmetry of B coincide with those of D.

1. Introduction and statement of the main result.

The relations between the shape of a domain and the eigenvalues of its Dirichlet or Neumann Laplacian have been intensively investigated since the 1920s when Faber [5] and Krahn [12] proved independently the famous eigenvalue isoperimetric inequality first conjectured by Rayleigh (1877): the first Dirichlet eigenvalue $\lambda_1(\Omega)$ of any bounded domain $\Omega \subset \mathbf{R^n}$ satisfies

$$\lambda_1(\Omega) \geq \lambda_1(\Omega^*),$$

where Ω^* is a ball having the same volume as Ω. We refer to the review papers of Ashbaugh [1, 2] and Henrot [9] for a survey of recent results on optimization problems involving eigenvalues.

The present work deals with the following eigenvalue optimization problem: Given a bounded domain D, we want to place an obstacle (or a hole) B, of fixed shape, inside D so as to maximize or minimize the fundamental eigenvalue λ_1 of the Laplacian or Schrödinger operator on $D \setminus B$ with zero Dirichlet conditions on the boundary.

In other words, the problem is to optimize the principal eigenvalue function $\rho \mapsto \lambda_1(D \setminus \rho(B))$, where ρ runs over the set of rigid motions such that $\rho(B) \subset D$.

The first result obtained in this direction concerned the case where both D and B are disks of given radii. Indeed, it follows from Hersch's work [10] that the maximum of λ_1 is achieved when the disks are concentric (see also [14]). This result has been extended to any dimension by several authors (see, e.g., Harrell, Kröger, and Kurata [8] and Kesavan [11]). Actually, Harrell, Kröger, and Kurata [8] gave a more general result showing that if the domain D satisfies an interior symmetry property with respect to a hyperplane P passing through the center of the spherical obstacle B

†Laboratoire de Mathématiques et Physique Théorique, UMR CNRS 6083, Université François Rabelais Tours, Parc de Grandmont, F-37200 Tours France (elsoufi@univ-tours.fr, kiwan@lmpt.univ-tours.fr).

(which means that the image by the reflection with respect to P of one component of $D \setminus P$ is contained in D), then the Dirichlet fundamental eigenvalue $\lambda_1(D \setminus B)$ decreases when the center of B moves perpendicularly to P in the direction of the boundary of D. In the particular case where both the domain D and the obstacle B are balls, this implies that the minimum of $\lambda_1(D \setminus B)$ corresponds to the limit case where B touches the boundary of D.

Notice that when the obstacle B is a disk, only translations of B may affect the eigenvalues of $D \setminus B$, and the optimal placement problem reduces to the choice of the center of B inside D.

In the present work we investigate a kind of dual problem in the sense that we consider a *nonspherical* obstacle B whose center of mass is fixed inside D, and we seek the optimal positions while turning B around its center.

It is of course hopeless to expect a universal solution to this problem. In fact, we will restrict our investigation to a class of domains satisfying a dihedral symmetry and monotonicity conditions.

Thus, let D be a simply connected plane domain and assume that the following conditions are satisfied:

(i) ($\mathbb{D}_n$-symmetry.) For an integer $n \geq 2$, D is invariant under the action of the dihedral group $\mathbb{D}_n$ of order $2n$ generated by the rotation $\rho_{\frac{2\pi}{n}}$ of angle $\frac{2\pi}{n}$ and a reflection S. Such a domain admits n axes of symmetry passing through the origin and such that the angle between 2 consecutive axes is $\frac{\pi}{n}$.

(ii) (Monotonicity of the boundary.) The distance $d(O,x)$ from the origin to a point x of the boundary of D is monotonous as a function of the argument of x, in a sector delimited by two consecutive symmetry axes.

Notice that assumption (i) guarantees that the center of mass of D is at the origin. Regular n-gones centered at the origin are the simplest examples of domains satisfying these assumptions. More generally, if g is any positive even $\frac{2\pi}{n}$-periodic continuous function that is monotonous on the interval $(0, \frac{\pi}{n})$, then the domain

$$D = \{re^{\mathbf{i}\theta}; \theta \in [0, 2\pi), 0 \leq r < g(\theta)\}$$

satisfies assumptions (i) and (ii). Actually, up to a rigid motion, any domain satisfying assumptions (i) and (ii) can be parametrized in such a manner.

It is worth noticing that, due to the monotonicity condition, the "distance to the origin" function on the boundary of D achieves its maximum and its minimum alternatively at the intersection points of ∂D with the $2n$ half-axes of symmetry. The n points of ∂D at maximal (resp., minimal) distance from the origin will be called "outer vertices" (resp., "inner vertices") of D.

Our main result is the following.

THEOREM 1. *Let D and B be two plane domains satisfying the assumptions of $\mathbb{D}_n$-symmetry and monotonicity* (i) *and* (ii) *above for an integer $n \geq 2$. Assume furthermore that B has C^2 boundary and that $\rho(B) \subset D$ for all $\rho \in SO(2)$. Then the fundamental Dirichlet eigenvalue $\lambda_1(D \setminus B)$ of $D \setminus B$ is optimized exactly when the axes of symmetry of B coincide with those of D.*

The maximizing configuration corresponds to the case where the outer vertices of B and D lie on the same half-axes of symmetry (we will then say that B occupies the "ON" position in D).

The minimizing configuration corresponds to the case where the outer vertices of B lie on the half-axes of symmetry passing through the inner vertices of D (this is what will be called the "OFF" position).

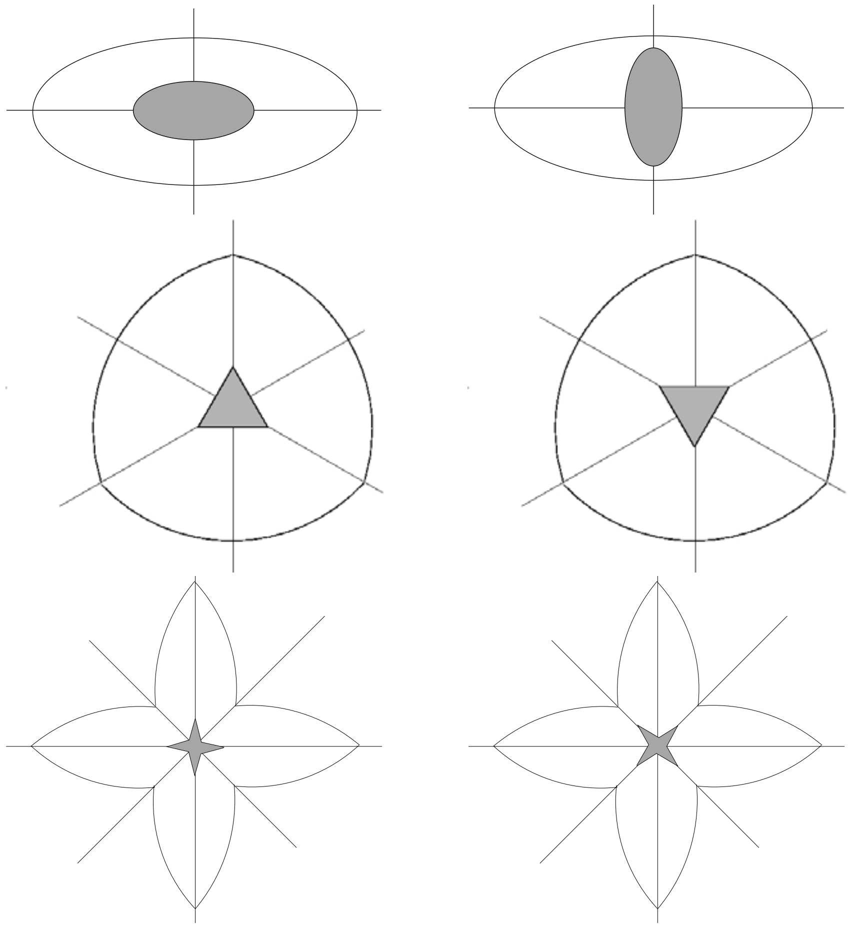

FIG. 1. *Examples of maximal (left) and minimal (right) configurations with* $n = 2$, 3, *and* 4, *respectively.*

Actually, we will prove that, except for the trivial case where D or B is a disk, the fundamental Dirichlet eigenvalue of $D \setminus B$ decreases gradually when B switches from "ON" to "OFF" (see Figure 1 for examples).

The main ingredients of the proof of Theorem 1 are Hadamard's variation formula for λ_1 and the technique of domain reflection initiated by Serrin [17] in a PDE setting.

Extensions of Theorem 1 to the following situations can be obtained up to slight changes in the proof (indeed, only the Hadamard formula should be replaced by the variation formula corresponding to the new functional):

1. *Soft obstacles*. Instead of considering the Dirichlet Laplacian on $D \setminus B$, we consider the Schrödinger-type operator

$$H(\alpha, B) := \Delta - \alpha\chi_B$$

acting on $H_0^1(D)$, where $\alpha > 0$ and χ_B is the indicator function of B. Optimization problems related to the fundamental eigenvalue of operators of this kind have been investigated in particular in [8] and [3]. Under the assumptions of Theorem 1 on D and B, for all $\alpha > 0$, the fundamental eigenvalue of $H(\alpha, B)$ achieves its maximum at the "ON" position and its minimum at the "OFF" position.

2. *Wells.* This case corresponds to the operator $H(\alpha, B)$ with $\alpha < 0$. Under the circumstances of Theorem 1, for all $\alpha < 0$, the first eigenvalue of $H(\alpha, B)$ achieves its maximum at the "OFF" position and its minimum at the "ON" position.
3. *Stationary problem.* The problem now is to optimize the Dirichlet energy $J(D \setminus B) := \int_{D\setminus B} |\nabla u|^2 dx$ of the unique solution u of the problem

$$\begin{cases} \Delta u = -1 & \text{in } D \setminus B, \\ u = 0 & \text{on } \partial(D \setminus B). \end{cases}$$

   This problem was treated in [11, section 2] in the case where both D and B are balls. Under the assumptions of Theorem 1 on D and B, one can prove that $J(D \setminus B)$ achieves its maximum when B is at the "ON" position and its minimum when B is at the "OFF" position.

2. Proof of the main result. Without loss of generality, we may assume that the domain D and the obstacle B are centered at the origin and are both symmetric with respect to the x_1-axis so that they can be parametrized in polar coordinates by

$$D = \{re^{\mathbf{i}\theta}; \theta \in [0, 2\pi), 0 \le r < g(\theta)\},$$

$$B = \{re^{\mathbf{i}\theta}; \theta \in [0, 2\pi), 0 \le r < f(\theta)\},$$

where f and g are two positive even $\frac{2\pi}{n}$-periodic functions which are *nondecreasing* on $(0, \frac{\pi}{n})$. To avoid technicalities, we suppose throughout that g is continuous and f is C^2. Extensions of our result to a wider class of domains would certainly be possible up to some additional technical difficulties.

The condition that the obstacle B can freely rotate around his center inside D, that is, $\rho(\bar{B}) \subset D$ for all $\rho \in SO(2)$, amounts to the following:

$$f\left(\frac{\pi}{n}\right) = \max_{0\le\theta\le 2\pi} f(\theta) < \min_{0\le\theta\le 2\pi} g(\theta) = g(0).$$

Let us denote, for all $t \in \mathbf{R}$, by ρ_t the rotation of angle t, that is, for all $\zeta \in \mathbf{R^2} \cong \mathbf{C}$, $\rho_t(\zeta) = e^{\mathbf{i}t}\zeta$, and set

$$B_t := \rho_t(B) \quad \text{and} \quad \Omega(t) := D \setminus B_t.$$

Let $\lambda(t)$ be the fundamental eigenvalue of the Dirichlet Laplacian on $\Omega(t)$. It is well known that, since it is simple, the first Dirichlet eigenvalue $\lambda(t)$ is a differentiable function of t (see [6, 15]). We denote by $u(t)$ the one parameter family of nonnegative first eigenfunctions satisfying, for all $t \in \mathbf{R}$,

$$\begin{cases} \Delta u(t) = -\lambda(t) u(t) & \text{in } \Omega(t), \\ u(t) = 0 & \text{on } \partial\Omega(t), \\ \int_{\Omega(t)} u^2(t) = 1. \end{cases}$$

The derivative of $\lambda(t)$ is then given by the following so-called Hadamard formula (see [4, 6, 7, 16]):

$$\lambda'(t) = \int_{\partial B_t} \left|\frac{\partial u(t)}{\partial \eta_t}\right|^2 \eta_t \cdot v \, d\sigma, \tag{1}$$

where η_t is the inward unit normal vector field of $\partial\Omega(t)$ (hence, along ∂B_t the vector η_t is outward with respect to B_t) and v denotes the restriction to $\partial\Omega(t) = \partial D \cup \partial B_t$ of the deformation vector field. In our case, the vector v vanishes on ∂D and is given by $v(\zeta) = \mathbf{i}\zeta$ for all $\zeta \in \partial B_t$.

Since both Ω and B are invariant by the dihedral group $\mathbb{D}_n$, it follows that, for all $t \in \mathbf{R}$, $\Omega(t + \frac{2\pi}{n}) = \Omega_t$. Moreover, if we denote by S_0 the reflection with respect to the x_1-axis, then we clearly have $\rho_{-t} = S_0 \circ \rho_t \circ S_0$, which gives $B_{-t} = S_0(B_t)$ and $\Omega_{-t} = S_0(\Omega_t)$. Hence, as a function of t, the first Dirichlet eigenvalue of Ω_t is even and periodic of period $\frac{2\pi}{n}$, that is, for all $t \in \mathbf{R}$,

$$\lambda\left(t + \frac{2\pi}{n}\right) = \lambda(t) \quad \text{and} \quad \lambda(-t) = \lambda(t).$$

Therefore, it suffices to investigate the variations of $\lambda(t)$ on the interval $\left[0, \frac{\pi}{n}\right]$, and Theorem 1 is a consequence of the following.

Theorem 2. *Assume that neither D nor B is a disk.*

(i) *For all $t \in \left(0, \frac{\pi}{n}\right)$, $\lambda'(t) < 0$. Hence, $\lambda(t)$ is strictly decreasing on $\left(0, \frac{\pi}{n}\right)$.*

(ii) *For all $k \in \mathbf{Z}$, $\lambda'(k\frac{\pi}{n}) = 0$ and $k\frac{\pi}{n}$, $k \in \mathbf{Z}$, are the only critical points of λ on $\mathbf{R}$.*

Hence, $\lambda(t)$ achieves its maximum for $t = 0 \mod \frac{2\pi}{n}$, which corresponds to the "ON" position, and its minimum for $t = \frac{\pi}{n} \mod \frac{2\pi}{n}$, which corresponds to the "OFF" position. Of course, if D or B is a disk, then the function $\lambda(t)$ is constant.

In what follows we will denote, for any $\alpha \in \mathbf{R}$, by z_α the $\theta = \alpha$ axis, that is, $z_\alpha := \{re^{\mathbf{i}\alpha};\ r \in \mathbf{R}\}$, and by z_α^+ the half-axis $\{re^{\mathbf{i}\alpha};\ r \geq 0\}$.

We start the proof with the following elementary lemma.

Lemma 1. *Let K be a plane domain defined in polar coordinates by $K = \{re^{\mathbf{i}\theta}; \theta \in [0, 2\pi), 0 \leq r < h(\theta)\}$, where h is a positive 2π-periodic function of class C^1, and let v be a vector field whose restriction to ∂K is given by*

$$v(\theta) := v(h(\theta)e^{\mathbf{i}\theta}) = \mathbf{i}h(\theta)e^{\mathbf{i}\theta} = h(\theta)e^{\mathbf{i}(\theta + \frac{\pi}{2})}.$$

We denote by η the unit outward normal vector field of ∂K. One has, at any point $h(\theta)e^{\mathbf{i}\theta}$ of ∂K where η is defined, the following:

(i) $\eta(\theta) := \eta(h(\theta)e^{\mathbf{i}\theta}) = \frac{h(\theta)e^{\mathbf{i}\theta} - \mathbf{i}h'(\theta)e^{\mathbf{i}\theta}}{\sqrt{h^2(\theta) + h'^2(\theta)}}$.

(ii) $\eta \cdot v(\theta) = \frac{-h(\theta)h'(\theta)}{\sqrt{h^2(\theta) + h'^2(\theta)}}$. *Hence, $\eta . v(\theta)$ has constant sign on an interval I If and only if h is monotonous in I.*

(iii) *If for some $\alpha > 0$, the domain K is symmetric with respect to the axis z_α, then the function $\eta \cdot v$ is antisymmetric with respect to this axis, that is,*

$$\eta \cdot v(\alpha + \theta) = -\eta \cdot v(\alpha - \theta).$$

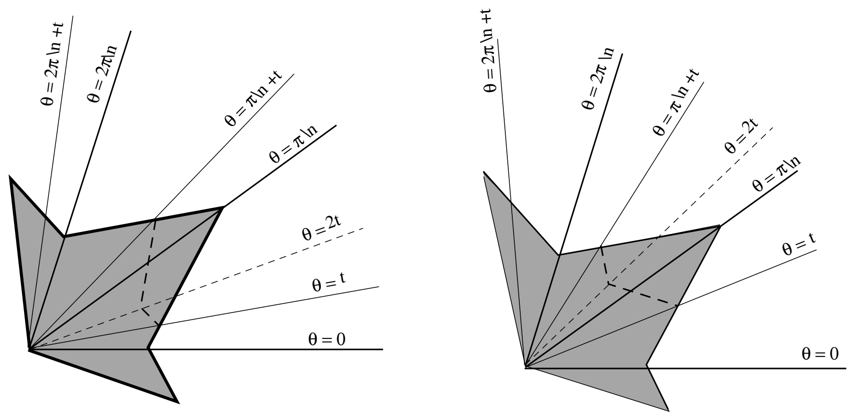
Proof. Assertions (i) and (ii) are direct consequences from the definition of K. The fact that K is symmetric with respect to the axis z_α implies that the function h satisfies $h(\alpha + \theta) = h(\alpha - \theta)$. Therefore, (iii) follows immediately from (ii). ◻

We will denote by S_α the symmetry with respect to the axis z_α. We will also denote, for $\alpha < \beta$, by $\sigma(\alpha, \beta)$ the sector delimited by z_α^+ and z_β^+, that is,

$$\sigma(\alpha, \beta) = \{re^{\mathbf{i}\theta}; r > 0 \text{ and } \alpha < \theta < \beta\}.$$

Lemma 2. *Let D be as above. For all $t \in \left(0, \frac{\pi}{n}\right)$, we have*

$$S_{\frac{\pi}{n}+t}\left(D \cap \sigma\left(\frac{\pi}{n} + t, \frac{2\pi}{n} + t\right)\right) \subseteq D \cap \sigma\left(t, \frac{\pi}{n} + t\right).$$



case $2t < \frac{\pi}{n}$ case $2t > \frac{\pi}{n}$

FIG. 2.

Moreover, if D is not a disk, then

$$S_{\frac{\pi}{n}+t}\left(\partial D \cap \sigma\left(\frac{\pi}{n}+t, \frac{2\pi}{n}+t\right)\right) \cap D \neq \emptyset.$$

Proof. The action of the symmetry $S_{\frac{\pi}{n}+t}$ is given in polar coordinates by $S_{\frac{\pi}{n}+t}(re^{\mathbf{i}\theta}) = re^{\mathbf{i}(2(\frac{\pi}{n}+t)-\theta)}$. Hence,

$$S_{\frac{\pi}{n}+t}\left(D \cap \sigma\left(\frac{\pi}{n}+t, \frac{2\pi}{n}+t\right)\right) = S_{\frac{\pi}{n}+t}(D) \cap \sigma\left(t, \frac{\pi}{n}+t\right).$$

Moreover, the domain D being parametrized by a positive even $\frac{2\pi}{n}$-periodic function $g(\theta)$, that is, $D = \{re^{\mathbf{i}\theta}; \theta \in [0, 2\pi), 0 \leq r < g(\theta)\}$, its image $S_{\frac{\pi}{n}+t}(D)$ can be parametrized in the same manner by the function $g^*(\theta) = g(\theta - 2t)$. Thus

$$S_{\frac{\pi}{n}+t}(D) \cap \sigma\left(t, \frac{\pi}{n}+t\right) = \left\{re^{\mathbf{i}\theta}; \theta \in \left(t, \frac{\pi}{n}+t\right), 0 \leq r < g(\theta - 2t)\right\}.$$

Therefore, we need to prove that $F(\theta) = g(\theta) - g^*(\theta)$ is nonnegative for every θ in the interval $(t, \frac{\pi}{n}+t)$. This will be possible thanks to the assumptions of symmetry (that is, g is even and $\frac{2\pi}{n}$-periodic) and monotonicity (that is, g is nondecreasing on $[0, \frac{\pi}{n}]$). Indeed, these properties imply that on the interval $\left(t, \frac{\pi}{n}+t\right)$,

- g achieves its maximum at $\theta = \frac{\pi}{n}$,
- g^* achieves its minimum at $\theta = 2t$.

Four cases must be considered separately (see Figure 2):

- If $t < \theta \leq \min\{2t, \frac{\pi}{n}\}$, we may write, since g is even, $F(\theta) = g(\theta) - g(2t - \theta)$, with $0 \leq 2t - \theta < \theta \leq \frac{\pi}{n}$. Since g is nondecreasing on $[0, \frac{\pi}{n}]$, we get $F(\theta) \geq 0$.
- If $\max\{2t, \frac{\pi}{n}\} \leq \theta < \frac{\pi}{n} + t$, we may write, since g is even and $\frac{2\pi}{n}$-periodic, $F(\theta) = g(2\frac{\pi}{n} - \theta) - g(\theta - 2t)$ with $0 \leq \theta - 2t < 2\frac{\pi}{n} - \theta \leq \frac{\pi}{n}$. Hence, $F(\theta) \geq 0$.
- If $2t < \frac{\pi}{n}$ and $2t \leq \theta \leq \frac{\pi}{n}$, then $0 \leq \theta - 2t < \theta \leq \frac{\pi}{n}$ and, then, $F(\theta) = g(\theta) - g(\theta - 2t) \geq 0$.
- If $2t > \frac{\pi}{n}$ and $\frac{\pi}{n} \leq \theta \leq 2t$, then $0 \leq 2t - \theta < 2\frac{\pi}{n} - \theta \leq \frac{\pi}{n}$ and, then, $F(\theta) = g(2\frac{\pi}{n} - \theta) - g(2t - \theta) \geq 0$.

Hence, $F(\theta)$ is nonnegative for all θ in $(t, \frac{\pi}{n}+t)$.

Now, if D is not a disk, then g is nonconstant on $[0, \frac{\pi}{n}]$. Following the arguments above, we deduce that the function $F(\theta)$ is positive somewhere on $(t, \frac{\pi}{n}+t)$, which means that $S_{\frac{\pi}{n}+t}\left(\partial D \cap \sigma\left(\frac{\pi}{n}+t, \frac{2\pi}{n}+t\right)\right)$ meets the interior of D. ∎

Proof of Theorem 2. Notice first that, since λ is an even and $\frac{2\pi}{n}$-periodic function of t, one immediately gets, for all $k \in \mathbf{Z}$, $\lambda(k\frac{\pi}{n}-t) = \lambda(k\frac{\pi}{n}+t)$ and, then,

$$\lambda'\left(k\frac{\pi}{n}\right) = 0.$$

Alternatively, one can deduce that $\lambda'\left(k\frac{\pi}{n}\right) = 0$ from Hadamard's variation formula (1) after noticing that the domain $\Omega(k\frac{\pi}{n})$ is symmetric with respect to the x_1-axis and that the first Dirichlet eigenfunction $u(k\frac{\pi}{n})$ satisfies $u \circ S_0 = u$, where S_0 is the symmetry with respect to the x_1-axis.

Let us fix a t in $\left(0, \frac{\pi}{n}\right)$ and denote by u the nonnegative first Dirichlet eigenfunction of $\Omega(t)$ satisfying $\int_{\Omega(t)} u^2 = 1$. The domain $\Omega(t)$ is clearly invariant by the rotation $\rho_{\frac{2\pi}{n}}$ of angle $\frac{2\pi}{n}$, and hence $u \circ \rho_{\frac{2\pi}{n}} = u$. On the other hand, the domain B being parametrized by a positive even $\frac{2\pi}{n}$-periodic function $f(\theta)$, that is, $B = \{re^{\mathbf{i}\theta}; \theta \in [0, 2\pi), 0 \le r < f(\theta)\}$, one has

$$B_t = \{re^{\mathbf{i}\theta}; \theta \in [0, 2\pi), 0 \le r < h(\theta)\},$$

with $h(\theta) = f(\theta - t)$. Hence, the function $\eta_t \cdot v$ is invariant by $\rho_{\frac{2\pi}{n}}$ (Lemma 1) and we have (Hadamard formula (1))

$$\lambda'(t) = \int_{\partial B_t} \left|\frac{\partial u}{\partial \eta_t}\right|^2 \eta_t \cdot v \; d\sigma = n \int_{\partial B_t \cap \sigma(t, \frac{2\pi}{n}+t)} \left|\frac{\partial u}{\partial \eta_t}\right|^2 \eta_t \cdot v \; d\sigma.$$

Since B_t is symmetric with respect to the axis $z_{\frac{\pi}{n}+t}$, we have (Lemma 1) $\eta_t \cdot v(\frac{\pi}{n} + t + \theta) = -\eta_t \cdot v(\frac{\pi}{n} + t - \theta)$ or, equivalently, $\eta_t \cdot v(x) = -\eta_t \cdot v(x^*)$, where x^* denotes the symmetric of x with respect to $z_{\frac{\pi}{n}+t}$. This yields

$$\lambda'(t) = n \int_{\partial B_t \cap \sigma(\frac{\pi}{n}+t, \frac{2\pi}{n}+t)} \left(\left|\frac{\partial u}{\partial \eta_t}(x)\right|^2 - \left|\frac{\partial u}{\partial \eta_t}(x^*)\right|^2\right) \eta_t \cdot v(x) \; d\sigma.$$

Notice that the function $h(\theta)$ is decreasing between $\frac{\pi}{n}+t$ and $\frac{2\pi}{n}+t$ and, then, $\eta_t \cdot v$ is nonnegative on $\partial B_t \cap \sigma(\frac{\pi}{n}+t, \frac{2\pi}{n}+t)$ (Lemma 1).

Let $H(t) := \Omega(t) \cap \sigma(\frac{\pi}{n}+t, \frac{2\pi}{n}+t)$. Applying Lemma 2, and since B_t is symmetric with respect to the axis $z_{\frac{\pi}{n}+t}$, one gets

$$S_{\frac{\pi}{n}+t}(H(t)) \subset \Omega(t) \cap \sigma\left(t, \frac{\pi}{n}+t\right).$$

Hence, the function $w(x) = u(x) - u(x^*)$ is well defined on $H(t)$ and satisfies $w(x) = 0$ for all x in $\partial H(t) \cap \left(\partial B_t \cup z_{\frac{\pi}{n}+t} \cup z_{\frac{2\pi}{n}+t}\right)$. Moreover, since u vanishes on ∂D and is positive inside $\Omega(t)$, $w(x) \le 0$ for all x in $\partial H(t) \cap \partial D$ and $w(x) < 0$ for certain x in $\partial H(t) \cap \partial D$ (recall that D is not a disk and apply the second part of Lemma 2).

Therefore, the nonconstant function w satisfies the following:

$$\begin{cases} \Delta w = -\lambda(t) w & \text{in } H(t), \\ w \le 0 & \text{on } \partial H(t). \end{cases}$$

Hence, w must be nonpositive on the whole of $H(t)$. Otherwise, a nodal domain $V \subset H(t)$ of w would have the same first Dirichlet eigenvalue as $\Omega(t)$. But, due to the invariance of $\Omega(t)$ by $\rho_{\frac{2\pi}{n}}$, the domain $\Omega(t)$ would contain n copies of V leading to a strong contradiction with the domain monotonicity theorem for eigenvalues. Therefore, $\Delta w \geq 0$ in $H(t)$ and w achieves its maximal value (i.e., zero) on $\partial B_t \cap \sigma(\frac{\pi}{n} + t, \frac{2\pi}{n} + t) \subset \partial H(t)$. The Hopf maximum principle (see [13, Theorem 7, Chapter 2]) then implies that, at any regular point x of $\partial B_t \cap \sigma(\frac{\pi}{n} + t, \frac{2\pi}{n} + t)$, one has

$$\frac{\partial w}{\partial \eta_t}(x) = \frac{\partial u}{\partial \eta_t}(x) - \frac{\partial u}{\partial \eta_t}(x^*) < 0.$$

It follows that $\lambda'(t) \leq 0$ and that the equality holds if and only if $\eta_t \cdot v \equiv 0$. By Lemma 1, this last equality occurs if and only if f is constant, which means that B is a disk. $\square$

A NEW LOOK AT EQUILIBRIA IN STEFAN-TYPE PROBLEMS IN THE PLANE*

PIOTR B. MUCHA† and PIOTR RYBKA†

Abstract. We study steady states of Stefan-type problems in the plane with the Gibbs–Thomson correction involving a general anisotropic energy density function. By a local analysis we prove the global result showing that the solution is the Wulff shape. The key element is a stability result which enables us to approximate singular models by regular ones.

Key words. Stefan-type problems, singular interfacial energies, Wulff shape, constant weighted mean curvature, steady states, monotone operators

AMS subject classifications. 53C21 (74E15)

DOI. 10.1137/060677124

1. Introduction.

An important aspect of studying dynamical systems is determining steady states and their stability properties. We have in mind a class of models of phase transitions involving the Gibbs–Thomson correction on the interface. They include the Stefan (see [Lu], [AW], [CR], [Ra], [FR], [GR1]) and Hele–Shaw problems (see [DE], [A]). In special cases the modeling system takes the following one-phase quasi-stationary form:

$$\begin{array}{lll} \Delta p = 0 & \text{in} & \Omega(t), \\ p = \kappa_\gamma & \text{on} & \partial\Omega(t), \\ \frac{\partial p}{\partial \mathbf{n}} = -V & \text{on} & \partial\Omega(t). \end{array} \tag{1.1}$$

This is a free boundary problem where we seek the time evolution of an open set $\Omega(t)$ in $\mathbb{R}^n$, $\mathbf{n}$ is the normal to the boundary, and V is the normal velocity of the interface $\partial\Omega(t)$. Here κ_γ is the weighted mean curvature, which is the most important object for us; it will be explained below and in more detail in section 3.

This system is augmented with initial data for Ω. The interpretation of p depends upon the phenomenon we wish to model with (1.1). In the Stefan problem this is the temperature; in the Hele–Shaw problem p is the fluid pressure; in the tumor growth model (see [FR]) p is the internal pressure of the proliferating tissue; in the crystal growth from vapor (see [GR1]) p is the supersaturation of the diffusing water vapor.

We want to stress the important fact that κ_γ in (1.1) is the weighted (anisotropic) mean curvature, i.e.,

$$\kappa_\gamma = \mathrm{div}_{\partial\Omega}(\nabla_\xi \bar{\gamma}|_{\xi=\mathbf{n}}). \tag{1.2}$$

This formula is correct for sufficiently smooth $\bar{\gamma}$. On the other hand, the case of low smoothness $\bar{\gamma}$ and singular $\partial\Omega$ will require special considerations.

Function $\bar{\gamma}$ is related to the anisotropy of the modeled process. Here we assume that function $\bar{\gamma} : \mathbb{R}^n \to \mathbb{R}$ is one-homogeneous, $\bar{\gamma}(x) > 0$ for $x \neq 0$, i.e.,

$$\bar{\gamma}(x) = |x|\gamma\left(\frac{x}{|x|}\right) \quad \text{if } x \neq 0, \qquad \bar{\gamma}(0) = 0, \tag{1.3}$$

while function γ depends essentially on the orientation, i.e., $\gamma : S^{n-1} \to \mathbb{R}$. In the terminology of [Gu, Chapter 7], function γ is called the interfacial energy, while $\bar{\gamma}$ is the extended energy.

Our goal is to study static solutions to (1.1), i.e.,

$$\begin{array}{lll} \Delta p = 0 & \text{in} & \Omega, \\ p = \operatorname{div}_{\partial\Omega}(\nabla_\xi \bar{\gamma}|_{\xi=\mathbf{n}}) & \text{on} & \partial\Omega, \\ \frac{\partial p}{\partial \mathbf{n}} = 0 & \text{on} & \partial\Omega. \end{array} \qquad |\Omega| \text{ is given,} \tag{1.4}$$

Momentarily, we are going to explain why the measure of Ω has to be fixed. By $(1.1)_{1,3}$ we conclude that $\int_{\partial\Omega(t)} V\, d\mathcal{H}^{n-1} = 0$, and hence the measure of $\Omega(t)$ is constant. Additionally from $(1.4)_{1,3}$ we conclude that $p \equiv \text{const}$, and thus, we get

$$\operatorname{div}_{\partial\Omega}(\nabla_\xi \bar{\gamma}|_{\xi=\mathbf{n}}) = \text{const} \qquad \text{and} \qquad |\Omega| \text{ is given.}$$

By a simple rescaling we arrive at a geometric problem expressed as a differential equation

$$\operatorname{div}_{\partial\Omega}(\nabla_\xi \bar{\gamma}|_{\xi=\mathbf{n}}) = 1. \tag{1.5}$$

At this moment we have to specify the assumptions on $\bar{\gamma}$. A minimal hypothesis, besides (1.3), which we impose is the *convexity* of $\bar{\gamma}$. Thus, we immediately conclude that $\bar{\gamma}$ is Lipschitz continuous.

Under such broad assumptions on $\bar{\gamma}$, making sense out of (1.5) requires some work. For example, in [BNP] and [GR2] a separate variational problem was considered for the definition of κ_γ. It is our desire to consider quite a general, as far as the smoothness is concerned, surface energy density function γ.

In our paper we consider a two-dimensional case of (1.5). That is, we look for a curve Γ which locally has a constant weighted mean curvature κ_γ. We show the existence of such a curve, which turns out to be the boundary of a region (in particular Γ is closed).

It is possible to adopt an energy point of view, interpret (1.5) as a critical point of surface energy functional $E(S) = \int_S \gamma(\mathbf{n}(x))\, d\mathcal{H}^{n-1}(x)$, and study its minimizers under the volume constraint. In fact this approach has been carried out; see [T], [FM], [Pa], [Mo], and references therein. In [T] Taylor gives the first rigorous proof of Wulff's theorem, stating that the only minimizer of E under the volume constraint is the Wulff shape. Later, various proofs of this result were found; see [FM] and references therein. Palmer [Pa] shows that the only stable smooth critical point of E is the Wulff shape. Morgan [Mo] studied equilibria of E, and he dropped the stability and smoothness assumptions. He showed that the only equilibrium is the Wulff shape.

An important assumption in the above papers is that they deal only with manifolds without boundary (e.g., closed curves). Here we adopt a different view, which we may call a local one. Namely, we can regard (1.5) as a *locally* defined differential equation. By this we mean that if (1.5) is given some appropriate data, then there exists a solution which is defined in a neighborhood of the data. Our goal, however, is *global*, to show that one can glue up those local solutions, and, despite the apparent freedom in choosing the data for the equation, one can obtain a uniquely defined geometric object: a closed manifold, in this case a closed curve.

We stress that we set a restricted goal to consider only the two-dimensional case. This leads to a significant simplification of (1.5) and the notion of its solution. However, thanks to this simplification we will be able to show interesting qualitative properties of obtained solutions. A solution to this equation will be a curve of class W^1_p, whose curvature satisfies (1.5) in an appropriate sense explained later; see section 3.

We may now state our main result.

THEOREM 1.1. *Let us suppose that $\bar\gamma : \mathbb{R}^2 \to \mathbb{R}$ is a one-homogeneous, convex function. Then there exists a solution to* (1.5). *Moreover, the solution defines a closed curve Γ, and it is unique up to a translation; namely, it is the Wulff shape of $\bar\gamma$.*

Let us stress that compared to the literature we have already mentioned, the closedness of curve Γ is a *conclusion* of our analysis, not its assumption. Moreover, we consider the weakest possible regularity assumptions on γ, i.e., only convexity of $\bar\gamma$. A general notion of the solution is introduced in the definition of section 3 by (3.13).

In order to prove this theorem, we first consider the regular case (we will make clear what this means for us). Careful analysis gives us a hint how to proceed for general $\bar\gamma$. We will see that it is easier to show the existence of local solutions to (1.5) than to show that they can be glued up to form a closed curve. The last task is simpler for regular curves, because we can use the power of the classical differential geometry. Our goal is reached through an appropriate stability theorem, which is our second important result.

THEOREM 1.2. *Let us assume that $1 \le p < \infty$ and $\bar\gamma, \bar\gamma_\epsilon : \mathbb{R}^2 \to \mathbb{R}$ are convex, one-homogeneous and $\gamma_\epsilon : S^1 \to \mathbb{R}$ are defined by* (1.3) *with $\bar\gamma$ replaced by $\bar\gamma_\epsilon$. We also assume that Γ_ϵ is a solution to*

$$\mathrm{div}_{\partial\Omega}(\nabla_\xi \bar\gamma_\epsilon|_{\xi=\mathbf{n}}) = 1$$

and Γ is a solution to (1.5). *If $\gamma_\epsilon \to \gamma$ in $W^1_p(S^1)$ as $\epsilon \to 0$, then possibly after a translation of Γ_ϵ it is true that $\Gamma_\epsilon \to \Gamma$ in W^1_p as submanifolds in $\mathbb{R}^2$.*

Let us first explain that convergence of Γ_ϵ means convergence of curves locally treated as graphs. The $W^1_p(S^1)$-space is the standard Sobolev space of functions, defined on the unit circle $S^1 = \{x \in \mathbb{R}^2 : |x| = 1\}$, integrable with its derivative with the pth power.

The last result enables us to approximate any low regularity problem by its suitable regularization. A crucial point here is the choice of a proper notion of convergence. At first it seems that the measures are the best spaces, because the second derivative of a convex function is in this space, or, equivalently, the first derivative belongs to the TV-space. However, from our point of view this setting does not appear to be appropriate, because we are not able to find any smooth approximations for the general case. Hence, we investigate the L_p-approach which implies a weaker topology, but it provides sufficient information. The method developed here gives us a tool to analyze the behavior of possible singularities appearing in our problem.

Let us draw a corollary from Theorem 1.2. If $\|x\|_p$ is the usual p-norm in $\mathbb{R}^2$, i.e., $\|x\|_p = (|x_1|^p + |x_2|^p)^{1/p}$ for $p < \infty$, and $\|x\|_\infty = \max\{|x_1|, |x_2|\}$, then we define γ_p

by means of (1.3) as $\gamma_p(x) = \|x\|_p$ for $x \in S^1$. It is a well-known fact that Γ_p, which is a solution to (1.5) with γ_p replacing γ, is given as a Wulff shape of $\|\cdot\|_p$; i.e., Γ_p is the unit ball of the norm $\|\cdot\|_q$, where $\frac{1}{p} + \frac{1}{q} = 1$. Thus, $\Gamma_p = \{\|x\|_q = 1\}$. We can easily see that, for any $r < \infty$, if $\gamma_p \to \gamma_\infty$ in W^1_r as $p \to \infty$, then $\Gamma_p \to \Gamma_\infty$ in W^1_r as submanifolds in $\mathbb{R}^2$.

We briefly describe the content of the paper. In section 2, we recall some well-known facts from the classical differential geometry and explain the meaning of (1.5). Moreover, we prove there Theorem 1.1 in the case of regular γ. This proof will be the starting point for further considerations. Next, we reformulate the problem as a differential inclusion in the case of general γ. In section 4 are the main results: Theorems 1.1 and 1.2 are proved. Finally, we analyze the qualitative properties of the obtained solutions.

2. Preliminary analysis. In this section we recall some facts and introduce further notation. Namely, we shall start by writing

$$\bar{\gamma}(x) = r\gamma(\varphi),$$

where $r = |x|$ and φ are defined by the relation $x = r(\cos\varphi, \sin\varphi)$.

Let us suppose that $s \mapsto \mathbf{x}(s)$ is an arc-length parameterization of a given smooth curve Γ, and then $\mathbf{t}(s) = \frac{d\mathbf{x}}{ds}(s)$ is a unit vector tangent to Γ. If Γ is the boundary of Ω, then we rewrite the left-hand side (LHS) of (1.5) to obtain

$$\operatorname{div}_{\partial\Omega}(\nabla_\xi \bar{\gamma}|_{\xi=\mathbf{n}}) = \mathbf{t} \cdot \frac{\partial}{\partial \mathbf{t}}(\nabla\bar{\gamma}(\mathbf{n})) \equiv \mathbf{t}(s) \cdot \frac{d}{ds}[\nabla\bar{\gamma}(\mathbf{n}(s))]. \tag{2.1}$$

While keeping in mind (2.1), we want to rewrite system (1.5) in a suitable coordinate system. For this purpose, we use the normal angle and subsequently the angle parameterization of Γ. Let us suppose first that $\mathbf{n}$ is a unit vector normal to Γ such that moving frame $\{\mathbf{n}, \mathbf{t}\}$ is a positively oriented basis of $\mathbb{R}^2$. Then the *normal angle* $\varphi(s)$ is defined as a smooth function of s through

$$\begin{aligned} \mathbf{n} = \mathbf{n}(s) = (\cos\varphi(s), \sin\varphi(s)), \\ \mathbf{t} = \mathbf{t}(s) = (-\sin\varphi(s), \cos\varphi(s)). \end{aligned} \tag{2.2}$$

We will refer to the range of the function $s \mapsto \varphi(s)$ as the *angle set.* With the help of this function we define a parameterization of our curve by

$$\mathbf{x}(s) = \int_{s_0}^{s} \mathbf{t}(\varphi(t))dt + \mathbf{v_0} = \int_{s_0}^{s} (-\sin\varphi(t), \cos\varphi(t))\, dt + \mathbf{v_0}, \tag{2.3}$$

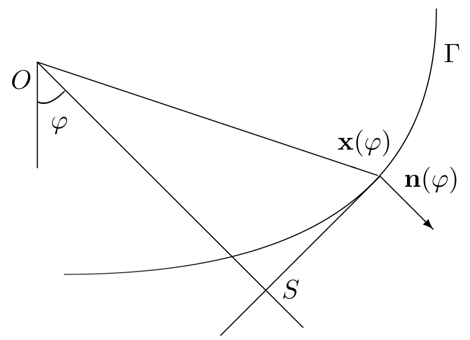
where $\mathbf{v_0}$ is a fixed point in $\mathbb{R}^2$. Let us write $\Gamma = \mathbf{x}(\mathbb{R})$. This formula is a direct result of the fact that s is an arc-length parameter.

The function

$$\frac{d\varphi}{ds}(s) = \kappa(s) \tag{2.4}$$

is the Euclidean curvature of Γ. It obeys the Frenet formulas: $\frac{d\mathbf{n}}{ds} = \kappa\mathbf{t}$, $\frac{d\mathbf{t}}{ds} = -\kappa\mathbf{n}$. In order to proceed, we assume for the moment that γ is at least C^2-smooth. Then (1.5) becomes

$$\left[\frac{d}{ds}\varphi\right][\mathbf{t} \cdot K(\mathbf{n}) \cdot \mathbf{t}] = 1, \tag{2.5}$$



$$P_0(\varphi) = \mathbf{x}(\varphi) \cdot \mathbf{n}(\varphi) = |OS|.$$

FIG. 1.

where

$$K = \begin{bmatrix} \bar{\gamma}_{11} & \bar{\gamma}_{12} \\ \bar{\gamma}_{21} & \bar{\gamma}_{22} \end{bmatrix} = \frac{1}{r}\left(\frac{d^2}{d\varphi^2}\gamma(\varphi) + \gamma(\varphi)\right) e_\varphi \otimes e_\varphi = d^2\bar{\gamma}(r\mathbf{n}) \tag{2.6}$$

and $e_\varphi(\varphi(s)) = \mathbf{t}(\varphi(s))$. Convexity of $\bar{\gamma}$ is equivalent to

$$\frac{d^2}{d\varphi^2}\gamma(\varphi) + \gamma(\varphi) \geq 0. \tag{2.7}$$

In the simplest case we will rule out the possibility of equality above. Let us stress that, because of one-homogeneity of $\bar{\gamma}$, this function cannot be strictly convex in the usual sense.

We shall call a smooth curve *strictly convex* if its curvature never vanishes (in the literature such curves are often called convex). Let us notice that for strictly convex curves an *angle parameterization* $\varphi \mapsto \mathbf{x}(\varphi)$ is possible, because the function $s \mapsto \varphi(s)$ is strictly increasing.

Finally, we shall call a surface energy density function γ *strictly stable at* φ_0 if $\frac{d^2\gamma}{d\varphi^2}(\varphi_0) + \gamma(\varphi_0) > 0$, and γ will be called *strictly stable* if $\frac{d^2\gamma}{d\varphi^2}(\varphi) + \gamma(\varphi) > 0$ holds for all φ. The last condition is a substitute for strict convexity of $\bar{\gamma}$. We shall call a surface energy function γ *regular* if it is smooth and strictly stable.

We expect that (2.5) yields a well-posed differential equation having local solutions. The main difficulty will be associated with proving that solutions can be glued up to form a closed curve. Our tool in solving this problem will be the classical concept of the support function. Let us supposes that Θ is the angle set of a curve Γ for a point O. The *support function* $P_0 : \Theta \to \mathbb{R}$ of Γ is defined by the formula (see Figure 1).

The meaning of $P_0(\varphi)$ is the distance from the tangent to Γ at $\mathbf{x}(\varphi)$ to the origin. One can easily check using the Frenet formula, (2.4), and $\frac{d\mathbf{n}}{d\varphi} = \mathbf{t}$ that P_0 satisfies the following equations:

$$\mathbf{x}(\varphi) = P_0(\varphi)\mathbf{n}(\varphi) + \frac{dP_0}{d\varphi}(\varphi)\mathbf{t}(\varphi), \qquad \frac{d^2P_0}{d\varphi^2}(\varphi) + P_0(\varphi) = \frac{1}{\kappa} \tag{2.8}$$

(see also [Bl, section 94], [Gu, equation (1.10)]).

LEMMA 2.1 ([Gu, Lemma 1A(b)]). *If Γ is a convex curve with curvature $\kappa(\varphi)$, and if P_0 is any solution to $(2.8)_2$ on the angle set of Γ, then $(2.8)_1$ is the angle parameterization of a curve which differs from Γ by at most a translation.*

Proof. Identity $(2.8)_1$ defines a curve uniquely up to a translation. Hence assuming that the curves—mentioned in the lemma—are different, we conclude that they have to intersect at least in one point. Let us consider the difference u between P_0 and the support function of Γ. It satisfies $\frac{d^2u}{d\varphi^2} + u = 0$. The general solution to this equation is $u(\varphi) = a_1 \cos\varphi + a_2 \sin\varphi \equiv \mathbf{a} \cdot \mathbf{n}(\varphi)$. However, $(2.8)_1$ determined two parameters for the intersection, and hence $a_1 = a_2 = 0$. Our claim follows. ◻

We are now ready for our first local result.

LEMMA 2.2. *Let us suppose that γ is smooth and strictly stable. Then there exists a unique local solution to* (2.5) *augmented with the initial condition $\varphi(s_0) = \varphi_0$.*

Proof. The assumption of the strict stability of γ implies that there exist positive numbers a_1 and a_2 such that, for each point $p = (x(s), y(s))$ of curve Γ defined by (2.3), matrix K satisfies

$$a_1|\xi|^2 \le \xi \cdot K(p) \cdot \xi \le a_2|\xi|^2 \quad \text{for any } \xi \in T\Gamma_p, \tag{2.9}$$

where $T\Gamma_p$ denotes the tangent space to Γ at point p.

In this case the existence as well as the uniqueness of solutions are obvious since we reduce the problem to the following elementary ordinary differential equation:

$$\frac{d}{ds}\varphi(s) = (\mathbf{t} \cdot K(\mathbf{n}(\varphi(s))) \cdot \mathbf{t})^{-1}, \tag{2.10}$$

with initial data $\varphi(s_0) = \varphi_0$.

By the strict convexity of γ constants a_1 and a_2 in (2.9) are prescribed globally, and the solution to (2.10) exists for all $s \in \mathbb{R}$. ◻

Subsequently, we will use the above lemma a number of times. It is the necessary step to establishing our first goal, stated below.

PROPOSITION 2.1. *Let us suppose that γ is regular, i.e., smooth and globally strictly stable. Then solutions to* (2.5) *yield a unique closed C^2-curve, Γ being the boundary of a domain Ω.*

Proof. By Lemma 2.2 we have the local existence as well as the uniqueness of solutions to (2.5) with initial data $\varphi(s_0) = \varphi_0$. Now we are going to show that the solution to (2.10) yield a closed curve Γ. First, let us note that by (2.6) and (2.10) we conclude that

$$\frac{d^2}{d\varphi^2}\gamma(\varphi) + \gamma(\varphi) = \frac{1}{\kappa(\varphi)}. \tag{2.11}$$

Because of the global strict stability of γ, function φ is an angle parameterization of a strictly convex curve. Moreover, due to (2.9) there is an interval $[s_0, s_0 + d)$ such that φ is on $[\varphi_0, \varphi_0 + 2\pi)$; i.e., the angle set of Γ is $[0, 2\pi)$. Hence, by Lemma 2.1 we conclude that P_0 and γ differ by $a_1 \cos\varphi + a_2 \sin\varphi$. Since γ is periodic we deduce that P_0 is periodic as well. Thus, we infer that the curve, whose support function is periodic, must be closed; see $(2.8)_1$ and Lemma 2.1. Now we need to exclude self-intersections of the sought curve Γ. This follows immediately from the fact that $\mathbf{x}(\varphi)$ given by (2.8) is 2π-periodic. ◻

Remarks. Let us stress that Lemma 2.2 yields angle parameterizations which are solutions to a differential equation with arbitrary initial data. We showed that the corresponding geometric object, i.e., a closed curve whose angle parameterization we have constructed, exists, and it is unique. The uniqueness is a consequence of the fact that the support functions coincide (up to a periodic function) with γ. Moreover, if

γ is strictly stable, then the locus of the vector function given by (2.8), i.e.,

$$\mathbf{x}(\varphi) = \gamma(\varphi)\mathbf{n}(\varphi) + \gamma'(\varphi)\mathbf{t}(\varphi), \tag{2.12}$$

is the boundary of the Wulff shape W_γ (see [Gu, Theorem 7P]). We recall that, by definition,

$$W_\gamma = \{p \in \mathbb{R}^2 :\ p \cdot \mathbf{n}(\varphi) \le \gamma(\varphi)\}. \tag{2.13}$$

In other words, we have proved Theorem 1.1 for smooth, globally stable γ's.

Inequality (2.7) has a geometric interpretation. We recall that the *Frank diagram* F_γ of a one-homogeneous function $\bar{\gamma}$ is defined by

$$F_\gamma = \{p \in \mathbb{R}^2 :\ \bar{\gamma}(p) = 1\} = \{(r, \varphi) :\ r = \gamma^{-1}(\varphi)\}. \tag{2.14}$$

It is well-known fact that convexity of F_γ is equivalent to convexity of $\bar{\gamma}$ (e.g., see [Gu, Theorem 7B]). Moreover, one can see that the strict stability of γ is equivalent to smoothness and convexity of F_γ.

We are now ready to discuss the weighted mean curvature (WMC) equation for a general anisotropy.

3. The general case of the WMC equation for curves. The goal of this section is to restate problem (1.5) for general γ and define a generalization of the solution—see (3.13).

The approach presented in section 2 is not suitable for γ, which is not of class C^2. For this purpose we return to (2.1) and rewrite it again. Namely, we notice that for smooth γ (1.5) is equivalent to

$$\frac{d}{ds}[(\nabla_\xi \bar{\gamma}|_{\xi=\mathbf{n}}) \cdot \mathbf{t}] - (\nabla_\xi \bar{\gamma}|_{\xi=\mathbf{n}}) \frac{d}{ds}\mathbf{t} = 1, \tag{3.1}$$

but due to (2.2) we see that $\frac{d}{ds}\mathbf{t} = -(\frac{d}{ds}\varphi)\mathbf{n}$; hence, the second term of the LHS of (3.1) reads

$$-(\nabla_\xi \bar{\gamma}|_{\xi=\mathbf{n}}) \frac{d}{ds}\mathbf{t} = \left(\frac{d}{ds}\varphi\right)(\nabla_\xi \bar{\gamma}|_{\xi=\mathbf{n}}) \cdot \mathbf{n}; \tag{3.2}$$

however, by one-homogeneity of $\bar{\gamma}$—see (1.3)—we have $(\nabla_\xi \bar{\gamma}|_{\xi=\mathbf{n}}) \cdot \mathbf{n} = \bar{\gamma}(\mathbf{n})$. Hence we get

$$-(\nabla_\xi \bar{\gamma}|_{\xi=\mathbf{n}})\left(\frac{d}{ds}\mathbf{t}\right) = \left(\frac{d}{ds}\varphi\right)\bar{\gamma}(\mathbf{n}(\varphi)) = \frac{d}{ds}\int_\vartheta^{\varphi(s)} \bar{\gamma}(\mathbf{n}(t))dt, \tag{3.3}$$

where ϑ will be fixed later. Thus, (3.1) takes the following form:

$$\frac{d}{ds}\left[(\nabla_\xi \bar{\gamma}|_{\xi=\mathbf{n}}) \cdot \mathbf{t} + \int_\vartheta^{\varphi(s)} \bar{\gamma}(\mathbf{n}(t))dt\right] = 1. \tag{3.4}$$

We notice that the definition of the normal vector (2.2) implies that $(\nabla_\xi \bar{\gamma}|_{\xi=\mathbf{n}}) \cdot \mathbf{t} = \frac{d}{d\varphi}\bar{\gamma}(\mathbf{n}(\varphi))$. Keeping this in mind we rewrite (3.4) as follows:

$$\frac{d}{ds}\frac{d}{d\varphi}\left[\bar{\gamma}(\mathbf{n}(\varphi)) + \int_\vartheta^{\varphi} d\psi \int_\vartheta^{\psi} \bar{\gamma}(\mathbf{n}(t))dt\right] = 1 \tag{3.5}$$

or in a concise form

$$\frac{d}{ds}\frac{d}{d\varphi}I^{\gamma}_{\vartheta}(\varphi) = 1, \tag{3.6}$$

where

$$I^{\gamma}_{\vartheta}(\varphi) = \bar{\gamma}(\mathbf{n}(\varphi)) + \int_{\vartheta}^{\varphi} d\psi \int_{\vartheta}^{\psi} \bar{\gamma}(\mathbf{n}(t))dt. \tag{3.7}$$

We will drop the superscript for fixed γ.

Equation (3.6) does not make sense for $\bar{\gamma}$ which are only Lipschitz continuous. However, we know that $\bar{\gamma}$ is convex, and this property of $\bar{\gamma}$ is equivalent to the following distributional relation:

$$\frac{d^2}{d\varphi^2}\gamma(\varphi) + \gamma(\varphi) \geq 0 \quad \text{in } \mathcal{D}'(S^1). \tag{3.8}$$

Let us make the following observation.

PROPOSITION 3.1. *If one-homogeneous function $\bar{\gamma} : \mathbb{R}^2 \to \mathbb{R}$ is convex, then the function*

$$\mathbb{R} \ni \varphi \to I_{\vartheta}(\varphi) \in \mathbb{R}$$

is also a convex function for fixed ϑ.

Proof. If $\bar{\gamma}$ is as above, i.e., $\bar{\gamma}(x) = |x|\gamma(\varphi)$, where $x = |x|(\cos\varphi, \sin\varphi)$, then by (2.6) convexity of $\bar{\gamma}$ is equivalent to inequality $\gamma'' + \gamma \geq 0$ in the sense of distributions (see (3.8)). Once we notice that $\frac{\partial^2}{\partial\varphi^2}I_{\vartheta}(\varphi) = \gamma'' + \gamma$, our claim follows. ∎

Thus, the subdifferential $\partial_{\varphi}I_{\vartheta}$ of a convex function I_{ϑ} is always well-defined. Hence, our task consists of finding a suitable section of $\partial_{\varphi}I_{\vartheta}$, and we can formally write (3.5) as the following inclusion:

$$\frac{d}{ds}\partial_{\varphi}\left[\bar{\gamma}(\mathbf{n}(\varphi)) + \int_{\vartheta}^{\varphi} d\psi \int_{\vartheta}^{\psi} \bar{\gamma}(\mathbf{n}(t))dt\right] \ni 1. \tag{3.9}$$

We will make it precise below. Let us first make some observations about I_{ϑ}. If γ is smooth, then $\frac{d}{d\varphi}I_{\vartheta_1}$ and $\frac{d}{d\varphi}I_{\vartheta_2}$ differ by a constant, i.e.,

$$\frac{d}{d\varphi}I_{\vartheta_1}(\varphi) = \frac{d}{d\varphi}I_{\vartheta_2}(\varphi) + \int_{\vartheta_1}^{\vartheta_2} \gamma(t)\, dt. \tag{3.10}$$

Let us notice that this identity will remain valid if γ is Lipschitz continuous and we replace $\frac{d}{d\varphi}$ with ∂_{φ}. Mere continuity of γ yields

$$I_{\vartheta}(2\pi + \varphi) = I_{\vartheta}(\varphi) + I_{\vartheta}(2\pi + \vartheta) - \gamma(\vartheta) + (\varphi - \vartheta)\int_{\vartheta}^{2\pi+\vartheta} \gamma(t)\, dt. \tag{3.11}$$

Indeed, for $\varphi \geq \vartheta$ we have

$$I_{\vartheta}(2\pi+\varphi) - I_{\vartheta}(2\pi+\vartheta) = \gamma(\varphi) - \gamma(\vartheta) + \int_{2\pi+\vartheta}^{2\pi+\varphi}\int_{\vartheta}^{2\pi+\vartheta} \gamma(t)\, dt d\psi + \int_{2\pi+\vartheta}^{2\pi+\varphi}\int_{2\pi+\vartheta}^{\psi} \gamma(t)\, dt d\psi.$$

Hence, (3.11) follows.

Suppose again that γ is smooth, and then we can infer from (3.10) that by an appropriate choice of ϑ we may achieve $\varphi(\bar{s}) = \bar{\varphi}$ for arbitrary $\bar{\varphi}$, $\bar{s} \in \mathbb{R}$.

Furthermore, let us integrate (3.5) over $[\bar{s}, s]$, where $\bar{s}$ is an arbitrary parameter and $s - \bar{s}$ is less than the length of the curve Γ we are looking for.

After integration we obtain

$$\frac{d}{d\varphi} I_\vartheta(\varphi(s)) - \frac{d}{d\varphi} I_\vartheta(\bar{\varphi}) = s - \bar{s}, \tag{3.12}$$

where $\bar{\varphi} = \varphi(\bar{s})$ may be chosen at will.

If γ is smooth, then the LHS of (3.12) is well-defined for all $\varphi \in \mathbb{R}$. However, this is no longer the case if γ is merely Lipschitz continuous. For such a γ, the LHS of (3.12) is well-defined only a.e.

Now we are in a position to define a notion of a generalized solution to (1.5) with minimal assumptions on $\bar{\gamma}$.

DEFINITION 3.1. *If γ is one-homogeneous and convex, then by a* solution to (1.5) *we mean a closed curve Γ whose angle parameterization $\varphi(\cdot)$ is a monotone (increasing) multivalued function, which can be treated locally as an L_1 function, and the following differential inclusion is valid:*

$$\partial_\varphi I_\vartheta(\varphi) \ni s - \bar{s} + s^\star \qquad a.e., \tag{3.13}$$

with initial data $\varphi|_{s=\bar{s}} = \bar{\varphi}$ and $s^\star \in \partial_\varphi I_\vartheta(\bar{\varphi})$. The inclusion (3.13) *holds for such s that $\varphi(s)$ is single-valued.*

Let us notice that (3.10) (with $\frac{d}{d\varphi}$ replaced by ∂_φ) again yields the possibility of choosing ϑ so that $\bar{s} = s^\star \in \partial_\varphi I_\vartheta(\bar{\varphi})$ for any $\bar{s}$, $\bar{\varphi} \in \mathbb{R}$. Thus, (3.13) will read

$$\partial_\varphi I_\vartheta(\varphi) \ni s. \tag{3.14}$$

We note an expected result.

COROLLARY 3.1. *Let us suppose that γ is smooth and a function $\varphi : \mathbb{R} \to \mathbb{R}$ such that $\varphi(\bar{s}) = \bar{\varphi}$ is a solution to* (3.13)*, and then φ is a solution to* (3.12)*. Moreover, if in addition γ is globally stable, then the solution is unique.*

Proof. This fact is obvious, once we realize that, for smooth γ, the function $I_\vartheta(\cdot)$ is also smooth and

$$\partial_\varphi I_\vartheta(\varphi) = \left\{ \frac{d}{d\varphi} I_\vartheta(\varphi) \right\},$$

where $\frac{d}{d\varphi} I_\vartheta(\varphi)$ is the usual derivative of $I_\vartheta(\varphi)$. The uniqueness of the solutions follows from strict monotonicity of $\partial_\varphi I_\vartheta(\varphi)$, provided that γ is strictly stable. □

4. The general existence and stability. In this section we prove Theorems 1.1 and 1.2. We want to proceed in a manner similar to that of section 2. We first show the local existence of solutions to (3.13), which replaces (2.5) for nonsmooth γ. However, in order to complete the proof of Theorem 1.1, we have to show that the solutions we have constructed yield closed curves. Indeed, this goal is achieved through an approximation procedure. We show for this purpose Theorem 1.2. It states that solutions to (3.13) depend continuously on $\bar{\gamma}$. Thus, the approximation of any energy density function γ by a sequence of smooth, strictly stable energy density functions γ_ϵ yields the desired result.

We begin with an analog of Lemma 2.2 for a nonsmooth energy density function.

PROPOSITION 4.1. *Let us suppose that $\bar{\gamma}$ is convex and one-homogeneous and ϑ is fixed. Then*

(a) *the multivalued operator* $\partial I_\vartheta : \mathbb{R} \to \mathbb{R}$ *is maximal monotone;*

(b) *for any* $s \in \mathbb{R}$ *there exists* $\varphi \in \mathbb{R}$ *a solution to* $\partial I_\vartheta(\varphi) \ni s$.

Proof. Part (a) is a conclusion from the general theory; see, e.g., [Ba] or [Br]. (b) By (3.11) we notice

$$\partial I_\vartheta(2\pi + \varphi) = \partial I_\vartheta(\varphi) + L(\gamma),$$

where $L(\gamma) = \int_\vartheta^{2\pi+\vartheta} \gamma(t)\, dt > 0$. We recall that γ is 2π-periodic, and thus $L(\gamma)$ is independent from θ. Since $R(\partial I_\vartheta)$, the range of ∂I_ϑ is connected and contains a sequence which is neither bounded from below nor from above, and we conclude that $R(\partial I_\vartheta)$ is equal to $\mathbb{R}$. ☐

Once we decide upon $\bar{s}$ and $\bar{\varphi}$, we fix ϑ, and we will drop for notational convenience the subscript ϑ. The choice of value $\bar{s}$ which is the beginning of counting the length of the solution curve seems irrelevant; however, it is not quite so. We will explain it momentarily. Since the function $\varphi \mapsto I(\varphi)$ is convex, then it has one-sided derivatives everywhere. They are equal; i.e., I is differentiable at all points of $\mathbb{R}$ except at most countably many where $\frac{d^- I}{d\varphi}(\psi) < \frac{d^+ I}{d\varphi}(\psi)$. In other words, the derivative $\frac{dI}{d\varphi}$ is well-defined a.e., and its graph $\Gamma(\frac{dI}{d\varphi})$ is a subset of ∂I. Since ∂I is maximal monotone, so is its inverse graph $(\partial I)^{-1}$. If we now consider any function $h : \mathbb{R} \to \mathbb{R}$, with $h(x) \in (\partial I)^{-1}(x)$, i.e., $\Gamma(h) \subset (\partial I)^{-1}$, then it is monotone and hence continuous, except possibly a countable number of points where h suffers jumps. For this reason, any two such functions differ on a set of measure zero and define a unique element of $L_{p(loc)}(\mathbb{R})$. This observation permits us to identify (when necessary) ∂I or $(\partial I)^{-1}$ with monotone functions defining unique elements of $L_{p(loc)}(\mathbb{R})$.

We are now ready for a definition. If we fix $\vartheta \in \mathbb{R}$ and a one-homogeneous convex γ, then we shall call $s^\star \in \mathbb{R}$ *a regular point of* I_ϑ^γ, if it is a continuity point of any function h defined on $\mathbb{R}$, such that $\Gamma(h) \subset (\partial I_\vartheta^\gamma)^{-1}$. This scant continuity of $(\partial I_\vartheta^\gamma)^{-1}$ will play an important role.

We stress that regularity of $s^\star$ depends upon ϑ; i.e., $s^\star$ may cease to be regular if we change ϑ. In particular, we may assume that in (3.13) $s_0 = s^\star - \bar{s}$ is a regular point, possibly after adjusting ϑ and $\bar{\varphi}$. In this case we obtain a unique definition of the solution

$$\varphi(\cdot) = (\partial I)^{-1}(\cdot + s_0), \tag{4.1}$$

where φ is treated as a multivalued function, but we can write $\{\varphi_0\} = (\partial I)^{-1}(s_0)$, because $(\partial I)^{-1}(s_0)$ is a singleton.

Part (b) of Proposition 4.1 immediately yields the existence of a solution to (3.13), that is, a function $\varphi : \mathbb{R} \to \mathbb{R}$, $\varphi(0) = \varphi_0$, which is an angle parameterization of a curve Γ we seek. We recall that this curve is given (up to a translation) by (2.3). We also notice that this formula yields the same result for all L^1 equivalent functions $\varphi(\cdot)$. We should comment on the domain of definition of $\mathbf{x}$, i.e., the length of Γ. We will also explain the meaning of $L(\gamma)$ and the role of regular points. We have just constructed a candidate for a solution.

PROPOSITION 4.2. *Let us suppose that* s_0, φ_0 *are fixed, and then*

(a) $(\partial I_\vartheta^\gamma)^{-1}[s_0, s_0 + L(\gamma)]$ *contains an interval of length* 2π*;*

(b) *if* $0 < b < L(\gamma)$ *and* s_0 *is a regular point of* I_ϑ^γ, *then* $(\partial I_\vartheta^\gamma)^{-1}[s_0, s_0 + b]$ *does not contain any interval of length* 2π.

Proof. Part (a) follows immediately from (3.11).

(b) For a regular point s_0 (3.11) takes the form

$$\frac{dI}{d\varphi}(\varphi_0+2\pi)=\frac{dI}{d\varphi}(\varphi_0)+L(\gamma). \tag{4.2}$$

Hence, $\frac{dI}{d\varphi}(\varphi_0+2\pi)>\frac{dI}{d\varphi}(\varphi_0)+b$, and our claim follows. ∎

We can draw some corollaries.

COROLLARY 4.1. *Let us suppose that s_0 is a regular point of I^{γ}_{ϑ} and curve Γ defined by* (2.3), *where $\varphi(\cdot)$ is given by* (4.1).

(a) *If γ is smooth and strictly stable, then the length of Γ, $d(\Gamma)$, is equal to $L(\gamma)$.*

(b) *If $\{\gamma_\epsilon\}$ is a sequence of smooth, strictly stable functions converging to γ_0 in $W^1_p(S^1)$, then $d(\Gamma_0)$ is equal to $L(\gamma_0)$.*

Proof. (a) By (4.2) we notice that $\varphi(s_0)+2\pi=\varphi(s_0+L(\gamma))$. Thus, we see that $d(\Gamma)=L(\gamma)$.

(b) If $\gamma_\epsilon\to\gamma_0$ in $W^1_p(S^1)$ and $\vartheta_\epsilon\to\vartheta_0$, then the parameterizations given by (2.3) converge as well, i.e., $\mathbf{x}_\epsilon\to\mathbf{x}_0$ in W^1_p. Thus,

$$L(\gamma_0)=\lim_{\epsilon\to0}L(\gamma_\epsilon)=\lim_{\epsilon\to0}d(\Gamma_\epsilon)=d(\Gamma_0),$$

and our claim follows. ∎

The key point is to show that indeed Γ is a closed curve. The main step toward this goal is the following result on the continuous dependence of solutions to (3.13) on the anisotropy $\bar\gamma$. For this purpose we will investigate solutions to (2.1), i.e., curves parameterized by $\mathbf{x}(\cdot)$ (see (2.3)), upon γ. The simple lemma below is our basic tool.

LEMMA 4.1. *Let $1\le p<\infty$ and $\gamma_\epsilon(\cdot)\to\gamma_0(\cdot)$ in $W^1_p(S^1)$; then there exists a sequence $\{\vartheta_\epsilon\}_{\epsilon>0}$ converging to ϑ_0, and for $I_\epsilon:=I^{\epsilon}_{\vartheta_\epsilon}$ we have*

$$(\partial I_\epsilon)^{-1}(\cdot)\to(\partial I_0)^{-1}(\cdot)\quad in\quad L_{p(loc)}(\mathbb{R}). \tag{4.3}$$

Moreover, if s_0 is a regular point of $I^{\gamma_0}_{\vartheta_0}$ (i.e., $\{\varphi_0\}=(\partial I_0)^{-1}(s_0)$), then we can find a sequence $\{s_\epsilon\}$ such that s_ϵ is a regular point of $I^{\gamma_\epsilon}_{\vartheta_\epsilon}$ (i.e., $\{\varphi_\epsilon\}=(\partial I_\epsilon)^{-1}(s_\epsilon)$) and $s_\epsilon\to s_0$.

Proof. Since $I_\epsilon=I^{\gamma_\epsilon}_{\vartheta_\epsilon}$, then for a.e. convergence of $\frac{d}{d\varphi}I_\epsilon$ to $\frac{d}{d\varphi}I_0$ it is necessary that $\vartheta_\epsilon\to\vartheta_0$. To show (4.3) it is enough to recall the definition (3.7) and recall that all $(\partial I_\epsilon)^{-1}$ are monotone. The last fact implies that our functions are continuous except at most countable sets, so the rest of Lemma 4.1 is clear, too. Once we realize that, the remaining details become quite elementary, and they are left to the interested reader. ∎

THEOREM 4.1. *If $1\le p<\infty$ and $\gamma_\epsilon\to\gamma_0$ in $W^1_p(S^1)$, then $\Gamma_\epsilon\to\Gamma_0$ in W^1_p.*

Proof. It is sufficient to show that φ_ϵ (the angle parameterization of Γ_ϵ) converges to φ_0, as long as $\mathbf{v_0}^\epsilon$ converges to $\mathbf{v_0}$; see (2.3). These functions are defined on intervals of changing length $d(\Gamma_\epsilon)$. However, due to convergence of $d(\Gamma_\epsilon)$ to $d(\Gamma_0)$, we may restrict our attention to functions φ_ϵ and φ_0 only on interval $[0,d(\Gamma_0)]$, which is sufficient to prove convergence in the L_p-space. By Lemma 4.1 by a proper choice of ϑ_0 and ϑ_ϵ we can make sure s_ϵ, s_0 are regular points, in particular

$$\{\varphi_0(0)\}=(\partial I_0)^{-1}(s_0),\qquad\{\varphi_\epsilon(0)\}=(\partial I_\epsilon)^{-1}(s_\epsilon),$$

and moreover $s_\epsilon\to s_0$. Subsequently we will identify $(\partial I_\epsilon)^{-1}$ with its L_p-representative.

Let us note that

$$\begin{aligned}\varphi_\epsilon(s)-\varphi_0(s)&=\partial I_\epsilon^{-1}[s+s_\epsilon]-\partial I_0^{-1}[s+s_0]\\&=\partial I_\epsilon^{-1}[s+s_\epsilon]-\partial I_0^{-1}[s+s_\epsilon]+\partial I_0^{-1}[s+s_\epsilon]-\partial I_0^{-1}[s+s_0].\end{aligned} \tag{4.4}$$

Since $\partial I_\epsilon^{-1} \to \partial I_0^{-1}$ in L_p on compact sets, we have

(4.5)

$$||\partial I_\epsilon^{-1}[\,\cdot + s_\epsilon] - \partial I_0^{-1}[\,\cdot + s_\epsilon]||_{L_p(0,d(\Gamma_0))} \leq \left(\int_0^{d(\Gamma_0)} |\partial I_\epsilon^{-1}(s+s_\epsilon) - \partial I_0^{-1}(s+s_\epsilon)|^p\,ds\right)^{1/p}$$
$$= \left(\int_{s_\epsilon}^{d(\Gamma_0)+s_\epsilon} |\partial I_\epsilon^{-1}(s) - \partial I_0^{-1}(s)|^p\,ds\right)^{1/p} \leq ||\partial I_\epsilon^{-1} - \partial I_0^{-1}||_{L_p(s_0-1,d(\Gamma_0)+s_0+1)} \to 0$$

as $\epsilon \to 0$. Next, we note that

$$||\partial I_0^{-1}(\,\cdot + s_\epsilon) - \partial I_0^{-1}(\,\cdot + s_0)||_{L_p(0,d(\Gamma_0))} \to 0, \tag{4.6}$$

which follows from convergence of s_ϵ to s_0 regularity of s_0 and continuity of the shift operator in the L_p-spaces for $p < \infty$.

As a consequence we get

$$\varphi_\epsilon(\cdot) \to \varphi_0(\cdot) \quad \text{in} \quad L_p(0, d(\Gamma_0)). \tag{4.7}$$

Lemma 4.1 implies $\Gamma_\epsilon \to \Gamma_0$ in W_p^1. ☐

Once the above theorem is at hand, we conclude that the limiting curve Γ_0 is closed.

Lemma 4.2. *Let us suppose that $\bar\gamma_0$ is one-homogeneous and convex and there exists a sequence $\bar\gamma_\epsilon$ of one-homogeneous, convex, and strictly stable functions such that $\gamma_\epsilon \to \gamma_0$ in $W_p^1(S^1)$. Then any curve Γ whose angle parameterization is a solution to* (3.13) *is a closed curve, and moreover it is the Wulff shape of $\bar\gamma_0$, up to translation.*

Proof. We have to prove that the curve Γ is closed. For smooth strictly convex γ's the answer is given by Proposition 2.1 in section 2.

Let us consider an arbitrary $\gamma_0(\cdot)$ and a curve Γ_0 given by solution φ to (3.13). Let us assume that Γ_0 is not closed; i.e., there exists $\varphi_0 \in [0, 2\pi)$ such that

$$\mathbf{x}_0(s(\varphi_0)) \neq \mathbf{x}_0(s(\varphi_0 + 2\pi)),$$

in particular

$$|\mathbf{x}_0(s(\varphi_0) - \mathbf{x}_0(s(\varphi_0 + 2\pi))| = T > 0 \tag{4.8}$$

for a number $T > 0$. Since γ_ϵ is a smooth approximation of γ_0 after a proper selection of $\mathbf{v_0}^\epsilon$ in (2.3), we guarantee that

$$||\Gamma_\epsilon - \Gamma||_{C(0,2\pi)} < T/3. \tag{4.9}$$

This is always possible having Theorem 4.1 at hand. But by Proposition 2.1 we know that Γ_ϵ is closed, so by (4.9) we have

(4.10)

$$|\mathbf{x}_0(s(\varphi_0)) - \mathbf{x}_0(s(\varphi_0 + 2\pi))| \leq |\mathbf{x}_0(s(\varphi_0) - \mathbf{x}_\epsilon(s(\varphi_0))| + |\mathbf{x}_\epsilon(s(\varphi_0)) - \mathbf{x}_\epsilon(s(\varphi_0 + 2\pi))|$$
$$+|\mathbf{x}_\epsilon(s(\varphi_0 + 2\pi)) - \mathbf{x}_0(s(\varphi_0 + 2\pi))| < T/3 + 0 + T/3 = 2/3T,$$

which contradicts (4.8). Finally, we know that Γ_ϵ is the Wulff shape of γ_ϵ. By (2.13) and the uniform convergence of γ_ϵ to γ_0, we deduce that Γ_0 defined by (4.1) and (2.3) is the Wulff shape of γ_0. ☐

In order to finish the proofs of Theorems 1.1 and 1.2, it is enough to note that finding a sequence approximating general function γ is elementary. For example, for a proper choice of smooth functions $\rho_\epsilon : S^1 \to \mathbb{R}$ converging to δ_1 on the circle, we may take

$$\gamma_\epsilon(\varphi) = \epsilon + \gamma \star \rho_\epsilon(\varphi). \tag{4.11}$$

Here $\gamma\star\rho_\epsilon$ denotes the convolution on S^1, and as a result γ_ϵ is smooth and 2π-periodic.

Hence Lemma 4.2 implies the first of our main results, stated in Theorem 1.1, i.e., the existence of φ fulfilling the definition of the generalized solution (3.13). Theorem 1.2 follows from Theorem 4.1. ∎

5. Properties of the solutions. Since our case concerns only plane domains, Hessian $K(\mathbf{n}(\cdot))$—see (2.6)—can be zero on an interval, i.e., $\gamma'' + \gamma = 0$ on (a, b). This in turn is equivalent to F_γ containing a line segment between the angles a and b, (see [Gu, Lemma 7D]). The Euclidean curvature of the Frank diagram is zero there. We want to control precisely the behavior of the system at such points, because singularities may appear there.

For general γ, we concentrate our attention only on the support of K, i.e., on the following set:

$$\operatorname{supp} K := \overline{\{\varphi \in S^1 : \mathbf{t}(\varphi) \cdot K(\mathbf{n}(\varphi)) \cdot \mathbf{t}(\varphi) \neq 0\}}. \tag{5.1}$$

It is implicitly understood that the points of nondifferentiability of γ belong to $\operatorname{supp} K$. Roughly speaking, $\operatorname{supp} K$ consists of points of strict stability of γ. Certainly, due to our previous considerations $(\partial I)^{-1}$ is single-valued and continuous on this set. In order to understand the whole structure of solutions we need to control the behavior of intervals $(a, b) \subset S^1$ such that

$$\mathbf{t}(\varphi) \cdot K(\mathbf{n}(\varphi)) \cdot \mathbf{t}(\varphi) \equiv 0 \qquad \text{for } \varphi \in (a, b). \tag{5.2}$$

In order to make our considerations precise we introduce the following definition. We call an interval (a, b) on which (5.2) holds *maximal* iff for any sufficiently small $\epsilon > 0$ there exist a_* and b^* such that $0 < a - a_* < \epsilon$, $0 < b^* - b < \epsilon$ and for all $w_a \in \partial I(a_*)$ and $w_b \in \partial I(b^*)$ the following relations are satisfied:

$$w_a < \partial I(a + \epsilon) \quad \text{and} \quad \partial I(b - \epsilon) < w_b. \tag{5.3}$$

Obviously, all points of interval (a, b) are continuity points of ∂I. However, we have no control over the behavior of the ends of this interval, which explains the form of (5.3). The above remarks imply that, to analyze the behavior on the interval (a, b), it is enough to consider sets $(a - \epsilon, b + \epsilon)$.

The control over these singularities is guaranteed by the following lemma.

LEMMA 5.1. *Let us suppose that γ is not strictly stable. If* (5.2) *holds, then for any solution $\varphi(\cdot)$ of system* (2.5) *with the range in* $\operatorname{supp} K$ *and for each interval* (a, b) *satisfying* (5.2) *there exists a parameter s_0 such that*

$$\lim_{s\to s_0{}^-} \varphi(s) \le a \quad \textit{and} \quad \lim_{s\to s_0^+} \varphi(s) \ge b. \tag{5.4}$$

Moreover, if (a, b) is maximal (in the meaning of (5.3)*), then*

$$\lim_{s\to s_0{}^-} \varphi(s) = a \quad \textit{and} \quad \lim_{s\to s_0^+} = b. \tag{5.5}$$

Proof. By considerations in the last section we can introduce a strictly stable approximation of the studied γ. We put:

$$\mathbf{t}(\varphi_\epsilon)\cdot K_\epsilon(\varphi_\epsilon)\cdot\mathbf{t}(\varphi_\epsilon)=\epsilon \qquad \text{for} \quad \varphi_\epsilon\in(a,b) \tag{5.6}$$

for $\epsilon > 0$ and

$$\mathbf{t}(\varphi_\epsilon)\cdot K_\epsilon(\varphi_\epsilon)\cdot\mathbf{t}(\varphi_\epsilon)=\mathbf{t}(\varphi_\epsilon)\cdot K(\varphi_\epsilon)\cdot\mathbf{t}(\varphi_\epsilon)+\epsilon \qquad \text{for} \quad S^1\setminus(a,b). \tag{5.7}$$

By (2.6) we can put $\gamma_\epsilon=\gamma+\epsilon$, getting (5.6) and (5.7). The above definition guarantees that $\gamma_\epsilon\to\gamma$ in W^1_p at least on a neighborhood of interval (a,b), and hence the application of Theorem 1.2 is possible.

Let us suppose that s_a is defined by the following relation $\varphi_\epsilon(s_a)=a$ if (a,b) is maximal. Otherwise, we require $\varphi_\epsilon(s_a)\le a$ in general. Then by (2.10) we see that for the approximation satisfying (5.6) we have

$$\frac{d}{ds}\varphi_\epsilon=\frac{1}{\epsilon} \quad \text{as} \quad \varphi\in(a,b), \tag{5.8}$$

and hence, we are able to find s_b such that $\varphi_\epsilon(s_b)=b$ in the “maximal” case or $\varphi_\epsilon(s_b)\ge b$ in general. Formula (5.8) yields $\varphi_\epsilon(s)=\frac{1}{\epsilon}(s-s_a)+a$, so we conclude that $s_b-s_a=\epsilon(b-a)$. Passing with ϵ to 0 we get at the limit $s_a=s_b=:s_0$. Remembering that φ_ϵ and φ are monotone we easily deduce (5.4). From the definition (5.3) we obtain (5.5). We can prove the same result by applying the approximation by regular γ_ϵ's defined by (4.11). However, this approach yields additional technical difficulties. Thus, one can conclude that any regular approximation of this case leads to (5.4) or (5.5), respectively. ∎

Remark. We are tempted to write formally at point s_0, where function φ has a jump, that

$$\frac{d}{ds}\varphi\Big|_{s=s_0}=(b-a)\delta(s-s_0).$$

From the geometrical point of view the sought curve Γ will have an interior angle of measure $(b-a)$ at point s_0.

Examples. Here we present examples of solutions which are constructed by our method. We present only the extreme cases: the isotropic and a crystalline $\bar\gamma$.

(1) The isotropic energy density is given by $\bar\gamma(x)=|x|$, i.e., $\gamma(\varphi)=1$. Let us take $\vartheta=0$, $s_0=0$; hence, $I(\varphi)=\bar\gamma(\mathbf{n}(\varphi))+\int_0^\varphi d\psi\int_0^\psi\bar\gamma(\mathbf{n}(t))dt=1+\frac{1}{2}\varphi^2$ and thus $\partial_\varphi I(\varphi)=\{\frac{d}{d\varphi}I(\varphi)\}=\{\varphi\}$ and $L(\gamma)=2\pi$. Equation (3.13) takes the form $\varphi(s)=s$. Then we conclude that the solution is a circle, whose length is given by $L(\gamma)=2\pi$.

(2) This case is sometimes called *crystalline*, because the Wulff shape is a polygon. We may consider the following anisotropy: $\bar\gamma(x)=\max\{|x_1|,|x_2|\}$, and hence

$$\gamma(\varphi)=\max\{|\cos\varphi|,|\sin\varphi|\}.$$

Elementary calculations, which are left to the interested reader (we may take $s_0=0,\vartheta=0$ in I), and Lemma 5.1 lead us to a conclusion that $d(\Gamma)=4\sqrt{2}$ and Γ is a square (up to translation) with vertexes at $(\pm1,0),(0,\pm1)$.

Acknowledgment. The second author thanks professor Robert Gulliver for pointing to his attention reference [Bl] and an enlightening discussion on the topic of Lemma 2.1.

WEAKLY COUPLED SCHRÖDINGER OPERATORS ON REGULAR METRIC TREES*

HYNEK KOVAŘÍK†

Abstract. Spectral properties of the Schrödinger operator $A_\lambda = -\Delta + \lambda V$ on regular metric trees are studied. It is shown that as λ goes to zero the asymptotical behavior of the negative eigenvalues of A_λ depends on the global structure of the tree.

Key words. Schrödinger operator, Sturm–Liouville problems, metric trees

1. Introduction.

The spectrum of a Schrödinger operator

$$-\Delta + \lambda V, \quad \lambda > 0, \quad \text{in} \quad L^2(\mathbb{R}^n)$$

is given by the disjoint union of the essential spectrum $\sigma_{ess}(-\Delta+\lambda V)$ and the discrete spectrum $\sigma_d(-\Delta+\lambda V)$. Under certain decay conditions on V at infinity the essential spectrum covers the half-line $[0,\infty)$ so that the discrete spectrum consists of negative eigenvalues of finite multiplicity. It is a well-known fact that the behavior of these eigenvalues for small values of λ depends on the spacial dimension n [11]. Namely, for $n < 3$ the negative eigenvalues of $-\Delta+\lambda V$ appear for any $\lambda > 0$, provided $\int_{\mathbb{R}^n} V < 0$, while for $n \geq 3$ the negative spectrum of $-\Delta+\lambda V$ remains empty for λ small enough. Moreover for the lowest eigenvalue $-\varepsilon(\lambda)$ of $-\Delta+\lambda V$ the following asymptotics hold true (see [11]):

$$n = 1 : \varepsilon(\lambda) \sim \lambda^2, \qquad \lambda \to 0, \tag{1}$$

$$n = 2 : \varepsilon(\lambda) \sim e^{-\lambda^{-1}}, \quad \lambda \to 0. \tag{2}$$

In this paper we want to find the asymptotic behavior of $\varepsilon(\lambda)$ for a Schrödinger operator

$$A_\lambda = -\Delta + \lambda V, \quad \lambda > 0, \quad \text{in} \quad L^2(\Gamma)$$

defined on a regular metric tree Γ. Such a metric tree consists of the set of vertices and the set of edges (branches), i.e., one-dimensional intervals connecting the vertices; see section 2 for details. Metric trees form a special subclass of so-called quantum graphs. The latter serve as mathematical models for nanotechnological devices that consist of connected very thin strips. The motion of an electron in such a "web" is then governed by the Schrödinger equation. Therefore the study of Laplace and Schrödinger operators on these structures has recently attracted considerable attention; see, e.g., [4, 5, 6, 7, 8, 9, 12, 13], and references therein.

We are interested in the spectral behavior of A_λ when $\lambda \to 0$. The intuitive expectation is that this should depend on the rate of the growth, or branching, of the tree Γ. In order to quantify this branching, we assign to Γ a so-called *global dimension* d; see Definition 2 below. Roughly speaking it tells us how fast the number of branches of Γ increases as a function of the distance from its root. If the latter grows with the power $d-1$ at infinity, then we say, in analogy with the Euclidean spaces, that d is the global dimension of Γ. We use the notation global in order to distinguish d from the local dimension, which is of course one. Since d can be in general any real number larger or equal to one, it is natural to ask how the weak coupling behavior looks for noninteger values of d and what the condition on V is under which the eigenvalues appear.

Our main result says (see Theorem 3 and section 5.2), that if $d \in [1,2]$ and $\int_\Gamma V < 0$, then A_λ possesses at least one negative eigenvalue for any $\lambda > 0$, and for λ small enough this eigenvalue is unique and satisfies

$$\begin{aligned} &\varepsilon(\lambda) \sim \lambda^{\frac{2}{2-d}}, \qquad 1 \le d < 2\,, \\ &\varepsilon(\lambda) \sim e^{-\lambda^{-1}}, \qquad d = 2. \end{aligned} \tag{3}$$

As expected, the faster the branching of Γ, i.e., larger d, the faster the eigenvalue tends to zero. The borderline is reached at $d = 2$, in which case $\varepsilon(\lambda)$ converges to zero faster than any power of λ similarly as in (2). Finally, if the tree grows too fast, i.e., $d > 2$, then the discrete spectrum of A_λ generically remains empty for λ small enough; see section 5.3. Note also that the condition $\int_\Gamma V < 0$ is almost optimal in the sense that if $\int_\Gamma V > 0$, then A_λ has no negative eigenvalues for small λ as shown in Theorem 3b.

To study the operator A_λ we make use of the decomposition (5), Theorem 1, which was proved in [8, 9]; see also [4]. In section 3.1 we introduce certain auxiliary operators, whose eigenvalues will give us the estimate on $\varepsilon(\lambda)$ from above and from below. In order to establish (3) we find the asymptotics of the lowest eigenvalues of the auxiliary operators, which are of the same order. This is done in section 5.1. In addition, in section 4 we give some estimates on the number of eigenvalues of the individual operators in the decomposition (5), which might be of an independent interest as well.

Throughout the text we will employ the notation $\alpha := d-1$ and $\nu := \frac{2-d}{2}$. For a real-valued function f and a real noninteger number μ, we will use the shorthand

$$f^\mu := \operatorname{sign} f\, |f|^\mu = \frac{f\,|f|^\mu}{|f|}.$$

Finally, given a self-adjoint operator T on a Hilbert space $\mathcal{H}$ we denote by $N_-(T;s)$ the number of eigenvalues, taking into account their multiplicities, of T on the left of the point s. For $s = 0$ we will write $N_-(T)$ instead of $N_-(T;0)$.

2. Preliminaries. We define a metric tree Γ with the root o following the construction given in [8]. Let $\mathcal{V}(\Gamma)$ be the set of vertices and $\mathcal{E}(\Gamma)$ be the set of edges of Γ. The distance $\rho(y,z)$ between any two points $y, z \in \Gamma$ is defined in a natural way as the length of the unique path connecting y and z. Consequently, $|y|$ is equal to $\rho(y,o)$. We write $y \preceq z$ if y lies on the unique simple path connecting o with z. For $y \preceq z$ we define

$$\langle y, z\rangle := \{x \in \Gamma \,:\, y \preceq x \preceq z\}.$$

If $e = \langle y, z\rangle$ is an edge, then y and z are its end points. For any vertex z its generation $Gen(z)$ is defined by

$$Gen(z) = \#\{x \in \mathcal{V} : o \prec x \preceq z\}.$$

For an edge $e \in \mathcal{E}(\Gamma)$ we define its generation as the generation of the vertex, from which e is emanating. The branching number $b(z)$ of the vertex z is equal to the number of edges emanating from z. We assume that $b(z) > 1$ for any $z \neq o$ and $b(o) = 1$.

Definition 1. *A tree* Γ *is called* regular *if all of the vertices of the same generation have equal branching numbers and all of the edges of the same generation have equal length.*

We denote by $t_k > 0$ the distance between the root and the vertices of the kth generation and by $b_k \in \mathbb{N}$ their corresponding branching number. For each $k \in \mathbb{N}$ we define the so-called branching function $g_k : \mathbb{R}_+ \to \mathbb{R}_+$ by

$$g_k(t) := \begin{cases} 0 & \text{if} \quad t < t_k, \\ 1 & \text{if} \quad t_k \le t < t_{k+1}, \\ b_{k+1}b_{k+2}\dots b_n & \text{if} \quad t_n \le t < t_{n+1},\ k < n, \end{cases}$$

and

$$g_0(t) := b_0\, b_1 \dots b_n, \quad t_n \le t < t_{n+1}.$$

It follows directly from the definition that

$$g_0(t) = \#\{x \in \Gamma : |x| = t\}.$$

Obviously $g_0(\cdot)$ is a nondecreasing function, and the rate of growth of g_0 determines the rate of growth of the tree Γ. In particular, if one denotes by $\Gamma(t) := \{x \in \Gamma : |x| \le t\}$ the "ball" of radius t, then g_0 tells us how fast the surface of $\Gamma(t)$ grows with t. This motivates the following.

Definition 2. *If there exist positive constants* a^-, a^+, *and* T_0, *such that for all* $t \ge T_0$ *the inequalities*

$$a^- \le \frac{g_0(t)}{t^{d-1}} \le a^+$$

hold true, then we say that d *is the* global dimension *of the tree* Γ.

We note that in the case of the so-called homogeneous metric trees treated in [12] the function $g_0(t)$ grows faster than any power of t. Formally, this corresponds to $d = \infty$ in the above definition. From now on we will work under the assumption that $d < \infty$.

3. Schrödinger operators on Γ. We will consider potential functions V which satisfy the following assumption.

Assumption A. $V : \mathbb{R}_+ \to \mathbb{R}$ *is measurable and bounded and* $\lim_{t\to\infty} V(t) = 0$.

For a given function V which satisfies Assumption A we define the Schrödinger operator A_λ as the self-adjoint operator in $L^2(\Gamma)$ associated with the closed quadratic form

$$Q_\lambda[u] := \int_\Gamma \left(|u'|^2 + \lambda V(|x|)\, |u|^2\right) dx,$$

with the form domain $D(Q) = H^1(\Gamma)$ consisting of all continuous functions u such that $u \in H^1(e)$ on each edge $e \in \mathcal{E}(\Gamma)$ and

$$\int_\Gamma \left(|u'|^2 + |u|^2\right)\, dx < \infty.$$

The domain of A_λ consists of all continuous functions u such that $u'(o) = 0$, $u \in H^2(e)$ for each $e \in \mathcal{E}(\Gamma)$ and such that at each vertex $z \in \mathcal{V}(\Gamma) \setminus \{o\}$ the matching conditions

$$u_-(z) = u_1(z) = \cdots = u_{b(z)}(z), \quad u_1'(z) + \cdots + u_{b(z)}'(z) = u_-'(z) \tag{4}$$

are satisfied, where u_- denotes the restriction of u on the edge terminating in z and u_j, $j = 1, \ldots, b(z)$, denote, respectively, the restrictions of u on the edges emanating from z; see [8] for details. Notice that A_λ satisfies the Neumann boundary condition at the root o.

The following result by Naimark and Solomyak (see [8, 9]), also established by Carlson in [4], makes it possible to reduce the spectral analysis of A_λ to the analysis of one-dimensional Schrödinger operators in weighted $L^2(\mathbb{R}_+)$ spaces.

THEOREM 1. *Let V be measurable and bounded, and suppose that Γ is regular. Then A_λ is unitarily equivalent to the following orthogonal sum of operators:*

$$A_\lambda \sim A_{\lambda,0} \oplus \sum_{k=1}^{\infty} \oplus\, A_{\lambda,k}^{[b_1 \ldots b_{k-1}(b_k - 1)]}. \tag{5}$$

Here the symbol $A_{\lambda,k}^{[b_1 \ldots b_{k-1}(b_k - 1)]}$ means that the operator $A_{\lambda,k}$ enters the orthogonal sum $[b_1 \ldots b_{k-1}(b_k - 1)]$ times. For each $k \in \mathbb{N}$ the corresponding self-adjoint operator $A_{\lambda,k}$ acts in $L^2((t_k, \infty),\, g_k)$ and is associated with the closed quadratic form

$$Q_k[f] = \int_{t_k}^\infty \left(|f'|^2 + \lambda V(t)\, |f|^2\right)\, g_k(t)\, dt,$$

whose form domain is given by the the weighted Sobolev space $D(Q_k) = H_0^1((t_k, \infty),\, g_k)$, which consists of all functions f such that

$$\int_{t_k}^\infty \left(|f'|^2 + |f|^2\right)\, g_k(t)\, dt < \infty, \quad f(t_k) = 0.$$

The operator $A_{\lambda,0}$ acts in the weighted space $L^2(\mathbb{R}_+, g_0)$ and is associated with the closed form

$$Q_0[f] = \int_0^\infty \left(|f'|^2 + \lambda V(t)\, |f|^2\right)\, g_0(t)\, dt,$$

with the form domain $D(Q_0) = H^1(\mathbb{R}_+,\, g_0)$, which consists of all functions f such that

$$\int_0^\infty \left(|f'|^2 + |f|^2\right)\, g_0(t)\, dt < \infty;$$

see also [13].

3.1. Auxiliary operators. Let d be the global dimension of Γ. Definition 2 implies that there exist positive constants b^- and b^+ such that

$$b^-\,(1+t)^\alpha =: g_k^-(t) \le g_k(t) \le g_k^+(t) := b^+(1+t)^\alpha\,, \quad t\in[t_k,\infty). \tag{6}$$

Now assume that the Rayleigh quotient

$$\frac{\int_{t_k}^\infty \left(|f'|^2+\lambda V(t)\,|f|^2\right)\, g_k(t)\,dt}{\int_{t_k}^\infty |f|^2\, g_k(t)\,dt}$$

of the operator $A_{\lambda,k}$, $k\ge 0$ is negative for some $f\in D(Q_k)$. From (6) follows that

$$\begin{aligned}\frac{\int_{t_k}^\infty \left(|f'|^2+\lambda V_k^-(t)\,|f|^2\right)\,(1+t)^\alpha\,dt}{\int_{t_k}^\infty |f|^2\,(1+t)^\alpha\,dt} &\le \frac{\int_{t_k}^\infty \left(|f'|^2+\lambda V(t)\,|f|^2\right)\, g_k(t)\,dt}{\int_{t_k}^\infty |f|^2\, g_k(t)\,dt}\\ &\le \frac{\int_{t_k}^\infty \left(|f'|^2+\lambda V_k^+(t)\,|f|^2\right)\,(1+t)^\alpha\,dt}{\int_{t_k}^\infty |f|^2\,(1+t)^\alpha\,dt},\end{aligned} \tag{7}$$

where

$$V_k^-(t) := \frac{g_k(t)}{g_k^-(t)}\,V(t), \quad V_k^+(t) := \frac{g_k(t)}{g_k^+(t)}\,V(t).$$

It is thus natural to introduce the auxiliary operators $A^\pm_{\lambda,k}$ acting in the Hilbert space $L^2((t_k,\infty),\,(1+t)^\alpha)$ and associated with the quadratic forms

$$Q_k^\pm[f] = \int_{t_k}^\infty \left(|f'|^2 + \lambda V_k^\pm(t)\,|f|^2\right)\,(1+t)^\alpha\,dt, \quad f\in D(Q_k), k\in\mathbb{N}_0. \tag{8}$$

The variational principle (see, e.g., [3]) and (7) thus imply that

$$N_-(A^+_{\lambda,k};s) \le N_-(A_{\lambda,k};s) \le N_-(A^-_{\lambda,k};s), \quad s\le 0,\ k\in\mathbb{N}_0. \tag{9}$$

Let $E_{n,k}(\lambda)$ be the nondecreasing sequence of negative eigenvalues of the operators $A_{\lambda,k}$, and let $E^\pm_{n,k}(\lambda)$ be the analogous sequences corresponding to the operators $A^\pm_{\lambda,k}$, respectively. In all of these sequences each eigenvalue occurs according to its multiplicity. Relation (9) and the variational principle then yield

$$E^-_{n,k}(\lambda) \le E_{n,k}(\lambda) \le E^+_{n,k}(\lambda), \quad k\in\mathbb{N}_0, n\in\mathbb{N}, \tag{10}$$

and

$$\inf\sigma_{ess}(A^-_{\lambda,k}) \le \inf\sigma_{ess}(A_{\lambda,k}) \le \inf\sigma_{ess}(A^+_{\lambda,k})\,, \quad k\in\mathbb{N}_0. \tag{11}$$

Next we introduce the transformation U by

$$(U\,f)(t) = (1+t)^{\alpha/2}\,f(t) =: \varphi(t),$$

which maps $L^2((t_k,\infty),(1+t)^\alpha)$ unitarily onto $L^2((t_k,\infty))$. We thus get the following.

Lemma 1. *Let V satisfy the assumptions of Theorem 1. Then*

(i) *for each $k \in \mathbb{N}$ the operators $A^{\pm}_{\lambda,k}$ are unitarily equivalent to the self-adjoint operators $B^{\pm}_{\lambda,k}$ in $L^2((t_k,\infty))$, which act as*

$$\left(B^{\pm}_{\lambda,k}\,\varphi\right)(t) = -\varphi''(t) + \frac{(d-1)(d-3)}{4(1+t)^2}\,\varphi(t) + \lambda V^{\pm}_k(t)\,\varphi(t), \tag{12}$$

and whose domains consist of all functions $\varphi \in H^2((t_k,\infty))$ such that

$$\varphi(t_k) = 0.$$

(ii) *$A^{\pm}_{\lambda,0}$ are unitarily equivalent to the self-adjoint operators $B^{\pm}_{\lambda,0}$ in $L^2(\mathbb{R}_+)$, acting as*

$$\left(B^{\pm}_{\lambda,0}\,\varphi\right)(t) = -\varphi''(t) + \frac{(d-1)(d-3)}{4(1+t)^2}\,\varphi(t) + \lambda\, V^{\pm}_0(t)\,\varphi(t), \tag{13}$$

with the domain that consists of all $\varphi \in H^2(\mathbb{R}_+)$ such that

$$\varphi'(0) = \frac{d-1}{2}\,\varphi(0). \tag{14}$$

Proof. For each $k \in \mathbb{N}_0$ we have

$$B^{\pm}_{\lambda,k} = U\,A^{\pm}_{\lambda,k}\,U^{-1}, \quad \|f\|_{L^2((t_k,\infty),\,(1+t)^\alpha)} = \|Uf\|_{L^2((t_k,\infty))}.$$

The statement of the lemma then follows by a direct calculation keeping in mind that the functions f from the domain of the operators $A^{\pm}_{\lambda,0}$ satisfy $f'(0) = 0$. ∎

Remark 1. If V satisfies Assumption A, then the inequalities (11) and standard arguments from the spectral theory of Schrödinger operators (see, e.g., [10, Chap. 13.4]) imply that

$$\inf\,\sigma_{ess}(A^-_{\lambda,k}) = \inf\,\sigma_{ess}(A_{\lambda,k}) = \inf\,\sigma_{ess}(A^+_{\lambda,k}) = 0 \quad \forall\, k \in \mathbb{N}_0.$$

Moreover, constructing suitable Weyl sequences for the operators $A_{\lambda,k}$ in the similar way as it was done in [13] for the Laplace operator, one can easily show that

$$\sigma_{ess}(A_{\lambda,k}) = [0,\infty) \quad \forall\, k \in \mathbb{N}_0. \tag{15}$$

4. Number of bound states. From Theorem 1 and (15) we can see that if V satisfies Assumption A, then

$$\sigma_{ess}\,(A_\lambda) = [0,\infty). \tag{16}$$

In order to analyze the discrete spectrum of A_λ we first study the number of bound states of the individual operators in the decomposition (5).

We start by proving an auxiliary proposition. Given a real-valued measurable bounded function $\tilde V$ we consider the self-adjoint operator $\tilde B_\lambda$ acting in $L^2(\mathbb{R}_+)$ as

$$\left(\tilde B_\lambda\,\varphi\right)(t) = -\varphi''(t) + \frac{(d-1)(d-3)}{4\,t^2}\,\varphi(t) + \lambda \tilde V(t)\,\varphi(t) \tag{17}$$

with the Dirichlet boundary condition at zero. This operator is associated with the closure of the quadratic form

$$\int_{\mathbb{R}_+} \left(|\varphi'(t)|^2 + \frac{(d-1)(d-3)}{4\,t^2}\;|\varphi(t)|^2 + \lambda \tilde V(t)\,|\varphi(t)|^2\right) dt$$

defined on $C_0^\infty(\mathbb{R}_+)$.

PROPOSITION 1. *Let $d \in [1,2)$. Assume that $\tilde V$ satisfies Assumption A and that $\int_0^\infty t\,|\tilde V(t)|\,dt < \infty$. Then*

$$N_-(\tilde B_\lambda) \le \lambda\,\tilde K(d) \int_0^\infty t\,|\tilde V(t)|\,dt, \tag{18}$$

where

$$\tilde K(d) = \frac{\pi}{2\sin(\nu\pi)\Gamma(1-\nu)\Gamma(1+\nu)}.$$

Proof. We write

$$\tilde B_\lambda = \tilde B_0 + \lambda\,\tilde V, \quad \tilde B_0 := -\frac{d^2}{d\,t^2} + \frac{(d-1)(d-3)}{4t^2}.$$

Moreover, without loss of generality we may assume that $\tilde V$ is negative and continuous. The statement for the general case then follows by a standard approximation argument.

By the Birman–Schwinger principle (see, e.g., [3]), the number of eigenvalues of $\tilde B_\lambda$ to the left of the point $-\kappa^2$ then does not exceed the trace of the operator

$$\lambda|\tilde V|^{1/2}\,(\tilde B_0+\kappa^2)^{-1}\,|\tilde V|^{1/2}.$$

The integral kernel $\tilde G(t,t',\kappa)$ of the operator $(\tilde B_0+\kappa^2)^{-1}$ can be calculated by using the Sturm–Liouville theory. We get

$$\tilde G(t,t',\kappa) = \begin{cases} \frac{\pi\,i}{4}\,v_1(t,\kappa)\,v_2(t',\kappa), & t \ge t', \\ \frac{\pi\,i}{4}\,v_1(t',\kappa)\,v_2(t,\kappa), & t < t', \end{cases} \tag{19}$$

with

$$\begin{aligned} v_1(t,\kappa) &= \sqrt{t}\;H_\nu^{(1)}(i\kappa t), \\ v_2(t,\kappa) &= \sqrt{t}\,H_\nu^{(1)}(i\kappa t) + \sqrt{t}\,H_\nu^{(2)}(i\kappa t), \end{aligned}$$

where $H_\nu^{(1)}$ (respectively, $H_\nu^{(2)}$) denote Hankel's functions of the first (respectively, second) kind; see, e.g., [14]. Since $\int_0^\infty t\,|\tilde V(t)|\,dt < \infty$, we can pass to the limit $\kappa \to 0$ in the corresponding integral, using the Lebesgue dominated convergence theorem, and calculate the trace to get

$$N_-(\tilde B_\lambda) \le \lambda \int_0^\infty |\tilde V(t)|\,|\tilde G(t,t,0)|\,dt = \lambda\,\tilde K(d) \int_0^\infty t\,|\tilde V(t)|\,dt. \tag{20}$$

Here we have used the fact that $\tilde G(t,t,\kappa) \to t\,\tilde K(d)$ pointwise as $\kappa \to 0$, which follows from the asymptotic behavior of the Hankel functions at zero; see, e.g., [1]. ∎

Remark 2. For $d = 1$ we have $\tilde K(1) = 1$, and (18) gives the well-known Bargmann inequality [2]. On the other hand, $\tilde K(d)$ diverges as $d \to 2$. This is expected because the operator $-\frac{d^2}{d\,t^2} - \frac{1}{4t^2} + \lambda V$ with Dirichlet boundary conditions. at zero does have at least one negative eigenvalue for any $\lambda > 0$ if the integral of V is negative.

Armed with Proposition 1 we can prove the following.

COROLLARY 1. *Let $1 \le d < 2$. Assume that V satisfies Assumption A and that $\int_0^\infty t\,|V(t)|\,dt < \infty$. Then*

$$N_-(A_{\lambda,0}) \le 1 + \lambda\,K(d) \int_0^\infty |V(t)|\,g_0(t)\,t^{2-d}dt. \tag{21}$$

Proof. We introduce the operator $A^D_{\lambda,0}$, which is associated with the quadratic form

$$Q^D_0[f] := \int_0^\infty \left(|f'|^2 + \lambda V(t)\,|f|^2\right)\, g_0(t)\, dt, \quad D(Q^D_0) = H^1_0(\mathbb{R}_+,\, g_0),$$

where $H^1_0(\mathbb{R}_+,\, g_0) := \{f \in H^1(\mathbb{R}_+,\, g_0),\ f(0) = 0\}$. First we observe that

$$a\, t^{d-1} \leq g_0(t), \quad t \in \mathbb{R}_+,$$

for a suitable $a > 0$. We can thus mimic the analysis of section 3.1 and define the operator $\tilde{A}_\lambda$ acting in $L^2(\mathbb{R}_+,\, t^{d-1})$ associated with the quadratic form

$$\tilde{Q}[f] = \int_0^\infty \left(|f'|^2 + \lambda \tilde{V}(t)\,|f|^2\right) t^{d-1}\, dt, \quad f \in D(Q), \tag{22}$$

where $D(Q) = H^1_0((\mathbb{R}_+),\, t^{d-1})$ and $\tilde{V}(t) := \frac{g_0(t)}{a\, t^{d-1}}\, V(t)$. Repeating the arguments of section 3.1 we claim that

$$N_-(A^D_{\lambda,0}) \leq N_-(\tilde{A}_\lambda)$$

and that $\tilde{A}_\lambda$ is unitarily equivalent to $\tilde{B}_\lambda$ by means of the transformation $\tilde{U}\, f(t) = t^{(d-1)/2}\, f(t)$, which maps $L^2(\mathbb{R}_+,\, t^{d-1})$ unitarily onto $L^2(\mathbb{R}_+)$. Since the codimension of $H^1_0(\mathbb{R}_+,\, g_0)$ in $H^1(\mathbb{R}_+,\, g_0)$ is equal to one, the variational principle gives

$$N_-(A_{\lambda,0}) \leq 1 + N_-(A^D_{\lambda,0}) \leq 1 + N_-(\tilde{A}_\lambda) = 1 + N_-(\tilde{B}_\lambda).$$

Application of Proposition 1 with $\tilde{K}(d) = a\, K(d)$ concludes the proof. □

Corollary 2. *Let $1 \leq d < 2$. Let V satisfy Assumption A, and assume that $\int_0^\infty t\,|V(t)|\, dt < \infty$. Then there exists $\lambda_c > 0$, so that for $\lambda \in [0, \lambda_c]$ the discrete spectra of the operators $A_{\lambda,k}$, $k \geq 1$, are empty. In particular we have*

$$\sigma_d\ (A_\lambda) = \sigma_d\ (A_{\lambda,0})\,, \quad 0 \leq \lambda \leq \lambda_c, \tag{23}$$

where the multiplicities of the eigenvalues are taken into account.

Proof. In view of Lemma 1 it suffices to show that the discrete spectra of the operators $B^-_{\lambda,k}$ for $k \geq 1$ are empty, provided λ is small enough. Since $(d-1)(d-3) \leq 0$, the following inequality holds true in the sense of quadratic forms:

$$B^-_{\lambda,k} \geq \mathcal{B}_{\lambda,k} := -\frac{d^2}{dt^2} + \frac{(d-1)(d-3)}{4(t-t_k)^2} + \lambda V^-_k(t), \tag{24}$$

where $\mathcal{B}_{\lambda,k}$ acts in $L^2((t_k, \infty))$ with Dirichlet boundary conditions at t_k. A simple translation $s = t - t_k$ then shows that $\mathcal{B}_{\lambda,k}$ is unitarily equivalent to the operator

$$-\frac{d^2}{ds^2} + \frac{(d-1)(d-3)}{4s^2} + \lambda V^-_k(s + t_k) \quad \text{in} \quad L^2(\mathbb{R}_+),$$

which is defined in the similar way as the operator $\tilde{B}_\lambda$ in (17). Since $\int_0^\infty s\,|V^-_k(s + t_k)|\, ds$ is uniformly bounded with respect to k, it follows from Proposition 1 that for λ small enough we have $N_-(\mathcal{B}_{\lambda,k}) = 0$ for all $k \geq 1$. In view of (24) this concludes the proof. □

5. Weak coupling.

5.1. The case $1 \le d < 2$. In this section we will show that if $d \in [1,2)$ and V is attractive in a certain sense, then the operator A_λ possesses at least one negative eigenvalue for any $\lambda > 0$. Since for small values of λ the discrete spectra of A_λ and $A_{\lambda,0}$ coincide (see Corollary 2), we will focus on the operator $A_{\lambda,0}$ only. More exactly, in view of (10), we will study the operators $B^\pm_{\lambda,0}$. Clearly we have

$$B^\pm_{\lambda,0} = B_0 + \lambda\, V_0^\pm, \quad B_0 := -\frac{d^2}{d\,t^2} + \frac{(d-1)(d-3)}{4(1+t)^2},$$

with the boundary condition $v'(0) = \frac{d-1}{2}\, v(0)$. Note that, by Lemma 1, the operator B_0 is nonnegative. We shall first calculate the Green function of B_0 at a point $-\kappa^2$, $\kappa > 0$, using the Sturm–Liouville theory again. In the same manner as in the previous section we obtain

$$G(t,t',\kappa) := \begin{cases} \frac{\pi}{4i\beta(\kappa)}\, v_1(t,\kappa)\, v_2(t',\kappa), & t \ge t', \\ \frac{\pi}{4i\beta(\kappa)}\, v_1(t',\kappa)\, v_2(t,\kappa), & t < t', \end{cases} \tag{25}$$

where

$$\begin{aligned} v_1(t,\kappa) &= \sqrt{1+t}\ H^{(1)}_\nu(i\kappa(1+t)), \\ v_2(t,\kappa) &= \sqrt{1+t}\ \Big(H^{(1)}_\nu(i\kappa(1+t)) - \beta(\kappa)\, H^{(2)}_\nu(i\kappa(1+t))\Big), \\ \beta(\kappa) &= \frac{H^{(1)}_{\nu-1}(i\kappa)}{H^{(2)}_{\nu-1}(i\kappa)}. \end{aligned}$$

Consider a function W which satisfies Assumption A. According to the Birman–Schwinger principle the operator $B_0 + \lambda W$ has an eigenvalue $-\kappa^2$ if and only if the operator

$$K(\kappa) := |W|^{1/2}\, (B_0 + \kappa^2)^{-1}\, W^{1/2}$$

has eigenvalue $-\lambda^{-1}$. The integral kernel of $K(\kappa)$ is equal to

$$K(t,t',\kappa) = |W(t)|^{1/2}\, G(t,t',\kappa)\, (W(t'))^{1/2}.$$

We will use the decomposition

$$K(t,t',\kappa) = L(t,t',\kappa) + M(t,t',\kappa),$$

with

$$L(t,t',\kappa) := \frac{\pi\, 2^{2\nu-1}\, \kappa^{-2\nu}}{(\Gamma(1-\nu))^2\, \sin(\nu\pi)}\ |W(t)|^{1/2}\, [(1+t)(1+t')]^{-\nu+\frac{1}{2}}\, W(t')^{1/2},$$

and denote by $L(\kappa)$ and $M(\kappa)$ the integral operators with the kernels $L(t,t',\kappa)$ and $M(t,t',\kappa)$ respectively. Furthermore, we denote by $M(0)$ the integral operator with the kernel

$$M(t,t',0) := C_M(\nu)\, \big(|W(t)| W(t')\, (1+t)(1+t')\big)^{\frac{1}{2}}\, \left(\frac{1+t}{1+t'}\right)^{\nu\, \mathrm{sign}\,(t-t')},$$

where

$$C_M(\nu) := -\frac{\pi}{2\sin(\nu\pi)\Gamma(1-\nu)\Gamma(1+\nu)}.$$

Lemma 2 in the appendix says that $M(\kappa)$ converges in the Hilbert–Schmidt norm to the operator $M(0)$ as $\kappa \to 0$, provided W decays fast enough at infinity. This allows us to prove the following.

THEOREM 2. *Let W satisfy Assumption A and let $\int_0^\infty (1+t)^{3-d}\,|W(t)|\,dt < \infty$, where $1 \le d \le 2$. Then the following statements hold true:*

(a) *If*

$$\int_0^\infty W(t)\,(1+t)^{d-1}\,dt < 0,$$

then the operator $B_0 + \lambda W$ has at least one negative eigenvalue for all $\lambda > 0$. For λ small enough this eigenvalue, denoted by $E(\lambda)$, is unique and satisfies

$$(E(\lambda))^{\frac{2-d}{2}} = C(\nu)\left(\lambda \int_0^\infty W(t)\,(1+t)^{d-1}\,dt + \mathcal{O}(\lambda^2)\right), \tag{26}$$

where

$$C(\nu) = \frac{\pi\, 2^{2\nu-1}}{(\Gamma(1-\nu))^2\,\sin(\nu\pi)}.$$

(b) *If*

$$\int_0^\infty W(t)\,(1+t)^{d-1}\,dt > 0,$$

then the operator $B_0 + \lambda W$ has no negative eigenvalues for λ positive and small enough.

Proof. Part (a). The operator $B_0 + \lambda W$ has eigenvalue $E = -\kappa^2$ if and only if the operator

$$\lambda K(\kappa) = \lambda M(\kappa) + \lambda L(\kappa)$$

has an eigenvalue -1 for certain $\kappa(\lambda)$. On the other hand, Lemma 1 and (9) imply that

$$N_-\left(B_0 + \lambda\,\frac{g_0}{g_0^+}\,V\right) \le N_-(A_{\lambda,0}).$$

The uniqueness of E, and so of $\kappa(\lambda)$, for λ small enough thus follows from (21) by taking $V = \frac{g_0^+}{g_0}\,W$. Next we note that by Lemma 2 for λ small we have $\lambda\,\|M(\kappa)\| < 1$ and

$$(I + \lambda K(\kappa))^{-1} = \left[I + \lambda(I + \lambda M(\kappa))^{-1}\,L(\kappa)\right]^{-1}\,(I + \lambda\,M(\kappa))^{-1}.$$

Hence $\lambda K(\kappa)$ has an eigenvalue -1 if and only if $\lambda(I + \lambda M(\kappa))^{-1}\,L(\kappa)$ has an eigenvalue -1. Since $\lambda(I + \lambda M(\kappa))^{-1}\,L(\kappa)$ is of rank one we get the equation for $\kappa(\lambda)$ in the form

$$\operatorname{tr}\left(\lambda(I + \lambda M(\kappa(\lambda))^{-1}\,L(\kappa(\lambda)))\right) = -1. \tag{27}$$

Using the decomposition

$$(I+\lambda M(\kappa))^{-1} = I - \lambda M(0) - \lambda(M(\kappa)-M(0)) + \lambda^2 M^2(\kappa)(I+\lambda M(\kappa))^{-1},$$

we obtain

$$\begin{aligned}
&\operatorname{tr}\left(\lambda(I+\lambda M(\kappa))^{-1}\, L(\kappa)\right)\\
&= \lambda\, C(\nu)\kappa^{-2\nu}\, \left(|W(t)|^{1/2}\,(1+t)^{-\nu+\frac12}, (I+\lambda M(\kappa))^{-1} W(t)^{1/2}\,(1+t)^{-\nu+\frac12}\right)\\
&= C(\nu)\,\kappa^{-2\nu}\left(\lambda\int_0^\infty W(t)\,(1+t)^{d-1}\,dt + \mathcal{O}(\lambda^2)\right).
\end{aligned}$$

It thus follows from (27) that

$$E^\nu(\lambda) = -\kappa^{2\nu}(\lambda) = C(\nu)\left(\lambda\int_0^\infty W(t)\,(1+t)^{d-1}\,dt + \mathcal{O}(\lambda^2)\right). \tag{28}$$

To finish the proof of part (a) of the theorem, we mimic the argument used in [11] and notice that if $(\varphi,(B_0+\lambda W)\,\varphi)<0$, then $(\varphi, W\varphi)<0$, since B_0 is nonnegative, and therefore $(\varphi,(B_0+\tilde\lambda W)\,\varphi)<0$ if $\lambda<\tilde\lambda$. So if $B_0+\lambda W$ has a negative eigenvalue for λ small enough, then, by the variational principle, it has at least one negative eigenvalue for all λ positive.

Part (b). From the proof of part (a) it can be easily seen that if

$$\int_0^\infty W(t)\,(1+t)^{d-1}\,dt > 0,$$

then $\operatorname{tr}\left(\lambda(I+\lambda M(\kappa))^{-1}\, L(\kappa)\right)$ is positive for λ small, and therefore $K(\kappa)$ cannot have an eigenvalue -1. □

Remark 3. Note that if

$$W_0 := \int_{\mathbb{R}^2_+} W(t)\,W(t')(1+t)^{1-\nu}(1+t')^{1-\nu}\left(\frac{1+t}{1+t'}\right)^{\nu\,\operatorname{sign}(t-t')} dt\,dt' < 0,$$

then the operator $B_0+\lambda W$ has a negative eigenvalue for λ small, positive or negative, also in the critical case when

$$\int_0^\infty W(t)\,(1+t)^{d-1}\,dt = 0.$$

Moreover, it follows from the proof of Theorem 2 that this eigenvalue then satisfies

$$E^\nu(\lambda) = C(\nu)\left(-\lambda^2\, C_M(\nu)\, W_0 + o\,(\lambda^2)\right), \quad \lambda\to 0. \tag{29}$$

As an immediate consequence of Theorem 2 and inequalities (10) we get the following.

Theorem 3. *Let V satisfy Assumption A, and let $\int_0^\infty (1+t)^{3-d}\,|V(t)|\,dt<\infty$, where $1\le d<2$. Then the following statements hold true:*

(a) *If*

$$\int_0^\infty V(t)\,g_0(t)\,dt = \int_\Gamma V(|x|)\,dx < 0,$$

then the operator A_λ has at least one negative eigenvalue $E_{1,0}(\lambda)$ for all $\lambda > 0$. For λ small enough this eigenvalue is unique and satisfies

$$C_1 \left| \lambda \int_\Gamma V(|x|)\, dx \right|^{\frac{2}{2-d}} \leq |E_{1,0}(\lambda)| \leq C_2 \left| \lambda \int_\Gamma V(|x|)\, dx \right|^{\frac{2}{2-d}} \tag{30}$$

for suitable positive constants C_1 and C_2.

(b) *If*

$$\int_0^\infty V(t)\, g_0(t)\, dt = \int_\Gamma V(|x|)\, dx > 0,$$

then the discrete spectrum of A_λ is empty for λ positive and small enough.

Proof. Part (a). From (10) we get

$$E^-_{1,0}(\lambda) \leq E_{1,0}(\lambda) \leq E^+_{1,0}(\lambda).$$

Moreover, by Lemma 1, $E^\pm_{1,0}(\lambda)$ are the lowest eigenvalues of operators $B^\pm_{\lambda,0}$. The existence and uniqueness of $E_{1,0}$ thus follows from part (a) of Theorem 2 applied with $W(t) = V_0^+(t)$ and $W(t) = V_0^-(t)$, respectively. At the same time, (26) implies (30).

Similarly, part (b) of the statement follows immediately from Lemma 1 and part (b) of Theorem 2 applied with $W(t) = V_0^-(t)$. □

Remark 4. We note that the strong coupling behavior of A_λ is, contrary to (30), typically one-dimensional, i.e., determined by the local dimension of Γ. Namely, if V is continuous and compactly supported, then the standard Dirichlet–Neumann bracketing technique shows that the Weyl asymptotic formula

$$\lim_{\lambda\to\infty} \lambda^{-\gamma-\frac{1}{2}} \sum_j |E_j|^\gamma = L^{cl}_{\gamma,1} \int_\Gamma |V|^{\gamma+\frac{1}{2}}\, dx, \quad \gamma \geq 0,$$

holds true, where E_j are the negative eigenvalues of A_λ and $L^{cl}_{\gamma,1} = \frac{\Gamma(\gamma+1)}{2\sqrt{\pi}\,\Gamma(\gamma+3/2)}$.

Remark 5. Notice that our result qualitatively agrees with the precise asymptotic formula for $\varepsilon(\lambda)$ on branching graphs with one vertex and finitely many edges which was found in [5]. Such graphs correspond to $d = 1$ in our setting.

5.2. The case $d = 2$. For $d = 2$ one can mimic the above procedure by replacing the Hankel functions $H^{(1,2)}_\nu$ by $H^{(1,2)}_0$. The latter have a logarithmic singularity at zero, and therefore it turns out that the lowest eigenvalue of A_λ then converges to zero exponentially fast. Indeed, here instead of (26) one obtains

$$E(\lambda) \sim -e^{-\lambda^{-1}}, \quad \lambda \to 0,$$

as for the two-dimensional Schrödinger operator; see [11]. Since the analysis of this case is completely analogous to the previous one, we skip it.

5.3. The case $d > 2$. Here we will show, under some assumptions on V, that for $d > 2$ and λ small enough the discrete spectrum of A_λ remains empty no matter what the sign of $\int_\Gamma V$ is.

Proposition 2. *Let $d > 2$, and let V satisfy Assumption A. If $V \in L^\infty(\mathbb{R}_+) \cap L^{p/2}(\mathbb{R}_+, g_0)$, with $p < d$, then there exists $\lambda_0 > 0$ such that the discrete spectrum of A_λ is empty for all $\lambda \in [0, \lambda_0]$.*

Proof. From the definition of the function g_k it follows that

$$\frac{\int_{t_k}^{\infty}\left(|f'|^2+\lambda V|f|^2\right)g_k(t)\,dt}{\int_{t_k}^{\infty}|f|^2 g_k(t)\,dt}=\frac{\int_{t_k}^{\infty}\left(|f'|^2+\lambda V|f|^2\right)g_0(t)\,dt}{\int_{t_k}^{\infty}|f|^2 g_0(t)\,dt}.$$

Since every function $f\in H_0^1((t_k,\infty),g_k)$ can be extended by zero to a function in $H^1(\mathbb{R}_+,g_0)$, the variational principle shows that

$$\sigma_d(A_{\lambda,0})=\emptyset \implies \sigma_d(A_{\lambda,k})=\emptyset \quad \forall\, k\geq 1.$$

Hence it suffices to prove the statement for the operator $A_{\lambda,0}$, i.e., to show that $A_{\lambda,0}$ is nonnegative. Consider a function $f\in D(Q_0)$. Since $f\in H^1(\mathbb{R}_+)$, which is continuously embedded in $L^\infty(\mathbb{R}_+)$, it follows that $f\to 0$ at infinity, and we can write

$$f(t)=-\int_t^\infty f'(s)\,ds.$$

In view of (6) we have $g_0^{-1}\in L^1(\mathbb{R}_+)$. Using the Cauchy–Schwarz inequality we thus find out that for any $q>q_0$, where $\frac{1}{q_0}+\frac{1}{d}=\frac{1}{2}$, the following estimate holds true:

$$\begin{aligned}\left(\int_0^\infty |f(t)|^q\,g_0(t)\,dt\right)^{\frac{1}{q}} &\leq \left(\int_0^\infty\left(\int_t^\infty |f'(s)|ds\right)^q g_0(t)\,dt\right)^{\frac{1}{q}}\\ &\leq\left(\int_0^\infty\left(\int_t^\infty |f'(s)|^2 g_0(s)\,ds\right)^{\frac{q}{2}}\left(\int_t^\infty\frac{ds}{g_0(s)}\right)^{\frac{q}{2}} g_0(t)\,dt\right)^{\frac{1}{q}}\\ &\leq C(q)\left(\int_0^\infty |f'(s)|^2\,g_0(s)\,ds\right)^{\frac{1}{2}}, \qquad (31)\end{aligned}$$

with a constant $C(q)$ independent of f. Take q such that $\frac{1}{q}+\frac{1}{p}=\frac{1}{2}$. The Hölder inequality and (31) then give

$$\begin{aligned}\int_0^\infty |V|\,|f|^2 g_0(t)\,dt &\leq\left(\int_0^\infty |V|^{p/2}\,g_0(t)\,dt\right)^{\frac{2}{p}}\left(\int_0^\infty |f|^q\,g_0(t)\,dt\right)^{\frac{2}{q}}\\ &\leq C^2(q)\int_0^\infty |f'|^2\,g_0(t)\,dt\left(\int_0^\infty |V|^{p/2}\,g_0(t)\,dt\right)^{\frac{2}{p}},\end{aligned}$$

which implies

$$Q_0[f]\geq\int_0^\infty |f'|^2\,g_0(t)\,dt\left[1-\lambda\,C^2(q)\left(\int_0^\infty |V|^{p/2}\,g_0(t)\,dt\right)^{\frac{2}{p}}\right].$$

To show that the negative spectrum of $A_{\lambda,0}$ is empty, it suffices to take λ small enough so that $Q_0[f]\geq 0$. $\square$

Appendix.

LEMMA 2. *Let W be bounded, and assume that $\int_0^\infty(1+t)^{1+2\nu}\,|W(t)|\,dt<\infty$. Then $M(\kappa)$ converges in the Hilbert–Schmidt norm to the operator $M(0)$ as $\kappa\to 0$.*

Proof. We first notice that $M(0)$ is Hilbert–Schmidt, since

$$\int_0^\infty\int_0^\infty |M(t,t',0)|^2\,dt\,dt'<\infty$$

by assumption. We will also need the asymptotic behavior of the Bessel functions with a purely imaginary argument near zero:

$$J_\nu(i\kappa(1+t)) = e^{i\pi\nu/2}\, I_\nu(\kappa(1+t)) \sim e^{i\pi\nu/2}\, \frac{\kappa^\nu(1+t)^\nu}{2^\nu\,\Gamma(\nu+1)}, \quad \kappa(1+t)\to 0; \tag{32}$$

see [1, 14]. From the definition of Hankel's functions we thus get

$$\beta(\kappa) = \frac{J_{1-\nu}(i\kappa) - e^{i(1-\nu)\pi}\, J_{\nu-1}(i\kappa)}{e^{i(\nu-1)\pi}\, J_{\nu-1}(i\kappa) - J_{1-\nu}(i\kappa)} \to -e^{-2i\nu\pi}, \quad \kappa\to 0.$$

This together with the asymptotics (32) implies

$$\lim_{\kappa\to 0} M(t,t',\kappa) = M(t,t',0)\,. \tag{33}$$

Now using the asymptotic behavior of Hankel's functions at infinity [1], we find out that

$$G(t,t',\kappa) \sim ((1+t)(1+t'))^{1/2}\ \frac{e^{-\kappa(t+t')} - \beta(\kappa)\, e^{-\kappa|t-t'|}}{\kappa\,(1+t)(1+t')^{1/2}}, \quad \kappa^2(1+t)(1+t')\to\infty.$$

Since $|\beta(\kappa)|$ is bounded, we obtain the following estimates:

(i). For $\kappa^2(1+t)(1+t')\geq 1$:

$$|K(t,t',\kappa)|, |L(t,t',\kappa)| \leq C\ |W(t')\,W(t)(1+t)(1+t')|^{1/2}\,.$$

(ii). For $\kappa^2(1+t)(1+t')<1$:

$$|M(t,t',\kappa)| \leq C'\,|W(t')\,W(t)\,|\left[1+((1+t)(1+t'))^{\nu+\frac{1}{2}}\right],$$

where we have used (33). Note that the constants C and C' may be chosen independent of κ, which enables us to employ the Lebesgue dominated convergence theorem to conclude that

$$\lim_{\kappa\to 0}\int_{\mathbb{R}_+^2} |M(t,t',\kappa) - M(t,t',0)|^2\, dt\, dt' = 0. \qquad \square$$

TOTAL VARIATION REGULARIZATION FOR IMAGE DENOISING, I. GEOMETRIC THEORY*

WILLIAM K. ALLARD†

Abstract. Let Ω be an open subset of $\mathbf{R}^n$, where $2 \leq n \leq 7$; we assume $n \geq 2$ because the case $n = 1$ has been treated elsewhere (see [S. S. Alliney, *IEEE Trans. Signal Process.*, 40 (1992), pp. 1548–1562] and is quite different from the case $n > 1$; we assume $n \leq 7$ because we will make use of the regularity theory for area minimizing hypersurfaces. Let $\mathcal{F}(\Omega) = \{f \in \mathbf{L}_1(\Omega) \cap \mathbf{L}_\infty(\Omega) : f \geq 0\}$. Suppose $s \in \mathcal{F}(\Omega)$ and $\gamma : \mathbb{R} \to [0, \infty)$ is locally Lipschitzian, positive on $\mathbb{R} \sim \{0\}$, and zero at zero. Let $F(f) = \int_\Omega \gamma(f(x) - s(x))\, d\mathcal{L}^n x$ for $f \in \mathcal{F}(\Omega)$; here $\mathcal{L}^n$ is Lebesgue measure on $\mathbb{R}^n$. Note that $F(f) = 0$ if and only if $f(x) = s(x)$ for $\mathcal{L}^n$ almost all $x \in \mathbb{R}^n$. In the denoising literature F would be called a *fidelity* in that it measures deviation from s, which could be a noisy grayscale image. Let $\epsilon > 0$ and let $F_\epsilon(f) = \epsilon \mathbf{TV}(f) + F(f)$ for $f \in \mathcal{F}(\Omega)$; here $\mathbf{TV}(f)$ is the total variation of f. A minimizer of F_ϵ is called a *total variation regularization of* s. Rudin, Osher, and Fatemi and Chan and Esedoḡlu have studied total variation regularizations where $\gamma(y) = y^2$ and $\gamma(y) = |y|$, $y \in \mathbb{R}$, respectively. As these and other examples show, the geometry of a total variation regularization is quite sensitive to changes in γ. Let f be a total variation regularization of s. The first main result of this paper is that the reduced boundaries of the sets $\{f > y\}$, $0 < y < \infty$, are embedded $C^{1,\mu}$ hypersurfaces for any $\mu \in (0, 1)$ where $n > 2$ and any $\mu \in (0, 1]$ where $n = 2$; moreover, the generalized mean curvature of the sets $\{f \geq y\}$ will be bounded in terms of y, ϵ and the magnitude of $|s|$ near the point in question. In fact, this result holds for a more general class of fidelities than those described above. A second result gives precise curvature information about the reduced boundary of $\{f > y\}$ in regions where s is smooth, provided F is convex. This curvature information will allow us to construct a number of interesting examples of total variation regularizations in this and in a subsequent paper. In addition, a number of other theorems about regularizations are proved.

Key words. total variation, regularization, image denoising

1. Introduction and statement of main results.

Throughout this paper, n is an integer, $2 \leq n \leq 7$, Ω is an open subset of $\mathbb{R}^n$, and $\mathcal{L}^n$ is Lebesgue measure on $\mathbb{R}^n$.

We require $n \geq 2$ because the problems we consider are very different in case $n = 1$; see [Alli]. We require $n \leq 7$ because we will be using the regularity theory of mass minimizing integral currents in $\mathbb{R}^n$ of codimension one; as is well known, these currents are free of interior singularities when $n \leq 7$ but may possess singularities if $n > 7$; see [FE, sect. 5.4.15]. This work is motivated by image denoising applications in which it is often the case that $1 \leq n \leq 4$.

After a fairly lengthy discussion of results which occur in a setting more general than that of denoising, we treat denoising in section 1.8. See also sections 1.9, 8, and 10 as well as the examples in section 11 for more on denoising.

1.1. Some basic notation and conventions.

Whenever $E \subset \Omega$ we frequently identify "E" with "1_E," the indicator function of E.

The first appearance of any term which is about to be defined will always appear in italics or be displayed.

†Department of Mathematics, Duke University, Durham, NC 27708-0320 (wka@math.duke.edu).

We let

$$\mathcal{F}(\Omega) = \{f \in \mathbf{L}_1(\Omega) \cap \mathbf{L}_\infty(\Omega) : f \geq 0\}$$

and

$$\mathcal{M}(\Omega) = \{D : D \subset \Omega \text{ and } 1_D \in \mathcal{F}(\Omega)\}\,;$$

thus a subset D of Ω belongs to $\mathcal{M}(\Omega)$ if and only if D is Lebesgue measurable and $\mathcal{L}^n(D) < \infty$. We endow $\mathbf{L}_1^{loc}(\Omega)$ with the topology induced by the seminorms $\mathbf{L}_1^{loc}(\Omega) \ni f \mapsto \int_K |f|\, d\mathcal{L}^n$ corresponding to compact subsets K of Ω. Whenever $f \in \mathbf{L}_1^{loc}(\Omega)$ and K is a compact subset of Ω we let

$$\mathbf{k}(f, K) = \{g \in \mathbf{L}_1^{loc}(\Omega) : g(x) = f(x) \text{ for } \mathcal{L}^n \text{ almost all } x \in \Omega \sim K\};$$

in other words, $g \in \mathbf{k}(f, K)$ if the support of the generalized function corresponding to $g - f$ is a subset of K. We let

$$\mathbf{k}(f) = \cup\{\mathbf{k}(f, K) : K \text{ is a compact subset of } \Omega\}.$$

Whenever D is a Lebesgue measurable subset of Ω and K is a compact subset of Ω we let

$$\mathbf{k}(D, K) = \{E : E \subset \Omega \text{ and } 1_E \in \mathbf{k}(1_D, K)\}$$

and

$$\mathbf{k}(D) = \cup\{\mathbf{k}(D, K) : K \text{ is a compact subset of } \Omega\}.$$

Whenever A, D, E are Lebesgue measurable subsets of Ω we let

$$\Sigma_A(D, E) = \mathcal{L}^n(A \cap ((D \sim E) \cup (E \sim D))) = \int_A |1_D - 1_E|\; d\mathcal{L}^n;$$

note that $\mathcal{M}(\Omega) \times \mathcal{M}(\Omega) \ni (D, E) \mapsto \Sigma_A(D, E)$ is a pseudometric on $\mathcal{M}(\Omega)$.

Whenever $a \in \mathbb{R}^n$ and $0 < r < \infty$ we let

$$\mathbf{U}^n(a, r) = \{x \in \mathbb{R}^n : |x - a| < r\} \quad \text{and} \quad \mathbf{B}^n(a, r) = \{x \in \mathbb{R}^n : |x - a| \leq r\}.$$

We let

$$\mathbf{int}, \quad \mathbf{cl}, \quad \text{and} \quad \mathbf{bdry}$$

stand for "interior," "closure," and "boundary," respectively, with respect to Ω.

Whenever $A \subset \mathbb{R}^n$ and a is an accumulation point of A we let

$$\mathbf{Tan}(A, a) = \bigcap_{0<r<\infty} \mathbf{cl}\,\{t(x - a) : 0 < t < \infty \text{ and } x \in A \cap (\mathbf{B}^n(a, r) \sim \{a\})\}$$

and

$$\mathbf{Nor}(A, a) = \bigcap_{w \in \mathbf{Tan}(A,a)} \{v \in \mathbb{R}^n : v \bullet w \leq 0\}.$$

Whenever $0 \le m < \infty$ we let

$$\mathcal{H}^m$$

be an m-dimensional Hausdorff measure on $\mathbb{R}^n$.

We let

$$\mathcal{X}(\Omega)$$

be the space of smooth compactly supported vector fields on Ω.

Whenever $y, z \in \mathbb{R}$ we let

$$y \vee z = \max\{y, z\}, \qquad y \wedge z = \min\{y, z\},$$

and we note that $y + z = y \vee z + y \wedge z$.

1.2. Total variation. This work is based on the notion of the total variation of a locally summable function, which we now define.

DEFINITION 1.1. *Suppose $f \in \mathbf{L}_1^{loc}(\Omega)$. Then $\mathbf{TV}(f, \cdot)$, the* total variation *of f, is the largest Borel regular measure on Ω such that, for any open subset U of Ω,*

$$\mathbf{TV}(f, U) = \sup\left\{ \int_U f \,\mathbf{div}\, X \, d\mathcal{L}^n : X \in \mathcal{X}(U) \text{ and } |X| \le 1 \right\}.$$

In particular, if f is C^1 on Ω and B is a Borel subset of Ω, then

$$\mathbf{TV}(f, B) = \int_B |\nabla f| \, d\mathcal{L}^n. \tag{1.1}$$

Moreover, if E a Lebesgue measurable subset of Ω with Lipschitz boundary, then $\mathbf{TV}(E, B)$ equals the $(n-1)$-dimensional Hausdorff measure of the intersection of the boundary of E with B.

Suppose $f \in \mathbf{L}_1^{loc}(\Omega)$. We say f is of *bounded variation on* Ω if $\mathbf{TV}(f, \Omega)$ is finite. If $\mathbf{TV}(f, \cdot)$ is a Radon measure on Ω, which will be the case if and only if $\mathbf{TV}(f, K) < \infty$ whenever K is a compact subset of Ω, we say f is of *locally bounded variation on* Ω. We let

$$\mathbf{BV}(\Omega) \quad \text{and} \quad \mathbf{BV}^{loc}(\Omega)$$

be the vector spaces of those $f \in \mathbf{L}_1(\Omega)$ which are of bounded variation on Ω and those $f \in \mathbf{L}_1^{loc}(\Omega)$ which are of locally bounded variation on Ω, respectively.

If E is a Lebesgue measurable subset of Ω, the *perimeter of* E is, by definition, $\mathbf{TV}(E, \Omega)$; we say E is of *locally finite perimeter* if $E \in \mathbf{BV}^{loc}(\Omega)$. As is well known, if $f \in \mathbf{BV}^{loc}(\Omega)$, then $\{f > y\}$ is of locally finite perimeter for $\mathcal{L}^1$ almost all y. As is well known, sets of locally finite perimeter have nice rectifiability properties; see section 2.8 below.

1.3. Total variation regularization.

DEFINITION 1.2. *Suppose $F : \mathcal{F}(\Omega) \to \mathbb{R}$ and $0 < \epsilon < \infty$. We let*

$$F_\epsilon : \mathcal{F}(\Omega) \to \mathbb{R} \cup \{\infty\},$$

the total variation regularization of F (with respect to ϵ)*, be defined by setting*

$$F_\epsilon(g) = \epsilon \mathbf{TV}(g) + F(g) \quad \text{for } g \in \mathcal{F}(\Omega).$$

We let

$$\mathbf{m}_\epsilon^{loc}(F) = \{f \in \mathcal{F}(\Omega) \cap \mathbf{BV}(\Omega) : F_\epsilon(f) \leq F_\epsilon(g) \text{ whenever } g \in \mathcal{F}(\Omega) \cap \mathbf{k}(f)\}.$$

All of the statements and proofs of this paper, after straightforward modification, go through with the condition "$f \geq 0$," omitted in the definition of $\mathcal{F}(\Omega)$; however, the modified statements and proofs often break into two cases because if $f \in \mathbf{L}_1(\Omega)$ and $y \in \mathbb{R}$, one can only be sure that $\mathcal{L}^n(\{f > y\}) < \infty$ if $y > 0$ and that $\mathcal{L}^n(\{f < y\}) < \infty$ if $y < 0$.

It will be useful to extend the foregoing notions to functionals defined on sets, as follows.

DEFINITION 1.3. *Suppose $M : \mathcal{M}(\Omega) \to \mathbb{R}$ and $0 < \epsilon < \infty$. We let*

$$M_\epsilon : \mathcal{M}(\Omega) \to \mathbb{R} \cup \{\infty\},$$

the total variation regularization of M (with respect to ϵ)*, be defined by setting*

$$M_\epsilon(E) = \epsilon\mathbf{TV}(E) + M(E) \quad \text{for } E \in \mathcal{M}(\Omega).$$

We let

$$\mathbf{n}_\epsilon^{loc}(M) = \{D \in \mathcal{M}(\Omega) \cap \mathbf{BV}(\Omega) : M_\epsilon(D) \leq M_\epsilon(E) \text{ whenever } E \in \mathcal{M}(\Omega) \cap \mathbf{k}(D)\}.$$

The main purpose of this paper is to study the geometry and regularity of the sets $\{f > y\}$ and $\{f \geq y\}$, $y \in (0, \infty)$, when $f \in \mathbf{m}_\epsilon^{loc}(F)$, provided F satisfies certain conditions which we now describe. We will relate these results to certain methods for image denoising.

1.4. Admissibility. Suppose

$$F : \mathcal{F}(\Omega) \to \mathbb{R}.$$

All our results will require F to be *admissible*, a notion we now define.

DEFINITION 1.4. *We say F is* admissible *if the restriction of F to any subset of $\mathcal{F}(\Omega)$ which is bounded with respect to $||\cdot||_{\mathbf{L}_\infty(\Omega)}$ is Lipschitz with respect to $||\cdot||_{\mathbf{L}_1(\Omega)}$.*

In other words, F is admissible if whenever $0 < Y < \infty$ we have

$$\mathbf{l}(F, Y) < \infty,$$

where $\mathbf{l}(F, Y)$ is the infimum of the set of $L \in (0, \infty)$ such that

$$|F(f) - F(g)| \leq L \int_\Omega |f - g| \, d\mathcal{L}^n$$

whenever $f, g \in \mathcal{F}(\Omega)$ and $\max\{||f||_{\mathbf{L}_\infty(\Omega)}, ||g||_{\mathbf{L}_\infty(\Omega)}\} \leq Y$.

The notion of admissibility extends naturally to functionals on sets, as follows.

DEFINITION 1.5. *Suppose $M : \mathcal{M}(\Omega) \to \mathbb{R}$. We let*

$$\mathbf{l}(M)$$

be the infimum of the set of $L \in (0, \infty)$ such that

$$|M(D) - M(E)| \leq L\, \Sigma_\Omega(D, E) \quad \text{whenever } D, E \in \mathcal{M}(\Omega).$$

We say M is admissible *if $\mathbf{l}(M) < \infty$.*

1.5. $\mathcal{B}_\lambda(\Omega)$ and $\mathcal{C}_\lambda(\Omega)$. These spaces will be indispensable in this work.

DEFINITION 1.6. *Suppose* $0 \le \lambda < \infty$. *We let*

$$\mathcal{B}_\lambda(\Omega)$$

be the set of those $f \in \mathbf{BV}^{loc}(\Omega)$ *such that for each compact subset* K *of* Ω *we have*

$$\mathbf{TV}(f,K) \le \mathbf{TV}(g,K) + \lambda \int_\Omega |f-g|\, d\mathcal{L}^n \quad \textit{whenever } g \in \mathbf{k}(f,K).$$

We let

$$\mathcal{C}_\lambda(\Omega)$$

be the set of those Lebesgue measurable subsets D *of* Ω *with locally finite perimeter such that for each compact subset* K *we have*

$$\mathbf{TV}(D,K) \le \mathbf{TV}(E,K) + \lambda \Sigma_\Omega(D,E) \quad \textit{whenever } E \in \mathbf{k}(D,K).$$

The following result is based on ideas found in [BDG].

THEOREM 1.1. *Suppose* $0 \le \lambda < \infty$ *and* $f \in \mathbf{BV}^{loc}(\Omega)$. *Then*

$$f \in \mathcal{B}_\lambda(\Omega) \;\Rightarrow\; \{f > y\} \in \mathcal{C}_\lambda(\Omega) \quad \textit{for } y \in \mathbb{R}.$$

Conversely, if Y *is a dense subset of* $\mathbb{R}$, *then*

$$\{f > y\} \in \mathcal{C}_\lambda(\Omega) \textit{ for } y \in Y \;\Rightarrow\; f \in \mathcal{B}_\lambda(\Omega).$$

An immediate corollary is that $D \in \mathcal{C}_\lambda(\Omega)$ if and only if $1_D \in \mathcal{B}_\lambda(\Omega)$.

More results on $\mathcal{C}_\lambda(\Omega)$ and $\mathcal{B}_\lambda(\Omega)$ may be found in section 5.1.

1.5.1. The regularity theorem for $\mathcal{C}_\lambda(\Omega)$. The proof of the following theorem is an exercise, carried out in section 5.4, in the use of techniques from geometric measure theory which have been in the literature for over thirty years.

Note that in the following theorem, θ *does not depend on* D.

THEOREM 1.2 (regularity). *Suppose* $0 < \mu < \infty$ *and* $0 < \beta < 1$. *There exists* θ *such that* $0 < \theta < 1$ *and with the following property:*

Suppose

(i) $a \in \mathbb{R}^n$ *and* $0 < R < \infty$;

(ii) $0 \le \lambda < \infty$, $\lambda R \le \theta$, *and* $D \in \mathcal{C}_\lambda(\mathbf{U}^n(a,R))$;

(iii) Γ *is the interior of the support of the generalized function corresponding to the indicator function of* D *and* M *is the boundary of* Γ *relative to* $\mathbf{U}^n(a,R)$.

Then $\Sigma_{\mathbf{U}^n(a,R)}(D,\Gamma) = 0$ *and* M *is an embedded hypersurface in* $\mathbf{U}^n(a,R)$ *of class* $C^{1,\mu}$; *moreover, if* N *is a continuous field of unit normals to* M *and* $r = \theta R$, *then*

$$|N(x) - N(w)| \le \beta\, (|x-w|/r)^\mu \quad \textit{whenever } x, w \in M \cap \mathbf{U}^n(a,r);$$

finally, if L *is a line perpendicular to* $\mathbf{Tan}(M,a)$, *then* L *intersects* $M \cap \mathbf{U}^n(a,r)$ *in at most one point.*

In case $n = 2$ *we may take* $\mu = 1$.

1.5.2. The relationship between admissibility and $\mathcal{C}_\lambda(\Omega)$. The following simple proposition relates the notion of admissibility to the spaces $\mathcal{B}_\lambda(\Omega)$.

PROPOSITION 1.1. *Suppose $F : \mathcal{F}(\Omega) \to \mathbb{R}$, F is admissible, $0 < \epsilon < \infty$, $f \in \mathbf{m}_\epsilon^{loc}(F)$, $Y = ||f||_{\mathbf{L}_\infty(\Omega)}$, and $\lambda = \mathbf{l}(F, Y)/\epsilon$.*

Then $f \in \mathcal{B}_\lambda(\Omega)$.

Proof. Suppose $g \in \mathbf{k}(f, K)$. Let $h = (g \wedge Y) \vee 0$. Then $h \in \mathbf{k}(f, K)$, so

$$\epsilon\,(\mathbf{TV}(f, K) - \mathbf{TV}(h, K)) \le F(h) - F(f) \le \mathbf{l}(F, Y) \int_\Omega |f - h|.$$

As is well known and shown in Proposition 2.3 below, $\mathbf{TV}(h, K) \le \mathbf{TV}(g, K)$, and it is evident that $\int_\Omega |f - h|\, d\mathcal{L}^n \le \int_\Omega |f - g|\, d\mathcal{L}^n$, so the proposition is proved. ∎

We leave the even simpler proof of the following proposition to the reader.

PROPOSITION 1.2. *Suppose $M : \mathcal{M}(\Omega) \to \mathbb{R}$, M is admissible, $0 < \epsilon < \infty$, $D \in \mathbf{n}_\epsilon^{loc}(M)$, and $\lambda = \mathbf{l}(M)/\epsilon$.*

Then $D \in \mathcal{C}_\lambda(\Omega)$.

Remark 1.1. Thus if $f \in \mathbf{m}_\epsilon^{loc}(F)$, where F is admissible, the regularity theorem, Theorem 1.2, for $\mathcal{C}_\lambda(\Omega)$ applies to the sets $\{f > y\}$, $0 < y < \infty$. In particular, if $n > 2$ and $0 < \mu < 1$ or if $n = 2$ and $0 < \mu \le 1$, the boundaries of the support of $[\{f > y\}]$, $0 < y < \infty$, are always embedded $C^{1,\mu}$ hypersurfaces.

In order to obtain yet more information about $\{f > y\}$ we need to assume more about F, as follows.

1.6. Locality.

DEFINITION 1.7. *Suppose $F : \mathcal{F}(\Omega) \to \mathbb{R}$. We say F is* local *if F is admissible and*

$$\hat{F}(f + g) = \hat{F}(f) + \hat{F}(g) \quad \textit{whenever } f, g \in \mathcal{F}(\Omega) \textit{ and } fg = 0,$$

where we have set

$$\hat{F}(f) = F(f) - F(0) \quad \textit{for } f \in \mathcal{F}(\Omega).$$

The notion of locality extends naturally to functionals on sets, as follows.

DEFINITION 1.8. *Suppose $M : \mathcal{M}(\Omega) \to \mathbb{R}$. We say M is* local *if M is admissible and*

$$\hat{M}(D \cup E) = \hat{M}(D) + \hat{M}(E) \quad \textit{whenever } D, E \in \mathcal{M}(\Omega) \textit{ and } D \cap E = \emptyset,$$

where we have set

$$\hat{M}(E) = M(E) - M(\emptyset) \quad \textit{for } E \in \mathcal{M}(\Omega).$$

The proofs of the following four propositions, which we carry out in section 6, are exercises in real variable theory.

PROPOSITION 1.3. *Suppose $M : \mathcal{M}(\Omega) \to \mathbb{R}$, M is admissible, and*

$$\mu(x) = \limsup_{r \downarrow 0} \frac{\hat{M}(\mathbf{B}^n(x, r))}{\mathcal{L}^n(\mathbf{B}^n(x, r))} \quad \textit{for } x \in \Omega.$$

Then M is local if and only if

$$M(E) = M(\emptyset) + \int_E m\, d\mathcal{L}^n \quad \textit{for } E \in \mathcal{M}(\Omega) \tag{1.2}$$

for some bounded Borel function $m : \Omega \to \mathbb{R}$, in which case $m(x) = \mu(x)$ for $\mathcal{L}^n$ almost all $x \in \Omega$.

PROPOSITION 1.4. *Suppose $F : \mathcal{F}(\Omega) \to \mathbb{R}$, F is admissible, and*

$$\kappa(x,y) = \limsup_{r\downarrow 0} \frac{\hat{F}(y 1_{\mathbf{B}^n(x,r)})}{\mathcal{L}^n(\mathbf{B}^n(x,r))} \quad \textit{for } (x,y) \in \Omega \times [0,\infty).$$

Then F is local if and only if

$$F(f) = F(0) + \int_\Omega k(x, f(x))\, d\mathcal{L}^n x \quad \textit{whenever } f \in \mathcal{F}(\Omega) \tag{1.3}$$

for some Borel function $k : \Omega \times [0,\infty) \to \mathbb{R}$ such that

(i) *$k(x,0) = 0$ for $\mathcal{L}^n$ almost all $x \in \Omega$;*

(ii) *whenever $0 < Y < \infty$ there is $L \in [0,\infty)$ such that if $0 \le y < z < Y$, then*

$$|k(x,y) - k(x,z)| \le L|y-z| \quad \textit{for } \mathcal{L}^n \textit{ almost all } x \in \Omega,$$

in which case, for each $y \in [0,\infty)$, $k(x,y) = \kappa(x,y)$ for $\mathcal{L}^n$ almost $x \in \Omega$.

Remark 1.2. Suppose $\beta : \mathbb{R} \to \mathbb{R}$ is locally Lipschitzian and

$$F(f) = \beta\left(\int_\Omega f\, d\mathcal{L}^n\right) \quad \text{for } f \in \mathcal{F}(\Omega).$$

It is evident that F is admissible but not local unless β is an affine function.

Perhaps a more interesting example is as follows. Suppose $K, s \in \mathbf{L}_1(\mathbb{R}^n)$ and

$$F(f) = \int_{\mathbb{R}^n} |K * f - s|\, d\mathcal{L}^n \quad \text{for } f \in \mathcal{F}(\mathbb{R}^n).$$

Evidently, $\mathbf{l}(F,Y) = ||K||_{\mathbf{L}_1(\mathbb{R}^n)} < \infty$ whenever $0 < Y < \infty$, so F is admissible. If κ is as in Proposition 1.4, we find that $\kappa(x,y) = |K(x)y - s(x)|$ for $\mathcal{L}^n$ almost all x and all $y \in (0,\infty)$. It is easy to see that F is not local if both $\{K > 0\}$ and $\{K < 0\}$ have positive Lebesgue measure.

PROPOSITION 1.5. *Suppose $F : \mathcal{F}(\Omega) \to \mathbb{R}$, F is admissible, κ is as in Proposition 1.4,*

$$u(x,y) = \limsup_{z\to y} \frac{\kappa(x,z) - \kappa(x,y)}{z-y} \quad \textit{for } (x,y) \in \Omega \times (0,\infty),$$

and, for each $y \in (0,\infty)$,

$$U_y(E) = \limsup_{z\to y} \frac{F(z1_E) - F(y1_E)}{z-y} \quad \textit{for } E \in \mathcal{M}(\Omega).$$

Then

(i) *u is a Borel function and $|u(x,y)| \le l(F,Y)$ whenever $x \in \Omega$ and $0 < y < Y < \infty$;*

(ii) *$|U_y(E)| \le l(F,Y)\mathcal{L}^n(E)$ whenever $0 < y < Y$ and $E \in \mathcal{M}(\Omega)$;*

(iii) *for any $f \in \mathcal{F}(\Omega)$, $(0,\infty) \ni y \mapsto U_y(\{f > y\})$ is a Borel function.*

Moreover, if F is local, then

(iv) *for* $\mathcal{L}^1$ *almost all* $y \in (0,\infty)$, U_y *is local,* $\mathbf{l}(U_y) \leq \mathbf{l}(F,Y)$ *whenever* $y < Y < \infty$, *and*

$$U_y(E) = \int_E u(x,y)\, d\mathcal{L}^n x \quad \textit{whenever } E \in \mathcal{M}(\Omega);$$

(v) *for any* $f \in \mathcal{F}(\Omega)$,

$$F(f) = F(0) + \int_0^\infty U_y(\{f > y\})\, d\mathcal{L}^1 y.$$

PROPOSITION 1.6. *Suppose* $F : \mathcal{F}(\Omega) \to \mathbb{R}$, F *is local,* κ *is as in Proposition* 1.4, *and* U_y, $0 < y < \infty$, *and* u *are as in Proposition* 1.5.

The following are equivalent:

(i) F *is convex.*

(ii) $\mathbb{R} \ni y \mapsto F(y 1_E)$ *is convex for any* $E \in \mathcal{M}(\Omega)$.

(iii) *For any* $x \in \Omega$,

$$\mathbb{R} \ni y \mapsto \kappa(x,y) \textit{ is convex.}$$

(iv) $\mathbb{R} \ni y \mapsto U_y(E)$ *is nondecreasing for any* $E \in \mathcal{M}(\Omega)$.

(v) *For any* $x \in \Omega$,

$$\mathbb{R} \ni y \mapsto u(x,y) \textit{ is nondecreasing.}$$

Moreover, if F *is convex and* $0 < y < \infty$, *then* U_y *is local and*

$$\lim_{z \downarrow y} U_z(E) = U_y(E) \quad \textit{whenever } E \in \mathcal{F}(\Omega). \tag{1.4}$$

Remark 1.3. Suppose $F : \mathcal{F}(\Omega) \to \mathbb{R}$, F is admissible, κ is as in Proposition 1.4,

$$l(x,y) = \liminf_{z \to y} \frac{\kappa(x,z) - \kappa(x,y)}{z - y} \quad \text{for } (x,y) \in \Omega \times (0,\infty),$$

and, for each $y \in (0,\infty)$,

$$L_y(E) = \liminf_{z \to y} \frac{F(z 1_E) - F(y 1_E)}{z - y} \quad \text{for } E \in \mathcal{M}(\Omega).$$

Modifying the proof of Proposition 1.5 in a straightforward way one finds that this proposition holds with u and U_y, $0 < y < \infty$, replaced by l and L_y, $0 < y < \infty$, respectively. Evidently, for any $E \in \mathcal{M}(\Omega)$ we have

$$L_y(E) \leq U_y(E) \quad \text{whenever } 0 < y < \infty$$

with equality for $\mathcal{L}^1$ almost all $y \in (0,\infty)$.

Moreover, if F is local, one finds that by modifying the proof of Proposition 1.6 in a straightforward way that this proposition holds with u and U_y, $0 < y < \infty$, replaced by l and L_y, $0 < y < \infty$, respectively, except that (1.4) must be replaced by

$$\lim_{z \uparrow y} L_z(E) = L_y(E) \quad \text{whenever } E \in \mathcal{F}(\Omega). \tag{1.5}$$

We will show at the end of section 6 that for all but countably many $y \in (0,\infty)$

$$L_y(E) = U_y(E) \quad \text{whenever } E \in \mathcal{M}(\Omega). \tag{1.6}$$

See section 1.9 for a natural example where $L_y \neq U_y$ for some $y \in (0,\infty)$.

1.6.1. When F is local and convex. Things get a lot more interesting when F is local and convex. An important result, which will be proved in section 6, is the following.

THEOREM 1.3. *Suppose $F : \mathcal{F}(\Omega) \to \mathbb{R}$, F is local and convex, and $f \in \mathbf{m}_\epsilon^{loc}(F)$. Then*

$$\{f \geq y\} \in \mathbf{n}_\epsilon^{loc}(L_y) \quad \textit{and} \quad \{f > y\} \in \mathbf{n}_\epsilon^{loc}(U_y) \quad \textit{whenever } 0 < y < \infty.$$

When I wrote the initial version of this paper I thought this theorem was completely new. I was wrong. As a referee has pointed out, essentially the following result appears as Proposition 2.2 of [CA2].

Suppose $s \in \mathcal{F}(\Omega)$,

$$F(g) = \frac{1}{2}\int_\Omega |g - s|^2 \, d\mathcal{L}^2 \quad \textit{for } g \in \mathbf{L}_2(\Omega),$$

$0 < \epsilon < \infty$, and $f \in \mathbf{L}_2(\Omega)$ is such that

$$\epsilon \mathbf{TV}(f, \Omega) + F(f) \leq \epsilon \mathbf{TV}(g, \Omega) + F(g) \quad \textit{for } g \in \mathbf{L}_2(\Omega).$$

Then $f(x) \geq 0$ for $\mathcal{L}^n$ almost all $x \in \Omega$ and, whenever $0 < y < \infty$,

$$\epsilon \mathbf{TV}(\{f > y\}) + U_y(\{f > y\}) \leq \epsilon \mathbf{TV}(E) + U_y(E) \quad \textit{for } E \in \mathcal{M}(\Omega),$$

where $U_y(E) = \int_E y - s \, d\mathcal{L}^n$ for $E \in \mathcal{M}(\Omega)$.

Note that f above is a *global* minimizer of $\mathbf{L}_2(\Omega) \ni g \mapsto \epsilon \mathbf{TV}(g, \Omega) + F(g)$. In fact, the method used to prove this result in [CA2] can be extended to a very general class of local and convex F's but still for global minimizers. For example, I do not see how to apply this method to the case when Ω has Lipschitz boundary and one minimizes in the class of f's with a given trace on the boundary of Ω, a situation in which Theorem 1.3 clearly applies.

The following theorem, which will be proved in section 6, is more than a converse of the preceding theorem. This result is of particular interest when $\gamma(y) = |y|$ for $y \in \mathbb{R}$ in section 1.8; it is the essential ingredient in the proof of Theorem 1.7.

THEOREM 1.4. *Suppose $F : \mathcal{F}(\Omega) \to \mathbb{R}$, F is local and convex, G is a $\mathcal{L}^n \times \mathcal{L}^1$ measurable subset of $\Omega \times (0, \infty)$ such that*

(i) $(\mathcal{L}^n \times \mathcal{L}^1)(G) < \infty$*;*
(ii) $\{y \in (0, \infty) : \{(x, y) \in G\} \neq \emptyset\}$ *is bounded;*
(iii) $\{x : (x, y) \in G\} \in \mathbf{n}_\epsilon^{loc}(U_y)$ *for $\mathcal{L}^1$ almost all $y \in (0, \infty)$,*

and $f : \Omega \to [0, \infty)$ is such that

$$f(x) = \mathcal{L}^1\{y : (x, y) \in G\} \quad \textit{for } x \in \Omega.$$

Then $f \in \mathbf{m}_\epsilon^{loc}(F)$.

It turns out that a set G as in the previous theorem is essentially unique, provided F is strictly convex. Simple examples in [CE] show this is not the case if F is merely convex. Bear in mind that f below is essentially unique because F is strictly convex.

THEOREM 1.5. *Suppose F, G, and f are as in the preceding theorem and F is strictly convex. Then*

$$(\mathcal{L}^n \times \mathcal{L}^1)((G \sim \{(x, y) : f(x) > y > 0\}) \cup (\{(x, y) : f(x) > y > 0\} \sim G)) = 0.$$

See section 9.3 for the proof.

1.7. Results on curvature. A good deal of the following theorem, which will be proved in section 7, is well known. If one assumes that M below is of class C^2, the formula for H in (1.7) may be derived by a straightforward variational argument which appears in [M]; in our case, in the light of the regularity theorem for $\mathcal{C}_\lambda(\Omega)$ we know only that M is of class $C^{1,\mu}$, $0 < \mu < 1$, so one must proceed a bit more carefully. We represent M locally as a graph of a function which satisfies an elliptic equation and appeal to higher regularity results for such equations as appear, for example, in [GT]. One may then obtain the second variation formula (1.8) which, obviously, is a *global* constraint on a member of $\mathbf{n}_\epsilon^{loc}(Z)$ to which it applies. I believe (1.8) is new; it will be used in section 11 and [AW2] when we construct minimizers.

See section 4 for the definitions of mean curvature and second fundamental form which we use.

THEOREM 1.6. *Suppose*

(i) $\zeta \in \mathbf{L}_\infty(\Omega)$ *and* $Z(E) = \int_E \zeta \, d\mathcal{L}^n$ *whenever* $E \in \mathcal{M}(\Omega)$*;*

(ii) U *is an open subset of* Ω*,* j *is a nonnegative integer,* $0 < \mu < 1$*, and* $\zeta | U$ *is of class* $C^{j,\mu}$*;*

(iii) $0 < \epsilon < \infty$ *and* $D \in \mathbf{n}_\epsilon^{loc}(Z)$*;*

(iv) Γ *is the intersection of* U *with the interior of the support of the generalized function corresponding to the indicator function of* D *and* M *is the boundary of* Γ *relative to* U*.*

Then $\Sigma_U(D, \Gamma) = 0$*,* M *is an embedded hypersurface of class* $C^{j+2,\mu}$*, and*

$$H(x) = -\frac{1}{\epsilon}\zeta(x)\nu(x) \quad \text{for } x \in M, \tag{1.7}$$

where H *is the mean curvature vector of* M *and* ν *is the unit normal along* M *which points out of* Γ*.*

Moreover, if ζ *is of class* C^1 *on* U *and* Q *is the square of the length of the second fundamental form of* M*, then*

$$\int_M \epsilon \left(|\nabla_M \phi(x)|^2 - \phi(x)^2 Q(x) \right) - \phi(x)^2 \nabla\zeta(x) \bullet \nu(x) \, d\mathcal{H}^{n-1}x \geq 0 \tag{1.8}$$

for any smooth compactly supported function ϕ *on* U*; here, for each* $x \in M$*,* $\nabla_M \phi(x)$ *is the orthogonal projection of* $\nabla\phi(x)$ *on* $\mathbf{Tan}(M, x)$*.*

In case $n = 2$ *we may take* $\mu = 1$*.*

This theorem will apply in the context of denoising if s as in section 1.8 is sufficiently regular in U.

1.8. Denoising. Suppose

(i) $s \in \mathcal{F}(\Omega)$;

(ii) $\gamma : \mathbb{R} \to [0, \infty)$, γ is locally Lipschitzian, γ is decreasing on $(-\infty, 0)$, $\gamma(0) = 0$, and γ is increasing on $(0, \infty)$;

(iii) $F(f) = \int_\Omega \gamma(f(x) - s(x)) \, d\mathcal{L}^n x$ for $f \in \mathcal{F}(\Omega)$.

Here s could be a grayscale representation of a degraded image which we wish to denoise. In the context of denoising F would be called a *fidelity*; it is a measure of how much f differs from s. If $0 < \epsilon < \infty$, the members of $\mathbf{m}_\epsilon^{loc}(F)$ would be called *total variation regularizations of* s *(with respect to the fidelity* F *and smoothing parameter* ϵ*).*

In the literature F_ϵ is often replaced by F_ϵ/ϵ and $\lambda = 1/\epsilon$ is thought of as a Lagrange multiplier.

For a very informative discussion of the use of total variation regularizations in the field of image processing, see the introduction of [CE]. We will not discuss image processing any further except to note that the notion of total variation regularization in image processing is useful for other purposes besides denoising.

Evidently, F is admissible, so Proposition 1.1 holds and the results of section 1.5 apply. It is also evident that F is local.

Let us now assume γ is convex. It follows that F is convex. Set

$$\alpha(y) = \liminf_{z\to y} \frac{\gamma(z)-\gamma(y)}{z-y} \quad \text{and} \quad \beta(y) = \limsup_{z\to y} \frac{\gamma(z)-\gamma(y)}{z-y} \qquad \text{for } y \in \mathbb{R}$$

and let L_y and U_y, $0 < y < \infty$, be as in Remark 1.3 and Proposition 1.5, respectively. It is a simple matter to verify that if $0 < y < \infty$ and $E \in \mathcal{M}(\Omega)$, then

$$L_y(E) = \int_E \alpha(y - s(x))\, d\mathcal{L}^n x \quad \text{and} \quad U_y(E) = \int_E \beta(y - s(x))\, d\mathcal{L}^n x. \tag{1.9}$$

In view of Theorem 1.3 the results of section 1.7 apply when α or β and s are sufficiently regular.

Of particular interest is when $1 \le p < \infty$ and

$$\gamma(y) = \frac{1}{p}|y|^p \quad \text{whenever } y \in \mathbb{R}. \tag{1.10}$$

Rudin, Osher, and Fatemi [ROF] studied the case $p = 2$ and Chan and Esedoḡlu [CE] studied the case $p = 1$. The results of section 1.7 will allow us to construct a number of interesting examples of minimizers in [AW2], a sequel to this paper; we believe these examples provide insights into the nature of total variation regularization. At the end of this paper we will determine $\mathbf{m}_\epsilon^{loc}(F)$ when $\Omega = \mathbb{R}^2$, s is the indicator function of a square, and γ is as in (1.10). Note that F is strictly convex if $p > 1$ and merely convex if $p = 1$.

Suppose $K \in \mathbf{L}_1(\mathbb{R}^n)$. Let

$$F(f) = \int_{\mathbb{R}^n} \gamma(K * f(x) - s(x))\, d\mathcal{L}^n x \quad \text{for } f \in \mathcal{F}(\mathbb{R}^n).$$

It is easy to see that F is admissible but not local except in degenerate situations. Nonetheless, the results of section 1.5 apply.

1.9. Some results on the Chan–Esedoḡlu functional. Suppose s, γ, F are as in section 1.8 with $\gamma(y) = |y|$ for $y \in \mathbb{R}$. Whenever $0 < y < \infty$ and $E \in \mathcal{M}(\Omega)$ we use (1.9) to obtain

$$L_y(E) = \mathcal{L}^n(E \cap \{y > s\}) - \mathcal{L}^n(E \cap \{y \le s\}) = \widehat{N_{\{y\le s\}}}(E),$$
$$U_y(E) = \mathcal{L}^n(E \cap \{y \ge s\}) - \mathcal{L}^n(E \cap \{y < s\}) = \widehat{N_{\{y< s\}}}(E),$$

where for each $S \in \mathcal{M}(\Omega)$ we have set

$$N_S(E) = \Sigma_\Omega(E, S) \quad \text{for } E \in \mathcal{M}(\Omega).$$

We use Theorem 1.4 to obtain interesting results about N_S, $S \in \mathcal{M}(\Omega)$, one of which is as follows; it was suggested by a similar result in a different context in [CA1] and will be used in [AW2] in determining $\mathbf{n}_\epsilon^{loc}(N_S)$, $0 < \epsilon < \infty$, for certain S, which in view of the above formulae for L_y and U_y, $0 < y < \infty$, and Theorem 1.3 will allow us to determine $\mathbf{m}_\epsilon^{loc}(F)$, $0 < \epsilon < \infty$, where $F(f) = \int_{\mathbb{R}^2} |f - 1_S| \, d\mathcal{L}^2$ for $f \in \mathcal{F}(\mathbb{R}^2)$.

THEOREM 1.7. *Suppose $S \in \mathcal{M}(\Omega)$, $0 < \epsilon < \infty$, and $\mathcal{A}$ is a nonempty subfamily of $\mathbf{n}_\epsilon^{loc}(N_S)$. Then*

$$\cap\mathcal{A} \in \mathbf{n}_\epsilon^{loc}(N_S) \quad \textit{and, provided } \mathcal{L}^n(\cup\mathcal{A}) < \infty, \quad \cup\,\mathcal{A} \in \mathbf{n}_\epsilon^{loc}(N_S).$$

2. Geometric measure theoretic background. We find the mathematical infrastructure of normal and integral currents to be convenient in carrying out this work. For that reason we will adopt, for the most part, the notation and terminology of [FE]; note the extensive glossary, list of notation, and index starting on page 669 of that book. We avoided using that notation and terminology in the introduction in order to make it more accessible to readers not familiar with [FE].

2.1. More notations and conventions. Suppose μ *measures* Ω, which is to say μ maps the power set of Ω countably subadditively into $[0, \infty]$; whenever $A \subset \Omega$ we let

$$\mu \llcorner A(B) = \mu(A \cap B) \quad \text{whenever } B \subset \Omega$$

and note that $\mu \llcorner A$ measures Ω.

Whenever f is a function mapping a subset of a normed vector space into another normed vector space, a is an interior point of the domain of f, and f is Fréchet differentiable at a, we let

$$\partial f(a)$$

be the Fréchet differential of f at a.

If V is a vector space, $v \in V$, and ψ belongs to the dual space of V, we frequently write

$$\langle v, \psi \rangle \quad \text{instead of} \quad \psi(v).$$

We use **spt** as an abbreviation for "support."

2.2. Spaces of smooth functions; currents. Whenever Y is a Banach space we let

$$\mathcal{E}(\Omega, Y) \quad \text{and} \quad \mathcal{D}(\Omega, Y)$$

be the space of smooth Y valued functions on Ω and the space of compactly supported members of $\mathcal{E}(\Omega, Y)$, respectively, with the strong topologies as described in [FE, sect. 4.1.1]. Thus $\mathcal{X}(\Omega) = \mathcal{D}(\Omega, \mathbb{R}^n)$.

We let

$$\mathcal{E}(\Omega) \quad \text{and} \quad \mathcal{D}(\Omega)$$

equal $\mathcal{E}(\Omega, \mathbf{R})$ and $\mathcal{D}(\Omega, \mathbf{R})$, respectively. For each nonnegative integer m we let

$$\mathcal{E}^m(\Omega) \quad \text{and} \quad \mathcal{D}^m(\Omega)$$

equal $\mathcal{E}(\Omega, Y)$ and $\mathcal{D}(\Omega, Y)$, respectively, with $Y = \bigwedge^m \mathbb{R}^n$. Thus $\mathcal{E}^m(\Omega)$ is the space of smooth differential m-forms on Ω, and $\mathcal{D}^m(\Omega)$ is the space of those members of $\mathcal{E}^m(\Omega)$ with compact support. We let

$$\mathcal{E}_m(\Omega) \quad \text{and} \quad \mathcal{D}_m(\Omega)$$

be the duals of $\mathcal{E}^m(\Omega)$ and $\mathcal{D}^m(\Omega)$, respectively. Thus $\mathcal{D}_m(\Omega)$ is the space of m dimensional *currents* on Ω, and $\mathcal{E}_m(\Omega)$ is the space of m-dimensional currents with compact support on Ω. We define the *boundary operator*

$$\partial : \mathcal{D}_m(\Omega) \to \mathcal{D}_{m-1}(\Omega)$$

by setting $\partial T(\omega) = T(d\omega)$ whenever $T \in \mathcal{D}_m(\Omega)$ and $\omega \in \mathcal{D}_{m-1}(\Omega)$; here d is exterior differentiation.

Suppose $T \in \mathcal{D}_m(\Omega)$. As in [FE, sect. 4.1.5] we let

$$||T||,$$

the *total variation measure of* T, be the largest Borel regular measure on Ω such that

$$||T||(G) = \sup\{|T(\omega)| : \omega \in \mathcal{D}^m(\Omega),\ ||\omega|| \le 1 \text{ and } \mathbf{spt}\,\omega \subset G\}$$

for each open subset G of Ω; here $||\cdot||$ is the *comass* which in case $m \in \{0, 1, n-1, n\}$ is the Euclidean norm; these are the only cases we will encounter in this paper. It follows immediately from this definition that

$$||T||(G) \le \liminf_{\nu\to\infty} ||S_\nu||(G) \quad \text{for any open subset } G \text{ of } \Omega \tag{2.1}$$

whenever S is a sequence in $\mathcal{D}_m(\Omega)$ such that $S_\nu(\omega) \to T(\omega)$ as $\nu \to \infty$ whenever $\omega \in \mathcal{D}^m(\Omega)$. We let

$$\mathbf{M}(T) = ||T||(\Omega)$$

and call this nonnegative extended real number the *mass* of T. We say T is *representable by integration* if $||T||$ is a Radon measure which is equivalent to the statement that $||T||(K) < \infty$ whenever K is a compact subset of Ω. If this is the case and $\overrightarrow{T}$ is the $||T||$ measurable function with values in $\{\xi \in \bigwedge_m \mathbb{R}^n : ||\xi|| = 1\}$ defined in [FE, sect. 4.1.7], there is a unique extension of T to the $||T||$ summable functions on Ω with values in $\bigwedge^m \mathbb{R}^n$, which we continue to denote by T, such that

$$T(\omega) = \int \langle \overrightarrow{T}(x), \omega(x) \rangle \, d||T||x$$

whenever ω is a $||T||$ summable function on Ω with values in $\bigwedge^m \mathbb{R}^n$. If $T \in \mathcal{D}_m(\Omega)$ is representable by integration, l is a nonnegative integer not exceeding m, and η is a bounded Borel function on Ω with values in $\bigwedge^l \mathbb{R}^n$, then we let

$$T \llcorner \eta \in \mathcal{D}_{m-l}(\Omega)$$

be such that

$$T \llcorner \eta(\omega) = \int \langle \overrightarrow{T}(x), (\eta \wedge \omega)(x) \rangle \, d||T||x \quad \text{for } \omega \in \mathcal{D}^{m-l}(\Omega).$$

2.3. The current corresponding to a locally summable function. We let

$$\mathbf{e}_1, \ldots, \mathbf{e}_n \quad \text{and} \quad \mathbf{e}^1, \ldots, \mathbf{e}^n$$

be the standard basis vectors and covectors for $\mathbb{R}^n$ and its dual space, respectively. We let

$$\mathbf{E}^n = \mathbf{e}^1 \wedge \cdots \wedge \mathbf{e}^n \in \bigwedge^n \mathbb{R}^n$$

be the standard orientation on $\mathbb{R}^n$.

We let

$$\mathbf{V}^n \in \mathcal{D}^n(\Omega) \tag{2.2}$$

be such that $\mathbf{V}^n(x) = \mathbf{E}^n$ for $x \in \Omega$.

DEFINITION 2.1. *Whenever* $f \in \mathbf{L}_1^{loc}(\Omega)$ *we define*

$$[f] \in \mathcal{D}_n(\Omega)$$

by setting

$$[f](\phi \mathbf{V}^n) = \int_\Omega \phi f \, d\mathcal{L}^n \quad \textit{whenever } \phi \in \mathcal{D}(\Omega).$$

Suppose $f \in \mathbf{L}_1^{loc}(\Omega)$. For any $X \in \mathcal{X}(\Omega)$ we have $d(X \lrcorner \mathbf{V}^n) = (-1)^{n-1}(\operatorname{div} X)\mathbf{V}^n$ so that

$$\partial[f](X \lrcorner \mathbf{V}^n) = (-1)^{n-1} \int f \operatorname{div} X \, d\mathcal{L}^n; \tag{2.3}$$

here $\lrcorner$ is as in [FE, sect. 1.5.1]. It follows that

$$\mathbf{TV}(f, B) = ||\partial[f]||(B) \quad \text{whenever } B \text{ is a Borel subset of } \Omega. \tag{2.4}$$

2.4. Mapping currents. Whenever $T \in \mathcal{D}_m(\Omega)$ and F is a smooth map from Ω to the open subset Γ of some Euclidean space whose restriction to the support of T is proper, we let

$$F_\# T \in \mathcal{D}_m(\Gamma)$$

be such that $F_\# T(\omega) = T(F^\# \omega)$ for any $\omega \in \mathcal{D}^m(\Gamma)$; here the *pullback* $F^\#$ is as in [FE, sect. 4.1.6]. If F carries Ω diffeomorphically onto Γ, T is representable by integration, and $\overrightarrow{T}(x)$ is decomposable for $||T||$ almost all $x \in \Omega$, then we have

$$\int b(y) \, d||F_\# T||y = \int b(F(x)) \left| \bigwedge\nolimits_m \partial F(x)(\overrightarrow{T}(x)) \right| d||T||x \tag{2.5}$$

for nonnegative Borel function b on Γ. By a simple approximation argument one need only assume that F is of class C^1 if T is representable by integration.

2.5. A mapping formula. Suppose Γ is an open subset of $\mathbb{R}^n$; $f \in \mathbf{L}_1^{loc}(\Omega)$; $F : \Omega \to \Gamma$ is locally Lipschitzian; the restriction of F to the support of $[f]$ is proper; A is the set of $y \in \Gamma$ such that $F^{-1}[\{y\}]$ is finite and such that if $F(x) = y$, then F is differentiable at x; and $g : \Gamma \to \mathbb{R}$ is such that

$$g(y) = \begin{cases} \sum_{x \in F^{-1}[\{y\}]} f(x) \operatorname{sgn} \det \partial F(x) & \text{if } y \in A, \\ 0 & \text{else.} \end{cases}$$

Then $g \in \mathbf{L}_1^{loc}(\Gamma)$ and

$$F_\#[f] = [g]. \tag{2.6}$$

In particular, if F is univalent and $\det \partial F(x) > 0$ for $\mathcal{L}^n$ almost all $x \in \Omega$, then

$$F_\#[f] = [f \circ F^{-1}].$$

See [FE, sect. 4.1.25] for the proof.

2.6. Slicing. Suppose m, l are positive integers, $m \geq l$, $T \in \mathcal{D}^m(\Omega)$, T is locally flat as defined in [FE, sect. 4.1.12], and $f : \Omega \to \mathbb{R}^l$ is locally Lipschitzian. Note that if both T and ∂T are representable by integration, then T is locally flat; this will always be the case when we apply slicing in this paper. For $y \in \mathbb{R}^l$ we follow [FE, sect. 4.3.1] and define

$$\langle T, f, y \rangle$$

the *slice of* T *in* $f^{-1}[\{y\}]$ to be that member of $\mathcal{D}_{m-l}(\Omega)$ which, if it exists, satisfies

$$\langle T, f, y\rangle(\psi) = \lim_{r \downarrow 0} \frac{T \llcorner [f^\#(\mathbf{B}^l(y,r) \wedge \mathbf{V}^l)](\psi)}{\mathcal{L}^l(\mathbf{B}^l(y,r))} \quad \text{whenever } \psi \in \mathcal{D}^{m-l}(\Omega),$$

where $T \llcorner [f^\#(\mathbf{B}^l(y,r) \wedge \mathbf{V}^l)]$ is defined as in [FE, sect. 4.3.1]. Then, by [FE, sect. 4.3.1], the slice $\langle T, f, y\rangle$ exists for $\mathcal{L}^l$ almost all y and satisfies

$$\mathbf{spt}\, \langle T, f, y\rangle \subset f^{-1}[\{y\}] \quad \text{and} \quad \partial\langle T, f, y\rangle = (-1)^l \langle \partial T, f, y\rangle. \tag{2.7}$$

Moreover, we have from [FE, sect. 4.3.2] that

$$\int \Phi(y)\langle T, f, y\rangle(\psi)\, d\mathcal{L}^l y = [T \llcorner f^\#(\Phi \wedge \mathbf{V}^l)](\psi) \tag{2.8}$$

whenever Φ is a bounded Borel function on $\mathbb{R}^l$ and $\psi \in \mathcal{D}^{m-l}(\Omega)$ and that

$$\int \left(\int b ||\langle T, f, y\rangle|| \right) d\mathcal{L}^l y = \int b\, d||T \llcorner f^\# \mathbf{V}^l]|| \tag{2.9}$$

whenever b is a nonnegative Borel function on Ω.

PROPOSITION 2.1. *Suppose K is a compact subset of Ω, $u(x) = \mathbf{dist}\,(x, K)$ for $x \in \Omega$, R is the supremum of the set of $r \in (0, \infty)$ such that $\{u \leq r\} \subset \Omega$, $f, g \in \mathbf{BV}^{loc}(\Omega)$, and*

$$h_r = g 1_{\{u \leq r\}} + f 1_{\{u > r\}} \quad \textit{for each } r \in (0, R).$$

Then $h_r \in \mathbf{BV}^{loc}(\Omega)$ for $\mathcal{L}^1$ almost all $r \in (0, R)$, and whenever $0 < r < s < R$ we have

$$\int_r^s ||\partial[h_\rho]||(\{u \leq \rho\})\, d\mathcal{L}^1\rho \leq \int_{\{r < u < s\}} |f - g|\, d\mathcal{L}^n + \int_r^s ||\partial[g]||(\{u \leq \rho\})\, d\mathcal{L}^1 \rho. \tag{2.10}$$

Proof. From [FE, sect. 4.2.1] and [FE, sect. 4.3.4] we find that

$$\partial[h_\rho] = \langle [g] - [f], u, \rho\rangle + (\partial[g]) \llcorner \{u \leq \rho\} + (\partial[f]) \llcorner \{u > \rho\}$$

for $\mathcal{L}^1$ almost all $\rho \in (0, R)$. Now multiply by $1_{\{u \leq \rho\}}$, integrate from r to s, and invoke (2.9). ◻

2.7. Densities and density ratios. Suppose μ measures Ω, m is a nonnegative integer, and $\alpha(m) = \mathcal{L}^m(\mathbf{U}^m(0,1))$. For each $a \in \Omega$ we set

$$\Theta^m(\mu, a, r) = \frac{\mu(\mathbf{B}(a,r))}{\alpha(m) r^m} \quad \text{whenever } 0 < r < \mathbf{dist}\,(a, \mathbb{R}^n \sim \Omega)$$

and

$$\Theta^m(\mu, a) = \lim_{r \to 0} \Theta^m(\mu, a, r),$$

provided this limit exists.

2.8. Sets of finite perimeter. Suppose E is a Lebesgue measurable subset of Ω. Proceeding as in [FE, sect. 4.5.5], we say $u \in \mathbb{R}^n$ is an *exterior normal to E at $b \in \Omega$* if $|u| = 1$ and

$$\Theta^n(\mathcal{L}^n \llcorner \{x \in E : (x-b) \bullet u > 0\} \cup \{x \in \Omega \sim E : (x-b) \bullet u < 0\}, b) = 0.$$

We let

$$\mathbf{n}_E$$

be the set of $(b, u) \in \Omega \times \mathbb{R}^n$ such that *either* u is an exterior normal to E at b *or* $u = 0$ and there is no exterior normal to E at b; note that $\mathbf{n}_E$ is a function with domain Ω. We let

$$\mathbf{b}(E),$$

the *reduced boundary of E*, be equal to the set of points $b \in \Omega$ such that there is an exterior normal to E at b.

THEOREM 2.1 (see [FE, sect. 4.5.6]). *Suppose E is a subset of Ω with locally finite perimeter. The following statements hold:*

(i) $\mathbf{b}(E)$ *is a Borel set which is countably $(\mathcal{H}^{n-1}, n-1)$ rectifiable.*

(ii) $||\partial[E]|| = \mathcal{H}^{n-1} \llcorner \mathbf{b}(E)$.

(iii) *For $\mathcal{H}^{n-1}$ almost all $b \in \mathbf{b}(E)$ we have*

$$*\mathbf{n}_E(b) = \overrightarrow{\partial[E]}(b) \quad \textit{and} \quad \Theta^{n-1}(||\partial[E]||, b) = 1;$$

here $*$ is the Hodge star operator *as defined in* [FE, sect. 1.7.8].

(iv) *For $\mathcal{H}^{n-1}$ almost all $b \in \Omega \sim \mathbf{b}(E)$, $\Theta^{n-1}(||\partial[E]||, b) = 0$ and*

$$\textit{either } \Theta^n(\mathcal{L}^n \llcorner E, b) = 0 \quad \textit{or} \quad \Theta^n(\mathcal{L}^n \llcorner (\Omega \sim E), b) = 0.$$

It follows that if E is a subset of Ω with locally finite perimeter, then

$$\partial[E](X \lrcorner \mathbf{V}^n) = (-1)^{n-1} \int X \bullet \mathbf{n}_E \, d||\partial[E]|| \quad \text{whenever } X \in \mathcal{X}(\Omega). \tag{2.11}$$

PROPOSITION 2.2. *Suppose E is a subset of Ω with finite perimeter and C is a closed convex subset of $\mathbb{R}^n$. Then*

$$\mathbf{M}(\partial[C \cap E]) \le \mathbf{M}(\partial[E]). \tag{2.12}$$

Proof. Let $\rho : \mathbb{R}^n \to C$ be such that $|x - \rho(x)| = \mathbf{dist}\,(x, C)$ for $x \in \mathbb{R}^n$. In case $\mathbf{spt}\,[E]$ is compact we infer from (2.6) that $[C \cap E] = \rho_\#[E]$ so that, as $\mathbf{Lip}\,\rho \le 1$, (2.12) holds. In case $\mathbf{spt}\,[E]$ is not compact we let $E_r = E \cap \mathbf{U}^n(0, r)$, $0 < r < \infty$, and apply the result just obtained together with (2.10) and (2.1). ∎

2.9. Basic facts about functions of bounded variation. Proofs of the following formulae, which are absolutely fundamental for this work, may be found in [FE, sect. 4.5.9, eq. (13)]. Suppose $f \in \mathbf{BV}^{loc}(\Omega)$; then $\mathbb{R} \ni y \mapsto \partial[\{f \ge y\}](\omega)$ is $\mathcal{L}^1$ summable and

$$\partial[f](\omega) = \int \partial[\{f > y\}](\omega) \, d\mathcal{L}^1 y \quad \text{whenever } \omega \in \mathcal{D}^{n-1}(\Omega); \tag{2.13}$$

moreover, if B is a Borel subset of Ω, then $\mathbb{R} \ni y \mapsto ||\partial[\{f > y\}]||(B)$ is $\mathcal{L}^1$ measurable and

$$||\partial[f]||(B) = \int ||\partial[\{f > y\}]||(B)\, d\mathcal{L}^1 y. \tag{2.14}$$

The following well-known theorem follows from (2.1) and the discussion in [FE, sect. 4.5.7] concerning locally flat currents of dimension n in Ω.

THEOREM 2.2 (compactness theorem). *Suppose C is a sequence of nonnegative real numbers and K is a sequence of compact subsets of Ω such that $\cup_{\nu=1}^{\infty} K_\nu = \Omega$. Then*

$$\bigcap_{\nu=1}^{\infty} \left\{ f \in \mathbf{BV}^{loc}(\Omega) : \int_{K_\nu} |f|\, d\mathcal{L}^n + ||\partial[f]||(K_\nu) \leq C_\nu \right\}$$

is a compact subset of $\mathbf{L}_1^{loc}(\Omega)$.

PROPOSITION 2.3. *Suppose $f \in \mathbf{BV}^{loc}(\Omega)$ and $y \in \mathbf{R}$. Then $f \wedge y, f \vee y \in \mathbf{BV}^{loc}(\Omega)$ and*

$$||\partial[f \wedge y]|| + ||\partial[f \vee y]|| = ||\partial[f]||. \tag{2.15}$$

Proof. Since $f + y = f \wedge y + f \vee y$ it is trivial that the right-hand side of (2.15) does not exceed the left-hand side of (2.15). Using (2.13) one readily shows that

$$[f \wedge y](\omega) = \int_{-\infty}^{y} [\{f \geq z\}](\omega)\, d\mathcal{L}^1 z \quad \text{and} \quad [f \vee y](\omega) = \int_{y}^{\infty} [\{f > y\}](\omega)\, d\mathcal{L}^1 y$$

whenever $\omega \in \mathcal{D}^n(\Omega)$. Applying ∂ one infers

$$||\partial[f \wedge y]|| \leq \int_{-\infty}^{y} ||\partial[\{f > y\}]||\, d\mathcal{L}^1 y \quad \text{and} \quad ||\partial[f \vee y]|| \leq \int_{y}^{\infty} ||\partial[\{f > y\}]||\, d\mathcal{L}^1 y.$$

By (2.14) the sum of the right-hand sides of these inequalities is $||\partial[f]||$. Thus the left-hand side of (2.15) does not exceed the right-hand side. $\square$

2.10. The "layer cake" formula. Chan and Esedoḡlu in [CE] call the following elementary formula the "layer cake" formula; it is indispensable in this work.

PROPOSITION 2.4. *Suppose f, g are real valued Lebesgue measurable functions on Ω. Then*

$$\int_\Omega |f - g|\, d\mathcal{L}^n = \int_{-\infty}^{\infty} \Sigma_\Omega(\{f > y\}, \{g > y\})\, d\mathcal{L}^1 y. \tag{2.16}$$

Proof. Apply Tonelli's theorem to calculate the $\mathcal{L}^n \times \mathcal{L}^1$ measure of $\{(x, y) \in \Omega \times \mathbb{R} : g(x) < y \leq f(x)\}$ and $\{(x, y) \in \Omega \times \mathbb{R} : f(x) < y \leq g(x)\}$ and add the results. $\square$

3. Deformations and variations. We suppose throughout this section that

(i) $X : \Omega \to \mathbb{R}^n$ is continuously differentiable and $K = \mathbf{spt}\, X$ is compact;

(ii) I is an open interval containing 0 such that if $t \in I$ and

$$h_t(x) = x + tX(x) \quad \text{for } x \in \Omega,$$

then h_t carries Ω diffeomorphically (in the C^1 sense) onto itself;

(iii) D is a Lebesgue measurable subset of Ω with locally finite perimeter and

$$E_t = \{h_t(x) : x \in D\} \quad \text{for } t \in I;$$

(iv) for $x \in \mathbf{b}(D)$

$$P(x) \text{ is orthogonal projection of } \mathbb{R}^n \text{ onto } \{v \in \mathbb{R}^n : v \bullet \mathbf{n}_D(x) = 0\},$$

$$l_1(x) = P(x) \circ \partial X(x) \circ P(x) \quad \text{and} \quad l_2(x) = P(x)^\perp \circ \partial X(x) \circ P(x).$$

Note that given X as in (i) there is always I as in (ii).

3.1. Some useful variational formulae.

PROPOSITION 3.1. *Suppose*

$$A(t) = ||\partial[E_t]||(K) \quad \textit{for each } t \in I.$$

Then A is smooth, and

$$\dot{A}(0) = \int a_1 \, d||\partial[D]|| \quad \textit{and} \quad \ddot{A}(0) = \int a_2 \, d||\partial[D]||,$$

where for $x \in \mathbf{b}(D)$ we have set

$$a_1(x) = \operatorname{trace} l_1(x) \quad \textit{and} \quad a_2(x) = a_1(x)^2 + \operatorname{trace}(l_2(x)^* \circ l_2(x) - l_1(x) \circ l_1(x)).$$

Proof. It follows from (2.6) that $[E_t] = h_{t\#}[D]$ and therefore $\partial[E_t] = h_{t\#}\partial[D]$ for any $t \in I$. Now recall from Theorem 2.1(iii) that $*\mathbf{n}_D(x) = \overrightarrow{\partial[D]}(x)$ for $||\partial[D]||$ almost all x, differentiate under the integral sign in (2.5), and use the formulae

$$\left(\frac{d}{dt}\right)^j \bigwedge\nolimits_{n-1} \partial h_t(x)(\overrightarrow{\partial[D]}(x))\Big|_{t=0} = a_j(x), \quad j = 1, 2, \quad x \in \mathbf{b}(D),$$

proofs of which may be found in [FE, sect. 5.1.8]. $\square$

Since $[E_t] - [D]$ is compactly supported, $([E_t] - [D])(\phi \mathbf{V}^n)$ is well defined in the following proposition.

PROPOSITION 3.2. *For any $\phi \in \mathcal{E}(\Omega)$ we have*

$$([E_t] - [D])(\phi \mathbf{V}^n) = \int_0^t \left(\int \phi(h_\tau(x)) \, W_\tau(x) \, d||\partial[D]||x \right) d\mathcal{L}^1\tau,$$

where, for each $t \in I$, we have set

$$W_t(x) = \left\langle X(x) \wedge \bigwedge\nolimits_{n-1} \partial h_t(x)(*\mathbf{n}_D(x)), \mathbf{E}^n \right\rangle \quad \textit{for } x \in \mathbf{b}(D).$$

Proof. For each $t \in I$ let $J_t = [0, t] \in \mathcal{D}_1(\mathbb{R})$ as in [FE, sect. 4.1.8]. From [FE, sect. 4.1.8] we have $||J_t \times \partial[D]|| = ||J_t|| \times ||\partial[D]||$ for each $t \in I$. From [FE, sect. 4.1.8] and Theorem 2.1(iii) we have

$$\overrightarrow{J_t \times \partial[D]}(\tau, x) = (1, 0) \wedge \overrightarrow{\partial[D]}(x) = (1, 0) \wedge *\mathbf{n}_D(x) \quad \text{for } (\tau, x) \in (0, t) \times \mathbf{b}(D).$$

Suppose $t \in I$. We obtain

$$[E_t] - [D] = h_{t\#}[D] - [D] = h_\#(J_t \times \partial[D])$$

from the homotopy formula of [FE, sect. 4.1.9]; the formula to be proved now follows from (2.5). ∎

PROPOSITION 3.3. *Suppose $\mathcal{L}^n(D) < \infty$, $\zeta \in \mathbf{L}_\infty(\Omega)$, and*

$$B(t) = \int_{E_t} \zeta \, d\mathcal{L}^n \quad \textit{for } t \in I.$$

If ζ is continuous, then B is continuously differentiable and

$$\dot{B}(0) = \int \zeta(X \bullet \mathbf{n}_D)\, d\|\partial[D]\|. \tag{3.1}$$

If ζ is continuously differentiable, then B is twice continuously differentiable and

$$\ddot{B}(0) = \int \big(\zeta Y + (\nabla\zeta \bullet X)X\big) \bullet \mathbf{n}_D \, d\|\partial[D]\|, \tag{3.2}$$

where for $x \in \mathbf{b}(D)$ we have set

$$Y(x) = (\operatorname{trace} l_1(x))X(x) - l_2(x)(X(x)).$$

Proof. Using straightforward approximations if necessary, we may assume that ζ is smooth. For each $t \in I$ and $x \in \mathbf{b}(D)$ let

$$\xi_t(x) = \bigwedge\nolimits_{n-1} \partial h_t(x)(*\mathbf{n}_D(x)) \quad \text{and} \quad W_t(x) = \langle \dot{h}_t(x) \wedge \xi_t(x), \mathbf{E}^n\rangle.$$

Suppose $x \in \mathbf{b}(D)$. Let $u_1, \ldots, u_n$ be an orthonormal sequence of vectors in $\mathbb{R}^n$ such that $u_1 = \mathbf{n}_D(x)$ and $*u_1 = u_2 \wedge \cdots \wedge u_n$; since $\langle u_1 \wedge *u_1, \mathbf{E}^n\rangle = 1$ we have

$$\langle w \wedge u_2 \wedge \cdots \wedge u_n, \mathbf{E}^n\rangle = w \bullet u_1 \langle u_1 \wedge *u_1, \mathbf{E}^n\rangle = w \bullet u_1 \quad \text{for any } w \in \mathbb{R}^n;$$

see [FE, sect. 1.7.8] for the properties of $*$.

It should now be clear from Proposition 3.2 that (3.1) holds.

Let $u^1, \ldots, u^n$ be the sequence of covectors dual to $u_1, \ldots, u_n$ and let $\omega_1, \ldots, \omega_n$ be those covectors such that $\partial X(x) = \sum_{j=1}^n \omega_j u_j$. We have

$$\begin{aligned}
\frac{d}{dt} W_t(x)\Big|_{t=0} &= X(x) \wedge \frac{d}{dt}\xi_t(x)\Big|_{t=0} \\
&= X(x) \wedge \sum_{i=2}^n \partial X(x)(u_i) \wedge \big(u^i \lrcorner\, \xi_0(x)\big) \\
&= X(x) \wedge \sum_{i=2}^n \sum_{j=1}^n \langle u_i, \omega_j\rangle u_j \wedge \big(u^i \lrcorner\, \xi_0(x)\big) \\
&= X(x) \wedge \sum_{i=1}^n \langle u_i, \omega_i\rangle u_i \wedge \big(u^i \lrcorner\, \xi_0(x)\big) \\
&\qquad + X(x) \wedge \sum_{i=2}^n \langle u_i, \omega_1\rangle u_1 \wedge \big(u^i \lrcorner\, \xi_0(x)\big) \\
&= ((\operatorname{trace} l_1(x) X(x) - l_2(x)(X(x))) \bullet \mathbf{n}_D(x))\, u_1 \wedge *u_1,
\end{aligned}$$

so (3.2) holds. ∎

4. Second fundamental forms and mean curvature. Suppose M is an embedded hypersurface of class C^2 in Ω.

The *second fundamental form of* M is the function Π on M whose value at $a \in M$ is a linear map from $\mathbf{Nor}(M,a)$ into the symmetric linear maps from $\mathbf{Tan}(M,a)$ to itself characterized by the requirement that if U is an open subset of $\mathbb{R}^n$, $a \in U \cap M$; $N : U \to \mathbb{R}^n$; N is of class C^1; and $N(x) \in \mathbf{Nor}(M,x)$ whenever $x \in U \cap M$, then

$$\Pi(a)(N(a))(v) \bullet w = \partial N(a)(v) \bullet w \quad \text{for } v, w \in \mathbf{Tan}(M,a).$$

The *mean curvature vector of* M is, by definition, the function H on M whose value at a point a of M is that member $H(a)$ of $\mathbf{Nor}(M,a)$ whose inner product with $u \in \mathbf{Nor}(M,a)$ is the trace of $\Pi(a)(u)$. In the classical literature the mean curvature vector is $1/(n-1)$ times H as defined here, hence the word "mean." It turns out the factor $1/(n-1)$ is inconvenient when one is working, as we will be, with the first variation of area; for this reason we omit it. The direction of the mean curvature vector, and not just its magnitude, will be important in this work.

If $a \in M$, the *length of* $\Pi(a)$ is, by definition, the square root of the sum of the squares of the eigenvalues of $\Pi(a)(u)$ whenever $u \in \mathbf{Nor}(M,a)$ and $|u| = 1$.

Suppose $f : \Omega \to \mathbb{R}$ is C^2; $\nabla f(x) \neq 0$ whenever $x \in \Omega$; y is in the range of f; and $M = \{f = y\}$, so M is an embedded hypersurface of class C^2 in Ω. It follows that if $a \in M$ then

$$\Pi(a)(\nabla f(a))(u) \bullet v = \partial(\nabla f)(a)(u) \bullet v \quad \text{whenever } u, v \in \mathbf{Tan}(M,a).$$

Suppose $\Omega = \mathbb{R}^n \sim \{0\}$, $f(x) = |x|^2/2$ for $x \in \Omega$, $0 < R < \infty$, and $M = \{x \in \mathbb{R}^n : |x| = R\}$. Then $\nabla f(x) = x$ for $x \in \Omega$. It follows that if $a \in M$ then

$$\Pi(a)(a)(v) \bullet w = \frac{v \bullet w}{|a|} \quad \text{whenever } v, w \in \mathbf{Tan}(M,a), \qquad H(a) = \frac{n-1}{R^2} a$$

and the length $\Pi(a)$ equals the square root of $(n-1)/R^2$.

5. The spaces $\boldsymbol{\mathcal{B}_\lambda(\Omega)}$ and $\boldsymbol{\mathcal{C}_\lambda(\Omega)}$, $\boldsymbol{0 \le \lambda < \infty}$. We suppose throughout this section that $0 \le \lambda < \infty$, and we study the spaces $\mathcal{B}_\lambda(\Omega)$ and $\mathcal{C}_\lambda(\Omega)$.

5.1. Basic results on $\boldsymbol{\mathcal{B}_\lambda(\Omega)}$ and $\boldsymbol{\mathcal{C}_\lambda(\Omega)}$. In what follows we will frequently make use of the following simple observation. *Suppose $f, g \in \mathbf{L}_1^{loc}(\Omega)$, K is a compact subset of Ω, $g \in \mathbf{k}(f,K)$, and $y \in \mathbb{R}$. Then*

$$\{g > y\} \in \mathbf{k}(\{f > y\}). \tag{5.1}$$

Moreover, $\geq$ may be replaced by any of $\leq$, $>$, and $<$.

Remark 5.1. It is an elementary corollary of Theorem 5.1 below that if D is an open subset of Ω with smooth boundary M and $D \in \mathcal{C}_\lambda(\Omega)$, then the length of the mean curvature vector of M does not exceed λ. The converse of this statement is false as one sees in case $\lambda = 0$ by considering a set whose boundary is an unstable minimal surface.

However, if $f : \Omega \to \mathbb{R}$ is smooth with nowhere vanishing gradient and, for each y in the range of f, the length of the mean curvature vector of $\{f = y\}$ never exceeds λ, then a simple calibration argument shows that $f \in \mathcal{B}_\lambda(\Omega)$.

LEMMA 5.1. *Suppose $f \in \mathcal{B}_\lambda(\Omega)$, $g \in \mathbf{BV}^{loc}(\Omega)$, K is a compact subset of Ω, $u(x) = \mathbf{dist}\,(x,K)$ for $x \in \Omega$, $0 < h < \infty$, and $\{u \le h\}$ is a compact subset of Ω.*

Then

$$||\partial[f]||(K) \leq ||\partial[g]||(\{u \leq h\}) + \left(\lambda + \frac{1}{h}\right) \int_{\{u \leq h\}} |f - g| \, d\mathcal{L}^n.$$

In particular,

$$||\partial[f]||(K) \leq \left(\lambda + \frac{1}{h}\right) \int_{\{u \leq h\}} |f - y| \, d\mathcal{L}^n \quad \textit{for } y \in \mathbb{R}.$$

Proof. For each $r \in (0, h)$ let $h_r = g1_{\{u \leq r\}} + f1_{\{u > r\}}$. Then $h_r \in \mathbf{k}(f, \{u \leq r\})$ and $f - h_r = (f - g)1_{\{u \leq r\}}$, so

$$||\partial[f]||(\{u \leq r\}) \leq ||\partial[h_r]||(\{u \leq r\}) + \lambda \int_{\{u \leq r\}} |f - g|.$$

Now integrate this inequality from 0 to h and make use of (2.10) to prove the first inequality; to obtain the second, set $g(x) = y$ for $x \in \Omega$. ∎

THEOREM 5.1. *Suppose* $\lambda \in [0, \infty)$, $f \in \mathcal{B}_\lambda(\Omega)$, *and* $y \in \mathbf{R}$. *Then*

$$\{f + y, yf, f \wedge y, f \vee y\} \subset \mathcal{B}_\lambda(\Omega).$$

Proof. Suppose K is a compact subset of Ω. Obviously, $0f = 0 \in \mathcal{B}_\lambda(\Omega)$. Suppose $y \in \mathbb{R} \sim \{0\}$ and $g \in \mathbf{k}(yf, K)$. Then $g/y \in \mathbf{k}(f, K)$, so

$$\begin{aligned} ||\partial[yf]||(K) &= |y| ||\partial[f]||(K) \\ &\leq |y| \left(||\partial[g/y]||(K) + \lambda \int_\Omega |f - g/y| \, d\mathcal{L}^n \right) \\ &= ||\partial[g]||(K) + \lambda \int_\Omega |yf - g| \, d\mathcal{L}^n. \end{aligned}$$

Thus $yf \in \mathcal{B}_\lambda(\Omega)$.

Suppose $g \in \mathbf{k}(f + y, K)$. Then $g - y \in \mathbf{k}(f, K)$, so

$$\begin{aligned} ||\partial[f + y]||(K) &= ||\partial[f]||(K) \\ &\leq ||\partial[g - y]||(K) + \lambda \int_\Omega |f - (g - y)| \, d\mathcal{L}^n \\ &= ||\partial[g]||(K) + \lambda \int_\Omega |(f + y) - g| \, d\mathcal{L}^n, \end{aligned}$$

and thus $f + y \in \mathcal{B}_\lambda(\Omega)$.

Suppose $g \in \mathbf{k}(f \wedge y, K)$. Let $h = g + (f \vee y) - y$. Then $f - h = f + y - (f \vee y) - g = f \wedge y - g$, so $h \in \mathbf{k}(f, K)$. Using Proposition 2.3 we estimate

$$\begin{aligned} ||\partial[f \wedge y]||(K) &+ ||\partial[f \vee y]||(K) \\ &= ||\partial[f]||(K) \\ &\leq ||\partial[h]||(K) + \lambda \int_K |f - h| \, d\mathcal{L}^n \\ &\leq ||\partial[g]||(K) + ||\partial[f \vee y]||(K) + \lambda \int_K |f \wedge y - g| \, d\mathcal{L}^n \end{aligned}$$

and conclude that $f \wedge y \in \mathcal{B}_\lambda(\Omega)$.

Finally, $f \vee y = -((-f) \wedge (-y)) \in \mathcal{B}_\lambda(\Omega)$. $\square$

THEOREM 5.2. *Suppose $\lambda \in [0, \infty)$, f is a sequence in $\mathcal{B}_\lambda(\Omega)$, $F \in \mathbf{L}_1^{loc}(\Omega)$, and $f_\nu \to F$ in $\mathbf{L}_1^{loc}(\Omega)$. Then $F \in \mathcal{B}_\lambda(\Omega)$ and*

$$||\partial[f_\nu]|| \to ||\partial[F]|| \quad \textit{weakly as } \nu \to \infty.$$

Proof. Let K be a compact subset of Ω, let $u(x) = \mathbf{dist}\,(x, K)$ for $x \in \Omega$, and let $R = \sup\{r \in (0, \infty) : \{u \leq r\} \subset \Omega\}$.

Suppose $h \in (0, R)$ and for each positive integer ν let y_ν be the average of f_ν on $\{u \leq h\}$. Let Y be the average value of F on $\{u \leq h\}$. From Lemma 5.1 we obtain

$$||\partial[f_\nu]||(K) \leq \left(\lambda + \frac{1}{h}\right) \int_{\{u \leq h\}} |f_\nu - y_\nu|\, d\mathcal{L}^n \to \left(\lambda + \frac{1}{h}\right) \int_{\{u \leq h\}} |F - Y|\, d\mathcal{L}^n$$

as $\nu \to \infty$. Since K is arbitrary we infer from (2.1) that $F \in \mathbf{BV}^{loc}(\Omega)$.

For any $r \in (0, R)$ we infer from Lemma 5.1 that

$$||\partial[f_\nu]||(K) \leq ||\partial[F]||(\{u \leq r\}) + \left(\lambda + \frac{1}{h}\right) \int_{\{u \leq h\}} |f_\nu - F|\, d\mathcal{L}^n$$

for any positive integer ν. Keeping in mind (2.1) we conclude that $||\partial[f_\nu]||$ converges weakly to $||\partial[F]||$ as $\nu \to \infty$.

We now show that $F \in \mathcal{B}_\lambda(\Omega)$. To this end, let $G \in \mathbf{BV}^{loc}(\Omega) \cap \mathbf{k}(F, K)$. For each positive integer ν and each $\rho \in (0, R)$ we let

$$g_{\nu,\rho} = G \llcorner \{u \leq \rho\} + f_\nu \llcorner \{u > \rho\},$$

we note that $g_{\nu,\rho} \in \mathbf{k}(f_\nu, \{u \leq \rho\})$ and $f_\nu - g_{\nu,\rho} = (f_\nu - G)1_{\{u \leq \rho\}}$, and we conclude that

$$||\partial[f_\nu]||(\{u \leq \rho\}) \leq ||\partial[g_{\nu,\rho}||(\{u \leq \rho\}) + \lambda \int_{\{u \leq \rho\}} |G - f_\nu|\, d\mathcal{L}^n.$$

Suppose $0 < r < R$ and ν is a positive integer. Keeping in mind that $G - f_\nu = F - f_\nu$ at $\mathcal{L}^n$ almost all points of $\Omega \sim K$, we integrate this inequality from 0 to r and use (2.10) to obtain

$$\begin{aligned} r||\partial[f_\nu]||(K) &\leq \int_0^r ||\partial[f_\nu]||(\{u \leq \rho\})\, d\mathcal{L}^1 \rho \\ &\leq \int_{\{0 < u < r\}} |F - f_\nu|\, d\mathcal{L}^n + r||\partial[G]||(\{u \leq r\}) \\ &\qquad + \lambda r \int_{\{u \leq r\}} |G - f_\nu|\, d\mathcal{L}^n. \end{aligned}$$

Letting $\nu \to \infty$ we find that

$$\limsup_{\nu \to \infty} ||\partial[f_\nu]||(K) \leq ||\partial[G]||(\{u \leq r\}) + \lambda \int_{\{u \leq r\}} |G - F|\, d\mathcal{L}^n.$$

Letting $r \downarrow 0$ we infer that

$$||\partial[F]||(K) \leq ||\partial[G]||(K) + \lambda \int_K |G - F|\, d\mathcal{L}^n,$$

as desired. $\square$

THEOREM 5.3. *The following statements hold:*
(i) *If $f \in \mathcal{B}_\lambda(\Omega)$ and $y \in \mathbb{R}$, then $\{f > y\} \in \mathcal{C}_\lambda(\Omega)$.*
(ii) *If $f \in \mathbf{BV}^{loc}(\Omega)$, $D = \{y \in \mathbb{R} : \{f > y\} \in \mathcal{C}_\lambda(\Omega)\}$, and D is dense in $\mathbb{R}$, then $f \in \mathcal{B}_\lambda(\Omega)$.*
(iii) *If $\mathcal{E}$ is a nonempty nested subfamily of $\mathcal{C}_\lambda(\Omega)$, then $\cup\mathcal{E}$ and $\cap\mathcal{E}$ belong to $\mathcal{C}_\lambda(\Omega)$.*
(iv) *$E \in \mathcal{C}_\lambda(\Omega)$ if and only if $1_E \in \mathcal{B}_\lambda(\Omega)$ whenever $E \subset \Omega$.*

Proof. We begin with a lemma.

LEMMA 5.2. *Suppose $f \in \mathbf{BV}^{loc}(\Omega)$, $D = \{y \in \mathbb{R} : \{f > y\} \in \mathcal{C}_\lambda(\Omega)\}$, and $\mathcal{L}^1(\mathbb{R} \sim D) = 0$. Then $f \in \mathcal{B}_\lambda(\Omega)$.*

Proof. Suppose K is a compact subset of Ω and $g \in \mathbf{BV}^{loc}(\Omega) \cap \mathbf{k}(f, K)$. Keeping in mind (5.1) we infer from (2.14) and (2.16) that

$$\begin{aligned} ||\partial[f]||(K) &= \int_{-\infty}^{\infty} ||\partial[1_{\{f>y\}}]||(K)\, d\mathcal{L}^1 y \\ &\le \int_{-\infty}^{\infty} \left(||\partial[1_{\{g>y\}}]||(K) + \lambda \int |1_{\{f>y\}} - 1_{\{g>y\}}|\, d\mathcal{L}^n \right) d\mathcal{L}^1 y \\ &= ||\partial[g]||(K) + \lambda \int |f-g|\, d\mathcal{L}^n. \qquad \square \end{aligned}$$

Suppose $E \in \mathcal{C}_\lambda(\Omega)$. Evidently, $\{1_E > y\} \in \mathcal{C}_\lambda(\Omega)$ for all $y \in \mathbb{R}$ so, by the lemma, $1_E \in \mathcal{B}_\lambda(\Omega)$. It being trivial that $\{E : 1_E \in \mathcal{B}_\lambda(\Omega)\}$ is a subset of $\mathcal{C}_\lambda(\Omega)$, we find that (iv) holds.

Suppose $\mathcal{E}$ is a nonempty nested subfamily of $\mathcal{C}_\lambda(\Omega)$. Choose a nondecreasing sequence A and a nonincreasing sequence B in $\mathcal{E}$ such that $1_{A_\nu} \to 1_{\cup\mathcal{E}}$ and $1_{B_\nu} \to 1_{\cap\mathcal{E}}$ in $\mathbf{L}_1^{loc}(\Omega)$, as $\nu \to \infty$. From Theorem 5.2 we infer that the indicator functions of $\cup\mathcal{E}$ and $\cap\mathcal{E}$ belong to $\mathcal{B}_\lambda(\Omega)$, so (iii) now follows from (iv).

Suppose f and D are as in (ii). Since D is dense in $\mathbb{R}$ we have for any $y \in \mathbb{R}$ that

$$\{f > y\} = \cup_{z \in (y,\infty)\cap D}\{f > z\},$$

so $\{f > y\} \in \mathcal{C}_\lambda(\Omega)$ by (iii). The lemma now implies (ii).

Finally, suppose $f \in \mathcal{B}_\lambda(\Omega)$ and $y \in \mathbb{R}$. For each positive integer ν let

$$g_\nu = \nu\left(\left((f-y) \wedge \frac{1}{\nu}\right) \vee 0\right)$$

and note that $g_\nu \in \mathcal{B}_\lambda(\Omega)$ by Theorem 5.1. One readily verifies that $g_\nu \uparrow 1_{\{f>y\}}$ as $\nu \uparrow \infty$ so that, by Theorem 5.2, $1_{\{f>y\}} \in \mathcal{B}_\lambda(\Omega)$, so $\{f > y\} \in \mathcal{C}_\lambda(\Omega)$ by (iv), and thus (i) holds. $\square$

5.2. Generalized mean curvature.

PROPOSITION 5.1. *Suppose $\lambda \in [0, \infty)$, $D \in \mathcal{C}_\lambda(\Omega)$, and $X \in \mathcal{X}(\Omega)$. Then*

$$\int \operatorname{trace} P(x) \circ \partial X(x) \circ P(x)\, d||\partial[D]||x \le \lambda \int |X|\, d||\partial[D]||,$$

where, for each $x \in \mathbf{b}(D)$, we have let $P(x)$ be an orthogonal projection of $\mathbb{R}^n$ onto $\{v \in \mathbb{R}^n : v \bullet \mathbf{n}_D(x) = 0\}$.

Remark 5.2. We restate this theorem in the language of [AW1]. Let V be the $(n-1)$-dimensional varifold in Ω naturally associated to $\partial[D]$ as in [AW1, sect. 3.5]; the preceding theorem says that

$$||\delta V|| \le \lambda ||V||,$$

where δV is as in [AW1, sect. 4.2].

Proof. Let us adopt the notation of section 3. In particular, $A(t) = ||\partial[E_t]||(K)$ for $t \in I$. For any positive $t \in I$ we infer from Proposition 3.2 that

$$\frac{A(t) - A(0)}{t} \leq \frac{\lambda}{t}||[E_t] - [D]||(K) \leq \frac{1}{t}\lambda \int_0^t \left(\int |X|||\partial \dot{h}_\tau(x)||^{n-1} \, d||\partial[D]||x \right) d\mathcal{L}^1\tau.$$

The estimate to be proved now follows from Proposition 3.1. $\square$

5.3. Consequences of the monotonicity theorem.

THEOREM 5.4. *Suppose* $\lambda \in [0, \infty)$, $D \in \mathcal{C}_\lambda(\Omega)$, $a \in \Omega$, *and* $R = \mathbf{dist}\,(a, \mathbb{R}^n \sim \Omega)$. *Then*

(i) $(0, R) \ni r \mapsto e^{\lambda r}\Theta^{n-1}(||\partial[D]||, a, r)$ *is nondecreasing;*

(ii) $\Theta^{n-1}(||\partial[D]||, a)$ *exists and depends uppersemicontinuously on* a*;*

(iii) $\Theta^{n-1}(||\partial[D]||, a) \geq 1$ *if* $a \in \mathbf{spt}\,\partial[D]$*;*

if $a \in \mathbf{spt}\,[D]$, *we have*

(iv) $e^{-\lambda r}\alpha(n-1)r^{n-1} \leq ||\partial[D]||(\mathbf{U}^n(a, r))$ *whenever* $0 < r < R$*;*

(v) $e^{-\lambda r}\frac{\alpha(n-1)}{n}r^n \leq (1 + \lambda r)\mathcal{L}^n(D \cap \mathbf{U}^n(a, r))$ *whenever* $0 < r < R$.

Proof. In view of Remark 5.2, (i) follows from the monotonicity theorem of [AW1, sect. 5.1]. (i) clearly implies (ii). (iii) is a consequence of Theorem 2.1(ii) and (iii). (iv) follows directly from (i) and (iii).

Suppose $0 < r < R$. For each $\rho \in (0, r)$ let $E_\rho = D \cap \{u > \rho\}$, where we have set $u(x) = |x - a|$ for $x \in \Omega$ and note that $E_\rho \in \mathbf{k}(E, \{u \leq \rho\})$, so

$$\begin{aligned} e^{-\lambda r}\alpha(n-1)\rho^{n-1} &\leq e^{-\lambda\rho}\alpha(n-1)\rho^{n-1} \\ &\leq ||\partial[D]||(\{u \leq \rho\}) \\ &\leq ||\partial[E_\rho]||(\{u \leq \rho\}) + \lambda\Sigma_\Omega(E_\rho, D). \end{aligned}$$

Now integrate this inequality over $(0, r)$ and make use of (2.10), with f and g there equal to 1_E and 0, respectively. $\square$

Remark 5.3. It follows from (iv) that if $\Omega = \mathbb{R}^n$ and $\mathcal{L}^n(D) < \infty$, then $\mathbf{spt}\,[D]$ is compact.

COROLLARY 5.1. *Suppose* $0 < R < \infty$, $0 < r < \infty$, $a \in \Omega$, $R + r \leq \mathbf{dist}\,(a, \mathbb{R}^n \sim \Omega)$, $f \in \mathcal{B}_\lambda(\Omega)$, *and*

$$Y = \{y \in \mathbb{R} : ||\partial[\{f > y\}]||(\mathbf{U}^n(a, R)) > 0\}.$$

Then

$$\mathcal{L}^1(Y)e^{-\lambda r}\alpha(n-1)r^{n-1} \leq ||\partial[f]||(\mathbf{U}^n(a, R + r))$$

and

$$\mathcal{L}^1(Y)e^{-\lambda r}\frac{\alpha(n-1)}{n}r^n \leq (1 + \lambda r)\int_{\mathbf{U}^n(a, R+r)} |f| \, d\mathcal{L}^n.$$

Proof. For each $y \in Y \sim \{0\}$ we apply Theorem 5.4 with D there equal to $\{f > y\}$ to a ball of radius r with center at a point b, where $\Theta^{n-1}(||\partial[\{f > y\}]||, b) = 1$. $\square$

5.4. Proof of the regularity theorem for $\mathcal{C}_\lambda(\Omega)$. In view of the regularity theorem of [AW1, sect. 8] the present regularity theorem, Theorem 1.2, will follow from the following lemma.

LEMMA 5.3. *Suppose*

$$1 < \zeta < \infty.$$

There exists $\eta \in (0,1)$ *such that if* $0 \le \lambda < \infty$, $a \in \mathbb{R}^n$, $0 < R < \infty$,

$$\lambda R \le \eta, \quad E \in \mathcal{C}_\lambda(\mathbf{U}^n(a,R)), \quad \textit{and} \quad a \in \mathbf{spt}\,\partial[E],$$

then

$$\Theta^{n-1}(||\partial[E]||, a, \eta R) \le \zeta.$$

Proof. Due to the way the various entities in the lemma change under application of homotheties and translations, we find that we may assume without loss of generality that $a = 0$ and $R = 1$.

Suppose the lemma were false. Then there would exist $\zeta \in (1,\infty)$; a sequence η in $(0,1)$ with limit zero; and sequences E, λ such that, for each positive integer ν,

$$\lambda_\nu \le \eta_\nu, \quad E_\nu \in \mathcal{C}_{\lambda_\nu}(\mathbf{U}^n(0,1)), \quad \text{and} \quad 0 \in \mathbf{spt}\,\partial[E_\nu]$$

but such that

$$\Theta^{n-1}(||\partial[E_\nu]||, 0, \eta_\nu) > \zeta. \tag{5.2}$$

From the monotonicity theorem we have

$$(0,1) \ni t \mapsto e^{\lambda_\nu t}\Theta^{n-1}(||\partial[E_\nu]||, 0, t) \quad \text{is nondecreasing} \tag{5.3}$$

for each positive integer ν.

Replacing E by a subsequence if necessary we may use Theorems 2.2 and 5.2 to obtain a Lebesgue measurable subset F of $\mathbf{U}^n(0,1)$ such that $E_\nu \to F$ in $\mathbf{L}_1^{loc}(\mathbf{U}^n(0,1))$ as $\nu \to \infty$,

$$F \in \bigcap_{\nu=1}^{\infty} \mathcal{C}_{\lambda_\nu}(\mathbf{U}^n(0,1)) = \mathcal{C}_0(\mathbf{U}^n(0,1)), \tag{5.4}$$

and

$$||\partial[E_\nu]|| \to ||\partial[F]|| \quad \text{weakly as } \nu \to \infty. \tag{5.5}$$

Letting B equal the set of $t \in (0,1)$ such that $||\partial[F]||(\{x \in \mathbb{R}^n : |x| = t\})$ is positive we observed that B is countable and infer from (5.5) and (2.1) that

$$\lim_{\nu\to\infty} \Theta^{n-1}(||\partial[E_\nu], 0, t) = \Theta^{n-1}(||\partial[F], 0, t) \quad \text{for any } t \in (0,1) \sim B.$$

This together with (5.2), Theorem 5.4, and the fact that $\lambda_\nu \to 0$ as $\nu \to \infty$ implies

$$\Theta^{n-1}(||\partial[F]||, 0, t) \ge \zeta \quad \text{whenever } t \in (0,1) \sim B. \tag{5.6}$$

As $F \in \mathcal{C}_0(\mathbf{U}^n(0,1))$ we find that $\partial[F]$ is an absolutely area minimizing integral current of dimension $n-1$ in $\mathbf{U}^n(0,1)$. As Theorem 2.1 implies that

$$\Theta^{n-1}(||\partial[F]||, x) = 1 \quad \text{for } ||\partial[F]|| \text{ almost all } x$$

it follows from the regularity theorem of [FE, sect. 5.4.15] that $\partial[F]$ is integration over an oriented $(n-1)$-dimensional real analytic hypersurface M of $\mathbf{U}^n(0,1)$. Consequently, $\Theta^{n-1}(||\partial[F]||, 0) = 1$, which is incompatible with (5.6). $\square$

5.4.1. The case $n = 2$. One can do a little better than the preceding theorem if $n = 2$, as follows. Let $\mathbf{w}(m) = \sqrt{1+m^2}$ for $m \in \mathbf{R}$. Suppose V and W are nonempty open intervals, $g : V \to W$ is continuously differentiable, $0 \le \lambda < \infty$, and

$$D = \{(v,w) \in V \times W : w < g(v)\} \in \mathcal{C}_\lambda(V \times W).$$

We will show that

$$\mathbf{Lip}(\mathbf{w}' \circ g') \le \lambda. \tag{5.7}$$

Note that if g is twice differentiable, then $(\mathbf{w}' \circ g')'$ is the curvature function of the graph of g.

We prove (5.7) as follows. Suppose $\phi \in \mathcal{D}(V)$ and for each $t \in \mathbb{R}$ let $g_t = g + t\phi$. Let I be an open interval containing 0 such that if $t \in I$, then $g_t(v) \in W$ whenever $v \in V$. Let $E_t = \{(v,w) \in V \times W : w < g_t(v)\}$ for $t \in I$. We have

$$(||\partial[D]|| - ||\partial[E_t]||)(V \times W) \le \lambda \Sigma_{V\times W}(D, E_t).$$

Now

$$\lim_{t\downarrow 0} \frac{1}{t}(||\partial[D]|| - ||\partial[E_t]||)(V \times W) = -\int_I \frac{d}{dt}\mathbf{w}(g' + t\phi')\big|_{t=0}\, d\mathcal{L}^1 = -\int_I (\mathbf{w}' \circ g')\phi'\, d\mathcal{L}^1$$

and

$$\lim_{t\downarrow 0} \frac{1}{t}\Sigma_{V\times W}(D, E_t) = \int_V |\phi|\, d\mathcal{L}^1.$$

To obtain (5.7) we let ϕ approximate plus or minus one times the indicator function of a compact subinterval of V.

6. Locality. Suppose M and μ are as in Proposition 1.3.

6.1. Proof of Proposition 1.3. If M has a representation as in (1.2) where m is a bounded Borel function, it is trivial that M is local.

Suppose M is local. Then $||\mu||_{\mathbf{L}_\infty(\Omega)} \le \mathbf{l}(M)$, which implies there is a unique Radon measure on Ω whose restriction to $\mathcal{M}(\Omega)$ equals $\hat{M}$. That (1.2) holds with $m = \mu$ follows from the theory of symmetrical derivation; see, for example, [FE, sect. 2.9].

6.2. Proof of Proposition 1.4. If F has a representation as in (1.3) where k satisfies (i) and (ii) of Proposition 1.4, it is trivial that M is local, and it follows from the theory of symmetrical derivation that for $0 < y < \infty$ we have $k(x,y) = \kappa(x,y)$ for $\mathcal{L}^n$ almost all $x \in \Omega$.

Suppose F is local. For any $y \in (0,\infty)$ we have that $\mathcal{M}(\Omega) \ni E \mapsto \hat{F}(y1_E)$ is local so that, by Proposition 1.3,

$$\hat{F}(y1_E) = \int_E \kappa(x,y)\, d\mathcal{L}^n x \quad \text{for } E \in \mathcal{M}(\Omega).$$

Given $f \in \mathcal{F}(\Omega)$ and $0 = y_0 < y_1 < y_2 < \cdots < y_N < \infty$ we infer from the locality of F that

$$\hat{F}\left(\sum_{i=1}^N y_i 1_{\{y_{i-1}<f\le y_i\}}\right) = \sum_{i=1}^N \hat{F}\left(y_i 1_{\{y_{i-1}<f\le y_i\}}\right) = \sum_{i=1}^N \int_{\{y_{i-1}<f\le y_i\}} \kappa(x,y_i)\, d\mathcal{L}^n x,$$

from which the representation for $F(f)$ in (1.3) easily follows using the admissibility of F, and (i) and (ii) of Proposition 1.4 hold with $k = \kappa$.

6.3. Proof of Proposition 1.5. (i), (ii), and (iii) are immediate.

For any $x \in \Omega$ we have that $(0,\infty) \ni y \mapsto \kappa(x,y)$ is absolutely continuous so that

$$\kappa(x, f(x)) = \int_0^{f(x)} u(x,z)\, d\mathcal{L}^1 z = \int_0^{\infty} u(x,z) 1_{\{f \geq z\}}(x)\, d\mathcal{L}^1 z.$$

Integrating this equation over Ω and invoking Fubini's theorem, we infer that

$$\int_\Omega \kappa(x, f(x))\, d\mathcal{L}^n x = \int_0^\infty \left(\int_{\{f \geq z\}} u(x,z)\, d\mathcal{L}^n x \right) d\mathcal{L}^1 z. \tag{6.1}$$

For each $E \in \mathcal{M}(\Omega)$ let $\zeta(E)$ be the set of $y \in (0,\infty)$ such that

$$U_y(E) = \int_E u(x,y)\, d\mathcal{L}^n x.$$

Since $(0,\infty) \ni y \mapsto \hat{F}(y 1_E)$ is absolutely continuous we find that

$$\hat{F}(y 1_E) = \int_0^y U_y(E)\, d\mathcal{L}^1 y \quad \text{whenever } y \in (0,\infty).$$

Now assume F is local. Applying Proposition 1.4 together with (6.1) with f equal to $y1_E$, we find that

$$\int_0^y \left(\int_E u(x,z)\, d\mathcal{L}^n x \right) d\mathcal{L}^1 z = \int_0^y U_z(E)\, d\mathcal{L}^1 z \quad \text{for } y \in (0,\infty),$$

which implies that $\mathcal{L}^1((0,\infty) \sim \zeta(E)) = 0$. Let $\mathcal{E}$ be a countable subfamily of $\mathcal{M}(\Omega)$ which is dense with respect to $\Sigma_\Omega(\cdot,\cdot)$ and let $Z = \cap\{\zeta(E) : E \in \mathcal{E}\}$. Since $\mathcal{M}(\Omega) \ni E \mapsto U_y(E)$ and $\mathcal{M}(\Omega) \ni E \mapsto \int_E u(x,y)\, d\mathcal{L}^n x$ are Lipschitzian with respect to $\Sigma_\Omega(\cdot,\cdot)$, we find that

$$U_y(E) = \int_E u(x,y)\, d\mathcal{L}^n x \quad \text{whenever } y \in Z \text{ and } E \in \mathcal{M}(\Omega). \tag{6.2}$$

Since $\mathcal{L}^1((0,\infty) \sim Z) = 0$ we find that (iv) of Proposition 1.5 holds.

Suppose $f \in \mathcal{F}(\Omega)$. Use (1.3) with $k = \kappa$ to represent $F(f)$. (v) now follows from (6.1) and (6.2).

6.4. Proof of Proposition 1.6. That (i) implies (ii) is immediate. That (ii) implies (iii) is a direct consequence of the subadditivity of $\limsup$. That (iii) implies (i) follows directly from (v) of Proposition 1.5. Thus (i), (ii), and (iii) are equivalent.

We leave the proof of the following elementary lemma to the reader.

LEMMA 6.1. *Suppose $g : \mathbb{R} \to \mathbb{R}$, g is absolutely continuous, and*

$$h(y) = \liminf_{z \to y} \frac{g(z) - g(y)}{z - y} \quad \textit{for } y \in \mathbb{R}.$$

Then g is convex if and only if h is nondecreasing. Moreover, if g is convex, then h is right continuous.

The lemma implies that (iii) and (v) are equivalent. Since the admissibility of F implies that $\mathbb{R} \ni y \mapsto \hat{F}(y_E)$ is locally Lipschitzian for any $E \in \mathcal{M}(\Omega)$, the lemma implies that (ii) and (iv) are equivalent.

The final assertion follows from the right continuity assertion of the lemma.

6.5. The class $\mathcal{G}(\Omega)$. Let

$$p : \Omega \times (0, \infty) \to \Omega \quad \text{and} \quad q : \Omega \times (0, \infty) \to (0, \infty)$$

carry $(x, y) \in \Omega \times (0, \infty)$ to x and y, respectively.

Whenever G is an $\mathcal{L}^n \times \mathcal{L}^1$ measurable subset of $\Omega \times (0, \infty)$ we let

$$[G] \in \mathcal{D}_{n+1}(\Omega \times (0, \infty))$$

be as in (2.2), with $\mathbf{V}^n$ there replaced by $(p^{\#}\mathbf{V}^n) \wedge dq$; that is,

$$[G](\psi(p^{\#}\mathbf{V}^n) \wedge dq) = \int_G \psi \, d(\mathcal{L}^n \times \mathcal{L}^1) \quad \text{whenever } \psi \in \mathcal{D}(\Omega \times (0, \infty)).$$

DEFINITION 6.1. *We let*

$$\mathcal{G}(\Omega)$$

be the family of Lebesgue measurable subsets G of $\Omega \times (0, \infty)$ such that

$$(\mathcal{L}^n \times \mathcal{L}^1)(G) < \infty \quad \textit{and} \quad q[\mathbf{spt}\,[G]] \textit{ is bounded.}$$

Note that if $G \in \mathcal{G}(\Omega)$, then for $\mathcal{L}^1$ almost all $y \in (0, \infty)$ we have $\{x : (x, y) \in G\} \in \mathcal{M}(\Omega)$.

DEFINITION 6.2. *Whenever $G \in \mathcal{G}(\Omega)$ we let*

$$G^{\downarrow} : \Omega \to \mathbb{R}$$

be such that

$$G^{\downarrow}(x) = \begin{cases} \mathcal{L}^1(\{y : (x, y) \in G\}) & \textit{if } \{y : (x, y) \in G\} \in \mathcal{M}((0, \infty)), \\ 0 & \textit{otherwise.} \end{cases}$$

Note that $G^{\downarrow} \in \mathcal{F}(\Omega)$ and $\int_\Omega G^{\downarrow} \, d\mathcal{L}^n = (\mathcal{L}^n \times \mathcal{L}^1)(G)$.

DEFINITION 6.3. *Whenever $f : \Omega \to [0, \infty)$ we let*

$$f^{\uparrow} = \{(x, y) \in \Omega \times (0, \infty) : f(x) > y\}.$$

Suppose $f : \Omega \to [0, \infty)$. Evidently,

$$f \in \mathcal{F}(\Omega) \iff f^{\uparrow} \in \mathcal{G}(\Omega).$$

Tonelli's theorem implies that

$$[(f^{\uparrow})^{\downarrow}] = [f] \quad \text{whenever } f \in \mathcal{F}(\Omega).$$

PROPOSITION 6.1. *Suppose $G \in \mathcal{G}(\Omega)$, $\phi \in \mathcal{D}(\Omega)$, and $\Psi \in \mathcal{E}((0, \infty))$. Then*

$$\begin{aligned} &p_{\#} \left(\partial[G] \llcorner \Psi \circ q\right) (\phi \mathbf{V}^{\mathbf{n}}) \\ &\quad = (-1)^n [G] \left(p^{\#}(\phi \mathbf{V}^n) \wedge (\Psi' \circ q) dq\right) \\ &\quad = (-1)^n \int_\Omega \phi(x) \left(\int_{\{y:(x,y) \in G\}} \Psi' \, d\mathcal{L}^1 \right) d\mathcal{L}^n x. \end{aligned} \tag{6.3}$$

Proof. The first equation follows from the fact that

$$d((\Psi \circ q) \wedge p^{\#}(\phi \mathbf{V}^n)) = (\Psi' \circ q) dq \wedge p^{\#}(\phi \mathbf{V}^n),$$

and the second follows from Fubini's theorem. ◻

COROLLARY 6.1. *Suppose $G \in \mathcal{G}(\Omega)$. Then*

$$[G^{\downarrow}] = (-1)^n p_{\#}\left((\partial[G]) \llcorner q\right) \quad \textit{and} \quad \partial[G^{\downarrow}] = (-1)^{n+1} p_{\#}((\partial[G]) \llcorner dq).$$

Proof. Letting $\Psi(y) = y$ for $y \in \mathbb{R}$ in the preceding proposition we deduce the first equation; the second equation is an immediate consequence of the first. ◻

PROPOSITION 6.2. *Suppose $G \in \mathcal{G}(\Omega)$ and $\partial[G]$ is representable by integration. Then*

$$||\partial[G^{\downarrow}]||(B) \leq \int_0^{\infty} ||\partial[\{x : (x, y) \in G\}]||(B)\, d\mathcal{L}^1 y \quad \textit{for any Borel subset } B \textit{ of } \Omega.$$

Proof. Suppose U is an open subset of Ω, $\omega \in \mathcal{D}^{n-1}(\Omega)$, $\mathbf{spt}\, \omega \subset U$, and $|\omega| \leq 1$. For each $y \in (0, \infty)$ let $i_y(x) = (x, y)$ for $x \in \Omega$. From [FE, sect. 4.3.8] we have

$$\langle [G], q, y \rangle = i_{y\#}[\{x : (x, y) \in G\}] \quad \text{for } \mathcal{L}^1 \text{ almost all } y.$$

From Corollary 6.1, (2.8), and (2.7) we find that

$$\begin{aligned} (-1)^{n+1} \partial[G^{\downarrow}](\omega)| &= ((\partial[G]) \llcorner dq)(p^{\#}\omega) \\ &= \int_0^{\infty} \langle \partial[G], q, y \rangle (p^{\#}\omega)\, d\mathcal{L}^1 y \\ &= -\int_0^{\infty} \partial[\{x : (x, y) \in G\}](\omega)\, d\mathcal{L}^1 y \\ &\leq \int_0^{\infty} ||\partial[\{x : (x, y) \in G\}]||(U)\, d\mathcal{L}^1 y, \end{aligned}$$

from which the inequality to be proved immediately follows. ◻

6.6. Proof of Theorems 1.3 and 1.4. We now assume $F : \mathcal{F}(\Omega) \to \mathbb{R}$, F is local, and F is convex. In order to prove the fundamental theorems, Theorems 1.3 and 1.4, we will use F to define a functional $F^{\uparrow}$ on subsets of $\Omega \times \mathbb{R}$, which will be very useful in analyzing $\mathbf{n}_{\epsilon}^{loc}(F)$. This is one of the main new ideas of the paper.

We leave to the reader the elementary proof of the following proposition.

PROPOSITION 6.3. *Suppose $G \in \mathcal{G}(\Omega)$. Then*

$$(0, \infty) \ni y \mapsto U_y(\{x : (x, y) \in G\}) \textit{ is } \mathcal{L}^1 \textit{ summable.}$$

DEFINITION 6.4. *Let*

$$F^{\uparrow} : \mathcal{G}(\Omega) \to \mathbb{R}$$

be such that

$$F^{\uparrow}(G) = F(0) + \int_0^{\infty} U_y(\{x : (x, y) \in G\})\, d\mathcal{L}^1 y \quad \textit{whenever } G \in \mathcal{G}(\Omega).$$

We have a useful comparison principle.

THEOREM 6.1. *We have*

$$F(G^{\downarrow}) \leq F^{\uparrow}(G) \quad \textit{whenever } G \in \mathcal{G}(\Omega).$$

Proof. As we shall see, the theorem will follow rather directly from the following lemma.

LEMMA 6.2. *Suppose $a \in \Omega$ and $E \in \mathcal{M}((0,\infty))$. Then*

$$\kappa(a, \mathcal{L}^1(E)) \leq \int_E u(a,y)\, d\mathcal{L}^1 y.$$

Proof. Suppose $\phi \in \mathcal{D}((0,\infty))$ and $0 \leq \phi \leq 1$. Let $\Phi \in \mathcal{E}((0,\infty))$ be such that $\Phi' = \phi$ and $\lim_{y \downarrow 0} \Phi(y) = 0$. Then

$$0 \leq \Phi(y) \leq y \quad \text{if } 0 < y < \infty. \tag{6.4}$$

Thus, as $(0,\infty) \ni y \mapsto \kappa(a,y)$ is absolutely continuous and $(0,\infty) \ni y \mapsto u(a,y)$ is nondecreasing, we have

$$\kappa(a, \Phi(y)) = \int_0^y u(a, \Phi(y))\phi(y)\, d\mathcal{L}^1 y \leq \int_0^y u(a,y)\phi(y)\, d\mathcal{L}^1 y \quad \text{for } 0 < y < \infty.$$

We complete the proof by letting ϕ approximate the indicator function of E. □

From the lemma we infer that

$$\kappa(x, G^{\downarrow}(x)) \leq \int_{\{y:(x,y)\in G\}} u(x,y)\, d\mathcal{L}^1 y \quad \text{for } \mathcal{L}^n \text{ almost all } x \in \Omega.$$

Integrating this inequality over Ω we use (iv) and (v) of Proposition 1.5 to obtain

$$F(G^{\downarrow}) - F(0) \leq \int_0^{\infty} U_y(\{x : (x,y) \in G\})\, d\mathcal{L}^1 y = F^{\uparrow}(G) - F(0),$$

as desired. □

6.7. Proof of Theorem 1.3. We may assume without loss of generality that $F = \hat{F}$. For each $y \in (0,\infty)$ we let $D_y = \{f > y\}$.

Suppose $0 < b < \infty$, K is a compact subset of Ω, and $E \in \mathbf{k}(D_b, K)$. We need to show that

$$\epsilon||\partial[D_b]||(K) + U_b(D_b) \leq \epsilon||\partial[E]||(K) + U_b(E). \tag{6.5}$$

Let $u(x) = \mathbf{dist}\,(x,K)$ for $x \in \Omega$ and let R be the supremum of the set of $r \in (0,\infty)$ such that $\{v \leq r\} \subset \Omega$. For each $(y,r) \in (0,\infty) \times (0,R)$ let

$$\begin{aligned} C_{y,r} &= (E \cap \{v \leq r\}) \cup (D_y \cap \{v > r\}) \in \mathcal{M}(\Omega), \\ a(y,r) &= \epsilon||\partial[D_y]||(\{v \leq r\}) + U_y(D_y), \\ b(y,r) &= \epsilon||\partial[C_{r,y}]||(\{v \leq r\}) + U_y(C_{r,y}). \end{aligned}$$

Let

$$W = \{(y,r) \in (0,\infty) \times (0,R) : a(y,r) \leq b(y,r)\}.$$

LEMMA 6.3. *For $\mathcal{L}^1$ almost all $y \in (0,\infty)$ we have*

$$a(y,r) \leq b(y,r)\} \quad \textit{for } \mathcal{L}^1 \textit{ almost all } r \in (0,R).$$

Proof. Suppose $r \in (0, R)$, B is a Borel subset of $(0, \infty)$, and

$$G = \{(x, y) \in \Omega \times ((0, \infty) \sim B) : x \in D_y\} \cup \{(x, y) \in \Omega \times B : x \in C_{y,r}\}.$$

Evidently, $G^{\downarrow}(x) = f(x)$ for $\mathcal{L}^n$ almost all $x \in \{v > r\}$, from which it follows that

$$\epsilon ||\partial[f]||(\{v \le r\}) + F(f) \le \epsilon ||\partial[G^{\downarrow}]||(\{v \le r\}) + F(G^{\downarrow}).$$

Let

$$P = \int_{(0,\infty)\sim B} ||\partial[D_y]||(\{v \le r\})\, d\mathcal{L}^1 y \quad \text{and} \quad Q = \int_{(0,\infty)\sim B} U_y(D_y)\, d\mathcal{L}^1 y.$$

We have

$$||\partial[f]||(\{v \le r\}) = P + \int_B ||\partial[D_y||(\{v \le r\})\, d\mathcal{L}^1 y \quad \text{and} \quad F(f) = Q + \int_B U_y(D_y)\, d\mathcal{L}^1 y.$$

From Corollary 6.1 and Proposition 6.2 we obtain

$$\begin{aligned} ||\partial[G^{\downarrow}]||(\{v \le r\}) &\le ||\partial[G] \llcorner dq||(\{v \le r\} \times (0, \infty)) \\ &= \int ||\partial[\{x : (x, y) \in G\}]||(\{v \le r\})\, d\mathcal{L}^1 y \\ &= P + \int_B ||\partial[C_{y,r}]||(\{v \le r\}). \end{aligned}$$

From (6.1) we obtain

$$F(G^{\downarrow}) \le F^{\uparrow}(G) = Q + \int_B U_y(C_{r,y})\, d\mathcal{L}^1 y,$$

which implies

$$\int_B a(y, r)\, d\mathcal{L}^1 y \le \int_B b(y, r)\, d\mathcal{L}^1 y.$$

Owing to the arbitrariness of B we infer that $a(y, r) \le b(y, r)$ for $\mathcal{L}^1$ almost all $y \in (0, \infty)$, so the lemma follows from Tonelli's theorem. $\square$

We have $(D_y \sim D_b) \cup (D_b \sim D_y) = \{b < f \le y\}$ whenever $b < y < \infty$, so that

$$\lim_{y \downarrow b} \Sigma_\Omega(D_y, D_b) = 0. \tag{6.6}$$

This implies that

$$\lim_{y \downarrow b} \Sigma_{\Omega \sim K}(D_y, E) = \lim_{y \downarrow b} \Sigma_{\Omega \sim K}(D_y, D_b) = 0. \tag{6.7}$$

By Proposition 1.5(iv) we have

$$\begin{aligned} |U_y(D_y) - U_b(D_b)| &\le |U_y(D_y) - U_y(D_b)| + |U_b(D_y) - U_b(D_b)| \\ &\le \mathbf{l}(F, Y)\Sigma_\Omega(D_y, D_b) + |U_b(D_y) - U_b(D_b)| \end{aligned}$$

as well as

$$|U_y(C_{y,r}) - U_y(E)| \le \mathbf{l}(F, Y)\Sigma_{\{u > r\}}(D_y, E) \le \mathbf{l}(F, Y)\Sigma_{\Omega \sim K}(D_y, D_b) \tag{6.8}$$

whenever $0 < y < Y < \infty$. With the help of (6.6) and Proposition 1.6 we infer that

$$\lim_{y \downarrow b} U_y(D_y) = U_b(D_b). \tag{6.9}$$

Suppose $0 < r < R$. Since (6.6) and (2.1) imply that

$$||\partial[D_b]||(K) \le \liminf_{y \downarrow b} ||\partial[D_y]||(\{u \le \rho\}) \quad \text{for } 0 < \rho < R,$$

we infer from (6.9) that

$$r\,(||\partial[D_b]||(K) + U_b(D_b)) \le \liminf_{y \downarrow b} \int_0^r a(y,\rho)\, d\mathcal{L}^1\rho. \tag{6.10}$$

Applying (2.10), with f there equal to 1_{D_y} and g there equal to 1_E, and using (6.6), (6.7), (6.8), and (6.9), we find that

(6.11)
$$\int_0^r b(y,\rho)\, d\mathcal{L}^1\rho \le \Sigma_{\{u>r\}}(D_y, E) + \int_0^r ||\partial[E]||(\{u \le \rho\})\, d\mathcal{L}^1\rho + \int_0^r U_y(C_{y,\rho})\, d\mathcal{L}^1\rho$$
$$\to \int_0^r ||\partial[E]||(\{u \le \rho\}) + U_b(E)\, d\mathcal{L}^1\rho \quad \text{as } y \downarrow b.$$

Using Lemma 6.2 and Tonelli's theorem we may choose a sequence y in (b,∞) with limit b such that

$$\mathcal{L}^1(\{r \in (0,R) : (y_\nu, r) \notin W\}) = 0 \quad \text{for } \nu = 1,2,3,\ldots.$$

Thus

$$\int_0^r a(y_\nu,\rho)\, d\mathcal{L}^1\rho \le \int_0^r b(y_\nu,\rho)\, d\mathcal{L}^1\rho,$$

so (6.10) and (6.11) imply

$$r\,(||\partial[D_b]||(K) + U_b(D_b)) \le \int_0^r ||\partial[E]||(\{u \le \rho\}) + U_b(E)\, d\mathcal{L}^1\rho;$$

dividing by r and letting $r \downarrow 0$ we obtain (6.5).

We leave it to the reader to modify the proof just given in a straightforward way to show that $\{f \ge b\} \in \mathbf{n}_\epsilon^{loc}(L_b)$.

6.8. Proof of Theorem 1.4. Let K be a compact subset of Ω and let $g \in \mathcal{F}(\Omega)$ such that $\mathbf{spt}\,[G^\downarrow - g] \subset K$.

Suppose $y \in (0,\infty)$. Since $G^\downarrow(x) = g(x)$ for $\mathcal{L}^n$ almost all $x \in \Omega \sim K$ we find that

$$\mathbf{spt}\,[\{G^\downarrow > y\}] - [\{g > y\}] \subset K,$$

so that if $\{x : (x,y) \in G\} \in \mathbf{n}_\epsilon^{loc}(U_y)$, we have

$$||\partial[\{G^\downarrow > y\}]||(K) + U_y(\{G^\downarrow > y\}) \le ||\partial[\{g > y\}]||(K) + U_y(\{g > y\}).$$

Integrating over $y \in (0, \infty)$ with respect to $\mathcal{L}^1$ and using Proposition 6.2, Theorem 6.1, (2.6), and Proposition 1.5(v), we find that

$$
\begin{aligned}
&||\partial[G^{\downarrow}]||(K) + F(G^{\downarrow}) \\
&\qquad \leq \int_0^\infty ||\partial[\{G^{\downarrow} > y\}]||(K)\, d\mathcal{L}^1 y + F^{\uparrow}(G) \\
&\qquad = \int_0^\infty ||\partial[\{G^{\downarrow} > y\}]||(K) + U_y(\{G^{\downarrow} > y\})\, d\mathcal{L}^1 y \\
&\qquad \leq \int_0^\infty ||\partial[\{g > y\}]||(K) + U_y(\{g > y\})\, d\mathcal{L}^1 y \\
&\qquad = ||\partial[g]||(K) + F(g).
\end{aligned}
$$

It remains to deal with (1.6). For each $E \in \mathcal{M}(\Omega)$ let $C(E)$ be the set of $y \in (0, \infty)$ such that $L_y(E) \neq U_y(E)$. Since $(0, \infty) \ni \mapsto F(y 1_E)$ is convex we find that $C(E)$ is countable. Now choose a countable subfamily $\mathcal{E}$ of $\mathcal{M}(\Omega)$ which is dense with respect to the pseudometric $\Sigma_\Omega(\cdot, \cdot)$. By a straightforward approximation argument, which we leave to the reader, we find that $L_y(D) = U_y(D)$ whenever $D \in \mathcal{M}(\Omega)$ and $y \notin \cup\{C(E) : E \in \mathcal{E}\}$.

7. Proof of Theorem 1.6. Theorem 1.6 will be proved by calculating the appropriate first and second variations, invoking the regularity theorem for $\mathcal{C}_\lambda(\Omega)$, and then utilizing higher regularity results for the minimal surface equation.

For each $x \in \mathbf{b}(D)$ we let $P(x)$ equal the orthogonal projection of $\mathbb{R}^n$ onto $\{v \in \mathbb{R}^n : v \bullet \mathbf{n}_D(x) = 0\}$.

We may assume without loss of generality that $U = \Omega$. It follows from Proposition 1.2 and Theorem 1.2 that $\Sigma_\Omega(D, \Gamma) = 0$, so $[D] = [\Gamma]$.

Part 1. Suppose $a \in M$. From Proposition 1.2 and Theorem 1.2 there are Ψ, V, r, g such that Ψ carries $\mathbb{R}^{n-1} \times \mathbb{R}$ isometrically onto $\mathbb{R}^n$, $\Psi(0,0) = a$, V is an open subset of $\mathbb{R}^{n-1}$, $0 \in V$, $0 < r < \infty$, $g : V \to (-r, r)$ is of class $C^{1,\mu}$, $\Psi[V \times (-r, r)] \subset \Omega$, and

$$\Gamma \cap \Psi[V \times (-r, r)] = \Psi[\{(v, w) \in V \times (-r, r) : w < g(v)\}].$$

Suppose $\phi \in \mathcal{D}(V)$. Choose an open interval I such that $0 \in I$ and $g(v) + t\phi(v) \in (-r, r)$ whenever $(v, t) \in V \times I$. For each $t \in I$ let

$$\Phi(t) = \epsilon \int_V \sqrt{1 + |\nabla(g + t\phi)|^2}\, d\mathcal{L}^{n-1} + \int_V \left(\int_{-r}^{(g+t\phi)(v)} \zeta(\Psi(v, w))\, d\mathcal{L}^1 w \right) d\mathcal{L}^{n-1} v.$$

Then $\Phi(0) \leq \Phi(t)$ whenever $t \in I$ since $D \in \mathbf{n}_\epsilon^{loc}(Z)$. Thus

$$0 = \Phi'(0) = \epsilon \int_V \frac{\nabla g \bullet \nabla \phi}{\sqrt{1 + |\nabla g|^2}}\, d\mathcal{L}^n + \int_V \zeta(\Psi(v, g(v)))\phi(v)\, d\mathcal{L}^n.$$

That is, g is a weak solution of

$$-\epsilon \operatorname{div} J^{-1} \nabla g + \zeta \circ \Psi \circ G = 0,$$

where we have set $J = \sqrt{1 + |\nabla g|^2}$ and $G(v) = (v, g(v))$ for $v \in V$.

Inasmuch as ∂g is Hölder continuous, standard results on regularity of weak solutions of elliptic equations, as found, for example, in [GT, sect. 8.3], imply that g is of class $C^{k+2,\mu}$. Since a is an arbitrary point of M we conclude that M is of class $C^{k+2,\mu}$, so M has a second fundamental form. Since $H(a) \bullet \mathbf{n}_\Gamma(a) = -\operatorname{div} J^{-1}\nabla g(0)$ we find that (1.7) holds.

Part 2. We now suppose ζ is continuously differentiable. Let Π, Q, H be as in section 4.

Since M is of class C^2 by Part 1 there is a map $N : \Omega \to \mathbb{R}^n$ of class C^1 such that $N|M = \mathbf{n}_\Gamma|M$.

Suppose $\phi \in \mathcal{D}(\Omega)$. Let $X = \phi N$, and let K; I; h_t, $t \in I$; E_t, $t \in I$; P; and a_1 and a_2 be as in section 3. Let Y be as in Proposition 3.3. Since $\partial X = (\partial\phi)N + \phi(\partial N)$ we find that

$$
\begin{aligned}
l_1 &= P \circ \partial(\phi N) \circ P = \phi\,(P \circ \partial N \circ P),\\
l_2 &= P^\perp \circ \partial(\phi N) \circ P = ((\partial\phi) \circ P)\,N,\\
\operatorname{trace} l_1 &= \phi(H \bullet N),\\
\operatorname{trace} l_2^* \circ l_2 &= |(\partial\phi) \circ P|^2,\\
\operatorname{trace} l_1 \circ l_1 &= \phi^2 Q.
\end{aligned} \tag{7.1}
$$

For each $t \in I$ let

$$\Phi(t) = \epsilon||\partial[E_t]||(K) + Z(E_t).$$

Let A and B be as in Propositions 3.1 and 3.3, respectively, so $\Phi(t) = \epsilon A(t) + B(t)$ for $t \in I$. Since $\Phi(0) \le \Phi(t)$ for $t \in I$ we have

$$0 \le \epsilon A''(0) + B''(0). \tag{7.2}$$

We have

$$
\begin{aligned}
a_2 &= (\operatorname{trace} l_1)^2 + \operatorname{trace}(l_2^* \circ l_2 - l_1 \circ l_1)\\
&= \phi^2(H \bullet N)^2 + |\partial\phi \circ P|^2 - \phi^2 Q^2\\
&= \phi^2 \frac{\zeta^2}{\epsilon^2} + |\partial\phi \circ P|^2 - \phi^2 Q^2.
\end{aligned}
$$

Making use of (1.7) we obtain

$$
\begin{aligned}
&\big(\zeta Y + (\nabla\zeta \bullet X)X\big) \bullet N\\
&\quad = (\zeta(\phi(H \bullet N)\phi N) - \nabla\zeta \bullet (\phi N)\phi N) \bullet N\\
&\quad = -\frac{\zeta^2}{\epsilon}\phi^2 + \phi^2(\nabla\zeta \bullet N).
\end{aligned}
$$

So (1.8) now follows from (7.2) and Propositions 3.1 and 3.3.

8. The denoising case revisited. Suppose

(i) s, γ, and F are as in section 1.8;

(ii) γ is convex and β is as in section 1.8;

(iii) U is an open subset of Ω, $z \in \mathbb{R}$, and

$$s(x) = z \quad \text{for } x \in U;$$

(iv) $0 < y < \infty$ and β is continuously differentiable near $y - z$;

(v) $0 < \epsilon < \infty$ and $f \in \mathbf{m}_\epsilon^{loc}(F)$;

(vi) Γ is the intersection of U with the interior of the support of $[\{f > y\}]$, and M is the intersection of U with the boundary of Γ;

(vii) H is the mean curvature vector of M, and Q is the square of the length of the second fundamental form of M.

From Theorems 1.3 and 1.6 we find that $[\Gamma] = [U \cap \{f > y\}]$, that

$$H(x) = -\frac{1}{\epsilon}\beta(y-z)\mathbf{n}_\Gamma(x) \quad \text{whenever } x \in M,$$

and that

$$\int_M |\nabla_M \phi(x)|^2 - \phi(x)^2 Q(x)\, d\mathcal{H}^{n-1}x \geq 0$$

for any $\phi \in \mathcal{D}(\Omega)$, where, for each $x \in M$, $\nabla_M \phi(x)$ is the orthogonal projection of $\nabla\phi(x)$ on $\mathbf{Tan}(M, x)$.

Now suppose $n = 2$, let $a \in M$, and let A be the connected component of a in M. If $\beta(y-z) = 0$, then A is a subset of a straight line. Suppose $\beta(y-z) \neq 0$ and let

$$R = \frac{\epsilon}{|\beta(y-z)|}.$$

Then A is an arc of a circle of radius R. Let c be the center of this circle. Then for each $a \in A$, there is an open subset G of U containing a such that

$$\Gamma \cap G = \begin{cases} \mathbf{U}^2(c, R) \cap G & \text{if } \beta(y-z) < 0, \\ (\mathbb{R}^n \sim \mathbf{U}^2(c, R)) \cap G & \text{if } \beta(y-z) > 0. \end{cases}$$

Finally, let L be the length of A. Since $Q(x) = 1/R^2$ for $x \in M$ we find that

$$\int_0^L \phi'(\sigma)^2 - \frac{1}{R^2}\phi(\sigma)^2\, d\mathcal{L}^1\sigma \geq 0$$

for all continuously differentiable $\phi : [0, L] \to \mathbb{R}$ which are differentiable on $(0, L)$ and which vanish at 0 and L. Letting $\phi(\sigma) = \sin(\pi\sigma/L)$ for $\sigma \in [0, L]$ we infer that

$$L \leq \pi R.$$

9. Some results for functionals on sets.

9.1. Proof of Theorem 1.7. We begin with a simple lemma.

LEMMA 9.1. *Suppose A is a nested sequence in $\mathbf{n}_\epsilon^{loc}(N_S)$. Then $\cap_{\nu=1}^\infty A_\nu \in \mathbf{n}_\epsilon^{loc}(N_S)$ and, provided $\mathcal{L}^n(\cup_{\nu=1}^\infty A_\nu) < \infty$, $\cup_{\nu=1}^\infty \in \mathbf{n}_\epsilon^{loc}(N_S)$.*

We leave to the reader the straightforward proof making use of (2.1) and cutoff arguments like those used in the proof of Theorem 5.2.

Let

$$F(f) = \int_\Omega |f - 1_S|\, d\mathcal{L}^n \quad \text{for } f \in \mathcal{F}(\Omega).$$

For each $y \in \mathbb{R}$ let U_y be as in Theorem 1.5. Recall from section 1.9 that

$$U_y = \begin{cases} 0 & \text{if } 1 \leq y < \infty, \\ \widehat{N_S} & \text{if } 0 < y < 1. \end{cases}$$

Suppose $A, B \in \mathcal{A}$ and $0 < a < b < c < 1$. Let

$$G = (A \times (0,b)) \cup (B \times (b,1)) \in \mathcal{G}(\Omega).$$

Then $\{x : (x,y) \in G\} \in \mathbf{n}_\epsilon^{loc}(U_y)$ whenever $0 < y < \infty$, so $G^\downarrow \in \mathbf{m}_\epsilon^{loc}(F)$ by Theorem 1.4. From Theorem 1.3 we infer that $A \cup B = \{G^\downarrow > a\} \in \mathbf{n}_\epsilon^{loc}(U_a)$ and $A \cap B = \{G^\downarrow > c\} \in \mathbf{n}_\epsilon^{loc}(U_c)$, so $A \cup B$ and $A \cap B$ belong to $\mathbf{n}_\epsilon^{loc}(N_S)$.

It follows that if $\mathcal{F}$ is a finite subfamily of $\mathcal{A}$, then $\cup\mathcal{F}$ and $\cap\mathcal{F}$ belong to $\mathbf{n}_\epsilon^{loc}(N_S)$.

Let B be a sequence in $\mathcal{A}$ such that

$$\lim_{\nu\to\infty} \mathcal{L}^n(B_\nu) = \inf\{\mathcal{L}^n(A) : A \in \mathcal{A}\}.$$

Since each of $\cap_{\nu=1}^N B_\nu$ belongs to $\mathbf{n}_\epsilon^{loc}(N_S)$ we infer from the preceding lemma that $C = \cap_{\nu=1}^\infty B_\nu \in \mathbf{n}_\epsilon^{loc}(N_S)$. It is clear that $\mathcal{L}^n(C \sim \cap\mathcal{A}) = 0$, so $\cap\mathcal{A} \in \mathbf{n}_\epsilon^{loc}(N_S)$.

Let us now assume $\mathcal{L}^n(\cup\mathcal{A}) < \infty$. Let D be a sequence in $\mathcal{A}$ such that

$$\lim_{\nu\to\infty} \mathcal{L}^n(D_\nu) = \sup\{\mathcal{L}^n(A) : A \in \mathcal{A}\}.$$

Since each of $\cup_{\nu=1}^N D_\nu$ belongs to $\mathbf{n}_\epsilon^{loc}(N_S)$ we infer from the preceding lemma that $E = \cup_{\nu=1}^\infty D_\nu \in \mathbf{n}_\epsilon^{loc}(N_S)$. It is clear that $\mathcal{L}^n(\cup\mathcal{A} \sim E) = 0$, so $\cup\mathcal{A} \in \mathbf{n}_\epsilon^{loc}(N_S)$.

9.2. A comparison principle. The following proposition and its proof were suggested by a similar result found in [CA1] in a different context.

PROPOSITION 9.1. *Suppose $M, N \in \mathbf{M}(\Omega)$, M and N are local, $0 < \epsilon < \infty$, $D \in \mathbf{n}_\epsilon^{loc}(M)$, $E \in \mathbf{n}_\epsilon^{loc}(N)$, and $\mathbf{spt}\,[D \cup E]$ is compact. Then*

$$\hat{N}(E \sim D) \le \hat{M}(E \sim D).$$

In particular, if

$$\hat{M}(G) < \hat{N}(G) \quad \textit{whenever } G \in \mathcal{M}(\Omega) \textit{ and } \mathcal{L}^n(G) > 0,$$

then

$$\mathcal{L}^n(E \sim D) = 0.$$

Proof. Without loss of generality we may assume $M = \hat{M}$ and $N = \hat{N}$. Since $\mathbf{spt}\,[D] \cup \mathbf{spt}\,[E] \subset \mathbf{spt}\,[D \cup E]$ we have

$$\epsilon\mathbf{M}(\partial[D]) + M(D) \le \epsilon\mathbf{M}(\partial[D \cup E]) + M(D \cup E)$$

and

$$\epsilon\mathbf{M}(\partial[E]) + N(E) \le \epsilon\mathbf{M}(\partial[D \cap E]) + N(D \cap E).$$

Also,

$$\begin{aligned}
&\mathbf{M}(\partial[D \cup E]) + \mathbf{M}(\partial[D \cap E]) \\
&\quad = \int_0^1 \mathbf{M}(\partial[\{1_D + 1_E > y\}])\, d\mathcal{L}^1 y + \int_1^2 \mathbf{M}(\partial[\{1_D + 1_E > y\}])\, d\mathcal{L}^1 y \\
&\quad = \mathbf{M}(\partial[1_D + 1_E]) \\
&\quad \le \mathbf{M}(\partial[D]) + \mathbf{M}(\partial[E]).
\end{aligned}$$

Since M and N are local it follows that

$$
\begin{aligned}
&\epsilon(\mathbf{M}(\partial[D]) + \mathbf{M}(\partial[E])) + M(D \sim E) + M(D \cap E) + N(E \sim D) + N(E \cap D)\\
&= \epsilon(\mathbf{M}(\partial[D]) + \mathbf{M}(\partial[E])) + M(D) + N(E)\\
&\leq \epsilon(\mathbf{M}(\partial[D \cup E]) + \mathbf{M}(\partial[D \cap E])) + M(D \cup E) + N(D \cap E)\\
&\leq \epsilon(\mathbf{M}(\partial[D]) + \mathbf{M}(\partial[E])) + M(D \cup E) + N(D \cap E)\\
&= \epsilon(\mathbf{M}(\partial[D]) + \mathbf{M}(\partial[E])) + M(D \sim E) + M(D \cap E) + M(E \sim D) + N(E \cap D). \qquad \square
\end{aligned}
$$

9.3. Proof of Theorem 1.5. Suppose $0 < y < z < \infty$. Since F is strictly convex we have

$$\beta(x, y) < \beta(x, z) \quad \text{for } \mathcal{L}^n \text{ almost all } x \in \Omega.$$

This in turn implies that $U_y(D) < U_z(D)$ whenever $D \in \mathcal{M}(\Omega)$. Applying Proposition 9.1 with M, N there equal to U_y, U_z and D, E there equal to $\{f > y\}, \{x : (x, z) \in G\}$ and $\{x : (x, y) \in G\}, \{f > z\}$, respectively, we infer that

$$\text{(i)} \qquad \mathcal{L}^n(\{x : (x, z) \in G\} \sim \{f > y\}) = 0$$

and

$$\text{(ii)} \qquad \mathcal{L}^n(\{f > z\} \sim \{x : (x, y) \in G\}) = 0.$$

Suppose $0 < w < \infty$. Letting $z = w$ and $y \uparrow w$ in (i) we find that

$$\mathcal{L}^n(\{x : (x, w) \in G\} \sim \{f \geq w\}) = 0.$$

Letting $y = w$ and $z \downarrow w$ in (ii) we find that

$$\mathcal{L}^n(\{f > w\} \sim \{x : (x, w) \in G\}) = 0.$$

Since $\mathcal{L}^n(\{f = w\}) = 0$ for all but countably many $w \in (0, \infty)$ we may use Tonelli's theorem to complete the proof.

10. Two useful theorems in the denoising case. We suppose throughout this subsection that $\gamma : \mathbb{R} \to \mathbb{R}$, γ is locally Lipschitzian, γ is decreasing on $(-\infty, 0)$, and γ is increasing on $(0, \infty)$. We let

$$F(f) = \int_\Omega \gamma(f(x) - s(x))\, d\mathcal{L}^n x \quad \text{whenever } f \in \mathcal{F}(\Omega).$$

10.1. A simple maximum principle.

Proposition 10.1. *Suppose* $0 < \epsilon < \infty$, $f \in \mathbf{m}_\epsilon^{loc}(F)$, *and*

$$u = \inf\{||1_{\Omega \sim K} f||_{\mathbf{L}_\infty(\Omega)} : K \textit{ is a compact subset of } \Omega\}.$$

Then $||f||_{\mathbf{L}_\infty(\Omega)} \leq u \vee ||s||_{\mathbf{L}_\infty(\Omega)}$.

Remark 10.1. It follows from Corollary 5.1 that $u = 0$ if $\Omega = \mathbb{R}^n$.

Proof. Suppose $u \vee ||s||_{\mathbf{L}_\infty(\Omega)} < M < \infty$. Then $K = \mathbf{spt}\,[f - f \wedge M]$ is a compact subset of Ω, so

$$
\begin{aligned}
&\int_{\{f > M\}} \gamma(f(x) - s(x)) - \gamma(M - s(x))\, d\mathcal{L}^n x\\
&\qquad = F(f) - F(f \wedge M)\\
&\qquad \leq \epsilon(||\partial[f \wedge M]||(K) - ||\partial[f]||(K))\\
&\qquad = -\int_M^\infty ||\partial[\{f > y\}]||(K)\, d\mathcal{L}^1 y\\
&\qquad \leq 0.
\end{aligned}
$$

If $f(x) > M > s(x)$, then $f(x) - s(x) > M - s(x) > 0$, so that $\gamma(f(x) - s(x)) - \gamma(M - s(x)) > 0$. Owing to the arbitrariness of M we find that the proposition holds. $\square$

THEOREM 10.1. *Suppose $\Omega = \mathbb{R}^n$, $0 < \epsilon < \infty$, $f \in \mathbf{m}_\epsilon^{loc}(F)$, and, for each $y \in (0, \infty)$,*

$$C(y) \text{ equals the closed convex hull of } \mathbf{spt}\,[\{s > y\}].$$

Then

$$\mathbf{spt}\,[\{f > y\}] \subset C(y) \quad \text{whenever } 0 < y < \infty.$$

Proof. Suppose $0 < b < \infty$. Let $g_b = f1_{\{f<b\}} + b1_{\{f \geq b\} \sim C(b)} + f1_{\{f \geq b\} \cap C(b)}$ and note that

$$\{g_b > y\} = \begin{cases} \{f > y\} & \text{if } y \leq b, \\ \{f > y\} \cap C(b) & \text{if } y > b \end{cases} \quad \text{whenever } y \in \mathbb{R}.$$

It follows from (2.12) that $\mathbf{M}(\partial[\{g_b > y\}]) \leq \mathbf{M}(\partial[\{f > y\}])$ whenever $y \in \mathbb{R}$.

Let $K_b = \mathbf{spt}\,[f - g_b]$. Since $\{f - g_b \neq 0\} \subset \{f > b\}$ we infer from Theorems 1.1 and 5.4(v) that K_b is compact. Since $f \in \mathbf{m}_\epsilon^{loc}(F)$ we infer with the help of (5.1) that

$$\begin{aligned}
\int_{\{f>b\} \sim C(b)} & \gamma(f(x) - s(x)) - \gamma(b - s(x))\, d\mathcal{L}^n x \\
&= F(f) - F(g_b) \\
&\leq \epsilon(||\partial[g_b]||(K_b) - ||\partial[f]||(K_b)) \\
&= \epsilon \int_b^\infty ||\partial[\{g_b > y\}]||(K_b) - ||\partial[\{f > y\}]||(K_b)\, d\mathcal{L}^1 y \\
&\leq 0,
\end{aligned}$$

which implies $\mathcal{L}^n(\{f > b\} \sim C(b)) = 0$. $\square$

10.1.1. Convex containment.

PROPOSITION 10.2. *Suppose $M \in \mathbf{M}(\mathbb{R}^n)$, M is local, C is a closed convex subset of $\mathbb{R}^n$, and*

$$M(E) \geq M(\emptyset) \quad \text{whenever } E \in \mathcal{M}(\mathbb{R}^n) \text{ and } \quad \mathcal{L}^n(E \cap C) = 0. \tag{10.1}$$

Then $\mathbf{spt}\,[D]$ is a compact subset of C whenever $D \in \mathbf{n}_\epsilon^{loc}(M)$.

Remark 10.2. Evidently, (10.1) is equivalent to the statement that $\mu(x) \geq 0$ for $\mathcal{L}^n$ almost all $x \in \mathbb{R}^n \sim C$, where μ is as in Proposition 1.3.

Proof. Suppose $D \in \mathbf{n}_\epsilon^{loc}(M)$. It follows from Proposition 1.2 and Theorem 5.4(iv) that $\mathbf{spt}\,[D]$ is compact. From (2.12) we find that

$$\mathbf{M}(\partial[C \cap D]) \leq \mathbf{M}(\partial[D]).$$

Moreover, as M is local and $D \in \mathbf{n}_\epsilon^{loc}(M)$,

$$\epsilon(\mathbf{M}(\partial[D]) - \mathbf{M}(\partial[D \cap C])) \leq M(D \cap C) - M(D) = M(\emptyset) - M(D \sim C) \leq 0.$$

Thus $\mathbf{M}(\partial[C \cap D]) = \mathbf{M}(\partial[D])$, so the theorem now follows from (2.12). $\square$

11. Some examples. Let

$$S = [-1,1] \times [-1,1] \in \mathcal{M}(\mathbb{R}^2),$$

suppose $1 \le p < \infty$, and let

$$F(g) = \frac{1}{p} \int |g - 1_S|^p \, d\mathcal{L}^2 \quad \text{whenever } g \in \mathcal{M}(\mathbb{R}^2).$$

We will determine $\mathbf{m}_\epsilon^{loc}(F)$, $0 < \epsilon < \infty$.

11.1. The sets $A_{i,r}$. For each $r \in (0,1]$ let

$$A_{0,r} = \{(1-r, 1-r) + r\{(\cos\theta, \sin\theta) : 0 \le \theta \le \pi/2\},$$

let $A_{i,r}$, $i = 1,2,3$, be a counterclockwise rotation about the origin of $A_{0,r}$ by $i\pi/2$, and let

$$C(r)$$

be the convex hull of $\cup_{i=0}^3 A_{i,r}$.

THEOREM 11.1. *Suppose* $0 < \epsilon < \infty$ *and*

$$T = \{[f] : f \in \mathbf{m}_\epsilon^{loc}(F)\}.$$

If $(1 + \sqrt{\pi}/2)\epsilon > 1$, *then*

$$T = \{0\}.$$

If $(1 + \sqrt{\pi}/2)\epsilon = 1$ *and* $p = 1$, *then*

$$T = \{t[1_{C(\epsilon)}] : 0 \le t \le 1\}.$$

If $(1 + \sqrt{\pi}/2)\epsilon < 1$ *and* $p = 1$, *then*

$$T = \{[1_{C(\epsilon)]}\}.$$

If $(1 + \sqrt{\pi}/2)\epsilon = 1$ *and* $p > 1$, *then*

$$T = \{0\}.$$

If $(1 + \sqrt{\pi}/2)\epsilon < 1$ *and* $p > 1$, *then*

$$T = \{[G^\downarrow]\},$$

where

$$Y = 1 - \left(1 + \sqrt{\pi}/2)\epsilon\right)^{1/(p-1)}$$

and

$$G = \left\{(x,y) : 0 < y < Y \text{ and } x \in C\left(\frac{\epsilon}{(1-y)^{p-1}}\right)\right\} \in \mathcal{G}(\mathbb{R}^2).$$

Proof. For each $y \in (0,\infty)$ let

$$Q_y = \{[D] : D \in \mathbf{n}_\epsilon^{loc}(U_y)\},$$

where U_y is as in Theorem 1.5.

Using (1.9) we find that $U_y(E) > 0$ whenever $1 < y < \infty$, $E \in \mathcal{M}(\mathbb{R}^n)$, and $\mathcal{L}^2(E) > 0$; since $U_y(\emptyset) = 0$ we find that

$$Q_y = \{0\} \quad \text{if } 1 < y < \infty.$$

Suppose $0 < y < 1$, let

$$Z = \begin{cases} 1 & \text{if } p = 1, \\ (1-y)^{p-1} & \text{if } p > 1, \end{cases} \quad \text{and let} \quad R = \frac{\epsilon}{Z}.$$

Suppose $R \leq 1$ and let

$$I = (U_y)_\epsilon \,(C(R)) = \epsilon \mathbf{M}(\partial[C(R)]) + U_y(C(R)).$$

We have

$$\epsilon \mathbf{M}(\partial[C(R)]) = \epsilon(4(2-2R) + 2\pi R)$$

and

$$U_y(C(R)) = -Z\mathcal{L}^2(C(R)) = -Z(4 - (4-\pi)R^2),$$

so

$$\begin{aligned} I &= \epsilon(4(2-2R) + 2\pi R) - Z(4 - (4-\pi)R^2) \\ &= \frac{-4Z^2 + 8\epsilon Z + (\pi - 4)\epsilon^2}{Z} \\ &= -4\frac{(Z - (1 + \sqrt{\pi}/2)\epsilon)(Z - (1 - \sqrt{\pi}/2)\epsilon)}{Z}. \end{aligned}$$

Since $R \leq 1$ we have

$$Z = \epsilon/R \geq \epsilon > (1 - \sqrt{\pi}/2)\epsilon.$$

Thus

$$I \begin{cases} < 0 = U_y(\emptyset) & \Leftrightarrow Z > (1 + \sqrt{\pi}/2)\epsilon, \\ = 0 = U_y(\emptyset) & \Leftrightarrow Z = (1 + \sqrt{\pi}/2)\epsilon, \\ > 0 = U_y(\emptyset) & \Leftrightarrow Z < (1 + \sqrt{\pi}/2)\epsilon. \end{cases}$$

Suppose $D \in \mathbf{n}_\epsilon^{loc}(U_y)$, $[D] \neq 0$, and $D = \mathbf{spt}\,[D]$. We claim that

$$R \leq 1 \quad \text{and} \quad D = C(R). \tag{11.1}$$

From Proposition 10.2 we infer that $D \subset S$. Let U equal the interior of S and let $M = U \cap \mathbf{bdry}\, D$. Then $U \cap M \neq \emptyset$ since otherwise we would have $D = S$, in which case M would have corners, which is incompatible with Theorem 1.2. Let A be a connected component of M. We infer from section 8 that A is an arc of a circle of radius R, the length of which does not exceed πR. Because D can have no corners we find that A meets the interior of the boundary of S tangentially. Thus (11.1) holds.

The theorem now follows from Theorems 1.3 and 1.4. $\square$

UNIQUENESS IN THE FABER–KRAHN INEQUALITY FOR ROBIN PROBLEMS*

DANIEL DANERS† AND JAMES KENNEDY†

Abstract. We prove uniqueness in the Faber–Krahn inequality for the first eigenvalue of the Laplacian with Robin boundary conditions, asserting that among all sufficiently smooth domains of fixed volume, the ball is the unique minimizer for the first eigenvalue. The method of proof, which avoids the use of any symmetrization, also works in the case of Dirichlet boundary conditions. We also give a characterization of all symmetric elliptic operators in divergence form whose first eigenvalue is minimal.

1. Introduction.

In this paper, we prove that the ball is the unique minimizer in the Faber–Krahn inequality for the first eigenvalue of the Robin boundary value problem

$$\begin{cases} -\Delta u = \lambda u & \text{in } \Omega, \\ \dfrac{\partial u}{\partial \nu} + \beta u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where $\Omega \subset \mathbb{R}^N, N \geq 2$, is a bounded C^2-domain with outward pointing unit normal ν and $\beta > 0$ is a constant. We build on the work of Daners [9] and Bossel [6], who proved a Faber–Krahn inequality for Robin problems, stating that among all Lipschitz domains Ω of fixed measure, the ball minimizes the first eigenvalue $\lambda_1 = \lambda_1(\Omega)$ of (1.1). The main purpose of this paper is to prove that the ball is the *unique* minimizer. More precisely, we will prove the following theorem.

THEOREM 1.1. *Suppose $\Omega \subset \mathbb{R}^N$ $(N \geq 2)$ is a bounded domain of class C^2, $B \subset \mathbb{R}^N$ is a ball with the same measure as Ω, and $\beta \in (0, \infty)$. Then $\lambda_1(B) \leq \lambda_1(\Omega)$ with equality if and only if $\Omega = B$ up to translation.*

If $\beta = \infty$, then the boundary condition in (1.1) becomes $u = 0$ and we have the Dirichlet problem

$$\begin{cases} -\Delta u = \lambda u & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases} \tag{1.2}$$

Denote the first eigenvalue by $\lambda_1(\Omega)$ as before. Our approach also allows us to recover uniqueness in the classical Faber–Krahn inequality for Dirichlet boundary conditions. Statements on uniqueness already appeared in [12, 18], although there were some unresolved issues about rigor at the time. A discussion about the difficulties arising in uniqueness theorems is given in [17, section II.8], where it is also noted that some

works, including the seminal book of Pólya and Szegö [21], omit the issue altogether. Moreover, most sources stating a uniqueness result, including the recent book [15, Remark 3.2.2], do not make precise assumptions on the domains. We therefore include a proof of the following theorem.

THEOREM 1.2 (Dirichlet problem). *Suppose $\Omega \subset \mathbb{R}^N$ $(N \geq 2)$ is an arbitrary bounded domain and $B \subset \mathbb{R}^N$ a ball with the same measure as Ω. Then $\lambda_1(B) \leq \lambda_1(\Omega)$ with equality if and only if Ω is a ball up to a set of capacity zero.*

Our proof of Theorem 1.1 makes use of a functional of the level sets of the first eigenfunction ψ of (1.1). This functional was used in [6, 9] to obtain a lower bound for $\lambda_1(\Omega)$. In this paper (see section 2) we strengthen that bound, which is then the critical ingredient in obtaining the uniqueness of the minimizer as stated in Theorem 1.1. The main idea then is to use the uniqueness in the geometric isoperimetric inequality to complete the proof of uniqueness. This is done in section 3. We will set up the proof so that it works for both Robin and Dirichlet problems, providing a new proof of uniqueness of the minimizer in case of the Dirichlet problem, at least if Ω is Wiener regular, which is the case if and only if the first eigenfunction of (1.2) is continuous in $\overline{\Omega}$.

In section 4 we provide an alternative proof of uniqueness. We show that if one level set of the first eigenfunction is a ball, then the domain is already a ball. Then we use the fact that $\lambda_1(\Omega) = \lambda_1(B)$ implies that most level sets are balls. We also include a proof of Theorem 1.2 in full generality at the end of section 4 using results on symmetrization from [7].

The final section is concerned with a classification of all elliptic operators which have the same first eigenfunction as the Laplace operator with the corresponding boundary conditions. We use this to classify all operators for which the first eigenvalue is minimal. This rectifies an error in [5, Theorem 3.8] and complements a counterexample in [16, section 3] by giving a complete classification (see Theorem 5.4).

2. A lower bound for the first eigenvalue. We will start by considering a problem with mixed Dirichlet and Robin boundary conditions, as was done in [9]. This is more general than what will ultimately be needed. We look at the mixed boundary value problem

$$\begin{cases} -\Delta u = \lambda u & \text{in } \Omega, \\ u = 0 & \text{on } \Gamma_0, \\ \dfrac{\partial u}{\partial \nu} + \beta u = 0 & \text{on } \Gamma_1 \end{cases} \tag{2.1}$$

on the C^2-domain Ω, where Γ_0, Γ_1 are disjoint open and closed subsets of $\partial\Omega$ with $\Gamma_0 \cup \Gamma_1 = \partial\Omega$. We assume that $\beta \in C^1(\Gamma_1)$, with $\beta(x) > 0$ for all $x \in \Gamma_1$. If $\Gamma_0 = \emptyset$, then we have a pure Robin problem, and if $\Gamma_1 = \emptyset$ we have a pure Dirichlet problem.

For open sets $U \subset \Omega$, we define the interior and exterior boundaries of U with respect to Ω by

$$\partial_i U := \partial U \cap \Omega \qquad \text{and} \qquad \partial_e U := \partial U \cap \partial\Omega,$$

respectively, so that $\partial U = \partial_i U \cup \partial_e U$, and $\partial_i U \cap \partial_e U = \emptyset$.

If $U \subset \Omega$ is open with $\overline{U} \cap \Gamma_0 = \emptyset$, and $\varphi \in C(\Omega)$ is nonnegative, then as in [9, section 2], we define the functional

$$H_\Omega(U, \varphi) := \frac{1}{|U|} \left(\int_{\partial_i U} \varphi \, d\sigma + \int_{\partial_e U} \beta \, d\sigma - \int_U |\varphi|^2 \, dx \right), \tag{2.2}$$

where $|U|$ denotes the Lebesgue measure of U and σ the $(N-1)$-dimensional Hausdorff measure on ∂U. Since φ is continuous on $\partial_i U$, these integrals are all well defined, although the first and last could be infinite for some choices of U and φ.

In the case of a pure Robin problem, we restrict our choice of test functions φ to a subset $M_\beta := M_\beta(\Omega)$ of $C(\Omega)$, namely

$$M_\beta := \left\{ u \in C(\Omega)\colon u \geq 0 \text{ in } \Omega \text{ and } \limsup_{x \to z} u(x) \leq \beta(z) \text{ for all } z \in \partial\Omega \right\}.$$

Observe that this restriction for Robin problems is a natural analogue of the unrestricted class $\{u \in C(\Omega)\colon u \geq 0 \text{ in } \Omega\}$ in the Dirichlet case, since in the latter case where $\beta = \infty$, we have $M_\infty = C(\Omega)$.

We are interested in the case where the subsets U are the level sets of the first eigenfunction ψ of (2.1). The first eigenvalue is simple, and the first eigenfunction can be chosen to be positive. We denote the level sets by

$$U_t := \{x \in \Omega\colon \psi(x) > t\} \tag{2.3}$$

and the level surfaces by

$$S_t := \{x \in \Omega\colon \psi(x) = t\}. \tag{2.4}$$

Then S_t coincides with the interior boundary $\partial_i U_t$ of U_t for almost all t. Now it is well known (see [1, Theorem 4.2]) that

$$\psi \in W_p^2(\Omega) \cap C^\infty(\Omega)$$

for all $p \in (1, \infty)$, and in particular, the level sets U_t are open. Moreover, by standard embedding theorems, $\psi \in C^1(\overline{\Omega})$. We can choose $\psi \geq 0$ and normalize it so that $\|\psi\|_\infty = 1$. We set

$$m := \min_{x \in \overline{\Omega}} \psi(x).$$

By the Hopf maximum principle, $\psi(x) > 0$ for all $\Omega \in \Gamma_1$, and ψ attains its minimum m on $\partial\Omega$. If $\Gamma_0 = \emptyset$, then $m > 0$; otherwise $m = 0$. Finally, we observe that $S_t = \emptyset$ if $t \notin (m, 1]$, and $\overline{U}_t \cap \Gamma_0 = \emptyset$ for all $t \in (m, 1)$.

Let $\varphi \in C(\Omega)$ be nonnegative and set

$$w := \varphi - \frac{|\nabla \psi|}{\psi}.$$

We will obtain a characterization of the functional H_Ω in terms of $\lambda_1(\Omega)$ and the function

$$F(t) := \int_t^1 \frac{1}{\tau} \int_{S_\tau} w \, d\sigma \, d\tau.$$

THEOREM 2.1. *Let w, F be as defined above. Then $F\colon (0,1] \to \mathbb{R}$ is locally absolutely continuous and*

$$H_\Omega(U_t, \varphi) = \lambda_1(\Omega) - \frac{1}{|U_t|} \left(\frac{1}{t} \frac{d}{dt} \big(t^2 F(t)\big) + \int_{U_t} |w|^2 \, dx \right) \tag{2.5}$$

for almost all $t \in (m, 1)$.

Proof. By [9, Lemma 3.3] the function F is absolutely continuous on $[\varepsilon, 1)$ for all $\varepsilon \in (0,1)$, and

$$F'(t) = -\frac{1}{t}\int_{S_t} w\,d\sigma \tag{2.6}$$

for almost all $t \in (0,1)$. Hence

$$\begin{aligned}\frac{1}{t}\frac{d}{dt}\bigl(t^2F(t)\bigr) &= \frac{1}{t}\bigl(2tF(t) + t^2F'(t)\bigr) = 2F(t) + tF'(t)\\ &= 2\int_t^1 \frac{1}{\tau}\int_{S_\tau} w\,d\sigma\,d\tau - \int_{S_t} w\,d\sigma\end{aligned}$$

for almost all $t \in (0,1)$. Therefore (2.5) is equivalent to the characterization

$$H_\Omega(U_t,\varphi) = \lambda_1(\Omega) + \frac{1}{|U_t|}\left(\int_{S_t} w\,d\sigma - 2\int_t^1 \frac{1}{\tau}\int_{S_\tau} w\,d\sigma\,d\tau - \int_{U_t}|w|^2\,dx\right) \tag{2.7}$$

for almost all $t \in (m,1)$, which was proved in [9, Theorem 2.2]. ∎

In the next two theorems we will use the characterization (2.5) of H_Ω to estimate the first eigenvalue from above. The theorems strengthen Theorems 3.1 and 3.5 of [9], respectively, giving a *strict inequality* for a *larger set* of $t \in (m,1)$ rather than just an inequality for some $t \in (m,1)$. That strict inequality is the key to proving the uniqueness of the minimizing domain.

The first of the theorems deals with the pure Robin problem, while the second deals with mixed or pure Dirichlet boundary conditions. Part of the proof of the latter requires a different method.

THEOREM 2.2. *Suppose that $\Gamma_0 = \emptyset$, and let $\varphi \in M_\beta$. If $\varphi \neq |\nabla\psi|/\psi$, then there exists a set $S \subset (m,1)$ of positive measure such that*

$$H_\Omega(U_t,\varphi) < \lambda_1(\Omega)$$

for all $t \in S$.

Proof. We give a proof by contradiction. Assume that $\varphi \neq |\nabla\psi|/\psi$ and that $H_\Omega(U_t,\varphi) \geq \lambda_1(\Omega)$ for almost all $t \in (m,1)$. By Theorem 2.1,

$$\frac{d}{dt}\bigl(t^2F(t)\bigr) = 2tF(t) + t^2F'(t) \leq -t\int_{U_t}|w|^2\,dx \leq 0 \tag{2.8}$$

for almost all $t \in (m,1)$. Using (2.6) we can also write the above inequality as

$$2F(t) + \int_{U_t}|w|^2\,dx \leq \int_{S_t} w\,d\sigma \tag{2.9}$$

for almost all $t \in (m,1)$. Now the fundamental theorem of calculus for absolutely continuous functions [22, Theorem 8.17] and (2.8) show that $t^2F(t)$ is nonincreasing on $(m,1)$. By assumption $\varphi \neq |\nabla\psi|/\psi$, so $w = \varphi - |\nabla\psi|/\psi \neq 0$. As $w \in C(\Omega)$ and $\bigcup_{t\in(m,1]} U_t = \Omega$, there exists $t \in (m,1)$ such that

$$\int_{U_t}|w|^2\,dx > 0. \tag{2.10}$$

Moreover, since the U_t are level sets, the map

$$t \mapsto \int_{U_t} |w|^2 \, dx$$

is nonincreasing, while

$$\int_{U_1} |w|^2 \, dx = 0$$

since $U_1 = \emptyset$ by definition. We now let

$$t^* = \sup \left\{ t \in (m,1)\colon \int_{U_t} |w|^2 \, dx > 0 \right\}.$$

From (2.10) we know that $t^* \in (m, 1]$, and thus

$$\frac{d}{dt}\bigl(t^2 F(t)\bigr) \leq -t \int_{U_t} |w|^2 \, dx < 0$$

for almost all $t \in (m, t^*)$. Hence $t^2 F(t)$ is strictly decreasing on (m, t^*). We showed earlier that $t^2 F(t)$ is nonincreasing on $[t^*, 1)$ and that F is continuous with $F(1) = 0$. It follows that there exist $\eta > 0$ and $t_0 \in (m, t^*)$ such that $F(t) > \eta$ for all $t \in (m, t_0]$. By [9, Lemma 2.3], there exist $t_1 \in (m, t_0]$ and $c > 0$ such that $\sigma(S_t) < c\sigma(\partial\Omega)$ for all $t \in (m, t_1]$. If we set

$$\varepsilon := \frac{\eta}{c\sigma(\partial\Omega)},$$

then by [9, Lemma 3.4], there exists $\delta > 0$ such that $w(x) \leq \varepsilon$ for all $x \in \Omega$ with $\operatorname{dist}(x, \partial\Omega) < \delta$. Since ψ attains a strict minimum on $\partial\Omega$, there exists $t \in (m, t_1]$ such that $\operatorname{dist}(x, \partial\Omega) < \delta$ for all $x \in S_t$. For such t, using (2.9), and by our choice of ε, η,

$$0 < 2\eta < 2F(t) \leq \int_{S_t} w \, d\sigma \leq \varepsilon\sigma(S_t) \leq \eta,$$

which is obviously a contradiction. Hence the assertion of the theorem follows. ∎

We next prove a similar result for problems involving Dirichlet boundary conditions on at least part of the boundary.

THEOREM 2.3. *Suppose $\Gamma_0 \neq \emptyset$, and suppose $\varphi \in C(\Omega)$ is nonnegative. If $\varphi \neq |\nabla\psi|/\psi$, then there exists a set $S \subset (0,1)$ of positive measure such that*

$$H_\Omega(U_t, \varphi) < \lambda_1(\Omega)$$

for all $t \in S$.

Proof. As with Theorem 2.2, we give a proof by contradiction. We assume that $\varphi \neq |\nabla\psi|/\psi$ and that $H_\Omega(U_t, \varphi) \geq \lambda_1(\Omega)$ for almost all $t \in (0, 1)$. As in the proof of Theorem 2.2, there exists $t^* \in (0, 1]$ satisfying

$$t^* = \sup \left\{ t \in (0,1)\colon \int_{U_t} |w|^2 \, dx > 0 \right\},$$

so that $G(t) := t^2 F(t)$ and $F(t)$ are positive and strictly decreasing on $(0, t^*)$ with $G(t^*) = G(1) = 0$. Hence

$$g(t) := \frac{1}{G(t)}$$

is well defined and strictly increasing on $(0, t^*)$. Since $F(t) \geq 0$ and

$$G'(t) = \frac{d}{dt}\big(t^2 F(t)\big) \leq -t \int_{U_t} |w|^2 \, dx \leq 0$$

as with (2.9), it follows that

$$\int_{S_t} w \, d\sigma \geq 2F(t) + \int_{U_t} |w|^2 \, dx \geq 0$$

for almost all $t \in (0,1)$. Hence, by the coarea formula (see [11, section 3.4.3] or [20, section 1.2.4]) and the Cauchy–Schwarz inequality,

$$\begin{aligned} G(t) = t^2 F(t) &= t \int_t^1 \frac{t}{\tau} \int_{S_\tau} w \, d\sigma \, d\tau \\ &\leq t \int_t^1 \int_{S_\tau} w \, d\sigma \, d\tau = t \int_{U_t} w |\nabla \psi| \, dx \\ &\leq t \left(\int_{U_t} |w|^2 \, dx \right)^{1/2} \left(\int_{U_t} |\nabla \psi|^2 \, dx \right)^{1/2} \end{aligned}$$

for all $t \in (0,1)$. By choice of t^*,

$$G'(t) = \frac{d}{dt}\big(t^2 F(t)\big) \leq -t \int_{U_t} |w|^2 \, dx < 0$$

for almost all $t \in (0, t^*)$. Combining these inequalities, we get

$$t g'(t) = -\frac{t G'(t)}{(G(t))^2} \geq \left(\int_{U_t} |\nabla \psi|^2 \, dx \right)^{-1} \geq c := \frac{1}{\|\nabla \psi\|^2}$$

for almost all $t \in (0, t^*)$. If we fix $t_1 \in (0, t^*)$, we therefore have $g'(t) > ct^{-1}$ for almost all $t \in (0, t_1]$. Since G is absolutely continuous and positive on $[\varepsilon, t^*)$ for all $\varepsilon \in (0, t^*)$, so is g. By the fundamental theorem of calculus for such functions (see [22, Theorem 8.17]),

$$g(t_1) \geq g(t_1) - g(\varepsilon) = \int_\varepsilon^{t_1} g'(\tau) \, d\tau \geq c \int_\varepsilon^{t_1} \frac{1}{\tau} \, d\tau = c(\log t_1 - \log \varepsilon)$$

for all $\varepsilon \in (0, t_1]$. Hence $-\log \varepsilon$ is bounded from above as $\varepsilon \to 0$, which is a contradiction. This completes the proof of the theorem. ∎

Remark 2.4. It was a consequence of Theorem 3.5 in [9] that for the Dirichlet case,

$$\lambda_1(\Omega) = \max_{\substack{\varphi \in C(\Omega) \\ \varphi \geq 0}} \left(\operatorname*{ess-inf}_{t \in (0,1)} H_\Omega(U_t, \varphi) \right) = \max_{\substack{\varphi \in C(\Omega) \\ \varphi \geq 0}} \left(\operatorname*{ess-inf}_{\substack{U \subset \Omega \text{ open} \\ \overline{U} \cap \Gamma_0 = \emptyset}} H_\Omega(U, \varphi) \right),$$

where the maximum is achieved by $\varphi := |\nabla \psi|/\psi$. Theorem 2.3 shows that in fact $|\nabla \psi|/\psi$ is the *unique* maximizer.

3. Proof of uniqueness. In this section we give a proof of the main uniqueness result stated in Theorem 1.1. We start with a brief discussion of (1.1) in the case where Ω is a ball. Assume that $\beta \in (0, \infty)$ is constant and that B is a ball of radius R centered at the origin. We will denote the first eigenvalue of (1.1) on B by $\lambda_1(B)$ and the corresponding eigenfunction by ψ^*. We choose $\psi^* \geq 0$ and normalize it so that $\|\psi^*\|_\infty = 1$. Since B is a ball, the eigenfunction is radially symmetric; that is, there exists a function $v \in C^1([0, R])$ satisfying $\psi^*(x) = v(|x|)$. Set

$$\varphi^* := \frac{|\nabla \psi^*|}{\psi^*}.$$

In fact, the eigenfunction is explicitly given in terms of Bessel functions by

$$\psi^*(x) = c|x|^{-(N/2-1)} J_{N/2-1}\left(\sqrt{\lambda_1(B)}|x|\right) \tag{3.1}$$

for some normalizing constant c. Since ψ^* is radially symmetric, it is constant on $\partial\Omega$, and hence by [9, Remark 3.2] we have $\varphi^* \in M_\beta$. Also by the radial symmetry of ψ^*,

$$g(|x|) := \varphi^*(x),$$

where $x \in B$. It is shown in [9, Lemma 4.1] that the function $g\colon (0, R) \to (0, \infty)$ is strictly increasing. Similar statements hold for Dirichlet boundary conditions, that is, (1.2).

In what follows, we will deal only with pure Robin boundary conditions. The proof for pure Dirichlet boundary conditions is very similar, with obvious modifications. The principal difference is that Theorem 2.3 is used in place of Theorem 2.2.

Suppose that Ω is a bounded C^2-domain for the problem (1.1), and let B be the ball having the same measure as Ω. As in [6, 9], we define a function $\varphi \in M_\beta$ by constructing a rearrangement of φ^*. Continuing with the notation of the previous section, we consider the level sets U_t and S_t as defined by (2.3) and (2.4), respectively. We will denote by B_r the ball of radius r centered at the origin, and let $r(t)$ be the radius of the ball with the same measure as U_t, that is, so that $|B_{r(t)}| = |U_t|$. Since Ω and B have the same measure and $U_m = \Omega$, we have $r(m) = R$. Given $t \in (m, 1]$ we define

$$\varphi(x) := g(r(t))$$

for all $x \in S_t$. Since Ω is a disjoint union of the sets S_t, $t \in (m, 1]$, the function $\varphi\colon \Omega \to (0, \infty)$ is well defined. From [9, Lemma 4.2] we have the following result.

LEMMA 3.1. *The function φ constructed above lies in $M_\beta(\Omega)$ and*

$$\lambda_1(B) = H_B(B_{r(t)}, \varphi^*) \leq H_\Omega(U_t, \varphi) \tag{3.2}$$

for all $t \in (m, 1)$.

The next two lemmas will allow us to conclude that almost all level sets U_t are concentric balls if $\lambda_1(\Omega) = \lambda_1(B)$. Theorem 2.2 will be essential for that.

LEMMA 3.2. *Suppose that Ω is a bounded C^2-domain such that $\lambda_1(\Omega) = \lambda_1(B)$. If we let φ denote the rearrangement of $\varphi^* = |\nabla\psi^*|/\psi^*$ as defined above, then $\varphi = |\nabla\psi|/\psi$, and $H_\Omega(U_t, \varphi) = \lambda_1(B)$ for almost all $t \in (m, 1)$.*

Proof. If $\lambda_1(\Omega) = \lambda_1(B)$, then by Lemma 3.1, $\lambda_1(\Omega) = \lambda_1(B) \le H_\Omega(U_t, \varphi)$ for all $t \in (m, 1)$. Hence by Theorem 2.2, $\varphi = |\nabla\psi|/\psi$, and hence by Theorem 2.1,

$$H_\Omega(U_t, \varphi) = \lambda_1(\Omega) = \lambda_1(B) \tag{3.3}$$

for almost all $t \in (m, 1)$. ◻

The following lemma makes the link to the uniqueness of the ball in the geometric isoperimetric inequality. Since it shows how the uniqueness in the geometric isoperimetric inequality is used, we repeat the proof given in [9, Remark 4.3].

LEMMA 3.3. *Suppose U_t is a Lipschitz domain for some $t \in (m, 1)$, and let φ be the rearranged function as above. Then $H_\Omega(U_t, \varphi) = \lambda_1(B)$ if and only if U_t is a ball and $\sigma(\partial_e U_t) = 0$.*

Proof. We know that $\lambda_1(B) = H_B(B_{r(t)}, \varphi^*)$ for all $t \in (m, 1)$. Also, since by construction the level sets of φ^* and φ have the same measure,

$$\int_{U_t} |\varphi|^2\, dx = \int_{B_{r(t)}} |\varphi^*|^2\, dx$$

for all $t \in (m, 1]$ (see [20, section 1.2.3]). Hence, using the definition of H_Ω and φ,

$$\begin{aligned} H_\Omega(U_t, \varphi) &= \frac{1}{|U_t|}\left(\int_{S_t} \varphi\, d\sigma + \int_{\partial_e U_t} \beta\, d\sigma - \int_{U_t} |\varphi|^2\, dx\right) \\ &= \frac{1}{|B_{r(t)}|}\left(g(r(t))\sigma(S_t) + \beta\sigma(\partial_e U_t) - \int_{B_{r(t)}} |\varphi^*|^2\, dx\right). \end{aligned}$$

If U_t is a ball with $\sigma(\partial_e U_t) = 0$, then $\sigma(S_t) = \sigma(\partial B_{r(t)})$, and

$$\begin{aligned} H_\Omega(U_t, \varphi) &= \frac{1}{|B_{r(t)}|}\left(g(r(t))\sigma(\partial B_{r(t)}) - \int_{B_{r(t)}} |\varphi^*|^2\, dx\right) \\ &= H_B(B_{r(t)}, \varphi^*) = \lambda_1(B). \end{aligned}$$

Conversely, if $H_\Omega(U_t, \varphi) = \lambda_1(B)$, then for this t,

$$g(r(t))\sigma(S_t) + \beta\sigma(\partial_e U_t) = g(r(t))\sigma(\partial B_{r(t)}).$$

Since $t \in (m, 1)$ and $0 < g(r(t)) < \beta$, this is only possible if

$$\int_{\partial_e U_t} \beta\, d\sigma = 0$$

and $\sigma(S_t) = \sigma(\partial B_{r(t)})$. As $\beta > 0$ on $\partial\Omega$ by assumption, we conclude that $\sigma(\partial_e U_t) = 0$. Now since ∂U_t is the disjoint union of S_t and $\partial_e U_t$, if $\sigma(\partial_e U_t) = 0$, then we get $\sigma(\partial U_t) = \sigma(\partial B_{r(t)})$. But we know that the ball is the unique minimizer of the isoperimetric inequality, at least among Lipschitz domains (see [8, Theorem 10.2.1]). Hence $U_t = B_{r(t)} + z$ for some $z \in \mathbb{R}^N$. ◻

The last ingredient we need in the proof of the main result is the following lemma, which will allow us to conclude that if U_t is a ball for some $t \in (m, 1)$, then all level sets interior to U_t are concentric balls.

LEMMA 3.4. *Assume $-\Delta u = \lambda u$ in Ω for some $\lambda > 0$. Suppose that for some $t \ge 0$, the level set $\{x \in \Omega : u(x) > t\} = B(x_0, r)$ for some $x_0 \in \Omega$ and $r > 0$. If*

$u \in C(\overline{B(x_0,r)})$ and $\sigma(\partial_e B(x_0,r)) = 0$, then u is radially symmetric with respect to x_0 in $B(x_0,r)$.

Proof. Set $v(x) := u(x) - t$. Then

$$-\Delta v = -\Delta u = \lambda u = \lambda(u-t) + \lambda t = \lambda v + \lambda t$$

in $B(x_0,r)$. Since $u \in C(\overline{B(x_0,r)})$ and $\sigma(\partial_e B(x_0,r)) = 0$, we get $u(x) = t$ for all $x \in \partial B(x_0,r)$, so $v = 0$ on $\partial B(x_0,r)$. Hence if we set $f(v) := \lambda v + \lambda t$, then v is a positive solution of the Dirichlet problem

$$\begin{cases} -\Delta v = f(v) & \text{in } B(x_0,r), \\ \quad v = 0 & \text{on } \partial B(x_0,r). \end{cases}$$

Clearly $f(v) \geq 0$ if $v \geq 0$, and by assumption, in $B(x_0,r)$, $u > t$, so $v = u - t > 0$. Hence by a result of Gidas, Ni, and Nirenberg (see [14, Corollary 3.5]), v is radially symmetric on $B(x_0,r)$ with respect to x_0. ☐

Remark 3.5. We could state Lemma 3.4 in greater generality. If the level set U_t is Steiner symmetric (see [14, Definition 3.2]), then the solution u will have the same symmetry. The proof is the same as the one we have given above, except that we refer to [14, Corollary 3.4].

We are now in a position to prove the main uniqueness theorem stated in the introduction.

Proof of Theorem 1.1. By Lemma 3.2, $H_\Omega(U_t,\varphi) = \lambda_1(B)$ for almost all $t \in (m,1)$, and so by Lemma 3.3, U_t is a ball for almost all $t \in (m,1)$. (Here we also use the property that U_t is Lipschitz for almost all t as shown in [9, Lemma 2.3].) For every such t, Lemma 3.3 also tells us that $\sigma(\partial_e U_t) = 0$, and so Lemma 3.4 applies. Hence the eigenfunction ψ corresponding to $\lambda_1(\Omega)$ is radially symmetric inside U_t, and all interior level sets U_τ, $\tau \in (t,1]$, are concentric balls. In particular, for all $t \in (m,1]$, the level sets U_t are concentric balls, and so $\Omega = \bigcup_{t\in(m,1]} U_t$ is a ball. ☐

The proof of equality in the case of Dirichlet boundary conditions in Theorem 1.2 is very similar to the one given above. We note that $\psi \in C(\overline{\Omega})$ if and only if Ω is Wiener (Dirichlet) regular (see [2, Corollary 2.5]). Hence in that case the level surfaces S_t are contained in Ω for all $t > 0$, and therefore the assertion of Theorem 2.3 is valid as is Lemma 3.3.

4. An alternative approach to uniqueness. In this section we show that if one of the level sets of the first eigenfunction of (1.1) is a ball, then Ω is already a ball. Combining that result with Lemma 3.3, we get an alternative proof for Theorem 1.1. Throughout this section we use the same notation as in the previous section.

PROPOSITION 4.1. *Suppose that $U_t \subset \Omega$ is a ball for some t with $\sigma(\partial_e U_t) = 0$ and that B is a ball concentric to U_t. If $x_0 \in \partial\Omega \cap \partial B$ is such that the outward pointing unit normals to B and Ω coincide at x_0, then $\lambda_1(\Omega) = \lambda_1(B)$.*

Proof. Suppose that U_t is a ball with $\sigma(\partial_e U_t) = 0$. Without loss of generality, we can assume that it is centered at $x = 0$. By Lemma 3.4 the function ψ is radially symmetric in U_t. Similarly to (3.1), ψ is therefore given by

$$\psi(x) = \tilde{\psi}(x) := c|x|^{-(N/2-1)} J_{N/2-1}\left(\sqrt{\lambda_1(\Omega)}|x|\right)$$

in U_t for some normalizing constant $c > 0$. By the unique continuation property of solutions to elliptic equations (see [4]), $\psi(x) = \tilde{\psi}(x)$ for all $x \in \Omega$. Moreover,

$$-\Delta\tilde{\psi} = \lambda_1(\Omega)\tilde{\psi}$$

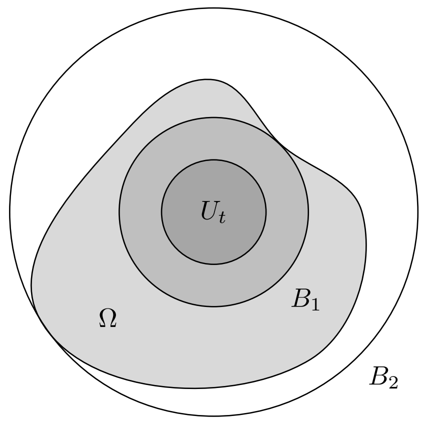

FIG. 4.1. *The balls B_1 and B_2.*

on $\mathbb{R}^N$. Now let B be a ball concentric to U_t and $x_0 \in \partial\Omega \cap \partial B$ such that the unit normals to B and Ω coincide at x_0. Note that $\psi(x_0) > 0$, so, if ν_B is the outer unit normal to B, then by the boundary conditions in (1.1),

$$\beta = -\frac{1}{\psi(x_0)}\frac{\partial\psi}{\partial\nu}(x_0) = -\frac{1}{\tilde{\psi}(x_0)}\frac{\partial\tilde{\psi}}{\partial\nu_B}(x_0).$$

Since $\tilde{\psi}$ is radially symmetric, $\tilde{\psi}$ satisfies the eigenvalue problem

$$\begin{cases} -\Delta u = \lambda_1(\Omega)u & \text{in } B,\\ \dfrac{\partial u}{\partial\nu_B} + \beta u = 0 & \text{on } \partial B. \end{cases}$$

As $\psi > 0$ and $\psi = \tilde{\psi}$ on Ω and $x_0 \in \partial\Omega \cap \partial B$, it follows that $\tilde{\psi} > 0$ on B by the radial symmetry. As $\lambda_1(B)$ is the only eigenvalue with a positive eigenfunction, we get $\lambda_1(\Omega) = \lambda_1(B)$. ∎

From the above we get as a corollary that if U_t is a ball for some t, then Ω is already a ball.

THEOREM 4.2. *Suppose that $U_t \subset \Omega$ is a ball for some t with $\sigma(\partial_e U_t) = 0$. Then Ω is a ball.*

Proof. Suppose that $U_t \subset \Omega$ is a ball with $\sigma(\partial_e U_t) = 0$ for some t. Assume without loss of generality that its center is at $x = 0$. Denote by B_r the open ball with radius r. We set

$$r_1 := \sup\{r > 0 \colon B_r \subset \Omega\} \quad \text{and} \quad r_2 := \inf\{r > 0 \colon \Omega \subset B_r\}$$

and let $B_i := B_{r_i}$ for $i = 1, 2$. Then

$$U_t \subset B_1 \subset \Omega \subset B_2 \tag{4.1}$$

as shown in Figure 4.1. Since Ω is smooth, ∂B_i is tangential to $\partial\Omega$ at some point on $\partial\Omega \cap \partial B_i$, so the outward pointing unit normals to B_i and Ω coincide at that point. Now Proposition 4.1 implies that $\lambda_1(B_1) = \lambda_1(\Omega) = \lambda_1(B_2)$. But $\lambda_1(B_r)$ is strictly decreasing in r, so $B_1 = B_2$. By (4.1) we conclude that Ω is a ball. ∎

Remark 4.3. The above also works for Dirichlet boundary conditions. We need only assume that $\Omega \subset \mathbb{R}^N$ is a bounded open connected set and conclude that Ω is a ball up to a set of capacity zero. To see this, suppose that U_t is a ball for some $t > 0$. As before, we assume its center is $x = 0$. We know that the eigenfunction ψ is discontinuous only at the irregular points, so $U_t \cap \partial\Omega$ consists of irregular points if nonempty. The set of irregular points has capacity zero (see [19, page 232]), so in particular it has surface measure zero on ∂U_t. Since U_t is a ball it follows that ψ is continuous on $\overline{U}_t$, so by the arguments in the proof of Lemma 3.4 the eigenfunction ψ is radially symmetric in U_t. Then as in the proof of Proposition 4.1, $\psi = \tilde{\psi}$ on Ω, and therefore ψ is continuous on $\overline{\Omega}$. Now let B be the smallest ball with center $x = 0$ containing Ω. Then since $\psi > 0$ in Ω and $\tilde{\psi}$ is radially symmetric, $\tilde{\psi} > 0$ on B. Hence $\lambda_1(\Omega) = \lambda_1(B)$, and thus by [3, Theorem 3.1] the set Ω coincides with the ball B up to a set of capacity zero.

We can now give an alternative proof of Theorem 1.1.

Alternative proof of Theorem 1.1. Suppose that $\lambda_1(\Omega) = \lambda_1(B)$, where B is a ball of the same measure as Ω. By Lemma 3.3 there is a level set U_t, which is a ball, and also $\overline{U}_t \subset \Omega$. Then Theorem 4.2 implies that Ω is a ball as claimed. $\square$

The above proof also applies in the case of Dirichlet boundary conditions, provided ψ is continuous on $\overline{\Omega}$. The reason that we use continuity is that otherwise we do not know whether Lemma 3.2 applies. There is, however, another proof based on symmetrization that works for arbitrary domains.

Proof of Theorem 1.2. Let Ω be a bounded domain and ψ the first eigenvalue of (1.2) normalized such that $\psi(x) > 0$ for all $x \in \Omega$ and $\|\nabla\psi\|_2 = 1$. We know that $\psi \in H_0^1(\Omega)$, so if we extend ψ by zero outside Ω, we may consider ψ as an element of $H^1(\mathbb{R}^N)$. Denote by ψ^* the spherical symmetric rearrangement of ψ (see [7, 21]). By the results in [7] we have $\psi^* \in H^1(\mathbb{R}^N)$ with $\|\psi^*\|_2 = 1$ and $\|\nabla\psi^*\|_2 \leq \|\nabla\psi\|_2$. By construction, ψ^* has support in the closure of a ball B of the same measure as Ω. Here we use that a function in $H_0^1(\Omega)$ is zero on Ω^c almost everywhere. As B has a smooth boundary, $\psi^* \in H_0^1(B)$, and thus by the variational characterization of the first eigenvalue,

$$\lambda_1(B) \leq \|\nabla\psi^*\|_2^2 \leq \|\nabla\psi\|_2^2 = \lambda_1(\Omega).$$

If $\lambda_1(B) = \lambda_1(\Omega)$, then from the above, $\|\nabla\psi^*\|_2^2 = \|\nabla\psi\|_2^2$. Also note that $\nabla\psi \neq 0$ almost everywhere in Ω by Remark 5.2(b) below. Hence [7, Theorem 1.1] implies that $\psi = \psi^*$ up to translation almost everywhere. Therefore, possibly after a translation, $\Omega = B$ up to a set of measure zero. We claim that $\Omega \subset B$. If not, then there exists a point $x_0 \in \Omega \cap B^c$. This is not possible since Ω is open, and therefore $\Omega \cap B^c$ has non-zero measure. Hence $\Omega \subset B$. But then $\lambda_1(\Omega) = \lambda_1(B)$ if and only if $\operatorname{cap}(B \setminus \Omega) = 0$ by [3, Theorem 3.1], completing the proof of Theorem 1.2. $\square$

5. Operators other than the Laplace operator.

For the remainder of the paper, we will consider the eigenvalue problem

$$\begin{cases} -\operatorname{div}\big(A(x)\nabla u(x)\big) = \lambda u & \text{in } \Omega, \\ u = 0 & \text{on } \Gamma_0, \\ \dfrac{\partial u}{\partial \nu_A} + \beta u = 0 & \text{on } \Gamma_1, \end{cases} \tag{5.1}$$

where $\Omega \subset \mathbb{R}^N$ is an open set, Γ_0 a closed subset of $\partial\Omega$ and $\Gamma_1 = \partial\Omega \setminus \Gamma_0$ Lipschitz, and

$$\frac{\partial u}{\partial \nu_A} := \big(A(x)\nabla u(x)\big) \cdot \nu$$

is the conormal derivative of u associated with the coefficient matrix A. Further assume that $A \in L_\infty(\Omega, \mathbb{R}^{N\times N})$ is such that $A(x)$ is symmetric and uniformly positive definite, that is, there exists $\alpha > 0$ such that

$$0 < \alpha \leq \inf_{|\xi|=1} \xi^T A(x)\xi$$

for almost all $x \in \Omega$. By replacing A with $\alpha^{-1}A$, we can assume without loss of generality that $\alpha = 1$, that is,

$$1 \leq \inf_{|\xi|=1} \xi^T A(x)\xi \tag{5.2}$$

for almost all $x \in \Omega$. Finally, assume that $\beta \in L_\infty(\Gamma_1)$ is nonnegative. Note that here we allow $\beta = 0$, that is, Neumann boundary conditions. The form associated with (5.1) is given by

$$a(u,v) = \int_\Omega \big(A(x)\nabla u(x)\big) \cdot \nabla v(x)\,dx + \int_{\Gamma_1} \beta(x)u(x)v(x)\,d\sigma.$$

It is well known that the above problem has a first eigenvalue, which is given by the variational characterization

$$\mu_1 = \inf_{\substack{u\in V\\ u\neq 0}} \frac{a(u,u)}{\|u\|_2^2},$$

where V is the closure of $C_c^\infty(\Omega \cup \Gamma_1)$ in $H^1(\Omega)$. The eigenvalue is simple and the corresponding eigenfunctions the only minimizers for the above quotient. We want to compare this eigenvalue to the first eigenvalue of

$$\begin{cases} -\Delta u = \lambda u & \text{in } \Omega,\\ u = 0 & \text{on } \Gamma_0,\\ \dfrac{\partial u}{\partial \nu} + \beta u = 0 & \text{on } \Gamma_1, \end{cases} \tag{5.3}$$

that is, the case where $A(x) = I$. The corresponding form is

$$b(u,v) := \int_\Omega \nabla u(x) \cdot \nabla v(x)\,dx + \int_{\Gamma_1} \beta(x)u(x)v(x)\,d\sigma.$$

Let λ_1 be the first eigenvalue of (5.3) and μ_1 the first eigenvalue of (5.1). By (5.2),

$$\frac{b(v,v)}{\|v\|_2^2} \leq \frac{a(v,v)}{\|v\|_2^2}$$

for all $v \in V$, and thus by the variational characterization of λ_1 and μ_1,

$$\lambda_1 \leq \mu_1. \tag{5.4}$$

We now characterize those matrices A for which the first eigenvalues of (5.1) and (5.3) are equal.

THEOREM 5.1. *Suppose $\Omega \subset \mathbb{R}^N$ is a bounded domain. Let λ_1 and ψ be the first eigenvalue and eigenfunction of* (5.3)*, and let μ_1 and φ be the first eigenvalue and eigenfunction of* (5.1)*. Then the following assertions are equivalent:*

(1) $\lambda_1 = \mu_1$*;*

(2) $\lambda_1 = \mu_1$ *and* $\varphi = c\psi$ *for some* $c \in \mathbb{R}$*;*

(3) $A(x)\nabla\psi(x) = \nabla\psi(x)$ *almost everywhere in* Ω*.*

Proof. Throughout the proof we normalize the eigenfunctions such that they are positive and that $\|\varphi\|_2 = \|\psi\|_2 = 1$. Suppose that $\lambda_1 = \mu_1$. Then by the variational characterization of the eigenvalues and (5.2),

$$\lambda_1 \leq b(\varphi, \varphi) \leq a(\varphi, \varphi) = \mu_1 = \lambda_1.$$

Hence $\lambda_1 = b(\varphi, \varphi)$, and thus by the simplicity and normalization of the eigenvalue λ_1, it follows that $\varphi = \psi$. Hence (1) implies (2).

If (2) holds, then by the variational characterization of λ_1 and μ_1,

$$b(\psi, \psi) = \lambda_1 = \mu_1 = a(\psi, \psi)$$

or equivalently, using the definitions of the form $a(\cdot\,,\cdot)$ and $b(\cdot\,,\cdot)$,

$$\int_\Omega \big(A(x)\nabla\psi(x) - \nabla\psi(x)\big) \cdot \nabla\psi(x)\, dx = 0.$$

Since $A(x) - I$ is positive semidefinite by (5.2), it follows that the above integrand is nonnegative, and thus

$$\big(A\nabla\psi - \nabla\psi\big) \cdot \nabla\psi = 0$$

almost everywhere. Since $A(x) - I$ is positive semidefinite and symmetric almost everywhere, we conclude that

$$A\nabla\psi - \nabla\psi = 0$$

almost everywhere in Ω, proving that (2) implies (3).

To prove that (3) implies (1), we again use the variational characterization of the first eigenvalue. By (3) we have

$$b(\psi, \psi) - a(\psi, \psi) = 0,$$

so by (5.4) and the variational characterization of the eigenvalues,

$$\mu_1 \geq \lambda_1 = b(\psi, \psi) = b(\psi, \psi) - a(\psi, \psi) + a(\psi, \psi) = a(\psi, \psi) \geq \mu_1,$$

and thus $\lambda_1 = \mu_1$ as claimed. $\square$

Remark 5.2. (a) If we have pure Neumann boundary conditions, the above theorem is, of course, trivial since then $\lambda_1 = \mu_1 = 0$ and the eigenfunctions $\varphi = \psi$ are constant. Hence every matrix A satisfies the conditions. In what follows we therefore assume that $\lambda_1 > 0$, and thus the eigenfunction is not constant.

(b) We also note that $\psi \in C^\infty(\Omega)$ always, so $\nabla\psi \in C^\infty(\Omega)$ as well. There is even a stronger statement, namely, that ψ is real analytic in Ω always (see [10, section V.4.2]). Moreover, if $\lambda_1 > 0$, then ψ and also $\nabla\psi(x)$ are nonconstant. By the real analyticity, $\nabla\psi \neq 0$ almost everywhere (see [13, section 3.1.24]).

Next we characterize those matrices A for which (3) of the above theorem is satisfied. For that purpose we look at a domain $\Omega \subset \mathbb{R}^2$ in the plane and let ψ denote the first eigenvalue of (5.3). Since $\nabla\psi \neq 0$ almost everywhere as shown above, $A_0(x) := A(x) - I$ must have rank strictly less than two. Note that the set of symmetric positive semidefinite (2×2)-matrices having a given nonzero vector (a, b) in their null space are precisely the matrices

$$t\begin{bmatrix} b^2 & -ab \\ -ab & a^2 \end{bmatrix}, \qquad t \geq 0.$$

Hence, as $\nabla\psi \neq 0$ almost everywhere,

$$A_0(x)\nabla\psi(x) = 0$$

if and only if

$$A_0(x) := m(x)\begin{bmatrix} \left(\dfrac{\partial\psi}{\partial y}\right)^2 & -\dfrac{\partial\psi}{\partial x}\dfrac{\partial\psi}{\partial y} \\ -\dfrac{\partial\psi}{\partial x}\dfrac{\partial\psi}{\partial y} & \left(\dfrac{\partial\psi}{\partial x}\right)^2 \end{bmatrix}$$

almost everywhere in Ω for some measurable function $m\colon \Omega \to [0, \infty)$. If we set $A(x) := I(x) + A_0(x)$, then $A(x)$ satisfies the condition in part (3) of Theorem 5.1. Hence there are many nontrivial operators having the same eigenvalue as the Laplace operator on Ω.

Remark 5.3. We can generalize the above to $\mathbb{R}^N$. We let M denote the set of real symmetric $N \times N$ matrices. Given a nonzero vector $\xi \in \mathbb{R}^N$, we are interested in the kernel of the map $S\colon M \to \mathbb{R}$ given by $A \to \xi^T A\xi$. Now $\dim M = (N+1)N/2$, and therefore

$$\dim(\ker S) = \frac{N(N+1)}{2} - 1 = \frac{N(N-1)}{2}.$$

Let $1 \leq k < \ell \leq N$ and $\xi = (\xi_1, \ldots, \xi_N)$. If ξ_k and ξ_ℓ are not both zero, define the matrices $A_{k\ell}$ with entries $a_{kk} = \xi_j^2$, $a_{jj} = \xi_k^2$, and $a_{kl} = a_{lk} = -\xi_k\xi_\ell$, and $a_{ij} = 0$ otherwise. If $\xi_k = \xi_\ell = 0$, let $a_{kk} = a_{\ell\ell} = 1$ and $a_{kl} = a_{lk} = -1$, and $a_{ij} = 0$ otherwise. Then the set of matrices $A_{k\ell}$, $1 \leq k < \ell \leq N$, is a linearly independent subset of $\ker S$. Since there are precisely $N(N-1)/2$ such matrices, they form a basis of $\ker S$.

Note that the matrices $A_{k\ell}$ are positive semidefinite, and by construction $A_{k\ell}\xi = 0$. It follows that every positive semidefinite matrix A with $A\xi = 0$ can be written in the form

$$A = \sum_{1 \leq k < \ell \leq N} m_{k\ell}A_{k\ell}$$

for $m_{k\ell} \geq 0$.

We now use this to characterize the operators for which $\lambda_1 = \mu_1$. To do so, we set $\xi = \nabla\psi(x)$ and look at the corresponding set of matrices $A_{k\ell}(x)$ as constructed above. This can be done since $\nabla\psi \neq 0$ almost everywhere in Ω as shown in Remark 5.2. Hence, by Theorem 5.1 we have $\lambda_1 = \mu_1$ if and only if there exist measurable functions $m_{k\ell}\colon \Omega \to [0,\infty)$ such that

$$A(x) = I + \sum_{1\leq k<\ell\leq N} m_{k\ell}(x)A_{k\ell}(x)$$

for almost all $x \in \Omega$.

We next apply the above to the special case where Ω is a ball, complementing a result in [16, section 3], giving a complete characterization of all symmetric operators in divergence form for Robin and Dirichlet problems having the same first eigenvalue as the Laplacian with the corresponding boundary conditions on a domain of the same measure.

THEOREM 5.4. *Suppose that $\beta \in (0,\infty)$ is constant and that μ_1 is the first eigenvalue of*

$$\begin{cases} -\operatorname{div}\bigl(A\nabla u\bigr) = \lambda u & \textit{in } \Omega, \\ \dfrac{\partial u}{\partial \nu_A} + \beta u = 0 & \textit{on } \partial\Omega, \end{cases} \tag{5.5}$$

where Ω is a domain of class C^2 and A satisfies (5.2)*. Let B be a ball of the same measure as Ω. Finally, denote the first eigenvalue of* (5.5) *by $\mu_1(\Omega)$ and a first eigenvalue of $\lambda_1(B)$ by ψ^*. Then $\mu_1(\Omega) = \lambda_1(B)$ if and only if $\Omega = B + z$ for some $z \in \mathbb{R}^N$ and $A(x-z)\nabla\psi^*(x) = \nabla\psi^*(x)$ almost everywhere.*

Proof. First suppose that $\lambda_1(B) = \mu_1(\Omega)$. By Theorem 1.1 and (5.4) we have

$$\lambda_1(B) \leq \lambda_1(\Omega) \leq \mu_1(\Omega) = \lambda_1(B),$$

implying that $\lambda_1(\Omega) = \mu_1(\Omega) = \lambda_1(B)$. From Theorem 1.1 we conclude that $\Omega = B+z$ for some $z \in \mathbb{R}^n$, and then Theorem 5.1 implies that $A(x-z)\nabla\psi^*(x) = \psi^*(x)$ almost everywhere in B. To prove the converse we again use Theorem 5.1 to conclude that $\lambda_1(B) = \mu_1(B)$ as claimed. □

Remark 5.5. Statements similar to the ones in Theorem 5.4 hold for Dirichlet boundary conditions. The only difference is that we can assume that Ω is an arbitrary bounded domain. Also a rather precise characterization of those operators for which $\mu_1(\Omega) = \lambda_1(B)$ follows from Remark 5.3.

Remark 5.6. We could look at even more general operators and characterize those for which $\mu_1(\Omega) = \lambda_1(B)$. We could look at

$$\begin{cases} -\operatorname{div}\bigl(A(x)\nabla u(x)\bigr) + b(x)u = \lambda u & \text{in } \Omega, \\ u = 0 & \text{on } \Gamma_0, \\ \dfrac{\partial u}{\partial \nu_A} + b_0 u = 0 & \text{on } \Gamma_1, \end{cases}$$

with $b \in L_\infty(\Omega)$ nonnegative and $b_0 \in L_\infty(\partial\Omega)$ such that $b_0 \geq \beta > 0$ ($\beta \in (0,\infty)$ constant). If μ_1 denotes the first eigenvalue of the above problem, then $\mu_1(\Omega) = \lambda_1(\Omega)$ implies that $b = 0$ and $b_0 = \beta$ almost everywhere. Clearly $\mu_1(\Omega) \geq \lambda_1(\Omega)$

by the variational characterization. Suppose now that $b > 0$ or $b_0 > \beta$ on a set of positive measure, and let φ denote the first eigenvalue of the above problem. The form corresponding to the above is

$$a_1(u,v) := \int_\Omega \big(A\nabla u\big) \cdot \nabla v + buv\,dx + \int_{\Gamma_1} b_0 uv\,d\sigma.$$

By the variational characterization

$$\lambda_1(\Omega) \leq \frac{b(\varphi,\varphi)}{\|\varphi\|_2^2} \leq \frac{a(\varphi,\varphi)}{\|\varphi\|_2^2} < \frac{a_1(\varphi,\varphi)}{\|\varphi\|_2^2} = \mu_1(\Omega)$$

as claimed. Here we use that $\varphi > 0$ on $\Omega \cup \Gamma_1$.

DIFFUSION MEDIATED TRANSPORT IN MULTIPLE STATE SYSTEMS*

STUART HASTINGS†, DAVID KINDERLEHRER‡, AND J. BRYCE MCLEOD†

Abstract. Intracellular transport in eukarya is attributed to motor proteins that transduce chemical energy into directed mechanical motion. Nanoscale motors like kinesins tow organelles and other cargo on microtubules or filaments, have a role separating the mitotic spindle during the cell cycle, and perform many other functions. The simplest description gives rise to a weakly coupled system of evolution equations. The transport process, to the mind's eye, is analogous to a biased coin toss. We describe how this intuition may be confirmed by a careful analysis of the cooperative effect among the conformational changes and potentials present in the equations.

Key words. Fokker–Planck, weakly coupled systems, molecular motor, transport

1. Introduction.

Motion in small live systems has many challenges, as famously discussed in Purcell [25]. Prominent environmental conditions are high viscosity and warmth. Not only is it difficult to move, but maintaining a course is rendered difficult by immersion in a highly fluctuating bath. Intracellular transport in eukarya is attributed to motor proteins that transduce chemical energy into directed mechanical motion. Proteins like kinesin function as nanoscale motors, towing organelles and other cargo on microtubules or filaments, have a role separating the mitotic spindle during the cell cycle, and perform many other functions. Because of the presence of significant diffusion, they are sometimes referred to as Brownian motors. Since a specific type tends to move in a single direction, for example, anterograde or retrograde to the cell periphery, these proteins are sometimes referred to as molecular ratchets. How do they overcome the issues posed by Purcell to provide the transport necessary for the activities of the cell?

There are many descriptions of the function of these proteins, or aspects of their thermodynamical behavior, beginning with Ajdari and Prost [1], Astumian [2], Doering, Ermentrout, and Oster [6], and Peskin, Ermentrout, and Oster [23]. For more recent work, note the review paper [26] and [27, Chapter 8]. Additional description is given in [8], [13], [17], [18], [21], [28]. The descriptions consist either in discussions of stochastic differential equations, which give rise to the distribution functions via the Chapman–Kolmogorov equation, or of distribution functions directly. In [5], we have suggested a dissipation principle approach for motor proteins like conventional kinesin, motivated by Howard [12]. The dissipation principle, which involves a Kantorovich–Wasserstein metric, identifies the environment of the system and gives rise to an implicit scheme from which evolution equations follow; see [3], [14], [15], [16], [19], [20], and more generally [29]. Most of these formulations consist, in the end,

of Fokker–Planck-type equations coupled via conformational change factors, typically known as weakly coupled parabolic systems. Our own is also distinguished because it has natural boundary conditions. To investigate transport properties, our attention is directed toward the stationary solution of such a system, as we explain below.

A special collaboration among the potentials and the conformational changes in the system must be present for transport to occur. To investigate this, we introduce the n-state system. Suppose that $\rho_1, \dots, \rho_n$ are partial probability densities defined on the unit interval $\Omega = (0, 1)$ satisfying

$$\begin{aligned} &\frac{d}{dx}\left(\sigma \frac{d\rho_i}{dx} + \psi_i' \rho_i\right) + \sum_{j=1,\dots,n} a_{ij}\rho_j = 0 \text{ in } \Omega, \\ &\sigma \frac{d\rho_i}{dx} + \psi_i' \rho_i = 0 \text{ on } \partial\Omega,\ i = 1, \dots n, \\ &\rho_i \geqq 0 \text{ in } \Omega,\ \int_\Omega (\rho_1 + \cdots + \rho_n) dx = 1. \end{aligned} \tag{1.1}$$

Here $\sigma > 0, \psi_1, \dots, \psi_n$ are smooth nonnegative functions of period $1/N$, and $A = (a_{ij})$ is a smooth rate matrix of period $1/N$, that is,

$$\begin{aligned} &a_{ii} \leqq 0,\ a_{ij} \geqq 0 \text{ for } i \neq j, \\ &\textstyle\sum_{i=1,\dots,n} a_{ij} = 0,\ j = 1, \dots, n. \end{aligned} \tag{1.2}$$

We shall also have occasion to enforce a nondegeneracy condition,

$$a_{ij} \not\equiv 0 \text{ in } \Omega,\ i, j = 1, \dots, n. \tag{1.3}$$

The conditions (1.2) mean that $P = \mathbf{1} + \tau A$, for $\tau > 0$ small enough, is a probability matrix. The condition (1.3), we shall see, ensures that none of the components of ρ are identically zero passive placeholders in the system. In this context, the potentials $\psi_1, \dots, \psi_n$ describe interactions among the states, the elements of the protein's structure, and the microtubule track, and the matrix A describes interchange of activity among the states. The system (1.1) are the stationary equations of the evolution system

$$\begin{aligned} &\frac{\partial\rho_i}{\partial t} = \frac{\partial}{\partial x}\left(\sigma \frac{\partial\rho_i}{\partial x} + \psi_i' \rho_i\right) + \sum_{j=1,\dots,n} a_{ij}\rho_j \quad \text{in } \Omega,\ t > 0, \\ &\sigma \frac{\partial\rho_i}{\partial x} + \psi_i' \rho_i = 0 \quad \text{on } \partial\Omega,\ t > 0,\ i = 1, \dots n, \\ &\rho_i \geqq 0 \text{ in } \Omega,\ \int_\Omega (\rho_1 + \cdots + \rho_n) dx = 1, \quad t > 0. \end{aligned} \tag{1.4}$$

Before proceeding further, let us discuss what we intend by transport. In a chemical or conformational change process, a reaction coordinate (or coordinates) must be specified. This is the independent variable. In a mechanical system, it is usually evident what this coordinate must be. In our situation, even though both conformational change and mechanical effects are present, it is natural to specify the distance along the motor track, the microtubule, here the interval Ω, as the independent variable. We interpret the migration of density to one end of the track during the evolution as evidence of transport.

We shall show in section 4 that the stationary solution of the system (1.1), which we denote by $\rho^\sharp$, is globally stable: given any solution $\rho(x,t)$ of (1.4),

$$\rho(x,t) \to \rho^\sharp(x) \text{ as } t \to \infty. \tag{1.5}$$

So the migration of density we referred to previously may be ascertained by inspection of $\rho^\sharp$. In what follows, we simply set $\rho = \rho^\sharp$.

If the preponderance of mass of ρ is distributed at one end of the track, our domain Ω, then transport is present. Our main result, stated precisely later in section 3, is that with suitable potentials $\psi_1, \ldots, \psi_n$ and with favorable coupling between them and the rate matrix A, there are constants K and M, independent of σ, such that

$$\sum_{i=1}^{n} \rho_i \left(x + \frac{1}{N} \right) \leqq K e^{-\frac{M}{\sigma}} \sum_{i=1}^{n} \rho_i(x), \; x \in \Omega, \; x < 1 - \frac{1}{N}, \tag{1.6}$$

for sufficiently small $\sigma > 0$. So from one period to the next, total mass decays exponentially as in Bernoulli trials with a biased coin.

In summary, transport results from functional relationships in the system (1.1) or (1.4). The actual proof is technical, as most proofs are these days, and a detailed explanation of the conditions we impose is given after Theorem 3.2, when the notation has been introduced. Here we briefly consider the main elements of our thinking. We also refer to [10] for a more extended discussion.

To favor transport, we wish to avoid circumstances that permit decoupling in (1.1), for example,

$$A\rho = 0, \text{ where } \rho = (\rho_1, \ldots, \rho_n),$$

since in this case the solution vector is periodic. Such circumstances may be related to various types of detailed balance conditions. In detailed balance, we would find that

$$a_{ij}\rho_j = a_{ji}\rho_i \quad \text{for all } i, j = 1, \ldots, n,$$

implying that $A\rho = 0$. For example, if it is possible to find a solution ρ of (1.1) that minimizes the free energy of the system

$$F(\eta) = \sum_{i=1\cdots n} \int_\Omega \left\{ \psi_i \eta_i + \sigma \eta_i \log \eta_i \right\} dx,$$

then $A\rho = 0$.

But avoiding these situations is not nearly sufficient. First we require that the potentials ψ_i have some asymmetry property. Roughly speaking, to favor transport to the left, toward $x = 0$, a period interval must have some subinterval where all the potentials ψ_j are increasing. In addition every point must have a neighborhood where at least one ψ_i is increasing. Some coupling among the n states must take place.

Now we explain the nature of the coupling we impose, the properties of the matrix A. As mentioned above, in any neighborhood in Ω, at least one ψ_i should be increasing to promote transport toward $x = 0$. Density tends to accumulate near the minima of the potentials, which correspond to attachment sites of the motor to the microtubule and its availability for conformational change. This typically would be where the matrix A is supported. In a neighborhood of such a minimum, states which are not favored for left transport should have the opportunity to switch to state i, so we impose $a_{ij} > 0$ for all of these states. The weaker assumption, insisting only that the state associated with potential achieving the minimum have this switching opportunity, is insufficient. This is a type of ergodic hypothesis saying that there must be mixing between at least one potential which transports left and all the ones which may not. Our hypothesis is not optimal, but some condition is necessary. One may consider, for example, simply adding new states to the system which are uncoupled to the original states. In fact, it is possible to construct situations where there is actually transport to the right by inauspicious choice of the supports of the a_{ij}, as we show in section 5.

Here we consider only (1.1), although many other and more complex situations are possible. One example is a system where there are many conformational changes, not all related to movement. For example, one may consider the system whose stationary state is

$$\begin{aligned} \frac{d}{dx}\left(\sigma\frac{d\rho_i}{dx} + \psi_i'\rho_i\right) + \sum_{j=1,\ldots,n} a_{ij}\rho_j = 0 \text{ in } \Omega, \quad i = 1,\ldots m,\\ \sum_{j=1,\ldots,n} a_{ij}\rho_j = 0 \text{ in } \Omega, \quad i = m+1,\ldots n,\\ \sigma\frac{d\rho_i}{dx} + \psi_i'\rho_i = 0 \text{ on } \partial\Omega,\ i = 1,\ldots m,\\ \rho_i \geqq 0 \text{ in } \Omega,\ \int_\Omega(\rho_1 + \cdots + \rho_n)dx = 1. \end{aligned} \tag{1.7}$$

One such example is in [10]. We leave additional such explorations to the interested reader. In Chipot, Hastings, and Kinderlehrer [4] (cf. also [9]), the two-component system was analyzed. As well as being valid for an arbitrary number of active components, our proof here is based on a completely different and more widely applicable approach.

2. Existence. There are several ways to approach the existence question for (1.1). In [4], we gave existence results based on the Schauder fixed point theorem and a second proof based on an ordinary differential equations shooting method. The Schauder proof extends to the current situation, and to higher dimensions, but the shooting method was limited to the two-state case. Here we offer a new ordinary differential equations method proof which is of interest because it separates existence from uniqueness and positivity, showing that existence is a purely algebraic property depending only on the second line in (1.2),

$$\sum_{i=1,\ldots,n} a_{ij} = 0,\ j = 1,\ldots,n, \tag{2.1}$$

while positivity and uniqueness rely on the more geometric nature of the inequalities. We shall prove Theorem 2.1 below, followed by a brief discussion of a stronger result whose proof is essentially the same. Recall that $\Omega = (0, 1)$.

THEOREM 2.1. *Assume that $\psi_i, a_{ij} \in C^2(\overline{\Omega}), i, j = 1,\ldots,n$, and that (2.1) holds. Then there exists a (nontrivial) solution $\rho = (\rho_1,\ldots,\rho_n)$ to the equations and boundary conditions in (1.1). Assume furthermore that (1.2) and (1.3) hold. Then ρ is unique and*

$$\rho_i(x) > 0 \textit{ in } \Omega \quad \textit{and} \quad \rho_i \in C^2(\overline{\Omega}),\ i = 1,\ldots,n.$$

Proof. Introduce

$$\phi_i = \sigma \frac{d\rho_i}{dx} + \psi_i' \rho_i \ \text{ in } \Omega,\ i = 1, \ldots, n.$$

Our system may be written as the system of $2n$ ordinary differential equations, where (2.1) holds:

$$\begin{aligned} \sigma \frac{d\rho_i}{dx} &= \phi_i - \psi_i' \rho_i, \quad i = 1, \ldots, n, \\ \frac{d\phi_i}{dx} &= -\textstyle\sum_{j=1,\ldots,n} a_{ij} \rho_j, \quad i = 1, \ldots, n. \end{aligned} \tag{2.2}$$

Let Φ denote the $2n \times 2n$ fundamental solution matrix of (2.2) with $\Phi(0) = \mathbf{1}$. Let Ψ be the $2n \times n$ matrix consisting of the first n columns of Φ. Then

$$\Psi = \begin{pmatrix} R \\ S \end{pmatrix},$$

where R and S are $n \times n$ matrix functions with $R(0) = \mathbf{1}$ and $S(0) = 0$. We wish to obtain a solution

$$\begin{pmatrix} \rho \\ \phi \end{pmatrix} = \Phi c$$

such that $\phi(0) = \phi(1) = 0$. To have $\phi(0) = 0$, we need the last n components of c to be zero, so

$$\begin{pmatrix} \rho \\ \phi \end{pmatrix} = \Psi d,$$

where d is the vector consisting of the first n components of c. We then need the last n components of $\Psi(1)d$ to be zero, namely,

$$S(1)d = 0. \tag{2.3}$$

Now in this setup, we have $\phi_i(0) = 0,\ i = 1, \ldots, n$, for each column of S and from (2.1),

$$\sum_{i=1,\ldots,n} \frac{d\phi_i}{dx}(x) = 0,\ x \in \Omega,$$

whence

$$\sum_{i=1,\ldots,n} \phi_i(x) = 0,\ x \in \Omega.$$

But this simply means that for each j

$$\sum_{i=1,\ldots,n} S_{ij}(x) = 0,$$

so the sum of the rows of S is zero for every $x \in \Omega$, i.e., det $S(x) = 0$, and so S is singular. Hence we can find a (nontrivial) solution to (2.3).

Now we assume (1.2) and (1.3). If the solution is positive, it is the unique solution. This follows a standard argument. Suppose that ρ is a positive solution and that ρ^* is a second solution. Then $\rho+\mu\rho^*$ is a solution for any constant μ and $\rho+\mu\rho^*>0$ in Ω for sufficiently small $|\mu|$. Increase $|\mu|$ until we reach the first value for which some ρ_i has a zero, say at $x_0 \in \Omega$. For this value of i we have that for $f=\rho+\mu\rho^*$, f_i has a minimum at x_0 and

$$-\frac{d}{dx}\left(\sigma\frac{df_i}{dx}+\psi_i' f_i\right)-a_{ii}f_i=\sum_{\substack{j=1,\dots,n\\ j\neq i}} a_{ij}f_j \geqq 0, \tag{2.4}$$

$$\sigma\frac{df_i}{dx}+\psi_i' f_i=0. \tag{2.5}$$

By an elementary maximum principle [24] (cf. also [4]), we have that $f_i \equiv 0$.

We now claim that $f\equiv 0$. Choose any f_j and assume that it does not vanish identically. Using the maximum principle as before, $f_j>0$. Now choose a point x_0 such that $a_{ij}(x_0)>0$. Substituting onto (2.4) we now have a contradiction because $f_i\equiv 0$. Thus there is at most one solution satisfying (1.1).

It now remains to show that there is a positive solution. We employ a continuation argument. Note that there is a particular case where $\psi_i'(x)\equiv 0$ for all i and $a_{ii}(x)=1-n$, and $a_{ij}(x)=1$ for $j\neq i$. The solution in this case is $\rho_i(x)=\frac{1}{n}$, with our normalization in (1.1). For the moment, it is convenient to use a different normalization in terms of the vector d found above: choose the unique $d=(d_1,\dots,d_n)^T$ satisfying $\max_i d_i=1$.

For the special case above with

$$\psi_i'=0,\quad a_{ii}=1-n,\quad \text{and}\quad a_{ij}=1,\ i\neq j,$$

we find that $d=(1,\dots,1)^T$. To abbreviate the system in vector notation, let ψ_0' and ψ' be the diagonal matrices of potentials $\psi_i'=0$ and ψ_i', respectively, and let A_0 and A denote the matrices of lower order coefficients. For each λ, $0\leqq\lambda\leqq 1$, we solve the problem

$$\begin{aligned}\sigma\frac{d^2\rho}{dx^2}+\frac{d}{dx}((\lambda\psi'+(1-\lambda)\psi_0')\rho)+(\lambda A+(1-\lambda)A_0)\rho=0 \text{ in } \Omega,\\ \sigma\frac{d\rho}{dx}+(\lambda\psi'+(1-\lambda)\psi_0')\rho=0 \text{ at } x=0,1.\end{aligned} \tag{2.6}$$

For $\lambda=0$, (2.6) has a unique solution satisfying $\max_i\rho_i(0)=1$, and this solution is positive. As long as the solution is positive, the argument given above shows that it is unique. As we increase λ from 0, the solution is continuous as a function of λ, since the vector d will be continuous as long as it is unique.

Let Λ denote the subset of $\lambda\in[0,1]$ for which there is a positive solution of (2.6). To show that $\Lambda\subset[0,1]$ is open, consider $\lambda_0\in\Lambda$ and a sequence of points in Λ^c, the complement of Λ, convergent to λ_0. For each of these there is a nonpositive solution of (2.6), and we may assume that the initial conditions d are bounded. Hence a subsequence converges to the initial condition for a nonpositive solution with $\lambda=\lambda_0$, which contradicts the uniqueness of the positive solution.

To show Λ is closed, again suppose the contrary and that $\hat\lambda$ is a limit point of Λ not in Λ. Now some component $\hat\rho_i$ must have a zero, and $\hat\rho_i\geqq 0$ in Ω. Then by the maximum principle used above, $\hat\rho_i\equiv 0$. We now repeat the argument above to conclude that $\hat{\rho}_j \equiv 0$ in Ω for all $j = 1, \dots, n$. But this is impossible because we have imposed the condition that $\max_i \hat{\rho}_i(0) = 1$. This implies that Λ is open, so $\Lambda = [0, 1]$.

Renormalizing to obtain total mass 1 completes the proof.

Condition (1.3) is more restrictive than necessary for uniqueness and positivity of the solution. For an improved result, recall that $P_\tau = \mathbf{1} + \tau A$, $\tau > 0$ small, is a probability matrix when (1.2) is assumed. A probability matrix P is ergodic if some power P^k has all positive entries. In this case it has an eigenvector with eigenvalue 1 whose entries are positive, corresponding to a unique stationary state of the Markov chain it determines and other well-known properties from the Perron–Frobenius theory. Such matrices are often called irreducible and sometimes even "regular." We may now state an improvement of Theorem 2.1

THEOREM 2.2. *In Theorem* 2.1 *replace condition* (1.3) *with*

$$\int_0^1 P_\tau(x)dx \quad \textit{is ergodic.}$$

Then the conclusions of Theorem 2.1 *hold.*

We outline the changes which must be made to prove this result. The previous proof relied on showing that if for some i, $\rho_i \equiv 0$, then $\rho_j \equiv 0$ for every j. This followed from the maximum principle and the feature of the equations that each constituent was nontrivially represented near at least one point $x_0 \in \Omega$. But suppose that $a_{ij} \equiv 0$ for some j. In this case we could have $\rho_j > 0$, and this has no effect on ρ_i.

Under the assumption that $\int_0^1 P_\tau(x)dx$ is ergodic, some nondiagonal element in the ith row of A is not identically zero. This means that there is a $\pi(i) \neq i$ such that $\rho_i \equiv 0$ implies that $\rho_{\pi(i)} \equiv 0$. We may repeat this argument since ergodicity implies that the permutation π can be chosen so that $\pi^m(i)$ cycles around the entire set of integers $1, \dots, n$.

This completes the proof of existence of a unique solution of the stationary system with $\max_i d_i = 1$. This solution is also positive. Renormalizing to obtain total mass 1 completes the proof.

3. Transport. As we observed in the existence proof of the last section, the condition (1.1) implies that

$$\sum_{i=1,\dots,n} \frac{d}{dx}\left(\sigma \frac{d\rho_i}{dx} + \psi_i' \rho_i\right) = 0,$$

so that

$$\sum_{i=1,\dots,n} \left(\sigma \frac{d\rho_i}{dx} + \psi_i' \rho_i\right) = \gamma = \text{ const.}$$

In the case of interest of kinesin-type models, the boundary condition of (1.1) implies that $\gamma = 0$. In other words,

$$\sum_{i=1,\dots,n} \left(\sigma \frac{d\rho_i}{dx} + \psi_i' \rho_i\right) = 0. \tag{3.1}$$

A simulation of typical behavior in a two-species system is given in Figure 3.1.

THEOREM 3.1. *Suppose that ρ is a positive solution of* (1.1), *where the coefficients a_{ij}, $i, j = 1, \dots, n$, and the ψ_i, $i = 1, \dots, n$, are smooth and $1/N$-periodic in $\overline{\Omega}$. Suppose that* (1.2) *holds and also that the following conditions are satisfied:*

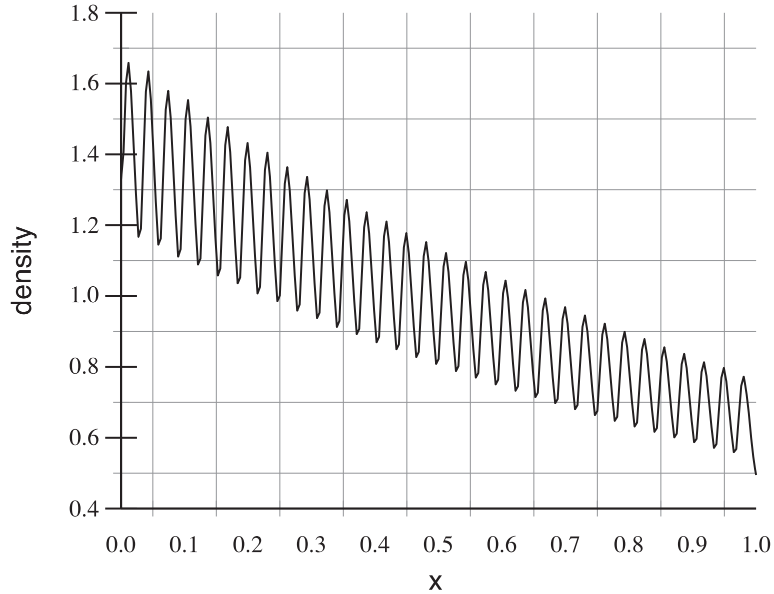

FIG. 3.1. *Transport in a two-species system with period* 16. *The abscissa shows the total density* $\rho_1 + \rho_2$. *In this computation,* ψ_2 *is a one-half period translate of* ψ_1, *and the support of the* $a_{ij}, i, j = 1, 2$, *is a neighborhood of the minima of the* $\psi_i, i = 1, 2$. *The simulation was executed with a semi-implicit scheme. Additional details are given at the conclusion of section* 5.

(i) *Each* ψ_i' *has only a finite number of zeros in* $\overline{\Omega}$.
(ii) *There is some interval in which* $\psi_i' > 0$ *for all* $i = 1, \dots, n$.
(iii) *In any interval in which no* ψ_i' *vanishes,* $\psi_j' > 0$ *in this interval for at least one* j.
(iv) *If* $I, |I| < 1/N$, *is an interval in which* $\psi_i' > 0$ *for* $i = 1, \dots, p$ *and* $\psi_i' < 0$ *for* $i = p+1, \dots, n$, *and* a *is a zero of at least one of the* ψ_k' *which lies within* ϵ *of the right-hand end of* I, *then for* ϵ *sufficiently small, there is at least one index* i, $i = 1, \dots, p$, *for which* $a_{ij} > 0$ *in* $(a - \eta, a)$ *for some* $\eta > 0$ *and for all* $j = p+1, \dots, n$.

Then there exist positive constants K, M *independent of* σ *and depending on the potentials* $\psi_i, i = 1, \dots, n$, *and the coefficients* $a_{ij}, i, j = i, \dots, n$, *such that*

$$\sum_{i=1}^{n} \rho_i \left(x + \frac{1}{N} \right) \leqq K e^{-\frac{M}{\sigma}} \sum_{i=1}^{n} \rho_i(x), \;\; x \in \Omega, \;\; x < 1 - \frac{1}{N}, \tag{3.2}$$

for sufficiently small σ.

Note that (3.1) holds under the hypotheses of the theorem. Also note that from (iv), where $a_{ij} > 0, j = p+1, \dots, n$, necessarily, $a_{ii} < 0$ according to (1.2). We shall prove Theorem 3.2 below. For this, it is convenient to consider a single-period interval rescaled to be $[0, 1]$. Theorem 3.1 then follows by rescaling and applying Theorem 3.2 to period intervals.

THEOREM 3.2. *Suppose that* ρ *is a positive solution of* (1.1), *where the coefficients* a_{ij}, $i, j = 1, \dots, n$, *and the* ψ_i, $i = 1, \dots, n$, *are smooth in* $[0, 1]$. *Suppose that* (1.2) *holds and also that the following conditions are satisfied:*

(i) *Each* ψ_i' *has only a finite number of zeros in* $[0, 1]$.

(ii) *There is some interval in which* $\psi_i' > 0$ *for all* $i = 1, \dots, n$.

(iii) *In any interval in which no* ψ_i' *vanishes,* $\psi_j' > 0$ *in this interval for at least one* j.

(iv) *If* I *is an interval in which* $\psi_i' > 0$ *for* $i = 1, \dots, p$ *and* $\psi_i' < 0$ *for* $i = p+1, \dots, n$, *and* a *is a zero of at least one of the* ψ_k' *which lies within* ϵ *of the right-hand end of* I, *then for* ϵ *sufficiently small, there is at least one* i, $i = 1, \dots, p$, *for which* $a_{ij} > 0$ *in* $(a - \eta, a)$ *for some* $\eta > 0$, $j = p+1, \dots, n$.

Then there exist positive constants K, M *independent of* σ *and depending on the potentials* $\psi_i, i = 1, \dots, n$, *and the coefficients* $a_{ij}, i, j = i, \dots, n$, *such that*

$$\sum_{i=1}^{n} \rho_i(1) \leqq K e^{-\frac{M}{\sigma}} \sum_{i=1}^{n} \rho_i(0) \tag{3.3}$$

for sufficiently small σ.

The conclusion of Theorem 3.2 is that the magnitude of the solution ρ, $\sum_{i=1}^{n} \rho_i$, is much smaller at $x = 1$ than at $x = 0$, or in terms of Theorem 3.1, that it is bounded above by an exponentially decreasing function for small σ. There is no suggestion that $\sum_{i=1}^{n} \rho_i$ is itself exponentially decreasing, and it is not. Indeed, the core of the mathematical argument is that $\sum \rho_i$ is exponentially decreasing on intervals where all ψ_i' are positive, while not significantly increasing in the remainder of [0,1]. The $\sum \rho_i$ may increase, even exponentially, in regions within δ of a zero of a ψ_i', but because the total length of these intervals is very small, the increase is outweighed by the decrease elsewhere. The argument in intervals where the signs of the ψ_i' are mixed is more delicate and relies on the coupling, as spelled out in (iv), the nonvanishing of some a_{ij} near the minima of ψ_i, and we briefly describe it below.

First let us assess how, essentially, the constants K, M depend on the parameters, especially the potentials ψ_i, by examining an interval where $\psi_i' > 0$ for all i. Such an interval exists by condition (ii) of the theorem. Let $[a, b]$ be such an interval and set

$$q(x) = \min_{i=1,\dots,n} \psi_i'(x).$$

From (3.1),

$$\frac{d}{dx}(\rho_1 + \cdots + \rho_n)(x) \leqq -\frac{1}{\sigma} q(x)(\rho_1 + \cdots + \rho_n)(x),$$

so that by integrating,

$$(\rho_1 + \cdots + \rho_n)(b) \leqq e^{-\frac{1}{\sigma}\int_a^b q\, ds}(\rho_1 + \cdots + \rho_n)(a).$$

If there are several such intervals, we just combine the effects, and this is the essence of how K, M (particularly M) depend on the ψ_i'. In other words, a Gronwall-type argument is successful here.

Now let us try to explain the role of the coupling. This comes into play when condition (iv) of the hypotheses holds. Suppose that $\nu \in \{1, \dots, p\}$ is a favorable index in the interval I and consider the νth equation

$$\sigma \rho_\nu'' + \psi_\nu' \rho_\nu' + \psi_\nu'' \rho_\nu + a_{\nu\nu}\rho_\nu + \sum_{j \neq \nu}^{n} a_{\nu j}\rho_j = 0. \tag{3.4}$$

Equation (3.4) represents a balance between ρ_ν and the other ρ_j. As seen in what follows, since the items in the Σ are nonnegative, they may be discarded and (3.4) can be employed to find an upper bound for ρ_ν on I, because ψ_ν is increasing. We can then exploit (3.4) to impede the growth of the unfavorable $\rho_j, j = p+1, \ldots, n$. Namely, $\{\rho_j\}$ cannot be too large without forcing ρ_ν to be negative. But this can be ensured only if the coupling is really there, namely, if $a_{\nu j} > 0$. This is the motivation for the ergodic-type hypothesis in (iv).

Proof of Theorem 3.2. Since each ψ_i' has only finitely many zeros, we can enclose these zeros with intervals of length 2δ, where $\delta > 0$ and small will be chosen later. The remainder of [0,1] consists of a finite number of closed intervals $J_m, m = 1, \ldots, M$, in which no ψ_i' vanishes, and so we have that $\psi_i' \geqq k(\delta) > 0$ or $\psi_i' \leqq -k(\delta) < 0$ for each i and some positive $k(\delta)$. From (iii), $k(\delta)$ may be chosen so that in at least one J_m, $\psi_i' \geqq k(\delta)$ for all i.

First we establish the exponential decay which governs the behavior of the solution. This will be a simple application of Gronwall's lemma. Consider an interval $I_0 = J_m$ for one of the m's where $\psi_i' \geq k(\delta)$ for all i. Suppose that

$$\sup_{I_0} \big\{ \inf_i \psi_i'(x) \big\} = K_0,$$

where, of course, K_0 is independent of δ for small δ. So there is a point $x_0 \in I_0$ where

$$\psi_i'(x_0) \geqq K_0, \quad i = 1, \ldots, n,$$

and

$$\psi_i'(x) \geqq \frac{1}{2} K_0, \quad |x - x_0| < L_0, \quad i = 1, \ldots, n,$$

for

$$L_0 = \frac{1}{2} \frac{K_0}{\max_{i=1\ldots n} \{\sup_{[0,1]} |\psi_i''|\}}.$$

Hence, from (3.1),

$$\frac{d}{dx} \sum_{i=1}^n \rho_i \leqq -\frac{K_0}{2\sigma} \sum_{i=1}^n \rho_i \quad \text{in } |x - x_0| < L_0,$$

so that

$$\sum_{i=1}^n \rho_i(x_0 + L_0) \leqq e^{-\frac{1}{\sigma} K_0 L_0} \sum_{i=1}^n \rho_i(x_0 - L_0).$$

Since $\sum_{i=1}^n \rho_i' \leqq 0$ in I_0, we have that

$$\left(\sum_{i=1}^n \rho_i \right)(\xi^*) \leqq e^{-\frac{1}{\sigma} K_0 L_0} \left(\sum_{i=1}^n \rho_i \right)(\xi), \quad \text{where } I_0 = [\xi, \xi^*]. \tag{3.5}$$

Indeed, we could extend I_0 to an interval in which we demand only that all $\psi_i' \geqq 0$.

Next consider an interval, say I_1, of length 2δ centered on a zero a of one of the ψ_i'. From (3.1) we have that

$$\left| \frac{d}{dx} \left(\sum_{i=1}^n \rho_i \right) \right| \leq \frac{K_1}{\sigma} \sum_{i=1}^n \rho_i \quad \text{in } I_1,$$

where

$$K_1 = \max_{i=1..n} \sup_{0 \leqq x \leqq 1} |\psi_i'|,$$

so that

$$\left(\sum_{i=1}^{n} \rho_i\right)(a+\delta) \leqq e^{\frac{1}{\sigma}2K_1\delta} \left(\sum_{i=1}^{n} \rho_i\right)(a-\delta). \tag{3.6}$$

There may be N such intervals, but over them all the exponential growth is only $\frac{2}{\sigma}NK_1\delta$, and we can choose δ sufficiently small, which does not affect K_0, L_0 so that

$$2NK_1\delta < K_0L_0.$$

Finally, with δ so chosen, we consider an interval $I_2 = [\alpha, \beta]$ where, say,

$$\begin{aligned} &\psi_i' \geqq k(\delta),\ \ i = 1, \dots, p, \\ &\psi_i' \leqq -k(\delta),\ \ i = p+1, \dots, n. \end{aligned} \tag{3.7}$$

We may assume that there is some overlap, that the endpoints α, β of I_2 are in 2δ intervals considered above. In the interval I_2, we shall bound $\rho_1, \dots, \rho_p$ on the basis of (3.7) above. We shall then argue that $\rho_{p+1}, \dots, \rho_n$ are necessarily bounded or, owing to the coupling of the equations, the positivity of $\rho_1, \dots, \rho_p$ would fail.

Write the equation for ρ_1 in the form

$$\sigma\rho_1'' + \psi_1'\rho_1' + \psi_1''\rho_1 + a_{11}\rho_1 + \sum_{j=2}^{n} a_{1j}\rho_j = 0, \tag{3.8}$$

so that

$$\frac{d}{dx}\left(\rho_1' e^{\frac{1}{\sigma}(\psi_1(x)-\psi_1(\alpha))}\right) = -\frac{1}{\sigma}\left\{(a_{11}+\psi_1'')\rho_1 + \sum_{j=2}^{n} a_{1j}\rho_j\right\} e^{\frac{1}{\sigma}(\psi_1(x)-\psi_1(\alpha))},$$

and carrying out the integration,

(3.9)

$$\rho_1'(x) = \rho_1'(\alpha)e^{\frac{1}{\sigma}(\psi_1(\alpha)-\psi_1(x)} - \frac{1}{\sigma}\int_\alpha^x \left\{(a_{11}+\psi_1'')\rho_1 + \sum_{j=2}^{n} a_{1j}\rho_j\right\} e^{\frac{1}{\sigma}(\psi_1(s)-\psi_1(x))} ds.$$

Now the $a_{1j}, j \geqq 2$, and the ρ_i are all nonnegative, so that we may neglect the large sum and find a constant K_2 for which

$$\rho_1'(x) \leqq \rho_1'(\alpha)e^{\frac{1}{\sigma}(\psi_1(\alpha)-\psi_1(x))} + \frac{K_2}{\sigma}\int_\alpha^x \rho_1(s)e^{\frac{1}{\sigma}(\psi_1(s)-\psi_1(x))} ds. \tag{3.10}$$

Note that for small σ,

$$\int_\alpha^x e^{\frac{1}{\sigma}(\psi_1(s)-\psi_1(x))} ds \leqq \int_\alpha^x e^{\frac{k(\delta)}{\sigma}(s-x)} ds \leqq \frac{\sigma}{k(\delta)}. \tag{3.11}$$

Integrating (3.10),

$$\begin{aligned}\rho_1(x) - \rho_1(\alpha) &\leqq \rho_1'(\alpha)\int_\alpha^x e^{\frac{1}{\sigma}(\psi_1(\alpha)-\psi_1(s))}ds + \frac{K_2}{\sigma}\int_\alpha^x\int_\alpha^t \rho_1(s)e^{\frac{1}{\sigma}(\psi_1(s)-\psi_1(t))}dsdt\\ &\leqq K(\delta)\sigma|\rho_1'(\alpha)| + K(\delta)\int_\alpha^x \max_{[\alpha,t]}\rho_1 dt,\end{aligned}$$

so that

$$\max_{[\alpha,x]}\rho_1 \leqq \rho_1(\alpha) + K(\delta)\sigma|\rho_1'(\alpha)| + K(\delta)\int_\alpha^x \max_{[\alpha,t]}\rho_1 dt.$$

We may now use Gronwall's lemma to obtain

$$\rho_1(x) \leqq K(\delta)\big\{\rho_1(\alpha) + \sigma|\rho_1'(\alpha)|\big\}, \quad \alpha \leqq x \leqq \beta. \tag{3.12}$$

If we insert this into (3.10), we obtain

$$\rho_1'(x) \leqq |\rho_1'(\alpha)| + K(\delta)\big\{\rho_1(\alpha) + \sigma|\rho_1'(\alpha)|\big\}, \quad \alpha \leqq x \leqq \beta. \tag{3.13}$$

Similar estimates hold for $\rho_2, \dots, \rho_p$.

Our attention is directed to $\rho_{p+1}, \dots, \rho_n$. Our first step is lower bounds for $\rho_1', \dots, \rho_p'$, for which it suffices to carry out the details for ρ_1'. We can use (3.12) to modify our formula (3.9). Using (3.11),

$$\begin{aligned}\rho_1'(x) \geqq \rho_1'(\alpha)e^{\frac{1}{\sigma}(\psi_1(\alpha)-\psi_1(x))} - \frac{1}{\sigma}\max_{I_2}\rho_1(\max_{I_2}|a_{11}+\psi_1''|)\int_\alpha^x e^{\frac{1}{\sigma}(\psi_1(s)-\psi_1(x))}ds\\ - \frac{1}{\sigma}\max_{[\alpha,x]}(\rho_2 + \cdots \rho_p + \rho_{p+1} + \cdots + \rho_n)\max_{1\leqq i\leqq n, i\neq 1}\max_{I_2} a_{1i}\int_\alpha^x e^{\frac{1}{\sigma}(\psi_1(s)-\psi_1(x))}ds.\end{aligned}$$

So, since by (3.12) we have bounds for $\rho_2, \dots, \rho_p$, we can write

$$\begin{aligned}\rho_1'(x) \geqq \rho_1'(\alpha)e^{\frac{1}{\sigma}(\psi_1(\alpha)-\psi_1(x))} - K(\delta)\big\{\rho_1(\alpha) + \sigma|\rho_1'(\alpha)|\big\}\\ - K(\delta)\max\nolimits_{[\alpha,x]}(\rho_{p+1} + \cdots + \rho_n), \quad \alpha \leqq x \leqq \beta.\end{aligned} \tag{3.14}$$

Similarly for $\rho_2', \dots, \rho_p'$.

With our technique we can handle only the sum $\rho_{p+1} + \cdots + \rho_n$ and not individual $\rho_i, p+1 \leqq i \leqq n$. From (3.1), and taking into account (3.12), (3.13), and the signs of the ψ_i',

$$\begin{aligned}\frac{d}{dx}(\rho_{p+1} + \cdots + \rho_n) &= -\frac{d}{dx}(\rho_1 + \cdots + \rho_p) - \frac{1}{\sigma}(\psi_1'\rho_1 \cdots + \psi_p'\rho_p)\\ &\quad - \frac{1}{\sigma}(\psi_{p+1}'\rho_{p+1} + \cdots + \psi_n'\rho_n)\\ &\geqq -\frac{K_1(\delta)}{\sigma}\sum_{i=1}^p\left(\rho_i(\alpha) + \sigma\left|\frac{d\rho_i}{dx}(\alpha)\right|\right)\\ &\quad + \frac{K_2(\delta)}{\sigma}\sum_{i=p+1}^n \rho_i \quad \text{in } I_2.\end{aligned} \tag{3.15}$$

Let

$$C(\alpha) = \sum_{i=1}^p\left(\rho_i(\alpha) + \left|\frac{d\rho_i}{dx}(\alpha)\right|\right),$$

which means (3.15) assumes a fortiori the form

$$\frac{d}{dx}(\rho_{p+1}+\cdots+\rho_n) \geqq -\frac{K_1(\delta)}{\sigma}C(\alpha)+\frac{K_2(\delta)}{\sigma}(\rho_{p+1}+\cdots+\rho_n). \tag{3.16}$$

We assert that

$$\rho_{p+1}+\cdots+\rho_n \leqq \frac{K_1(\delta)}{K_2(\delta)}C(\alpha), \quad \alpha \leqq x \leqq \beta-\delta. \tag{3.17}$$

Suppose the contrary and that

$$A > 1 \quad \text{and}$$

$$(\rho_{p+1}+\cdots+\rho_n)(x^*) > \frac{AK_1(\delta)C(\alpha)}{K_2(\delta)} \text{ for some } x^* \in [\alpha, \beta-\delta]. \tag{3.18}$$

This continues to hold in $[x^*, \beta]$, since at a first $x \in I_2$, where it fails, (3.16) would imply that $\rho_{p+1}+\cdots+\rho_n$ were increasing, which is not possible. Indeed, integrating (3.16) between points $x^*, x \in I_2$ with $x^* < x$, we have that

$$\begin{aligned}(\rho_{p+1}+\cdots+\rho_n)(x) &\geqq (\rho_{p+1}+\cdots+\rho_n)(x^*)e^{\frac{K_2(\delta)}{\sigma}(x-x^*)}\\ &\quad+\frac{K_1(\delta)}{K_2(\delta)}C(\alpha)(1-e^{\frac{K_2(\delta)}{\sigma}(x-x^*)})\\ &\geqq \frac{AK_1(\delta)}{K_2(\delta)}C(\alpha)e^{\frac{K_2(\delta)}{\sigma}(x-x^*)}+\frac{K_1(\delta)}{K_2(\delta)}C(\alpha)(1-e^{\frac{K_2(\delta)}{\sigma}(x-x^*)})\\ &= (A-1)\frac{K_1(\delta)}{K_2(\delta)}C(\alpha)e^{\frac{K_2(\delta)}{\sigma}(x-x^*)}+\frac{K_1(\delta)}{K_2(\delta)}C(\alpha), \quad x^*, x \in I_2. \end{aligned} \tag{3.19}$$

Now let us suppose, without loss of generality, that (iv) holds for $i = 1$, that is, we can find a $K_3(\delta) > 0$ such that

$$\sum_{i=p+1}^{n} a_{1j}\rho_j \geqq K_3(\delta)(\rho_{p+1}+\cdots+\rho_n) \quad \text{ in } [\beta-\delta, \beta]. \tag{3.20}$$

Keep in mind that

$$e^{\frac{K_2(\delta)}{\sigma}(x-x^*)} \geqq e^{\frac{K_2(\delta)}{\sigma}\frac{1}{4}\delta} = e^{\frac{K_4(\delta)}{\sigma}} \quad \text{for } \beta-\frac{1}{4}\delta \leqq x \leqq \beta.$$

Then we have from (3.9)

$$\begin{aligned}\frac{d\rho_1}{dx}(x) &\leqq \frac{d\rho_1}{dx}(\alpha)e^{-\frac{1}{\sigma}(\psi_1(x)-\psi_1(\alpha))}+\frac{K(\delta)}{\sigma}C(\alpha)\int_\alpha^x e^{\frac{1}{\sigma}(\psi_1(s)-\psi_1(x))}ds\\ &\quad-\frac{(A-1)K_1(\delta)K_3(\delta)C(\alpha)}{K_2(\delta)}e^{\frac{1}{\sigma}K_4(\delta)}\\ &\leqq \frac{d\rho_1}{dx}(\alpha)e^{-\frac{1}{\sigma}(\psi_1(x)-\psi_1(\alpha))}+K(\delta)C(\alpha)\\ &\quad-\frac{(A-1)K_1(\delta)K_3(\delta)C(\alpha)}{K_2(\delta)}e^{\frac{1}{\sigma}K_4(\delta)} \text{ for } \beta-\frac{1}{4}\delta \leqq x \leqq \beta.\end{aligned}$$

Above, $\psi_1(x) > \psi_1(\alpha)$, so the exponential in the first term on the right may be neglected. From the trivial inequality

$$\begin{aligned} 0 \leqq \rho_1(x) &= \rho_1(\alpha) + \int_\alpha^x \rho_1'(s)ds \\ &\leqq C(\alpha) + \int_\alpha^x \rho_1'(s)ds, \end{aligned}$$

we have that

$$\begin{aligned} 0 \leqq \frac{\rho_1(x)}{C(\alpha)} &\leqq 1 + \int_\alpha^x (1+K(\delta))ds - \int_{\beta-\frac{1}{4}\delta}^{\beta-\frac{1}{8}\delta} (A-1)\frac{K_1(\delta)}{K_2(\delta)}K_3(\delta)e^{\frac{K_4(\delta)}{\sigma}}ds \\ &\leqq 1 + (1+K(\delta))(\beta-\alpha) - (A-1)\frac{K_1(\delta)}{K_2(\delta)}K_3(\delta)e^{\frac{K_4(\delta)}{\sigma}}\frac{1}{8}\delta \qquad (3.21) \\ &\quad \text{for } \beta - \frac{1}{8}\delta \leqq x \leqq \beta. \end{aligned}$$

Since $A > 1$, the above cannot hold for arbitrarily small σ independent of δ because the extreme right-hand side of (3.21) becomes negatively infinite as $\sigma \to 0$. This proves (3.17). Note that the size of σ determined by (3.21) depends on the geometrical features of the potentials $\psi_i, i = 1, \dots, n$, but not on $C(\alpha)$, that is, the magnitude of the solution ρ.

The theorem now follows by concatenating the three cases.

4. Stability of the stationary solution. In this section we discuss the trend to stationarity of solutions of the time-dependent system (1.4). We have the following stability theorem.

THEOREM 4.1. *Let $\rho(x,t)$ denote a solution of* (1.4) *with initial data*

$$\rho(x,0) = f(x) \qquad (4.1)$$

satisfying

$$f_i(x) \geqq 0,\ i = 1,\dots,n,\ \textit{and} \sum_{i=1,\dots,n} \int_\Omega f_i dx = 1.$$

Then there are positive constants K and ω such that

$$|\rho(x,t) - \rho_0(x)| \leqq Ke^{-\omega t} \text{ as } t \to \infty, \qquad (4.2)$$

where ρ_0 is the stationary positive solution obtained in Theorem 2.1.

Thus the stationary positive solution is globally stable. One proof of this was given in [4] for $n = 2$, and this proof may be extended to general n. A proof based on monotonicity of an entropy function is given in [22]. A different type of monotonicity result showing that the solution operator is an L^1-contraction is given in [11]. Here we outline a different way of viewing the problem based on inspection of the semigroup generated by the operator, written in vector form,

$$S\rho = \sigma\frac{\partial^2\rho}{\partial x^2} + \frac{\partial}{\partial x}(\psi'\rho) + A\rho, \qquad (4.3)$$

with natural boundary conditions. All the methods known to us are based on ideas from positive operators via Perron–Frobenius–Krein–Rutman generalizations or on closely related monotonicity methods.

We need the result that (4.3) has a real eigenvalue λ_0, which is simple and has an associated positive eigenfunction, and that all other eigenvalues λ satisfy Re $\lambda < \lambda_0$.

This is a standard result (see, for example, Zeidler [30]) obtained using the ideas of positive operators, but to assist the reader and for completeness we give a sketch of the proof. We define e^S by writing the solution of (1.4) in terms of (4.3) as

$$\rho(x,t) = e^{tS} f(x). \tag{4.4}$$

This is consistent with the notions of exponent, since

$$e^{(t+s)S} = e^{tS} e^{sS}$$

just expresses the fact that the solution at time $t+s$ is just the solution after time s followed by a further time t. We note that e^S is a positive operator, since $f \geqq 0$ implies $\rho \geq 0$, making use of the maximum principle [24], and it is compact, since it is essentially an integration. And so e^S has a real eigenvalue, e^{λ_0}, which is simple and has a positive eigenfunction. Further, it is simple to see, for example, by solving the equation explicitly, that if S has an eigenvalue λ, then e^S has an eigenvalue e^λ, and vice versa. Thus S has a real eigenvalue λ_0, which is simple and has a positive eigenfunction. Further, the fact that all the other eigenvalues e^λ of e^S have $|e^\lambda| < e^{\lambda_0}$ implies that all other eigenvalues λ of S have Re $\lambda < \lambda_0$, as required.

We assume that the positive initial data f is normalized so that

$$\sum_{i=1,\ldots,n} \int_\Omega f_i dx = 1, \tag{4.5}$$

as in (1.1).

Now form the Laplace transform

$$\hat{\rho}\,(x,\lambda) = \int_0^\infty e^{-\lambda t} \rho\,(x,t)\,dt, \quad \mathrm{Re}\,\lambda > 0,$$

and (4.4) gives

$$\hat{\rho}\,(\cdot,\lambda) = (\lambda I - S)^{-1} f, \tag{4.6}$$

and $\hat{\rho}$ is analytic in λ for $\mathrm{Re}\,\lambda > 0$, but (4.6) allows us to extend this into the left half plane except for an isolated singularity at $\lambda = 0$, for in our problem the fact that we have a positive stationary solution implies that the real eigenvalue λ_0 is given by $\lambda_0 = 0$. The usual inversion formula gives

$$\rho(x,t) = \frac{1}{2\pi i} \int_{\gamma - i\infty}^{\gamma + i\infty} e^{\lambda t} \hat{\rho}(x,\lambda) d\lambda, \ \gamma > 0. \tag{4.7}$$

Now for finite γ and ν, with ν large, and with $\lambda = \gamma + i\nu$,

$$\|(\lambda I - S)^{-1}\| = O\left(\frac{1}{\nu}\right). \tag{4.8}$$

For we can write

$$\begin{aligned} -(T\rho)_i &= \sigma \frac{d^2 \rho_i}{dx^2} + \frac{d}{dx}(\psi_i' \rho_i) + (A\rho)_i \\ &= \sigma \frac{d}{dx}(e^{-\frac{1}{\sigma}\psi_i} \phi_i') - (a'\phi)_i \\ &= -(M\phi)_i, \end{aligned}$$

where $\phi_i = e^{\frac{1}{\sigma}\psi_i}\rho_i$ and $a'_{ij} = a_{ij}e^{-\frac{1}{\sigma}\psi_i}$. The boundary conditions here are

$$\phi_i'(0) = \phi_i'(1) = 0,\ i = 1, \ldots, n.$$

Now consider

$$\lambda I - S = \lambda I + T = \lambda I + M$$

and

$$((M + \lambda I)\phi, \phi) = \sum_{i=1,\ldots,n} \int_\Omega [(M + \lambda I)\phi]_i \,\bar{\phi}_i dx. \tag{4.9}$$

The first term in M is self-adjoint, which gives a real contribution, and the second contribution in (4.9) is certainly

$$O\left\{\sum_{i=1,\ldots,n} \int_\Omega |\phi_i|^2 dx\right\}.$$

Thus if ν is sufficiently large,

$$im((M + \lambda I)\phi, \phi) \geqq \frac{1}{2}\nu \sum_{i=1,\ldots,n} \int_\Omega |\phi_i|^2 dx,$$

from which (4.8) follows easily.

Given the initial data f, we write

$$f = c\rho_0 + \rho^*,$$

where ρ^* is orthogonal to the positive eigenfunction, say ρ_0^*, of the adjoint operator of S. This determines c uniquely, since

$$c(\rho_0, \rho_0^*) = (f, \rho_0^*),$$

and $(\rho_0, \rho_0^*) \neq 0$ inasmuch as $\rho_{0,i} > 0, \rho_{0,i}^* > 0$. Then by the Fredholm alternative, we can solve, for any small λ,

$$(S - \lambda I)\phi = \rho^*,$$

uniquely if we insist that the solution is orthogonal to ρ_0. Then $(S - \lambda I)^{-1}\rho^*$ is bounded, and

$$\begin{aligned}(S - \lambda I)^{-1} f &= c\,(S - \lambda I)^{-1}\rho_0 + O\,(1)\\ &= -\lambda^{-1}c\rho_0 + O\,(1)\end{aligned}$$

as $\lambda \to 0$, showing that the pole of $(S - \lambda I)^{-1}$ at $\lambda = 0$ has residue $-c\rho_0$ so that we can now move the line of integration in (4.7) from $\gamma > 0$ to $\gamma < 0$. The contribution from the pole is $c\rho_0$, and the contribution from large λ is small by (4.8). Further, once this move is made, the contribution from the vertical line is of the form $O(e^{-\omega t})$. In all, therefore,

$$\rho\,(x, t) = c\rho_0 + O\left(e^{-\omega t}\right),$$

as required. Note that $c = 1$ since

$$\sum_{i=1,\ldots,n} \int_\Omega \rho_i dx = \sum_{i=1,\ldots,n} \int_\Omega \rho_{0,i} dx.$$

5. Discussion and some conditions for "reverse" transport. We now investigate what may happen if the conditions on the ψ_i in Theorem 3.1 are satisfied but those on the a_{ij} are not. In particular, we note that condition (iv) of Theorem 3.1 requires that if a is the minimum of one of the ψ_k, then some a_{ij} has support containing an interval $(a-\eta, a)$ to the left of a. We will show that without this condition, a_{ij} can be found such that the direction of transport is in the opposite direction from that described in Theorem 3.1. We remark that the necessity of some positivity condition on the a_{ij} to get transport is obvious, for if the a_{ij} are all identically zero, for example, or satisfy conditions that permit the functional F of the introduction to be minimized, then the solutions of (1.1) are periodic. What we look for in the following example is a situation in which there is transport, but in the opposite direction from that predicted by Theorem 3.1 even though the conditions on the ψ_i in that theorem are satisfied.

In constructing our example, we will specialize to $n = 2$, a two-state system. We also reverse direction. By this we mean that conditions (ii) and (iii) in Theorem 3.1, for $n = 2$, will be replaced by the following:

(ii′) *There is some interval in which $\psi_i' < 0$ for $i = 1, 2$.*

(iii′) *In any interval in which neither ψ_i' vanishes, $\psi_j' < 0$ in this interval for at least one j.*

For (iv) we substitute a simpler condition which could be used in Theorem 3.1 as well, as it implies (iv).

(iv′) *There is a neighborhood of each local minimum of ψ_1 or ψ_2 in which $a_{ij} \neq 0$ for all (i, j).*

Figure 5.1 shows potentials satisfying (ii′) and (iii′).

We then have the following corollary of Theorem 3.1.

COROLLARY 5.1. *If the hypotheses of Theorem* 3.1 *when $n = 2$ are satisfied, except that* (ii′), (iii′), *and* (iv′) *replace* (ii), (iii), *and* (iv), *then there exist constants K_1, K_2 independent of σ such that*

$$\sum_{i=1}^{2} \rho_i(x) \leq K_1 e^{-\frac{K_2}{\sigma}} \sum_{i=1}^{2} \rho_i\left(x + \frac{1}{N}\right) \text{ for } x \in \Omega,\ x \leq 1 - \frac{1}{N}.$$

We will now construct an example for the case $N = 1$ where conditions (i), (ii′), and (iii′) are satisfied, but not condition (iv′). Figure 5.1 shows conformation coefficients which do not satisfy (iv), and Figure 5.2 shows the resulting solution. Our example is constructed initially using δ-functions for the a_{ij}, and with this class of rate coefficients we are able to show that there is a $c > 0$ such that for sufficiently small σ,

$$\rho_1(1) + \rho_2(1) < e^{-\frac{c}{\sigma}}(\rho_1(0) + \rho_2(0)). \tag{5.1}$$

At the end we briefly discuss a slightly weaker form of reverse transport which we can then obtain for continuous coefficients.

Assume that ψ_1 has a minimum at $y_1 = 0$ followed by a maximum at $z_1 \in (0, 1)$ and then a second minimum at 1, with $\psi_1(0) = \psi_1(1)$. Further assume that ψ_2 has a minimum at $y_2 \in (z_1, 1)$ followed by a maximum at $z_2 \in (y_2, 1)$, and $\psi_2(0) = \psi_2(1)$. Finally assume that $\psi_i' \neq 0$ except at the minima and maxima specified above. Then $0 = y_1 < z_1 < y_2 < z_2 < 1$. There is no point where both $\psi_1' \geqq 0$ and $\psi_2' \geqq 0$, and so when the a_{ij} are all nonzero on $[0, 1]$, transport will be to the right as given in Corollary 5.1.

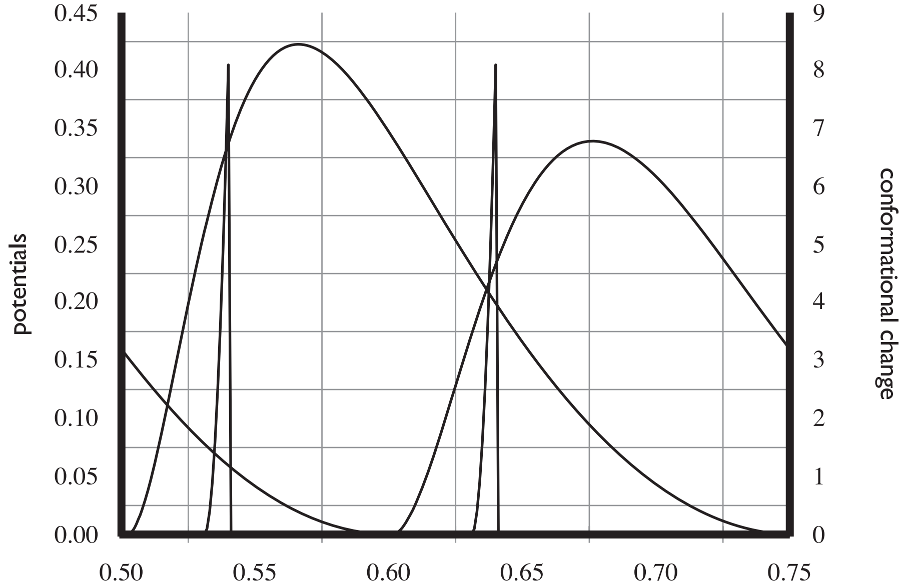

Fig. 5.1. *A period interval showing potentials and conformation coefficients which do not satisfy hypothesis* (iv′) *of Corollary* 3.2.

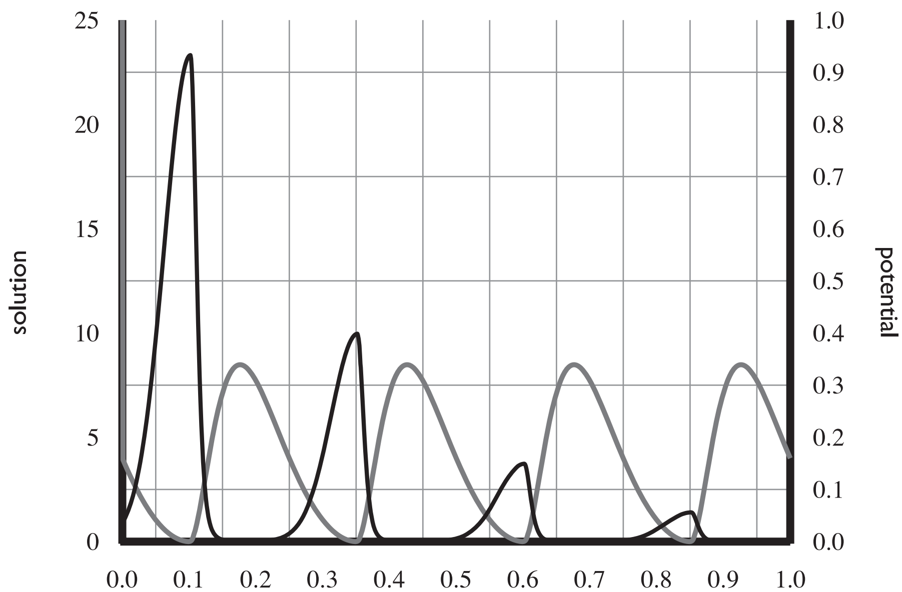

Fig. 5.2. *Reverse transport computed using the potentials and conformation coefficients shown in Figure* 5.1. *The simulation was done with XPP* [7].

But we will now choose new a_{ij} to give transport to the left.

Obviously, condition (iv′) must be violated. Choose a point $x_1 \in (y_1, z_1)$ and a point $x_2 \in (y_2, z_2)$. Then

$$0 = y_1 < x_1 < z_1 < y_2 < x_2 < z_2 < 1. \tag{5.2}$$

We consider the system

$$
\begin{aligned}
&(\sigma\rho_1' + \psi_1'\rho_1)' = (\delta(x-x_1) + \delta(x-x_2))(\rho_1 - \rho_2), \\
&(\sigma\rho_2' + \psi_2'\rho_2)' = (\delta(x-x_1) + \delta(x-x_2))(\rho_2 - \rho_1),
\end{aligned} \tag{5.3}
$$

with boundary conditions

$$
\sigma\rho_i' + \psi_i'\rho_i = 0 \text{ at } x = 0, 1 \text{ for } i = 1, 2. \tag{5.4}
$$

We wish to find further conditions which imply inequality (5.1) for some $c > 0$ and sufficiently small σ.

We follow the technique in [4] and let $\phi_i = \sigma\rho_i' + \psi_1'\rho_i$. Adding the equations in (5.3) shows that $\phi_1 + \phi_2$ is constant, and applying the boundary conditions shows that $\phi_1 + \phi_2 = 0$. This leads to the system

$$
\begin{aligned}
\sigma\rho_1' &= \phi - \psi_1'\rho_1, \\
\sigma\rho_2' &= -\phi - \psi_2'\rho_2, \\
\phi' &= (\delta(x-x_1) + \delta(x-x_2))(\rho_1 - \rho_2),
\end{aligned} \tag{5.5}
$$

where $\phi = \phi_1 = -\phi_2$.

Having obtained (5.5) under the conditions $\phi_i = 0$ at $x = 0, 1$, we now weaken these conditions, assuming only that $\phi_1 + \phi_2 = 0$. In this way, the same analysis applies to any period interval of the functions ψ_i, thus showing that if $N > 1$, decay occurs in each period interval. Therefore in (5.5) it is not assumed that $\phi(0)$ or $\phi(1)$ vanish. The only assumption made is that $\rho_i > 0$ on the entire interval, for $i = 1, 2$.

Observe that ϕ takes a jump of amount $\rho_1(x_j) - \rho_2(x_j)$ at each x_j. Further, ϕ is constant in the intervals $[0, x_1), (x_1, x_2), (x_2, 1]$. Let $\phi_j = \phi(y_j)$. Then

$$
\rho_i(x_j) = \rho_i(y_j)\, e^{\frac{\psi_i(y_j) - \psi_i(x_j)}{\sigma}} + (-1)^{i-1}\phi_j \int_{y_j}^{x_j} \frac{1}{\sigma} e^{\frac{\psi_i(s) - \psi_i(x_j)}{\sigma}} ds,
$$

$i = 1, 2$. Hence,

$$
\begin{aligned}
\rho_1(x_j) - \rho_2(x_j) = {} & \rho_1(y_j)\, e^{\frac{\psi_1(y_j) - \psi_1(x_j)}{\sigma}} - \rho_2(y_j)\, e^{\frac{\psi_2(y_j) - \psi_2(x_j)}{\sigma}} \\
& + \phi_j \int_{y_j}^{x_j} \frac{1}{\sigma} \left(e^{\frac{\psi_1(s) - \psi_1(x_j)}{\sigma}} + e^{\frac{\psi_2(s) - \psi_2(x_j)}{\sigma}} \right) ds.
\end{aligned}
$$

For $i = 1, 2$ let

$$
\begin{aligned}
&a_i = \frac{\psi_i(y_1)}{\sigma},\ b_i = \frac{\psi_i(x_1)}{\sigma},\ c_i = \frac{\psi_i(x_2)}{\sigma}, \\
&A_i = \int_0^{x_1} \frac{1}{\sigma} e^{\frac{\psi_i(s)}{\sigma}} ds,\ B_i = \int_{x_1}^{x_2} \frac{1}{\sigma} e^{\frac{\psi_i(s)}{\sigma}} ds,\ C_i = \int_{x_2}^{1} \frac{1}{\sigma} e^{\frac{\psi_i(s)}{\sigma}} ds.
\end{aligned} \tag{5.6}
$$

Since $\psi_i(0) = \psi_i(1)$, we eventually obtain (computation facilitated by Maple)

$$
\begin{aligned}
\rho_1(1) &= k_{11}\rho_1(0) - k_{12}\rho_2(0) + k_{13}\phi(0), \\
\rho_2(1) &= -k_{21}\rho_1(0) + k_{22}\rho_2(0) - k_{23}\phi(0),
\end{aligned}
$$

where

$$k_{11} = 1 + e^{-b_1}B_1 + e^{-b_1}C_1 + e^{-c_1}C_1 + e^{-b_1-c_1}B_1C_1 + e^{-b_1-c_2}B_2C_1$$

and $k_{12}, \ldots, k_{23}$ are similar expressions in terms of the constants defined in (5.6).

As in [4], we solve each of the inequalities $\rho_1(1) > 0$, $\rho_2(1) > 0$ for $\phi(0)$ and substitute the result into the other of these two relations. We find that

$$\rho_1(1) \le \frac{k_{11}k_{23} - k_{21}k_{13}}{k_{23}}\rho_1(0) + \frac{k_{13}k_{22} - k_{12}k_{23}}{k_{23}}\rho_2(0),$$

$$\rho_2(1) \le \frac{k_{11}k_{23} - k_{13}k_{21}}{k_{13}}\rho_1(0) + \frac{k_{13}k_{22} - k_{12}k_{23}}{k_{13}}\rho_2(0).$$

The desired decay relation (5.1) follows by showing that under certain additional conditions the four fractional coefficients

$$\frac{k_{11}k_{23} - k_{21}k_{13}}{k_{13}}, \quad \frac{k_{11}k_{23} - k_{21}k_{13}}{k_{23}}, \quad \frac{k_{13}k_{22} - k_{12}k_{23}}{k_{13}}, \quad \frac{k_{13}k_{22} - k_{12}k_{23}}{k_{23}} \tag{5.7}$$

tend to zero exponentially as $\sigma \to 0$.

Further Maple computation (checked with Scientific Workplace) shows, for example, that

$$\begin{aligned} k_{11}k_{23} - k_{21}k_{13} &= \frac{A_2}{e^{a_2}} + \frac{B_2}{e^{a_2}} + \frac{C_2}{e^{a_2}} + A_2\frac{B_1}{e^{a_2}e^{b_1}} + A_2\frac{C_1}{e^{a_2}e^{b_1}} + A_2\frac{B_2}{e^{a_2}e^{b_2}} + A_2\frac{C_1}{e^{a_2}e^{c_1}} \\ &+ A_2\frac{C_2}{e^{a_2}e^{b_2}} + B_2\frac{C_1}{e^{a_2}e^{c_1}} + A_2\frac{C_2}{e^{a_2}e^{c_2}} + B_2\frac{C_2}{e^{a_2}e^{c_2}} + A_2B_1\frac{C_1}{e^{a_2}e^{b_1}e^{c_1}} + A_2B_1\frac{C_2}{e^{a_2}e^{b_1}e^{c_2}} \\ &+ A_2B_2\frac{C_1}{e^{a_2}e^{b_2}e^{c_1}} + A_2B_2\frac{C_2}{e^{a_2}e^{b_2}e^{c_2}}. \end{aligned}$$

Many cancellations have occurred, eliminating terms in which four or five integrals are multiplied. Similar formulas are obtained for the other expressions in (5.7).

In estimating the integrals, first consider B_1. We will say that $f \propto g$ if there are positive numbers α and β such that for sufficiently small σ, $\alpha < \frac{f}{g} < \beta$. We then have

$$B_1 = \int_{x_1}^{x_2} e^{\frac{\psi_1(s)}{\sigma}}ds \propto \sigma^k e^{\frac{\psi_{1,\max}}{\sigma}}$$

for some $k > 0$ and with $\psi_{1,\max} = \psi_1(z_1) = \max_x \psi_1(x)$. Also, for possibly different values of k,

$$\begin{aligned} &A_1 \propto \sigma^k e^{b_1},\ A_2 \propto \sigma^k e^{a_2}, \\ &B_2 \propto \sigma^k \left(e^{b_2} + e^{c_2}\right),\ C_1 \propto \sigma^k \left(e^{c_1} + e^{a_1}\right),\ C_2 \propto \sigma^k e^{\frac{\psi_{2,\max}}{\sigma}}. \end{aligned}$$

From (5.6) and (5.2), we see that for small σ the two largest terms among $A_1, A_2, B_1, B_2, C_1, C_2$, $e^{a_1}, e^{a_2}, e^{b_1}, e^{b_2}, e^{c_1}$, and e^{c_2} are B_1 and C_2.

For the moment we let $d_i = \frac{\psi_{i,\max}}{\sigma}$ and set

$$\begin{aligned} &A_1 = e^{b_1},\ A_2 = e^{a_2}, \\ &B_1 = e^{d_1},\ B_2 = e^{b_2} + e^{c_2}, \\ &C_1 = e^{c_1} + e^{a_1},\ C_2 = e^{d_2}. \end{aligned}$$

We will find also that to get the desired backward transport, we need to take x_2 close to the maximum of ψ_2. Therefore for now we will set $x_2 = z_2$, so that $c_2 = d_2$. Finally, we can assume without loss of generality that $a_1 = 0$. The additional conditions we will give for backwards transport for small σ are that the inequalities (5.8) and (5.9) below hold and that x_2 is sufficiently close to y_2.

We then have

$$\begin{aligned} k_{11}k_{23} - k_{21}k_{13} = {}& \frac{1}{e^{b_1}} + \frac{2}{e^{c_1}} + \frac{3}{e^{a_2}}e^{b_2} + \frac{1}{e^{b_1}}e^{c_1} + \frac{3}{e^{b_1}}e^{d_1} + \frac{4}{e^{a_2}}e^{d_2} + \frac{4}{e^{b_2}}e^{d_2} \\ & + \frac{1}{e^{a_2}}\frac{e^{b_2}}{e^{c_1}} + \frac{1}{e^{b_1}e^{c_1}}e^{d_1} + \frac{1}{e^{a_2}e^{c_1}}e^{d_2} + \frac{1}{e^{b_2}e^{c_1}}e^{d_2} + 6 \end{aligned}$$

and similar expressions for $k_{22}k_{13} - k_{12}k_{23}$, k_{13}, and k_{23}.

We now assume that $d_1 > \max\{b_1, c_1\}$, $a_1 = 0 < \min\{b_1, c_1\}$, and $d_2 > \max\{a_2, b_2\}$. We compare terms pairwise wherever possible, eliminating the term which is necessarily smaller as $\sigma \to 0$. This results in the asymptotic relations

$$\begin{aligned} k_{11}k_{23} - k_{21}k_{13} &\propto \frac{3}{e^{b_1}}e^{d_1} + \frac{4}{e^{a_2}}e^{d_2} + \frac{4}{e^{b_2}}e^{d_2}, \\ k_{22}k_{13} - k_{12}k_{23} &\propto 6e^{d_1} + 4\frac{e^{b_1}}{e^{b_2}}e^{d_2}, \\ k_{13} &\propto 4e^{d_1} + 2\frac{e^{a_2}}{e^{b_2}}e^{d_1}, \\ k_{23} &\propto \frac{2}{e^{a_2}e^{c_1}}e^{d_1}e^{d_2} + \frac{1}{e^{b_2}e^{c_1}}e^{d_1}e^{d_2}. \end{aligned}$$

From these we conclude that the four fractions in question are exponentially small as $\sigma \to 0$ if in addition to the previous assumptions we have

$$d_2 - a_2 < d_1 - b_1 < d_2 - b_2 \tag{5.8}$$

and

$$d_1 > b_1 + c_1. \tag{5.9}$$

(If $a_1 \neq 0$, this becomes $d_1 + a_1 > b_1 + c_1$.)

By continuity we see that these inequalities will also suffice if c_2 is sufficiently close to d_2. The conclusions also hold with the factors σ^k included in the asymptotic expressions, since these don't affect the exponential limits.

Finally we wish to obtain a result with continuous functions for the a_{ij}. Here we don't have a limit result as $\sigma \to 0$. But suppose that $\varepsilon > 0$ is given, and for (5.3)–(5.4), we choose σ so small that for any positive solution,

$$\sum_{i=1}^{n} \rho_i(1) < \varepsilon \sum_{i=1}^{n} \rho_i(0).$$

Then for this σ, the same inequality will hold for continuous functions a_{ij} sufficiently close in the $\mathcal{L}_1$ norm to the δ-functions in (5.3)–(5.4).

In this paragraph we discuss the simulation parameters for Figure 3.1. Simulations, of which this is a sample, were executed with a semi-implicit scheme and run in Maple. In this case, for potentials we took $\psi_1(x) = \psi_1^0(2^4x)$ and $\psi_2(x) = \psi_2^0(2^4x)$ with $\psi_1^0(\xi) = \frac{1}{4}(\cos(\pi(\frac{2\xi}{\xi+1})))^2$ and $\psi_2^0(\xi) = \psi_1^0(\xi - \frac{1}{2})$. The matrix elements were $-a_{11} = a_{12} = a_{21} = -a_{22}$ with $a_{12}(x) = a^0(2^4x)$, where $a^0(\xi) = \frac{1}{2}(\cos 2\pi(\xi - \frac{1}{4}))^6$. The diffusion constant $\sigma = 2^{-7}$.

Acknowledgments. We take this opportunity to thank our collaborators Michel Chipot and Michal Kowalczyk for their help. We also thank Bard Ermentrout, Michael Grabe, William Troy, and Jonathan Rubin, and the Mathematical Biology Seminar of the University of Pittsburgh for generosity of spirit and their interest. We thank the referees for their comments.

SYNCHRONIZATION OF DISCRETE-TIME DYNAMICAL NETWORKS WITH TIME-VARYING COUPLINGS*

WENLIAN LU[†‡], FATIHCAN M. ATAY[†], AND JÜRGEN JOST[†§]

Abstract. We study the local complete synchronization of discrete-time dynamical networks with time-varying couplings. Our conditions for the temporal variation of the couplings are rather general and include variations in both the network structure and the reaction dynamics; the reactions could, for example, be driven by a random dynamical system. A basic tool is the concept of the Hajnal diameter, which we extend to infinite Jacobian matrix sequences. The Hajnal diameter can be used to verify synchronization, and we show that it is equivalent to other quantities which have been extended to time-varying cases, such as the projection radius, projection Lyapunov exponents, and transverse Lyapunov exponents. Furthermore, these results are used to investigate the synchronization problem in coupled map networks with time-varying topologies and possibly directed and weighted edges. In this case, the Hajnal diameter of the infinite coupling matrices can be used to measure the synchronizability of the network process. As we show, the network is capable of synchronizing some chaotic map if and only if there exists an integer $T > 0$ such that for any time interval of length T, there exists a vertex which can access other vertices by directed paths in that time interval.

Key words. synchronization, dynamical networks, time-varying coupling, Hajnal diameter, projection joint spectral radius, Lyapunov exponents, spanning tree

1. Introduction. Synchronization of dynamical processes on networks is presently an active research topic. It represents a mathematical framework that on the one hand can elucidate—desired or undesired—synchronization phenomena in diverse applications. On the other hand, the synchronization paradigm is formulated in such a manner that powerful mathematical techniques from dynamical systems and graph theory can be utilized. A standard version is

$$x^i(t+1) = f^i(x^1(t), x^2(t), \ldots, x^m(t)), \quad i = 1, 2, \ldots, m, \tag{1.1}$$

where $t \in \mathbb{Z}^+ = \{0, 1, 2, \ldots\}$ denotes the discrete time, $x^i(t) \in \mathbb{R}$ denotes the state variable of unit (vertex) i, and for $i = 1, 2, \ldots, m$, $f^i : \mathbb{R}^m \to \mathbb{R}$ is a C^1 function. This dynamical systems formulation contains two aspects. One of them is the reaction dynamics at each node or vertex of the network. The other one is the coupling structure, that is, whether and how strongly the dynamics at one node is directly influenced by the states of the other nodes.

Equation (1.1) clearly is an abstraction and simplification of synchronization problems found in applications. On the basis of understanding the dynamics of (1.1), research should then move on to more realistic scenarios. Therefore, in the present work, we address the question of synchronization when the right-hand side of (1.1) is allowed to vary in time. Thus, not only the dynamics itself is a temporal process, but

also the underlying structure changes in time, albeit in some applications that may occur on a slower time scale.

The essence of the hypotheses on $f = [f^1, \dots, f^m]$ needed for synchronization results (to be stated in precise terms shortly) is that synchronization is possible as an invariant state, that is, when the dynamics starts on the diagonal $[x, \dots, x]$, it will stay there, and that this diagonal possesses a stable attracting state. The question about synchronization then is whether this state is also attracting for dynamical states $[x^1, \dots, x^m]$ outside the diagonal, at least locally, that is, when the components x^i are not necessarily equal but close to each other. This can be translated into a question about transverse Lyapunov exponents, and one typically concludes that the existence of a synchronized attractor in the sense of Milnor. In our contribution, we can already strengthen this result by concluding (under appropriate assumptions) the existence of a synchronized attractor in the strong sense instead of only in the weaker sense of Milnor. (We shall call this local complete synchronization.) This comes about because we achieve a reformulation of the synchronization problem in terms of Hajnal diameters (a concept to be explained below).

Our work, however, goes beyond that. As already indicated, our main contribution is that we can study the local complete synchronization of general coupled networks with time-varying coupling functions, in which each unit is dynamically evolving according to

$$x^i(t+1) = f_t^i(x^1(t), x^2(t), \dots, x^m(t)), \quad i = 1, 2, \dots, m. \tag{1.2}$$

This formulation, in fact, covers both aspects described above, the reaction dynamics as well as the coupling structure. The main purpose of the present paper then is to identify general conditions under which we can prove synchronization of the dynamics (1.2). Thus, we can handle variations of the reaction dynamics as well as those of the underlying network topology. We shall mention below various applications where this is of interest.

Before that, however, we state our technical hypothesis on the right-hand side of (1.2): for each $t \in \mathbb{Z}^+$, $f_t^i : \mathbb{R}^m \to \mathbb{R}$ is a C^1 function with the following hypothesis.

(H_1) *There exists a* C^1 *function* $f(s) : \mathbb{R} \to \mathbb{R}$ *such that*

$$f_t^i(s, s, \dots, s) = f(s)$$

holds for all $s \in \mathbb{R}$, $t \in \mathbb{Z}^+$, *and* $i = 1, 2, \dots, m$. *Moreover, for any compact set* $K \subset \mathbb{R}^m$, f_t^i *and the Jacobian matrices* $[\partial f_t^i / \partial x^j]_{i,j=1}^m$ *are all equicontinuous in* K *with respect to* $t \in \mathbb{Z}^+$ *and the latter are all nonsingular in* K.

This hypothesis ensures that the diagonal synchronization manifold

$$\mathcal{S} = \left\{ [x^1, x^2, \dots, x^m]^\top \in \mathbb{R}^m : \; x^i = x^j, \; i, j = 1, 2, \dots, m \right\}$$

is an invariant manifold for the evolution (1.2). If $x^1(t) = x^2(t) = \cdots = x^m(t) = s(t)$ denotes the synchronized state, then

$$s(t+1) = f(s(t)). \tag{1.3}$$

For the synchronized state (1.3), we assume the existence of an attractor, as follows.

(H_2) *There exists a compact asymptotically stable attractor* A *for* (1.3). *That is*, (i) $A \subset \mathbb{R}$ *is a forward invariant set*; (ii) *for any neighborhood* U *of* A *there* *exists a neighborhood* V *of* A *such that* $f^n(V) \subset U$ *for all* $n \in \mathbb{Z}^+$; (iii) *for any sufficiently small neighborhood* U *of* A, $f^n(U)$ *converges to* A, *in the sense that for any neighborhood* V, *there exists* n_0 *such that* $f^n(U) \subset V$ *for* $n \geq n_0$; (iv) *there exists* $s^* \in A$ *for which the* ω*-limit set is* A.

Let A^m denote the Cartesian product $A \times \cdots \times A$ (m times). Local complete synchronization (synchronization for simplicity) is defined in the sense that the set $\mathcal{S} \cap A^m = \{[x, \dots, x] : x \in A\}$ is an asymptotically stable attractor in $\mathbb{R}^m$. That is, for the coupled dynamical system (1.2), differences between components converge to zero if the initial states are picked sufficiently near $\mathcal{S} \cap A^m$, i.e., if the components are all close to the attractor A and if their differences are sufficiently small. In order to show such a synchronization, one needs a third hypothesis (H_3) that in technical terms is about Lyapunov exponents transverse to the diagonal. That is, while the dynamics on the attractor may well be expanding (the attractor might be chaotic), the transverse directions need to be suitably contracting to ensure synchronization. The corresponding hypothesis (H_3) will be stated below (see (3.2)) because it requires the introduction of crucial technical concepts.

It is an important aspect of our work that we shall derive the attractivity here in the classical sense, and not in the sense of Milnor, i.e., not only some set of positive measure, but a full neighborhood is attracted. For details about the difference between Milnor attractors and asymptotically stable attractors, see [1, 2]. Usually, when studying synchronization, one derives only the existence of a Milnor attractor; see [3].

The motivation for studying (1.2) comes from the well-known coupled map lattices (CML) [4], which can be written as follows:

$$x^i(t+1) = f(x^i(t)) + \sum_{j=1}^{m} L_{ij} f(x^j(t)),\ i = 1, 2, \dots, m, \tag{1.4}$$

where $f : \mathbb{R} \to \mathbb{R}$ is a differentiable map and $L = [L_{ij}]_{i,j=1}^m \in \mathbb{R}^{m \times m}$ is the diffusion matrix, which is determined by the topological structure of the network and satisfies $L_{ij} \geq 0$ for all $i \neq j$, and $\sum_{j=1}^m L_{ij} = 0$ for all $i = 1, 2, \dots, m$. Letting $x = [x^1, x^2, \dots, x^m]^\top \in \mathbb{R}^m$, $F(x) = [f(x^1), f(x^2), \dots, f(x^m)]^\top \in \mathbb{R}^m$, and $G = I_m + L$, where I_m denotes the identity matrix of dimension m, the CML (1.4) can be written in the matrix form

$$x(t+1) = GF(x(t)), \tag{1.5}$$

where $G = [G_{ij}]_{i,j=1}^m \in \mathbb{R}^{m \times m}$ denotes the coupling and satisfies $G_{ij} \geq 0$ for $i \neq j$ and $\sum_{j=1}^m G_{ij} = 1$ for all $i = 1, 2, \dots, m$. So, if $G_{ii} \geq 0$ holds for all $i = 1, 2, \dots, m$, then G is a stochastic matrix.

Recently, synchronization of CML has attracted increasing attention [3, 5, 6, 7, 8]. Linear stability analysis of the synchronization manifold was proposed and transverse Lyapunov exponents were used to analyze the influence of the topological structure of networks. In [1], conditions for generalized transverse stability were presented. If the transverse (normal) Lyapunov exponents are negative, a chaotic attractor on an invariant submanifold can be asymptotically stable over the manifold. In [9, 10] it was shown that chaos synchronization in a network of nonlinear continuous-time or discrete-time dynamical systems, respectively, is possible if and only if the corresponding graph has a spanning tree. However, synchronization analysis has so far been limited to autonomous systems, where the interactions between the vertices (state components) are static and do not vary through time.

In the social, natural, and engineering real world, the topology of the network often varies through time. In communication networks, for example, one must consider dynamical networks of moving agents. Since the agents are moving, some of the existing connections can fail simply due to occurrence of an obstacle between agents. Also, some new connections may be created when one agent enters the effective region of other agents [11]. On top of that, randomness may also occur. In a communication network, the information channel of two agents at each time may be random [12]. When an error occurs at some time, the connections in the system will vary. In [11, 12, 13], synchronization of multiagent networks was considered where the state of each vertex is adapted according to the states of its connected neighbors with switching connecting topologies. This multiagent dynamical network can be written in discrete-time form as

$$x^i(t+1) = \sum_{j=1}^{m} G_{ij}(t)x^j(t),\ i = 1, 2, \dots, m, \tag{1.6}$$

where $x^j(t) \in \mathbb{R}$ is the state variable of vertex j and $[G_{ij}(t)]_{i,j=1}^m$, $t \in \mathbb{Z}^+$, are stochastic matrices. In [14] a convexity-conserving coupling function was considered that is equivalent to the linear coupling function in (1.6). It was found that the connectivity of the switching graphs plays a key role in the synchronization of multiagent networks with switching topologies. Also, in the recent literature [15, 16, 17], synchronization of continuous-time dynamical networks with time-varying topologies was studied. The time-varying couplings investigated, however, are specific, with either symmetry [15], node balance [16], or fixed time average [17].

Therefore, it is natural to investigate the synchronization of CML with general time-varying connections as

$$x(t+1) = G(t)F(x(t)), \tag{1.7}$$

where $G(t) = [G_{ij}(t)]_{i,j=1}^m \in \mathbb{R}^{m\times m}$ denotes the coupling matrix at time t and $F(x) = [f(x_1), \dots, f(x_n)]^\top$ is a differentiable function. We shall address this problem in the context of the general coupled system (1.2).

Let

$$x(t) = \begin{bmatrix} x^1(t) \\ x^2(t) \\ \vdots \\ x^m(t) \end{bmatrix} \quad \text{and} \quad F_t(x(t)) = \begin{bmatrix} f_t^1(x^1(t), \cdots, x^m(t)) \\ f_t^2(x^1(t), \cdots, x^m(t)) \\ \vdots \\ f_t^m(x^1(t), \cdots, x^m(t)) \end{bmatrix}.$$

Equation (1.2) can be rewritten in matrix form:

$$x(t+1) = F_t(x(t)). \tag{1.8}$$

The time-varying coupling can have a special form and may be driven by some other dynamical system. Let $\mathcal{Y} = \{\Omega, \mathcal{F}, P, \theta^{(t)}\}$ denote a metric dynamical system (MDS), where Ω is the metric state space, $\mathcal{F}$ is the σ-algebra, P is the probability measure, and $\theta^{(t)}$ is a semiflow satisfying $\theta^{(t+s)} = \theta^{(t)} \circ \theta^{(s)}$ and $\theta^{(0)} = \mathrm{id}$, where id denotes the identity map. Then the coupled system can be regarded as a random dynamical system (RDS) driven by $\mathcal{Y}$:

$$x(t+1) = F(x(t), \theta^{(t)}\omega),\ t \in \mathbb{Z}^+,\ \omega \in \Omega. \tag{1.9}$$

In fact, one can regard the dynamical system (1.9) as a skew product semiflow,

$$\begin{aligned}&\Theta : \mathbb{Z}^+ \times \Omega \times \mathbb{R}^m \to \Omega \times \mathbb{R}^m,\\ &\Theta^{(t)}(\omega, x) = (\theta^{(t)}\omega, x(t)).\end{aligned}$$

Furthermore, the coupled system can have the form

$$x(t+1) = F(x(t), u(t)),\ t \in \mathbb{Z}^+, \tag{1.10}$$

where u belongs to some function class $\mathcal{U}$ and may be interpreted as an external input or force. Then, defining $[\theta^{(t)}u](\tau) = u(t+\tau)$ as a shift map, the system (1.10) has the form of (1.9). In this paper, we first investigate the general time-varying case of the system (1.8) and also apply our results to systems of the form (1.9).

To study synchronization of the system (1.8), we use its variational equation by linearizing it. Consider the difference $\delta x^i(t) = x^i(t) - f^{(t-t_0)}(s_0)$. This implies that $\delta x^i(t) - \delta x^j(t) = x^i(t) - x^j(t)$ holds for all $i, j = 1, 2, \ldots, m$. We have

$$\delta x^i(t+t_0) = \sum_{j=1}^{m} \frac{\partial f^i_{t+t_0-1}}{\partial x^j}(f^{(t-1)}(s_0))\delta x^j(t+t_0-1),\ i = 1, 2, \ldots, m, \tag{1.11}$$

where for simplicity we use the notation $\frac{\partial f^i_{t+t_0-1}}{\partial x^j}(f^{(t-1)}(s_0))$ to denote $\frac{\partial f^i_{t+t_0-1}}{\partial x^j}$ $(f^{(t-1)}$ $(s_0), \ldots, f^{(t-1)}(s_0))$. Let

$$\delta x(t) = \begin{bmatrix} \delta x^1(t) \\ \vdots \\ \delta x^m(t) \end{bmatrix}, \quad D_t(s) = \left[\frac{\partial f^i_t}{\partial x^j}(s)\right]_{i,j=1}^{m}.$$

The variational equation (1.11) is written in matrix form,

$$\delta x(t+t_0) = D_{t+t_0-1}(f^{(t-1)}(s_0))\delta x(t+t_0-1). \tag{1.12}$$

For the Jacobian matrix, the following lemma is an immediate consequence of hypothesis (H_1).

LEMMA 1.1.

$$\sum_{j=1}^{m} \frac{\partial f^i_t}{\partial x_j}(s, s, \ldots, s) = f'(s), \quad i = 1, 2, \ldots, m \quad \textit{and} \quad t \in \mathbb{Z}^+.$$

Namely, all rows of the Jacobian matrix $[\partial f^i_t/\partial x_j]^m_{i,j=1}$ evaluated on the synchronization manifold $\mathcal{S}$ have the same sum, which is equal to $f'(s)$.

As a special case, if the time variation is driven by some dynamical system $\mathcal{Y} = \{\Omega, \mathcal{F}, P, \theta^{(t)}\}$, then the variational system does not depend on the initial time t_0, but only on (s_0, ω). Thus, the Jacobian matrix can be written in the form $D(f^{(t)}(s_0), \theta^{(t)}\omega) = D_t(f^{(t)}(s))$, by which the variational system can be written as

$$\delta x(t+1) = D(f^{(t)}(s_0), \theta^{(t)}\omega)\delta x(t). \tag{1.13}$$

In this paper, we first extend the concept of the Hajnal diameter to general matrices. A matrix with Hajnal diameter less than one has the property of compressing the convex hull of $\{x^1, \ldots, x^m\}$. Consequently, for an infinite sequence of time-varying

Jacobian matrices, the average compression rate can be used to verify synchronization. Since the Jacobian matrices have identical row sums, the (skew) projection along the diagonal synchronization direction can be used to define the projection joint spectral radius, which equals the Hajnal diameter. Furthermore, we show that the Hajnal diameter is equal to the largest Lyapunov exponent along directions transverse to the synchronization manifold; hence, it can also be used to determine whether the coupled system (1.2) can be synchronized.

Second, we apply these results to discuss the synchronization of the CML with time-varying couplings. As we shall show, the Hajnal diameter of infinite coupling stochastic matrices can be utilized to measure the synchronizability of the coupling process. More precisely, the coupled system (1.7) synchronizes if the sum of the logarithm of the Hajnal diameter and the largest Lyapunov exponent of the uncoupled system is negative. Using the equivalence of the Hajnal diameter, projection joint spectral radius, and transverse Lyapunov exponents, we study some particular examples for which the Hajnal diameter can be computed, including static coupling, a finite coupling set, and a multiplicative ergodic stochastic matrix process. We also present numerical examples to illustrate our theoretical results.

The connection structure of the CML (1.5) naturally gives rise to a graph, where each unit can be regarded as a vertex. Hence, we associate the coupling matrix G with a graph $\Gamma = (V, E)$, with the vertex set $V = \{1, 2, \ldots, m\}$ and the edge set $E = \{e_{ij}\}$, where there exists a directed edge from vertex j to vertex i if and only if $G_{ij} > 0$. The graphs we consider here are assumed to be simple (that is, without loops and multiple edges) but are allowed to be directed and weighted. That is, we do not assume a symmetric coupling scheme.

We extend this idea to an infinite graph sequence $\{\Gamma(t)\}$. That is, we regard a time-varying graph as a graph process $\{\Gamma(t)\}_{t\in\mathbb{Z}^+}$. Define $\Gamma(t) = [V, E(t)]$, where $V = \{1, 2, \ldots, m\}$ denotes the vertex set and $E(t) = \{e_{ij}(t)\}$ denotes the edge set of the graph at time t. The time-varying coupling matrix $G(t)$ might then be regarded as a function of the time-varying graph sequence, i.e., $G(t) = G(\Gamma(t))$. A basic problem that arises is determining which kind of sequence can ensure the synchrony of the coupled system for some chaotic synchronized state $s(t + 1) = f(s(t))$. As we shall show, the property that the union of the $\Gamma(t)$ contains a spanning tree is important for synchronizing chaotic maps. We prove that under certain conditions, the coupling graph process can synchronize some chaotic maps if and only if there exists an integer $T > 0$ such that there exists at least one vertex j from which any other vertex can be accessible within a time interval of length T.

This paper is organized as follows. In section 2, we present some definitions and lemmas on the Hajnal diameter, projection joint spectral radius, projection Lyapunov exponents, and transverse Lyapunov exponents for generalized Jacobian matrix sequences as well as stochastic matrix sequences. In section 3, we study the synchronization of the generalized coupled discrete-time systems with time-varying couplings (1.2). In section 4, we discuss the synchronization of the CML with time-varying couplings (1.7) and study the relation between synchronizability and coupling graph process topologies. In addition, we present some examples where synchronizability is analytically computable. In section 5, we present numerical examples to illustrate the theoretical results, and we conclude the paper in section 6.

2. Preliminaries. In this section we present some definitions and lemmas on matrix sequences. First, we extend the definitions of the Hajnal diameter and the projection joint spectral radius, introduced in [18, 19, 20] for stochastic matrices, to generalized time-varying matrix sequence. Furthermore, we extend Lyapunov exponents and projection Lyapunov exponents to the general time-varying case and discuss their relation. Second, we specialize these definitions to stochastic matrix sequences and introduce the relation between a stochastic matrix sequence and graph topology.

2.1. General definitions. We study the generalized time-varying linear system

$$u(t+t_0+1) = L_{t+t_0}(\varrho^{(t)}(\phi))u(t+t_0), \tag{2.1}$$

where $\varrho^{(t)}$ is defined by a random dynamical system $\{\Phi, \mathcal{B}, P, \varrho^{(t)}\}$, where Φ denotes the state space, $\mathcal{B}$ the σ-algebra on Φ, P the probability measure, and $\varrho^{(t)}$ a semiflow. Studying the linear system (2.1) comes from the variational system of the coupled system (1.2). For the variational system (1.12), $\varrho^{(t)}(\cdot)$ represents the synchronized state flow $f^{(t)}(\cdot)$. And, if $L_t(\cdot)$ is independent of t, then the linear system (2.1) can be rewritten as

$$u(t+1) = L(\varrho^{(t)}(\phi))u(t). \tag{2.2}$$

Thus, it can represent the variational system (1.13) as a special case, where $\varrho^{(t)}$ is the product flow $(f^{(t)}(\cdot), \theta^{(t)}(\cdot))$. Hence, the linear system (2.1) can unify the two cases of variational systems (1.12), (1.13) of the coupled system (1.2), (1.9).

For this purpose, we define a generalized matrix sequence map $\mathcal{L}$ from $\mathbb{Z}^+ \times \Phi$ to $2^{\mathbb{R}^{m\times m}}$,

$$\begin{aligned} \mathcal{L} : \mathbb{Z}^+ \times \Phi &\to 2^{\mathbb{R}^{m\times m}} \\ (t_0, \phi) &\mapsto \{L_{t+t_0}(\varrho^{(t)}\phi)\}_{t\in\mathbb{Z}^+}, \end{aligned} \tag{2.3}$$

where $2^{\mathbb{R}^{m\times m}}$ denotes the set containing all subsets of $\mathbb{R}^{m\times m}$. In [18, 19], the concept of the Hajnal diameter was introduced to describe the compression rate of a stochastic matrix. We extend it to general matrices below.

Definition 2.1. *For a matrix L with row vectors $g_1, \dots, g_m$ and a vector norm $\|\cdot\|$ in $\mathbb{R}^m$, the Hajnal diameter of L is defined by*

$$\mathrm{diam}(L, \|\cdot\|) = \max_{i,j} \|g_i - g_j\|.$$

We also introduce the Hajnal diameter for a matrix sequence map $\mathcal{L}$.

Definition 2.2. *For a generalized matrix sequence map $\mathcal{L}$, the Hajnal diameter of $\mathcal{L}$ at $\phi \in \Phi$ is defined by*

$$\mathrm{diam}(\mathcal{L}, \phi) = \overline{\lim_{t\to\infty}} \sup_{t_0 \geq 0} \left\{ \mathrm{diam} \left(\prod_{k=t_0}^{t_0+t-1} L_k(\varrho^{(k-t_0)}\phi) \right) \right\}^{\frac{1}{t}},$$

where $\prod$ denotes the left matrix product: $\prod_{k=1}^n A_k = A_n \times A_{n-1} \times \cdots \times A_1$.

The Hajnal diameter for the infinite matrix sequence map $\mathcal{L}$ does not depend on the choice of the norm. In fact, all norms in a Euclidean space are equivalent and any additional factor is eliminated by the power $1/t$ and the limit as $t \to \infty$.

Let $\mathcal{H} \subset \mathbb{R}^{m\times m}$ be a class of matrices having the property that all row sums are the same. Thus, all matrices in $\mathcal{H}$ share the common eigenvector $e_0 = [1, 1, \dots, 1]^\top$, where the corresponding eigenvalue is the row sum of the matrix. Then the projection joint spectral radius can be defined for a generalized matrix sequence map $\mathcal{L}$, similar to that introduced in [20] as follows.

DEFINITION 2.3. *Suppose $\mathcal{L}(t_0,\phi) \subset \mathcal{H}$ for $t_0 \in \mathbb{Z}^+$ and $\phi \in \Phi$. Let $\mathcal{E}_0$ be the subspace spanned by the synchronization direction $e_0 = [1,1,\dots,1]^\top$, and let P be any $(m-1)\times m$ matrix with exact kernel $\mathcal{E}_0$. We denote by $\hat{L} \in \mathbb{R}^{(m-1)\times(m-1)}$ the (skew) projection of matrix $L \in \mathcal{H}$ as the unique solution of*

$$PL = \hat{L}P. \tag{2.4}$$

The projection joint spectral radius of the generalized matrix sequence map $\mathcal{L}$ is defined as

$$\hat{\rho}(\mathcal{L},\phi) = \overline{\lim_{t\to\infty}} \sup_{t_0\geq 0} \left\| \prod_{k=t_0}^{t_0+t-1} \hat{L}_k(\varrho^{(k-t_0)}\phi) \right\|^{\frac{1}{t}}.$$

One can see that $\hat{\rho}(\mathcal{L},\phi)$ is independent of the choice of the matrix norm $\|\cdot\|$ induced by the vector norm. The following lemma shows that it is also independent of the choice of the matrix P.

LEMMA 2.4. *Suppose $\mathcal{L}(t_0,\phi) \subset \mathcal{H}$ for all $t_0 \geq 0$ and $\phi \in \Phi$. Then*

$$\hat{\rho}(\mathcal{L},\phi) = \operatorname{diam}(\mathcal{L},\phi).$$

A proof is given in the appendix.

The Lyapunov exponents are often used to study evolution of the dynamics [5, 6]. Here, we extend the definitions of Lyapunov exponents to general time-varying cases.

DEFINITION 2.5. *For the coupled system* (1.2)*, the Lyapunov exponent of the matrix sequence map $\mathcal{L}$ initiated by $\phi \in \Phi$ in the direction $u \in \mathbb{R}^m$ is defined as*

$$\lambda(\mathcal{L},\phi,u) = \overline{\lim_{t\to\infty}} \frac{1}{t} \sup_{t_0\geq 0} \log \left\| \prod_{k=t_0}^{t+t_0-1} L_k(\varrho^{(k-t_0)}\phi)u \right\|. \tag{2.5}$$

The projection along the synchronization direction e_0 can also define a Lyapunov exponent, called the projection Lyapunov exponent:

$$\hat{\lambda}(\mathcal{L},\phi,v) = \overline{\lim_{t\to\infty}} \frac{1}{t} \sup_{t_0\geq 0} \log \left\| \prod_{k=t_0}^{t+t_0-1} \hat{L}_k(\varrho^{(k-t_0)}\phi)v \right\|, \tag{2.6}$$

where $\hat{L}_k(\varrho^k\phi)$ is the projection of matrix $L_k(\varrho^k\phi)$ as defined in Definition 2.3.

It can be seen that the definition of the generalized Lyapunov exponent above satisfies the basic properties of Lyapunov exponents.[1] For more details about generalized Lyapunov exponents, we refer to [22].

LEMMA 2.6. *Suppose $\mathcal{L}(t_0,\phi) \subset \mathcal{H}$ for all $\phi \in \Phi$ and $t_0 \geq 0$. Then*

$$\sup_{v\in\mathbb{R}^{m-1},v\neq 0} \hat{\lambda}(\mathcal{L},\phi,v) = \log\hat{\rho}(\mathcal{L},\phi) = \log\operatorname{diam}(\mathcal{L},\phi).$$

A proof is given in the appendix.

[1]This kind of definition of characteristic exponent is similar to the Bohl exponent used to study uniform stability of time-varying systems in [21].

This lemma implies that the projection joint spectral radius gives the largest Lyapunov exponent in directions transverse to the synchronization direction e_0 of the matrix sequence map $\mathcal{L}$.

When the time dependence arises from being totally driven by some random dynamical system, we can write the generalized matrix sequence map $\mathcal{L}$ as $\mathcal{L}(\phi) = \{L(\varrho^{(t)}\phi)\}_{t\in\mathbb{Z}^+}$ since it is independent of t_0 and is just a map on Φ. As introduced in [23], we have specific definitions for Lyapunov exponents of the time-varying system (2.2) as follows.

For the linear system (2.2), the Lyapunov exponent of the matrix sequence map $\mathcal{L}$ initiated by $\phi \in \Phi$ in the direction $u \in \mathbb{R}^m$ is defined as

$$\lambda(\mathcal{L}, \phi, u) = \overline{\lim_{t\to\infty}} \frac{1}{t} \log \left\| \prod_{k=0}^{t-1} L(\varrho^{(k)}\phi) u \right\|. \tag{2.7}$$

If $\mathcal{L}(\phi) \subset \mathcal{H}$ for all $\phi \in \Phi$, then the Lyapunov exponent in the synchronization direction e_0 is

$$\lambda(\mathcal{L}, \phi, e_0) = \overline{\lim_{t\to\infty}} \frac{1}{t} \log \sum_{k=0}^{t-1} |c(k)|, \tag{2.8}$$

where $c(k)$ denotes the corresponding common row sum at each time k. The projection along the synchronization direction e_0 can also define a Lyapunov exponent, called the projection Lyapunov exponent:

$$\hat{\lambda}(\mathcal{L}, \phi, v) = \overline{\lim_{t\to\infty}} \frac{1}{t} \log \left\| \prod_{k=0}^{t-1} \hat{L}_k(\varrho^{(k)}\phi) v \right\|, \tag{2.9}$$

where $\hat{L}(\varrho^k\omega)$ is the (skew) projection of matrix $L(\varrho^k\omega)$. Also, the Hajnal diameter and projection joint spectral radius become

$$\operatorname{diam}(\mathcal{L}, \phi) = \overline{\lim_{t\to\infty}} \left\{ \operatorname{diam} \left(\prod_{k=0}^{t-1} L(\varrho^{(t)}\phi) \right) \right\}^{\frac{1}{t}}, \quad \hat{\rho}(\mathcal{L}, \phi) = \overline{\lim_{t\to\infty}} \left\| \prod_{k=0}^{t-1} \hat{L}(\varrho^{(k)}\phi) \right\|^{\frac{1}{t}}.$$

According to Lemmas 2.4 and 2.6, $\log \operatorname{diam}(\mathcal{L}, \phi) = \log \hat{\rho}(\mathcal{L}, \phi) = \sup_{v\in\mathbb{R}^{m-1}, v\neq 0} \hat{\lambda}$ $(\mathcal{L}, \phi, v)$. Let λ_0 be the Lyapunov exponent along the synchronization direction e_0 and let $\lambda_1, \lambda_2, \ldots, \lambda_{m-1}$ be the remaining Lyapunov exponents for the initial condition ϕ, counted with multiplicities.

LEMMA 2.7. *Suppose that $\mathcal{L}(\phi) \subset \mathcal{H}$ is time-independent. Let the matrix $D(t) = [D_{ij}(t)]_{i,j=1}^m$ denote the matrix $L(\varrho^{(t)}\phi)$ and let $c(t)$ denote the corresponding common row sum of $D(t)$. If*

1. $\lim_{t\to\infty} 1/t \sum_{k=0}^{t-1} \log |c(k)| = \lambda_0$,
2. $\overline{\lim}_{t\to\infty} 1/t \log^+ |D_{ij}(t)| \leq 0$ *for all* $i, j = 1, 2, \ldots, m$, *where* $\log^+(z) = \max \{\log z, 0\}$,

then

$$\log \operatorname{diam}(\mathcal{L}, \phi) = \log \hat{\rho}(\mathcal{L}, \phi) = \sup_{i\geq 1} \lambda_i.$$

A proof is given in the appendix.

Using the concept of the Hajnal diameter, we can define (uniform) synchronization of the nonautonomous system (1.2) as follows.

DEFINITION 2.8. *The coupled system* (1.2) *is said to be (uniformly locally completely) synchronized if there exists* $\eta > 0$ *such that for any* $\epsilon > 0$ *there exists* $T > 0$ *such that the inequality*

$$\operatorname{diam}\big([x^1(t), x^2(t), \dots, x^m(t)]^\top\big) \leq \epsilon \tag{2.10}$$

holds for all $t > t_0 + T$, $t_0 \geq 0$, *and* $x^i(t_0)$, $i = 1, 2, \dots, m$, *in the* η *neighborhood of* $s(t_0)$ *of a synchronized state* $s(t)$.

2.2. Stochastic matrix sequences. The above definitions can also be used to deal with stochastic matrix sequences.

DEFINITION 2.9. *A matrix* $G \in \mathbb{R}^{m\times m}$ *is said to be a stochastic matrix if its elements are nonnegative and each row sum is* 1.

We consider here the general time-varying case without the assumption of an underlying random dynamical system and write a stochastic matrix sequence as $\mathcal{G} = \{G(t)\}_{t\in\mathbb{Z}^+}$. The case that the time variation is driven by some dynamical system can be regarded as a special one.

DEFINITION 2.10. *The Hajnal diameter of* $\mathcal{G}$ *is defined as*

$$\operatorname{diam}(\mathcal{G}) = \overline{\lim_{t\to\infty}} \sup_{t_0\geq 0} \left(\operatorname{diam} \prod_{k=t_0}^{t_0+t-1} G(k)\right)^{\frac{1}{t}} \tag{2.11}$$

and the projection joint spectral radius for $\mathcal{G}$ *is*

$$\hat{\rho}(\mathcal{G}) = \overline{\lim_{t\to\infty}} \sup_{t_0\geq 0} \left\| \prod_{k=t_0}^{t_0+t-1} \hat{G}(k) \right\|^{\frac{1}{t}}, \tag{2.12}$$

where $\hat{G}(t)$ *is the projection of* $G(t)$, *as in Definition* 2.3.

Then, from Lemma 2.4, we have the following.

LEMMA 2.11. $\operatorname{diam}(\mathcal{G}) = \hat{\rho}(\mathcal{G})$.

To estimate the Hajnal diameter of a product of stochastic matrices, we use the concept of scrambling introduced in [20].

DEFINITION 2.12. *A stochastic matrix* $G = [G_{ij}]_{i,j=1}^m \in \mathbb{R}^{m\times m}$ *is said to be scrambling if for any* i, j *there exists an index* k *such that* $G_{ik} \neq 0$ *and* $G_{jk} \neq 0$.

For $g_i = [g_{i,1}, \dots, g_{i,m}] \in \mathbb{R}^m$ and $g_j = [g_{j,1}, \dots, g_{j,m}] \in \mathbb{R}^m$, define

$$g_i \wedge g_j = \big[\min(g_{i,1}, g_{j,1}), \dots, \min(g_{i,m}, g_{j,m})\big].$$

We use the following quantity introduced in [18, 19] to measure scramblingness:

$$\eta(G) = \min_{i,j} \|g_i \wedge g_j\|_1,$$

where $\|\cdot\|_1$ is the norm given by $\|x\|_1 = \sum_{i=1}^m |x_i|$ for $x = [x_1, \dots, x_m] \in \mathbb{R}^m$. It is clear that $0 \leq \eta(G) \leq 1$ and that $\eta(G) > 0$ if and only if G is scrambling. Thus, the well-known Hajnal inequality has the following generalized form.

LEMMA 2.13 (generalized Hajnal inequality [20, Theorem 6]). *For any vector norm in* $\mathbb{R}^m$ *and any two stochastic matrices* G *and* H,

$$\operatorname{diam}(GH) \leq (1 - \eta(G))\operatorname{diam}(H). \tag{2.13}$$

The concepts of projection joint spectral radius and the Hajnal diameter are linked to the ergodicity of stochastic matrix sequences. We can extend the ergodicity for a matrix set [20, 24] to a matrix sequence as follows.

DEFINITION 2.14 (ergodicity [14, Definition 1]). *A stochastic matrix sequence $\Sigma = \{G(t)\}_{t\in\mathbb{Z}^+}$ is said to be ergodic if for any t_0 and $\epsilon > 0$ there exists $T > 0$ such that for any $t > T$ and some norm $\|\cdot\|$,*

$$\operatorname{diam}\left(\prod_{s=t_0}^{t_0+t-1} G(s)\right) \leq \epsilon. \tag{2.14}$$

Moreover, if for any $\epsilon > 0$ there exists $T > 0$ such that inequality (2.14) *holds for all $t \geq T$ and $t_0 \geq 0$, $\mathcal{G}$ is said to be uniformly ergodic.*

A stochastic matrix $G = [G_{ij}]_{i,j=1}^m$ can be associated with a graph $\Gamma = [V, E]$, where $V = \{1, 2, \ldots, m\}$ denotes the vertex set and $E = \{e_{ij}\}$ the edge set, in the sense that there exists an edge from vertex j to i if and only if $G_{ij} > 0$. Let $\Gamma_1 = [V, E_1]$ and $\Gamma = [V, E_2]$ be two simple graphs with the same vertex set. We also define the union $\Gamma_1 \bigcup \Gamma_2 = [V, E_1 \bigcup E_2]$ (merging multiple edges). It can be seen that for two stochastic matrices G_1 and G_2 with the same dimension and positive diagonal elements, the edge set of $\Gamma_1 \bigcup \Gamma_2$ is contained in that of the corresponding graph of the product matrix $G_1 G_2$. In this way, we can define the union of the graph sequence $\{\Gamma(t)\}_{t\in\mathbb{Z}^+}$ across the time interval $[t_1, t_2]$ by $\bigcup_{k=t_1}^{t_2} \Gamma(k) = [V, \bigcup_{k=t_1}^{t_2} E(k)]$. The following concepts for graphs can be found, e.g., in [25].

DEFINITION 2.15. *A graph Γ is said to have a spanning tree if there exists a vertex, called the root, such that for each other vertex j there exists at least one directed path from the root to vertex j.*

It follows that $\{\Gamma(t)\}_{t\in\mathbb{Z}^+}$ has a spanning tree across the time interval $[t_1, t_2]$ if the union of $\{\Gamma(t)\}_{t\in\mathbb{Z}^+}$ across $[t_1, t_2]$ has a spanning tree. This is equivalent to the existence of a vertex from which all other vertices can be accessible across $[t_1, t_2]$.

DEFINITION 2.16. *A graph Γ is said to be scrambling if for any different vertices i and j there exists a vertex k such that there exist edges from k to i and from k to j.*

It follows that a stochastic matrix G is scrambling if and only if the corresponding graph Γ is scrambling.

LEMMA 2.17 (see [24, Lemma 4]). *Let $G(1), G(2), \ldots, G(m-1)$ be stochastic matrices with positive diagonal elements, where each of the corresponding graphs $\Gamma(1)$, $\Gamma(2), \ldots, \Gamma(m-1)$ have spanning trees. Then $\prod_{k=1}^{m-1} G(k)$ is scrambling.*

Suppose now that the stochastic matrix sequence $\mathcal{G}$ is driven by some metric dynamical system $\mathcal{Y} = \{\Omega, \mathcal{F}, P, \theta^{(t)}\}$. We write $\mathcal{G}$ as $\{G(t) = G(\theta^{(t)}\omega)\}_{t\in\mathbb{Z}^+}$, where $\omega \in \Omega$. Then, as stated in section 2.1, we can define the Lyapunov exponents.

DEFINITION 2.18. *The Lyapunov exponent of the stochastic matrix sequence $\mathcal{G}$ is defined as*

$$\sigma(\mathcal{G}, \omega, u) = \overline{\lim_{t\to\infty}} \frac{1}{t} \log \left\| \prod_{k=0}^{t-1} G(\theta^t \omega) u \right\|.$$

The projection Lyapunov exponents is defined as

$$\hat{\sigma}(\mathcal{G}, \omega, u) = \overline{\lim_{t\to\infty}} \frac{1}{t} \log \left\| \prod_{k=0}^{t-1} \hat{G}(\theta^t \omega) u \right\|,$$

where $\hat{G}(\cdot)$ is the projection of $G(\cdot)$ as defined in Definition 2.3.

For a given $\omega \in \Omega$, one can see that $\mathrm{diam}(\mathcal{G})$ and $\hat{\rho}(\mathcal{G})$ both equal the largest Lyapunov exponent of $\mathcal{G}$ in directions transverse to the synchronization direction under several mild conditions.

In closing this section, we list some notation to be used in the remainder of the paper. The matrix $\hat{L}$ denotes the (skew) projection of the matrix L along the vector e introduced in Definition 2.3, and $\hat{\mathcal{L}}$ is the (skew) projection of the matrix sequence map $\mathcal{L}$ along e. For $x = (x^1, \dots, x^m)^\top \in \mathbb{R}^m$, the average $\frac{1}{m}\sum_{i=1}^m x^i$ of x is denoted by $\bar{x}$. The notation $\|\cdot\|$ denotes some vector norm in the linear space $\mathbb{R}^m$, and also the matrix norm in $\mathbb{R}^{m\times m}$ induced by this vector norm. $f^{(t)}(s_0)$ denotes the t-iteration of the map f with initial condition s_0. We let $x(t, t_0, x_0)$ be the solution of the coupled system (1.2) with initial condition $x(t_0) = x_0$, which we sometimes abbreviate as $x(t)$.

3. Generalized synchronization analysis. For the variational system (1.12), similar to subsection 2.1, we denote by $\mathcal{D}$ the Jacobian sequence map in the generalized sense; i.e., $\mathcal{D}$ is a map from $\mathbb{Z}^+ \times \mathbb{R}$ to $2^{\mathbb{R}^{m\times m}}$: $\mathcal{D}(t_0, s_0) = \{D_{t+t_0}(f^{(t)}(s_0))\}_{t\in\mathbb{Z}^+} \subset \mathcal{H}$ for all $t_0 \in \mathbb{Z}^+$ and $s_0 \in A$. Furthermore, letting

$$B(t, t_0) = \prod_{k=t_0}^{t+t_0-1} D_k(f^{(k-t_0)}(s_0)),$$

we can rewrite the variational system (1.12) as follows:

$$\delta x(t + t_0) = D_{t+t_0-1}(f^{(t-1)}(s_0))\delta x(t + t_0 - 1) = B(t, t_0)\delta x(t_0). \tag{3.1}$$

From Definitions 2.2 and 2.3, we have

$$\mathrm{diam}(\mathcal{D}, s_0) = \overline{\lim_{t\to\infty}} \sup_{t_0\ge 0} \left\{ \mathrm{diam}\left(\prod_{k=t_0}^{t_0+t-1} D_k(f^{(k-t_0)}(s_0)) \right) \right\}^{\frac{1}{t}},$$
$$\hat{\rho}(\mathcal{D}, s_0) = \overline{\lim_{t\to\infty}} \sup_{t_0\ge 0} \left\| \prod_{k=t_0}^{t_0+t-1} \hat{D}_k(f^{(k-t_0)}(s_0)) \right\|^{\frac{1}{t}}.$$

We will also refer to the following hypothesis.

(H_3)

$$\sup_{s_0\in A} \mathrm{diam}(\mathcal{D}, s_0) < 1. \tag{3.2}$$

THEOREM 3.1. *If hypotheses* (H_1)–(H_3) *hold, then the compact set* $A^m \bigcap \mathcal{S}$ *is a uniformly asymptotically stable attractor of the coupled system* (1.2) *in* $\mathbb{R}^m$; *i.e., the coupled system* (1.2) *is uniformly locally completely synchronized.*

Proof. Let

$$\mathrm{diam}(\mathcal{D}, t_0, t, s_0) = \mathrm{diam}\left(\prod_{k=t_0}^{t_0+t-1} D_k\big(f^{(k-t_0)}(s_0)\big) \right),$$
$$\mathrm{diam}(\mathcal{D}, t, s_0) = \sup_{t_0\ge 0} \left\{ \mathrm{diam}\left(\prod_{k=t_0}^{t_0+t-1} D_k(f^{(k-t_0)}(s_0)) \right) \right\}.$$

According to (H_3), letting $1 > d > \sup_{s_0\in A} \mathrm{diam}(\mathcal{D}, s_0)$ and n_0 satisfy $d^{n_0} < \frac{1}{3}$, for any $s_0 \in A$, there exists $n(s_0) \ge n_0$ such that $\mathrm{diam}(\mathcal{D}, t, s_0) < d$ holds for all $t \geq n(s_0)$. By equicontinuity (H_1) and compactness (H_2), there must exist a finite integer set $\mathcal{V} = \{n_1, n_2, \ldots, n_v\}$ satisfying $n_i \geq n_0$ for all $i = 1, 2, \ldots, v$ and a neighborhood U of A such that for any $s_0 \in U$ there exists $n_j \in \mathcal{V}$ such that $\mathrm{diam}\big(\prod_{k=t_0}^{t_0+n_j-1} D_k(f^{(k-t_0)}(s_0))\big) < d^{n_j} < \frac{1}{3}$ holds for all $t_0 \geq 0$.

By hypothesis (H_2), there exists a compact neighborhood W of A such that $U \supset W \supset A$, $f(W) \subset W$, and $\bigcap_{n\geq 0} f^{(n)}(W) = A$ [26]. Let

$$a = \min_{n\in\mathcal{V}} d_H(f^{(n)}(W), W) > 0,$$

where $d_H(\cdot,\cdot)$ denotes the Hausdorff metric in $\mathbb{R}$. Then define a compact set

$$W_\alpha = \left\{ x = (x^1, \ldots, x^m) \in \mathbb{R}^m : \max_{1\leq i\leq m} |x^i - \bar{x}| \leq \alpha \text{ and } \bar{x} \in W \right\}.$$

By the mean value theorem, we have

$$f_k^i(x^1(k), \ldots, x^m(k)) - f(s(k), \ldots, s(k)) = \sum_{j=1}^{m} \frac{\partial f_k^i}{\partial x^j}(\xi_k^{ij}),$$

where ξ_k^{ij} belongs to the closed interval induced by the two ends $x^i(k)$ and $s(k)$. Denote by $D_k(\xi_k)$ the matrix $[\partial f_k^i(\xi_k^{ij})/\partial x^j]_{i,j=1}^m$.

Let $\alpha > 0$ be sufficiently small so that for each $x_0 \in W_\alpha$ with $s(t_0) = \bar{x}_0$ and $x(t_0) = x_0$, there exists $t_1 \in \mathcal{V}$ such that

$$|x^i(t_1, t_0, x_0) - f^{(t_1-t_0)}(\bar{x}_0)| \leq \frac{a}{2},$$
$$\mathrm{diam}\left(\prod_{k=t_0}^{t_0+t_1-1} D_k(\xi_k) \right) < \frac{1}{2}$$

hold for all $t_0 \geq 0$. Then, for any $x_0 \in W_\alpha$, $\bar{x}_0 \in W$, we have

$$\delta x(t_1 + t_0) = \prod_{k=t_0}^{t_1+t_0-1} D_k(\xi(k))\delta x_0 = \tilde{B}(t_1, t_0)\delta x_0,$$

where $\tilde{B}(t_1, t_0) = \prod_{k=t_0}^{t_1+t_0-1} D_k(\xi(k))$. Then

$$\begin{aligned} |\delta x^i(t_1 + t_0) - \delta x^j(t_1 + t_0)| &\leq \sum_{k=1}^{m} |\tilde{B}_{ik}(t_1, t_0) - \tilde{B}_{jk}(t_1, t_0)||\delta x_0^j| \\ &\leq \mathrm{diam}(\tilde{B}(t_1, t_0)) \max_{1\leq i\leq m} |x_0^i - \bar{x}_0|. \end{aligned}$$

Thus, we conclude that

$$\max_{1\leq i,j\leq m} |x^i(t_1 + t_0) - x^j(t_1 + t_0)| \leq \frac{1}{2} \max_{1\leq i,j\leq m} |x_0^i - x_0^j|.$$

By the definition of W_α, we see that $x(t_1 + t_0) \in W_{\alpha/2}$. With initial time $t_0 + t_1$, we can continue this phase and afterwards obtain

$$\lim_{t\to\infty} |x^i(t) - x^j(t)| = 0, \ i, j = 1, 2, \ldots, m,$$

uniformly with respect to $t_0 \in \mathbb{Z}^+$ and $x_0 \in W_\alpha$. Therefore, the coupled system (1.2) is uniformly synchronized. Furthermore, we obtain that $A^m \bigcap \mathcal{S}$ is a uniformly asymptotically stable attractor for the coupled system (1.2), and the convergence rate can be estimated by $O(\{\sup_{s_0\in A}\operatorname{diam}(\mathcal{D}, s_0)\}^t)$ since d is chosen arbitrarily greater than $\sup_{s_0\in A}\operatorname{diam}(\mathcal{D}, s_0)$. The theorem is proved. □

Remark 1. The idea of the above proof comes from that of Theorem 2.12 in [1], with a modification for the time-varying case. In Theorem 2.12 in [1], the authors used normal Lyapunov exponents to prove asymptotic stability of the original autonomous system for the case when it is asymptotically stable in an invariant manifold. In this paper, we directly use the Hajnal diameter of the left product of the infinite Jacobian matrix sequence map to measure the transverse differences of the collections of spatial states. Furthermore, we consider a nonautonomous system here due to time-varying couplings.

Following Lemma 2.4 gives us the following.

COROLLARY 3.2. *If* $\sup_{s_0\in A}\hat{\rho}(\mathcal{D}, s_0) < 1$, *then the coupled system* (1.2) *is uniformly synchronized.*

Consider the special case that the coupled system (1.9) is an RDS on an MDS $\mathcal{Y} = \{\Omega, \mathcal{F}, P, \theta^{(t)}\}$. We can write this coupled system (1.9) as a product dynamical system $\{A\times\Omega, \mathbf{F}, \mathbf{P}, \Theta^{(t)}\}$, where $\mathbf{F}$ is the product σ-algebra on $A\times\Omega$, $\mathbf{P}$ denotes the probability measure, and $\Theta^{(t)}(s_0, \omega) = (\theta^{(t)}\omega, f^{(t)}(s_0))$. Let $D(f^{(t)}(s_0), \theta^{(t)}\omega)$ denote the Jacobian matrix at time t. By Definition 2.5, the Lyapunov exponents for the coupled system (1.9) can be written as follows:

$$\lambda(u, s_0, \omega) = \overline{\lim_{t\to\infty}}\frac{1}{t}\log\left\|\prod_{k=0}^{t-1} D(f^{(k)}(s_0), \theta^{(k)}\omega)u\right\|.$$

It can be seen that the Lyapunov exponent along the diagonal synchronization direction e_0 is

$$\lambda(e_0, s_0, \omega) = \overline{\lim_{t\to\infty}}\frac{1}{t}\sum_{k=0}^{t-1}\log|c(k)|,$$

where $c(k)$ is the common row sum of $D(f^{(k)}(s_0), \theta^{(k)}\omega)$. Let $\lambda_0 = \lambda(e_0, s_0, \omega)$, $\lambda_1, \dots, \lambda_{m-1}$ be the Lyapunov exponents (counting multiplicity) of the dynamical system $\mathcal{L}$ with the initial condition (s_0, ω). From Lemma 2.7, we conclude that $\sup_{i\geq 1}\lambda_i = \log\hat{\rho}(F, s_0, \omega) = \log\operatorname{diam}(F, s_0, \omega)$. If the probability $\mathbf{P}$ is ergodic, then the Lyapunov exponents exist for almost all $s_0 \in A$ and $\omega \in \Omega$, and furthermore they are independent of (s_0, ω).

COROLLARY 3.3. *Suppose that hypotheses* (H_1)–(H_2) *and the assumptions in Lemma* 2.7 *hold. Suppose further that* $A\times\Omega$ *is compact in the weak topology defined in this RDS*, *the semiflow* $\Theta^{(t)}$ *is continuous*, *the Jacobian matrix* $D(\cdot,\cdot)$ *is nonsingular and continuous on* $A\times\Omega$, *and*

$$\sup_{\mathbf{P}\in\mathrm{Erg}_\Theta(\mathrm{A}\times\Omega)}\sup_{i\geq 1}\lambda_i < 0,$$

where $\mathrm{Erg}_\Theta(\mathrm{A}\times\Omega)$ *denotes the ergodic probability measure set supported in* $\{A\times\Omega, \mathbf{F}, \Theta^{(t)}\}$. *Then the coupled system* (1.9) *is uniformly locally completely synchronized.*

Proof. By Theorem 2.8 in [1], we have

$$\sup_{\mathbf{P}\in Erg_\Theta(A\times\Omega)}\lambda_{\max}(\hat{\mathcal{D}}, \mathbf{P}) = \sup_{\|u\|=1,(s_0,\omega)\in A\times\Omega}\overline{\lim_{t\to\infty}}\frac{1}{t}\log\left\|\prod_{k=0}^{t-1}\hat{D}(f^{(k)}(s_0), \theta^{(k)}\omega)u\right\|,$$

where $\hat{\mathcal{D}}$ is the projection of the intrinsic matrix sequence map $\mathcal{D}$ and $\lambda_{\max}(\hat{\mathcal{D}}, \mathbf{P})$ denotes the largest Lyapunov exponent of $\hat{\mathcal{D}}$ according to the ergodic probability $\mathbf{P}$ (the value for almost all (s_0, ω) according to $\mathbf{P}$). From Lemmas 2.4, 2.6, and 2.7, it follows that

$$\begin{aligned}\sup_{\mathbf{P}\in\mathrm{Erg}_\Theta(\mathrm{A}\times\Omega)} \sup_{i\geq 1} \lambda_i &= \sup_{\mathbf{P}\in\mathrm{Erg}_\Theta(\mathrm{A}\times\Omega)} \lambda_{\max}(\hat{\mathcal{D}}, \mathbf{P}) = \sup_{(s_0,\omega)\in A\times\Omega} \lambda_{\max}(\hat{\mathcal{D}}, s_0, \omega)\\ &= \sup_{(s_0,\omega)\in A\times\Omega} \log\hat{\rho}(\mathcal{D}, s_0, \omega) = \sup_{(s_0,\omega)\in A\times\Omega} \log \mathrm{diam}(\mathcal{D}, s_0, \omega).\end{aligned}$$

The corollary is proved as a direct consequence from Theorem 3.1. □

Remark 2. If λ_0 is the largest Lyapunov exponent, then $V = \{u : \ \lambda(u) < \lambda_0\}$ constructs a subspace of $\mathbb{R}^m$ which is transverse to the synchronization direction e_0. Corollary 3.3 implies that if all Lyapunov exponents in the transverse directions are negative, then the coupled system (1.2) is synchronized. Otherwise, if λ_0 is not the largest Lyapunov exponent, then $\sup_{i\geq 1}\lambda_i < 0$ implies that the largest exponent is negative, which means that the synchronized solution $s(t)$ is itself asymptotically stable through the evolution (1.9).

Remark 3. From Lemma 2.7, it can also be seen that when computing $\rho(\mathcal{D})$, it is sufficient to compute the largest Lyapunov exponent of $\hat{\mathcal{D}}$. In [1], the authors proved for an autonomous dynamical system that if all Lyapunov exponents of the normal directions, namely, the Lyapunov exponents for $\hat{\mathcal{D}}$, are negative, then the attractor in the invariant submanifold is an attractor in $\mathbb{R}^m$ (or a more general manifold). In this paper, we extend the proof of Theorem 2.12 in [1] to the general time-varying coupled system (1.2) by discussing the relation between the Hajnal diameter and transverse Lyapunov exponents. In the following sections, we continue the synchronization analysis for nonautonomous dynamical systems.

4. Synchronization analysis of CML with time-varying topologies. Consider the following coupled system with time-varying topologies:

$$x^i(t+1) = \sum_{j=1}^{m} G_{ij}(t) f(x^j(t)), \quad i = 1, 2, \ldots, m, \ t \in \mathbb{Z}^+, \tag{4.1}$$

where $f(\cdot) : \mathbb{R} \to \mathbb{R}$ is C^1 continuous and $G(t) = [G_{ij}(t)]_{i,j=1}^m$ is a stochastic matrix. In matrix form,

$$x(t+1) = G(t)F(x(t)). \tag{4.2}$$

Since the coupling matrix $G(t)$ is a stochastic matrix, the diagonal synchronization manifold is invariant and we have the uncoupled (or synchronized) state as

$$s(t+1) = f(s(t)). \tag{4.3}$$

We suppose that for the synchronized state (4.3), there exists an asymptotically stable attractor A with the (maximum) Lyapunov exponent

$$\mu = \sup_{s_0\in A} \overline{\lim_{t\to\infty}} \frac{1}{t} \sum_{k=0}^{t-1} \log|f'(s(k))|.$$

System (4.1) is a special form of (1.2) satisfying the equicontinuous condition (H_1). Linearizing system (4.1) about the synchronized state yields the variational equation

$$\delta x^i(t+1) = \sum_{j=1}^{m} G_{ij}(t) f'(s(t)) \delta x^i(t), \ i = 1, 2, \ldots, m,$$

and

$$\mathrm{diam}\left(\prod_{k=t_0}^{t_0+t-1} G(k) f'(f^{(k-t_0)}(s_0))\right) = \mathrm{diam}\left(\prod_{k=t_0}^{t_0+t-1} G(k)\right) \left|\prod_{l=0}^{t} f'(f^{(l)}(s_0))\right|.$$

Denote the stochastic matrix sequence $\{G(t)\}_{t\in\mathbb{Z}^+}$ by $\mathcal{G}$. Thus, the Hajnal diameter of the variational system is $\mathrm{diam}(\mathcal{G})e^{\mu}$. Using Theorem 3.1, we have the following result.

THEOREM 4.1. *Suppose that the uncoupled system $s(t+1) = f(s(t))$ satisfies hypothesis* (H_2) *with Lyapunov exponent μ. Let $\mathcal{G} = \{G(t)\}_{t\in\mathbb{Z}^+}$. If*

$$\mathrm{diam}(\mathcal{G})e^{\mu} < 1, \tag{4.4}$$

then the coupled system (4.1) *is synchronized.*

From Theorem 4.1, one can see that the quantity $\mathrm{diam}(\mathcal{G})$ as well as other equivalent quantities such as the projection joint spectral radius and the Lyapunov exponent, can be used to measure the synchronizability of the time-varying coupling, i.e., the coupling stochastic matrix sequence $\mathcal{G}$. A smaller value of $\mathrm{diam}(\mathcal{G})$ implies a better synchronizability of the time-varying coupling topology. If the uncoupled system (4.3) is chaotic, i.e., $\mu > 0$, then the necessary condition for synchronization condition (4.4) is $\mathrm{diam}(\mathcal{G}) < 1$. So, it is important to investigate under what conditions $\mathrm{diam}(\mathcal{G}) < 1$ holds.

Suppose that the stochastic matrix set $\mathcal{M}$ satisfies the following hypotheses.

(H_4) *$\mathcal{M}$ is compact and there exists $r > 0$ such that for any $G = [G_{ij}]_{i,j=1}^m \in \mathcal{M}$, $G_{ij} > 0$ implies $G_{ij} \geq r$ and all diagonal elements $G_{ii} > r$, $i = 1, 2, \ldots, m$.*

We denote the graph sequence corresponding to the stochastic matrix sequence $\mathcal{G}$ by $\mathbf{\Gamma} = \{\Gamma(t)\}_{t\in\mathbb{Z}^+}$. Then we have the following result.

THEOREM 4.2. *Suppose that the stochastic matrix sequence $\mathcal{G} \subset \mathcal{M}$ satisfies hypothesis* (H_4). *Then the following statements are equivalent:*

1. $\mathrm{diam}(\mathcal{G}) < 1$;
2. *there exists $T > 0$ such that for any t_0 the graph $\bigcup_{k=t_0}^{t_0+T} \Gamma(k)$ has a spanning tree*;
3. *the stochastic matrix sequence $\mathcal{G}$ is uniformly ergodic.*

Proof. We first show that (3) $\Rightarrow$ (2) by reduction to absurdity. Let $B(t_0, t) = \prod_{k=t_0}^{t_0+t-1} G(k)$. Since $\mathcal{G}$ is uniformly ergodic, there must exist $T > 0$ such that $\mathrm{diam}(B(t_0, T)) < 1/2$ holds for any $t_0 \geq 0$. So, $v = \prod_{k=t_0}^{t_0+T-1} G(k)u$ satisfies

$$\max_{1\leq i,j\leq m} |v_i - v_j| \leq \mathrm{diam}(B(t_0, T))\|u\|_\infty \leq \frac{1}{2}\|u\|_\infty. \tag{4.5}$$

If the second condition does not hold, then there exists t_T such that the union $\bigcup_{k=t_T}^{t_T+T-1} \Gamma(k)$ does not have a spanning tree. That is, there exist two vertices v_1 and v_2 such that for any vertex z there is either no directed path from z to v_1 or no directed path from z to v_2. Let U_1 (U_2) be the vertex set which can reach v_1 (v_2, respectively) across $[t_T, t_T + T - 1]$. This implies that U_1 and U_2 are disjoint across $[t_T, t_T + T - 1]$ and no edge starts outside of U_1 (U_2) and ends in U_1 (U_2). Furthermore, considering the Frobenius form of $G(t)$, one can see that the elements in the corresponding rows of U_1 (U_2) with columns associated with the complementary set of U_1 (U_2) are all zeros. Let

$$u_i = \begin{cases} 1, & i \in U_1, \\ 0, & i \in U_2, \\ \text{any value in } (0,1), & \text{otherwise.} \end{cases}$$

We have

$$v_i = \begin{cases} 1, & i \in U_1, \\ 0, & i \in U_2, \\ \in [0,1], & \text{otherwise}. \end{cases}$$

This implies that $\max_{1\le i,j\le m} |v_i - v_j| \ge 1 = \|u\|_\infty$, which contradicts (4.5). Therefore, (3) $\Rightarrow$ (2) can be concluded.

We next show (2) $\Rightarrow$ (1). Applying Lemma 2.17, there exists $T > 0$ such that $\prod_{k=t_0}^{t_0+T-1} G(k)$ is scrambling for any t_0. There exists $\delta > 0$ such that $\eta(B(T,t_0)) > \delta > 0$ for all $t_0 \ge 0$ because of the compactness of the set $\mathcal{M}$. So,

$$\begin{aligned} \operatorname{diam}(B(t,t_0)) &= \operatorname{diam}\left\{ B\left(\operatorname{mod}(t,T), t_0 + \left[\frac{t}{T}\right] T\right) \prod_{k=1}^{[\frac{t}{T}]} B(T, t_0 + (k-1)T) \right\} \\ &\le \operatorname{diam}\left\{ \prod_{k=1}^{[\frac{t}{T}]} B(t_0 + kT - 1, t_0 + (k-1)T) \right\} \\ &\le 2(1-\delta)^{[\frac{t}{T}]} \end{aligned} \tag{4.6}$$

holds for any $t_0 \ge 0$. Here, $[t/T]$ denotes the largest integer less than t/T and $\operatorname{mod}(t,T)$ denotes the modulus of the division $t \div T$. Thus,

$$\operatorname{diam}(\mathcal{G}) \le (1-\delta)^{\frac{1}{T}} < 1.$$

This proves (2) $\Rightarrow$ (1). Since (1) $\Rightarrow$ (3) is clear, the theorem is proved. ∎

Remark 4. According to Lemma 2.17, it can be seen that the union of graphs across any time interval of length T has a spanning tree if and only if a union of graphs across any time interval of length $(m-1)T$ is scrambling.

Moreover, from [27], we conclude more results on the ergodicity of stochastic matrix sequences as follows.

PROPOSITION 4.3. *The implication* (1) $\Rightarrow$ (2) $\Rightarrow$ (3) *holds for the following statements:*

1. $\operatorname{diam}(\mathcal{G}) < 1$*;*
2. $\mathcal{G}$ *is ergodic;*
3. *for any* $t_0 \ge 0$*, the union* $\bigcup_{k\ge t_0} \Gamma(k)$ *has a spanning tree.*

Remark 5. It should be pointed out that the implications in Proposition 4.3 cannot be reversed. Counterexamples can be found in [14]. However, in [14], it is also proved under certain conditions that if the stochastic matrices have the property that $G_{ij} > 0$ if and only if $G_{ji} > 0$, then statement 2 is equivalent to statement 3.

Assembling Theorem 4.2, Proposition 4.3, and the results in [14], it can be shown that, for $\mathcal{G} \subset \mathcal{M}$, the implications

$$A_1 \Leftrightarrow A_2 \Leftrightarrow A_3 \Rightarrow A_4 \Rightarrow A_5$$

hold regarding the following statements:

- $\mathcal{A}_1$: $\operatorname{diam}(\mathcal{G}) < 1$.
- $\mathcal{A}_2$: there exists $T > 0$ such that the union across any T-length time interval $[t_0.t_0 + T]$: $\bigcup_{k=t_0}^{t_0+T} \Gamma(k)$ has a spanning tree.
- $\mathcal{A}_3$: $\mathcal{G}$ is uniformly ergodic.
- $\mathcal{A}_4$: $\mathcal{G}$ is ergodic.

- $\mathcal{A}_5$: for any t_0, the union across $[t_0, \infty)$: $\bigcup_{k \geq t_0} \Gamma(k)$ has a spanning tree.

In the following, we present some special classes of examples of CML with time-varying couplings. These classes were widely used to describe discrete-time networks and were studied in some recent papers [5, 6, 20, 27]. The synchronization criterion for these classes can be verified by numerical methods. Thus, the synchronizability diam($\mathcal{G}$) of the time-varying couplings can also be computed numerically.

4.1. Static topology. If $G(t)$ is a static matrix, i.e., $G(t) = G$ for all $t \in \mathbb{Z}^+$, then we can write the coupled system (4.1) as

$$x(t+1) = GF(x(t)). \tag{4.7}$$

PROPOSITION 4.4. *Let* $1 = \sigma_0, \sigma_1, \sigma_2, \dots, \sigma_{m-1}$ *be the eigenvalues of* G *ordered by* $1 \geq |\sigma_1| \geq |\sigma_2| \geq \cdots \geq |\sigma_{m-1}|$. *If* $|\sigma_1| e^{\mu} < 1$, *then the coupled system* (4.7) *is synchronized.*

Proof. Let $v_0 = e_0$ and choose column vectors $v_1, v_2, \dots, v_{m-1}$ in $\mathbb{R}^m$ such that $v_0, v_1, \dots, v_{m-1}$ is an orthonormal basis for $\mathbb{R}^m$. Let $A = [v_0, v_1, \dots, v_{m-1}]$. Then

$$A^{-1}GA = \begin{bmatrix} 1 & \alpha \\ 0 & \hat{G} \end{bmatrix},$$

where the eigenvalues of $\hat{G}$ are $\sigma_1, \dots, \sigma_{m-1}$. By the Householder theorem (see Theorem 4.2.1 in [28]), for any $\epsilon > 0$, there must exist a norm in $\mathbb{R}^m$ such that with its induced matrix norm,

$$|\sigma_1| \leq \|\hat{G}\| \leq |\sigma_1| + \epsilon.$$

Since ϵ is arbitrary, for the static stochastic matrix sequence $\mathcal{G}_0 = \{G, G, \dots, \}$, it can be concluded that $\hat{\rho}(\mathcal{G}_0) = |\sigma_1|$. Using Theorem 4.1, the conclusion follows. Moreover, it can also be obtained that the convergence rate is $O((|\sigma_1| e^{\mu})^t)$. ∎

Remark 6. Similar results have been obtained by several papers concerning synchronization of CML with static connections (see [5, 6, 8, 29]). Here, we have proved this result in a different way as a consequence of our main result.

4.2. Finite topology set. Let $\mathcal{Q}$ be a compact stochastic matrix set satisfying (H_4). Consider the following inclusions:

$$x(t+1) \in \mathcal{Q}F(x(t)), \tag{4.8}$$

i.e.,

$$x(t+1) = G(t)F(x(t)), \tag{4.9}$$

$$G(t) \in \mathcal{Q}. \tag{4.10}$$

Then the synchronization of the coupled system (4.8) can be formulated as follows.

DEFINITION 4.5. *The coupled inclusion system* (4.8) *is said to be synchronized if, for any stochastic matrix sequence* $\mathcal{G} \subset \mathcal{Q}$, *the coupled system* (4.9) *is synchronized.*

In [20], the authors defined the Hajnal diameter and projection joint spectral radius for a compact stochastic matrix set.

DEFINITION 4.6. *For the stochastic matrix set* $\mathcal{Q}$, *the Hajnal diameter is given by*

$$\operatorname{diam}(\mathcal{Q}) = \overline{\lim_{t\to\infty}} \sup_{G(k)\in\mathcal{Q}} \left\{ \operatorname{diam}\left(\prod_{k=0}^{t-1} G(k) \right) \right\}^{\frac{1}{t}},$$

and the projection joint spectral radius is

$$\hat{\rho}(\mathcal{Q}) = \overline{\lim_{t\to\infty}} \left\{ \sup_{G(k)\in\mathcal{Q}} \left\| \prod_{k=0}^{t-1} \hat{G}(k) \right\| \right\}^{\frac{1}{t}}.$$

The following result is from [20].

LEMMA 4.7. *Suppose $\mathcal{Q}$ is a compact set of stochastic matrices. Then*

$$\mathrm{diam}(\mathcal{Q}) = \hat{\rho}(\mathcal{Q}).$$

Using Theorem 4.1, we have the following.

THEOREM 4.8. *If* $\mathrm{diam}(\mathcal{Q})e^{\mu} < 1$, *then the coupled system* (4.8) *is synchronized.*

Moreover, we conclude that the synchronization is uniform with respect to $t_0 \in \mathbb{Z}^+$ and stochastic matrix sequences $\mathcal{G} \subset \mathcal{Q}$. Furthermore, we have the following result on synchronizability of the stochastic matrix set $\mathcal{Q}$.

PROPOSITION 4.9. *Let $\mathcal{Q}$ be a compact set of stochastic matrices satisfying hypothesis* (H_4). *Then the following statements are equivalent:*

- $\mathcal{B}_1$: $\mathrm{diam}(\mathcal{Q}) < 1$.
- $\mathcal{B}_2$: *for any stochastic matrix sequence $\mathcal{G} \subset \mathcal{Q}$, $\mathcal{G}$ is ergodic.*
- $\mathcal{B}_3$: *each corresponding graph of a stochastic matrix $G \in \mathcal{Q}$ has a spanning tree.*

Proof. The implication $\mathcal{B}_1 \Rightarrow \mathcal{B}_2 \Rightarrow \mathcal{B}_3$ is clear by Proposition 4.3. And $\mathcal{B}_3 \Rightarrow \mathcal{B}_1$ can be obtained by the proof of Theorem 4.2 since $\mathcal{Q}$ is a finite set of stochastic matrices satisfying hypothesis (H_4). ∎

Remark 7. By the methods introduced in [30, 31, 32], $\hat{\rho}(\mathcal{Q})$ can be computed to arbitrary precision for a finite set $\mathcal{Q}$ despite a large computational complexity.

4.3. Multiplicative ergodic topology sequence. Consider the stochastic matrix sequence $\mathcal{G} = \{G(t)\}_{t\in\mathbb{Z}^+}$ driven by some dynamical system $\mathcal{Y} = \{\Omega, \mathcal{F}, P, \theta^{(t)}\}$, i.e., $\mathcal{G} = \{G(\theta^{(t)}\omega)\}$ for some continuous map $G(\cdot)$. Recall the Lyapunov exponent for $\mathcal{G}$:

$$\sigma(v,\omega) = \overline{\lim_{t\to\infty}} \frac{1}{t} \log \left\| \prod_{k=0}^{t-1} G(\theta^{(k)}\omega)v \right\|.$$

It is clear that $\sigma(e_0,\omega) = 0$ for all ω and $\sigma(v,\omega) \le 0$ for all ω and $v \in \mathbb{R}^m$. So, the linear subspace

$$L_\omega = \{v, \sigma(v,\omega) < 0\}$$

denotes the directions transverse to the synchronization manifold. If P is an ergodic measure for the MDS $\mathcal{Y}$, then $\sigma(u,\omega)$ and $L(\omega)$ are the same for almost all ω with respect to P [33]. Then we can let σ_1 be the largest Lyapunov exponent of $\mathcal{G}$ transverse to the synchronization direction e_0. By Theorem 4.1 and Corollary 3.3, we have the following.

THEOREM 4.10. *Suppose that $\theta^{(t)}$ is a continuous semiflow*, $G(\cdot)$ *is continuous on all $\omega \in \Omega$ and nonsingular*, *and Ω is compact. If*

$$\sup_{\mathrm{Erf}_\theta(\Omega)} \sigma_1 + \mu < 0,$$

then the coupled system (4.1) *is synchronized.*

Remark 8. There are many papers discussing the computation of multiplicative Lyapunov exponents; for example, see [34, 35]. In particular, [36] discussed the Lyapunov exponents for the product of infinite matrices. By Lemma 2.7, we can compute the largest projection Lyapunov exponent which equals σ_1. We will illustrate this in the following section.

5. Numerical illustrations. In this section, we will numerically illustrate the theoretical results on synchronization of CML with time-varying couplings. In these examples, the coupling matrices are driven by random dynamical systems which can be regarded as stochastic processes. Then the projection Lyapunov exponents are computed numerically by the time series of coupling matrices. In this way, we can verify the synchronization criterion and analyze synchronizability numerically. Consider the following coupled map network with time-varying topology:

$$x^i(t+1) = \frac{1}{\sum\limits_{k=1}^{m} A_{ik}(t)} \sum_{j=1}^{m} A_{ij}(t) f(x^j(t)),\ \ i = 1, 2, \dots, m, \tag{5.1}$$

where $x^i(t) \in \mathbb{R}$ and $f(s) = \alpha s(1-s)$ is the logistic map with $\alpha = 3.9$, which implies that the Lyapunov exponent of f is $\mu \approx 0.5$. The stochastic coupling matrix at time t is

$$G(t) = [G_{ij}(t)]_{i,j=1}^{m} = \left[\frac{A_{ij}(t)}{\sum\limits_{j=1}^{m} A_{ij}(t)}\right]_{i,j=1}^{m}.$$

5.1. Blinking scale-free networks. The blinking scale-free network is a model initiated by a scale-free network and evolves with malfunction and recovery. At time $t = 0$, the initial graph $\Gamma(0)$ is a scale-free network introduced in [37]. At each time $t \geq 1$, every vertex i malfunctions with probability $p \ll 1$. If vertex i malfunctions, all edges linked to it disappear. In addition, a malfunctioned vertex recovers after a time interval T and then causes the reestablishment of all edges linked to it in the initial graph $\Gamma(0)$. The coupling $A_{ij}(t) = A_{ji}(t) = 1$ if vertex j is connected to i at time t; otherwise, $A_{ij}(t) = A_{ji}(t) = 0$ and $A_{ii}(t) = 1$ for all $i, j = 1, 2, \dots, m$.

In Figure 1, we show the convergence of the second Lyapunov exponent σ_1 during the topology evolution with different malfunction probability p. We measure synchronization by the variance $K = 1/(m-1)\langle\sum_{i=1}^{m}(x^i(t) - \bar{x}(t))^2\rangle$, where $\langle\cdot\rangle$ denotes the time average, and we denote $W = \sigma_1 + \mu$. We pick the evolution time length to be 1000 and choose initial conditions randomly from the interval $(0, 1)$. In Figure 2, we show the variation of K and W with respect to the malfunction probability p. It can be seen that the region where W is negative coincides with the region of synchronization, i.e., where K is near zero.

5.2. Blurring directed graph process. A blurring directed graph process is one where each edge weight is a modified Wiener process. In details, the graph process is started with a directed weighted graph $\Gamma(0)$ of which for each vertex pair (i, j), one of two edges $A_{ij}(0)$ and $A_{ji}(0)$ is a random variable uniformly distributed between 1 and 2, and the other is zero with equal probability, for all $i \neq j$; $A_{ii}(0) = 0$ for all $i = 1, 2, \dots, m$. At each time $t \geq 1$, for each $A_{ij}(t-1) \neq 0$, $i \neq j$ we denote the

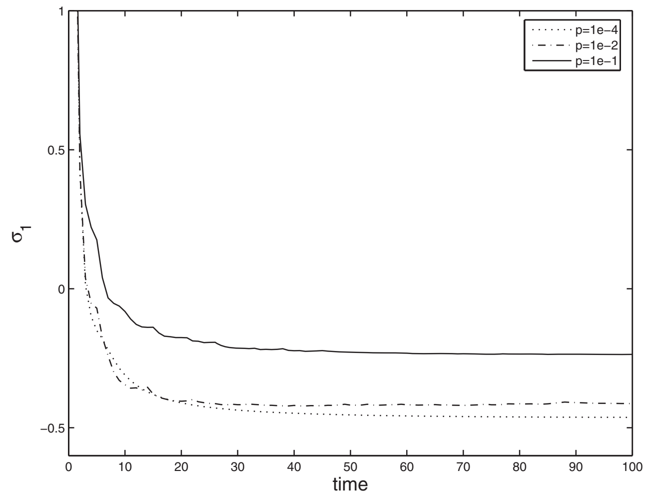

FIG. 1. *Convergence of the second Lyapunov exponent σ_1 for the blinking topology during the topology evolution with the same recovery time $T = 3$ and different malfunction probabilities $p = 10^{-1}$, $p = 10^{-2}$, and $p = 10^{-4}$. The initial scale-free graph is constructed by the method introduced in* [37] *with network size* 500 *and average degree* 12.

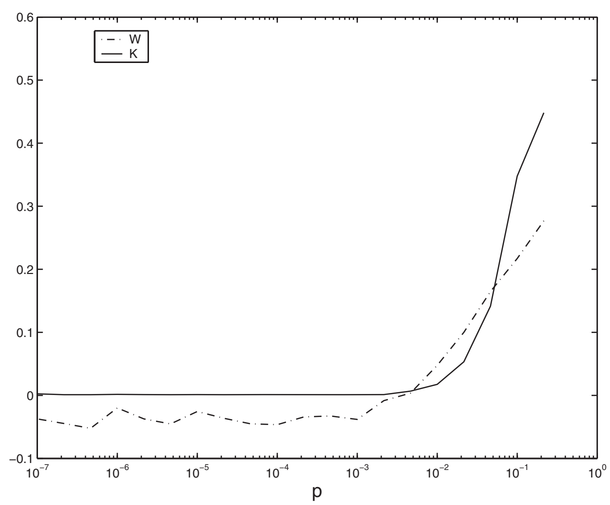

FIG. 2. *Variation of K and W with respect to p for the blinking topology.*

difference $A_{ij}(t) - A_{ij}(t-1)$ by a Gaussian distribution $\mathcal{N}(0, r^2)$ which is statistically independent for all $i \neq j$ and $t \in \mathbb{Z}^+$. If this results in $A_{ij}(t)$ being negative, a weight will be added to the reversal orientation, i.e., $A_{ji}(t) = |A_{ij}(t)|$ and $A_{ij}(t) = 0$. Moreover, if as a result of the process above there exists some index i such that $A_{ij} = 0$ holds for all $j = 1, 2, \ldots, m$, then pick $A_{ii}(t) = 1$.

In Figure 3, we show the convergence of the second Lyapunov exponent σ_1 during the topology evolution for different values of the Gaussian distribution variance r. Picking $r = 0.05$, we show the synchronization of the coupled system (5.1). Let $K(t) = 1/(m-1)\langle\sum_{i=1}^{m}(x^i(t) - \bar{x}(t))^2\rangle_t$, where $\langle\cdot\rangle_t$ denotes the time average from

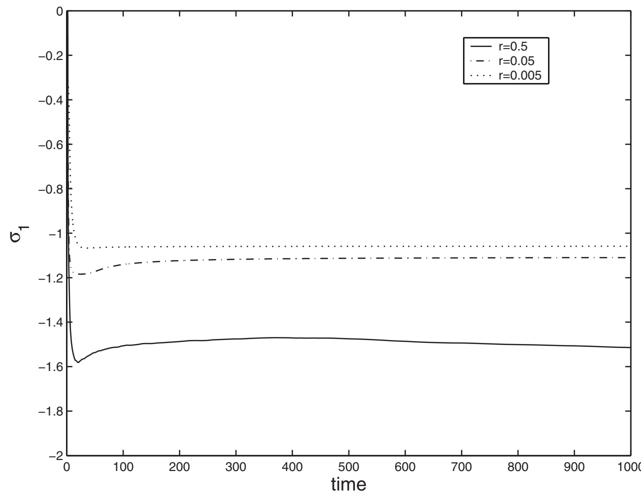

FIG. 3. *Convergence of the second Lyapunov exponent σ_1 for the blurring graph process during the topology evolution with Gaussian variance $r = 0.5$, 0.05, 0.005, and the size of the network $m = 100$.*

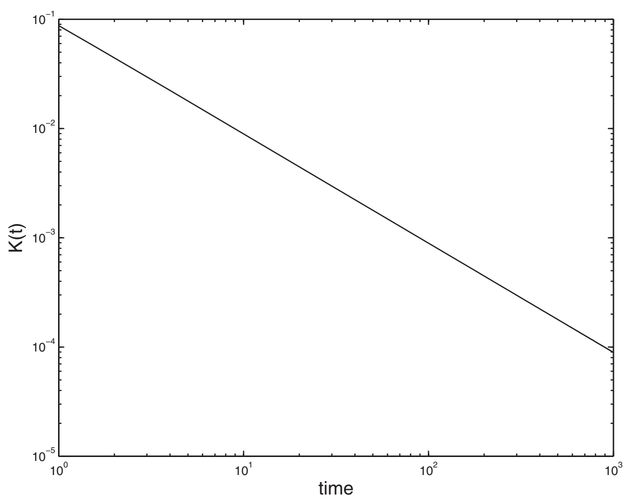

FIG. 4. *Variation of $K(t)$ with respect to time for the blurring graph process.*

0 to t. Since $W = \sigma_1 + \mu$ is about -0.6, i.e., less than zero, the coupled system is synchronized. Figure 4 shows in logarithmic scale the convergence of $K(t)$ to zero.

6. Conclusion. In this paper, we have presented a synchronization analysis for discrete-time dynamical networks with time-varying topologies. We have extended the concept of the Hajnal diameter to generalized matrix sequences to discuss the synchronization of the coupled system. Furthermore, this quantity is equivalent to other widely used quantities such as the projection joint spectral radius and transverse Lyapunov exponents, which we have also extended to the time-varying case. Thus, these results can be used to discuss the synchronization of the CML with time-varying couplings. The Hajnal diameter is utilized to describe synchronizability of the time-varying couplings and obtain a criterion guaranteeing synchronization. Time-varying couplings can be regarded as a stochastic matrix sequence associated with a sequence of graphs. Synchronizability is tightly related to the topology. As we have shown, the statement that $\mathrm{diam}(\mathcal{G}) < 1$, i.e., that chaotic synchronization is possible, is equivalent to saying that there exists an integer T such that the union of the graphs across any time interval of length T has a spanning tree. The methodology will be similarly extended to higher-dimensional maps elsewhere.

Appendix.

Proof of Lemma 2.4. The proof of this lemma comes from [20] with a minor modification. First, we show $\mathrm{diam}(\mathcal{L},\phi) \le \hat{\rho}(\mathcal{L},\phi)$. Let J be any complement of $\mathcal{E}_0$ in $\mathbb{R}^m$ with a basis $u_0,\dots,u_{m-1}$ such that $u_0 = e_0$. Let $A = [u_0, u_1, \dots, u_{m-1}]$, which is nonsingular. Then, for any $t > t_0$ and $t_0 \ge 0$,

$$A^{-1}L_t(\varrho^{(t-t_0)}\phi)A = \begin{bmatrix} c(t) & \alpha_t \\ 0 & \hat{L}_t(\varrho^{(t-t_0)}\phi) \end{bmatrix},$$

where $c(t)$ denotes the row sum of $L_t(\varrho^{(t-t_0)}\phi)$ which is also the eigenvalue corresponding eigenvector e, and $\hat{L}_t(\varrho^{(t-t_0)}\phi)$ can be the solution of linear equation (2.4) with P composed of the rows of A^{-1} except the first row. For any $d > \hat{\rho}(\mathcal{L},\phi)$, there exists $T > 0$ such that the inequality

$$\left\| \prod_{k=t_0}^{t_0+t-1} \hat{L}_k(\varrho^{(k-t_0)}\phi) \right\| \le d^t$$

holds for all $t \ge T$ and $t_0 \ge 0$. Let

$$A^{-1}\prod_{k=t_0}^{t_0+t-1} L_k(\varrho^{(k-t_0)}\phi)A = \begin{bmatrix} \prod_{k=t_0}^{t_0+t-1} c(k) & \alpha_t \\ 0 & \prod_{k=t_0}^{t_0+t-1} \hat{L}_k(\varrho^{(k-t_0)}\phi) \end{bmatrix}.$$

Then

$$\begin{aligned} &\left\| A^{-1}\prod_{k=t_0}^{t_0+t-1} L_k(\varrho^{(k-t_0)}\phi)A - \begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \left(\prod_{k=t_0}^{t_0+t-1} c(k), \alpha_t \right) \right\| \\ &= \left\| \begin{bmatrix} 0 & 0 \\ 0 & \prod_{k=t_0}^{t_0+t-1} \hat{L}_k(\varrho^{(k-t_0)}\phi) \end{bmatrix} \right\| \le Cd^t \end{aligned}$$

holds for some constant $C > 0$. Therefore,

$$\left\| \prod_{s=t_0}^{t_0+t-1} L_k(\varrho^{(k-t_0)}\phi) - A \begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \left(\prod_{k=t_0}^{t_0+t-1} c(k), \alpha_t \right) A^{-1} \right\| \le C_1 d^t,$$

$$\left\| \prod_{k=t_0}^{t_0+t-1} L_k(\varrho^{(k-t_0)}\phi) - e \cdot q \right\| \le C_1 d^t,$$

where $q = \big[\prod_{k=t_0}^{t_0+t-1} c(k), \alpha_t\big] A^{-1}$ and C_1 is a positive constant. It says that all row vectors of $\prod_{k=t_0}^{t_0+t-1} L_k(\varrho^{(k-t_0)}\phi)$ lie inside the $C_1 d^m$ neighborhood of q. Hence,

$$\mathrm{diam}\bigg(\prod_{k=t_0}^{t_0+t-1} L_k(\varrho^{(k-t_0)}\phi)\bigg) \le C_2 d^t$$

for some constant $C_2 > 0$, all $t \ge T$, and $t_0 \ge 0$. This implies that $\mathrm{diam}(\mathcal{L}, \phi) \le d$. Since d is arbitrary, $\mathrm{diam}(\mathcal{L}, \phi) \le \hat{\rho}(\mathcal{L}, \phi)$ can be concluded.

Second, we show that $\hat{\rho}(\mathcal{L}, \phi) \le \mathrm{diam}(\mathcal{L}, \phi)$. For any $d > \mathrm{diam}(\mathcal{L}, \phi)$, there exists $T > 0$ such that

$$\mathrm{diam}\bigg(\prod_{k=t_0}^{t_0+t-1} L_k(\varrho^{(k-t_0)}\phi)\bigg) \le d^t$$

holds for all $t \ge T$ and $t_0 \ge 0$. Letting q be the first row of $\prod_{k=t_0}^{t_0+t-1} L_k(\varrho^{(k-t_0)}\phi)$, we have

$$\bigg\|\prod_{k=t_0}^{t_0+t-1} L_k(\varrho^{(k-t_0)}\phi) - e \cdot q\bigg\| \le C_3 d^t$$

for some positive constant C_3. Let A be defined as above. Then

$$\bigg\|A^{-1}\prod_{k=t_0}^{t_0+t-1} L_k(\varrho^{(k-t_0)}\phi) A - A^{-1} e \cdot q A\bigg\| \le C_4 d^t,$$

i.e.,

$$\left\|\begin{bmatrix} \prod_{k=t_0}^{t_0+t-1} c(k) & \alpha_t \\ 0 & \prod_{k=t_0}^{t_0+t-1} \hat{L}_k(\varrho^{(k-t_0)}\phi) \end{bmatrix} - \begin{bmatrix} \gamma & \beta \\ 0 & 0 \end{bmatrix}\right\| \le C_4 d^t$$

holds for some γ and β. This implies that

$$\bigg\|\prod_{k=t_0}^{t_0+t-1} \hat{L}_k(\varrho^{(k-t_0)}\phi)\bigg\| \le C_5 d^t$$

holds for all $t \ge T$, $t_0 \ge 0$, and some $C_5 > 0$. Therefore, $\hat{\rho}(\mathcal{L}, \phi) \le d$. The proof is completed since d is chosen arbitrarily. ◻

Proof of Lemma 2.6. Let $\hat{\lambda}_{\max} = \sup_{v \in \mathbb{R}^{m-1}} \hat{\lambda}(\mathcal{L}, \phi, v)$. First, it is easy to see that $\log \hat{\rho}(\mathcal{L}, \phi) \ge \hat{\lambda}_{\max}$. We will show $\log \hat{\rho}(\mathcal{L}, \phi) = \hat{\lambda}_{\max}$. Otherwise, there exists $d \in (\exp(\hat{\lambda}_{\max}), \hat{\rho}(\mathcal{L}, \phi))$. By the properties of Lyapunov exponents, for any normalized orthogonal basis $u_1, u_2, \ldots, u_{m-1} \in \mathbb{R}^{m-1}$ with Lyapunov exponent $\hat{\lambda}(\mathcal{L}, \phi, u_i) = \hat{\lambda}_i$, we have, for any $u \in \mathbb{R}^{m-1}$, $\hat{\lambda}(\mathcal{L}, \phi, u) = \hat{\lambda}_{i_u}$, where $i_u \in \{1, 2, \ldots, m-1\}$. $\hat{\rho}(\mathcal{L}, \phi) > d$ implies that there exist $t_0 \ge 0$ and a sequence t_n with $\lim_{n\to\infty} t_n = +\infty$ such that

$$\bigg\|\prod_{k=t_0}^{t_n+t_0-1} \hat{L}_k(\varrho^{(k-t_0)}\phi)\bigg\| > d^{t_n}$$

for all $n \geq 0$. That is, there also exists a sequence $v_n \in \mathbb{R}^{m-1}$ with $\|v_n\| = 1$ such that

$$\left\| \prod_{k=t_0}^{t_n+t_0-1} \hat{L}_k(\varrho^{(k-t_0)}\phi)v_n \right\| > d^{t_n}.$$

There exists a subsequence of v_n (still denoted by v_n) with $\lim_{n\to\infty} v_n = v^*$. Let $\delta v_n = v_n - v^*$. We have

$$\left\| \prod_{k=t_0}^{t_n+t_0-1} \hat{L}_k(\varrho^{(k-t_0)}\phi)v^* \right\| \geq \left\| \prod_{k=t_0}^{t_n+t_0-1} \hat{L}_k(\varrho^{(k-t_0)}\phi)v_n \right\| - \left\| \prod_{k=t_0}^{t_n+t_0-1} \hat{L}_k(\varrho^{(k-t_0)}\phi)\delta v_n \right\|.$$

Note that we can write $\delta v_n = \sum_{i=1}^{m-1} \delta x_n^i u_i$, where $\delta x_n^i \in \mathbb{R}$ with $\lim_{n\to\infty} \delta x_n^i = 0$. So, there exists an integer N such that $\| \prod_{k=t_0}^{t_n+t_0-1} \hat{L}_k(\varrho^{(k-t_0)}\phi)\delta v_n\| \leq \big(\sum_{i=1}^{m-1} |\delta x_n^i|\big) d^{t_n}$ holds for all $n \geq N$. Then we have

$$\left\| \prod_{k=t_0}^{t_n+t_0-1} \hat{L}_k(\varrho^{(k-t_0)}\phi)v^* \right\| \geq d^{t_n} - d^{t_n}\left(\sum_{i=1}^{m-1} |\delta x_n^i| \right) \geq C d^{t_n}$$

for all $n \geq N$ and some $C > 0$. This implies $\max_{v\in\mathbb{R}^m} \hat{\lambda}(\mathcal{L}, \phi, v) \geq \log d$, which contradicts the assumption $d \in (\exp(\hat{\lambda}_{\max}), \hat{\rho}(\mathcal{L}, \phi))$. Hence, $\hat{\lambda}_{\max} = \log \hat{\rho}(\mathcal{L}, \phi)$. $\square$

Proof of Lemma 2.7. Recall that $\{\Phi, \mathcal{B}, P, \varrho^{(t)}\}$ denotes a random dynamical system, where Φ denotes the state space, $\mathcal{B}$ denotes the σ-algebra, P denotes the probability measure, and $\varrho^{(t)}$ denotes the semiflow. For a given $\phi \in \Phi$ we denote $L(\varrho^{(t)}\phi)$ by $L(t)$. Let $A = [u_1, u_2, \ldots, u_m] \in \mathbb{R}^{m\times m}$, where $u_1, \ldots, u_m$ denotes a basis of $\mathbb{R}^m$ and $u_1 = e$,

$$A^{-1} = \begin{bmatrix} v_1 \\ v_2 \\ \vdots \\ v_m \end{bmatrix} \in \mathbb{R}^{m\times m}$$

is the inverse of A with

$$\bar{L}(t) = A^{-1}L(t)A = \begin{bmatrix} c(t) & \alpha^\top(t) \\ 0 & \hat{L}(t) \end{bmatrix},\ \hat{L}(t) = A_1^* D(t) A_1,\ \alpha^\top(t) = v_1 L(t) A_1,$$

where $A_1 = [u_2, \ldots, u_m] \in \mathbb{R}^{m\times(m-1)}$, and

$$A_1^* = \begin{bmatrix} v_2 \\ \vdots \\ v_m \end{bmatrix} \in \mathbb{R}^{(m-1)\times m}.$$

One can see that the set of Lyapunov exponents of the dynamical system $\{\bar{L}(t)\}_{t\in\mathbb{Z}^+}$ are the same as those of $\{L(t)\}_{t\in\mathbb{Z}^+}$. For any $z(0) = [x(0), y(0)] \in \mathbb{R}^m$, where $x(0) \in \mathbb{R}$ and $y(0) \in \mathbb{R}^{m-1}$, this evolution $z(t+1) = \bar{L}(t)z(t)$ leads to

$$z(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c(t-1)x(t-1) + \alpha^\top(t-1)y(t-1) \\ \hat{L}(t-1)y(t-1) \end{bmatrix}.$$

So, we have

$$
\begin{aligned}
y(t) &= \prod_{k=0}^{t-1} \hat{L}(k) y(0), \\
x(t) &= \prod_{k=0}^{t-1} c(k) x(0) + \sum_{k=1}^{t} \prod_{p=t-k+1}^{t-1} c(p) \alpha^{\top}(t-k) \prod_{q=0}^{t-k-1} \hat{L}(q) y(0).
\end{aligned} \tag{A.1}
$$

If the upper bound is less than the lower bound for the left matrix product $\prod$, then the product should be the identity matrix. In the following, we denote by $\hat{\mathcal{L}}$ the projection sequence map of $\mathcal{L}$ and will prove this lemma for two cases.

Case 1. $\lambda_0 \leq \log \hat{\rho}(\mathcal{L}, \phi)$. Since $\hat{\rho}(\mathcal{L}, \phi)$ is just the largest Lyapunov exponent of $\hat{\mathcal{L}}$ defined by $\hat{\lambda}$, from conditions 1 and 2, one can see that for any $\epsilon > 0$, there exists $T > 0$ such that for any $t \geq T$ it holds that $|\alpha(t)| \leq e^{\epsilon t}$, $\left\| \prod_{k=0}^{t-1} \hat{L}(k) \right\| \leq e^{(\hat{\lambda}+\epsilon)t}$, and $e^{(\lambda_0-\epsilon)t} \leq |\prod_{k=0}^{t-1} c(k)| \leq e^{(\lambda_0+\epsilon)t}$. Thus, we can obtain

$$
\begin{aligned}
\prod_{k=t-k+1}^{t-1} |c(p)| &= \prod_{p=0}^{t-1} |c(p)| \times \frac{1}{\prod\limits_{p=0}^{t-k} |c(p)|} \\
&= \begin{cases} e^{(\lambda_0+\epsilon)(t)} e^{-(\lambda_0-\epsilon)(t-k+1)}, & k \leq t-T+1, \\ e^{(\lambda_0+\epsilon)(t-1)} \max\limits_{T \geq q \geq 0} \left(\prod\limits_{p=0}^{q} |c(p)| \right)^{-1}, & t-1 \geq k \geq t-T. \end{cases}
\end{aligned}
$$

Then we have

$$
\begin{aligned}
|x(t)| &\leq \prod_{k=0}^{t-1} |c(k)||x(0)| + \sum_{k=1}^{t-T+1} \prod_{p=t-k+1}^{t-1} |c(p)||\alpha^{\top}(t-k)| \prod_{q=0}^{t-k-1} \|\hat{L}(q)\| \|y(0)\| \\
&\quad + \sum_{k=t-T}^{t-1} \prod_{p=t-k+1}^{t-1} |c(p)| \|\alpha^{\top}(t-k)\| \prod_{q=0}^{t-k-1} \|\hat{L}(q)\| \|y(0)\| \\
&\leq e^{(\lambda_0+\epsilon)t} + \sum_{k=1}^{t-T+1} e^{(\lambda_0+\epsilon)(t-1)} e^{\epsilon t} e^{-(\lambda_0-\epsilon)(t-k)} e^{(\hat{\lambda}+\epsilon)(t-k)} + M_1 e^{(\lambda_0+\epsilon)(t-1)} \\
&\leq e^{(\hat{\lambda}+\epsilon)t} + e^{(\hat{\lambda}+4\epsilon)t} e^{-(\lambda_0+\epsilon)} \sum_{k=1}^{t-T+1} e^{(-\hat{\lambda}+\lambda_0-3\epsilon)k} + M_1 e^{(\lambda_0+\epsilon)t} \\
&\leq M_2 e^{(\hat{\lambda}+4\epsilon)t},
\end{aligned}
$$

where

$$
M_1 = (T+1) \max_{T \geq q \geq 0} \left(\prod_{p=0}^{q} |c(p)| \right)^{-1} e^{\epsilon T} \left(\prod_{p=0}^{q} \|\hat{L}(p)\| \right) \|y(0)\|,
$$

$$
M_2 = 1 + M_1 + e^{-(\lambda_0+\epsilon)} \sum_{k=1}^{\infty} e^{-3\epsilon k}.
$$

So,

$$\overline{\lim_{t\to\infty}}\frac{1}{t}\log\|z(t-1)\|\le\hat{\lambda}+4\epsilon$$

holds for all $z(0)\in\mathbb{R}^m$. Noting that $\hat{\lambda}$ must be less than the largest Lyapunov exponent of $\mathcal{L}$, we conclude that $\hat{\lambda}$ is the largest Lyapunov exponent. This implies the conclusion of the lemma.

Case 2. $\lambda_0>\hat{\lambda}$. Note that for any $\epsilon\in(0,(\lambda_0-\hat{\lambda})/3)$ there exists T such that

$$\prod_{k=0}^{t}|c^{-1}(k)|\|\alpha^\top(t)\|\prod_{l=0}^{t}\|\hat{L}(l)\|\le Ce^{(-\lambda_0+\hat{\lambda}+3\epsilon)t} \tag{A.2}$$

for all $t\ge T$ and some constant $C>0$. Let

$$x=-\sum_{t=0}^{\infty}\prod_{k=0}^{t}c^{-1}(k)\alpha^\top(t)\prod_{l=0}^{t-1}\hat{L}(l)y,$$

which in fact exists and is finite according to inequality (A.2). Then let

$$V_\phi=\left\{z=\left[\begin{array}{c}x\\ y\end{array}\right]:\ x+\sum_{t=0}^{\infty}\prod_{k=0}^{t}c^{-1}(k)\alpha^\top(t)\prod_{l=0}^{t-1}\hat{L}(l)y=0\right\}$$

be the transverse space. For any $\left[\begin{smallmatrix}x(0)\\ y(0)\end{smallmatrix}\right]\in V_\phi$,

$$x(t)=-\sum_{k=t}^{\infty}\prod_{p=t}^{k}c^{-1}(p)\alpha^\top(k)\prod_{q=0}^{k-1}\hat{L}(q)y(0).$$

Noting that there exists $T>0$ such that $\prod_{p=t}^{k}|c^{-1}(p)|\le e^{(-\lambda_0+\epsilon)(k-t)+2\epsilon t}$ for all $t\ge T$, we have

$$\begin{aligned}|x(t)|&\le\sum_{k=t}^{\infty}\prod_{p=t}^{k}|c^{-1}(p)|\|\alpha^\top(k)\|\left\|\prod_{q=0}^{k-1}\hat{L}(q)\right\|\|y(0)\|\\&\le\sum_{k=t}^{\infty}e^{(-\lambda_0+\epsilon)(k-t)}e^{2\epsilon t}e^{\epsilon k}e^{(\hat{\lambda}+\epsilon)k}\\&\le\left\{\sum_{k=t}^{\infty}e^{(-\lambda_0+\hat{\lambda}+3\epsilon)(k-t)}\right\}e^{(\hat{\lambda}+4\epsilon)t}\le M_2e^{(\hat{\lambda}+4\epsilon)t}\end{aligned}$$

for all $t\ge T$and some constants $M_2>0$. So, it can be concluded that

$$\overline{\lim_{t\to\infty}}\frac{1}{t}\log\|z(t-1)\|\le\hat{\lambda}+4\epsilon.$$

Since ϵ is chosen arbitrarily, there exists an $(m-1)$-dimensional subspace $V_\phi=\{z=[x\,y]^\top:\ x=-\sum_{t=0}^{\infty}\prod_{k=0}^{t}c^{-1}(k)\alpha^\top(t)\prod_{l=0}^{t-1}\hat{L}(l)y\}$ of which the largest Lyapunov exponent is less than $\hat{\lambda}$. The largest Lyapunov exponent of V_ϕ is clearly greater than $\hat{\lambda}$. Therefore, we conclude that $\hat{\lambda}$, i.e., $\log(\hat{\rho}(L))$, is the largest Lyapunov exponent of L except for λ_0. The proof is completed. ∎

ON DIFFUSION INDUCED SEGREGATION IN TIME-DEPENDENT DOMAINS*

THOMAS BLESGEN†

Abstract. This article is concerned with the derivation and analysis of a model for diffusion induced segregation phenomena in the physically relevant case that the domain representing the crystal grows in time. A mathematical model is formulated where the phase parameter is a function of bounded variation and the equations are completed with the Gibbs–Thomson law. Based on suitable a priori bounds, methods from geometric measure theory are applied to derive suitable compactness properties which allow us to show the existence of weak solutions in three space dimensions.

Key words. phase transitions, dynamics of phase boundary, Gibbs–Thomson law

DOI. 10.1137/060652336

1. Introduction.

Diffusion induced segregation (DIS) processes represent a particular class of phase change problems in solids that has been widely studied in mineralogy and crystallography. Typical of DIS is that the segregation starts only after the concentration of one selected component that diffuses into the single crystal from outside exceeds a certain threshold. DIS phenomena are very interesting for geological applications, as the segregation is irreversible and rock samples with DIS can be regarded as a natural geological clock. One prominent application of DIS is the attempt to estimate the time scale for magma ascending from the mantle of the earth by the investigation of a specimen with the so-called chalcopyrite disease within sphalerite. Mineralogical experiments on this particular example were first carried out in [5] and [6] under isothermal conditions. These articles explain conclusively the rearrangement of the lattice as well as the qualitative mechanism responsible for DIS. A collection of experiments revealing DIS phenomena is available in [5] and [6], and the results are compared with geological observations of DIS.

In order to get a better understanding of chalcopyrite disease within sphalerite, a first phase-field model based on partial differential equations with a modified Allen–Cahn equation was developed in [10]. More advanced simulations on the related ternary system of sphalerite, chalcopyrite, and cubanite are done in [11]. A general existence and uniqueness result for the mathematical formulation derived in [10] is contained in [7]. More sophisticated numerical simulations can be found in [8], where ab initio methods are used on a large scale to approximately compute the physical free energies. The results of the ab initio computations are validated with quantum mechanical and molecular dynamics calculations. In particular, the results in [8] provide *quantitative* predictions.

As is explained in [10], the mathematical model developed in earlier articles neglects the attachment of sulphur ions which lead to a growth of the crystal during

the experiments. Instead, the domain Ω representing the crystal was assumed to be time-independent.

In this article we will close this gap. In the model presented in section 2, boundary conditions on the chemical potential are assumed which are close to the physical reality and which allow the domain to grow. These boundary conditions are connected to a generalized Gibbs–Thomson law. The rest of the paper is devoted to the proof of the existence of weak solutions. We follow the ansatz in [2] which is classical by now. In section 4, a time-discrete scheme is introduced.

We apply methods from geometric measure theory to show suitable a priori bounds and to establish the compactness in space and time of the time-discrete solution. The central argument is Lemma 7.7. In the subset of large discrete-interface velocities its proof is based on the construction of a Besicovitch-type covering that fails for space dimensions $n > 3$. In the set of a small discrete-interface velocity the proof relies on Bernstein's theorem, which is known to hold for space dimensions $n \leq 8$. The other key argument in the proof is Lemma 6.4, which requires $n \geq 3$; see the essential estimate (6.11). Due to these restrictions, the main lemmas are formulated for $n = 3$.

We mention that the employed techniques and results are related to the Stefan problem and the Mullins–Sekerka flow (see in particular the articles [18], [19], [17], [28], and [25]) and also can be transferred to applications in shape optimization problems.

For $h > 0$, time-discrete solutions are constructed in section 4, and it is shown in Theorem 7.4 that for a subsequence χ_h (the characteristic function of a set Ω_h^I) and a function $\chi \in L^1(\Omega_T, \{0, 1\})$,

$$\chi_h \to \chi \qquad \text{in } L^1(\Omega_T)$$

as $h \searrow 0$. Unfortunately, this does *not* imply that

$$|\nabla \chi_h| \rightharpoonup |\nabla \chi| \qquad \text{in } \mathrm{rca}(\Omega_T).$$

(Here $\mathrm{rca}(\Omega_T)$ denotes the space of all regular countable measures on Ω_T.) Therefore we require the following technical assumption from (8.1):

$$\int_{\Omega_T} |\nabla \chi_h| \to \int_{\Omega_T} |\nabla \chi| \qquad \text{as } h \searrow 0,$$

which is needed to prevent a loss of area when passing to the limit. Condition (8.1) is not new. In connection to the Stefan problem with Gibbs–Thomson law, it was stated previously in [19]. Condition (8.1) can also be found in [1].

In general, (8.1) does not hold and is violated because of the following concentration or oscillation effects at the reduced boundary:

1. Several parts of the boundary $\partial^* \Omega_h^I$ meet in the limit.
2. Oscillations of the boundary reduce the area in the limit.

One possible way to avoid condition (8.1) is to construct varifold solutions. For a two-phase flow described by the Navier–Stokes equations, this has been done in [22].

Finally, we remark that for the investigated mathematical system, we cannot expect the uniqueness of solutions. The reason is the same as for the Stefan problem with the Gibbs–Thomson law; see [18] for a proof.

2. Derivation of the model. Let $\Omega \subset \mathbb{R}^n$ be a box chosen large enough such that for times $0 \leq t \leq T$ with given stop time $T > 0$ a time-dependent set $\Omega^I = \Omega^I(t) \subset \mathbb{R}^n$ is contained in Ω. For the proof of existence of weak solutions, we will set

$n = 3$. We assume that Ω is a bounded domain with Lipschitz boundary. We call the set $\Omega^I(t)$ the *inner domain*, as it represents the growing crystal at time t surrounded by a second copper rich mineral. This second phase occupies $\Omega^{II} := \Omega \setminus \overline{\Omega^I}$ which we call the *outer domain*.

We introduce the two space-time cylinders $\Omega_T := \Omega \times (0,T)$, $\Omega_T^I := \Omega^I(t) \times (0,T)$, and by $\theta > 0$ we denote the constant temperature.

We introduce for $1 \le i \le 4$ functions $n_i : \Omega_T \to \mathbb{N}$ which determine the number of lattice positions in Ω_T occupied by species i. The n_i are related to the species by

$$n_1 \ldots \mathrm{Fe}^{3+}, \quad n_2 \ldots \mathrm{Fe}^{2+}, \quad n_3 \ldots \mathrm{Zn}^{2+}, \quad n_4 \ldots \mathrm{Cu}^{+}.$$

Similarly, by n_v we denote the number of vacant lattice positions.

We point out that even though the crystal grows due to the attachment of sulphur ions, the mathematical model does not require a variable for the sulphur concentration. This is because the attachment of S^{2-} is a consequence of the oxidation of Fe, leading to Shottky defects in the crystal. This is explained in detail in [7].

We introduce the vector $m = (m_1, \ldots, m_4)$, where

$$m_i(x,t) := \frac{n_i(x,t)}{\sum_{j=1}^4 n_j(x,t) + n_v(x,t)}, \quad 1 \le i \le 4,$$

is the number density of the ith constituent in Ω_T. We assume that we have a perfect crystal without impurities such that no further constituents need to be considered.

The variable m_5 specifies the electron density. The condition of electric neutrality leads to the formula

$$m_5 = 3m_1 + 2m_2 + 2m_3 + m_4 - 2. \tag{2.1}$$

The coefficients of m_i in (2.1) refer to the positive ionization of the ith constituent, and 2 is subtracted in the formula due to the attachment of S^{2-} ions.

In Ω_T^I the free energy density is given by

$$\begin{aligned} f_I(m) = k_B\theta \left[\sum_{i=1}^4 m_i \ln m_i + \left(1 - \sum_{i=1}^4 m_i\right) \ln \left(1 - \sum_{i=1}^4 m_i\right)\right] \\ + \sum_{i=1}^4 \sum_{j=1}^4 \alpha_{ij} m_i m_j + \sum_{i=1}^4 \beta_i m_i. \end{aligned} \tag{2.2}$$

The matrix $A := (\alpha_{ij})_{1 \le i,j \le 4}$ is symmetric and positive definite with constant coefficients, β_i are positive enthalpic constants, and k_B denotes the Boltzmann constant. The first term $\sum_i m_i \ln m_i$ in (2.2) is the entropic contribution to the free energy as it counts all possible configurations with a given vector m. The second summand with coefficients $\alpha_{ij} = \alpha_{ji}$ measures the elastic energy; i.e., $\alpha_{ij} m_i m_j$ is the contribution due to the interaction of ion i with ion j; see [10] for further details.

For the free energy of the outer phase and for given small $\delta > 0$, we make the ansatz

$$f_{II}(m) = k_B\theta \left[\sum_{i=1}^4 m_i \ln m_i - (\ln \delta + 1) \sum_{i=1}^2 m_i \right]. \tag{2.3}$$

The chemical potential of the ith constituent fulfills for $1 \le i \le 4$ (see (2.13) below)

$$\mu_i = \frac{\partial f_I}{\partial m_i}(m) \quad \text{in } \Omega^I, \qquad \mu_i = \frac{\partial f_{II}}{\partial m_i}(m) \quad \text{in } \Omega^{II}. \tag{2.4}$$

Ansatz (2.3) is chosen such that $\mu_i = k_B\theta \ln(m_i/\delta)$ and μ_i is positive in Ω^{II} for $m_i > \delta$ and $i = 1, 2$.

The oxidation process Fe^{3+}+e^- $\leftrightarrow$ Fe^{2+} in Ω^I_T is formally modeled as a reaction. The reaction vector r^I in Ω^I is given by (see [15] for a general explanation)

$$r^I = (r_1^I, -r_1^I, 0, 0), \qquad r_1^I = r_1^I(m) = k_1 m_2 - k_2 m_5 \tag{2.5}$$

with positive reaction rates k_1, k_2.

The conservation of mass leads to the formulation $\partial_t m_i = -\mathrm{div}(J_i) + r_i(m)$. Onsager's postulate [20], [21] states that the thermodynamic flux J is linearly related to the thermodynamic force. In our case, the thermodynamic forces are the negative chemical potential gradients, and we obtain the phenomenological equations (see [16, p. 137])

$$J_i = -\sum_{j=1}^{4} L_{ij} \nabla \mu_j, \quad 1 \le i \le 4, \tag{2.6}$$

with a mobility tensor $L = (L_{ij})_{1 \le i,j \le M}$ that may depend on μ. The Onsager reciprocity law [20], [21], [16] states that L has to be symmetric, which we assume in the following. To simplify the existence theory, we will further assume that L is positive definite.

The coefficients of L depend on the domain as $L = L^I$ in Ω^I and $L = L^{II}$ in Ω^{II}. The diffusion rates measured for Cu^+ and Zn^{2+} are of the same order and are about 1000 times larger than the diffusivities of Fe^{3+} and Fe^{2+}. Mathematically, we look at an idealized situation, where we set $L^{II}_{ij} := 0$ for $i \ne j$ (this means no cross diffusion) and L^{II}_{11}, $L^{II}_{22} \sim \varepsilon$ and L^{II}_{33}, $L^{II}_{44} \sim \frac{1}{\varepsilon}$. For small $\varepsilon > 0$, this gives rise to the following boundary conditions on $\partial\Omega^I$:

$$-\sum_{j=1}^{4} L^I_{ij}(\mu) \nabla \mu_j \vec{n} = m_i v \qquad \text{for } i = 1, 2, \tag{2.7}$$

$$\mu_i = \varphi_i \qquad \text{for } i = 3, 4. \tag{2.8}$$

The parameter v denotes the speed with which the interface moves outward, $\vec{n}$ is the unit outer normal to Ω^I, and φ_1, φ_2 are two given constants invariant in time and space.

We have the diffusion equations

$$\partial_t m_i = \mathrm{div}\left(\sum_{j=1}^{4} L^I_{ij} \nabla \mu_j\right) + r^I_i(m) \qquad \text{in } \Omega^I, \tag{2.9}$$

$$\partial_t m_i = \mathrm{div}\Big(L^{II}_{ii} \nabla \mu_i\Big) + r^{II}_i(\mu) \qquad \text{in } \Omega^{II}. \tag{2.10}$$

Experimentally it is observed that the outer domain contains only a very small amount of Fe^{3+}, Fe^{2+} except in a small strip near Ω^I. To ensure this condition for the mathematical system if the free boundary $\partial\Omega^I \cap \partial\Omega^{II}$ moves inward, i.e., if $v < 0$, we make the ansatz

$$r^{II}(\mu) = -\frac{1}{\gamma}(\mu_1, \mu_2, 0, 0), \tag{2.11}$$

where $\gamma > 0$ is a small constant related to the thickness of the Fe-containing strip close to Ω^I.

The model is formulated for small positive parameters γ, δ, and ε, but we will show in sections 5 and 7 that the existence theory remains valid in the limit $\gamma, \delta, \varepsilon \searrow 0$; see in particular the assumptions (A1)–(A4) in section 6 on the time-discrete problem.

We postulate that the set $\Omega_0^I := \Omega^I(t = 0)$ has a finite perimeter. For the characteristic function $\chi(\cdot, 0) : \Omega \to \{0, 1\}$ of $\Omega^I(t = 0)$, this means

$$\int_\Omega |\nabla\chi(t = 0)| = \|\chi(t = 0)\|_{BV(\Omega)} < \infty.$$

The condition $\|\chi\|_{BV(\Omega)} < \infty$ means that χ is a function of bounded variation in Ω; see [29], [30]. The symbol $H^{1,2}(\Omega) \subset L^2(\Omega)$ denotes the Sobolev space of functions with first weak derivatives in the Hilbert space $L^2(\Omega)$.

We consider a physical system with surface tension, so the total free energy F is given by

$$F(\chi, \mu) := \int_\Omega |\nabla\chi| + \int_{\partial\Omega^I} v + \int_\Omega (\chi f_I^*(\mu) + (1 - \chi) f_{II}^*(\mu)). \tag{2.12}$$

Here, $f_I^*(\mu)$, $f_{II}^*(\mu)$ are the Legendre–Fenchel transforms of $f_I(\mu)$, $f_{II}(\mu)$ defined by

$$f_I^*(\mu) := \sup_m \{\mu \cdot m - f_I(m)\}, \qquad f_{II}^*(\mu) := \sup_m \{\mu \cdot m - f_{II}(m)\}.$$

In these definitions, $\cdot$ denotes the inner product, i.e., $\mu \cdot m = \sum_{i=1}^4 \mu_i m_i$. If there can be no ambiguity, we drop $\cdot$ and simply write μm in this article.

The use of f_I^* and f_{II}^* exploits duality properties of the problem and allows us to formulate the free energy F as a function of μ and not of m. The Legendre–Fenchel transformation is a frequently used tool in mechanics and originates from convex analysis. General references to the Legendre–Fenchel transformation are [24] and [3]. In the context of diffusion problems, the ansatz (2.12) goes back to [4].

The mathematical description of the system is completed with the condition

$$F(\chi, \mu) \to \min, \tag{2.13}$$

where μ is fixed and fulfills the constraints (2.9), (2.10) and the minimum is sought for $\chi \in BV(\Omega; \{0, 1\})$. When restricting to smooth deformations of $\partial\Omega^I(t)$, the stationarity of F with respect to characteristic functions $\chi \in BV(\Omega; \{0, 1\})$ for fixed μ leads to the Gibbs–Thomson law

$$H + v = f_{II}^*(\mu) - f_I^*(\mu), \tag{2.14}$$

and H is the mean curvature of the interface $\partial\Omega^I(t)$. Below, (2.14) is replaced by the weaker condition (W2) from section 3 that requires less regularity on χ.

The vector m is obtained from μ by the splitting

$$m = \chi m_I + (1 - \chi) m_{II}, \tag{2.15}$$

where the mass vector m_I in the inner domain $\Omega^I(t)$ and the mass vector m_{II} in the outer domain are determined implicitly by

$$\mu = \frac{\partial f_I}{\partial m}(m_I) \quad \text{in } \Omega^I(t), \qquad \mu = \frac{\partial f_{II}}{\partial m}(m_{II}) \quad \text{in } \Omega \setminus \Omega^I(t). \tag{2.16}$$

The free energy densities f_I and f_{II} are strictly convex functions, so (2.16) is meaningful. The decomposition (2.15), (2.16) is essential for the further understanding of this article.

In summary, we are concerned with the free energy minimization (2.13) under the constraints

$$\partial_t(\chi m) = \operatorname{div}(\chi L^I(\mu)\nabla\mu) + \chi r^I(m) \qquad \text{in } \Omega, t > 0, \tag{2.17}$$

$$\partial_t((1-\chi)m) = \operatorname{div}((1-\chi)L^{II}(\mu)\nabla\mu) + (1-\chi)r^{II}(\mu) \qquad \text{in } \Omega, t > 0, \tag{2.18}$$

with r^I, r^{II} given by (2.5), (2.11), where $m(t)$ fulfills (2.15), (2.16), and equipped with the initial conditions

$$\chi(\cdot,0) = \chi_0 \qquad \text{in } \Omega, \tag{2.19}$$

$$\mu(\cdot,0) = \mu_0 \qquad \text{in } \Omega. \tag{2.20}$$

Equation (2.20) also determines $m(t=0)$ with (2.16). Motivated by (2.7) and (2.8), the functions of initial data $\chi_0 \in BV(\Omega)$ and $\mu_0 \in H^{1,2}(\Omega)$ must fulfill the compatibility conditions

$$\mu_{01} = \mu_{02} = 0 \qquad \text{in } \left\{ x \in \Omega \,\middle|\, \operatorname{dist}(x, \overline{\Omega^I(t=0)}) \geq \sqrt{\varepsilon} \right\}, \tag{2.21}$$

$$\mu_{03} = \psi_3, \quad \mu_{04} = \psi_4 \qquad \text{in } \Omega \setminus \overline{\Omega^I(t=0)}, \tag{2.22}$$

where ψ_3, $\psi_4 \in H^{1,2}(\Omega \setminus \overline{\Omega^I(t=0)})$. As the free energy in the outer phase depends on the parameter $\delta > 0$, we demand that, for a constant C independent of δ,

$$\int_{\Omega\setminus\overline{\Omega^I(t=0)}} f_{II}(m(t=0)) \leq C \qquad \text{uniformly in } \delta > 0. \tag{2.23}$$

The system is subject to the boundary conditions (2.7), (2.8), and

$$\mu_i = 0 \quad \text{for } i = 1,2 \qquad \text{on } \partial\Omega \times (0,T), \tag{2.24}$$

$$\mu_i = \varphi_i \quad \text{for } i = 3,4 \qquad \text{on } \partial\Omega \times (0,T). \tag{2.25}$$

For later use we want to introduce some notation. Let

$$\mu^N := (\mu_1, \mu_2), \qquad \mu^D := (\mu_3, \mu_4).$$

The vector m is decomposed in m^N, m^D accordingly.

We define $\hat{f}_{II}^{D,*}(m^N, \mu^D)$ as the partial Legendre–Fenchel transformation of $f_{II}(m)$ with respect to m, that is,

$$\hat{f}_{II}^{D,*}(m^N, \mu^D) := \sup_{m^D} \left\{ \mu^D m^D - f_{II}((m^N, m^D)) \right\}.$$

Due to the form of f_{II}, we may write

$$\hat{f}_{II}^{D,*}(m^N, \mu^D) = f_{II}^{D,*}(\mu^D) - f_{II}^N(m^N),$$

where we introduced the functions

$$f_{II}^N(m^N) := k_B\theta \left(\sum_{i=1}^{2} m_i \ln m_i - \sum_{i=1}^{2} (\ln\delta + 1) m_i \right),$$

$$f_{II}^{D,*}(\mu^D) := \sup_{m^D} \left\{ \mu^D m^D - f_{II}^D(m^D) \right\},$$

$$f_{II}^D(m^D) := k_B\theta \left(\sum_{i=3}^{4} m_i \ln m_i \right).$$

As a prerequisite to the existence theory, we mention the validity of the second law of thermodynamics, which in the isothermal setting reads

$$\frac{d}{dt} F(\chi, \mu) \leq 0.$$

For a direct proof of this inequality see [7]. So it holds that

$$\begin{aligned} \partial_t \int_\Omega \Big[\chi(f_I(m) - m\varphi) + (1-\chi)(f_{II}(m) - m\varphi) \Big] \\ \geq \partial_t \int_\Omega |\nabla\chi| + \partial_t \int_{\partial\Omega^I} v + \int_\Omega \Big(\chi L^I(\mu) + (1-\chi) L^{II}(\mu) \Big) |\nabla\mu|^2 \\ - \int_\Omega (\chi r^I(m) + (1-\chi) r^{II}(\mu))\mu. \end{aligned} \tag{2.26}$$

In (2.26) it holds that

$$- \int_\Omega r\mu := - \int_\Omega (\chi r^I + (1-\chi) r^{II})\mu \geq 0. \tag{2.27}$$

Physically, $-\int_\Omega r\mu$ is the production of entropy due to chemical reactions.

In order to show (2.27), we compute with (2.5)

$$- \sum_{i=1}^{4} r_i^I \mu_i = r_1^I(\mu_2 - \mu_1) = q_I(r_1^I, m_2) + q_I^*(\mu^N, m_2), \tag{2.28}$$

where

$$q_I(r_1^I, m_2) := k_B\theta \left[(k_1 m_2 - r_1^I) \ln \left(1 - \frac{r_1^I}{k_1 m_2} \right) + r_1^I \right],$$

$$q_I^*(\mu^N, m_2) := k_1 m_2 \left[\mu_2 - \mu_1 + k_B\theta \left(\exp\left(\frac{\mu_1 - \mu_2}{k_B\theta} \right) - 1 \right) \right].$$

The function q_I^* denotes, as above, the Legendre–Fenchel transform of q_I. We can check elementarily that the functions q_I and q_I^* are nonnegative, which proves (2.27).

Motivated by (2.11), we define for further use (see (2.26) and (4.3))

$$q_{II}^*(\mu^N) := -\frac{1}{2\gamma}|\mu^N|^2.$$

With (2.28) we have found a general formulation for the reaction terms based on duality. We remark that condition (2.27) can also be derived from an Arrhenius ansatz for the reaction rates; see [7], [9].

Integrating (2.26) with respect to time, we get the a priori estimate

$$\begin{aligned}(2.29)\quad &\sup_{t\in(0,T)}|\nabla\chi(t)| + \int_{\Omega_T}(\chi L^I(\mu) + (1-\chi)L^{II}(\mu))|\nabla\mu|^2 \\ &\quad - \int_{\Omega_T}(\chi r^I(m) + (1-\chi)r^{II}(\mu))\mu + \int_0^T\int_{\partial\Omega^I(t)} v \\ &\leq \int_\Omega \Big(\chi f_I(m) + (1-\chi)f_{II}(m)\Big)(t=T) + \int_\Omega m(0)\varphi - \int_\Omega m(T)\varphi \\ &\quad - \int_\Omega \Big(\chi f_I(m) + (1-\chi)f_{II}(m)\Big)(t=0).\end{aligned}$$

Since $f_{II}(t=0)$ is bounded due to estimate (2.23), we get the boundedness of the right-hand side of (2.29). As L^I, L^{II} are positive definite, we obtain estimates for the functions χ, μ and velocity v. These estimates will be improved later.

3. Weak solutions. We want to briefly specify the class of solutions we are looking for. We call the triple (m, μ, χ) a *weak solution* of the system (2.17)–(2.25) if (2.13) holds, $m = m(\mu)$ is given by (2.15), (2.16), and if (μ, χ) solve the following weak formulations:

(W1) For all $\xi \in C^1([0,T]\times\overline{\Omega};\mathbb{R}^3)$ with $\xi(T) = 0$, it holds that

$$-\int_{\Omega_T}\chi m\partial_t\xi = -\int_{\Omega_T}\chi L^I(\mu)\nabla\mu\nabla\xi + \int_{\Omega_T}\chi r_I(m)\xi + \int_\Omega \chi(t{=}0)m(t{=}0)\xi(t{=}0),$$

$$\begin{aligned}-\int_{\Omega_T}(1-\chi)m\partial_t\xi = &-\int_{\Omega_T}(1-\chi)L^{II}(\mu)\nabla\mu\nabla\xi + \int_{\Omega_T}(1-\chi)r^{II}(\mu)\xi \\ &+ \int_\Omega(1-\chi(t=0))m(t=0)\xi(t=0).\end{aligned}$$

(W2) For all $\zeta \in C^1([0,T]\times\overline{\Omega};\mathbb{R}^3)$ with $\zeta = 0$ on $\partial\Omega\times(0,T)$, it holds that

$$\int_{\Omega_T}\left(\mathrm{div}\zeta - \frac{\nabla\chi}{|\nabla\chi|}\nabla\zeta\frac{\nabla\chi}{|\nabla\chi|}\right)|\nabla\chi| + \int_{\Omega_T} v\zeta\nabla\chi = \int_{\Omega_T}(f_{II}^*(\mu) - f_I^*(\mu))\zeta\nabla\chi.$$

(W3) For all $\xi \in C^1([0,T]\times\overline{\Omega};\mathbb{R})$ with $\xi = 0$ on $\partial\Omega\times(0,T)$ and $\xi(T) = 0$, it holds that

$$\int_{\Omega_T}\chi\partial_t\xi + \int_\Omega \chi_{\Omega_0^I}\xi(0) = -\int_{\Omega_T} v\xi|\nabla\chi|.$$

In [19], further explanations can be found concerning (W2) and (W3).

4. Time-discrete scheme. For fixed $h > 0$, we consider in Ω the time-discrete scheme

$$\chi(t)m(t) - \chi(t-h)m(t-h) = h\,\mathrm{div}[\chi(t-h)L^I(\mu(t-h))\nabla\mu(t)] + \chi(t-h)hr^I(m(t)), \tag{4.1}$$

$$(1-\chi(t))m(t) - (1-\chi(t-h))m(t-h) = h\,\mathrm{div}[(1-\chi(t-h))L^{II}(\mu(t-h))\nabla\mu(t)] + (1-\chi(t-h))hr^{II}(\mu(t)). \tag{4.2}$$

This is an implicit time discretization, except for the coefficients $L^I(\mu)$, $L^{II}(\mu)$, and χ which are treated explicitly. Also we briefly wrote $\mu(t)$ for $\mu(\chi(t))$ and set $\chi(t) := \chi_0$, $m(t) := m(t=0)$ for $-h \le t < 0$.

For given $\chi(t-h)$, $\mu(t-h)$, let the discrete free energy functional be given by

$$\begin{aligned} F_h(\chi(t),\mu(t)) = &\int_\Omega |\nabla\chi(t)| + \int_{\Omega^I(t)\triangle\Omega^I(t-h)} \frac{1}{h}\mathrm{dist}(\cdot,\partial\Omega^I(t-h)) + \int_\Omega m(t-h)\mu(t) \\ &+\int_\Omega \Big[\chi(t)f_I^*(\mu(t)) + (1-\chi(t))f_{II}^*(\mu(t))\Big] \\ &+ h\int_\Omega \Big[\chi(t-h)L^I(\mu(\chi(t-h))) + (1-\chi(t-h))L^{II}(\mu(\chi(t-h)))\Big]|\nabla\mu(t)|^2 \\ &+\int_\Omega \chi(t-h)hq_I^*(\mu^N(t), m_2(t)) - \int_\Omega (1-\chi(t-h))hq_{II}^*(\mu^N(t)). \end{aligned} \tag{4.3}$$

Here we used the notation $A\triangle B := (A\setminus B)\cup(B\setminus A)$ for the symmetrized difference of two sets A and B.

We construct the time-discrete solution $\chi_h \in L^\infty(0,T;\, BV(\Omega;\{0,1\}))$ in the following way. Let $T = hN$. At time $t = 0$, $\Omega^I(t=0)$ and μ_0 are given. For discrete-time values $t = kh$, $k = 1,\ldots,N$, the function $\chi_h(t)$ with $\mu_h(t) = \mu_h(\chi_h(t))$ fulfilling the constraints (4.1), (4.2) iteratively solves the energy minimization problem

$$F_h(\chi_h(t),\mu_h) \to \min \tag{4.4}$$

in the class $BV(\Omega;\{0,1\})$. The discrete mapping m_h is computed from χ_h, μ_h with the help of (2.15), (2.16). We continue χ_h to arbitrary $t \in (0,T)$ by setting

$$\chi_h(t) := \chi_h(kh) \qquad \text{for } t \in ((k-1)h, kh].$$

We introduce the discrete velocity of the interface by

$$v_h(x) := \frac{1}{h}\mathrm{dist}(x,\partial\Omega^I(t-h)). \tag{4.5}$$

The following lemma is a modification of an argument which was used (but not proved) in [19].

LEMMA 4.1 (weak mean curvature equation). *The minimum (χ_h,μ_h) of F_h satisfies the weak mean curvature equation*

$$\begin{aligned} &\int_\Omega \left(\mathrm{div}\zeta - \frac{\nabla\chi_h}{|\nabla\chi_h|}\nabla\zeta\frac{\nabla\chi_h}{|\nabla\chi_h|}\right)|\nabla\chi_h| + \int_\Omega v_h\zeta\nabla\chi_h \\ &\quad= \int_\Omega \Big(f_{II}^*(\mu_h(\chi_h)) - f_I^*(\mu_h(\chi_h))\Big)\zeta\nabla\chi_h \end{aligned}$$

for all $\zeta \in C_0^1(\Omega; \mathbb{R}^3)$.

Proof. We compute the first variation of F_h with respect to deformations of $\Omega^I(t)$; i.e., we compute

$$\frac{d}{ds} F_h(\chi_h \circ \zeta_s, \mu_h(\chi_h \circ \zeta_s))\Big|_{s=0}$$

for all $\zeta \in C_0^1(\Omega; \mathbb{R}^3)$ with $\zeta_0(x) = x$, $\partial_s \zeta_s(x) = \zeta(\zeta_s(x))$. With $\chi_h := \chi_h(t)$ we obtain

$$\begin{aligned}
&\int_\Omega \left(\mathrm{div}\zeta - \frac{\nabla \chi_h}{|\nabla \chi_h|} \nabla \zeta \frac{\nabla \chi_h}{|\nabla \chi_h|} \right) |\nabla \chi_h| + \int_\Omega v_h \zeta \nabla \chi_h \\
&+ \int_\Omega \Big(f_I^*(\mu_h(\chi_h)) - f_{II}^*(\mu_h(\chi_h)) \Big) \zeta \nabla \chi_h \\
&= - \int_\Omega m_h \mu_\zeta + \int_\Omega m_h(t-h) \mu_\zeta \\
&+ h \int_\Omega \mathrm{div} \Big[\Big(\chi_h(t-h) L^I(\mu_h(\chi_h(t-h))) + (1-\chi_h(t-h)) L^{II}(\mu_h(\chi_h(t-h))) \Big) \nabla \mu_h(\chi_h) \Big] \mu_\zeta \\
&+ h \int_\Omega \Big(\chi_h(t-h) r^I(m_h) + (1-\chi_h(t-h)) r^{II}(\mu_h(\chi_h)) \Big) \mu_\zeta,
\end{aligned}$$

where $\mu_\zeta := \mu_h(\chi_h(\zeta(\zeta_s)))$. As the right-hand side is zero, the lemma is proved. ∎

5. A priori estimates. In this section we show a priori estimates for the time-discrete solution. Together with the compactness results, they are the main ingredients for the existence proof.

Generically, we denote by C various constants that may change from estimate to estimate.

LEMMA 5.1 (a priori estimates for the time-discrete solution).

(i) *The following a priori estimate holds*:

(5.1)
$$\begin{aligned}
&\sup_{t \in (0,T)} \int_\Omega |\nabla \chi_h(t)| + \frac{1}{h^2} \int_0^T \int_{\Omega^I(t) \triangle \Omega^I(t-h)} \mathrm{dist}(\cdot, \partial\Omega^I(t-h)) \\
&+ \frac{1}{2\gamma} \int_{\Omega_T} (1 - \chi_h(t-h)) |\mu_h^N|^2 \\
&+ \int_{\Omega_T} \Big(\chi_h(t-h) L^I(\mu_h(\chi_h(t-h))) + (1-\chi_h(t-h)) L^{II}(\mu_h(\chi_h(t-h))) \Big) |\nabla \mu_h(\chi_h)|^2 \\
&\le \int_\Omega \Big(\chi_h f_I(m_h) + (1-\chi_h) f_{II}(m_h) \Big)(t = T) \\
&- \int_\Omega \Big(\chi_h f_I(m_h) + (1-\chi_h) f_{II}(m_h) \Big)(t = 0).
\end{aligned}$$

(ii) *For the chemical potential and the time derivative of* m, *it holds that*

$$\int_{\Omega_T} \chi_h(t-h) |\nabla \mu_h(t)|^2 \le C, \tag{5.2}$$

$$\int_{\Omega_T}(1-\chi_h(t-h))|\nabla\mu_h^N(t)|^2 \le C\varepsilon^{-1}, \tag{5.3}$$

$$\int_{\Omega_T}(1-\chi_h(t-h))|\nabla\mu_h^D(t)|^2 \le C\varepsilon, \tag{5.4}$$

$$\int_{\Omega_T}(1-\chi_h(t-h))|\mu_h^N(t)|^2 \le C\gamma, \tag{5.5}$$

$$\int_{\Omega_T}\|\chi_h\partial_t^h m_h\|^2_{H^{-1}(\Omega)} \le C. \tag{5.6}$$

Proof. (i) Due to the minimality of (χ_h,μ_h) with respect to F_h, we have

$$F_h(\chi_h(t),\mu_h(t)) \le F_h(\tilde\chi,\mu_h(\tilde\chi)) \qquad \text{for all } \tilde\chi\in BV(\Omega;\{0,1\}). \tag{5.7}$$

When choosing $\tilde\chi := \chi_h(t-h)$ in (5.7), we find

$$\int_\Omega|\nabla\chi_h(t)| + \int_{\Omega^I(t)\triangle\Omega^I(t-h)}\frac{1}{h}\mathrm{dist}(\cdot,\partial\Omega(t-h)) + \int_\Omega m_h(t-h)\mu_h(\chi_h(t))$$

$$-\int_\Omega\Big[\chi_h f_I(m_h(t)) + (1-\chi_h(t))f_{II}(m_h(t)) - m_h(t)\mu_h(\chi_h(t))\Big]$$

$$+h\int_\Omega\Big[\chi_h(t-h)L^I(\mu_h(\chi_h(t-h)))+(1-\chi_h(t-h))L^{II}(\mu_h(\chi_h(t-h)))\Big]|\nabla\mu_h(\chi_h(t))|^2$$

$$+h\int_\Omega\chi_h(t-h)q_I^*(\mu_h^N(\chi_h(t)),m_{h,2}(t)) - h\int_\Omega(1-\chi_h(t-h))q_{II}^*(\mu_h^N(\chi_h(t)))$$

$$\le \int_\Omega|\nabla\chi_h(t-h)| - \int_\Omega\Big[\chi_h(t-h)f_I(m_h(t-h)) + (1-\chi_h(t-h))f_{II}(m_h(t-h))\Big]$$

$$+h\int_\Omega\Big[\chi_h(t-h)L^I(\mu_h(\chi_h(t-h)))+(1-\chi_h(t-h))L^{II}(\mu_h(\chi_h(t-h)))\Big]|\nabla\mu_h(\chi_h(t-h))|^2$$

$$+h\int_\Omega\chi_h(t-h)q_I^*(\mu_h^N(\chi_h(t-h)),m_{h,2}(t-h)) - h\int_\Omega(1-\chi_h(t-h))q_{II}^*(\mu_h^N(\chi_h(t-h))).$$

We rewrite this and first observe that q_I, $q_I^*\ge 0$, $q_{II}^*\le 0$. Additionally,

$$-\int_\Omega\chi_h(t)f_I(m_h(t)) - \chi_h(t-h)f_I(m_h(t-h))$$

$$-\int_\Omega(1-\chi_h(t))f_{II}(m_h(t)) - (1-\chi_h(t-h))f_{II}(m_h(t-h))$$

$$= -\int_\Omega\Big[\chi_h(t)\Big(f_I(m_h(t))-f_I(m_h(t-h))\Big) + (1-\chi_h(t))\Big(f_{II}(m_h(t))-f_{II}(m_h(t-h))\Big)\Big]$$

$$-\int_\Omega h\partial_t^h\chi_h(t)\Big(f_I(m_h(t-h)) - f_{II}(m_h(t-h))\Big).$$

The second integral on the right is nonnegative due to (4.4). The first integral on the right, from the definition of the chemical potential μ, can be estimated from above by

$$-\int_\Omega \mu_h(\chi_h(t))m_h(t-h).$$

With this result, $F_h(\chi_h(t),\mu_h(t)) \le F_h(\chi_h(t-h),\mu_h(\chi_h(t-h)))$ finally becomes

(5.8)

$$\begin{aligned}
&\partial_t^h \int_\Omega |\nabla\chi_h| + \frac{1}{h^2}\int_{\Omega^I(t)\triangle\Omega^I(t-h)} \operatorname{dist}(\cdot,\partial\Omega(t-h)) + \frac{1}{2\gamma}\int_\Omega (1-\chi_h(t-h))|\mu_h^N|^2 \\
&\quad + \int_\Omega \Big(\chi_h(t-h)L^I(\mu_h(\chi_h(t-h))) + (1-\chi_h(t-h))L^{II}(\mu_h(\chi_h(t-h)))\Big)|\nabla\mu_h(\chi_h)|^2 \\
&\le \partial_t^h\left(\int_\Omega \chi_h f_I(m_h) + \int_\Omega (1-\chi_h)f_{II}(m_h)\right).
\end{aligned}$$

Integration in time proves (i).

(ii) This follows directly from (i) and (4.1), (4.2). ∎

6. A density lemma. Now we show a density lemma that establishes a strong geometric property of the sets $\Omega^I(t)$.

LEMMA 6.1. *For any $\mu \in H^{1,2}(\Omega;\mathbb{R}^4)$, it holds that*

$$\|f_{II}^*(\mu) - f_I^*(\mu)\|_{L^\infty(\Omega_T)} \le \|f_I\|_{L^\infty((0,T)\times\mathbb{R}^4)} + \|f_{II}\|_{L^\infty((0,T)\times\mathbb{R}^4)}.$$

Proof. Directly from the definitions of f_I^* and f_{II}^*, we see that

$$f_{II}^*(\mu) - f_I^*(\mu) = \sup_{\tilde m}\{\tilde m\cdot\mu - f_{II}(\tilde m)\} - \sup_{\tilde m}\{\tilde m\cdot\mu - f_I(\tilde m)\} \le f_I(m) - f_{II}(m).$$

The analogous estimate of $f_I^*(\mu) - f_{II}^*(\mu)$ gives

$$\|f_{II}^*(\mu) - f_I^*(\mu)\|_{L^\infty} \le \|f_I\|_{L^\infty} + \|f_{II}\|_{L^\infty},$$

which proves the lemma. ∎

We recall the following results from geometric measure theory. For a proof see, for instance, [29], [13].

THEOREM 6.2 (trace operator in BV). *Let $\Omega \subset \mathbb{R}^n$ be an open bounded set and let $\partial\Omega$ be Lipschitz. Then there exists a trace operator* $\operatorname{tr} : BV(\Omega) \to L^1(\partial\Omega, d\mathcal{H}^{n-1})$ *such that for given $f \in BV(\Omega)$,*

$$\int_\Omega f\operatorname{div}\varphi = -\int_\Omega \varphi\cdot\nabla f + \int_{\partial\Omega} \operatorname{tr} f(\varphi\cdot\vec n)d\mathcal{H}^{n-1} \qquad \text{for all } \varphi \in C^1(\mathbb{R}^n,\mathbb{R}^n),$$

where $\vec n$ is the unit outer normal to $\partial\Omega$. Furthermore,

$$\lim_{\varrho\searrow 0}\left(\varrho^{-n}\int_{B_\varrho(x)\cap\Omega} |f(y) - \operatorname{tr} f(x)|dy\right) = 0 \qquad \text{for } d\mathcal{H}^{n-1} - \text{almost all } x \in \partial\Omega.$$

If $E \subset\subset \Omega$ is an open set with a Lipschitz boundary, then $f_{|E} \in BV(E)$ and $f_{|\Omega\setminus\overline{E}} \in BV(\Omega\setminus\overline{E})$ have traces on ∂E. In what follows, we write $f_E^- := \operatorname{tr}(f_{|E})$ and $f_E^+ := \operatorname{tr}(f_{|\Omega\setminus\overline{E}})$. We mention for later use the equality

$$\int_{\partial E} |f_E^- - f_E^+|d\mathcal{H}^{n-1} = \int_{\partial E} |\nabla f|d\mathcal{H}^{n-1}. \tag{6.1}$$

Finally, by χ_E we denote the characteristic function of a set E.

THEOREM 6.3 (isoperimetric inequalities). *Let $\Omega \subset \mathbb{R}^n$ be a bounded set with $\chi_\Omega \in BV(\mathbb{R}^n)$. Then it holds that*

$$\gamma_n \left(\int_{\mathbb{R}^n} \chi_\Omega \right)^{\frac{n-1}{n}} \leq \int_{\mathbb{R}^n} |\nabla \chi_\Omega|, \tag{6.2}$$

$$\min \left\{ \left(\int_{B_\varrho(x)} \chi_\Omega \right)^{\frac{n}{n-1}}, \left(\int_{B_\varrho(x)} \chi_\Omega^c \right)^{\frac{n}{n-1}} \right\} \leq C(n) \int_{B_\varrho(x)} |\nabla \chi_\Omega| \quad \textit{for all } B_\varrho(x) \subset \mathbb{R}^n, \tag{6.3}$$

where $\gamma_n := n\omega_n^{\frac{1}{n}}$ and $\omega_n := \mathcal{L}^n(B_1(0))$ are dimensional constants.

Now we show the following geometric property of the sets $\Omega^I(t)$.

LEMMA 6.4 (density lemma). *Let $\kappa_1 := \frac{1}{4^3}$ and let $\chi_h(t)$ be a minimizer of the functional $F_h(\chi_h(t), \mu_h(\chi_h(t)))$. Then for all $x \in \partial\Omega^I(t)$ and for all $\varrho > 0$ which satisfy*

$$\varrho \leq \frac{\gamma_3}{2\omega_3^{\frac{1}{3}} (\|f_I\|_{L^\infty} + \|f_{II}\|_{L^\infty} + h^{-1} \|\mathrm{dist}(\cdot, \partial\Omega^I(t-h))\|_{L^\infty(\Omega^I(t) \triangle \Omega^I(t-h))})} \tag{6.4}$$

it holds that

$$\kappa_1 \leq \omega_3^{-1} \varrho^{-3} \int_{B_\varrho(x)} \chi_h(t) \leq 1 - \kappa_1. \tag{6.5}$$

Proof. (i) Estimate from below.

Let $\varrho > 0$ satisfy (6.4) and $x \in \partial\Omega^I(t)$ be given. Recall that $\chi_{\Omega^I(t)} = \chi_h(t)$ and recall the notions χ_h^+, χ_h^- introduced after Theorem 6.2. Consider generally $\Omega \subset \mathbb{R}^n$.

First, we show that $\Omega^I(t) \cap B_\varrho(x)$ consists of only one radial component, i.e.,

$$\int_{\partial B_r(x)} \chi_h^- d\mathcal{H}^{n-1} + \int_{\partial B_r(x)} \chi_h^+ d\mathcal{H}^{n-1} > 0 \qquad \text{for all } 0 < r < \varrho. \tag{6.6}$$

Assume (6.6) does not hold for a radius $r \in (0, \varrho)$. We use (5.7) with $\tilde{\chi} := \chi_{\Omega^I(t) \setminus B_r(x)}$ and find

$$\begin{aligned} \int_\Omega |\nabla \chi_h(t)| - \int_\Omega |\nabla \tilde{\chi}| &\leq \int_{B_r(x)} \frac{1}{h} \|\mathrm{dist}(\cdot, \partial\Omega^I(t-h))\|_{L^\infty(\Omega^I \triangle \Omega^I(t-h))} \chi_h(t) \\ &\quad + \int_{B_r(x)} \Big(f_{II}^*(\mu_h(\chi_h(t))) - f_I^*(\mu_h(\chi_h(t))) \Big) \chi_h(t) \\ &\leq \int_{B_r(x)} C_1(h) \chi_h(t), \end{aligned} \tag{6.7}$$

where, led by Lemma 6.1, we introduced the constant

$$C_1(h) := \|f_I\|_{L^\infty} + \|f_{II}\|_{L^\infty} + h^{-1} \|\mathrm{dist}(\cdot, \partial\Omega^I(t-h))\|_{L^\infty(\Omega^I(t) \triangle \Omega^I(t-h))}.$$

Now we use the equalities

$$\int_{\mathbb{R}^n} |\nabla \chi_{\Omega^I(t)\cap B_r(x)}| = \int_{B_r(x)} |\nabla \chi_{\Omega^I(t)}| + \int_{\partial B_r(x)} \chi^-_{\Omega^I(t)} d\mathcal{H}^{n-1},$$

$$\int_{\mathbb{R}^n} |\nabla \chi_{\Omega^I(t)\setminus B_r(x)}| = \int_{\mathbb{R}^n\setminus B_r(x)} |\nabla \chi_{\Omega^I(t)}| + \int_{\partial B_r(x)} \chi^+_{\Omega^I(t)} d\mathcal{H}^{n-1}$$

and the isoperimetric inequality (6.2) to conclude that

$$\begin{aligned}
&\int_{B_r(x)} C_1(h)\chi_{\Omega^I(t)} \\
&\quad \geq \int_{\mathbb{R}^n} |\nabla \chi_{\Omega^I(t)}| - \int_{\mathbb{R}^n\setminus B_r(x)} |\nabla \chi_{\Omega^I(t)}| - \int_{\partial B_r(x)} \chi^+_{\Omega^I(t)} d\mathcal{H}^{n-1} \\
&\quad = \int_{B_r(x)} |\nabla \chi_{\Omega^I(t)}| - \int_{\partial B_r(x)} \chi^+_{\Omega^I(t)} d\mathcal{H}^{n-1} \\
&\quad = \int_{\mathbb{R}^n} |\nabla \chi_{\Omega^I(t)\cap B_r(x)}| - \int_{\partial B_r(x)} \chi^+_{\Omega^I(t)} d\mathcal{H}^{n-1} - \int_{\partial B_r(x)} \chi^-_{\Omega^I(t)} d\mathcal{H}^{n-1} \\
&\quad \geq \gamma_n \left(\int_{B_r(x)} \chi_{\Omega^I(t)}\right)^{\frac{n-1}{n}} - \int_{\partial B_r(x)} \chi^+_{\Omega^I(t)} d\mathcal{H}^{n-1} - \int_{\partial B_r(x)} \chi^-_{\Omega^I(t)} d\mathcal{H}^{n-1}.
\end{aligned}$$

Since we assumed that (6.6) is false, the last two boundary integrals on the right can be estimated from below by zero, and we end up with

$$\gamma_n \leq C_1(h) \left(\int_{B_r(x)} \chi_{\Omega^I(t)}\right)^{\frac{1}{n}} \leq C_1(h)\omega_n^{\frac{1}{n}}\varrho.$$

This is a contradiction to (6.4), so (6.6) is proved.

A similar technique is now used for proving the bound from below in (6.5). This time, we use in (5.7) the comparison function

$$\tilde{\chi} := \chi_{\Omega^I(t)\setminus(B_{\frac{\varrho}{2}+\sigma}(x)\setminus B_{\frac{\varrho}{2}-\sigma}(x))}$$

with $0 < \sigma < \frac{\varrho}{2}$. Let

$$V(\sigma) := \mathcal{L}^n\Big(\Omega^I(t) \cap (B_{\frac{\varrho}{2}+\sigma}(x) \setminus B_{\frac{\varrho}{2}-\sigma}(x))\Big).$$

With this choice of $\tilde{\chi}$, (5.7) yields

$$\int_\Omega |\nabla \chi_{\Omega^I(t)}| - \int_\Omega |\nabla \tilde{\chi}| \leq C_1(h)V(\sigma). \tag{6.8}$$

Similar to the above, we have the identities

$$\int_{\mathbb{R}^n} |\nabla \chi_{\Omega^I(t)\cap(B_{\frac{\varrho}{2}+\sigma}(x)\setminus B_{\frac{\varrho}{2}-\sigma}(x))}|$$
$$= \int_{B_{\frac{\varrho}{2}+\sigma}(x)\setminus B_{\frac{\varrho}{2}-\sigma}(x)} |\nabla \chi_{\Omega^I(t)}| + \int_{\partial B_{\frac{\varrho}{2}+\sigma}(x)} \chi^-_{\Omega^I(t)} d\mathcal{H}^{n-1}$$
$$+ \int_{\partial B_{\frac{\varrho}{2}-\sigma}(x)} \chi^+_{\Omega^I(t)} d\mathcal{H}^{n-1},$$

$$\int_{\mathbb{R}^n} |\nabla \chi_{\Omega^I(t)\setminus(B_{\frac{\varrho}{2}+\sigma}(x)\setminus B_{\frac{\varrho}{2}-\sigma}(x))}|$$
$$= \int_{\mathbb{R}^n\setminus(B_{\frac{\varrho}{2}+\sigma}(x)\setminus B_{\frac{\varrho}{2}-\sigma}(x))} |\nabla \chi_{\Omega^I(t)}| + \int_{\partial B_{\frac{\varrho}{2}+\sigma}(x)} \chi^+_{\Omega^I(t)} d\mathcal{H}^{n-1}$$
$$+ \int_{\partial B_{\frac{\varrho}{2}-\sigma}(x)} \chi^-_{\Omega^I(t)} d\mathcal{H}^{n-1}.$$

With these two equalities and (6.8), we compute with (6.2)

$$C_1(h)V(\sigma) \geq \gamma_n V(\sigma)^{\frac{n-1}{n}} - \int_{\partial B_{\frac{\varrho}{2}+\sigma}(x)} \chi^-_{\Omega^I(t)} d\mathcal{H}^{n-1} - \int_{\partial B_{\frac{\varrho}{2}-\sigma}(x)} \chi^+_{\Omega^I(t)} d\mathcal{H}^{n-1}$$
$$- \int_{\partial B_{\frac{\varrho}{2}+\sigma}(x)} \chi^+_{\Omega^I(t)} d\mathcal{H}^{n-1} - \int_{\partial B_{\frac{\varrho}{2}-\sigma}(x)} \chi^-_{\Omega^I(t)} d\mathcal{H}^{n-1} \tag{6.9}$$
$$= \gamma_n V(\sigma)^{\frac{n-1}{n}} - 2\frac{d}{d\sigma}V(\sigma). \tag{6.10}$$

The last equality holds for almost all $0 < \sigma < \frac{\varrho}{2}$.

From the definition of $V(\sigma)$ and the upper bound (6.4) on ϱ, we directly find

$$V(\sigma) \leq \omega_n \varrho^n \leq \frac{\gamma_n^n}{((n-1)C_1(h))^n},$$

implying at once

$$C_1(h) \leq \frac{\gamma_n}{(n-1)V(\sigma)^{\frac{1}{n}}}.$$

Using the last inequality in (6.10) finally shows the crucial estimate

$$\frac{d}{d\sigma}V(\sigma) \geq \frac{\gamma_n}{2}V(\sigma)^{\frac{n-1}{n}} - \frac{\gamma_n}{2(n-1)}V(\sigma)^{\frac{n-1}{n}} = \frac{\gamma_n}{2}\frac{n-2}{n-1}V(\sigma)^{\frac{n-1}{n}}. \tag{6.11}$$

We integrate (6.11) from $0 < \sigma < \frac{\varrho}{2}$. We see directly

$$\int_0^{\frac{\varrho}{2}} \frac{d}{d\sigma}V(\sigma)\,d\sigma = V(\varrho/2) - V(0) = \int_{B_\varrho(x)} \chi_h(t).$$

For $n = 3$ the integration of (6.11) therefore yields

$$\int_{B_\varrho(x)} \chi_h(t) \geq \frac{\omega_3}{4^3}\varrho^3 = \kappa_1\omega_3\varrho^3,$$

which proves the lower bound in (6.5).

(ii) The upper bound in (6.5) can be derived in the same way as in (i) by replacing $\Omega^I(t)$ with its complement. Obviously,

$$\int_\Omega |\nabla\chi_{\Omega^I(t)}| = \int_\Omega |\nabla\chi_{\mathbb{R}^n\setminus\Omega^I(t)}|.$$

Now we consider minimizers $\tilde{\chi}(t)$ of $\tilde{F}_h(\tilde{\chi}, \tilde{\mu}(\tilde{\chi}))$, where the functional $\tilde{F}_h$ is defined as F_h in (4.3), but with χ replaced by $1-\chi$ and $1-\chi$ replaced by χ.

Then we redo the proof of (i) for the functional $\tilde{F}_h$. We obtain

$$\omega_n^{-1}\varrho^{-n}\int_{B_\varrho(x)} \chi_h(t) \leq 1-\kappa_1.$$

This shows the bound from above in (6.5) and ends the proof. $\square$

COROLLARY 6.5. *Let $\chi_h := \chi_{\Omega^I(t)}$ be a minimizer of the functional $F_h(\chi, \mu(\chi))$ and let $\kappa_2 := \frac{1}{2^3}$. Then for any $\varrho > 0$ and any pair (x, y) with $x \in \partial\Omega^I(t)$, $y \in B_\varrho(x)$, and*

$$\|f_I\|_{L^\infty} + \|f_{II}\|_{L^\infty} \leq \frac{1}{h}\mathrm{dist}(y, \partial\Omega^I(t-h)), \tag{6.12}$$

it holds that

$$\kappa_2 \leq \omega_3^{-1}\varrho^{-3}\int_{B_\varrho(x)} \chi_h(t) \qquad \text{if } x \in \overline{\Omega^I(t)}\setminus\Omega^I(t-h),$$

$$\omega_3^{-1}\varrho^{-3}\int_{B_\varrho(x)} \chi_h(t) \leq 1-\kappa_2 \qquad \text{if } x \in \Omega^I(t-h)\setminus\overline{\Omega^I(t)}.$$

The assertion remains valid if the assumption $x \in \partial\Omega^I(t)$ is replaced by $x \in \Omega$.

Proof. The proof is again similar to the proof of Lemma 6.4. Let $\varrho > 0$ satisfy (6.12). First, we consider the case $x \in \overline{\Omega^I(t)}\setminus\Omega^I(t-h)$ and show that (6.6) holds. First consider generally $\Omega \subset \mathbb{R}^n$. We exploit (5.7) with $\tilde{\chi} := \chi_{\overline{\Omega^I(t)}\setminus B_\varrho(x)}$. Assuming that (6.6) is violated for a radius $r \in (0, \varrho)$, we obtain, analogous to (6.7),

$$\int_\Omega |\nabla\chi_{\Omega^I(t)}| - \int_\Omega |\nabla\tilde{\chi}| \leq \int_{B_r(x)} C_2(h, y)\chi_{\Omega^I(t)}dy \leq 0, \tag{6.13}$$

where we have, according to (6.12),

$$C_2(h, y) := \|f_I\|_{L^\infty} + \|f_{II}\|_{L^\infty} - \frac{1}{h}\mathrm{dist}(y, \partial\Omega^I(t-h)) \leq 0.$$

From (6.13) and (6.2) we conclude that

$$\gamma_n\left(\int_{B_\varrho(x)} \chi_{\Omega^I(t)}\right)^{\frac{n-1}{n}} \leq 0,$$

which is a contradiction.

The analogue to (6.9) is

$$\gamma_n V(\sigma)^{\frac{n-1}{n}} - \int_{\partial B_{\frac{\varrho}{2}+\sigma}(x)} \left(\chi^-_{\Omega^I(t)} + \chi^+_{\Omega^I(t)}\right) d\mathcal{H}^{n-1}$$

$$- \int_{\partial B_{\frac{\varrho}{2}-\sigma}(x)} \left(\chi^-_{\Omega^I(t)} + \chi^+_{\Omega^I(t)}\right) d\mathcal{H}^{n-1} \leq 0,$$

and from that we can proceed as in the proof of Lemma 6.4.

The other case, $x \in \Omega^I(t-h) \setminus \overline{\Omega^I(t)}$, is treated similarly by considering the functional $\tilde{F}$ on the complementary set $(\Omega^I(t))^C$. ∎

Corollary 6.6. *Under the assumptions of Corollary* 6.5 *there exists a constant* C *independent of* h *such that for all* $\varrho > 0$,

$$\int_{B_\varrho(x)} |\nabla \chi_h| \leq C\varrho^2. \tag{6.14}$$

Proof. The proof is analogous to Corollary 6.5. Let $x \in \overline{\Omega^I(t)} \setminus \Omega^I(t-h)$. We use (5.7) with $\tilde{\chi} := \chi_{\overline{\Omega^I(t)} \setminus \Omega(t-h)}$. With condition (6.12) we find

$$\int_{B_\varrho(x)} |\nabla \chi_{\Omega^I(t)}| \leq \int_{\partial B_\varrho(x)} \chi^+_{\Omega^I(t)} d\mathcal{H}^2,$$

and therefore

$$\int_{B_\varrho(x)} |\nabla \chi_{\Omega^I(t)}| \leq \mathcal{H}^2(\partial B_\varrho(x)) \leq C\varrho^2.$$

The other case, $x \in \Omega^I(t-h) \setminus \Omega^I(t)$, can be proved in the same way. ∎

The model (2.17)–(2.25) was formulated for small positive parameters γ, δ, and ε. As will become clear in what follows, the existence theory remains valid if $\gamma = \gamma(h)$, $\delta = \delta(h)$, and $\varepsilon = \varepsilon(h)$ are functions that tend to 0 as $h \searrow 0$. The convergence of the discrete solution to the limit problem can be ensured, provided the following four conditions are met.

The functions $\delta(h) > 0$ and $\varepsilon(h) > 0$ fulfill

(A1) $\lim_{h\searrow 0} h^{\frac{1}{2}} \ln(\delta(h)) = 0$,

(A2) $\lim_{h\searrow 0} (\delta(h)\varepsilon^{-1}(h)) = 0$,

(A3) $\lim_{h\searrow 0} (h^{\frac{1}{4}}\varepsilon^{-\frac{3}{4}}(h)) = 0$,

(A4) $\lim_{h\searrow 0} (h^{\frac{1}{3}}\varepsilon^{-1}) = 0$.

Now we can formulate an estimate on the discrete velocity of the interface.

Lemma 6.7 (L^∞-bound on the discrete velocity). *For any* $h > 0$, *there exists a positive constant* C *independent of* h *such that*

$$\left\| \frac{1}{h} \mathrm{dist}(\cdot, \partial\Omega(t-h)) \right\|_{L^\infty(\Omega^I(t) \triangle \Omega^I(t-h))} < Ch^{-\frac{1}{2}}$$

uniformly in time.

Proof. Without loss of generality, we restrict our attention to the case $x \in \overline{\Omega^I(t)} \setminus \Omega^I(t-h)$. The other case, $x \in \Omega^I(t-h) \setminus \Omega^I(t)$, is treated in the same way.

The proof is done by contradiction. Assume that there exists an $x \in \partial\Omega^I(t)$ such that

$$\frac{1}{h}\operatorname{dist}(x, \partial\Omega^I(t-h)) \geq l h^{-\frac{1}{2}} \qquad \text{for all } l \in \mathbb{N}. \tag{6.15}$$

We use again (5.7) with $\tilde{\chi} := \chi_{\Omega^I(t)\setminus B_{\frac{l}{2}\sqrt{h}}(x)}$ to find

$$\begin{aligned}\int_\Omega |\nabla\tilde{\chi}| - \int_\Omega |\nabla\chi_{\Omega^I(t)}| \geq \int_{\Omega^I(t)\cap B_{\frac{l}{2}\sqrt{h}}(x)} \frac{1}{h}\operatorname{dist}(\cdot, \partial\Omega^I(t-h))\\ - \int_{B_{\frac{l}{2}\sqrt{h}}(x)} \Big(\|f_I\|_{L^\infty} + \|f_{II}\|_{L^\infty}\Big)\chi_{\Omega^I(t)}.\end{aligned} \tag{6.16}$$

The left-hand side of (6.16) can be estimated from above as follows:

$$\begin{aligned}&\int_\Omega |\nabla\chi_{\Omega^I(t)\setminus B_{\frac{l}{2}\sqrt{h}}(x)}| - \int_\Omega |\nabla\chi_{\Omega^I(t)}|\\ &= - \int_{B_{\frac{l}{2}\sqrt{h}}(x)} |\nabla\chi_{\Omega^I(t)}| + \int_{\partial B_{\frac{l}{2}\sqrt{h}}(x)} \chi^+_{\Omega^I(t)} d\mathcal{H}^{n-1}\\ &\leq \mathcal{H}^{n-1}(\partial B_{\frac{l}{2}\sqrt{h}}(x)) = n\left(\frac{l}{2}\sqrt{h}\right)^{n-1}\omega_n.\end{aligned}$$

By Assumption (6.15), the last estimate applied to (6.16) yields

$$\frac{l}{2}h^{-\frac{1}{2}}\int_{B_{\frac{l}{2}\sqrt{h}}(x)} \chi_{\Omega^I(t)} \leq n\left(\frac{l}{2}\sqrt{h}\right)^{n-1}\omega_n + \Big(\|f_I\|_{L^\infty} + \|f_{II}\|_{L^\infty}\Big)\left(\frac{l}{2}\sqrt{h}\right)^n.$$

From assumption (A1), it follows that condition (6.12) is fulfilled. For $n = 3$, we apply Corollary 6.5 and find

$$\frac{l}{2}h^{-\frac{1}{2}}\kappa_2\left(\frac{l}{2}\sqrt{h}\right)^3\omega_3 \leq 3\left(\frac{l}{2}\sqrt{h}\right)^2\omega_3 + \Big(\|f_I\|_{L^\infty} + \|f_{II}\|_{L^\infty}\Big)\left(\frac{l}{2}\sqrt{h}\right)^3.$$

This is a contradiction for sufficiently large l. ∎

LEMMA 6.8 (improved density lemma). *Let $\chi_h(t)$ be a minimizer of the functional $F_h(\chi_h, \mu_h(\chi_h))$. Then there exists a constant C independent of h such that for all $\varrho > 0$ with $\varrho \leq C\sqrt{h}$,*

$$\kappa_1 \leq \omega_3^{-1}\varrho^{-3}\int_{B_\varrho(x)} \chi_h(t) \leq 1 - \kappa_1 \qquad \textit{for all } x \in \partial\Omega^I(t). \tag{6.17}$$

Proof. This follows directly from Lemmas 6.4 and 6.7. ∎

7. Compactness properties of the discrete solution. We proceed with compactness properties of the time-discrete solution χ_h.

LEMMA 7.1 (compactness in space). *For every unit vector $e \in \mathbb{R}^3$, it holds uniformly in h that*

$$\lim_{s\searrow 0}\int_{\Omega_T} |\chi_h(x+se, t) - \chi_h(x,t)| = 0. \tag{7.1}$$

Proof. The claim follows from the a priori estimate (5.1) after observing that

$$\int_\Omega |\chi(\cdot + se) - \chi| \le s \int_\Omega |\nabla \chi|$$

for arbitrary functions $\chi \in BV(\Omega)$. ∎

LEMMA 7.2 (compactness of χ_h in time I). *There exists a constant C such that the discrete solution χ_h satisfies*

$$\int_0^{T-\tau} \int_\Omega |\chi_h(x, t+\tau) - \chi_h(x,t)| < c\tau \qquad \textit{for any } \tau > 0.$$

Proof. First, we consider the case $\tau = kh$ for $k \in \mathbb{N}$. Writing the integrand as a telescopic sum, we see that

$$\begin{aligned}
&\int_0^{T-\tau} \int_\Omega |\chi_h(x,t+\tau) - \chi_h(x,t)| \\
&\quad \le \int_0^{T-\tau} \int_\Omega \sum_{l=1}^k |\chi_h(x, t+lh) - \chi_h(x, t+(l-1)h)| \\
&\quad = \int_0^{T-\tau} \int_\Omega \sum_{l=1}^k h |\partial_t^{-h} \chi_h(x, t+lh)| \le \tau \int_0^T \int_\Omega |\partial_t^{-h} \chi_h(x,t)|.
\end{aligned}$$

Consequently, the proof is finished if we can show that

$$\int_{\Omega_T} |\partial_t^{-h} \chi_h| = \sum_{k=1}^N |\Omega^I(kh) \triangle \Omega^I((k-1)h)| < C \tag{7.2}$$

for a constant C which is independent of h. In order to prove (7.2), we notice that

$$\begin{aligned}
\Omega^I(t) \triangle \Omega^I(t-h) \subset &\Big\{ x \in \Omega^I(t) \triangle \Omega^I(t-h) \,\Big|\, \operatorname{dist}(x, \partial\Omega(t-h)) > c_1 h \Big\} \\
&\cup \Big\{ x \in \Omega^I(t) \triangle \Omega^I(t-h) \,\Big|\, \operatorname{dist}(x, \partial\Omega(t-h)) \le c_1 h \Big\} \\
&=: E_1(t) \cup E_2(t),
\end{aligned}$$

where c_1 is a small positive constant. It remains to shows that the sets $E_1(t)$, $E_2(t)$ for $t = lh$ and $1 \le l \le N$ are bounded. For $E_1(t)$ we have, as a consequence of the free energy inequality (2.26),

$$\begin{aligned}
|E_1(t)| &< \frac{1}{2c_1} \int_{\Omega^I(t) \triangle \Omega^I(t-h)} \operatorname{dist}(\cdot, \Omega^I(t-h)) \\
&\le h \partial_t^h \left[\int_\Omega \Big(\chi_h f_I(m_h) + (1-\chi_h) f_{II}(m_h) \Big) \right](t).
\end{aligned}$$

Discrete integration in time gives

$$\begin{aligned}
\sum_{l=1}^N |E_1(lh)| \le &\int_\Omega \Big(\chi_h f_I(m_h) + (1-\chi_h) f_{II}(m_h) \Big)(t = T) \\
&- \int_\Omega \Big(\chi_h f_I(m_h) + (1-\chi_h) f_{II}(m_h) \Big)(t = 0) \le C.
\end{aligned}$$

In order to show that $E_2(t)$ is bounded, we cover $E_2(t)$ with a family $\mathcal{B}$ of balls with radius $2c_1h$ and center points $x \in \partial\Omega^I(t-h)$. The Besicovitch covering lemma ensures that the covering can be chosen such that any point in $E_2(t)$ is contained in at most M different balls in $\mathcal{B}$, where $M \in \mathbb{N}$ is a fixed number.

With the help of the density lemma, Lemma 6.8, we see that there exists a constant $c_2 > 0$ such that

$$\int_{B_\varrho(x)} \chi_{\Omega^I(t)\triangle\Omega^I(t-h)} \leq \omega_3 \varrho^3 \leq c_2 \varrho \min\left\{ \left(\int_{B_\varrho(x)} \chi_{\Omega^I(t-h)} \right)^{\frac{2}{3}}, \left(\int_{B_\varrho(x)} \chi_{\mathbb{R}^3\setminus\Omega^I(t-h)} \right)^{\frac{2}{3}} \right\}. \tag{7.3}$$

The right-hand side of (7.3) can be bounded with the help of the isoperimetric inequality (6.3) which proves

$$\int_{B_\varrho(x)} \chi_{\Omega^I(t)\triangle\Omega^I(t-h)} \leq c_2 \varrho \int_{B_\varrho(x)} |\nabla \chi_{\Omega^I(t-h)}|.$$

This estimate holds for each ball $B \in \mathcal{B}$, and the union over all elements of $\mathcal{B}$ yields

$$|E_2(lh)| \leq c_1 c_2\, M h \int_\Omega |\nabla \chi_{\Omega^I((l-1)h)}|.$$

After summation, we get

$$\sum_{l=1}^{N} |E_2(lh)| \leq \sum_{l=1}^{N} c_2 h \int_\Omega |\nabla \chi_{\Omega^I((l-1)h)}| \leq C.$$

The generalization to arbitrary $\tau \in (0,T)$ is straightforward. $\square$

LEMMA 7.3 (compactness of χ_h in time II). *The discrete solution χ_h fulfills*

$$\int_\Omega |\chi_h(x,t+\tau) - \chi_h(x,t)| \leq C\tau^{\frac{1}{2}}$$

for all $h \leq \tau \leq T - t$.

Proof. Assume that $\tau = kh$ and $t = mh$ for $k, m \in \mathbb{N}$. As in Lemma 7.2, we conclude that

$$\int_\Omega |\chi_h(x,t+\tau) - \chi_h(x,t)| \leq \int_\Omega \sum_{l=0}^{k-1} |\chi_h(x,(m+l+1)h) - \chi_h(x,(m+l)h)| = \sum_{l=0}^{k-1} |\Omega^I((m+l+1)h) \triangle \Omega^I((m+l)h)|.$$

Therefore it is enough to prove

$$\sum_{l=0}^{k-1} |\Omega^I((m+l+1)h) \triangle \Omega^I((m+l)h)| \leq C\tau^{\frac{1}{2}}.$$

Here we consider the decomposition

$$\Omega^I(t)\triangle\Omega^I(t-h) \subset \left\{ x\in\Omega^I(t)\triangle\Omega^I(t-h) \,\middle|\, \mathrm{dist}(x,\partial\Omega(t-h)) > \frac{c_2}{4}h^{\frac{3}{2}} \right\}$$

$$\cup\left\{ x\in\Omega^I(t)\triangle\Omega^I(t-h) \,\middle|\, \mathrm{dist}(x,\partial\Omega(t-h)) \le \frac{c_2}{4}h^{\frac{3}{2}} \right\},$$

where c_2 is the constant of (7.3). The proof follows as in Lemma 7.2, where we can invoke Lemma 6.8 with $\varrho = \frac{c_2}{2}h^{\frac{1}{2}}$. We obtain

$$\sum_{l=0}^{k-1} |\Omega^I((m+l+1)h)\triangle\Omega^I((m+l)h)| \le c_2 h^{\frac{1}{2}} \le C\tau^{\frac{1}{2}}.$$

The generalization to arbitrary τ and t is straightforward. ◻

THEOREM 7.4 (compactness of χ_h). *There exist a subsequence of χ_h and a function $\chi \in L^1(\Omega_T,\{0,1\})$ such that*

$$\chi_h \to \chi \qquad \textit{in } L^1(\Omega_T).$$

For almost all $t\in(0,T)$, the function $\chi(t)$ is in $BV(\Omega)$ and is a characteristic function of a set $\Omega^I(t)\subset\Omega$. Additionally, we have the convergence of the Radon measures

$$\nabla\chi_h \rightharpoonup \nabla\chi \qquad \textit{in } \ \mathrm{rca}(\Omega_T).$$

Proof. This is a direct consequence of the compactness properties established in Lemmas 7.1 and 7.2. ◻

LEMMA 7.5 (estimate of the discrete velocity I). *There exists a constant C such that for sufficiently large speed s,*

$$\int_{\{|v_h|>s\}\cap\Omega_T} |v_h||\nabla\chi_h| < Cs^{-1}.$$

Proof. We restrict the proof to the case $x\in\overline{\Omega^I(t)}\setminus\Omega^I(t-h)$; case $x\in\Omega^I(t-h)\setminus\Omega^I(t)$ can be proved accordingly.

Let $t = kh$ with $k\in\mathbb{N}$. For given $s>0$, we fix $l\in\mathbb{N}$ and consider those $x\in\partial\Omega^I(t)$ with $x\in\partial\Omega^I(t)\cap\{2^l s<|v_h|\le 2^{l+1}s\}$.

We cover the set

$$\partial\Omega^I(t)\cap\left\{ z\in\Omega \,\middle|\, 2^l s < |v_h(z,t)| \le 2^{l+1}s \right\}$$

with a family of balls $B\in\mathcal{B}_l$, each ball having a center $x\in\partial\Omega^I(t)$ and a radius $\frac{hs}{2}$.

By construction it holds that

$$\begin{aligned}
\int_{(\Omega^I(t)\setminus\Omega^I(t-h))\cap B_{\frac{hs}{2}}(x)} |v_h| \quad &\ge \int_{(\Omega^I(t)\setminus\Omega^I(t-h))\cap B_{\frac{hs}{2}}(x)} \left(2^l s - \frac{1}{2}sh\right) \\
&> \int_{(\Omega^I(t)\setminus\Omega^I(t-h))\cap B_{\frac{hs}{2}}(x)} C2^l s \\
&= \int_{\Omega^I(t)\cap B_{\frac{hs}{2}}(x)} C2^l s = C2^l s \int_{B_{\frac{hs}{2}}(x)} \chi_h(t).
\end{aligned}$$

With Corollary 6.5 this implies the estimate

$$\int_{(\Omega^I(t)\setminus\Omega^I(t-h))\cap B_{\frac{hs}{2}}(x)} |v_h| > C2^l s^4 h^3.$$

With $|v_h| < 2^{l+1}s$ and Corollary 6.6 we find the upper estimate

$$\int_{B_{\frac{hs}{2}}(x)} |v_h||\nabla\chi_h| < \int_{B_{\frac{hs}{2}}(x)} 2^{l+1}s|\nabla\chi_h| \le C2^{l+1}s^3h^2.$$

Consequently,

$$\int_{B_{\frac{hs}{2}}(x)} |v_h||\nabla\chi_h| < Ch^{-1}s^{-1}\int_{(\Omega^I(t)\setminus\Omega^I(t-h))\cap B_{\frac{hs}{2}}(x)} |v_h|$$

for every ball $B \in \mathcal{B}_l$. When taking the union of all balls in $\mathcal{B}_l$, we arrive at

$$\int_{\{2^l s<|v_h|\le 2^{l+1}s\}} |v_h||\nabla\chi_h| < Cs^{-1}h^{-1}\int_{\{(2^l-\frac{1}{2})s<|v_h|<(2^{l+1}+\frac{1}{2})s\}\cap(\Omega^I(t)\triangle\Omega^I(t-h))} |v_h|.$$

Summation over all $l \in \mathbb{N}$ yields

$$\int_{\{|v_h|>s\}\cap\Omega^I(t)} |v_h||\nabla\chi_h| < Ch^{-1}s^{-1}\int_{\Omega^I(t)\triangle\Omega^I(t-h)} |v_h|,$$

and after integration in time,

$$\int_{\{|v_h|>s\}\cap\Omega_T} |v_h||\nabla\chi_h| < Ch^{-1}s^{-1}\int_0^T\int_{\Omega^I(t)\triangle\Omega^I(t-h)} |v_h| \le Cs^{-1}.$$

The last inequality follows from the a priori estimate (5.1) in Lemma 5.1. ∎

LEMMA 7.6 (estimate on the discrete velocity II). *There exists a constant C such that*

$$\int_{\Omega_T} v_h^2|\nabla\chi_h| < C.$$

Proof. We need only prove the assertion if $|v_h| > s$ for some $s > 0$ chosen large. As in Lemma 7.5, let $t = kh$ for $k = 1,\dots,N$ and $x \in \partial\Omega^I(t) \cap \{2^l s < |v_h| \le 2^{l+1}s\}$ for fixed $l \in \mathbb{N}$. Again we restrict the proof to the case $x \in \overline{\Omega^I(t)} \setminus \Omega^I(t-h)$.

We cover the set $\partial\Omega^I(t) \cap \{2^l s < |v_h| \le 2^{l+1}s\}$ by a family of balls $B \in \mathcal{B}_l$ each with radius $2^{l-1}sh$ and center points $x \in \partial\Omega^I(t)$. As in Lemma 7.5, we find

$$\int_{(\Omega^I(t)\setminus\Omega^I(t-h))\cap B_{2^{l-1}sh}(x)} |v_h| > \int_{(\Omega^I(t)\setminus\Omega^I(t-h))\cap B_{2^{l-1}sh}(x)} C2^l s \ge C2^{4l-3}h^3s^4.$$

On the other hand,

$$\int_{B_{2^{l-1}sh}(x)} v_h^2|\nabla\chi_h| \le C(2^{l+1}s)^2(2^{l-1}sh)^2 = C2^{4l-6}h^2s^4.$$

A comparison yields

$$\int_{B_{2^{l-1}sh}(x)} v_h^2|\nabla\chi_h| < Ch^{-1}\int_{(\Omega^I(t)\setminus\Omega^I(t-h))\cap B_{2^{l-1}sh}(x)} |v_h|.$$

Now we can proceed as in Lemma 7.5. ∎

LEMMA 7.7 (error in the discrete velocity). *For all test functions $\xi \in C_0^0(\Omega_T\,;\mathbb{R})$, it holds that*

$$\lim_{h\searrow 0}\int_{\Omega_T}\left(\frac{1}{h}\mathrm{dist}(\cdot,\partial\Omega^I(t-h))|\nabla\chi_h| - \partial_t^{-h}\chi_h\right)\xi = 0.$$

Proof. The principle of the proof is taken from [19]; see also [27] and [26].

We subdivide the proof into two parts. The first part studies the region where the discrete velocity is high. We will show the lemma for $\Omega\subset\mathbb{R}^3$; however, the following proof fails for space dimensions $n\geq 4$.

We cover the set $\Omega^I(t)\triangle\Omega^I(t-h)$ by a family $\mathcal{B}(t)$ of balls, each with radius $h^{\frac12}$ and with center $x\in\Omega^I(t)\triangle\Omega^I(t-h)$. Let

$$\mathcal{B} := \mathcal{B}(h)\cup\mathcal{B}(2h)\cup\cdots\cup\mathcal{B}(Nh).$$

(i) By $\mathcal{B}_1\subset\mathcal{B}$ we denote that subfamily of $\mathcal{B}$ with the property that for every ball B in $\mathcal{B}_1$ there exists a $z\in B\cap(\Omega^I(t)\triangle\Omega^I(t-h))$ with

$$\mathrm{dist}(z,\Omega^I(t-h)) > h^{\frac{9}{16}}. \tag{7.4}$$

Again it is enough to consider the case $x\in\overline{\Omega^I(t)}\setminus\Omega^I(t-h)$. We fix a ball B in $\mathcal{B}_1$. With Corollary 6.5 and (7.4) we obtain

$$\int_{B_{\frac12 h^{9/16}}(x)\cap(\Omega^I(t)\setminus\Omega^I(t-h))}|v_h| > C\frac{h^{-\frac{7}{16}}}{2}\left(\frac{h^{\frac{9}{16}}}{2}\right)^3 = Ch^{\frac54}.$$

This implies

$$\int_{B_{\sqrt{h}}(x)}|\partial_t^{-h}\chi_h| \leq C\int_{B_{\sqrt{h}}(x)}\frac{1}{h}\leq Ch^{\frac12}\leq Ch^{-\frac34}\int_{B_{\frac12 h^{9/16}}(z)\cap(\Omega^I(t)\setminus\Omega^I(t-h))}|v_h|$$
$$\leq ch^{-\frac34}\int_{B_{2\sqrt{h}}(x)\cap(\Omega^I(t)\setminus\Omega^I(t-h))}|v_h|. \tag{7.5}$$

The last estimate, (7.5), holds because

$$B_{\frac12 h^{9/16}}(z)\subset B_{2\sqrt{h}}(x).$$

A further bound can be obtained from Lemma 6.7 and Corollary 6.6:

$$\int_{B_{\sqrt{h}}(x)}|v_h||\nabla\chi_h|\leq Ch^{-\frac12}(h^{\frac12})^2\leq Ch^{\frac12}$$
$$\leq Ch^{-\frac34}\int_{B_{2\sqrt{h}}(x)\cap(\Omega^I(t)\setminus\Omega^I(t-h))}|v_h|. \tag{7.6}$$

When combining estimates (7.5) and (7.6) we obtain, after taking the union of all balls $B\in\mathcal{B}_1$ and after integration in time,

$$\int_0^T\int_{\mathcal{B}_1}\left(|\partial_t^{-h}\chi_h| + |v_h||\nabla\chi_h|\right)\leq Ch^{-\frac34}\int_0^T\int_{\Omega^I(t)\setminus\Omega^I(t-h)}|v_h|\leq Ch^{\frac14}. \tag{7.7}$$

The last inequality in (7.7) is a consequence of the a priori estimate on v_h found in Lemma 5.1. With (7.7) the lemma is shown for the regions with fast discrete velocity v_h and $x \in \overline{\Omega^I(t)} \setminus \Omega^I(t-h)$.

(ii) Now we discuss the regions in Ω with small discrete velocity. Let $\mathcal{B}_2 := \mathcal{B} \setminus \mathcal{B}_1$. By construction,

$$\operatorname{dist}(z, \partial\Omega^I(t-h)) \leq h^{\frac{9}{16}} \tag{7.8}$$

for any ball $B \in \mathcal{B}_2$ and any $z \in B$. Let $\beta := \frac{17}{32}$.

For $t = kh$, $1 \leq k \leq N$, we consider the subcover $\tilde{\mathcal{B}}_2(t)$ of $\mathcal{B}_2(t)$ with balls of radius $h^\beta = h^{\frac{17}{32}}$ and center $x \in \partial\Omega^I(t)$. Also, let $\tilde{\mathcal{B}}_2 := \cup_{k=1}^N \tilde{\mathcal{B}}_2(kh)$.

The following strong assumption is sufficient to prove part (ii).

For every ball $B \in \tilde{\mathcal{B}}_2$ there exists a $\nu \in S^2$ such that

$$\max\left\{ \|\nu_1 - \nu\|_{L^\infty(B)}, \|\nu_2 - \nu\|_{L^\infty(B)} \right\} \leq \omega(h), \tag{7.9}$$

where ν_1, ν_2 denote the unit outer normals to $\Omega^I(t)$ and $\Omega^I(t-h)$, respectively. The function $\omega(h)$ converges uniformly to 0 in every ball $B \in \tilde{\mathcal{B}}_2$.

It is evident that (7.9) implies the assertion of the lemma. Indeed, (7.9) is a very strong condition as it controls the variation of the normals, and thus we obtain directly

$$\left| \int_B \partial_t^{-h} \chi_h - v_h |\nabla \chi_h| \right| \leq \omega(h) \int_B |\partial_t^{-h} \chi_h|$$

for all balls $B \in \tilde{\mathcal{B}}_2$. Taking the union over all balls in $\tilde{\mathcal{B}}_2(t)$ and using discrete integration in time yields, for test functions $\xi \in C^0(\Omega_T; \mathbb{R})$,

$$\left| \int_0^T \int_{\mathcal{B}_2(t)} \Big(\partial_t^{-h} \chi_h - v_h |\nabla \chi_h| \Big) \xi \right| \leq \|\xi\|_{L^\infty(\Omega_T)} \, \omega(h) \int_{\Omega_T} |\partial_t^{-h} \chi_h| \leq C\omega(h).$$

The last estimate follows from the bound on $\|\partial_t^{-h} \chi_h\|_{L^1(\Omega_T)}$ provided in Lemma 7.2.

So it remains to prove (7.9). We will use Bernstein's theorem (see [14], [13], and [12]) for $n = 8$.

Assume that (7.9) does not hold. Then there exists a subsequence of balls $B_{h^\beta}(x_h)$ such that for all ν the norms $\|\nu_{\Omega^I(t)} - \nu\|_{L^\infty(B)}$, $\|\nu_{\Omega^I(t-h)} - \nu\|_{L^\infty(B)}$ do not converge to 0. We blow up the balls $B_{\sqrt{h}}(x_h)$ with a factor $h^{-\beta}$ and shift them such that we obtain a sequence of balls with radius $h^{\frac{1}{2}-\beta}$ and center at 0. These scaled and translated balls will be denoted by $\Omega_h^\beta(t)$. The characteristic functions to $\Omega_h^\beta(t)$ are minimizers of the scaled functional F_h given by (4.3). The compactness of $BV(\Omega)$ with respect to L^1-convergence implies that we can find a subsequence of $\chi_{\Omega_h^\beta(t)}$ and a subsequence of $\chi_{\Omega_h^\beta(t-h)}$ (both denoted as the original sequence) such that

$$\chi_h^\beta(t) := \chi_{\Omega_h^\beta(t)} \to \chi_{\mathcal{T}_1}, \quad \chi_{\Omega_h^\beta(t-h)} \to \chi_{\mathcal{T}_2} \qquad \text{in } L^1_{\mathrm{loc}}(\mathbb{R}^3)$$

for two sets $\mathcal{T}_1$, $\mathcal{T}_2$. Since the velocity term in the rescaled functional is scaled by a factor $h^{2\beta}$, due to Lemma 6.7 we find

$$h^{2\beta} \int_{\Omega_h^\beta(t) \triangle \Omega_h^\beta(t-h)} \frac{1}{h} \operatorname{dist}(\cdot, \partial\Omega^\beta(t-h)) \leq C h^{2\beta} h^{-\frac{1}{2}} h^{-\beta} = C h^{\beta - \frac{1}{2}}.$$

This shows that the velocity term in the rescaled functional converges to 0 for $h \searrow 0$. Due to (5.9), this also holds for the other terms in the scaled functional, except for the area term $\int_{\Omega_h^\beta} |\nabla \chi_h^\beta|$. This implies that the sets $\mathcal{T}_1$, $\mathcal{T}_2$ are area-minimizing in $\mathbb{R}^3$. Bernstein's theorem thus yields that $\mathcal{T}_i$ are half-spaces.

From the bound on the discrete velocity (7.8) we learn that

$$\operatorname{dist}(\cdot, \partial\Omega_h^\beta(t-h)) \le h^{\frac{9}{16}} h^{-\beta} \to 0 \qquad \text{on } B_{h^{\frac{1}{2}-\beta}}(x_h) \cap (\Omega_h^\beta(t) \triangle \Omega_h^\beta(t-h)).$$

This gives $\mathcal{T}_1 = \mathcal{T}_2 =: \mathcal{T}$ and $0 \in \partial\mathcal{T}$. Without loss of generality, we may assume

$$\mathcal{T} = \{z \in \mathbb{R}^3 \mid z_3 < 0\},$$

implying $\nu = (0,0,1)$ for the normal to the minimizing set $\mathcal{T}$.

Let $\varrho > 0$ be fixed. Our construction implies

$$\lim_{h \searrow 0} \varrho^{-3} \int_{B_\varrho(z)} |\nu_1 - \nu|^2 |\nabla \chi_h^\beta| = 0 \qquad \text{uniformly for } z \in B_1(0) \cap \partial\Omega_h^\beta(t).$$

Now we apply the excess-decay-lemma; see, for instance, [29]. It states that

$$\lim_{h \searrow 0} |\nu_1(z) - \nu| = 0 \qquad \text{uniformly for } z \in B_1(0) \cap \partial\Omega_h^\beta(t).$$

The same statement holds for ν_2 and $\Omega_h^\beta(t-h)$. Thus, after rescaling with factor h^β, this gives a contradiction, and (7.9) is proved. ∎

8. Convergence of the discrete solution. We still have to verify that the discrete solutions converge to the solution of the continuous equations. We will prove this in a series of lemmas.

From Theorem 7.4 it does not follow that

$$|\nabla \chi_h| \rightharpoonup |\nabla \chi| \qquad \text{in } \operatorname{rca}(\Omega_T).$$

For the proofs of this section we therefore make the assumption

$$\int_{\Omega_T} |\nabla \chi_h| \to \int_{\Omega_T} |\nabla \chi| \qquad \text{as } h \searrow 0, \tag{8.1}$$

where χ is the function of Theorem 7.4.

First, we show the existence of a velocity v that satisfies (W3).

LEMMA 8.1 (existence of a limit velocity). *Let χ be the characteristic function specified in Theorem* 7.4. *Then there exists a velocity function v which satisfies*

$$v \in L^1((0,T); L^1(\Omega; |\nabla \chi(t)|))$$

such that (W3) *is fulfilled.*

Proof. Discrete integration by parts yields

$$\int_{\Omega_T} \xi \partial_t^{-h} \chi_h + \frac{1}{h} \int_\Omega \int_0^h \chi_{\Omega_0^I} \xi = - \int_{\Omega_T} \chi_h \partial_t^h \xi \tag{8.2}$$

for all $\xi \in C^\infty(\overline{\Omega} \times [0,T]; \mathbb{R})$ with $\xi(T) = 0$.

As was shown in Lemma 7.2, there exists a constant C independent of h such that

$$\int_{\Omega_T} |\partial_t^{-h}\chi_h| < C.$$

Therefore there exists a subsequence of $\partial_t^{-h}\chi_h$ with

$$\partial_t^{-h}\chi_h \rightharpoonup \nu \qquad \text{in } \mathrm{rca}(\Omega_T).$$

With Lemma 7.7 we find at once that

$$v_h|\nabla\chi_h| \rightharpoonup \nu \qquad \text{in } \mathrm{rca}(\Omega_T). \tag{8.3}$$

We prove now that ν is absolutely continuous with respect to the measure $|\nabla\chi|$. Let $E \subset \Omega_T$ with $|\nabla\chi(E)| = 0$. From our assumption (8.1) we infer that there exists a function $g : \mathbb{R} \to \mathbb{R}$ with $g(h) \searrow 0$ as $h \searrow 0$ such that

$$|\nabla\chi_h(E)| \leq g(h).$$

Due to Lemma 7.5 it follows that

$$\begin{aligned}\int_E |v_h||\nabla\chi_h| &= \int_{\{|v_h|\leq s\}\cap E} |v_h||\nabla\chi_h| + \int_{\{|v_h|>s\}\cap E} |v_h||\nabla\chi_h| \\ &\leq sg(h) + Cs^{-1}.\end{aligned}$$

The right-hand side of this estimate can be made arbitrarily small for small h, and thus

$$\lim_{h\searrow 0}\int_E |v_h||\nabla\chi_h| = 0.$$

This shows that $\nu(E) = 0$ and proves the absolute continuity of ν. The existence of $v \in L^1(0,T);\ L^1(\Omega; |\nabla\chi(t)|)$ satisfying

$$\nu = v|\nabla\chi| \tag{8.4}$$

follows now from the Radon–Nikodym theorem.

The measures $v_h|\nabla\chi_h|$ and $v|\nabla\chi|$ are absolutely continuous in time, and furthermore we can approximate ξ in (8.2) by functions with compact support. Passing to the limit $h \searrow 0$ gives (W3). $\square$

LEMMA 8.2 (convergence of the advection term in the weak curvature equation). *Let χ be the characteristic function specified in Theorem* 7.4 *and v be the function specified in Lemma* 8.1. *Then it holds that*

$$\lim_{h\searrow 0}\int_{\Omega_T} v_h\zeta\nabla\chi_h = \int_{\Omega_T} v\zeta\nabla\chi$$

for all $\zeta \in C^1([0,T]\times\overline{\Omega};\mathbb{R}^3)$ with $\zeta = 0$ on $\partial\Omega\times(0,T)$.

Proof. As $|\nabla\chi|$ is a Radon measure, there exists for any $\varepsilon > 0$ a vector-valued mapping $g_\varepsilon \in C^0(\Omega_T;\mathbb{R}^3)$, $|g_\varepsilon| \leq 1$, such that

$$\int_{\Omega_T} |\nabla\chi| - \int_{\Omega_T} g_\varepsilon\nabla\chi < \varepsilon.$$

Consequently,

$$\lim_{h\searrow 0}\left(\int_{\Omega_T}|\nabla\chi_h| - \int_{\Omega_T} g_\varepsilon\nabla\chi_h\right) = \int_{\Omega_T}|\nabla\chi| - \int_{\Omega_T} g_\varepsilon\nabla\chi < \varepsilon. \tag{8.5}$$

With the notation

$$\nu_h := \frac{\nabla\chi_h}{|\nabla\chi_h|}, \qquad \nu := \frac{\nabla\chi}{|\nabla\chi|},$$

we find

$$\begin{aligned}\int_{\Omega_T}(\nu_h - g_\varepsilon)^2|\nabla\chi_h| &= \int_{\Omega_T}(1-2g_\varepsilon\nu_h + g_\varepsilon^2)|\nabla\chi_h| = \int_{\Omega_T}(2-2g_\varepsilon\nu_h+g_\varepsilon^2-1)|\nabla\chi_h|\\ &\le 2\int_{\Omega_T}(1-g_\varepsilon\nu_h)|\nabla\chi_h|.\end{aligned}$$

This estimate in combination with (8.5) yields

$$\lim_{h\searrow 0}\int_{\Omega_T}(\nu_h-g_\varepsilon)^2|\nabla\chi_h| < 2\varepsilon. \tag{8.6}$$

This result, together with Hölder's inequality and the boundedness of $(\int_{\Omega_T}|\nabla\chi_h|)^{\frac{1}{2}}$, implies

$$\lim_{h\searrow 0}\int_{\Omega_T}|\nu_h-g_\varepsilon||\nabla\chi_h| \le C\lim_{h\to 0}\left(\int_{\Omega_T}(\nu_h-g_\varepsilon)^2|\nabla\chi_h|\right)^{\frac{1}{2}} \le C(2\varepsilon)^{\frac{1}{2}}.$$

In the same way, we compute with Lemma 7.6 and Hölder's inequality

$$\begin{aligned}\lim_{h\searrow 0}\int_{\Omega_T}|v_h||g_\varepsilon-\nu_h||\nabla\chi_h| &\le \left(\int_{\Omega_T}|v_h|^2|\nabla\chi_h|\right)^{\frac{1}{2}}\left(\int_{\Omega_T}(\nu_h-g_\varepsilon)^2|\nabla\chi_h|\right)^{\frac{1}{2}}\\ &\le C(2\varepsilon)^{\frac{1}{2}}. \end{aligned}\tag{8.7}$$

Now we are prepared to show the assertion of the lemma. We see that

$$\begin{aligned}\left|\int_{\Omega_T} v_h\zeta\nabla\chi_h - v\zeta\nabla\chi\right| &= \left|\int_{\Omega_T} v_h\zeta\nu_h|\nabla\chi_h| - v\zeta\nu|\nabla\chi|\right|\\ &\le \left|\int_{\Omega_T} v_h\zeta\nu_h|\nabla\chi_h| - v\zeta g_\varepsilon|\nabla\chi|\right| + \left|\int_{\Omega_T} v\zeta g_\varepsilon|\nabla\chi| - v\zeta\nu|\nabla\chi|\right|\\ &=: I_1(\varepsilon,h) + I_2(\varepsilon).\end{aligned}$$

We estimate I_1 and I_2 independently. For the first integral, we have

$$I_1(\varepsilon,h) \le \int_{\Omega_T}|v_h||\zeta||\nu_h-g_\varepsilon||\nabla\chi_h| + \left|\int_{\Omega_T} v_h\zeta g_\varepsilon|\nabla\chi_h| - v\zeta g_\varepsilon|\nabla\chi|\right|. \tag{8.8}$$

Estimate (8.7) confirms the convergence of the first integral in (8.8), the properties (8.3) and (8.4) lead to the convergence of the second integral, and thus

$$\lim_{\varepsilon\searrow 0}\lim_{h\searrow 0} I_1(\varepsilon,h) \le \lim_{\varepsilon\searrow 0} C\varepsilon^{\frac{1}{2}} = 0.$$

For the integral $I_2(\varepsilon)$ we get directly

$$I_2(\varepsilon) \le \omega(\varepsilon)$$

for a function $\omega(\varepsilon)$ that tends to 0 as ε tends to 0. In conclusion we have found that

$$\lim_{h\searrow 0}\left|\int_{\Omega_T} v_h\zeta\nabla\chi_h - v\zeta\nabla\chi\right| = 0,$$

and the proof is finished. $\square$

LEMMA 8.3 (convergence of the weak curvature term). *Let χ be the characteristic function specified in Theorem* 7.4. *Then it holds that*

$$\lim_{h\searrow 0}\int_{\Omega_T} \nu_h\nabla\zeta\nu_h|\nabla\chi_h| = \int_{\Omega_T}\nu\nabla\zeta\nu|\nabla\chi|$$

for all $\zeta \in C^1([0,T]\times\overline{\Omega};\mathbb{R}^3)$ with $\zeta = 0$ on $\partial\Omega\times(0,T)$.

Proof. For $\varepsilon > 0$ and the family g_ε of mappings introduced in Lemma 8.2, one has

$$\begin{aligned}\left|\int_{\Omega_T}\nu_h\nabla\zeta\nu_h|\nabla\chi_h| - \int_{\Omega_T}\nu\nabla\zeta\nu|\nabla\chi|\right| \le{}& \left|\int_{\Omega_T}\nu_h\nabla\zeta\nu_h|\nabla\chi_h| - \int_{\Omega_T} g_\varepsilon\nabla\zeta g_\varepsilon|\nabla\chi_h|\right|\\ &+\left|\int_{\Omega_T} g_\varepsilon\nabla\zeta g_\varepsilon|\nabla\chi_h| - \int_{\Omega_T} g_\varepsilon\nabla\zeta g_\varepsilon|\nabla\chi|\right|\\ &+\left|\int_{\Omega_T} g_\varepsilon\nabla\zeta g_\varepsilon|\nabla\chi| - \int_{\Omega_T}\nu\nabla\zeta\nu|\nabla\chi|\right|.\end{aligned}$$

With the help of (8.6) and (8.1) we see that the right-hand side of this estimate converges to 0 as $h\searrow 0$ and $\varepsilon\searrow 0$. $\square$

It is well known that condition (8.1), together with the convergence of $\chi_h \to \chi$ in $L^1(\Omega_T)$ as stated in Theorem 7.4, implies the convergence of the mean curvature term. This is a consequence of the lemma of Reshetnyak, which we state for the reader's convenience.

LEMMA 8.4 (lemma of Reshetnyak). *Let μ_h be a sequence of vector-valued measures in $\Omega\subset\mathbb{R}^n$ with*

$$\mu_h \to \mu \qquad \text{in } \mathrm{rca}(\Omega;\mathbb{R}^n)$$

and

$$|\mu_h|(\Omega) \to |\mu|(\Omega).$$

Then for all bounded continuous functions in $S^{n-1}\times\Omega$ it holds that

$$f\left(\frac{\mu_h}{|\mu_h|},\cdot\right)|\mu_h| \rightharpoonup f\left(\frac{\mu}{|\mu|},\cdot\right)|\mu| \qquad \text{in } \mathrm{rca}(\Omega;\mathbb{R}^n),$$

where $\frac{\mu}{|\mu|}$ *is defined by the Radon–Nikodym theorem.*

Proof. The proof is similar to the proof of Lemma 8.3; see [23]. ◻

Now we discuss the convergence of the discrete chemical potentials.

LEMMA 8.5 (convergence of μ_h^D). *There exists a function* $\mu^D \in L^2(0,T;\, H^{1,2}(\Omega))$ *and a subsequence* μ_h^D *such that for* $h \searrow 0$,

$$\mu_h^D \rightharpoonup \mu^D \qquad \textit{in } L^2(0,T;\, H^{1,2}(\Omega))$$

and

$$(1-\chi)\mu_D = (1-\chi)\varphi \qquad \textit{for almost every } (x,t) \in \Omega_T.$$

We recall that φ are the boundary conditions on μ^D given by (2.25).

Proof. Due to the a priori estimates, we have for a constant C independent of h that

$$\int_{\Omega_T} |\nabla \mu_h^D|^2 \le C.$$

Together with the boundary conditions for μ_h^D and the Poincaré inequality, this yields

$$\|\mu_h^D\|_{L^2(0,T;\, H^{1,2}(\Omega))} \le C.$$

The second assertion of the lemma follows directly from the a priori estimate, which ensures

$$\int_{\Omega_T} (1-\chi_h(t-h))|\nabla \mu_h^D|^2 \to 0 \qquad \text{for } h \searrow 0.$$

This proves the lemma. ◻

LEMMA 8.6 (convergence of μ_h^N). *There exists a function* $\mu^N \in L^2(0,T; H^{1,\frac{3}{2}}(\Omega))$ *and a subsequence* μ_h^N *such that for* $h \searrow 0$,

$$\mu_h^N \rightharpoonup \mu^N \qquad \textit{in } L^2(0,T;\, L^{\frac{3}{2}}(\Omega)),$$

with

$$(1-\chi)\mu^N = 0 \qquad \textit{for almost every } (x,t) \in \Omega_T.$$

Proof. For any $h > 0$, let $\alpha = \alpha(h) > 0$ be a small real number with $\alpha(h) \searrow 0$ as $h \searrow 0$. We define the mapping $\mu_h^{N,\alpha}$ by

$$\mu_h^{N,\alpha} := \begin{cases} (|\mu_h^N| - \alpha)_+ \frac{\mu_h^N}{|\mu_h^N|} & \text{if } \mu_h^N \neq 0, \\ 0 & \text{else.} \end{cases}$$

For this truncated chemical potential, we compute with the chain rule

$$\begin{aligned}
&\int_{\Omega_T}(1-\chi_h(t-h))|\nabla\mu_h^{N,\alpha}|^{\frac{3}{2}}\\
&\quad=\int_{\Omega_T\cap\{|\mu_h^{N,\alpha}|>\alpha\}}(1-\chi_h(t-h))|\nabla\mu_h^{N,\alpha}|^{\frac{3}{2}}\\
&\quad\le\int_{\Omega_T\cap\{|\mu_h^{N,\alpha}|>\alpha\}}(1-\chi_h(t-h))|\nabla\big((\mu_h^{N,\alpha})^{\frac{5}{4}}\big)|^{\frac{3}{2}}\alpha^{-\frac{3}{8}}\\
&\quad=\frac{5}{4}\alpha^{-\frac{3}{8}}\int_{\Omega_T\cap\{|\mu_h^{N,\alpha}|>\alpha\}}(1-\chi_h(t-h))|\mu_h^{N,\alpha}|^{\frac{3}{8}}|\nabla\mu_h^{N,\alpha}|^{\frac{3}{2}}\\
&\quad\le\frac{5}{4}\alpha^{-\frac{3}{8}}\left(\int_{\Omega_T}(1-\chi_h(t-h))|\nabla\mu_h^{N,\alpha}|^2\right)^{\frac{3}{4}}\left(\int_{\Omega_T}(1-\chi_h(t-h))|\mu_h^{N,\alpha}|^{\frac{3}{2}}\right)^{\frac{1}{4}},
\end{aligned}$$

where Hölder's inequality was used to get the last line.

We apply the a priori estimates (5.3) and (5.5) and obtain

$$\int_{\Omega_T}(1-\chi_h(t-h))|\nabla\mu_h^{N,\alpha}|^{\frac{3}{2}}\le C\alpha^{-\frac{3}{8}}\varepsilon^{-\frac{3}{4}}\gamma^{\frac{3}{16}}\le C.$$

Here we choose $\alpha(h)$ such that $\alpha^{-\frac{3}{8}}\varepsilon^{-\frac{3}{4}}\gamma^{\frac{3}{16}}$ is bounded uniformly in h. So we have found that

$$\int_{\Omega_T}|\nabla\mu_h^{N,\alpha}|^{\frac{3}{2}}\le C.$$

With the boundary conditions for μ_h^N, this ensures the existence of a subsequence, again denoted by $\mu_h^{N,\alpha}$, and the existence of a function $\mu^{N,\alpha}\in L^2(0,T;\,H^{1,\frac{3}{2}}(\Omega))$ with

$$\mu_h^{N,\alpha}\rightharpoonup\mu^{N,\alpha}\qquad\text{in } L^2(0,T;\,H^{1,\frac{3}{2}}(\Omega)).$$

Also we can pick a subsequence $\alpha(h)$ with

$$\mu^{N,\alpha}\rightharpoonup\mu^{N}\qquad\text{in } L^2(0,T;\,H^{1,\frac{3}{2}}(\Omega))$$

for a suitable $\mu^N\in L^2(0,T;\,H^{1,\frac{3}{2}}(\Omega))$.

Finally, by definition of $\mu_h^{N,\alpha}$, we have for every $\alpha\ge 0$ and every $h>0$,

$$\|\mu_h^N-\mu_h^{N,\alpha}\|_{L^2(0,T;\,L^{\frac{3}{2}}(\Omega))}\le C\alpha.$$

By construction it thus holds for $h\searrow 0$ that

$$\mu_h^{N}\rightharpoonup\mu^{N}\qquad\text{in } L^2(0,T;\,L^{\frac{3}{2}}(\Omega)).$$

The second claim of the lemma is again a consequence of the a priori estimate (5.5), which shows as $\gamma(h)\searrow 0$ for $h\searrow 0$,

$$\int_{\Omega_T}(1-\chi_h(t-h))|\mu_h^N|^2\to 0\qquad\text{as } h\searrow 0.$$

This ends the proof. $\square$

Lemma 8.7. *Let χ be the characteristic function specified in Theorem* 7.4. *Then it holds that*

$$\lim_{h\searrow 0}\int_{\Omega_T} f_{II}^*(\mu_h)\zeta\nabla\chi_h = \int_{\Omega_T} K\zeta\nabla\chi$$

for all $\zeta \in C^1([0,T]\times\overline{\Omega};\mathbb{R}^3)$ with $\zeta = 0$ on $\partial\Omega\times(0,T)$, where $K := f_{II}^{D,*}(\varphi)$.

Proof. We reformulate the left-hand side. For a test function $\zeta \in C^1([0,T]\times\overline{\Omega};\mathbb{R}^3)$ with $\zeta = 0$ on $\partial\Omega\times(0,T)$, we compute

$$\begin{aligned}\int_{\Omega_T} f_{II}^*(\mu_h)\zeta\nabla\chi_h &= \int_{\Omega_T}(1-\chi_h)f_{II}^{D,*}(\mu_h^D)\operatorname{div}(\zeta) + \int_{\Omega_T}(1-\chi_h)m_h^D\nabla\mu_h^D\zeta\\ &\quad+\int_{\Omega_T}(1-\chi_h)f_{II}^{N,*}(\mu_h^N)\operatorname{div}(\zeta) + \int_{\Omega_T}(1-\chi_h)m_h^N\nabla\mu_h^N\zeta\\ &=: I_1 + I_2 + I_3 + I_4.\end{aligned}$$

Using the convexity of $f_{II}^{D,*}$ and Lemma 8.5, we have for I_1,

$$\lim_{h\searrow 0}\int_{\Omega_T}(1-\chi_h)f_{II}^{D,*}(\mu_h^D)\operatorname{div}(\zeta) = \int_{\Omega_T}(1-\chi)f_{II}^{D,*}(\varphi)\operatorname{div}(\zeta).$$

So it remains to show that $I_k \to 0$ as $h\searrow 0$ for $k = 2,3,4$. For I_2 this results from

$$|I_2| \le C\int_{\Omega_T}|\chi_h(t-h)-\chi_h||\nabla\mu_h^D||\zeta| + \int_{\Omega_T}(1-\chi_h(t-h))|\nabla\mu_h^D||\zeta|,$$

and the a priori estimates and Lemma 7.2 yield, as desired, $|I_2|\searrow 0$ as $h\searrow 0$.

From $\mu = \frac{\partial f_{II}}{\partial m}$ in $\Omega\setminus\overline{\Omega^I}$ we get

$$m_i^N = \exp(\mu_i^N)\delta \qquad \text{for } i = 1,2$$

and consequently,

$$f_{II}^{N,*}(\mu_h^N) = k_B\theta\delta\sum_{i=1}^{2}\exp\left(\frac{\mu_{h,i}^N}{k_B\theta}\right).$$

Lemma 8.6 therefore implies $|I_3|\searrow 0$ as $\delta(h)\searrow 0$.

Finally,

$$|I_4| = C\left|\int_{\Omega_T}\delta(1-\chi_h)\exp(\mu^N)\nabla\mu_h^N\right| \le C\delta\varepsilon^{-1},$$

where we use again the a priori estimates and Hölder's inequality. With assumption (A2) we obtain $|I_2|\searrow 0$ as $h\searrow 0$, and the lemma is proved. $\square$

Lemma 8.8. *Let χ be the characteristic function specified in Theorem* 7.4. *Then it holds that*

$$\lim_{h\searrow 0}\int_{\Omega_T} f_I^*(\mu_h)\zeta\nabla\chi_h = \int_{\Omega_T} f_I^*(\mu)\zeta\nabla\chi$$

for all $\zeta \in C^1([0,T]\times\overline{\Omega};\mathbb{R}^3)$ *with* $\zeta = 0$ *on* $\partial\Omega\times(0,T)$*, where* $\mu = (\mu^N,\mu^D)$.

Proof. We reformulate the left-hand side. For a test function $\zeta \in C^1([0,T]\times\overline{\Omega};\mathbb{R}^3)$ with $\zeta = 0$ on $\partial\Omega\times(0,T)$, we compute

$$\int_{\Omega_T} f_I^*(\mu_h)\zeta\nabla\chi_h = -\int_{\Omega_T}\chi_h f_I^*(\mu_h)\mathrm{div}(\zeta) - \int_{\Omega_T}\chi_h m_h\nabla\mu_h\zeta. \tag{8.9}$$

From the convexity of f_I^* together with Lemmas 8.5 and 8.6, it follows directly that

$$\lim_{h\searrow 0}\int_{\Omega_T}\chi_h f_I^*(\mu_h)\mathrm{div}(\zeta) = \int_{\Omega_T}\chi_h f_I^*(\mu^N,\mu^D)\mathrm{div}(\zeta).$$

The proof is finished if we can show the convergence of the second integral on the right-hand side in (8.9) for $h\searrow 0$, but this is quite involved.

We use the definition

$$m_h^\beta := \begin{cases} m_h & \text{if } \beta < |m_h| < 1-\beta,\\ 0 & \text{else}\end{cases}$$

to reformulate the second integral on the right in (8.9). Since $\frac{\partial f_I^*}{\partial\mu}(\mu)$ is locally a Lipschitz function, we have for arbitrary vectors μ_1, μ_2,

$$\left|\frac{\partial f_I^*}{\partial\mu}(\mu_1) - \frac{\partial f_I^*}{\partial\mu}(\mu_2)\right| \le C|\mu_1-\mu_2|,$$

where C depends on μ_1, μ_2 and $C\to\infty$ for μ_1, $\mu_2\to\infty$. So we can estimate

$$\begin{aligned}
&\int_{\Omega_T}\chi_h|\nabla m_h^\beta|^{\frac32}\\
&\quad\le \int_{\Omega_T}\chi_h(t-h)|\nabla m_h^\beta|^{\frac32} + \int_{\Omega_T}|\chi_h-\chi_h(t-h)|\,|\nabla m_h^\beta|^{\frac32}\\
&\quad\le C\left(\int_{\Omega_T}\chi_h(t-h)|\nabla m_h^\beta|^2\right)^{\frac34} + C\left(\int_{\Omega_T}|\chi_h-\chi_h(t-h)|\right)^{\frac14}\left(\int_{\Omega_T}|\nabla m_h^\beta|^2\right)^{\frac34}\\
&\quad\le C(\varepsilon^{-\frac34}h^{\frac14}+1).
\end{aligned}$$

Due to assumption (A3) the right-hand side converges to 0 as $h\searrow 0$.

For functions $\varphi,\psi\in C^\infty(B_1(0);\mathbb{R}^+)$ we introduce mollifiers φ_ϱ and ψ_σ by setting $\varphi_\varrho(x) := \varrho^{-3}\varphi(x/\varrho)$ and $\psi_\sigma(t) := \sigma^{-3}\psi(t/\sigma)$. It holds that $\operatorname{supp}\varphi_\varrho\subset B_\varrho(0)$, $\operatorname{supp}\psi_\sigma\subset B_\sigma(0)$. We consider sequences (ϱ,σ) with $\sigma^{\frac12}\varrho^{-1}\to 0$. Then we have the estimate

$$\begin{aligned}
&\int_{\Omega_T}|(\chi_h m_h^\beta)*\varphi_\varrho*\psi_\sigma - \chi_h m_h^\beta|\\
&\quad\le \int_{\Omega_T}|(\chi_h m_h^\beta)*\varphi_\varrho*\psi_\sigma - (\chi_h m_h^\beta)*\varphi_\varrho| + \int_{\Omega_T}|(\chi_h m_h^\beta)*\varphi_\varrho - \chi_h m_h^\beta|\\
&\quad\le C\sigma^{\frac12}\varrho^{-1}\|\partial_t^h(\chi_h m_h^\beta)\|_{L^2(0,T;\,H^{-1,2}(\Omega))} + C\varrho\left(\int_{\Omega_T}|\nabla(\chi_h m_h^\beta)|+1\right).
\end{aligned}$$

Taking (5.6) into account, we arrive at

$$\int_{\Omega_T} |(\chi_h m_h^\beta) * \varphi_\varrho * \psi_\sigma - \chi_h m_h^\beta| \le C(\sigma^{\frac{1}{2}}\varrho^{-1} + \varrho),$$

which holds uniformly in h. It follows that there exists a subsequence of $\chi_h m_h^\beta$ (denoted as the original sequence) and a function $\Gamma \in L^1(\Omega_T)$ such that

$$\chi_h m_h^\beta \to \Gamma \qquad \text{in } L^1(\Omega_T). \tag{8.10}$$

Additionally,

$$\|\chi_h m_h - \Gamma\|_{L^1(\Omega_T)} \le \|\chi_h m_h - \chi_h m_h^\beta\|_{L^1(\Omega_T)} + \|\chi_h m_h^\beta - \Gamma\|_{L^1(\Omega_T)},$$

and the right side of this estimate converges to 0 for $h \searrow 0$. With (8.10) this ensures the strong convergence of a subsequence $\chi_h m_h$ in $L^1(\Omega_T)$. Furthermore we know that there exists a subsequence of m_h such that for any $1 \le p < \infty$,

$$m_h \to m \qquad \text{in } L^p(\Omega_T) \text{ for } h \searrow 0.$$

This yields $\chi_h m_h \rightharpoonup \chi m$ in $L^p(\Omega_T)$ and finally,

$$\chi_h m_h \to \chi m \qquad \text{in } L^p(\Omega_T) \text{ for } h \searrow 0. \tag{8.11}$$

Next we will show that

$$\chi_h \nabla \mu_h \zeta \rightharpoonup \chi \nabla \mu \zeta \qquad \text{in } L^2(0,T;\, L^{\frac{6}{5}}(\Omega)).$$

We use again the mapping $\mu_h^{N,\alpha}$ from the proof of Lemma 8.6. We define the mapping $\mu_{h,\alpha}^N$ by

$$\mu_{h,\alpha}^N := \begin{cases} \min\{\alpha, |\mu_h^{N,\alpha}|\}\frac{\mu_h^N}{|\mu_h^N|} & \text{if } \mu_h^N \ne 0, \\ 0 & \text{else.} \end{cases}$$

From the definition of $\mu_{h,\alpha}^N$ we find

$$\begin{aligned} \left| \int_{\Omega_T} \chi_h(t-h)\nabla\mu_{h,\alpha}^N \zeta \right| &\le C \int_{\Omega_T} |\mu_{h,\alpha}^N||\nabla(\chi_h(t-h)\zeta)| \\ &\le C\alpha \int_{\Omega_T} |\nabla(\chi_h(t-h)\zeta)| \le C\alpha. \end{aligned} \tag{8.12}$$

Since $\alpha(h) \searrow 0$ as $h \searrow 0$, we have for $h \searrow 0$ the convergence

$$\int_{\Omega_T} \chi_h(t-h)\nabla\mu_h^{N,\alpha}\zeta \to \int_{\Omega_T} \chi\nabla\mu^N\zeta,$$

which with (8.12) leads to

$$\int_{\Omega_T} \chi_h(t-h)\nabla\mu_h^N\zeta \to \int_{\Omega_T} \chi\nabla\mu^N\zeta \qquad \text{for } h \searrow 0. \tag{8.13}$$

From the a priori estimates, we can deduce

$$\chi_h(t-h)\nabla\mu_h^N \rightharpoonup \Lambda \qquad \text{in } L^2(0,T;\, L^2(\Omega)),$$

and therefore

$$\int_{\Omega_T} \chi_h(t-h)\nabla\mu_h^N\zeta \to \int_{\Omega_T} \Lambda\zeta \qquad \text{for } h \searrow 0. \tag{8.14}$$

From (8.13) and (8.14) we obtain

$$\int_{\Omega_T} (\chi\nabla\mu^N - \Lambda)\zeta = 0 \qquad \text{for all } \zeta \in C^1([0,T]\times\overline{\Omega};\, \mathbb{R}^3) \text{ with } \zeta = 0 \text{ on } \partial\Omega\times(0,T).$$

Consequently,

$$\chi\nabla\mu^N = \Lambda \qquad \text{for almost every } (x,t) \in \Omega_T.$$

So we have shown that

$$\chi_h(t-h)\nabla\mu_h^N\zeta \rightharpoonup \chi\nabla\mu^N\zeta \qquad \text{in } L^2(0,T;\, L^2(\Omega)) \qquad \text{for } h \searrow 0.$$

Fix an arbitrary $g \in L^2(0,T;\, L^6(\Omega))$. We rewrite the integrand in the form

$$\int_{\Omega_T} \chi_h\nabla\mu_h^N\zeta g = \int_{\Omega_T} (\chi_h - \chi_h(t-h))\nabla\mu_h^N\zeta g + \int_{\Omega_T} \chi_h(t-h)\nabla\mu_h^N\zeta g.$$

With Lemma 7.3 and Hölder's inequality, we can find the estimate

$$\begin{aligned} &\left| \int_{\Omega_T} (\chi_h - \chi_h(t-h))\nabla\mu_h^N\zeta g \right| \\ &\quad \le C\left(\int_{\Omega} |\chi_h - \chi_h(t-h)|\right)^{\frac{2}{3}} \left(\int_{\Omega_T} |\mu_h^N|^2\right)^{\frac{1}{2}} \|g\|_{L^2(0,T;\, L^6(\Omega))} \\ &\quad \le Ch^{\frac{1}{3}}\varepsilon^{-1}\|g\|_{L^2(0,T;\, L^6(\Omega))}. \end{aligned}$$

With assumption (A4) this yields

$$\chi_h\nabla\mu_h^N\zeta \rightharpoonup \chi\nabla\mu^N\zeta \qquad \text{in } L^2(0,T;\, L^{\frac{6}{5}}(\Omega)) \qquad \text{for } h \searrow 0. \tag{8.15}$$

Statements (8.11) and (8.15) combined give

$$\int_{\Omega_T} \chi_h m_h^N \nabla\mu_h^N\zeta \to \int_{\Omega_T} \chi m^N\nabla\mu^N\zeta \qquad \text{for } h \searrow 0.$$

The proof of convergence for the Dirichlet data is analogous. Now we can pass to the limit $h \searrow 0$ in (8.9). □

The following theorem is now a direct consequence of the lemmas shown above.

THEOREM 8.9 (existence of weak solutions). *Let $\Omega \subset \mathbb{R}^3$ be an open bounded set with Lipschitz boundary and let the no-loss-of-area condition* (8.1) *hold. Let $\chi_0 \in BV(\Omega)$, $\mu_0 \in H^{1,2}(\Omega)$. Then there exists (m,μ,χ,v) with*

$$\chi \in L^\infty(0,T;\, BV(\Omega;\, \{0,1\})), \quad \operatorname{supp}\chi(t) \subset\subset \Omega \quad \textit{for all } 0 < t < T,$$

$$v \in L^1(0,T;\, L^1(\Omega;\mathbb{R};|\nabla\chi(t)|)),$$

$$\mu = (\mu^N,\mu^D), \qquad \mu^N \in L^2(0,T;\, H^{1,\frac{3}{2}}(\Omega)), \quad \mu^D \in L^2(0,T;\, H^{1,2}(\Omega)),$$

$$(1-\chi)\mu^N = 0, \quad (1-\chi)\mu^D = (1-\chi)\varphi \qquad \textit{for almost all } (x,t) \in \Omega_T$$

such that (m,μ,χ) is a weak solution in the sense of section 3.

THE BOUNDARY BEHAVIOR OF BLOW-UP SOLUTIONS RELATED TO A STOCHASTIC CONTROL PROBLEM WITH STATE CONSTRAINT*

TOMMASO LEONORI† AND ALESSIO PORRETTA†

Abstract. We consider solutions of the equation $-\Delta u + \lambda u + |\nabla u|^q = f$, which blow up uniformly at the boundary of a smooth domain, that can be interpreted as the value function of a state constraint control problem for a Brownian motion. We prove a complete asymptotic expansion of the gradient at the boundary, giving the precise behavior of normal and tangent components. The result is achieved by proving Lipschitz regularity for $u - S$, where S is an explicit singular corrector term. As the main motivation and application of our result, we characterize the behavior of the singular optimal control law and of the constrained dynamics near the boundary.

Key words. nonlinear elliptic equations, boundary blow-up solutions, asymptotic expansion, state constraint problem for the Brownian motion

1. Introduction.

In this work we study the solutions of the following elliptic equation:

$$-\Delta u + |\nabla u|^q + \lambda u = f(x) \qquad \text{in} \;\; \Omega \tag{1.1}$$

which satisfy the singular boundary condition

$$u(x) \to +\infty \quad \text{as } x \to \partial\Omega, \tag{1.2}$$

where Ω is a bounded smooth subset in $\mathbb{R}^N$, $N \geq 2$. In (1.1), we assume that $1 < q \leq 2$, $\lambda > 0$, and f satisfies suitable regularity conditions.

Let us stress that the condition $1 < q \leq 2$ is necessary in order that solutions satisfying (1.2) exist. Indeed, if $q > 2$, any solution of (1.1) can be proved to be bounded (universally) and Hölder continuous up to the boundary (see [17]); hence, the maximal trace in that case is bounded: This explains why the study of (1.1) for $q > 2$ needs, in general, a completely different approach.

The study of solutions of (1.1)–(1.2) was suggested in a pioneering paper by Lasry and Lions [15] motivated by a state constraint problem for the Brownian motion, which was roughly presented in an intuitive way as the problem of "constraining a Brownian motion in a given domain by controlling its drift." More precisely, given a Brownian motion B_t (on a standard probability space) and a diffusion process X_t which solves the stochastic differential equation

$$\begin{cases} dX_t = a_t dt + dB_t, \\ X_0 = x \in \Omega, \end{cases} \tag{1.3}$$

they considered the problem of finding optimal feedback controls (i.e., controls $a_t = a(X_t)$, where $a \in C(\Omega; \mathbb{R}^N)$) such that X_t never leaves the domain Ω. Clearly, as

explained in [15], a control has to be singular (at $\partial\Omega$) in order to realize a similar state constraint (for a nondegenerate diffusion). The criterion for optimality was given by the cost functional

$$J(x,a) = E\int_0^\infty \left\{ f(X_t) + C_q\,|a(X_t)|^{q'} \right\} e^{-\lambda\, t}dt, \tag{1.4}$$

where E is the expected value, $q' = \frac{q}{q-1}$, $C_q = (q-1)q^{-\frac{q}{q-1}}$, and $e^{-\lambda t}$ is a discount factor. Then the value function

$$u(x) = \inf_{a\in\mathcal{A}} J(x,a), \quad \mathcal{A} = \{a \in C(\Omega) : X_t \in \Omega\, \forall t > 0, \text{a.s.}\} \tag{1.5}$$

was proved to be the maximal solution of (1.1). We note that here there was no restriction on q, but for $q > 1$. Then, in the case $1 < q \le 2$, they proved that u is the unique solution of (1.1)–(1.2) (in the sense that $u \in W^{2,p}_{\rm loc}(\Omega)$ for any $p < \infty$ and satisfies (1.2) uniformly) and moreover that the optimal feedback state control law is given by

$$a(\cdot) = -q|\nabla u(\cdot)|^{q-2}\nabla u(\cdot); \tag{1.6}$$

i.e., $a(X_t)$ is the unique optimal control. Some asymptotic estimates for u were also proved (in [15] and also in [2]) and in particular that

$$\begin{cases} u(x) \sim C^* d(x)^{-\frac{2-q}{q-1}} \quad \text{as} \quad d(x) \to 0 \qquad \text{if } 1 < q < 2, \\ u(x) \sim -\log(d(x)) \quad \text{as} \quad d(x) \to 0 \qquad \text{if } q = 2, \end{cases} \tag{1.7}$$

where, for $x \in \Omega$, $d(x)$ denotes the distance to the boundary of Ω and C^* is a universal constant, precisely $C^* = \frac{(q-1)^{-\frac{2-q}{q-1}}}{2-q}$.

Let us note that the rate of explosion decreases as q gets close to 2, which is consistent with the fact that, when $q > 2$, solutions of (1.1) are bounded. Further results for the case $q > 2$ can be found in [15], although a characterization of the optimal control law such as (1.6) is missing in that case.

Once more, we stress that we will restrict to the range $1 < q \le 2$, when blow-up solutions exist, and moreover, after the results in [15], the unique optimal control $a(X_t)$ is explicitly given through (1.6). In particular, this gives significant motivation for studying the asymptotic behavior of ∇u, which locally determines, near the boundary, the constrained dynamics (1.3). A first estimate in this sense has been proved in [18], using (1.7) and scaling and blow-up arguments, precisely that

$$\lim_{x\to x_0\in\partial\Omega} \quad d(x)^{\frac{1}{q-1}}\nabla u(x) = (q-1)^{-\frac{1}{q-1}}\,\nu(x_0), \tag{1.8}$$

where $\nu(x)$ is the outward unit vector on $\partial\Omega$. Note that $(q-1)^{-\frac{1}{q-1}} = C^*\frac{2-q}{q-1}$, so that (1.8) is the expected "derivation" of (1.7). Moreover, from (1.7) and (1.8) we observe that the first order asymptotic behavior of u and ∇u depends only on q and is described by the one-dimensional solution of the corresponding ODE.

The aim of the present paper is to give a more precise description of the blow-up of ∇u in order both to point out the influence of the geometry of the domain (by looking at second order effects) and to get a complete picture of the local behavior, near the boundary, of the controlled dynamics. In particular, by studying the asymptotic expansion of ∇u, we are able to detail the roles of normal and tangential directions and the influence of the boundary curvature in the behavior of the optimal control law defined in (1.6). To give a rough idea of the main consequence of our results, we are going to prove that the optimal control is tangentially bounded, it blows up pointing in the inward normal direction, and it achieves its maximum in those points (close to the boundary) where the domain has a maximal mean curvature. Actually this proves (as intuition suggests, when a uniform diffusion is constrained) that the control has to be "stronger" where the domain is more curved.

The above-mentioned properties are contained in the following result on the asymptotic behavior of the optimal (feedback state) control law:

$$a(x) = -q|\nabla u(x)|^{q-2}\nabla u(x). \tag{1.9}$$

Notation. Let us stress that from now on we will denote by $d(x)$ (often simply d) a positive smooth function such that $d(x) \equiv \mathrm{dist}(x, \partial\Omega)$ in a suitable inner neighborhood of $\partial\Omega$. Moreover, we will indicate by $\nu(x) = -\nabla d(x)$ (hence $\nu(x)$ is the outward unit normal vector if $x \in \partial\Omega$) and by $\tau(x)$ any unit vector field at x which satisfies $\tau(x) \cdot \nu(x) = 0$.

Observe that, since Ω will be assumed to be at least of class C^2, any $x \in \Omega$ lying in a sufficiently small neighborhood of the boundary admits a unique projection onto $\partial\Omega$, denoted as $\overline{x} = Proj_{\partial\Omega}(x)$. Moreover, for $\varsigma \in \partial\Omega$, we denote by $H(\varsigma)$ the mean curvature of $\partial\Omega$ computed at ς.

Finally, we write $f(x) = O(g(x))$ in order to say that $|f(x)| \le C\,|g(x)|$ in Ω.

THEOREM 1.1. *Let Ω be a smooth bounded open subset of $\mathbb{R}^N$, and let $H(\overline{x})$ be the mean curvature of $\partial\Omega$ computed at $\overline{x}$, where $\overline{x}$ is the projection of x on $\partial\Omega$.*

Let $f \in W^{1,\infty}(\Omega)$, let u be the unique solution of (1.1)–(1.2) *and $a(x)$ be the optimal control law* (1.9). *Then for any $1 < q < 2$ we have, as $d(x) \to 0$,*

$$a(x) = -\frac{q'}{d(x)}\nu(x) - \frac{q'(N-1)}{2}H(\overline{x})\nu(x) + \eta(x), \tag{1.10}$$

where $\eta(x)$ is such that

$$|\eta(x)| = \begin{cases} O(d^{\frac{2-q}{q-1}}(x)) & \text{if } \ \frac{3}{2} < q < 2, \\ O(d(x)\log d(x)) & \text{if } \ q = \frac{3}{2}, \\ O(d(x)) & \text{if } \ 1 < q < \frac{3}{2}. \end{cases}$$

If $q = 2$, we have, as $d(x) \to 0$,

$$a(x) = -\frac{2}{d(x)}\nu(x) - (N-1)[H(\overline{x}) + o(1)]\nu(x) + \psi(x)\tau(x), \tag{1.11}$$

where $\tau(x) \in \mathbb{R}^N$, $|\tau| = 1$, $\tau \cdot \nu = 0$, and $\psi \in L^\infty(\Omega)$.

To our knowledge, such characterization of the behavior of singular feedback controls related to (1.3)–(1.5) is new in the literature. Actually, similar state constraint problems have been considered in previous works mainly in the case of degenerate diffusions and bounded controls and for a bounded value function (see also, e.g., [7], [6], [13], [14], and references therein), while the case of nondegenerate diffusions and a singular value function seems not to have been developed since the reference work [15].

The results in Theorem 1.1 are the main consequence of our study of second order terms in the asymptotics of the gradient of solutions of (1.1)–(1.2). Note that the estimate (1.8) already implies that $\frac{\partial u(x)}{\partial \tau} = o(\frac{\partial u(x)}{\partial \nu})$ as $d(x) \to 0$, and hence that tangential effects are of lower order. Actually we improve that estimate by proving the following.

THEOREM 1.2. *Let Ω be a smooth bounded open subset of $\mathbb{R}^N$ and $f \in W^{1,\infty}(\Omega)$, and let u be the unique solution of* (1.1)–(1.2). *Then we have, as $d(x) \to 0$, (with the above notations):*

$$\frac{\partial u(x)}{\partial \nu} = \frac{(q-1)^{-\frac{1}{q-1}}}{d(x)^{\frac{1}{q-1}}} \left[1 + \frac{(N-1)H(\overline{x})}{2} d(x) + o(d(x))\right] \qquad \forall\, 1 < q \leq 2, \tag{1.12}$$

and

$$\begin{cases} \frac{\partial u(x)}{\partial \tau} \in L^\infty(\Omega) & \text{if } \frac{3}{2} < q \leq 2, \\ \frac{\partial u(x)}{\partial \tau} = O\left(|\log d|\right) & \text{if } q = \frac{3}{2}, \\ \frac{\partial u(x)}{\partial \tau} = O\left(d^{\frac{2q-3}{q-1}}\right) & \text{if } 1 < q < \frac{3}{2}. \end{cases} \tag{1.13}$$

Note that if $q \leq \frac{3}{2}$ one has that $\frac{\partial u}{\partial \tau}$ blows up, but the optimal control law (1.9), which is the only relevant quantity for the dynamics, always remains tangentially bounded. Actually, the precise behavior of the tangential gradient represents a significant improvement with respect to the estimate (1.8) and, together with the second order terms of normal gradient, allows one to regard the dyamics near the boundary as

$$\begin{cases} dX_t = V(X_t)dt + dB_t, \\ X_0 = x \in \Omega, \end{cases}$$

where $V(x) = -[\frac{q'}{d(x)} + \frac{q'(N-1)}{2} H(\overline{x})]\nu(x)$ (here $q < 2$). Note that this corresponds to a linearization of (1.1), and the behavior of the process can then be described explicitly. In particular, observe how the drift acts differently on points which have the same distance to the boundary but different curvatures.

Let us point out that curvature effects in the boundary blow-up of solutions of elliptic equations were already observed previously in the case of semilinear equations with absorption zeroth order terms. In that context, it was recently proved in [10], [4] (see also references therein) how second order terms in the blow-up of u precisely depend on the mean curvature of the boundary. These results, which also motivated our work, are obtained through a refined construction of sub- and supersolutions. However, in the context of solutions of (1.1)–(1.2), the main local features of the blow-up are observed in the asymptotic behavior of ∇u, which cannot be studied using only comparison functions. Therefore, in some sense our results extend those proved in a different context in [10], [4], although we use a completely different method. Indeed, our estimates on ∇u in (1.12)–(1.13) are not derived by some asymptotic estimate on u, as was the case, for instance, for (1.8), which is proved in [18] using (1.7) and a scaling argument. A similar technique based on second order estimates for u is not possible here unless it is restricted to a smaller range of values of q (see section 3.2 for more details). We develop instead a totally different approach which, through a regularity result for solutions of (1.1)–(1.2), directly leads to a complete asymptotic expansion of ∇u as a vector field.

More precisely, we introduce as a corrector term the formal asymptotic expansion $S = d(x)^{-\frac{2-q}{q-1}} \sum_{k=0}^{m} \sigma_k d(x)^k$ (note that u rescales like $d(x)^{-\frac{2-q}{q-1}}$ from (1.7); this is for $q < 2$), and we prove that $u - S$ is Lipschitz in Ω, up to a suitable (unique and explicit) choice of the coefficients σ_k. As a consequence, we obtain all singular terms in the asymptotic expansion of ∇u. In order to give a proper statement of this result, which is the main content of the article, we denote by α the following number:

$$\alpha = \frac{2-q}{q-1}, \tag{1.14}$$

and we observe that

$$\begin{cases} \alpha = 0 & \iff \quad q = 2\,, \\ 0 < \alpha < 1 & \iff \quad \frac{3}{2} < q < 2, \\ \alpha \geq 1 & \iff \quad 1 < q \leq \frac{3}{2}. \end{cases}$$

THEOREM 1.3. *Let $1 < q \leq 2$ and $u(x)$ be the solution of* (1.1)–(1.2). *Assume that $\partial\Omega \in C^r$, $r = [\alpha] + 5$, and $f(x)$ is a $W^{1,\infty}(\Omega)$ function. Then there exist smooth functions $\sigma_0, \sigma_1, \ldots, \sigma_{[\alpha]+1}$, which can be explicitly determined, such that setting*

$$\begin{cases} S = \sum_{k=0}^{[\alpha]+1} \sigma_k d^{k-\alpha} & \text{if } \alpha \notin \mathbb{N}, \\ S = \sum_{k=0}^{\alpha-1} \sigma_k d^{k-\alpha} + \sigma_\alpha \log d + \sigma_{\alpha+1} d \log d & \text{if } \alpha \in \mathbb{N},\ \alpha \geq 1, \\ S = -\log d & \text{if } \alpha = 0, \end{cases} \tag{1.15}$$

we have

$$u - S \in W^{1,\infty}(\Omega).$$

As a consequence, we have for any $\alpha > 0$:

- *if $\alpha \notin \mathbb{N}$:*

$$\begin{cases} \frac{\partial u(x)}{\partial \nu} - \frac{\alpha C^*}{d^{\alpha+1}} + \sum_{k=1}^{[\alpha]+1} \left[\frac{(k-\alpha)\sigma_k(x)}{d^{\alpha-k+1}(x)} - \frac{\nabla \sigma_{k-1}(x)\cdot\nu}{d^{\alpha-k+1}(x)} \right] \in L^\infty(\Omega), \\ \frac{\partial u(x)}{\partial \tau} - \sum_{k=1}^{[\alpha]} \frac{\nabla\sigma_k(x)\cdot\tau}{d^{\alpha-k}} \in L^\infty(\Omega); \end{cases} \tag{1.16}$$

- *if $\alpha \in \mathbb{N}$:*

$$\begin{cases} \frac{\partial u(x)}{\partial \nu} - \frac{\alpha C^*}{d^{\alpha+1}} + \sum_{k=1}^{\alpha-1} \left[\frac{(k-\alpha)\sigma_k(x)}{d^{\alpha-k+1}(x)} - \frac{\nabla \sigma_{k-1}(x)\cdot\nu}{d^{\alpha-k+1}(x)} \right] + \frac{(\sigma_\alpha - \nabla\sigma_{\alpha-1}\cdot\nu)}{d(x)} \in L^\infty(\Omega), \\ \frac{\partial u(x)}{\partial \tau} - \sum_{k=1}^{\alpha-1} \frac{\nabla\sigma_k(x)\cdot\tau}{d^{\alpha-k}} - (\nabla\sigma_\alpha\cdot\tau)\log d(x) \in L^\infty(\Omega). \end{cases} \tag{1.17}$$

[Let us observe, with respect to the above statement, that, due to (1.14), one has $\alpha \in \mathbb{N} \iff \frac{q}{q-1} \in \mathbb{N}$; i.e., the case $\alpha \in \mathbb{N}$ corresponds to having a cost of integer power type in the functional (1.4).]

The proof of Theorem 1.3 will be given in section 2, consisting of two main ideas. The first one is to look at the equation satisfied by the function $z = u - S$, keeping in mind the first estimate (1.8). Indeed, thanks to (1.8) we have that, near the boundary, $|\nabla z| = o(|\nabla S|)$, which suggests us to write the equation of z as

$$-\Delta z + \lambda z + |\nabla z + \nabla S|^q - |\nabla S|^q = f + F,$$

where $F = \Delta S - \lambda S - |\nabla S|^q$. Here we can prove that $|\nabla z + \nabla S|^q - |\nabla S|^q$ behaves similarly as $q|\nabla S|^q \nabla z \cdot \frac{\nabla S}{|\nabla S|^2} \sim -C\frac{\nabla z \cdot \nabla d}{d}$, so that the left-hand side is a singular but regularizing operator with respect to z. Second, choosing the coefficients of S in a way that F is smooth, we obtain gradient estimates depending only on the regularity of f. These gradient estimates, which are the crucial point in our proof, are obtained by using the classical Bernstein method (see [8]) largely developed by Serrin and Lions (see, e.g., [19], [17], [16], [5]), although we use here a slightly different approach which is more adapted to our situation. Last but not least, we are interested in getting global estimates for the gradients in the whole of Ω and not merely local interior estimates. Following ideas in [17], [16], we make it possible by working with a Neumann-type condition at the boundary. Thus we introduce a regular approximation u_n of the solution u of (1.1)–(1.2), constructed through the following Neumann-type problems:

$$\begin{cases} -\Delta u_n + \lambda u_n + |\nabla u_n|^q = f_n & \text{in } \Omega, \\ \dfrac{\partial u_n}{\partial \nu} = \dfrac{\partial S_n}{\partial \nu} & \text{on } \partial\Omega, \end{cases}$$

where $S_n = \sum_{k=0}^{m} \sigma_k (d(x)+\frac{1}{n})^{k-\alpha}$ (which, for n fixed, is not singular). Here we prove a uniform (in n) version of the preliminary estimates (1.7) and (1.8), and then we prove the Bernstein-type estimates on $z_n = u_n - S_n$, obtaining the Lipschitz regularity claimed in Theorem 1.3.

Note that the results of Theorems 1.1 and 1.2 immediately follow from (1.16)–(1.17) by computing σ_0 and σ_1 (in particular, one has $\sigma_0 = C^*$). Only in the case where $q = 2$ we need more information in order to get (1.12) (and then (1.11)), which will be proved with a simple blow-up argument. In fact, we will show that the normal derivative of $u - S$ tends to zero on the boundary, refining the result in Theorem 1.3.

Finally, let us point out that the regularity condition on f in Theorem 1.3 (and consequently in Theorems 1.1–1.2) can be highly weakened, thanks to our approach to Bernstein's estimates. This will be detailed in section 3, where we prove an extended version of Theorem 1.3 in the case of f singular at the boundary (see Theorem 3.2) as well as an intermediate result (such as Hölder-type regularity for $u - S$) in cases where the singularity of f does not allow $u - S$ to be Lipschitz.

2. Proof of Theorem 1.3.

In order to simplify some expressions, we set $\lambda = 1$ in (1.1); in fact, our results are not really affected by changing the values of λ (see also Remark 2.8).

2.1. The case $1 < q < 2$: Preliminary results.

Let us introduce some notations: For $1 < q < 2$ we set

$$\alpha = \frac{2-q}{q-1} \quad \text{and} \quad C^* = \frac{(q-1)^{-\alpha}}{2-q}, \tag{2.1}$$

and we will often use the following properties of α and C^*:

$$q(\alpha+1) = \alpha + 2 \quad \text{and} \quad (\alpha C^*)^q = \alpha(\alpha+1)C^*. \tag{2.2}$$

Moreover from now on we denote

$$d_n(x) = d(x) + \frac{1}{n},$$

and we will indicate by C various constants (independent on n) whose value may vary from line to line. Finally, we will write $f(x) = O(g(x))$ in order to say that $|f(x)| \leq C\,|g(x)|$ in Ω.

Since we need a suitable smooth approximation of the solution of (1.1)– (1.2), we will consider the sequence $\{u_n\}$ of solutions of the Neumann problem:

$$\begin{cases} -\Delta u_n + u_n + |\nabla u_n|^q = f_n(x) & \text{in}\,\Omega, \\ \dfrac{\partial u_n}{\partial \nu} = \dfrac{\partial S_n}{\partial \nu} & \text{on}\,\partial\Omega, \end{cases} \tag{2.3}$$

where f_n is a suitable regular approximation of f and

$$S_n = C^* d_n(x)^{-\alpha} + \psi(x) d_n(x)^{1-\alpha},$$

with $\psi(x)$ smooth (to be precised later).

Observe that, for fixed n, f_n and S_n being smooth, the existence of a classical solution $u_n \in C^2(\overline{\Omega})$ is a standard result (see, e.g., [16]). The goal of this subsection is to prove the following preliminary result.

Proposition 2.1. *Let u_n be a solution of* (2.3)*, with $1 < q < 2$. Assume that $f_n = O(d_n^{-\alpha-1})$, $|\nabla f_n| \leq C\, d_n^{-\alpha-2}$, and $S_n = C^* d_n^{-\alpha} + \psi(x) d_n^{1-\alpha}$, with $\psi(x)$ smooth. Then we have*

$$|\nabla u_n| \leq C d_n^{-\alpha-1} \qquad \textit{in } \Omega, \tag{2.4}$$

and

$$\lim_{d_n(x)\to 0} |d_n^{\alpha+1}(x) \nabla u_n(x) - \alpha C^* \nu(x)| = 0. \tag{2.5}$$

Note that, since $d_n(x) = d(x) + \frac{1}{n}$, the limit as $d_n(x) \to 0$ means that both n tends to ∞ and $d(x) \to 0$, as a two-variable limit.

The proof of Proposition 2.1 will be achieved through the following lemmas, which contain first order (uniform) estimates for u_n of the same kind as (1.7) and (1.8) proved in [15] and in [18], respectively.

Lemma 2.2. *Let u_n be a solution of* (2.3)*. Then there exists $C > 0$ such that:*

- *for* $0 < \alpha < 1$

$$|u_n - C^* d_n^{-\alpha}| \leq C, \tag{2.6}$$

- *for* $\alpha = 1$

$$\left| u_n - \frac{C^*}{d_n} \right| \leq C \left| \log d_n \right|, \tag{2.7}$$

- *for* $\alpha > 1$,

$$|u_n - C^* d_n^{-\alpha}| \leq C d_n^{1-\alpha}, \tag{2.8}$$

where α and C^* have been defined in (2.1).

Proof. Let us first consider $0 < \alpha < 1$ and

$$\overline{\psi}_n(x) = C^* d_n^{-\alpha} - M_0 d_n^{1-\alpha} + M_1,$$

where $M_0,\ M_1 > 0$. We have

$$
\begin{aligned}
&-\Delta\overline{\psi}_n + |\nabla\overline{\psi}_n|^q + \overline{\psi}_n - f_n(x) \\
&= -\alpha(\alpha+1)C^* d_n^{-\alpha-2} + \Delta d\alpha C^* d_n^{-\alpha-1} - \alpha M_0(1-\alpha)d_n^{-\alpha-1} + M_0(1-\alpha)d_n^{-\alpha} \\
&\quad + (\alpha C^*)^q d_n^{-q(\alpha+1)}\left|1 + \frac{M_0(1-\alpha)}{\alpha C^*}d_n\right|^q + C^* d_n^{-\alpha} - M_0 d_n^{1-\alpha} + M_1 - f_n(x).
\end{aligned}
$$

Thus, using (2.1)–(2.2), after standard computations (here we use that, in a neighborhood of $t = 0$, $(1+t)^q = 1 + qt + O(t^2)$) we find

(2.9)
$$
-\Delta\overline{\psi}_n + |\nabla\overline{\psi}_n|^q + \overline{\psi}_n - f_n(x) \geq \left[2M_0(1-\alpha) + \alpha C^*\Delta d\right] d_n^{-\alpha-1} - f_n(x) + O(d_n^{-\alpha}) + M_1.
$$

Moreover

$$
\frac{\partial\overline{\psi}_n}{\partial\nu} = \alpha C^* n^{\alpha+1} + (1-\alpha)M_0 n^{\alpha} \quad \text{on } \partial\Omega. \tag{2.10}
$$

Hence, by choosing M_0 and M_1 large enough we get that the right-hand side of (2.9) is positive and, by (2.10), $\partial_\nu\overline{\psi}_n \geq \partial_\nu S_n$ on $\partial\Omega$, so that $\overline{\psi_n}(x)$ turns out to be a supersolution for (2.3).

Similarly, arguing as above, there exist $M_2,\ M_3 > 0$ such that

$$
\underline{\psi}_n(x) = C^* d_n^{-\alpha} + M_2 d_n^{1-\alpha} - M_3
$$

is a subsolution for (2.3). Hence by the maximum principle we deduce that

$$
\underline{\psi}_n(x) \leq u_n(x) \leq \overline{\psi}_n(x),
$$

so that (2.6) holds true.

In the same way we prove estimates (2.7) and (2.8) by choosing, respectively,

$$
\overline{\psi}_n(x) = \frac{4}{d_n} - M_0\log d_n + M_1, \qquad \underline{\psi}_n(x) = \frac{4}{d_n} + M_2\log d_n - M_3, \quad \text{if } \alpha = 1,
$$

and

$$
\overline{\psi}_n(x) = C^* d_n^{-\alpha} + M_0 d_n^{1-\alpha} + M_1, \qquad \underline{\psi}_n(x) = C^* d_n^{-\alpha} - M_2 d_n^{1-\alpha} - M_3, \quad \text{if } \alpha > 1,
$$

where $M_i > 0$ are large enough, for $i = 0, 1, 2, 3$. □

Remark 2.3. Let us note that (2.6), (2.7), and (2.8) imply

$$
\lim_{d_n(x)\to 0} |d_n^{\alpha}(x)u_n(x) - C^*| = 0. \tag{2.11}
$$

We will often use this weaker result later. We also remark that in order to obtain (2.11) it is enough to ask that $f_n = O(d_n^{-\gamma})$, with $\gamma < \alpha + 2$. The proof is similar but for a different choice of the sub and supersolutions; for instance, it is enough to choose $\overline{\psi_n}(x) = C^* d_n(x)^{-\alpha} + \rho_n(x)$, where $\rho_n(x) = O(d_n(x)^{2-\gamma})$.

The next lemma will be very useful in getting global Bernstein-type estimates, as, for instance, in [17], [16]. Indeed it allows us to get information about the normal derivative of a weighted power of the gradient of a solution of (2.3). Observe that the homogeneous Neumann condition is crucial in order to prove such a result.

LEMMA 2.4. *Let η be a smooth (say, $C^2(\overline{\Omega})$) function such that*

$$\frac{\partial \eta}{\partial \nu} = 0 \quad on \ \ \partial\Omega,$$

and let $\Phi(s) \in C^1(0,a)$, $a > 0$, be a positive increasing function such that,

$$\forall 0 < s < a, \qquad \Phi'(s) - C_0\Phi(s) > 0, \tag{2.12}$$

where $C_0 = 2\|D^2 d\|_\infty$. Then

$$\frac{\partial}{\partial \nu}\Big[|\nabla \eta|^2 \Phi(d)\Big] \le 0 \quad on\ \partial\Omega. \tag{2.13}$$

Remark 2.5. Let us observe that both $\Phi(s) = s^\beta$ and $\Phi(s) = e^{\theta(s)}$ satisfy condition (2.12) for any $\beta > 0$ and for any increasing $\theta(s)$ such that $\theta(0) = 0$ and $\theta'(0) > C_0$, respectively. Moreover, we remark that if $\Phi(s)$ satisfies (2.12), the same is true for $\Phi(s + \frac{1}{n})$ if n is large enough.

Proof. Let us compute

$$\frac{\partial |\nabla \eta|^2 \Phi(d)}{\partial \nu} = -\Phi'(d)|\nabla \eta|^2 + 2\Phi(d)\,(D^2\eta\,\nabla\eta\,\nu)\,;$$

since η satisfies the homogeneous Neumann boundary condition, there exists $\mu(x)$ such that on $\partial\Omega$ we have

$$\mu\nu = D(\nabla\eta\cdot\nu) = D^2\eta\ \nu + D\nu\nabla\eta.$$

Thus using again the boundary condition $\frac{\partial \eta}{\partial \nu} = 0$ and since $D\nu = -D^2 d$, we get

$$\frac{\partial |\nabla \eta|^2 \Phi(d)}{\partial \nu} = -\Phi'(d)|\nabla \eta|^2 + 2\Phi(d) D^2 d\,\nabla\eta\,\nabla\eta \le |\nabla\eta|^2\Big[2\Phi(d)\|D^2 d\|_\infty - \Phi'(d)\Big],$$

and by (2.12) we deduce (2.13). ∎

Here we prove a first estimate on the gradient of the solution of the problem (a suitable translation of (2.3)):

$$\begin{cases} -\Delta z_n + z_n + |\nabla z_n + G_n|^q = F_n & \text{in } \Omega, \\ \dfrac{\partial z_n}{\partial \nu} = 0 & \text{on } \partial\Omega. \end{cases} \tag{2.14}$$

LEMMA 2.6. *Let $z_n \in C^2(\overline{\Omega})$ be a solution of* (2.14), *where G_n and F_n are a vector field and a function, respectively, such that*

$$|G_n| \le C d_n^{-\alpha-1}, \quad |DG_n| \le C d_n^{-\alpha-2}, \quad |F_n| \le C d_n^{-\alpha-2}, \quad |\nabla F_n| \le C d_n^{-\alpha-3}. \tag{2.15}$$

Then we have

$$|\nabla z_n| \le C d_n^{-\alpha-1}. \tag{2.16}$$

Proof. Observe first that the maximum principle and the assumptions on F_n and G_n imply $|z_n| \le C\, d_n^{-\alpha-2}$. Let us define $w_n = |\nabla z_n|^2 e^{\theta d_n}$, where θ is a positive number. By Lemma 2.4 we have, for θ and n large enough,

$$\frac{\partial w_n}{\partial \nu} \le 0 \quad \text{on}\,\partial\Omega. \tag{2.17}$$

On the other hand,

$$\Delta w_n = \theta^2 w_n + \theta \Delta d w_n + 2\theta \nabla w_n \cdot \nabla d - 2\theta^2 w_n + 2e^{\theta d_n}\left[\nabla \Delta z_n \cdot \nabla z_n + |D^2 z_n|^2\right],$$

and so, since by the Cauchy–Schwarz inequality

$$|D^2 z_n|^2 \geq \frac{1}{N}(\Delta z_n)^2,$$

we have, recalling that $\Delta z_n = z_n + |\nabla z_n + G_n|^q - F_n$,
(2.18)

$$\begin{aligned}\Delta w_n \geq (-\theta^2 + \theta\Delta d) w_n + 2\theta \nabla w_n \cdot \nabla d + 2e^{\theta d_n}\Bigg[\frac{1}{N}\left(|\nabla z_n + G_n|^q + z_n - F_n\right)^2 \\ + q\nabla z_n \cdot (D^2 z_n + DG_n)\frac{\nabla z_n + G_n}{|\nabla z_n + G_n|^{2-q}} - \nabla F_n \cdot \nabla z_n + |\nabla z_n|^2\Bigg].\end{aligned}$$

Since $|z_n| \leq C\, d_n^{-\alpha-2}$, we have

$$\frac{1}{N}\left(|\nabla z_n + G_n|^q + z_n - F_n\right)^2 \geq c_N |\nabla z_n + G_n|^{2q} - C\, d_n^{-2(\alpha+2)} - |F_n|^2.$$

Moreover, the Young inequality with exponents $(\frac{2q}{q-1}, \frac{2q}{q+1})$ implies

$$\left|\frac{\nabla z_n + G_n}{|\nabla z_n + G_n|^{2-q}} \cdot \Big(D^2 z_n + DG_n\Big)\nabla z_n\right|$$

$$\leq \frac{c_N}{2q}|\nabla z_n + G_n|^{2q} + C\left|\frac{1}{2}\nabla|\nabla z_n|^2 + DG_n \nabla z_n\right|^{\frac{2q}{q+1}},$$

and similarly, for all $\delta > 0$, we have

$$|\nabla F_n \cdot \nabla z_n| \leq \delta |\nabla z_n|^{2q} + \frac{C}{\delta^{\frac{1}{2q-1}}}|\nabla F_n|^{\frac{2q}{2q-1}}.$$

Thus we get from (2.18)

$$\begin{aligned}-\Delta w_n + c_N e^{\theta d_n}|\nabla z_n + G_n|^{2q} \leq (\theta^2 - 2 - \theta\Delta d) w_n \\ - 2\theta \nabla w_n \cdot \nabla d + 2e^{\theta d_n}\Bigg[\delta|\nabla z_n|^{2q} + \frac{C}{\delta^{\frac{1}{2q-1}}}|\nabla F_n|^{\frac{2q}{2q-1}} \\ + C\left|\frac{1}{2}\nabla|\nabla z_n|^2 + DG_n\nabla z_n\right|^{\frac{2q}{q+1}} + C\, d_n^{-2(\alpha+2)} + |F_n|^2\Bigg].\end{aligned} \tag{2.19}$$

Let us note that, since $\frac{2q}{q+1} > 1$ ($q > 1$) and $\nabla|\nabla z_n|^2 = e^{-\theta d_n}(\nabla w_n - \theta w_n \nabla d)$, we have

(2.20)
$$\left|\frac{1}{2}\nabla|\nabla z_n|^2 + DG_n\nabla z_n\right|^{\frac{2q}{q+1}} \le \tilde{C}\left[|\nabla w_n|^{\frac{2q}{q+1}} + |w_n|^{\frac{2q}{q+1}} + \Big(|DG_n||\nabla z_n|\Big)^{\frac{2q}{q+1}}\right]$$
$$\le \tilde{C}\left[|\nabla w_n|^{\frac{2q}{q+1}} + |w_n|^{\frac{2q}{q+1}}\right] + \eta|\nabla z_n|^{2q} + C\eta^{-\frac{1}{q}}|DG_n|^2,$$

where η is any positive constant. Using that, by convexity,

$$|\nabla z_n + G_n|^{2q} \ge \frac{1}{2^{2q-1}}|\nabla z_n|^{2q} - |G_n|^{2q},$$

we deduce from (2.19) and (2.20), choosing δ and η small enough:

$$-\Delta w_n + \tilde{C}_N|\nabla z_n|^{2q} \le w_n(\theta^2 - 2 - \theta\Delta d) - 2\theta\nabla w_n\cdot\nabla d + Ce^{\theta d_n}\Big[|\nabla F_n|^{\frac{2q}{2q-1}}$$
$$+ |\nabla w_n|^{\frac{2q}{q+1}} + w_n^{\frac{2q}{q+1}} + |DG_n|^2 + |G_n|^{2q} + C\, d_n^{-2(\alpha+2)} + |F_n|^2\Big].$$

Finally, since $\frac{2q}{q+1} < q$, using the Young inequality and that $1 \le e^{\theta d_n} \le C_\Omega$, we conclude that there exists $\tau > 0$ and constants C_0, $C_1 > 0$ such that

$$-\Delta w_n + \tau w_n^q - C_0|\nabla w_n|^{\frac{2q}{q+1}} \le C_1\left(|\nabla F_n|^{\frac{2q}{2q-1}} + |DG_n|^2 + |G_n|^{2q} + |F_n|^2 + d_n^{-2(\alpha+2)}\right).$$

The above inequality and (2.17) say that w_n is a subsolution for the problem

$$\begin{cases} -\Delta\psi + \tau\psi^q - C_0|\nabla\psi|^{\frac{2q}{q+1}} = \tilde{F}_n & \text{in } \Omega,\\ \dfrac{\partial\psi}{\partial\nu} = 0 & \text{on } \partial\Omega,\end{cases}$$

where

$$\tilde{F}_n = C_1\left(|\nabla F_n|^{\frac{2q}{2q-1}} + |DG_n|^2 + |G_n|^{2q} + |F_n|^2 + d_n^{-2(\alpha+2)}\right).$$

Let us note that from (2.15), using that

$$\frac{2q}{2q-1}(\alpha+3) = 2q(\alpha+1) = 2(\alpha+2), \tag{2.21}$$

we obtain that $|\tilde{F}_n| \le C_F d_n^{-2(\alpha+2)}$. In order to prove (2.16), let us prove that $\varphi = t d_n^{-2(\alpha+1)}$ is a supersolution for large $t \in \mathbb{R}^+$. First let us observe that $\frac{\partial\varphi}{\partial\nu} \ge 0$; moreover

$$-\Delta\varphi + \tau\varphi^q - C_0|\nabla\varphi|^{\frac{2q}{q+1}}$$
$$= -t(2\alpha+2)(2\alpha+3)d_n^{-2(\alpha+2)} + t(2\alpha+2)d_n^{-2\alpha-3}\Delta d + \tau t^q d_n^{-2q(\alpha+1)} - C_0 t^{\frac{2q}{q+1}} d_n^{-\frac{2q}{q+1}(2\alpha+3)},$$

and using (2.21), recalling once again that $q > \frac{2q}{q+1}$, we have, for t large,

$$-\Delta\varphi + \tau\varphi^q - C_0|\nabla\varphi|^{\frac{2q}{q+1}} - C_F d_n^{-2(\alpha+2)} \ge \frac{1}{2}t^q d_n^{-2(\alpha+2)} - C_F d_n^{-2(\alpha+2)} - C.$$

Thus there exists $t^* > 0$ such that the right-hand side of the previous inequality is positive and the maximum principle lets us conclude that $w_n \leq \varphi$ and finally (2.16). ◻

Our next step consists in a refinement of (2.16) which sounds like the asymptotic estimate (1.8) proved in [18], though here we need a uniform estimate with respect to n as well. We will use for this purpose a scaling and blow-up argument for which we need a suitable localization near the boundary. Let us denote $\Sigma = \partial\Omega$ and

$$\Omega_\rho = \{x \in \Omega \ : \ d(x) < \rho\} \ .$$

Given a generic point on $\partial\Omega$, let us denote by $(\sigma_1, \ldots, \sigma_{N-1})$ its coordinates in some local chart and by $\overline{x}(\sigma)$ its representation in Cartesian coordinates. It is well known (see, e.g., [12]) that if Ω is of class C^k, $k > 1$, then there exists a positive number ρ such that any point x in Ω_ρ can be represented as

$$x = \delta\hat{n} + \overline{x},$$

where $\overline{x}$ is the projection of x onto $\partial\Omega$, $\hat{n}$ is the inward normal computed at $\overline{x}$, and $\delta = d(x)$ =dist$(x, \partial\Omega)$. Since $\overline{x}$ and $\hat{n}$ are functions of σ, we have $x = \delta\hat{n}(\sigma) + \overline{x}(\sigma)$, and the mapping $x \to (\delta, \sigma)$ is a C^{k-1} diffeomorphism of Ω_ρ onto $(0, \rho) \times U$, where $U \subset \mathbb{R}^{N-1}$ is an open set. If we denote by $T(x)$ this mapping, in the new coordinates (δ, σ) the Laplace operator takes the form

$$\Delta_x = \frac{1}{|\det(DT^{-1})|} \ \mathrm{div}_{\ \delta,\sigma} \left(A(\delta, \sigma)\nabla_{\delta,\sigma}\right), \tag{2.22}$$

where $A(\delta, \sigma) = (a_{ij})$ is defined by $a_{ij} = |\det(DT^{-1})| \, \nabla T_i \cdot \nabla T_j$ (see, e.g., [9]). However, since $\nabla d(x) \cdot \nabla\sigma_j(x) = 0$ for any $j = 1, \ldots, N-1$ (the projection of x is invariant along the normal), then we have $a_{1i} = a_{i1} = 0$ for $i = 2, \ldots, N$, while $a_{11} = |\nabla d(x)|^2$ and $a_{ij} = \nabla\sigma_{i-1} \cdot \nabla\sigma_{j-1}$ for $i, j = 2, \ldots, N$. Let us note that A has regular coefficients since Ω is smooth, and moreover A is uniformly elliptic. In order to fix the ideas, we may consider that the curve Σ is locally the graph of a smooth function f and hence that $\overline{x}(\sigma) = (\sigma, f(\sigma))$, $f : U \subset \mathbb{R}^{N-1} \mapsto \mathbb{R}$. In that case one explicitly computes $|\det(DT^{-1})| = \sqrt{1 + |\nabla f|^2} + O(\delta)$, which shows that the map T and T^{-1} are nondegenerate and yields the ellipticity of A (in a neighborhood of the boundary).

In the next lemma, we are going to use such a local change of coordinates $x \mapsto (\delta, \sigma)$ in order to straighten the boundary: The main advantage is that the matrix $A(\delta, \sigma)$ has zeros in the first row and column but for the term a_{11}. The reader familiar with differential geometry will also recognize in (2.22) the form of the Laplacian in curvilinear coordinates, since it can be rewritten as

$$\Delta_x = \frac{1}{\sqrt{g}} \frac{\partial}{\partial\delta} \left(\sqrt{g} \frac{\partial}{\partial\delta}\right) + \frac{1}{\sqrt{g}} \sum_{i=1}^{N-1} \frac{\partial}{\partial\sigma_i} \left(\sqrt{g}\, g^{ij} \frac{\partial}{\partial\sigma_j}\right), \tag{2.23}$$

where the last part, when $\delta = 0$, is nothing but the Laplace–Beltrami operator. Let us recall (see also [12]) that (2.23) may be used to compute the mean curvature at a given point $x_0 \in \partial\Omega$ in terms of the distance function. Indeed, by choosing σ_i as the principal directions at x_0 (hence the matrix A is diagonal at x_0), one can verify that

$$\Delta d\,|_{\partial\Omega} = -(N-1)H(\sigma), \tag{2.24}$$

where we indicate by $H(\sigma)$ the mean curvature of Σ at σ.

LEMMA 2.7. *Let* $z_n \in C^2(\overline{\Omega})$ *be a solution of* (2.14) *such that*

$$\lim_{d_n(x)\to 0} z_n(x)d_n^{\alpha}(x) = 0. \tag{2.25}$$

Assume moreover that (2.15) *holds true. Then*

$$\lim_{d_n(x)\to 0} d_n^{\alpha+1}(x)|\nabla z_n(x)| = 0. \tag{2.26}$$

Proof. We argue by contradiction: Let us suppose that there exists $\overline{\varepsilon}$ and a sequence $x_j \in \Omega$ such that $d(x_j) + \frac{1}{n_j} < \frac{1}{j}$ and

$$d_{n_j}^{\alpha+1}(x_j)|\nabla z_{n_j}(x_j)| > \overline{\varepsilon}. \tag{2.27}$$

Let us denote $\delta_j = d(x_j)$; we can extract a subsequence j_k such that $x_{j_k} \to x_0 \in \partial\Omega$ and

$$\frac{1}{1+\delta_{j_k} n_{j_k}} \to l \in [0,1]. \tag{2.28}$$

We localize then around x_0 using the system of local coordinates introduced above: In a neighborhood J of x_0 (with $\{x_j\} \subset J\cap\Omega$) we define a map $T : J\cap\Omega \to (0,\rho_0)\times U$ for some $\rho_0 > 0$, $U \subset \mathbb{R}^{N-1}$ such that, if $y = (y_1, y') = T(x)$, we have $y_1 = d(x) \in (0,\rho_0)$ and $y' \in U$ denotes the local coordinates in $\mathbb{R}^{N-1}$ of the projection of x on the boundary. With respect to the above presentation, we changed only the notations, setting $y = (\delta,\sigma)$, $\delta = y_1$, $\sigma = y'$. Moreover we set $T(x_0) = (0, y'_0)$, and without loss of generality, we may assume that $U = B(y'_0, R)$ for some $R > 0$.

Define now $v_n(y) = z_n(x) = z_n(T^{-1}(y))$, so that $\nabla z_n(x) = DT(x)\nabla v_n(y)$. Then the map T changes (2.14) into

$$\begin{cases} -\dfrac{1}{|\det(T^{-1})|} \operatorname{div}(A\nabla v_n) + |DT\,\nabla v_n + \tilde{G}_n|^q + v_n = \tilde{F}_n & \text{in } (0,\rho_0)\times B(y'_0,R), \\ A\nabla v_n \cdot e_1 = 0 & \text{on } \{y_1 = 0\}\times B(y'_0,R), \end{cases} \tag{2.29}$$

where $A(y)$ is the matrix defined as in (2.22), $\tilde{F}_n(y) = F_n(x)$, and $\tilde{G}_n(y) = G_n(x)$. Clearly from (2.25) we know that

$$\lim_{d_n(y)\to 0} v_n(y)d_n^{\alpha}(y) = 0, \qquad \text{where } d_n(y) = y_1 + \frac{1}{n}. \tag{2.30}$$

Moreover we are in the hypotheses of Lemma 2.6 so that $|\nabla z_n| \le C d_n^{-\alpha-1}$, which in turn yields

$$|DT\,\nabla v_n(y)| \le C\left(y_1 + \frac{1}{n}\right)^{-\alpha-1}. \tag{2.31}$$

We will contradict (2.27) by proving that

$$\left(\delta_{j_k} + \frac{1}{n_{j_k}}\right)^{\alpha+1} \nabla v_{n_{j_k}}(y_{j_k}) \to 0, \tag{2.32}$$

where $y_{j_k} = T(x_{j_k}) = (\delta_{j_k}, y'_{j_k})$, which converges toward $(0, y'_0)$.

For simplicity, we denote henceforth $\delta_k = \delta_{j_k}$, $n_k = n_{j_k}$, and $y'_k = y'_{j_k}$. Let us introduce the rescaled variable $\xi = (\xi_1, \xi')$ defined by

$$y = \begin{cases} y_1 = \left(\delta_k + \frac{1}{n_k}\right)\xi_1, \\ y' = \left(\delta_k + \frac{1}{n_k}\right)\xi' + y'_k. \end{cases}$$

Then ξ belongs to a domain D_k such that $D_k(\xi) \subset \mathbb{R}^N_+$ and

$$\left\{\xi \in \mathbb{R}^N_+ \ : \ \xi = (\xi_1, \xi'),\, 0 < \xi_1 < \frac{\rho_0}{\delta_k + \frac{1}{n_k}},\, \xi' \in B\left(0, \frac{R}{2(\delta_k + \frac{1}{n_k})}\right)\right\} \subset D_k(\xi);$$

hence $D_k(\xi)$ tends to $\mathbb{R}^N_+$ as $k \to \infty$. Now we set

$$\begin{aligned} v_k(\xi) &= \left(\delta_k + \frac{1}{n_k}\right)^{\alpha} v_{n_k}(y) \\ &= \left(\delta_k + \frac{1}{n_k}\right)^{\alpha} v_{n_k}\left(\left(\delta_k + \frac{1}{n_k}\right)\xi_1, \left(\delta_k + \frac{1}{n_k}\right)\xi' + y'_k\right). \end{aligned} \tag{2.33}$$

Since, using assumption (2.15), (2.31), and that $q(\alpha+1) = \alpha+2$, we have

$$|DT\,\nabla v_n + \tilde{G}_n|^q + |v_n| + |\tilde{F}_n| \le C\left(y_1 + \frac{1}{n}\right)^{-\alpha-2},$$

by rescaling (2.29) we get that v_k solves an equation of the type

$$-\operatorname{div}\Big(A_k(\xi)\nabla v_k(\xi)\Big) = H_k(\xi) \quad \text{in} \quad \mathcal{D}_k(\xi),$$

where $A_k(\xi) = A(y)$ and H_k is a sequence satisfying, in D_k,

$$|H_k| \le C\left(\delta_k + \frac{1}{n_k}\right)^{\alpha+2}\left(y_1 + \frac{1}{n_k}\right)^{-\alpha-2} = C\left[\frac{1}{\xi_1 + \frac{1}{n_k\delta_k+1}}\right]^{\alpha+2}. \tag{2.34}$$

Note that, since

$$d_{n_k}(y) = y_1 + \frac{1}{n_k} = \left(\delta_k + \frac{1}{n_k}\right)\left[\xi_1 + \frac{1}{n_k\delta_k + 1}\right], \tag{2.35}$$

(2.28) implies

$$\frac{\left(\delta_k + \frac{1}{n_k}\right)}{d_{n_k}(y)} = \frac{1}{\xi_1 + \frac{1}{n_k\delta_k+1}} \to \frac{1}{\xi_1 + l}. \tag{2.36}$$

In particular, by (2.30) and (2.33), $v_k(\xi)$ converges to 0 in $C^0_{\mathrm{loc}}(\overline{\mathbb{R}^N_+})$ if $l > 0$ or in $C^0_{\mathrm{loc}}(\mathbb{R}^N_+)$ if $l = 0$.

Observe that the points $y_k = (\delta_k, y'_k)$ correspond to $\xi_k = (\frac{n_k\delta_k}{\delta_k n_k+1}, 0)$, so that $\xi_k \to (1-l, 0)$ and ξ_k reaches the boundary of $\mathbb{R}^N_+$ only if $l = 1$. We distinguish henceforth two cases: If $l \ne 1$, the sequence ξ_k is contained in a fixed compact $K \subset \mathbb{R}^N_+$, so we only need to reason away from $\xi_1 = 0$. Since from (2.34) we have that

H_k is locally uniformly bounded in $\mathbb{R}^N_+$, Theorem 9.11 in [12] allows us to obtain a local $W^{2,p}_{\mathrm{loc}}(\mathbb{R}^N_+)$ bound for any $p>1$ and consequently the $C^1_{\mathrm{loc}}(\mathbb{R}^N_+)$ compactness for $v_k(\xi)$. Then we deduce that $v_k(\xi)\to 0$ in $C^1_{\mathrm{loc}}(\mathbb{R}^N_+)$, and computing ∇v_k on ξ_k we get

$$\nabla v_k(\xi_k) = \left(\delta_k + \frac{1}{n_k}\right)^{\alpha+1} \nabla v_{n_k}(\delta_k, y'_k) \longrightarrow 0, \tag{2.37}$$

which is (2.32).

If $l=1$, the sequence $\xi_k = (\frac{n_k\delta_k}{\delta_k n_k+1}, 0) \to (0,0)$, and hence we need a C^1 compactness up to the boundary. This can be done, for instance, in the same spirit of [11], by extending through reflection the problem on the whole of $\mathbb{R}^N$. Thus set $v_k^*(\xi)$ as

$$v_k^*(\xi) = \begin{cases} v_k(\xi_1,\xi') & \text{if } \xi\in D_k, \\ v_k(-\xi_1,\xi') & \text{if } \xi\in D_k^*, \end{cases}$$

where $D_k^* = \{(\xi_1,\xi') : (-\xi_1,\xi')\in D_k\}$, and similarly the matrix $A_k^*(\xi)$ and the datum $H_k^*(\xi)$ as

$$A_k^*(\xi) = \begin{cases} A_k(\xi_1,\xi') & \text{if } \xi\in D_k, \\ A_k(-\xi_1,\xi') & \text{if } \xi\in D_k^*, \end{cases} \quad \text{and} \quad H_k^*(\xi) = \begin{cases} H_k(\xi_1,\xi') & \text{if } \xi\in D_k, \\ H_k(-\xi_1,\xi') & \text{if } \xi\in D_k^*. \end{cases}$$

Note that in the reflected problem the mixed terms $a_{1k}(\xi_1,\xi')$, with $k\neq 1$, change into $-a_{1k}(-\xi_1,\xi')$: However, our change of coordinates gives $a_{1k}=0$ for $k\neq 1$ and hence we really have $A_k^*(\xi_1,\xi') = A_k(-\xi_1,\xi')$ for $\xi_1<0$. This allows us to deduce that A_k^* is continuous across the hyperplane $\xi_1=0$, and actually A_k^* is Lipschitz continuous on $\mathbb{R}^N$ with the same Lipschitz constant as A_k.

Using the boundary condition

$$A\nabla v_n\cdot e_1 = 0 \quad \text{on } \{\xi_1=0\},$$

then $v_k^*(\xi)$ solves

$$-\operatorname{div}\,(A_k^*(\xi)\nabla v_k^*(\xi)) = H_k^*(\xi) \quad \text{in} \quad \overline{D_k\cup D_k^*}^{\,o}.$$

Clearly we have $\overline{D_k\cup D_k^*}\to\mathbb{R}^N$ as $k\to+\infty$. Moreover, since $l=1$, we deduce from (2.28) and (2.34) that H_k^* is locally uniformly bounded in $\mathbb{R}^N$, in particular in any compact neighborhood of $\xi=0$. Similarly (2.30) and (2.33) imply, using (2.36) with $l=1$, that $v_k\to 0$ in $C^0_{\mathrm{loc}}(\overline{\mathbb{R}^N_+})$, and hence v_k^* converges to zero uniformly on compact sets. Finally, by regularity of A_k and by definition of A_k^* we deduce that A_k^* is equi-Lipschitz continuous, so that Calderon–Zygmund regularity applies. Applying again Theorem 9.11 in [12] to v_k^*, we obtain a local $W^{2,p}_{\mathrm{loc}}(\mathbb{R}^N)$ bound for any $p>1$ and then the $C^1_{\mathrm{loc}}(\mathbb{R}^N)$ compactness for $v_k^*(\xi)$. Consequently $v_k(\xi)$ converges to 0 in $C^1_{\mathrm{loc}}(\overline{\mathbb{R}^N_+})$, and therefore $\nabla v_k(\xi_k)\to 0$, where $\xi_k = (\frac{n_k\delta_k}{\delta_k n_k+1}, 0)$. Thus we obtain (2.37), and hence (2.32) holds in any case. This contradicts (2.27). ◻

Collecting the results of Lemmas 2.2, 2.6, and 2.7, we have all of the ingredients for the proof of Proposition 2.1.

Proof of Proposition 2.1 Let us observe that since $S_n = C^* d_n^{-\alpha} + \psi(x) d_n^{1-\alpha}$, with $\psi(x)$ smooth,

$$|S_n|\le C d_n^{-\alpha}, \quad |\nabla S_n|\le C d_n^{-\alpha-1}, \quad |D^2 S_n|\le C d_n^{-\alpha-2}, \quad \text{and} \quad |D^3 S_n|\le C d_n^{-\alpha-3},$$

and moreover $z_n = u_n - S_n$ solves

$$\begin{cases} -\Delta z_n + z_n + |\nabla z_n + \nabla S_n|^q = f_n(x) + \Delta S_n - S_n & \text{in } \Omega, \\ \dfrac{\partial z_n}{\partial \nu} = 0 & \text{on } \partial\Omega. \end{cases}$$

We can first apply Lemma 2.2 to u_n, which implies (see (2.11) and the definition of S_n) that $z_n d_n^\alpha \to 0$ as $d_n \to 0$. Subsequently Lemmas 2.6 and 2.7 applied to z_n give that $|\nabla z_n| \le C d_n^{-\alpha-1}$ and $d_n^{\alpha+1} \nabla z_n \to 0$ as $d_n \to 0$. By the definition of S_n, we deduce (2.4) and (2.5). ∎

2.2. Bernstein-type estimates. Now we come to the proof of Theorem 1.3; to this purpose, we consider the solutions u_n of (2.3), and we look for Lipschitz estimates on the translated function

$$z_n = u_n - S_n.$$

The choice of the "corrector term" S_n will be explained below; unfortunately, this choice (uniquely determined) will be slightly different according to whether $\alpha = \frac{2-q}{q-1}$ belongs to $\mathbb{N}$ or not, so that we have to treat separately some details of the two situations. However, in any case the function S_n will satisfy the assumptions of Proposition 2.1, in particular $S_n = C^* d_n^{-\alpha} + O(d_n^{1-\alpha})$ and, what is more important, $\nabla S_n = -\alpha\, C^* d_n^{-\alpha-1} \nabla d + O(d_n^{-\alpha})$. Therefore, estimate (2.5) implies that $d_n^{\alpha+1} \nabla u_n - d_n^{\alpha+1} S_n \to 0$ as $d_n \to 0$, which means that $|\nabla z_n| = o(d_n^{-\alpha-1}) = o(|\nabla S_n|)$. This fact plays a crucial role in the estimates below, and this is why we needed the preliminary Proposition 2.1 (except for $q = 2$, i.e., $\alpha = 0$).

Proof of Theorem 1.3. *Case* 1: $\alpha \notin \mathbb{N}$. Let us set

$$S_n = \sum_{k=0}^{m} \sigma_k d_n^{k-\alpha},$$

where $m = [\alpha] + 1$, $\sigma_0 = C^*$ (defined in (2.2)), and σ_k, $k = 1, \dots, m$, are smooth functions we will fix later. Let also f_n be a smooth approximation of f. Then let u_n be the solution of (2.3), and define $z_n = u_n - S_n$ so that z_n satisfies

$$\frac{\partial z_n}{\partial \nu} = 0 \quad \text{on} \quad \partial\Omega \tag{2.38}$$

and the following equation:

$$-\Delta z_n + z_n + |\nabla z_n + \nabla S_n|^q - |\nabla S_n|^q = f_n - F_n \quad \text{in} \quad \Omega, \tag{2.39}$$

where

$$F_n = -\Delta S_n + S_n + |\nabla S_n|^q. \tag{2.40}$$

Applying Proposition 2.1, and rephrasing (2.4) and (2.5) in terms of z_n, we get

$$|\nabla z_n| \le C d_n^{-\alpha-1} \qquad \text{in } \Omega, \tag{2.41}$$

$$d_n^{\alpha+1} \nabla z_n \to 0 \quad \text{as } d_n \to 0. \tag{2.42}$$

Step 1. We apply Bernstein's method on $|\nabla z_n|^2$ weighted with a suitable power of d_n, so let us define

$$w_n = |\nabla z_n|^2 d_n^\beta,$$

where β is a positive number. First, by Lemma 2.4 and (2.38), we deduce the condition on the normal derivative of w_n on the boundary, namely,

$$\frac{\partial w_n}{\partial \nu} \leq 0 \quad \text{on} \quad \partial\Omega.$$

Moreover, computing the Laplacian of w_n we observe that it satisfies

$$\Delta w_n = -\beta(\beta+1) d_n^\beta \frac{|\nabla z_n|^2}{d_n^2} + \beta d_n^{\beta-1} \Delta d |\nabla z_n|^2 + 2\beta \frac{\nabla w_n \cdot \nabla d}{d_n} + d_n^\beta [\Delta |\nabla z_n|^2], \tag{2.43}$$

and

$$\Delta |\nabla z_n|^2 = 2\left(\nabla z_n \cdot \nabla \Delta z_n + |D^2 z_n|^2\right). \tag{2.44}$$

Using (2.39) we have

$$\nabla z_n \cdot \nabla \Delta z_n = |\nabla z_n|^2 + H \cdot \nabla z_n + \nabla F_n \cdot \nabla z_n - \nabla f_n \cdot \nabla z_n, \tag{2.45}$$

where, recalling that $q(\alpha+1) = \alpha+2$,

$$H = \nabla(|\nabla z_n + \nabla S_n|^q - |\nabla S_n|^q) = \nabla\left(\frac{|d_n^{\alpha+1}\nabla z_n + d_n^{\alpha+1}\nabla S_n|^q - |d_n^{\alpha+1}\nabla S_n|^q}{d_n^{\alpha+2}}\right).$$

Now let us compute

$$\nabla S_n = \sum_{k=0}^m (k-\alpha)\sigma_k d_n^{k-\alpha-1}\nabla d + d_n^{k-\alpha}\nabla\sigma_k,$$

and we set

$$T = d_n^{\alpha+1}\nabla S_n = \sum_{k=0}^m (k-\alpha)\sigma_k d_n^k \nabla d + d_n^{k+1}\nabla\sigma_k; \qquad \xi = d_n^{\alpha+1}\nabla z_n + T.$$

Note that, since $\sigma_0 = C^*$, T can be written more explicitly as

$$T = -\alpha C^* \nabla d + \sum_{k=1}^m (k-\alpha)\sigma_k d_n^k \nabla d + d_n^{k+1}\nabla\sigma_k = -\alpha C^*\nabla d + O(d_n). \tag{2.46}$$

In particular both $|T|$ and $|\xi|$ (due to (2.42)) do not vanish in a suitable neighborhood of $\partial\Omega$, and we have

$$|T|^{q-2} = (\alpha C^*)^{q-2} + o(1) \quad \text{and} \quad |\xi|^{q-2} = (\alpha C^*)^{q-2} + o(1). \tag{2.47}$$

We compute then

$$H \cdot \nabla z_n = \nabla\left(\frac{|\xi|^q - |T|^q}{d_n^{\alpha+2}}\right) \cdot \nabla z_n =$$

$$-(\nabla d \cdot \nabla z_n)\frac{(\alpha+2)}{d_n^{\alpha+3}}[|\xi|^q - |T|^q] + \frac{q}{d_n^{\alpha+2}}|\xi|^{q-2} D\xi\,\xi\,\nabla z_n - \frac{q}{d_n^{\alpha+2}}|T|^{q-2} DT\,T\,\nabla z_n\,;$$

since by the definition of ξ (we use now the notation $(a\otimes b)cd=(a\cdot c)(b\cdot d)$ for vector fields)

$$|\xi|^{q-2}D\xi\xi\nabla z_n = |\xi|^{q-2}\Big[(\alpha+1)d_n^{\alpha}\nabla z_n\otimes\nabla d + d_n^{\alpha+1}D^2 z_n\Big]\xi\nabla z_n \\ + |\xi|^{q-2}DT(d_n^{\alpha+1}\nabla z_n + T)\nabla z_n,$$

we obtain

$$H\cdot\nabla z_n = -(\nabla d\cdot\nabla z_n)\frac{(\alpha+2)}{d_n^{\alpha+3}}[|\xi|^q - |T|^q] \\ + \frac{q|\xi|^{q-2}}{d_n^{\alpha+2}}\left[(\alpha+1)(\nabla d\cdot\nabla z_n)(\nabla z_n\cdot\xi)d_n^{\alpha} + \frac{d_n^{\alpha+1}}{2}\nabla|\nabla z_n|^2\cdot\xi\right] \\ + \frac{q|\xi|^{q-2}DT\nabla z_n\nabla z_n}{d_n} + \frac{q}{d_n^{\alpha+2}}\left[|\xi|^{q-2} - |T|^{q-2}\right]DT\,T\,\nabla z_n.$$

Let us observe that

$$\Big||\xi|^q - |T|^q - q d_n^{\alpha+1}|T|^{q-2}\nabla z_n\cdot T\Big| \le C|\nabla z_n|^2 d_n^{2\alpha+2}$$

and

$$\Big||\xi|^{q-2} - |T|^{q-2}\Big| \le C|\nabla z_n| d_n^{\alpha+1}, \tag{2.48}$$

so that

$$H\cdot\nabla z_n \ge -q\frac{(\alpha+2)}{d_n^2}(\nabla d\cdot\nabla z_n)(\nabla z_n\cdot T)|T|^{q-2} - C|\nabla d\cdot\nabla z_n|\frac{|\nabla z_n|^2 d_n^{2\alpha+2}}{d_n^{\alpha+3}} \\ + \frac{q(\alpha+1)}{d_n^2}(\nabla d\cdot\nabla z_n)(\nabla z_n\cdot\xi)|T|^{q-2} - \frac{C}{d_n^2}|\nabla d\cdot\nabla z_n|\,|\nabla z_n\cdot\xi||\nabla z_n|d_n^{\alpha+1} \\ + \frac{q|\xi|^{q-2}}{2d_n}\nabla|\nabla z_n|^2\cdot\xi + \frac{q|\xi|^{q-2}DT\nabla z_n\nabla z_n}{d_n} - C\frac{|\nabla z_n|^2}{d_n}.$$

In the third term on the right, we write that $\xi = T + d_n^{\alpha+1}\nabla z_n$. Then, using (2.42) and (2.47), we can simplify the previous inequality by writing

$$H\cdot\nabla z_n \ge -\frac{q}{d_n^2}(\nabla d\cdot\nabla z_n)(\nabla z_n\cdot T)|T|^{q-2} \\ + \frac{q|\xi|^{q-2}}{2d_n}\nabla|\nabla z_n|^2\cdot\xi - \frac{|\nabla z_n|^2}{d_n^2}\omega_n,$$

where (here and later) ω_n is some function satisfying

$$|\omega_n| \le C(d_n + |\nabla z_n| d_n^{\alpha+1}). \tag{2.49}$$

Note that (2.42) implies $\omega_n\to 0$ as $d_n\to 0$. Now we use (2.46), (2.47), and the algebraic relations in (2.2) (i.e., $(C^*\alpha)^{q-1}=\alpha+1$, $q(\alpha+1)=\alpha+2$), and we deduce

$$H\cdot\nabla z_n \ge (\alpha+2)\left(\frac{\nabla d\cdot\nabla z_n}{d_n}\right)^2 + \frac{q|\xi|^{q-2}}{2d_n}\nabla|\nabla z_n|^2\cdot\xi - \frac{|\nabla z_n|^2}{d_n^2}\omega_n.$$

Substituting the previous inequality into (2.45) we finally get

$$\begin{aligned}\nabla z_n \cdot \nabla \Delta z_n &\geq |\nabla z_n|^2 + \nabla F_n \cdot \nabla z_n - \nabla f_n \cdot \nabla z_n \\ &+ (\alpha+2)\left(\frac{\nabla d \cdot \nabla z_n}{d_n}\right)^2 + \frac{q|\xi|^{q-2}}{2d_n}\nabla|\nabla z_n|^2 \cdot \xi - \frac{|\nabla z_n|^2}{d_n^2}\omega_n.\end{aligned} \tag{2.50}$$

Moreover since

$$\nabla|\nabla z_n|^2 = \frac{\nabla w_n}{d_n^\beta} - \beta\frac{|\nabla z_n|^2}{d_n}\nabla d \tag{2.51}$$

we have, recalling that $\xi = d_n^{\alpha+1}\nabla z_n + T$,

$$\begin{aligned}\frac{q|\xi|^{q-2}}{2d_n}\nabla|\nabla z_n|^2 \cdot \xi &= -\beta\frac{q|\xi|^{q-2}}{2d_n^2}|\nabla z_n|^2\nabla d \cdot T \\ -\beta\frac{q|\xi|^{q-2}}{2}\frac{|\nabla z_n|^2}{d_n^2}\nabla d \cdot \nabla z_n\, d_n^{\alpha+1} &+ \frac{q|\xi|^{q-2}}{2}d_n^{-\beta-1}\nabla w_n \cdot \xi.\end{aligned}$$

Then using (2.42) we get from (2.50)

$$\begin{aligned}\nabla\Delta z_n \cdot \nabla z_n &\geq |\nabla z_n|^2 + \nabla F_n \cdot \nabla z_n - \nabla f_n \cdot \nabla z_n + (\alpha+2)\left(\frac{\nabla d \cdot \nabla z_n}{d_n}\right)^2 \\ &-\beta\frac{q|\xi|^{q-2}}{2d_n^2}|\nabla z_n|^2\nabla d \cdot T + \frac{q|\xi|^{q-2}}{2}d_n^{-\beta-1}\nabla w_n \cdot \xi - \frac{|\nabla z_n|^2}{d_n^2}\omega_n.\end{aligned} \tag{2.52}$$

Here we use again (2.46), (2.47), and (2.2), so that

$$-\beta\frac{q|\xi|^{q-2}}{2d_n^2}|\nabla z_n|^2\nabla d \cdot T = \beta\frac{(\alpha+2)}{2d_n^2}|\nabla z_n|^2[1+o(1)].$$

We conclude then from (2.52), since $\omega_n = o(1)$ as $d_n \to 0$,

$$\begin{aligned}\nabla\Delta z_n \cdot \nabla z_n &\geq |\nabla z_n|^2 + \nabla F_n \cdot \nabla z_n - \nabla f_n \cdot \nabla z_n \\ +(\alpha+2)\left(\frac{\nabla d \cdot \nabla z_n}{d_n}\right)^2 &+ \beta\frac{(\alpha+2)}{2d_n^2}|\nabla z_n|^2[1+o(1)] + \frac{q|\xi|^{q-2}}{2}d_n^{-\beta-1}\nabla w_n \cdot \xi.\end{aligned} \tag{2.53}$$

Using the above inequality in (2.43) and (2.44), we finally obtain

$$\begin{aligned}-\Delta w_n + 2w_n + \beta(\alpha+1-\beta)d_n^\beta\frac{|\nabla z_n|^2}{d_n^2}(1+o(1)) + 2(\alpha+2)\left(\frac{\nabla d \cdot \nabla z_n}{d_n}\right)^2 d_n^\beta \\ + 2\beta\frac{\nabla w_n \cdot \nabla d}{d_n} + \frac{q|\xi|^{q-2}}{d_n}\nabla w_n \cdot \xi \\ + 2d_n^\beta\nabla F_n \cdot \nabla z_n - 2d_n^\beta\nabla f_n \cdot \nabla z_n + 2d_n^\beta|D^2 z_n|^2 \leq 0.\end{aligned} \tag{2.54}$$

Now let us write explicitly the term F_n defined in (2.40), i.e.,

$$\begin{aligned}F_n &= -\Delta S_n + S_n + |\nabla S_n|^q \\ = -\sum_{k=0}^m (k-\alpha)&\left[(k-\alpha-1)\sigma_k d_n^{k-\alpha-2} + (\Delta d + 2\nabla\sigma_k \cdot \nabla d)d_n^{k-\alpha-1}\right] + \Delta\sigma_k d_n^{k-\alpha} \\ &+ \sum_{k=0}^m \sigma_k d_n^{k-\alpha} + \frac{1}{d_n^{\alpha+2}}\left|\sum_{k=0}^m (k-\alpha)\sigma_k d_n^k\nabla d + d_n^{k+1}\nabla\sigma_k\right|^q.\end{aligned} \tag{2.55}$$

Recall that $\sigma_0 = C^*$ is a constant: Then we can write last term as

$$\frac{1}{d_n^{\alpha+2}}\left|\sum_{k=0}^{m}(k-\alpha)\sigma_k d_n^k \nabla d + d_n^{k+1}\nabla\sigma_k\right|^q = \sum_{k=0}^{m} l_k d_n^{k-\alpha-2} + O(d_n^{m-\alpha-1}),$$

where $l_0 = (\alpha\sigma_0)^q$ and l_k, $k = 1, \dots, m$ are coefficients that depend on $\sigma_0, \dots, \sigma_k$, precisely

$$l_k = -q(k-\alpha)(\alpha\sigma_0)^{q-1}\sigma_k + \tilde{l}_k(\sigma_0, \dots, \sigma_{k-1}), \quad 1 \le k \le [\alpha]+1.$$

Hence, since $q(\alpha\sigma_0)^{q-1} = \alpha + 2$ (see (2.2)) and $m = [\alpha]+1$, we have from (2.55)

$$F_n = \sum_{k=1}^{m}\left[(\alpha-k)(k+1)\sigma_k + \psi_k(\sigma_0, \dots, \sigma_{k-1})\right] d_n^{k-\alpha-2} + O(d_n^{[\alpha]-\alpha})$$

for some functions ψ_k. Then by induction we can choose $\sigma_k = -\frac{\psi_k(\sigma_0,\dots,\sigma_{k-1})}{(\alpha-k)(k+1)}$ in order to have

$$|F_n| = \left| -\Delta S_n + S_n + |\nabla S_n|^q\right| = O\left(d_n^{[\alpha]-\alpha}\right)$$

and

$$|\nabla F_n \cdot \nabla z_n| \le C d_n^{[\alpha]-\alpha-1}\left(|\nabla d \cdot \nabla z_n| + d_n\,|\nabla z_n|\right).$$

Consequently, by Young's inequality we have

$$|\nabla F_n \cdot \nabla z_n| \le \frac{(\alpha+2)}{2}\frac{|\nabla d \cdot \nabla z_n|^2}{d_n^2} + C\left(d_n^{2([\alpha]-\alpha)} + |\nabla z_n|^2\right). \tag{2.56}$$

Thus in a suitable neighborhood Ω_{δ_0} of $\partial\Omega$, we have that w_n solves

$$\begin{aligned} &-\Delta w_n + 2w_n + \beta(\alpha+1-\beta)\,\frac{w_n}{d_n^2}\,(1+o(1)) + (\alpha+2)\left(\frac{\nabla d\cdot\nabla z_n}{d_n}\right)^2 d_n^\beta \\ &\quad + \frac{q|\xi|^{q-2}}{d_n}\nabla w_n\cdot\xi + 2\beta\frac{\nabla w_n\cdot\nabla d}{d_n} - 2d_n^\beta\nabla f_n\cdot\nabla z_n \le C\,d_n^{\beta+2([\alpha]-\alpha)}. \end{aligned} \tag{2.57}$$

By Young's inequality, we have for all $\varepsilon > 0$

$$2d_n^\beta|\nabla f_n\cdot\nabla z_n| \le \varepsilon\frac{w_n}{d_n^2} + C_\varepsilon d_n^{2+\beta}\,|\nabla f_n|^2 \le \varepsilon\frac{w_n}{d_n^2} + C_\varepsilon. \tag{2.58}$$

Here we set $\beta < \alpha+1$ and δ_0, n_0 such that in Ω_{δ_0} and for $n > n_0$ we have $\beta(\alpha+1-\beta)\,(1+o(1)) \ge c > 0$: Hence, fixing ε small enough and dropping positive terms, we get for some constants c_0, $C_0 > 0$

(2.59)
$$-\Delta w_n + 2w_n + c_0\frac{w_n}{d_n^2} + 2\beta\frac{\nabla w_n\cdot\nabla d}{d_n} + \frac{q|\xi|^{q-2}}{d_n}\nabla w_n\cdot\xi \le C_0\left(1 + \frac{d_n^\beta}{d_n^{2(\alpha-[\alpha])}}\right) \quad \text{in} \quad \Omega_{\delta_0},$$

with the condition

$$\frac{\partial w_n}{\partial\nu} \le 0 \quad \text{on} \quad \partial\Omega.$$

Since

$$C_0\left(1+\frac{d_n^\beta}{d_n^{2(\alpha-[\alpha])}}\right)\le\frac{C_1}{d_n^2},$$

the maximum principle implies that

$$\max_{\Omega_{\delta_0}} w_n\le\frac{C_1}{c_0}+\max_{\partial\Omega_{\delta_0}\setminus\partial\Omega} w_n,$$

and last term is uniformly bounded thanks to (2.41): Then,

$$\forall\, 0<\beta<\alpha+1,\quad |\nabla z_n|^2\le C d_n^{-\beta}\qquad\text{in}\quad\Omega. \tag{2.60}$$

Step 2. In order to get a uniform $L^\infty(\Omega)$ estimate on ∇z_n, now we deal with

$$w_n=e^{\theta(d_n)}|\nabla z_n|^2, \tag{2.61}$$

where $\theta(s)$ is a positive increasing function such that $\theta(0)=0$. Then w_n satisfies in Ω

$$\begin{aligned}&-\Delta w_n+\left[\theta''(d_n)+\theta'(d_n)^2+\theta'(d_n)\Delta d\right]w_n\\&+2e^{\theta(d_n)}\theta'(d_n)\nabla|\nabla z_n|^2\cdot\nabla d+2e^{\theta(d_n)}(|D^2z_n|^2+\nabla z_n\cdot\nabla(\Delta z_n))=0.\end{aligned} \tag{2.62}$$

Following previous computations we obtain (2.50); then since

$$\nabla|\nabla z_n|^2=\nabla w_n e^{-\theta(d_n)}-\theta'(d_n)|\nabla z_n|^2\nabla d \tag{2.63}$$

we get

$$\begin{aligned}\nabla z_n\cdot\nabla\Delta z_n&\ge|\nabla z_n|^2+\nabla F_n\cdot\nabla z_n-\nabla f_n\cdot\nabla z_n+(\alpha+2)\left(\frac{\nabla d\cdot\nabla z_n}{d_n}\right)^2\\&+\frac{q|\xi|^{q-2}}{2d_n}e^{-\theta(d_n)}\nabla w_n\cdot\xi-\theta'(d_n)\frac{q|\xi|^{q-2}}{2d_n}|\nabla z_n|^2\nabla d\cdot\xi-\frac{|\nabla z_n|^2}{d_n^2}\omega_n.\end{aligned}$$

Here recall that $\xi=d_n^{\alpha+1}\nabla z_n+T$; we use (2.46), (2.47), and the relations between q, α, C^* in (2.2), and we obtain, similarly as we did for (2.53), that

$$\begin{aligned}\nabla\Delta z_n\cdot\nabla z_n&\ge|\nabla z_n|^2+\nabla F_n\cdot\nabla z_n-\nabla f_n\cdot\nabla z_n+\frac{\alpha+2}{d_n^2}(\nabla d\cdot\nabla z_n)^2\\&+\frac{q|\xi|^{q-2}}{2d_n}e^{-\theta(d_n)}\nabla w_n\cdot\xi+\frac{(\alpha+2)\theta'(d_n)}{2d_n}|\nabla z_n|^2[1+o(1)]-\omega_n\frac{|\nabla z_n|^2}{d_n^2},\end{aligned}$$

where ω_n satisfies (2.49). Choosing $\sigma_1,\dots,\sigma_m$ as before we have

$$\nabla F_n\cdot\nabla z_n\ge-\frac{\alpha+2}{2}\frac{(\nabla z_n\cdot\nabla d)^2}{d_n^2}-C\left[d_n^{2([\alpha]-\alpha)}+|\nabla z_n|^2\right], \tag{2.64}$$

so we conclude that

$$\begin{aligned}\nabla\Delta z_n\cdot\nabla z_n&\ge|\nabla z_n|^2-\nabla f_n\cdot\nabla z_n+\frac{\alpha+2}{2d_n^2}(\nabla d\cdot\nabla z_n)^2\\&+\frac{q|\xi|^{q-2}}{2d_n}e^{-\theta(d_n)}\nabla w_n\cdot\xi+\frac{(\alpha+2)\theta'(d_n)}{2d_n}|\nabla z_n|^2[1+o(1)]-\omega_n\frac{|\nabla z_n|^2}{d_n^2}-Cd_n^{2([\alpha]-\alpha)}.\end{aligned}$$

Substituting the above inequality into (2.62) and using (2.63), we find

$$\begin{aligned}
&-\Delta w_n + 2w_n + \left[\frac{(\alpha+2)\theta'(d_n)}{d_n} + \theta''(d_n) - \theta'(d_n)^2 + \theta'(d_n)\Delta d - \frac{2\omega_n}{d_n^2}\right] w_n \\
&\quad + \frac{\alpha+2}{d_n^2}(\nabla d\cdot\nabla z_n)^2 e^{\theta(d_n)} + \frac{q|\xi|^{q-2}}{d_n}\nabla w_n\cdot\xi + 2\theta'(d_n)\nabla w_n\cdot\nabla d \\
&\quad + 2e^{\theta(d_n)}|D^2 z_n|^2 \le 2e^{\theta(d_n)}[\nabla f_n\cdot\nabla z_n + C d_n^{2([\alpha]-\alpha)}].
\end{aligned} \tag{2.65}$$

Several choices of functions $\theta(s)$ are now possible (see also the results in section 3): For instance, if we take $\theta(s) = s^\eta$, $\eta > 0$, we get

$$\frac{(\alpha+2)\theta'(d_n)}{d_n} + \theta''(d_n) - \theta'(d_n)^2 + \theta'(d_n)\Delta d - \frac{2\omega_n}{d_n^2} \ge \frac{\eta(\alpha+1+\eta)}{d_n^{2-\eta}}(1+o(1)) - \frac{2\omega_n}{d_n^2}.$$

However, by the definition of ω_n in (2.49), using now (2.60) with $\beta \le \alpha$ implies that

$$\omega_n \le C(d_n + |\nabla z_n| d_n^{\alpha+1}) \le C\, d_n, \tag{2.66}$$

and hence, for any $\eta < 1$,

$$\left[\frac{(\alpha+2)\theta'(d_n)}{d_n} + \theta''(d_n) - \theta'(d_n)^2 + \theta'(d_n)\Delta d - \frac{2\omega_n}{d_n^2}\right] \ge \frac{\eta(\alpha+1+\eta)}{d_n^{2-\eta}}(1+o(1)).$$

Using Young's inequality to take care of the term with f_n, we deduce from (2.65)

$$\begin{aligned}
&-\Delta w_n + 2w_n + \frac{\eta(\alpha+1+\eta)}{d_n^{2-\eta}}(1+o(1))w_n + \frac{\alpha+2}{d_n^2}(\nabla d\cdot\nabla z_n)^2 e^{\theta(d_n)} \\
&\quad + \frac{q|\xi|^{q-2}}{d_n}\nabla w_n\cdot\xi + 2\theta'(d_n)\nabla w_n\cdot\nabla d \le C[1 + d_n^{2([\alpha]-\alpha)}].
\end{aligned} \tag{2.67}$$

Observe that for any $\eta > 0$ the function e^{s^η} satisfies Lemma 2.4, and hence

$$\frac{\partial w_n}{\partial \nu} \le 0 \quad \text{on} \quad \partial\Omega.$$

Therefore, by applying the maximum principle we easily conclude from (2.67) as soon as $\eta < 1 + [\alpha] - \alpha$:

$$|\nabla z_n| \le C\left[1 + \max_{\partial\Omega_{\delta_0}\setminus\partial\Omega} |\nabla z_n|\right] \quad \text{in} \quad \Omega_{\delta_0},$$

and the last term is uniformly bounded by (2.41). This proves a uniform Lipschitz estimate for z_n (recall that z_n is locally uniformly bounded). Then standard results imply that z_n converges to a function z such that $z+S$ is a solution of (1.1)–(1.2), and hence the uniqueness result implies that $z = u-S$. We conclude that $u-S$ is Lipschitz, and this regularity, decomposed on normal and tangentials directions, yields (1.16).

Case 2: $\alpha \in \mathbb{N}$, $\alpha \ne 0$. The only difference between the two cases lies in the formal expansion of u_n. Indeed we have to modify S_n as follows:

$$S_n = \sum_{k=0}^{\alpha-1} \sigma_k(x) d_n^{k-\alpha} + \sigma_\alpha(x)\log d_n + \sigma_{\alpha+1}(x) d_n \log d_n + \tilde\sigma_{\alpha+1}(x) d_n, \tag{2.68}$$

where again $\sigma_0 = C^*$ and $\tilde\sigma_{\alpha+1}$, σ_i, $i = 0, \ldots, \alpha+1$, are smooth functions to be fixed. Hence now we have (after standard computations)

$$T = d_n^{\alpha+1}\nabla S_n = -\alpha C^*\nabla d + \sum_{k=1}^{\alpha-1} d_n^k[(k-\alpha)\sigma_k\nabla d + \nabla\sigma_{k-1}] + d_n^\alpha(\sigma_\alpha\nabla d + \nabla\sigma_{\alpha-1}) \tag{2.69}$$

$$+\, d_n^{\alpha+1}\left[\log d_n(\nabla\sigma_\alpha + \sigma_{\alpha+1}\nabla d) + (\sigma_{\alpha+1} + \tilde\sigma_{\alpha+1})\nabla d + d_n \log d_n \nabla\sigma_{\alpha+1} + d_n\nabla\tilde\sigma_{\alpha+1}\right].$$

Then, as in (2.46), we have that $T = -\alpha\, C^*\nabla d + O(d_n)$ and (2.47) still holds, so we can argue as above until we obtain (2.54). The choice of S_n is involved in the regularity of F_n defined in (2.40): In fact we find

$$\begin{aligned} &-\Delta S_n + S_n + |\nabla S_n|^q \\ &= -\sum_{k=0}^{\alpha-1}(k-\alpha)\left[(k-\alpha-1)\sigma_k d_n^{k-\alpha-2} + (\Delta d + 2\nabla\sigma_k\cdot\nabla d)d_n^{k-\alpha-1}\right] + \Delta\sigma_k d_n^{k-\alpha} \\ &\quad + \sigma_\alpha\, d_n^{-2} - [\sigma_\alpha\Delta d + \nabla\sigma_\alpha\nabla d + \sigma_{\alpha+1}]\, d_n^{-1} + \tau(x)\log d_n \\ &\quad + \sum_{k=0}^{\alpha-1}\sigma_k d_n^{k-\alpha} + \frac{1}{d_n^{\alpha+2}}\left|d_n^{\alpha+1}\nabla S_n\right|^q, \end{aligned}$$

where τ is smooth (say, $W^{1,\infty}(\Omega)$). From the expression in (2.69), we notice that by choosing $\sigma_{\alpha+1} = -\nabla\sigma_\alpha\cdot\nabla d$ we can write the last term as

$$\frac{1}{d_n^{\alpha+2}}\left|d_n^{\alpha+1}\nabla S_n\right|^q = \sum_{k=0}^{\alpha+1} l_k d_n^{k-\alpha-2} + \tau_1(x)\log d_n,$$

where τ_1 is smooth, $l_0 = (\alpha C^*)^q$ and the l_k, $k = 1, \ldots, \alpha+1$, are coefficients that depend on $\sigma_0, \ldots, \sigma_k$ as follows:

$$\begin{aligned} l_k &= -q(k-\alpha)(\alpha C^*)^{q-1}\sigma_k + \tilde l(\sigma_0, \ldots, \sigma_{k-1}), \quad 1 \le k \le \alpha-1, \\ l_\alpha &= q(\alpha C^*)^{q-1}\sigma_\alpha + \tilde l(\sigma_0, \ldots, \sigma_{\alpha-1}), \\ l_{\alpha+1} &= q(\alpha C^*)^{q-1}(\sigma_{\alpha+1} + \tilde\sigma_{\alpha+1}) + \tilde l(\sigma_0, \ldots, \sigma_\alpha). \end{aligned}$$

Hence, using $q(\alpha C^*)^{q-1} = \alpha + 2$, as in Case 1 we can choose by induction σ_k, $k = 1, \ldots, \alpha$ (which are the same as in the previous case), and $\tilde\sigma_{\alpha+1}$ in a way that

$$|F_n| = O(|\log d_n|)$$

and

$$|\nabla F_n\cdot\nabla z_n| \le C d_n^{-1}\left(|\nabla z_n\cdot\nabla d| + d_n|\log d_n||\nabla z_n|\right).$$

Then, by Young's inequality,

$$|\nabla F_n\cdot\nabla z_n| \le \frac{(\alpha+2)}{2}\left(\frac{|\nabla z_n\cdot\nabla d|}{d_n}\right)^2 + C(|\log d_n|^2 + |\nabla z_n|^2), \tag{2.70}$$

which replaces (2.56). We conclude as in the previous case by getting estimate (2.60), and then, using again (2.70), as in Step 2 we obtain the Lipschitz estimate and the claimed regularity for $u - S$. We deduce the asymptotic development (1.17) (using again that $\sigma_{\alpha+1} = -\nabla\sigma_\alpha \cdot \nabla d$).

Case 3: $\alpha = 0$. We recall that $\alpha = 0$ means $q = 2$: This case in fact is much simpler than the previous ones, since (2.39) reads as

$$-\Delta z_n + z_n + |\nabla z_n|^2 + 2\nabla z_n \cdot \nabla S_n = f_n - F_n$$

and there is no need to use Taylor's expansion of the nonlinearity (this is why Lemma 2.7 is not needed). In particular, the computation of $\nabla z_n \nabla \Delta z_n$ is straightforward, and one can easily follow the previous steps. As far as the choice of S_n is concerned, this is exactly as in (2.68), which here assumes the simple form $S_n = -\log(d_n) + \frac{\Delta d}{2}\, d_n$. ∎

We observe that the computation of the functions σ_k in the previous theorem can be done explicitly. In particular, it turns out that

$$\sigma_1(x) = \frac{(q-1)^{-\frac{1}{q-1}}}{1-\alpha}\,\frac{\Delta d(x)}{2} \quad \text{if } \alpha \neq 1, \ \ \sigma_1(x) = \frac{(q-1)^{-\frac{1}{q-1}}\Delta d(x)}{2} \quad \text{if } \alpha = 1,$$

and hence, recalling (2.24),

$$\begin{aligned} \sigma_1(x) &= \frac{(q-1)^{-\frac{1}{q-1}}}{1-\alpha}\,\frac{(N-1)}{2} H(\overline{x}) \quad \text{if } \alpha \neq 1, \\ \sigma_1(x) &= \frac{(q-1)^{-\frac{1}{q-1}}(N-1)}{2} H(\overline{x}) \quad \text{if } \alpha = 1. \end{aligned} \tag{2.71}$$

Remark 2.8. Nothing really changes in the proof of Theorem 1.3 according to the value of λ appearing in (1.1), but for the possibly different values of the coefficients σ_k defining the corrector term S. However, the first two terms $\sigma_0 = C^*$ and σ_1 defined in (2.71) would remain the same for solutions of (1.1), independently of the value of λ, and so the conclusions of Theorems 1.2 and 1.1. In particular, let us stress that the gradient estimates remain valid for the solution of the ergodic problem, which is well defined from the results in [15].

2.3. The case $q = 2$ and Theorem 1.3 refined. Let us complete here the proof of Theorems 1.2 and 1.1 by getting an improved asymptotic estimate for the case $q = 2$.

PROPOSITION 2.9. *Let $\Omega \in C^5$ and f be in $W^{1,\infty}(\Omega)$. Let $u(x)$ be the unique solution of*

$$\begin{cases} -\Delta u + u + |\nabla u|^2 = f(x) & \textit{in} \quad \Omega, \\ u(x) \to +\infty & \textit{as} \quad d(x) \to 0. \end{cases} \tag{2.72}$$

Then

$$\lim_{d(x)\to 0} \frac{\partial u(x)}{\partial \nu} - \left(\frac{1}{d(x)} - \frac{\Delta d(x)}{2}\right) = 0. \tag{2.73}$$

Proof. Let us set $S = -\log d(x) + \frac{\Delta d}{2} d(x)$ and $z = u - S$. Applying Theorem 1.3 we have that z is Lipschitz continuous, which implies

$$|\nabla(u(x) + \log d(x))| \leq C \quad \text{in} \quad \Omega. \tag{2.74}$$

From (2.74), $u+\log d$ can be extended continuously to $\partial\Omega$ and for all $x_0\in\partial\Omega$,

$$|u(x)+\log d(x)-\rho(x_0)|\le C|x-x_0|, \tag{2.75}$$

where $\rho(x_0)=(u+\log d)|_{x_0}$. Let us consider now a point $P_0\in\Omega$ close to the boundary such that its projection on $\partial\Omega$ coincides with x_0, and let us introduce in $B(P_0,d_0)$, $d_0=|x_0-P_0|$, a new system of coordinates $(\eta_1,\dots,\eta_N)=(\eta_1,\eta')$ such that the origin O coincides with x_0 and the η_1-axis coincides with $\nabla d(x_0)=-\nu(x_0)$. Since the equation is invariant with respect to rotations and translations, $u(\eta)$ still solves (2.72), and estimate (2.75) holds true. We introduce the rescaled variable $\xi=\frac{\eta}{\delta}$, i.e.,

$$\xi_1=\frac{\eta_1}{\delta},\qquad \xi'=\frac{\eta'}{\delta}\quad \forall\delta>0,$$

and we define

$$v_\delta(\xi)=\frac{u(\delta\xi)+\log d(\delta\xi)-\frac{\Delta d(x_0)d(\delta\xi)}{2}-\rho(x_0)}{\delta}. \tag{2.76}$$

Hence $v_\delta(\xi)$ solves the following equation:

$$\begin{gathered}-\Delta v_\delta+\delta^2 v_\delta-2\delta\frac{\nabla v_\delta\cdot\nabla d(\delta\xi)}{d(\delta\xi)}+\delta|\nabla v_\delta|^2+\delta\Delta d(x_0)\nabla v_\delta\cdot\nabla d(\delta\xi)\\ +\frac{\delta}{d(\delta\xi)}(\Delta d(\delta\xi)-\Delta d(x_0))+\delta\left(\frac{\Delta d(x_0)}{2}\right)^2-\delta\frac{\Delta d(x_0)\Delta d(\delta\xi)}{2}-\delta\log d(\delta\xi)\\ +\delta\frac{\Delta d(x_0)}{2}d(\delta\xi)+\delta\rho(x_0)-\delta f(\delta\xi)=0,\end{gathered} \tag{2.77}$$

in the domain D_δ, where

$$D_\delta=\left\{(\xi_1,\xi')\,:\,\left(\xi_1-\frac{d_0}{\delta}\right)^2+|\xi'|^2\le\left(\frac{d_0}{\delta}\right)^2\right\}.$$

Note that $D_\delta\to\mathbb{R}^N_+$ as $\delta\to 0$. Moreover, from (2.74) and (2.75), we have $|v_\delta|\le C|\xi|$ and $|\nabla v_\delta|\le C$, and hence v_δ is bounded in $W^{1,\infty}_{loc}(\mathbb{R}^N_+)$. Now, by regularity of the function $d(x)$, we have $d(\eta)=\eta_1+O(|\eta|^2)$, and hence

$$d(\delta\xi)=\delta\xi_1+\delta^2O(|\xi|^2),$$

so that both $\frac{d(\delta\xi)}{\delta}$ and $\frac{\delta}{d(\delta\xi)}$ are locally bounded in D_δ. Then we can apply the Calderon–Zygmund theorem to (2.77) which implies that v_δ is bounded in $W^{2,p}_{\mathrm{loc}}(\mathbb{R}^N_+)$, for all $p>1$, and consequently, by Sobolev embedding, it is locally relatively compact in $C^1(\mathbb{R}^N_+)$. Letting $\delta\to 0$, since $\nabla d(\delta\xi)$ converges toward $e_1=(1,0,\dots,0)$, we find that, up to subsequences, v_δ converges toward a solution v of the equation

$$-\Delta v-2\frac{\nabla v\cdot e_1}{\xi_1}=0\quad\text{in}\quad \mathbb{R}^N_+, \tag{2.78}$$

with the additional information that $|\nabla v|\le C$ and $|v(\xi)|\le c|\xi|$. We claim now that $\partial_{\xi_1}v=0$ for any solution v of (2.78) having these properties. Indeed, let us derive (2.78) with respect to the ξ_1 direction so that $z=\partial_{\xi_1}v$ solves

$$-\Delta z-2\frac{\nabla z\cdot e_1}{\xi_1}+2\frac{z}{\xi_1^2}=0\quad\text{in}\quad\mathbb{R}^N_+,\quad z\in L^\infty(\mathbb{R}^N_+), \tag{2.79}$$

and, say, $|z| \le M$. Standard arguments imply that (2.79) has a maximal and a minimal solution in the class $|z| \le M$. Indeed, if we take a sequence D_ε of smooth bounded domains with $d(D_\varepsilon, \partial\mathbb{R}^N_+) = \varepsilon$, $D_{\varepsilon_1} \subset D_{\varepsilon_2}$, for all $\varepsilon_2 < \varepsilon_1$ such that $D_\varepsilon \to \mathbb{R}^N_+$ as $\varepsilon \to 0$, then we can construct a maximal solution $Z(\xi)$ as the limit of solutions in D_ε of the problem

$$\begin{cases} -\Delta z_\varepsilon - 2\dfrac{\nabla z_\varepsilon \cdot e_1}{\xi_1} + 2\dfrac{z_\varepsilon}{\xi_1^2} = 0 & \text{in } D_\varepsilon, \\ z_\varepsilon = M & \text{on } \partial D_\varepsilon. \end{cases}$$

Note that by the strong maximum principle, $0 \le z_\varepsilon \le M$ and $z \le z_\varepsilon$ for any other solution of (2.79) with $|z| \le M$, and hence the limit Z is maximal in this class. Since the equation is invariant with respect to translations along $\xi_2, \dots, \xi_N$, the maximality of Z implies that $Z(\xi) = Z(\xi_1)$. In the same way, since the equation is linear, we construct a minimal solution that depends only on ξ_1. However, the associated ODE

$$\psi''(s)s^2 + 2s\psi'(s) - 2\psi = 0, \quad s \in (0, +\infty),$$

is a standard Euler equation which admits a unique bounded solution $\psi = 0$. Therefore the maximal and minimal solutions are zero, and hence $z \equiv 0$.

As a consequence, whatever subsequence v_δ is converging in $C^1_{\mathrm{loc}}(\mathbb{R}^N_+)$, we find that $\partial_{\xi_1} v_\delta \to 0$, which yields, by the definition of v_δ and since $e_1 = \nabla d(x_0) = \nabla d(\delta\xi) + O(\delta)$,

$$\nabla v_\delta \cdot \nabla d(\delta\xi) = \nabla u(\delta\xi) \cdot \nabla d(\delta\xi) + \frac{1}{d(\delta\xi)} - \frac{\Delta d(x_0)}{2} \to 0. \tag{2.80}$$

Now observe that in a neighborhood of $\partial\Omega$ any point $x \in \Omega$ can be represented as $x = x_0 + \delta\nabla d(x_0)$ for some $x_0 \in \partial\Omega$, with $\delta = d(x)$. This corresponds to $\xi = (1, 0 \dots, 0)$ in the previous framework, and using (2.80) with $\xi = (1, 0 \dots, 0)$ we can deduce (2.73). $\square$

We can now complete the results stated in the introduction.

Proof of Theorem 1.2. The result is a consequence of Theorem 1.3 and Proposition 2.9, with the characterization of σ_1 in (2.71). $\square$

Proof of Theorem 1.1. Both (1.10) and (1.11) follow straightforward from Theorem 1.2, expanding

$$a(x) = -q|\nabla u(x)|^{q-2}\nabla u(x)$$

near the boundary of Ω. $\square$

Remark 2.10. Let us remark that if $q = 2$ the optimal control law $a(x)$ in general is not tangentially zero (differently than for $1 < q < 2$). Indeed, it is enough to take Ω as the unit ball in $\mathbb{R}^N$ and, in polar coordinates, define $u(x) = \psi(\rho) + \varphi(\theta)$, where ρ is the radial coordinate and θ is the angular one. If ψ is the radial explosive solution of $-\Delta\psi + \psi + |\nabla\psi|^2 = 0$, then u solves

$$-\Delta u + u + |\nabla u|^2 = f, \quad u(x) \to +\infty \quad \text{as } x \to \partial\Omega,$$

where $f = \frac{1}{\rho^2}\left[-\Delta_\theta\varphi + |\nabla_\theta\varphi|^2\right] + \varphi$. Here $a(x) = 2\nabla u(x)$, and its tangential component may not vanish on the boundary. Note that f can be taken as smooth as desired.

Similarly one can show that the results in Theorem 1.2 are optimal both in the normal and in the tangential components and that these latter ones have not in general a universal behavior (independent of f) as is the case for the normal derivative.

The idea of the proof of Proposition 2.9 can be used in order to improve the result of Theorem 1.3 concerning the normal derivative of u: Indeed from Theorem 3.2 we have that $u - S$ is Lipschitz continuous, so that we can look at the equation solved by the rescaled function

$$v_\delta(\xi) = \frac{u(\delta\xi) - S(\delta\xi) - \rho(x_0)}{\delta},$$

where $x_0 \in \partial\Omega$, $\rho(x_0) = (u(x) - S(x))|_{x_0}$, and we are using the same notations as in the above proof. Arguing as before, we can prove that $\partial_{\xi_1} v_\delta \to 0$ and hence that $\frac{\partial(u-S)}{\partial\nu}$ tends to zero at the boundary. This allows us to refine the estimate on the normal component of ∇u.

Corollary 2.11. *Let the assumptions of Theorem* 1.3 *hold true. Then we have*

$$\nabla(u - S)\nabla d \to 0 \quad \text{as } d(x) \to 0,$$

which yields in particular, for any $1 < q < 2$,

$$\begin{cases} \frac{\partial u(x)}{\partial \nu} = \frac{\alpha C^*}{d^{\alpha+1}} - \sum_{k=0}^{[\alpha]+1} \left[\frac{(k-\alpha)\sigma_k(x)}{d^{\alpha-k+1}(x)} - \frac{\nabla\sigma_{k-1}(x)\cdot\nu}{d^{\alpha-k+1}(x)} \right] + o(1) & \text{if } \alpha \notin \mathbb{N}, \\ \frac{\partial u(x)}{\partial \nu} = \frac{\alpha C^*}{d^{\alpha+1}} - \sum\limits_{k=1}^{\alpha-1} \left[\frac{(k-\alpha)\sigma_k(x)}{d^{\alpha-k+1}(x)} - \frac{\nabla\sigma_{k-1}(x)\cdot\nu}{d^{\alpha-k+1}(x)} \right] - \frac{(\sigma_\alpha - \nabla\sigma_{\alpha-1}\cdot\nu)}{d(x)} + o(1) & \text{if } \alpha \in \mathbb{N}. \end{cases}$$

3. Extensions and remarks.

3.1. The case of singular data f. Here we extend the results of Theorem 1.3 (and consequently those of Theorems 1.1 and 1.2) by considering data f possibly singular at the boundary. This is possible by taking full advantage of our use of weighted Bernstein-type estimates in the proof of Theorem 1.3, which allows us to treat data f with weighted regularity. A first result in this sense was essentially contained in the intermediate estimate (2.60) given in the proof of Theorem 1.3, which can be used to get Hölder-type estimates when a Lipschitz regularity cannot be expected.

Theorem 3.1. *Let $u(x)$ be the solution of* (1.1)–(1.2), *and for any* $0 < \beta < \alpha + 1$ *set*

$$m_\alpha^\beta = \left[\alpha - \frac{\beta}{2}\right] + 1.$$

Let

$$S = \begin{cases} S = \sum_{k=0}^{m_\alpha^\beta} \sigma_k d^{k-\alpha} & \text{if } \alpha \notin \mathbb{N}, \\ S = \sum_{k=0}^{\min(\alpha-1, m_\alpha^\beta)} \sigma_k d^{k-\alpha} + \sigma_\alpha^\beta \log d & \text{if } \alpha \in \mathbb{N},\ \alpha \geq 1, \\ S = -\log d & \text{if } \alpha = 0, \end{cases} \tag{3.1}$$

where the coefficients σ_k are as in Theorem 1.3, $\sigma_\alpha^\beta = \sigma_\alpha$ *if* $m_\alpha^\beta = \alpha$ *and* $\sigma_\alpha^\beta = 0$ *if* $m_\alpha^\beta \leq \alpha - 1$.

Assume that $\partial\Omega \in C^r$, $r = m_\alpha^\beta + 4$, *and* $f(x) \in W^{1,\infty}_{\text{loc}}(\Omega)$ *satisfies*

$$|\nabla f| \leq \frac{C}{d^{2+\frac{\beta}{2}}}. \tag{3.2}$$

Then we have

$$|\nabla u - \nabla S| \leq \frac{C}{d^{\frac{\beta}{2}}}, \tag{3.3 (i)}$$

$$\textit{If } \beta < 2, \textit{ then } u - S \textit{ belongs to } C^{0,1-\frac{\beta}{2}}(\overline{\Omega}). \tag{3.4 (ii)}$$

Proof. We come back to Step 1 of the proof of Theorem 1.3, with the same notations. Now, if f satisfies (3.2), we can construct (e.g., by convolution) a smooth approximation f_n satisfying a similar estimate

$$|\nabla f_n| \leq \frac{C}{d_n^{2+\frac{\beta}{2}}} \quad \text{in } \Omega,$$

where $d_n = d(x) + \frac{1}{n}$ as before. Then instead of (2.58) we obtain

$$2d_n^\beta |\nabla f_n \cdot \nabla z_n| \leq \varepsilon \frac{w_n}{d_n^2} + C_\varepsilon d_n^{2+\beta} |\nabla f_n|^2 \leq \varepsilon \frac{w_n}{d_n^2} + \frac{C_\varepsilon}{d_n^2}, \tag{3.5}$$

where $w_n = d_n^\beta |\nabla z_n|^2$. Note that now S is truncated so that F_n defined in (2.40) satisfies $F_n = O(d_n^{m_\alpha^\beta - \alpha - 1})$. Then similarly as in (2.59) we obtain, in a neighborhood Ω_{d_0} near the boundary, that u_n solves

$$-\Delta w_n + 2w_n + c_0 \frac{w_n}{d_n^2} + 2\beta \frac{\nabla w_n \cdot \nabla d}{d_n} + \frac{q|\xi|^{q-2}}{d_n} \nabla w_n \cdot \xi \leq C_0 \left(1 + d_n^{-2(\alpha - \frac{\beta}{2} - [\alpha - \frac{\beta}{2}])} + \frac{1}{d_n^2}\right)$$

equipped with the boundary condition

$$\frac{\partial w_n}{\partial \nu} \leq 0 \quad \text{on } \partial\Omega.$$

The maximum principle still allows one to conclude that $|\nabla z_n| \leq C d_n^{-\frac{\beta}{2}}$, which yields (3.3). In the particular case that $\frac{\beta}{2} < 1$, one can prove (see, e.g., [17]) that (3.3) implies the global Hölder regularity of $u - S$ stated in (ii). ◻

Note that, in terms of the asymptotic expansion for solutions of (1.1)–(1.2), (3.3) implies that $\nabla u = \nabla S + O(d^{-\frac{\beta}{2}})$, which is a sort of truncation of the complete expansion (1.16)–(1.17).

Let us see now that Theorem 1.3 can be extended even to cases when f blows up at the boundary.

THEOREM 3.2. *Let $u(x)$ be the solution of* (1.1)–(1.2). *Assume that $\partial\Omega \in C^r$, $r = [\alpha] + 5$, and $f(x)$ is a $W^{1,\infty}_{\mathrm{loc}}(\Omega)$ function such that*

$$|\nabla f| \leq \frac{\gamma(d)}{d^2}, \tag{3.6}$$

where $\gamma(s)$ is a positive nondecreasing function satisfying $\int_0^1 \frac{\gamma(s)}{s} ds < \infty$.

Let $S(x)$ be defined in (1.15). *Then we have that*

$$u - S \in W^{1,\infty}(\Omega).$$

In particular, the conclusion of Theorem 1.3 *holds true.*

Proof. We use the same notations and closely follow the proof of Theorem 1.3; hence z_n is solution of (2.38)–(2.39), where f_n is an approximation of f satisfying

$$|\nabla f_n| \le C\frac{\gamma(d_n)}{d_n^2}.$$

First note that the conclusion of Step 1 (estimate (2.60)) follows as in Theorem 3.1, since (3.6) implies (3.2) for any $\beta > 0$. Set now

$$w_n = e^{\theta(d_n)}|\nabla z_n|^2$$

as in Step 2 of the proof of Theorem 1.3. By choosing $\theta(s) = \int_0^s \frac{\gamma(t)}{t}dt$ we obtain from (2.65)

(3.7)

$$\begin{aligned}
-\Delta w_n &+ \left[\frac{(\alpha+2)\gamma(d_n)}{d_n^2} + \frac{\gamma'(d_n)d_n - \gamma(d_n)}{d_n^2} - \frac{\gamma(d_n)^2}{d_n^2} + \frac{\gamma(d_n)}{d_n}\Delta d - \frac{\omega(d_n)}{d_n^2}\right] w_n \\
&+ 2w_n + \frac{\alpha+2}{d_n^2}e^{\theta(d_n)}(\nabla d\cdot\nabla z_n)^2 + \frac{q|\xi|^{q-2}}{d_n}\nabla w_n\cdot\xi + 2\frac{\gamma(d_n)}{d_n}\nabla w_n\cdot\nabla d \\
&+2e^{\theta(d_n)}|D^2 z_n|^2 \le 2e^{\theta(d_n)}\left[\nabla f_n\cdot\nabla z_n + C\max\left(d_n^{2([\alpha]-\alpha)}, |\log(d_n)|\right)\right],
\end{aligned}$$

where $\max(d_n^{2([\alpha]-\alpha)}, |\log(d_n)|)$ depends only whether $\alpha\in\mathbb{N}$ or not. Observe that, since $\gamma(0) = 0$ and γ is nondecreasing,

$$\begin{aligned}
&\left[\frac{(\alpha+2)\gamma(d_n)}{d_n^2} + \frac{\gamma'(d_n)d_n - \gamma(d_n)}{d_n^2} - \frac{\gamma(d_n)^2}{d_n^2} + \frac{\gamma(d_n)}{d_n}\Delta d - \frac{\omega(d_n)}{d_n^2}\right] \\
&\qquad\ge \left[\frac{(\alpha+1+o(1))\gamma(d_n)}{d_n^2} - \frac{\omega(d_n)}{d_n^2}\right].
\end{aligned}$$

Now we use (3.6) to deduce

$$|2e^{\theta(d_n)}\nabla f_n\cdot\nabla z_n| \le \varepsilon\frac{\gamma(d_n)}{d_n^2}e^{\theta(d_n)}|\nabla z_n|^2 + C_\varepsilon|\nabla f_n|^2\frac{d_n^2}{\gamma(d_n)} \le \varepsilon\frac{\gamma(d_n)}{d_n^2}w_n + C_\varepsilon\frac{\gamma(d_n)}{d_n^2}.$$

Therefore, by choosing ε small we finally get from (3.7)

$$\begin{aligned}
-\Delta w_n + 2w_n &+ \left[\frac{(\alpha+1)\gamma(d_n)}{d_n^2}(1+o(1)) - \frac{\omega(d_n)}{d_n^2}\right] w_n + (\alpha+2)e^{\theta(d_n)}\left(\frac{\nabla d\cdot\nabla z_n}{d_n}\right)^2 \\
&+ 2\frac{\gamma(d_n)}{d_n}\nabla w_n\cdot\nabla d + \frac{q|\xi|^{q-2}}{d_n}\nabla w_n\cdot\xi \le C_0\left[\frac{\gamma(d_n)}{d_n^2} + \max\left(d_n^{2([\alpha]-\alpha)}, |\log(d_n)|\right)\right].
\end{aligned}$$

Without loss of generality we may assume that $\gamma(s) \ge \max(s^{2([\alpha]+1-\alpha)}, s^\eta)$ with $\eta < 1$: In particular, by using (2.66) as in Theorem 1.3, we have $\omega(d_n) = o(\gamma(d_n))$. Therefore we obtain for positive constants c_0, C_1:

$$-\Delta w_n + 2w_n + \frac{c_0\,\gamma(d_n)}{d_n^2}w_n + 2\frac{\gamma(d_n)}{d_n}\nabla w_n\cdot\nabla d + \frac{q|\xi|^{q-2}}{d_n}\nabla w_n\cdot\xi \le C_1\,\frac{\gamma(d_n)}{d_n^2}.$$

Moreover, since for s small, $\frac{\gamma(s)}{s} - 2\|D^2 d\|_\infty > 0$, Lemma 2.4 can be applied, and we have

$$\frac{\partial w_n}{\partial\nu} \le 0 \qquad \text{on } \partial\Omega.$$

Using the maximum principle we conclude that

$$w_n = e^{\theta(d_n)}|\nabla z_n|^2 \le C,$$

which yields $|\nabla z_n|^2 \le C$, and then in the limit as $n \to +\infty$ the Lipschitz regularity of $z = u - S$. $\square$

Remark 3.3. Several variants of the results above could be done by varying the weight function, i.e., by reasoning on $w = \Phi(d)|\nabla z|^2$ with possibly different functions Φ rather than those used above. An example is given by using $\Phi(d) = |\log d|^{-2}$: In this case, assuming f such that $|\nabla f| \le \frac{C}{d^2}$, one can prove that $|\nabla(u - s)| \le C|\log d|$.

Remark 3.4. A different approach to the results of Theorem 3.1 or 3.2 can be done if we can expand f as

$$f(x) = \sum_{j=0}^{m_f} \varphi_j d^{j-\gamma}, \tag{3.8}$$

where φ_j are smooth functions and $\gamma < \alpha + 2$. In this case we can modify the so-called "corrector term" S to get rid of the singular part of f. Indeed we can define S as

$$S = \sum_{k=0}^{m} \sigma_k d^{k-\alpha} + \sum_{j=0}^{m_f} \psi_j d^{j+2-\gamma}$$

and choose the functions ψ_j (depending on the φ_j's) to reduce the problem to the case of smooth data f. Actually requiring (3.8) means that $d^\gamma f$ is smooth, which is a stronger assumption than $|\nabla f| \le \frac{C}{d^{\gamma+1}}$: For instance, if $x_0 \in \partial\Omega$, then $f(x) = |x - x_0|^{-\gamma}$ satisfies $|\nabla f| \le C d^{-\gamma-1}$ but $d^\gamma f \notin C^0(\Omega)$.

In particular, if we assume the condition that $d(x)f$ is smooth (which is more demanding than (3.6) as regards the tangential behavior but possibly less strong in the normal component), then the result of Theorem 3.2 still holds true. This suggests that (3.6) may possibly be relaxed as far as the normal derivative of f is concerned, but we suspect it to be optimal due to tangential effects. On the other hand, we observe that the assumption (3.2) in Theorem 3.1 is optimal in order to get the intermediate estimate (3.3).

Remark 3.5. In the case of data f singular at the boundary, the method of proof of Theorem 1.3 may be used (although this extension is not trivial) to obtain a stabilization result as follows: Let u_1 and u_2 be solutions of (1.1)–(1.2) corresponding to different data f_1 and f_2 such that $|\nabla f_i| = O(d^{-\gamma})$, with $\gamma < \alpha + 2$. Then one has $\|\nabla(u_1 - u_2)\|_{L^\infty(\Omega)} \le C(1 + \|\nabla(f_1 - f_2)\|_{L^\infty(\Omega)})$.

3.2. Expansion of ∇u via blow-up argument. As pointed out in the introduction, the typical approach used in previous papers (see, e.g., the works [1], [3], [18], and references therein) for the asymptotic development of the gradient of explosive solutions consists in deriving the behavior of ∇u via scaling and blow-up once a precise estimate on the asymptotics of u has been established. In the present context, one could rephrase this method as follows: If one knows that

$$u(x) - S_k(x) = o(d^{k-\alpha}), \tag{3.9}$$

where $S_k(x)$ are the first $k+1$ terms in the formal expansion of u introduced in (1.15), then one can expect to prove that $\nabla u - \nabla S_k(x) = o(d^{k-\alpha-1})$. Indeed, this is the method used in [18] to get estimate (1.8) for solutions of (1.1)–(1.2), which the reader has also found in Lemma 2.7 in a similar version for the approximating solutions. Let us point out that this alternative approach works provided $\alpha > k$, i.e., if the translated function $u(x) - S_k(x)$ is still explosive. Recalling the value of $\alpha = \frac{2-q}{q-1}$, this means, for instance, that the second order terms of the expansion ($k = 1$ in (3.9)) can be recovered with this method provided $q < \frac{3}{2}$. Thus, although the result of Theorem 1.3 is clearly more general and complete, in some particular cases the approach via blow-up may still provide some intermediate results on the expansion of ∇u at the boundary, with the advantage of requiring slightly weaker assumptions on f (namely, no assumption on ∇f is required) and on $\partial\Omega$. It may be of interest to state explicitly this result.

THEOREM 3.6. *Let Ω be of class C^{k+3}, and let $u(x)$ be the unique solution of* (1.1)–(1.2). *Let f be such that $d^{\alpha+2-k}|f|$ is bounded and tends to zero at the boundary, and suppose $\alpha > k$, $k \in \mathbb{N}$, $k \geq 1$. Then*

$$d^{\alpha+1-k}(x)\left(\frac{\partial u(x)}{\partial \nu} - \frac{\partial S_k(x)}{\partial \nu}\right) \to 0 \quad \text{as} \quad d(x) \to 0, \tag{3.10}$$

and

$$d^{\alpha+1-k}(x)\left(\frac{\partial u(x)}{\partial \tau} - \frac{\partial S_k(x)}{\partial \tau}\right) \to 0 \quad \text{as} \quad d(x) \to 0, \tag{3.11}$$

where $S_k(x)$ are the first $k+1$ terms in the formal expansion introduced in (1.15).

The result of the above theorem generalizes, in some sense, the first order estimate proved in [18] (that is, (3.10)–(3.11) for $k = 0$). We also stress that from (3.10)–(3.11) with $k = 1$ we already can deduce an estimate on the control law which is weaker than (1.10) but requires weaker hypotheses, i.e., $\partial\Omega \in C^4$ and $f(x) = o(d^{-\alpha-1})$; namely, we have for $\alpha > 1$ (i.e. $q < \frac{3}{2}$)

$$a(x) = -\frac{q'}{d(x)}\,\nu(x) - \frac{q'(N-1)}{2} H(\overline{x})\,\nu(x) + o(1) \qquad \text{as} \qquad d(x) \to 0.$$

Sketch of the proof. Suppose $\alpha \notin \mathbb{N}$ (otherwise, the proof is slightly different). It is easy to prove, via sub- and supersolutions, that if $\alpha > k$, $k \in \mathbb{N}$, then (3.9) holds true. Note that, in order to get such an estimate, we use the regularity of the boundary and the assumption on $f(x)$. Then we use the same blow-up framework as in Proposition 2.9: We fix $x_0 \in \partial\Omega$, $d_0 > 0$ (small) and $P_0 = x_0 + d_0 \nabla d(x_0)$, and we denote by (η_1, η') a system of coordinates (obtained by translation and rotation) such that the origin $O \equiv x_0$ and the η_1-axis coincides with $\nabla d(x_0) = -\nu(x_0)$. Let $\eta \in B(P_0, d_0 - \delta)$, and, for any $0 < \delta < d_0$, define the rescaled variable $\xi = \frac{\eta - O_\delta}{\delta}$, where $O_\delta = (\delta, 0, \ldots, 0)$, and the rescaled function

$$v_\delta(\xi) = \frac{u(\eta) - S_{k-1}(\eta)}{\delta^{-\alpha+k}} = \frac{u(\delta\xi + O_\delta) - S_{k-1}(\delta\xi + O_\delta)}{\delta^{-\alpha+k}}.$$

Since u solves (1.1), by computing we find that v_δ solves for ξ in a domain $D_\delta \to \mathbb{R}^N_+$:

$$-\Delta v_\delta + \delta^2 v_\delta + H(\xi, \nabla v_\delta) = F_\delta(\delta\xi + O_\delta), \tag{3.12}$$

where (recall that $\eta = \delta\xi + O_\delta$)

$$H(\xi, p) = \delta^{\alpha+2-k}\left(\left|p\,\delta^{k-\alpha} + \nabla S_{k-1}(\eta)\right|^q - |\nabla S_{k-1}(\eta)|^q\right)$$

and

$$-\delta^{k-\alpha-2} F_\delta(\eta) = -\Delta S_{k-1}(\eta) + S_{k-1}(\eta) + |\nabla S_{k-1}(\eta)|^q - f(\eta).$$

Now by choosing σ_j as in Theorem 1.3 and using also the hypotesis on f, we have that the right-hand side is $O(d(\eta)^{k-2-\alpha})$; moreover, since $d(x)$ is smooth, we have $d(\eta) = \delta(1+\xi_1)+\delta^2 O(|\xi|^2)$, and consequently both $\frac{d(\eta)}{\delta}$ and $\frac{\delta}{d(\eta)}$ are locally uniformly bounded on $\mathbb{R}^N_+$. Therefore we deduce that $F_\delta(\eta)$ is a locally uniformly bounded function. Similarly, if we write

$$H(\xi, \nabla v_\delta) = \nabla v_\delta \cdot G_\delta(\xi), \quad \text{where} \quad G_\delta(\xi) = \int_0^1 H_p(\xi, t\nabla v_\delta(\xi))dt,$$

by computing $H_p(\xi, tp)$ and using that $|\nabla v_\delta| = o(\delta^{-1})$ (in consequence of (1.8)) and the growth of S_{k-1}, we have that $G_\delta(\xi)$ is locally bounded in $\mathbb{R}^N_+$. Since (by (3.9)) $v_\delta(\xi)$ is locally bounded as well, we can use the Calderon–Zygmund regularity for (3.12), and with a bootstrap argument and the Sobolev embedding theorem we deduce that $v_\delta(\xi)$ is compact in $C^1_{\mathrm{loc}}(\mathbb{R}^N_+)$. However, thanks to (3.9) we have that $(\frac{d(\eta)}{\delta})^{\alpha-k} v_\delta(\xi) \to \sigma_k(x_0)$; hence $\nabla v_\delta(\xi) \to (k-\alpha)(1+\xi_1)^{k-\alpha-1}\sigma_k(x_0)\,\nabla d(x_0)$. Estimates (3.10) and (3.11) are a consequence of this convergence. $\square$

3.3. Generalizations. With the approach of the present paper, it is possible to get similar results as in Theorem 1.3 for possibly more general examples than (1.1), as, for instance, if we consider

$$-\Delta u + \psi(x, \nabla u) + u = f(x) \qquad \text{in} \quad \Omega,$$

always coupled with explosive boundary condition (1.2). Let us mention that the method of proof of Theorem 1.3 still works if, for instance, we assume that $\psi(x,\xi) = |\xi|^q + H(x,\xi)$, where $H(x,\xi)$ is a C^1 function satisfying, for $|\xi|$ large enough, the growth conditions

$$\begin{aligned}
&|H_\xi| \le C|\xi|^r d(x)^{-\gamma},\\
&|H_\xi(x,\xi) - H_\xi(x,\eta)| \le (|\xi|+|\eta|)^{r-1}|\xi-\eta| d(x)^{-\gamma}, \qquad \text{with } \tfrac{r}{q-1}+\gamma<1,\\
&|H_x(x,\xi) - H_x(x,\eta)| \le (|\xi|+|\eta|)^{s}|\xi-\eta| d(x)^{-t-1}, \qquad \text{with } \tfrac{s}{q-1}+t<1,
\end{aligned}$$

provided we choose the corrector term S in a way that $-\Delta S + S + \psi(x, \nabla S)$ is not too singular at the boundary. Of course, this last step may turn out to be rather complicated and may change drastically the form of the expansion S depending on the structure of $\psi(x,\xi)$. However, if we have that $|H(x,\xi)| \le C|\xi|^{q-1}$, then one can take S of the same form as in (1.15) but for possibly different coefficients σ_k; this happens, for instance, in the example $\psi(x,\xi) = |\xi|^q + B(x)\cdot\xi$, with $B(x)$ smooth. In this latter case the influence of B on the solution can be seen even in the second term in the expansion of the gradient (which will not depend merely on the mean curvature). Similarly, we can also consider an example of an absorption-reaction term of the type $\psi(x,\xi) = |\xi|^q - |\xi|^p$: If $0 < p \le q-1$, then the same result as in Theorem 1.3 holds true, with the same corrector function S defined in (1.15). On the other hand, if we have $q-1 < p < q$, the same method of proof can be applied, but the construction of S needs to be suitably adapted (with quite long and tedious computations due to the superposition of the two terms).

Acknowledgment. We warmly thank J. Droniou for his kind advice concerning Lemma 2.7 and for pointing out to us the related reference [11].

AN INVERSE PROBLEM FOR A DYNAMICAL LAMÉ SYSTEM WITH RESIDUAL STRESS*

VICTOR ISAKOV†, JENN-NAN WANG‡, AND MASAHIRO YAMAMOTO§

Abstract. In this paper we prove Hölder and Lipschitz stability estimates for determining all coefficients of a dynamical Lamé system with residual stress, including the density, Lamé parameters, and the residual stress, by three pairs of observations from the whole boundary or from a part of it. These estimates imply first uniqueness results for determination of all parameters in the residual stress systems from few boundary measurements. Our essential assumptions are that the Lamé system possesses a suitable pseudoconvex function, residual stress is small, and three sets of the initial data satisfy some independence condition.

Key words. elasticity system with residual stress, inverse problem, Carleman estimates

AMS subject classifications. 35R30, 74B10

DOI. 10.1137/060669115

1. Introduction. We consider an elasticity system with residual stress. This system is anisotropic; i.e., it exhibits elastic properties with different values when measured in various directions. The assumption about isotropy is too restrictive in most important applications, although it allows deeper mathematical analysis of direct, and especially inverse, problems. While the theory of the unique solvability of direct problems in a quite general anisotropic case is relatively well developed [3], almost nothing is known about determination of anisotropic elastic parameters from additional boundary value data (i.e., about inverse problems).

We handle the simplest anisotropy, known as the Lamé system with residual stress, which is a small perturbation of the classical isotropic Lamé system, by a scalar anisotropic second order operator. Smallness of perturbation is motivated by applications to material science [14]. Assuming that speeds of propagation of shear and compression waves in an unperturbed system satisfy some pseudoconvexity-type conditions (which exclude trapped elastic rays) and that three sets of initial conditions are in a certain sense independent, we obtain first uniqueness and stability results about identification of all nine elastic parameters of an isotropic medium with residual stress from lateral boundary observations. When observation time and the observed part of the boundary are arbitrary, we explicitly describe a domain where coefficients are guaranteed to be unique, and we give a Hölder stability estimate. When observation time is sufficiently large and observation is from the whole lateral boundary, we derive Lipschitz stability estimates. These estimates indicate the possibility of a numerical solution of an inverse problem with high resolution and therefore

a substantial applied potential.

While our assumptions exclude zero initial data (most natural in many applications), recent progress in generating wave fields by interior sources in geophysics, material sciences, and medicine, and also by a substantial amount of historical seismic data from earthquakes (which are interior sources), make our assumptions more realistic.

Let Ω be an open bounded domain in $\mathbb{R}^3$ with boundary $\partial\Omega \in C^8$. The residual stress is modeled by a symmetric second-rank tensor $R(x) = (r_{jk}(x))_{j,k=1}^3 \in C^7(\overline{\Omega})$ which is divergence free

$$\text{div} R = 0 \quad \text{in} \quad \Omega \tag{1.1}$$

and satisfies the boundary condition

$$R\nu = 0 \quad \text{on} \quad \partial\Omega, \tag{1.2}$$

where $\text{div}R$ is a vector-valued function with components given by

$$(\text{div}R)_j = \sum_{k=1}^{3} \partial_k r_{jk}, \quad 1 \le j \le 3.$$

In this paper, $x = (x_1, x_2, x_3) \in \mathbf{R}^3$ and $\nu = (\nu_1, \nu_2, \nu_3)^\top$ is the unit outer normal vector to $\partial\Omega$. Here and below, differential operators ∇ and Δ, without subscripts, are with respect to x variables. Let $Q = \Omega \times (-T, T)$ and $\mathbf{u} = (u_1, u_2, u_3)^\top : Q \to \mathbb{R}^3$ be the displacement vector in Q. We note that $\epsilon(\mathbf{u}) = (\nabla\mathbf{u} + \nabla\mathbf{u}^\top)/2$ is the strain tensor. We consider the initial boundary value problem

$$\mathbf{A}_E\mathbf{u} := \rho\partial_t^2\mathbf{u} - \mu\Delta\mathbf{u} - (\lambda+\mu)\nabla(\text{div}\,\mathbf{u}) - (\nabla\lambda)\text{div}\,\mathbf{u} - 2\epsilon(\mathbf{u})\nabla\mu - \text{div}((\nabla\mathbf{u})R) = 0 \text{ in } Q, \tag{1.3}$$

$$\mathbf{u} = \mathbf{u}_0, \quad \partial_t\mathbf{u} = \mathbf{u}_1 \quad \text{on} \quad \Omega \times \{0\}, \tag{1.4}$$

$$\mathbf{u} = \mathbf{g} \quad \text{on} \quad \partial\Omega \times (-T, T), \tag{1.5}$$

where ρ is density and λ and μ are Lamé parameters depending only on x and satisfying inequalities

$$\varepsilon_1 < \mu, \quad \varepsilon_1 < \rho, \quad \varepsilon_1 < \lambda + \mu \quad \text{on} \quad \Omega \tag{1.6}$$

for some positive constant ε_1. Hereafter, we use E to represent the set of elastic coefficients in (1.3), i.e., $E = (\rho, \lambda, \mu, R)$. We will assume that $\rho \in C^6(\overline{\Omega})$ and $\lambda, \mu \in C^7(\overline{\Omega})$. The system (1.3) can be written as

$$\rho\, \partial_t^2\mathbf{u} - \text{div}\,\sigma(\mathbf{u}) = 0,$$

where $\sigma(\mathbf{u}) = \lambda(\text{tr}\,\epsilon)I + 2\mu\epsilon + R + (\nabla\mathbf{u})R$ is a stress tensor. Note that the term div R does not appear in (1.3) due to (1.1). Also, due to the same condition, we can see that

$$(\text{div}((\nabla\mathbf{u})R))_i = \sum_{j,k=1}^{3} r_{jk}\partial_j\partial_k u_i, \quad 1 \le i \le 3.$$

To make sure that problem (1.3) with (1.4) and (1.5) is well-posed, it suffices to assume that

$$\|R\|_{C^1(\overline{\Omega})} < \varepsilon_0 \tag{1.7}$$

for some (small) constant $\varepsilon_0 > 0$. Assumption (1.7) is also motivated by material science applications [14]. Indeed, residual stress of interest to engineers is due to past thermal changes in steel production which do not significantly change the elastic properties of steel. It is not hard to see that if ε_0 is sufficiently small, then the boundary value problem (1.3)–(1.5) is hyperbolic, and hence for any initial data $(\mathbf{u}_0, \mathbf{u}_1) \in H^1(\Omega) \times L^2(\Omega)$ and lateral Dirichlet data $\mathbf{g} \in C^1([-T,T]; H^1(\Omega))$, $\mathbf{u}_0 = \mathbf{g}$ on $\partial\Omega \times \{0\}$, there exists a unique solution $\mathbf{u}(\cdot; E; \mathbf{u}_0, \mathbf{u}_1, \mathbf{g}) \in C([-T,T]; H^1(\Omega))$ to (1.3)–(1.5).

In this paper we are interested in the following inverse problem: Let Γ be an open subset of $\partial\Omega$ with $\partial\Gamma \in C^1$. Determine density ρ, Lamé parameters λ, μ, and the residual stress R (a total of nine functions) from Cauchy-type data $(\mathbf{u}, \sigma(\mathbf{u})\nu)$ on $\Gamma \times (-T,T)$, where $\mathbf{u} = \mathbf{u}(\cdot; E; \mathbf{u}_0, \mathbf{u}_1, \mathbf{g})$, given for a finite number of pairs of initial data $(\mathbf{u}_0, \mathbf{u}_1)$.

We will address uniqueness and stability issues. Our main focus is on stability, since stability implies uniqueness. This work is a sequel to our recent paper [11], where we demonstrated uniqueness of only R assuming known constant ρ, λ, μ. Our method is based on Carleman estimates techniques initiated by Bukhgeim and Klibanov [2]. For works on Carleman estimates and related inverse problems for scalar equations, we refer to books [1] and [12] for further details and references. The method of [2] was modified for scalar equations in the paper of Imanuvilov and Yamamoto [6]. It was found by Imanuvilov, Isakov, and Yamamoto [8] that this modification allows one to obtain uniqueness and stability for coefficients of systems of equations; in particular, in [8] there is a first uniqueness result for all three elastic parameters ρ, λ, μ of isotropic elasticity. For further results on identification of the isotropic Lamé system we refer to [7]. For Carleman estimates and uniqueness of the continuation for the residual stress system (1.3) and for identification of the source term and R with given constant ρ, λ, μ, we refer to [10], [11], [13]. In the case of many boundary measurements and zero initial data, there are only partial results on identification of residual stress [5], [15]. In the present work we will show that we can determine all nine parameters in (1.3)–(1.5) by three pairs of Cauchy data. We will derive a Hölder stability estimate in the convex hull of the observation surface Γ and a Lipschitz stability estimate for (ρ, λ, μ, R) in Ω when $\Gamma = \partial\Omega$ and observation time T is large.

We are now ready to state our main results. Let $d = \inf |x|$ and $D = \sup |x|$ over $x \in \Omega$. We will assume that

$$0 < d. \tag{1.8}$$

Let θ be a positive number. For a function $c \in C^1(\overline{\Omega})$ we introduce the condition

$$\theta^2 < c \quad \text{and} \quad \theta^2 c + D\theta\sqrt{c}|\nabla c| + \frac{1}{2} c\, x \cdot \nabla c < c^2 \quad \text{on} \quad \overline{\Omega}. \tag{1.9}$$

Let $\varepsilon_0 > 0$ be given as in (1.7), $M > 0$ be arbitrarily fixed, and $\mathcal{E}_{\varepsilon_0, M}$ be the class of functions (elastic parameters) defined by

$$\begin{aligned}\mathcal{E}_{\varepsilon_0,M} = \quad & \{(\rho, \lambda, \mu, R) : \ \|\rho\|_{C^6(\overline{\Omega})} + \|\lambda\|_{C^7(\overline{\Omega})} + \|\mu\|_{C^7(\overline{\Omega})} + \|R\|_{C^6(\overline{\Omega})} < M : \\ & \rho, \lambda, \mu \text{ satisfy (1.6) and } c = \frac{\mu}{\rho},\ c = \frac{\lambda + 2\mu}{\rho} \text{ satisfy (1.9),} \\ & R \text{ is symmetric and satisfies (1.1), (1.2), and (1.7)}\}.\end{aligned}$$

To study the inverse problem, we need not only the well-posedness of (1.3)–(1.5) but also some extra regularity of the solution $\mathbf{u}$. To achieve the latter property, the initial and Dirichlet data $(\mathbf{u}_0, \mathbf{u}_1, \mathbf{g})$ are required to satisfy some smoothness and compatibility conditions. More precisely, we will assume that $\mathbf{u}_0 \in H^9(\Omega), \mathbf{u}_1 \in H^8(\Omega)$, and $\mathbf{g} \in C^8([-T,T]; H^1(\partial\Omega)) \cap C^5([-T,T]; H^4(\partial\Omega))$ and that they satisfy standard compatibility conditions of order 8 at $\partial\Omega \times \{0\}$. By using energy estimates [3] and Sobolev embedding theorems as in [8], one can show that

$$\|\partial_x^\alpha \partial_t^\beta \mathbf{u}\|_{C^0(\overline{Q})} \leq C \tag{1.10}$$

for $|\alpha| \leq 2$ and $0 \leq \beta \leq 5$. We will use three sets of initial data $(\mathbf{u}_0(\cdot;j), \mathbf{u}_1(\cdot;j))$, $j = 1,2,3$. To guarantee uniqueness in the inverse problem, we impose some nondegeneracy condition on the initial data. Namely, let $\mathbf{M}$ denote the 18×13 matrix

$$\begin{pmatrix}
\mu\Delta\mathbf{u}_0(\cdot;1) + (\lambda+\mu)\nabla(\operatorname{div}\mathbf{u}_0(\cdot;1)) & \operatorname{div}\mathbf{u}_0(\cdot;1)I_3 & 2\epsilon(\mathbf{u}_0(\cdot;1)) & \mathbf{R}(\mathbf{u}_0(\cdot;1)) \\
\mu\Delta\mathbf{u}_1(\cdot;1) + (\lambda+\mu)\nabla(\operatorname{div}\mathbf{u}_1(\cdot;1)) & \operatorname{div}\mathbf{u}_1(\cdot;1)I_3 & 2\epsilon(\mathbf{u}_1(\cdot;1)) & \mathbf{R}(\mathbf{u}_1(\cdot;1)) \\
\mu\Delta\mathbf{u}_0(\cdot;2) + (\lambda+\mu)\nabla(\operatorname{div}\mathbf{u}_0(\cdot;2)) & \operatorname{div}\mathbf{u}_0(\cdot;2)I_3 & 2\epsilon(\mathbf{u}_0(\cdot;2)) & \mathbf{R}(\mathbf{u}_0(\cdot;2)) \\
\mu\Delta\mathbf{u}_1(\cdot;2) + (\lambda+\mu)\nabla(\operatorname{div}\mathbf{u}_1(\cdot;2)) & \operatorname{div}\mathbf{u}_1(\cdot;2)I_3 & 2\epsilon(\mathbf{u}_1(\cdot;2)) & \mathbf{R}(\mathbf{u}_1(\cdot;2)) \\
\mu\Delta\mathbf{u}_0(\cdot;3) + (\lambda+\mu)\nabla(\operatorname{div}\mathbf{u}_0(\cdot;3)) & \operatorname{div}\mathbf{u}_0(\cdot;3)I_3 & 2\epsilon(\mathbf{u}_0(\cdot;3)) & \mathbf{R}(\mathbf{u}_0(\cdot;3)) \\
\mu\Delta\mathbf{u}_1(\cdot;3) + (\lambda+\mu)\nabla(\operatorname{div}\mathbf{u}_1(\cdot;3)) & \operatorname{div}\mathbf{u}_1(\cdot;3)I_3 & 2\epsilon(\mathbf{u}_1(\cdot;3)) & \mathbf{R}(\mathbf{u}_1(\cdot;3))
\end{pmatrix},$$

where I_3 is the 3×3 identity matrix, and where $\mathbf{R}(\mathbf{v})$ is a 3×6 matrix defined by

$$\mathbf{R}(\mathbf{v}) = \begin{pmatrix} \partial_1^2\mathbf{v} & 2\partial_1\partial_2\mathbf{v} & 2\partial_1\partial_3\mathbf{v} & \partial_2^2\mathbf{v} & 2\partial_2\partial_3\mathbf{v} & \partial_3^2\mathbf{v} \end{pmatrix}. \tag{1.11}$$

We will assume that

(1.12) there exists a 13×13 minor of $\mathbf{M}$ such that the absolute value of its determinant is greater than some constant $\varepsilon_2 > 0$ on $\overline{\Omega}$.

One can check that $\mathbf{u}_0(\cdot;1) = (x_1x_2, 0, 0)^\top$, $\mathbf{u}_1(\cdot;1) = (0,0,0)^\top$, $\mathbf{u}_0(\cdot;2) = (x_1, x_2, x_3)^\top$, $\mathbf{u}_1(\cdot;2) = (0, x_2, x_3)$, $\mathbf{u}_0(\cdot;3) = (x_1^2, x_2^2, x_3^2)^\top$, and $\mathbf{u}_1(\cdot;3) = (x_2x_3, x_1x_3, x_1x_2)^\top$ satisfy (1.12). Here, 13 row vectors from rows 2 and 7–18 are linearly independent on $\overline{\Omega}$. In fact, the direct calculations yield that the absolute value of the determinant of 13×13 minor is $2^{10}(\lambda(x) + \mu(x))$, and we can choose $\varepsilon_2 = 2^{10}\varepsilon_1$ in (1.12), where $\varepsilon_1 > 0$ is given in (1.6).

Condition (1.12) does not hold physically, but for the identification of the residual stress, the density, and the Lamé coefficients we have to set up the system by choosing initial values artificially, e.g., in a laboratory. The above example of such initial values suggests that there may be many choices for it.

We will use the following notation.

C, γ are generic constants depending only on $\Omega, T, \delta, \varepsilon_0, \varepsilon_1, \varepsilon_2, M, \mathbf{u}_0(\cdot;j), \mathbf{u}_1(\cdot;j)$, $j = 1,2,3$ (any other dependence will be indicated). $\|\cdot\|_{(k)}(Q)$ is the norm in the Sobolev space $H^k(Q)$. $Q(\varepsilon) = Q \cap \{\varepsilon < |x|^2 - \theta^2t^2 - d_1^2\}$ and $\Omega(\varepsilon) = \Omega \cap \{\varepsilon < |x|^2 - d_1^2\}$, where $d_1 \geq d$. Let $\mathbf{u}(;1;j)$ and $\mathbf{u}(;2;j)$ be solutions of (1.3), (1.4) with initial data $(\mathbf{u}_0(;j), \mathbf{u}_1(;j))$, for $j = 1,2,3$, corresponding to sets of coefficients $E_1 = (\rho_1, \lambda_1, \mu_1, R_1)$ and $E_2 = (\rho_2, \lambda_2, \mu_2, R_2)$, respectively. We will consider the Dirichlet data (displacements) as measurements (observations). We introduce the norm of the differences of the data as

$$F = \sum_{j=1}^{3}\sum_{\beta=2}^{4}(\|\partial_t^\beta(\mathbf{u}(;2;j) - \mathbf{u}(;1;j))\|_{(\frac{5}{2})}(\Gamma \times (-T,T))$$
$$+\|\partial_t^\beta\sigma(\mathbf{u}(;2;j) - \mathbf{u}(;1;j))\nu\|_{(\frac{3}{2})}(\Gamma \times (-T,T))).$$

This data norm includes the fourth order time derivatives and is technically necessary for our proof of the Lipschitz stability in the inverse problem. Because we have to obtain a suitable number of equations in 13 unknown functions ρ, λ, μ, r_{jk} ($1 \le j \le k \le 3$) in terms of data, we will use also $\partial_t^3 \mathbf{u}(\ ;k;j)$, $j = 1,2,3$ at $t = 0$ (see (3.9)). For that, we need L^2-estimates of $\partial_t^4 \mathbf{u}$ in (x,t) in the Carleman estimate, which yield estimates of $\partial_t^3 \mathbf{u}(\ ;k;j)$ at $t = 0$ (see (3.12)).

We first state the Hölder-type estimate for determining coefficients in $\Omega(\varepsilon)$.

THEOREM 1.1. *Assume that the domain Ω satisfies* (1.8) *and for some d_1 ($\ge d$),*

$$|x|^2 - d_1^2 < 0 \text{ when } x \in (\partial\Omega \setminus \Gamma) \text{ and } D^2 - \theta^2 T^2 - d_1^2 < 0. \tag{1.13}$$

Let the initial data $(\mathbf{u}_0(;j), \mathbf{u}_1(;j))$, $j = 1,2,3$, satisfy (1.12) *with $\lambda = \lambda_1, \mu = \mu_1$.*

Then there exist ε_0 and constants $C, \gamma \in (0,1)$ such that for $E_1, E_2 \in \mathcal{E}_{\varepsilon_0,M}$ with

$$\lambda_1 = \lambda_2 \quad \text{and} \quad \mu_1 = \mu_2 \quad \text{on} \quad \Gamma, \tag{1.14}$$

one has

$$\|\rho_1-\rho_2\|_{(0)}(\Omega(\varepsilon))+\|\lambda_1-\lambda_2\|_{(0)}(\Omega(\varepsilon))+\|\mu_1-\mu_2\|_{(0)}(\Omega(\varepsilon))+\|R_1-R_2\|_{(0)}(\Omega(\varepsilon)) \le CF^\gamma. \tag{1.15}$$

Remark 1.2. If $d_1 < D$, then the second condition in (1.13) implies that

$$\frac{D^2 - d_1^2}{\theta^2} < T^2.$$

In other words, the observation time T needs to be sufficiently large. In this case, we can determine elastic parameters in the domain $\Omega(\varepsilon)$. The domain $\Omega(\varepsilon)$ is discussed in [9, section 3.4].

If Γ is the whole lateral boundary and T is sufficiently large, then a much stronger (and in a certain sense the best possible) Lipschitz stability estimate holds.

THEOREM 1.3. *Let $d_1 = d$. Assume that*

$$\frac{D^2 - d^2}{\theta^2} < T^2 < \frac{d^2}{\theta^2}. \tag{1.16}$$

Let the initial data $(\mathbf{u}_0(;j), \mathbf{u}_1(;j))$, $j = 1,2,3$, satisfy (1.12) *with $\lambda = \lambda_1, \mu = \mu_1$, and $\Gamma = \partial\Omega$.*

Then there exists ε_0 in (1.7) *and C such that for $E_1, E_2 \in \mathcal{E}_{\varepsilon_0,M}$ satisfying the conditions*

$$\rho_1 = \rho_2,\ R_1 = R_2,\ \partial^\alpha \lambda_1 = \partial^\alpha \lambda_2, \text{and } \partial^\alpha \mu_1 = \partial^\alpha \mu_2 \text{ on } \Gamma \text{ when } |\alpha| \le 1, \tag{1.17}$$

one has

$$\|\rho_1 - \rho_2\|_{(0)}(\Omega) + \|\lambda_1 - \lambda_2\|_{(0)}(\Omega) + \|\mu_1 - \mu_2\|_{(0)}(\Omega) + \|R_1 - R_2\|_{(0)}(\Omega) \le CF. \tag{1.18}$$

Remark 1.4. Condition (1.16) is needed for pseudoconvexity of weight function φ in Carleman estimates in the next sections and generally cannot be removed. Existence of T is guaranteed by the condition $D^2 < 2d^2$. Under the additional assumption $e \cdot \nabla c(x) \le 0, x \in \Omega$ for some direction e, the condition $D^2 < 2d^2$ can be achieved by using translation $x = y + Le$ with large L.

As mentioned previously, the proofs of these theorems rely on Carleman estimates. We briefly describe the needed Carleman estimates in section 2. Using this estimate we will prove in section 3 the Hölder stability estimate (1.15). In section 4, we derive the Lipschitz stability estimate for our inverse problem.

2. Carleman estimate. In this section we will collect Carleman estimates needed to solve our inverse problem. Their proofs can be found in [10] and [11]. Let $\psi(x,t) = |x|^2 - \theta^2 t^2 - d_1^2$ and $\varphi(x,t) = \exp(\frac{\eta}{2}\psi(x,t))$. Due to conditions (1.9) and (1.13) and known sufficient conditions of pseudoconvexity [9, Theorem 3.4.1], we can fix (large) $\eta > 0$ so that the phase function φ is strongly pseudoconvex on $\overline{Q(0)}$ with respect to

$$\frac{\rho}{\mu}\partial_t^2 - \Delta, \qquad \frac{\rho}{\lambda+2\mu}\partial_t^2 - \Delta.$$

Similarly, (1.9) and the second inequality in (1.16) guarantee strong pseudoconvexity of φ on $\bar{Q}$.

THEOREM 2.1. *There are constants ε_0 and C such that under the conditions of Theorem 1.3 for $E \in \mathcal{E}_{\varepsilon_0,M}$,*

(2.1)
$$\int_Q (\tau|\nabla_{x,t}\mathbf{u}|^2 + \tau|\nabla_{x,t}\mathrm{div}\,\mathbf{u}|^2 + \tau|\nabla_{x,t}\mathrm{curl}\,\mathbf{u}|^2 + \tau^3|\mathbf{u}|^2 + \tau^3|\mathrm{div}\,\mathbf{u}|^2 + \tau^3|\mathrm{curl}\,\mathbf{u}|^2)e^{2\tau\varphi}$$
$$\leq C \int_Q (|\mathbf{A}_E\mathbf{u}|^2 + |\nabla(\mathbf{A}_E\mathbf{u})|^2)e^{2\tau\varphi}$$

for all $\mathbf{u} \in H_0^3(Q)$, and under the conditions of Theorem 1.1,

$$\int_{Q(0)} (\tau^2|\mathbf{u}|^2 + |\mathrm{div}\,\mathbf{u}|^2 + |\mathrm{curl}\,\mathbf{u}|^2 + \tau^{-1}|\nabla\mathbf{u}|^2)e^{2\tau\varphi} \leq C \int_{Q(0)} |\mathbf{A}_E\mathbf{u}|^2 e^{2\tau\varphi} \tag{2.2}$$

for all $\mathbf{u} \in H_0^2(Q(0))$.

The Carleman estimates of Theorem 2.1 form our basic tool for treating the inverse problem. The basic idea in proving Theorem 2.1 is to reduce (1.3) to an extended system of dimension 7 for $(\mathbf{u}, \mathrm{div}\,\mathbf{u}, \mathrm{curl}\,\mathbf{u})$. The resulting new system is not principally diagonalized. However, when the residual stress R is small, the second derivatives of $\mathbf{u}$ can be bounded by first derivatives of $\mathrm{div}\,\mathbf{u}$ and $\mathrm{curl}\,\mathbf{u}$. We refer to [10] and [11] for detailed computations. For the case considered here, we need only verify the strong pseudoconvexity of φ on $\overline{Q}$ or on $\bar{Q}$. Under conditions (1.9), (1.13) or (1.16) one can check that φ satisfies the required property when ε_0 is small and η is large (see [9] or [10]). An estimate similar to (2.2) was also derived in [8].

In order to use (2.1), it is required that the Cauchy data of the solution and the source term vanish on the lateral boundary. To handle nonvanishing Cauchy data, the following lemma is useful.

LEMMA 2.2. *For any pair of $(\mathbf{g}_0, \mathbf{g}_1) \in H^{\frac{5}{2}}(\partial\Omega \times (-T,T)) \times H^{\frac{3}{2}}(\partial\Omega \times (-T,T))$, we can find a vector-valued function $\mathbf{u}^* \in H^3(Q)$ such that*

$$\mathbf{u}^* = \mathbf{g}_0, \quad \sigma(\mathbf{u}^*)\nu = \mathbf{g}_1, \quad \mathbf{A}_E\mathbf{u}^* = 0 \quad \textit{on} \quad \partial\Omega \times (-T,T),$$

and

$$\|\mathbf{u}^*\|_{(3)}(Q) \leq C(\|\mathbf{g}_0\|_{(\frac{5}{2})}(\partial\Omega \times (-T,T)) + \|\mathbf{g}_1\|_{(\frac{3}{2})}(\partial\Omega \times (-T,T))) \tag{2.3}$$

for some $C > 0$, provided ε_0 in (1.7) is sufficiently small.

Proof. By standard extension theorems for any $\mathbf{g}_2 \in H^{\frac{1}{2}}(\partial\Omega \times (-T,T))$ we can find $\mathbf{u}^{**} \in H^3(Q)$ so that

$$\mathbf{u}^{**} = \mathbf{g}_0, \quad \sigma(\mathbf{u}^{**})\nu = \mathbf{g}_1, \quad \partial_\nu^2\mathbf{u}^{**} = \mathbf{g}_2 \quad \text{on} \quad \partial\Omega \times (-T,T)$$

and

$$\|\mathbf{u}^{**}\|_{(3)}(Q) \le C(\|\mathbf{g}_2\|_{(\frac{1}{2})}(\partial\Omega \times (-T,T)) + \|\mathbf{g}_1\|_{(\frac{3}{2})}(\partial\Omega \times (-T,T)) \\ + \|\mathbf{g}_0\|_{(\frac{5}{2})}(\partial\Omega \times (-T,T))).$$

Since $\partial\Omega \times (-T,T)$ is noncharacteristic with respect to $\mathbf{A}_E$ provided (1.6) holds and ε_0 is small, the condition $\mathbf{A}_E\mathbf{u}^{**} = 0$ on $\partial\Omega \times (-T,T)$ is equivalent to the fact that $\mathbf{g}_2$ can be written as a linear combination (with C^1 coefficients) of $\partial_t^2\mathbf{g}_0$ and tangential derivatives of $\mathbf{g}_0$ (up to second order) and of $\mathbf{g}_1$ (up to first order) along $\partial\Omega$. In particular,

$$\|\mathbf{g}_2\|_{(\frac{1}{2})}(\partial\Omega \times (-T,T)) \le C(\|\mathbf{g}_1\|_{(\frac{3}{2})}(\partial\Omega \times (-T,T)) + \|\mathbf{g}_0\|_{(\frac{5}{2})}(\partial\Omega \times (-T,T))).$$

Choosing $\mathbf{g}_2$ as this linear combination, we obtain (2.3). ∎

To handle $\nabla\lambda$ and $\nabla\mu$ in (1.3), we need other Carleman estimates. We first derive the estimate needed in the proof of Theorem 1.1. Let d_1 be given as in Theorem 1.1. Then we can see that $\partial\Omega(\varepsilon) = (\Gamma \cup \{|x|^2 = d_1^2 + \varepsilon\}) \cap \bar{\Omega}$.

Lemma 2.3. *Let $f \in C^1(\overline{\Omega})$ satisfy $f|_\Gamma = 0$. Then*

$$\tau \int_{\Omega(\varepsilon)} |f(x)|^2 e^{2\tau\varphi(x,0)} dx \le C \int_{\Omega(\varepsilon)} |\nabla f(x)|^2 e^{2\tau\varphi(x,0)} dx. \tag{2.4}$$

Proof. Denote $\varphi_0(x) = \varphi(x,0)$. Let $g = e^{\tau\varphi_0} f$; then $e^{\tau\varphi_0}\nabla f = \nabla g - \tau\nabla\varphi_0 g$. Note that $g|_\Gamma = 0$. We observe that $\nabla\varphi_0(x) = \eta x\varphi_0(x)$, and thus on $\partial\Omega(\varepsilon) \setminus \Gamma$ with the unit outer normal $\nu(= -x/|x|)$,

$$\partial_\nu\varphi_0(x) = \nabla\varphi_0 \cdot \nu = -\eta|x|\varphi_0(x). \tag{2.5}$$

Using integration by parts and (2.5), we have that

$$\begin{aligned}
&\int_{\Omega(\varepsilon)} |\nabla g - \tau\nabla\varphi_0 g|^2 \\
&\quad = \int_{\Omega(\varepsilon)} |\nabla g|^2 + \tau^2 \int_{\Omega(\varepsilon)} |\nabla\varphi_0 g|^2 - 2\tau \int_{\Omega(\varepsilon)} \nabla g \cdot \nabla\varphi_0 g \\
&\quad \ge -\tau \int_{\Omega(\varepsilon)} \nabla\varphi_0 \cdot \nabla(g^2) \\
&\quad = -\tau \int_{\partial\Omega(\varepsilon)\setminus\Gamma} \partial_\nu\varphi_0 g^2 + \tau \int_{\Omega(\varepsilon)} \Delta\varphi_0 g^2 \\
&\quad = \tau \int_{\partial\Omega(\varepsilon)\setminus\Gamma} \eta|x|\varphi_0(x) g^2(x) d\Gamma(x) + \tau \int_{\Omega(\varepsilon)} (3\eta + \eta^2|x|^2)\varphi_0 g^2(x) dx \\
&\quad \ge C \int_{\Omega(\varepsilon)} g^2,
\end{aligned}$$

which implies (2.4). ∎

The following estimate is useful in proving Theorem 1.3 (see also [8, Lemma 3.6]).

Corollary 2.4. *Let $f \in C^1(\overline{\Omega})$ and $f = 0$ on $\partial\Omega$. Then we have*

$$\tau \int_\Omega |f(x)|^2 e^{2\tau\varphi(x,0)} dx \le C \int_\Omega |\nabla f(x)|^2 e^{2\tau\varphi(x,0)} dx.$$

3. Hölder stability for the determination of coefficients. In this section we prove the first main result of the paper, Theorem 1.1. Let us denote $\mathbf{u}(;j) = \mathbf{u}(;2;j) - \mathbf{u}(;1;j)$ for $j = 1,2,3$, and $\mathbf{F} = (f_1, f_2, \ldots, f_9, R)^\top$, where $f_1 = \rho_1 - \rho_2$, $f_2 = \lambda_1 - \lambda_2$, $f_3 = \mu_1 - \mu_2$, $(f_4, f_5, f_6)^\top = \nabla f_2$, $(f_7, f_8, f_9)^\top = \nabla f_3$, and

$$R^\top = \begin{pmatrix} r_{11} \\ r_{12} \\ r_{13} \\ r_{22} \\ r_{23} \\ r_{33} \end{pmatrix} = \begin{pmatrix} r_{1,11} - r_{2,11} \\ r_{1,12} - r_{2,12} \\ r_{1,13} - r_{2,13} \\ r_{1,22} - r_{2,22} \\ r_{1,23} - r_{2,23} \\ r_{1,33} - r_{2,33} \end{pmatrix}.$$

Subtracting equations (1.3) for $\mathbf{u}(;1;j)$ from the equations for $\mathbf{u}(;2;j)$ yields

$$\mathbf{A}_{E_2}\mathbf{u}(;j) = \mathcal{A}(\mathbf{u}(;1;j))\mathbf{F} \quad \text{on} \quad Q, \tag{3.1}$$

where

$$\begin{aligned} \mathcal{A}(\mathbf{v})\mathbf{F} = \quad & -f_1\partial_t^2\mathbf{v} + (f_2 + f_3)\nabla(\operatorname{div}\mathbf{v}) + f_3\Delta\mathbf{v} + \operatorname{div}\mathbf{v}(f_4, f_5, f_6)^\top \\ & + 2\epsilon(\mathbf{v})(f_7, f_8, f_9)^\top + \sum_{j,k=1}^{3} r_{jk}\partial_j\partial_k\mathbf{v} \end{aligned}$$

and

$$\mathbf{u}(;j) = \partial_t\mathbf{u}(;j) = 0 \quad \text{on} \quad \Omega \times \{0\}. \tag{3.2}$$

Differentiating (3.1) in t and using the time-independence of the coefficients of the system, we get

$$\mathbf{A}_{E_2}\mathbf{U}(;j) = \mathcal{A}(\mathbf{U}(;1;j))\mathbf{F} \quad \text{on} \quad Q, \tag{3.3}$$

where

$$\mathbf{U}(;j) = \begin{pmatrix} \partial_t^2\mathbf{u}(;j) \\ \partial_t^3\mathbf{u}(;j) \\ \partial_t^4\mathbf{u}(;j) \end{pmatrix}, \quad \mathbf{U}(;1;j) = \begin{pmatrix} \partial_t^2\mathbf{u}(;1;j) \\ \partial_t^3\mathbf{u}(;1;j) \\ \partial_t^4\mathbf{u}(;1;j) \end{pmatrix},$$

and

$$\mathcal{A}(\mathbf{U}(;1;j)) = \begin{pmatrix} \mathcal{A}(\partial_t^2\mathbf{u}(;1;j)) \\ \mathcal{A}(\partial_t^3\mathbf{u}(;1;j)) \\ \mathcal{A}(\partial_t^4\mathbf{u}(;1;j)) \end{pmatrix}.$$

By extension theorems for Sobolev spaces, there exists $\mathbf{U}^*(;j) \in H^2(Q)$ such that

$$\mathbf{U}^*(;j) = \mathbf{U}(;j),\ \sigma(\mathbf{U}^*(;j))\nu = \sigma(\mathbf{U}(;j))\nu \quad \text{on} \quad \Gamma \times (-T,T) \tag{3.4}$$

and

$$\|\mathbf{U}^*(;j)\|_{(2)}(Q) \le C(\|\mathbf{U}(;j)\|_{(\frac{3}{2})}(\Gamma \times (-T,T)) + \|\sigma(\mathbf{U})(;j)\nu\|_{(\frac{1}{2})}(\Gamma \times (-T,T))) \le CF \tag{3.5}$$

for all $j = 1,2,3$ due to the definitions of $\mathbf{u}(;j), \mathbf{U}(;j)$, and F. We now introduce $\mathbf{V}(;j) = \mathbf{U}(;j) - \mathbf{U}^*(;j)$. Then

$$\mathbf{A}_{E_2}\mathbf{V}(;j) = \mathcal{A}(\mathbf{U}(;1;j))\mathbf{F} - \mathbf{A}_{E_2}\mathbf{U}^*(;j) \quad \text{on} \quad Q \tag{3.6}$$

and

$$\mathbf{V}(;j) = \sigma(\mathbf{V})(;j)\nu = 0 \quad \text{on} \quad \Gamma \times (-T,T). \tag{3.7}$$

To use the Carleman estimate (2.2), we introduce a cut-off function $\chi \in C^2(\mathbb{R}^4)$ such that $0 \le \chi \le 1$, $\chi = 1$ on $Q(\frac{\varepsilon}{2})$, and $\chi = 0$ on $Q \setminus Q(0)$. By the Leibniz formula,

$$\mathbf{A}_{E_2}(\chi\mathbf{V}(;j)) = \chi\mathbf{A}_{E_2}(\mathbf{V}(;j)) + \mathbf{A}_1\mathbf{V}(;j) = \chi\mathcal{A}\mathbf{F} - \chi\mathbf{A}_{E_2}\mathbf{U}^*(;j) + \mathbf{A}_1\mathbf{V}(;j)$$

due to (3.6). Here (and below) $\mathbf{A}_1$ denotes a first order matrix differential operator with coefficients uniformly bounded by $C(\varepsilon)$. By the choice of χ, $\mathbf{A}_1\mathbf{V}(;j) = 0$ on $Q(\frac{\varepsilon}{2})$. It is not hard to see that (3.7) implies that $\mathbf{V}(;j) = \partial_\nu\mathbf{V}(;j) = 0$ on $\Gamma\times(-T,T)$. Hence due to the first condition of (1.13), the function $\chi\mathbf{V}(;j) \in H_0^2(Q(0))$ (see, for example [4, Corollary 1.5.1.6, p. 39]). Observe, that $\chi = 0$ is zero near the non-C^8-smooth part of $\partial Q(0)$, and therefore we can use results for C^8-smooth domains by slightly extending $Q(0)$. So we can apply to $\chi\mathbf{V}(;j)$ the Carleman estimate (2.2) to get

$$\int_Q \tau|\chi\mathbf{V}(;j)|^2 e^{2\tau\varphi}$$

$$\le C\int_Q (|\mathbf{F}|^2 + |\mathbf{A}_{E_2}(\mathbf{U}^*(;j))|^2)e^{2\tau\varphi} + C\int_{Q\setminus Q(\frac{\varepsilon}{2})} |\mathbf{A}_1\mathbf{V}(;j)|^2 e^{2\tau\varphi}$$

$$\le C\left(\int_Q |\mathbf{F}|^2 e^{2\tau\varphi} + F^2 e^{2\tau\Phi} + C(\varepsilon)e^{2\tau\varepsilon_1}\right), \tag{3.8}$$

where $\Phi = \sup\varphi$ over Q and $\varepsilon_1 = e^{\frac{\eta\varepsilon}{4}}$. To get the last inequality, we used the bounds (3.5) and (1.10).

On the other hand, from (1.3), (3.1), (3.2) we have

$$\rho_2\partial_t^2\mathbf{u}(;j) = \mathcal{A}(\mathbf{u}(;1;j))\mathbf{F},$$

$$\rho_2\partial_t^3\mathbf{u}(;j) = \mathcal{A}(\partial_t\mathbf{u}(;1;j))\mathbf{F}$$

on $\Omega\times\{0\}$. We now want to rearrange the formulas above. Let $\mathbf{a}_{kj} = -\partial_t^{2+k}\mathbf{u}(0;1;j)$, $\mathbf{b}_{kj} = \nabla(\operatorname{div}\mathbf{u}_k(;j))$, $\mathbf{c}_{kj} = \Delta\mathbf{u}_k(;j)+\nabla\operatorname{div}\mathbf{u}_k(;j)$, $\mathbf{B}_{kj} = \operatorname{div}\mathbf{u}_k(;j)$, $\mathbf{C}_{kj} = 2\epsilon(\mathbf{u}_k(;j))$, and $\mathbf{R}_{kj} = \mathbf{R}(\mathbf{u}_k(;j))$ (see the definition of $\mathbf{R}$ in (1.11)), where $k = 0, 1$ and $j = 1, 2, 3$. Using that $\mathbf{u}(;1;j) = \mathbf{u}_0(;j), \partial_t\mathbf{u}(;1;j) = \mathbf{u}_1(;j)$ on $\Omega\times\{0\}$, we have

$$\begin{pmatrix} \mathbf{a}_{01} & \mathbf{B}_{01}I_3 & \mathbf{C}_{01} & \mathbf{R}_{01} \\ \mathbf{a}_{11} & \mathbf{B}_{11}I_3 & \mathbf{C}_{11} & \mathbf{R}_{11} \\ \mathbf{a}_{02} & \mathbf{B}_{02}I_3 & \mathbf{C}_{02} & \mathbf{R}_{02} \\ \mathbf{a}_{12} & \mathbf{B}_{12}I_3 & \mathbf{C}_{12} & \mathbf{R}_{12} \\ \mathbf{a}_{03} & \mathbf{B}_{03}I_3 & \mathbf{C}_{03} & \mathbf{R}_{03} \\ \mathbf{a}_{13} & \mathbf{B}_{13}I_3 & \mathbf{C}_{13} & \mathbf{R}_{13} \end{pmatrix} \begin{pmatrix} f_1 \\ f_4 \\ \vdots \\ f_9 \\ r_{11} \\ \vdots \\ r_{33} \end{pmatrix} = \rho_2 \begin{pmatrix} \partial_t^2\mathbf{u}(,0;1) \\ \partial_t^3\mathbf{u}(,0;1) \\ \partial_t^2\mathbf{u}(,0;2) \\ \partial_t^3\mathbf{u}(,0;2) \\ \partial_t^2\mathbf{u}(,0;3) \\ \partial_t^3\mathbf{u}(,0;3) \end{pmatrix} - \begin{pmatrix} \mathbf{b}_{01} & \mathbf{c}_{01} \\ \mathbf{b}_{11} & \mathbf{c}_{11} \\ \mathbf{b}_{02} & \mathbf{c}_{02} \\ \mathbf{b}_{12} & \mathbf{c}_{12} \\ \mathbf{b}_{03} & \mathbf{c}_{03} \\ \mathbf{b}_{13} & \mathbf{c}_{13} \end{pmatrix} \begin{pmatrix} f_2 \\ f_3 \end{pmatrix} \tag{3.9}$$

on Ω. From the system (1.3) at $t=0$ and from this system differentiated in t and taken at $t=0$, we obtain

$$
\begin{aligned}
\mathbf{a}_{kj} &= -\frac{\mu_1}{\rho_1}\Delta\mathbf{u}_k(;j) - \frac{\lambda_1+\mu_1}{\rho_1}\nabla(\operatorname{div}\mathbf{u}_k(;j)) - \operatorname{div}\mathbf{u}_k(;j)\frac{\nabla\lambda_1}{\rho_1}\\
&\quad -2\epsilon(\mathbf{u}_k(;j))\frac{\nabla\mu_1}{\rho_1} - \sum_{\ell,m=1}^{3} r_{1,\ell m}\partial_\ell\partial_m\mathbf{u}_k(;j)\\
&= -\frac{\mu_1}{\rho_1}\Delta\mathbf{u}_k(;j) - \frac{\lambda_1+\mu_1}{\rho_1}\nabla(\operatorname{div}\mathbf{u}_k(;j)) - \mathbf{B}_{kj}\frac{\nabla\lambda_1}{\rho_1}\\
&\quad -\mathbf{C}_{kj}\frac{\nabla\mu_1}{\rho_1} - \sum_{\ell,m=1}^{3} r_{1,\ell m}\partial_\ell\partial_m\mathbf{u}_k(;j)
\end{aligned}
\tag{3.10}
$$

when $k=0,1$ and $j=1,2,3$.

We now consider the matrix on the left-hand side of (3.9). Using (3.10), one can add to the first column the remaining columns multiplied by suitable factors such that $-\operatorname{div}\mathbf{u}_k(;j)\frac{\nabla\lambda_1}{\rho_1}$, $-2\epsilon(\mathbf{u}_k(;j))\frac{\nabla\mu_1}{\rho_1}$, and $-\sum_{\ell,m=1}^{3} r_{1,\ell m}\partial_\ell\partial_m\mathbf{u}_k(;j)$ are eliminated from the first column of this matrix. Then we multiply the first column of the new matrix by $-\rho_1$. We end up with the matrix $\mathbf{M}$ defined in section 1. Obviously, determinants of corresponding minors of the matrix on the left side of (3.9) and of the matrix $\mathbf{M}$ are the same. It follows from condition (1.12) and bounds (1.10) that

$$
|\mathbf{F}|^2 \le C\left(\sum_{j=1}^{3}\sum_{\beta=2}^{3}|\partial_t^\beta\mathbf{u}(0;j)|^2 + |f_2|^2 + |f_3|^2\right) \quad \text{on} \quad \overline{\Omega}. \tag{3.11}
$$

Since $\chi(\cdot,T)=0$,

$$
\int_\Omega |\chi\partial_t^\beta\mathbf{u}(;j)|^2(x,0)e^{2\tau\varphi(x,0)}dx = -\int_0^T \partial_t\left(\int_\Omega |\chi\partial_t^\beta\mathbf{u}(;j)|^2(x,t)e^{2\tau\varphi(x,t)}dx\right)dt
$$

$$
\le \int_Q 2\chi^2(|\partial_t^{\beta+1}\mathbf{u}(;j)||\partial_t^\beta\mathbf{u}(;j)| + \tau|\partial_t\varphi||\partial_t^\beta\mathbf{u}(;j)|^2)e^{2\tau\varphi} + 2\int_{Q\setminus Q(\frac{\varepsilon}{2})}|\partial_t^\beta\mathbf{u}(;j)|^2\chi|\partial_t\chi|e^{2\tau\varphi},
$$

where $\beta=2,3$. The right side does not exceed

$$
C\left(\int_Q \tau|\chi\mathbf{U}(;j)|^2e^{2\tau\varphi} + C(\varepsilon)\int_{Q\setminus Q(\frac{\varepsilon}{2})}|\mathbf{U}(;j)|^2e^{2\tau\varphi}\right)
$$

$$
\le C\left(\int_Q \tau|\chi\mathbf{V}(;j)|^2e^{2\tau\varphi} + C(\varepsilon)\int_{Q\setminus Q(\frac{\varepsilon}{2})}|\mathbf{U}(;j)|^2e^{2\tau\varphi} + \tau\int_Q|\mathbf{U}^*(;j)|^2e^{2\tau\varphi}\right)
$$

because $\mathbf{U}(;j)=\mathbf{V}(;j)+\mathbf{U}^*(;j)$. Using that $\chi=1$ on $\Omega(\frac{\varepsilon}{2})$, $\varphi<\varepsilon_1$ on $Q\setminus Q(\frac{\varepsilon}{2})$, and $\varphi<\Phi$ on Q from these inequalities, from (3.8), (3.5), and (1.10) we set

$$
\int_{\Omega(\frac{\varepsilon}{2})}|\partial_t^\beta\mathbf{u}(0;j)|^2e^{2\tau\varphi(,0)} \le C\left(\int_Q|\mathbf{F}|^2e^{2\tau\varphi} + C(\varepsilon)e^{2\tau\varepsilon_1} + \tau e^{2\tau\Phi}F^2\right) \tag{3.12}
$$

for $\beta=2,3$ and $j=1,2,3$. Using that $\chi=1$ on $\Omega(\frac{\varepsilon}{2})$, from (3.11) and (3.12) we obtain

$$\int_{\Omega(\frac{\varepsilon}{2})} |\mathbf{F}|^2 e^{2\tau\varphi(,0)} \leq C\left(\int_{Q(\frac{\varepsilon}{2})} |\mathbf{F}|^2 e^{2\tau\varphi} + \tau e^{2\tau\Phi} F^2 + C(\varepsilon) e^{2\tau\varepsilon_1} + \int_{\Omega(\frac{\varepsilon}{2})} (|f_2|^2 + |f_3|^2) e^{2\tau\varphi(,0)} \right), \tag{3.13}$$

where we also split Q in the right side of (3.12) into $Q(\frac{\varepsilon}{2})$ and its complement and used that $|\mathbf{F}| \leq C$ and $\varphi < \varepsilon_1$ on the complement.

To eliminate the first integral in the right side of (3.13), we observe that

$$\int_{Q(\frac{\varepsilon}{2})} |\mathbf{F}|^2(x) e^{2\tau\varphi(x,t)} dxdt \leq \int_{\Omega(\frac{\varepsilon}{2})} |\mathbf{F}|^2(x) e^{2\tau\varphi(x,0)} \left(\int_{-T}^{T} e^{2\tau(\varphi(x,t)-\varphi(x,0))} dt \right) dx.$$

Due to our choice of function φ, we have $\varphi(x,t) - \varphi(x,0) < 0$ when $t \neq 0$. Hence by the Lebesgue theorem the inner integral (with respect to t) converges to 0 as τ goes to infinity. By reasons of continuity of φ, this convergence is uniform with respect to $x \in \Omega$. Choosing $\tau > C$ we therefore can absorb the integral over $Q(\frac{\varepsilon}{2})$ in the right side of (3.13) by the left side and arrive at the inequality

$$\int_{\Omega(\frac{\varepsilon}{2})} |\mathbf{F}|^2 e^{2\tau\varphi(,0)} \leq C \left(\tau e^{2\tau\Phi} F^2 + C(\varepsilon) e^{2\tau\varepsilon_1} + \int_{\Omega(\frac{\varepsilon}{2})} (|f_2|^2 + |f_3|^2) e^{2\tau\varphi(,0)} \right). \tag{3.14}$$

On the other hand, to eliminate the last integral on the right side of (3.14), we use Lemma 2.3 with condition (1.14) to get

$$\int_{\Omega(\frac{\varepsilon}{2})} (|f_2|^2 + |f_3|^2) e^{2\tau\varphi(,0)} \leq \frac{C}{\tau} \int_{\Omega(\frac{\varepsilon}{2})} (|\nabla f_2|^2 + |\nabla f_3|^2) e^{2\tau\varphi(,0)}. \tag{3.15}$$

Using (3.15) with large τ and the inequality $\tau \leq e^{\tau}$, we absorb the last integral in the right side of (3.14) into the left side and obtain

$$\int_{\Omega(\frac{\varepsilon}{2})} |\mathbf{F}|^2 e^{2\tau\varphi(,0)} \leq C(e^{2\tau(\Phi_1+1)} F^2 + C(\varepsilon) e^{2\tau\varepsilon_1}).$$

Letting $\varepsilon_2 = e^{\frac{\eta\varepsilon}{2}} \leq \varphi$ on $\Omega(\varepsilon)$ and dividing both parts by $e^{2\tau\varepsilon_2}$ yields

$$\int_{\Omega(\varepsilon)} |\mathbf{F}|^2 \leq C(\tau e^{2\tau(\Phi+1-\varepsilon_2)} F^2 + e^{-2\tau(\varepsilon_2-\varepsilon_1)}) \leq C(\varepsilon)(e^{2\tau(\Phi+1)} F^2 + e^{-2\tau(\varepsilon_2-\varepsilon_1)}) \tag{3.16}$$

since $\tau e^{-2\tau\varepsilon_2} < C(\varepsilon)$. If $\frac{1}{C} \leq F$, then bound (1.15) is obvious because the left side in (1.15) is less than C. So to prove (1.15) it suffices to assume that $F < \frac{1}{C}$. Then $\tau = \frac{-logF}{\Phi+1+\varepsilon_2-\varepsilon_1} > C$, and we can use this τ in (3.16). Due to the choice of τ,

$$e^{-2\tau(\varepsilon_2-\varepsilon_1)} = e^{2\tau(\Phi+1)} F^2 = F^{2\frac{\varepsilon_2-\varepsilon_1}{\Phi+1+\varepsilon_2-\varepsilon_1}},$$

and from (3.16) we obtain (1.15) with $\gamma = \frac{\varepsilon_2-\varepsilon_1}{\Phi+1+\varepsilon_2-\varepsilon_1}$. The proof of Theorem 1.1 is now complete.

4. Lipschitz stability for the determination of coefficients. In this section we will prove Theorem 1.3. The key ingredient is the following Lipschitz stability estimate for the Cauchy problem for the system $\mathbf{A}_E\mathbf{u} = \mathbf{f}$.

THEOREM 4.1. *Suppose that* Ω *and* T *satisfy the assumptions of Theorem* 1.3. *Let* $\mathbf{u} \in (H^3(Q))^3$ *solve the Cauchy problem*

$$\begin{cases} \mathbf{A}_E\mathbf{u} = \mathbf{f} & \text{in} \quad Q, \\ \mathbf{u} = \sigma_\nu(\mathbf{u}) = 0 & \text{on} \quad \partial\Omega \times (-T, T) \end{cases} \tag{4.1}$$

with $\mathbf{f} \in L^2((-T,T); H^1(\Omega))$ *and* $\mathbf{f} = 0$ *on* $\partial\Omega \times (-T,T)$. *Furthermore, assume that* (1.7) *holds for sufficiently small* ε_0.

Then there exists a constant $C > 0$ *such that*

$$\|\mathbf{u}\|^2_{H^1(Q)} + \|\operatorname{div}\mathbf{u}\|^2_{H^1(Q)} + \|\operatorname{curl}\mathbf{u}\|^2_{H^1(Q)} \le C\|\mathbf{f}\|^2_{L^2((-T,T);H^1(\Omega))}. \tag{4.2}$$

This estimate was proved in [11].

By virtue of (4.2) and an equivalence of the norms $\|\mathbf{u}\|_{(1)}(\Omega)$ and of

$$\|\operatorname{div}\mathbf{u}\|_{(0)}(\Omega) + \|\operatorname{curl}\mathbf{u}\|_{(0)}(\Omega) + \|\mathbf{u}\|_{(0)}(\Omega)$$

in $H^1_0(\Omega)$ (e.g., [3, pp. 358–359]), it is not hard to derive the following.
