COROLLARY 4.2. *Under the conditions of Theorem* 4.1,

$$\|\mathbf{u}\|_{(0)}(Q) + \|\nabla_{x,t}\mathbf{u}\|_{(0)}(Q) + \|\partial_t\nabla\mathbf{u}\|_{(0)}(Q) \le C\|\mathbf{f}\|_{L^2((-T,T);H^1(\Omega))}. \tag{4.3}$$

Now we are ready to prove Theorem 1.3. We will use the notations in section 3. Recall that

$$\mathbf{A}_{E_2}\mathbf{U}(;1;j) = \mathcal{A}(\mathbf{U}(;1;j))\mathbf{F},$$

where

$$\begin{aligned} \mathcal{A}(\mathbf{U}(;1;j))\mathbf{F} \quad = \quad & -f_1\partial_t^2\mathbf{U}(;1;j) + (f_2+f_3)\nabla(\operatorname{div}\mathbf{U}(;1;j)) + f_3\Delta\mathbf{U}(;1;j) \\ & + \operatorname{div}\mathbf{U}(;1;j)(f_4,f_5,f_6)^\top + 2\epsilon(\mathbf{U}(;1;j))(f_7,f_8,f_9)^\top \\ & + \sum_{j,k=1}^{3} r_{jk}\partial_j\partial_k\mathbf{U}(;1;j). \end{aligned}$$

So, from (1.17) we have

$$\mathbf{A}_{E_2}\mathbf{U}(;j) = 0 \quad \text{on} \quad \partial\Omega \times (-T,T). \tag{4.4}$$

Furthermore, in view of Lemma 2.2, there exists $\mathbf{U}^*(;j) \in H^3(Q)$ such that

$$\mathbf{U}^*(;j) = \mathbf{U}(;j), \quad \sigma(\mathbf{U}^*(;j))\nu = \sigma(\mathbf{U}(;j))\nu, \quad \mathbf{A}_{E_2}\mathbf{U}^*(;j) = 0 \quad \text{on} \quad \partial\Omega \times (-T,T) \tag{4.5}$$

and

$$\|\mathbf{U}^*(;j)\|_{(3)}(Q) \le C(\|\mathbf{U}(;j)\|_{(\frac{5}{2})}(\partial\Omega\times(-T,T)) + \|\sigma(\mathbf{U})(;j)\nu\|_{(\frac{3}{2})}(\partial\Omega\times(-T,T))) \le CF \tag{4.6}$$

due to the definition of F. As before, we set $\mathbf{V}(;j) = \mathbf{U}(;j) - \mathbf{U}^*(;j)$. Due to (4.4) and (4.5), we get

$$\mathbf{V}(;j) = \sigma(\mathbf{V})(;j)\nu = 0, \quad \mathbf{A}_{E_2}\mathbf{V}(;j) = 0 \quad \text{on} \quad \partial\Omega \times (-T,T). \tag{4.7}$$

With (4.7), applying Corollary 4.2 to (3.6), (3.7) and using (4.6) gives

$$(4.8)\quad \|\mathbf{V}(;j)\|^2_{(0)}(Q)+\|\nabla_{x,t}\mathbf{V}(;j)\|^2_{(0)}(Q)+\|\partial_t\nabla\mathbf{V}(;j)\|^2_{(0)}(Q)\le C(\|\mathbf{F}\|_{(1)}(\Omega)^2+F^2)$$

for $j=1,2,3$.

On the other hand, as in the proof of Theorem 1.1 we will bound the right side of (4.8) by $\mathbf{V}$. To use the Carleman estimate (2.1) we need to cut off $\mathbf{V}(;j)$ near $t=T$ and $t=-T$. We first observe that from the definition,

$$1\le\varphi(x,0),\qquad x\in\Omega,$$

and from condition (1.16),

$$\varphi(x,T)=\varphi(x,-T)<1\quad\text{when}\quad x\in\overline{\Omega}.$$

So there exists a $\delta>\frac{1}{C}$ such that

$$(4.9)\qquad 1-\delta<\varphi\quad\text{on}\quad\Omega\times(0,\delta),\qquad\varphi<1-2\delta\quad\text{on}\quad\Omega\times(T-2\delta,T).$$

We now choose a smooth cut-off function $0\le\chi_0(t)\le 1$ such that $\chi_0(t)=1$ for $-T+2\delta<t<T-2\delta$ and $\chi(t)=0$ for $|t|>T-\delta$. As in the argument before (3.8) (see also Lemma A.1 in [13]), from (4.7) we derive that $\mathbf{V}(;j)=\partial_\nu\mathbf{V}(;j)=0$ on $\partial\Omega\times(-T,T)$. Then since $\partial\Omega\times(-T,T)$ is not characteristic with respect to $\mathbf{A}_E$ the third equation in (4.7) implies that $\partial_\nu^2\mathbf{V}(;j)=0$ on $\partial\Omega\times(-T,T)$. Summing up, $\mathbf{V}(;j)=\partial_\nu\mathbf{V}(;j)=\partial_\nu^2\mathbf{V}(;j)=0$ on $\partial\Omega\times(-T,T)$. Now from known results about traces in Sobolev spaces [4], as above we conclude that $\chi_0\mathbf{V}(;j)\in H_0^3(Q)$. Using the Leibniz formula

$$\mathbf{A}_{E_2}(\chi_0\mathbf{V}(;j))=\chi_0\mathcal{A}(\mathbf{U}(;1;j))\mathbf{F}-\chi_0\mathbf{A}_{E_2}\mathbf{U}^*(;j)+2\rho_2(\partial_t\chi_0)\partial_t\mathbf{V}(;j)+\rho_2(\partial_t^2\chi_0)\mathbf{V}(;j)$$

and Carleman estimate (2.1) yields

$$\int_Q\chi_0^2(\tau^3|\mathbf{V}(;j)|^2+\tau|\nabla\mathbf{V}(;j)|^2)e^{2\tau\varphi}$$

$$\le C\left(\int_Q(|\mathbf{F}|^2+|\nabla\mathbf{F}|^2+|\mathbf{A}_{E_2}\mathbf{U}^*(;j)|^2+|\nabla(\mathbf{A}_{E_2}\mathbf{U}^*)(;j)|^2)e^{2\tau\varphi}\right.$$

$$\left.+\int_{\Omega\times\{T-2\delta<|t|<T\}}(|\mathbf{V}(;j)|^2+|\nabla_{x,t}\mathbf{V}(;j)|^2+|\partial_t\nabla\mathbf{V}(;j)|^2\right)e^{2\tau\varphi})$$

$$\le C\left(\int_Q(|\mathbf{F}|^2+|\nabla\mathbf{F}|^2)e^{2\tau\varphi}+e^{2\tau\Phi}F^2+e^{2\tau(1-2\delta)}\int_\Omega(|\mathbf{F}|^2+|\nabla\mathbf{F}|^2)\right),$$

where we let $\Phi = \sup_Q \varphi$ and used (4.6), (4.8), (4.9). Since $\mathbf{U}(;j) = \mathbf{V}(;j) + \mathbf{U}^*(;j)$, from (4.6) we obtain

$$\int_Q \chi_0^2(\tau^3|\mathbf{U}(;j)|^2 + \tau|\nabla\mathbf{U}(;j)|^2)e^{2\tau\varphi}$$

$$\leq C\left(\tau^3 e^{2\tau\Phi}F^2 + \int_\Omega \left(\int_{-T}^T e^{2\tau\varphi(x,t)}dt + e^{2\tau(1-2\delta)}\right)(|\mathbf{F}|^2 + |\nabla\mathbf{F}|^2)(x)\right)dx. \tag{4.10}$$

Utilizing (3.2) and (1.12), similarly to deriving (3.11), we get from (3.9) that

$$|\mathbf{F}|^2 + |\nabla\mathbf{F}|^2 \leq C\left(\sum_{j=1}^3 \sum_{\substack{\beta=2,3;\\ k=0,1}} |\partial_t^\beta \nabla^k \mathbf{u}(0;j)|^2 + \sum_{k=0,1}(|\nabla^k f_2|^2 + |\nabla^k f_3|^2)\right). \tag{4.11}$$

Therefore, by (4.11) and Corollary 2.4 (with conditions (1.17) for Lamé coefficients), we have

$$\int_\Omega (|\mathbf{F}|^2 + |\nabla\mathbf{F}|^2)e^{2\tau\varphi(,0)}$$

$$\leq C\left(\int_\Omega \sum_{j=1}^3 \sum_{\substack{\beta=2,3;\\ k=0,1}} |\partial_t^\beta \nabla^k \mathbf{u}(0;j)|^2 e^{2\tau\varphi(,0)} + \int_\Omega \sum_{k=0,1}(|\nabla^k f_2|^2 + |\nabla^k f_3|^2)e^{2\tau\varphi(,0)}\right)$$

$$\leq -C\int_0^T \partial_t\left(\int_\Omega \sum_{j=1}^3 \sum_{\substack{\beta=2,3;\\ k=0,1}} \chi_0^2 |\partial_t^\beta \nabla^k \mathbf{u}(;j)|^2(x,t)e^{2\tau\varphi(x,t)}dx\right)dt$$
$$+\frac{C}{\tau}\int_\Omega (|\mathbf{F}|^2 + |\nabla\mathbf{F}|^2)e^{2\tau\varphi(;0)}.$$

Choosing τ large, we eliminate the last term and obtain

$$\int_\Omega (|\mathbf{F}|^2 + |\nabla\mathbf{F}|^2)e^{2\tau\varphi(,0)}$$

$$\leq C\int_Q \chi_0^2 \sum_{j=1}^3 \sum_{\substack{\beta=2,3;\\ k=0,1}} (|\partial_t^\beta \nabla^k \mathbf{u}(;j)||\partial_t^{\beta+1}\nabla^k \mathbf{u}(;j)| + \tau|\partial_t\varphi||\partial_t^\beta \nabla^k \mathbf{u}(;j)|^2)e^{2\tau\varphi}$$

$$+C\int_{\Omega\times(T-2\delta,T)} \chi_0|\partial_t\chi_0| \sum_{j=1}^3 \sum_{\beta=2,3;k=0,1} |\partial_t^\beta \nabla^k \mathbf{u}(;j)|^2 e^{2\tau\varphi}.$$

Now as in the proofs of section 3, the right side is less than

$$C\left(\int_Q \tau\chi_0^2(|\mathbf{U}(;j)|^2+|\nabla\mathbf{U}(;j)|^2)e^{2\tau\varphi}+\int_{\Omega\times(T-2\delta,T)}(|\mathbf{U}(;j)|^2+|\nabla\mathbf{U}(;j)|^2)e^{2\tau\varphi}\right)$$

$$\leq C\left(\int_Q \tau\chi_0^2(|\mathbf{U}(;j)|^2+|\nabla\mathbf{U}(;j)|^2)e^{2\tau\varphi}+e^{2\tau(1-2\delta)}(\|\mathbf{F}\|^2_{(1)}(\Omega)+F^2)\right),$$

where we used equality $\mathbf{U}(;j)=\mathbf{U}^*(;j)+\mathbf{V}(;j)$ and (4.6), (4.8). From the two previous bounds and (4.10) we conclude that

$$\int_\Omega(|\mathbf{F}|^2+|\nabla\mathbf{F}|^2)e^{2\tau\varphi(,0)} \leq C\left(\tau^3e^{2\tau\Phi}F^2+\int_\Omega\left(\int_{-T}^{T}e^{2\tau\varphi(,t)}dt+e^{2\tau(1-2\delta)}\right)(|\mathbf{F}|^2+|\nabla\mathbf{F}|^2)\right). \tag{4.12}$$

Due to our choice of φ, $1\leq\varphi(,0), \varphi(,t)-\varphi(,0)<0$ when $t\neq 0$. Thus by the Lebesgue theorem as in the proofs of section 3, we have

$$2C\left(\int_{-T}^{T}e^{2\tau\varphi(,t)}dt+e^{2\tau(1-\delta)}\right)\leq e^{2\tau\varphi(,0)}$$

uniformly on Ω when $\tau>C$. Hence choosing and fixing such large τ, we eliminate the second term on the right side of (4.12). The proof of Theorem 1.3 is now complete.

5. Conclusion. While natural in some applications, the assumption about the smallness of residual stress is restrictive. In our opinion it can be relaxed by using the methods of papers [8], [11], and this paper. More restrictive and much more difficult to remove is the condition that the initial data are not zero. At present, even for scalar isotropic hyperbolic equations, global uniqueness of the speed of propagation or of the potential from few lateral boundary measurements is an open and outstanding research problem (see, for example, [9]). Moreover, in the case of zero initial data, general anisotropic hyperbolic operators (and hence systems) cannot be uniquely determined by all lateral boundary measurements (Dirichlet-to-Neumann map). In fact, a large gauge transformation group changes equations inside Ω without affecting the lateral boundary data. Hence (special) nonzero initial data are necessary for the complete identification of such equations and systems.

Of substantial interest is uniqueness in inverse problems for more general anisotropic systems, for example, for dynamical elasticity systems with transversal isotropy. For such systems there are no Carleman estimates or uniqueness of the continuation results. On the other hand, such systems are quite important for applications to geophysics, material science, and medicine, and they are notorious mathematical challenges.

EXISTENCE AND UNIQUENESS OF GLOBAL STRONG SOLUTIONS FOR ONE-DIMENSIONAL COMPRESSIBLE NAVIER–STOKES EQUATIONS*

A. MELLET† AND A. VASSEUR†

Abstract. We consider Navier–Stokes equations for compressible viscous fluids in one dimension. It is a well-known fact that if the initial datum are smooth and the initial density is bounded by below by a positive constant, then a strong solution exists locally in time. In this paper, we show that under the same hypothesis, the density remains bounded by below by a positive constant uniformly in time, and that strong solutions therefore exist globally in time. Moreover, while most existence results are obtained for positive viscosity coefficients, the present result holds even if the viscosity coefficient vanishes with the density. Finally, we prove that the solution is unique in the class of weak solutions satisfying the usual entropy inequality. The key point of the paper is a new entropy-like inequality introduced by Bresch and Desjardins for the shallow water system of equations. This inequality gives additional regularity for the density (provided such regularity exists at initial time).

Key words. Navier–Stokes, compressible, nonconstant viscosity coefficients, strong solutions, uniqueness, mono-dimensional

DOI. 10.1137/060658199

1. Introduction.

This paper is devoted to the existence of global strong solutions of the following Navier–Stokes equations for compressible isentropic flow:

$$\rho_t + (\rho u)_x = 0, \tag{1.1}$$

$$(\rho u)_t + (\rho u^2)_x + p(\rho)_x = (\mu(\rho)\, u_x)_x, \qquad (x,t) \in \mathbb{R} \times \mathbb{R}_+, \tag{1.2}$$

with possibly degenerate viscosity coefficient.

Throughout the paper, we will assume that the pressure $p(\rho)$ obeys a gamma type law

$$p(\rho) = \rho^\gamma, \qquad \gamma > 1, \tag{1.3}$$

(though more general pressure laws could be taken into account).

The viscosity coefficient $\mu(\rho)$ is often assumed to be a positive constant. However, it is well known that the viscosity of a gas depends on the temperature, and thus on the density (in the isentropic case). For example, the Chapman–Enskog viscosity law for hard sphere molecules predicts that $\mu(\rho)$ is proportional to the square root of the temperature (see [7]). In the case of monoatomic gas ($\gamma = 5/3$), this leads to $\mu(\rho) = \rho^{1/3}$. More generally, $\mu(\rho)$ is expected to vanish as a power of the ρ on the vacuum. In this paper, we consider degenerate viscosity coefficients that vanish for $\rho = 0$ at most like ρ^α for some $\alpha < 1/2$. In particular, the cases $\mu(\rho) = \nu$ and $\mu(\rho) = \nu\rho^{1/3}$ (with ν positive constant) are included in our result (see conditions (2.3)–(2.4) for details).

One-dimensional Navier–Stokes equations have been studied by many authors when the viscosity coefficient μ is a positive constant. The existence of weak solutions was first established by Kazhikhov and Shelukhin [16] for smooth enough data close to the equilibrium (bounded away from zero). The case of discontinuous data (still bounded away from zero) was addressed by Shelukhin [24, 25, 26] and then by Serre [22, 23] and Hoff [12]. First results concerning vanishing initial density were also obtained by Shelukhin [27]. In [14], Hoff proved the existence of global weak solutions with large discontinuous initial data, possibly having different limits at $x = \pm\infty$. Moreover, he proved that the constructed solutions have strictly positive densities (vacuum states cannot form in finite time). In dimension greater than two, similar results were obtained by Matsumura and Nishida [19] for smooth data and Hoff [13] for discontinuous data close to the equilibrium. The first global existence result for initial density that are allowed to vanish was due to Lions (see [17]). The result was later improved by Feireisl [10] and Feireisl, Novotný, and Petzeltová [11].

Another question is that of the regularity and uniqueness of the solutions. This problem was first analyzed by Solonnikov [29] for smooth initial data and for small time. However, the regularity may blow-up as the solution gets close to vacuum. This leads to another interesting question of whether vacuum may arise in finite time. Hoff and Smoller [15] show that any weak solution of the Navier–Stokes equations in one space dimension do not exhibit vacuum states, provided that no vacuum states are present initially. More precisely, they showed that if the initial data satisfies

$$\int_E \rho_0(x)\,dx > 0$$

for all open subsets $E \subset \mathbb{R}$, then

$$\int_E \rho(x,t)\,dx > 0$$

for every open subset $E \subset \mathbb{R}$ and for every $t \in [0,T]$.

The main theorem of this paper states that the strong solutions constructed by Solonnikov in [29] remain bounded away from zero uniformly in time (i.e., vacuum never arises) and are thus defined globally in time. This result can be seen as the equivalent of the result of Hoff in [13] for strong solutions instead of weak solutions. Another interest of this paper is the fact that unlike all the references mentioned above, the result presented here is valid with degenerate viscosity coefficients.

Note that compressible Navier–Stokes equations with degenerate viscosity coefficients have been studied before (see, for example, [18, 21, 31, 32]. All of those papers, however, are devoted to the case of compactly supported initial data and to the description of the evolution of the free boundary. We are interested here in the opposite situation in which vacuum never arises.

The new tool that allows us to obtain those results is an entropy inequality that was derived by Bresch and Desjardins in [2] for the multi-dimensional Korteweg system of equations (which corresponds to the case $\mu(\rho) = \rho$ and with an additional capillary term) and later generalized by the same authors (see [4]) to include other density-dependent viscosity coefficients. In the one dimensional case, a similar inequality was introduced earlier by Vaĭgant [30] for flows with constant viscosity (see also Shelukhin [28]).

The main interest of this inequality is to provide further regularity for the density. When $\mu(\rho) = \rho$, for instance, it implies that the gradient of $\sqrt{\rho}$ remains bounded for all time, provided it was bounded at time $t = 0$. This has very interesting consequences for many hydrodynamic equations. In [28], Shelukhin establishes the existence of a unique weak solution for one-dimensional flows with constant viscosity coefficient. In higher dimension, Bresch, Desjardin, and Lin use this inequality to establish the stability of weak solutions for the Korteweg system of equations in [6] and Bresch and Desjardin use this inequality for the compressible Navier–Stokes equations with an additional quadratic friction term in [3]. In [20], we establish the stability of weak solutions for the compressible isentropic Navier–Stokes equations in dimension 2 and 3 (without any additional terms). We also refer to [5] for recent developments concerning the full system of compressible Navier–Stokes equations (for heat conducting fluids).

At this point, we want to stress the fact that in dimension 2 and higher, this inequality holds only when the two viscosity coefficients satisfy a relation that considerably restricts the range of admissible coefficients (and in particular implies that one must have $\mu(0) = 0$). This necessary condition disappears in dimension 1, as the two viscosity coefficients become one (the derivation of the inequality is also much simpler in one dimension).

Another particularity of the dimension 1, is that the inequality gives control on some negative powers of the density (this is not true in higher dimensions). This will allow us to show that vacuum cannot arise if it was not present at time $t = 0$.

Finally, we point out that the present result is very different from that of [20] where the density was allowed to vanish (and the difficulty was to control the velocity u on the vacuum). Naturally, a result similar to that of [20] holds in dimension one, though it is not the topic of this paper.

Our main result is made precise in the next section. Section 3 is devoted to the derivation of the fundamental entropy inequalities and a priori estimates. The existence part of Theorem 2.1 is proved in section 4. The uniqueness is addressed in section 5.

2. The result.

Following Hoff in [14], we work with positive initial data having (possibly different) positive limits at $x = \pm\infty$: We fix constant velocities u_+ and u_- and constant positive density $\rho_+ > 0$ and $\rho_- > 0$, and we let $\overline{u}(x)$ and $\overline{\rho}(x)$ be two smooth monotone functions satisfying

$$\overline{\rho}(x) = \rho_\pm \quad \text{when } \pm x \geq 1, \quad \overline{\rho}(x) > 0 \quad \forall x \in \mathbb{R}, \tag{2.1}$$

and

$$\overline{u}(x) = u_\pm \quad \text{when } \pm x \geq 1. \tag{2.2}$$

We recall that the pressure satisfies $p(\rho) = \rho^\gamma$ for some $\gamma > 1$ and we assume that there exists a constant $\nu > 0$ such that the viscosity coefficient $\mu(\rho)$ satisfies

$$\begin{aligned} &\mu(\rho) \geq \nu\rho^\alpha && \forall \rho \leq 1 && \text{for some } \alpha \in [0, 1/2), \\ &\mu(\rho) \geq \nu && \forall \rho \geq 1, && \end{aligned} \tag{2.3}$$

and

$$\mu(\rho) \leq C + Cp(\rho) \qquad \forall \rho \geq 0. \tag{2.4}$$

Note that (2.4) is only a restriction on the growth of μ for large ρ. Examples of admissible viscosity coefficients include $\mu(\rho) = \nu$ and $\mu(\rho) = \rho^{1/3}$.

Our main theorem is the following.

THEOREM 2.1. *Assume that the initial data $\rho_0(x)$ and $u_0(x)$ satisfy*

$$0 < \underline{\kappa}_0 \le \rho_0(x) \le \overline{\kappa}_0 < \infty, \quad \rho_0 - \overline{\rho} \in H^1(\mathbb{R}), \quad u_0 - \overline{u} \in H^1(\mathbb{R}), \tag{2.5}$$

for some constants $\underline{\kappa}_0$ and $\overline{\kappa}_0$. Assume also that $\mu(\rho)$ verifies (2.3) *and* (2.4)*. Then there exists a global strong solution (ρ, u) of* (1.1)–(1.3) *on $\mathbb{R}^+ \times \mathbb{R}$ such that for every $T > 0$:*

$$\rho - \overline{\rho} \in L^\infty(0, T; H^1(\mathbb{R})),$$
$$u - \overline{u} \in L^\infty(0, T; H^1(\mathbb{R})) \cap L^2(0, T; H^2(\mathbb{R})).$$

Moreover, for every $T > 0$, there exist constants $\underline{\kappa}(T)$ and $\overline{\kappa}(T)$ such that

$$0 < \underline{\kappa}(T) \le \rho(x,t) \le \overline{\kappa}(T) < \infty \qquad \forall (t,x) \in (0,T) \times \mathbb{R}.$$

Finally, if $\mu(\rho) \ge \nu > 0$ for all $\rho \ge 0$, if μ is uniformly Lipschitz and if $\gamma \ge 2$, then this solution is unique in the class of weak solutions satisfying the usual entropy inequality (3.7)*.*

Note that the assumption (2.5) on the initial data implies, in particular, that the initial entropy (or relative entropy) is finite.

When the viscosity coefficient $\mu(\rho)$ satisfies

$$\mu(\rho) \ge \nu > 0 \qquad \forall \rho \ge 0, \tag{2.6}$$

the existence of a smooth solution for small time is a well-known result. More precisely, we have the following proposition.

PROPOSITION 2.2 (see [29]). *Let (ρ_0, u_0) satisfy* (2.5) *and assume that μ satisfies* (2.6)*, then there exists $T_0 > 0$ depending on $\underline{\kappa}_0$, $\overline{\kappa}_0$, $||\rho_0 - \overline{\rho}||_{H^1}$, and $||u_0 - \overline{u}||_{H^1}$ such that* (1.1)–(1.3) *has a unique solution (ρ, u) on $(0, T_0)$ satisfying*

$$\rho - \overline{\rho} \in L^\infty(0, T_1, H^1(\mathbb{R})), \qquad \partial_t \rho \in L^2((0,T_1) \times \mathbb{R}),$$
$$u - \overline{u} \in L^2(0, T_1; H^2(\mathbb{R})), \qquad \partial_t u \in L^2((0,T_1) \times \mathbb{R})$$

for all $T_1 < T_0$.
Moreover, there exist some $\underline{\kappa}(t) > 0$ and $\overline{\kappa}(t) < \infty$ such that $\underline{\kappa}(t) \le \rho(x,t) \le \overline{\kappa}(t)$ for all $t \in (0, T_0)$.

In view of this proposition, we see that if we introduce a truncated viscosity coefficient $\mu_n(\rho)$,

$$\mu_n(\rho) = \max(\mu(\rho), 1/n),$$

then there exist approximated solutions (ρ_n, u_n) defined for small time $(0, T_0)$ (T_0 possibly depending on n). To prove Theorem 2.1, we only have to show that (ρ_n, u_n) satisfies the following bounds uniformly with respect to n and T large:

$$\underline{\kappa}(T) \le \rho_n \le \overline{\kappa}(T) \quad \forall t \in [0,T],$$
$$\rho_n - \overline{\rho} \in L^\infty(0, T; H^1(\mathbb{R})),$$
$$u_n - \overline{u} \in L^\infty(0, T; H^1(\mathbb{R})).$$

In the next section, we derive the entropy inequalites that will be used to obtain the necessary bounds on ρ_n and u_n.

3. Entropy inequalities. In its conservative form, (1.1)–(1.3) can be written as

$$\partial_t U + \partial_x[A(U)] = \begin{bmatrix} 0 \\ (\mu(\rho)u_x)_x \end{bmatrix}$$

with the state vector

$$U = \begin{bmatrix} \rho \\ \rho\, u \end{bmatrix} = \begin{bmatrix} \rho \\ m \end{bmatrix}$$

and the flux

$$A(U) = \begin{bmatrix} \rho\, u \\ \rho\, u^2 + \rho^\gamma \end{bmatrix} = \begin{bmatrix} m \\ \dfrac{m^2}{\rho} + \rho^\gamma \end{bmatrix}.$$

It is well known that

$$\mathscr{H}(U) = \rho\frac{u^2}{2} + \frac{1}{\gamma-1}\rho^\gamma = \frac{m^2}{2\rho} + \frac{1}{\gamma-1}\rho^\gamma$$

is an entropy for the system of equations (1.1)–(1.3). More precisely, if (ρ, u) is a smooth solution, then we have

$$\partial_t \mathscr{H}(U) + \partial_x\big[F(U) - \mu(\rho)uu_x\big] + \mu(\rho)u_x^2 = 0 \tag{3.1}$$

with

$$F(U) = \rho u\frac{u^2}{2} + \frac{\gamma}{\gamma-1}u\rho^\gamma.$$

In particular, by integrating (3.1) with respect to x, we immediately see that

$$\frac{d}{dt}\int_{\mathbb{R}} \left[\rho\frac{u^2}{2} + \frac{1}{\gamma-1}\rho^\gamma\right] dx + \int_{\mathbb{R}} \mu(\rho)|u_x|^2\, dx \le 0. \tag{3.2}$$

However, since we are looking for solutions $\rho(x,t)$ and $u(x,t)$ which converge to $\rho_\pm$ and $u_\pm$ at $\pm\infty$, we do not expect the entropy to be integrable. It is thus natural to work with the relative entropy instead of the entropy.

The relative entropy is defined for any functions U and $\tilde{U}$ by

$$\begin{aligned} \mathscr{H}(U|\tilde{U}) &= \mathscr{H}(U) - \mathscr{H}(\tilde{U}) - D\mathscr{H}(\tilde{U})(U - \tilde{U}) \\ &= \rho(u-\tilde{u})^2 + p(\rho|\tilde{\rho}), \end{aligned}$$

where $p(\rho|\tilde{\rho})$ is the relative entropy associated to $\frac{1}{\gamma-1}\rho^\gamma$:

$$p(\rho|\tilde{\rho}) = \frac{1}{\gamma-1}\rho^\gamma - \frac{1}{\gamma-1}\tilde{\rho}^\gamma - \frac{\gamma}{\gamma-1}\tilde{\rho}^{\gamma-1}(\rho-\tilde{\rho}).$$

Note that, since p is strictly convex, $p(\rho|\tilde{\rho})$ is nonnegative for every ρ and $p(\rho|\tilde{\rho}) = 0$ if and only if $\rho = \tilde{\rho}$.

We recall that $\overline{\rho}(x)$ and $\overline{u}(x)$ are smooth functions satisfying (2.1) and (2.2), and we denote

$$\overline{U} = \begin{bmatrix} \overline{\rho} \\ \overline{\rho}\,\overline{u} \end{bmatrix}.$$

It is easy to check that there exists a positive constant C (depending on $\inf \overline{\rho}$) such that for every ρ and for every $x \in \mathbb{R}$, we have

$$\rho + \rho^\gamma \leq C[1 + p(\rho|\overline{\rho})], \tag{3.3}$$

$$\liminf_{\rho \to 0} p(\rho|\overline{\rho}) \geq C^{-1}. \tag{3.4}$$

The first inequality we will use in the proof of Theorem 2.1 is the usual relative entropy inequality for compressible Navier–Stokes equations.

LEMMA 3.1. *Let ρ, u be a solution of* (1.1)–(1.3) *satisfying the entropy inequality*

$$\partial_t \mathscr{H}(U) + \partial_x[F(U) - \mu(\rho) u u_x] + \mu(\rho)|u_x|^2 \leq 0. \tag{3.5}$$

Assume that the initial data (ρ_0, u_0) satisfies

$$\int_{\mathbb{R}} \mathscr{H}(U_0|\overline{U})\, dx = \int_{\mathbb{R}} \left[\rho_0 \frac{(u_0 - \overline{u})^2}{2} + p(\rho_0|\overline{\rho})\right] dx < +\infty. \tag{3.6}$$

Then, for every $T > 0$, there exists a positive constant $C(T)$ such that

$$\sup_{[0,T]} \int_{\mathbb{R}} \left[\rho \frac{(u - \overline{u})^2}{2} + p(\rho|\overline{\rho})\right] dx + \int_0^T \int_{\mathbb{R}} \mu(\rho)|u_x|^2\, dx\, dt \leq C(T). \tag{3.7}$$

The constant $C(T)$ depends only on $T > 0$, $\overline{U}$, the initial value U_0, γ, and the constant C appearing in (2.4).

Note that when both $\overline{\rho}$ and ρ_0 are bounded above and below away from zero, it is easy to check that

$$p(\rho_0|\overline{\rho}) \leq C(\rho_0 - \overline{\rho})^2,$$

and thus (3.6) holds under the assumptions of Theorem 2.1.

Proof of Lemma 3.1. First, we have (by a classical but tedious computation; see [8]) that

$$\begin{aligned}
\partial_t \mathscr{H}(U|\overline{U}) = {} & \big[\partial_t \mathscr{H}(U) + \partial_x(F(U) - \mu(\rho) u \partial_x u)\big] - \partial_t \mathscr{H}(\overline{U}) \\
& - \partial_x[F(U) - \mu(\rho) u \partial_x u] + \partial_x[DF(\overline{U})(U - \overline{U})] \\
& - D^2\mathscr{H}(\overline{U})[\partial_t \overline{U} + \partial_x A(\overline{U})](U - \overline{U}) \\
& - D\mathscr{H}(\overline{U})[\partial_t U + \partial_x A(U)] \\
& + D\mathscr{H}(\overline{U})[\partial_t \overline{U} + \partial_x A(\overline{U})] \\
& + D\mathscr{H}(\overline{U}) \partial_x[A(U|\overline{U})],
\end{aligned}$$

where the relative flux is defined by

$$\begin{aligned}
A(U|\overline{U}) &= A(U) - A(\overline{U}) - DA(\overline{U}) \cdot (U - \overline{U}) \\
&= \begin{bmatrix} 0 \\ \rho(u - \overline{u})^2 + (\gamma - 1) p(\rho|\overline{\rho}) \end{bmatrix}.
\end{aligned}$$

Since U is a solution of (1.1)–(1.3) and satisfies the entropy inequality, and using the fact that $\overline{U} = (\overline{\rho}, \overline{\rho u})$ satisfies (2.1) and (2.2) (and, in particular, $\partial_t \overline{U} = 0$), we deduce that

$$
\begin{aligned}
\partial_t \mathscr{H}(U|\overline{U}) \leq & -\mu(\rho)|\partial_x u|^2 \\
& -D^2\mathscr{H}(\overline{U})[\partial_x A(\overline{U})](U-\overline{U}) \\
& -D_2\mathscr{H}(\overline{U})[\partial_x(\mu(\rho)\partial_x u)] \\
& +D\mathscr{H}(\overline{U})\partial_x[A(U|\overline{U})] \\
& +D\mathscr{H}(\overline{U})[\partial_x A(\overline{U})] \\
& -\partial_x[F(U)-\mu(\rho)uu_x]+\partial_x[DF(\overline{U})(U-\overline{U})],
\end{aligned}
$$

where $D_2\mathscr{H}(\overline{U}) = \overline{u}$. We now integrate with respect to $x \in \mathbb{R}$, using the fact that supp $(\partial_x\overline{U}) \in [-1,1]$, and we get

$$
\begin{aligned}
& \frac{d}{dt}\int_{\mathbb{R}} \mathscr{H}(U|\overline{U})\,dx + \int_{\mathbb{R}} \mu(\rho)|\partial_x u|^2 \\
& \quad \leq -\int_{-1}^{1} D^2\mathscr{H}(\overline{U})[\partial_x A(\overline{U})](U-\overline{U})\,dx \\
& \qquad + \int_{-1}^{1} (\partial_x \overline{u})\mu(\rho)\partial_x u\,dx \\
& \qquad - \int_{-1}^{1} \partial_x[D\mathscr{H}(\overline{U})]A(U|\overline{U})\,dx \\
& \qquad - \int_{-1}^{1} \partial_x[D\mathscr{H}(\overline{U})]A(\overline{U})\,dx.
\end{aligned}
$$

Writing

$$
\left|\int_{-1}^{1} (\partial_x\overline{u})\mu(\rho)\partial_x u\,dx\right| \leq \|\partial_x \overline{u}\|_{L^\infty}^2 \int_{-1}^{1} \mu(\rho)\,dx + \frac{1}{2}\int_{-1}^{1} \mu(\rho)|\partial_x u|^2\,dx\,,
$$

it follows that there exists a constant C depending on $||\overline{U}||_{W^{1,\infty}}$ such that

$$
\begin{aligned}
& \frac{d}{dt}\int_{\mathbb{R}} \mathscr{H}(U|\overline{U})\,dx + \frac{1}{2}\int_{\mathbb{R}} \mu(\rho)\,|\partial_x u|^2 \\
& \quad \leq C + C\int_{-1}^{1} |U-\overline{U}|\,dx + C\int_{-1}^{1} |A(U|\overline{U})|\,dx \\
& \qquad + C\int_{-1}^{1} \mu(\rho)\,dx. \qquad (3.8)
\end{aligned}
$$

To conclude, we need to show that the right-hand side can be controlled by $\mathscr{H}(U|\overline{U})$. First, we note that

$$
|A(U|\overline{U})| \leq \max(1,(\gamma-1))\mathscr{H}(U|\overline{U}),
$$

and that (3.3) and (2.4) yield

$$
\int_{-1}^{1} \mu(\rho)\,dx \leq C + \int_{\mathbb{R}} p(\rho|\overline{\rho})\,dx. \qquad (3.9)
$$

Next, using (3.3) we get

$$
\begin{aligned}
\int_{-1}^{1} |U-\overline{U}|\,dx &\le \int_{-1}^{1} |\rho-\overline{\rho}|\,dx + \int_{-1}^{1} \rho|u-\overline{u}|\,dx + \int_{-1}^{1} |\overline{u}(\rho-\overline{\rho})|\,dx \\
&\le C\int_{-1}^{1} (1+p(\rho|\overline{\rho}))\,dx \\
&\quad + \left(\int_{-1}^{1} \rho\,dx\right)^{1/2} \left(\int_{-1}^{1} \rho(u-\overline{u})^2\,dx\right)^{1/2} \\
&\le C\int_{-1}^{1} (1+p(\rho|\overline{\rho}))\,dx \\
&\quad + \left(\int_{-1}^{1} (1+p(\rho|\overline{\rho}))\,dx\right)^{1/2} \left(\int_{-1}^{1} \mathscr{H}(U|\overline{U})\,dx\right)^{1/2} \\
&\le C\int_{-1}^{1} \mathscr{H}(U|\overline{U})\,dx + C.
\end{aligned}
$$

So (3.8) becomes

$$
\frac{d}{dt}\int_{\mathbb{R}} \mathscr{H}(U|\overline{U})\,dx + \frac{1}{2}\int_{\mathbb{R}} \mu(\rho)\,|\partial_x u|^2 \le C + C\int_{-1}^{1} |\mathscr{H}(U|\overline{U})|\,dx,
$$

and Gronwall's lemma gives Lemma 3.1.

For further reference, we note that this also implies that

$$
\frac{d}{dt}\int_{\mathbb{R}} \mathscr{H}(U|\overline{U})\,dx \le C(T). \qquad \square \tag{3.10}
$$

Unfortunately, it is a well-known fact that the estimates provided by Lemma 3.1 are not enough to prove the stability of the solutions of (1.1)–(1.3). The key tool of this paper is thus the following lemma.

Lemma 3.2. *Assume that $\mu(\rho)$ is a C^2 function, and let (ρ, u) be a solution of* (1.1)–(1.3) *such that*

$$
u-\overline{u} \in L^2((0,T);H^2(\mathbb{R})), \quad \rho-\overline{\rho} \in L^\infty((0,T);H^1(\mathbb{R})), \quad 0 < m \le \rho \le M. \tag{3.11}
$$

Then there exists $C(T)$ such that the following inequality holds:

$$
\begin{aligned}
&\sup_{[0,T]} \int \left[\frac{1}{2}\rho\big|(u-\overline{u}) + \partial_x(\varphi(\rho))\big|^2 + p(\rho|\overline{\rho})\right] dx \\
&\qquad + \int_0^T \int_{\mathbb{R}} \partial_x(\varphi(\rho))\partial_x(\rho^\gamma)\,dx\,dt \le C(T),
\end{aligned} \tag{3.12}
$$

with φ such that

$$
\varphi'(\rho) = \frac{\mu(\rho)}{\rho^2}. \tag{3.13}
$$

The constant $C(T)$ depends only on $T > 0$, $(\overline{\rho}, \overline{u})$, the initial value U_0, γ, and the constant C appearing in (2.4).

Since the viscosity coefficient $\mu(\rho)$ is nonnegative, (3.13) implies that $\varphi(\rho)$ is increasing. The lemma thus implies that

$$\sup_{[0,T]} \int \left[\frac{1}{2}\rho \big| (u-\overline{u}) + \partial_x(\varphi(\rho)) \big|^2 + p(\rho|\overline{\rho}) \right] dx \leq C(T),$$

which, together with Lemma 3.1, yields

$$||\sqrt{\rho}\partial_x(\varphi(\rho))||_{L^\infty(0,T;L^2(\Omega))} = 2||\mu(\rho)(\rho^{-1/2})_x||_{L^\infty(0,T;L^2(\Omega))} \leq C(T).$$

This inequality will be the cornerstone of the proof of Theorem 2.1 which is detailed in the next section.

As mentioned in the introduction, Lemma 3.2 relies on a new mathematical entropy inequality that was first derived by Bresch and Desjardins in [2] and [4] in dimension 2 and higher. Of course, the computations are much simpler in dimension 1.

We stress the fact that it is important to know exactly what regularity is needed on ρ and u to establish this inequality. Indeed, unlike inequality (3.7) which is quite classical, there is no obvious way to regularize the system (1.1)–(1.3) while preserving the structure necessary to derive (3.12). Fortunately, it turns out that (3.11), which is the natural regularity for strong solutions, is enough to justify the computations, as we will see in the proof.

Proof. We have to show that

$$\frac{d}{dt}\int \left[\frac{1}{2}\rho|u-\overline{u}|^2 + \rho(u-\overline{u})(\varphi(\rho))_x + \frac{1}{2}\rho(\varphi(\rho))_x^2 \right] dx + \frac{d}{dt}\int p(\rho|\overline{\rho})\, dx$$

is bounded

Step 1. From the proof of the previous lemma (see (3.10)), we already know that

$$\frac{d}{dt}\int \left[\frac{1}{2}\rho|u-\overline{u}|^2 \right] dx + \frac{d}{dt}\int p(\rho|\overline{\rho})\, dx \leq C(T). \tag{3.14}$$

Step 2. Next we show that

$$\begin{aligned} \frac{d}{dt}\int \rho\frac{(\varphi(\rho))_x^2}{2}\, dx = &-\int \rho^2\varphi'(\rho)(\varphi(\rho))_x u_{xx}\, dx \\ &-\int (2\rho\varphi'(\rho) + \rho^2\varphi''(\rho))\rho_x(\varphi(\rho))_x u_x\, dx. \end{aligned} \tag{3.15}$$

This follows straightforwardly from (1.1) when the second derivatives of the density are bounded in $L^2((0,T)\times\mathbb{R})$. In that case, it is worth mentioning that the right-hand side can be rewritten as

$$\int \rho^2\varphi'(\rho)(\varphi(\rho))_{xx} u_x\, dx.$$

However, we do not have any bounds on ρ_{xx}. It is thus important to justify the derivation of (3.15).

First, we point out that (3.15) makes sense when (ρ,u) satisfies only (3.11) (we recall that since $\overline{\rho}$ and $\overline{u}$ are constant outside $(-1,1)$, (3.11) implies that $\rho_x \in L^\infty((0,T);L^2(\mathbb{R}))$ and $u_x \in L^2((0,T);H^1(\mathbb{R}))$). Moreover, we note that the computation only makes use of the continuity equation. The rigorous derivation of (3.15) (under assumption (3.11)) can thus be achieved by carefully regularizing the continuity equation. The details are presented in the appendix (see Lemma A.1).

Step 3. Next, we evaluate the derivative of the cross-product:

$$\begin{aligned}\frac{d}{dt}\int \rho(u-\overline{u})\partial_x(\varphi(\rho))\,dx\\ &=\int \partial_x(\varphi(\rho))\partial_t(\rho(u-\overline{u}))\,dx+\int \rho(u-\overline{u})\partial_t\partial_x(\varphi(\rho))\,dx\\ &=\int \partial_x(\varphi(\rho))\partial_t(\rho(u-\overline{u}))\,dx-\int(\rho(u-\overline{u}))_x\varphi'(\rho)\partial_t\rho\,dx\,.\end{aligned}\tag{3.16}$$

Multiplying (1.2) by $\partial_x\varphi(\rho)$, we get

$$\begin{aligned}\int \partial_x(\varphi(\rho))\partial_t(\rho(u-\overline{u}))\,dx &=\int \partial_x(\varphi(\rho))\partial_t(\rho u)\,dx-\int \partial_x(\varphi(\rho))(\partial_t\rho)\overline{u}\,dx\\ &=\int(\varphi(\rho))_x(\mu(\rho)u_x)_x\,dx\\ &\quad-\int \partial_x(\varphi(\rho))\partial_x(\rho^\gamma)\,dx\\ &\quad-\int \partial_x(\varphi(\rho))\partial_x(\rho u^2)\,dx\\ &\quad+\int \varphi'(\rho)(\rho u)_x\rho_x\overline{u}\,dx.\end{aligned}$$

The continuity equation easily yields

$$\int(\rho(u-\overline{u}))_x\varphi'(\rho)\partial_t\rho\,dx=-\int((\rho u)_x)^2\varphi'(\rho)\,dx+\int(\rho\overline{u})_x(\rho u)_x\varphi'(\rho)\,dx.$$

Note that those equalities hold as soon as ρ and u satisfy (3.11).

Step 4. If φ and μ satisfy (3.13), then we have

$$\begin{aligned}\int(\varphi(\rho))_x(\mu(\rho)u_x)_x\,dx &=\int \rho^2\varphi'(\rho)(\varphi(\rho))_xu_{xx}\,dx\\ &\quad\int(2\rho\varphi'(\rho)+\rho^2\varphi''(\rho))\rho_x(\varphi(\rho))_xu_x\,dx,\end{aligned}$$

so (3.15) and (3.16) yield

$$\begin{aligned}\frac{d}{dt}\left\{\int \rho(u-\overline{u})\partial_x\varphi(\rho)+\rho\frac{|\partial_x\varphi(\rho)|^2}{2}\,dx\right\}+\int \partial_x\varphi(\rho)\partial_x(\rho^\gamma)\,dx\\ =-\int \partial_x(\varphi(\rho))\partial_x(\rho u^2)\,dx+\int((\rho u)_x)^2\varphi'(\rho)\,dx\\ +\int(\rho u)_x\varphi'(\rho)[\rho_x\overline{u}-(\rho\overline{u})_x]\,dx\\ =\int \varphi'(\rho)[-\rho_x(\rho u^2)_x+((\rho u)_x)^2]\,dx-\int(\rho u)_x\varphi'(\rho)\rho\overline{u}_x\,dx\\ =\int \rho^2\varphi'(\rho)u_x^2\,dx-\int(\rho u)_x\varphi'(\rho)\rho\overline{u}_x\,dx,\end{aligned}$$

and using (3.13), we deduce

$$\frac{d}{dt}\left\{\int \rho(u-\overline{u})\partial_x\varphi(\rho)+\rho\frac{|\partial_x\varphi(\rho)|^2}{2}\,dx\right\}+\int \partial_x\varphi(\rho)\partial_x(\rho^\gamma)\,dx$$
$$=\int \mu(\rho)(u_x)^2\,dx-\int \mu(\rho)u_x\overline{u}_x\,dx-\int \rho\,\partial_x(\varphi(\rho))u\,\overline{u}_x\,dx. \tag{3.17}$$

Moreover, since $\overline{u}_x$ has support in $(-1,1)$ and using the bounds given by Lemma 3.1 and inequality (3.9), it is readily seen that the right-hand side in this equality is bounded by

$$C\int_{\mathbb{R}}\mu(\rho)|u_x|^2\,dx+C\int_{-1}^{1}\mu(\rho)\,dx+C\int\rho|\partial_x\varphi(\rho)|^2\,dx+C\int_{-1}^{1}\rho u^2\,dx$$
$$\leq C\int\mu(\rho)|u_x|^2\,dx+C\int_{\mathbb{R}}p(\rho,\overline{\rho})\,dx+C\int_{\mathbb{R}}\rho|(u-\overline{u})+\partial_x\varphi(\rho)|^2\,dx+C(T).$$

Putting (3.17) and (3.14) together, we deduce

$$\frac{d}{dt}\int_{\mathbb{R}}\left[\frac{1}{2}\rho\big|(u-\overline{u})+\partial_x(\varphi(\rho))\big|^2+p(\rho|\overline{\rho})\right]dx+\int_{\mathbb{R}}\partial_x(\varphi(\rho))\partial_x(\rho^\gamma)\,dx$$
$$\leq C\int_{\mathbb{R}}\mu(\rho)|u_x|^2\,dx+C\int_{\mathbb{R}}\left[\frac{1}{2}\rho|(u-\overline{u})+\partial_x\varphi(\rho)|^2+p(\rho,\overline{\rho})\right]dx+C(T).$$

Finally, using the bounds on the viscosity from Lemma 3.1 and Gronwall's inequality we easily deduce (3.12). ∎

4. Proof of Theorem 2.1. In this section, we prove the existence part of Theorem 2.1.

The proof relies on the following proposition.

PROPOSITION 4.1. *Assume that the viscosity coefficient μ satisfies* (2.3)–(2.4) *and consider initial data (ρ_0,u_0) satisfying* (2.5). *Then for all $T>0$ there exist some constants $C(T)$, $\underline{\kappa}(T)$, and $\overline{\kappa}(T)$ such that for any strong solution $(\rho,\,u)$ of* (1.1)–(1.3) *with initial data (ρ_0,u_0), defined on $(0,T)$ and satisfying*

$$\rho-\overline{\rho}\in L^\infty(0,T,H^1(\mathbb{R}))\,,\qquad \partial_t\rho\in L^2((0,T)\times\mathbb{R})\,,$$
$$u-\overline{u}\in L^2(0,T;H^2(\mathbb{R}))\,,\qquad \partial_t u\in L^2((0,T)\times\mathbb{R}),$$

with ρ and ρ^{-1} bounded, the following bounds hold:

$$0<\underline{\kappa}(T)\leq\rho(t)\leq\overline{\kappa}(T)\quad \forall t\in[0,T],$$
$$\|\rho-\overline{\rho}\|_{L^\infty(0,T;H^1(\mathbb{R}))}\leq C(T),$$
$$\|u-\overline{u}\|_{L^\infty(0,T;H^1(\mathbb{R}))}\leq C(T).$$

Moreover, the constants $C(T)$, $\underline{\kappa}(T)$, and $\overline{\kappa}(T)$ depend on μ only through the constant C arising in (2.3) *and* (2.4).

Proof of Theorem 2.1. We define $\mu_n(\rho)$ to be the following positive approximation of the viscosity coefficient:

$$\mu_n(s)=\max(\mu(s),1/n).$$

Notice that μ_n verifies

$$\mu\leq\mu_n\leq\mu+1.$$

In particular, μ_n satisfies (2.3) and (2.4) with some constants that are independent on n.

Next, for all $n > 0$, we let (ρ_n, u_n) be the strong solution of (1.1)–(1.3) with $\mu = \mu_n$:

$$\begin{aligned}&\rho_t + (\rho u)_x = 0,\\ &(\rho u)_t + (\rho u^2)_x + p(\rho)_x = (\mu_n(\rho)\, u_x)_x.\end{aligned}$$

This solution exists at least for small time $(0, T_0)$ thanks to Proposition 2.2 (note that T_0 may depend on n). Proposition 4.1 then implies that for all $T > 0$ there exists $C(T)$, $\overline{\kappa}(T)$, and $\underline{\kappa}(T) > 0$, independent on n, such that

$$\begin{aligned}&\underline{\kappa}(T) \le \rho_n(t) \le \overline{\kappa}(T) \quad \forall t \in [0, T],\\ &\|\rho_n - \overline{\rho}\|_{L^\infty(0,T;H^1(\mathbb{R}))} \le C(T),\\ &\|u_n - \overline{u}\|_{L^\infty(0,T;H^1(\mathbb{R}))} \le C(T).\end{aligned}$$

In particular, we can take $T_0 = \infty$ in Proposition 2.2 (for all n). Moreover, since the bound from below for the density is uniform in n for any $T > 0$, by taking n large enough (namely $n \ge 1/\underline{\kappa}(T)$), it is readily seen that (ρ_n, u_n) is a solution of (1.1)–(1.3) on $[0, T]$ with the nontruncated viscosity coefficient $\mu(\rho)$. From the uniqueness of the solution of Proposition 2.2, we see that, passing to the limit in n, we get the desired global solution of (1.1)–(1.3). □

The rest of this section is thus devoted to the proof of Proposition 4.1. First, we will show that ρ is bounded from above and from below uniformly by some positive constants. Then we will investigate the regularity of the velocity by some standard arguments for parabolic equations.

4.1. A priori estimates. Since the initial datum (ρ_0, u_0) satisfies (2.5), we have

$$\int \rho_0 (u_0 - \overline{u})^2\, dx < \infty \quad \text{and} \quad \int_\Omega \rho_0 |\partial_x(\varphi(\rho_0))|^2\, dx < +\infty.$$

Moreover, $(\rho,\, u)$ satisfies (3.11), so we can use the inequalities stated in Lemmas 3.1 and 3.2. We deduce the following estimates, which we shall use throughout the proof of Proposition (4.1):

$$\begin{aligned}&||\sqrt{\rho}(u - \overline{u})||_{L^\infty(0,T;L^2(\Omega))} \le C(T),\\ &||\rho||_{L^\infty(0,T;L^1_{\text{loc}} \cap L^\gamma_{\text{loc}}(\Omega))} \le C(T),\\ &||\rho - \overline{\rho}||_{L^\infty(0,T;L^1(\Omega))} \le C(T),\\ &||\sqrt{\mu(\rho)}(u)_x||_{L^2(0,T;L^2(\Omega))} \le C(T).\end{aligned} \tag{4.1}$$

and

$$\begin{aligned}&||\mu(\rho)\partial_x(\rho^{-1/2})||_{L^\infty(0,T;L^2(\Omega))} \le C(T),\\ &||\sqrt{\mu(\rho)}\partial_x(\rho^{\gamma/2-1/2})||_{L^2(0,T;L^2(\Omega))} \le C(T).\end{aligned} \tag{4.2}$$

4.2. Uniform bounds for the density. The first proposition shows that no vacuum states can arise.

PROPOSITION 4.2. *For every $T > 0$, there exists a constant $\underline{\kappa}(T) > 0$ such that*

$$\rho(x, t) \ge \underline{\kappa}(T) \qquad \forall (x, t) \in \mathbb{R} \times [0, T].$$

The proof of this proposition will follow from two lemmas. The first is as follows.

LEMMA 4.3. *For every $T > 0$, there exist $\delta > 0$ and $R(T)$ such that for every $x_0 \in \mathbb{R}$ and $t_0 > 0$, there exists $x_1 \in [x_0 - R(T),\ x_0 + R(T)]$ with*

$$\rho(x_1, t_0) > \delta.$$

This nice result can be found in [14]. We give a proof of it for the sake of completeness.

Proof. Let $\delta > 0$ be such that

$$p(\rho|\overline{\rho}) \geq \frac{C^{-1}}{2} \qquad \forall \rho < \delta$$

(such a δ exists thanks to (3.4)). Then, if

$$\sup_{x \in [x_0 - R, x_0 + R]} \rho(x, t_0) < \delta,$$

we then have

$$\int p(\rho|\overline{\rho})\, dx \geq C^{-1} R,$$

and since the integral in the left-hand side is bounded by a constant (see Lemma 3.1), a suitable choice of R leads to a contradiction. ◻

LEMMA 4.4. *Let*

$$w(x,t) = \inf(\rho(x,t), 1) = 1 - (1 - \rho(x,t))_+.$$

Then there exists $\varepsilon > 0$ and a constant $C(T)$ such that

$$||\partial_x w^{-\varepsilon}||_{L^\infty(0,T;L^2(\mathbb{R}))} \leq C(T).$$

Proof. We have

$$\partial_x w = \partial_x \rho 1_{\{\rho \leq 1\}}.$$

In particular, (4.2) gives

$$\left\| \frac{\mu(w)}{w^{3/2}} w_x \right\|_{L^\infty(0,T;L^2(\Omega))} \leq C$$

so using (2.3) we deduce that

$$||w^{\alpha - 3/2} \partial_x w||_{L^\infty(0,T;L^2(\Omega))} = ||\partial_x w^{\alpha - 1/2}||_{L^\infty(0,T;L^2(\Omega))} \leq C,$$

and the result follows with $\varepsilon = 1/2 - \alpha > 0$. ◻

Proof of Proposition 4.2. Together with Sobolev–Poincaré inequality, Lemmas 4.3 and 4.4 yield that $w^{-\varepsilon}$ is bounded in $L^\infty((0,T) \times \mathbb{R})$:

$$w^{-\varepsilon}(x,t) \leq C(T) \qquad \forall (x,t) \in \mathbb{R} \times (0,T).$$

This yields Proposition 4.2 with $\underline{\kappa}(T) = C(T)^{-1/\varepsilon}$. ◻

Next, we find a bound for the density in L^∞.

PROPOSITION 4.5. *For every $T > 0$, there exist a constant $\overline{\kappa}(T)$ such that*

$$\rho(x,t) \le \overline{\kappa}(T) \qquad \forall (x,t) \in \mathbb{R} \times (0,T).$$

Proof. Let $s = (\gamma - 1)/2$, then (3.12) with (2.3) and (3.13) yields $\partial_x(\rho^s)$ bounded in $L^2((0,T)\times\mathbb{R})$. Moreover, for every compact subset K of $\mathbb{R}$, we have

$$\begin{aligned}\int_K |\partial_x \rho^s|\,dx &= \int_K |\rho^{s-1}\partial_x\rho|\,dx \\ &\le \left(\int_K \rho^{1+2s}\,dx\right)^{1/2}\left(\int_K \frac{1}{\rho^3}(\partial_x\rho)^2\,dx\right)^{1/2} \\ &\le \left(\int_K \rho^{\gamma}\,dx\right)^{1/2}\left(\int_K \rho\varphi'(\rho)^2(\partial_x\rho)^2\,dx\right)^{1/2}\end{aligned}$$

and so using (3.3) we get

$$\int_K |\partial_x\rho^s|\,dx \le C\left(|K| + \int_K p(\rho|\overline{\rho})\,dx\right)^{1/2}\left(\int_K \rho\varphi'(\rho)^2(\partial_x\rho)^2\,dx\right)^{1/2}.$$

Since

$$\rho^s \le 1 + \rho^{\gamma},$$

we deduce that

$$\rho^s \text{ is bounded in } L^{\infty}\left(0,T; W^{1,1}_{\mathrm{loc}}(\mathbb{R})\right),$$

and the $W^{1,1}(K)$ norm of $\rho^s(t,\cdot)$ only depends on $|K|$. Sobolev imbedding thus yields Proposition 4.5. ∎

PROPOSITION 4.6. *There exists a constant $C(T)$ such that*

$$\|\rho(x,t) - \overline{\rho}(x)\|_{L^{\infty}(0,T;H^1(\mathbb{R}))} \le C(T).$$

Proof. Proposition 4.5 yields

$$\begin{aligned}\int (\partial_x\rho)^2\,dx &\le \overline{\kappa}^3 \int \frac{1}{\rho^3}(\partial_x\rho)^2\,dx \\ &\le \overline{\kappa}^3 \int \frac{\rho}{(\mu(\rho))^2}(\phi'(\rho))^2(\partial_x\rho)^2\,dx \\ &\le \frac{\nu\overline{\kappa}^3}{\inf(1,\underline{\kappa}^{2\alpha})}\int \rho(\partial_x\phi(\rho))^2\,dx \\ &\le C(T),\end{aligned}$$

and the result follows. ∎

4.3. Uniform bounds for the velocity.

PROPOSITION 4.7. *There exists a constant $C(T)$ such that*

$$\|u - \overline{u}\|_{L^2(0,T;H^2(\mathbb{R}))} \le C(T)$$

and

$$\|\partial_t u\|_{L^2(0,T;L^2(\mathbb{R}))} \le C(T).$$

In particular, $u-\overline{u}\in C^0(0,T;H^1(\mathbb{R}))$.

Proof. First, we show that $u-\overline{u}$ is bounded in $L^2(0,T;H^1(\mathbb{R}))$. Since $\rho\geq\kappa>0$, and using (2.3), it is readily seen that there exists a constant $\nu'>0$ such that

$$\mu(\rho(x,t))\geq\nu' \qquad \forall(x,t)\in\mathbb{R}\times[0,T],$$

and so (3.7) gives

$$\partial_x u \text{ is bounded in } L^2((0,T)\times\mathbb{R})$$

and

$$u-\overline{u} \text{ is bounded in } L^\infty(0,T;L^2(\mathbb{R})).$$

Therefore $u-\overline{u}$ is bounded in $L^2(0,T;H^1(\mathbb{R}))$.

Note that this implies that $\partial_t\rho$ is bounded in $L^2((0,T)\times\mathbb{R})$. Since $\rho-\overline{\rho}$ is bounded in $L^\infty(0,T;H^1)$, it follows (see [1], for example) that

$$\rho\in\mathcal{C}^{s_0}((0,T)\times\mathbb{R})$$

for some $s_0\in(0,1)$.

Next, we rewrite (1.2) as follows:

$$\partial_t u-\left(\frac{\mu(\rho)}{\rho}u_x\right)_x=-\gamma\rho^{\gamma-2}\rho_x+\overline{u}u_x+(\partial_x(\varphi(\rho))-(u-\overline{u}))u_x, \tag{4.3}$$

where we recall that φ, which is defined by $\varphi'(\rho)=\mu(\rho)/\rho^2$, is the function arising in the new entropy inequality (see Lemma 3.2).

In order to deduce some bounds on u, we need to control the right-hand side of (4.3). The first term, $\rho^{\gamma-2}\rho_x$, is bounded in $L^\infty(0,T;L^2(\mathbb{R}))$ (thanks to Proposition 4.6). The second term is bounded in $L^2((0,T)\times\mathbb{R})$ since $\overline{u}$ is in L^∞. For the last part, we write (using Hölder inequality and interpolation inequality):

$$\begin{aligned}
&||\partial_x(\varphi(\rho))-(u-\overline{u})u_x||_{L^2(0,T;L^{4/3}(\mathbb{R}))}\\
&\quad\leq||\partial_x(\varphi(\rho))-(u-\overline{u})||_{L^\infty(0,T;L^2(\mathbb{R}))}||u_x||_{L^2(0,T;L^4(\mathbb{R}))}\\
&\quad\leq||\partial_x(\varphi(\rho))-(u-\overline{u})||_{L^\infty(L^2)}||u_x||^{2/3}_{L^2(L^2)}||u_x||^{1/3}_{L^2(0,T;W^{1,4/3}(\mathbb{R}))}\\
&\quad\leq C||u_x||^{1/3}_{L^2(0,T;W^{1,4/3}(\mathbb{R}))}
\end{aligned}$$

(here we make use of (3.12) and Proposition 4.2). So regularity results for parabolic equation of the form (4.3) (note that the diffusion coefficient is in $\mathcal{C}^{s_0}((0,T)\times\mathbb{R})$) yield

$$||u_x||_{L^2(0,T;W^{1,4/3}(\mathbb{R}))}\leq C||u_x||^{1/3}_{L^2(0,T;W^{1,4/3}(\mathbb{R}))}+C,$$

and so

$$||u_x||_{L^2(0,T;W^{1,4/3}(\mathbb{R}))}\leq C.$$

Using Sobolev inequalities, it follows that u_x is bounded in $L^2(0,T;L^\infty(\mathbb{R}))$.

Finally, we can now see that the right-hand side in (4.3) is bounded in $L^2(0,T;L^2(\mathbb{R}))$, and classical regularity results for parabolic equations give

$$u-\overline{u} \text{ is bounded in } L^2(0,T;H^2(\mathbb{R}))$$

and

$$\partial_t u \text{ is bounded in } L^2(0,T;L^2(\mathbb{R})),$$

which concludes the proof. ∎

It is now readily seen that Proposition 4.1 follows from Propositions 4.2, 4.5, 4.6, and 4.7.

5. Uniqueness. In this last section, we establish the uniqueness of the global strong solution in a large class of weak solutions satisfying the usual entropy inequality. This result can be rewritten as follows.

PROPOSITION 5.1. *Assume that*

$$\mu(\rho) \geq \nu > 0 \quad \forall \rho \geq 0,$$

and that there exists a constant C such that

$$|\mu(\rho) - \mu(\tilde{\rho})| \leq C|\rho - \tilde{\rho}| \quad \forall \rho, \tilde{\rho} \geq 0.$$

Assume moreover that $\gamma \geq 2$, and let (ρ, u) be the solution of (1.1)–(1.3) *given by Theorem* 2.1.

If $(\tilde{\rho}, \tilde{u})$ is a weak solution of (1.1)–(1.3) *with initial data (ρ_0, u_0) and satisfies the entropy inequality* (3.5) *and relative entropy bound* (3.7)*, and if*

$$\lim_{x\to\pm\infty} (\tilde{\rho} - \rho_\pm) = 0\,, \qquad \lim_{x\to\pm\infty} (\tilde{u} - u_\pm) = 0,$$

then

$$(\tilde{\rho}, \tilde{u}) = (\rho, u).$$

Notice that we do not need to assume that $\tilde{\rho}$ does not vanish; this proposition will be a consequence of the following lemma.

LEMMA 5.2. *Let $\tilde{U} = (\tilde{\rho}, \tilde{\rho}\tilde{u})$ be a weak solution of* (1.1)–(1.3) *satisfying the inequality* (3.5)*, and let $U = (\rho, \rho u)$ be a strong solution of* (1.1)–(1.3) *satisfying the equality* (3.1)*. Assume, moreover, that $\tilde{U}$ and U are such that*

$$\lim_{x\to\pm\infty} (\tilde{\rho} - \rho) = 0\,, \qquad \lim_{x\to\pm\infty} (\tilde{u} - u) = 0. \tag{5.1}$$

Then we have

$$\begin{aligned} \frac{d}{dt}\int_{\mathbb{R}} \mathscr{H}(\tilde{U}|U)\,dx &+ \int_{\mathbb{R}} \mu(\tilde{\rho})\,[\partial_x(\tilde{u}-u)]^2 \\ &\leq C\int |\partial_x u|\mathscr{H}(\tilde{U}|U)\,dx \\ &\quad - \int_{\mathbb{R}} \partial_x u[\mu(\tilde{\rho}) - \mu(\rho)]\,[\partial_x(\tilde{u}-u)]\;dx \\ &\quad + \int_{\mathbb{R}} \frac{\partial_x(\mu(\rho)\partial_x u)}{\rho}\,(\tilde{\rho}-\rho)\,(u-\tilde{u})\,dx. \end{aligned} \tag{5.2}$$

The proof of this lemma relies only on the structure of the equation and not on the properties of the solutions. We postpone it to the end of this section.

Proof of Proposition 5.1. In order to prove Proposition 5.1, we have to show that the last two terms in (5.2) can be controlled by the relative entropy $\mathscr{H}(\tilde{U}|U)$ and the viscosity. Since $\gamma \geq 2$ and $\rho \geq \overline{\kappa} > 0$, we note that there exists C such that

$$p(\tilde{\rho}|\rho) \geq C|\tilde{\rho}-\rho|^2 \quad \forall \tilde{\rho} \geq 0.$$

Then, we can write

$$\begin{aligned}
&\left|\int_{\mathbb{R}} \partial_x u[\mu(\tilde{\rho})-\mu(\rho)]\,[\partial_x(\tilde{u}-u)]\;dx\right| \\
&\qquad \leq C\|\partial_x u\|_{L^\infty(\mathbb{R})}\left(\int_{\mathbb{R}}|\tilde{\rho}-\rho|^2\,dx\right)^{1/2}\left(\int_{\mathbb{R}}|\partial_x(\tilde{u}-u)|^2\,dx\right)^{1/2} \\
&\qquad \leq C\|\partial_x u\|^2_{L^\infty(\mathbb{R})}\int_{\mathbb{R}}|\tilde{\rho}-\rho|^2\,dx+\frac{1}{4}\int_{\mathbb{R}}\mu(\tilde{\rho})|\partial_x(\tilde{u}-u)|^2\,dx \\
&\qquad \leq C\|\partial_x u\|^2_{L^\infty(\mathbb{R})}\int_{\mathbb{R}}\mathscr{H}(\tilde{U}|U)\,dx+\frac{1}{4}\int_{\mathbb{R}}\mu(\tilde{\rho})|\partial_x(\tilde{u}-u)|^2\,dx
\end{aligned}$$

which does the trick for the first of the last two terms in (5.2). For the last term, we see that if we had $\partial_x(\mu(\rho)\partial_x u)$ bounded in $L^\infty((0,T)\times\mathbb{R})$, a similar computation would apply. However, writing

$$\partial_x(\mu(\rho)\partial_x u) = \mu'(\rho)(\partial_x\rho)\,(\partial_x u)+\mu(\rho)\partial_{xx}u$$

it is readily seen that $\partial_x(\mu(\rho)\partial_x u)$ is only bounded in $L^2((0,T)\times\mathbb{R})$. For that reason, we need to control $|\tilde{u}-u|$ in L^∞, which is made possible by the following lemma.

LEMMA 5.3. *Let $\tilde{\rho} \geq 0$ be such that $\int p(\tilde{\rho}|\overline{\rho})\,dx < +\infty$. Then there exists a constant C (depending on $\int p(\tilde{\rho}|\overline{\rho})\,dx$) such that for any regular function h:*

$$\|h\|_{L^\infty(\mathbb{R})} \leq C\left(\int_{\mathbb{R}}\tilde{\rho}|h|^2\,dx\right)^{1/2}+C\left(\int_{\mathbb{R}}|h_x|^2\,dx\right)^{1/2}.$$

Using Lemma 5.3 with $h=\tilde{u}-u$, we deduce that

$$\begin{aligned}
&\int_{\mathbb{R}}\frac{\partial_x(\mu(\rho)\partial_x u)}{\rho}\,(\tilde{\rho}-\rho)\,(u-\tilde{u})\,dx \\
&\leq \left\|\frac{\partial_x(\mu(\rho)\partial_x u)}{\rho}\right\|_{L^2(\mathbb{R})}\|\tilde{\rho}-\rho\|_{L^2(\mathbb{R})}\|u-\tilde{u}\|_{L^\infty(\mathbb{R})} \\
&\leq C\left\|\frac{\partial_x(\mu(\rho)\partial_x u)}{\rho}\right\|_{L^2(\mathbb{R})}\mathscr{H}(\tilde{U}|U)^{\frac{1}{2}}\left(\mathscr{H}(\tilde{U}|U)^{\frac{1}{2}}+\left(\int_R|\partial_x(u-\tilde{u})|^2\,dx\right)^{\frac{1}{2}}\right) \\
&\leq C\left\|\frac{\partial_x(\mu(\rho)\partial_x u)}{\rho}\right\|^2_{L^2(\mathbb{R})}\mathscr{H}(\tilde{U}|U)+\frac{1}{4}\int_R\mu(\tilde{\rho})|\partial_x(u-\tilde{u})|^2\,dx.
\end{aligned}$$

So (5.2) becomes

$$\frac{d}{dt}\int_{\mathbb{R}}\mathscr{H}(\tilde{U}|U)\,dx+\frac{1}{2}\int_{\mathbb{R}}\mu(\tilde{\rho})\,[\partial_x(\tilde{u}-u)]^2 \leq C(t)\int\mathscr{H}(\tilde{U}|U)\,dx,$$

where $C(t)\in L^1(0,T)$. The Gronwall lemma, together with the fact that

$$\mathscr{H}(\tilde{U}|U)(t=0)=0,$$

yields Proposition 5.1. ◻

Proof of Lemma 5.3. Using (3.4), we see that there exists some $\delta > 0$ and C such that

$$|\{x \in \mathbb{R};\ \tilde{\rho} \leq \delta\}| \leq C \int_{\mathbb{R}} p(\tilde{\rho}|\overline{\rho})\, dx.$$

We take $R = C \int p(\tilde{\rho}|\overline{\rho})\, dx + 1$. Then, for every x_0 in $\mathbb{R}$, we know that in the interval $(x_0 - R/2, x_0 + R/2)$, $\tilde{\rho}$ is larger than δ, which is a set of measure at least 1. We denote by ω this set:

$$\omega = (x_0 - R/2, x_0 + R/2) \cap \{\tilde{\rho} \geq \delta\}.$$

Then, for all $x \in \omega$, we have

$$|h(x_0)| \leq |h(x)| + \int_{x_0}^{x} |h_x(y)|\, dy \leq |h(x)| + R^{1/2} \left(\int_{\mathbb{R}} |h_x(y)|^2\, dy \right)^{1/2}.$$

Integrating with respect to x in ω, we deduce that

$$\begin{aligned} |h(x_0)| &\leq \frac{1}{|\omega|} \int_{\omega} |h|\, dx + R^{1/2} \left(\int_{\mathbb{R}} |h_x|^2\, dx \right)^{1/2} \\ &\leq \frac{1}{|\omega|^{1/2}} \left(\int_{\omega} |h|^2\, dx \right)^{1/2} + R^{1/2} \left(\int_{\mathbb{R}} |h_x|^2\, dx \right)^{1/2}. \end{aligned}$$

Finally, since $\tilde{\rho} \geq \delta$ in ω, we have

$$|h(x_0)| \leq \frac{1}{\delta^{1/2} |\omega|^{1/2}} \left(\int_{\omega} \tilde{\rho} |h|^2\, dx \right)^{1/2} + R^{1/2} \left(\int_{\mathbb{R}} |h_x|^2\, dx \right)^{1/2},$$

and since $|\omega| \geq 1$, the result follows. ◻

Proof of Lemma 5.2. To prove the lemma, it is convenient to note that the system (1.1)–(1.3) can be rewritten in the form

$$\partial_t U_i + \partial_x A_i(U) = \partial_x \big[B_{ij}(U) \partial_x \left(D_j \mathscr{H}(U) \right) \big],$$

where $B(U)$ is a positive symmetric matrix and $D\mathscr{H}$ denotes the derivative (with respect to U) of the entropy $\mathscr{H}(U)$ associated with the flux $A(U)$. The existence of such an entropy is equivalent to the existence of an entropy flux function F such that

$$D_j F(U) = \sum_i D_i \mathscr{H}(U) D_j A_i(U) \tag{5.3}$$

for all U. Then strong solutions of (1.1)–(1.3) satisfy

$$\partial t \mathscr{H}(U) + \partial_x F(U) - \partial_x (B(U) \partial_x D\mathscr{H}(U)) D\mathscr{H}(U) = 0.$$

In our case, we have

$$A(U) = \begin{bmatrix} m \\ \dfrac{m^2}{\rho} + \rho^\gamma \end{bmatrix} = \begin{bmatrix} \rho u \\ \rho u^2 + \rho^\gamma \end{bmatrix}$$

and

$$B(U) = \mu(\rho) \left[\begin{array}{cc} 0 & 0 \\ 0 & 1 \end{array} \right].$$

Then, a careful computation (using (5.3)) yields

$$\begin{aligned}
&\partial_t \mathscr{H}(\tilde{U}|U) \\
&\quad = \left[\partial_t \mathscr{H}(\tilde{U}) + \partial_x(F(\tilde{U})) - \partial_x(B(\tilde{U})\partial_x D\mathscr{H}(\tilde{U}))D\mathscr{H}(\tilde{U})\right] \\
&\qquad - \left[\partial_t \mathscr{H}(U) + \partial_x F(U) - \partial_x(B(U)\partial_x D\mathscr{H}(U))D\mathscr{H}(U)\right] \\
&\qquad -\partial_x[F(\tilde{U}) - F(U)] \\
&\qquad -D^2\mathscr{H}(U)[\partial_t U + \partial_x A(U) - \partial_x\left(B(U)\partial_x\left(D\mathscr{H}(U)\right)\right)](\tilde{U} - U) \\
&\qquad -D\mathscr{H}(U)[\partial_t \tilde{U} + \partial_x A(\tilde{U}) - \partial_x(B(\tilde{U})\partial_x(D\mathscr{H}(\tilde{U})))] \\
&\qquad +D\mathscr{H}(U)[\partial_t U + \partial_x A(U) - \partial_x(B(U)\partial_x\left(D\mathscr{H}(U)\right))] \\
&\qquad +\partial_x[DF(U)(\tilde{U} - U)] \\
&\qquad +D\mathscr{H}(U)\partial_x[A(\tilde{U}|U)] \\
&\qquad +\partial_x[B(\tilde{U})\partial_x D\mathscr{H}(\tilde{U}) - B(U)\partial_x D\mathscr{H}(U)][D\mathscr{H}(\tilde{U}) - D\mathscr{H}(U)] \\
&\qquad +\partial_x(B(U)\partial_x D\mathscr{H}(U))D\mathscr{H}(\tilde{U}|U),
\end{aligned}$$

where the relative flux is defined by

$$A(\tilde{U}|U) = A(\tilde{U}) - A(U) - DA(U)\cdot(\tilde{U} - U).$$

Using the fact that $\tilde{U}$ and U are solutions satisfying the natural entropy inequality and equality, we deduce that

$$\begin{aligned}
&\partial_t \mathscr{H}(\tilde{U}|U) \\
&\quad \leq -\partial_x[F(\tilde{U}) - F(U)] + \partial_x[DF(U)(\tilde{U} - U)] \\
&\qquad +D\mathscr{H}(U)\partial_x[A(\tilde{U}|U)] \\
&\qquad +\partial_x[B(\tilde{U})\partial_x D\mathscr{H}(\tilde{U}) - B(U)\partial_x D\mathscr{H}(U)][D\mathscr{H}(\tilde{U}) - D\mathscr{H}(U)] \\
&\qquad +\partial_x(B(U)\partial_x D\mathscr{H}(U))D\mathscr{H}(\tilde{U}|U).
\end{aligned}$$

Integrating with respect to x and using (5.1), we deduce that

$$\begin{aligned}
&\frac{d}{dt}\int_{\mathbb{R}} \mathscr{H}(\tilde{U}|U)\,dx \\
&\leq -\int \partial_x[D\mathscr{H}(U)]A(\tilde{U}|U)\,dx \\
&\quad -\int_{\mathbb{R}}[B(\tilde{U})\partial_x D\mathscr{H}(\tilde{U}) - B(U)\partial_x D\mathscr{H}(U)]\partial_x[D\mathscr{H}(\tilde{U}) - D\mathscr{H}(U)]dx \\
&\quad +\int_{\mathbb{R}} \partial_x[B(U)\partial_x D\mathscr{H}(U)]D\mathscr{H}(\tilde{U}|U)\,dx.
\end{aligned}$$

Finally, we check that

$$\partial_x[D\mathscr{H}(U)]A(\tilde{U}|U) = (\partial_x u)[\rho(u-\tilde{u})^2 + (\gamma-1)p(\rho|\tilde{\rho})]\,,$$

$$\partial_x[B(U)\partial_x D\mathscr{H}(U)]D\mathscr{H}(\tilde{U}|U) = \frac{\partial_x(\mu(\rho)\partial_x u)}{\rho}\,(\tilde{\rho}-\rho)\,(u-\tilde{u}),$$

and

$$\begin{aligned}
&[B(\tilde U)\partial_x D\mathscr{H}(\tilde U) - B(U)\partial_x D\mathscr{H}(U)]\partial_x[D\mathscr{H}(\tilde U) - D\mathscr{H}(U)]\\
&\qquad = [\mu(\tilde\rho)\partial_x\tilde u - \mu(\rho)\partial_x u]\,\partial_x\,[\tilde u - u]\\
&\qquad = \mu(\tilde\rho)\,[\partial_x\tilde u - \partial_x u]^2 + \partial_x u[\mu(\tilde\rho) - \mu(\rho)]\partial_x\,[\tilde u - u]\,.
\end{aligned}$$

It follows that

$$\begin{aligned}
&\frac{d}{dt}\int_{\mathbb{R}} \mathscr{H}(\tilde U|U)\,dx + \int_{\mathbb{R}} \mu(\tilde\rho)\,[\partial_x(\tilde u - u)]^2\\
&\quad \le C\int |\partial_x u|\mathscr{H}(\tilde U|U)\,dx\\
&\qquad - \int_{\mathbb{R}} \partial_x u[\mu(\tilde\rho) - \mu(\rho)]\,[\partial_x(\tilde u - u)]\;dx\\
&\qquad + \int_{\mathbb{R}} \frac{\partial_x(\mu(\rho)\partial_x u)}{\rho}\,(\tilde\rho - \rho)\,(u - \tilde u)\,dx.
\end{aligned}$$

which gives the lemma. ∎

Appendix. Proof of equality (3.15).

LEMMA A.1. *Let* (ρ, u) *satisfy* (3.11) *and*

$$\begin{cases} \partial_t\rho + \partial_x(\rho\, u) = 0,\\ \rho(x,0) = \rho_0(x). \end{cases} \tag{A.1}$$

Then (ρ, u) *satisfies* (3.15).

Proof. We denote by h_ε the convolution of any function h by a mollifier. Convoluting (A.1) by the mollifier, we get

$$\partial_t\rho_\varepsilon + \partial_x(\rho_\varepsilon u) = r_\varepsilon,$$

where

$$r_\varepsilon = \partial_x(\rho_\varepsilon u) - \partial_x(\rho u)_\varepsilon.$$

Since ρ_ε is now a smooth function, a straightforward computation yields

$$\begin{aligned}
&\frac{d}{dt}\int \rho_\varepsilon\frac{(\varphi(\rho_\varepsilon)_x)^2}{2}\,dx\\
&\qquad - \int (\rho_\varepsilon)^2\varphi'(\rho_\varepsilon)\varphi(\rho_\varepsilon)_x u_{xx}\,dx\\
&\qquad - \int (2\rho_\varepsilon\varphi'(\rho_\varepsilon) + (\rho_\varepsilon)^2\varphi''(\rho_\varepsilon))(\rho_\varepsilon)_x\varphi(\rho_\varepsilon)_x u_x\,dx\\
&\qquad\qquad = \int \rho_\varepsilon\varphi(\rho_\varepsilon)_x(\varphi'(\rho_\varepsilon)r_\varepsilon)_x\,dx.
\end{aligned} \tag{A.2}$$

In order to pass to the limit $\varepsilon \to 0$, we note that

$$\rho_\varepsilon - \overline{\rho} \longrightarrow \rho - \overline{\rho} \quad \text{ in } L^\infty(0,T;H^1(\mathbb{R})) \text{ strong},$$

which is enough to take the limit in the left-hand side of (A.2) (note that it implies the strong convergence in $L^\infty(0,T;L^\infty(\mathbb{R}))$). To show that the right-hand side goes to zero, we only need to show that r_ε goes to zero in $L^2(0,T;H^1(\mathbb{R}))$ strong (and thus in $L^2(0,T;L^\infty(\mathbb{R}))$). We write

$$\begin{aligned}\partial_x r_\varepsilon = 2[&\partial_x\rho_\varepsilon\partial_x u - (\partial_x\rho\,\partial_x u)_\varepsilon]\\ &+\rho_\varepsilon\partial_{xx}u - (\rho\,\partial_{xx}u)_\varepsilon\\ &+\partial_{xx}\rho_\varepsilon u - (\partial_{xx}\rho\,u)_\varepsilon.\end{aligned}$$

The first two terms converge to zero thanks to the strong convergence of ρ_ε in $L^\infty(0,T;H^1(\mathbb{R}))$. For the last term, we note that

$$\partial_x\rho\in L^\infty(0,T;L^2(\mathbb{R}))\quad\text{ and }\quad u\in L^2(0,T;W^{1,\infty}(\mathbb{R}))$$

so the strong convergence to zero in $L^2((0,T)\times\mathbb{R})$ follows from Lemma II.1 in [9] from DiPerna and Lions. $\square$

ASYMPTOTIC ANALYSIS OF PHASE FIELD FORMULATIONS OF BENDING ELASTICITY MODELS*

XIAOQIANG WANG†

Abstract. In this paper, we give the asymptotic analysis of sharp interface analysis of the phase field function in some phase field models for Willmore's problem and equilibrium lipid bilayer cell membrane problems. We derive the explicit expression of the asymptotic expansion of the phase field functions minimizing the Willmore energy. Based on the structure of the phase field functions obtained via the asymptotic analysis, we can then demonstrate the consistency of phase field models and the sharp interface models. Also some error estimates of energy and Euler number formulae are further analyzed. Some numerical experiments are performed to verify our assumptions and results. The results of this paper lead to a better understanding of the structure of the phase field functions in the phase field models for Willmore's problem and the equilibrium configurations of the lipid vesicle membranes.

Key words. phase field, Willmore's problem, elastic bending energy, lipid membrane, asymptotic expansion, spectral method, numerical simulation, approximation

1. Introduction.

Willmore's problem [26] is a classical problem to minimize the mean curvature square energy of a compact surface Γ:

$$W = \int_\Gamma H^2 \, dS, \tag{1.1}$$

where $H = (k_1 + k_2)/2$ is the mean curvature and k_1 and k_2 are the two principal curvatures. For the equilibrium surface Γ minimizing the Willmore energy, the mean curvature H and the Gaussian curvature $K = k_1 k_2$ of Γ satisfy

$$\Delta_\Gamma H + 2H(H^2 - K) = 0, \tag{1.2}$$

which is the Euler–Lagrange equation of Willmore's problem.

Willmore's problem is closely related to the equilibrium shapes of biological lipid bilayer membranes, as shown in the bending elasticity model, first developed by Canham, Evans, and Helfrich [15, 19, 21]. Biomembranes are mostly composed by lipid molecules, which form a special bilayer structure of the membrane [20]. Due to the bending property of the lipid bilayer structure, in the bending elasticity model, the elastic bending energy is formulated by

$$W_c = \frac{\kappa}{2} \int_\Gamma (H - c)^2 \, dS, \tag{1.3}$$

where H is the mean curvature of the membrane surface Γ, c is the spontaneous curvature used to describe some physical or chemical difference between the inside and the outside of the membrane, and κ is the bending rigidity of the bilayer membrane.

The equilibrium membrane configurations are the minimizers of the elastic bending energy (1.3). Some constraints may apply, such as a given surface area and fixed cell volume to account for the effects of density change and osmotic pressure [7].

Some analytical and computational methods for computing the equilibrium shapes have been developed in the past few years [1, 2, 4, 16, 22, 27]. The computational methods include the direct methods such as front tracking [23, 14], volume of fluid (VOF) [18], and level set methods [3]. Another important computational method was developed recently in [7] and [11, 12, 8, 24, 25], using a phase field function to build up a general energetic variational framework. There are several advantages to using the phase field method. It can easily handle the topological changes of the shapes, and it can be formulated within a unified energetic framework, easy to understand and implement.

The basic idea of phase field formulations is to introduce a phase field function φ defined on a physical (computational) domain Ω to label the inside and the outside of the membrane Γ. We visualize that the level set $\{x : \varphi(x) = 0\}$ gives the surface Γ, while $\{x : \varphi(x) > 0\}$ represents the inside of Γ and $\{x : \varphi(x) \leq 0\}$ the outside. Define the following modified Willmore energy:

$$W(\varphi) = \int_\Omega \frac{\epsilon}{2} \left(\Delta\varphi - \frac{1}{\epsilon^2}\varphi(\varphi^2 - 1) \right)^2 dx, \tag{1.4}$$

where ϵ is a *transition* parameter that is taken to be very small. $W(\varphi)$ is a phase field translation of mean curvature energy (1.1) or the elastic bending energy (1.3) without the spontaneous curvature. For the elastic bending energy (1.3) with spontaneous curvature, the phase field translation is [11]

$$W_c(\varphi) = \int_\Omega \frac{\epsilon}{2} \left(\Delta\varphi - \frac{1}{\epsilon^2}(\varphi^2 - 1)(\varphi + \sqrt{2}c\epsilon) \right)^2 dx, \tag{1.5}$$

and the goal of the phase field model is to minimize $W(\varphi)$. Some constraints such as the fixed inside volume and the surface area may apply. In [6, 7, 8], some numerical schemes and discretization techniques have been developed for the phase field model. The theoretical analysis to the convergence of those numerical schemes is given in [5]. They have been successfully implemented and used in the numerical simulation of the membrane deformation. Various equilibrium solution branches and energy diagrams have been obtained, including interesting new three-dimensional solutions. Also, the shapes found in numerical experiments are coincident with the biophysical experiments and other theoretical methods for this problem.

There are basic issues about this phase field model requiring further consideration. One of them is to prove the consistency of the phase field model with the sharp interface Willmore's problem or the bending elasticity model for small ϵ. In other words, it is needed to verify that when phase field function φ minimizes $W(\varphi)$, the zero level set of φ is the desired surface Γ minimizing the Willmore energy (1.1) or the elastic bending energy (1.3), as the interfacial width parameter $\epsilon \to 0$. In [10], some positive results have been presented regarding the consistency. Some preliminary analyses for this consistency problem have been provided there, based on an assumption that the phase field function can be asymptotically expanded by

$$\varphi(x) = q(d(x)/\epsilon) + \epsilon h + g, \tag{1.6}$$

where $q \in C^2(\mathbf{R})$, $h \in C^2(\Omega)$ are independent of ϵ, and $\|\nabla^k g\|_{L^\infty} = o(\epsilon)$ for $k = 0, \ldots, 4$.

Our recent numerical experiments indicate that the above ansatz assumption is too restrictive in general. The purpose of this paper is to weaken the asymptotic expansion assumptions in formula (1.6) and derive the detailed expressions of the terms up to the third order. For example, we prove that the expansion to the second order term is

$$\varphi(x) = \tanh\left(\frac{d(x)}{\sqrt{2}\epsilon}\right) + 4\epsilon^2(H^2 - K)p\left(\frac{d(x)}{\epsilon}\right) + O(\epsilon^3), \tag{1.7}$$

where p is a given function independent of ϵ and Γ. Obviously, the second order term does not satisfy $\|\nabla^k g\|_{L^\infty} = o(\epsilon)$ for $k = 0, \ldots, 4$. Further expansion to the third order term reveals more details of the structure of the phase field function φ so that the consistency of the phase field model and the sharp interface model can still be verified.

The asymptotic analysis in this paper provides a firm mathematical foundation to the phase field models. With this theory, not only do we have the consistency of a phase field model with sharp interface models, but we can also perform error estimates of the phase field models, which leads to some very interesting identities. More importantly, it leads to a better understanding of the phase field formulations, which may shed light on the phase field modeling of other kinds of problems.

The paper is organized as follows. In the second section, we first make some assumptions on the asymptotic expansion of the phase field function, and the exact formulation for the leading, first, second, and third order terms are obtained. Based on the third order approximation, in the third section we can easily get the equilibrium state equation and the Willmore flow force, which can be used to prove the consistency of the phase field model and the sharp interface model. We generalize the problem to the spontaneous curvature case in section four. The error estimations of the phase field models are given in the fifth section. An interesting relationship between some Euler number formulae and the elastic bending energy is also derived in this section. Some numerical experiments are performed in the sixth section to verify our theory. Finally we draw the conclusion and give some further considerations.

2. Asymptotic analysis of phase field functions. In this section, we will give the asymptotic analysis of phase field functions for Willmore's problem. First, we will introduce some assumptions for the asymptotic expansions of phase field functions based on some geometric notation. Then some very useful lemmas will be introduced, from which we derive the forms of the expansion term by term.

2.1. Geometric notation and phase field model assumptions. Suppose the surface Γ is smooth and compact. We can find a constant c, such that within the domain $D_\Gamma = \{x|\mathrm{dist}(x, \Gamma) < c\}$, we can have a set of smooth surfaces $\{\Gamma_l\}_{i \in A}$ such that

$$D_\Gamma \subset \bigcup_{l \in A} \Gamma_l, \qquad \Gamma_a \cap \Gamma_b = \emptyset \quad \text{if} \quad a \neq b.$$

Therefore, for any point $x \in D_\Gamma$, we can get $a \in A$ such that $x \in \Gamma_a$. We can define a *normal direction* $\vec{n}(x)$ by the normal direction of Γ_a at point x. Further, we denote the *integral curve* along the normal direction through x by γ_x, and we assume that the constant c is small enough such that every integral curve has a unique intersection with any Γ_l. The *distance* from any point $x \in D_\Gamma$ to Γ_i is defined by the length of the integral curve γ_x between Γ_a and Γ_i. We call Γ_a and Γ_b *parallel* if the distance between any point of Γ_a and Γ_b is a constant, and we denote the *distance* of Γ_a and Γ_b by this constant.

Without proof, we can always find a set of parallel surfaces of Γ. Denote Γ by Γ_0. A *sign* is the distance between Γ and any parallel surface, positive to the inside surfaces and negative to the outside surfaces. We use the signed distance to denote the index of the surface. For example, Γ_d has a distance d to Γ_0.

Suppose $x \in \Gamma_d$, and the *distance function* $d(x)$ is defined by d, the distance between Γ_d and Γ, or the signed length from point x along the integral curve γ_x of normal direction to Γ_0. With this definition, the normal direction

$$\vec{n}(x) = \nabla d(x).$$

For any point $x \in \Gamma_l$, the *mean curvature* $H(x)$ and *Gaussian curvature* $K(x)$ are defined by the mean curvature and Gaussian curvature of Γ_l at point x. It is known that

$$H(x) = -\frac{1}{2}\Delta d(x),$$

and $H(x)$ is a smooth function in domain D_Γ.

We also define $x|_\Gamma = \gamma_x \cap \Gamma$, the *projection* of point x on Γ along the integral curve of ∇d.

As we are mainly concerned with the phase field function theory, some of the above geometry facts are used without any proof.

Remark 2.1. Note that we do not define the distance function $d(x)$ by the Euclid distance between x and Γ.

For a phase field function φ defined on a computational domain Ω, for any $\epsilon > 0$, denote

$$f(\varphi) = \Delta\varphi - \frac{1}{\epsilon^2}(\varphi^2 - 1)\varphi. \tag{2.1}$$

The variational problem is to minimize

$$W(\varphi) = \frac{\epsilon}{2}\int_\Omega f(\varphi(x))^2\, dx. \tag{2.2}$$

Denote the minimizer of (2.2) by φ. Denote Γ_0 by $\{x|\varphi(x) = 0\}$.

Now we make the following assumptions:

(A1) Γ is a smooth compact surface, and the set of parallel surfaces Γ_l exists.

(A2) φ is a function that can be expanded by

$$\varphi(x) = \sum_{n=0}^{\infty} \epsilon^n q_n\left(\frac{d(x)}{\epsilon}, x|_\Gamma\right),$$

where $q_i \in C^\infty(\bar{\mathbf{R}} \times \Gamma)$ independent of ϵ and bounded.

(A3) $\Phi(\epsilon, t, x) = \sum_{n=0}^{\infty} \epsilon^n q_n(t, x) \in C^\infty(\mathbf{R}^2 \times \Gamma)$.

(A4) $\lim_{\epsilon\to 0}\varphi(x) = 1$ if $d(x) > 0$; $\lim_{\epsilon\to 0}\varphi(x) = -1$ if $d(x) < 0$; and $\lim_{\epsilon\to 0} \nabla^n\varphi(x) = 0$ for $x \in \partial D_\Gamma$ and any $n \geq 0$.

Remark 2.2. Assumption (A2) is the main point. It describes how φ depends on ϵ. Assumption (A1) is natural. (A3) ensures boundedness of the partial derivatives of φ on x. (A4) gives the boundary condition for doing integration by parts.

These assumptions weaken the ansatz in [10], which assumes that q_0 is only a function of d/ϵ, and q_1 and q_2 depend only on x. Here we assume that q_0, q_1, and

q_2 depend on both d/ϵ and x, as in a standard two-scale analysis. Our result in section 2.3 shows that q_2 does depend on both, and not x alone.

For simplicity, we ignore the parameters $\frac{d(x)}{\epsilon}$ and $x|_\Gamma$ when doing so would cause no confusion, but one should always keep them in mind. This may also apply to the notation $O(\epsilon^k)$ and $o(\epsilon^k)$. For example,

$$q_n = q_n\left(\frac{d(x)}{\epsilon}, x|_\Gamma\right). \tag{2.3}$$

We also denote the kth directive

$$q_n^{(k)} = (\partial_1^k q_n)\left(\frac{d(x)}{\epsilon}, x|_\Gamma\right). \tag{2.4}$$

Sometimes, we denote the error term functions

$$e_i = \sum_{n=i}^{\infty} \epsilon^{n-i} q_n. \tag{2.5}$$

Using the above notation, we have the following two useful identities:

$$\nabla q_n = \frac{1}{\epsilon} q_n' \nabla d + \nabla_\Gamma q_n = \frac{1}{\epsilon} q_n' \nabla d + O(1), \tag{2.6}$$

$$\begin{aligned} \Delta q_n &= \frac{1}{\epsilon^2} q_n'' + \frac{1}{\epsilon} q_n' \Delta d + \frac{1}{\epsilon} \nabla_\Gamma q_n' \cdot \nabla d + \Delta_\Gamma q_n \\ &= \frac{1}{\epsilon^2} q_n'' + \frac{1}{\epsilon} q_n' \Delta d + \Delta_\Gamma q_n = \frac{1}{\epsilon^2} q_n'' - \frac{2H}{\epsilon} q_n' + O(1). \end{aligned} \tag{2.7}$$

2.2. Several lemmas. Now we introduce several useful lemmas.

LEMMA 2.3.

$$\nabla H \cdot \nabla d = 2H^2 - K, \tag{2.8}$$

$$\nabla K \cdot \nabla d = 2HK, \tag{2.9}$$

$$\Delta H = \Delta_\Gamma H + 4H(H^2 - K). \tag{2.10}$$

Proof. Suppose two principal curvatures are $k_1(x)$ and $k_2(x)$. It is easy to know that $\nabla k_i \cdot \nabla d = k_i^2$ for $i = 1, 2$. Therefore

$$\nabla H \cdot \nabla d = \frac{1}{2}(k_1^2 + k_2^2) = 2H^2 - K,$$

$$\nabla K \cdot \nabla d = k_1 k_2^2 + k_1^2 k_2 = 2HK,$$

$$\begin{aligned} \Delta H &= \Delta_\Gamma H + \nabla \cdot ((\nabla H \cdot \nabla d)\nabla d) \\ &= \Delta_\Gamma H + \nabla \cdot ((2H^2 - K)\nabla d) \\ &= \Delta_\Gamma H + \nabla(2H^2 - K) \cdot \nabla d + (2H^2 - K)\Delta d \\ &= \Delta_\Gamma H + 4H(2H^2 - K) - 2HK - 2H(2H^2 - K) \\ &= \Delta_\Gamma H + 4H(H^2 - K). \qquad \square \end{aligned}$$

LEMMA 2.4. *For two smooth functions f and g, assume $f(d(x)/\epsilon, x|_\Gamma)|_{\partial\Omega} = f'(d(x)/\epsilon, x|_\Gamma)|_{\partial\Omega} = g(d(x)/\epsilon, x|_\Gamma)|_{\partial\Omega} = g'(d(x)/\epsilon, x|_\Gamma)|_{\partial\Omega} = 0$. We have*

$$\int_\Omega fg'\,dx = -\int_\Omega (f' - 2Hf\epsilon)g\,dx, \tag{2.11}$$

$$\int_\Omega Hfg'\,dx = \int_\Omega (Kf\epsilon - Hf')g\,dx, \tag{2.12}$$

$$\int_\Omega Kfg'\,dx = -\int_\Omega Kf'g\,dx, \tag{2.13}$$

$$\int_\Omega fg''\,dx = \int_\Omega (f'' - 4Hf'\epsilon + 2Kf\epsilon^2)g\,dx, \tag{2.14}$$

$$\int_\Omega Hfg''\,dx = \int_\Omega (Hf'' - 2Kf'\epsilon)g\,dx, \tag{2.15}$$

$$\int_\Omega H^2fg'\,dx = -\int_\Omega \big(2H(H^2-K)f\epsilon + H^2f'\big)g\,dx, \tag{2.16}$$

where $H(x)$ is the mean curvature and $K(x)$ is the Gaussian curvature.

Remark 2.5. *Here we hide the parameters $d(x)/\epsilon$ and $x|_\Gamma$ for f, g, and their derivatives.*

Proof. Because the proofs are similar, here we give the proof for only the first three equations.

Since $\nabla g = \frac{1}{\epsilon}g'\nabla d + \nabla_\Gamma g$ and $\nabla_\Gamma g \cdot \nabla d = 0$, we know that

$$g' = \epsilon(\nabla g \cdot \nabla d - \nabla_\Gamma g \cdot \nabla d) = \epsilon \nabla g \cdot \nabla d.$$

Then

$$\begin{aligned}\int_\Omega fg'\,dx &= \epsilon\int_\Omega f\nabla g\cdot\nabla d\,dx\\ &= -\epsilon\int_\Omega g\nabla f\cdot\nabla d + gf\Delta d\,dx\\ &= -\int_\Omega (f' - 2Hf\epsilon)g\,dx.\end{aligned}$$

From Lemma 2.3, we have

$$\begin{aligned}\int_\Omega Hfg'\,dx &= \epsilon\int_\Omega Hf\nabla g\cdot\nabla d\,dx\\ &= -\epsilon\int_\Omega \nabla(Hf)\cdot\nabla dg - 2H(Hfg)\,dx\\ &= -\int_\Omega (\nabla H\cdot\nabla d)fg\epsilon + Hf'g - 2H^2fg\epsilon\,dx\\ &= -\int_\Omega (2H^2-K)fg\epsilon + Hf'g - 2H^2fg\epsilon\,dx\\ &= \int_\Omega (Kf\epsilon - Hf')g\,dx,\end{aligned}$$

$$\begin{aligned}\int_\Omega Kfg'\,dx &= \epsilon\int_\Omega Kf\nabla g\cdot\nabla d\,dx\\ &= -\epsilon\int_\Omega \nabla(Kf)\cdot\nabla dg - 2H(Kfg)\,dx\\ &= -\int_\Omega(\nabla K\cdot\nabla d)fg\epsilon + Kf'g - 2HKfg\epsilon\,dx\\ &= -\int_\Omega Kf'g\,dx. \qquad\square\end{aligned}$$

LEMMA 2.6. *For two smooth functions f and g, assume $f(d(x)/\epsilon, x|_\Gamma)|_{\partial\Omega} = g(d(x)/\epsilon, x|_\Gamma)|_{\partial\Omega} = 0$. We have*

$$\int_\Omega f\Delta_\Gamma g\,dx = \int_\Omega \Delta_\Gamma fg\,dx. \tag{2.17}$$

Proof. First we have

$$\nabla g = \frac{1}{\epsilon}g'\nabla d + \nabla_\Gamma g,$$

$$\Delta g = \frac{1}{\epsilon^2}g'' - \frac{2H}{\epsilon}g' + \Delta_\Gamma g.$$

From Lemmas 2.3 and 2.4, we have

$$\begin{aligned}\int_\Omega f\Delta_\Gamma g\,dx &= \int_\Omega f\left(\Delta g - \frac{1}{\epsilon^2}g'' + \frac{2H}{\epsilon}g'\right)\,dx\\ &= \int_\Omega \Delta fg - \frac{1}{\epsilon^2}(f'' - 4Hf'\epsilon + 2Kf\epsilon^2)g + \frac{2}{\epsilon}(Kf\epsilon - Hf')g\,dx\\ &= \int_\Omega\left(\Delta f - \frac{1}{\epsilon^2}f'' + \frac{2H}{\epsilon}f'\right)g\\ &= \int_\Omega \Delta_\Gamma fg\,dx. \qquad\square\end{aligned}$$

LEMMA 2.7. *Suppose $f\in C^0(\Omega)$ and $p\in L^1(\mathbf{R})$ satisfy the bound*

$$\max_{|t|>s}|p(t)t| \le \frac{C}{s^m}, \quad m>1. \tag{2.18}$$

Then

$$\lim_{\epsilon\longrightarrow 0}\frac{1}{\epsilon}\int_\Omega p(d(x)/\epsilon)f(x)\,dx = \int_{-\infty}^{\infty}p(t)\,dt\int_\Gamma f(s)dS. \tag{2.19}$$

Please refer to [10] for the proof of Lemma 2.7.

LEMMA 2.8.

$$\begin{aligned}&\frac{1}{\epsilon}\int_\Omega p(d(x)/\epsilon)f(x|_\Gamma)\,dx\\ &\quad= \int_{-\infty}^{\infty}p(t)\,dt\int_\Gamma f(s)dS + \epsilon\int_{-\infty}^{\infty}p(t)t\,dt\int_\Gamma 2f(s)H(s)dS\\ &\qquad + \epsilon^2\int_{-\infty}^{\infty}p(t)t^2\,dt\int_\Gamma f(s)K(s)dS + o(\epsilon^3).\end{aligned} \tag{2.20}$$

Proof. The volume differential dx is a product of area differential $d\Gamma_s$, and ds is the length differential of the integral curve along ∇d. As $d\Gamma_s$ is a function of s, it is known that $(d\Gamma_s)' = -2Hd\Gamma_s$. (One can get this using the Jacobian notion. Please refer to [10] for the proof of Lemma 2.7.) Then

$$(d\Gamma_s)'' = (-2Hd\Gamma_s)' = -2(\nabla H \cdot \nabla d)d\Gamma_s - 2H(-2Hd\Gamma_s) = 2Kd\Gamma_s.$$

It follows that

$$d\Gamma_s = (1 - 2Hs + Ks^2 + O(s^3))d\Gamma.$$

Now

$$\begin{aligned}
\frac{1}{\epsilon}\int_\Omega p(d(x)/\epsilon)f(x|_\Gamma)\,dx &= \frac{1}{\epsilon}\int_\Omega p(s/\epsilon)f(x|_\Gamma)\,d\Gamma_s ds \\
&= \frac{1}{\epsilon}\int_\Omega p(s/\epsilon)f(x|_\Gamma)\,(1 - 2Hs + Ks^2 + O(s^3))d\Gamma ds \\
&= \int_{-\infty}^{\infty} p(t)\,dt \int_\Gamma f(s)d\Gamma + \epsilon\int_{-\infty}^{\infty} p(t)t\,dt\int_\Gamma 2f(s)H(s)d\Gamma \\
&\quad + \epsilon^2\int_{-\infty}^{\infty} p(t)t^2\,dt\int_\Gamma f(s)K(s)d\Gamma + o(\epsilon^3).
\end{aligned}$$

Corresponding to our notation convention, we can replace $d\Gamma$ by dS, and this gives the lemma. $\square$

Furthermore, we can prove the following lemma.

LEMMA 2.9. *Suppose $f \in C^2(\Omega)$ and $p \in L^1(\mathbf{R})$ satisfy the bound*

$$\max_{|t|>s} |p(t)t^3| \le \frac{C}{s^m}, \quad m > 1. \tag{2.21}$$

Then

$$\begin{aligned}
&\frac{1}{\epsilon}\int_\Omega p(d(x)/\epsilon)f(x)\,dx \\
&\quad = \int_{-\infty}^{\infty} p(t)\,dt\int_\Gamma f(x)dS + \epsilon\int_{-\infty}^{\infty} p(t)t\,dt\int_\Gamma -2fH + \nabla f\cdot\nabla d\,dS \\
&\quad + \epsilon^2\int_{-\infty}^{\infty} p(t)t^2\,dt\int_\Gamma fK - 2(\nabla f\cdot\nabla d)H + \frac{1}{2}\nabla(\nabla f\cdot\nabla d)\cdot\nabla d\,dS \\
&\quad + O(\epsilon^3).
\end{aligned} \tag{2.22}$$

Proof. We can expand the function f along the integration curve of ∇d by

$$f(x) = f(x|_\Gamma) + d(\nabla f\cdot\nabla d)(x|_\Gamma) + \frac{1}{2}d^2(\nabla(\nabla f\cdot\nabla d)\cdot\nabla d)(x|_\Gamma) + O(d^3).$$

Applying Lemmas 2.7 and 2.8, we get

$$
\begin{aligned}
&\frac{1}{\epsilon}\int_\Omega p(d(x)/\epsilon) f(x)\,dx \\
&\quad= \frac{1}{\epsilon}\int_\Omega p(d(x)/\epsilon) f(x|_\Gamma)\,dx + \frac{1}{\epsilon}\int_\Omega p(d(x)/\epsilon) d(x)(\nabla f\cdot\nabla d)(x|_\Gamma)\,dx \\
&\qquad+ \frac{1}{\epsilon}\int_\Omega p(d(x)/\epsilon)\frac{1}{2}d^2(x)(\nabla(\nabla f\cdot\nabla d)\cdot\nabla d)(x|_\Gamma)\,dx + O(\epsilon^3) \\
&\quad= \int_{-\infty}^{\infty} p(t)\,dt\int_\Gamma f(x)dS + \epsilon\int_{-\infty}^{\infty} p(t)t\,dt\int_\Gamma -2fH dS + \epsilon^2\int_{-\infty}^{\infty} p(t)t^2\,dt\int_\Gamma fK dS \\
&\qquad+ \epsilon\int_{-\infty}^{\infty} p(t)t\,dt\int_\Gamma (\nabla f\cdot\nabla d)dS + \epsilon^2\int_{-\infty}^{\infty} p(t)t^2\,dt\int_\Gamma -2(\nabla f\cdot\nabla d)H dS \\
&\qquad+ \epsilon^2\int_{-\infty}^{\infty} p(t)t^2\,dt\int_\Gamma \frac{1}{2}(\nabla(\nabla f\cdot\nabla d)\cdot\nabla d)dS + O(\epsilon^3) \\
&\quad= \int_{-\infty}^{\infty} p(t)\,dt\int_\Gamma f(x)dS + \epsilon\int_{-\infty}^{\infty} p(t)t\,dt\int_\Gamma -2fH + \nabla f\cdot\nabla d\,dS \\
&\qquad+ \epsilon^2\int_{-\infty}^{\infty} p(t)t^2\,dt\int_\Gamma fK - 2(\nabla f\cdot\nabla d)H + \frac{1}{2}\nabla(\nabla f\cdot\nabla d)\cdot\nabla d\,dS + O(\epsilon^3). \qquad \square
\end{aligned}
$$

2.3. Asymptotic approximation. With assumptions (A1)–(A4), now we can get the exact form of q_i term by term.

THEOREM 2.10. *With assumptions* (A1)–(A4), *we have*

$$q_0(t) = \tanh\left(\frac{t}{\sqrt{2}}\right).$$

Remark 2.11. Because $q_0 \in C^\infty(\bar{\mathbf{R}}\times\Gamma)$, it actually means $q_0(t,x) = \tanh(\frac{t}{\sqrt{2}})$, a function depending only on the first parameter.

Proof. As $\varphi = q_0 + \epsilon e_1$, we have

$$
\begin{aligned}
f(\varphi) &= \Delta\varphi - \frac{1}{\epsilon^2}(\varphi^2-1)\varphi \\
&= \frac{1}{\epsilon^2}(q_0+\epsilon e_1)'' + \frac{1}{\epsilon}(q_0+\epsilon e_1)'\Delta d - \frac{1}{\epsilon^2}(\varphi^2-1)\varphi + O(1) \\
&= \frac{1}{\epsilon^2}(q_0'' - (q_0^2-1)q_0) + O(\epsilon^{-1}).
\end{aligned}
$$

To minimize $W(\varphi) = \frac{\epsilon}{2}\int_\Omega f^2\,dx$, we have that q_0 minimizes

$$\int_\Omega (q_0'' - (q_0^2-1)q_0)^2\,dx,$$

which results in

$$q_0'' - (q_0^2-1)q_0 = 0.$$

From assumption (A4), $q_0(\infty) = 1$, $q_0(-\infty) = -1$. It follows that

$$q_0(t) = \tanh\left(\frac{t}{\sqrt{2}}\right). \qquad \square$$

With Theorem 2.10, we have

$$\begin{aligned} f(q_0) &= \Delta q_0 - \frac{1}{\epsilon^2}(q_0^2 - 1)q_0 \\ &= \frac{1}{\epsilon} q_0' \Delta d + \frac{1}{\epsilon^2} q_0'' - \frac{1}{\epsilon^2}(q_0^2 - 1)q_0 = -\frac{2H}{\epsilon} q_0', \end{aligned} \tag{2.23}$$

and we can expand f by

$$\begin{aligned} f(\varphi) &= \Delta\varphi - \frac{1}{\epsilon^2}(\varphi^2 - 1)\varphi \\ &= \Delta(q_0 + \epsilon e_1) - \frac{1}{\epsilon^2}(q_0^2 - 1)q_0 - \frac{1}{\epsilon}(3q_0^2 - 1)e_1 - 3q_0 e_1^2 - \epsilon e_1^3 \\ &= f(q_0) + \epsilon\Delta e_1 - \frac{1}{\epsilon}(3q_0^2 - 1)e_1 - 3q_0 e_1^2 - \epsilon e_1^3 \\ &= -\frac{2H}{\epsilon} q_0' + \epsilon\Delta e_1 - \frac{1}{\epsilon}(3q_0^2 - 1)e_1 - 3q_0 e_1^2 - \epsilon e_1^3. \end{aligned} \tag{2.24}$$

THEOREM 2.12. *With assumptions* (A1)–(A4), *we have*

$$q_1 = 0.$$

Proof. From assumption (A3), $e_1 = O(\epsilon)$. From (2.24), we have

$$\begin{aligned} f(\varphi) &= -\frac{2H}{\epsilon} q_0' + \epsilon\Delta e_1 - \frac{1}{\epsilon}(3q_0^2 - 1)e_1 + O(1) \\ &= -\frac{2H}{\epsilon} q_0' + \epsilon\Delta q_1 - \frac{1}{\epsilon}(3q_0^2 - 1)q_1 + O(1) \\ &= -\frac{2H}{\epsilon} q_0' + \epsilon\left(-2H\frac{1}{\epsilon} q_1' + \frac{1}{\epsilon^2} q_1''\right) - \frac{1}{\epsilon}(3q_0^2 - 1)q_1 + O(1) \\ &= -\frac{2H}{\epsilon} q_0' + \frac{1}{\epsilon} q_1'' - \frac{1}{\epsilon}(3q_0^2 - 1)q_1 + O(1). \end{aligned}$$

To minimize $W(\varphi) = \frac{\epsilon}{2}\int_\Omega f^2\,dx$, we have that q_1 minimizes

$$\begin{aligned} W(\varphi) &= \frac{\epsilon}{2}\int_\Omega \left(-\frac{2H}{\epsilon} q_0' + \frac{1}{\epsilon} q_1'' - \frac{1}{\epsilon}(3q_0^2 - 1)q_1 + O(1)\right)^2 dx \\ &= \frac{\epsilon}{2}\int_\Omega \left(-\frac{2H}{\epsilon} q_0'\right)^2 + \left(\frac{1}{\epsilon} q_1'' \frac{1}{\epsilon}(3q_0^2 - 1)q_1\right)^2 dx \\ &\quad - \frac{1}{\epsilon}\int_\Omega H q_0'(q_1'' - (3q_0^2 - 1)q_1)\,dx + O(\epsilon). \end{aligned}$$

From Lemma 2.4

$$\int_\Omega H q_0' q_1'' \, dx = \int_\Omega H q_0''' q_1 \, dx + O(\epsilon).$$

Because $q_0'' = (q_0^2 - 1)q_0$, $q_0''' = (3q_0^2 - 1)q_0'$, we have

$$W(\varphi) = \frac{1}{2\epsilon} \int_\Omega 4H^2 (q_0')^2 + (q_1'' - (3q_0^2 - 1)q_1)^2 \, dx + O(\epsilon).$$

Therefore to minimize $W(\varphi)$, we get

$$q_1'' - (3q_0^2 - 1)q_1 = 0.$$

Since $q_0(0) = 0$, $\varphi(0) = 0$, assumption (A4) gives $q_1(0) = 0$, and since $q_0(\infty) = \varphi(\infty) = 1$, we have $q_1(\infty) = 0$. Similarly, $q_1(-\infty) = 0$. Then the only solution is that $q_1 = 0$. $\square$

THEOREM 2.13. *With assumptions* (A1)–(A4), *we have*

$$q_2 = 4(H^2 - K)p_2, \qquad i.e., \; q_2\left(\frac{d(x)}{\epsilon}, x|_\Gamma\right) = 4(H^2(x|_\Gamma) - K(x|_\Gamma))p\left(\frac{d(x)}{\epsilon}\right),$$

where $x|_\Gamma$ is the projection of point x on Γ along the integral curve of ∇d, and p_2 is an independent function satisfying the one-dimensional ODE

$$p_2''(t) - (3q_0^2(t) - 1)p_2(t) = \frac{1}{2} q_0'(t) t \tag{2.25}$$

with $p_2(\pm\infty) = p_2(0) = 0$.

Proof. Since $q_1 = 0$, $e_1 = \epsilon e_2$. From (2.24), we have

$$\begin{aligned} f(\varphi) &= -\frac{2H}{\epsilon} q_0' + \epsilon^2 \Delta e_2 - (3q_0^2 - 1)e_2 + O(\epsilon^2) \\ &= -\frac{2H}{\epsilon} q_0' - 2H\epsilon e_2' + e_2'' - (3q_0^2 - 1)e_2 + O(\epsilon^2). \end{aligned} \tag{2.26}$$

Now, $W(q_0)$ is already fixed due to Theorem 2.10, and

$$\begin{aligned} W(\varphi) - W(q_0) &= \frac{\epsilon}{2} \int_\Omega (f(\varphi) + f(q_0))(f(\varphi) - f(q_0)) \, dx \\ &= \frac{\epsilon}{2} \int_\Omega (2f(q_0) - 2H\epsilon e_2' + e_2'' - (3q_0^2 - 1)e_2 + O(\epsilon^2)) \\ &\quad (-2H\epsilon e_2' + e_2'' - (3q_0^2 - 1)e_2 + O(\epsilon^2)) \, dx \\ &= \frac{\epsilon}{2} \int_\Omega 2f(q_0)(-2H\epsilon e_2' + e_2'' - (3q_0^2 - 1)e_2 + O(\epsilon^2)) \\ &\quad + (-2H\epsilon e_2' + e_2'' - (3q_0^2 - 1)e_2 + O(\epsilon^2))^2 \, dx \\ &= R_1 + R_2. \end{aligned}$$

First from Lemma 2.4, we have

$$
\begin{aligned}
R_1 &= \frac{\epsilon}{2}\int_\Omega 2f(q_0)(-2H\epsilon e_2' + e_2'' - (3q_0^2-1)e_2 + O(\epsilon^2))\,dx \\
&= -\int_\Omega 2Hq_0'(-2H\epsilon e_2' + e_2'' - (3q_0^2-1)e_2 + O(\epsilon^2))\,dx \\
&= \int_\Omega 4H^2\epsilon q_0' e_2'\,dx - \int_\Omega 2Hq_0'(e_2'' - (3q_0^2-1)e_2) + O(\epsilon^2)\,dx \\
&= \int_\Omega -4H^2\epsilon q_0'' e_2 + O(\epsilon^2)\,dx - \int_\Omega 2(Hq_0''' - 2Kq_0''\epsilon)e_2 \\
&\quad - 2Hq_0'(3q_0^2-1)e_2 + O(\epsilon^2)\,dx \\
&= \int_\Omega -4(H^2-K)\epsilon q_0'' e_2 + O(\epsilon^2)\,dx
\end{aligned}
$$

and

$$
\begin{aligned}
R_2 &= \frac{\epsilon}{2}\int_\Omega (-2H\epsilon e_2' + e_2'' - (3q_0^2-1)e_2 + O(\epsilon^2))^2\,dx \\
&= \frac{\epsilon}{2}\int_\Omega (e_2'' - (3q_0^2-1)e_2)^2 + O(\epsilon)\,dx \\
&= \frac{\epsilon}{2}\int_\Omega (q_2'' - (3q_0^2-1)q_2)^2 + O(\epsilon)\,dx.
\end{aligned}
$$

Altogether, we have

$$
W(\varphi) - W(q_0) = \frac{\epsilon}{2}\int_\Omega -8(H^2-K)q_0''q_2 + (q_2'' - (3q_0^2-1)q_2)^2\,dx + O(\epsilon^2).
$$

Also, the curvature functions $H(x)$ and $K(x)$ are smooth functions around Γ, and from Lemma 2.9 we have

$$
\int_\Omega -8(H^2-K)q_0''q_2\,dx = \int_\Omega -8(H^2-K)|_\Gamma q_0''q_2\,dx + O(\epsilon^2).
$$

Now, taking $q_2 = 4(H^2-K)p_2$, that is, $q_2(d(x)/\epsilon, x|_\Gamma) = 4(H^2(x|_\Gamma) - K(x|_\Gamma))$ $p_2(d(x)/\epsilon, x|_\Gamma)$, we have $q_2'' = 4(H^2-K)p_2''$, and

$$
\begin{aligned}
&W(\varphi) - W(q_0) \\
&\quad = \epsilon\int_\Omega 16(H^2-K)|_\Gamma^2\left(-q_0''p_2 + \frac{1}{2}(p_2'' - (3q_0^2-1)q_2)^2\right) + O(\epsilon)\,dx \\
&\quad = \epsilon\int_\Gamma 16(H^2-K)^2\int_{\gamma_s} -q_0''p_2 + \frac{1}{2}(p_2'' - (3q_0^2-1)q_2)^2\,ds\,dS + O(\epsilon^3). \qquad (2.27)
\end{aligned}
$$

To minimize $W(\varphi)$, p_2 is independent of ϵ and $x|_\Gamma$, minimizing

$$
\int_{\gamma_s} -q_0''p_2 + \frac{1}{2}(p_2'' - (3q_0^2-1)p_2)^2\,ds.
$$

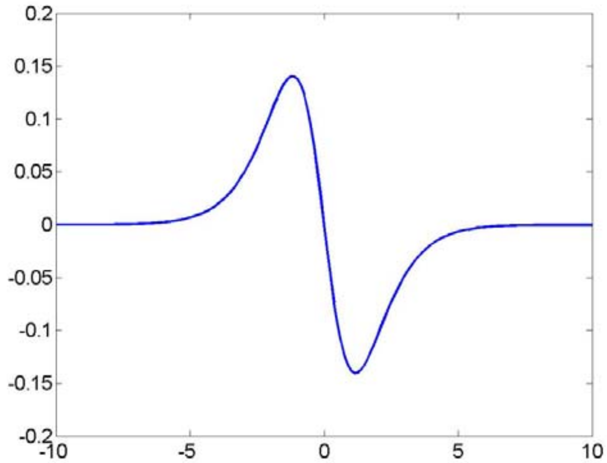

FIG. 2.1. *The second order term function $p_2(x)$.*

Changing the parameter d/ϵ to t, we have p_2 minimizing

$$E(p) = \int_{-\infty}^{\infty} -q_0(q_0^2-1)p_2 + \frac{1}{2}(p_2'' - (3q_0^2-1)p_2)^2\, dt.$$

We denote

$$s_2 = p_2'' - (3q_0^2-1)p_2. \tag{2.28}$$

Taking a variation of $E(p)$, we have

$$\frac{\delta E}{\delta p_2} = -(q_0^2-1)q_0 + s_2'' - (3q_0^2-1)s_2 = 0. \tag{2.29}$$

From assumption (A4) and $q_0(t) = \tanh(t/\sqrt{2})$ and $q_1 = 0$, we know that $p_2(\pm\infty) = p_2''(\pm\infty) = 0$. Then $s_2(\pm\infty) = 0$. Solving (2.29), we get

$$s_2 = \frac{1}{2}q_0' t.$$

Substituting it into (2.28) gives the result. □

Remark 2.14. Function p_2 can be numerically calculated by solving (2.25). A plot of p_2 is given in Figure 2.1. Theorem 2.13 states that φ depends not only on the distance function $d(x)$ but also on the local curvature properties.

For a sphere we always have $H^2(x) - K(x) = 0$ for every point $x \in \Omega$. Following Theorem 2.13 we directly have the following corollary.

COROLLARY 2.15. *If surface Γ is a sphere, we have $q_2 = 0$.*

Remark 2.16. Corollary 2.15 states that the phase field function is at least third order convergent in ϵ to the tanh profile for a sphere. Actually, we can easily verify that the phase field function is an exactly tanh function for a sphere.

THEOREM 2.17. *With assumptions* (A1)–(A4), *for given $x|_\Gamma$, we have $q_3(t, x|_\Gamma)$ minimizing*

$$\int_{-\infty}^{\infty} -Qq_3 + \frac{1}{2}(q_3'' - (3q_0^2-1)q_3)^2\, dt,$$

where $Q(t,x|_\Gamma) = 8H(H^2-K)(x|_\Gamma)[2q_0'(t) + 3q_0''(t)t] + 2\Delta_\Gamma H(x|_\Gamma)q_0'(t)$.

Proof. For computational purpose, we denote $G = 4(H^2-K)|_\Gamma$. Then $e_2 = q_2 + \epsilon e_3 = Gp_2 + \epsilon e_3$, and

$$\begin{aligned}\Delta q_2 = \nabla\cdot(\nabla q_2) &= \nabla\cdot\left(\nabla_\Gamma G p_2 + G\frac{p_2'}{\epsilon}\nabla d\right)\\ &= G\frac{p_2''}{\epsilon^2} - 2HG\frac{p_2'}{\epsilon} + \Delta_\Gamma G p_2.\end{aligned}$$

From (2.24) and $e_1 = \epsilon e_2$, we have

$$\begin{aligned} f(\varphi) &= -\frac{2H}{\epsilon}q_0' + \epsilon^2\Delta e_2 - (3q_0^2-1)e_2 - 3\epsilon^2 q_0 e_2^2 + O(\epsilon^4)\\ &= -\frac{2H}{\epsilon}q_0' + Gp_2'' - 2HGp_2'\epsilon + \Delta_\Gamma G p_2\epsilon^2 + \epsilon e_3'' - 2H\epsilon^2 e_3' + \Delta_\Gamma e_3\epsilon^3\\ &\quad - (3q_0^2-1)Gp_2 - \epsilon(3q_0^2-1)e_3 - 3G^2q_0p_2^2\epsilon^2 - 6Gq_0pe_3\epsilon^3 + O(\epsilon^4)\\ &= -\frac{2H}{\epsilon}q_0' + (Gp_2'' - (3q_0^2-1)Gp_2) + \epsilon(-2HGp_2' + e_3'' - (3q_0^2-1)e_3)\\ &\quad + \epsilon^2(\Delta_\Gamma G p_2 - 2He_3' - 3G^2q_0p_2^2) + \epsilon^3(\Delta_\Gamma e_3 - 6Gq_0p_2e_3) + O(\epsilon^4)\\ &= f(q_0) + a + \epsilon b + \epsilon^2 c + \epsilon^3 d + O(\epsilon^4),\end{aligned}$$

where

$$a = Gp_2'' - (3q_0^2-1)Gp_2, \tag{2.30}$$

$$b = -2HGp_2' + e_3'' - (3q_0^2-1)e_3, \tag{2.31}$$

$$c = \Delta_\Gamma G p_2 - 2He_3' - 3G^2q_0p_2^2, \tag{2.32}$$

$$d = \Delta_\Gamma e_3 - 6Gq_0p_2e_3. \tag{2.33}$$

Then

$$\begin{aligned} &W(\varphi) - W(q_0)\\ &\quad = \frac{\epsilon}{2}\int_\Omega (f(\varphi)+f(q_0))(f(\varphi)-f(q_0))\,dx\\ &\quad = \frac{\epsilon}{2}\int_\Omega 2f(q_0)(a+\epsilon b+\epsilon^2 c+\epsilon^3 d+O(\epsilon^4)) + (a+\epsilon b+\epsilon^2 c+\epsilon^3 d+O(\epsilon^4))^2\,dx\\ &\quad = \frac{\epsilon}{2}\int_\Omega 2f(q_0)a + [2f(q_0)b\epsilon + a^2] + \epsilon[2f(q_0)c\epsilon + 2ab]\\ &\qquad + \epsilon^2[2f(q_0)d\epsilon + 2ac + b^2] + O(\epsilon^3)\,dx.\end{aligned}$$

Below we focus on the terms involving q_3. We use ellipses to denote all the terms not involving q_3. First, $\int_\Omega 2f(q_0)a\,dx$ is independent of q_3. Then from Lemma 2.4

$$\begin{aligned}\int_\Omega 2f(q_0)b\epsilon\,dx &= \int_\Omega 2f(q_0)(-2HGp_2')\epsilon + 2f(q_0)(e_3'' - (3q_0^2-1)e_3)\epsilon\,dx\\ &= \int_\Omega \cdots - 4Hq_0'(e_3'' - (3q_0^2-1)e_3)\,dx\\ &= \int_\Omega \cdots - 4[Hq_0''' - 2Kq_0''\epsilon - Hq_0'(3q_0^2-1)]e_3\,dx\\ &= \int_\Omega \cdots + 8Kq_0''e_3\epsilon\,dx.\end{aligned}$$

$\int_\Omega a^2\,dx$ is also independent of q_3.

$$\begin{aligned}\epsilon\int_\Omega 2f(q_0)c\epsilon\,dx &= \epsilon\int_\Omega -4Hq_0'(\Delta_\Gamma Gp_2 - 2He_3' - 3G^2q_0p_2^2)\,dx\\ &= \epsilon\int_\Omega \cdots + 8(-2H(H^2-K)q_0'\epsilon - H^2q_0'')e_3 + \cdots\,dx\\ &= \int_\Omega \cdots - 16H(H^2-K)q_0'e_3\epsilon^2 - 8H^2q_0''e_3\epsilon\,dx.\\ \epsilon\int_\Omega 2ab\,dx &= \epsilon\int_\Omega \cdots + 2a(e_3'' - (3q_0^2-1)e_3)\,dx\\ &= \int_\Omega \cdots + 2(a'' - 4Ha'\epsilon + 2Ka\epsilon^2)e_3\epsilon - 2(3q_0^2-1)ae_3\epsilon\,dx\\ &= \int_\Omega \cdots + 2a''e_3\epsilon - 8Ha'e_3\epsilon^2 - 2(3q_0^2-1)ae_3\epsilon + O(\epsilon^3)\,dx.\\ \epsilon^2\int_\Omega \epsilon 2f(q_0)d\,dx &= \int_\Omega -4Hq_0'\Delta_\Gamma e_3\epsilon^2 + 24HGq_0'q_0p_2e_3\epsilon^2\,dx.\\ \epsilon^2\int_\Omega 2ac\,dx &= \epsilon^2\int_\Omega 2a(\Delta_\Gamma Gp_2 - 2He_3' - 3G^2q_0p_2^2)\,dx\\ &= \epsilon^2\int_\Omega \cdots - 4[Ka\epsilon - Ha']e_3\,dx\\ &= \int_\Omega \cdots + O(\epsilon^3) + 4Ha'e_3\epsilon^2\,dx.\\ \epsilon^2\int_\Omega b^2\,dx &= \epsilon^2\int_\Omega \cdots - 4HGp_2'(e_3'' - (3q_0^2-1)e_3) + (e_3'' - (3q_0^2-1)e_3)^2\,dx\\ &= \int_\Omega \cdots - 4HG(p_2''' - (3q_0^2-1)p_2')e_3\epsilon^2 + (e_3'' - (3q_0^2-1)e_3)^2\epsilon^2\\ &\quad + O(\epsilon^3)\,dx.\end{aligned}$$

Combining all the items involving q_3 above, we need to minimize

$$\begin{aligned}E(e_3) = &\int_\Omega 8Kq_0''e_3\epsilon - 16H(H^2-K)q_0'e_3\epsilon^2 - 8H^2q_0''e_3\epsilon + 2a''e_3\epsilon - 8Ha'e_3\epsilon^2\\&- 2(3q_0^2-1)ae_3\epsilon - 4Hq_0'\Delta_\Gamma e_3\epsilon^2 + 24HGq_0'q_0p_2e_3\epsilon^2 + 4Ha'e_3\epsilon^2\\&- 4HG(p_2'''-(3q_0^2-1)p_2')e_3\epsilon^2 + (e_3''-(3q_0^2-1)e_3)^2\epsilon^2 + O(\epsilon^3)\,dx\\=&\int_\Omega [-8(H^2-K)q_0'' + 2a'' - 2(3q_0^2-1)a]e_3\epsilon\\&+ [-16H(H^2-K)q_0'e_3 - 4Ha'e_3 - 4Hq_0'\Delta_\Gamma e_3 + 24HGq_0'q_0p_2e_3\\&- 4HG(p_2'''-(3q_0^2-1)p_2')e_3]\epsilon^2 + (e_3''-(3q_0^2-1)e_3)^2\epsilon^2 + O(\epsilon^3)\,dx.\end{aligned}$$

Now we can simplify above $E(e_3)$. From (2.28), we have $a = Gs_2 = Gq_0't/2$, $a'' - (3q_0^2-1)a = G(q_0^2-1)q_0 = Gq_0''$, $s_2' = p_2''' - (3q_0^2-1)p_2' - 6q_0q_0'p_2$, and from Lemmas 2.9 and 2.6,

$$\int_\Omega -4Hq_0'\Delta_\Gamma e_3\,dx = \int_\Omega -4H_\Gamma q_0'\Delta_\Gamma e_3\,dx + O(\epsilon) = \int_\Omega -4\Delta_\Gamma Hq_0'e_3\,dx + O(\epsilon).$$

From Lemma 2.9, since $\nabla(H^2-K)\cdot\nabla d = 4H(H^2-K)$,

$$\begin{aligned}\int_\Omega -8(H^2-K)q_0''e_3\epsilon\,dx &= \int_\Omega -8[(H^2-K)|_\Gamma + 4H(H^2-K)|_\Gamma d]q_0''e_3\epsilon + O(\epsilon^3)\,dx\\&= \int_\Omega -2[G + 4H_\Gamma Gd]q_0''e_3\epsilon + O(\epsilon^3)\,dx.\end{aligned}$$

Altogether we have

$$\begin{aligned}E(e_3) = &\epsilon^2\int_\Omega \left[-16H(H^2-K)q_0' - 8HGs_2' - 4\Delta_\Gamma Hq_0' - 8H_\Gamma G\frac{d}{\epsilon}q_0''\right]e_3\\&+ (e_3''-(3q_0^2-1)e_3)^2 + O(\epsilon)\,dx\\=&\epsilon^2\int_\Omega 4H(H^2-K)(x|_\Gamma)\left[-4q_0' - 8s_2' - 8\frac{d}{\epsilon}q_0''\right]q_3 - 4\Delta_\Gamma H(x|_\Gamma)q_0'q_3\\&+ (q_3''-(3q_0^2-1)q_3)^2 + O(\epsilon)\,dx.\end{aligned}$$

Since $s_2 = q_0't/2$, denoting $Q = 8H(H^2-K)(x|_\Gamma)[2q_0'(t) + 3q_0''(t)t] + 2\Delta_\Gamma H(x|_\Gamma)q_0'(t)$, we have q_3 minimizing

$$E(e_3) = 2\epsilon^2\int_\Omega -Qq_3 + \frac{1}{2}(q_3''-(3q_0^2-1)q_3)^2\,dx.$$

From Lemma 2.7,

$$E(e_3) = 2\epsilon^3\int_\Gamma\int_{-\infty}^{\infty} -Qq_3 + \frac{1}{2}(q_3''-(3q_0^2-1)q_3)^2\,dt\,dS + o(\epsilon^3).$$

Therefore, for any given $x|_\Gamma$, $q_3(t, x|_\Gamma)$ minimizes

$$\int_{-\infty}^{\infty} -Qq_3 + \frac{1}{2}(q_3''-(3q_0^2-1)q_3)^2\,dt. \qquad \square$$

A direct corollary from Theorem 2.17 is that the equilibrium surface Γ must satisfy

$$\Delta_\Gamma H + 2H(H^2 - K) = 0.$$

Because this result is very important, we discuss it in section 3.

3. Equilibrium state and Willmore force of surface Γ. Based on Theorems 2.10, 2.12, 2.13, and 2.17, we have the following theorem about the equilibrium surface Γ in the phase field model.

THEOREM 3.1. *With assumptions* (A1)–(A4), *if φ minimizes energy $W(\varphi)$ defined in* (1.4), Γ, *the zero level set of φ asymptotically satisfies that*

$$\Delta_\Gamma H + 2H(H^2 - K) = 0. \tag{3.1}$$

Proof. Since φ minimizes energy $W(\varphi)$, we have that

$$\varphi = q_0 + \epsilon^2 q_2 + \epsilon^3 q_3 + O(\epsilon^4),$$

where q_3 minimizes

$$\int_{-\infty}^{\infty} -Qq_3 + \frac{1}{2}(q_3'' - (3q_0^2 - 1)q_3)^2 \, dt, \tag{3.2}$$

where $Q = 8H(H^2 - K)[2q_0' + 3q_0''t] + 2\Delta_\Gamma H q_0'$.

Now, denote $s_3 = q_3'' - (3q_0^2 - 1)q_3$. Taking the variation of (3.2), we have that

$$s_3'' - (3q_0^2 - 1)s_3 = Q. \tag{3.3}$$

From assumption (A4), we have that $q_3(\pm\infty) = q_3'(\pm\infty) = 0$. Then $s_3(\pm\infty) = s_3'(\pm\infty) = 0$. Now noticing that

$$q_0'' = q_0(q_0^2 - 1), \quad (q_0')'' - (3q_0^2 - 1)q_0' = 0 \,,$$

from (3.3) we have that

$$\begin{aligned} \int_{-\infty}^{\infty} Qq_0' \, dt &= \int_{-\infty}^{\infty} [s_3'' - (3q_0^2 - 1)s_3]q_0' \, dt \\ &= \int_{-\infty}^{\infty} s_3[(q_0')'' - (3q_0^2 - 1)q_0'] \, dt = 0. \end{aligned} \tag{3.4}$$

On the other hand,

$$\begin{aligned} \int_{-\infty}^{\infty} Qq_0' \, dt &= \int_{-\infty}^{\infty} [8H(H^2 - K)[2q_0' + 3q_0''t] + 2\Delta_\Gamma H q_0']q_0' \, dt \\ &= 8H(H^2 - K) \int_{-\infty}^{\infty} [2(q_0')^2 + 3q_0''q_0't] \, dt + 2\Delta_\Gamma H \int_{-\infty}^{\infty} (q_0')^2 \, dt \\ &= (\Delta_\Gamma H + 2H(H^2 - K)) \int_{-\infty}^{\infty} 2(q_0')^2 \, dt. \end{aligned}$$

Comparing this with (3.4), we have

$$\Delta_\Gamma H + 2H(H^2 - K) = 0. \qquad \square$$

Equation (3.1) is exactly the Willmore identity for Willmore's problem. Theorem 3.1 verifies that the equilibrium state of the phase field model is consistent with that of the sharp interface model. Equation (3.1) is a necessary condition for the existence of function q_3. If surface Γ does not satisfy (3.1), then to minimize the phase field energy $W(\varphi)$, we can still choose optimal q_0, q_1, and q_2 but not q_3. This is the main reason why the gradient flow in [7, 8] works, which will be explained below.

In our phase field model in finding the equilibrium shape of Γ, we first start from an initial phase field function φ^0, whose zero level set is Γ^0. Then we search a lower energy state along the gradient flow of $W(\varphi)$. Denote the gradient by

$$g(\varphi) = \frac{\partial W(\varphi)}{\partial \varphi} = \epsilon \Delta f(\varphi) - \frac{1}{\epsilon}(3\varphi^2 - 1) f(\varphi), \tag{3.5}$$

where f is defined in (2.1). The gradient flow is as flowing

$$\varphi_t = -g(\varphi) \tag{3.6}$$

with initial condition $\varphi|_{t=0} = \varphi^0$. In [7, 8] we developed several numerical schemes for the gradient flow (3.6), including a fully implicit scheme solving by Newton's method and some semi-implicit or explicit schemes. With the asymptotic analysis in section 2.3, we can now explain why the surface Γ moves along the gradient flow by using a kind of explicit scheme.

Suppose at step n that we have phase field φ^n with zero level set Γ^n. With the explicit surface Γ^n, for the next step along the gradient we get the fastest descent of the energy. With the asymptotic expansion, obviously we can select

$$\varphi^{n+1}(x) = \tanh\left(\frac{d(x, \Gamma^n)}{\sqrt{2}\epsilon}\right) + 4\epsilon^2 (H^2(x|_{\Gamma^n}) - K(x|_{\Gamma^n})) p\left(\frac{d(x, \Gamma^n)}{\epsilon}\right) + \epsilon^3 q_3^{n+1} + \cdots .$$

Now, the gradient flow of φ is actually the gradient flow of q_3 while q_0, q_1, and q_2 are fixed to be optimal. Based on Theorem 2.17, the gradient flow of q_3 is

$$q_{3,t} = -Q + s_3'' - (3q_0^2 - 1)s_3.$$

Theorem 3.1 states that if Γ^n is not an equilibrium shape along the gradient flow of q_3, we cannot get an optimal q_3. Actually along the gradient flow of q_3, we get $q_3(\Gamma^n) \neq 0$, i.e., Γ^n is not the zero level set anymore! With a small time step, along the gradient flow of q_3, Γ^n moves to be Γ^{n+1} with a decreasing energy $W(\varphi^{n+1}) < W(\varphi^n)$. This process will stop until Γ reaches an equilibrium state.

We can also describe how the zero level set Γ moves along the gradient flow. With the movement of level set Γ_d, we have $\varphi(x(t), t) = d$. Then $\varphi_t + \nabla\varphi \cdot \dot{x}(t) = 0$. Denote the induced elastic force in the phase field model by ξ_ϵ. Based on the relation between momentum and energy, we have

$$\xi_\epsilon \cdot \dot{x} = -W_t = -\frac{\partial W(\varphi)}{\partial \varphi}\varphi_t = -\frac{\partial W(\varphi)}{\partial \varphi}(-\nabla\varphi \cdot \dot{x}),$$

which results in the formula for the elastic force in the phase field model:

$$\xi_\epsilon = \frac{\partial W(\varphi)}{\partial \varphi}\nabla\varphi. \tag{3.7}$$

One can refer to [12, 10] for more discussions about it.

On the other hand, it is known [26, 17] that the Willmore flow force, the gradient of the sharp interface Willmore energy (1.1), is given by

$$(\Delta_\Gamma H + 2H(H^2 - K))\vec{n}(x), \tag{3.8}$$

where $\vec{n}(x)$ is the normal vector on Γ. A basic question of phase field models minimizing (1.4) is to verify the consistency of these two forces as $\epsilon \to 0$. In another words, we need to verify

$$\lim_{\epsilon\to 0} \xi_\epsilon \sim c(\Delta_\Gamma H + 2H(H^2 - K))\vec{n}(x), \tag{3.9}$$

where a constant c may apply. Unlike the sharp interface model, in the phase field model the elastic force exists everywhere but concentrates around the transition layer. Therefore we can only do a weak form of (3.9). Some preliminary analyses of formula (3.9) are given in [12, 10].

Now in the case where Γ is not an equilibrium shape, although there is no optimal selection of q_3, we can still have the optimal selection of q_0, q_1, and q_2. Further, we have the following theorem for the weak form of (3.9).

THEOREM 3.2. *With assumptions* (A1)–(A4), *for zero level set* Γ *if* φ *minimizes* $W(\varphi)$ *to the second order term, we have*

$$\int_\Omega -\xi_\epsilon \cdot v\, dx = \frac{4\sqrt{2}}{3}\int_\Gamma (\Delta_\Gamma H + 2H(H^2 - K))\vec{n}\cdot v\, dx + O(\epsilon)$$

for any continuous vector field v.

Remark 3.3. A major improvement over the method in [12, 10] is that we do not make any special assumptions on v, such as a divergence-free condition.

In general, the normal direction is defined as pointing towards the outside of Γ. But the normal direction $\vec{n}(x)$ defined by ∇d is towards the inside of Γ because we set the distance function d positive inside and negative outside. This difference results in the negative sign before ξ_ϵ.

Proof. In this proof, we need to expand the phase field function with the third order term, i.e.,

$$\varphi(x) = q_0\left(\frac{d(x)}{\epsilon}, x|_\Gamma\right) + \epsilon^2 q_2\left(\frac{d(x)}{\epsilon}, x|_\Gamma\right) + \epsilon^3 q_3\left(\frac{d(x)}{\epsilon}, x|_\Gamma\right) + O(\epsilon^3).$$

From (2.26) we have that

$$f(\varphi) = -\frac{2H}{\epsilon}q_0' + (q_2'' - (3q_0^2 - 1)q_2) + \epsilon[-2Hq_2' + q_3'' - (3q_0^2 - 1)q_3] + O(\epsilon^2). \tag{3.10}$$

Denote that

$$a = q_2'' - (3q_0^2 - 1)q_2; \tag{3.11}$$

$$b = q_3'' - (3q_0^2 - 1)q_3. \tag{3.12}$$

We have

$$f = -\frac{2H}{\epsilon}q_0' + a + \epsilon[-2Hq_2' + b] + O(\epsilon^2).$$

To calculate Δf, first we obtain

$$\begin{aligned}\Delta(Hq_0') &= \Delta H q_0' + 2(\nabla H\cdot\nabla d)\frac{1}{\epsilon}q_0'' + H(-2H)\frac{1}{\epsilon}q_0'' + H\frac{1}{\epsilon^2}q_0''' \\ &= \Delta H q_0' + 2(H^2-K)\frac{1}{\epsilon}q_0'' + H\frac{1}{\epsilon^2}q_0'''\end{aligned}$$

and

$$\Delta(Hq_2') = H\frac{1}{\epsilon^2}q_2''' + O\left(\frac{1}{\epsilon}\right).$$

Second, from (2.7) we have that

$$\begin{aligned}\Delta a &= \frac{1}{\epsilon^2}a'' - \frac{2H}{\epsilon}a' + O(1),\\ \Delta b &= \frac{1}{\epsilon^2}b'' + O\left(\frac{1}{\epsilon}\right).\end{aligned}$$

Altogether we have that

$$\epsilon\Delta f = -\frac{2H}{\epsilon^2}q_0''' - \frac{4}{\epsilon}(H^2-K)q_0'' - 2\Delta H q_0' + \frac{1}{\epsilon}a'' - 2Ha' - 2Hq_2''' + b'' + O(\epsilon).$$

And because

$$\begin{aligned}\frac{1}{\epsilon}(3\varphi^2-1)f &= \frac{1}{\epsilon}(3q_0^2 - 1 + 6q_0q_2\epsilon^2 + O(\epsilon^3))f\\ &= -\frac{2H}{\epsilon^2}(3q_0^2-1)q_0' + \frac{1}{\epsilon}(3q_0^2-1)a\\ &\quad + (3q_0^2-1)[-2Hq_2' + b] - 12Hq_0q_0'q_2 + O(\epsilon),\end{aligned}$$

we have

$$\begin{aligned}g(\varphi) &= \epsilon\Delta f(\varphi) - \frac{1}{\epsilon}(3\varphi^2-1)f(\varphi)\\ &= -\frac{4}{\epsilon}(H^2-K)q_0'' - 2\Delta H q_0' + \frac{1}{\epsilon}[a'' - (3q_0^2-1)a] + [b'' - (3q_0^2-1)b]\\ &\quad - 2Ha' - 2Hq_2''' + 2Hq_2'(3q_0^2-1) + 12Hq_0q_0'q_2 + O(\epsilon)\\ &= -\frac{4}{\epsilon}(H^2-K)q_0'' - 2\Delta H q_0' + \frac{1}{\epsilon}[a'' - (3q_0^2-1)a]\\ &\quad + [b'' - (3q_0^2-1)b] - 4Ha' + O(\epsilon).\end{aligned}$$

From Theorem 2.13, we have

$$a'' - (3q_0^2-1)a = 4(H^2-K)|_\Gamma(q_0^2-1)q_0.$$

Then

$$\begin{aligned}g(\varphi) &= -\frac{4}{\epsilon}(H^2-K)q_0'' - 2\Delta H q_0' + \frac{4}{\epsilon}(H^2-K)|_\Gamma q_0''\\ &\quad + [b'' - (3q_0^2-1)b] - 4Ha' + O(\epsilon),\end{aligned}$$

because

$$-\frac{4}{\epsilon}(H^2-K)q_0''+\frac{4}{\epsilon}(H^2-K)|_\Gamma q_0''=-\frac{4}{\epsilon}(\nabla(H^2-K)\cdot\nabla d)dq_0''+O(\epsilon)$$
$$=-16H(H^2-K)(q_0''t)+O(\epsilon)$$

and

$$4Ha'=16H(H^2-K)(q_0't/2)'=8H(H^2-K)(q_0''t+q_0');$$

also from Lemma 2.3, $\Delta H=\Delta_\Gamma H+4H(H^2-K)$; altogether we have that

$$\begin{aligned}g(\varphi)&=-16H(H^2-K)(q_0''t)-2\Delta_\Gamma Hq_0'-8H(H^2-K)q_0'\\&\quad-8H(H^2-K)(q_0''t+q_0')+[b''-(3q_0^2-1)b]+O(\epsilon)\\&=-Q+[b''-(3q_0^2-1)b]+O(\epsilon),\end{aligned}\tag{3.13}$$

where $Q=8H(H^2-K)[2q_0'+3q_0''t]+2\Delta_\Gamma Hq_0'$.

For any continuous vector field $v(x)$, from Lemma 2.8, $\int_{-\infty}^{\infty}[b''-(3q_0^2-1)b]q_0'\,dt=\int_{-\infty}^{\infty}[q_0'''-(3q_0^2-1)q_0']b\,dt=0$, and $\int_{-\infty}^{\infty}q_0''q_0'tdt=-\frac{1}{2}\int_{-\infty}^{\infty}(q_0')^2\,dt$, we have

$$\begin{aligned}\int_\Omega-\xi_\epsilon\cdot v\,dx&=\int_\Omega-g(\varphi)\nabla\varphi\cdot v\,dx\\&=\int_\Omega(Q-[b''-(3q_0^2-1)b]+O(\epsilon))\left(\frac{1}{\epsilon}q_0'\nabla d+O(1)\right)\cdot v\,dx\\&=\int_\Omega\frac{1}{\epsilon}(Q-[b''-(3q_0^2-1)b])q_0'\nabla d\cdot v\,dx+O(\epsilon)\\&=\int_{-\infty}^{\infty}[2q_0'+3q_0''t]q_0'\,dt\int_\Gamma 8H(H^2-K)\vec{n}\cdot v\,dx\\&\quad+\int_{-\infty}^{\infty}(q_0')^2\,dt\int_\Gamma 2\Delta_\Gamma H\vec{n}\cdot v\,dx\\&\quad-\int_{-\infty}^{\infty}[b''-(3q_0^2-1)b]q_0'\,dt\int_\Gamma\vec{n}\cdot v\,dx+O(\epsilon)\\&=\int_{-\infty}^{\infty}2(q_0')^2\,dt\int_\Gamma(\Delta_\Gamma H+2H(H^2-K))\vec{n}\cdot v\,dx+O(\epsilon)\\&=\frac{4\sqrt{2}}{3}\int_\Gamma(\Delta_\Gamma H+2H(H^2-K))\vec{n}\cdot v\,dx+O(\epsilon).\qquad\square\end{aligned}$$

If Γ is the equilibrium state, from Theorem 2.17 we have

$$b''-(3q_0^2-1)b=Q.$$

Then from (3.13) we have

$$g(\varphi)=O(\epsilon).$$

This result is trivial, because in the equilibrium state, eventually we have $g(\varphi)=0$. We can even reverse the above analysis to get another proof of Theorems 2.10, 2.12, 2.13, and 2.17.

4. Effect of spontaneous curvature. With the presence of spontaneous curvature c, we denote

$$f_c(\varphi) = \Delta\varphi - \frac{1}{\epsilon^2}(\varphi^2 - 1)(\varphi + \sqrt{2}c\epsilon), \tag{4.1}$$

and the elastic bending energy with spontaneous curvature is given by [11]

$$W_c(\varphi) = \frac{\epsilon}{2}\int_\Omega f_c(\varphi)^2\,dx. \tag{4.2}$$

The variation of $W_c(\varphi)$ is denoted by

$$g_c(\varphi) = \epsilon\Delta f_c(\varphi) - \frac{1}{\epsilon}(3\varphi^2 - 1 + 2\sqrt{2}c\epsilon\varphi)f_c(\varphi). \tag{4.3}$$

For simplicity, here we consider only the case with constant spontaneous curvature.

First, we have the following theorem about the asymptotic expansion of the phase field function minimizing energy $W_c(\varphi)$.

THEOREM 4.1. *With assumptions* (A1)–(A4), *in the spontaneous curvature case we have*

$$q_0(t) = \tanh\left(\frac{t}{\sqrt{2}}\right), \tag{4.4}$$

$$q_1 = 0, \tag{4.5}$$

$$q_2 = 4(H^2 - K + 2cH - c^2)p_2, \tag{4.6}$$

where p_2 is defined in Theorem 2.13.

Proof. Expanding

$$\varphi = q_0 + \epsilon q_1 + \epsilon^2 q_2 + \epsilon^3 q_3 + O(\epsilon^4)$$

and denoting

$$a_0 = q_0'' - (q_0^2 - 1)q_0,$$
$$a_i = q_i'' - (3q_0^2 - 1)q_i, \quad i = 1, 2, 3,$$

we have

$$\begin{aligned}\Delta\varphi = &\frac{1}{\epsilon^2}(q_0'' + \epsilon q_1'' + \epsilon^2 q_2'' + \epsilon^3 q_3'')\\ &-\frac{2H}{\epsilon}(q_0' + \epsilon q_1' + \epsilon^2 q_2') + \Delta_\Gamma(q_0' + \epsilon q_1') + O(\epsilon^2)\end{aligned}$$

and

$$\begin{aligned}\frac{1}{\epsilon^2}(\varphi^2 - 1)\varphi &= \frac{1}{\epsilon^2}[q_0^2 - 1 + \epsilon(2q_0q_1) + \epsilon^2(q_1^2 + 2q_0q_2) + \epsilon^3(2q_0q_3 + 2q_1q_2)\\ &\quad + O(\epsilon^4)](q_0 + \epsilon q_1 + \epsilon^2 q_2 + \epsilon^3 q_3 + O(\epsilon^4))\\ &= \frac{1}{\epsilon^2}[(q_0^2 - 1)q_0 + \epsilon(3q_0^2 - 1)q_1 + \epsilon^2((3q_0^2 - 1)q_2 + 3q_0q_1^2)\\ &\quad + \epsilon^3((3q_0^2 - 1)q_3 + 6q_0q_1q_2 + q_1^3) + O(\epsilon^4)].\end{aligned}$$

Therefore

$$f(\varphi) = \frac{1}{\epsilon^2}a_0 + \frac{1}{\epsilon}[a_1 - 2Hq_0'] + [a_2 - 2Hq_1' + \Delta_\Gamma q_0' - 3q_0q_1^2]$$
$$+ \epsilon[a_3 - 2Hq_2' + \epsilon\Delta_\Gamma q_1' - 6q_0q_1q_2 - q_1^3] + O(\epsilon^2).$$

Since

$$\frac{\sqrt{2}c}{\epsilon}(\varphi^2 - 1) = \frac{\sqrt{2}c}{\epsilon}(q_0^2 - 1) + 2\sqrt{2}cq_0q_1 + \sqrt{2}c\epsilon(q_1^2 + 2q_0q_2) + O(\epsilon^2),$$

we have

$$\begin{aligned}
f_c(\varphi) &= f(\varphi) - \frac{\sqrt{2}c}{\epsilon}(\varphi^2 - 1)\\
&= \frac{1}{\epsilon^2}a_0 + \frac{1}{\epsilon}[a_1 - 2Hq_0' - \sqrt{2}c(q_0^2 - 1)]\\
&\quad + [a_2 - 2Hq_1' + \Delta_\Gamma q_0' - 3q_0q_1^2 - 2\sqrt{2}cq_0q_1]\\
&\quad + \epsilon[a_3 - 2Hq_2' + \epsilon\Delta_\Gamma q_1' - 6q_0q_1q_2 - q_1^3 - \sqrt{2}c(q_1^2 + 2q_0q_2)] + O(\epsilon^2).
\end{aligned}$$

(1) To minimize $W_c(\varphi) = \frac{\epsilon}{2}\int_\Omega f_c(\varphi)^2\,dx$, we need to minimize $\int_\Omega a_0^2\,dx$. Then

$$a_0 = 0 \quad \Rightarrow \quad q_0(t) = \tanh\left(\frac{t}{\sqrt{2}}\right).$$

(2) Now we need to minimize

$$\int_\Omega (a_1 - 2Hq_0' - \sqrt{2}c(q_0^2 - 1))^2\,dx = \int_\Omega (a_1 - 2(H - c)q_0')^2\,dx.$$

Since

$$\begin{aligned}
\int_\Omega (H - c)q_0'a_1\,dx &= \int_\Omega (H - c)q_0'(q_1'' - (3q_0^2 - 1)q_1)\,dx\\
&= \int_\Omega (H - c)(q_0''' - (3q_0^2 - 1)q_0')q_1\,dx + O(\epsilon) = O(\epsilon),
\end{aligned}$$

we have

$$a_1 = 0 \quad \Rightarrow \quad q_1 = 0.$$

(3) Now we have that

$$f_c(\varphi) = -\frac{2}{\epsilon}(H - c)q_0' + a_2 + \epsilon(a_3 - 2Hq_2' - 2\sqrt{2}cq_0q_2) + O(\epsilon^2).$$

Then we need to minimize

$$\int_\Omega -\frac{4}{\epsilon}(H - c)q_0'a_2 + a_2^2 - 4(H - c)q_0'(a_3 - 2Hq_2' - 2\sqrt{2}cq_0q_2)\,dx.$$

Since

$$
\begin{aligned}
&-\frac{4}{\epsilon}\int_\Omega (H-c)q_0' a_2\,dx\\
&\quad = -\frac{4}{\epsilon}\int_\Omega (H-c)q_0'(q_2''-(3q_0^2-1)q_2)\,dx - \frac{4}{\epsilon}\int_\Omega (H-c)(q_0'''-(3q_0^2-1)q_0')q_2\\
&\qquad -2Kq_0''\epsilon q_2 + 4Hcq_0''\epsilon q_2 + O(\epsilon^2)\,dx\,dx = \int_\Omega 8(K-2cH)q_0''q_2 + O(\epsilon)\,dx
\end{aligned}
$$

and similarly $\int_\Omega -4(H-c)q_0' a_3\,dx = \int_\Omega O(\epsilon)\,dx$, we need to minimize

$$
\int_\Omega 8(K-2cH)q_0''q_2 - 8H(H-c)q_0''q_2 - 8c(H-c)q_0''q_2 + a_2^2\,dx,
$$

i.e.,

$$
\int_\Omega -8(H^2-K+2cH-c^2)q_0''q_2 + a_2^2\,dx.
$$

Then we have

$$
q_2 = 4(H^2-K+2cH-c^2)p_2,
$$

where p_2 is defined in Theorem 2.13. ∎

We also have the following theorem about the Willmore flow force and the equilibrium state of the shape with spontaneous curvature.

THEOREM 4.2. *With assumptions* (A1)–(A4), *if* φ *minimizes the energy* $W_c(\varphi)$, *the equilibrium state of* Γ *in the phase field model asymptotically satisfies*

$$
\Delta_\Gamma H + 2H(H^2-K) + 2Kc - 2Hc^2 = 0. \tag{4.7}
$$

And if φ *minimizes the* $W_c(\varphi)$ *to the second order term with the zero level set* Γ, *the elastic force satisfies*

$$
\int_\Omega -\xi_\epsilon \cdot v\,dx = \frac{4\sqrt{2}}{3}\int_\Gamma (\Delta_\Gamma H + 2H(H^2-K) + 2Kc - 2Hc^2)\vec{n}\cdot v\,dx + O(\epsilon)
$$

for any continuous vector field v.

Proof. We can continue with the proof of Theorem 4.1 to calculate $g_c(\varphi)$. From

$$
f_c(\varphi) = -\frac{2}{\epsilon}(H-c)q_0' + a_2 + \epsilon(a_3 - 2Hq_2' - 2\sqrt{2}cq_0q_2) + O(\epsilon^2),
$$

we have

$$
\begin{aligned}
\epsilon\Delta f_c = &-\frac{2H}{\epsilon^2}q_0''' - \frac{4}{\epsilon}(H^2-K)q_0'' - 2\Delta H q_0' + \frac{1}{\epsilon}a_2'' - 2Ha_2' - 2Hq_2''' + a_3''\\
&+ 2c\left(\frac{1}{\epsilon^2}q_0''' - \frac{2H}{\epsilon}q_0''\right) - 2\sqrt{2}c(q_0q_2)'' + O(\epsilon)
\end{aligned}
$$

and

$$
\begin{aligned}
&\frac{1}{\epsilon}(3\varphi^2-1+2\sqrt{2}c\epsilon\varphi)f_c\\
&\quad=\frac{1}{\epsilon}(3q_0^2-1+6q_0q_2\epsilon^2+2\sqrt{2}c\epsilon q_0+O(\epsilon^3))f_c\\
&\quad=-\frac{2(H-c)}{\epsilon^2}(3q_0^2-1)q_0'+\frac{1}{\epsilon}[(3q_0^2-1)a_2-4\sqrt{2}c(H-c)q_0q_0']\\
&\qquad+(3q_0^2-1)(a_3-2Hq_2'-2\sqrt{2}cq_0q_2)+2\sqrt{2}cq_0a_2-12(H-c)q_0q_0'q_2+O(\epsilon).
\end{aligned}
$$

Then

$$
\begin{aligned}
g_c(\varphi)&=\epsilon\Delta f_c-\frac{1}{\epsilon}(3\varphi^2-1+2\sqrt{2}c\epsilon\varphi)f_c\\
&=-\frac{4}{\epsilon}(H^2-K)q_0''-2\Delta Hq_0'+\frac{1}{\epsilon}(a_2''-(3q_0^2-1)a_2)+(a_3''-(3q_0^2-1)a_3)\\
&\quad-2Ha_2'-2Hq_2'''-\frac{4}{\epsilon}cHq_0''-2\sqrt{2}c(q_0q_2)''-\frac{4}{\epsilon}c(H-c)q_0''\\
&\quad+2Hq_2'(3q_0^2-1)+2\sqrt{2}cq_0q_2(3q_0^2-1)\\
&\quad-2\sqrt{2}cq_0a_2+12(H-c)q_0q_0'q_2+O(\epsilon)\\
&=-\frac{4}{\epsilon}(H^2-K+2cH-c^2)q_0''+\frac{1}{\epsilon}(a_2''-(3q_0^2-1)a_2)-2\Delta Hq_0'\\
&\quad+(a_3''-(3q_0^2-1)a_3)-4Ha_2'-2\sqrt{2}c(q_0q_2)''+2\sqrt{2}cq_0q_2(3q_0^2-1)\\
&\quad-2\sqrt{2}cq_0(q_2''-(3q_0^2-1)q_2)-12cq_0q_0'q_2+O(\epsilon)\\
&=-Q+(a_3''-(3q_0^2-1)a_3)+O(\epsilon).
\end{aligned}
$$

Now we derive Q. Because $a_2''-(3q_0^2-1)a_2=4(H^2-K+2cH-c^2)|_\Gamma q_0''$, we have

$$
\begin{aligned}
&-\frac{4}{\epsilon}(H^2-K+2cH-c^2)q_0''+\frac{1}{\epsilon}(a_2''-(3q_0^2-1)a_2)\\
&\quad=-\frac{4}{\epsilon}(\nabla(H^2-K+2cH-c^2)\cdot\nabla d)dq_0''+O(\epsilon)\\
&\quad=[-16H(H^2-K)-8c(2H^2-K)](q_0''t)+O(\epsilon).
\end{aligned}
$$

Also, $\Delta H=\Delta_\Gamma H+4H(H^2-K)$ and

$$
\begin{aligned}
-4Ha_2'&=-16H(H^2-K+2cH-c^2)s_2'\\
&=-8H(H^2-K+2cH-c^2)(q_0''t+q_0').
\end{aligned}
$$

Altogether,

$$\begin{aligned}
Q &= [16H(H^2-K)+8c(2H^2-K)](q_0''t)+2\Delta_\Gamma H q_0'+8H(H^2-K)q_0'\\
&\quad +8H(H^2-K+2cH-c^2)(q_0''t+q_0')\\
&\quad -4\sqrt{2}c[q_0''q_2-q_0'q_2'-q_0q_2''+q_0q_2(3q_0^2-1)]\\
&= 8H(H^2-K)(3q_0''t+2q_0')+2\Delta_\Gamma H q_0'+8c(2H^2-K)(q_0''t)\\
&\quad +8Hc(2H-c)(q_0''t+q_0')-4\sqrt{2}c[q_0''q_2-q_0'q_2'-q_0q_2''+q_0q_2(3q_0^2-1)].
\end{aligned}$$

When φ minimizes $W_c(\varphi)$, $g_c(\varphi)=0$. It follows that

$$a_3''-(3q_0^2-1)a_3=Q.$$

Therefore

$$\int_{-\infty}^{\infty} Qq_0'\,dt=0,$$

since

$$\int_{-\infty}^{\infty} q_0''tq_0'\,dt=-\frac{1}{2}\int_{-\infty}^{\infty}(q_0')^2\,dt$$

and

$$\begin{aligned}
&\int_{-\infty}^{\infty}[q_0''q_2-q_0'q_2'-q_0q_2''+q_0q_2(3q_0^2-1)]q_0'\,dx\\
&\quad=\int_{-\infty}^{\infty}[q_0''q_0'+2q_0'q_0''-(q_0q_0')''+q_0q_0'(3q_0^2-1)]q_2\,dx\\
&\quad=\int_{-\infty}^{\infty}[q_0q_0'''+q_0q_0'(3q_0^2-1)]q_2\,dx=0.
\end{aligned}$$

Finally we have

$$\begin{aligned}
\int_{-\infty}^{\infty} Qq_0'\,dt &= [4H(H^2-K)+2\Delta_\Gamma H-4c(2H^2-K)+4Hc(2H-c)]\int_{-\infty}^{\infty}(q_0')^2\,dt\\
&= [\Delta_\Gamma H+2H(H^2-K)+2Kc-2Hc^2]\int_{-\infty}^{\infty}2(q_0')^2\,dt=0.
\end{aligned}$$

It follows that

$$\Delta_\Gamma H+2H(H^2-K)+2Kc-2Hc^2=0,$$

which is the equilibrium equation for Γ.

On the other hand, if we have optimal q_0, q_1, and q_2, regardless of q_3 we have a nonequilibrium Γ, since $g_c(\varphi)=-Q+(a_3''-(3q_0^2-1)a_3)+O(\epsilon)$. The elastic force satisfies

$$\begin{aligned}
\int_\Omega -\xi_\epsilon \cdot v\,dx &= \int_\Omega -g_c(\varphi)\nabla\varphi\cdot v\,dx \\
&= \int_\Omega (Q-(a_3''-(3q_0^2-1)a_3)+O(\epsilon))\left(\frac{1}{\epsilon}q_0'\nabla d+O(1)\right)\cdot v\,dx \\
&= \int_\Omega \frac{1}{\epsilon}Qq_0'\nabla d\cdot v\,dx - \int_\Omega \frac{1}{\epsilon}(a_3''-(3q_0^2-1)a_3)q_0'\nabla d\cdot v\,dx + O(\epsilon) \\
&= \int_{-\infty}^{\infty} 2(q_0')^2\,dt \int_\Gamma [\Delta_\Gamma H + 2H(H^2-K)+2Kc-2Hc^2]\vec{n}\cdot v\,dx \\
&\quad - \int_{-\infty}^{\infty} 2(q_0'''-(3q_0^2-1)q_0')a_3\,dt\int_\Gamma \vec{n}\cdot v\,dx + O(\epsilon) \\
&= \frac{4\sqrt{2}}{3}\int_\Gamma [\Delta_\Gamma H + 2H(H^2-K)+2Kc-2Hc^2]\vec{n}\cdot v\,dx + O(\epsilon)
\end{aligned}$$

for any continuous vector field v. ∎

Remark 4.3. Theorem 4.2 also proved that the phase field model is consistent with the sharp interface case, in which the elastic bending energy is defined by

$$W_c(\Gamma) = \int_\Gamma (H-c)^2\,dS = \int_\Gamma H^2\,dS - 2c\int_\Gamma H\,dS + c^2|\Gamma|.$$

One can refer to [26] for the variations for the three items:

$$\begin{aligned}
\int_\Gamma H^2\,dS &\quad\rightarrow\quad \Delta_\Gamma H + 2H(H^2-K), \\
\int_\Gamma H\,dS &\quad\rightarrow\quad -K, \\
|\Gamma| = \int_\Gamma dS &\quad\rightarrow\quad -2H.
\end{aligned}$$

Actually, this theorem gives us the confidence to state that if we use a phase field function φ with a special kind of profile q to formulate a kind of energy $W(\varphi)$, with φ preserving the profile in the process minimizing $W(\varphi)$, the results of our phase field model should be consistent with those of the sharp interface model.

5. Error estimates. From the discussion of section 3 we know that if Γ is an equilibrium shape, we can expand the phase field function φ up to the third order term due to Theorems 2.10, 2.12, 2.13, and 2.17; if Γ is not an equilibrium shape, in the process of gradient flow to minimize phase field energy $W(\varphi)$, we can still expand φ to the second order term. In this section, we use the approximation of φ in the second order term to do some error estimates. The error estimate of the elastic bending energy further verifies the consistency of the phase field model with the sharp interface model. Besides the elastic bending energy formula, we can also estimate the error of some Euler number formulae derived from the tanh profile, and these error estimates can give us some new identities.

LEMMA 5.1.

$$W(q_0(d(x)/\epsilon)) = \frac{4\sqrt{2}}{3}\int_\Gamma H^2\,dS + 2C_1\epsilon^2\int_\Gamma (4H^4 - 5H^2K + K^2)\,ds + O(\epsilon^3),$$

where $C_1 = \int_{-\infty}^{\infty}(q_0')^2t^2\,dt \approx 0.608050.$

Proof. From (2.23), we have

$$W(q_0) = \frac{\epsilon}{2}\int_\Omega f(q_0)^2\,dx = \frac{1}{2\epsilon}\int_\Omega 4H^2(q_0')^2\,dx.$$

From Lemma 2.9, we have

$$\begin{aligned} W(q_0) = {} & 2\int_\Gamma H^2\,dS\int_{-\infty}^{\infty}(q_0')^2\,dt + 2\epsilon\int_\Gamma -2H^3 + 2H(2H^2-K)\,dS\int_{-\infty}^{\infty}(q')^2t\,dt \\ & + 2\epsilon^2\int_\Gamma H^2K - 2H(2H(2H^2-K)) \\ & + (12H^4 - 10H^2K + K^2)\,dS\int_{-\infty}^{\infty}(q_0')^2t^2\,dt + O(\epsilon^3) \\ = {} & \frac{4\sqrt{2}}{3}\int_\Gamma H^2\,dS + 2\epsilon^2\int_\Gamma (4H^4 - 5H^2K + K^2)\,ds\int_{-\infty}^{\infty}(q_0')^2t^2\,dt + O(\epsilon^3). \qquad \square \end{aligned}$$

THEOREM 5.2 (error estimate of energy). *If* φ *minimizes* $W(\varphi)$, *then*

$$W(\varphi) - \frac{4\sqrt{2}}{3}\int_\Gamma H^2\,dS = 6C_1\epsilon^2\int_\Gamma H^2(H^2-K)\,dS + O(\epsilon^3), \tag{5.1}$$

where $C_1 = \int_{-\infty}^{\infty}(q_0')^2t^2\,dt \approx 0.608050.$

Proof. From Theorem 2.13, equation (2.27), we have

$$\begin{aligned} W(\varphi) - W(q_0(d/\epsilon)) = 16\epsilon^2\left(\int_\Gamma (H^2-K)^2\,dS\right)\int_{-\infty}^{\infty} & -q_0''p_2 \\ & + \frac{1}{2}(p_2'' - (3q_0^2-1)p_2)^2 + O(\epsilon)\,dt. \end{aligned}$$

Because $p_2'' - (3q_0^2-1)p_2 = s_2 = q_0't/2$ and $s_2'' - (3q_0^2-1)s_2 = q_0''$, we have that

$$\begin{aligned} & \int_{-\infty}^{\infty} -q_0''p_2 + \frac{1}{2}(p_2'' - (3q_0^2-1)p_2)^2 + O(\epsilon)\,dt \\ & = \int_{-\infty}^{\infty} -(s_2'' - (3q_0^2-1)s_2)p_2 + \frac{1}{2}s_2^2 + O(\epsilon)\,dt \\ & = \int_{-\infty}^{\infty} -(p_2'' - (3q_0^2-1)p_2)s_2 + \frac{1}{2}s_2^2 + O(\epsilon)\,dt \\ & = \int_{-\infty}^{\infty} -\frac{1}{2}s_2^2 + O(\epsilon)\,dt = -\frac{1}{8}C_1 + O(\epsilon), \end{aligned}$$

where $C_1 = \int_{-\infty}^{\infty} (q_0')^2 t^2 \, dt$. Then

$$W(\varphi) - W(q_0) = -2C_1\epsilon^2 \int_\Gamma (H^2 - K)^2 \, dS + O(\epsilon^3).$$

From Lemma 5.1, we have that

$$W(\varphi) - \frac{4\sqrt{2}}{3} \int_\Gamma H^2 \, dS = 6C_1\epsilon^2 \int_\Gamma H^2(H^2 - K) \, dS + O(\epsilon^3). \tag{5.2}$$ ∎

Now, denote

$$\chi(\varphi) = -\frac{3\sqrt{2}\epsilon}{16\pi} \int_\Omega \left(\Delta\varphi - \frac{1}{\epsilon^2}\varphi(\varphi^2 - 1)\right) \frac{1}{\epsilon^2}(\varphi^2 - 1)\varphi \, dx. \tag{5.3}$$

The following lemma states that $\chi(q_0)$ is an approximation of the Euler number of Γ.

LEMMA 5.3.

$$\chi(q_0) = \chi(\Gamma) + O(\epsilon).$$

Proof. Lemma 2.3 gives $K = 2H^2 - \nabla H \nabla d$, with Lemma 2.9, and the Euler number

$$\begin{aligned}
\chi(\Gamma) &= \frac{1}{4\pi} \int_\Gamma K \, dS = \frac{3}{16\sqrt{2}\epsilon\pi} \int_\Omega K(q_0^2 - 1)^2 \, dx + O(\epsilon) \\
&= \frac{3}{16\sqrt{2}\epsilon\pi} \int_\Omega 2H^2(q_0^2 - 1)^2 - \nabla H \nabla d (q_0^2 - 1)^2 \, dx + O(\epsilon) \\
&= \frac{3}{16\sqrt{2}\epsilon\pi} \int_\Omega 2H^2(q_0^2 - 1)^2 + H\Delta d(q_0^2 - 1)^2 + 4H(q_0^2 - 1)q_0 \nabla d \nabla q_0 \, dx + O(\epsilon) \\
&= \frac{3}{4\sqrt{2}\epsilon\pi} \int_\Omega H(q_0^2 - 1)q_0 \nabla d \nabla q_0 \, dx + O(\epsilon) \\
&= -\frac{3}{8\epsilon^2\pi} \int_\Omega H(q_0^2 - 1)^2 q_0 \, dx + O(\epsilon) \\
&= -\frac{3\sqrt{2}\epsilon}{16\pi} \int_\Omega \left(\Delta q_0 - \frac{1}{\epsilon^2} q_0(q_0^2 - 1)\right) \frac{1}{\epsilon^2}(q_0^2 - 1)q_0 \, dx + O(\epsilon).
\end{aligned}$$ ∎

We have the following error estimate. One can refer to [13] for the first proof of Lemma 5.3 and more discussions of formula (5.3).

THEOREM 5.4 (error estimate of the Euler number). *If φ minimizes $W(\varphi)$, we have*

$$\chi(\varphi) = \frac{3}{16\pi\sqrt{2}} W(\varphi) + O(\epsilon).$$

Proof.

$$\begin{aligned}
\chi(\varphi)-\chi(q_0) &= -\frac{3\sqrt{2}\epsilon}{16\pi}\int_\Omega (f(\varphi)-f(q_0))\frac{1}{\epsilon^2}(\varphi^2-1)\varphi \\
&\quad + f(q_0)\frac{1}{\epsilon^2}((\varphi^2-1)\varphi-(q_0^2-1)q_0)\,dx \\
&= -\frac{3\sqrt{2}\epsilon}{16\pi}\int_\Omega (\epsilon^2\Delta e_2-(3q_0^2-1)e_2+O(\epsilon^2))\frac{1}{\epsilon^2}(\varphi^2-1)\varphi \\
&\quad - \frac{2H}{\epsilon}q_0'((3q_0^2-1)e_2+O(\epsilon^2))\,dx \\
&= -\frac{3\sqrt{2}\epsilon}{16\pi}\int_\Omega (\epsilon^2\Delta e_2-(3q_0^2-1)e_2+O(\epsilon^2)) \\
&\quad \times\left(\frac{1}{\epsilon^2}(q_0^2-1)q_0+O(1)\right)+O\left(\frac{1}{\epsilon}\right)\,dx \\
&= -\frac{3\sqrt{2}\epsilon}{16\pi}\int_\Omega (\epsilon^2\Delta e_2-(3q_0^2-1)e_2)\frac{1}{\epsilon^2}(q_0^2-1)q_0+O\left(\frac{1}{\epsilon}\right)\,dx \\
&= -\frac{3\sqrt{2}\epsilon}{16\pi}\int_\Omega (-2H\epsilon e_2'+e_2''-(3q_0^2-1)e_2)\frac{1}{\epsilon^2}(q_0^2-1)q_0+O\left(\frac{1}{\epsilon}\right)\,dx \\
&= -\frac{3\sqrt{2}\epsilon}{16\pi}\int_\Omega (e_2''-(3q_0^2-1)e_2)\frac{1}{\epsilon^2}(q_0^2-1)q_0+O\left(\frac{1}{\epsilon}\right)\,dx.
\end{aligned}$$

From Theorem 2.13, we have

$$e_2''-(3q_0^2-1)e_2 = q_2''-(3q_0^2-1)q_2+O(\epsilon) = 2(H^2-K)q_0't+O(\epsilon).$$

Therefore

$$\begin{aligned}
\chi(\varphi)-\chi(q_0) &= -\frac{3\sqrt{2}\epsilon}{16\pi}\int_\Omega \frac{2}{\epsilon^2}(H^2-K)|_\Gamma q_0(q_0^2-1)q_0't+O\left(\frac{1}{\epsilon}\right)\,dx \\
&= -\frac{6\sqrt{2}}{16\pi}\left(\int_\Gamma H^2-K\,dS\right)\left(\int_{-\infty}^{\infty} q_0''q_0't\,dt\right)+O(\epsilon).
\end{aligned}$$

Because

$$\int_{-\infty}^{\infty} q_0''q_0't\,dt = -\frac{1}{2}\int_{-\infty}^{\infty}(q_0')^2\,dt = -\frac{\sqrt{2}}{3}\,,$$

we have

$$\chi(\varphi)-\chi(q_0) = \frac{1}{4\pi}\int_\Gamma H^2-K\,dS+O(\epsilon). \tag{5.4}$$

Since $\chi(q_0)=\frac{1}{4\pi}\int_\Gamma K\,dS+O(\epsilon)$, we get

$$\chi(\varphi) = \frac{1}{4\pi}\int_\Gamma H^2\,dS+O(\epsilon).$$

From Theorem 5.2, we have

$$W(\varphi) = \frac{4\sqrt{2}}{3} \int_\Gamma H^2 \, dS + O(\epsilon^2).$$

Then we have

$$\chi(\varphi) = \frac{3}{16\pi\sqrt{2}} W(\varphi) + O(\epsilon). \qquad \square$$

Remark 5.5. Theorem 5.4 states that unlike $\chi(q_0)$, we cannot use $\chi(\varphi)$ to calculate the Euler number of Γ. It is unfortunate that the Euler number $\chi(q_0)$ in (5.4) is canceled out. Otherwise we could get a modified Euler number formula.

For any $n \geq 1$, denote

$$\chi_n(\varphi) = -\frac{n\sqrt{2}\epsilon}{8\pi\beta} \int \left(\Delta\varphi - \frac{1}{\epsilon^2}\varphi(\varphi^2 - 1) \right) \frac{1}{\epsilon^2} (\varphi^2 - 1)^{n-1} \varphi \, dx, \tag{5.5}$$

where $\beta = \int_{-1}^{1} (1 - x^2)^{n-1} \, dx$. We can prove that $\chi_n(q_0)$ is also an approximation of the Euler number $\chi(\Gamma)$. Actually formula (5.3) is a special case of χ_n with $n = 2$. And similar to the proof of Theorem 5.4, we have

$$\chi_n(\varphi) = \frac{3}{16\pi\sqrt{2}} W(\varphi) + O(\epsilon)$$

for every $n \geq 1$.

6. Numerical experiments. In this section, numerical experiments are performed to verify the results of this paper. We do not verify the expansion of φ directly. Instead, we try to verify Theorem 5.4. Our experiments start from some initial shapes represented by φ^0. Following the gradient flow of $W(\varphi)$, finally we reach some equilibrium shapes of Willmore's problem. In this process, we verify the relation of $\chi(\varphi)$ to $W(\varphi)$ as stated by Theorem 5.4.

Our experiments here are performed in the three-dimensional axis-symmetrical case. We do not add any volume and surface area constraints so that we can focus on the Willmore flow of the surface. Here we use the Fourier spectral method in order to get high accuracy results. One may refer to [7, 8, 11] for some detailed descriptions of the numerical schemes of the gradient flow (3.6), and [5] gives the convergence analysis of those schemes.

The numerical simulations presented in this paper are concerned with the z-axial symmetrical cases. The computational domain is taken to be $[-\pi, \pi]^2$ of the $x - z$ plane, which is divided into a 128×128 mesh. Our first experiment starts from a torus with the initial phase field function selected to be q_0:

$$\begin{aligned} \varphi^0(x) &= q_0(d(x)/\epsilon) \\ &= \tanh\left(\left(0.25\pi - \sqrt{(x_1 - 0.5\pi\cos\theta)^2 + (x_2 - 0.5\pi\sin\theta)^2 + x_3^2} \right) / (\sqrt{2}\epsilon) \right), \end{aligned}$$

where $\theta = \cos^{-1}(x_1/\|x\|)$. The parameter $\epsilon = 3h = 0.1473$. A cross section of the initial shape is given in the left panel of Figure 6.1. It is not an equilibrium shape and it gradually changes to an equilibrium shape (right panel of Figure 6.1) along the gradient flow.

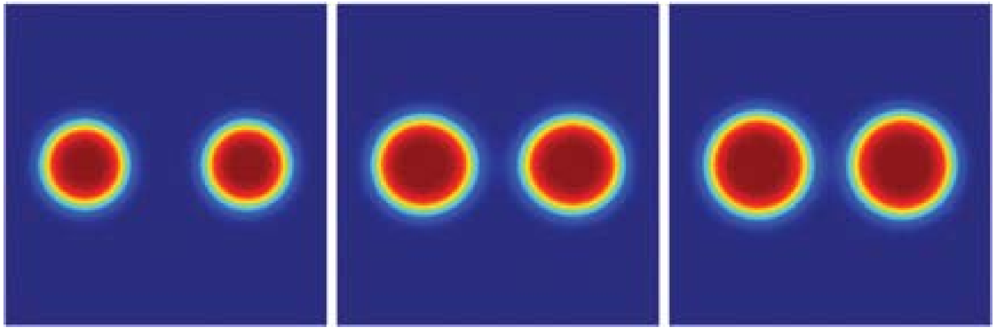

FIG. 6.1. *Cross-section views of the deformation of a torus into an equilibrium shape (time* $t = 0.00, 1.07, 4.45$*).*

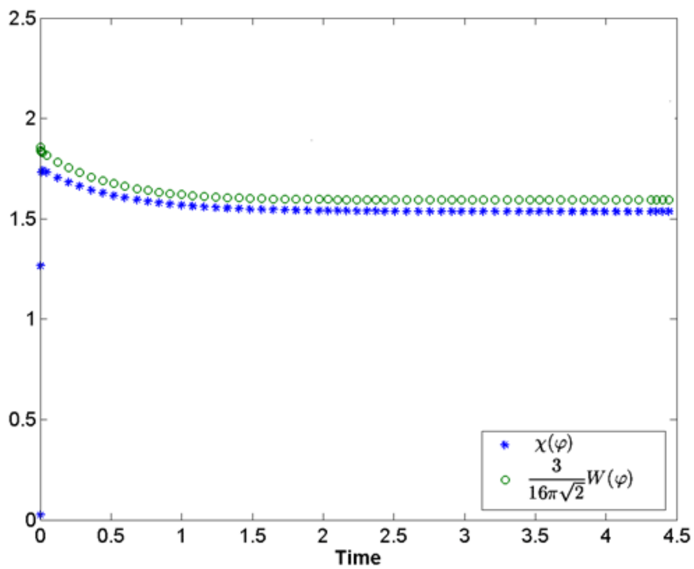

FIG. 6.2. *The plot of* $\chi(\varphi)$ *and* $3W(\varphi)/(16\pi\sqrt{2})$.

Figure 6.2 gives the plot of $\chi(\varphi)$ and $3W(\varphi)/(16\pi\sqrt{2})$. In the beginning, because $\varphi = q_0$, $\chi(\varphi) = 0.02$, which is close to the Euler number of a torus 0. Along the gradient flow, the value of $\chi(\varphi)$ approaches $3W(\varphi)/(16\pi\sqrt{2})$ very quickly. And during most of the gradient flow, they keep very close to each other. The difference is about 0.0576, which is relatively small compared to their value ($< 3.75\%$). And this difference decreases as we decrease the value of ϵ. This experiment is redone for $\epsilon = 2h$, and the difference changes to 0.0253, which is about 1.63% of their value.

Our second experiment is performed to simulate the merging of two spheres on a 128 grid mesh size with $\epsilon = 2h = 0.0982$. The cross-section views are given in Figure 6.3. Figure 6.4 gives the plot of $\chi(\varphi)$ and $3W(\varphi)/(16\pi\sqrt{2})$. Most of the time ($t > 1.0$), the value of φ coincides perfectly with the value of $3W(\varphi)/(16\pi\sqrt{2})$. There is a jump of φ before the merging of the two spheres. To analyze this jump, we show in Figure 6.5 the plot of the cross-section views around their merging time. From this graph, we can clearly see a singular point when their surfaces come to a

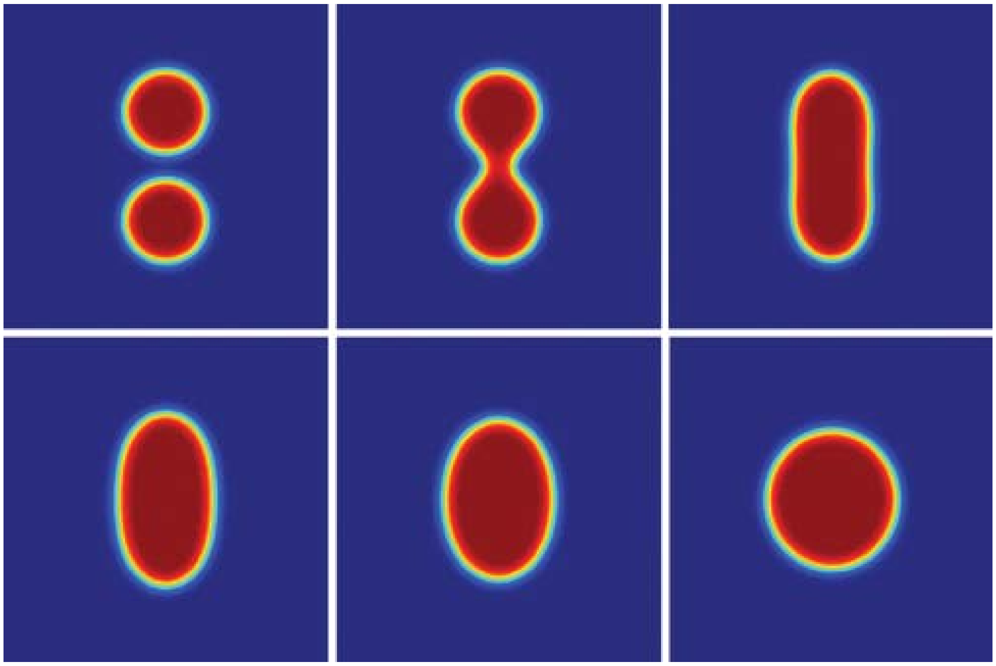

FIG. 6.3. *Cross-section views of the merging of two spheres (time* $t = 0.00, 1.08, 2.06, 3.04, 4.03,$ 7.89*).*

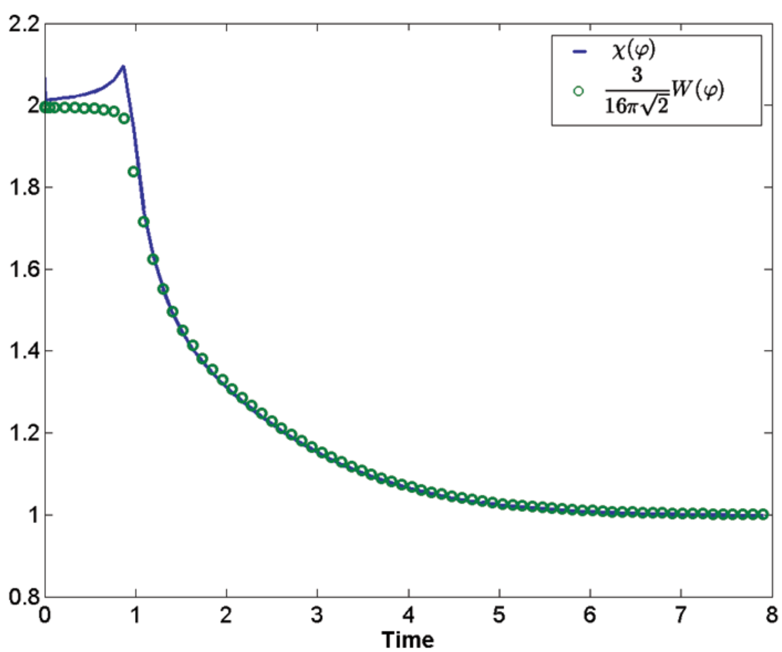

FIG. 6.4. *The plot of* $\chi(\varphi)$ *and* $3W(\varphi)/(16\pi\sqrt{2})$.

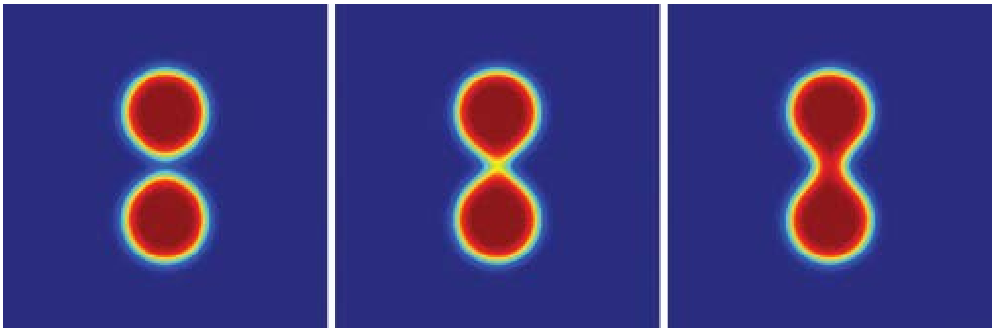

FIG. 6.5. *Cross-section views of the merging of two spheres (time* $t = 0.87, 0.97, 1.08$*).*

self-intersection. This singular point results in the nonsmoothness of the distance function and further results in the jump before their merging together. One may refer to [9] for more detailed analysis of the effect of singular points in retrieving the topological information within the phase field framework.

These experiments give numerical verification of Theorem 5.4 that $\varphi = 3W(\varphi)/(16\pi\sqrt{2}) + O(\epsilon)$, which is derived by the asymptotic analysis of section 2.3 under a general ansatz.

7. Conclusion. In this paper, we derived an explicit asymptotic expansion of the phase field functions minimizing the Willmore energy and elastic bending energy based on some relaxed assumptions. Those assumptions and approximations are verified by our numerical experiments. The asymptotic analysis results of the phase field functions are used to proved the consistency of the phase field model with the sharp interface model. They are further used to derive some error estimates of the energy and some formulae for the Euler number. The detailed analysis in this paper presents a clear structure of the phase field function and provides us a better understanding of why the phase phase models for Willmore's problem or the equilibrium lipid vesicle membrane problem have been so successful in modeling those problems.

Some future work can be pursued. First, we may study how some constraints, such as the volume/surface area constraints, change the profile of the phase field functions. Second, we can conduct some three-dimensional experiments to verify the expansion of the phase field functions. Finally, we can do more analysis on other formulae for the elastic bending energy and derive highly accurate formulae to detect the Euler number and other geometric and topological information of the surface within the phase field framework.

Acknowledgments. The author wishes to thank Prof. Qiang Du and Prof. Chun Liu for insightful discussions and collaborations on this subject.

SPHERICALLY SYMMETRIC ISENTROPIC COMPRESSIBLE FLOWS WITH DENSITY-DEPENDENT VISCOSITY COEFFICIENTS*

ZHENHUA GUO†, QUANSEN JIU‡, AND ZHOUPING XIN§

Abstract. We prove the existence of global weak solutions to the compressible Navier–Stokes equations with density-dependent viscosity coefficients when the initial data are large and spherically symmetric by constructing suitable aproximate solutions. We focus on the case where those coefficients vanish on vacuum. The solutions are obtained as limits of solutions in annular regions between two balls, and the equations hold in the sense of distribution in the entire space-time domain. In particular, we prove the existence of spherically symmetric solutions to the Saint–Venant model for shallow water.

Key words. compressible Navier–Stokes, density-dependent viscosity, weak solutions

1. Introduction.

The compressible Navier–Stokes equations with density-dependent viscosity coefficients can be written as

$$\rho_t + \operatorname{div}(\rho \mathbf{U}) = 0, \tag{1.1}$$

$$(\rho \mathbf{U})_t + \operatorname{div}(\rho \mathbf{U} \otimes \mathbf{U}) - \operatorname{div}(h(\rho) D(\mathbf{U})) - \nabla(g(\rho)\operatorname{div}\mathbf{U}) + \nabla P(\rho) = 0, \tag{1.2}$$

where $t \in (0, +\infty)$ and $\mathbf{x} \in \mathbb{R}^N, N = 2, 3$, $\rho(\mathbf{x}, t), \mathbf{U}(\mathbf{x}, t)$, and $P(\rho) = \rho^\gamma (\gamma > 1)$ stand for the fluid density, velocity, and pressure, respectively,

$$D(\mathbf{U}) = \frac{\nabla \mathbf{U} +^t \nabla \mathbf{U}}{2}$$

is the strain tensor, and $h(\rho)$ and $g(\rho)$ are the Lamé viscosity coefficients satisfying

$$h(\rho) > 0, \quad h(\rho) + N g(\rho) \geq 0. \tag{1.3}$$

In the past several decades, significant progress on the system (1.1)–(1.2) with positive constant viscosity coefficients has been achieved by many authors. Concerning the global existence and the large-time behavior of solutions for sufficiently small data, the system (1.1)–(1.2) (as well as the full compressible Navier–Stokes equations) is well-understood in the sense that if the data are small perturbations of an uniform nonvacuum state, then there exists a (smooth or weak) solution which is time-asymptotically stable (see [21]). The situation, however, becomes more complex

when the data are large, and a number of important questions, for example, the existence of global solutions in the case of heat-conducting gases and the uniqueness of weak solutions, still remain open. The first general result on weak solutions was obtained by Lions in [19], in which he used the method of weak convergence to obtain global weak solutions provided that the specific heat ratio γ is appropriately large, for example, $\gamma \geq 3N/(N+2)$, $N = 2, 3$. There have been many generalizations of this result: see [5, 6, 14, 7, 10, 15, 23], and the references therein.

It is noted that, in dealing with large amplitude solutions, one has to face the possible appearance of a vacuum state in general. However, as observed in [9, 26, 20], the compressible Navier–Stokes equations with constant viscosity coefficients behave singularly in the presence of vacuum. By some physical considerations, Liu, Xin, and Yang in [20] introduced the modified compressible Navier–Stokes equations with density-dependent viscosity coefficients for isentropic fluids. As presented in [20], in deriving the compressible Navier–Stokes equations from the Boltzmann equations by the Chapman–Enskog expansions, the viscosity depends on the temperature and correspondingly depends on the density for isentropic cases. Meanwhile, in geophysical flows, many mathematical models correspond to (1.1)–(1.2) (see [1, 3, 19]). In particular, the viscous Saint–Venant system for shallow water is expressed exactly as (1.1)–(1.2) with $N = 2, h(\rho) = \rho, g(\rho) = 0$, and $\gamma = 2$. Shallow water equations are to describe vertically averaged flows in three-dimensional shallow domains in term of the mean velocity $\mathbf{U}$ and the variation of the depth ρ due to the free surface (see [19, 3]), which is widely used in geophysical flows. Global smooth solutions for data close to equilibrium were established in [24], and related topics have been extensively studied in [1, 3], and the references therein. Nevertheless, the global existence of weak solutions for large data to the shallow water equations or more generally to the multidimensional compressible Navier–Stokes equations (1.1)–(1.2) ($N = 2, 3$) is still open. This is mainly due to the facts, that for these models, new mathematical challenges are encountered. First, we cannot preclude spontaneous cavitation (vacuum appearing) for the solutions of (1.1) and (1.2) even if the initial data are far from the vacuum. Second, when dealing with vanishing viscosity coefficients on vacuum, the velocity cannot even be defined when the density vanishes, and hence we will have no uniform estimates for the velocity. Finally, the system (1.1)–(1.2) is highly degenerate at vacuum.

For one-dimensional compressible Navier–Stokes equations (1.1) and (1.2) with $h(\rho) = \rho^\alpha, g(\rho) = 0 (\alpha \in (0, 1))$, there is much literature on the well-posedness theory of the solutions (see [11, 13, 17, 20, 25, 27, 28], and the references therein). In particular, initial-boundary-value problems for one-dimensional (1.1)–(1.2) with $h(\rho) = \rho^\alpha (\alpha > 1/2)$ and $P = \rho^\gamma (\gamma \geq 1)$ were studied by Li, Li, and Xin recently in [18], and interesting phenomena of vacuum vanishing and blowup of solutions were found there. However, few results are available for multidimensional problems. The first multidimensional result is due to Bresch, Desjardins, and Lin [3], where they showed the L^1 stability of weak solutions for the Korteweg system (with the Korteweg stress tensor $k\rho\nabla\triangle\rho$), and their result was later improved in [1] to include the case of vanishing capillarity ($k = 0$) but with an additional quadratic friction term $r\rho|\mathbf{U}|\mathbf{U}$. An interesting new entropy estimate is established in [3] in an priori way, which provides some high regularity for the density. Recently, Mellet and Vasseur [22] proved the L^1 stability of weak solutions of the system of (1.1)–(1.2) based on the new entropy estimate, extending the corresponding L^1 stability results of [3, 1] to the case $r = k = 0$. Meanwhile, although L^1 stability is considered as one of the main steps to prove the existence of weak solutions, the global existence of weak solutions of the compressible Navier–Stokes equations with density-dependent viscosity (1.1)–(1.2) is still open in the multidimensional cases. The key issue now is how to construct approximate solutions satisfying the a priori estimates required in the L^1 stability analysis. It seems highly nontrivial to do so due to the degeneracy of the viscosities near vacuum and the additional entropy inequality to be held in the construction of approximate solutions. Very recently, Bresch and Desjardins constructed approximate solutions for the two-dimensional viscous shallow water systems with drag terms or a capillarity term and for the compressible Navier–Stokes equations with cold pressure (see [2]) and proved the global existence of weak solutions to these systems (see [2, 4]). However, this construction of the approximate solutions in [2] seems not applicable to building approximate solutions for the standard compressible Navier–Stokes equations with density-dependent viscosity coefficients.

In our paper, we will construct a class of approximate solutions and furthermore prove the global existence of weak solutions for spherically symmetric solutions of the compressible Navier–Stokes equations with the viscosity coefficients depending on the density. For simplicity of the presentation, in this paper we will give only the proof of the global existence of the three-dimensional spherically symmetric solutions of (1.1)–(1.2) with $h(\rho) = \rho, g(\rho) = 0$. Our result holds true for general $h(\rho) = \rho^\alpha, g(\rho) = (\alpha - 1)\rho^\alpha$ for some $\alpha > \frac{N-1}{N}(N = 2, 3)$. More general $h(\rho)$ and $g(\rho)$ satisfying $g(\rho) = \rho h'(\rho) - h(\rho)$ and other restrictions given in [22] can be handled in a similar way. It should be noted that the shallow water equations corresponding to the case of $N = 2, \alpha = 1, \gamma = 2$ in (1.1)–(1.2) are covered, and therefore we obtain the global spherically symmetric solutions of the shallow water equations.

It seems to be difficult to adapt the analysis in [6, 19] due to the degeneracy of the viscosities near vacuum which may appear. Thus we construct the approximate solutions by solving the approximate systems of (1.1)–(1.2) with $h^\varepsilon(\rho) = h(\rho) + \varepsilon\rho^\beta, g^\varepsilon(\rho) = g(\rho)+\varepsilon(\beta-1)\rho^\beta$ for some fixed $0 < \beta < 1$ ($\beta = 3/4$, for example) instead of $h(\rho), g(\rho)$ in (1.1)–(1.2). This is motivated by the approach of Jiang, Xin, and Zhang [13], in which the one-dimensional case is considered and $h(\rho)$ can be regarded as ρ^α, and $g(\rho) = (\alpha - 1)\rho^\alpha$ for $0 < \alpha < 1$. However, compared with the one-dimensional equations, there are some new difficulties encountered for radial symmetric three-dimensional Navier–Stokes systems. In particular, the three-dimensional spherically symmetric equations become singular at $r = 0$, and more new source terms appear in both Eulerian and Lagrangian radial symmetric equations (see (2.6)–(2.7) in section 2 and (3.11) in section 3), which lead to some difficulties in obtaining the lower bound of the density. Therefore we will use the radial symmetric system only on the annular domain $\Omega_\varepsilon = \Omega \setminus \bar{B}_\varepsilon(0)$, where Ω is a ball of radius R centered at the origin in $\mathbb{R}^3$ and $B_\varepsilon(0)$ is a ball with radius ε and center 0, to exclude the singularity at the origin when we construct approximate solutions, and rewrite the Lagrangian equation as a new form (see (3.21) in section 3) which makes it possible to obtain the lower bounds of the approximate solutions.

By the approach mentioned above, we can obtain a class of approximate solutions with the required a priori uniform estimates such as energy estimates and entropy estimates. However, it should be noted that such approximate solutions are defined and estimated on the annular domain $\Omega_\varepsilon = \Omega \setminus \bar{B}_\varepsilon(0)$, and the L^1-stability analysis as in [22] can provide the convergence of the terms in (1.1)–(1.2) for the approximate solutions away from $r = 0$. Thus, to take the limit of the approximate solutions to obtain weak solutions which are defined on the entire domain Ω, we need to define the approximate solutions on $B_\varepsilon(0)$. Note that the usual zero extensions as in [8, 10] are not suitable here, since such extension would yield that $\nabla\sqrt{\rho}$ belongs to $L^\infty(0,T;L^2_{loc}(\Omega\setminus\{0\}))$ only so that the nonlinear diffusion terms in the definition of weak solutions (see (2.15)) will not make sense. An appropriate extension is presented in this paper, one of whose advantages is that it preserves the uniform $L^\infty(0,T;H^1(\Omega))$ estimate of $\sqrt{\rho^\varepsilon}$ such that we can obtain the convergence of the pressure term $(\rho^\varepsilon)^\gamma$ and the diffusion terms which are difficult to be dealt with due to the density-dependent viscosity coefficients. Also, though it seems difficult to obtain some uniform estimates for $\mathbf{U}^j$ separately because of the possible appearance of the vacuum, an extra estimate for $\mathrm{esssup}_{0\le t\le T}\int_\Omega \rho^j|\mathbf{U}^j|^{2+\eta}dx$, with some small $\eta\in(0,1)$, guarantees the convergence of the nonlinear convection terms.

The subsequent contents of the paper are organized as follows. In section 2 we will present the main result of this paper. In section 3 we will show various a priori estimates of the solutions. In this section, the estimates depending on ε, especially the lower bound of the density, are building blocks for constructing the approximate solutions and entropy estimates. On the other hand, the estimates independent of ε are the starting point for the convergence of the approximate solutions. Based on these, in section 4, we will first construct approximate solutions and then take the limits to obtain the global existence of weak solutions of the original system.

2. Main result. Set $h(\rho)=\rho$ and $g(\rho)=0$ in (1.1)–(1.2). The isentropic compressible Navier–Stokes equations become

$$\rho_t+\mathrm{div}(\rho\mathbf{U})=0, \tag{2.1}$$

$$(\rho\mathbf{U})_t+\mathrm{div}(\rho\mathbf{U}\otimes\mathbf{U})-\mathrm{div}(\rho D(\mathbf{U}))+\nabla P(\rho)=0 \tag{2.2}$$

for $t\in(0,+\infty)$ and $\mathbf{x}\in\mathbb{R}^3$.

We are concerned with spherically symmetric solutions to (2.1)–(2.2) in a ball Ω of radius R centered at the origin in $\mathbb{R}^3$. To this end, we denote

$$|\mathbf{x}|=r,\quad \rho(\mathbf{x},t)=\rho(r,t),\quad \mathbf{U}(\mathbf{x},t)=u(r,t)\frac{\mathbf{x}}{r}. \tag{2.3}$$

The initial and boundary conditions of (2.1)–(2.2) are

$$(\rho,\rho\mathbf{U})|_{t=0}=(\rho_0,\mathbf{m}_0), \tag{2.4}$$

$$\mathbf{m}=\rho\mathbf{U}=0 \text{ on } \partial\Omega. \tag{2.5}$$

For simplicity, we will take $D(\mathbf{U})=\nabla\mathbf{U}$ in (2.2), though the full strain tensor could be considered in a similar way. This leads to the following system of equations for $r>0$:

$$\rho_t+(\rho u)_r+\frac{2\rho u}{r}=0, \tag{2.6}$$

$$(\rho u)_t+(\rho u^2+\rho^\gamma)_r+\frac{2\rho u^2}{r}-(\rho u_r)_r-\rho\left(\frac{2u}{r}\right)_r=0, \tag{2.7}$$

with the initial condition

$$(\rho,\rho u)|_{t=0}=(\rho_0,m_0) \tag{2.8}$$

and the boundary conditions

$$\rho u(0,t)=0,\quad \rho u(R,t)=0. \tag{2.9}$$

It is easy to get the following usual a priori energy estimate for smooth solutions to (2.6), (2.7), and (2.9):

$$\frac{d}{dt}\int_0^R \left(\frac{1}{2}\rho u^2 + \frac{1}{\gamma-1}\rho^\gamma\right) r^2 dr + \int_0^R \rho(u_r^2 r^2 + 2u^2) dr \le 0. \tag{2.10}$$

Morover, the system (2.1)–(2.2) admits an additional a priori estimate, as observed by Bresch, Desjardins, and Lin [3], which reads as follows.

LEMMA 2.1 (see [22]). *Assume that $h(\rho)$ and $g(\rho)$ are two C^2 functions such that*

$$g(\rho) = \rho h'(\rho) - h(\rho)$$

holds true. Then the following inequality holds for smooth solutions of (1.1)–(1.2) *with $\rho > 0$:*

$$\frac{d}{dt}\int_\Omega \left(\frac{1}{2}\rho|\mathbf{U} + \nabla\varphi(\rho)|^2 + \frac{1}{\gamma-1}\rho^\gamma\right) dx + \int_\Omega \nabla\varphi(\rho)\cdot\nabla\rho^\gamma dx \le 0, \tag{2.11}$$

with φ such that

$$\varphi'(\rho) = \frac{h'(\rho)}{\rho}.$$

In particular, for three-dimensional spherically symmetric equations (2.6)–(2.7), one has the following.

LEMMA 2.2. *If (ρ, u) is a smooth solution to* (2.6)–(2.9)*, with $\rho > 0$, then the following inequality holds:*

$$\frac{d}{dt}\int_0^R \left\{\frac{1}{2}\rho u^2 + \rho_r u + |(\sqrt{\rho})_r|^2\right\} r^2 dr + \int_0^R \frac{4}{\gamma}((\rho^{\gamma/2})_r r)^2 dr \le 0. \tag{2.12}$$

Now we give a definition of weak solutions to (2.1)–(2.5).

DEFINITION 2.1. *A pair $(\rho, \mathbf{U})$ is said to be a weak solution to* (2.1)–(2.2) *provided that*

(1) $\rho \ge 0$ *a.e., and*

$$\rho \in L^\infty(0,T; L^1(\Omega)\cap L^\gamma(\Omega)) \cap C([0,\infty); W^{1,\infty}(\Omega)^*),$$
$$\sqrt{\rho} \in L^\infty(0,T; H^1(\Omega)), \sqrt{\rho}\mathbf{U} \in L^\infty(0,T; L^2(\Omega)),$$

where $W^{1,\infty}(\Omega)^*$ is the dual space of $W^{1,\infty}(\Omega)$;

(2) *for any $t_2 \ge t_1 \ge 0$ and any $\zeta \in C^1(\bar\Omega \times [t_1, t_2])$, the mass equation* (2.1) *holds in the following sense:*

$$\int_\Omega \rho\zeta dx|_{t_1}^{t_2} = \int_{t_1}^{t_2}\int_\Omega (\rho\zeta_t + \rho\mathbf{U}\cdot\nabla\zeta) dxdt; \tag{2.13}$$

(3) *for any $\psi = (\psi^1, \psi^2, \psi^3) \in C^2(\bar\Omega \times [0,T])$ satisfying $\psi(\mathbf{x}, t) = 0$ on $\partial\Omega$ and $\psi(\mathbf{x}, T) = 0$, it holds that*

$$\begin{aligned}&\int_\Omega \mathbf{m_0}\cdot\psi(0,\cdot)dx + \int_0^T\int_\Omega [\sqrt{\rho}(\sqrt{\rho}\mathbf{U})\cdot\partial_t\psi + \sqrt{\rho}\mathbf{U}\otimes\sqrt{\rho}\mathbf{U} : \nabla\psi] dxdt\\ &+ \int_0^T\int_\Omega \rho^\gamma \mathrm{div}\psi dxdt + \langle\rho\nabla\mathbf{U}, \nabla\psi\rangle = 0,\end{aligned} \tag{2.14}$$

where the diffusion term makes sense when written as

$$\langle \rho\nabla\mathbf{U}, \nabla\psi\rangle = -\int_0^T\int_\Omega \sqrt{\rho}(\sqrt{\rho}\mathbf{U})\cdot\Delta\psi dxdt$$
$$-2\int_0^T\int_\Omega(\sqrt{\rho}\mathbf{U})\cdot(\nabla\sqrt{\rho}\cdot\nabla)\psi dxdt. \tag{2.15}$$

We remark that, in the definition of the weak solution, (2.15) implies $\rho\nabla U \in L^2(0,T;W^{-1,1}(\Omega))$, which follows from the fact that $\sqrt{\rho}\in L^\infty(0,T;H^1(\Omega))$, $\sqrt{\rho}\mathbf{U}\in L^\infty(0,T;L^2(\Omega))$. This will be shown in section 4.

In this paper, we will construct global three-dimensional spherically symmetric weak solutions to (2.1)–(2.2) with the initial-boundary conditions (2.4)–(2.5). The initial data are assumed to satisfy

$$\rho_0 \geq 0 \text{ a.e. in } \Omega; \quad \mathbf{m}_0 = 0 \text{ a.e. on } \{x\in\Omega|\rho_0(x)=0\}; \tag{2.16}$$

$$\rho_0\in W^{1,2}(\Omega); \quad \frac{\mathbf{m}_0^2}{\rho_0}\in L^1(\Omega); \quad \frac{\mathbf{m}_0^{2+\eta}}{\rho_0^{1+\eta}}\in L^1(\Omega), \tag{2.17}$$

where $\eta\in(0,1)$ is some small constant. It follows from (2.17) that

$$\rho_0\mathbf{U}_0^{2+\eta}\in L^1(\Omega); \quad \rho_0\mathbf{U}_0^2\in L^1(\Omega). \tag{2.18}$$

The main result of this paper can be stated as follows.

THEOREM 2.1. *For $N = 3$ and $1 < \gamma < 3$, if the initial data have the form*

$$\rho_0 = \rho_0(|\mathbf{x}|), \quad \mathbf{U}_0 = u_0(|\mathbf{x}|)\frac{\mathbf{x}}{r}$$

and satisfy (2.16)–(2.17)*, then the initial-boundary-value problem* (2.1)–(2.5) *has a global spherically symmetric weak solution*

$$\rho = \rho(|\mathbf{x}|,t), \quad \mathbf{U} = u(|\mathbf{x}|,t)\frac{\mathbf{x}}{r}$$

satisfying, for all $T > 0$,

$$\rho(\mathbf{x},t)\in C([0,T];L^{\frac{3}{2}}(\Omega)), \quad \sqrt{\rho}\mathbf{U}\in L^\infty(0,T;L^2(\Omega)), \tag{2.19}$$

$$\int_\Omega \rho(\mathbf{x},t)dx = \int_\Omega \rho_0(\mathbf{x})dx. \tag{2.20}$$

Moreover, it holds that

$$\sup_{t\in[0,T]}\int_\Omega\left(\frac{1}{2}\rho|\mathbf{U}|^2 + \frac{1}{\gamma-1}\rho^\gamma + |\nabla\sqrt{\rho}|^2 + \rho|U|^{2+\eta}\right)dx \leq C, \tag{2.21}$$

where C is a constant.

Remark 2.1. In fact, our analysis applies to slightly more general viscosity coefficients $h(\rho)$ and $g(\rho)$. For instance, our results hold true for the following situations:

(1) $h(\rho) = \rho^\alpha$ and $g(\rho) = (\alpha-1)\rho^\alpha$, with $\alpha > \frac{N-1}{N}$, where the restriction of α results from the Lamé viscosity coefficients relation (1.3) and the usual energy estimates.

(2) $h(\rho)$ and $g(\rho)$ satisfy the relation

$$g(\rho) = \rho h'(\rho) - h(\rho)$$

and some additional restrictions given in [22].

Remark 2.2. It can be checked easily that, for $N = 2$, the conclusions in Theorem 2.1 hold true for any $\gamma > 1$. Consequently, we obtain the existence of a global spherically symmetric solution to the Saint–Venant model for shallow water, which is a particular case of (2.1)–(2.2) with $N = 2, h(\rho) = \rho, g(\rho) = 0$, and $\gamma = 2$ (see [3, 19]).

Remark 2.3. It should be noted that the boundary condition (2.5) is appropriate from the physical point of view, since, if the vacuum appears on the boundary, the velocity itself is meaningless and the momentum can be controllable. On the other hand, if no vacuum appears on the boundary, the boundary condition (2.5) is equivalent to $\mathbf{U}(R, t) = 0$.

To make sense of the boundary condition (2.5) for weak solutions in Theorem 2.1, we note that $\mathbf{U} = u(r)\frac{\mathbf{x}}{r}$ and ρu satisfy

$$\int_0^R \rho\varphi r^2 dr|_{t_1}^{t_2} = \int_{t_1}^{t_2} \int_0^R (\rho\varphi_t + \rho u\varphi_r) r^2 dr dt \tag{2.22}$$

for functions $\varphi \in C^1([0, R] \times [t_1, t_2])$; see (4.25) in Proposition 4.5 in section 4. In fact, (2.22) holds for any φ which is Lipschitz continuous. In particular, set $\varphi(r, t) = \varphi_1(t)\varphi_2(r)$, where $\varphi_1(t)$ and $\varphi_2(r)$ are Lipschitz continuous functions satisfying $\varphi_1(t) \equiv 1$ in $[t_1, t_2]$ and

$$\varphi_2(r) = \begin{cases} 1, & r \in [0, R - \delta], \\ 1 - \frac{1}{\delta}(r - (R - \delta)), & r \in [R - \delta, R]. \end{cases}$$

Substituting $\varphi_1(t)$ and $\varphi_2(r)$ into (2.22) and using (2.20), one gets

$$\begin{aligned} \frac{1}{\delta}\left|\int_{t_1}^{t_2}\int_{R-\delta}^R \rho u r^2 dr dt\right| \leq \Bigg| &\int_{R-\delta}^R \rho(r, t_2)(\varphi_2(r) - 1) r^2 dr \\ &- \int_{R-\delta}^R \rho(r, t_1)(\varphi_2(r) - 1) r^2 dr \Bigg| \to 0 \end{aligned}$$

as $\delta \to 0$. This implies that $(\rho u)(R, t) = 0$ in the sense of trace.

3. Approximate solutions and their estimates. The key point of the proof of Theorem 2.1 is to construct smooth approximate solutions satisfying the a priori estimates required in the L^1-stability analysis. The crucial issue is to obtain lower and upper bounds of the density, as mentioned in the introduction. To this end, we study the following system as an approximate system of (2.1)–(2.2):

$$\rho_t + \operatorname{div}(\rho\mathbf{U}) = 0, \tag{3.1}$$

$$\begin{aligned} &(\rho\mathbf{U})_t + \operatorname{div}(\rho\mathbf{U} \otimes \mathbf{U}) - \operatorname{div}((\rho + \varepsilon\rho^{\frac{3}{4}})\nabla\mathbf{U}) + \nabla\left(\frac{\varepsilon}{4}\rho^{\frac{3}{4}}\operatorname{div}\mathbf{U}\right) \\ &\quad + \nabla P(\rho) = 0, \end{aligned} \tag{3.2}$$

where $\varepsilon > 0$ is a constant.

When $\rho(\mathbf{x},t)=\rho(r,t), \mathbf{U}(\mathbf{x},t)=u(r,t)\frac{\mathbf{x}}{r}$, (3.1)–(3.2) becomes

$$\rho_t+(\rho u)_r+\frac{2\rho u}{r}=0, \tag{3.3}$$

$$(\rho u)_t+(\rho u^2+\rho^\gamma)_r+\frac{2\rho u^2}{r}+(\rho+\varepsilon\rho^{\frac{3}{4}})_r\frac{2u}{r}=\left(\left(\rho+\frac{3\varepsilon}{4}\rho^{\frac{3}{4}}\right)\left(u_r+\frac{2u}{r}\right)\right)_r \tag{3.4}$$

for $r>0$. We will first construct the smooth solution of (3.3)–(3.4) in the truncated region $0<\varepsilon<r<R$ with the initial condition

$$(\rho,\rho u)(r,0)=(\rho_0+\varepsilon,m_0),$$

and boundary conditions

$$u(r,t)|_{r=\varepsilon}=0,\quad u(r,t)|_{r=R}=0. \tag{3.5}$$

For approximate solutions with a positive lower bound for the density, (3.5) is equivalent to $\rho u(r,t)|_{r=\varepsilon}=0$ and $\rho u(r,t)|_{r=R}=0$.

We assume that the initial data are smooth and satisfy the bounds (2.16)–(2.17) with constants independent of ε. As discussed in the introduction, we shall eventually take a sequence of inner radii ε_j tending to 0. From now on, the dependence on j will be suppressed if there would be no confusion.

In the following, we will state the energy and entropy estimates which have been presented in the preceding section for these approximate solutions.

LEMMA 3.1. *Let $(\rho^\varepsilon,u^\varepsilon)$ be smooth solutions to* (3.3)–(3.4) *defined on* $[\varepsilon,R]\times[0,T]$ *with boundary conditions* (3.5) *such that* $\rho^\varepsilon>0$. *Then there exists a constant* C *independent of* ε *such that*

$$\int_\varepsilon^R \rho^\varepsilon(r,t)r^2dr\le C, \tag{3.6}$$

$$\begin{aligned}&\int_\varepsilon^R\left(\frac{1}{2}\rho^\varepsilon(u^\varepsilon)^2+\frac{1}{\gamma-1}(\rho^\varepsilon)^\gamma\right)r^2dr\\&+\int_0^T\int_\varepsilon^R\left(\rho^\varepsilon+\frac{\varepsilon}{4}(\rho^\varepsilon)^{\frac{3}{4}}\right)((u_r^\varepsilon)^2r^2+(u^\varepsilon)^2)drdt\le C,\end{aligned} \tag{3.7}$$

$$\begin{aligned}&\int_\varepsilon^R\frac{1}{2}\rho^\varepsilon\left|u^\varepsilon+(\log\rho^\varepsilon)_r+\frac{3\varepsilon}{4}(\rho^\varepsilon)^{-\frac{5}{4}}\rho_r^\varepsilon\right|^2r^2dr\\&+\int_0^T\int_\varepsilon^R\left(\gamma(\rho^\varepsilon)^{\gamma-2}+\frac{3\varepsilon}{4}\gamma(\rho^\varepsilon)^{\gamma-\frac{9}{4}}\right)|\rho_r^\varepsilon|^2r^2drdt\le C.\end{aligned} \tag{3.8}$$

Remark 3.1. Note that $h_\varepsilon(\rho)=\rho+\varepsilon\rho^{\frac{3}{4}}$ and $g_\varepsilon(\rho)=-\frac{\varepsilon}{4}\rho^{\frac{3}{4}}$ satisfy the relation $g_\varepsilon(\rho)=\rho h_\varepsilon'(\rho)-h_\varepsilon(\rho)$. In general, one can choose to approximate the system (2.1)–(2.2) by taking

$$h_\varepsilon(\rho)=\rho+\varepsilon\rho^\alpha,\quad g_\varepsilon(h)=\varepsilon(\alpha-1)\rho^\alpha,$$

which satisfy

$$g_\varepsilon(\rho)=\rho h_\varepsilon'(\rho)-h_\varepsilon(\rho),$$

where $\frac{N-1}{N}<\alpha<1, N=2,3$. We take $\alpha=\frac{3}{4}$ for the three-dimensional case here.

To guarantee the global existence of these approximate solutions, we need to give some detailed estimates on the density. We start with the following pointwise bounds for ρ^ε.

LEMMA 3.2. *Given $\varepsilon > 0$, there is an absolute constant C independent of ε such that*

$$0 \le \rho^\varepsilon(r,t) \le \frac{C}{\varepsilon^2} \tag{3.9}$$

for $\varepsilon \le r \le R$ and $t \ge 0$.

Proof. To simplify the presentation, we drop the superscript ε. Let $r(t)$ denote a particle path, i.e.,

$$\frac{dr(t)}{dt} = u(r(t),t).$$

Then along the particle path, (3.3) can be solved to get

$$\rho(r(t),t)r^2 = \rho_0(r(0))r(0)^2 e^{-\int_0^t u_r(r(s),s)ds},$$

which implies that $\rho \ge 0$ provided that $\rho_0 \ge 0$.

It follows from (3.7) and (3.8) that

$$\int_\varepsilon^R \frac{\rho_r^2}{\rho} r^2 dr \le C \tag{3.10}$$

for some absolute constant C independent of ε.

Then the second inequality in (3.9) follows from (3.6) and (3.10). The proof of the lemma is finished. ∎

To derive the a priori estimates about the velocity of the approximate solutions, the crucial step is to obtain the lower bound of the density. To this end, we introduce Lagrangian coordinates for the radial system (3.3)–(3.4) as follows. Let $\varepsilon > 0$ be fixed, and define

$$x(r,t) = \int_\varepsilon^r \rho r^2 dr, \tau = t.$$

Set $\int_\varepsilon^1 \rho r^2 dr = 1$ for any fixed $\varepsilon > 0$ without loss of generality. Then

$$\frac{\partial x}{\partial r} = \rho r^2, \quad \frac{\partial x}{\partial t} = -\rho u r^2, \quad \frac{\partial \tau}{\partial r} = 0, \quad \frac{\partial \tau}{\partial t} = 1.$$

Then the system (3.3)–(3.4) becomes

$$\begin{cases} \rho_\tau + \rho^2(r^2u)_x = 0, \\ r^{-2}u_\tau + (\rho^\gamma)_x = [(\rho^2 + \frac{3\varepsilon}{4}\rho^{\frac{7}{4}})(r^2u)_x]_x - (\rho + \varepsilon\rho^{\frac{3}{4}})_x \frac{2u}{r} \end{cases} \tag{3.11}$$

for $\tau > 0$ and $0 \le x \le 1$.

The corresponding initial data are

$$(\rho, \rho u)(\cdot, 0) = (\rho_0 + \varepsilon, m_0),$$

and the boundary conditions are

$$u(0,\tau) = 0, \quad u(1,\tau) = 0. \tag{3.12}$$

For this system, the following a priori estimates hold.

LEMMA 3.3. *For all $\tau \in [0,T]$, it holds that*

$$\int_0^1 \left(\frac{u^2(x,\tau)}{2} + \frac{\rho^{\gamma-1}(x,\tau)}{\gamma-1}\right) dx + \int_0^\tau \int_0^1 \left(\frac{2u^2}{r^2} + \rho^2 u_x^2 r^4\right) dxds$$
$$+ \left(1-\frac{\lambda}{2}\right) \int_0^\tau \int_0^1 \varepsilon \frac{u^2}{\rho^{\frac14} r^2} dxds + \left(\frac34 - \frac{1}{2\lambda}\right) \int_0^\tau \int_0^1 \varepsilon \rho^{\frac74} u_x^2 r^4 dxds$$
$$\leq \int_0^1 \left(\frac{u_0^2}{2} + \frac{\rho_0^{\gamma-1}}{\gamma-1}\right) dx, \tag{3.13}$$

where $\lambda \in (\frac23, 2)$, and

$$0 \leq \rho(x,\tau) \leq C(\varepsilon, T), \tag{3.14}$$

$$\varepsilon \leq r(x,\tau) \leq R, \tag{3.15}$$

$$\int_0^1 u^4 dx + \int_0^\tau \int_0^1 \left(\frac{4u^4}{r^2} + 6\rho^2 u^2 u_x^2 r^4 + \frac{2\varepsilon u^4}{\rho^{\frac14} r^2} + \varepsilon \rho^{\frac74} u^2 u_x^2 r^4\right) dxds$$
$$\leq \int_0^1 u_0^4 dx + C(\varepsilon, T). \tag{3.16}$$

Proof. By multiplying $(3.11)_2$ by $r^2 u$ and using $(3.11)_1$ and some standard manipulations, one gets

$$\frac{d}{d\tau} \int_0^1 \left(\frac{u^2}{2} + \frac{\rho^{\gamma-1}}{\gamma-1}\right) dx + \int_0^1 \left(\frac{2u^2}{r^2} + \rho^2 u_x^2 r^4\right) dx + \int_0^1 \left\{\varepsilon \frac{u^2}{\rho^{\frac14} r^2} + \frac34 \varepsilon \rho^{\frac74} u_x^2 r^4\right\} dx$$
$$= \varepsilon \int_0^1 \rho^{\frac34} u u_x r dx \leq \frac{\lambda}{2} \int_0^1 \frac{\varepsilon u^2}{\rho^{\frac14} r^2} dx + \frac{1}{2\lambda} \int_0^1 \varepsilon \rho^{\frac74} u_x^2 r^4 dx$$

for any $\lambda \in (\frac23, 2)$. Thus (3.13) holds.

Next, (3.14) follows from Lemma 3.2, and (3.15) holds trivially.

Now we prove (3.16). By multiplying $(3.11)_2$ by $r^2 u^3$ and using $(3.11)_1$ and integration by parts, we have by direct computation that

$$\frac14 \frac{d}{d\tau} \int_0^1 u^4 dx + \int_0^1 \left(\frac{2u^4}{r^2} + 3\rho^2 u^2 u_x^2 r^4\right) dx + \int_0^1 \left(\frac{\varepsilon u^4}{\rho^{\frac14} r^2} + \frac94 \varepsilon \rho^{\frac74} u^2 u_x^2 r^4\right) dx$$
$$= 2\int_0^1 \varepsilon \rho^{\frac34} u^3 u_x r dx + \int_0^1 \left(\rho^{\gamma-1} \frac{2u^3}{r} + 3\rho^\gamma u^2 u_x r^2\right) dx. \tag{3.17}$$

Using Hölder and Young's inequality and Lemma 3.2, one can bound each term of the right-hand side of (3.17) as follows:

$$2\varepsilon \int_0^1 \rho^{\frac34} u^3 u_x r dx \leq \frac12 \int_0^1 \frac{\varepsilon u^4}{\rho^{\frac14} r^2} dx + 2\int_0^1 \varepsilon \rho^{\frac74} u^2 u_x^2 r^4 dx;$$
$$2\int_0^1 \rho^{\gamma-1} \frac{u^3}{r} dx \leq 2\left(\int_0^1 \rho^{4(\gamma-1)} r^2 dx\right)^{\frac14} \left(\int_0^1 \frac{u^4}{r^2} dx\right)^{\frac34} \leq \frac12 \int_0^1 \frac{u^4}{r^2} dx + C;$$

and

$$
\begin{aligned}
3\int_0^1 \rho^\gamma u^2 u_x r^2 dx &\le \frac{3}{2}\int_0^1 \rho^2 u^2 u_x^2 r^4 dx + \frac{3}{2}\left(\int_0^1 \rho^{4\gamma-4} r^2 dx\right)^{\frac{1}{2}} \left(\int_0^1 \frac{u^4}{r^2} dx\right)^{\frac{1}{2}} \\
&\le \frac{3}{2}\int_0^1 \rho^2 u^2 u_x^2 r^4 dx + \frac{1}{2}\int_0^1 \frac{u^4}{r^2} dx + C.
\end{aligned}
$$

Putting the above three estimates into (3.17) yields

$$
\frac{1}{4}\frac{d}{d\tau}\int_0^1 u^4 dx + \int_0^1 \left(\frac{u^4}{r^2} + \frac{3}{2}\rho^2 u^2 u_x^2 r^4\right) dx + \int_0^1 \left(\frac{\varepsilon u^4}{2\rho^{\frac{1}{4}} r^2} + \frac{1}{4}\varepsilon \rho^{\frac{7}{4}} u^2 u_x^2 r^4\right) dx \le C,
$$

which implies (3.16) directly. ∎

The following estimate can be obtained by modifying the analysis in [13].

LEMMA 3.4. *There is a positive constant* $C = C(\varepsilon, T, \|u_0\|_{L^4}, \|(\rho_0^{\frac{3}{4}})_x\|_{L^4})$ *such that*

$$
\int_0^1 ((\rho^{\frac{3}{4}})_x)^4 (x,\tau) dx \le C \tag{3.18}
$$

for any $\tau \in [0,T]$.

Proof. $(3.11)_1$ can be rewritten as

$$
(\rho + \varepsilon \rho^{\frac{3}{4}})_{x\tau} = -\left[\left(\rho^2 + \frac{3\varepsilon}{4}\rho^{\frac{7}{4}}\right)(r^2 u)_x\right]_x . \tag{3.19}
$$

Thus, substituting (3.19) into $(3.11)_2$ yields

$$
r^2(\rho + \varepsilon \rho^{\frac{3}{4}})_{x\tau} + (\rho + \varepsilon\rho^{\frac{3}{4}})_x 2ur = -u_\tau - (\rho^\gamma)_x r^2. \tag{3.20}
$$

Direct computation shows that

$$
\frac{\partial r}{\partial \tau} = u.
$$

Consequently, (3.20) becomes

$$
(r^2(\rho + \varepsilon\rho^{\frac{3}{4}})_x)_\tau = -u_\tau - (\rho^\gamma)_x r^2. \tag{3.21}
$$

Integrating over $[0,t]$ shows that

$$
\begin{aligned}
&u(x,t) - u_0(x) + \int_0^t (\rho^\gamma)_x r^2(x,s) ds \\
&= r_0^2 \left(\frac{4}{3}\rho_0^{\frac{1}{4}} + \varepsilon\right)\partial_x\left(\rho_0^{\frac{3}{4}}\right) - r^2\left(\frac{4}{3}\rho^{\frac{1}{4}} + \varepsilon\right)\partial_x\left(\rho^{\frac{3}{4}}\right).
\end{aligned} \tag{3.22}
$$

By multiplying (3.22) by $(\partial_x(\rho^{\frac{3}{4}})r^2)^3$ and integrating over $[0,1]$ with respect to x, one gets

$$
\begin{aligned}
\int_0^1 \left(\frac{4}{3}\rho^{\frac{1}{4}} + \varepsilon\right)\left(\partial_x(\rho^{\frac{3}{4}})r^2\right)^4 dx \le C\left(\int_0^1 \left(\partial_x\left(\rho^{\frac{3}{4}}\right)r^2\right)^4 dx\right)^{\frac{3}{4}} \Bigg\{ &\|u-u_0\|_{L^4} \\
+ \left\|\partial_x\left(\rho_0^{\frac{3}{4}}\right)\right\|_{L^4} + \left(\int_0^t \|\partial_x \rho^\gamma\|_{L^4}^4 ds\right)^{\frac{1}{4}} &\Bigg\}.
\end{aligned} \tag{3.23}
$$

Using Lemma 3.3, $\varepsilon \le r, r_0 \le R$, and Young's inequality, one gets from (3.23) that there is a positive constant C depending on $\varepsilon, T, \|u_0\|_{L^4}$, and $\|(\rho_0^{\frac{3}{4}})_x\|_{L^4}$ such that

$$\varepsilon \int_0^1 (\partial_x(\rho^{\frac{3}{4}})r^2)^4 dx \le \frac{\varepsilon}{2} \int_0^1 (\partial_x(\rho^{\frac{3}{4}})r^2)^4 dx + C\int_0^t \int_0^1 (\partial_x \rho^\gamma)^4 dxds + C, \tag{3.24}$$

whence

$$\int_0^1 (\partial_x(\rho^{\frac{3}{4}}))^4 dx \le C + C\int_0^t \max_{[0,1]}(\rho^{4\gamma-3}) \int_0^1 (\partial_x(\rho^{\frac{3}{4}}))^4 dxds. \tag{3.25}$$

By applying Gronwall's inequality to (3.25) and making use of Lemma 3.2, we obtain

$$\int_0^1 (\partial_x(\rho^{\frac{3}{4}}))^4 dx \le C. \tag{3.26}$$

This completes the proof. □

Now we can obtain a positive lower bound for the density.

LEMMA 3.5. *There is a positive constant* $C = C(\varepsilon, T, \|u_0\|_{L^4}, \|(\rho_0^{\frac{3}{4}})_x\|_{L^4})$ *such that*

$$\rho(x,\tau) \ge C \tag{3.27}$$

for all $x \in [0,1]$ *and* $\tau \in [0,T]$.

Proof. Set $v(x,\tau) = \frac{1}{\rho(x,\tau)}$, and $V(\tau) = \max_{[0,1]\times[0,\tau]} v(x,s)$. Then $(3.11)_1$ becomes $v_\tau = (ru)_x$, which implies that $\int_0^1 v(x,\tau)dx = \int_0^1 v(x,0)dx \le C_0$, due to (3.12). Then it follows from Sobolev's embedding $W^{1,1}([0,1]) \hookrightarrow L^\infty([0,1])$ that, for any $0 < \beta < 1$,

$$\begin{aligned} v^\beta(x,\tau) &\le \int_0^1 v^\beta(x,\tau)dx + \int_0^x |\partial_x v^\beta| dx \\ &\le \left(\int_0^1 v dx\right)^\beta + \beta\int_0^x v^{\beta+\frac{3}{4}} \left|\frac{\rho_x}{\rho^{\frac{1}{4}}}\right| dx \\ &\le C + C\beta V^\beta \left(\int_0^1 v dx\right)^{\frac{3}{4}} \left(\int_0^1 ((\rho^{\frac{3}{4}})_x)^4 dx\right)^{\frac{1}{4}} \le C + C\beta V^\beta. \end{aligned} \tag{3.28}$$

Thus by choosing $\beta > 0$ small enough, which may depend on ε and T, we obtain

$$V(T) \le C,$$

where C is a positive constant depending on $\varepsilon, T, \|u_0\|_{L^4}$, and $\|(\rho_0^{\frac{3}{4}})_x\|_{L^4}$. The proof of the lemma is completed. □

Remark 3.2. When we construct approximate solutions in section 4.1, the initial data ρ_0, u_0 will be replaced by the mollified ones $\rho_0^{\varepsilon,\delta}, u_0^{\varepsilon,\delta}$ (see section 4.1 for more details), and hence the positive constant in Lemmas 3.4 and 3.5 will be replaced by a positive constant which depends on $\varepsilon, T, \|u_0^{\varepsilon,\delta}\|_{L^4}$, and $\|[(\rho_0^{\varepsilon,\delta})^{\frac{3}{4}}]_x\|_{L^4}$.

4. Proof of Theorem 2.1. In this section, we will prove Theorem 2.1 by completing the constructions of approximate solutions, applying the a priori bounds of sections 2 and 3 to take appropriate limits.

4.1. The existence of the approximate solutions. Consider the following approximate system in Lagrangian coordinates:

$$\begin{cases} \rho_\tau + \rho^2 (r^2 u)_x = 0, \\ r^{-2} u_\tau + (\rho^\gamma)_x = [(\rho^2 + \frac{3\varepsilon}{4}\rho^{\frac{7}{4}})(r^2 u)_x]_x - (\rho + \varepsilon \rho^{\frac{3}{4}})_x \frac{2u}{r} \end{cases} \tag{4.1}$$

for $\tau > 0, 0 \le x \le 1$, with

$$(\rho, \rho u)(\cdot, 0) = (\rho_0 + \varepsilon, m_0)$$

and

$$u(0,\tau) = 0, \ u(1,\tau) = 0.$$

First we regularize the initial data as follows. Let J_δ be a standard mollifier (in r) of width δ. Let $(\rho_0 + \varepsilon, u_0)$ be the initial data in Eulerian coordinates, where $u_0 = \frac{m_0}{\rho_0 + \varepsilon}$.

(1) Extend $\rho_0 + \varepsilon$ continuously outside $[\varepsilon, R]$ by taking $\rho_0(\varepsilon) + \varepsilon$ on $[0, \varepsilon]$ and $\rho_0(R) + \varepsilon$ on $[R, \infty)$, mollify with J_δ, restrict it to $[\varepsilon, R]$, and then multiply by a constant to normalize the total mass to be

$$M_0 = \int_0^R (\rho_0 + \varepsilon) r^2 dr.$$

The resulting density function is denoted by $\rho_0^{\varepsilon,\delta}(r)$.

(2) Redefine u_0 to be zero on $[0, \varepsilon + 2\delta]$ and $[R - 2\delta, R]$, and then mollify it with J_δ to get the smooth approximate initial velocity denoted by $u_0^{\varepsilon,\delta}(r)$. Note that $u_0^{\varepsilon,\delta}(r)$ is identically zero on a neighborhood of $r = \varepsilon$ and $r = R$.

The resulting data $(\rho_0^{\varepsilon,\delta}, u_0^{\varepsilon,\delta})$ then satisfy the hypotheses (2.16)–(2.17) (uniformly bounded on ε and δ). For any fixed $\varepsilon > 0$, we denote the corresponding initial data in Lagrangian coordinates by $(\rho_0^\delta, u_0^\delta)$. Then $\rho_0^\delta \in C^{1+\beta}[0,1]$ and $u_0^\delta \in C^{2+\beta}[0,1]$ for any $0 < \beta < 1$. Moreover,

$$\rho_0^\delta \to \rho_0 + \varepsilon \text{ in } W^{1,2}([0,1]), \quad u_0^\delta \to u_0 \text{ in } L^2([0,1]) \tag{4.2}$$

as $\delta \to 0$ and

$$u_0^\delta(0,\tau) = u_0^\delta(1,\tau) = 0.$$

Now consider the initial-boundary-value problem (4.1) with the initial data $(\rho_0 + \varepsilon, u_0)$ replaced by $(\rho_0^\delta, u_0^\delta)$. Note, however, that ε is fixed and positive at this stage of the argument, so that there are no singularities in the equations, and the construction of these approximate solutions is essentially an one-dimensional problem. For this problem one can apply the standard argument (see [12, 16], for instance) to obtain the existence of a unique local solution (ρ^δ, u^δ), with $\rho^\delta, \rho^\delta_x, \rho^\delta_{\tau x}, u^\delta, u^\delta_x, u^\delta_\tau, u^\delta_{xx} \in C^{\beta,\beta/2}([0,1] \times [0,T^*])$ for some $T^* > 0$. It follows from Lemmas 3.2–3.5 and (4.2) that ρ^δ is bounded from below and above, $(u^\delta)^2$ and ρ^δ_x are bounded in $L^\infty([0,T]; L^2)$, and u^δ_x is bounded in $L^2([0,T]; L^2)$ for any $T > 0$ because of $\varepsilon < r < R$. Furthermore, one can differentiate the equations (4.1) and apply the energy method to derive bounds of high-order derivatives of (ρ^δ, u^δ). Then we can apply the Schauder theory for linear parabolic equations to conclude that the $C^{\beta,\beta/2}([0,1] \times [0,T])$-norms of ρ^δ, ρ^δ_x, $\rho^\delta_{\tau x}$, u^δ, u^δ_x, u^δ_τ and, u^δ_{xx} are bounded a priorily. Therefore, we can continue the local solution globally in time and obtain that there exists a unique global solution (ρ^δ, u^δ) of (4.1) with the initial data (ρ_0, u_0) replaced by $(\rho_0^\delta, u_0^\delta)$ such that, for any $T > 0$,

$$\rho^\delta, \rho_x^\delta, \rho_{\tau x}^\delta, u^\delta, u_x^\delta, u_\tau^\delta, u_{xx}^\delta \in C^{\beta,\beta/2}([0,1]\times[0,T])$$

for some $0<\beta<1$, and $\rho^\delta > 0$ on $[0,1]\times[0,T]$. This can be done in a similar way as in [14]. Thus the solution, which can be denoted as $(\rho^{\varepsilon,\delta}, u^{\varepsilon,\delta})$, satisfies (4.1). By transforming it into Euler coordinates again by

$$x = \int_\varepsilon^r \rho(r,\tau) r^2 dr, \tau = t,$$

we can obtain the solutions $(\rho^{\varepsilon,\delta}(r,t), u^{\varepsilon,\delta}(r,t))$ to the approximate system (3.3)–(3.4), and consequently Lemma 3.1 holds for these approximate solutions.

4.2. The passage to limit. So far, $(\rho^{\varepsilon,\delta}, u^{\varepsilon,\delta})$ are defined on $\varepsilon \le r \le R$. To take the limit $\{\varepsilon_j, \delta_j\} \to 0$, we extend $\rho^{\varepsilon_j,\delta_j}(r,t), u^{\varepsilon_j,\delta_j}(r,t)$ to the whole domain Ω in the following way:

$$\tilde\rho^{\varepsilon_j,\delta_j} = \begin{cases} \rho^{\varepsilon_j,\delta_j}(r,t),\ r\in[\varepsilon_j, R], \\ \rho^{\varepsilon_j,\delta_j}(\varepsilon_j,t),\ r\in[0,\varepsilon_j], \end{cases} \tag{4.3}$$

$$\tilde u^{\varepsilon_j,\delta_j} = \begin{cases} u^{\varepsilon_j,\delta_j}(r,t),\ r\in[\varepsilon_j, R], \\ 0,\ r\in[0,\varepsilon_j]. \end{cases} \tag{4.4}$$

For simplicity, we denote the obtained approximate solutions $\{\tilde\rho^{\varepsilon_j,\delta_j}, \tilde u^{\varepsilon_j,\delta_j}\}$ by $\{\rho^j, u^j\}$. Let $\rho^j(\mathbf{x},t) = \rho^j(r,t), \mathbf{U}^j(\mathbf{x},t) = u^j(r,t)\frac{\mathbf{x}}{r}$, and denote $\Omega_\varepsilon = \Omega\backslash B_\varepsilon(0)$ for $\epsilon > 0$ and $\Omega_{\frac1n} = \Omega\backslash B_{\frac1n}(0)$ for $n = 1,2,\ldots$.

The following then follows from Lemma 3.1.

Lemma 4.1. *There exists a constant C independent of ε and δ such that*

$$\sup_{t\in[0,T]} \int_{\Omega_{\varepsilon_j}} \rho^j(x,t)dx \le C, \tag{4.5}$$

$$\begin{aligned}&\sup_{t\in[0,T]} \int_{\Omega_{\varepsilon_j}} \left(\frac12 \rho^j|\mathbf{U}^j|^2 + \frac{1}{\gamma-1}(\rho^j)^\gamma\right)(x,t)dx + \int_0^T\int_{\Omega_{\varepsilon_j}} \rho^j|\nabla\mathbf{U}^j|^2(x,t)dxdt \\ &\quad + \frac14\int_0^T\int_{\Omega_{\varepsilon_j}} \varepsilon(\rho^j)^{\frac34}|\nabla\mathbf{U}^j|^2(x,t)dxdt \le C,\end{aligned} \tag{4.6}$$

$$\begin{aligned}&\sup_{t\in[0,T]} \int_{\Omega_{\varepsilon_j}} \frac12\rho^j\left|\mathbf{U}^j + \nabla\log\rho^j + \frac34\varepsilon(\rho^j)^{-\frac54}\nabla\rho^j\right|^2(x,t)dx \\ &\quad + \int_0^T\int_{\Omega_{\varepsilon_j}} \left(\frac4\gamma|\nabla(\rho^j)^{\frac\gamma2}|^2 + \frac{48\varepsilon\gamma}{(4\gamma-1)^2}|\nabla(\rho^j)^{\frac{4\gamma-1}{8}}|^2\right)(x,t)dxdt \le C.\end{aligned} \tag{4.7}$$

Moreover, the following uniform estimate holds:

$$\sup_{t\in[0,T]}\left(\|\sqrt{\rho^j}\|_{H^1(\Omega)} + \int_\Omega \rho^j|\mathbf{U}^j|^2\right) \le C. \tag{4.8}$$

Proof. (4.5)–(4.7) follow directly from Lemma 3.1. It suffices to prove (4.8).

First, it holds that

$$\sup_{t\in[0,T]} \|\nabla\sqrt{\rho^j}\|_{L^2(\Omega)} \le C, \tag{4.9}$$

where C is a constant independent of ε and δ. Indeed, in view of the extension (4.3), one has

$$\partial_i\sqrt{\rho^j}(x,t) = \begin{cases} \partial_i\sqrt{\rho^j}, & x\in\Omega_{\varepsilon_j}, t\in[0,T],\\ 0, & x\in\overline{B}_{\varepsilon_j}, t\in[0,T]\end{cases}$$

for $i=1,2,3$. Consequently, (4.9) follows from (4.6) and (4.7).

Next, we verify that

$$\sup_{t\in[0,T]} \|\sqrt{\rho^j}\|_{L^2(\Omega)} \le C, \tag{4.10}$$

where C is a constant independent of ε and δ.

Thanks to the upper bound estimates of the density (3.9) and (4.5), one has

$$\begin{aligned}&\sup_{t\in[0,T]}\int_0^R \rho^j r^2 dr \le \sup_{t\in[0,T]}\int_0^{\varepsilon_j} \rho^j r^2 dr + \sup_{t\in[0,T]}\int_{\varepsilon_j}^R \rho^j r^2 dr\\ &\le \frac{C}{\varepsilon_j^2}\int_0^{\varepsilon_j} r^2 dr + C \le \frac{C\varepsilon_j}{3} + C \le C\end{aligned}$$

for all $0<\varepsilon_j<R$, which yields (4.10). The first part of (4.8) follows from (4.9) and (4.10). The other part of (4.8) can be checked easily, and the proof of the lemma is finished. ∎

Remark 4.1. Compared with the usual zero extensions in [10, 12], the extensions (4.3) and (4.4) keep the $L^\infty(0,T;H^1(\Omega))$-norm of $\sqrt{\rho^j}$, which will be used later.

PROPOSITION 4.1. *There exists a subsequence of $\{\rho^j\}$, still denoted by itself, such that, as $j\to\infty$,*

$$\rho^j(\mathbf{x},t)\to\rho(\mathbf{x},t) \tag{4.11}$$

strongly in $C([0,T],L^{3/2}(\Omega))$. Moreover, $\rho(\mathbf{x},t)=\rho(r,t)$ is a spherically symmetric function.

Proof. It follows from (4.8) that $\sqrt{\rho^j}$ is bounded in $L^\infty(0,T;L^q(\Omega))$ for $q\in[2,6]$. Thus ρ^j is bounded in $L^\infty(0,T;L^3(\Omega))$, and $\rho^j\mathbf{U}^j=\sqrt{\rho^j}\sqrt{\rho^j}\mathbf{U}^j$ is bounded in $L^\infty(0,T;L^{3/2}(\Omega))$ due to (4.8). The continuity equation yields that $\partial_t\rho^j$ is bounded in $L^\infty(0,T;W^{-1,3/2}(\Omega))$. Moreover, since $\nabla\rho^j=2\sqrt{\rho^j}\nabla\sqrt{\rho^j}$, we have that $\nabla\rho^j$ is bounded in $L^\infty(0,T;L^{3/2}(\Omega))$. Hence (4.11) is obtained thanks to the Aubin–Lions lemma. Clearly, $\rho(\mathbf{x},t)=\rho(r,t)$ is spherically symmetric. ∎

PROPOSITION 4.2. *Suppose that $1<\gamma<3$. Then $(\rho^j)^\gamma$ converges to ρ^γ strongly in $L^1((0,T);L^1(\Omega))$.*

Proof. This follows directly from the fact that ρ^j is bounded in $L^\infty(0,T;L^3(\Omega))$ and (4.12). ∎

The following proposition will enable us to take the limit in the nonlinear convection term.

PROPOSITION 4.3. *If $1<\gamma<3$ and*

$$\int_0^R \rho_0|u_0|^{2+\eta} r^2 dr \le C, \tag{4.12}$$

then the following estimate is true:

$$\frac{d}{dt}\int_{\varepsilon_j}^R \rho^j \frac{|u^j|^{2+\eta}}{2+\eta} r^2 dr + \int_{\varepsilon_j}^R \left(\frac{3}{4}\rho^j + \frac{\varepsilon}{8}(\rho^j)^{\frac{3}{4}}\right)|u^j|^\eta (u_r^j)^2 r^2 dr$$
$$+\int_{\varepsilon_j}^R \left(\frac{7}{4}\rho^j + \frac{3\varepsilon}{8}(\rho^j)^{\frac{3}{4}}\right)|u^j|^{\eta+2} dr \le C$$

for some small $\eta \in (0,1)$. *In particular,*

$$\int_{\Omega_{\varepsilon_j}} \rho^j \frac{|\mathbf{U}^j|^{2+\eta}}{2+\eta} dx \le C, \tag{4.13}$$

where $\Omega_{\varepsilon_j} = \Omega \setminus B_{\varepsilon_j}(0)$ *and* C *is a constant independent of* ε *and* δ.

To prove Proposition 4.3, we need the following lemma.

LEMMA 4.2. *The pressure* $(\rho^j)^\gamma$ *is bounded in* $L^{\frac{5}{3}}((0,T); L^{\frac{5}{3}}(\Omega_{\varepsilon_j}))$.

Proof. It follows from Lemma 4.1 that $(\rho^j)^{\gamma/2} \in L^2(0,T;H^1(\Omega_{\varepsilon_j}))$, and hence $(\rho^j)^\gamma \in L^1(0,T;L^3(\Omega_{\varepsilon_j}))$. Since $(\rho^j)^\gamma$ is bounded in $L^\infty(0,T;L^1(\Omega_{\varepsilon_j}))$ by (4.6), the Hölder inequality gives

$$\|(\rho^j)^\gamma\|_{L^{5/3}((0,T)\times\Omega_{\varepsilon_j})} \le \|(\rho^j)^\gamma\|^{2/5}_{L^\infty(0,T;L^1(\Omega_{\varepsilon_j}))} \|(\rho^j)^\gamma\|^{3/5}_{L^1(0,T;L^3(\Omega_{\varepsilon_j}))} \le C,$$

where C is independent of ε and δ. This finishes the proof of the lemma. ∎

Now we can prove Proposition 4.3.

Proof of Proposition 4.3. Let $\eta \in (0, \frac{1}{2})$. Multiplying (3.4) by $r^2 u^j |u^j|^\eta$ and integrating the resulting equation yield

$$\int_{\varepsilon_j}^R \rho^j \partial_t \frac{|u^j|^{2+\eta}}{2+\eta} r^2 dr + \int_{\varepsilon_j}^R \rho^j u^j \left(\frac{|u^j|^{2+\eta}}{2+\eta}\right)_r r^2 dr$$
$$+(1+\eta)\int_{\varepsilon_j}^R \left(\rho^j + \frac{3\varepsilon_j}{4}(\rho^j)^{\frac{3}{4}}\right)|u^j|^\eta (u_r^j)^2 r^2 dr$$
$$+\int_{\varepsilon_j}^R (2\rho^j + \varepsilon_j(\rho^j)^{\frac{3}{4}})|u^j|^{\eta+2} dr + \int_{\varepsilon_j}^R |u^j|^\eta\, u^j\, |((\rho^j)^\gamma)_r|\, r^2 dr$$
$$\le \left(\varepsilon_j + \frac{\eta\varepsilon_j}{2}\right)\int_{\varepsilon_j}^R (\rho^j)^{\frac{3}{4}} |u^j|^{\eta+1}|u_r^j| r dr$$
$$\le \left(\frac{\varepsilon_j}{2} + \frac{\eta\varepsilon_j}{4}\right)\left[\int_{\varepsilon_j}^R (\rho^j)^{\frac{3}{4}}|u^j|^\eta (u_r^j)^2 r^2 dr + \int_{\varepsilon_j}^R (\rho^j)^{\frac{3}{4}}|u^j|^{\eta+2} dr\right].$$

It follows that

$$\int_{\varepsilon_j}^R \rho^j \partial_t \frac{|u^j|^{2+\eta}}{2+\eta} r^2 dr + \int_{\varepsilon_j}^R \rho^j u^j \left(\frac{|u^j|^{2+\eta}}{2+\eta}\right)_r r^2 dr$$
$$+\int_{\varepsilon_j}^R \left(\rho^j + \frac{\varepsilon_j}{8}(\rho^j)^{\frac{3}{4}}\right)|u^j|^\eta (u_r^j)^2 r^2 dr + \int_{\varepsilon_j}^R \left(2\rho^j + \frac{3\varepsilon_j}{8}(\rho^j)^{\frac{3}{4}}\right)|u^j|^{\eta+2} dr$$
$$+\int_{\varepsilon_j}^R |u^j|^\eta u^j ((\rho^j)^\gamma)_r r^2 dr \le 0. \tag{4.14}$$

Moreover, multiplying (3.3) by $\frac{r^2|u^j|^{\eta+2}}{2+\eta}$ and integrating by parts show that

$$\int_{\varepsilon_j}^R \frac{|u^j|^{2+\eta}}{2+\eta}\partial_t\rho^j r^2 dr - \int_{\varepsilon_j}^R \rho^j u^j \left(\frac{|u^j|^{2+\eta}}{2+\eta}\right)_r r^2 dr = 0. \tag{4.15}$$

Summing over (4.14) and (4.15) leads to

$$\begin{aligned} &\frac{d}{dt}\int_{\varepsilon_j}^R \rho^j \frac{|u^j|^{2+\eta}}{2+\eta} r^2 dr + \int_{\varepsilon_j}^R \left(\rho^j + \frac{\varepsilon_j}{8}(\rho^j)^{\frac{3}{4}}\right)|u^j|^\eta (u_r^j)^2 r^2 dr \\ &+ \int_{\varepsilon_j}^R \left(2\rho^j + \frac{3\varepsilon_j}{8}(\rho^j)^{\frac{3}{4}}\right)|u^j|^{\eta+2} dr \le \left|\int_{\varepsilon_j}^R |u^j|^\eta\, u^j\, |((\rho^j)^\gamma)_r|\, r^2 dr\right|. \end{aligned} \tag{4.16}$$

Noting that

$$\begin{aligned} &\left|\int_{\varepsilon_j}^R |u^j|^\eta\, u^j\, |((\rho^j)^\gamma)_r|\, r^2 dr\right| \\ &\le (1+\eta)\left|\int_{\varepsilon_j}^R |u^j|^\eta |u_r^j| (\rho^j)^\gamma r^2 dr\right| + 2\int_{\varepsilon_j}^R |u^j|^{\eta+1}(\rho^j)^\gamma r dr \\ &\le \frac{1}{4}\int_{\varepsilon_j}^R \rho^j |u^j|^\eta |u_r^j|^2 r^2 dr + C\int_{\varepsilon_j}^R (\rho^j)^{2\gamma-1}|u^j|^\eta r^2 dr + 2\int_{\varepsilon_j}^R |u^j|^{\eta+1}(\rho^j)^\gamma r dr \\ &\le \frac{1}{4}\int_{\varepsilon_j}^R \rho^j |u^j|^\eta |u_r^j|^2 r^2 dr + C\int_{\varepsilon_j}^R ((\rho^j)^{2\gamma-1-\frac{\eta}{2}})^{\frac{2}{2-\eta}} r^2 dr + C \\ &\quad + C(R)\int_{\varepsilon_j}^R (\rho^j)^{(\gamma-\frac{\eta+1}{\eta+2})(2+\eta)} r^2 dr + \frac{1}{4}\int_{\varepsilon_j}^R \rho^j |u^j|^{2+\eta} dr, \end{aligned}$$

we obtain from (4.16) that

$$\begin{aligned} &\frac{d}{dt}\int_{\varepsilon_j}^R \rho^j \frac{|u^j|^{2+\eta}}{2+\eta} r^2 dr + \int_{\varepsilon_j}^R \left(\frac{3}{4}\rho^j + \frac{\varepsilon_j}{8}(\rho^j)^{\frac{3}{4}}\right)|u^j|^\eta (u_r^j)^2 r^2 dr \\ &+ \int_{\varepsilon_j}^R \left(\frac{7}{4}\rho^j + \frac{3\varepsilon_j}{8}(\rho^j)^{\frac{3}{4}}\right)|u^j|^{\eta+2} dr \\ &\le C\int_{\varepsilon_j}^R (\rho^j)^{(2\gamma-1-\frac{\eta}{2})\frac{2}{2-\eta}} r^2 dr + C(R)\int_{\varepsilon_j}^R (\rho^j)^{(\gamma-\frac{\eta+1}{\eta+2})(2+\eta)}\, r^2 dr + C. \end{aligned} \tag{4.17}$$

Using Lemma 4.2, one can check easily that the right-hand side of (4.17) is bounded for small η under the condition

$$2\gamma - 1 < \frac{5}{3}\gamma,$$

which is satisfied if $1 < \gamma < 3$. The proof of the proposition is finished. □

It is noted that (4.12) is satisfied due to (2.17). Moreover, it follows from (4.4) and (4.13) that

$$\int_\Omega \rho^j \frac{|\mathbf{U}^j|^{2+\eta}}{2+\eta} dx \le C. \tag{4.18}$$

Consequently, since

$$\int_\Omega (\rho^j|\mathbf{U}^j|^2)^{1+\zeta}dx \le \left(\int_\Omega \rho^j|\mathbf{U}^j|^{2+\eta}dx\right)^{\frac{2+2\zeta}{2+\eta}} \left(\int_\Omega (\rho^j)^{1+\frac{(2+\eta)\zeta}{\eta-2\zeta}}dx\right)^{\frac{\eta-2\zeta}{2+\eta}},$$

and as ζ is small enough, we deduce the following.

COROLLARY 4.1. *If $1<\gamma<3$, then $\sqrt{\rho^j}\mathbf{U}^j$ is bounded in $L^\infty(0,T;L^{2+2\zeta}(\Omega))$ for some small $\zeta>0$.*

Thanks to Propositions 4.1 and 4.3, Corollary 4.1, and Lemmas 4.4 and 4.6 in [25], we have the following.

PROPOSITION 4.4. (1) *Up to a subsequence, $\mathbf{m}^j=\rho^j\mathbf{U}^j$ converges strongly in $L^1((0,T)\times\Omega_{\frac{1}{n}})$ and $L^2(0,T;L^{1+\zeta}(\Omega_{\frac{1}{n}}))$ to some $\mathbf{m}(\mathbf{x},t)$ for any positive integer n.*

(2) *$\sqrt{\rho^j}\mathbf{U}^j$ converges strongly in $L^2((0,T)\times\Omega_{\frac{1}{n}})$ to $\frac{\mathbf{m}}{\sqrt{\rho}}$ (defined to be zero when $m=0$) for any positive integer n. In particular, $\mathbf{m}(x,t)=0$ a.e. on $\{\rho(\mathbf{x},t)=0\}$, and there exists a function $\mathbf{U}(\mathbf{x},t)$ such that*

$$\mathbf{m}(\mathbf{x},t)=\rho(\mathbf{x},t)\mathbf{U}(\mathbf{x},t).$$

This proposition can be proved exactly as in [22], and the details will be omitted.

The following then follows from Propositions 4.1 and 4.4.

COROLLARY 4.2. *Let $m^j(r,t)=\rho^ju^j(r,t)$. Then*

(1) *there exists a function $m(r,t)$ such that $\mathbf{m}(\mathbf{x},t)=m(r,t)\frac{\mathbf{x}}{r}$ and $m^j(r,t)=\rho^ju^j(r,t)$ converges to $m(r,t)$ strongly in $L^2(0,T;L^{1+\zeta}_{loc}((0,R);r^2dr))$;*

(2) *there exists a function $u(r,t)$ such that $\mathbf{U}(\mathbf{x},t)=u(r,t)\frac{\mathbf{x}}{r}$ and the quantity $\sqrt{\rho^j}u^j$ converges strongly in $L^2((0,T);L^2_{loc}((0,R);r^2dr))$ to $\frac{m}{\sqrt{\rho}}$ (defined to be zero when $m=0$).*

Proof. Since $\mathbf{m}^j(\mathbf{x},t)=m^j(r,t)\frac{\mathbf{x}}{r}$, so $m^j(r,t)=|\mathbf{m}^j(x,t)|$ converges almost everywhere to $m(r,t)=|\mathbf{m}(\mathbf{x},t)|$ due to the fact that $\mathbf{m}^j(\mathbf{x},t)$ converges almost everywhere to $\mathbf{m}(x,t)$ by the first part of Proposition 4.4. Therefore $\mathbf{m}(\mathbf{x},t)=m(r,t)\frac{\mathbf{x}}{r}$. Moreover, noting that $\rho(\mathbf{x},t)=\rho(r,t)$ by Proposition 4.1 and $\mathbf{m}(\mathbf{x},t)=\rho(\mathbf{x},t)\mathbf{U}(\mathbf{x},t)$ by Proposition 4.4, we obtain

$$m(r,t)\frac{\mathbf{x}}{r}=\rho(r,t)\mathbf{U}(\mathbf{x},t).$$

Therefore there exists a spherically function $u(r,t)$ such that $m(r,t)=\rho u(r,t)$.

The rest of the corollary follows directly from Proposition 4.4, and the proof of the corollary is finished. ◻

Now we show that $(\rho,\mathbf{U})$ obtained in Propositions 4.1–4.4 satisfy the weak form of (2.1), that is, (2.13) holds.

PROPOSITION 4.5. *Let $(\rho,\mathbf{U})$ be the limit described as in Propositions 4.1–4.4. Then (2.13) holds. Moreover, $\rho\in C([0,\infty);W^{1,\infty}(\Omega)^*)$.*

Proof. We first derive the weak form of (3.3). For any $\varphi(r,t)\in C^1([0,R]\times[t_1,t_2])$, it follows from (3.3), (4.3), and (4.4) that

$$\begin{aligned}&\int_0^R \rho^j\varphi r^2dr|_{t_1}^{t_2}-\int_{t_1}^{t_2}\int_0^R(\rho^j\varphi_t+\rho^ju^j\varphi_r)r^2drdt\\ &=\int_0^{\varepsilon_j}\rho^j\varphi r^2dr|_{t_1}^{t_2}-\int_{t_1}^{t_2}\int_0^{\varepsilon_j}\rho^j\varphi_tr^2drdt,\end{aligned}\tag{4.19}$$

Due to Proposition 4.1, it holds that

$$\int_0^R \rho^j \varphi r^2 dr \to \int_0^R \rho\varphi r^2 dr \tag{4.20}$$

and

$$\int_{t_1}^{t_2}\int_0^R \rho^j \varphi_t r^2 drdt \to \int_{t_1}^{t_2}\int_0^R \rho\varphi_t r^2 drdt \tag{4.21}$$

as $j \to \infty$.

It follows from (4.8) that $\sqrt{\rho^j}$ is bounded in $L^\infty(0,T;L^q(\Omega))$ for $q \in [2,6]$. Thus $\sqrt{\rho^j}$ (or its subsequence) converges strongly in $L^2(0,T;L^2(\Omega))$ to $\sqrt{\rho}$ due to Proposition 4.1. Moreover, Corollary 4.1 yields that $\sqrt{\rho^j}u^j$ is bounded in $L^\infty(0,T;L^{2+2\zeta}(\Omega))$ for some small $\zeta > 0$, and Corollary 4.2 yields that $\sqrt{\rho^j}u^j$ converges almost everywhere to $\sqrt{\rho}u$. Hence $\sqrt{\rho^j}u^j$ converges strongly to $\sqrt{\rho}u$ in $L^2(0,T;L^2(\Omega))$. So

$$\begin{aligned}&\int_{t_1}^{t_2}\int_0^R \rho^j u^j \varphi_r r^2 drdt = \int_{t_1}^{t_2}\int_0^R \sqrt{\rho^j}(\sqrt{\rho^j}u^j)\varphi_r r^2 drdt \to\\ &\int_{t_1}^{t_2}\int_0^R \sqrt{\rho}(\sqrt{\rho}u)\varphi_r r^2 drdt = \int_{t_1}^{t_2}\int_0^R \rho u\varphi_r r^2 drdt\end{aligned} \tag{4.22}$$

as $j \to \infty$.

Moreover, we have

$$\begin{aligned}&\left|\max_{t\in[0,T]}\int_0^{\varepsilon_j} \rho^j\varphi r^2 dr\right| \le C\max_{t\in[0,T]}\left(\int_0^R (\rho^j)^{\frac{3}{2}} r^2 dr\right)^{\frac{2}{3}}(\varepsilon_j)^{\frac{1}{3}}\\ &\le C(\varepsilon_j)^{\frac{1}{3}} \to 0\end{aligned} \tag{4.23}$$

and, similarly,

$$\begin{aligned}&\left|\int_{t_1}^{t_2}\int_0^{\varepsilon_j} \rho^j\varphi_t r^2 drdt\right|\\ &\le C(\varepsilon_j)^{\frac{1}{3}} \to 0\end{aligned} \tag{4.24}$$

as $j \to \infty$.

Therefore, in view of (4.20)–(4.24), by taking limit $j \to \infty$ in (4.19), we obtain

$$\int_0^R \rho\varphi r^2 dr|_{t_1}^{t_2} = \int_{t_1}^{t_2}\int_0^R (\rho\varphi_t + \rho u\varphi_r) r^2 drdt. \tag{4.25}$$

Now let $\zeta : \bar{\Omega} \times [t_1,t_2] \to \mathbb{R}$ be any C^1 function. Define

$$\varphi(r,t) := \int_S \zeta(ry,t)dS_y,$$

where the integral is over the unit sphere $S = S^2$ in $\mathbb{R}^3$. Then it follows from (4.25) that

$$\int_\Omega \rho\zeta(x,\cdot)dx|_{t_1}^{t_2} = \int_{t_1}^{t_2}\int_\Omega \{\rho\zeta_t + \rho(x,t)\mathbf{U}\cdot\nabla\zeta\}(x,t)dxdt.$$

This establishes the weak form of the mass equation.

Now we prove that $\rho \in C([0,\infty); W^{1,\infty}(\Omega)^*)$. If ϕ is a C^1 function of x, then by the continuity equation we have

$$\begin{aligned}
&\left|\int_\Omega \rho\phi dx|_{t_1}^{t_2}\right| = \left|\int_{t_1}^{t_2}\int_\Omega \rho(x,t)\mathbf{U}\cdot\nabla\phi dxdt\right| \\
&\le \|\nabla\phi\|_{L^\infty}\int_{t_1}^{t_2}\left(\int_\Omega \rho dx\right)^{1/2}\left(\int_\Omega \rho|\mathbf{U}|^2dx\right)^{1/2}dt \\
&\le C(T)\|\nabla\phi\|_{L^\infty}|t_2-t_1|.
\end{aligned}$$

This implies that

$$\|\rho(\cdot,t_2)-\rho(\cdot,t_1)\|_{W^{1,\infty}(\Omega)^*} \le C(T)|t_2-t_1|$$

for all $t_1,t_2\in[0,T]$. The proof of the proposition is complete. ∎

In the following, we prove that $(\rho,\mathbf{U})$ satisfies (2.14).

PROPOSITION 4.6. *Let* $(\rho,\mathbf{U})$ *be the limit described as in Propositions* 4.1–4.4. *Then* (2.14) *holds.*

Proof. Let ϕ be a C^2-function on $[0,R]\times[0,T]$ with $\phi(0,t)=\phi(R,t)=0$ for all $t\in[0,T]$. Then it follows from (3.4) that

$$\begin{aligned}
&\int_{\varepsilon_j}^R \rho_0^j u_0^j\phi(r,0)r^2dr + \int_0^T\int_{\varepsilon_j}^R\left(\rho^j u^j\phi_t + \rho^j(u^j)^2\phi_r + (\rho^j)^\gamma\left(\phi_r+\frac{2\phi}{r}\right)\right)r^2drdt \\
&-\int_0^T\int_{\varepsilon_j}^R \rho^j\left(u_r^j\phi_r+\frac{2u^j\phi}{r^2}\right)r^2drdt = \int_0^T\int_{\varepsilon_j}^R\frac{3}{4}\varepsilon_j(\rho^j)^{\frac34}\left(u_r^j+\frac{2u^j}{r}\right)\left(\phi_r+\frac{2}{r}\phi\right)r^2drdt \\
&-\int_0^T\int_{\varepsilon_j}^R\varepsilon_j(\rho^j)^{\frac34}\left(\frac{2u_r^j\phi}{r}+\frac{2u^j\phi_r}{r}+\frac{2}{r^2}u^j\phi\right)r^2drdt+\varepsilon_b^j, \qquad (4.26)
\end{aligned}$$

where

$$\varepsilon_b^j = \int_0^T\left\{\left[\rho^j+\frac34\varepsilon_j(\rho^j)^{\frac34}u_r^j\right](\varepsilon_j,t)\varepsilon_j^2\phi(\varepsilon_j,t)-\varepsilon_j^2(\rho^j)^\gamma(\varepsilon_j,t)\phi(\varepsilon_j,t)\right\}dt. \qquad (4.27)$$

We claim that

$$\lim_{\varepsilon_j\to0^+}\varepsilon_b^j = 0. \qquad (4.28)$$

To check this, we drop the superscript j and denote ε_j by ε for convenience. First, we show that

$$\lim_{\varepsilon\to0^+}\varepsilon^2\int_0^T\rho^\gamma(\varepsilon,t)\phi(\varepsilon,t)dt = 0. \qquad (4.29)$$

Indeed, note that

$$\begin{aligned}
&\left|\varepsilon^2\int_0^T\rho^\gamma(\varepsilon,t)\phi(\varepsilon,t)dt\right| \le \max_{0\le t\le T}|\phi(\varepsilon,t)|\int_0^T\varepsilon^2\rho^\gamma(\varepsilon,t)dt \\
&\le \max_{0\le t\le T}|\phi(\varepsilon,t)|\left[\int_0^T\int_\varepsilon^R\rho^\gamma(r,t)r^2drdt+\int_0^T\int_\varepsilon^R|\partial_r(\rho^\gamma)(r,t)|r^2drdt\right].
\end{aligned}$$

Since

$$\int_0^T\int_\varepsilon^R \rho^\gamma(r,t)r^2drdt \le C_0$$

and

$$\begin{aligned}\int_0^T\int_\varepsilon^R |\partial_r(\rho^\gamma)|r^2drdt &= 2\int_0^T\int_\varepsilon^R |\rho^{\frac{\gamma}{2}}||\partial_r(\rho^{\frac{\gamma}{2}})|r^2drdt\\ &\le \int_0^T\int_\varepsilon^R \rho^\gamma r^2drdt + \int_0^T\int_\varepsilon^R |\partial_r(\rho^{\frac{\gamma}{2}})|^2r^2drdt \le C_0\end{aligned}$$

due to (4.6) and (4.7), (4.29) follows from the fact that $\lim_{\varepsilon\to0^+}\max_{0\le t\le T}|\phi(\varepsilon,t)|=0$ since $\phi(0,t)\equiv 0$ and $\phi\in C^2$. Next, we show that

$$\lim_{\varepsilon\to0^+}\int_0^T(\rho u_r)(\varepsilon,t)\phi(\varepsilon,t)\varepsilon^2dt=0. \tag{4.30}$$

Thanks to (3.3) and the boundary condition that $u(\varepsilon,t)=0$, one has

$$\rho_t(\varepsilon,t)+\rho(\varepsilon,t)\partial_r u(\varepsilon,t)=0.$$

Thus,

$$\begin{aligned}&\lim_{\varepsilon\to0^+}\int_0^T(\rho u_r)(\varepsilon,t)\phi(\varepsilon,t)\varepsilon^2dt = \lim_{\varepsilon\to0^+}\left(-\varepsilon^2\int_0^T\partial_t\rho(\varepsilon,t)\phi(\varepsilon,t)dt\right)\\ &=\lim_{\varepsilon\to0^+}\left[\varepsilon^2\rho_0(\varepsilon)\phi(\varepsilon,0)+\varepsilon^2\int_0^T\rho(\varepsilon,t)\partial_t\phi(\varepsilon,t)dt\right]=\lim_{\varepsilon\to0^+}\left[\varepsilon^2\int_0^T\rho(\varepsilon,t)\partial_t\phi(\varepsilon,t)dt\right].\end{aligned}$$

On the other hand, it is easy to get

$$\begin{aligned}\varepsilon^2\left|\int_0^T\rho(\varepsilon,t)\partial_t\phi(\varepsilon,t)dt\right| &\le \varepsilon^{2-\frac{2}{\gamma}}\left(\varepsilon^2\int_0^T\rho^\gamma(\varepsilon,t)dt\right)^{\frac{1}{\gamma}}||\partial_t\phi(\varepsilon,\cdot)||_{L^{\frac{\gamma}{\gamma-1}}}\\ &\le C_0\,\varepsilon^{2-\frac{2}{\gamma}}\to 0\end{aligned}$$

as $\varepsilon\to0^+$. Hence (4.30) holds. Similarly, one can show that

$$\lim_{\varepsilon\to0^+}\frac{3}{4}\varepsilon\int_0^T\varepsilon^2\left(\rho^{\frac{3}{4}}u_r\right)(\varepsilon,t)\phi(\varepsilon,t)=0. \tag{4.31}$$

Indeed, it follows from (3.3) and $u(\varepsilon,t)=0$ that

$$\frac{3}{4}\int_0^T\varepsilon^3\left(\rho^{\frac{3}{4}}u_r\right)(\varepsilon,t)\phi(\varepsilon,t)dt=\varepsilon^3\rho_0^{\frac{3}{4}}(\varepsilon)\phi(\varepsilon,0)+\int_0^T\varepsilon^3\rho^{\frac{3}{4}}(\varepsilon,t)\partial_t\phi(\varepsilon,t)dt.$$

Since

$$\varepsilon^3\left|\int_0^T\rho^{\frac{3}{4}}(\varepsilon,t)\partial_t\phi(\varepsilon,t)dt\right|\le\varepsilon^{3(\frac{2\gamma-1}{2\gamma})}\left(\varepsilon^2\int_0^T\rho^\gamma(\varepsilon,t)dt\right)^{\frac{3}{4\gamma}}||\partial_t\phi(\varepsilon,\cdot)||_{L^{\frac{4\gamma}{4\gamma-3}}},$$

(4.31) follows. Now (4.28) is a consequence of (4.29)–(4.31).

Now, for any $\psi = (\psi^1, \psi^2, \psi^3) \in C^2(\bar{\Omega} \times [0, T])$ satisfying $\psi(x, t) = 0$ for all $x \in \partial\Omega$ and $\psi(x, T) = 0$, we set

$$\phi(r, t) = \int_S \psi(ry, t) \cdot y \, dS_y, \tag{4.32}$$

with $S = S^2$ being the unit sphere in $\mathbb{R}^3$, and transform the terms of (4.26) into integrals in Cartesian coordinates. Noting that

$$(r^2\phi)_r = \partial_r \int_{|x| \le r} \operatorname{div} \psi(x, t) dx = r^2 \int_S (\psi^i)_{x_i}(ry, t) dS_y,$$

we have by direct calculations that

$$\begin{aligned} &- \int_0^T \int_{\varepsilon_j}^R \rho^j \left(u_r^j \phi_r + \frac{2u^j \phi}{r^2} \right) r^2 dr dt \\ =&- \int_0^T \int_{\Omega_{\varepsilon_j}} \rho^j \nabla (\mathbf{U}^j)^i : \nabla \psi^i dx dt. \end{aligned}$$

Similarly, one has

$$\int_0^T \int_{\varepsilon_j}^R \frac{3}{4} \varepsilon_j (\rho^j)^{\frac{3}{4}} \left(u_r^j + \frac{2u^j}{r} \right) \left(\phi_r + \frac{2}{r} \phi \right) r^2 dr dt = \int_0^T \int_{\Omega_{\varepsilon_j}} \frac{1}{4} \varepsilon_j (\rho^j)^{\frac{3}{4}} \operatorname{div} \mathbf{U}^j \operatorname{div} \psi dx dt,$$

and

$$- \int_0^T \int_{\varepsilon_j}^R \varepsilon_j (\rho^j)^{\frac{3}{4}} \left(2 \frac{u_r^j \phi}{r} + 2 \frac{u^j \phi_r}{r} + \frac{2}{r^2} u^j \phi \right) r^2 dr dt = - \int_0^T \int_{\Omega_{\varepsilon_j}} \varepsilon_j (\rho^j)^{\frac{3}{4}} \nabla \mathbf{U}^j : \nabla \psi dx dt.$$

Thus, it follows from (4.26) that

$$\begin{aligned} &\int_{\Omega_{\varepsilon_j}} \rho_0^j \mathbf{U}_0^j \cdot \psi(0, x) dx + \int_0^T \int_{\Omega_{\varepsilon_j}} \Big\{ \sqrt{\rho^j} (\sqrt{\rho^j} \mathbf{U}^j) \cdot \partial_t \psi + \sqrt{\rho^j} \mathbf{U}^j \otimes \sqrt{\rho^j} \mathbf{U}^j : \nabla \psi \Big\} dx dt \\ &+ \int_0^T \int_{\Omega_{\varepsilon_j}} (\rho^j)^\gamma \operatorname{div} \psi dx dt - \int_0^T \int_{\Omega_{\varepsilon_j}} \rho^j \nabla \mathbf{U}^j : \nabla \psi dx dt \\ =& \frac{1}{4} \varepsilon_j \int_0^T \int_{\Omega_{\varepsilon_j}} (\rho^j)^{\frac{3}{4}} \operatorname{div} \mathbf{U}^j \operatorname{div} \psi dx dt - \varepsilon_j \int_0^T \int_{\Omega_{\varepsilon_j}} (\rho^j)^{\frac{3}{4}} \nabla \mathbf{U}^j : \nabla \psi dx dt + \varepsilon_b^j. \end{aligned}$$

Thanks to (4.4), one has

$$\begin{aligned} &\int_\Omega \rho_0^j \mathbf{U}_0^j \cdot \psi(0, \cdot) dx + \int_0^T \int_\Omega \left\{ \sqrt{\rho^j} (\sqrt{\rho^j} \mathbf{U}^j) \cdot \partial_t \psi + \sqrt{\rho^j} \mathbf{U}^j \otimes \sqrt{\rho^j} \mathbf{U}^j : \nabla \psi \right\} dx dt \\ &\qquad + \int_0^T \int_\Omega (\rho^j)^\gamma \operatorname{div} \psi dx dt - \int_0^T \int_\Omega \rho^j \nabla \mathbf{U}^j : \nabla \psi dx dt \\ =& \int_0^T \int_{B_{\varepsilon_j}} (\rho^j)^\gamma \operatorname{div} \psi dx dt + \frac{\varepsilon_j}{4} \int_0^T \int_{\Omega_{\varepsilon_j}} (\rho^j)^{\frac{3}{4}} \operatorname{div} \mathbf{U}^j \operatorname{div} \psi dx dt \\ &- \varepsilon_j \int_0^T \int_{\Omega_{\varepsilon_j}} (\rho^j)^{\frac{3}{4}} \nabla \mathbf{U}^j : \nabla \psi dx dt + \varepsilon_b^j. \end{aligned} \tag{4.33}$$

We proceed to show that each term on the left-hand side of (4.33) converges to a corresponding term in (2.14) and each term on the right-hand side of (4.33) vanishes as $j \to \infty$.

First, the proof of the convergence of $\rho^j \mathbf{U}^j \phi_t$ is similar to that of (4.22).

Next, it holds that

$$\begin{aligned}
&\left| \int_0^T \int_\Omega \left[\sqrt{\rho^j}\mathbf{U}^j \otimes \sqrt{\rho^j}\mathbf{U}^j - \sqrt{\rho}\mathbf{U} \otimes \sqrt{\rho}\mathbf{U} \right] : \nabla\psi dxdt \right| \\
\leq & \|\nabla\psi\|_{L^\infty} \int_0^T \int_{B_{\frac{1}{n}}} (|\sqrt{\rho^j}\mathbf{U}^j|^2 + \sqrt{\rho}|\mathbf{U}|^2) dxdt \\
&+ \left| \int_0^T \int_{\Omega_{\frac{1}{n}}} \left[\sqrt{\rho^j}\mathbf{U}^j \otimes \sqrt{\rho^j}\mathbf{U}^j - (\sqrt{\rho}\mathbf{U} \otimes \sqrt{\rho}\mathbf{U}) : \nabla\psi \right] dxdt \right|
\end{aligned} \tag{4.34}$$

for any positive integer n.

By virtue of Proposition 4.3, one has

$$\begin{aligned}
\int_0^T \int_{B_{\frac{1}{n}}} |\sqrt{\rho^j}\mathbf{U}^j|^2 dxdt \leq & \left(\int_0^T \int_{B_{\frac{1}{n}}} \rho^j dxdt \right)^{\frac{\eta}{2+\eta}} \left(\int_0^T \int_{B_{\frac{1}{n}}} \rho^j |\mathbf{U}^j|^{2+\eta} dxdt \right)^{\frac{2}{2+\eta}} \\
\leq & C \left(\int_0^T \int_{B_{\frac{1}{n}}} \rho^j dxdt \right)^{\frac{\eta}{2+\eta}}.
\end{aligned}$$

As proved in Proposition 4.5, the following convergence holds:

$$\begin{aligned}
\int_0^T \int_{B_{\frac{1}{n}}} \rho^j dxdt \leq & C(T) \left(\int_0^T \int_{B_{\frac{1}{n}}} (\rho^j)^3 dxdt \right)^{\frac{1}{3}} |B_{\frac{1}{n}}|^{\frac{2}{3}} \\
\leq & C(T) |B_{\frac{1}{n}}|^{\frac{2}{3}} \to 0
\end{aligned} \tag{4.35}$$

as $n \to \infty$, where (4.8) has been used. Consequently, it holds that

$$\int_0^T \int_{B_{\frac{1}{n}}} |\sqrt{\rho^j}\mathbf{U}^j|^2 dxdt \to 0,$$

uniformly on j, as $n \to \infty$. Also,

$$\int_0^T \int_{B_{\frac{1}{n}}} |\sqrt{\rho}\mathbf{U}|^2 dxdt \leq \lim\inf_{j\to\infty} \int_0^T \int_{B_{\frac{1}{n}}} |\sqrt{\rho^j}\mathbf{U}^j|^2 dxdt \to 0$$

as $n \to \infty$. It follows from (4.34) and Proposition 4.4 that

$$\int_0^T \int_\Omega \sqrt{\rho^j}\mathbf{U}^j \otimes \sqrt{\rho^j}\mathbf{U}^j : \nabla\psi dxdt \to \int_0^T \int_\Omega \sqrt{\rho}\mathbf{U} \otimes \sqrt{\rho}\mathbf{U} : \nabla\psi dxdt \tag{4.36}$$

as $j \to \infty$. Concerning the pressure term, Proposition 4.2 implies that

$$\int_0^T \int_\Omega (\rho^j)^\gamma \operatorname{div}\psi \, dxdt \to \int_0^T \int_\Omega \rho^\gamma \operatorname{div}\psi \, dxdt, \qquad j \to \infty. \tag{4.37}$$

Concerning the diffusion terms on the left-hand side of (4.33), we obtain after integration by parts that

$$\begin{aligned}\int_0^T\int_\Omega \rho^j\nabla\mathbf{U}^j:\nabla\psi dxdt = &-\int_0^T\int_\Omega \sqrt{\rho^j}(\sqrt{\rho^j}\mathbf{U}^j)\cdot\Delta\psi dxdt\\ &-2\int_0^T\int_\Omega(\sqrt{\rho^j}\mathbf{U}^j)\cdot(\nabla\sqrt{\rho^j}\cdot\nabla)\psi dxdt.\end{aligned}\tag{4.38}$$

Using Propositions 4.2–4.4, one can prove the convergence for the first term on the right-hand side of (4.38) as follows:

$$\int_0^T\int_\Omega \sqrt{\rho^j}(\sqrt{\rho^j}\mathbf{U}^j)\Delta\phi dxdt \to \int_0^T\int_\Omega \sqrt{\rho}(\sqrt{\rho}\mathbf{U})\Delta\phi dxdt\tag{4.39}$$

as $j\to\infty$, in a similar way as in the proof of (4.22).

Due to Lemma 4.1, it holds that

$$\|\nabla\sqrt{\rho^j}\|_{L^\infty(0,T;L^2(\Omega))}\le C,$$

and hence there exists a function $g\in L^2(0,T;L^2(\Omega))$ such that

$$\nabla\sqrt{\rho^j}\rightharpoonup g \quad \text{weakly in} \quad L^2(0,T;L^2(\Omega)).$$

Meanwhile, by Proposition 4.1, up to a subsequence, $\sqrt{\rho^j}$ converges almost everywhere to $\sqrt{\rho}$. Combining the fact that $\sqrt{\rho^j}$ is uniformly bounded in $L^\infty(0,T;L^6(\Omega))$, one has

$$\sqrt{\rho^j}\rightharpoonup \sqrt{\rho} \quad \text{weakly in} \quad L^2(0,T;L^2(\Omega)),$$

and hence $g=\nabla\sqrt{\rho}$. Consequently, it yields

$$\nabla\sqrt{\rho^j}\rightharpoonup \nabla\sqrt{\rho} \quad \text{weakly in} \quad L^2(0,T;L^2(\Omega)).$$

Due to Propositions 4.3 and 4.4, we finally obtain

$$\begin{aligned}&-2\int_0^T\int_\Omega(\sqrt{\rho^j}\mathbf{U}^j)\cdot(\nabla\sqrt{\rho^j}\cdot\nabla)\psi dxdt\to\\ &-2\int_0^T\int_\Omega(\sqrt{\rho}\mathbf{U})\cdot(\nabla\sqrt{\rho}\cdot\nabla)\psi dxdt.\end{aligned}\tag{4.40}$$

Substituting (4.39) and (4.40) into (4.38) yields

$$\begin{aligned}&\int_0^T\int_\Omega \rho^j\nabla\mathbf{U}^j:\nabla\psi dxdt\to\langle\rho\nabla\mathbf{U},\nabla\psi\rangle\\ &\equiv-\int_0^T\int_\Omega\sqrt{\rho}(\sqrt{\rho}\mathbf{U})\cdot\Delta\psi dxdt-2\int_0^T\int_\Omega(\sqrt{\rho}\mathbf{U})\cdot(\nabla\sqrt{\rho}\cdot\nabla)\psi dxdt.\end{aligned}\tag{4.41}$$

Up to now, we have proved that the terms on the left-hand side of (4.33) converge to corresponding ones in (2.14) as $j\to\infty$. In the following, we prove that each term on the right-hand side of (4.33) vanishes as $j\to\infty$.

Since $\sqrt{\rho^j}$ is uniformly bounded in $L^\infty(0,T;L^6(\Omega))$ due to (4.8), it holds that

$$\left|\int_0^T\int_{B_{\varepsilon_j}}(\rho^j)^\gamma \mathrm{div}\psi dxdt\right|\le C\left(\int_0^T\int_{B_{\varepsilon_j}}(\rho^j)^3dxdt\right)^{\frac{\gamma}{3}}|B_{\varepsilon_j}|^{\frac{3-\gamma}{3}}\le C|B_{\varepsilon_j}|^{\frac{3-\gamma}{3}} \tag{4.42}$$

for $1<\gamma<3$, which tends to zero as $\varepsilon_j\to 0$.

With the help of Lemma 4.1 again, one has

$$\begin{aligned}&\left|\frac{\varepsilon_j}{4}\int_0^T\int_{\Omega_{\varepsilon_j}}(\rho^j)^{\frac34}\mathrm{div}\mathbf{U}^j\mathrm{div}\psi dxdt\right|\\ \le& C\sqrt{\varepsilon_j}\left(\varepsilon_j\int_0^T\int_{\Omega_{\varepsilon_j}}(\rho^j)^{\frac34}|\nabla\mathbf{U}^j|^2dxdt\right)^{\frac12}\left(\int_0^T\int_{\Omega_{\varepsilon_j}}(\rho^j)^{\frac34}dxdt\right)^{\frac12}\\ \le& C\sqrt{\varepsilon_j}. \end{aligned}\tag{4.43}$$

Similarly, one has

$$\left|\varepsilon_j\int_0^T\int_{\Omega_j}(\rho^j)^{\frac34}\nabla\mathbf{U}^j:\nabla\psi dxdt\right|\le C\sqrt{\varepsilon_j}. \tag{4.44}$$

It follows from (4.28) and (4.42)–(4.44) that each term on the right hand side of (4.33) converges to 0 as $j\to\infty$.

Taking the limit $j\to\infty$ in (4.33), we finish the proof of the proposition. ◻

Now we are ready to prove Theorem 2.1.

Proof of Theorem 2.1. The weak forms of the mass and momentum equations (2.13) and (2.14) follow from Propositions 4.5 and 4.6, respectively. The first part in the definition of the weak solutions (see Definition 2.1) follows from Lemmas 3.2 and 4.1 and Proposition 4.5. Moreover, $\rho\in C([0,T];L^{\frac32}(\Omega))$ and the equation of mass conservation (2.20) are obtained by Propositions 4.1 and 4.5. The estimate (2.21) is due to Lemma 4.1 and (4.18). Finally, the radial symmetry of the weak solutions is a consequence of Corollary 4.2. The proof of Theorem 2.1 is thus finished.

Acknowledgment. The authors thank the anonymous referees for their valuable suggestions to improve the presentation of the paper.

WAVE-NUMBER-EXPLICIT BOUNDS IN TIME-HARMONIC SCATTERING*

SIMON N. CHANDLER-WILDE† AND PETER MONK‡

Abstract. In this paper we consider the problem of scattering of time-harmonic acoustic waves by a bounded, sound soft obstacle in two and three dimensions, studying dependence on the wave number in two classical formulations of this problem. The first is the standard weak formulation in the part of the exterior domain contained in a large sphere, with an exact Dirichlet-to-Neumann map applied on the boundary. The second formulation is as a second kind boundary integral equation in which the solution is sought as a combined single- and double-layer potential. For the variational formulation we obtain, in the case when the obstacle is starlike, explicit upper and lower bounds which show that the inf-sup constant decreases like k^{-1} as the wave number k increases. We also give an example where the obstacle is not starlike and the inf-sup constant decreases at least as fast as k^{-2}. For the boundary integral equation formulation, if the boundary is also Lipschitz and piecewise smooth, we show that the norm of the inverse boundary integral operator is bounded independently of k if the coupling parameter is chosen correctly. The methods we use also lead to explicit bounds on the solution of the scattering problem in the energy norm when the obstacle is starlike. The dependence of these bounds on the wave number and on the geometry is made explicit.

Key words. nonsmooth boundary, a priori estimate, inf-sup constant, Helmholtz equation, oscillatory integral operator

1. Introduction.

In this paper we consider the classical problem of scattering of a time-harmonic acoustic wave by a bounded, sound soft obstacle occupying a compact set $\Omega \subset \mathbb{R}^n$ ($n = 2$ or 3). The wave propagates in the exterior domain $\Omega_e = \mathbb{R}^n \setminus \Omega$, and the boundedness of the scatterer implies that there is an $R > 0$ such that $\{x \in \mathbb{R}^n : |x| > R\} \subset \Omega_e$. We suppose that the medium of propagation outside Ω_e is homogeneous, isotropic, and at rest, and that a time-harmonic ($\mathrm{e}^{-\mathrm{i}\omega t}$ time dependence) pressure field u^i is incident on Ω. Denoting by $c > 0$ the speed of sound, we assume that u^i is an entire solution of the Helmholtz (or reduced wave) equation with wave number $k = \omega/c > 0$. Then the problem we consider is to find the resulting time-harmonic acoustic pressure field u which satisfies the Helmholtz equation

$$\Delta u + k^2 u = 0 \quad \text{in } \Omega_e \tag{1.1}$$

and the sound soft boundary condition

$$u = 0 \quad \text{on } \Gamma := \partial\Omega_e, \tag{1.2}$$

and is such that the scattered part of the field, $u^s := u - u^i$, satisfies the Sommerfeld radiation condition

$$\frac{\partial u^s}{\partial r} - \mathrm{i}ku^s = o(r^{-(n-1)/2}) \tag{1.3}$$

as $r := |x| \to \infty$, uniformly in $\hat{x} := x/r$. (This latter condition expresses mathematically that the scattered field u^s is outgoing at infinity; see, e.g., [14]). It is well known that this problem has exactly one solution under the constraint that u and ∇u be locally square integrable; see, e.g., [34].

The aim of this paper is to understand the behavior, in the important but difficult high frequency limit $k \to \infty$, of two standard reformulations of this problem. Both reformulations are used extensively, for theoretical analysis and for practical numerical computation. The first is a weak formulation in the bounded domain $D_R := \{x \in \Omega_e : |x| < R\}$, for some $R > R_0 := \sup_{x\in\Omega} |x|$. This formulation is expressed in terms of the Dirichlet-to-Neumann map T_R, for the canonical domain $G_R := \{x : |x| > R\}$ with boundary $\Gamma_R := \{x : |x| = R\}$. The mapping T_R takes Dirichlet data $g \in C^\infty(\Gamma_R)$ to the corresponding Neumann data $T_R g := \frac{\partial v}{\partial r}|_{\Gamma_R}$, where v denotes the solution to the Helmholtz equation in G_R which satisfies the Sommerfeld radiation condition and the boundary condition $v = g$ on Γ_R. It is standard that the mapping T_R extends to a bounded map $T_R : H^{1/2}(\Gamma_R) \to H^{-1/2}(\Gamma_R)$.

Let V_R denote the closure of $\{v|_{D_R} : v \in C_0^\infty(\Omega_e)\} \subset H^1(D_R)$ in the norm of $H^1(D_R)$. It is well known (e.g., [39]), and follows easily by integration by parts, that u satisfies the scattering problem if and only if the restriction of u to D_R satisfies the following variational problem: find $u \in V_R$ such that

$$b(u, v) = G(v), \quad v \in V_R. \tag{1.4}$$

Here G is an antilinear functional that depends on the incident field (for details see section 3), while $b(\cdot, \cdot)$ is the sesquilinear form on $V_R \times V_R$ defined by

$$b(u, v) := \int_{D_R} (\nabla u \cdot \nabla \bar{v} - k^2 u\bar{v})\, dx - \int_{\Gamma_R} \gamma\bar{v} T_R \gamma u\, ds, \tag{1.5}$$

where $\gamma : V_R \to H^{1/2}(\Gamma_R)$ is the usual trace operator. Equation (1.4) is our first standard reformulation of the scattering problem.

To introduce our second reformulation, let $\Phi(x, y)$ denote the standard free-space fundamental solution of the Helmholtz equation given, in the two-dimensional (2D) and three-dimensional (3D) cases, by

$$\Phi(x, y) := \begin{cases} \dfrac{\mathrm{i}}{4} H_0^{(1)}(k|x - y|), & n = 2, \\[2ex] \dfrac{\mathrm{e}^{\mathrm{i}k|x-y|}}{4\pi|x - y|}, & n = 3, \end{cases}$$

for $x, y \in \mathbb{R}^n$, $x \neq y$. It was proposed independently by Brakhage and Werner [4], Leis [33], and Panich [40], as a means to obtain an integral equation uniquely solvable at all wave numbers, to look for a solution to the scattering problem in the form of the *combined single- and double-layer potential*

$$u^s(x) \;:=\; \int_\Gamma \frac{\partial \Phi(x, y)}{\partial \nu(y)} \varphi(y)\, ds(y) - \mathrm{i}\eta \int_\Gamma \Phi(x, y)\varphi(y)\, ds(y), \quad x \in \Omega_e, \tag{1.6}$$

for some nonzero value of the *coupling parameter* $\eta \in \mathbb{R}$. (In this equation $\partial/\partial\nu(y)$ is the derivative in the normal direction, the unit normal $\nu(y)$ directed into Ω_e.) It follows from standard boundary trace results for single- and double-layer potentials that u^s, given by (1.6), satisfies the scattering problem if and only if φ satisfies a second kind boundary integral equation on Γ (see section 4 for details). This integral equation, in operator form, is

$$(I + K - \mathrm{i}\eta S)\varphi = 2g, \tag{1.7}$$

where I is the identity operator, S and K are single- and double-layer potential operators, defined by (4.1) and (4.2) below, and $g := -u^i|_\Gamma$ is the Dirichlet data for the scattered field on Γ.

Choosing $\eta \neq 0$ ensures that (1.6) is uniquely solvable. Precisely,

$$A := I + K - \mathrm{i}\eta S$$

is invertible as an operator on $C(\Gamma)$ when Γ is sufficiently smooth, e.g., of class C^2 (see [4] or [14]). The case of nonsmooth (Lipschitz) Γ has been considered recently in [9] (see also [37]), where it is shown that A is invertible as an operator on the Sobolev space $H^s(\Gamma)$ for $0 \leq s \leq 1$.

While it is established that each of these formulations is well-posed, precisely that A^{-1} is a bounded operator on $H^s(\Gamma)$, $0 \leq s \leq 1$, in the case of (1.6), and that the sesquilinear form $b(\cdot,\cdot)$ satisfies the inf-sup condition, that

$$\alpha := \inf_{0 \neq u \in V_R} \sup_{0 \neq v \in V_R} \frac{|b(u,v)|}{\|u\|_{V_R}\|v\|_{V_R}} > 0, \tag{1.8}$$

in the case of the formulation (1.4), there is little information in the literature on how the stability constants $\|A^{-1}\|$ and α depend on k, particularly in the limit as $k \to \infty$.

This lack of theoretical understanding is unfortunate for a number of reasons. In the first place, both formulations (and similar formulations for other boundary conditions on Γ) are used extensively for numerical computation. Much research in recent years has been aimed at efficient solvers in the difficult high frequency case, where the scatterer Γ, and thus the region D_R, are large in diameter compared to the wavelength, so that the solution u is highly oscillatory and standard discretization methods require very many degrees of freedom. This effort has included many important developments for the solution of (1.6) and similar integral equations, including higher order boundary element or Nyström schemes (e.g., [22]), fast multipole methods (e.g., [17]), generalized boundary element methods using oscillatory basis functions (e.g., [5, 32, 19]), and preconditioners for iterative solvers (e.g., [12]). Similarly, for the solution of (1.4) at high frequency, important recent developments have included the use of higher order *hp*-finite element methods (e.g., [2, 18]), the use of oscillatory basis functions (e.g., [31] and, for methods based on more general variational formulations, [7, 21]), and ray-based techniques (e.g., [28]).

An essential ingredient in the development of numerical analysis for these methods, in particular analysis which seeks to determine the behavior of algorithms as the wave number increases, is an understanding of how the stability constants of numerical schemes depend on the wave number. Quantification of the dependence on k of $\|A^{-1}\|$ and α, i.e., of stability constants for the continuous formulation, is an important step in this direction.

An additional and important practical issue in connection to (1.6) is how to choose the parameter η. A natural criterion when using (1.6) for numerical computation is to choose η so as to minimize the condition number cond $A := \|A\| \, \|A^{-1}\|$ (e.g., Kress and Spassov [30] and Kress [29]). To determine this optimal choice, information on the dependence of $\|A^{-1}\|$ on k and η is required and will be obtained in section 4.

Given the practical importance of the questions we will address, it is not surprising that a number of relevant investigations have been carried out previously. In particular, a number of authors have studied (1.6), or related integral equations, in the canonical case when Γ is a cylinder or sphere, i.e., $\Gamma = \Gamma_R$ for some $R > 0$, especially with the aim of determining η so as to minimize the $L^2(\Gamma)$ condition number of A [30, 29, 3, 23, 6, 19]. Particularly relevant are the results of Giebermann [23], which have recently been completed and put on a rigorous footing by Dominguez, Graham, and Smyshlyaev [19]. It is shown in [19] that, in the 2D case, if the choice $\eta = k$ is made, then

$$\|A^{-1}\|_2 \leq 1 \tag{1.9}$$

for all sufficiently large k (we are using $\|\cdot\|_2$ to denote both the norm on $L^2(\Gamma)$ and the induced operator norm on the space of bounded linear operators on $L^2(\Gamma)$). This result is obtained as a consequence of the coercivity result that

$$\Re(A\psi, \psi) \geq \|\psi\|_2^2 \quad \forall \psi \in L^2(\Gamma), \tag{1.10}$$

where $(\cdot, \cdot)$ is the usual scalar product on $L^2(\Gamma)$. The same coercivity result, but without an explicit value for the constant, is shown in the 3D case [19], so that, for the case when Γ is a sphere, it also holds that $\|A^{-1}\|_2 = O(1)$ as $k \to \infty$. We note that, even for these canonical cases, establishing such bounds is not straightforward and depends on explicit calculations of the spectrum of A and careful estimates of Bessel functions uniformly in argument and order.

Research of relevance to the wave number dependence of (1.4) has also been carried out. Indeed an explicit estimate of the dependence of the inf-sup constant on the wave number has been made previously in two cases. The first is what may be thought of as a one-dimensional (1D) analogue of (1.4), with $V_R := \{u \in H^1(0,1) : u(0) = 0\}$ and $b(\cdot, \cdot)$ defined by $b(u, v) := \int_0^1 u'\bar{v}' - k^2 u\bar{v} dx - \mathrm{i}k\bar{v}(1)u(1)$. The results for this case, due to Ihlenburg and Babuška [26, 27], summarized in [25], are obtained via explicit calculations of the Green's function for the corresponding boundary value problem, i.e., the solution of $u'' + k^2 u = \delta_y$ on $(0, 1)$ with $u(0) = 0$, $u'(1) = \mathrm{i}ku(1)$, where δ_y is the delta distribution supported at $y \in (0, 1)$. For this 1D problem it is shown that, for some constants $C_1 \leq C_2$, the inf-sup constant given by (1.8), with $\|u\|_{V_R}^2 = \int_0^1 |u'|^2 dx$, satisfies

$$\frac{C_1}{k} \leq \alpha \leq \frac{C_2}{k}. \tag{1.11}$$

Closer still to the results of this paper is the work of Melenk [35] (see also Cummings and Feng [16]), who considers the Helmholtz equation in a bounded domain D, which is either convex or sufficiently smooth and starlike, with the impedance boundary condition $\frac{\partial u}{\partial \nu} = \mathrm{i}k\eta u$ on ∂D, with the normal directed out of D and $\eta > 0$. The sesquilinear form in their case is $b : H^1(D) \times H^1(D) \to \mathbb{C}$ given by

$$b(u, v) := \int_D (\nabla u \cdot \nabla \bar{v} - k^2 u\bar{v}) \, dx - \mathrm{i}k\eta \int_\Gamma \gamma\bar{v}\gamma u \, ds. \tag{1.12}$$

With this definition of $b(\cdot,\cdot)$ they show that their inf-sup constant α satisfies

$$\alpha \geq \frac{C}{k}, \tag{1.13}$$

for some constant $C > 0$. The technique of argument used in [35] and [16] is to derive a Rellich-type identity, this technique being of wide applicability in obtaining a priori estimates for solutions of boundary value problems for strongly elliptic systems of PDEs; see, e.g., [38, 36, 34]. This approach, essentially a carefully chosen application of the divergence theorem, appears to depend essentially on the starlike nature of the domain to obtain the wave-number-explicit bound (1.13).

The arguments of [35] and [16] will be one ingredient of the methods we use in this paper. The general structure of the arguments, though little of the detail, will borrow heavily from two of our own recent papers [10, 8], where we show results analogous to those presented here, but for the case of *rough surface scattering*, i.e., the case where Γ is unbounded and is the graph of some bounded continuous function, and Ω_e is its epigraph. Assuming that the axes are oriented so that Γ is bounded in the x_n-direction, i.e., $f_- \leq x_n \leq f_+$ for $x = (x_1, \ldots, x_n) \in \Gamma$, for some constants f_- and f_+, the analogous sesquilinear form to (1.5) for this case is given by the same formula, provided that one redefines D_R and Γ_R by $D_R := \{x \in \Omega_e : x_n < R\}$ and $\Gamma_R := \{x \in \Omega_e : x_n = R\}$, chooses $R \geq f_+$, and sets T_R to be the Dirichlet-to-Neumann map for the Helmholtz equation in the upper half-space $\{x : x_n > f_+\}$. This Dirichlet-to-Neumann map is given explicitly as a composition of a multiplication operator and Fourier transform operators. With this definition of the sesquilinear form $b(\cdot,\cdot)$ and with the inf-sup constant defined by (1.8) with

$$\|u\|_{V_R} := \left\{ \int_{D_R} \left(|\nabla u|^2 + k^2 |u|^2 \right) dx \right\}^{1/2}, \tag{1.14}$$

we show in [10] the explicit bound for the rough surface problem

$$\alpha \geq (1 + \sqrt{2}\,\kappa\,(\kappa + 1)^2)^{-1}, \tag{1.15}$$

where $\kappa := k(R - f_-)$. In [8] we study an integral equation formulation for the same problem in the case when, additionally, the function of which Γ is the graph is continuously differentiable. For the integral equation formulation (1.7) for this problem (with the twist that S and K are defined with the standard fundamental solution $\Phi(x, y)$ replaced by the Dirichlet Green's function for a half-space containing Ω_e), we show the bound

$$||A^{-1}||_2 < 2 + 2L + 4L^2 + \frac{k}{\eta} \left(2 + 5L + 3L^{3/2} \right), \tag{1.16}$$

where L is the maximum surface slope.

We note that Claeys and Haddar [13] have recently adapted the arguments of [10] to study 3D acoustic scattering from an unbounded sound soft rough tubular surface, as an initial model of electromagnetic scattering by an infinite wire with a perturbed surface. They study a weak formulation which can be written in the form (1.4) with a sesquilinear form which can be written as (1.5), provided that one redefines Γ_R to be the infinite cylinder $\Gamma_R := \{x \in \mathbb{R}^3 : x_1^2 + x_2^2 = R^2\}$, D_R to be that part of the region outside the tubular surface but inside Γ_R, and T_R to be the appropriate Dirichlet-to-Neumann map for the Helmholtz equation in the region exterior to Γ_R. Their emphasis is on showing well-posedness for this problem, including showing that the inf-sup condition (1.8) holds, rather than on obtaining explicitly the k-dependence, but their results do imply a lower bound on α, that $\alpha^{-1} = O(k^3)$ as $k \to \infty$, the same k-dependence as for (1.15).

In this paper we will obtain analogous bounds to (1.11), (1.15), and (1.16) for the problem of scattering by a bounded sound soft obstacle. A major obstacle in achieving this aim is understanding the behavior of the Dirichlet-to-Neumann map T_R in sufficient detail. We address this issue in section 2, where our main new result is Lemma 2.1, a subtle property of radiating solutions of the Helmholtz equation, whose proof depends on a detailed understanding of monotonicity properties of Bessel functions. This lemma is essential to our results and, we expect, will be of value in deducing explicit bounds for a range of other wave scattering problems.

In section 3 we study the formulation (1.4). Our main results are, first, the upper bound on the inf-sup constant (1.8), which holds with no constraint on Γ, that

$$\alpha \leq \frac{C_1}{kR} + \frac{C_2}{k^2R^2},$$

where the constants $C_1 \geq 2\sqrt{2}$ and C_2 depend on the shape of the domain. (Our norm $\|\cdot\|_{V_R}$ in (1.8) is the wave number dependent norm given by (1.14).) In the case that the scattering obstacle Ω is starlike in the sense that $x \in \Omega$ implies $sx \in \Omega$ for $0 \leq s < 1$, we also show a lower bound, so that it holds that

$$\frac{1}{5 + 4\sqrt{2}kR} \leq \alpha \leq \frac{C_1}{kR} + \frac{C_2}{k^2R^2}. \tag{1.17}$$

We note that this bound establishes that, when Ω is starlike, α decreases like k^{-1} as $k \to \infty$ (cf. (1.11)). Finally, we produce an example (scattering by two parallel plates) for which

$$\alpha \leq \frac{C}{k^2R^2}$$

for some constant C and unbounded sequence of values of k, showing that the lower bound in (1.17) need not hold if Ω is not starlike. We emphasize that these appear to be the first bounds on the inf-sup constant in the literature for any problem of time-harmonic scattering by a bounded obstacle in more than one dimension that make the dependence on the wave number explicit.

We turn in section 4 to the integral equation formulation (1.7). We restrict our attention to the case when Ω is starlike and Γ is Lipschitz and piecewise smooth (e.g., a starlike polyhedron). Our main result is a bound on $\|A^{-1}\|_2$ (Theorem 4.3) as a function of three geometrical parameters and the ratio k/η of the wave number to the coupling parameter. Importantly this bound shows that, if the ratio k/η is kept fixed, then $\|A^{-1}\|_2$ remains bounded as $k \to \infty$. In particular, if the choice $\eta = k$ is made, then, for $kR_0 \geq 1$,

$$\|A^{-1}\|_2 \leq \frac{1}{2}\left(1 + \theta(4\theta + 4n + 1)\right), \tag{1.18}$$

where $n = 2$ or 3 is the dimension, $\theta := R_0/\delta_-$, and $\delta_- > 0$ is the essential infimum of $x \cdot \nu$ over the surface Γ (for example, $\theta = 1$ for a sphere, and $\theta = \sqrt{3}$ for a cube). A sharper (but more complicated) bound is given in Corollary 4.4. We note that a value of η/k in the range $1/2 \leq \eta/k \leq 1$ has been recommended based on studies of the integral operator A for circular and spherical geometries [30, 29, 3, 23, 19] as minimizing, approximately, the L^2 condition number of A.

We emphasize that the only results comparable to (1.18) to date are the bounds discussed above for the case when Γ is a circle or sphere, obtained by methods specialized to circular/spherical geometry. Even for this geometry the only completely explicit bound is (1.9), shown to hold for a circle for all sufficiently large k. Our general methods give the bound (4.15) for this case, which is almost as sharp a result, implying that, for every $\beta > 5/2$, $\|A^{-1}\|_2 \leq \beta$ for all sufficiently large kR_0, where R_0 is the radius of the circle.

2. Preliminaries. It is convenient to separate in an initial section two key lemmas which are essential ingredients in the arguments we will make to obtain wavenumber-explicit bounds for both of our formulations of the scattering problem, and to gather here other material common to both formulations.

Our arguments in this paper will depend on explicit representations for solutions of the Helmholtz equation in the exterior of a large ball. These depend in turn on explicit properties of cylindrical and spherical Bessel functions. For $\nu \geq 0$, let J_ν and Y_ν denote the usual Bessel functions of the first and second kind of order ν (see, e.g., [1] for definitions) and let $H_\nu^{(1)} := J_\nu + \mathrm{i}Y_\nu$ denote the corresponding Hankel function of the first kind of order ν. Of course, where C_ν denotes any linear combination of J_ν and Y_ν, it holds that C_ν is a solution of Bessel's equation of order ν, i.e.,

$$z^2 C_\nu''(z) + zC_\nu'(z) + (z^2 - \nu^2)C_\nu(z) = 0. \tag{2.1}$$

In the 3D case it is convenient to work also with the spherical Bessel functions j_m, y_m, and $h_m^{(1)} := j_m + \mathrm{i}y_m$ for $m = 0, 1, \ldots$. These can be defined directly (see, e.g., Nédélec [39]) by recurrence relations which imply that $h_m^{(1)}(z) = \mathrm{e}^{\mathrm{i}z}p_m(z^{-1})$, where p_m is a polynomial of degree m with $p_m(0) = 1$. Alternatively, the spherical Bessel functions can be defined in terms of the usual Bessel functions via the relations

$$j_m(z) = \sqrt{\frac{\pi}{2z}} J_{m+1/2}(z), \quad y_m(z) = \sqrt{\frac{\pi}{2z}} Y_{m+1/2}(z). \tag{2.2}$$

It is convenient to introduce the notation

$$M_\nu(z) := |H_\nu^{(1)}(z)|, \quad N_\nu(z) := |H_\nu^{(1)\prime}(z)|.$$

The arguments we make depend on the fact that $M_\nu(z)$ is decreasing on the positive real axis for $\nu \geq 0$; indeed, for $\nu \geq \frac{1}{2}$ it holds that $zM_\nu^2(z)$ is nonincreasing [42, sect. 13.74]. This latter fact, together with the asymptotics of $M_\nu(z)$ [1, eq. (9.2.28)] that

$$M_\nu(z) = \sqrt{\frac{2}{\pi z}} + O(z^{-5/2}) \text{ as } z \to \infty, \tag{2.3}$$

implies that

$$zM_\nu^2(z) \geq \frac{2}{\pi} \quad \text{for } z > 0,\ \nu \geq \frac{1}{2}. \tag{2.4}$$

It follows easily from the Bessel equation (2.1) that

$$(z^2 - \nu^2)\frac{d}{dz}\left(M_\nu^2(z)\right) + \frac{d}{dz}\left(z^2 N_\nu^2(z)\right) = 0.$$

Thus, defining the function A_ν for $\nu \geq 0$ by

$$A_\nu(z) := M_\nu^2(z)(z^2 - \nu^2) + z^2 N_\nu^2(z) - \frac{4z}{\pi}, \quad z > 0, \tag{2.5}$$

it holds that

$$A'_\nu(z) = 2zM_\nu^2(z) - \frac{4}{\pi}. \tag{2.6}$$

Thus $A'_\nu(z) \geq 0$ for $\nu \geq \frac{1}{2}$ and $z > 0$ by (2.4). Further, from (2.3) and the same asymptotics for N_ν [1, eq. (9.2.30)], i.e.,

$$N_\nu(z) = \sqrt{\frac{2}{\pi z}} + O(z^{-5/2}) \text{ as } z \to \infty,$$

it follows that $A_\nu(z) \to 0$ as $z \to \infty$ for $\nu \geq 0$. Thus

$$A_\nu(z) \leq 0 \quad \text{for } z > 0,\ \nu \geq \frac{1}{2}. \tag{2.7}$$

It is convenient in the following key lemma and later to use the notation $G_R := \{x : |x| > R\}$ for $R > 0$. In addition, throughout this paper $\nabla_T v$ denotes the tangential component of ∇v, i.e., $\nabla_T v := \nabla v - \nu \partial v / \partial \nu$.

LEMMA 2.1. *Suppose that, for some $R_0 > 0$, $v \in C^2(G_{R_0})$ satisfies the Helmholtz equation* (1.1) *in G_{R_0} and the Sommerfeld radiation condition* (1.3)*. Then, for $R > R_0$,*

$$\Im \int_{\Gamma_R} \bar{v} \frac{\partial v}{\partial r}\, ds \geq 0, \quad \Re \int_{\Gamma_R} \bar{v} \frac{\partial v}{\partial r}\, ds \leq 0, \tag{2.8}$$

and

$$\Re \int_{\Gamma_R} \bar{v} \frac{\partial v}{\partial r}\, ds + R \int_{\Gamma_R} \left(k^2 |v|^2 + \left| \frac{\partial v}{\partial r} \right|^2 - |\nabla_T v|^2 \right) ds \leq 2kR\, \Im \int_{\Gamma_R} \bar{v} \frac{\partial v}{\partial r}\, ds. \tag{2.9}$$

Remark 2.2. The first two inequalities (2.8) are well known; see, for example, Nédélec [39]. The third inequality appears to be new, but we note that an analogous inequality [11, Lemma 6.1], [10, Lemma 2.2] has been used extensively in the mathematical analysis of problems of scattering by unbounded rough surfaces. This inequality (proved easily by Fourier transform methods) can be viewed as a (formal) limit of (2.9) in the limit $R \to \infty$. Closer still to (2.9) is the recent inequality of Claeys and Haddar [13, Lemma 4.4], who study the Dirichlet-to-Neumann map for the Helmholtz equation in the exterior of an infinite cylinder in $\mathbb{R}^3$. In fact, their inequality implies, at least formally, the following less sharp version of (2.9) in the 2D case: for every $\rho_0 > 0$ there exists a constant $C > 0$ such that, provided that $kR > \rho_0$,

$$2\Re \int_{\Gamma_R} \bar{v} \frac{\partial v}{\partial r}\, ds + R \int_{\Gamma_R} \left(k^2 |v|^2 + \left| \frac{\partial v}{\partial r} \right|^2 - |\nabla_T v|^2 \right) ds \leq C(1 + kR)\, \Im \int_{\Gamma_R} \bar{v} \frac{\partial v}{\partial r}\, ds.$$

Proof. Note first that, by standard elliptic regularity results, it holds that $v \in C^\infty(G_{R_0})$. We now deal with the 2D and 3D cases separately.

Suppose first that $n = 2$. Choose $R_1 \in (R_0, R)$. Introducing standard cylindrical polar coordinates, we expand v on Γ_{R_1} as the Fourier series

$$v(x) = \sum_{m\in\mathbb{Z}} a_m \mathrm{e}^{\mathrm{i}m\theta},$$

where (R_1, θ) are the polar coordinates of x. Since $v \in C^\infty(\Gamma_{R_1})$ it holds that the series is rapidly converging, i.e., that $a_m = o(|m|^{-p})$ as $|m| \to \infty$ for every $p > 0$. It is standard that the corresponding Fourier series representation of v in G_{R_1} is

$$v(x) = \sum_{m\in\mathbb{Z}} a_m \mathrm{e}^{\mathrm{i}m\theta} \frac{H^{(1)}_{|m|}(kr)}{H^{(1)}_{|m|}(kR_1)}, \tag{2.10}$$

where (r, θ) are now the polar coordinates of x, and that this series, and all its partial derivatives with respect to r and θ, converge absolutely and uniformly in G_{R_1}. Hence, defining $c_m := (|a_m|^2 + |a_{-m}|^2)/|H^{(1)}_m(kR_1)|^2$ and $\rho := kR$, and using the orthogonality of $\{\mathrm{e}^{\mathrm{i}m\theta} : m \in \mathbb{Z}\}$, we see that

$$\begin{aligned}
\int_{\Gamma_R} \bar{v}\frac{\partial v}{\partial r}\, ds &= 2\pi\rho \sum_{m\in\mathbb{Z}} |a_m|^2 \frac{\overline{H^{(1)}_{|m|}(\rho)}\, {H^{(1)}_{|m|}}'(\rho)}{|H^{(1)}_{|m|}(kR_1)|^2} \\
&= 2\pi\rho \sum_{m=0}^{\infty} c_m \left(\Re\left(\overline{H^{(1)}_m(\rho)}\, {H^{(1)}_m}'(\rho)\right) + \mathrm{i}\,(J_m(\rho)Y_m'(\rho) - J_m'(\rho)Y_m(\rho))\right) \\
&= \sum_{m=0}^{\infty} c_m \left(\pi\rho \frac{d}{d\rho}\left(M_m^2(\rho)\right) + 4\mathrm{i}\right), \qquad (2.11)
\end{aligned}$$

where in the last step we have used the Wronskian formula [1, eq. (9.1.16)], i.e.,

$$\pi\rho(J_\nu(\rho)Y_\nu'(\rho) - J_\nu'(\rho)Y_\nu(\rho)) = 2. \tag{2.12}$$

Since $M_m(\rho)$ is decreasing on $(0, \infty)$ we see that (2.8) holds.

Similarly, noting that $|\nabla_T v| = R^{-1}|\partial v/\partial\theta|$, we calculate that

$$R\int_{\Gamma_R} \left(k^2|v|^2 + \left|\frac{\partial v}{\partial r}\right|^2 - |\nabla_T v|^2\right) ds = 2\pi \sum_{m=0}^{\infty} c_m \left(M_m^2(\rho)(\rho^2 - m^2) + \rho^2 N_m^2(\rho)\right).$$

From this equation and (2.11), and recalling the definition (2.5), we see that we will complete the proof of (2.9) if we can show the inequality

$$\frac{\rho}{2}\frac{d}{d\rho}\left(M_m^2(\rho)\right) + A_m(\rho) \le 0 \tag{2.13}$$

for $\rho > 0$ and $m = 0, 1, \ldots$.

By (2.7) and since M_m is decreasing on $(0, \infty)$, we see that (2.13) holds for $\rho > 0$ and $m \in \mathbb{N}$. To finish the proof of (2.9) in the case $n = 2$ we need to show (2.13) for $m = 0$, i.e., that

$$A(\rho) := \frac{\rho}{2}\frac{d}{d\rho}\left(M_0^2(\rho)\right) + A_0(\rho) \le 0, \quad \rho > 0.$$

Now $A(\rho) = \rho(J_0(\rho)J_0'(\rho) + Y_0(\rho)Y_0'(\rho)) + A_0(\rho)$; thus, using (2.1) and (2.6), it follows that

$$A'(\rho) = A_0'(\rho) + \rho\left(N_0^2(\rho) - M_0^2(\rho)\right) = \rho\left(M_0^2(\rho) + N_0^2(\rho)\right) - \frac{4}{\pi} = \frac{A_0(\rho)}{\rho}.$$

Thus

$$\frac{d}{d\rho}\left(\frac{A(\rho)}{\rho}\right) = \frac{A'(\rho)}{\rho} - \frac{A(\rho)}{\rho^2} = -\frac{1}{2\rho}\frac{d}{d\rho}\left(M_0^2(\rho)\right) \geq 0.$$

Also, since from the standard large argument asymptotics of the Bessel functions, $A(\rho)/\rho \to 0$ as $\rho \to \infty$, it follows that $A(\rho) \leq 0$ for $\rho > 0$. This completes the proof for $n = 2$.

We turn now to the 3D case for which we make analogous arguments, though the details are different. Again we choose $R_1 \in (R_0, R)$. Introducing standard spherical polar coordinates (r, θ, ϕ), we expand v on Γ_{R_1} as the spherical harmonic expansion

$$v(x) = \sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{\ell} a_\ell^m Y_\ell^m(\theta, \phi), \tag{2.14}$$

where (R_1, θ, ϕ) are the spherical polar coordinates of x and the functions Y_ℓ^m, $m = -\ell, \dots, \ell$, are the standard spherical harmonics of order ℓ (see, for example, [39, Theorem 2.4.4]). We recall (e.g., [39]) that $\{Y_\ell^m : \ell = 0, 1, \dots,\ m = -\ell, \dots, \ell\}$ is a complete orthonormal sequence in $L^2(S)$, where $S := \{x : |x| = 1\}$ is the unit sphere, and an orthogonal sequence in $H^1(S)$. Since $v \in C^\infty(\Gamma_{R_1}) \supset H^m(S)$, for all $m \in \mathbb{N}$, it holds that the series is rapidly converging, i.e., that $a_\ell^m = o(|\ell|^{-p})$ as $|\ell| \to \infty$ for every $p > 0$ [39].

The solution of the Dirichlet problem for the Helmholtz equation in the exterior of a sphere is discussed in detail in [39]. It follows from (2.14) and [39, eq. (2.6.55)] that, for $x \in G_{R_1}$,

$$v(x) = \sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{\ell} a_\ell^m Y_\ell^m(\theta, \phi)\frac{h_\ell^{(1)}(kr)}{h_\ell^{(1)}(kR_1)}, \tag{2.15}$$

where (r, θ, ϕ) are now the polar coordinates of x, and hence that [39, eqs. (2.6.70)–(2.6.74)]

$$\frac{\partial v}{\partial r}(x) = k\sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{\ell} a_\ell^m Y_\ell^m(\theta, \phi)\frac{{h_\ell^{(1)}}'(kr)}{h_\ell^{(1)}(kR_1)}, \tag{2.16}$$

$$\nabla_T v(x) = \frac{1}{r}\sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{\ell} a_\ell^m \nabla_S Y_\ell^m(\theta, \phi)\frac{h_\ell^{(1)}(kr)}{h_\ell^{(1)}(kR_1)},$$

where ∇_S is the surface gradient operator on S and

$$\int_S |\nabla_S Y_\ell^m|^2\, ds = \ell(\ell + 1). \tag{2.17}$$

Hence, using the orthonormality in $L^2(S)$ of the spherical harmonics Y_ℓ^m, we see that, where $c_\ell := |h_\ell^{(1)}(kR_1)|^{-2} \sum_{m=-\ell}^{\ell} |a_\ell^m|^2$ and $\rho := kR$,

$$\int_{\Gamma_R} \bar{v} \frac{\partial v}{\partial r}\, ds = R^2 \int_S \bar{v}(R\hat{x}) \frac{\partial v}{\partial r}(R\hat{x})\, ds(\hat{x}) = R\rho \sum_{\ell=0}^{\infty} c_\ell\, \overline{h_\ell^{(1)}(\rho)} h_\ell^{(1)\prime}(\rho)$$

$$= R \sum_{\ell=0}^{\infty} c_\ell \left(\frac{\rho}{2} \frac{d}{d\rho} \left(|h_\ell^{(1)}(\rho)|^2 \right) + \frac{\mathrm{i}}{\rho} \right), \tag{2.18}$$

where in the last step we have used (2.2) and (2.12). Recalling that $|h_\ell^{(1)}(\rho)| = \sqrt{\pi/(2\rho)} M_{\ell+1/2}(\rho)$ is decreasing on $(0,\infty)$, we see that (2.8) holds.

Similarly, but also using the orthogonality of the surface gradients $\nabla_S Y_\ell^m$ in $L^2(S)$ and (2.17), we calculate that

$$\int_{\Gamma_R} \left(k^2 |v|^2 + \left| \frac{\partial v}{\partial r} \right|^2 - |\nabla_T v|^2 \right) ds$$
$$= \sum_{\ell=0}^{\infty} c_\ell \left(|h_\ell^{(1)}(\rho)|^2 (\rho^2 - \ell(\ell+1)) + \rho^2 |h_\ell^{(1)\prime}(\rho)|^2 \right).$$

Thus

$$\Re \int_{\Gamma_R} \bar{v} \frac{\partial v}{\partial r}\, ds + R \int_{\Gamma_R} \left(k^2 |v|^2 + \left| \frac{\partial v}{\partial r} \right|^2 - |\nabla_T v|^2 \right) ds - 2kR\, \Im \int_{\Gamma_R} \bar{v} \frac{\partial v}{\partial r}\, ds$$
$$= \frac{1}{k} \sum_{\ell=0}^{\infty} c_\ell B_\ell(\rho),$$

where

$$B_\ell(\rho) := \frac{\rho^2}{2} \frac{d}{d\rho} \left(|h_\ell^{(1)}(\rho)|^2 \right) + |h_\ell^{(1)}(\rho)|^2 \rho (\rho^2 - \ell(\ell+1)) + \rho^3 |h_\ell^{(1)\prime}(\rho)|^2 - 2\rho.$$

But straightforward calculations, using the definitions (2.2), yield that

$$B_\ell(\rho) = \frac{\pi}{2} A_{\ell+1/2}(\rho), \quad \rho > 0,\ \ell = 0, 1, \ldots.$$

Thus, applying (2.7), we see that $B_\ell(\rho) \le 0$ for $\ell = 0, 1, \ldots$ and $\rho > 0$, which completes the proof of (2.9). ∎

The following lemma is another key component in obtaining our wave-number-explicit bounds. Of course, the first equation is just a special case of Green's first theorem. The second is a Rellich–Payne–Weinberger identity, essentially that used in [35] to obtain an estimate for the solution of the Helmholtz equation with impedance boundary condition in an interior domain (see also [16]). In the case $k = 0$ it is a special case of a general identity for second order strongly elliptic operators given in Lemma 4.22 of [34] (see also [38, Chapter 5]). For completeness, we include the short proof of this key step in our arguments.

LEMMA 2.3. *Suppose that $G \subset \mathbb{R}^n$ is a bounded Lipschitz domain and that $v \in H^2(G)$. Then, for every $k \geq 0$, where $g := \Delta v + k^2 v$ and the unit normal vector ν is directed out of G, it holds that*

$$\int_G \left(|\nabla v|^2 - k^2|v|^2 + g\bar{v}\right)\, dx = \int_{\partial G} \bar{v}\,\frac{\partial v}{\partial \nu}\, ds \tag{2.19}$$

and

$$\int_G \left((2-n)|\nabla v|^2 + nk^2|v|^2 + 2\Re\left(gx\cdot\nabla\bar{v}\right)\right)\, dx$$

$$= \int_{\partial G} \left(x\cdot\nu \left(k^2|v|^2 + \left|\frac{\partial v}{\partial \nu}\right|^2 - |\nabla_T v|^2 \right) + 2\Re\left(x\cdot\nabla_T \bar{v}\,\frac{\partial v}{\partial \nu}\right)\right)\, ds. \tag{2.20}$$

Proof. In the case $v \in C^2(\bar{G})$, these equations are a consequence of the divergence theorem, $\int_G \nabla\cdot F dx = \int_{\partial G} f\cdot\nu ds$, which holds for every vector field $F \in C^1(\bar{G})$ (see, e.g., McLean [34] for the case when G is Lipschitz). Equation (2.19) follows by applying the divergence theorem to the identity $|\nabla v|^2 - k^2|v|^2 + g\bar{v} = \nabla\cdot(\bar{v}\nabla v)$ integrated over G. Equation (2.20) follows by applying the divergence theorem to the identity

$$(2-n)|\nabla v|^2 + nk^2|v|^2 + 2\Re\left(gx\cdot\nabla\bar{v}\right) = \nabla\cdot\left[x\left(k^2|v|^2 - |\nabla v|^2\right) + 2\Re\left(x\cdot\nabla\bar{v}\nabla v\right)\right]$$

integrated over G, and then noting that $x\cdot\nabla v = x\cdot\nu\frac{\partial v}{\partial\nu} + x\cdot\nabla_T v$ on ∂G. The extension from $C^2(\bar{G})$ to $H^2(G)$ follows by the density of $C^2(\bar{G})$ in $H^2(G)$ and by the continuity of the trace operator $\gamma : H^1(G) \to H^{1/2}(\partial G)$. ∎

3. The scattering problem and weak formulation. In this section we formulate the scattering problem precisely, state its weak formulation, and obtain explicit lower bounds on the inf-sup constant (1.8), using the results of the previous section.

To state precisely the scattering problem we wish to solve, let $H_0^1(\Omega_e) \subset H^1(\Omega_e)$ denote the closure of $C_0^\infty(\Omega_e)$, the set of C^∞ functions on Ω_e that are compactly supported, in the norm of the Sobolev space $H^1(\Omega_e)$. Let $H_0^{1,\mathrm{loc}}(\Omega_e)$ denote the set of those functions, v, that are locally integrable on Ω_e and satisfy that $\psi\chi \in H_0^1(\Omega_e)$ for every compactly supported $\chi \in C^\infty(\bar{\Omega}_e) := \{v|_{\bar{\Omega}_e} : v \in C^\infty(\mathbb{R}^n)\}$. Then our scattering problem can be stated as follows. For simplicity of exposition we restrict our attention throughout to two specific cases. The first is when the incident wave u^i is the plane wave

$$u^i(x) := \mathrm{e}^{\mathrm{i}kx_1}, \quad x \in \mathbb{R}^n. \tag{3.1}$$

THE PLANE WAVE SCATTERING PROBLEM. *Given $k > 0$, find $u \in H_0^{1,\mathrm{loc}}(\Omega_e) \cap C^2(\Omega_e)$ such that u satisfies the Helmholtz equation* (1.1) *in Ω_e, and $u^s := u - u^i$ satisfies the Sommerfeld radiation condition* (1.3) *as $r = |x| \to \infty$, uniformly in $\hat{x} = x/r$.*

The above is the scattering problem that we will focus on in this paper. But it is essential to our methods of argument in this section to also consider the following scattering problem where the source of the acoustic excitation is due to a compactly supported source region in Ω_e.

THE DISTRIBUTED SOURCE SCATTERING PROBLEM. *Given $k > 0$ and $g \in L^2(\Omega_e)$ which is compactly supported, find $u \in H_0^{1,\mathrm{loc}}(\Omega_e)$ such that u satisfies the inhomogeneous Helmholtz equation*

$$\Delta u + k^2 u = g \quad \text{in } \Omega_e \tag{3.2}$$

in a distributional sense, and u satisfies the Sommerfeld radiation condition (1.3) *as $r = |x| \to \infty$, uniformly in $\hat{x} = x/r$.*

Recall that, for $R > R_0 := \sup_{x\in\Omega} |x|$, we define $D_R := \{x \in \Omega_e : |x| < R\}$ and $V_R := \{v|_{D_R} : v \in H_0^1(\Omega_e)\} \subset H^1(D_R)$. We note that V_R is a closed subspace of $H^1(D_R)$. Throughout this section, $(\cdot,\cdot)$ will denote the standard scalar product on $L^2(D_R)$ and $\|\cdot\|_2$ the corresponding norm; i.e.,

$$(u, v) := \int_{D_R} u\bar{v}\,dx, \quad \|v\|_2 := (v, v)^{1/2} = \left\{\int_{D_R} |v|^2\,dx\right\}^{1/2}.$$

It is convenient to equip V_R with a wave number dependent norm, equivalent to the usual norm on $H^1(D_R)$ and defined by (1.14).

As discussed in section 1, our first reformulation of the plane wave scattering problem is the following weak formulation: find $u \in V_R$ such that

$$b(u, v) = G(v), \quad v \in V_R. \tag{3.3}$$

In this equation b is the bounded sesquilinear form on V_R given by (1.5), and $G \in V_R^*$, the dual space of V_R, is given by

$$G(v) = \int_{\Gamma_R} \bar{v}\left(\frac{\partial u^i}{\partial r} - T_R u^i\right) ds. \tag{3.4}$$

As defined in section 1, the operator $T_R : H^{1/2}(\Gamma_R) \to H^{-1/2}(\Gamma_R)$, which occurs in both (1.5) and (3.4), is the Dirichlet-to-Neumann map. Explicitly, in the 2D case, if $\phi \in H^{1/2}(\Gamma_R)$ has the Fourier series expansion

$$\phi(x) = \sum_{m\in\mathbb{Z}} a_m \mathrm{e}^{\mathrm{i}m\theta},$$

where (R, θ) are the polar coordinates of x, then (see (2.10) or [25])

$$T_R\phi(x) = k \sum_{m\in\mathbb{Z}} a_m \mathrm{e}^{\mathrm{i}m\theta} \frac{H_{|m|}^{(1)\prime}(kr)}{H_{|m|}^{(1)}(kR)}, \quad x \in \Gamma_R. \tag{3.5}$$

Similarly, in the 3D case, if $\phi \in H^{1/2}(\Gamma_R)$ has the expansion in spherical harmonics

$$\phi(x) = \sum_{\ell=0}^{\infty} \sum_{m=-\ell}^{\ell} a_\ell^m Y_\ell^m(\theta, \phi),$$

where (R, θ, ϕ) are the spherical polar coordinates of x, then (see (2.16) or [39])

$$T_R\phi(x) = k \sum_{\ell=0}^{\infty} \sum_{m=-\ell}^{\ell} a_\ell^m Y_\ell^m(\theta, \phi) \frac{h_\ell^{(1)\prime}(kr)}{h_\ell^{(1)}(kR)}, \quad x \in \Gamma_R, \tag{3.6}$$

where both series (3.5) and (3.6) are convergent in the norm of $H^{-1/2}(\Gamma_R)$. Moreover, from Lemma 2.1, we have the following key properties of T_R (see [39]).

COROLLARY 3.1. *For all $R > 0$ and all $\phi \in H^{1/2}(\Gamma_R)$ it holds that*

$$\Re \int_{\Gamma_R} \bar{\phi} T_R \phi \, ds \leq 0 \text{ and } \Im \int_{\Gamma_R} \bar{\phi} T_R \phi \, ds \geq 0.$$

That the plane wave scattering problem and the weak formulation (3.3) are equivalent is standard. Precisely, we have the following result (see, e.g., [25] or [39]).

THEOREM 3.2. *If u is a solution to the plane wave scattering problem, then $u|_{D_R} \in V_R$ satisfies* (3.3). *Conversely, suppose $u \in V_R$ satisfies* (3.3), *let $F_R := \gamma u^s$ be the trace of $u^s = u - u^i$ on Γ_R, and extend the definition of $u = u^i + u^s$ to Ω_e by setting $u^s|_{G_R}$ to be the solution of the Dirichlet problem in G_R, with data F_R on Γ_R (this solution is given explicitly by* (2.10) *and* (2.15), *in the cases $n = 2$ and $n = 3$, respectively). Then this extended function satisfies the plane wave scattering problem.*

In the case that $\text{supp}(g) \subset \overline{D_R}$, the distributed source scattering problem is equivalent, in the same precise sense as in the above theorem, to the following variational problem: find $u \in V_R$ such that

$$b(u, v) = -(g, v), \quad v \in V_R. \tag{3.7}$$

It is well known that both scattering problems have exactly one solution. Indeed this follows from the above equivalence and the fact that the variational problem (3.3) has exactly one solution $u \in V_R$ for every $G \in V_R^*$ (see, e.g., [25, 39]). In turn, this follows from uniqueness for the scattering problem (which follows from Rellich's lemma [14]) and from the fact that $b(\cdot, \cdot)$ satisfies a Gårding inequality [25, 39] (the first inequality in Corollary 3.1 plays a role here together with the compactness of the embedding operator from V_R to $L^2(D_R)$). Further, we have the following standard stability estimate (see [25, Remark 2.20]).

LEMMA 3.3. *The inf-sup condition* (1.8) *holds and, for all $u \in V_R$ and $\mathcal{G} \in V_R^*$ satisfying* (3.3), *it holds that*

$$\|u\|_{V_R} \leq C \|\mathcal{G}\|_{V_H^*}, \tag{3.8}$$

with $C = \alpha^{-1}$. Conversely, if there exists $C > 0$ such that, for all $u \in V_R$ and $\mathcal{G} \in V_R^*$ satisfying (3.3), *the bound* (3.8) *holds, then the inf-sup condition* (1.8) *holds with $\alpha \geq C^{-1}$.*

The second part of the above lemma shows that we obtain a lower bound on the inf-sup constant α if we show the bound (3.8) for all $u \in V_R$ and $\mathcal{G} \in V_R^*$ satisfying (3.3), and this will be the strategy that we will employ to obtain wave-number-explicit lower bounds on α. The following lemma reduces the problem of establishing (3.8) to that of establishing an a priori bound for solutions of the special case (3.7). The proof (very close to that of [10, Lemma 4.5]) depends on the observation that if $u \in V_R$ satisfies (3.3), then $u = u_0 + w$, where $u_0, w \in V_R$ satisfy

$$b_0(u_0, v) = \mathcal{G}(v) \quad \text{ and } \quad b(w, v) = 2k^2(u_0, v) \quad \forall v \in V_R,$$

where $b_0 : V_R \times V_R \to \mathbb{C}$ is defined by

$$b_0(u, v) = (\nabla u, \nabla v) + k^2(u, v) - \int_{\Gamma_R} \gamma \overline{v} \, T_R \gamma u \, ds, \quad u, v \in V_R.$$

It follows from Corollary 3.1 that $\Re\, b_0(v,v) \geq \|v\|^2_{V_R}$, $v \in V_R$, so that $\|u_0\|_{V_R} \leq \|\mathcal{G}\|_{V_R^*}$ by Lax–Milgram, and (3.9) and (1.14) imply that $\|w\|_{V_R} \leq 2k\tilde{C}\|u_0\|_2 \leq 2\tilde{C}\|\mathcal{G}\|_{V_R^*}$.

LEMMA 3.4. *Suppose there exists $\tilde{C} > 0$ such that, for all $u \in V_R$ and $g \in L^2(D_R)$ satisfying* (3.7), *it holds that*

$$\|u\|_{V_R} \leq k^{-1}\tilde{C}\,\|g\|_2. \tag{3.9}$$

Then, for all $u \in V_R$ and $\mathcal{G} \in V_R^*$ satisfying (3.3), *the bound* (3.8) *holds with $C \leq 1 + 2\,\tilde{C}$.*

We have reduced the problem of obtaining lower bounds on the inf-sup constant to the problem of obtaining a bound on the solution to a scattering problem, namely the distributed source scattering problem stated above. We will shortly bootstrap to the case where we require no smoothness on Γ, but our first bound on the solution to this problem is restricted to the case where Γ is smooth and Ω is starlike. Specifically, we require the following assumption.

Assumption 1. Let $S := \{x \in \mathbb{R}^n : |x| = 1\}$. For some $f \in C^\infty(S, \mathbb{R})$ with $\min_{\hat{x}\in S} f(\hat{x}) > 0$, it holds that $\Gamma = \{f(\hat{x})\hat{x} : \hat{x} \in S\}$.

LEMMA 3.5. *Suppose that Assumption* 1 *holds, u is a solution to the distributed source scattering problem, $R > R_0$, and* $\mathrm{supp}(g) \subset \overline{D_R}$. *Then*

$$k\|u\|_{V_R} \leq (n - 1 + 2\sqrt{2}kR)\|g\|_2. \tag{3.10}$$

Proof. Since D_R is a smooth domain, by standard elliptic regularity results [24] we have that $u \in H^{2,\mathrm{loc}}(D_R)$. Thus we can apply Lemma 2.3 to u in D_R to get, by adding $n-1$ times the real part of (2.19) to (2.20), that

$$\int_{D_R} \left(|\nabla u|^2 + k^2|u|^2 + \Re\left(g(2x\cdot\nabla\bar{u} + (n-1)\bar{u})\right)\right)\,dx = -\int_\Gamma x\cdot\nu\left|\frac{\partial u}{\partial\nu}\right|^2 ds$$
$$+ \int_{\Gamma_R}\left(R\left(k^2|u|^2 + \left|\frac{\partial u}{\partial r}\right|^2 - |\nabla_T u|^2\right) + \Re\left((n-1)\bar{u}\,\frac{\partial u}{\partial r}\right)\right)\,ds,$$

where we have also used the Dirichlet boundary condition (1.2), that is, $u = 0$ on Γ.

Since $x\cdot\nu > 0$ on Γ, applying Lemma 2.1 and then using (2.19), we see that

$$\int_{D_R}\left(|\nabla u|^2 + k^2|u|^2 + \Re\left(g(2x\cdot\nabla\bar{u} + (n-1)\bar{u})\right)\right)\,dx$$
$$\leq 2kR\,\Im\int_{\Gamma_R}\bar{u}\frac{\partial u}{\partial r}\,ds = 2kR\,\Im\int_{D_R} g\bar{u}\,dx.$$

Applying the Cauchy–Schwarz inequality and noting that

$$2ab \leq \epsilon a^2 + \frac{b^2}{\epsilon}, \tag{3.11}$$

for $a, b \geq 0$, $\epsilon > 0$, we deduce that

$$\|u\|^2_{V_R} \leq (n-1+2kR)\|g\|_2\|u\|_2 + 2R\|g\|_2\|\nabla u\|_2$$
$$\leq \frac{1}{2}\|u\|^2_{V_R} + \frac{\|g\|_2^2}{2k^2}(4k^2R^2 + (n-1+2kR)^2).$$

Thus

$$k^2\|u\|_{V_R}^2 \le \|g\|_2^2(4k^2R^2 + (n-1+2kR)^2),$$

from which (3.10) follows. ∎

Combining Lemmas 3.3, 3.4, and 3.5, we obtain the following corollary.

COROLLARY 3.6. *If Assumption* 1 *is satisfied, then the inf-sup condition* (1.8) *holds with* $\alpha^{-1} \le 1 + 2(n-1+2\sqrt{2}kR) \le 5 + 4\sqrt{2}kR$.

We proceed now to establish that Lemma 3.5 and Corollary 3.6 hold if Ω is starlike. Precisely, we require only the following, relaxed version of Assumption 1.

Assumption 2. It holds that $0 \notin \Omega_e$ and, if $x \in \Omega_e$, then $sx \in \Omega_e$ for every $s > 1$.

To establish these generalizations we first prove the following technical lemma (cf. [10, Lemma 4.10]).

LEMMA 3.7. *If Assumption* 2 *holds, then, for every* $\phi \in C_0^\infty(\Omega_e)$ *and* $R > R_0$, *there exists* $f \in C^\infty(S,\mathbb{R})$ *with* $\min_{\hat{x}\in S} f(\hat{x}) > 0$ *such that*

$$\operatorname{supp}\phi \subset \Omega_e' := \{sf(\hat{x}) \in \mathbb{R}^n : \hat{x} \in S,\ s > 1\}$$

and $\overline{G_R} \subset \Omega_e' \subset \Omega_e$.

Proof. Clearly, it is sufficient to consider the case when $R = 1$. So suppose $R = 1$, let $U := \operatorname{supp}\phi \cup \Gamma_1$, let $B := \{sx : x \in U,\ s \ge 1\}$, and let $\delta := \operatorname{dist}(U,\Gamma)/4$, so that $\operatorname{dist}(B,\Gamma) = \operatorname{dist}(U,\Gamma) = 4\delta$ and $0 < \delta \le \frac{1}{4}$. Let $B_\delta := \{x \in \mathbb{R}^n : \operatorname{dist}(x,B) < 2\delta\}$.

Let $N \in \mathbb{N}$ and $S_j \subset S$, $j = 1,\dots,N$, be such that each S_j is measurable and nonempty, $S_j \cap S_m = \emptyset$ for $j \ne m$, $S = \bigcup_{j=1}^N S_j$, and $\operatorname{diam}(S_j) \le \delta$, $j = 1,\dots,N$. For $j = 1,\dots,N$ choose $\hat{x}_j \in S_j$ and let

$$f_j := \inf\{|x| : x \in B_\delta,\ x/|x| \in S_j\}.$$

Then $2\delta \le f_j \le 1 - 2\delta$, $j = 1,\dots,N$. Define $\tilde{f} : S \to \mathbb{R}$ by

$$\tilde{f}(\hat{x}) := f_j \quad \text{ if } \hat{x} \in S_j,\ j = 1,\dots,N.$$

Then $\tilde{f} \in L^\infty(S,\mathbb{R})$; in fact, $\tilde{f}$ is a simple function and $2\delta \le \tilde{f}(\hat{x}) \le 1 - 2\delta$, $\hat{x} \in S$. Choose ϵ with $0 < \epsilon < \delta$ and let $J \in C^\infty[0,2]$ be such that $J \ge 0$, $J(t) = 0$ if $\epsilon^2/2 \le t \le 2$ and, where $e_3 := (0,0,1)$, such that $\int_S J(1 - e_3\cdot\hat{y})\,ds(\hat{y}) = 1$, so that $\int_S J(1 - \hat{x}\cdot\hat{y})\,ds(\hat{y}) = 1$, $\hat{x} \in S$. Define $f \in C^\infty(S,\mathbb{R})$ by

$$f(\hat{x}) := \int_S J(1 - \hat{x}\cdot\hat{y})\tilde{f}(\hat{y})\,ds(\hat{y}), \quad \hat{x} \in S,$$

and let Ω_e' be defined as in the statement of the lemma. Then f and Ω_e' have the properties claimed.

To see that this is true first note that, since $J(1 - \hat{x}\cdot\hat{y}) = 0$ if $|\hat{x} - \hat{y}| \ge \epsilon$,

$$\min_{|\hat{y}-\hat{x}|\,<\,\epsilon} |\tilde{f}(\hat{y})| \le f(\hat{x}) \le \max_{|\hat{y}-\hat{x}|\,<\,\epsilon} |\tilde{f}(\hat{y})|, \quad \hat{x} \in S, \tag{3.12}$$

so that $\overline{G_1} \subset \Omega_e'$. Now every $\hat{y} \in S$ is an element of S_j, for some $j \in \{1,\dots,N\}$, and $\tilde{f}(\hat{y}) = f_j$ and $|\hat{y} - \hat{x}_j| \le \delta$. Thus it follows from (3.12) that, for every $\hat{x} \in S$, $f(\hat{x}) \le f_m$ for some m for which $|\hat{x}_m - \hat{x}| < \epsilon + \delta$. Now let $x = f_m\hat{x}$, $y = f_m\hat{x}_m$. Then $|x - y| \le |\hat{x} - \hat{x}_m| < \epsilon + \delta$, and $\operatorname{dist}(y,B) = 2\delta$, so that

$$\operatorname{dist}(x,B) \ge \operatorname{dist}(y,B) - |x - y| \ge 2\delta - (\epsilon + \delta) > 0.$$

Thus $x \notin B$, and so $f(\hat{x})\hat{x} \notin B$. Thus $U \subset B \subset \Omega'_e$, and so $\operatorname{supp}\phi \subset U \subset \Omega'_e$.

Arguing similarly, for all $\hat{x} \in S$, $f(\hat{x}) \geq f_m$ for some m for which $|\hat{x}_m - \hat{x}| < \epsilon + \delta$. Defining $x = f_m\hat{x}$ and $y = f_m\hat{x}_m$, it holds that

$$\operatorname{dist}(x, B) \leq \operatorname{dist}(y, B) + |x - y| \leq 2\delta + \epsilon + \delta < 4\delta,$$

so that $x \in \Omega_e$ and hence $f(\hat{x})\hat{x} \in \Omega_e$. Thus, for all $\hat{x} \in S$, $s\hat{x} \in \Omega_e$ for $s > f(\hat{x})$; i.e., $\Omega'_e \subset \Omega_e$. $\square$

With this preliminary lemma we can proceed to show that Lemma 3.5 holds whenever Assumption 2 holds. In this final lemma (cf. [10, Lemma 4.11]) we use explicitly the fact that $b(\cdot, \cdot)$ is bounded. In fact, examining the definition (1.5), clearly we have that

$$|b(u, v)| \leq c\|u\|_{V_R}\|v\|_{V_R}, \quad u, v \in V_R, \tag{3.13}$$

where $c := 1 + \|\gamma\|^2\|T_R\|$ and $\|\gamma\|$ denotes the norm of the trace operator $\gamma : V_R \to H^{1/2}(\Gamma_R)$, while $\|T_R\|$ denotes the norm of T_R as a mapping from $H^{1/2}(\Gamma_R)$ to $H^{-1/2}(\Gamma_R)$.

Lemma 3.8. *Suppose that Assumption* 2 *holds, u is a solution to the distributed source scattering problem, $R > R_0$, and* $\operatorname{supp}(g) \subset \overline{D_R}$. *Then the bound* (3.10) *holds.*

Proof. Let $\tilde{V} := \{\phi|_{D_R} : \phi \in C_0^\infty(\Omega_e)\}$. Then $\tilde{V}$ is dense in V_R. Recall that the distributed source scattering problem is equivalent to (3.7). Suppose u satisfies (3.7) and choose a sequence $(u_m) \subset \tilde{V}$ such that $\|u_m - u\|_{V_R} \to 0$ as $m \to \infty$. Then $u_m = \phi_m|_{D_R}$, with $\phi_m \in C_0^\infty(\Omega_e)$, and, by Lemma 3.7, there exists $f_m \in C^\infty(S, \mathbb{R})$ with $\min f > 0$ such that $\operatorname{supp}\phi_m \subset \Omega_e^{(m)}$ and $\overline{G_R} \subset \Omega_e^{(m)} \subset \Omega_e$, where $\Omega_e^{(m)} := \{sf_m(\hat{x}) \in \mathbb{R}^n : \hat{x} \in S, s > 1\}$. Let $V_R^{(m)}$ and b_m denote the space and sesquilinear form corresponding to the domain $\Omega_e^{(m)}$. That is, where $D_R^{(m)} := \Omega_e^{(m)} \setminus \overline{G_R}$, $V_R^{(m)}$ is defined by $V_R^{(m)} := \{\phi|_{D_R^{(m)}} : \phi \in H_0^1(\Omega_e^{(m)})\}$ and b_m is given by (1.5) with D_R and V_R replaced by $D_R^{(m)}$ and $V_R^{(m)}$, respectively. Then $D_R^{(m)} \subset D_R$ and, if $v_m \in V_R^{(m)}$ and v denotes v_m extended by zero from $D_R^{(m)}$ to D_R, it holds that $v \in V_R$. Via this extension by zero, we can regard $V_R^{(m)}$ as a subspace of V_R and regard u_m as an element of $V_R^{(m)}$.

For all $v \in V_R^{(m)} \subset V_R$, we have

$$b_m(u_m, v) = b(u_m, v) = -(g, v) - b(u - u_m, v).$$

Let u'_m and $u''_m \in V_R^{(m)}$ be the unique solutions of

$$b_m(u'_m, v) = -(g, v), \quad b_m(u''_m, v) = -b(u - u_m, v) \quad \forall v \in V_R^{(m)}.$$

Clearly $u_m = u'_m + u''_m$ and, by Lemma 3.5, $\|u'_m\|_{V_R^{(m)}} \leq k^{-1}\tilde{C}\|g\|_2$, where $\tilde{C} = n - 1 + 2\sqrt{2}kR$, while, by (3.13), Lemma 3.3, and Corollary 3.6,

$$\|u''_m\|_{V_R^{(m)}} \leq c(1 + 2\tilde{C})\|u - u_m\|_{V_R}.$$

Thus $\|u\|_{V_R} = \lim_{m\to\infty} \|u_m\|_{V_R^{(m)}} \leq k^{-1}\tilde{C}\|g\|_2$. $\square$

Combining Lemmas 3.3, 3.4, and 3.8, we obtain the following generalization of Corollary 3.6, which is our main lower bound on the inf-sup constant and the main result of this section.

COROLLARY 3.9. *If Assumption 2 is satisfied, then the inf-sup condition* (1.8) *holds with* $\alpha^{-1} \le 1 + 2(n-1+2\sqrt{2}kR) \le 5 + 4\sqrt{2}kR$.

We finish the section by obtaining two upper bounds on the inf-sup constant, which will show, among other things, that the above bound is sharp in its dependence on k in the limit $k \to \infty$.

To obtain these bounds we modify the construction of Ihlenburg [25] for a weak formulation of a 1D Helmholtz problem. We note first that, for every nonzero $w \in V_R$,

$$\alpha \le \sup_{0 \ne v \in V_R} \frac{|b(w,v)|}{\|w\|_{V_R}\|v\|_{V_R}}.$$

Now choose $w \in V_R \cap H^2(D_R)$ such that $w = \nabla w = 0$ on Γ_R. Then, integrating by parts, for $v \in V_R$,

$$|b(w,v)| = \left| \int_{D_R} \left(\nabla w \cdot \nabla \bar{v} - k^2 w \bar{v} \right) dx \right| = \left| \int_{D_R} \left(\Delta w + k^2 w \right) \bar{v}\, dx \right|.$$

Thus, and recalling the definition (1.14),

$$\frac{|b(w,v)|}{\|w\|_{V_R}\|v\|_{V_R}} \le \frac{\|\Delta w + k^2 w\|_2 \|v\|_2}{\|w\|_{V_R}\|v\|_{V_R}} \le \frac{\|\Delta w + k^2 w\|_2}{k^2\|w\|_2}. \tag{3.14}$$

Now define $u(x) = \mathrm{e}^{\mathrm{i}kx_1} w(x)$. Then the above bound holds with w replaced by u, and

$$\Delta u(x) + k^2 u(x) = \left(2\mathrm{i}k \frac{\partial w(x)}{\partial x_1} + \Delta w(x) \right) \mathrm{e}^{\mathrm{i}kx_1}$$

so that

$$\frac{|b(u,v)|}{\|u\|_{V_R}\|v\|_{V_R}} \le \frac{\|\Delta u + k^2 u\|_2}{k^2\|u\|_2} = \frac{\|2\mathrm{i}k \frac{\partial w}{\partial x_1} + \Delta w\|_2}{k^2\|w\|_2}.$$

We have shown most of the following lemma.

LEMMA 3.10. *Suppose* $w \in V_R \cap H^2(D_R)$ *is such that* $\gamma w = \gamma \nabla w = 0$ *and* w *is nonzero. Then the inf-sup constant* (1.8) *is bounded above by*

$$\alpha \le \frac{C_1}{kR} + \frac{C_2}{k^2R^2},$$

where $C_1 := 2R\|\frac{\partial w}{\partial x_1}\|_2/\|w\|_2$, $C_2 := R^2\|\Delta w\|_2/\|w\|_2$, *and* $C_1 \ge 2\sqrt{2} \approx 2.83$.

Proof. It remains only to show the last inequality. Since $\gamma w = 0$, we can approximate w in the $H^1(D_R)$ norm arbitrarily closely by $\tilde{w} \in C_0^\infty(D_R)$. Then $C_1 \ge 2\sqrt{2}$ follows by a standard Friedrichs inequality (e.g. [10, Lemma 3.4]) which gives that $\|\tilde{w}\|_2 \le (R/\sqrt{2})\|\frac{\partial \tilde{w}}{\partial x_1}\|_2$. ∎

We note that in the case that Assumption 2 holds so that Corollary 3.9 applies, we have both upper and lower bounds on the inf-sup constant, namely (1.17), where C_1 and C_2 are as defined in Lemma 3.10.

The left-hand bound in (1.17) holds for every domain Ω_e satisfying Assumption 2. To check its sharpness, let us consider the case when $\Omega = \{0\}$ and $D = \mathbb{R}^n \setminus \{0\}$. In this special case, $V_R = H^1(D_R)$, and the solution of the plane wave scattering problem is just $u = u^i$; i.e., the scattered field is zero. Taking in this case $w(x) = F(|x|/R)$, where $F(t) := (1-t^2)^2$, we calculate that

$$C_1 = 2\sqrt{\frac{\int_0^1 (F'(t))^2 t^{n-1} dt}{n\int_0^1 (F(t))^2 t^{n-1} dt}} = \begin{cases} 2\sqrt{30}/3 \approx 3.65, & n = 2, \\ 2\sqrt{33}/3 \approx 3.83, & n = 3. \end{cases}$$

Thus, defining $c_- := (4\sqrt{2})^{-1}$, for this example the bounds (1.17) bracket $kR\alpha$ fairly tightly, predicting that, in the limit $kR \to \infty$, $kR\alpha$ is in the range $[c_-, C_1]$ with $C_1/c_- \le 8\sqrt{66}/3 \approx 21.7$.

The above results show that $k\alpha$ is bounded above in the limit $k \to \infty$ and is also bounded below if Assumption 2 holds. If Assumption 2 does not hold, then α may not be bounded below by a multiple of k^{-1}. The following example shows this behavior. It is convenient in this example to write $x \in \mathbb{R}^n$ as $x = (\tilde{x}, x_n)$, where $\tilde{x} = (x_1, \dots, x_{n-1})$.

Choose $A > 0$ and let $\Omega := \Omega_+ \cup \Omega_-$, where $\Omega_\pm := \{x \in \mathbb{R}^n : x_n = \pm A,\ |\tilde{x}| \le A\}$, so that Ω consists of two parallel lines of length $2A$ distance $2A$ apart in the 2D case, and two parallel disks of radius A in the 3D case. Choose $R > R_0 = \sqrt{2}A$ and define the function w by

$$w(x) := \begin{cases} \cos(kx_n)F(|\tilde{x}|/A), & |\tilde{x}| \le A,\ |x_n| \le A, \\ 0 & \text{otherwise,} \end{cases}$$

and suppose that $k \in \Lambda := \{(m + 1/2)\pi/A : m \in \mathbb{N}\}$. Then $w \in V_R \cap H^2(D_R)$ and $w = \nabla w = 0$ on Γ_R, so that (3.14) holds. Further,

$$\Delta w(x) + k^2 w(x) = \begin{cases} A^{-2}\cos(kx_n)\tilde{F}(|\tilde{x}|/A), & |\tilde{x}| \le A,\ |x_n| \le A, \\ 0 & \text{otherwise,} \end{cases}$$

where $\tilde{F}(t) := F''(t) + (n-2)F'(t)/t$. Thus, for $k \in \Lambda$, the inf-sup constant is bounded above by

$$\alpha \le \frac{\|\Delta w + k^2 w\|_2}{k^2\|w\|_2} = \frac{C_n^*}{k^2A^2}, \tag{3.15}$$

where $C_n^* := \sqrt{\int_0^1 \tilde{F}^2(t)t^{n-2}dt / \int_0^1 F^2(t)t^{n-2}dt}$.

4. Integral equation formulations. In this section we will obtain estimates explicit in the wave number for integral equation formulations of scattering problems, focusing on the plane wave scattering problem introduced in section 3 and on the integral equation (1.7) and its adjoint.

Throughout this section we assume, essential to the integral equation method, a degree of regularity of the domain, namely that Ω_e is Lipschitz (which implies that the interior of Ω, denoted $\Omega_i = \mathbb{R}^n \setminus \bar{\Omega}_e$ is also Lipschitz). We note that the invertibility of the integral equation (1.7) and its adjoint for the general Lipschitz case has recently been established in [9, section 2], by combining known results for layer-potentials on Lipschitz domains in [41, 20, 36, 34].

Given a domain G, let $H^1(G;\Delta) := \{v \in H^1(G) : \Delta v \in L^2(G)\}$ (Δ being the Laplacian in a weak sense). This is a Hilbert space with the norm $\|v\|_{H^1(G;\Delta)} := \{\int_G [|v|^2 + |\nabla v|^2 + |\Delta v|^2]dx\}^{1/2}$. If G is Lipschitz, then there is a well-defined normal derivative operator [34], the unique bounded linear operator $\partial_\nu : H^1(G;\Delta) \to H^{-1/2}(\partial G)$ which satisfies

$$\partial_\nu v = \frac{\partial v}{\partial \nu} := \nu \cdot \nabla v$$

almost everywhere on Γ, when $v \in C^\infty(\bar{G})$.

Our integral equation formulations will be based on standard acoustic layer potentials and their normal derivatives. In the case when the domain Ω_e is Lipschitz, for $\varphi \in L^2(\Gamma)$ we define the *single-layer potential operator* by

$$S\varphi(x) \;:=\; 2\int_\Gamma \Phi(x,y)\varphi(y)\,ds(y), \quad x \in \Gamma, \tag{4.1}$$

and the *double-layer potential operator* by

$$K\varphi(x) \;:=\; 2\int_\Gamma \frac{\partial\Phi(x,y)}{\partial\nu(y)}\varphi(y)\,ds(y), \quad x \in \Gamma, \tag{4.2}$$

where the normal ν is directed into Ω_e. We also define the operator K', which arises from taking the normal derivative of the single-layer potential, by

$$K'\varphi(x) = 2\int_\Gamma \frac{\partial\Phi(x,y)}{\partial\nu(x)}\varphi(y)\,ds(y), \quad x \in \Gamma. \tag{4.3}$$

We note that the right-hand sides of (4.1)–(4.3) are well defined at least for almost all $x \in \Gamma$, where (4.1) is understood in a Lebesgue sense (that $S\varphi(x)$ is well defined in this sense for almost all $x \in \Gamma$ follows from Young's inequality), while the double-layer potential and $K'\varphi$ must be understood as Cauchy principal values [36]. Further, all three operators are bounded operators on $L^2(\Gamma)$ [36]. In fact [34], it holds that, for $|s| \le 1/2$,

$$\begin{aligned} S &: H^{s-1/2}(\Gamma) \to H^{s+1/2}(\Gamma),\\ K &: H^{s+1/2}(\Gamma) \to H^{s+1/2}(\Gamma),\\ K' &: H^{s-1/2}(\Gamma) \to H^{s-1/2}(\Gamma), \end{aligned}$$

and these mappings are bounded.

These operators can also be characterized as traces on Γ of single- and double-layer potentials defined in Ω_e and Ω_i. Introducing, temporarily, the notation $\partial_\nu^\pm$ with ∂_ν^+ and ∂_ν^- denoting the exterior and interior normal derivative operators, mapping, respectively, $H^1(\Omega_e;\Delta)$ and $H^1(\Omega_i;\Delta)$ to $H^{-1/2}(\Gamma)$, it holds that [34]

$$K'\varphi = \left(\partial_\nu^+\mathcal{S} + \partial_\nu^-\mathcal{S}\right)\varphi, \quad \varphi \in H^{-1/2}(\Gamma), \tag{4.4}$$

where $\mathcal{S}$ is defined by

$$\mathcal{S}\varphi(x) \;:=\; \int_\Gamma \Phi(x,y)\varphi(y)\,ds(y), \quad x \in \mathbb{R}^n. \tag{4.5}$$

It is shown in, e.g., McLean [34] that $\mathcal{S} : H^{-1/2}(\Gamma) \to H^{1,\mathrm{loc}}(\mathbb{R}^n)$, and clearly $(\Delta + k^2)\mathcal{S}\varphi = 0$ in $\mathbb{R}^n \setminus \Gamma$, so that the right-hand side of (4.5) defines a bounded operator on $H^{-1/2}(\Gamma)$.

From [15, Theorem 3.12] and [34, Theorems 7.15, 9.6] it follows that, if u satisfies the plane wave scattering problem, then a form of Green's representation theorem holds, namely

$$u(x) = u^i(x) - \int_\Gamma \Phi(x,y)\partial_\nu u(y)\,ds(y), \quad x \in \Omega_e. \tag{4.6}$$

Two integral equations for $\partial_\nu u$ can be obtained by taking the trace and the normal derivative, respectively, of (4.6) on Γ, namely $0 = u^i - \mathcal{S}\partial_\nu u$ and $\partial_\nu u = \partial_\nu u^i - \partial_\nu \mathcal{S}\partial_\nu u$. Note that, to simplify the notation, we have not explicitly used the trace operator γ in these equations or later in this section. Its presence is assumed implicitly. Since [34] we have the jump relations that on Γ we have $2\mathcal{S}\varphi = S\varphi$ and $2\partial_\nu \mathcal{S}\varphi = -\varphi + K'\varphi$, for $\varphi \in H^{-1/2}(\Gamma)$, we can write these equations as

$$S\partial_\nu u = 2u^i, \quad \partial_\nu u + K'\partial_\nu u = 2\partial_\nu u^i.$$

It is well known (e.g., [14]) that each of these integral equations fails to be uniquely solvable if $-k^2$ is an eigenvalue of the Laplacian in Ω for, respectively, Dirichlet and Neumann boundary conditions, but that a uniquely solvable integral equation is obtained by taking an appropriate linear combination of the above equations. Clearly, for every $\eta \in \mathbb{R}$ it follows from the above equations that

$$A'\partial_\nu u = f, \tag{4.7}$$

where

$$A' := I + K' - \mathrm{i}\eta S,$$

I is the identity operator, and

$$f(x) := 2\frac{\partial u^i}{\partial \nu}(x) - 2\mathrm{i}\eta u^i(x), \quad x \in \Gamma.$$

We have shown the first part of the following theorem, which is standard (e.g., [14]) in the case when Γ is smooth; for the extension to the case of Lipschitz Γ see [9].

THEOREM 4.1. *If u satisfies the plane wave scattering problem, then, for every $\eta \in \mathbb{R}$, $\partial_\nu u \in H^{-1/2}(\Gamma)$ satisfies the integral equation* (4.7). *Conversely, if $\phi \in H^{-1/2}(\Gamma)$ satisfies $A'\phi = f$, for some $\eta \in \mathbb{R} \setminus \{0\}$, and u is defined in Ω_e by* (4.6), *with $\partial_\nu u$ replaced by ϕ, then u satisfies the plane wave scattering problem and $\partial_\nu u = \phi$.*

Note that, since we know that the plane wave scattering problem is uniquely solvable, this theorem implies that the integral equation (4.7) has exactly one solution in $H^{-1/2}(\Gamma)$.

The integral equation (4.7) is an example of a so-called *direct* integral equation formulation, obtained by applying Green's theorem to the original scattering problem. A related, *indirect* integral equation formulation, dating back to Brakhage and Werner [4], Leis [33], and Panich [40], is obtained by looking for a solution to the scattering problem in the form (1.6) for some density $\varphi \in H^{1/2}(\Gamma)$ and some $\eta \in \mathbb{R} \setminus \{0\}$. This combined single- and double-layer potential is in $C^2(\Omega_e)$, satisfies the Helmholtz equation and Sommerfeld radiation condition, and is in $H^{1,\mathrm{loc}}(\Omega_e)$ [34]. Thus it satisfies the plane wave scattering problem if and only if it satisfies the boundary condition that $u^s = -u^i$ on Γ. Using the standard jump relations for Lipschitz domains [34], we see that this holds if and only if the integral equation (1.7) is satisfied, i.e., if and only if

$$A\varphi = 2g,$$

where $g(x) := -u^i(x)$, $x \in \Gamma$, is the required Dirichlet data on Γ, and $A := I + K - \mathrm{i}\eta S$. This is the integral equation formulation introduced in [4, 33, 40].

Note that the above mapping properties of S, K, and K' imply that, for $|s| \le 1/2$,

$$A : H^{s+1/2}(\Gamma) \to H^{s+1/2}(\Gamma), \quad A' : H^{s-1/2}(\Gamma) \to H^{s-1/2}(\Gamma), \tag{4.8}$$

and these mappings are bounded. It is shown, moreover, in [9] (or see [37] for the case A' and $s = 0$), by combining the standard arguments for these integral equations when Γ is smooth (see, e.g., [14]) with known properties of integral operators on Lipschitz domains [41, 20, 36, 34], that, for $\eta \in \mathbb{R} \setminus \{0\}$, these mappings are bijections, which of course implies that their inverses are bounded by the Banach theorem. Further [36], K' is the adjoint of K, and S is self-adjoint, so that A' is the adjoint of A in the same sense, namely that

$$(\phi, A\psi)_\Gamma = (A'\phi, \psi)_\Gamma \quad \text{for } \phi \in L^2(\Gamma),\ \psi \in L^2(\Gamma), \tag{4.9}$$

where $(\phi, \psi)_\Gamma := \int_\Gamma \phi\psi ds$. Since $H^1(\Gamma)$ is dense in $H^{-1}(\Gamma)$ and the mappings (4.8) are bounded, it follows by density that the duality relation (4.9) holds, more generally, for $\phi \in H^{-s-1/2}(\Gamma)$ and $\psi \in H^{s+1/2}(\Gamma)$, provided that $|s| \le 1/2$. This implies that the norms of A and A^{-1} as operators on $H^{s+1/2}(\Gamma)$ coincide with those of A' and ${A'}^{-1}$, respectively, as operators on $H^{-s-1/2}(\Gamma)$ for $|s| \le 1/2$. In particular, we note that

$$\|A^{-1}\|_2 = \|{A'}^{-1}\|_2, \tag{4.10}$$

where, here and in the remainder of the paper, $\|\cdot\|_2$ denotes both the norm on $L^2(\Gamma) = H^0(\Gamma)$ and the induced norm on the space of bounded linear operators on $L^2(\Gamma)$.

Following this preparation, we show now the main result of this section, which is an explicit bound on $\|A^{-1}\|_2 = \|{A'}^{-1}\|_2$ in terms of the geometry of Γ and the wave number, in the case when Ω is starlike and Lipschitz. For brevity and to simplify the arguments somewhat we also assume that Γ is piecewise smooth. Precisely, we make the following assumption, which is intermediate between Assumptions 1 and 2 introduced in section 3.

Assumption 3. *For some $f \in C^{0,1}(S, \mathbb{R})$ with $\min_{\hat{x} \in S} f(\hat{x}) > 0$, it holds that $\Gamma = \{f(\hat{x})\hat{x} : \hat{x} \in S\}$. Further, for some $M \in \mathbb{N}$, it holds that $S = \overline{\cup_{j=1}^M S_j}$, with each S_j open in S, $S_{sing} := S \setminus \cup_{j=1}^M S_j$ a set of zero (surface) measure, and $f|_{S_j} \in C^2(S_j, \mathbb{R})$ for $j = 1, \ldots, M$.*

Remark 4.2. As an important example, we note that Assumption 3 is satisfied if Γ is a polyhedron, provided that the interior of Ω, $\Omega_i = \mathbb{R}^n \setminus \bar{\Omega}_e$, is starlike with respect to the origin; i.e., $x \in \Omega_i$ implies $sx \in \Omega_i$ for $0 \le s \le 1$. Explicitly the function f is then defined by $f(\hat{x}) := \max\{s > 0 : s\hat{x} \in \Omega\}$, and, if $\Gamma_1, \ldots, \Gamma_M$ denote the sides of Γ (each Γ_j open in Γ) and $\Gamma_{sing} := \Gamma \setminus \cup_{j=1}^M \Gamma_j$ denote the edges and corners of Γ, then Assumption 3 holds with $S_j := f^{-1}(\Gamma_j)$, $j = 1, \ldots, M$ and $\Gamma_{sing} = f(S_{sing})$.

Note that, if Assumption 3 holds (and, more generally, whenever Γ is piecewise smooth), the integrals (4.2) and (4.3) are well defined in the ordinary Lebesgue sense almost everywhere on Γ, in fact, provided that $x \notin \Gamma_{sing} = f(S_{sing})$. Note also that if Assumption 3 holds, then $0 < \delta_- \le \delta_+ \le R_0$, where

$$\delta_- := \inf_{x \in \Gamma \setminus \Gamma_{sing}} (x \cdot \nu), \quad \delta_+ := \sup_{x \in \Gamma \setminus \Gamma_{sing}} (x \cdot \nu),$$

and $R_0 = \max_{x \in \Gamma} |x|$. Let us also define

$$\delta^* := \sup_{x \in \Gamma \setminus \Gamma_{sing}} |x - (x \cdot \nu)\nu| \le R_0.$$

The main result of this section is the following theorem. We postpone the proof until the end of the section.

THEOREM 4.3. *Suppose that Assumption* 3 *holds and* $\eta \in \mathbb{R} \setminus \{0\}$. *Then*

$$\|A^{-1}\|_2 = \|A'^{-1}\|_2 \leq B, \tag{4.11}$$

where

$$B := \frac{1}{2} + \left[\left(\frac{\delta_+}{\delta_-} + \frac{4\delta^{*2}}{\delta_-^2}\right)\left[\frac{\delta_+}{\delta_-}\left(\frac{k^2}{\eta^2}+1\right) + \frac{n-2}{\delta_-|\eta|} + \frac{\delta^{*2}}{\delta_-^2}\right] + \frac{(1+2kR_0)^2}{2\delta_-^2\eta^2}\right]^{1/2}.$$

To help make the expression for B more comprehensible, let us consider some examples. Suppose first that Γ is a circle or sphere; i.e., $\Gamma = \{x : |x| = R_0\}$. Then $\delta_- = \delta_+ = R_0$ and $\delta^* = 0$, and thus

$$B = \frac{1}{2} + \left[1 + \frac{k^2}{\eta^2} + \frac{n-2}{R_0|\eta|} + \frac{(1+2kR_0)^2}{2R_0^2\eta^2}\right]^{1/2}. \tag{4.12}$$

In the 2D case that Γ is a regular polygon (centered on the origin) with M sides, $\delta_- = \delta_+ = R_0\cos(\pi/M)$ and $\delta^* = R_0\sin(\pi/M)$; thus

$$B = \frac{1}{2} + \left[\left(1 + 4\tan^2\frac{\pi}{M}\right)\left[1 + \frac{k^2}{\eta^2} + \tan^2\frac{\pi}{M}\right] + \frac{(1+2kR_0)^2}{2R_0^2\eta^2\cos^2(\pi/M)}\right]^{1/2}. \tag{4.13}$$

In the limit $M \to \infty$ this recovers (4.12), and for a square ($M = 4$) this simplifies to

$$B = \frac{1}{2} + \left[10 + 5\frac{k^2}{\eta^2} + \frac{(1+2kR_0)^2}{R_0^2\eta^2}\right]^{1/2}. \tag{4.14}$$

Similarly, for the cube $\Omega = \{x : |x_j| \leq a,\ j = 1,2,3\}$ of side-length $2a$ we have $\delta_- = \delta_+ = a$, $\delta^* = \sqrt{2}a$, and $R_0 = \sqrt{3}a$, so that

$$B = \frac{1}{2} + 3\left[3 + \frac{k^2}{\eta^2} + \frac{1}{a|\eta|} + \frac{(1+2\sqrt{3}ka)^2}{18a^2\eta^2}\right]^{1/2}.$$

We note that (4.12) can be compared with the results of Dominguez, Graham, and Smyshlyaev [19], who have shown, when Γ is a circle, the bound (1.9) for all sufficiently large k if the choice $\eta = k$ is made. Our results Theorem 4.3 and (4.12) predict for the circle that, if we choose $\eta = k$,

$$\|A^{-1}\|_2 \leq \frac{1}{2} + \left[2 + \frac{(1+2kR_0)^2}{2k^2R_0^2}\right]^{1/2}. \tag{4.15}$$

The right-hand side of this equation is a decreasing function of kR_0 on $(0,\infty)$ which approaches the limit 2.5 as $kR_0 \to \infty$. Thus our results show for a circle that, for every $\theta > 2.5$, $\|A^{-1}\|_2 \leq \theta$ for all sufficiently large kR_0. This bound is close to the result of [19] although we use much more general methods than the explicit calculation of eigenfunctions and eigenvectors used in [19], which are only available for a circular geometry. On the other hand, the authors also show, importantly, the coercivity (1.10), which our methods do not seem to be well adapted to obtain.

If we follow Dominguez, Graham, and Smyshlyaev [19] and choose $\eta = k$, we obtain the following simplification of the bound in Theorem 4.3 for the case $kR_0 \geq 1$. To obtain the second inequality we use that $\delta_+/\delta_- \leq \theta$ and $\delta^*/\delta_- \leq \theta$.

COROLLARY 4.4. *If Assumption* 3 *holds, $\eta = k$, and $kR_0 \geq 1$, then*

$$\|A^{-1}\|_2 = \|A'^{-1}\|_2 \leq \frac{1}{2} + \left[\left(\frac{\delta_+}{\delta_-} + \frac{4\delta^{*2}}{\delta_-^2}\right)\left[2\frac{\delta_+}{\delta_-} + \frac{(n-2)R_0}{\delta_-} + \frac{\delta^{*2}}{\delta_-^2}\right] + \frac{9R_0^2}{2\delta_-^2}\right]^{1/2}$$
$$\leq \frac{1}{2}\left(1 + \theta(4\theta + 4n + 1)\right),$$

where $\theta := R_0/\delta_-$.

We finish the section by providing a proof of Theorem 4.3. Clearly, given that we already know that A and A' are invertible as operators on $L^2(\Gamma)$ and we have (4.10), this theorem is implied as a corollary of the following lemma (cf. [8, Lemma 3.3]).

LEMMA 4.5. *Suppose that Assumption* 3 *holds and $\eta \in \mathbb{R} \setminus \{0\}$. Then, for all $\varphi \in L^2(\Gamma)$,*

$$||A'\varphi||_2 \geq B^{-1}||\varphi||_2. \tag{4.16}$$

Proof. Let $Y \subset L^2(\Gamma)$ denote the set of those functions φ that are Hölder continuous and are supported in $\Gamma \setminus \Gamma_{sing}$. Since Y is dense in $L^2(\Gamma)$ and A' is bounded on $L^2(\Gamma)$, it is sufficient to show that (4.16) holds for all $\varphi \in Y$.

Thus suppose $\varphi \in Y$, and define the single-layer potential u by

$$u(x) := \int_\Gamma \Phi(x,y)\varphi(y)ds(y) = \int_{\tilde{\Gamma}} \Phi(x,y)\varphi(y)ds(y), \quad x \in \mathbb{R}^n,$$

where $\tilde{\Gamma} \subset \Gamma \setminus \Gamma_{sing}$ is the support of φ. From standard properties of the single-layer potential (e.g., [14]) we have that $u \in C(\mathbb{R}^3) \cap C^2(\mathbb{R}^n \setminus \tilde{\Gamma})$. Further, it follows from [14, Theorem 2.17] that ∇u can be continuously extended from Ω_e to $\bar{\Omega}_e$ and from Ω_i to Ω, with limiting values on Γ given by

$$\nabla u_\pm(x) = \int_{\tilde{\Gamma}} \nabla_x \Phi(x,y)\varphi(y)ds(y) \mp \frac{1}{2}\varphi(x)\nu(x), \quad x \in \Gamma, \tag{4.17}$$

where, as before, $\nu(x)$ is the unit normal vector at x, directed into Ω_e, and

$$\nabla u_\pm(x) := \lim_{\epsilon \to 0+} \nabla u(x \pm \epsilon\nu(x)), \quad x \in \Gamma.$$

We note from (4.17) that the tangential part of ∇u, $\nabla_T u$, is continuous across Γ. On the other hand, the normal derivative jumps across Γ, with

$$\frac{\partial u_\pm}{\partial \nu}(x) = \frac{1}{2}\left[K'\varphi(x) \mp \varphi(x)\right], \quad x \in \Gamma \setminus \Gamma_{sing}. \tag{4.18}$$

Since also $u(x) = \frac{1}{2}S\varphi(x)$, $x \in \Gamma$, defining

$$g := \frac{1}{2}A'\varphi = \frac{1}{2}(I + K' - \mathrm{i}\eta S)\varphi,$$

we see that

$$\frac{\partial u_-}{\partial \nu}(x) - \mathrm{i}\eta u(x) = g(x), \quad x \in \Gamma \setminus \Gamma_{sing}. \tag{4.19}$$

Further, from (4.18) we see that

$$\frac{\partial u_-}{\partial \nu}(x) - \frac{\partial u_+}{\partial \nu}(x) = \varphi(x), \quad x \in \Gamma \setminus \Gamma_{sing}. \tag{4.20}$$

Note that to complete the proof we have to show that

$$||\varphi||_2 \leq 2B||g||_2. \tag{4.21}$$

We will achieve this by bounding the normal derivatives of u on Γ via applications of Lemma 2.3 in Ω_i and in D_R, for some $R > R_0$.

Before proceeding we note first that (2.19) and (2.20) do hold with v replaced by u and $G = \Omega_i$ or $G = D_R$, although we have not shown that $u \in H^2(G)$ so that we cannot apply Lemma 2.3 directly. To derive these equations when $G = \Omega_i$, we can first apply Lemma 2.3 with $v = u$ and $G = s\Omega_i$, for $s \in (0, 1)$, and then take the limit $s \to 1^-$, noting that $\Delta u + k^2 u = 0$ in Ω_i and $u \in C^1(\Omega)$. Arguing similarly, these equations also hold with v replaced by u and $G = D_R$. Thus, recalling that our normal vector ν on Γ points out of Ω_e, we have, taking the imaginary part of (2.19) with $v = u$ and $G = \Omega_i$ or $G = D_R$, the identities

$$\Im \int_\Gamma \bar{u} \, \frac{\partial u_-}{\partial \nu} \, ds = 0, \tag{4.22}$$

$$\Im \int_\Gamma \bar{u} \, \frac{\partial u_+}{\partial \nu} \, ds = \Im \int_{\Gamma_R} \bar{u} \, \frac{\partial u}{\partial r} \, ds. \tag{4.23}$$

Taking $v = u$ and $G = \Omega_i$ and adding (2.20) to $(n-2)$ times the real part of (2.19) gives

$$\begin{aligned} 2k^2 \int_\Omega |u|^2 \, dx = \int_\Gamma \Bigg(& x \cdot \nu \left(k^2|u|^2 + \left| \frac{\partial u_-}{\partial \nu} \right|^2 - |\nabla_T u|^2 \right) \\ & + \Re \left([(n-2)\bar{u} + 2x \cdot \nabla_T \bar{u}] \, \frac{\partial u_-}{\partial \nu} \right) \Bigg) \, ds. \end{aligned} \tag{4.24}$$

Finally, taking $v = u$ and $G = D_R$, for some $R > R_0$, and adding (2.20) to the real part of (2.19), we have

$$\begin{aligned} & \int_{D_R} \left((3-n)|\nabla u|^2 + (n-1)k^2|u|^2 \right) \, dx \\ &= -\int_\Gamma \left(x \cdot \nu \left(k^2|u|^2 + \left| \frac{\partial u_+}{\partial \nu} \right|^2 - |\nabla_T u|^2 \right) + \Re \left([\bar{u} + 2x \cdot \nabla_T \bar{u}] \, \frac{\partial u_+}{\partial \nu} \right) \right) \, ds \\ & \quad + \int_{\Gamma_R} \left(\left(k^2|u|^2 + \left| \frac{\partial u}{\partial r} \right|^2 - |\nabla_T u|^2 \right) + \Re \left(\bar{u} \, \frac{\partial u}{\partial r} \right) \right) \, ds. \end{aligned} \tag{4.25}$$

Using these four identities and Lemma 2.1 we will complete the proof.

We start by using (4.19) to replace $\partial u_- / \partial \nu$ in (4.22). Applying Cauchy–Schwarz, we see that

$$|\eta| \, \|u\|_2^2 = \left| \Im \int_\Gamma \bar{u} g ds \right| \leq \|u\|_2 \|g\|_2,$$

so that

$$\|u\|_2 \le |\eta|^{-1}\|g\|_2. \tag{4.26}$$

Alternatively, from (4.22) we have that

$$\Re \int_\Gamma \mathrm{i}\eta\bar{u}\frac{\partial u_-}{\partial \nu}\,ds = 0,$$

and, using (4.19) and Cauchy–Schwarz, we see that

$$\left\|\frac{\partial u_-}{\partial \nu}\right\|_2 \le \|g\|_2. \tag{4.27}$$

It remains to bound the L^2 norm of $\partial u_+/\partial\nu$ in terms of $\|g\|_2$. To achieve this goal we first bound $\|\nabla_T\|_2$ using (4.24). From this equation we have that

$$\begin{aligned}\delta_-\|\nabla_T u\|_2^2 &\le \int_\Gamma x\cdot\nu|\nabla_T u|^2\,ds\\ &\le \delta_+k^2\|u\|_2^2 + \delta_+\left\|\frac{\partial u_-}{\partial \nu}\right\|_2^2 + [(n-2)\|u\|_2 + 2\delta^*\|\nabla_T u\|_2]\left\|\frac{\partial u_-}{\partial \nu}\right\|_2,\end{aligned}$$

where we have used that $|x\cdot\nabla_T u| = |(x-(x\cdot\nu)\nu)\cdot\nabla_T u|$. From (4.26) and (4.27) it follows that

$$\delta_-\|\nabla_T u\|_2^2 \le \left[\delta_+\left(\frac{k^2}{\eta^2}+1\right) + \frac{n-2}{|\eta|}\right]\|g\|_2^2 + 2\delta^*\|\nabla_T u\|_2\|g\|_2.$$

Finally, applying (3.11) to the last term on the right-hand side, we deduce that

$$\frac{\delta_-}{2}\|\nabla_T u\|_2^2 \le \left[\delta_+\left(\frac{k^2}{\eta^2}+1\right) + \frac{n-2}{|\eta|} + 2\frac{\delta^{*2}}{\delta_-}\right]\|g\|_2^2$$

so that

$$\|\nabla_T u\|_2 \le \left[2\frac{\delta_+}{\delta_-}\left(\frac{k^2}{\eta^2}+1\right) + \frac{2(n-2)}{\delta_-|\eta|} + 2\frac{\delta^{*2}}{\delta_-^2}\right]^{1/2}\|g\|_2. \tag{4.28}$$

To finish the proof, we start from (4.25), apply Lemma 2.1, which is valid since u is a radiating solution of the Helmholtz equation, and then use (4.23) to see that

$$\delta_-\left\|\frac{\partial u_+}{\partial \nu}\right\|_2^2 \le \int_\Gamma x\cdot\nu\left|\frac{\partial u_+}{\partial \nu}\right|^2\,ds$$

$$\le \int_\Gamma\left(x\cdot\nu|\nabla_T u|^2 + \Re\left([\bar{u}+2x\cdot\nabla_T\bar{u}]\,\frac{\partial u_+}{\partial \nu}\right) + 2kR\Im\left(\bar{u}\frac{\partial u_+}{\partial \nu}\right)\right)ds.$$

Applying Cauchy–Schwarz and (3.11), we see that

$$\begin{aligned}\delta_-\left\|\frac{\partial u_+}{\partial \nu}\right\|_2^2 &\le \delta_+\|\nabla_T u\|_2^2 + (1+2kR)\|u\|_2\left\|\frac{\partial u_+}{\partial \nu}\right\|_2 + 2\delta^*\|\nabla_T u\|_2\left\|\frac{\partial u_+}{\partial \nu}\right\|_2\\ &\le \left(\delta_+ + \frac{4\delta^{*2}}{\delta_-}\right)\|\nabla_T u\|_2^2 + \frac{\delta_-}{2}\left\|\frac{\partial u_+}{\partial \nu}\right\|_2^2 + \frac{(1+2kR)^2}{\delta_-}\|u\|_2^2.\end{aligned}$$

Hence, and using (4.26) and (4.28),

$$\begin{aligned}\left\|\frac{\partial u_+}{\partial \nu}\right\|_2^2 &\le 2\left(\frac{\delta_+}{\delta_-}+\frac{4\delta^{*2}}{\delta_-^2}\right)\|\nabla_T u\|_2^2 + \frac{2(1+2kR)^2}{\delta_-^2}\|u\|_2^2 \\ &\le 4\left[\left(\frac{\delta_+}{\delta_-}+\frac{4\delta^{*2}}{\delta_-^2}\right)\left[\frac{\delta_+}{\delta_-}\left(\frac{k^2}{\eta^2}+1\right)+\frac{(n-2)}{\delta_-|\eta|}+\frac{\delta^{*2}}{\delta_-^2}\right]+\frac{(1+2kR)^2}{2\delta_-^2\eta^2}\right]\|g\|_2^2.\end{aligned}$$

This bound holds for all $R > R_0$ and hence also for $R = R_0$. Combining this bound with (4.27) we see that we have shown (4.21) and thus have finished the proof of the lemma. ∎

ON THE CAUCHY PROBLEM FOR THE p-SYSTEM AT A JUNCTION*

RINALDO M. COLOMBO† AND MAURO GARAVELLO‡

Abstract. We present a model for the description of a nonviscous isentropic or isothermal fluid crossing a junction. Aiming at an extension of the usual Euler equations, we neglect the effects of friction against the walls of the pipes, but the reaction constraints at the junction are considered. The well posedness of the Cauchy problem is proved, and some qualitative properties of the model are described.

Key words. p-system, hyperbolic systems of conservation laws, Cauchy problem, compressible fluids, gas dynamics

1. Introduction. Consider n rectilinear tubes exiting a junction. For $l = 1, \ldots, n$, the direction and section of the lth tube are described, respectively, by the direction and the norm of a vector $\nu_l \in \mathbb{R}^3 \setminus \{0\}$. All tubes are filled with the same nonviscous isentropic (or isothermal) fluid, and friction along the walls is neglected. The resulting system can be modeled through n copies of the one-dimensional p-system in Eulerian coordinates:

$$\left\{ \begin{array}{l} \partial_t \rho_l + \partial_x q_l = 0, \\ \partial_t q_l + \partial_x \left(\dfrac{q_l^2}{\rho_l} + p(\rho_l) \right) = 0, \end{array} \right. \qquad \begin{array}{rcl} t & \in & [0, +\infty[\,, \\ x & \in & [0, +\infty[\,, \\ l & \in & \{1, \ldots, n\}\,. \end{array} \tag{1.1}$$

Here, t is time, and, along the lth tube, x is the abscissa, ρ_l is the fluid density, and q_l is the linear momentum density. The pressure law $p = p(\rho)$ is the same for all tubes.

This paper aims to study the Cauchy problem for (1.1). Therefore, we introduce below coupling conditions among the tubes that depend on the relative sizes and positions of the tubes. These conditions neglect friction at the junction; nevertheless the total linear momentum is *not* conserved due to the presence of the junction, and its variation depends on $\nu_1, \ldots, \nu_n$ (see also Example 1 below).

The key condition, written using the linear momentum flow $P(\rho, q) = \frac{q^2}{\rho} + p(\rho)$, reads

$$\lim_{x \to 0+} P\left(q_l(t,x), \rho_l(t,x)\right) = \lim_{x \to 0+} P\left(q_h(t,x), \rho_h(t,x)\right) \tag{P}$$

for all $l, h = 1, \ldots, n$, and for almost every (a.e.) $t > 0$. In the static case $q_l = 0$, it amounts to the equality of the hydrostatic pressure. Note that in (P) the geometry of the junction is hidden in the vectors ν_l that identify the direction of the tube. Indeed,

the connection between (1.1) and the full three-dimensional (3D) Euler equations is achieved through the functions

$$\rho(t;\mathbf{x}) = \sum_{l=1}^{n} \rho_l(t, \mathbf{x}\cdot\hat{\nu}_l)\,\chi_{T_l}(\mathbf{x}) \quad \text{and} \quad \mathbf{q}(t;\mathbf{x}) = \sum_{l=1}^{n} q_l(t, \mathbf{x}\cdot\hat{\nu}_l)\,\chi_{T_l}(\mathbf{x})\,\hat{\nu}_l\,,$$

where T_l is the region in the lth tube, $\mathbf{x}$ is the space variable, and $\hat{\nu}_l = \nu_l/\|\nu_l\|$. As usual, χ_T is the characteristic function of T; i.e., $\chi_T(\mathbf{x}) = 1$ if $\mathbf{x} \in T$, while $\chi_T(\mathbf{x}) = 0$ if $\mathbf{x} \notin T$. Here we approximate the intrinsically 3D nature of the real junction assuming that the fluid speed in the lth pipe is parallel to ν_l and that the different pipes interact at a unique single point. The total linear momentum is then

$$Q(t) = \int_{\mathbb{R}^3} \mathbf{q}(t,\mathbf{x})\,d\mathbf{x} = \sum_{l=1}^{n} \int_0^{+\infty} q_l(t,x)\,\nu_l\,dx.$$

Straightforward computations based on the 3D Euler equations (see [9]) show that if (ρ_l, q_l) is in $\mathbf{L^1} \cap \mathbf{BV}$, then the variation of the total linear momentum on $\bigcup_{l=1}^{n} T_l$ during the time interval $[t_1, t_2]$ is

$$\begin{aligned} Q(t_2) - Q(t_1) &= \iiint_{\bigcup_l T_l} \left(\mathbf{q}(t_2;\mathbf{x}) - \mathbf{q}(t_1;\mathbf{x})\right) d\mathbf{x} \\ &= \int_{t_1}^{t_2} \sum_{l=1}^{n} P\left(\rho_l(t,0+), q_l(t,0+)\right) \nu_l\,dt\,. \end{aligned}$$

The latter term above is the variation in the total linear momentum and is due to the junction. Condition (P) says that

$$Q(t_2) - Q(t_1) = \int_{t_1}^{t_2} \sum_{l=1}^{n} P\left(\rho_l(t,0+), q_l(t,0+)\right) \nu_l dt = \left(\int_{t_1}^{t_2} P_*(t)\,dt\right) \sum_{l=1}^{n} \nu_l$$

for a suitable function P_* of time. Hence, (P) implies that the reaction constraint due to the junction is directed along $\sum_l \nu_l$; i.e.,

$$\text{(Q)} \qquad \left(\sum_{l=1}^{n} P\left(\rho_l(t,0+), q_l(t,0+)\right) \nu_l\right) \in \left(\mathbb{R} \sum_{l=1}^{n} \nu_l\right).$$

This condition depends heavily on the geometry of the junction and is equivalent to (P) as soon as $\nu_1, \ldots, \nu_n$ are linearly independent; see Lemma 2.2.

In the case of $n = 2$ ducts with different sections, our model can be compared to the limit situation of [18, 19] corresponding to a delta source; see [14]. The case of a "kink," i.e., $n = 2$ nonparallel ducts having the same section, was considered in [17]. In these papers, the variation in the total linear momentum is quantified through a source term. In the present model, no source term is specified, and the modulus of the reaction constraint is not assumed to be known. On the contrary, here only the *direction* of the reaction constraint is used, and it is assumed to depend only on the geometry of the junction.

The friction against the pipes' walls is neglected here. When considered, it can be described through standard source terms along the pipes and a Dirac delta at the junction, using, for example, the techniques in [14, 17]. The present results are also preliminary to the study of more complicated networks. However, as the results in [13] also show, well posedness depends on the geometry of the network.

Our choice of considering the subsonic case is motivated by the relevance of this situation for applications. From the analytic point of view, as will be clear by the proofs below, the only relevant constraints are that (i) the total number of positive characteristic speeds must be equal to the number of pipes, and (ii) no transonic wave arises.

The main technique we use is the so-called wave-front tracking method; see [4, 10]. Therefore, we base our analysis on the solution to the Riemann problem at the junction, as in [8, 9]. This concept of solution is a natural extension of the classical Lax solution and reduces to it in the case of two ducts with the same section. Furthermore, it ensures the well posedness for the Riemann problem; hence the present definition is different from that introduced in [2, 3].

Similarly to the well posedness results found in the literature for the general p-system [4, 10], the well posedness of the Cauchy problem at a junction is proved below in the case where the initial data are a sufficiently small perturbation of a stationary solution.

There are a large number of papers dealing with various fluid-dynamical models in networks. Concerning car traffic in a network, we refer to the book [13] and to the papers [5, 6, 9, 11, 12, 16]. Concerning the evolution of gas in a network, see, for example, [2, 3, 8, 9]. Networks of open channels are studied with different techniques in [15].

Section 2 describes the model and recalls the solution to the Riemann problem at the junction, as defined in [8, 9]. Qualitative properties of the solution to the Riemann problem and numerical examples are also provided. Section 3 is devoted to the well posedness of solutions to the Cauchy problem. Finally, section 4 contains the technical details of the proofs.

2. The model. This section is devoted to definitions and results of the Riemann problem at a junction; see also [8, 9]. The physics of the fluid is described by the following usual condition on the pressure law in (1.1).

(EoS) The **E**quation **o**f **S**tate of the fluid, i.e., the pressure law $p = p(\rho)$, satisfies $p \in \mathbf{C^2}(\mathbb{R}^+; \mathbb{R}^+)$, $p(0) = 0$, $p' > 0$, and $p'' \geq 0$.

We denote $\mathbb{R}^+ = [0, +\infty[$ and $\mathring{\mathbb{R}}^+ =]0, +\infty[$. A typical example is the γ-law

$$p(\rho) = p_* \cdot (\rho/\rho_*)^\gamma \tag{2.1}$$

for fixed constants $\rho_*, p_* > 0$ and $\gamma \geq 1$. Other quantities relevant in the study of (1.1) are

$$\begin{aligned}
\text{flow of the linear momentum:} \quad & P(\rho, q) = \frac{q^2}{\rho} + p(\rho),\\
\text{total energy:} \quad & E(\rho, q) = \frac{q^2}{2\rho} + \rho \int_{\rho_*}^{\rho} \frac{p(r)}{r^2}\, dr,\\
\text{flow of the total energy:} \quad & F(\rho, q) = \frac{q}{\rho} \cdot \left(E(\rho, q) + p(\rho)\right).
\end{aligned}$$

We refer below to P as to the *dynamic pressure*. As is well known (see [10, formula (3.3.21)]), the pair (E, F) plays the role of the (mathematical) entropy-entropy flux pair.

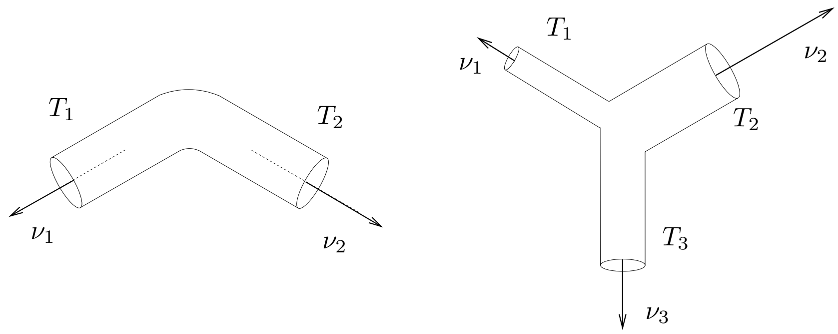

FIG. 2.1. *Examples of junctions and notation used in section* 3.

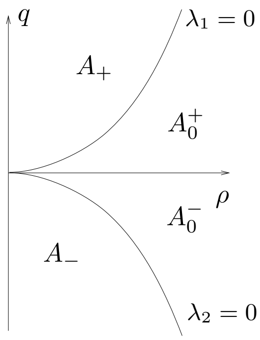
We introduce the regions



$$
\begin{aligned}
A_- &= \left\{\mathbb{R}^+ \times \mathbb{R} \colon \lambda_2(\rho, q) < 0\right\},\\
A_0^- &= \left\{\mathbb{R}^+ \times \mathbb{R} \colon \lambda_2(\rho, q) \geq 0,\ q \leq 0\right\},\\
A_0^+ &= \left\{\mathbb{R}^+ \times \mathbb{R} \colon \lambda_1(\rho, q) \leq 0,\ q \geq 0\right\},\\
A_+ &= \left\{\mathbb{R}^+ \times \mathbb{R} \colon \lambda_1(\rho, q) > 0\right\},\\
A_0 &= A_0^- \cup A_0^+.
\end{aligned}
$$

Above, as usual, λ_i is the ith characteristic speed; see (4.1) for its expression and for other relations holding for the p-system. We shall often refer to A_0 as the *subsonic* region.

Consider n ducts exiting a single junction. Each tube is modeled by $\mathbb{R}^+$, and the junction is at $x = 0$. The lth pipe is described by a vector ν_l parallel to it that exits the junction and whose norm $\|\nu_l\|$ is equal to the section of the duct; see Figure 2.1. For instance, standard Riemann problems correspond to (2.2) with $n = 2$ and $\nu_1 + \nu_2 = 0$. This choice makes the geometry of the junction intrinsic to the structure of the model; see Example 1 below.

Assigning at time $t = 0$ a constant initial state $(\bar{\rho}_l, \bar{q}_l) \in \mathbb{R}^+ \times \mathbb{R}$ in each of the n ducts exiting a junction ($l \in \{1, \ldots, n\}$), we have a *Riemann problem at the junction*:

$$
(2.2) \qquad \left\{
\begin{array}{ll}
\partial_t \rho_l + \partial_x q_l = 0, & t \in \mathbb{R}^+,\\
\partial_t q_l + \partial_x \left(\dfrac{q_l^2}{\rho_l} + p(\rho_l)\right) = 0, & \begin{array}{l} x \in \mathbb{R}^+,\\ l \in \{1, \ldots, n\},\end{array}\\
(\rho_l, q_l)(0, x) = (\bar{\rho}_l, \bar{q}_l), & (\bar{\rho}_l, \bar{q}_l) \in \mathring{\mathbb{R}}^+ \times \mathbb{R}.
\end{array}
\right.
$$

DEFINITION 2.1. *A* solution *to the Riemann problem* (2.2) *is a self-similar function* $(\rho, q) \in \mathbf{BV}(\mathbb{R}^+ \times \mathbb{R}^+; (\mathring{\mathbb{R}}^+ \times \mathbb{R})^n)$ *such that the following hold:*

(L) *For all* $l = 1, \ldots, n$, *the function* $(t, x) \to (\rho_l, q_l)(t, x)$ *is self-similar and coincides with the restriction to* $x \in \mathring{\mathbb{R}}^+$ *of the* ***L****ax solution to the standard Riemann* *problem*

$$\begin{cases} \partial_t \rho_l + \partial_x q_l = 0, \\ \partial_t q_l + \partial_x \left(\dfrac{q_l^2}{\rho_l} + p(\rho_l) \right) = 0, \\ (\rho_l, q_l)(0,x) = \begin{cases} (\bar\rho_l, \bar q_l) & \textit{if } x > 0, \\ (\rho_l, q_l)(1, 0+) & \textit{if } x < 0 \,. \end{cases} \end{cases}$$

(M) ***M**ass is conserved at the junction; i.e., for a.e. $t > 0$,*

$$\sum_{l=1}^{n} \|\nu_l\| \, q_l(t, 0+) = 0 \,.$$

(P) *The trace of the dynamic **P**ressure P is the same along all tubes; i.e., there exists a positive P_* such that for $l = 1, \ldots, n$,*

$$P\left(\rho_l(t, 0+), q_l(t, 0+)\right) = P_* \,.$$

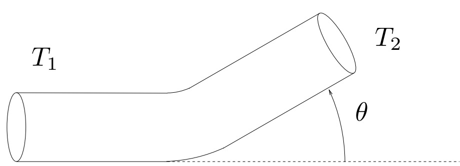
(E) *At the junction, **E**ntropy may not decrease; i.e., for a.e. $t > 0$,*

$$\sum_{l=1}^{n} \|\nu_l\| \, F\left(\rho_l(t, 0+), q_l(t, 0+)\right) \leq 0 \,.$$

Condition **(L)** implies that waves exiting the junction are standard Lax solutions to suitable Riemann problems. Hence, waves produced by the solution to (2.2) have positive speed in each duct, and the trace at the junction is constant in time.

The next example shows that, in Definition 2.1, geometry is hidden in the vectors $\nu_1, \ldots, \nu_n$.

Example 1. Consider an elbow of an angle $\pi - \theta$ between two tubes having the same section, so that $n = 2$, $\nu_1 = [-1 \quad 0]^T$, and $\nu_2 = [\cos\theta \quad \sin\theta]^T$.



Choose initial data $(\bar\rho_1, \bar q_1)$ and $(\bar\rho_2, \bar q_2)$. According to the conservation of mass **(M)**, which is part of Definition 2.1, if these data are in *equilibrium* (in the sense that no wave arises in the corresponding Riemann problem (2.2)), then the variation in the total linear momentum is $\Delta Q = \bar q_1 \nu_1 - \bar q_2 \nu_2 = \bar q_1 \left(\nu_1 + \nu_2\right)$. Note that ΔQ is directed along $\nu_1 + \nu_2$, coherently with (Q) and, moreover, $\|\Delta Q\| = |\bar q_1| \sqrt{2(1 - \cos\theta)}$, exactly as in [17, formula (0.3)].

As anticipated in the introduction, the independence of **(P)** from the geometry is only apparent. Indeed, **(P)** implies the more explicitly geometric condition (Q) and is equivalent to it as soon as $\nu_1, \ldots, \nu_n$ are linearly independent.

LEMMA 2.2. *For any n-tuple of pipes,* **(P)** $\Longrightarrow$ (Q). *Moreover, if $\nu_1, \ldots, \nu_n$ are linearly independent, then* **(P)** $\Longleftrightarrow$ (Q).

The proof is immediate. Note that **(P)** gives $n - 1$ conditions, while (Q) provides a number of conditions equal to the dimension of $\left(\sum \nu_l\right)^\perp$. In particular, with more than three tubes, **(P)** and (Q) may not be equivalent.

The results in [8, 9] can be slightly modified to cover the present case and ensure that the Riemann problem (2.2) with Definition 2.1 enjoys the same properties of standard Riemann problems with the standard Lax solutions [4, section 5.3]. In fact, we have the following proposition.

PROPOSITION 2.3. *Let p satisfy* (EoS). *Fix $n \in \mathbb{N}$ with $n \geq 2$ and a positive P_*. Choose n initial states satisfying*

$$(2.3) \qquad (\bar{\rho}_i, \bar{q}_i) \in \mathring{A}_0, \quad \sum_{i=1}^{n} \|\nu_i\| \bar{q}_i = 0, \quad P(\bar{\rho}_i, \bar{q}_i) = P_*, \quad \sum_{i=1}^{n} \|\nu_i\| F(\bar{\rho}_i, \bar{q}_i) < 0.$$

Then, for every $C > 0$, there exists $\delta > 0$ such that for all n-tuples of initial states $(\widetilde{\rho}, \widetilde{q}) \in (\mathring{\mathbb{R}}^+ \times \mathbb{R})^n$ with $|\bar{\rho}_i - \widetilde{\rho}_i| + |\bar{q}_i - \widetilde{q}_i| < \delta$, the Riemann problem (2.2) *admits a unique solution $(\rho, q) = (\rho, q)(t, x)$ in the sense of Definition* 2.1 *satisfying*

$$(2.4) \qquad |\rho_i(t,x) - \bar{\rho}_i| + |q_i(t,x) - \bar{q}_i| < C,$$

for every $i \in \{1, \ldots, n\}$, $t \in \mathbb{R}^+$, and $x \in \mathbb{R}^+$. Moreover, in the case $n = 2$, $\nu_1 + \nu_2 = 0$, the map $(t, x) \to (\rho_*, q_*)(t, x)$ is the standard Lax solution to (1.1) *with data*

$$(\rho, q)(0, x) = \begin{cases} (\bar{\rho}_1, -\bar{q}_1) & \text{if} \quad x < 0, \\ (\bar{\rho}_2, \bar{q}_2) & \text{if} \quad x > 0 \end{cases}$$

if and only if the map

$$(2.5) \qquad (t, x) \to \begin{cases} (\rho_*, -q_*)(t, -x) & \text{if} \quad x \leq 0, \\ (\rho_*, q_*)(t, x) & \text{if} \quad x \geq 0 \end{cases}$$

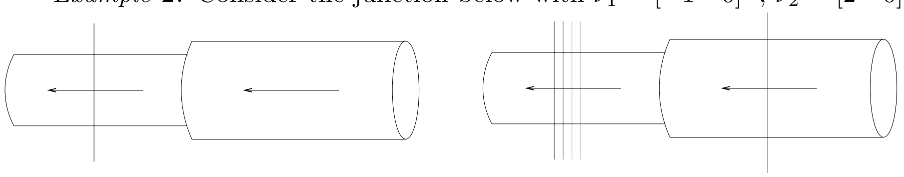
solves (2.2) *with data $(\bar{\rho}_1, \bar{q}_1)$ and $(\bar{\rho}_2, \bar{q}_2)$ in the sense of Definition* 2.1.

The proof is as in [8, 9]. Here, aiming both at the well posedness of the Riemann problem and at the qualitative properties of the solutions to (2.2), we consider some effects of interactions at the junction.

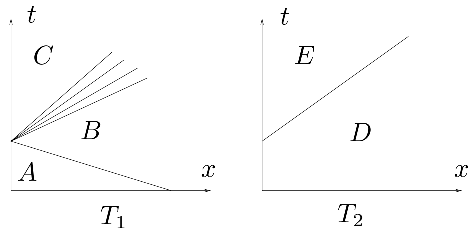
PROPOSITION 2.4. *Let p satisfy* (EoS). *Fix $n \in \mathbb{N}$ with $n \geq 2$ and a positive P_*. Choose n initial states $(\bar{\rho}_l, \bar{q}_l)$ satisfying* (2.3) *and thus producing a stationary solution for the Riemann problem. Then, there exists $\delta > 0$ such that if in the lth duct a rarefaction (resp., a shock) of the first family connecting $(\bar{\rho}_l, \bar{q}_l)$ with a state $(\rho_l^r, q_l^r) \in \mathring{A}_0$ satisfying $|(\bar{\rho}_l, \bar{q}_l) - (\rho_l^r, q_l^r)| < \delta$ reaches the junction, then a rarefaction (resp., a shock) propagates in all the other pipes.*

The proof is deferred to section 4. Here we give three numerical examples, where we used the γ-law (2.1) with $\gamma = 1.4$, $\rho_* = 1$, and $p_* = 1$.

Example 2. Consider the junction below with $\nu_1 = [-1 \quad 0]^T$, $\nu_2 = [2 \quad 0]^T$.



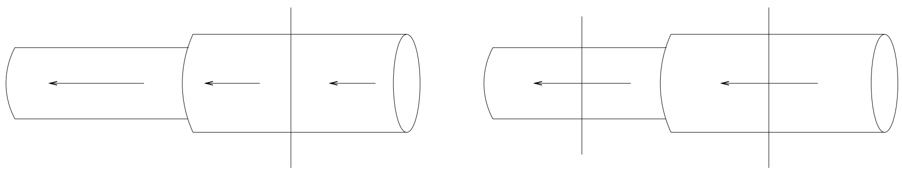
The arrows indicate the direction of the fluid. A 1-shock heads from the left toward the junction. Before the interaction the states (ρ, q) from left to right are as shown below:



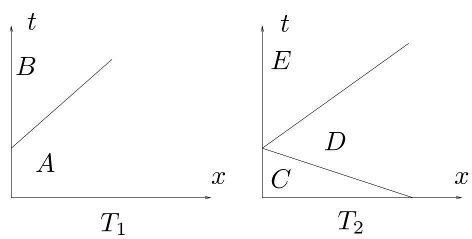
$$
\begin{aligned}
A &= (2.00001, 1.29999),\\
B &= (2.10000, 1.22504),\\
C &= (2.09816, 1.21891),\\
D &= (2.34829, -0.649996),\\
E &= (2.38388, -0.609455).
\end{aligned}
$$

After the interaction, a shock propagates in the pipe to the right, and a rarefaction is reflected to the left.

Example 3. Consider the same pipes as in Example 2.



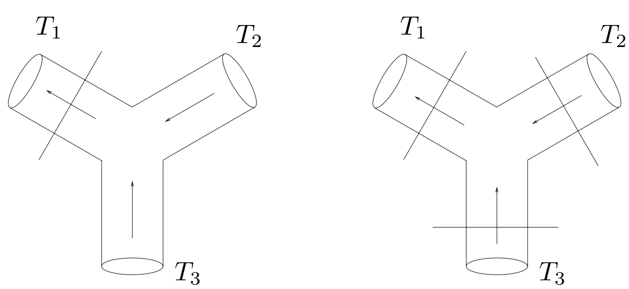
A 1-shock moves from the larger duct toward the smaller one:



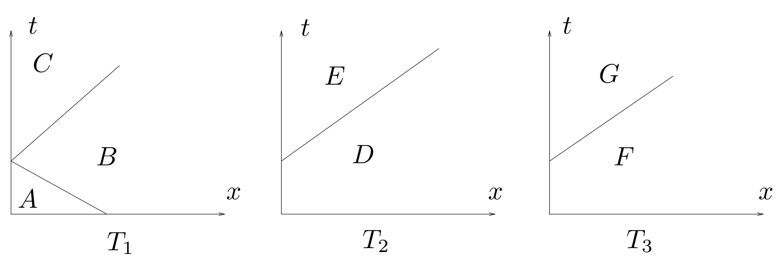
$$
\begin{aligned}
A &= (2.00001, 1.29999),\\
B &= (2.13796, 1.58483),\\
C &= (2.34829, -0.649996),\\
D &= (2.50000, -0.913070),\\
E &= (2.61032, -0.792455).
\end{aligned}
$$

After the interaction, a shock is reflected back to the right, and another shock is refracted in the smaller tube.

Example 4. We now consider an example with three pipes. Let $\nu_1 = [-1 \quad 0]^T$, $\nu_2 = [1/2 \quad \sqrt{3}/2]^T$, and $\nu_3 = [1/2 \quad -\sqrt{3}/2]^T$; i.e., all tubes have the same sections, and $\sum \nu_l = 0$.



The tubes are in equilibrium. A 1-shock approaches the junction along tube 1.



$$\begin{array}{ll} A = (1.0363, 1.0802), & D = (1.6273, -0.57179), \\ B = (1.6000,\ 0.79276), & E = (1.7694, -0.42680), \\ C = (1.6007,\ 0.79407), & F = (1.6528, -0.50842), \\ & G = (1.7847, -0.36827). \end{array}$$

Then, the resulting interaction at the junction forms a shock in each tube.

3. Analytical results. Consider the *Cauchy problem at a junction* with n pipes, i.e., the problem

$$\left\{\begin{array}{ll} \partial_t \rho_l + \partial_x q_l = 0, & t \in \mathbb{R}^+, \\ \partial_t q_l + \partial_x \left(\dfrac{q_l^2}{\rho_l} + p(\rho_l)\right) = 0, & x \in \mathbb{R}^+, \\ & l \in \{1, \ldots, n\}, \\ (\rho, q)(0, x) = (\rho_o, q_o)(x), & (\rho_o, q_o) \in \mathbf{L^1}\left(\mathbb{R}^+; (\mathring{\mathbb{R}}^+ \times \mathbb{R})^n\right). \end{array}\right. \tag{3.1}$$

For $(\rho, q) \in \mathbf{L^1}(\mathbb{R}^+; (\mathring{\mathbb{R}}^+ \times \mathbb{R})^n)$ attaining values in a neighborhood of a fixed $(\hat\rho, \hat q) \in (\mathring{\mathbb{R}}^+ \times \mathbb{R})^n$, with a slight abuse of notation, we introduce

$$\|(\rho, q)\|_{\mathbf{L^1}} = \sum_{l=1}^n \|(\rho_l, q_l)\|_{\mathbf{L^1}} \quad \text{and} \quad \mathrm{TV}\,(\rho, q) = \sum_{l=1}^n \mathrm{TV}\,(\rho_l, q_l)\,.$$

The natural extension of the usual definition of a weak entropy solution to the present case is the following.

DEFINITION 3.1. *Fix $(\hat\rho, \hat q) \in (\mathring{\mathbb{R}}^+ \times \mathbb{R})^n$ and $T \in\,]0, +\infty]$. A weak solution to* (3.1) *is a map $(\rho, q) \in \mathbf{C^0}([0, T]; (\hat\rho, \hat q) + \mathbf{L^1}(\mathbb{R}^+; (\mathring{\mathbb{R}}^+ \times \mathbb{R})^n))$ such that for all $\varphi \in \mathbf{C_c^\infty}(]-\infty, T[\, \times \mathbb{R}^+; \mathbb{R})$*

$$\sum_{l=1}^n \left(\int_0^T \!\! \int_{\mathbb{R}^+} (\rho_l\, \partial_t \varphi + q_l\, \partial_x \varphi)\, dx\, dt + \int_{\mathbb{R}^+} \rho_{o,l}(x)\, \varphi(0, x)\, dx\right) \|\nu_l\| = 0,$$

$$\left(\int_0^T \!\! \int_{\mathbb{R}^+} (q_l \partial_t \varphi + P_l \partial_x \varphi)\, dx dt + \int_{\mathbb{R}^+} q_{o,l}(x)\, \varphi(0, x)\, dx\right) \|\nu_l\| = \int_0^T P_*(t) \varphi(t, 0) dt$$

for all $l = 1, \ldots, n$ and for a suitable $P_* \in \mathbf{L^1}([0, T]; \mathbb{R}^+)$. The weak solution (ρ, q) is entropic if for all $\varphi \in \mathbf{C_c^\infty}(] - \infty, T[\times \mathbb{R}^+; \mathbb{R}^+)$

$$\sum_{l=1}^n \left(\int_0^T \!\! \int_{\mathbb{R}^+} (E_l\, \partial_t \varphi + F_l\, \partial_x \varphi)\, dx\, dt + \int_{\mathbb{R}^+} E(\rho_{o,l}, q_{o,l})\, \varphi(0, x)\, dx\right) \|\nu_l\| \geq 0,$$

where $E_l = E(\rho_l, q_l)$ and $F_l = F(\rho_l, q_l)$.

Above, the condition on the second equation clearly reflects **(P)**. A similar condition related to (Q) is

$$\sum_{l=1}^n \left(\int_0^T \!\! \int_{\mathbb{R}^+} (q_l\, \partial_t \varphi + P_l\, \partial_x \varphi)\, dx\, dt + \int_{\mathbb{R}^+} q_{o,l}(x)\, \varphi(0, x)\, dx\right) \nu_l \in \left(\mathbb{R} \sum_{l=1}^n \nu_l\right).$$

A simple condition for (ρ, q) to be a weak entropy solution is provided by the following lemma.

LEMMA 3.2. *Let $n \in \mathbb{N}$ with $n \geq 2$ and $\nu_1, \ldots, \nu_n \in \mathbb{R}^3$ be pairwise distinct. Fix a state $(\hat\rho, \hat q) \in (\mathring{\mathbb{R}}^+ \times \mathbb{R})^n$ and $T \in\,]0, +\infty]$. If the map $(\rho, q) \in \mathbf{C^0}([0, T]; (\hat\rho, \hat q) + \mathbf{L^1}(\mathbb{R}^+; (\mathring{\mathbb{R}}^+ \times \mathbb{R})^n))$ satisfies*

1. *for* $l = 1, \ldots, n$, *each map* (ρ_l, q_l) *is a weak entropy solution to* (1.1) *for* $x \in \mathring{\mathbb{R}}^+$ *and* $t \in \mathbb{R}^+$,
2. *for a.e.* $t \in \mathring{\mathbb{R}}^+$, *the trace* $(\bar\rho_l, \bar q_l)(t) = \lim_{x \to 0+} (\rho_l, q_l)(t, x)$ *is the initial data of a stationary solution to the Riemann problem* (2.2) *in the sense of Definition* 2.1,

then it is a weak solution to (3.1).

The proof is an adaptation of [9, Propositions 2.1, 2.2, and 3.2] and is omitted. We proceed to the main result of this paper: the well posedness of the solution to the Cauchy problem for the p-system at a junction.

THEOREM 3.3. *Fix an n-tuple of subsonic states* $(\hat\rho, \hat q) \in (\mathring{A}_0)^n$, *giving a stationary solution to the Riemann problem* (2.2), *in the sense of Definition* 2.1, *with entropy flux strictly negative. Then, there exist positive constants* δ_0, L *and a map* $S\colon [0, +\infty[\times \mathcal{D} \to \mathcal{D}$, *with the following properties*:

1. $\mathcal{D} \supseteq \{(\rho, q) \in (\hat\rho, \hat q) + \mathbf{L^1}(\mathbb{R}^+; (\mathring{\mathbb{R}}^+ \times \mathbb{R})^n)\colon \mathrm{TV}(\rho, q) \le \delta_0\}$.
2. *For* $(\rho, q) \in \mathcal{D}$, $S_0(\rho, q) = (\rho, q)$ *and for* $s, t \ge 0$, $S_s S_t(\rho, q) = S_{s+t}(\rho, q)$.
3. *For* $(\rho, q), (\rho', q') \in \mathcal{D}$ *and* $s, t \ge 0$,
$$\|S_t(\rho, q) - S_s(\rho', q')\|_{\mathbf{L^1}} \le L \cdot (\|(\rho, q) - (\rho', q')\|_{\mathbf{L^1}} + |t - s|).$$
4. *If* $(\rho, q) \in \mathcal{D}$ *is piecewise constant, then for* $t > 0$ *sufficiently small,* $S_t(\rho, q)$ *coincides with the juxtaposition of the solutions to Riemann problems centered at the points of jumps or at the junction.*

Moreover, for every $(\rho, q) \in \mathcal{D}$, *the map* $t \to S_t(\rho, q)$ *is a weak entropy solution to the Cauchy problem* (3.1) *in the sense of Definition* 3.1.

Note that 1–4 above are the natural extension of the definition of the standard Riemann semigroup [4, Definition 9.1] to the Cauchy problem (3.1). In general, the linear momentum fails to be conserved. Indeed, the following estimate holds.

PROPOSITION 3.4. *Let* $n \in \mathbb{N}$ *with* $n \ge 2$ *and* $\nu_1, \ldots, \nu_n \in \mathbb{R}^3$ *be pairwise distinct. Fix* $(\hat\rho, \hat q) \in (\mathring{\mathbb{R}}^+ \times \mathbb{R})^n$ *and* $T \in]0, +\infty]$. *Let* $(\rho, q) \in \mathbf{C^0}([0, T]; (\hat\rho, \hat q) + \mathbf{L^1}(\mathbb{R}^+; (\mathring{\mathbb{R}}^+ \times \mathbb{R})^n))$ *be a solution to* (1.1) *in the sense of Definition* 2.1. *Then,*

$$Q(t_2) - Q(t_1) = \left(\int_{t_1}^{t_2} P_*(t)\, dt \right) \sum_{l=1}^{n} \nu_l,$$

where, for $l = 1, \ldots, n$ *and a.e.* $t_1, t_2 \in [0, T]$, $P_*(t) = P(\rho_l(t, 0^+), q_l(t, 0^+))$.

The proof is similar to that of [9, Proposition 3.2] and is omitted. The term on the right-hand side above is the impulse of the reaction constraint and describes the defect in the conservation of the total linear momentum.

4. Technical details. The first part of this section deals with the basic properties of the p-system and with the proof of Proposition 2.4. Subsection 4.2 describes the wave-front tracking construction and the estimates for the existence and well posedness of the Cauchy problem.

In this section, we use the notation $u = [\rho \quad q]^T$.

4.1. Properties of the *p*-system. We recall here basic formulas of the p-system (1.1) valid for a pressure law satisfying **(EoS)**. Throughout, $c(\rho) = \sqrt{p'(\rho)}$ denotes the sound speed. Let λ_i be the ith eigenvalue corresponding to the ith right eigenvector r_i of the Jacobian of the flow $f(\rho, q) = [q \;\; q^2/\rho + p(\rho)]^T$. We have

$$
\begin{aligned}
&\lambda_1(\rho, q) = \tfrac{q}{\rho} - c(\rho)\,, && \lambda_2(\rho, q) = \tfrac{q}{\rho} + c(\rho)\,,\\
&r_1(\rho, q) = \begin{bmatrix} \rho \\ q - \rho c(\rho) \end{bmatrix}, && r_2(\rho, q) = \begin{bmatrix} \rho \\ q + \rho c(\rho) \end{bmatrix},\\
&\nabla\lambda_1 \cdot r_1 = -c(\rho) - \rho c'(\rho), && \nabla\lambda_2 \cdot r_2 = c(\rho) + \rho c'(\rho).
\end{aligned}
\tag{4.1}
$$

The speeds of $1,2$-shock waves between (ρ_o, q_o) and the state at density ρ are

$$\Lambda_{\frac{1}{2}}(\rho, \rho_o, q_o) = \frac{q_o}{\rho_o} \mp \sqrt{\frac{\rho}{\rho_o} \cdot \frac{p(\rho) - p(\rho_o)}{\rho - \rho_o}}.$$

The (forward) $1,2$-Lax curves have the expressions

$$
L_1(\rho; \rho_o, q_o) = \begin{cases} \dfrac{\rho}{\rho_o} q_o - \rho \displaystyle\int_{\rho_o}^{\rho} \frac{c(r)}{r}\, dr & \text{if } \rho < \rho_o, \\ \dfrac{\rho}{\rho_o} q_o - \sqrt{\dfrac{\rho}{\rho_o} (\rho - \rho_o)\,(p(\rho) - p(\rho_o))} & \text{if } \rho > \rho_o, \end{cases}
$$

$$
L_2(\rho; \rho_o, q_o) = \begin{cases} \dfrac{\rho}{\rho_o} q_o - \sqrt{\dfrac{\rho}{\rho_o} (\rho - \rho_o)\,(p(\rho) - p(\rho_o))} & \text{if } \rho < \rho_o, \\ \dfrac{\rho}{\rho_o} q_o + \rho \displaystyle\int_{\rho_o}^{\rho} \frac{c(r)}{r}\, dr & \text{if } \rho > \rho_o \end{cases}
$$

(see Figure 4.1, right), while the reversed $1,2$-Lax curves exiting $(\bar\rho, \bar q)$ are

$$
\begin{aligned}
L_1^-(\rho; \bar\rho, \bar q) &= \begin{cases} \dfrac{\rho}{\bar\rho} \bar q + \sqrt{\dfrac{\rho}{\bar\rho} (\bar\rho - \rho)\,(p(\bar\rho) - p(\rho))} & \text{if } \rho < \bar\rho, \\ \dfrac{\rho}{\bar\rho} \bar q - \rho \displaystyle\int_{\bar\rho}^{\rho} \frac{c(r)}{r} dr & \text{if } \rho > \bar\rho, \end{cases}\\
L_2^-(\rho; \bar\rho, \bar q) &= \begin{cases} \dfrac{\rho}{\bar\rho} \bar q + \sqrt{\dfrac{\rho}{\bar\rho} (\rho - \bar\rho)\,(p(\rho) - p(\bar\rho))} & \text{if } \rho > \bar\rho, \\ \dfrac{\rho}{\bar\rho} \bar q - \rho \displaystyle\int_{\rho}^{\bar\rho} \frac{c(r)}{r} dr & \text{if } \rho < \bar\rho. \end{cases}
\end{aligned}
\tag{4.2}
$$

Proof of Proposition 2.4. For simplicity denote with u_l the states $(\bar\rho_l, \bar q_l)$. Assume that in a pipe, say 1, a shock wave connecting u_1 with $u_1^r = (\rho_1^r, q_1^r)$ arrives at the junction. Clearly $\rho_1 < \rho_1^r$. We have

$$\frac{d}{d\rho} P(\rho, L_1(\rho; u_1))_{|\rho=\rho_1} = (\lambda_1(u_1))^2 > 0,$$

and thus $P(u_1) < P(u_1^r)$. Denote with $\tilde u_1 \in A_0$ the point of the reversed Lax curve of the second family through u_1^r having dynamical pressure equal to $P(u_1)$. The n-tuple $(\tilde u_1, u_2, \ldots, u_n)$ does not provide a stationary solution to the Riemann problem at the junction, since the sum in **(M)** is less than 0. Therefore the solution to the Riemann problem has a dynamical pressure $P_* > P(u_1)$. Since the dynamical pressure P is strictly increasing along the reversed Lax curves of the second family [8, Lemma 1], we conclude that shock waves are generated in all pipes, except the first one.

Similar considerations hold in the case of a rarefaction wave. ∎

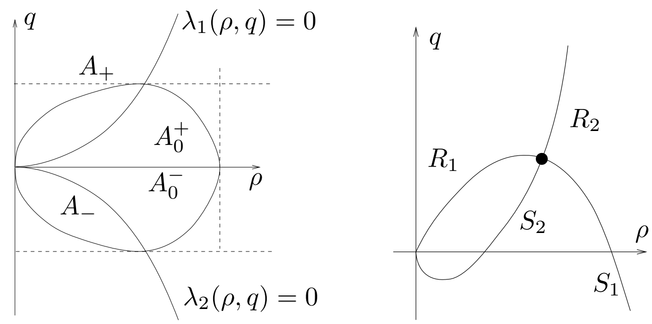


FIG. 4.1. *Left*: *the regions* A_-, $A_0^{\pm}$, A_+ *and a level curve of the dynamic pressure. Right*: *the Lax forward curves for* (1.1).

4.2. Wave-front tracking with the junction. This subsection is devoted to the proof of Theorem 3.3. To do this, we introduce a wave-front tracking approximation for our Cauchy problem and a functional measuring the distance in $\mathbf{L^1}$ between two piecewise constant solutions. The construction of a solution to (3.1) is given adapting the wave-front tracking technique; see [4, Chapter 7] or [10, Chapter 14].

Define $\hat{u}_l = (\hat{\rho}_l, \hat{q}_l)$ for $l = 1, \ldots, n$. Let $\hat{\delta} > 0$ be such that $B(\hat{u}_l, \hat{\delta}) \subset \mathring{A}_0$ for $l = 1, \ldots, n$ and introduce the compact set $\mathcal{B} = \prod_{l=1}^n \overline{B(\hat{u}_l, \hat{\delta})}$.

Approximate the initial datum u_o with a sequence $u_{o,\nu}$ of piecewise constant initial data each having a finite number of discontinuities so that $\lim_{\nu \to +\infty} \|u_{o,\nu} - u_o\|_{\mathbf{L^1}} = 0$. Then, at the junction and at each point of jump in the approximate initial datum along the ducts, we solve the corresponding Riemann problem. The Riemann problem at the junction is solved according to Definition 2.1. If the total variation of the initial datum is sufficiently small, then Theorem 2 in [8] assures the existence and uniqueness of the solution to the Riemann problem. We approximate each rarefaction wave with a rarefaction fan, i.e., by means of (nonentropic) shock waves traveling at the characteristic speed of the state to the right of the shock.

This construction can be extended up to the first time $\bar{t}_1$ at which two waves interact in a duct or a wave hits the junction. Clearly, at time $\bar{t}_1$ the functions so constructed are piecewise constant with a finite number of discontinuities. Hence, at any subsequent interaction or collision with the junction, we repeat the previous construction with the following provisions:

1. No more than two waves interact at the same point or at the junction.
2. A rarefaction fan of the ith family produced by the interaction between an ith rarefaction and any other wave is *not* split any further.
3. When the product of the strengths of two interacting waves falls below a threshold $\check{\varepsilon}$, then we let the waves cross each other, their size being unaltered, and introduce a *nonphysical* wave with speed $\hat{\lambda}$, with $\hat{\lambda} > \sup_u \lambda_2(u)$; see [4, Chapter 7] and the refinement [1].

In the present case, we have to complete the above algorithm by stating how the Riemann problem at the junction is to be solved. At time $t = 0$ and whenever a physical wave with size greater than $\check{\varepsilon}$ hits the junction, the accurate solver is used; i.e., the exact solution as in Definition 2.1 is approximated by replacing rarefaction waves with rarefaction fans. When a wave with strength smaller than $\check{\varepsilon}$ hits the junction, then we let it be reflected into a nonphysical wave with speed $\hat{\lambda}$, and no wave in any other duct is produced.

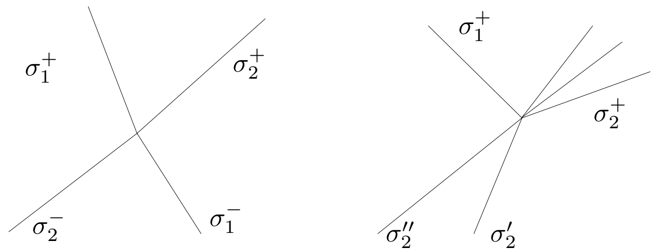

FIG. 4.2. *Interactions in the* (t, x) *plane and notation for the standard interaction estimates in Lemma* 4.1.

Repeating this procedure recursively, we construct a wave-front tracking sequence of approximate solutions u_ν in the sense of [4, Definition 7.1].

A key role in wave-front tracking is played by interaction estimates. At interactions of waves in a duct, we have the following classical result.

LEMMA 4.1. *There exists a constant* K *with the following property.*

1. *If there is an interaction in a duct between two waves* σ_1^- *and* σ_2^-, *respectively of the first and the second family, producing the waves* σ_1^+ *and* σ_2^+ *(see Figure* 4.2, *left), then*

$$\left|\sigma_1^+ - \sigma_1^-\right| + \left|\sigma_2^+ - \sigma_2^-\right| \leq K \cdot \left|\sigma_1^- \sigma_2^-\right| . \tag{4.3}$$

2. *If there is an interaction in a duct between two waves* σ_i' *and* σ_i'' *of the same* i*th family producing waves of total size* σ_1^+ *and* σ_2^+ *(see Figure* 4.2, *right, for the case* $i = 2$*), then*

$$\begin{aligned} \left|\sigma_1^+ - (\sigma_1'' + \sigma_1')\right| + \left|\sigma_2^+\right| &\leq K \cdot |\sigma_1' \sigma_1''| \qquad \text{if } i = 1, \\ \left|\sigma_1^+\right| + \left|\sigma_2^+ - (\sigma_2'' + \sigma_2')\right| &\leq K \cdot |\sigma_2' \sigma_2''| \qquad \text{if } i = 2. \end{aligned}$$

3. *If there is an interaction in a duct between two physical waves* σ_1^- *and* σ_2^- *producing a nonphysical wave* σ_3^+ *(see Figure* 4.3, *left), then*

$$\left|\sigma_3^+\right| \leq K \cdot \left|\sigma_1^- \sigma_2^-\right|.$$

4. *If there is an interaction in a duct between a physical wave* σ *and a nonphysical wave* σ_3^- *producing a physical wave* σ *and a nonphysical wave* σ_3^+ *(see Figure* 4.3, *right), then*

$$\left|\sigma_3^+\right| - \left|\sigma_3^-\right| \leq K \cdot \left|\sigma \sigma_3^-\right|.$$

For a proof of this result see [4, Chapter 7]. Remember that nonphysical waves cannot interact with the junction or with other nonphysical waves.

In the case of the junction, with the notation in Figure 4.4, we have the following result.

PROPOSITION 4.2. *Let* (EoS) *hold. There exist* $\delta_J > 0$ *and* $K_J \geq 1$ *with the following property. For any* $\bar{u} \in \mathcal{B}$ *that yields a stationary solution to the Riemann problem* (2.2), *for any* 1*-waves* $\sigma_l^- \in \,]-\delta_J, \delta_J[$ *hitting the junction and producing the* 2*-waves* σ_l^+, *it holds that*

$$\sum_{l=1}^{n} \left|\sigma_l^+\right| \leq K_J \cdot \sum_{l=1}^{n} \left|\sigma_l^-\right| . \tag{4.4}$$

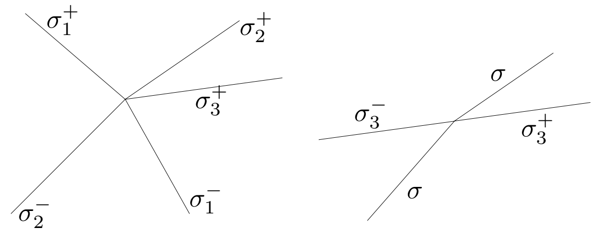

FIG. 4.3. *Left: in the* (t, x) *plane, a nonphysical wave arises, and right: a nonphysical wave interacts with a physical one.*

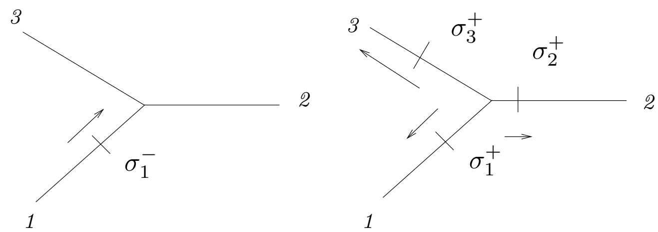

FIG. 4.4. *Notation for Proposition* 4.2: *in the physical space, before the interaction (left) and after the interaction (right).*

Proof. We recall that, similarly to the proof of [8, Theorem 1], the densities ρ_l^+ after the interaction solve

$$\sum_{l=1}^{n} \|\nu_l\| \, L_2^-(\rho_l^+; \rho_l^-, L_1(\rho_l^-; \bar{u})) = 0,$$

$$P(\rho_l^+, L_2^-(\rho_l^+; L_1(\rho_l^-; \bar{u}))) = P(\rho_{l-1}^+, L_2^-(\rho_{l-1}^+; L_1(\rho_{l-1}^-; \bar{u}))).$$

Applying the implicit function theorem in a neighborhood of $\rho_l^- = \rho_l^+ = \bar{\rho}$, we obtain $(\rho_1^+, \dots, \rho_n^+)$ as a function of $(\rho_1^-, \dots, \rho_n^-)$. Moreover,

$$\sum_{l=1}^{n} \left|\rho_l^+ - \bar{\rho}\right| \le \tilde{K} \cdot \sum_{l=1}^{n} \left|\rho_l^- - \bar{\rho}\right|.$$

Pass now to the arc-length parametrization, since in $\mathcal{B}$ the arc-length is a bi-Lipschitz function of the density variation. More precisely, the unknowns $\partial_{\rho_1^-} \rho_l^+$ solve the linear system $Ax = b$, where, setting $\lambda_i(l) = \lambda_i(\bar{\rho}_l, \bar{q}_l)$,

$$A = \begin{bmatrix} \|\nu_1\|\lambda_2(1) & \|\nu_2\|\lambda_2(2) & \|\nu_3\|\lambda_2(3) & \dots & \|\nu_n\|\lambda_2(n) \\ (\lambda_2(1))^2 & -(\lambda_2(2))^2 & 0 & \dots & 0 \\ (\lambda_2(1))^2 & 0 & -(\lambda_2(3))^2 & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots \\ (\lambda_2(1))^2 & 0 & 0 & \dots & -(\lambda_2(n))^2 \end{bmatrix},$$

$$b = \|\nu_1\|\lambda_1(1) \begin{bmatrix} 1 & \lambda_2(1) + 2\frac{q}{\rho} & \lambda_2(1) + 2\frac{q}{\rho} & \cdots & \lambda_2(1) + 2\frac{q}{\rho} \end{bmatrix}^T.$$

This concludes the proof. $\square$

Define $K_1 = 2KK_J + 1$. Fix a wave-front tracking approximate solution u_ν. For $t > 0$ and $l \in \{1, \dots, n\}$, we denote with $x_{l,\alpha}$ $(\alpha \in J_l(u))$ the positions of the discontinuities of the approximate solution in the lth duct and with $\sigma_{l,1,\alpha}$, $\sigma_{l,2,\alpha}$, $\sigma_{l,3,\alpha}$ the strengths of the waves of the first family, the second family, and the nonphysical waves at $x_{l,\alpha}$, respectively. Introduce the Glimm-type functionals

$$V(t) = \sum_{l=1}^{n} \sum_{\alpha \in \mathcal{J}_l} [2\,K_J \cdot |\sigma_{l,1,\alpha}| + |\sigma_{l,2,\alpha}| + |\sigma_{l,3,\alpha}|],$$

$$Q(t) = \sum_{l=1}^{n} \sum \{ |\sigma_{l,i,\alpha}\,\sigma_{l,j,\beta}| \colon (\sigma_{l,i,\alpha}, \sigma_{l,j,\beta}) \in \mathcal{A}_l \},$$

$$\Upsilon(t) = V(t) + K_1 \cdot Q(t), \tag{4.5}$$

where $\mathcal{A}_l$ denotes the set of approaching waves in the lth duct; see [4].

The functionals above are well defined for every $t > 0$ at which no interaction happens. Suppose now that at a time $\tau > 0$ there is an interaction between $k \in \{1, \ldots, n\}$ waves $\sigma_{k,1,\alpha}$ of the first family and the junction. This interaction produces n waves $\sigma'_{l,2,\alpha}$ of the second family. Thus

$$\Delta V(\tau) \le \sum_{l=1}^{n} [\,|\sigma'_{l,2,\alpha}| - 2\,K_J\,|\sigma_{l,1,\alpha}|\,] \;\le\; -K_J \sum_{l=1}^{n} |\sigma_{l,1,\alpha}|,$$

$$\Delta Q(\tau) \le K_J V(\tau-) \sum_{l=1}^{n} |\sigma_{l,1,\alpha}|,$$

$$\Delta \Upsilon(\tau) \le K_J \cdot [K_1\, V(\tau-) - 1] \cdot \sum_{l=1}^{n} \left|\sigma^-_{l,1,\alpha}\right|.$$

Suppose now that an interaction between two waves $\sigma_{l,i,\alpha}$, $\sigma'_{l,j,\beta}$ happens in a duct at time τ. We deduce that

$$\Delta V(\tau) \le 2KK_J \left|\sigma_{l,i,\alpha}\sigma'_{l,j,\beta}\right|,$$

$$\Delta Q(\tau) \le K \left|\sigma_{l,i,\alpha}\sigma'_{l,j,\beta}\right| V(\tau-) - \left|\sigma_{l,i,\alpha}\sigma'_{l,j,\beta}\right|,$$

$$\Delta \Upsilon(\tau) \le \left|\sigma_{l,i,\alpha}\sigma'_{l,j,\beta}\right| [K(2K_J + K_1 V(\tau-)) - K_1].$$

We have thus proved the following basic result.

PROPOSITION 4.3. *Let* $\delta_1 = (1/(2K_1)) \min\{1/K, 1\}$. *At any interaction time* $\tau > 0$*, if* $V(\tau-) < \delta_1$*, then* $\Delta\Upsilon(\tau) < 0$ *with* Υ *defined in* (4.5).

Proof of Theorem 3.3. Let δ_1 be as in Proposition 4.3 and define

$$\tilde{\mathcal{D}} = \{ u \in (\hat\rho, \hat q) + (\mathbf{PC} \cap \mathbf{L^1}(\mathbb{R}^+; (\mathring{\mathbb{R}}^+ \times \mathbb{R})^n)) \colon \Upsilon(u) \le \delta_1 \}.$$

There exists $C_1 > 0$ such that $\frac{1}{C_1}\,\mathrm{TV}\,(u)(t,\cdot) \le V(t) \le C_1\,\mathrm{TV}\,(u)(t,\cdot)$ for all $u \in \tilde{\mathcal{D}}$. Any initial datum in $\tilde{\mathcal{D}}$ yields an approximate solution to (1.1) attaining values in $\tilde{\mathcal{D}}$ by Proposition 4.3, and thus, by classical arguments (see [4]), for all initial data in $\mathcal{D}$ a solution to (3.1) exists for every $t > 0$ and attains values in $\mathcal{D}$, where $\mathcal{D}$ is the $\mathbf{L^1}$ closure of $\tilde{\mathcal{D}}$. Hence, statements 1 and 2 in Theorem 3.3 clearly hold. The limit orbits $t \to S_t u$ are indeed solutions in the sense of Definition 3.1; note that the existence of the trace $P_*(t)$ at the junction follows from Definition 2.1 and [7, Proposition 5.3].

We pass now to the well posedness of the Cauchy problem. Consider two ε–wave-front tracking approximate solutions u_1 and u_2. Define the functional

$$\Phi(u_1, u_2) = \sum_{l=1}^{n} \sum_{i=1}^{2} \int_0^{+\infty} |s_{l,i}(x)|\, W_{l,i}(x)\, dx\,, \tag{4.6}$$

where $s_{l,i}(x)$ measures the strengths of the ith shock wave in the lth duct at point x (see [4, Chapter 8]) and the weights $W_{l,i}$ are defined by

$$W_{l,i}(x) = 1 + \kappa_1 \, A_{l,i}(x) + \kappa_1 \, \kappa_2 \, [\Upsilon(u_1) + \Upsilon(u_2)].$$

Here Υ is the functional defined in (4.5), while the $A_{l,i}$ are defined by

$$\begin{aligned} A_{l,i}(x) = {} & \sum \left\{ |\sigma_{l,k_\alpha,\alpha}| : \begin{array}{l} x_\alpha < x, \ i < k_\alpha \leq 2, \\ x_\alpha > x, \ 1 \leq k_\alpha < i, \end{array} \right\} \\ & + \left\{ \begin{array}{ll} \sum \left\{ |\sigma_{l,i,\alpha}| : \begin{array}{l} x_\alpha < x, \ \alpha \in J(u_1), \\ x_\alpha > x, \ \alpha \in J(u_2), \end{array} \right\} & \text{if } q_{l,i}(x) < 0, \\ \sum \left\{ |\sigma_{l,i,\alpha}| : \begin{array}{l} x_\alpha < x, \ \alpha \in J(u_2), \\ x_\alpha > x, \ \alpha \in J(u_1), \end{array} \right\} & \text{if } q_{l,i}(x) \geq 0; \end{array} \right. \end{aligned}$$

see [4, Chapter 8]. We first fix κ_1, κ_2 so that δ_0 in the definition of $\mathcal{D}$ can be chosen to satisfy $1 \leq W_{l,i}(x) \leq 2$ for every $l \in \{1, \ldots, n\}$, $i \in \{1, 2\}$, and $x \geq 0$. Hence the functional Φ is equivalent to the $\mathbf{L^1}$ distance; i.e.,

$$\Phi(u_1, u_2) \geq \frac{1}{C_2} \cdot \|u_1 - u_2\|_{\mathbf{L^1}} \quad \text{and} \quad \Phi(u_1, u_2) \leq C_2 \cdot \|u_1 - u_2\|_{\mathbf{L^1}}$$

for a positive constant C_2. The same calculations as in [4, Chapter 8] show that, at any time $t > 0$ when an interaction happens neither in u_1 nor in u_2,

$$\frac{d}{dt} \Phi(u_1(t), u_2(t)) \leq C_3 \, \varepsilon \,, \tag{4.7}$$

where C_3 is a suitable positive constant depending only on a bound on the total variation of the initial data. If $t > 0$ is an interaction time for u_1 or u_2, then, by Proposition 4.3, $\Delta[\Upsilon(u_1(t)) + \Upsilon(u_2(t))] < 0$ and, choosing κ_2 large enough, we obtain

$$\Delta \Phi(u_1(t), u_2(t)) < 0 \,. \tag{4.8}$$

Thus, $\Phi(u_1(t), u_2(t)) - \Phi(u_1(s), u_2(s)) \leq C_2 \, \varepsilon \, (t - s)$ for every $0 \leq s \leq t$, proving statement 3. Statement 4 follows by standard arguments. $\square$

CONVERGENCE OF GIBBS MEASURES ASSOCIATED WITH SIMULATED ANNEALING*

DENNIS D. COX†, ROBERT M. HARDT‡, AND PETR KLOUČEK§

Abstract. We give a sufficient condition for a sequence of Gibbs measures dominated by Lebesgue measure to converge to a singular measure concentrated on a submanifold. The limiting measure is absolutely continuous with respect to Hausdorff (Riemannian) measure on the submanifold, and a formula for its density is given. These results have implications for simulated annealing algorithms on a continuous state space when the set of minimizers of the objective function is more complex than a finite set of points. Under regularity conditions, the limiting measure is concentrated on the highest dimensional submanifold of the set of minimizers, so that lower dimensional components of the minimizing set are essentially lost. A generalization of the main result treats multiple limits within submanifolds, which could be useful for constrained optimization with simulated annealing. An example is given which shows that if the conditions of the theorem do not hold, then unexpected results may occur.

Key words. Gibbs measure, Hausdorff measure, simulated annealing, Markov chain Monte Carlo methods, differential inclusions

1. Introduction.

We consider some measure theoretic problems that arise in the context of simulated annealing. Simulated annealing (SA) [22], [16] is a stochastic optimization algorithm that mimics the physical process of a thermodynamic system settling into the state of minimal energy while lowering the temperature. It is usually considered in a discrete state space setting when the objective has multiple minima, but continuous state space simulated annealing has found many applications [5], [6], [21]. The version of the SA algorithm we consider here is in the Metropolis–Hastings (MH) family of algorithms, which is one of the main methods for Markov chain Monte Carlo (MCMC). We also consider continuous state space simulated annealing with equality constraints that can be expressed as the zero set of a nonnegative function. One approach for dealing with the constraints is a relaxation method wherein one adds a nonnegative multiple of the constraint function to the objective and lets the multiplier go to infinity. The work in the present paper indicates that without appropriate conditions, the procedure may not converge to the desired constrained minimum. Other authors have considered similar approaches to constrained simulated annealing (see [28], [14]).

We first consider an unconstrained problem. Suppose our goal is to find the set

$$\operatorname*{Argmin}_{x\in\mathbb{R}^n} J(x),$$

where J is a continuous function, bounded below, and $J(x) \to \infty$ as $|x|_{\mathbb{R}^n} \to \infty$ sufficiently fast so that

$$Z_\lambda^{-1} \;=\; \int_{\mathbb{R}^n} e^{-\lambda J(x)}\,dx \;<\; \infty$$

for some $\lambda > 0$. We may then define a probability density function

$$f_\lambda(x) \;=\; Z_\lambda e^{-\lambda J(x)}. \tag{1.1}$$

The corresponding probability distribution, P_λ, given for any Borel subset B of $\mathbb{R}^n$ by

$$P_\lambda(B) = \int_B f_\lambda\,(x)\;dx, \tag{1.2}$$

is known as a *Gibbs measure*. In a thermodynamic setting, x represents the state of the system, and $\lambda = (kT)^{-1}$, where k is Boltzmann's constant and T is temperature. Using MCMC methods it is possible to construct ergodic Markov chains $\{\boldsymbol{X}_k\}_{k=0}^\infty$ whose distribution approaches a *stationary distribution* which is P_λ [12].

The idea behind SA is to concentrate the Gibbs measure on the set of minima by letting $T \to 0$, i.e., $\lambda \to \infty$. Then the simulated values of the Markov chain will be close to a minimum with high probability. This convergence will not necessarily be uniform on the set of minima. Note that there are two limits taking place here: we must simulate a realization from the Markov chain $\{\boldsymbol{X}_{m,\lambda} : m = 1, 2, \ldots\}$ and stop at a large value of m so that the probability distribution for $\boldsymbol{X}_{m,\lambda}$ is close to P_λ. Then we increase λ (which changes the dynamics of the Markov chain) and run, say, m_1 more simulations with the new value, increase λ again, etc.

Next consider constrained optimization problems. Suppose that J_0 and J_1 are nonnegative functions satisfying conditions similar to those for J, and that we wish to find the minimizers of J_0 when x is constrained to the set

$$M \;=\; \{x \in \mathbb{R}^n \mid J_1\,(x) \;=\; 0\}\,. \tag{1.3}$$

One approach to solving the constrained minimization problem is to apply SA to the Gibbs measure P_{λ_0,λ_1} with density

$$\begin{aligned} f\,(x;\lambda_0,\lambda_1) &\overset{\text{def}}{=} Z_{\lambda_0,\lambda_1} e^{-\lambda_0 J_0(x)-\lambda_1 J_1(x)},\\ Z^{-1}_{\lambda_0,\lambda_1} &\overset{\text{def}}{=} \textstyle\int_{\mathbb{R}^n} e^{-\lambda_0 J_0(x)-\lambda_1 J_1(x)}\,dx. \end{aligned} \tag{1.4}$$

One could then let $\lambda_1 \to \infty$ so that the Gibbs measure will concentrate on the constraint set M, and then afterwards let $\lambda_0 \to \infty$ to find the minima on the constraint set M. One question we address in this article is, Under what conditions could we expect P_{λ_0,λ_1} to concentrate on the set of constrained minima as $\lambda_1 \to \infty$ and then $\lambda_0 \to \infty$? One might conjecture that as $\lambda_1 \to \infty$, the limit of P_{λ_0,λ_1} would be a measure on the constraint set M which is absolutely continuous (dominated by) a Hausdorff measure on M and the density with respect to a Hausdorff measure being a multiple of $e^{-\lambda_0 J_0}$. The first main result of this paper, stated in section 3, gives sufficient conditions for the first part of the conjecture to hold. In particular, under regularity assumptions about the constraint function J_1, the constraint set M will be a disjoint union of submanifolds, and the limiting measure will concentrate on the highest dimensional submanifold. Further, there may be nonconstant factors in the density for the limiting measure that come from the Hessian $D^2 J_1$. In section 3 we also give a generalization which treats the case of multiple limits, with the occurrence of a new factor in the limiting measure that indicates the degree of "orthogonality" of the multiple constraints on the common constraint set. Some examples of these theorems are given in section 4. Other examples in this section, which are not covered by the results of section 3, show that the support of the limiting measure P_{λ_1,λ_2} as $\lambda_1 \to \infty$ can be a subset of the constraint set which does not include the constrained minima of J_2.

Our main objective here is to initiate the development of a theory for handling these limiting Gibbs measures in complex situations. The paper is organized as follows. We discuss the SA and constrained SA in more detail in section 2 and show how the results here pertain to the limiting behavior of these algorithms. The main results are stated in section 3. In section 4 we present three examples, two of which exemplify the main theorems and one where the limit of the Gibbs measure can be determined through ad hoc methods. Further possible applications are discussed in section 5, including the problem which motivated our study, namely, solving differential inclusions which are used for modeling functional materials. The remaining sections present technical details of the proofs of the theorems.

2. Simulated annealing. We will first define the MH algorithm, which eventually generates an approximate sample from a given probability density function $f(\cdot)$ on $\mathbb{R}^n$. Consider a family of "proposal" distributions $R(x,\cdot)$, where for each fixed x, $R(x,\cdot)$ is a Borel probability measure on $\mathbb{R}^n$. Suppose that $R(x,\cdot)$ has density $r(x,\cdot)$ with respect to Lebesgue measure. Starting from some initial state $\boldsymbol{X}_0$, we will recursively generate new states. Given the current state $\boldsymbol{X}_m$, the next state $\boldsymbol{X}_{m+1}$ is generated as follows:

Step 1. Generate a "proposal for the new state," $\boldsymbol{X} \in \mathbb{R}^n$, from the measure $R(\boldsymbol{X}_m,\cdot)$.

Step 2. Compute

$$\alpha(\boldsymbol{X}_m,\boldsymbol{X}) = \frac{f(\boldsymbol{X})r(\boldsymbol{X},\boldsymbol{X}_m)}{f(\boldsymbol{X}_m)r(\boldsymbol{X}_m,\boldsymbol{X})}.$$

Step 3. Let $W \in [0,1)$ be a random number drawn from the uniform distribution on $[0,1)$. Then

$$\boldsymbol{X}_{m+1} = \begin{cases} \boldsymbol{X} & \text{if} \quad W < \alpha(\boldsymbol{X}_m,\boldsymbol{X}), \\ \boldsymbol{X}_m & \text{otherwise.} \end{cases}$$

Note that if $\alpha(\boldsymbol{X}) \geq 1$, then the proposal $\boldsymbol{X}$ is automatically accepted, and thus there is no point in even generating the W in Step 3. Under very general conditions [26] the limiting distribution as $m \to \infty$ of $\{\boldsymbol{X}_m\}_m$ will have the probability density function f. This convergence takes place in total variation norm on measures at an exponential rate.

If the proposal density r satisfies a "reversibility" property, i.e., $r(x,y) = r(y,x)$, $x,y \in \mathbb{R}^n$, then the algorithm is identical to the original Metropolis algorithm and

$\alpha(\boldsymbol{X}) = f(\boldsymbol{X})/f(\boldsymbol{X}_m)$. An example of a reversible proposal distribution is any Gaussian distribution with the mean x, e.g.,

$$r(x, y) = (2\pi\sigma^2)^{-n/2}\ e^{-|x-y|^2/(2\sigma^2)}, \tag{2.1}$$

where $|x|$ indicates the norm of the vector $x \in \mathbb{R}^n$.

Now we describe an SA algorithm. Consider a sequence $\lambda_k \to \infty$. Starting with $k = 1$, replace f above by f_{λ_k} as given in (1.1) and run the MH algorithm until $\boldsymbol{X}_{m_k}$ has a distribution which is sufficiently close to the one with density f_{λ_k}. Now, increment k and start with $\boldsymbol{X}_{m_k}$ and repeat the MH algorithm. As long as we require that the total variation distance between the distribution of $\boldsymbol{X}_{m_k}$ and the distribution with density f_{λ_k} tends to 0 as $k \to \infty$, then it is clear that the limiting distribution of $\boldsymbol{X}_m$ will be the same as the limiting distribution of the Gibbs measures. This motivates our study of the limits of these Gibbs measures. There are various papers that consider the convergence of SA (e.g., [15], [13]). The basic idea is that $\boldsymbol{X}_m$ will converge to a global minimum of J as long as the temperature goes to 0 but not too fast.

Assuming a reversible proposal distribution for the SA algorithm described above, we see that a proposal $\boldsymbol{X}$ is automatically accepted if $f_{\lambda_k}(\boldsymbol{X}) \geq f_{\lambda_k}(\boldsymbol{X}_m)$, i.e., if the proposed $\boldsymbol{X}$ has value of the objective no larger than the current value, and the proposal is accepted with some positive probability if $0 < f_{\lambda_k}(\boldsymbol{X}) < f_{\lambda_k}(\boldsymbol{X}_m)$. This latter type of uphill step allows the Markov chain to avoid getting stuck in local minima. As the temperature go to 0 (i.e., $\lambda_k \to \infty$), the probability distribution for the state of the system becomes concentrated near the global minima of J. Keeping the temperature from cooling too quickly avoids getting stuck in local minima.

For constrained optimization problems, we can consider multiple temperatures as in (1.4). We then modify the SA algorithm so that both $\lambda_0 \to \infty$ and $\lambda_1 \to \infty$, slowly enough so that the distribution of each X_m is close to the appropriate Gibbs measure with density $f(\cdot; \lambda_0, \lambda_1)$. This methodology has been proposed in the discrete setting in [28]. The results stated in the next section show that the Gibbs measure will converge to a constrained minimum under certain conditions, and an example given in section 4 shows that this convergence can fail if the conditions of the theorems in section 3 are not valid.

3. Statement of the main results. For our first result, we consider a slight generalization of a Gibbs measure with density as in (1.1). For $\lambda > 0$ and nonnegative continuous functions h, J on $\mathbb{R}^n$ we assume that

$$Z_\lambda^{-1} \ = \ \int_{\mathbb{R}^n} h(x) e^{-\lambda J(x)}\, dx \ < \ \infty,$$

and then we have a probability density function

$$f(x; \lambda) \ = \ Z_\lambda h(x) e^{-\lambda J(x)} \tag{3.1}$$

and corresponding probability measure

$$P_\lambda(B) \ = \ \int_B f(x; \lambda)\, dx,$$

defined for Borel measurable subsets B of $\mathbb{R}^n$. We investigate the behavior of P_λ as $\lambda \to \infty$.

We will use *weak convergence of probability measures.* Suppose $\{P_m : m \in \mathbb{Z}\}$ is a sequence of probability measures and P is a fixed probability measure, all defined on the Borel sets $\mathcal{E}$ of a given Polish space E. *Weak convergence of* P_m *to* P, denoted $P_m \Rightarrow P$, means that

$$\int \phi dP_m \to \int \phi dP \qquad \text{for all bounded continuous real valued functions } \phi. \tag{3.2}$$

We note that $P_m \Rightarrow P$ is equivalent to the following (cf. Theorem 2.1 of [3]):

$$P_m(B) \to P(B) \qquad \text{for all Borel sets of } E \text{ such that } P(\partial B) = 0. \tag{3.3}$$

Recall that the probability distributions in the MH algorithm converge in total variation norm to the stationary distribution. However, convergence in total variation is not possible here since the limiting measure is mutually singular with each of the Gibbs measures. Convergence in total variation means $\sup_B |P_n(B) - P(B)| \to 0$.

For a function ψ with domain and range in some Euclidean spaces, we say $\psi \in C^{k,\alpha}(\Omega)$ (where $k \geq 0$ is an integer and $\alpha \in (0,1]$) if $D^k\psi$ exists, is continuous in Ω, and satisfies a uniform Hölder condition

$$\left|D^k\psi(x) - D^k\psi(y)\right| \;\leq\; C\,|x-y|^\alpha \quad \text{for} \quad x,\, y \,\in\, \Omega.$$

We say that an n-dimensional manifold M is $C^{k,\alpha}$ if it has a $C^{k,\alpha}$-atlas, i.e., a partition into finitely many open sets (in the relative topology of M), and each open set in the partition is homeomorphic with $\mathbb{R}^n$ by a $C^{k,\alpha}$ homeomorphism whose inverse is also $C^{k,\alpha}$.

Now we state our first result.

THEOREM 3.1. *Assume the following*:

(A1) $h \in C^0(\mathbb{R}^n)$ *is bounded, and* $J \in C^{3,\alpha}(\mathbb{R}^n)$.

(A2) $h \geq 0$, *and* $J \geq 0$.

(A3) *For some* $p > 0$, $J(x) \geq \|x\|^p$ *for all* $\|x\|$ *sufficiently large.*

(A4) $M = \{x \in \mathbb{R}^n : J(x) = 0\}$ *is nonempty and bounded.*

(A5) *There exist a bounded disjoint open set* $U_1, U_2, \ldots, U_j$ *and integers* $0 \leq m_1 < m_2 < \cdots < m_j \leq n$ *satisfying the following*:

- (a) $M \subset U = U_1 \cup U_2 \cup \cdots \cup U_j$.
- (b) *Each set* $M_i = M \cap U_i$ *is a* $C^{2,\alpha}$ *smooth* m_i*-dimensional manifold.*
- (c) *On each* M_i, *the Hessian* D^2J *is nonnegative definite and has constant rank* $n - m_i$ *for* $i = 1, \ldots, j$.
- (d) *For some* $a \in M_1$, $h(a) > 0$.

Let $\mathcal{H}^{n-k_1}$ *be the* $(n-k_1)$*-dimensional Hausdorff measure on* M_1, *and let* $\Lambda(a)$ *be the product of the* k_1 *positive eigenvalues of* $D^2J(a)$ *for* $a \in M_1$. *Then*

$$P_\lambda \;\Rightarrow\; P \text{ as } \lambda \to \infty,$$

where, for any Borel set $B \subset \mathbb{R}^n$,

$$P(B) = Z \int_{M_1 \cap B} h(a)\,\Lambda(a)^{-1/2}\, d\mathcal{H}^{n-k_1}(a)$$

with

$$Z^{-1} = \int_{M_1} h(a)\,\Lambda(a)^{-1/2}\, d\mathcal{H}^{n-k_1}(a)\,.$$

Observe that, as $\lambda \to \infty$, the probability measures P_λ concentrate only on the highest dimensional stratum M_1 of $M = J^{-1}\{0\}$ and do not produce any lower dimensional measures on $M_2 \cup \cdots \cup M_j$.

Sections 6–8 gather material necessary for the proof of Theorem 3.1 in section 9. We note that special cases of this result are certainly well known; in particular, if M is zero-dimensional, i.e., a finite set of points $\{x_1, \ldots, x_m\}$, then by Laplace's method of asymptotic expansion [4], it is easy to see that the Gibbs measures will converge weakly to the probability measure on the discrete set of points with probabilities proportional to $h(x_i) \det D^2 J(x_i)$, $1 \le i \le m$.

Next we discuss a generalization of the main result to treat multiple limits. First, the ambient space $\mathbb{R}^n$ is replaced by a compact n-dimensional Riemannian manifold N. Consider probability measures of the form

$$dP_{\lambda_1\lambda_2\cdots\lambda_j} \;=\; Z_{\lambda_1\lambda_2\cdots\lambda_j} h(x) e^{-\lambda_1 J_1(x) - \lambda_2 J_2(x) - \cdots - \lambda_j J_j(x)}\, d\mathcal{H}^n(x). \tag{3.4}$$

Here the Hausdorff measure $\mathcal{H}^n$ is the standard Riemannian volume measure of N. We consider limits of the form

$$\lim_{\lambda_1\to\infty} \lim_{\lambda_2\to\infty} \cdots \lim_{\lambda_j\to\infty} P_{\lambda_1\lambda_2\cdots\lambda_j}.$$

If $J : N \longrightarrow \mathbb{R}$ is a smooth function, then the Riemannian Hessian of J at $a \in N$ is the bilinear form on the tangent space $T_a N$ whose value at (v, v) for $v \in T_a N$ is simply the initial second derivative of J along a geodesic starting at a with initial velocity v. In case the x_i are geodesic normal coordinates at a, this Hessian is represented at a by the usual matrix $\frac{\partial^2}{\partial x_i \partial x_j} J(a)$. We will also need the properties of the wedge product [25], specifically that if $v_1, \ldots, v_k$ are n-dimensional vectors, then $|v_1 \wedge \cdots \wedge v_k|$ is the k-dimensional volume of the k-dimensional parallelopiped $\{\sum_{i=1}^k t_i v_i : 0 \le t_i \le 1\}$.

THEOREM 3.2. *Suppose that $p > 0$ and that, for $i = 0, \ldots, j$, J_i is a nonnegative $C^{3,\alpha}$ function on N. Suppose also that each set $M_i = J_i^{-1}\{0\}$ is a $C^{3,\alpha}$ smooth compact $(n - k_i)$-dimensional submanifold on which the Riemannian Hessian $D^2 J_i$ is a nonnegative definite operator with range E_i of constant dimension k_i. With $k = k_1 + \cdots + k_j$, we also assume that the M_i intersect transversally (i.e., the E_i are linearly independent), giving the $(n - k)$-dimensional manifold*

$$M \;=\; \{x \in N : J_1(x) = J_2(x) = \cdots = J_j(x) = 0\}$$

on which the total Hessian $D^2(J_1 + \cdots + J_j)$ has range E of constant dimension k. Assume $h(a) > 0$ for some $a \in M$.

For $\lambda_1, \ldots, \lambda_j \ge 1$, let $P_{\lambda_1\cdots\lambda_j}$ be the probability measure on N given in (3.4), *where $h(x)$ is a bounded continuous function. Then*

$$P_{\lambda_1\cdots\lambda_j} \Rightarrow P \quad \text{as} \quad \lambda_1, \ldots, \lambda_j \to \infty, \ \textit{regardless of the order},$$

where, for any Borel set $B \subset \mathbb{R}^n$,

$$P(B) \;=\; Z \int_{M \wedge B} e^{-J_0(a)}\, \Lambda_1(a)^{-1/2} \cdots \Lambda_j(a)^{-1/2} \Theta(a)\, d\mathcal{H}^{n-k}(a).$$

Here

$$Z^{-1} \;= \int_M e^{-J_0}\, \Lambda_1^{-1/2} \cdots \Lambda_j^{-1/2} \Theta\, d\mathcal{H}^{n-k},$$

$\Lambda_i(a)$ *is the product of the* k_i *positive eigenvalues of* $D^2 J_i(a)$, *and*

$$\Theta(a) \;=\; |v_1^1 \wedge \cdots \wedge v_{k_1}^1 \wedge \cdots \wedge v_1^j \wedge \cdots \wedge v_{k_j}^j|,$$

where $\{v_1^i, \ldots, v_{k_i}^i\}$ *is an orthonormal basis for* $E_i(a)$ *for* $i = 1, \ldots, j$.

The proof of this result is given in section 9.2.

4. Examples. We will consider in depth three examples. The first is an application of Theorem 3.1, and the second of Theorem 3.2. The third example is similar to the first, but the hypotheses of Theorem 3.1 are not met, and using ad hoc calculations we show that the limiting measure is not the desired one. This example also shows that the order of taking the limits in a setting like Theorem 3.2 can matter when the hypotheses are violated.

4.1. Example 1. Consider the following two functions on $\mathbb{R}^2$:

$$J_1(x) \stackrel{\text{def}}{=} \left(|x|^2 - 1\right)^2, \tag{4.1}$$

$$J_2(x) \stackrel{\text{def}}{=} \begin{cases} x_1^2 x_2^2 & \text{if } |x|^2 < 2, \\ x_1^2 x_2^2 + \left(|x|^2 - 2\right)^4 & \text{if } |x|^2 \geq 2. \end{cases} \tag{4.2}$$

Let

$$g(x; \lambda_1, \lambda_2) \stackrel{\text{def}}{=} e^{-\lambda_1 J_1(x) - \lambda_2 J_2(x)},$$

$$Z_{\lambda_1,\lambda_2}^{-1} \stackrel{\text{def}}{=} \int_{\mathbb{R}^2} g(x; \lambda_1, \lambda_2) dx,$$

and let us define the normalized densities and the corresponding Gibbs measures as follows:

$$f(x; \lambda_1, \lambda_2) \stackrel{\text{def}}{=} Z_{\lambda_1,\lambda_2}\, g(x; \lambda_1, \lambda_2), \tag{4.3}$$

$$R(B; \lambda_1, \lambda_2) \stackrel{\text{def}}{=} \int_B g(x; \lambda_1, \lambda_2) dx, \tag{4.4}$$

$$P(B; \lambda_1, \lambda_2) \stackrel{\text{def}}{=} \int_B f(x; \lambda_1, \lambda_2) dx. \tag{4.5}$$

In the above definitions, B denotes a Borel set in $\mathbb{R}^2$.

Consider the limit $\lambda_1 \to \infty$ with λ_2 fixed. This could arise if we consider simulated annealing for the constrained optimization problem

$$\operatorname{Argmin}\{J_2(x) \,|\, x \in M\}, \qquad \text{where } M = \{x \in \mathbb{R}^2 \,|\, J_1(x) = 0\}.$$

We can apply Theorem 3.1 to find the limiting Gibbs measure in this case. Assumptions (A1)–(A3) and (A5) clearly hold. The set M where $J_1 = 0$ is the unit circle centered at the origin, S_1; hence (A4) is satisfied.

The Hessian of J_1 is given by

$$D^2 J_1(x_1, x_2) = \begin{pmatrix} 4\left(3x_1^2 + x_2^2 - 1\right) & 8x_1 x_2 \\ 8x_1 x_2 & 4\left(x_1^2 + 3x_2^2 - 1\right) \end{pmatrix}.$$

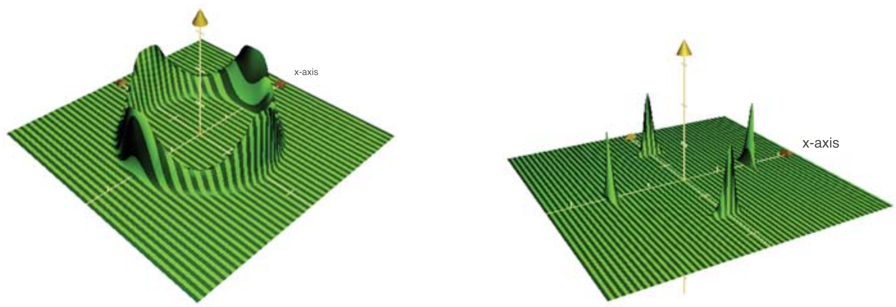

FIG. 1. *Plot of the unnormalized Gibbs density* $e^{-(\lambda_1 J_1(x)+\lambda_2 J_2(x))}$ *in Example* 1. *The picture on the left is a plot with* $\lambda_1 = 60$ *and* $\lambda_2 = 5$. *The picture on the right is a plot with* $\lambda_1 = 460$ *and* $\lambda_2 = 50$.

In particular,

$$D^2 J_1(x_1, 0) = \begin{pmatrix} 4\left(3x_1^2 - 1\right) & 0 \\ 0 & 4\left(x_1^2 - 1\right) \end{pmatrix}.$$

Thus, along the x_1-axis the eigenvalues are given by the diagonal entries, and the eigenvectors are the corresponding coordinate vectors. Noting that J_1 is rotationally symmetric, we see that

$$\operatorname{rank} D^2 J_1(x) = \begin{cases} 2 & \text{if } |x|^2 \neq 1 \text{ or } \frac{1}{3}, \\ 1 & \text{otherwise,} \end{cases}$$

and $D^2 J_1(x)$ is nonnegative definite for $|x|^2 \geq 1/3$. Thus in assumption (A5), $j = 1$ and we may take $U = U_1 = \{x : 1/\sqrt{3} < |x| < \sqrt{2}\}$, and the rank of the Hessian on $M = M_1$, which is the unit circle, is $k_1 = 1$. Consequently, it follows from Theorem 3.1 that

$$P(\cdot; \lambda_1, \lambda_2) \Rightarrow P_1(\cdot; \lambda_2) \qquad \text{as } \lambda_1 \to +\infty,$$

where $P_1(\cdot; \lambda_2)$ has a density with respect to $\mathcal{H}^1$ on S_1 which is proportional to $e^{-\lambda_2 J_2(x)}$. Here, $\mathcal{H}^1$ may be thought of as "arc-length measure."

It is easy to check that

$$P_1(\cdot; \lambda_2) \Rightarrow \frac{1}{4} \sum_{x \in \{(0,\pm 1),(\pm 1,0)\}} \delta_x(\cdot) \qquad \text{as } \lambda_2 \to +\infty, \tag{4.6}$$

which is the uniform probability distribution on the four points that minimize J_2 subject to $J_1 = 0$. This is clearly the desirable outcome in this case. Figure 1 illustrates this convergence.

4.2. Example 2. Here we give an example illustrating Theorem 3.2. Letting M be some compact two-dimensional Riemannian manifold which contains a subset isometric to the square $[-3, 3] \times [-3, 3] \subset R^2$, we will simply use the coordinate system of the latter set. Let J_1 be as in (4.1) and let

$$J_3(x) \ \stackrel{\text{def}}{=}\ \left((x_1 - 1)^2 + 2x_2^2 - 3x_2\right)^2.$$

Using the linear isomorphism

$$L(x_1, x_2) = (x_1 - 1, 2(x_2 + 3/4)),$$

we see that $J_3(x) = J_4(L(x))$, where $J_4(y) = (|y|^2 - 3/2)^2$. Since the rank of the Hessian is invariant under a linear transformation, we see as in Example 1 in section 4.1 that the rank of the Hessian $D^2 J_3$ equals 1 on the ellipse $J_3^{-1}\{0\}$. This ellipse crosses the unit circle $M_1 = J_1^{-1}\{0\}$ orthogonally at $a = (1, 0)$ with slope 0, and nonorthogonally at $a = (0, 1)$ with slope 2. In fact, for a smooth function on a planar region, the slope of $u^{-1}\{0\}$ at a point with $\frac{\partial u}{\partial x_2} \neq 0$ is given by the formula

$$-\frac{\partial u/\partial x_1}{\partial u/\partial x_2},$$

and we may apply this with $u(x_1, x_2) = (x_1 - 1)^2 + 2x_2^2 - 3x_2$. So we may compute

$$\Theta(a) \ = \ |(0,1) \wedge (1,0)| \ = \ 1, \qquad \Theta(b) \ = \ |(1,0) \wedge (2/\sqrt{5}, 1/\sqrt{5})| \ = \ 1/\sqrt{5}\ .$$

Thus, if P_{λ_1,λ_3} is the corresponding Gibbs measure as in Theorem 3.2, then

$$P_{\lambda_1,\lambda_3} \ \Rightarrow \ \frac{\sqrt{5}}{1+\sqrt{5}}\delta_a \ + \ \frac{1}{1+\sqrt{5}}\delta_b \ \ \textit{as}\ \lambda_1, \lambda_3 \to \infty.$$

Note that, unlike in the previous example, we do not obtain a uniform distribution on the set of constrained minima. If SA is applied in this case, we are more likely to find the point a than b. The nonuniform distribution here comes from the factor in Theorem 3.2 that comes from the factor Θ, but one could also obtain such nonuniformity from the factors Λ_i. While this does not affect the convergence of SA to a minimum, one may wish to explore the set of all minima, and a nonuniform distribution would then not be desirable.

4.3. Example 3. We use the same functions (4.1)–(4.3), but now we let $\lambda_2 \to \infty$ holding λ_1 fixed. This would arise from applying SA to a constrained optimization problem in which the objective from the previous example becomes a constraint and vice versa, i.e., if we attempt to solve

$$\mathrm{Argmin}\{J_1(x) \,|\, x \in M\}, \qquad \text{where } M = \{x \in \mathbb{R}^2 \,|\, J_2(x) = 0\}.$$

We cannot apply Theorem 3.1 to this situation because assumption (A5) is not valid. (Note that our complicated expression for J_2 is constructed so that $\int \exp[-\lambda J_2] < \infty$ for all $\lambda > 0$ and J_2 is $C^{3,\alpha}$.) The Hessian of J_2 is given by

$$D^2 J_2(x) = \begin{pmatrix} 2x_2^2 & 4x_1x_2 \\ 4x_1x_2 & 2x_1^2 \end{pmatrix} \qquad \text{if } |x|^2 \leq 2.$$

Its eigenvalues are

$$x^2 + y^2 \pm \sqrt{x^4 + 14y^2x^2 + y^4}.$$

Consequently, for $|x|^2 < 2$,

$$\operatorname{rank} D^2 J_2(x_1, x_2) = \begin{cases} 2 & \text{if } x_1 \neq 0 \text{ and } x_2 \neq 0, \\ 1 & \text{if } x_1 = 0 \text{ or } x_2 = 0 \text{ and } x_1 \neq x_2, \\ 0 & \text{if } x_1 = x_2 = 0. \end{cases}$$

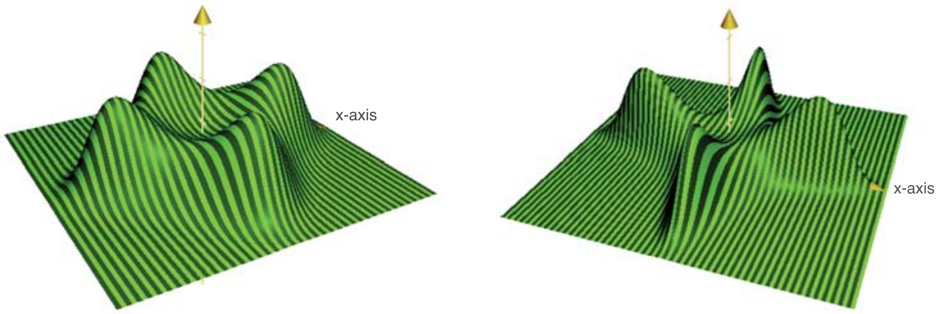

FIG. 2. *Plot of the unnormalzied Gibbs density* $e^{-(\lambda_1 J_1(x_1,x_2)+\lambda_2 J_2(x_1,x_2))}$ *in Example* 3. *The picture on the left is a plot with* $\lambda_1 = 1$ *and* $\lambda_2 = 5$, *and the one on the right is with* $\lambda_1 = 1$ *and* $\lambda_2 = 30$.

Since the set $M = J_2^{-1}(0)$ consists of the segments of the x and y axes for which $|x| \le 2$, the rank of the Hessian drops from being 1 on $M \setminus \{0\}$ to 0 at the origin. Figure 2 suggests that the limiting measure is concentrated along the axes near the desired constrained minima. However, this picture is misleading, as we shall prove.

Let B be a neighborhood of $0 \in \mathbb{R}^2$ of the form

$$B = (-\epsilon, \epsilon) \times (-\epsilon, \epsilon).$$

We will show that

$$R(B^c; \lambda_1, \lambda_2) = o(R(B; \lambda_1, \lambda_2)) \qquad \text{as } \lambda_2 \to \infty, \tag{4.7}$$

where R is the unnormalized Gibbs measure in (4.4). From this it easily follows that

$$P(\cdot; \lambda_1, \lambda_2) \Rightarrow \delta_0 \qquad \text{as } \lambda_2 \to \infty.$$

To estimate the left-hand side of (4.7), define

$$Q(\lambda_2) = \int_0^\epsilon \int_0^\epsilon e^{-\lambda_2 x_1^2 x_2^2}\, dx_1\, dx_2.$$

Then clearly

$$R(B; \lambda_1, \lambda_2) \asymp Q(\lambda_2),$$

where we use $\asymp$ to indicate that the left-hand side is bounded above and below by finite positive multiples of the right-hand side, where the constants do not depend on λ_2. By direct calculation

$$Q(\lambda_2) = \tfrac{\sqrt{\pi}}{2\sqrt{\lambda_2}} \int_0^{\sqrt{\lambda_2}\epsilon^2} \tfrac{1}{v}\, \mathrm{Erf}(v) dv, \qquad \text{where} \qquad \mathrm{Erf}(z) = \frac{2}{\sqrt{\pi}} \int_0^z e^{-x^2} dx,$$

is the Error function [1]. Using the properties that $\mathrm{Erf}(z) \sim \frac{2}{\sqrt{\pi}} z$ as $z \to 0$ and $\mathrm{Erf}(z) \to 1$ as $z \to \infty$, it follows that for $\lambda_2 > \epsilon^{-4}$,

$$R(B; \lambda_1, \lambda_2) \asymp \lambda_2^{-1/2} \log \lambda_2. \tag{4.8}$$

It is clear from the proof of Theorem 3.1 (see (9.2)–(9.5)) that $R(B^c;\lambda_1,\lambda_2)$ is asymptotically dominated by the $R(\cdot;\lambda_1,\lambda_2)$ measure of the tubular neighborhoods of the intersection of the coordinate axes with B^c and the disk $|x|^2 \le 2$, and that

$$R(B^c;\lambda_1,\lambda_2) \asymp \lambda_2^{-1/2}. \tag{4.9}$$

Combining (4.8) and (4.9) gives the result (4.7).

As seen in the first example, we can take $\lambda_1 \to \infty$ and then $\lambda_2 \to \infty$ and get the "right answer," but the calculation here shows that we cannot take the limits in the other order and get the desired result. Note that Theorem 3.2 does not apply here either for the same reason as for Theorem 3.1: the appropriate Hessian does not have constant rank on the required set.

5. Further applications and discussion.

5.1. Applications to materials science. Differential inclusions are a modeling methodology that has found application in material science. Unlike a differential equation where an exact relationship for the derivative is given, in a differential inclusion the derivative is required to lie in a specified set. In the materials science applications, the set corresponds to microscale crystalline configurations and typically consists of a finite number of allowed gradients (first derivatives) and all rotations of them. For more material on differential inclusions, including theory, methods, and application, see [2], [19], [8], [18], [24], [23], [9], and the references therein.

In this section, we consider a simple example which has almost all of the features of the models used in practice. Let $\Omega = [0,1]^2$ be the unit square in $\mathbb{R}^2$. Suppose that we wish to find a weakly differentiable function $u : \Omega \to \mathbb{R}$ satisfying the following conditions:

(i) u is continuous (continuity condition);
(ii) $u(x) = g(x)$ for $x \in \partial\Omega$, where g is given (boundary condition);
(iii) $|\nabla u| = 1$ in Ω (gradient constraint).

If a solution exists, it can be found by solving the constrained optimization problem

$$\min \int_{\partial\Omega} (g(s) - u(s))^2\, dS \quad \text{subject to } |\nabla u| = 1 \ \text{ a.e. in } \Omega \ \text{ and } \ u \in C^0(\Omega).$$

This is a nonconvex minimization problem with numerous local minima (see, e.g., [7]); thus SA is a reasonable approach. We consider a finite dimensional approximation u_h which is piecewise affine with different parameters in each element of a triangular partition of Ω. For simplicity, we first subdivide Ω into squares, then subdivide the squares by a diagonal (cf. Figure 4). We will suppose that the continuity condition is enforced, but the gradient constraint is relaxed. With continuity the function u_h in one of the subdivision squares is determined by its values at the four corners of the square; denote them by $v = (v_1, v_2, v_3, v_4)$, as indicated in Figure 4. An SA approach of the type discussed in section 2 could be based on first using the modified objective $\lambda_1 J_1(u) + \lambda_2 J_2(u)$, where J_1 and J_2 correspond to the boundary and gradient constraints, respectively, e.g.,

$$J_1(u_h) = \int_{\partial\Omega} (g(s) - u_h(s))^2\, dS, \tag{5.1}$$

$$J_2(u_h) = \int_{\Omega} \left(|\nabla u_h(x)|^2 - 1\right)^2 dx. \tag{5.2}$$

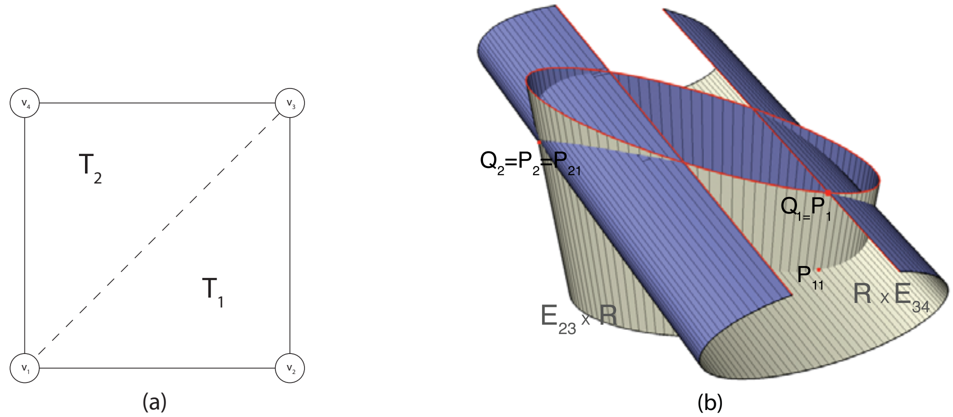

FIG. 3. (a) *The left plot indicates the labeling for a square element in the subdivision of* Ω. (b) *The plot on the right shows* $(E_{23} \times \mathbb{R}) \cap (\mathbb{R} \times E_{34})$ *corresponding to the gradient constraints in each of the two triangular subregions. At the points* Q_1 *and* Q_2 *the Hessian of the gradient constraint functional drops in rank.*

Now we show that this Lagrangian formulation has the same problems as the example in section 4.3, namely, that assumption (A5) of Theorem 3.1 is violated. Consider a single square with its two triangular elements in the partition of Ω. For simplicity, we assume that the side length is 1. If we set $v_1 = 0$, then we imbed the problem in a visualizable three-dimensional space. Consider the set of values (v_2, v_3, v_4) satisfying the gradient constraint in the lower triangular element, namely,

$$|\nabla u_h|^2 = |(v_2, v_3 - v_2)|^2 = 1.$$

Define an ellipse in the (v_2, v_3) coordinate plane

$$E_{23} = \{(v_2, v_3) : |(v_2, v_3 - v_2)|^2 = 1\}.$$

Then the set of values (v_2, v_3, v_4) satisfying the gradient constraint in the lower triangular element is given by the cylindrical surface $E_{23} \times \mathbb{R}$. We can parameterize the surface with $(\alpha, z) \in [0, 2\pi) \times \mathbb{R}$; i.e., the surface $E_{23} \times \mathbb{R}$ is the graph of the map

$$(\alpha, z) \mapsto (\cos(\alpha), \sin(\alpha) + \cos(\alpha), z), \qquad \alpha \in [0, 2\pi), \quad z \in \mathbb{R}.$$

Similarly, we can define an ellipse

$$E_{34} = \{(v_3, v_4) \mid |(v_3 - v_4, v_4)|^2 = 1\},$$

and then the set of values (v_2, v_3, v_4) satisfying the gradient constraint in the upper triangular element is given by the cylindrical surface $\mathbb{R} \times E_{34}$. The corresponding parameterization is (β, y), where $\mathbb{R} \times E_{34}$ is the graph of the map

$$(\beta, y) \mapsto (y, \sin(\beta) + \cos(\beta), \sin(\beta)), \qquad \beta \in [0, 2\pi), \quad y \in \mathbb{R}.$$

The intersection of these two cylindrical surfaces is a pair of ellipses which intersect as depicted by the right-hand panel in Figure 3. Note that the continuity constraint means that the gradient in the upper triangular region must be identical with the

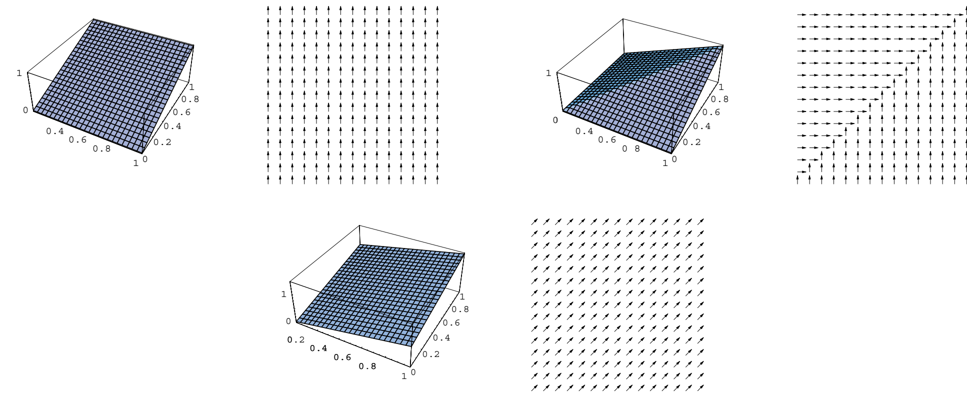

FIG. 4. *Three possible solutions for the differential inclusion $|\nabla u_h| = 1$ and $u_h \in C^0(\Omega)$ which are piecewise affine in the triangular elements.*

gradient in the lower region or else it has to be the reflection about the diagonal of the gradient in the lower region. Hence, either $\beta = \alpha$ and then we obtain a single affine function throughout the square or $\beta = \pi/2 - \alpha \pmod{2\pi}$ and then we obtain a piecewise affine solution with different parameters in the upper and lower triangular elements. For a given $\alpha \in [0, 2\pi)$ (which specifies a unit length gradient in the lower triangular element), there will typically be two values of β (corresponding to a unit length gradient in the upper triangular element), except when the gradient is parallel with the diagonal boundary, i.e., $\alpha = \pi/4$ and $\alpha = 5\pi/4$. Examples of such continuous piecewise affine functions with unit length gradients are shown in Figure 4. The points $\alpha = \pi/4$ and $\alpha = 5\pi/4$ correspond to the points Q_2 and Q_1 in Figure 3(b), respectively. The corresponding u_h with $\alpha = \pi/4$ and its gradient field are given in the last plot in Figure 4 where necessarily $\beta = \pi/4$ for the gradient in the upper triangular element.

The analogy to Example 3 in section 4.3 is as follows. The above discussion shows that there exist points in the constraint set which are the intersections of two smooth one-dimensional manifolds. Since the sum of the rank of the Hessian and the dimension of the tangent space of the manifold is bounded above by the dimension of the ambient space, we know the rank of the Hessian is ≤ 2 at all points on the constraint set, but ≤ 1 at Q_1 and Q_2. Thus, this example will clearly violate the assumptions of our theorems. Using complicated arguments based on elementary considerations (symmetries of the constraint set and properties of quartic polynomials), we can show that the Hessian has rank 1 at Q_1 and Q_2, and at some points outside of Q_1 and Q_2 (namely, the other vertices of the ellipses), it has rank 2. Based on numerical calculations, we conjecture that it has rank 2 at all points except Q_1 and Q_2, similarly to Example 3 in section 4.3. A natural conjecture would be that the same phenomenon that occurred in Example 3 will occur here: as the multiplier corresponding to the gradient constraint $\lambda_2 \to \infty$, the limiting measure will concentrate on the points $\alpha = \pi/4$ and $\alpha = 5\pi/4$. However, the same type of reasoning suggests that along boundaries between triangular elements in different squares, there will be a tendency for the gradient to align itself with the direction of the boundary. Because of all of these interactions, we do not know how this affects the behavior of an SA solution to this problem, but it does suggest that there will be difficulties with such an approach. Clearly further extension of the results given here is necessary to provide insight. The strain densities described in [19], [20], [18], [17], and [2] provide a similar implementation of the gradient constraints for the microscale modeling of crystalline materials. We believe that these will have similar problems.

5.2. Potential application to Bayesian statistics. While SA has been our prime motivation for developing the results in section 3, we believe they may have implications for other applications of MCMC, and specifically for Bayesian statistics. In the Bayesian framework, as one obtains more samples, the negative log likelihood in the neighborhood of the true value of the parameter behaves like $nJ_1(\theta)$, where n is the sample size, θ is a variable value of the parameter, and J_1 is a fixed function (see [27]) which is minimized at the true parameter value. Thus, the posterior density is approximated by

$$g_n(\theta) \;=\; Z_n \exp[-J_0(\theta) - nJ_1(\theta)],$$

where J_0 is the negative logarithm of the prior density. This approximation is valid as long as there is a unique true value of the parameter. Bayesian methods are being applied to more and more complicated models, and some models may lack identifiability; i.e., there are multiple parameter values giving the same likelihood. In regular cases, the set of possible true values will be a manifold, and Theorem 3.1 may prove useful for obtaining asymptotic approximations of the posterior.

5.3. Generalizations. Here we mention some generalizations that would be desirable. The assumption of Theorem 3.1 we have found most problematic is that the set M must be a smooth compact manifold. We believe that it should be possible to extend the results to more general sets M, possibly with restrictions on J and h. Developing a more general theory that would cover examples similar to the one in section 4.3 would also be of interest.

6. Nearest point projection for a submanifold. Recall that, for any Borel set $A \subset \mathbb{R}^n$ (or even any metric space A) and any number $k \geq 0$, the k-dimensional Hausdorff measure $\mathcal{H}^k(A)$ is defined [11, sect. 2.10.2]. It is normalized so that, for integer k in $\mathbb{R}^k$, $\mathcal{H}^k$ coincides with the k-dimensional Lebesgue measure. In a higher dimensional $\mathbb{R}^n$, the restriction of $\mathcal{H}^k$ to a k-dimensional C^1 submanifold M coincides with the Riemannian volume measure on M for the metric induced from $\mathbb{R}^n$. In particular, a k-dimensional ball of radius r in $\mathbb{R}^k$,

$$\mathbb{B}_r^k(a) \;\equiv\; \{x \in \mathbb{R}^k \,:\, |x-a| < r\}\ ,$$

has

$$\mathcal{H}^k(\mathbb{B}_r^k(a)) \;=\; \alpha_k r^k, \tag{6.1}$$

where α_k is the k-dimensional Lebesgue measure of the unit ball in $\mathbb{R}^k$.

Our notation for an integral with respect to a (lower dimensional) Hausdorff measure will have the form

$$\int_A f(a)\, d\mathcal{H}^k a \qquad \text{or} \qquad \int_A f\, d\mathcal{H}^k,$$

while our integrals with respect to the (top dimensional) Lebesgue measure will keep the standard notation

$$\int_U f(x)\, dx \qquad \text{rather than} \qquad \int_U f(x)\, d\mathcal{H}^n x.$$

In particular, we have the polar coordinate formula for a Lebesgue integrable function f on the ball $\mathbb{B}_R(0) \equiv \mathbb{B}^n_R(0)$,

$$\int_{\mathbb{B}_R(0)} f(x)\,dx \;=\; \int_{S^{n-1}} \int_0^R f(r\omega)\, r^{n-1}\, dr\, d\mathcal{H}^{n-1}\omega,$$

where S^{n-1} is the $(n-1)$-dimensional unit sphere in $\mathbb{R}^n$. One readily checks that

$$\mathcal{H}^{n-1}(S^{n-1}) \;=\; n\,\alpha_n \tag{6.2}$$

by differentiating (6.1).

For any vector subspace T of $\mathbb{R}^n$, the orthogonal projection

$$\Pi_T \;:\; \mathbb{R}^n \;\to\; T$$

is the linear map which takes any point $x \in \mathbb{R}^n$ to the unique point $\Pi_T(x)$ in T that is *nearest* to x.

Suppose that M is a compact m-dimensional $C^{2,\alpha}$ submanifold of $\mathbb{R}^n$. Then the m-dimensional *tangent space* T_aM and $(n-m)$-dimensional *normal space* $(T_aM)^\perp$ are continuously differentiable functions of $a \in M$. We can use the function

$$\operatorname{dist}(x, M) \;=\; \inf\{|x-a| \;:\; a \in M\}$$

to define a "tubular" neighborhood of M on which there is a well-defined nearest point map Π_M whose differential at a point x is close to the orthogonal projection of $\mathbb{R}^n$ onto $T_{\Pi_M(x)}M$. Specifically, we have the following lemma.

LEMMA 6.1. *There are positive constants δ and C depending only on M so that if*

$$U = \{x \in \mathbb{R}^n \;:\; \mathit{dist}(x, M) < \delta\},$$

then the following hold:

(1) *Every point $x \in U$ has a unique nearest point $\Pi_M(x)$ in M.*
(2) *The map Π_M is $C^{1,\alpha}$ smooth.*
(3) *For all $x \in U$,*

$$\|D\Pi_M(x) \;-\; \Pi_{T_{\Pi_M(x)}M}\| \;\le\; C|\Pi_M(x) - x|^\alpha.$$

(4) *The m-dimensional Jacobian*

$$\mathcal{J}_m\Pi_M \equiv \|\wedge_m D\Pi_M\| = \sqrt{\det\left((D\Pi_M)\circ(D\Pi_M)^*\right)}$$

(see [11, *sect.* 3.2.22]*) satisfies*

$$|\,\mathcal{J}_m\Pi_M(x) \;-\; 1\,| \;\le\; C|\Pi_M(x) - x|^\alpha$$

for all $x \in U$.

Proof. As discussed, for example, in [10], the nearest point neighborhood property of a compact C^2 submanifold M depends on its curvature bound. In fact (1) and (2) hold specifically by taking

$$\delta \;=\; \left(\max_{a\in m}\|A_M(a)\|\right)^{-1},$$

where A_M is the second fundamental form of M. For $a \in M$, $D\Pi_M(a) = \Pi_{T_aM}$. Since, for a compact $C^{2,\alpha}$ submanifold M, the map Π_M is $C^{1,\alpha}$ bounded in some compact neighborhood of M, we obtain (3) by slightly shrinking δ. Finally for (4) we note that the linear map $\Pi_{T_{\Pi(x)}M}$, being an orthogonal projection onto an m-dimensional space, has m-dimensional Jacobian equal to 1. Since $\sqrt{t}$ is smooth near $t = 1$, the estimate follows from (3) and the formula for $\mathcal{J}_m$. $\square$

For each $a \in M$ note that the set $\Pi_M^{-1}\{a\}$ is simply an $(n-m)$-dimensional flat disk normal to M at a; in fact,

$$\Pi_M^{-1}\{a\} \;=\; \{y + a \,:\, y \in (T_aM)^\perp \,:\, |y| < \delta\}.$$

Integrals over a tubular neighborhood may be computed using the Jacobian $\mathcal{J}_m\Pi_M$.

LEMMA 6.2. *For any bounded continuous function ψ on $\mathbb{R}^n$,*

$$\int_U \psi(x)\,dx \;=\; \int_M \left(\int_{\Pi_M^{-1}\{a\}} \psi \cdot (\mathcal{J}_m\Pi_M)^{-1}\,d\mathcal{H}^{n-m} \right) d\mathcal{H}^m a.$$

Proof. We may apply the (coarea) change of variable formula [11, sect. 3.2.22, expression (3)] for the map $\Pi_M : U \to M$,

$$\int_U \phi(x)(\mathcal{J}_m\Pi_M)(x)\,dx \;=\; \int_M \left(\int_{\Pi_M^{-1}\{a\}} \phi\,d\mathcal{H}^{n-m} \right) d\mathcal{H}^m a,$$

with $\phi(x) = \psi(x) \cdot (\mathcal{J}_m\Pi_M)^{-1}(x)$. $\square$

For use in section 9.2, we next observe that the following holds.

Lemmas 6.1 *and* 6.2 *continue to hold in the case when the ambient space $\mathbb{R}^n$ is replaced by an n-dimensional Riemannian manifold N.*

Concerning Lemma 6.2, one additional observation is required. In the general Riemannian case, each set $\Pi_M^{-1}\{a\}$, for $a \in M$, is now a uniformly smooth (but possibly curved) $(n-m)$-dimensional disk in N normal to M. It may be parameterized by the planar disk in the normal space,

$$N_\delta(a) \;\equiv\; \{v \in (T_aM)^\perp \;:\; |v| < \delta\} \;\subset\; T_aN.$$

LEMMA 6.3. *There exist positive δ and C and, for every point $a \in M$, a $C^{1,\alpha}$ function G_a mapping $N_\delta(a)$ diffeomorphically onto $\Pi_M^{-1}\{a\}$ so that $G_a(0) = a$, $DG_a(0)$ is an isometry, and, for every $y \in N_\delta(a)$,*

$$\|DG_a(y) - DG_a(0)\| \;\le\; C|y|^\alpha;$$

hence,

$$|y| \;\le\; dist(G_a(y), a) \;\le\; |y| \,+\, C|y|^{1+\alpha}, \tag{6.3}$$

and

$$|\,\mathcal{J}_{n-m}G_a(y) \;-\; 1\,| \;\le\; C|y|^\alpha, \tag{6.4}$$

where $\mathcal{J}_{n-m}G_a = \sqrt{\det\left((DG_a)^* \circ (DG_a)\right)}$.

Proof. The desired parameterizing map G_a is obtained by simply restricting the Riemannian exponential map Exp_a^N to the normal disk $N_\delta(a)$. The estimates all follow from properties of this exponential map. In particular, as a varies over the compact submanifold M, all estimates are uniform because of the $C^{0,\alpha}$ bound on the sectional curvature of M. ∎

Lemma 6.2 is now replaced by the following lemma.

LEMMA 6.4. *For any bounded continuous function ψ on N,*

$$\int_U \psi(x)\,dx = \int_M \left(\int_{\Pi_M^{-1}\{a\}} \psi\cdot(\mathcal{J}_m\Pi_M)^{-1}\,d\mathcal{H}^{n-m}\right) d\mathcal{H}^m(a)$$

$$= \int_M \left(\int_{N_\delta(a)} \psi(G_a(y))\cdot(\mathcal{J}_m\Pi_M)^{-1}(G_a(y))\cdot\mathcal{J}_{n-m}(G_a(y))\,dy\right) d\mathcal{H}^m(a)\,.$$

Proof. The first equality follows from [11, sect. 3.2.22, expression (3)] as in the proof of Lemma 6.2. For the second equality, we then apply the (area) change of variable formula [11, sect. 3.2.5] for the map $G_a : N_\delta(a) \to \Pi_M^{-1}\{a\}$,

$$\int_{N_\delta(a)} \phi(G_a(y))\cdot(\mathcal{J}_{n-m}G_a)(y)\,dy \;=\; \int_{\Pi_M^{-1}\{a\}} \phi\; d\mathcal{H}^{n-m}$$

with $\phi = \psi\cdot(\mathcal{J}_m\Pi_M)^{-1}$. ∎

7. Expansion of a nonnegative function of fixed nondegeneracy.

PROPOSITION 7.1. *Suppose that F is a nonnegative, $C^{3,\alpha}$ smooth function on an open subset of $\mathbb{R}^n$, the zero set $M = F^{-1}\{0\}$ is an embedded $C^{2,\alpha}$ submanifold, and rank$\frac{\partial^2 F}{\partial x_i\partial x_j} \equiv n-m$ on M. For each compact subset A of M there are positive constants C, δ so that for each $a \in A$,* grad$F(a)$ *vanishes and the symmetric matrix $\frac{\partial^2 F}{\partial x_i\partial x_j}(a)$ has, counting multiplicities, m zero eigenvalues and $n-m$ positive eigenvalues*

$$\mu_1(a) \;\le\; \mu_2(a) \;\le\; \cdots \;\le\; \mu_{n-m}(a),$$

which are continuous in a with a positive minimum and a finite maximum. Also there is an orthogonal rotation Γ_a of $\mathbb{R}^n$ so that

$$\Gamma_a(\{0\}\times\mathbb{R}^{n-m}) \;=\; (T_aM)^\perp$$

and

$$\left| F(a+\Gamma_a(x)) \;-\; \sum_{i=1}^{m-n} \frac{1}{2}\mu_i(a)(x_{m+i}-a_{m+i})^2 \right| \;\le\; C\left(\sup_{\mathbb{B}_\delta(a)} \|D^3F\|\right)|x-a|^3$$

for all $x \in \mathbb{B}_\delta(0)$.

Proof. Note that for each $a \in M$ and each vector $v \in \mathbb{R}^n$, the function $F_v(t) = F(a+tv)$ has a minimum at $t=0$. So $v\cdot$grad$F(a) = \frac{dF_v}{dt}\big|_{t=0} = 0$, and

$$0 \;\le\; \left.\frac{d^2F_v}{dt^2}\right|_{t=0} \;=\; \left.\frac{d}{dt}v\cdot \mathrm{grad}F(a+tv)\right|_{t=0} \;=\; \sum_{i,j} v_i \frac{\partial^2 F}{\partial x_i\partial x_j}(a)v_j.$$

Thus grad$F(a) = 0$, and all the eigenvalues of $\frac{\partial^2 F}{\partial x_i\partial x_j}(a)$ are nonnegative. In general, the full collection of eigenvalues of a square matrix, being the complex roots of the characteristic polynomial, varies continuously as the matrix varies; see, e.g., [11]. Here, by assumption, for $a \in M$, the matrix $\left(\frac{\partial^2 F}{\partial x_i \partial x_j}\right)(a)$ has, counting multiplicities, precisely m zero eigenvalues and precisely $n-m$ nonzero, hence positive, eigenvalues. So, under ordering by size, these positive eigenvalues become continuous functions on M. By the compactness of M, μ_1 has a positive minimum and μ_{n-m} a finite maximum.

For $a \in A$, we let $v_1, \dots, v_n$ be orthonormal eigenvectors of the symmetric matrix $\left(\frac{\partial^2 F}{\partial x_i \partial x_j}\right)(a)$ corresponding to the eigenvalues $0, \dots, 0, \mu_1(a), \dots, \mu_{n-m}(a)$, and choose the rotation Γ_a of $\mathbb{R}^n$ satisfying $\Gamma_a(\mathbf{e}_i) = v_i$ for $i = 1, \dots, n$. With $H_a(x) = a + \Gamma_a(x)$, we deduce that the matrix $\left(\frac{\partial^2 (F \circ H_a)}{\partial x_i \partial x_j}\right)(0)$ is diagonal with the first m eigenvalues being zero and the $(m+i)$th eigenvalue being $\mu_i(a)$ for $i = 1, \dots, n-m$. Since also $(F \circ H_a)(0) = 0$, $\operatorname{grad}(F \circ H_a)(0) = 0$, and $\|D^2 F\|$ is bounded in some neighborhood of M, the second order Taylor expansion for $F \circ G_a$ now proves the last inequality of the proposition. ◻

8. Some integrals.

LEMMA 8.1. *For* $k = 1, 2, \dots,$

$$\int_0^\infty e^{-\lambda t^2} t^{k-1}\, dt \;=\; \beta_k \lambda^{-\frac{k}{2}},$$

where

$$\beta_k \;=\; \begin{cases} 2^{-\frac{k}{2}}(k-2)(k-4)\cdots(2) & \textit{for } k \textit{ even,} \\ 2^{-\frac{k-1}{2}}(k-2)(k-4)\cdots(3)\cdot\sqrt{\pi} & \textit{for } k \textit{ odd.} \end{cases}$$

Proof. The substitution $s = \sqrt{\lambda} t$ gives the factor $\lambda^{-\frac{k}{2}}$ and reduces to the case $\lambda = 1$.

Integration by parts gives

$$\int_0^\infty e^{-t^2} t^{k-1}\, dt \;=\; \frac{-1}{2}\int_0^\infty t^{k-2}\, d(e^{-t^2}) \;=\; \frac{k-2}{2}\int_0^\infty e^{-t^2} t^{k-3}\, dt.$$

This may be applied with k replaced by $k-2, k-4, \dots$, finally giving the formula

$$\int_0^\infty e^{-t^2} t^{2j}\, dt \;=\; \begin{cases} 2^{-\frac{k-2}{2}}(k-2)(k-4)\cdots(2)\cdot\int_0^\infty e^{-t^2} t\, dt & \text{for } k \text{ even} \\ 2^{-\frac{k-1}{2}}(k-2)(k-4)\cdots(3)\cdot\int_0^\infty e^{-t^2}\, dt & \text{for } k \text{ odd.} \end{cases}$$

Of course, substituting $s = t^2$ gives $\int_0^\infty e^{-t^2} t\, dt = \frac{1}{2}$, and the last integral is found by the usual polar coordinate trick

$$\left(\int_0^\infty e^{-t^2}\, dt\right)^2 = \int_0^\infty \int_0^\infty e^{-x^2-y^2}\, dx\, dy = \int_0^{2\pi}\int_0^\infty e^{-r^2} r\, dr\, d\theta$$
$$= \frac{2\pi}{2}\int_0^\infty e^{-u}\, du = \pi. \qquad ◻$$

COROLLARY 8.2.

(8.1) $$\lim_{\lambda\to\infty} \lambda^{\frac{k}{2}} \int_0^\infty e^{-\lambda t^2} t^j\, dt \;=\; 0 \quad \textit{for any integer } j > k-1,$$

and

$$\lim_{\lambda\to\infty} \lambda^{\frac{k}{2}} \int_\delta^\infty e^{-\lambda t^2} t^{k-1}\, dt \;=\; 0 \qquad \textit{for any } \delta > 0. \tag{8.2}$$

Proof. Applying Lemma 8.1 with $k = j+1$ gives the first conclusion because $\lambda^{(-j+k-1)/2} \to 0$ as $\lambda \to \infty$. For the second, we change variables $s = \lambda^{1/2} t$ to see that

$$\lambda^{\frac{k}{2}} \int_\delta^\infty e^{-\lambda t^2} t^{k-1}\, dt \;=\; \lambda^{\frac{k}{2}} \lambda^{-\frac{k-1}{2}} \lambda^{-1/2} \int_{\lambda^{1/2}\delta}^\infty e^{-s^2} s^{k-1}\, ds \;\to\; 0 \quad \text{as } \lambda \to \infty$$

because $\int_0^\infty e^{-s^2} s^{k-1}\, ds < \infty$. ◻

COROLLARY 8.3. *For $\delta > 0$ and $0 < \mu_1 \le \mu_2 \le \cdots \le \mu_k < \infty$,*

$$\lim_{\lambda\to\infty} \lambda^{\frac{k}{2}} \int_{\mathbb{B}^k_\delta(0)} e^{-\frac{1}{2}\lambda(\mu_1 y_1^2 + \cdots + \mu_k y_k^2)}\, dy = 2^{k/2}\Lambda^{-1/2} k \alpha_k \beta_k,$$

where $\Lambda = \mu_1 \cdots \mu_k$, α_k is as in (6.1), *and β_k is as in Lemma* 8.1.

Proof. One can explicitly compute the integral over the k-dimensional elliptical region

$$E^k_\delta \;=\; \{\, y \in \mathbb{R}^k \;:\; \mu_1 y_1^2 + \cdots + \mu_1 y_k^2 \;<\; 2\delta^2 \,\},$$

because $E^k_\delta = L(\mathbb{B}^k_\delta(0))$, where

$$L(z_1, \ldots, z_k) \;=\; ((2/\mu_1)^{1/2} z_1, \ldots, (2/\mu_k)^{1/2} z_k) \quad \text{for } (z_1, \ldots, z_k) \in \mathbb{R}^k\ .$$

Using the change of variables $y = L(z)$ with $dy = (\mathcal{J}_k L)\, dz = 2^{k/2}\Lambda^{-1/2} dz$, as well as polar coordinates, Lemma 8.1, and (8.2), we find that

$$\begin{aligned}
&\lambda^{\frac{k}{2}} \int_{E^k_\delta} e^{-\frac{1}{2}\lambda(\mu_1 y_1^2 + \cdots + \mu_k y_k^2)}\, dy \\
&\quad = \; 2^{k/2}\Lambda^{-1/2} \lambda^{\frac{k}{2}} \int_{B^k_\delta} e^{-\lambda|z|^2}\, dz \\
&\quad = \; 2^{k/2}\Lambda^{-1/2} \lambda^{\frac{k}{2}} \int_{S^{k-1}} \int_0^\delta e^{-\lambda r^2} r^{k-1}\, dr\, d\mathcal{H}^{k-1} \\
&\quad = \; 2^{k/2}\Lambda^{-1/2} \lambda^{\frac{k}{2}} k \alpha_k \int_0^\delta e^{-\lambda r^2} r^{k-1}\, dr \\
&\quad = \; 2^{k/2}\Lambda^{-1/2} k \alpha_k \lambda^{\frac{k}{2}} \left(\int_0^\infty e^{-\lambda r^2} r^{k-1}\, dr \;-\; \int_\delta^\infty e^{-\lambda r^2} r^{k-1}\, dr \right) \\
&\quad \to 2^{k/2}\Lambda^{-1/2} k \alpha_k \beta_k \;-\; 0 \qquad\qquad \text{as } \lambda \to \infty.
\end{aligned}$$

We get precisely the same limit with E^k_δ replaced by the ball $\mathbb{B}^k_\delta(0)$ because we have the inclusions

$$\mathbb{B}^k_\gamma(0) \subset \mathbb{B}^k_\delta(0) \subset \mathbb{B}^k_\epsilon(0) \qquad \text{and} \qquad \mathbb{B}^k_\gamma(0) \subset E^k_\delta(0) \subset \mathbb{B}^k_\epsilon(0)$$

with $\gamma = \min\{\delta, (2/\mu_k)^{1/2}\delta\}$ and $\epsilon = \max\{\delta, (2/\mu_1)^{1/2}\delta\}$ and we have

$$\lim_{\lambda\to\infty} \lambda^{\frac{k}{2}} \int_{\mathbb{B}^k_\epsilon(0)\setminus\mathbb{B}^k_\gamma(0)} e^{-\frac{1}{2}\lambda(\mu_1 y_1^2+\cdots+\mu_k y_k^2)}\,dy \le \lim_{\lambda\to\infty} \lambda^{\frac{k}{2}} \int_{\mathbb{B}^k_\epsilon(0)\setminus\mathbb{B}^k_\gamma(0)} e^{-\frac{1}{2}\lambda(\mu_1|y|^2)}\,dy$$

$$\le \lim_{\lambda\to\infty} k\alpha_k\lambda^{\frac{k}{2}} \int_\gamma^\infty e^{-\frac{1}{2}\lambda(\mu_1 r^2)} r^{k-1}\,dr = 0$$

by (8.2). ◻

LEMMA 8.4. *Suppose $0 \le k \le n$, F is a nonnegative continuous function on $\mathbb{R}^n$, $p > 0$, and $F(y) \ge |y|^p$ whenever $|y|$ is sufficiently large. Then, for any bounded open neighborhood U of $F^{-1}\{0\}$,*

$$\lim_{\lambda\to\infty} \lambda^{k/2} \int_{\mathbb{R}^n\setminus U} e^{-\lambda F(y)}\,dy \;=\; 0.$$

Proof. We may assume $p < 2$. Choose $R > 0$ so that $\overline{U} \subset \mathbb{B}_R(0)$ and $F(y) \ge |y|^p$ whenever $|y| \ge R$. On the bounded region $\mathbb{B}_R(0)\setminus U$, F has a positive lower bound ε, and

$$\lambda^{k/2} e^{-\lambda F(y)} \;\le\; \lambda^{k/2} e^{-\lambda\varepsilon} \;\to\; 0$$

uniformly as $\lambda \to \infty$. Thus

$$\lim_{\lambda\to\infty} \lambda^{k/2} \int_{\mathbb{B}_R(0)\setminus U} e^{-\lambda F(y)}\,dy \;=\; 0.$$

For the remaining set $\mathbb{R}^k \setminus \mathbb{B}_R(0)$, we use polar coordinates and change variables $s = \lambda^{1/p} t$ to see that

$$\lambda^{k/2} \int_{\mathbb{R}^n\setminus\mathbb{B}_R(0)} e^{-\lambda F(y)}\,dy \le n\alpha_{n-1}\lambda^{k/2} \int_R^\infty e^{-\lambda t^p} t^{n-1}\,dt$$

$$= n\alpha_{n-1}\lambda^{\frac{k}{2}-\frac{n-1}{p}-\frac{1}{p}} \int_{\lambda^{1/p}R}^\infty e^{-s^p} s^{n-1}\,ds \;\to\; 0$$

as $\lambda \to \infty$ because $\frac{k}{2} - \frac{n}{p} \le 0$ and $\int_0^\infty e^{-s^p} s^{n-1}\,ds < \infty$. ◻

9. Proof of main theorems.

9.1. Proof of Theorem 3.1. We begin by noting that without loss of generality, we may set $h \equiv 1$. To show the dependence of the measures on h, let $P_\lambda^{(h)}$ denote the Gibbs measures in Theorem 3.1 and $P^{(h)}$ the limiting measure. For any bounded continuous ϕ, since ϕh is bounded and continuous by our assumptions, if the theorem holds when $h \equiv 1$, then we have

$$\int \phi h\, dP_\lambda^{(1)} \;\to\; \int \phi h\, dP^{(1)},$$

and noting that $\int h\, dP^{(1)} > 0$ by our assumption (A5)(d), we have

$$\int \phi\, dP_\lambda^{(h)} \;=\; \frac{\int \phi h\, dP_\lambda^{(1)}}{\int h\, dP_\lambda^{(1)}} \;\to\; \frac{\int \phi h\, dP^{(1)}}{\int h\, dP^{(1)}} \;=\; \int \phi\, dP^{(h)}.$$

First we treat the case $j = 1$ where the Hessian $D^2 J$ has constant rank $k = k$ on the submanifold $M = M_1 = J^{-1}\{0\}$. Taking $F = J$ and $M = J^{-1}\{0\}$, we choose δ and $U \subset U_1$ as in Lemma 6.1 and Proposition 7.1 with $m = n - k$. In the remainder of the proof, we will occasionally enlarge C, finitely many times, without changing the notation. Nevertheless, the constant C will always just depend on n and J.

Let ϕ be a bounded continuous function on $\mathbb{R}^n$ and ε be any positive number with

$$\varepsilon \;<\; \min\left\{\frac{1}{2}, \frac{1}{2C}\right\},$$

where C is as in Lemma 6.1.

First we may assume that the δ and corresponding tubular neighborhood U in Lemma 6.1 are small enough so that, for any point $x \in U$ and nearest point $a = \Pi_M(x) \in M$, one has

$$|x - a| \;<\; \delta \;<\; \varepsilon, \quad |\phi(x) - \phi(a)| \;<\; \varepsilon. \tag{9.1}$$

For λ sufficiently large, we have, by Lemma 8.4, that

$$\lambda^{\frac{k}{2}} \int_{\mathbb{R}^n \setminus U} \phi(x) e^{-\lambda J(x)}\, dx \;\leq\; \big(\sup|\phi|\big)\, \lambda^{\frac{k}{2}} \int_{\mathbb{R}^n \setminus U} e^{-\lambda J(x)}\, dx \;<\; \varepsilon. \tag{9.2}$$

For the integral over U, we use Lemma 6.2 with ψ replaced by $\phi e^{-\lambda J}$ to write

$$\lambda^{\frac{k}{2}} \int_U \phi(x) e^{-\lambda J(x)}\, dx = \lambda^{\frac{k}{2}} \int_M \left(\int_{\Pi_M^{-1}(a)} z_a(x)\, d\mathcal{H}^k(x) \right) d\mathcal{H}^{n-k}(a), \tag{9.3}$$

where

$$z_a(x) \overset{\text{def}}{=} \phi(x) \cdot e^{-\lambda J(x)} \cdot \mathcal{J}_k \Pi_M(x)\,.$$

We will first make upper estimates. For the first factor with $\Pi_M(x) = a$, we use (9.1) to see that

$$\phi(x) \;\leq\; \phi(a) \;+\; \varepsilon.$$

For the third factor, we use Lemma 6.1 to obtain

$$\mathcal{J}_k \Pi_M(x) \;\leq\; (1 + C\varepsilon^\alpha).$$

Combining these and changing C, we now have the upper bound

$$\begin{aligned} &\lambda^{\frac{k}{2}} \int_U \phi(x) e^{-\lambda J(x)}\, dx \\ &\quad\leq \lambda^{\frac{k}{2}} (1 + C\varepsilon^\alpha) \int_M (\phi(a) + \varepsilon) \int_{\Pi_M^{-1}\{a\}} e^{-\lambda J(x)}\, d\mathcal{H}^k(x)\, d\mathcal{H}^{n-k}(a). \end{aligned} \tag{9.4}$$

The remaining second factor in z_α is in the last integral. To estimate this, we rotate coordinates as in Proposition 7.1 with $F = J$ and use Corollary 8.3 with $k = k$, and

(8.1) with $k = k+2$ to deduce that

$$
\begin{aligned}
\lambda^{\frac{k}{2}} \int_{\Pi_M^{-1}\{a\}} e^{-\lambda J(x)}\, d\mathcal{H}^k(x) &\le \lambda^{\frac{k}{2}} \int_{\mathbb{B}_\delta(0)} e^{-\lambda(\sum_{i=1}^k \frac{1}{2}\mu_i(a) y_i^2)} e^{C\lambda|y|^3}\, dy \\
&\le \lambda^{\frac{k}{2}} \int_{\mathbb{B}_\delta(0)} e^{-\lambda(\sum_{i=1}^k \frac{1}{2}\mu_i(a) y_i^2)} (1 + 2C\lambda|y|^3)\, dy \\
&\le \lambda^{\frac{k}{2}} \int_{\mathbb{B}_\delta(0)} e^{-\lambda(\sum_{i=1}^k \frac{1}{2}\mu_i(a) y_i^2)}\, dy + 2C\lambda^{\frac{k+2}{2}}\, k\alpha_k \int_0^\infty e^{-\frac{1}{2}\lambda\mu_1(a) r^2} r^{3+k-1}\, dr \\
&\longrightarrow 2^{\frac{k}{2}} \Lambda^{-1/2}(a)\, k\alpha_k\beta_k + 0 \quad \text{as } \lambda \to \infty,
\end{aligned} \tag{9.5}
$$

where $\Lambda(a) = \mu_1(a) \ldots \mu_k(a)$. Taking the $\limsup_{\lambda\to\infty}$ in (9.4) along with (9.5), recalling (9.2), and then letting $\varepsilon \downarrow 0$, we conclude that

$$
\limsup_{\lambda\to\infty} \lambda^{\frac{k}{2}} \int_{\mathbb{R}^n} \phi(x) e^{-\lambda J(x)}\, dx \;\le\; 2^{\frac{k}{2}}\, k\alpha_k\beta_k \int_M \phi(a)\Lambda^{-1/2}(a)\, d\mathcal{H}^{n-k}(a). \tag{9.6}
$$

Next, arguing in the same manner using lower bounds gives the inequality

$$
\liminf_{\lambda\to\infty} \lambda^{\frac{k}{2}} \int_{\mathbb{R}^n} \phi(x) e^{-\lambda J(x)}\, dx \;\ge\; 2^{\frac{k}{2}}\, k\alpha_k\beta_k \int_M \phi(a)\Lambda^{-1/2}(a)\, d\mathcal{H}^{n-k}(a). \tag{9.7}
$$

This essentially finishes the proof. For the normalization, we define, for $\lambda > 1$,

$$
Y_\lambda \;=\; \left(2^{\frac{k}{2}}\, k\alpha_k\beta_k\right)^{-1} Z\lambda^{\frac{k}{2}},
$$

where

$$
Z \;=\; \left(\int_M \Lambda^{-1/2}(a)\, d\mathcal{H}^{n-k}(a) \right)^{-1}
$$

as before. We now apply (9.6) and (9.7) first with $\phi \equiv 1$ to see that

$$
\lim_{\lambda\to\infty} \frac{Y_\lambda}{Z_\lambda} \;=\; \lim_{\lambda\to\infty} Y_\lambda \int_{\mathbb{R}^n} e^{-\lambda J(x)}\, dx \;=\; 1,
$$

and second with the general bounded continuous ϕ to obtain the conclusion

$$
\begin{aligned}
\lim_{\lambda\to\infty} Z_\lambda \int_{\mathbb{R}^n} \phi(x) e^{-\lambda J(x)}\, dx = &\lim_{\lambda\to\infty} Y_\lambda \int_{\mathbb{R}^n} \phi(x) e^{-\lambda J(x)}\, dx \\
= &\; Z \int_M \phi(a)\Lambda^{-1/2}(a)\, d\mathcal{H}^{n-k}(a),
\end{aligned}
$$

which gives the desired convergence of measures $P_\lambda \Rightarrow P$.

Finally we consider the case $j > 1$ of Theorem 3.1 involving the extra disjoint compact submanifolds $M_2, \ldots, M_j$ on each of which the Hessian $D^2 J$ has constant rank strictly larger than k_1, which is its rank on M_1. Now we will repeat most of the above arguments and again use the factor $\lambda^{k_1/2}$ to try to estimate

$$
\lambda^{\frac{k_1}{2}} \int_{\mathbb{R}^n} \phi(x) e^{-\lambda J(x)}\, dx
$$

as $\lambda \to \infty$. As before we may, by Lemma 8.4, restrict our integration to any fixed neighborhood U of M. We take $U = U_1 \cup \cdots \cup U_j$, where each U_i is, as before, a sufficiently small (depending on a given ε and test function ϕ) tubular neighborhood of M_i.

For the region U_1, we find, by estimating the upper and lower bounds just as before, that

$$\lim_{\lambda\to\infty} \lambda^{\frac{k_1}{2}} \int_{U_1} \phi(x) e^{-\lambda J(x)}\, dx \;=\; 2^{\frac{k_1}{2}}\, k_1 \alpha_{k_1} \beta_{k_1} \int_{M_1} \Lambda^{-1/2}(a)\, d\mathcal{H}^{n-k_1}(a), \tag{9.8}$$

where $\Lambda(a)$ is, as before, the product of the k_1 positive eigenvalues of $D^2 J(a)$ for $a \in M_1$.

However, for any region U_i with $i = 2, \ldots, j$, one finds that, with $a \in M_i$, in place of (9.5), one has the upper estimate

(9.9)

$$\begin{aligned}
&\lambda^{\frac{k_1}{2}} \int_{\Pi_M^{-1}\{a\}} e^{-\lambda J(x)}\, d\mathcal{H}^{k_i}(x) \\
&\quad \le\; \lambda^{\frac{k_1}{2}} \int_{\mathbb{B}_\delta(0)} e^{-\frac{1}{2}\lambda\mu_1(a)|y|^2)} (1 \;+\; 2C\lambda|y|^3)\, dy \\
&\quad =\; \lambda^{\frac{k_1}{2}}\, k_i \alpha_{k_i} \int_0^\infty e^{-\frac{1}{2}\lambda\mu_1(a) r^2} r^{k_i - 1}\, dr \;+\; 2C\lambda^{\frac{k_1+2}{2}}\, k_i \alpha_{k_i} \int_0^\infty e^{-\frac{1}{2}\lambda\mu_1(a) r^2} r^{3+k_i-1}\, dr \\
&\quad \longrightarrow\; 0 + 0 \quad \text{as } \lambda \to \infty
\end{aligned}$$

by (8.1), because $k_i > k_1$ and $3 + k_i > k_1 + 2$. It follows that, for any bounded continuous ϕ on $\mathbb{R}^n$,

$$\lim_{\lambda\to\infty} \lambda^{\frac{k_1}{2}} \int_{U_i} \phi(x) e^{-\lambda J(x)}\, dx \;=\; 0 \tag{9.10}$$

for $i = 2, \ldots, j$. With

$$Y_\lambda \;=\; \left(2^{\frac{k_1}{2}}\, k_1 \alpha_{k_1} \beta_{k_1}\right)^{-1} Z \lambda^{\frac{k_1}{2}},$$

we conclude from (8.1), (9.8), and (9.10) as before that, as $\lambda \to \infty$, $Y_\lambda / Z_\lambda \to 1$ and

$$Z_\lambda \int_{\mathbb{R}^n} \phi(x) e^{-\lambda J(x)}\, dx \;\to\; Z \int_{M_1} \phi(a) \Lambda^{-1/2}(a)\, d\mathcal{H}^{n-k_1} a,$$

which completes the proof. $\square$

9.2. Multiple limit theorem. Multiple constraints generated by functions $J_1, J_2, \ldots, J_j$ lead to consideration of Gibbs measures obtained from multiple limits $\lim_{\lambda_1\to\infty} \lim_{\lambda_2\to\infty} \cdots \lim_{\lambda_j\to\infty}$. With suitable nondegeneracy assumptions on the Hessians of the J_i, one expects to obtain consecutively suitably weighted Hausdorff measures on lower and lower dimensional submanifolds. As before, it suffices to prove the case $h \equiv 1$. To inductively follow this procedure, one first needs to verify the following proposition.

PROPOSITION 9.1. *Theorem* 3.1 *remains true if* $\mathbb{R}^n$ *is replaced by an* n*-dimensional complete Riemannian manifold* N, *the term* $D^2 J$ *is replaced by the Riemannian Hessian, and the Lebesgue measure on* $\mathbb{R}^n$ *is replaced by the standard* n*-dimensional Hausdorff measure on* N.

Proof. The proof follows exactly as in section 9.1 using Riemannian normal coordinates in the expansions until we need to apply Lemma 6.4 instead of Lemma 6.2 and replace the right-hand side of (9.3) by

$$\lambda^{\frac{k}{2}} \int_M \left(\int_{N_\delta(a)} \phi(G_a(y)) \cdot e^{-\lambda J(G_a(y))} \cdot \mathcal{J}_{n-k} G_a(y) \cdot \mathcal{J}_k(G_a(y))\, dy \right) d\mathcal{H}^{n-k} a\,, \tag{9.11}$$

where G_a is given in Lemma 6.3. Note that, by our choice of U, also small enough for Lemma 6.3, and by (9.1), one has, with $x = G_a(y) \in U$ (hence $a = \Pi_M(x)$), that

$$|y| \;\leq\; \mathrm{dist}(x,a) \;<\; \delta \;<\; \varepsilon\,.$$

We estimate the first three factors of (9.11) as before in our estimate of (9.3). Although it is no longer true that $\mathcal{J}_{n-k} G_a \equiv 1$, we may use (6.4) to estimate the new factor $\mathcal{J}_{n-k} G_a(y)$. The fourth factor is also estimated using Lemma 6.3 to obtain

$$\mathcal{J}_k(G_a(y)) \;\leq\; 1 + C\varepsilon^\alpha.$$

Combining these and changing C, we now have the upper bound

$$\lambda^{\frac{k}{2}} \int_U \phi(x) e^{-\lambda J(x)}\, d\mathcal{H}^n x \leq\; \lambda^{\frac{k}{2}} (1 + C\varepsilon^\alpha) \int_M (\phi(a) + \varepsilon) \int_{N_\delta(a)} e^{-\lambda J(G_a(y))}\, dy\, d\mathcal{H}^{n-k} a,$$

which corresponds to (9.4). The remainder of the proof now follows precisely as before in section 9. ∎

9.3. Proof of Theorem 3.2. For each $a \in M$ and $1 \leq h < i \leq j$, the subspaces $E_h(a)$ and $E_i(a)$ have zero-dimensional intersection because the span of $E_1(a), \ldots, E_j(a)$ is of dimension $k = k_1 + \cdots + k_j$. In the special case they are all *mutually orthogonal*, the Hessian matrices $D^2 J_1(a), \ldots, D^2 J_j(a)$ may be simultaneously diagonalized. We now find the expansion in the fiber, $\Pi_W^{-1}\{a\}$, that $\lambda_1 J_1 + \cdots + \lambda_n J_j$ now has the form

$$\begin{aligned} &\frac{1}{2}\big[\lambda_1 \mu_{n-k+1} y_{n-k+1}^2 + \cdots + \lambda_1 \mu_{n-k+k_1} y_{n-k+k_1}^2 + \cdots \\ &\qquad + \lambda_j \mu_{n-k_j+1} y_{n-k_j+1}^2 + \cdots + \lambda_j \mu_n y_n^2\big] \;+\; \text{higher order terms.} \end{aligned}$$

We may now estimate terms as in the proofs in section 9, including that of Proposition 9.1. In taking any limit $\lambda_i \to \infty$, the remaining factors $e^{-\lambda_j J_j}$ may be treated as part of the test function in the weak convergence. The mutual orthogonality also implies that $\Theta \equiv 1$, and we thus obtain Theorem 3.2 in the orthogonal case.

In the general transverse (but not necessarily orthogonal) case, we can make a smooth change of coordinates of a full neighborhood U of each $a \in M$ so that, at each $x \in U \cap M$, the differential of the transformation preserves $E(x)^\perp$ and transforms $E(x)$ by taking the vectors chosen from some orthonormal bases of $E_1(x), \ldots, E_j(x)$ (which by assumption span $\mathbb{R}^n$) to a single orthonormal basis of $E(x)$. With this change of variables, we may compute the desired integrals over U and then use the orthogonality as above. This change of variable that makes the E_i mutually orthogonal gives rise to a new n-dimensional Jacobian term, which is precisely Θ on $U \cap M$. The desired limiting formula follows. ∎

SPHERICAL SOLUTIONS TO A NONLOCAL FREE BOUNDARY PROBLEM FROM DIBLOCK COPOLYMER MORPHOLOGY*

XIAOFENG REN† AND JUNCHENG WEI‡

Abstract. The Γ-limit of the Ohta–Kawasaki density functional theory of diblock copolymers is a nonlocal free boundary problem. For some values of block composition and the nonlocal interaction, an equilibrium pattern of many spheres exists in a three-dimensional domain. A subrange of the parameters is found where the multiple sphere pattern is stable. This stable pattern models the spherical phase in the diblock copolymer morphology. The spheres are approximately round. They satisfy an equation that involves their mean curvature and a quantity that depends nonlocally on the whole pattern. The locations of the spheres are determined via a Green's function of the domain.

Key words. spherical phase, diblock copolymer morphology, sphere coarsening, interface oscillation

1. Introduction. A diblock copolymer melt is a soft material, characterized by fluid-like disorder on the molecular scale and a high degree of order at a longer length scale. A molecule in a diblock copolymer is a linear subchain of A-monomers grafted covalently to another subchain of B-monomers. Because of the repulsion between the unlike monomers, the different type subchains tend to segregate, but as they are chemically bonded in chain molecules, segregation of subchains cannot lead to a macroscopic phase separation. Only a local microphase separation occurs: microdomains rich in A-monomers and microdomains rich in B-monomers emerge as a result. These microdomains form patterns that are known as morphology phases. Various phases, including lamellar, cylindrical, spherical, and gyroid, have been observed in experiments. See Bates and Fredrickson [1] for more on block copolymers.

This paper deals with the spherical phase of the block copolymer morphology (Figure 1.1, Plot 1). Let $a \in (0,1)$ be the block composition fraction which is the number of the A-monomers divided by the number of all the A- and B-monomers in a chain molecule. The spherical phase occurs when a is relatively close to 0 (or close to 1), and the A-monomers (or B-monomers, respectively) form small balls in space.

The model we use here is a nonlocal free boundary problem derived from the Ohta–Kawasaki density functional theory of diblock copolymers [18]. Let D be a bounded and sufficiently smooth domain in R^3 occupied by a diblock copolymer melt in the spherical phase. Let E be a subset of D where A-monomers concentrate. Then $D\backslash E$ is the subset where B-monomers concentrate. Denote the part of the boundary of E that is in D by $\partial_D E$ which is the set of the interfaces separating the A-rich microdomains from the B-rich microdomains. Denote the Lebesgue measure of E by $|E|$. Given a block composition fraction $a \in (0,1)$, one has $|E| = a|D|$.

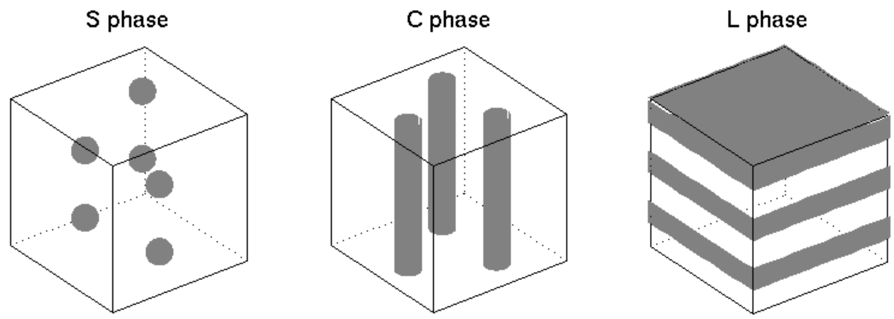

FIG. 1.1. *The spherical, cylindrical, and lamellar morphology phases commonly observed in diblock copolymer melts. The dark color indicates the concentration of type A monomers, and the white color indicates the concentration of type B monomers.*

Moreover, there exists a number λ such that at every point on $\partial_D E$

$$H(\partial_D E) + \gamma(-\Delta)^{-1}(\chi_E - a) = \lambda. \tag{1.1}$$

Here $H(\partial_D E)$ is the mean curvature of $\partial_D E$ viewed from E, γ is a positive parameter, and χ_E is the characteristic function of E, i.e. $\chi_E(x) = 1$ if $x \in E$, and $\chi_E(x) = 0$ if $x \in D \backslash E$. The expression $(-\Delta)^{-1}(\chi_E - a)$ is the solution v of the problem

$$-\Delta v = \chi_E - a \text{ in } D, \qquad \partial_\nu v = 0 \text{ on } \partial D, \qquad \overline{v} = 0,$$

where the bar over a function is the average of the function over its domain, i.e.,

$$\overline{v} = \frac{1}{|D|} \int_D v(x)\, dx.$$

Because $(-\Delta)^{-1}$ is a nonlocal operator defined from $\{q \in L^2(D) : \overline{q} = 0\}$ to itself, the free boundary problem (1.1) is nonlocal.

Equation (1.1) is the Euler–Lagrange equation of the free energy J of the system. The functional J is given by

$$J(E) = |D\chi_E|(D) + \frac{\gamma}{2} \int_D |(-\Delta)^{-1/2}(\chi_E - a)|^2\, dx, \quad E \in \Sigma. \tag{1.2}$$

The admissible set Σ of the functional J is the collection of all measurable subsets of D of measure $a|D|$ and of finite perimeter, i.e.,

$$\Sigma = \{E \subset D : E \text{ is Lebesgue measurable}, \ |E| = a|D|, \ \chi_E \in BV(D)\}. \tag{1.3}$$

Here $BV(D)$ is the space of functions of bounded variation on D. In (1.2), $|D\chi_E|(D)$ is the perimeter of E. When ∂E is smooth, this is merely the surface area of $\partial_D E$. For a more general E, χ_E is a BV-function and $D\chi_E$ is a vector valued finite measure. We denote the magnitude of this measure by $|D\chi_E|$ which is a positive, finite measure. The perimeter of E is defined to be the size of D under this measure. The operator $(-\Delta)^{-1/2}$ is the positive square root of $(-\Delta)^{-1}$.

The main difficulty in (1.1) stems from the nonlocal term. Without it, i.e., if $\gamma = 0$, (1.1) would just be the equation of constant mean curvature. However with the nonlocal term the curvature of a solution in general is not constant. One exception occurs in the study of the lamellar phase (Figure 1.1, Plot 3) where interfaces are parallel planes (Ren and Wei [20, 23]). The solution we are looking for in this paper is a union of a number of disconnected sets each of which is close to a small round ball. The solution is hence termed a spherical solution.

Nishiura and Ohnishi [16] formulated the Ohta–Kawasaki theory on a bounded domain as a singularly perturbed variational problem with a nonlocal term and also identified the free boundary problem (1.1). Ren and Wei [20] showed that (1.2) is a Γ-limit of the singularly perturbed variational problem. See the last section for more discussion on the Ohta–Kawasaki theory and Γ-convergence.

Since then much work has been done mathematically to these problems. The lamellar phase (Figure 1.1, Plot 3) is studied by Ren and Wei [20, 22, 23, 27, 28], Fife and Hilhorst [9], Choksi and Ren [4], Chen and Oshita [2], and Choksi and Sternberg [6]. The result obtained by Müller [15] is related to the lamellar phase in the case $a = 1/2$, as observed in [16]. Radially symmetric bubble and ring patterns are studied by Ren and Wei [21, 26, 29]. The gyroid phase is numerically studied by Teramoto and Nishiura [33]. Triblock copolymers are studied by Ren and Wei [24, 25]. A diblock copolymer/homopolymer blend is studied by Choksi and Ren [5]. Also, see Ohnishi et al. [17] and Choksi [3].

The cylindrical phase (Figure 1.1, Plot 2) is studied by Ren and Wei [31, 30], in which a variant of the Lyapunov–Schmidt reduction procedure is developed to study a cross section of Figure 1.1, Plot 2. A pattern with a number of approximate small discs is found which satisfies the two-dimensional version of (1.1). In two dimensions, $\partial_D E$ is a union of curves and $H(\partial_D E)$ is the curvature of the curves.

In this paper we adapt the Lyapunov–Schmidt reduction procedure to three dimensions to construct spherical solutions. These solutions look like Figure 1.1, Plot 1. They model the spherical phase of diblock copolymer morphology.

The main results are presented in section 2. Our strategy to prove them consists of setting up a first approximation (section 3) and through linearization (sections 4 and 5) and fixed point argument (sections 6 and 7) solving a projected version of the full problem (up to spherical harmonics of order 0 and 1 corresponding to translations and changes in volume). This reduces the infinite dimensional variational problem to a finite dimensional minimization problem in centers and radii. After finding a minimum of the finite dimensional problem, we show that it is indeed an exact solution of the full problem, using a tricky reparametrization argument (section 8).

Our construction yields, in addition, information on the spectra of linearization, interpreted as forms of stability-instability.

Compared to the two-dimensional case, the study of the linearized problem is more involved here. In two dimensions the corresponding linearized problem is analyzed by the Fourier series method. Here in three dimensions we use spherical harmonics to diagonalize the linearized operator (see Lemma 5.1). More differences between the two-dimensional and the three-dimensional cases are given in section 9.

2. Main results. The Green's function of $-\Delta$ is denoted by G. It is a sum of two parts:

$$G(x,y) = \frac{1}{4\pi|x-y|} + R(x,y). \tag{2.1}$$

The first part on the right-hand side of (2.1) is the fundamental solution in three dimensions. The second part is the regular part of $G(x,y)$, denoted by $R(x,y)$. The

Green's function satisfies
(2.2)

$$-\Delta_x G(x,y) = \delta(x-y) - \frac{1}{|D|} \text{ in } D, \quad \partial_{\nu(x)} G(x,y) = 0 \text{ on } \partial D, \quad \overline{G(\cdot,y)} = 0 \ \forall y \in D.$$

Here Δ_x is the Laplacian with respect to the x-variable of G, and $\nu(x)$ is the outward normal direction at $x \in \partial D$. We set

$$F(\xi_1, \xi_2, \ldots, \xi_K) = \sum_{k=1}^{K} R(\xi_k, \xi_k) + \sum_{k=1}^{K} \sum_{l=1, l\neq k}^{K} G(\xi_k, \xi_l), \tag{2.3}$$

for $\xi_k \in D$ and $\xi_k \neq \xi_l$ if $k \neq l$. Because $G(x,y) \to \infty$ if $|x-y| \to 0$ and $R(x,x) \to \infty$ if $x \to \partial D$, F admits at least one global minimum.

The average sphere radius is

$$\rho = \left(\frac{3a|D|}{4\pi K}\right)^{1/3}. \tag{2.4}$$

The main result of this paper is the following existence theorem.

THEOREM 2.1. *Let $K \geq 2$ be an integer.*

1. *For every $\epsilon > 0$ there exists $\delta > 0$, depending on ϵ, K, and D only, such that if*

$$\gamma\rho^3 > 3 + \epsilon, \tag{2.5}$$

$$\left|\gamma\rho^3 - \frac{3(n+2)(2n+1)}{2}\right| > \epsilon n^2 \ \forall\ n = 2,3,4,\ldots, \tag{2.6}$$

and

$$\rho < \delta, \tag{2.7}$$

then there exists a solution E of (1.1).

2. *The solution E is a union of K approximate balls. The radius of each ball is close to ρ.*
3. *Let the centers of these balls be $\zeta_1, \zeta_2, \ldots, \zeta_K$. Then $\zeta = (\zeta_1, \zeta_2, \ldots, \zeta_K)$ is close to a global minimum of the function F.*

The precise meaning that each component of E is close to a ball of radius ρ is given in (8.18). As ρ (or a) tends to 0, ζ converges to a global minimum of F, possibly along a subsequence.

We have opted for a rather general existence theorem. The solution found in the theorem is not necessarily stable. The stability of the solution depends on how (2.6) is satisfied.

THEOREM 2.2. *If* (2.6) *is satisfied because*

$$\gamma\rho^3 - \frac{3(n+2)(2n+1)}{2} < -\epsilon n^2 \ \forall\ n \geq 2, \tag{2.8}$$

then the spherical solution is stable. Otherwise if (2.6) *is satisfied but*

$$\epsilon n^2 < \gamma\rho^3 - \frac{3(n+2)(2n+1)}{2}, \ \textit{and}\ \gamma\rho^3 - \frac{3(n+3)(2n+3)}{2} < -\epsilon(n+1)^2 \tag{2.9}$$

for some $n \geq 2$, then the spherical solution is unstable.

When we delete intervals around $\frac{3(n+2)(2n+1)}{2}$, $n = 2, 3, \ldots$, in (2.6), the width of the intervals, $2\epsilon n^2$, grows as n becomes large. At some point an interval will include nearby members in the sequence $\frac{3(n+2)(2n+1)}{2}$. When this happens, $\gamma\rho^3$ cannot be placed above such $\frac{3(n+2)(2n+1)}{2}$. This implies that there exists $C(\epsilon) > 0$ depending on ϵ such that

$$\gamma < \frac{C(\epsilon)}{\rho^3}. \tag{2.10}$$

A little computation shows that $C(\epsilon)$ is

$$C(\epsilon) = \frac{3}{2}\left(\frac{6+\sqrt{36+18\epsilon}}{2\epsilon}+2\right)\left(\frac{6+\sqrt{36+18\epsilon}}{\epsilon}+1\right).$$

Combining (2.10) with (2.5) we see that ρ and γ are in a somewhat narrow parameter range

$$\rho < \delta, \quad \frac{3+\epsilon}{\rho^3} < \gamma < \frac{C(\epsilon)}{\rho^3}, \tag{2.11}$$

and $\gamma\rho^3$ must stay away from the sequence $\frac{3(n+2)(2n+1)}{2}$, $n = 2, 3, \ldots$, in the sense of (2.6). From (2.11) one sees that ρ must be small and γ be appropriately large.

We may assign a negative gradient flow to J and consider a dynamic counterpart of (1.1) (see [16]). The condition (2.5) prevents coarsening in such a dynamic process. By coarsening we mean that some balls become larger and other balls shrink and disappear.

The gap condition (2.6) controls interface oscillation. Interface oscillation refers to a phenomenon that oscillations appear on the boundary of a ball. The gap condition also suggests bifurcations to oscillating solutions. Elsewhere gap conditions have appeared in constructing layered solutions for singularly perturbed problems. See Malchiodi and Montenegro [12], del Pino, Kowalczyk, and Wei [8], Pacard and Ritoré [19], and the references therein.

The solution found in Theorem 2.1 may be unstable because of interface oscillation. The condition (2.8) in Theorem 2.2 eliminates this possibility. Under (2.8), ϵ must be no greater than 3, and ρ and γ must satisfy a more stringent requirement

$$\rho < \delta, \quad \frac{3+\epsilon}{\rho^3} < \gamma < \frac{30-4\epsilon}{\rho^3}. \tag{2.12}$$

This means that $\gamma\rho^3$ must stay to the left of the sequence $\frac{3(n+2)(2n+1)}{2}$, $n = 2, 3, \ldots$. If (2.9) holds, then we have an unstable mode that tends to bring oscillations to the spheres.

The spheres in the solution we construct are approximately round, with the same approximate radius. Theorem 2.1, part 3 asserts that the sphere centers must minimize F approximately.

We can even determine the optimal number of balls in a spherical pattern. Because of (2.11), we write

$$\gamma = \frac{\mu}{a} = \frac{\mu}{\left(\frac{4\pi K}{3|D|}\right)\rho^3}. \tag{2.13}$$

Now a and μ are the parameters of the problem. We hold μ fixed and make a and hence ρ small.

With (2.13) and (2.4) the leading order of the free energy is calculated from the formula in Lemma 8.1,

$$4\pi\rho^2 K + \frac{\gamma}{2}\left(\frac{8\pi\rho^5 K}{15}\right) = 4\pi K^{1/3}\left(\frac{3a|D|}{4\pi}\right)^{2/3} + \frac{\mu 4\pi}{15a}\left(\frac{3a|D|}{4\pi}\right)^{5/3} K^{-2/3}. \tag{2.14}$$

With respect to K the last quantity is minimized at

$$K = \frac{|D|\mu}{10\pi}. \tag{2.15}$$

Note that the choice (2.15) of K does not violate the condition (2.12), since, with this K,

$$\gamma = \frac{\mu}{a} = \mu\frac{3|D|}{K4\pi\rho^3} = \mu\frac{3|D|}{4\pi\rho^3}\frac{10\pi}{\mu|D|} = \frac{30}{4\rho^3}. \tag{2.16}$$

Equation (2.15) gives the optimal number of spheres in a spherical pattern.

3. Approximate solutions. Throughout the rest of this paper we are given $\epsilon > 0$, and γ and ρ satisfy (2.5) and (2.6).

Let U_1 be a small neighborhood in D^K of the set $\{\eta : F(\eta) = \min_{\xi\in D^K} F(\xi)\}$, and U_2 be the set

$$U_2 = \Big\{(r_1, r_2, \dots, r_K) \in R^K : r_k \in ((1-\delta_2)\rho, (1+\delta_2)\rho), \\ k = 1, 2, \dots, K, \quad \sum_{k=1}^{K} \frac{4\pi r_k^3}{3} = a|D|\Big\}. \tag{3.1}$$

The constant δ_2 is positive, small, and depends on ϵ. It will be fixed later in the proofs of Lemmas 5.3 and 8.2. Define

$$U = U_1 \times U_2. \tag{3.2}$$

Let $\xi_1, \xi_2, \dots, \xi_K$ be K distinct points in D such that $\xi = (\xi_1, \xi_2, \dots, \xi_K)$ is in U_1, and $r = (r_1, r_2, \dots, r_K)$ is in U_2. Denote the ball centered at ξ_k of radius r_k by B_k. The union of the B_k's is B:

$$B = \bigcup_{k=1}^{K} B_k = \bigcup_{k=1}^{K} \{x \in R^3 : |x - \xi_k| < r_k\}. \tag{3.3}$$

With U_1 close to $\{\eta : F(\eta) = \min_{\kappa\in D^K} F(\kappa)\}$ and ρ sufficiently small, the B_k's are all inside D and disjoint.

LEMMA 3.1. *When E is B, the left-hand side of* (1.1) *is*

$$\frac{1}{r_k} + \gamma\left[\frac{r_k^2}{3} + \frac{4\pi r_k^3}{3}R(\xi_k, \xi_k) + \sum_{l\neq k}\frac{4\pi r_l^3}{3}G(\xi_k, \xi_l)\right] + O(\rho)$$

at each $\xi_k + r_k\theta_k$, where $\theta_k \in S^2$ and S^2 is the unit sphere.

Proof. At a boundary point $\xi_k + r_k\theta_k$ of B_k, the curvature is $\frac{1}{r_k}$.

We compute $v_k = (-\Delta)^{-1}(\chi_{B_k} - \frac{4\pi r_k^3}{3|D|})$. Define

$$P_k(x) = \begin{cases} -\frac{|x-\xi_k|^2}{6} + \frac{r_k^2}{2} & \text{if } |x-\xi_k| < r_k \\ \frac{r_k^3}{3|x-\xi_k|}, & \text{if } |x-\xi_k| \geq r_k. \end{cases}$$

Then $-\Delta P_k = \chi_{B_k}$. Write $v_k(x) = P_k(x) + Q_k(x,\xi_k)$. Clearly

$$-\Delta Q_k(x,\xi_k) = -\frac{4\pi r_k^3}{3|D|},\ \partial_{\nu(x)} Q_k(x,\xi_k) = -\partial_\nu \frac{4\pi r_k^3}{3}\frac{1}{4\pi|x-\xi_k|}$$
$$\text{on } \partial D,\ \overline{Q_k(\cdot,\xi_k)} = -\overline{P_k}.$$

From (2.2) we see that $Q_k(x,\xi_k)$ and $\frac{4\pi r_k^3}{3}R(x,\xi_k)$ satisfy the same equation and the same boundary condition, where R is the regular part of the Green's function G. Therefore they can differ only by a constant. This constant is $\overline{Q_k(\cdot,\xi_k)} - \frac{4\pi r_k^3}{3}\overline{R(\cdot,\xi_k)}$. But $\overline{v_k} = \overline{G(\cdot,\xi_k)} = 0$ implies that this constant is

$$-\overline{P_k} + \frac{4\pi r_k^3}{3}\overline{\frac{1}{4\pi|x-\xi_k|}} = \frac{4\pi r_k^5}{3}\frac{1}{10|D|}$$

by direct calculation. Hence

$$Q_k(x,\xi_k) = \frac{4\pi r_k^3}{3}R(x,\xi_k) + \frac{4\pi}{3}\frac{r_k^5}{10|D|}$$

and

$$v_k(x) = P_k(x) + \frac{4\pi r_k^3}{3}R(x,\xi_k) + \frac{4\pi}{3}\frac{r_k^5}{10|D|}. \tag{3.4}$$

Let $v = (-\Delta)^{-1}(\chi_B - a) = \sum_l v_l$. Then at $\xi_k + r_k\theta_k$

$$\begin{aligned} v(\xi_k + r_k\theta_k) &= \frac{r_k^2}{3} + \frac{4\pi r_k^3}{3}R(\xi_k + r_k\theta_k, \xi_k) + \sum_{l\neq k}\frac{4\pi r_l^3}{3}G(\xi_k + r_k\theta_k, \xi_l) \\ &\quad + \sum_{l=1}^{K}\frac{4\pi}{3}\frac{r_l^5}{10|D|} \\ &= \frac{r_k^2}{3} + \frac{4\pi r_k^3}{3}R(\xi_k,\xi_k) + \sum_{l\neq k}\frac{4\pi r_l^3}{3}G(\xi_k,\xi_l) + O(\rho^4). \end{aligned} \tag{3.5}$$

The lemma follows from (2.10). ∎

LEMMA 3.2. *The free energy of B is*

$$\begin{aligned} J(B) = \sum_{k=1}^{K} 4\pi r_k^2 + \frac{\gamma}{2}\Bigg\{ &\sum_{k=1}^{K}\left[\frac{8\pi r_k^5}{15} + \left(\frac{4\pi}{3}\right)^2 r_k^6 R(\xi_k,\xi_k)\right] \\ &+ \sum_{k=1}^{K}\sum_{l=1, l\neq k}^{K}\left(\frac{4\pi}{3}\right)^2 r_k^3 r_l^3 G(\xi_k,\xi_l) + \sum_{k=1}^{K}\sum_{l=1}^{K}\left(\frac{4\pi}{3}\right)^2\left(\frac{r_k^3 r_l^5}{10|D|} + \frac{r_k^5 r_l^3}{10|D|}\right)\Bigg\}. \end{aligned}$$

Proof. The local part of the free energy is just $\sum_{k=1}^K 4\pi r_k^2$.
The nonlocal part of the free energy is

$$\begin{aligned}
&\int_D |(-\Delta)^{-1/2}(\chi_B - a)|^2\,dx \\
&\quad = \int_D (\chi_B - a)v(x)\,dx \; = \; \sum_{l=1}^K \int_{B_l} v(x)\,dx \\
&\quad = \sum_{l=1}^K \sum_{k=1}^K \int_{B_l} v_k(x)\,dx \; = \; \sum_{l=1}^K \sum_{k=1}^K \left[\int_{B_l} P_k(x)\,dx + \int_{B_l} Q_k(x,\xi_k)\,dx\right].
\end{aligned}$$

There are two possibilities. When $l = k$, from the definition of P_k we find

$$\int_{B_k} P_k(x)\,dx = \frac{8\pi r_k^5}{15}. \tag{3.6}$$

For the integral of Q_k, we have

$$\int_{B_k} Q_k(x,\xi_k)\,dx = \frac{4\pi r_k^3}{3}\int_{B_k} R(x,\xi_k)\,dx + \left(\frac{4\pi}{3}\right)^2 \frac{r_k^8}{10|D|}.$$

Since $R(x,\xi_k) - \frac{1}{6|D|}|x-\xi_k|^2$ is harmonic in x, by the mean value theorem for harmonic functions

$$\begin{aligned}
\int_{B_k} R(x,\xi_k)\,dx &= \int_{B_k}\left(R(x,\xi_k) - \frac{1}{6|D|}|x-\xi_k|^2\right)dx + \int_{B_k}\frac{1}{6|D|}|x-\xi_k|^2\,dx \\
&= \frac{4\pi r_k^3}{3}R(\xi_k,\xi_k) + \frac{4\pi}{3}\frac{r_k^5}{10|D|}. \qquad (3.7)
\end{aligned}$$

Hence

$$\int_{B_k} v_k\,dx = \frac{8\pi r_k^5}{15} + \left(\frac{4\pi}{3}\right)^2 r_k^6 R(\xi_k,\xi_k) + \left(\frac{4\pi}{3}\right)^2 \frac{r_k^8}{5|D|}.$$

When $l \neq k$, for $x \in B_l$, since P_k is harmonic,

$$\begin{aligned}
\int_{B_l} v_k\,dx &= \int_{B_l} P_k\,dx + \frac{4\pi r_k^3}{3}\int_{B_l} R(x,\xi_k)\,dx + \left(\frac{4\pi}{3}\right)^2 \frac{r_k^5 r_l^3}{10|D|} \\
&= \frac{4\pi}{3} r_l^3 \frac{r_k^3}{3|\xi_k - \xi_l|} + \frac{4\pi r_k^3}{3}\left[\int_{B_l}\left(R(x,\xi_k) - \frac{1}{6|D|}|x-\xi_l|^2\right)dx\right. \\
&\quad \left. + \int_{B_l}\frac{1}{6|D|}|x-\xi_l|^2\,dx\right] + \left(\frac{4\pi}{3}\right)^2 \frac{r_k^5 r_l^3}{10|D|} \\
&= \left(\frac{4\pi}{3}\right)^2 \frac{r_k^3 r_l^3}{4\pi|\xi_k - \xi_l|} + \left(\frac{4\pi}{3}\right)^2 r_k^3 r_l^3 R(\xi_k,\xi_l) + \left(\frac{4\pi}{3}\right)^2 \left(\frac{r_k^3 r_l^5}{10|D|} + \frac{r_k^5 r_l^3}{10|D|}\right).
\end{aligned}$$

Finally the nonlocal part of the free energy is

$$\begin{aligned}\int_D (\chi_B - a) v\, dx = &\sum_{k=1}^K \left[\frac{8\pi r_k^5}{15} + \left(\frac{4\pi}{3}\right)^2 r_k^6 R(\xi_k, \xi_k) \right] \\ &+ \sum_{k=1}^K \sum_{l=1, l\neq k}^K \left[\left(\frac{4\pi}{3}\right)^2 \frac{r_k^3 r_l^3}{4\pi|\xi_k - \xi_l|} + \left(\frac{4\pi}{3}\right)^2 r_k^3 r_l^3 R(\xi_k, \xi_l) \right] \\ &+ \sum_{k=1}^K \sum_{l=1}^K \left(\frac{4\pi}{3}\right)^2 \left(\frac{r_k^3 r_l^5}{10|D|} + \frac{r_k^5 r_l^3}{10|D|} \right). \end{aligned} \tag{3.8}$$

The lemma now follows. □

4. Perturbed spheres. We perturb each ball B_k considered in the last section. A perturbed ball denoted by E_{ϕ_k} is described by a function $\phi_k = \phi_k(\theta_k)$, $\theta_k \in S^2$:

$$E_{\phi_k} = \{\xi_k + t\theta_k : \ \theta_k \in S^2, \ t \in [0, (r_k^3 + \phi_k(\theta_k))^{1/3}]\}. \tag{4.1}$$

Each ϕ_k is small compared to r_k^3 so that $r_k^3 + \phi_k(\theta_k)$ is positive. Each θ_k is identified by its longitude and latitude $(\theta_{k,1}, \theta_{k,2})$, namely

$$\theta_k = (\cos\theta_{k,1} \sin\theta_{k,2}, \ \sin\theta_{k,1} \sin\theta_{k,2}, \ \cos\theta_{k,2}). \tag{4.2}$$

The ϕ_k's satisfy

$$\sum_{k=1}^K \int_{S^2} \phi_k(\theta_k)\, d\theta_k = 0. \tag{4.3}$$

Here the integral is a surface integral over S^2 and

$$d\theta_k = \sin\theta_{k,2}\, d\theta_{k,1} d\theta_{k,2} \tag{4.4}$$

is the surface element on S^2. Hence the total volume inside the perturbed spheres remains fixed:

$$\begin{aligned}\sum_{k=1}^K |E_{\phi_k}| &= \sum_k \int_{S^2} \int_0^{(r_k^3 + \phi_k(\theta_k))^{1/3}} t^2\, dt d\theta_k \\ &= \sum_k \int_{S^2} \left(\frac{r_k^3}{3} + \frac{\phi_k(\theta_k)}{3} \right) d\theta_k = \sum_k \frac{4\pi r_k^3}{3} = a|D|. \end{aligned}$$

The union of the E_{ϕ_k}'s is E_ϕ:

$$E_\phi = \bigcup_{k=1}^K E_{\phi_k}. \tag{4.5}$$

With these notations $B = E_0$.

We let $\theta = (\theta_1, \theta_2, \dots, \theta_K)$ and $\phi(\theta) = (\phi_1(\theta_1), \phi_2(\theta_2), \dots \phi_K(\theta_K))$. To express surface area in terms of ϕ_k, first define

$$L(s, p, q, \beta) = s^{-1/3} \sqrt{\frac{p^2}{9\sin^2\beta} + \frac{q^2}{9} + s^2}, \tag{4.6}$$

and then define

$$L_k\left(\phi_k, \frac{\partial \phi_k}{\partial \theta_{k,1}},\ \frac{\partial \phi_k}{\partial \theta_{k,2}},\ \theta_{k,2}\right) = r_k^2 L\left(1+\frac{\phi_k}{r_k^3},\ \frac{1}{r_k^3}\frac{\partial \phi_k}{\partial \theta_{k,1}},\ \frac{1}{r_k^3}\frac{\partial \phi_k}{\partial \theta_{k,2}},\ \theta_{k,2}\right). \tag{4.7}$$

The surface area of $\partial_D E_\phi$ can be expressed as

$$\sum_{k=1}^K |D\chi_{E_{\phi_k}}|(D) = \sum_{k=1}^K \int_{S^2} L_k\left(\phi_k, \frac{\partial \phi_k}{\partial \theta_{k,1}},\ \frac{\partial \phi_k}{\partial \theta_{k,2}},\ \theta_{k,2}\right) d\theta_k. \tag{4.8}$$

The nonlocal part of J in (1.2) may be written in terms of ϕ as

$$\frac{\gamma}{2}\int_D |(-\Delta)^{-1/2}(\chi_{E_\phi}-a)|^2\,dx = \frac{\gamma}{2}\int_{E_\phi}\int_{E_\phi} G(x,y)\,dxdy. \tag{4.9}$$

The first variation of J can now be written as

$$J'(E_\phi)(w) = \sum_{k=1}^K \int_{S^2}\left[\frac{\partial L_k}{\partial \phi_k}w_k + \frac{\partial L_k}{\partial \phi_{k,1}}w_{k,1} + \frac{\partial L_k}{\partial \phi_{k,2}}w_{k,2}\right] d\theta_k \tag{4.10}$$

$$+ \sum_{k=1}^K \int_{S^2} w_k(\theta_k)\left[\sum_{l=1}^K \frac{\gamma}{3}\int_{E_{\phi_l}} G(\xi_k+(r_k^3+\phi_k(\theta_k))^{1/3}\theta_k, y)\,dy\right] d\theta_k. \tag{4.11}$$

Here we have used shorthand notations $\phi_{k,1} = \frac{\partial \phi_k}{\partial \theta_{k,1}}$ and $\phi_{k,2} = \frac{\partial \phi_k}{\partial \theta_{k,2}}$, and so on. From (4.10) we define a second order, quasilinear elliptic operator

$$\mathcal{H}_k(\phi_k)(\theta_k) = \frac{1}{\sin\theta_{k,2}}\left[\frac{\partial L_k}{\partial \phi_k}\sin\theta_{k,2} - \frac{\partial}{\partial \theta_{k,1}}\left(\frac{\partial L_k}{\partial \phi_{k,1}}\sin\theta_{k,2}\right) - \frac{\partial}{\partial \theta_{k,2}}\left(\frac{\partial L_k}{\partial \phi_{k,2}}\sin\theta_{k,2}\right)\right]. \tag{4.12}$$

This is just the mean curvature of the perturbed sphere ∂E_{ϕ_k} at $\xi_k+(r_k^3+\phi_k(\theta_k))^{1/3}\theta_k$, multiplied by $\frac{1}{3}$. The second part (4.11) of the first variation of J gives rise to a nonlocal operator

$$\phi \to \sum_{l=1}^K \frac{\gamma}{3}\int_{E_{\phi_l}} G(\xi_k+(r_k^3+\phi_k(\theta_k))^{1/3}\theta_k, y)\,dy. \tag{4.13}$$

This is just

$$\frac{\gamma}{3}(-\Delta)^{-1}(\chi_{E_\phi}-a)(\xi_k+(r_k^3+\theta_k)^{1/3}\theta_k),$$

the nonlocal part of (1.1) at $\xi_k+(r_k^3+\phi_k(\theta_k))^{1/3}\theta_k$ multiplied by $\frac{1}{3}$.

There are two cases in the sum over l in (4.13); when $l=k$ we write

$$\frac{\gamma}{3}\int_{E_{\phi_k}} G(\xi_k+(r_k^3+\phi_k(\theta_k))^{1/3}\theta_k, y)\,dy$$
$$= \frac{\gamma}{3}\int_{E_{\phi_k}} \frac{dy}{4\pi|\xi_k+(r_k^3+\phi_k(\theta_k))^{1/3}\theta_k - y|} + \frac{\gamma}{3}\int_{E_{\phi_k}} R(\xi_k+(r_k^3+\phi_k(\theta_k))^{1/3}\theta_k, y)\,dy.$$

We denote the last two terms by

$$\mathcal{A}_k(\phi_k)(\theta_k) = \frac{\gamma}{3}\int_{E_{\phi_k}} \frac{dy}{4\pi|\xi_k + (r_k^3 + \phi_k(\theta_k))^{1/3}\theta_k - y|}, \tag{4.14}$$

$$\mathcal{B}_k(\phi_k)(\theta_k) = \frac{\gamma}{3}\int_{E_{\phi_k}} R(\xi_k + (r_k^3 + \phi_k(\theta_k))^{1/3}\theta_k, y)\, dy. \tag{4.15}$$

When $l \neq k$ in (4.13) we let

$$\mathcal{C}_{kl}(\phi_k, \phi_l)(\theta_k) = \frac{\gamma}{3}\int_{E_{\phi_l}} G(\xi_k + (r_k^3 + \phi_k(\theta_k))^{1/3}\theta_k, y)\, dy. \tag{4.16}$$

The left-hand side of (1.1) (multiplied by $\frac{1}{3}$) now becomes

$$\mathcal{H}_k(\phi_k)(\theta_k) + \mathcal{A}_k(\phi_k)(\theta_k) + \mathcal{B}_k(\phi_k)(\theta_k) + \sum_{l\neq k}\mathcal{C}_{kl}(\phi_k, \phi_l)(\theta_k)$$

at $\xi_k + (r_k^3 + \phi_k(\theta_k))^{1/3}\theta_k$. Let us define

$$\mathcal{S} = (\mathcal{S}_1, \mathcal{S}_2, \ldots, \mathcal{S}_K), \tag{4.17}$$

where

$$\mathcal{S}_k(\phi)(\theta_k) = \mathcal{H}_k(\phi_k)(\theta_k) + \mathcal{A}_k(\phi_k)(\theta_k) + \mathcal{B}_k(\phi_k)(\theta_k) + \sum_{l\neq k}\mathcal{C}_{kl}(\phi_k, \phi_l)(\theta_k) + \lambda(\phi). \tag{4.18}$$

Here $\lambda(\phi)$ is a number, independent of k. It is given by

$$\lambda(\phi) = -\frac{1}{K}\sum_{k=1}^{K}\overline{\left[\mathcal{H}_k(\phi_k) + \mathcal{A}_k(\phi_k) + \mathcal{B}_k(\phi_k) + \sum_{l\neq k}\mathcal{C}_{kl}(\phi_k, \phi_l)\right]}. \tag{4.19}$$

The bar over the quantity here stands for the average of the quantity over S^2. With this definition of λ,

$$\sum_{k=1}^{K}\overline{\mathcal{S}_k(\phi_k)} = 0. \tag{4.20}$$

The operator $\mathcal{S}$ maps from

$$\mathcal{X} = \left\{\phi = (\phi_1, \phi_2, \ldots, \phi_K):\ \phi_k \in W^{2,p}(S^2),\ k = 1, 2, \ldots, K,\ \ \sum_{k=1}^{K}\overline{\phi_k} = 0\right\} \tag{4.21}$$

to

$$\mathcal{Y} = \left\{q = (q_1, q_2, \ldots, q_K):\ q_k \in L^p(S^2),\ k = 1, 2, \ldots, K,\ \ \sum_{k=1}^{K}\overline{q_k} = 0\right\}. \tag{4.22}$$

For technical reasons p is assumed to be in the range

$$2 < p < \infty. \tag{4.23}$$

This guarantees that $D\phi_k$ is continuous, a fact needed in the proof of Lemma 6.1. Equation (1.1) now becomes

$$\mathcal{S}(\phi) = 0. \tag{4.24}$$

By defining

$$\mathcal{C} = (\mathcal{C}_1, \mathcal{C}_2, \dots, \mathcal{C}_K), \text{ where } \mathcal{C}_k(\phi_1, \phi_2, \dots, \phi_K) = \sum_{l \neq k} \mathcal{C}_{kl}(\phi_k, \phi_l), \tag{4.25}$$

we write

$$\mathcal{S} = \mathcal{H} + \mathcal{A} + \mathcal{B} + \mathcal{C} + \lambda. \tag{4.26}$$

In the map $\mathcal{S}$ the inputs $\phi_1, \phi_2, \dots, \phi_k$ interact only in $\mathcal{C}$ and λ. The other operators can be written in the block matrix form

$$\mathcal{H} = \begin{bmatrix} \mathcal{H}_1 & 0 & \dots & 0 \\ 0 & \mathcal{H}_2 & \dots & 0 \\ \dots & \dots & \dots & \dots \\ 0 & 0 & \dots & \mathcal{H}_K \end{bmatrix}, \ \mathcal{A} = \begin{bmatrix} \mathcal{A}_1 & 0 & \dots & 0 \\ 0 & \mathcal{A}_2 & \dots & 0 \\ \dots & \dots & \dots & \dots \\ 0 & 0 & \dots & \mathcal{A}_K \end{bmatrix}, \ \mathcal{B} = \begin{bmatrix} \mathcal{B}_1 & 0 & \dots & 0 \\ 0 & \mathcal{B}_2 & \dots & 0 \\ \dots & \dots & \dots & \dots \\ 0 & 0 & \dots & \mathcal{B}_K \end{bmatrix}, \tag{4.27}$$

where each entry in a matrix is an operator from $W^{2,p}(S^2)$ to $L^p(S^2)$. The scalar operator λ gives the projection $-(\lambda(\phi), \lambda(\phi), \dots, \lambda(\phi))$ of $\mathcal{H}(\phi) + \mathcal{A}(\phi) + \mathcal{B}(\phi) + \mathcal{C}(\phi)$ to the one-dimensional space spanned by $(1, 1, \dots, 1)$.

Let us write the first Fréchet derivatives of these operators. For simplicity we write

$$\phi_{k,i} = \frac{\partial \phi_k}{\partial \theta_{k,i}}, \ \phi_{k,ij} = \frac{\partial^2 \phi_k}{\partial \theta_{k,ij}}, \ u_{k,i} = \frac{\partial u_k}{\partial \theta_{k,i}}, \ u_{k,ij} = \frac{\partial^2 u_k}{\partial \theta_{k,ij}}.$$

Calculations show that

$$\mathcal{H}_k'(\phi_k)(u_k) = \frac{\partial \mathcal{H}_k}{\partial \phi_k} u_k + \sum_{i=1}^{2} \frac{\partial \mathcal{H}_k}{\partial \phi_{k,i}} u_{k,i} + \sum_{i,j=1}^{2} \frac{\mathcal{H}_k}{\partial \phi_{k,ij}} u_{k,ij}, \tag{4.28}$$

$$\begin{aligned} \mathcal{A}_k'(\phi_k)(u_k)(\theta_k) &= \frac{\gamma}{9} \int_{S^2} \frac{u_k(\omega_k)\, d\omega_k}{4\pi |(r_k^3 + \phi_k(\theta_k))^{1/3}\theta_k - (r_k^3 + \phi_k(\omega_k))^{1/3}\omega_k|} \\ &\quad - \frac{\gamma u_k(\theta_k)}{9(r_k^3 + \phi_k(\theta_k))^{2/3}} \int_{\tilde{E}_{\phi_k}} \frac{((r_k^3 + \phi_k(\theta_k))^{1/3}\theta_k - y) \cdot \theta_k}{4\pi |(r_k^3 + \phi_k(\theta_k))^{1/3}\theta_k - y|^3}\, dy. \end{aligned} \tag{4.29}$$

$$\begin{aligned} &\mathcal{B}_k'(\phi_k)(u_k)(\theta_k) \\ &\quad = \frac{\gamma}{9} \int_{S^2} u_k(\omega_k) R(\xi_k + (r_k^3 + \phi_k(\theta_k))^{1/3}\theta_k, \xi_k + (r_k^3 + \phi_k(\omega_k))^{1/3}\omega_k)\, d\omega_k \\ &\quad + \frac{\gamma u_k(\theta_k)}{9(r_k^3 + \phi_k(\theta_k))^{2/3}} \int_{E_{\phi_k}} \nabla R(\xi_k + (r_k^3 + \phi_k(\theta_k))^{1/3}\theta_k, y) \cdot \theta_k\, dy. \end{aligned} \tag{4.30}$$

$$\begin{aligned} &\mathcal{C}_{kl}'(\phi_k, \phi_l)(u_k, u_l)(\theta_k) \\ &\quad = \frac{\gamma}{9} \int_{S^2} u_l(\omega_l) G(\xi_k + (r_k^3 + \phi_k(\theta_k))^{1/3}\theta_k, \xi_l + (r_l^3 + \phi_l(\omega_l))^{1/3}\omega_l)\, d\omega_l \\ &\quad + \frac{\gamma u_k(\theta_k)}{9(r_k^3 + \phi_k(\theta_k))^{2/3}} \int_{E_{\phi_l}} \nabla G(\xi_k + (r_k^3 + \phi_k(\theta_k))^{1/3}\theta_k, y) \cdot \theta_k\, dy. \end{aligned} \tag{4.31}$$

In $\mathcal{A}'_k$, $\tilde{E}_{\phi_k} = E_{\phi_k} - \xi_k$ is a shift of E_{ϕ_k}. The center of $\tilde{E}_{\phi_k}$ is 0. The derivative

$$\lambda'(\phi_1, \phi_2, \ldots, \phi_K)(u_1, u_2, \ldots, u_K) \tag{4.32}$$

is so chosen that

$$\sum_{k=1}^{K} \overline{\mathcal{S}'_k(u)} = 0. \tag{4.33}$$

5. A linear operator. Let $\mathcal{L}$ be the linearized operator of $\mathcal{S}$ at $\phi = 0$, i.e.,

$$\mathcal{L} = \mathcal{S}'(0). \tag{5.1}$$

Going back to (4.28), (4.29), (4.30), and (4.31) we find that

$$\begin{aligned}
\mathcal{H}'_k(0)(u_k) &= -\frac{1}{9r_k^4}\left[\frac{1}{\sin^2\theta_{k,2}}\frac{\partial^2 u_k}{\partial\theta_{k,1}^2} + \frac{\partial^2 u_k}{\partial\theta_{k,2}^2} + \cot\theta_{k,2}\frac{\partial u_k}{\partial\theta_{k,2}}\right] - \frac{2}{9r_k^4}u,\\
\mathcal{A}'_k(0)(u_k)(\theta_k) &= \frac{\gamma}{9r_k}\int_{S^2}\frac{u_k(\omega_k)\,d\omega_k}{4\pi|\theta_k-\omega_k|} - \frac{\gamma u_k(\theta_k)}{27r_k},\\
\mathcal{B}'_k(0)(u_k)(\theta_k) &= \frac{\gamma}{9}\int_{S^2} u_k(\omega_k)R(\xi_k + r_k\theta_k, \xi_k + r_k\omega_k)\,d\omega_k\\
&\quad + \frac{\gamma u_k(\theta_k)}{9r_k^2}\int_{B_k}\nabla R(\xi_k + r_k\theta_k, y)\cdot\theta_k\,dy,\\
\mathcal{C}'_{kl}(0,0)(u_k,u_l)(\theta_k) &= \frac{\gamma}{9}\int_{S^2} u_l(\omega_l)G(\xi_k + r_k\theta_k, \xi_l + r_l\omega_l)\,d\omega_l\\
&\quad + \frac{\gamma u_k(\theta_k)}{9r_k^2}\int_{B_l}\nabla G(\xi_k + r_k\theta_k, y)\cdot\theta_k\,dy.
\end{aligned}$$

The derivation of $\mathcal{A}'_k(0)$ is explained in more detail in Appendix A.

Let us separate $\mathcal{L}$ to a dominant part $\mathcal{L}_1$ and a minor part $\mathcal{L}_2$. We define $\mathcal{L}_{1,k}$, the kth component of $\mathcal{L}_1$, to be

$$\mathcal{L}_{1,k}(u)(\theta_k) = \mathcal{H}'_k(0)(u_k)(\theta_k) + \mathcal{A}'_k(0)(u_k)(\theta_k) + l_1(u).$$

The real valued linear operator l_1 is independent of k. It is so chosen that $\mathcal{L}_1$ maps from $\mathcal{X}$ to $\mathcal{Y}$. The rest of $\mathcal{L}$ is denoted by $\mathcal{L}_2$.

We are more interested in the operators $\Pi\mathcal{L}$ and $\Pi\mathcal{L}_1$, where Π is the orthogonal projection operator from $\mathcal{Y}$ to

$$\mathcal{Y}_* = \{q = (q_1, \ldots, q_K) \in \mathcal{Y} :\ q_k \perp H_1,\ q_k \perp 1,\ k = 1, \ldots, K\}. \tag{5.2}$$

Here H_1 is the space of spherical harmonics of degree 1. See, for instance, [10] for more on spherical harmonics. The operator $\Pi\mathcal{L}$ is defined on

$$\mathcal{X}_* = \{\phi = (\phi_1, \ldots, \phi_K) \in \mathcal{X} :\ \phi_k \perp H_1,\ \phi_k \perp 1,\ k = 1, \ldots, K\}. \tag{5.3}$$

We use the same Π to denote the orthogonal projection from

$$L^2(S^2) \text{ to } \{q_k \in L^2(S^2) : q_k \perp H_1,\ q_k \perp 1\}. \tag{5.4}$$

LEMMA 5.1. *Consider $\Pi\mathcal{L}_1$ as an operator from $\mathcal{X}_*$ to $\mathcal{Y}_*$. The eigenvalues of $\Pi\mathcal{L}_1$ are*

$$\lambda_{k,n} = \frac{(n-1)(n+2)}{9r_k^4} - \frac{\gamma}{9r_k}\left[\frac{2(n-1)}{3(2n+1)}\right], \quad k = 1,2,\dots,K, \ n = 2,3,4,\dots \tag{5.5}$$

whose multiplicity is $2n+1$. The corresponding eigenvectors are the spherical harmonics of degree n; i.e., H_n is the eigenspace associated with $\lambda_{k,n}$.

Proof. In $\mathcal{X}_*$, $\mathcal{L}_1$ is simplified to

$$\begin{aligned}\mathcal{L}_{1,k}(u) = &-\frac{1}{9r_k^4}\left[\frac{1}{\sin^2\theta_{k,2}}\frac{\partial^2 u_k}{\partial\theta_{k,1}^2} + \frac{\partial^2 u_k}{\partial\theta_{k,2}^2} + \cot\theta_{k,2}\frac{\partial u_k}{\partial\theta_{k,2}}\right] - \frac{2u_k}{9r_k^4}\\ &+ \frac{\gamma}{9r_k}\int_{S^2}\frac{u_k(\omega_k)\,d\omega_k}{4\pi|\theta_k-\omega_k|} - \frac{\gamma u_k(\theta_k)}{27r_k},\end{aligned}$$

for each k. This is a diagonalized operator. Note that in $\mathcal{X}_*$, $\Pi\mathcal{L}_1 = \mathcal{L}_1$. To find the spectrum of $\mathcal{L}_1$ in $\mathcal{X}_*$ we consider the effect of $\mathcal{L}_1$ on the spherical harmonics $h \in H_n$ of degree n. Since

$$\frac{1}{\sin^2\theta_{k,2}}\frac{\partial^2}{\partial\theta_{k,1}^2} + \frac{\partial^2}{\partial\theta_{k,2}^2} + \cot\theta_2\frac{\partial}{\partial\theta_{k,2}} := \Delta_{S^2} \tag{5.6}$$

is the Laplacian–Beltrami operator on the unit sphere,

$$-\left[\frac{1}{\sin^2\theta_{k,2}}\frac{\partial^2 h}{\partial\theta_{k,1}^2} + \frac{\partial^2 h}{\partial\theta_{k,2}^2} + \cot\theta_2\frac{\partial h}{\partial\theta_{k,2}}\right] = n(n+1)h. \tag{5.7}$$

In Appendix B we find that

$$\int_{S^2}\frac{h(\omega)\,d\omega}{4\pi|\theta-\omega|} = \frac{h(\theta)}{2n+1}. \tag{5.8}$$

Following (5.7) and (5.8) one deduces that

$$\mathcal{L}_{1,k}(h) = \left[\frac{n(n+1)-2}{9r_k^4} + \frac{\gamma}{9r_k}\left(\frac{1}{2n+1} - \frac{1}{3}\right)\right]h. \tag{5.9}$$

This proves the lemma. □

The second part of $\mathcal{L}$ is minor.

LEMMA 5.2. *There exists $C > 0$ independent of ξ, r, ρ, and γ such that*

$$\|\mathcal{L}_2(u)\|_{L^p} \le \frac{C}{\rho^2}\|u\|_{L^p}$$

for all $u \in \mathcal{Y}_*$. A similar estimate holds if the two p's above are replaced by 2.

Proof. Let $\mathcal{L}_{2,k}$ be the kth component of $\mathcal{L}_2$. Then

$$\begin{aligned}\mathcal{L}_{2,k}(u)(\theta_k) = &\frac{\gamma}{9}\int_{S^2} u_k(\omega_k)(R(\xi_k + r_k\theta_k, \xi_k + r_k\omega_k) - R(\xi_k,\xi_k))\,d\omega_k\\ &+ \frac{\gamma u_k(\theta_k)}{9r_k^2}\int_{B_k}\nabla R(\xi_k + r_k\theta_k, y)\cdot\theta_k\,dy\\ &+ \sum_{l\neq k}\frac{\gamma}{9}\int_{S^2} u_l(\omega_l)(G(\xi_k + r_k\theta_k, \xi_l + r_l\omega_l) - G(\xi_k,\xi_l))\,d\omega_l\\ &+ \sum_{l\neq k}\frac{\gamma u_k(\theta_k)}{9r_k^2}\int_{B_l}\nabla G(\xi_k + r_k\theta_k, y)\cdot\theta_k\,dy\\ &+ l_2(u),\end{aligned}$$

where $l_2(u)$ is real valued and independent of k. It is included so that $\mathcal{L}_2(u)$ is in $\mathcal{Y}$.

Because

$$\begin{aligned}R(\xi_k + r_k\theta_k, \xi_k + r_k\omega_k) - R(\xi_k,\xi_k) &= O(\rho),\\ G(\xi_k + r_k\theta_k, \xi_l + r_l\omega_l) - G(\xi_k,\xi_l) &= O(\rho),\end{aligned}$$

we obtain that

$$\left\|\frac{\gamma}{9}\int_{S^2} u_k(\omega_k)(R(\xi_k + r_k\theta_k, \xi_k + r_k\omega_k) - R(\xi_k,\xi_k))\,d\omega_k\right\|_{L^p} \le C\gamma\rho\|u\|_{L^p}$$
$$\left\|\frac{\gamma}{9}\int_{S^2} u_l(\omega_l)(G(\xi_k + r_k\theta_k, \xi_l + r_l\omega_l) - G(\xi_k,\xi_l))\,d\omega_l\right\|_{L^p} \le C\gamma\rho\|u_k\|_{L^p}.$$

Since the volume of B_k is $\frac{4\pi r_k^3}{3}$,

$$\left\|\frac{\gamma u_k(\theta_k)}{9r_k^2}\int_{B_k}\nabla R(\xi_k + r_k\theta_k, y)\cdot\theta_k\,dy\right\|_{L^p} \le C\gamma\rho\|u_k\|_{L^p}$$
$$\left\|\frac{\gamma u_k(\theta_k)}{9r_k^3}\int_{B_l}\nabla G(\xi_k + r_k\theta_k, y)\cdot\theta_k\,dy\right\|_{L^p} \le C\gamma\rho\|u_k\|_{L^p}.$$

The condition

$$\sum_{k=1}^{K}\overline{\mathcal{L}_{2,k}(u)(\theta_k)} = 0$$

implies that

$$|l_2(u)| \le C\gamma\rho\|u\|_{L^p}.$$

The lemma then follows, with the help of (2.10). $\square$

LEMMA 5.3.

1. *For* $u \in \mathcal{X}_*$

$$\|u\|_{W^{2,p}} \le C\rho^4\|\Pi\mathcal{L}u\|_{L^p}.$$

2. *The operator* $\Pi\mathcal{L}$ *is invertible from* $\mathcal{X}_*$ *to* $\mathcal{Y}_*$.
3. *If* (2.8) *holds,*

$$\|u\|_{W^{1,2}}^2 \le C\rho^4\langle\Pi\mathcal{L}u, u\rangle.$$

Proof. From Lemma 5.1 we have

$$\frac{|\lambda_{k,n}|}{n^2} = \frac{n-1}{9r_k^4 n}\left|\frac{n+2}{n} - \frac{2\gamma r_k^3}{3(2n+1)n}\right| > \frac{n-1}{18r_k^4 n}\left|\frac{n+2}{n} - \frac{2\gamma\rho^3}{3(2n+1)n}\right|$$

if δ_2 in the definition (3.1) of U_2 is small enough. Then (2.6) implies that

$$\frac{|\lambda_{k,n}|}{n^2} > \frac{(n-1)}{18r_k^4 n}\frac{2\epsilon n}{3(2n+1)} \geq \frac{C}{\rho^4}, \quad n = 2, 3, \ldots.$$

If we expand u_k by spherical harmonics

$$u_k = \sum_{n=2}^{\infty}\sum_{l=1}^{2n+1} c_{n,l}h_{n,l},$$

where $h_{n,l}$, $l = 1, \ldots, 2n+1$, form an orthonormal basis in H_n, then

$$-\Delta_{S^2}u_k = \sum_{n=2}^{\infty}\sum_{l=1}^{2n+1} n(n+1)c_{n,l}h_{n,l}, \ \mathcal{L}_{1,k}u_k = \sum_{n=2}^{\infty}\sum_{l=1}^{2n+1} \lambda_{k,n}c_{n,l}h_{n,l}.$$

Our estimate on $|\lambda_{k,n}|$ shows that

$$\|\Delta_{S^2}u_k\|_{L^2}^2 = \sum_{n=2}^{\infty}\sum_{l=1}^{2n+1} n^2(n+1)^2c_{n,l}^2 \leq C\rho^8\sum_{n=2}^{\infty}\sum_{l=1}^{2n+1}\lambda_{k,n}^2c_{n,l}^2 = C\rho^8\|\mathcal{L}_{1,k}u_k\|_{L^2}^2.$$

The standard elliptic theory implies that

$$\|u\|_{W^{2,2}} \leq C\|\Delta_{S^2}u\|_{L^2} \leq C\rho^4\|\Pi\mathcal{L}_1(u)\|_{L^2}. \tag{5.10}$$

To prove part 1 of Lemma 5.3, we divide $\Pi\mathcal{L}_1$ into

$$\Pi\mathcal{L}_{1,k} = -\frac{1}{9r_k^4}\Delta_{S^2} + \mathcal{M}_k, \tag{5.11}$$

where Δ_{S^2} is defined in (5.6), and $\mathcal{M} = (\mathcal{M}_1, \mathcal{M}_2, \ldots, \mathcal{M}_K)$ is defined by (5.11). The standard elliptic estimate asserts that

$$\|u_k\|_{W^{2,p}} \leq C\|\Delta_{S^2}u_k\|_{L^p},$$

which by (5.11) is turned to

$$\begin{aligned}\|u_k\|_{W^{2,p}} &\leq C\|9r_k^4\mathcal{M}_k u - 9r_k^4\Pi\mathcal{L}_{1,k}u\|_{L^p}\\ &\leq C\rho^4(\|\mathcal{M}_k u\|_{L^p} + \|\Pi\mathcal{L}_{1,k}u\|_{L^p}).\end{aligned}$$

One observes that

$$\|\mathcal{M}u\|_{L^p} \leq \frac{C}{\rho^4}\|u\|_{L^p} \leq \frac{C}{\rho^4}\|u\|_{W^{2,2}},$$

where the last inequality comes from the Sobolev embedding $W^{2,2}(S^2) \to W^{1,p}(S^2) \subset L^p(S^2)$ for any $p \geq 1$. Hence when $p > 2$, by (5.10) we deduce that

$$\begin{aligned}\|u_k\|_{W^{2,p}} &\leq C\rho^4(\rho^{-4}\|u\|_{W^{2,2}} + \|\Pi\mathcal{L}_{1,k}u\|_{L^p})\\ &\leq C\rho^4(\|\Pi\mathcal{L}_{1,k}u\|_{L^2} + \|\Pi\mathcal{L}_{1,k}u\|_{L^p})\\ &\leq C\rho^4\|\Pi\mathcal{L}_{1,k}u\|_{L^p}.\end{aligned}$$

Lemma 5.2 implies that

$$\|\Pi\mathcal{L}u\|_{L^p} \geq \|\Pi\mathcal{L}_1 u\|_{L^p} - \|\Pi\mathcal{L}_2 u\|_{L^p} \geq \frac{C}{\rho^4}\|u\|_{W^{2,p}} - \frac{C}{\rho^2}\|u\|_{L^p} \geq \frac{C}{\rho^4}\|u\|_{W^{2,p}}$$

for small ρ. This proves part 1 of Lemma 5.3.

Part 2 of Lemma 5.3 follows from the Fredholm alternative.

When (2.8) holds,

$$\frac{\lambda_{k,n}}{n^2} = \frac{n-1}{9r_k^4 n}\left(\frac{n+2}{n} - \frac{2\gamma r_k^3}{3(2n+1)n}\right) > \frac{n-1}{18r_k^4 n}\frac{2\epsilon n}{3(2n+1)} \geq \frac{C}{\rho^4}, \quad n = 2, 3, \ldots,$$

if δ_2 in (3.1) is small. This implies that, with the help of expansion by spherical harmonics,

$$\begin{aligned}\langle \Pi\mathcal{L}_{1,k}(u_k), u_k\rangle &= \sum_{n=2}^{\infty}\sum_{l=1}^{2n+1}\lambda_{k,n}c_{n,l}^2 \;\geq\; \frac{C}{\rho^4}\sum_{n=2}^{\infty}\sum_{l=1}^{2n+1} n(n+1)c_{n,l}^2 \\ &= \frac{C}{\rho^4}\langle -\Delta_{S^2}u_k, u_k\rangle \;=\; \frac{C}{\rho^4}\langle \nabla u_k, \nabla u_k\rangle \;\geq\; \frac{C}{\rho^4}\|u\|_{W^{1,2}}^2.\end{aligned}$$

Using the estimate of Lemma 5.2 with p replaced by 2, we find that

$$\langle \Pi\mathcal{L}(u), u\rangle = \langle \Pi\mathcal{L}_1(u), u\rangle + \langle \Pi\mathcal{L}_2(u), u\rangle \geq \frac{C}{\rho^4}\|u\|_{W^{1,2}}^2 - \frac{C}{\rho^2}\|u\|_{L^2}^2 \geq \frac{C}{\rho^4}\|u\|_{W^{1,2}}^2.$$

This proves part 3 of Lemma 5.3. □

6. The second Fréchet derivative.

LEMMA 6.1. *Suppose that $\|\phi\|_{W^{2,p}} \leq c\rho^3$, where c is sufficiently small. The following estimates hold:*

1. $\|\mathcal{H}_k''(\phi_k)(u_k, v_k)\|_{L^p} \leq \frac{C}{\rho^7}\|u_k\|_{W^{2,p}}\|v_k\|_{W^{2,p}}$.
2. $\|\mathcal{A}_k''(\phi_k)(u_k, v_k)\|_{L^p} \leq \frac{C}{\rho^7}\|u_k\|_{W^{1,p}}\|v_k\|_{W^{1,p}}$.
3. $\|\mathcal{B}_k''(\phi_k)(u_k, v_k)\|_{L^p} \leq \frac{C}{\rho^5}\|u_k\|_{W^{1,p}}\|v_k\|_{W^{1,p}}$.
4. $\|\mathcal{C}_{kl}''(\phi_k, \phi_l)(u_k, u_l)(v_k, v_l)\|_{L^p} \leq \frac{C}{\rho^5}(\|u_k\|_{W^{1,p}} + \|u_l\|_{W^{1,p}})(\|v_k\|_{W^{1,p}} + \|v_l\|_{W^{1,p}})$.
5. $|\lambda''(\phi)(u, v)| \leq \frac{C}{\rho^7}\|u\|_{W^{2,p}}\|v\|_{W^{2,p}}$.

Proof. Note that by taking c small, we keep $r_k^3 + \phi_k$ positive, so ∂E_{ϕ_k} is a perturbed sphere.

The mean curvature operator $\mathcal{H}_k$ is elliptic and quasilinear. Its second Fréchet derivative is calculated from (4.28):

$$\begin{aligned}&\mathcal{H}_k''(\phi_k, D\phi_k, D^2\phi_k)(u_k, v_k) \\ &= \frac{\partial^2\mathcal{H}_k}{\partial\phi_k^2}u_k v_k + \sum_{i=1}^{2}\frac{\partial^2\mathcal{H}_k}{\partial\phi_k\partial\phi_{k,i}}(u_k v_{k,i} + u_{k,i}v_k) + \sum_{i,j=1}^{2}\frac{\partial^2\mathcal{H}_k}{\partial\phi_{k,i}\partial\phi_{k,j}}(u_{k,i}v_{k,j} + u_{k,j}v_{k,i}) \\ &\quad + \sum_{l,m=1}^{2}\frac{\partial^2\mathcal{H}_k}{\partial\phi_k\partial\phi_{k,lm}}(u_k v_{k,lm} + u_{k,lm}v_k) + \sum_{i,l,m=1}^{2}\frac{\partial^2\mathcal{H}_k}{\partial\phi_{k,i}\partial\phi_{k,lm}}(u_{k,i}v_{k,lm} + u_{k,lm}v_{k,i}).\end{aligned}$$

It is important to note that because $\mathcal{H}_k$ is quasilinear, i.e., it is linear in $D^2\phi_k$, the term

$$\sum_{i,j,l,m=1}^{2} \frac{\partial^2 \mathcal{H}_k}{\partial \phi_{k,ij} \partial \phi_{k,lm}} (u_{k,ij} v_{k,lm} + u_{k,lm} v_{k,ij})$$

is 0 and hence absent in $\mathcal{H}_k''$. The Sobolev embedding $W^{1,p} \to L^\infty$ and $\|\phi_k\|_{W^{2,p}} \le c\rho^3$ for a small c implies that $|\phi_k| \le C\rho^3$ and $|D\phi_k| \le C\rho^3$. From the definition (4.12) of $\mathcal{H}_k$ we have the pointwise estimate

$$\begin{aligned} &|\mathcal{H}_k''(\phi_k, D\phi_k, D^2\phi_k)(u_k, v_k)| \\ &\le \frac{C}{\rho^7} \left(\left| \frac{D^2\phi_k}{r_k^3} \right| |u_k|\,|v_k| + \left| \frac{D^2\phi_k}{r_k^3} \right| |u_k|\,|Dv_k| + \left| \frac{D^2\phi_k}{r_k^3} \right| |Du_k|\,|v_k| \right. \\ &\quad \left. + \left| \frac{D^2\phi_k}{r_k^3} \right| |Du_k|\,|Dv_k| + |u_k|\,|D^2 v_k| + |D^2 u_k|\,|v_k| + |Du_k|\,|D^2 v_k| + |D^2 u_k|\,|Dv_k| \right), \end{aligned}$$

when θ_k is some distance away from the two poles (where $\theta_{k,2} = 0$ or π) of S^2. Near the two poles one can use a different parametrization of S^2 so that the same pointwise estimate holds. The same Sobolev embedding implies that

$$\|\mathcal{H}_k''(\phi)(u_k, v_k)\|_{L^p} \le \frac{C}{\rho^7} \|u_k\|_{W^{2,p}} \|v_k\|_{W^{2,p}}. \tag{6.1}$$

This proves part 1 of Lemma 6.1.

We now turn to part 2 of Lemma 6.1. In our estimation of $\mathcal{A}_k''$ and $\mathcal{B}_k''$ we drop the subscript k in most quantities. The second Fréchet derivative of $\mathcal{A}_k$ is calculated from (4.29):

$$\mathcal{A}_k''(\phi)(u,v) = A_1(\phi)(u,v) + A_2(\phi)(u,v) + A_3(\phi)(u,v) + A_4(\phi)(u,v) + A_5(\phi)(u,v), \tag{6.2}$$

where

$$\begin{aligned} A_1(\phi)(u,v) &= -\frac{\gamma v(\theta)\theta}{108\pi(r^3+\phi(\theta))^{2/3}} \cdot \int_{S^2} K(\theta,\omega) u(\omega)\, d\omega, \\ A_2(\phi)(u,v) &= -\frac{\gamma u(\theta)\theta}{108\pi(r^3+\phi(\theta))^{2/3}} \cdot \int_{S^2} K(\theta,\omega) v(\omega)\, d\omega, \\ A_3(\phi)(u,v) &= \frac{\gamma}{108\pi} \int_{S^2} K(\theta,\omega) \cdot \omega \frac{u(\omega)v(\omega)}{(r^3+\phi(\omega))^{2/3}}\, d\omega, \\ A_4(\phi)(u,v) &= -\frac{\gamma u(\theta) v(\theta)}{108\pi(r^3+\phi(\theta))^{4/3}} \\ &\quad \times \int_{\tilde{E}_{\phi_k}} \frac{|(r^3+\phi(\theta))^{1/3}\theta - y|^2 - 3((r^3+\phi(\theta))^{1/3} - \theta\cdot y)^2}{|(r^3+\phi(\theta))^{1/3}\theta - y|^5}\, dy, \\ A_5(\phi)(u,v) &= \frac{2\gamma u(\theta)v(\theta)}{108\pi(r^3+\phi(\theta))^{5/3}} \int_{\tilde{E}_{\phi_k}} \frac{((r^3+\phi(\theta))^{1/3}\theta - y)\cdot\theta}{|(r^3+\phi(\theta))^{1/3}\theta - y|^3} dy. \end{aligned}$$

Recall that $\tilde{E}_{\phi_k}$ in A_4 and A_5 is $E_{\phi_k} - \xi_k$. The kernel K is

$$K(\theta,\omega) = \frac{(r^3+\phi(\theta))^{1/3}\theta - (r^3+\phi(\omega))^{1/3}\omega}{|(r^3+\phi(\theta))^{1/3}\theta - (r^3+\phi(\omega))^{1/3}\omega|^3}. \tag{6.3}$$

Here we encounter a singular integral operator

$$\mathcal{K}(u)(\theta) = \int_{S^2} K(\theta,\omega)u(\omega)\,d\omega. \tag{6.4}$$

A variant of the Calderon–Zygmund estimate [32, Theorem 1] is applicable to this operator:

$$\|\mathcal{K}(u)\|_q \le \frac{C}{\rho^2}\|u\|_{L^q}$$

for any $q \in (1,\infty)$. In [32] the kernel takes the form $K(x-y)$. To meet this requirement, we can transform (6.4) to an integral on the perturbed sphere ∂E_{ϕ_k}, then $K(\theta,\omega)$ becomes $\frac{x-y}{|x-y|^3}$, where $x, y \in \partial E_{\phi_k}$.

For $\|\phi\|_{W^{2,p}} \le c\rho^3$ with a small c, we consider

$$\|\mathcal{A}_k''(\phi)(u,v)\|_{L^p} \le \sum_{i=1}^{5}\|A_i(\phi)(u,v)\|_{L^p}.$$

For sufficiently large q

$$\|A_1(\phi)(u,v)\|_{L^p} \le \frac{C}{\rho^7}\|v_k\|_{L^q}\|\mathcal{K}(u_k)\|_{L^q} \le \frac{C}{\rho^7}\|v_k\|_{L^q}\|u_k\|_{L^q} \le \frac{C}{\rho^7}\|u_k\|_{W^{1,p}}\|v_k\|_{W^{1,p}}.$$

Similarly

$$\|A_2(\phi)(u,v)\|_{L^p} \le \frac{C}{\rho^7}\|u\|_{W^{1,p}}\|v_k\|_{W^{1,p}}.$$

Regarding A_3 we have, using the Calderon–Zygmund estimate in L^p and the Sobolev embedding theory,

$$\|A_3(\phi)(u,v)\|_{L^p} \le \frac{C}{\rho^7}\|uv\|_{L^p} \le \frac{C}{\rho^7}\|u\|_{W^{1,p}}\|v\|_{W^{1,p}}.$$

For A_4, the integral

$$\int_{\tilde{E}_{\phi_k}} \frac{|(r^3+\phi(\theta))^{1/3}\theta - y|^2 - 3((r^3+\phi(\theta))^{1/3} - \theta\cdot y)^2}{|(r^3+\phi(\theta))^{1/3}\theta - y|^5}\,dy$$

is a convergent improper integral defined by its principal part. It is of order 1 and uniformly bounded with respect to θ. In the case of ϕ equal to 0, it may be explicitly computed. (See Appendix C.) Therefore

$$\|A_4(\phi)(u,v)\|_{L^p} \le \frac{C}{\rho^7}\|uv\|_{L^p} \le \frac{C}{\rho^7}\|u\|_{W^{1,p}}\|v\|_{W^{1,p}}.$$

For A_5, because of the mild singularity, we easily find that

$$\|A_5(\phi)(u,v)\|_{L^p} \le \frac{C}{\rho^7}\|u\|_{W^{1,p}}\|v\|_{W^{1,p}}.$$

Now we have

$$\|\mathcal{A}_k''(\phi)(u_k,v_k)\|_{L^p} \le \frac{C}{\rho^7}\|u_k\|_{W^{1,p}}\|v_k\|_{W^{1,p}}.$$

This proves part 2 of Lemma 6.1.

The kernel R in $\mathcal{B}_k$ is a smooth function. Calculations from (4.30) show that

$$\begin{aligned}
&\mathcal{B}_k''(\phi)(u,v)(\theta)\\
&\quad = \frac{\gamma v(\theta)}{27(r^3+\phi(\theta))^{2/3}} \int_{S^2} u(\omega) D_1 R(\xi + (r^3+\phi(\theta))^{1/3}\theta, \xi + (r^3+\phi(\omega))^{1/3}\omega)\cdot\theta\, d\omega\\
&\qquad \frac{\gamma u(\theta)}{27(r^3+\phi(\theta))^{2/3}} \int_{S^2} v(\omega) D_1 R(\xi + (r^3+\phi(\theta))^{1/3}\theta, \xi + (r^3+\phi(\omega))^{1/3}\omega)\cdot\theta\, d\omega\\
&\qquad + \frac{\gamma}{27}\int_{S^2} \frac{u(\omega)v(\omega)}{(r^3+\phi(\omega))^{2/3}} D_2 R(\xi + (r^3+\phi(\theta))^{1/3}\theta, \xi + (r^3+\phi(\omega))^{1/3}\omega)\cdot\theta\, d\omega\\
&\qquad + \frac{\gamma u(\theta)v(\theta)}{27(r^3+\phi(\theta))^{4/3}} \int_{E_{\phi_k}} D_1^2 R(\xi + (r^3+\phi(\theta))^{1/3}\theta, y)\theta\cdot\theta\, dy\\
&\qquad - \frac{2\gamma u(\theta)v(\theta)}{27(r^3+\phi(\theta))^{5/3}} \int_{E_{\phi_k}} D_1 R(\xi + (r^3+\phi(\theta))^{1/3}\theta, y)\cdot\theta\, dy,
\end{aligned}$$

where D_1 and D_2 refer to the derivatives of R with respect to its first and second arguments, respectively. $D_1^2 R$ is the second derivative matrix of R with respect to the first argument of R. Part 3 of Lemma 6.1 is now proved easily.

The function G is also smooth in $\mathcal{C}$. We restore subscripts in the rest of this section. Similar to $\mathcal{B}_k''$, we find from (4.31) that

$$\begin{aligned}
&\mathcal{C}_{kl}''(\phi_k,\phi_l)(u_k,u_l)(v_k,v_l)(\theta_k)\\
&\quad = \frac{\gamma v_k(\theta_k)}{27(r_k^3+\phi_k(\theta_k))^{2/3}} \int_{S^2} u_l(\omega_l) D_1 G(\xi_k + (r_k^3+\phi_k(\theta_k))^{1/3}\theta_k, \xi_l\\
&\qquad + (r_l^3+\phi_l(\omega_l))^{1/3}\omega_l)\cdot\theta_k\, d\omega_l\\
&\qquad + \frac{\gamma u_k(\theta_k)}{27(r_k^3+\phi_k(\theta_k))^{2/3}} \int_{S^2} v_l(\omega_l) D_1 G(\xi_k + (r_k^3+\phi_k(\theta_k))^{1/3}\theta_k, \xi_l\\
&\qquad + (r_l^3+\phi_l(\omega_l))^{1/3}\omega_l)\cdot\theta_k\, d\omega_l\\
&\qquad + \frac{\gamma}{27}\int_{S^2} \frac{u_l(\omega_l)v_l(\omega_l)}{(r_l^3+\phi_l(\omega_l))^{2/3}} D_2 G(\xi_k + (r_k^3+\phi_k(\theta_k))^{1/3}\theta_k, \xi_l\\
&\qquad + (r_l^3+\phi_l(\omega_l))^{1/3}\omega_l)\cdot\omega_l\, d\omega_l\\
&\qquad + \frac{\gamma u_k(\theta_k)v_k(\theta_k)}{27(r_k^3+\phi_k(\theta_k))^{4/3}} \int_{E_{\phi_l}} D_1^2 G(\xi_k + (r_k^3+\phi_k(\theta_k))^{1/3}\theta_k, y)\theta_k\cdot\theta_k\, dy\\
&\qquad - \frac{2\gamma u_k(\theta_k)v_k(\theta_k)}{27(r_k^3+\phi_k(\theta_k))^{5/2}} \int_{E_{\phi_l}} D_1 G(\xi_k + (r_k^3+\phi_k(\theta_k))^{1/3}\theta_k, y)\cdot\theta_k\, dy.
\end{aligned}$$

Part 4 of Lemma 6.1 then follows.

Part 5 of Lemma 6.1 follows from parts 1–4 and the fact that

$$\begin{aligned}
0 &= \sum_k \overline{S_k''(\phi)(u,v)}\\
&= \sum_k \overline{\mathcal{H}_k''(\phi_k)(u_k,v_k)} + \sum_k \overline{\mathcal{A}_k''(\phi_k)(u_k,v_k)} + \sum_k \overline{\mathcal{B}_k''(\phi_k)(u_k,v_k)}\\
&\quad + \sum_k \overline{\mathcal{C}_k''(\phi)(u)} + K\lambda''(\phi)(u,v). \qquad \square
\end{aligned}$$

7. Reduction to $4K-1$ dimensions. We view $\mathcal{S}$ as a nonlinear operator from $\mathcal{X}$ to $\mathcal{Y}$. In this section it will be proved that, for each $(\xi, r) \in U$, a $\varphi(\cdot, \xi, r)$ exists such that $\varphi(\cdot, \xi, r) \in \mathcal{X}_*$ and

(7.1)
$$\mathcal{S}_k(\varphi)(\theta_k) = A_{k,1}\cos\theta_{k,1}\sin\theta_{k,2} + A_{k,2}\sin\theta_k\sin\theta_{k,2} + A_{k,3}\cos\theta_{k,2} + A_k, \quad k = 1, 2, \dots, K$$

for some numbers $A_{k,1}, A_{k,2}, A_{k,3}, A_k$. Note that φ is sought in $\mathcal{X}_*$. Each $\phi \in \mathcal{X}_*$ satisfies

$$\int_{S^2} \phi_k(\theta_k)\, d\theta_k = 0, \quad k = 1, 2, \dots, K, \tag{7.2}$$

$$\int_{S^2} \phi_k(\theta_k)\cos\theta_{k,1}\sin\theta_{k,2}\, d\theta_k = 0, \quad k = 1, 2, \dots, K, \tag{7.3}$$

$$\int_{S^2} \phi_k(\theta_k)\sin\theta_{k,1}\sin\theta_{k,2}\, d\theta_k = 0, \quad k = 1, 2, \dots, K, \tag{7.4}$$

$$\int_{S^2} \phi_k(\theta_k)\cos\theta_{k,2}\, d\theta_k = 0, \quad k = 1, 2, \dots, K. \tag{7.5}$$

The condition (7.2) means that $\phi_k \perp H_0$, the space of spherical harmonics of degree 0, and the conditions (7.3–7.5) state that $\phi_k \perp H_1$.

Write (7.1) as

$$\Pi\mathcal{S}(\varphi) = 0, \tag{7.6}$$

where Π is the orthogonal projection operator from $\mathcal{Y}$ to $\mathcal{Y}_*$. In the next section we will find a particular (ξ, r), say (ζ, s) at which $A_{k,1} = A_{k,2} = A_{k,3} = A_k = 0$, i.e., $\mathcal{S}(\varphi(\cdot, \zeta, s)) = 0$. This means that by finding φ we reduce the original problem (1.1) to a problem of finding a (ζ, s) in a $4K-1$ dimensional set U.

Recall $\mathcal{L}$, the linearized operator of $\mathcal{S}$ at $\phi = 0$. Expand $\mathcal{S}(\phi)$ as

$$\mathcal{S}(\phi) = \mathcal{S}(0) + \mathcal{L}(\phi) + \mathcal{N}(\phi), \tag{7.7}$$

where $\mathcal{N}$ is a higher order term defined by (7.7). Turn (7.6) to a fixed point form

$$\phi = -(\Pi\mathcal{L})^{-1}(\Pi\mathcal{S}(0) + \Pi\mathcal{N}(\phi)). \tag{7.8}$$

LEMMA 7.1. *There exists $\varphi = \varphi(\theta, \xi, r)$ such that for every $(\xi, r) \in U$, $\varphi(\cdot, \xi, r) \in \mathcal{X}_*$ solves* (7.8) *and $\|\varphi\|_{W^{2,p}} \le c\rho^5$, where c is a sufficiently large constant independent of ξ, r, ρ, and γ.*

Proof. To use the contraction mapping principle, let

$$\mathcal{T}(\phi) = -(\Pi\mathcal{L})^{-1}(\Pi\mathcal{S}(0) + \Pi\mathcal{N}(\phi)) \tag{7.9}$$

be an operator defined on

$$D(\mathcal{T}) = \{\phi \in \mathcal{X}_* : \|\phi\|_{W^{2,p}} \le c\rho^5\}, \tag{7.10}$$

where the constant c is sufficiently large and will be determined shortly.

Lemma 3.1 shows that

$$\mathcal{S}_k(0)(\theta_k) - \lambda(0) = \frac{1}{3r_k} + \frac{\gamma}{3}\left[\frac{r_k^2}{3} + \frac{4\pi r_k^3}{3}R(\xi_k, \xi_k) + \sum_{l \ne k}\frac{4\pi r_l^3}{3}G(\xi_k, \xi_l)\right] + O(\rho).$$

Each $\mathcal{S}_k(0)$ is sum of a number independent of θ_k and a quantity of order $O(\rho)$. After we apply the projection operator Π the number vanishes and

$$\|\Pi\mathcal{S}(0)\|_{L^p} = O(\rho). \tag{7.11}$$

By Lemma 5.3 we find

$$\|(\Pi\mathcal{L})^{-1}\Pi\mathcal{S}(0)\|_{W^{2,p}} \le C\rho^5. \tag{7.12}$$

For $\mathcal{N}(\phi)$ we decompose it into three parts. The first is $\mathcal{N}_1$ whose kth component is

$$\mathcal{N}_{1,k}(\phi_k) = \mathcal{H}_k(\phi_k) - \mathcal{H}_k(0) - \mathcal{H}_k'(0)(\phi_k) \tag{7.13}$$

which is $\mathcal{H}_k(\phi)$ minus its linear approximation at 0. Lemma 6.1, part 1, shows that

$$\|\mathcal{N}_1(\phi)\|_{L^p} \le \frac{C}{\rho^7}\|\phi\|^2_{W^{2,p}}. \tag{7.14}$$

The second part of $\mathcal{N}$, denoted by $\mathcal{N}_2$, is $\mathcal{A}(\phi)+\mathcal{B}(\phi)+\mathcal{C}(\phi)$ minus its linear approximation, i.e.,

$$\mathcal{N}_2(\phi) = \mathcal{A}(\phi)-\mathcal{A}(0)-\mathcal{A}'(0)(\phi)+\mathcal{B}(\phi)-\mathcal{B}(0)-\mathcal{B}'(0)(\phi)+\mathcal{C}(\phi)-\mathcal{C}(0)-\mathcal{C}'(0)(\phi). \tag{7.15}$$

Lemma 6.1, parts 2, 3, and 4, implies that

$$\|\mathcal{N}_2(\phi)\|_{L^p} \le \frac{C}{\rho^7}\|\phi\|^2_{W^{1,p}}. \tag{7.16}$$

The third part of $\mathcal{N}$, which is denoted by $\mathcal{N}_3$, merely gives a constant so that

$$\sum_k \overline{\mathcal{N}_k(\phi)} = \sum_k \overline{\mathcal{N}_{1,k}(\phi)} + \sum_k \overline{\mathcal{N}_{2,k}(\phi)} + K\mathcal{N}_3(\phi) = 0.$$

It follows that

$$|\mathcal{N}_3(\phi)| \le \frac{C}{\rho^7}\|\phi\|^2_{W^{2,p}}. \tag{7.17}$$

Therefore we deduce, from (7.14), (7.16), (7.17), and with the help of Lemma 5.3, that

$$\|\mathcal{N}(\phi)\|_{L^p} \le \frac{C}{\rho^7}\|\phi\|^2_{W^{2,p}}, \tag{7.18}$$

$$\|(\Pi\mathcal{L})^{-1}\Pi\mathcal{N}(\phi)\|_{W^{2,p}} \le \frac{C}{\rho^3}\|\phi\|^2_{W^{2,p}}. \tag{7.19}$$

Using (2.10), (7.12), (7.10), and (7.19) we find

$$\|\mathcal{T}(\phi)\|_{W^{2,p}} \le C\rho^5 + Cc^2\rho^7 \le c\rho^5$$

if c is sufficiently large and ρ sufficiently small. Therefore $\mathcal{T}$ is a map from $D(\mathcal{T})$ into itself.

Next we show that $\mathcal{T}$ is a contraction. For $\mathcal{N}_1$ we note that

$$\mathcal{N}_1(\phi_1) - \mathcal{N}_1(\phi_2) = \mathcal{H}(\phi_1) - \mathcal{H}(\phi_2) - \mathcal{H}'(0)(\phi_1 - \phi_2).$$

Therefore using Lemma 6.1, part 1, we obtain

$$\begin{aligned}
&\|\mathcal{H}(\phi_1)-\mathcal{H}(\phi_2)-\mathcal{H}'(0)(\phi_1-\phi_2)\|_{L^p}\\
&\quad\le \|\mathcal{H}'(\phi_2)(\phi_1-\phi_2)-\mathcal{H}'(0)(\phi_1-\phi_2)\|_{L^p}+\frac{C}{\rho^7}\|\phi_1-\phi_2\|^2_{W^{2,p}}\\
&\quad\le \frac{C}{\rho^7}\|\phi_2\|_{W^{2,p}}\|\phi_1-\phi_2\|_{W^{2,p}}+\frac{C}{\rho^7}\|\phi_1-\phi_2\|^2_{W^{2,p}}\\
&\quad\le \frac{C}{\rho^7}(\|\phi_1\|_{W^{2,p}}+\|\phi_2\|_{W^{2,p}})\|\phi_1-\phi_2\|_{W^{2,p}}.
\end{aligned}$$

This shows that

$$\|\mathcal{N}_1(\phi_1)-\mathcal{N}_2(\phi_2)\|_{L^p}\le \frac{C}{\rho^2}\|\phi_1-\phi_2\|_{W^{2,p}}. \tag{7.20}$$

For $\mathcal{N}_2$ we note that

$$\begin{aligned}
\mathcal{N}_2(\phi_1)-\mathcal{N}_2(\phi_2)&=\mathcal{A}(\phi_1)-\mathcal{A}(\phi_2)-\mathcal{A}'(0)(\phi_1-\phi_2)+\mathcal{B}(\phi_1)-\mathcal{B}(\phi_2)\\
&\quad-\mathcal{B}'(0)(\phi_1-\phi_2)+\mathcal{C}(\phi_1)-\mathcal{C}(\phi_2)-\mathcal{C}'(0)(\phi_1-\phi_2).
\end{aligned}\tag{7.21}$$

Therefore using Lemma 6.1, part 2, we obtain

$$\begin{aligned}
&\|\mathcal{A}(\phi_1)-\mathcal{A}(\phi_2)-\mathcal{A}'(0)(\phi_1-\phi_2)\|_{L^p}\\
&\quad\le \|\mathcal{A}'(\phi_2)(\phi_1-\phi_2)-\mathcal{A}'(0)(\phi_1-\phi_2)\|_{L^p}+\frac{C}{\rho^7}\|\phi_1-\phi_2\|^2_{W^{1,p}}\\
&\quad\le \frac{C}{\rho^7}\|\phi_2\|_{W^{1,p}}\|\phi_1-\phi_2\|_{W^{1,p}}+\frac{C}{\rho^7}\|\phi_1-\phi_2\|^2_{W^{1,p}}\\
&\quad\le \frac{C}{\rho^7}(\|\phi_1\|_{W^{1,p}}+\|\phi_2\|_{W^{1,p}})\|\phi_1-\phi_2\|_{W^{1,p}}.
\end{aligned}$$

Similarly using Lemma 6.1, parts 3 and 4, we deduce

$$\begin{aligned}
\|\mathcal{B}(\phi_1)-\mathcal{B}(\phi_2)-\mathcal{B}'(0)(\phi_1-\phi_2)\|_{L^p}&\le \frac{C}{\rho^5}(\|\phi_1\|_{W^{1,p}}+\|\phi_2\|_{W^{1,p}})\|\phi_1-\phi_2\|_{W^{1,p}}\\
\|\mathcal{C}(\phi_1)-\mathcal{C}(\phi_2)-\mathcal{C}'(0)(\phi_1-\phi_2)\|_{L^p}&\le \frac{C}{\rho^5}(\|\phi_1\|_{W^{1,p}}+\|\phi_2\|_{W^{1,p}})\|\phi_1-\phi_2\|_{W^{1,p}}.
\end{aligned}$$

From (7.21) we conclude that

$$\begin{aligned}
\|\mathcal{N}_2(\phi_1)-\mathcal{N}_2(\phi_2)\|_{L^p}&\le \frac{C}{\rho^7}(\|\phi_1\|_{W^{1,p}}+\|\phi_2\|_{W^{1,p}})\|\phi_1-\phi_2\|_{W^{1,p}}\\
&\le \frac{C}{\rho^2}\|\phi_1-\phi_2\|_{W^{1,p}}.
\end{aligned}\tag{7.22}$$

We also have

$$\|\mathcal{N}_3(\phi_1)-\mathcal{N}_3(\phi_2)\|_{L^p}\le \frac{C}{\rho^2}\|\phi_1-\phi_2\|_{W^{2,p}}. \tag{7.23}$$

Hence, following (7.20), (7.22), and (7.23), we find that

$$\begin{aligned}
&\|\mathcal{T}(\phi_1)-\mathcal{T}(\phi_2)\|_{W^{2,p}}\\
&\quad=\|(\Pi\mathcal{L})^{-1}\Pi\mathcal{N}(\phi_1)-(\Pi\mathcal{L})^{-1}\Pi\mathcal{N}(\phi_2)\|_{W^{2,p}}\le C\rho^2\|\phi_1-\phi_2\|_{W^{2,p}},
\end{aligned}\tag{7.24}$$

i.e., that $\mathcal{T}$ is a contraction map if ρ is sufficiently small. A fixed point φ exists. □

Since φ satisfies $\|\phi\|_{W^{2,p}} \le c\rho^5$, by taking ρ small we see that $r_k^3 + \varphi_k$ remains positive. ∂E_{φ_k} is a perturbed sphere.

Denote $\mathcal{S}'(\varphi)$ by $\tilde{\mathcal{L}}$. We derive a lemma for $\tilde{\mathcal{L}}$ similar to Lemma 5.3.

LEMMA 7.2. *Let Π be the same projection operator from $\mathcal{X}$ to $\mathcal{X}_*$.*

1. *There exists $C > 0$ such that for all $u \in \mathcal{X}_*$*

$$\|u\|_{W^{2,p}} \le C\rho^4 \|\Pi\tilde{\mathcal{L}}(u)\|_{L^p}.$$

2. *If (2.8) holds, then*

$$\|u\|^2_{W^{1,2}} \le C\rho^4 \langle \Pi\tilde{\mathcal{L}}(u), u\rangle.$$

Proof. By Lemma 5.3, part 1, Lemma 6.1, and the fact $\|\varphi\|_{W^{2,p}} = O(\rho^5)$, we deduce that

$$\begin{aligned}
\|\Pi\tilde{\mathcal{L}}(u)\|_{L^p} &\ge \|\Pi\mathcal{L}(u)\|_{L^p} - \|\Pi(\tilde{\mathcal{L}} - \mathcal{L})(u)\|_{L^p}\\
&\ge \frac{C}{\rho^4}\|u\|_{W^{2,p}} - \frac{C}{\rho^7}\|\varphi\|_{W^{2,p}}\|u\|_{W^{2,p}}\\
&\ge \frac{C}{\rho^4}\|u\|_{W^{2,p}} - \frac{C}{\rho^2}\|u\|_{W^{2,p}} \ \ge\ \frac{C}{\rho^4}\|u\|_{W^{2,p}}
\end{aligned}$$

when ρ is small. This proves part 1 of Lemma 7.2.

Write $\tilde{\mathcal{L}} = \mathcal{H}'(\varphi) + \mathcal{A}'(\varphi) + \mathcal{B}'(\varphi) + \mathcal{C}'(\varphi) + \lambda'(\varphi)$. Then, according to (4.7),

$$\langle \mathcal{H}_k'(\varphi_k)(u_k), u_k\rangle = \int_{S^2}\left[\frac{\partial^2 L_k}{\partial \phi_k^2}u_k^2 + 2\sum_{i=1}^2 \frac{\partial^2 L_k}{\partial\phi_k\partial\phi_{k,i}}u_k u_{k,i} + \sum_{i,j=1}^2 \frac{\partial^2 L_k}{\partial\phi_{k,i}\partial\phi_{k,j}}u_{k,i}u_{k,j}\right]d\theta_k,$$

and a similar expression holds if we replace φ_k and $\varphi_{k,i}$ by 0 in the last formula.

With $\|\varphi\|_{W^{2,p}} = O(\rho^5)$, calculations show that

$$\begin{aligned}
&|\langle(\mathcal{H}_k'(\varphi_k) - \mathcal{H}_k'(0))u_k, u_k\rangle|\\
&\quad\le \left|\int_{S^2}\left(\frac{\partial^2 L_k(\varphi_k)}{\partial\phi_k^2} - \frac{\partial^2 L_k(0)}{\partial\phi_k^2}\right)u_k^2\,d\theta_k\right|\\
&\qquad + 2\sum_{i=1}^2\left|\int_{S^2}\left(\frac{\partial^2 L_k(\varphi_k)}{\partial\phi_k\partial\phi_{k,i}} - \frac{\partial^2 L_k(0)}{\partial\phi_k\partial\phi_{k,i}}\right)u_k u_{k,i}\,d\theta_k\right|\\
&\qquad + \sum_{i,j=1}^2\left|\int_{S^2}\left(\frac{\partial^2 L_k(\varphi_k)}{\partial\phi_{k,i}\partial\phi_{k,j}} - \frac{\partial^2 L_k(0)}{\partial\phi_{k,i}\partial\phi_{k,j}}\right)u_{k,i}u_{k,j}\,d\theta_k\right|\\
&\quad\le \frac{C}{\rho^2}\|u\|^2_{L^2} + \frac{C}{\rho^2}\|u\|_{L^2}\|Du\|_{L^2} + \frac{C}{\rho^2}\|Du\|^2_{L^2} \ \le\ \frac{C}{\rho^2}\|u\|^2_{W^{1,2}}.
\end{aligned} \tag{7.25}$$

Next we estimate $\|(\mathcal{A}_k'(\varphi_k) - \mathcal{A}_k'(0))u_k\|_{L^2}$ and revisit $\mathcal{A}_k''$. Arguing as in the proof of Lemma 6.1, part 2, we deduce that

$$\|\mathcal{A}_k''(\phi)(u_k, v_k)\|_{L^2} \le \frac{C}{\rho^7}\|u_k\|_{W^{1,2}}\|v_k\|_{W^{1,2}}.$$

This implies that in this lemma

$$\|(\mathcal{A}_k'(\varphi) - \mathcal{A}_k'(0))u_k\|_{L^2} \le \frac{C}{\rho^7}C\rho^5\|u_k\|_{W^{1,2}} \le \frac{C}{\rho^2}\|u_k\|_{W^{1,2}}.$$

Simpler arguments show that

$$\|(\mathcal{B}_k'(\varphi)-\mathcal{B}_k'(0))u_k\|_{L^2}\le \frac{C}{\rho^2}\|u_k\|_{W^{1,2}},\quad \|(\mathcal{C}'(\varphi)-\mathcal{C}'(0))u\|_{L^2}\le \frac{C}{\rho^2}\|u\|_{W^{1,2}}.$$

We obtain that

$$\|(\mathcal{A}'(\varphi)+\mathcal{B}'(\varphi)+\mathcal{C}'(\varphi)-\mathcal{A}'(0)-\mathcal{B}'(0)-\mathcal{C}'(0))u\|_{L^2}\le \frac{C}{\rho^2}\|u\|_{W^{1,2}}. \tag{7.26}$$

If (2.8) holds, we combine Lemma 5.3, part 3, (7.25), and (7.26) to deduce that

$$\langle \Pi\tilde{\mathcal{L}}(u),u\rangle=\langle \Pi\mathcal{L}(u),u\rangle+\langle \Pi(\tilde{\mathcal{L}}-\mathcal{L})u,u\rangle\ge \frac{C}{\rho^4}\|u\|^2_{W^{1,2}}-\frac{C}{\rho^2}\|u\|^2_{W^{1,2}}\ge \frac{C}{\rho^4}\|u\|^2_{W^{1,2}},$$

proving the second part. ∎

One consequence of Lemma 7.2, part 1, is an estimate of $\frac{\partial\varphi}{\partial\xi_{l,j}}$.

LEMMA 7.3. *The fixed point φ satisfies $\left\|\frac{\partial\varphi}{\partial\xi_{l,j}}\right\|_{W^{2,p}}=O(\rho^4)$, $l=1,2,\dots,K$, $j=1,2,3$.*

Proof. We prove this lemma by the implicit function theorem. Fix $l\in\{1,2,\dots,K\}$ and $j\in\{1,2,3\}$. Differentiating $\Pi\mathcal{S}(\varphi)$ with respect to $\xi_{l,j}$ we find that, for $k=1,2,\dots,K$, if $k=l$, then

$$\begin{aligned}\frac{\partial\Pi\mathcal{S}_l(\varphi)}{\partial\xi_{l,j}}&=\Pi\tilde{\mathcal{L}}_l\left(\frac{\partial\varphi}{\partial\xi_{l,j}}\right)+\Pi\frac{\gamma}{3}\\&\quad\times\int_{E_{\varphi_l}}\left[\frac{\partial R(\xi_l+(r_l^3+\varphi_l(\theta_l))^{1/3}\theta_l,y)}{\partial x_j}+\frac{\partial R(\xi_l+(r_l^3+\varphi_l(\theta_l))^{1/3}\theta_l,y)}{\partial y_j}\right]dy\\&\quad+\sum_{m\ne l}\Pi\frac{\gamma}{3}\int_{E_{\varphi_m}}\frac{\partial G(\xi_l+(r_l^3+\varphi_l(\theta_l))^{1/3}\theta_l,y)}{\partial x_j}\,dy,\end{aligned}$$

and if $k\ne l$,

$$\frac{\partial\Pi\mathcal{S}_k(\varphi)}{\partial\xi_{l,j}}=\Pi\tilde{\mathcal{L}}_k\left(\frac{\partial\varphi}{\partial\xi_{l,j}}\right)+\Pi\frac{\gamma}{3}\int_{E_{\varphi_l}}\frac{\partial G(\xi_k+(r_k^3+\varphi_k(\theta_k))^{1/3}\theta_k,y)}{\partial y_j}\,dy.$$

Here $R=R(x,y)$ and $G=G(x,y)$. It is clear that

$$\begin{aligned}\Bigg\|\frac{\gamma}{3}\int_{E_{\varphi_l}}\Bigg[&\frac{\partial R(\xi_l+(r_l^3+\varphi_l(\theta_l))^{1/3}\theta_l,y)}{\partial x_j}\\&+\frac{\partial R(\xi_l+(r_l^3+\varphi_l(\theta_l))^{1/3}\theta_l,y)}{\partial y_j}\Bigg]dy\Bigg\|_{L^p}=O(\gamma\rho^3),\end{aligned}$$

$$\left\|\frac{\gamma}{3}\int_{E_{\varphi_m}}\frac{\partial G(\xi_l+(r_l^3+\varphi_l(\theta_l))^{1/3}\theta_l,y)}{\partial x_j}\,dy\right\|_{L^p}=O(\gamma\rho^3),$$

$$\left\|\frac{\gamma}{3}\int_{E_{\varphi_l}}\frac{\partial G(\xi_k+(r_k^3+\varphi_k(\theta_k))^{1/3}\theta_k,y)}{\partial y_j}\,dy\right\|_{L^p}=O(\gamma\rho^3).$$

Therefore

$$\frac{\partial \Pi \mathcal{S}(\varphi)}{\partial \xi_{l,j}} = \Pi \tilde{\mathcal{L}} \left(\frac{\partial \varphi}{\partial \xi_{l,j}} \right) + W,$$

where $\|W\|_{L^p} = O(\gamma \rho^3) = O(1)$.

On the other hand

$$\frac{\partial \Pi \mathcal{S}(\varphi)}{\partial \xi_{l,j}} = 0,$$

since $\Pi \mathcal{S}(\varphi) = 0$.

By Lemma 7.2 we deduce that

$$\left\| \frac{\partial \varphi}{\partial \xi_{l,j}} \right\|_{W^{2,p}} \leq C \rho^4 O(1) \leq C \rho^4. \qquad \square$$

8. Solving the reduced problem. We now turn to solve $\mathcal{S}(\phi) = 0$.

LEMMA 8.1. *$J(E_\varphi) = J(B) + O(\rho^6)$. More explicitly*

$$J(E_\varphi) = \sum_{k=1}^{K} 4\pi r_k^2 + \frac{\gamma}{2} \Bigg\{ \sum_{k=1}^{K} \left[\frac{8\pi r_k^5}{15} + \left(\frac{4\pi}{3} \right)^2 r_k^6 R(\xi_k, \xi_k) \right] + \sum_{k=1}^{K} \sum_{l=1, l \neq k}^{K} \left(\frac{4\pi}{3} \right)^2 r_k^3 r_l^3 G(\xi_k, \xi_l) \Bigg\} + O(\rho^5).$$

Here $J(E_\varphi) = J(E_{\varphi(\cdot,\xi,r)})$ can be considered as a function of (ξ, r).

Proof. Expanding $J(E_\varphi)$ yields

$$J(E_\varphi) = J(B) + \sum_k \int_{S^2} \mathcal{S}_k(0) \varphi_k \, d\theta_k + \frac{1}{2} \sum_k \int_{S^2} \mathcal{L}_k(\varphi) \varphi_k \, d\theta_k + O(\rho^8). \tag{8.1}$$

The error term $O(\rho^8)$ in (8.1) is obtained in the same way that (7.18) is derived.

On the other hand $\Pi \mathcal{S}(\varphi) = 0$ implies that

$$\Pi(\mathcal{S}_k(0) + \mathcal{L}_k(\varphi) + \mathcal{N}_k(\varphi)) = 0,$$

where $\mathcal{N}$ is given in (7.7) and estimated in (7.18). We multiply the last equation by φ_k and integrate to derive

$$\int_{S^2} \mathcal{S}_k(0) \varphi_k \, d\theta_k + \int_{S^2} \mathcal{L}(\varphi_k) \varphi_k \, d\theta_k = O(\rho^8).$$

We can now rewrite (8.1) as

$$J(E_\varphi) = J(B) + \frac{1}{2} \sum_k \int_{S^2} \mathcal{S}_k(0) \varphi_k \, d\theta_k + O(\rho^8).$$

Note that $\mathcal{S}_k(0)$ is the sum of a number independent of θ_k and a quantity of order ρ by Lemma 3.1. Since φ_k satisfies (7.2), the inner product of the number and φ_k is zero, and hence

$$\int_{S^2} \mathcal{S}_k(0) \varphi_k \, d\theta = O(\rho^6).$$

Therefore

$$J(E_\varphi) = J(B) + O(\rho^6).$$

Lemma 3.2 implies that

$$\begin{aligned} J(E_\varphi) &= \sum_{k=1}^K 4\pi r_k^2 + \frac{\gamma}{2}\Bigg\{ \sum_{k=1}^K \left[\frac{8\pi r_k^5}{15} + \left(\frac{4\pi}{3}\right)^2 r_k^6 R(\xi_k,\xi_k)\right] \\ &\quad + \sum_{k=1}^K \sum_{l=1,l\neq k}^K \left(\frac{4\pi}{3}\right)^2 r_k^3 r_l^3 G(\xi_k,\xi_l) \\ &\quad + \sum_{k=1}^K \sum_{l=1}^K \left(\frac{4\pi}{3}\right)^2 \left(\frac{r_k^3 r_l^5}{10|D|} + \frac{r_k^5 r_l^3}{10|D|}\right)\Bigg\} + O(\rho^6) \\ &= \sum_{k=1}^K 4\pi r_k^2 + \frac{\gamma}{2}\Bigg\{ \sum_{k=1}^K \left[\frac{8\pi r_k^5}{15} + \left(\frac{4\pi}{3}\right)^2 r_k^6 R(\xi_k,\xi_k)\right] \\ &\quad + \sum_{k=1}^K \sum_{l=1,l\neq k}^K \left(\frac{4\pi}{3}\right)^2 r_k^3 r_l^3 G(\xi_k,\xi_l)\Bigg\} + O(\rho^5). \end{aligned}$$

This proves the lemma. ∎

LEMMA 8.2. *When ρ is sufficiently small, $J(E_{\varphi(\cdot,\xi,r)})$ is minimized at some $(\xi, r) = (\zeta, s) \in U$. As $\rho \to 0$, $\frac{s}{\rho} \to (1, 1, \ldots, 1)$, and $\zeta \to \zeta_0$ along a subsequence where $\zeta_0 \in U_1$ is a global minimum of F.*

Proof. Let us rescale the problem with

$$R = \frac{r}{\rho}, \quad \tilde{J}(\xi, R) = \frac{2}{\gamma\rho^5} J(E_{\varphi(\cdot,\xi,r)}), \quad (\xi, R) \in U_1 \times \tilde{U}_2,$$

where

$$\tilde{U}_2 = \left\{(R_1, R_2, \ldots, R_K) : \ 1 - \delta_2 < R_k < 1 + \delta_2, \ \sum_{k=1}^K R_k^3 = K\right\}$$

is a scaled version of U_2. Note that by (2.5) and Lemma 8.1 that

$$\begin{aligned} \tilde{J}(\xi, R) &= \frac{8\pi}{\gamma\rho^3} \sum_{k=1}^K R_k^2 + \sum_{k=1}^K \frac{8\pi R_k^5}{15} \\ &\quad + \rho\left(\frac{4\pi}{3}\right)^2 \left[\sum_{k=1}^K (R_k^6 R(\xi_k,\xi_k)) + \sum_{k=1}^K \sum_{l\neq k} R_k^3 R_l^3 G(\xi_k,\xi_l)\right] + O(\rho^3). \end{aligned}$$

Again by (2.5) we may assume that along a subsequence

$$\frac{8\pi}{\gamma\rho^3} \to b_0 \le \frac{8\pi}{(3+\epsilon)\pi}, \text{ as } \rho \to 0. \tag{8.2}$$

Let (ζ, S) be the global minimum of $\tilde{J}$ on the closure of $U_1 \times \tilde{U}_2$. Here $S = \frac{s}{\rho}$. Let $(\zeta, S) \to (\zeta_0, S_0)$ along a subsequence as ρ tends to 0. First we claim that

$S_0 = (1, 1, \ldots, 1)$. Suppose this is false, i.e., $S_0 \neq (1, 1, \ldots, 1)$. Then as ρ tends to 0,

$$\begin{aligned}\tilde{J}(\zeta, (1, \ldots, 1)) - \tilde{J}(\zeta, S) &= \sum_k \frac{8\pi}{\gamma\rho^3} + \sum_k \frac{8\pi}{15} - \sum_k \frac{8\pi S_k^2}{\gamma\rho^3} - \sum_k \frac{8\pi S_k^5}{15} + O(\rho) \\ &\to \sum_k b_0 + \sum_k \frac{8\pi}{15} - \sum_k b_0 S_{0,k}^2 - \sum_k \frac{8\pi S_{0,k}^5}{15}.\end{aligned}$$

Because of (8.2) and the constraint $\sum_k S_{0,k}^3 = K$, it is easy to show that the last line is negative if δ_2 in (3.1) is small enough, depending on ϵ. For, under (8.2), the function

$$x \to b_0 x^{2/3} + \frac{8\pi}{15} x^{5/3}$$

is convex when x is near 1. The last assertion then follows from the Jensen's inequality, when x takes values $S_{0,k}^3$. This is a contradiction to that (ζ, S) is a minimum of $\tilde{J}$.

Next we claim that ζ_0 minimizes F in U_1. Suppose this is false. Let η be a minimum of F in U_1. Then $F(\eta) < F(\zeta_0)$. Consider

$$\begin{aligned}\frac{1}{\rho}\left(\frac{3}{4\pi}\right)^2 (\tilde{J}(\eta, S) - \tilde{J}(\zeta, S)) &= \sum_{k=1}^K S_k^6 R(\eta_k, \eta_k) + \sum_{k=1}^K \sum_{l \neq k} S_k^3 S_l^3 G(\eta_k, \eta_l) \\ &\quad - \sum_{k=1}^K S_k^6 R(\zeta_k, \zeta_k) - \sum_{k=1}^K \sum_{l \neq k} S_k^3 S_l^3 G(\zeta_k, \zeta_l) + O(\rho^2) \\ &\to F(\eta) - F(\zeta_0) \ < \ 0, \text{ as } \rho \to 0,\end{aligned}$$

another contradiction to that (ζ, S) minimizes $\tilde{J}$. Note that $(\zeta, S) \in U_1 \times \tilde{U}_2$ when ρ is small, since $(\zeta_0, S_0) \in U_1 \times \tilde{U}_2$. $\square$

We show that $\varphi(\cdot, \zeta, s)$ is an exact solution of (1.1) in the next two lemmas. The first shows that $A_k = 0$ in (7.1) at $\xi = \zeta$ and $r = s$.

Lemma 8.3. *At $\xi = \zeta$ and $r = s$, $\mathcal{S}_k(\varphi(\cdot, \zeta, s))(\theta_k) = A_{k,1} \cos\theta_{k,1} \sin\theta_{k,2} + A_{k,2} \sin\theta_{k,1} \sin\theta_{k,2} + A_{k,3} \cos\theta_{k,2}$.*

Proof. At each $(\xi, r) \in U$, let

$$p_k = r_k^3, \quad q_k = s_k^3. \tag{8.3}$$

Calculations show that

$$\begin{aligned}\frac{\partial J(E_\varphi)}{\partial p_k} &= \sum_{l=1}^K \int_{S^2} [\mathcal{S}_l(\varphi) - \lambda(\varphi)] \frac{\partial(p_l + \varphi_l)}{\partial p_k}\, d\theta_l \\ &= \int_{S^2} [\mathcal{S}_k(\varphi) - \lambda(\varphi)] \left(1 + \frac{\partial \varphi_k}{\partial p_k}\right) d\theta_k + \sum_{l \neq k} \int_{S^2} [\mathcal{S}_l(\varphi) - \lambda(\varphi)] \frac{\partial \varphi_l}{\partial p_k}\, d\theta_l \\ &= \int_{S^2} (A_{k,1} \cos\theta_{k,1} \sin\theta_{k,2} + A_{k,2} \sin\theta_{k,1} \sin\theta_{k,2} + A_{k,3} \cos\theta_{k,2} \\ &\qquad + A_k - \lambda(\varphi)) \left(1 + \frac{\partial \varphi_k}{\partial p_k}\right) d\theta_k\end{aligned}$$

$$+\sum_{l\neq k}\int_{S^2}(A_{l,1}\cos\theta_{l,1}\sin\theta_{l,2}+A_{l,2}\sin\theta_{l,1}\sin\theta_{l,2}+A_{l,3}\cos\theta_{l,2}$$
$$+A_l-\lambda(\varphi))\frac{\partial\varphi_l}{\partial p_k}\,d\theta_l$$
$$=4\pi A_k-4\pi\lambda(\varphi).$$

Here we have used the facts that

$$\frac{\partial\varphi_l}{\partial p_k}\perp\cos\theta_{l,1}\sin\theta_{l,2},\ \sin\theta_{l,1}\sin\theta_{l,2},\ \cos\theta_{l,2},\ 1$$

which follow from $\varphi\in\mathcal{X}_*$.

On the other hand at the minimum $p=q$ and $\xi=\zeta$ with respect to p, we must have

$$\frac{\partial J(E_\varphi)}{\partial p_k}|_{\xi=\zeta,p=q}=\mu$$

for all $k=1,2,\dots,K$. Here μ is a Lagrange multiplier coming from the constraint

$$\sum_{k=1}^K p_k=\frac{3a|D|}{4\pi}.$$

Therefore we deduce that

$$A_k=\frac{\mu}{4\pi}+\lambda$$

which is independent of k. By (4.20) we derive that $\sum_{k=1}^K A_k=0$, and then we conclude that each A_k must be 0. $\square$

Next we show that $A_{k,1}$, $A_{k,2}$, and $A_{k,3}$ in (7.1) are 0 at $\xi=\zeta$ and $r=s$. The proof uses a tricky reparametrization technique.

LEMMA 8.4. *At $\xi=\zeta$ and $r=s$, $\mathcal{S}(\varphi(\cdot,\zeta,s))=0$.*

Proof. To simplify notations in this proof, we do not explicitly indicate the dependence of φ on r, i.e., we write $\varphi(\cdot,\xi)$ instead of $\varphi(\cdot,\xi,r)$. For each $\xi_k=(\xi_{k,1},\xi_{k,2},\xi_{k,3})$ near ζ_k we reparametrize $\partial_D E_{\varphi_k(\cdot,\xi)}$. Let ζ_k be the center of new polar coordinates, $r_k^3+\psi_k$ the new radius cube, and η_k the new angle. A point on $\partial_D E_{\varphi_k(\cdot,\xi)}$ is described as $\zeta_k+(r_k^3+\psi_k)^{1/3}\eta_k$. It is related to the old polar coordinates via

$$\zeta_k+(r_k^3+\psi_k)^{1/3}\eta_k=\xi_k+(r_k^3+\varphi_k)^{1/3}\theta_k. \tag{8.4}$$

In the new coordinates E_{φ_k} becomes E_{ψ_k}. It is viewed as a perturbation of the ball centered at ζ_k with radius r_k. The perturbation is described by ψ_k which is a function of η_k and ξ.

The main effect of the new coordinates is to "freeze" the center. The center of the new polar system is ζ_k which is fixed while the center of the old polar system is ξ_k which varies in D.

We now consider the derivative of $J(E_{\varphi(\cdot,\xi)})=J(E_{\psi(\cdot,\xi)})$ with respect to ξ_k. On one hand, at $\xi=\zeta$ and $r=s$,

$$\frac{\partial J(E_{\psi(\cdot,\xi)})}{\partial\xi_{k,j}}|_{\xi=\zeta}=\frac{\partial J(E_{\varphi(\cdot,\xi)})}{\partial\xi_{k,j}}|_{\xi=\zeta}=0,\quad j=1,2,3, \tag{8.5}$$

since ζ is a minimum.

On the other hand calculations show that

$$\frac{\partial J(E_{\psi(\cdot,\xi)})}{\partial \xi_{k,j}} = \sum_{l=1}^{K} \int_{S^2} \mathcal{S}_l(\psi(\cdot,\xi))(\eta_l) \frac{\partial \psi_l}{\partial \xi_{k,j}}\, d\eta_l. \tag{8.6}$$

We emphasize that (8.6) is obtained under the reparametrized coordinates, in which the dependence of $J(E_{\psi(\cdot,\xi)})$ on ξ is reflected only in the dependence of ψ on ξ. Had we calculated in the original coordinates, ξ would have appeared also in the nonlocal part of J through $R(\xi_l + \cdots, \xi_l + \cdots)$ and $G(\xi_k + \cdots, \xi_l + \cdots)$. The result would have been very different from (8.6). See the proof of Lemma 7.3 which involves differentiation with respect to ξ in the original coordinates. In the derivation of (8.6) we have used the fact that $\sum_l \int_{S^2} \psi_l \, d\eta_l = 0$ which implies that $\sum_l \int_{S^2} \frac{\partial \psi_l}{\partial \xi_{k,j}}\, d\eta_l = 0$, so that $\sum_l \int_{S^2} \lambda(\psi) \frac{\partial \psi_l}{\partial \xi_{k,j}}\, d\eta_l = 0$, where $\lambda(\psi)$ is part of

$$\mathcal{S}_l(\psi) = \mathcal{H}_l(\psi) + \mathcal{A}_l(\psi) + \mathcal{B}_l(\psi) + \mathcal{C}_l(\psi) + \lambda(\psi),$$

and we can reach the right-hand side of (8.6).

The expression $\mathcal{S}(\phi)$ is invariant under reparametrization, i.e.,

$$\mathcal{S}_l(\varphi(\cdot,\xi))(\theta_l) = \mathcal{S}_l(\psi(\cdot,\xi))(\eta_l). \tag{8.7}$$

Now we return to the original coordinate system and integrate with respect to θ_l in (8.6). Then

$$\frac{\partial J(E_{\psi(\cdot,\xi)})}{\partial \xi_{k,j}} = \sum_{l=1}^{K} \int_{S^2} \mathcal{S}_l(\varphi(\cdot,\xi))(\theta_l) \frac{\partial \psi_l(\eta_l(\theta_l,\xi),\xi)}{\partial \xi_{k,j}} \left| \frac{\partial(\eta_{l,1},\eta_{l,2})}{\partial(\theta_{l,1},\theta_{l,2})} \right| \frac{\sin \eta_{l,2}}{\sin \theta_{l,2}}\, d\theta_l. \tag{8.8}$$

There are two cases: $l = k$ and $l \neq k$. We start with the first case. Recall that ψ_k and η_k are defined implicitly as functions of θ_k and ξ by (8.4). Let us agree that $\psi_k = \psi_k(\eta_k, \xi)$ is a function of η_k and ξ. Set $\Psi_k(\theta_k,\xi) = \psi_k(\eta_k(\theta_k,\xi),\xi)$. To simplify notations let us set

$$g = (r_k^3 + \Psi_k)^{1/3}, \quad \tilde{g} = (r_k^3 + \varphi_k)^{1/3}. \tag{8.9}$$

Implicit differentiation shows that, with the help of Lemmas 7.1 and 7.3,

$$\begin{bmatrix} \frac{\partial \eta_{k,1}}{\partial \theta_{k,1}} & \frac{\partial \eta_{k,1}}{\partial \theta_{k,2}} & \frac{\partial \eta_{k,1}}{\partial \xi_{k,1}} & \frac{\partial \eta_{k,1}}{\partial \xi_{k,2}} & \frac{\partial \eta_{k,1}}{\partial \xi_{k,3}} \\ \frac{\partial \eta_{k,2}}{\partial \theta_{k,1}} & \frac{\partial \eta_{k,2}}{\partial \theta_{k,2}} & \frac{\partial \eta_{k,2}}{\partial \xi_{k,1}} & \frac{\partial \eta_{k,2}}{\partial \xi_{k,2}} & \frac{\partial \eta_{k,2}}{\partial \xi_{k,3}} \\ \frac{\partial \Psi_k}{\partial \theta_{k,1}} & \frac{\partial \Psi_k}{\partial \theta_{k,2}} & \frac{\partial \Psi_k}{\partial \xi_{k,1}} & \frac{\partial \Psi_k}{\partial \xi_{k,2}} & \frac{\partial \Psi_k}{\partial \xi_{k,3}} \end{bmatrix} = -M^{-1}N, \tag{8.10}$$

where

$$M^{-1} = \begin{bmatrix} g\sin\eta_{k,1}\sin\eta_{k,2} & -g\cos\eta_{k,1}\cos\eta_{k,2} & -\frac{\cos\eta_{k,1}\sin\eta_{k,2}}{3g^2} \\ -g\cos\eta_{k,1}\sin\eta_{k,2} & -g\sin\eta_{k,1}\cos\eta_{k,2} & -\frac{\sin\eta_{k,1}\sin\eta_{k,2}}{3g^2} \\ 0 & g\sin\eta_{k,2} & -\frac{\cos\eta_{k,2}}{3g^2} \end{bmatrix}^{-1}$$

$$= \frac{1}{\sin\eta_{k,2}}\begin{bmatrix} \frac{\sin\eta_{k,1}}{g} & -\frac{\cos\eta_{k,1}}{g} & 0 \\ -\frac{\cos\eta_{k,1}\cos\eta_{k,2}\sin\eta_{k,2}}{g} & -\frac{\sin\eta_{k,1}\cos\eta_{k,2}\sin\eta_{k,2}}{g} & \frac{\sin^2\eta_{k,2}}{g} \\ -3g^2\cos\eta_{k,1}\sin^2\eta_{k,2} & -3g^2\sin\eta_{k,1}\sin^2\eta_{k,2} & -3g^2\cos\eta_{k,2}\sin\eta_{k,2} \end{bmatrix}$$

and $N = [N_{ij}]$ is a 3 by 5 matrix given by

$$N_{11} = \frac{\cos\theta_{k,1}\sin\theta_{k,2}}{3\tilde{g}^2}\frac{\partial\varphi_k}{\partial\theta_{k,1}} - \tilde{g}\sin\theta_{k,1}\sin\theta_{k,2},$$
$$N_{12} = \frac{\cos\theta_{k,1}\sin\theta_{k,2}}{3\tilde{g}^2}\frac{\partial\varphi_k}{\partial\theta_{k,2}} + \tilde{g}\cos\theta_{k,1}\cos\theta_{k,2}, \quad N_{13} = 1 + \frac{\cos\theta_{k,1}\sin\theta_{k,2}}{3\tilde{g}^2}\frac{\partial\varphi_k}{\partial\xi_{k,1}},$$
$$N_{14} = \frac{\cos\theta_{k,1}\sin\theta_{k,2}}{3\tilde{g}^2}\frac{\partial\varphi_k}{\partial\xi_{k,2}}, \quad N_{15} = \frac{\cos\theta_{k,1}\sin\theta_{k,2}}{3\tilde{g}^2}\frac{\partial\varphi_k}{\partial\xi_{k,3}}$$
$$N_{21} = \frac{\sin\theta_{k,1}\sin\theta_{k,2}}{3\tilde{g}^2}\frac{\partial\varphi_k}{\partial\theta_{k,1}} + \tilde{g}\cos\theta_{k,1}\sin\theta_{k,2},$$
$$N_{22} = \frac{\sin\theta_{k,1}\sin\theta_{k,2}}{3\tilde{g}^2}\frac{\partial\varphi_k}{\partial\theta_{k,2}} + \tilde{g}\sin\theta_{k,1}\cos\theta_{k,2},$$
$$N_{23} = \frac{\sin\theta_{k,1}\sin\theta_{k,2}}{3\tilde{g}^2}\frac{\partial\varphi_k}{\partial\xi_{k,1}}, \quad N_{24} = 1 + \frac{\sin\theta_{k,1}\sin\theta_{k,2}}{3\tilde{g}^2}\frac{\partial\varphi_k}{\partial\xi_{k,2}},$$
$$N_{25} = \frac{\sin\theta_{k,1}\sin\theta_{k,2}}{3\tilde{g}^2}\frac{\partial\varphi_k}{\partial\xi_{k,3}}, \quad N_{31} = \frac{\cos\theta_{k,2}}{3\tilde{g}^2}\frac{\partial\varphi_k}{\partial\theta_{k,1}},$$
$$N_{32} = \frac{\cos\theta_{k,2}}{3\tilde{g}^2}\frac{\partial\varphi_k}{\partial\theta_{k,2}} - \tilde{g}\sin\theta_{k,2}, \quad N_{33} = \frac{\cos\theta_{k,2}}{3\tilde{g}^2}\frac{\partial\varphi_k}{\partial\xi_{k,1}},$$
$$N_{34} = \frac{\cos\theta_{k,2}}{3\tilde{g}^2}\frac{\partial\varphi_k}{\partial\xi_{k,2}}, \quad N_{35} = 1 + \frac{\cos\theta_{k,2}}{3\tilde{g}^2}\frac{\partial\varphi_k}{\partial\xi_{k,3}}.$$

We write N as

$$\sin\theta_{k,2}\begin{bmatrix} \begin{matrix}-\tilde{g}\sin\theta_{k,1}\\ +O(\rho^3)\end{matrix} & \begin{matrix}\frac{\tilde{g}\cos\theta_{k,1}\cos\theta_{k,2}}{\sin\theta_{k,2}}\\ +O(\rho^3)\end{matrix} & \begin{matrix}\frac{1}{\sin\theta_{k,2}}\\ +O(\rho^2)\end{matrix} & O(\rho^2) & O(\rho^2) \\ \begin{matrix}\tilde{g}\cos\theta_{k,1}\\ +O(\rho^3)\end{matrix} & \begin{matrix}\frac{\tilde{g}\sin\theta_{k,1}\cos\theta_{k,2}}{\sin\theta_{k,2}}\\ +O(\rho^3)\end{matrix} & O(\rho^2) & \begin{matrix}\frac{1}{\sin\theta_{k,2}}\\ +O(\rho^2)\end{matrix} & O(\rho^2) \\ \frac{O(\rho^3)}{\sin\theta_{k,2}} & -\tilde{g} + \frac{O(\rho^3)}{\sin\theta_{k,2}} & \frac{O(\rho^2)}{\sin\theta_{k,2}} & \frac{O(\rho^2)}{\sin\theta_{k,2}} & \frac{1}{\sin\theta_{k,2}} + \frac{O(\rho^2)}{\sin\theta_{k,2}} \end{bmatrix}.$$

At $\xi = \zeta$, we have $\eta = \theta$ and $\Psi = \varphi$. Multiplying M^{-1} and N we deduce that (8.10) becomes

(8.11)

$$\begin{bmatrix} 1+O(\rho^2) & O(\rho^2) & -\frac{\sin\theta_{k,1}}{\sin\theta_{k,2}g}+O(\rho) & \frac{\cos\theta_{k,1}}{\sin\theta_{k,2}g}+O(\rho) & O(\rho) \\ O(\rho^2) & 1+O(\rho^2) & \frac{\cos\theta_{k,1}\cos\theta_{k,2}}{g}+O(\rho) & \frac{\sin\theta_{k,1}\cos\theta_{k,2}}{g}+O(\rho) & -\frac{\sin\theta_{k,2}}{g}+O(\rho) \\ O(\rho^5) & O(\rho^5) & 3g^2\cos\theta_{k,1}\sin\theta_{k,2}+O(\rho^4) & 3g^2\sin\theta_{k,1}\sin\theta_{k,2}+O(\rho^4) & 3g^2\cos\theta_{k,2}+O(\rho^4) \end{bmatrix}$$

when $\xi = \zeta$.

We have found from (8.11) that at $\xi = \zeta$,

$$\left(\frac{\partial\Psi_k}{\partial\xi_{k,1}}, \frac{\partial\Psi_k}{\partial\xi_{k,2}}, \frac{\partial\Psi_k}{\partial\xi_{k,3}}\right)|_{\xi=\zeta} = 3r_k^2\theta_k + O(\rho^4). \tag{8.12}$$

To compute $\frac{\partial\psi_k}{\partial\xi_{k,j}}$, we invert $\eta_k = \eta_k(\xi, \theta_k)$ to express $\theta_k = \Theta_k(\eta_k, \xi)$. Then

$$\frac{\partial\psi_k}{\partial\xi_{k,j}} = \frac{\partial\Psi_k}{\partial\xi_{k,j}} + \frac{\partial\Psi_k}{\partial\theta_{k,1}}\frac{\partial\Theta_{k,1}}{\partial\xi_{k,j}} + \frac{\partial\Psi_k}{\partial\theta_{k,2}}\frac{\partial\Theta_{k,2}}{\partial\xi_{k,j}}.$$

At $\xi = \zeta$, since, by (8.11),

$$\frac{\partial\Psi_k}{\partial\theta_{k,m}}|_{\xi=\zeta} = O(\rho^5) \tag{8.13}$$

and

$$\begin{aligned} \begin{bmatrix} \frac{\partial\Theta_{k,1}}{\partial\xi_{k,1}} & \frac{\partial\Theta_{k,1}}{\partial\xi_{k,2}} & \frac{\partial\Theta_{k,1}}{\partial\xi_{k,3}} \\ \frac{\partial\Theta_{k,2}}{\partial\xi_{k,1}} & \frac{\partial\Theta_{k,2}}{\partial\xi_{k,2}} & \frac{\partial\Theta_{k,2}}{\partial\xi_{k,3}} \end{bmatrix}_{\xi=\zeta} &= -\begin{bmatrix} \frac{\partial\eta_{k,1}}{\partial\theta_{k,1}} & \frac{\partial\eta_{k,1}}{\partial\theta_{k,2}} \\ \frac{\partial\eta_{k,2}}{\partial\theta_{k,1}} & \frac{\partial\eta_{k,2}}{\partial\theta_{k,2}} \end{bmatrix}^{-1} \begin{bmatrix} \frac{\partial\eta_{k,1}}{\partial\xi_{k,1}} & \frac{\partial\eta_{k,1}}{\partial\xi_{k,2}} & \frac{\partial\eta_{k,1}}{\partial\xi_{k,3}} \\ \frac{\partial\eta_{k,2}}{\partial\xi_{k,1}} & \frac{\partial\eta_{k,2}}{\partial\xi_{k,2}} & \frac{\partial\eta_{k,2}}{\partial\xi_{k,3}} \end{bmatrix} \\ &= \frac{O\left(\frac{1}{\rho}\right)}{\sin\theta_{k,2}}, \end{aligned} \tag{8.14}$$

we deduce that

$$\left(\frac{\partial\psi_k}{\partial\xi_{k,1}}, \frac{\partial\psi_k}{\partial\xi_{k,2}}, \frac{\partial\psi_k}{\partial\xi_{k,3}}\right)|_{\xi=\zeta} = 3r_k^2\theta_k + \frac{O(\rho^4)}{\sin\theta_{k,2}}(1,1,1). \tag{8.15}$$

The second case $l \neq k$ is similar, for which we omit the details of our computation. At $\xi = \zeta$, we have

$$\left(\frac{\partial\psi_l}{\partial\xi_{k,1}}, \frac{\partial\psi_l}{\partial\xi_{k,2}}, \frac{\partial\psi_l}{\partial\xi_{k,3}}\right)|_{\xi=\zeta} = \frac{O(\rho^4)}{\sin\theta_{l,2}}(1,1,1). \tag{8.16}$$

Following (8.15), (8.16), and the fact that $|\frac{\partial(\eta_{l,1},\eta_{l,2})}{\partial(\theta_{l,1},\theta_{l,2})}|_{\xi=\zeta} = 1 + O(\rho^2)$, we find that (8.8) becomes

$$\begin{aligned}
\frac{\partial J(E_{\psi(\cdot,\xi)})}{\partial \xi_{k,1}}|_{\xi=\zeta} &= \int_{S^2} \mathcal{S}_k(\varphi) \Bigg(3r_k^2 \cos\theta_{k,1} \sin\theta_{k,2} \\
&\quad + \frac{O(\rho^4)}{\sin\theta_{k,2}} \Bigg) \, d\theta_k + \sum_{l\neq k} \int_{S^2} \mathcal{S}_l(\varphi) \frac{O(\rho^4)}{\sin\theta_{l,2}} \, d\theta_l, \\
\frac{\partial J(E_{\psi(\cdot,\xi)})}{\partial \xi_{k,2}}|_{\xi=\zeta} &= \int_{S^2} \mathcal{S}_k(\varphi) \Bigg(3r_k^2 \sin\theta_{k,1} \sin\theta_{k,2} \\
&\quad + \frac{O(\rho^4)}{\sin\theta_{k,2}} \Bigg) \, d\theta_k + \sum_{l\neq k} \int_{S^2} \mathcal{S}_l(\varphi) \frac{O(\rho^4)}{\sin\theta_{l,2}} \, d\theta_l, \\
\frac{\partial J(E_{\psi(\cdot,\xi)})}{\partial \xi_{k,3}}|_{\xi=\zeta} &= \int_{S^2} \mathcal{S}_k(\varphi) \left(3r_k^2 \cos\theta_{k,2} + \frac{O(\rho^4)}{\sin\theta_{k,2}} \right) \, d\theta_k \\
&\quad + \sum_{l\neq k} \int_{S^2} \mathcal{S}_l(\varphi) \frac{O(\rho^4)}{\sin\theta_{l,2}} \, d\theta_l.
\end{aligned}$$

Now we combine (7.1), (8.5), and the above to derive that at $\xi = \zeta$ and $r = s$,

$$\begin{aligned}
&A_{k,1} \int_{S^2} \cos\theta_{k,1} \sin\theta_{k,2} \left(3r_k^2 \cos\theta_{k,1} \sin\theta_{k,2} + \frac{O(\rho^4)}{\sin\theta_{k,2}} \right) d\theta_k + A_{k,2} O(\rho^4) \\
&\quad + A_{k,3} O(\rho^4) + \sum_{l\neq k} A_{l,1} O(\rho^4) + \sum_{l\neq k} A_{l,2} O(\rho^4) + \sum_{l\neq k} A_{l,3} O(\rho^4) = 0, \\
&A_{k,1} O(\rho^4) + A_{k,2} \int_{S^2} \sin\theta_{k,1} \sin\theta_{k,2} \left(3r_k^2 \sin\theta_{k,1} \sin\theta_{k,2} + \frac{O(\rho^4)}{\sin\theta_{k,2}} \right) d\theta_k \\
&\quad + A_{k,3} O(\rho^4) + \sum_{l\neq k} A_{l,1} O(\rho^4) + \sum_{l\neq k} A_{l,2} O(\rho^4) + \sum_{l\neq k} A_{l,3} O(\rho^4) = 0, \\
&A_{k,1} O(\rho^4) + A_{k,2} O(\rho^4) + A_{k,3} \int_{S^2} \cos\theta_{k,2} \left(3r_k^2 \cos\theta_{k,2} + \frac{O(\rho^4)}{\sin\theta_{k,2}} \right) d\theta_k \\
&\quad + \sum_{l\neq k} A_{l,1} O(\rho^4) + \sum_{l\neq k} A_{l,2} O(\rho^4) + \sum_{l\neq k} A_{l,3} O(\rho^4) = 0.
\end{aligned}$$

Writing the system in matrix form

$$\left(\begin{bmatrix} 4\pi r_1^2 & 0 & 0 & 0 & \dots & 0 & 0 \\ 0 & 4\pi r_1^2 & 0 & 0 & \dots & 0 & 0 \\ 0 & 0 & 4\pi r_1^2 & 0 & \dots & 0 & 0 \\ .. & & & & & & \\ .. & & & & & & \\ 0 & 0 & 0 & 0 & \dots & 4\pi r_K^2 & 0 \\ 0 & 0 & 0 & 0 & \dots & 0 & 4\pi r_K^2 \end{bmatrix} + O(\rho^4) \right) \begin{bmatrix} A_{1,1} \\ A_{1,2} \\ A_{1,3} \\ \dots \\ \dots \\ A_{K,2} \\ A_{K,3} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ \dots \\ \dots \\ 0 \\ 0 \end{bmatrix} \tag{8.17}$$

we deduce, since (8.17) is nonsingular when ρ is small, that $A_{k,1} = A_{k,2} = A_{k,3} = 0$. ☐

The existence part of Theorem 2.1 follows from Lemma 8.4. The centers ζ_k and radii s_k of the spheres are found in Lemma 8.2. In Lemma 7.1 we see that

$\|\varphi\|_{W^{2,p}} \le c\rho^5$, which implies that the radius of a sphere is approximately

$$(s_k^3 + \varphi_k(\theta_k))^{1/3} = s_k + \frac{O(|\varphi_k(\theta_k)|)}{\rho^2} = s_k + O(\rho^3). \tag{8.18}$$

By Lemma 8.2, ζ is close to a minimum of F and s_k is close to ρ. The formula in Lemma 8.1 gives the free energy of our solution.

In Theorem 2.2, a solution is termed stable if it is a local minimizer of J in the space

$$U \times \left\{ \phi = (\phi_1, \dots, \phi_K) : \ |\rho^3 + \phi_k| \ge \frac{\rho^3}{2}, \ \phi_k \in W^{1,2}(S^2), \right. \\ \left. \phi_k \perp 1, \ \phi_k \perp H_1, \ k = 1, 2, \dots, K \right\}. \tag{8.19}$$

The condition $|\rho^3 + \phi_k| \ge \frac{\rho^3}{2}$ ensures that J is well defined in this space. Under the condition (2.8), Lemma 7.2, part 2, shows that each $\varphi(\cdot, \xi, r)$ we found in Lemma 7.1 locally minimizes J, with fixed $(\xi, r) \in U$, in $\{\phi : \ |\rho^3 + \phi_k| \ge \frac{\rho^3}{2}, \ \phi_k \in W^{1,2}(S^2), \ \phi_k \perp 1, \ \phi_k \perp H_1\}$. On the other hand $\varphi(\cdot, \zeta, s)$ minimizes $J(E_{\varphi(\cdot,\xi,r)})$ with respect to ξ and r. Hence $\varphi(\cdot, \zeta, s)$ is a local minimizer of J in (8.19).

If (2.9) holds, then we can find one eigenvalue $\lambda_{k,n}$ of $\mathcal{L}_1$, Lemma 5.1, for some $n \in \{2, 3, \dots\}$ such that

$$\lambda_{k,n} < -\frac{C}{\rho^4}, \quad \langle \mathcal{L}_1(e_{k,n}), e_{k,n} \rangle < -\frac{C}{\rho^4} \|e_{k,n}\|^2_{W^{1,2}},$$

where $e_{k,n}$ is an eigenvector corresponding to $\lambda_{k,n}$. By Lemma 5.2, the last inequality implies that

$$\langle \mathcal{L}(e_{k,n}), e_{k,n} \rangle < -\frac{C}{\rho^4} \|e_{k,n}\|^2_{W^{1,2}}.$$

Then by Lemma 6.1, parts 2, 3, and 4, and (7.25) in the proof of Lemma 7.2,

$$\langle \tilde{\mathcal{L}}(e_{k,n}), e_{k,n} \rangle < -\frac{C}{\rho^4} \|e_{k,n}\|^2_{W^{1,2}}.$$

Therefore the solution is unstable.

9. Discussion. The functional (1.2) is derived as a Γ-limit of the free energy functional in the Ohta–Kawasaki theory of diblock copolymers in [20]. Ohta and Kawasaki use a function u on D to describe the density of A-monomers and $1 - u$ to describe the density of B-monomers. The free energy of a diblock copolymer is

$$I(u) = \int_D \left[\frac{\varepsilon^2}{2} |Du|^2 + W(u) + \frac{\sigma}{2} |(-\Delta)^{-1/2}(u - a)|^2 \right] dx, \tag{9.1}$$

where u is in

$$\{u \in H^1(D) : \overline{u} = a\}. \tag{9.2}$$

The ε in (9.1) is not to be confused with the ϵ that has appeared in this paper. The function W is a balanced double-well potential such as $W(u) = \frac{1}{4}u^2(1 - u)^2$. There are three positive parameters in (9.1): ε, σ, and a, where ε is small and a is in $(0, 1)$.

These three-dimensionless parameters are related to several physical parameters of a diblock copolymer system. See [29] for the precise relationships between the dimensionless parameters here and the physical parameters.

If we take σ to be of order ε, i.e., by setting

$$\sigma = \varepsilon\gamma \tag{9.3}$$

for some γ independent of ε, then as ε tends to 0, the limiting problem of $\varepsilon^{-1}I$ turns out to be

$$J(E) = \tau|D\chi_E|(D) + \frac{\gamma}{2}\int_D |(-\Delta)^{-1/2}(\chi_E - a)|^2\,dx \tag{9.4}$$

which is the same as the J in (1.2) except for the additional constant τ here. This constant is known as the surface tension and is given by

$$\tau = \int_0^1 \sqrt{2W(q)}\,dq. \tag{9.5}$$

The functional (9.4) is defined on the same admissible set Σ, (1.3). In this paper we have taken $\tau = 1$ without loss of generality.

The theory of Γ-convergence was developed by De Giorgi [7], Modica and Mortola [14], Modica [13], and Kohn and Sternberg [11]. It was proved that $\varepsilon^{-1}I$ Γ-converges to J in the following sense.

PROPOSITION 9.1 (see Ren and Wei [20]).

1. *For every family* $\{u_\varepsilon\}$ *of functions in* (9.2) *satisfying* $\lim_{\varepsilon\to 0} u_\varepsilon = \chi_E$ *in* $L^2(D)$,

$$\liminf_{\varepsilon\to 0} \varepsilon^{-1}I(u_\varepsilon) \geq J(E).$$

2. *For every* E *in* Σ, *there exists a family* $\{u_\varepsilon\}$ *of functions in* (9.2) *such that* $\lim_{\varepsilon\to 0} u_\varepsilon = \chi_E$ *in* $L^2(D)$, *and*

$$\limsup_{\varepsilon\to 0} \varepsilon^{-1}I(u_\varepsilon) \leq J(E).$$

The relationship between I and J becomes more clear when a result of Kohn and Sternberg [11] was used to show the following.

PROPOSITION 9.2 (see Ren and Wei [20]). *Let* $\delta > 0$ *and* $E \in \Sigma$ *be such that* $J(E) < J(F)$ *for all* $\chi_F \in B_\delta(\chi_E)$ *with* $F \neq E$, *where* $B_\delta(\chi_E)$ *is the open ball of radius* δ *centered at* χ_E *in* $L^2(D)$. *Then there exists* $\varepsilon_0 > 0$ *such that for all* $\varepsilon < \varepsilon_0$ *there exists* $u_\varepsilon \in B_{\delta/2}(\chi_E)$ *with* $I(u_\varepsilon) \leq I(u)$ *for all* $u \in B_{\delta/2}(\chi_E)$. *In addition* $\lim_{\varepsilon\to 0} \|u_\varepsilon - \chi_E\|_{L^2(D)} = 0$.

The existence of a stable solution $E_{\varphi(\cdot,\zeta,s)}$ to (1.1) in the sense of Theorem 2.1 does not quite imply the existence of a local minimizer, close to $\chi_{E_{\varphi(\cdot,\zeta,s)}}$ in $L^2(D)$, of I. One must show that $E_{\varphi(\cdot,\zeta,s)}$ is a strict local minimizer in the sense of Proposition 9.2. This issue requires more study.

Our work is the first mathematically rigorous confirmation of the spherical phase of diblock copolymer morphology. This phase, depicted in Figure 1.1, plot 1, has been observed in experiments for some time [1]. Our earlier work [31, 30] in two dimensions gave a mathematical proof of the existence of the cylindrical phase of diblock copolymer morphology; see Figure 1.1, plot 2. The results obtained here are analogous to the ones obtained in [30], but there are some notable differences.

In two dimensions we studied a cross section of the cylindrical phase and constructed a stable solution which is a union of many small, approximate discs under the condition that

$$\frac{1+\epsilon}{\rho^3 \log \frac{1}{\rho}} < \gamma < \frac{12-4\epsilon}{\rho^3}. \tag{9.6}$$

Here ρ is the average disc radius defined by $\rho = \sqrt{\frac{a|D|}{K\pi}}$. Note that the two bounds for γ in (9.6) are of different orders. Recall that in three dimensions we have (2.12), i.e.,

$$\frac{3+\epsilon}{\rho^3} < \gamma < \frac{30-4\epsilon}{\rho^3}, \tag{9.7}$$

where the two bounds are of the same order. In experiments it is more likely to see the cylindrical phase than the spherical phase (see [1]). The different bounds in (9.6) and (9.7) appear to offer an explanation.

In (8.18) we have proved that the perturbed "radius" is

$$(s_k^3 + \varphi_k(\theta_k))^{1/3} = s_k + O(\rho^3). \tag{9.8}$$

In other words the deviation of the "radius" of a perturbed ball from an exact ball is of the order $O(\rho^3)$. However, in two dimensions the corresponding quantity is

$$(s_k^2 + \varphi_k(\theta_k))^{1/2} = s_k + O(\rho^2), \tag{9.9}$$

a fact found after the proof of [30, Theorem 2.1]. The approximate balls in the spherical solution found here are more round than the approximate discs in the cylindrical solution found in [30].

Appendix A. We drop the subscript k in this appendix. The derivative of $\mathcal{A}$ at 0 has two terms according to (4.29). The first is

$$\frac{\gamma}{9r_k}\int_{S^2} \frac{u(\omega)}{4\pi|\theta-\omega|}\, d\omega.$$

The second is

$$-\frac{\gamma u(\theta)}{9r_k}\int_{B_1(0)} \frac{(\theta-y)\cdot\theta}{4\pi|\theta-y|^2}\, dy$$

for which we calculate the integral. Here $B_1(0)$ is the unit ball. This integral is independent of $\theta \in S^2$ so without loss of generality we assume that $\theta = (0,0,1)$. Write $y = (r\cos p, r\sin p, y_3)$ in the cylindrical coordinates. Then the integral becomes

$$\int_{B_1(0)} \frac{(\theta-y)\cdot\theta}{4\pi|\theta-y|^2}\, dy = \frac{1}{4\pi}\int_{-1}^{1}\int_0^{2\pi}\int_0^{\sqrt{1-y_3^2}} \frac{(1-y_3)r\, dr\, dp\, dy_3}{[(1-y_3)^2+r^2]^{3/2}} = \frac{1}{3}.$$

Appendix B. The integral operator

$$h(\theta) \to \int_{S^2} \frac{h(\omega)\, d\omega}{|\theta-\omega|} \tag{B.1}$$

acts on spherical harmonics $h \in H_n$ in a simple way. Here H_n is the space of spherical harmonics of degree n on S^2. In general one has

$$\int_{S^2} \Phi(\theta \cdot \omega) h(\omega)\, d\omega = \alpha_n(\Phi) h(\theta), \tag{B.2}$$

where

$$\alpha_n(\Phi) = 2\pi \int_{-1}^{1} \Phi(t) P_n(t)\, dt. \tag{B.3}$$

See, for instance, [10, Theorem 3.4.1]. Here P_n is the nth Legendre polynomial. In our case

$$\frac{1}{|\theta - \omega|} = \frac{1}{\sqrt{2 - 2\theta \cdot \omega}},$$

so we take

$$\Phi(t) = \frac{1}{\sqrt{2 - 2t}}. \tag{B.4}$$

The classical representation of Legendre polynomials in terms of generating functions [10, Formula 3.3.39]

$$\frac{1}{(1 + r^2 - 2rt)^{1/2}} = \sum_{n=0}^{\infty} P_n(t) r^n, \quad r, t \in (-1, 1) \tag{B.5}$$

shows that

$$\int_{-1}^{1} \frac{P_n(t)\, dt}{(1 + r^2 - 2rt)^{1/2}} = r^n \int_{-1}^{1} P_n^2(t)\, dt = \frac{2r^n}{2n+1},$$

where the orthogonality of the Legendre polynomials is used [10, Formula 3.3.16]:

$$\int_{-1}^{1} P_n(t) P_m(t)\, dt = \frac{2\delta_{nm}}{2n+1}.$$

By sending $r \to 1$ we find that

$$\alpha_n(\Phi) = \frac{4\pi}{2n+1}. \tag{B.6}$$

Appendix C. Here we calculate the improper integral

$$\int_{B_1(0)} \frac{|\theta - y|^2 - 3(1 - \theta \cdot y)^2}{|\theta - y|^5}\, dy, \tag{C.1}$$

where $B_1(0)$ is the unit ball centered at 0. This integral is independent of $\theta \in S^2$. We take $\theta = (0,0,1)$. Let $z = (0,0,1) - y$ and set $z = (r\cos p, r\sin p, z_3)$ in cylindrical coordinates. Then

$$\begin{aligned}
&\int_{B_1(0)} \frac{|\theta - y|^2 - 3(1 - \theta \cdot y)^2}{|\theta - y|^5}\, dy \\
&\quad = \int_{B_1(0,0,1)} \frac{|z|^2 - 3z_3^2}{|z|^5}\, dz \\
&\quad = \int_0^2 \int_0^{\sqrt{1-(1-z_3)^2}} \int_0^{2\pi} \frac{(r^2 + z_3^2) - 3z_3^2}{(r^2 + z_3^2)^{5/2}} r\, dp dr dz_3 \;=\; -\frac{8\pi}{3}.
\end{aligned}$$

ON CONVERGENCE OF SOLUTIONS OF FRACTAL BURGERS EQUATION TOWARD RAREFACTION WAVES*

GRZEGORZ KARCH†, CHANGXING MIAO‡, AND XIAOJING XU§

Abstract. In this paper, the large time behavior of solutions of the Cauchy problem for the one-dimensional fractal Burgers equation $u_t + (-\partial_x^2)^{\alpha/2}u + uu_x = 0$ with $\alpha \in (1, 2)$ is studied. It is shown that if the nondecreasing initial datum approaches the constant states $u_\pm$ ($u_- < u_+$) as $x \to \pm\infty$, respectively, then the corresponding solution converges toward the rarefaction wave, i.e., the unique entropy solution of the Riemann problem for the nonviscous Burgers equation.

Key words. fractal Burgers equation, asymptotic behavior, rarefaction wave, Riemann problem, Lévy process

AMS subject classifications. 60J60, 35B40, 35K55, 35Q53

DOI. 10.1137/070681776

1. Introduction. The goal of this work is to study asymptotic properties of solutions of the Cauchy problem for the nonlocal conservation law

$$u_t + \Lambda^\alpha u + uu_x = 0, \quad x \in \mathbb{R},\ t > 0, \tag{1.1}$$

$$u(0, x) = u_0(x), \tag{1.2}$$

where $\Lambda^\alpha = (-\partial^2/\partial x^2)^{\alpha/2}$ is the pseudodifferential operator defined via the Fourier transform

$$\widehat{(\Lambda^\alpha v)}(\xi) = |\xi|^\alpha \widehat{v}(\xi). \tag{1.3}$$

Following [3], we will call (1.1) the fractal Burgers equation. Equations of this type appear in the study of growing interfaces in the presence of self-similar hopping surface diffusion [19]. Moreover, in their recent papers, Jourdain, Méléard, and Woyczyński [13, 14] gave probabilistic motivations for studying equations with the anomalous diffusion when the Laplacian (the generator of the Wiener process) is replaced by a more general pseudodifferential operator generating the Lévy process. In particular, the authors of [14] studied problem (1.1)–(1.2), where the initial condition u_0 is assumed to be a nonconstant function with bounded variation on $\mathbb{R}$. In other words, a.e. on $\mathbb{R}$,

$$u_0(x) = c + \int_{-\infty}^{x} m(dy) = c + H * m(x) \tag{1.4}$$

with $c \in \mathbb{R}$, m being a finite signed measure on $\mathbb{R}$, and $H(y)$ denoting the unit step function $\mathbb{1}_{\{y\geq 0\}}$. Observe that the gradient $v(x,t) = u_x(x,t)$ satisfies

$$v_t + \Lambda^\alpha v + (vH * v)_x = 0, \quad v(\cdot, 0) = m. \tag{1.5}$$

If m is a probability measure on $\mathbb{R}$, (1.5) is a nonlinear Fokker–Planck equation. In the case of an arbitrary finite signed measure, the authors of [14] associated (1.5) with a suitable nonlinear martingale problem. Next, they studied the convergence of systems of particles with jumps as the number of particles tends to $+\infty$. As a consequence, the weighted empirical cumulative distribution functions of the particles converge to the solution of the martingale problem connected to (1.5). This phenomenon is called the *propagation of chaos* for problem (1.1)–(1.2), and we refer the reader to [14] for more details and additional references.

Motivated by the results from [14], we study problem (1.1)–(1.2) under the crucial assumption $\alpha \in (1, 2)$ and with the initial condition of the form (1.4). In our main result, we assume that u_0 is a function satisfying

$$u_0 - u_- \in L^1((-\infty, 0)) \quad \text{and} \quad u_0 - u_+ \in L^1((0, +\infty)) \quad \text{with} \quad u_- < u_+, \tag{1.6}$$

where $u_- = c$ and $u_+ - u_- = \int_{\mathbb{R}} m(dx)$.

It is well known (cf. [11, 20, 10] and Lemma 2.4 below) that the asymptotic profile as $t \to \infty$ of solutions of the viscous Burgers equation

$$u_t - u_{xx} + uu_x = 0 \tag{1.7}$$

(i.e., (1.1) with $\alpha = 2$) supplemented with an initial datum satisfying (1.6) is given by the so-called rarefaction wave. This is the continuous function

$$w^R(x,t) = W^R(x/t) = \begin{cases} u_-\,, & x/t \leq u_-, \\ x/t\,, & u_- \leq x/t \leq u_+, \\ u_+\,, & x/t \geq u_+, \end{cases} \tag{1.8}$$

which is the unique entropy solution of the following Riemann problem:

$$w_t^R + w^R w_x^R = 0, \tag{1.9}$$

$$w^R(x,0) = w_0^R(x) = \begin{cases} u_-\,, & x < 0, \\ u_+\,, & x > 0. \end{cases} \tag{1.10}$$

Below, we use the solution of the Burgers equation (1.7) with the initial datum (1.10) as the smooth approximation of the rarefaction wave (1.8).

The authors of this work were inspired by the fundamental paper of Il'in and Oleinik [11] who showed the convergence toward rarefaction waves of solutions of the nonlinear equation $u_t - u_{xx} + f(u)_x = 0$ under a strict convexity assumption imposed on f. That idea was next extended in several different directions, and we refer the reader to, e.g., [10, 18, 20, 21, 23, 24] for an overview of known results and additional references.

In this work, we contribute to the existing theory by developing tools which allow us to obtain analogous results for equations with a nonlocal and anomalous diffusion. Basic properties of solutions (namely, their existence and the regularity) of quasilinear evolution equations with $(-\Delta)^{\alpha/2}$, $\alpha \in (1, 2)$, (or, more generally, with the

Lévy diffusion) were shown in [8, 9]. On the other hand, one may expect singularities in finite time of solutions of (1.1) with $\alpha \in (0,1)$; see [2] for more details. If $u_0 \in L^1(\mathbb{R})$, Biler, Karch, and Woyczyński [4] proved that the large time asymptotics of solutions of (1.1)–(1.2) is described by the self-similar fundamental solution of equation $v_t + \Lambda^\alpha v = 0$. Analogous asymptotic properties of solutions of multidimensional generalizations of problem (1.1)–(1.2) with $u_0 \in L^1(\mathbb{R}^N)$ were studied in [5, 6]. Here, we would like also to report the recent progress in the understanding of properties of solutions of the quasi-geostrophic equation with an anomalous diffusion; cf. [7, 15] and the references therein.

The purpose of the present paper is to prove the convergence of solutions of the Cauchy problem for the fractal Burgers equations (1.1)–(1.2) toward rarefaction waves. We state our main result in the following theorem.

THEOREM 1.1. *Let $\alpha \in (1,2)$. Assume that $w^R = w^R(x,t)$ is the rarefaction wave* (1.8). *Denote by $u = u(x,t)$ the unique solution of problem* (1.1)–(1.2) *corresponding to the initial datum u_0 of the form* (1.4) *and satisfying* (1.6) *(cf. Theorem* 2.1*). For every $p \in ((3-\alpha)/(\alpha-1), \infty]$ there exists $C > 0$ independent of t such that*

$$\|u(t) - w^R(t)\|_p \le Ct^{-[\alpha-1-(3-\alpha)/p]/2} \log(2+t)$$

for all $t > 0$.

Remark 1.1. The proof of Theorem 1.1 does not work for $\alpha \in (0,1]$. In fact, our preliminary computations confirm that, in this case, one should expect completely different asymptotic profiles of solutions. First of all, the initial value problem (1.1)–(1.2) has the unique global-in-time entropy solution for every $u_0 \in L^\infty(\mathbb{R})$ and $\alpha \in (0,1]$ due to the recent work of Alibaud [1]. We expect these solutions to be regular for nondecreasing initial conditions, namely, in this case when shocks do not form for the nonviscous Burgers equation $u_t + uu_x = 0$. Using the uniqueness result from [1] combined with a standard scaling technique, one can show that (1.1) with $\alpha = 1$ has self-similar solutions of the form $u(x,t) = U(x/t)$. These profiles determine the large time asymptotics of solutions to the initial value problem (1.1)–(1.2) with $\alpha = 1$. If $\alpha \in (0,1)$, the Duhamel principle applied to problem (1.1)–(1.2) (cf. (2.10)) allows us to derive asymptotic profiles of solutions in the form

$$U_\alpha(x/t^{1/\alpha}) = \int_{-\infty}^{x/t^{1/\alpha}} P_\alpha(z)\,dz,$$

where the function P_α is as defined below (see (2.11) and (2.12)). Precise statements of these results and their proofs will be published in [12].

Remark 1.2. Our result has an important probabilistic interpretation, because the rarefaction wave (1.8) with $u_- = 0$ and $u_+ = 1$ is the probability distribution function corresponding to the uniform distribution on the interval $[0,t]$. On the other hand, the results announced in the remark above say that solutions to (1.1)–(1.2) with $\alpha \in (0,1)$ converge as $t \to \infty$ toward the symmetric α-stable laws and toward a one-parameter family of new laws solving the nonlinear equation (1.1) if $\alpha = 1$.

Remark 1.3. The result from Theorem 1.1 and its proof hold true also for $\alpha = 2$ (observe that $(3-\alpha)/(\alpha-1) \to 1$ as $\alpha \to 2$). However, we pass over this case for simplicity of the exposition and because the large time asymptotics of solutions of the Burgers equation (1.7) is well known; see Lemma 2.4.

In the next section, we gather several preliminary properties of the operator Λ^α and of solutions of problem (1.1)–(1.2). Theorem 1.1 is shown in section 3. In section 4, we discuss possible generalizations of our main result.

Notation. For $1 \le p \le \infty$, the L^p-norm of a Lebesgue measurable, real-valued function v defined on $\mathbb{R}$ is denoted by $\|v\|_p$. For a finite signed measure m on $\mathbb{R}$, we put $\|m\| = |m|(\mathbb{R})$, where $|m|$ is the total variation of m. The Fourier transform of v is $\widehat{v}(\xi) \equiv (2\pi)^{-1/2} \int_{\mathbb{R}} e^{-ix\xi} v(x)\, dx$. Given a function $v = v(x)$, we are going to use the decomposition $v = v^+ - v^-$, where as usual $v^- = \max\{0, -v\}$ and $v^+ = \max\{0, v\}$. The constants (always independent of t) will be denoted by the same letter C, even if they may vary from line to line. Occasionally, we write, e.g., $C = C(\alpha, \ell)$ when we want to emphasize the dependence of C on parameters α and ℓ.

2. Preliminary results. We begin by recalling that the basic questions on the existence and the uniqueness of solutions of problem (1.1)–(1.2) have been answered in [8, 9].

THEOREM 2.1 (see [8, Thm. 1.1], [9, Thm. 7]). *Let $\alpha \in (1, 2)$ and $u_0 \in L^\infty(\mathbb{R})$. There exists the unique solution $u = u(x,t)$ of problem* (1.1)–(1.2) *in the following sense: for all $T > 0$,*

$$u \in C_b((0, T) \times \mathbb{R}) \textit{ and, for all } a \in (0, T),\ u \in C_b^\infty((a, T) \times \mathbb{R}),$$

$$u \textit{ satisfies } (1.1) \textit{ on } (0, T) \times \mathbb{R},$$

$$u(t, \cdot) \to u_0 \textit{ in } L^\infty(\mathbb{R}) \textit{ weak-}*, \textit{ as } t \to 0.$$

Moreover, the following inequality holds true:

$$\|u(t)\|_\infty \le \|u_0\|_\infty \quad \textit{for all} \quad t > 0. \tag{2.1}$$

The main goal of this section is to complete this result by additional properties of u_x if the initial conditions are of the form (1.4).

THEOREM 2.2. *Let $\alpha \in (1, 2)$. Assume that the initial datum u_0 can be written in the form* (1.4) *for a constant $c \in \mathbb{R}$ and a signed finite measure m on $\mathbb{R}$. Then the solution $u = u(x,t)$ of problem* (1.1)–(1.2) *satisfies $u_x \in C((0,T]; L^p(\mathbb{R}))$ for each $1 \le p \le \infty$ and every $T > 0$.*

Consider u and $\widetilde{u}$ to be two such solutions with initial conditions u_0 and $\widetilde{u}_0$, respectively. Suppose that $\widetilde{u}_x(x,t)$ is nonnegative a.e. and $u_0 - \widetilde{u}_0 \in L^1(\mathbb{R})$. Then

$$\|u(t) - \widetilde{u}(t)\|_1 \le \|u_0 - \widetilde{u}_0\|_1 \tag{2.2}$$

for all $t > 0$.

THEOREM 2.3. *Under the assumption of Theorem* 2.2, *if the measure m in the initial datum* (1.4) *is nonnegative, we have*

(i) *$u_x(x,t) \ge 0$ for all $x \in \mathbb{R}$ and $t > 0$;*

(ii) *for every $p \in [1, \infty]$ there exists $C = C(p) > 0$ such that*

$$\|u_x(t)\|_p \le t^{-1+1/p} \|m\|^{1/p}. \tag{2.3}$$

In the proofs of Theorems 2.2 and 2.3 as well as in our study of the large time asymptotics, we shall require several properties of the operator Λ^α and of the semigroup of linear operators generated by it. First of all, note that the operator defined by (1.3) has the integral representation for every $\alpha \in (1,2)$ (cf., e.g., [9, Thm. 1])

$$\Lambda^\alpha w(x) = -C(\alpha) \int_{\mathbb{R}} \frac{w(x+z) - w(x) - w_x(x) z}{|z|^{1+\alpha}}\, dz. \tag{2.4}$$

This formula allows us to apply Λ^α to functions which are bounded and sufficiently smooth but not, however, necessarily decaying at infinity.

LEMMA 2.1. *Let $1 < \alpha < 2$. For every $p \in [1, \infty]$ there exists $C = C(p, \alpha) > 0$ such that*

$$\|\Lambda^\alpha w\|_p \le C \|w_x\|_p^{2-\alpha} \|w_{xx}\|_p^{\alpha-1} \tag{2.5}$$

for all functions w satisfying $w_x, w_{xx} \in L^p(\mathbb{R})$.

Proof. We can easily deduce the interpolation inequality (2.5) from (2.4). Indeed, it follows from the Taylor formula that for any fixed $R > 0$ we have

$$\begin{aligned}\|\Lambda^\alpha w\|_p &\le C\|w_{xx}\|_p \int_{|z|\le R} |z|^{1-\alpha}\, dz + C\|w_x\|_p \int_{|z|>R} |z|^{-\alpha}\, dz \\ &\le C\left(R^{2-\alpha}\|w_{xx}\|_p + R^{1-\alpha}\|w_x\|_p\right).\end{aligned}$$

Choosing $R = \|w_x\|_p/\|w_{xx}\|_p$ we complete the proof of inequality (2.5). ∎

Now, we prove the Nash inequality for the operator Λ^α.

LEMMA 2.2. *Let $0 < \alpha$. There exists a constant $C_N > 0$ such that*

$$\|w\|_2^{2(1+\alpha)} \le C_N \|\Lambda^{\alpha/2} w\|_2^2 \|w\|_1^{2\alpha} \tag{2.6}$$

for all functions w satisfying $w \in L^1(\mathbb{R})$ and $\Lambda^{\alpha/2} w \in L^2(\mathbb{R})$.

Proof. For every $R > 0$, we decompose the L^2-norm of the Fourier transform of w as follows:

$$\begin{aligned}\|w\|_2^2 &= C\int_{\mathbb{R}} |\widehat{w}(\xi)|^2\, d\xi \\ &\le C\|\widehat{w}\|_\infty^2 \int_{|\xi|\le R} d\xi + CR^{-\alpha}\int_{|\xi|>R} |\xi|^\alpha |\widehat{w}(\xi)|^2\, d\xi \\ &\le CR\|w\|_1^2 + CR^{-\alpha}\|\Lambda^{\alpha/2} w\|_2^2.\end{aligned}$$

For $R = \left(\|\Lambda^{\alpha/2} w\|_2^2/\|w\|_1^2\right)^{1/(1+\alpha)}$ we obtain (2.6). ∎

LEMMA 2.3. *Let $0 \le \alpha \le 2$. For every $p > 1$, we have*

$$\int_{\mathbb{R}} (\Lambda^\alpha w)|w|^{p-2} w\, dx \ge \frac{4(p-1)}{p^2} \int_{\mathbb{R}} \left(\Lambda^{\frac{\alpha}{2}} |w|^{\frac{p}{2}}\right)^2\, dx \tag{2.7}$$

for all $w \in L^p(\mathbb{R})$ such that $\Lambda^\alpha w \in L^p(\mathbb{R})$. If $\Lambda^\alpha w \in L^1(\mathbb{R})$, we obtain

$$\int_{\mathbb{R}} (\Lambda^\alpha w) \operatorname{sgn} w\, dx \ge 0, \tag{2.8}$$

and if $w, \Lambda^\alpha w \in L^2(\mathbb{R})$, it follows that

$$\int_{\mathbb{R}} (\Lambda^\alpha w) w^+\, dx \ge 0 \quad \text{and} \quad \int_{\mathbb{R}} (\Lambda^\alpha w) w^-\, dx \ge 0, \tag{2.9}$$

where $w^+ = \max\{0, w\}$ and $w^- = \max\{0, -w\}$.

Inequality (2.7) is well known in the theory of sub-Markovian operators and its statement and proof are given, e.g., in [17, Thm. 2.1 combined with the Beurling–Deny condition (1.7)]; see also [7, 15]. Observe that if $\alpha = 2$, integrating by parts we obtain (2.7) with the equality. Inequality (2.8) (called the Kato inequality) is used in [9] to construct entropy solutions of (1.1) and it can be easily deduced from [9, Lem. 1] by an approximation argument (see also [3, inequality (3.5)]). The proof of (2.9) can be found, for example, in [17, Prop. 1.6].

We also recall that, by Duhamel's principle, the solution of problem (1.1)–(1.2) can be written in the equivalent integral form

$$u(t) = S_\alpha(t)u_0 - \int_0^t S_\alpha(t-\tau)u(\tau)u_x(\tau)\,d\tau, \tag{2.10}$$

where

$$S_\alpha(t)u_0 = p_\alpha(t) * u_0(x). \tag{2.11}$$

Here, the fundamental solution $p_\alpha(x,t)$ of the linear equation $\partial_t v + \Lambda^\alpha v = 0$ can be computed via the Fourier transform $\widehat{p}_\alpha(\xi,t) = e^{-t|\xi|^\alpha}$. Hence,

$$p_\alpha(x,t) = t^{-1/\alpha}P_\alpha(xt^{-1/\alpha}),$$

where P_α is the inverse Fourier transform of $e^{-|\xi|^\alpha}$. It is well known that for every $\alpha \in (0,2]$ the function P_α has the property $\int_{\mathbb{R}} P_\alpha(x)\ dx = 1$ and it is smooth, nonnegative, and satisfies

$$0 \le P_\alpha(x) \le C(1+|x|)^{-(\alpha+1)} \qquad \text{and} \qquad |\partial_x P_\alpha(x)| \le C(1+|x|)^{-(\alpha+2)} \tag{2.12}$$

for a constant C and all $x \in \mathbb{R}$. Using these properties of the convolution operator $S_\alpha(t)$ defined by (2.11) we obtain the estimates

$$\|S_\alpha(t)v\|_p \le Ct^{-(1-1/p)/\alpha}\|v\|_1, \tag{2.13}$$

$$\|(S_\alpha(t)v)_x\|_p \le Ct^{-(1-1/p)/\alpha-1/\alpha}\|v\|_1 \tag{2.14}$$

for every $p \in [1,\infty]$ and all $t > 0$. Moreover, we can replace v in (2.13) and (2.14) by any signed measure m. In that case, $\|v\|_1$ should be replaced by $\|m\|$.

Proof of Theorem 2.2. It follows from the integral equation (2.10) that u_x is the solution of

$$u_x(t) = S_\alpha(t)m - \int_0^t \partial_x S_\alpha(t-\tau)V(\tau)u_x(\tau)\,d\tau, \tag{2.15}$$

where $V(x,t) = u(x,t)$ is treated as given and is smooth and bounded. Now the standard argument involving the Banach fixed point theorem allows us to show that the "linear" equation (2.15) has a unique solution in $C((0,T];L^p(\mathbb{R}))$ for each $p \in [1,\infty]$ and every $T > 0$. Here, we should use the following estimate of the operator $\mathcal{T}(u)$ defined by the right-hand side of (2.15):

$$\begin{aligned}\|\mathcal{T}(u)(t)\|_p &\le \|S_\alpha(t)m\|_p + \int_0^t \|\partial_x S_\alpha(t-\tau)V(\tau)u_x(\tau)\|_p\,d\tau \\ &\le Ct^{-(1-1/p)/\alpha}\|m\| + C\sup_{\tau\in[0,T]}\|V(\tau)\|_\infty \int_0^t (t-\tau)^{-1/\alpha}\|u_x(\tau)\|_p\,d\tau,\end{aligned}$$

which is the immediate consequence of (2.13) and (2.14). Let us skip the other details of this well-known argument (cf. [22]).

Now, we prove inequality (2.2). A direct calculation shows that the function $v(x,t) = u(x,t) - \widetilde{u}(x,t)$ satisfies

$$v_t + \Lambda^\alpha v + \frac{1}{2}(v^2 + 2v\widetilde{u}))_x = 0. \tag{2.16}$$

First, we multiply (2.16) by $\operatorname{sgn} v = v|v|^{-1}$:

$$\frac{d}{dt}\int_{\mathbb{R}} |v|\,dx + \int_{\mathbb{R}} (\Lambda^\alpha v)\operatorname{sgn} v\,dx + \frac{1}{2}\int_{\mathbb{R}} [v^2 + 2v\widetilde{u})]_x \operatorname{sgn} v\,dx = 0.$$

The second term is nonnegative by (2.8). To show the same property for the third term, we replace the sgn function by smooth and nondecreasing $\varphi = \varphi(x)$. In this case, we obtain

$$\int_{\mathbb{R}} [v^2 + 2v\widetilde{u}]_x \varphi(v) dx = -\int_{\mathbb{R}} (v^2 + 2v\widetilde{u})\varphi'(v) v_x\,dx = -\int_{\mathbb{R}} \Psi(v)_x\,dx + \int_{\mathbb{R}} \widetilde{u}_x \Phi(v)\,dx,$$

where $\Psi(s) = \int_0^s z^2\varphi'(z)\,dz$ and $\Phi(s) = \int_0^s 2z\varphi'(z)\,dz$. Obviously, the first term on the right-hand side is equal to zero and the second one is nonnegative because $\widetilde{u}_x \ge 0$ and $\Phi(s) \ge 0$ for all $s \in \mathbb{R}$. Now, the standard approximation argument gives $\int_{\mathbb{R}} [v^2 + 2v\widetilde{u}]_x \operatorname{sgn} v\,dx \ge 0$. Hence, $\|v(t)\|_1 = \|u(t) - \widetilde{u}(t)\|_1 \le \|u_0 - \widetilde{u}_0\|_1 = \|v_0\|_1$ for all $t > 0$. $\square$

Proof of Theorem 2.3. To show part (i) of Theorem 2.3, we deal first with the smooth initial datum u_0 satisfying $u_{0,x}(x) \ge 0$ and $u_{0,x} \in L^p(\mathbb{R})$ for every $p \in [1,\infty]$. In this case, differentiating (1.1) with respect to x we have

$$(u_x)_t + \Lambda^\alpha u_x + (uu_x)_x = 0. \tag{2.17}$$

Note the well-known property

$$\int_{\mathbb{R}} v_t v^-\,dx = \int_{v\le 0} v_t^- v^-\,dx = \frac{1}{2}\frac{d}{dt}\int_{v\le 0} (v^-)^2\,dx.$$

Hence, multiplying (2.17) by u_x^-, integrating the resulting equation over $\mathbb{R}$, and integrating by parts on the right-hand side, we obtain

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_{u_x\le 0} (u_x^-)^2\,dx + \int_{\mathbb{R}} (\Lambda^\alpha u_x)u_x^-\,dx &= -\int_{u_x\le 0} (uu_x^-)_x u_x^-\,dx \\ &= -\frac{1}{2}\int_{u_x\le 0} (u_x^-)^3\,dx.\end{aligned}$$

Since $\int_{\mathbb{R}} (\Lambda^\alpha u_x)u_x^-\,dx \ge 0$ by (2.9) and $\int_{u_x\le 0} (u_x^-(x,0))^2\,dx = 0$ by the assumption imposed on u_0, the Gronwall inequality implies $\int_{u_x\le 0} (u_x^-(x,t))^2\,dx = 0$ for all $t \ge 0$. Consequently, $u_x^-(x,t) \equiv 0$ and the proof of (i) for regular initial conditions is finished.

Now, the proof of (i) for the solution $u = u(x,t)$ corresponding to the initial datum u_0 of the form (1.4) with the nonnegative finite measure m can be completed by the following approximation argument. We consider the sequence of regular initial conditions u_0^n as in the first part of this proof. Moreover, we assume that $u_{0,x}^n$ converges weakly to m and $\|u_0^n - u_0\|_1 \to 0$ as $n \to \infty$. Inequality (2.2) allows us to prove that the corresponding solutions $u^n(\cdot,t)$ satisfy $\|u^n(\cdot,t) - u(\cdot,t)\|_1 \to 0$ as $n \to \infty$ for any $t > 0$. Hence, there is a subsequence $n_k \to \infty$ such that $u^{n_k}(x,t) \to u(x,t)$ a.e. Since each $u^n(x,t)$ is nondecreasing as a function of x, the same conclusion holds true for $u(x,t)$.

In order to show inequality (2.3), we first observe that integrating (2.15) over $\mathbb{R}$ and using the equalities

$$\int_{\mathbb{R}} S_\alpha(t)m\,dx = \int_{\mathbb{R}} m(dx) \quad \text{and} \quad \int_{\mathbb{R}} \partial_x S_\alpha(t-\tau)(u(\tau)u_x(\tau))\,dx = 0,$$

we obtain the identity $\int_{\mathbb{R}} u_x(x,t)\,dx = \int_{\mathbb{R}} m(dx)$, which for nonnegative u_x means

$$\|u_x(t)\|_1 = \|m\| \quad \text{for all} \quad t > 0. \tag{2.18}$$

Now, for fixed $p \in (1,\infty)$ and $u_x \geq 0$, we multiply (2.17) by u_x^{p-1} and integrate the resulting equation over $\mathbb{R}$. After some manipulations involving integrations by parts on the right-hand side, we arrive at

$$\begin{aligned} \frac{1}{p}\frac{d}{dt}\|u_x(t)\|_p^p + \int_{\mathbb{R}} u_x^{p-1}\Lambda^\alpha u_x\,dx &= -\int_{\mathbb{R}} (uu_x)_x u_x^{p-1}\,dx \\ &= -\frac{p-1}{p}\int_{\mathbb{R}} u_x^{p+1}\,dx. \end{aligned} \tag{2.19}$$

Recall now that $\int_{\mathbb{R}} u_x^{p-1}\Lambda^\alpha u_x\,dx \geq 0$ by inequality (2.7). Moreover, it follows from the Hölder inequality combined with (2.18) that

$$\|u_x(t)\|_p^{p^2/(p-1)} \leq \|u_x(t)\|_{p+1}^{p+1}\|m\|^{1/(p-1)}.$$

Applying those two inequalities to (2.19) (note that $u_x \geq 0$) we obtain the following differential inequality for $\|u_x(t)\|_p^p$:

$$\frac{d}{dt}\|u_x(t)\|_p^p \leq -(p-1)\|m\|^{-1/(p-1)}\left(\|u_x(t)\|_p^p\right)^{p/(p-1)}.$$

Integrating it we complete the proof of (2.3) for any $p \in (1,\infty)$.

The case of $p = \infty$ is obtained immediately by passing to the limit $p \to \infty$ in inequality (2.3). $\square$

We conclude this section by recalling some results on smooth approximations of rarefaction waves, namely, the solutions of the following Cauchy problem:

$$w_t - w_{xx} + ww_x = 0, \tag{2.20}$$

$$w(x,0) = w_0(x) = \begin{cases} u_-, & x < 0, \\ u_+, & x > 0. \end{cases} \tag{2.21}$$

LEMMA 2.4. *Let $u_- < u_+$. Problem* (2.20)–(2.21) *has the unique, smooth, global-in-time solution $w(x,t)$ satisfying that*

(i) *$u_- < w(t,x) < u_+$ and $w_x(t,x) > 0$ for all $(x,t) \in \mathbb{R}\times(0,\infty)$;*

(ii) *for every $p \in [1, \infty]$, there exists a constant $C = C(p,u_-,u_+) > 0$ such that*

$$\|w_x(t)\|_p \leq Ct^{-1+1/p}, \quad \|w_{xx}(t)\|_p \leq Ct^{-3/2+1/(2p)}$$

and

$$\|w(t) - w^R(t)\|_p \leq Ct^{-(1-1/p)/2}$$

for all $t > 0$, where $w^R(x,t)$ is the rarefaction wave (1.8).

All results stated in Lemma 2.4 are deduced from the explicit formula for solutions of (2.20)–(2.21) and detailed calculations can be found in [10], with some additional improvements contained in [16, sect. 3].

3. Convergence toward rarefaction waves. For simplicity of the exposition, we split the proof of Theorem 1.1 into a sequence of lemmas.

LEMMA 3.1. *Let $\alpha \in (1,2)$. Assume that u and $\widetilde{u}$ are two solutions of problem* (1.1)–(1.2) *with initial conditions u_0 and $\widetilde{u}_0$, both of the form* (1.4) *with finite signed measures m and $\widetilde{m}$, respectively. Suppose, moreover, that the measure $\widetilde{m}$ of $\widetilde{u}_0$ is nonnegative and $u_0 - \widetilde{u}_0 \in L^1(\mathbb{R})$. Then, for every $p \in [1,\infty]$ there exists a constant $C = C(p) > 0$ such that*

$$\|u(t) - \widetilde{u}(t)\|_p \le Ct^{-(1-1/p)/\alpha}\|u_0 - \widetilde{u}_0\|_1 \tag{3.1}$$

for all $t > 0$.

Proof. In our reasoning, we denote $v(x,t) = u(x,t) - \tilde{u}(x,t)$ which satisfies (2.16). It follows from Theorem 2.2, inequality (2.2), that $\|v(t)\|_1 \le \|v_0\|_1$.

Now, we multiply (2.16) by $|v|^{p-2}v$ with $p > 1$:

$$\frac{1}{p}\frac{d}{dt}\int_{\mathbb{R}} |v|^p\,dx + \int_{\mathbb{R}} (\Lambda^\alpha v)(|v|^{p-2}v)\,dx + \frac{1}{2}\int_{\mathbb{R}} [v^2 + 2v\widetilde{u}]_x |v|^{p-2}v\,dx = 0. \tag{3.2}$$

The third term on the left-hand side of (3.2) is nonnegative by the following calculations:

$$\begin{aligned} \int_{\mathbb{R}} [v^2 + 2v\widetilde{u}]_x |v|^{p-2}v\,dx &= \int_{\mathbb{R}} 2v_x|v|^p\,dx + \int_{\mathbb{R}} 2\widetilde{u}v_x|v|^{p-2}v\,dx + \int_{\mathbb{R}} 2\widetilde{u}_x|v|^p\,dx \\ &= 2\left(1 - \frac{1}{p}\right)\int_{\mathbb{R}} \widetilde{u}_x|v|^p\,dx \ge 0, \end{aligned} \tag{3.3}$$

because $\int_{\mathbb{R}} v_x|v|^p\,dx = 0$ and $\widetilde{u}_x \ge 0$. Hence, using inequality (2.7), we obtain from (3.2)

$$\frac{d}{dt}\int_{\mathbb{R}} |v|^p\,dx + 4\left(1 - \frac{1}{p}\right)\int_{\mathbb{R}} (\Lambda^{\alpha/2}|v|^{p/2})^2\,dx \le 0. \tag{3.4}$$

From now on, we proceed by induction. Applying the Nash inequality (2.6) combined with (2.2), we deduce from (3.4) with $p = 2$ the following differential inequality:

$$\frac{d}{dt}\|v(t)\|_2^2 + 2C_N^{-1}\|v_0\|_1^{-2\alpha}\|v(t)\|_2^{2(1+\alpha)} \le 0,$$

which, after integration, leads to

$$\|v(t)\|_2 \le C_1\|v_0\|_1 t^{-1/(2\alpha)} \quad \text{with} \quad C_1 = (C_N/2\alpha)^{1/(2\alpha)}. \tag{3.5}$$

This is estimate (3.1) with $p = 2$.

Suppose now that

$$\|v(t)\|_{2^n} \le C_n t^{-(1-2^{-n})/\alpha}\|v_0\|_1 \quad \text{for all} \quad t > 0. \tag{3.6}$$

We consider (3.4) with $p = 2^{n+1}$, where the second term is estimated, first, by the Nash inequality (2.6) with $w = |v|^{2^n}$, and next, by the inductive hypothesis (3.6). This two-step estimate leads to the differential inequality

$$\frac{d}{dt}\|v(t)\|_{2^{n+1}}^{2^{n+1}} + 4(1-2^{-n-1})C_N^{-1}(C_n\|v_0\|_1)^{-\alpha 2^{n+1}} t^{2^{n+1}-2}\left(\|v(t)\|_{2^{n+1}}^{2^{n+1}}\right)^{1+\alpha} \le 0.$$

Integrating it we obtain

$$\|v(t)\|_{2^{n+1}} \le C_{n+1} t^{-(1-2^{-n-1})/\alpha}\|v_0\|_1 \quad \text{for all} \quad t>0 \tag{3.7}$$

with

$$C_{n+1} = C_n\left((C_N/(2\alpha))^{1/\alpha}\right)^{2^{-n-1}}\left(2^{n2^{-n-1}}\right)^{1/\alpha}.$$

This is inequality (3.1) for any $p = 2^{n+1}$ with $n \in \mathbb{N}$.

We leave to the reader the proof that $\limsup_{n\to\infty} C_n < \infty$. Hence, passing to the limit $n \to \infty$ in (3.7) we obtain inequality (3.1) for $p = \infty$.

The Hölder inequality

$$\|v\|_p \le \|v\|_{2^n}^{2^{n+1}/p-1}\|v\|_{2^{n+1}}^{2-2^{n+1}/p}$$

completes the proof for every $p \in (2^n, 2^{n+1})$. $\square$

LEMMA 3.2. *Let $\alpha \in (1,2)$. Assume that $w = w(x,t)$ is the smooth approximation of the rarefaction wave, namely, the solution of problem* (2.20)–(2.21). *Then for each $t_0 > 0$ we have*

$$\int_{t_0}^{\infty}\|w_{xx}(t)\|_p\,dt < \infty \quad \textit{for every} \quad p \in (1,\infty]$$

and

$$\int_{t_0}^{t}\|\Lambda^\alpha w(t)\|_p\,dt \le C\log(2+t) \quad \textit{for} \quad p = \frac{3-\alpha}{\alpha-1}$$

for all $t \ge t_0$ and $C > 0$ independent of t.

Proof. It follows from the decay estimates recalled in Lemma 2.4 that

$$\int_{t_0}^{\infty}\|w_{xx}(t)\|_p\,dt \le C\int_{t_0}^{\infty} t^{-3/2+1/(2p)}\,dt < \infty \quad \text{for every} \quad p \in (1,\infty].$$

By the interpolation inequality (2.5) and Lemma 2.4, we obtain

$$\begin{aligned}\|\Lambda^\alpha w(t)\|_p &\le C(1+t)^{(-1+1/p)(2-\alpha)}(1+t)^{(-3/2+1/(2p))(\alpha-1)}\\ &= C(1+t)^{-(1+\alpha)/2+(3-\alpha)/(2p)}.\end{aligned}$$

Hence, the rate of decay on the right-hand side equals -1 for $p = (3-\alpha)/(\alpha-1)$. $\square$

LEMMA 3.3. *Let $\alpha \in (1,2)$. Assume that $u = u(x,t)$ is the solution of* (1.1)–(1.2) *and $w = w(x,t)$ is the solution of* (2.20)–(2.21). *Suppose that $u_0 - w_0 \in L^p(\mathbb{R})$ for $p = (3-\alpha)/(\alpha-1)$. Then*

$$\|u(t) - w(t)\|_p \le C\log(2+t).$$

Proof. Denoting $v = u - w$, we see that this new function satisfies

$$v_t + \Lambda^\alpha v + \frac{1}{2}[v^2 + 2vw]_x = -\Lambda^\alpha w + w_{xx}.$$

We multiply this equation by $|v|^{p-2}v$ and we integrate over $\mathbb{R}$ to obtain

$$\begin{aligned} &\frac{1}{p}\frac{d}{dt}\int |v|^p\, dx + \int (\Lambda^\alpha v)(|v|^{p-2}v)\, dx + \frac{1}{2}\int [v^2 + 2vw]_x |v|^{p-2}v\, dx \\ &= \int (-\Lambda^\alpha w + w_{xx})(|v|^{p-2}v)\, dx. \end{aligned} \tag{3.8}$$

It follows from Lemma 2.3 that $\int_{\mathbb{R}}(\Lambda^\alpha v)(|v|^{p-2}v)\ dx \geq 0$. The third term on the left-hand side of (3.8) is nonnegative by Lemma 2.4 and the same argument as the one used in the proof of Lemma 3.1; cf. identity (3.3). Moreover, using the Hölder inequality, we have

$$\left| \int_{\mathbb{R}} (-\Lambda^\alpha w + w_{xx})(|v|^{p-2}v)\, dx \right| \leq (\|\Lambda^\alpha w\|_p + \|w_{xx}\|_p)\|v\|_p^{p-1}.$$

Consequently, (3.8) implies the following differential inequality:

$$\frac{d}{dt}\|v(t)\|_p^p \leq p\left(\|\Lambda^\alpha w(t)\|_p + \|w_{xx}(t)\|_p\right)\|v(t)\|_p^{p-1},$$

which, after integration, leads to

$$\|v(t)\|_p \leq \|v(t_0)\|_p + \int_{t_0}^t \|\Lambda^\alpha w(\tau)\|_p + \|w_{xx}(\tau)\|_p\, d\tau.$$

The proof is completed by the result stated in Lemma 3.2. □

Now, we are in a position to prove the main result of this paper.

Proof of Theorem 1.1. First, we consider the auxiliary solution $\widetilde{u} = \widetilde{u}(x,t)$ of the fractal Burgers equation (1.1) with the step-like initial condition (1.10). In this case, the measure $\widetilde{m} = (u_+ - u_-)\delta_0$ is nonnegative; hence by Theorem 2.3, $\widetilde{u}_x \geq 0$, and by Lemma 3.1,

$$\|u(t) - \widetilde{u}(t)\|_p \leq Ct^{-(1-1/p)/\alpha}\|u_0 - \widetilde{u}_0\|_1$$

for every $p \in [1,\infty]$ and all $t > 0$.

Next, we compare $\widetilde{u}$ with the smooth approximation of the rarefaction wave that is with the solution $w = w(x,t)$ of (2.20)–(2.21) (note that $\widetilde{u}_0 = w_0$). By Theorem 2.2 and Lemma 2.4, we obtain

$$\|\widetilde{u}_x(t)\|_\infty + \|w_x(t)\|_\infty \leq Ct^{-1}.$$

Moreover, using the Gagliardo–Nirenberg inequality

$$\|v\|_p \leq C\|v_x\|_\infty^a \|v\|_{p_0}^{1-a}, \tag{3.9}$$

valid for any $1 < p_0 < p \leq \infty$ and $a = (1/p_0 - 1/p)/(1 + 1/p_0)$, we have

$$\begin{aligned} \|\widetilde{u}(t) - w(t)\|_p &\leq C(\|\widetilde{u}_x(t)\|_\infty + \|w_x(t)\|_\infty)^a \|\widetilde{u}(t) - w(t)\|_{p_0}^{1-a} \\ &\leq Ct^{-a}\|\widetilde{u}(t) - w(t)\|_{p_0}^{1-a}. \end{aligned}$$

Choosing $p_0 = (3-\alpha)/(\alpha-1)$ (hence $a = [\alpha - 1 - (3-\alpha)/p]/2$), by Lemma 3.3, we conclude that $\|\widetilde{u}(t) - w(t)\|_p \le Ct^{-a}\log(2+t)$ for every $p \in (p_0, \infty]$. Here, we are allowed to use Lemma 3.3 because $\widetilde{u}_0 - w_0 \in L^1(\mathbb{R}) \cap L^\infty(\mathbb{R}) \subset L^p(\mathbb{R})$ for every $p \in [1,\infty]$.

Finally, it follows from Lemma 2.4 that the large time asymptotics of $w(t)$ is described in $L^p(\mathbb{R})$ by the rarefaction wave $w^R(x,t)$.

The proof is complete because for $1 < \alpha < 2$ we have $(1-1/p)/\alpha > (1-1/p)/2$. Moreover, since $1 < p_0 < p$, we have $(1-1/p)/2 > (1/p_0 - 1/p)/(1+1/p_0)$. $\square$

4. Additional comments and possible generalizations. Our main result is stated and shown in the simplest case of (1.1); however, several generalizations are possible.

First of all, the operator Λ^α can be replaced by the Lévy operator $\mathcal{L}$ which is a pseudodifferential operator defined by the symbol $a = a(\xi) \ge 0$, $\widehat{\mathcal{L}v}(\xi) = a(\xi)\widehat{v}(\xi)$. Here, the function $e^{-ta(\xi)}$ should be positive definite, so the symbol $a(\xi)$ can be represented by the Lévy–Khintchine formula in the Fourier variables

$$a(\xi) = ib\xi + Q(\xi) + \int_{\mathbb{R}} \left(1 - e^{-i\eta\xi} - i\eta\xi\, \mathbb{1}_{\{|\eta|<1\}}(\eta)\right) \Pi(d\eta). \tag{4.1}$$

Here, $b \in \mathbb{R}$ is fixed, $Q(\xi) = q\xi^2$ with some $q \ge 0$, and Π is a Borel measure such that $\Pi(\{0\}) = 0$ and $\int_{\mathbb{R}} \min(1, |\eta|^2)\,\Pi(d\eta) < \infty$.

Detailed analysis of conservation laws with the anomalous diffusion operator $\mathcal{L}$ is contained in [4, 5, 6]. Here, we would like to emphasize that the fundamental nature of the operator $\mathcal{L}$ is clear from the perspective of the probability theory. It represents the most general form of the generator of a stochastically continuous Markov process with independent and stationary increments. This fact was our basic motivation for the development of the theory presented above.

In order to show the convergence toward rarefaction waves of solutions of conservation laws with the Lévy operator, we need the counterparts of estimates (2.13)–(2.14) of the semigroup of linear operators $e^{-t\mathcal{L}}$ generated by $-\mathcal{L}$. They are valid, e.g., under the assumption that the symbol a of $\mathcal{L}$ has the form

$$a(\xi) = \ell|\xi|^\alpha + k(\xi), \tag{4.2}$$

where $\ell > 0$, $1 < \alpha \le 2$, and k is a symbol of another Lévy operator $\mathcal{K}$ such that

$$\lim_{\xi \to 0} \frac{k(\xi)}{|\xi|^\alpha} = 0. \tag{4.3}$$

The assumptions (4.2) and (4.3) are fulfilled, for example, by *multifractal diffusion operators*

$$\mathcal{L} = -a_0\partial_x^2 + \sum_{j=1}^{k} a_j(-\partial_x^2)^{\alpha_j/2}$$

with $a_0 \ge 0$, $a_j > 0$, $1 < \alpha_j < 2$, and $\alpha = \min_{1\le j\le k} \alpha_j$. We refer the reader to [5, 6] for the reasoning leading to the decay estimates of solutions of nonlinear problems with an operator $\mathcal{L}$ satisfying (4.2)–(4.3). That argument can be directly adapted to obtain counterparts of Theorem 2.2 and Lemma 3.1 with Λ^α replaced by $\mathcal{L}$. Note here that the L^p-L^q estimates of the semigroup $e^{-t\mathcal{L}}$ are equivalent to a certain Nash inequality; see [17, 5] and the references therein.

Our result also holds true if we replace the nonlinear term uu_x in (1.1) by $f(u)_x$ with a strictly convex C^2-function f (as in the paper of Il'in and Oleinik [11]) satisfying $f''(u) \geq \kappa$ for some fixed $\kappa > 0$ and all $u \in \mathbb{R}$. Under this assumption, we immediately generalize Theorem 2.2 and we obtain the decay estimate (2.3).

In order to show the counterpart of Lemma 3.1, we should use the assumption $f''(u) \geq \kappa$ and replace equalities (3.3) by the following (recall that $v = u - \widetilde{u}$):

$$\int_{\mathbb{R}} [f(u) - f(\widetilde{u})]_x |v|^{p-2} v \, dx \geq \kappa \left(1 - \frac{1}{p}\right) \int_{\mathbb{R}} \widetilde{u}_x |v|^p \, dx \geq 0.$$

This argument, however, is known and used systematically, e.g., in [24, inequality (3.5)] (see also [11, 20, 21, 23]); hence we skip the other details.

Acknowledgment. This paper was partially written while the first author was enjoying the hospitality and support of the Institute of Applied Physics and Computational Mathematics in Beijing.

Γ-CONVERGENCE OF POWER-LAW FUNCTIONALS, VARIATIONAL PRINCIPLES IN L^∞, AND APPLICATIONS*

MARIAN BOCEA† AND VINCENZO NESI‡

Abstract. Two Γ-convergence results for a general class of power-law functionals are obtained in the setting of $\mathcal{A}$-quasiconvexity. New variational principles in L^∞ are introduced, allowing for the description of the yield set in the context of a simplified model of polycrystal plasticity. A number of highly degenerate nonlinear partial differential equations arise as Aronsson equations associated with these variational principles.

Key words. $\mathcal{A}$-quasiconvexity, Aronsson equations, Γ-convergence, Euler–Lagrange equations, lower semicontinuity, dielectric breakdown, polycrystal plasticity, strength set, yield set, yield surface

DOI. 10.1137/060672388

1. Introduction.

One of the main motivations of this work is the development of a general theory that allows for the characterization of the yield set in the context of *polycrystal plasticity* by means of suitable variational principles in L^∞. From the mathematical point of view the results of the present paper cover two related but simpler problems pertaining to highly nonlinear conducting media. These can be seen as simplified versions of polycrystal plasticity in the context of antiplane shear (see [37]). We will now describe the physical motivations in the more familiar framework of polycrystal plasticity.

A *polycrystal* is a collection of single crystals (*grains*) bonded together in different orientations; the microstructure of the polycrystal, which consists of the shapes and orientations of the grains, is called the *texture* of the polycrystal. In addition to the material properties of the grains, the behavior of polycrystalline solids is highly influenced by their texture. Understanding how the behavior of a polycrystal depends on its texture is crucial from the technological point of view in that it provides important guidelines for specific material processing.

The *yield* of a single crystalline material is described by a closed convex subset K of the space of stresses $\mathbb{M}^{3\times3}_{\mathrm{sym}}$ (symmetric 3×3 real matrices); any stress field $\sigma : \Omega \to \mathbb{M}^{3\times3}_{\mathrm{sym}}$ in the crystal occupying the region $\Omega \subset \mathbb{R}^3$ is subject to the pointwise constraint

$$\sigma(x) \in K,\ x \in \Omega.$$

In the context of rigid perfectly plastic crystals the set K is called the *yield set*. Rigid perfectly plastic behavior is characterized by the fact that the crystal can only withstand stresses in the interior of the set K; i.e., the material does not exhibit plastic deformation when subject to a stress σ such that $\sigma(x) \in \mathrm{int}(K)$, $x \in \Omega$, but,

on the other hand, the material will deform at a certain strain rate when $\sigma(x) \in \partial K$ for some $x \in \Omega$. The boundary ∂K of the yield set is called the *yield surface*.

The texture of a polycrystal is described by a piecewise constant rotation-valued function $R : \Omega \to \mathrm{SO}(3)$, where $R(x)$ is constant in each grain and indicates the orientation of the grain which contains the point $x \in \Omega$. If the yield set of the reference single crystal is K, the stress in the polycrystal occupying the region $\Omega \subset \mathbb{R}^3$ must satisfy the constraint

$$\sigma(x) \in R(x)KR^T(x), \; x \in \Omega. \tag{1.1}$$

The effective behavior of the polycrystal is then described by the constraints induced on the average stress $\overline{\sigma} := \fint_\Omega \sigma(x)dx$; the set of all average stresses $\overline{\sigma}$ when σ satisfies the pointwise constraint (1.1) and the equilibrium equation,

$$\operatorname{div} \sigma = 0 \text{ in } \Omega, \tag{1.2}$$

is called the *yield set of the polycrystal*. Precisely,

$$K_{\text{eff}} := \left\{ \overline{\sigma} := \fint_\Omega \sigma(x)dx \; : \; (1.1) \text{ and } (1.2) \text{ hold} \right\}.$$

Yield in a crystalline solid is usually associated with a finite number of *slip systems* which depend on the atomic lattice, each determined by a pair (n_k, m_k) of orthogonal vectors, where n_k is the normal to the *slip plane* and m_k is the *direction of slip*. In this case, we have

$$K = \left\{ A \in \mathbb{M}^{3\times3}_{\text{sym}} \; : \; \langle A, \mu_k \rangle \le \tau_k^{\text{critical}}, k = 1, \ldots, s \right\},$$

where s stands for the number of slip systems, τ_k^{critical} is the *critical shear stress* for the kth slip system, and

$$\mu_k := \frac{1}{2}\left(m_k \otimes n_k + n_k \otimes m_k\right)$$

is the kth *slip tensor*. The goal of polycrystal plasticity is to describe the yield set K_{eff}, given K and some information on the texture of the polycrystal. The complexity of the problem has led to the introduction of alternative schemes designed to estimate the macroscopic response of polycrystals without solving the equilibrium equation (1.2) directly. The estimate introduced by Sachs [42] assumes that the stress is constant throughout the polycrystal, leading to

$$K_{\text{Sachs}} := \left\{ \sigma \in \mathbb{M}^{3\times3}_{\text{sym}} \; : \; (1.1) \text{ holds} \right\}.$$

On the other hand, the estimate introduced by Taylor [49] assumes that the strain rate is constant throughout the polycrystal, giving

$$K_{\text{Taylor}} := \left\{ \overline{\sigma} := \fint_\Omega \sigma(x)dx \; : \; (1.1) \text{ holds} \right\}.$$

Since

$$K_{\text{Sachs}} \subseteq K_{\text{eff}} \subseteq K_{\text{Taylor}},$$

it follows that the Sachs and Taylor estimates lead to bounds on the yield set K_{eff}. This was first recognized by Bishop and Hill [11]. In much more recent developments, Kohn and Little [37] studied in detail a simpler model working in particular in the context of antiplane shear. They showed that in two dimensions the Sachs bound is optimal and gave a better estimate for the Taylor bound. Goldsztein [30] improved the results in [37] by proposing a better estimate for K_{Taylor} having the same scaling law. In [31] he showed that this scaling law is essentially optimal. The corresponding problems in three dimensions for model problems involving gradients and divergence-free fields were addressed by Garroni and Kohn [27]. In both settings they found that the Sachs bound is optimal; in the case of gradients they provided an improved estimate for the Taylor bound which scales differently for certain reference crystals, while in the divergence-free case they proved that the Taylor bound has the optimal scaling law.

From the mathematical standpoint, polycrystal plasticity has been justified for many years by means of the dual of a $W^{1,1}$ problem. This formulation has been studied in a classical series of papers by Bouchittè and Suquet. We refer the reader to [12] for the original work and to [37] for a minimal overview. Much more recently, the study of these problems has been justified in a different way. The first paper in this direction is due to Garroni, Nesi, and Ponsiglione [28], where the authors considered first failure dielectric breakdown. Mathematically, they treated a case in which the variable is a gradient field. The main contribution is to show that the so-called *strength* or *yield* set can be characterized via Γ-convergence in an alternative way. Here we address a similar but mathematically distinct problem, namely, the characterization of effective yield sets defined in terms of divergence-free fields. We achieve this goal in the context of electrical resistivity in section 6 of the paper. We will comment later on the differences between this alternative point of view and the classical one; we point out that both the new and the classical derivations give rise to the same effective yield set, but the new derivation preserves some memory of the approximation that has been used to derive it. We refer the reader to sections 5 and 6 of the paper. For example, in the "gradient" case, treated in [28], one is naturally led to an interesting connection with the study of some generalizations of the infinity-Laplace equation

$$\Delta_\infty u := \sum_{i,j=1}^{N} \frac{\partial u}{\partial x_i} \frac{\partial u}{\partial x_j} \frac{\partial^2 u}{\partial x_i \partial x_j} = 0. \tag{1.3}$$

This equation has been introduced by Aronsson in his influential work in connection with the problem of minimal extensions of Lipschitz maps [2], [3], [4], [5], [6], and its study has received a great deal of attention in the last decade. An excellent account on this topic is given in the survey paper by Aronsson, Crandall, and Juutinen [7]. We also refer the reader to the recent work of Evans and Yu [24] for a review of some basic properties of the solution to (1.3), as well as for some new interesting results.

Let us go back to the main contribution of the present paper. It has long been recognized that in the mathematical study of materials the key question that one must understand is the interaction between *linear* partial differential equations (the balance laws) and *nonlinear* pointwise constraints (the constitutive laws). This is the underlying motivation for the general theory of compensated compactness as developed by Murat and Tartar (see, e.g., [39], [47], [48]). In this paper we generalize the Γ-convergence results of [28] to more general linear PDE constraints on the underlying fields, in the framework of $\mathcal{A}$-quasiconvexity (see [19], [25]). This allows us to consider situations which have not been studied so far, most notably the case of solenoidal fields (divergence-free fields), which is relevant to treating extreme resistivity. Actual plasticity would require an extra constraint, namely, one should consider divergence-free matrix fields which are symmetric. This further generalization does not seem to be a serious obstacle to the analysis, but it would require a rather long digression so we will address this issue elsewhere.

The paper is organized as follows. In section 2 we give the definition of $\mathcal{A}$-quasiconvexity, state a lower semicontinuity result of Fonseca and Müller [25], and recall the definition of De Giorgi's Γ-convergence. In section 3 we prove two Γ-convergence results for power-law functionals in the general setting of $\mathcal{A}$-quasiconvexity. Section 4 is devoted to specializing the abstract results of the previous section to two different special cases. The first one deals with curl-free fields, where we generalize results in [28] by making milder assumptions on the functionals under consideration. We focus on power-law-type materials and discuss the meaning of our results in the context of effective conductivity. In the second part of section 4 we specialize the Γ-convergence results of section 3 to the case where the underlying fields are divergence free. This leads to a new derivation, whose meaning is discussed in the context of effective resistivity. We conclude this section by briefly recalling the duality behind effective conductivity and effective resistivity, and we explain the connection with the literature treating bounds for effective properties of nonlinear composites in the context of constitutive laws of power-law type (see [28], [40], [41], [44], [45], [46]). Section 5 treats dielectric breakdown as a particular instance of our general results. We define the effective strength domain for electrically conducting media and explain the relation with the new variational principle and the associated Aronsson equation, leading to the study of the infinity-Laplace equation. In section 6 we define the effective strength set K_{eff} (which one may call yield set, with a slight abuse of language) in the context of electrical resistivity, we propose a new variational principle by means of a minimization problem in L^∞, and we provide the first characterization of K_{eff} in terms of this new object. We end the first part of section 6 by explaining some of the issues that remain to be addressed via homogenization. The new variational principle in L^∞ leads naturally to interesting new systems of partial differential equations which arise as the Aronsson equations associated with the supremal functionals under consideration. The formal derivation of these systems, as well as several remarks, are left for the second part of section 6.

2. Preliminaries. Let N, d, l be positive integers, $1 \leq p \leq +\infty$, and consider a family $A^{(1)}, A^{(2)}, \dots, A^{(N)} \in \operatorname{Lin}(\mathbb{R}^d; \mathbb{R}^l)$. We define $\mathcal{A} : L^p(\Omega; \mathbb{R}^d) \to W^{-1,p}(\Omega; \mathbb{R}^l)$ by

$$\mathcal{A}v := \sum_{i=1}^{N} A^{(i)} \frac{\partial v}{\partial x_i}, \tag{2.1}$$

where Ω is an open, bounded domain in $\mathbb{R}^N$. Note that each $A^{(i)}$ is represented by an $l \times d$ matrix, and $\frac{\partial v}{\partial x_i}(x)$ is represented by a d-dimensional column vector, so that each term $A^{(i)} \frac{\partial v}{\partial x_i}(x)$ is an l-dimensional column vector. Consider the operator $\mathbb{A} : \mathbb{R}^N \to \operatorname{Lin}(\mathbb{R}^d; \mathbb{R}^l)$, defined as a linear combination of the given family $A^{(1)}, A^{(2)}, \dots, A^{(N)}$ with real coefficients. Precisely, we set

$$\mathbb{A}(w) := \sum_{i=1}^{N} w_i A^{(i)},$$

where $w = (w_1, \ldots, w_N) \in \mathbb{R}^N$. In what follows we will assume that $\mathcal{A}$ satisfies the *constant rank property* (see [39]):

$$\text{there exists } r \in \mathbb{N} \text{ such that rank } \mathbb{A}(w) = r \text{ for all } w \in S^{N-1}. \tag{2.2}$$

The constant rank property plays a central role in the theory of compensated compactness developed by Murat [39] and Tartar [47], [48]. Situations where (2.2) fails are much less understood (see, e.g., [38]). In what follows, and throughout the paper, $Q := (0,1)^N$ is the unit cube in $\mathbb{R}^N$.

DEFINITION 2.1. *A function $g : \mathbb{R}^d \to \mathbb{R}$ is said to be $\mathcal{A}$-quasiconvex if*

$$g(A) \leq \int_Q g(A + w(x))dx$$

for all $A \in \mathbb{R}^d$ and all Q-periodic $w \in C^\infty(Q; \mathbb{R}^d)$ such that $\mathcal{A}(w) = 0$ and $\int_Q w(x)dx = 0$.

The notion of $\mathcal{A}$-quasiconvexity (without the assumption of periodicity of the test functions) has been first investigated by Dacorogna [19]. Under the assumption of constant rank property (2.2) of the operator $\mathcal{A}$, Fonseca and Müller have shown in [25] that if $\Omega \subset \mathbb{R}^N$ is an open, bounded set, $(u, v) : \Omega \to \mathbb{R}^m \times \mathbb{R}^d$ is measurable, and $g : \Omega \times \mathbb{R}^m \times \mathbb{R}^d \to \mathbb{R}$ is a normal integrand, then the $\mathcal{A}$-quasiconvexity of $g(x, u, \cdot)$ is a necessary and sufficient condition for the sequential lower semicontinuity of integrals of the form

$$(u, v) \mapsto \int_\Omega g(x, u(x), v(x))dx$$

along sequences that satisfy $u_n \to u$ in measure, $v_n \to v$ in L^p, and $\mathcal{A}v_n \to 0$ in $W^{-1,p}$. We will explicitly need only the sufficiency part of their result for $1 \leq p < +\infty$. Precisely, we have the following proposition.

PROPOSITION 2.2 (see [25, Theorem 3.7]). *Let $1 \leq p < +\infty$, and suppose that $g : \Omega \times \mathbb{R}^m \times \mathbb{R}^d \to [0, +\infty)$ is a normal integrand such that $z \mapsto g(x, u, z)$ is $\mathcal{A}$-quasiconvex and continuous for $\mathcal{L}^N$-a.e. $x \in \Omega$ and all $u \in \mathbb{R}^m$. Assume further that there exists a locally bounded function $a : \Omega \times \mathbb{R}^m \to [0, +\infty)$ such that*

$$0 \leq g(x, u, v) \leq a(x, u)(1 + |v|^p)$$

for $\mathcal{L}^N$-a.e. $x \in \Omega$ and all $(u, v) \in \mathbb{R}^m \times \mathbb{R}^d$. If

$$u_n \to u \textit{ in measure},$$

$$v_n \rightharpoonup v \textit{ in } L^p(\Omega; \mathbb{R}^d), \tag{2.3}$$

and

$$\mathcal{A}v_n \to 0 \textit{ in } W^{-1,p}(\Omega; \mathbb{R}^l), \tag{2.4}$$

then

$$\int_\Omega g(x, u(x), v(x))dx \leq \liminf_{n\to\infty} \int_\Omega g(x, u_n(x), v_n(x))dx. \tag{2.5}$$

We remark that if $p = +\infty$, then (2.5) still holds provided that in (2.3) the weak convergence of v_n to v in $L^p(\Omega; \mathbb{R}^d)$ is replaced by the weak* convergence in

$L^\infty(\Omega;\mathbb{R}^d)$, and in (2.4) $\mathcal{A}v_n \to 0$ in $W^{-1,p}(\Omega;\mathbb{R}^l)$ is replaced by $\mathcal{A}v_n \equiv 0$. In this case the growth condition on g is not needed (see [25]). We end this section by recalling the definition of De Giorgi's Γ-convergence (see [21], [22]) in metric spaces. For a comprehensive introduction to the subject we refer the reader to the monograph by Dal Maso [20]. See also [13].

DEFINITION 2.3. *Let X be a metric space. A sequence $\{I_p\}$ of functionals $I_p : X \to \overline{\mathbb{R}} := \mathbb{R}\cup\{+\infty\}$ is said to $\Gamma(X)$-converge to $I : X \to \overline{\mathbb{R}}$ (we write $\Gamma(X) - \lim_{p\to\infty} I_p = I$) if the following hold:*

(i) *for every $u \in X$ and $\{u_p\} \subset X$ such that $u_p \to u$ in X, we have*

$$I(u) \leq \liminf_{p\to\infty} I_p(u_p);$$

(ii) *for every $u \in X$ there exists a sequence $\{u_p\} \subset X$ such that $u_p \to u$ in X and*

$$I(u) = \lim_{p\to\infty} I_p(u_p).$$

The sequence $\{u_p\}$ in (ii) *is called a* recovery sequence *for the Γ-limit.*

3. Γ-convergence results in a general setting. In this section we prove two Γ-convergence results. The first one should be seen as a justification of a simplified plasticity model by a nonclassical route. Let Ω be an open, bounded domain in $\mathbb{R}^N (N \geq 1)$, and let $f : \Omega \times \mathbb{R}^d \to [0,+\infty)$ be a Carathéodory integrand satisfying the following hypotheses:

$$f(x,\cdot) \text{ is } \mathcal{A}\text{-quasiconvex for } \mathcal{L}^N\text{-a.e. } x \in \Omega; \tag{3.1}$$

there exist constants $c, C > 0$ such that

$$c|v| \leq f(x,v) \leq C\,(1+|v|) \text{ for } \mathcal{L}^N\text{-a.e. } x \in \Omega \text{ and all } v \in \mathbb{R}^d. \tag{3.2}$$

Let $I_p : L^1(\Omega;\mathbb{R}^d) \to [0,+\infty]$ be defined by

$$I_p(w) := \begin{cases} \dfrac{1}{p}\displaystyle\int_\Omega f(x,w(x))^p dx & \text{if } w \in L^p(\Omega;\mathbb{R}^d)\cap \ker\mathcal{A}, \\ +\infty & \text{otherwise.} \end{cases}$$

THEOREM 3.1. *Define $I_\infty : L^1(\Omega;\mathbb{R}^d) \to [0,+\infty]$ by*

$$I_\infty(w) := \begin{cases} 0 & \text{if } f(x,w(x)) \leq 1 \text{ for } \mathcal{L}^N\text{-a.e. } x\in\Omega,\ \mathcal{A}w = 0, \\ +\infty & \text{otherwise.} \end{cases}$$

Then

(i) *for every $w \in L^1(\Omega;\mathbb{R}^d)$ and $\{w_p\} \subset L^1(\Omega;\mathbb{R}^d)$ such that $w_p \rightharpoonup w$ weakly in $L^1(\Omega;\mathbb{R}^d)$, we have*

$$I_\infty(w) \leq \liminf_{p\to\infty} I_p(w_p); \tag{3.3}$$

(ii) *for every $w \in L^1(\Omega;\mathbb{R}^d)$, there exists a sequence $\{w_p\} \subset L^1(\Omega;\mathbb{R}^d)$ such that $w_p \to w$ in $L^1(\Omega;\mathbb{R}^d)$, and*

$$\limsup_{p\to\infty} I_p(w_p) \leq I_\infty(w). \tag{3.4}$$

In particular,

$$\Gamma(L^1(\Omega;\mathbb{R}^d)) - \lim_{p\to\infty} I_p = I_\infty.$$

Proof. Let $\{w_p\} \subset L^1(\Omega;\mathbb{R}^d)$ be such that $w_p \rightharpoonup w$ weakly in $L^1(\Omega;\mathbb{R}^d)$. We will show that (3.3) holds. In view of the coercivity condition in (3.2), we may assume, without loss of generality, that

$$w_p \in L^p(\Omega;\mathbb{R}^d),\ \ \mathcal{A}w_p = 0, \tag{3.5}$$

and

$$\liminf_{p\to\infty} I_p(w_p) = \lim_{p\to\infty} I_p(w_p) < +\infty. \tag{3.6}$$

Let $x \in \Omega$ be a Lebesgue point for $f(\cdot, w(\cdot)) \in L^1(\Omega)$. For any ball $B(x,r) \subset \Omega$ and for p sufficiently large, we have

$$\begin{aligned}\int_{B(x,r)} f(y, w_p(y))dy &\le \left(\int_\Omega (f(y,w_p(y)))^p\, dy\right)^{1/p} \left(\mathcal{L}^N(B(x,r))\right)^{(p-1)/p}\\ &= (I_p(w_p))^{1/p}\, p^{1/p} \left(\mathcal{L}^N(B(x,r))\right)^{(p-1)/p},\end{aligned}$$

where we have used Hölder's inequality. Letting $p \to \infty$, we obtain that

$$\limsup_{p\to\infty} \int_{B(x,r)} f(y, w_p(y))dy \le \mathcal{L}^N(B(x,r)). \tag{3.7}$$

Taking (3.1), (3.2), and (3.5) into account, we may apply Proposition 2.2 and we deduce that

$$\int_{B(x,r)} f(y, w(y))dy \le \liminf_{p\to\infty} \int_{B(x,r)} f(y, w_p(y))dy.$$

Thus, in view of (3.7),

$$\frac{1}{\mathcal{L}^N(B(x,r))} \int_{B(x,r)} f(y, w(y))dy \le 1.$$

Since $\mathcal{L}^N$-a.e. $x \in \Omega$ is a Lebesgue point for $f(\cdot, w(\cdot))$, passing to the limit $r \to 0^+$ in the last equation yields

$$f(x, w(x)) \le 1 \quad \text{for } \mathcal{L}^N\text{-a.e. } x \in \Omega.$$

It follows that $I_\infty(w) = 0$, and this implies that (3.3) holds. To complete the proof, we need to show that for any $w \in L^1(\Omega;\mathbb{R}^d)$, there exists a recovery sequence for the Γ-limit, that is, a sequence $\{w_p\} \subset L^1(\Omega;\mathbb{R}^d)$ with $w_p \to w$ in $L^1(\Omega;\mathbb{R}^d)$ and such that (3.4) holds.

To this aim, assume, without loss of generality, that $I_\infty(w) = 0$. Thus, $f(x, w(x)) \le 1$ for $\mathcal{L}^N$-a.e. $x \in \Omega$ and $\mathcal{A}w = 0$. By (3.2), $w \in L^\infty(\Omega;\mathbb{R}^d)$, and thus we may choose $\{w_p\} = \{w\}$ as a recovery sequence. Indeed,

$$I_p(w_p) = \frac{1}{p}\int_\Omega f(x, w(x))^p dx \le \frac{1}{p}\mathcal{L}^N(\Omega),$$

which implies that $\lim_{p\to\infty} I_p(w_p) = 0 = I_\infty(w)$. We conclude that (3.4) holds. ☐

We will now describe an alternative derivation of the model. The goal is to obtain a limiting functional which is less degenerate than I_∞. We follow [28], where a similar approach was used in the gradient case.

Define $J_p : L^1(\Omega;\mathbb{R}^d) \to [0,+\infty]$ by

$$J_p(w) := \begin{cases} \left(\displaystyle\int_\Omega f(x,w(x))^p dx\right)^{1/p} & \text{if } w \in L^p(\Omega;\mathbb{R}^d) \cap \ker\mathcal{A}, \\ +\infty & \text{otherwise.} \end{cases}$$

THEOREM 3.2. *Let $J_\infty : L^1(\Omega;\mathbb{R}^d) \to [0,+\infty]$ be defined by*

$$J_\infty(w) := \begin{cases} \operatorname{ess\,sup}_{x\in\Omega} f(x,w(x)) & \textit{if } w \in L^\infty(\Omega;\mathbb{R}^d) \cap \ker\mathcal{A}, \\ +\infty & \textit{otherwise.} \end{cases}$$

Then

(i) *for every $w \in L^1(\Omega;\mathbb{R}^d)$ and $\{w_p\} \subset L^1(\Omega;\mathbb{R}^d)$ such that $w_p \rightharpoonup w$ weakly in $L^1(\Omega;\mathbb{R}^d)$, we have*

$$J_\infty(w) \le \liminf_{p\to\infty} J_p(w_p); \tag{3.8}$$

(ii) *for every $w \in L^1(\Omega;\mathbb{R}^d)$, there exists a sequence $\{w_p\} \subset L^1(\Omega;\mathbb{R}^d)$ such that $w_p \to w$ in $L^1(\Omega;\mathbb{R}^d)$ and*

$$\limsup_{p\to\infty} J_p(w_p) \le J_\infty(w). \tag{3.9}$$

In particular,

$$\Gamma(L^1(\Omega;\mathbb{R}^d)) - \lim_{p\to\infty} J_p = J_\infty.$$

Proof. Let $\{w_p\} \subset L^1(\Omega;\mathbb{R}^d)$ be such that $w_p \rightharpoonup w$ weakly in $L^1(\Omega;\mathbb{R}^d)$. We need to show that (3.8) holds. Extract a subsequence (not relabeled) such that

$$w_p \in L^p(\Omega;\mathbb{R}^d),\ \mathcal{A}w_p = 0, \tag{3.10}$$

and

$$\liminf_{p\to\infty} J_p(w_p) = \lim_{p\to\infty} J_p(w_p) < +\infty. \tag{3.11}$$

In view of (3.1) and Jensen's inequality, for any $q \ge 1$, $f(x,\cdot)^q$ is $\mathcal{A}$-quasiconvex for $\mathcal{L}^N$-a.e. $x \in \Omega$. In addition, by (3.2),

$$c^q|v|^q \le f(x,v)^q \le 2^{q-1}C^q\,(1+|v|^q) \tag{3.12}$$

for $\mathcal{L}^N$-a.e. $x \in \Omega$ and all $v \in \mathbb{R}^d$. For any $p > q > 1$, we have

$$\|w_p\|_{L^q(\Omega;\mathbb{R}^d)} \le C J_p(w_p),$$

where $C > 0$ is a constant which depends only on $\mathcal{L}^N(\Omega)$. Thus, by (3.11), $\{w_p\}$ is bounded in $L^q(\Omega;\mathbb{R}^d)$. Up to a subsequence (not relabeled) $w_p \rightharpoonup w$ weakly in

$L^q(\Omega;\mathbb{R}^d)$, as $p \to \infty$. Taking (3.10) and (3.12) into account and in view of the $\mathcal{A}$-quasiconvexity and continuity of $f(x,\cdot)^q$ for $\mathcal{L}^N$-a.e. $x \in \Omega$, we are again in position to apply Proposition 2.2. We obtain

$$\int_\Omega f(x,w(x))^q dx \le \liminf_{p\to\infty} \int_\Omega f(x,w_p(x))^q dx. \tag{3.13}$$

On the other hand, by means of elementary arguments, we have that

$$\left(\liminf_{p\to\infty} \int_\Omega f(x,w_p(x))^q dx\right)^{1/q} \le \limsup_{p\to\infty} \left(\int_\Omega f(x,w_p(x))^q dx\right)^{1/q}. \tag{3.14}$$

In view of (3.13) and (3.14), we deduce that

$$J_q(w) \le \limsup_{p\to\infty} J_q(w_p) \le \mathcal{L}^N(\Omega)^{\frac{1}{q}} \lim_{p\to\infty} J_p(w_p) \tag{3.15}$$

for all $q \ge 1$, where the last inequality follows from the fact that

$$J_q(w_p) \le \mathcal{L}^N(\Omega)^{\frac{1}{q}-\frac{1}{p}} J_p(w_p).$$

By a localization argument similar to the one used in the proof of Theorem 3.1 it can be shown that $f(\cdot,w(\cdot)) \in L^\infty(\Omega)$. It follows that $J_q(w) \to \|f(\cdot,w(\cdot))\|_{L^\infty(\Omega)}$ as $q \to \infty$. Thus, sending $q \to \infty$ in (3.15) we obtain that (3.8) holds.

It remains to prove (3.9). Let $w \in L^1(\Omega;\mathbb{R}^d)$, and consider the sequence $\{w_p\} \subset L^1(\Omega;\mathbb{R}^d)$, where $w_p := w$ for all $p \in \mathbb{N}$. To verify that (3.9) holds we assume, without loss of generality, that $w \in L^\infty(\Omega;\mathbb{R}^d)$ and $\mathcal{A}w = 0$, so that $J_\infty(w) < +\infty$. We have

$$\limsup_{p\to\infty} J_p(w_p) = \limsup_{p\to\infty} \|f(\cdot,w(\cdot))\|_{L^p(\Omega)} = J_\infty(w),$$

which concludes the proof. ∎

4. Effective conductivity and resistivity. In this section we specialize the previous results to cover effective conductivity and effective resistivity for the important class of power-law materials. In this context, the use of convex duality has been exploited by many authors both from the mathematical point of view (see, e.g., [23] and [26]) and from the point of view of applications to materials science, more specifically to the issue of bounding effective behavior in this nonlinear setting (see [44], [45], [46]).

4.1. Conductivity: The curl-free case. In this section we consider the situation where the differential constraint $\mathcal{A}w = 0$ reduces to requiring $w : \Omega \subset \mathbb{R}^N \to \mathbb{R}^N$ to satisfy curl $w = 0$, i.e.,

$$\frac{\partial w_k}{\partial x_i} - \frac{\partial w_i}{\partial x_k} = 0,\ 1 \le i,k \le N.$$

In this case $d = N$, and we may rewrite these partial differential equations as $\mathcal{A}w = 0$, where

$$\mathcal{A}w := \sum_{r=1}^N A^{(r)} \frac{\partial w}{\partial x_r}$$

with $A^{(r)} \in \mathrm{Lin}(\mathbb{R}^N, \mathbb{R}^{N^2})$ given by

$$A^{(r)}_{(ik),p} := \delta_{ri}\delta_{pk} - \delta_{rk}\delta_{pi},\ 1 \le i,k,p,r \le N.$$

It can be shown that $\mathcal{A}$ satisfies the constant rank property (see (2.2) and [25]). In fact, for every $w \in S^{N-1}$, $\ker(\mathbb{A}(w)) = \mathrm{span}\{w\}$, and thus we have that $\dim(\ker(\mathbb{A}(w))) = 1$.

Let $f : \Omega \times \mathbb{R}^N \to [0, +\infty)$ be defined by $f(x, v) := \langle \Sigma(x)v, v\rangle^{\frac{1}{2}}$, where $\Sigma \in L^\infty\left(\Omega; \mathbb{M}^{N\times N}_{\mathrm{sym}}\right)$ satisfies the ellipticity bounds

$$\frac{1}{K}|\xi|^2 \le \langle \Sigma(x)\xi, \xi\rangle \le K|\xi|^2 \tag{4.1}$$

for $\mathcal{L}^N$-a.e. $x \in \Omega$ and all $\xi \in \mathbb{R}^N$, where $K \ge 1$ is a real constant. Note that f satisfies our hypotheses (3.1) and (3.2). With these particular choices one can recover the results of Garroni, Nesi, and Ponsiglione [28] as corollaries of Theorems 3.1 and 3.2.

Corollary 4.1 (see [28, Proposition 2.1]). *Let $G_p : L^1(\Omega; \mathbb{R}^d) \to [0, +\infty]$ be defined by*

$$G_p(u) := \begin{cases} \dfrac{1}{p}\displaystyle\int_\Omega \langle \Sigma(x)\nabla u(x), \nabla u(x)\rangle^{\frac{p}{2}}\,dx & \text{if } u \in W^{1,p}(\Omega), \\ +\infty & \text{otherwise.} \end{cases}$$

Then

$$\Gamma(L^1(\Omega; \mathbb{R}^d)) - \lim_{p\to\infty} G_p = G_\infty,$$

where $G_\infty : L^1(\Omega; \mathbb{R}^d) \to [0, +\infty]$ is given by

$$G_\infty(u) := \begin{cases} 0 & \text{if } \left|\Sigma^{\frac{1}{2}}(x)\nabla u(x)\right| \le 1 \text{ for } \mathcal{L}^N\text{-a.e. } x \in \Omega, \\ +\infty & \text{otherwise.} \end{cases}$$

Corollary 4.2 (see [28, Proposition 2.6]). *Define $F_p : L^1(\Omega; \mathbb{R}^d) \to [0, +\infty]$ by*

$$F_p(u) := \begin{cases} \left(\displaystyle\int_\Omega \langle \Sigma(x)\nabla u(x), \nabla u(x)\rangle^{\frac{p}{2}}\,dx\right)^{1/p} & \text{if } u \in W^{1,p}(\Omega), \\ +\infty & \text{otherwise.} \end{cases}$$

Then

$$\Gamma(L^1(\Omega; \mathbb{R}^d)) - \lim_{p\to\infty} F_p = F_\infty,$$

where $F_\infty : L^1(\Omega; \mathbb{R}^d) \to [0, +\infty]$ is given by

$$F_\infty(u) := \begin{cases} \left\|\Sigma^{\frac{1}{2}}\nabla u\right\|_{L^\infty(\Omega)} & \text{if } u \in W^{1,\infty}(\Omega), \\ +\infty & \text{otherwise.} \end{cases}$$

In [28] the authors are interested in the case with isotropic phases and therefore they set $\Sigma(x) = \lambda^2(x)\mathrm{Id},\ x \in \Omega$, for some $\lambda \in L^\infty(\Omega)$.

Let us now focus on the periodic case for simplicity. In what follows, for $1 \le p \le +\infty$, we denote by $L^p_\sharp(Q)$ and $W^{1,p}_\sharp(Q)$ the spaces of Q-periodic functions belonging to $L^p_{\rm loc}(\mathbb{R}^N)$ and $W^{1,p}_{\rm loc}(\mathbb{R}^N)$, respectively, where $Q := (0,1)^N$ is the unit cube in $\mathbb{R}^N$. We assume that Σ is defined on Q, and we define the effective conductivity as follows:

$$g_p(\xi) := \inf \left\{ \mathcal{G}_p(u) \,:\, u \in W^{1,p}_{\sharp}(Q) + \xi \cdot x,\ \int_Q u(y)\,dy = 0 \right\}, \tag{4.2}$$

where

$$\mathcal{G}_p(u) := \int_Q \langle \Sigma(x)\nabla u(x), \nabla u(x)\rangle^{\frac{p}{2}}\,dx. \tag{4.3}$$

Next, we make the (very strong) assumption that g_p depends on ξ only through its norm. This gives

$$g_p(\xi) = (h_{p,\rm eff})^{\frac{p}{2}}|\xi|^p \tag{4.4}$$

for some number $h_{p,\rm eff}$ which will be interpreted as the effective conductivity. Let us remark for later purposes that the minimizer of (4.2) (see also (4.3)) is a weak solution of the anisotropic p-Laplace-type equation

$$\begin{cases} \operatorname{div}\left(\langle \Sigma(x)\nabla u(x), \nabla u(x)\rangle^{\frac{p-2}{2}} \Sigma(x)\nabla u(x)\right) = 0 & \text{if } x \in Q, \\ u \in W^{1,p}_{\sharp}(Q) + \xi \cdot x. \end{cases} \tag{4.5}$$

4.2. Resistivity: The divergence-free case. Now we consider the situation where the differential constraint $\mathcal{A}w = 0$ becomes div $w = 0$. In this case $d = N$, and we take

$$A^{(i)}_j := \delta_{ij},\ 1 \le i,j \le N.$$

Note that the constant rank condition is again satisfied, since for every $w \in S^{N-1}$ we have

$$\ker(\mathbb{A}(w)) = \left\{ v \in \mathbb{R}^N \ :\ \sum_{i=1}^N A^{(i)} w_i(v) = 0 \right\} = \{ v \in \mathbb{R}^N \ :\ w \cdot v = 0\},$$

which gives rank $(\mathbb{A}(w)) = \dim(\ker \mathbb{A}(w)) = N - 1$.

Let $f : \Omega \times \mathbb{R}^N \to [0, +\infty)$ be defined by $f(x,v) := \langle A(x)v, v\rangle^{\frac{1}{2}}$, where $A \in L^\infty\left(\Omega; \mathbb{M}^{N\times N}_{\rm sym}\right)$ satisfies the ellipticity bounds

$$\frac{1}{K}|\xi|^2 \le \langle A(x)\xi, \xi\rangle \le K|\xi|^2 \tag{4.6}$$

for $\mathcal{L}^N$-a.e. $x \in \Omega$ and all $\xi \in \mathbb{R}^N$, where $K \ge 1$ is a real constant. Note that f satisfies (3.1) and (3.2).

With these particular choices, we obtain the following corollaries of Theorems 3.1 and 3.2.

COROLLARY 4.3. *Let $T_q, T_\infty : L^1(\Omega;\mathbb{R}^N) \to [0, +\infty]$ be defined by*

$$T_q(b) := \begin{cases} \dfrac{1}{q}\displaystyle\int_\Omega \langle A(x)b(x), b(x)\rangle^{\frac{q}{2}}\,dx & \textit{if } b \in L^q(\Omega;\mathbb{R}^N),\ \operatorname{div} b = 0, \\ +\infty & \textit{otherwise} \end{cases}$$

and

$$T_\infty(b) := \begin{cases} 0 & \textit{if } \langle A(x)b(x), b(x)\rangle \le 1 \textit{ for } \mathcal{L}^N\textit{-a.e. } x \in \Omega, \\ +\infty & \textit{otherwise.} \end{cases}$$

Then

$$\Gamma(L^1(\Omega;\mathbb{R}^N)) - \lim_{q\to\infty} T_q = T_\infty.$$

Corollary 4.4. *Define* $S_q, S_\infty : L^1(\Omega;\mathbb{R}^N) \to [0,+\infty]$ *by*

$$S_q(b) := \begin{cases} \left(\int_\Omega \langle A(x)b(x), b(x)\rangle^{\frac{q}{2}}\, dx\right)^{1/q} & \textit{if } b \in L^q(\Omega;\mathbb{R}^N),\ \mathrm{div}\ b = 0, \\ +\infty & \textit{otherwise} \end{cases}$$

and

$$S_\infty(b) := \begin{cases} \|\langle Ab, b\rangle^{\frac{1}{2}}\|_{L^\infty(\Omega)} & \textit{if } b \in L^\infty(\Omega;\mathbb{R}^N),\ \mathrm{div}\ b = 0, \\ +\infty & \textit{otherwise.} \end{cases}$$

Then

$$\Gamma(L^1(\Omega;\mathbb{R}^N)) - \lim_{q\to\infty} S_q = S_\infty.$$

Let us now focus again on the periodic case, for simplicity. We assume that A is defined on the unit cube $Q = (0,1)^N$ and define the effective resistivity as follows:

$$t_q(\eta) := \inf\left\{\mathcal{T}_q(b) \,:\, b \in L^q_\sharp(Q;\mathbb{R}^N) + \eta,\ \mathrm{div}\ b = 0\right\}, \tag{4.7}$$

where

$$\mathcal{T}_q(b) := \int_Q \langle \Sigma^{-1}(x)b(x), b(x)\rangle^{\frac{q}{2}}\, dx. \tag{4.8}$$

Note that we have chosen

$$A \equiv \Sigma^{-1}, \tag{4.9}$$

where $\Sigma \in L^\infty\left(Q;\mathbb{M}^{N\times N}_{\mathrm{sym}}\right)$ is such that (4.1) holds. As in the previous case, we assume the dependence of $t_q(\eta)$ upon η is only through its norm. In this way, one has that

$$t_q(\eta) = (\rho_{q,\mathrm{eff}})^{\frac{q}{2}}|\eta|^q \tag{4.10}$$

for some number $\rho_{q,\mathrm{eff}}$ which we interpret as effective resistivity. The crucial fact is that, with the definitions (4.4) and (4.10), one has

$$h_{p,\mathrm{eff}} = \frac{1}{\rho_{q,\mathrm{eff}}}, \tag{4.11}$$

where $q = p'$ is the Hölder conjugate exponent of p, i.e., $\frac{1}{p} + \frac{1}{q} = 1$. Let us briefly explain where condition (4.11) comes from. We need the following well-known observations. Given $p \in (1,+\infty)$, if u_p solves (4.5), then the vector field

$$b_p := \langle \Sigma\nabla u_p, \nabla u_p\rangle^{\frac{p-2}{2}}\Sigma\nabla u_p \tag{4.12}$$

belongs to $L^q(Q;\mathbb{R}^N)$ and it is divergence free. Moreover, $b_p \in L^\infty_\sharp(Q;\mathbb{R}^N) + \eta$ for some vector $\eta \in \mathbb{R}^N$ which can be explicitly computed in terms of ξ and $h_{p,\mathrm{eff}}$. The Euler–Lagrange equations associated with (4.7) (see also (4.8)) are given by

$$\begin{cases} \operatorname{curl}\left(\left\langle \Sigma^{-1}b, b\right\rangle^{\frac{q-2}{2}} \Sigma^{-1}b\right) = 0 & \text{in } Q, \\ \operatorname{div} b = 0, & \text{in } Q, \\ b \in L^\infty_\sharp(Q;\mathbb{R}^N) + \eta. \end{cases} \tag{4.13}$$

We will derive such systems in the next section, where we need to address the issue of the limiting case $q \to +\infty$. It is easy to check that b_p does indeed solve the system (4.13) if one defines the vector η by

$$\eta := h_{p,\mathrm{eff}}^{\frac{p}{2}} |\xi|^{p-2}\xi. \tag{4.14}$$

In addition, one has the pointwise relation

$$\langle \Sigma\nabla u_p, \nabla u_p\rangle^{\frac{p}{2}} = \langle \Sigma^{-1}b_p, b_p\rangle^{\frac{q}{2}}, \tag{4.15}$$

which implies that

$$\int_Q \langle \Sigma\nabla u_p, \nabla u_p\rangle^{\frac{p}{2}}\, dx = \int_Q \langle \Sigma^{-1}b_p, b_p\rangle^{\frac{q}{2}}\, dx.$$

The above equation is equivalent to

$$h_{p,\mathrm{eff}}^{\frac{p}{2}} |\xi|^p = \rho_{q,\mathrm{eff}}^{\frac{q}{2}} |\eta|^q,$$

which, in view of (4.14), gives (4.11). The above calculations explain why in the literature about bounding nonlinear energies one looks simultaneously at both a variational principle in terms of gradient fields and one in terms of divergence-free fields. A lower bound on the effective conductivity relative to the exponent p is equivalent to an upper bound on the effective resistivity relative to the exponent q, and conversely.

5. Power-law and dielectric breakdown. In this section we formulate the strategy for our new definition of the effective yield set. This issue will be given a clear physical interpretation. However, as we shall see, a number of mathematical questions arise. We explain our results by specializing them to electrically conducting materials, since in this context our analysis is complete. We follow in part the exposition in [28], focusing on the simplest possible nontrivial situation.

5.1. Effective strength set for conducting materials. Suppose that we are given a material that occupies the domain $\Omega := \Omega_1 \cup \Omega_2$ which, for simplicity, will be taken to be the unit cube $Q = (0,1)^N$ $(N \geq 2)$. Given $0 < \alpha_1 < \alpha_2$, let $\alpha \in L^\infty(\Omega;[\alpha_1,\alpha_2])$ and, for $p > 1$ and $\xi \in \mathbb{R}^N$, consider

$$F_p(u) := \left(\frac{1}{p}\int_\Omega \alpha(x)^{\frac{p}{2}} |\nabla u(x)|^p dx\right)^{\frac{1}{p}} \tag{5.1}$$

and set

$$f_p(\xi) := \inf\left\{F_p(u) \,:\, u \in W^{1,p}_\sharp(\Omega) + \xi\cdot x\right\}. \tag{5.2}$$

We regard $f_p(\xi)$ as the overall (or effective) conductivity of the body in the direction $\xi \in \mathbb{R}^N$. With the notation of section 4, if we assume isotropy, we have

$$f_p(\xi) = \left(\frac{h_{p,\mathrm{eff}}^{\frac{1}{2}}}{p^{\frac{1}{p}}} \right) |\xi|. \tag{5.3}$$

The terminology is as follows. The material occupying the domain Ω is a two-phase composite whose conductivity is locally isotropic, given by the measurable function $\alpha(x) = \chi_{\Omega_1}(x)\alpha_1 + \chi_{\Omega_2}(x)\alpha_2$. The unknown is the "microgeometry," i.e., the set Ω_1, which is completely determined by its characteristic function χ_{Ω_1} with $\chi_{\Omega_2} = 1 - \chi_{\Omega_1}$. It is assumed that the relative volume fractions θ_1 and $\theta_2 = 1 - \theta_1$ are given with

$$\theta_1 = \frac{\mathcal{L}^N(\Omega_1)}{\mathcal{L}^N(\Omega)}. \tag{5.4}$$

The goal is to characterize (for every vector ξ) the closure of the range of $f_p(\xi)$ as χ_1 varies within the class of characteristic functions of measurable subsets Ω_1 of Ω satisfying (5.4). This kind of material is often of power-law type and has been studied extensively. The typical approach, in a large part of the engineering literature (see, for instance, the influential work of Hutchinson [32]), is to consider p as a "fitting parameter." In other words, one takes the viewpoint that due to too many nonlinear effects, it is hard to choose a priori the right "constitutive law." For given p, one would have the electric field of the form $e(x) = \nabla u(x)$ and the nonlinear response $b(x) = \alpha(x)^{\frac{p}{2}} |\nabla u(x)|^{p-2} \nabla u(x)$ with the constitutive law div $b = 0$. In other words, $u \in W^{1,p}_{\mathrm{loc}}(\Omega)$ and it solves (4.5) exactly as the minimizers of (4.3).

For given "microgeometry" (i.e., for given sets Ω_1 and Ω_2) one obtains the real number $f_p(\xi)$ given by (5.2) and (5.3). However, while the microgeometry is kept fixed, $f_p(\xi)$ varies with p (monotonically, by Jensen's inequality). Therefore, if one can measure the effective response of the material, one can choose p in such a way that will make the theoretical answer as accurate as possible. With this in mind, one can immediately understand why long ago people have been trying to take limits as $p \to \infty$ for this type of problem. Actually, as in, for instance, [32], calculations are often performed for "large" p. In [32, p. 109], "large" p means $p = 8$, and $p = +\infty$ is "extrapolated."

The mathematical approach has been quite different. We refer the reader to the work of Bouchitté and Suquet (see, e.g., [12]). A more direct approach has been proposed in [28], and this is the ancestor of what we do in the present paper. The idea is to pass to the limit as $p \to \infty$ in the sense of Γ-convergence. In particular, this new idea makes it possible to rigorously justify statements which were previously taken for granted. In fact, one achieves more naturally a very direct link between the minimizers of (5.2) and (at least one) minimizer of the new variational problem associated with F_∞ (the Γ-limit). Let us briefly review the classical approach versus the new one.

Within the classical approach, one considers $\alpha \in L^\infty(\Omega; [\alpha_1, \alpha_2])$ as above, $\lambda := \alpha^{\frac{1}{2}}$, and defines, for $u \in W^{1,\infty}(\Omega)$,

$$G_\infty(u) := \begin{cases} 0 & \text{if } |\lambda(x)\nabla u(x)| \le 1 \text{ for } \mathcal{L}^N\text{-a.e. } x \in \Omega, \\ +\infty & \text{otherwise} \end{cases}$$

and

$$g_\infty(\xi) := \inf \left\{ G_\infty(u) \,:\, u \in W^{1,\infty}_\sharp(\Omega) + \xi \cdot x \right\}. \tag{5.5}$$

Then the "strength" set (which is called yield set in plasticity) K_{eff} can be defined by

$$K_{\text{eff}} := \{\xi \in \mathbb{R}^N \,:\, g_\infty(\xi) = 0\}. \tag{5.6}$$

In this approach, the link between the minimizers of F_p and those of G_∞ is unclear. In particular it is not clear, a priori, whether $\lim_{p\to\infty} f_p(\xi)$ (which exists, by monotonicity) is indeed related to the value $g_\infty(\xi)$. The new approach is more transparent and direct: define

$$F_\infty(u) := ||\lambda \nabla u||_{L^\infty(\Omega)} \tag{5.7}$$

and

$$f_\infty(\xi) := \inf\left\{F_\infty(u) \,:\, u \in W^{1,\infty}_\sharp(\Omega) + \xi \cdot x\right\}. \tag{5.8}$$

As a direct consequence of Corollary 4.2 (see also [28]) one has

$$K_{\text{eff}} = \{\xi \in \mathbb{R}^N \,:\, f_\infty(\xi) \le 1\}. \tag{5.9}$$

Moreover, up to a subsequence, the minimizers of F_p converge to *some* minimizer of F_∞. In addition, $p \mapsto f_p(\xi)$ is continuous.

Another important advantage of this approach is that it strongly suggests an interesting connection with the infinity-Laplace equation. This is highlighted in the next subsection.

5.2. Infinity-harmonic functions. Let us explain this in the context developed in [28]. Assume that the material under consideration fills a regular body Ω, and that it is not only isotropic but also homogeneous. In this case $\alpha(x) \equiv \lambda(x) \equiv 1$, and the functional F_∞ in (5.7) becomes

$$F_\infty(u) = ||\nabla u||_{L^\infty(\Omega)}. \tag{5.10}$$

The problem of minimizing (in a properly interpreted sense) this functional represents the prototype for a series of related problems belonging to the emerging area of *calculus of variations in* L^∞. In this context, the functional F_∞ is strongly connected to the infinity-Laplace equation (1.3)—its associated Euler–Lagrange (Aronsson) equation, whose solutions must be understood in the viscosity sense. We will give more details shortly. However, before doing this, let us remark that these solutions lose many of the properties enjoyed by the solutions of the Euler–Lagrange equations associated with the functionals F_p. From the physical perspective, these phenomena are much less surprising. We refer the reader to sections 3 and 4 of [28] and to [27] for some examples.

The minimization of the functional F_p, subject to given boundary conditions, leads in the usual way to the associated Euler–Lagrange equation. It was first observed by Aronsson [2], [3], [4], [5], [6] in the one-dimensional case that minimization problems (properly interpreted) for supremal functionals such as (5.10) also lead to partial differential equations. We outline below, for the convenience of the reader, the formal derivation of the Aronsson equation associated with F_∞, as a limiting ($p \to \infty$) case of the Euler–Lagrange equations associated with F_p. For $\lambda \equiv 1$, this has been made rigorous in [10], where it was shown that weak solutions of the Euler–Lagrange equations associated with the p-Dirichlet integrals converge (up to a subsequence) to *viscosity* solutions of the limiting equation.

For $p \geq 1$ and when λ is smooth, minimizers of $F_p(u) := \frac{1}{p}\int_\Omega |\lambda(x)\nabla u(x)|^p dx$ in $W^{1,p}(\Omega)$, subject to given boundary conditions, solve the associated Euler–Lagrange equation

$$-\mathrm{div}\left(\lambda^p|\nabla u|^{p-2}\nabla u\right) = 0, \tag{5.11}$$

which may be rewritten as

$$\frac{p-2}{2}\lambda^{p-4}|\nabla u|^{p-4}\langle\nabla(\lambda^2|\nabla u|^2), \lambda^2\nabla u\rangle + \lambda^{p-2}|\nabla u|^{p-2}\mathrm{div}(\lambda^2\nabla u) = 0. \tag{5.12}$$

For $p > 2$, after division by $\frac{p-2}{2}\lambda^{p-4}|\nabla u|^{p-4}$, (5.12) becomes

$$\langle\nabla(\lambda^2|\nabla u|^2), \lambda^2\nabla u\rangle + \frac{2}{p-2}\lambda^2|\nabla u|^2\mathrm{div}(\lambda^2\nabla u) = 0. \tag{5.13}$$

Note that at least the necessary condition that must hold in order to divide by $\frac{p-2}{2}\lambda^{p-4}|\nabla u|^{p-4}$ in (5.12) is satisfied because the left-hand side of (5.13) also vanishes when either $\lambda = 0$ or $\nabla u = 0$. Formally letting $p \to +\infty$, we obtain the equation

$$\langle\nabla(\lambda^2|\nabla u|^2), \lambda^2\nabla u\rangle = 0. \tag{5.14}$$

In the general case, where F_p is given by the formula in Corollary 4.2 with Σ not necessarily isotropic, (5.14) should be replaced by

$$\langle\nabla\langle\Sigma\nabla u, \nabla u\rangle, \Sigma\nabla u\rangle = 0. \tag{5.15}$$

When $\lambda \equiv 1$ in (5.14), (5.11) reduces to the p-Laplace equation

$$\Delta_p u := \mathrm{div}(|\nabla u|^{p-2}\nabla u) = 0, \tag{5.16}$$

while (5.14) becomes

$$\Delta_\infty u = 0, \tag{5.17}$$

where Δ_∞ denotes the infinity-Laplace operator, which on smooth, real-valued functions u is defined by the formula

$$\Delta_\infty u := \sum_{i,j=1}^{N} \frac{\partial u}{\partial x_i}\frac{\partial u}{\partial x_j}\frac{\partial^2 u}{\partial x_i \partial x_j}. \tag{5.18}$$

The infinity-Laplace equation (5.17) has been introduced in the fundamental work of Aronsson [4], [5] as the candidate for the Euler–Lagrange equation associated with a properly interpreted minimization problem for supremal functionals (5.10). Precisely, we say that $u \in W^{1,\infty}(\Omega) \cap C(\overline{\Omega})$ is an *absolutely minimizing Lipschitz extension* (abbreviated AMLE) if

$$\|\nabla u\|_{L^\infty(D)} \leq \|\nabla v\|_{L^\infty(D)}$$

whenever $D \subset \Omega$ is open, and $v \in W^{1,\infty}(D) \cap C(\overline{D})$ is such that $u_{|\partial D} = v_{|\partial D}$. Aronsson showed that a necessary and sufficient condition for a smooth u to be an AMLE is that u solves (5.17) in the classical sense. On the other hand, he also noticed that (5.17) does not always have a classical solution. Motivated by the work in [4], [5], Jensen showed in [33] that every AMLE u is indeed a solution of the infinity-Laplace equation in the viscosity sense (see [18], [17]). We recall that u is called a viscosity solution of the infinity-Laplace equation if it is simultaneously a viscosity subsolution and a viscosity supersolution of (5.17):

(i) (u is a viscosity subsolution of (5.17)) for every local maximum point $x \in \Omega$ of $u - \varphi$, where φ is C^2 in some neighborhood of x, we have $-\Delta_\infty \varphi(x) \leq 0$;

(ii) (u is a viscosity supersolution of (5.17)) for every local minimum point $x \in \Omega$ of $u - \varphi$, where φ is C^2 in some neighborhood of x, we have $-\Delta_\infty \varphi(x) \geq 0$.

In addition, Jensen proved the maximum principle for solutions of (5.17) and, consequently, settled the crucial question regarding uniqueness of solutions. Generalizations of these ideas to minimization problems for generic supremal functionals of the form $\|f(\cdot, u(\cdot), \nabla u(\cdot))\|_{L^\infty(\Omega)}$ have been considered by Juutinen [34] and Barron, Jensen, and Wang [9], among others. We need to emphasize here that in order to be truly relevant for the study of composite materials, a theory would need to be valid with no smoothness assumptions on the coefficients. To our knowledge, such a theory is not yet available. A recent work by Juutinen [35] describes a promising approach.

6. The effective strength set for electrical resistivity. In this section we explore some applications of the Γ-convergence results obtained in section 3. Our results are motivated by the study of the yield set in polycrystal plasticity. Here, we address the mathematically very similar problem of electrical resistivity. The mathematical gap consists of the fact that in the former problem one should consider divergence-free matrix fields which are constrained to be symmetric, a constraint which we are allowed to neglect in the latter. Handling the extra constraint necessary to treat polycrystal plasticity does not seem to be a serious obstacle to the analysis, but it would require a rather long digression so we will address this issue elsewhere. We begin by providing a characterization of the effective strength set in the context of electrical resistivity in terms of the new L^∞ functionals acting on divergence-free fields. A formal derivation of the Aronsson equations associated with our new variational principle follows.

6.1. Effective strength for resistive materials. In this subsection the goal is to characterize the effective strength set K_{eff}, defined by (6.7), in the context of electrical resistivity. This is achieved in Proposition 6.2. Consider

$$j_q^{\text{eff}}(\eta) := \inf \left\{ \left(\int_Q f(x, b(x) + \eta)^q dx \right)^{1/q} : b \in L^q(Q; \mathbb{R}^N), \int_Q b \, dx = 0, \operatorname{div} b = 0 \right\}. \tag{6.1}$$

We note that the infimum in (6.1) is attained. This is an easy consequence of the lower semicontinuity result stated in Proposition 2.2.

PROPOSITION 6.1. *Let $f : Q \times \mathbb{R}^N \to \mathbb{R}$ be a Carathéodory integrand satisfying* (3.1) *and* (3.2). *For any $\eta \in \mathbb{R}^N$, $j_q^{\text{eff}}(\eta)$ converges to $j_\infty^{\text{eff}}(\eta)$ given by*

$$j_\infty^{\text{eff}}(\eta) := \inf \left\{ \operatorname*{ess\,sup}_{x \in Q} f(x, b(x) + \eta) : \ b \in L^\infty(Q; \mathbb{R}^N), \int_Q b \, dx = 0, \operatorname{div} b = 0 \right\}. \tag{6.2}$$

Moreover, if $b_q^{(\eta)}$ is a minimizer of the problem (6.1), *then, up to a subsequence, the sequence $\{b_q^{(\eta)}\}$ converges weakly in $L^1(Q; \mathbb{R}^N)$ to a minimizer $b^{(\eta)}$ of* (6.2).

Proposition 6.1 can be seen as a consequence of standard arguments regarding the convergence of minima and minimizers of Γ-converging functionals (see, e.g., [14] and [20]). For the convenience of the reader, we provide below a more elementary self-contained proof.

Proof. Let $\eta \in \mathbb{R}^N$, and let $b_q^{(\eta)} \in L^q(Q;\mathbb{R}^N)$ be such that $\int_Q b_q^{(\eta)}\, dx = 0$, $\operatorname{div} b_q^{(\eta)} = 0$, and

$$\left(\int_Q f(x, b_q^{(\eta)}(x) + \eta)^q dx\right)^{1/q} = j_q^{\text{eff}}(\eta). \tag{6.3}$$

We distinguish two cases.

Case 1.

$$\limsup_{q\to\infty} \left(\int_Q f(x, b_q^{(\eta)}(x) + \eta)^q dx\right)^{1/q} = +\infty.$$

We claim that in this case $j_\infty^{\text{eff}}(\eta) = +\infty$ as well. Indeed, if this were not the case, there would exist $b \in L^\infty(Q;\mathbb{R}^N)$ such that $\int_Q b\, dx = 0$, $\operatorname{div} b = 0$, and

$$\operatorname*{ess\,sup}_{x\in Q} f(x, b(x) + \eta) < j_\infty^{\text{eff}}(\eta) + 1 < +\infty.$$

Since b is admissible for $j_q^{\text{eff}}(\eta)$, we have

$$\left(\int_Q f(x, b_q^{(\eta)}(x) + \eta)^q dx\right)^{1/q} \leq \left(\int_Q f(x, b(x) + \eta)^q dx\right)^{1/q}$$

$$\leq \left(\int_Q \left(\operatorname*{ess\,sup}_{x\in Q} f(x, b(x) + \eta)\right)^q dx\right)^{1/q} \leq j_\infty^{\text{eff}}(\eta) + 1.$$

It follows that

$$\limsup_{q\to\infty} \left(\int_Q f(x, b_q^{(\eta)}(x) + \eta)^q dx\right)^{1/q} \leq j_\infty^{\text{eff}}(\eta) + 1,$$

a contradiction.

Case 2.

$$\limsup_{q\to\infty} \left(\int_Q f(x, b_q^{(\eta)}(x) + \eta)^q dx\right)^{1/q} < +\infty.$$

In view of the coercivity condition in (3.2), the sequence $\{b_q^{(\eta)} + \eta\}$ is bounded in $L^q(Q;\mathbb{R}^N)$. Extract a subsequence (not relabeled) such that $b_q^{(\eta)} \rightharpoonup b^{(\eta)}$ weakly in $L^1(Q;\mathbb{R}^N)$ with $\operatorname{div} b^{(\eta)} = 0$ and $\int_Q b^{(\eta)} dx = 0$. By Theorem 3.2, we deduce that

$$J_\infty(b^{(\eta)} + \eta) \leq \liminf_{q\to\infty} \left(\int_Q f(x, b_q^{(\eta)}(x) + \eta)^q dx\right)^{1/q} < +\infty. \tag{6.4}$$

In particular, $b^{(\eta)} \in L^\infty(Q;\mathbb{R}^N)$. We have

$$\begin{aligned}\limsup_{q\to\infty} j_q^{\rm eff}(\eta) &= \limsup_{q\to\infty}\left(\int_Q f(x, b_q^{(\eta)}(x)+\eta)^q dx\right)^{1/q}\\ &\le \limsup_{q\to\infty}\left(\int_Q f(x, b^{(\eta)}(x)+\eta)^q dx\right)^{1/q} = \operatorname*{ess\,sup}_{x\in Q} f(x, b^{(\eta)}(x)+\eta)\\ &\le \liminf_{q\to\infty} j_q^{\rm eff}(\eta),\end{aligned}$$

where we have used (6.3) and (6.4). Thus, $\lim_{q\to\infty} j_q^{\rm eff}(\eta)$ exists, and

$$\operatorname*{ess\,sup}_{x\in Q} f(x, b^{(\eta)}(x)+\eta) = \lim_{q\to\infty} j_q^{\rm eff}(\eta).$$

It remains to show that

$$\operatorname*{ess\,sup}_{x\in Q} f(x, b^{(\eta)}(x)+\eta) = j_\infty^{\rm eff}(\eta). \tag{6.5}$$

Clearly, $j_\infty^{\rm eff}(\eta) \le \operatorname{ess\,sup}_{x\in Q} f(x, b^{(\eta)}(x)+\eta)$. To show the converse inequality, consider $b \in L^\infty(Q;\mathbb{R}^N)$ such that div $b = 0$ and $\int_Q b\; dx = 0$. We have

$$\begin{aligned}\operatorname*{ess\,sup}_{x\in Q} f(x, b(x)+\eta) &= \lim_{q\to\infty}\left(\int_Q f(x, b(x)+\eta)^q dx\right)^{1/q}\\ &\ge \lim_{q\to\infty} j_q^{\rm eff}(\eta) = \operatorname*{ess\,sup}_{x\in Q} f(x, b^{(\eta)}(x)+\eta).\end{aligned}$$

Passing to the infimum over all fields b satisfying the admissibility conditions, we obtain that $j_\infty^{\rm eff}(\eta) \ge \operatorname{ess\,sup}_{x\in Q} f(x, b^{(\eta)}(x)+\eta)$. It follows that (6.5) holds. ∎

Consider now the situation where the pointwise constraint on the stress (current) may be written in the form

$$\sigma(x) \in \left\{\eta \in \mathbb{R}^N \;:\; f(x,\eta) \le 1\right\}, \tag{6.6}$$

where $f : Q \times \mathbb{R}^N \to \mathbb{R}$ satisfies our hypotheses (3.1) and (3.2). In the context of (first failure) models of dielectric breakdown for composites made of two isotropic phases, considered by Garroni, Nesi, and Ponsiglione in [28], the constraint (6.6) is replaced by the requirement that the electric field ∇u satisfy $\nabla u(x) \in K(x)$, where

$$K(x) = \left\{\eta \in \mathbb{R}^2 \;:\; \lambda(x)|\eta| \le 1\right\}$$

with $\lambda(x)$ being a combination of the characteristic functions of the phases. Thus, in that case, $K(x)$ is a disc whose radius varies from point to point. Such a model is concerned with electrical conductivity, and therefore the relevant fields are curl free. In dimension $N \ge 3$, if one wants to model electrical resistivity, then the right differential constraint is that the relevant fields are divergence free. In view of the pointwise constraint (6.6), the yield set of the polycrystal becomes

$$K_{\text{eff}} = \Bigg\{\eta \in \mathbb{R}^N \ : \ \text{there exists } \sigma \in L^\infty(Q;\mathbb{R}^N) \text{ such that } \eta = \int_Q \sigma(x)dx,$$
$$\text{div } \sigma = 0, f(x,\sigma(x)) \leq 1, \mathcal{L}^N\text{-a.e. } x \in Q\Bigg\}$$
$$= \Bigg\{\eta \in \mathbb{R}^N \ : \ \text{there exists } \sigma \in L^\infty(Q;\mathbb{R}^N) \text{ such that } \int_Q \sigma(x)dx = 0,$$
$$\text{div } \sigma = 0, f(x,\sigma(x)+\eta) \leq 1, \mathcal{L}^N\text{-a.e. } x \in Q\Bigg\}. \tag{6.7}$$

We are now in position to describe K_{eff} by means of the L^∞ variational principle (6.2).

PROPOSITION 6.2. *Let $N \in \{2,3\}$, and let $f : Q \times \mathbb{R}^N \to \mathbb{R}$ be a Carathéodory function satisfying* (3.1) *and* (3.2). *The yield set of a conducting polycrystal whose current (stress) σ satisfies the pointwise constraint* (6.6) *at almost every point and the equilibrium equation* div $\sigma = 0$ *is described by*

$$K_{\text{eff}} = \left\{\eta \in \mathbb{R}^N \ : \ j_\infty^{\text{eff}}(\eta) \leq 1\right\}. \tag{6.8}$$

Proof. Let $\eta \in K_{\text{eff}}$. By (6.7), there exists $\sigma \in L^\infty(Q;\mathbb{R}^N)$ such that $\int_Q \sigma(x)dx = 0$, div $\sigma = 0$, and with $f(x,\sigma(x)+\eta) \leq 1$ for $\mathcal{L}^N$-a.e. $x \in Q$. We obtain that $j_\infty^{\text{eff}}(\eta) \leq \operatorname{ess\,sup}_{x\in Q} f(x,\sigma(x)+\eta) \leq 1$. Conversely, let $\eta \in \mathbb{R}^N$ be such that

$$j_\infty^{\text{eff}}(\eta) \leq 1. \tag{6.9}$$

Let $\{\sigma_n\} \subset L^\infty(Q;\mathbb{R}^N)$ be a sequence such that div $\sigma_n = 0$, $\int_Q \sigma_n(x)dx = 0$ for any $n \in \mathbb{N}$, and

$$\lim_{n\to\infty} \operatorname*{ess\,sup}_{x\in Q} f(x,\sigma_n(x)+\eta) = j_\infty^{\text{eff}}(\eta). \tag{6.10}$$

Taking (3.2) into account, we may extract a subsequence of $\{\sigma_n\}$ (not relabeled) such that $\sigma_n \rightharpoonup \sigma$ weakly* in $L^\infty(Q;\mathbb{R}^N)$, with div $\sigma = 0$, and $\int_Q \sigma(x)dx = 0$. Let $x \in Q$ be a Lebesgue point for $f(\cdot,\sigma(\cdot)+\eta)$. By (3.1), and in view of Proposition 2.2, we have that

$$\int_{B(x,r)} f(y,\sigma(y)+\eta)dy \leq \liminf_{n\to\infty} \int_{B(x,r)} f(y,\sigma_n(y)+\eta)dy$$

for sufficiently small $r > 0$. Thus, (6.10) yields

$$\frac{1}{\mathcal{L}^N(B(x,r))} \int_{B(x,r)} f(y,\sigma(y)+\eta)dy \leq j_\infty^{\text{eff}}(\eta).$$

Letting $r \to 0^+$, and since a.e. point $x \in Q$ is a Lebesgue point for $f(\cdot,\sigma(\cdot)+\eta)$, we deduce that $f(x,\sigma(x)+\eta) \leq j_\infty^{\text{eff}}(\eta)$ for $\mathcal{L}^N$-a.e. $x \in Q$. Taking (6.9) into account, we deduce that $\eta \in K_{\text{eff}}$. Thus, (6.8) holds. ∎

Let us remark that, although our new definition of K_{eff} provided by Proposition 6.2 is novel, the study of bounds on the effective strength set in this context is not. Kohn and Little [37] considered the case of antiplane shear in the two-dimensional case, and there the corresponding sets $K(x)$ are rectangles whose orientation varies from point to point. In this case their analysis is equivalently performed on both curl-free fields and symmetrized gradients. A similar study is considered in [27], where some interesting new bounds are proved in three dimensions for both gradients and divergence-free fields.

An interesting open question is whether j_∞^{eff}, which enters the expression of K_{eff} in (6.8), can be recovered in the general case as a relevant energy density via homogenization. Let us assume that $f : \mathbb{R}^N \times \mathbb{R}^d \to \mathbb{R}$ is a Carathéodory function, $(0,1)^N$-periodic in its first variable. For $\varepsilon > 0$, define $J_{p,\varepsilon} : L^1(\Omega;\mathbb{R}^d) \to [0,+\infty]$ by

$$J_{p,\varepsilon}(v) := \begin{cases} \left(\int_\Omega f\left(\frac{x}{\varepsilon}, v(x)\right)^p dx\right)^{1/p} & \text{if } v \in L^p(\Omega;\mathbb{R}^d) \cap \ker\mathcal{A}, \\ +\infty & \text{otherwise,} \end{cases}$$

where $\mathcal{A}$ is a constant rank operator (see (2.1)). If $f(x,\cdot)$ is $\mathcal{A}$-quasiconvex and if (3.2) holds we have, in view of Theorem 3.2, that $J_{p,\varepsilon}$ $\Gamma(L^1(\Omega;\mathbb{R}^d))$-converges as $p \to \infty$ to $J_{\infty,\varepsilon} : L^1(\Omega;\mathbb{R}^d) \to [0,+\infty]$ defined by

$$J_\varepsilon(u;\Omega) := \begin{cases} \operatorname*{ess\,sup}_{x\in\Omega} f\left(\frac{x}{\varepsilon}, v(x)\right) & \text{if } v \in L^\infty(\Omega;\mathbb{R}^d) \cap \ker\mathcal{A}, \\ +\infty & \text{otherwise.} \end{cases}$$

A first step toward answering the above question is to decide whether the Γ-limit (as $\varepsilon \to 0^+$) of F_ε with respect to the weak* topology of $L^\infty(\Omega;\mathbb{R}^d)$ may itself be written in supremal form. If this is the case, under which assumptions on f is j_∞^{eff} the supremand of the Γ-limit? General homogenization and relaxation results for integral functionals in the context of $\mathcal{A}$-quasiconvexity have been studied by Braides, Fonseca, and Leoni in [15]. We also refer the reader to the recent paper by Ansini and Garroni [1] where, in the divergence-free case $\mathcal{A}v = \operatorname{div} v$, some of the general arguments of [15] are simplified and more explicit constructions are given. Except for some recent progress in the unconstrained case and in the curl-free case (see, e.g., [29]), the corresponding questions for supremal functionals are yet to be addressed. We remark that the condition on f which should be relevant in this context is the necessary and sufficient condition for the weak* lower semicontinuity in $L^\infty(\Omega;\mathbb{R}^d)$ of supremal functionals of the type

$$v \;\mapsto\; \operatorname*{ess\,sup}_{x\in\Omega} f(x, v(x)).$$

For the general case of constant rank PDE constraints on the fields v such a condition has not yet been identified. In the unconstrained scalar case, which corresponds to $\mathcal{A} \equiv 0$, it is known (see Barron, Jensen, and Wang [8]) that the necessary and sufficient condition for lower semicontinuity is the *level set convexity* of $f(x,\cdot)$, that is, for $\mathcal{L}^N$-a.e. $x \in \Omega$ and every $u \in \mathbb{R}^m$, the sets $\{v \in \mathbb{R}^d : f(x,v) \le \gamma\}$ are convex for any choice of $\gamma \in \mathbb{R}$. For the case $v = \nabla u$ in a vectorial setting, corresponding to the particular choice $\mathcal{A} = 0 \Leftrightarrow \operatorname{curl} u = 0$, the necessary and sufficient condition for the lower semicontinuity of the functional $W^{1,\infty}(\Omega;\mathbb{M}^{m\times N}) \ni u \mapsto \operatorname{ess\,sup}_{x\in\Omega} f(x,\nabla u(x))$ with respect to the weak* topology in $W^{1,\infty}(\Omega;\mathbb{M}^{m\times N})$ has been identified in [8] as being the *strong Morrey quasiconvexity* of f in the last variable. Let $Q = (0,1)^N$. A Borel measurable map $g : \mathbb{M}^{m\times N} \to \mathbb{R}$ is said to be strong Morrey quasiconvex if for any $\varepsilon > 0$, each $A \in \mathbb{M}^{m\times N}$, and any $K > 0$, there exists $\delta = \delta(\varepsilon, K, A) > 0$ such that if $\varphi \in W^{1,\infty}(Q;\mathbb{R}^m)$ satisfies

$$\|\nabla\varphi\|_{L^\infty(Q;\mathbb{M}^{m\times N})} \le K, \quad \max_{x\in\partial Q} |\varphi(x)| \le \delta,$$

then

$$g(A) \le \operatorname*{ess\,sup}_{x\in Q} g(A + \nabla\varphi(x)) + \varepsilon.$$

In the curl-free case the question of whether the corresponding j_∞^{eff} arises directly as a relevant energy density via homogenization has been answered affirmatively by Briani, Garroni, and Prinari in [16] under the assumption of level set convexity on $f(x,\cdot)$.

6.2. The new Aronsson equations suggested by power-law resistivity. In what follows we will focus on Corollary 4.4, and motivated by the results of the previous subsection we derive the Euler–Lagrange equation associated with the minimization of S_q. Next we identify, via a formal limiting procedure as $q \to \infty$, the candidate for the Euler–Lagrange equation (the Aronsson equation) corresponding to the minimization problem of the Γ-limit S_∞.

For $q \ge 1$ and A smooth, any minimizer b of S_q subject to appropriate boundary conditions must satisfy

$$S_q(b) \le S_q(b + t\varphi)$$

for any $t \in \mathbb{R}$ and any $\varphi \in C_c^\infty(\Omega;\mathbb{R}^N)$ such that div $\varphi = 0$ in Ω. Thus, for any such φ, we must have

$$\frac{\mathrm{d}}{\mathrm{d}t} S_q(b + t\varphi)_{|t=0} = 0. \tag{6.11}$$

Since

$$\begin{aligned}
&\frac{\mathrm{d}}{\mathrm{d}t} S_q(b + t\varphi)\\
&\quad = \frac{1}{q}\left(\int_\Omega \langle Ab + tA\varphi, b + t\varphi\rangle^{\frac{q}{2}}\, dx\right)^{\frac{1}{q}-1} \frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega \langle Ab + tA\varphi, b + t\varphi\rangle^{\frac{q}{2}}\, dx\\
&\quad = \frac{1}{2}\left(\int_\Omega \langle Ab + tA\varphi, b + t\varphi\rangle^{\frac{q}{2}}\, dx\right)^{\frac{1}{q}-1}\\
&\qquad \times \int_\Omega \langle Ab + tA\varphi, b + t\varphi\rangle^{\frac{q-2}{2}} \Big(\langle A\varphi, b\rangle + \langle Ab, \varphi\rangle + 2t\langle A\varphi, \varphi\rangle\Big) dx,
\end{aligned}$$

(6.11) becomes

$$\int_\Omega \Big\langle \langle A(x)b(x), b(x)\rangle^{\frac{q-2}{2}} \left(\left(A^T(x) + A(x)\right) b(x)\right), \varphi(x)\Big\rangle\, dx = 0 \tag{6.12}$$

for all $\varphi \in C_c^\infty(\Omega;\mathbb{R}^N)$, where A^T stands for the transpose of A.

Testing in (6.12) with $\varphi = \text{curl}\,\xi$, for $\xi \in C_c^\infty(\Omega)$, we find that b must satisfy the system

$$\begin{cases} \text{curl}\left[\langle Ab,b\rangle^{\frac{q-2}{2}}\left(A^T+A\right)b\right]=0 & \text{in } \Omega,\\ \text{div}\; b=0 & \text{in } \Omega \end{cases} \tag{6.13}$$

in the sense of distributions.

We now focus on the physically more relevant case $N=3$. Note that we may rewrite the left-hand side of the first equation in (6.13) as

$$\begin{aligned} &\text{curl}\left[\langle Ab,b\rangle^{\frac{q-2}{2}}\left(A^T+A\right)b\right]\\ &\quad=\langle Ab,b\rangle^{\frac{q-2}{2}}\text{curl}\left[\left(A^T+A\right)b\right]+\left(\frac{q-2}{2}\langle Ab,b\rangle^{\frac{q-4}{2}}\nabla\langle Ab,b\rangle\right)\wedge\left(A^T+A\right)b\\ &\quad=\langle Ab,b\rangle^{\frac{q-2}{2}}\text{curl}\left[\left(A^T+A\right)b\right]\\ &\qquad+\frac{q-2}{2}\langle Ab,b\rangle^{\frac{q-4}{2}}\left(\left([D(Ab)]^T b+[Db]^T Ab\right)\wedge\left(A^T+A\right)b\right), \end{aligned}$$

where $u\wedge v := (u_2v_3-u_3v_2, u_3v_1-u_1v_3, u_1v_2-u_2v_1)$ is the exterior (cross) product of $u=(u_1,u_2,u_3)$ and $v=(v_1,v_2,v_3)$ in $\mathbb{R}^3$.

Thus, for $q>4$, we may rewrite the system (6.13) as

$$\begin{cases} \left([D(Ab)]^T b+[Db]^T Ab\right)\wedge\left(A^T+A\right)b & \\ \qquad +\frac{2}{q-2}\langle Ab,b\rangle\text{curl}\left[\left(A^T+A\right)b\right]=0 & \text{in } \Omega,\\ \text{div}\; b=0 & \text{in } \Omega \end{cases} \tag{6.14}$$

after formally dividing the first equation in (6.13) by $\frac{q-2}{2}\langle Ab,b\rangle^{\frac{q-4}{2}}$. Note that at least the necessary condition which must hold in order to perform the division is satisfied, since on the set where $\langle Ab,b\rangle=0$ the resulting expression also vanishes.

The limiting system as $q\to\infty$ reads

$$\begin{cases} \left([D(Ab)]^T b+[Db]^T Ab\right)\wedge\left(A^T+A\right)b=0 & \text{in } \Omega,\\ \text{div}\; b=0 & \text{in } \Omega. \end{cases} \tag{6.15}$$

In the isotropic and homogeneous case, where A is taken to be the identity matrix in $\mathbb{M}^{3\times 3}$, the systems (6.14) and (6.15) become

$$\begin{cases} \left([Db]^T b\right)\wedge b+\frac{1}{q-2}|b|^2\text{curl}\; b=0 & \text{in } \Omega,\\ \text{div}\; b=0 & \text{in } \Omega \end{cases} \tag{6.16}$$

and

$$\begin{cases} \left([Db]^T b\right)\wedge b=0 & \text{in } \Omega,\\ \text{div}\; b=0 & \text{in } \Omega, \end{cases} \tag{6.17}$$

respectively. Thus, smooth solutions of (6.17) are solenoidal vector fields b whose values at $x \in \Omega$ are eigenvectors of $[Db(x)]^T$. Equivalently, (6.17) can be written as

$$\begin{cases} b \wedge \nabla |b|^2 = 0 & \text{in } \Omega, \\ \operatorname{div} b = 0 & \text{in } \Omega. \end{cases} \tag{6.18}$$

Comparing with the curl-free situation, the system (6.13) (in the isotropic, homogeneous case $A = \mathrm{Id} \in \mathbb{M}^{N \times N}$) can be viewed as being dual to the p-Laplace equation (5.16) which reduces to the usual Laplace equation $\Delta u = 0$ (u is *harmonic*) when $p = 2$. Similarly, if $q = 2$, (6.13) becomes (again, take $A = \mathrm{Id} \in \mathbb{M}^{N \times N}$)

$$\begin{cases} \operatorname{curl} b = 0 & \text{in } \Omega, \\ \operatorname{div} b = 0 & \text{in } \Omega. \end{cases} \tag{6.19}$$

Equivalently, with $b(x_1, \ldots, x_N) = (b_1(x_1, \ldots, x_N), \ldots, b_N(x_1, \ldots, x_N))$, this is a Riesz system of partial differential equations

$$\begin{cases} \frac{\partial b_i}{\partial x_j} = \frac{\partial b_j}{\partial x_i} \ (i, j = 1, \ldots, N) & \text{in } \Omega, \\ \sum_{i=1}^N \frac{\partial b_i}{\partial x_i} = 0 & \text{in } \Omega, \end{cases}$$

a generalized Cauchy–Riemann system (see Stein and Weiss [43]). Indeed, in the two-dimensional case (6.19) is, simply, the system of Cauchy–Riemann equations

$$\begin{cases} \frac{\partial b_2}{\partial x_1} = \frac{\partial b_1}{\partial x_2} & \text{in } \Omega, \\ \frac{\partial b_2}{\partial x_2} = -\frac{\partial b_1}{\partial x_1} & \text{in } \Omega. \end{cases} \tag{6.20}$$

In this case $b_1 - ib_2$ is an analytic function of $z = x_1 + ix_2$, and $b = (b_1, b_2)$ is the gradient of a harmonic function in the region Ω. Vector-valued functions $b = (b_1, \ldots, b_N) : \Omega \subset \mathbb{R}^N \to \mathbb{R}^N$ which are gradients of harmonic functions in Ω are called *generalized analytic* [43].

Viscosity solutions of the infinity-Laplace equation (5.17) arising in the curl-free case are called *infinity-harmonic functions*. In view of the duality described above, we will loosely refer to the solutions of (6.17) as *infinity analytic* (although the notion of solution to (6.17) will later need to be understood in an appropriate sense). We conjecture that the system (6.17) (or, equivalently, (6.18)) is the correct "Aronsson equation" associated with the minimization of the supremal functional

$$b \ \mapsto \ \operatorname*{ess\,sup}_{x \in \Omega} |b(x)| \tag{6.21}$$

considered on divergence-free fields b. However, many basic questions about the system (6.17) will need to be answered in order to justify this properly. For example, is it true that, in the spirit of the results available in the curl-free case, absolute (local) minimizers of (6.21) are infinity analytic? In particular, in which sense do absolute minimizers solve the system (6.17)? Are they the unique solution of this system? Unlike in the curl-free case, where one shows that absolute minimizers of $u \mapsto \operatorname{ess\,sup}_{x \in \Omega} |\nabla u(x)|$ are solutions to the infinity-Laplace equation in the viscosity sense (note that here u is a scalar function), the method of viscosity solutions may not be the right tool for the study of (6.17) (whose solutions must be vector fields). To overcome this difficulty, we need to pursue alternative methods, capable of handling the vectorial case. Perhaps the most outstanding problem along these lines is to understand whether an efficient weak formulation for the system (6.15) can be identified in the case of nonsmooth coefficients A.

Finally, we would like to comment very briefly on the limiting cases of the usual (p, q)-Hölder duality (here, $q = p'$, with $\frac{1}{p} + \frac{1}{p'} = 1$) when $p \to \infty$ (which corresponds to $q \to 1^+$) or $q \to \infty$ (equivalently, $p \to 1^+$). In the context of power-law materials at "level" p, convex duality is fully understood. Guided by the duality between the p-Laplace equation (5.16) and the system (6.16) (as we have already seen, these equations correspond to dual variational principles), it is not hard to see, formally, that when $p \to 1^+$ in (5.16) one has that u satisfies the 1-Laplace equation (see, e.g., [36])

$$\operatorname{div}\left(\frac{\nabla u}{|\nabla u|}\right) = 0, \tag{6.22}$$

while when $q \to 1^+$ in (6.16), b satisfies the system

$$\operatorname{curl}\left(\frac{b}{|b|}\right) = 0. \tag{6.23}$$

Again, heuristically, if u_1 is a solution to (6.22), then the field b_1 defined by

$$b_1 := \frac{\nabla u_1}{|\nabla u_1|} \tag{6.24}$$

is divergence free, and we have $|b_1|^2 = 1$ a.e. Therefore, b_1 is a solution of (6.18) (or, equivalently, (6.17)), which is the limiting ($q \to \infty$) system associated with (6.16). On the other hand, if one starts from a field b_1 which satisfies (6.23), one is given a function u_1 such that

$$\nabla u_1 := \frac{b_1}{|b_1|}. \tag{6.25}$$

It is not hard to check that u_1 formally satisfies $\Delta_\infty u_1 = 0$.

Whether a satisfactory mathematical theory can be developed to justify these statements in some appropriate weak sense is an intriguing open question which we believe deserves further investigation.

Acknowledgment. The authors would like to thank the anonymous referees for several constructive suggestions which have helped improve the exposition.

NEWTONIAN LIMIT FOR WEAKLY VISCOELASTIC FLUID FLOWS OF OLDROYD TYPE*

LUC MOLINET† AND RAAFAT TALHOUK‡

Abstract. This paper is concerned with regular flows of incompressible weakly viscoelastic fluids which obey a differential constitutive law of Oldroyd type. We study the Newtonian limit for weakly viscoelastic fluid flows in $\mathbb{R}^N$ or $\mathbb{T}^N$ for $N = 2, 3$, when the Weissenberg number (relaxation time measuring the elasticity effect in the fluid) tends to zero. More precisely, we prove that the velocity field and the extrastress tensor converge in their existence spaces (we examine the Sobolev-H^s theory and the Besov-$B_2^{s,1}$ theory to reach the critical case $s = N/2$) to the corresponding Newtonian quantities. This convergence results are established in the case of "ill-prepared" data. We deduce, in the two-dimensional case, a new result concerning the global existence of weakly viscoelastic fluid flow. Our approach makes use of essentially two ingredients: the stability of the null solution of the viscoelastic fluid flow and the damping effect, on the difference between the extrastress tensor and the tensor of rate of deformation, induced by the constitutive law of the fluid.

Key words. viscoelastic fluids, global existence, Newtonian limit

1. Introduction, main results, and notations.

In this paper we investigate the Newtonian limit of weakly viscoelastic fluid flows of Oldroyd type in $\Omega = \mathbb{R}^N$ or $\Omega = \mathbb{T}^N$.

The dynamics of homogeneous, isothermic, and incompressible fluid flows is described by the partial differential derivatives system given by

$$\left\{ \begin{array}{rcl} \rho\Big(u' + (u.\nabla)u\Big) & = & f + \operatorname{div}\sigma, \\ \operatorname{div} u & = & 0. \end{array} \right. \tag{1}$$

Here $\rho > 0$ is the (constant) density and f is the external density body forces. $u = u(t, x)$ is the velocity vector field and $\sigma = \sigma(t, x)$ is the symmetric stress tensor, which is split into two parts: $\sigma = -pId + \tau$, where $-pId$ is the spherical part ($p = p(t, x)$ the hydrodynamics pressure) and τ is the tangential part or the extrastress tensor. The fluid is called Newtonian if τ can be expressed linearly in terms of the rate of strain tensor $\mathbf{D}[u] = \frac{1}{2}(\nabla u + \nabla u^T)$, i.e.,

$$\tau = 2\eta\mathbf{D}[u], \tag{2}$$

where η is the viscosity coefficient of the fluid (in this case (1) is the Navier–Stokes system). A fluid for which (2) is not valid is called non-Newtonian or complex fluid.

Unfortunately no universal constitutive law exists for non-Newtonian fluids (see, for instance, [10]). In this paper we consider a class of fluids with memory. For this

kind of fluid, the extrastress tensor at a time t depends on $\mathbf{D}[u]$ and its history. A model taking into account this property is the Oldroyd one. The constitutive law of Oldroyd's type [9] is given by

$$\tau + \lambda_1 \frac{\mathcal{D}_a \tau}{\mathcal{D}t} = 2\eta \left(\mathbf{D} + \lambda_2 \frac{\mathcal{D}_a \mathbf{D}}{\mathcal{D}t} \right), \tag{3}$$

where $0 \leq \lambda_2 < \lambda_1$, λ_1 is the relaxation time, and λ_2 is the retardation time. The symbol $\frac{\mathcal{D}_a}{\mathcal{D}t}$ denotes an objective (frame indifferent) tensor derivative (see [10]). More precisely,

$$\frac{\mathcal{D}_a \tau}{\mathcal{D}t} = \tau' + (u \cdot \nabla)\tau + \tau \mathbf{W} - \mathbf{W}\tau - a(\mathbf{D}\tau + \tau \mathbf{D})$$

with $\mathbf{W}[u] = \frac{1}{2}(\nabla u - \nabla u^T)$ the vorticity tensor and a a real number verifying $-1 \leq a \leq 1$. The limit case $\lambda_1 > 0$ and $\lambda_2 = 0$ corresponds to a purely elastic fluid (which is excluded in our analysis), while the limit case $\lambda_1 = \lambda_2 = 0$ corresponds to a viscous Newtonian fluid.

The constitutive law (3) is not under an evolution form. This equation can be transformed into a transport equation by splitting the extrastress tensor into two parts $\tau_s + \tau_p$, where τ_s corresponds to a Newtonian part (the solvant) and τ_p to the elastic part (the polymer). Setting $\tau_s = 2\eta(1-\omega)\mathbf{D}[u]$, with ω defined by $0 \leq \omega = 1 - \frac{\lambda_2}{\lambda_1} \leq 1$, it follows from (3) that τ_p satisfies the following transport equation:

$$\tau_p + \lambda_1 \frac{\mathcal{D}_a \tau_p}{\mathcal{D}t} = 2\eta\omega \mathbf{D}[u]. \tag{4}$$

From now on we shall denote $\tau_p = \tau$ and rewrite (1) and (4) by using dimensionless variables, and we obtain the following partial differential system:

$$\left\{ \begin{array}{rcl} \mathrm{Re}\,(u' + (u.\nabla)u) - (1-\omega)\Delta u + \nabla p &=& f + \mathrm{div}\,\tau \\ \mathrm{div}\, u &=& 0 \\ \varepsilon\Big(\tau' + (u.\nabla)\tau + \mathbf{g}(\nabla u, \tau)\Big) + \tau &=& 2\omega \mathbf{D}[u] \end{array} \right. \quad \text{in } \Omega, \tag{5}$$

where $\mathbf{g}$ is a bilinear tensor-valued mapping defined by

$$\mathbf{g}(\nabla u, \tau) = \tau \mathbf{W}[u] - \mathbf{W}[u]\tau - a(\mathbf{D}[u]\tau + \tau\, \mathbf{D}[u]),$$

$\mathrm{Re} = \rho \frac{UL}{\eta}$ and $\varepsilon = \lambda_1 \frac{U}{L}$ are, respectively, the well-known Reynolds number and the Weissenberg number (U and L represent a typical velocity and typical length of the flow). It is worth noticing that the Weissenberg number is usually denoted by We. Here, since we will make the Weissenberg number tend to zero, we prefer to denote it by ε. It is crucial to note that when $\varepsilon = 0$, (5) reduces to the incompressible Navier–Stokes system

$$\left\{ \begin{array}{rcl} \mathrm{Re}\,(v' + (v.\nabla)v) - \Delta v + \nabla p &=& f \\ \mathrm{div}\, v &=& 0 \end{array} \right. \quad \text{in } \Omega\,. \tag{6}$$

On the other hand, from the definition of the retardation parameter we observe that $\omega = 1 - \mu/\varepsilon$, where $0 \leq \mu < \varepsilon$ is given by $\mu = \lambda_2 \frac{U}{L}$. Therefore, the Newtonian limit of (5) is actually a limit with two parameters ε and μ. To simplify the study we could drop a parameter by assuming that the rate μ/ε (or equivalently ω) is constant as

ε tends to zero. In this work, instead of doing this, we will only impose a uniform upper bound on $\omega\,(= 1 - \mu/\varepsilon)$ with respect to ε.

System (5) is completed by the following initial conditions:

$$u_{|t=0} = u_0 \quad \text{and} \quad \tau_{|t=0} = \tau_0. \tag{7}$$

Our approach is quite general and uses the two following ingredients.

• The stability of the null solution of (5) for a fixed ε (see [1] on $\mathbb{R}^N$ or $\mathbb{T}^N$ and [6], [4], [8] for the case of a bounded domain).

• The damping of factor $1/\varepsilon$ on the quantity $\tau - 2\omega\mathbf{D}[u]$ induced by equation $(5)_3$.

Our results in the Sobolev spaces are valid for $\Omega = \mathbb{R}^N$ or $\mathbb{T}^N$, but to simplify the expository we will only consider $\Omega = \mathbb{R}^N$ and give the necessary modification to handle the periodic case.

The main idea is to cut u and τ in low and high frequencies at a level depending on $1/\varepsilon$. Roughly speaking, forgetting the nonlinear terms, the high frequency part of $u-v$ (v is the Newtonian solution; see (6) associated with the initial data u_0) will satisfy the homogeneous system linearized around the null solution plus a nonhomogeneous part containing a high frequency term of v. But by the Lebesgue monotone convergence theorem, this term will tend to zero in the appropriate norms. The stability of the null solution (cf. [1], [6]) will then force the high frequencies of $u - v$ and $\varepsilon^{1/2}\tau$ to remain small (recall that $(u - v)(0) = 0$). On the other hand, the remaining frequencies will tend to zero due to the damping effect on $\tau - 2\omega\mathbf{D}[u]$ which we will use in the same time as a smoothing effect. We will describe the main steps of the proof in section 1.3.

Note that our analysis is in the spirit of numerous works on the incompressible limit of compressible Navier–Stokes equations (see, for instance, [2] and the references therein). However, our analysis is in some aspects easier since there is a damping effect relating to the small parameter whereas in the incompressible limit it is a dispersive effect.

To our knowledge, no such result exists in the literature concerning our study, i.e., the Newtonian limit of non-Newtonian fluid flows. Moreover, our global existence result for regular weakly viscoelastic fluids flow in dimension two (see Corollary 1.1) is new and, in particular, not contained in the global existence results of [1].

1.1. Function spaces and notations. In what follows, C denotes a positive constant which may differ at each appearance. When writing $x \backsimeq y$ (for x and y two nonnegative real numbers), we mean that there exist C_1 and C_2 two positive constants (which do not depend on x and y) such that $C_1 x \le y \le C_2 x$. When writing $x \lesssim y$ (for x and y two nonnegative real numbers), we mean that there exists C_1 a positive constant (which does not depend on x and y) such that $x \le C_1 y$.

$\mathcal{P}$ will denote the Leray projector on solenoidal vector fields. For $1 \le p, q \le \infty$, we denote by $\|\cdot\|_{L^p}$ the usual Lebesgue norm on $\Omega = \mathbb{R}^N$,

$$\|v\|_{L^p} = \left(\int_{\mathbb{R}^N} |v|^p(x)\,dx\right)^{1/p}$$

and by $\|\cdot\|_{L^q_t L^p}$ the space-time Lebesgue norm on $]0,t[\times\Omega$,

$$\|v\|_{L^q_t L^p} = \left[\int_0^t \|v(\tau)\|^q_{L^p}\,d\tau\right]^{1/q}$$

with the obvious modification for $p, q = \infty$. For $s \in \mathbb{R}$, we denote by $\|\cdot\|_{H^s}$ the usual Sobolev norms on $\Omega = \mathbb{R}^N$,

$$\|v\|_{H^s} = \left(\int_{\mathbb{R}^N} (1+|\xi|^2)^s |\hat{v}(\xi)|^2 \, d\xi\right)^{1/2},$$

where $\hat{v}$ is the Fourier transform of v. The corresponding scalar product will be denoted by $((\cdot,\cdot))_{H^s}$. Finally, for any $\varepsilon > 0$ we introduce the following Fourier projectors:

$$\widehat{P_\varepsilon f}(\xi) = \chi_{[0,\varepsilon^\alpha]}(|\xi|)\hat{f}(\xi) \quad \text{and} \quad \widehat{Q_\varepsilon f}(\xi) = \chi_{]\varepsilon^\alpha,\infty[}(|\xi|)\hat{f}(\xi), \tag{8}$$

where $\alpha > 0$ will be specified later.

1.1.1. Homogeneous Besov spaces. Let ψ be in $\mathcal{S}(\mathbb{R})$ such that $\hat{\psi}$ is supported by the set $\{z \,/\, 2^{-1} \le |z| \le 2\}$ and such that

$$\sum_{j\in\mathbb{Z}} \hat{\psi}(2^{-j}z) = 1\,,\ z \neq 0. \tag{9}$$

Define φ by

$$\hat{\varphi} = 1 - \sum_{j\ge 1} \hat{\psi}(2^{-j}z), \tag{10}$$

and observe that $\varphi \in \mathcal{D}(\mathbb{R})$, $\hat{\varphi}$ is supported by the ball $\{z \,/\, |z| \le 2\}$, and $\hat{\varphi} = 1$ for $|z| \le 1$. We denote now by Δ_j and S_j the convolution operators on $\mathbb{R}^N$ whose symbols are, respectively, given by $\hat{\psi}(2^{-j}|\xi|)$ and $\hat{\varphi}(2^{-j}|\xi|)$ where $\xi \in \mathbb{R}^N$ and $|\xi| = \sqrt{\xi_1^2 + \cdots + \xi_N^2}$. Also we define the operator $\tilde{\Delta}_j$ by

$$\tilde{\Delta}_j = \Delta_{j-1} + \Delta_j + \Delta_{j+1}$$

which satisfies

$$\tilde{\Delta}_j \circ \Delta_j = \Delta_j.$$

For $s \in \mathbb{R}$, the homogeneous Besov space $B_2^{s,1}(\mathbb{R}^N)$ (to simplify the notation we will simply denote it by $B^s(\mathbb{R}^N)$) is the completion of $\mathcal{S}(\mathbb{R}^N)$ with respect to the seminorm

$$\|f\|_{B^s} = \big\|\{2^{js}\|\Delta_j(f)\|_{L^2}\}\big\|_{l^1(\mathbb{Z})}. \tag{11}$$

1.2. Main results.

THEOREM 1.1. *Let $N = 2, 3$ and let $(u_0, \tau_0) \in H^s(\mathbb{R}^N) \times H^s(\mathbb{R}^{N^2})$ and $f \in L^2_{\mathrm{loc}}(\mathbb{R}; H^{s-1})$ with $s > N/2$. Let v be the Newtonian solution satisfying* (6) *with initial data u_0 and let $0 < T_0 \le \infty$ such that $v \in C([0,T_0]; H^s)$. Then for any $\delta \in]0,1[$ there exists*

$$\varepsilon_0 = \varepsilon_0(N, \mathrm{Re}, \delta, \|v\|_{L^\infty_{T_0}H^s}, \|\nabla v\|_{L^2_{T_0}H^s}, \|\tau_0\|_{H^s}, \|\mathcal{P}f\|_{L^2_{T_0}H^{s-1}}) > 0$$

such that for any $0 < \varepsilon < \varepsilon_0$ the system (5)*, with*

$$0 < \omega \le 1 - \delta, \tag{12}$$

admits a unique solution

$$u_\varepsilon \in C([0,T_0];H^s), \quad \nabla u_\varepsilon \in L^2(0,T_0;H^s),\ \tau_\varepsilon \in C([0,T_0];H^s).$$

Moreover,

$$u_\varepsilon \underset{\varepsilon\to 0}{\longrightarrow} v \text{ in } C([0,T_0];H^s), \tag{13}$$

$$\tau_\varepsilon - 2\omega\mathbf{D}[u_\varepsilon] \underset{\varepsilon\to 0}{\longrightarrow} 0 \text{ in } L^2(0,T_0;H^s), \tag{14}$$

$$\varepsilon^{1/2}\tau_\varepsilon \underset{\varepsilon\to 0}{\longrightarrow} 0 \text{ in } C([0,T_0];H^s). \tag{15}$$

Recalling that in dimension two, the solution of the Newtonian problem exists for all positive times, we deduce the following result.

COROLLARY 1.1. *In dimension two there exists*

$$\varepsilon_0 = \varepsilon_0(\mathrm{Re},\delta,\|v\|_{L^\infty_\infty H^s},\|\nabla v\|_{L^2_\infty H^s},\|\tau_0\|_{H^s},\|\mathcal{P}f\|_{L^2_\infty H^{s-1}}) > 0$$

such that for any $0<\varepsilon<\varepsilon_0$ *the solution of* (5) *given by Theorem* 1.1 *exists for all positive times.*

Remark 1.1. Note that Theorem 1.1 is a convergence result for "ill-prepared" data. Indeed the quantity $\tau_0 - 2\omega\mathbf{D}[u_0]$ is not assumed to be small with ε. Moreover, this is a singular limit result since τ and $\mathbf{D}[u]$ do not belong to the same function space. In particular, $\mathbf{D}[u_0]$ is not as the same level of Sobolev regularity as τ_0.

Remark 1.2. According to the introduction, the Newtonian limit process is actually a limit process with two parameters ε and μ tending to zero with $0\le\mu<\varepsilon$. The assumption (12) of Theorem 1.1 means that we impose the following additional conditions on the rate μ/ε as (ε,μ) tends to zero $(0,0)$:

$$\delta \le \frac{\mu}{\varepsilon} = \frac{\lambda_2}{\lambda_1} < 1$$

for some fixed $1>\delta>0$.

As mentioned in the introduction, the use of Besov spaces enables us to reach the critical index $s=N/2$.

THEOREM 1.2. *Let* $N=2,3$ *and let* $(u_0,\tau_0)\in B^{N/2-1}(\mathbb{R}^N)\times B^{N/2}(\mathbb{R}^{N^2})$ *and* $f\in L^1_{\mathrm{loc}}(B^{N/2-1})$. *Let* v *be the Newtonian solution satisfying* (6) *with initial data* u_0 *and let* $0<T_0\le\infty$ *such that* $v\in C([0,T_0];B^{N/2-1})$. *There exist* $0<\omega_0<1$ *and* $\varepsilon_0=\varepsilon_0(N,\mathrm{Re},\omega_0,\|\tau_0\|_{B^{N/2}},\mathcal{P}f,u_0)>0$ *such that for any* $0<\varepsilon<\varepsilon_0$ *the system* (5), *with* $0<\omega\le\omega_0$, *admits a unique solution*

$$u_\varepsilon \in C([0,T_0];B^{N/2-1}), \quad u_\varepsilon \in L^1(0,T_0;B^{N/2+1}),\ \tau_\varepsilon \in C([0,T_0];B^{N/2}).$$

Moreover,

$$u_\varepsilon \underset{\varepsilon\to 0}{\longrightarrow} v \text{ in } C([0,T_0];B^{N/2-1}), \tag{16}$$

$$\tau_\varepsilon - 2\omega\mathbf{D}[u_\varepsilon] \underset{\varepsilon\to 0}{\longrightarrow} 0 \text{ in } L^1(0,T_0;B^{N/2}), \tag{17}$$

$$\varepsilon^{1/2}\tau_\varepsilon \underset{\varepsilon\to 0}{\longrightarrow} 0 \text{ in } C([0,T_0];B^{N/2})\,. \tag{18}$$

In dimension two, using the classical global existence result in B^0 for the Newtonian problem (see, for instance, [2]), we get the following corollary.

Corollary 1.2. *In dimension two there exists*

$$\varepsilon_0 = \varepsilon_0(\mathrm{Re}, \omega_0, \|v\|_{L^\infty_\infty B^0}, \|\nabla v\|_{L^1_\infty B^2}, \|\tau_0\|_{B^1}, \|\mathcal{P}f\|_{L^1_{T_0}B^0})$$

such that for any $0<\varepsilon<\varepsilon_0$ *the solution of* (5) *given by Theorem* 1.2 *exists for all positive times.*

In the surcritical case, $s>N/2$, we get similar results by considering nonhomogeneous Besov spaces. Note that ε_0 then depends explicitly on some norms of v.

Theorem 1.3. *For* $s>N/2$*, Theorem* 1.2 *and Corollary* 1.2 *also hold by replacing the function spaces* $B^{N/2-1}$ *by* $B^{s-1}\cap B^{N/2-1}$ *and* $B^{N/2}$ *by* $B^s\cap B^{N/2}$*. Moreover,* ε_0 *will depend now explicitly on some norms of* v *and* $\mathcal{P}f$*. More precisely, for* $s>N/2$*, we have*

$$\varepsilon_0 = \varepsilon_0(N, \mathrm{Re}, \omega_0, \|v\|_{L^\infty_{T_0}B^{N/2-1}}, \|\nabla v\|_{L^1_{T_0}B^s}, \|\tau_0\|_{B^{N/2}}, \|\mathcal{P}f\|_{L^1_{T_0}B^{N/2-1}}).$$

1.3. Sketch of the proof of Theorem 1.1. In this subsection we want to explain the main steps of the proof of Theorem 1.1. Note that Theorem 1.2 follows from the same arguments. To simplify we drop the nonlinear terms in (5). The first step consists in noticing that $W := u - v$ satisfies the following system:

$$\begin{cases} \mathrm{Re}\, W_t - (1-\omega)Q_\varepsilon\Delta W - P_\varepsilon\Delta W = P_\varepsilon\mathcal{P}(\mathrm{div}\,\tau - \omega\Delta u) \\ \qquad\qquad\qquad\qquad -\omega Q_\varepsilon\Delta v + Q_\varepsilon\mathcal{P}\mathrm{div}\,\tau, \\ \mathrm{div}\, W = 0, \\ \varepsilon\tau_t + Q_\varepsilon\tau = 2\omega Q_\varepsilon\mathbf{D}[W] + 2\omega Q_\varepsilon\mathbf{D}[v] - P_\varepsilon(\tau - 2\omega\mathbf{D}[u]), \end{cases} \tag{19}$$

where P_ε and Q_ε are the projectors on, respectively, the low and the high frequencies defined in (8).

Projecting on the high frequencies with Q_ε (see (8) for the definition), proceeding as in [1], it is easy to check that we get a differential inequality close to

$$\frac{d}{dt}\Big(\|Q_\varepsilon W\|^2_{H^s} + \varepsilon\|Q_\varepsilon\tau\|^2_{H^s}\Big) + \|Q_\varepsilon\nabla W\|^2_{H^s} + \|Q_\varepsilon\tau\|^2_{H^s} \lesssim \|Q_\varepsilon\nabla v\|^2_{H^s},$$

where we drop all the constants to clarify the presentation. Therefore, since $W(0)=0$, $\varepsilon\to 0$, and, by the Lebesgue monotone convergence theorem, $\|Q_\varepsilon\nabla v\|_{L^2_{T_0}H^s}\to 0$, we infer that $\|Q_\varepsilon W\|_{L^\infty_{T_0}H^s}$ goes to zero with ε. Now, to treat the low frequency part, we observe that, computing $P_\varepsilon(19)_3 - \frac{2\omega}{\mathrm{Re}}\mathbf{D}[(19)_1]$ and taking the H^{s-1}-scalar product of the resulting equation with $Z := \tau - 2\omega\mathbf{D}[u]$, we obtain something like

$$\frac{d}{dt}\|P_\varepsilon Z\|^2_{H^{s-1}} + \frac{1}{\varepsilon}\|P_\varepsilon Z\|^2_{H^{s-1}} \lesssim \|P_\varepsilon\tau\|^2_{H^s} + \|P_\varepsilon f\|^2_{H^{s-1}}. \tag{20}$$

On the other hand, $P_\varepsilon(19)_3$ can be rewritten as

$$\varepsilon P_\varepsilon\tau_t + \varepsilon^\beta P_\varepsilon\tau = 2\omega\varepsilon^\beta P_\varepsilon\mathbf{D}[W] + 2\omega\varepsilon^\beta P_\varepsilon\mathbf{D}[v] - (1-\varepsilon^\beta)P_\varepsilon Z,$$

where $0 < \beta < 1$ will be specified later. Therefore, taking the H^s-scalar product of this last equality with τ and adding with the scalar product of $(19)_1$ with W, we get a differential inequality close to

$$\frac{d}{dt}\Big(\|P_\varepsilon W\|_{H^s}^2+\varepsilon\|P_\varepsilon\tau\|_{H^s}^2\Big)+\|P_\varepsilon\nabla W\|_{H^s}^2+\varepsilon^\beta\|P_\varepsilon\tau\|_{H^s}^2\lesssim\varepsilon^{-\beta}\|P_\varepsilon Z\|_{H^s}^2+\varepsilon^\beta\|P_\varepsilon\nabla v\|_{H^s}^2.$$

Adding this last inequality and $\varepsilon^{2\beta}(20)$ we finally obtain

$$\begin{aligned}\frac{d}{dt}\Big(\|P_\varepsilon W\|_{H^s}^2 + \varepsilon\|P_\varepsilon\tau\|_{H^s}^2\Big) + \|P_\varepsilon\nabla W\|_{H^s}^2 + \varepsilon^\beta\|P_\varepsilon\tau\|_{H^s}^2 + \varepsilon^{2\beta-1}\|P_\varepsilon Z\|_{H^{s-1}}^2 \\ \lesssim \varepsilon^{2\beta}\|P_\varepsilon f\|_{H^{s-1}}^2 + \varepsilon^\beta\|P_\varepsilon\nabla v\|_{H^s}^2\end{aligned}$$

since $\varepsilon^{-\beta}\|P_\varepsilon Z\|_{H^s}^2 \le \varepsilon^{-\beta}\varepsilon^{-2\alpha}\|P_\varepsilon Z\|_{H^{s-1}}^2 \le \frac{\varepsilon^{2\beta-1}}{4}\|P_\varepsilon Z\|_{H^{s-1}}^2$ as soon as $1-3\beta-2\alpha > 0$. This last inequality enables us to conclude for the low frequency part. Note that we used the damping effect also as a smoothing effect.

2. Proof of Theorem 1.1. Let us recall the following existence theorem proven by Chemin and Masmoudi [1].

THEOREM 2.1. *Let $(u_0,\tau_0) \in H^s(\mathbb{R}^N) \times H^s(\mathbb{R}^{N^2})$ with $s > N/2$. Then there exists a unique positive maximal time T^* and a unique solution*

$$(u,\tau) \in C([0,T^*[;H^s) \cap L^2_{\mathrm{loc}}(0,T^*;H^{s+1}) \times C([0,T^*[;H^s).$$

Moreover, if $T^* < \infty$, then for all $N/2 < s' \le s$

$$\limsup_{t\nearrow T^*}\Big(\|u(t)\|_{H^{s'}} + \|\tau(t)\|_{H^{s'}}\Big) = +\infty. \tag{21}$$

Remark 2.1. Actually in [1] the following sharper blowup condition is derived:

$$T^* < \infty \Longrightarrow \int_0^{T^*} \|\nabla u(t)\|_{L^\infty} + \|\tau(t)\|_{L^\infty}^2\,dt = +\infty,$$

but for our purpose the classical blowup condition (21) will be sufficient.

Let us also recall a commutator estimate and classical Leibniz rules for fractional derivatives.

LEMMA 2.2. *Let Δ be the Laplace operator on $\mathbb{R}^N$, $N \ge 1$. Denote by J^s the operator $(1-\Delta)^{s/2}$.*

- *For every $s > N/2$,*

$$\|[J^s,f]g\|_{L^2(\mathbb{R}^N)} \lesssim \|\nabla f\|_{H^s(\mathbb{R}^N)}\|g\|_{H^{s-1}(\mathbb{R}^N)}. \tag{22}$$

- *For every $s > 0$, $1 < q,q' \le \infty$, and $1 < r,p,p' < \infty$ with $1/p+1/q = 1/p'+1/q' = 1/r$,*

$$\|J^s(fg)\|_{L^r(\mathbb{R}^N)} \lesssim \|J^s f\|_{L^p(\mathbb{R}^N)}\|g\|_{L^q(\mathbb{R}^N)} + \|f\|_{L^{q'}(\mathbb{R}^N)}\|J^s g\|_{L^{p'}(\mathbb{R}^N)}. \tag{23}$$

- *For every p,r,t such that $r,p \ge t$ and $r+p-t > N/2$,*

$$\|fg\|_{H^t(\mathbb{R}^N)} \lesssim \|f\|_{H^p(\mathbb{R}^N)}\|g\|_{H^r(\mathbb{R}^N)}. \tag{24}$$

Proof. Estimates (23) and (24) are classical and can be found in [7] and [5]. Estimate (22) is a variant of Kato–Ponce's commutator estimates. It is proven in [12] in dimension one but the proof works also in dimensions two and three. ∎

To treat some nonlinear terms in dimension two we will need, moreover, the following Gagliardo–Nirenberg-type inequality (see, for instance, [3]).

LEMMA 2.3. *Let $N \geq 2$, for $u \in H^1(\mathbb{R}^N)$ the following Sobolev-type inequality holds for any $2 \leq p < +\infty$ such that $\frac{1}{2} - \frac{1}{N} \leq \frac{1}{p}$:*

$$\|u\|_{L^p(\mathbb{R}^N)} \lesssim \|u\|_{L^2(\mathbb{R}^N)}^{(\frac{N}{p}-\frac{N}{2}+1)} \|\nabla u\|_{L^2(\mathbb{R}^N)}^{(\frac{N}{2}-\frac{N}{p})}. \tag{25}$$

2.1. Estimate on $W = u - v$ and $\varepsilon^{1/2}\tau$. We start by deriving a differential inequality for the H^s-norms of W and $\varepsilon^{1/2}\tau$. The high frequency part of this inequality is directly inspired by the stability proof of the null solution in [1]. This will enable us to control the very high frequency part $(Q_\varepsilon u, Q_\varepsilon \tau)$ of the solution. The other part $(P_\varepsilon u, P_\varepsilon \tau)$ will be treated by using the damping effect.

For $\varepsilon > 0$ fixed, Theorem 2.1 gives the existence and uniqueness of the solution $(u_\varepsilon, \tau_\varepsilon)$ of (5) in $C([0, T_\varepsilon^*[; H^s) \cap L^2_{\mathrm{loc}}(0, T_\varepsilon^*; H^{s+1}) \times C([0, T_\varepsilon^*[; H^s)$ for some $T_\varepsilon^* > 0$. To simplify the notations, we drop the index ε on u and τ in what follows. Setting

$$Z = \tau - 2\omega \mathbf{D}[u]$$

we have the following estimates.

LEMMA 2.4. *For $\varepsilon > 0$ small enough, the solution (u, τ) of (5) satisfies, for all $0 < t < T_\varepsilon^*$ and $0 < \beta < 1$,*

$$\begin{aligned}
&\frac{d}{dt}\Big(\frac{\mathrm{Re}}{2}\|W\|_{H^s}^2 + \frac{\varepsilon}{4\omega}\|\tau\|_{H^s}^2\Big) + \frac{1}{4}\|P_\varepsilon \nabla W\|_{H^s}^2 + \frac{(1-\omega)}{2}\|Q_\varepsilon \nabla W\|_{H^s}^2 \\
&\quad + \frac{1}{4\omega}\|Q_\varepsilon \tau\|_{H^s}^2 + \frac{\varepsilon^\beta}{4\omega}\|P_\varepsilon \tau\|_{H^s}^2 \\
&\quad \leq \left(1 + \frac{4\varepsilon^{-\beta}}{\omega}\right)\|P_\varepsilon Z\|_{H^s}^2 + 4\omega\|Q_\varepsilon \nabla v\|_{H^s}^2 + 8\omega\varepsilon^\beta\|P_\varepsilon \nabla v\|_{H^s}^2 \\
&\quad + \frac{C\,\mathrm{Re}}{(1-\omega)^2}(\|\nabla u\|_{H^s}^2 + \|\nabla v\|_{H^s}^2)\|W\|_{H^s}^2 + \frac{C}{\omega}\,\varepsilon^{2-\beta}\|\nabla u\|_{H^s}^2\|\tau\|_{H^s}^2
\end{aligned} \tag{26}$$

whenever $0 < \omega < 1$. Moreover, for $0 < \omega \leq 10^{-2}$, it holds that

$$\begin{aligned}
&\frac{d}{dt}\Big(\frac{\mathrm{Re}}{4}\|W\|_{H^s}^2 + \frac{\varepsilon}{2}\|\tau\|_{H^s}^2\Big) + \frac{1}{8}\|P_\varepsilon \nabla W)\|_{H^s}^2 + \frac{(1-\omega)}{4}\|Q_\varepsilon \nabla W\|_{H^s}^2 \\
&\quad + \frac{1}{4}\|Q_\varepsilon \tau\|_{H^s}^2 + \frac{\varepsilon^\beta}{4}\|P_\varepsilon \tau\|_{H^s}^2 \\
&\quad \leq (1 + 4\varepsilon^{-\beta})\|P_\varepsilon Z\|_{H^s}^2 + 8\omega^2\|Q_\varepsilon \nabla v\|_{H^s}^2 + 8\omega^2\varepsilon^\beta\|P_\varepsilon \nabla v\|_{H^s}^2 \\
&\quad + \frac{C\ \mathrm{Re}}{(1-\omega)^2}(\|\nabla u\|_{H^s}^2 + \|\nabla v\|_{H^s}^2)\|W\|_{H^s}^2 + C\,\varepsilon^{2-\beta}\|\nabla u\|_{H^s}^2\|\tau\|_{H^s}^2.
\end{aligned} \tag{27}$$

Proof. Notice that W verifies the equation

$$\begin{aligned}
\mathrm{Re}\Big(W_t + \mathcal{P}(u.\nabla)W\Big) - \Delta W &= \mathcal{P}\mathrm{div}\,\tau - \omega\Delta u - \ \mathrm{Re}\ \mathcal{P}(W.\nabla)v \\
&= P_\varepsilon \mathcal{P}\Big(\mathrm{div}\,\tau - \omega\Delta u\Big) - \omega Q_\varepsilon \Delta v \\
&\quad + Q_\varepsilon \mathcal{P}\mathrm{div}\,\tau - \omega Q_\varepsilon \Delta W - \ \mathrm{Re}\ \mathcal{P}(W.\nabla)v.
\end{aligned} \tag{28}$$

Therefore, multiplying scalarly (28) by W in $H^s(\mathbb{R}^N)$, using the Cauchy–Schwarz inequality, Lemma 2.2, and that u is divergence free, we obtain

$$\begin{aligned}\frac{1}{2}\mathrm{Re}\frac{d}{dt}\|W\|^2_{H^s} &+ \|P_\varepsilon \nabla W\|^2_{H^s} + (1-\omega)\|Q_\varepsilon \nabla W\|^2_{H^s}\\ &\leq ((Q_\varepsilon \mathrm{div}\,\tau, W))_{H^s} + \|P_\varepsilon Z\|_{H^s}\|\nabla W\|_{H^s} + \omega\|Q_\varepsilon\nabla v\|_{H^s}\|Q_\varepsilon \nabla W\|_{H^s}\\ &\quad + C\ \mathrm{Re}\left|((J^s(u.\nabla)W, J^sW))_{L^2}\right| +\ \mathrm{Re}\left|((J^s(W.\nabla)v, J^sW))_{L^2}\right|.\end{aligned}\tag{29}$$

To estimate the second to the last term of (29), we rewrite it with the help of a commutator and apply the Cauchy–Schwarz inequality to the term containing this commutator to get

$$\left|((J^s(u.\nabla)W, J^sW))_{L^2}\right| \leq \left|(((u.\nabla)J^sW, J^sW))\right| + \left\|[J^s,(u.\nabla)]W\right\|_{L^2}\|J^sW\|_{L^2}.$$

Since u is divergence free, the first term of the right-hand side of this last inequality cancels by integration by parts. Estimating the second term, thanks to Lemma 2.2, we then obtain

$$\left|((J^s(u.\nabla)W, J^sW))_{L^2}\right| \leq C\,\|\nabla u\|_{H^s}\|\nabla W\|_{H^s}\|W\|_{H^s}.$$

Now, to estimate the last term of the right-hand side of (29) we have to distinguish the cases $N = 2$ and $N = 3$.

• $N = 3$. Then by Lemma 2.2 and the Hölder, Sobolev, and Young inequalities, we get

$$\begin{aligned}\left|((J^s(W.\nabla)v, J^sW))_{L^2}\right| &\leq \|J^s(W.\nabla)v\|_{L^{6/5}}\|J^sW\|_{L^6}\\ &\lesssim \Big(\|J^sW\|_{L^2}\|\nabla v\|_{L^3} + \|W\|_{L^3}\|J^s\nabla v\|_{L^2}\Big)\|J^s\nabla W\|_{L^2}\\ &\lesssim \|W\|_{H^s}\|\nabla v\|_{H^s}\|\nabla W\|_{H^s}.\end{aligned}$$

• $N = 2$. In this case, using Hölder's inequality and Lemmas 2.2 and 2.3 we infer that

$$\begin{aligned}\left|((J^s(W.\nabla)v), J^sW))_{L^2}\right| &\leq \|J^s(W.\nabla)v\|_{L^{3/2}}\|J^sW\|_{L^3}\\ &\lesssim \Big(\|J^sW\|_{L^6}\|\nabla v\|_{L^2} + \|W\|_{L^6}\|J^s\nabla v\|_{L^2}\Big)\|J^sW\|_{L^3}\\ &\lesssim \|J^sW\|_{L^6}\|J^s\nabla v\|_{L^2}\|J^sW\|_{L^3}\\ &\lesssim \|W\|_{H^s}\|\nabla v\|_{H^s}\|\nabla W\|_{H^s}.\end{aligned}$$

By Young's inequalities it thus follows from (29) that

$$\begin{aligned}\frac{\mathrm{Re}}{2}\frac{d}{dt}\|W\|^2_{H^s} &+ \frac{3}{4}\|P_\varepsilon\nabla W\|^2_{H^s} + \frac{(1-\omega)}{2}\|Q_{>\varepsilon}\nabla W\|^2_{H^s}\\ &\leq ((Q_\varepsilon \mathrm{div}\,\tau, W))_{H^s} + \|P_\varepsilon Z\|^2_{H^s} + \frac{\omega^2}{4(1-\omega)}\|Q_\varepsilon\nabla v\|^2_{H^s}\\ &\quad + \frac{C\ \mathrm{Re}}{(1-\omega)^2}\Big(\|\nabla u\|^2_{H^s} + \|\nabla v\|^2_{H^s}\Big)\|W\|^2_{H^s}.\end{aligned}\tag{30}$$

On the other hand, for $0 < \beta < 1$, observing that

$$\begin{aligned}\tau - 2\omega\mathbf{D}[u] &= Q_\varepsilon\tau - 2\omega Q_\varepsilon(\mathbf{D}[W] + \mathbf{D}[v])\\ &\quad + (1-\varepsilon^\beta)P_\varepsilon Z + \varepsilon^\beta\Big(P_\varepsilon\tau - 2\omega P_\varepsilon(\mathbf{D}[W] + \mathbf{D}[v])\Big),\end{aligned}$$

we deduce from (5) that τ satisfies the equation

$$\varepsilon\Big(\tau_t + (u.\nabla)\tau + g(\nabla u,\tau)\Big) + Q_\varepsilon\tau + \varepsilon^\beta P_\varepsilon\tau = 2\omega Q_\varepsilon\mathbf{D}[W] + 2\omega Q_\varepsilon\mathbf{D}[v] \\ +2\omega\varepsilon^\beta P_\varepsilon\mathbf{D}[W] + 2\omega\varepsilon^\beta P_\varepsilon\mathbf{D}[v] - (1-\varepsilon^\beta)P_\varepsilon Z.$$

Taking the H^s-scalar product of this equation with τ and using Lemma 2.2 and the Cauchy–Schwarz and Young inequalities we get

$$\frac{\varepsilon}{2}\frac{d}{dt}\|\tau\|^2_{H^s} + \frac{1}{2}\|Q_\varepsilon\tau\|^2_{H^s} + \frac{\varepsilon^\beta}{2}\|P_\varepsilon\tau\|^2_{H^s} \le 2\omega((Q_\varepsilon\mathbf{D}[W],\tau))_{H^s} + 8\varepsilon^{-\beta}\|P_\varepsilon Z\|^2_{H^s} \\ +8\omega^2\|Q_\varepsilon\nabla v\|^2_{H^s} + 8\omega^2\varepsilon^\beta(\|P_\varepsilon\nabla W\|^2_{H^s} + \|P_\varepsilon\nabla v\|^2_{H^s}) \\ +C\,\varepsilon^{2-\beta}\|\nabla u\|^2_{H^s}\|\tau\|^2_{H^s}. \tag{31}$$

We now separate the two cases.

• $\omega \neq 0$. Then, adding (30) and (31)/2ω we notice that the first term in the right-hand side of (30) and (31) cancel each other and (26) follows. This gives (26) for ε small enough since $\beta > 0$.

• $0 < \omega \le 10^{-2}$. Then adding (30)/2+(31), estimating the two remaining H^s-scalar products by integration by parts and using the Cauchy–Schwarz and Young inequalities, one obtains (27). □

2.2. Estimate on $Z = \tau - 2\omega\mathbf{D}[u]$. We will now take advantage of the damping effect on $Z = \tau - 2\omega\mathbf{D}[u]$.

LEMMA 2.5. *The solution (u,τ) of (5) satisfies, for all ε small enough and $0 < t < T^*_\varepsilon$,*

$$\frac{1}{2}\frac{d}{dt}\|Z\|^2_{H^{s-1}} + \frac{1}{2\varepsilon}\|Z\|^2_{H^{s-1}} \le \frac{4\omega}{\mathrm{Re}\,(1-\omega)}\|\mathcal{P}f\|^2_{H^{s-1}} + \frac{(1+\omega)^2}{\mathrm{Re}\,(1-\omega)}\|\tau\|^2_{H^s} \\ +\frac{4}{1-\omega}(\mathrm{Re}\|\nabla u\|^2_{H^s} + \|\tau\|^2_{H^s})\|u\|^2_{H^s}. \tag{32}$$

Proof. We apply $\frac{2\omega}{\mathrm{Re}}\mathbf{D}[\cdot]$ to $(5)_1$ and substract the resulting equation from $(5)_2$ to obtain

$$Z_t - \frac{(1-\omega)}{\mathrm{Re}}\Delta Z + \frac{1}{\varepsilon}Z = -f_1 - f_2, \tag{33}$$

where

$$f_1 = \frac{2\omega}{\mathrm{Re}}\mathbf{D}[\mathcal{P}\mathrm{div}\,\tau] - \frac{(1-\omega)}{\mathrm{Re}}\Delta\tau + \frac{2\omega}{\mathrm{Re}}\mathbf{D}[\mathcal{P}f] - 2\omega\mathbf{D}[\mathcal{P}(u.\nabla)u]$$

and

$$f_2 = \mathcal{P}(u.\nabla)\tau + g(\nabla u,\tau).$$

Taking the H^{s-1}-scalar product of (33) with Z we get

$$\frac{1}{2}\frac{d}{dt}\|Z\|^2_{H^{s-1}} + \frac{(1-\omega)}{4\ \mathrm{Re}}\|\nabla Z\|^2_{H^{s-1}} + \frac{1}{\varepsilon}\|Z\|^2_{H^{s-1}} \\ \le C\,\frac{(1+\omega)^2}{\mathrm{Re}\,(1-\omega)}\|\tau\|^2_{H^s} + \frac{4\omega}{\mathrm{Re}\,(1-\omega)}\|\mathcal{P}f\|^2_{H^{s-1}} \\ +\frac{4\omega\ \mathrm{Re}}{1-\omega}\|(u.\nabla)u\|^2_{H^{s-1}} + 4\|(u.\nabla)\tau\|^2_{H^{s-1}} + \|\mathbf{g}(\nabla u,\tau)\|^2_{H^{s-1}}, \tag{34}$$

where we used that

$$\begin{aligned}\frac{2\omega}{\mathrm{Re}}\Big|((\mathbf{D}[\mathcal{P}\mathrm{div}\,\tau], Z))_{H^{s-1}}\Big| &\le C\frac{2\omega}{\mathrm{Re}}\|\mathrm{div}\,\tau\|_{H^{s-1}}\|\nabla Z\|_{H^{s-1}}\\ &\le \frac{1-\omega}{8\ \mathrm{Re}}\|\nabla Z\|^2_{H^{s-1}} + C\,\frac{\omega^2}{\mathrm{Re}\,(1-\omega)}\|\tau\|^2_{H^s}.\end{aligned}$$

Finally to control the nonlinear terms we notice that, thanks to (24),

$$\|a.\nabla b\|_{H^{s-1}} \lesssim \|a\|_{H^s}\|\nabla b\|_{H^{s-1}}$$

which concludes the proof of (32). $\square$

2.3. Convergence to the Newtonian flow. We give here the proof in the case $10^{-2} \le \omega \le 1-\delta$. The case $0 < \omega \le 10^{-2}$ is simpler and can be handled in the same way by using (27) instead of (26).

Adding (26) and $\varepsilon^{2\beta}$(32), we obtain for ε small enough

$$\begin{aligned}&\frac{d}{dt}\left(\frac{\mathrm{Re}}{2}\|W\|^2_{H^s} + \frac{\varepsilon}{4\omega}\|\tau\|^2_{H^s} + \frac{\varepsilon^{2\beta}}{2}\|Z\|^2_{H^{s-1}}\right)\\ &\quad + \frac{(1-\omega)}{4}\|\nabla W\|^2_{H^s} + \frac{1}{8\omega}(\|Q_\varepsilon\tau\|^2_{H^s} + \varepsilon^\beta\|P_\varepsilon\tau\|^2_{H^s}) + \frac{\varepsilon^{2\beta-1}}{4}\|Z\|^2_{H^{s-1}}\\ &\quad \le 8\omega^2\|Q_\varepsilon\nabla v\|^2_{H^s} + 8\omega^2\varepsilon^\beta\|P_\varepsilon\nabla v\|^2_{H^s} + C\,\varepsilon^{1-\beta}\|\nabla u\|^2_{H^s}\,\frac{\varepsilon}{4\omega}\|\tau\|^2_{H^s}\\ &\quad\quad + \frac{C\ \mathrm{Re}}{(1-\omega)^2}(\|\nabla v\|^2_{H^s} + \|\nabla u\|^2_{H^s})\|W\|^2_{H^s}\\ &\quad\quad + C\frac{\varepsilon^{2\beta}}{(1-\omega)}\left[\frac{1}{\mathrm{Re}}\|\mathcal{P}f\|^2_{H^{s-1}} + (\mathrm{Re}\|\nabla u\|^2_{H^s} + \|\tau\|^2_{H^s})\|u\|^2_{H^s}\right].\end{aligned}\tag{35}$$

Here, we used that for ε small enough,

$$\frac{(1+\omega)^2}{\mathrm{Re}\,(1-\omega)}\varepsilon^{2\beta}\|\tau\|^2_{H^s} \le \frac{\varepsilon^\beta}{8\omega}\|\tau\|^2_{H^s}$$

and

$$\left(1 + \frac{4\varepsilon^{-\beta}}{\omega}\right)\|P_\varepsilon Z\|^2_{H^s} \le (1 + 20^2\varepsilon^{-\beta})\varepsilon^{-2\alpha}\|P_\varepsilon Z\|^2_{H^{s-1}} \le \frac{\varepsilon^{2\beta-1}}{4}\|Z\|^2_{H^{s-1}}$$

as soon as $\beta > 0$ and $1 - 3\beta - 2\alpha > 0$.

From now on to simplify we thus take $(\alpha, \beta) = (1/8, 1/8)$. Setting

$$\begin{aligned}X_s(t) &= \frac{\mathrm{Re}}{2}\|W(t)\|^2_{H^s} + \frac{\varepsilon}{4\omega}\|\tau(t)\|^2_{H^s} + \frac{\varepsilon^{2\beta}}{2}\|Z\|^2_{H^{s-1}}\\ &\quad + \int_0^t \frac{(1-\omega)}{4}\|\nabla W\|^2_{H^s} + \frac{1}{8}\|Q_\varepsilon\tau\|^2_{H^s} + \frac{\varepsilon^\beta}{8}\|P_\varepsilon\tau\|^2_{H^s} + \frac{\varepsilon^{2\beta-1}}{4}\|Z\|^2_{H^{s-1}}\,ds,\end{aligned}$$

we infer that X_s satisfies the following differential inequality:

$$\begin{aligned}\frac{d}{dt}X_s &\le 8\omega^2\|Q_\varepsilon\nabla v\|^2_{H^s} + 8\omega^2\varepsilon^\beta\|P_\varepsilon\nabla v\|^2_{H^s} + C\frac{\varepsilon^{2\beta}}{\mathrm{Re}\,(1-\omega)}\|\mathcal{P}f\|^2_{H^{s-1}}\\ &\quad + C(\ \mathrm{Re}\,,\delta)\Big[\varepsilon^{2\beta}\|\tau\|^2_{H^s} + \|\nabla u\|^2_{H^s} + \|\nabla v\|^2_{H^s}\Big]X_s\\ &\quad + C\frac{\varepsilon^\beta}{(1-\omega)}(\mathrm{Re}\varepsilon^\beta\|\nabla u\|^2_{H^s} + \varepsilon^\beta\|\tau\|^2_{H^s})\|v\|^2_{H^s},\end{aligned}\tag{36}$$

where we rewrite u as $W+v$ and use the triangle inequality when necessary. Hence, Gronwall's inequality leads to

$$\begin{aligned} X_s(t) \le \exp\Big[C(\,\mathrm{Re}\,,\delta)\Big(\varepsilon^{2\beta}\|\tau\|^2_{L^2_tH^s} + \|\nabla u\|^2_{L^2_tH^s} + \|\nabla v\|^2_{L^2_tH^s}\Big)\Big] \\ \Big[X_s(0) + 8\omega^2\|Q_\varepsilon \nabla v\|^2_{L^2_tH^s} + 8\varepsilon^\beta\|\nabla v\|^2_{L^2_tH^s} + C\frac{\varepsilon^{2\beta}}{\mathrm{Re}\,\delta}\|\mathcal{P}f\|^2_{L^2_tH^{s-1}} \\ +\frac{\varepsilon^\beta}{\delta}(\mathrm{Re}\,\varepsilon^\beta\|\nabla u\|^2_{L^2_tH^s} + \varepsilon^\beta\|\tau\|^2_{L^2_tH^s})\|v\|^2_{L^\infty_tH^s}\Big]. \end{aligned} \tag{37}$$

Rewriting u as $v+W$, we finally obtain

$$\begin{aligned} X_s(t) \le \exp\Big[C(\,\mathrm{Re}\,,\delta)\Big(\|\nabla v\|^2_{L^2_tH^s} + X_s(t)\Big)\Big] \\ \Big[X_s(0) + 8\omega^2\|Q_\varepsilon \nabla v\|^2_{L^2_tH^s} + 8\varepsilon^\beta\|\nabla v\|^2_{L^2_tH^s} + C\frac{\varepsilon^{2\beta}}{\mathrm{Re}\ \delta}\|\mathcal{P}f\|^2_{L^2_tH^{s-1}} \\ + C\frac{(1+\mathrm{Re})\varepsilon^\beta}{\delta}\|v\|^2_{L^\infty_tH^s}X_s(t) + C\frac{\mathrm{Re}\,\varepsilon^{2\beta}}{\delta}\|v\|^2_{L^\infty_tH^s}\|\nabla v\|^2_{L^2_tH^s}\Big], \end{aligned} \tag{38}$$

where

$$X_s(0) = \frac{\varepsilon}{4\omega}\|\tau_0\|^2_{H^s} + \frac{\varepsilon^{2\beta}}{2}\|\tau_0 - 2\omega\mathbf{D}[u_0]\|^2_{H^{s-2}}. \tag{39}$$

Let us now assume that $T^*_\varepsilon \le T_0$. Since (38) holds for any $N/2 < s' < s$, noticing that

$$\|Q_\varepsilon \nabla v\|_{L^2_tH^{s'}} \le \varepsilon^{\alpha(s-s')}\|\nabla v\|_{L^2_tH^s},$$

we deduce from (38), (39), and the continuity of $t \mapsto X_{s'}(t)$ that there exists

$$\varepsilon_0(s, \|\tau_0\|_{H^s}, \|u_0\|_{H^s}, \|\nabla v\|_{L^2_{T_0}H^s}, \|v\|_{L^\infty_{T_0}H^s}) > 0$$

such that for any $0<\varepsilon<\varepsilon_0$ and any $0<t<T^*_\varepsilon$,

$$X_{s'}(t) \le C\,\varepsilon^{\min(\beta, 2\alpha(s-s'))} \le C\varepsilon^{\min(1,s-s')/8} \tag{40}$$

which contradicts (21) of Theorem 2.1. This ensures that $T^*_\varepsilon > T_0$. Now, since by Lebesgue monotone convergence theorem

$$\|Q_\varepsilon \nabla v\|_{L^2_{T_0}H^s} \underset{\varepsilon\to 0}{\longrightarrow} 0, \tag{41}$$

it follows from (38) and (39) that $X_s(T_0) \to 0$ as $\varepsilon \to 0$. This proves (13) and (15). To prove (14) we observe that from this last limit and (41), $\|Q_\varepsilon(\tau - 2\omega\mathbf{D}[u])\|_{L^2_{T_0}H^s} \to 0$ and $\varepsilon^{2\beta-1}\|P_\varepsilon(\tau - 2\omega\mathbf{D}[u])\|^2_{L^2_{T_0}H^{s-1}} \to 0$. This yields the result by Bernstein inequality since $2\beta - 1 + 2\alpha < 0$.

2.4. The periodic setting. Let us give here the modifications needed to handle the case $\Omega = \mathbb{T}^N$, $N = 2,3$. It is worth noticing that Lemma 2.2 holds also with $\Omega = \mathbb{T}^N$. On the other hand, the Sobolev inequality (2.3) does not hold for general functions in $\mathbb{T}^N$ but holds, for instance, for zero mean-value functions. Note that if $f(t)$ has mean value zero for all time $t \ge 0$, then using the invariance by Galilean transformations, $u \mapsto u(t, x - z\,t) + z$ with $z \in \mathbb{R}^3$, we can assume that u has zero mean value for all time and we are done. Otherwise, we have only to care about the treatment of the nonlinear term $(W.\nabla)v$ in (28). Denoting by $\underline{W}$ the L^2-projection of W on zero mean-value functions, we rewrite $(W.\nabla)v$ as

$$(W.\nabla)v = (\underline{W}.\nabla)v + \left(\int_\Omega W\right)\nabla v. \tag{42}$$

We take the H^s-scalar product of (28) with $\underline{W}$ and add with the L^2-scalar product of (28) with W. The H^s-scalar product coming from the first term of the right-hand side of (42) can be treated as in $\mathbb{R}^N$. For the second term, we observe that

$$\begin{aligned}\left|\left(\left(\left(\int_\Omega W\right)\nabla v, \underline{W}\right)\right)_{H^s}\right| &= \left|\int_\Omega W\right| \left|((\nabla v, \underline{W}))_{H^s}\right| \\ &\lesssim \|W\|_{L^2}\|\nabla v\|_{H^s}\|\nabla \underline{W}\|_{H^{s-1}}.\end{aligned}$$

On the other hand, concerning the L^2-scalar product we notice that

$$\begin{aligned}\left|\left(\left((W.\nabla)v, W\right)\right)_{L^2}\right| &= \left|\left(\left((\underline{W}.\nabla)v, W\right)\right)_{L^2} + \left(\int_\Omega W\right)\left(\left(\nabla v, \underline{W}\right)\right)_{L^2}\right| \\ &\lesssim \|\underline{W}\|_{L^6}\|\nabla v\|_{L^2}\|W\|_{L^3} + \left|\int_\Omega W\right|\|\nabla v\|_{L^2}\|\underline{W}\|_{L^2} \\ &\lesssim \|W\|_{H^s}\|\nabla W\|_{L^2}\|\nabla v\|_{L^2}.\end{aligned}$$

We thus obtain, exactly as in (30),

$$\begin{aligned}\frac{\mathrm{Re}}{2}\frac{d}{dt}\Big(\|\underline{W}\|_{H^s}^2 + \|W\|_{L^2}^2\Big) + \frac{3}{4}\|P_\varepsilon \nabla W\|_{H^s}^2 + \frac{(1-\omega)}{2}\|Q_{>\varepsilon}\nabla W\|_{H^s}^2 \\ \le ((Q_\varepsilon \operatorname{div}\tau, \underline{W}))_{H^s} + \|P_\varepsilon Z\|_{H^s}^2 + \frac{\omega^2}{4(1-\omega)}\|Q_\varepsilon \nabla v\|_{H^s}^2 \\ + \frac{C\ \mathrm{Re}}{(1-\omega)^2}\left(\|\nabla u\|_{H^s}^2 + \|\nabla v\|_{H^s}^2\right)\|W\|_{H^s}^2.\end{aligned}$$

The remainder of the analysis is now exactly the same as in $\mathbb{R}^N$.

3. Proof of Theorems 1.2 and 1.3. In this section we prove a convergence result in the Besov spaces $B_2^{s-1,1}$, $s \ge N/2$. It will require a smallness assumption on the retardation parameter ω but, on the other hand, will enable us to reach the critical regularity space for (5). Note that our smallness assumption on the retardation parameter is the same as the one in [1] to get the stability of the null solution in such function spaces.

Let us recall the following well-posedness result derived in [1].

THEOREM 3.1. *Let $(u_0, \tau_0) \in B^{s-1}(\mathbb{R}^N) \cap B^{N/2-1}(\mathbb{R}^N) \times B^s(\mathbb{R}^{N^2}) \cap B^{N/2}(\mathbb{R}^{N^2})$ with $s \ge N/2$. Then there exist a unique positive maximal time T^* and a unique solution*

$$(u,\tau) \in C([0,T^*[; B^{s-1}\cap B^{N/2-1}) \cap L^1_{\mathrm{loc}}(0,T^*; B^{s+1}\cap B^{N/2+1}) \times C([0,T^*[; B^s \cap B^{N/2}).$$

Moreover, if $T^* < \infty$, then

$$\limsup_{t \nearrow T^*}\Big(\|u(t)\|_{B^{N/2-1}} + \|\tau(t)\|_{B^{N/2}}\Big) = +\infty. \tag{43}$$

We will make use of the following classical commutator and product estimates (see, for instance, [1], [2], and [11]).

LEMMA 3.2. *For all* $s \in]1-N/2, 1+N/2[$ *we have*

$$\|\tilde{\Delta}_j[(a.\nabla), \Delta_j]b\|_2 \lesssim 2^{-j(s-1)}\gamma_j \|\nabla a\|_{B^{N/2+1}} \|b\|_{B^{s-1}} \tag{44}$$

with $\|\gamma_j\|_{L^1(\mathbb{Z})} \lesssim 1$.

For all $s_1, s_2 \le N/2$ with $s_1 + s_2 > 0$ it holds that

$$\|ab\|_{B^{s_1+s_2-N/2}} \lesssim \|a\|_{B^{s_1}} \|b\|_{B^{s_2}} \,. \tag{45}$$

For any $\varepsilon > 0$ we divide $\mathbb{Z}$ into the three following subsets:

$$I := \mathbb{Z}_-^* = \{j \in \mathbb{Z}, 0 < 2^j < 1\}, \quad J_\varepsilon := \{j \in \mathbb{Z}, 1 \le 2^j \le \varepsilon^{-\alpha}\}, \quad \text{and}$$
$$K_\varepsilon := \{j \in \mathbb{Z}, 2^j > \varepsilon^{-\alpha}\},$$

and for any subset $N \subset \mathbb{Z}$ we denote by $\|\cdot\|_{B^s_N}$ the seminorm

$$\|u\|_{B^s_N} = \sum_{j \in N} 2^{js} \|\Delta_j u\|_{L^2} \,.$$

3.1. Estimate on W and $\varepsilon\tau$.

LEMMA 3.3. *The solution* $(u, \varepsilon\tau)$ *of* (5) *satisfies, for all* $0 < t < T^*$,

$$\begin{aligned}
&\frac{d}{dt}\Big(\mathrm{Re}\|W\|_{B^{s-1}} + 4\varepsilon\|\tau\|_{B^s}\Big) \\
&\quad + [(1-\omega)/2 - 16\omega]\|W\|_{B^{s+1}_{K_\varepsilon}} + \|W\|_{B^{s+1}_{I\cup J_\varepsilon}} + 2\|\tau\|_{B^s_{K_\varepsilon}} + 2\varepsilon^\beta \|\tau\|_{B^s_{I\cup J_\varepsilon}} \\
&\quad \le 5\|Z\|_{B^s_{I\cup J_\varepsilon}} + 16\omega\|v\|_{B^{s+1}_{K_\varepsilon}} + 16\omega\varepsilon^\beta(\|W\|_{B^{s+1}_{I\cup J_\varepsilon}} + \|v\|_{B^{s+1}_{I\cup J_\varepsilon}}) \\
&\quad + C\,\varepsilon\mu_1 \|u\|_{B^{N/2+1}} \|\tau\|_{B^s} + C\,(\|u\|_{B^{N/2+1}} + \|v\|_{B^{N/2+1}})\|W\|_{B^{s-1}}.
\end{aligned} \tag{46}$$

Proof. Applying Δ_j to (28) we have for $j \in J_\varepsilon$,

$$\begin{aligned}
&\mathrm{Re}\Big(\partial_t \Delta_j W + \mathcal{P}(u.\nabla)\Delta_j W\Big) - (1-\omega)\Delta_j \Delta W \\
&\quad = -\omega \Delta_j \Delta v + \Delta_j \mathcal{P}\mathrm{div}\,\tau + \mathrm{Re}\,\tilde{\Delta}_j \mathcal{P}[(u.\nabla), \Delta_j]W + \mathrm{Re}\,\Delta_j \mathcal{P}(W.\nabla)v
\end{aligned} \tag{47}$$

and for $j \in I$,

$$\begin{aligned}
&\mathrm{Re}\Big(\partial_t \Delta_j W + \mathcal{P}(u.\nabla)\Delta_j W\Big) - \Delta_j \Delta W \\
&\quad = \Delta_j Z + \mathrm{Re}\,\tilde{\Delta}_j \mathcal{P}[(u.\nabla), \Delta_j]W + \mathrm{Re}\,\Delta_j \mathcal{P}(W.\nabla)v \,.
\end{aligned} \tag{48}$$

Taking the scalar product in $L^2(\mathbb{R}^N)$ of (47) with $\Delta_j W$, using that W is divergence free and using the Cauchy–Schwarz inequality we get

$$\begin{aligned}
&\frac{1}{2}\,\mathrm{Re}\,\frac{d}{dt}\|\Delta_j W\|_2^2 + (1-\omega)\|\nabla \Delta_j W\|_2^2 \\
&\qquad \le \|\Delta_j W\|_2 \Big(\omega\|\Delta_j \Delta v\|_2 + \|\Delta_j \mathrm{div}\,\tau\|_2 \\
&\qquad\qquad + \mathrm{Re}\,\|\tilde{\Delta}_j P[(u.\nabla), \Delta_j]W\|_2 + \mathrm{Re}\,\|\Delta_j P(W.\nabla)v\|_2\Big).
\end{aligned} \tag{49}$$

We use now that, according to Bernstein inequality, $\|\nabla \Delta_j W\|_2 \ge 2^{j-1}\|\Delta_j W\|_2$ and divide (49) by $\|\Delta_j W\|_2$. Then, estimating the commutator term, thanks to (44), and the last term, thanks to (45), with $s_1 = s - 1$ and $s_2 = N/2$, using Bernstein inequalities, it follows that

$$\begin{aligned} \mathrm{Re}\, \frac{d}{dt}\|\Delta_j W\|_2 + \frac{(1-\omega)}{2} 2^{2j}\|\Delta_j W\|_2 &\le 2\|\Delta\Delta_j v\|_{L^2} + 2\|\Delta_j \mathrm{div}\,\tau\|_2 \\ &\quad + \gamma_j 2^{-j(s-1)}(\|u\|_{B^{N/2+1}} + \|v\|_{B^{N/2+1}})\|W\|_{B^{s-1}} \end{aligned} \tag{50}$$

with $\|(\gamma_j)\|_{l^1(\mathbb{Z})} \lesssim 1$. Multiplying by $2^{j(s-1)}$ and summing in $j \in K_\varepsilon$, it follows that

$$\begin{aligned} \mathrm{Re}\, \frac{d}{dt}\|W\|_{B^{s-1}_{K_\varepsilon}} + \frac{(1-\omega)}{2}\|W\|_{B^{s+1}_{K_\varepsilon}} - 2\|\tau\|_{B^s_{K_\varepsilon}} \\ \le (\|u\|_{B^{N/2+1}} + \|v\|_{B^{N/2+1}})\|W\|_{B^{s-1}}\,. \end{aligned} \tag{51}$$

Proceeding in the same way with (48) but summing in $j \in I \cup J_\varepsilon$, we obtain

$$\begin{aligned} \mathrm{Re}\, \frac{d}{dt}\|W\|_{B^{s-1}_{I\cup J_\varepsilon}} + \frac{1}{2}\|W\|_{B^{s+1}_{I\cup J_\varepsilon}} - \|Z\|_{B^s_{I\cup J_\varepsilon}} \\ \le (\|u\|_{B^{N/2+1}} + \|v\|_{B^{N/2+1}})\|W\|_{B^{s-1}}\,. \end{aligned} \tag{52}$$

Now, for $j \in \mathbb{Z}$, we infer from (5) that

$$\begin{aligned} &\varepsilon\partial_t\Delta_j\tau + \varepsilon(u.\nabla)\Delta_j\tau + \Delta_j\tau \\ &\quad = 2\omega\Delta_j\mathbf{D}[u] - \varepsilon[(u.\nabla),\Delta_j]\tau + \varepsilon\Delta_j\mathbf{g}(\nabla u,\tau)\,. \end{aligned} \tag{53}$$

Rewriting $\Delta_j(\tau - 2\omega\mathbf{D}[u])$ as $\Delta_j(\tau - 2\omega\mathbf{D}[W] - 2\omega\mathbf{D}[v])$ for $j \in K_\varepsilon$ and as

$$\varepsilon^\beta\Delta_j\tau - 2\omega\varepsilon^\beta\Delta_j(\mathbf{D}[W] + \mathbf{D}[v]) + (1-\varepsilon^\beta)\Delta_j Z$$

for $j \in I \cup J_\varepsilon$, similar considerations as above lead to the two following inequalities:

$$\begin{aligned} \varepsilon\frac{d}{dt}\|\tau\|_{B^s_{K_\varepsilon}} + \|\tau\|_{B^s_{K_\varepsilon}} &\le 4\omega\|W\|_{B^{s+1}_{K_\varepsilon}} \\ &\quad + 4\omega\|v\|_{B^{s+1}_{K_\varepsilon}} + C\,\varepsilon\,\|u\|_{B^{N/2+1}}\|\tau\|_{B^s} \end{aligned} \tag{54}$$

and

$$\begin{aligned} \varepsilon\frac{d}{dt}\|\tau\|_{B^s_{I\cup J_\varepsilon}} + \varepsilon^\beta\|\tau\|_{B^s_{I\cup J_\varepsilon}} &\le \|Z\|_{B^s_{I\cup J_\varepsilon}} + 4\omega\varepsilon^\beta\|W\|_{B^{s+1}_{I\cup J_\varepsilon}} \\ &\quad + 4\omega\varepsilon^\beta\|v\|_{B^{s+1}_{I\cup J_\varepsilon}} + C\,\varepsilon\,\|u\|_{B^{N/2+1}}\|\tau\|_{B^s}. \end{aligned} \tag{55}$$

Adding (51) + (52) + 4((55) + (54)), (46) follows. ∎

3.2. Estimate on $\boldsymbol{\tau - 2\omega\mathbf{D}[u]}$.

LEMMA 3.4.

$$\begin{aligned} \frac{d}{dt}\|Z\|_{B^{s-2}_{J_\varepsilon}} + \frac{1}{\varepsilon}\|Z\|_{B^{s-2}_{J_\varepsilon}} &\le \frac{(1+\omega)}{\mathrm{Re}}\|\tau\|_{B^s_{J_\varepsilon}} + \|\mathcal{P}f\|_{B^{s-1}_{J_\varepsilon}} \\ &\quad + C\,\alpha\ln(\varepsilon^{-1})\Big(\|u\|_{B^{N/2+1}} + \|\tau\|_{B^{N/2}}\Big)\|u\|_{B^{s-1}}, \end{aligned} \tag{56}$$

$$\begin{aligned} \frac{d}{dt}\|Z\|_{B^s_I} + \frac{1}{\varepsilon}\|Z\|_{B^s_I} &\le \frac{(1+\omega)}{\mathrm{Re}}\|\tau\|_{B^s_I} + \|\mathcal{P}f\|_{B^{s-1}_I} \\ &\quad + C\Big(\|u\|_{B^{N/2+1}} + \|\tau\|_{B^{N/2}}\Big)\|u\|_{B^{s-1}}. \end{aligned} \tag{57}$$

Proof. Applying Δ_j to (33) and taking the L^2-scalar product with $\Delta_j Z$ we get

$$\frac{d}{dt}\|\Delta_j Z\|_{L^2} + \frac{(1-\omega)}{2\ \mathrm{Re}}2^{2j}\|\Delta_j Z\|_{L^2} + \frac{1}{\varepsilon}\|\Delta_j Z\|_{L^2} \lesssim \|\Delta_j f_1\|_{L^2} + \|\Delta_j f_2\|_{L^2},$$

where

$$f_1 = \frac{2\omega}{\mathrm{Re}}\mathbf{D}[\mathcal{P}\mathrm{div}\,\tau] - \frac{(1-\omega)}{\mathrm{Re}}\Delta\tau + \frac{2\omega}{\mathrm{Re}}\mathbf{D}[\mathcal{P}f] - 2\omega\mathbf{D}[\mathcal{P}(u.\nabla)u]$$

and

$$f_2 = \mathcal{P}(u.\nabla)\tau + g(\nabla u, \tau).$$

Multiplying this inequality by $2^{j(s-2)}$ and summing in $j \in J_\varepsilon$, we infer that

$$\begin{aligned}\frac{d}{dt}\|Z\|_{B^{s-2}_{J_\varepsilon}} + \frac{(1-\omega)}{2\ \mathrm{Re}}\|Z\|_{B^{s}_{J_\varepsilon}} + \frac{1}{\varepsilon}\|Z\|_{B^{s-2}_{J_\varepsilon}} \le \frac{(1+\omega)}{\mathrm{Re}}\|\tau\|_{B^{s}_{J_\varepsilon}} + \|\mathcal{P}f\|_{B^{s-1}_{J_\varepsilon}} \\ +\|(u.\nabla)u\|_{B^{s-1}_{J_\varepsilon}} + \|(u.\nabla)\tau\|_{B^{s-2}_{J_\varepsilon}} + \|\mathbf{g}(\nabla u,\tau)\|_{B^{s-2}_{J_\varepsilon}}.\end{aligned} \tag{58}$$

For $s > 1$ we estimate the nonlinear term thanks to (45) with, respectively, $(s_1, s_2) = (s-1, N/2)$, $(s-1, N/2-1)$, and $(s-2, N/2)$. For $s = 1$ (of course $N = 2$) we estimate the first nonlinear term in the same way and use the following lemma to estimate the two last ones. This lemma follows directly from the definitions of I and J_ε and the fact that, for $|s| \le N/2$, the usual product maps continuously[1] $B^{-s,1} \times B^{s,1}$ into $B^{-N/2,\infty}$ (see, for instance, [11]). Note, in particular, that $|J_\varepsilon| \lesssim \alpha \ln(\varepsilon^{-1})$. $\square$

LEMMA 3.5. *For all $s_1, s_2 \le N/2$ with $s_1 + s_2 = 0$ it holds that*

$$\|a\,b\|_{B^{-N/2}_{J_\varepsilon}} \lesssim \alpha \ln(\varepsilon^{-1})\|a\|_{B^{s_1}}\|b\|_{B^{s_2}} \tag{59}$$

and

$$\|a\,b\|_{B^{-N/2+2}_{I}} \lesssim \|a\|_{B^{s_1}}\|b\|_{B^{s_2}}. \tag{60}$$

We apply this lemma with $(s_1, s_2) = (0, 0)$ and $(-1, 1)$ for, respectively, the second and the third nonlinear term of (58) to complete the proof of (56). Finally (57) can be easily obtained in the same way by using that $\|a\|_{B^s_I} \le \|a\|_{B^{s'}_I}$ for $s' \le s$ and (60).

3.3. Convergence to the Newtonian flow. From now on we set $\gamma(\omega) = (1-\omega)/2 - 16\omega$ and assume that $0 \le \omega \le \omega_0$ with $\gamma(\omega_0) > 0$.

We proceed as in section 2.3. For $0 < \beta < 1$, we add (46) and $\varepsilon^{2\beta}((56) + (57))$ to get

$$\begin{aligned}&\frac{d}{dt}\Big(\mathrm{Re}\|W\|_{B^{s-1}} + 4\varepsilon\|\tau\|_{B^s} + \varepsilon^{2\beta}(\|Z\|_{B^{s-2}_{J_\varepsilon}} + \|Z\|_{B^s_I})\Big) + \gamma(\omega_0)\|W\|_{B^{s+1}_{K_\varepsilon}} \\ &\quad + \|W\|_{B^{s+1}_{I\cup J_\varepsilon}} + 2\|\tau\|_{B^s_{K_\varepsilon}} + \varepsilon^{\beta}\|\tau\|_{B^s_{I\cup J_\varepsilon}} + \frac{\varepsilon^{2\beta-1}}{2}(\|Z\|_{B^{s-2}_{J_\varepsilon}} + \|Z\|_{B^s_I}) \\ &\le 16\omega\|v\|_{B^{s+1}_{K_\varepsilon}} + 16\omega\varepsilon^{\beta}\|v\|_{B^{s+1}_{I\cup J_\varepsilon}} + \varepsilon^{2\beta}\|\mathcal{P}f\|_{B^{s-1}_{I\cup J_\varepsilon}} \\ &\quad + C\,\varepsilon\|u\|_{B^{N/2+1}}\|\tau\|_{B^s} + C\,(\|u\|_{B^{N/2+1}} + \|v\|_{B^{N/2+1}})\|W\|_{B^{s-1}} \\ &\quad + C\,\alpha\varepsilon^{2\beta}\ln(\varepsilon^{-1})(\|u\|_{B^{N/2+1}} + \|\tau\|_{B^{N/2}})\,\|v\|_{B^{s-1}}.\end{aligned} \tag{61}$$

[1]For $1 \le p \le \infty$, $\|f\|_{B^{s,p}} = \big\|\{2^{js}\|\Delta_j(f)\|_{L^2}\}\big\|_{l^p(\mathbb{Z})}$.

Here we used that for ε small enough, $\varepsilon^\beta \le \min(16\gamma(\omega_0), \frac{\mathrm{Re}}{4})$, $\varepsilon^{2\beta-1}/2 \ge 5$, and

$$5\|Z\|_{B^s_{J_\varepsilon}} \lesssim \varepsilon^{-2\alpha}\|Z\|_{B^{s-2}_{J_\varepsilon}} \le \frac{\varepsilon^{2\beta-1}}{2}\|Z\|_{B^{s-2}_{J_\varepsilon}}$$

as soon as

$$0<\alpha<1/2 \quad \text{and} \quad 0<2\beta<1-2\alpha\,. \tag{62}$$

From now on we set $(\alpha,\beta)=(1/8,1/8)$ so that (62) is satisfied. Setting

$$\begin{aligned}X_s(t) =\ & \mathrm{Re}\,\|W(t)\|_{B^{s-1}} + 4\varepsilon\|\tau\|_{B^s} + \varepsilon^{2\beta}\|Z\|_{B^{s-2}_{I\cup J_\varepsilon}}\\ &+\int_0^t \frac{\gamma(\omega_0)}{2}\|W\|_{B^{s+1}} + \Big(\|\tau\|_{B^s_{K_\varepsilon}} + \varepsilon^\beta\|\tau\|_{B^s_{I\cup J_\varepsilon}}\Big) + \frac{\varepsilon^{2\beta-1}}{2}\Big(\|Z\|_{B^{s-2}_{J_\varepsilon}} + \|Z\|_{B^s_I}\Big)\,ds,\end{aligned}$$

we infer that

$$\begin{aligned}\frac{d}{dt}X_s(t) \le\ & 16\omega\|v\|_{B^{s+1}_{K_\varepsilon}} + 16\omega\varepsilon^\beta\|v\|_{B^{s+1}_{I\cup J_\varepsilon}} + \varepsilon^{2\beta}\|\mathcal{P}f\|_{B^{s-1}_{I\cup J_\varepsilon}}\\ &+C(\mathrm{Re}\,,\omega)\Big[\|W\|_{B^{N/2+1}} + \|v\|_{B^{N/2+1}} + \varepsilon^{2\beta}\ln(\varepsilon^{-1})\|\tau\|_{B^{N/2}}\Big]X_s\\ &+C\,\alpha\varepsilon^{2\beta}\ln(\varepsilon^{-1})(\|v\|_{B^{N/2+1}} + \|W\|_{B^{N/2+1}} + \|\tau\|_{B^{N/2}})\,\|v\|_{B^{s-1}}.\end{aligned}$$

By Gronwall's lemma we infer that

$$\begin{aligned}X_s(t) \le\ & \exp\Big(C(\omega,\ \mathrm{Re}\,)\Big(\|v\|_{L^1_tB^{N/2+1}} + X_{N/2}(t)\Big)\Big)\\ &\Big[X_s(0) + 16\omega\|v\|_{L^1_tB^{s+1}_{K_\varepsilon}} + 16\omega\varepsilon^\beta\|v\|_{L^1_tB^{s+1}_{I\cup J_\varepsilon}} + \varepsilon^{2\beta}\|\mathcal{P}f\|_{L^1_tB^{s-1}_{I\cup J_\varepsilon}}\\ &+C\,\alpha\ln(\varepsilon^{-1})\varepsilon^\beta\Big(X_{N/2}(t)\|v\|_{L^\infty_tB^{s-1}} + \varepsilon^\beta\|v\|_{L^1_tB^{s-1}}\|v\|_{L^\infty_tB^{s-1}}\Big)\Big],\end{aligned} \tag{63}$$

where

$$X_s(0) = 4\varepsilon\|\tau_0\|_{B^s} + \varepsilon^{2\beta}\Big(\|\tau_0 - 2\omega\mathbf{D}[u_0]\|_{B^s_I} + \|\tau_0 - 2\omega\mathbf{D}[u_0]\|_{B^{s-2}_{J_\varepsilon}}\Big)\,. \tag{64}$$

Assuming that $T^*_\varepsilon \le T_0$ and noticing that

$$\|v\|_{L^1_{T_0}B^{N/2+1}_{K_\varepsilon}} \to 0 \text{ as } \varepsilon \to 0, \tag{65}$$

we deduce from (63) and (64) and the continuity of $t \mapsto X_{N/2}(t)$ that there exists $\varepsilon_0 = \varepsilon_0(N, \|\tau_0\|_{B^{N/2}}, \mathcal{P}f, u_0)$ such that for any $0<\varepsilon<\varepsilon_0$ and any $0<t<T^*_\varepsilon$,

$$X_{N/2}(t) \le \Lambda(\varepsilon)$$

with $\Lambda(\varepsilon) \searrow 0$ as $\varepsilon \to 0$. This contradicts (43) of Theorem 3.1 and thus ensures that $T^*_\varepsilon > T_0$. The convergence results (16) and (18) follow as well. To prove (17) we notice that from this last limit and (65), $\|\tau - 2\omega\mathbf{D}[u]\|_{L^1_{T_0}B^{N/2}_{K_\varepsilon}} \to 0$, $\varepsilon^{2\beta-1}\|\tau - 2\omega\mathbf{D}[u]\|_{L^1_{T_0}B^{N/2}_I} \to 0$, and $\varepsilon^{2\beta-1}\|\tau - 2\omega\mathbf{D}[u]\|_{L^1_{T_0}B^{N/2-2}_{J_\varepsilon}} \to 0$. This gives the result since $2\beta - 1 + 2\alpha \le 0$ and thus

$$\|\tau - 2\omega\mathbf{D}[u]\|_{L^1_{T_0}B^s_{J_\varepsilon}} \lesssim \varepsilon^{-2\alpha}\|\tau - 2\omega\mathbf{D}[u]\|_{L^1_{T_0}B^{s-2}_{J_\varepsilon}} \lesssim \varepsilon^{2\beta-1}\|\tau - 2\omega\mathbf{D}[u]\|_{L^1_{T_0}B^{s-2}_{J_\varepsilon}}.$$

Finally, for $s > N/2$, the proof follows the same lines using that

$$\|v\|_{L^1_{T_0} B^{N/2+1}_{K_\varepsilon}} \le \varepsilon^{\alpha(s-N/2)} \|v\|_{L^1_{T_0} B^{s+1}_{K_\varepsilon}} \tag{66}$$

and thus with

$$\varepsilon_0 = \varepsilon_0(N, \|\tau_0\|_{B^{N/2}}, \|u_0\|_{B^{N/2-1}}, \|v\|_{L^1_{T_0} B^{s+1}_{K_\varepsilon}}, \|\mathcal{P} f\|_{L^1_{T_0} B^{N/2-1}}).$$

This completes the proof of Theorems 1.2 and 1.3. ∎

Acknowledgment. The authors are grateful to the referees for useful remarks.

INVERSE SCATTERING FOR SCHRÖDINGER-TYPE OPERATORS WITH INTERFACE CONDITIONS ACROSS SMOOTH SURFACES*

STEPHEN O'DELL†

Abstract. We consider direct and inverse scattering for the Laplace–Beltrami operator with electromagnetic potentials in domains with smooth surfaces upon which we impose interface conditions. The boundary conditions used encompass physical models of imperfect transmission arising in acoustics, quantum scattering, semiconductors, and geophysics. We prove uniqueness of the location of the surfaces and the interface conditions from the fixed-energy scattering amplitude. If the surface encloses a compact region, we also prove uniqueness of the Dirichlet-to-Neumann operator at the boundary of the obstacle.

Key words. inverse scattering, interface conditions, transmission problems

1. Introduction. Consider the Laplace–Beltrami operator with electromagnetic potentials in $\mathbb{R}^n$:

$$L = \left(\sum_{j,k} \frac{1}{\sqrt{g}} \left(-i\frac{\partial}{\partial x_j} + A_j(x) \right) \sqrt{g} g^{jk}(x) \left(-i \frac{\partial}{\partial x_k} + A_k(x) \right) \right) + V(x), \tag{1.1}$$

where all the coefficients are real-valued and $L = -\triangle$ for $|x| \geq R$. In its full form, this operator is the Hamiltonian for a quantum particle in an electromagnetic field constrained to a Riemannian manifold. It also can be used to model wave propagation in anisotropic media. Here, $A(x) = (A_1(x), \ldots, A_n(x))$ is the magnetic potential, $V(x)$ is the electric potential, and $\sum_{j,k} g_{jk}(x)\, dx^j \otimes dx^k$ is a metric with determinant $g(x)$. In this paper, we study inverse scattering for this operator when it is defined with interface conditions across smooth embedded surfaces.

To explain this in detail, we fix some bounded open connected domain Ω with smooth boundary $\partial\Omega$. Define the boundary operators,

$$\gamma^0_\pm u(x) = \lim_{x\to\partial\Omega^\pm} u(x), \tag{1.2}$$

$$\gamma^1_\pm u(x) = \lim_{x\to\partial\Omega^\pm} \sum_{j,k} g^{jk} \left(\frac{\partial u}{\partial x_j} + iA_j u \right) \nu_k(x) \left(\sum_{p,r} g^{pr}(x)\nu_p(x)\nu_r(x) \right)^{-\frac{1}{2}}, \tag{1.3}$$

where the positive limit denotes that it is taken from the exterior and ν is the outward pointing unit normal (with respect to the Euclidean metric). Let L^e and L^i be operators of the form (1.1) with smooth coefficients $\{g_e^{jk}, A_j^e, V^e\}$ and $\{g_i^{jk}, A_j^i, V^i\}$, respectively. Now consider the time-independent scattering problem:

$$(L^e - k^2)(e^{ik\omega\cdot x} + w(x,k\omega)) = 0 \text{ in } \mathbb{R}^n\backslash\Omega, \tag{1.4}$$

$$(L^i - k^2)w(x,k\omega) = 0 \text{ in } \Omega, \tag{1.5}$$

with interface conditions,

$$\begin{pmatrix} \gamma_-^0 w \\ \gamma_-^{1,i} w \end{pmatrix} = \begin{pmatrix} a(x) & b(x) \\ c(x) & d(x) \end{pmatrix} \begin{pmatrix} \gamma_+^0 (e^{ik\omega\cdot x} + w) \\ \gamma_+^{1,e} (e^{ik\omega\cdot x} + w) \end{pmatrix}, \tag{1.6}$$

and outgoing radiation conditions,

$$\frac{\partial w}{\partial r}(x, k\omega) - ikw(x, k\omega) = o\left(\frac{1}{r^{\frac{n-1}{2}}}\right), \quad w(x, k\omega) = O\left(\frac{1}{r^{\frac{n-1}{2}}}\right). \tag{1.7}$$

In what follows, we denote the matrix in (1.6) as $T(x)$ and refer to it as the interface matrix, or transfer matrix. It is worthwhile to remark that we make no assumptions here on the coefficients or the interface to guarantee there is in fact a boundary. This allows us to use the above problem to also study *transmission cracks* which occur if $L^e = L^i$ everywhere and $T = I$ on some subset of the boundary. Similarly this boundary value problem also covers the case when there may just be a "tear" in the coefficients, i.e., L^i and L^e smoothly connect and T is trivial on some subset of the boundary.

Let us briefly formulate the scattering problem. The direct problem is to show there exists a solution $w(x, k\omega)$ solving (1.4)–(1.7) that has the asymptotic form,

$$w(x, k\omega) = e^{ik\omega\cdot x} + a\left(\frac{x}{|x|}, \omega, k\right)\frac{e^{ik|x|}}{|x|^{\frac{n-1}{2}}} + O\left(\frac{1}{|x|^{\frac{n+1}{2}}}\right), \tag{1.8}$$

where $a(\theta, \omega, k)$ is the scattering amplitude for some $k > 0$. The inverse problem is to show that the scattering amplitude uniquely characterizes the perturbations to the exterior coefficients. For the transmission obstacles given above, this entails showing that the location of the boundary and the transfer matrix is uniquely determined everywhere that at least one of the following holds: (1) The coefficients are not smooth across $\partial\Omega$, or (2) $T \neq I$. Also, we want to prove that the Dirichlet-to-Neumann operator is uniquely determined on $\partial\Omega$.

Without *any* further restrictions on the transfer matrix or the coefficients, there are some constant factors by which we can change the interface and interior coefficients which do not affect the fixed energy scattering amplitude. Moreover, altering the coefficients and interfaces in this manner will produce a different obstacle. Indeed, we prove that the scattering operator can distinguish two such obstacles, whereas the fixed-energy scattering amplitude cannot. In most practical applications, however, the boundary conditions (1.6) are subject to constraints which remove these degeneracies. This is discussed in detail in section 2.2. In the interest of obtaining the most general results, we prove the uniqueness of the inverse problem up to these constants and then interpret the results in physically interesting cases afterward.

Our main theorems, as well as some background, are given in section 2. In section 2.1, we formulate our result on the forward problem and in section 2.2 cite physical examples in which these boundary conditions arise. In section 2.3 the results on the inverse problem are given, and in section 2.4 we discuss previous work on scattering from transmission obstacles and interfaces.

The plan of the remainder of the paper is as follows. After reviewing preliminary material on semigeodesic coordinates, layer potentials, and wave front sets in section 3, we solve the direct problem in section 4 by reducing the problem to a system of pseudodifferential equations on $\partial\Omega$. In section 5, we solve the inverse problem when there are only electric potentials. In this case the analysis of certain boundary operators is simplified since the first two terms of the symbol of the Dirichlet-to-Neumann operator are known. In section 6, the full symbol of the Dirichlet-to-Neumann operator is recalled and we formulate a theorem on boundary determination in the presence of anisotropic media and electromagnetic potentials. This prepares us to solve the general inverse problem in section 7 in which case a much more exhaustive analysis is required to prove the uniqueness.

2. Results and background.

2.1. The direct problem.

2.1.1. Self-adjointness. Consider the scattering problem (1.4)–(1.7). Let $\sqrt{\tilde{g}^e}$ and $\sqrt{\tilde{g}^i}$ denote the determinant of the restriction of the metrics to the boundary $\partial\Omega$. We say the boundary conditions are *self-adjoint* if:

$$a(x)d(x) - b(x)c(x) = \frac{\sqrt{\tilde{g}^e}(x)}{\sqrt{\tilde{g}^i}(x)}. \tag{2.1}$$

The reason for this definition is that if we define L to be an operator equal to L^i on Ω and L^e on $\mathbb{R}^n\backslash\Omega$, and impose interface conditions of the form (1.6) on $\partial\Omega$, then the adjoint of L, as defined in the L^2-inner product, will be the same as L if and only if (2.1) holds. This is proved in section 4.2. We also show there that (2.1) is equivalent to the energy flux being equal on each side of the boundary.

The distinction between self-adjoint and nonself-adjoint conditions is relevant since it affects the solvability of the forward problem. In particular, it is in general not possible to prove the uniqueness with nonself-adjoint boundary conditions. Nonetheless, we prove solvability off of a discrete set of energies in this case.

2.1.2. Results on the direct problem. We always assume that

$$a > 0,\ \ d > 0,\ \text{ and } \det T \neq 0, \tag{2.2}$$

and either

$$b \neq 0 \text{ on all of } \partial\Omega \text{ or } b = 0 \text{ on all of } \partial\Omega, \tag{2.3}$$

or

$$\exists \Delta \subset \partial\Omega \text{ open with } \partial\Delta \text{ smooth s.t. } \operatorname{Re} b \neq 0 \text{ on } \Delta \text{ and } b = 0 \text{ on } \partial\Omega\backslash\overline{\Delta}. \tag{2.4}$$

The term $b(x)$ requires special consideration since it contributes to the leading term of the system of pseudodifferential equations to which the direct problem is reduced. The conditions in (2.4) describe an analogue of partially coated obstacles for transmission obstacles, which we introduce to model transmission obstacles with a resistive coating on a subset of the boundary. Finally, assume a, c, and d are smooth everywhere and b is smooth on $\overline{\Delta}$ and $\partial\Omega\backslash\Delta$. Unless otherwise stated, we always assume that (2.2) holds with either (2.3) or (2.4) for every transfer matrix.

Our main result on the direct scattering problem is the following.

THEOREM 2.1. *Say T satisfies* (2.2) *and* (2.3) *or* (2.4). *Then for all but a discrete set of $k \in (0,\infty)$ there exists a solution to* (1.4)–(1.7) *of the form*

$$w(x, k\omega) = a(\theta, \omega, k)\frac{e^{ik|x|}}{|x|^{\frac{n-1}{2}}} + O\left(\frac{1}{|x|^{\frac{n+1}{2}}}\right) \tag{2.5}$$

as $|x| \to \infty, \theta = \frac{x}{|x|}$. *Moreover, if also*

$$\mathrm{Im} b \le 0, \quad \mathrm{Im} c \ge 0, \qquad \textit{and} \qquad ad - \bar{b}c = \frac{\sqrt{\tilde{g}^e}}{\sqrt{\tilde{g}^i}}, \tag{2.6}$$

then the discrete set is empty. In particular, (1.4)–(1.7) *is solvable for all* $k > 0$ *in the self-adjoint case.*

These results are proved in section 4.

2.2. Physical background. It is worthwhile to briefly relate our problem explicitly to the case of acoustic scattering in anisotropic media. In this situation, to model the inhomogeneities, one uses an operator of the general form

$$L' = -\sum_{j,k=1}^{n} \frac{\partial}{\partial x_j} \gamma^{jk}(x) \frac{\partial}{\partial x_k} + \eta(x), \tag{2.7}$$

where we assume $\eta(x) = 0$ and $\gamma^{jk}(x) = \delta_{jk}$ for $|x|$ large. For $n \ge 3$ we can set $g^{jk} = (\det\{\gamma^{jk}\})^{\frac{1}{2-n}} \gamma^{jk}$ and multiply through by $\sqrt{g}$ in (1.4) to obtain an operator of the form (2.7). Moreover, it is straightforward to check that (if $A_j = 0$),

$$\sum_{j,k} \gamma^{jk}(x) \left(\frac{\partial u}{\partial x_k} \right)_+ \nu^k = \gamma_+^{1,L} u(x) \sqrt{\tilde{g}^e}. \tag{2.8}$$

Thus, an interface for operators of the form (2.7) has the form

$$\begin{pmatrix} \gamma_-^0 u \\ \sum_{j,k} \gamma_i^{jk}(x)(\frac{\partial u}{\partial x_k})_+ \nu^k \end{pmatrix} = \begin{pmatrix} a'(x) & b'(x) \\ c'(x) & d'(x) \end{pmatrix} \begin{pmatrix} u_+ \\ \sum_{j,k} \gamma_e^{jk}(x)(\frac{\partial u}{\partial x_k})_- \nu^k \end{pmatrix}, \tag{2.9}$$

where for g^{jk} and γ^{jk} related as above,

$$\begin{pmatrix} a'(x) & b'(x) \\ c'(x) & d'(x) \end{pmatrix} = \begin{pmatrix} a(x) & b(x)(\sqrt{\tilde{g}^e}) \\ c(x)(\sqrt{\tilde{g}^i})^{-1} & d(x)(\sqrt{\tilde{g}^e})(\sqrt{\tilde{g}^i})^{-1} \end{pmatrix}. \tag{2.10}$$

Despite the simpler form of the transfer matrix, we will always use the Laplace–Beltrami operator even when discussing acoustic wave propagation in anisotropic media since using the Laplace–Beltrami considerably simplifies some of the calculations, especially when it is necessary to make coordinate changes.

We now discuss some physical examples. Recall that the natural transmission conditions at an interface have the form

$$\gamma_+^0 u - \gamma_-^0 u = 0, \tag{2.11}$$

$$\gamma_+^{1,e} u \sqrt{\tilde{g}^e} - \gamma_-^{1,i} u \sqrt{\tilde{g}^i} = 0. \tag{2.12}$$

A simple application of the Green's function yields these conditions. Note there are no density terms for operators of the form (2.7).

Imperfect interfaces occur originally in the study of elastodynamic waves passing between two different elastic media which are not in perfect contact. Interpreted in the context of acoustic waves, the boundary conditions have the form

$$\gamma_+^0 u - \gamma_-^0 u = \alpha(x) \left[\gamma_-^{1,i} u \sqrt{\tilde{g}^i} + \gamma_+^{1,e} u \sqrt{\tilde{g}^e} \right], \tag{2.13}$$

$$\gamma_+^{1,e} u \sqrt{\tilde{g}^e} - \gamma_-^{1,i} u \sqrt{\tilde{g}^i} = \beta(x) \left[\gamma_-^0 u + \gamma_+^0 u \right]. \tag{2.14}$$

See [3] and [34] for background and references. Physically, we can interpret α and β as the relative compressibility and permeability of a thin membrane separating the two regions [34]. These interface conditions are easily converted into boundary conditions of the form (1.6) and the resultant interface matrix looks like

$$T = \frac{1}{1-\alpha\beta}\begin{pmatrix} 1+\alpha\beta & -2\alpha(\sqrt{\tilde{g}^e}) \\ -2\beta(\sqrt{\tilde{g}^i})^{-1} & (1+\alpha\beta)(\sqrt{\tilde{g}^e})(\sqrt{\tilde{g}^i})^{-1} \end{pmatrix}. \tag{2.15}$$

Of course, for operators of the form (2.7), the interface matrix does not have the density terms.

In the case $\beta = 0$, the boundary conditions are known as spring-contact boundary conditions. For background on their use, see the review given in [3]. In this paper the authors also derive a more accurate mathematical model (than the spring-contact boundary conditions) for 2-dimensional sound harmonic waves separated by a thin layer which turn out to be of the form (2.11)–(2.12), except that (2.12) has an additional correction term dependent on second order tangential derivatives at the surface.

The resistive and conductive transmission boundary conditions, which arise in geophysics, are also of this form (see [1] and the references therein). Resistive conditions arise if α is complex-valued and $\beta = 0$ in (2.13)–(2.14), and conductive conditions are given by assuming β is complex-valued and $\alpha = 0$ in (2.13)–(2.14).

In quantum scattering the simplest example of boundary conditions of the form (1.6) arises in the model of an electron wave passing through a δ-like potential. Assuming the media is Euclidean for simplicity, then if $V(x) = \kappa\delta_{\partial\Omega}$, it is easy to derive the transfer matrix will have the form (see [13])

$$T = \begin{pmatrix} 1 & 0 \\ \kappa & 1 \end{pmatrix}.$$

In general, the boundary conditions describing scattering from electric potentials of the above form are given by (2.13)–(2.14) with $\alpha = 0$.

Finally, transfer matrix boundary conditions have also been in use for many years in the effective mass method which is used to model the electronic states of semiconducting materials containing abrupt interfaces between materials of different compositions. Transfer matrix heterojunctions, as they are known in the literature, are used in this context to connect wave functions, known as envelopes, across regions of different chemical compositions and through barriers of yet a third material. See [2] and [32] for a review of their use as well as various physical interpretations of the matrix elements.

2.3. Results on the inverse problem.

2.3.1. Nonuniqueness. Consider (1.4)–(1.7). There are two types of alterations as follows which do not affect the scattering amplitude:

1. $T \to \tau T$ for $\tau > 0$.
2.

$$\begin{pmatrix} \Omega \\ T \\ g^{jk} \\ A_j \\ V \end{pmatrix} \to \begin{pmatrix} \Omega \\ \begin{pmatrix} \rho^{-\frac{n}{2}} & 0 \\ 0 & \rho^{1-\frac{n}{2}} \end{pmatrix} T \\ \rho^2 g^{jk} \\ A_j \\ \rho^2 V + k^2(1-\rho^2) \end{pmatrix} \quad \text{for } \rho > 0.$$

When describing physical phenomena, the model of a transmission obstacle will generally be selected in such a fashion that these constants do not arise. Shortly we will discuss a number of restrictions that remove these constants.

The first type of nonuniqueness results from the fact that if we multiply the interface by a constant, we can multiply the solution on the interior by the inverse of that constant without affecting the solution on the exterior. Of course, this type of degeneracy will not affect the full scattering operator and is somewhat trivial.

The second type of nonuniqueness is obtained by replacing (L^i-k^2) by $\rho^2(L^i-k^2)$ in (1.5) and then changing the interface matrix accordingly. The precise powers of ρ are selected in such a way that self-adjoint boundary conditions remain self-adjoint. Note that as a result of this type of nonuniqueness, there are always an infinite number of obstacles which are not identical to the background but which nonetheless are "invisible" to the scattering amplitude at a given fixed energy. Such obstacles, moreover, are distinguishable from the background by the scattering operator. It is worthwhile to formulate some restrictions as follows which force the constants to be one:

$\tau = 1$ if any of the following hold:
- The boundary conditions are self-adjoint.
- Any nonzero element of the interface matrix is fixed.

$\rho = 1$ if any of the following hold:
- $d(x) = (\sqrt{\tilde{g}^e})(\sqrt{\tilde{g}^i})^{-1}a(x)$.
- $g_e^{jk} = g_i^{jk} = \delta_{jk}$.
- $V^e = V^i = 0$.
- Any nonzero element of the interface matrix is fixed.

Note that for imperfect interfaces, the boundary conditions (2.15) are self-adjoint and $d(x) = (\sqrt{\tilde{g}^e})(\sqrt{\tilde{g}^i})^{-1}a(x)$ so that both τ and ρ are 1. The resistive and conductive boundary conditions, as well as the boundary conditions describing scattering from delta-like potentials, are a subset of imperfect interface boundary conditions (2.15).

In order to simplify notation in the future, we say $(L_1 - k^2)$ and $\rho^2(L_2 - k^2)$ *smoothly connect in the normal direction at* $x_0 \in \partial\Omega$ if for all p,

$$\left(\frac{\partial}{\partial\nu}\right)^p g_1^{jk}(x_0) = \rho^2 \left(\frac{\partial}{\partial\nu}\right))^p g_2^{jk}(x_0, \quad \left(\frac{\partial}{\partial\nu}\right)^p A_j^1(x_0) = \left(\frac{\partial}{\partial\nu}\right)^p A_j^2(x_0), \text{ and}$$

$$\left(\frac{\partial}{\partial\nu}\right)^p V_1(x_0) = \rho^2 \left(\frac{\partial}{\partial\nu}\right)^p (V_2(x_0) + k^2(1-\rho^2)). \tag{2.16}$$

2.3.2. Inverse problem. Our main result is that the fixed-energy scattering amplitude uniquely determines the obstacles up to the constant factors described above. We interpret these results in the case of imperfect interfaces afterwards. First, consider the location and let an obstacle be defined by three elements $\{\Omega, T, L^i\}$. Ω is a subset of $\mathbb{R}^n$, T is the interface matrix, and L^i is an operator of the form (1.1) which describes the physical properties of the interior of the obstacle.

THEOREM 2.2. *Consider scattering from an obstacle* $\{\Omega, T, L^i\}$ *as in problem* (1.4)–(1.7)*, where* T *satisfies* (2.2) *and* (2.3) *or* (2.4)*. Then* $a(\theta,\omega,k)$ *for* $\theta,\omega \in S^{n-1}$ *and some fixed* $k>0$ *uniquely determines the location of all points* $x_0 \in \partial\Omega$ *at which there does not exist* $\tau > 0, \rho > 0$ *such that*

1. $T(x_0) = \tau \begin{pmatrix} \rho^{-\frac{n}{2}} & 0 \\ 0 & \rho^{1-\frac{n}{2}} \end{pmatrix}$ *and*
2. $\rho^2(L^i - k^2)$ *and* $(L^e - k^2)$ *smoothly connect in the normal direction at* x_0.

When the constants are one, this means we uniquely determine all points on the boundary, where either $T \neq I$ or the coefficients do not smoothly connect. Now consider the boundary conditions. Below, Λ_j denotes the Dirichlet-to-Neumann operator on $\partial\Omega$ for the operator $L_j^i - k^2$ and $\sigma(\Lambda_j)$ is its full symbol (see section 6).

THEOREM 2.3. *Assume we are given two obstacles* $\{\Omega, T_1, L_1^i\}$ *and* $\{\Omega, T_2, L_2^i\}$ *with* T_1 *and* T_2 *satisfying* (2.2) *and* (2.3) *or* (2.4) *along with their respective scattering data* $a_1(\theta,\omega,k)$ *and* $a_2(\theta,\omega,k)$*. Then* $a_1(\theta,\omega,k) = a_2(\theta,\omega,k)$ *for* $\theta,\omega \in S^{n-1}$ *and some* $k > 0$ *implies there exists* $\tau > 0$, $\rho > 0$ *such that,*

$$T_1(x) = \tau \begin{pmatrix} \rho^{-\frac{n}{2}} & 0 \\ 0 & \rho^{1-\frac{n}{2}} \end{pmatrix} T_2(x) \text{ and } \sigma(\Lambda_1) = \rho\sigma(\Lambda_2).$$

Also, if k^2 *is not a Dirichlet eigenvalue for either* L_1^i *or* L_2^i *on* Ω*, then* $\Lambda_1 = \rho\Lambda_2$.

These results are proved in sections 5 and 7. As is proved in section 6 the equality of the symbols of the Dirichlet-to-Neumann operators implies that $(L_1^i - k^2)$ and $\rho^2(L_2^i - k^2)$ smoothly connect on the boundary in the sense of (2.16).

For imperfect interfaces (2.13) and (2.14), the results are as follows.

THEOREM 2.4. $a(\theta,\omega,k)$ *for* $\theta,\omega \in S^{n-1}$ *and some fixed* $k > 0$ *uniquely determines the location of all points* $x_0 \in \partial\Omega$ *at which it is not the case that*

1. $\alpha(x_0) = 0$, $\beta(x_0) = 0$ *and*
2. L^i *and* L^e *smoothly connect in the normal direction at* x_0.

THEOREM 2.5. *Assume* Ω *is known. Then* $a_1(\theta,\omega,k) = a_2(\theta,\omega,k)$ *for* $\theta,\omega \in S^{n-1}$ *and some* $k > 0$ *implies,*

$$\alpha_1(x) = \alpha_2(x),\ \beta_1(x) = \beta_2(x),\ \sigma(\Lambda_1) = \sigma(\Lambda_2).$$

Also, if k^2 *is not a Dirichlet eigenvalue for either* L_1 *or* L_2 *on* Ω*, then* $\Lambda_1 = \Lambda_2$.

These theorems are proved using Theorems 2.2 and 2.3. Since Theorems 2.2 and 2.3 are the more general results, we focus our attention on them throughout the paper.

2.4. Historical remarks and overview of approach. Already there has been extensive study of direct and inverse scattering from transmission obstacles in the case of perfectly transmitting interfaces and constant isotropic media on the interior and exterior (see the review article [5] and books [6] and [7] for a full history). The most general results in this case are due to Kirsch and Päivärinta [21], in which the authors consider the scattering problem for transmission obstacles embedded in known electric inhomogeneities with boundary conditions of the form

$$T = \begin{pmatrix} \tau & 0 \\ 0 & 1 \end{pmatrix}$$

(with τ constant) and containing unknown electric potentials. Here τ represents the inverse of the density of the interior constant isotropic media so that these boundary conditions are in fact self-adjoint. They prove that the fixed energy scattering data uniquely determine the location of the obstacle, the boundary conditions, and the interior electric potentials.

Recently there has also been greater focus on the scattering problem when the obstacle contains anisotropic media (see [4], [7], [9], [15], [27], and [28]). The anisotropic media is modeled in these papers using an operator of the form $\nabla \circ A(x)\nabla$ and the inverse scattering problem of determining the location is solved under various restrictions on $A(x)$. The recovery of the interior media is not considered in these papers.

As is well known, for $n \geq 3$ this problem is equivalent to the one we consider with a Laplace–Beltrami operator. A closely related problem is obtained by allowing inhomogeneous media on the interior (i.e., media with variable, isotropic density). The related direct scattering problem is considered by Martin [24] and Werner [35] and the inverse problem by Isakov [20]. The main result of [20] is that the fixed energy scattering data uniquely determine the location of the obstacle as well as the media at the boundary of the obstacle. Inhomogeneous media are covered by our work for $n \geq 3$ by using the metric $g_{jk}(x) = \rho(x)^{\frac{2-n}{2}}\delta_{jk}$, where ρ is the inhomogeneous density.

There has been little previous work on general boundary conditions of the type we consider. The only results we are aware of with off-diagonal elements in the transfer matrix are for resistive and conductive boundary conditions (see [1], [14], [16], and [33]) with the Helmholtz equation on the interior and exterior. In these papers the direct scattering problem is solved and in [16] and [33] it is shown the fixed-energy scattering data uniquely determine the boundary conditions and the location of an obstacle with conductive interfaces. Finally, we are unaware of previous work with nonself-adjoint boundary conditions.

To solve the inverse problem we investigate the behavior of the singularity of the Green's function near the boundary of obstacles. The idea to consider the behavior of the Green's function is originally due to Isakov [20]. We obtain a precise formula for the singularity of the Green's function in terms of the interface matrix and the symbol of the Dirichlet-to-Neumann operator as the pole approaches some point on the boundary. This is different approach than the one used by Isakov [20], Kirsch and Päivärinta [21], and Hettlich [16] in that we focus on the singularity itself, rather than on the behavior of the solution on the interior or on a subset of the boundary as the pole approaches the obstacle. See also [8] for a further discussion on the use of the fundamental solution in inverse scattering problems.

A similar formula for the singularity of the Green's function has been obtained by Potthast and Stratis [29] for a transmission obstacle with boundary conditions of the form

$$T = \begin{pmatrix} 1 & 0 \\ 0 & \beta \neq 1 \end{pmatrix}$$

without exterior or interior potentials and with the same wave number on the interior as the exterior.

For the recovery of the boundary conditions and the Dirichlet-to-Neumann operator, the main idea is to analyze the symbol of the boundary operator,

$$(\Lambda^i \circ b - d)^{-1}(\Lambda^i \circ a - c),$$

on $\partial\Omega$ which we prove is uniquely determined from the singularity as well. Here $(\Lambda^i \circ b - d)^{-1}$ really represents a parametrix of the pseudodifferential operator $\Lambda^i \circ b - d$ (the invertibility does not necessarily hold). We show that one can extract all the necessary information, i.e., the interface conditions and the symbol of the Dirichlet-to-Neumann operator, from this operator, where to explicitly calculate the full symbol we use the full symbol of the Dirichlet-to-Neumann as derived in [12] and [23].

3. Preliminaries. In this section we collect some basic facts about semigeodesic coordinates, layer potentials, and wave front sets that will be fundamental for our analysis.

First, we recall the semigeodesic (i.e., boundary normal) coordinates at the surface $\partial\Omega$. In semigeodesic coordinates around some $p \in \partial\Omega$, $\partial\Omega$ has coordinates $(x', 0)$ and the outward pointing normal to the surface points in the positive x_n direction. Let us briefly recall their construction. For each $q \in \partial\Omega$, define $\gamma_q : (-\epsilon, \epsilon) \to \mathbb{R}^n$ to be the unit-speed geodesic with q at $\gamma_q(0)$ and normal to $\partial\Omega$ there and such that $t < 0$ implies $\gamma_q(0) \in \Omega$. Now let $(\hat{x}_1, \ldots, \hat{x}_{n-1})$ be any local coordinates for $\partial\Omega$ near some $p \in \partial\Omega$. We can extend the coordinates smoothly into $\mathbb{R}^n\backslash\Omega$ and into Ω by having them be constant along each normal geodesic γ_q. If we take $\hat{x}_n$ to be the parameter along each γ_q, then one can check that $(\hat{x}_1, \ldots, \hat{x}_{n-1}, \hat{x}_n)$ form coordinates in $\mathbb{R}^n$ in some neighborhood of p. Note that in these coordinates, $\hat{x}_n = 0$ implies $\hat{x} \in \partial\Omega$ and the metric will have the form

$$\hat{g} = \sum_{j,k=1}^{n-1} \hat{g}_{jk}(\hat{x})\, d\hat{x}^j \otimes d\hat{x}^k + d\hat{x}^n \otimes d\hat{x}^n.$$

Often when there is no chance of confusion we will use $(x_1, \ldots, x_n)$ also as the semi-geodesic coordinates (e.g., $\partial\Omega$ will have coordinates $(x', 0)$). Also, we shall denote a function f in the semi-geodesic coordinates $\hat{f}$.

It is particularly important to note that the selection of the coordinates on $\partial\Omega$ is arbitrary since often we will want to compare different or unknown metrics on $\partial\Omega$. In particular, assume g^e and g^i are metrics as above and let $(\hat{x}_1, \ldots, \hat{x}_{n-1})$ be any local coordinates on $\partial\Omega$. Then we can form separate semigeodesic coordinates for g^e and g^i in a neighborhood of some point $p \in \partial\Omega$ of the form $(\hat{x}_1, \ldots, \hat{x}_{n-1}, \hat{x}_{n^e})$ and $(\hat{x}_1, \ldots, \hat{x}_{n-1}, \hat{x}_{n^i})$.

We will use the following notation when using pseudodifferential operators. Below let $\mathscr{S}$ be the class of Schwartz functions and H^s the standard Sobolev spaces. See, for example, [10] or [30]. Let X be an open set in $\mathbb{R}^n$ and recall the symbol classes $S^m(X \times \mathbb{R}^n)$ of Hörmander [19].

Definition 3.1. *$a \in S^m(X \times \mathbb{R}^n)$ if $a \in C^\infty(X \times \mathbb{R}^n)$ and*

$$\left|\partial_\xi^\alpha \partial_x^\beta a(x, \xi)\right| \le C_{\alpha,\beta}(1 + |\xi|)^{m-|\alpha|}, \qquad x \in X, \quad \xi \in \mathbb{R}^n.$$

S^m is called the space of symbols of order m.

Definition 3.2. *If $a(x, \xi) \in S^m(X \times \mathbb{R}^n)$, the operator $a(x, D) \in L^m(X)$ is defined on $\mathscr{S}(X)$ by*

$$a(x, D)u(x) = \frac{1}{(2\pi)^n} \int_{\mathbb{R}^n} e^{ix\cdot\xi} a(x, \xi)\tilde{u}(\xi)\, d\xi.$$

We say $a(x, D)$ is a pseudodifferential operator of order m. Moreover, $a(x, D)$ can be extended to a continuous operator from $H^s_{comp}(X) \to H^{s-m}_{loc}(X)$.

Finally, recall that the operator $a(x, D)$ is *properly supported* if its kernel,

$$K(x, y) = \frac{1}{(2\pi)^n} \int_{\mathbb{R}^n} e^{i(x-y)\cdot\xi} a(x, \xi)\, d\xi$$

is properly supported. We say a kernel $K(x, y)$ is properly supported if, for every compact $M \subseteq X$, $\{(x, y) \in \text{supp } K : x \in M \text{ or } y \in M\}$ is compact.

Now let L be an operator of the form (1.1) and let $G(x, y, k)$ denote the fundamental solution for $L - k^2$ with the outgoing radiation conditions (as constructed in [26], for example). Then the single layer potential S on $\partial\Omega$ is defined by

$$S\phi(x) = \int_{\partial\Omega_j} G(x, y)\phi(y)\, dS_y. \tag{3.1}$$

This is smoothing from $\partial\Omega$ to $\mathbb{R}^n\backslash\partial\Omega$ which means it is of order $-\infty$. We are particularly interested in its behavior as a map from functions on the boundary into itself as obtained when x is restricted to the boundary. Let S_+, respectively, S_-, denote the operator obtained when x is restricted to $\partial\Omega$ limiting from above, respectively, below. Both are the sum of a properly supported elliptic pseudodifferential operator on $\partial\Omega$ of order -1 and a term with a smoothing kernel. The latter condition means the kernel is in $C^\infty(X\times X)$.

Although this is already well known, a brief outline of this fact is given below since it will often be necessary to refer to the construction of layer potentials. For simplicity assume we are on a half-space and that we are a given an operator of the form $L-k^2$ that is equal to zero outside some large ball with fundamental solution $G(x,y)$. Modulo smoothing terms, this is the situation obtained by restricting to a local coordinate chart using the semigeodesic coordinates. Now,

$$G(x,y)=\frac{1}{(2\pi)^n}\int_{\mathbb{R}^n}e^{i(x-y)\cdot\xi}r(x,\xi)\,d\xi+S(x,y), \tag{3.2}$$

where $S(x,y)$ is $C^\infty(\mathbb{R}^n\times\mathbb{R}^n)$, $r(x,\xi)$ is the symbol of the parametrix for $L-k^2$, and the integral is defined as an oscillatory integral. Let $\phi(x')\in C_0^\infty(\mathbb{R}^{n-1})$. Then the single layer potential is defined as follows:

$$\begin{aligned}\lim_{x_n\downarrow 0}&\int_{\mathbb{R}^{n-1}}G(x,y',0)\phi(y')\,dy'\\
&=\lim_{x_n\downarrow 0}\frac{1}{(2\pi)^n}\int_{\mathbb{R}^n}\int_{\mathbb{R}^n}e^{i(x-y)\cdot\xi}r(x,\xi)(\phi(y')\otimes\delta(y_n))\,d\xi\,dy\\
&=\frac{1}{(2\pi)^{n-1}}\int_{\mathbb{R}^{n-1}}\int_{\mathbb{R}^{n-1}}e^{i(x'-y')\cdot\xi'}\left(\lim_{x_n\downarrow 0}\frac{1}{2\pi}\int_{\mathbb{R}}e^{ix_n\cdot\xi_n}r(x,\xi)\,d\xi_n\right)\phi(y')\,d\xi'\,dy'\\
&=\frac{1}{(2\pi)^{n-1}}\int_{\mathbb{R}^{n-1}}e^{i(x'-y')\cdot\xi'}\left(\int^+r(x',0,\xi)\,d\xi_n\right)\phi(y')\,dy',\end{aligned}$$

where $\int^+$ is equal to i times the sum of residues in the upper half-plane (see Chapter 18 of [19] for a more detailed account). Using that

$$r(x',0,\xi)=\frac{1}{\xi_n^2+\sum^{n-1}\hat{g}^{jk}(x')\xi_j\xi_k}+\frac{(\frac{\partial_{x_n}\sqrt{\hat{g}}}{\sqrt{\hat{g}}}(x')-2\hat{A}_n(x'))\xi_n}{(\xi_n^2+\sum^{n-1}\hat{g}^{jk}(x')\xi_j\xi_k)^2}+O\left(\frac{1}{\xi_n^4}\right),$$

where the $\hat{g}$ denotes we are in semigeodesic coordinates, it is easy to derive the principal symbol of the layer potential (as well as its jump relations). Let S_+ (respectively, S_-) denote the operator obtained from (3.1) by taking the limit of x from above (respectively, below). Also, let $(\frac{\partial S}{\partial\nu_x})_\pm$ denote the conormal derivative of the single layer potentials, i.e., (1.3) without the terms due to the magnetic potential.

Theorem 3.3. *$S_\pm$ and $(\frac{\partial S}{\partial\nu_x})_\pm$ are each equal to the sum of a properly supported elliptic pseudodifferential operator and a term with a smooth kernel. The principal symbols are*

$$\sigma_{-1}(S_\pm)=\frac{1}{2\sqrt{\sum_{j,k}^{n-1}\hat{g}^{jk}(x',0)\xi_j\xi_k}},$$

$$\sigma_0\left(\left(\frac{\partial S}{\partial\nu_x}\right)_\pm\right)=\mp\frac{1}{2}.$$

Also,

$$S_+ - S_- = 0, \qquad \left(\frac{\partial S}{\partial \nu_x}\right)_+ - \left(\frac{\partial S}{\partial \nu_x}\right)_- = -I. \tag{3.3}$$

We now recall some basic facts about wave front sets of distributions from [18] and [19]. Given a compactly supported distribution $v \in \mathcal{E}'(\mathbb{R}^n)$, let $\tilde{v}(\xi)$ be its Fourier transform and define the cone $\Sigma(v)$ to be all $\eta \in \mathbb{R}^n \backslash \{0\}$ having no conic neighborhood V such that

$$|\tilde{v}(\xi)| \le C_N(1+|\xi|)^{-N}, \qquad N \in N, \quad \xi \in V.$$

For X an open set in $\mathbb{R}^n$ and $u \in \mathcal{D}'(X)$, define for $x \in X$,

$$\Sigma_x(u) = \bigcap_{\substack{\phi \in C_0^\infty(X) \\ \phi(x) \ne 0}} \Sigma(\phi u).$$

Then,

$$WF(u) = \{(x,\xi) \in X \times (\mathbb{R}^n \backslash 0); \xi \in \Sigma_x(u)\}.$$

As a specific example, note $WF(\delta(x-y)) = y \times \mathbb{R}^n \backslash \{0\}$, since $\tilde{\delta} = 1$.

Now we consider characteristic sets and wave front sets of pseudodifferential operators. Let $A \in L^m$ be an operator with principal symbol $a(x,\xi) \in S^m(T^*(X))$. We say A is noncharacteristic at $(x_0,\xi_0) \in T^*(X)\backslash 0$ if $ab - 1 \in S^{-1}$ in a conic neighborhood of (x_0,ξ_0) for some $b \in S^{-m}$. Denote by Char A the set of characteristic points of A. In particular, note Char $P = \emptyset$ for any elliptic differential operator. This leads to an alternate definition of the wave front set:

$$WF(u) = \bigcap_{\substack{A \in L^m(X),\, m \in \mathbb{R} \\ A\, prop.\, supp. \\ Au \in C^\infty(X)}} \mathrm{Char}\ A,$$

from which it is easy to prove the following theorem.

THEOREM 3.4. *If $A \in L^m(X)$ is properly supported and $u \in \mathcal{D}'(X)$, then*

$$WF(u) \subset WF(Au) \cup \mathrm{Char} A.$$

As an example relevant to us, if $G(x,y)$ is the fundamental solution for $L - k^2$, then $WF(G(x,y)) = y \times \mathbb{R}^n \backslash \{0\}$ since $L - k^2$ is elliptic and $WF(\delta(x-y)) = y \times \mathbb{R}^n \backslash \{0\}$.

The last part of the theory we need to recall is the definition of the wave front set of a pseudodifferential operator. Let $A \in L^m(X)$ be a properly supported pseudodifferential operator with symbol $a(x,\xi) \in S^m$ as above. Then its kernel is

$$K_A(x,y) = \int_{R^n} e^{i(x-y)\cdot\xi} a(x,\xi)\, d\xi,$$

where the integral is defined as an oscillatory integral. Suppose Char $A = X \times \Gamma_A(x)$ for some $\Gamma_A(x) \subseteq \mathbb{R}^n \backslash \{0\}$. Then one can check that for any fixed $y \in X$,

$$WF(K_A(x,y)) = y \times \Gamma_A(y). \tag{3.4}$$

See, for example, Proposition 18.1.26 in [19]. In light of (3.2), this gives an alternate proof that $WF(G(x,y)) = y \times \mathbb{R}^n \backslash \{0\}$.

Our interest in wave front sets is due to the next two propositions.

PROPOSITION 3.5. $WF(\lim_{y \downarrow x^* \in \partial\Omega} G(x,y)|_{x \in \partial\Omega}) = x^* \times S^{n-2}$.

Proof. By a discussion analogous to that preceding Theorem 3.3, it is easy to see that modulo a smoothing kernel, $\lim_{y \downarrow x^* \partial\Omega} G(x,y)|_{x \in \partial\Omega}$ is the kernel of an elliptic pseudodifferential operator (in the variables x and x^*). Therefore the claim follows from (3.4). ∎

PROPOSITION 3.6. *Say $P_1(x,D)$ and $P_2(x,D)$ are two elliptic pseudodifferential operators on $\mathbb{R}^n$ and $u \in \mathcal{D}'(\mathbb{R}^n)$ is a distribution with wave front set $WF(u) = 0 \times \mathbb{R}^n \backslash \{0\}$. Then $P_1 u = P_2 u + f$ for some $f \in C^\infty(\mathbb{R}^n)$ implies that $\sigma(P_1)(0,\xi) = \sigma(P_2)(0,\xi)$.*

Proof. This is an immediate consequence of Theorem 3.4. ∎

4. The direct problem. Consider scattering from a general transmission obstacle as in (1.4)–(1.7). Because it significantly complicates the problem when b is both zero and nonzero, we initially assume that either

$$b(x) = 0 \text{ for all } x \in \partial\Omega \tag{4.1}$$

or

$$b(x) \neq 0 \text{ for all } x \in \partial\Omega. \tag{4.2}$$

In section 4.1, we will solve the direct problem, assuming T satisfies (2.2), (2.6), and (4.1), or (4.2), and then in section 4.2 we consider the nonself-adjoint problem when just (2.2) and (4.1) or (4.2) is satisfied. Finally, in section 4.3 we solve the problem for general scatterers when only (2.2) and (2.3) or (2.4) hold by considering a mixed boundary value problem and using the results of the previous sections.

First, recall the following lemma from [7] and [26].

LEMMA 4.1. *If u satisfies $(-\triangle - k^2)u = 0$ outside of B_S and u satisfies the outgoing radiation conditions*

$$\frac{\partial}{\partial r} u(x) - iku(x) = o\left(\frac{1}{r^{\frac{n-1}{2}}}\right), \quad u = O\left(\frac{1}{r^{\frac{n-1}{2}}}\right), \tag{4.3}$$

then

$$u = a(\theta)\frac{e^{ik|x|}}{|x|^{\frac{n-1}{2}}} + O\left(\frac{1}{|x|^{\frac{n+1}{2}}}\right) \tag{4.4}$$

when $|x| \to \infty$, $\theta = \frac{x}{|x|}$.

Now consider the boundary value problem,

$$(L^e - k^2)u(x) = f^e(x) \text{ in } \mathbb{R}^n \backslash \Omega, \tag{4.5}$$

$$(L^i - k^2)u(x) = f^i(x) \text{ in } \Omega, \tag{4.6}$$

$$\begin{pmatrix} u_- \\ \gamma_-^{1,i} u \end{pmatrix} = \begin{pmatrix} a(x) & b(x) \\ c(x) & d(x) \end{pmatrix} \begin{pmatrix} u_+ \\ \gamma_+^{1,e} u \end{pmatrix}, \tag{4.7}$$

$$\frac{\partial}{\partial r} u(x) - iku(x) = o\left(\frac{1}{r^{\frac{n-1}{2}}}\right), \quad u = O\left(\frac{1}{r^{\frac{n-1}{2}}}\right), \tag{4.8}$$

where $f^e \in C_0^\infty(\mathbb{R}^n \backslash \Omega)$ and $f^i \in C^\infty(\Omega)$.

4.1. Dissipative conditions. We begin with the uniqueness.

LEMMA 4.2. *Say u satisfies* (4.5)–(4.8) *with $f^e=0$, $f^i=0$ and T satisfies* (2.2) *and* (2.6)*. Then u is equal to* 0 *in $\mathbb{R}^n$.*

Proof. Applying Green's formula to the identity,

$$0=\int_{B_R\backslash\Omega}(L^e-k^2)u\overline{u}\,\sqrt{g^e}\,dx-\int_{\Omega}(L^i-k^2)u\overline{u}\,\sqrt{g^i}\,dx,$$

taking the imaginary part of both sides, plugging the expansion (4.4) into the integral over ∂B_R, and letting R tend to infinity, we obtain

$$\int_{S^{n-1}}k\,|a(\theta)|^2\,d\theta=\ \mathrm{Im}\ \left[\int_{\partial\Omega}\gamma_+^{1,e}u\overline{u_+}\,\sqrt{\tilde{g}^e}dS_x-\int_{\partial\Omega}\gamma_-^{1,i}u\overline{u_-}\,\sqrt{\tilde{g}^i}dS_x\right].\tag{4.9}$$

Using the boundary conditions (4.7) and also (2.2) and (2.6),

$$\begin{aligned}\gamma_-^{1,i}u\overline{u_-}\sqrt{\tilde{g}^i}&=\left[\left(cu_++d\gamma_+^{1,e}u\right)\overline{\left(au_++b\gamma_+^{1,e}u\right)}\right]\sqrt{\tilde{g}^i}\\&=\left[ac\,|u_+|^2+\overline{b}d\left|\gamma_+^{1,e}u\right|^2+ad\overline{u_+}\gamma_+^{1,e}u+\overline{b}cu_+\overline{\gamma_+^{1,e}u}\right]\sqrt{\tilde{g}^i}\\&=ac\,|u_+|^2\sqrt{\tilde{g}^i}+\overline{b}d\left|\gamma_+^{1,e}u\right|^2\sqrt{\tilde{g}^i}+\overline{u_+}\gamma_+^{1,e}u\sqrt{\tilde{g}^e}\\&\qquad+2\overline{b}c\ \mathrm{Re}\ u_+\overline{\gamma_+^{1,e}u}\sqrt{\tilde{g}^i}.\end{aligned}$$

Plugging this into (4.9) and utilizing that $-\overline{b}d$ and $-ac$ are each less than zero by (2.2) and (2.6), we get

$$\begin{aligned}\int_{S^{n-1}}k\,|a(\theta)|^2\,d\theta&\leq\ \mathrm{Im}\ \int_{\partial\Omega}-2\overline{b}c\ \mathrm{Re}\ u_+\overline{\gamma_+^{1,e}u}\sqrt{\tilde{g}^i}\,dS_x\\&\leq 0.\end{aligned}$$

Note $\overline{b}c$ has no imaginary part as a result of (2.6). Therefore $u=O(\frac{1}{|x|^{\frac{n+1}{2}}})$ and so Rellich's lemma and unique continuation imply $u=0$ in $\mathbb{R}^n\backslash\Omega$ (see, e.g., [26]). The boundary conditions give us that $u_-|_{\partial\Omega}=0$ and $\gamma_-^{1,i}u=0$, which by the uniqueness of the Cauchy problem implies $u=0$ in Ω (see, for example, [17]). ∎

To prove Theorem 2.1 assuming (2.2), (2.6), and (4.1) or (4.2), we will construct the Green's function for (4.5)–(4.8).

THEOREM 4.3. *Assume T satisfies* (2.2), (2.6)*, and* (4.1) *or* (4.2)*. Then there exists unique $G^e(x,y,k)$ and $G^i(x,y,k)$ that solve* (4.5)–(4.8) *with $f^e(x)=\delta(x-y)$ and $f^i(x)=\delta(x-y)$.*

Proof. Let $\tilde{G}^e(x,y)$ and $\tilde{G}^i(x,y)$ be the outgoing the Green's functions for (L^e-k^2) and (L^i-k^2) in $\mathbb{R}^n$ as constructed in [26]. Note $\tilde{G}^e(x,y)=E_+(x-y)$ for x,y large, where $E_+(x-y)$ is the outgoing fundamental solution of the Helmholtz equation. We look for G^e and G^i in the form

$$\begin{aligned}G^e(x,y)&=\tilde{G}^e(x,y)+S^e\phi^e(x,y),\\G^i(x,y)&=\tilde{G}^i(x,y)+S^i\phi^i(x,y),\end{aligned}$$

where S^e and S^i are single layer potentials for $\tilde{G}^e$ and $\tilde{G}^i$ on $\partial\Omega$ as defined in section 3. Fix $y\in\mathbb{R}^n\backslash\Omega$. Then the boundary conditions (4.7) give us the following system of pseudodifferential equations on $\partial\Omega$:

$$\begin{pmatrix} S^i_- & -aS^e_+ - b\gamma^{1,e}_+ S^e \\ \gamma^{1,i}_- S^i & -cS^e_+ - d\gamma^{1,e}_+ S^e \end{pmatrix} \begin{pmatrix} \phi^i(x,y) \\ \phi^e(x,y) \end{pmatrix} = \begin{pmatrix} -\tilde{G}^i(x,y)|_{\partial\Omega} + a\tilde{G}^e(x,y)|_{\partial\Omega} + b\gamma^{1,e}_+ \tilde{G}^e \\ -\gamma^{1,i}_- \tilde{G}^i(x,y) + c\tilde{G}^e(x,y)|_{\partial\Omega} + d\gamma^{1,e}_+ \tilde{G}^e \end{pmatrix}. \tag{4.10}$$

We want to show that the matrix B of pseudodifferential operators on the left-hand side is uniquely invertible. Note B is bounded $L^2(\partial\Omega)\otimes L^2(\partial\Omega) \to L^2(\partial\Omega)\otimes L^2(\partial\Omega)$. In Corollary 4.6 we show that B is Fredholm with index 0.

Assuming this for now, we have only to show that B is injective. Say first that k^2 is not a Dirichlet eigenvalue of L^e on Ω. In this case, suppose the right-hand side of (4.10) is equal to zero and let $y^e(x) = S^e_+\phi^e(x)$ and $y^i(x) = S^i_-\phi^i(x)$. Then y^e, y^i solve the transmission problem (4.5)–(4.8) with $f^e = 0$ and $f^i = 0$. Lemma 4.2 implies

$$\begin{aligned} y^e(x) &= 0 \text{ in } \mathbb{R}^n\backslash\Omega, \\ y^i(x) &= 0 \text{ in } \Omega. \end{aligned}$$

Using the jump relations given in Theorem 3.3, we see that y^i solves $(L^i - k^2)y^i = 0$ in $\mathbb{R}^n\backslash\Omega$ and $y^i|_{\partial\Omega} = 0$. Therefore it is easy to see that $y^i = 0$ in $\mathbb{R}^n\backslash\Omega$ (see, for example, [26]) and so another application of the jump relations implies $\phi^i = 0$. Similarly, y^e solves $(L^e - k^2)y^e = 0$ in Ω and $y^e|_{\partial\Omega} = 0$. Therefore since we are assuming k^2 is not a Dirichlet eigenvalue for L^e on Ω, y^e must be identically zero in Ω and another application of the jump relations proves that $\phi^e = 0$.

In the case that k^2 is a Dirichlet eigenvalue for L^e on Ω there are a number of methods we could use to solve the problem. One would be to use different layer potentials (like the ones used in [26]) or use a sum of single and double layer potentials as is utilized in [6]. Instead, here we will alter the equation on the interior of Ω following the approach taken in [11]. In particular, pick some constant q such that k^2 is not a Dirichlet eigenvalue of $L^e + q$ on Ω. Let χ_Ω be the distribution equal to 1 on $\overline{\Omega}$ and 0 everywhere else. One can construct the Green's function $G^e(x,y)$ to solve

$$(L^e + \chi_\Omega q - k^2)G^e(x,y) = \delta(x-y)$$

as in [11] and it will have the same jump relations as those given in Theorem 3.3. Therefore the preceding argument with this alteration to the exterior Green's function can be used. □

Define the Green's function $G(x,y)$ for $y \notin \partial\Omega$ by

$$G(x,y) = \begin{cases} G^e(x,y), & x \in \mathbb{R}^n\backslash\Omega; \\ G^i(x,y), & x \in \Omega. \end{cases} \tag{4.11}$$

In particular, for $f(x) \in C_0^\infty(\mathbb{R}^n)$,

$$Gf(x) = \begin{cases} \int_{\mathbb{R}^n} G^e(x,y)f(y)\,dy, & x \in \mathbb{R}^n\backslash\Omega; \\ \int_{\mathbb{R}^n} G^i(x,y)f(y)\,dy, & x \in \Omega, \end{cases} \tag{4.12}$$

where to avoid $y \in \partial\Omega$, we can interpret the integrals as being over $\mathbb{R}^n\backslash\partial\Omega$ since $\partial\Omega$ is a set of Lebesgue measure zero.

Proof of Theorem 2.1 (*in the dissipative case and assuming either* (4.1) *or* (4.2)). Letting $v(x,k\omega) = G[-(L^e - k^2)e^{ik\omega\cdot x}]$, we look for a solution to (1.4)–(1.7) of the form

$$w(x,k\omega) = \begin{cases} v(x,k\omega) + S^e\psi^e(x), & x \in \mathbb{R}^n\backslash\Omega; \\ v(x,k\omega) + S^i\psi^i(x), & x \in \Omega, \end{cases}$$

for two smooth functions $\psi^e(x)$ and $\psi^i(x)$ on $\partial\Omega$. Plugging $w(x,k\omega)$ into (1.6) leads to a system of pseudodifferential equations on $\partial\Omega$ of the form (4.10) with, of course, different functions on the right-hand side. This is solvable as in the proof of the previous theorem. That $w(x,k\omega)$ has the correct asymptotics follows from Lemma 4.1. $\square$

4.2. General nonself-adjoint problem. First, we find the boundary conditions of the adjoint problem.

THEOREM 4.4. *The adjoint boundary value problem to* (4.5)–(4.8) *has transfer matrix*

$$T^*(x) = \frac{\sqrt{\tilde{g}^e}}{\sqrt{\tilde{g}^i}} \frac{1}{ad - \overline{bc}} \begin{pmatrix} a(x) & \overline{b(x)} \\ \overline{c(x)} & d(x) \end{pmatrix}$$

in place of T and the solution v must satisfy the incoming radiation conditions

$$\frac{\partial}{\partial r}v(x) + ikv(x) = o\left(\frac{1}{r^{\frac{n-1}{2}}}\right),\ v = O\left(\frac{1}{r^{\frac{n-1}{2}}}\right) \tag{4.13}$$

instead of the outgoing radiation conditions (4.8).

Note $(T^*)^* = T$.

Proof. Assume u is a solution to (4.5)–(4.8) for some f^e and f^i. Then the adjoint boundary conditions are, by definition, the conditions that a function v in the domain of $L^e - k^2$ on $\mathbb{R}^n\backslash\Omega$ and in the domain of $L^i - k^2$ on Ω must satisfy so that

$$\begin{aligned} &\int_{\mathbb{R}^n\backslash\Omega}(L^e - k^2)u\bar{v}\sqrt{g^e}\,dx + \int_\Omega (L^i - k^2)u\bar{v}\sqrt{g^i}\,dx \\ &= \int_{\mathbb{R}^n\backslash\Omega} u\overline{(L^e - k^2)v}\sqrt{g^e}\,dx + \int_\Omega u\overline{(L^i - k^2)v}\sqrt{g^i}\,dx. \end{aligned} \tag{4.14}$$

Here $(L^e - k^2)$ and $(L^i - k^2)$ are self-adjoint on $L^2(\mathbb{R}^n, \sqrt{g^e}\,dx)$ and $L^2(\mathbb{R}^n, \sqrt{g^i}\,dx)$, respectively.

Integrating over some large ball B_R instead of $\mathbb{R}^n$ in (4.14) and applying Green's formula, we obtain

$$\begin{aligned} &-\int_{\partial B_R}\frac{\partial u}{\partial r}\bar{v}\,dS_x + \int_{\partial\Omega}\gamma_+^{1,e}u\bar{v}\sqrt{\tilde{g}^e}\,dS_x - \int_{\partial\Omega}\gamma_-^{1,i}u\bar{v}\sqrt{\tilde{g}^i}\,dS_x \\ &= -\int_{\partial B_R} u\overline{\frac{\partial v}{\partial r}}\,dS_x + \int_{\partial\Omega} u\overline{\gamma_+^{1,e}v}\sqrt{\tilde{g}^e}\,dS_x - \int_{\partial\Omega} u\overline{\gamma_-^{1,i}v}\sqrt{\tilde{g}^i}\,dS_x. \end{aligned}$$

It is easy to see that in order for the integrals over ∂B_R to vanish, v must satisfy the incoming radiation conditions. Assuming this to be the case and taking the limit as $R \to \infty$, the remaining integrals over $\partial\Omega$ will give us the form of T^*. In particular, we must have

$$\left\langle \gamma_+^{1,e}u, v_+\right\rangle_{\sqrt{\tilde{g}^e}} - \left\langle \gamma_-^{1,i}u, v_-\right\rangle_{\sqrt{\tilde{g}^i}} = \left\langle u_+, \gamma_+^{1,e}v\right\rangle_{\sqrt{\tilde{g}^e}} - \left\langle u_-, \gamma_-^{1,i}v\right\rangle_{\sqrt{\tilde{g}^i}},$$

where we use the notation $\langle f, g\rangle_h = \int_{\partial\Omega} f\overline{g}\, h\, dS_x$. Plugging in the boundary conditions (4.7) this becomes

$$\left\langle \frac{1}{ad-bc}(-cu_- + a\gamma_-^{1,i}u), v_+ \right\rangle_{\sqrt{\tilde{g}^e}} - \left\langle \gamma_-^{1,i}u, v_- \right\rangle_{\sqrt{\tilde{g}^i}}$$
$$= \left\langle \frac{1}{ad-bc}(du_- - b\gamma_-^{1,i}u), \gamma_+^{1,e}v \right\rangle_{\sqrt{\tilde{g}^e}} - \left\langle u_-, \gamma_-^{1,i}v \right\rangle_{\sqrt{\tilde{g}^i}}$$

and reorganizing,

$$\left\langle u_-, \frac{1}{\overline{ad-bc}}(-\overline{c}v_+ - d\gamma_+^{1,e}v^e) \right\rangle_{\sqrt{\tilde{g}^e}} + \left\langle \gamma_-^{1,i}u, \frac{1}{\overline{ad-bc}}(av_+ + \overline{b}\gamma_+^{1,e}v) \right\rangle_{\sqrt{\tilde{g}^e}}$$
$$= -\left\langle u_-, \gamma_-^{1,i}v \right\rangle_{\sqrt{\tilde{g}^i}} + \left\langle \gamma_-^{1,i}u, v_- \right\rangle_{\sqrt{\tilde{g}^i}}.$$

It follows that

$$\begin{pmatrix} v_- \\ \gamma_-^{1,i}v \end{pmatrix} = \frac{\sqrt{\tilde{g}^e}}{\sqrt{\tilde{g}^i}} \frac{1}{\overline{ad-bc}} \begin{pmatrix} a(x) & \overline{b(x)} \\ \overline{c(x)} & d(x) \end{pmatrix} \begin{pmatrix} v_+ \\ \gamma_+^{1,e}v \end{pmatrix}$$

which completes the proof. □

It follows from this result that the problem is self-adjoint when both (2.2) and (2.6) are satisfied and b and c have no imaginary component. This is not surprising since Im $\overline{u_+}\gamma_+^{1,e}u$ and Im $\overline{u_-}\gamma_-^{1,i}u$ physically represent the exterior and interior flux at the boundary and, as shown in the proof of Lemma 4.2, they are equal precisely when (2.2) and (2.6) hold and the imaginary components of the off-diagonal terms are zero.

We now finish the proof of Theorem 2.1 by constructing the Green's function for (4.5)–(4.8) when the transfer matrix is assumed only to satisfy (2.2) and (4.1) or (4.2).

THEOREM 4.5. *Assume T satisfies* (2.2) *and* (4.1) *or* (4.2). *Then for all but a discrete set of $k > 0$, there exists $G^e(x, y, k)$ and $G^i(x, y, k)$ that solve* (4.5)–(4.8) *with $f^e = \delta(x - y)$ and $f^i = \delta(x - y)$.*

Proof. We will prove this by constructing $G(x, y, z)$ for all but a discrete set of z in $\mathbb{C}$. Note that for all but a discrete set of $z \in \mathbb{C}$, there exists fundamental solutions for $L^e - z^2$ and $L^i - z^2$ in $\mathbb{R}^n$, $G^e(x, y, z)$, and $G^i(x, y, z)$, where for $z > 0$ these fundamental solutions have the outgoing radiation conditions (see [26]). In fact we know the poles must occur on the imaginary axis. Define $\mathcal{K}$ to be this discrete subset of $\mathbb{C}$. In order to solve the transmission problem for z outside of this discrete set, as in the proof of Theorem 4.3 the problem is reduced to showing the invertibility of the matrix of pseudodifferential operators on $\partial\Omega$:

$$M = \begin{pmatrix} S_-^i & -aS_+^e - b\gamma_+^{1,e}S^e \\ \gamma_-^{1,i}S^i & -cS_+^e - d\gamma_+^{1,e}S^e \end{pmatrix}. \tag{4.15}$$

Here the layer potentials are with respect to the operators $G^e(x, y, z)$ and $G^i(x, y, z)$ on $\partial\Omega$. Let

$$\Lambda = \left\{ z \in \mathbb{C} : \frac{\pi}{2} - \epsilon < \arg z < \frac{\pi}{2} + \epsilon \right\}$$

and let $(x_1, \ldots, x_{n-1}, 0)$ be local coordinates for $\partial\Omega$ around some point $y \in \partial\Omega$. Furthermore, let $\hat{g}_i^{jk}$ and $\hat{g}_e^{jk}$ be the restriction of the interior and exterior metrics to $\partial\Omega$ with respect to this coordinate system. Then in some neighborhood of y, the layer potentials have the following symbols in the calculus of the pseudodifferential operators with a parameter for $z \in \Lambda\backslash\mathcal{K}$ (see [26] and [30]):

$$\begin{aligned}
S^i_-(x', \xi', z) &= \frac{1}{2\sqrt{\sum_{j,k=1}^{n-1} \hat{g}_i^{jk}(x', 0)\xi_j\xi_k - z^2}} + R^i_{-2}(x', \xi', z),\\
S^e_+(x', \xi', z) &= \frac{1}{2\sqrt{\sum_{j,k=1}^{n-1} \hat{g}_e^{jk}(x', 0)\xi_j\xi_k - z^2}} + R^e_{-2}(x', \xi', z),\\
\gamma_+^{1,e} S^e(x', \xi', z) &= \frac{1}{2} + T^i_{-1}(x', \xi', z),\\
\gamma_-^{1,i} S^i(x', \xi', z) &= -\frac{1}{2} + T^e_{-1}(x', \xi', z).
\end{aligned}$$

Here R^i_{-2} and R^e_{-2} are bounded pseudodifferential operators (quantized in the calculus with a parameter) on $\partial\Omega$ of order -2, and T^e_{-1} and T^i_{-1} represent operators of order -1.

Therefore,

$$M(x', \xi', z) = \begin{pmatrix} \frac{1}{2\ell_1^i(z)} & -\frac{a}{2\ell_1^e(z)} + \frac{b}{2} - bT^e_{-1}(z) \\ \frac{1}{2} + T^i_{-1}(z) & -\frac{c}{2\ell_1^e(z)} + \frac{d}{2} + dT^e_{-1}(z) \end{pmatrix} + R_{-2}(z),$$

where $\ell_1^i(x', \xi', z) = (\sum_{j,k=1}^{n-1} \hat{g}_i^{jk}(x', 0)\xi_j\xi_k - z^2)^{\frac{1}{2}}$ and $\ell_1^e(x', \xi', z)$ is defined similarly. Also, $R_{-2}(x', \xi', z) \in S^{-2}(\partial\Omega \times \partial\Omega \times \mathbb{R}^{n-1}, \Lambda)$.

Assume $z \in \Lambda\backslash\mathcal{K}$ and $|z| \geq R$ for some large R. Since we are assuming either (4.1) or (4.2), it is not difficult to construct an operator $B(z) \in L^{-2}(\partial\Omega \times \partial\Omega, \Lambda)$ with symbol $B(x', \xi', z) \in S^{-2}(\partial\Omega \times \partial\Omega \times \mathbb{R}^{2n}, \Lambda)$ such that

$$M(z)B(z) = I + T(z), \tag{4.16}$$

where

$$\|T(z)\|_{L^2(\partial\Omega)\times L^2(\partial\Omega)} \leq \frac{C}{1 + |z|}$$

and T is compact on the same space. Thus, $(I+T(z))^{-1}$, and hence $M(z)^{-1}$, exists for $z \in (\Lambda\backslash\mathcal{K}) \cap \{|z| \geq R\}$ for some large $R > 0$. Now let $B'(z)$ be a parametrix for $M(z)$ constructed using the regular pseudodifferential calculus (i.e., the Kohn–Nirenberg quantization). Then, $M(z)B'(z) = I + T'(z)$ for some compact $T'(z)$. Moreover, $(I + T'(z))^{-1}$ exists for $z \in (\Lambda\backslash\mathcal{K}) \cap \{|z| \geq R\}$ since $M(z)^{-1}$ is invertible there. Since $T'(z)$ is an operator-valued meromorphic function of z on $L^2(\partial\Omega) \times L^2(\partial\Omega)$, $(I + T'(z))^{-1}$, and hence $M(z)^{-1}$, exists for all but a discrete set of $z \in \mathbb{C}$ (see [31]). Note it was necessary to consider separately $T(z), B(z)$ and $T'(z), B'(z)$ since the construction of $B(z)$ and $T(z)$ becomes problematic on the positive real axis (because the denominator of the principal symbol of the single layer potential may be zero there in the parameter-dependent calculus). ∎

COROLLARY 4.6. *$M(z)$ is Fredholm with index 0 for all $z \in \mathbb{C}\backslash\mathcal{K}$.*

Proof. This is true for $M(z)$ with $z \in (\Lambda\backslash\mathcal{K}) \cap \{|z| \geq R\}$ since $M(z)$ is Fredholm by (4.16) and invertible. Moreover, $M(z_1) - M(z_2)$ is compact on $L^2(\partial\Omega) \times L^2(\partial\Omega)$ since z appears only on terms of order -1. ∎

The following theorem relates the Green's function and its adjoint. Note that by arguments similar to those given in [26], the set of $k > 0$ on which $G(x, y, k)$ and $G^*(x, y, k)$ exist coincides.

THEOREM 4.7. *Say $k > 0$ is such that $G(x, y, k)$ and $G^*(x, y, k)$ exist and assume $x, y \notin \partial\Omega$. Then $G^*(x, y, k) = \overline{G(y, x, k)}$.*

Proof. Define L to be the operator equal to L^e in $\mathbb{R}^n \backslash \Omega$ and equal to L^i in Ω. Let $f, g \in C_0^\infty(\mathbb{R}^n)$. Then

$$\begin{aligned}
&\langle f, G^* g\rangle_{L^2(B_R)} \\
&\quad = \left\langle (L - k^2) G f, G^* g\right\rangle_{L^2(B_R)} \\
&\quad = \left\langle G f, (L^* - k^2) G^* g\right\rangle_{L^2(B_R)} - \int_{\partial B_R} \frac{\partial G f}{\partial r} \overline{G^* g} - G f \frac{\overline{\partial G^* g}}{\partial r}\, dS_x.
\end{aligned}$$

As R tends to infinity the integral over ∂B_R tends to zero since Gf and $\overline{G^* g}$ satisfy the outgoing radiation conditions. Thus,

$$\langle f, G^* g\rangle_{L^2(\mathbb{R}^n \backslash \Omega)} = \langle G f, g\rangle_{L^2(\mathbb{R}^n \backslash \Omega)}$$

for all $f, g \in C_0^\infty(\mathbb{R}^n \backslash \Omega)$ from which it follows that $G^*(x, y) = \overline{G(y, x)}$. ◻

Note in the self-adjoint case this proves $G(x, y, k) = \overline{G(y, x, k)}$ for all $k > 0$.

4.3. Direct problem for general obstacles. We now prove the full result for obstacles satisfying only (2.2) and (2.3) or (2.4).

Proof of Theorem 2.1 *for general transmission obstacles.* Let T be a transfer matrix satisfying (2.2) and (2.3) or (2.4). It suffices to solve (4.10). Let $b'(x)$ be a smooth extension of $b(x)$ onto all $\partial\Omega$ which equals $b(x)$ on Δ. Then define

$$M = \begin{pmatrix} S_-^i & -a S_+^e - b' \gamma_+^{1,e} S^e \\ \gamma_-^{1,i} S^i & -c S_+^e - d \gamma_+^{1,e} S^e \end{pmatrix} \tag{4.17}$$

and

$$M_0 = \begin{pmatrix} S_-^i & -a S_+^e \\ \gamma_-^{1,i} S^i & -c S_+^e - d \gamma_+^{1,e} S^e \end{pmatrix}. \tag{4.18}$$

As in [26] (see also [10]), solving (4.10) reduces to finding $\vec{g} \in \mathring{H}^{\frac{1}{2}}(\Delta)$, solving

$$\rho_\Delta (M M_0^{-1}) \vec{g} = \vec{f} \tag{4.19}$$

for $\vec{f} \in H^{-\frac{1}{2}}(\Delta)$. Here $\mathring{H}^s(\Delta)$ denotes the subspace of $H^s(\Delta)$ consisting of functions with support in $\overline{\Delta}$. It is easy to see that

$$M M_0^{-1} = \begin{pmatrix} I + Q_1 & P_0 \\ 0 & I \end{pmatrix},$$

where P_0 and Q_1 are pseudodifferential operators of orders 0 and 1 on $\partial\Omega$. In fact, after a trivial but lengthy calculation we find (in semigeodesic coordinates)

$$\sigma(Q_1)(x', \xi') = -b(x') \left(\frac{a(x')}{\ell_1^e(x', \xi')} + \frac{d(x')}{\ell_1^i(x', \xi')} \right)^{-1} + \cdots.$$

Since Q_1 has a strongly elliptic principal symbol by (2.4), it follows that $(I+Q_1)$ is Fredholm with index 0. Therefore $\rho_\Delta(MM_0^{-1})$ is also Fredholm with index 0. In the self-adjoint case, or more generally whenever (2.6) holds, the necessary uniqueness follows by Lemma 4.2 and the proof in this case is finished.

For the nonself-adjoint case, since Q_1 is elliptic, we can find a matrix of pseudo differential operators B such that

$$\rho_\Delta(MM_0^{-1})Bf = \rho_\Delta(I+T_{-1})f.$$

Therefore using the parameter-dependent pseudodifferential calculus as in section 4.2, we can prove invertibility for all but a discrete set of $k>0$.

We remark that the ϕ^e and ϕ^i obtained by the above argument are both in $H^{\frac{1}{2}}(\partial\Omega)$, which implies the Green's functions $G^e(x,y)$ and $G^i(x,y)$ are in $H^2(\mathbb{R}^n\backslash\Omega)$ and $H^2(\Omega)$ away from the pole. This means the application of Green's formula is valid in the uniqueness proofs, or in establishing the scattering amplitude uniquely determines the Green's function (as below). See [26] for a more detailed discussion. $\square$

4.4. The Green's function and the scattering amplitude. Assume we are given two obstacles, $\{\Omega_1, T_1(x), L_1\}$ and $\{\Omega_2, T_2(x)\, L_2\}$, along with their respective scattering data, $a_1(\theta,\omega,k)$ and $a_2(\theta,\omega,k)$. We recall the following theorem from [26] (where Theorem 4.4 establishes that the adjoint the Green's function exists).

THEOREM 4.8. *$a_1(\theta,\omega,k)=a_2(\theta,\omega,k)$ for $\theta,\omega\in S^{n-1}$ implies $G_1(x,y,k)=G_2(x,y,k)$ for $x,y\in\mathbb{R}^n\backslash\overline{(\Omega_1\cup\Omega_2)}$ and $x\neq y$.*

Strictly speaking the proof of the theorem requires all the obstacles to be impenetrable. However, the alterations for the case of transmission obstacles are minor. Note this theorem holds even when the boundary conditions are nonself-adjoint.

This also establishes the equivalence of the scattering problem and the inverse boundary value problem on the boundary of a ball large enough to contain all the scatterers. See [26].

5. Inverse problem for constant isotropic media with electric potentials. For this entire section assume $L^e=-\triangle+V^e(x)-k^2$ and $L^i=-\triangle+V^i-k^2$. By assuming the metrics are the same (and known) at the surface of the scatterer and that there are no magnetic potentials, we avoid some difficult technicalities while still preserving the general idea of all of the proofs. After recalling the symbol of the Dirichlet-to-Neumann operator in section 6, as well as formulating some basic properties on boundary determination, we will be prepared for the more exhaustive analysis required in the case of a nontrivial metric and electromagnetic potentials given in section 7.

5.1. Location. First, we analyze the behavior of the singularity of the Green's function in a neighborhood of the boundary of an obstacle.

We say the obstacle Ω is *well defined at* x_0 if $x_0\notin\partial\Delta$ and at least one of the following holds:

1. $T(x_0)\neq\tau I$ for some $\tau>0$.
2. V^e and V^i do not smoothly connect along the normal direction at x_0.

The following lemma proves a singularity develops in $G^e(x,y)-\tilde{G}^e(x,y)$ as y approaches $x\in\partial\Omega$, which is well defined, and the subsequent corollary gives an exact formula for the principal symbol of the single layer potential of $G^e(x,y)$ obtained as $y\downarrow x^*\in\partial\Omega$.

LEMMA 5.1. *$\partial\Omega$ is well defined at x_0 if and only if*

$$\lim_{y\downarrow x^*\in\partial\Omega}\big(G^e(x,y)-\tilde{G}^e(x,y)\big)=\lim_{y\downarrow x^*\in\partial\Omega}S^e_+\phi^e(x,y)\notin C^\infty(B_\epsilon(x^*)\cap\partial\Omega).$$

Proof. Say first that k^2 is not a Dirichlet eigenvalue of either $-\triangle+V^e$ or $-\triangle+V^i$ on Ω. This restriction will be removed at the end of the proof. Note the Dirichlet-to-Neumann operator for $-\triangle+V^i(x)-k^2$ on Ω, $\Lambda^i(k)$ can be written $\gamma_-^{1,i}S^i(S_-^i)^{-1}$. Fix $y\in\mathbb{R}^n\backslash\overline{\Omega}$. We rewrite (4.10) in the form

$$\begin{aligned}&\Lambda^i\circ\big[aS_+^e\phi^e(x,y)+b\gamma_+^{1,e}S^e\phi^e(x,y)-\tilde{G}^i+a\tilde{G}^e(x,y)+b\gamma_+^{1,e}\tilde{G}^e(x,y)\big]\\&\quad=cS_+^e\phi^e(x,y)+d\gamma_+^{1,e}S^e\phi^e(x,y)-\gamma_-^{1,i}\tilde{G}^i(x,y)+c\tilde{G}^e(x,y)+d\gamma_+^{1,e}\tilde{G}^e(x,y).\end{aligned}$$

Define $\Lambda_e^e=-\gamma_+^{1,e}S^e(S_+^e)^{-1}$ to be the Dirichlet-to-Neumann operator of the exterior problem for $-\triangle+V^e(x)-k^2$ (with outgoing radiation conditions) and Λ^e the Dirichlet-to-Neumann operator for $-\triangle+V^e(x)-k^2$ on Ω. Using that $\Lambda^i\tilde{G}^i(x,y)=\gamma_-^{1,i}\tilde{G}^i(x,y)$, we can rewrite the above equation as

$$\begin{aligned}&\big[\Lambda^i\circ a-\Lambda^i\circ b\circ\Lambda_e^e-c+d\circ\Lambda_e^e\big](S_+^e\phi^e)(x,y)\\&\quad=-\big[\Lambda^i\circ a+\Lambda^i\circ b\circ\Lambda^e-c-d\circ\Lambda^e\big]\tilde{G}^e(x,y).\end{aligned}$$

Also since $\Lambda_e^e=-\Lambda^e+(S_\pm^e)^{-1}$,

$$\begin{aligned}&\big[\Lambda^i\circ a-\Lambda^i\circ b\circ\Lambda_e^e-c+d\circ\Lambda_e^e\big](S_+^e\phi^e)(x,y)\\&\quad=\big[d\circ(S_\pm^e)^{-1}-\Lambda^i\circ b\circ(S_\pm^e)^{-1}\big]\tilde{G}^e(x,y)\\&\qquad-\big[\Lambda^i\circ c-\Lambda^i\circ b\circ\Lambda_e^e-c+d\circ\Lambda_e^e\big]\tilde{G}^e(x,y).\end{aligned}$$

We want to invert the operator on the left-hand side, at least, at the symbol level, in order to obtain a formula for the singularity of $S_+^e\phi^e(x,y^*)$ as $y\downarrow x^*\in\partial\Omega$. Now,

$$\begin{aligned}&\sigma\big[\Lambda^i\circ a-\Lambda^i\circ b\circ\Lambda_e^e-c+d\circ\Lambda_e^e\big]\\&\quad=a\ell_1^e-b\ell_1^e\ell_1^i+d\ell_1+bm_{-1}(x,\xi)+T_{-2}(x,\xi),\end{aligned}$$

where $m_{-1}(x,\xi)$ is some operator of order -1. Let P be a local parametrix of $\big[\Lambda^i\circ a-\Lambda^i\circ b\circ\Lambda_e^e-c+d\circ\Lambda_e^e\big]$ which exists since we are assuming $x^*\notin\partial\Delta$. Then, in an appropriate neighborhood of x^*,

$$\begin{aligned}G^e(x,y)-\tilde{G}^e(x,y)&=S_+^e\phi^e(x,y)\\&\sim-\tilde{G}^e(x,y)+P\big[d\circ(S_\pm^e)^{-1}-\Lambda^i\circ b\circ(S_+^e)^{-1}\big]\tilde{G}^e(x,y),\end{aligned}\tag{5.1}$$

where $\sim$ denotes equality modulo C^∞. In the following corollary we use the above formula to find the principal symbol of the single layer potential of $G^e(x,y)$ obtained by taking the limit as $y\downarrow x^*\in\partial\Omega$. For now, it suffices to show that a singularity necessarily develops in (5.1) as $y\downarrow x^*\in\partial\Omega$, which will be the case unless

$$\sigma(P\big[d\circ(S_\pm^e)^{-1}-\Lambda^i\circ b\circ(S_+^e)^{-1}\big])=1\tag{5.2}$$

for all x in a neighborhood of x^*. This condition is sufficient by Proposition 3.6.

For all $x_0\in\partial\Omega$ near x^*, we see that equality of both sides of (5.2) is equivalent to

$$\sigma\big[\Lambda^i\circ a+\Lambda^i\circ b\circ\Lambda^e-c-d\circ\Lambda^e\big](x_0,\xi)=0$$

or

$$\sigma\big[\Lambda^i\circ a+\Lambda^i\circ b\circ\Lambda^e\big](x_0,\xi)=\sigma\big[c+d\circ\Lambda^e\big](x_0,\xi).$$

However, for this to be true we need $b(x_0) = 0$ and $\sigma(\Lambda^i \circ a)(x_0) = \sigma(d \circ \Lambda^e + c)(x_0)$. Using the composition formula for pseudodifferential operators, this becomes

$$\ell_1 a + \ell_0 a + \sum_j \partial_{\xi_j} \ell_1 D_{x_j} a + \cdots = d\ell_1 + d\ell_0 + c + \cdots .$$

From the coefficient of ℓ_1 we see that $a = d$ and it follows that $\sum \partial_{\xi_j} \ell_1 D_{x_j} a$ and c must equal zero. The former implies $a = \tau$ for some constant τ. Of course if the boundary conditions are self-adjoint, $\tau = 1$. Therefore $\sigma(\Lambda^i) = \sigma(\Lambda^e)$. It is well-known that the symbol of the Dirichlet-to-Neumann operator uniquely determines the electric potential, along with all its normal derivatives, at the surface (see [22] or the following section). This contradicts that the obstacle is well defined at x^* and proves a singularity must form in (5.1) as $y \downarrow x^* \in \partial\Omega$.

It still remains to consider the case when k^2 is a Dirichlet eigenvalue of $-\triangle + V^i(x)$ on Ω. In this case, let $\phi^i(x), \phi^e(x)$ be solutions to the equation

$$\begin{aligned} &\begin{pmatrix} S^i_- & -aS^e_+ - b\gamma^{1,e}_+ S^e \\ \gamma^{1,i}_- S^i & -cS^e_+ - d\gamma^{1,e}_+ S^e \end{pmatrix} \begin{pmatrix} \phi^i(x,y) \\ \phi^e(x,y) \end{pmatrix} \\ &\sim \begin{pmatrix} -\tilde{G}^i(x,y)|_{\partial\Omega} + a\tilde{G}^e(x,y)|_{\partial\Omega} + b\gamma^{1,e}_+ \tilde{G}^e \\ -\gamma^{1,i}_- \tilde{G}^i(x,y) + c\tilde{G}^e(x,y)|_{\partial\Omega} + d\gamma^{1,e}_+ \tilde{G}^e \end{pmatrix} \end{aligned} \tag{5.3}$$

in some neighborhood of x^*. Specifically, as discussed in Theorem 4.5, there exists a parametrix of the matrix of pseudodifferential operators on the left-hand side. We want ϕ^i and ϕ^e to be the functions obtained by applying this parametrix to the right-hand side. Since neither $(S^i_-)^{-1}$ nor $(S^e_+)^{-1}$ necessarily exists, we understand these terms to refer to parametrices too. The proof then proceeds in the same fashion. ∎

The following corollary of (5.1) gives the principal symbol of the transpose of the layer potential of $G^e(x,y)$ on $\partial\Omega$.

Corollary 5.2. *Let $(S^e_+)^t$ refer to the transpose of the single layer potential of $G^e(x,y)$ on $\partial\Omega$. Then if $b \neq 0$ at x_0,*

$$\sigma_{-1}((S^e_+)^t)(x_0,\xi') = \frac{1}{\sqrt{\sum_{j,k}^{n-1} \hat{g}^{jk}_e(x',0)\xi_j\xi_k}},$$

and if $b(x_0) = 0$,

$$\sigma_{-1}((S^e_+)^t)(x_0,\xi') = \frac{1}{(\frac{a}{d}+1)\sqrt{\sum_{j,k}^{n-1} \hat{g}^{jk}_e(x',0)\xi_j\xi_k}}$$

where we are in local, semigeodesic coordinates.

Note that if $T = I$, we recover the principal symbol of the usual single layer potential on $\partial\Omega$ for $\tilde{G}^e(x,y)$ as given in Theorem 3.3.

It is now easy to show that the location of the obstacle is uniquely determined everywhere it is well defined. Assume $\{\Omega_1, T_1(x), L_1\}$ and $\{\Omega_2, T_2(x), L_2\}$ are two obstacles well defined on $\Gamma_1 \subseteq \partial\Omega_1$ and $\Gamma_2 \subseteq \partial\Omega_2$. Let $G_1(x,y)$ and $G_2(x,y)$ be their respective Green's functions.

Theorem 5.3. *If $G^e_1(x,y) = G^e_2(x,y)$ for all $x,y \in \mathbb{R}^n \backslash \overline{(\Omega_1 \cup \Omega_2)}$ and $x \neq y$, then $\Gamma_1 = \Gamma_2$.*

Proof. Say there exists a point $x^* \in \Gamma_2$ such that $x^* \in \mathbb{R}^n \backslash (\Omega_1 \cup \overline{\Gamma_1})$, where the closure of Γ_1 is taken with respect to $\partial\Omega$. Fix some neighborhood Γ such that

$x^* \in \Gamma \subset \Gamma_2$ and $\Gamma \cap \overline{\Gamma_1} = \emptyset$. Then, by Lemma 5.1,

$$\lim_{y \downarrow x^*} G_2^e(x,y) - \tilde{G}^e(x,y) \notin C^\infty(\Gamma).$$

On the other hand, since x^* is a positive distance away from Γ_1, it is easy to see that

$$\lim_{y \downarrow x^*} G_1^e(x,y) - \tilde{G}^e(x,y) \in C^\infty(\Gamma).$$

This is a contradiction and proves the theorem. □

5.2. Transfer matrix and Dirichlet-to-Neumann operator. The following theorem proves the transfer matrix and the full symbol of the Dirichlet-to-Neumann operator are uniquely determined on the boundary. Also, if the Dirichlet-to-Neumann operator on the boundary exists, we show it is uniquely determined.

THEOREM 5.4. *Assume $G^e(x,y)$ is known for all x and y in $\mathbb{R}^n \backslash \Omega$. This uniquely determines $T(x)$ (up to the constant τ), $\sigma(\Lambda^i)$, and, if k^2 is not a Dirichlet eigenvalue of $-\triangle + V^i$ on Ω, $\Lambda^i(k)$ itself is uniquely determined.*

Proof. First, we show the transfer matrix is uniquely determined. Assume that k^2 is not a Dirichlet eigenvalue of $-\triangle + V^i(x)$ on Ω so that Λ^i exists. This restriction is easily removed, as discussed at the end of the proof of Lemma 5.1.

The proof will rely on an analysis of the symbol of the operator

$$(d - \Lambda^i \circ b)^{-1}(\Lambda^i \circ a - c),$$

where $(d - \Lambda^i \circ b)^{-1}$ refers to the parametrix for $d - \Lambda^i \circ b$. We first need to show that this pseudodifferential operator on $\partial\Omega$ is uniquely determined from $G^e(x,y)$.

We know that

$$\begin{pmatrix} \gamma_-^0 G^i(x,y) \\ \gamma_-^{1,i} G^i(x,y) \end{pmatrix} = \begin{pmatrix} a(x) & b(x) \\ c(x) & d(x) \end{pmatrix} \begin{pmatrix} \gamma_+^0 G^e(x,y) \\ \gamma_+^{1,e} G^e(x,y) \end{pmatrix}. \tag{5.4}$$

Rewriting this by using that $\gamma_-^{1,i} G^i(x,y) = \Lambda^i G^i(x,y)$, we obtain for $y \in \mathbb{R}^n \backslash \overline{\Omega}$ and $x \in \partial\Omega$ that

$$(\Lambda^i \circ a - c) G^e(x,y) = (d - \Lambda^i \circ b)\gamma_+^{1,e} G^e(x,y).$$

Since $(d - \Lambda^i \circ b)$ is elliptic, the previous equality implies

$$\Big[(\Lambda^i \circ b(x) - d(x))^{-1}(\Lambda^i \circ a(x) - c(x))\Big] G^e(x,y) \sim -\gamma_+^{1,e} G^e(x,y). \tag{5.5}$$

Note this holds only in a local neighborhood of any point on the boundary that is not in $\partial\Delta$.

Fix some $x_0 \in \partial\Omega \backslash \partial\Delta$. Since $\gamma_+^{1,e} G^e(x,y)$ is known for all $y \in \mathbb{R}^n \backslash \overline{\Omega}$, so is the limit as $y \downarrow x_0 \in \partial\Omega$. Now, by Corollary 5.2 and Proposition 3.5, $WF(G^e(x,x_0)|_{\partial\Omega}) = x_0 \times S^{n-2}$ since this is true of $\tilde{G}^e(x,x_0)$. Therefore the symbol of the operator acting on $G^e(x,x_0)$ is uniquely determined by Proposition 3.6.

This reduces the problem to showing that

$$\mathcal{B}(x_0,\xi) = \sigma\Big[(\Lambda^i \circ b - d)^{-1}(\Lambda^i \circ a - c)\Big](x_0,\xi) \tag{5.6}$$

uniquely determines $a(x_0), b(x_0), c(x_0)$, and $d(x_0)$ which will be accomplished by analyzing the symbol.

Recall that the symbol of the Dirichlet-to-Neumann operator on $\partial\Omega$ has the form (in local semigeodesic coordinates around x_0)

$$\sigma(\Lambda^i)(x',\xi') = \ell_1(x',\xi') + \ell_0(x',\xi') + \ell_{-1}(x',\xi') + \cdots, \tag{5.7}$$

where $\ell_1 = (\sum_{j,k}^{n-1} \hat{g}_i^{jk}(x',0)\xi_j\xi_k)^{\frac{1}{2}}$ and ℓ_0 does not depend on $V(x)$ (see [22] or section 6). It will considerably simplify the notation in the future to define the product,

$$\Pi_j\big(p,q\big)(x,\xi) = \sum_{|\alpha|=j} \partial_\xi^\alpha p(x,\xi) D_x^\alpha q(x,\xi)/\alpha!. \tag{5.8}$$

Also, in analyzing the symbol, we separate the proof into the cases where $b = 0$ and $b \neq 0$. Note we can immediately tell whether $b = 0$ in some neighborhood of x_0 or whether $b \neq 0$ there by the asymptotics of $G^e(x,y)$ given in Corollary 5.2. Finally, it is worth mentioning that if we consider only the self-adjoint case, the analysis of the symbol can be simplified.

First, consider the simpler case in which $b(x) = 0$ for all x in some neighborhood of x_0. Then at x_0 and in local semigeodesic coordinates around $x_0 \in \partial\Omega$, (5.6) looks like

$$\begin{aligned} \mathcal{B}(x_0,\xi') &= \sigma\Big[\frac{1}{d}\circ\Lambda^i\circ a - \frac{c}{d}\Big](x_0,\xi') \\ &= \frac{a}{d}\ell_1 + \frac{1}{d}\Pi_1(\ell_1,a) + \frac{a}{d}\ell_0 + \frac{c}{d} + \cdots. \end{aligned} \tag{5.9}$$

Thus, at any x_0, we uniquely determine $\frac{a}{d}$, $\frac{1}{d}\Pi_1(\ell_1,a)$, and $\frac{c}{d}$. We claim this uniquely determines the transfer matrix (up to a constant). Say we had two transfer matrices with elements a_1, c_1, d_1 and a_2, c_2, d_2. Then

$$\frac{a_1}{d_1} = \frac{a_2}{d_2}, \tag{5.10}$$

$$\Pi_1(\ell_1,a_1) = \frac{d_1}{d_2}\Pi_1(\ell_2,a_2), \tag{5.11}$$

$$\frac{c_1}{d_1} = \frac{c_2}{d_2}. \tag{5.12}$$

Thus by (5.10),

$$\Pi_1(\ell_1,a_1) = \Pi_1\left(\ell_1,\frac{d_1}{d_2}a_2\right) = \frac{d_1}{d_2}\Pi_1(\ell_1,a_2) + a_2\Pi_1\left(\ell_1,\frac{d_1}{d_2}\right)$$

which combined with (5.11) implies that $\frac{d_1}{d_2} = \tau > 0$ is a constant everywhere. Therefore, (5.10) and (5.12) imply that $a_1 = \tau a_2$ and $c_1 = \tau c_2$.

A much more detailed analysis is needed when $b(x) \neq 0$. Let $t = \det T$. We claim, in local semigeodesic coordinates around any $x_0 \in \partial\Omega$ (and in a sufficiently small neighborhood such that $b \neq 0$),

$$\begin{aligned} \mathcal{B}(x',\xi') = \frac{a}{b} &+ \frac{1}{\ell_1}\Big[\frac{t}{b^2}\Big] \\ &+ \frac{1}{\ell_1^2}\Big[\frac{t}{b^2}\left(\frac{d}{b} - \ell_0 - \frac{1}{\ell_1}\Pi_1(\ell_1,\ell_1)\right) + \frac{1}{b}\Pi_1\left(\ell_1,\frac{t}{b}\right)\Big] + \cdots. \end{aligned} \tag{5.13}$$

Before obtaining this formula, we show this finishes the proof that the transfer matrix is uniquely determined.

Given two transfer matrices, we know

$$\frac{a_1}{b_1} = \frac{a_2}{b_2}, \tag{5.14}$$

$$\frac{t_1}{b_1^2} = \frac{t_2}{b_2^2}, \tag{5.15}$$

$$\frac{d_1}{b_1} = \frac{d_2}{b_2}, \tag{5.16}$$

$$\Pi_1\left(\ell_1, \frac{t_1}{b_1}\right) = \frac{b_1}{b_2}\Pi_1\left(\ell_1, \frac{t_2}{b_2}\right). \tag{5.17}$$

Now, (5.15) implies

$$\Pi_1\left(\ell_1, \frac{t_1}{b_1}\right) = \Pi_1\left(\ell_1, \frac{b_1}{b_2}\frac{t_2}{b_2}\right) = \frac{b_1}{b_2}\Pi_1\left(\ell_1, \frac{t_2}{b_2}\right) + \frac{t_2}{b_2}\Pi_1\left(\ell_1, \frac{b_1}{b_2}\right)$$

which in view of (5.17) implies that there exists a constant $\tau > 0$ such that $\frac{b_1}{b_2} = \tau$. Therefore (5.14), (5.15), and (5.16) finish the claim. That this is the same constant as it is on the set where $b = 0$ follows by the continuity and positivity of a and d on all of $\partial\Omega$.

To prove the symbol has the form (5.13) we will solve for $\mathcal{B}(x', \xi') = \sum_{j=0}^{\infty} r_{-j}(x', \xi')$ using the composition formula for pseudodifferential operators. By (5.6),

$$\sigma(\Lambda^i \circ b - d) \circ \sigma(\mathcal{B}) = \sigma(\Lambda^i \circ a - c).$$

Plugging in the symbol of the Dirichlet-to-Neumann operator (5.7) we obtain (up to terms of order -2)

$$\begin{aligned}\big[\ell_1 b + \Pi_1(\ell_1, b) + \ell_0 b - d + \Pi_2(\ell_1, b) + \Pi_1(\ell_0, b) + \ell_{-1} b\big] \circ \big[r_0 + r_{-1} + r_{-2}\big] \\ = \ell_1 a + \Pi_1(\ell_1, a) + \ell_0 a - c + \Pi_2(\ell_1, a) + \Pi_1(\ell_0, a) + \ell_{-1} a + \cdots .\end{aligned}$$

Equating terms by order of homogeneity, this becomes

$$(\ell_1 b) r_0 = \ell_1 a, \tag{5.18}$$

$$(\ell_1 b) r_{-1} + \big[\Pi_1(\ell_1, b) + \ell_0 b - d\big] r_0 + \Pi_1(\ell_1 b, r_0) = \Pi_1(\ell_1, a) + \ell_0 a - c, \tag{5.19}$$

$$\begin{aligned}&(\ell_1 b) r_{-2} + \big[\Pi_1(\ell_1, b) + \ell_0 b - d\big] r_{-1} + \big[\Pi_2(\ell_1, b) + \Pi_1(\ell_0, b) + \ell_{-1} b\big] r_0 \\ &\quad + \Pi_2(\ell_1 b, r_0) + \Pi_1(\ell_1 b, r_{-1}) + \Pi_1([\Pi_1(\ell_1, b) + \ell_0 b - d], r_0) \\ &\qquad = \Pi_2(\ell_1, a) + \Pi_1(\ell_0, a) + \ell_{-1} a.\end{aligned} \tag{5.20}$$

From (5.18) we see that $r_0 = \frac{a}{b}$. Thus, (5.19) can be rewritten

$$(\ell_1 b) r_{-1} + \Pi(\ell_1, b)\frac{a}{b} + \ell_0 a - \frac{ad}{b} + \Pi_1\left(\ell_1 b, \frac{a}{b}\right) = \Pi_1(\ell_1, a) + \ell_0 a - c.$$

A simple calculation shows that

$$\Pi_1\left(\ell_1 b, \frac{a}{b}\right) = b\Pi_1\left(\ell_1, \frac{a}{b}\right) = \Pi_1(\ell_1, a) - \frac{a}{b}\Pi_1(\ell_1, b),$$

so that (5.19) can be simplified to,

$$(\ell_1 b) r_{-1} - \frac{ad}{b} = -c.$$

Therefore

$$r_{-1} = \frac{1}{\ell_1}\left(\frac{ad}{b^2} - \frac{c}{b}\right) = \frac{1}{\ell_1}\left(\frac{ad-bc}{b^2}\right).$$

Plugging in the formulas for r_0 and r_{-1} and expanding the term $\Pi_1(\ell_0 b, \frac{a}{b})$ as above, (5.20) becomes

$$\begin{aligned}(\ell_1 b)r_{-2} &+ \frac{a}{b}\Pi_2\left(\ell_1, b\right) + \Pi_2\left(\ell_1 b, \frac{a}{b}\right) + \Pi_1\left(\Pi_1(\ell_1, b), \frac{a}{b}\right) \\ &+ \frac{\det T}{\ell_1 b^2}\left[\Pi_1(\ell_1, b) + \ell_0 b - d\right] + \Pi_1\left(\ell_1 b, \frac{\det T}{\ell_1 b^2}\right) = \Pi_2(\ell_1, a).\end{aligned}$$

A trivial, but lengthy, calculation shows that

$$\Pi_2\left(\ell_1 b, \frac{a}{b}\right) = \Pi_2(\ell_1, a) - \frac{a}{b}\Pi_2(\ell_1, b) - \Pi_1\left(\Pi_1(\ell_1, b), \frac{a}{b}\right).$$

Plugging this into the previous equation, expanding $\Pi_1(\ell_1 b, \frac{\det T}{\ell_1 b^2})$ as previously, and solving for r_{-2} we finish the proof of (5.13).

Finally, we show that for k^2 not a Dirichlet eigenvalue of Ω, the Dirichlet-to-Neumann operator Λ^i on $\partial\Omega$ is uniquely determined. By (5.4), we know

$$\Lambda^i\Big(a(x)G^e(x,y) + b(x)\gamma_+^{1,e}G^e(x,y)\Big) = c(x)G^e(x,y) + d(x)\gamma_+^{1,e}G^e(x,y)$$

for $y \in \mathbb{R}^n\backslash\Omega$. Therefore it suffices to note that $a(x)G^e(x,y) + b(x)\gamma_+^{1,e}G^e(x,y)$ for $y \in \mathbb{R}^n\backslash\Omega$ is dense in $L^2(\partial\Omega)$, which is proved in the following lemma. ∎

LEMMA 5.5. *If k^2 is not a Dirichlet eigenvalue of $-\triangle + V^i(x)$ on Ω, then for any open set $\mathcal{O} \subset \mathbb{R}^n\backslash\Omega$,*

$$\{a(x)G^e(x,y) + b(x)\gamma_+^{1,e}G^e(x,y) : y \in \mathcal{O}\}$$

is dense in $L^2(\partial\Omega)$.

Proof. Say

$$u(y) = \int_{\partial\Omega} a(x)G^e(x,y) + b(x)\gamma_+^{1,e}G^e(x,y)\phi(x)\, dS_x = 0 \text{ for all } y \in \mathcal{O}.$$

Then, using the boundary conditions, it follows that

$$u(y) = \int_{\partial\Omega} G^i(x,y)\phi(x)\, dS_x = 0 \text{ for all } y \in \mathcal{O}$$

and so by unique continuation, $u = 0$ in $\mathbb{R}^n\backslash\Omega$. Therefore $u_+(y) = 0$ on $\partial\Omega$ and $\gamma_+^{1,i}u(y) = 0$ on $\partial\Omega$. Since k^2 is not a Dirichlet eigenvalue of $-\triangle + V^i(y) - k^2$ on Ω and, by the jump relations, $u_-(y) = 0$, it follows that $\gamma_-^{1,i}u = 0$. Another application of the jump relations then shows $\phi(y) = 0$. ∎

Theorems 5.3 and 5.4, along with Theorem 4.8, finishes the proof of Theorems 2.2 and 2.3 when there are no magnetic potentials and the media is Euclidean.

6. The symbol of the Dirichlet-to-Neumann operator and boundary determination. In this section we recall the symbol of the Dirichlet-to-Neumann operator and prove that it uniquely determines g, A, and V at the boundary of the obstacle modulo gauge transformations and diffeomorphisms of the metric that do not affect the operator at the boundary. Note these results hold for complex-valued electromagnetic potentials as well.

Let L be a Schrödinger operator of the form

$$Lu(x) = \left(\sum_{j,k} \frac{1}{\sqrt{g}}\big(D_j + A_j(x)\big)\sqrt{g}g^{jk}(x)\big(D_k + A_k(x)\big)\right) u(x) + q(x)u(x)$$

with $(A_1(x), \ldots, A_n)$ and $q(x)$ infinitely smooth, and fix some compact, connected subset $\Omega \subset \mathbb{R}^n$. Consider the boundary value problem for $f \in H^{\frac{1}{2}}(\partial\Omega)$,

$$Lu = 0 \text{ in } \Omega,$$
$$u|_{\partial\Omega} = f.$$

Then the Dirichlet-to-Neumann map, $\Lambda : H^{\frac{1}{2}}(\partial\Omega) \to H^{-\frac{1}{2}}(\partial\Omega)$, is defined by

$$\Lambda f = \sum_{j,k} g^{jk}\left(\frac{\partial u}{\partial x_j} + iA_j u\right)\nu_k(x)\left(\sum_{p,r} g^{pr}(x)\nu_p(x)\nu_r(x)\right)^{-\frac{1}{2}}, \tag{6.1}$$

where ν is the outward pointing normal in Euclidean coordinates.

Before introducing the symbol, it will help to simplify the operator. In a neighborhood of an arbitrary point $x_0 \in \partial\Omega$ introduce semigeodesic coordinates (which we shall continue to denote by $x = (x', x_n)$) so that $x_n = 0$ is the equation of $\partial\Omega$. In these coordinates,

$$\begin{aligned}\hat{L}(x, D)\hat{u} &= D_n^2\hat{u}(x) + L_n(x, D)\hat{u}(x)\\ &\quad + \sum_{j,k}^{n-1} \frac{1}{\sqrt{\hat{g}}}(D_j + \hat{A}_j(x))\sqrt{\hat{g}}\hat{g}^{jk}(x)(D_k + \hat{A}_k(x))\hat{u}(x) + \hat{q}(x)\hat{u}(x),\end{aligned}$$

where

$$L_n(x, D) = (E_n(x) + \hat{A}_n(x))D_n + \hat{A}_n D_n + (E_n + \hat{A}_n)\hat{A}_n + D_n\hat{A}_n).$$

Above, as well as in what follows, $E_j(x) = \frac{D_j(\sqrt{g})}{\sqrt{g}} = \frac{D_j(\sqrt{\hat{g}})}{\sqrt{\hat{g}}}$ $(1 \le j \le n)$. We now select a gauge $\kappa(x)$ such that $\kappa(x', 0) = 1$ and

$$A_n'(x) = \hat{A}_n(x) + \frac{D_n\kappa(x)}{\kappa(x)} = 0.$$

Note κ is easily found by assuming $\kappa(x) = e^{-i\psi(x)}$ for some $\psi(x)$ equal to zero on the boundary. We then have

$$L' = D_n^2 + E_nD_n + \sum_{j,k}^{n-1} \frac{1}{\sqrt{\hat{g}}}(D_j + \hat{A}_j)\sqrt{\hat{g}}\hat{g}^{jk}(D_k + \hat{A}_k)\hat{u} + \hat{q},$$

which we will rewrite in the form

$$\begin{aligned}L'(x, D) &= D_n^2 + E_n(x)D_n + q_2(x, D') + q_1(x, D')\\ &\quad + 2\sum_{j,k}^{n-1} A_j'(x)\hat{g}^{jk}(x)D_k + G(x),\end{aligned}$$

where

$$q_2(x, D') = \sum_{j,k}^{n-1} \hat{g}^{jk}(x) D_j D_k,$$

$$q_1(x, D') = \sum_{j,k}^{n-1} (\hat{g}^{jk}(x) E_j(x) + D_j \hat{g}^{jk}(x)) D_k,$$

and

$$G(x) = \sum_{j,k}^{n-1} (E_j(x) + A'_j + D_j)(\hat{g}^{jk} A_k) + \hat{q}(x).$$

If we define Λ' to be the Dirichlet-to-Neumann operator corresponding to the operator L', then $\Lambda' f = \frac{\partial \hat{u}(x',0)}{\partial x_n}$ and $\Lambda' f = \Lambda f$.

We want to show the symbol of the Dirichlet-to-Neumann operator uniquely determines the value of $\hat{g}$, A', and $\hat{q}$, as well as all their normal derivatives, on the boundary. Here $\hat{g}|_{\partial\Omega}$ is independent of a diffeomorphism of the metric and the $A'_j(x)\,(1 \le j \le n-1)$ are the result of specifying a particular gauge (i.e., one that makes $\hat{A_n}(x) = 0$). Therefore the metric and potentials, along with all powers of their normal derivatives, are uniquely defined at the boundary. Boundary determination from the symbol of the Dirichlet-to-Neumann operator has been proven by Kohn and Vogelius [22] for the case $g_{jk} = \delta_{jk}$ and $A = 0$; by Lee and Uhlmann [23] for arbitrary g and $A = 0, V = 0$; and by Nakamura, Sun, and Uhlmann [25] and Eskin [12] for $g_{jk} = \delta_{jk}$ and real-valued A, V. We slightly improve these results to show the uniqueness for arbitrary $\{g, A, V\}$ by investigating not only terms of a specific order of homogeneity in the symbol but also terms of a specific type of homogeneity. To explain what is meant by type, note both ξ_j and $(\xi_j \xi_l)((\sum_{p,r} g^{pr} \xi_p \xi_r)^{\frac{1}{2}})^{-\frac{1}{2}}$ are of order 1 but are of different type.

The following theorem gives the exact symbol of the Dirichlet-to-Neumann operator. For the proof see [12], [22], [23], or [25].

THEOREM 6.1. *The symbol of the Dirichlet-to-Neumann operator is*

$$\sigma(\Lambda')(x', \xi') = \ell_1(x', \xi') + \ell_0(x', \xi') + \ell_{-1}(x', \xi') + \ell_{-2}(x', \xi') + \cdots,$$

where

$$\ell_1(x', \xi') = \sqrt{q_2(x, \xi)} = \sqrt{\sum_{j,k}^{n-1} \hat{g}^{jk}(x', 0) \xi_j \xi_k},$$

$$\ell_0(x', \xi') = -\frac{1}{2\ell_1} \left(\Pi_1(\ell_1, \ell_1) - q_1 - \partial_{x_n} \ell_1 + E_n \ell_1 + \sum_{j,k}^{n-1} A'_j \hat{g}^{jk}(x', 0) \xi_k \right),$$

$$\ell_{-1}(x', \xi') = -\frac{1}{2\ell_1} \left(\sum_{\substack{0 \le p,r, \le 1 \\ K = p+r}} \Pi_K(\ell_p, \ell_r) + \partial_{x_n} \ell_0 - E_n \ell_0 - G \right),$$

and for $m<0$,

$$\ell_{m-1}(x',\xi') = -\frac{1}{2\ell_1}\left(\sum_{\substack{m\le p,r\le 1\\ K=p+r-m}} \Pi_K(\ell_p,\ell_r) + \partial_{x_n}\ell_m - E_n\ell_m\right).$$

The expansion gives us an immediate corollary on boundary determination.

Corollary 6.2. $\sigma(\Lambda')$ *uniquely determines* (*for all* $p>0$ *and* $1\le j\le n-1$) $(\frac{\partial}{\partial x_n})^p\hat{g}|_{\{x_n=0\}}$, $(\frac{\partial}{\partial x_n})^p A'_j|_{\{x_n=0\}}$, $(\frac{\partial}{\partial x_n})^p\hat{q}(x)|_{\{x_n=0\}}$.

Proof. In ℓ_1^2, $\hat{g}^{\alpha\beta}$ is the coefficient of $\xi_\alpha\xi_\beta$ so that $\hat{g}^{\alpha\beta}$, as well as all their derivatives in directions tangent to the boundary, are uniquely determined.

Define $\tilde{A} = (\{\hat{g}\}_{\alpha,\beta=1}^{n-1})^{-1}A'$. The only new information in ℓ_0 is the appearance of $\frac{\partial\hat{g}^{\alpha\beta}}{\partial x_n}$ for $1\le\alpha,\beta\le n-1$ and $\tilde{A}_j$ for $1\le j\le n-1$. These occur in the following manner:

$$\frac{\partial\hat{g}^{\alpha\beta}(x)}{\partial x_n} \text{ is part of the coefficient of } \frac{\xi_\alpha\xi_\beta}{\sum\hat{g}^{pr}\xi_p\xi_r},$$
$$\tilde{A}_j(x) \text{ is part of the coefficient of } \frac{\xi_j}{(\sum\hat{g}^{pr}\xi_p\xi_r)^{\frac{1}{2}}}.$$

Note the other terms in the expansion are known from ℓ_0. Thus, from ℓ_0 we obtain $\frac{\partial\hat{g}^{\alpha\beta}}{\partial x_n}$ for $1\le\alpha,\beta\le n-1$, and $\tilde{A}_j$. It is now easy to see that new information occurs in a manner which uniquely determines the desired values. Specifically, on the term ℓ_{1-k},

$$\frac{\partial^k\hat{g}^{\alpha\beta}(x',0)}{\partial(x_n)^k} \text{ is part of the coefficient of } \frac{\xi_\alpha\xi_\beta}{(\sum\hat{g}^{pr}\xi_p\xi_r)^{\frac{k+1}{2}}},$$
$$\frac{\partial^{k-1}\tilde{A}_j(x',0)}{\partial(x_n)^{k-1}} \text{ is part of the coefficient of } \frac{\xi_j}{(\sum\hat{g}^{pr}\xi_p\xi_r)^{\frac{k}{2}}},$$
$$\frac{\partial^{k-2}\hat{q}(x',0)}{\partial(x_n)^{k-2}} \text{ is part of the coefficient of } \frac{1}{(\sum\hat{g}^{pr}\xi_p\xi_r)^{\frac{k-1}{2}}}.$$

This implies the claim (note we can recover A' from $\tilde{A}$). ∎

7. Inverse problem for anisotropic media and electromagnetic potentials. Our arguments will closely follow those in section 5. In order to avoid excessive indices, we denote $p_j = \ell_1^{(j)}$ below.

Lemma 7.1. *Say* $p_1^{-2}\Pi_1(p_1,p_1) = p_2^{-2}\Pi_1(p_2,p_2)$ *and* $p_1 = fp_2$. *Then* f *is constant.*

Proof. Substituting the latter into the former, we obtain,

$$\Pi_1(p_1,p_1) = f^2\Pi_1(p_2,p_2). \tag{7.1}$$

On the other hand,

$$\Pi_1(p_1,p_1) = \Pi_1(fp_2,fp_2) = f^2\Pi_1(p_2,p_2) + fp_2\Pi_1(p_2,f). \tag{7.2}$$

Therefore (7.1) and (7.2) imply that $\Pi_1(p_2,f)=0$, from which it follows that f must be constant. ∎

First, let us show the location is uniquely determined. We say an obstacle is *well defined at* x_0 if conditions (i) and (ii) in Theorem 2.2 do not hold for any pair of $\sigma > 0$ and $\rho > 0$. Analogously to Lemma 5.1, we obtain the following.

LEMMA 7.2. $\{\Omega, T, L^i\}$ *is well defined at* x^* *if and only if*

$$\lim_{y\downarrow x^*\in\partial\Omega}\big(G^e(x,y)-\tilde{G}^e(x,y)\big)=\lim_{y\downarrow x^*\in\partial\Omega}S^e_+\phi^e(x,y)\notin C^\infty(\partial\Omega).$$

Proof. By the same reasoning as in the proof of Lemma 5.1, we know a singularity in $\tilde{G}^e(x,y)-G^e(x,y)$ will form as $y\downarrow x\in\partial\Omega$ unless

$$\sigma\big[\Lambda^i\circ a+\Lambda^i\circ b\circ\Lambda^e\big](x_0,\xi)=\sigma\big[c+d\circ\Lambda^e\big](x_0,\xi).$$

Assume this is true. Then $b=0$ and $\sigma(\Lambda^i\circ a)=\sigma(c+d\circ\Lambda^e)$. Therefore

$$\ell^i_1 a+\Pi_1(\ell^i_1,a)+\ell^i_0 a=d\ell^e_1+d\ell^e_0+c+\cdots$$

and using the expansion of ℓ_0,

$$\begin{aligned}\ell^i_1 a+\Pi_1(\ell^i_1,a)-a\frac{1}{2\ell^i_1}&\left(\Pi_1(\ell^i_1,\ell_1)-q^i_1-\partial_{x_{n_i}}\ell^i_1+E^i_n\ell^i_1+\sum_{j,k}^{n-1}(A^i)'_j\hat{g}^{jk}_i(x',0)\xi_k\right)\\ =d\ell^e_1-d\frac{1}{2\ell^e_1}&\left(\Pi_1(\ell^e_1,\ell^e_1)-q^e_1-\partial_{x_{n_e}}\ell^e_1+E^e_n\ell^e_1+\sum_{j,k}^{n-1}(A^e)'_j\hat{g}^{jk}_e(x',0)\xi_k\right)+c.\end{aligned}$$

Immediately we see that $\ell^e_1 a=\ell^i_1 d$ and $\frac{a}{\ell^i_1}\Pi_1(\ell^i_1,\ell^i_1)=\frac{d}{\ell^e_1}\Pi_1(\ell^e_1,\ell^e_1)$ which implies, by Lemma 7.1, there exists a constant ρ such that $\frac{a}{d}=\rho$ and $\frac{\ell^e_1}{\ell^i_1}=\rho$. Since the magnetic potentials are real and the terms $\frac{q^e_1 a}{\ell^e_1}$ and $\frac{q^i_1 d}{\ell^i_1}$ are equal by the previous statement, it follows that $\Pi_1(\ell_1,a)=0$ (since these terms are of a specific homogeneity type). Thus there exists τ such that $a=\tau\rho^{-\frac{n}{2}}$. Therefore $d=\tau\rho^{1-\frac{n}{2}}$ and so $c=0$. We leave it to the reader to verify that in the self-adjoint case, $\tau=1$. $\square$

Note we have proved the following corollary which is of interest in its own right.

COROLLARY 7.3. $\sigma(\Lambda_1\circ f)=\sigma(g\circ\Lambda_2)$ *implies that* f/g *is constant.*

The principal symbol of the single layer potentials can now be calculated.

COROLLARY 7.4. *For* $b\neq 0$,

$$\sigma_{-1}((S^e_+)^t)=\frac{1}{\sqrt{\sum_{j,k}^{n-1}\hat{g}^{jk}_e(x',0)\xi_j\xi_k}},$$

and for $b=0$,

$$\sigma_{-1}((S^e_+)^t)=\frac{1}{(\frac{a}{d}\frac{\ell^i_1}{\ell^e_1}+1)\sqrt{\sum_{j,k}^{n-1}\hat{g}^{jk}_e(x',0)\xi_j\xi_k}},$$

where we are in local, semigeodesic coordinates.

Analogously to Theorem 5.4, we have the following.

THEOREM 7.5. *Given* $G_1(x,y)$ *and* $G_2(x,y)$ *such that* $G^e_1(x,y)=G^e_2(x,y)$ *for all* x *and* y *in* $\mathbb{R}^n\backslash\Omega$, *it follows that there exists a constant* $\rho>0$ *such that*

$$T_1(x)=\begin{pmatrix}\rho^{-\frac{n}{2}} & 0\\ 0 & \rho^{1-\frac{n}{2}}\end{pmatrix}T_2(x),\ \sigma(\Lambda^i_1)=\rho\sigma(\Lambda^i_2),$$

and if k^2 is not a Dirichlet eigenvalue for either $L_1^i - k^2$ or $L_2^i - k^2$ on Ω, then $\Lambda_1^i = \rho\Lambda_2^i$.

Proof. As in the proof of Theorem 5.4, we know that $G_j^e(x,y)$ $(j=1,2)$ uniquely determines the operator

$$\mathcal{B}_j(x,\xi) = \sigma\big[(\Lambda^i \circ b - d)^{-1}(\Lambda^i \circ a - c)\big](x_0,\xi).$$

Also, as mentioned in the proof of Theorem 5.4, we can tell whether $b=0$ or $b \neq 0$ in the neighborhood of any $x_0 \notin \partial\Delta$ by the asymptotics of $G_j^e(x,y)$ given in the previous corollary. Therefore $b_1(x) = 0$ when $b_2(x) = 0$.

We will consider only the case that $b_j(x) \neq 0$ since the other case follows similarly. Using (x',ξ') to denote we are in local semigeodesic coordinates and restricting to a sufficiently small neighborhood,

$$\begin{aligned}\mathcal{B}_j(x',\xi') = \frac{a_j}{b_j} + \frac{1}{\ell_1^{(j)}}\left[\frac{t_j}{b_j^2}\right] \\ + \frac{1}{(\ell_1^{(j)})^2}\left[\frac{t_j}{b_j^2}\left(\frac{d_j}{b_j} - \ell_0^{(j)} - \frac{1}{\ell_1^{(j)}}\Pi_1(\ell_1^{(j)},\ell_1^{(j)})\right) + \frac{1}{b_j}\Pi_1\left(\ell_1^{(j)},\frac{t_j}{b_j}\right)\right] + \cdots .\end{aligned}$$

Equating terms by order and type of homogeneity in the equality $\mathcal{B}_1(x',\xi') = \mathcal{B}_2(x',\xi')$, we get

$$\frac{a_1}{b_1} = \frac{a_2}{b_2}, \tag{7.3}$$

$$\frac{1}{p_1}\frac{t_1}{b_1^2} = \frac{1}{p_2}\frac{t_2}{b_2^2}, \tag{7.4}$$

$$\frac{1}{p_1^2}\frac{t_1}{b_1^2}\left(\frac{d_1}{b_1} + \frac{D_{n_1}(\sqrt{\hat g_1})}{\sqrt{\hat g_1}} - \frac{\partial_{x_{n_1}}p_1}{p_1}\right) = \frac{1}{p_2^2}\frac{t_2}{b_2^2}\left(\frac{d_2}{b_2} + \frac{D_{n_2}(\sqrt{\hat g_2})}{\sqrt{\hat g_2}} - \frac{\partial_{x_{n_2}}p_2}{p_2}\right), \tag{7.5}$$

$$\frac{1}{p_1^2}\Pi_1(p_1,p_1) = \frac{1}{p_2^2}\Pi_1(p_2,p_2), \tag{7.6}$$

$$\frac{1}{p_1^2 b_1}\Pi_1\left(p_1,\frac{t_1}{b_1}\right) + \frac{t_1}{b_1^2}\frac{1}{p_1^2}\sum A_j^{1'}\hat g_1^{jk}\xi_k = \frac{1}{p_2^2 b_2}\Pi_1\left(p_2,\frac{t_2}{b_2}\right) + \frac{t_2}{b_2^2}\frac{1}{p_2^2}\sum A_j^{2'}\hat g_2^{jk}\xi_k. \tag{7.7}$$

Note in (7.7) we really should have included $\frac{t_1}{b_1^2}\frac{1}{p_1^2}\frac{q_1^{(1)}}{p_1}$ and $\frac{t_2}{b_2^2}\frac{1}{p_2^2}\frac{q_2^{(1)}}{p_2}$. However, we will not need (7.7) until it already will have been proven that these terms are equal. From (7.6) and (7.4), we see that there exists a constant ρ such that

$$\frac{p_1}{p_2} = \frac{t_1}{t_2}\left(\frac{b_2}{b_1}\right)^2 = \rho. \tag{7.8}$$

Now,

$$\begin{aligned}\Pi_1\left(p_1,\frac{t_1}{b_1}\right) &= \Pi_1\left(\rho p_2, \rho\frac{b_1}{b_2}\frac{t_2}{b_2}\right) \\ &= \rho^2\Pi_1\left(p_2,\frac{b_1}{b_2}\frac{t_2}{b_2}\right) \\ &= \rho^2\frac{b_1}{b_2}\Pi_1\left(p_2,\frac{t_2}{b_2}\right) + \rho^2\frac{t_2}{b_2}\Pi_1\left(p_2,\frac{b_1}{b_2}\right).\end{aligned}$$

Plugging this result into (7.7), we obtain

$$\frac{c^2}{p_1^2}\frac{b_2}{b_1}\frac{t_2}{b_2^2}\Pi_1\left(p_2,\frac{b_1}{b_2}\right)+\frac{t_1}{b_1^2}\frac{1}{p_1^2}\sum A_j^{1'}\hat{g}_1^{jk}\xi_k=\frac{t_2}{b_2^2}\frac{1}{p_2^2}\sum A_j^{2'}\hat{g}_2^{jk}\xi_k.$$

Using that the magnetic potentials are real-valued and that $\frac{t_1}{b_1^2}$ and $\frac{t_2}{b_2^2}$ have a real constant proportionality, it follows that $\Pi_1(p_2,\frac{b_1}{b_2})=0$. Thus there exists a constant ρ such that $\frac{b_1}{b_2}=\tau\rho^{-\frac{n}{2}}$ and, hence, $\frac{t_1}{t_2}=\tau^2\rho^{n-1}$. To finish the unique determination, we need to analyze (7.5) in order to show that $\frac{d_1}{b_1}=\rho\frac{d_2}{b_2}$. There are two possibilities for the terms of the form $\frac{\partial_{x_n}p}{p}$: either (1) $\partial_{x_n}\hat{g}^{jk}=\tau\hat{g}^{jk}$ for all j,k and some $\tau>0$, or (2) this is not the case. In case (2), the term has homogeneity type $\frac{\xi_a}{p}$ which is distinguishable from homogeneity type 1. Note that if case (2) holds for $\hat{g}_1$, then it also holds for $\hat{g}_2$ since the symbols are equal. In this case, $\partial_{x_{n_1}}\hat{g}_1^{jk}$ and $\partial_{x_{n_2}}\hat{g}_2^{jk}$ are uniquely determined (and proportional to one another). Therefore so are the terms involving the determinants. Consequently, the above relation between $\frac{d_1}{b_1}$ and $\frac{d_2}{b_2}$ must hold. On the other hand, if case (1) holds for both g_1 and g_2, then a calculation shows that

$$\frac{D_{n_1}(\sqrt{\hat{g}_1})}{\sqrt{\hat{g}_1}}-\frac{\partial_{x_{n_1}}p_1}{p_1}=\frac{n\tau}{i}-\tau$$

and the same relation (times the proper proportionality constant) holds for g_2 so that again we get the desired relation between $\frac{d_1}{b_1}$ and $\frac{d_2}{b_2}$.

The case when $b(x)=0$ follows by analyzing the symbol in the same fashion.

Now assume k^2 is not a Dirichlet eigenvalue on Ω for either L_1 or L_2. By (5.4), we know (for $j=1,2$)

$$\Lambda_j\Big(a_j(x)G_j^e(x,y)+b_j(x)\gamma_+^{1,e}G_j^e(x,y)\Big)=c_j(x)G_j^e(x,y)+d_j(x)\gamma_+^{1,e}G_j^e(x,y)$$

for $y\in\mathbb{R}^n\backslash\Omega$. By Lemma 5.5, the behavior of the Dirichlet-to-Neumann operator on the above functions determines the operator. The above relations on the elements of the transfer matrix therefore imply $\Lambda_1=\rho\Lambda_2$. □

By Lemma 7.2, we can apply Theorem 5.3 to locate the obstacle. Therefore, Lemma 7.2 and Theorem 7.5 prove Theorems 2.2 and 2.3.

Acknowledgments. The author thanks Gregory Eskin for initially suggesting work on transmission problems, as well as for his constant guidance and support. He is also deeply indebted to Michael Hitrik and James Ralston for numerous discussions during the preparation of this paper.

EXPLICIT SOLUTIONS FOR A CLASS OF NONLINEAR PDEs THAT ARISE IN ALLOCATION PROBLEMS*

PAUL DUPUIS† AND JIM X. ZHANG‡

Abstract. To exploit large deviation approximations for allocation and occupancy problems one must solve a deterministic optimal control problem (or equivalently, a calculus of variations problem). As this paper demonstrates, and in sharp contrast to the great majority of large deviation problems for processes with state dependence, for allocation problems one can construct more or less explicit solutions. Two classes of allocation problems are studied. The first class considers objects of a single type with a parameterized family of placement probabilities. The second class considers only equally likely placement probabilities but allows for more than one type of object. In both cases, we identify the Hamilton–Jacobi–Bellman equation, whose solution characterizes the minimal cost, explicitly construct solutions, and identify the minimizing trajectories. The explicit construction is possible because of the very tractable properties of the relative entropy function with respect to optimization.

Key words. explicit solutions, allocation, occupancy problems, nonlinear PDE, large deviations, calculus of variations

1. Introduction.

Allocation and occupancy problems are concerned with the random placement of objects into containers. The objects (usually referred to as balls or tokens) can be of a single type or many, in which case they are often distinguished by "color." The containers are variously called urns or cells and have many interpretations such as physical partitions (photo-electric receptors in a grid) and temporal partitions (the days of the year).

There are also many rules for how a given ball may be assigned to a given cell. The simplest such rule, in the context of a single color, uses what are called Maxwell–Boltzmann (MB) statistics. Here, each cell is equally likely to receive each ball. Other rules consider the balls as being placed sequentially, and the likelihood that a given ball is placed in a given cell depends on the current contents of that cell (relative to the contents of all other cells). Examples in this category are Bose–Einstein (BE) statistics, for which a cell that already contains balls is more likely to receive the next ball, and Fermi–Dirac (FD) statistics, where the reverse holds. The precise definitions of BE and FD will be given below.

A key random variable associated with an allocation is the *empirical measure*. After all (or some) of the balls have been placed, one can form the (random) probability measure $(\eta_0, \eta_1, \ldots)$ on $\{0, 1, \ldots\}$, with η_0 equal to the fraction of cells that are empty, η_1 the fraction that contain 1, etc. For example, one could be particularly concerned that at least 90% of the cells are nonempty after the random allocation. In

this case one is interested in the distribution of the first component of the empirical measure, and in particular $P\{\eta_0 \le 0.1\}$.

While methods from combinatorial probability provide exact formulas for certain classes of allocation problems, they do not apply universally, nor are they always of great practical utility; see the discussion in [2] on this point. Hence one turns to approximations. The simplest approximation is a law of large numbers (LLN) limit, under which the number of cells and number of balls placed into the cells both tend to ∞ with some fixed ratio. If η is indexed by the number of cells n, then the LLN limit identifies the (deterministic) probability distribution that η^n tends to as $n \to \infty$. This identifies the "typical" behavior of the allocation scheme for large n. The limit can often be identified as the solution to a system of ordinary differential equations (ODEs) at time t (and for an appropriate initial condition), where t is limiting ratio of the number of balls to the number of cells, i.e., the mean number of balls per cell.

If in contrast one is concerned with probabilities of atypical behavior, then one considers large deviation asymptotics. For example, if it is usual that 50% of the cells are empty when n is large, then under some technical assumptions large deviation asymptotics assert that $-\frac{1}{n}\log P\{\eta_0 \le 0.1\}$ tends to some constant $c > 0$, thus identifying the exponential rate of decay of the probability. The parameter c is usually identified as the solution of a calculus of variations problem, and using the well-known relation between problems in calculus of variations and Hamilton–Jacobi equations, c can also be characterized as the value (at a particular point) of the solution to a nonlinear partial differential equation (PDE).

The explicit identification of c is in general a daunting task. Whilst there are a small number of cases for which analytic expressions are available, in most cases one must attempt numerical approximation, and so one is limited to only low dimensional problems (i.e., in our setting to the first few components of the empirical distribution). Even putting aside the restriction of numerical methods to low dimensions, one would prefer analytic expressions for c since they have many other uses. Beyond simply identifying the rate of decay, analytic expressions for c can be used

- to characterize the most likely way that a rare event will occur,
- to construct efficient Monte Carlo schemes (known as importance sampling schemes) for nonasymptotic approximations, and
- in statistical estimation and model inference for occupancy models.

The purpose of the present paper is to show that explicit solutions can be obtained for the PDEs that are associated with a wide variety of allocation problems and to introduce techniques that can be applied to even broader classes of problems. As remarked previously, explicit solutions are not common. Among the classes of nonlinear, first order PDEs with explicit solutions (in general dimension) are those associated with the linear quadratic regulator and those linked to the Hopf–Lax formula. Both these examples exploit some significant underlying simplification. In the first example it is the fact that the value function for the control problem is expected to be quadratic in the spatial variable, and in the second example it is the independence of the running cost from the state variable. The optimization problems related to allocation problems are qualitatively quite different from either of these, as can be seen from both the form of the value functions and the structure of the minimizing trajectories. There is significant state dependence and no a priori obvious form for the value function. In the setting of allocation problems, it seems that the attractive properties of the *relative entropy* function are largely responsible for the existence of explicit solutions. It is these properties which allow for convenient calculation and representation of the various derivatives in terms of Lagrange multipliers, the key ingredient in the proof.

In the next section we analyze the single color model. After introducing the general model and formally reviewing the large deviation context, we discuss a formal and heuristic derivation of the explicit solution. The associated Hamilton–Jacobi–Bellman (HJB) equation is then introduced, and a solution is proposed in the form of a finite dimensional minimization problem that can be easily and efficiently solved using Lagrange multiplier techniques. The value of the minimization problem is shown to be smooth for an appropriate class of terminal costs, its derivatives are characterized via multipliers, and the HJB equation is shown to hold. The section concludes with the identification of the minimizing trajectories. The third and final section repeats these steps for a model with different colors.

2. Allocation models with differing assignment probabilities.

2.1. Probabilistic background and the variational problem. In this section, we formulate a general single color occupancy problem. After describing the model, we outline the relevant large deviation properties on path space and the related variational problems.

In the occupancy problem considered here cells are distinguished according to the number of balls contained therein. The full collection of models will be indexed by a parameter a. This parameter takes values in the set $(0, \infty] \cup \{-1, -2, \ldots, \}$, and its interpretation is as follows. Suppose that a ball is about to be thrown, and that any two cells (labeled, say, A and B) are selected. A cell is said to be of *category* i if it contains i balls. Suppose that cell A is of category i, while B is of category j. Then the probability that the ball is thrown into cell A, conditioned on the state of all the cells, and that the ball is thrown into either cell A or B, is

$$\frac{a+i}{(a+i)+(a+j)}.$$

When $a = \infty$ we interpret this to mean that the two cells are equally likely. Also, when $a < 0$ we use this ratio to define the probabilities only when $0 \leq i \vee j \leq -a$ and $i < -a$ or $j < -a$, so the formula gives a well-defined probability. The probability that a ball is placed in a cell of category $-a$ is 0. Thus under this model, cells can only be of category $0, 1, \ldots, -a$, and we only throw balls into categories $0, 1, \ldots, -a-1$.

When $a \in (0, \infty)$, cells that already contain balls are more likely to receive the next ball. When $a < 0$ the opposite is true. The cases $a = 1$, $a = \infty$, $a \in -\mathbb{N}$ correspond to what were called Bose–Einstein statistics, Maxwell–Boltzmann statistics, and Fermi–Dirac statistics, respectively, in the introduction.

Suppose that before we throw a ball there are already tn balls in all the cells, and that the occupancy state is $(x_0, x_1, \ldots, x_{I+})$. Here $x_i, i = 0, 1, \ldots, I$, denotes the fraction of cells that contain i balls, and x_{I+} denotes the fraction containing more than I balls. Throughout this paper we use this convention so that the state space of the occupancy process is finite dimensional. (Explicit formulas analogous to the ones derived here also hold in the infinite dimensional case, though one must be more careful in defining the PDE.) When the occupancy state is $(x_0, x_1, \ldots, x_{I+})$, the "un-normalized" or "relative" probability of throwing into a category i cell with $i \leq I$ is simply $(a+i)x_i$. Let us temporarily abuse notation, and let $x_{I+1}, x_{I+2}, \ldots$ denote the exact fraction in each category i with $i > I$. Since there are tn balls in the cells before we throw, $\sum_{i=0}^{\infty} i x_i = t$. Thus the (normalized and true) probability that the ball is placed in a cell that contains exactly i balls, $i = 0, 1, \ldots, I$, is $\frac{a+i}{a+t} x_i$, and the probability that the ball is placed in a cell that has more than I balls is $1 - \sum_{j=0}^{I} \frac{a+j}{a+t} x_j$.

In order to define both the LLN and large deviation approximations, it is convenient to introduce an occupancy *process*. We introduce a time variable t that ranges from 0 to T. At a time t that is of the form l/n, with $0 \leq l \leq \lfloor nT \rfloor$ an integer, l balls have been thrown. Let $X^n(t) = \left\{ X_0^n(t), X_1^n(t), \ldots, X_I^n(t), X_{I+}^n(t) \right\}$ be the *occupancy state* at that time. As noted previously, $X_i^n(t)$ denotes the fraction of cells that contain i balls at time t, $i = 0, 1, \ldots, I$, and $X_{I+}^n(t)$ the fraction of cells that contain more than I balls. The definition of X^n is extended to all $t \in [0, T]$ not of the form l/n by piecewise linear interpolation. Note that $X^n(t)$ is indeed a probability vector in $\mathbb{R}^{I+2}$. If

$$\mathcal{S}_I \doteq \left\{ x \in \mathbb{R}^{I+2} : x_i \geq 0,\ 0 \leq i \leq I+1, \quad \text{and} \quad \sum_{i=0}^{I+1} x_i = 1 \right\},$$

then for any $t \in [0, T], X^n(t) \in \mathcal{S}_I$. Thus X^n takes values in $\mathcal{U} \doteq C([0, T], \mathcal{S}_I)$. We equip $\mathcal{U}$ with the usual supremum norm and on $\mathcal{S}_I$ we take the usual L_1 norm. The generator of X^n sampled at times of the form $t = l/n$ is

$$\begin{aligned}
\mathcal{L}^n f(x, t) &= nE\left[f(X^n(t + 1/n)) - f(X^n(t)) | X^n(t) = x \right] \\
&= n \sum_{k=0}^{I} \left(\frac{a+k}{a+t} \right) x_k \left[f(x + (e_{k+1} - e_k)/n) - f(x) \right],
\end{aligned}$$

where e_k are the standard basis unit vectors.

It is often the case that one is interested in the large deviation properties at the terminal time T (i.e., those of $X^n(T)$) and for a general initial condition of the form $X^n(t) = (x_0, \ldots, x_{I+})$. Here there is often a detour—one first identifies the large deviation properties of the *process*, and then solves for the large deviation properties of $X^n(T)$ via the so-called contraction principle. This theorem represents the sought after exponential rate of decay as the solution to a calculus of variations problem, and therein lies the link to a PDE.

For our purposes an informal description of the process level large deviation properties will suffice. We first define the *rate function* on path space. Given (x, t) and a continuous trajectory φ with $\varphi(t) = x$, the rate $\mathcal{I}(\varphi; x, t)$ identifies the decay rate for the probability that X^n is in a small neighborhood of φ:

$$\begin{aligned}
&\lim_{\delta \downarrow 0} \limsup_{n \to \infty} -\frac{1}{n} \log P \left\{ \sup_{t \leq s \leq T} |X^n(s) - \varphi(s)| < \delta \,\middle|\, X^n(t) = x^n \right\} \\
&= \lim_{\delta \downarrow 0} \liminf_{n \to \infty} -\frac{1}{n} \log P \left\{ \sup_{t \leq s \leq T} |X^n(s) - \varphi(s)| < \delta \,\middle|\, X^n(t) = x^n \right\} \\
&= \mathcal{I}(\varphi; x, t).
\end{aligned}$$

Here x^n is any sequence of initial conditions that can occur with positive probability and which satisfy $x^n \to x$ as $n \to \infty$. The proof of such a result and the identification of the rate function are given in [7]. $\mathcal{I}(\varphi; x, t)$ can be represented as the integral, over $[t, T]$, of a nonnegative "cost" which measures the likelihood that the increments of X^n follow the increments of φ, with higher cost corresponding to lower likelihood (the LLN trajectory has zero cost). The integral form of $\mathcal{I}(\varphi; x, t)$ is a consequence of the Markov property.

The specific form of $\mathcal{I}(\varphi; x, t)$ is as follows. Define the linear map $M : \mathcal{S}_I \mapsto \mathbb{R}^{I+2}$

$$M_i[\theta] = \begin{cases} -\theta_0, & i = 0, \\ \theta_{i-1} - \theta_i, & 1 \le i \le I, \\ \theta_I, & i = I+1. \end{cases}$$

Let $\varphi \in \mathcal{U}$ be given with $\varphi(t) = x$. Suppose there is a Borel measurable function $\theta : [t, T] \longmapsto \mathcal{S}_I$ such that for any $s \in [t, T]$,

$$\varphi(s) = \varphi(t) + \int_t^s M[\theta](u) du. \tag{2.1}$$

We interpret $\theta_i(s)$ as the rate at which balls are thrown into cells that contain i balls at time s. This rate will be viewed as a perturbation of the LLN limit rate at which balls would be thrown, and the cost for this perturbation will measure the likelihood that sure a perturbation occurs (with large cost corresponding to unlikely perturbations).

The mapping $M[\theta]$ accounts for the fact that when a ball is placed in a category i cell X_i^n decreases by $1/n$ and X_{i+1}^n increases by $1/n$. The rates $\theta(s)$ are unique in the sense that if another $\tilde{\theta} : [t, T] \longmapsto \mathcal{S}_I$ satisfies (2.1), then $\tilde{\theta} = \theta$ a.e. on $[t, T]$. We call φ a *valid* occupancy state process if there exists $\theta : [t, T] \longmapsto \mathcal{S}_I$ satisfying (2.1). In this case θ is called the occupancy rate process associated with φ. For $x \in \mathbb{R}^{I+2}$ and $t \in [0, -a1_{\{a<0\}} + \infty 1_{\{a>0\}})$, define the vector $\rho(t, x) \in \mathbb{R}^{I+2}$ by

$$\rho_k(t, x) = \frac{a+k}{a+t} x_k \qquad \text{for } k = 0, 1, \ldots, I, \tag{2.2}$$

and

$$\rho_{I+}(t, x) = 1 - \sum_{k=0}^{I} \frac{a+k}{a+t} x_k.$$

For each a, $\rho_k(t, x)$ gives the LLN limiting probability that at time t the next ball will be placed in a category k cell, given that the statistics of model a are used and that $X^n(t) = x$. A direct calculation shows that if

$$x \in \mathcal{S}_I \quad \text{and} \quad \sum_{k=0}^{I+1} k x_k \le t, \tag{2.3}$$

then $\rho(t, x)$ is indeed a probability vector in $\mathbb{R}^{I+2}$, i.e., $\rho(t, x) \in \mathcal{S}_I$. It is easy to observe that if φ is valid, then $\varphi(s)$ satisfies (2.3) for all $s \in [0, T]$. This shows that $\rho(s, \varphi(s)) \in \mathcal{S}_I$. For future use we define

$$\tau(x, t) \doteq \left(t - \sum_{k=0}^{I} k x_k \right) \Big/ x_{I+} \tag{2.4}$$

if $x_{I+} > 0$ and $\tau(x, t) \doteq I + 1$ if $x_{I+} = 0$. Thus $\tau(x, t)$ can be interpreted as the mean number of balls per cell among those of category $I+$. With this notation,

$$\rho_{I+}(x, t) = (a + \tau(x, t)) x_{I+1} / (a + t), \tag{2.5}$$

and so $\rho_{I+}(x, t)$ in some sense takes a form very similar to that of $\rho_k(x, t)$ for $k = 0, 1, \ldots, I$.

Let $\delta > 0$ be small. Observe that the occupancy state will not change very much over $[t, t+\delta]$ while $n\delta$ balls are placed into cells. Let θ denote the empirical measure on the categories where these balls are placed. Then the new occupancy state is the sum of the old state plus $\delta M[\theta]$. Since the change in state is determined by an empirical distribution for (at least approximately) independent and identically distributed (iid) random variables, Sanov's theorem [1, Theorem 2.2.1] suggests that the cost appearing in the integral representation for $\mathcal{I}(\varphi; x, t)$ should be defined in terms of the famous *relative entropy* function. For two probability measures α and β on a Polish space $\mathcal{A}$, the relative entropy of α with respect to β is defined by

$$R(\alpha||\beta) \doteq \int_{\mathcal{A}} \left(\log \frac{d\alpha}{d\beta}\right) d\alpha$$

whenever α is absolutely continuous with respect to β (and with the convention that $0 \log 0 = 0$). In all other cases we set $R(\alpha||\beta) = \infty$. When two probability vectors ρ and $\nu \in \mathcal{S}_I$ appear in the relative entropy function, we interpret them as probability measures on the simplex $\{0, 1, \ldots, I, I+1\}$, and thus

$$R(\rho||\nu) \doteq \sum_{i=0}^{I+1} \rho_i \log \frac{\rho_i}{\nu_i}.$$

Important properties of relative entropy are that it is nonnegative, jointly convex, and lower semicontinuous in (α, β), and $R(\alpha||\beta) = 0$ if and only if $\alpha = \beta$ [1, Lemma 1.4.3].

As observed, when $\varphi(s)$ is *valid,* $\rho(s, \varphi(s)) \in \mathcal{S}_I$, which makes $R(\theta(s)||\rho(s, \varphi(s)))$ well defined. If in addition $\varphi(t) = x$, define

$$\mathcal{I}(\varphi; x, t) = \int_t^T R(\theta(s)||\rho(s, \varphi(s)))ds. \tag{2.6}$$

If φ is not valid or $\varphi(t) \neq x$, then define $\mathcal{I}(\varphi; x, t) = \infty$.

This defines the rate function for the models introduced at the beginning of this section. Now suppose that one wishes to approximate probabilities involving $X^n(T)$. Since the probability that X^n (as a process) is close to a given trajectory φ decays exponentially, decay rates of quantities such as $P\{X^n(T) \in A | X^n(t) = x^n\}$ can (under appropriate regularity conditions on A) be found as follows. Among all trajectories φ with $\varphi(t) = x$ and $\varphi(T) \in A$, identify the one with the *smallest* decay rate c. Then c is also the exponential decay rate of $P\{X^n(T) \in A | X^n(t) = x^n\}$. Hence the variational problem to be solved is

$$V(x, t) = \inf_{\varphi:\varphi(t)=x \textit{ and } \varphi(T)\in A} \mathcal{I}(\varphi; x, t). \tag{2.7}$$

If one is interested in expected values other than probabilities, then variational problems of the more general form

$$V(x, t) = \inf_{\varphi:\varphi(t)=x} [\mathcal{I}(\varphi; x, t) + F(\varphi(T))] \tag{2.8}$$

arise, and one is often particularly interested in the initial condition that corresponds to starting with all cells empty: $t = 0, x_0 = 1$ and $x_k = 0, k > 0$. We will refer to this as the *empty* initial condition.

Not all initial conditions are *feasible* in the sense that they can be reached with finite cost from the empty initial condition. Feasibility in this context depends on the underlying parameter a.

DEFINITION 2.1 (feasible domain). *Define $\mathcal{D}_a$, the feasible domain for the occupancy model with parameter a, as follows:*

- *When $a > 0$,*

$$\mathcal{D}_a \doteq \left\{ (x,t) \in \mathcal{S}_I \times [0,T) : x_{I+1} > 0 \text{ and } t > \sum_{i=0}^{I+1} i x_i \right\}$$
$$\bigcup \left\{ (x,t) \in \mathcal{S}_I \times [0,T) : x_{I+1} = 0 \text{ and } t = \sum_{i=0}^{I} i x_i \right\};$$

- *and when $a < 0$ and $I = -a - 1$,*

$$\mathcal{D}_a \doteq \left\{ (x,t) \in \mathcal{S}_I \times [0,T) : t = \sum_{i=0}^{I+1} i x_i \right\}.$$

In the first case the second set in the union reflects the fact that when $x_{I+1} = 0$ the number of balls thrown is exactly $\sum_{i=0}^{I} i x_i$, and similarly for the second case. When $a \in -\mathbb{N}$ it is only possible to throw balls into the categories $0, 1, \dots, -a-1$, and the only possible categories are $0, 1, \dots, -a$. Thus if there are n cells, there can at most be $-an$ balls thrown, and therefore $T \le -a$. When $T = -a$ all the cells have exactly $-a$ balls, which is not an interesting case to study. As a consequence, throughout this paper we assume $T < -a$. Also, because of the restriction on the possible categories we can (without loss) assume that $I = -a - 1$. Hence for $a < 0$ we assume without loss that

$$T < -a, \quad I = -a - 1. \tag{2.9}$$

2.2. LLN limits and formal derivation of the explicit solution. When constructing explicit solutions one needs some insight into the form of the solution. In this section we present a formal derivation of an explicit solution to (2.8) for the case $F(x) = 1_y(x) \cdot \infty$. Before doing so we calculate the LLN limits of the occupancy processes, a necessary ingredient in the solution.

Equations for the LLN limits can easily be derived directly, or alternatively by noting that they are the zero cost trajectories in the variational problem (2.8) with $F \equiv 0$. It will suffice to consider initial conditions of the form $x = e_k, k = 0, 1, \dots, I$, where $(e_k)_j$ is 1 if $j = k$ and 0 otherwise. Since the relative entropy vanishes only if $\theta(s) = \rho(s, \varphi(s))$, the LLN limits can be characterized by the system of ODEs

$$\dot{\varphi}(s) = M[\rho(s, \varphi(s))], \quad \varphi(t) = e_k. \tag{2.10}$$

Since the LLN limit is desired for all components of the occupancy process, we use the infinite system rather than the system truncated at $I+$. These are easy to solve because the equation for the jth component depends only on the $(j-1)$st component, and so one can solve first for the kth component and then bootstrap. To write the solution in explicit form, we need some notation. For all $a \in \mathbb{R}$, $a \neq 0$, and $i \in \mathbb{N}$, let

$$\binom{a}{i} \doteq \frac{\prod_{j=0}^{i-1}(a-j)}{i!}.$$

Note that if $a \in \mathbb{N}$ and $i > a$, then $\binom{a}{i} = 0$, and that if $a \notin \mathbb{N} \cup \{0\}$ and $i \in \mathbb{N}$, then $\binom{a}{i} \neq 0$. For $i \in \mathbb{N} \cup \{0\}$ and $a > 0, s \geq 0$ or $a \in -\mathbb{N}, 0 \leq s \leq -a$, define

$$\mathcal{Q}_i^a(s) \doteq \left(-\frac{s}{a}\right)^i \binom{-a}{i} \left(1 + \frac{s}{a}\right)^{-a-i}.$$

One can easily check that the solution to (2.10) is $\varphi_i(s) = 0$ if $i < k$, and

$$\varphi_{k+i}(s) = \mathcal{Q}_i^{a+k}\left(\frac{a+k}{a+t}(s-t)\right)$$

if $i \geq 0$. In the limit $a \to \infty$ (MB statistics) one obtains the Poisson distribution

$$\mathcal{Q}_i^{a+k}\left(\frac{a+k}{a+t}(s-t)\right) \to \mathcal{P}_i(s-t) = e^{-(s-t)}(s-t)^i/i!.$$

For the remainder of this section we assume $a \neq \infty$, with the understanding that analogous statements for $a = \infty$ can be obtained by passing to the limit.

We next present a formal and heuristic solution to the variational problem (2.7) that is based on probabilistic intuition. We do not attempt to directly solve for the minimizing φ, but rather heuristically derive an alternate rate function for $X^n(T)$. This alternative rate function is based on a different construction of the process. However, since rate functions are unique it should coincide with (2.7) when $A = \{y\}$. Recall that the variational problem is intended to approximate the normalized logarithm of a probability. If one decomposes a probability into products or conditional products, this will correspond to a decomposition of the quantity being minimized as a sum.

We wish to solve (2.7) when $A = \{y\}$. Suppose that x_i is interpreted as the size of the "pool" of cells that at time t are in category i. Hence there are approximately nx_i cells in pool i. The cells in a given pool are fixed for the rest of the construction. Let π_i^k denote the probability that a cell of category k at time t ends up being a cell of category $k+i$ at time T. Then satisfaction of the terminal constraint requires

$$y_i = \sum_{k=0}^{i} x_k \pi_{i-k}^k, \quad 0 \leq i \leq I, \qquad y_{I+1} = 1 - \sum_{k=0}^{I} y_k.$$

We use $y \doteq x \times \pi$ as shorthand for the last display. We require that the π^k be probabilities, and also require a constraint that corresponds to the fact that $n(T-t)$ balls will be placed in the prelimit problem:

$$x_k \sum_{j=0}^{\infty} \pi_j^k = x_k, \quad 0 \leq k \leq I+1, \quad \sum_{k=0}^{I+1} x_k \sum_{j=0}^{\infty} j\pi_j^k = T-t. \tag{2.11}$$

Let $\mathcal{F}(x,t;y,T)$ denote the set of $\pi = (\pi^0, \pi^1, \ldots, \pi^I, \pi^{I+1})$ which satisfy the last two displays. A terminal point y is *feasible* (for the given initial time and condition) if $\mathcal{F}(x,t;y,T)$ is not empty.

Owing to the fact that the un-normalized relative probabilities are *affine* in the number of balls currently in each cell, we can consider the allocation from a different perspective. We first study the random evolution of the number of balls contained in each distinct pool of cells (recall that the partition of cells into pools is determined by their status at time t). Because the un-normalized probabilities are affine, this can be done without knowing the details of how the balls are to be placed *within* the pool. This process is also Markovian, and its large deviation properties are easy to identify.

Once we know the total number of balls that will end up in each pool, we then consider the question of how they are distributed among cells within the pool. Here we make an approximation that is formal but reasonable. If the number of cells within a pool is large, then the statistical dependence between any two cells should be low. If the dependence in some sense disappears in the limit $n \to \infty$, then one might guess that the rate function for the empirical distribution within the pool is given by Sanov's theorem, where the distribution of the random number of balls within each cell is just the LLN distribution appropriate to that particular pool. By Sanov's theorem the rate function for the empirical distribution within the pool is a certain relative entropy. However, we must also impose the constraint on the (previously determined) number of balls that were placed into this particular pool, which adds a constraint to the rate function. Finally, the overall rate function is found by combining these two rates (allocation between pools and allocation within each pool). The function found in this manner will be proved to be the solution to the calculus of variations problem.

An argument based on Sanov's theorem shows that the variational problem for the allocation between the pools is

$$\inf \int_t^T R\left(u(s)\,\|w(s)\right) ds,$$

where

$$w_k(s) = \frac{(a+k)x_k + \int_t^s u_k(\tau)d\tau}{a+s}$$

is the probability that a ball is placed into pool k at time s. This is, in un-normalized form, equal to ax_k+[number of balls per cell in pool k]x_k, and the normalization is just $a+s$. The initial and terminal conditions are

$$w_k(t) = \frac{(a+k)x_k}{a+t}, \quad w_k(T) = \frac{(a+k)x_k + z_k(T-t)}{a+T},$$

where z_k is the mean number of additional balls per unit time put into pool k. The Euler–Lagrange equations for this problem are easily constructed and solved, and one obtains as the optimal trajectory

$$w_k(s) = \frac{1}{s+a}\left((a+k)x_k + (s-t)z_k\right)$$

(of course satisfaction of the Euler–Lagrange equations is not, in general, a sufficient condition for optimality, but since our discussion is simply to motivate the form of the solution, this point is of no consequence). The cost is

$$\int_t^T R\left([(s+a)w(s)]'\,\|w(s)\right) ds,$$

and for the optimal trajectory,

$$[(s+a)w_k(s)]' = z_k.$$

The integral can be explicitly evaluated and equals

$$\sum_{k=0}^{I+} z_k \cdot (T-t) \cdot \log\left(\frac{a+t}{a+k} \cdot \frac{z_k}{x_k}\right)$$
$$-\sum_{k=0}^{I+} [x_k \cdot (a+k) + z_k \cdot (T-t)] \cdot \log\left(\frac{a+k+\frac{z_k}{x_k}(T-t)}{a+k+\frac{a+k}{a+t}(T-t)}\right).$$

This identifies the first part of the overall rate function.

The second part is found by considering placement within each pool. The mean additional number of balls per cell in pool k is $(z_k/x_k)(T-t)$. According to the LLN, the number of additional balls in a typical cell from pool k has distribution $\mathcal{Q}^{a+k}\big(\frac{z_k}{x_k}(T-t)\big)$ if $k \le I$ and $\mathcal{Q}^{a+\tau(x,t)}\big(\frac{z_{I+}}{x_{I+}}(T-t)\big)$ if $k = I+$. Approximating the true empirical measure within a given pool by that of the empirical measure for iid random variables with the corresponding distribution, one formally obtains from Sanov's theorem the rate function $R\big(\pi^k \| \mathcal{Q}^{a+k}\big(\frac{z_k}{x_k}(T-t)\big)\big)$, together with the constraint $\sum_{i=0}^{\infty} i\pi_i^k = \frac{z_k}{x_k}(T-t)$ on the number of balls placed in pool k. Combining the different contributions from the various pools with the contribution due to the allocation between the pools and then applying the terminal constraint, one (again formally) obtains the rate function

$$\inf\left\{\sum_{k=0}^{I} x_k R\left(\pi^k \,\middle\|\, \mathcal{Q}^{a+k}\left(\frac{z_k}{x_k}(T-t)\right)\right)\right.$$
$$+ x_{I+} R\left(\pi^{I+} \,\middle\|\, \mathcal{Q}^{a+\tau(x,t)}\left(\frac{z_{I+}}{x_{I+}}(T-t)\right)\right) + \sum_{k=0}^{I+} z_k \cdot (T-t) \cdot \log\left(\frac{a+t}{a+k} \cdot \frac{z_k}{x_k}\right)$$
$$\left.-\sum_{k=0}^{I+} [x_k \cdot (a+k) + z_k \cdot (T-t)] \cdot \log\left(\frac{a+k+\frac{z_k}{x_k}(T-t)}{a+k+\frac{a+k}{a+t}(T-t)}\right)\right\},$$

where the infimum is over all π and z such that $\sum_{i=0}^{\infty} i\pi_i^k = \frac{z_k}{x_k}(T-t)$ and $x \times \pi = y$. However, a straightforward calculation using the specific form of $\mathcal{Q}^a$ and $\sum_{i=0}^{\infty} i\pi_i^k = \frac{z_k}{x_k}(T-t)$ gives

$$R\left(\pi^k \,\middle\|\, \mathcal{Q}^{a+k}\left(\frac{a+k}{a+t}(T-t)\right)\right) - R\left(\pi^k \,\middle\|\, \mathcal{Q}^{a+k}\left(\frac{z_k}{x_k}(T-t)\right)\right)$$
$$= \frac{z_k}{x_k}(T-t) \cdot \log\left(\frac{a+t}{a+k} \cdot \frac{z_k}{x_k}\right) - (a+k) \cdot \log\left(\frac{a+k+\frac{z_k}{x_k}(T-t)}{a+k+\frac{a+k}{a+t}(T-t)}\right)$$
$$- \frac{z_k}{x_k}(T-t) \cdot \log\left(\frac{a+k+\frac{z_k}{x_k}(T-t)}{a+k+\frac{a+k}{a+t}(T-t)}\right),$$

with an analogous result for $k = I+$. If follows that the rate function can be written in the simpler form

$$\inf_{\pi: x \times \pi = y}\left\{\sum_{k=0}^{I} x_k R\left(\pi^k \,\middle\|\, \mathcal{Q}^{a+k}\left(\frac{a+k}{a+t}(T-t)\right)\right)\right.$$
$$\left.+ x_{I+} R\left(\pi^{I+} \,\middle\|\, \mathcal{Q}^{a+\tau(x,t)}\left(\frac{a+\tau(x,t)}{a+t}(T-t)\right)\right)\right\},$$

with the infimum over z no longer necessary.

Let

$$\mathcal{J}(x,t;y) \doteq \inf_{\substack{\varphi\in C([t,T],\mathcal{S}_I)\\ \varphi(t)=x,\varphi(T)=y}} \mathcal{I}(x,t;\varphi). \tag{2.12}$$

The formal derivation just given suggests the following result, in which we also simplify further where the special cases of FD and MB statistics allow.

THEOREM 2.2 (explicit formula for the rate function). *Consider an initial condition $(x,t)\in\mathcal{D}_a$ and a feasible terminal condition y. If $a\in(0,\infty)$, define $\tau(x,t)$ by* (2.4)*. Then the quantity $\mathcal{J}(x,t;y)$ defined in* (2.12) *has the representation*

$$\begin{aligned}\mathcal{J}(x,t;y) = \min_{\pi\in\mathcal{F}(x,t;y,T)} \Bigg\{ &\sum_{k=0}^{I} x_k R\left(\pi^k \middle\| \mathcal{Q}^{a+k}\left(\frac{a+k}{a+t}(T-t)\right)\right)\\ &+ x_{I+1} R\left(\pi^{I+1} \middle\| \mathcal{Q}^{a+\tau(x,t)}\left(\frac{a+\tau(x,t)}{a+t}(T-t)\right)\right)\Bigg\}.\end{aligned}$$

If $a\in-\mathbb{N}$ with $I=-a-1$, then $\tau(x,t)=I+1$ and

$$\mathcal{J}(x,t;y) = \min_{\pi\in\mathcal{F}(x,t;y,T)} \left\{\sum_{k=0}^{I+1} x_k R\left(\pi^k \middle\| \mathcal{Q}^{a+k}\left(\frac{a+k}{a+t}(T-t)\right)\right)\right\}.$$

In the final case of $a=\infty$, we have

$$\mathcal{J}(x,t;y) = \min_{\pi\in\mathcal{F}(x,t;y,T)} \left\{\sum_{k=0}^{I+1} x_k R\left(\pi^k \,\|\mathcal{P}(T-t)\right)\right\}.$$

Remark 2.3. Although the minimization problems in Theorem 2.2 appear to be infinite dimensional, they can in fact be reduced to finite dimensional problems. This is because if π^k is the minimizer, then π^k_j takes a prescribed form for $j>I$. In fact, all π^k_j can be represented in terms of no more than $I+3$ Lagrange multipliers as in (2.20) below.

2.2.1. The Hamilton–Jacobi–Bellman equation. Given Theorem 2.2 one can solve the problem with a general terminal condition F. Conversely, if the problem with terminal cost can be solved for a sufficiently broad class of F, one can derive Theorem 2.2. This is how we will prove the theorem, and moreover, the proof will be based on the fact that finite dimensional representations analogous to those in Theorem 2.2, but with these terminal costs, are *classical sense* solutions to the associated PDE. The proof also has a number of side benefits, such as convenient representations for the various derivatives of the solution in terms of Lagrange multipliers.

The calculus of variations problem (2.8) has a natural control interpretation, where $\theta(s)$, $t\le s\le T$, is the control, $\dot\varphi(s)=M[\theta](s)$ are the dynamics, $R(\theta(s)||\rho(s,\varphi(s)))$ is the running cost, and $F(x)$ is the terminal cost. It is expected that if we define

$$V(x,t) \doteq \inf_{\varphi\in C([t,T],\mathcal{S}_I),\varphi(t)=x} \left\{\int_t^T R(\theta(s)||\rho(s,\varphi(s)))\,ds + F(\varphi(T))\right\}, \tag{2.13}$$

then $V(x,t)$ is a weak sense solution to the HJB equation

$$W_t + H(W_x, x, t) = 0$$

and terminal condition

$$W(x,T) = F(x).$$

Here the Hamiltonian $H(p,x,t)$ is defined by

$$H(p,x,t) \doteq \inf_{\theta\in\mathcal{S}_I} \left[\langle p, M[\theta]\rangle + R\left(\theta \,\|\rho\left(t,x\right)\right)\right]$$

and W_t and W_x denote the partial derivative with respect to t and gradient in x, respectively. Note that by the representation formula [1, Proposition 1.4.2], the infimum in the definition of $H(p,x,t)$ can be evaluated, yielding

$$\text{(2.14)}\qquad \left\{ \begin{array}{c} W_t = \log\left(\sum_{k=0}^{I} x_k \left(\frac{a+k}{a+t}\right)\exp\left(W_{x_k} - W_{x_{k+1}}\right) + x_{I+1}\left(\frac{a+\tau(x,t)}{a+t}\right)\right), \\ W(x,T) = F(x). \end{array}\right.$$

Note the use of the convenient expression (2.5) for $\rho_{I+}(x,t)$.

For a general smooth F, (2.14) need not have a smooth (C^1) solution. However, for affine terminal costs $F(x) = \langle \ell, x\rangle + b$ there is a C^1 solution (it is in fact the unique solution), and as remarked above, these solutions can be used to carry out a fairly complete analysis of the problem with more general terminal conditions. Indeed, for a general (proper) convex terminal cost $F(x)$, the Legendre transform gives a representation of the form

$$F(x) = \sup_{\beta\in\mathbb{R}^{I+2}} \left[\langle \beta, x\rangle - h(\beta)\right]$$

for some proper convex function h. Let $V^F(x,t)$ denote the solution (explicit or otherwise) to the calculus of variations problem (2.13) with terminal cost $F(\cdot)$. Then one can show

$$V^F(x,t) = \sup_{\beta\in\mathbb{R}^{I+2}} V^{\{\langle\beta,\cdot\rangle - h(\beta)\}}(x,t),$$

and an analogous formula for $U^F(x,t) \doteq \inf[\mathcal{J}(x,t;y) + F(y)]$. Given Proposition 2.4 below, $V^F = U^F$ then follows. Since $\infty \cdot 1_{\{y\}^c}$ is a proper convex function, the formula can be extended even further to very general F.

Observe that W is a solution of just the PDE alone (i.e., without the terminal condition) if and only if $W + c$ is a solution for any real number c. Since x is a probability vector, we can write

$$F(x) = \langle \ell, x\rangle + b = \sum_{i=0}^{I} (\ell_i - \ell_{I+1}) x_i + \ell_{I+1} + b,$$

and so by the previous sentence it suffices to prove the representation under the conditions $\ell_{I+1} = 0$ and $b = 0$.

2.3. Explicit solution for affine terminal costs.

PROPOSITION 2.4. *Consider $(x,t) \in \mathcal{D}_a$ and $F(y) = \langle \ell, y \rangle$, where $\ell \in \mathbb{R}^{I+2}$ and $\ell_{I+1} = 0$. Define*

$$V(x,t) \doteq \inf_{\varphi \in C([t,T],\mathcal{S}_I),\varphi(t)=x} \left\{ \int_t^T R\left(\theta(s) || \rho\left(s, \varphi(s)\right)\right) ds + F(\varphi(T)) \right\},$$

and

$$(2.15)\quad U(x,t) \doteq \min_{\pi \in \mathcal{F}(x,t;T)} \left\{ \sum_{k=0}^{I} x_k R\left(\pi^k \middle\| \mathcal{Q}^{a+k}\left(\frac{a+k}{a+t}(T-t)\right)\right) \right. \\ \left. + x_{I+1} R\left(\pi^{I+1} \middle\| \mathcal{Q}^{a+\tau(x,t)}\left(\frac{a+\tau(x,t)}{a+t}(T-t)\right)\right) + F(x \times \pi) \right\},$$

where $\pi \in \mathcal{F}(x,t;T)$ means that π satisfies the constraints in (2.11)*. Then $V(x,t) = U(x,t)$.*

The proof of this result is given in the next subsection. We close this subsection with remarks on the LLN limit distributions.

We will use the fact that if $a \in \mathbb{R}$ and $|z| < 1$, then the binomial expansion

$$(1+z)^{-a} = \sum_{i=0}^{\infty} \binom{-a}{i} z^i, \qquad \binom{a}{i} \doteq \frac{\prod_{j=0}^{i-1}(a-j)}{i!}$$

is valid, and if $-a \in \mathbb{N}$, then the sum contains only a finite number of nonzero terms and is valid for all $z \in \mathbb{R}$. Recall that for $i \in \mathbb{N} \cup \{0\}$ and $a > 0, s \geq 0$ or $a \in -\mathbb{N}, 0 \leq s \leq -a$, then

$$\mathcal{Q}_i^a(s) \doteq \left(-\frac{s}{a}\right)^i \binom{-a}{i} \left(1 + \frac{s}{a}\right)^{-a-i}.$$

If $a > 0, s \geq 0$, and $|s\theta/(a+s)| < 1$, then the binomial expansion gives

$$\begin{aligned}\sum_{i=0}^{\infty} \mathcal{Q}_i^a(s)\theta^i &= \sum_{i=0}^{\infty} \left(-\frac{s}{a}\right)^i \binom{-a}{i} \left(1+\frac{s}{a}\right)^{-a-i} \theta^i \\ &= \left(1+\frac{s}{a}\right)^{-a} \sum_{i=0}^{\infty} \left(-\frac{s}{s+a}\theta\right)^i \binom{-a}{i} \\ &= \left(1+\frac{s}{a}\right)^{-a} \left(1 - \frac{s\theta}{s+a}\right)^{-a} \\ &= \left(1 + \frac{s}{a} - \frac{s\theta}{a}\right)^{-a} \\ &= \left(1 + \frac{s}{a}(1-\theta)\right)^{-a}.\end{aligned}$$

We thus have the following expressions, where the second one may be justified by a very similar calculation (when $|s\theta/(a+s)| < 1$):

$$(2.16)\quad \sum_{i=0}^{\infty} \mathcal{Q}_i^a(s)\theta^i = \left(1 + \frac{s}{a}(1-\theta)\right)^{-a}, \quad \sum_{i=0}^{\infty} i\mathcal{Q}_i^a(s)\theta^i = s\theta\left(1 + \frac{s}{a}\left(1-\theta\right)\right)^{-a-1}.$$

Note also that when $-a \in \mathbb{N}$ and $0 \le s \le -a$ the number of nonzero summands is finite and the formulas again hold. If $-a \in \mathbb{N}$ and $0 \le s \le -a$ or $a > 0$ and $s \ge 0$, then $\mathcal{Q}_i^a(s) \ge 0$ for $i \in \mathbb{N} \cup \{0\}$. Letting $\theta \uparrow 1$ in the first expression shows that under these conditions $\mathcal{Q}_i^a(s)$ defines a probability measure on $\mathbb{N} \cup \{0\}$. When $a = 0$ we use the limiting values

$$\mathcal{Q}_0^0(s) = 1,\ \mathcal{Q}_i^0(s) = 0$$

for all $i \in \mathbb{N}$ and $s \ge 0$. For later use note that similar calculations show that if $-a \in \mathbb{N}$ and $0 \le s \le -a$ or $a > 0$, $s \ge 0$, and $s/(a+s) < 1$, then

$$\sum_{i=0}^{\infty} i^2 \mathcal{Q}_i^a(s) - \left[\sum_{i=0}^{\infty} i \mathcal{Q}_i^a(s) \right]^2 = s + \frac{s^2}{a}. \tag{2.17}$$

2.3.1. Analysis of the finite dimensional minimization problem. We now focus on proving Proposition 2.4. We will do so by proving that $U(x,t)$ is a classical sense solution to the HJB equation (2.14). A modification of the standard verification argument [4] can then be used to show that $V(x,t) = U(x,t)$. The classical verification argument consists of two parts. One first considers any valid occupancy process and control (φ, θ) for the initial condition (x,t). If U is a smooth solution to the PDE (2.14) in neighborhood of $\{(\varphi(s), s) : t \le s \le T\}$ and if $U(\varphi(T), T) = \langle \varphi(T), \ell \rangle$, then the chain rule implies that the cost along this trajectory is at least $U(x,t)$. The reverse inequality is proved by defining an optimal feedback control through the HJB equation, using this control to construct a trajectory, and then verifying (once again via the chain rule) that the cost for this control is $U(x,t)$. The characterization of $V(x,t)$ as an infimum over all valid occupancy processes and controls that start at (x,t) then gives $V(x,t) = U(x,t)$. However, we have to clarify here what is meant by a "classical sense" solution to (2.14). The difficulty is that $U(x,t)$ is only well defined on the set $\mathcal{D}_a$, which does not have an interior.

Given any point $(x,t) \in \mathcal{D}_a$, we will prove that one can extend $U(x,t)$ smoothly to a neighborhood of (x,t) in $\mathbb{R}^{I+2} \times \mathbb{R}$. To be more precise, for any such (x,t) we will show there exists a neighborhood $\mathcal{U} \subset \mathbb{R}^{I+2} \times \mathbb{R}$ of (x,t) and a function $\bar{U} \in C^\infty(\mathcal{U}, \mathbb{R})$, such that $\bar{U}(y,s) = U(y,s)$ for $(y,s) \in \mathcal{U} \cap \mathcal{D}_a$, and that $\bar{U}$ satisfies (2.14) in $\mathcal{U} \cap \mathcal{D}_a$. One can then use $\bar{U}$ in place of U in the verification argument, since any feasible trajectory will never leave $\mathcal{D}_a$.

To analyze $U(x,t)$ we formulate an appropriate Lagrangian. Let

$$\begin{aligned} f(x,t;\pi) \doteq \sum_{k=0}^{I} x_k R\left(\pi^k \,\middle\|\, \mathcal{Q}^{a+k}\left(\frac{a+k}{a+t}(T-t) \right) \right) \\ + x_{I+1} R\left(\pi^{I+1} \,\middle\|\, \mathcal{Q}^{a+\tau(x,t)}\left(\frac{a+\tau(x,t)}{a+t}(T-t) \right) \right) + \langle \ell, x \times \pi \rangle \end{aligned} \tag{2.18}$$

and for a set of Lagrange multipliers $\Lambda \doteq (\lambda, \mu) = (\lambda_0, \lambda_1, \ldots, \lambda_I, \lambda_{I+1}, \mu)$, let

$$\begin{aligned} &L(x,t;\Lambda;\pi) \\ &\quad \doteq f(x,t;\pi) + \sum_{k=0}^{I+1} \lambda_k x_k \left(1 - \sum_{j=0}^{\infty} \pi_j^k \right) + \mu \left(T - t - \sum_{k=0}^{I+1} x_k \sum_{j=0}^{\infty} j \pi_j^k \right). \end{aligned} \tag{2.19}$$

It follows from the definition of $U(x,t)$ that $U(x,t) = \inf_\pi \sup_\Lambda L(x,t;\Lambda;\pi)$.

Note that by the joint convexity of relative entropy, $L(x,t;\Lambda;\pi)$ is convex in π. Thus (2.15) is a standard convex programming problem with linear constraints, except that the minimization is over a variable π which is infinite dimensional. Hence the standard Lagrange multiplier method does not apply directly. If we temporarily ignore this issue, then to guess the form of the minimizer one would of course set $D_\pi L(x,t;\Lambda;\pi)=0$ to get $\pi=\pi(x,t;\Lambda)$, where D_π stands for the gradient in π and

$$\begin{aligned}
&\pi_j^k\,(x,t;\Lambda) = \mathcal{Q}_j^{a+k}\left(\frac{a+k}{a+t}(T-t)\right)e^{\lambda_k-1+j\mu-\ell_{k+j}}\\
&\qquad k=0,1,\ldots,I \text{ and } j\geq 0,\\
&\pi_j^{I+1}\,(x,t;\Lambda) = \mathcal{Q}_j^{a+\tau(x,t)}\left(\frac{a+\tau(x,t)}{a+t}(T-t)\right)e^{\lambda_{I+1}-1+j\mu}.
\end{aligned} \tag{2.20}$$

Here, for notational simplicity, we extend ℓ in Proposition 2.4 by letting $\ell_i=0$ when $i>I$. Note in particular that $\{\pi^k\}$ will depend on x only when $k=I+1$. Observe also that setting $D_\Lambda L(x,t;\Lambda;\pi)=0$ gives the constraints (2.11). For any $(x,t)\in\mathbb{R}^{I+2}\times\mathbb{R}$ and $\Lambda\in\mathbb{R}^{I+3}$, let $\pi(x,t;\Lambda)$ be determined by (2.20) and define $G:\mathbb{R}^{I+2}\times\mathbb{R}\times\mathbb{R}^{I+3}\mapsto\mathbb{R}^{I+3}$ by

$$G_k(x,t;\Lambda) = \left(1-\sum_{j=0}^{\infty}\pi_j^k\,(x,t;\Lambda)\right),\qquad k=0,1,\ldots,I+1,$$

$$G_{I+2}(x,t;\Lambda) = \left(T-t-\sum_{k=0}^{I+1}x_k\sum_{j=0}^{\infty}j\pi_j^k\,(x,t;\Lambda)\right).$$

In the next theorem we show that the $\pi(x,t;\lambda)$ defined in (2.20) indeed give the minimizer of (2.15).

Theorem 2.5. *For any $(x,t)\in\mathcal{D}_a$ define $U(x,t)$ by* (2.15). *Then there exists $\Lambda\in\mathbb{R}^{I+3}$ so that $G(x,t;\Lambda)=0$, and $\pi(x,t;\Lambda)$ is a minimizer of* (2.15). *Thus $U(x,t)=L\big(x,t;\Lambda;\pi(x,t;\Lambda)\big)$. In addition, the Λ that satisfies $G(x,t;\Lambda)=0$ is unique. Hence if $G(x,t;\Lambda)=0$ for some $\Lambda\in\mathbb{R}^{I+3}$, then $\pi(x,t;\Lambda)$ is a minimizer of* (2.15).

The proof is divided into three lemmas. For a point $(x,t)\in\mathcal{D}_a$, quantities of the following sort will appear frequently in the proofs of the lemmas:

$$\begin{aligned}
\bar\pi_j^k &\doteq \mathcal{Q}_j^{a+k}\left(\frac{a+k}{a+t}(T-t)\right)\\
\bar\pi_j^{I+1} &\doteq \mathcal{Q}_j^{a+\tau(x,t)}\left(\frac{a+\tau(x,t)}{a+t}(T-t)\right)\\
&\text{for } k=0,1,\ldots,I;\quad j=0,1,\ldots.
\end{aligned} \tag{2.21}$$

In particular, it will often be the case that (2.16) must be invoked, with a there replaced by $a+k$ [or $a+\tau(x,t)$] and s there replaced by the corresponding argument in the expression above. We note that the conditions required for (2.16) will always hold so long as $t\in[0,T]$. This is straightforward to check in the case of $a>0$. For the case $-a\in\mathbb{N}$, it uses that $-a=I+1$, $T\leq -a$, and that always $\tau(x,t)=I+1$. Thus, for example, for any $k\in\{0,\ldots,-a\}$ and $t\in[0,T]$, $(a+k)(T-t)/(a+t)\geq 0$ and $(T-t)/(-a-t)\leq 1$ shows that $(a+k)(T-t)/(a+t)\leq -a-k$, as required for (2.16).

LEMMA 2.6 (general properties). *For any* $(x,t) \in \mathcal{D}_a$ *define* $U(x,t)$ *by* (2.15). *Then* $\mathcal{F}(x,t;T)$ *is nonempty, minimizing measures* π^* *exist, and if* k *is such that* $x_k > 0$ *and* $j \in \{0,1,\ldots\}$, *then*

$$\bar{\pi}_j^k > 0 \quad \textit{implies} \quad \pi_j^{*k} > 0. \tag{2.22}$$

Proof. According to (2.16) the quantities in (2.21) are probabilities that satisfy (2.11). This shows that $\mathcal{F}(x,t;T)$ is nonempty. Next note that with this notation, we can rewrite (2.18) as

$$f(x,t;\pi) = R\left(x \otimes \pi \,\|x \otimes \bar{\pi}\,\right) + \langle \ell, x \times \pi \rangle, \tag{2.23}$$

where $(x \otimes \pi)_{i,j} = x_i \pi_j^i$. Since the relative entropy has compact level sets in the first argument [1, Lemma 1.4.3(c)], the existence of a minimizer of (2.15) follows. In addition, because of the strict convexity in that argument we know that the minimizer is unique up to those $\left\{\pi_\cdot^k\right\}$ with $x_k > 0$.

For a general initial condition (x,t) let $\mathcal{K} \doteq \{k : x_k > 0\}$. Then the choice of $\left\{\pi_\cdot^k : k \notin \mathcal{K}\right\}$ will not affect either the constraint (2.11) or the objective function (2.23). Hence we can consider the equivalent minimization problem over $\mathcal{M}_{(x,t)} = \left\{\pi_j^k : k \in \mathcal{K}, j = 0,1,\ldots\right\}$. As discussed in the previous paragraph, a minimizer in $\mathcal{M}_{(x,t)}$ exists and is unique. Let this minimizer be denoted π^*.

Lastly we must show (2.22). Let $\pi^\epsilon \doteq (1-\epsilon)\pi^* + \epsilon\bar{\pi}$, where $\bar{\pi}$ is defined in (2.21), and let $f(\epsilon) = f(x,t;\pi^\epsilon)$. By computing the derivative of $f(\epsilon)$ explicitly, it is readily observed that if (2.22) does not hold, then $f'(\epsilon) \to -\infty$ as $\epsilon \to 0$. Thus (2.22) must be true since otherwise π^* is not the minimizer. $\square$

LEMMA 2.7 (characterization of the minimizer). *For any* $(x,t) \in \mathcal{D}_a$ *define* $U(x,t)$ *by* (2.15). *Then there exists* $\Lambda \in \mathbb{R}^{I+3}$ *so that* $G(x,t;\Lambda) = 0$, *and* $\pi(x,t;\Lambda)$ *is a minimizer of* (2.15).

Proof. We want to argue that the minimizers must take the form of (2.20). However, there is a difficulty since $\mathcal{M}_{(x,t)}$ can be infinite dimensional. To deal with this we use a truncation argument adapted from one in [2]. For any $N \in \mathbb{N}$ let

$$T^{(N)} \doteq \sum_{k\in\mathcal{K}} x_k \sum_{j=0}^{N} j\pi_j^{*k}, \quad \alpha_k^{(N)} \doteq \sum_{j=0}^{N} \pi_j^{*k}, \quad k \in \mathcal{K},$$

and also let

$$f^{(N)}(x,t;\pi) \doteq f(x,t;\hat{\pi}),$$

where

$$\begin{aligned} \hat{\pi}_j^k &= \pi_j^k \quad &&\text{for } k \in \mathcal{K}, j \le N,\\ \hat{\pi}_j^k &= \pi_j^{*k} \quad &&\text{for } k \in \mathcal{K}, j > N. \end{aligned}$$

Since π^* is the minimizer of (2.15), we automatically obtain

$$U(x,t) = \min_{\pi} f^{(N)}(x,t;\pi), \tag{2.24}$$

where the minimum is subject to the constraints

$$\sum_{k\in\mathcal{K}} x_k \sum_{j=0}^{N} j\pi_j^{k} = T^{(N)}, \quad \sum_{j=0}^{N} \pi_j^{k} = \alpha_k^{(N)}, \quad k \in \mathcal{K}.$$

We can now apply the standard Lagrange multiplier method to (2.24). The first step is to formulate the Lagrangian for this finite dimensional problem:

$$L^N(x,t;\Lambda;\pi)$$
$$\doteq f^N(x,t;\pi) + \sum_{k\in\mathcal{K}} \lambda_k^{(N)} x_k \left(\alpha_k^{(N)} - \sum_{j=0}^{N} \pi_j^k\right) + \mu^{(N)}\left(T^{(N)} - \sum_{k=0}^{I+1} x_k \sum_{j=0}^{N} j\pi_j^k\right).$$

We have that $\left\{\pi_j^{*k} : k \in \mathcal{K}, j \le N\right\}$ satisfies the constraints in (2.24), and by (2.22) we know that $\pi_j^{*k} > 0$ if $\bar\pi_j^k > 0$. Hence by [6, Corollary 28.2.2] and [6, Theorem 28.3] applied to (2.24), there must exist a set of Lagrange multipliers $\lambda_k^{(N)}, \mu^{(N)}$ so that the minimizer of (2.24) π_j^{*k} has the form

$$\pi_j^{*k} = \bar\pi_j^k e^{\lambda_k^{(N)} - 1 + j\mu^{(N)} - \ell_{k+j}} \tag{2.25}$$

for $k \in \mathcal{K}$ and $0 \le j \le N$. If $k + j > I$, then since $\ell_{k+j} = 0$,

$$\frac{\pi_{j+1}^{*k}}{\pi_j^{*k}} = C \cdot e^{\mu^{(N)}},$$

where C does not depend on N. Thus $\mu^{(N)}$ is independent of N, and hence $\lambda^{(N)}$ is also independent of N. Since the choice of N is arbitrary, we then know that for all $k \in \mathcal{K}$ and $j = 0, 1, \dots, \pi_j^{*k}$ indeed has the form in (2.20) for a suitable choice of λ_k and μ. For $k \notin \mathcal{K}$, we can simply define π_j^{*k} as in (2.25) and then solve for λ_k from the normalization constraint $\sum_{j=0}^{\infty} \pi_j^{*k} = 1$. When defined in this way, $\Lambda^* = (\lambda_0, \dots, \lambda_{I+1}, \mu)$ automatically satisfies $G(x,t;\Lambda^*) = 0$.

For $k \in \mathcal{K}$ the corresponding λ_k are a Kuhn–Tucker vector as in [6, Corollary 28.2.2], and hence each $\lambda_k < \infty$. However, for $k \notin \mathcal{K}$ the finiteness of λ_k is not automatic.

To show the finiteness, we first insert the explicit form of $\pi_j^{I+1}(x,t;\Lambda)$ from (2.20) into $G_{I+1}(x,t,\Lambda) = 0$ to obtain

$$\sum_{j=0}^{\infty} \mathcal{Q}_j^{a+\tau(x,t)}\left(\frac{a+\tau(x,t)}{a+t}(T-t)\right) e^{\lambda_{I+1} - 1 + j\mu} = 1.$$

Using (2.16) to evaluate the sum gives

$$\lambda_{I+1} = (a+\tau(x,t)) \log\left(\frac{a+T-e^{\mu}(T-t)}{a+t}\right) + 1.$$

For notational simplicity define

$$\eta(t,\mu) \doteq \log\left(\frac{a+T-e^{\mu}(T-t)}{a+t}\right), \qquad \lambda(x,t;\mu) \doteq (a+\tau(x,t))\eta(t,\mu) + 1. \tag{2.26}$$

Then $\lambda_{I+1} = \lambda(x,t;\mu)$. Choose $C < \infty$ such that $|\ell_k| \le C$ for $0 \le k \le I$. Then

$$\sum_{j=0}^{\infty} \bar\pi_j^k e^{\lambda_k - 1 + j\mu - C} \le \sum_{j=0}^{\infty} \pi_j^k(x,t;\Lambda) \le \sum_{j=0}^{\infty} \bar\pi_j^k e^{\lambda_k - 1 + j\mu + C}.$$

A calculation of the same sort that gave the display above (2.26) gives

$$(a+k)\eta(t,\mu)+1-C \leq \lambda_k \leq (a+k)\eta(t,\mu)+1+C, \qquad k=0,\ldots,I.$$

Hence $\lambda_k < \infty$ so long as $\lambda_i < \infty$ for some $i = 0,1,\ldots,I,I+1$, which is true by [6, Corollary 28.2.2]. This completes the proof that for any $(x,t) \in \mathcal{D}_a$ there exists $\Lambda \in \mathbb{R}^{I+3}$ so that $G(x,t;\Lambda) = 0$ and $\pi(x,t;\Lambda)$ is a minimizer of (2.15). ◻

The next lemma will focus on the claim that for $(x,t) \in \mathcal{D}_a$, there is only one Λ that satisfies $G(x,t,\Lambda) = 0$, which together with the previous lemma completes the proof of Theorem 2.5.

LEMMA 2.8 (uniqueness of characterization). *For $(x,t) \in \mathcal{D}_a$, there is only one $\Lambda \in \mathbb{R}^{I+3}$ such that $G(x,t,\Lambda) = 0$.*

Proof. Recalling the definition of $\bar{\pi}$ in (2.21), notice that (2.20) is simply

$$\pi_j^k(x,t;\Lambda) = \bar{\pi}_j^k e^{\lambda_k - 1 + j\mu - \ell_{k+j}} \quad \text{for } k = 0,1,\ldots,I+1, \quad j = 0,1,\ldots.$$

As noted previously, for any $(x,t) \in \mathcal{D}_a$ we can assume that each $\{\bar{\pi}_\cdot^k\}$ is a valid probability vector. Thus $\pi_j^k(x,t;\Lambda) \geq 0$ and for each k at least one of $\{\pi_j^k(x,t;\Lambda), j = 0,1,\ldots\}$ is strictly positive. If

$$\alpha_k \doteq \sum_{j=0}^{\infty} \pi_j^k(x,t;\Lambda), \qquad T_k \doteq \sum_{j=0}^{\infty} j\pi_j^k(x,t;\Lambda),$$

then $\alpha_k > 0$ for each $k = 0,1,\ldots,I,I+1$, and any $\Lambda \in \mathbb{R}^{I+3}$. Using the particular dependency of $\pi_j^k(x,t;\Lambda)$ on Λ, one can compute

$$\begin{cases} \frac{\partial \pi_j^k(x,t;\Lambda)}{\partial \lambda_k} &= \pi_j^k(x,t;\Lambda), \\ \frac{\partial \pi_j^k(x,t;\Lambda)}{\partial \mu} &= j\pi_j^k(x,t;\Lambda), \\ \frac{\partial \pi_j^k(x,t;\Lambda)}{\partial \lambda_l} &= 0, \quad l \neq k. \end{cases}$$

It is straightforward to construct a dominating function of the form $\bar{\pi}_j^k \cdot C \cdot D^j$ for suitable constants C and D, and hence by the Lebesgue dominated convergence theorem one can compute $D_\Lambda G(x,t;\Lambda)$ explicitly as

$$\begin{pmatrix} -\alpha_0 & \cdots & 0 & -T_0 \\ \vdots & \cdots & \vdots & \vdots \\ 0 & \cdots & -\alpha_{I+1} & -T_{I+1} \\ -x_0 T_0 & \cdots & -x_{I+1}T_{I+1} & -\sum_{k=0}^{I+1} x_k \sum_{j=0}^{\infty} j^2 \pi_j^k(x,t;\Lambda) \end{pmatrix}.$$

Using elementary row operations to make the matrix upper triangular, we see that $\{-\alpha_k : k = 0,1,\ldots,I+1\}$ and $\sum_{k=0}^{I+1} \frac{x_k}{\alpha_k} T_k^2 - \sum_{k=0}^{I+1} x_k \sum_{j=0}^{\infty} j^2 \pi_j^k(x,t;\Lambda)$ are the eigenvalues of $D_\Lambda G(x,t;\Lambda)$. We have already observed that $\alpha_k > 0$ for all $k = 0,1,\ldots,I+1$. Also, for every $k = 0,1,\ldots,I+1$ the Cauchy–Schwarz inequality implies

$$\left(\sum_{j=0}^{\infty} j^2 \pi_j^k(x,t;\Lambda)\right)\left(\sum_{j=0}^{\infty} \pi_j^k(x,t;\Lambda)\right) \geq \left(\sum_{j=0}^{\infty} j\pi_j^k(x,t;\Lambda)\right)^2.$$

It is easy to verify that the necessary condition for equality [$\pi_j^k = j^2\pi_j^k$ for all j] does not hold. Hence the inequality is strict, and therefore

$$\left(\sum_{j=0}^{\infty} j^2 \pi_j^k(x,t;\Lambda)\right) > \frac{T_k^2}{\alpha_k}.$$

Thus $D_\Lambda G(x,t;\Lambda)$ is negative definite for all $\Lambda \in \mathbb{R}^{I+3}$.

Now we can prove the uniqueness of Λ. Suppose there are two different $\Lambda_1, \Lambda_2 \in \mathbb{R}^{I+3}$ such that $G(x,t;\Lambda_i) = 0,\ i = 1,2$. Define $\Lambda(\epsilon) \doteq \epsilon\Lambda_1 + (1-\epsilon)\Lambda_2$ and

$$h(\epsilon) \doteq \langle G(x,t;\Lambda(\epsilon)), \Lambda_1 - \Lambda_2\rangle.$$

Then $h'(\epsilon) = (\Lambda_1 - \Lambda_2)^T \cdot D_\Lambda G \cdot (\Lambda_1 - \Lambda_2)$. Since $D_\Lambda G(x,t;\Lambda)$ is always negative definite, $h'(\epsilon) < 0$ for all $0 < \epsilon < 1$. However, $h(0) = h(1) = 0$. This contradiction shows that $G(x,t;\Lambda) = 0$ has a unique solution in Λ. $\square$

The next theorem considers differentiability properties of $U(x,t)$. As mentioned previously, we first extend the definition of $U(x,t)$ to a neighborhood of (x,t) in $\mathbb{R}^{I+2} \times \mathbb{R}$, label this extension $\bar{U}(x,t)$, and then show $\bar{U}(x,t)$ is differentiable in the normal Euclidean sense. For our needs (a verification argument) the function $\bar{U}(x,t)$ can be used in lieu of $U(x,t)$.

THEOREM 2.9. *Fix $(x,t) \in \mathcal{D}_a$ and define $U(x,t)$ by* (2.15). *Then there is an open neighborhood $\mathcal{U}$ of (x,t) and an extension $\bar{U}$ of U from $\mathcal{D}_a \cap \mathcal{U}$ to $\mathcal{U}$ which is differentiable on $\mathcal{U}$.*

Proof. By Theorem 2.5, for any $(x,t) \in \mathcal{D}_a$ there exists Λ so that $G(x,t;\Lambda) = 0$ and $U(x,t) = L\big(x,t;\Lambda,\pi(x,t;\Lambda)\big)$. A natural approach to proving smoothness would be to apply the implicit function theorem. Recall that $\tau(x,t)$ is defined as the mean number of balls per cell in category $I+$ in (2.4). A difficulty with a direct application of the implicit function theorem is that this nonsmooth function appears in the constraints involving G_{I+1} and G_{I+2}. To avoid this difficulty we consider an equivalent but less obvious formulation of the constraint.

As discussed above (2.26), if the Lagrange multiplier λ_{I+1} is set to $\lambda(x,t;\mu)$, then the constraint $G_{I+1}(x,t;\Lambda) = 0$ will hold automatically. We will work with the reduced set of multipliers $\tilde{\Lambda} \doteq \{\lambda_0, \ldots, \lambda_I, \mu\}$ and the definition

$$\Lambda\left(x,t;\tilde{\Lambda}\right) \doteq \{\lambda_0, \lambda_1, \ldots, \lambda_I, \lambda(x,t;\mu), \mu\}. \tag{2.27}$$

Setting

$$H(x,t;\tilde{\Lambda}) \doteq L\left(x,t;\Lambda\left(x,t;\tilde{\Lambda}\right);\pi\left(x,t;\Lambda\left(x,t;\tilde{\Lambda}\right)\right)\right) \tag{2.28}$$

gives $U(x,t) = H(x,t;\tilde{\Lambda})$.

To apply the implicit function theorem we must show that there are smooth constraints that characterize $\tilde{\Lambda}$. For $i = 0,\ldots,I$ we use $\tilde{G}_i(x,t;\tilde{\Lambda}) = 0$, where $\tilde{G}_i(x,t;\tilde{\Lambda}) = G_i(x,t;\Lambda)$. These constraints are equivalent since π_j^k does not depend on λ_{I+1} for $k \le I$. Since $G_{I+1}(x,t;\Lambda) = 0$ holds automatically, we need only define $\tilde{G}_{I+1}$ so that $\tilde{G}_{I+1}(x,t;\tilde{\Lambda}) = 0$ is equivalent to $G_{I+2}(x,t;\Lambda) = 0$. We have

$$G_{I+2}(x,t;\Lambda) = T - t - \sum_{k=0}^{I} x_k \sum_{j=0}^{\infty} j\pi_j^k(x,t;\Lambda) - x_{I+1}\sum_{j=0}^{\infty} j\pi_j^{I+1}(x,t;\Lambda),$$

and thus set

$$\tilde{G}_{I+1}(x,t;\tilde{\Lambda}) \doteq G_{I+2}(x,t;\Lambda(x,t;\tilde{\Lambda})). \tag{2.29}$$

Since $\pi_j^k(\cdot)$ does not depend on λ_{I+1} when $k \le I$ we abuse notation and write the terms of the form $\pi_j^k(x,t;\Lambda(x,t;\tilde{\Lambda}))$ as $\pi_j^k(x,t;\tilde{\Lambda})$. Thus

$$\tilde{G}_{I+1}(x,t;\tilde{\Lambda}) = T - t - \sum_{k=0}^{I} x_k \sum_{j=0}^{\infty} j\pi_j^k(x,t;\tilde{\Lambda}) - x_{I+1}\sum_{j=0}^{\infty} j\pi_j^{I+1}(x,t;\Lambda(x,t;\tilde{\Lambda})).$$

Since for $(x,t) \in \mathcal{D}_a$ the value Λ such that $G(x,t;\Lambda) = 0$ exists and is unique, the value $\tilde{\Lambda}$ such that $\tilde{G}(x,t;\tilde{\Lambda}) = 0$ exists and is also unique.

We have that $D_{\tilde{\Lambda}}\tilde{G}(x,t;\tilde{\Lambda})$ equals

$$\begin{pmatrix} -\alpha_0 & \cdots & 0 & -T_0 \\ \vdots & \cdots & \vdots & \vdots \\ 0 & \cdots & -\alpha_I & -T_I \\ -x_0T_0 & \cdots & -x_IT_I & D_\mu \tilde{G}_{I+1}(x,t;\tilde{\Lambda}) \end{pmatrix},$$

where it is only the last entry that must be identified.

We pause to introduce a convention which will be used in the remainder of the paper. Whenever a differential operator of the form D_x precedes a composed function, the derivative is computed via the chain rule for precisely those arguments where a composed dependence on x is made explicit in the notation. Thus in computing $D_\mu \tilde{G}_{I+1}(x,t;\tilde{\Lambda})$ we use (2.29) and calculations in the last section to get

$$\begin{aligned} &D_\mu \tilde{G}_{I+1}(x,t;\tilde{\Lambda}) \\ &= D_\mu G_{I+2}(x,t;\lambda_0,\ldots,\lambda_I,\lambda(x,t;\mu),\mu) \\ &= D_\mu G_{I+2}(x,t;\lambda_0,\ldots,\lambda_I,\lambda_{I+1},\mu) + D_{\lambda_{I+1}} G_{I+2}(x,t;\lambda_0,\ldots,\lambda_I,\lambda_{I+1},\mu)\cdot D_\mu\lambda(x,t;\mu) \\ &= -\sum_{k=0}^{I+1} x_k \sum_{j=0}^{\infty} j^2 \pi_j^k(x,t;\Lambda(x,t;\tilde{\Lambda})) - x_{I+1}T_{I+1}\cdot D_\mu \lambda_{I+1}(x,t;\mu). \end{aligned}$$

It will be useful to express π^{I+1} in the $\mathcal{Q}^a(s)$ notation. We have

$$\pi_j^{I+1} = Q_j^{a+\tau(x,t)}\left(\frac{a+\tau(x,t)}{a+t}(T-t)\right)e^{\lambda_{I+1}-1}e^{j\mu}.$$

Recall that λ_{I+1} is chosen to make this a probability measure. By (2.16),

$$e^{\lambda_{I+1}-1} = \left(1 + \frac{T-t}{a+t}(1-e^\mu)\right)^{a+\tau(x,t)}.$$

Hence using a little algebra we can write

$$\begin{aligned} &\pi_j^{I+1} \\ &= \left(-\frac{T-t}{a+t}\right)^j \binom{-a-\tau(x,t)}{j} \left(1+\frac{T-t}{a+t}\right)^{-a-\tau(x,t)-j} e^{j\mu}\left(1+\frac{T-t}{a+t}(1-e^\mu)\right)^{a+\tau(x,t)} \\ &= \left(-\frac{e^\mu(T-t)}{a+T-e^\mu(T-t)}\right)^j \binom{-a-\tau(x,t)}{j} \left(\frac{a+T}{a+T-e^\mu(T-t)}\right)^{-a-\tau(x,t)-j} \\ &= Q_j^{a+\tau(x,t)}\left(\frac{e^\mu(T-t)(a+\tau(x,t))}{a+T-e^\mu(T-t)}\right). \end{aligned}$$

Again using (2.16),

$$T_{I+1} = \sum_{j=0}^{\infty} j\pi_j^{I+1}(x,t;\Lambda(x,t;\tilde{\Lambda})) = \frac{e^{\mu}(a+\tau(x,t))(T-t)}{a+T-e^{\mu}(T-t)}. \tag{2.30}$$

Recalling the definition

$$\lambda(x,t;\mu) = (a+\tau(x,t))\log\left(\frac{a+T-e^{\mu}(T-t)}{a+t}\right),$$

a direct calculation shows $D_\mu\lambda(x,t;\mu) = -T_{I+1}$, and hence

$$D_\mu\tilde{G}_{I+1}(x,t;\tilde{\Lambda}) = -\sum_{k=0}^{I+1} x_k \sum_{j=0}^{\infty} j^2\pi_j^k(x,t;\Lambda(x,t;\tilde{\Lambda})) + x_{I+1}T_{I+1}^2. \tag{2.31}$$

Since $\alpha_{I+1} = 1$, the eigenvalues of $D_{\tilde{\Lambda}}\tilde{G}(x,t;\tilde{\Lambda})$ are $-\alpha_0, -\alpha_1, \ldots, -\alpha_I$ and $\sum_{k=0}^{I+1}\frac{x_k}{\alpha_k}T_k^2 - \sum_{k=0}^{I+1} x_k \sum_{j=1}^{\infty} j^2\pi_j^k(x,t;\Lambda(x,t;\tilde{\Lambda}))$. By the same argument as was used for $D_\Lambda G(x,t;\Lambda)$ these are all negative, and hence $D_{\tilde{\Lambda}}\tilde{G}(x,t;\tilde{\Lambda})$ is invertible.

We next claim that $D_{\tilde{\Lambda}}\tilde{G}$ is smooth in (x,t). One can check that the only potentially difficult component is $D_\mu\tilde{G}_{I+1}(x,t;\tilde{\Lambda})$, and of this the only nontrivial part is

$$x_{I+1}\left(\sum_{j=0}^{\infty} j^2\pi_j^{I+1}(x,t;\Lambda(x,t;\tilde{\Lambda})) - T_{I+1}^2\right).$$

Using (2.17) and some algebra shows this term equals

$$-x_{I+1}(a+\tau(x,t))\cdot\frac{(t-T)e^{\mu}(a+T)}{[e^{\mu}(t-T)+a+T]^2}.$$

Although $\tau(x,t)$ is not smooth, $x_{I+1}(a+\tau(x,t))$ is always smooth, and thus $D_\mu\tilde{G}$ is smooth in (x,t). Note that the denominator does not vanish since $\eta(t,\mu) > -\infty$.

Therefore $\tilde{G}(\cdot;\cdot)$ is smooth in a neighborhood of $(x,t;\tilde{\Lambda})$. By the implicit function theorem, for any $(x,t)\in\mathcal{D}_a$ there exists a neighborhood $\mathcal{U}\subset\mathbb{R}^{I+1}\times\mathbb{R}$ of (x,t), a neighborhood $\mathcal{V}\subset\mathbb{R}^{I+2}$ of $\tilde{\Lambda}$, and a C^∞ function $g:\mathcal{U}\mapsto\mathcal{V}$, so that $\tilde{\Lambda} = g(x,t)$ and for every $(y,s)\in\mathcal{U}$, $\tilde{G}(y,s;g(y,s)) = 0$. Define

$$\bar{U}(y,s) = H(y,s;g(y,s)).$$

Since $g(y,s)$ is smooth in $\mathcal{U}$, $\bar{U}\in C^\infty(\mathcal{U},\mathbb{R})$, and by Theorem 2.5 $\bar{U}(y,s) = U(y,s)$ for $(y,s)\in\mathcal{U}\cap\mathcal{D}_a$. ∎

The next theorem expresses the derivatives in terms of the Lagrange multipliers.

THEOREM 2.10. *Fix $(x,t)\in D_a$, and let $\tilde{\Lambda}^*$ be the associated Lagrange multiplier. We have*

$$\begin{cases} D_{x_k}\bar{U}(x,t) - D_{x_{k+1}}\bar{U}(x,t) = \lambda_k^* - \lambda_{k+1}^* + \eta^*, \qquad k = 0,1,\ldots,I-1, \\ D_{x_I}\bar{U}(x,t) - D_{x_{I+1}}\bar{U}(x,t) = \lambda_I^* - 1 - (a+I)\eta^* \end{cases}$$

and $D_tU(x,t) = \eta^* - \mu^*$.

Proof. Consider any point $(x,t)\in\mathcal{D}_a$ and let $\tilde{\Lambda}^*$ be the associated Lagrange multiplier. By Theorem 2.9 there exists $\mathcal{U}\subset\mathbb{R}^{I+1}\times\mathbb{R}$ a neighborhood of (x,t),

$\mathcal{V} \subset \mathbb{R}^{I+2}$ a neighborhood of $\tilde{\Lambda}^*$, and a C^∞ function $\tilde{\Lambda} : \mathcal{U} \mapsto \mathcal{V}$ such that $\bar{U}(y,s) \doteq H(y,s;\tilde{\Lambda}(y,s))$ satisfies $\bar{U}(y,s) = U(y,s)$ for any $(y,s) \in \mathcal{U} \cap \mathcal{D}_a$.

Keeping in mind the convention regarding differential operators,

$$\begin{aligned} D_{x_k}\bar{U}(x,t) &= D_{x_k}H(x,t;\tilde{\Lambda}(x,t)) \\ &= D_{x_k}H(x,t;\tilde{\Lambda}^*) + D_{\tilde{\Lambda}}H(x,t;\tilde{\Lambda}^*)D_{x_k}\tilde{\Lambda}(x,t). \end{aligned}$$

Thus in the first line $H(x,t;\tilde{\Lambda}(x,t))$ is considered as the composed function of (x,t) (which by definition is $\bar{U}(x,t)$), and we take derivatives with respect to two arguments and evaluate at (x,t). In the second line, $D_{x_k}H(x,t;\tilde{\Lambda}^*)$ means $H(x,t;\tilde{\Lambda}^*)$ is now a function of the independent variables $(x,t,\tilde{\Lambda}^*)$ and we take derivatives with respect to x_k and then evaluate it at $(x,t;\tilde{\Lambda}^*)$. In all calculations, vectors are interpreted as row vectors.

With the notation established, we can proceed. Note that by definition (2.28),

$$\begin{aligned} &D_{\tilde{\Lambda}}H(x,t;\tilde{\Lambda}) \\ &= D_\Lambda L\left(x,t;\Lambda;\pi\right) D_{\tilde{\Lambda}}\Lambda\left(x,t;\tilde{\Lambda}\right) + D_\pi L\left(x,t;\Lambda;\pi\right) D_{\tilde{\Lambda}}\pi\left(x,t;\Lambda\left(x,t;\tilde{\Lambda}\right)\right). \end{aligned}$$

Since $\Lambda^* = \Lambda(x,t;\tilde{\Lambda}^*)$ and π^* are chosen so that $D_\pi L\left(x,t;\Lambda^*;\pi^*\right) = D_\Lambda L\left(x,t;\Lambda^*;\pi^*\right) = 0$, we have $D_{\tilde{\Lambda}}H(x,t;\tilde{\Lambda}^*) = 0$. This gives

$$D_{x_k}\bar{U}(x,t) = D_{x_k}H(x,t;\tilde{\Lambda}^*), \qquad k = 0,1,\ldots,I+1. \tag{2.32}$$

By the same argument, we have $D_t\bar{U}(x,t) = D_tH(x,t;\tilde{\Lambda}^*)$.

Next, we insert the explicit form of $\pi(x,t;\Lambda)$ from (2.20) into (2.19) to get

$$\begin{aligned} &L(x,t;\Lambda,\pi(x,t;\Lambda)) \\ &= \sum_{k=0}^{I+1} x_k \sum_{j=0}^{\infty} \left[\lambda_k - 1 + j\mu\right] \pi_j^k(x,t;\Lambda) + \sum_{k=0}^{I+1} \lambda_k x_k \left(1 - \sum_{j=0}^{\infty} \pi_j^k(x,t;\Lambda)\right) \\ &\quad + \mu\left(T - t - \sum_{k=0}^{I+1} x_k \sum_{j=0}^{\infty} j\pi_j^k(x,t;\Lambda)\right) \\ &= -\sum_{k=0}^{I} x_k \sum_{j=0}^{\infty} \pi_j^k(x,t;\Lambda) - x_{I+1}\sum_{j=0}^{\infty} \pi_j^{I+1}(x,t;\Lambda) + \sum_{k=0}^{I+1} \lambda_k x_k + \mu\left(T-t\right). \end{aligned}$$

In the definition of $H(x,t;\tilde{\Lambda})$, λ_{I+1} is replaced by $\lambda(x,t;\mu)$ so that automatically $\sum_{j=0}^{\infty} \pi_j^{I+1}(x,t;\Lambda) = 1$. Using $x_{I+1}\lambda(x,t;\mu) - x_{I+1} = x_{I+1}(a+\tau(x,t))\eta(t,\mu)$ from (2.26) and the definition of $\tau(x,t)$,

$$\begin{aligned} H(x,t;\tilde{\Lambda}) &= \sum_{k=0}^{I} x_k\lambda_k + \mu(T-t) - \sum_{k=0}^{I} x_k \sum_{j=0}^{\infty} \pi_j^k(x,t;\tilde{\Lambda}) \\ &\quad + x_{I+1}(a+\tau(x,t))\eta(t,\mu) \\ &= \sum_{k=0}^{I} x_k\lambda_k + \mu(T-t) - \sum_{k=0}^{I} x_k \sum_{j=0}^{\infty} \pi_j^k(x,t;\tilde{\Lambda}) \\ &\quad + a\left(1 - \sum_{k=0}^{I} x_k\right)\eta(t,\mu) + \left(t - \sum_{k=0}^{I} kx_k\right)\eta(t,\mu). \end{aligned}$$

Recall from the explicit expression (2.20) that for $k = 0, 1, \dots, I$, $\pi_j^k(x, t; \Lambda)$ does not depend on x or on λ_{I+1}. Hence the x dependence can be omitted in $\pi_j^k(x, t; \tilde{\Lambda})$ in the last display, and we do so from now on.

By (2.32),

$$\bar{U}_{x_k} = \lambda_k^* - 1 - (a + k)\eta^*, \qquad k = 0, 1, \dots, I,$$

and $\bar{U}_{x_{I+1}} = 0$, where $\eta^* = \eta(t, \mu^*)$. This implies the first claim of the theorem. Similarly

$$\begin{aligned}
&D_t\bar{U}(x,t)\\
&= D_t H(x, t; \tilde{\Lambda}^*)\\
&= \eta^* - \mu^* - D_t\left\{\sum_{k=0}^{I} x_k \sum_{j=0}^{\infty} \pi_j^k(t; \tilde{\Lambda}^*)\right\} + \left\{a\left(1 - \sum_{k=0}^{I} x_k\right) + \left(t - \sum_{k=0}^{I} k x_k\right)\right\} D_t\eta(t, \mu^*)\\
&= \eta^* - \mu^* - D_t\left\{\sum_{k=0}^{I} x_k \sum_{j=0}^{\infty} \pi_j^k(t; \tilde{\Lambda}^*)\right\} + x_{I+1}(a + \tau(x,t))D_t\eta(t, \mu^*).
\end{aligned}$$

We now will verify that

$$-D_t\left\{\sum_{k=0}^{I} x_k \sum_{j=0}^{\infty} \pi_j^k(t; \tilde{\Lambda}^*)\right\} + x_{I+1}(a + \tau(x,t))D_t\eta(t; \mu^*) = 0, \tag{2.33}$$

which implies $D_t U(x,t) = \eta^* - \mu^*$. By the explicit formula for $\pi_j^k(t; \tilde{\Lambda})$ in (2.20) and the definition of $\mathcal{Q}_j^a(s)$, for all $k = 0, 1, \dots, I; j = 0, 1, \dots$

$$D_t\pi_j^k(t; \tilde{\Lambda}) = j\pi_j^k(t; \tilde{\Lambda})\frac{a + T}{(t - T)(a + t)} + \frac{(a + k + j)}{a + t}\pi_j^k(t; \tilde{\Lambda}).$$

A suitable dominating function can be found, and thus by the Lebesgue dominated convergence theorem,

$$\begin{aligned}
&D_t\left\{\sum_{k=0}^{I} x_k \sum_{j=0}^{\infty} \pi_j^k(t; \tilde{\Lambda})\right\}\\
&= \sum_{k=0}^{I} x_k \sum_{j=0}^{\infty}\left[j\pi_j^k(t; \tilde{\Lambda})\frac{a + T}{(t - T)(a + t)} + \frac{(a + k + j)}{a + t}\pi_j^k(t; \tilde{\Lambda})\right].
\end{aligned}$$

Using that $\pi(x, t; \Lambda^*)$ satisfies the constraint (2.11) and some elementary algebra,

$$\begin{aligned}
&D_t\left\{\sum_{k=0}^{I} x_k \sum_{j=0}^{\infty} \pi_j^k(t; \tilde{\Lambda}^*)\right\}\\
&= -\frac{x_{I+1}\sum_{j=0}^{\infty} j\pi_j^{I+1}(x, t; \Lambda^*)}{t - T} - \frac{x_{I+1}(a + \tau(x,t))}{a + t}.
\end{aligned}$$

Equation (2.30) and the definition of η in (2.26) give

$$T_{I+1} = \frac{T - t}{a + t}(a + \tau(x,t))e^{\mu^* - \eta^*}, \tag{2.34}$$

and hence

$$D_t \left\{ \sum_{k=0}^{I} x_k \sum_{j=0}^{\infty} \pi_j^k(t;\tilde{\Lambda}^*) \right\} = -\frac{a+\tau(x,t)}{a+t} x_{I+1} \left(1 - e^{\mu^*-\eta^*}\right). \tag{2.35}$$

The definition of $\eta(t,\mu)$ in (2.26) and $(a+t)e^{\eta} = a+T-e^{\mu}(T-t)$ gives

$$D_t\eta(t,\mu) = \frac{e^{\mu}}{a+T-(T-t)e^{\mu}} - \frac{1}{a+t} = \frac{e^{\mu-\eta}-1}{a+t}.$$

Finally, combining this with (2.35) gives (2.33). ☐

Our final theorem shows that $\bar{U}$ satisfies the HJB equation (2.14) in the classical sense on $\mathcal{U}$. When combined with a standard verification argument as in [4], this will imply $V(x,t) = \bar{U}(x,t) = U(x,t)$ on $\mathcal{D}_a$.

THEOREM 2.11. *$\bar{U}$ satisfies* (2.14) *on $\mathcal{D}_a$.*

Proof. Having derived various expressions for the derivatives of $\bar{U}$ in terms of the Lagrange multipliers in Theorem 2.10, to show that $\bar{U}(x,t)$ satisfies the PDE (2.14) it remains to show

$$e^{-\mu^*+\eta^*} = \sum_{k=0}^{I-1} x_k \frac{a+k}{a+t} e^{\lambda_k^*-\lambda_{k+1}^*+\eta^*} + x_I \frac{a+I}{a+t} e^{\lambda_I^*-1-(a+I)\eta^*} + x_{I+1}\frac{a+\tau(x,t)}{a+t}. \tag{2.36}$$

Recall from (2.20) that for $k=0,1,\ldots,I$ and $j\geq 0$,

$$\pi_j^{*k} = \mathcal{Q}_j^{a+k}\left(\frac{a+k}{a+t}(T-t)\right) e^{\lambda_k^*-1+j\mu^*-\ell_{k+j}}.$$

Using the definition of $\mathcal{Q}_j^{a+k}$, for $k=0,1,\ldots,I-1$,

$$\pi_j^{*k+1} = \frac{(j+1)(a+t)}{(a+k)(T-t)} \pi_{j+1}^{*k} e^{\lambda_{k+1}^*-\lambda_k^*} e^{-\mu^*}.$$

Now sum both sides from $j=0$ to ∞ and use the fact that $\sum_{j=0}^{\infty}\pi_j^{*k}=1$ to get

$$e^{\lambda_k^*-\lambda_{k+1}^*} = e^{-\mu^*}\cdot \frac{(a+t)\sum_{j=1}^{\infty} j\pi_j^{*k}}{(T-t)(a+k)} \quad \text{for } k=0,1,\ldots,I-1. \tag{2.37}$$

Inserting (2.37) into (2.36), a little algebra shows that satisfaction of the PDE is equivalent to

$$\begin{aligned}(T-t) &= \sum_{k=0}^{I-1} x_k \sum_{j=0}^{\infty} j\pi_j^{*k} + x_I \frac{a+I}{a+t}(T-t)e^{\lambda_I^*-1-(a+I+1)\eta^*+\mu^*} \\ &\quad + x_{I+1}\frac{a+\tau(x,t)}{a+t}(T-t)e^{-\eta^*+\mu^*}.\end{aligned} \tag{2.38}$$

Since $\pi_j^{*I} = \mathcal{Q}_j^{a+I}\left(\frac{a+I}{a+t}(T-t)\right)e^{\lambda_I^*-1+j\mu^*}$ for $j\geq 1$, by (2.16),

$$\begin{aligned}\sum_{j=1}^{\infty} j\pi_j^{*I} &= \sum_{j=1}^{\infty} j\mathcal{Q}_j^{a+I}\left(\frac{a+I}{a+t}(T-t)\right)e^{\lambda_I^*-1+j\mu^*} \\ &= \frac{T-t}{a+t}(a+I)e^{\lambda_I^*-1-\eta^*(a+I+1)+\mu^*},\end{aligned} \tag{2.39}$$

where the last equality uses the definition of η in (2.26).

Inserting (2.34) and (2.39) into $\sum_{k=0}^{I+1} x_k \sum_{j=0}^{\infty} j\pi_j^k = T - t$, we then have

$$(T-t) = \sum_{k=0}^{I-1} x_k \sum_{j=0}^{\infty} j\pi_j^{*k} + x_I \frac{a+I}{a+t}(T-t)e^{\lambda_I^* - 1 - \eta^*(a+I+1)+\mu^*} + x_{I+1}\frac{a+\tau(x,t)}{a+t}(T-t)e^{-\eta^*+\mu^*}.$$

We have thus verified (2.38), which completes the proof that $\bar{U}$ satisfies (2.14). ∎

2.4. Minimizing trajectories. The minimizing trajectories associated with the calculus of variations problem have important qualitative and computational uses. Perhaps the most important is that they identify the most likely way a rare event will occur [5].

Identification of the minimizing trajectories in the MB case was done in [2] using the Euler–Lagrange equations, a system of nonlinear ODEs. The solutions to these equation are called extremals, and in general being an extremal is neither a necessary nor sufficient condition for minimality. In [2], a direct but detailed argument using Lagrange multiplier techniques was used to show the extremals were indeed minimizers. Here we take a different tack. We start in [2] with a two-parameter family of solutions to the Euler–Lagrange equations that identify the extremals. The two parameters are themselves characterized as the solution to a pair of nonlinear algebraic equations. These parameters and the form of the extremals suggest values for the Lagrange multipliers in the explicit representation (2.15), and indeed it is shown that characterizing equations $G(x,t;\Lambda) = 0$ for the unique Lagrange multipliers are satisfied. Having identified the minimal cost, all that remains is to show that the cost along the extremal is the same as this minimal value. This is done by explicitly evaluating an integral.

The main goal of this section is to argue that the extremals are minimizers and exhibit the relation between the two parameters used to identify the extremals and the Lagrange multipliers used in the formula for the minimal cost. Not all details will be given, and to simplify the presentation only the initial condition with $t = 0$ and all cells empty is considered. The statement of the case of general initial conditions is exactly analogous to Theorem 2.8 in [2], and any details that are omitted are similar to ones appearing in [2]. In addition, we present only the case $a \in (0,\infty)$. In this case it is simpler to work with an infinite dimensional version of the extremals. This is analogous to what is called the *exponential* case in [2]. The arguments for the cases $a = \infty$ and $a < 0$ are analogous to that of $a \in (0,\infty)$. As noted above, the case $a = \infty$ has already been considered in [2]. In the case $a < 0$, the extremals satisfy $\varphi_I = 0$. Because of this the arguments are somewhat simpler than in the case of $a > 0$, and it is analogous to the *polynomial* case of [2].

In the case of the empty initial condition the extremal can be identified as follows. Let $y \in \mathcal{S}_I$ be given. Then a family of solutions to the Euler–Lagrange equations for the problem of minimizing the cost subject to this terminal condition are

$$\varphi_0(t) = C\mathcal{Q}_0^a(\rho t) + \sum_{k=0}^{I} \left(y_k - C\mathcal{Q}_k^a(\rho T)\right)\left(1 - \frac{t}{T}\right)^k,$$

$$\varphi_i(t) = \frac{t^i}{i!}(-1)^i \varphi_0^{(i)}(t), \quad 1 \le i \le I,$$

$$\varphi_{I+}(t) = 1 - \sum_{i=0}^{I} \varphi_i(t).$$

This is exactly analogous to the form found in [2] for the special case of $a = \infty$, with the Poisson distribution $\mathcal{P}(t)$ in that case replaced by the family of probability distributions $\mathcal{Q}^a(t)$. It is useful to extend the definition of $\varphi_i(t)$ to $\varphi_i(t) = C\mathcal{Q}_i^a(\rho t)$ for $i > I$, while maintaining the distinction between $\varphi_{I+}(t)$ and $\varphi_I(t)$.

The parameters $\rho > 0$ and $C \geq 0$ are chosen so that the measure corresponding to $\varphi_i(T)$ is a probability measure, and moreover, one for which the number of balls per cell at time T equals T. Specifically, ρ is chosen so that

$$\frac{\rho T - \sum_{i=0}^{I} i\mathcal{Q}_i^a(\rho T)}{1 - \sum_{i=0}^{I} \mathcal{Q}_i^a(\rho T)} = \frac{T - \sum_{i=0}^{I} iy_i}{1 - \sum_{i=0}^{I} y_i}$$

holds, and then

$$C \doteq \frac{1 - \sum_{i=0}^{I} y_i}{1 - \sum_{i=0}^{I} \mathcal{Q}_i^a(\rho T)} = \frac{T - \sum_{i=0}^{I} iy_i}{\rho T - \sum_{i=0}^{I} i\mathcal{Q}_i^a(\rho T)}.$$

Solutions to these equations exist for $\rho \in (0, \infty)$ and $C \in [0, \infty)$ and are unique.

To show that this is indeed a minimizing trajectory we relate the constants ρ and C to the Lagrange multipliers appearing in the finite dimensional representation (2.15). Recall that the minimizer to this problem takes the form

$$\pi_j^0(1, 0; \Lambda) = \mathcal{Q}_j^a(T)e^{\lambda_0 - 1 + j\mu - \ell_j},$$

with $\ell_j = 0$ if $j > I$. Using the form of the minimizing trajectory, at time $t = T$,

$$\begin{aligned} &\varphi_j(T) = y_j, && 0 \leq j \leq I, \\ &\varphi_j(T) = C\mathcal{Q}_j^a(\rho T), && I < j. \end{aligned}$$

Thus for all $j > I$ we will want

$$\mathcal{Q}_j^a(T)e^{\lambda_0 - 1 + j\mu} = C\mathcal{Q}_j^a(\rho T).$$

Since

$$\frac{\mathcal{Q}_j^a(\rho T)}{\mathcal{Q}_j^a(T)} = \frac{\left(\frac{-\rho T}{a+\rho T}\right)^j \left(\frac{a+\rho T}{a}\right)^{-a}}{\left(\frac{-T}{a+T}\right)^j \left(\frac{a+T}{a}\right)^{-a}} = \rho^j \left(\frac{a+T}{a+\rho T}\right)^j \left(\frac{a+T}{a+\rho T}\right)^a,$$

this suggests

$$\begin{aligned} \mu &= \log \rho + \log\left(\frac{a+T}{a+\rho T}\right), \\ \lambda_0 - 1 &= a \log\left(\frac{a+T}{a+\rho T}\right) + \log C, \end{aligned}$$

and

$$\ell_k = -\log y_k + \log \mathcal{Q}_k^a(\rho T) + \log C$$

when $k \leq I$. Hence the minimizing trajectory for a problem with a finite terminal cost ℓ will terminate at a point y with each $y_k > 0$, an assumption we make for the rest of this section. The argument when one or more $y_k = 0$ can be handled by a limiting argument. We remark in passing that similar considerations allow one to explicitly identify the Lagrange multipliers for all initial conditions (x,t) that lie on the extremal in terms of C, ρ, and the values y_k.

To show that $\pi^0(1,0;\Lambda)$ is the minimizing probability measure in (2.15) the constraints (2.11) must be demonstrated. One constraint is that $\pi^0_j(1,0;\Lambda)$ be a probability measure. Since the definitions of the Lagrange multipliers enforce $\pi^0_j(1,0;\Lambda) = \varphi_j(T)$, this follows from $\sum_{i=0}^I y_i = 1 - C + C\sum_{i=0}^I \mathcal{Q}^a_i(\rho T)$ and

$$\sum_{j=0}^{\infty} \varphi_j(T) = \sum_{j=0}^{I} y_j + \sum_{j=I+1}^{\infty} C\mathcal{Q}^a_j(\rho T) = 1 - C + C = 1.$$

The only other constraint to check is the conservation condition:

$$\begin{aligned}
\sum_{j=0}^{\infty} j\pi^0_j(1,0;\Lambda) &= \sum_{j=0}^{\infty} j\mathcal{Q}^a_j(T)e^{\lambda_0 - 1 + j\mu - \ell_j} \\
&= \sum_{j=0}^{\infty} jC\mathcal{Q}^a_j(\rho T) + \sum_{j=0}^{I} jy_j - \sum_{j=0}^{I} jC\mathcal{Q}^a_j(\rho T) \\
&= C\rho T - \sum_{j=0}^{I} jC\mathcal{Q}^a_j(\rho T) + \sum_{j=0}^{I} jy_j \\
&= T - \sum_{i=0}^{I} iy_i + \sum_{j=0}^{I} jy_j \\
&= T,
\end{aligned}$$

where the equations characterizing C and ρ are used for the fourth equality.

We have identified the optimal measure for the terminal cost ℓ. To complete the argument that φ is a minimizer we need only show that the cost along this trajectory equals

$$\begin{aligned}
&R\left(\pi^0(1,0;\Lambda) \,\|\, \mathcal{Q}^a(T)\right) \\
&= \sum_{j=0}^{\infty} \pi^0_j(1,0;\Lambda) \log\left(\frac{\pi^0_j(1,0;\Lambda)}{\mathcal{Q}^a_j(T)}\right) \\
&= \sum_{j=0}^{\infty} \mathcal{Q}^a_j(T)e^{\lambda_0 - 1 + j\mu - \ell_j} \log\left(e^{\lambda_0 - 1 + j\mu - \ell_j}\right) \\
&= \sum_{j=0}^{I} y_j \log\left(\frac{y_j}{\mathcal{Q}^a_j(T)}\right) + \sum_{j=I+1}^{\infty} C\mathcal{Q}^a_j(\rho T) \log\left(\frac{C\mathcal{Q}^a_j(\rho T)}{\mathcal{Q}^a_j(T)}\right) \\
&= \sum_{j=0}^{\infty} \varphi_j(T) \log\left(\frac{\varphi_j(T)}{\mathcal{Q}^a_j(T)}\right) \\
&= \sum_{j=0}^{\infty} \varphi_j(T) \log\left(\varphi_j(T)\right) - \sum_{j=0}^{\infty} \varphi_j(T) \log\left(\mathcal{Q}^a_j(T)\right)
\end{aligned}$$

$$
\begin{aligned}
&= \sum_{j=0}^{\infty} \varphi_j(T) \log\left(\varphi_j(T)\right) \\
&\quad - \sum_{j=0}^{\infty} \varphi_j(T) \left[\log\left(\frac{T}{a}\right)^j + \log\left(\frac{\prod_{k=0}^{j-1}(a+k)}{j!}\right) + \log\left(\frac{a+T}{a}\right)^{-a-j} \right] \\
&= \sum_{j=0}^{\infty} \varphi_j(T) \log\left(\varphi_j(T)\right) - T \log\left(\frac{T}{a}\right) + (a+T)\log\left(\frac{a+T}{a}\right) \\
&\quad - \sum_{j=0}^{\infty} \varphi_j(T) \log\left(\frac{\prod_{k=0}^{j-1}(a+k)}{j!}\right).
\end{aligned}
$$

The notion of a completely monotone function is useful here. Although it is clear from the construction of the Lagrange multipliers that $\varphi_j(T)$ is a probability measure, the same cannot be said yet for $\varphi_j(t)$. A monotone function γ is completely monotone on $[0,T]$ if it is infinitely differentiable on $[0,T]$ and if for all $t \in [0,T]$ and $i \geq 0$,

$$(-1)^i \gamma^{(i)}(t) \geq 0.$$

The same argument as [2, p. 2794] shows that $\varphi_0(t)$ is completely monotone on $[0,T]$, and hence for all $t \in [0,T]$ and $i \geq 0$, $\varphi_i(t) \geq 0$. From the explicit formula for $\varphi_0(t)$ we actually have $(-1)^i \varphi_0^{(i)}(t) > 0$ for $t \in (0,T)$. It is also easy to show that for all $t \in [0,T]$ and $i \geq 0$, $\varphi_i(t)$ can be interpreted as the ith term in the Taylor series expansion of $\varphi_0(0)$ about t, and so for each t, $\{\varphi_i(t), i = 0, 1, \ldots\}$ is a probability measure on $\{0, 1, \ldots\}$.

To evaluate the cost

$$\int_0^T R\left(\theta \,\|\rho(t,\varphi(t))\right) dt,$$

it is convenient to work, as in [2], with the cumulative occupancy functions

$$\psi_j(t) = \sum_{i=0}^{j} \varphi_i(t).$$

The dynamics then take the form $\psi_j^{(1)}(t) = -\theta_j(t)$, and so with the convention $\psi_{-1}(t) = 0$ the cost can be expressed as

$$
\begin{aligned}
\int_0^T \Bigg[\sum_{i=0}^{I} -\psi_i^{(1)}(t) \log\left(\frac{-\psi_i^{(1)}(t)}{\frac{a+i}{a+t}\left(\psi_i(t) - \psi_{i-1}(t)\right)}\right) + \left(1 + \psi_0^{(1)}(t) + \cdots + \psi_I^{(1)}(t)\right) \\
\times \log\left(\frac{1 + \psi_0^{(1)}(t) + \cdots + \psi_I^{(1)}(t)}{\frac{a}{a+t}\left(1 - \psi_I(t)\right) + \frac{1}{a+t}\sum_{k=I+1}^{\infty} k\left(\psi_k(t) - \psi_{k-1}(t)\right)}\right) \Bigg] dt.
\end{aligned}
$$

We have

$$
\begin{aligned}
-\psi_i^{(1)}(t) &= -\sum_{k=0}^{i} \varphi_i^{(1)}(t) \\
&= -\sum_{k=0}^{i} \frac{(-t)^k}{k!} \psi_0^{(k+1)}(t) + \sum_{k=1}^{i} \frac{(-t)^{k-1}}{(k-1)!} \psi_0^{(k)}(t) \\
&= -\frac{(-t)^i}{i!} \psi_0^{(i+1)}(t),
\end{aligned}
$$

and so

$$\frac{-\psi_i^{(1)}(t)}{\varphi_i(t)} = \frac{-\frac{(-t)^i}{i!}\psi_0^{(i+1)}(t)}{\frac{(-t)^i}{i!}\psi_0^{(i)}(t)} = \frac{-\psi_0^{(i+1)}(t)}{\psi_0^{(i)}(t)}.$$

Since for $i > I$,

$$\begin{aligned}
\frac{-\psi_i^{(1)}(t)}{\frac{a+i}{a+t}\left(\psi_i(t) - \psi_{i-1}(t)\right)} &= \frac{a+t}{a+i}\frac{-\varphi_0^{(i+1)}(t)}{\varphi_0^{(i)}(t)} \\
&= \frac{a+t}{a+i}\frac{\mathcal{Q}_{i+1}^a(\rho t)(i+1)}{\mathcal{Q}_i^a(\rho t)t} \\
&= \frac{a+t}{a+i}\frac{(-\rho t)(-a-i)}{(a+\rho t)t} \\
&= \frac{(a+t)\rho}{a+\rho t}
\end{aligned}$$

and

$$\begin{aligned}
&\frac{1+\psi_0^{(1)}(t)+\cdots+\psi_I^{(1)}(t)}{\frac{a}{a+t}\left(1-\psi_I(t)\right)+\frac{1}{a+t}\sum_{k=I+1}^{\infty}k\left(\psi_k(t)-\psi_{k-1}(t)\right)} \\
&= \frac{\sum_{i=I+1}^{\infty}-\frac{(-t)^i}{i!}\varphi_0^{(i+1)}(t)}{\frac{a}{a+t}\left(\sum_{i=I+1}^{\infty}\frac{(-t)^i}{i!}\varphi_0^{(i)}(t)\right)+\frac{1}{a+t}\sum_{i=I+1}^{\infty}i\frac{(-t)^i}{i!}\varphi_0^{(i)}(t)} \\
&= \frac{\sum_{i=I+1}^{\infty}-\frac{(-t)^i}{i!}\varphi_0^{(i+1)}(t)}{\frac{a+i}{a+t}\left(\sum_{i=I+1}^{\infty}\frac{(-t)^i}{i!}\varphi_0^{(i)}(t)\right)},
\end{aligned}$$

we can write the integral as

$$\int_0^T\sum_{i=0}^{\infty}-\psi_i^{(1)}(t)\log\left(\frac{-\psi_i^{(1)}(t)}{\frac{a+i}{a+t}\left(\psi_i(t)-\psi_{i-1}(t)\right)}\right)dt.$$

In several places below we will need the existence of a dominating function to justify the interchange of summation and integration. A suitable function can be found using the same calculations as those used to establish (2.16). Also, this dominating function will work only on closed subintervals of $(0, T)$, and so a careful argument will first evaluate the integral on $[\varepsilon, T-\varepsilon]$ and then use monotone convergence to take the limit $\varepsilon \downarrow 0$.

We evaluate the integral by the following calculation, each line of which is explained below:

$$
\begin{aligned}
&\int_0^T \sum_{i=0}^{\infty} -\psi_i^{(1)}(t) \log\left(\frac{a+t}{a+i}\frac{-\psi_0^{(i+1)}(t)}{\psi_0^{(i)}(t)}\right) dt \\
&= \int_0^T \sum_{i=0}^{\infty} \left(-\psi_i^{(1)}(t)\log\left|\psi_0^{(i+1)}(t)\right| + \psi_i^{(1)}(t)\log\left|\psi_0^{(i)}(t)\right| - \psi_i^{(1)}(t)\log(a+i)\right) dt \\
&\quad + \int_0^T \left(\sum_{i=0}^{\infty} -\psi_i^{(1)}(t)\right)\log(a+t)\, dt \\
&= \int_0^T \sum_{i=0}^{\infty}\left[\left(\psi_i^{(1)}(t) - \psi_{i-1}^{(1)}(t)\right)\log\left|\psi_0^{(i)}(t)\right| - \psi_i^{(1)}(t)\log(a+i)\right] dt \\
&\quad + \int_0^T \log(a+t)\, dt \\
&= \sum_{i=0}^{\infty}\left(\left[\varphi_i(t)\log\left|\psi_0^{(i)}(t)\right|\right]_0^T + \int_0^T\left(\sum_{i=0}^{\infty} -\psi_i^{(1)}(t)\right) dt + \sum_{i=0}^{\infty}\left[\psi_i(t)\right]_0^T \log(a+i)\right) \\
&\quad + (a+T)\log(a+T) - (a+T) - a\log a + a \\
&= \sum_{i=0}^{\infty}\left(\left[\varphi_i(T)\log\left|\varphi_0^{(i)}(T)\right| - \varphi_i(0)\log\left|\varphi_0^{(i)}(0)\right|\right]_0^T + \log(a+i)\left(\sum_{k=0}^{i}\varphi_i(T) - \sum_{k=0}^{i}\varphi_i(0)\right)\right) \\
&\quad + T + (a+T)\log(a+T) - (a+T) - a\log a + a \\
&= \sum_{i=0}^{\infty}\left(\varphi_i(T)\log\left(\varphi_i(T)i!/T^i\right) - \log(a+i)\left(\sum_{k=i+1}^{\infty}\varphi_k(T)\right)\right) \\
&\quad + (a+T)\log(a+T) - a\log a \\
&= \sum_{i=0}^{\infty}\left(\varphi_i(T)\log\varphi_i(T) \;\; + \sum_{i=0}^{\infty}\varphi_i(T)\log(i!) - \varphi_i(T)\log\left(\prod_{k=0}^{i-1}(a+k)\right)\right) \\
&\quad - T\log T + (a+T)\log(a+T) - a\log a \\
&= \sum_{i=0}^{\infty}\varphi_i(T)\log\varphi_i(T) + \sum_{i=0}^{\infty}\varphi_i(T)\log\left(\frac{i!}{\prod_{k=0}^{i-1}(a+k)}\right) \\
&\quad - T\log T + (a+T)\log(a+T) - a\log a.
\end{aligned}
$$

The first line separates the $a+t$ term in the logarithm. The second equality uses the convention $\psi_{-1}(t) = 0$ and that $\sum_{i=0}^{\infty} -\psi_i^{(1)}(t) = 1$ (all balls go into some cell). The third line uses integration by parts and the fourth uses the definition of the cumulative occupancies. The fifth line uses the definition of φ_i in terms of derivatives of φ_0, and the sixth equality uses summation by parts. Since

$$
-T\log\left(\frac{T}{a}\right) + (a+T)\log\left(\frac{a+T}{a}\right) = -T\log T + (a+T)\log(a+T) - a\log a,
$$

the cost along this trajectory equals the minimum, and the argument is complete.

3. Allocation models with balls of different color. In this section we extend the techniques to the case of allocation models where the balls are of more than one type. To keep the notation simple, we actually consider just two colors, the extension to the more general case being straightforward. Another simplification is that we consider only MB statistics. The interested reader can combine the methods from this section and the last to treat more general statistical models.

3.1. Coloration process. We construct an allocation model with colored balls as follows. Balls are thrown into one of n cells sequentially. The throwing process is modeled by a collection of iid random variables, each uniformly distributed on the set $\{1,\dots,n\}$, with each value of the set corresponding to a cell. There is also a coloration process. At each discrete time a ball is assigned color $Y_l^n \in \{1,2\}$ and then placed into the cell determined by the throwing process. These two processes are independent.

The occupancy process in this case is defined as follows. The natural state space is

$$S_{I,J} \doteq \left\{ x \in \mathbb{R}^{I+2} \times \mathbb{R}^{J+2} : x_{i,j} \geq 0, 0 \leq i \leq I+1, 0 \leq j \leq J+1, \sum_{i=0}^{I+1}\sum_{j=0}^{J+1} x_{i,j} = 1 \right\}.$$

If $i \in \{0,\dots,I\}$ and $j \in \{0,\dots,J\}$, then $X_{i,j}^n(l/n)$ is the fraction of cells containing exactly i color-1 and j color-2 balls when l balls have been thrown. In an analogous fashion $X_{I+,j}^n(l/n), X_{i,J+}^n(l/n)$ and $X_{I+,J+}^n(l/n)$ are defined. By definition $X_{0,0}^n(0) \doteq 1$, and $X_{i,j}^n(0) \doteq 0$ for all other values of (i,j).

To describe the large deviation asymptotics of these allocation processes we must specify those of the coloration processes. Cumulative coloration processes $\{r^n, n \in \mathbb{N}\}$ are defined for $t = l/n$ by

$$r_1^n\left(\frac{l}{n}\right) \doteq \frac{1}{n}\sum_{k=1}^{l} 1_{\{Y_k^n = 1\}}, \quad r_2^n\left(\frac{l}{n}\right) \doteq \frac{1}{n}\sum_{k=1}^{l} 1_{\{Y_k^n = 2\}}.$$

We will assume that these processes satisfy a large deviations principle with a rate function of the form $J(\phi) = \int_0^T c(\dot{\phi}(s))ds$. Thus $c(\dot{\phi}(s))$ is a measure of the local (in time) log likelihood that a fraction $\dot{\phi}_i(s)$ of the balls are color i. A mild technical assumption that is needed to prove a large deviations result for the occupancy process is that $c(a) = 0$ for some point a with $a_i > 0, i = 1,2$. Since c is a rate function, there is at least one probability vector a at which $c(a) = 0$. The assumption that this occurs at a point where both components are positive is very mild and means simply that the LLN limit cannot concentrate exclusively on one color.

Examples of coloration processes which satisfy these properties are *deterministic, iid*, and *Markovian*. In the iid case colors are selected by an iid sequence of random variables. In the Markov case the color is chosen by a finite state ergodic Markov chain. The so-called deterministic case seeks to achieve a deterministic fraction a_k of color k, with $a_k \in (0,1)$. This can be done as follows. If N_{l-1}^k balls of color k have been thrown in the first $l-1$ throws (with $N_{l-1}^1 + N_{l-1}^2 = l-1$), and if $N_{l-1}^1/n \leq a_1 l/n$, then we color the lth ball 1, and otherwise color it 2.

The specific form for c in all these cases is spelled out in [3]. For reasons to be explained below, the focus in this paper will be on the iid and deterministic cases, where $c(\rho)$ equals $R(\rho\,\|a)$ and $\infty \cdot 1_{\{a\}^c}(\rho)$, respectively. Under a suitable restriction needed to ensure convexity that is also described below, the same methods can be applied to the Markovian case as well.

3.2. Variational problem and PDE. For this problem the feasible domain is

$$\mathcal{D} \doteq \left\{ (x,t) \in S_{I,J} \times [0,T) : \sum_{i=0}^{I} x_{i,J+1} + \sum_{j=0}^{J} x_{I+1,j} + x_{I+1,J+1} > 0 \text{ and} \right.$$
$$\left. t > \sum_{i=0}^{I+1}\sum_{j=0}^{J+1} x_{i,j} \text{ or } \sum_{i=0}^{I} x_{i,J+1} + \sum_{j=0}^{J} x_{I+1,j} + x_{I+1,J+1} = 0 \text{ and } t = \sum_{i=0}^{I}\sum_{j=0}^{J} x_{i,j} \right\}.$$

We next describe the large deviations variational problem. Recall that $S_{I,J}$ are the set of all probability measures on $\{0, I+1\} \times \{0, J+1\}$, which can also be interpreted as real $(I+2) \times (J+2)$ matrices. For $\alpha \in S_{I,J}$ define the linear maps

$$M^1_{i,j}[\alpha] = \alpha_{i-1,j} 1_{\{i \geq 1\}} - \alpha_{i,j} 1_{\{i \leq I\}}, M^2_{i,j}[\alpha] = \alpha_{i,j-1} 1_{\{j \geq 1\}} - \alpha_{i,j} 1_{\{j \leq J\}}.$$

The rate function for the coloration over an interval $[t,T]$ is assumed to be of the form $\int_t^T c(\rho) ds$, where $\rho(s) = (\rho_1(s), \rho_2(s))$ are the colored fractions at time s. The local (in time) and total coloration fractions satisfy $q_k = \int_t^T \rho_k(s) ds/[T-t]$, and for a trajectory of the form $(\rho_1(s), \rho_2(s)) = (q_1, q_2)$, the cost is of course $[T-t]c(q)$. The rate function for the occupancy process on path space is then

$$\mathcal{I}(x,t;\varphi) = \inf_{\theta,\rho} \int_t^T \left[\rho_1 R(\theta^1 \,\|\varphi\,) + \rho_2 R(\theta^2 \,\|\varphi\,) + c(\rho) \right] ds,$$

where the infimum is over all θ, ρ such that

$$\varphi(u) - \varphi(t) = \int_t^u \left(\rho_1 M^1[\theta^1] + \rho_2 M^2[\theta^2] \right) ds.$$

For a terminal cost F we consider

$$V(x,t) = \inf_{\varphi \in C([t,T], S_{I,J}), \varphi(t) = x} \left\{ \mathcal{I}(x,t;\varphi) + F(\varphi(T)) \right\}.$$

Then V should be a weak sense solution to

$$W_t + H(W_x, x, t) = 0$$

and the terminal condition, where

$$H(p,x,t) = \inf_{\rho,\theta^1,\theta^2} \left[\left\langle p, \rho_1 M^1[\theta^1] + \rho_2 M^2[\theta^2] \right\rangle + \rho_1 R(\theta^1 \,\|x\,) + \rho_2 R(\theta^2 \,\|x\,) + c(\rho) \right].$$

If $b(\gamma)$ is the Legendre transform $b(\gamma) = \sup_\rho [\langle \gamma, \rho \rangle - c(\rho)]$, then we can also write

$$\begin{aligned} H(p,x,t) &= -\sup_\rho \left[-\sum_{m=1,2} \rho_m \left(\inf_{\theta^m} [\langle p, M^m[\theta^m] \rangle + R(\theta^m \,\|x\,)] \right) - c(\rho) \right] \\ &= -b\left(-\inf_{\theta^1} \left[\left\langle p, M^1[\theta^1] \right\rangle + R(\theta^1 \,\|x\,) \right], -\inf_{\theta^2} \left[\left\langle p, M^2[\theta^2] \right\rangle + R(\theta^2 \,\|x\,) \right] \right). \end{aligned}$$

The variational formula for exponential integrals in terms of relative entropy [1, Proposition 1.4.2] asserts that

$$\begin{aligned}
\inf_{\theta^1}\left[\left\langle p, M^1\left[\theta^1\right]\right\rangle + R(\theta^1\,\|x\,)\right] &= \inf_{\theta^1}\left[\sum_{i,j,i\geq 1} p_{i,j}\theta^1_{i-1,j} - \sum_{i,j,i\leq I} p_{i,j}\theta^1_{i,j} + R(\theta^1\,\|x\,)\right]\\
&= \inf_{\theta^1}\left[\sum_{i,j,i\leq I}(p_{i+1,j}-p_{i,j})\theta^1_{i,j} + R(\theta^1\,\|x\,)\right]\\
&= -\log\left(\sum_{i,j,i\leq I} e^{-(p_{i+1,j}-p_{i,j})}x_{i,j} + \sum_{i,j,i=I+1} x_{i,j}\right).
\end{aligned}$$

Using the analogous formula for $m=2$, one obtains

$$\begin{aligned}
H(p,x,t) = -b\Bigg[&\log\left(\sum_{i,j,i\leq I} e^{-(p_{i+1,j}-p_{i,j})}x_{i,j} + \sum_{i,j,i=I+1} x_{i,j}\right),\\
&\log\left(\sum_{i,j,j\leq J} e^{-(p_{i,j+1}-p_{i,j})}x_{i,j} + \sum_{i,j,j=J+1} x_{i,j}\right)\Bigg].
\end{aligned} \tag{3.1}$$

3.3. Explicit solution. Let $\pi_{i,j}(r_1,r_2)$ denote the probability of throwing r_m additional balls of color m, $m=1,2$, into cells of category (i,j), and let $q=(q_1,q_2)$ be the fraction of balls of colors $(1,2)$. For $x\in S_{I,J}$, we say that $(\pi,q)\in\mathcal{F}(x,t;y,T)$ if for all i,j,

$$x_{i,j}\sum_{r_1,r_2=0}^{\infty}\pi_{i,j}(r_1,r_2) = x_{i,j}, \quad \sum_{i=0}^{I+1}\sum_{j=0}^{J+1} x_{i,j}\sum_{r_1,r_2=0}^{\infty} r_m\pi_{i,j}(r_1,r_2) = q_m(T-t)$$

for $m=1,2$ and

$$\begin{aligned}
y_{k,l} &= \sum_{i=0}^{k}\sum_{j=0}^{l} x_{i,j}\pi_{i,j}(k-i,l-j),\\
y_{I+1,l} &= \sum_{r=0}^{\infty}\sum_{i=0}^{I+1}\sum_{j=0}^{l} x_{i,j}\pi_{i,j}(I+1-i+r,l-j),\\
y_{k,J+1} &= \sum_{r=0}^{\infty}\sum_{i=0}^{k}\sum_{j=0}^{J+1} x_{i,j}\pi_{i,j}(k-i,J+1-j+r),\\
y_{l+1,J+1} &= \sum_{s=0}^{\infty}\sum_{r=0}^{\infty}\sum_{i=0}^{I+1}\sum_{j=0}^{J+1} x_{i,j}\pi_{i,j}(I+1-i+s,J+1-j+r).
\end{aligned}$$

We also denote y by $x\times\pi$. If the coloration turns out to be (q_1,q_2), then there are $q_m(T-t)n$ balls of color m thrown, and the LLN limit for the empirical fraction of cells of category (i,j) is $\mathcal{P}_i(q_1(T-t))\mathcal{P}_j(q_2(T-t))$.

The same sort of argument as in section 2.2 then suggests that the explicit form for the solution to the variational problem should be

$$\min_{(\pi,q)\in\mathcal{F}(x,t;y,T)}\left\{\sum_{i=0}^{I+1}\sum_{j=0}^{J+1}x_{i,j}R\left(\pi_{i,j}\left\|\mathcal{P}(q_1(T-t))\times\mathcal{P}(q_2(T-t))\right.\right)+(T-t)c(q)\right\}.$$

However, an interesting feature of the case with color is that the quantity being minimized in this formula is not always convex. In a previous paper [3], a useful assumption that guaranteed the convexity of the large deviation rate on path space was that $c(\rho)+h(\rho)$ be convex, where $h(\rho)$ is the entropy function $h(\rho)\doteq-\rho_1\log\rho_1-\rho_2\log\rho_2$. We will show that this same condition, not surprisingly, gives convexity here as well. Let a be the point with $a_i>0, i=1,2$, for which $c(a)=0$. Then we can write, under the constraint that relates $\pi_{i,j}$ and q_m,

$$\begin{aligned}
&\sum_{i=0}^{I+1}\sum_{j=0}^{J+1}x_{i,j}R\left(\pi_{i,j}\left\|\mathcal{P}(q_1(T-t))\times\mathcal{P}(q_2(T-t))\right.\right)+(T-t)c(q)\\
&=\sum_{i=0}^{I+1}\sum_{j=0}^{J+1}x_{i,j}\sum_{k=0}^{\infty}\sum_{l=0}^{\infty}\pi_{i,j}(k,l)\log\left(\frac{\pi_{i,j}(k,l)}{\mathcal{P}_k(a_1(T-t))\mathcal{P}_l(a_2(T-t))}\right)\\
&\quad+\sum_{i=0}^{I+1}\sum_{j=0}^{J+1}x_{i,j}\sum_{k=0}^{\infty}\sum_{l=0}^{\infty}\pi_{i,j}(k,l)\left[(T-t)c(q)-\log\left(\left[\frac{q_1}{a_1}\right]^k\left[\frac{q_2}{a_2}\right]^l\right)\right]\\
&=\sum_{i=0}^{I+1}\sum_{j=0}^{J+1}x_{i,j}R\left(\pi_{i,j}\left\|\mathcal{P}(a_1(T-t))\times\mathcal{P}(a_2(T-t))\right.\right)+(T-t)\left[c(q)-R(q\,\|a)\right].
\end{aligned}$$

The mapping $q\to[c(q)-R(q\,\|a)]$ is convex if and only if $c(q)+h(q)$ is convex, and so convexity of $c(q)+h(q)$ is sufficient for the minimization problem to be convex in $(\pi_{i,j},q_m)$. Note that in the deterministic case this condition holds with strict convexity, and that in the iid case $c(q)+h(q)$ is convex but never strictly convex (it is in fact always linear in q). Hence this is in a certain sense a borderline case, and one for which there may be nonuniqueness of minimizers. In the case of Markov coloring the condition may or may not hold; see [3] for further details.

This alternative rewriting of the objective function also has a practical benefit, in that the quantity to be minimized is now the sum of a convex function of π and a convex function of q, with no "cross terms." As a consequence, the formulas for $\pi_{i,j}$ and q_m also separate, and hence can be solved for explicitly in terms of the multipliers.

Having already restricted our attention to the case where $c(q)+h(q)$ is convex, we now make a final restriction. To parallel the very explicit computations of the single color model, we need a specific form for c, and in particular a form that allows us to solve for the minimizers in terms of multipliers. This can be done when the rate function for the coloration has a representation in terms of relative entropy, which is the case for all the models introduced previously. The particular form we choose is $c(q)=bR(q\,\|a)$, where $b\in(1,\infty)$. The limit $b\uparrow\infty$ gives the deterministic coloration with parameters a_1 and a_2, and the limit $b\downarrow 1$ gives the iid coloration with parameters a_1 and a_2.

Define

$$\mathcal{J}(x,t;y)\doteq\inf_{\substack{\varphi\in C([t,T],\mathcal{S}_{I,J})\\ \varphi(t)=x,\varphi(T)=y}}\mathcal{I}(x,t;\varphi).$$

THEOREM 3.1. *Consider the allocation problem with either the deterministic or iid coloration process with parameters $a_1 > 0$ and $a_2 > 0$, an initial condition $(x, t) \in \mathcal{D}$, and a feasible terminal condition y. Then the quantity $\mathcal{J}(x, t; y)$ has the representation*

$$\min_{(\pi,q)\in\mathcal{F}(x,t;y,T)} \left\{ \sum_{i=0}^{I+1}\sum_{j=0}^{J+1} x_{i,j} R\left(\pi_{i,j} \,\|\mathcal{P}(a_1(T-t))\times\mathcal{P}(a_2(T-t))\right) + (T-t)(b-1)R(q\,\|a) \right\}.$$

Proof. We will prove the representation for $b \in (1, \infty)$. Taking limits and using monotonicity in b will then establish the corresponding result for $b = 1$ and $b = \infty$. The same line of argument as in the single color case is followed. Hence we consider linear terminal conditions $F(y) = \langle y, \ell\rangle$ with $\ell = \ell_{i,j}, i = 0, \ldots, I+1, j = 0, \ldots, J+1$, and define

$$\begin{aligned} U(x,t) = \inf \Bigg\{ & \sum_{i=0}^{I+1}\sum_{j=0}^{J+1} x_{i,j} R\left(\pi_{i,j} \,\|\mathcal{P}(a_1(T-t))\times\mathcal{P}(a_2(T-t))\right) \\ & + (T-t)(b-1)R(q\,\|a) + \langle \ell, x\times\pi\rangle \Bigg\}. \end{aligned}$$

The infimum is over $\mathcal{F}(x, t, T)$, which is defined to be the set of all collections $(\pi_{i,j}, q_m)$ such that

$$\sum_{i=0}^{I+1}\sum_{j=0}^{J+1} x_{i,j} \sum_{r_1=0}^{\infty}\sum_{r_2=0}^{\infty} r_m \pi_{i,j}(r_1, r_2) = q_m(T-t), \qquad m = 1, 2,$$

and

$$q_m \geq 0, \quad m = 1, 2, \quad q_1 + q_2 = 1.$$

To study this problem, define

$$\begin{aligned} & f(x,t;\pi,q) \\ & \doteq \sum_{i=0}^{I+1}\sum_{j=0}^{J+1} x_{i,j} R\left(\pi_{i,j} \,\|\mathcal{P}(a_1(T-t))\times\mathcal{P}(a_2(T-t))\right) + (T-t)(b-1)R(q\,\|a) + \langle \ell, x\times\pi\rangle, \end{aligned}$$

introduce Lagrange multipliers $\Lambda = (\lambda_{i,j}, i = 0, \ldots, I+1, j = 0, \ldots, J+1; \mu_m, m = 1, 2; \theta)$, and define

$$\begin{aligned} L(x,t;\Lambda,\pi,q) \doteq{}& f(x,t;\pi,q) + \sum_{i=0}^{I+1}\sum_{j=0}^{J+1} \lambda_{i,j} x_{i,j} \left(1 - \sum_{k=0}^{\infty}\sum_{l=0}^{\infty} \pi_{i,j}(k,l)\right) \\ & + \sum_{m=1,2} \mu_m \left(q_m(T-t) - \sum_{i=0}^{I+1}\sum_{j=0}^{J+1} x_{i,j} \sum_{r_1=0}^{\infty}\sum_{r_2=0}^{\infty} r_m \pi_{i,j}(r_1,r_2)\right) \\ & + \theta(1 - q_1 - q_2). \end{aligned}$$

Analogously to the single color case,

$$\pi_{i,j}(k,l;x,t;\Lambda) = \mathcal{P}_k(a_1(T-t))\mathcal{P}_l(a_2(T-t))e^{\lambda_{i,j}-1+k\mu_1+l\mu_2-\ell_{i+k,j+l}}.$$

The equation for q is

$$(T-t)(b-1)\left[\log\left(\frac{q_m}{a_m}\right)+1\right]+\mu_m(T-t)-\theta=0,$$

so that

$$q_m(x,t;\Lambda)=a_m e^{-\frac{\mu_m}{b-1}}e^{\frac{\theta}{(T-t)(b-1)}}e^{-1}.$$

For $i=0,\dots,I,I+1, j=0,\dots,J,J+1$ and $m=1,2$ let

$$\begin{aligned}
G_{i,j}(x,t;\Lambda) &= \left(1-\sum_{k=0}^{\infty}\sum_{l=0}^{\infty}\pi_{i,j}(k,l;x,t;\Lambda)\right),\\
G_m(x,t;\Lambda) &= \left(q_m(x,t;\Lambda)(T-t)-\sum_{i=0}^{I+1}\sum_{j=0}^{J+1}x_{i,j}\sum_{k=0}^{\infty}\sum_{l=0}^{\infty}r_m\pi_{i,j}(k,l;x,t;\Lambda)\right),\\
G_3(x,t;\Lambda) &= (1-q_1(x,t;\Lambda)-q_2(x,t;\Lambda)). \qquad \square
\end{aligned}$$

When discussing uniqueness of the multipliers we must work with a matrix indexed by the subscripts of these functions, and the particular ordering of the i,j as subscripts is unimportant.

We next present three lemmas that are analogues of ones proved in the case of a single color. Since the proofs of the first two are also direct analogues they are omitted.

LEMMA 3.2 (general properties). *For any $(x,t)\in\mathcal{D}$, $\mathcal{F}(x,t;T)$ is nonempty, minimizing measures π^* exist, and if $x_{i,j}>0$, then $\pi^*_{i,j}(k,l)>0$ for all k and l.*

LEMMA 3.3 (characterization of the minimizer). *For any $(x,t)\in\mathcal{D}$ there exists $\Lambda\in\mathbb{R}^{(I+2)\times(J+2)+3}$ so that $G(x,t;\Lambda)=0$, and $\pi_{i,j}(k,l;x,t;\Lambda)$, $q_m(x,t;\Lambda)$ is a minimizer in the definition of $U(x,t)$.*

LEMMA 3.4 (uniqueness of characterization). *For $(x,t)\in\mathcal{D}$, there is only one $\Lambda\in\mathbb{R}^{(I+2)\times(J+2)+3}$ such that $G(x,t,\Lambda)=0$.*

Proof. We have

$$\begin{cases}
\frac{\partial\pi_{i,j}(k,l;x,t;\Lambda)}{\partial\lambda_{i,j}} &= \pi_{i,j}(k,l;x,t;\Lambda),\\
\frac{\partial\pi_{i,j}(k,l;x,t;\Lambda)}{\partial\mu_1} &= k\pi_{i,j}(k,l;x,t;\Lambda),\\
\frac{\partial\pi_{i,j}(k,l;x,t;\Lambda)}{\partial\mu_2} &= l\pi_{i,j}(k,l;x,t;\Lambda),\\
\frac{\partial q_m(x,t;\Lambda)}{\partial\mu_m} &= -\frac{1}{b-1}q_m(x,t;\Lambda),\\
\frac{\partial q_m(x,t;\Lambda)}{\partial\theta} &= \frac{1}{(T-t)(b-1)}q_m(x,t;\Lambda),
\end{cases}$$

and all other partial derivatives are zero. As in the single color case it is enough to show the negative definiteness of $D_\Lambda G$. Using a suitable dominating function to justify the interchange of differentiation and summation and the definitions

$$\begin{aligned}
\alpha_{i,j} &= \sum_{k,l=0}^{\infty}\pi_{i,j}(k,l;x,t;\Lambda),\\
T_m^{i,j} &= \sum_{r_1,r_2=0}^{\infty}r_m\pi_{i,j}(r_1,r_2;x,t;\Lambda),\\
C_{1,1} &= \sum_{i=0}^{I+1}\sum_{j=0}^{J+1}x_{i,j}\sum_{r_1,r_2=0}^{\infty}r_1^2\pi_{i,j}(r_1,r_2;x,t;\Lambda),
\end{aligned}$$

$$C_{2,2} = \sum_{i=0}^{I+1}\sum_{j=0}^{J+1} x_{i,j} \sum_{r_1,r_2=0}^{\infty} r_2^2 \pi_{i,j}(r_1,r_2;x,t;\Lambda),$$
$$C_{1,2} = \sum_{i=0}^{I+1}\sum_{j=0}^{J+1} x_{i,j} \sum_{r_1,r_2=0}^{\infty} r_1 r_2 \pi_{i,j}(r_1,r_2;x,t;\Lambda),$$

$D_\Lambda G$ equals [with $q_m = q_m(x,t;\Lambda)$]

$$\begin{pmatrix} -\alpha_{0,0} & \cdots & 0 & -T_1^{0,0} & -T_2^{0,0} & 0 \\ \vdots & \ddots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & -\alpha_{I+1,J+1} & -T_1^{I+1,j+1} & -T_2^{I+1,j+1} & 0 \\ -x_{0,0}T_1^{0,0} & \cdots & -x_{I+1,J+1}T_1^{I+1,J+1} & -\frac{T-t}{b-1}q_1 - C_{1,1} & -C_{1,2} & -\frac{1}{b-1}q_1 \\ -x_{0,0}T_2^{0,0} & \cdots & -x_{I+1,J+1}T_2^{I+1,J+1} & -C_{1,2} & -\frac{T-t}{b-1}q_2 - C_{2,2} & -\frac{1}{b-1}q_2 \\ 0 & \cdots & 0 & \frac{1}{b-1}q_1 & \frac{1}{b-1}q_2 & -\frac{q_1+q_2}{(T-t)(b-1)} \end{pmatrix}.$$

Since diagonalizing all, save the lower right 3×3 submatrix, produces strictly negative values on the diagonal, we need only check the negative definiteness of

$$\begin{pmatrix} \sum_{i,j}\frac{x_{i,j}}{\alpha_{i,j}}(T_1^{i,j})^2 - \frac{T-t}{b-1}q_1 - C_{1,1} & \sum_{i,j}\frac{x_{i,j}}{\alpha_{i,j}}T_1^{i,j}T_2^{i,j} - C_{1,2} & -\frac{1}{b-1}q_1 \\ \sum_{i,j}\frac{x_{i,j}}{\alpha_{i,j}}T_1^{i,j}T_2^{i,j} - C_{1,2} & \sum_{i,j}\frac{x_{i,j}}{\alpha_{i,j}}(T_2^{i,j})^2 - \frac{T-t}{b-1}q_2 - C_{2,2} & -\frac{1}{b-1}q_2 \\ \frac{1}{b-1}q_1 & \frac{1}{b-1}q_2 & -\frac{q_1+q_2}{(T-t)(b-1)} \end{pmatrix}.$$

Since

$$\begin{pmatrix} -\frac{T-t}{b-1}q_1 & 0 & -\frac{1}{b-1}q_1 \\ 0 & -\frac{T-t}{b-1}q_2 & -\frac{1}{b-1}q_2 \\ \frac{1}{b-1}q_1 & \frac{1}{b-1}q_2 & -\frac{q_1+q_2}{(T-t)(b-1)} \end{pmatrix}$$

is obviously negative definite, we need only check the 2×2 matrix

$$\begin{pmatrix} \sum_{i,j}\frac{x_{i,j}}{\alpha_{i,j}}(T_1^{i,j})^2 - C_{1,1} & \sum_{i,j}\frac{x_{i,j}}{\alpha_{i,j}}T_1^{i,j}T_2^{i,j} - C_{1,2} \\ \sum_{i,j}\frac{x_{i,j}}{\alpha_{i,j}}T_1^{i,j}T_2^{i,j} - C_{1,2} & \sum_{i,j}\frac{x_{i,j}}{\alpha_{i,j}}(T_2^{i,j})^2 - C_{2,2} \end{pmatrix}.$$

However, letting $\pi_{i,j}(r_1,r_2) = \pi_{i,j}(r_1,r_2;x,t;\Lambda)$ and pre- and postmultiplying by the nonzero vector (z_1,z_2) produces

$$\sum_{i,j}\frac{x_{i,j}}{\alpha_{i,j}}\left(\sum_{r_1,r_2}(z_1r_1+z_2r_2)\pi_{i,j}(r_1,r_2)\right.$$
$$\left. - \sum_{r_1,r_2}(z_1r_1+z_2r_2)^2\pi_{i,j}(r_1,r_2)\cdot\sum_{r_1,r_2}\pi_{i,j}(r_1,r_2)\right) \le 0.$$

Thus the entire matrix is negative definite. □

Since we have restricted our attention to the case of MB there is no analogue of the nonsmooth function $\tau(x,t)$, and hence the existence of a smooth extension of U to a neighborhood of $\mathcal{D}$ follows directly from the implicit function theorem. The next result expresses the derivatives in terms of the multipliers.

THEOREM 3.5. *Fix $(x,t) \in D$, and let Λ^* be the associated Lagrange multiplier. Then*

$$D_{x_{i,j}} U(x,t) = (\lambda^*_{i,j} - 1)$$

and

$$D_t U(x,t) = (b-1) - \frac{\theta^*}{(T-t)}.$$

Proof. With

$$H(x,t;\Lambda) \doteq L(x,t;\Lambda,\pi_{i,j}(\cdot,x,t;\Lambda), q_m(x,t;\Lambda))$$

we can write

$$U(x,t) = H(x,t;\Lambda(x,t)),$$

where $\Lambda(x,t)$ is the unique solution to the constraint equations. Then

$$D_{x_{i,j}} U(x,t) = D_{x_{i,j}} H(x,t;\Lambda^*) + D_\Lambda H(x,t;\Lambda^*) D_{x_{i,j}} \Lambda(x,t).$$

As in the single color case $D_\Lambda H(x,t;\Lambda^*) = 0$, and so $D_{x_{i,j}} U(x,t) = D_{x_{i,j}} H(x,t;\Lambda^*)$, and an analogous argument also gives $D_t U(x,t) = D_t H(x,t;\Lambda^*)$. Note that both $\pi_{i,j}(k,l;x,t;\Lambda)$ and $q_m(x,t;\Lambda)$ are actually independent of x, and hence can be written as $\pi_{i,j}(k,l;t;\Lambda)$ and $q_m(t;\Lambda)$. Keeping in mind the t dependence but temporarily suppressing both t and Λ^* in the notation, we will use

$$(T-t)(b-1)R(q\,\|a) = -(T-t)\left[q_1\mu_1^* + q_2\mu_2^*\right] + [\theta^* - (T-t)(b-1)](q_1+q_2).$$

The quantity to be differentiated is thus

$$\begin{aligned}
&\sum_{i=0}^{I+1}\sum_{j=0}^{J+1} x_{i,j} \sum_{k=0}^{\infty}\sum_{l=0}^{\infty} \left[\lambda^*_{i,j} - 1 + k\mu_1^* + l\mu_2^*\right] \pi_{i,j}(k,l) - (T-t)\left[q_1\mu_1^* + q_2\mu_2^*\right] \\
&\quad + [\theta^* - (T-t)(b-1)](q_1+q_2) \\
&\quad + \sum_{i=0}^{I+1}\sum_{j=0}^{J+1} \lambda^*_{i,j} x_{i,j} \left(1 - \sum_{k=0}^{\infty}\sum_{l=0}^{\infty} \pi_{i,j}(k,l)\right) \\
&\quad + \sum_{m=1,2} \mu_m^* \left(q_m(T-t) - \sum_{i=0}^{I+1}\sum_{j=0}^{J+1} x_{i,j} \sum_{r_1=0}^{\infty}\sum_{r_2=0}^{\infty} r_m \pi_{i,j}(r_1,r_2)\right) \\
&\quad + \theta^*(1-q_1-q_2) \\
&= -\sum_{i=0}^{I+1}\sum_{j=0}^{J+1} x_{i,j} \sum_{k=0}^{\infty}\sum_{l=0}^{\infty} \pi_{i,j}(k,l) - (T-t)(b-1)(q_1+q_2) + \sum_{i=0}^{I+1}\sum_{j=0}^{J+1} \lambda^*_{i,j} x_{i,j} + \theta^*.
\end{aligned}$$

Since

$$\begin{aligned}
\frac{\partial \pi_{i,j}(k,l;t;\Lambda)}{\partial t} &= e^{\lambda_{i,j} - 1 + k\mu_1 + l\mu_2 - \ell_{i+k,j+l}} \frac{\partial \mathcal{P}_k(a_1(T-t))\mathcal{P}_l(a_2(T-t))}{\partial t} \\
&= \frac{e^{\lambda_{i,j} - 1 + k\mu_1 + l\mu_2 - \ell_{i+k,j+l}}}{k!l!} \frac{\partial e^{-(T-t)} a_1^k (T-t)^k a_2^l (T-t)^l}{\partial t} \\
&= \left[1 - \frac{k}{T-t} - \frac{l}{T-t}\right] \pi_{i,j}(k,l;t;\Lambda)
\end{aligned}$$

and

$$\frac{\partial q_m(t;\Lambda)}{\partial t} = \left[\frac{\theta}{(T-t)^2(b-1)}\right] q_m(t;\Lambda),$$

it follows that

$$D_{x_{i,j}} U(x,t) = (\lambda^*_{i,j} - 1)$$

and

$$\begin{aligned} D_t U(x,t) &= -\sum_{i=0}^{I+1}\sum_{j=0}^{J+1} x_{i,j} \sum_{k=0}^{\infty}\sum_{l=0}^{\infty}\left[1 - \frac{k}{T-t} - \frac{l}{T-t}\right]\pi_{i,j}(k,l) \\ &\quad + (b-1)\,(q_1+q_2) - \frac{\theta^*}{(T-t)}\,(q_1+q_2) \\ &= -1 + q_1 + q_2 + (b-1) - \frac{\theta^*}{(T-t)} \\ &= (b-1) - \frac{\theta^*}{(T-t)}. \qquad \square \end{aligned}$$

For the particular rate function of interest here,

$$\begin{aligned} b(\gamma) &= \sup\left[\langle \gamma, q\rangle - bR(q\,\|a\,)\right] \\ &= -b\inf\left[-\frac{1}{b}\langle \gamma, q\rangle + R(q\,\|a\,)\right] \\ &= b\log\left(e^{\frac{\gamma_1}{b}}a_1 + e^{\frac{\gamma_2}{b}}a_2\right). \end{aligned}$$

Hence by (3.1), the PDE to be satisfied by U takes the form

$$\begin{aligned} &W_t - b\log\left(\left(\sum_{i,j,i\le I} e^{-(W_{x_{i+1,j}} - W_{x_{i,j}})}x_{i,j} + \sum_{i,j,i=I+1} x_{i,j}\right)^{\frac{1}{b}} a_1\right. \\ &\qquad \left. + \left(\sum_{i,j,j\le J} e^{-(W_{x_{i,j+1}} - W_{x_{i,j}})}x_{i,j} + \sum_{i,j,j=J+1} x_{i,j}\right)^{\frac{1}{b}} a_2\right) = 0. \end{aligned} \tag{3.2}$$

THEOREM 3.6. *U satisfies* (3.2) *on $\mathcal{D}$.*

Proof. By Theorem 3.5, this will be true if

(3.3)

$$\begin{aligned} &(b-1) - \frac{\theta^*}{(T-t)} - b\log\left(\left(\sum_{i,j,i\le I} e^{-(\lambda^*_{i+1,j} - \lambda^*_{i,j})}x_{i,j} + \sum_{i,j,i=I+1} x_{i,j}\right)^{\frac{1}{b}} a_1\right. \\ &\qquad\qquad \left. + \left(\sum_{i,j,j\le J} e^{-(\lambda^*_{i,j+1} - \lambda^*_{i,j})}x_{i,j} + \sum_{i,j,j=J+1} x_{i,j}\right)^{\frac{1}{b}} a_2\right) = 0. \end{aligned}$$

For $i \le I$,

$$\frac{\pi_{i+1,j}(k,l)}{\pi_{i,j}(k+1,l)} = \frac{e^{\lambda_{i+1,j}-\lambda_{i,j}} e^{-\mu_1}(k+1)}{a_1(T-t)}.$$

Summing on k and l gives

$$e^{\lambda_{i,j}-\lambda_{i+1,j}} = \frac{e^{-\mu_1}}{a_1(T-t)} \sum_{r_1,r_2} r_1 \pi_{i,j}(r_1,r_2),$$

and the analogous formula

$$e^{\lambda_{i,j}-\lambda_{i,j+1}} = \frac{e^{-\mu_2}}{a_2(T-t)} \sum_{r_1,r_2} r_2 \pi_{i,j}(r_1,r_2)$$

applies for $j \le J$. We also have

$$1 = \frac{e^{-\mu_2}}{a_2(T-t)} \sum_{r_1,r_2} r_2 \pi_{I+1,j}(r_1,r_2) = \frac{e^{-\mu_2}}{a_2(T-t)} \sum_{r_1,r_2} r_2 \pi_{i,J+1}(r_1,r_2)$$

if $j \le J+1$ or $i \le I+1$. Hence

$$\sum_{i,j,i\le I} e^{-(\lambda^*_{i+1,j}-\lambda^*_{i,j})} x_{i,j} + \sum_{i,j,i=I+1} x_{i,j} = e^{-\mu_1^*} \frac{q_1}{a_1},$$

$$\sum_{i,j,j\le J} e^{-(\lambda^*_{i,j+1}-\lambda^*_{i,j})} x_{i,j} + \sum_{i,j,j=J+1} x_{i,j} = e^{-\mu_2^*} \frac{q_2}{a_2}.$$

Now $q_1 + q_2 = 1$ implies

$$\begin{aligned} 0 &= \log\left(q_1(t;\Lambda) + q_2(t;\Lambda)\right) \\ &= \log\left(a_1 e^{-\frac{\mu_1}{b-1}} e^{\frac{\theta}{(T-t)(b-1)}-1} + a_2 e^{-\frac{\mu_2}{b-1}} e^{\frac{\theta}{(T-t)(b-1)}-1}\right) \\ &= \log\left(a_1 e^{-\frac{\mu_1}{b-1}} + a_2 e^{-\frac{\mu_2}{b-1}}\right) + \frac{\theta}{(T-t)(b-1)} - 1. \end{aligned}$$

The left-hand side of (3.3) becomes

$$\begin{aligned} &(b-1) - \frac{\theta^*}{(T-t)} - b\log\left(\left(e^{-\mu_1^*} q_1/a_1\right)^{\frac{1}{b}} a_1 + \left(e^{-\mu_2^*} q_2/a_2\right)^{\frac{1}{b}} a_2\right) \\ &= (b-1) - \frac{\theta^*}{(T-t)} - b\log\left(\left(e^{-\mu_1^*} e^{-\frac{\mu_1^*}{b-1}} e^{\frac{\theta^*}{(T-t)(b-1)}-1}\right)^{\frac{1}{b}} a_1\right. \\ &\qquad\qquad \left. + \left(e^{-\mu_2^*} e^{-\frac{\mu_2^*}{b-1}} e^{\frac{\theta^*}{(T-t)(b-1)}-1}\right)^{\frac{1}{b}} a_2\right) \\ &= -(b-1) + \frac{\theta^*}{(T-t)} - b\left[\log\left(\left(e^{-\frac{b\mu_1^*}{b-1}}\right)^{\frac{1}{b}} a_1 + \left(e^{-\frac{b\mu_2^*}{b-1}}\right)^{\frac{1}{b}} a_2\right) + \frac{\theta^*}{b(T-t)(b-1)} - \frac{1}{b}\right] \\ &= -b + \frac{b\theta^*}{(T-t)(b-1)} - \frac{b\theta^*}{(T-t)(b-1)} + b \\ &= 0, \end{aligned}$$

and the theorem is proved. $\square$

3.4. Minimizing trajectories. We end this section by stating without proof the form of the minimizing trajectories. As in the case of a single color we consider only the empty initial condition. In contrast with that case, here the minimizing q must be determined first via Lagrange multipliers. Once q is given, we define

$$\varphi_{0,0}(t_1,t_2) \doteq C\mathcal{P}_0(\rho q_1 t_1)\mathcal{P}_0(\rho q_2 t_2) + \sum_{k=0}^{I}\sum_{l=0}^{J}(y_{k,l} - C\mathcal{P}_k(\rho q_1 T)\mathcal{P}_l(\rho q_2 T))\left(1-\frac{t_1}{T}\right)^k\left(1-\frac{t_2}{T}\right)^l$$

and

$$\varphi_{i,j}(t_1,t_2) \doteq \frac{(-t_1)^i}{i!}\frac{(-t_2)^j}{j!}\varphi_{0,0}^{(i,j)}(t_1,t_2).$$

In terms of these functions we set

$$\varphi_{i,j}(t) \doteq \varphi_{i,j}(t,t),$$

and for $i \le I$ and $j \le J$,

$$\varphi_{I+,j}(t) = \sum_{i=I+1}^{\infty}\varphi_{i,j}(t),\ \varphi_{i,J+}(t) = \sum_{j=J+1}^{\infty}\varphi_{i,j}(t),\ \varphi_{I+J+}(t) = \sum_{i=I+1}^{\infty}\sum_{j=J+1}^{\infty}\varphi_{i,j}(t).$$

With q determined via Lagrange multipliers, the parameters $\rho > 0$ and $C \ge 0$ are chosen so that

$$\frac{\rho T - \sum_{i=0}^{I}\sum_{j=0}^{J}(i+j)\mathcal{P}_i(\rho q_1 T)\mathcal{P}_j(\rho q_2 T)}{1-\sum_{i=0}^{I}\sum_{j=0}^{J}\mathcal{P}_i(\rho q_1 T)\mathcal{P}_j(\rho q_2 T)} = \frac{T-\sum_{i=0}^{I}\sum_{j=0}^{J}(i+j)y_{i,j}}{1-\sum_{i=0}^{I}\sum_{j=0}^{J}y_{i,j}}$$

and

$$C \doteq \frac{1-\sum_{i=0}^{I}\sum_{j=0}^{J}y_{i,j}}{1-\sum_{i=0}^{I}\sum_{j=0}^{J}\mathcal{P}_i(\rho q_1 T)\mathcal{P}_j(\rho q_2 T)} = \frac{T-\sum_{i=0}^{I}\sum_{j=0}^{J}(i+j)y_{i,j}}{\rho T - \sum_{i=0}^{I}\sum_{j=0}^{J}(i+j)\mathcal{P}_i(\rho q_1 T)\mathcal{P}_j(\rho q_2 T)}.$$

The proof that these trajectories achieve the minimal cost parallels that of the single color case, with an appropriate modification of the notion of completely monotone that is suitable for functions of two independent variables.

LONG-TIME EXISTENCE OF SMOOTH SOLUTIONS FOR THE RAPIDLY ROTATING SHALLOW-WATER AND EULER EQUATIONS*

BIN CHENG† AND EITAN TADMOR‡

Abstract. We study the stabilizing effect of rotational forcing in the nonlinear setting of two-dimensional shallow-water and more general models of compressible Euler equations. In [*Phys. D*, 188 (2004), pp. 262–276] Liu and Tadmor have shown that the pressureless version of these equations admit a global smooth solution for a large set of subcritical initial configurations. In the present work we prove that when rotational force dominates the pressure, it *prolongs* the lifespan of smooth solutions for $t \lesssim \ln(\delta^{-1})$; here $\delta \ll 1$ is the ratio of the pressure gradient measured by the inverse squared Froude number, relative to the dominant rotational forces measured by the inverse Rossby number. Our study reveals a "nearby" periodic-in-time approximate solution in the small δ regime, upon which hinges the long-time existence of the exact smooth solution. These results are in agreement with the close-to-periodic dynamics observed in the "near-inertial oscillation" (NIO) regime which follows oceanic storms. Indeed, our results indicate the existence of a smooth, "approximate periodic" solution for a time period of *days*, which is the relevant time period found in NIO obesrvations.

Key words. shallow-water equations, rapid rotation, pressureless equations, critical threshold, two-dimensinoal Euler equations, long-time existence

1. Introduction and statement of main results.

We are concerned here with two-dimensional systems of nonlinear Eulerian equations driven by pressure and rotational forces. It is well known that in the absence of rotation, these equations experience a finite-time breakdown: for generic smooth initial conditions, the corresponding solutions will lose C^1-smoothness due to shock formation. The presence of rotational forces, however, has a stabilizing effect. In particular, the pressureless version of these equations admit global smooth solutions for a large set of so-called subcritical initial configurations [17]. It is therefore a natural extension to investigate the balance between the regularizing effects of rotation versus the tendency of pressure to enforce finite-time breakdown (we mention in passing the recent work [21] on a similar regularizing balance of different competing forces in the one-dimensional Euler–Poisson equations). In this paper we prove the long-time existence of rapidly rotating flows characterized by "nearby" periodic flows. Thus, rotation *prolongs* the lifespan of smooth solutions over increasingly long time periods, which grow longer as the rotation forces become more dominant over pressure.

Our model problem is the rotational shallow water (RSW) system of equations. This system models largescale geophysical motions in a thin layer of fluid under the

influence of the Coriolis rotational forcing (see, e.g., [18, section 3.3], [10, section 2.1]),

$$\partial_t h + \nabla \cdot (h\mathbf{u}) = 0, \tag{1.1a}$$

$$\partial_t \mathbf{u} + \mathbf{u} \cdot \nabla \mathbf{u} + g\nabla h - f\mathbf{u}^\perp = 0. \tag{1.1b}$$

It governs the unknown velocity field $\mathbf{u} := \big(u^{(1)}(t,x,y), u^{(2)}(t,x,y)\big)$ and height $h := h(t,x,y)$, where g and f stand for the gravitational constant and the Coriolis frequency, respectively. Recall that (1.1a) observes the conservation of mass and (1.1b) describe balance of momentum by the pressure gradient, $g\nabla h$, and rotational forcing, $f\mathbf{u}^\perp := f\big(u^{(2)}, -u^{(1)}\big)$.

For convenience, we rewrite system (1.1) in terms of rescaled, nondimensional variables. To this end, we introduce the characteristic scales, H for total height h, D for height fluctuation $h-H$, U for velocity u, L for spatial length, and correspondingly, L/U for time, and we make the change of variables

$$\mathbf{u} = \mathbf{u}'\left(\frac{t'L}{U}, x'L, y'L\right)U, \qquad h = H + h'\left(\frac{t'L}{U}, x'L, y'L\right)D.$$

Discarding all the primes, we arrive at a nondimensional system,

$$\partial_t h + \mathbf{u} \cdot \nabla h + \left(\frac{H}{D} + h\right)\nabla \cdot \mathbf{u} = 0,$$

$$\partial_t \mathbf{u} + \mathbf{u} \cdot \nabla \mathbf{u} + \frac{gD}{U^2}\nabla h - \frac{fL}{U}\mathbf{u}^\perp = 0.$$

We are concerned here with the regime where the pressure gradient and compressibility are of the same order, $\frac{gD}{U^2} \approx \frac{H}{D}$. Thus we arrive at the (symmetrizable) RSW system,

$$\partial_t h + \mathbf{u} \cdot \nabla h + \left(\frac{1}{\sigma} + h\right)\nabla \cdot \mathbf{u} = 0, \tag{1.2a}$$

$$\partial_t \mathbf{u} + \mathbf{u} \cdot \nabla \mathbf{u} + \frac{1}{\sigma}\nabla h - \frac{1}{\tau}J\mathbf{u} = 0. \tag{1.2b}$$

Here σ and τ, given by

$$\sigma := \frac{U}{\sqrt{gH}}, \quad \tau := \frac{U}{fL}, \tag{1.2c}$$

are, respectively, the Froude number measuring the inverse pressure forcing and the Rossby number measuring the inverse rotational forcing. We use J to denote the 2×2 rotation matrix $J := \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$.

To trace their long-time behavior, we approximate (1.2a), (1.2b) with the successive iterations,

$$\partial_t h_j + \mathbf{u}_{j-1} \cdot \nabla h_j + \left(\frac{1}{\sigma} + h_j\right)\nabla \cdot \mathbf{u}_{j-1} = 0, \qquad j = 2, 3, \ldots, \tag{1.3a}$$

$$\partial_t \mathbf{u}_j + \mathbf{u}_j \cdot \nabla \mathbf{u}_j + \frac{1}{\sigma}\nabla h_j - \frac{1}{\tau}J\mathbf{u}_j = 0, \qquad j = 1, 2, \ldots, \tag{1.3b}$$

subject to initial conditions, $h_j(0,\cdot) = h_0(\cdot)$ and $\mathbf{u}_j(0,\cdot) = \mathbf{u}_0(\cdot)$. Observe that, given j, (1.3a,b) are only weakly coupled through the dependence of $\mathbf{u}_j$ on h_j, so that we need only specify the initial height h_1. Moreover, for $\sigma \gg \tau$, the momentum equations (1.2b) are "approximately decoupled" from the mass equation (1.2a) since rotational forcing is substantially dominant over pressure forcing. Therefore, a first approximation of constant height function will enforce this decoupling, serving as the starting point of the above iterative scheme,

$$h_1 \equiv \text{constant}. \tag{1.3c}$$

This, in turn, leads to the first approximate velocity field, $\mathbf{u}_1$, satisfying the pressureless equations,

$$\partial_t \mathbf{u}_1 + \mathbf{u}_1 \cdot \nabla \mathbf{u}_1 - \frac{1}{\tau} J \mathbf{u}_1 = 0, \quad \mathbf{u}_1(0, \cdot) = \mathbf{u}_0(\cdot). \tag{1.4}$$

Liu and Tadmor [17] have shown that there is a "large set" of so-called subcritical initial configurations $\mathbf{u}_0$, for which the pressureless equations (1.4) admit global smooth solutions. Moreover, the pressureless velocity $\mathbf{u}_1(t, \cdot)$ is in fact $2\pi\tau$-periodic in time. The regularity of $\mathbf{u}_1$ is discussed in section 2.

Having the pressureless solution, $(h_1 \equiv \text{constant}, \mathbf{u}_1)$ as a first approximation for the RSW solution $(h, \mathbf{u})$, in section 3 we introduce an improved approximation of the RSW equations, $(h_2, \mathbf{u}_2)$, which solves an "adapted" version of the second iteration $(j = 2)$ of (1.3). This improved approximation satisfies a specific linearization of the RSW equations around the pressureless velocity $\mathbf{u}_1$, with only a one-way coupling between the momentum and the mass equations. Building on the regularity and periodicity of the pressureless velocity $\mathbf{u}_1$, we show that the solution of this linearized system subject to subcritical initial data $(h_0, \mathbf{u}_0)$, is globally smooth; in fact, both $h_2(t, \cdot)$ and $\mathbf{u}_2(t, \cdot)$ retain $2\pi\tau$-periodicity in time.

Next, we turn to estimating the deviation between the solution of the linearized RSW system, $(h_2, \mathbf{u}_2)$, and the solution of the full RSW system, $(h, \mathbf{u})$. To this end, we introduce a new nondimensional parameter,

$$\delta := \frac{\tau}{\sigma^2} = \frac{gH}{fLU},$$

measuring the *relative* strength of rotation versus the pressure forcing, and we assume that rotation is the dominant forcing in the sense that $\delta \ll 1$. Using the standard energy method, we show in Theorem 4.1 and the follow-up Remark 4.1 that, starting with H^m subcritical initial data, the RSW solution $\big(h(t, \cdot), \mathbf{u}(t, \cdot)\big)$ remains sufficiently close to $\big(h_2(t, \cdot), \mathbf{u}_2(t, \cdot)\big)$ in the sense that

$$\|h(t, \cdot) - h_2(t, \cdot)\|_{H^{m-3}} + \|\mathbf{u}(t, \cdot) - \mathbf{u}_2(t, \cdot)\|_{H^{m-3}} \lesssim \frac{e^{C_0 t}\delta}{(1 - e^{C_0 t}\delta)^2},$$

where constant $C_0 = \widehat{C}_0(m, |\nabla \mathbf{u}_0|_\infty, |h_0|_\infty) \cdot \|\mathbf{u}_0, h_0\|_m$. In particular, we conclude that for a large set of subcritical initial data, the RSW equations (1.2) admit smooth, "approximate periodic" solutions for long time, $t \le t_\delta := \ln(\delta^{-1})$, in the rotationally dominant regime $\delta \ll 1$.

We comment that our formal notion of "approximate periodicity" emphasizes the existence of a periodic approximation $(h_2, \mathbf{u}_2)$ nearby the actual flow $(h, \mathbf{u})$, with an up-to $O(\delta) \ll 1$-error for sufficiently long time. Therefore, strong rotation stabilizes the flow by imposing on it approximate periodicity, which in turn postpones finite-time breakdown of classical solutions for a long time. A convincing example is provided by the so-called "near-inertial oscillation" (NIO) regime, which is observed during the days that follow oceanic storms; see, e.g., [22]. These NIOs are triggered when storms pass by (large U's) and only a thin layer of the oceans is reactive (small aspect ratio H/L), corresponding to $\delta = \frac{gH}{fLU} \ll 1$. Specifically, with Rossby number $\tau \sim \mathcal{O}(0.1)$ and Froude number $\sigma \sim \mathcal{O}(1)$ we find $\delta \sim 0.1$, which yields the existence of a smooth, "approximate periodic" solution for $t \sim 2$ days. We note that the clockwise rotation of cyclonic storms on the Northern Hemisphere produce negative vorticity, which is a preferred scenario of the subcritical condition (2.1b). Our results are consistent with the observations regarding the stability and approximate periodicity of the NIO regime.

Next, we generalize our result to Euler systems describing the isentropic gasdynamics, in section 4.2, and ideal gasdynamics, in section 4.3. We regard these two systems as successive generalizations of the RSW system using the following formalism:

$$\partial_t \rho + \nabla \cdot (\rho \mathbf{u}) = 0, \tag{1.5a}$$

$$\partial_t \mathbf{u} + \mathbf{u} \cdot \nabla \mathbf{u} + \rho^{-1} \nabla \widetilde{p}(\rho, S) = fJ\mathbf{u}, \tag{1.5b}$$

$$\partial_t S + \mathbf{u} \cdot \nabla S = 0. \tag{1.5c}$$

Here, the physical variables ρ, S are, respectively, the density and entropy. We use $\widetilde{p}(\rho, S)$ for the gas-specific pressure law relating pressure to density and entropy. For the ideal gasdynamics, the pressure law is given as $\widetilde{p} := A\rho^\gamma e^S$, where A, γ are two gas-specific physical constants. The isentropic gas equations correspond to constant S, for which the entropy equation (1.5c) becomes redundant. Setting $A = g, \gamma = 2$ yields the RSW equations with ρ playing the same role as h.

The general Euler system (1.5) can be symmetrized by introducing a "normalized" pressure function,

$$p := \frac{\sqrt{\gamma}}{\gamma - 1} \widetilde{p}^{\frac{\gamma-1}{2\gamma}}(\rho, S),$$

and by replacing the density equation (1.5a) with a pressure equation,

$$\partial_t p + \mathbf{u} \cdot \nabla p + \frac{\gamma - 1}{2} p \nabla \cdot \mathbf{u} = 0. \tag{1.5d}$$

We then nondimensionalize the above system (1.5b), (1.5c), (1.5d) into

$$\begin{aligned} \partial_t p + \mathbf{u} \cdot \nabla p + \frac{\gamma - 1}{2} \left(\frac{1}{\sigma} + p \right) \nabla \cdot \mathbf{u} = 0, \\ \partial_t \mathbf{u} + \mathbf{u} \cdot \nabla \mathbf{u} + \frac{\gamma - 1}{2} \left(\frac{1}{\sigma} + p \right) e^{\sigma S} \nabla p = \frac{1}{\tau} J\mathbf{u}, \\ \partial_t S + \mathbf{u} \cdot \nabla S = 0. \end{aligned}$$

The same methodology introduced for the RSW equations still applies to the more general Euler system, independent of the pressure law. In particular, our first approximation, the pressureless system, remains the same as in (1.4) since it ignores any effect of pressure. We then obtain the second approximation $(p_2, \mathbf{u}_2, S_2)$ (or $(p_2, \mathbf{u}_2)$ in the isentropic case) from a specific linearization around the pressureless velocity $\mathbf{u}_1$. Thanks to the fact that h, p, and S share a similar role as passive scalars transported by $\mathbf{u}$, the same regularity and periodicity argument can be employed for $(p_2, \mathbf{u}_2, S_2)$

in these general cases as for $(h_2, \mathbf{u}_2)$ in the RSW case. The energy estimate, however, needs careful modification for the ideal gas equations due to additional nonlinearity. Finally, we conclude in Theorem 4.2 and 4.3 that, in the rotationally dominant regime $\delta \ll 1$, the exact solution stays "close" to the globally smooth, $2\pi\tau$-periodic approximate solution $(p_2, \mathbf{u}_2, S_2)$ for long time in the sense that, starting with H^m subcritical data, the following estimate holds true for time $t \lesssim \ln(\delta^{-1})$:

$$\|p(t,\cdot) - p_2(t,\cdot)\|_{m-3} + \|\mathbf{u}(t,\cdot) - \mathbf{u}_2(t,\cdot)\|_{m-3} + \|S(t,\cdot) - S_2(t,\cdot)\|_{m-3} < \frac{e^{C_0 t}\delta}{1 - e^{C_0 t}\delta}.$$

Our results confirm the stabilization effect of rotation in the nonlinear setting, when it interacts with the slow components of the system, which otherwise tend to destabilize of the dynamics. The study of such interaction is essential to the understanding of rotating dynamics, primarily to geophysical flows. We can mention only a few works from the vast literature available on this topic, and we refer the reader to the recent book of Chemin et al. [6], and the references therein, for a state-of-the-art of the mathematical theory for rapidly rotating flows. Embid and Majda [7, 8] studied the singular limit of RSW equations under the two regimes $\tau^{-1} \sim \sigma^{-1} \to \infty$ and $\tau^{-1} \sim \mathcal{O}(1)$, $\sigma^{-1} \to \infty$. Extensions to more general skew-symmetric perturbations can be found in the work of Gallagher [9]. The series of works of Babin, Mahalov, and Nicolaenko (consult [1, 2, 3, 4, 5] and references therein) establish long-term stability effects of the rapidly rotating three-dimensional Euler, Navier–Stokes, and primitive equations. Finally, we mention the work of Zeitlin, Reznik, and Ben Jelloul [23, 24] which categorize several relevant scaling regimes and, correspondingly, derive formal asymptotics in the nonlinear setting.

We comment here that the approach pursued in the above literature relies on identifying the limiting system as $\tau \to 0$, which filters out fast scales. The full system is then approximated to a first order by this slowly evolving limiting system. A rigorous mathematical foundation along these lines was developed by Schochet [19], which can be traced back to the earlier works of Klainerman and Majda [13] and Kreiss [14] (see also [20]). The key point was the separation of (linear) fast oscillations from the slow scales. The novelty of our approach, inspired by the critical threshold phenomena [16], is to adopt the rapidly oscillating and fully *nonlinear* pressureless system as a first approximation and then consider the full system as a perturbation of this fast scale. This enables us to preserve both slow and fast dynamics, and especially, the rotation-induced time periodicity.

2. First approximation—the pressureless system. We consider the pressureless system

$$\partial_t \mathbf{u}_1 + \mathbf{u}_1 \cdot \nabla \mathbf{u}_1 - \frac{1}{\tau} J \mathbf{u}_1 = 0 \tag{2.1a}$$

subject to initial condition $\mathbf{u}_1(0,\cdot) = \mathbf{u}_0(\cdot)$. We begin by recalling the main theorem in [17] regarding the global regularity of the pressureless equations (2.1a).

THEOREM 2.1. *Consider the pressureless equations* (2.1a) *subject to C^1-initial data $\mathbf{u}_1(0,\cdot) = u_0(\cdot)$. Then, the solution $\mathbf{u}_1(t,\cdot)$ stays C^1 for all time if and only if the initial data satisfy the critical threshold condition,*

$$\tau\omega_0(x) + \frac{\tau^2}{2}\eta_0^2(x) < 1 \quad \textit{for all } x \in \mathbb{R}^2. \tag{2.1b}$$

Here, $\omega_0(x) = -\nabla \times \mathbf{u}_0(x) = \partial_y u_0 - \partial_x v_0$ is the initial vorticity and $\eta_0(x) := \lambda_1 - \lambda_2$ is the (possibly complex-valued) spectral gap associated with the eigenvalues of gradient *matrix* $\nabla\mathbf{u}_0(x)$. *Moreover, these globally smooth solutions,* $\mathbf{u}_1(t,\cdot)$, *are* $2\pi\tau$*-periodic in time.*

In [17], Liu and Tadmor gave two different proofs of (2.1b). One was based on the spectral dynamics of $\lambda_j(\nabla\mathbf{u})$; the other was based on the flow map associated with (2.1a), and here we note yet another version of the latter, based on the Riccati-type equation satisfied by the gradient matrix $M =: \nabla\mathbf{u}_1$,

$$M' + M^2 = \tau^{-1}JM.$$

Here $\{\cdot\}' := \partial_t + \mathbf{u}_1\cdot\nabla$ denotes differentiation along the particle trajectories

$$\Gamma_0 := \{(x,t) \mid \dot{x}(t) = \mathbf{u}_1(x(t),t),\ x(t_0) = x_0\}. \tag{2.2}$$

Starting with $M_0 = M(t_0,x_0)$, the solution of this equation along the corresponding trajectory Γ_0 is given by

$$M = e^{tJ/\tau}\left(I + \tau^{-1}J\left(I - e^{tJ/\tau}\right)M_0\right)^{-1}M_0,$$

and a straightforward calculation based on the Cayley–Hamilton theorem (for computing the inverse of a matrix) shows that

$$\max_{t,x}|\nabla\mathbf{u}_1| = \max_{t,x}|M| = \max_{t,x}\left|\frac{\text{polynomial}(\tau, e^{tJ/\tau}, \nabla\mathbf{u}_0)}{(1-\tau\omega_0 - \frac{\tau^2}{2}\eta_0^2)_+}\right|. \tag{2.3}$$

Thus the critical threshold (2.1b) follows. The periodicity of $\mathbf{u}_1$ is proved upon integrating $\mathbf{u}_1{}' = \frac{1}{\tau}Ju$ and $x' = \mathbf{u}_1$ along particle trajectories Γ_0. It turns out both $x(t)$ and $\mathbf{u}_1(t,x(t))$ are $2\pi\tau$-periodic, which clearly implies that $\mathbf{u}_1(t,\cdot)$ shares the same periodicity. It follows that there exists a critical Rossby number, $\tau_c := \tau_c(\nabla\mathbf{u}_0)$, such that the pressureless solution, $\mathbf{u}_1(t,\cdot)$, remains smooth for global time whenever $\tau \in (0,\tau_c)$. This emphasizes the stabilization effect of the rotational forcing for a "large" class of subcritical initial configurations, [17, section 1.2]. Observe that the critical threshold τ_c *need not* be small, and in fact, $\tau_c = \infty$ for rotational initial data such that $\eta_0^2 < 0$, $\omega_0 < \sqrt{-\eta_0^2}$. We shall always limit ourselves, however, to a *finite* value of the critical threshold, τ_c.

In the next corollary we show that, in fact, the pressureless solution retains higher-order smoothness of the subcritical initial data. To this end, we introduce the following notations.

Notations. Here and below, $\|\cdot\|_m$ denotes the usual H^m-Sobolev norm over the two-dimensional torus $\mathbb{T}^2$ and $|\cdot|_\infty$ denotes the L^∞ norm. We abbreviate $a \lesssim_m b$ for $a \le cb$ whenever the constant c depends only on the dimension m. We let $\widehat{C}_0$ denote m-dependent constants that have possible nonlinear dependence on the initial data $|h_0|_\infty$ and $|\nabla\mathbf{u}_0|_\infty$. The constant, $C_0 := \widehat{C}_0\cdot\|(h_0,\mathbf{u}_0)\|_m$, will be used for estimates involving Sobolev regularity, emphasizing that C_0 depends *linearly* on the H^m-size of initial data, h_0 and $\mathbf{u}_0)\|$, and possibly nonlinearly on their L^∞-size.

COROLLARY 2.2. *Fix an integer* $m > 2$ *and consider the pressureless system* (2.1a) *subject to subcritical initial data,* $u_0 \in H^m$. *Then, there exists a critical value* $\tau_c := \tau_c(\nabla\mathbf{u}_0) < \infty$ *such that for* $\tau \in (0,\tau_c]$ *we have, uniformly in time,*

$$|\nabla\mathbf{u}_1(t,\cdot)|_\infty \le \widehat{C}_0, \tag{2.4a}$$

$$\|\mathbf{u}_1(t,\cdot)\|_m \le C_0. \tag{2.4b}$$

Proof. We recall the expression for $|\nabla \mathbf{u}_1|_\infty$ in (2.3). By a continuity argument, there exists a value $\tau_c > 0$ such that $1 - \tau\omega_0 - \frac{\tau^2}{2}\eta_0^2 > 0$ for all $\tau \in (0, \tau_c]$, which in turn implies (2.4a) with a constant $\widehat{C}_0$ that depends on $|\nabla \mathbf{u}_0|_\infty$ and on τ_c.

Having control on the L^∞ norm of $\nabla \mathbf{u}_1$, we employ the standard energy method to obtain the inequality,

$$\frac{d}{dt}\|\mathbf{u}_1(t,\cdot)\|_m \lesssim_m |\nabla \mathbf{u}_1(t,\cdot)|_{L^\infty}\|\mathbf{u}_1(t,\cdot)\|_m.$$

Since $\mathbf{u}_1(t,\cdot)$ is $2\pi\tau$-periodic, it suffices to consider its energy growth over $0 \leq t < 2\pi\tau < 2\pi\tau_c$. Combining with estimate (2.4a) and solving the above Gronwall inequality, we prove the H^m estimate (2.4b). ∎

3. Second approximation—the linearized system. Once we establish the global properties of the pressureless velocity $\mathbf{u}_1$, it can be used as the starting point for a second iteration of (1.3). We begin with the approximate height, h_2, governed by (1.3a),

$$\partial_t h_2 + \mathbf{u}_1 \cdot \nabla h_2 + \left(\frac{1}{\sigma} + h_2\right)\nabla \cdot \mathbf{u}_1 = 0, \qquad h_2(0,\cdot) = h_0(\cdot). \tag{3.1}$$

Recall that $\mathbf{u}_1$ is the solution of the pressureless system (2.1a) subject to *subcritical* initial data $\mathbf{u}_0$, so that $\mathbf{u}_1(t,\cdot)$ is smooth, $2\pi\tau$-periodic in time. The following key lemma shows that the periodicity of $\mathbf{u}_1$ imposes the same periodicity on passive scalars transported by such $\mathbf{u}_1$'s.

LEMMA 3.1. *Let scalar function w be governed by*

$$\partial_t w + \nabla \cdot (\mathbf{u}_1 w) = 0, \tag{3.2}$$

where $\mathbf{u}_1(t,\cdot)$ is a globally smooth, $2\pi\tau$-periodic solution of the pressureless equations (2.1a)*. Then $w(t,\cdot)$ is also $2\pi\tau$-periodic.*

Proof. Let $\phi := \nabla \times \mathbf{u}_1 + \tau^{-1}$ denote the so-called relative vorticity. By (2.1a) it satisfies the same equation that w does, namely,

$$\partial_t \phi + \nabla \cdot (\mathbf{u}_1 \phi) = 0.$$

Coupled with (3.2), it is easy to verify that the ratio w/ϕ satisfies a transport equation

$$\big(\partial_t + \mathbf{u}_1 \cdot \nabla\big)\frac{w}{\phi} = 0,$$

which in turn implies that w/ϕ remains constant along the trajectories Γ_0 in (2.2). But (2.1a) tells us that $\mathbf{u}_1{}' = \frac{J}{\tau}\mathbf{u}_1$, yielding $\mathbf{u}_1(t, x(t)) = e^{\frac{t}{\tau}J}\mathbf{u}_0(x_0)$. We integrate to find $x(2\pi\tau) = x(0)$, namely, the trajectories come back to their initial positions at $t = 2\pi\tau$. Therefore

$$\frac{w}{\phi}(2\pi\tau, x_0) = \frac{w}{\phi}(0, x_0) \quad \text{for all } x_0\text{'s}.$$

Since the above argument is time invariant, it implies that $w/\phi(t,\cdot)$ is $2\pi\tau$-periodic. The conclusion follows from the fact that $\mathbf{u}_1(t,\cdot)$ and thus $\phi(t,\cdot)$ are $2\pi\tau$-periodic. ∎

Equipped with this lemma we conclude the following.

THEOREM 3.2. *Consider the mass equation* (3.1) *on a two-dimensional torus, $\mathbb{T}^2$, linearized around the pressureless velocity field $\mathbf{u}_1$ and subject to subcritical initial data $(h_0, \mathbf{u}_0) \in H^m(\mathbb{T}^2)$ with $m > 5$. It admits a globally smooth solution,*

$h_2(t,\cdot) \in H^{m-1}(\mathbb{T}^2)$, which is $2\pi\tau$-periodic in time, and the following upper bounds hold uniformly in time,

$$|h_2(t,\cdot)|_\infty \leq \widehat{C}_0 \left(1 + \frac{\tau}{\sigma}\right), \tag{3.3a}$$

$$\|h_2(t,\cdot)\|_{m-1} \leq C_0 \left(1 + \frac{\tau}{\sigma}\right). \tag{3.3b}$$

Proof. Apply Lemma 3.1 with $w := \sigma^{-1} + h_2$ to (3.1) to conclude that h_2 is also $2\pi\tau$-periodic. We turn to examining the regularity of h_2. First, its L^∞ bound (3.3a) is studied using the L^∞ estimate for scalar transport equations, which yields an inequality for $|h_2|_\infty = |h_2(t,\cdot)|_\infty$,

$$\frac{d}{dt}|h_2|_\infty \leq |\nabla \cdot \mathbf{u}_1|_\infty (\sigma^{-1} + |h_2|_\infty).$$

Combined with the L^∞ estimate of $\nabla \mathbf{u}_1$ in (2.4a), this Gronwall inequality implies

$$|h_2|_\infty \leq e^{\widehat{C}_0 t}|h_0|_\infty + \frac{1}{\sigma}\left(e^{\widehat{C}_0 t} - 1\right).$$

As before, due to the $2\pi\tau$-periodicity of h_2 and the subcritical condition $\tau \leq \tau_c$, we can replace the first t on the right with τ_c, the second t with $2\pi\tau$, and then (3.3a) follows.

For the H^{m-1} estimate (3.3b), we use the energy method and the Gagliardo–Nirenberg inequality to obtain a similar inequality for $|h_2|_{m-1} = |h_2(t,\cdot)|_{m-1}$,

$$\frac{d}{dt}\|h_2\|_{m-1} \lesssim_m |\nabla \mathbf{u}_1|_\infty \|h_2\|_{m-1} + \left(\frac{1}{\sigma} + |h_2|_\infty\right)\|\mathbf{u}_1\|_m.$$

Applying the estimate on $\mathbf{u}_1$ in (2.4) and the L^∞ estimate on h_2 in (3.3a), we find the above inequality shares a similar form as the previous one. Thus the estimate (3.3b) follows by the same periodicity and subcriticality argument as for (3.3a). We note in passing the *linear* dependence of C_0 on $\|(h_0, \mathbf{u}_0)\|_m$. ∎

To continue with the second approximation, we turn to the approximate momentum equation (1.3b) with $j = 2$,

$$\partial_t \mathbf{u}_2 + \mathbf{u}_2 \cdot \nabla \mathbf{u}_2 + \frac{1}{\sigma}\nabla h_2 - \frac{1}{\tau} J \mathbf{u}_2 = 0. \tag{3.4}$$

The following *splitting* approach will lead to a simplified linearization of (3.4) which is "close" to (3.4) and still maintains the nature of our methodology. The idea is to treat the nonlinear term and the pressure term in (3.4) separately, resulting in two systems for $\widetilde{\mathbf{v}} \approx \mathbf{u}_2$ and $\widehat{\mathbf{v}} \approx \mathbf{u}_2$,

$$\partial_t \widetilde{\mathbf{v}} + \widetilde{\mathbf{v}} \nabla \cdot \widetilde{\mathbf{v}} - \frac{1}{\tau} J \widetilde{\mathbf{v}} = 0, \tag{3.5a}$$

$$\partial_t \widehat{\mathbf{v}} + \frac{1}{\sigma}\nabla h_2 - \frac{1}{\tau} J \widehat{\mathbf{v}} = 0, \tag{3.5b}$$

subject to the same initial data $\widetilde{\mathbf{v}}(0,\cdot) = \widehat{\mathbf{v}}(0,\cdot) = \mathbf{u}_0(\cdot)$.

The first system (3.5a), ignoring the pressure term, is identified as the pressureless system (2.1) and therefore is solved as

$$\widetilde{\mathbf{v}} = \mathbf{u}_1,$$

while the second system (3.5b), ignoring the nonlinear advection term, is solved using Duhamel's principle,

$$\begin{aligned}\widehat{\mathbf{v}}(t,\cdot) &= e^{tJ/\tau}\left(\mathbf{u}_0(t,\cdot) - \int_0^t \frac{e^{-sJ/\sigma}}{\sigma}\nabla h_2(s,\cdot)\,ds\right)\\ &\approx e^{tJ/\tau}\left(\mathbf{u}_0(t,\cdot) - \int_0^t \frac{e^{-sJ/\sigma}}{\sigma}\nabla h_2(t,\cdot)\,ds\right)\\ &= e^{tJ/\tau}\mathbf{u}_0(t,\cdot) + \frac{\tau}{\sigma}J(I - e^{tJ/\tau})\nabla h_2(t,\cdot).\end{aligned}$$

Here, we make an approximation by replacing $h_2(s,\cdot)$ with $h_2(t,\cdot)$ in the integrand, which introduces an error of order τ, taking into account the $2\pi\tau$ periodicity of $h(t,\cdot)$.

Now, synthesizing the two solutions listed above, we make a correction to $\widehat{\mathbf{v}}$ by replacing $e^{tJ/\tau}\mathbf{u}_0$ with $\mathbf{u}_1$. This gives the final form of our approximate velocity field $\mathbf{u}_2$ (with tolerable abuse of notations)

$$\mathbf{u}_2 := \mathbf{u}_1 + \frac{\tau}{\sigma}J(I - e^{tJ/\tau})\nabla h_2(t,\cdot). \tag{3.6a}$$

A straightforward computation shows that this velocity field, $\mathbf{u}_2$, satisfies the approximate momentum equation

$$\partial_t \mathbf{u}_2 + \mathbf{u}_1\cdot\nabla\mathbf{u}_2 + \frac{1}{\sigma}\nabla h_2 - \frac{1}{\tau}{\mathbf{u}_2}^{\perp} = R, \tag{3.6b}$$

where

(3.6c)

$$\begin{aligned} R &:= \frac{\tau}{\sigma}J(I - e^{tJ/\tau})(\partial_t + \mathbf{u}_1\cdot\nabla)\nabla h_2(t,\cdot)\\ \text{(by (3.1))}\qquad &= -\frac{\tau}{\sigma}J(I - e^{tJ/\tau})\left[(\nabla\mathbf{u}_1)^\top\nabla h_2 + \nabla\left(\left(\frac{1}{\sigma} + h_2\right)\nabla\cdot\mathbf{u}_1\right)\right].\end{aligned}$$

Combining Theorem 3.2 on $h_2(t,\cdot)$ with the Gagliardo–Nirenberg inequality, we arrive at the following corollary on periodicity and regularity of $\mathbf{u}_2$.

Corollary 3.3. *Consider the velocity field $\mathbf{u}_2$ in* (3.6) *subject to subcritical initial data $(h_0,\mathbf{u}_0)\in H^m(\mathbb{T}^2)$ with $m>5$. Then, $\mathbf{u}_2(t,\cdot)$ is $2\pi\tau$-periodic in time, and the following upper bound, uniformly in time, holds:*

$$\|\mathbf{u}_2 - \mathbf{u}_1\|_{m-2} \le C_0\frac{\tau}{\sigma}\left(1 + \frac{\tau}{\sigma}\right).$$

In particular, since $\|\mathbf{u}_1\|_m \le C_0$ for subcritical τ, we conclude that $\mathbf{u}_2(t,\cdot)$ has the Sobolev regularity,

$$\|\mathbf{u}_2\|_{m-2} \le C_0\left(1 + \frac{\tau}{\sigma} + \frac{\tau^2}{\sigma^2}\right).$$

We close this section by noting that the second iteration led to an approximate RSW system linearized around the pressureless velocity field $\mathbf{u}_1$, (i.e., system (3.1),(3.6)), which governs our improved, $2\pi\tau$-periodic approximation, $(h_2(t,\cdot),\mathbf{u}_2(t,\cdot))\in H^{m-1}(\mathbb{T}^2)\times H^{m-2}(\mathbb{T}^2)$.

4. Long-time existence of approximate periodic solutions.

4.1. The shallow-water equations. How close is $(h_2(t,\cdot),\mathbf{u}_2(t,\cdot))$ to the exact solution $(h(t,\cdot),\mathbf{u}(t,\cdot))$? Below we shall show that their distance, measured in $H^{m-3}(\mathbb{T}^2)$, does not exceed $\frac{e^{C_0 t}\delta}{1-e^{C_0 t}\delta}$. Thus for sufficiently small δ, the RSW solution $(h,\mathbf{u})$ is *"approximate periodic"* which in turn implies its long-time stability. This is the content of our main result.

THEOREM 4.1. *Consider the RSW equations on a fixed two-dimensional torus,*

$$\partial_t h + \mathbf{u}\cdot\nabla h + \left(\frac{1}{\sigma}+h\right)\nabla\cdot\mathbf{u} = 0, \tag{4.1a}$$

$$\partial_t \mathbf{u} + \mathbf{u}\cdot\nabla\mathbf{u} + \frac{1}{\sigma}\nabla h - \frac{1}{\tau}J\mathbf{u} = 0 \tag{4.1b}$$

subject to subcritical initial data $(h_0,\mathbf{u}_0)\in H^m(\mathbb{T}^2)$ with $m>5$ and $\alpha_0 := \min(1+\sigma h_0(\cdot))>0$. Let

$$\delta = \frac{\tau}{\sigma^2}$$

denote the ratio between the Rossby number τ and the squared Froude number σ, with subcritical $\tau \le \tau_c(\nabla\mathbf{u}_0)$ so that (2.1b) holds. Assume $\sigma\le 1$ for a substantial amount of pressure forcing in (4.1b). Then, there exists a constant C_0, depending only on m, τ_c, α_0, and in particular depending linearly on $\|(h_0,\mathbf{u}_0)\|_m$, such that the RSW equations admit a smooth, "approximate periodic" solution in the sense that there exists a nearby $2\pi\tau$-periodic solution, $(h_2(t,\cdot),\mathbf{u}_2(t,\cdot))$, such that

$$\|p(t,\cdot)-p_2(t,\cdot)\|_{m-3} + \|\mathbf{u}(t,\cdot)-\mathbf{u}_2(t,\cdot)\|_{m-3} \le \frac{e^{C_0 t}\delta}{1-e^{C_0 t}\delta}. \tag{4.2}$$

Here p is the "normalized height" such that $1+\frac{1}{2}\sigma p = \sqrt{1+\sigma h}$, and correspondingly, p_2 satisfies $1+\frac{1}{2}\sigma p_2 = \sqrt{1+\sigma h_2}$.

It follows that the lifespan of the RSW solution $t \lesssim t_\delta := \ln(\delta^{-1})$ is prolonged due to the rapid rotation $\delta \ll 1$, and in particular, it tends to infinity when $\delta\to 0$.

Proof. We compare the solution of the RSW system (4.1a), (4.1b) with the solution $(h_2,\mathbf{u}_2)$ of approximate RSW system (3.1), (3.6). To this end, we rewrite the latter in the equivalent form,

(4.3a)

$$\partial_t h_2 + \mathbf{u}_2\cdot\nabla h_2 + \left(\frac{1}{\sigma}+h_2\right)\nabla\cdot\mathbf{u}_2 = (\mathbf{u}_2-\mathbf{u}_1)\cdot\nabla h_2 + \left(\frac{1}{\sigma}+h_2\right)\nabla\cdot(\mathbf{u}_2-\mathbf{u}_1),$$

(4.3b)

$$\partial_t \mathbf{u}_2 + \mathbf{u}_2\cdot\nabla\mathbf{u}_2 + \frac{1}{\sigma}\nabla h_2 - \frac{1}{\tau}J\mathbf{u}_2 = (\mathbf{u}_2-\mathbf{u}_1)\cdot\nabla\mathbf{u}_2 + R.$$

The approximate system differs from the exact one, (4.1a), (4.1b), in the residuals on the RHS of (4.3a), (4.3b). We will show that they have an amplitude of order δ. In particular, the comparison in the rotationally dominant regime, $\delta \ll 1$, leads to a long-time existence of a smooth RSW solution, which remains "nearby" the time-periodic solution, $(h_2,\mathbf{u}_2)$. To show that $(h_2,\mathbf{u}_2)$ is indeed an approximate solution for the RSW equations, we proceed as follows.

We first symmetrize both systems so that we can employ the standard energy method for nonlinear hyperbolic systems. To this end, we set the new variable ("normalized height") p such that $1+\frac{1}{2}\sigma p=\sqrt{1+\sigma h}$. Compressing notation with $\mathbf{U}:=(p,\mathbf{u})^\top$, we transform (4.1a), (4.1b) into the *symmetric hyperbolic* quasi-linear system

$$\partial_t\mathbf{U}+B(\mathbf{U},\nabla\mathbf{U})+K[\mathbf{U}]=0. \tag{4.4}$$

Here $B(\mathbf{F},\nabla\mathbf{G}):=A_1(\mathbf{F})\mathbf{G}_x+A_2(\mathbf{F})\mathbf{G}_y$, where A_1,A_2 are bounded linear functions with values being symmetric matrices, and $K[\mathbf{F}]$ is a skew-symmetric linear operator so that $\langle K[\mathbf{F}],\mathbf{F}\rangle=0$. By standard energy arguments, (see, e.g., [12, 13, 15]), the symmetric form of (4.4) yields an exact RSW solution $\mathbf{U}$, which stays smooth for finite time $t\lesssim 1$. The essence of our main theorem is that for small δ's, rotation *prolongs* the lifespan of classical solutions up to $t\sim\mathcal{O}(\ln\delta^{-1})$. To this end, we symmetrize the approximate system (4.3a), (4.3b) using a new variable p_2 such that $1+\frac{1}{2}\sigma p_2=\sqrt{1+\sigma h_2}$. Compressing notation with $\mathbf{U_2}:=(p_2,\mathbf{u}_2)^\top$, we have

$$\partial_t\mathbf{U_2}+B(\mathbf{U_2},\nabla\mathbf{U_2})+K(\mathbf{U_2})=\mathbf{R}, \tag{4.5}$$

where the residual $\mathbf{R}$ is given by

$$\mathbf{R}:=\left[\begin{array}{lll}(\mathbf{u}_2-\mathbf{u}_1)\cdot\nabla p_2 & + & \left(\frac{2}{\sigma}+p_2\right)\nabla\cdot(\mathbf{u}_2-\mathbf{u}_1)\\ (\mathbf{u}_2-\mathbf{u}_1)\cdot\nabla\mathbf{u}_2 & - & R\end{array}\right],$$

with R defined as in (3.6c). We will show $\mathbf{R}$ is small which in turn, using the symmetry of (4.4) and (4.5), will imply that $\|\mathbf{U}-\mathbf{U_2}\|_{m-3}$ is equally small. Indeed, thanks to the fact that $H^{m-3}(\mathbb{T}^2)$ is an algebra for $m>5$, every term in the above expression is upper-bounded in H^{m-3}, by the quadratic products of the terms $\|\mathbf{u}_1\|_m,\|p_2\|_{m-1},\|\mathbf{u}_2\|_{m-2},\|\mathbf{u}_2-\mathbf{u}_1\|_{m-2}$, up to a factor of $\mathcal{O}(1+\frac{1}{\sigma})$. The Sobolev regularity of these terms, $\mathbf{u}_1,\mathbf{u}_2$, and p_2, is guaranteed, respectively, in Corollary 2.2, Corollary 3.3, and Theorem 3.2. Moreover, the nonvacuum condition, $1+\sigma h_0\geq\alpha_0>0$, implies that $1+\sigma h_2$ remains uniformly bounded from below, and by standard arguments (carried out in the appendix), $\|p_2\|_{m-2}\leq C_0(1+\tau/\sigma)$. Summing up, the residual $\mathbf{R}$ does not exceed,

$$\|\mathbf{R}\|_{m-3}\leq C_0^2\left(\delta+\frac{\tau}{\sigma}+\cdots+\frac{\tau^4}{\sigma^4}\right)\lesssim C_0^2\delta \tag{4.6}$$

for subcritical $\tau\in(0,\tau_c)$ and under scaling assumptions $\delta<1$, $\sigma<1$.

We now claim that the same $\mathcal{O}(\delta)$-upperbound holds for the error $\mathbf{E}:=\mathbf{U_2}-\mathbf{U}$, for a long time, $t\lesssim t_\delta$. Indeed, subtracting (4.4) from (4.5), we find the error equation

$$\partial_t\mathbf{E}+B(\mathbf{E},\nabla\mathbf{E})+K[\mathbf{E}]=-B(\mathbf{U_2},\nabla\mathbf{E})-B(\mathbf{E},\nabla\mathbf{U_2})+\mathbf{R}.$$

By the standard energy method using integration by parts and Sobolev inequalities, while utilizing the symmetric structure of B and the skew-symmetry of K, we arrive at

$$\frac{d}{dt}\|\mathbf{E}\|_{m-3}^2\lesssim_m\|\mathbf{E}\|_{m-3}^3+\|\mathbf{U_2}\|_{m-2}\|\mathbf{E}\|_{m-3}^2+\|\mathbf{R}\|_{m-3}\|\mathbf{E}\|_{m-3}.$$

Using the regularity estimates of $\mathbf{U_2}=(p_2,\mathbf{u}_2)^\top$ and the upper bounds on $\mathbf{R}$ in (4.6), we end up with an energy inequality for $\|\mathbf{E}(t,\cdot)\|_{m-3}$,

$$\frac{d}{dt}\|\mathbf{E}\|_{m-3}\lesssim_m\|\mathbf{E}\|_{m-3}^2+C_0\|\mathbf{E}\|_{m-3}+C_0^2\delta,\quad\|\mathbf{E}(0,\cdot)\|_{m-3}=0.$$

A straightforward integration of this forced Riccati equation (consult, for example, [16, section 5]) shows that the error $\|\mathbf{E}\|_{m-3}$ does not exceed

$$\|\mathbf{U}(t,\cdot)-\mathbf{U_2}(t,\cdot)\|_{m-3} \leq \frac{e^{C_0 t}\delta}{1-e^{C_0 t}\delta}. \tag{4.7}$$

In particular, the RSW equations admits an "approximate periodic" $H^{m-3}(\mathbb{T}^2)$-smooth solution for $t \leq \frac{1}{C_0}\ln(\delta^{-1})$ for $\delta \ll 1$. $\square$

Remark 4.1. The estimate on the actual height function h follows by applying the Gagliardo–Nirenberg inequality to $h-h_2 = p(1+\frac{\sigma}{4}p)-p_2(1+\frac{\sigma}{4}p_2) = (p-p_2)(1+\frac{\sigma}{4}(p-p_2)+\frac{\sigma}{2}p_2)$,

$$\|h(t,\cdot)-h_2(t,\cdot)\|_{m-3} \lesssim \frac{e^{C_0 t}\delta}{(1-e^{C_0 t}\delta)^2}.$$

Our result is closely related to observations of near inertial oscillations (NIOs) in oceanography (see, e.g., [22]). These NIOs are mostly seen after a storm blows over the oceans. They exhibit almost periodic dynamics with a period consistent with the Coriolis force and stay stable for about 20 days, which is a long-time scale relative to many oceanic processes such as the storm itself. This observation agrees with our theoretical result regarding the stability and periodicity of RSW solutions. In terms of physical scales, our rotationally dominant condition, $\delta = \frac{gH}{fLU} \ll 1$, provides a physical characterization of this phenomenon. Indeed, NIOs are triggered when storms pass by (large U) and only a thin layer of the oceans is reactive (small aspect ratio H/L). Upon using the multilayer model ([18, section 6.16]), we consider scales $f = 10^{-4}s^{-1}, L = 10^5 m, H = 10^2 m, U = 1ms^{-1}, g = 0.01ms^{-2}$ (reduced gravity due to density stratification—consult [18, section 1.3]). With this parameter setting $\delta = 0.1$, and Theorem 4.1 implies the existence of a smooth, approximate periodic solution over a time scale of $\ln(\delta^{-1})L/U \approx 2$ days. We note in passing that most cyclonic storms on the Northern Hemisphere rotate clockwise, yielding a negative vorticity, $\omega_0 = \partial_y u_0 - \partial_x v_0 < 0$, which is a preferred scenario of the subcritical condition (2.1b) assumed in Theorem 4.1.

4.2. The isentropic gasdynamics. In this section we extend Theorem 4.1 to rotational two-dimensional Euler equations for isentropic gas,

$$\partial_t \rho + \nabla\cdot(\rho\mathbf{u}) = 0, \tag{4.8a}$$

$$\partial_t \mathbf{u} + \mathbf{u}\cdot\nabla\mathbf{u} + \rho^{-1}\nabla\widetilde{p}(\rho) - f\mathbf{u}^{\perp} = 0. \tag{4.8b}$$

Here, $\mathbf{u} := (u^{(1)}, u^{(2)})^{\top}$ is the velocity field, ρ is the density, and $\widetilde{p} = \widetilde{p}(\rho)$ is the pressure, which for simplicity is taken to be that of a polytropic gas, given by the γ-power law,

$$\widetilde{p}(\rho) = A\rho^{\gamma}. \tag{4.8c}$$

The particular case $A = g/2, \gamma = 2$ corresponds to the RSW equations (1.1a), (1.1b). The following argument for long term existence of the two-dimensional rapidly rotating isentropic equations applies, with minor modifications, to the more general pressure laws, $\widetilde{p}(\rho)$, which induce the hyperbolicity of (4.8a).

We first transform the isentropic Euler equations (4.8a) into their nondimensional form,

$$\partial_t \rho + \mathbf{u} \cdot \nabla \rho + \left(\frac{1}{\sigma} + \rho \right) \nabla \cdot \mathbf{u} = 0,$$
$$\partial_t \mathbf{u} + \mathbf{u} \cdot \nabla \mathbf{u} + \frac{1}{\sigma^2} \nabla (1 + \sigma\rho)^{\gamma - 1} - \frac{1}{\tau} J\mathbf{u} = 0,$$

where the Mach number σ plays the same role as the Froude number in the RSW equation. In order to utilize the technique developed in the previous section, we introduce a new variable h by setting $1+\sigma h = (1+\sigma\rho)^{\gamma-1}$, so that the new variables, $(h, \mathbf{u})$, satisfy

$$\partial_t h + \mathbf{u} \cdot \nabla h + (\gamma - 1) \left(\frac{1}{\sigma} + h \right) \nabla \cdot \mathbf{u} = 0, \tag{4.9a}$$

$$\partial_t \mathbf{u} + \mathbf{u} \cdot \nabla \mathbf{u} + \frac{1}{\sigma} \nabla h - \frac{1}{\tau} J\mathbf{u} = 0. \tag{4.9b}$$

This is an analogue to the RSW equations (4.1a), (4.1b), except for the additional factor $(\gamma - 1)$ in the mass equation (4.9a). We can therefore duplicate the steps which led to Theorem 4.1 to obtain a long-time existence for the rotational Euler equations (4.9a), (4.9b). We proceed as follows.

An approximate solution is constructed in two steps. First, we use the $2\pi\tau$-periodic pressureless solution ($h_1 \equiv$ constant, $\mathbf{u}_1(t, \cdot)$) for subcritical initial data $(h_0, \mathbf{u}_0)$. Second, we construct a $2\pi\tau$-periodic solution $(h_2(t, \cdot), \mathbf{u}_2(t\cdot))$ as the solution to an approximate system of the isentropic equations, *linearized* around the pressureless velocity $\mathbf{u}_1$,

$$\partial_t h_2 + \mathbf{u}_1 \cdot \nabla h_2 + (\gamma - 1) \left(\frac{1}{\sigma} + h_2 \right) \nabla \cdot \mathbf{u}_1 = 0,$$
$$\mathbf{u}_2 := \mathbf{u}_1 + \frac{\tau}{\sigma} J \left(I - e^{tJ/\tau} \right) \nabla h_2(t, \cdot).$$

In the final step, we compare $(h, \mathbf{u})$ with the $2\pi\tau$-periodic approximate solution, $(h_2, \mathbf{u}_2)$. To this end, we symmetrize the corresponding systems using $\mathbf{U} = (p, \mathbf{u})^\top$ with the normalized density function p satisfying $1+\frac{1}{2}\sqrt{\frac{1}{\gamma-1}}\sigma p = \sqrt{1+\sigma h}$. Similarly, the approximate system is symmetrized with the variables $\mathbf{U_2} = (p_2, \mathbf{u}_2)$, where $1+\frac{1}{2}\sqrt{\frac{1}{\gamma-1}}\sigma p_2 = \sqrt{1+\sigma h_2}$. We conclude with the following.

THEOREM 4.2. *Consider the rotational isentropic equations on a fixed two-dimensional torus,* (4.9a), (4.9a)*, subject to subcritical initial data* $(\rho_0, \mathbf{u}_0) \in H^m(\mathbb{T}^2)$ *with* $m > 5$ *and* $\alpha_0 := \min(1 + \sigma\rho_0(\cdot)) > 0$.
Let

$$\delta = \frac{\tau}{\sigma^2}$$

denote the ratio between the Rossby and the squared Mach numbers, with subcritical $\tau \le \tau_c(\nabla \mathbf{u}_0)$ *so that* (2.1b) *holds. Assume* $\sigma < 1$ *for a substantial amount of pressure in* (4.9a)*. Then, there exists a constant* C_0*, depending only on* m, $\|(\rho_0, \mathbf{u}_0)\|_m$, τ_c*, and* α_0 *such that the RSW equations admit a smooth, "approximate periodic" solution in the sense that there exists a nearby* $2\pi\tau$*-periodic solution* $(\rho_2(t, \cdot), \mathbf{u}_2(t, \cdot))$ *such that*

$$\|p(t, \cdot) - p_2(t, \cdot)\|_{m-3} + \|\mathbf{u}(t, \cdot) - \mathbf{u}_2(t, \cdot)\|_{m-3} \le \frac{e^{C_0 t}\delta}{1 - e^{C_0 t}\delta}. \tag{4.10}$$

Here, p is the normalized density function satisfying $1+\sigma p = (1+\sigma\rho)^{\frac{\gamma-1}{2}}$, and p_2 results from the same normalization for ρ_2.

It follows that the lifespan of the isentropic solution $t \lesssim t_\delta := 1+\ln(\delta^{-1})$ is prolonged due to the rapid rotation $\delta \ll 1$, and in particular, it tends to infinity when $\delta \to 0$.

Remark 4.2. For the actual density functions, $\rho - \rho_2 = \frac{1}{\sigma}[(1+\sigma p)^{\frac{2}{\gamma-1}} - (1+\sigma p_2)^{\frac{2}{\gamma-1}}] = \int_0^1 C_\gamma [1+\sigma(\theta(p-p_2)+p_2)]^{\frac{2}{\gamma}-1}\, d\theta$,

$$\|\rho(t,\cdot) - \rho_2(t,\cdot)\|_{m-3} \lesssim \frac{e^{C_0 t}\delta}{(1-e^{C_0 t}\delta)^{\frac{2}{\gamma-1}}},$$

in the physically relevant regime $\gamma \in (1,3)$.

4.3. The ideal gasdynamics. We turn our attention to the full Euler equations in the two-dimensional torus,

$$\begin{gathered}\partial_t \rho + \nabla\cdot(\rho\mathbf{u}) = 0,\\ \partial_t \mathbf{u} + \mathbf{u}\cdot\nabla\mathbf{u} + \rho^{-1}\nabla\widetilde{p}(\rho,S) = fJ\mathbf{u},\\ \partial_t S + \mathbf{u}\cdot\nabla S = 0,\end{gathered}$$

where the pressure law is given as a function of the density, ρ and the specific entropy S, $\widetilde{p}(\rho,S) := \rho^\gamma e^S$. It can be symmetrized by defining a new variable—the "normalized" pressure function,

$$p := \frac{\sqrt{\gamma}}{\gamma-1}\widetilde{p}^{\frac{\gamma-1}{2\gamma}},$$

and by replacing the density equation (4.11a) by a (normalized) pressure equation, so that the above system is recast into an equivalent and symmetric form (see, e.g., [12, 11])

$$\begin{gathered}e^S\partial_t p + e^S\mathbf{u}\cdot\nabla p + C_\gamma e^S p\nabla\cdot\mathbf{u} = 0,\\ \partial_t\mathbf{u} + \mathbf{u}\cdot\nabla\mathbf{u} + C_\gamma e^S p\nabla p = fJu, \qquad C_\gamma := \frac{\gamma-1}{2},\\ \partial_t S + \mathbf{u}\cdot\nabla S = 0.\end{gathered}$$

It is the exponential function, e^S, involved in *triple* products such as $e^S p\nabla p$, that makes the ideal gas system a nontrivial generalization of the RSW and isentropic gas equations.

We then proceed to the nondimensional form by substitution,

$$\mathbf{u} \to \mathrm{U}u', \quad p \to \mathrm{P}(1+\sigma p'), \quad S = \ln(p\rho^{-\gamma}) \to \ln(\mathrm{P}\mathrm{R}^{-\gamma}) + \sigma S'.$$

After discarding all the primes, we arrive at a nondimensional system

$$e^{\sigma S}\partial_t p + e^{\sigma S}\mathbf{u}\cdot\nabla p + C_\gamma\left(\frac{e^{\sigma S}-1}{\sigma} + e^{\sigma S}p\right)\nabla\cdot\mathbf{u} = -C_\gamma\frac{1}{\sigma}\nabla\cdot\mathbf{u}, \tag{4.11a}$$

$$\partial_t\mathbf{u} + \mathbf{u}\cdot\nabla\mathbf{u} + C_\gamma\left(\frac{e^{\sigma S}-1}{\sigma} + e^{\sigma S}p\right)\nabla p = -C_\gamma\frac{1}{\sigma}\nabla p + \frac{1}{\tau}Ju, \tag{4.11b}$$

$$\partial_t S + \mathbf{u}\cdot\nabla S = 0, \tag{4.11c}$$

where σ and τ are, respectively, the Mach and the Rossby numbers. With abbreviated notation, $\mathbf{U} := (p, \mathbf{u}, S)^\top$, the equations above amount to a symmetric hyperbolic system written in the compact form,

$$A_0(S)\partial_t \mathbf{U} + A_1(\mathbf{U})\partial_x \mathbf{U} + A_2(\mathbf{U})\partial_y \mathbf{U} = K[\mathbf{U}]. \tag{4.12}$$

Here, $A_i (i = 0, 1, 2)$ are symmetric-matrix-valued functions, *nonlinear* in $\mathbf{U}$, and in particular, A_0 is always positive definite. The linear operator K is skew-symmetric so that $\langle K[\mathbf{U}], \mathbf{U}\rangle = 0$.

Two successive approximations are then constructed based on the iterations (1.3), starting with $j = 1$,

$$\begin{aligned} p_1 &\equiv \text{constant}, \\ \partial_t \mathbf{u}_1 + \mathbf{u}_1 \cdot \nabla \mathbf{u}_1 &= \frac{1}{\tau} J \mathbf{u}_1, \\ S_1 &\equiv \text{constant}. \end{aligned}$$

Identified as the pressureless solution, $\mathbf{u}_1$ is used to linearize the system, resulting in the following approximation:

$$\partial_t p_2 + \mathbf{u}_1 \cdot \nabla p_2 + C_\gamma p_2 \nabla \cdot \mathbf{u}_2 = -C_\gamma \frac{1}{\sigma} \nabla \cdot \mathbf{u}_2, \tag{4.13a}$$

$$\mathbf{u}_2 - \mathbf{u}_1 = \frac{\tau}{\sigma} J(I - e^{tJ/\tau}) C_\gamma e^{\sigma S_2}(1 + \sigma p_2)\nabla p_2, \tag{4.13b}$$

$$\partial_t S_2 + \mathbf{u}_1 \cdot \nabla S_2 = 0. \tag{4.13c}$$

The $2\pi\tau$-periodicity and global regularity of $\mathbf{U}_2 := (p_2, \mathbf{u}_2, S_2)^\top$ follow along the same lines outlined for the RSW equations in section 3 (and therefore omitted), together with the following nonlinear estimate for $e^{\sigma S}$:

$$\|e^{\sigma S} - 1\|_m = \left\| \sum_{j=1}^{\infty} \frac{(\sigma S)^j}{j!} \right\|_m \lesssim_m \sum_{j=1}^{\infty} \frac{(C_m |\sigma S|_\infty)^{j-1}}{j!} \|\sigma S\|_m = \frac{e^{C_m|\sigma S|_\infty} - 1}{C_m |\sigma S|_\infty} \|\sigma S\|_m;$$

for the latter, we apply recursively the Gagliardo–Nirenberg inequality to typical terms $\|(\sigma S)^j\|_m$. Notice the entropy variables (both the exact and approximate ones) satisfy a transport equation and therefore are conserved along particle trajectories, which implies that the L^∞ norm of the entropy variable is an invariant. Thus we arrive at an estimate

$$\|e^{\sigma S} - 1\|_m \leq \sigma \widehat{C}_0 \|S\|_m. \tag{4.14}$$

Of course, the same type of estimate holds for the approximate entropy, S_2.

Finally, we subtract the approximate system (4.13) from the exact system (4.12), arriving at an error equation for $\mathbf{E} := \mathbf{U} - \mathbf{U}_2$ that shares the same form as the RSW system in section 4.1, except that $A_i(\mathbf{U}) - A_i(\mathbf{U}_2) \neq A_i(\mathbf{U} - \mathbf{U}_2)$ due to nonlinearity, which is essentially quadratic in the sense that [1]

$$\begin{aligned} \|A_i(\mathbf{U}) - A_i(\mathbf{U}_2)\|_n &\lesssim \|\mathbf{U} - \mathbf{U}_2\|_n^2 + \|\mathbf{U} - \mathbf{U}_2\|_n, \qquad i = 0, 1, 2, \\ A_i(\mathbf{U}) - A_i(\mathbf{U}_2)\|_{W^{1,\infty}} &\lesssim \|\mathbf{U} - \mathbf{U}_2\|_{W^{1,\infty}}^2 + \|\mathbf{U} - \mathbf{U}_2\|_{W^{1,\infty}}, \qquad i = 0, 1, 2. \end{aligned}$$

[1] Consider a typical term of A_i, e.g., $e^{\sigma S} p$. Applying (4.14) together with the Gagliardo–Nirenberg inequality to $e^{\sigma S} - e^{\sigma S_2} = e^{\sigma S_2}(e^{\sigma(S - S_2) - 1})$, we can show $\|e^{\sigma S} - e^{\sigma S_2}\|_n \lesssim \|S - S_2\|_n$. The estimate on $\|e^{\sigma S} p - e^{\sigma S_2} p_2\|_n$ then follows by applying identity $ab - a_2 b_2 = (a - a_2)(b - b_2) + (a - a_2) b_2 + a_2(b - b_2)$ together with the triangle inequality and the Gagliardo–Nirenberg inequality. Here regularity of S_2 and p_2 is a priori known.

where $n > 2$. This additional nonlinearity manifests itself as three more multiplications in the energy inequality,

$$\frac{d}{dt}\|\mathbf{E}\|_{m-3} \lesssim \|\mathbf{E}\|_{m-3}^5 + \cdots + \|\mathbf{E}\|_{m-3} + \delta, \qquad \|\mathbf{E}(0,\cdot)\|_{m-3} = 0,$$

whose solution (developed around a simple root of the quintic polynomial on the right) has the same asymptotic behavior as for the quadratic Riccati equations derived in the previous sections.

THEOREM 4.3. *Consider the (symmetrized) rotational Euler equations on a fixed two-dimensional torus* (4.11) *subject to subcritical initial data* $(p_0, \mathbf{u}_0, S_0) \in H^m(\mathbb{T}^2)$ *with* $m > 5$. *Let*

$$\delta = \frac{\tau}{\sigma^2}$$

denote the ratio between the Rossby and the squared Mach numbers, with subcritical $\tau \le \tau_c(\nabla \mathbf{u}_0)$ *so that* (2.1b) *holds. Assume* $\sigma < 1$ *for a substantial amount of pressure forcing in* (4.11b). *Then, there exists a constant* C, *depending only on* m, $\|(p_0, \mathbf{u}_0, S_0)\|_m$, τ_c, *such that the ideal gas equations admit a smooth, "approximate periodic" solution in the sense that there exists a nearby* $2\pi\tau$*-periodic solution,* $(p_2(t,\cdot), \mathbf{u}_2(t,\cdot), S_2(t,\cdot))$ *such that*

(4.15)

$$\|p(t,\cdot) - p_2(t,\cdot)\|_{m-3} + \|\mathbf{u}(t,\cdot) - \mathbf{u}_2(t,\cdot)\|_{m-3} + \|S(t,\cdot) - S_2(t,\cdot)\|_{m-3} \le \frac{e^{C_0 t}\delta}{1 - e^{C_0 t}\delta}.$$

It follows that the lifespan of the ideal gas solution, $t \lesssim t_\delta := \ln(\delta^{-1})$, *is prolonged due to the rapid rotation* $\delta \ll 1$, *and in particular, it tends to infinity when* $\delta \to 0$.

5. Appendix. Staying away from vacuum. We will show the following proposition on the new variable p_2 defined in section 4.1.

PROPOSITION 5.1. *Let* p_2 *satisfy*

$$1 + \frac{1}{2}\sigma p_2 = \sqrt{1 + \sigma h_2}, \tag{5.1}$$

where h_2 *is defined as in* (3.1), *that is,*

$$\partial_t h_2 + \mathbf{u}_1 \cdot \nabla h_2 + \left(\frac{1}{\sigma} + h_2\right) \nabla \cdot \mathbf{u}_1 = 0 \tag{5.2}$$

subject to initial data $h_2(0,\cdot) = h_0(\cdot)$ *that satisfies the nonvacuum condition* $1 + \sigma h_0(\cdot) \ge \alpha_0 > 0$. *Then,*

$$|p_2|_\infty \le \widehat{C}_0 \left(1 + \frac{\tau}{\sigma}\right),$$

$$\|p_2\|_n \le C_0 \left(1 + \frac{\tau}{\sigma}\right).$$

The proof of this proposition follows in two steps. First, we show that the L^∞ and H^n norms of $p_2(0,\cdot)$ are dominated by $h_2(0,\cdot)$ due to the nonvacuum condition. Second, we derive the equation for p_2 and obtain regularity estimates using similar techniques from section 4.1.

Step 1. For simplicity, we use $p := p_2(0,\cdot)$ and $h := h_2(0,\cdot)$.
Differentiation of (5.1) yields

$$p = \frac{2h}{\sqrt{1+\sigma h}+1}, \quad \nabla p = \frac{\nabla h}{\sqrt{1+\sigma h}}.$$

Clearly, $|p|_\infty \le |h|_\infty$. The above identities, together with the nonvacuum condition, imply

$$\|p\|_1 \le 2\|h\|_1 \quad \text{and} \quad |\nabla p|_{L^\infty} \le \frac{|\nabla h|_{L^\infty}}{\sqrt{\alpha_0}}.$$

For higher derivatives of p, we use the following recursive relation. Rewrite (5.1) as $p + \frac{1}{4}\sigma p^2 = h$ and then take the kth derivative on both sides,

$$D^k p + \frac{1}{4}\sigma 2pD^k p + \frac{1}{4}\sigma\left(D^k(q^2) - 2pD^k p\right) = D^k h$$

so that taking the L^2 norm of this equation yields

$$I - II := \left\|\left(1+\frac{1}{2}\sigma p\right)D^k p\right\|_0 - \frac{1}{4}\sigma\left\|D^k(q^2) - 2pD^k p\right\|_0 \le \|D^k h\|_0.$$

Furthermore, we find $I \ge \sqrt{\alpha_0}\|D^k p\|_0$ by (5.1) and the nonvacuum condition. We also find $II \lesssim_n |\nabla p|_\infty \|p\|_{|k|-1}$ by the Gagliardo–Nirenberg inequalities. Thus we arrive at a recursive relation

$$\|p\|_{|k|} \le \widehat{C}_0(\|p\|_{|k|-1} + \|h\|_{|k|}),$$

which implies that the H^n norm of $p_2(0,\cdot) = p$ is dominated by $\|h_2(0,\cdot)\|_n = \|h\|_n$.

Step 2. We derive an equation for p_2 using relation (5.1) and equation (5.2),

$$\partial_t p_2 + 2\mathbf{u}_1\cdot\nabla p_2 + \left(\frac{1}{\sigma} + p_2\right)\nabla\cdot\mathbf{u}_1 = 0.$$

This equation resembles the formality of the approximate mass equation (3.1) for h_2, and thus we apply a similar technique to arrive at the same regularity estimate for p_2,

$$|p_2(t,\cdot)|_\infty \le \widehat{C}_0\left(1+\frac{\tau}{\sigma}\right),$$
$$\|p_2(t,\cdot)\|_n \le C_0\left(1+\frac{\tau}{\sigma}\right).$$

ON SOME PROPERTIES OF TRAVELING WATER WAVES WITH VORTICITY*

EUGEN VARVARUCA†

Abstract. We prove that for a large class of vorticity functions the crests of any corresponding traveling gravity water wave of finite depth are necessarily points of maximal horizontal velocity. We also show that for waves with nonpositive vorticity the pressure everywhere in the fluid is larger than the atmospheric pressure. A related a priori estimate for waves with nonnegative vorticity is also given.

Key words. water waves, vorticity, maximum principle

DOI. 10.1137/070697513

1. Introduction.

In this article we consider the classical hydrodynamical problem concerning traveling two-dimensional gravity water waves with vorticity. This problem has attracted considerable interest in recent years, starting with the systematic study of Constantin and Strauss [8] on periodic waves of finite depth.

The problem arises from the following physical situation. A wave of permanent form moves with constant speed on the surface of an incompressible flow, the bottom of the flow domain being horizontal. With respect to a frame of reference moving with the speed of the wave, the flow is steady and occupies a fixed region Ω in the upper half of the (x, y)-plane, which lies between the real axis $\mathcal{B} := \{(x, 0) : x \in \mathbb{R}\}$ and some a priori unknown free surface $\mathcal{S} := \{(x, \eta(x)) : x \in \mathbb{R}\}$, where η is a periodic function. Since the fluid is incompressible, the flow can be described by a (relative) stream function ψ which is periodic in the horizontal direction and satisfies the following equations and boundary conditions:

$$\Delta\psi = -\gamma(\psi) \quad \text{in } \Omega, \tag{1.1a}$$

$$\psi = B \quad \text{on } \mathcal{B}, \tag{1.1b}$$

$$\psi = 0 \quad \text{on } \mathcal{S}, \tag{1.1c}$$

$$|\nabla\psi|^2 + 2gy = Q \quad \text{on } \mathcal{S}, \tag{1.1d}$$

$$\psi_y < 0 \quad \text{in } \Omega, \tag{1.1e}$$

where B, g, and Q are positive constants. Equation (1.1a) involves a vorticity function $\gamma : [0, B] \to \mathbb{R}$ and expresses the fact that the vorticity of the flow $\omega := -\Delta\psi$ and the stream function ψ are functionally dependent. Equations (1.1b) and (1.1c) mean that the bottom and the free surface are streamlines, while (1.1d) means that the pressure at the surface of the flow is a constant. The relative velocity of the fluid particles is given by $(\psi_y, -\psi_x)$. The requirement (1.1e) means that the horizontal velocity of each fluid particle is smaller than the speed of the wave and is motivated both by field observations and by laboratory experiments; see [8] for references. It is customary [8]

to assume that the constants g, B and the vorticity function γ are given. The problem consists in determining the curves $\mathcal{S}$ for which there exists a function ψ in Ω which satisfies (1.1a)–(1.1e) for some value of the parameter Q. For a full justification of the equivalence between the problem of seeking solution triples $(\mathcal{S}, \psi, Q)$ of (1.1) and that of seeking traveling-wave solutions of the two-dimensional Euler equations, the reader is referred to [8].

When $\gamma \equiv 0$, the corresponding flow is called irrotational. Nowadays the mathematical theory dealing with this situation contains a wealth of results, mostly obtained during the last three decades, concerning the existence of large-amplitude solutions and their properties. Global bifurcation theories were given for various types of waves (periodic or solitary of finite depth; periodic of infinite depth) by Keady and Norbury [14] and by Amick and Toland [1, 2]. Moreover, it was shown by Toland [20] and McLeod [16] that in the closure of these continua of solutions there exist waves with stagnation points at their crests, a stagnation point being one at which the relative fluid velocity is zero, i.e., $|\nabla\psi| = 0$. The existence of such waves, called "extreme waves," was predicted by Stokes [18], who also conjectured that their profiles necessarily have corners with included angle of 120° at the crests. This conjecture was proved independently by Amick, Fraenkel, and Toland [3] and by Plotnikov [17]. Recently, the method of [3] was simplified and extended in [22].

On the other hand, when $\gamma \not\equiv 0$, the flow is called rotational or with vorticity, and significant advances in the corresponding mathematical theory have been made only in the last few years. The existence of global continua of smooth solutions was proved by Constantin and Strauss [8] for the periodic finite depth problem, and by Hur [13] for the related problem of periodic waves of infinite depth. For the solutions found in [8, 13] the wave profiles have exactly one crest and one trough per minimal period, are monotone between crests and troughs, and have a vertical axis of symmetry. (The symmetry assumption is in fact not a restriction since, for any vorticity function, any wave profile with the above monotonicity properties is necessarily symmetric [5, 11].) Of particular significance is the fact that the continuum of solutions found in [8] contains waves for which the values of $\max_{\overline{\Omega}} \psi_y$ are arbitrarily close to 0. Thus it is natural to expect that, as in the irrotational case, waves with stagnation points, referred to above as "extreme waves," exist for many vorticity functions, and that they can be obtained as limits, in a suitable sense, of certain sequences of regular waves found in [8]. In the case of constant vorticity, numerical evidence [15, 19] strongly points to the existence of extreme waves for any negative vorticity and for small positive vorticity, and also indicates that, for large positive vorticity, continua of solutions bifurcating from a line of trivial solutions develop into overhanging profiles (a situation which is not possible in the irrotational case; see [23] for references) and do not approach extreme waves. Further references to numerical investigations of waves with vorticity can be found in [15].

One of the questions addressed in this article concerns the location of the points at which the maximum over $\overline{\Omega}$ of the relative horizontal velocity ψ_y is attained for smooth waves with vorticity. In the irrotational case, the crests of the wave are the only such points; see Toland [21]. Very recently, Constantin and Strauss [9, Theorem 4.1] showed that this is also the case for the waves in the continuum in [8] under the assumption that γ is a nonpositive constant which satisfies a smallness condition involving B and g. Here we prove, with a novel approach, a slightly weaker result under substantially more general assumptions. Namely, for wave profiles with finitely many local extrema on a period, if the vorticity function γ satisfies $\gamma \leq 0$ and $\gamma' \geq 0$ everywhere on $[0, B]$, then any point of maximal relative horizontal velocity must lie on the free surface and the crests are necessarily such points. An immediate consequence of this result is that, whenever $\gamma \leq 0$ and $\gamma' \geq 0$, the continuum of solutions in [8] contains waves for which the values of $|\nabla\psi|$ at their crests are arbitrarily close to 0. Thus in this case the existence of waves with stagnation points at their crests is to be particularly expected.

Another contribution of this article is that we establish some new a priori bounds for waves corresponding to vorticity functions γ which do not change sign, without any assumptions on γ'. When $\gamma \leq 0$, the estimate in question means that the pressure everywhere in the fluid is larger than the atmospheric pressure. This estimate is the main ingredient in the proof of the previously mentioned result concerning the location of the points where $\max_{\overline{\Omega}} \psi_y$ is attained. When $\gamma \geq 0$, a slightly different, but related, estimate is given. Both these estimates play an essential role in the investigation in [24] concerning the existence of extreme waves with vorticity and the Stokes conjecture.

The proofs here are based on simple applications of the maximum principle [12, Chapters 2 and 3]. Analogous results to those of this article hold in the case of periodic rotational waves of infinite depth. They will be presented, together with some applications, in a subsequent article.

Of the many other directions in which the theory of traveling gravity water waves, with or without vorticity, has seen recent progress and is currently being further developed, we mention here only a few: variational formulations [7], stability [10], and properties of the fluid particle trajectories [4, 6].

2. The main results. We always deal with classical solutions of (1.1), in the sense that $\gamma \in C^1([0,B])$, $\eta \in C^3(\mathbb{R})$, $\psi \in C^3(\overline{\Omega})$. We assume that η is a periodic function of minimal period $2L$, and that ψ is $2L$-periodic in the horizontal direction. However, we do not assume that η has exactly one local maximum and one local minimum per minimal period.

Let $\hat{\Gamma} : [0,B] \to \mathbb{R}$ be given by

$$\hat{\Gamma}(s) = \int_0^s \gamma(t)\,dt \quad \text{for all } s \in [0,B]. \tag{2.1}$$

(Note that in [8] a function Γ is considered which is related to $\hat{\Gamma}$ by $\hat{\Gamma}(s) = -\Gamma(-s)$. The quantity of interest both here and there is $\hat{\Gamma}(\psi)$, which is denoted there by $-\Gamma(-\psi)$; we find our notation more convenient.) Let us also consider the function $R : \overline{\Omega} \to \mathbb{R}$ given by

$$R = \frac{1}{2}|\nabla\psi|^2 + gy - \frac{1}{2}Q + \hat{\Gamma}(\psi). \tag{2.2}$$

The function R is (up to a constant) the negative of the pressure in the fluid domain; see [8].

Our next result shows that when γ is everywhere nonpositive the pressure in the fluid domain is larger than the atmospheric pressure.

Theorem 2.1. *Suppose that $\gamma(s) \leq 0$ for all $s \in [0,B]$. Then $R \leq 0$ in $\overline{\Omega}$.*

Remark 2.2. Under the much more restrictive assumptions that

$$\gamma \leq 0, \quad \gamma' \leq 0 \quad \text{and} \quad -\psi_y(x,0)\gamma(B) \geq -g \text{ for all } x \in \mathbb{R},$$

the conclusion of Theorem 2.1 was previously obtained in [9, Example 3.1].

The importance of the inequality $R \le 0$ in $\overline{\Omega}$ in relation to the monotonicity of ψ_y along the free surface $\mathcal{S}$ was first recognized for waves with vorticity by Constantin and Strauss [9, Proposition 3.4]. We give here a slightly more general statement of their result and a somewhat more direct proof.

THEOREM 2.3. *Let $\eta : \mathbb{R} \to \mathbb{R}$ be such that there exists $N \in \mathbb{N}$ and points $x_0 < x_1 < \cdots < x_{2N} = x_0 + 2L$ with the property that $\eta'(x_j) = 0$ for all $j \in \{0, \ldots, 2N\}$, η is strictly increasing on $[x_{2j}, x_{2j+1}]$ for all $j \in \{0, \ldots, N-1\}$, and η is strictly decreasing on $[x_{2j-1}, x_{2j}]$ for all $j \in \{1, \ldots, N\}$. Suppose that $R \le 0$ in $\overline{\Omega}$. Then the function $x \mapsto \psi_y(x, \eta(x))$ is increasing on $[x_{2j}, x_{2j+1}]$ for all $j \in \{0, \ldots, N-1\}$ and decreasing on $[x_{2j-1}, x_{2j}]$ for all $j \in \{1, \ldots, N\}$. Therefore, $\max_{\mathcal{S}} \psi_y$ is attained at the points of maximal height on $\mathcal{S}$.*

The preceding result leads with little effort to one concerning the location of the points where $\max_{\overline{\Omega}} \psi_y$ is attained.

THEOREM 2.4. *Let $\eta : \mathbb{R} \to \mathbb{R}$ be as in Theorem 2.3. Suppose that $\gamma(s) \le 0$ and $\gamma'(s) \ge 0$ for all $s \in [0, B]$. Then any point at which $\max_{\overline{\Omega}} \psi_y$ is attained lies on $\mathcal{S}$, and the crests of the wave are necessarily such points.*

Remark 2.5. For a more restrictive class of wave profiles and under the assumption that γ is a nonpositive constant which satisfies

$$g^2 \ge 2g(-2B\gamma^3)^{1/2} - 2B\gamma^3,$$

Constantin and Strauss [9, Theorem 4.1] proved that the crests of the wave are the only points at which $\max_{\overline{\Omega}} \psi_y$ is attained. This slightly stronger conclusion does not seem to be readily obtainable by the methods used in the proof of Theorem 2.4.

The next result gives a new estimate in the case when γ is everywhere nonnegative, which is in the same spirit as that of Theorem 2.1. Let us consider the function $T : \overline{\Omega} \to \mathbb{R}$ given by

$$T := R - \varpi\psi, \tag{2.3}$$

where R is given by (2.2) and

$$\varpi := \frac{1}{2} \max_{s \in [0,B]} \gamma(s). \tag{2.4}$$

THEOREM 2.6. *Suppose that $\gamma(s) \ge 0$ for all $s \in [0, B]$. Then $T \le 0$ in $\overline{\Omega}$.*

3. Proofs of the main results. A simple calculation shows that, everywhere in $\overline{\Omega}$,

$$R_x = \psi_y\psi_{xy} - \psi_x\psi_{yy}, \tag{3.1a}$$
$$R_y = \psi_x\psi_{xy} - \psi_y\psi_{xx} + g, \tag{3.1b}$$

and

$$\Delta R = 2\psi_{xy}^2 - 2\psi_{xx}\psi_{yy}. \tag{3.2}$$

Proof of Theorem 2.1. Note that $R = 0$ everywhere on the free surface $\mathcal{S}$. We claim that the maximum of R over $\overline{\Omega}$ must be attained on $\mathcal{S}$.

Observe first that, since $R_y = g > 0$ everywhere on the bottom $\mathcal{B}$, $\max_{\overline{\Omega}} R$ cannot be attained anywhere on $\mathcal{B}$.

Suppose now that $\max_{\overline{\Omega}} R$ is attained at some point A in Ω. Then necessarily

$$R_x(A) = 0, \quad R_y(A) = 0, \quad \Delta R(A) \leq 0.$$

It follows from this, (3.1), and (3.2) that

$$\psi_y(A)\psi_{xy}(A) = \psi_x(A)\psi_{yy}(A), \tag{3.3a}$$

$$\psi_x(A)\psi_{xy}(A) < \psi_y(A)\psi_{xx}(A), \tag{3.3b}$$

$$\psi_{xy}^2(A) \leq \psi_{xx}(A)\psi_{yy}(A). \tag{3.3c}$$

Since (1.1e) holds, it follows that $\psi_y(A) < 0$. We now distinguish two cases, depending on whether or not $\psi_{yy}(A) = 0$.

If $\psi_{yy}(A) = 0$, then (3.3a) implies that $\psi_{xy}(A) = 0$. It then follows from (3.3b) that $\psi_{xx}(A) < 0$, and hence $\gamma(\psi(A)) = -\Delta\psi(A) > 0$, which contradicts the assumption that $\gamma(s) \leq 0$ for all $s \in [0, B]$.

If $\psi_{yy}(A) \neq 0$, then it follows from (3.3a) and (3.3b) that

$$\frac{\psi_y(A)\psi_{xy}^2(A)}{\psi_{yy}(A)} < \psi_y(A)\psi_{xx}(A).$$

It then follows from this and (3.3c) that $\psi_{yy}(A) < 0$. We now deduce from (3.3c) that $\psi_{xx}(A) \leq 0$, and therefore $\gamma(\psi(A)) = -\Delta\psi(A) > 0$, which again contradicts the assumption that $\gamma(s) \leq 0$ for all $s \in [0, B]$.

We conclude that the maximum of R over $\overline{\Omega}$ must be attained on $\mathcal{S}$, which implies that $R \leq 0$ in $\overline{\Omega}$. This completes the proof of Theorem 2.1. □

Proof of Theorem 2.3. The proof is based on a remarkable, though straightforward to verify, identity observed by Toland [21] in the irrotational case and by Constantin and Strauss [9] in the general case:

$$\frac{d}{dx}\left[\frac{1}{2}\psi_y^2(x, \eta(x))\right] = R_x(x, \eta(x)) \quad \text{for all } x \in \mathbb{R}. \tag{3.4}$$

Since $R \leq 0$ in $\overline{\Omega}$ and $R = 0$ on $\mathcal{S}$, the required result concerning the monotonicity of $x \mapsto \psi_y(x, \eta(x))$ is immediate from (3.4). It follows that

$$\max_{\mathcal{S}} \psi_y = \max_{j \in \{0,\dots,N-1\}} \psi_y(x_{2j+1}, \eta(x_{2j+1})). \tag{3.5}$$

But for every $j \in \{0, \dots, 2N\}$, $\psi_x(x_j, \eta(x_j)) = 0$ and therefore

$$\psi_y(x_j, \eta(x_j)) = -(Q - 2g\eta(x_j))^{1/2}.$$

Hence $\max_{\mathcal{S}} \psi_y$ is attained at the points of maximal height on $\mathcal{S}$. This completes the proof of Theorem 2.3. □

Proof of Theorem 2.4. It follows from (1.1a) that

$$\Delta\psi_y = -\gamma'(\psi)\psi_y \quad \text{in } \Omega.$$

Since $\psi_y < 0$ in Ω and $\gamma'(s) \geq 0$ for all $s \in [0, B]$, it follows immediately from the maximum principle that $\max_{\overline{\Omega}} \psi_y$ cannot be attained anywhere in Ω.

We now show that $\max_{\overline{\Omega}} \psi_y$ cannot be attained anywhere on $\mathcal{B}$ either. This is trivial when $\gamma(B) < 0$, since then $\psi_{yy} = -\gamma(B) > 0$ everywhere on $\mathcal{B}$. When

$\gamma(B) = 0$, we use a reflection argument. Let $\tilde{\gamma} : [0, 2B] \to \mathbb{R}$ be an extension of γ such that $\tilde{\gamma}(s) = -\gamma(2B - s)$ for all $s \in (B, 2B]$. Let Ω^R be the reflection of Ω into $\mathcal{B}$,

$$\widetilde{\Omega} := \Omega \cup \mathcal{B} \cup \Omega^R,$$

and $\tilde{\psi} : \widetilde{\Omega} \to \mathbb{R}$ be an extension of ψ such that $\tilde{\psi}(x, y) = 2B - \psi(x, -y)$ for all $(x, y) \in \Omega^R$. Then it is easily checked that $\tilde{\gamma} \in C^1([0, 2B])$, $\tilde{\psi} \in C^3(\widetilde{\Omega})$ and

$$\Delta\tilde{\psi} = -\tilde{\gamma}(\tilde{\psi}) \quad \text{in } \widetilde{\Omega}.$$

Since $\tilde{\psi}_y < 0$ in $\widetilde{\Omega}$ and $\tilde{\gamma}'(s) \geq 0$ for all $s \in [0, 2B]$, the maximum principle yields the required result.

We conclude that $\max_{\overline{\Omega}} \psi_y$ can only be attained on $\mathcal{S}$. Next note that, since $\gamma(s) \leq 0$ for all $s \in [0, B]$, Theorem 2.1 shows that $R \leq 0$ in $\overline{\Omega}$. An application of Theorem 2.3 now yields that $\max_{\overline{\Omega}} \psi_y$ is attained at the crests of the wave. This completes the proof of Theorem 2.4. ∎

Proof of Theorem 2.6. Note first that $T_y = g - \varpi\psi_y > 0$ everywhere on $\mathcal{B}$, so that the maximum of T over $\overline{\Omega}$ cannot be attained anywhere on $\mathcal{B}$.

Next note from (3.2) that

$$\Delta R \geq -\frac{1}{2}\gamma^2(\psi) \quad \text{in } \Omega.$$

Since

$$\Delta T = \Delta R + \varpi\gamma(\psi),$$

it is immediate, upon using (2.4) and the assumption that $\gamma(s) \geq 0$ for all $s \in [0, B]$, that T is a subharmonic function in Ω. Therefore, the maximum of T over $\overline{\Omega}$ cannot be attained anywhere in Ω.

We conclude that $\max_{\overline{\Omega}} T$ must be attained somewhere on $\mathcal{S}$. Since $T = 0$ everywhere on $\mathcal{S}$, it follows that $T \leq 0$ in $\overline{\Omega}$. This completes the proof of Theorem 2.6. ∎

Acknowledgments. I am grateful to John Toland and Markus Lilli for many useful discussions, and to the anonymous referees for suggestions which helped improve the presentation.

EXISTENCE AND UNIQUENESS OF SOLUTIONS TO A NONLOCAL EQUATION WITH MONOSTABLE NONLINEARITY*

JÉRÔME COVILLE†, JUAN DÁVILA‡, AND SALOMÉ MARTÍNEZ‡

Abstract. Let $J \in C(\mathbb{R})$, $J \geq 0$, $\int_{\mathbb{R}} J = 1$ and consider the nonlocal diffusion operator $\mathcal{M}[u] = J \star u - u$. We study the equation $\mathcal{M}u + f(x, u) = 0$, $u \geq 0$, in $\mathbb{R}$, where f is a KPP-type nonlinearity, periodic in x. We show that the principal eigenvalue of the linearization around zero is well defined and that a nontrivial solution of the nonlinear problem exists if and only if this eigenvalue is negative. We prove that if, additionally, J is symmetric, then the nontrivial solution is unique.

Key words. nonlocal dispersal, monostable, existence and uniqueness, convolution operator

1. Introduction.

Reaction-diffusion equations have been used to describe a variety of phenomena in combustion theory, bacterial growth, nerve propagation, epidemiology, and spatial ecology [13, 12, 15, 19]. However, in many situations, such as in population ecology, dispersal is better described as a long range process rather than as a local one, and integral operators appear as a natural choice. Let us mention in particular the seminal work of Kolmogorov, Petrovsky, and Piskunov [16], who in 1937 introduced a model for the dispersion of gene fractions involving a nonlocal linear operator and a nonlinearity of the form $u(1-u)$, which many authors now call a KPP-type nonlinearity.

Nonlocal dispersal operators usually take the form $\mathcal{M}[u] = \int_{\mathbb{R}^N} k(x, y)u(y)dy - u(x)$, where $k \geq 0$ and $\int_{\mathbb{R}^N} k(y, x)dy = 1$ for all $x \in \mathbb{R}^N$. They have been mainly used in discrete time models [17], while continuous time versions have also been recently considered in population dynamics [14, 18]. Steady state and travelling wave solutions for single equations have been studied in the case $k(x, y) = J(x - y)$, with J even, for some specific reaction nonlinearities in [1, 10, 8, 2, 6, 21].

In this work we restrict ourselves to one dimension and take

$$k(x, y) = J(x - y).$$

We are interested in the existence/nonexistence and uniqueness of solutions of the following problem:

$$\mathcal{M}[u] + f(x, u) = 0 \quad \text{in } \mathbb{R}, \tag{1.1}$$

where $f(x, u)$ is a KPP-type nonlinearity, periodic in x, and

$$\mathcal{M}[u] := J \star u - u. \tag{1.2}$$

We assume that J satisfies

$$J \in C(\mathbb{R}), \quad J \geq 0, \quad \int_{\mathbb{R}} J = 1, \tag{1.3}$$

$$\text{there exist } a < 0 < b \text{ such that } J(a) > 0,\ J(b) > 0. \tag{1.4}$$

On f we assume that

$$\begin{cases} f \in C(\mathbb{R} \times [0,\infty)) \text{ and is differentiable with respect to } u, \\ \text{for each } u,\ f(\cdot,u) \text{ is periodic with period } 2R, \\ f_u(\cdot,0) \text{ is Lipschitz}, \\ f(\cdot,0) \equiv 0 \text{ and } f(x,u)/u \text{ is decreasing with respect to } u, \\ \text{there exists } M > 0 \text{ such that } f(x,u) \leq 0 \text{ for all } u \geq M \text{ and all } x. \end{cases} \tag{1.5}$$

The model example of such a nonlinearity is

$$f(x,u) = u(a(x) - u),$$

where $a(x)$ is periodic and Lipschitz.

In a recent work, Berestycki, Hamel, and Roques [2] studied the analogue of (1.1) with a divergence operator in a periodic setting. More precisely, they considered

$$-\nabla \cdot (A(x)\nabla u) = f(x,u), \quad x \in \mathbb{R}^N, \quad u \geq 0, \tag{1.6}$$

where $A(x)$ is a symmetric matrix of class $C^{1,\alpha}$, periodic with respect to all variables and uniformly elliptic, and f is C^1 and satisfies (1.5). They showed existence of nontrivial solutions provided the linearization of the equation around zero has a negative first periodic eigenvalue.

We prove the following result.

THEOREM 1.1. *Assume J satisfies* (1.3), (1.4) *and f satisfies* (1.5). *Then there exists a nontrivial, periodic solution of* (1.1) *if and only if*

$$\lambda_1(\mathcal{M} + f_u(x,0)) < 0,$$

where λ_1 is the principal eigenvalue of the linear operator $-(\mathcal{M} + f_u(x,0))$ in the set of $2R$-periodic continuous functions. Moreover, if $\lambda_1 \geq 0$, then any nonnegative bounded solution is identically zero.

To prove Theorem 1.1, we first need to show that the principal periodic eigenvalue of $-(\mathcal{M} + f_u(x,0))$ is well defined. Let us introduce some notation:

$$C_{per}(\mathbb{R}) = \{u : \mathbb{R} \to \mathbb{R} \mid u \text{ is continuous and } 2R\text{-periodic}\},$$

$$C^{0,1}_{per}(\mathbb{R}) = \{u : \mathbb{R} \to \mathbb{R} \mid u \text{ is Lipschitz and } 2R\text{-periodic}\}.$$

THEOREM 1.2. *Suppose $a(x) \in C^{0,1}_{per}(\mathbb{R})$. Then the operator $-(\mathcal{M} + a(x))$ has a unique principal eigenvalue λ_1 in $C_{per}(\mathbb{R})$; that is, there is a unique $\lambda_1 \in \mathbb{R}$ such that*

$$\mathcal{M}[\phi_1] + a(x)\phi_1 = -\lambda_1\phi_1 \quad \text{in } \mathbb{R} \tag{1.7}$$

admits a positive solution $\phi_1 \in C_{per}(\mathbb{R})$. Moreover, λ_1 is simple, that is, the space of $C_{per}(\mathbb{R})$ solutions to (1.7) *is one dimensional.*

In [2] the authors proved that (1.6) has at most one nontrivial bounded solution, and that it has to be periodic. A similar result is true for the nonlocal problem (1.1), but this time we need J to be symmetric, that is,

$$J(x) = J(-x) \quad \text{for all } x \in \mathbb{R}. \tag{1.8}$$

Note, however, that for the existence result, Theorem 1.1, we do not need this condition.

THEOREM 1.3. *Assume J satisfies* (1.3), (1.4), (1.8) *and f satisfies* (1.5). *Let u be a nonnegative, bounded solution to* (1.1) *and let λ_1 be the principal eigenvalue of the operator $-(\mathcal{M} + f_u(x, 0))$ with periodic boundary conditions.*

(a) *If $\lambda_1 < 0$, then either $u \equiv 0$ or $u \equiv p$, where p is the positive periodic solution of Theorem* 1.1.

(b) *If $\lambda_1 \geq 0$, then $u \equiv 0$.*

Part (b) of the preceding theorem is already covered in Theorem 1.1 and does not depend on the symmetry of J.

When f is independent of x and satisfies (1.5), the principal eigenvalue of $-(\mathcal{M} + f'(0))$ is given by $\lambda_1 = -f'(0)$ and ϕ_1 is just a constant. Thus in this case Theorem 1.1 says that a bounded, nonnegative, nontrivial solution exists if and only if $f'(0) > 0$, and this solution is just the constant u_0 such that $f(u_0) = 0$. Assuming that J is symmetric, Theorem 1.3 then implies that the constant u_0 is the unique solution in the class of nonnegative, bounded functions.

Recently, considering a nonperiodic nonlinearity f, Berestycki, Hamel, and Rossi [3] analyzed the analogue of Theorem 1.3 for general elliptic operators in $\mathbb{R}^N$, finding sufficient conditions that ensure existence and uniqueness of a positive bounded solution. It is natural to ask whether the periodicity of f and the symmetry of J are crucial hypotheses in Theorem 1.3. We believe that this is the case, since a general nonlocal operator such as (1.2) may contain a transport term, and a standing wave connecting the steady states of the system could appear. We shall investigate further this issue in a forthcoming work.

Hypothesis (1.4) implies that the operator $\mathcal{M}$ satisfies the strong maximum principle. Suppose, for instance, that J satisfies (1.3), (1.4). If $u \in C(\mathbb{R})$ satisfies $\mathcal{M}[u] \geq 0$ in $\mathbb{R}$, then u cannot achieve a global maximum without being constant (see [9]). However, we will need the following version.

THEOREM 1.4. *Assume J satisfies* (1.3), (1.4) *and let $c \in L^\infty(\mathbb{R})$. If $u \in L^\infty(\mathbb{R})$ satisfies $u \leq 0$ a.e. and $\mathcal{M}[u] + c(x)u \geq 0$ a.e. in $\mathbb{R}$, then $\operatorname{ess\,sup}_K u < 0$ for all compact $K \subset \mathbb{R}$ or $u = 0$ a.e. in $\mathbb{R}$.*

If f satisfies the stronger hypothesis that, for any x, $f(x, u)$ is concave with respect to u, then actually the periodic solution p of Theorem 1.1 is continuous. To see this notice that from the strong maximum principle, Theorem 1.4, $J \star p > 0$ in $\mathbb{R}$. The concavity of f with respect to u implies that for any x the map $u \mapsto u - f(x, u)$ is strictly increasing whenever $u - f(x, u) > 0$. Then from the continuity of $J \star p$ and (1.1), which can be rewritten as in the form $J \star p = p - f(x, p)$, we deduce that p is continuous.

In section 2 we review some spectral theory and give the argument of Theorem 1.2. Then we prove Theorem 1.1 in section 3 and the uniqueness result, Theorem 1.3(a), in section 4. We leave for an appendix a proof of Theorem 1.4.

2. Some spectral theory. In this section we deal with the principal eigenvalue problem (1.7). Before stating our result, let us recall some basic spectral results for positive operators due to Edmunds, Potter, and Stuart [11] which are extensions of the Krein–Rutmann theorem for positive noncompact operators.

A cone in a real Banach space X is a nonempty closed set K such that for all $x, y \in K$ and all $\alpha \geq 0$ one has $x + \alpha y \in K$, and if $x \in K$, $-x \in K$, then $x = 0$. A cone K is called reproducing if $X = K - K$. A cone K induces a partial ordering in X by the relation $x \leq y$ if and only if $x - y \in K$. A linear map or operator $T : X \to X$ is called positive if $T(K) \subseteq K$. The dual cone K^* is the set of functionals $x^* \in X^*$ which are positive, that is, such that $x^*(K) \subset [0, \infty)$.

If $T : X \to X$ is a bounded linear map on a complex Banach space X, its essential spectrum (according to Browder [5]) consists of those λ in the spectrum of T such that at least one of the following conditions holds: (1) the range of $\lambda I - T$ is not closed, (2) λ is a limit point of the spectrum of T, (3) $\cup_{n=1}^{\infty} \ker((\lambda I - T)^n)$ is infinite dimensional. The radius of the essential spectrum of T, denoted by $r_e(T)$, is the largest value of $|\lambda|$ with λ in the essential spectrum of T. For more properties of $r_e(T)$ see [20].

Theorem 2.1 (Edmunds, Potter, and Stuart [11]). *Let K be a reproducing cone in a real Banach space X, and let $T \in \mathcal{L}(X)$ be a positive operator such that $T^p(u) \geq cu$ for some $u \in K$ with $\|u\| = 1$, some positive integer p, and some positive number c. Then if $c^{\frac{1}{p}} > r_e(T)$, T has an eigenvector $v \in K$ with associated eigenvalue $\rho \geq c^{\frac{1}{p}}$ and T^* has an eigenvector $v^* \in K^*$ corresponding to the eigenvalue ρ.*

A proof of this theorem can be found in [11]. If the cone K has nonempty interior and T is strongly positive, i.e., $u \geq 0$, $u \neq 0$ implies $Tu \in \operatorname{int}(K)$, then ρ is the unique $\lambda \in \mathbb{R}$ for which there exists nontrivial $v \in K$ such that $Tv = \lambda v$ and ρ is simple; see [22].

Proof of Theorem 1.2. For convenience, in this proof we write the eigenvalue problem

$$\mathcal{M}[u] + a(x)u = -\lambda u$$

in the form

$$\mathcal{L}[u] + b(x)u = \mu u, \tag{2.1}$$

where

$$\mathcal{L}[u] = J \star u, \quad b(x) = a(x) + k, \quad \mu = -\lambda + 1 + k,$$

and $k > 0$ is a constant such that $\inf_{[-R,R]} b > 0$.

Observe that $\mathcal{L} : C_{per(\mathbb{R})} \to C_{per}(\mathbb{R})$ is compact ($C_{per}(\mathbb{R})$ is endowed with the norm $\|u\|_{L^\infty([-R,R])}$). Indeed, let $u_n \in C_{per}(\mathbb{R})$ be a bounded sequence, say $\|u_n\|_{L^\infty([-R,R])} \leq B$. Let $\epsilon > 0$ and let A be large enough so that $\int_{|x| \geq A} J \leq \epsilon$. Since J is uniformly continuous in $[-R - 2A, R + 2A]$ there is $\delta > 0$ such that $|J(z_1) - J(z_2)| \leq \frac{\epsilon}{2(A+R)}$ for $z_1, z_2 \in [-R - 2A, R + 2A]$ with $|z_1 - z_2| \leq \delta$. Then for $x_1, x_2 \in [-R, R]$,

$$\begin{aligned}
|\mathcal{L}[u_n](x_1) - \mathcal{L}[u_n](x_2)| &\leq \int_{\mathbb{R}} |J(x_1 - y) - J(x_2 - y)| \, |u_n(y)| \, dy \\
&\leq 2B\epsilon + B \int_{-R-A}^{R+A} |J(x_1 - y) - J(x_2 - y)| \, dy \\
&\leq 3B\epsilon.
\end{aligned}$$

This shows that $\mathcal{L}[u_n]$ is equicontinuous, and therefore by the Arzelà–Ascoli theorem, $\mathcal{L}[u_n]$ is relatively compact.

Let us now establish some useful lemma.

LEMMA 2.2. *Suppose $b(x) \in C^{0,1}(\mathbb{R})$ is $2R$-periodic, $b(x) > 0$, and let $\sigma := \max_{[-R,R]} b(x)$. Then there exist $p \in \mathbb{N}, \delta > 0$, and $u \in C_{per}(\mathbb{R})$, $u \geq 0$, $u \not\equiv 0$, such that*

$$\mathcal{L}^p u + b(x)^p u \geq (\sigma^p + \delta)u.$$

Observe that the proof of Theorem 1.2 will then easily follow from the above lemma. Indeed, if the lemma holds, then since u and b are nonnegative and $\mathcal{L}$ is a positive operator, we easily see that

$$(\mathcal{L} + b(x))^p[u] \geq \mathcal{L}^p[u] + b(x)^p u \geq (\sigma^p + \delta)u.$$

Using the compactness of the operator $\mathcal{L}$, we have $r_e(\mathcal{L} + b(x)) = r_e(b(x))=\sigma$, and thus $(\sigma^p + \delta)^{\frac{1}{p}} > r_e(\mathcal{L} + b(x))$ and Theorem 2.1 applies. Finally, we observe that the principal eigenvalue is simple since the cone of positive $2R$-periodic functions has nonempty interior and, for a sufficiently large p, the operator $(\mathcal{L} + b)^p$ is strongly positive. $\square$

Let us now turn our attention to the proof of the above lemma.

Proof of Lemma 2.2. Recall that for $p \in \mathbb{N} \setminus \{0\}$, $J \star^p u := J \star (J \star^{p-1} u)$ is well defined by induction and satisfies $J \star^p u = \mathcal{J}_p \star u$ with $\mathcal{J}_p$ defined as follows:

$$\mathcal{J}_p := \underbrace{J \star J \star \cdots \star J \star J}_{p \text{ times}}.$$

By (1.4) it follows that there exists $p \in \mathbb{N}$ such that $\inf_{(-2R-1,2R+1)} \mathcal{J}_p > 0$. Using the definition of $\mathcal{L}$, a short computation shows that

$$\mathcal{L}^p[u] := \int_{-R}^{R} \widetilde{\mathcal{J}}_p(x,y)u(y)\,dy$$

with $\widetilde{\mathcal{J}}_p(x,y) = \sum_{k\in\mathbb{Z}} \mathcal{J}_p(x + 2kR - y)$. Following the idea of Hutson et al. [14], consider now the following function:

$$v(x) := \begin{cases} \frac{\eta(x)}{b^p(x_0)-b^p(x)+\gamma} & \text{in } \Omega_{2\epsilon} := (x_0 - 2\epsilon, x_0 + 2\epsilon), \\ 0 & \text{elsewhere,} \end{cases}$$

where $x_0 \in (-R,R)$ is a point of maximum of $b(x)$, $\epsilon > 0$ is chosen such that $(x_0 - 2\epsilon, x_0 + 2\epsilon) \subset (-R,R)$, γ is a positive constant that we will define later on, and η is a smooth function such that $0 \leq \eta \leq 1$, $\eta(x) = 1$ for $|x - x_0| \leq \epsilon$, $\eta(x) = 0$ for $|x - x_0| \geq 2\epsilon$. Let us compute $\mathcal{L}^p[v] + b^p(x)v - \sigma^p v$:

$$\begin{aligned} \mathcal{L}^p[v] + b^p(x)v - \sigma^p v &= \int_{x_0-\epsilon}^{x_0+\epsilon} \widetilde{\mathcal{J}}_p(x,y)\frac{dy}{b^p(x_0) - b^p(y) + \gamma} + \int_{\Omega_{2\epsilon}\setminus\Omega_\epsilon} \widetilde{\mathcal{J}}_p(x,y)v(y)\,dy \\ &\quad + (b^p(x) - b^p(x_0))v \\ &\geq \int_{x_0-\epsilon}^{x_0+\epsilon} \widetilde{\mathcal{J}}_p(x,y)\frac{dy}{b^p(x_0) - b^p(y) + \gamma} + (b^p(x) - b^p(x_0))v \\ &\geq \int_{x_0-\epsilon}^{x_0+\epsilon} \widetilde{\mathcal{J}}_p(x,y)\frac{dy}{b^p(x_0) - b^p(y) + \gamma} - 1. \end{aligned}$$

Using that $\inf_{(-2R-1,2R+1)} \mathcal{J}_p > 0$, it follows that $\widetilde{\mathcal{J}}_p(x,y) \geq c > 0$ for $x, y \in (-R,R)$. Hence

$$\int_{x_0-\epsilon}^{x_0+\epsilon} \widetilde{\mathcal{J}}_p(x,y) \frac{dy}{b^p(x_0)-b^p(y)+\gamma} \geq c \int_{x_0-\epsilon}^{x_0+\epsilon} \frac{dy}{k|x_0-y|+\gamma},$$

where k is the Lipschitz constant for b^p. Using this inequality in the above estimate yields

$$\mathcal{L}^p[v] + b^p(x)v - \sigma^p v \geq c \int_{x_0-\epsilon}^{x_0+\epsilon} \frac{dy}{k|x_0-y|+\gamma} - 1.$$

Therefore we have

$$\begin{aligned}\mathcal{L}^p[v] + b^p(x)v - (\sigma^p+\delta)v &\geq \frac{2c}{k}\log\left(1+\frac{k\epsilon}{\gamma}\right) - 1 - \delta v \\ &\geq \frac{2c}{k}\log\left(1+\frac{k\epsilon}{\gamma}\right) - 1 - \frac{\delta}{\gamma}.\end{aligned}$$

Choosing now $\gamma > 0$ small so that $\frac{2c}{k}\log(1+\frac{k\epsilon}{\gamma}) - 1 > \frac{1}{2}$ and $\delta = \frac{\gamma}{4}$, we end up with

$$\mathcal{L}^p[v] + b^p(x)v - (\sigma^p+\delta)v \geq \frac{1}{4} > 0. \qquad \square$$

3. Existence of solutions.

Proof of Theorem 1.1. We follow the argument developed by Berestycki, Hamel, and Roques in [2].

First assume that $\lambda_1 < 0$. From Theorem 1.2 there exists a positive eigenfunction ϕ_1 such that

$$\mathcal{M}[\phi_1] + f_u(x,0)\phi_1 = -\lambda_1\phi_1 \geq 0.$$

Computing $\mathcal{M}[\epsilon\phi_1] + f(x,\epsilon\phi_1)$, it follows that

$$\begin{aligned}\mathcal{M}[\epsilon\phi_1] + f(x,\epsilon\phi_1) &= f(x,\epsilon\phi_1) - f_u(x,0)\epsilon\phi_1 - \lambda_1\epsilon\phi_1 \\ &= -\lambda_1\epsilon\phi_1 + o(\epsilon\phi_1) > 0.\end{aligned}$$

Therefore, for $\epsilon > 0$ small, $\epsilon\phi_1$ is a periodic subsolution of (1.1). By definition of f, any constant M sufficiently large is a periodic supersolution of the problem. Choosing M so large that $\epsilon\phi_1 \leq M$ and using a basic iterative scheme yields the existence of a positive periodic solution u of (1.1).

Let us now turn our attention to the nonexistence setting and assume that $\lambda_1 \geq 0$. Let u be a bounded nonnegative solution of (1.1). Observe that $\gamma\phi_1$ is a periodic supersolution for any positive γ. Indeed,

$$\begin{aligned}\mathcal{M}[\gamma\phi_1] + f(x,\gamma\phi_1) &< \mathcal{M}[\gamma\phi_1] + f_u(x,0)\gamma\phi_1 \\ &\leq -\lambda_1\gamma\phi_1 \leq 0.\end{aligned}$$

Since $\phi_1 \geq \delta$ for some positive δ we may define the following quantity:

$$\gamma^* := \inf\{\gamma > 0 | u \leq \gamma\phi_1\}.$$

We have the following claim.

CLAIM 3.1. $\gamma^* = 0$.

Observe that we end the proof of the theorem by proving the above claim.

Proof of the claim. Assume that $\gamma^* > 0$. Since $v := u - \gamma^*\phi_1$ satisfies $v \le 0$ in $\mathbb{R}$ and

$$\mathcal{M}[v] + c(x)v \ge 0 \quad \text{in } \mathbb{R},$$

where $c(x) = \frac{f(x,u)-f(x,\gamma^*\phi_1)}{v}$ by the strong maximum principle, Theorem 1.4, we have the following possibilities:

- either $u \equiv \gamma^*\phi_1$, or
- there exists a sequence of points $(x_n)_{n\in\mathbb{N}}$ such that $|x_n| \to +\infty$ and $\lim_{n\to+\infty} \gamma^*\phi_1(x_n) - u(x_n) = 0$.

In the first case we get the following contradiction:

$$0 = \mathcal{M}[\gamma^*\phi_1] + f(x, \gamma^*\phi_1) < \mathcal{M}[\gamma^*\phi_1] + f_u(x,0)\gamma^*\phi_1 \le 0.$$

Hence $\gamma^* = 0$.

In the second case we argue as follows. Let $(y_n)_{n\in\mathbb{N}}$ be a sequence of points satisfying, for all n, $y_n \in [-R, R]$ and $x_n - y_n \in 2R\mathbb{Z}$. Up to extraction of a subsequence, $y_n \to \bar{y}$. Now consider the following sequence of functions $u_n := u(. + x_n)$, $\phi_n := \phi_1(. + x_n)$, and $w_n := \gamma^*\phi_n - u_n$ so that $w_n > 0$ in $\mathbb{R}$. Since $\mathcal{M}$ is translation invariant and f is periodic, u_n and $\phi_n > 0$ satisfy

$$\mathcal{M}[u_n] + f(x + y_n, u_n) = 0 \quad \text{in } \mathbb{R},$$

$$\mathcal{M}[\gamma^*\phi_n] + f_u(x + y_n, 0)\gamma^*\phi_n \le 0 \quad \text{in } \mathbb{R}.$$

It follows that

$$J \star w_n \le a_n(x)w_n,$$

where

$$a_n(x) = 1 - \frac{\gamma^* f_u(x + y_n, 0)\phi_n - f(x + y_n, u_n)}{\gamma^*\phi_n - u_n}.$$

Since $w_n > 0$ we see that a_n is well defined and $a_n \ge 0$. Using that $f(x,u)/u$ is nonincreasing with respect to u we have $f(x, \gamma^*\phi_n) \le \gamma^* f_u(x,0)\phi_n$. This implies

$$\frac{\gamma^* f_u(x + y_n, 0)\phi_n - f(x + y_n, u_n)}{\gamma^*\phi_n - u_n} \ge \frac{f(x + y_n, \gamma^*\phi_n) - f(x + y_n, u_n)}{\gamma^*\phi_n - u_n} \ge -C.$$

Thus

$$0 \le a_n \le C + 1 \quad \text{in } \mathbb{R} \quad \text{for all } n,$$

with C independent of n. Observe that

$$J \star w_n(0) = a_n(0)(\gamma^*\phi_1(x_n) - u(x_n)) \to 0,$$

which implies

$$\int_{\mathbb{R}} J(-y)w_n(y)\,dy \to 0 \quad \text{as } n \to +\infty.$$

Similarly,

$$J \star J \star w_n(0) = J \star (a_n w_n)(0) = \int_{\mathbb{R}} J(-y) a_n(y) w_n(y)\, dy,$$

but

$$\int_{\mathbb{R}} J(-y) a_n(y) w_n(y)\, dy \le \|a_n\|_{L^\infty} \int_{\mathbb{R}} J(-y) w_n(y)\, dy \to 0.$$

Hence

$$J \star J \star w_n(0) = \int_{\mathbb{R}} (J \star J)(-y) w_n(y)\, dy \to 0 \quad \text{as } n \to +\infty.$$

Defining

$$\mathcal{J}_k := \underbrace{J \star \cdots \star J}_{k \text{ times}},$$

we see that for any fixed $k \in \mathbb{N}$,

$$\int_{\mathbb{R}} \mathcal{J}_k(-y) w_n(y)\, dy \to 0 \quad \text{as } n \to +\infty.$$

By (1.4) the support of $\mathcal{J}_k$ increases to all of $\mathbb{R}$ as $k \to +\infty$. Thus we may find a new subsequence such that $w_n \to 0$ a.e. in $\mathbb{R}$ as $n \to +\infty$. Since ϕ_1 is periodic and continuous, $\phi_n(x) \to \bar{\phi}(x)$ uniformly with respect to x, where $\bar{\phi}(x) = \phi(x + \bar{y})$. Hence $\bar{u}(x) = \lim_{n\to+\infty} u_n(x)$ exists a.e. and is given by $\bar{u}(x) = \gamma^* \bar{\phi}$. By dominated convergence, $\bar{u}$ is a solution to

$$\mathcal{M}[\bar{u}] + f(x + \bar{y}, \bar{u}) = 0,$$

while by uniform convergence

$$\mathcal{M}[\gamma^* \bar{\phi}] + f_u(x + \bar{y}, 0)\gamma^* \bar{\phi} \le 0 \quad \text{in } \mathbb{R}.$$

Since $\bar{u} = \gamma^* \bar{\phi}$ it follows that $f(x + \bar{y}, \gamma^* \bar{\phi}) \equiv f_u(x + \bar{y}, 0)\gamma^* \bar{\phi}$. This contradicts the fact that $f(x, u)/u$ is decreasing in u. Hence, $\gamma^* = 0$. ∎

4. Uniqueness when *J* is symmetric. Throughout this section we assume that J is symmetric. For the proof of Theorem 1.3 we follow the ideas in [2].

Proof of Theorem 1.3. Part (b) of this theorem is contained in Theorem 1.1 so we concentrate on part (a).

Let p denote the positive periodic solution to (1.1) constructed in Theorem 1.1 and let $u \ge 0$, $u \not\equiv 0$ be a bounded solution. We will prove that $u \equiv p$.

We show first that $u \le p$. Set

$$\gamma^* := \inf\{\gamma > 0 \mid u \le \gamma p\}.$$

Note that γ^* is well defined because u is bounded and p is bounded below by a positive constant. We claim that

$$\gamma^* \le 1.$$

Suppose that $\gamma^* > 1$ and note that $u \le \gamma^* p$. By Theorem 1.4 either $u \equiv \gamma^* p$ or $\operatorname{ess\,inf}_K(\gamma^* p - u) > 0$ for all compact $K \subset \mathbb{R}$. The first possibility leads to $f(x, \gamma^* p) = \gamma^* f(x,p)$ for all $x \in \mathbb{R}$, which is not possible if $\gamma^* > 1$. In the second case there exists a sequence $(x_n)_{n\in\mathbb{N}}$ such that $|x_n| \to +\infty$ and $\lim_{n\to+\infty} \gamma^* p(x_n) - u(x_n) = 0$. Let $(y_n)_{n\in\mathbb{N}}$ be a sequence satisfying $y_n \in [-R,R]$ and $x_n - y_n = k_n 2R$ for some $k_n \in \mathbb{Z}$. We may assume that $y_n \to \bar{y}$. Let $u_n := u(.+x_n)$, which satisfies

$$\mathcal{M}[u_n] + f(x+y_n, u_n) = 0.$$

Let $w_n = \gamma^* p(.+y_n) - u_n \ge 0$. Then $w_n > 0$ in $\mathbb{R}$ and

$$J \star w_n = a_n(x) w_n,$$

where

$$a_n(x) = 1 - \frac{\gamma^* f(x+y_n, p(x+y_n)) - f(x+y_n, u_n(x))}{\gamma^* p(x+y_n) - u_n(x)}.$$

Since $w_n > 0$ we deduce that a_n is well defined and $a_n \ge 0$. Using that $f(x,u)/u$ is nonincreasing with respect to u and the fact that $\gamma^* > 1$, we have $f(x,\gamma^* p) \le \gamma^* f(x,p)$. This implies

$$\frac{\gamma^* f(x,p) - f(x,u)}{\gamma^* p - u} \ge \frac{f(x,\gamma^* p) - f(x,u)}{\gamma^* p - u} \ge -C.$$

Thus

$$0 \le a_n \le C+1 \quad \text{in } \mathbb{R} \quad \text{for all } n,$$

with C independent of n. Observe that

$$J \star w_n(0) = a_n(0)(\gamma^* p(y_n) - u(x_n)) = a_n(0)(\gamma^* p(x_n) - u(x_n)) \to 0,$$

which implies

$$\int_{\mathbb{R}} J(-y) w_n(y)\, dy \to 0 \quad \text{as } n \to +\infty.$$

Similarly,

$$J \star J \star w_n(0) = J \star (a_n w_n)(0) = \int_{\mathbb{R}} J(-y) a_n(y) w_n(y)\, dy,$$

but

$$\int_{\mathbb{R}} J(-y) a_n(y) w_n(y)\, dy \le \|a_n\|_{L^\infty} \int_{\mathbb{R}} J(-y) w_n(y)\, dy \to 0.$$

Hence

$$J \star J \star w_n(0) = \int_{\mathbb{R}} (J \star J)(-y) w_n(y)\, dy \to 0 \quad \text{as } n \to +\infty.$$

Defining

$$\mathcal{J}_k := \underbrace{J \star \cdots \star J}_{k \text{ times}},$$

we see that for all $k \in \mathbb{N}$,

$$\int_{\mathbb{R}} \mathcal{J}_k(-y)w_n(y)\,dy \to 0 \quad \text{as } n \to +\infty.$$

Hypothesis (1.4) implies that the support of $\mathcal{J}_k$ converges to all of $\mathbb{R}$ as $k \to +\infty$. Therefore, for a subsequence, $w_n \to 0$ a.e. in $\mathbb{R}$ as $n \to +\infty$. Since p is periodic, for possibly a new subsequence $p(x+y_n) \to p(x+\bar{y})$ a.e. Hence, $\bar{u}(x) = \lim_{n\to+\infty} u_n(x)$ exists a.e. and by dominated convergence, $\bar{u}$ is a solution to

$$\mathcal{M}[\bar{u}] + f(x+\bar{y}, \bar{u}) = 0. \tag{4.1}$$

But since $w_n \to 0$ a.e. we have $\bar{u} = \gamma^* p(\cdot + \bar{y})$. Thus $\gamma^* p(\cdot+\bar{y})$ is a solution to (4.1), which is impossible for $\gamma^* > 1$ as argued before.

The proof that $p \le u$ is analogous, but a key point is to prove first that under the conditions of Theorem 1.3 any nontrivial, nonnegative solution is bounded below by a positive constant. This is the content of Proposition 4.1. $\square$

PROPOSITION 4.1. *Assume that J satisfies* (1.3), (1.4), *and* (1.8), *f satisfies* (1.5), *and that the operator $-(\mathcal{M} - f_u(x,0))$ has a negative principal periodic eigenvalue. Suppose that u is a nonnegative, bounded solution to* (1.1). *Then $u \equiv 0$ or there exists a constant $c > 0$ such that*

$$u(x) \ge c \quad \textit{for all } x \in \mathbb{R}.$$

The basic tool to prove Proposition 4.1, following an idea in [2], is to study the principal eigenvalue of the linearized operator in bounded domains. More precisely, let $\Omega = (-r, +r)$ and $a\colon \Omega \to \mathbb{R}$ be Lipschitz. We consider the eigenvalue problem in Ω with "Dirichlet boundary condition" in the following sense:

$$\begin{cases} \mathcal{M}[\varphi] + a(x)\varphi = -\lambda\varphi & \text{in } \Omega, \\ \varphi(x) = 0 \quad \text{for all } x \notin \Omega, \\ \varphi|_{\overline{\Omega}} \text{ is continuous.} \end{cases} \tag{4.2}$$

We show that the principal eigenvalue for (4.2) exists and converges to the principal periodic eigenvalue as $r \to +\infty$. The first step is to establish variational characterizations of these eigenvalues, which is the argument that requires the symmetry of J.

LEMMA 4.2. *Let $\Omega \subset \mathbb{R}$ be a bounded open interval. Assume that J satisfies* (1.3), (1.4), *and* (1.8), *and let $a\colon \Omega \to \mathbb{R}$ be Lipschitz. Then there exists a smallest λ_1 such that* (4.2) *has a nontrivial solution. This eigenvalue is simple and the eigenfunctions are of constant sign in Ω. Moreover,*

$$\lambda_1 = \min_{\varphi \in C(\overline{\Omega})} -\frac{\int_\Omega (\mathcal{M}[\widetilde{\varphi}] + a(x)\varphi)\varphi}{\int_\Omega \varphi^2}, \tag{4.3}$$

where $\widetilde{\varphi}$ denotes the extension by 0 *of φ to $\mathbb{R}$ and the minimum is attained.*

The statement and the proof are analogous to those of Theorem 3.1 in [14] except that here we do not assume that $J(0) > 0$. A different formula for the principal eigenvalue with a Dirichlet boundary condition appears in [7], where it is used to characterize the rate of decay of solutions to a linear evolution equation.

Proof. Define the operator $X[\varphi] = \int_\Omega J(x-y)\,\varphi(y)\,dy$ for $\varphi \in C(\overline{\Omega})$. Then $X : C(\overline{\Omega}) \to C(\overline{\Omega})$ is compact. Let $c_0 > 0$ be such that $\inf_\Omega a(x) + c_0 > 0$ and define $\widetilde{a} = a + c_0$. The eigenvalue problem (4.2) is equivalent to the following: find $\varphi \in C(\overline{\Omega})$ and $\lambda \in \mathbb{R}$ such that

$$X[\varphi] + \widetilde{a}\varphi = (-\lambda + 1 + c_0)\varphi \quad \text{in } \Omega.$$

A calculation similar to Lemma 2.2 shows that there exists an integer p, $u \in C(\overline{\Omega})$, and $\delta > 0$ such that

$$(X + \widetilde{a})^p u \geq \left(\left(\max_{\overline{\Omega}} \widetilde{a}\right)^p + \delta\right) u \quad \text{in } \Omega. \tag{4.4}$$

Using Theorem 2.1 we deduce that the operator $X + \widetilde{a}$ has a unique principal eigenvalue $\rho > 0$ and a principal eigenvector $\varphi_1 \in C(\overline{\Omega})$. Let $\lambda = 1 + c_0 - \rho$ so that $X[\varphi_1] + a(x)\varphi_1 = (1-\lambda)\varphi_1$. From (4.4) we deduce that σ_+ defined by

$$\sigma_+ = \sup_{\varphi \in C(\overline{\Omega})} \frac{\int_\Omega (X[\varphi] + a(x)\varphi)\varphi}{\int_\Omega \varphi^2} \tag{4.5}$$

satisfies

$$\sigma_+ \geq 1 - \lambda > \max_{\overline{\Omega}} a. \tag{4.6}$$

Now, using the same argument as in [14] we deduce that the supremum in (4.5) is achieved. Indeed, it is standard [4] that the spectrum of $\hat{X} + a(x)$ is to the left of σ_+ and that there exists a sequence $\varphi_n \in C(\overline{\Omega})$ such that $\|\varphi_n\|_{L^2(\Omega)} = 1$ and $\|(X + a(x) - \sigma_+)\varphi_n\|_{L^2(\Omega)} \to 0$ as $n \to +\infty$. By compactness of $X : L^2(\Omega) \to C(\overline{\Omega})$ for a subsequence, $\lim_{n\to+\infty} X[\varphi_n]$ exists in $C(\overline{\Omega})$. Then, using (4.6), we see that $\varphi_n \to \varphi$ in $L^2(\Omega)$ for some φ and $(X + a)\varphi = \sigma_+\varphi$. This equation implies $\varphi \in C(\overline{\Omega})$, and hence σ_+ is a principal eigenvalue for the operator X and by uniqueness of this eigenvalue we have $\sigma_+ = 1 - \lambda$. ◻

LEMMA 4.3. *Assume that J satisfies* (1.3), (1.4), *and* (1.8) *and that $a\colon \mathbb{R} \to \mathbb{R}$ is a $2R$-periodic, Lipschitz function. Then the principal eigenvalue of the operator $-(\mathcal{M} + a(x))$ in $C_{per}(\mathbb{R})$ is given by*

$$\lambda_1(a) = \inf_{\|\varphi\|_{L^2(\mathbb{R})}=1} -\int_{\mathbb{R}} (\mathcal{M}[\varphi] + a(x)\varphi)\varphi \tag{4.7}$$

$$= \min_{\varphi \in C_{per}(\mathbb{R})} -\frac{\int_{-R}^{R} (\mathcal{M}[\varphi] + a(x)\varphi)\varphi}{\int_{-R}^{R} \varphi^2}. \tag{4.8}$$

Proof. By Theorem 1.2 we know that there exists a unique principal eigenvalue $\lambda_1(a)$ of the operator $-(\mathcal{M} + a)$ in $C_{per}(\mathbb{R})$. Let $\phi_1 \in C_{per}(\mathbb{R})$ denote a positive eigenfunction associated with $\lambda_1(a)$. We normalize ϕ_1 such that

$$\int_{-R}^{R} \phi_1^2 = 2R. \tag{4.9}$$

On the other hand, the quantity

$$\widetilde{\lambda}_1(a) = \inf_{\varphi \in C_{per}(\mathbb{R})} -\frac{\int_{-R}^{R} (\mathcal{M}[\varphi] + a(x)\varphi)\varphi}{\int_{-R}^{R} \varphi^2}$$

is also an eigenvalue of $-(\mathcal{M}+a)$ on $C_{per}(\mathbb{R})$ with a positive eigenfunction. By uniqueness of the principal eigenvalue, $\lambda_1(a)=\widetilde{\lambda}_1(a)$.

We claim that

$$\inf_{\|\varphi\|_{L^2(\mathbb{R})}=1} -\int_{\mathbb{R}} (\mathcal{M}[\varphi]+a(x)\varphi)\varphi \le \lambda_1(a).$$

Indeed, for $r>0$ let $\eta_r\in C_0^\infty(\mathbb{R})$ be such that $0\le \eta_r\le 1$, $\eta_r(x)=1$ for $|x|\le r$, $\eta_r(x)=0$ for $|x|\ge r+1$. It will be sufficient to show that

$$\lim_{r\to+\infty} \frac{\int_{\mathbb{R}}(\mathcal{M}[\phi_1\eta_r]+a\phi_1\eta_r)\phi_1\eta_r}{\int_{\mathbb{R}}(\phi_1\eta_r)^2} = -\lambda_1(a). \tag{4.10}$$

By (4.9) we have

$$\int_{\mathbb{R}} (\phi_1\eta_r)^2 = 2r+O(1) \quad \text{ as } r\to+\infty. \tag{4.11}$$

Let $0<\theta<1$. Then

$$\begin{aligned} |\mathcal{M}[\phi_1](x)-\mathcal{M}[\phi_1\eta_r]| &\le \|\phi_1\|_{L^\infty}\int_{|x-z|\ge r}|J(z)|\,dz \\ &\le \|\phi_1\|_{L^\infty}\int_{|z|\ge(1-\theta)r}|J(z)|\,dz \quad \text{for all } |x|\le\theta r \\ &= o(1) \quad \text{uniformly for all } |x|\le \theta r. \end{aligned} \tag{4.12}$$

We split the integral

$$\int_{\mathbb{R}}(\mathcal{M}[\phi_1\eta_r]+a\phi_1\eta_r)\phi_1\eta_r = \int_{|x|\le\theta r}\dots dx + \int_{|x|\ge\theta r}\dots dx. \tag{4.13}$$

Using $\eta_r(x)=1$ for $|x|\le\theta r$ and (4.12) we see that

$$\begin{aligned} \int_{|x|\le\theta r}(\mathcal{M}[\phi_1\eta_r]+a\phi_1\eta_r)\phi_1\eta_r &= \int_{|x|\le\theta r}(\mathcal{M}[\phi_1\eta_r]+a\phi_1)\phi_1 \\ &= \int_{|x|\le\theta r}(\mathcal{M}[\phi_1]+a\phi_1+o(1))\phi_1 \\ &= -2\theta\lambda_1(a)r+o(r) \quad \text{ as } r\to+\infty. \end{aligned}$$

The second integral in (4.13) is bounded by

$$\left|\int_{|x|\ge\theta r}(\mathcal{M}[\phi_1\eta_r]+a\phi_1\eta_r)\phi_1\eta_r\right| \le C(1-\theta)r. \tag{4.14}$$

Thus from (4.11)–(4.14) we conclude that

$$\left|\frac{\int_{\mathbb{R}}(\mathcal{M}[\phi_1\eta_r]+a\phi_1\eta_r)\phi_1\eta_r}{\int_{\mathbb{R}}(\phi_1\eta_r)^2}+\lambda_1(a)\right| \le C(1-\theta)+o(1),$$

which proves (4.10).

To establish (4.7) it remains to verify that

$$\lambda_1(a) \le -\frac{\int_{\mathbb{R}}(\mathcal{M}[\varphi]+a(x)\varphi)\varphi}{\int_{\mathbb{R}}\varphi^2} \quad \text{for all } \varphi\in C_c(\mathbb{R}). \tag{4.15}$$

By uniqueness of the principal eigenvalue we have

$$\lambda_1(a) = \inf_{\varphi\in C_{per}(\Omega_k)} -\frac{\int_{-kR}^{kR}(\mathcal{M}[\varphi]+a(x)\varphi)\varphi}{\int_{-kR}^{kR}\varphi^2}, \tag{4.16}$$

where

$$\Omega_k = (-kR, kR) \quad \text{ for } k\ge 1$$

and $C_{per}(\Omega_k)$ is the set of continuous $2kR$-periodic functions on $\mathbb{R}$.

Fix $\varphi\in C_c(\mathbb{R})$ and consider k large enough so that $\operatorname{supp}(\varphi)\subseteq\Omega_k$. Consider now φ_k the $4kR$-periodic extension of φ. Since $\varphi_k\in C_{per}(\Omega_{2k})$, (4.16) yields

$$\lambda_1(a) \le -\frac{\int_{-2kR}^{2kR}(\mathcal{M}[\varphi_k]+a(x)\varphi_k)\varphi_k}{\int_{-2kR}^{2kR}\varphi_k^2} = -\frac{\int_{\mathbb{R}}(\mathcal{M}[\varphi_k]+a(x)\varphi)\varphi}{\int_{\mathbb{R}}\varphi^2}. \tag{4.17}$$

For $|x|\le kR$ we have

$$|\mathcal{M}[\varphi_k](x)-\mathcal{M}[\varphi](x)| \le \|\varphi\|_{L^\infty}\int_{|y|\ge 2kR}|J(x-y)|\,dy \le \|\varphi\|_{L^\infty}\int_{|z|\ge kR}|J(z)|\,dz.$$

Hence

$$\lim_{k\to+\infty}\int_{\mathbb{R}}(\mathcal{M}[\varphi_k]+a(x)\varphi)\varphi = \int_{\mathbb{R}}(\mathcal{M}[\varphi]+a(x)\varphi)\varphi. \tag{4.18}$$

Thanks to (4.17) and (4.18), we conclude the validity of (4.15). ◻

LEMMA 4.4. *Assume J satisfies* (1.3), (1.4), *and* (1.8) *and that $a\colon\mathbb{R}\to\mathbb{R}$ is a $2R$-periodic, Lipschitz function. Let $\lambda_{r,y}$ be the principal eigenvalue of* (4.2) *for*

$$\Omega_{r,y} = B_r(y)$$

and let $\lambda_1(a)$ denote the principal eigenvalue of $-(\mathcal{M}+a(x))$ in $C_{per}(\mathbb{R})$. Then

$$\lim_{r\to+\infty}\lambda_{r,y} = \lambda_1(a).$$

Moreover, the applications $y\mapsto\lambda_{r,y}$ and $y\mapsto\varphi_{r,y}$ are periodic. The periodicity of the application $y\mapsto\varphi_{r,y}$ is understood as follows:

$$\varphi_{r,y+2R}(x) = \varphi_{r,y}(x-2R).$$

Proof. For convenience we write

$$\lambda_r = \lambda_{r,y}$$

and let φ_r be a positive eigenfunction of (4.2) in Ω_r.

By the variational characterization (4.3) we see that $r \mapsto \lambda_r$ is nonincreasing, and hence $\lim_{r\to+\infty} \lambda_r$ exists. Moreover, using (4.7) we have

$$\lambda_r \geq \lambda_1(a) \quad \text{for all } r > 0. \tag{4.19}$$

Let $\phi_1 \in C_{per}(\mathbb{R})$ be a positive eigenfunction of $-(\mathcal{M} + a(x))$ with eigenvalue $\lambda_1(a)$ normalized such that

$$\int_{-R}^{R} \phi_1^2 = 2R.$$

Let $\eta_r \in C_0^\infty(\mathbb{R})$ be such that $0 \leq \eta \leq 1$,

$$\eta_r(x) = 1 \text{ for } |x - y| \leq r - 1, \qquad \eta_r(x) = 0 \text{ for } |x - y| \geq r$$

and such that $\|\eta_r\|_{C^2(\mathbb{R})} \leq C$ with C independent of r. Arguing in the same way as in the proof of Lemma 4.3 we obtain

$$\lim_{r\to+\infty} \frac{\int_{\mathbb{R}}(\mathcal{M}[\phi_1\eta_r] + a\phi_1\eta_r)\phi_1\eta_r}{\int_{\mathbb{R}}(\phi_1\eta_r)^2} = -\lambda_1(a).$$

Since

$$\lambda_r \leq -\frac{\int_{\mathbb{R}}(\mathcal{M}[\phi_1\eta_r] + a\phi_1\eta_r)\phi_1\eta_r}{\int_{\mathbb{R}}(\phi_1\eta_r)^2}$$

we conclude that

$$\lim_{r\to+\infty} \lambda_r \leq \lambda_1(a).$$

This and (4.19) prove the desired result.

Let us now show the periodicity of the applications $y \mapsto \lambda_{r,y}$ and $y \mapsto \varphi_{r,y}$. Replace y by $y+2R$ in the above problem (4.2) and let us denote by $\lambda_{r,y+2R}$ and $\varphi_{r,y+2R}$ the corresponding principal eigenvalue and the associated positive eigenfunction:

$$\mathcal{M}[\varphi_{r,y+2R}] + a(x)\varphi_{r,y+2R} = -\lambda_{r,y+2R}\varphi_{r,y+2R} \quad \text{ in } B_r(y + 2R).$$

We take the following normalization:

$$\int_{\Omega_{r,y+2R}} \varphi_{r,y+2R}^2(x)\,dx = 1.$$

Let us defined $\psi(x) := \varphi_{r,y+2R}(x + 2R)$ for any $x \in B_r(y)$. A short computation shows that

$$\mathcal{M}[\psi](x) = \mathcal{M}[\varphi]_{r,y+2R}(x + 2R).$$

Therefore, using the periodicity of $a(x)$, we have

$$\mathcal{M}[\psi](x) + a(x + 2R)\psi(x) = \lambda_{r,y+2R}\psi \quad \text{in } B_r(y),$$

$$\mathcal{M}[\psi](x) + a(x)\psi(x) = \lambda_{r,y+2R}\psi \quad \text{in } B_r(y).$$

Thus, $\lambda_{r,y+2R}$ is a principal eigenvalue of the problem (4.2) with $\Omega_{r,y} = B_r(y)$. Hence, by uniqueness of the principal eigenvalue we have $\lambda_{r,y} = \lambda_{r,y+2R}$ and $\psi = \gamma\varphi_{r,y}$ for some positive γ. Using the normalization, it follows that $\gamma = 1$. Therefore, $\varphi_{r,y}(x) = \varphi_{r,y+2R}(x+2R)$; in other words

$$\varphi_{r,y+2R}(x) = \varphi_{r,y}(x-2R). \qquad \square$$

Remark 4.5. The proof of Lemma 4.4 yields the slightly stronger conclusion that the convergence

$$\lim_{r\to+\infty} \lambda_{r,y} = \lambda_1(a)$$

is uniform with respect to $y \in \mathbb{R}$, since $\lambda_{r,y}$ is continuous in y.

Proof of Proposition 4.1. Let $u \geq 0$ be a bounded solution to (1.1) such that $u \not\equiv 0$. By the strong maximum principle (Theorem 1.4) we must have $\inf_K u > 0$ for compact sets $K \subset \mathbb{R}$.

Given $y \in \mathbb{R}$ and $r > 0$ we write $\Omega_{r,y} = (y-r, y+r)$, $\lambda_{r,y}$ the principal eigenvalue of $-(\mathcal{M} + f_u(x,0))$ with Dirichlet boundary condition in $\Omega_{r,y}$ as in (4.2), and $\varphi_{r,y}$ a positive Dirichlet eigenfunction normalized so that

$$\int_{\Omega_{r,y}} \varphi_{r,y}^2 = 1.$$

Since the principal eigenvalue $\lambda_1 := \lambda_1(f_u(x,0))$ of $-(\mathcal{M} + f_u(x,0))$ with periodic boundary conditions is negative by hypothesis, by Lemma 4.4 and Remark 4.5 we may fix $r > 0$ large enough so that

$$\lambda_{r,y} < \lambda_1/2 \quad \text{for all } y \in \mathbb{R}.$$

Note that for $x \in \Omega_{r,y}$,

$$\begin{aligned} \mathcal{M}[\gamma\varphi_{r,y}] + f(x,\gamma_{r,y}) &= -\lambda_{r,y}\gamma\varphi_{r,y} - f_u(x,0)\gamma\varphi_{r,y} + f(x,\gamma\varphi_{r,y}) \\ &\geq -\lambda_1/2\gamma\varphi_{r,y} - f_u(x,0)\gamma\varphi_{r,y} + f(x,\gamma\varphi_{r,y}) \\ &\geq 0 \end{aligned}$$

if $0 \leq \gamma \leq \gamma_0$ with γ_0 fixed suitably small. For $x \notin \Omega_{y,r}$ we have $\varphi_{y,r}(x) = 0$ and $\mathcal{M}[\varphi_{r,y}] \geq 0$. Thus

$$\mathcal{M}[\gamma\varphi_{r,y}] + f(x,\gamma\varphi_{r,y}) \geq 0 \quad \text{in } \mathbb{R} \tag{4.20}$$

for all $0 < \gamma < \gamma_0$.

We claim that

$$\gamma_0\varphi_{r,y} \leq u \quad \text{in } \mathbb{R} \qquad \text{for all } y \in \mathbb{R}. \tag{4.21}$$

This proves the proposition because there is a positive constant c such that $\varphi_{r,y}(y) \geq c$ for all $y \in \mathbb{R}$ since the application $y \mapsto \varphi_{r,y}$ is periodic and $\varphi_{r,y}(y) > 0$ for any $y \in [-2R, 2R]$.

Now, to prove (4.21) fix $y \in \mathbb{R}$ and set

$$\gamma^* = \sup\{\, \gamma > 0 \,/\, \gamma\varphi_{r,y} \leq u \text{ in } \mathbb{R}\}.$$

Since $\inf_K u > 0$ for compact sets $K \subset \mathbb{R}$ and $\varphi_{r,y}$ has compact support we see that $\gamma^* > 0$. Assume that $\gamma^* < \gamma_0$. Then by (4.20), $\gamma^* \varphi_{r,y}$ is a subsolution of (1.1) while u is a solution. By the strong maximum principle (Theorem 1.4) either $\gamma^* \varphi_{r,y} \equiv u$ in $\mathbb{R}$ or $\inf_K (u - \gamma^* \varphi_{r,y}) > 0$ for compact sets $K \subset \mathbb{R}$. The former case is impossible because u is strictly positive, while the latter case yields a contradiction with the definition of γ^*. It follows that $\gamma^* \geq \gamma_0$ as desired. ∎

Appendix. In this appendix we give a short proof of Theorem 1.4. We assume that J satisfies (1.3), (1.4), $c \in L^\infty(\mathbb{R})$, and $u \in L^\infty(\mathbb{R})$ satisfies

$$\begin{aligned} &u \leq 0 \quad \text{a.e. in } \mathbb{R}, \\ &\mathcal{M}[u] + cu \geq 0 \quad \text{a.e. in } \mathbb{R}. \end{aligned} \tag{A.1}$$

For $\epsilon > 0$ define

$$u_\epsilon(x) = \frac{1}{2\epsilon} \int_{x-\epsilon}^{x+\epsilon} u.$$

Then u_ϵ is continuous in $\mathbb{R}$, $u_\epsilon \leq 0$, and $u_\epsilon \to u$ a.e. as $\epsilon \to 0$. There are two cases:

(1) for any closed interval I one has $\limsup_{\epsilon \to 0} \sup_I u_\epsilon < 0$, or

(2) for some closed interval I one has $\limsup_{\epsilon \to 0} \sup_I u_\epsilon = 0$.

If case (1) occurs, we see that for all closed intervals I we have $\operatorname{ess\,sup}_I u < 0$. Assume case (2) holds. Let I be a closed interval and $\epsilon_n \to 0$ be such that $\lim_{n \to +\infty} u_{\epsilon_n}(x_n) = 0$, where $x_n \in I$ is such that $\sup_I u_{\epsilon_n} = u_{\epsilon_n}(x_n)$. Integrating (A.1) from $x_n - \epsilon_n$ to $x_n + \epsilon_n$ and dividing by $2\epsilon_n$, we have

$$J \star u_{\epsilon_n}(x_n) \geq u_{\epsilon_n}(x_n) - \frac{1}{2\epsilon_n} \int_{x_n - \epsilon_n}^{x_n + \epsilon_n} cu.$$

But, since $u \leq 0$ a.e.,

$$\left| \frac{1}{2\epsilon_n} \int_{x_n - \epsilon_n}^{x_n + \epsilon_n} cu \right| \leq -\|c\|_{L^\infty} u_{\epsilon_n}(x_n) \to 0.$$

Hence

$$\liminf_{n \to +\infty} J \star u_{\epsilon_n}(x_n) \geq 0.$$

We may assume that $x_n \to x \in I$. Then by dominated convergence,

$$J \star u_{\epsilon_n}(x_n) = \int_{\mathbb{R}} J(x_n - y) u_{\epsilon_n}(y)\, dy \to \int_{\mathbb{R}} J(x - y) u(y)\, dy.$$

This shows that $u = 0$ a.e. in $x - \operatorname{supp}(J)$. Now, for any x_1 in the interior of $x - \operatorname{supp}(J)$ we have $J \star u(x_1) \geq 0$, which shows that $u = 0$ a.e. in $x - 2\operatorname{supp}(J)$, where $2\operatorname{supp}(J) = \operatorname{supp}(J) + \operatorname{supp}(J)$. Note that assumption (1.4) implies that $k \operatorname{supp}(J)$ covers all of $\mathbb{R}$ as $k \to +\infty$, where $k \operatorname{supp}(J)$ is defined inductively as $(k-1)\operatorname{supp}(J) + \operatorname{supp}(J)$. Repeating the previous argument we deduce that $u = 0$ a.e. in $\mathbb{R}$. ∎

STRUCTURE OF THE LINEARIZED GRAVITATIONAL VLASOV–POISSON SYSTEM CLOSE TO A POLYTROPIC GROUND STATE*

MOHAMMED LEMOU†, FLORIAN MÉHATS‡, AND PIERRE RAPHAËL§

Abstract. We deal in this paper with a generalized gravitational Vlasov–Poisson system that covers the three- and four-dimensional cases as well as the three-dimensional ultrarelativistic case. This system admits polytropic stationary solutions which are orbitally stable. We study in this paper the linear system obtained after a linearization close to these ground states and prove that the linearized flow displays at most algebraic instabilities. The heart of the proof is the derivation of a positivity property for the linearized Hamiltonian that implies a "quantitative" proof of the orbital stability statement. Our strategy follows the analysis by Weinstein [*SIAM J. Math. Anal.*, 16 (1985), pp. 472–491], who obtained similar results for the nonlinear Schrödinger equation that turned out to be fundamental preliminary properties for the further description of the fine qualitative properties of the Hamiltonian system.

Key words. gravitation, kinetic equations, Vlasov–Poisson, linearization, polytrope, stability, variational analysis

1. Introduction.

1.1. The gravitational Vlasov–Poisson system.

We consider in this paper the following generalized gravitational Vlasov–Poisson system:

$$\text{(1.1)}\quad \text{(VP)}\quad \begin{cases} \partial_t f + |v|^{\alpha-2} v \cdot \nabla_x f - E_f \cdot \nabla_v f = 0, \quad (t,x,v) \in \mathbb{R}_+ \times \mathbb{R}^N \times \mathbb{R}^N, \\ f(t=0,x,v) = f_0(x,v) \geq 0 \end{cases}$$

in the range of parameters

$$(N,\alpha) \in \{(3,1),(3,2),(4,2)\} \tag{1.2}$$

and where we denote, for a given distribution $f \geq 0$,

$$E_f(x) = \nabla_x \phi_f\,, \quad \phi(x) = -\frac{1}{N(N-2)\omega_N}\frac{1}{|x|^{N-2}} \star \rho_f, \quad \rho_f(x) = \int_{\mathbb{R}^N} f(x,v)\,dv, \tag{1.3}$$

ω_N being the volume of the unit ball in $\mathbb{R}^N$ ($\omega_3 = \frac{4\pi}{3}$ and $\omega_4 = \frac{\pi^2}{2}$). Our range of parameters (1.2) covers the three following situations.

(1) The three-dimensional gravitational Vlasov–Poisson system $(N,\alpha) = (3,2)$ which describes the mechanical state of a stellar system subject to its own gravity (see, for instance, [4, 9]) and whose classical solutions are global in time; see Lions and Perthame [28], Pfaffelmoser [33], Schaeffer [38].

(2) Classical calculations show that this model should be correct only for low velocities and if high velocities occur, special relativistic corrections should be introduced; see Van Kampen and Felderhof [41] and Glassey and Schaeffer [11, 12]. A more accurate model is then provided by the relativistic three-dimensional Vlasov–Poisson system

(1.4)
$$\text{(RVP)} \quad \begin{cases} \partial_t f + \dfrac{v}{\sqrt{1+|v|^2}} \cdot \nabla_x f - E_f \cdot \nabla_v f = 0, \quad (t,x,v) \in \mathbb{R}_+ \times \mathbb{R}^3 \times \mathbb{R}^3, \\ f(t=0,x,v) = f_0(x,v) \geq 0. \end{cases}$$

A major difference with the three-dimensional (VP) is that this system may develop finite time blowup singularities (see [10, 11]), and a preliminary model problem is given by the three-dimensional ultrarelativistic (VP) system which is (1.1) with $(N,\alpha) = (3,1)$.

(3) The four-dimensional Vlasov–Poisson system $(N,\alpha) = (4,2)$ is a fundamental mathematical model for the study of the singularity formation (see [22, 23]), which shares a critical structure similar to (1.4) but admits extra fundamental invariances, and in particular an explicit pseudoconformal symmetry.

A natural space to study the (VP) system is the energy space

$$\mathcal{E} = \{f \geq 0 \ \text{ with } \ |f|_{\mathcal{E}} = |f|_{L^1} + |f|_{L^p} + ||v|^\alpha f|_{L^1} < +\infty\}$$

for $p_{crit} < p < +\infty$, where

$$p_{crit} = \frac{N\alpha + (\alpha+2)N - N^2}{2\alpha + (\alpha+2)N - N^2} = \begin{cases} 9/7 & \text{for } \ (N,\alpha) = (3,2), \\ 2 & \text{for } \ (N,\alpha) = (4,2), \\ 3/2 & \text{for } \ (N,\alpha) = (3,1). \end{cases} \tag{1.5}$$

Recall that (1.1) satisfies *formally* some conservation laws: $\forall\, q \in [1,p]$ the L^q norm of a solution f is independent of time, as well as the Hamiltonian defined by

$$\mathcal{H}(f) = \frac{1}{\alpha} \int_{\mathbb{R}^{2N}} |v|^\alpha f - \frac{1}{2} \int_{\mathbb{R}^N} |E_f|^2. \tag{1.6}$$

Moreover, a large group of symmetries leaves (1.1) invariant: if $f(t,x,v)$ solves (1.1), then $\forall (t_0, x_0, \lambda_0, \mu_0) \in \mathbb{R} \times \mathbb{R}^N \times \mathbb{R}_+^* \times \mathbb{R}_+^*$, so does

$$\frac{\mu_0^{N-\alpha}}{\lambda_0^2} f\left(\frac{t+t_0}{\lambda_0 \mu_0^{\alpha-1}}, \frac{x+x_0}{\lambda_0}, \mu_0 v \right). \tag{1.7}$$

The case $\alpha = 2$ also enjoys the Galilean invariance: if $f(t,x,v)$ solves (1.1), then $\forall v_0 \in \mathbb{R}^N$, so does $f(t, x+v_0 t, v+v_0)$.

In the classical case corresponding to $\alpha = 2$, the existence of weak solutions for (1.1) in the energy space $\mathcal{E}$ is due to Horst and Hunze [19] and Diperna and Lions [7, 8]. These solutions verify an upper bound on the Hamiltonian

$$\mathcal{H}(f(t)) \leq \mathcal{H}(f_0) \tag{1.8}$$

and the exact conservation of the L^q norm

$$\forall 1 \leq q \leq p, \qquad |f(t)|_{L^q} = |f_0|_{L^q}. \tag{1.9}$$

In the ultrarelativistic case $\alpha = 1$, we are not aware of any result concerning the Cauchy theory for (1.1).

In the energy space, we have the interpolation estimate

$$\forall f \in \mathcal{E}, \qquad |E_f|_{L^2}^2 \le C_p \, ||v|^\alpha f|_{L^1}^{\theta_1} \, |f|_{L^p}^{\theta_2} \, |f|_{L^1}^{\theta_3} \tag{1.10}$$

with

$$\theta_1 = \frac{N-2}{\alpha}, \qquad \theta_2 = \frac{(N-2)p}{N(p-1)}, \qquad \theta_3 = 2 - \theta_1 - \theta_2. \tag{1.11}$$

Note that we have $0 < \theta_i < 2$ for $i = 1, 2, 3$ in the range of parameters (1.2) and $p_{crit} < p < +\infty$. In particular, for $(N, \alpha) = (3, 2)$, $\theta_1 = \frac{1}{2}$ and thus the bound on the Hamiltonian (1.8) and the conservation of the L^1, L^p norms imply a uniform bound on the kinetic energy, hence the existence of a global weak solution to (1.1); on the contrary for $(N, \alpha) \in \{(3, 1), (4, 2)\}$, $\theta_1 = 1$ and a blowup can indeed occur from a classical virial identity; see [11]. The blowup problem in this case is of critical nature in the sense that the strength of the kinetic and the potential energy in the Hamiltonian is the same; see [22] for a further discussion on this problem.

1.2. Linear and nonlinear stability. Our aim in this paper is to study the properties of the linear flow close to a specific class of stationary solutions, the so-called polytropic ground states. This is a classical problem related to the question of the linear and nonlinear stability of the stationary solutions which has been addressed in a number of works for the case of the three-dimensional gravitational Vlasov–Poisson system (1.1) for $(N, \alpha) = (3, 2)$.

A large class of stationary solutions to (1.1) for $(N, \alpha) = (3, 2)$ of the form $f(t, x, v) = F(e)$, where $e = \frac{|v|^2}{2} + \phi(x)$, has been constructed in [2] by solving the associated nonlinear radial ODE. Two classical strategies then emerge to prove the nonlinear stability of such solutions: variational techniques for those stationary solutions that can be obtained as minimizers of a well-chosen functional; direct linearization techniques using the conservation of the Hamiltonian and coercivity properties of the linearized energy.

The first approach has been used in particular by Guo [13], Guo and Rein [14, 15, 16], and Rein [35] where part of these steady states including the polytropes have been obtained as minimizers of appropriately chosen energy-Casimir functionals under a constraint of prescribed mass. As observed in [22] (see also Sánchez and Soler [37]), a direct application of the original concentration technique introduced by Lions in [26, 27] allows one to recover the orbital stability of a two-parameter family of ground states—while the energy-Casimir technique covers only one-parameter families—in the energy space by proving the strong relative compactness up to space translation of the minimizing sequences of the problem

$$\min_{f \ge 0, \quad |f|_{L^1} = M_1, \quad |j(f)|_{L^1} = M_j} \mathcal{H}(f) \tag{1.12}$$

for a large class of convex functions j. Note that the two-parameter family is in correspondence with the two-parameter scaling invariance of the Vlasov–Poisson system. Here a difficulty arises, however, which is that uniqueness for (1.12) is known only in two special cases: (i) when $j(f) = f^p$, which is the case of polytropes where uniqueness follows directly from the scaling invariance of the polytropic equation (1.17);

(ii) when the minimizer of (1.12) is also a minimizer of the following one-constraint minimization problem:

$$\min_{f\geq 0,\quad |f|_{L^1}+|j(f)|_{L^1}=M} \mathcal{H}(f), \tag{1.13}$$

which can easily be proved to hold for a large subclass of solutions to (1.12), and then one may use Schaeffer's uniqueness result [39]. Using extra scaling invariances in the case of the polytrope, we have the following result which was proved for $\alpha = 2$ and $N = 3, 4$ in [22] and easily adapts to $(N, \alpha) = (3, 1)$.

PROPOSITION 1.1 (variational characterization of the ground state [22]). *Let (N, α) satisfy (1.2), $p \in (p_{crit}, +\infty)$, and $(\theta_i)_{1\leq i\leq 3}$ be given by (1.11). The minimization problem*

$$\inf_{f\in\mathcal{E},\, f\neq 0} \frac{||v|^\alpha f|_{L^1}^{\theta_1}\, |f|_{L^p}^{\theta_2}\, |f|_{L^1}^{\theta_3}}{|E_f|_{L^2}^2} \tag{1.14}$$

is attained on the four-parameter family

$$\gamma Q\left(\frac{x-x_0}{\lambda}, \mu v\right), \qquad (\gamma, \lambda, \mu, x_0) \in \mathbb{R}_+^* \times \mathbb{R}_+^* \times \mathbb{R}_+^* \times \mathbb{R}^N. \tag{1.15}$$

Here Q is the polytropic ground state

$$Q_{\alpha,p,N}(x,v) = \begin{cases} \left(-1 - \dfrac{|v|^\alpha}{\alpha} - \phi_Q(x)\right)^{\frac{1}{p-1}} & \text{for } \frac{|v|^\alpha}{\alpha} + \phi_Q(x) < -1, \\ 0 & \text{for } \frac{|v|^\alpha}{\alpha} + \phi_Q(x) > -1, \end{cases} \tag{1.16}$$

where ϕ_Q is the unique nontrivial radial solution to

$$-\frac{1}{r^{N-1}}\frac{d}{dr}(r^{N-1}\phi_Q') + \gamma_{\alpha,p,N}(-1-\phi_Q)_+^{\frac{1}{p-1}+\frac{N}{\alpha}} = 0, \qquad \phi(r) \to 0 \quad \text{as} \quad r \to +\infty, \tag{1.17}$$

$\gamma(\alpha, p, N)$ is given by

$$\gamma_{\alpha,p,N} = \sigma_N \int_0^1 (\alpha t)^{\frac{N-\alpha}{\alpha}} (1-t)^{\frac{1}{p-1}}\, dt. \tag{1.18}$$

For $(N, \alpha) = (3, 2)$, Q is moreover orbitally stable in the energy space by the flow of (1.1) and orbital stability up to an additional scaling invariance holds as well for $(N, \alpha) = (4, 2)$; see [22], Sánchez and Soler [37], and also Hadzic [18].

THEOREM 1.2 (orbital stability of the ground state for $(N, \alpha) = (3, 2)$). *Let $(N, \alpha) = (3, 2)$ and $p_{crit} < p < +\infty$. Then $\forall\ \eta > 0$, there exists $\delta(\eta) > 0$ such that the following holds true. Let $f_0 \in \mathcal{E}$ with*

$$\mathcal{H}(f_0) - \mathcal{H}(Q) \leq \delta(\eta), \qquad |f_0|_{L^1} \leq |Q|_{L^1} + \delta(\eta), \qquad |f_0|_{L^p} \leq |Q|_{L^p} + \delta(\eta),$$

and let $f(t) \in L^\infty([0, +\infty), \mathcal{E}_p)$ be a weak solution to (1.1) satisfying (1.9) and (1.8). Then there exists a translation shift $x(t) \in \mathbb{R}^N$ such that

$$\forall t \geq 0, \quad |f(t, x + x(t), v) - Q|_{\mathcal{E}} < \eta.$$

A similar statement holds in the critical case $(N, \alpha) = (4, 2)$ up to an additional time-dependent rescaling of the solution; see [22] for precise statements.

A different strategy to attack the question of the nonlinear stability is to consider coercivity properties of the linearized Hamiltonian as already performed in the pioneering works by Antonov [1]. Let us for simplicity restrict our attention to the case of the polytropes of Proposition 1.1. Consider the energy-Casimir functional which is formally conserved by the flow of (1.1):

$$\mathcal{H}_C(f) = \frac{|f|_{L^p}^p}{p} + |f|_{L^1} + \mathcal{H}(f) = \int_{\mathbb{R}^{2N}} \left(\frac{|f|^p}{p} + f + \frac{|v|^\alpha}{\alpha} f \right) - \frac{1}{2} \int_{\mathbb{R}^N} |E_f|^2. \tag{1.19}$$

Then this functional is continuously differentiable on $\mathcal{E}$, and Q is a critical point in the following sense: let

$$K = \mathrm{Supp}(Q) = \left\{ (x,v) \in \mathbb{R}^N \times \mathbb{R}^N \quad \text{such that} \quad \frac{|v|^\alpha}{\alpha} + \phi_Q(x) + 1 \le 0 \right\},$$

then from (1.16) and (1.19),

$$\forall f \in \mathcal{C}_0^\infty(K), \quad d\mathcal{H}_C(Q) f = \int_{\mathbb{R}^{2N}} \left(Q^{p-1} + 1 + \frac{|v|^\alpha}{\alpha} + \phi_Q \right) f = 0.$$

The Hessian on $C_0^\infty(K)$ is given by

$$d^2\mathcal{H}_C(Q)(f,f) = (p-1) \int_K Q^{p-2} f^2 - \int_{\mathbb{R}^N} |E_f|^2. \tag{1.20}$$

The understanding of the coercivity properties of this quadratic form in sufficiently strong norms will allow us to prove from a simple bootstrap argument the nonlinear stability of the polytrope. Of course this approach can be generalized to any stationary solution and in particular provides a strategy to prove nonlinear stability without any variational structure. This problem has been addressed in several places in both the physics and mathematics literature. It is known that this quadratic form will be coercive for a well-chosen class of perturbations called "admissible" perturbations; see, for example, [40, 20, 32]. A similar approach has been used recently by Guo and Rein [17] to prove conditional stability for the King-type steady states of the Vlasov–Poisson system and by Rein and Hadzic [36] for the relativistic gravitational Vlasov–Poisson system. However, this kind of structure requires us to restrict the class of the perturbation theory, whereas the perturbations authorized in the present paper are in an open set of the energy space, which contains in particular these "admissible" perturbations. A different approach was developed by Wan [42] which obtains coercivity results for a large class of quadratic forms similar to (1.20), which imply the proof of the nonlinear stability of ground states for a large class of nonvariational problems. However, the specific case of the polytropes or more generally the solutions to (1.12) do not enter this theory due to their lack of $\mathcal{C}^1$ regularity on the boundary of their domain. Eventually, the linearized Vlasov–Poisson system close to a large class of ground states was also considered in Batt, Morrison, and Rein [3], but their analysis is restricted to stationary solutions for which the quadratic form of the linearized energy-Casimir functional is the sum of two positive terms and thus directly coercive. In particular, none of the ground states obtained from variational techniques in the energy space in, for example, [16] or [22] is covered by this analysis.

Let us stress the fact that for the polytropes which have a nice variational characterization, the sharp understanding of the coercivity properties of the quadratic form (1.20) allows a *quantification* of the orbital stability statement which is crucial for the further understanding of the properties of the flow of (1.1) close to Q. By "sharp" we mean a precise understanding of the instability directions. This situation is similar to the one for the nonlinear Schrödinger equation $iu_t = -\Delta u - |u|^{p-1}u$ or the Korteweg–de Vries (KdV) equation $u_t + (u_{xx} + u^p)_x = 0$. Indeed, both these Hamiltonian systems admit, for a suitable range of the parameter p, ground-state-type stationary solutions which are orbitally stable; see Cazenave and Lions [6]. For these two systems, another proof of the orbital stability has been given by Weinstein [43, 44] by linearizing the conservation laws around the ground state and studying the coercivity properties of the obtained quadratic forms. Moreover, this work provided a preliminary investigation of the dispersive structure of the linearized operator close to the ground state. The obtained estimates are the *starting point* of a number of recent works regarding the dynamical stability of some specific solutions to these systems; see, for example, Martel, Merle, and Tsai [30] for the stability of the multisolitary waves for the KdV equation, or Bourgain and Wang [5] and Merle and Raphaël [31] for the stability of some nonlinear blowup dynamics for the nonlinear Schrödinger (NLS) system.

1.3. Statement of the results. Our aim in this paper is to adapt for (1.1) Weinstein's analysis in [43], which is the starting point for the further investigation of the nonlinear dynamics of (1.1). In a forthcoming work [24], we will, in particular, prove the existence and the stability of self-similar solutions for the three-dimensional relativistic Vlasov–Poisson system (1.4), and the proof will partly rely on the understanding of the linearized operator close to the ground state as studied in this paper. More generally, our aim, as with the NLS system, is to be able to *quantify* the orbital stability statement of Theorem 1.2, and the obtained estimates are one of the keys to further understand the *dynamical* couplings induced by the flow near Q. Let us consider the quadratic form (1.20) obtained by linearizing the energy-Casimir functional near the polytrope Q:

$$d^2\mathcal{H}_C(Q)(f,f) = (p-1)\int_K Q^{p-2}\, f^2 - \int_{\mathbb{R}^N} |E_f|^2.$$

Even though this quadratic form is not positive on its domain, we claim that we can deduce from the variational structure of Q given by Proposition 1.1 the sharp coercive structure of this quadratic form. More precisely, let us denote by

$$(f,g) = \int_K fg\, dxdv$$

the $L^2(K, dxdv)$ scalar product and consider on K the weighted L^2 measure associated with Q :

$$d\mu = Q^{p-2}\, dxdv.$$

For $f \in L^2(K, d\mu)$, we introduce the linear operator

$$\mathcal{M}f = \left((p-1)Q^{p-2}f + \phi_f\right)\mathbf{1}_K, \tag{1.21}$$

related to the quadratic form

$$(\mathcal{M}f, f) = (p-1)\int_K Q^{p-2}\, f^2 - \int_{\mathbb{R}^N} |E_f|^2, \tag{1.22}$$

and claim the following theorem.

THEOREM 1.3 (coercivity of the linearized energy-Casimir functional). *Let* (N, α) *satisfy* (1.2) *and* $p_{crit} < p < +\infty$. *Then the quadratic form* $(\mathcal{M}f, f)$ *defined by* (1.22) *is continuous and self-adjoint on* $L^2(K, d\mu)$ *and there exists a universal constant* $\delta = \delta(N, \alpha, p) > 0$ *such that* $\forall f \in L^2(K, d\mu)$, *we have*

(i) *if* $N \neq \alpha + 2$,

$$(\mathcal{M}f, f) \geq \delta \int_K f^2\, Q^{p-2} dx dv - \frac{1}{\delta}\left\{\left(f, \frac{|v|^\alpha}{\alpha} + \phi_Q\right)^2 + \sum_{i=1}^N (f, x_i)^2\right\};$$

(ii) *if* $N = \alpha + 2$,

$$(\mathcal{M}f, f) \geq \delta \int_K f^2\, Q^{p-2} dx dv - \frac{1}{\delta}\left\{\left(f, \frac{|v|^\alpha}{\alpha} + \phi_Q\right)^2 + \sum_{i=1}^N (f, x_i)^2 + (f, |v|^{2-\alpha}|x|^2)^2\right\}.$$

Following [44], Theorem 1.3 provides a *quantitative* proof of the orbital stability of the ground state Q. Let us stress again the fact that this improvement is one of the key ingredients of the *nonlinear dynamical* analysis of the three-dimensional relativistic Vlasov–Poisson system in the forthcoming work [24].

The quadratic form $(\mathcal{M}f, f)$ is intimately related to the linearized Vlasov–Poisson system which is obtained by linearizing (1.1) around Q:

$$\text{(LVP)} \quad \begin{cases} \partial_t f + \mathcal{L} f = 0, \\ f(t=0, x, v) = f_0(x, v) \end{cases} \tag{1.23}$$

with

$$\mathcal{L} f = |v|^{\alpha-2} v \cdot \nabla_x f - E_Q \cdot \nabla_v f - E_f \cdot \nabla_v Q. \tag{1.24}$$

For a specific set of initial data, the linearized energy-Casimir functional $(\mathcal{M}f, f)$ is conserved by the flow of (1.24), and this allows us to prove that the linearized system (1.23) displays at most algebraic instabilities. More precisely, consider the space

$$\mathcal{L}\mathcal{E} = \{f \in L^1_{loc}(\mathbb{R}^{2N}) \ \text{ with } \ f\mathbf{1}_K \in L^2(K, d\mu) \ \text{ and } \ f\mathbf{1}_{K^c} \in \mathcal{E}\}, \tag{1.25}$$

where $K^c = \mathbb{R}^{2N} \setminus K$. Then we have the following theorem.

THEOREM 1.4 (algebraic instability for the linearized equations). *Let* $(N, \alpha) \in \{(3, 2), (4, 2)\}$ *and* $f_0 \in \mathcal{L}\mathcal{E}$. *Then* (1.23) *admits a unique solution* $f(t) = e^{-t\mathcal{L}} f_0 \in C(\mathbb{R}_+, \mathcal{L}\mathcal{E})$. *Moreover, we have the following estimates.*

(i) *General dynamics: There holds the growth estimate*

$$\forall t \in \mathbb{R}_+, \qquad \left|e^{-t\mathcal{L}} f_0\right|_{\mathcal{L}\mathcal{E}} \leq C\,(1 + t^k)\,|f_0|_{\mathcal{L}\mathcal{E}} \tag{1.26}$$

with $k = 2$ *for* $N = 3$, $k = 3$ *for* $N = 4$.

(ii) *Dynamics on* K: *There holds a decomposition* $L^2(K, d\mu) = M \oplus S$ *where the spaces* M, S *are both invariant through the flow* $e^{-t\mathcal{L}}$ *and* S *is finite-dimensional. Moreover, we have,* $\forall t \in \mathbb{R}_+$,

$$\forall g_0 \in M, \quad \left|e^{-t\mathcal{L}} g_0\right|_{L^2(K,d\mu)} \leq C\,|g_0|_{L^2(K,d\mu)}\,, \tag{1.27}$$

$$\forall g_0 \in S, \quad \left|e^{-t\mathcal{L}} g_0\right|_{L^2(K,d\mu)} \leq \begin{cases} C\,(1+t)\,|g_0|_{L^2(K,d\mu)} & \textit{for} \quad N = 3, \\ C\,(1+t^2)\,|g_0|_{L^2(K,d\mu)} & \textit{for} \quad N = 4. \end{cases}$$

In fact, we have a complete understanding of the dispersive properties of the flow $e^{-t\mathcal{L}}$. On the support of K, the decomposition $L^2(K, d\mu) = M \oplus S$ is explicit; see Lemma 3.4. S is the so-called finite-dimensional "flag" space which contains the algebraic instabilities generated by the large group of symmetries (1.7). On the contrary, the linear dynamics are bounded on M according to (1.27). Note that *no further dispersion holds* due to the fact that the quadratic form $(\mathcal{M}f, f)$ is conserved by the flow for $\mathrm{Supp}(f) \subset K$ and K is a compact set.

Now let $\mathrm{Supp}(f_0) \subset K^c$; then the solution decomposes into a part supported on K and a part supported outside K. For this last part, the flow (1.23) reduces exactly to the linear transport by the gravitational field E_Q which is explicit. Note that the characteristic curves of this field are contained in the level sets of $e(x,v) = \frac{|v|^\alpha}{\alpha} + \phi_Q$ and are trapped for $e < 0$, hence no dispersion occurs again, and nontrapped for $e \geq 0$, hence an explicit linear dispersion holds. The part supported on K is proved to grow at most algebraically, thanks to a Gronwall-type argument, and this concludes the proof of Theorem 1.4. □

Remark 1. We have focused in this paper on the polytropic ground states only. Let us recall that the class of ground states solutions is much wider and a large set of convex functions j is known to generate a ground state $Q(j)$; see [16, 22]. If we aim at treating the case of a minimizer obtained from (1.12) for a more general convex function j, a classical difficulty will occur which is the understanding of the kernel of the linearized operator. For $j(f) = f^p$, this kernel is explicit; see Lemma 2.4. A similar statement is unknown for general j. Note that similar issues are in fact addressed in Wan [42].

2. Coercivity of the linearized energy-Casimir functional. This section is devoted to the proof of Theorem 1.3. We shall adapt to our setting the analysis by Weinstein [43]. The proof relies on two main ingredients: the variational characterization of the ground state, as given by Proposition 1.1, and the complete description of the kernel of $\mathcal{M}$. This last fact relies in part on the uniqueness of the ground state Q, which is typically a delicate problem for NLS- type equations (see Weinstein [43], Kwong [21], and Maris [29]), but it is simple in our case, thanks to the scaling invariance of (1.17).

2.1. The linearized problem for the potential. In this subsection, we study the linearized problem around ϕ_Q of the nonlinear elliptic equation (1.17). We will in particular give an explicit description of the kernel of the corresponding Schrödinger operator that implies the explicit description of the kernel of $\mathcal{M}$.

The nonlinear elliptic equation (1.17) linearized around ϕ_Q is

$$\mathcal{A}\phi = 0 \quad \text{with} \quad \mathcal{A} = -\Delta - V_Q$$

and with

$$V_Q(x) = \gamma_{\alpha,p,N}\left(\frac{N}{\alpha} + \frac{1}{p-1}\right)(-1-\phi_Q(x))_+^{\frac{N}{\alpha}-\frac{p-2}{p-1}} = \frac{1}{p-1}\int_{\frac{|v|^\alpha}{\alpha}<-\phi_Q(x)-1} \frac{dv}{Q^{p-2}(x,v)}, \tag{2.1}$$

where $\gamma_{\alpha,p,N}$ was defined by (1.18). Note that $\frac{N}{\alpha} - \frac{p-2}{p-1} > 0$ under (1.2) and thus V_Q is a continuous function with compact support on $\mathbb{R}^N$. Hence, classical operator theory (see, e.g., Reed and Simon [34, Theorems XIII.15 and XIII.12]) gives that the operator $\mathcal{A}$ on $L^2(\mathbb{R}^N)$ with the domain $H^2(\mathbb{R}^N)$ is self-adjoint, and that its spectrum can be written as

$$\sigma(\mathcal{A}) = \{\lambda_i < 0\}_{1\leq i\leq I} \cup [0,+\infty), \tag{2.2}$$

where $\{\lambda_i < 0\}_{1\leq i\leq I}$ is the finite set of nonpositive eigenvalues with finite multiplicity and $[0,+\infty)$ is the essential spectrum of $\mathcal{A}$. 0 may be an eigenvalue. We shall denote by $(\psi_j)_{1\leq j\leq J}$, $|\psi_j|_{L^2} = 1$, the finite set of eigenvectors associated with the nonpositive eigenvalues that are well localized in space from standard argument.

Let $\dot{H}^1$ be the completion of $C_0^\infty(\mathbb{R}^N)$ with respect to the norm $|u|_{\dot{H}^1} = |\nabla u|_{L^2}$, or equivalently,

$$\dot{H}^1 = \left\{\phi \in L^1_{loc}(\mathbb{R}^N) : \quad \frac{\phi}{\sqrt{1+|x|^2}} \in L^2(\mathbb{R}^N) \text{ and } \nabla\phi \in L^2(\mathbb{R}^N)\right\}.$$

We have the following coercivity property.

LEMMA 2.1 (coercivity of the linearized problem close to ϕ_Q). *Let (α, N, p) be as in Theorem* 1.3. *Then the set of functions $\phi \in \dot{H}^1$ such that $\mathcal{A}\phi = 0$ in the distributional sense coincides with the kernel of $\mathcal{A}$ which can be characterized as*

$$\mathrm{Ker}(\mathcal{A}) = \mathrm{span}\{\partial_{x_i}\phi_Q\}_{1\leq i\leq N}. \tag{2.3}$$

Moreover, there exists $c_0 > 0$ such that $\forall \phi \in \dot{H}^1$ with radial symmetry,

$$\int_{\mathbb{R}^N} |\nabla\phi|^2 - \int_{\mathbb{R}^N} V_Q\,|\phi|^2 \geq c_0 \int |\nabla\phi|^2 - \frac{1}{c_0}\sum_{j=1}^{J}(\phi,\psi_j)^2. \tag{2.4}$$

Proof of Lemma 2.1. We follow Weinstein's strategy [43, proof of Proposition 2.8b]; see also Maris [29].

Step 1. Decomposition into spherical harmonics. Let $\phi \in \mathrm{Ker}(\mathcal{A})$. Then

$$-\Delta\phi = V_Q\phi \quad \text{with} \quad \phi \in \dot{H}^1 \hookrightarrow L^{\frac{2N}{N-2}}; \tag{2.5}$$

hence $\phi \in C^2(\mathbb{R}^N)$ from standard elliptic theory. One can thus decompose ϕ into spherical harmonics. More precisely, let $\mathcal{P}_k$ be the space of spherical harmonics of degree k, with dim $\mathcal{P}_k = a_k = C^k_{N+k-1} - C^k_{N+k-3}$, and for each k, let $\{Y_i^k\}_{1\leq i\leq a_i}$ be the L^2 orthonormal basis of $\mathcal{P}_k$. Then ϕ has a unique expansion

$$\phi(x) = \sum_{k=0}^{+\infty}\sum_{i=1}^{a_k} \varphi_{k,i}(|x|)\, Y_i^k\left(\frac{x}{|x|}\right) \tag{2.6}$$

with

$$\varphi_{k,i}(|x|) = \int_{S^{N-1}} \phi(|x|\theta)Y_i^k(\theta)d\theta \ \to 0 \ \text{ as } |x| \to +\infty. \tag{2.7}$$

Since the potential V_Q has radial symmetry, (2.5) implies

$$\mathcal{A}_k\,\varphi_{k,i} = 0 \qquad \text{with } \mathcal{A}_k = -\frac{d^2}{dr^2} - \frac{N-1}{r}\frac{d}{dr} + \frac{k(k+N-2)}{r^2} - V_Q(r). \tag{2.8}$$

Let $r_Q > 0$ be the unique solution to

$$\phi_Q(r_Q) = -1. \tag{2.9}$$

Then the potential V_Q is compactly supported on $[0, r_Q]$. Hence one can solve (2.8) explicitly outside its support with the constraint $\varphi_{k,i} \in L^\infty(\mathbb{R})$ deduced from $\phi \in L^\infty(\mathbb{R}^N)$ and (2.6). We get

$$\forall k \geq 0, \quad \forall i \in \{1, \ldots, a_k\}, \quad \forall r > r_Q, \qquad \varphi_{k,i}(r) = \frac{C_{k,i}}{r^{k+N-2}} \tag{2.10}$$

for some constant $C_{k,i}$.

Observe now that (2.3) is equivalent to

$$\varphi_{k,i} = 0 \;\text{ when }\; k \neq 1 \;\text{ and }\; \varphi_{1,i}(r) = a_{1,i}\, \phi_Q'(r) \;\text{ for }\; 1 \leq i \leq N. \tag{2.11}$$

Step 2. The case $k \geq 1$. Let $k \geq 1$. Observe that (2.10) implies $\phi_{k,i} \in H_r^1$, where H_r^1 denotes the set of H^1 distributions of $\mathbb{R}^N$ with radial symmetry. We now take the derivative of (1.17) with respect to the radial coordinate r and get after direct calculations

$$\mathcal{A}_1\, \phi_Q' = 0.$$

Therefore ϕ_Q' is an eigenfunction of $\mathcal{A}_1$ corresponding to the eigenvalue zero. Observe from (1.17) that ϕ_Q' is nonnegative on $(0, +\infty)$ and it follows from standard spectral analysis [34] that it is the ground state of $\mathcal{A}_1$ on H_r^1. We conclude that

$$\forall w \in H_r^1, \qquad (\mathcal{A}_1 w, w) \geq 0 \qquad \text{and} \qquad (\mathrm{Ker}\mathcal{A}_1)_{H_r^1} = \mathrm{span}(\phi_Q'), \tag{2.12}$$

and the case $k = 1$ of (2.11) follows.

For $k \geq 2$, we have from (2.8),

$$0 = (\mathcal{A}_k \phi_{k,i}, \phi_{k,i}) = (\mathcal{A}_1 \phi_{k,i}, \phi_{k,i}) + (k(k+N-2) - (N-1)) \int_0^{+\infty} |\phi_{k,i}|^2\, r^{N-3}\, dr,$$

which gives $\phi_{k,i} = 0$, thanks to the positivity of $\mathcal{A}_1$ (2.12), and the case $k \geq 2$ in (2.10) is also solved.

Step 3. The case $k = 0$. The remaining case $k = 0$ has to be treated in a different way. The fact that $\varphi_0 = 0$ is a consequence of the scaling structure of the ϕ_Q equation (1.17). Indeed, φ_0 solves

$$\mathcal{A}_0\, \varphi_0 = \left(-\frac{d^2}{dr^2} - \frac{N-1}{r}\frac{d}{dr} - V_Q \right) \varphi_0 = 0 \tag{2.13}$$

and, by (2.10), satisfies $\varphi_0(r) = \frac{C_0}{r^{N-2}}$ for r large enough. In particular,

$$\varphi_0(r) \to 0 \;\text{ as }\; r \to +\infty. \tag{2.14}$$

Note also that from the C^2 regularity of ϕ, $\varphi_0'(0) = 0$.

Now let

$$h = -1 - \phi_Q \;\text{ and }\; \beta = \frac{2\alpha(p-1)}{\alpha + (N-\alpha)(p-1)}. \tag{2.15}$$

We claim that

$$\mathcal{A}_0\, H = 0 \qquad \text{with } H(r) = \beta h(r) + r h'(r). \tag{2.16}$$

Indeed, for $\lambda > 0$, let $h_\lambda(r) = \lambda^\beta h(\lambda r)$. From (1.17) and the above choice of β, h_λ solves

$$\left(-\frac{d^2}{dr^2} - \frac{N-1}{r}\frac{d}{dr}\right) h_\lambda - \gamma_{\alpha,p,N}\,(h_\lambda)_+^{\frac{1}{p-1}+\frac{N}{\alpha}} = 0.$$

Differentiating this expression with respect to λ and evaluating the result at $\lambda = 1$ yield (2.16). We now observe from (2.10), (2.15), and (2.16) that $H(r) \to -\beta \neq 0$ as $r \to +\infty$. From standard ODE analysis, all the solutions to (2.13) with a vanishing derivative at $r = 0$ are proportional. Since $H'(0) = -(\beta+1)\phi_Q'(0) = 0$, both functions φ_0 and H are proportional, which implies by (2.14) that φ_0 is identically zero and concludes the proof of (2.11). The proof of (2.3) is now complete.

Step 4. *Proof of* (2.4). We now conclude the proof of (2.4), which follows from standard variational arguments. We briefly sketch the proof for the sake of completeness. Let the quadratic form

$$(\mathcal{A}\phi, \phi) = \int |\nabla\phi|^2 dx - \int V_Q\,|\phi|^2 dx$$

be continuous on $\dot{H}^1$ since V_Q is compactly supported. Let Λ be the set of $\phi \in \dot{H}^1$ with radial symmetry such that

$$(\phi, \psi_j) = 0 \qquad \text{for } j = 1, \dots, J. \tag{2.17}$$

Note that these L^2 scalar products are well defined since the ψ_k's are well localized in space. The spectral property (2.2) implies

$$\forall \phi \in \Lambda \cap L^2(\mathbb{R}^N), \qquad (\mathcal{A}\phi, \phi) \geq 0. \tag{2.18}$$

From a standard density argument, (2.18) holds also on Λ. We claim that, in fact,

$$\inf_{\phi\in\Lambda,\,|\nabla\phi|_{L^2}=1} (\mathcal{A}\phi, \phi) > 0. \tag{2.19}$$

This, together with the continuity of the quadratic form $(\mathcal{A}\phi, \phi)$ on $\dot{H}^1$, now implies (2.4).

Proof of (2.19). We argue by contradiction and consider a sequence ϕ_n such that

$$\phi_n \in \Lambda, \qquad (\mathcal{A}\phi_n, \phi_n) \to 0 \qquad \text{and} \qquad |\nabla\phi_n|_{L^2} = 1. \tag{2.20}$$

Up to a subsequence, $\phi_n \rightharpoonup \phi$ in $\dot{H}^1_r$. Moreover, since the Sobolev embedding $\dot{H}^1 \hookrightarrow L^{\frac{2N}{N-2}}$ is locally compact, we have $\phi \in \Lambda$ and

$$1 - (\mathcal{A}\phi_n, \phi_n) = \int V_Q\,|\phi_n|^2 \to \int V_Q\,|\phi|^2 = 1 \qquad \text{as } n \to +\infty.$$

By lower semicontinuity, $|\nabla\phi|_{L^2} \leq 1$ and thus $(\mathcal{A}\phi, \phi) \leq 0$. Since $\phi \in \Lambda$, this implies

$$(\mathcal{A}\phi, \phi) = 0, \qquad |\nabla\phi|_{L^2} = 1, \tag{2.21}$$

and the convergence $\phi_n \to \phi$ holds in the strong $\dot{H}^1$ topology. Hence $\inf(\mathcal{A}\phi, \phi)$ is attained and the Euler–Lagrange equation of this constrained variational problem reads

$$-\lambda\Delta\phi - V_Q\phi = \sum_{j=1}^{J} b_j\,\psi_j. \tag{2.22}$$

We take the L^2 inner product of (2.22) with ϕ and get $\lambda|\nabla\phi|^2_{L^2} = \int V_Q\,|\phi|^2 = 1$, thanks to the orthogonality conditions (2.20). Thus $\lambda = 1$ and (2.22) becomes

$$\mathcal{A}\phi = \sum_{j=1}^{J} b_j\,\psi_j. \tag{2.23}$$

Taking the scalar product of (2.23) with ψ_{j_0} now gives

$$b_{j_0} = (\mathcal{A}\phi, \psi_{j_0}) = \lambda_{j_0}(\phi, \psi_{j_0}) = 0,$$

where we also used (2.17) again. Hence $b_{j_0} = 0$ and $\phi \in \mathrm{Ker}(\mathcal{A})$ from (2.23). It remains to remark that (2.3) and the radial symmetry of ϕ imply that $\phi = 0$, which contradicts (2.21). The proof of (2.19) is complete. $\square$

This concludes the proof of Lemma 2.1. $\square$

2.2. Variational estimates and proof of Theorem 1.3. In this subsection, we study the linear operator $\mathcal{M}$, defined by (1.21) on $L^2(K, d\mu)$, and prove Theorem 1.3.

Let us start with the following continuity result.

LEMMA 2.2 (continuity of $\mathcal{M}$ on $L^2(K, d\mu)$). *Let (α, N, p) be as in Theorem 1.3. Then the quadratic form $(\mathcal{M}f, f)$ is continuous and self-adjoint on $L^2(K, d\mu)$. Moreover, let a sequence $f_n \in L^2(K, d\mu)$ be such that*

$$f_n \rightharpoonup f \quad \text{in } L^2(K, d\mu). \tag{2.24}$$

Then

$$E_{f_n} \to E_f \quad \text{in } L^2(\mathbb{R}^N). \tag{2.25}$$

Proof of Lemma 2.2. Let the potential V_Q be as given by (2.1). Then from the Cauchy–Schwarz inequality, $\forall f \in L^2(K, d\mu)$,

$$|\rho_f(x)| = \left|\int_K f(x,v)\,dv\right| \le \left((p-1)\int_K f^2(x,v)\,Q^{p-2}dv\right)^{1/2} (V_Q(x))^{1/2}. \tag{2.26}$$

Observe now that the potential V_Q is a continuous function with compact support on $\mathbb{R}^N$. Thus (2.26) implies $\rho_f \in L^1 \cap L^2(\mathbb{R}^N)$ with $\mathrm{Supp}(\rho_f) \subset \{|x| \le r_Q\}$ (r_Q is defined by (2.9)). Sobolev embeddings now imply $E_f \in L^2(\mathbb{R}^N)$ and the continuity of $\mathcal{M}$ on $L^2(K, d\mu)$ follows. The fact that $\mathcal{M}$ is self-adjoint follows from integration by parts.

Now let a sequence f_n satisfy (2.24). The estimate (2.26) gives an $L^1 \cap L^2$ bound for ρ_{f_n}, and thus E_{f_n} is locally compact in $L^2(\mathbb{R}^N)$ from Sobolev embeddings. Observe now that $|x| > 2r_Q$ and $|x-y| < r_Q$ imply $|y| > |x| - r_Q > \frac{|x|}{2}$, and thus

$$|E_f(x)| \le C\int_{|x-y|\le r_Q} \frac{|\rho_f(x-y)|}{|y|^{N-1}}\,dy \le C\frac{2^{N-1}}{|x|^{N-1}}|\rho_f|_{L^1}.$$

We conclude that E_{f_n} is L^2 compact and (2.25) follows. This concludes the proof of Lemma 2.2. $\square$

We now claim the following positivity property for $\mathcal{M}$ that is a consequence of the variational characterization of Q as given by Proposition 1.1 and is the very heart of the proof of Theorem 1.3.

LEMMA 2.3 (positivity of $\mathcal{M}$ induced by the variational structure of Q). *Let (α, N, p) be as in Theorem* 1.3. *Let $f \in L^2(K, d\mu)$ with*

$$\left(f, \frac{|v|^\alpha}{\alpha} + \phi_Q\right) = 0. \tag{2.27}$$

Then the quadratic form defined by (1.22) *satisfies*

$$(\mathcal{M}f, f) \geq 0. \tag{2.28}$$

Proof of Lemma 2.3. Let $f \in C_0^\infty(K)$. Then for any η small enough, $Q + \eta f \in \mathcal{E}$. Let $J_{\alpha,p,N}$ be the functional defined by (1.14) and denote $J(\eta) = J_{\alpha,p,N}(Q+\eta f)$. The variational characterization of Q given by Proposition 1.1 implies

$$J'(0) = 0, \qquad J''(0) \geq 0. \tag{2.29}$$

Now, from a direct computation using the identities

$$\omega := \frac{\alpha\theta_1}{||v|^\alpha Q|_{L^1}} = \frac{\theta_2}{|Q|_{L^p}^p} = \frac{\theta_3}{|Q|_{L^1}} = \frac{2}{|E_Q|_{L^2}^2}$$

obtained during the construction of Q (see [22]), we get

$$\begin{aligned}(\mathcal{M}f, f) = \frac{J''(0)}{\omega J(0)} + \omega \left\{ \frac{\alpha+2-N}{N-2} \left(f, \frac{|v|^\alpha}{\alpha}\right)^2 + \frac{p}{\theta_2}\left(f, Q^{p-1}\right)^2 + \frac{1}{\theta_3}(f,1)^2 \right\} \\ + \omega \left(f, \frac{|v|^\alpha}{\alpha} + \phi_Q\right)\left(f, \frac{|v|^\alpha}{\alpha} - \phi_Q\right).\end{aligned}$$

Note that $3 \leq N \leq \alpha + 2$ in the range of parameters (1.2), and thus (2.29) and the orthogonality condition (2.27) now imply (2.28). The general case $f \in L^2(K, d\mu)$ follows by density. This concludes the proof of Lemma 2.3. □

The second key to the proof of Theorem 1.3 is the fact that the kernel of $\mathcal{M}$ is explicit and in particular $\mathcal{M}$ is invertible when restricted to radially symmetric distributions. Moreover, some inverses are explicit as a consequence of the action of the large group of symmetries (1.7).

LEMMA 2.4 (explicit description of the kernel of $\mathcal{M}$). *Let (α, N, p) be as in Theorem* 1.3. *Then*

$$\mathrm{Ker}\,(\mathcal{M}) = \left\{f \in L^2(K, d\mu) \text{ with } \mathcal{M}f = 0\right\} = \mathrm{span}\{\partial_{x_i} Q\}_{1\leq i\leq N}. \tag{2.30}$$

Moreover, let

$$S_1 = \frac{N-\alpha}{2}\, x \cdot \nabla_x Q - v \cdot \nabla_v Q\,, \qquad S_2 = -x \cdot \nabla_v Q\,, \qquad S_3 = \mathcal{M}^{-1}\left(\frac{|v|^{2-\alpha}|x|^2}{2}\right). \tag{2.31}$$

Then we have the following identities:

$$\mathcal{M}S_1 = \alpha\left(\frac{|v|^\alpha}{\alpha} + \phi_Q\right)\mathbf{1}_K\,, \qquad \mathcal{M}S_2 = x \cdot v\,|v|^{\alpha-2}\,\mathbf{1}_K\,, \qquad \mathcal{M}S_3 = \frac{|v|^{2-\alpha}|x|^2}{2}\,\mathbf{1}_K. \tag{2.32}$$

Proof of Lemma 2.4.

Step 1. Description of Ker($\mathcal{M}$). We claim that

$$\operatorname{span}\{\partial_{x_i}Q\}_{1\le i\le N}\subset \operatorname{Ker}(\mathcal{M}).$$

Indeed, we rewrite (1.16) of Q as

$$\left(Q^{p-1}+\frac{|v|^\alpha}{\alpha}+\phi_Q+1\right)\mathbf{1}_K=0 \tag{2.33}$$

and take a derivative with respect to $(x_i)_{1\le i\le N}$ to derive

$$\left((p-1)Q^{p-2}\partial_{x_i}Q+\partial_{x_i}\phi_Q\right)\mathbf{1}_K=0. \tag{2.34}$$

In particular,

$$\int_{\mathbb{R}^{2N}}Q^{p-2}\,(\partial_{x_i}Q)^2=\frac{1}{p-1}\int_{\mathbb{R}^N}(\partial_{x_i}\phi_Q)^2\,V_Q<+\infty,$$

where V_Q is the potential defined by (2.1), and thus $\partial_{x_i}Q\in L^2(K,d\mu)$. Using also $\partial_{x_i}\phi_Q=\phi_{\partial_{x_i}Q}$, we deduce from (2.34) that $\partial_{x_i}Q\in\operatorname{Ker}(\mathcal{M})$.

Now let $f\in\operatorname{Ker}(\mathcal{M})$. For $(x,v)\in K$ we have

$$(p-1)Q^{p-2}f(x,v)+\phi_f(x)=0 \tag{2.35}$$

and thus, $\forall |x|\le r_Q$,

$$\Delta\phi_f(x)=\rho_f(x)=-\frac{1}{p-1}\int_K\frac{\phi_f(x)}{Q^{p-2}(x,v)}\,dv=-\phi_f(x)\,V_Q(x). \tag{2.36}$$

For $|x|>r_Q$, $\rho_f(x)=0$, so (2.36) still holds. We conclude that ϕ_f belongs to the kernel of the operator $\mathcal{A}=-\Delta-V_Q$ on $\dot H^1$. By Lemma 2.1, there exists $\{c_i\}_{1\le i\le N}$ such that

$$\phi_f=\sum_{i=1}^N c_i\,\partial_{x_i}\phi_Q.$$

It follows from (2.34) and (2.35) that

$$f=\sum_{i=1}^N c_i\,\partial_{x_i}Q$$

and this concludes the proof of (2.30).

Step 2. Derivation of the algebraic identities (2.32). The first identity in (2.32) is a consequence of the scaling invariance of (2.33). For a parameter $\mu>0$, define

$$Q_\mu(x,v)=\mu^{N-\alpha}Q(x,\mu v).$$

Then the corresponding microscopic energy defined by

$$e(x,v)=\frac{|v|^\alpha}{\alpha}+\phi_Q(x)$$

scales according to $e_\mu(x,v) = \frac{1}{\mu^\alpha}\, e(x,\mu v)$. We thus compute from (2.33)

$$\left(\mu^{-(p-1)(N-\alpha)}\, Q_\mu^{p-1} + \mu^\alpha e_\mu(x,v) + 1\right) \mathbf{1}_{(x,\mu v)\in K} = 0. \tag{2.37}$$

Differentiating this relation with respect to μ and evaluating the result at $\mu = 1$ yield

$$(p-1)Q^{p-2}R - (p-1)(N-\alpha)Q^{p-1} + |v|^\alpha = 0 \quad \text{on} \quad K,$$

where we have denoted

$$R = (N-\alpha)Q + v\cdot\nabla_v Q = \frac{dQ_\mu}{d\mu}_{|\mu=1}.$$

Noting that

$$\phi_R = -\alpha\phi_Q \quad \text{from} \quad \rho_R = \int ((N-\alpha)Q + v\cdot\nabla_v Q)\, dv = -\alpha\rho_Q,$$

we get the following intermediate identity:

$$\mathcal{M}R = (p-1)(N-\alpha)Q^{p-1} - \alpha\left(\frac{|v|^\alpha}{\alpha} + \phi_Q\right). \tag{2.38}$$

We now rescale the x variable in Q and set for $\lambda > 0$:

$$Q_\lambda(x,v) = \frac{1}{\lambda^2}\, Q\left(\frac{x}{\lambda}, v\right).$$

The microscopic energy scales according to $e_\lambda(x,v) = e\left(\frac{x}{\lambda}, v\right)$ and (2.33) becomes

$$\left(\lambda^{2(p-1)}\, Q_\lambda^{p-1} + e_\lambda(x,v) + 1\right) \mathbf{1}_{(x/\lambda,v)\in K} = 0.$$

We differentiate this expression with respect to λ and evaluate the result at $\lambda = 1$ to get

$$-(p-1)Q^{p-2}\widetilde{R} + 2(p-1)Q^{p-1} - x\cdot\nabla_x\phi_Q = 0 \qquad \text{on } K,$$

where we have denoted

$$\widetilde{R} = 2Q + x\cdot\nabla_x Q = -\frac{dQ_\lambda}{d\lambda}_{|\lambda=1}.$$

Now noting that

$$\phi_{\widetilde{R}} = x\cdot\nabla_x\phi_Q,$$

we get the second intermediate inequality

$$\mathcal{M}\widetilde{R} = 2(p-1)Q^{p-1}. \tag{2.39}$$

Multiplying (2.39) by $\frac{N-\alpha}{2}$ and subtracting (2.38) yield the first identity in (2.32).

The second identity in (2.32) can be proved by a direct computation, noting simply that

$$\phi_{S_2} = 0 \qquad \text{from} \quad \rho_{S_2} = -\int x\cdot\nabla_v Q dv = 0$$

and that by (1.16)

$$\nabla_v Q = -\frac{1}{p-1}\,\frac{v\,|v|^{\alpha-2}}{Q^{p-2}}. \tag{2.40}$$

Finally, the last identity in (2.32) is obvious as soon as we are able to define S_3 according to (2.31). To this aim, we recall that since Q is radially symmetric, we have $\int_{\mathbb{R}^{2N}} |v|^{2-\alpha}|x|^2\partial_{x_i} Q = 0$ for $1 \le i \le N$, and (2.30) implies that $\frac{|v|^{2-\alpha}|x|^2}{2} \in \mathrm{Ker}(\mathcal{M})^{\perp}$. Hence Lemma 2.3 and the Lax–Milgram theorem ensure the invertibility of $\mathcal{M}$ on $\mathrm{Ker}(\mathcal{M})^{\perp}$ and (2.31) defines S_3 in $L^2(K, d\mu)$ without ambiguity.

This concludes the proof of Lemma 2.4. ◻

We are now in position to conclude the proof of Theorem 1.3, which follows from standard variational techniques.

Proof of Theorem 1.3. Let $\mathcal{I}$ be the set of $f \in L^2(K, d\mu)$ with

$$\left\{ \begin{array}{ll} \left(f, \dfrac{|v|^\alpha}{\alpha} + \phi_Q\right) = (f, x_i) = 0, \quad 1 \le i \le N, & \text{if } N-\alpha \neq 2, \\ \left(f, \dfrac{|v|^\alpha}{\alpha} + \phi_Q\right) = (f, x_i) = (f, |v|^{2-\alpha}|x|^2) = 0, \quad 1 \le i \le N, & \text{if } N-\alpha = 2. \end{array} \right. \tag{2.41}$$

Note that the L^2 inner products are well defined as, $\forall f \in L^2(K, d\mu)$ and $g \in L^\infty(K)$,

$$\begin{aligned} |(f,g)| &\le |g|_{L^\infty}\left(\int_K f^2\,Q^{p-2}\,dxdv\right)^{1/2}\left(\int_K \frac{1}{Q^{p-2}}\,dxdv\right)^{1/2} \\ &\le C|g|_{L^\infty}\,|f|_{L^2(K,d\mu)}\,|V_Q|_{L^\infty}^{1/2} \end{aligned}$$

with V_Q defined by (2.1). We now claim that

$$I = \inf_{f\in\mathcal{I},\ |f|_{L^2(K,d\mu)}=1} (\mathcal{M}f, f) > 0. \tag{2.42}$$

Since $(\mathcal{M}\cdot,\cdot)$ is a continuous quadratic form, (2.42) and the definition (2.41) of $\mathcal{I}$ imply the coercivity property of Theorem 1.3.

Proof of (2.42). Arguing by contradiction and using the positivity property of Lemma 2.3, we let a sequence f_n be such that

$$f_n \in \mathcal{I}, \qquad \int_K f_n^2\,Q^{p-2} = 1 \quad\text{and}\quad (\mathcal{M}f_n, f_n) \to 0 \quad\text{as}\quad n \to +\infty. \tag{2.43}$$

Up to a subsequence, $f_n \rightharpoonup f$ in $L^2(K, d\mu)$ and thus $f \in \mathcal{I}$ with

$$\int_K f^2\,Q^{p-2}\,dxdv \le 1. \tag{2.44}$$

Now by Lemma 2.2, $E_{f_n} \to E_f$ in $L^2(\mathbb{R}^N)$. Since, by (2.43), we have $|E_{f_n}|_{L^2}^2 \to p-1$, we deduce that $|E_f|_{L^2}^2 = p-1$ and thus $f \neq 0$. Moreover, (2.44) implies $(\mathcal{M}f, f) \le 0$ and thus $(\mathcal{M}f, f) = 0$ from Lemma 2.3 and $f \in \mathcal{I}$. This implies $\int_K f^2\,Q^{p-2} = 1$ and the infimum I defined by (2.42) is attained at f.

We now write down the Euler–Lagrange equation for this constrained minimization problem and get the existence of Lagrange multipliers β, $(\gamma_i)_{1\le i\le N}$, κ, τ such that

$$\mathcal{M}f = \beta\,Q^{p-2}f + \sum_{i=1}^N \gamma_i\,x_i\,\mathbf{1}_K + \kappa\left(\frac{|v|^\alpha}{\alpha} + \phi_Q\right)\mathbf{1}_K \qquad \text{for } N-\alpha \neq 2, \tag{2.45}$$

(2.46)

$$\mathcal{M}f = \beta\, Q^{p-2} f + \sum_{i=1}^{N} \gamma_i\, x_i\, \mathbf{1}_K + \kappa \left(\frac{|v|^\alpha}{\alpha} + \phi_Q \right) \mathbf{1}_K + \tau\, |v|^{2-\alpha} |x|^2\, \mathbf{1}_K \qquad \text{for } N-\alpha = 2.$$

Take the $L^2(K, dxdv)$ inner product of (2.45) or (2.46) with f, use $(\mathcal{M}f, f) = 0$, the orthogonality conditions (2.41), and $\int f^2 Q^{p-2} dxdv = 1$ to obtain $\beta = 0$. Then take the inner product of (2.45) or (2.46) with $\partial_{x_i} Q$ for $1 \le i \le N$ to get

$$-\gamma_i \int Q = (\mathcal{M}f, \partial_{x_i} Q) = (f, \mathcal{M}\partial_{x_i} Q) = 0,$$

where we used (A.2) from the appendix and (2.30). Hence the γ_i's are all zero.

Now let $N-\alpha \neq 2$ and take the inner product of (2.45) with S_1 defined by (2.31). Using (2.32), we get

$$\kappa \left(\frac{|v|^\alpha}{\alpha} + \phi_Q, S_1 \right) = (\mathcal{M}f, S_1) = (f, \mathcal{M}S_1) = \alpha \left(f, \frac{|v|^\alpha}{\alpha} + \phi_Q \right) = 0.$$

Since, by (A.1) given in the appendix, in the subcritical case $N-\alpha \neq 2$ the factor of κ is not zero, we deduce that $\kappa = 0$. Hence $\mathcal{M}f = 0$. From (2.30), we thus have the existence of $(c_i)_{1 \le i \le n}$ such that

$$f = \sum_{i=1}^{N} c_i\, \partial_{x_i} Q.$$

Multiplying this expression by x_i and integrating, we deduce from (2.41) that $c_i = 0$ for $i = 1, \ldots, N$, and thus $f = 0$, which which is absurd.

Let $N-\alpha = 2$. Taking the inner product of (2.46) with S_1 and using (A.1), (2.32), and (2.41), we get

$$0 = (f, \mathcal{M}S_1) = (\mathcal{M}f, S_1) = \tau(|v|^{2-\alpha}|x|^2, S_1) = -\alpha\tau \int |v|^{2-\alpha}|x|^2 Q \quad \text{and thus} \quad \tau = 0.$$

Now take the inner product of (2.46) with S_3 (defined by (2.31)). By the orthogonality condition (2.41) we have

$$\kappa \left(\frac{|v|^\alpha}{\alpha} + \phi_Q, S_3 \right) = (\mathcal{M}f, S_3) = (f, \mathcal{M}S_3) = \left(f, \frac{|v|^{2-\alpha}|x|^2}{2} \right) = 0,$$

so we deduce from (A.5) that $\kappa = 0$ and $\mathcal{M}f = 0$. The end of the proof is then identical to the case $N-\alpha \neq 2$.

This concludes the proof of Theorem 1.3. ∎

3. The linearized Vlasov–Poisson system in dimension 3 or 4. In this section, we fix $\alpha = 2$ and take $N = 3$ or $N = 4$ and prove Theorem 1.4.

3.1. Well-posedness of the linearized Vlasov–Poisson system. We prove in this subsection the well-posedness of the linearized equation (1.23) and some conservation laws associated with this flow.

We start with a technical lemma stating a few useful properties of the $\mathcal{LE}$ space defined by (1.25) that is a natural space for the study of the linearized Vlasov–Poisson problem.

LEMMA 3.1 (embedding of the $\mathcal{E}$ space). *The space $\mathcal{LE}$ is continuously embedded into $L^1(\mathbb{R}_x^N \times \mathbb{R}_v^N) \cap L^{\frac{2N}{N+2}}(\mathbb{R}_x^N, L^1(\mathbb{R}_v^N))$. Moreover, there exists a constant C such that*

$$\forall f \in \mathcal{LE}, \qquad |E_f|_{L^2} \le C|f|_{\mathcal{LE}}. \tag{3.1}$$

Proof of Lemma 3.1. Let $f \in \mathcal{LE}$ and decompose this function into $f = f^i + f^e$ with $f^i = f\mathbf{1}_K \in L^2(K, d\mu)$ and $f^e = f\mathbf{1}_{K^c} \in \mathcal{E}$. By (2.26) we have

$$|f^i|_{L^1} + |f^i|_{L_x^2 L_v^1} \le C|f^i|_{L^2(K,d\mu)},$$

and, by the standard interpolation inequality,

$$|f^e|_{L^1} + |f^e|_{L_x^q L_v^1} \le C|f^e|_{\mathcal{E}}$$

with $q = \frac{(N+2)p-N}{Np-N+2}$. The assumption $p > p_{crit}$ ensures that $q > \frac{2N}{N+2}$, thus, noting also that $2 > \frac{2N}{N+2}$, we get

$$|f|_{L^1} + |f|_{L_x^{\frac{2N}{N+2}} L_v^1} \le C|f|_{\mathcal{LE}}.$$

The estimate (3.1) of the field now follows from the Poisson equation and the generalized Young inequality. This concludes the proof of Lemma 3.1. □

We now state the well-posedness of the linearized Vlasov–Poisson system (1.23) that is the main result of this subsection.

PROPOSITION 3.2 (properties of the linearized flow in $\mathcal{E}$). *Let $(N, \alpha) = (3, 2)$ or $(4, 2)$. Let $f_0 \in L^1(\mathbb{R}^N \times \mathbb{R}^N)$. Then (1.23) admits a unique weak solution $e^{-t\mathcal{L}} f_0 \in C(\mathbb{R}_+, L^1(\mathbb{R}^N \times \mathbb{R}^N))$. Assume, moreover, that $f_0 \in \mathcal{LE}$ and decompose it as follows:*

$$f_0 = f_0^i + f_0^e \quad \text{with} \quad f_0^i = f_0\, \mathbf{1}_K\,, \quad f_0^e = f_0\, \mathbf{1}_{K^c}. \tag{3.2}$$

Let $f^i(t) = e^{-t\mathcal{L}} f_0^i$, $f^e(t) = e^{-t\mathcal{L}} f_0^e$. Then $\forall t \ge 0$, we have $f(t) = e^{-t\mathcal{L}} f_0 = f^i(t) + f^e(t) \in \mathcal{LE}$ and the following conservation laws hold: $\forall t \ge 0$,

$$\text{Supp } f^i(t) \subset K, \quad \left(\mathcal{M}f^i, f^i\right)(t) = \left(\mathcal{M}f_0^i, f_0^i\right), \tag{3.3}$$

$$\int_{K^c} \left(1 + \frac{|v|^2}{2} + \phi_Q(x,v)\right) f^e(t,x,v)\, dxdv = \int_{K^c} \left(1 + \frac{|v|^2}{2} + \phi_Q\right) f_0^e\, dxdv, \tag{3.4}$$

$$\forall q \in [1,p], \qquad |f^e(t)|_{L^q(K^c)} = |f_0^e|_{L^q}, \tag{3.5}$$

$$\left(\mathcal{M}f^e, f^e\right)(t) = -2\int_0^t \int_K f^e(s)\, v \cdot E_{f^e \mathbf{1}_{K^c}}(s) ds. \tag{3.6}$$

Here we extended the operator $\mathcal{M}$ to $\mathcal{LE}$ by

$$\mathcal{M}f = \left((p-1)Q^{p-2} f + \phi_{f\mathbf{1}_K}\right) \mathbf{1}_K = \mathcal{M}(f\mathbf{1}_K). \tag{3.7}$$

Remark 2. From (3.3), $L^2(K, d\mu)$ is invariant under the flow (1.23) and the linearized energy-Casimir functional $(\mathcal{M}f, f)$ is conserved by the flow. This is, however, no longer true for a general initial data and the error to the conservation law is measured by (3.6).

Proof of Proposition 3.2.

Step 1. Transport by E_Q. Let $\mathcal{T}$ be the linear transport operator induced by the field of the ground state Q:

$$\mathcal{T} = v \cdot \nabla_x - E_Q \cdot \nabla_v. \tag{3.8}$$

Thanks to the regularity of the field $E_Q = \nabla_x \phi_Q$, one can define the characteristics associated with $\mathcal{T}$. For (t, x, v), we denote by $X(s; t, x, v)$, $V(s; t, x, v)$ the global solution of the differential system

$$\frac{d}{ds}X = V, \qquad \frac{d}{ds}V = -E_Q(X), \qquad X(s=t) = x, \qquad V(s=t) = v. \tag{3.9}$$

Recall that the energy is an invariant of this system, i.e., $\frac{1}{2}|V(s;t,x,v)|^2 + \phi_Q(X(s;t,x,v))$ is independent of s, and that for any s, t the Jacobian of the Lagrangian change of variable

$$(x, v) \mapsto (X(s; t, x, v), V(s; t, x, v)) \tag{3.10}$$

is equal to 1. An important consequence of the energy invariant and the fact that Q is a function of the microscopic energy is that a characteristic curve cannot cross the boundary of the support Q: K and K^c are both invariant along the flow (3.9).

Step 2. Well-posedness of (1.23) in L^1. It is a simple consequence of the existence of the characteristics curves (3.9) and we briefly sketch the proof for the sake of completeness. Let $T > 0$ and introduce the following mapping on $\mathcal{C}([0,T], L^1(\mathbb{R}^N \times \mathbb{R}^N))$: for f in this space, $G(f)$ is defined as the unique weak solution g of

$$\partial_t g + v \cdot \nabla_x g - E_Q \cdot \nabla_v g = E_f \cdot \nabla_v Q\,, \qquad g(t=0) = f_0, \tag{3.11}$$

given, thanks to the characteristics, by

$$\begin{aligned} G(f)(t,x,v) &= f_0(X(0;t,x,v), V(0;t,x,v)) \\ &\quad + \int_0^t (E_f \cdot \nabla_v Q)\,(s, X(s;t,x,v), V(s;t,x,v))\,ds. \end{aligned} \tag{3.12}$$

It is useful to note that $f \in \mathcal{C}([0,T], L^1(\mathbb{R}^N \times \mathbb{R}^N))$ implies $\rho_f \in \mathcal{C}([0,T], L^1(\mathbb{R}^N))$ and thus $E_f \in \mathcal{C}([0,T], L^{\frac{N}{N-1},\infty})$, where $L^{\frac{N}{N-1},\infty}$ stands for the weak $L^{\frac{N}{N-1}}$ space (or Marcinkiewicz space). Hence $E_f \in L^1_{loc}(\mathbb{R}^N)$. Observe from (2.40) that

$$\int_{\mathbb{R}^N} |\nabla_v Q(x,v)|\,dv \le C V_Q(x)$$

is bounded on $\mathbb{R}^N$ and compactly supported. Thus the right-hand side of (3.11) belongs to $\mathcal{C}([0,T], L^1(\mathbb{R}^N \times \mathbb{R}^N))$ and $\forall t \in [0,T]$,

$$|E_f \cdot \nabla_v Q|_{L^1}(t) \le C\,|f|_{L^1}(t).$$

Integrating (3.12) on $\mathbb{R}^N \times \mathbb{R}^N$ and performing the Lagrangian change of coordinate (3.10), we get for any $f_1, f_2 \in C([0,T], L^1(\mathbb{R}^N \times \mathbb{R}^N))$

$$|G(f_1) - G(f_2)(t)|_{L^1} \le C \int_0^t |f_1 - f_2|_{L^1}(s)\,ds.$$

This is enough to conclude by the Banach fixed point theorem for T small enough. We have proved that (1.23) admits a unique solution that satisfies

(3.13)

$$f(t,x,v)=f_0(X(0;t,x,v),V(0;t,x,v))+\int_0^t (E_f\cdot\nabla_v Q)\,(s,X(s;t,x,v),V(s;t,x,v))\,ds.$$

Step 3. Well-posedness in $\mathcal{LE}$. Now let $f=f^i+f^e\in\mathcal{LE}$. The simple remarks that K and K^c remain invariant under the flow of the characteristics (3.9) and that the source term $E_f\cdot\nabla_v Q$ in (1.23) is supported on K enable us to conclude that Supp $f^i\subset K$ and that $h:=f^e\,\mathbf{1}_{K^c}=f\,\mathbf{1}_{K^c}$ solves in the weak sense the equation

$$\partial_t h+v\cdot\nabla_x h-E_Q\cdot\nabla_v h=0\,,\qquad h(t=0)=f_0^e. \tag{3.14}$$

It is clear then that $f^e\,\mathbf{1}_{K^c}\geq 0$ a.e. on $\mathbb{R}_+\times\mathbb{R}^N\times\mathbb{R}^N$ and that (3.4) and (3.5) hold (recall that $\frac{|v|^2}{2}+\phi_Q$ is invariant along the characteristics). Note that the boundedness of ϕ_Q in L^∞, (3.4), and (3.5) with $q=1$ implies a uniform bound for $|f^e\,\mathbf{1}_{K^c}(t)|_{\mathcal{E}}$.

We now square (3.13), multiply by Q^{p-2}, and integrate over K to get

$$\begin{aligned}|f(t)|^2_{L^2(K,d\mu)}&\leq 2|f_0|^2_{L^2(K,d\mu)}\\&\quad+C(t)\textstyle\int_0^t\int_K\Big(Q^{p-2}\,|E_f\cdot\nabla_v Q|^2\Big)(s,X(s;t,x,v),V(s;t,x,v))\,dsdxdv,\end{aligned}$$

where we used the fact that $Q(x,v)=Q(X(s;t,x,v),V(s;t,x,v))$. Then, performing again the Lagrangian change of variable (3.10) and noting from (2.40) that

$$Q^{p-2}\,|\nabla_v Q|^2=\frac{|v|\,|\nabla_v Q|}{p-1}\in L^\infty(\mathbb{R}^N_x,L^1(\mathbb{R}^N_v)),$$

we obtain

$$\begin{aligned}|f(t)|^2_{L^2(K,d\mu)}\quad&\leq 2|f_0|^2_{L^2(K,d\mu)}+C\int_0^t|E_f|^2_{L^2(\mathbb{R}^N)}(s)\,ds\\&\leq 2|f_0|^2_{L^2(K,d\mu)}+C\int_0^t|f(t)|^2_{\mathcal{LE}}(s)\,ds,\end{aligned}$$

where we used (3.1). Since we already have $|f\,\mathbf{1}_{K^c}|_{\mathcal{E}}\leq C\ \forall\ t$, this is enough to conclude with the Gronwall lemma that the function f belongs to $L^\infty_{loc}(\mathbb{R}_+,\mathcal{LE})$.

Step 4. Derivation of the conservation laws. It remains to prove the conservation laws (3.3) and (3.6). To this aim, let us first define a suitable regularization of f. Let $n\in\mathbb{N}^*$ and let f_0^n be a sequence of $C_0^\infty(\mathbb{R}^N\times\mathbb{R}^N)\cap\mathcal{LE}$ functions which converges to f_0 in the $\mathcal{LE}$ topology as $n\to+\infty$. Consider now a nonnegative $C^\infty(\mathbb{R})$ function θ such that $\theta(u)=1$ for $u\geq 1$ and $\theta(u)=0$ for $u\leq 1/2$ and let

(3.15)

$$\theta^n(x,v)=\theta\left(n\left|1+\frac{|v|^2}{2}+\phi_Q(x)\right|\right),\qquad\chi^n(x,v)=\theta\left(n\left(-1-\frac{|v|^2}{2}-\phi_Q(x)\right)\right).$$

Now, we define f^n as the solution of the following problem, which can be constructed by a fixed point procedure similarly as above:

$$\partial_t f^n+v\cdot\nabla_x f^n-E_Q\cdot\nabla_v f^n=\theta^n\,E_{f^n}\cdot\nabla_v Q\,,\qquad f^n(t=0)=f_0^n. \tag{3.16}$$

Since the function $\theta^n\,\nabla_v Q$ is C^∞, it is readily seen that f^n is a sequence of C^∞ function that converges to f^n in the $\mathcal{LE}$ topology as $n\to+\infty$.

Now, from (3.16) and (2.40), we get

(3.17)
$$\begin{aligned}\frac{d}{dt}\int_{\mathbb{R}^{2N}} Q^{p-2}(f^n)^2 dxdv &= 2\int_K Q^{p-2} f^n\,\theta^n\,E_{f^n}\cdot\nabla_v Q\,dxdv\\ &= -\frac{2}{p-1}\int_K f^n\,\chi^n\,v\cdot E_{f^n}\,dxdv\\ &= -\frac{2}{p-1}\int_K f^n\chi^n\,v\cdot E_{f^n\chi^n}\,dxdv - \frac{2}{p-1}\int_K f^n\chi^n\,v\cdot E_{f^n(1-\chi^n)}\,dxdv\\ &= \frac{2}{p-1}\int_{\mathbb{R}^N}\phi_{f^n\chi^n}\nabla_x\cdot\left(\int_{\mathbb{R}^N} vf^n\,\chi^n\,dv\right)dx - \frac{2}{p-1}\int_K f^n\chi^n\,v\cdot E_{f^n(1-\chi^n)}\,dxdv,\end{aligned}$$

where we used the equation $v\cdot\nabla_x Q - E_Q\cdot\nabla_v Q = 0$ and noted that θ^n and χ^n coincide on K. Multiply now (3.16) by χ^n. Since χ^n is a function of the energy $\frac{|v|^2}{2}+\phi_Q(x)$, we have

$$\partial_t(f^n\chi^n) + v\cdot\nabla_x(f^n\chi^n) - E_Q\cdot\nabla_v(f^n\chi^n) = (\chi^n)^2\,E_{f^n}\cdot\nabla_v Q. \tag{3.18}$$

Besides, for the same reason, the function $(\chi^n)^2\,\nabla_v Q$ is an exact derivative with respect to v. Hence an integration of (3.18) with respect to v yields

$$\partial_t\int_{\mathbb{R}^N}(f^n\chi^n)\,dv + \nabla_x\cdot\left(\int_{\mathbb{R}^N} vf^n\,\chi^n\,dv\right) = 0$$

and, by the Poisson equation, the first integral in the right-hand side of (3.17) can be rewritten as follows:

$$\frac{2}{p-1}\int_{\mathbb{R}^N}\phi_{f^n\chi^n}\nabla_x\cdot\left(\int_{\mathbb{R}^N} vf^n\,\chi^n\,dv\right)dx = \frac{1}{p-1}\frac{d}{dt}\int_K \phi_{f^n\chi^n}\,f^n\chi^n\,dxdv.$$

Finally,

$$\begin{aligned}(\mathcal{M}(f^n\chi^n), f^n\chi^n)(t) &= (\mathcal{M}(f_0^n\chi^n), f_0^n\chi^n)\\ &\qquad -2\int_0^t\int_K f^n(s)\chi^n\,v\cdot E_{f^n(1-\chi^n)}(s)\,dxdvds.\end{aligned}$$

Since, $\forall\ T>0$, $f^n\to f$ in $L^\infty((0,T),\mathcal{L}\mathcal{E})$ as $n\to+\infty$, one can pass to the limit in the various terms of this identity, thanks to Lemma 3.1 (recall that v is bounded on K). Applying this inequality to f^i and f^e leads, respectively, to (3.3) and (3.6).

This concludes the proof of Proposition 3.2. ∎

Let us conclude this section with the following commutation formula that will be useful in the next subsections.

Lemma 3.3 (commutation formula). *Let $f_0\in\mathcal{L}\mathcal{E}$ and let $f(t)=e^{-t\mathcal{L}}f_0$ be the corresponding weak solution of* (1.23). *Let $h\in L^2(K,d\mu)\cap C^1(\mathring{K})$ be such that $\mathcal{L}h\in L^2(K,d\mu)$. Then*

$$(f(t),\mathcal{M}h) = (f_0,\mathcal{M}h) + \int_0^t (f(s),\mathcal{M}\mathcal{L}h)\,ds - \int_0^t\int_K v\cdot\left(hE_{f\mathbf{1}_{K^c}}\right)(s)ds. \tag{3.19}$$

Moreover, for $1\le i\le N$, we have

$$(f(t),x_i\,\mathbf{1}_K) = (f_0,x_i\,\mathbf{1}_K) + \int_0^t (f(s),v_i\,\mathbf{1}_K)\,ds. \tag{3.20}$$

Proof of Lemma 3.3. Let us observe the following algebraic identity, which follows from a direct computation: Let $\mathcal{L}$, $\mathcal{T}$, $\mathcal{M}$ be, respectively, given by (1.24), (3.8), and (1.21). Then

$$\forall f \in L^2(K, d\mu), \quad \mathcal{L} f = \frac{1}{(p-1)Q^{p-2}} \mathcal{T}(\mathcal{M} f) \tag{3.21}$$

in the sense of distributions.

Introduce then the smooth function θ^n defined by (3.15) and let $\widetilde{f_0^n}$ be a C_0^∞ regularization of f_0. Then, setting $f_0^n = \widetilde{f_0^n}\,\theta^n$, we define f^n as the classical solution of (3.16). One can see that $f^n \to f$ in $\mathcal{L}\mathcal{E}$ as $n \to +\infty$. Moreover, since the flow (3.9) preserves the energy and θ^n depends only on the energy, the support of f^n is included in the support of θ^n, where h is C^1. We split $f^n = f_i^n \mathbf{1}_K + f_e^n \mathbf{1}_{K^c} = f_i^n + f_e^n$ with $f_{i,e}^n$ smooth from the support localization of f^n, and thus

$$\frac{d}{dt}(f^n, \mathcal{M}h) = -(\mathcal{L} f^n, \mathcal{M}h) = -(\mathcal{L} f_i^n, \mathcal{M}h) - (\mathcal{L} f_e^n, \mathcal{M}h).$$

The first term is computed using (3.21), the self-adjointness of $\mathcal{M}$, the skew-adjointness of $\mathcal{T}$, and the fact that $\mathcal{T}(F(e)) = 0$ for any function F:

$$\begin{aligned} -(\mathcal{L} f_i^n, \mathcal{M}h) &= -\left(\frac{1}{(p-1)Q^{p-2}} \mathcal{T}(\mathcal{M} f_i^n), \mathcal{M}h\right) = \left(\mathcal{M} f_i^n, \mathcal{T}\left[\frac{1}{(p-1)Q^{p-2}} \mathcal{M}h\right]\right) \\ &= (\mathcal{M} f_i^n, \mathcal{L}h) = (f_i^n, \mathcal{M}\mathcal{L}h) = (f^n, \mathcal{M}\mathcal{L}h). \end{aligned}$$

For the second term, we use that f_e^n and $\mathcal{M}h$ have disjoint support to compute

$$-(\mathcal{L} f_e^n, \mathcal{M}h) = \int_{\mathbb{R}^N} E_{f_e^n} \cdot \nabla_v Q (p-1) Q^{p-2} h = -\int_K hv \cdot E_{f_e^n}$$

from (2.40). We then integrate in time and pass to the limit as $n \to +\infty$, and (3.19) follows. The second identity (3.20) can be proved by a similar regularization procedure and by direct calculations. This concludes the proof of Lemma 3.3. $\square$

Remark 3. If the support of f_0 is in K, then (3.19) becomes simpler:

$$(f(t), \mathcal{M}h) = (f_0, \mathcal{M}h) + \int_0^t (f(s), \mathcal{M}\mathcal{L}h)\, ds. \tag{3.22}$$

3.2. The linearized dynamics on the support of Q. From Proposition 3.2, the solution $e^{-t\mathcal{L}} f_0$ of (1.23) remains supported on K when it has this property at $t = 0$. In this section we estimate the action of the linearized Vlasov–Poisson system on $L^2(K, d\mu)$.

Let us start by introducing the following decomposition of $L^2(K, d\mu)$ whose proof is given in the appendix.

Lemma 3.4 (decomposition of $L^2(K, d\mu)$). *Let $(N, \alpha) \in \{(3,1), (3,2), (4,2)\}$. There holds the decomposition*

$$L^2(K, d\mu) = M \oplus S,$$

where M is defined as the set of $f \in L^2(K, d\mu)$ with

$$\begin{cases} \textit{for } N \neq \alpha + 2, & \left(f, \dfrac{|v|^\alpha}{\alpha} + \phi_Q\right) = (f, x_i) = (f, v_i) = 0, \quad 1 \le i \le N, \\ \textit{for } N = \alpha + 2, & \left(f, \dfrac{|v|^\alpha}{\alpha} + \phi_Q\right) = (f, x \cdot v|v|^{\alpha-2}) = (f, |x|^2 |v|^{2-\alpha}) \\ & \qquad = (f, x_i) = (f, v_i) = 0, \quad 1 \le i \le N, \end{cases}$$

and S is defined, thanks to the functions S_i given by (2.31), *according to*

$$\begin{cases} \textit{if } N \neq \alpha+2, \textit{ then } S = \operatorname{span}\{S_1\ , \partial_{x_i} Q\ ,\ \partial_{v_i} Q\ ,\ 1 \leq i \leq N\}\,, \\ \textit{if } N = \alpha+2, \textit{ then } S = \operatorname{span}\{S_1\ ,\ S_2\ ,\ S_3\ , \partial_{x_i} Q\ , \partial_{v_i} Q\ ,\ 1 \leq i \leq N\}\,. \end{cases}$$

Our main claim is now that S and M are invariant under the linearized flow (1.23). The subspace S is the so-called *flag space* and contains the algebraically growing modes induced by the large set of symmetries (1.7), while the free evolution remains bounded on M in the $\mathcal{LE}$ norm.

PROPOSITION 3.5 (splitting of the motion). *Let $(N,\alpha) \in \{(3,2),(4,2)\}$. Consider the decomposition $L^2(K,d\mu) = M \oplus S$, where the spaces M, S are defined in Lemma* 3.4. *Then M and S are both invariant under the linearized flow* (1.23) *and there holds: $\forall t \in \mathbb{R}_+$,*

$$\forall g_0 \in M, \quad \left|e^{-t\mathcal{L}} g_0\right|_{L^2(K,d\mu)} \leq C\,|g_0|_{L^2(K,d\mu)}\,, \tag{3.23}$$

$$\forall g_0 \in S, \quad \left|e^{-t\mathcal{L}} g_0\right|_{L^2(K,d\mu)} \leq \begin{cases} C\,(1+t)\,|g_0|_{L^2(K,d\mu)} & \textit{for} \quad N=3, \\ C\,(1+t^2)\,|g_0|_{L^2(K,d\mu)} & \textit{for} \quad N=4. \end{cases} \tag{3.24}$$

Proof of Proposition 3.5.

Step 1. The evolution on S. The free evolution is explicit on S. Indeed, letting $N = 3,4$ and $(S_i)_{1\leq i\leq 3}$ be defined by (2.31), we claim that

$$\mathcal{L}S_1 = 0 \qquad \mathcal{L}(\partial_{x_i} Q) = 0, \qquad \mathcal{L}(\partial_{v_i} Q) = -\partial_{x_i} Q, \tag{3.25}$$

and the extra relations for $N = 4$:

$$\mathcal{L}S_2 = S_1\,, \qquad \mathcal{L}S_3 = S_2. \tag{3.26}$$

Proof of (3.25) *and* (3.26). They follow from (2.32) and (3.21). Let us prove (3.26). In the interior of K, $(S_i)_{1\leq i\leq 3}$ are smooth. We then compute using (2.32): $\forall (x,v) \in \overset{\circ}{K}$,

$$\mathcal{L}S_2 = \frac{1}{(p-1)Q^{p-2}}\,\mathcal{T}(\mathcal{M}S_2) = \frac{1}{(p-1)Q^{p-2}}\mathcal{T}(x\cdot v) = \frac{1}{(p-1)Q^{p-2}}(|v|^2 - x\cdot E_Q).$$

We now take the derivative of (2.33) in x and v to get

$$E_Q + (p-1)Q^{p-2}\nabla_x Q = 0, \qquad v + (p-1)Q^{p-2}\nabla_v Q = 0,$$

and thus

$$\mathcal{L}S_2 = \frac{1}{(p-1)Q^{p-2}}(|v|^2 - x\cdot E_Q)\mathbf{1}_K = -v\cdot\nabla_v Q + x\cdot\nabla_x Q = S_1.$$

Similarly,

$$\begin{aligned} \mathcal{L}S_3 &= \frac{1}{(p-1)Q^{p-2}}\,\mathcal{T}(\mathcal{M}S_3) = \frac{1}{(p-1)Q^{p-2}}\,\mathcal{T}\left(\frac{|x|^2}{2}\right) \\ &= \frac{x\cdot v}{(p-1)Q^{p-2}} = -x\cdot\nabla_v Q = S_2, \end{aligned}$$

where we used (2.40). In order to conclude the proof of (3.26), we use the following technical remark. Let $h \in L^2(K, d\mu)$ such that $h \in C^1(\overset{\circ}{K})$ and denote by $(\mathcal{T}h)_K$ the function defined pointwise on $\overset{\circ}{K}$ and continued by zero outside K. Assume that $(\mathcal{T}h)_K \in L^1(K)$. Then, due to the fact that the boundary of K is a level set of the microscopic energy, the distribution $\mathcal{T}h$ defined as the distributional derivative of h by the derivation $\mathcal{T}$ and $(\mathcal{T}h)_K$ coincide in $\mathcal{D}'(\mathbb{R}^N \times \mathbb{R}^N)$. Applying this with $h = S_1$ or S_2 concludes the proof of (3.26). Next (3.25) follows similarly and is left to the reader.

Now let $g_0 \in S$, i.e., according to Lemma 3.4,

$$\text{if } N = 3, \qquad g_0 = \alpha\, S_1 + \sum_{i=1}^{N} \delta_i\, \partial_{x_i} Q + \sum_{i=1}^{N} \epsilon_i\, \partial_{v_i} Q,$$
$$\text{if } N = 4, \qquad g_0 = \alpha\, S_1 + \beta\, S_2 + \gamma\, S_3 + \sum_{i=1}^{N} \delta_i\, \partial_{x_i} Q + \sum_{i=1}^{N} \epsilon_i\, \partial_{v_i} Q.$$

From (3.25) and (3.26), the evolution $e^{-t\mathcal{L}} g_0$ is explicit:

$$\text{if } N = 3, \quad e^{-t\mathcal{L}} g_0 = \alpha\, S_1 + \sum_{i=1}^{N} (\epsilon_i\, t + \delta_i)\, \partial_{x_i} Q + \sum_{i=1}^{N} \epsilon_i\, \partial_{v_i} Q,$$
$$\text{if } N = 4, \quad e^{-t\mathcal{L}} g_0 = \left(\frac{\gamma}{2} t^2 - \beta t + \alpha\right) S_1 + (-\gamma t + \beta)\, S_2 + \gamma\, S_3$$
$$+ \sum_{i=1}^{N} (\epsilon_i\, t + \delta_i)\, \partial_{x_i} Q + \sum_{i=1}^{N} \epsilon_i\, \partial_{v_i} Q,$$

which shows the stability of S and (3.24) is proved.

Step 2. The evolution on M. Now let $g_0 \in M$. From (3.25) and (3.26), we have $\mathcal{M}\mathcal{L}S_1 = 0$ and for $N = 4$, $\mathcal{M}\mathcal{L}S_2 = \mathcal{M}S_1$, $\mathcal{M}\mathcal{L}S_3 = \mathcal{M}S_2$. Hence Lemma 3.3 and Remark 3 give

$$\frac{d}{dt}(e^{-t\mathcal{L}} g_0, \mathcal{M}S_1) = 0, \tag{3.27}$$

and, if $N = 4$,

$$\frac{d}{dt}(e^{-t\mathcal{L}} g_0, \mathcal{M}S_2) = (e^{-t\mathcal{L}} g_0, \mathcal{M}S_1), \qquad \frac{d}{dt}(e^{-t\mathcal{L}} g_0, \mathcal{M}S_3) = (e^{-t\mathcal{L}} g_0, \mathcal{M}S_2). \tag{3.28}$$

Furthermore, noting that $\mathcal{M}\partial_{v_i} Q = -v_i$, we deduce from (3.25), (3.22), (3.20), and (2.30) that for $1 \le i \le N$,

$$\frac{d}{dt}(e^{-t\mathcal{L}} g_0, v_i) = (e^{-t\mathcal{L}} g_0, \mathcal{M}\partial_{x_i} Q) = 0, \qquad \frac{d}{dt}(e^{-t\mathcal{L}} g_0, x_i) = (e^{-t\mathcal{L}} g_0, v_i). \tag{3.29}$$

Recalling from Lemma 3.4 and from (2.32) that M can be characterized as the set of $f \in L^2(K, d\mu)$ with

$$\begin{cases} \text{for } N = 3, \quad (f, \mathcal{M}S_1) = (f, x_i) = (f, v_i) = 0, \quad 1 \le i \le N, \\ \text{for } N = 4, \quad (f, \mathcal{M}S_j) = (f, x_i) = (f, v_i) = 0, \quad 1 \le j \le 3,\ 1 \le i \le N, \end{cases}$$

we infer from (3.27), (3.28), and (3.29) that $g_0 \in M$ implies $e^{-t\mathcal{L}} g_0 \in M\ \forall\ t \ge 0$. The uniform bound (3.23) on $e^{-t\mathcal{L}} g$ in $\mathcal{L}\mathcal{E}$ now follows from the conservation of the linearized energy-Casimir functional (3.3) and the coercivity property of Theorem 1.3 which ensures that the quadratic form $(\mathcal{M}\,\cdot, \cdot)$ is coercive on M. This concludes the proof of Proposition 3.5. $\square$

3.3. Proof of Theorem 1.4. We are now in position to conclude the proof of Theorem 1.4.

Let $f_0 = f_0^i + f_0^e \in \mathcal{L}\mathcal{E}$ according to the decomposition (3.2) and denote by, respectively, $f^i(t) = e^{-t\mathcal{L}} f_0^i$, $f^e(t) = e^{-t\mathcal{L}} f_0^e$ the corresponding solutions to (1.23). The evolution of f^i is already controlled, thanks to Proposition 3.5. It remains to study the evolution of f^e, which is not supported a priori in K^c and may spread onto the whole space.

From Proposition 3.2, we have already

$$|f^e\, \mathbf{1}_{K^c}|_{\mathcal{E}}\,(t) \le C\; |f_0^e|_{\mathcal{E}} = C\; |f_0^e|_{\mathcal{L}\mathcal{E}}.$$

In particular,

$$|E_{f^e \mathbf{1}_{K^c}}|_{L^2} \le C\; |f_0^e|_{\mathcal{L}\mathcal{E}}. \tag{3.30}$$

It remains to bound $f^e \mathbf{1}_K$. Using Lemma 3.3 with $h = S_1$, $h = S_2$, $h = S_3$, and $h = \partial_{v_i} Q$ (the S_i's are defined in (2.31)), we obtain successively

$$\left|\left(f^e, \left(\frac{|v|^2}{2} + \phi_Q\right) \mathbf{1}_K\right)\right|(t) \le C(1+t)\,|f_0^e|_{\mathcal{L}\mathcal{E}},$$

$$|(f^e, v_i \mathbf{1}_K)|\,(t) \le C(1+t)\,|f_0^e|_{\mathcal{L}\mathcal{E}},$$

$$|(f^e, x_i \mathbf{1}_K)|\,(t) \le C(1+t^2)\,|f_0^e|_{\mathcal{L}\mathcal{E}},$$

and, if $N = 4$,

$$|(f^e, x\cdot v \mathbf{1}_K)|\,(t) \le C(1+t^2)\,|f_0^e|_{\mathcal{L}\mathcal{E}},$$

$$\left|\left(f^e, |x|^2 \mathbf{1}_K\right)\right|(t) \le C(1+t^3)\,|f_0^e|_{\mathcal{L}\mathcal{E}},$$

where we applied Lemma 2.4 and also used (3.30) to bound the various terms $\int_K hv \cdot E_{\mathbf{1}_{K^c}}(s) ds$. Therefore, Theorem 1.3 implies that

$$|f^e(t)|^2_{L^2(K,d\mu)} \le C|(\mathcal{M} f^e, f^e)|(t) + C(1+t^{2\alpha})\,|f_0^e|^2_{\mathcal{L}\mathcal{E}}$$

with $\alpha = 2$ if $N = 3$ and $\alpha = 3$ if $N = 4$. Now, one deduces from (3.6) and (3.30) that

$$\begin{aligned} |f^e(t)|^2_{L^2(K,d\mu)} &\le C\,|(\mathcal{M} f^e, f^e)|\,(t) + C(1+t^{2\alpha})\,|f_0^e|^2_{\mathcal{L}\mathcal{E}} \\ &\le C(1+t^{2\alpha})\,|f_0^e|^2_{\mathcal{L}\mathcal{E}} + C\; |f_0^e|_{\mathcal{L}\mathcal{E}} \int_0^t |f^e(s)|_{L^2(K,d\mu)} ds, \end{aligned}$$

and (1.26) follows from a standard sublinear Gronwall lemma. This concludes the proof of Theorem 1.4. ∎

Appendix. This appendix is devoted to the proof of the orthogonal decomposition $L^2(K, d\mu) = M \oplus S$ of Lemma 3.4.

Proof of Lemma 3.4. Explicit computations using the identities

$$||v|^\alpha Q|_{L^1} = \frac{N-2}{2}\,|E_Q|_{L^2}^2 = \int_{\mathbb{R}^{2N}} x\cdot\nabla_x\phi_Q\, Q\,dxdv$$

lead to

$$\left(\frac{|v|^\alpha}{\alpha} + \phi_Q\,, S_1\right) = (N-\alpha-2)\frac{(2\alpha+(\alpha+2)N-N^2)}{4\alpha}\,|E_Q|_{L^2}^2\,. \tag{A.1}$$

Moreover, integrations by parts yield

$$\big(x_i\,,\,\partial_{x_j}Q\big) = \big(v_i\,,\,\partial_{v_j}Q\big) = -\delta_{ij}\int Q\,,\quad 1\le i\le N,\quad 1\le j\le N, \tag{A.2}$$

and the radial symmetry of Q implies that

$$0 = \left(\frac{|v|^\alpha}{\alpha} + \phi_Q\,, S_2\right) = \left(\frac{|v|^\alpha}{\alpha} + \phi_Q\,, \partial_{x_i}Q\right) = \left(\frac{|v|^\alpha}{\alpha} + \phi_Q\,, \partial_{v_i}Q\right),\quad 1\le i\le N, \tag{A.3}$$

$$(x_i\,, S_j) = 0,\quad 1\le i\le N,\quad 1\le j\le 3. \tag{A.4}$$

Let $N\neq\alpha+2$ and $f\in L^2(K,d\mu)$. We look for λ, $(\delta_i)_{1\le i\le N}$, $(\epsilon_i)_{1\le i\le N}$ such that

$$\tilde f = f - \lambda S_1 - \sum_{i=1}^N \delta_i\,\partial_{x_i}Q - \sum_{i=1}^N \epsilon_i\,\partial_{v_i}Q \in M.$$

Taking the inner product of $\tilde f$ with $\frac{|v|^\alpha}{\alpha} + \phi_Q$ and using (A.1) and (A.3), we get

$$\lambda = \left(f, \frac{|v|^\alpha}{\alpha} + \phi_Q\right)\left[(N-\alpha-2)\frac{(2\alpha+(\alpha+2)N-N^2)}{4\alpha}\,|E_Q|_{L^2}^2\right]^{-1}.$$

Taking the inner product of $\tilde f$ with x_i or v_i and using (A.4) and (A.2), we get

$$\delta_i = (f, x_i)\left[-\int Q\right]^{-1},\quad \epsilon_i = (f, v_i)\left[-\int Q\right]^{-1},\qquad 1\le i\le N.$$

Since λ, the δ_i's, and the ϵ_i's are uniquely defined in order to ensure $\tilde f\in M$, the result is proved.

Let $N=\alpha+2$. By explicit computations and using the symmetries of Q, we get

$$\alpha\left(\frac{|v|^\alpha}{\alpha} + \phi_Q\,, S_3\right) = (\mathcal{M}S_1, S_3) = (S_1, \mathcal{M}S_3) = \left(S_1, \frac{|v|^{2-\alpha}|x|^2}{2}\right) = -\,\frac{\alpha}{2}\int |v|^{2-\alpha}|x|^2 Q, \tag{A.5}$$

$$\big(|v|^{2-\alpha}|x|^2, S_2\big) = \big(|v|^{2-\alpha}|x|^2, \partial_{x_i}Q\big) = \big(|v|^{2-\alpha}|x|^2, \partial_{v_i}Q\big) = 0,\quad 1\le i\le N, \tag{A.6}$$

$$\big(x\cdot v|v|^{\alpha-2}, S_1\big) = \big(x\cdot v|v|^{\alpha-2}, \partial_{x_i}Q\big) = \big(x\cdot v|v|^{\alpha-2}, \partial_{v_i}Q\big) = 0,\quad 1\le i\le N, \tag{A.7}$$

$$\big(x \cdot v|v|^{\alpha-2}, S_3\big) = (\mathcal{M}S_2, S_3) = (S_2, \mathcal{M}S_3) = 0, \tag{A.8}$$

$$\big(x \cdot v|v|^{\alpha-2}, S_2\big) = \int |x|^2 Q + (\alpha-2)\int (x\cdot v)^2 |v|^{\alpha-4} Q. \tag{A.9}$$

Let $f \in L^2(K, d\mu)$. We deduce from (A.1)–(A.9) that

$$\tilde{f} = f - \lambda S_1 - \beta S_2 - \gamma S_3 - \sum_{i=1}^{N} \delta_i\, \partial_{x_i} Q - \sum_{i=1}^{N} \epsilon_i\, \partial_{v_i} Q \in M$$

if and only if

$$\gamma = \left(f, \frac{|v|^\alpha}{\alpha} + \phi_Q\right)\left[-\frac{1}{2}\int |v|^{2-\alpha}|x|^2 Q\right]^{-1},$$

$$\lambda = \left[\big(f, |v|^{2-\alpha}|x|^2\big) - \gamma\left(S_3, |v|^{2-\alpha}|x|^2\right)\right]\left[-\alpha\int |v|^{2-\alpha}|x|^2 Q\right]^{-1},$$

$$\beta = \big(f, x\cdot v|v|^{\alpha-2}\big)\left[\int |x|^2 Q + (\alpha-2)\int (x\cdot v)^2|v|^{\alpha-4} Q\right]^{-1},$$

$$\delta_i = (f, x_i)\left[-\int Q\right]^{-1}, \quad \epsilon_i = (f, v_i)\left[-\int Q\right]^{-1}, \quad 1 \le i \le N,$$

where we have successively taken the inner product of $\tilde{f}$ with $\frac{|v|^\alpha}{\alpha} + \phi_Q$, $|v|^{2-\alpha}|x|^2$, $x\cdot v|v|^{\alpha-2}$, x_i, and v_i. This concludes the proof of Lemma 3.4. ∎

HOMOGENIZATION OF DEGENERATE TWO-PHASE FLOW EQUATIONS WITH OIL TRAPPING*

BEN SCHWEIZER†

Abstract. We consider the one-dimensional degenerate two-phase flow equations as a model for water drive in oil recovery. The effect of oil trapping is observed in strongly heterogeneous materials with large variations in the permeabilities and in the capillary pressure curves. In such materials, a vanishing oil saturation may appear at interior interfaces and inhibit the oil recovery. We introduce a free boundary problem that separates a critical region with locally vanishing permeabilities from a strictly parabolic region and we give a rigorous derivation of the effective conservation law.

Key words. degenerate parabolic equation, effective equations, free boundary problems, two-phase flow

1. Introduction. The equations of two-phase flow describe the motion of two immiscible fluids in a porous medium, e.g., the flow of oil and water in rock. The equations are a challenging subject of modern analysis, in particular due to the nonlinear and degenerate coefficient functions, the permeabilities of the two phases, and the capillary pressure.

Oil trapping is an effect in media with large variations in the coefficients. Well known to experimentalists [13, 14], the mathematical analysis of this effect was initiated in [5, 10, 9]. Let us consider the process of oil recovery from a medium that consists of a mixture of fine and coarse materials. Starting with a high oil saturation u and a high oil pressure p, after some time, the oil pressure falls below the entry pressure of oil in the fine material. From this point on, despite a positive saturation in the coarse material, oil can be trapped in regions that are surrounded by fine material.

In this work we analyze a one-dimensional medium that consists of two materials, distributed periodically with period $\varepsilon > 0$ and with different permeabilities k and different capillary pressures p_c. We denote the saturation function of the corresponding solutions by u^ε. Our aim is to find a macroscopic or effective equation, i.e., an equation that characterizes weak limits u^0 of the family u^ε for $\varepsilon \to 0$. An effective equation allows us to determine, e.g., in a numerical scheme, the averaged profile of the solution u^ε without resolving the scale $\varepsilon > 0$.

With the method of two-scale convergence developed in [1] and measure-theoretic tools from [3] we rigorously derive the macroscopic equation

$$\partial_t u^0 + \operatorname{div} \mathcal{F}(u^0, \partial_x u^0) = 0$$

with a nonlinear function $\mathcal{F}$ that is determined by the coefficient functions through a finite-dimensional nonlinear problem. The effective flux function reflects the effect of oil trapping: it satisfies $\mathcal{F}(u, v) = 0$ for all $v \in \mathbb{R}$ and all $u \leq u^*/2$, where u^* is the residual oil saturation in the coarse material. Our contribution continues the

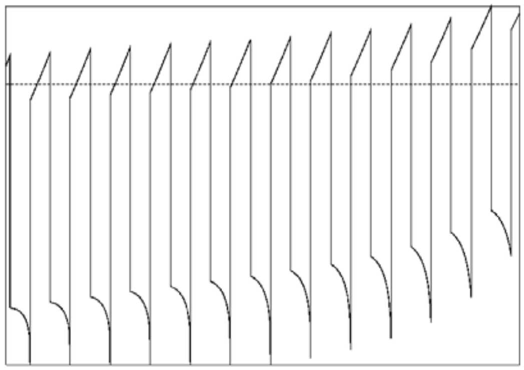

FIG. 1. *Oil saturation u^ε, zoomed view. Due to different capillary pressure curves in fine and coarse material, the saturation has jumps and oil is trapped in the coarse material. The saturation vanishes at some points. At these points, the permeability degenerates, but the infinite slope $\partial_x u^\varepsilon = -\infty$ makes transport of oil still possible. This figure is an unpublished numerical result and courtesy of I. S. Pop.*

analysis of [10, 9], where effective equations were formally derived with an asymptotic expansion. In [10], which contains various scalings and treats our scaling as the "capillary limit," the authors mention the specific difficulties in the homogenization of nonlinear equations and do not attempt a rigorous derivation of the effective equations. In fact, in [9] a different law is derived by starting with another ansatz; our analysis recovers the nonlinear function of [9]. For rigorous homogenization results of nonlinear equations we refer the reader to [7] for a double porosity model, to [6] for a stochastic setting, and to [4, 17] for models of capillary hysteresis. All these results concern the case of nondegenerate coefficients.

We want to highlight two difficulties in the homogenization process. The first concerns the nonlinear structure of the equations: loosely speaking, fluxes are of the form $g(u^\varepsilon)\partial_x u^\varepsilon$. In order to pass to the two-scale limit in such a term, we need a strong convergence of the argument in the nonlinear function. The strong convergence is usually obtained from estimates for first derivatives. This procedure cannot be performed in our case, since u^ε is an oscillatory function with jumps, and certainly not strongly convergent. The key point in the derivation of macroscopic equations in Proposition 1 is the compactness result of (3.14).

The second difficulty regards the degeneracy of the permeabilities. A strictly positive permeability k results in L^2-estimates for spatial derivatives and allows us to use the compactness result. But the effect of oil trapping appears precisely in the case that, in parts of the domain, the saturation vanishes; see Figure 1. In this situation, a vanishing permeability appears and no estimate for gradients is available. Our analysis uses the technique of a free boundary description in order to proceed. We decompose the domain into a "good" region G of strictly positive saturation and a "bad" region B; see Figure 2. We then derive the effective equations separately: in region G we use two-scale convergence (Proposition 1) to find the effective equations in Corollary 1. In region B, instead, the limit equations are trivial and are derived in the form of two-sided a priori estimates. The main point is then the continuity condition across the free boundary shown in Proposition 2. This condition allows us to combine the equations again into a single equation on the whole domain. The method exploits that oscillations of the free boundary do not appear; this is ensured by the boundary and initial conditions which imply a monotonicity of the free boundary.

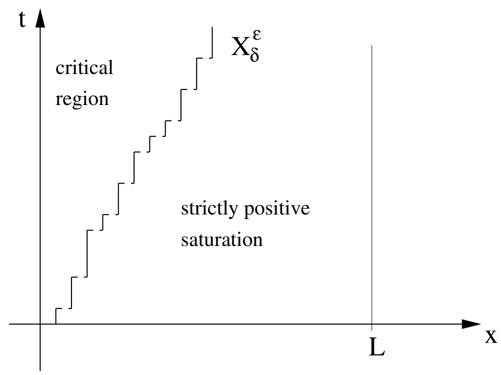

FIG. 2. *A free boundary separating the critical region from a region of uniformly positive saturation and permeability. The graph illustrates that the free boundary is discontinuous for $\varepsilon > 0$.*

As a by-product of our description, we learn more about qualitative features of solutions. We may define an experimentally observable free boundary $X_0^\varepsilon : (0,T) \to \mathbb{R}$ as the smallest function such that in all points (x,t) with $x > X_0^\varepsilon(t)$ the saturation u^ε is strictly positive. We now ask about properties of the limiting function $\tilde{X}_0^0(t) := \lim_{\varepsilon\to 0} X_0^\varepsilon(t)$. We prove in Lemma 6 that the corresponding limit curve $\{(x,t) : x = \tilde{X}_0^0(t)\}$ is contained in the critical domain $B \subset \bar{\Omega}_T$. Thus, the effective solution provides bounds for the experimentally observable free boundary. In particular, if it can be shown that the limit equation allows only solutions u^0 with $u^0 > u^*/2$ on Ω_T, then the experimentally observable free boundary must vanish in the limit $\varepsilon \to 0$.

Oil trapping in one-dimensional domains. We denote pressure and saturation of the oil phase by $p = p_1 = p_{oil}$ and $u = u_{oil}$ and the corresponding quantities of the water phase by $p_2 = p_{water}$ and $u_{water} = 1 - u$. The absolute permeability is denoted by k and the relative permeabilities by $k_{r,1} = k_{rel,oil}$ and $k_{r,2} = k_{rel,water}$. The equations in primary variables are the conservation laws for oil and water combined with the Darcy law for the velocities and the capillary pressure relation:

$$\partial_t u = \nabla \cdot (k(x)k_{r,1}(u)\nabla p_1), \tag{1.1}$$

$$-\partial_t u = \nabla \cdot (k(x)k_{r,2}(u)\nabla p_2), \tag{1.2}$$

$$p_1 - p_2 = p_c(u). \tag{1.3}$$

Summing the conservation laws and inserting the relation between the pressure functions yields, with $K(x,u) = k(x)(k_{r,1}(u) + k_{r,2}(u))$, and writing now p instead of p_1,

$$\nabla \cdot (K(x,u)\nabla p - k(x)k_{r,2}(u)\nabla[p_c(u)]) = 0. \tag{1.4}$$

One may regard this as an elliptic equation for p that defines the relation between p and u. Together with this relation, at least formally, (1.1) is an evolution equation for u.

In this work we study only the one-dimensional case with spatial domain $x \in \Omega = (0,L)$. Equation (1.4) then implies that the expression in parentheses is constant in space. Physically, the constant describes the total flux and we write

$$K(x,u)\partial_x p - k(x)k_{r,2}(u)\partial_x[p_c(x,u)] = -q_0. \tag{1.5}$$

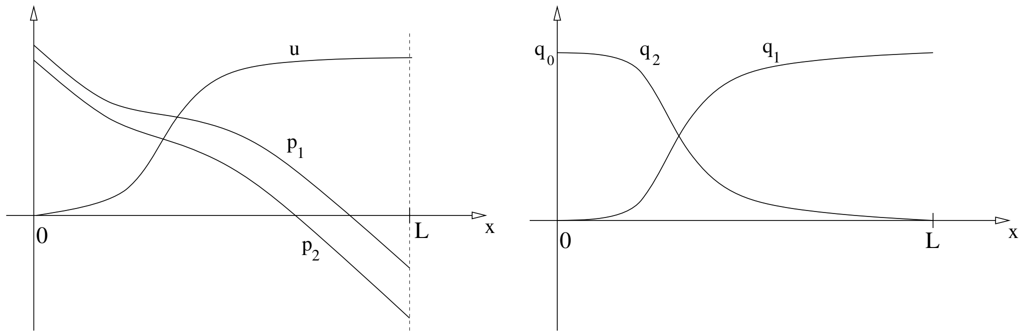

FIG. 3. *Typical solutions for homogeneous materials. Left: The typical shape of oil saturation u, oil pressure p_1, and water pressure p_2. Right: Shape of oil flux $q_1 = -k_1(x,u)\partial_x p_1$ and water flux $q_2 = -k_2(x,u)\partial_x p_2$ for the chosen boundary conditions. The curves illustrate the shape for the standard equations with spatially homogeneous coefficient functions. The solutions of the effective equations in the oil trapping problem look similar, but they exhibit a residual oil saturation $u \geq u^*/2$.*

In order to describe imbibition from the left, we assume $q_0 > 0$. The value of q_0 is given to us by the boundary conditions.[1] In order to find a single evolution equation, we solve (1.5) for $\partial_x p$. With the shorthand $k_i(x,u) = k(x)k_{r,i}(u)$ we find

$$\partial_x p = -q_0 \frac{1}{K(x,u)} + \frac{k_2(x,u)}{K(x,u)} \partial_x [p_c(x,u)]. \tag{1.6}$$

Inserting into (1.1) yields

$$\partial_t u = -\partial_x \left(f(u) - k(x)\lambda(u)\partial_x [p_c(x,u)] \right) \tag{1.7}$$

with

$$f(u) := q_0 \frac{k_{r,1}(u)}{k_{r,1}(u) + k_{r,2}(u)}, \qquad \lambda(u) := \frac{k_{r,1}(u)k_{r,2}(u)}{k_{r,1}(u) + k_{r,2}(u)}.$$

Equation (1.7) is an evolution equation of the form $\partial_t u + \partial_x F = 0$, where F is given by

$$F(x,u) := f(u) - k(x)\lambda(u)\partial_x [p_c(x,u)].$$

The qualitative shape of solutions is shown in Figure 3. We emphasize that the coefficient functions are degenerate,

$$k_{r,1}(s) \to 0, \ f(s) \to 0, \ \lambda(s) \to 0 \ \text{ for } s \to 0.$$

Less critical in this context is an additional degeneracy $\partial_s p_c(s) \to 0$ for $s \to 0$. Regarding high oil saturation we have $k_{r,2}(s) \to 0$ and $\lambda(s) \to 0$ for $s \to 1$. Our interest here is in the degeneracies for $s \to 0$, and we consider a physical situation where the saturation remains bounded away from 1 for all times.

[1]One choice of the boundary conditions is the following. At the inlet, $x = 0$, pure water enters the medium at a given rate; hence we have $u = 0$ at the left boundary and $q_0 > 0$ given. At the right boundary, $x = L$, only the nonwetting fluid oil can exit; hence $k_2(L, u(L))\partial_x p_2(L) = 0$ or, equivalently, $-k_1(L, u(L))\partial_x p_1(L) = q_0$. Notationally simpler is to impose a fixed saturation at the right boundary; we will therefore work with $u(0) = 0$ and $p_c(u(L)) = p_{max}$ in what follows.

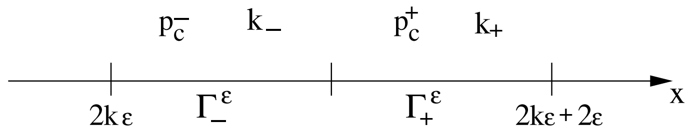

FIG. 4. *Interfaces inside the material.* Γ_-^ε *is a region with a fine material and* Γ_+^ε *is a region with a coarse material. The permeabilities satisfy* $k_+ > k_-$*, the capillary pressure curves* ${p_c}^+(s) < {p_c}^-(s)$ *for all s.*

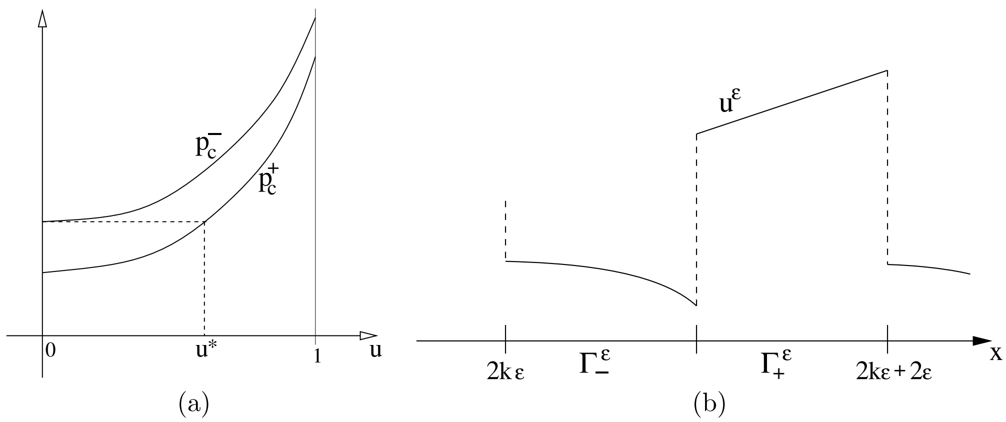

FIG. 5. (a) *The graphs* ${p_c}^+$ *and* ${p_c}^-$*.* (b) *Typical shape of a solution* $u^\varepsilon(.,t)$ *in a small interval* $(2k\varepsilon, 2k\varepsilon + 2\varepsilon)$*. The pressures* p_i *and the fluxes* q_i *are almost constant, and the capillary pressure* ${p_c}^\varepsilon(x, u^\varepsilon(x,t))$ *is continuous in x; hence the saturation* u^ε *jumps from high values on* Γ_+^ε *to low values on* Γ_-^ε*.*

Oscillatory coefficient functions. In this work we are interested in oscillatory coefficients $k_i^\varepsilon = k_i^0(x/\varepsilon, u)$ and ${p_c}^\varepsilon = {p_c}^0(x/\varepsilon, u)$. To simplify, we consider oscillations between two different coefficient functions. We distinguish the subdomains $\Gamma_-^\varepsilon := \varepsilon(2\mathbb{Z} + (0,1)) \cap (0,L)$ and $\Gamma_+^\varepsilon := \varepsilon(2\mathbb{Z} + (1,2)) \cap (0,L)$. For later use we additionally introduce $\Gamma^\varepsilon := \Gamma_+^\varepsilon \cup \Gamma_-^\varepsilon$ for the spatial domain without the interfaces.

We study coefficients as sketched in Figure 4:

$$k^\varepsilon(x) = \begin{cases} k_+ & \text{for } x \in \Gamma_+^\varepsilon, \\ k_- & \text{for } x \in \Gamma_-^\varepsilon, \end{cases} \qquad {p_c}^\varepsilon(x,u) = \begin{cases} {p_c}^+(u) & \text{for } x \in \Gamma_+^\varepsilon, \\ {p_c}^-(u) & \text{for } x \in \Gamma_-^\varepsilon. \end{cases} \tag{1.8}$$

A typical shape of ${p_c}^\pm$ is indicated in Figure 5(a); the corresponding local behavior of solutions is shown in Figure 5(b). The minimal pressure in Γ_-^ε with a positive saturation is $p_{min}^- = \lim_{u \searrow 0} {p_c}^-(u)$. Of importance is the residual oil saturation u^* in the coarse material, i.e., in Γ_+^ε. It is defined by the relation ${p_c}^+(u^*) = p_{min}^-$.

Our aim is to study solutions of (1.7) for this choice of coefficients. Understanding the equations in the distributional sense means to demand at the interfaces $\xi \in \varepsilon\mathbb{Z}$ the continuity of flux and capillary pressure. Since the capillary pressure curves are multivalued in general, we demand for all $\xi \in \varepsilon\mathbb{Z}$

$$F(\xi - 0, u(\xi - 0)) = F(\xi + 0, u(\xi + 0)), \tag{1.9}$$

$$p_c(\xi - 0, u(\xi - 0)) \cap p_c(\xi + 0, u(\xi + 0)) \neq \emptyset. \tag{1.10}$$

Here, we use the notation $h(x \pm 0)$ for $\lim_{\pm\delta \searrow 0} h(x + \delta)$, or, if $h \in H^1$, for the corresponding trace. Relation (1.10) is a compact way to write the standard interface condition for the capillary pressure which was derived in [5]. We use set-valued capillary pressure functions that assign to the saturations $s = 0$ and $s = 1$ an interval, e.g., ${p_c}^-(\xi, 0) := (-\infty, p^-_{min}]$ for $\xi \in \Gamma^\varepsilon_-$. In this way, if the saturation vanishes at one side of the interface, the pressure at the other side must be below the entry pressure p_{min}, but the exact value is not determined. The classical description of (1.10) is that we necessarily are in one of the following situations: (a) at both sides, the saturation is strictly between 0 and 1, and the capillary pressures on both sides coincide; (b) we have $s = 0$ at side A, $s \in (0, 1)$ at side B, and there holds $p_c \le p_{min}$, where p_c is evaluated at side B and p_{min} at side A; (c) we have $s = 0$ at both sides; (d) an analogous case with $s = 1$ on one side.

In the next step we write the equations in a compact and symmetric form. The conservation law (1.7) is recovered in (1.11) with $g^\pm(u) := k_\pm\, \lambda(u)\, \partial_u {p_c}^\pm(u)$ and $f^\pm(u) := f(u)$.

Mathematical description and main result. We assume that the coefficients are x-independent on each set $\Gamma^\varepsilon_\pm$,

$$g^\varepsilon(x,u) := \begin{cases} g^+(u) & \text{for } x \in \Gamma^\varepsilon_+, \\ g^-(u) & \text{for } x \in \Gamma^\varepsilon_-, \end{cases} \qquad f^\varepsilon(x,u) := \begin{cases} f^+(u) & \text{for } x \in \Gamma^\varepsilon_+, \\ f^-(u) & \text{for } x \in \Gamma^\varepsilon_-. \end{cases}$$

We study the conservation law

$$\begin{aligned} &\partial_t u^\varepsilon + \partial_x F^\varepsilon = 0 \text{ on } \Gamma^\varepsilon, \\ &F^\varepsilon = f^\varepsilon(x, u^\varepsilon) - g^\varepsilon(x, u^\varepsilon)\partial_x u^\varepsilon, \\ &F^\varepsilon \text{ and } {p_c}^\varepsilon(x, u^\varepsilon) \text{ are continuous in } \mathbb{Z}\varepsilon. \end{aligned} \tag{1.11}$$

Here, the continuity is understood in the classical sense for F^ε, and in the sense of (1.10) for ${p_c}^\varepsilon$. From now on, we study solution sequences u^ε to this equation, complemented with the initial condition ${p_c}^\varepsilon(u^\varepsilon)|_{t=0} = p_{max}$ on $(0, L)$ for some initial pressure value $p_{max} \in ({p_c}^-(0), {p_c}^+(1))$. As boundary conditions we impose $u^\varepsilon(0, t) = 0$ and ${p_c}^\varepsilon(u^\varepsilon(L, t)) = p_{max}$ for all $t \in (0, T)$. Throughout we assume the following monotonicity and regularity of the coefficient functions.

Assumptions. On flux and diffusivity we assume $0 \le f^\pm \in C^0([0, 1], \mathbb{R})$, $0 \le g^\pm \in C^{0,1}([0, 1], \mathbb{R})$, $f^-(0) = g^-(0) = 0$. Furthermore, $f^\pm \le c g^\pm$ on the interval $[0, ({p_c}^+)^{-1}(p_{max})]$ for some constant $c > 0$, and $f^\pm > 0$ on $(0, 1)$. On the capillary pressure we assume ${p_c}^+ \le {p_c}^-$ with strictly monotone functions ${p_c}^\pm \in C^1([0, 1], \mathbb{R})$.

Our main theorem is the rigorous derivation of effective equations. They are characterized by a nonlinear flux function $\mathcal{F} : [0, 1] \times \mathbb{R} \to \mathbb{R}$, which is constructed in (3.1)–(3.7). For the particular choice of coefficients considered there, our flux function $\mathcal{F}$ coincides with that of [9].

THEOREM 1. *Let $(u^\varepsilon, F^\varepsilon)$ be a family of entropy solutions to* (1.11) *on $\Omega_T = (0, L)\times(0, T)$, as in Definition* 1 *of section* 2*, satisfying the above boundary conditions. Then, for a subsequence $\varepsilon \to 0$ and for appropriate limiting functions, we find*

$$u^\varepsilon \rightharpoonup u^0 \text{ in } L^\infty(\Omega_T) \text{ weak-}\star, \quad F^\varepsilon \rightharpoonup F^0 \text{ in } L^2(\Omega_T) \text{ weakly.}$$

The limits satisfy the conservation law

$$\partial_t u^0 + \partial_x F^0 = 0 \tag{1.12}$$

in the distributional sense on Ω_T. The limit $u^0 \in L^\infty(\Omega_T)$ has the distributional derivative $\partial_x u^0 \in L^1(\Omega_T)$. The flux satisfies the relation

$$F^0 = \mathcal{F}(u^0, \partial_x u^0) \text{ almost everywhere in } \Omega_T \tag{1.13}$$

with the nonlinear function $\mathcal{F}(u, \partial_x u) = \mathcal{F}_0(u) - \mathcal{D}(u)\partial_x u$ defined in (3.1)–(3.7).

The remaining sections are devoted to the proof of Theorem 1 and are organized as follows. In section 2 we construct entropy solutions and derive comparison and monotonicity results. Section 3 is devoted to a two-scale homogenization result for regions with a strictly positive saturation. The homogenization in the general situation with degenerate solutions is performed in section 4. We introduce a description with a free boundary, derive the effective equations in the critical region, and determine the continuity condition across the free boundary.

The analysis of the limit problem (1.12), (1.13) is not the aim of this contribution. Interesting questions concern the existence and uniqueness of solutions to this degenerate problem, and the position of the free boundary $X(t) := \sup\{x : u^0(x,t) = u^*/2\}$. We note that the results of [2] cannot be applied to the equations in the above form, since, for a degenerate function $\mathcal{D}(u)$, the ellipticity assumption (Assumption 1.1(3)) of [2] is not satisfied. But the special structure $\mathcal{F}(u, \partial_x u) = \mathcal{F}_0(u) - \mathcal{D}(u)\partial_x u$ allows us to introduce formally a new variable U with $\partial_x U = \mathcal{D}(u)\partial_x u$ such that with $u = b(U)$ and $a(u, \partial_x U) = -\mathcal{F}_0(u) + \partial_x U$, the results of [2] and [15] may be applicable. The appearance of free boundaries is well known in porous-media-type equations; we refer the reader to [11] for results on the one-dimensional degenerate Cauchy problem $\partial_t u = \partial_x^2[a(u)] + \partial_x[b(u)]$ regarding existence, uniqueness, regularity, and speed of propagation of the free boundary.

Notation. The value of the constant C in estimates may change from one line to the next. For a set Q the function $\mathbf{1}_Q$ denotes the characteristic function $\mathbf{1}_Q(x) = 1$ for $x \in Q$ and $\mathbf{1}_Q(x) = 0$ for $x \notin Q$.

2. Entropy solutions and monotonicity.

2.1. Entropy solutions and regularity. In this section we sketch a solution concept that allows us to derive comparison principles for solutions. For other existence and uniqueness results we refer the reader to [8] and [12], where methods of [2] are extended to two-phase flow. An existence proof that uses a smoothing of the jump condition is performed in [5]. We refer the reader to [16] for a discussion of approximation schemes to degenerate equations that are also used below.

We always assume $p_{max} \in ({p_c}^-(0), {p_c}^+(1))$ and consider only boundary conditions as described above. We use the notion of a *family of regularized equations*: We assume that, for a sequence $\eta \searrow 0$, we have coefficient functions $g_\eta^\pm \in C^1([0,1], \mathbb{R})$, $f_\eta^\pm = f^\pm$, and ${p_c}^{\pm,\eta} \in C^1([0,1], \mathbb{R})$ that are strictly monotone and satisfy the same inequalities as the original coefficients. The equations are regularized in the sense that $g_\eta^\pm \geq \eta$, ${p_c}^{\pm,\eta}$ is single valued, and ${p_c}^{-,\eta}(0) = {p_c}^{+,\eta}(0)$. They approximate the original equation in the sense that ${p_c}^{+,\eta} = {p_c}^+$ on $(0,1)$, $g_\eta^\pm \to g^\pm$ uniformly on $[0,1]$, and ${p_c}^{-,\eta} \to {p_c}^-$ uniformly on compact subsets of $(0,1]$. By an appropriate choice of the regularization we can additionally achieve that the family $g_\eta^\pm \, \partial_u {p_c}^{\pm,\eta}$ is uniformly bounded on $[0,1]$.

In the following definition we use the primitive $G^\varepsilon(x,u)$ of g^ε, i.e., the function with $\partial_u G^\varepsilon(x,u) = g^\varepsilon(x,u)$ and $G^\varepsilon(x,0) = 0$. Since $g^\varepsilon(.,u)$ is piecewise constant, we can interpret the term $g^\varepsilon(u^\varepsilon)\partial_x u^\varepsilon$ as the distribution $\partial_x G^\varepsilon(x,u^\varepsilon)|_{\Gamma^\varepsilon \times (0,T)}$. Since we will work with $\partial_x G^\varepsilon(x,u) \, \mathbf{1}_{\Gamma^\varepsilon}(x) \in L^2(\Omega_T)$, we have well-defined traces $G^\varepsilon(x,u^\varepsilon)|_{\partial\Gamma^\varepsilon \times (0,T)}$. Since $G^\varepsilon(x,.)$ is invertible, this defines also traces of u^ε and gives a precise meaning to the interface conditions.

We write the interface condition (1.10) in a more reader-friendly form, considering ${p_c}^-$ as multivalued and ${p_c}^+$ as a function.

DEFINITION 1. *A saturation-flux pair* $(u^\varepsilon, F^\varepsilon)$ *is a weak solution of* (1.11) *on* $\Omega_T = (0,L)\times(0,T)$ *if* $u^\varepsilon \in L^\infty(\Omega_T,[0,1])$ *and* $F^\varepsilon \in L^2(\Omega_T)$ *satisfy*

$$
\begin{aligned}
\partial_t u^\varepsilon + \partial_x F^\varepsilon = 0 \qquad & \textit{in } \mathcal{D}'(\Omega_T),\\
F^\varepsilon = f^\varepsilon(u^\varepsilon) - \partial_x[G^\varepsilon(u^\varepsilon)] \qquad & \textit{in } \mathcal{D}'(\Gamma^\varepsilon\times(0,T)),\\
{p_c}^+(u^\varepsilon(2k\varepsilon-0)) \in {p_c}^-(u^\varepsilon(2k\varepsilon+0)) \qquad & \forall k\in\mathbb{Z}, 2k\varepsilon\in(0,L),\\
{p_c}^+(u^\varepsilon(2k\varepsilon+\varepsilon+0)) \in {p_c}^-(u^\varepsilon(2k\varepsilon+\varepsilon-0)) \qquad & \forall k\in\mathbb{Z}, 2k\varepsilon\in(0,L).
\end{aligned}
$$

A weak solution $(u^\varepsilon, F^\varepsilon)$ *is called an* entropy solution *if there exists a family of regularized equations and a corresponding family of solutions* $(u^\varepsilon_\eta, F^\varepsilon_\eta)$ *with* $u^\varepsilon_\eta \to u^\varepsilon$ *in* $L^2(\Omega_T)$ *and* $F^\varepsilon_\eta \rightharpoonup F^\varepsilon$ *in* $L^2(\Omega_T)$ *for* $\eta\to 0$.

LEMMA 1 (existence and a priori estimate). *For every* $\varepsilon>0$, *there exists an entropy solution* $(u^\varepsilon, F^\varepsilon)$. *With a constant* C *independent of* ε *there hold* $\|F^\varepsilon\|_{L^2(\Omega_T)} \le C$ *and the following regularity on the domain of positive saturation: For all* $\delta>0$ *there exists* C_δ *independent of* ε *such that*

$$
\int_0^T\int_0^L |\partial_x u^\varepsilon|^2 \mathbf{1}_{\{u^\varepsilon\ge\delta\}}\mathbf{1}_{\Gamma^\varepsilon} \le C_\delta. \tag{2.1}
$$

Proof. The regularized system ($\eta>0$) is a parabolic problem with finitely many transmission points and can be solved by standard methods. The maximum principle implies the bounds $0\le u^\varepsilon_\eta\le 1$. They allow us to select a subsequence $\eta\to 0$ and a weak $L^2(\Omega_T)$-limit u^ε. The monotonicity in t, shown in Lemma 3, implies the boundedness of $\partial_t u^\varepsilon_\eta \in L^1(\Omega_T)$. Estimate (2.1) for $\eta>0$ provides uniform bounds for the positive part $(u^\varepsilon_\eta-\delta)_+ \in L^2((0,T),H^1(\Gamma^\varepsilon))$; hence the sequence $(u^\varepsilon_\eta-\delta)_+$ is precompact in $L^2(\Omega_T)$ for every $\delta>0$. Choosing a diagonal sequence we find a subsequence with $u^\varepsilon_\eta\to u^\varepsilon$ strongly in $L^2(\Omega_T)$.

Below we derive an estimate for the sequence $F^\varepsilon_\eta\in L^2(\Omega_T)$ and thus, by boundedness of f^ε, there is also a uniform bound for $\partial_x G^\varepsilon_\eta(x,u^\varepsilon_\eta)\,\mathbf{1}_{\Gamma^\varepsilon}\in L^2(\Omega_T)$. We can choose a weakly convergent subsequence $F^\varepsilon_\eta \rightharpoonup F^\varepsilon$ in $L^2(\Omega_T)$ and find also $G^\varepsilon_\eta(u^\varepsilon_\eta)\to G^\varepsilon(u^\varepsilon)$ by the strong convergence of u^ε_η. This implies that the pair $(u^\varepsilon,F^\varepsilon)$ solves the conservation law and the characterization of F^ε of the second equation.

The solutions of the regularized problems satisfy the interface inclusions as equalities and we have a weak convergence of $\partial_x G(u^\varepsilon_\eta)$. The trace theorem implies that the limit u^ε satisfies again the interface conditions, and hence it is a weak solution of (1.11).

We now verify the a priori estimates, omitting everywhere the index $\eta>0$. We multiply the conservation law

$$
\partial_t u^\varepsilon + \partial_x[f(u^\varepsilon) - g^\varepsilon(u^\varepsilon)\partial_x u^\varepsilon] = 0 \text{ on } \Gamma^\varepsilon
$$

by the continuous function ${p_c}^\varepsilon(u^\varepsilon) - p_{max}$ and integrate by parts. Interior boundary integrals vanish due to the continuity of the flux. The right boundary integral vanishes because of the boundary condition ${p_c}^\varepsilon(L,u^\varepsilon(L,t)) = p_{max}$. We obtain

$$
\begin{aligned}
&\int_0^T\int_{\Gamma^\varepsilon}[{p_c}^\varepsilon(u^\varepsilon)-p_{max}]\partial_t u^\varepsilon + \int_0^T\int_{\Gamma^\varepsilon} g^\varepsilon(u^\varepsilon)\partial_x u^\varepsilon\,\partial_x[{p_c}^\varepsilon(u^\varepsilon)]\\
&\quad = \int_0^T\int_{\Gamma^\varepsilon} f^\varepsilon(u^\varepsilon)\,\partial_x[{p_c}^\varepsilon(u^\varepsilon)] + \int_0^T [f(u^\varepsilon)-g^\varepsilon(u^\varepsilon)\partial_x u^\varepsilon]_{x=0}\,({p_c}^{-,\eta}(0)-p_{max}).
\end{aligned}
$$

For the flux at the left boundary, which appears in the last integral, we calculate, using $\varphi(x,t) = L - x$,

$$\begin{aligned}
-L\int_0^T [f(u^\varepsilon) - g^\varepsilon(u^\varepsilon)\partial_x u^\varepsilon]_{x=0} &= \int_0^T \int_0^L \partial_x([f(u^\varepsilon) - g^\varepsilon(u^\varepsilon)\partial_x u^\varepsilon]\varphi) \\
&= \int_0^T \int_0^L \partial_x[f(u^\varepsilon) - g^\varepsilon(u^\varepsilon)\partial_x u^\varepsilon]\varphi - \int_0^T \int_0^L [f(u^\varepsilon) - g^\varepsilon(u^\varepsilon)\partial_x u^\varepsilon] \\
&= -\int_0^T \int_0^L \partial_t u^\varepsilon \varphi - \int_0^T \int_0^L [f(u^\varepsilon) - g^\varepsilon(u^\varepsilon)\partial_x u^\varepsilon] \\
&\le L^2 + C + \int_{\Omega_T} g^\varepsilon(u^\varepsilon)|\partial_x u^\varepsilon|.
\end{aligned}$$

We continue the above calculation, exploiting that ${p_c}^\varepsilon(u^\varepsilon)\partial_t u^\varepsilon$ is the time derivative of a bounded function, and use the uniform positivity $\partial_u {p_c}^\varepsilon \ge c_0 > 0$ and the bound $f^\pm \le c g^\pm$:

$$\int_0^T \int_{\Gamma^\varepsilon} g^\varepsilon(u^\varepsilon)\partial_u {p_c}^\varepsilon(u^\varepsilon)|\partial_x u^\varepsilon|^2 \le C + C\int_0^T \int_{\Gamma^\varepsilon} g^\varepsilon(u^\varepsilon)\partial_u {p_c}^\varepsilon(u^\varepsilon)|\partial_x u^\varepsilon|.$$

Application of the Cauchy–Schwarz inequality yields, by the boundedness of $g^\varepsilon\, \partial_u {p_c}^\varepsilon$, a bound for the left-hand side, independent of ε and η. Exploiting once more $\partial_u {p_c}^\varepsilon \ge c_0$ and $g^\pm > 0$ on $(0,1]$, this implies (2.1). It furthermore shows that the family $F^\varepsilon = [f(u^\varepsilon) - g^\varepsilon(x,u^\varepsilon)\partial_x u^\varepsilon]\mathbf{1}_{\Gamma^\varepsilon}$ is uniformly bounded in $L^2(\Omega_T)$. ∎

2.2. Comparison principles and monotonicity. In this subsection we derive results for entropy solutions of (1.11) and assume always the above boundary conditions and the initial condition ${p_c}^\varepsilon(u^\varepsilon(.,0)) = p_{max}$ on $(0,L)$ for $p_{max} \in ({p_c}^-(0), {p_c}^+(1))$.

LEMMA 2 (lower bound for u^ε). *There exist $\delta_0 > 0$ and $\varepsilon_0 > 0$ such that for all $\delta \in (0,\delta_0)$ and $\varepsilon \in (0,\varepsilon_0)$ the following holds. Let $(a,b) \subset (0,L)$ with $a,b \in 2\varepsilon\mathbb{Z} + \varepsilon$, and let u^ε be an entropy solution of* (1.11) *with*

$$u^\varepsilon(a-0,t) \ge \delta,\ u^\varepsilon(b-0,t) \ge \delta \quad \forall t \in (0,t_0).$$

Then there holds $u^\varepsilon \ge \delta$ on $(a,b)\times(0,t_0)$.

Proof. It is sufficient to show the claim for the regularized solutions u^ε_η and to take the limit $\eta \to 0$. We therefore perform all calculations for the more regular solutions u^ε_η, but we omit in what follows the fixed index η.

Our aim is to construct a 2ε-periodic stationary subsolution $U(y) = U^\varepsilon_\delta(y) \ge \delta$ for $y \in [a,b]$. For a parameter $q \in \mathbb{R}_+$ which denotes the constant flux of the subsolution, we define $U = U(.,q) : [0,2\varepsilon] \to \mathbb{R}$, $y \mapsto U(y)$ as the solution of

$$f^\varepsilon(y,U(y)) - g^\varepsilon(y,U(y))\,\partial_y U(y) = q \quad \text{in} \quad (0,\varepsilon)\cup(\varepsilon,2\varepsilon), \tag{2.2}$$

$$U(\varepsilon - 0) = \delta, \quad U(\varepsilon+0) = ({p_c}^+)^{-1}({p_c}^-(\delta)). \tag{2.3}$$

We note that, by the positivity of g^ε, (2.2) is an ordinary differential equation which can be solved locally with the boundary condition (2.3). The smallness of $\varepsilon > 0$ and the fact that $q - f^\varepsilon(y,\delta)$ becomes positive for $\delta \to 0$ imply that solutions can be defined on the whole intervals $(0,\varepsilon)$ and $(\varepsilon, 2\varepsilon)$. The solution operator defines a family of functions $U(.,q)$ and the continuous function $G = G_\delta : \mathbb{R}_+ \to \mathbb{R}$:

$$G(q) := {p_c}^+(U(2\varepsilon-0)) - {p_c}^-(U(0+0)).$$

Our aim is to choose the parameter $q = q^*$ with $G(q^*) = 0$ such that the function $U = U(.,q^*)$ can be extended to a 2ε-periodic stationary solution of (1.11).

For two special values of q we can evaluate the sign of $G(q)$. For $q_1 = f^-(\delta)$, the solution $U(.,q_1) = \delta$ is constant on the interval $(0,\varepsilon)$. On the interval $(\varepsilon, 2\varepsilon)$ the derivative $\partial_y U$ is positive by the positivity of $f^+(u^*)$; here we exploit the continuity of $f^\pm$, $f^-(0) = 0$ and the smallness of δ and ε. We find that

$$G(q_1) \geq {p_c}^+(U(\varepsilon + 0)) - {p_c}^-(\delta) = 0.$$

On the other hand, for $q_2 = f^+(U(\varepsilon+0))$, the solution $U(.,q_2)$ is constant on the interval $(\varepsilon, 2\varepsilon)$ and decreasing on $(0,\varepsilon)$. Monotonicity of ${p_c}^\pm$ implies $G(q_2) \leq 0$. By continuity, there is a critical value $q^* = q^*(\delta,\varepsilon) \in [q_1, q_2]$ with $G(q^*) = 0$, and we use $U = U(.,q^*)$ in what follows.

We now define the subsolution $U^\varepsilon(x,t)$ as the 2ε-periodic continuation of $U^\varepsilon_{\delta e^{-\lambda t}}(x)$, where we replaced δ by $\delta e^{-\lambda t}$ for a small constant $\lambda > 0$. We claim that u^ε can never touch the subsolution U^ε. Because $\partial_t U^\varepsilon < 0$, this is the standard comparison principle for all points x that are not contained in $\varepsilon\mathbb{Z}$. Let us assume that $t > 0$ is the first time instance at which the solutions touch each other and that, for a point $x \in \varepsilon\mathbb{Z}$, we have $u^\varepsilon(x+0,t) = U^\varepsilon(x+0,t)$. Since u^ε and U^ε both satisfy the p_c-jump condition, there also holds $u^\varepsilon(x-0,t) = U^\varepsilon(x-0,t)$. Then, because $u^\varepsilon(.,t) \geq U^\varepsilon(.,t)$, we have $\partial_x u^\varepsilon(x+0,t) \geq \partial_x U^\varepsilon(x+0,t)$ and $\partial_x u^\varepsilon(x-0,t) \leq \partial_x U^\varepsilon(x-0,t)$. The subsolution U^ε has the continuous flux $q^*(\delta e^{-\lambda t}, \varepsilon)$ and u^ε also has a continuous flux; since also $f(u^\varepsilon) = f(U^\varepsilon)$ and the same for g in the point x, the derivatives must coincide, $\partial_x u^\varepsilon(x+0,t) = \partial_x U^\varepsilon(x+0,t)$. As a consequence, also the fluxes of u^ε and U^ε coincide in x. In $(x+0,t)$ it holds that

$$-\partial_x[f^\varepsilon(u^\varepsilon) - g^\varepsilon(u^\varepsilon)\cdot\partial_x u^\varepsilon] = \partial_t u^\varepsilon < 0 = -\partial_x[f^\varepsilon(U^\varepsilon) - g^\varepsilon(U^\varepsilon)\cdot\partial_x U^\varepsilon],$$

and hence $\partial_x^2 u^\varepsilon < \partial_x^2 U^\varepsilon$, which is a contradiction to $u^\varepsilon \geq U^\varepsilon$. ∎

LEMMA 3 (monotonicity of u^ε). *Let u^ε be an entropy solution of* (1.11) *as above. Then the following hold:*

1. *Decay in time. The map $t \mapsto u^\varepsilon(x,t)$ is monotonically nonincreasing for almost every x.*
2. *Monotonicity in space. The map $k \mapsto u^\varepsilon(2k\varepsilon + y, t)$ is monotonically nondecreasing for every $t \in (0,T)$ and every $y \in [0, 2\varepsilon]$.*

Proof. As in the last proof, it suffices to verify the monotonicity for the approximate solutions $u = u^\varepsilon_\eta$. We therefore study, for the strictly positive coefficient $g = g(x,u) \geq \eta$ and the strictly monotone single-valued function $p_c = p_c(x,u)$, solutions u of

$$\begin{aligned} \partial_t u + \partial_x\left(f(x,u) - g(x,u)\partial_x u\right) &= 0,\\ [p_c(x,u)] &= 0,\\ [f(x,u) - g(x,u)\partial_x u(x)] &= 0, \end{aligned}$$

where the last two relations hold in points $x \in \mathbb{Z}\varepsilon$. By regularity theory for strictly parabolic equations we may assume that u is a classical solution of the above system.

Proof of part 1. We claim that $\partial_t u \leq 0$ holds on G. Indeed, the function $v = -\partial_t u$ is nonnegative at $t = 0$ and the equations are, with $\kappa = 0$,

$$\begin{aligned} \partial_t v + \partial_x\left(f_u(x,u)\cdot v - g_u(x,u)\cdot v\partial_x u - g(x,u)\partial_x v\right) &= \kappa,\\ [\partial_u p_c(x,u)\cdot v] &= 0,\\ [f_u(x,u)\cdot v - g_u(x,u)\cdot v\partial_x u(x) - g(x,u)\partial_x v(x)] &= 0. \end{aligned}$$

The boundary conditions are $v(0,t) = v(L,t) = 0$ for all $t \in (0,T)$. In order to show that v remains nonnegative, it suffices to show that the solutions v_κ of the above system with small right-hand side $\kappa \in \mathbb{R}$, $\kappa > 0$, remain nonnegative.

Let $t > 0$ be the first time instance such that $v_\kappa(.,t)$ has a zero in x. By the standard comparison principle, the zero cannot be in $(0,L) \setminus \varepsilon\mathbb{Z}$. Let us therefore assume $x \in \varepsilon\mathbb{Z}$. The first jump condition implies that, with v_κ vanishing on one side of x, it vanishes on both sides. Continuity implies $v_\kappa(.,t) \geq 0$, and hence we have the geometric conditions $\partial_x v_\kappa(x-0,t) \leq 0$ and $\partial_x v_\kappa(x+0,t) \geq 0$. The second jump condition then implies that $\partial_x v_\kappa = 0$ from both sides. The geometric condition $\partial_t v_\kappa(x,t) \leq 0$, together with $\kappa > 0$, implies

$$\partial_x \left(f_u(x,u) \cdot v_\kappa - g_u(x,u) \cdot v_\kappa \partial_x u - g(x,u)\partial_x v_\kappa\right) > 0$$

in the vicinity of x. We conclude that $\partial_x^2 v_\kappa < 0$ and thus a contradiction to $v_\kappa \geq 0$.

Proof of part 2. We claim that the function $v(x,t) = u(x+2\varepsilon,t) - u(x,t)$, defined on $(0, L-2\varepsilon)\times[0,T]$, is nonnegative for all times. Indeed, $v(.,0) = 0$ initially, and there hold $v(0,t) \geq 0$ and $v(L-2\varepsilon,t) \geq 0$ for all $t \in (0,T)$. With $u_+(x,t) := u(x+2\varepsilon,t)$, the equations for $v = u_+ - u$ read

$$\begin{aligned} \partial_t v + \partial_x \left(f(x,u_+) - f(x,u) - g(x,u_+)\partial_x u_+ + g(x,u)\partial_x u\right) = 0,& \\ [p_c(x,u_+) - p_c(u)] = 0,& \\ [f(x,u_+) - g(x,u_+)\partial_x u_+(x) - f(x,u) + g(x,u)\partial_x u(x)] = 0;& \end{aligned}$$

the last two lines indicate again jumps over the interface points. With appropriate evaluation points $\zeta_j(x,t)$ between $u(x,t)$ and $u_+(x,t)$ we may write this as

$$\begin{aligned} &\partial_t v + \partial_x \left(f_u(.,\zeta_1)v - g_u(.,\zeta_2)v\partial_x u_+ - g(.,u)\partial_x v\right) = 0, \\ &\{\partial_u p_c(.,\zeta_3)v\}(k\varepsilon + 0) = \{\partial_u p_c(.,\zeta_4)v\}(k\varepsilon - 0), \\ &\{f_u(.,\zeta_5)v - g_u(.,\zeta_6)v\partial_x u_+ - g(.,u)\partial_x v\}(k\varepsilon + 0) \\ &\qquad = \{f_u(.,\zeta_7)v - g_u(.,\zeta_8)v\partial_x u_+ - g(.,u)\partial_x v\}(k\varepsilon - 0) \end{aligned}$$

for $x = k\varepsilon$ with $k \in \mathbb{Z}$. Starting from this system for v, the nonnegativity of v follows as in part 1. ∎

LEMMA 4 (bounds for averages of u^ε). *Let u^ε be a family of entropy solutions of* (1.11) *as above.*

1. *Lower bound for averages. There exists $c \in \mathbb{R}$ such that for all $\varepsilon > 0$ and all $k \in \mathbb{Z}$ with $(2k\varepsilon - \varepsilon, 2k\varepsilon + \varepsilon) \subset (0,L)$, there holds*

$$\int_{2k\varepsilon-\varepsilon}^{2k\varepsilon+\varepsilon} u^\varepsilon(.,t) \geq \varepsilon(u^* - c\varepsilon). \tag{2.4}$$

2. *Upper bound for averages. For every $\rho > 0$ there exist $\tau > 0$, $\delta > 0$, and $\varepsilon_0 > 0$ such that for all $\varepsilon \in (0,\varepsilon_0)$, $k \in \mathbb{Z}$ with $(2k\varepsilon - \varepsilon, 2k\varepsilon + \varepsilon) \subset (0,L)$, and $t > \tau\varepsilon^2$,*

$$u^\varepsilon(2k\varepsilon + \varepsilon - 0, t - \tau\varepsilon^2) \leq \delta \quad \Rightarrow \quad \int_{2k\varepsilon-\varepsilon}^{2k\varepsilon+\varepsilon} u^\varepsilon(.,t) \leq \varepsilon(u^* + \rho). \tag{2.5}$$

Proof. We consider again approximate solutions u_η^ε from the definition of entropy solutions.

Proof of part 1. We approximate additionally the boundary condition at the left boundary by the artificial condition $u_\eta^\varepsilon(0,t) = \delta$. The subsolutions U^ε of Lemma 2 satisfy $U^\varepsilon \geq u^* - O(\varepsilon)$ on Γ_+^ε, independent of $\delta > 0$, such that $u_\eta^\varepsilon \geq U^\varepsilon$ provides (2.4).

Proof of part 2. We assume the contrary. Then, for some $\rho > 0$, for arbitrary $\tau > 0$, $\delta > 0$, there exists a sequence $\varepsilon_m \to 0$ such that inequality (2.5) fails to hold for some k and t. Now let $\rho > 0$ be such a value. Below we give an explicit choice of τ and δ that leads to a contradiction. We study now sequences of points k_m and time instances $t_m \geq \tau\varepsilon_m^2$ at which (2.5) fails for the sequence u^{ε_m}, which we continue up to time $2T$. We define the rescaled solutions

$$\begin{aligned}\tilde{U}^m &: (-1,1) \times (0, T/\varepsilon_m^2) \to \mathbb{R},\\ \tilde{U}^m(y,s) &:= u^{\varepsilon_m}(2k_m\varepsilon_m + \varepsilon_m y, t_m - \tau\varepsilon_m^2 + \varepsilon_m^2 s)\end{aligned}$$

and recall that we assume the failure of (2.5), that is,

$$\tilde{U}^m(1-0, s=0) \leq \delta, \quad \int_{-1}^{1} \tilde{U}^m(y,\tau)\, dy > u^* + \rho.$$

We now construct a function U^m which serves as an upper bound for $\tilde{U}^m$. We define U^m as the solution of the system

$$\begin{aligned}&\partial_s U^m + \partial_y \left(\varepsilon_m f(U^m) - g(U^m)\partial_y U^m\right) = 0 \text{ on } (-1,1) \setminus \{0\},\\ &U^m(1-0) = \delta, \quad U^m(-1+0) = ({p_c}^+)^{-1}({p_c}^-(\delta)),\\ &{p_c}^+(U^m(0-0)) = {p_c}^-(U^m(0+0)),\\ &[\varepsilon_m f(U^m) - g(U^m)\partial_y U^m](0-0) = [\varepsilon_m f(U^m) - g(U^m)\partial_y U^m](0+0),\end{aligned}$$

but now augmented with the initial condition $p_c(U^m(., s=0)) \equiv p_{max}$. As in the above proofs, exploiting $\tilde{U}^m(1-0,0) \leq \delta$ and the monotonicity of $\tilde{U}^m$, one derives the comparison principle $\tilde{U}^m \leq U^m$. The limit $U^\infty := \lim_{m\to\infty} U^m$ exists and solves the above system with ε_m replaced by 0. The solution U^∞ approaches, as $s \to \infty$, the stationary solution

$$\bar{U}^\infty(y) = \begin{cases}({p_c}^+)^{-1}({p_c}^-(\delta)) & \text{for } y \in (-1,0),\\ \delta & \text{for } y \in (0,1).\end{cases}$$

We can now derive a contradiction. Given $\rho > 0$, we choose $\delta > 0$ such that $\int_{-1}^1 \bar{U}^\infty(y)\, dy < u^* + \rho/3$. We then choose a time instance $\tau > 0$ such that $\int_{-1}^1 (U^\infty(y,\tau) - \bar{U}^\infty(y))\, dy < \rho/3$. With these choices we have

$$u^* + \rho < \int_{-1}^1 \tilde{U}^m(y,\tau)\, dy \leq \int_{-1}^1 U^m(y,\tau)\, dy \to \int_{-1}^1 U^\infty(y,\tau)\, dy \leq u^* + 2\rho/3,$$

a contradiction. ◻

3. Homogenization for a positive saturation. We next define the nonlinear flux function $\mathcal{F}(u^0, v^0)$ that maps an average oil saturation u^0 with an average slope v^0 to the effective flux. The continuity of the capillary pressure imposes a restriction on the values of u^0. Let $U \in [0,1]$ solve ${p_c}^-(U) = {p_c}^+(1)$. Then, with $u^0_{max} := (1+U)/2$, the flux function is a map

$$\mathcal{F} : [0, u^0_{max}] \times \mathbb{R} \mapsto \mathbb{R}, \ (u^0, v^0) \mapsto \mathcal{F}(u^0, v^0).$$

We set $\mathcal{F}(u^0, v^0) := 0$ for all (u^0, v^0) with $u^0 \leq u^*/2$ and construct $\mathcal{F}$ for other values with the help of nonlinear equations. For $(u^0, v^0) \in (u^*/2, u^0_{max}] \times \mathbb{R}$, the following system determines $(u_+, u_-) \in [0,1]^2$, representing typical values of u^ε in $\Gamma^\varepsilon_\pm$:

$$u_+ + u_- = 2u^0, \tag{3.1}$$

$$p_c{}^+(u_+) = p_c{}^-(u_-). \tag{3.2}$$

The monotonicity of $p_c{}^\pm$ assures the unique solvability of (3.1)–(3.2). We introduce auxiliary real numbers $u_{+,x}$ and $u_{-,x}$ that will describe the average slope of u_+ and u_- on a macroscopic scale. They are determined by

$$u_{+,x} + u_{-,x} = 2v^0, \tag{3.3}$$

$$\partial_u p_c{}^+(u_+)\, u_{+,x} = \partial_u p_c{}^-(u_-)\, u_{-,x}. \tag{3.4}$$

This linear system has a unique solution $u_{\pm,x}$ that depends linearly on v_0. We note that, for $v^0 \geq 0$, the average slope satisfies $0 \leq u_{\pm,x} \leq 2v^0$. We next introduce the pair $(v_+, v_-) \in \mathbb{R}^2$ which describes the typical derivatives of u^ε inside a single interval of $\Gamma^\varepsilon_\pm$. They are determined by

$$f^+(u_+) - g^+(u_+)v_+ = f^-(u_-) - g^-(u_-)v_-, \tag{3.5}$$

$$\partial_u p_c{}^+(u_+)v_+ + \partial_u p_c{}^-(u_-)v_- = \partial_u p_c{}^+(u_+)\, u_{+,x} + \partial_u p_c{}^-(u_-)\, u_{-,x}. \tag{3.6}$$

The unique solution $v_\pm$ depends in an affine way on $u_{\pm,x}$. We now define the effective flux function $\mathcal{F}$ as

$$\mathcal{F}(u^0, v^0) := f^+(u_+) - g^+(u_+)v_+, \tag{3.7}$$

where (u_+, v_+) is determined by the system (3.1)–(3.6) of nonlinear equations. For fixed $u \in [0, u^0_{max}]$, the map $\mathcal{F}(u, .)$ is affine. We may therefore also write $\mathcal{F}$ in the form

$$\mathcal{F}(u^0, v^0) = \mathcal{F}_0(u^0) - \mathcal{D}(u^0)v^0.$$

A flux function of this form appears also in [10] and [9]. We note that $\mathcal{F}$ is continuous: For $u^0 = u^*/2$, the solution of system (3.1)–(3.2) is $u_- = 0$ and $u_+ = u^*$, and hence $f^-(u_-) = g^-(u_-) = 0$, and (3.5) yields $\mathcal{F}(u^0, v^0) = 0$.

PROPOSITION 1 (homogenization). *Let $G = (a,b) \times (0, t_0)$ be a subdomain of $\Omega_T = (0,L) \times (0,T)$, $\delta, \varepsilon_0 > 0$ positive real numbers, and u^ε a family of solutions of* (1.11) *with*

$$u^\varepsilon \geq \delta \qquad \text{on } G \quad \forall \varepsilon \leq \varepsilon_0, \tag{3.8}$$

$$u^\varepsilon \rightharpoonup u^0, \quad F^\varepsilon \rightharpoonup F^0 \qquad \text{weakly in } L^2(G). \tag{3.9}$$

Then $u^0 \in L^2(G)$ solves $\partial_t u^0 + \partial_x F^0 = 0$ in the distributional sense on G and has a space derivative $\partial_x u^0 \in L^2(G)$, and, with $\mathcal{F}$ from (3.7)*, the following flux relation holds almost everywhere:*

$$F^0 = \mathcal{F}(u^0, \partial_x u^0). \tag{3.10}$$

Proof. The distributional conservation law is satisfied by the weak convergences. Exploiting the strictly positive diffusivity, (2.1) provides an estimate for the regular part of the derivative, and $\partial_x u^\varepsilon(x,t)\mathbf{1}_{\Gamma^\varepsilon}(x)$ is bounded in $L^2(G)$. In the subsequent proof we will define various two-scale limits for the above functions. For them we derive the relations (3.1)–(3.6), $F^0 = f^+(u_+) - g^+(u_+)v_+$, and $\partial_x u^0 = v^0 \in L^2(G)$. With these verifications, the proof is complete.

Step 1. *Two-scale limits and* (3.1). The uniform $L^2(G)$-bounds allow us to consider the two-scale limits

$$\begin{aligned} u^\varepsilon &\rightharpoonup u_0(x,t,y) \text{ two-scale},\\ \partial_x u^\varepsilon \mathbf{1}_{\Gamma^\varepsilon}(x) &\rightharpoonup v_0(x,t,y) \text{ two-scale}. \end{aligned}$$

The $L^2(G)$-estimate for $\partial_x u^\varepsilon$ immediately implies that u_0 is independent of y on the sets $(0,1)$ and $(1,2)$. Indeed, let $y \mapsto \varphi(y)$ be smooth with support contained in one of the two sets. We find, for $\Phi^\varepsilon(x) = \varepsilon\psi(x)\varphi(x/\varepsilon)$,

$$0 \leftarrow \int_G \partial_x u^\varepsilon \Phi^\varepsilon = \int_G u^\varepsilon \partial_x \Phi^\varepsilon \to \int_G \int_0^2 u_0(x,t,y)\psi(x)\partial_y\varphi(y)\, dy\, dx\, dt.$$

We conclude that u_0 has the special form

$$u_0(x,t,y) = u_-(x,t)\mathbf{1}_{(0,1)}(y) + u_+(x,t)\mathbf{1}_{(1,2)}(y). \tag{3.11}$$

The weak limit u^0 of the sequence u^ε coincides with the y-average of u_0; hence (3.11) implies relation (3.1).

We claim that also v_0 is piecewise constant. To see this, we use the test function $\Phi^\varepsilon(x,t) = \varepsilon\psi(x,t)\varphi(x/\varepsilon)$ with $\psi \in C_0^\infty(G)$ and exploit the equation. We assume here that φ is supported in $(1,2)$. We will verify the limit of the second line (marked with an exclamation mark) in the next step of the proof:

$$\begin{aligned} 0 \leftarrow \int_G \partial_t u^\varepsilon \Phi^\varepsilon &= \int_G f^\varepsilon(u^\varepsilon)\partial_x\Phi^\varepsilon - \int_G g^\varepsilon(u^\varepsilon)\partial_x u^\varepsilon \partial_x \Phi^\varepsilon \\ &\overset{!}{\to} \int_G \int_1^2 f^+(u_+(x,t))\, \psi(x,t)\partial_y\varphi(y)\, dy\, dx\, dt \\ &\quad - \int_G \int_1^2 g^+(u_+(x,t))v_0(x,t,y)\, \psi(x,t)\partial_y\varphi(y)\, dy\, dx\, dt. \end{aligned} \tag{3.12}$$

The first integral vanishes since φ is compactly supported in $(1,2)$ and we conclude that v_0 is independent of y, since u_+ is positive by the lower bound on u^ε. We can perform the same calculations with φ supported in $(0,1)$ to find the same equality with $+$ replaced by $-$,

$$v_0(x,t,y) = v_-(x,t)\mathbf{1}_{(0,1)}(y) + v_+(x,t)\mathbf{1}_{(1,2)}(y). \tag{3.13}$$

In particular, the quantities $u_\pm = u_\pm(x)$ and $v_\pm = v_\pm(x)$ that appear in (3.1)–(3.6) are now defined. For brevity, we will often suppress the dependence on t in the following.

Step 2. *Compactness.* To abbreviate notation we write $I = (a,b)$ for the spatial interval and set $\mathbf{1}_k := \mathbf{1}_{(2k\varepsilon, 2k\varepsilon+2\varepsilon)}$, $\mathbf{1}_k^- := \mathbf{1}_{(2k\varepsilon, 2k\varepsilon+\varepsilon)}$, and $\mathbf{1}_k^+ := \mathbf{1}_{(2k\varepsilon+\varepsilon, 2k\varepsilon+2\varepsilon)}$. We furthermore set $\mathbf{1}_+^\varepsilon := \sum_k \mathbf{1}_k^+$ and $\mathbf{1}_-^\varepsilon := \sum_k \mathbf{1}_k^-$. Our aim in this step of the proof is the following result. Let $h : [0,1] \to \mathbb{R}$ be a continuous function. Then

$$h(u^\varepsilon(x))\mathbf{1}_-^\varepsilon(x) - h(u_-(x))\mathbf{1}_-^\varepsilon(x) \to 0 \text{ strongly in } L^2(G), \tag{3.14}$$

and likewise for $-$ replaced by $+$. We note that this result justifies, with $h = g^+$, the convergence in (3.12). We emphasize that (3.14) is not a consequence of the previous results. For its proof we must control variations of u^ε on points in $2\mathbb{Z}\varepsilon$. Loosely speaking, it must jump down in $2k\varepsilon + 2\varepsilon$ as much as it jumped up in $2k\varepsilon + \varepsilon$.

In order to derive (3.14) we consider the capillary pressure function $P^\varepsilon(x) = {p_c}^\varepsilon(x, u^\varepsilon(x))$. This function has no jumps across interfaces, and hence the spatial derivative has no singular parts. On Γ^ε we have the estimate $|\partial_x P^\varepsilon| \le C|\partial_x u^\varepsilon|$, and therefore a uniform estimate for $P^\varepsilon \in L^2((0,t_0), H^1(I))$.

We have seen in Lemma 3 that $t \mapsto u^\varepsilon(x,t)$ is monotone for almost every $x \in I$. By the monotonicity of ${p_c}^\pm$, this implies the monotonicity of $t \mapsto P^\varepsilon(x,t)$. For the strong solutions of the strictly parabolic equations of the proposition we therefore have $|\partial_t P^\varepsilon| = -\partial_t P^\varepsilon$, and an integration yields $\|\partial_t P^\varepsilon\|_{L^1(G)} \le L\|P^\varepsilon\|_{L^\infty(G)}$, which is uniformly bounded. The spatial and the temporal regularity together provide the boundedness of P^ε in $W^{1,1}(G)$, hence the precompactness of P^ε in $L^1(G)$. Exploiting once more the uniform bound in $L^\infty(G)$, we find a subsequence that converges strongly in $L^2(G)$ and almost everywhere in G to a limit $P^0 \in L^2(G)$.

The convergence almost everywhere can be exploited to conclude the strong convergence of u^ε as claimed in (3.14). Since $(P^\varepsilon - P^0)\mathbf{1}^\varepsilon_- \to 0$ pointwise, also

$$u^\varepsilon \mathbf{1}^\varepsilon_- - ({p_c}^-)^{-1}(P^0)\mathbf{1}^\varepsilon_- \to 0 \tag{3.15}$$

pointwise almost everywhere and, by the uniform boundedness, also strongly in $L^2(G)$. In order to identify the limit function we recall that $u^\varepsilon \mathbf{1}^\varepsilon_- \to u_-(x)\mathbf{1}_{(0,1)}(y)$ in the sense of two-scale convergence. On the other hand, again in the sense of two-scale convergence, $({p_c}^-)^{-1}(P^0(x))\mathbf{1}^\varepsilon_-(x) \to ({p_c}^-)^{-1}(P^0)(x)\mathbf{1}_{(0,1)}(y)$, and hence $({p_c}^-)^{-1}(P^0) = u_-$.

We can now also apply a nonlinear continuous function h to both expressions in (3.15) and find $h(u^\varepsilon)\mathbf{1}^\varepsilon_- - h(u_-)\mathbf{1}^\varepsilon_- \to 0$ pointwise almost everywhere. By the uniform bounds for u^ε, this provides (3.14).

Step 3. *Derivation of the continuity conditions* (3.2) *and* (3.5) *and the flux equality.* With the help of (3.14) it is not difficult to derive the continuity conditions. The strong convergence $P^\varepsilon \to P^0$ in $L^2(G)$, together with $P^0 \in L^2((0,t_0), H^1(I))$, implies

$${p_c}^\varepsilon(u^\varepsilon)\mathbf{1}^\varepsilon_+ - {p_c}^\varepsilon(u^\varepsilon)\mathbf{1}^\varepsilon_- = P^\varepsilon \mathbf{1}^\varepsilon_+ - P^\varepsilon \mathbf{1}^\varepsilon_- \rightharpoonup 0 \text{ in } L^2(G).$$

On the other hand, by (3.14) and the two-scale convergences,

$$\begin{aligned}
{p_c}^\varepsilon(u^\varepsilon)\mathbf{1}^\varepsilon_+ - {p_c}^\varepsilon(u^\varepsilon)\mathbf{1}^\varepsilon_- &= {p_c}^+(u^\varepsilon)\mathbf{1}^\varepsilon_+ - {p_c}^-(u^\varepsilon)\mathbf{1}^\varepsilon_- \\
&= {p_c}^+(u_+)\mathbf{1}^\varepsilon_+ - {p_c}^-(u_-)\mathbf{1}^\varepsilon_- + o(1) \\
&\rightharpoonup \frac{1}{2}({p_c}^+(u_+) - {p_c}^-(u_-)).
\end{aligned}$$

Comparison of the two limits yields (3.2).

For the derivation of (3.5) we consider a test function $\varphi \in C_0^\infty((0,2),\mathbb{R})$, and $\Phi^\varepsilon(x) = \varepsilon\psi(x,t)\varphi(x/\varepsilon)$ as above. Exploiting (3.14) we find

$$\begin{aligned}
0 \leftarrow \int_G \partial_t u^\varepsilon \Phi^\varepsilon &= \int_G f(u^\varepsilon)\partial_x \Phi^\varepsilon - \int_G g^\varepsilon(u^\varepsilon)\partial_x u^\varepsilon \partial_x \Phi^\varepsilon \\
\to \int_G \int_0^1 & f^-(u_-)\psi\, \partial_y \varphi\, dy + \int_G \int_1^2 f^+(u_+)\psi\, \partial_y\varphi\, dy \\
- \int_G \int_0^1 & g^-(u_-)v_-\, \psi\partial_y \varphi\, dy - \int_G \int_1^2 g^+(u_+)v_+\, \psi \partial_y \varphi\, dy \\
= \int_G \psi\, & \left[f^-(u_-) - f^+(u_+)\right]\varphi(1) - \int_G \psi\, \left[g^-(u_-)v_- - g^+(u_+)v_+\right]\varphi(1).
\end{aligned}$$

Since ψ was arbitrary, this yields (3.5). In order to derive the flux equality, we exploit once more (3.14) and calculate

$$\begin{aligned} F^\varepsilon &= f^\varepsilon(u^\varepsilon) - g^\varepsilon(u^\varepsilon)\partial_x u^\varepsilon \\ &= [f^+(u^\varepsilon) - g^+(u^\varepsilon)\partial_x u^\varepsilon]\mathbf{1}_+^\varepsilon + [f^-(u^\varepsilon) - g^-(u^\varepsilon)\partial_x u^\varepsilon]\mathbf{1}_-^\varepsilon \\ &\rightharpoonup \frac{1}{2}[f^+(u_+) - g^+(u_+)v_+] + \frac{1}{2}[f^-(u_-) - g^-(u_-)v_-], \end{aligned}$$

which, because of (3.5), is the result for F^0.

Step 4. *The quantities* $u_{\pm,x}$ *and relation* (3.3). Our aim is to derive $u_{-,x} := \partial_x u_- \in L^2(G)$. Loosely speaking, we need an estimate for the oscillations of u^ε on Γ_-^ε. Such an estimate is the consequence of the corresponding estimate for the capillary pressures P^ε. Our construction serves also as a preparation for Step 5.

We introduce a function $\hat{P}^\varepsilon$ as a piecewise affine approximation of P^ε,

$$\begin{aligned} \hat{P}^\varepsilon(2k\varepsilon) &= \frac{1}{\varepsilon}\int_{2k\varepsilon}^{2k\varepsilon+\varepsilon} P^\varepsilon \qquad \forall k, \\ \hat{P}^\varepsilon \text{ affine on } &(2k\varepsilon, 2k\varepsilon + 2\varepsilon) \quad \forall k. \end{aligned}$$

Exploiting the $L^2((0,t_0),H^1(I))$-regularity of P^ε we find $\hat{P}^\varepsilon \to P^0$. Furthermore, as a projection of P^ε onto the space of piecewise affine functions, the projections $\hat{P}^\varepsilon$ are again bounded in $L^2((0,t_0),H^1(\Omega))$. Choosing a subsequence, we may assume

$$\partial_x \hat{P}^\varepsilon = \sum_k \mathbf{1}_k \frac{1}{2\varepsilon^2}\int_{2k\varepsilon}^{2k\varepsilon+\varepsilon} [P^\varepsilon(.+2\varepsilon) - P^\varepsilon(.)] \rightharpoonup \partial_x P^0 \text{ in } L^2(G).$$

We can now relate the function $\hat{P}^\varepsilon$ with a piecewise linear function $\hat{u}^\varepsilon$ that approximates u_-,

$$\begin{aligned} \hat{u}^\varepsilon(2k\varepsilon) &= \frac{1}{\varepsilon}\int_{2k\varepsilon}^{2k\varepsilon+\varepsilon} u^\varepsilon \qquad \forall k, \\ \hat{u}^\varepsilon \text{ affine on } &(2k\varepsilon, 2k\varepsilon + 2\varepsilon) \quad \forall k \end{aligned}$$

with derivative

$$\partial_x \hat{u}^\varepsilon = \sum_k \mathbf{1}_k \frac{1}{2\varepsilon^2}\int_{2k\varepsilon}^{2k\varepsilon+\varepsilon} [u^\varepsilon(.+2\varepsilon) - u^\varepsilon(.)].$$

We claim that the sequence $\partial_x \hat{u}^\varepsilon$ is uniformly bounded in $L^2(G)$. Our aim is to compare $\partial_x \hat{P}^\varepsilon$ with $\partial_u {p_c}^-(u_-) \cdot \partial_x \hat{u}^\varepsilon$. To this end we write the pressure derivative with the fundamental theorem and the function $\xi(x,\lambda) := \lambda u^\varepsilon(x+2\varepsilon) + (1-\lambda)u^\varepsilon(x)$ as

$$\partial_x \hat{P}^\varepsilon = \sum_k \mathbf{1}_k \frac{1}{2\varepsilon^2}\int_{2k\varepsilon}^{2k\varepsilon+\varepsilon} \left\{ \int_0^1 \partial_u {p_c}^-(\xi(x,\lambda))\, d\lambda \right\} [u^\varepsilon(x+2\varepsilon) - u^\varepsilon(x)]\, dx.$$

The nonnegativity of the integrand provided by Lemma 3 and the lower bound for $\partial_u {p_c}^-$ imply a uniform bound for $\partial_x \hat{u}^\varepsilon \in L^2(G)$. In particular, we may assume that $\hat{u}^\varepsilon$ converges strongly in $L^2(G)$; the limit is easily identified with the weak limit u_-.

Furthermore, choosing a subsequence, we may assume that $\partial_x \hat{u}^\varepsilon$ converges weakly in $L^2(G)$. Denoting the limit function by $u_{-,x}$ we have

$$\partial_x \hat{u}^\varepsilon \rightharpoonup u_{-,x} := \partial_x u_- \text{ in } L^2(G).$$

In a similar way one constructs functions $\tilde{u}^\varepsilon$ that approximate u_+ with $\partial_x \tilde{u}^\varepsilon$ bounded in $L^2(G)$. We may assume that also this sequence converges weakly, $\partial_x \tilde{u}^\varepsilon \rightharpoonup u_{+,x} := \partial_x u_+$ in $L^2(G)$.

The weak convergences $\hat{u}^\varepsilon \rightharpoonup u_-$ and $\tilde{u}^\varepsilon \rightharpoonup u_+$, together with (3.1), imply $\hat{u}^\varepsilon + \tilde{u}^\varepsilon \rightharpoonup 2u^0$. Then the distributional derivatives converge as well, and we conclude (3.3) with $v^0 = \partial_x u^0 \in L^2(G)$.

Step 5. *Derivation of* (3.4) *and* (3.6). We have seen that the capillary pressure functions P^ε are bounded in $L^2((0,t_0), H^1(I))$ and that we may therefore assume $\partial_x P^\varepsilon \rightharpoonup \partial_x P^0$ in $L^2(G)$. In this last step of the proof we calculate the derivative $\partial_x P^0$ in three different ways.

The most direct approach is to calculate with the chain rule, exploiting (3.14) in the second equality,

$$\begin{aligned}
\partial_x P^0 \leftharpoonup \partial_x P^\varepsilon &= \partial_u {p_c}^-(u^\varepsilon)\, \partial_x u^\varepsilon\, \mathbf{1}_-^\varepsilon + \partial_u {p_c}^+(u^\varepsilon)\, \partial_x u^\varepsilon\, \mathbf{1}_+^\varepsilon \\
&= \partial_u {p_c}^-(u_-)\, \partial_x u^\varepsilon\, \mathbf{1}_-^\varepsilon + \partial_u {p_c}^+(u_+)\, \partial_x u^\varepsilon\, \mathbf{1}_+^\varepsilon + o(1) \\
&\rightharpoonup \frac{1}{2}\partial_u {p_c}^-(u_-)\, v_- + \frac{1}{2}\partial_u {p_c}^+(u_+)\, v_+.
\end{aligned}$$

We will now calculate $\partial_x P^0$ in a different way. We introduce the function $P^{*,\varepsilon} := {p_c}^-(\hat{u}^\varepsilon)$. The monotonicity of $\hat{u}^\varepsilon$ in t implies a compactness and allows us to assume the strong and the pointwise almost everywhere convergence $\hat{u}^\varepsilon \to u_-$. We calculate with the chain rule

$$\partial_x P^{*,\varepsilon} = \partial_u {p_c}^-(\hat{u}^\varepsilon) \cdot \partial_x \hat{u}^\varepsilon \rightharpoonup \partial_u {p_c}^-(u_-) \cdot u_{-,x} \text{ in } L^2(G).$$

On the other hand, $P^{*,\varepsilon} = {p_c}^-(\hat{u}^\varepsilon) \to {p_c}^-(u_-) = P^0$, and therefore the distributional limits coincide,

$$\partial_x P^0 = \partial_u {p_c}^-(u_-) \cdot u_{-,x}.$$

The above calculation can also be performed with averages over the set Γ_ε^+ and with the function p_c^+. We find the analogous formula $\partial_x P^0 = \partial_u p_c^+(u_+) \cdot u_{+,x}$ and thus (3.4). In (3.6) we use the symmetric version

$$\partial_x P^0 = \frac{1}{2}\partial_u {p_c}^+(u_+) u_{+,x} + \frac{1}{2}\partial_u {p_c}^-(u_-) u_{-,x}\ .$$

From our first calculation of $\partial_x P^0$ we see that the weighted average of $u_{+,x}$ and $u_{-,x}$ coincides with the weighted average of v_+ and v_-, as claimed in (3.6). ∎

As a preparation for the investigation of the interface condition in the free boundary value problem, we investigate the regularity of solutions in the region of strictly positive saturation.

LEMMA 5 (Hölder's estimate). *We consider a family of entropy solutions u^ε and fix positive numbers C_0 and δ. We assume that $t \in (0,T)$ is a time instance of bounded energy in the sense that*

$$\int_{\Gamma^\varepsilon} |\partial_x u^\varepsilon(.,t)|^2\, \mathbf{1}_{\{u^\varepsilon \geq \delta/2\}} \leq C_0^2. \tag{3.16}$$

Then there exist a constant $C_L = C_L(\delta)$*, independent of* C_0 *and* ε*, and a constant* $\varepsilon_0 = \varepsilon_0(\delta, C_0)$ *such that the following hold:*

1. *Let* $a = 2k\varepsilon + \varepsilon \in (0, L)$ *with* $k \in \mathbb{Z}$ *and* $u^\varepsilon(a - 0, t) \geq \delta$*, and let* $b \in 2\mathbb{Z}\varepsilon + \varepsilon$*,* $b > a$*. Then*

$$|u^\varepsilon(b - 0, t) - u^\varepsilon(a - 0, t)| \leq C_L C_0 \sqrt{|b - a|}. \tag{3.17}$$

2. *For all* $\varepsilon \leq \varepsilon_0(\delta, C_0)$ *there holds*

$$u^\varepsilon(2k\varepsilon + \varepsilon - 0, t) \geq \delta \quad \Rightarrow \quad u^\varepsilon(2k\varepsilon - \varepsilon - 0, t) \geq \delta/2. \tag{3.18}$$

Proof. Cellwise estimate and (3.17). The monotonicity of Lemma 3, together with the lower bound of Lemma 2, implies $u^\varepsilon \geq \delta$ on $(a, L) \times (0, t_0)$, and hence (3.16) provides an $L^2(\Gamma^\varepsilon)$-bound for the spatial derivative. We claim that locally, across a single interval $(2k\varepsilon + \varepsilon, 2k\varepsilon + 3\varepsilon)$, we can control differences of the u^ε values by the integral of the derivative. Indeed, with the variables

$$\begin{aligned} &y_0 := u^\varepsilon(2k\varepsilon + \varepsilon - 0, t), \quad y_1 := u^\varepsilon(2k\varepsilon + 2\varepsilon + 0, t), \quad y_2 := u^\varepsilon(2k\varepsilon + 3\varepsilon - 0, t), \\ &z_0 := u^\varepsilon(2k\varepsilon + \varepsilon + 0, t), \quad z_1 := u^\varepsilon(2k\varepsilon + 2\varepsilon - 0, t), \end{aligned}$$

we have the relations

$$\begin{aligned} y_2 - y_1 &= \int_{2k\varepsilon+2\varepsilon}^{2k\varepsilon+3\varepsilon} \partial_x u^\varepsilon(.,t) =: \Delta_1, \\ z_1 - z_0 &= \int_{2k\varepsilon+\varepsilon}^{2k\varepsilon+2\varepsilon} \partial_x u^\varepsilon(.,t) =: \Delta_2, \\ z_0 &= \Phi(y_0) \text{ and } z_1 = \Phi(y_1) \quad \text{for } \Phi(y) := ({p_c}^+)^{-1}({p_c}^-(y)). \end{aligned}$$

They imply

$$y_2 = y_1 + \Delta_1 = \Phi^{-1}(z_0 + \Delta_2) + \Delta_1 = \Phi^{-1}(\Phi(y_0) + \Delta_2) + \Delta_1.$$

Since Φ and its inverse Φ^{-1} have a bounded derivative on $\{y \geq \delta\}$ we conclude the local estimate

$$|y_2 - y_0| \leq C_L(\delta)\,(|\Delta_1| + |\Delta_2|) \leq C_L \int_{2k\varepsilon+\varepsilon}^{2k\varepsilon+3\varepsilon} |\partial_x u^\varepsilon(.,t)| \mathbf{1}_{\Gamma^\varepsilon}. \tag{3.19}$$

Adding the inequalities (3.19) from $k = (a - \varepsilon)/(2\varepsilon)$ to $k' = (b - \varepsilon)/(2\varepsilon) - 1$, we find

$$\begin{aligned} |u^\varepsilon(b - 0, t) - u^\varepsilon(a - 0, t)| &\leq C_L \int_a^b |\partial_x u^\varepsilon(.,t)| \mathbf{1}_{\Gamma^\varepsilon} \\ &\leq C_L\, |b - a|^{1/2} \left(\int_a^L |\partial_x u^\varepsilon(.,t)|^2 \mathbf{1}_{\Gamma^\varepsilon} \right)^{1/2}. \end{aligned}$$

This is estimate (3.17).

Implication (3.18) *on jumps.* Let C_0 be fixed and let t be a time instance with $\|\partial_x u^\varepsilon(.,t) \mathbf{1}_{\{u^\varepsilon \geq \delta/2\}} \mathbf{1}_{\Gamma^\varepsilon}\|_{L^2}^2 \leq C_0$. As shown in (3.19), we have the estimate

$$\begin{aligned} |u^\varepsilon(2k\varepsilon + \varepsilon - 0) - u^\varepsilon(2k\varepsilon - \varepsilon - 0)| &\leq c \left(\int_{2k\varepsilon-\varepsilon}^{2k\varepsilon+\varepsilon} |\partial_x u^\varepsilon(.,t)|^2 \mathbf{1}_{\Gamma^\varepsilon} \right)^{1/2} \sqrt{\varepsilon} \\ &\leq c C_0 \sqrt{\varepsilon}, \end{aligned}$$

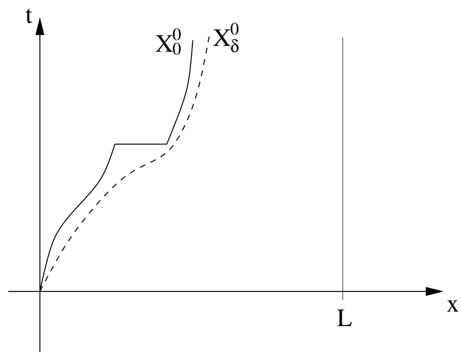

FIG. 6. *Possible shapes of the free boundaries X_δ^0 and X_0^0. We know that they are monotone and that $X_\delta^0 \to X_0^0$ pointwise almost everywhere. With the above graphs we illustrate that X_0^0 may have jumps and that we cannot expect $X_\delta^0(t) \to X_0^0(t)$ for every $t > 0$.*

at least if we can assume (for the last inequality) that the saturation satisfies $u^\varepsilon \geq \delta/2$ in every point of the interval $(2k\varepsilon - \varepsilon, 2k\varepsilon + \varepsilon)$. We choose $\varepsilon_0 = \varepsilon_0(\delta, C_0)$ such that $c\,C_0\sqrt{\varepsilon_0} \leq \delta/4$. The arguments above can be repeated for every point x in the interval $(2k\varepsilon, 2k\varepsilon + \varepsilon)$. Continuity of u^ε inside the interval allows us to conclude that $u^\varepsilon(2k\varepsilon + 0) \geq 3\delta/4$. We repeat the argument on the interval $(2k\varepsilon - \varepsilon, 2k\varepsilon)$ and find the result. ∎

4. The free boundary problem. We study, for $\delta > 0$ and $\varepsilon > 0$, the free boundary separating the region of uniformly positive saturation from the rest:

$$X_\delta^\varepsilon(t) := \inf\left\{x \in (0, L) \cap (2\varepsilon\mathbb{Z} + \varepsilon) : \ u^\varepsilon(x - 0, t) \geq \delta\right\}, \tag{4.1}$$

$$X_0^\varepsilon(t) := \inf_{\delta > 0} X_\delta^\varepsilon(t). \tag{4.2}$$

We set $X_\delta^\varepsilon(t) = L$ if the infimum is taken over the empty set.

LEMMA 6. *There are sequences $\varepsilon_k \searrow 0$ and $\delta_m \searrow 0$ such that, for every $\varepsilon = \varepsilon_k$ and every $\delta = \delta_m$, the following hold:*

1. *The maps $t \mapsto X_\delta^\varepsilon(t)$ and $t \mapsto X_0^\varepsilon(t)$ are monotonically nondecreasing.*
2. *The following limits hold pointwise for almost every t, and the limits are monotone functions:*

$$X_\delta^0(t) = \lim_{k\to\infty} X_\delta^{\varepsilon_k}(t), \qquad X_0^0(t) = \lim_{m\to\infty} X_{\delta_m}^0(t),$$
$$X_0^\varepsilon(t) = \lim_{m\to\infty} X_{\delta_m}^\varepsilon(t), \qquad \tilde{X}_0^0(t) = \lim_{k\to\infty} X_0^{\varepsilon_k}(t).$$

   We can select an upper semicontinuous representative $t \mapsto X(t)$ of the L^1-function $t \mapsto X_0^0(t)$.
3. *There holds $X_\delta^0 \leq X_{\delta'}^0$ for all $\delta \leq \delta'$ and $\tilde{X}_0^0 \leq X_0^0$.*

Proof. Figure 6 indicates possible shapes of X_0^0 and X_δ^0 and recalls the fact that these functions need not be continuous. Lemma 3 provides that the function $t \mapsto u^\varepsilon(x, t)$ is monotonically nonincreasing. This implies the monotonicity of the free boundaries stated in statement 1. The monotonicity of the family of functions $t \mapsto X_\delta^\varepsilon$ implies the uniform boundedness in $BV([0, T], \mathbb{R})$, and hence we can extract subsequences that converge strongly in L^1 and pointwise almost everywhere. Limits of monotone functions are again monotone. Since BV-functions have only countably many jumps, we find an upper semicontinuous representative.

The monotonicity in δ is an immediate consequence of the definition of X^ε_δ. It justifies the infimum of (4.2) and implies $X^\varepsilon_0 \le X^\varepsilon_\delta$, which carries over in the limit $k \to \infty$ as $\tilde{X}^0_0 \le X^0_\delta$. The limit $\delta_m \to 0$ yields statement 3. ∎

With the help of the limiting free boundaries we can transform the results of Proposition 1 into the following statement.

COROLLARY 1 (limit equations in region G). *Let $t \mapsto X(t)$ be as in Lemma 6 and G the open domain:*

$$G := \{(x,t) \in (0,L) \times (0,T) : x > X(t)\}.$$

Let (u^0, F^0) be limits of entropy solutions $(u^\varepsilon, F^\varepsilon)$ as in Theorem 1 and $G' \Subset G$ a subset of G. Then there holds $\partial_x u^0 \in L^2(G')$ and F^0 satisfies on G' the relation $F^0 = \mathcal{F}(u^0, \partial_x u^0)$.

Proof. The function X is monotone and the closure of G' is a compact subset of G; hence G' can be covered by a finite collection of sets $G_0 = (x_0, L) \times (0, t_0)$ with $x_0 > X(t_0)$. It suffices to verify the statements on one such subset G_0. Our aim is to find $\varepsilon_0 > 0$ and $\delta > 0$ such that $u^\varepsilon \ge \delta$ on G_0 for all $\varepsilon \le \varepsilon_0$. Once this is done, the application of Proposition 1 yields the result.

We start by choosing $\eta > 0$ such that $x_0 - \eta > X(t_0 + \eta)$, which is possible, since X is upper semicontinuous, and hence $\limsup_{\eta \searrow 0} X(t_0 + \eta) \le X(t_0) < x_0$. We now choose $\delta > 0$ such that

$$x_0 - \frac{\eta}{2} > X^0_\delta \left(t_0 + \frac{\eta}{2}\right). \tag{4.3}$$

In order to verify that for a small $\delta > 0$ relation (4.3) is satisfied, we exploit that by monotonicity $X(t) < x_0 - \eta$ for all $t \in (t_0 + \eta/2, t_0 + \eta)$. The strong L^2-convergence $X^0_\delta \to X$ and Egoroff's theorem imply that, for $\delta > 0$ small, $|X^0_\delta - X| < \eta/2$ except for a set of t's with measure less than $\eta/2$. For such δ there necessarily exists $s \in (t_0 + \eta/2, t_0 + \eta)$ with $X^0_\delta(s) < x_0 - \eta/2$. By monotonicity of X^0_δ, relation (4.3) holds.

We finally want to choose, in a similar way, a number $\varepsilon_0 > 0$ with $x_0 > X^\varepsilon_\delta(t_0)$. We have $X^0_\delta(t) < x_0 - \eta/2$ for all $t \in (t_0, t_0 + \eta/2)$. By Egoroff's theorem we find $\varepsilon_0 > 0$ such that, for all $\varepsilon \le \varepsilon_0$, we find some $s \in (t_0, t_0 + \eta/2)$ such that $X^\varepsilon_\delta(s) < x_0$. The monotonicity of $X^\varepsilon_\delta(s)$ implies $x_0 > X^\varepsilon_\delta(t_0)$ and thus $G_0 \subset (X^\varepsilon_\delta(t_0), L) \times (0, t_0)$. The definition of X^ε_δ implies the desired lower bound for the sequence u^ε on the left boundary of the domain $(X^\varepsilon_\delta(t_0), L) \times (0, t_0)$. Lemma 2 yields the lower bound on the whole domain. ∎

PROPOSITION 2 (limit equations in region B). *In the domain*

$$B := \{(x,t) \in (0,L) \times (0,T) : x \le X(t)\},$$

there holds that $u^0 \equiv \frac{u^*}{2}$ and $F^0 \equiv 0$ almost everywhere. The function u^0 has no jump across $\partial B \cap \Omega_T$ in the following sense: Let $T_0 \in (0,T]$ be a time instance with $X(T_0) < L$, and let A_r, $r > 0$, be a family of averages of u^0,

$$A_r := \frac{1}{T_0 \cdot r} \int_0^{T_0} \int_0^r u^0(X(t) + s, t)\, ds\, dt. \tag{4.4}$$

Then A_r satisfies

$$A_r \to \frac{u^*}{2} \text{ for } r \to 0.$$

Proof. We select monotone sequences $\delta_j \to 0$ and $\varepsilon_m \to 0$ with the convergences of the free boundaries as in Lemma 6 and with $u^{\varepsilon_m} \to u^0$ weakly in $L^2(\Omega_T)$. Almost all time instances $t \in (0,T)$ are points of continuity of the function $X(.)$ and of all functions $X^0_{\delta_j}(.)$, $j \in \mathbb{N}$. Furthermore, in almost every point $t \in (0,T)$ the convergences of Lemma 6 hold. In the following we consider only time instances t with all these properties.

Step 1. *On B it holds that $u^0 = u^*/2$.* We note that $u^0 \geq u^*/2$ follows immediately from the lower bound in Lemma 4.

For the upper bound let $(x,t) \in B$ be with t as above and with $x < X(t)$. Moreover, let $\rho > 0$ be arbitrary. We choose $\tau > 0$ and an index $j \in \mathbb{N}$ such that, for $\delta = \delta_j$, implication (2.5) of Lemma 4 holds. Since X has no jump in t we find $t' < t$ with $x < X(t')$. By monotonicity in δ, we have $x < X^0_\delta(t')$. We choose $r > 0$ smaller than $\frac{1}{2}(X^0_\delta(t') - x)$; for later use we also demand $r < \frac{1}{2}(t - t')$. We find $m_0 > 0$ such that, for all $m \geq m_0$, additionally $r < X^{\varepsilon_m}_\delta(t') - x$. We may choose m_0 large enough to satisfy additionally $\tau\varepsilon^2_{m_0} < t - t' - r$ and $\varepsilon_{m_0} < \varepsilon_0$ of Lemma 4. The upper bound of Lemma 4 provides, for $\varepsilon = \varepsilon_m$ with $m \geq m_0$,

$$u^\varepsilon(2k\varepsilon + \varepsilon - 0, t') \leq \delta \quad \Rightarrow \quad \int_{2k\varepsilon-\varepsilon}^{2k\varepsilon+\varepsilon} u^\varepsilon(., t' + \tau\varepsilon^2) \leq \varepsilon(u^* + \rho).$$

By construction, the assertion is satisfied for all $k \in \mathbb{Z}$ with $2k\varepsilon + \varepsilon \leq x + r$. The monotone decay of u^ε in t implies

$$\frac{1}{|B_r((x,t))|} \int_{B_r((x,t))} u^{\varepsilon_m} \leq \frac{1}{2}(u^* + \rho). \tag{4.5}$$

This carries over to the weak limit u^0. Since ρ is arbitrary, we have the upper bound in B by the Lebesgue differentiation theorem.

Step 2. *Boundary condition.* We assume that a small number $\rho > 0$ is given; our aim is to choose $r > 0$ small to have $A_r \leq u^*/2 + c\rho$ for some universal constant c. We recall that A_r is defined with an integration over the thin region

$$U_r := \{(x,t) \in \Omega_{T_0} : X(t) < x < X(t) + r\}.$$

We use the numbers $\delta_0 > 0$ and $\tau > 0$ that appear in the upper bound for averages in Lemma 4 and choose $\delta = \delta_j < \delta_0/2$. We consider the ε-dependent set

$$E_0 := \left\{(x,t) \in \Omega_{T_0} : x \in (0,L), \int_0^L |\partial_x u^\varepsilon(.,t)|^2 \, \mathbf{1}_{\{u^\varepsilon \geq \delta/2\}} > C_0^2 \right\},$$

where we denote by $\partial_x u^\varepsilon$ the regular part of the derivative. Choosing C_0 large enough we achieve $|E_0 \cap U_r| \leq \rho r T_0$ for all ε. This is possible since by estimate (2.1) the time integral over the above spatial integral is bounded. We now choose $r > 0$ small enough to satisfy, with $C_L = C_L(\delta/2)$ of Lemma 5, $C_L C_0 (4r)^{1/2} \leq \delta$.

In order to show the upper bound for A_r we may still choose $\varepsilon > 0$ small. We define further ε-dependent exceptional sets as

$$\begin{aligned}
E_1 &:= \left\{(x,t) \in \Omega_{T_0} : x \in (0,L), |X^\varepsilon_\delta(t) - X^0_\delta(t)| \geq r\right\}, \\
E_1' &:= \left\{(x,t) \in \Omega_{T_0} : x \in (0,L), t \geq \tau\varepsilon^2, |X^\varepsilon_\delta(t - \tau\varepsilon^2) - X^0_\delta(t - \tau\varepsilon^2)| \geq r\right\}, \\
E_2 &:= \left\{(x,t) \in \Omega_{T_0} : X^\varepsilon_\delta(t - \tau\varepsilon^2) \leq x \leq X^\varepsilon_\delta(t)\right\}, \\
E_3 &:= \left\{(x,t) \in \Omega_{T_0} : |X(t) - X(t - \tau\varepsilon^2)| \geq r\right\}.
\end{aligned}$$

For the first set we achieve $|E_1| \le \rho r T_0$ for all small ε by the L^1-convergence $X^\varepsilon_\delta \to X^0_\delta$. The set E_1' is obtained from E_1 by a shift, and hence this set also satisfies $|E_1'| \le \rho r T_0$. The set E_2 is contained in a $\tau\varepsilon^2$-neighborhood of the free boundary

$$\Sigma^\varepsilon_\delta := \left\{ (x,t) \in \Omega_{T_0} : \lim_{s \nearrow t} X^\varepsilon_\delta(s) \le x \le \lim_{s \searrow t} X^\varepsilon_\delta(s) \right\}.$$

The set $\Sigma^\varepsilon_\delta$ is a curve of finite length, and hence we achieve $|E_2| \le \rho r T_0$ for $\varepsilon > 0$ small. Finally, $|E_3| \le \rho r T_0$ for $\varepsilon > 0$ small, since X is a BV-function. We may additionally impose on ε that $\varepsilon < r$ and $\varepsilon < \varepsilon_0(\delta, C_0)$; the latter allows us to use the implication of Lemma 5 outside the set E_0,

$$u^\varepsilon(2k\varepsilon + \varepsilon - 0, t) \ge \delta \quad \Rightarrow \quad u^\varepsilon(2k\varepsilon - \varepsilon - 0, t) \ge \delta/2. \tag{4.6}$$

We note that the set

$$E_0' := \left\{ (x,t) \in (0,L) \times (\tau\varepsilon^2, T_0) : \int_0^L |\partial_x u^\varepsilon(.,t-\tau\varepsilon^2)|^2 \,\mathbf{1}_{\{u^\varepsilon(.,t-\tau\varepsilon^2)\ge\delta/2\}} > C_0^2 \right\}$$

also satisfies $|E_0' \cap U_r| \le \rho r T_0$, since it is obtained by a shift of the set E_0.

After these preparations, let us now consider an arbitrary point $(x,t) = (2k\varepsilon + \varepsilon, t) \in U_r \setminus (E_0 \cup E_0' \cup E_1 \cup E_1' \cup E_2 \cup E_3)$. We distinguish two cases.

Case (i). $u^\varepsilon(x,t)$ is small, $x = 2k\varepsilon + \varepsilon < X^\varepsilon_\delta(t)$. Since (x,t) is not contained in E_2, we also have $x < X^\varepsilon_\delta(t - \tau\varepsilon^2)$. Lemma 4 can be applied with the point $(2k\varepsilon + \varepsilon, t - \varepsilon^2\tau)$ and yields

$$\int_{2k\varepsilon-\varepsilon}^{2k\varepsilon+\varepsilon} u^\varepsilon(.,t) \le \varepsilon(u^* + \rho).$$

Case (ii). $u^\varepsilon(x,t)$ is large, $x = 2k\varepsilon + \varepsilon \ge X^\varepsilon_\delta(t)$. We will derive the smallness of $u^\varepsilon(x,t)$ with the help of the Hölder-type estimate of Lemma 5 and conclude again with Lemma 4.

We start by setting $t' := t - \tau\varepsilon^2$ and denote by k' the integer with $2k'\varepsilon + \varepsilon = x' := X^\varepsilon_\delta(t')$. The definition of X^ε_δ implies $u^\varepsilon(x' - 0, t') \ge \delta$, $(x', t') \notin E_0'$ allows us to use (4.6) at the time instance t', and we conclude that $\delta/2 \le u^\varepsilon(2k'\varepsilon - \varepsilon - 0, t') < \delta$. The lower bound allows us to apply the first part of Lemma 5 with $a = 2k'\varepsilon - \varepsilon$ and $b = x = 2k\varepsilon + \varepsilon$. We find

$$u^\varepsilon(x - 0, t') \le u^\varepsilon(2k'\varepsilon - \varepsilon - 0, t') + C_L(\delta/2)\, C_0 (4r)^{1/2} \le \delta + \delta = 2\delta.$$

We used here $(x,t) \notin E_3$ and $(x,t) \notin E_1'$ such that

$$\begin{aligned} x - x' &= (x - X(t)) + (X(t) - X(t')) + (X(t') - X^0_\delta(t')) + (X^0_\delta(t') - X^\varepsilon_\delta(t')) \\ &\le r + r + 0 + r = 3r. \end{aligned}$$

Another application of the upper bound of Lemma 4 yields also in this case

$$\int_{2k\varepsilon-\varepsilon}^{2k\varepsilon+\varepsilon} u^\varepsilon(.,t) \le \varepsilon(u^* + \rho).$$

In both cases we find the same estimate for averages of u^ε. Summation over k and an integration over $t \in (0, T_0)$ yield

$$\frac{1}{T_0 \cdot r} \int_{U_r} u^\varepsilon \le \frac{u^*}{2} + c\rho + O(\varepsilon) \frac{1}{T_0 \cdot r}.$$

The factor c covers the error induced by the exceptional sets, and the error term $O(\varepsilon)$ is induced by the integration over a boundary strip of width 2ε that is necessary to cover U_r with intervals of the form $(2k\varepsilon, 2k\varepsilon + 2\varepsilon)$. We take the limit $\varepsilon \to 0$. Since $\rho > 0$ is arbitrary, we find (4.4).

Step 3. *On B it holds that $F^0 = 0$.* We have shown in Step 1 that u^0 is constant in B, and hence the conservation law implies $\partial_x F^0 = 0$ and we have $F^0(x,t) = F^0(t)$ for almost all $(x,t) \in B$. Our aim is to conclude $F^0(t) = 0$ for almost all t.

Inequality $F^0 \le 0$. For the approximate solutions u^ε, the boundary condition $u^\varepsilon(0,t) = 0$, together with $f(0) = 0$, $g \ge 0$, and $u^\varepsilon \ge 0$, implies $F^\varepsilon(0,t) = \mathrm{trace}\{f(u^\varepsilon) - g(u^\varepsilon)\partial_x u^\varepsilon\} \le 0$. This can be written in a weak form as

$$\int_0^T \int_0^L \{u^\varepsilon \cdot \partial_t \varphi + F^\varepsilon \cdot \partial_x \varphi\} \ge 0 \quad \forall \varphi \in C_0^\infty((0,T) \times [0,L)),\ \varphi \ge 0.$$

We can take the limit $\varepsilon \to 0$ in these integrals and conclude that $F^0 \le 0$ on B from $\partial_t u^0 = 0$.

Inequality $F^0 \ge 0$. This inequality is not a consequence of the boundary conditions but must be concluded with the help of the positivity of the global convection term $f(u)$. We consider an arbitrary rectangle $U \Subset B$ and a number $q > 0$ and show for some m_0 that

$$F^{\varepsilon_m} \ge -q \quad \text{ on } U \text{ for all } m \ge m_0.$$

Once this is shown, we have $F^0 \ge 0$ almost everywhere on B.

We fix the rectangle $U \Subset B$ and the number $q > 0$. We choose $\delta > 0$ small compared to $q \cdot \inf\{x : (x,t) \in U\} > 0$ and refer the reader to the end of the proof for the precise choice. We now select m_0 such that, for all $m \ge m_0$, (i) $x \le X^\varepsilon_{\delta/2}(t)$ for all $(x,t) \in U$, (ii) $u^\varepsilon(x,t) \le \delta$ for all $(x,t) \in U$ with $x \in \Gamma^\varepsilon_-$, (iii) $u^*/2 \le u^\varepsilon(x,t) \le (u^*+1)/2$ for all $(x,t) \in U$ with $x \in \Gamma^\varepsilon_-$. The existence of such an m_0 follows from the BV-convergence $X^\varepsilon_{\delta/2} \to X^0_{\delta/2}$, the argument of (3.18), and the lower bound for averages. We now assume that, for some $(x,t) \in U$ and some $m \ge m_0$,

$$F^{\varepsilon_m}(x,t) = f^{\varepsilon_m}(x, u^{\varepsilon_m}(x,t)) - g^{\varepsilon_m}(x, u^{\varepsilon_m}(x,t))\partial_x u^{\varepsilon_m}(x,t) < -q$$

and derive a contradiction.

Since $\partial_x F^\varepsilon = -\partial_t u^\varepsilon$ is nonnegative, F^ε is monotonically increasing and we have

$$-g^\varepsilon(x, u^{\varepsilon_m}(x',t))\partial_x u^\varepsilon(x',t) = F^\varepsilon(x',t) - f^\varepsilon(x, u^{\varepsilon_m}(x',t)) \le F^\varepsilon(x',t) \le -q$$

for all $x' \in (0,x)$. This implies that $u^\varepsilon(.,t)$ is increasing on $\Gamma^\varepsilon_- \cap (0,x)$, and on $\Gamma^\varepsilon_+ \cap (0,x)$ it is strictly increasing with a lower bound

$$\partial_x u^\varepsilon \ge \frac{q}{g^*} \text{ with } g^* := \sup_{\xi \in (u^*/2, (1+u^*)/2)} g(\xi) > 0.$$

The monotonicity of $p_c{}^\pm$ implies that u^ε is increasing on $(0,x) \cap 2\varepsilon\mathbb{Z}$ with an average slope of at least $q/2g^*$. The boundary condition $u^\varepsilon(0,t) = 0$ leads to

$$u^\varepsilon(x,t) \ge \frac{q}{2g^*} x > \delta$$

if δ was chosen with $\delta < q \inf\{x : (x,t) \in U\}/2g^*$. This is in contradiction with $u^\varepsilon(x,t) \le \delta$ of (ii). The proof of $F^0 = 0$ on B is complete. $\square$

Proof of Theorem 1. A priori estimates for u^ε and F^ε are shown in Lemma 1 of section 2, and we may therefore select weakly convergent subsequences. The weak convergences allow us to take the distributional limit in the conservation law and we find (1.12).

In Lemma 6 we constructed a monotone function $X : [0,T] \to \mathbb{R}$ such that $G = \{(x,t)|x > X(t)\} \subset \Omega_T$ is an open set. In Proposition 2 we derived $u^0 \equiv u^*/2$ and $F^0 = 0$ almost everywhere on $B := \Omega_T \setminus G$; since $\mathcal{F}$ satisfies $\mathcal{F}(u^*/2, \zeta) = 0$ for all $\zeta \in \mathbb{R}$, (1.13) holds pointwise almost everywhere on B. Corollary 1 provides $\partial_x u^0 \in L^2_{loc}(G)$ and (1.13) on G.

We already know that $\partial_x u^0$ is an L^2_{loc}-function on $\Omega_T \setminus \Sigma$ for $\Sigma = \partial G \cap \partial B$. Lemma 3 implies that $\partial_x u^0$ is nonnegative, and the boundedness of u^0 implies that the derivative $\partial_x u^0$ is a nonnegative measure on Ω_T. Each slice $u^0(.,t)$ is a BV-function, and hence the singular part of the measure $\partial_x u^0$ is concentrated on Σ and regular with respect to the one-dimensional Hausdorff measure. Proposition 2 shows that this singular part of the measure $\partial_x u^0$ vanishes. We thus verified the statement $\partial_x u^0 \in L^1(\Omega_T)$. $\square$

BOUNDARY HOMOGENIZATION AND REDUCTION OF DIMENSION IN A KIRCHHOFF–LOVE PLATE*

DOMINIQUE BLANCHARD†, ANTONIO GAUDIELLO‡, AND TARAS A. MEL'NYK§

Abstract. We investigate the asymptotic behavior, as ε tends to 0^+, of the transverse displacement of a Kirchhoff–Love plate composed of two domains $\Omega_\varepsilon^+ \cup \Omega_\varepsilon^- \subset \mathbb{R}^2$ depending on ε in the following way. The set Ω_ε^+ is a union of fine teeth, having small cross section of size ε and constant height, ε-periodically distributed on the upper side of a horizontal thin strip with vanishing height h_ε, as ε tends to 0^+. The structure is clamped on the top of the teeth, with a free boundary elsewhere, and subjected to a transverse load. As ε tends to 0^+, we obtain a "continuum" bending model of rods in the limit domain of the comb, while the limit displacement is independent of the vertical variable in the rescaled (with respect to h_ε) strip. We show that the displacement in the strip is equal to the displacement on the base of the teeth if $h_\varepsilon \gg \varepsilon^4$. However, if the strip is thin enough (i.e., $h_\varepsilon \simeq \varepsilon^4$), we show that microscopic oscillations of the displacement in the strip, between the basis of the teeth, may produce a limit average field different from that on the base of the teeth; i.e., a discontinuity in the transmission condition may appear in the limit model.

1. Introduction.

Consider a bounded three-dimensional (3D) plate with small thickness and with middle surface $\Omega_\varepsilon^+ \cup \Omega_\varepsilon^- \subset \mathbb{R}^2$ like a comb, where ε is a small positive parameter. Precisely, Ω_ε^+ is a set of fine teeth, with small cross section of size ε and constant height, ε-periodically distributed on the upper side of a horizontal thin strip Ω_ε^- having a small height h_ε (see Figure 1). The structure is clamped on the top of the teeth, with a free boundary elsewhere, and subjected to a transverse load (see Remark 2.3 for other compatible boundary conditions). The transverse displacement is assumed to satisfy the Kirchhoff–Love equation.

The problem under investigation here pertains to the field of stationary problems posed on a domain which has a so-called *rough boundary* or *highly oscillating boundary*. Boundary-value problems involving rough boundaries appear in many fields of physics and engineering sciences such as the scattering of acoustic waves on small periodic obstacles, the free vibrations of strongly nonhomogeneous elastic bodies, and the behavior of fluids over rough walls or of coupled fluid-solid periodic structures. The reader can find a detailed bibliography about this subject in [2], [4], and [16]. More generally, for the study of thin structures and multistructures, we refer the reader to the following monographs: [7], [9], [12], [13], [14], [17], [19], [20], [22], and the references therein.

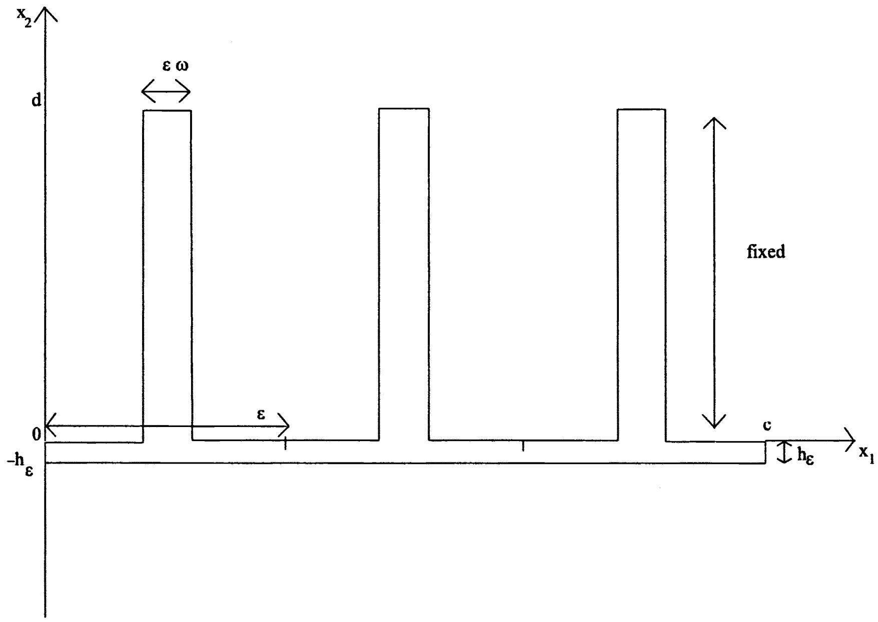

FIG. 1. *The middle surface of our 3D plate.*

A physical example for the specific model and structure considered here appears in MEMS[1] acceleration sensors (see [15]) where the acceleration component in the direction of the motion corresponds to a transverse load applied over the thin strip and the deformation of the teeth is then proportional to the acceleration itself. These sensors are widely used in automotive applications (antilock braking system (ABS), electronic stability program (ESP), airbags, etc.). Our geometrical structure can also model a thin elastic grid used to filter a liquid flow in which case the transverse external forces are due to the action of the fluid on the grid (turn Figure 1 upside down).

It is often impossible to approach these problems directly with numerical methods, because the rough boundary of a comb requires a large number of mesh points in their neighborhood. Thus, the computational cost associated with such a problem grows rapidly when the scale of periodicity gets smaller. Moreover, it can occur that the required discretization step becomes too small for the machine precision. Then, the goal is to construct accurate and numerically implementable asymptotic approximations.

The aim of this paper is to mark a first step in this direction by finding, via an asymptotic analysis as ε tends to zero, a handier limit model which approximates the Kirchhoff–Love equation in the comb. In our case, the asymptotic analysis is still more complicated in consequence of the competition between the parameter of periodicity ε and the parameter of thickness h_ε which vanishes as ε tends to zero.

According to an idea introduced by Ciarlet and Destuynder (see [8]), the terms in the thin strip Ω_ε^- are rescaled in a fixed domain Ω^-. Moreover, in the following, Ω^+ denotes the "limit domain" of the teeth (see Figure 2). In the limit process, under suitable convergence assumptions on the rescaled loads, we obtain, in Ω^+, a

[1]Microelectromechanical systems.

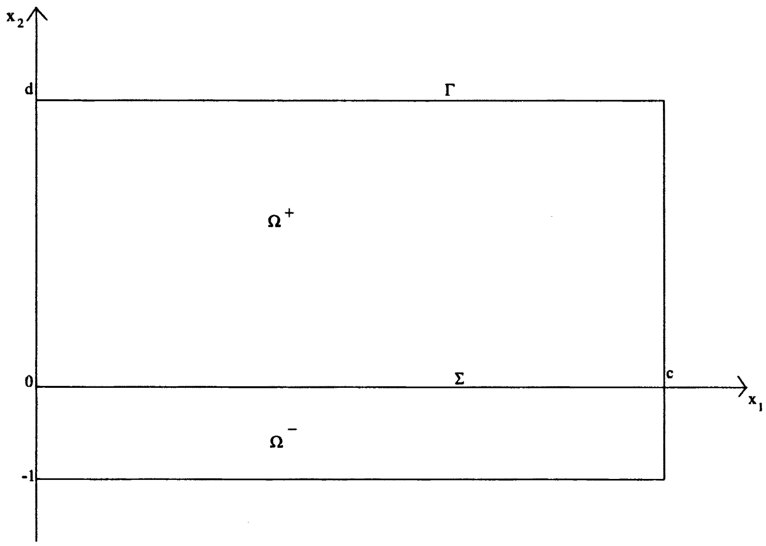

FIG. 2. *The limit middle surface.*

continuum bending model of rods subjected to a force f depending on the limit of the transverse loads on the teeth. The rods are clamped on the upper side Γ and subjected on the lower side Σ to applied forces but without applied momentum. The forces on Σ depend on the limit density g of the transverse loads on the thin strip Ω_ε^- and on the measure of the cross section of the reference tooth.

The limit solution is independent of the vertical variable in Ω^- and meets a Dirichlet transmission condition between Ω^+ and Ω^- if $h_\varepsilon \gg \varepsilon^4$, or if $h_\varepsilon \simeq \varepsilon^4$ and if g is negligible. However, if the strip is thin enough, i.e., $h_\varepsilon \simeq \varepsilon^4$, and the transverse loads on the thin strip are strong enough, a discontinuity in the Dirichlet transmission condition appears. Roughly speaking, this means that microscopic oscillations of the displacement in the strip, between the basis of the teeth of Ω_ε^+, produce a limit average field different from that on the base of the teeth.

Now, we give a short review on problems involving rough boundaries with two small geometrical parameters in competition. As far as we know, these problems have been recently treated in [3], [5], and [6]. Precisely, in [3] and [6] the authors studied the asymptotic behavior of a monotone nonlinear second-order Neumann problem, with growth $p-1$ ($p \in\ ]1,+\infty[$), in a multidomain of $\mathbb{R}^N$ ($N \geq 2$) composed of a "forest" of cylinders with fixed height and small cross section of size ε, distributed with ε-periodicity upon an asymptotically flat part of thickness h_ε. They proved that $h_\varepsilon = \varepsilon^p$ is a critical size for the thickness of the thin domain. In [5], the homogenization process for the junction of a periodic family of elastic rods with a thin elastic plate is studied in the setting of the linearized elasticity. Here different critical sizes appear leading to various limit models: bending-bending model for the rods and the two-dimensional (2D) plate, rigid-bending, or microscopic effects. In [11] the authors considered a thin multidomain of $\mathbb{R}^N$ ($N \geq 2$) consisting (e.g., in a 3D setting) of only one vertical rod upon a horizontal disk. In this thin multidomain they introduced a bulk energy density of the kind $W(D^2U)$, where W is a convex function with growth $p \in\ ]1,+\infty[$. By assuming that the two volumes tend to zero with the same rate, under suitable boundary conditions, they showed that the limit problem is uncoupled if $1 < p \leq \frac{N-1}{2}$, "partially" coupled if $\frac{N-1}{2} < p \leq N-1$, and coupled if $N-1 < p$.

The main difficulty in analyzing the problem considered in the present paper is twofold and it is essentially due to the fourth order of the Kirchhoff–Love model. First, deriving a priori estimates on the displacement for this operator and for an oscillating domain after rescaling is more intricate than for second-order problems. Second, as far as the homogenization process is concerned, the use of the method of oscillating test functions, introduced by Tartar in [21], is also more complicated than for second-order problems since here we have to take into account also the oscillations of the second derivatives of the solution.

Our paper is organized as follows. In section 2 the problem and the main results are stated. In section 3, by making use of the results proved in [3], some a priori norm-estimates are obtained. In section 4, these estimates provide some convergence results in L^2-norm, in the weak topology of L^2, or in the setting of the two-scale convergence method, proposed by Nguetseng in [18] and developed by Allaire in [1]. For convenience of the reader, in this section we also recall the definition and the main properties of the two-scale convergence. Finally, in section 5, the limit problem is derived by making use of the method of oscillating test functions.

2. Statement of the problem and main results. Let $\omega =]a,b[$ with $0 < a < b < 1$, $c, d \in]0,+\infty[$, and let $\{\varepsilon\}$, $\{h_\varepsilon\} \subset]0,1[$ be two sequences converging to zero. For every ε, consider the 3D plate with small thickness $t > 0$ and with middle surface $\Omega_\varepsilon^+ \cup \Omega_\varepsilon^- \subset \mathbb{R}^2$ having the shape of a comb (see Figure 1), where

$$\Omega_\varepsilon^+ = \bigcup_{\{k\in\mathbb{N}:\, \varepsilon b+\varepsilon k<c\}} (\varepsilon\omega + \varepsilon k) \times [0, d[$$

is a set of fine teeth of small cross section $\varepsilon\omega$ and constant height d, ε-periodically distributed on the upper basis of the thin strip:

$$\Omega_\varepsilon^- =]0, c[\times] - h_\varepsilon, 0[,$$

which has a vanishing height h_ε and constant basis. Moreover, denote by Γ_ε the top of the teeth of the middle surface:

$$\Gamma_\varepsilon = \bigcup_{\{k\in\mathbb{N}:\, \varepsilon b+\varepsilon k<c\}} (\varepsilon\omega + \varepsilon k) \times \{d\}.$$

When the plate is clamped on $\Gamma_\varepsilon \times] - \frac{t}{2}, \frac{t}{2}[$, with a free boundary on $(\partial(\Omega_\varepsilon^+ \cup \Omega_\varepsilon^-) \setminus \Gamma_\varepsilon) \times] - \frac{t}{2}, \frac{t}{2}[$, and it is subjected to a transverse load, the Kirchhoff–Love equation satisfied by the transverse displacement U_ε of the middle surface $\Omega_\varepsilon^+ \cup \Omega_\varepsilon^-$ is given by (see pages 205–207 in [10])

$$\text{(2.1)} \quad \begin{cases} \dfrac{Et^3}{12(1-\mu^2)} \Delta^2 U_\varepsilon = F_\varepsilon \text{ in } \Omega_\varepsilon^+ \cup \Omega_\varepsilon^-, \\ U_\varepsilon = \partial_n U_\varepsilon = 0 \text{ on } \Gamma_\varepsilon, \\ \Delta U_\varepsilon + (1-\mu)\left(2n_1 n_2 \partial^2_{x_1 x_2} U_\varepsilon - n_2^2 \partial^2_{x_1} U_\varepsilon - n_1^2 \partial^2_{x_2} U_\varepsilon\right) = 0 \\ \qquad\qquad\qquad\qquad \text{on } \partial(\Omega_\varepsilon^+ \cup \Omega_\varepsilon^-) \setminus \Gamma_\varepsilon, \\ \partial_n \Delta U_\varepsilon + (1-\mu)\partial_\tau \left[n_1 n_2 \left(\partial^2_{x_2} U_\varepsilon - \partial^2_{x_1} U_\varepsilon\right) + (n_1^2 - n_2^2)\partial^2_{x_1 x_2} U_\varepsilon\right] = 0 \\ \qquad\qquad\qquad\qquad \text{on } \partial(\Omega_\varepsilon^+ \cup \Omega_\varepsilon^-) \setminus \Gamma_\varepsilon, \end{cases}$$

where $F_\varepsilon \in L^2(\Omega^+ \cup \Omega_\varepsilon^-)$ represents the transverse load, $\Omega^+ =]0,c[\, \times\,]0,d[$ is the "limit domain" of the comb, $n = (n_1, n_2)$ and τ denote the exterior unit normal and the unit tangent to $\Omega_\varepsilon^+ \cup \Omega_\varepsilon^-$, respectively, $\mu \in]0, \frac{1}{2}[$ is the Poisson ratio, and $E > 0$ is the Young modulus of the plate. In the following, M will denote the flexural rigidity modulus of the plate, i.e.,

$$M = \frac{Et^3}{12(1-\mu^2)}. \tag{2.2}$$

We work on the weak formulation of problem (2.1) (see pages 205–207 in [10]):

(2.3)
$$\begin{cases} U_\varepsilon \in H^2(\Omega_\varepsilon^+ \cup \Omega_\varepsilon^-), \;\; U_\varepsilon = \partial_n U_\varepsilon = 0 \text{ on } \Gamma_\varepsilon, \\[2mm] M \displaystyle\int_{\Omega_\varepsilon^+ \cup \Omega_\varepsilon^-} \Delta U_\varepsilon \Delta V + (1-\mu)\left(2\partial^2_{x_1x_2} U_\varepsilon \, \partial^2_{x_1x_2} V - \partial^2_{x_1} U_\varepsilon \, \partial^2_{x_2} V - \partial^2_{x_2} U_\varepsilon \, \partial^2_{x_1} V\right) dx \\[2mm] \qquad\qquad = \displaystyle\int_{\Omega_\varepsilon^+ \cup \Omega_\varepsilon^-} F_\varepsilon V dx \quad \forall V \in H^2(\Omega_\varepsilon \cup \Omega_\varepsilon^-) : V = \partial_n V = 0 \text{ on } \Gamma_\varepsilon. \end{cases}$$

The goal of our paper is to study the asymptotic behavior of problem (2.3) as ε tends to zero. To this aim, by following an idea of Ciarlet and Destuynder (see [8]), problem (2.3) can be reformulated on a domain independent of h_ε by using the maps

$$(x_1, x_2) \in \Omega^- =]0,c[\, \times\,]-1,0[\longrightarrow (x_1, h_\varepsilon x_2) \in \Omega_\varepsilon^-.$$

Namely, by setting

$$\begin{cases} f_\varepsilon(x) = F_\varepsilon(x) & \text{a.e. } x \in \Omega^+, \\ f_\varepsilon(x) = F_\varepsilon(x_1, h_\varepsilon x_2) & \text{a.e. } x \in \Omega^-, \end{cases} \qquad \begin{cases} u_\varepsilon(x) = U_\varepsilon(x) & \text{a.e. } x \in \Omega_\varepsilon^+, \\ u_\varepsilon(x) = U_\varepsilon(x_1, h_\varepsilon x_2) & \text{a.e. } x \in \Omega^-, \end{cases} \tag{2.4}$$

and $\Omega_\varepsilon = \Omega_\varepsilon^+ \cup \Omega^-$, it turns out that u_ε belongs to the following space:

$$\begin{aligned} V_\varepsilon = \big\{ & v \in H^1(\Omega_\varepsilon) \; : \; v^+ \in H^2(\Omega_\varepsilon^+), \; v^- \in H^2(\Omega^-), \\ & v = 0, \; Dv = 0 \text{ on } \Gamma_\varepsilon, \; \partial_{x_1} v^+ = \partial_{x_1} v^- \text{ on } \Sigma \setminus \partial\Omega_\varepsilon, \\ & h_\varepsilon \partial_{x_2} v^+ = \partial_{x_2} v^- \text{ on } \Sigma \setminus \partial\Omega_\varepsilon \big\}, \end{aligned}$$

where $v^+ = v_{|_{\Omega_\varepsilon^+}}$, $v^- = v_{|_{\Omega^-}}$, $\Sigma =]0,c[\, \times \{0\}$ (note that, since $v = 0$ on Γ_ε, the boundary condition $\partial_n v = 0$ on Γ_ε is equivalent to $Dv = 0$ on Γ_ε). Moreover, u_ε is the unique solution of the following problem:

(2.5)
$$\begin{cases} u_\varepsilon \in V_\varepsilon, \\ M \displaystyle\int_{\Omega_\varepsilon^+} \Delta u_\varepsilon \Delta v + (1-\mu)\left(2\partial^2_{x_1x_2} u_\varepsilon\, \partial^2_{x_1x_2} v - \partial^2_{x_1} u_\varepsilon\, \partial^2_{x_2} v - \partial^2_{x_2} u_\varepsilon\, \partial^2_{x_1} v\right) dx \\ +Mh_\varepsilon \displaystyle\int_{\Omega^-} \left(\partial^2_{x_1} u_\varepsilon + \frac{1}{h_\varepsilon^2}\partial^2_{x_2} u_\varepsilon\right)\left(\partial^2_{x_1} v + \frac{1}{h_\varepsilon^2}\partial^2_{x_2} v\right) dx \\ +M(1-\mu)h_\varepsilon \displaystyle\int_{\Omega^-} 2\frac{1}{h_\varepsilon}\partial^2_{x_1x_2} u_\varepsilon\, \frac{1}{h_\varepsilon}\partial^2_{x_1x_2} v - \partial^2_{x_1} u_\varepsilon \frac{1}{h_\varepsilon^2}\partial^2_{x_2} v - \frac{1}{h_\varepsilon^2}\partial^2_{x_2} u_\varepsilon\, \partial^2_{x_1} v\, dx \\ = \displaystyle\int_{\Omega_\varepsilon^+} f_\varepsilon v dx + h_\varepsilon \int_{\Omega^-} f_\varepsilon v dx \quad \forall v \in V_\varepsilon. \end{cases}$$

The study of the asymptotic behavior of problem (2.5) will be performed under the following assumption:

$$\begin{cases} f_{\varepsilon|_{\Omega^+}} \to f \text{ strongly in } L^2(\Omega^+), \\ h_\varepsilon f_{\varepsilon|_{\Omega^-}} \to g \text{ strongly in } L^2(\Omega^-), \end{cases} \tag{2.6}$$

as ε tends to zero. Moreover, the following spaces will be involved:

(2.7)
$$W^2(\Omega^+) = \left\{ v \in L^2(\Omega^+) \ :\ \partial_{x_2} v \in L^2(\Omega^+),\ \partial^2_{x_2} v \in L^2(\Omega^+),\ v = \partial_{x_2} v = 0 \text{ on } \Gamma \right\},$$

where $\Gamma =]0, c[\, \times \{d\}$ and

$$H^2_{per}(]0,1[) = \left\{ v \in H^2(]0,1[) \ :\ v(0) = v(1),\ v'(0) = v'(1) \right\}$$

with v' denoting the first derivative of v. Note that $H^2_{per}(]0,1[)$ is the closure of $C^\infty_{per}([0,1])$ with respect to the $H^2(]0,1[)$-norm, where $C^\infty_{per}([0,1])$ is the set of functions in $C^\infty(\mathbb{R})$ which are 1-periodic.

In the following, $\widetilde{v}$ denotes the zero-extension to Ω^+ of any function v defined in a subset of Ω^+, and

$$|\omega| = b - a. \tag{2.8}$$

We will show that the limit problem depends on

$$\lim_{\varepsilon \to 0} \frac{\varepsilon^4}{h_\varepsilon} = l \in [0, +\infty[\tag{2.9}$$

and $\int_{-1}^0 g(x_1, x_2) dx_2$. Precisely, the following main result will be proved.

Theorem 2.1. *Let u_ε be the unique solution of problem* (2.5). *Let $W^2(\Omega^+)$ be the space defined in* (2.7). *Assume* (2.6) *and* (2.9). *Then,*

$$\begin{gathered} \widetilde{u_\varepsilon} \rightharpoonup |\omega| u \textit{ weakly in } W^2(\Omega^+), \\ \widetilde{\partial^2_{x_1} u_\varepsilon} \rightharpoonup -\mu|\omega|\partial^2_{x_2} u \textit{ weakly in } L^2(\Omega^+), \\ \widetilde{\partial^2_{x_1x_2} u_\varepsilon} \rightharpoonup 0 \textit{ weakly in } L^2(\Omega^+), \end{gathered}$$

as $\varepsilon \to 0$, where u is the unique solution of the following problem:

$$
(2.10) \qquad \begin{cases} u \in W^2(\Omega^+), \\ |\omega| \dfrac{Et^3}{12} \displaystyle\int_{\Omega^+} \partial^2_{x_2} u \, \partial^2_{x_2} v \, dx = |\omega| \int_{\Omega^+} f v \, dx \\ + \displaystyle\int_0^c \left(\int_{-1}^0 g(x_1, x_2) \, dx_2 \right) v(x_1, 0) \, dx_1 \quad \forall v \in W^2(\Omega^+) \end{cases}
$$

with $|\omega|$ defined in (2.8)*, $\mu \in]0, \frac{1}{2}[$ the Poisson ratio, $E > 0$ the Young modulus, t denoting the small thickness of the* 3*D plate (see problem* (2.1)*), and f and g given by* (2.6)*. Moreover,*

$$
\|\partial_{x_2} u_\varepsilon\|_{L^2(\Omega^-)} \leq C h_\varepsilon^{\frac{3}{4}},
$$

$$
\left\|\partial^2_{x_1 x_2} u_\varepsilon\right\|_{L^2(\Omega^-)} \leq C h_\varepsilon^{\frac{1}{2}}, \quad \left\|\partial^2_{x_2} u_\varepsilon\right\|_{L^2(\Omega^-)} \leq C h_\varepsilon^{\frac{3}{2}}
$$

for every ε, where C is a positive constant independent of ε, and

$$
(2.11) \qquad u_\varepsilon \rightharpoonup u_{|\Sigma} + \int_0^1 v_0 \, dy_1 \ \textit{weakly in } L^2(\Omega^-),
$$

as $\varepsilon \to 0$, where $v_0 = 0$ if $l = 0$ in (2.9)*, while if $l \in]0, +\infty[$, $v_0 \, (= v_0(x_1, y_1))$ is the unique solution of the following problem:*

$$
(2.12) \qquad \begin{cases} v_0 \in L^2(]0, c[, H^2_{per}(]0, 1[)), \\ v_0(x_1, y_1) = 0 \ \textit{in }]0, c[\, \times \, \omega, \\ \dfrac{Et^3}{12} \dfrac{1}{l} \displaystyle\int_{]0,c[\, \times \,]0,1[} \partial^2_{y_1} v_0(x_1, y_1) \partial^2_{y_1} \varphi(x_1, y_1) dx_1 dy_1 \\ = \displaystyle\int_{]0,c[\, \times \,]0,1[} \left(\int_{-1}^0 g(x_1, x_2) dx_2 \right) \varphi\,(x_1, y_1) \, dx_1 dy_1 \\ \qquad \forall \varphi \in L^2(]0, c[, H^2_{per}(]0, 1[)) : \varphi\,(x_1, y_1) = 0 \ \textit{in }]0, c[\, \times \, s\omega \end{cases}
$$

with $u_{|\Sigma}$ denoting the function in $L^2(\Omega^-)$ independent of x_2 and equal, on Σ, to the trace of the solution u of (2.10)*. Furthermore, the convergence of the energies holds:*

$$
\begin{aligned}
\lim_{\varepsilon \to 0} \Bigg\{ & \frac{Et^3}{12(1-\mu^2)} \int_{\Omega^+_\varepsilon} |\Delta u_\varepsilon|^2 + 2(1-\mu) \left(|\partial^2_{x_1 x_2} u_\varepsilon|^2 - \partial^2_{x_1} u_\varepsilon \, \partial^2_{x_2} u_\varepsilon \right) dx \\
& + \frac{Et^3}{12(1-\mu^2)} h_\varepsilon \int_{\Omega^-} \Bigg[\left| \partial^2_{x_1} u_\varepsilon + \frac{1}{h^2_\varepsilon} \partial^2_{x_2} u_\varepsilon \right|^2 \\
& + 2(1-\mu) \left(\left| \frac{1}{h_\varepsilon} \partial^2_{x_1 x_2} u_\varepsilon \right|^2 - \frac{1}{h^2_\varepsilon} \partial^2_{x_2} u_\varepsilon \, \partial^2_{x_1} u_\varepsilon \right) \Bigg] dx \Bigg\} \\
& = \frac{Et^3}{12} \left(|\omega| \int_{\Omega^+} |\partial^2_{x_2} u|^2 dx + \frac{1}{l} \int_{]0,c[\, \times \,]0,1[} \left| \partial^2_{y_1} v_0(x_1, y_1) \right|^2 dx_1 dy_1 \right),
\end{aligned}
$$

where $\infty \cdot 0$ means 0.

Proof. Theorem 2.1 is an immediate consequence of Proposition 4.3, Corollary 4.4, and Propositions 5.1 and 5.2 (see sections 4 and 5). For the sake of clarity, we detail the proof of (2.11) and (2.12). If $l = 0$ in (2.9), convergence (4.6), Corollary 4.4, and (ii) of Proposition 4.2 provide that

$$u_\varepsilon \rightharpoonup \int_0^1 u_0(\cdot, y_1)\, dy_1 = u_{|\Sigma} \text{ weakly in } L^2(\Omega^-).$$

If $l > 0$, by setting $v_0(x_1, y_1) = u_0(x_1, y_1) - u_{|\Sigma}(x_1, 0)$ in $]0, c[\, \times \omega$, convergence (4.6), equality (4.10), and (ii) of Proposition 4.2 provide that

$$u_\varepsilon \rightharpoonup \int_0^1 u_0(\cdot, y_1)\, dy_1 = u_{|\Sigma} + \int_0^1 v_0(\cdot, y_1) dy_1 \text{ weakly in } L^2(\Omega^-),$$

and, by virtue of (5.9) (since $\partial^2_{y_1} u_0 = \partial^2_{y_1} v_0$), v_0 is the unique solution of the following problem:

$$\begin{cases} v_0 \in L^2(]0, c[, H^2_{per}(]0, 1[)), \\ v_0(x_1, y_1) = 0 \text{ in }]0, c[\, \times \omega, \\ M\dfrac{1-\mu^2}{l} \displaystyle\int_{]0,c[\, \times\,]0,1[} \partial^2_{y_1} v_0(x_1, y_1) \partial^2_{y_1} \varphi(x_1, y_1) dx_1 dy_1 \\ = \displaystyle\int_{]0,c[\, \times\,]0,1[} \left(\int_{-1}^0 g(x_1, x_2) dx_2 \right) \varphi\,(x_1, y_1)\, dx_1 dy_1 \\ \qquad\qquad \forall \varphi \in L^2(]0, c[, H^2_{per}(]0, 1[)) : \varphi\,(x_1, y_1) = 0 \text{ in }]0, c[\, \times \omega, \end{cases}$$

which coincides with problem (2.12) by virtue of definition (2.2). Note that, in problem (2.12), $v_0 = 0$ if $\int_{-1}^0 g(x_1, x_2) dx_2 = 0$ a.e. in $]0, c[$.

The convergences of the energies are obtained by passing to the limit, as ε tends to zero, in (2.5) with $v = u_\varepsilon$ and by making use of assumption (2.6), the convergences of $\{\widetilde{u_\varepsilon}\}_\varepsilon$, and the equation satisfied by u and v_0. □

Remark 2.2. Problems (2.10) and (2.12) are the weak formulation of the following problems:

$$\begin{cases} \dfrac{Et^3}{12} \dfrac{\partial^4 u}{\partial x_2^4} = f \text{ in } \Omega^+, \\ u = \dfrac{\partial u}{\partial x_2} = 0 \text{ on } \Gamma, \\ \dfrac{\partial^2 u}{\partial x_2^2} = 0 \text{ on } \Sigma, \\ \dfrac{\partial^3 u}{\partial x_2^3} = \dfrac{12}{|\omega| E t^3} \displaystyle\int_{-1}^0 g(x_1, x_2)\, dx_2 \text{ on } \Sigma, \end{cases} \tag{2.13}$$

and for a.e. $x_1 \in]0, c[$

$$
(2.14) \qquad \begin{cases}
\dfrac{Et^3}{12}\dfrac{1}{l}\dfrac{\partial^4 v_0}{\partial y_1^4}(x_1, y_1) = \displaystyle\int_{-1}^{0} g(x_1, x_2)dx_2 \text{ for } y_1 \in]0, a[, \\[2ex]
\dfrac{Et^3}{12}\dfrac{1}{l}\dfrac{\partial^4 v_0}{\partial y_1^4}(x_1, y_1) = \displaystyle\int_{-1}^{0} g(x_1, x_2)dx_2 \text{ for } y_1 \in]b, 1[, \\[2ex]
v_0(x_1, a) = \dfrac{\partial v_0}{\partial y_1}(x_1, a) = v_0(x_1, b) = \dfrac{\partial v_0}{\partial y_1}(x_1, b) = 0, \\[2ex]
v_0(x_1, 0) = v_0(x_1, 1), \\[2ex]
\dfrac{\partial v_0}{\partial y_1}(x_1, 0) = \dfrac{\partial v_0}{\partial y_1}(x_1, 1), \\[2ex]
\dfrac{\partial^2 v_0}{\partial y_1^2}(x_1, 0) = \dfrac{\partial^2 v_0}{\partial y_1^2}(x_1, 1), \\[2ex]
\dfrac{\partial^3 v_0}{\partial y_1^3}(x_1, 0) = \dfrac{\partial^3 v_0}{\partial y_1^3}(x_1, 1), \\[2ex]
v_0(x_1, y_1) = 0 \text{ for } y_1 \in \omega =]a, b[,
\end{cases}
$$

respectively.

The solution of problem (2.14) can be explicitly computed by solving a linear system of 8 equations with 8 unknowns. Then, for a.e. $x_1 \in]0, c[$, it results that

$$
(2.15) \quad v_0(x_1, y_1) = \begin{cases}
\dfrac{l}{2Et^3}(a - y_1)^2(1 - b + y_1)^2 \displaystyle\int_{-1}^{0} g(x_1, x_2)dx_2 \text{ for } y_1 \in [0, a[, \\[2ex]
0 \text{ for } y_1 \in \omega = [a, b], \\[2ex]
\dfrac{l}{2Et^3}(1 + a - y_1)^2(b - y_1)^2 \displaystyle\int_{-1}^{0} g(x_1, x_2)dx_2 \text{ for } y_1 \in]b, 1],
\end{cases}
$$

and consequently

$$
(2.16) \quad \begin{aligned}
&\int_0^1 v_0(x_1, y_1)\, dy_1 \\
&= \frac{l}{2Et^3}\left\{ \frac{1}{30} + \frac{a}{6} + \frac{a^2}{3} + \frac{a^3}{3} + \frac{a^4}{6} + \frac{a^5}{30} - \frac{b}{6} - \frac{2ab}{3} - a^2 b - \frac{2a^3 b}{3} - \frac{a^4 b}{6} \right. \\
&\quad \left. + \frac{b^2}{3} + ab^2 + a^2 b^2 + \frac{a^3 b^2}{3} - \frac{b^3}{3} - \frac{2ab^3}{3} - \frac{a^2 b^3}{3} + \frac{b^4}{6} + \frac{ab^4}{6} - \frac{b^5}{30} \right\} \int_{-1}^{0} g(x_1, x_2)dx_2.
\end{aligned}
$$

In the limit domain Ω^+ of the comb, we obtain a continuum bending model of rods subjected to a force f, clamped on the upper side Γ, and subjected on the lower side Σ to applied forces but without applied momentum. The forces on Σ depend on the limit density g of the transverse loads on the thin strip Ω_ε^- and on the measure of the cross section ω of the reference tooth. The force f depends on the limit of the transverse loads on the teeth.

The limit solution meets a Dirichlet transmission condition between Ω^+ and the rescaled strip Ω^- if $h_\varepsilon \gg \varepsilon^4$, or if $h_\varepsilon \simeq \varepsilon^4$ and $\int_{-1}^0 g(x_1,x_2)dx_2 = 0$ a.e. in $]0,c[$. However, if the strip is thin enough and the transverse loads on the thin strip are strong enough, i.e., $h_\varepsilon \simeq \varepsilon^4$ and $\int_{-1}^0 g(x_1,x_2)dx_2 \neq 0$ in a subset of $]0,c[$ with positive measure, a discontinuity in the Dirichlet transmission condition appears. Roughly speaking, this means that microscopic oscillations of the displacement in the strip, between the basis of the teeth of Ω_ε^+, produce a limit average field different from that on the base of the teeth. We point out that (2.15) provides that $\int_0^1 v_0(x_1,y_1)\,dy_1 \neq 0$ in a subset of $]0,c[$ with positive measure if and only if $\int_{-1}^0 g(x_1,x_2)dx_2 \neq 0$ in the same subset. Consequently, by taking into account the definition of g in (2.6), for obtaining the additional term in (2.11) when $h_\varepsilon \simeq \varepsilon^4$, it is necessary that the transverse loads in the thin strip Ω_ε^- are strong enough to avoid that $\lim_{\varepsilon\to 0}(h_\varepsilon \int_{\Omega_\varepsilon^-} |F_\varepsilon|^2 dx) = 0$. For instance, if $F_\varepsilon = \varepsilon^{-4\alpha}$ in Ω_ε^-, the additional term in the displacement of the strip intervenes when $\alpha = 1$ and it is given by formula (2.16) with $g = 1$; it does not appear when $\alpha < 1$.

As regards the Laplacian, in [6] the authors proved that $h_\varepsilon \simeq \varepsilon^2$ is a critical size for the thickness of the thin strip. In particular, if $h_\varepsilon \ll \varepsilon^2$, they gave an example in which $g = 0$ and the sequence of the solutions is not even bounded in $L^1(\Omega^-)$. In our paper, as regards the case $h_\varepsilon \ll \varepsilon^4$, we think that a deterministic limit model may hardly be expected, but we have no example to validate it.

Remark 2.3. Let us give a few comments about the boundary condition on $\partial(\Omega_\varepsilon^+ \cup \Omega_\varepsilon^-)$. Indeed, it is physically reasonable to assume that the plate is clamped on a part of its boundary. An alternative to the condition $U_\varepsilon = \partial_n U_\varepsilon = 0$ on Γ_ε could be to impose $U_\varepsilon = \partial_n U_\varepsilon = 0$ on $]0,c[\, \times \{-h_\varepsilon\}$ (i.e., on the lower lateral surface of the 3D plate modeled by the 2D plate Ω_ε^-). A similar and easier analysis than that developed below shows that, in this case, the limit problem (2.13) (also when $\lim_{\varepsilon\to 0}\frac{\varepsilon^4}{h_\varepsilon} = +\infty$) is replaced by the following one:

$$\begin{cases} \dfrac{Et^3}{12}\dfrac{\partial^4 u}{\partial x_2^4} = f \text{ in } \Omega^+, \\[2ex] \dfrac{\partial^2 u}{\partial x_2^2} = \dfrac{\partial^3 u}{\partial x_2^3} = 0 \text{ on } \Gamma, \\[2ex] u = \dfrac{\partial u}{\partial x_2} = 0 \text{ on } \Sigma. \end{cases}$$

Moreover, it results that (see Remark 3.3)

$$u_\varepsilon \to 0 \text{ strongly in } H^1(\Omega^-),$$

and in this case there are no oscillations in the strip.

Concerning the original problem (2.3), the result below immediately follows from Theorem 2.1.

COROLLARY 2.4. *Let U_ε be the solution of problem* (2.3) *under the assumptions of Theorem* 2.1 *with $\{f_\varepsilon\}_\varepsilon$ defined by* (2.4).

Then, it results that

$$
\begin{gathered}
\widetilde{U_\varepsilon} \rightharpoonup |\omega| u \text{ weakly in } W^2(\Omega^+),\\
\widetilde{\partial^2_{x_1} U_\varepsilon} \rightharpoonup -\mu|\omega|\partial^2_{x_2} u \text{ weakly in } L^2(\Omega^+),\\
\widetilde{\partial^2_{x_1x_2} U_\varepsilon} \rightharpoonup 0 \text{ weakly in } L^2(\Omega^+),\\
\lim_{\varepsilon\to 0} \frac{1}{|\Omega^-_\varepsilon|}\int_{\Omega^-_\varepsilon} U_\varepsilon\, dx = \frac{1}{c}\int_0^c \left(u_{|\Sigma} + \int_0^1 v_0 dy_1 \right) dx_1,
\end{gathered}
$$

$$
\begin{aligned}
\lim_{\varepsilon\to 0} \frac{1}{|\Omega^-_\varepsilon|^\alpha}\int_{\Omega^-_\varepsilon} \partial_{x_2} U_\varepsilon dx &= \lim_{\varepsilon\to 0} \frac{1}{|\Omega^-_\varepsilon|^\beta}\int_{\Omega^-_\varepsilon} \partial^2_{x_1x_2} U_\varepsilon dx\\
&= \lim_{\varepsilon\to 0} \frac{1}{|\Omega^-_\varepsilon|^\beta}\int_{\Omega^-_\varepsilon} \partial^2_{x_2} U_\varepsilon dx = 0 \quad \forall\alpha < \frac{3}{4}, \forall\beta < \frac{1}{2},
\end{aligned}
$$

where u is the weak solution of problem (2.13)*, $u_{|\Sigma}$ denotes the trace of u on Σ, and $v_0 = 0$ if $l = 0$ in* (2.9)*, while if $l \in]0,+\infty[$, $v_0\,(= v_0(x_1, y_1))$ is the solution of problem* (2.14)*. Furthermore, the energies converge in the sense that*

$$
\begin{aligned}
&\lim_{\varepsilon\to 0}\left(\frac{Et^3}{12(1-\mu^2)} \int_{\Omega^+_\varepsilon \bigcup \Omega^-_\varepsilon} |\Delta U_\varepsilon|^2 + 2(1-\mu)\left(|\partial^2_{x_1x_2}U_\varepsilon|^2 - \partial^2_{x_1}U_\varepsilon\, \partial^2_{x_2}U_\varepsilon\right) dx \right)\\
&\quad = \frac{Et^3}{12}\left(|\omega| \int_{\Omega^+} |\partial^2_{x_2} u|^2 dx + \frac{1}{l}\int_{]0,c[\ \times\ ]0,1[} \left|\partial^2_{y_1} v_0(x_1,y_1)\right|^2 dx_1 dy_1 \right),
\end{aligned}
$$

where $\infty \cdot 0$ means 0.

3. A priori norm-estimates. Define

$$
D^2(v) = \begin{pmatrix} \partial^2_{x_1} v & \partial^2_{x_1x_2} v \\ \partial^2_{x_1x_2} v & \partial^2_{x_2} v \end{pmatrix}, \qquad v \in H^2(\Omega^+_\varepsilon);
$$

$$
D^2_\varepsilon(v) = \begin{pmatrix} \partial^2_{x_1} v & \dfrac{1}{h_\varepsilon}\partial^2_{x_1x_2} v \\ \dfrac{1}{h_\varepsilon}\partial^2_{x_1x_2} v & \dfrac{1}{h^2_\varepsilon}\partial^2_{x_2} v \end{pmatrix}, \qquad v \in H^2(\Omega^-),
$$

for every ε. This section is devoted to proving the following a priori norm-estimates.

PROPOSITION 3.1. *Let u_ε be the solution of problem* (2.5)*. Assume* (2.9) *and* (2.6)*. Then, there exists a positive constant C, independent of ε, such that*

$$
\|u_\varepsilon\|_{H^2(\Omega^+_\varepsilon)} \le C, \tag{3.1}
$$

$$
\left\| h_\varepsilon^{\frac{1}{2}} D^2_\varepsilon(u_\varepsilon) \right\|_{(L^2(\Omega^-))^4} \le C \tag{3.2}
$$

for every ε.

To prove Proposition 3.1, the following result is required.

LEMMA 3.2. *There exists a positive constant C, independent of ε, such that*

$$\|v\|^2_{L^2(\Omega^-)} \le C\left(\|v\|^2_{L^2(\Sigma\setminus\partial\Omega_\varepsilon)} + \varepsilon^2\|\partial_{x_1}v\|^2_{L^2(\Omega^-)} + \|\partial_{x_2}v\|^2_{L^2(\Omega^-)}\right) \quad \forall v \in H^1(\Omega^-); \tag{3.3}$$

$$\|v\|^2_{L^2(\Sigma\setminus\partial\Omega_\varepsilon)} \le C\left(\|v\|^2_{L^2(\Omega^+_\varepsilon)} + \|\partial_{x_2}v\|^2_{L^2(\Omega^+_\varepsilon)}\right) \quad \forall v \in H^1(\Omega^+_\varepsilon); \tag{3.4}$$

$$\|v\|^2_{H^2(\Omega^+_\varepsilon)} \le C\left\|D^2v\right\|^2_{\left(L^2(\Omega^+_\varepsilon)\right)^4} \quad \forall v \in \left\{v \in H^2(\Omega^+_\varepsilon)\ :\ v=0,\ Dv=0\ on\ \Gamma_\varepsilon\right\} \tag{3.5}$$

for every ε.

Proof. The proof of inequality (3.3) is performed in the proof of Proposition 3.3 in [3]. Standard arguments using Poincaré inequality and Sobolev trace theorem lead to inequalities (3.4) and (3.5). Obviously, boundary conditions $v = 0$ and $Dv = 0$ on Γ_ε intervene for obtaining estimate (3.5). In the case of other boundary conditions, see Remark 3.3. ∎

Proof of Proposition 3.1. In the following, C denotes any positive constant independent of ε.

By choosing $v = u_\varepsilon$ in (2.5), it results that

$$\begin{aligned}
&M\int_{\Omega^+_\varepsilon} \left|\partial^2_{x_1}u_\varepsilon\right|^2 + \left|\partial^2_{x_2}u_\varepsilon\right|^2 + 2\mu\partial^2_{x_1}u_\varepsilon\,\partial^2_{x_2}u_\varepsilon + 2(1-\mu)\left|\partial^2_{x_1x_2}u_\varepsilon\right|^2 dx\\
&+Mh_\varepsilon\int_{\Omega^-} \left|\partial^2_{x_1}u_\varepsilon\right|^2 + \left|\frac{1}{h^2_\varepsilon}\partial^2_{x_2}u_\varepsilon\right|^2 + 2\mu\partial^2_{x_1}u_\varepsilon\,\frac{1}{h^2_\varepsilon}\partial^2_{x_2}u_\varepsilon + 2(1-\mu)\left|\frac{1}{h_\varepsilon}\partial^2_{x_1x_2}u_\varepsilon\right|^2 dx\\
&= \int_{\Omega^+_\varepsilon} f_\varepsilon u_\varepsilon dx + h_\varepsilon\int_{\Omega^-} f_\varepsilon u_\varepsilon dx
\end{aligned}$$

for every ε. Consequently, by taking into account that $-\alpha^2-\beta^2 \le 2\alpha\beta$, for $\alpha,\beta\in\mathbb{R}$, and by making use of assumption (2.6), one obtains that

$$\begin{aligned}
&\int_{\Omega^+_\varepsilon} \left|\partial^2_{x_1}u_\varepsilon\right|^2 + \left|\partial^2_{x_2}u_\varepsilon\right|^2 - \mu\left|\partial^2_{x_1}u_\varepsilon\right|^2 - \mu\left|\partial^2_{x_2}u_\varepsilon\right|^2 + 2(1-\mu)\left|\partial^2_{x_1x_2}u_\varepsilon\right|^2 dx\\
&+h_\varepsilon\int_{\Omega^-} \left|\partial^2_{x_1}u_\varepsilon\right|^2 + \left|\frac{1}{h^2_\varepsilon}\partial^2_{x_2}u_\varepsilon\right|^2 - \mu\left|\partial^2_{x_1}u_\varepsilon\right|^2 - \mu\left|\frac{1}{h^2_\varepsilon}\partial^2_{x_2}u_\varepsilon\right|^2 + 2(1-\mu)\left|\frac{1}{h_\varepsilon}\partial^2_{x_1x_2}u_\varepsilon\right|^2 dx\\
&\le C\left(\|u_\varepsilon\|_{L^2(\Omega^+_\varepsilon)} + \|u_\varepsilon\|_{L^2(\Omega^-)}\right)
\end{aligned}$$

for every ε, that is,

$$\left\|D^2u_\varepsilon\right\|^2_{\left(L^2(\Omega^+_\varepsilon)\right)^4} + h_\varepsilon\left\|D^2_\varepsilon u_\varepsilon\right\|^2_{(L^2(\Omega^-))^4} \le C\left(\|u_\varepsilon\|_{L^2(\Omega^+_\varepsilon)} + \|u_\varepsilon\|_{L^2(\Omega^-)}\right) \tag{3.6}$$

for every ε.

On the other hand, by applying (3.3) three times and by recalling that $\partial_{x_2} u_\varepsilon^- = h_\varepsilon \partial_{x_2} u_\varepsilon^+$ on $\Sigma \setminus \partial\Omega_\varepsilon$, one obtains that

$$
\begin{aligned}
&\|u_\varepsilon\|^2_{L^2(\Omega^-)} \leq C \left(\|u_\varepsilon\|^2_{L^2(\Sigma\setminus\partial\Omega_\varepsilon)} + \varepsilon^2 \|\partial_{x_1} u_\varepsilon\|^2_{L^2(\Omega^-)} + \|\partial_{x_2} u_\varepsilon\|^2_{L^2(\Omega^-)} \right) \\
&\leq C \|u_\varepsilon\|^2_{L^2(\Sigma\setminus\partial\Omega_\varepsilon)} \\
&\quad + C\varepsilon^2 \left(\|\partial_{x_1} u_\varepsilon\|^2_{L^2(\Sigma\setminus\partial\Omega_\varepsilon)} + \varepsilon^2 \left\|\partial^2_{x_1} u_\varepsilon\right\|^2_{L^2(\Omega^-)} + \left\|\partial^2_{x_1x_2} u_\varepsilon\right\|^2_{L^2(\Omega^-)} \right) \\
&\quad + C \left(\left\|\partial_{x_2} u_\varepsilon^-\right\|^2_{L^2(\Sigma\setminus\partial\Omega_\varepsilon)} + \varepsilon^2 \left\|\partial^2_{x_1x_2} u_\varepsilon\right\|^2_{L^2(\Omega^-)} + \left\|\partial^2_{x_2} u_\varepsilon\right\|^2_{L^2(\Omega^-)} \right) \\
&= C \left(\|u_\varepsilon\|^2_{L^2(\Sigma\setminus\partial\Omega_\varepsilon)} + \varepsilon^2 \|\partial_{x_1} u_\varepsilon\|^2_{L^2(\Sigma\setminus\partial\Omega_\varepsilon)} + \left\|h_\varepsilon \partial_{x_2} u_\varepsilon^+\right\|^2_{L^2(\Sigma\setminus\partial\Omega_\varepsilon)} \right) \\
&\quad + C \left(\varepsilon^4 \left\|\partial^2_{x_1} u_\varepsilon\right\|^2_{L^2(\Omega^-)} + \varepsilon^2 \left\|\partial^2_{x_1x_2} u_\varepsilon\right\|^2_{L^2(\Omega^-)} + \left\|\partial^2_{x_2} u_\varepsilon\right\|^2_{L^2(\Omega^-)} \right)
\end{aligned}
$$

for every ε, from which, by taking into account (3.4) and that $\varepsilon < 1$ and $h_\varepsilon < 1$, it follows that

$$
\begin{aligned}
&\|u_\varepsilon\|^2_{L^2(\Omega^-)} \\
&\leq C \left(\|u_\varepsilon\|^2_{H^2(\Omega_\varepsilon^+)} + \varepsilon^4 \left\|\partial^2_{x_1} u_\varepsilon\right\|^2_{L^2(\Omega^-)} + \left\|\partial^2_{x_1x_2} u_\varepsilon\right\|^2_{L^2(\Omega^-)} + \left\|\partial^2_{x_2} u_\varepsilon\right\|^2_{L^2(\Omega^-)} \right) \\
&= C \Bigg[\|u_\varepsilon\|^2_{H^2(\Omega_\varepsilon^+)} \\
&\quad + h_\varepsilon \left(\frac{\varepsilon^4}{h_\varepsilon} \left\|\partial^2_{x_1} u_\varepsilon\right\|^2_{L^2(\Omega^-)} + h_\varepsilon \left\| \frac{1}{h_\varepsilon} \partial^2_{x_1x_2} u_\varepsilon \right\|^2_{L^2(\Omega^-)} + h_\varepsilon^3 \left\| \frac{1}{h_\varepsilon^2} \partial^2_{x_2} u_\varepsilon \right\|^2_{L^2(\Omega^-)} \right) \Bigg] \\
&\leq C \Bigg[\|u_\varepsilon\|^2_{H^2(\Omega_\varepsilon^+)} \\
&\quad + h_\varepsilon \left(\frac{\varepsilon^4}{h_\varepsilon} \left\|\partial^2_{x_1} u_\varepsilon\right\|^2_{L^2(\Omega^-)} + \left\| \frac{1}{h_\varepsilon} \partial^2_{x_1x_2} u_\varepsilon \right\|^2_{L^2(\Omega^-)} + \left\| \frac{1}{h_\varepsilon^2} \partial^2_{x_2} u_\varepsilon \right\|^2_{L^2(\Omega^-)} \right) \Bigg]
\end{aligned} \tag{3.7}
$$

for every ε.

By combining (3.6) with (3.7), making use of (3.5), and assuming that the limit (2.9) is finite, one has that

$$
\|u_\varepsilon\|^2_{H^2(\Omega_\varepsilon^+)} + h_\varepsilon \left\|D^2_\varepsilon u_\varepsilon\right\|^2_{(L^2(\Omega^-))^4} \leq C \left(\|u_\varepsilon\|^2_{H^2(\Omega_\varepsilon^+)} + h_\varepsilon \left\|D^2_\varepsilon u_\varepsilon\right\|^2_{(L^2(\Omega^-))^4} \right)^{\frac{1}{2}}
$$

for every ε, which provides estimates (3.1) and (3.2). $\square$

Remark 3.3. Let us remark that in the case of the alternative boundary conditions mentioned in Remark 2.3, deriving of estimates (3.1) and (3.2) is easier (and they hold true also when $\lim_{\varepsilon\to 0} \frac{\varepsilon^4}{h_\varepsilon} = +\infty$). Indeed, they follow easily from (3.6) by using

$\partial_{x_2} u_\varepsilon^- = h_\varepsilon \partial_{x_2} u_\varepsilon^+$ on $\Sigma \setminus \partial\Omega_\varepsilon$ and the Poincaré inequality in Ω^- (which is licit since one has that $u_\varepsilon = \partial_{x_2} u_\varepsilon = 0$ on $]0, c[\, \times \{-1\}$). We point out that now inequality (3.2) provides that $u_\varepsilon \to 0$ strongly in $H^1(\Omega^-)$.

Corollary 3.4. *Let u_ε be the solution of problem* (2.5). *Assume* (2.9) *and* (2.6). *Then, there exists a positive constant C, independent of ε, such that*

$$\left\|\varepsilon^2 \partial^2_{x_1} u_\varepsilon\right\|_{L^2(\Omega^-)} \leq C, \tag{3.8}$$

$$\left\|\frac{1}{h_\varepsilon^{\frac{1}{2}}} \partial^2_{x_1 x_2} u_\varepsilon\right\|_{L^2(\Omega^-)} \leq C, \tag{3.9}$$

$$\left\|\frac{1}{h_\varepsilon^{\frac{3}{2}}} \partial^2_{x_2} u_\varepsilon\right\|_{L^2(\Omega^-)} \leq C, \tag{3.10}$$

$$\left\|\frac{1}{h_\varepsilon^{\frac{3}{4}}} \partial_{x_2} u_\varepsilon\right\|_{L^2(\Omega^-)} \leq C, \tag{3.11}$$

$$\left\|\varepsilon \partial_{x_1} u_\varepsilon\right\|_{L^2(\Omega^-)} \leq C, \tag{3.12}$$

$$\left\|u_\varepsilon\right\|_{L^2(\Omega^-)} \leq C \tag{3.13}$$

for every ε.

Proof. Estimates (3.8), (3.9), and (3.10) follow immediately from estimate (3.2). By combining estimate (3.2) with inequalities (3.3) and (3.4) and by recalling that $\partial_{x_2} u_\varepsilon^- = h_\varepsilon \partial_{x_2} u_\varepsilon^+$ on $\Sigma \setminus \partial\Omega_\varepsilon$, it is easy to obtain (3.11), (3.12), and (3.13). ∎

4. Convergence results. For convenience of the reader, we recall the definition and the main properties of the two-scale convergence. We refer the reader to [1] and [18] for the proofs.

Definition 4.1. *Let $\mathcal{O} \subset \mathbb{R}^N$ and $Y =]0,1[^N$. A sequence $\{v_\varepsilon\}_\varepsilon \subset L^2(\mathcal{O})$ is said to two-scale converge to a limit $v \in L^2(\mathcal{O} \times Y)$ if, for any function ϕ in $C_0^\infty\left(\mathcal{O}, C^\infty_{per}(Y)\right)$, it results that*

$$\lim_{\varepsilon \to 0} \int_{\mathcal{O}} v_\varepsilon(x) \phi\left(x, \frac{x}{\varepsilon}\right) dx = \int_{\mathcal{O} \times Y} v(x,y)\phi(x,y)\, dxdy.$$

Proposition 4.2. *Let $\mathcal{O} \subset \mathbb{R}^N$ and $Y =]0,1[^N$.*

(i) *Let $\{v_\varepsilon\}_\varepsilon \subset L^2(\mathcal{O})$ be a sequence converging to v strongly in $L^2(\mathcal{O})$. Then, $\{v_\varepsilon\}_\varepsilon$ two-scale converges to the same limit v.*

(ii) *Let $\{v_\varepsilon\}_\varepsilon \subset L^2(\mathcal{O})$ be a bounded sequence, two-scale converging to $v \in L^2(\mathcal{O} \times Y)$. Then, $\{v_\varepsilon\}$ converges to $\int_Y v(\cdot, y) dy$ weakly in $L^2(\mathcal{O})$.*

(iii) *Let $\{v_\varepsilon\}_\varepsilon$ be a bounded sequence in $L^2(\mathcal{O})$. Then, there exist a subsequence of $\{\varepsilon\}$, still denoted by $\{\varepsilon\}$, and a function $v \in L^2(\mathcal{O} \times Y)$ such that $\{v_\varepsilon\}_\varepsilon$ two-scale converges to v.*

(iv) *Let $\{v_\varepsilon\}_\varepsilon \subset W^{1,2}(\mathcal{O})$ be a sequence such that $\{v_\varepsilon\}_\varepsilon$ and $\{\varepsilon D v_\varepsilon\}_\varepsilon$ are bounded in $L^2(\mathcal{O})$ and $(L^2(\mathcal{O}))^N$, respectively. Then, there exist a subsequence of $\{\varepsilon\}$, still* *denoted by* $\{\varepsilon\}$, *and a function* $v \in L^2(\mathcal{O}, W^{1,2}_{per}(Y))$ *such that* $\{v_\varepsilon\}_\varepsilon$ *and* $\{\varepsilon D v_\varepsilon\}_\varepsilon$ *two-scale converge to* v *and* $D_y v$, *respectively.*

The a priori norm-estimates of the solution u_ε of problem (2.5), obtained in section 3, provide the following convergence result.

PROPOSITION 4.3. *Let* u_ε *be the solution of problem* (2.5). *Let* $W^2(\Omega^+)$ *be the space defined in* (2.7). *Assume* (2.6) *and* (2.9). *Then,*

$$\|\partial_{x_2} u_\varepsilon\|_{L^2(\Omega^-)} \leq C h_\varepsilon^{\frac{3}{4}}, \tag{4.1}$$

$$\left\|\partial^2_{x_1 x_2} u_\varepsilon\right\|_{L^2(\Omega^-)} \leq C h_\varepsilon^{\frac{1}{2}}, \quad \left\|\partial^2_{x_2} u_\varepsilon\right\|_{L^2(\Omega^-)} \leq C h_\varepsilon^{\frac{3}{2}} \tag{4.2}$$

for every ε, *where* C *is a positive constant independent of* ε. *Moreover, there exist a subsequence of* $\{\varepsilon\}$, *still denoted by* $\{\varepsilon\}$, $u \in W^2(\Omega^+)$, $\eta, \zeta \in L^2(\Omega^+)$, $u_0(= u_0(x_1, y_1)) \in L^2(]0, c[, H^2_{per}(]0,1[))$, *and* $\xi(= \xi((x_1,x_2),(y_1,y_2))) \in L^2(\Omega^- \times]0,1[^2)$ *such that*

$$\widetilde{u_\varepsilon} \rightharpoonup |\omega| u \text{ weakly in } W^2(\Omega^+), \tag{4.3}$$

$$\widetilde{\partial^2_{x_1} u_\varepsilon} \rightharpoonup \eta \text{ weakly in } L^2(\Omega^+), \tag{4.4}$$

$$\widetilde{\partial^2_{x_1 x_2} u_\varepsilon} \rightharpoonup \zeta \text{ weakly in } L^2(\Omega^+), \tag{4.5}$$

$$\{u_\varepsilon^-\}_\varepsilon \text{ two-scale converges to } u_0, \tag{4.6}$$

$$\{\varepsilon \partial_{x_1} u_\varepsilon^-\}_\varepsilon \text{ two-scale converges to } \partial_{y_1} u_0, \tag{4.7}$$

$$\{\varepsilon^2 \partial^2_{x_1} u_\varepsilon^-\}_\varepsilon \text{ two-scale converges to } \partial^2_{y_1} u_0, \tag{4.8}$$

$$\left\{\frac{1}{h_\varepsilon^{\frac{3}{2}}} \partial^2_{x_2} u_\varepsilon^-\right\}_\varepsilon \text{ two-scale converges to } \xi, \tag{4.9}$$

as $\varepsilon \to 0$, *and*

$$u_0(x_1, y_1) = u_{|\Sigma}(x_1, 0) \text{ in }]0, c[\, \times \omega. \tag{4.10}$$

Proof. Estimates (4.1) and (4.2) follow from estimates (3.11), (3.9), and (3.10). Convergences (4.3), (4.4), and (4.5) are a consequence of estimate (3.1). Estimates (3.13), (3.12), (3.8), (4.1), and (4.2) provide convergences (4.6), (4.7), and (4.8) with $u_0 \in L^2(\Omega^-, H^2_{per}(]0,1[))$. Moreover, u_0 is independent of x_2, too. In fact, it results that

$$0 = \lim_{\varepsilon \to 0} \int_{\Omega^-} \partial_{x_2} u_\varepsilon \varphi\left(x, \frac{x_1}{\varepsilon}\right) dx = - \lim_{\varepsilon \to 0} \int_{\Omega^-} u_\varepsilon \partial_{x_2} \varphi\left(x, \frac{x_1}{\varepsilon}\right) dx$$

$$= - \int_{\Omega^- \times]0,1[} u_0(x, y_1) \partial_{x_2} \varphi(x, y_1)\, dx dy_1 \quad \forall \varphi \in C_0^\infty\left(\Omega^- \times\,]0,1[\right).$$

Convergence (4.9) springs from estimate (3.10).

Finally, statement (4.10) can be obtained by arguing as in the proof of Proposition 6.4 in [6]. More precisely, let χ_ω be the $]0,1[$-periodic extension to $\mathbb{R}$ of the characteristic function of $\omega =]a,b[$ with respect to $]0,1[$. Then, by proceeding as in the proof of (6.7) in [6], i.e., by using mainly (4.1) and (4.6), one obtains that

$$\left\{u_\varepsilon^-(\cdot,0)\chi_\omega\left(\frac{\cdot}{\varepsilon}\right)\right\}_\varepsilon \text{ two-scale converges to } u_0\chi_\omega, \tag{4.11}$$

as $\varepsilon \to 0$. On the other hand, by proceeding as in the proof of (6.13) in [6], i.e., by using mainly (3.1), one proves that

$$\{\widetilde{u_\varepsilon^+}(\cdot,0)\}_\varepsilon \text{ two-scale converges to } u(\cdot,0)\chi_\omega, \tag{4.12}$$

as $\varepsilon \to 0$. Finally, in order to obtain (4.10) it is enough to pass to the two-scale limit in

$$u_\varepsilon^-(x_1,0)\chi_\omega\left(\frac{x_1}{\varepsilon}\right) = \widetilde{u_\varepsilon^+}(x_1,0) \text{ for a.e. } x_1 \in]0,c[,$$

as $\varepsilon \to 0$, and to make use of (4.11) and (4.12). $\square$

If $l = 0$ in (2.9), then u_0 can be completely identified in terms of u.

COROLLARY 4.4. *Let u_ε be the solution of problem* (2.5). *Assume* (2.9)*, with $l = 0$, and* (2.6). *Let $u \in W^2(\Omega^+)$ and $u_0 \in L^2(]0,c[,H^2_{per}(]0,1[))$ be satisfying Proposition* 4.3. *Then,*

$$u_0(x_1,y_1) = u_{|\Sigma}(x_1,0) \textit{ in }]0,c[\times]0,1[. \tag{4.13}$$

Proof. Assumption (2.9) with $l = 0$ and estimate (3.2) ensure that

$$\varepsilon^2\partial^2_{x_1}u_\varepsilon \to 0 \text{ strongly in } L^2(\Omega^-),$$

as $\varepsilon \to 0$. Consequently, by virtue of (4.8), it results that

$$\partial^2_{y_1}u_0 = 0 \text{ in }]0,c[\times]0,1[. \tag{4.14}$$

By combining (4.10) with (4.14), one obtains (4.13). $\square$

5. The limit problem. The following proposition is devoted to identify the limit problem in Ω^+.

PROPOSITION 5.1. *Let u_ε be the solution of problem* (2.5). *Assume* (2.9) *and* (2.6). *Let $u \in W^2(\Omega^+)$ and η, $\zeta \in L^2(\Omega^+)$ satisfy Proposition* 4.3. *Then,*

$$\eta = -\mu|\omega|\partial^2_{x_2}u \textit{ a.e. in } \Omega^+, \tag{5.1}$$

$$\zeta = 0 \textit{ a.e. in } \Omega^+, \tag{5.2}$$

and $u \in W^2(\Omega^+)$ is the unique solution of

$$\begin{aligned} &M|\omega|(1-\mu^2)\int_{\Omega^+}\partial^2_{x_2}u\partial^2_{x_2}v\,dx \\ &= |\omega|\int_{\Omega^+}fv\,dx + \int_0^c\left(\int_{-1}^0 g(x_1,x_2)\,dx_2\right)v(x_1,0)\,dx_1 \quad \forall v \in W^2(\Omega^+), \end{aligned} \tag{5.3}$$

where $\mu \in]0, \frac{1}{2}[$ is the Poisson ratio, $M > 0$ represents the flexural rigidity modulus of the plate (see problem (2.5)), and f, $g \in L^2(\Omega^-)$ are given by (2.6).

Proof. At first, claim (5.1) will be proved. To this aim, choose $v(x_1, x_2) = \varepsilon^2 \psi_1(\frac{x_1}{\varepsilon}) \varphi(x_1, x_2)$ as test function in (2.5), where ψ_1 is the 1-periodic function defined by $\psi_1(y_1) = \frac{1}{2} y_1(y_1 - 1)$ in $[0, 1]$ and $\varphi \in C_0^\infty(\Omega^+)$ (point out that $v \in C^\infty(\overline{\Omega_\varepsilon^+}) \bigcap C_0(\Omega^+) \subset V_\varepsilon$). Then, it results that

$$
\begin{aligned}
&M \int_{\Omega_\varepsilon^+} \Delta u_\varepsilon \left(\varphi + 2\varepsilon \psi_1' \left(\frac{x_1}{\varepsilon}\right) \partial_{x_1} \varphi + \varepsilon^2 \psi_1 \left(\frac{x_1}{\varepsilon}\right) \partial_{x_1}^2 \varphi + \varepsilon^2 \psi_1 \left(\frac{x_1}{\varepsilon}\right) \partial_{x_2}^2 \varphi \right) dx \\
&+M(1-\mu) \int_{\Omega_\varepsilon^+} 2\partial_{x_1 x_2}^2 u_\varepsilon \left(\varepsilon \psi_1' \left(\frac{x_1}{\varepsilon}\right) \partial_{x_2} \varphi + \varepsilon^2 \psi_1 \left(\frac{x_1}{\varepsilon}\right) \partial_{x_1 x_2}^2 \varphi \right) dx \\
&-M(1-\mu) \int_{\Omega_\varepsilon^+} \partial_{x_1}^2 u_\varepsilon \varepsilon^2 \psi_1 \left(\frac{x_1}{\varepsilon}\right) \partial_{x_2}^2 \varphi \, dx \\
&-M(1-\mu) \int_{\Omega_\varepsilon^+} \partial_{x_2}^2 u_\varepsilon \left(\varphi + 2\varepsilon \psi_1' \left(\frac{x_1}{\varepsilon}\right) \partial_{x_1} \varphi + \varepsilon^2 \psi_1 \left(\frac{x_1}{\varepsilon}\right) \partial_{x_1}^2 \varphi \right) dx \\
&= \int_{\Omega_\varepsilon^+} f_\varepsilon \varepsilon^2 \psi_1 \left(\frac{x_1}{\varepsilon}\right) \varphi \, dx
\end{aligned} \tag{5.4}
$$

for every ε. By passing to the limit, as $\varepsilon \to 0$, in (5.4) and by making use of (4.3), (4.4), (4.5), and (2.6), it is easy to see that

$$
\int_{\Omega^+} \eta \varphi + \mu |\omega| \partial_{x_2}^2 u \varphi \, dx = 0 \quad \forall \varphi \in C_0^\infty(\Omega^+),
$$

which provides (5.1).

In the next step, it will be proved that the function $\zeta \in L^2(\Omega^+)$ is independent of x_2. To this aim, choose $v(x_1, x_2) = \varepsilon \psi_2(\frac{x_1}{\varepsilon}) \varphi(x_1, x_2)$ as test function in (2.5), where ψ_2 is the 1-periodic function defined by $\psi_2(y_1) = -y_1 + \frac{1}{2}$ in $[0, 1[$ and $\varphi \in C_0^\infty(\Omega^+)$ (point out that $v \in C^\infty(\overline{\Omega_\varepsilon^+})$ and supp $v \subset \Omega^+$, consequently $v \in V_\varepsilon$). Then, it results that

$$
\begin{aligned}
&M \int_{\Omega_\varepsilon^+} \Delta u_\varepsilon \left(-2\partial_{x_1} \varphi + \varepsilon \psi_2 \left(\frac{x_1}{\varepsilon}\right) \partial_{x_1}^2 \varphi + \varepsilon \psi_2 \left(\frac{x_1}{\varepsilon}\right) \partial_{x_2}^2 \varphi \right) dx \\
&+M(1-\mu) \int_{\Omega_\varepsilon^+} 2\partial_{x_1 x_2}^2 u_\varepsilon \left(-\partial_{x_2} \varphi + \varepsilon \psi_2 \left(\frac{x_1}{\varepsilon}\right) \partial_{x_1 x_2}^2 \varphi \right) dx \\
&-M(1-\mu) \int_{\Omega_\varepsilon^+} \partial_{x_1}^2 u_\varepsilon \varepsilon \psi_2 \left(\frac{x_1}{\varepsilon}\right) \partial_{x_2}^2 \varphi \, dx \\
&-M(1-\mu) \int_{\Omega_\varepsilon^+} \partial_{x_2}^2 u_\varepsilon \left(-2\partial_{x_1} \varphi + \varepsilon \psi_2 \left(\frac{x_1}{\varepsilon}\right) \partial_{x_1}^2 \varphi \right) dx \\
&= \int_{\Omega_\varepsilon^+} f_\varepsilon \varepsilon \psi_2 \left(\frac{x_1}{\varepsilon}\right) \varphi \, dx
\end{aligned} \tag{5.5}
$$

for every ε. By passing to the limit, as $\varepsilon \to 0$, in (5.5) and by making use of (4.3), (4.4), (4.5), (2.6), and (5.1), it is easy to see that

$$\int_{\Omega^+} 2\mu|\omega|\partial^2_{x_2} u \partial_{x_1}\varphi - 2\mu|\omega|\partial^2_{x_2} u \partial_{x_1}\varphi - 2(1-\mu)\zeta\partial_{x_2}\varphi \, dx = 0 \quad \forall \varphi \in C_0^\infty(\Omega^+),$$

that is,

$$\int_{\Omega^+} \zeta \partial_{x_2}\varphi \, dx = 0 \quad \forall \varphi \in C_0^\infty(\Omega^+),$$

which provides that ζ is independent of x_2.

In the third step, claim (5.2) will be proved. To this aim, choose

$$v(x_1, x_2) = \begin{cases} \varepsilon\psi_2\left(\dfrac{x_1}{\varepsilon}\right)\phi(x_2)\varphi(x_1) \text{ in } \Omega^+_\varepsilon, \\ \\ \varepsilon\psi_2\left(\dfrac{x_1}{\varepsilon}\right)\varphi(x_1) \text{ in } \Omega^- \end{cases}$$

as test function in (2.5), where ψ_2 is defined as above, $\phi \in C^\infty([0,d])$ is such that $\phi = 1$ in $[0, \frac{d}{4}]$, $\phi = 0$ in $[\frac{3d}{4}, d]$, and $\varphi \in C_0^\infty(]0,c[)$ (it is evident that $v \in V_\varepsilon$). Then, it results that

$$\begin{aligned}
& M\int_{\Omega^+_\varepsilon} \Delta u_\varepsilon \left(-2\phi\partial_{x_1}\varphi + \varepsilon\psi_2\left(\frac{x_1}{\varepsilon}\right)\phi\partial^2_{x_1}\varphi + \varepsilon\psi_2\left(\frac{x_1}{\varepsilon}\right)\varphi\partial^2_{x_2}\phi\right) dx \\
& + M(1-\mu)\int_{\Omega^+_\varepsilon} 2\partial^2_{x_1x_2} u_\varepsilon \left(-\varphi\partial_{x_2}\phi + \varepsilon\psi_2\left(\frac{x_1}{\varepsilon}\right)\partial_{x_1}\varphi\partial_{x_2}\phi\right) dx \\
& - M(1-\mu)\int_{\Omega^+_\varepsilon} \partial^2_{x_1} u_\varepsilon \varepsilon\psi_2\left(\frac{x_1}{\varepsilon}\right)\varphi\partial^2_{x_2}\phi \, dx \\
& - M(1-\mu)\int_{\Omega^+_\varepsilon} \partial^2_{x_2} u_\varepsilon \left(-2\phi\partial_{x_1}\varphi + \varepsilon\psi_2\left(\frac{x_1}{\varepsilon}\right)\phi\partial^2_{x_1}\varphi\right) dx \\
& + Mh_\varepsilon^{\frac{1}{2}}\int_{\Omega^-} h_\varepsilon^{\frac{1}{2}}\partial^2_{x_1} u_\varepsilon \left(-2\partial_{x_1}\varphi + \varepsilon\psi_2\left(\frac{x_1}{\varepsilon}\right)\partial^2_{x_1}\varphi\right) dx \\
& + Mh_\varepsilon^{\frac{1}{2}}\int_{\Omega^-} \mu\frac{1}{h_\varepsilon^{\frac{3}{2}}}\partial^2_{x_2} u_\varepsilon \left(-2\partial_{x_1}\varphi + \varepsilon\psi_2\left(\frac{x_1}{\varepsilon}\right)\partial^2_{x_1}\varphi\right) dx \\
& = \int_{\Omega^+_\varepsilon} f_\varepsilon\varepsilon\psi_2\left(\frac{x_1}{\varepsilon}\right)\phi\varphi \, dx + \int_{\Omega^-} h_\varepsilon f_\varepsilon\varepsilon\psi_2\left(\frac{x_1}{\varepsilon}\right)\varphi \, dx
\end{aligned} \tag{5.6}$$

for every ε. By passing to the limit, as $\varepsilon \to 0$, in (5.6) and by making use of (4.3), (4.4), (4.5), (5.1), (3.2), and (2.6), it is easy to see that

$$\int_{\Omega^+} \zeta\varphi\partial_{x_2}\phi \, dx = 0 \quad \forall \varphi \in C_0^\infty(]0,c[),$$

from which, by recalling the assumptions on ϕ and that ζ is independent of x_2, it follows that

$$\int_0^c \zeta(x_1)\varphi(x_1) \, dx = 0 \quad \forall \varphi \in C_0^\infty(]0,c[),$$

that is, (5.2).

Now, the limit problem satisfied by u will be identified. To this aim, choose

$$v(x_1,x_2)=\begin{cases}\varphi(x_1,x_2) \text{ in } \Omega_\varepsilon^+,\\ \varphi(x_1,0)+h_\varepsilon x_2\left(\partial_{x_2}\varphi\right)(x_1,0) \text{ in } \Omega^-\end{cases}$$

as test function in (2.5), where $\varphi\in C^\infty(\overline{\Omega^+})$ and $\varphi=0$, $D\varphi=0$ on Γ. Then, it results that

(5.7)

$$\begin{aligned}
&M\int_{\Omega_\varepsilon^+}\Delta u_\varepsilon\Delta\varphi+(1-\mu)\left(2\partial^2_{x_1x_2}u_\varepsilon\,\partial^2_{x_1x_2}\varphi-\partial^2_{x_1}u_\varepsilon\,\partial^2_{x_2}\varphi-\partial^2_{x_2}u_\varepsilon\,\partial^2_{x_1}\varphi\right)dx\\
&+Mh_\varepsilon^{\frac12}\int_{\Omega^-}\left(h_\varepsilon^{\frac12}\partial^2_{x_1}u_\varepsilon+\frac{1}{h_\varepsilon^{\frac32}}\partial^2_{x_2}u_\varepsilon\right)\left(\left(\partial^2_{x_1}\varphi\right)(x_1,0)+h_\varepsilon x_2\left(\partial^3_{x_1^2x_2}\varphi\right)(x_1,0)\right)dx\\
&+M(1-\mu)\int_{\Omega^-}2\partial^2_{x_1x_2}u_\varepsilon\left(\partial^2_{x_2x_1}\varphi\right)(x_1,0)\,dx\\
&-M(1-\mu)h_\varepsilon^{\frac12}\int_{\Omega^-}\frac{1}{h_\varepsilon^{\frac32}}\partial^2_{x_2}u_\varepsilon\left(\left(\partial^2_{x_1}\varphi\right)(x_1,0)+h_\varepsilon x_2\left(\partial^3_{x_1^2x_2}\varphi\right)(x_1,0)\right)\,dx\\
&=\int_{\Omega_\varepsilon^+}f_\varepsilon\varphi dx+h_\varepsilon\int_{\Omega^-}f_\varepsilon\left(\varphi(x_1,0)+h_\varepsilon x_2\left(\partial_{x_2}\varphi\right)(x',0)\right)dx
\end{aligned}$$

for every ε. By passing to the limit, as $\varepsilon\to 0$, in (5.7), making use of (4.3), (4.4), (4.5), (5.1), (5.2), (3.2), and (2.6), and recalling that

$$\chi_{\Omega_\varepsilon^+}\rightharpoonup|\omega| \text{ weakly in } L^2(\Omega^+),$$

it is easy to see that

(5.8)

$$\begin{aligned}
&M|\omega|(1-\mu^2)\int_{\Omega^+}\partial^2_{x_2}u\partial^2_{x_2}\varphi\,dx=|\omega|\int_{\Omega^+}f\varphi\,dx\\
&+\int_0^c\left(\int_{-1}^0 g(x_1,x_2)\,dx_2\right)\varphi(x_1,0)\,dx_1\quad\forall\varphi\in C^\infty(\overline{\Omega^+})\ :\ \varphi=0,\ D\varphi=0 \text{ on } \Gamma,
\end{aligned}$$

which, by density arguments, provides that $u\in W^2(\Omega^+)$ is the unique solution of (5.3). ☐

Now, the limit problem in Ω^- will be identified. Point out that the two-scale convergence method will be explicitly used in Proposition 5.2, while it is not necessary in Proposition 5.1 for identifying the limit problem in Ω^+.

Proposition 5.2. *Let u_ε be the solution of problem* (2.5). *Assume* (2.9), *with*

$l \in]0,+\infty[$, and (2.6). Let $u_0 \in L^2(]0,c[, H^2_{per}(]0,1[))$ satisfy Proposition 4.3. Then,

$$M\frac{1-\mu^2}{l}\int_{]0,c[\,\times\,]0,1[}\partial^2_{y_1}u_0(x_1,y_1)\partial^2_{y_1}\varphi(x_1,y_1)dx_1dy_1$$

(5.9)
$$=\int_{]0,c[\,\times\,]0,1[}\left(\int_{-1}^0 g(x_1,x_2)dx_2\right)\varphi\left(x_1,y_1\right)dx_1dy_1$$

$$\forall\varphi \in L^2(]0,c[, H^2_{per}(]0,1[)) : \varphi\left(x_1,y_1\right) = 0 \text{ in }]0,c[\,\times\,\omega,$$

where $\mu \in]0,\frac{1}{2}[$ is the Poisson ratio, $M > 0$ represents the flexural rigidity modulus of the plate (see problem (2.5)), and $g \in L^2(\Omega^-)$ is given by (2.6).

Proof. In the following, ε takes values in a subsequence satisfying Proposition 4.3.

The proof of (5.9) will be performed in two steps.

At first, it will be proved that

(5.10)
$$\int_{-1}^0\int_0^1 \xi((x_1,x_2),(y_1,y_2))dx_2dy_2 = -\mu l^{-\frac{1}{2}}\partial^2_{y_1}u_0(x_1,y_1) \text{ a.e. in }]0,c[\,\times\,(]0,1[),$$

where $\xi \in L^2(\Omega^- \times]0,1[^2)$ satisfies Proposition 4.3. To this aim, choose

$$v(x_1,x_2) = \begin{cases} 0 & \text{in } \Omega^+_\varepsilon, \\ h_\varepsilon^{\frac{3}{2}}x_2^2\varphi\left(x_1,\dfrac{x_1}{\varepsilon}\right) & \text{in } \Omega^- \end{cases}$$

as test function in (2.5), where $\varphi\ (= \varphi(x_1,y_1)) \in C_0^\infty(]0,c[\,\times\,(]0,1[))$ (point out that $\varphi(x_1,\cdot)$ admits an intrinsic 1-periodic extension on $\mathbb{R}$). Then, it results that

(5.11)
$$\begin{aligned}
&Mh_\varepsilon\int_{\Omega^-}\partial^2_{x_1}u_\varepsilon\partial^2_{x_1}\left(h_\varepsilon^{\frac{3}{2}}x_2^2\varphi\left(x_1,\frac{x_1}{\varepsilon}\right)\right)dx\\
&+Mh_\varepsilon\int_{\Omega^-}\partial^2_{x_1}u_\varepsilon\frac{1}{h_\varepsilon^2}\partial^2_{x_2}\left(h_\varepsilon^{\frac{3}{2}}x_2^2\varphi\left(x_1,\frac{x_1}{\varepsilon}\right)\right)dx\\
&+Mh_\varepsilon\int_{\Omega^-}\frac{1}{h_\varepsilon^2}\partial^2_{x_2}u_\varepsilon\ \partial^2_{x_1}\left(h_\varepsilon^{\frac{3}{2}}x_2^2\varphi\left(x_1,\frac{x_1}{\varepsilon}\right)\right)dx\\
&+Mh_\varepsilon\int_{\Omega^-}\frac{1}{h_\varepsilon^2}\partial^2_{x_2}u_\varepsilon\frac{1}{h_\varepsilon^2}\partial^2_{x_2}\left(h_\varepsilon^{\frac{3}{2}}x_2^2\varphi\left(x_1,\frac{x_1}{\varepsilon}\right)\right)dx\\
&+M(1-\mu)h_\varepsilon\int_{\Omega^-}2\frac{1}{h_\varepsilon}\partial^2_{x_1x_2}u_\varepsilon\ \frac{1}{h_\varepsilon}\partial^2_{x_1x_2}\left(h_\varepsilon^{\frac{3}{2}}x_2^2\varphi\left(x_1,\frac{x_1}{\varepsilon}\right)\right)\\
&-M(1-\mu)h_\varepsilon\int_{\Omega^-}\partial^2_{x_1}u_\varepsilon\frac{1}{h_\varepsilon^2}\partial^2_{x_2}\left(h_\varepsilon^{\frac{3}{2}}x_2^2\varphi\left(x_1,\frac{x_1}{\varepsilon}\right)\right)\\
&-M(1-\mu)h_\varepsilon\int_{\Omega^-}\frac{1}{h_\varepsilon^2}\partial^2_{x_2}u_\varepsilon\,\partial^2_{x_1}\left(h_\varepsilon^{\frac{3}{2}}x_2^2\varphi\left(x_1,\frac{x_1}{\varepsilon}\right)\right)\,dx\\
&=h_\varepsilon\int_{\Omega^-}f_\varepsilon h_\varepsilon^{\frac{3}{2}}x_2^2\varphi\left(x_1,\frac{x_1}{\varepsilon}\right)dx
\end{aligned}$$

for every ε.

Now, pass to the limit, as $\varepsilon \to 0$, in each term of (5.11), after having simplified the second term with the sixth one, as well as the third with the seventh. At first, Note that the assumption $l \neq 0$ in (2.9) gives $\lim_{\varepsilon\to 0} \frac{h_\varepsilon^2}{\varepsilon} = \lim_{\varepsilon\to 0} \frac{h_\varepsilon^2}{\varepsilon^2} = \lim_{\varepsilon\to 0} \frac{h_\varepsilon^{\frac{1}{2}}}{\varepsilon} = 0$ and $\lim_{\varepsilon\to 0} \frac{h_\varepsilon^{\frac{1}{2}}}{\varepsilon^2} = l^{-\frac{1}{2}}$.

From (2.9), with $l \in]0, +\infty[$, and estimate (3.2) it follows that

$$\begin{aligned}
&\lim_{\varepsilon\to 0}\left(h_\varepsilon \int_{\Omega^-} \partial^2_{x_1} u_\varepsilon \partial^2_{x_1}\left(h_\varepsilon^{\frac{3}{2}} x_2^2 \varphi\left(x_1, \frac{x_1}{\varepsilon}\right)\right) dx\right) \\
&= \lim_{\varepsilon\to 0} \int_{\Omega^-} h_\varepsilon^{\frac{1}{2}} \partial^2_{x_1} u_\varepsilon x_2^2 \left(h_\varepsilon^2 \partial^2_{x_1}\varphi + 2\frac{h_\varepsilon^2}{\varepsilon}\partial^2_{x_1 y_1}\varphi + \frac{h_\varepsilon^2}{\varepsilon^2}\partial^2_{y_1}\varphi\right)\left(x_1, \frac{x_1}{\varepsilon}\right) dx = 0.
\end{aligned} \tag{5.12}$$

From (2.9), with $l \in]0, +\infty[$, and (4.8) it follows that

$$\begin{aligned}
&\lim_{\varepsilon\to 0} \int_{\Omega^-} h_\varepsilon \partial^2_{x_1} u_\varepsilon \frac{1}{h_\varepsilon^2}\partial^2_{x_2}\left(h_\varepsilon^{\frac{3}{2}} x_2^2 \varphi\left(x_1, \frac{x_1}{\varepsilon}\right)\right) dx = \lim_{\varepsilon\to 0}\int_{\Omega^-} h_\varepsilon^{\frac{1}{2}} \partial^2_{x_1} u_\varepsilon 2\varphi\left(x_1, \frac{x_1}{\varepsilon}\right) dx \\
&= \lim_{\varepsilon\to 0}\int_{\Omega^-} 2\frac{h_\varepsilon^{\frac{1}{2}}}{\varepsilon^2}\varepsilon^2 \partial^2_{x_1} u_\varepsilon \varphi\left(x_1, \frac{x_1}{\varepsilon}\right) dx = 2l^{-\frac{1}{2}} \int_{]0,c[\ \times\ ]0,1[} \partial^2_{y_1} u_0(x_1, y_1)\varphi(x_1, y_1) dx_1 dy_1.
\end{aligned} \tag{5.13}$$

From (2.9), with $l \in]0, +\infty[$, and the second estimate in (4.2) (which involves $\lim_{\varepsilon\to 0} \|\partial^2_{x_2} u_\varepsilon\|_{L^2(\Omega^-)} = 0$) it follows that

$$\begin{aligned}
&\lim_{\varepsilon\to 0}\int_{\Omega^-} h_\varepsilon \frac{1}{h_\varepsilon^2}\partial^2_{x_2} u_\varepsilon\ \partial^2_{x_1}\left(h_\varepsilon^{\frac{3}{2}} x_2^2 \varphi\left(x_1, \frac{x_1}{\varepsilon}\right)\right) dx \\
&= \lim_{\varepsilon\to 0}\int_{\Omega^-} \partial^2_{x_2} u_\varepsilon x_2^2 \left(h_\varepsilon^{\frac{1}{2}} \partial^2_{x_1}\varphi + 2\frac{h_\varepsilon^{\frac{1}{2}}}{\varepsilon}\partial^2_{x_1 y_1}\varphi + \frac{h_\varepsilon^{\frac{1}{2}}}{\varepsilon^2}\partial^2_{y_1}\varphi\right)\left(x_1, \frac{x_1}{\varepsilon}\right) dx = 0.
\end{aligned} \tag{5.14}$$

From (4.9) it follows that

$$\begin{aligned}
&\lim_{\varepsilon\to 0}\int_{\Omega^-} h_\varepsilon \frac{1}{h_\varepsilon^2}\partial^2_{x_2} u_\varepsilon \frac{1}{h_\varepsilon^2}\partial^2_{x_2}\left(h_\varepsilon^{\frac{3}{2}} x_2^2 \varphi\left(x_1, \frac{x_1}{\varepsilon}\right)\right) dx = \lim_{\varepsilon\to 0}\int_{\Omega^-} \frac{1}{h_\varepsilon^{\frac{3}{2}}}\partial^2_{x_2} u_\varepsilon 2\varphi\left(x_1, \frac{x_1}{\varepsilon}\right) dx \\
&= 2\int_{\Omega^-\times]0,1[^2} \xi((x_1, x_2), (y_1, y_2))\varphi(x_1, y_1)\, d(x_1, x_2) d(y_1, y_2).
\end{aligned} \tag{5.15}$$

From (2.9), with $l \in]0, +\infty[$, and the first estimate in (4.2) it follows that

$$\begin{aligned}
&\lim_{\varepsilon\to 0}\int_{\Omega^-} h_\varepsilon 2\frac{1}{h_\varepsilon}\partial^2_{x_1 x_2} u_\varepsilon\ \frac{1}{h_\varepsilon}\partial^2_{x_1 x_2}\left(h_\varepsilon^{\frac{3}{2}} x_2^2 \varphi\left(x_1, \frac{x_1}{\varepsilon}\right)\right) dx \\
&= \lim_{\varepsilon\to 0}\int_{\Omega^-} 4\partial^2_{x_1 x_2} u_\varepsilon\, x_2 \left(h_\varepsilon^{\frac{1}{2}} \partial_{x_1}\varphi + \frac{h_\varepsilon^{\frac{1}{2}}}{\varepsilon}\partial_{y_1}\varphi\right)\left(x_1, \frac{x_1}{\varepsilon}\right) dx = 0.
\end{aligned} \tag{5.16}$$

From (2.6) it follows that

$$\lim_{\varepsilon\to 0}\int_{\Omega^-} h_\varepsilon f_\varepsilon h_\varepsilon^{\frac{3}{2}} x_2^2 \varphi\left(x_1, \frac{x_1}{\varepsilon}\right) dx = 0. \tag{5.17}$$

Then, by passing to the limit, as $\varepsilon \to 0$, in (5.11) and by making use of (5.12)–(5.17), one obtains that

$$
\begin{aligned}
&2l^{-\frac{1}{2}} \int_{]0,c[\ \times\ ]0,1[} \partial^2_{y_1} u_0(x_1, y_1)\varphi(x_1, y_1) dx_1 dy_1 \\
&+2 \int_{\Omega^- \times]0,1[^2} \xi((x_1, x_2), (y_1, y_2))\varphi\,(x_1, y_1)\, d(x_1, x_2) d(y_1, y_2) \\
&-(1-\mu) 2l^{-\frac{1}{2}} \int_{]0,c[\ \times\ ]0,1[} \partial^2_{y_1} u_0(x_1, y_1)\varphi(x_1, y_1) dx_1 dy_1 = 0 \quad \forall \varphi \in C_0^\infty(]0, c[\ \times (]0, 1[)),
\end{aligned}
$$

that is, (5.10).

Now, to prove (5.9), choose $v(x_1, x_2) = \varphi(x_1, \frac{x_1}{\varepsilon})$ as test function in (2.5), where $\varphi\,(= \varphi\,(x_1, y_1)) \in C^\infty\left([0, c], C^\infty_{per}\,([0, 1])\right)$ such that $\varphi\,(x_1, y_1) = 0$ in $[0, c] \times\ \overline{\omega}$. Then, it results that

(5.18)

$$
\begin{aligned}
&M h_\varepsilon \int_{\Omega^-} \partial^2_{x_1} u_\varepsilon \partial^2_{x_1} \left(\varphi\left(x_1, \frac{x_1}{\varepsilon}\right)\right) dx + M h_\varepsilon \int_{\Omega^-} \frac{1}{h_\varepsilon^2} \partial^2_{x_2} u_\varepsilon\ \partial^2_{x_1} \left(\varphi\left(x_1, \frac{x_1}{\varepsilon}\right)\right) dx \\
&- M(1-\mu) h_\varepsilon \int_{\Omega^-} \frac{1}{h_\varepsilon^2} \partial^2_{x_2} u_\varepsilon\ \partial^2_{x_1} \left(\varphi\left(x_1, \frac{x_1}{\varepsilon}\right)\right)\, dx = h_\varepsilon \int_{\Omega^-} f_\varepsilon \varphi\left(x_1, \frac{x_1}{\varepsilon}\right) dx
\end{aligned}
$$

for every ε.

Pass to the limit, as $\varepsilon \to 0$, in each term of (5.18).

From (2.9), with $l \in]0, +\infty[$, and (4.8) it follows that

$$
\begin{aligned}
&\lim_{\varepsilon \to 0} \int_{\Omega^-} h_\varepsilon \partial^2_{x_1} u_\varepsilon \partial^2_{x_1} \left(\varphi\left(x_1, \frac{x_1}{\varepsilon}\right)\right) dx \\
&= \lim_{\varepsilon \to 0} \int_{\Omega^-} \frac{h_\varepsilon^{\frac{1}{2}}}{\varepsilon^2} \varepsilon^2 \partial^2_{x_1} u_\varepsilon \left(h_\varepsilon^{\frac{1}{2}} \partial^2_{x_1} \varphi + 2 \frac{h_\varepsilon^{\frac{1}{2}}}{\varepsilon} \partial^2_{x_1 y_1} \varphi + \frac{h_\varepsilon^{\frac{1}{2}}}{\varepsilon^2} \partial^2_{y_1} \varphi \right) \left(x_1, \frac{x_1}{\varepsilon}\right) dx \qquad (5.19) \\
&= \frac{1}{l} \int_{]0,c[\ \times\ ]0,1[} \partial^2_{y_1} u_0(x_1, y_1) \partial^2_{y_1} \varphi(x_1, y_1) dx_1 dy_1.
\end{aligned}
$$

From (2.9), with $l \in]0, +\infty[$, (4.9), and (5.10) it follows that

$$
\begin{aligned}
&\lim_{\varepsilon \to 0} \int_{\Omega^-} h_\varepsilon \frac{1}{h_\varepsilon^2} \partial^2_{x_2} u_\varepsilon\ \partial^2_{x_1} \left(\varphi\left(x_1, \frac{x_1}{\varepsilon}\right)\right) dx \\
&= \lim_{\varepsilon \to 0} \int_{\Omega^-} \frac{1}{h_\varepsilon^{\frac{3}{2}}} \partial^2_{x_2} u_\varepsilon \left(h_\varepsilon^{\frac{1}{2}} \partial^2_{x_1} \varphi + 2 \frac{h_\varepsilon^{\frac{1}{2}}}{\varepsilon} \partial^2_{x_1 y_1} \varphi + \frac{h_\varepsilon^{\frac{1}{2}}}{\varepsilon^2} \partial^2_{y_1} \varphi \right) \left(x_1, \frac{x_1}{\varepsilon}\right) dx \\
&= \int_{\Omega^- \times]0,1[^2} \xi((x_1, x_2), (y_1, y_2)) \frac{1}{l^{\frac{1}{2}}} \partial^2_{y_1} \varphi\,(x_1, y_1)\, d(x_1, x_2) d(y_1, y_2) \qquad (5.20) \\
&= -\frac{\mu}{l} \int_{]0,c[\ \times\ ]0,1[} \partial^2_{y_1} u_0(x_1, y_1) \partial^2_{y_1} \varphi(x_1, y_1) dx_1 dy_1.
\end{aligned}
$$

From (2.6) it follows that

$$\lim_{\varepsilon \to 0} \int_{\Omega^-} h_\varepsilon f_\varepsilon \varphi \left(x_1, \frac{x_1}{\varepsilon} \right) dx = \int_{\Omega^- \times]0,1[} g(x_1, x_2) \varphi (x_1, y_1) \, d(x_1, x_2) dy_1. \tag{5.21}$$

Then, by passing to the limit, as $\varepsilon \to 0$, in (5.18) and by making use of (5.19)–(5.21), one obtains that

$$M \frac{1-\mu^2}{l} \int_{]0,c[\ \times \ ]0,1[} \partial^2_{y_1} u_0(x_1, y_1) \partial^2_{y_1} \varphi(x_1, y_1) dx_1 dy_1$$

$$= \int_{]0,c[\ \times \ ]0,1[} \left(\int_{-1}^{0} g(x_1, x_2) dx_2 \right) \varphi (x_1, y_1) \, dx_1 dy_1$$

$$\forall \varphi \in C^\infty \left([0, c], C^\infty_{per} ([0, 1]) \right) \text{ such that } \varphi (x_1, y_1) = 0 \text{ in } [0, c] \times \overline{\omega},$$

which provides (5.9) by density arguments. $\square$

ON THE DYNAMICS OF LIQUID-VAPOR PHASE TRANSITION*

KONSTANTINA TRIVISA†

Abstract. We consider a multidimensional model for the dynamics of liquid-vapor phase transitions. In the present context, liquid and vapor are treated as different species with different volume fractions and different molecular weights. The model presented here is a prototype of a "binary fluid mixture" and is formulated by a system that generalizes the Navier–Stokes(–Fourier) equations in Eulerian coordinates. This system takes now a new form due to the choice of rather complex constitutive relations that can accommodate appropriately the physical context. The setting of the problem presented in this work is motivated by physical considerations. The transport fluxes satisfy rather general constitutive laws, the viscosity and heat conductivity depend on the temperature, and the pressure law is a nonlinear function of the temperature depending on the mass density fraction of the vapor (liquid) in the fluid as well as the molecular weights of the individual species. The existence of globally defined weak solutions of the relevant system of partial differential equations that generalizes the Navier–Stokes(–Fourier) equations for compressible fluids is established by using weak convergence methods, and compactness and interpolation arguments in the spirit of Feireisl [*Dynamics of Viscous Compressible Fluids*, Oxford University Press, Oxford, 2004] and Lions [*Mathematical Topics in Fluid Mechanics, Vol.* 2, The Clarendon Press, Oxford University Press, New York, 1998].

Key words. Navier–Stokes system, compressible fluids, liquid-vapor phase transitions, binary fluid mixtures, oscillation and concentration phenomena

1. Introduction.

A multidimensional model is presented for the liquid-vapor phase transition formulated by the Navier–Stokes equations in Euler coordinates. In the present context, these equations express the conservation of mass, the balance of momentum and energy, and the balance of species density.

Consider a pure fluid which exhibits liquid-vapor phase changes. In the macroscopic description adopted here $\rho = \rho(t,x)$ denotes the *density* of the *mixture*, $\mathbf{u} = \mathbf{u}(t,x)$ its average *velocity*, and $\theta = \theta(t,x)$ the *temperature*, while $\rho_1 = \rho f_1$ is the density of 1-species (vapor) with $f_1 = f_1(x,t)$ denoting the *mass density fraction* of vapor in the fluid at time $t \in \mathbb{R}$ and at the spatial position $x \in \Omega \subset \mathbb{R}^N,\ N = 3$. These *macroscopic variables* provide a precise characterization of the state of the mixture, which in the present context consists of the species vapor and liquid. The balance of the species density is given by

$$\textit{balance of species density:} \qquad \partial_t(\rho f_1) + \mathrm{div}(\rho f_1 \mathbf{u}) + \mathrm{div}\mathcal{F}_1 = w_1.$$

Here and in what follows,

- $f_i(x,t)$ is the volume fraction of the i species. Vapor and liquid fill up the space, namely,

$$f_1 + f_2 = 1. \tag{1.1}$$

http://www.siam.org/journals/sima/39-6/65239.html

†Department of Mathematics, University of Maryland, College Park, MD 20742-4015 (trivisa@math.umd.edu).

- $\rho_i(x,t)$ is the density of the i species

$$\rho_i = \rho f_i, \quad \rho = \rho_1 + \rho_2. \tag{1.2}$$

- w_i is the reaction rate function denoting the mass of the i species produced per unit volume per time unit. In accordance with the *conservation of mass*:

$$\partial_t \rho + \mathrm{div}(\rho \mathbf{u}) = 0,$$

 we have

$$w_1 + w_2 = 0. \tag{1.3}$$

The *momentum conservation equation* can be written as

$$\textit{balance of momentum:} \qquad \partial_t(\rho \mathbf{u}) + \mathrm{div}(\rho \mathbf{u} \otimes \mathbf{u}) + \nabla p = \mathrm{div}\mathbb{S},$$

where ρ is the *total mass density*, $\mathbf{u} \otimes \mathbf{u}$ is the tensor product of *velocity* vectors, p denotes the *pressure*, while $\mathbb{S}$ is the *viscous stress tensor*.

Finally, the *energy conservation equation* reads

$$\textit{balance of energy:} \qquad \partial_t(\rho e) + \mathrm{div}(\rho \mathbf{u} e) + \mathrm{div}\, \mathbf{q} = \mathbb{S} : \nabla u - p\mathrm{div}\mathbf{u}.$$

The physical properties of the mixture are expressed through *constitutive relations*, which specify the relation of the *viscous stress tensor* $\mathbb{S}$, the *heat flux* $\mathbf{q}$, the pressure p, and the internal energy e to the *macroscopic variables*. The hypotheses on the constitutive laws and on the special features of the model are the following.

1.1. Constitutive relations.

- The viscous stress tensor $\mathbb{S}$ is given by *Newton's viscosity formula*

$$\mathbb{S} = \mu(\theta)\left(\nabla \mathbf{u} + \nabla \mathbf{u}^T - \frac{2}{3}\mathrm{div}\mathbf{u}\, \mathbb{I}\right) + \zeta(\theta)\, \mathrm{div}\mathbf{u}\, \mathbb{I}, \tag{1.4}$$

  where the *shear viscosity* μ and the *bulk viscosity* ζ are supposed to be nonnegative and continuously differentiable functions of the absolute temperature.

- The pressure in the portion occupied by the ith component $p_i = p(\rho_i, \theta)$ depends in a crucial way on the volume fraction f_i. In the case where the fluid is in *pure* phase, either (pure) vapor or (pure) liquid, the pressure can be determined quite accurately through experiments. Let us denote by $p_1 = p(\rho_1, \theta)$ and $p_2 = p(\rho_2, \theta)$ the pressure of pure vapor phase and liquid phase, respectively, with ρ_i the density of the ith component and θ the temperature of the mixture (see Figure 1.1). The density at which the pressures of the individual species coincide, namely, $p_1(m, \theta) = p_2(M, \theta) = p_0$, is known as the *Maxwell equilibrium density* and corresponds to $\rho = m(\theta), \rho = M(\theta)$ in Figure 1.1. At this density, both species, liquid and vapor, coexist and are (as we say) *in equilibrium*, and in this case the pressure can be measured in experiments. On the other hand, the region that corresponds to rapid *phase transition,* namely, the area where the material instantly decomposes into liquid, vapor, or their mixtures ($\rho \in (a, b)$ in Figure 1.1), is highly unstable. As a consequence this part of the so-called *van der Waals* pressure curve (the dashed line in Figure 1.1) cannot be measured in experiments and it is

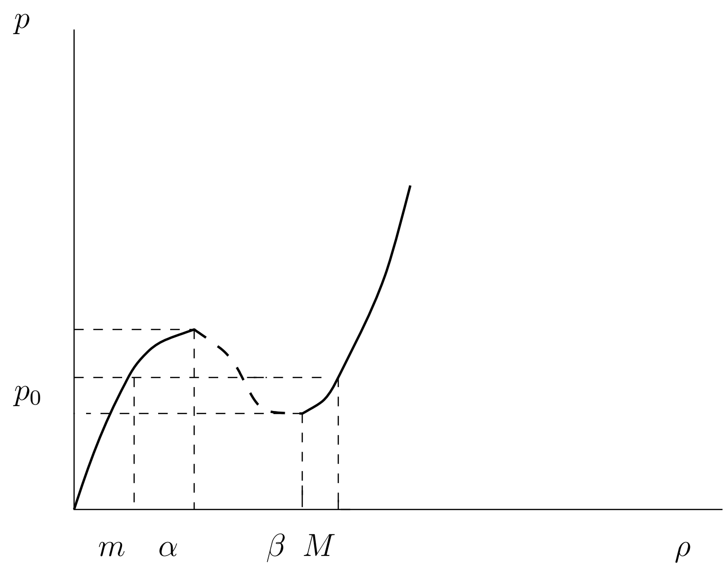

FIG. 1.1. *Pressure.*

regarded as artificial (see also the discussion in Fan [18], Fan and Slemrod [19], Slemrod [29], and the references therein).

As in Fan [18], we proceed considering only the physically relevant part (the part observed in experiments) and we extend each component of the function $p(\rho, \theta)$ continuously as shown in Figure 1.2. This extension may appear at first a bit artificial; however, this part of the pressure does not really affect the outcome, as indicated by physical experiments. In other words, we treat liquid and vapor as different species and specify the transition of the phases by the reaction rate equation for w_1.

Taking the above discussion into consideration, we assume the *Dalton-type law* for the pressure of the mixture, namely,

$$p = p_R + p_B + p_e, \tag{1.5}$$

where the term p_B satisfies *Boyle's law* for the individual species

$$p_B = \frac{\rho_1 R\theta}{m_1} + \frac{\rho_2 R\theta}{m_2}, \tag{1.6}$$

where m_i denotes the molecular weight of the ith component, $p_e = p_e(\rho)$ is the so-called *elastic pressure* whose properties will be discussed in what follows, while p_R accounts for *radiation effects.* We remark that the *elastic pressure* may include higher order terms as in the *Beattie–Bridgman model,* where the state equation for the pressure includes an *elastic* component of the form

$$p_e(\rho) = \beta_1\rho^2 + \beta_2\rho^3 + \beta_3\rho^4$$

for appropriate constants β_i (see [1], [20]).

The point of view presented here takes into consideration the classical as well as the *quantum* aspects associated with the fluid. In the quantum case, the

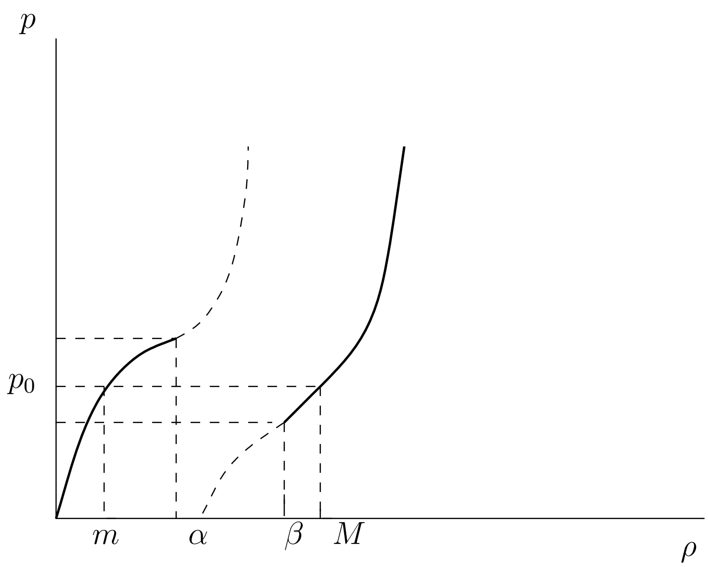

FIG. 1.2. *Modified pressure.*

presence of the photons affects the total pressure p in the fluid. As a result the pressure function now includes an additional (*radiation*) component p_R, which is related to the absolute temperature θ through the *Stefan–Boltzmann law*

$$p_R = \frac{a}{3}\theta^4 \quad \text{with} \quad a > 0 \quad \textit{a constant}.$$

The underlying assumption here (cf. [14], [24], [28]) is that the *high temperature radiation* is at thermal equilibrium with the fluid. Analogously, standard thermodynamic relations require that the specific internal energy of the fluid be also augmented by the term

$$e_R = e_R(\rho, \theta) = \frac{a}{\rho}\theta^4.$$

We remark that *radiation effects* are of particular interest in *astrophysical plasma models* [4].

The pressure therefore satisfies, in the present context, the general law

$$p = \frac{a}{3}\theta^4 + \frac{\rho_1 R\theta}{m_1} + \frac{\rho_2 R\theta}{m_2} + p_e(\rho).$$

Taking into consideration (1.1), (1.2) the pressure law now takes the form

$$p = \frac{a}{3}\theta^4 + \frac{\rho}{m_2}R\theta + R\left(1 - \frac{m_1}{m_2}\right)\frac{\rho_1}{m_1}\theta + p_e(\rho).$$

The molecular weight of the vapor is significantly less than that of the liquid, namely, $m_1 \ll m_2$, which implies that the constant

$$L = \left(1 - \frac{m_1}{m_2}\right)\frac{1}{m_1} > 0, \tag{1.7}$$

and so the pressure law becomes

$$p = \frac{a}{3}\theta^4 + \frac{R}{m_2}\rho\theta + LR\rho_1\theta + p_e(\rho).$$

Motivated by the above discussion, here and in what follows, the pressure law has the form

$$p(\rho, \theta, \rho_1) = p_{radiation} + p_{thermal} + p_{elastic},$$

$$p(\rho, \theta, \rho_1) = \frac{a}{3}\theta^4 + \theta\left[\frac{R}{m_2}p_\theta(\rho) + LRp_\theta(\rho_1)\right] + [p_e(\rho) + p_e(\rho_1)] \tag{1.8}$$

with p_e the *elastic pressure* and p_θ the *thermal pressure* which are functions satisfying certain structural properties to be specified in section 2.3.

- The *internal energy* e satisfies a general constitutive law $e = e(\rho, \theta, \rho_1)$, namely,

$$\rho e = \rho e(\rho, \theta, \rho_1) = a\theta^4 + \frac{c_v}{m_2}\rho\theta + Lc_v\rho_1\theta + \rho P_e(\rho) + \rho_1 P_e(\rho_1) \tag{1.9}$$

with c_v the *specific heat* and

$$P_e(\rho) = \int_1^\rho \frac{p_e(z)}{z^2}\, dz \tag{1.10}$$

denoting the so-called *elastic potential*.

- We treat vapor and liquid as different species, each having its own density ρ_1 and ρ_2, pressure p_1 and p_2, molecular weight m_1 and m_2, but with both components having the same temperature at each point of the mixture.
- The *diffusion flux* $\mathcal{F}_i$ is determined by the law

$$\mathcal{F}_i = -D\rho_i\nabla\log(\rho_i\theta) \tag{1.11}$$

with D denoting the *species diffusion coefficient*, which in accordance with the kinetic theory of gases is a function of the form

$$D(\rho_1) \approx \frac{d}{\rho_1},\ d = \text{constant}.$$

Taking the above into consideration, here and in what follows, the diffusion flux $\mathcal{F}_i$ is of the form

$$\mathcal{F}_i = -d\nabla\log(\rho_i\theta). \tag{1.12}$$

- The *heat flux* $\mathbf{q} = \mathbf{q}(\rho, \rho_i, \theta, \nabla\theta)$ is given by a very general law and consists in the present context of two parts:

$$\mathbf{q} = \mathbf{q_F} + \mathbf{q_{f_i}}. \tag{1.13}$$

The first term $\mathbf{q_F}$ is determined by the *Fourier law,* while the second term $\mathbf{q_{f_i}}$ accounts for the effects of *enthalpy*, which is carried across the surface by the individual species, namely,

$$\begin{cases} \mathbf{q_F} = -\kappa_F(\rho, \theta)\nabla\theta, \\ \mathbf{q_{f_i}} = -\frac{9\gamma-5}{4}Ld\theta\nabla\log(\rho_i\theta), \end{cases} \tag{1.14}$$

where L is the constant introduced in (1.7). The term $\mathbf{q_{f_i}}$ constitutes an additional contribution to $\mathbf{q}$ in *binary* and *multicomponent* systems.

- The function w_1 is the so-called reaction rate function which governs the growth of vapor in the fluid. In general, w_1 consists of two parts, w_{growth} and $w_{nucleation}$. The former accounts for the creation of nuclei of new phase, while the latter describes the subsequent growth of these nuclei,

$$w_1 = w_{growth} + w_{nucleation}.$$

The species production rates w_i are continuous functions of the absolute temperature θ and the species densities ρ_1, ρ_2. For the sake of simplicity, we shall assume that

$$-\underline{c}_1 \le w_1(\theta, \rho_1, \rho_2) \le \bar{c}_1 \quad \text{for all } \theta \ge 0,\ 0 \le \rho_1, \rho_2 \le \rho.$$

Typical examples are presented in [12], [13] in the context of combustion theory, where the rate function is typically given by the *Arrhenius law*, as well as in Fan [18] and Fan and Slemrod [19] in the physical setting of *liquid-vapor* phase transition. In that context, w_1 is the probability of collision between the particles of liquid and vapor multiplied by a parameter known as the *rate parameter*.

Multiplying the *conservation of mass* equation by $(\rho P_e(\rho))'$ we obtain

$$\partial_t(\rho P_e(\rho)) + \mathrm{div}(\rho P_e(\rho)\mathbf{u}) + p_e(\rho)\mathrm{div}\mathbf{u} = 0. \tag{1.15}$$

Analogously,

$$\partial_t(\rho_1 P_e(\rho_1)) + \mathrm{div}(\rho_1 P_e(\rho_1)\mathbf{u}) + p_e(\rho_1)\mathrm{div}\mathbf{u} = (\rho_1 P_e(\rho_1))'\mathrm{div}[\nabla \log(\rho_1\theta)],$$

and so the *conservation of energy equation* yields the *thermal equation*

(1.16)
$$\partial_t\left[a\theta^4 + \frac{c_v}{m_2}\rho\theta + Lc_v\rho_1\theta + \rho_1 P_e(\rho_1)\right] + \mathrm{div}\left[\left(a\theta^4 + \frac{c_v}{m_2}\rho\theta + Lc_v\rho_1\theta + \rho_1 P_e(\rho_1)\right)\mathbf{u}\right]$$
$$+\,\mathrm{div}\mathbf{q} = \mathbb{S} : \nabla\mathbf{u} - \left[\frac{a}{3}\theta^4 + \frac{R}{m_2}\theta p_\theta(\rho) + LR\theta p_\theta(\rho_1) + p_e(\rho_1)\right]\mathrm{div}\mathbf{u} - \sum_{i=1}^{2} h_k w_k$$

with h_k denoting the *formation enthalpies.*

The *internal energy* is related to the *specific entropy* s through a rather general *thermodynamic relation*

$$\theta\mathbf{D}s = \mathbf{D}e + p\mathbf{D}\left(\frac{1}{\rho}\right) - \sum_{i=1}^{2} g_i\mathbf{D}\rho_i, \tag{1.17}$$

where $\mathbf{D}$ denotes the total differential and g_i a quantity that depends on the specific *physical context* and is typically a function of the temperature of the mixture, the formation enthalpies h_k and the formation entropies [25].

If the motion is smooth, starting from the *energy balance*, and in accordance with (1.17), we derive now the *entropy* equation, which now reads

$$\partial_t(\rho s) + \mathrm{div}(\rho s\mathbf{u}) + \mathrm{div}\left[-\frac{k(\theta)}{\theta}\nabla\theta - (\rho s_{f_1})Ld\nabla\log(\rho_1\theta)\right] = \mathbf{r}. \tag{1.18}$$

Here $\mathbf{r}$ denotes the *entropy production*, which is expressed by

$$\mathbf{r} = \frac{1}{\theta}\left(\mathbb{S} : \nabla u + k(\theta)\frac{|\nabla\theta|^2}{\theta} + L\theta d|\nabla \log(\rho_1\theta)|^2 - \sum_{i=1}^{2} g_i w_i\right). \tag{1.19}$$

In accordance with the *second law of thermodynamics* we assume here that

$$\sum_{i=1}^{2} g_i w_i \leq 0,$$

so that the *entropy production rate* (1.19) is nonnegative.

The *specific entropy* s is given by

$$s = s_F + s_{f_1}, \tag{1.20}$$

where

$$\begin{cases} s_F = \frac{4a}{3}\frac{\theta^3}{\rho} + \frac{c_v}{m_2}\log(\theta) - \frac{R}{m_2}P_\theta(\rho), \\ \rho_1 s_{f_1} = Lc_v\rho_1\log(\theta) - LR\rho_1 P_\theta(\rho_1) - LR\rho_1\log(\rho_1) \end{cases} \tag{1.21}$$

with

$$P_\theta(\rho) = \int_1^\rho \frac{p_\theta(z)}{z^2}\,dz.$$

The reader should contrast the form of the entropy in the present context to the form of the entropy in earlier articles (cf. [12], [13], [14], [20]) to see the effect of the presence of the individual components in the mixture.

In the case of a general nonsmooth motion now, and in the spirit of the second law of thermodynamics as given in Truesdell [32], we can only assert that

$$\begin{aligned} &\partial_t[\rho\,(s_F + s_{f_1})] + \operatorname{div}\left[\rho\,(s_F + s_{f_1})\mathbf{u}\right] + \operatorname{div}\left(-\frac{k(\theta)}{\theta}\nabla\theta - (\rho s_{f_1})Ld\nabla\log(\rho_1\theta)\right) \\ &\qquad \geq \frac{1}{\theta}\left(\mathbb{S} : \nabla u + k(\theta)\frac{|\nabla\theta|^2}{\theta} + L\theta d|\nabla\log(\rho_1\theta)|^2 - \sum_{i=1}^{2} g_i w_i\right). \end{aligned} \tag{1.22}$$

The equations which characterize the liquid-vapor *phase transition* now read

$$\partial_t\rho + \operatorname{div}(\rho\mathbf{u}) = 0, \tag{1.23}$$

$$\partial_t(\rho\mathbf{u}) + \operatorname{div}(\rho\mathbf{u}\otimes\mathbf{u}) + \nabla p = \operatorname{div}\mathbb{S}, \tag{1.24}$$

$$\partial_t(\rho s) + \operatorname{div}(\rho s\mathbf{u}) + \operatorname{div}\left[-\frac{k(\theta)}{\theta}\nabla\theta, -(\rho s_{f_1})Ld\nabla\log(\rho_1\theta)\right] = \mathbf{r}, \tag{1.25}$$

$$\partial_t(\rho_1) + \operatorname{div}(\rho_1\mathbf{u}) + \operatorname{div}\mathcal{F}_1 = w_1. \tag{1.26}$$

We assume that the mixture occupies a bounded domain $\Omega \subset \mathbb{R}^N$, $N = 3$, of class $C^{2+\nu}, \nu > 0$, and the whole physical system is both mechanically and thermally isolated. The following boundary conditions hold:

$$\mathbf{u}|_{\partial\Omega} = 0, \quad \mathbf{q}\cdot\mathbf{n}|_{\partial\Omega} = 0, \quad \mathcal{F}\cdot\mathbf{n}|_{\partial\Omega} = 0, \tag{1.27}$$

where $\mathbf{n}$ denotes the outer normal vector to $\partial\Omega$.

In accordance with the above discussion we infer that the *total energy*

$$E = \frac{1}{2}\rho\left(|\mathbf{u}|^2 + e\right) \tag{1.28}$$

is constant of motion, specifically,

$$\frac{d}{dt}\int_\Omega E(t)dx = 0. \tag{1.29}$$

We consider the following initial conditions:

$$\begin{cases} \rho(0,\cdot) = \rho_0, \\ (\rho\,\mathbf{u})(0,\cdot) = \mathbf{m}_0, \\ (\rho\, s)(0,\cdot) = \rho_0 s_0, \\ (\rho_1)(0,\cdot) = \rho_{1_0}, \end{cases} \tag{1.30}$$

together with the compatibility condition

$$\mathbf{m}_0 = 0 \quad \text{on the set} \quad \{x \in \Omega |\ \rho_0(x) = 0\}. \tag{1.31}$$

The objective of this work is to establish the global existence of weak solutions to this initial boundary value problem with large initial data. This article extends earlier work on phase transitions [12], [13] (see also [24]) since it now takes into consideration both the species concentration as well as the unique character of the individual components as given by their distinct molecular weights. The constitutive relations presented here, which differ from the ones given in [12], [13], [24], are able to accommodate both *binary* and *multicomponent* fluid *mixtures*, while at the same time yielding nonnegative *entropy production* in the spirit of the *second law of thermodynamics* as presented in Truesdell [32]. We remark that the complexity of the constitutive relations necessitates the derivation of delicate estimates on the *new* macroscopic variable $\rho_1 = \rho f$. The reader should contrast these estimates to the ones in [12], [13], [24], where the focus was on estimates of the mass fraction density. For results on the one-dimensional setting, we refer the reader to the articles [5], [6], [7]. Related results for multicomponent models are presented in [16], [23], [25], [31].

Moreover, some of the difficulties arising in the execution of our program involve the following issues:

- Obtaining boundness of the *oscillation defect measure* (essential for the *strong* convergence of the density ρ) requires the special treatment of additional terms in the pressure and the equations.
- The presence of extra terms in the entropy production can be handled only by deriving new *energy* and *entropy* estimates.
- The pressure estimates need *refinement* in dealing with *concentration* phenomena.

The methods of use are *weak convergence methods* and *compactness arguments* in the spirit of Feireisl [20] and Lions [27]. At the heart of the analysis lies the quantity

$$p - \left(\frac{4}{3}\mu + \zeta\right)\mathrm{div}\mathbf{u},$$

known as the *effective viscous pressure*. The *weak continuity* property of the *effective viscous pressure* was first shown by Lions [27] for the *barotropic* Navier–Stokes equations, where $p = p(\rho)$ and with constant viscosity coefficients. This result was extended to include the case of general temperature-dependent viscosity coefficients by Feireisl [21] with the aid of delicate commutator estimates in the spirit of Coifman and Meyer [8]. We remark that our analysis is valid for viscosity coefficients depending only on the absolute temperature and are, in the present context, independent of the viscosity. This may be viewed as a weakness of the present theory; it is, however, physically relevant in the context of sufficient diluted fluid mixtures (cf. Becker [1]).

In section 6 we establish the weak continuity of the *effective viscous pressure*, which involves showing that the following relation holds true:

$$\overline{\left(p(\rho,\theta,\rho_1) - \left(\frac{4}{3}\mu(\theta) + \zeta(\theta)\right)\mathrm{div}\mathbf{u}\right)b(\rho)}$$
$$= \left(\overline{p(\rho,\theta,\rho_1)}\,\overline{b(\rho)} - \frac{4}{3}(\overline{\mu(\theta)} + \overline{\zeta(\theta)})\mathrm{div}\mathbf{u}\right)\overline{b(\rho)}$$

for any bounded function b.

In the center of the analysis lies also the requirement that ρ is a *renormalized solution* of the continuity equation, a notion introduced by DiPerna and Lions [10], [11]. The role of this concept is twofold in the sense that it helps us deal both with the problem of *density oscillations* as well as with the problem of temperature *concentration phenomena*.

Another *key* ingredient in evaluating the propagation of density oscillations is in fact showing *boundness* of a suitable *oscillation defect measure*, which is typically expressed in terms of certain cutoff functions (cf. Feireisl [20]). We remark that the choice of the constitutive relations affects in a crucial way the form of this *measure*.

The outline of this article is as follows. In sections 2 and 3 we present the *weak formulation* of the problem and state the main result. Our analysis relies on the concept of *variational solution*, which provides us with the appropriate space setting for the *admissible* solutions of our system. The reader should contrast the notion of *variational solution* presented in this work to earlier notions for relevant phase transition models [14], [12], [13], [24].

In section 4 we introduce a series of approximating problems constituting a three-level approximating scheme. This scheme consists of a set of regularized equations (see also [12], [13], [20]). The regularization appears in terms of additional ε and δ quantities accounting for *artificial viscosity* and *artificial pressure*. In section 5 we obtain uniform bounds (*energy* and *entropy* estimates) necessary as we let the artificial viscosity ε go to zero in section 6. Here, the weak continuity of the *effective viscous pressure* needs to be established in order to obtain suitable estimates on the density component ρ.

In section 7 we recover the original system by letting δ go to zero, getting rid of the *artificial pressure* term $\{\delta\rho^\beta\}$. This process requires the introduction of a suitable family of functions

$$T_k(z) = kT\left(\frac{z}{k}\right) \quad \text{for} \quad z \in \mathbb{R}, \quad k = 1, 2, \dots,$$

where $T \in C^\infty$ is a suitable cutoff function, whose choice depends in a crucial way on the particular physical context, namely, on the choice of constitutive relations for the equation of state for the pressure and other quantities in the system as well as the assumptions on the viscosity coefficients. The main goal here is to show that the so-called *oscillation defect measure*

$$osc_{\beta+1}[\rho_\delta \to \rho]((0,T)\times\Omega) = \sup_{k\geq 1}\left(\limsup_{\delta\to 0}\int_0^T\int_\Omega |T_k(\rho_\delta) - T_k(\rho)|^{\beta+1} dxdt\right)$$

is bounded.

Related results on phase-transition models are presented in [12], [13] in the context of combustion models and in [14], [20], [21], [24] for related models in fluids and astrophysics. We refer the reader also to [23] for further discussion on *multicomponent reacting flows*.

The setting of the present article is motivated by physical considerations presented in a series of articles by Fan [18], Fan and Slemrod [19], and Slemrod [29]. For related work on van der Waals fluids and the issue of nonuniqueness of phase transition near the Maxwell line we refer the reader to Benzoni-Gavage [2] and the references therein, while for general discussion on nucleation phenomena we refer the reader to Springer [30].

2. Weak formulation. Our objective in this article is the solvability of the initial boundary value problem (1.23)–(1.26), together with (1.27) and (1.30), for *large* initial data. To this end, we need to rely on the concept of *variational solution*. Philosophically, this *weak* formulation is connected to the *balance laws* of continuum physics. *Balance laws* are typically expressed in the form of integral identities and therefore no additional requirement on the regularity of the integrand quantities is imposed.

2.1. Dissipation of energy. In the framework of weak solutions, it is common to replace the (formally derived) classical *entropy equality* by an *inequality* (cf. Truesdell [32]). This is due to the possible *loss* of some part of the kinetic energy of the system. This loss of energy appears mathematically in the form of a measure, while in the physical setting, this portion of the energy may be regarded as a new part of the spatial domain. For further remarks on the topic, we refer the reader to Feireisl [20] for relevant discussion in the context of compressible fluids, as well as to Dafermos [9] for relevant discussion in the context of hyperbolic conservation laws.

The *variational formulation* of the entropy production is given by

$$\begin{aligned}(2.1)\qquad &\int_0^T\!\!\int_\Omega \left\{(\rho s)\,\partial_t\phi + (\rho s)\mathbf{u}\cdot\nabla\phi + \left[\frac{-k(\theta)}{\theta}\nabla\theta - (\rho s_{f_1})Ld\nabla\log(\rho_1\theta)\right]\cdot\nabla\phi\right\}dxdt\\ &\leq \int_0^T\!\!\int_\Omega\left\{-\frac{\mathbb{S}:\nabla\mathbf{u}}{\theta} - \frac{k(\theta)|\nabla\theta|^2}{\theta^2} - Ld|\nabla\log(\rho_1\theta)|^2 - \sum_{i=1}^2 g_i w_i\right\}\phi\,dx\,dt\end{aligned}$$

for any nonnegative function $\phi\in\mathcal{D}((0,T)\times\mathbb{R}^N)$.

Note that the fact that θ appears in the denominator in the above relation $\left\{\frac{\mathbb{S}:\nabla\mathbf{u}}{\theta}\right\}$ indicates that the absolute temperature θ must be positive in order for (2.1) to be meaningful.

Motivated by this discussion, we introduce now the notion of a *variational solution* to the initial boundary value problem (1.23)–(1.26) together with (1.27), (1.30), and (1.31).

2.2. The class of admissible solutions. In this section we present the class of admissible solutions for our system (1.23)–(1.26) motivated by the underlying physical principles of continuum physics.

DEFINITION 2.1. *We say that* $(\rho, \mathbf{u}, \theta, \rho_1)$ *is a variational solution of the initial boundary value problem* (1.23)–(1.26) *on the interval* $(0,T)$ *if it satisfies the following properties:*

• *The continuity equation* (1.1) *is satisfied in the sense of renormalized solutions, specifically*

$$\rho \in C([0,T]; L^1(\Omega)) \cap L^\infty(0,T; L^\gamma(\Omega)),\ \rho(0,\cdot) = \rho_0$$

satisfying the continuity equation (1.1) *in the sense of* $\mathcal{D}'((0,T)\times\mathbb{R}^3)$ *provided that* $\rho, \mathbf{u}$ *were extended to be zero outside* Ω*:*

$$\mathbf{u} \in L^2(0,T; W_0^{1,2}(\Omega;\mathbb{R}^3)), \quad \rho\mathbf{u} \in L^\infty(0,T; L^1(\Omega;\mathbb{R}^3)),$$

and the integral identity

$$\int_0^T\int_\Omega (\rho B(\rho)\partial_t\phi + \rho B(\rho)\mathbf{u}\cdot\nabla_x\phi - b(\rho)\mathrm{div}_x\mathbf{u})\ dxdt = -\int_\Omega \rho_0 B(\rho_0)\phi(0,\cdot)dx$$

holds for any test function $\phi \in \mathcal{D}([0,T)\times\bar{\Omega})$ *and any*

$$b \in BC[0,\infty),\ B(\rho) = B(1) + \int_1^\rho \frac{b(z)}{z^2}\ dz. \tag{2.2}$$

• *The density of the individual component* ρ_1 *is a nonnegative measurable function belonging to the space*

$$\rho_1 \in L^\infty(0,T; L^\gamma(\Omega)), \quad \log(\rho_1) \in L^2(0,T; W^{1,2}(\Omega)),$$

while the temperature θ *is a nonnegative function such that*

$$\theta, \log(\theta) \in L^2(0,T; W^{1,2}(\Omega)),$$

and the integral identity

$$\int_0^T\int_\Omega \rho_1\partial_t\phi + \rho_1\mathbf{u}\cdot\nabla_x\phi + \mathcal{F}\cdot\nabla_x\phi\, dxdt = \int_0^T\int_\Omega w_1\phi\, dxdt - \int_\Omega \rho_{1_0}\phi(0,\cdot)dx \tag{2.3}$$

holds for any test function $\phi \in \mathcal{D}'([0,T)\times\bar{\Omega})$.

• *The momentum balance equation* (1.2) *is satisfied in the sense of distributions. Moreover, the pressure* $p \in L^1((0,T)\times\Omega)$ *is related to the state variables* ρ, ρ_1, *and* θ *through the constitutive equation* (1.8), *the viscous stress tensor* $\mathbb{S} \in L^1(0,T; L^1(\Omega;\mathbb{R}^{3\times3}))$ *is given by Newton's law of viscosity* (1.4), *while*

$$\rho\mathbf{u}\otimes\mathbf{u} \in L^1(0,T; L^1(\Omega;\mathbb{R}^{3\times3})).$$

• *The entropy* ρs *is determined by the formula* (1.21). *The density of the individual component* ρ_1 *as well as the absolute temperature are positive a.a. on* $(0,T)\times\Omega$, *and the integral inequality*

$$\begin{aligned}&\int_0^T\int_\Omega \{(\rho s)\,\partial_t\phi + (\rho s)\mathbf{u}\cdot\nabla\phi + \mathbf{q}\cdot\nabla\phi\}\,dxdt\\ &\leq \int_0^T\int_\Omega \left\{-\frac{\mathbb{S}:\nabla\mathbf{u}}{\theta} - \frac{k(\theta)|\nabla\theta|^2}{\theta^2} - Ld|\nabla\log(\rho_1\theta)|^2 - \sum_{i=1}^2 \rho g_i w_i\right\}\phi\,dx\,dt\end{aligned} \tag{2.4}$$

holds for any nonnegative function $\varphi \in \mathcal{D}((0,T)\times\mathbb{R}^N)$.

Moreover,

$$\operatorname*{ess\,lim}_{t\to 0+} \int_\Omega \rho s(t)\,\phi\,dx \geq \int_\Omega \rho_0 s_0\,\phi\,dx \ \ \textit{for any nonnegative } \phi \in \mathcal{D}(\Omega),$$

where

$$\begin{aligned}\rho_0 s_0 = {}& \frac{4a}{3}\theta_0^3 + \frac{c_v}{m_2}\rho_0\log(\theta_0) - \rho_0 P_\theta(\rho_0) + Mc_v\rho_{1_0}\log(\theta_0)\\ & - MR\rho_{1_0}P_\theta(\rho_{1_0}) - MR\rho_{1_0}\log(\rho_{1_0}).\end{aligned}$$

• *As there is no flux of energy through the kinematic boundary we require the* total energy $E(t)$ *to be constant of motion, that is,*

$$\int_0^T\int_\Omega E(t)\,\partial_t\psi\,dx\,dt = 0 \quad \textit{for any} \quad \psi\in\mathcal{D}(0,T). \tag{2.5}$$

• *The functions* $\rho, \rho\,\mathbf{u}, \rho\,\theta$, *and* ρ_1 *satisfy the initial conditions* (1.30) *in the weak sense,*

$$\begin{cases}\operatorname*{ess\,lim}_{t\to 0+}\displaystyle\int_\Omega \rho(t)\,\eta\,dx = \int_\Omega \rho_0\,\eta\,dx,\\ \operatorname*{ess\,lim}_{t\to 0+}\displaystyle\int_\Omega (\rho\,\mathbf{u})(t)\cdot\nu\,dx = \int_\Omega \mathbf{m}_0\cdot\nu\,dx,\\ \operatorname*{ess\,lim}_{t\to 0+}\displaystyle\int_\Omega (\rho\,\theta)(t)\,\eta dx = \int_\Omega \rho_0\,\theta_0\,\eta\,dx,\\ \operatorname*{ess\,lim}_{t\to 0+}\displaystyle\int_\Omega \rho_1(t)\,\eta\,dx = \int_\Omega \rho_{1_0}\,\eta\,dx\end{cases} \tag{2.6}$$

for all $\eta\in\mathcal{D}(\Omega)$.

2.3. Assumptions.

Pressure. The pressure p obeys the general pressure law (1.8), where the *elastic* pressure p_e and the *thermal* pressure p_θ are continuously differentiable functions of the density and in addition satisfy the properties (see also [20], [12], [13])

$$\begin{cases}p_e(0)=0,\\ p_e'(\rho)\geq a_1\rho^{\gamma-1}-c_1, \quad a_1>0,\\ p_e(\rho)\leq a_2\rho^\gamma + c_2,\end{cases} \qquad \begin{cases}p_\theta(0)=0,\\ p_\theta'(\rho)\geq 0,\\ p_\theta(\rho)\leq a_3\rho^G + c_3\end{cases} \tag{2.7}$$

with

$$\gamma\geq 2, \quad \gamma > \frac{4G}{3}.$$

Transport coefficients.

• The *viscosity parameters* depend on the absolute temperature in the following fashion:

$$\begin{cases}0<\underline{\mu}(1+\theta^\alpha)\leq\mu(\theta)\leq\bar{\mu}(1+\theta^\alpha),\\ 0<\underline{\zeta}\theta^\alpha\leq\zeta(\theta)\leq\bar{\zeta}(1+\theta^\alpha)\end{cases} \tag{2.8}$$

for $\alpha\geq\frac{1}{2}$.

• The *heat conductivity* obeys the rule

$$\begin{cases} k = k_C(\theta) + \sigma\theta^3, \\ 0 < \underline{k}_C \le k_C(\theta) \le \bar{k}_C(1+\theta^3), \end{cases} \tag{2.9}$$

where the term $\{\sigma\theta^3\}$ with $\sigma > 0$ accounts for the *radiative* effects.

3. Main results. We are now ready to state the existence result for the initial boundary value problem introduced in section 1.

THEOREM 3.1. *Let $\Omega \subset \mathbb{R}^3$ be a bounded domain with a boundary $\partial\Omega \in C^{2+\nu}, \nu > 0$. Suppose that the pressure p is determined by the equation of state* (1.21) *with $a > 0$ and p_e and p_θ satisfying* (1.8)*. In addition, let the viscous stress tensor $\mathbb{S}$ be given by* (1.4)*, where μ and ζ are continuous differentiable globally Lipschitz functions of θ satisfying* (2.8)*. Similarly, let the heat flux $\mathbf{q}$ be given by* (1.14) *with $k(\theta)$ satisfying* (2.9)*. Finally, assume that the initial data $\rho_0, \mathbf{m}_0, \theta_0, \rho_{1_0}$ satisfy*

$$\begin{cases} \rho_0 \ge 0,\ \rho_0 \in L^\gamma(\Omega), \\ \mathbf{m}_0 \in [L^1(\Omega)]^3,\ \frac{|\mathbf{m}_0|^2}{\rho_0} \in L^1(\Omega), \\ \theta_0 \in L^\infty(\Omega),\ 0 < \underline{\theta} \le \theta_0(x) \le \bar{\theta} \text{ for a.e. } x \in \Omega, \\ \rho_{1_0} \ge 0,\ \rho_{1_0} \in L^\gamma(\Omega). \end{cases} \tag{3.1}$$

Then, for any given $T > 0$ the initial boundary value problem (1.1)–(1.4)*, together with* (1.27)–(1.30) *and* (1.31)*, has a variational solution on $(0,T) \times \Omega$.*

In the remaining part of this paper we will carry out the strategy outlined in the introduction. The proof of this theorem will be given in detail in sections 4, 5, 6, and 7.

4. Solvability of approximating problems. In this section we construct a sequence of approximate problems by adding appropriate regularizations in (1.23)–(1.26).

Taking into account (2.7), the elastic pressure component $p_e(\rho)$ of the pressure can be decomposed in two parts p_m and p_b:

$$p_e(\rho) = p_m(\rho) + p_b(\rho),$$

where the former p_m is a nondecreasing function, the latter p_b is a bounded function on $[0,\infty)$, while both are elements in $C([0,\infty))$ (see also [14], [13]). The reason for this decomposition will be apparent in what follows, where the properties of the two components will be instrumental in obtaining useful *energy* and *entropy* estimates.

4.1. Faedo–Galerkin approximations. Let

$$X_n = \operatorname{span}\{\eta_j\}_{j=1}^n$$

be a finite-dimensional space with $\eta_j \in \mathcal{D}(\Omega;\mathbb{R}^3)$, $j = 1,2,\ldots,$ a dense subset in $C_0^1(\bar{\Omega};\mathbb{R}^3)$.

The approximate velocities $\mathbf{u}_n \in C([0,T];X_n)$ satisfy a set of integral equations of the form

$$\begin{aligned} \int_\Omega \rho\mathbf{u}_n(\tau)\cdot\eta\,dx - \int_\Omega \mathbf{m}_{0,\delta}\cdot\eta &= \int_0^\tau\int_\Omega (\rho\mathbf{u}_n\otimes\mathbf{u}_n - \mathbb{S}_n) : \nabla\eta\,dxdt \\ &+ \int_0^\tau\int_\Omega \left(p_m(\rho) + p_m(\rho_1) + \frac{a}{3}\theta^4 + \frac{R}{m_2}\theta p_\theta(\rho) + LR\theta p_\theta(\rho_1) + \delta\rho^\beta\right)\operatorname{div}\eta\,dxdt \\ &+ \int_0^\tau\int_\Omega [p_b(\rho) + p_b(\rho_1)]\operatorname{div}\eta - \varepsilon[\nabla\mathbf{u}_n\nabla\rho]\cdot\eta\,dxdt \end{aligned} \tag{4.1}$$

for any test function $\eta \in X_n = \operatorname{span}\{\eta_j\}_{j=1}^n$, $\eta_j \in \mathcal{D}(\Omega)^N$, and all $\tau \in [0,T]$.

Having replaced the momentum equation with a family of integral relations, we are ready to introduce a sequence of approximate problems obtained by adding appropriate regularization ε- and δ-terms to the set of original partial differential equations. The addition of these extra terms yields a new set of equations which are easier to solve assuming that ε and δ are fixed. The challenge in this approach arises in passing to the limit for $\varepsilon \to 0$ and $\delta \to 0$. The sequence of approximate problems is presented below.

Modified continuity equation. The density $\rho = \rho[\mathbf{u}_n]$ is determined as the (unique) solution of the initial boundary value problem

$$\begin{cases} \partial_t \rho + \operatorname{div}(\rho \mathbf{u}_n) = \varepsilon \Delta \rho, \\ \quad \nabla \rho \cdot \mathbf{n}|_{\partial\Omega} = 0, \\ \quad \rho(0,\cdot) = \rho_{0,\delta} \end{cases} \tag{4.2}$$

with the initial approximation of the density $\rho_{0,\delta} \in C^{2+\nu}(\bar{\Omega})$ also satisfying

$$\begin{cases} 0 < \delta \le \rho_{0,\delta} \le \delta^{-\frac{1}{2\beta}} \quad \text{on} \quad \Omega, \\ \rho_{0,\delta} \to \rho_0 \quad \text{in} \quad L^\gamma(\Omega), \quad |\{\rho_{0,\delta} < \rho_0\}| \to 0 \quad \text{for} \quad \delta \to 0. \end{cases}$$

With the aid of the *maximum principle* the problem (4.2) admits the a priori estimate

$$\begin{aligned} &\left(\inf_{x\in\Omega} \rho(0,x) \right) \exp\left(- \int_0^t \|\operatorname{div}\mathbf{u}_n(s)\|_{L^\infty(\Omega)}\, ds \right) \\ &\quad \le \rho(t,x) \\ &\quad \le \left(\sup_{x\in\Omega} \rho(0,x) \right) \exp\left(\int_0^t \|\operatorname{div}\mathbf{u}_n(s)\|_{L^\infty(\Omega)}\, ds \right); \end{aligned}$$

in particular the (approximate) density of the mixture has positive lower and upper bounds provided that we have control of the norm of $\{\operatorname{div}\mathbf{u}_n\}$.

For fixed ε, the solvability of the regularized problem for the continuity equation (4.2) is obtained by a simple fixed point argument (see [20]).

Modified thermal equation. Now, given $\rho, \mathbf{u}_n$, the temperature will be viewed as a solution of the regularized thermal energy equation in $(0,T) \times \Omega$ supplemented with boundary and initial conditions as follows:

(4.3)

$$\begin{cases} \partial_t \left[a\theta^4 + \frac{c_v}{m_2}\rho\theta + LR\rho_1\theta + \rho_1 P_e(\rho_1) \right] + \operatorname{div}\left[\left(a\theta^4 + \frac{c_v}{m_2}\rho\theta + L\rho_1\theta + \rho_1 P_e(\rho_1) \right) \mathbf{u}_n \right] \\ -\operatorname{div}\left[(\kappa_C(\rho,\theta) + \delta\theta^3)\nabla\theta + \frac{9\gamma-5}{4} Ld\theta \nabla \log(\rho_1\theta) \right] = \varepsilon |\nabla\rho|^2 \left(\frac{p_m'(\rho)}{\rho} + \delta\beta\rho^{\beta-2} \right) \\ + \mathbb{S}_n : \nabla\mathbf{u}_n - \left[\frac{a}{3}\theta^4 + \frac{R}{m_2}\theta p_\theta(\rho) + L\theta p_e(\rho_1) + p_e(\rho_1) \right] \operatorname{div}\mathbf{u}_n - \sum_{i=1}^2 h_i w_i, \end{cases}$$

$$\begin{aligned} &\nabla\theta \cdot \mathbf{n}|_{\partial\Omega} = 0, \\ &\theta(0,\cdot) = \theta_{0,\delta}. \end{aligned}$$

The functions $\theta_{0,\delta} \in C^{2+\nu}(\bar{\Omega})$ satisfy in addition

$$\begin{cases} \nabla\theta_{0,\delta} \cdot \mathbf{n}|_{\partial\Omega} = 0, \quad 0 < \underline{\theta} < \theta_{0,\delta} \le \bar{\theta} \quad \text{on} \quad \Omega, \\ \theta_{0,\delta} \to \theta_0 \quad \text{in} \quad L^1(\Omega) \quad \delta \to 0. \end{cases}$$

The viscous stress tensor $\mathbb{S}_n$ is given by

$$\mathbb{S}_n = \mu(\theta)\left(\nabla \mathbf{u}_n + \nabla \mathbf{u}_n{}^T - \frac{2}{3}\mathrm{div}\mathbf{u}_n\,\mathbb{I}\right) + \zeta(\theta)\,\mathrm{div}\mathbf{u}_n\,\mathbb{I}.$$

The modified thermal equation (4.3) is a nondegenerate parabolic equation with respect to $U = \theta^4$ with sublinear coefficients, and hence the existence of the solution temperature θ_n follows easily (we refer the reader also to [12], [13], [14], [26], where relevant equations were treated).

By applying the classical maximum principle argument we can conclude that the temperature $\theta = \theta(t,x)$ is strictly positive, namely,

$$\theta(t,x) \geq \bar{C} > 0 \quad \text{for } t \in [0,T], x \in \Omega.$$

We can therefore divide the modified thermal energy equation by θ in order to obtain the approximate entropy balance,

$$\begin{aligned}
&\partial_t(\rho s) + \mathrm{div}(\rho s \mathbf{u}_n) + \mathrm{div}\left(-\frac{\kappa_C(\theta_n) + \delta\theta^3}{\theta}\nabla\theta - s_{f_1} L d \nabla \log(\rho_1\theta)\right) \\
&\quad = \left(\frac{\mathbb{S}_n : \nabla \mathbf{u}_n}{\theta} + \frac{\kappa_C(\theta) + \delta\theta^3}{\theta^2}|\nabla\theta|^2 + Ld|\nabla\log(\rho_1\theta)|^2 - \sum_{k=1}^{2} g_k w_k\right) \\
&\qquad + \frac{\varepsilon\delta\Gamma}{\theta}\rho^{\Gamma-2}|\nabla\rho|^2 + \frac{c_v}{m_2}(\log(\theta_n) - 1)(\varepsilon\Delta\rho_n + w_1(\rho_1,\rho_2,\theta) - \varepsilon\Delta\rho_{1_n}).
\end{aligned} \tag{4.4}$$

Modified species conservation equation. The regularized species conservation equation is now given as

$$\begin{cases}
\partial_t(\rho_1) + \mathrm{div}(\rho_1\mathbf{u}_n) = \varepsilon\Delta\rho_1 + w_1(\rho_1,\rho_2,\theta) + \mathrm{div}(d\nabla\log(\rho_1\theta)), \\
\nabla\rho_1 \cdot \mathbf{n}|_{\partial\Omega} = 0, \\
\rho_1(0,\cdot) = \rho_{1_{0,\delta}}.
\end{cases} \tag{4.5}$$

In accordance with physical considerations, we require that the density of the individual component be less than the total density of the mixture, namely,

$$\rho_1 = \rho f_1 \leq \rho.$$

This property will be used in what follows to improve the time integrability of certain terms such as $\{\rho_1\mathbf{u}\}, \{\rho_1\log(\theta)\mathbf{u}\}$.

Finally, the initial approximations of the mass fraction of the reactant $\rho_{1_{0,\delta}} \in C^{2+\nu}(\bar{\Omega})$ satisfy

$$\begin{cases}
\nabla\rho_{1_{0,\delta}} \cdot \mathbf{n}|_{\partial\Omega} = 0, \quad 0 \leq \rho_{1_{0,\delta}} \leq \rho_0 \quad \text{on} \quad \Omega, \\
\rho_{1_{0,\delta}} \to \rho_{1_0} \quad \text{in} \quad L^1(\Omega) \quad \delta \to 0.
\end{cases}$$

The regularized species conservation equation (4.5) is a parabolic quasi-linear equation. Applying standard techniques [17], [26] one can deduce the existence of solutions (see [20], [12], [13]). Finally, the solvability of the regularized momentum equation is given by the Faedo–Galerkin method, with ρ, θ, ρ_1 obtained from (4.2), (4.3), (4.5).

We remark that an important consideration in the above construction is the necessity of keeping the total energy constant at each step of the approximation. The addition of the artificial pressure $\{\delta\rho^{\beta-2}\}$ terms, on the other hand, is essential in ensuring that the pressure estimates hold true even as the artificial viscosity vanishes and in resolving some technical issues related to temperature estimates.

This approach yields for any fixed $n = 1, 2, \ldots$ a sequence of approximate solutions $\{\rho_n, \mathbf{u}_n, \theta_n, \rho_{1_n}\}$ for the system (4.2)–(4.5) defined on the whole time interval $(0, T)$.

5. The second-level approximate solutions. Relation (4.1) can now be expressed as

$$\begin{aligned}\int_\Omega \partial_t(\rho_n\mathbf{u}_n)\cdot\eta\,dx &= \int_\Omega [\rho\mathbf{u}_n\otimes\mathbf{u}_n - \mathbb{S}_n] : \nabla\eta\,dx \\ &\quad + \int_\Omega \left[p_m(\rho) + p_m(\rho_1) + \frac{a}{3}\theta^4 + \frac{R}{m_2}\theta p_\theta(\rho) \right. \\ &\qquad \left. + L\theta p_\theta(\rho_1) + \delta\rho^\beta\right]\mathrm{div}\eta\,dx \\ &\quad + \int_\Omega \{[p_b(\rho) + p_b(\rho_1)]\mathrm{div}\eta - \varepsilon[\nabla\mathbf{u}_n\nabla\rho]\cdot\eta\}\,dx, \end{aligned} \tag{5.1}$$

supplemented with the initial conditions

$$\int_\Omega \rho_n\mathbf{u}_n\cdot\eta\,dx = \int_\Omega \mathbf{m}_{0,\delta}\cdot\eta\,dx$$

to be satisfied for any $\eta \in X_n$ with the initial momenta $\mathbf{m}_{0,\delta}$ given by

$$\mathbf{m}_{0,\delta}(x) = \begin{cases}\mathbf{m}_0 & \text{if} \quad \rho_{0,\delta}(x) \geq \rho_0(x), \\ 0 & \text{for} \quad \rho_{0,\delta}(x) < \rho_0(x).\end{cases}$$

5.1. Energy and entropy estimates. The existence of the approximate solution sequence $\{\rho_n, \mathbf{u}_n, \theta_n, \rho_{1_n}\}$ has now been established and we are ready to proceed with the program outlined in section 4.

Considering a suitable choice of test functions $\eta = \mathbf{u}_n(t)$ in (4.1), integrating in space both the (regularized) thermal energy equation (4.3) and the species conservation equation (4.5), and adding the resulting relations give rise to an energy equality of the form

$$\begin{aligned}&\frac{d}{dt}\int_\Omega \left[\frac{1}{2}\rho_n|\mathbf{u}_n|^2 + \rho_n P_m(\rho_n) + \rho_{1_n}P_e(\rho_{1_n}) + \frac{\delta}{\beta-1}\rho_n^\beta + a\theta_n^4 + \frac{c_v}{m_2}\rho_n\theta_n + Lc_v\rho_{1_n}\theta\right]dx \\ &\quad = \int_\Omega [p_b(\rho_n) + p_b(\rho_{1_n})]\mathrm{div}\mathbf{u}_n dx + \int_\Omega w_1(\rho_1,\rho_2,\theta)dx - \varepsilon\int_\Omega \Delta\rho_{1_n}dx\end{aligned} \tag{5.2}$$

with

$$P_m(\rho) = \int_1^\rho \frac{p_m(z)}{z^2}dz.$$

The approximate entropy balance (4.4) now yields the entropy inequality

$$\begin{aligned}&\partial_t(\rho_n s_n) + \mathrm{div}(\rho_n s_n\mathbf{u}_n) + \mathrm{div}\left(-\frac{\kappa_C(\theta_n) + \delta\theta_n^3}{\theta_n}\nabla\theta_n - s_{f_{1_n}}Ld\nabla\log(\rho_{1_n}\theta_n)\right) \\ &\qquad \geq \left(\frac{\mathbb{S}_n : \nabla\mathbf{u}_n}{\theta_n} + \frac{\kappa_C(\theta_n) + \delta\theta_n^3}{\theta_n^2}|\nabla\theta_n|^2 + Ld|\nabla\log(\rho_{1_n}\theta_n)|^2 - \sum_{k=1}^2 g_k w_k\right) \\ &\qquad + \frac{c_v}{m_2}(\log(\theta_n) - 1)\left(\varepsilon\Delta\rho_n + w_1(\rho_1,\rho_2,\theta) - \varepsilon\Delta\rho_{1n}\right).\end{aligned} \tag{5.3}$$

The regularized continuity equation (4.2) multiplied by ρ_n and integrated over Ω yields

$$\frac{d}{dt}\int_\Omega \frac{1}{2}\rho_n^2 dx + \varepsilon \int_\Omega |\nabla \rho_n|^2 dx = -\frac{1}{2}\int_\Omega \rho_n^2 \mathrm{div}\mathbf{u}_n dx. \tag{5.4}$$

Now (5.2), (5.3), (5.4) give rise to

$$\begin{aligned}
&\frac{d}{dt}\int_\Omega \bigg[\frac{1}{2}\rho_n|\mathbf{u}_n|^2 + \rho_n P_m(\rho_n) + \rho_{1_n} P_m(\rho_{1_n}) + \frac{\delta}{\beta-1}\rho_n^\beta \\
&\qquad + a\theta_n^4 + \frac{c_v}{m_2}\rho_n\theta_n + Lc_v\rho_{1_n}\theta_n\bigg] dx \\
&\quad + \frac{d}{dt}\int_\Omega \left(\frac{1}{2}\rho_n^2 - \rho_n(s_{F_n} + s_{f_{1_n}}) + \rho_{1n} + \varepsilon|\nabla\rho_n|^2 + \varepsilon\Delta\rho_{1n}\right) dx \\
&\quad + \int_\Omega \left(\frac{\mathbb{S}_n : \nabla\mathbf{u}_n}{\theta_n} + \frac{\kappa_C(\theta_n) + \delta\theta_n^3}{\theta_n^2}|\nabla\theta_n|^2 + Kd|\nabla\log(\rho_{1_n}\theta_n)|^2 - \sum_{k=1}^2 g_k w_k\right) dx \\
&\le \int_\Omega \left(p_b(\rho_n) + p_b(\rho_{1_n}) - \frac{1}{2}\rho_n^2\right)\mathrm{div}\mathbf{u}_n dx + \int_\Omega \frac{c_v}{m_2}(\log(\theta_n) - 1) w_1(\rho_1,\rho_2,\theta) dx \\
&\quad + \varepsilon\int_\Omega \frac{c_v}{m_2}\left(\nabla\log(\theta_n)\nabla\rho_n + (\log(\theta_n)-1)\Delta\rho_{1n}\right) dx.
\end{aligned} \tag{5.5}$$

5.2. Dissipation estimates. Starting from *Newton's law for viscosity* and using the hypotheses (2.8) on viscosity coefficients and Hölder's inequality, we deduce (see also [14], [13]) that

$$|\nabla\mathbf{u}_n + \nabla\mathbf{u}_n^t|^b \le c\left(\theta_n^{\alpha-1}|\nabla\mathbf{u}_n + \nabla\mathbf{u}_n^t|^2 + \theta_n^4\right), \quad \text{where } b = \frac{8}{5-\alpha}. \tag{5.6}$$

Moreover, the hypothesis (2.9) on the *heat conductivity* gives us the following bounds on the *absolute temperature*:

$$\int_\Omega |\nabla\log(\theta_n)|^2 + |\nabla\theta_n^{\frac{3}{2}}|^2 dx \le \int_\Omega \frac{\kappa_C(\theta_n) + \sigma\theta_n^3}{\theta_n^2}|\nabla\theta_n|^2 dx. \tag{5.7}$$

As stated in Definition 2.1 the total energy is constant of motion. Boundness of the total energy and properties (2.7) give rise to the following estimates:

$$\begin{aligned}
\sqrt{\rho_n}|\mathbf{u}_n| &\quad \text{bounded in} \quad L^\infty(0,T;L^2(\Omega)),\\
\rho_n &\quad \text{bounded in} \quad L^\infty(0,T;L^\beta(\Omega)),\\
\rho_{1n} &\quad \text{bounded in} \quad L^\infty(0,T;L^\beta(\Omega)),
\end{aligned}$$

and

$$\operatorname*{ess\,sup}_{t\in(0,T)}\int_\Omega \theta_n^4(t)\, dx \le c.$$

In addition, taking into consideration (5.5), (5.6), and (5.7) we get the following estimates:

$$\sup_{t\in[0,T]}\left\{\|\rho_n\|_{L^\beta(\Omega)}+\|\rho_n|\mathbf{u}_n|^2\|_{L^1(\Omega)}+\|\rho_n\theta_n\|_{L^1(\Omega)}+\|\rho_{1_n}\|_{L^\beta(\Omega)}\right\}\le c(\delta), \tag{5.8}$$

$$\sup_{t\in[0,T]}\left\{\|\log(\theta_n)\|_{L^1(\Omega)}+\|\rho_n\log(\theta_n)\|_{L^1(\Omega)}+\|\theta_n\|_{L^4(\Omega)}\right\}\le c(\delta), \tag{5.9}$$

$$\sup_{t\in[0,T]}\left\{\|\rho_{1_n}\log(\theta_n)\|_{L^1(\Omega)}+\|\rho_{1_n}\theta_n\|_{L^1(\Omega)}+\|\rho_{1_n}\log(\rho_{1_n})\|_{L^1(\Omega)}\right\}\le c(\delta), \tag{5.10}$$

$$\int_0^T\!\!\int_\Omega \frac{\mathbb{S}_n:\nabla\mathbf{u}_n}{\theta_n}+|\nabla\log(\theta_n)|^2+|\nabla\theta_n^{\frac{3}{2}}|^2+\varepsilon|\nabla\rho_n|^2+||\nabla\log(\rho_{1_n}\theta_n)|^2|dxdt\le c(\delta), \tag{5.11}$$

and

$$\|\mathbf{u}_n\|_{L^b(0,T;W_0^{1,b}(\Omega))}\le c(\delta)\quad \text{with } b=\frac{8}{5-\alpha}. \tag{5.12}$$

LEMMA 5.1. *For the density of the individual species ρ_{1_n}, the following hold true:*

$$\begin{cases}\log(\rho_{1_n}) & \textit{is bounded in}\quad L^2([0,T];W^{1,2}(\Omega)),\\ \varepsilon\nabla\sqrt{\rho_{1_n}} & \textit{is bounded in}\quad L^2([0,T];L^2(\Omega)).\end{cases} \tag{5.13}$$

Proof. Multiplying the regularized species conservation equations by $F'(\rho_{1_n})$ with $F(\rho_{1_n})=\rho_{1_n}\log(\rho_{1_n})$ and using the boundary conditions, we obtain

$$\begin{aligned}&\int_\Omega F(\rho_{1_n})(t)\,dx+\int_0^t\int_\Omega|\nabla\log(\rho_{1_n})|^2\,dxds+\varepsilon\int_0^t\int_\Omega\frac{|\nabla\rho_{1_n}|^2}{\rho_{1_n}}\,dxdt\\ &\qquad=\int_\Omega F(\rho_{1_n})(0)\,dx-\int_0^t\int_\Omega\rho_{1_n}\mathrm{div}\mathbf{u}_n\,dxds\\ &\qquad\quad-\int_0^t\int_\Omega\nabla\log(\rho_{1_n})\nabla\log(\theta_n)\,dx\,ds-\int_0^t\int_\Omega F'(\rho_{1_n})\omega\,dxdt.\end{aligned}$$

The last relation implies that

$$\begin{aligned}&\int_\Omega\rho_{1_n}\,\log(\rho_{1_n})(t)\,dx+c\int_0^t\int_\Omega|\nabla\log(\rho_{1_n})|^2\,dxds+\varepsilon\int_0^t\int_\Omega|\nabla\sqrt{\rho_{1_n}}|^2\,dxds\\ &\le\int_\Omega\rho_{1_n}\,\log(\rho_{1_n})(0)\,dx+\int_0^t\int_\Omega\rho_{1_n}\,\mathrm{div}\mathbf{u}_n\,dxds+\tilde{c}\int_0^t\int_\Omega|\nabla\log(\theta_n)|^2dxds\\ &\quad-\int_0^t\int_\Omega(\log(\rho_{1_n})+1)\omega\,dxds.\end{aligned}$$

The term

$$\int_0^t\int_\Omega|\nabla\log(\theta_n)|^2\,dxds$$

can be controlled using the estimates (5.11), whereas the term

$$\int_0^t\int_\Omega\rho_{1_n}\,\mathrm{div}\mathbf{u}_n\,dxds\le\|\rho_{1_n}\|_{L^2(\Omega)}\|\mathrm{div}\mathbf{u}\|_{L^2(\Omega)}$$

can be balanced using (5.8) and (5.12).

Therefore,

$$\begin{aligned} \int_\Omega \rho_{1_n} \log(\rho_{1_n})(t)\,dx + c\int_0^t \int_\Omega |\nabla \log(\rho_{1_n})|^2\,dxds + \varepsilon \int_0^t \int_\Omega |\nabla\sqrt{\rho_{1_n}}|^2\,dxdt \\ \le \int_\Omega \rho_{1_n} \log(\rho_{1_n})(0)\,dx + c_2, \end{aligned} \tag{5.14}$$

or equivalently

$$\begin{aligned} \|\rho_{1_n}\log(\rho_{1_n})(t)\|_{L^1(\Omega)} + c_1\int_0^t \|\nabla\log(\rho_{1_n})\|^2_{L^2(\Omega)}\,dt + \int_0^t \|\nabla\sqrt{\rho_{1_n}}\|^2_{L^2(\Omega)}\,dt \\ \le \|\rho_{1_n}\log(\rho_{1_n})(0)\|_{L^1(\Omega)} + c_2. \end{aligned}$$

This estimate yields the result. □

Starting from the continuity equation and taking into consideration standard compactness arguments by the aid of (5.8)–(5.12), we get

$$\rho_n \longrightarrow \rho \quad \text{in } C([0,T], L^\beta_{weak}(\Omega)),$$

and analogously

$$\rho_{1_n} \longrightarrow \rho_1 \quad \text{in } C([0,T], L^\beta_{weak}(\Omega)).$$

By using the estimates obtained in the previous steps we can assume

$$\mathbf{u}_n \longrightarrow \mathbf{u} \quad \text{weakly in } L^b(0,T;W_0^{1,b}(\Omega)),$$

$$\rho_n\mathbf{u}_n \longrightarrow \rho\mathbf{u} \quad \text{weakly-}^* \text{ in } L^\infty(0,T;L^{\frac{2\beta}{\beta+1}}(\Omega)),$$

where ρ, $\mathbf{u}$ satisfy (4.2) together in the sense of distribution. Taking now into account that the species density ρ_{1_n} is a nonnegative function satisfying the additional requirement $\rho_{1_n} \le \rho_n$ we have that

$$\int_0^t \int_\Omega \rho_{1_n}|\mathbf{u}_n|^2\,dxdt \le \int_0^t \int_\Omega \rho_n|\mathbf{u}_n|^2\,dxdt < C < \infty$$

by the boundness of the total energy. In particular,

$$\rho_{1_n}\mathbf{u}_n \longrightarrow \rho_1\mathbf{u} \quad \text{weakly-}^* \text{ in } L^\infty(0,T;L^{\frac{2\beta}{\beta+1}}(\Omega)),$$

where ρ_{1_n}, $\mathbf{u}$ satisfy the regularized species conservation equation (4.5). It is also worth noting at this point that *weak convergence preserves inequalities*, and therefore the requirement that we imposed in the construction of the approximating procedure leading to the estimate satisfied by the approximate densities, namely,

$$0 \le \rho_{1_n} \le \rho_n$$

will also be verified in what follows for the corresponding limiting quantities.

5.3. Gradient density estimate. Using standard $L^p - L^q$ estimates for the regularized continuity equation (4.2) and taking into consideration (5.8)–(5.12), we get, in the spirit of Feireisl [20],

$$\varepsilon^p \int_0^T \|\nabla \rho_n\|_{L^{\frac{2\beta}{\beta+1}}(\Omega);\mathbb{R}^3} dt \leq c(\delta, p) \quad \text{for any} \quad p \in [1, \infty).$$

Using now the Sobolev embedding theorem $W_0^{1,r}(\Omega) \subset L^{\frac{3r}{3-r}}(\Omega)$ and standard interpolation estimates, we get

$$\varepsilon \|\nabla \rho_n\|_{L^q(0,T;L^q(\Omega;\mathbb{R}^3))} \quad \text{for some} \quad q > r' \quad \text{with} \quad r = \frac{8}{5-\alpha}.$$

In fact, one can improve the estimates on ρ_n at this point using the L^p-theory of parabolic equations to obtain the following lemma.

LEMMA 5.2. *There exists $p > 1$ such that*

$$\partial_t \rho_n, \ \Delta \rho_n \quad \textit{are bounded in } L^p((0,T) \times \Omega),\ p > 1,$$

independently of n. Consequently, the limit functions ρ, $\mathbf{u}$ satisfy (4.2) a.e. on $(0,T) \times \Omega$, whereas the boundary condition and initial condition hold in the sense of traces.

Proof. The result is obtained by applying the L^p-theory of parabolic equations. This process is rather standard; we included above some of the basic steps for completeness and refer the reader to [20], [22], [14], [26]. $\square$

Similarly, the following lemma holds true.

LEMMA 5.3. *There exists $p > 1$ such that*

$$\partial_t \rho_{1_n}, \ \Delta \rho_{1_n} \quad \textit{are bounded in } L^p((0,T) \times \Omega),\ p > 1,$$

independently of n. Consequently, the limit functions ρ_1, $\mathbf{u}$ satisfy (4.5) a.e. on $(0,T) \times \Omega$, whereas the boundary condition and initial condition hold in the sense of traces.

The following lemma will be useful in order to obtain the pointwise convergence of the temperature sequence θ_n.

LEMMA 5.4. *Let $\Omega \subset \mathbb{R}^N$, $N \geq 2$, be a bounded Lipschitz domain and $\Lambda \geq 1$ a given constant. Let $\rho \geq 0$ be a measurable function satisfying*

$$0 < M \leq \int_\Omega \rho dx, \quad \int_\Omega \rho^\beta \leq K \quad \textit{for} \quad \beta > \frac{2N}{N+2}.$$

Then there exists a constant $c = c(M,K)$ such that

$$\|v\|_{L^2(\Omega)} \leq c(M,K) \left(\|\nabla v\|_{L^2(\Omega)} + \left(\int_\Omega \rho |v|^{\frac{1}{\Lambda}} \right)^\Lambda \right)$$

for any $v \in W^{1,2}(\Omega)$.

Proof. For the proof we refer the reader to Lemma 5.1 in [14]. $\square$

Using the Poincaré inequality, as presented in Lemma 5.4, as well as the estimates on $\{\nabla \log(\theta_n)\}, \{\nabla \theta_n^{\frac{3}{2}}\}$ in (5.11), we deduce uniform bounds on $\log(\theta)$ and $\theta^{\frac{3}{2}}$. Therefore, it is possible to extract a subsequence of θ_n such that

$$\begin{cases} \theta_n \longrightarrow \theta \quad \text{weakly in} \quad L^2(0,T;W^{1,2}(\Omega)), \\ \theta_n \longrightarrow \theta \quad \text{weakly-* in} \quad L^\infty(0,T;L^4(\Omega)), \\ \log(\theta_n) \longrightarrow \overline{\log(\theta)} \quad \text{weakly in} \quad L^2(0,T;W^{1,2}(\Omega)). \end{cases} \tag{5.15}$$

Using now the fact that $\{\rho_n \log(\theta_n), \rho_{1_n} \log(\theta_n)\}$ satisfy the entropy inequality (5.3), we deduce that

$$\begin{cases} \rho_n \log(\theta_n) & \text{bounded in } L^\infty(0,T;L^1(\Omega)) \cap L^2(0,T;L^{\frac{6\beta}{\beta+6}}(\Omega)), \\ \rho_n \mathbf{u}_n \log(\theta_n) & \text{bounded in } L^2(0,T;L^{\frac{6\beta}{4\beta+3}}(\Omega)) \end{cases}$$

and

$$\begin{cases} \rho_{1_n} \log(\theta_n) & \text{bounded in } L^\infty(0,T;L^1(\Omega)) \cap L^2(0,T;L^{\frac{6\beta}{\beta+6}}(\Omega)), \\ \rho_{1_n} \mathbf{u}_n \log(\theta_n) & \text{bounded in } L^2(0,T;L^{\frac{6\beta}{4\beta+3}}(\Omega)). \end{cases}$$

5.4. Pointwise convergence for the temperature. The following lemma will be very useful in what follows.

LEMMA 5.5. *Let $\Omega \subset \mathbb{R}^N$, $N \geq 2$, be a bounded Lipschitz domain. Let $\{v_n\}$ be a sequence of functions bounded in*

$$L^2(0,T;L^q(\Omega)) \cap L^\infty(0,T;L^1(\Omega)), \quad q > \frac{2N}{N+2}.$$

Furthermore, assume that

$$\partial_t v_n \geq g_n \quad in \quad \mathcal{D}'((0,T)\times\Omega),$$

where the distributions g_n are bounded in the space $L^1(0,T;W^{-m,p}(\Omega))$ for $m \geq 1$, $p > 1$. Then

$$v_n \longrightarrow v \quad in\ L^2(0,T;W^{-1,2}(\Omega))$$

passing to a subsequence as the case may be.

Proof. The proof is given in Lemma 6.3 of Chapter 6 in [20]. $\square$

By a direct application of Lemma 5.5 to the sequence

$$\left\{ \frac{4a}{3}\theta^3 + \frac{c_v}{m_2}\rho_n \log(\theta_n) + Lc_v\rho_{1_n}\log(\theta_n) \right\},$$

we get

$$\begin{cases} \frac{4a}{3}\theta^3 + \frac{c_v}{m_2}\rho_n \log(\theta_n) + Lc_v\rho_{1_n}\log(\theta_n) \\ \qquad\qquad\qquad \downarrow \\ \frac{4a}{3}\bar{\theta}3 + \frac{c_v}{m_2}\rho\,\overline{\log(\theta)} + Lc_v\rho_1\,\overline{\log(\theta)} \\ \qquad\qquad\qquad\qquad\qquad \text{weakly in} \quad L^2(0,T;W^{-1,2}(\Omega)). \end{cases}$$

Using now (5.15) we can conclude that

$$\begin{cases} \int_0^T\!\int_\Omega \left(\frac{4a}{3}\theta^3 + \frac{c_v}{m_2}\rho_n \log(\theta_n) + L\rho_{1_n}\log(\theta_n) \right)\theta_n dxdt, \\ \qquad\qquad\qquad \downarrow \\ \int_0^T\!\int_\Omega \left(\frac{4a}{3}\bar{\theta}^3 + \frac{c_v}{m_2}\rho\,\overline{\log(\theta)} + Lc_v\rho_1\,\overline{\log(\theta)} \right)\theta dxdt. \end{cases}$$

Since the function

$$y \to \left\{ \frac{4a}{3}y^3 + \frac{c_v}{m_2}\rho\log(y) + Lc_v\rho_1\log(y) \right\}$$

is nondecreasing we have

$$\theta_n \longrightarrow \theta \quad \text{strongly in} \quad L^1((0,T)\times\Omega). \tag{5.16}$$

Now by interpolation arguments we have that

$$\begin{cases} \theta_n \longrightarrow \theta & \text{strongly in} \quad L^p((0,T)\times\Omega) \quad \text{for} \quad p>4, \\ \mathbb{S}_n \longrightarrow \mathbb{S} & \text{weakly in} \quad L^q((0,T)\times\Omega) \quad \text{for} \quad q>1. \end{cases} \tag{5.17}$$

Similarly, we get

$$\rho_n \longrightarrow \rho \quad \text{in } L^p((0,T)\times\Omega) \text{ for } p>\beta. \tag{5.18}$$

By using the same argument as in [12] we have

$$\rho_n\mathbf{u}_n \longrightarrow \rho\mathbf{u} \quad \text{in } C\left([0,T]; L^{\frac{2\beta}{\beta+1}}_{weak}(\Omega)\right),$$

which allows us to pass to the limit and to get that the limit functions ρ, $\mathbf{u}$, θ satisfy the *regularized momentum equation* in $\mathcal{D}'((0,T)\times\Omega)$.

In the same way we can let $n\to\infty$ in the energy inequality (5.2) in order to get

$$\begin{aligned} &\int_0^T\!\!\int_\Omega \partial_t\psi\left(\frac{1}{2}\rho|\mathbf{u}|^2+\rho P_m(\rho)+\rho_1P_m(\rho_1)+\frac{\delta}{\beta-1}\rho^\beta+a\theta^4+\frac{c_v}{m_2}\rho\theta+Lc_v\rho_1\theta\right)dxdt \\ &\quad=\int_\Omega\left(\frac{1}{2}\frac{\mathbf{m}_{0,\delta}}{\rho_{0,\delta}}+\rho_{0,\delta}P_m(\rho_{0,\delta})+\rho_{1_0,\delta}P_m(\rho_{1_{0,\delta}})+\frac{\delta}{\beta-1}\rho_{0,\delta}^\beta+a\theta_{0,\delta}^4\right)\,dx \\ &\qquad+\int_\Omega\left(\frac{c_v}{m_2}\rho_{0,\delta}\theta_{0,\delta}+Lc_v\rho_{1_{0,\delta}}\theta_{0,\delta}\right)dx \\ &\qquad+\int_0^T\int_\Omega\psi\left([p_b(\rho)+p_b(\rho_1)]\mathrm{div}\mathbf{u}+w_1(\rho_1,\rho_2,\theta)-\varepsilon\Delta\rho_1\right)dxdt \end{aligned} \tag{5.19}$$

for any $\psi\in C^\infty[0,T]$, $\psi(0)=1$, $\psi(T)=0$, $\partial_t\psi\le 0$. The following two lemmas will be useful in what follows.

LEMMA 5.6. *Let $\Omega\subset\mathbb{R}^N$ be a bounded Lipschitz domain. Suppose that ρ is a given nonnegative function satisfying*

$$0<M\le\int_\Omega\rho\,dx,\quad \int_\Omega\rho^\beta\,dx<K,\quad \beta>\frac{2N}{N+2}.$$

(a) *Then the following two statements are equivalent:*
   (i) *The function θ is strictly positive a.e. on Ω,*

$$\rho|\log(\theta)|\in L^1(\Omega) \quad \textit{and} \quad \frac{\nabla\theta}{\theta}\in L^2(\Omega).$$

   (ii) *The function $\log(\theta)$ belongs to the Sobolev space $W^{1,2}(\Omega)$. Moreover, if this is the case, then*

$$\nabla\log(\theta)=\frac{\nabla\theta}{\theta} \quad \textit{a.e. on } \Omega.$$

(b) *The following two statements are equivalent:*

(i) *Let* ρ_1 *be a nonnegative function such that* $\rho_1 = \rho f_1$. *The quantities*

$$|\log(\rho_1\theta)| \in L^1(\Omega), \qquad \frac{\nabla(\rho_1\,\theta)}{\rho_1\theta} \in L^2(\Omega),$$

and the function $\rho_1\theta$ *is strictly positive a.e. on* Ω.

(ii) *The function* $\log(\rho_1\theta)$ *belongs to the Sobolev space* $W^{1,2}(\Omega)$. *Moreover,*

$$\nabla\log(\rho_1\theta) = \frac{\nabla\rho_1}{\rho_1} + \frac{\nabla\theta}{\theta} \quad \text{a.e. on } \Omega.$$

Proof. The proof of part (a) follows using a line of arguments similar to the ones given in [14]. We shall give only some comments on part (b). Letting $\log(\rho_1\theta) \in W^{1,2}(\Omega)$, it follows that the product $\rho_1\theta$ is positive a.e. on Ω. Then one can use the Sobolev embedding theorem to conclude that

$$|\log(\rho_1\theta)| \in L^1(\Omega) \quad \text{is integrable.}$$

The converse follows easily (see also [14]). $\square$

LEMMA 5.7. *Let* $\theta_n \to \theta$ *in* $L^2((0,T)\times\Omega$ *and let* $\log(\theta_n) \to \overline{\log(\theta)}$ *weakly in* $L^2((0,T))\times\Omega$. *Then* θ *is strictly positive a.e. on* $(0,T)\times\Omega$ *and* $\log(\theta) = \overline{\log(\theta)}$.

Proof. For the proof we refer the reader to [14]. $\square$

Using the above analysis we can now pass to the limit in the entropy inequality (5.3) to get

$$\begin{aligned}
&\int_0^T\!\!\int_\Omega \left\{\partial_t\varphi[\rho(s_F+s_{f_1})] + \nabla\varphi[\rho(s_F+s_{f_1})] - \left(\frac{\kappa_C(\theta)+\sigma\theta^3}{\theta}\nabla\theta\right)\nabla\varphi\right\}dxdt\\
&\le \int_\Omega \varepsilon\left(\frac{c_v}{m_2}\nabla[\varphi(\log\theta-1)]\nabla\rho + \Delta\rho_{1_n}\varphi\right)dx\\
&\quad - \int_0^T\!\!\int_\Omega \varphi\left(\frac{S:\nabla\mathbf{u}}{\theta} + \frac{\kappa_C(\theta)+\sigma\theta^3}{\theta^3}|\nabla\theta|^2\right)dxdt\\
&\quad - \int_0^T\!\!\int_\Omega \varphi\left(\frac{c_v}{m_2}(\log(\theta)-1)w_1(\rho_1,\rho_2,\theta)\right)dxdt\\
&\quad - \int_\Omega \varphi(0)[\rho_{0,\delta}(s_{F_{0,\delta}} + s_{f_{1_{0,\delta}}})]dx
\end{aligned} \tag{5.20}$$

for any test function φ, $\varphi \in C^\infty([0,T]\times\Omega)$, $\varphi \ge 0$, $\varphi(T) = 0$.

6. The vanishing viscosity limit. Our aim in this section is to let the artificial viscosity ε go to zero in the family of approximate solutions $\{\rho_\varepsilon, \mathbf{u}_\varepsilon, \theta_\varepsilon, \rho_{1_\varepsilon}\}$ constructed in the previous section. We remark that during this process we expect loss of regularity of ρ_ε due to the fact that the parabolic regularization $\varepsilon\Delta\rho_\varepsilon$ now vanishes. The main difficulty is to establish the strong convergence of the density ρ_ε.

6.1. Refined pressure estimates. Our goal in this section is to improve the estimates on the pressure, which so far yield only that p is bounded in the nonreflexive space $L^\infty(0,T,L^1(\Omega))$, by improving the integrability properties of the modified pressure

$$p(\rho_\varepsilon, \mathbf{u}_\varepsilon, \theta_\varepsilon, \rho_{1_\varepsilon}) + \delta\rho_\varepsilon^\beta.$$

We employ the method known as the *multipliers technique* introduced by Lions in [27] for the barotropic case and by Feireisl in [20] for handling the full system. This method involves placing a particular choice of test functions, namely,

$$\varphi(t,x) = \chi(t)\mathcal{B}[\rho_\varepsilon^\nu], \quad \chi \in \mathcal{D}(0,T),\ 0 \le \chi \le 1,$$

in the weak formulation of the momentum equation.

The quantity $\mathcal{B}[v]$ represents a suitable set of solutions to the problem (see [20])

$$\operatorname{div}(\mathcal{B}[v]) = v - \frac{1}{|\Omega|}\int_\Omega v dx \quad \text{in } \Omega, \quad \mathcal{B}[v]|_{\partial\Omega} = 0.$$

Integrating the modified pressure against suitable test functions yields the following integral relation:

$$\int_0^T \int_\Omega \left(p_e(\rho_\varepsilon) + \frac{a}{3}\theta_\varepsilon^4 + \frac{R}{m_2}\theta_\varepsilon p_\theta(\rho_\varepsilon) + L\theta_\varepsilon p_\theta(\rho_{1_\varepsilon}) + \delta\rho_\varepsilon^\beta \right) \rho_\varepsilon^\nu \, dxdt = \sum_{j=1}^8 \mathcal{L}_{j_\varepsilon}, \tag{6.1}$$

where ν is a positive constant and

$$\begin{cases} \mathcal{L}_{1_\varepsilon} = \int_0^T \chi \left(\int_\Omega p_e(\rho_\varepsilon) + \frac{a}{3}\theta_\varepsilon^4 + \frac{R}{m_2}\theta_\varepsilon p_\theta(\rho_\varepsilon) + L\theta_\varepsilon p_\theta(\rho_{1_\varepsilon}) + \delta\rho_\varepsilon^\beta dx \right) dt, \\ \mathcal{L}_{2_\varepsilon} = \int_0^T \chi \int_\Omega \mathbb{S}_\varepsilon : \nabla\mathcal{B}\left[\rho_\varepsilon - \frac{1}{|\Omega|}\right] dxdt, \\ \mathcal{L}_{3_\varepsilon} = -\int_0^T \chi \int_\Omega [\rho_\varepsilon \mathbf{u}_\varepsilon \otimes \mathbf{u}_\varepsilon] : \nabla\mathcal{B}\left[\rho_\varepsilon - \frac{1}{|\Omega|}\right] dxdt, \\ \mathcal{L}_{4_\varepsilon} = \varepsilon \int_0^T \chi \int_\Omega (\nabla\mathbf{u}_\varepsilon \nabla\rho_\varepsilon) \cdot \mathcal{B}\left[\rho_\varepsilon - \frac{1}{|\Omega|}\right] dxdt, \\ \mathcal{L}_{5_\varepsilon} = -\int_0^T \chi \int_\Omega \rho_\varepsilon \nabla\psi_\varepsilon \cdot \mathcal{B}\left[\rho_\varepsilon - \frac{1}{|\Omega|}\right] dxdt, \\ \mathcal{L}_{6_\varepsilon} = \int_0^T \partial_t\chi \int_\Omega \rho_\varepsilon \mathbf{u}_\varepsilon \cdot \mathcal{B}\left[\rho_\varepsilon - \frac{1}{|\Omega|}\right] dxdt, \\ \mathcal{L}_{7_\varepsilon} = -\varepsilon \int_0^T \chi \int_\Omega \rho_\varepsilon \mathbf{u}_\varepsilon \cdot \mathcal{B}[\Delta\rho_\varepsilon] \, dxdt, \\ \mathcal{L}_{8_\varepsilon} = \int_0^T \chi \int_\Omega \rho_\varepsilon \mathbf{u}_\varepsilon \cdot \mathcal{B}[\operatorname{div}(\rho_\varepsilon \mathbf{u}_\varepsilon)] \, dxdt. \end{cases}$$

Taking now into consideration the estimates in (5.8)–(5.12) as well as Lemma 5.1 and following the same line of arguments as in [14], [20], we show that the quantities $\mathbb{S}_\varepsilon, \rho_\varepsilon \mathbf{u} \otimes \mathbf{u}$ are bounded in $L^p((0,T)\times\Omega)$ for a certain $p > 1$. Using now the fact that the operator

$$\mathcal{B} : \left\{ f \in L^p(\Omega) | \int_\Omega f dx = 0 \right\} \to [W_0^{1,p}(\Omega)]^3$$

introduced earlier is a bounded linear operator, namely,

$$\|\mathcal{B}[f]\|_{[W_0^{1,p}(\Omega)]^3} \le c(p)\|f\|_{L^p(\Omega)} \quad \text{for any} \quad 1 < p < \infty,$$

we conclude that the integrals $\mathcal{L}_{1_\varepsilon}$–$\mathcal{L}_{3_\varepsilon}$ and $\mathcal{L}_{5_\varepsilon}$ are bounded uniformly with ε. The integral $\mathcal{L}_{4_\varepsilon}$ can be controlled using a standard density gradient estimate (see [20], [14], [12], [13]), while the other integrals can be controlled using standard embedding theorems and further properties of the operator $\mathcal{B}$. Therefore, there exist $\nu > 0$ and a positive constant $c(\delta)$ independent of ε by which

$$\int_0^T \int_\Omega \left(p_e(\rho_\varepsilon) + \frac{a}{3}\theta_\varepsilon^4 + \frac{R}{m_2}\theta_\varepsilon p_\theta(\rho_\varepsilon) + L\theta_\varepsilon p_\theta(\rho_{1_\varepsilon}) + \delta\rho_\varepsilon^\beta \right) \rho_\varepsilon^\nu \, dxdt \le c(\delta).$$

Moreover,

$$\int_0^T \int_\Omega \rho_\delta^{\gamma+\nu} + \delta \rho_\delta^{\beta+\nu}\, dxdt \le c(\delta).$$

6.2. Strong convergence of the temperature. Taking into consideration estimates (5.8)–(5.12) we may now assume that

$$\begin{cases} \theta_\varepsilon \longrightarrow \theta & \text{weakly in } L^2(0,T;W^{1,2}(\Omega)), \\ \theta_\varepsilon \longrightarrow \theta & \text{weakly-* in } L^\infty(0,T;L^4(\Omega)), \\ \log(\theta_\varepsilon) \longrightarrow \overline{\log(\theta)} & \text{weakly in } L^2(0,T;W^{1,2}(\Omega)), \end{cases} \tag{6.2}$$

$$\begin{cases} \rho_\varepsilon \longrightarrow \rho & \text{in } C([0,T], L^\beta_{weak}(\Omega)), \\ \rho_{1_\varepsilon} \longrightarrow \rho_1 & \text{in } C([0,T], L^\beta_{weak}(\Omega)), \\ \mathbf{u}_\varepsilon \longrightarrow \mathbf{u} & \text{weakly in } L^b(0,T;W_0^{1,b}(\Omega)), \\ \rho_\varepsilon \mathbf{u}_\varepsilon \longrightarrow \rho \mathbf{u} & \text{in } C([0,T], L^{\frac{2\beta}{\beta+1}}(\Omega)). \end{cases} \tag{6.3}$$

Combining (6.2) and (6.3) we obtain

$$\begin{cases} \rho_\varepsilon \log(\theta_\varepsilon)\mathbf{u}_\varepsilon \longrightarrow \rho \overline{\log\theta}\mathbf{u} & \text{weakly in } L^p((0,T)\times\Omega) \text{ for } p>1, \\ \rho_{1_\varepsilon} \log(\theta_\varepsilon)\mathbf{u}_\varepsilon \longrightarrow \rho_1 \overline{\log(\theta)}\mathbf{u} & \text{weakly in } L^p((0,T)\times\Omega) \text{ for } p>1. \end{cases} \tag{6.4}$$

Following a similar procedure to the one of the previous section we end up with

$$\theta_\varepsilon \longrightarrow \theta \quad \text{strongly in } L^2((0,T)\times\Omega). \tag{6.5}$$

6.3. Strong convergence for the density. The aim in this section is to show the strong convergence of density sequence ρ_ε. This involves understanding the time evolution of the *defect* measure

$$\mathcal{B}_{dft}[\rho_\varepsilon - \rho] = \int_\Omega [\, \overline{\rho\log(\rho)}(t) - \rho\log(\rho)(t)\,]dx. \tag{6.6}$$

Consider now the renormalized version of the regularized continuity equation

$$\begin{aligned} &\partial_t \beta(\rho_\varepsilon) + \operatorname{div}(\beta(\rho_\varepsilon)\mathbf{u}_\varepsilon) + (\beta'(\rho_\varepsilon)\rho_\varepsilon - \beta(\rho_\varepsilon))\operatorname{div}\mathbf{u}_\varepsilon \\ &\qquad = \varepsilon \operatorname{div}(\chi_\Omega \nabla \beta(\rho_\varepsilon)) - \varepsilon \chi_\Omega \beta''(\rho_\varepsilon)|\nabla\rho_\varepsilon|^2 \quad \text{in} \quad \mathcal{D}'((0,T)\times\mathbb{R}^3) \end{aligned}$$

with $\beta \in C^2[0,\infty), \beta(0)=0$, a convex function, β', β'' bounded, and χ_Ω the characteristic function on Ω. By a suitable approximation of $z \to z\log z$ by smooth convex functions we deduce for $\varepsilon \to 0$ (see also [14], [13])

$$\mathcal{B}_{dft}[\rho_\varepsilon - \rho] \le \int_0^\tau \int_\Omega [\, \rho\operatorname{div}\mathbf{u} - \overline{\rho\operatorname{div}\mathbf{u}}\,]dxdt \tag{6.7}$$

for a.e. $\tau \in [0,T]$.

In what follows we employ the *multipliers technique* as in Feireisl [20] and Lions [27], which involves placing the quantities

$$\varphi(t,x) = \psi(t)\eta(x)(\nabla\Delta^{-1})[\rho_\varepsilon], \quad \psi \in \mathcal{D}(0,T), \quad \eta \in \mathcal{D}(\Omega),$$

as test functions in the (approximate) momentum equation. Let us introduce the following quantity:

$$\mathbf{C}(\rho,\mathbf{u},\theta,\rho_1)=p_e(\rho)+p_e(\rho_1)+\frac{R}{m_2}\theta p_\theta(\rho)+L\theta p_\theta(\rho_1)+\delta\rho^\beta-\left(\left(\zeta(\theta)-\frac{2}{3}\right)+2\mu(\theta)\right)\mathrm{div}\mathbf{u}.$$

Using now the smoothing properties of the operator $\{\nabla\Delta^{-1}\}$ we get (see also [14], [13])

$$\begin{aligned}\lim_{\varepsilon\to0}\int_0^T\int_\Omega \psi\eta\left[\mathbf{C}(\rho_\varepsilon,\mathbf{u}_\varepsilon,\theta_\varepsilon,\rho_{1_\varepsilon})\right]\rho_\varepsilon\,dxdt\\ =\int_0^T\int_\Omega\psi\eta\Bigg[\overline{p_e(\rho)}+\overline{p_e(\rho_1)}+\frac{R}{m_2}\theta\overline{p_\theta(\rho)}+L\theta\overline{p_\theta(\rho_1)}+\delta\overline{\rho^\beta}\\ -\left(\left(\zeta(\theta)-\frac{2}{3}\right)+2\mu(\theta)\right)\mathrm{div}\mathbf{u}\Bigg]\rho\,dxdt\\ +\left[\left(I^1-\lim_{\epsilon\to0}I^1_\epsilon\right)+2\left(\lim_{\epsilon\to0}I^2_\epsilon-I^2\right)\right]\end{aligned}\tag{6.8}$$

with

$$\begin{aligned}I^1&=\int_0^T\int_\Omega\psi\eta\mathbf{u}\cdot(\rho\mathcal{R}[\rho\mathbf{u}]-\mathcal{R}[\rho](\rho\mathbf{u}))\,dxdt,\\ I^1_\epsilon&=\int_0^T\int_\Omega\psi\eta\mathbf{u}_\varepsilon\cdot(\rho\mathcal{R}[\rho_\varepsilon\mathbf{u}_\varepsilon]-\mathcal{R}[\rho_\varepsilon](\rho_\varepsilon\mathbf{u}_\varepsilon))\,dxdt,\\ I^2&=\int_0^T\int_\Omega\psi(\mathcal{R}[\eta\mu(\theta)\nabla\mathbf{u}]-\eta\mu(\theta)\mathcal{R}[\nabla\mathbf{u}])\rho\,dxdt,\\ I^2_\epsilon&=\int_0^T\int_\Omega\psi(\mathcal{R}[\eta\mu(\theta_\varepsilon)\nabla\mathbf{u}_\varepsilon]-\eta\mu(\theta_\varepsilon)\mathcal{R}[\nabla\mathbf{u}_\varepsilon])\rho_\varepsilon\,dxdt,\end{aligned}$$

where

$$\mathcal{R}[\mathbb{A}]=\sum_{i,j}\mathcal{R}_{i,j}[A_{i,j}],\quad \mathcal{R}=\mathcal{R}_{i,j}[v]=\mathcal{F}^{-1}_{\xi\to x}\left[\frac{\xi_i\xi_j}{|\xi|^2}\mathcal{F}_{x\to\xi}[v]\right].$$

Using now the continuity property of the bilinear form

$$[v,\mathbf{w}]\to v\mathcal{R}[\mathbf{w}]-\mathcal{R}[v]\mathbf{w},$$

one obtains as in [22], [20], [27] that

$$\lim_{\varepsilon\to0}I^1_\varepsilon=I^1.$$

The convergence

$$\lim_{\varepsilon\to0}I^2_\varepsilon=I^2$$

is obtained following the analysis presented in [20], [15] in the spirit of Coifman and Meyer [8].

Now relation (6.8), together with the strong convergence of $\{\theta_\varepsilon\}$, yields

$$\rho\mathrm{div}\mathbf{u}-\overline{\rho\mathrm{div}\mathbf{u}}\le\frac{1}{\zeta(\theta)-\frac{2}{3}+\mu(\theta)}(\mathcal{P}_1+\mathcal{P}_2+\mathcal{P}_3),$$

where

$$\mathcal{P}_1 = \overline{p_e(\rho)}\rho - \overline{p_e(\rho)\rho} + \overline{p_e(\rho_1)}\rho - \overline{p_e(\rho_1)\rho},$$

$$\mathcal{P}_2 = \frac{R\theta}{m_2}(p_\theta(\rho) - \overline{p_\theta(\rho)}) + L\theta(p_\theta(\rho_1) - \overline{p_\theta(\rho_1)}), \quad \mathcal{P}_3 = \overline{\rho^\beta}\rho - \overline{\rho^{\beta+1}}.$$

We can see immediately that $\mathcal{P}_2 \leq 0$, $\mathcal{P}_3 \leq 0$, while

$$\mathcal{P}_1 \leq \overline{p_b(\rho)}\rho - \overline{p_b(\rho)\rho} + \overline{p_b(\rho_1)}\rho - \overline{p_b(\rho_1)\rho},$$

where p_b is the bounded, nonmonotone component of the *elastic pressure*. Using (6.7) we get

$$\int_\Omega \left(\overline{\rho \log(\rho)} - \rho \log(\rho)\right)(s)dx \leq \frac{1}{\underline{\mu}} \int_0^s \int_\Omega \overline{p_b(\rho)}\rho - \overline{p_b(\rho)\rho}\, dxdt,$$

which yields

$$\mathcal{B}_{dft}[\rho_\varepsilon - \rho] \leq \frac{\Lambda}{\underline{\mu}} \int_0^\tau \mathcal{B}_{dft}[\rho_\varepsilon - \rho] dx,$$

and consequently

$$\mathcal{B}_{dft}[\rho_\varepsilon - \rho] = 0,$$

which implies that

$$\rho_\varepsilon \longrightarrow \rho \quad \text{in } L^1((0,T) \times \Omega). \tag{6.9}$$

6.4. The limit process in the field equations ($\varepsilon \to 0$). We are now ready to let $\varepsilon \to 0$ in the field equations. By the aid of the estimates obtained above, we have, passing to a subsequence if needed, that

$$\begin{cases} \rho_\varepsilon \to \rho \quad \text{in} \quad C([0,T]; L^\beta(\Omega)), \\ \mathbf{u}_\varepsilon \to \mathbf{u} \quad \text{weakly in} \quad L^2(0,T; W_0^{1,2}(\Omega; \mathbb{R}^3)), \\ \varepsilon \mathrm{div}(\chi_\Omega \nabla \rho_\varepsilon) \to 0 \quad \text{in} \quad L^2(0,T; W^{-1,2}(\mathbb{R}^N)); \end{cases} \tag{6.10}$$

therefore, the limit functions ρ, $\mathbf{u}$ satisfy the continuity equation in the sense of distributions. From the energy estimates established above, we have

$$\begin{cases} \varepsilon \nabla \mathbf{u}_\varepsilon \nabla \rho_\varepsilon \to 0 & \text{in } L^1(0,T; L^1(\Omega)), \\ \varepsilon \mathrm{div}(\chi_\Omega \nabla \rho_{1_\varepsilon}) \to 0 & \text{in } L^2(0,T; W^{-1,2}(\mathbb{R}^N)). \end{cases}$$

Keeping in mind the estimates (6.10), we get

$$\rho_\varepsilon \mathbf{u}_\varepsilon \to \rho \mathbf{u}, \quad \rho_{1_\varepsilon} \mathbf{u}_\varepsilon \to \rho_1 \mathbf{u} \quad \text{in } C\left([0,T]; L_{weak}^{\frac{2\beta}{\beta+1}}(\Omega)\right).$$

The limit functions ρ, $\mathbf{u}$, θ, and ρ_1 satisfy in the sense of distributions $\mathcal{D}'((0,T) \times \Omega)$ the momentum equation

$$\partial_t(\rho \mathbf{u}) + \mathrm{div}(\rho \mathbf{u} \otimes \mathbf{u}) + \nabla \left(\overline{p_e(\rho)} + \frac{R}{m_2}\theta \overline{p_\theta(\rho)} + \frac{a}{3}\theta^4 + LR\theta p_\theta(\overline{\rho_1}) + \delta \overline{\rho^\beta}\right) = \mathrm{div}\mathbb{S}.$$

The *species conservation equation* is also verified in $\mathcal{D}'((0,T)\times\Omega)$ by the limit function sequences ρ, $\mathbf{u}$, θ, and ρ_1 by virtue of the estimates above. Now passing to the limit in the energy equality (5.19) comes as a consequence of the estimates established earlier and so we recover the total energy balance,

(6.11)

$$-\int_0^T\int_\Omega \partial_t\psi\left(\frac{1}{2}\rho|\mathbf{u}|^2+\rho P_e(\rho)+\rho_1 P_e(\rho_1)+\frac{\delta}{\beta-1}\rho^\beta+a\theta^4+\frac{c_v}{m_2}\rho\theta+Lc_v\,\rho_1\theta\right)dxdt$$
$$=\int_\Omega\left(\frac{1}{2}\frac{\mathbf{m}_{0,\delta}}{\rho_{0,\delta}}+\rho_{0,\delta}P_e(\rho_{0,\delta})+\rho_{1_{0,\delta}}P_e(\rho_{1_{0,\delta}})+\frac{\delta}{\beta-1}\rho_{0,\delta}^\beta+a\theta_{0,\delta}^4\right.$$
$$\left.+\frac{c_v}{m_2}\rho_{0,\delta}+Lc_v\,\rho_{1_{0,\delta}}\theta_{0,\delta}\right)dx$$

for any $\psi\in C^\infty[0,T]$, $\psi(0)=1$, $\psi(T)=0$, $\partial_t\psi\le 0$. Similarly, sending $\varepsilon\to 0$ in (5.20),

$$\begin{aligned}&\int_0^T\int_\Omega \partial_t\varphi[\rho(s_F+s_{f_1})]+\nabla\varphi[\rho(s_F+s_{f_1})]-\left(\frac{\kappa_C(\theta)+\sigma\theta^3}{\theta}\nabla\theta\right)\nabla\varphi dxdt\\
&\le\int_0^T\int_\Omega\varphi\left(\frac{S:\nabla\mathbf{u}}{\theta}+\frac{\kappa_C(\theta)+\sigma\theta^3}{\theta^3}|\nabla\theta|^2\right)dxdt\\
&\quad-\int_0^T\int_\Omega\varphi\left(\frac{c_v}{m_2}(\log(\theta)-1)w_1(\rho_1,\rho_2,\theta)\right)dxdt\\
&\quad-\int_\Omega\varphi(0)[\rho_{0,\delta}(s_{F_{0,\delta}}+s_{f_{1_{0,\delta}}})]dx\end{aligned}\tag{6.12}$$

for any test function φ, $\varphi\in C^\infty([0,T]\times\Omega)$, $\varphi\ge 0$, $\varphi(T)=0$.

7. Passing to the limit in the artificial pressure term. In this last part we pass to the limit for $\delta\to 0$ in the sequence ρ_δ, $\mathbf{u}_\delta$, θ_δ, ρ_{1_δ} of the approximate solutions constructed in the previous section.

Taking into consideration the energy equality (6.11) we have

$$\begin{cases}\rho_\delta\in L^\infty(0,T;L^\gamma(\Omega)),\\ \sqrt{\rho_\delta}\mathbf{u}_\delta\in L^\infty(0,T;L^2(\Omega)),\end{cases}\qquad\begin{cases}\rho_\delta\theta_\delta\in L^\infty(0,T;L^1(\Omega)),\\ \theta_\delta\in L^\infty(0,T;L^4(\Omega)),\end{cases}\tag{7.1}$$

$$\begin{cases}\rho_{1_\delta}\in L^\infty(0,T;L^\gamma(\Omega)),\\ \sqrt{\rho_{1_\delta}}\mathbf{u}_\delta\in L^\infty(0,T;L^2(\Omega)),\\ \rho_{1,\delta}\theta\in L^\infty(0,T;L^1(\Omega)).\end{cases}\tag{7.2}$$

By applying now the same procedure as in section 5 we get the following refined estimate for ρ_δ:

$$\rho_\delta^{\gamma+\nu}+\delta\rho_\delta^{\beta+\nu}\quad\text{is bounded in } L^1((0,T)\times\Omega),\ \nu>1.\tag{7.3}$$

The relation

$$\int_0^T\int_\Omega\frac{\mathbb{S}_\delta:\nabla\mathbf{u}_\delta}{\theta_\delta}+|\nabla\log(\theta_\delta)|^2+|\nabla\theta_\delta^{\frac{3}{2}}|^2+\varepsilon|\nabla\rho_\delta|^2+||\nabla\log(\rho_{1_\delta}\theta_\delta)|^2|dxdt\le c(\delta)$$

is now valid using the energy estimates obtained in our earlier analysis. This last relation implies, in particular, that

$$\|\mathbf{u}_\delta\|_{L^b(0,T;W_0^{1,b}(\Omega))} \le c(\delta) \quad \text{with } b = \frac{8}{5-\alpha}, \tag{7.4}$$

and in combination with Lemma 5.4,

$$\|\log(\theta_\delta)\|_{L^2(0,T;W^{1,2}(\Omega))} + \|\theta_\delta^{\frac{3}{2}}\|_{L^2(0,T;W^{1,2}(\Omega))} \le \tilde{C},$$

yielding

$$\begin{cases} \theta_\delta^{3/2} \in L^2(0,T;W^{1,2}(\Omega)), \\ \log(\theta_\delta) \in L^2(0,T;W^{1,2}(\Omega)), \end{cases} \qquad \begin{cases} \mathbb{S}_\delta \in L^a(0,T;L^s(\Omega)), \\ \text{with } a = \frac{8}{5-\alpha},\ s = \frac{8}{7-\alpha}. \end{cases} \tag{7.5}$$

The bound of $\mathbb{S}_\delta \in L^a(0,T;L^s(\Omega))$ for the values of α and β specified above is a direct consequence of Hölder's inequality. Therefore,

$$\begin{cases} \rho_\delta \longrightarrow \rho & \text{in} \quad C([0,T], L^\gamma_{weak}(\Omega)), \\ \mathbf{u}_\delta \longrightarrow \mathbf{u} & \text{weakly in} \quad L^b(0,T;W_0^{1,b}(\Omega)), \end{cases} \tag{7.6}$$

where ρ, $\mathbf{u}$ satisfy (1.23) in $\mathcal{D}'((0,T)\times\mathbb{R}^3)$. We can also verify using the earlier analysis that

$$\begin{cases} \rho_\delta \mathbf{u}_\delta \longrightarrow \rho\mathbf{u} & \text{in} \quad C([0,T], L^{\frac{\gamma}{\gamma+1}}(\Omega)), \\ \log(\theta_\delta) \longrightarrow \overline{\log(\theta)} & \text{weakly in} \quad L^2(0,T;W^{1,2}(\Omega)), \\ \rho_\delta \log(\theta_\delta) \longrightarrow \rho\overline{\log(\theta)} & \text{weakly in} \quad L^2(0,T;L^{\frac{6\gamma}{6+\gamma}}(\Omega)), \\ \rho_\delta \log(\theta_\delta)\mathbf{u}_\delta \longrightarrow \rho\overline{\log(\theta)}\mathbf{u} & \text{weakly in} \quad L^2(0,T;L^{\frac{6\gamma}{3+4\gamma}}(\Omega)), \end{cases} \tag{7.7}$$

whereas estimates involving ρ_1, namely,

$$\begin{cases} \rho_{1_\delta} \mathbf{u}_\delta \longrightarrow \rho_1\mathbf{u} & \text{in} \quad C([0,T], L^{\frac{\gamma}{\gamma+1}}(\Omega)), \\ \rho_{1_\delta} \log(\theta_\delta) \longrightarrow \rho_1\overline{\log(\theta)} & \text{weakly in} \quad L^2(0,T;L^{\frac{6\gamma}{6+\gamma}}(\Omega)), \\ \rho_{1_\delta} \log(\theta_\delta)\mathbf{u}_\delta \longrightarrow \rho_1\overline{\log(\theta)}\mathbf{u} & \text{weakly in} \quad L^2(0,T;L^{\frac{6\gamma}{3+4\gamma}}(\Omega)), \end{cases} \tag{7.8}$$

are obtained using (7.2), (7.4), and (7.5).

7.1. Pointwise convergence of the temperature. Next we show the strong convergence of the temperature sequence. In analogy with the above analysis, the entropy inequality (6.12) in combination with Lemma 5.5 yields

$$\begin{cases} \frac{4a}{3}\theta_\delta^3 + \frac{c_v}{m_2}\rho_\delta \log(\theta_\delta) - \rho_\delta P_\theta(\rho_\delta) + Lc_v\rho_{1_\delta}\log(\theta_\delta) - LR\rho_{1_\delta}P_\theta(\rho_{1_\delta}) \\ \qquad\qquad\qquad\qquad\qquad\qquad \downarrow \\ \frac{4a}{3}\overline{\theta^3} + \frac{c_v}{m_2}\rho\overline{\log(\theta)} - \overline{\rho_\delta P_\theta(\rho_\delta)} + Lc_v\overline{\rho_1\log(\theta)} - LR\overline{\rho_1 P_\theta(\rho_1)} \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{in} \quad L^2(0,T;W^{-1,2}(\Omega)). \end{cases}$$

We remark that in the present context

$$\begin{cases} \rho_\delta\, P_\theta(\rho_\delta) \quad \text{is bounded in} \quad L^\infty(0,T;L^{\frac{\gamma}{G}}(\Omega)) \quad \text{with} \quad \frac{\gamma}{G} > \frac{4}{3}, \\ \rho_{1_\delta}\, P_\theta(\rho_\delta) \quad \text{is bounded in} \quad L^\infty(0,T;L^{\frac{\gamma}{G}}(\Omega)) \quad \text{with} \quad \frac{\gamma}{G} > \frac{4}{3}. \end{cases} \tag{7.9}$$

In particular, we have

$$\begin{cases} \int_0^T\int_\Omega \left(\frac{4a}{3}\theta_\delta^3 + \frac{c_v}{m_2}\rho_\delta \log(\theta_\delta) - \rho_\delta P_\theta(\rho_\delta) + Lc_v\rho_{1_\delta}\log(\theta_\delta) - LR\rho_{1_\delta}P_\theta(\rho_{1_\delta})\right)\theta_\delta dxdt, \\ \downarrow \\ \int_0^T\int_\Omega \left(\frac{4a}{3}\overline{\theta^3} + \frac{c_v}{m_2}\rho\overline{\log(\theta)} - \overline{\rho P_\theta(\rho)} + Lc_v\overline{\rho_1\log(\theta)} - LR\overline{\rho_1 P_\theta(\rho_1)}\right)\theta dxdt, \end{cases}$$

where we have used (6.3) and (6.4) to obtain that as $\delta \to 0$

$$\begin{cases} \lim \int_0^T\int_\Omega \rho_\delta \log(\theta_\delta)\theta_\delta dxdt = \int_0^T\int_\Omega \rho\,\overline{\log(\theta)}\theta\, dxdt, \\ \lim \int_0^T\int_\Omega \rho_{1_\delta}\ \log(\theta_\delta)\theta_\delta\, dxdt = \int_0^T\int_\Omega \rho_1\,\overline{\log(\theta)}\theta\, dxdt. \end{cases}$$

In addition, taking into consideration that ρ is a *renormalized solution* of the continuity equation and using a standard approximation argument, we get

$$\begin{cases} \rho_\delta P_\theta(\rho_\delta) \to \overline{\rho P_\theta(\rho)} & \text{in} \quad C([0,T]; L^{\frac{\gamma}{G}}_{weak}(\Omega)), \\ \rho_{1_\delta}P_\theta(\rho_{1_\delta}) \to \overline{\rho_1 P_\theta(\rho_1)} & \text{in} \quad C([0,T]; L^{\frac{\gamma}{G}}_{weak}(\Omega)). \end{cases}$$

Therefore (6.3), (6.4) yield

$$\begin{cases} \int_0^T\int_\Omega \left(\frac{4a}{3}\theta_\delta^3 + \frac{c_v}{m_2}\rho_\delta\log(\theta_\delta) + Lc_v\rho_{1_\delta}\log(\theta_\delta)\right)\theta_\delta dxdt, \\ \downarrow \\ \int_0^T\int_\Omega \left(\frac{4a}{3}\overline{\theta^3} + \frac{c_v}{m_2}\rho\overline{\log(\theta)} + Lc_v\overline{\rho_1\log(\theta)}\right)\theta dxdt, \end{cases}$$

which in turn implies

$$\theta_\delta \longrightarrow \theta \quad \text{in } L^2((0,T)\times\Omega).$$

7.2. Pointwise convergence of the density. In order to pass to the limit we need the strong convergence of the density. The main part consists in showing that the oscillation defect measure $osc_{\beta+1}[\rho_\delta \to \rho]$ defined by

$$osc_{\beta+1}[\rho_\delta \to \rho]((0,T)\times\Omega) = \sup_{k\geq 1}\left(\limsup_{\delta\to 0}\int_0^T\int_\Omega |T_k(\rho_\delta) - T_k(\rho)|^{\beta+1}dxdt\right) \tag{7.10}$$

is bounded. Here $T_k(\rho)$ are cutoff functions:

$$T_k(y) = T\left(\frac{y}{k}\right) \qquad \text{with } T \in C^\infty(\mathbb{R}) \text{ a concave function,}$$

$$T(x) = x \quad \text{for} \quad 0 \leq x \leq 1, \quad T(x) = 2 \quad \text{if} \quad y \geq 3.$$

In order to show that $\rho, \mathbf{u}$ represent a *renormalized* solution of (1.23) we have to show that the oscillation defect measure associated with $\{\rho_\delta\}$ is bounded.

Taking into account that $\rho_1 \leq \rho$ we estimate the amplitude of oscillations as in [14] (see also [20]); namely, we write

$$\begin{cases} p_e(\rho) = p_e^{(c)}(\rho) + p_e^{(m)}(\rho) + p_e^{(b)}(\rho), \\ p_e(\rho_1) = p_e^{(c)}(\rho_1) + p_e^{(m)}(\rho_1) + p_e^{(b)}(\rho_1) \end{cases}$$

with $p_e^{(b)}$ uniformly bounded on $[0,\infty)$, $p_e^{(m)}$ nondecreasing, and $p_e^{(b)}$ a convex function satisfying

$$\begin{cases} p^{(c)}(\rho) \geq a\rho^{\gamma} \quad \text{with} \quad a > 0, \\ p^{(c)}(\rho_1) \geq a\rho_1^{\gamma} \quad \text{with} \quad a > 0. \end{cases}$$

Next, taking into account the monotonicity property of some of the quantities present in the pressure we get

$$\text{(7.11)} \quad \begin{cases} \overline{p_\theta(\rho)T_k(\rho)} \geq \overline{p_\theta(\rho)}\ \overline{T_k(\rho)}, \\ \overline{p_\theta(\rho_1)T_k(\rho)} \geq \overline{p_\theta(\rho_1)}\ \overline{T_k(\rho)}, \end{cases} \qquad \begin{cases} \overline{p_e^{(m)}(\rho)T_k(\rho)} \geq \overline{p_e^{(m)}(\rho)}\overline{T_k(\rho)}, \\ \overline{p_e^{(m)}(\rho_1)T_k(\rho)} \geq \overline{p_e^{(m)}(\rho_1)}\overline{T_k(\rho)}, \end{cases}$$

which yield first that

$$\begin{aligned} &\limsup_{\delta\to 0} \int_0^T \int_\Omega |T_k(\rho_\delta) - T_k(\rho)|^{\beta+1}\, dxdt \\ &\quad \leq \limsup_{\delta\to 0} \int_0^T \int_\Omega \Big| [p_e^{(b)}(\rho_\delta) + p_e^{(b)}(\rho_{1_\delta})] \\ &\qquad + \left(\left(\zeta(\theta) - \frac{2}{3} \right) + 2\mu(\theta) \right) \operatorname{div}\mathbf{u}_\delta \Big| |T_k(\rho_\delta) - T_k(\rho)|\, dxdt, \end{aligned}$$

and in what follows taking into consideration the properties (2.8) of the transport coefficients and the estimates derived above and following a line of argument similar to that presented in [14], [20], [13], we have that

$$osc_{\beta+1}[\rho_\delta \to \rho]((0,T)\times\Omega) < \infty.$$

Now we use the fact that $\rho, \mathbf{u}$ represent a *renormalized solution* of (1.23) on $(0,T)\times\Omega$ (cf. Proposition 6.3 in [20]).

PROPOSITION 7.1. *Let $\Omega \subset \mathbb{R}^N$ be a domain. Assume that $\rho_\delta \geq 0$, and that $\mathbf{u}_\delta$ is a sequence of renormalized solutions to* (1.23) *on $(0,T)\times\Omega$ such that*

$$\text{(7.12)} \qquad \begin{cases} \rho_\delta \to \rho \quad \textit{weakly-* in} \quad L^\infty(0,T;L^\gamma(\Omega)), \quad \gamma > 1, \\ \mathbf{u}_\delta \to \mathbf{u} \quad \textit{weakly in} \quad L^r(0,T;W^{1,r}(\Omega;\mathbb{R}^N)), \quad r > 1, \end{cases}$$

where

$$\gamma > \frac{Nr}{(N+1)r - N} \quad \textit{if} \quad r < N.$$

Furthermore, assume that

$$osc_p[\rho_\delta \to \rho]((0,T)\times\Omega) < \infty$$

for a certain p such that

$$\frac{1}{p} + \frac{1}{r} < 1.$$

Then the limit functions $\rho, \mathbf{u}$ represent a renormalized solution of (1.23) *on* $(0,T)\times\Omega$.

Note that in our case $r = \frac{8}{5-\alpha} > \frac{3}{2}$ and so all the requirements of Proposition 7.1 are valid. Therefore we get that

$$\rho_\delta \longrightarrow \rho \quad \text{strongly in } L^1((0,T)\times\Omega). \tag{7.13}$$

Property (7.10) implies now that the continuity equation (1.23) holds true in the sense of distribution. Furthermore, the bound (7.3) yields that

$$\delta\rho^\beta \longrightarrow 0 \quad \text{in } L^{\frac{\beta+\nu}{\beta}}((0,T)\times\Omega),$$

and the momentum equation (1.24) is recovered as $\delta \to 0$.

The *species conservation equation* now can be also verified using Proposition 7.1 and the estimates in (7.2). In addition, the strong convergence of the density sequence ρ_δ, together with the estimates established above, allows us to pass to the limit both in the energy equality (6.11) and in the entropy inequality (6.12). The proof of Theorem 3.1 has now been established.

REACHABLE AND UNREACHABLE SETS IN THE SCATTERING PROBLEM FOR THE ACOUSTICAL EQUATION IN $\mathbb{R}^3$*

MIKHAIL I. BELISHEV† AND ALEXSEI F. VAKULENKO†

Abstract. The scattering problem is to find $u = u^f(x,t)$ satisfying $u_{tt} - \Delta u + qu = 0$, $(x,t) \in \mathbb{R}^3 \times (-\infty, \infty)$; $u\mid_{|x|<-t} = 0$, $t < 0$; $\lim_{s\to\infty} su((s+\tau)\omega, -s) = f(\tau,\omega)$, $(\tau,\omega) \in [0,\infty) \times S^2$ for a real-valued smooth compactly supported potential $q = q(x)$ and a control $f \in \mathcal{F} = L_2([0,\infty); L_2(S^2))$. The corresponding control problem is as follows: given $y \in \mathcal{H} = L_2(\mathbb{R}^3)$ find $f \in \mathcal{F}$ provided $u^f(\cdot,0) = y$; the reachable set is $\mathcal{U} = \{u^f(\cdot,0) \mid f \in \mathcal{F}\}$; the subspace of unreachable states is $\mathcal{D} = \mathcal{H} \ominus \mathcal{U}$. The main subject of the paper is the structure of $\mathcal{U}$ and $\mathcal{D}$. We present an example of the finite energy solution u^f satisfying $u^f|_{|x|<|t|} = 0$, i.e., vanishing simultaneously in the past and future cones (reversing wave) and we introduce the set of points at which such a "reverse effect" occurs. The existence of reversing waves turns out to be equivalent to the lack of controllability $\mathcal{D} \neq \{0\}$. Cauchy data of such waves belong to the classes $D_\mp$ of the incoming and outgoing data simultaneously; in other words, $D_- \cap D_+ \neq \{0\}$. Also, simple conditions on f ensuring $\|u^f(\cdot,t)\|_{\mathcal{H}} \le c\|f\|_{\mathcal{F}}$ for all $t \in (-\infty,\infty)$ are described. We plan to apply these results to the dynamical (time-domain) inverse problem, that is, determination of potential from the dynamical scattering data. The study of controllability is the first step towards solving this problem by the boundary control method.

Key words. 3D acoustical equation, time-domain scattering problem, control problem, reachable sets, reversing waves, stop points, stability conditions

Introduction. In this section, we first introduce related notions, then formulate the problem, state the main results, and finally discuss the motivation and give some other comments.

0.1. Dynamical system. We denote $B_r := \{x \in \mathbb{R}^3 \mid |x| < r\}$, $S^2 := \{\theta \in \mathbb{R}^3 \mid |\theta| = 1\}$, $\Sigma := (0,\infty) \times S^2$. Let $q = q(x)$, $x \in \mathbb{R}^3$, be a real-valued smooth (everywhere in the paper "smooth" means C^∞-smooth) compactly supported function (*potential*), $\operatorname{supp} q \subset \overline{B}_{r_*}$. The system under consideration is

$$u_{tt} - \Delta u + qu = 0, \qquad (x,t) \in \mathbb{R}^3 \times (-\infty, 0), \tag{0.1}$$

$$u\mid_{|x|<-t} = 0, \qquad t < 0, \tag{0.2}$$

$$\lim_{s\to+\infty} su((s+\tau)\theta, -s) = f(\tau,\theta), \qquad (\tau,\theta) \in \overline{\Sigma}, \tag{0.3}$$

where f is a control, $u = u^f(x,t)$ is a solution (*wave*). The value $t = 0$ is referred to as a final moment; however, in what follows we also deal with problem (0.1)–(0.3) for all $t \in (-\infty, \infty)$.

0.2. Spaces, sets, operators. With a dynamical system (0.1)–(0.3) one associates the following:

- an *outer space* of controls $\mathcal{F} := L_2([0,\infty); L_2(S^2))$ and its subspaces
$$\mathcal{F}^\xi := \{f \in \mathcal{F} \mid \operatorname{supp} f \subset [\xi,\infty)\}, \quad \xi \geq 0,$$
consisting of the *delayed controls*;
- an *inner space* of states $\mathcal{H} := L_2(\mathbb{R}^3)$ (we consider a wave $u^f(\cdot,t)$ as a time-dependent element of $\mathcal{H}$) and its subspaces
$$\mathcal{H}^\xi := \left\{y \in \mathcal{H} \mid \operatorname{supp} y \subset \mathbb{R}^3 \setminus B_\xi\right\}, \quad \xi \geq 0;$$
- a *control operator* $W : \mathcal{F} \to \mathcal{H}$
$$Wf := u^f(\cdot,0)$$
and the subspace of *null controls*
$$\mathcal{N} := \operatorname{Ker} W = \left\{f \in \mathcal{F} \mid u^f(\cdot,0) = 0\right\};$$
- the *reachable sets*
$$\mathcal{U}^\xi := W\mathcal{F}^\xi = \left\{u^f(\cdot,0) \mid f \in \mathcal{F}^\xi\right\}, \quad \xi \geq 0$$
(we also denote $\mathcal{U}^0$ by $\mathcal{U}$); by hyperbolicity of problem (0.1)–(0.3) one has $\mathcal{U}^\xi \subset \mathcal{H}^\xi$;
- the defect subspaces (*unreachable sets*)
$$\mathcal{D}^\xi := \mathcal{H}^\xi \ominus \mathcal{U}^\xi, \quad \xi \geq 0$$
(we denote $\mathcal{D}^0 =: \mathcal{D} = \mathcal{H} \ominus \mathcal{U}$).

We introduce also the *polyharmonic subspaces* $\mathcal{A}^\xi \subset \mathcal{H}^\xi$,
$$\mathcal{A}^\xi := \operatorname{clos}\ \left\{a \in \mathcal{H}^\xi \mid \exists \,\text{integer}\, p \geq 1 :\ (-\Delta + q)^p\, a = 0 \ \text{ in } \mathbb{R}^3 \setminus \overline{B}_\xi\right\}, \quad \xi \geq 0$$
(the closure in $\mathcal{H}$; $\overline{B}_0 := \{0\}$), and denote $\mathcal{A} := \mathcal{A}^0$. It is easy to see that $\dim \mathcal{A}^\xi = \infty$ for $\xi > 0$.

The evolution of system (0.1)–(0.3) is governed by a self-adjoint operator $H : \mathcal{H} \to \mathcal{H}$, $\operatorname{Dom} H = H^2(\mathbb{R}^3)$, $Hy = (-\Delta + q)y$. This operator can have at most a finite number of negative eigenvalues of finite multiplicity, whereas its absolutely continuous spectrum fills $[0,\infty)$. The spectral point $\lambda = 0$ can also belong to the point spectrum $\sigma_p(H)$, so that $\operatorname{Ker} H$ can be a nonzero finite-dimensional subspace in $\mathcal{H}$ (see [14]).

0.3. The results. A control problem for system (0.1)–(0.3) is set up as follows: given $y \in \mathcal{H}$ find $f \in \mathcal{F}$ such that

$$u^f(\cdot,0) = y. \tag{0.4}$$

Loosely speaking, we deal with a "wave shaping": managing the control, one needs to create the incoming (from infinity) wave of prescribed shape. We consider also the same problem for delayed controls $f \in \mathcal{F}^\xi$.

To study the solvability of (0.4) is to investigate the structure of the reachable sets $\mathcal{U}, \mathcal{U}^\xi$ or, equivalently, of the defect subspaces $\mathcal{D}, \mathcal{D}^\xi$. Our main result is the following.

THEOREM 0.1. (i) *The sets* $\mathcal{U}^\xi$ *are closed. The relations*

$$\mathcal{A}^\xi \subseteq \mathcal{D}^\xi, \quad \xi \geq 0; \quad \mathrm{Ker} H \subseteq \mathcal{A} \subseteq \mathcal{D} \tag{0.5}$$

and

$$\dim \mathrm{Ker} H \leq \dim \mathcal{D} = \dim \mathcal{N} < \infty \tag{0.6}$$

hold.

(ii) *If* $||q||_{L^\infty(B_{r_*})}$ *is small enough, then* $\mathcal{U} = \mathcal{H}$ *and* $\mathcal{D} = \{0\}$.

(iii) *If the potential is radially symmetric, i.e.,* $q = q(|x|)$, *then*

$$\mathcal{D}^\xi = \mathcal{A}^\xi, \quad \xi \geq 0; \quad \mathcal{D} = \mathrm{Ker}\, H. \tag{0.7}$$

In control theory the equality $\mathcal{U} = \mathcal{H}$ is interpreted as an *exact controllability* of system (0.1)–(0.3). Thus, for small potentials the controllability occurs, whereas in the case of radial q the only obstacle for controllability is $0 \in \sigma_p(H)$. The latter is not true in the general case: we construct an example of (not radial) potential such that $0 \notin \sigma_p(H)$ (i.e., $\mathrm{Ker}\, H = \{0\}$) but $\mathcal{D} \neq \{0\}$, realizing the strict inequality in (0.6).

The presence of the defect $\mathcal{D} \neq \{0\}$ is equivalent to the existence of null controls producing the waves, which exhibit rather curious behavior. If $f \in \mathcal{N}$, then u^f is an L_2-solution of (0.1)–(0.3) satisfying $u^f(\cdot, 0) = 0$. As a consequence, the function

$$w^f(x,t) := \begin{cases} \int_{-\infty}^{t} u^f(x,s)\, ds, & t \leq 0, \\ \int_{-\infty}^{-t} u^f(x,s)\, ds, & t > 0, \end{cases}$$

turns out to be a finite (positive) energy solution of the acoustical equation (0.1) in $\mathbb{R}^3 \times (-\infty, \infty)$ satisfying

$$w^f \mid_{|x|<|t|} = 0, \quad w^f_t \mid_{t=0} = 0, \quad w^f(\cdot, -t) = w^f(\cdot, t),$$

i.e., vanishing in the past and future characteristic cones simultaneously. Thus, w^f is a wave, which comes from infinity, stops at the moment $t = 0$, and then returns back to infinity along the same trajectory. An amazing peculiarity of such a behavior is that this wave possesses a back front: it leaves $\mathrm{supp}\, q$ with no residual perturbation. A noticeable fact is that the existence of such reversing waves is equivalent to the lack of controllability of the system.

The Cauchy data of the reversing wave $\{w^f(\cdot, 0), w^f_t(\cdot, 0)\} = \{y, 0\}$ belong to the energy class (see [10], [13]). At the same time, since $w^f \mid_{|x|<|t|} = 0$, the pair $\{y, 0\}$ belongs to the classes D_- and D_+ of the incoming and outgoing data simultaneously and, thus, provides an example of $D_+ \cap D_- \neq \{0\}$. A noticeable fact is that such an intersection is possible even in the case $\mathrm{Ker}\ H = \{0\}$. Perhaps this example is new: we did not succeed in finding analogues in literature.

The origin $x = 0$ plays the role of a point which stops the reversing waves. We introduce the set $\Upsilon[q] \subset \mathbb{R}^3$ of such points and hope that it proves to be an interesting object for further investigations.

At the end of the paper we present the orthogonality conditions on a control f ensuring L_2-stability of the trajectory: $\|u^f(\cdot, t)\|_{\mathcal{H}} \leq c\|f\|_{\mathcal{F}}$ holds for all $t \in (-\infty, \infty)$ if and only if $(f, g_k)_{\mathcal{F}} = 0$, $k = 1, \ldots, p$, where g_k are determined by the negative spectrum of H in an explicit way.

0.4. Motivation and comments.

- In the future, we plan to apply the results of this paper to the dynamical (time-domain) inverse problem that is to recover the potential q from the response operator R of system (0.1)–(0.3) (see section 2.4). By hyperbolicity of the system, this operator depends *locally* on potential: its part $R\mid_{\mathcal{F}^\xi}$ is determined by the restriction $q\mid_{\mathbb{R}^3\setminus B_\xi}$. Correspondingly, the recovering procedure should be local in the following sense: given $R\mid_{\mathcal{F}^\xi}$ it must recover $q\mid_{\mathbb{R}^3\setminus B_\xi}$. In other words, knowing the response of the system on delayed controls $f\in\mathcal{F}^\xi$, one must determine the potential in the domain $\mathbb{R}^3\setminus B_\xi$ filled with delayed incoming waves $u^f(\cdot,0)$. Such a locality is a specific feature of the *boundary control (BC) method*, which is an approach to inverse problems based upon their connections with control theory [2]. It is the approach, which motivates the study of $\mathcal{U}^\xi$ and $\mathcal{D}^\xi$: by philosophy of the BC method, analysis of controllability of a system is the first step towards solving the corresponding inverse problem.
- Dealing with the scattering problem of such a kind, one cannot avoid parallels to the Lax–Phillips theory (LPT) and we do comment on such parallels in the text. However, our presentation is independent. One of the reasons is that at the moment we do not fully recognize the place of our central object $\mathcal{D}^\xi$ in the context of LPT. Also, we deal mainly with L_2-solutions u^f (not with a complete state $\{u^f,u^f_t\}$) since for the incoming waves, the component u^f_t is determined by u^f. In addition, we prefer L_2-norms avoiding the indefinite energy $\int_{\mathbb{R}^3}u_t^2+|\nabla u|^2+qu^2$.
- Our paper extends the results of [5], which deals with $q=0$, to the perturbed case.

1. Unperturbed system. Here, dealing mainly with the case $q=0$, we present some results of [5] and supplement them with geometrical optics relations used in what follows.

1.1. Expansions over spherical harmonics. Let $Y_l^m(\theta)$, $l\geq 0$, $m=-l,-l+1,\dots,0,\dots,l-1,l$, be the standard spherical functions (*harmonics*) satisfying

$$-\Delta_\omega Y_l^m=l(l+1)Y_l^m\quad\text{on}\quad S^2$$

(Δ_ω is the Beltrami–Laplace operator) and constituting an orthonormal basis in $L_2(S^2)$. The unperturbed system is

$$u_{tt}-\Delta u=0,\qquad (x,t)\in\mathbb{R}^3\times(-\infty,0),\tag{1.1}$$

$$u\mid_{|x|<-t}=0,\tag{1.2}$$

$$\lim_{s\to\infty}su((s+\tau)\theta,-s)=f(\tau,\theta),\qquad(\tau,\theta)\in[0,\infty)\times S^2;\tag{1.3}$$

its outer and inner spaces can be represented, respectively, in the form

$$\mathcal{H}=\oplus\sum_{l,m}\mathcal{H}_{lm}\ ,\quad \mathcal{H}_{lm}:=\left\{y=\frac{v(r)}{r}\,Y_l^m(\omega)\ \middle|\ \int_0^\infty v^2(r)dr<\infty\right\}\tag{1.4}$$

(we denote $\sum_{l,m}:=\sum_{l=0}^\infty\sum_{m=-l}^{m=l}$, $r:=|x|$, $\omega:=\frac{x}{|x|}$ and keep these notations in what follows) and

$$\mathcal{F}=\oplus\sum_{l,m}\mathcal{F}_{lm}\ ,\quad \mathcal{F}_{lm}=\left\{f=g(\tau)\,Y_l^m(\omega)\ \middle|\ \int_0^\infty g^2(\tau)dr<\infty\right\}.\tag{1.5}$$

1.2. Partial problems. Choose an $f \in \mathcal{F}$. Separating variables in (1.1)–(1.3) in accordance with decompositions (1.4), (1.5), we represent

$$f(\tau, \theta) = \sum_{l,m} f_{lm}(\tau)\, Y_l^m(\theta) \tag{1.6}$$

and look for the solution $u = u^f(x,t)$ in the form

$$u^f(x,t) = \sum_{l,m} \frac{u_{lm}(r,t)}{r}\, Y_l^m(\omega)\,, \tag{1.7}$$

which reduces (1.1)–(1.3) to a series of *partial problems*

$$u_{tt} - u_{rr} + \frac{l(l+1)}{r^2}\, u = 0, \qquad (r,t) \in (0,\infty) \times (-\infty, 0), \tag{1.8}$$

$$u\,|_{r<-t} = 0, \tag{1.9}$$

$$\lim_{s\to\infty} u(s+\tau, -s) = f(\tau), \qquad \tau \in [0,\infty). \tag{1.10}$$

Solving them for $f = f_{lm}(\tau)$, we get the solution $u = u_{lm}(r,t)$ and arrive at the following results (e.g., see [5]).

(i) The partial problem can be solved explicitly: for any $\phi \in C_0^\infty(0,\infty)$ the function

$$u^f(r,t) = r^l \left(\frac{\partial}{\partial r}\frac{1}{r}\right)^l \phi(r+t) \tag{1.11}$$

satisfies (1.8)–(1.10) with

$$f(\tau) = \left(\frac{d}{d\tau}\right)^l \phi(\tau). \tag{1.12}$$

For controls of the form (1.12), the inclusion $\operatorname{supp} f \subset [a,b] \subset (0,\infty)$ implies

$$\operatorname{supp} u^f(\cdot, t) \subset [a-t, b-t]$$

and, hence, the solution is compactly supported for all times t. One more important fact is that the class of controls

$$L_l := \left(\frac{d}{d\tau}\right)^l C_0^\infty(0,\infty), \quad l = 0, 1, \dots,$$

as well as each of its subclasses

$$L_l^{(k)} := \left(\frac{d}{d\tau}\right)^k L_l\ , \quad k = 0, 1, \dots,$$

are dense in $L_2(0,\infty)$. Note also the density of the classes $\left(\int_0^\tau\right) L_l^{(k)}$ for $l + k > 0$.

(ii) Representations (1.11)–(1.12) determine the map $W^l : f \mapsto u^f(\cdot, 0)$, which is an isometric operator from $L_2(0,\infty)$ to $L_2(0,\infty)$. Its extension to $L_2(0,\infty)$ turns out to be a unitary operator, which we denote also by W^l. The L_2-solutions of (1.8)–(1.10) can be introduced through this operator by

$$u^f(\cdot, t) := W^l T_t f, \quad t \le 0, \tag{1.13}$$

where T_t is a shift operator,

$$(T_t f)(\tau) := \begin{cases} 0, & 0 \le \tau \le |t|, \\ f(\tau - |t|), & \tau \ge |t|. \end{cases}$$

(iii) The reachable sets of system (1.8)–(1.10) are

$$U_l^\xi := W^l L_2(\xi, \infty), \quad \xi \ge 0,$$

where $L_2(\xi,\infty) := T_\xi L_2(0,\infty)$ is the class of delayed controls; the defect subspaces (unreachable sets) are

$$D_l^\xi := L_2(\xi,\infty) \ominus U_l^\xi, \quad \xi \ge 0.$$

The following characterization of the defect is obtained in [5].

Assign a function $a = a(r) \in L_2(0,\infty)$ to a class A_l^ξ if $\operatorname{supp} a \subset [\xi, \infty)$ and there exists an integer $p > 1$ such that

$$\left[-\frac{d^2}{dr^2} + \frac{l(l+1)}{r^2}\right]^p a = 0, \quad r > \xi. \tag{1.14}$$

For an $a \in A_l^\xi$, define $\operatorname{rank} a$ as the minimal p providing (1.14), and put

$$\operatorname{rank} A_l^\xi := \max_{a \in A_l^\xi} \operatorname{rank} a.$$

Then, one has

$$D_0^\xi = A_0^\xi = \{0\}\ , \quad \xi \ge 0 \tag{1.15}$$

(that is commented on as "s-waves are controllable"), whereas for $l \ge 1$ the set A_l^ξ turns out to be a finite-dimensional subspace,

$$\dim A_l^\xi = \operatorname{rank} A_l^\xi = d(l) := \frac{l}{2} + \frac{1-(-1)^l}{4},$$

spanned on a basis

$$\frac{\chi(r-\xi)}{r^l},\ \frac{\chi(r-\xi)}{r^{l-2}}, \dots, \frac{\chi(r-\xi)}{r^{\frac{3+(-1)^l}{2}}}, \tag{1.16}$$

where $\chi(s) := \frac{1}{2}[1 + \operatorname{sign} s]$ is the Heaviside function. As is shown in [5], the equality

$$D_l^\xi = A_l^\xi\ , \quad l \ge 0,\ \xi > 0, \tag{1.17}$$

holds. For $\xi = 0$, the functions (1.16) do not belong to $L_2(0,\infty)$ and, hence,

$$D_l^0 = A_l^0 = \{0\}. \tag{1.18}$$

1.3. Control operator. Returning from the partial problems to system (1.1)–(1.3), we define its L_2-solutions in accordance with (1.6), (1.7), (1.13): for $f \in \mathcal{F}$ we set

$$u^f(x,t) := \sum_{l,m} \frac{1}{r} \left(W^l T_t \Pi_{lm} f\right)(r)\, Y_l^m(\omega), \tag{1.19}$$

where $\Pi_{lm} : \mathcal{F} \to L_2(0,\infty)$,

$$(\Pi_{lm} f)(\tau) := \int_{S^2} f(\tau,\theta)\, Y_l^m(\theta)\, d\theta\,, \quad \tau \geq 0.$$

By this, the control operator of the unperturbed system $W_0 : \mathcal{F} \to \mathcal{H}$, $W_0 f = u^f(\cdot, 0)$ is unitary[1] and the relation

$$u^f(\cdot,t) = W_0 T_t f, \quad t \leq 0, \tag{1.20}$$

holds (see (1.13)). It is easy to verify that an L_2-solution u^f satisfies (1.1) also in the sense of distributions and, as an $\mathcal{H}$-valued function of time (*trajectory*), belongs to the class $C((-\infty,0];\mathcal{H})$. Moreover, considering (1.1)–(1.3) for all times, one has $u^f \in C((-\infty,\infty);\mathcal{H})$. For a smooth control f vanishing near $\tau = 0$, the solution u^f is smooth and can be represented in the well-known form: assuming f extended to $\tau < 0$ by zero one has

$$u^f(x,t) = \frac{1}{2\pi} \int_{S^2} \frac{\partial f}{\partial \tau}(t + x\cdot\theta, \theta)\, d\theta \tag{1.21}$$

(e.g., see [10]). This formula yields

$$(W_0 f)(x) = \frac{1}{2\pi} \int_{S^2} \frac{\partial f}{\partial \tau}(x\cdot\theta, \theta)\, d\theta. \tag{1.22}$$

For the later use, it is convenient to introduce one more special class of controls and the corresponding solutions. Define

$$\mathcal{L}_{lm} := \{f \in \mathcal{F} \mid \ f = g(\tau)\, Y_l^m(\theta), g \in L_l\}$$

(see section 1.2(i)) and consider the class of controls

$$\mathcal{L} := \left[\oplus \sum_{l,m} \mathcal{L}_{lm}\right] \cap C_0^\infty(\Sigma),$$

which is dense in $\mathcal{F}$. Its subclasses

$$\mathcal{L}^{(k)} := \left(\frac{\partial}{\partial \tau}\right)^k \mathcal{L}\,, \quad k = 1,2,\ldots,$$

are also dense. In addition, note that $\mathcal{L}^{(k)} \cap \mathcal{F}^\xi$ is dense in $\mathcal{F}^\xi$ for every $\xi \geq 0$.

If $f \in \mathcal{L}$ and $\operatorname{supp} f \subset [a,b] \times S^2 \subset \Sigma$, then, in accordance with the results of section 1.2(i), representation (1.7) yields

$$\operatorname{supp} u^f(\cdot,t) \subset \overline{B}_{b-t} \setminus B_{a-t}, \quad t \leq 0. \tag{1.23}$$

[1]This fact also easily follows from LPT.

Thus, the controls $f \in \mathcal{L}$ produce the waves compactly supported in $\mathbb{R}^3$.

The space of controls contains the Sobolev class

$$\mathcal{F}_1 := \left\{ f \in \mathcal{F} \;\middle|\; \frac{\partial f}{\partial \tau} \in \mathcal{F} \right\}$$

equipped with the norm $\|f\|_1^2 = \|f\|_{\mathcal{F}}^2 + \|\frac{\partial f}{\partial \tau}\|_{\mathcal{F}}^2$ and its subclass

$$\mathcal{F}_{1,0} := \{ f \in \mathcal{F}_1 \;\big|\; f|_{\tau=0} = 0 \},$$

the set $\mathcal{L}$ being dense in $\mathcal{F}_{1,0}$.

Take an $f \in \mathcal{L}$. Integrating by parts with regard to the isometry of the control operator and property (1.23), we have

$$\begin{aligned}
\|f\|_1^2 &= \|f\|_{\mathcal{F}}^2 + \left(\frac{\partial f}{\partial \tau}, \frac{\partial f}{\partial \tau} \right)_{\mathcal{F}} = \|f\|_{\mathcal{F}}^2 - \left(\frac{\partial^2 f}{\partial \tau^2}, f \right)_{\mathcal{F}} \\
&= \|u^f(\cdot, 0)\|_{\mathcal{H}}^2 - \left(u^{\frac{\partial^2 f}{\partial \tau^2}}(\cdot, 0), u^f(\cdot, 0) \right)_{\mathcal{H}} = \|u^f(\cdot, 0)\|_{\mathcal{H}}^2 - \left(u^f_{tt}(\cdot, 0), u^f(\cdot, 0) \right)_{\mathcal{H}} \\
&= \|u^f(\cdot, 0)\|_{\mathcal{H}}^2 - \left(\Delta u^f(\cdot, 0), u^f(\cdot, 0) \right)_{\mathcal{H}} = \|u^f(\cdot, 0)\|_{H^1(\mathbb{R}^3)}^2 .
\end{aligned}$$

Extending to $f \in \mathcal{F}_{1,0}$, we obtain an isometric embedding

$$W_0 \mathcal{F}_{1,0} \subset H^1(\mathbb{R}^3). \tag{1.24}$$

This simple straightforward derivation demonstrates the utility of the class $\mathcal{L}$. However, (1.24) can be derived from LPT (see [10]).

1.4. Observation operator. The adjoint operator $W_0^* : \mathcal{H} \to \mathcal{F}$ plays the role of an *observation operator* of system (1.1)–(1.3). Since W_0 is unitary, one has $W_0^* = W_0^{-1}$, which relates W_0^* to the Radon transform

$$(\mathcal{R}y)(\tau, \theta) := \int_{\sigma \cdot \theta = \tau} y(\sigma)\, d\sigma, \quad (\tau, \theta) \in \Sigma,$$

as follows. For any $y \in C_0^\infty(\mathbb{R}^3)$, by the Radon inversion formula one has

$$\begin{aligned}
y(x) &= -\frac{1}{8\pi^2} \Delta_x \int_{S^2} (\mathcal{R}y)(x \cdot \theta, \theta)\, d\theta = -\frac{1}{8\pi^2} \int_{S^2} \left[\frac{\partial^2}{\partial \tau^2} \mathcal{R}y \right] (x \cdot \theta, \theta)\, d\theta \\
&= \frac{1}{2\pi} \int_{S^2} \frac{\partial}{\partial \tau} \left[-\frac{1}{4\pi} \frac{\partial}{\partial \tau} \mathcal{R}y \right] (x \cdot \theta, \theta)\, d\theta = \langle \text{see (1.22)} \rangle \\
&= \left(W_0 \left[-\frac{1}{4\pi} \frac{\partial}{\partial \tau} \mathcal{R}y \right] \right)(x);
\end{aligned}$$

hence,

$$W_0^* = W_0^{-1} = -\frac{1}{4\pi} \frac{\partial}{\partial \tau} \mathcal{R}\,, \tag{1.25}$$

whereas the isometry of W_0^* corresponds to the classical Plancherel formula for $\mathcal{R}$ (see [7], [8], [10]).

The embedding

$$W_0^* H^1(\mathbb{R}^3) \subset \mathcal{F}_1 \tag{1.26}$$

will be used below; it easily follows from the properties of the Radon transform and (1.25).

1.5. Controllability. To describe the structure of the sets $\mathcal{U}^\xi$ and $\mathcal{D}^\xi$ in the unperturbed case one needs merely to reformulate the results of section 1.2(iii).

Recall that the polyharmonic subspaces $\mathcal{A}^\xi$ are defined at the end of section 0.2. In the case $q = 0$, by this definition and in accordance with (1.4), one easily gets

$$\mathcal{A}^\xi = \oplus \sum_{l,m} \left\{ y \in \mathcal{H}_{lm} \;\middle|\; y = \frac{a(r)}{r}\, Y_l^m(\omega), a \in A_l^\xi \right\}.$$

By virtue of (1.15)–(1.18), the equalities

$$\mathcal{D}^\xi = \mathcal{A}^\xi, \quad \xi > 0; \quad \mathcal{D}^0 = \mathcal{A}^0 = \{0\} \tag{1.27}$$

hold (see [5]). Thus, for $\xi > 0$ the defect sets are infinite dimensional, whereas the reachable sets $\mathcal{U}^\xi = W_0\mathcal{F}^\xi$ are the *closed* subspaces determined by infinite number of orthogonality conditions: $y = \sum_{l,m} \frac{y_{lm}(r)}{r}\, Y_l^m(\omega)$ belongs to $\mathcal{U}^\xi$ if and only if $y_{lm} \perp A_l^\xi$.

1.6. Geometrical optics. Here we modify representations (1.21) and (1.22), extending them to the case of controls with $f\,|_{\tau=0} \neq 0$. Such controls with a jump at $\tau = 0$ produce the waves with a jump at the characteristic cone $\{(x,t) \mid |x| = |t|\}$, i.e., at the forward front of the wave. The geometrical optics formulae express the amplitude of the jump of u^f through $f\,|_{\tau=0}$.

Fix $\omega \in S^2$ and define

$$\pi_b(\omega) := \begin{cases} \left\{\theta \in S^2 \mid \omega \cdot \theta = b\right\}, & b \in [-1,1], \\ \emptyset, & |b| > 1. \end{cases}$$

The set $\pi_b(\omega)$ is a parallel on the unit sphere with the north pole ω, the length of the parallel is equal to $2\pi\sqrt{1-b^2}$; $\pi_0(\omega)$ is the equator; $\pi_{\pm 1}(\omega) = \pm\omega$. For a function g on S^2, denote by

$$[g]_b(\omega) := \begin{cases} \frac{1}{2\pi\sqrt{1-b^2}} \int_{\pi_b(\omega)} g(\theta)\, d\theta, & b \in [-1,1], \\ g(-\omega), & b = -1, \\ g(\omega), & b = 1, \\ 0, & |b| > 1, \end{cases}$$

the mean value of g on the parallel.

Lemma 1.1. *For $f \in \mathcal{F}_1$, the representation*

$$u^f(x,t) = \frac{1}{2\pi} \int_{S^2} f_\tau(t + r\omega\cdot\theta, \theta)\, d\theta + \frac{1}{r}\, [f(0,\cdot)]_{-\frac{t}{r}}(\omega) \tag{1.28}$$

holds, where $r = |x|$, $\omega = \frac{x}{|x|}$, and f_τ is understood as a classical (Sobolev) derivative of $f|_{\tau>0}$, the derivative being extended to $\tau < 0$ by zero.

Proof. Let us begin with $f \in \mathcal{F}_1 \cap C^1(\overline{\Sigma})$. Fix $\varepsilon > 0$ and denote

$$f^\varepsilon(\tau,\omega) := \begin{cases} 0, & \tau < 0, \\ \frac{f(0,\omega)}{\varepsilon}\,\tau, & 0 \le \tau < \varepsilon, \\ f(\tau - \varepsilon, \omega), & \varepsilon \le \tau < \infty. \end{cases}$$

Approximating $f^\varepsilon \in \mathcal{F}_{1,0}$ by smooth controls, we easily extend (1.21) to $f = f^\varepsilon$ and get

$$u^{f^\varepsilon}(x,t) = \frac{1}{2\pi}\int_{S^2}\frac{\partial f^\varepsilon}{\partial\tau}(t + x\cdot\theta,\theta)\,d\theta = \frac{1}{2\pi\varepsilon}\int_{0\le t+x\cdot\theta<\varepsilon} f(0,\theta)\,d\theta$$
$$+\frac{1}{2\pi}\int_{t+x\cdot\theta\ge\varepsilon} f_\tau(t + x\cdot\theta-\varepsilon,\theta)\,d\theta =: \, I_\varepsilon + II_\varepsilon. \tag{1.29}$$

To analyze I_ε, we introduce polar coordinates: choose $\omega',\omega'' \in S^2$ such that $\{\omega,\omega',\omega''\}$ form a Cartesian basis in $\mathbb{R}^3$ and define $\varphi = \varphi(\theta) \in [0, 2\pi)$, $\psi = \psi(\theta) \in [0,\pi]$ by $\cos\varphi = \omega'\cdot\theta$, $\sin\varphi = \omega''\cdot\theta$, $\cos\psi = \omega\cdot\theta$. Since the set of integration in I_ε is determined by the inequalities

$$\frac{-t}{r} \le \omega\cdot\theta \le \frac{-t}{r} + \frac{\varepsilon}{r},$$

one has

$$I_\varepsilon = \frac{1}{2\pi\varepsilon}\int_0^{2\pi}d\varphi\int_{\arccos[\frac{-t}{r}+\frac{\varepsilon}{r}]}^{\arccos\frac{-t}{r}} f\left(0,\theta(\varphi,\psi)\right)\sin\psi\,d\psi$$
$$= \frac{1}{2\pi}\int_0^{2\pi}d\varphi\,\frac{1}{\varepsilon}\int_{\frac{-t}{r}}^{\frac{-t}{r}+\frac{\varepsilon}{r}} f\left(0,\theta\left(\varphi,\arccos\eta\right)\right)\,d\eta.$$

Fix x,t such that $|x| > -t$. Sending $\varepsilon \to 0$ we get

$$I_\varepsilon \to \frac{1}{2\pi r}\int_0^{2\pi} f\left(0,\theta\left(\varphi,\arccos\frac{-t}{r}\right)\right)\,d\varphi = \frac{1}{r}\,[f(0,\cdot)]_{-\frac{t}{r}}(\omega).$$

By the continuity of f_τ, the limit passage in II_ε for fixed x,t gives

$$II_\varepsilon \to \frac{1}{2\pi}\int_{t+x\cdot\omega\ge0} f_\tau(t + x\cdot\theta,\theta)\,d\theta = \int_{S^2} f_\tau(t + r\omega\cdot\theta,\theta)\,d\theta.$$

Hence, the right-hand side (r.h.s.) of (1.29) tends pointwise in $\{(x,t) \mid 0 \le -t < |x|\}$ to the r.h.s. of (1.28). At the same time, $f_\varepsilon \to f$ in $\mathcal{F}$ that implies $u^{f^\varepsilon}(\cdot,t) \to u^f(\cdot,t)$ in $\mathcal{H}$, and we arrive at representation (1.28). For $(x,t) : |x| < -t$ the representation takes the trivial form $0 = 0$.

If $f \in \mathcal{F}_1$, then the value $f|_{\tau=0}$ is well defined as an element of $L_2(S^2)$, as well as $[f(0,\cdot)]_b(\cdot) \in L_2(S^2)$.[2] Therefore, approximating f by elements of $\mathcal{F}_1 \cap C^1(\overline{\Sigma})$ in $\mathcal{F}_1$-norm and passing to the limit, we justify (1.28). $\square$

A peculiarity of formula (1.28) is that, for a fixed t, the summands in its r.h.s. not necessarily belong to $\mathcal{H} = L_2(\mathbb{R}^3)$ individually. The formula represents the wave $u^f(\cdot,t)$ in a neighborhood of $x = 0$ and enables one to analyze its behavior near the forward front $\{x \in \mathbb{R}^3 \mid |x| = -t\}$. Namely, if x approaches the front ($|x| \to -t + 0$), then the first summand vanishes (since $\operatorname{mes}\{\theta \in S^2 \mid t + x\cdot\omega \ge 0\} \to 0$), whereas the second summand tends to the limit $r^{-1}[f(0,\cdot)]_1(\omega) = r^{-1}f(0,\omega)$. Summarizing, we get the relation

$$u^f(x,t)|_{x=(-t+0)\omega} = -\frac{f(0,\omega)}{t}\,, \tag{1.30}$$

[2] See the comments in section 1.7.

which is a typical geometrical optics formula.

Fixing $x \neq 0$ and taking $t = 0$ in (1.28), we represent the unperturbed control operator in the form

$$(W_0 f)(x) = \frac{1}{2\pi} \int_{S^2} f_\tau(r\omega \cdot \theta, \theta)\, d\theta + \frac{1}{r}\, [f(0, \cdot)]_0(\omega), \quad x \in \mathbb{R}^3. \tag{1.31}$$

The first summand belongs to $H^1_{\mathrm{loc}}(\mathbb{R}^3)$. Indeed, choose an (arbitrarily large) $r' > 0$ and $\eta = \eta(\tau) \in C^\infty[0, \infty)$ such that $\eta\mid_{[0,r']} = 1, \eta\mid_{[r'+1,\infty)} = 0$. Then, representing

$$\begin{aligned} f(\tau, \cdot) &= \eta(\tau)[f(\tau, \cdot) - f(0, \cdot)] + \{\eta(\tau) f(0, \cdot) + [1 - \eta(\tau)] f(\tau, \cdot)\} \\ &= f_1(\tau, \cdot) + f_2(\tau, \cdot) \end{aligned}$$

with $f_1 \in \mathcal{F}_{1,0}$ and $\operatorname{supp}(f_2)_\tau \subset [r', \infty)$, we have

$$\int_{S^2} f_\tau(r\omega \cdot \theta, \theta)\, d\theta = \int_{S^2} f_{1\tau}(r\omega \cdot \theta, \theta)\, d\theta + \int_{S^2} f_{2\tau}(r\omega \cdot \theta, \theta)\, d\theta = I_1(x) + I_2(x),$$

where $I_1 = W_0 f_1 \in H^1(\mathbb{R}^3)$ (see (1.24)) and $\operatorname{supp} I_2 \subset \mathbb{R}^3 \setminus B_{r'}$. The second summand in (1.31) is singular at $x = 0$ and does not belong to $H^1_{\mathrm{loc}}(\mathbb{R}^3)$.

1.7. Comments.

- In [5] we introduced one more representation of W_0^* through the so-called M transform. This transform is constructed from the jumps appearing as a result of projecting the functions on the reachable sets (see also [3]).
- The map $g \mapsto [g]_b(\cdot)$ is known as the Minkowski–Funk transform [7]; for $|b| < 1$ it is a compact operator in $L_2(S^2)$.
- Most probably, formulae (1.28), (1.30) are known but we did not succeed in finding exact references.

2. Perturbed system. We study system (0.1)–(0.3) and prepare auxiliary results required for further investigation of its controllability.

2.1. Representation of u^f. Recall that the potential is assumed compactly supported: $\operatorname{supp} q \subset \overline{B}_{r_*}$.

One possible way to establish the solvability of problem (0.1)–(0.3) for all $t \in (-\infty, \infty)$ is to present it in the form

$$(u - u_0^f)_{tt} - \Delta(u - u_0^f) = -qu, \qquad (x, t) \in \mathbb{R}^3 \times (-r_*, \infty), \tag{2.1}$$

$$(u - u_0^f)\mid_{t<-r_*} = 0, \tag{2.2}$$

where u_0^f is the solution of (1.1)–(1.3) and, applying the Poisson–Kirchhoff formula, to reduce to a Volterra-type equation

$$u(x, t) = u_0^f(x, t) - \frac{1}{4\pi} \int_{B_{t+r_*}(x)} \frac{q(\eta) u(\eta, t + r_* - |x - \eta|)}{|x - \eta|} d\eta, \tag{2.3}$$

which can be analyzed by standard methods (e.g., see [15]). If $f \in C_0^\infty(\Sigma)$, the solution $u = u^f(x, t)$ is classical (smooth).

The second representation is derived as follows. Analyzing (2.3), one establishes the well-known property of finiteness of the domain of influence, which leads to

$$\operatorname{supp}(u^f - u_0^f) \subset \{(x, t) \mid t \geq -r_*, -t \leq |x| \leq 2r_* + t\}$$

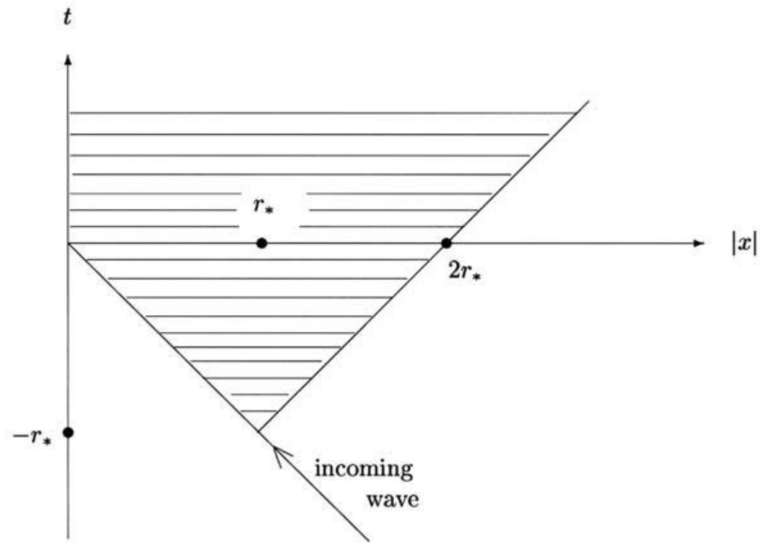

FIG. 2.1. *The set* supp $(u^f - u_0^f)$.

(this support is shadowed on Figure 2.1). Therefore, for times $t \le 0$ the problem for the difference $u^f - u_0^f$ can be reduced to the cylinder $B_{2r_*} \times [-r_*, 0]$ and written in the form

$$\begin{aligned}
&(u - u_0^f)_{tt} - \Delta(u - u_0^f) = -qu, \qquad (x,t) \in\ B_{2r_*} \times (-r_*, 0),\\
&(u - u_0^f)\mid_{t=-r_*} = (u - u_0^f)_t \mid_{t=-r_*} = 0, \qquad x \in \overline{B}_{2r_*},\\
&(u - u_0^f)\mid_{\Sigma^{r_*}} = 0,
\end{aligned}$$

where $\Sigma^{r_*} := \partial B_{2r_*} \times [-r_*, 0]$. Then, by an operator version of the Duhamel formula, one has

$$\left[u(\cdot,t) - u_0^f(\cdot,t)\right]\Big|_{B_{2r_*}\times[-r_*,0]} = -L^{-\frac{1}{2}} \int_{-r_*}^{t} \sin\left[(t-s)L^{\frac{1}{2}}\right] Y\left[q(\cdot)u(\cdot,s)\right] ds,$$

where $L : L_2(B_{2r_*}) \to L_2(B_{2r_*})$, Dom $L = H^2(B_{2r_*}) \cap H_0^1(B_{2r_*})$, $Ly = -\Delta y$; $Y : L^2(\mathbb{R}^3) \to L^2(B_{2r_*})$ is a reduction, $Yy := y\mid_{B_{2r_*}}$. Returning to $\mathbb{R}^3$, we get

$$u(\cdot,t) = u_0^f(\cdot,t) - Y^* L^{-\frac{1}{2}} \int_{-r_*}^{t} \sin\left[(t-s)L^{\frac{1}{2}}\right] Y\left[q(\cdot)u(\cdot,s)\right] ds. \tag{2.4}$$

The third representation uses a spectral decomposition of the operator $H = -\Delta + q$ (see the end of section 0.2). Let $\{E_\lambda\}_{\lambda\in\mathbb{R}} : E_\lambda = E_{\lambda-0}$ be its spectral measure, $\mathcal{H}_- := E_0\mathcal{H}$ be the subspace of negative spectrum, $\mathcal{H}_0 := (E_{+0} - E_0)\mathcal{H} = \operatorname{Ker} H$, and $\mathcal{H}_+ := (I - E_{+0})\mathcal{H}$, so that $\mathcal{H} = \mathcal{H}_- \oplus \mathcal{H}_0 \oplus \mathcal{H}_+$. Let $\varphi_1, \varphi_2, \dots, \varphi_p$ and $\varphi_1^0, \varphi_2^0, \dots, \varphi_n^0$ be the orthonormal bases in $\mathcal{H}_-$ and $\mathcal{H}_0$, respectively, $H\varphi_k = -\varkappa_k^2\varphi_k$, $\varkappa_k > 0$, $H\varphi_k^0 = 0$. Solving the problem

$$\begin{aligned}
&u_{tt} + Hu = 0, \qquad t \in (-\infty, \infty),\\
&u\mid_{t=0} = u^f(\cdot,0), \quad u_t\mid_{t=0} = u_t^f(\cdot,0)
\end{aligned}$$

by the Fourier method, we get

$$
\begin{aligned}
u^f(\cdot,t) = \sum_{k=1}^{p}&\left\{\cosh \varkappa_k t\, \left(u^f(\cdot,0),\varphi_k\right)_{\mathcal{H}} + \frac{\sinh \varkappa_k t}{\varkappa_k}\left(u^f_t(\cdot,0),\varphi_k\right)_{\mathcal{H}}\right\}\varphi_k \\
&+ \sum_{k=1}^{n}\left\{\mathbf{1}(t)\, \left(u^f(\cdot,0),\varphi^0_k\right)_{\mathcal{H}} + t(u^f_t(\cdot,0),\varphi^0_k)_{\mathcal{H}}\right\}\varphi^0_k \\
&+ \int_{+0}^{\infty}\left\{\cos\sqrt{\lambda}\,t\; dE_\lambda\, u^f(\cdot,0) + \frac{\sin\sqrt{\lambda}\,t}{\sqrt{\lambda}}\, dE_\lambda\, u^f_t(\cdot,0)\right\}. \qquad (2.5)
\end{aligned}
$$

Each of the representations mentioned above can be used for introducing a generalized solution of (0.1)–(0.3) and proving its existence and uniqueness. For instance, considering (2.4) as a second-order Volterra equation in the space $C([-r_*,0];\mathcal{H})$, it is easy to establish its solvability and the estimates

$$
\begin{aligned}
\|u^f(\cdot,t)\|_{\mathcal{H}} \;&\le\; \|u^f\|_{C([-r_*,0];\mathcal{H})} \;\le\; c_q\|u^f_0\|_{C([-r_*,0];\mathcal{H})} \\
&= \langle \text{see } (1.20)\rangle \;=\; c_q \sup_{t\in[-r_*,0]}\|W_0T_tf\|_{\mathcal{H}} = c_q\|f\|_{\mathcal{F}} \qquad (2.6)
\end{aligned}
$$

(with regard to isometry of W_0 and T_t), where a constant c_q is determined by r_* and $\|q\|_{L_\infty(B_{r_*})}$. Then the solution of (2.4) is claimed to be an L_2-solution of (0.1)–(0.3) for $f\in\mathcal{F}$.

Note in addition that for $f\in\mathcal{L}$,

$$
\operatorname{diam}\operatorname{supp} u^f(\cdot,t) < \infty, \quad t\in(-\infty,\infty), \qquad (2.7)
$$

holds. Indeed, for $t<-r_*$ one has $u^f(\cdot,t) = u^f_0(\cdot,t)$ and, hence, $\operatorname{supp} u^f(\cdot,t)$ is a compact set (see (1.23)). For $t\in[-r_*,\infty)$ this property is preserved by finiteness of domain of influence. Surely, the diameter tends to infinity as $t\to\infty$.

2.2. Control operator. Along with L_2-solution u^f of (0.1)–(0.3), the operator $W:\mathcal{F}\to\mathcal{H}$, $Wf = u^f(\cdot,0)$ is well defined and bounded: $\|W\|\le c_q$ (see (2.6)). The solution can be represented through the control operator in the form

$$
u^f(\cdot,t) = WT_tf, \qquad t\le 0. \qquad (2.8)
$$

Putting $t=0$ in (2.4) and changing $s\to -s$ in the integral, we obtain

$$
u^f(\cdot,t) = u^f_0(\cdot,t) - Y^*L^{-\frac12}\int_0^{r_*}\sin\left[sL^{\frac12}\right]Y\left[q(\cdot)u(\cdot,-s)\right]\,ds.
$$

By (2.8), this is equivalent to an operator relation

$$
W = W_0 - K, \qquad (2.9)
$$

where

$$
K = Y^*L^{-\frac12}\int_0^{r_*}\sin\left[sL^{\frac12}\right]Y\hat{q}\,WT_s\,ds
$$

and $\hat{q}$ multiplies functions by $q(\cdot)$. Since $L^{-\frac12}$ maps $L_2(B_{2r_*})$ onto $H^1_0(B_{2r_*})$ continuously, the operator $K:\mathcal{F}\to\mathcal{H}$ is compact, $\operatorname{Ran}K\subset Y^*H^1_0(B_{2r_*})\subset H^1(\mathbb{R}^3)$, and the evident estimate

$$
\|K\| \le \lambda_*^{-\frac12} r_* c_q \|q\|_{L_\infty(B_{r_*})} \qquad (2.10)
$$

holds, where $\lambda_* > 0$ is the lowest eigenvalue of L.

Recall the definitions $\mathcal{N} := \operatorname{Ker} W$, $\mathcal{U} := W\mathcal{F} = \operatorname{Ran} W$, and $\mathcal{D} := \mathcal{H} \ominus \mathcal{U}$ (see section 0.2). Since W_0 is unitary and K is compact, (2.9) and Fredholm's theorems lead to $\dim \mathcal{N} = \dim \mathcal{D} < \infty$, proving part of (0.6). Recall also that $\mathcal{F}^\xi = T_\xi \mathcal{F}$ is the subspace of delayed controls. Later we will use the following property of the control operator.

LEMMA 2.1. *The relation $\mathcal{F}^\xi \cap \mathcal{N} = \{0\}$, $\xi > 0$, holds.*

Proof. Fix $\xi > 0$ and choose $f \in \mathcal{F}^\xi \cap \mathcal{N}$. We shall show that $f = 0$.

Since $f \in \mathcal{N}$, one has $u^f(\cdot, 0) = 0$ and, hence, the odd extension

$$u(\cdot, t) = \begin{cases} u^f(\cdot, t), & t < 0, \\ -u^f(\cdot, -t), & t \geq 0, \end{cases}$$

turns out to be a solution of the class $C((-\infty, \infty); \mathcal{H})$ of the equation

$$u_{tt} - \Delta u + qu = 0, \qquad (x, t) \in \mathbb{R}^3 \times (-\infty, \infty). \tag{2.11}$$

Since $f \in \mathcal{F}^\xi$ implies $\operatorname{supp} u^f \subset \{(x, t) \mid |x| \geq -t + \xi\}$, such a solution satisfies $\operatorname{supp} u \subset \{(x, t) \mid |x| \geq |t| + \xi\}$ and, hence,

$$u = 0, \qquad (x, t) \in B_\xi \times (-\infty, \infty). \tag{2.12}$$

Applying the Fourier transform in (2.11), (2.12), we see that the function

$$\tilde{u}(x, k) = \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{ikt} u(x, t)\, dt$$

satisfies

$$-k^2 \tilde{u} - \Delta \tilde{u} + q\tilde{u} = 0, \qquad x \in \mathbb{R}^3,$$

and

$$\tilde{u}(x, k) = 0, \quad x \in B_\xi, \tag{2.13}$$

for all $k \in (-\infty, \infty)$. By the well-known uniqueness theorem for homogeneous second-order elliptic equations (see [9]), (2.13) implies $\tilde{u} = 0$ everywhere in $\mathbb{R}^3$. Hence, $u = 0$, $u^f = 0$, and finally $f = 0$. ∎

2.3. Observation operator. A dynamical system

$$v_{tt} - \Delta v + qv = 0, \qquad (x, t) \in \mathbb{R}^3 \times (-\infty, 0), \tag{2.14}$$

$$v\,|_{t=0} = 0, \quad v_t\,|_{t=0} = y, \qquad x \in \mathbb{R}^3, \tag{2.15}$$

is called *dual* to system (0.1)–(0.3). For $y \in \mathcal{H}$, its L^2-solution $v = v^y(x, t)$ can be introduced through an equivalent integral equation

$$v(x, t) = -\frac{1}{4\pi|t|} \int_{\partial B_{|t|}(x)} y(\sigma)\, d\sigma - \frac{1}{4\pi} \int_{B_{|t|}(x)} \frac{q(\eta) v(\eta, |t| - |x - \eta|)}{|x - \eta|}\, d\eta \tag{2.16}$$

($B_r(x)$ is a ball centered at x) obtained by applying the Poisson–Kirchhoff formula to (2.14), (2.15). This Volterra-type equation has a unique solution $v^y \in C_{\mathrm{loc}}((-\infty, 0]; \mathcal{H})$.

With the dual system one associates the observation operator $O : \mathcal{H} \to \mathcal{F}$, $\mathrm{Dom}\, O = \mathcal{S}$ (the Schwartz class of the smooth rapidly decaying functions):

$$(Oy)(\tau,\omega) := \lim_{s\to\infty} s \left[\frac{\partial v^y}{\partial t} + \frac{\partial v^y}{\partial r}\right]((s+\tau)\omega, -s),$$

where $\frac{\partial}{\partial r} := \frac{\partial}{\partial |x|} = \frac{x}{|x|}\cdot\nabla$. The well-posedness of this definition (i.e., the existence of the pointwise limit belonging to $\mathcal{F}$) can be seen from (2.16): for smooth y, the solution v^y is classical (smooth) and straightforward calculations lead to

$$\begin{aligned}
&\lim_{s\to\infty} s \left[\frac{\partial v^y}{\partial t} + \frac{\partial v^y}{\partial r}\right]((s+\tau)\omega, -s)\\
&\quad = -\frac{1}{4\pi}\frac{\partial}{\partial\tau}\int_{\omega\cdot\sigma=\tau} y(\sigma)\, d\sigma + \frac{1}{4\pi}\int_{\omega\cdot\eta\geq\tau} q(\eta)\, v_t^y(\eta, \tau-\omega\cdot\eta)\, d\eta,
\end{aligned}\tag{2.17}$$

where the first summand in the r.h.s. is $W_0^* y$ (see (1.25)), and the second one is smooth and compactly supported on $\overline{\Sigma}$. Since $|y|, |\nabla y|$ rapidly decrease at infinity, the limit turns out to be uniform with respect to $(\tau,\omega)\in\overline{\Sigma}$.

The following result clarifies a duality of systems (0.1)–(0.3) and (2.14), (2.15).

Lemma 2.2. *The relation $O^* = W$ is valid.*

Proof. For $y \in \mathrm{Dom}\, O$ and $f \in \mathcal{L}$, the solutions u^f and v^f are smooth and (2.7) holds. Integrating by parts, one has

$$\begin{aligned}
0 &= \int_{B_s\times[-s,0]} \left[u_{tt}^f - \Delta u^f + q u^f\right] v^y\, dxdt\\
&= \int_{B_s} dx \left[u_t^f v^y - u^f v_t^f\right]\Big|_{t=-s}^{t=0} - \int_{\partial B_s\times[-s,0]} \left[\frac{\partial u^f}{\partial r} v^y - u^f \frac{\partial v^y}{\partial r}\right] d\sigma dt\\
&\quad + \int_{B_s\times[-s,0]} u^f \left[v_{tt}^y - \Delta v^y + q v^y\right] dxdt\\
&= \langle \text{see } (2.14), (2.15)\rangle\\
&= -\left\{\int_{B_s} u^f(\cdot,0) y\, dx + \int_{B_s} \left[u_t^f v^y - u^f v_t^y\right]\Big|_{t=-s} dx\right\}\\
&\quad - \left\{\int_{-s}^0 dt \int_{\partial B_s} \left[\frac{\partial u^f}{\partial r} v^y - u^f \frac{\partial v^y}{\partial r}\right] d\sigma\right\}\\
&=: -I(s) - II(s),
\end{aligned}\tag{2.18}$$

where $s > 0$ is a large parameter. Since $u^f|_{|x|<-t} = 0$, one has $u^f(\cdot,-s)|_{B_s} = u_t^f(\cdot,-s)|_{B_s} = 0$ and, hence,

$$I(s) \to \int_{\mathbb{R}^3} u^f(\cdot,0) y\, dx = (Wf, y)_{\mathcal{H}}\tag{2.19}$$

as $s\to\infty$. Changing variables $t \to \tau - s$, $\sigma \to s^2\omega$, one gets

$$II(s) = \int_{[0,s]\times S^2} s^2 \left[\frac{\partial u^f}{\partial r} v^y - u^f \frac{\partial v^f}{\partial r}\right](s\omega, \tau-s)\, d\tau d\omega.\tag{2.20}$$

For $y \in \mathcal{L}$, the set $\mathrm{supp}\, f \subset \overline{\Sigma}$ is compact and one can show that the limit in (0.3) is uniform with respect to $(\tau,\omega)\in\overline{\Sigma}$, whereas the asymptotic

$$s u^f(s\omega, \tau - s) = f(\tau,\omega) + o(1)\tag{2.21}$$

is differentiable:

$$\frac{d}{ds}[su^f(s\omega,\tau-s)]=o(1).$$

This implies

$$u^f(s\omega,\tau-s)+s\left[\frac{\partial u^f}{\partial r}-\frac{\partial u^f}{\partial t}\right](s\omega,\tau-s)=o(1)$$

and, combining these asymptotics, we get

$$\begin{aligned} s\frac{\partial u^f}{\partial r}(s\omega,\tau-s)&=s\frac{\partial u^f}{\partial t}(s\omega,\tau-s)+o(1)\\ &=\frac{\partial}{\partial\tau}u^f(s\omega,\tau-s)+o(1)\end{aligned}$$

uniformly with respect to $(\tau,\omega)\in\overline{\Sigma}$. Substituting the asymptotics in (2.20), we have

$$\begin{aligned} II(s)=\int_{[0,s]\times S^2}\Bigg\{&\left[s\frac{\partial}{\partial\tau}u^f(s\omega,\tau-s)\right][sv^y(s\omega,\tau-s)]\\ &-[su^f(s\omega,\tau-s)]\left[s\frac{\partial v^y}{\partial r}(s\omega,\tau-s)\right]\Bigg\}\,d\tau d\omega+o(1).\end{aligned}$$

Integrating by parts in the first summand in $\{\cdots\}$ and taking into account the relations

$$u^f(s\omega,0)\big|_{s\gg1}=0,\quad u^f(s\omega,-s)=0$$

provided by $f\in\mathcal{L}$, one obtains

$$II(s)=-\int_{[0,s]\times S^2}\left[su^f(s\omega,\tau-s)\right]s\left[\frac{\partial v^y}{\partial t}+\frac{\partial v^y}{\partial r}\right](s\omega,\tau-s)\,d\tau d\omega+o(1).$$

Passing to the limit with regard to (2.21), we get

$$II(s)\to-\int_{[0,s]\times S^2}f(\tau,\omega)\left\{\lim_{s\to\infty}s\left[\frac{\partial v^y}{\partial t}+\frac{\partial v^y}{\partial r}\right](s\omega,\tau-s)\right\}d\tau d\omega=-(f,Oy)_{\mathcal{F}}. \tag{2.22}$$

Finally, sending $s\to\infty$ in (2.18) and taking into account (2.19), (2.22), we arrive at

$$0=-(Wf,y)_{\mathcal{H}}+(f,Oy)_{\mathcal{F}},$$

which leads to the assertion of the lemma in view of density of the used f's and y's in $\mathcal{F}$ and $\mathcal{H}$, respectively. ∎

Let us discuss some consequences of this result. The eigenfunctions φ_k of the negative spectrum of H possess the well-known asymptotic as $|x|\to\infty$:

$$\varphi_k(x)=\alpha_k(\omega)\,\frac{e^{-\varkappa_k r}}{r}\,\left[1+o(1)\right]. \tag{2.23}$$

Put $y=\varphi_k$ in (2.14), (2.15); the solution of the dual problem is

$$v^{\varphi_k}(x,t)=\frac{\sinh\varkappa_k t}{\varkappa_k}\,\varphi_k(x). \tag{2.24}$$

Using (2.23), (2.24), one can find the limit, which defines the observation operator, by straightforward calculation and then, applying Lemma 2.2, obtain

$$(W^*\varphi_k)(\tau,\omega) = \alpha_k(\omega)\, e^{-\varkappa_k \tau}, \quad (\tau,\omega) \in \Sigma. \tag{2.25}$$

In the case of $0 \in \sigma_p(H)$ the eigenfunctions φ_k^0 have the asymptotics

$$\varphi_k^0(x) = \frac{\alpha_k^0(\omega)}{r^2}\,[1 + o(1)]\,. \tag{2.26}$$

Considering the dual problem with $y = \varphi_k^0$, we have

$$v^{\varphi_k^0}(x,t) = t\,\varphi_k^0(x). \tag{2.27}$$

Using (2.26), (2.27), one can obtain the equality

$$(W^*\varphi_k^0)(\tau,\omega) = 0, \quad (\tau,\omega) \in \Sigma\,,$$

which yields

$$\operatorname{Ker} H \subset \operatorname{Ker} W^*. \tag{2.28}$$

One more general fact is the embedding $W^*H^1(\mathbb{R}^3) \subset \mathcal{F}_1$, which can be derived from (1.26), (2.17), and Lemma 2.2.

2.4. Response operator. Dealing with system (0.1)–(0.3) for all times $t \in (-\infty,\infty)$, one associates with it a *response operator* $R : \mathcal{F} \to \mathcal{F}$, $\operatorname{Dom} R = \mathcal{L}$,

$$(Rf)(\tau,\omega) := \lim_{s\to+\infty} s u^f((s+\tau)\omega, s), \quad (\tau,\omega) \in \Sigma.$$

The well-posedness of this definition can be verified as follows. If $f \in \mathcal{L}$ and $\operatorname{supp} f \subset [a,b]\times S^2$ $(a > 0)$, then property (1.23) and the finiteness of domain of influence imply

$$u_0^f\big|_{0\le t\le |x|+a} = 0, \quad u^f\big|_{0\le t\le |x|-2r_*} = 0$$

for a large enough $|x|$ (see Figure 2.2: $\operatorname{supp} u_0^f$ and $\operatorname{supp} u^f$ are shadowed; $l_\tau = \{(x,t) \mid x = (s+\tau)\omega,\ t = s;\ s \ge 0\}$ is a space-time ray; the dotted line is the cone $|x| = |t|$).

As a result, $s u_0^f((s+\tau)\omega, s)\,|_{\tau\ge 0}= 0$ for large enough s and, taking into account the asymptotic

$$s - |(s+\tau)\omega - \eta| \to \omega\cdot\eta - \tau + o(1),$$

the passage to the limit in (2.3) easily leads to

$$\begin{aligned}(Rf)(\tau,\omega) &= \lim_{s\to\infty} s u^f((s+\tau)\omega, s)\\ &= -\frac{1}{4\pi}\int_{\omega\cdot\eta\ge\tau-r_*} q(\eta)\, u^f(\eta, \omega\cdot\eta - \tau + r_*)\, d\eta.\end{aligned} \tag{2.29}$$

This justifies the definition and provides also a representation of the response operator. Note a simple consequence of (2.29): since for $\tau > 2r_*$ the domain of integration does not intersect $\operatorname{supp} q$, one has $Rf\,|_{\tau>2r_*}= 0$, i.e., $\operatorname{supp} Rf \subset [0,2r_*]$. Using the same representation, one can show that R acts continuously from $\mathcal{F}$ to $C([0,2r_*]\times S^2)$ and

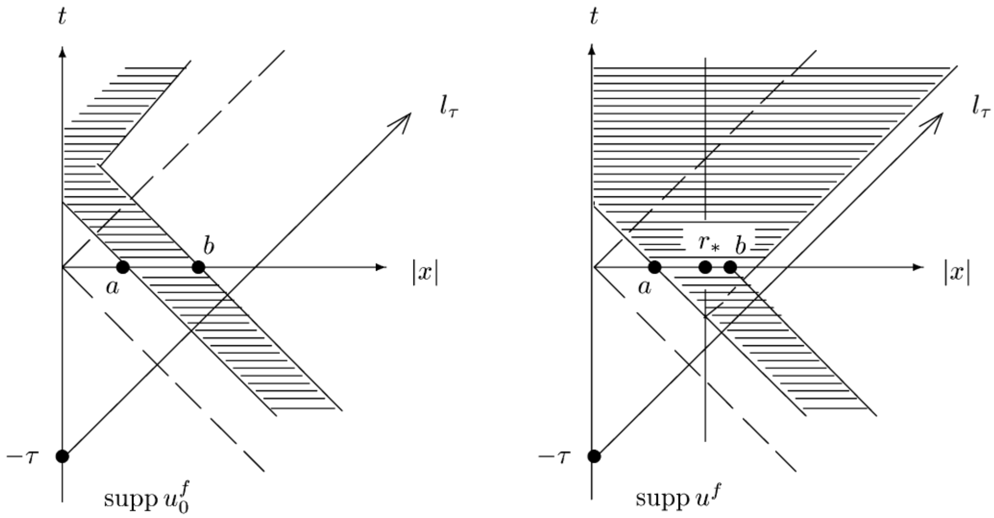

Fig. 2.2. *The supports.*

is a compact operator in $\mathcal{F}$. Hence, R can be extended to $\mathcal{F}$, representation (2.29) remaining in force for $f \in \mathcal{F}$.

An important property of R is the local character of its dependence on the potential: the response of the system on delayed controls $R\mathcal{F}^\xi$ is determined by $q\,|_{\mathbb{R}^3 \setminus B^\xi}$, $\xi \geq 0$. One more general property, following from the time independence of q is the relation $RT_\xi = T_\xi^* R$, $\xi \geq 0$ and its consequence

$$R\,\frac{\partial}{\partial\tau} f = -\,\frac{\partial}{\partial\tau}\,Rf, \quad f \in \mathcal{F}_{1,0}. \tag{2.30}$$

Note in addition that the operator R can be identified with some block of the scattering operator of LPT in the translation representation.

2.5. Connecting operator. A map $C : \mathcal{F} \to \mathcal{F}$,

$$C := W^* W,$$

is called a *connecting operator* of system (0.1)–(0.3). By this definition, for $f, g \in \mathcal{F}$, one has

$$(Cf, g)_{\mathcal{F}} = (Wf, Wg)_{\mathcal{H}} = \left(u^f(\cdot, 0), u^g(\cdot, 0)\right)_{\mathcal{H}}, \tag{2.31}$$

i.e., C connects the Hilbert metrics of the outer and inner spaces.

Lemma 2.3. *The relation*

$$C = I + R \tag{2.32}$$

holds.

Proof. Take $f, g \in \mathcal{L}$ and let u^f, u^g be the corresponding solutions of problem (0.1)–(0.3) considered for all times $t \in (-\infty, \infty)$. Blagovestchenskii's function

$$b(s,t) := \left(u^f(\cdot, s),\, u^g(\cdot, t)\right)_{\mathcal{H}}, \quad -\infty < s, t < \infty,$$

is well defined by (2.7) and possesses the following properties.

(i) Function b satisfies the wave equation

$$b_{tt} - b_{ss} = 0. \tag{2.33}$$

Indeed

$$\begin{aligned}\left[\frac{\partial^2}{\partial t^2} - \frac{\partial^2}{\partial s^2}\right] b(s,t) &= \int_{\mathbb{R}^3} \left[u^f(x,s)u^g_{tt}(x,t) - u^f_{ss}(x,s)u^g(x,t)\right]\, dx \\ &= \int_{\mathbb{R}^3} \left\{u^f(x,s)\left[\Delta u^g(x,t) - q(x)u^g(x,t)\right]\right. \\ &\qquad \left. - \left[\Delta u^f(x,s) - q(x)u^f(x,s)\right] u^g(x,t)\right\}\, dx \\ &= \int_{\mathbb{R}^3} \left[u^f(x,s)\Delta u^g(x,t) - \Delta u^f(x,s)u^g(x,t)\right]\, dx = 0\end{aligned}$$

by compactness of $\operatorname{supp} u^f(\cdot,t)$ and $\operatorname{supp} u^g(\cdot,t)$.

(ii) The relation

$$\lim_{s\to\infty} b(-s,-s) = (f,g)_{\mathcal{F}} \tag{2.34}$$

holds. Indeed, let $\operatorname{supp} f, \operatorname{supp} g \subset (0,\beta] \times S^2$ $(\beta < \infty)$. Since u^f and u^g vanish in the past cone one has

$$\begin{aligned} b(-s,-s) &= \int_{\mathbb{R}^3} u^f(x,-s)\, u^g(x,-s)\, dx = \int_{|x|>-s} \\ &= \langle \text{see } (1.23)\rangle = \int_s^{s+\beta} dr\ r^2 \int_{S^2} u^f(r\omega,-s)\, u^g(r\omega,-s)\, d\omega \\ &= \int_0^\beta d\tau (s+\tau)^2 \int_{S^2} u^f((s+\tau)\omega,-s)\, u^g((s+\tau)\omega,-s)\, d\omega \\ &= \int_0^\beta d\tau (1+\frac{\tau}{s})^2 \int_{S^2} \left[su^f((s+\tau)\omega,-s)\right]\left[su^g((s+\tau)\omega,-s)\right]\, d\omega \\ &= \langle \text{see } (0.3)\rangle \to (f,g)_{\mathcal{F}} \quad \text{as} \quad s\to\infty. \end{aligned}$$

(iii) The relation

$$\lim_{s\to\infty} b(s,-s) = (Rf,g)_{\mathcal{F}} \tag{2.35}$$

holds. Indeed,

$$\begin{aligned} b(s,-s) &= \int_{\mathbb{R}^3} u^f(x,s)\, u^g(x,-s)\, dx = \langle \text{see } (1.23)\rangle \\ &= \int_s^{s+\beta} dr\ r^2 \int_{S^2} u^f(r\omega,s)\, u^g(r\omega,-s)\, d\omega \\ &= \int_0^\beta d\tau \left[1+\frac{\tau}{s}\right]^2 \int_{S^2} \left[su^f((s+\tau)\omega,s)\right]\left[su^g((s+\tau)\omega,-s)\right] d\omega \\ &\to (Rf,g)_{\mathcal{F}} \quad \text{as } s\to\infty. \end{aligned}$$

(iv) The relation

$$\lim_{s\to\infty} b(0,-s) = 0 \tag{2.36}$$

is valid. Indeed,

$$b(0,-s) = \int_{\mathbb{R}^3} u^f(x,0)\, u^g(x,-s)\, dx\Big|_{s\gg 1} = 0$$

since $\operatorname{supp} u^f(\cdot,0) \subset B_\beta$ and $\operatorname{supp} u^f(\cdot,-s) \subset \mathbb{R}^3 \setminus B_s$.

Since b satisfies (2.33), it is a sum of two D'Alembert solutions:

$$b(s,t) = \Phi(s+t) + \Psi(s-t).$$

At the same time, relations (2.34)–(2.36) imply

$$(f,g)_{\mathcal{F}} = \Phi(-\infty) + \Psi(0), \quad (Rf,g)_{\mathcal{F}} = \Phi(0) + \Psi(\infty), \quad 0 = \Phi(-\infty) + \Psi(\infty).$$

Combining these equalities, one gets

$$\begin{aligned}(f,g)_{\mathcal{F}} + (Rf,g)_{\mathcal{F}} &= \Phi(0) + \Psi(0) = b(0,0)\\ &= \big(u^f(\cdot,0), u^g(\cdot,0)\big)_{\mathcal{H}} = \ \langle \text{see (2.31)} \rangle \ = (Cf,g)_{\mathcal{F}}\end{aligned}$$

and, hence, $Cf = f + Rf$ for $f \in \mathcal{L}$. By density of $\mathcal{L}$, we arrive at (2.32). $\square$

The result of the lemma connects null controls $f \in \mathcal{N}$ with the response operator: since $\operatorname{Ker} C = \operatorname{Ker} W =: \mathcal{N}$, representation (2.32) implies

$$\mathcal{N} = \operatorname{Ker}\,(I + R)\,. \tag{2.37}$$

Therefore $f = -Rf$ and, by virtue of the inclusion $\operatorname{supp}\, Rf \subset [0, 2r_*]$, equality (2.37) implies $\operatorname{supp}\, f \subset [0, 2r_*]$.

One more consequence is the representation

$$R = -W_0^* K - K^* W_0 + K^* K$$

following from (2.32) and (2.9).

3. Controllability. Here we prove Theorem 0.1 and study the structure of the defect subspaces in more detail.

3.1. Sets $\mathcal{U}^\xi$. Recall that the objects in use are defined in section 0.2.

Fix $\xi \geq 0$. Since $W = W_0 - K$, where W_0 is unitary and K is compact, it follows from the result of Lemma 2.1 and the Fredholm theory that the operator W maps $\mathcal{F}^\xi$ onto $W\mathcal{F}^\xi = \mathcal{U}^\xi$ isomorphically. Hence, the reachable sets $\mathcal{U}^\xi$ are closed subspaces and $\mathcal{U}^\xi \subset \mathcal{H}^\xi$ holds.

Let us prove the first of inclusions (0.5). Let $a \in \mathcal{A}^\xi$ be such that $(-\Delta + q)^p a = 0$ in $\mathbb{R}^3 \setminus \overline{B}_\xi$; take $g \in \mathcal{F}^\xi \cap \mathcal{L}$ and put $f = (\frac{\partial}{\partial \tau})^{2p} g$. Since the potential q does not depend on time, the solution u^f of (0.1)–(0.3) satisfies

$$u^f(\cdot,0) = u^{(\frac{\partial}{\partial\tau})^{2p} g}(\cdot,0) = \left(\frac{\partial^2}{\partial t^2}\right)^p u^g(\cdot,0) = (\Delta - q)^p\, u^g(\cdot,0).$$

Therefore

$$\begin{aligned}\big(a, u^f(\cdot,0)\big)_{\mathcal{H}} &= \int_{\mathbb{R}^3} a(x)\,(\Delta - q)^p\, u^g(x,0)\, dx\\ &= \langle \text{see (2.7)} \rangle = \int_{\mathbb{R}^3} [(\Delta - q)^p\, a(x)]\, u^g(x,0)\, dx = 0.\end{aligned} \tag{3.1}$$

Since the set of f's used in this calculation is dense in $\mathcal{F}^\xi$ (see section 1.3), the set of the corresponding waves $u^f(\cdot,0)$ is dense in $\mathcal{U}^\xi = W\mathcal{F}^\xi$. Thus, $a \perp \mathcal{U}^\xi$ and, hence, $\mathcal{A}^\xi \subset \mathcal{H}^\xi \ominus \mathcal{U}^\xi = \mathcal{D}^\xi$. In addition, if $\xi > 0$, then $\dim \mathcal{A}^\xi = \infty$ and, hence, $\dim \mathcal{D}^\xi = \infty$.

For proving the second relation of (0.5), it is enough to take $p = 1$ in (3.1). Another argument is relation (2.28) implying $\operatorname{Ker} H \subset \operatorname{Ker} W^* = \mathcal{H} \ominus \operatorname{Ran} W = \mathcal{H} \ominus \mathcal{U} = \mathcal{D}$. Thus, part (i) of the theorem is proved.

By (2.10), for small enough $\|g\|_{L_\infty(B_{r^*})}$ one has $\|K\| < 1$ and $W = W_0 - K$ turns out to be an isomorphism. This implies $\mathcal{U} = \mathcal{H}$, $\mathcal{D} = \{0\}$, and proves part (ii).

Postponing the further proof, let us comment on the obtained results. Thus, at the moment $t = 0$ the delayed incoming waves fill the subdomain $\mathbb{R}^3 \setminus B_\xi$, but the set of such waves $\mathcal{U}^\xi$ is not complete in $\mathcal{H}^\xi = L_2(\mathbb{R}^3 \setminus B_\xi)$ as $\xi > 0$ and, moreover, $\dim \mathcal{H}^\xi \ominus \mathcal{U}^\xi = \infty$. In the meantime, such a completeness occurs in the case of a bounded domain. Namely, consider the problem

$$u_{tt} - \Delta u + q = 0, \quad (x,t) \in B_T \times (-T,0), \tag{3.2}$$

$$u\,|_{t=-T} = u_t\,|_{t=-T} = 0 \quad \text{in } B_T, \tag{3.3}$$

$$u\,|_{\Sigma^T} = f, \tag{3.4}$$

where $\Sigma^T = \partial B_T \times [-T,0]$, $u = u^f(x,t)$ is a solution. Denote

$$\mathcal{F}^T := L_2(\Sigma^T),\ \ \mathcal{F}^{T,\xi} := \left\{ f \in \mathcal{F}^T \;\middle|\; \operatorname{supp} f \subset \partial B_T \times [-T+\xi, 0] \right\},$$

$$\mathcal{H} := L_2(B_T),\ \ \mathcal{H}^\xi := \{ y \in \mathcal{H} \mid \operatorname{supp} y \subset \overline{B}_T \setminus B_\xi \};$$

introduce the reachable sets

$$\mathcal{U}^\xi := \{ u^f(\cdot,0) \mid f \in \mathcal{F}^{T,\xi} \}.$$

By finiteness of the domains of influence, the inclusion $\mathcal{U}^\xi \subset \mathcal{H}^\xi$ holds. The well-known fact derived from the fundamental Holmgren–John–Tataru theorem (e.g., see [2]) is the density of this inclusion:

$$\operatorname{clos} \mathcal{U}^\xi = \mathcal{H}^\xi, \quad 0 \le \xi \le T, \tag{3.5}$$

which is interpreted as an *approximate controllability* of system (3.2)–(3.5) in subdomains filled with waves. Problem (0.1)–(0.3) may be considered as a limit case of (3.2)–(3.4) as $T \to \infty$: loosely speaking, system (0.1)–(0.3) is governed by controls located at the sphere of infinite radius. However, the properties of the reachable sets turn out to be different: comparing (3.5) and (0.5), we state a lack of controllability in the limit case.[3] One more noteworthy difference is that in a finite ball equality (3.5) fails without the closure (see [1]), whereas in the limit case $\mathcal{U}^\xi$ is closed.

The following result shows that, studying the general properties of the reachable sets, it is hardly possible to find a simple characterization of their elements.

LEMMA 3.1. *If $\xi > 0$ and u is a compactly supported element of $\mathcal{U}^\xi$, then the set $\mathbb{R}^3 \setminus \operatorname{supp} u$ is disconnected.*

Sketch of the proof. Assume the opposite: there exists a nonzero compactly supported $u \in \mathcal{U}^\xi$ such that $\mathbb{R}^3 \setminus \operatorname{supp} u$ is an (open) connected set.

[3]This lack of controllability is in a sense partially compensated by the following property. It can be shown that for any ξ, ξ' such that $0 \le \xi < \xi' < \infty$, one has $\operatorname{clos}\{u^f(\cdot,0)|_{B_{\xi'} \setminus B_\xi} \mid f \in \mathcal{F}^\xi\} = L_2(B_{\xi'} \setminus B_\xi)$, i.e., the forward parts of delayed incoming waves possess a local completeness.

Since $\mathcal{U}^\xi$ is closed, one has $u = u^f(\cdot,0)$ for some $0 \neq f \in \mathcal{F}^\xi$. The function

$$w(x,t) = \begin{cases} u^f(x,t), & t \le 0, \\ -u^f(x,-t), & t > 0, \end{cases}$$

is a solution of

$$w_{tt} - \Delta w + qw = -2u^f(\cdot,0)\,\delta'$$

($\delta = \delta(t)$ is the Dirac function) satisfying

$$w(\cdot,t)\big|_{B_\xi} = 0, \quad t \in (-\infty,\infty).$$

Its Fourier transform $\tilde{w}^f(\cdot,k)$ satisfies

$$\Delta\tilde{w} + (k^2 - q)\tilde{w} = 2ik\,u^f(\cdot,0)$$

and

$$\tilde{w}\big|_{B_\xi} = 0, \quad k \in (-\infty,\infty).$$

Hence, out of $\operatorname{supp} u^f(\cdot,0)$ the function $\tilde{w}$ is a solution of a homogeneous elliptic equation, which vanishes identically on B_ξ. By [9], $\tilde{w} = 0$ everywhere in $\mathbb{R}^3 \setminus \operatorname{supp} u^f(\cdot,0)$. In particular,

$$\tilde{w}(\cdot,k)\big|_{\mathbb{R}^3\setminus B_{\xi'}} = 0, \quad k \in (-\infty,\infty),$$

for large enough ξ' provided $\operatorname{supp}\, u^f(\cdot,0) \subset \overline{B}^{\xi'} \setminus B^\xi$. This leads to

$$w(\cdot,t)\big|_{\mathbb{R}^3\setminus B_{\xi'}} = 0, \quad t \in (-\infty,\infty),$$

yields $u^f = 0$ in $[\mathbb{R}^3 \setminus B_{\xi'}] \times (-\infty, 0]$ and implies $f = 0$, which contradicts the assumption $f \neq 0$. $\square$

This rather subtle result is of general character for systems governed by hyperbolic equations (see [1], [3], [4]).

3.2. Radial potential. Here we prove relations (0.7). Thus, in this section we deal with the case $q = q(r)$.

In this case, the sets $\mathcal{A}^\xi$, $\mathcal{D}^\xi$, and $\mathcal{U}^\xi$ are invariant with respect to rotations and, hence, are reduced by spherical harmonics. Namely,

$$\mathcal{A}^\xi = \oplus\sum_{l,m} \mathcal{A}^\xi{}_{lm}\,, \quad \mathcal{A}^\xi{}_{lm} := \left\{ y \in \mathcal{H}^\xi \;\middle|\; y(x) = \frac{a(r)}{r}\, Y_l^m(\omega), a \in A_l^\xi \right\},$$

where A_l^ξ are defined in the same way as in unperturbed case, replacing (1.14) by

$$\left(-\frac{d^2}{dr^2} + \frac{l(l+1)}{r^2} + q(r)\right)^p a \;=\; 0, \quad r > \xi.$$

As well as in the unperturbed case, the ODE theory implies $\operatorname{rank} A_l^\xi = \dim A_l^\xi = d(l)$ as $\xi > 0$. Quite analogously,

$$\mathcal{U}^\xi = \oplus\sum_{l,m} \mathcal{U}^\xi{}_{lm}, \quad \mathcal{U}^\xi{}_{lm} = W\mathcal{F}^\xi{}_{lm},$$

$$\mathcal{D}^\xi = \oplus\sum_{l,m} \mathcal{D}^\xi{}_{lm}, \quad \mathcal{D}^\xi{}_{lm} = \mathcal{H}^\xi{}_{lm} \ominus \mathcal{U}^\xi{}_{lm} \supset \mathcal{A}^\xi{}_{lm},$$

where

$$\mathcal{F}^{\xi}{}_{lm} := \mathcal{F}_{lm} \cap \mathcal{F}^{\xi}, \quad \mathcal{H}^{\xi}{}_{lm} := \mathcal{H}_{lm} \cap \mathcal{H}^{\xi}$$

(see (1.4), (1.5)). Marking the objects corresponding to $q = 0$ by the index $\{\,\mathring{}\,\}$, one has evidently

$$\mathcal{A}^{\xi}{}_{lm}\;\big|_{\;\xi > r_*} = \mathring{\mathcal{A}}^{\xi}_{lm}, \quad \mathcal{U}^{\xi}{}_{lm}\;\big|_{\;\xi > r_*} = \mathring{\mathcal{U}}^{\xi}_{lm}, \quad \mathcal{D}^{\xi}{}_{lm}\;\big|_{\;\xi > r_*} = \mathring{\mathcal{D}}^{\xi}_{lm}.$$

We say that a family of subspaces $\{\mathcal{B}^{\xi}\}$ is continuous with respect to ξ if the orthogonal projection on $\mathcal{B}^{\xi}$ is continuous in the strong operator topology. By Lemma 2.1, as $\xi > 0$ the control operator W maps $\mathcal{F}^{\xi}{}_{lm}$ onto $\mathcal{U}^{\xi}{}_{lm}$ isomorphically. Therefore, since $\{\mathcal{F}^{\xi}{}_{lm}\}_{\xi>0}$ is continuous, the family $\{\mathcal{U}^{\xi}{}_{lm}\}_{\xi>0}$ is also continuous. Accordingly, $\{\mathcal{D}^{\xi}{}_{lm}\}_{\xi>0}$ is continuous, which implies $\dim \mathcal{D}^{\xi}{}_{lm} = \text{const} \le \infty$. In the meantime,

$$\begin{aligned}\dim \mathcal{D}^{\xi}{}_{lm}\;\big|_{\;\xi > r_*} &= \dim \mathring{\mathcal{D}}^{\xi}_{lm} = \langle \text{see (1.27)} \rangle = \dim \mathring{\mathcal{A}}^{\xi}{}_{lm} \\ &= (2l+1) \dim A^{\xi}_{l} = \langle \text{see section 1.2(iii)} \rangle = (2l+1)\, d(l) < \infty;\end{aligned}$$

hence, $\dim \mathcal{D}^{\xi}{}_{lm} = (2l+1)d(l)$ for all $\xi > 0$. On the other hand, by ODE theory one has $\dim \mathcal{A}^{\xi}{}_{lm} = \dim \mathring{\mathcal{A}}^{\xi}_{lm}$ for all $\xi > 0$. Therefore, the evident inclusion $\mathcal{D}^{\xi}{}_{lm} \supset \mathcal{A}^{\xi}{}_{lm}$ leads to $\mathcal{D}^{\xi}{}_{lm} = \mathcal{A}^{\xi}{}_{lm}$ and, finally, to $\mathcal{D}^{\xi} = \mathcal{A}^{\xi}$, $\xi > 0$.

Let us prove that $\mathcal{D} = \mathcal{A} = \operatorname{Ker} H$. If $h \in \mathcal{D}$, then $h\big|_{\mathbb{R}^3 \setminus B_\xi} \in \mathcal{D}^{\xi}$ and, hence, for $\xi > 0$ we have $h\big|_{\mathbb{R}^3 \setminus B_\xi} \in \mathcal{A}^{\xi}$. Therefore, representing $h(x) = \sum_{l,m} \frac{h_{lm}(r)}{r}\, Y^m_l(\omega)$ for $g := h_{lm}$ we have

$$\left(-\frac{d^2}{dr^2} + \frac{l(l+1)}{r^2} + q(r)\right)^{p} g = 0, \quad r > 0, \tag{3.6}$$

with an integer $p > 0$. If $\xi > r_*$, then $g|_{(\xi,\infty)} \in \mathring{A}^{\xi}{}_{l}$ and, hence, $g|_{(\xi,\infty)}$ satisfies

$$\left(-\frac{d^2}{dr^2} + \frac{l(l+1)}{r^2}\right)^{d(l)} g = 0, \quad r > \xi \tag{3.7}$$

(see (1.14)). Comparing (3.6) with (3.7), we conclude that (3.6) holds for $p = d(l)$.

Since g is an L_2-solution of (3.6) with $p = d(l)$, by the ODE theory it has the differentiable asymptotic $g|_{r\to 0} = O(r^{l+1})$, whereas $g|_{r>r_*}$ is a linear combination of the solutions (1.16). From this it easily follows that $\frac{g(r)}{r}\, Y^m_l(\omega) \in \operatorname{Dom} H^j$ as $j = 1, 2, \dots, d(l)$ and, hence, $\frac{g(r)}{r}\, Y^m_l(\omega) \in \operatorname{Ker} H^{d(l)}$. Since H is a self-adjoint operator, the last inclusion implies $\frac{g(r)}{r}\, Y^m_l(\omega) \in \operatorname{Ker} H$ and, returning to the element h, we get $h \in \operatorname{Ker} H$. Thus, $\mathcal{D} \subset \operatorname{Ker} H$, whereas the converse inclusion has been proved in section 3.1. Thus, we arrive at $\mathcal{D} = \operatorname{Ker} H$.

The proof of Theorem 0.1 is completed.

3.3. Example of $\mathcal{D} \neq \operatorname{Ker} H = \{0\}$. The result of this section shows that, in the general (not radial) case, the defect subspace is not exhausted by Ker H. Here, dealing with the operator H for different q's, we denote it by H_q.

Take a smooth compactly supported q' such that $\operatorname{Ker} H_{q'} \neq \{0\}$ (it does exist; see [14]) and choose $\varphi' \in \operatorname{Ker} H_{q'}$, so that

$$(-\Delta + q')\, \varphi' = 0 \quad \text{in } \mathbb{R}^3.$$

By ellipticity, one has $\varphi' \in C^\infty(\mathbb{R}^3)$. Let x_0 and a (small) $\varepsilon > 0$ be such that $\varphi'(x) \geq \text{const} > 0$, $x \in B_\varepsilon(x_0)$. Construct a function

$$\varphi''(x) = \begin{cases} \varphi'(x), & x \in \mathbb{R}^3 \setminus B_\varepsilon(x_0), \\ \geq \frac{\text{const}}{2}, & x \in B_\varepsilon(x_0) \setminus B_{\frac{\varepsilon}{2}}(x_0), \\ \frac{1}{|x-x_0|}, & x \in B_{\frac{\varepsilon}{2}}(x_0) \setminus \{x_0\}, \end{cases}$$

such that $\varphi'' \in C^\infty(\mathbb{R}^3 \setminus \{x_0\})$ and define

$$q''(x) = \begin{cases} q'(x), & x \in \mathbb{R}^3 \setminus B_\varepsilon(x_0), \\ \frac{\Delta\varphi''(x)}{\varphi''(x)}, & x \in B_\varepsilon(x_0) \setminus \{x_0\}, \\ 0, & x = x_0. \end{cases}$$

It is easy to see that $q'' \in C_0^\infty(\mathbb{R}^3)$ and φ'' satisfies

$$(-\Delta + q'')\,\varphi'' = 0 \quad \text{in } \mathbb{R}^3 \setminus \{x_0\}.$$

Note also that $q'' = 0$ in $B_{\frac{\varepsilon}{2}}(x_0)$.

Defining $\varphi(x) := \varphi''(x - x_0)$, $q(x) := q''(x - x_0)$, we get

$$\varphi \in \mathcal{H}, \quad (-\Delta + q)\,\varphi = 0 \quad \text{in } \mathbb{R}^3 \setminus \{0\},$$

which obviously implies $\varphi \in \mathcal{A} \subset \mathcal{D}$. In the meantime, $\varphi \notin \operatorname{Ker} H_q$ because φ is singular at $x = 0$, whereas $\operatorname{Ker} H_q \subset C^\infty(\mathbb{R}^3)$.

If $\operatorname{Ker} H_q = \{0\}$, then the required example is provided. If, accidentally, $\operatorname{Ker} H_q \neq \{0\}$, then one can deform q, preserving nontrivial defect but gaining $\operatorname{Ker} H_q = \{0\}$. This can be done in the following way. For simplicity we assume that $\lambda = 0$ is an ordinary eigenvalue: $\dim \operatorname{Ker} H_q = 1$.

Take $0 \neq \psi \in \operatorname{Ker} H_q$. Such an element satisfies $(-\Delta + q)\,\psi = 0$ and, hence,

$$\psi(x) = -\frac{1}{4\pi} \int_{\mathbb{R}^3} \frac{q(y)\psi(y)}{|x-y|}\,dy, \qquad x \in \mathbb{R}^3. \tag{3.8}$$

If $\operatorname{supp} q \subset \overline{B}_{r_*}$, then $\Delta\psi = 0$ in $\mathbb{R}^3 \setminus \overline{B}_{r_*}$; therefore, $\psi \in L_2(\mathbb{R}^3)$ implies $\psi = O(r^{-2})$ as $r \to \infty$.

Take a ball $B \subset B_{2r_*} \setminus \overline{B}_{r_*}$ (ensuring $q|_B = 0$) such that $\varphi|_B \neq 0$, where φ has been constructed above. Choose $\eta \in C_0^\infty(\mathbb{R}^3)$, $\operatorname{supp} \eta \subset B$; define a function $\varphi_\varepsilon := \varphi + \varepsilon\eta$ and a deformation of q by

$$q_\varepsilon := \frac{\Delta\varphi_\varepsilon}{\varphi_\varepsilon} = \frac{\Delta\varphi + \varepsilon\Delta\eta}{\varphi + \varepsilon\eta} = \frac{\Delta\varphi}{\varphi} + \varepsilon\frac{\Delta\eta}{\varphi} + o(\varepsilon) = q + \varepsilon\frac{\Delta\eta}{\varphi} + o(\varepsilon).$$

Note that q_ε is analytic with respect to ε and $q_\varepsilon = q$ out of B. We shall show that the assumption $\operatorname{Ker} H_{q_\varepsilon} \neq \{0\}$, $\varepsilon \in (0, \varepsilon_0)$, leads to a contradiction.

Reducing (3.8) to B_{2r_*}, we get an integral equation

$$\psi(x) = (G_q\psi)(x) := -\frac{1}{4\pi} \int_{B_{2r_*}} \frac{q(y)\psi(y)}{|x-y|}\,dy, \qquad x \in B_{2r_*}.$$

By the same arguments, for $\psi_\varepsilon \in \operatorname{Ker} H_{q_\varepsilon}$, we have

$$\psi_\varepsilon(x) = -\frac{1}{4\pi} \int_{B_{2r_*}} \frac{q_\varepsilon(y)\psi_\varepsilon(y)}{|x-y|}\,dy, \qquad x \in B_{2r_*}.$$

The analyticity implies $\psi_\varepsilon = \psi + \varepsilon h + o(\varepsilon)$ as $\varepsilon \to 0$. Substituting this asymptotic and the asymptotic of q_ε in the last equation, we easily obtain

$$h(x) + \frac{1}{4\pi}\int_{B_{2r_*}} \frac{q(y)h(y)}{|x-y|}\,dy = -\frac{1}{4\pi}\int_{B_{2r_*}} \frac{\frac{\Delta\eta}{\varphi}(y)\psi(y)}{|x-y|}\,dy =: g(x), \quad x \in B_{2r_*},$$

so that h solves this integral equation. Note also the asymptotic $g|_{r\to\infty} = r^{-1}$.

The solvability of the last equation is equivalent to the orthogonality condition $g \perp \mathrm{Ker}\,(I - G_q{}^*)$ in $L_2(B_{2r_*})$. In the meantime, writing $(-\Delta + q)\psi = 0$ in the form

$$\Delta\psi(x) = -\frac{q(x)}{4\pi}\int_{\mathbb{R}^3} \frac{\Delta\psi(y)}{|x-y|}\,dy \ = -\frac{q(x)}{4\pi}\int_{B_{2r_*}} \frac{\Delta\psi(y)}{|x-y|}\,dy, \qquad x \in \mathbb{R}^3,$$

we conclude that $\Delta\psi|_{B_{2r_*}} \in \mathrm{Ker}\,(I - G_q{}^*)$. Therefore, by the orthogonality one has

$$0 = (\Delta\psi, g)_{L_2(B_{2r_*})} = \int_{B_{2r_*}} \Delta\psi(x)g(x)\,dx = \int_{\mathbb{R}^3} \Delta\psi(x)g(x)\,dx.$$

Integrating by parts with regard to the asymptotics of ψ and g (as $r \to \infty$), we have

$$\begin{aligned} 0 &= \int_{\mathbb{R}^3} \psi(x)\Delta g(x)\,dx = \int_{\mathbb{R}^3} dx\ \psi(x)\left[\frac{\Delta\eta}{\varphi}\psi\right](x)\ dx \\ &= \int_B \eta(x)\left[\Delta\frac{\psi^2}{\varphi}\right](x)\,dx = 2\int_B \eta(x)\frac{|\psi(x)\nabla\varphi(x) - \varphi(x)\nabla\psi(x)|^2}{\varphi^3(x)}\,dx. \end{aligned}$$

In the last equality we have used the fact that φ and ψ are harmonic in B in view of $q|_B = 0$. By arbitrariness of η, we have $|\psi\nabla\varphi - \varphi\nabla\psi|\,|_B = 0$. Hence, φ and ψ are proportional in B and, by ellipticity, everywhere. The latter is impossible since ψ is smooth, whereas φ has a singularity at $x = 0$.

This contradiction shows that one can choose $\varepsilon > 0$ provided $\mathrm{Ker}\,H_{q_\varepsilon} = \{0\}$, and we assume such an ε chosen. Then, the corresponding function φ_ε belongs to $\mathcal{H}$ and satisfies $(-\Delta + q_\varepsilon)\,\varphi_\varepsilon = 0$ in $\mathbb{R}^3 \setminus \{0\}$, and $\varphi_\varepsilon = \frac{1}{r}$ near $x = 0$. Therefore, $\varphi_\varepsilon \in \mathcal{A}_{q_\varepsilon} \subset \mathcal{D}_{q_\varepsilon}$ and we have $\mathcal{D}_{q_\varepsilon} \neq \{0\}$ although $\mathrm{Ker}\ H_{q_\varepsilon} = \{0\}$. Thus, the condition $0 \in \sigma_p(H)$ is sufficient but not necessary for the lack of controllability.

3.4. General properties of $h \in \mathcal{D}$. Here we detail the behavior of unreachable elements near $x = 0$.

Lemma 3.2. *For $h \in \mathcal{D}$, the representation*

$$h(x) = \frac{\alpha(\omega)}{r} + \tilde{h}(x) \tag{3.9}$$

holds with $\alpha \in L_2(S^2)$ and $\tilde{h} \in H^1_{\mathrm{loc}}(\mathbb{R}^3)$.

Proof. By virtue of (2.9), an element $h \in \mathcal{D} = \mathrm{Ker}\,W^*$ satisfies $(W_0 - K)^*\,h = 0$; this implies

$$h = W_0 K^* h. \tag{3.10}$$

The control $f = K^*h$ can be written in the form

$$f = \int_0^{r^*} T_s^* W^*\ \hat{q}\ Y^* \sin\left[sL^{\frac{1}{2}}\right] L^{-\frac{1}{2}} Y h\,ds$$

(see (2.9)). Analyzing step by step this representation, we have $L^{-\frac{1}{2}}Yh \in H^1(B_{2r^*})$; a function $\hat{q}\,Y^* \sin[sL^{\frac{1}{2}}]L^{-\frac{1}{2}}Yh$ belongs to $H^1(\mathbb{R}^3)$ and is supported in B_{2r^*} for any s; W^* transfers this function to a control of the class $\mathcal{F}_1$ supported in $[0, 2r^*]$; this control is transferred by the left (reduced) shift T_s^* to a control of the same class supported on $[0, 2r^* - s]$. At last, the integration gives $f \in \mathcal{F}_1$, $\operatorname{supp} f \subset [0, 2r^*]$.

Representing by (3.10) $h = W_0 f$, in accordance with (1.31) one obtains

$$h = \frac{\alpha(\omega)}{r} + \tilde{h},$$

where $\alpha = [f(0, \cdot)]_0$ and $\tilde{h} = \frac{1}{2\pi} \int_{S^2} f_\tau(x \cdot \theta, \theta)\, d\theta \in H^1_{\mathrm{loc}}(\mathbb{R}^3)$. $\square$

If $h \in \operatorname{Ker} H \subset \mathcal{D}$, then h is smooth and α in (3.9) equals zero. The singular element $\varphi \in \mathcal{D}$ constructed in section 3.3 is of the form $\varphi = \frac{1}{r} + \tilde{h}$, so that its α equals 1. In this connection, the following question remains open: Do there exist the defect elements with variable α? Furthermore, we know no simple conditions (besides a smallness of q) ensuring $\mathcal{D} = \{0\}$. For instance, does $q \geq 0$ imply $\mathcal{D} = \{0\}$? Is the presence of the negative spectrum of H necessary for $\mathcal{D} \neq \{0\}$? These natural questions are so far open.

3.5. Reversing waves and s-points. Let the potential q be such that $\mathcal{D} \neq \{0\}$. In this case, $\mathcal{N} \neq \{0\}$ (see (0.6)) and there exists a null control $f \neq 0$ such that $u^f(\cdot, 0) = Wf = 0$. It is easily proved that, owing to the last equality, the function

$$u^f_-(\cdot, t) := \begin{cases} u^f(\cdot, t), & t \leq 0, \\ -u^f(\cdot, -t), & t > 0, \end{cases}$$

turns out to be an L_2-solution of problem (0.1)–(0.3) in $\mathbb{R}^3 \times (-\infty, \infty)$. This solution is odd with respect to time and vanishes in $\{(x, t) \mid |x| < |t|\}$, i.e., in the past and future light cones simultaneously.

As a consequence, the function

$$w^f(x, t) = \int_{-\infty}^{t} u^f(x, s)\, ds, \quad (x, t) \in \mathbb{R}^3 \times (-\infty, \infty),$$

is an even L_2-solution of the acoustical equation in $\mathbb{R}^3 \times (-\infty, \infty)$ also vanishing in both of the cones. As one can show, w^f is a finite energy solution:

$$\int_{\mathbb{R}^3} \left\{ \left[w^f_t(x, t) \right]^2 + \left| \nabla w^f(x, t) \right|^2 + q(x) \left[w^f(x, t) \right]^2 \right\} dx = \mathrm{const} > 0$$

and, hence, its Cauchy data $\{w^f(\cdot, 0), w^f_t(\cdot, 0)\} = \{y, 0\}$ belong to the energy class (see [10], [13]). At the same time, since $w^f \mid_{|x|<|t|} = 0$, the pair $\{y, 0\}$ belongs to the classes D_- and D_+ of the incoming and outgoing data simultaneously. Therefore, we get an example of $\{y, 0\} \in D_+ \cap D_- \neq \{0\}$. Note that such an intersection is possible even in the case Ker $H = \{0\}$.

From the physical point of view, the behavior of the waves u^f_- and w^f is very curious. They come from infinity, penetrate into supp q, and interact with the potential. Then the waves return back to infinity, leaving supp q with no trace remaining. The absence of the residual perturbation in supp q is amazing and, probably, may be interpreted as a subtle interference effect. The existence of such reversing waves is equivalent to the lack of controllability of system (0.1)–(0.3).

In the effect described above, the origin $x = 0$ plays the role of a point, which in a sense stops the reversing waves. This observation motivates the following definition. For $s \in \mathbb{R}^3$, we denote the shift of q by $q_s(x) = q(x - s)$ (recall that $\sigma(H_{q_s}) = \sigma(H_q)$). An $s \in \mathbb{R}^3$ is said to be a *stop point* (s-*point*) of the potential q if $\operatorname{Ker} H_q = \{0\}$ and $\mathcal{D}_{q_s} \neq \{0\}$. The set of s-points is denoted by $\Upsilon[q]$.

Loosely speaking, the potential q makes the space inhomogeneous and the set $\Upsilon[q]$ consists of points that can stop incoming waves. We hope this set is worthy of further investigation. At the moment our knowledge about $\Upsilon[q]$ is exhausted by the following observations.

- *Connection with the operator extensions*: Assuming again $\operatorname{Ker} H = \{0\}$, fix $s \in \mathbb{R}^3$, and consider the operators $L_p : \mathcal{H} \to \mathcal{H}$, $\operatorname{Dom} L_p = \{y \in C_0^\infty(\mathbb{R}^3) \mid y = 0 \text{ near } s\}$, $L_p y = (-\Delta + q)^p y$; $p = 1, 2, \ldots$. Every L_p is a densely defined symmetric semibounded operator and hence has the self-adjoint semibounded extensions. If at least one L_p possesses an extension $\tilde{L_p}$ with $\operatorname{Ker} \tilde{L_p} \neq \{0\}$, then $s \in \Upsilon[q]$. Perhaps this gives a characterization of s-points.
- *Connection with the factorization problem*: If $x = 0 \in \Upsilon[q]$, then the s-matrix associated with potential q does not admit the factorization in the sense of Newton [11].
- *Model example*: Consider a singular potential $q = \delta(x)$. Understanding $-\Delta - \delta$ in a proper sense (see [6], [12]), one can show that this operator has only one eigenvalue $\lambda = -1$ and $\Upsilon[\delta] = S^2$. Other examples of this sort motivate the following conjecture: any potential with negative spectrum has a nonempty set of s-points.

3.6. Stability. Here we present necessary and sufficient conditions providing a global L_2-boundedness of a trajectory of system (0.1)–(0.3). We use the same notations as in (2.5), (2.23) and denote $g_k := W^* \varphi_k \in \mathcal{F}$ (see (2.25)).

LEMMA 3.3. *The estimate $\|u^f(\cdot, t)\|^2_{\mathcal{H}} \le c\|f\|_{\mathcal{F}}$ holds for all $t \in (-\infty, \infty)$ if and only if $(f, g_k)_{\mathcal{F}} = 0$, $k = 1, 2, \ldots, p$.*

Proof. (i) *Orthogonality $\Rightarrow$ stability*: For $t \le 0$ one has

$$\|u^f(\cdot, t)\|_{\mathcal{H}} = \langle \text{see } (2.8) \rangle = \|W T_t f\|_{\mathcal{H}} \le \|W\| \|f\|_{\mathcal{F}},$$

so that $u^f \mid_{t<0}$ is bounded. Suppose $t > 0$. Take $f \in C_0^\infty(\Sigma)$ and find the Fourier coefficients in (2.5):

$$\begin{aligned}
&\cosh \varkappa_k t \left(u^f(\cdot, 0), \varphi_k\right)_{\mathcal{H}} + \frac{\sinh \varkappa_k t}{\varkappa_k} \left(u^f_t(\cdot, 0), \varphi_k\right)_{\mathcal{H}} \\
&= \frac{e^{\varkappa_k t}}{2} \left(u^f(\cdot, 0) + \frac{1}{\varkappa_k}\, u^f_t(\cdot, 0), \varphi_k\right)_{\mathcal{H}} + \frac{e^{-\varkappa_k t}}{2} \left(u^f(\cdot, 0) - \frac{1}{\varkappa_k}\, u^f_t(\cdot, 0), \varphi_k\right)_{\mathcal{H}} \\
&= \frac{e^{\varkappa_k t}}{2} \left(W \left[f + \frac{1}{\varkappa_k}\, f_\tau\right], \varphi_k\right)_{\mathcal{H}} + \frac{e^{-\varkappa_k t}}{2} \left(W \left[f - \frac{1}{\varkappa_k}\, f_\tau\right], \varphi_k\right)_{\mathcal{H}} \\
&= \langle \text{see } (2.25) \rangle = \frac{e^{\varkappa_k t}}{2} \left(f + \frac{1}{\varkappa_k}\, f_\tau, g_k\right)_{\mathcal{F}} + \frac{e^{-\varkappa_k t}}{2} \left(f - \frac{1}{\varkappa_k}\, f_\tau, g_k\right)_{\mathcal{F}} = e^{\varkappa_k t} \left(f, g_k\right)_{\mathcal{F}}
\end{aligned}$$

(we have used $(\frac{1}{\varkappa_k} f_\tau, g_k)_{\mathcal{F}} = (f, g_k)_{\mathcal{F}}$) and

$$\begin{aligned}
&1(t) \left(u^f(\cdot, 0), \varphi^0_k\right)_{\mathcal{H}} + t \left(u^f_t(\cdot, 0), \varphi^0_k\right)_{\mathcal{H}} \\
&\quad = 1(t) \left(W f, \varphi^0_k\right)_{\mathcal{H}} + t \left(W f_\tau, \varphi^0_k\right)_{\mathcal{H}} = \langle \text{see } (2.28) \rangle = 0.
\end{aligned}$$

Now (2.5) can be written in the form

$$u^f(\cdot,t) = \sum_{k=1}^{p} e^{\varkappa_k t}(f, g_k)_{\mathcal F}\ \varphi_k$$
$$+\int_{+0}^{\infty}\left\{\cos\sqrt{\lambda}t\, dE_\lambda\, u^f(\cdot,0) + \frac{\sin\sqrt{\lambda}t}{\sqrt{\lambda}}\, dE_\lambda\, u^f_t(\cdot,0)\right\}, \tag{3.11}$$

whereas the orthogonality condition leads to

$$u^f(\cdot,t) = \int_{+0}^{\infty}\left\{\cos\sqrt{\lambda}t\, dE_\lambda\, u^f(\cdot,0) + \frac{\sin\sqrt{\lambda}t}{\sqrt{\lambda}}\, dE_\lambda u^f_t(\cdot,0)\right\}, \tag{3.12}$$

so that $u^f(\cdot,t)$ belongs to the subspace $\mathcal{H}_+ = (I - E_{-0})\,\mathcal{H}$ of absolutely continuous spectrum of H. Since $f \perp g_k$ implies $f_\tau \perp g_k$, the same is valid for $u^{f_\tau(\cdot,t)} = u^f_t(\cdot,t) \in \mathcal{H}_+$.

To estimate the norm of the wave u^f represented by (3.12) let us assume in addition that $(Jf)(\tau,\omega) = \int_0^\tau f(s,\omega)\,ds \in C_0^\infty(\Sigma)$. The set of such f's is dense in $\mathcal{F}$ and $u^{Jf}(\cdot,0) \in \operatorname{Dom} H$, $u^{Jf}(\cdot,0) \perp \operatorname{Ker} H$. Now, we have the inequality

$$\|u^f(\cdot,t)\|^2_{\mathcal H} \le 2\left[\left\|\int_{+0}^{\infty}\cos\sqrt{\lambda}t\, dE_\lambda\, u^f(\cdot,0)\right\|^2_{\mathcal H}\right.$$
$$\left. + \left\|\int_{+0}^{\infty}\frac{\sin\sqrt{\lambda}t}{\sqrt{\lambda}}\, dE_\lambda\, u^f_t(\cdot,0)\right\|^2_{\mathcal H}\right] =: 2\,[I(t) + II(t)] \tag{3.13}$$

and the evident estimate

$$I(t) \le \|u^f(\cdot,0)\|^2_{\mathcal H} \le \|W\|^2 \|f\|^2_{\mathcal F}. \tag{3.14}$$

The part of the operator H in $\mathcal{H} \ominus \operatorname{Ker} H$ is injective; its part $H_+ := H\,(I - E_{-0})$ acting in $\mathcal{H}_+$ is a positive injective operator. This enables one to represent

$$u^{Jf}(\cdot,0) = H^{-1}Hu^{Jf}(\cdot,0) = H^{-1}\left(-u^{Jf}_{tt}(\cdot,0)\right)$$
$$= -H^{-1}u^{(Jf)_{tt}}(\cdot,0) = -H^{-1}u^{f_\tau}(\cdot,0) = -H^{-1}u^f_t(\cdot,0)$$

and to get

$$\left(u^{Jf}(\cdot,0), u^f_t(\cdot,0)\right)_{\mathcal H} = -\left(H^{-1}u^f_t(\cdot,0), u^f_t(\cdot,0)\right)_{\mathcal H}$$
$$= -\left\|H_+^{-\frac12}u^f_t(\cdot,0)\right\|^2_{\mathcal H}.$$

On the other hand,

$$\left(u^{Jf}(\cdot,0), u^f_t(\cdot,0)\right)_{\mathcal H} = \left(u^{Jf}(\cdot,0), u^{f_\tau}(\cdot,0)\right)_{\mathcal H}$$
$$= \langle\text{see } (2.31), (2.32)\rangle = \left([I+R]\,Jf, f_\tau\right)_{\mathcal F}$$
$$= -\left(\frac{\partial}{\partial\tau}\,[I+R]\,Jf, f\right)_{\mathcal F} = \langle\text{see } (2.30)\rangle$$
$$= -\left([I-R]\,f, f\right)_{\mathcal F} = \langle\text{see } (2.32)\rangle$$
$$= -\left([2I - C]\,f, f\right)_{\mathcal F},$$

and we obtain

$$\begin{aligned}\left\|H_+^{-\frac{1}{2}} u_t^f(\cdot,0)\right\|_{\mathcal{H}}^2 &= ([2I-C]\,f,f)_{\mathcal{F}} \\ &\leq (2+\|C\|)\,\|f\|_{\mathcal{F}}^2 = \left(2+\|W\|^2\right)\|f\|_{\mathcal{F}}^2.\end{aligned}$$

Thereafter, we can estimate the second norm in (3.13):

$$\begin{aligned}II(t) &= \left\|\int_{+0}^{\infty} \frac{\sin\sqrt{\lambda}t}{\sqrt{\lambda}}\,dE_\lambda\,u_t^f(\cdot,0)\right\|_{\mathcal{H}}^2 = \left\|\int_{+0}^{\infty} \sin\sqrt{\lambda}t\,dE_\lambda H_+^{-\frac{1}{2}}\,u_t^f(\cdot,0)\right\|_{\mathcal{H}}^2 \\ &\leq \left\|H_+^{-\frac{1}{2}} u_t^f(\cdot,0)\right\|_{\mathcal{H}}^2 \leq \left(2+\|W\|^2\right)\|f\|_{\mathcal{F}}^2.\end{aligned}$$

Substituting this and (3.14) in (3.13), we get the estimate

$$\left\|u^f(\cdot,t)\right\|_{\mathcal{H}}^2 \leq \left(3+\|W\|^2\right)\|f\|_{\mathcal{F}}^2 \tag{3.15}$$

on a dense set of controls f. Extending (3.15) to $\mathcal{F}$, we conclude that $u^f(\cdot,t)$ is bounded in $\mathcal{H}$ uniformly with respect to $t\in(-\infty,\infty)$.

(ii) *Stability* $\Rightarrow$ *orthogonality*: If the orthogonality does not hold, by (3.11) we have

$$\left\|u^f(\cdot,t)\right\|_{\mathcal{H}}^2 \geq \sum_{k=1}^{p} e^{2\varkappa_k t}(f,g_k)_{\mathcal{F}}^2 \to \infty \quad \text{as } t\to\infty,$$

so that $u^f\,|_{t>0}$ is unbounded, i.e., the trajectory is not stable. $\square$

3.7. Comments.

- Probably, the equality $\mathcal{A}^\xi = \mathcal{D}^\xi$, $\xi>0$ (see (0.5)), is valid and not only for radial potentials.
- Let us repeat once again an open problem of the principal nature: Is $\sigma_p(H)\neq\{\emptyset\}$ equivalent to $\mathcal{D}\neq\{0\}$?
- As we saw in section 3.5, if $0\in\Upsilon[q]$ and $f\in\mathcal{N}$, then the solution u_-^f is a reversing wave satisfying $u_-^f\,|_{|x|<|t|}=0$. Its Fourier transform $\tilde{u}_-^f(x,k) = \frac{1}{2\pi}\int_{-\infty}^{\infty} e^{ikt}u_-^f(x,t)\,dt = \frac{1}{2\pi}\int_{-|x|}^{|x|} e^{ikt}u_-^f(x,t)\,dt$ satisfies

  $$\left[-\Delta+(q-k^2)\right]\tilde{u}(\cdot,k)=0 \quad \text{in } \mathbb{R}^3$$

  and, hence, is an eigenfunction of continuous spectrum of H, which is an *entire function* of k. Such eigenfunctions are associated with each point of $\Upsilon[q]$. It would be interesting to compare them with the entire (with respect to k) solutions introduced in [11] and investigate their properties: completeness, orthogonality, asymptotic as $|x|,|k|\to\infty$, etc.

Acknowledgments. We thank W. Lionheart for kind consultations and are grateful to the referees for many suggested corrections and helpful remarks.

DECAY ESTIMATES OF A TANGENTIAL DERIVATIVE TO THE LIGHT CONE FOR THE WAVE EQUATION AND THEIR APPLICATION*

SOICHIRO KATAYAMA† AND HIDEO KUBO‡

Abstract. We consider wave equations in three space dimensions and obtain new weighted L^∞-L^∞ estimates for a tangential derivative to the light cone. As an application, we give a new proof of the global existence theorem, which was originally proved by Klainerman and Christodoulou, for systems of nonlinear wave equations under the null condition. Our new proof has the advantage of using neither the scaling nor the Lorentz boost operators.

Key words. nonlinear wave equation, null condition, global existence

AMS subject classification. 35L70

DOI. 10.1137/070694417

1. Introduction.

Solutions to the Cauchy problem for nonlinear wave equations with quadratic nonlinearity in three space dimensions may blow up in finite time no matter how small initial data are, and we have to impose some special condition on the nonlinearity to get global solutions. The null condition is one of such conditions and is associated with the null forms Q_0 and Q_{ab}, which are given by

$$Q_0(v,w;c) = (\partial_t v)(\partial_t w) - c^2(\nabla_x v)\cdot(\nabla_x w), \tag{1.1}$$

$$Q_{ab}(v,w) = (\partial_a v)(\partial_b w) - (\partial_b v)(\partial_a w) \quad (0 \le a < b \le 3) \tag{1.2}$$

for $v = v(t,x)$ and $w = w(t,x)$, where c is a positive constant corresponding to the propagation speed, $\partial_0 = \partial_t = \partial/\partial t$, and $\partial_j = \partial/\partial x_j$ $(j = 1,2,3)$. More precisely, let $c > 0$ and consider the Cauchy problem for

$$\square_c u_i = F_i(u, \partial u, \nabla_x \partial u) \quad \text{in } (0,\infty)\times\mathbb{R}^3 \quad (1 \le i \le m) \tag{1.3}$$

with initial data

$$u = \varepsilon f \text{ and } \partial_t u = \varepsilon g \quad \text{at } t = 0, \tag{1.4}$$

where $\square_c = \partial_t^2 - c^2\Delta_x$, $u = (u_j)$, $\partial u = (\partial_a u_j)$, and $\nabla_x \partial u = (\partial_k \partial_a u_j)$ with $1 \le j \le m$, $1 \le k \le 3$, and $0 \le a \le 3$, while ε is a positive parameter. Let $F = (F_i)_{1\le i\le m}$ be quadratic around the origin in its arguments and the system be quasi-linear. In other words, we assume that each F_i has the form

$$F_i(u, \partial u, \nabla_x \partial u) = \sum_{\substack{1\le j\le m\\ 1\le k\le 3,\ 0\le a\le 3}} c_{ka}^{ij}(u,\partial u)\partial_k\partial_a u_j + d_i(u,\partial u), \tag{1.5}$$

where $c^{ij}_{ka}(u, \partial u) = O(|u| + |\partial u|)$ and $d_i(u, \partial u) = O(|u|^2 + |\partial u|^2)$ around $(u, \partial u) = (0, 0)$. Without loss of generality, we may assume $c^{ij}_{k\ell} = c^{ij}_{\ell k}$ for $1 \le i, j \le m$ and $1 \le k, \ell \le 3$. In addition, we always assume the symmetry condition

$$c^{ij}_{ka} = c^{ji}_{ka} \quad \text{for } 1 \le i, j \le m, \quad 1 \le k \le 3, \text{ and } 0 \le a \le 3.$$

Then it is well known that the null condition (for the above system (1.3)) is satisfied if and only if the quadratic terms of F_i $(1 \le i \le m)$ can be written as linear combinations of the null forms $Q_0(u_j, \partial^\alpha u_k; c)$ and $Q_{ab}(u_j, \partial^\alpha u_k)$ with $1 \le j, k \le m$, $0 \le a < b \le 3$, and $|\alpha| \le 1$, where $\partial^\alpha = \partial_0^{\alpha_0} \partial_1^{\alpha_1} \partial_2^{\alpha_2} \partial_3^{\alpha_3}$ for a multi-index $\alpha = (\alpha_0, \alpha_1, \alpha_2, \alpha_3)$ (refer to [3] and [14] for the precise description of the null condition). Klainerman [14] and Christodoulou [3] proved the following global existence theorem independently by different methods.

THEOREM 1.1 (Klainerman [14], Christodoulou [3]). *Suppose that the null condition is satisfied. Then, for any f, $g \in C_0^\infty(\mathbb{R}^3; \mathbb{R}^m)$, there exists a positive constant ε_0 such that the Cauchy problem* (1.3)–(1.4) *admits a unique global solution $u \in C^\infty([0, \infty) \times \mathbb{R}^3; \mathbb{R}^m)$ for any $\varepsilon \in (0, \varepsilon_0]$.*

Christodoulou used the so-called conformal method which is based on Penrose's conformal compactification of Minkowski space. On the other hand, Klainerman used the vector field method and showed the above theorem by deriving some decay estimates in the original coordinates. In Klainerman's proof, he introduced vector fields

$$L_{c,j} = \frac{x_j}{c}\partial_t + ct\partial_j \quad (1 \le j \le 3), \quad \Omega_{ij} = x_i \partial_j - x_j \partial_i \quad (1 \le i < j \le 3),$$

which are the generators of the Lorentz group, and the scaling operator

$$S = t\partial_t + x \cdot \nabla_x.$$

These vector fields play an important role in getting Klainerman's weighted L^1-L^∞ estimates for wave equations (see also Hörmander [5]). In addition, using them, we can see that an extra decay factor is expected from the null forms. For example, we have

$$(1.6) \qquad Q_0(v, w; c) = \frac{1}{t + r}\Big\{(\partial_t v)\big(Sw + cL_{c,r}w\big) - c\sum_{j=1}^{3}(L_{c,j}v)(\partial_j w) - c^2(Sv)(\partial_r w) + c^2 \sum_{j \ne k} \omega_k (\Omega_{jk} v)(\partial_j w)\Big\},$$

where $r = |x|$, $\omega = (\omega_1, \omega_2, \omega_3) = x/r$, $\partial_r = \sum_{j=1}^3 \omega_j \partial_j$, $L_{c,r} = \sum_{j=1}^3 \omega_j L_{c,j}$, and $\Omega_{ij} = -\Omega_{ji}$ for $1 \le j < i \le 3$.

Among the above vector fields, the Lorentz boost fields $L_{c,j}$ depend on the propagation speed c, and they are unfavorable when we consider the multiple speed case. Thus, the vector field method without the Lorentz boost fields was developed by many authors (see Kovalyov [17, 18], Klainerman and Sideris [16], Yokoyama [25], Kubota and Yokoyama [19], Sideris and Tu [23], Sogge [24], Hidano [4], Katayama [9, 11], and Katayama and Yokoyama [13], for example). In place of (1.6), the following identity was used in the above works relating to the null condition for the multiple speed case:

$$
\begin{aligned}
(1.7)\qquad Q_0(v,w;c) = {} & \frac{1}{t^2}(Sv+(ct-r)\partial_r v)(Sw-(ct+r)\partial_r w) \\
& + \frac{c}{t}\left\{(Sv)(\partial_r w)-(\partial_r v)(Sw)\right\} + \frac{c^2}{r}\sum_{j\neq k}\omega_k(\partial_j v)(\Omega_{jk}w),
\end{aligned}
$$

whose variant was introduced by Hoshiga and Kubo [6]. Equation (1.7) leads to a good estimate in the region $r > \delta t$ with some small $\delta > 0$, because r is equivalent to $t+r$ in this region. Note that the operator S is still used in (1.7), and this is the only reason why S was adopted in [9, 19, 25], because these works are based on variants of L^∞-L^∞ estimates due to John [7] and Kovalyov [17], where only ∂_a and Ω_{ij} are used (see Lemma 3.2 below).

Our aim here is to get rid of not only $L_{c,j}$, but also S from the estimate of the null forms, and prove Theorem 1.1 using only ∂_a and Ω_{jk}. Though the usage of the scaling operator S has not caused any serious difficulty in the study of the Cauchy problem for nonlinear wave equations so far, we believe that it is worthwhile developing a simple approach with a smaller set of vector fields. For this purpose, we make use of the identity

$$
\begin{aligned}
(1.8)\qquad Q_0(v,w;c) = {} & \frac{1}{2}\big\{(D_{+,c}v)(D_{-,c}w)+(D_{-,c}v)(D_{+,c}w)\big\} \\
& + \frac{c^2}{r}\sum_{j\neq k}\omega_k(\partial_j v)(\Omega_{jk}w),
\end{aligned}
$$

where $D_{\pm,c} = \partial_t \pm c\partial_r$. Note that this identity was already used implicitly to obtain identities like (1.7) (see [23], for example). In view of (1.8), what we need to treat the null forms is an enhanced decay estimate for the tangential derivative $D_{+,c}$ to the light cone. We can say that, in the previous works, this enhanced decay has been observed through

$$
D_{+,c} = \frac{1}{t}\big(S+(ct-r)\partial_r\big) \text{ or } D_{+,c} = \frac{1}{ct+r}\big(cS+cL_{c,r}\big)
$$

with the help of S or also $L_{c,r} = \sum_{j=1}^3 \omega_j L_{c,j}$.

In this paper, we take a different approach. We will establish the enhanced decay of $D_{+,c}u$ for the solution u to the wave equation directly. We formulate it as a weighted L^∞-L^∞ estimate in Theorem 2.1 below, which is our main ingredient in this paper. The point is that such an estimate can be derived by using only ∂_a and Ω_{ij}. This type of approach to $D_{+,c}$ goes back to the work of John [8].

2. The main result. Before stating our result precisely, we introduce several notations. We put $Z = \{Z_a\}_{1\le a\le 7} = \{(\partial_a)_{0\le a\le 3}, (\Omega_{jk})_{1\le j<k\le 3}\}$. For a multi-index $\alpha = (\alpha_1,\dots,\alpha_7)$, we define $Z^\alpha = Z_1^{\alpha_1}Z_2^{\alpha_2}\cdots Z_7^{\alpha_7}$. For a function $v = v(t,x)$ and a nonnegative integer s, we define

$$
(2.1)\qquad |v(t,x)|_s = \sum_{|\alpha|\le s}|Z^\alpha v(t,x)| \text{ and } \|v(t,\cdot)\|_s = \big\||v(t,\cdot)|_s\big\|_{L^2(\mathbb{R}^3)}.
$$

We put $\langle a\rangle = \sqrt{1+a^2}$ for $a \in \mathbb{R}$. Let c be a positive constant, and we fix arbitrary positive constants c_j $(1 \le j \le N)$ (our theorem is true for any choice of these constants c_j, but when we apply our estimate to nonlinear problems, we usually choose c_j as the propagation speeds and N as the number of different propagation speeds in the system; c is also chosen from these propagation speeds). We define

$$w(t,r) = w(t,r;c_1,\dots,c_N) = \min_{0\le j\le N} \langle c_j t - r\rangle \tag{2.2}$$

with $c_0 = 0$, and we define

$$A_{\rho,\mu,s}[G;c](t,x) = \sup_{(\tau,y)\in\Lambda_c(t,x)} |y|\,\langle \tau+|y|\rangle^{\rho}\, w(\tau,|y|)^{1+\mu}|G(\tau,y)|_s \tag{2.3}$$

for $\rho,\mu \ge 0$, a nonnegative integer s, and a smooth function $G = G(t,x)$, where $\Lambda_c(t,x) = \{(\tau,y)\in[0,t]\times\mathbb{R}^3\,;\, |y-x|\le c(t-\tau)\}$. We also define

$$B_{\rho,s}[\phi,\psi;c](t,x) = \sup_{y\in\Lambda'_c(t,x)} \langle |y|\rangle^{\rho}\left(|\phi(y)|_{s+1} + |\psi(y)|_s\right) \tag{2.4}$$

for $\rho \ge 0$, a nonnegative integer s, and smooth functions ϕ and ψ on $\mathbb{R}^3$, where $\Lambda'_c(t,x) = \{y\in\mathbb{R}^3\,;\,|y-x|\le ct\}$.

The following theorem is our main result.

Theorem 2.1. *Assume $1\le\kappa\le 2$ and $\mu>0$.*

(i) *Let u be the solution to*

$$\Box_c u = G \quad \text{in } (0,\infty)\times\mathbb{R}^3$$

with initial data $u = \partial_t u = 0$ at $t=0$. Then there exists a positive constant C, depending on κ and μ, such that

$$\langle |x|\rangle\,\langle t+|x|\rangle\,\langle ct-|x|\rangle^{\kappa-1}\{\log(2+t+|x|)\}^{-1}\,|D_{+,c}u(t,x)| \le CA_{\kappa,\mu,2}[G;c](t,x) \tag{2.5}$$

for $(t,x)\in(0,\infty)\times\mathbb{R}^3$ with $x\ne 0$, where $A_{\kappa,\mu,2}$ is given by (2.3).

Moreover, if $1<\kappa<2$, then for any $\delta>0$, there exists a constant C, depending on κ, μ, and δ, such that

$$\langle t+|x|\rangle^2\,\langle ct-|x|\rangle^{\kappa-1}\,|D_{+,c}u(t,x)| \le CA_{\kappa,\mu,2}[G;c](t,x) \tag{2.6}$$

for $(t,x)\in(0,\infty)\times\mathbb{R}^3$ satisfying $|x|>\delta t$.

(ii) *Let u^* be the solution to*

$$\Box_c u^* = 0 \text{ in } (0,\infty)\times\mathbb{R}^3$$

with initial data $u^* = \phi$ and $\partial_t u^* = \psi$ at $t=0$. Then we have

$$\langle |x|\rangle\,\langle t+|x|\rangle\,\langle ct-|x|\rangle^{\kappa-1}\,|D_{+,c}u^*(t,x)| \le CB_{\kappa+\mu+1,2}[\phi,\psi;c](t,x) \tag{2.7}$$

for $(t,x)\in(0,\infty)\times\mathbb{R}^3$ with $x\ne 0$, where $B_{\kappa+\mu+1,2}$ is given by (2.4).

Remark.

1. Similar estimates for radially symmetric solutions are obtained by Katayama [11].

2. Suppose that $A_{\kappa,\mu,2}[G;c](t,x)$ is bounded on $[0,\infty)\times\mathbb{R}^3$ for some $\kappa\in[1,2)$ and $\mu>0$ and that u solves $\Box_c u=G$ with zero initial data. Then, from Lemma 3.2 below, we see that u and ∂u decay like $\langle t\rangle^{-1}\,\Psi_{\kappa-1}(t)$ along the light cone $ct=|x|$, where $\Psi_\rho(t)=\log(2+t)$ if $\rho=0$, and $\Psi_\rho(t)=1$ if $\rho>0$. Compared with this decay rate, we find from (2.5) and (2.6) that $D_{+,c}u$ gains extra decay of $\langle t\rangle^{-1}$ and behaves like $\langle t\rangle^{-2}\,\Psi_{\kappa-1}(t)$ along the light cone.

3. For tangential derivatives $T_{c,j}=(x_j/|x|)\partial_t+c\partial_j$ $(1\le j\le 3)$, Alinhac showed that

$$\left(\int_0^t\int_{\mathbb{R}^3}\big(1+\big|c\tau-|x|\big|\big)^{-\rho}|T_{c,j}u(\tau,x)|^2dxd\tau\right)^{1/2}$$

with $\rho>1$ is bounded by $\|\partial u(0,\cdot)\|_{L^2(\mathbb{R}^3)}+\int_0^t\|\Box_c u(\tau,\cdot)\|_{L^2(\mathbb{R}^3)}d\tau$ (see [1], for example). Observe that $T_{c,j}$ is closely connected to $D_{+,c}$. In fact, we have $D_{+,c}=\sum_{j=1}^3(x_j/|x|)T_{c,j}$. Though Alinhac's estimate does not need S and means enhanced decay of tangential derivatives implicitly, it seems difficult to recover a pointwise decay estimate from his weighted space-time estimate. On the other hand, Sideris and Thomases [22] obtained the estimate for $\big\|\big(1+\big|ct+|\cdot|\big|\big)T_{c,j}u(t,\cdot)\big\|_{L^2(\mathbb{R}^3)}$; however, S is used in their estimate.

4. The exterior problem for systems of nonlinear wave equations with the single or multiple speed(s) is also widely studied (see Metcalfe, Nakamura, and Sogge [20] and Metcalfe and Sogge [21] and the references cited therein). In the exterior domains, because of their unbounded coefficients on the boundary, the Lorentz boosts are unlikely to be applicable even for the single speed case. This is another reason why the vector field method without the Lorentz boosts is widely studied. In addition, S also causes a technical difficulty in the exterior problems. We will discuss the exterior problem in a subsequent paper, and we will not go into further details here.

We will prove Theorem 2.1 in the next section, after stating some known weighted L^∞-L^∞ estimates for wave equations. Though we can apply our theorem to exclude S from the proof of the multiple speed version of Theorem 1.1 in [9, 19, 25], we concentrate on the single speed case for simplicity, and we will give a new proof, without using S and $L_{c,j}$, of Theorem 1.1 in section 4 as an application of our main theorem.

Throughout this paper, various positive constants, which may change line by line, are denoted just by the same letter C.

3. Proof of Theorem 2.1. For $c>0$, $\phi=\phi(x)$, and $\psi=\psi(x)$, we write $U_c^*[\phi,\psi]$ for the solution u to the homogeneous wave equation $\Box_c u=0$ in $(0,\infty)\times\mathbb{R}^3$ with initial data $u=\phi$ and $\partial_t u=\psi$ at $t=0$. Similarly, for $c>0$ and $G=G(t,x)$, we write $U_c[G]$ for the solution u to the inhomogeneous wave equation $\Box_c u=G$ in $(0,\infty)\times\mathbb{R}^3$ with initial data $u=\partial_t u=0$ at $t=0$.

For $U_c^*[\phi,\psi]$ we have the following.

Lemma 3.1. *Let $c>0$. Then, for $\kappa>1$, we have*

$$\begin{aligned}(3.1)\qquad &\langle t+|x|\rangle\,\langle ct-|x|\rangle^{\kappa-1}\,|U_c^*[\phi,\psi](t,x)|\\ &\qquad\le C\sup_{y\in\Lambda_c'(t,x)}\langle|y|\rangle^{\kappa}\,(\langle|y|\rangle\,|\phi(y)|_1+|y|\,|\psi(y)|)\end{aligned}$$

for $(t,x)\in[0,\infty)\times\mathbb{R}^3$.

For the proof, see Katayama and Yokoyama [13, Lemma 3.1] (see also Asakura [2] and Kubota and Yokoyama [19]).

After the pioneering work of John [7], a wide variety of weighted L^∞-L^∞ estimates for $U_c[G]$ and $\partial U_c[G]$ have been obtained (see [2, 9, 10, 12, 13, 17, 18, 19, 25]). Here we restrict our attention to what will be used directly in our proofs of Theorems 1.1 and 2.1.

LEMMA 3.2. *Let* $c>0$. *Define*

$$\Phi_\rho(t,r)=\begin{cases}\log\big(2+\langle t+r\rangle\,\langle t-r\rangle^{-1}\big) & \text{if } \rho=0,\\ \langle t-r\rangle^{-\rho} & \text{if } \rho>0,\end{cases} \tag{3.2}$$

$$\Psi_\rho(t)=\begin{cases}\log(2+t) & \text{if } \rho=0,\\ 1 & \text{if } \rho>0.\end{cases} \tag{3.3}$$

Assume $\kappa\ge 1$ *and* $\mu>0$. *Then we have*

$$\langle t+|x|\rangle\,\Phi_{\kappa-1}(ct,|x|)^{-1}|U_c[G](t,x)|\le CA_{\kappa,\mu,0}[G;c](t,x), \tag{3.4}$$

$$\langle |x|\rangle\,\langle ct-|x|\rangle^{\kappa}\,\Psi_{\kappa-1}(t)^{-1}|\partial U_c[G](t,x)|\le CA_{\kappa,\mu,1}[G;c](t,x) \tag{3.5}$$

for $(t,x)\in[0,\infty)\times\mathbb{R}^3$, *where* $A_{\kappa,\mu,s}[G;c]$ *is given by* (2.3).

Proof. For the proof of (3.4), see Katayama and Yokoyama [13, equation (3.6) in Lemma 3.2, and section 8] for $\kappa>1$ and Katayama [11] for $\kappa=1$.

Next we consider (3.5) with $\kappa>1$. From Lemma 8.2 in [13], we find that (3.5) with $\partial U_c[G]$ replaced by $U_c[\partial G]$ is true. Now (3.5) follows immediately from Lemma 3.1, because we have $\partial_a U_c[G]=U_c[\partial_a G]+\delta_{a0}U_c^*[0,G(0,\cdot)]$ for $0\le a\le 3$ with the Kronecker delta δ_{ab}, and $\langle |y|\rangle^{\kappa+1}\,|y|\,|G(0,y)|\le CA_{\kappa,\mu,1}[G;c](t)$ (note that we have $w(0,r)=\langle r\rangle$). Equation (3.5) for the case $\kappa=1$ can be treated similarly (see [19] and [9]). $\square$

Note that we will use (3.5) in the proof of Theorem 1.1 but not in that of Theorem 2.1.

Now we are in a position to prove Theorem 2.1. Suppose that all the assumptions in Theorem 2.1 are fulfilled. Without loss of generality, we may assume $c=1$.

For simplicity of exposition, we write $D_\pm$ for $D_{\pm,1}=\partial_t\pm\partial_r$. Similarly, $U^*[\phi,\psi]$, $U[G]$, $A_{\rho,\mu,s}(t,x)$, and $B_{\rho,s}(t,x)$ denote $U_1^*[\phi,\psi]$, $U_1[G]$, $A_{\rho,\mu,s}[G;1](t,x)$, and $B_{\rho,s}[\phi,\psi;1](t,x)$, respectively.

First we prove (2.5). Assume $0<r=|x|\le 1$. We have

$$|D_+u|\le|\partial_t u|+|\nabla_x u|\le\sum_{0\le a\le 3}|U[\partial_a G]|+|U^*[0,G(0,\cdot)]|\,.$$

From (3.4) in Lemma 3.2, we get

$$\langle t+r\rangle\,\Phi_{\kappa-1}(t,r)^{-1}\,|U[\partial_a G](t,x)|\le CA_{\kappa,\mu,1}(t,x), \tag{3.6}$$

while Lemma 3.1 leads to

$$\begin{aligned}\langle t+r\rangle\,\langle t-r\rangle^{\kappa}\,|U^*[0,G(0,\cdot)](t,x)|&\le C\sup_{y\in\Lambda_1'(t,x)}|y|\,\langle |y|\rangle^{\kappa+1}\,|G(0,y)|\\&\le CA_{\kappa,\mu,0}(t,x).\end{aligned}$$

Thus we obtain (2.5) for $0<|x|\le 1$.

We set $v(t,r,\omega) = ru(t,r\omega)$ for $r > 0$ and $\omega \in S^2$. Then we have

$$D_-D_+v(t,r,\omega) = rG(t,r\omega) + \frac{1}{r}\sum_{1\le j<k\le 3}\Omega_{jk}^2 u(t,r\omega). \tag{3.7}$$

Let $r = |x| \ge 1$ and $1 \le \kappa \le 2$. From (3.4), we get

$$\begin{aligned}\frac{1}{r}\sum_{1\le j<k\le 3}|\Omega_{jk}^2 u(t,r\omega)| &\le C\langle r\rangle^{-1}\langle t+r\rangle^{-1}\Phi_{\kappa-1}(t,r)A_{\kappa,\mu,2}(t,r\omega)\\ &\le C\langle t+r\rangle^{-\kappa}(\langle r\rangle^{-1}+\langle t-r\rangle^{-1})A_{\kappa,\mu,2}(t,r\omega),\end{aligned} \tag{3.8}$$

where $\Phi_{\kappa-1}$ is from (3.2). It is easy to see that

$$|rG(t,r\omega)| \le \langle t+r\rangle^{-\kappa} w(t,r)^{-1-\mu}A_{\kappa,\mu,0}(t,r\omega). \tag{3.9}$$

Note that we have

$$A_{\kappa,\mu,s}(\tau,(t+r-\tau)\omega) \le A_{\kappa,\mu,s}(t,r\omega) \quad \text{for } 0 \le \tau \le t.$$

Therefore, by (3.7), (3.8), and (3.9), we get

$$\begin{aligned}|D_+v(t,r,\omega)| &= \left|\int_0^t \frac{d}{d\tau}(D_+v)(\tau,t+r-\tau,\omega)d\tau\right|\\ &= \left|\int_0^t (D_-D_+v)(\tau,t+r-\tau,\omega)d\tau\right|\\ &\le C\langle t+r\rangle^{-\kappa}A_{\kappa,\mu,2}(t,r\omega)\int_0^t\langle t+r-\tau\rangle^{-1}d\tau\\ &\quad + C\langle t+r\rangle^{-\kappa}A_{\kappa,\mu,2}(t,r\omega)\int_0^t\langle t+r-2\tau\rangle^{-1}d\tau\\ &\quad + C\langle t+r\rangle^{-\kappa}A_{\kappa,\mu,0}(t,r\omega)\int_0^t w(\tau,t+r-\tau)^{-1-\mu}d\tau\\ &\le C\langle t+r\rangle^{-\kappa}A_{\kappa,\mu,2}(t,r\omega)\log(2+t+r).\end{aligned} \tag{3.10}$$

Since we have

$$rD_+u(t,r\omega) = D_+v(t,r,\omega) - u(t,r\omega),$$

from (3.10) and (3.4), we obtain

$$\langle r\rangle\langle t+r\rangle\langle t-r\rangle^{\kappa-1}|D_+u(t,x)| \le C\log(2+t+|x|)A_{\kappa,\mu,2}(t,x)$$

for $r = |x| \ge 1$. This completes the proof of (2.5).

To prove (2.6), we first note that $\langle t+r\rangle \le C\langle r\rangle$ for $r > \delta t$. Let $1 < \kappa < 2$. By the first line of (3.8), we have

$$\frac{1}{r}\sum_{1\le j<k\le 3}|\Omega_{jk}^2 u(t,r\omega)| \le C\langle t+r\rangle^{-2}\langle t-r\rangle^{-\kappa+1}A_{\kappa,\mu,2}(t,r\omega) \tag{3.11}$$

for $r > \max\{\delta t, 1\}$. Obviously $r > \max\{\delta t, 1\}$ yields $t + r - \tau > \max\{\delta\tau, 1\}$ for $0 \le \tau \le t$. Hence following similar lines to (3.10), we obtain

$$|D_+ v(t, r, \omega)| \le C \langle t + r\rangle^{-\kappa} A_{\kappa,\mu,2}(t, r\omega) \quad \text{ for } r \ge \max\{\delta t, 1\}.$$

This immediately implies (2.6), because we already know that $|D_+u|$ (resp., $|D_+u - r^{-1}D_+v|$) has the desired bound for $(\delta t <)r \le 1$ (resp., $r \ge \max\{\delta t, 1\}$).

Now we are going to prove (2.7). Lemma 3.1 immediately implies

$$\langle t + |x|\rangle \langle t - |x|\rangle^{\kappa+\mu-1} |D_+u^*(t, x)| \le CB_{\kappa+\mu+1,1}(t, x),$$

which is better than (2.7) for $0 < |x| \le 1$. Lemma 3.1 also implies

$$\begin{aligned} \frac{1}{r} \sum_{1\le j<k\le 3} &|\Omega^2_{jk} u^*(t, x)| \\ &\le C \langle r\rangle^{-1} \langle t + r\rangle^{-1} \langle t - r\rangle^{1-\kappa-\mu} B_{\kappa+\mu+1,2}(t, x) \\ &\le C \langle t + r\rangle^{-\kappa} (\langle r\rangle^{-1-\mu} + \langle t - r\rangle^{-1-\mu})B_{\kappa+\mu+1,2}(t, x) \end{aligned} \tag{3.12}$$

for $r = |x| \ge 1$. Set $v^*(t, r, \omega) = ru^*(t, r\omega)$ for $r \ge 0$ and $\omega \in S^2$. For $r \ge 1$, similarly to (3.10), we get

$$\begin{aligned} |D_+v^*(t, r, \omega)| &= \left|(D_+v^*)(0, t + r, \omega) + \int_0^t (D_-D_+v^*)(\tau, t + r - \tau, \omega)d\tau\right| \\ &\le C \langle t + r\rangle^{-\kappa} B_{\kappa+1,0}(t, r\omega) \\ &\quad + C \langle t + r\rangle^{-\kappa} B_{\kappa+\mu+1,2}(t, r\omega) \int_0^t \langle t + r - \tau\rangle^{-1-\mu} d\tau \\ &\quad + C \langle t + r\rangle^{-\kappa} B_{\kappa+\mu+1,2}(t, r\omega) \int_0^t \langle t + r - 2\tau\rangle^{-1-\mu} d\tau \\ &\le C \langle t + r\rangle^{-\kappa} B_{\kappa+\mu+1,2}(t, r\omega), \end{aligned}$$

which ends up with

$$\langle r\rangle \langle t + r\rangle \langle t - r\rangle^{\kappa-1} |D_+u^*(t, x)| \le CB_{\kappa+\mu+1,2}(t, x)$$

for $r = |x| \ge 1$. This completes the proof of (2.7). ∎

4. Proof of Theorem 1.1. As an application of Theorem 2.1, we give a new proof of Theorem 1.1. First we derive estimates for the null forms.

LEMMA 4.1. *Let c be a positive constant, and $v = (v_1, \dots, v_M)$. Suppose that Q is one of the null forms. Then, for a nonnegative integer s, there exists a positive constant C_s, depending only on c and s, such that*

$$\begin{aligned} |Q(v_j, v_k)|_s \le C_s\Bigg\{&|\partial v|_{[s/2]} \sum_{|\alpha|\le s} |D_{+,c}Z^\alpha v| + |\partial v|_s \sum_{|\alpha|\le[s/2]} |D_{+,c}Z^\alpha v| \\ &+ \frac{1}{r}\big(|\partial v|_{[s/2]}|v|_{s+1} + |v|_{[s/2]+1}|\partial v|_s\big)\Bigg\}. \end{aligned}$$

Proof. The case $Q = Q_0$ and $s = 0$ follows immediately from (1.8). We can obtain similar identities for other null forms by using

$$(\partial_t, \nabla_x) = \left(\frac{1}{2}, -\frac{x}{2cr}\right) D_{-,c} + \left(\frac{1}{2}, \frac{x}{2cr}\right) D_{+,c} - \left(0, \frac{x}{r^2} \wedge \Omega\right)$$

with $\Omega = (\Omega_{23}, -\Omega_{13}, \Omega_{12})$ (see (5.2) in Sideris and Tu [23, Lemma 5.1]), and we can show the desired estimate for $s = 0$. Since $Z^\alpha Q(v_j, v_k)$ can be written in terms of $Q_0(Z^\beta v_j, Z^\gamma v_k; c)$ and $Q_{ab}(Z^\beta v_j, Z^\gamma v_k)$ $(0 \le a < b \le 3)$ with $|\beta| + |\gamma| \le |\alpha|$, the desired estimate for general s follows immediately. $\square$

Now we are going to prove Theorem 1.1. Without loss of generality, we may assume $c = 1$. Assume that the assumptions in Theorem 1.1 are fulfilled. Let u be the solution to (1.3)–(1.4) on $[0, T) \times \mathbb{R}^3$, and we set

$$\begin{aligned} e_{\rho,k}(t,x) = &\langle t + |x|\rangle \langle t - |x|\rangle^\rho |u(t,x)|_{k+2} + \langle |x|\rangle \langle t - |x|\rangle^{\rho+1} |\partial u(t,x)|_{k+1} \\ &+ \chi(t,x) \langle t + |x|\rangle^2 \langle t - |x|\rangle^\rho \sum_{|\alpha| \le k} |D_{+,1} Z^\alpha u(t,x)| \end{aligned}$$

for $\rho > 0$ and a positive integer k, where $\chi(t,x) = 1$ if $|x| > (1+t)/2$, while $\chi(t,x) = 0$ if $|x| \le (1+t)/2$. We fix $\rho \in (1/2, 1)$ and $s \ge 8$, and assume that

$$\sup_{0 \le t < T} \|e_{\rho,s}(t,\cdot)\|_{L^\infty(\mathbb{R}^3)} \le M\varepsilon \tag{4.1}$$

holds for some large $M (> 0)$ and small $\varepsilon (> 0)$, satisfying $M\varepsilon \le 1$. Our goal here is to get (4.1) with M replaced by $M/2$. Once such an estimate is established, it is well known that we can obtain Theorem 1.1 by the so-called bootstrap (or continuity) argument.

In the following we always assume M is large enough, and ε is sufficiently small. For simplicity of exposition, we will not write dependence of nonlinearities on the unknowns explicitly. Namely we abbreviate $F(u, \partial u, \nabla_x \partial u)(t,x)$ as $F(t,x)$, and so on.

First we evaluate the energy. For any nonnegative integer $k \le 2s$, (4.1) implies

$$|F^{(2)}(t,x)|_k \le CM\varepsilon \langle |x|\rangle^{-1} \langle t - |x|\rangle^{-1-\rho} |\partial u(t,x)|_{k+1}, \tag{4.2}$$

where $F^{(2)}$ denotes the quadratic terms of F. Put $H = F - F^{(2)}$, and $Zu = (Z_1 u, \dots, Z_7 u)$. Since we have

$$\langle r\rangle^{-1} \langle t - r\rangle^{-1} \le C \langle t + r\rangle^{-1} \quad \text{for any } (t,r) \in [0,\infty) \times [0,\infty), \tag{4.3}$$

and since $\langle |x|\rangle^{-1} |Zu| \le C|\partial u|$, from (4.1) we obtain

$$\begin{aligned} |H(t,x)|_k &\le C\big(|u|^3 + |(u, \partial u)|^2_{[k/2]+1} (|Zu|_{k-1} + |\partial u|_{k+1})\big) \\ &\le CM^3\varepsilon^3 \langle t + |x|\rangle^{-3} \langle t - |x|\rangle^{-3\rho} \\ &\quad + CM^2\varepsilon^2 \langle t + |x|\rangle^{-1} \langle t - |x|\rangle^{-2\rho} |\partial u(t,x)|_{k+1} \end{aligned} \tag{4.4}$$

for any nonnegative integer $k \le 2s$. Similarly to (4.2) and (4.4), using (4.3), we obtain

$$|F_{i,\alpha}(t,x)| \le CM\varepsilon(1+t)^{-1} |\partial u(t,x)|_{2s} + CM^3\varepsilon^3 \langle t + |x|\rangle^{-3} \langle t - |x|\rangle^{-3\rho} \tag{4.5}$$

for $|\alpha| \le 2s$, where

$$F_{i,\alpha} = Z^\alpha F_i - \sum_{j,k,a} c^{ij}_{ka} \partial_k \partial_a (Z^\alpha u_j)$$

with c^{ij}_{ka} coming from (1.5). It is easy to see that

$$\| \langle t + |\cdot| \rangle^{-3} \langle t - |\cdot| \rangle^{-3\rho} \|_{L^2(\mathbb{R}^3)} \le C(1+t)^{-2} \tag{4.6}$$

for $\rho > 1/2$. Therefore, from (4.5), we obtain

$$\|F_{i,\alpha}(t,\cdot)\|_{L^2} \le CM\varepsilon(1+t)^{-1}\|\partial u(t,\cdot)\|_{2s} + CM^3\varepsilon^3(1+t)^{-2}$$

for $|\alpha| \le 2s$. We also have

$$\sum_{j,k,a} |c^{ij}_{ka}(t,x)|_1 \le CM\varepsilon(1+t)^{-1}.$$

Now, applying the energy inequality for the systems of perturbed wave equations $\Box_1(Z^\alpha u_i) - \sum_{j,k,a} c^{ij}_{ka}\partial_k\partial_a(Z^\alpha u_j) = F_{i,\alpha}$, we find

$$\frac{d}{dt}\|\partial u(t,\cdot)\|_{2s} \le CM\varepsilon(1+t)^{-1}\|\partial u(t,\cdot)\|_{2s} + CM^3\varepsilon^3(1+t)^{-2},$$

and the Gronwall lemma leads to

$$\|\partial u(t,\cdot)\|_{2s} \le C(\varepsilon + M^3\varepsilon^3)(1+t)^{C_0 M\varepsilon} \le CM\varepsilon(1+t)^{C_0 M\varepsilon} \tag{4.7}$$

with an appropriate positive constant C_0 which is independent of M (note that the energy inequality for the systems of perturbed wave equations is available because of the symmetry condition).

In the following, we repeatedly use Theorem 2.1 and Lemmas 3.1 and 3.2 with the choice of $N = 1$ and $c_1 = 1 (= c)$. In other words, from now on we put $w(t,r) = \min\big\{\langle r \rangle, \langle t - r \rangle\big\}$. Note that we have

$$\langle r \rangle^{-1} \langle t - r \rangle^{-1} \le C \langle t + r \rangle^{-1} w(t,r)^{-1}, \tag{4.8}$$

which is more precise than (4.3).

By (4.7) and the Sobolev-type inequality

$$\langle |x| \rangle \, |v(t,x)| \le C\|v(t,\cdot)\|_2,$$

whose proof can be found in Klainerman [15], we see that

$$\langle |x| \rangle \, |\partial u(t,x)|_{2s-2} \le CM\varepsilon(1+t)^{C_0 M\varepsilon}. \tag{4.9}$$

Using (4.8) and (4.9), from (4.2) and (4.4) with $k = 2s-3$, we obtain

$$|F(t,x)|_{2s-3} \le CM^2\varepsilon^2 \langle r \rangle^{-1} \langle t + |x| \rangle^{-1} w(t,|x|)^{-2\rho}(1+t)^{C_0 M\varepsilon},$$

which implies

$$A_{1+\nu,2\rho-1,2s-3}[F;1](t,x) \le CM^2\varepsilon^2 \langle t + |x| \rangle^{C_0 M\varepsilon + \nu}, \tag{4.10}$$

where ν is a positive constant to be fixed later (note that we have $\langle \tau+|y|\rangle \le \langle t+|x|\rangle$ for $(\tau,y)\in\Lambda_1(t,x)$). Since $2\rho>1$ and $1+\nu>1$, by Lemmas 3.1 and 3.2 with Theorem 2.1, we obtain

$$\begin{aligned} (4.11)\qquad e_{0,2s-5}(t,x) &\le e_{\nu,2s-5}(t,x) \le C\varepsilon + CM^2\varepsilon^2 \langle t+|x|\rangle^{C_0M\varepsilon+\nu} \\ &\le CM\varepsilon \langle t+|x|\rangle^{C_0M\varepsilon+\nu}. \end{aligned}$$

Finally, we are going to estimate $e_{\rho,s}(t,x)$. By (4.11) and (4.2) with $k=2s-6$, we have

$$|F^{(2)}(t,x)|_{2s-6} \le CM^2\varepsilon^2 \langle t+|x|\rangle^{-2-\rho+C_0M\varepsilon+\nu} \langle |x|\rangle^{-2}$$

for (t,x) satisfying $|x|\le (t+1)/2$. On the other hand, (4.1), (4.11), and Lemma 4.1 imply

$$|F^{(2)}(t,x)|_{2s-6} \le CM^2\varepsilon^2 \langle t+|x|\rangle^{-3+C_0M\varepsilon+\nu} \langle t-|x|\rangle^{-1-\rho}$$

for (t,x) satisfying $|x|\ge (t+1)/2$. Summing up, we obtain

$$(4.12)\qquad |F^{(2)}(t,x)|_{2s-6} \le CM^2\varepsilon^2 \langle |x|\rangle^{-1} \langle t+|x|\rangle^{-2+C_0M\varepsilon+\nu} w(t,|x|)^{-1-\rho}.$$

By the first line of (4.4) with $k=2s-6$, using (4.1) and (4.11), we get

$$(4.13)\qquad |H(t,x)|_{2s-6} \le CM^3\varepsilon^3 \langle |x|\rangle^{-1} \langle t+|x|\rangle^{-2+C_0M\varepsilon+\nu} w(t,|x|)^{-2\rho}.$$

Equations (4.12) and (4.13) yield

$$(4.14)\qquad |F(t,x)|_{2s-6} \le CM^2\varepsilon^2 \langle |x|\rangle^{-1} \langle t+|x|\rangle^{-2+C_0M\varepsilon+\nu} w(t,|x|)^{-2\rho}.$$

Now we fix some ν satisfying $0<\nu<1-\rho$, and assume that ε is sufficiently small to satisfy $-2+C_0M\varepsilon+\nu\le -1-\rho$. Then from (4.14) we find that

$$(4.15)\qquad A_{1+\rho,2\rho-1,2s-6}[F;1](t,x) \le CM^2\varepsilon^2.$$

Since we have $s+2\le 2s-6$, $1+\rho>1$, and $2\rho>1$, from Theorem 2.1, Lemmas 3.1 and 3.2, we obtain

$$(4.16)\qquad e_{\rho,s}(t,x) \le C_1\big(\varepsilon + M^2\varepsilon^2\big)$$

for $(t,x)\in[0,T)\times\mathbb{R}^3$, with an appropriate positive constant C_1 which is independent of M. Finally, if M is large enough to satisfy $4C_1\le M$, and ε is small enough to satisfy $C_1M\varepsilon\le 1/4$, by (4.16) we obtain

$$(4.17)\qquad \sup_{0\le t<T} \|e_{\rho,s}(t,\cdot)\|_{L^\infty(\mathbb{R}^3)} \le \frac{M}{2}\varepsilon,$$

which is the desired result. This completes the proof. $\square$

AN INVERSE PROBLEM FOR A NONLINEAR PARABOLIC EQUATION WITH APPLICATIONS IN POPULATION DYNAMICS AND MAGNETICS*

BARBARA KALTENBACHER† AND MICHAEL V. KLIBANOV‡

Abstract. The parabolic equation of this paper is a nonlinear one with the unknown coefficient depending on the derivative of the solution. A uniqueness result is proven by the method of Carleman estimates. The applicability of this result is illustrated for parameter identification problems in population dynamics and magnetics. For the latter application, we provide numerical results using a reconstruction method based on a multiharmonic formulation of the problem.

Key words. parameter identification, uniqueness, Carleman estimates

DOI. 10.1137/070685907

1. Introduction.

Nonlinear parabolic PDEs arise in a large variety of applications ranging from combustion theory via environmental pollution, population dynamics, and nonlinear magnetics to the theory of the economic growth. Since the coefficient depending nonlinearly on the solution of the PDE is often not accessible to direct measurements, its determination from boundary measurements is an important task.

In this paper we consider the question of identifiability, i.e., whether this coefficient function can be uniquely determined from the given data. While there exist results on the situation that the coefficient depends on values of the solution (as it is relevant, e.g., in nonlinear heat conduction), here we concentrate on the problem when this coefficient is a function of the derivative of the solution (as typical for nonlinear magnetics; cf., e.g., [2]) or where the equation is in nondivergence form (e.g., in diffusion models for population dynamics; cf. [1]).

To prove our uniqueness theorem, we apply the method of Carleman estimates; see, e.g., [3], [4], [5], [6], [7], [8], [9], [10], [11], [12], [18], [19], [20], [21], [22], [23], [24] for this method. The majority of works on this method is concerned with linear equations in which the unknown coefficients depend on spatial variables. Nonlinear parabolic equations were treated by this technique in [8], [18], [20], and Chapter 4 of [21]. Our inverse problem is a problem with the data resulting from a single measurement event. In the case of multiple measurements, uniqueness theorems for inverse problems for nonlinear parabolic equations with unknown coefficients depending on solutions and their first derivatives were proven in [13]. The case of single measurement data for such equations was considered in, e.g., [8], [18], [20], [21], and [24]. However, in these works the unknown coefficient depends on the solution of the original parabolic equation (as well as on some spatial variables in the multidimensional case [20], [21]). The case of the dependence on derivatives of the solution was not considered.

Another significantly new element here is that the unknown coefficient $k\,(u_x)$ is involved together with its first derivative. This leads to the necessity to prove some new estimates for Volterra-like integrals in which Carleman weight functions (CWFs) are involved; see Lemmata 3 and 4. In the past such estimates were established only for t-dependent integrals [3], [4], [5], [6], [7], [8], [9], [10], [11], [12], [18], [19], [20], [21], [22], [23], [24]. Now, however, we also consider the z-dependence (Lemma 3). In addition, such estimates for iterated integrals (Lemma 4) were not previously established.

In the next five paragraphs we briefly outline the idea of the proof of the uniqueness theorem. First, we differentiate the original parabolic PDE with respect to x to obtain a new PDE with respect to the function $v(x,t) = u_x(x,t)$, the x-derivative of the original solution $u(x,t)$. Next, in order to be in a position of applicability of the above-mentioned method of Carleman estimates, we "transform" the function $v(x,t)$ into the spatial variable z using the change of variables (4.6), which is $v\,(w(z,t),t) = z$. Naturally, by the implicit function theorem we need the condition $v_x(x,t) = u_{xx}(x,t) \neq 0$. Hence, for the sake of definiteness, we impose $u_{xx}\,(x,t) \geq \alpha = const. > 0$; see (3.3). Next, we obtain a linear ordinary differential equation (ODE) of second order with respect to the function $\widetilde{k}(z)$, where $\widetilde{k}(z) = k_1(z) - k_2(z)$ is the difference of two possible target coefficients, and we need to prove that this difference equals zero.

Note that the idea of considering ODEs with respect to the unknown coefficients is new, because such ODEs were not considered in the past works on the method of Carleman estimates for inverse problems. Because of the presence of the factor z at $\widetilde{k}''(z)$, we need to impose condition (3.6) in order to avoid the singularities in that equation. We represent the solution of that ODE via Volterra-like integrals. Since the function $k(z)$ is independent of t, we follow one of the ideas of the original work [4] (also, see [19], [21]) differentiating with respect to t and, thus, "eliminating" the function $\widetilde{k}(z)$ from the resulting equation. Next, using the differentiation with respect to z, we obtain an integral differential equation with respect to the function $p\,(z,t) = (w_{1t} - w_{2t})\,(z,t)$, where functions w_1 and w_2 correspond to the coefficients k_1 and k_2, respectively.

However, two major difficulties of the latter equation compared with the above listed previous works on the method of Carleman estimates for inverse problems are the following: (a) it contains not only t-dependent Volterra-like integrals (like the ones in the past) but also z-dependent integrals as well as "mixed" (z,t)-dependent Volterra-like integrals; and (b) second order derivatives p_{zz} are involved as parts of integrands. The element (a) arises because of the solution of the above ODE, thus ultimately because the unknown coefficient is involved in the original PDE together with its derivative. The element (b) is due to the nonlinearity of the original PDE. To overome (a), we need to establish new estimates from the above for those "new" Volterra-like integrals in which CWFs are involved (Lemmata 3 and 4). Note that such estimates cannot be proven in the same way as Carleman estimates are proven for differential operators, because the structure of Volterra-like integral operators is different from the structure of differential operators.

It is not straightforward to deal with (b) because the term with the second z-derivative stands with a small factor $1/\lambda$ in the Carleman estimate (4.50) for the parabolic operator $\partial_t - h_1\partial_z^2$. To overcome (b), we modify one of the ideas of [19]. Namely, we rescale variables (z,t) via the change of variables (4.30), which causes some technical difficulties and rather long formulas, because we need to figure out carefully the appearance of a small factor γ. As a result, this rescaling leads to the appearance of γ in the resulting integral differential inequality (4.43). The latter, as well as Lemmata 2–4, enable us to come up with the "standard" inequality (4.54), after which the proof is similar to previous works.

However, the move from the rescaling (4.30) to (4.54) can be done only if one considers a small part of the rectangle R' in (4.31), rather than the whole rectangle "at once," thus "exhausting" the entire R' via a sequence of small δ-steps. Note that it is unclear at this point whether the method of [11] for an inverse parabolic problem can be adapted to our case to obtain a Lipschitz stability estimate, since it is unclear whether it is possible to obtain analogues of Lemmata 3 and 4 if using the CWF of [12]. It is also unclear whether the method of [12] for hyperbolic equations can be adapted in this case, because of the necessity to exhaust the entire domain via a sequence of small rectangles. Another important difference with the hyperbolic case of [12] is that the Carleman estimate for a hyperbolic operator does not include derivatives involved in the principal part of that operator, unlike the parabolic case (see Lemma 1 for the latter). However, we do need that "inclusion" because some integrals in (4.43) contain the second order derivative p_{zz}, and our estimate should incorporate it in the left-hand side.

The paper is organized as follows. In section 2, we state the inverse problem under consideration, and in section 3 we formulate our uniqueness result. The proof of this theorem is given in section 4. Section 5 describes two applications, namely in population dynamics and in nonlinear magnetics. For the latter, the final section (section 6) provides numerical results obtained with a method based on a multiharmonic formulation.

2. Statement of the problem. The forward problem is

$$u_t = \left(k\left(u_x\right)u_x\right)_x\,, \quad (x,t) \in (0,L)\times(0,T)\,, \tag{2.1}$$

$$u\left(x,0\right) = r(x), \quad x \in (0,L)\,, \tag{2.2}$$

$$u\left(0,t\right) = f_0\left(t\right), \quad u(L,t) = f_1\left(t\right), \quad t \in (0,T)\,, \tag{2.3}$$

or with $v(x,t) = u_x(x,t)$, i.e., $u(x,t) = \int_0^x v(\xi,t)\,d\xi + f_0(t)$,

$$v_t = \left(k\left(v\right)v\right)_{xx}\,, \quad (x,t) \in (0,L)\times(0,T)\,, \tag{2.4}$$

$$v\left(x,0\right) = r'(x), \quad x \in (0,L)\,, \tag{2.5}$$

$$(k(v)v)_x(0,t) = f_0'(t), \quad (k(v)v)_x(L,t) = f_1'(t), \quad t \in (0,T)\,, \tag{2.6}$$

which results from the previous setting by differentiation with respect to the space variable. Naturally, it is assumed that the function $k(z) \in C^1\left(\mathbb{R}\right)$ and

$$k\left(z\right) \geq k_0 = const. > 0 \quad \forall z \in \mathbb{R}. \tag{2.7}$$

It is well known that it is difficult to investigate the question of uniqueness of coefficient inverse problems for parabolic equations unless one assumes that the solution of the forward problem is known at $t = \varepsilon \in (0,T)$. In the latter case, however, one does not need to assume knowledge of the initial condition at $\{t = 0\}$; see, e.g., [5], [11], and sections 3.3.1 and 3.3.2 in [21]. In other words, one needs to assume that knowledge of the initial condition (2.2) is replaced with knowledge of the function $u(x,\varepsilon)$ for an arbitrary $\varepsilon \in (0,T)$; also see section 5 for a physical interpretation. Because of this, we formulate the inverse problem as follows.

Inverse problem. Assume that (2.1) is satisfied for $(x,t) \in (0,L) \times (-c,T)$, where $c \in (0,T]$ is an arbitrary number, and the function $u(x,0) = r(x)$ in (2.2) is known, and assume that boundary conditions $f_0(t)$ and $f_1(t)$ are satisfied for $t \in (-c,T)$. Also, assume that the following two functions $g_0(t)$ and $g_1(t)$ are given:

$$u_x(0,t) = g_0(t), \quad u_x(L,t) = g_1(t), \quad t \in (-c,T). \tag{2.8}$$

Let the interval (a,b) be the range of the function $u_x(x,t)$ for $(x,t) \in (0,L) \times (-c,T)$, i.e., $a \le u_x(x,t) \le b$. Determine the interval (a,b) as well as the unknown coefficient $k(z)$ for $z \in (a,b)$.

3. Uniqueness theorem. The following uniqueness theorem holds.

THEOREM 1. *Let the conditions of the statement of the inverse problem be satisfied. Suppose that there exist two functions $k_1(z)$ and $k_2(z)$ satisfying condition* (2.7) *and such that*

$$zk_i'(z) + k_i(z) \ge const. > 0 \quad \forall z \in \mathbb{R}, \quad i = 1,2. \tag{3.1}$$

Let $u_1(x,t)$ and $u_2(x,t)$ be two corresponding solutions of the forward problem (2.1)–(2.3) *satisfying the same Neumann boundary conditions* (2.8) *and such that*

$$\partial_t^s \partial_x^j u_i \in C([0,L] \times [-c,T]) \quad \text{for } s = 0,1; \quad j = 0,1,2,3; \quad i = 1,2. \tag{3.2}$$

Assume also that in $(0,L) \times (-c,T)$

$$\partial_x^2 u_i \ge \alpha = const. > 0, \quad i = 1,2. \tag{3.3}$$

In addition, let

$$g_0'(t) \ge 0, \quad t \in (-c,T), \tag{3.4}$$

$$g_1(t) \equiv const. = \widetilde{g}, \quad t \in (-c,T). \tag{3.5}$$

Also, assume that there exists a number $\varepsilon \in (0,T)$ such that

$$0 \notin [g_0(\varepsilon), \widetilde{g}] \tag{3.6}$$

and

$$k_1(z) = k_2(z), \quad z \in (g_0(-c), g_0(\varepsilon)). \tag{3.7}$$

Denote $a = g_0(-c), b = \widetilde{g}$. Then the range of both functions u_{1x} and u_{2x} coincides with the interval (a,b) and $k_1(z) = k_2(z)$ for $z \in (a,b)$. Furthermore, it is not necessary to know the boundary condition $f_1(t)$ in (2.3).

Observe that by (2.8), (3.3), and (3.5)

$$g_0(t) \le g_0(T) < \widetilde{g}, t \in [-c,T]. \tag{3.8}$$

Hence, it should be demonstrated in the proof of this theorem that the function $k(z)$ can be uniquely determined for $z \in [g_0(\varepsilon), \widetilde{g}]$. It follows from (3.3) and (3.4) that the range of the function $u_x(x,t)$ is the interval (a,b) indicated in Theorem 1.

Remark.

- As to the boundary condition $f_1(t)$ in (2.3), it is not actually used in the proof. Instead, only the boundary condition $g_1(t)$ is used at $x = L$.

- To explain the condition (3.5), we note that if it is not satisfied, then one should apply the above outlined method (see the introduction) to the domain with curvilinear boundaries $z = g_0(t)$, which is the left boundary, and $z = g_1(t)$, the right boundary. While we actually avoid working with the left boundary assuming (3.7) (see (4.25)–(4.27)), we cannot avoid the right boundary. In the latter case, however, we would need to assume that the function $k(g_1(t))$ is known. So, the condition (3.5) is imposed to avoid the curvilinear right boundary and thus not to use the latter assumption.
- Note that the smoothness condition (3.2) can be guaranteed via imposing certain assumptions on the coefficient $k(z)$, the unknown "initial" condition $u(x,-c)$, and boundary conditions (2.3) (although it is not necessary to actually know the function $u(x,-c)$).
- Conditions (3.3) might also be guaranteed via applying the maximum principle and imposing additional conditions on the functions f_0, f_1, g_0, g_1, but this is outside the scope of this publication.
- Note that (3.1), (3.4)–(3.7) follow sometimes from the physics of the problem; see, e.g., section 5 below.

4. Proof of Theorem 1.

4.1. An integral differential equation. We first obtain an integral differential equation which does not contain the difference $(k_1 - k_2)(z)$. Let $(k(z), u(x,t))$ be one of the pairs $(k_i(z), u_i(x,t))$, $i = 1, 2$. Rewrite (2.1) in the form

$$u_t = [k'(u_x)\, u_x + k(u_x)]\, u_{xx}. \tag{4.1}$$

Denote $v(x,t) = u_x(x,t)$. Differentiating (4.1) with respect to x, we obtain the following equation for the function v:

$$v_t = [k'(v)\, v + k(v)]\, v_{xx} + [k''(v)\, v + 2k'(v)]\, v_x^2, (x,t) \in (0,L) \times (-c,T). \tag{4.2}$$

By (3.1), $k'(v)\, v + k(v) \geq \mathit{const.} > 0$, which implies that (4.1) is of the parabolic type. In addition, (4.1), (2.2), (2.3), (2.8), and (3.5) imply that

$$v(x,0) = r'(x), \tag{4.3}$$

$$v(0,t) = g_0(t), \quad v(L,t) = \widetilde{g} = \mathit{const.}, \tag{4.4}$$

$$v_x(0,t) = \frac{f_0'(t)}{k(g_0(t)) + k'(g_0(t))\, g_0(t)} := s_0(t), \tag{4.5}$$

$$v_x(L,t) = \frac{f_1'(t)}{k(\widetilde{g}) + k'(\widetilde{g})\, \widetilde{g}} := s_1(t).$$

Note that by (2.8), (3.7), and (4.1) the function $s_0(t)$ is the same for both pairs (u_1, k_1) and (u_2, k_2) as long as $t \in (-c, \varepsilon)$. On the other hand, the function $s_1(t)$ would even be unknown if we would assume f_1 to be known, because the numbers $k(\widetilde{g}), k'(\widetilde{g})$ are unknown.

We now "turn" the function $v(x,t)$ into a spatial variable z. To do so, we notice that by (3.3), $v_x(x,t) \geq \alpha = \mathit{const.} > 0$. Hence, we can introduce a new function $w(z,t)$ using the implicit function theorem as

$$v(w(z,t), t) = z. \tag{4.6}$$

By (3.8), $g_0(t) < z < \widetilde{g}$. Hence, the function $w(z,t)$ is defined in the domain D with curvilinear boundaries,

$$D = \{(z,t) : g_0(-c) < g_0(t) < z < \widetilde{g}, t \in (-c,T)\}. \tag{4.7}$$

Using (4.6), express derivatives of the function v via derivatives of the function w,

$$u_{xx}(w(z,t),t) = v_x(w(z,t),t) = \frac{1}{w_z(z,t)}, \tag{4.8}$$

$$v_t(w(z,t),t) = -\frac{w_t(z,t)}{w_z(z,t)},$$

$$v_{xx}(w(z,t),t) = -\frac{w_{zz}(z,t)}{w_z^3(z,t)}.$$

Hence, conditions (4.2)–(4.5) become

$$w_t = \frac{[k'(z)z + k(z)]}{w_z^2} w_{zz} - \frac{k''(z)z + 2k'(z)}{w_z}, \quad (z,t) \in D, \tag{4.9}$$

$$w(z,0) = \widetilde{r}(z), \tag{4.10}$$

$$w(g_0(t),t) = 0, \tag{4.11}$$

$$w_z(g_0(t),t) = \frac{1}{s_0(t)}, \quad t \in (-c,\varepsilon), \tag{4.12}$$

$$w(\widetilde{g},t) = L. \tag{4.13}$$

Here $\widetilde{r}(z)$ is the function inverse to the function $r'(x)$, i.e., $r'(\widetilde{r}(z)) = z$. The interval $t \in (-c,\varepsilon)$ is emphasized in (4.12) because the function $s_0(t)$ is known only on this interval.

Denote $q(z,t) = w_1(z,t) - w_2(z,t), \widetilde{k}(z) = k_1(z) - k_2(z)$, where functions w_1 and w_2 correspond to functions u_1 and u_2, respectively. We need to prove that

$$q(z,t) = 0 \text{ in } D \tag{4.14}$$

and

$$\widetilde{k}(z) = 0 \text{ for } z \in (a,b). \tag{4.15}$$

Using the formula

$$a_1 b_1 - a_2 b_2 = (a_1 - a_2) b_1 + (b_1 - b_2) a_2 \quad \forall a_1, a_2, b_1, b_2 \in \mathbb{R},$$

we obtain from (4.9) the following equation for the function q:

$$\begin{aligned} q_t &= h_1(z,t) q_{zz} + h_2(z,t) q_z \\ &\quad - \left[z\widetilde{k}''(z) + \widetilde{k}'(z) \left(2 - \frac{z}{w_{2z}} w_{2zz} \right) - \frac{\widetilde{k}(z)}{w_{2z}} w_{2zz} \right] \frac{1}{w_{2z}} \quad \text{in } D, \end{aligned} \tag{4.16}$$

where

$$h_1(z,t) = \frac{k_1'(z)z + k_1(z)}{w_{1z}^2(z,t)},$$

$$h_2(z,t) = -\left(k_1'(z)z + k_1(z)\right)\frac{w_{1z}+w_{2z}}{w_{1z}^2 w_{2z}^2} w_{2zz} + \frac{k_1''(z)\,z + 2k_1'(z)}{w_{1z}w_{2z}}.$$

Hence, functions

$$h_1, h_2 \in C^1\left(\overline{D}\right) \tag{4.17}$$

and (see (3.1), (3.3))

$$\beta_1 \le h_1 \le \beta_2, \quad |h_{1z}| + |h_{1t}| \le \beta_3 \quad \text{in } \overline{D}, \tag{4.18}$$

where β_1, β_2, and β_3 are certain positive constants. In addition, conditions (4.10)–(4.13) imply that

$$q(z,0) = 0, \tag{4.19}$$

$$q(g_0(t), t) = 0, \quad t \in (-c, T), \tag{4.20}$$

$$q_z(g_0(t), t) = 0, \quad t \in (-c, \varepsilon), \tag{4.21}$$

$$q(\widetilde{g}, t) = 0. \tag{4.22}$$

By (3.4), $g_0(\varepsilon) \ge g_0(-c)$. Hence, by (3.7),

$$\widetilde{k}(z) = 0 \quad \text{for } z \in (g_0(-c), g_0(\varepsilon)). \tag{4.23}$$

Hence, we obtain from (4.16)

$$q_t = h_1(z,t)\, q_{zz} + h_2(z,t)\, q_z, \quad (z,t) \in \{g_0(t) < z < g_0(\varepsilon), -c < t < \varepsilon\}. \tag{4.24}$$

Hence, (4.20), (4.21), (4.24), and the well-known unique continuation theorem for parabolic equations with lateral Cauchy data (see, e.g., section 2.2.2 in [21] for this theorem) imply that

$$q(z,t) = 0, \quad (z,t) \in \{g_0(t) < z < g_0(\varepsilon), -c < t < \varepsilon\}.$$

Thus, we will now consider (4.16) in the rectangle R,

$$R = \{(z,t) : g_0(\varepsilon) < z < \widetilde{g},\ t \in (-\varepsilon, \varepsilon)\}.$$

Conditions (4.20), (4.21), and (4.23) are replaced with

$$q(g_0(\varepsilon), t) = 0, \quad t \in (-\varepsilon, \varepsilon), \tag{4.25}$$

$$q_z(g_0(\varepsilon), t) = 0, \quad t \in (-\varepsilon, \varepsilon), \tag{4.26}$$

$$\widetilde{k}(g_0(\varepsilon)) = \widetilde{k}'(g_0(\varepsilon)) = 0. \tag{4.27}$$

Since the range of the function $u_x(x,t)$ coincides with the interval (a,b), it is sufficient to derive from (4.16), (4.25)–(4.27) that

$$q(z,t) = 0 \quad \text{in } R \tag{4.28}$$

and

$$\widetilde{k}(z) = 0 \quad \text{for } z \in (g_0(\varepsilon), \widetilde{g}). \tag{4.29}$$

Thus, from now on we will consider (4.16) only in the rectangle R. Note that while two boundary conditions (4.25) and (4.26) are given at the left side of R, only one boundary condition (4.22) is given at its right side.

Since the first term in the right-hand side of the Carleman estimate (4.50) (subsection 4.2) stands with the small factor $1/\lambda$, and the estimate of Lemma 2 (subsection 4.3) also gives this factor, we can apply the Carleman estimate successfully only if a small factor stands at the Volterra t-integrals with the second z-derivative p_{zz}; see (4.43). For this reason we rescale variables as

$$(z, t) \leftrightarrow (\sqrt{\gamma} z^*, \gamma t^*), \tag{4.30}$$

where $\gamma \in (0, 1)$ is a small constant which we will choose later. The rectangle R becomes

$$R' = \left\{ (z^*, t^*) : \frac{g_0(\varepsilon)}{\sqrt{\gamma}} < z^* < \frac{\widetilde{g}}{\sqrt{\gamma}},\ t \in \left(-\frac{\varepsilon}{\gamma}, \frac{\varepsilon}{\gamma} \right) \right\}. \tag{4.31}$$

Then for any function $Y(z, t) \in C^1\left(\overline{R}\right)$

(4.32)

$$|\partial_{z^*} Y(\sqrt{\gamma} z^*, \gamma t^*)| \le \sqrt{\gamma} \|\partial_z Y(z, t)\|_{C(\overline{R})}, \quad |\partial_{t^*} Y(\sqrt{\gamma} z^*, \gamma t^*)| \le \gamma \|\partial_t Y(z, t)\|_{C(\overline{R})}.$$

Since we need to work carefully with the new variables, we do not keep the same notations as for the old variables for them. Also, because of (3.2) and (3.6), there exists a positive constant b such that either $g_0(\varepsilon) < \widetilde{g} \le -b$ or $b \le g_0(\varepsilon) < \widetilde{g}$. Hence, we will assume without loss of generality that $1 \le g_0(\varepsilon) < \widetilde{g}$. Therefore, by (4.32),

$$1 \le \sqrt{\gamma} z^* \le \widetilde{g} \quad \text{in } R'. \tag{4.33}$$

Denote $\widehat{k}(z^*) := \widetilde{k}(\sqrt{\gamma} z^*)$, $s(z^*, t^*) := q(\sqrt{\gamma} z^*, \gamma t^*)$, $\widehat{w}(z^*, t^*) := w(\sqrt{\gamma} z^*, \gamma t^*)$, and $\widehat{h}_i(z^*, t^*) := h_i(\sqrt{\gamma} z^*, \gamma t^*)$, $i = 1, 2$. Below, derivatives of $\widehat{k}(z^*)$ are understood as derivatives with respect to z^*.

Equation (4.16) now becomes

(4.34)

$$\begin{aligned}
& s_{t^*}(z^*, t^*) \\
& = \left\{ \widehat{h}_1 s_{z^* z^*} + \sqrt{\gamma} \widehat{h}_2 s_{z^*} \right\} (z^*, t^*) \\
& \quad - \left[(\sqrt{\gamma} z^*) \widehat{k}''(z^*) + \widehat{k}'(z^*) \left(2\sqrt{\gamma} - \frac{\sqrt{\gamma} z^*}{\widehat{w}_{2z^*}(z^*, t^*)} \widehat{w}_{2z^* z^*}(z^*, t^*) \right) \right. \\
& \qquad \left. - \frac{\sqrt{\gamma} \widehat{k}(z^*)}{\widehat{w}_{2z^*}(z^*, t^*)} \widehat{w}_{2z^* z^*}(z^*, t^*) \right] \frac{1}{w_{2z}\left(\sqrt{\gamma} z^*, \gamma t^*\right)}
\end{aligned}$$

in R'.

Note that it is convenient to keep the z-derivative instead of the z^*-derivative in the multiplier $1/w_{2z}$ in (4.34). Our next goal is to obtain an ODE for the function $\widehat{k}(z^*)$ and solve it via Volterra-like integrals. Resolving (4.34) with respect to $\widehat{k}''(z^*)$, we obtain

$$\widehat{k}''(z^*) = -w_{2z}(\sqrt{\gamma}z^*, \gamma t^*)\left[s_{t^*} - \widehat{h}_1 s_{z^*z^*} - \sqrt{\gamma}\widehat{h}_2 s_{z^*}\right](z^*, t^*) \cdot \frac{1}{\sqrt{\gamma}z^*}$$

$$+ d_1(z^*, t^*)\widehat{k}'(z^*) + d_2(z^*, t^*)\widehat{k}(z^*). \tag{4.35}$$

Using (4.33), we obtain that $0 < \widetilde{g}^{-1} \leq (\sqrt{\gamma}z^*)^{-1} \leq 1$ and functions $d_1,\, d_2 \in C^1(\overline{R}')$. By (4.27),

$$\widehat{k}(z^*) = \int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*} \widehat{k}'(y)\, dy.$$

Hence, using again (4.27), we obtain from (4.35)

$$\widehat{k}'(z^*) = \int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*} d_1(y, t^*)\, \widehat{k}'(y) dy + \int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*} d_2(y, t^*)\, d\tau \int_{g_0(\varepsilon)/\sqrt{\gamma}}^{\tau} \widehat{k}'(y) dy_1$$

$$+ \int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*} w_{2z}(\sqrt{\gamma}y, \gamma t^*)\left[s_{t^*} - \widehat{h}_1 s_{z^*z^*} - \sqrt{\gamma}\widehat{h}_2 s_{z^*}\right](y, t^*)\, \frac{1}{\sqrt{\gamma}y} dy.$$

Considering this as a Volterra integral equation with respect to $\widehat{k}'(z^*)$ and solving it via successive approximations, we obtain

$$\widehat{k}'(z^*) = \int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*} w_{2z}(\sqrt{\gamma}y, \gamma t^*)\left[s_{t^*} - \widehat{h}_1 s_{z^*z^*} - \sqrt{\gamma}\widehat{h}_2 s_{z^*}\right](y, t^*) \frac{1}{\sqrt{\gamma}y} dy$$

$$+ \int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*} G(z^*, y, t^*)\, w_{2z}(\sqrt{\gamma}y, \gamma t^*)\left[s_{t^*} - \widehat{h}_1 s_{z^*z^*} - \sqrt{\gamma}\widehat{h}_2 s_{z^*}\right](y, t^*) dy, \tag{4.36}$$

where the functions $G, G_{z^*}, G_{t^*}, G_{t^*z^*} \in C(\overline{R}')$ and

$$G(z^*, z^*, t^*) = G_{t^*}(z^*, z^*, t^*) = 0. \tag{4.37}$$

Denote $p(z^*, t^*) = s_{t^*}(z^*, t^*)$. Then (4.19) leads to

$$s(z^*, t^*) = \int_0^{t^*} p(z^*, \tau)\, d\tau. \tag{4.38}$$

Denote

$$N(z^*, t^*) = w_{2z}(\sqrt{\gamma}z^*, \gamma t^*). \tag{4.39}$$

Above and below, the function $w_{2z}\left(\sqrt{\gamma}z^*, \gamma t^*\right)$ is understood as follows: First we calculate the derivative $\partial_z w_2(z, t)$. Next we substitute in this derivative $z = \sqrt{\gamma}z^*, t = \gamma t^*$. Hence, by (3.2), (4.3), and (4.8),

$$\frac{1}{\beta} \leq N(z^*, t^*) \leq \frac{1}{\alpha} \tag{4.40}$$

and by (4.32) and (4.39),

$$N_{t^*}\left(z^*,t^*\right)\le\frac{\gamma}{\alpha}, \tag{4.41}$$

where the positive constant β is independent of γ (and so is α, of course; see (3.3)).

Differentiate (4.36) with respect to t^*. Since $\partial_t\widehat{k}'(z^*)\equiv 0$, we obtain using (4.38)

$$\begin{aligned}
&\int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*}\left\{N\left[p_{t^*}-\widehat{h}_1p_{z^*z^*}-\sqrt{\gamma}\widehat{h}_2p_{z^*}\right]\right\}(y,t^*)\,\frac{dy}{\sqrt{\gamma}y}+\int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*}\left(N_{t^*}p\right)(y,t^*)\,\frac{dy}{\sqrt{\gamma}y}\\
&-\int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*}\left[\left(N\widehat{h}_1\right)_{t^*}(y,t^*)\int_0^{t^*}p_{z^*z^*}\left(y,\tau\right)d\tau\right]\frac{dy}{\sqrt{\gamma}y}\\
&-\int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*}\left[\sqrt{\gamma}\left(N\widehat{h}_2\right)_{t^*}(y,t^*)\int_0^{t^*}p_{z^*}\left(y,\tau\right)d\tau\right]\frac{dy}{\sqrt{\gamma}y}\\
&+\int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*}G\left(z^*,y,t^*\right)\left\{N\left[p_{t^*}-\widehat{h}_1p_{z^*z^*}-\sqrt{\gamma}\widehat{h}_2p_{z^*}\right]\right\}(y,t^*)\,dy\\
&+\int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*}G_{t^*}\left(z^*,y,t^*\right)\Bigg\{N\left(y,t^*\right)\Bigg[p\left(y,t^*\right)-\widehat{h}_1\left(y,t^*\right)\int_0^{t^*}p_{z^*z^*}\left(y,\tau\right)d\tau\\
&\qquad\qquad-\sqrt{\gamma}\widehat{h}_2\left(y,t^*\right)\int_0^{t^*}p_{z^*}\left(y,\tau\right)d\tau\Bigg]\Bigg\}\,dy\\
&+\int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*}G\left(z^*,y,t^*\right)\left(N_{t^*}p\right)(y,t^*)\,dy\\
&-\int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*}G\left(z^*,y,t^*\right)\left[\left(N\widehat{h}_1\right)_{t^*}(y,t^*)\int_0^{t^*}p_{z^*z^*}\left(y,\tau\right)d\tau\right]dy\\
&-\int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*}G\left(z^*,y,t^*\right)\left[\sqrt{\gamma}\left(N\widehat{h}_2\right)_{t^*}(y,t^*)\int_0^{t^*}p_{z^*}\left(y,\tau\right)d\tau\right]dy\;=\;0.
\end{aligned}$$

Differentiate this equality with respect to z^* and use (4.37). We obtain

$$
\begin{aligned}
&\left\{N\left[p_{t^*}-\widehat{h}_1 p_{z^*z^*}-\sqrt{\gamma}\widehat{h}_2 p_{z*}\right]\right\}(z^*,t^*)+\left(N_{t^*}p\right)(z^*,t^*)\\
&-\left(N\widehat{h}_1\right)_{t^*}(z^*,t^*)\int_0^{t^*}p_{z^*z^*}(z^*,\tau)\,d\tau-\sqrt{\gamma}\left(N\widehat{h}_2\right)_{t^*}(z^*,t^*)\int_0^{t*}p_{z^*}(z^*,\tau)\,d\tau\\
&+\sqrt{\gamma}z^*\int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*}G_{z^*t^*}(z^*,y,t^*)\left\{N(y,t^*)\left[p(y,t^*)-\widehat{h}_1(y,t^*)\int_0^{t^*}p_{z^*z^*}(y,\tau)\,d\tau\right.\right.\\
&\qquad\qquad\left.\left.-\sqrt{\gamma}\widehat{h}_2(y,t^*)\int_0^{t^*}p_{z^*}(y,\tau)\,d\tau\right]\right\}dy\\
&+\sqrt{\gamma}z^*\int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*}G_{z^*}(z^*,y,t^*)\left(N_{t^*}p\right)(y,t^*)\,dy\\
&-\sqrt{\gamma}z^*\int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*}G_{z^*}(z^*,y,t^*)\left[\left(N\widehat{h}_1\right)_{t^*}(y,t^*)\int_0^{t^*}p_{z^*z^*}(y,\tau)\,d\tau\right]dy\\
&-\sqrt{\gamma}z^*\int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*}G_{z^*}(z^*,y,t^*)\left[\sqrt{\gamma}\left(N\widehat{h}_2\right)_{t^*}(y,t^*)\int_0^{t^*}p_{z^*}(y,\tau)\,d\tau\right]dy\;=\;0.
\end{aligned}
\tag{4.42}
$$

Here and below, M denotes different positive constants independent of both γ and the function p. Note that by (4.32), (4.33), the right inequality in (4.40), and (4.41),

$$\left\|\left(N\widehat{h}_1\right)_{t^*}\right\|_{C\left(\overline{R}'\right)}+\left\|\left(N\widehat{h}_2\right)_{t^*}\right\|_{C\left(\overline{R}'\right)}+\left\|N_{t^*}\right\|_{C\left(\overline{R}'\right)}\le M\gamma$$

and

$$\left\|G_{z^*t^*}\right\|_{C\left(\overline{R}''\right)}+\left\|G_{t^*}\right\|_{C\left(\overline{R}''\right)}\le M\gamma,$$

where

$$R''=\left\{\frac{g_0(\varepsilon)}{\sqrt{\gamma}}<z^*<\frac{\widetilde{g}}{\sqrt{\gamma}}\right\}\times R'.$$

Hence, dividing both sides of (4.42) by N and using the left inequality in (4.40), we obtain an integral differential equation, from which the integral differential inequality (4.43) follows immediately, where

$$
\begin{aligned}
&\left|p_{t^*}-\widehat{h}_1 p_{z^*z^*}\right|(z^*,t^*)\\
&\le M\left[|p|+|p_{z^*}|\right](z^*,t^*)+M\gamma sgn(t^*)\int_0^{t^*}\left|p_{z^*z^*}(z^*,\tau)\right|d\tau\\
&\quad+M\gamma sgn(t^*)\int_0^{t^*}\left|p_{z^*}(z^*,\tau)\right|d\tau+M\int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*}\left|p(y,t^*)\right|dy\\
&\quad+M\gamma sgn(t^*)\int_{g_0(\varepsilon)/\sqrt{\gamma}}^{z^*}\int_0^{t^*}\left[|p_{z^*z^*}|+|p_{z^*}|\right](y,\tau)\,d\tau dy\quad\text{ in } R',
\end{aligned}
\tag{4.43}
$$

where

$$sgn(t^*) = \left\{ \begin{array}{c} 1 \text{ if } t^* > 0 \\ -1 \text{ if } t^* < 0 \end{array} \right\}.$$

Hence,

$$sgn(t^*) \int_0^{t^*} |.| \, d\tau = \left| \int_0^{t^*} |.| \, d\tau \right|.$$

Remark. Since we have now singled out the small factor γ, starting from (4.44), below we use old notations for the variables $(z^*, t^*) := (z, t)$ for brevity, keeping in mind, however, that we have not actually returned to old variables.

Since $p = s_{t^*}$, (4.25) and (4.26) imply zero Cauchy data at $\{z = \frac{g_0(\varepsilon)}{\sqrt{\gamma}}\}$,

$$p\left(\frac{g_0\left(\varepsilon\right)}{\sqrt{\gamma}}, t\right) = p_z\left(\frac{g_0\left(\varepsilon\right)}{\sqrt{\gamma}}, t\right) = 0, \quad t \in \left(-\frac{\varepsilon}{\gamma}, \frac{\varepsilon}{\gamma}\right). \tag{4.44}$$

It is well known that when applying Carleman estimates, it is often more convenient to work with inequalities rather than with equations; see, e.g., [21]. The goal of the next three subsections is to prove that (4.43) and (4.44) imply that $p(z,t) = 0$ in R', which in turn obviously implies (4.28) and (4.29).

4.2. Carleman estimate. Let $\xi = const. \in (0,1)$. Introduce the function $\psi(z,t)$ by

$$\psi\left(z,t\right) = \left(z - \frac{g_0\left(\varepsilon\right)}{\sqrt{\gamma}}\right) + t^2 + \xi.$$

Choose an arbitrary constant $\delta > 0$ such that

$$\delta < \min\left[1, \frac{\widetilde{g} - g_0\left(\varepsilon\right)}{\sqrt{\gamma}}, \left(\frac{\varepsilon}{\gamma}\right)^2\right].$$

Denote

$$K_\delta = \left\{(z,t) : \psi\left(z,t\right) < \xi + \delta, z > \frac{g_0\left(\varepsilon\right)}{\sqrt{\gamma}}\right\}.$$

Hence, the boundary ∂K_δ of the domain K_δ is

$$\partial K_\delta = \partial_1 K_\delta \cup \partial_2 K_\delta, \tag{4.45}$$

where

$$\partial_1 K_\delta = \left\{(z,t) : z = \frac{g_0\left(\varepsilon\right)}{\sqrt{\gamma}}, t^2 < \delta\right\}, \tag{4.46}$$

$$\partial_2 K_\delta = \left\{(z,t) : \left(z - \frac{g_0\left(\varepsilon\right)}{\sqrt{\gamma}}\right) + t^2 + \xi = \xi + \delta, z > 0\right\}. \tag{4.47}$$

Hence, by (4.44) and (4.46),

$$p \mid_{\partial_1 K_\delta} = p_z \mid_{\partial_1 K_\delta} = 0. \tag{4.48}$$

By (4.31), $K_\delta \subset R'$. Clearly $K_{\delta'} \subset K_\delta$ for all $\delta' \in (0,\delta)$.

Let $\lambda, \nu > 1$ be two large parameters which we will choose later. Introduce the CWF $\varphi(z,t)$ by

$$\varphi(z,t) = \exp\left(\lambda \psi^{-\nu}\right). \tag{4.49}$$

Lemma 1 (Carleman estimate; see, e.g., section 2.2 in [21] and section 1 of Chapter 4 in [22]). *There exist a sufficiently large number $\nu = \nu_0 = \nu_0(\xi,\delta,\beta_1,\beta_2,\beta_3)$ (see (4.18) for β_1,β_2,β_3) and a positive constant $C = C(\xi,\delta,\beta_1,\beta_2,\beta_3)$, both ν_0 and C independent of the number γ, such that for all values of the parameter $\lambda > 1$ and all functions $u \in C^{2,1}\left(\overline{K}_\delta\right)$ the following pointwise Carleman estimate holds in K_δ:*

$$(u_t - h_1 u_{zz})^2 \varphi^2 \geq \frac{C}{\lambda}\left(u_t^2 + u_{zz}^2\right)\varphi^2 + C\lambda u_z^2 \varphi^2 + C\lambda^3 u^2 \varphi^2 + U_z + V_t, \tag{4.50}$$

where functions U and V satisfy

$$|U| + |V| \leq C\lambda\left[u_t^2 + u_z^2 + \lambda^2 u^2\right]\varphi^2. \tag{4.51}$$

Below, C denotes different positive constants dependent on numbers $\xi,\delta,\beta_1,\beta_2,\beta_3$ but independent of the number γ.

4.3. Estimates of integrals. While (4.50) provides an estimate of the left-hand side of the inequality (4.43) from below, we also need to estimate its right-hand side from above in the presence of the CWF φ. It is not a problem to estimate $M^2\left[|p| + |p_z|\right]\varphi^2$. However, the presence of Volterra-like integrals in (4.43) presents a difficulty. In the above cited previous works [4], [5], [6], [7], [8], [9], [10], [11], [12], [18], [19], [20], [21], [22], [23], [24] only integrals with respect to time t,

$$\int_0^t (.)\, d\tau,$$

were estimated (Lemma 2). A new element of this publication is Lemmata 3 and 4, which are concerned with estimates of integrals

$$\int_{g_0(\varepsilon)}^z (.)\, dy, \quad \int_{g_0(\varepsilon)}^z \int_0^t (.)\, d\tau dy.$$

The z-integration occurs because of the involvement of both the function $\widetilde{k}$ and its derivatives $\widetilde{k}', \widetilde{k}''$ in (4.16), which was not the case in the past.

Lemma 2 (see [21, p. 77]). *The following estimate holds for all real valued functions $f \in L_2(K_\delta)$:*

$$\int_{K_\delta}\left(\int_0^t f(z,\tau)\, d\tau\right)^2 \varphi^2 dz dt \leq \frac{C}{\lambda}\int_{K_\delta} f^2(z,t)\,\varphi^2 dz dt \quad \forall \lambda > 1.$$

We now prove the following lemma.

Lemma 3. *The following estimate holds for all real valued functions $f \in L_2(K_\delta)$:*

$$\int_{K_\delta}\left(\int_{g_0(\varepsilon)}^z f(y,t)\, dy\right)^2 \varphi^2 dz dt \leq \frac{C}{\lambda^2}\int_{K_\delta} f^2(z,t)\,\varphi^2 dz dt \quad \forall \lambda > 1.$$

Proof.

$$\int_{K_\delta}\left(\int_{g_0(\varepsilon)}^{z} f(y,t)\,dy\right)^2\varphi^2 dzdt=\int_{-\sqrt{\delta}}^{\sqrt{\delta}}dt\int_0^{\delta-t^2}\left(\int_{g_0(\varepsilon)}^{z} f(y,t)\,dy\right)^2\varphi^2 dz. \tag{4.52}$$

We have by (4.49)

$$\begin{aligned}
&\int_0^{\delta-t^2}\left(\int_{g_0(\varepsilon)}^{z} f(y,t)\,dy\right)^2\varphi^2 dz\\
&\quad=\int_0^{\delta-t^2}\left(\int_{g_0(\varepsilon)}^{z} f(y,t)\,dy\right)^2\exp\left[2\lambda\left(z+t^2+\xi\right)^{-\nu}\right]dz\\
&\quad=\frac{1}{2\lambda\nu}\int_0^{\delta-t^2}\left(\int_{g_0(\varepsilon)}^{z} f(y,t)\,dy\right)^2\psi^{\nu+1}\frac{d}{dz}\left[-\exp\left(2\lambda\psi^{-\nu}\right)\right]dz\\
&\quad\le\frac{(\xi+\delta)^{\nu+1}}{2\lambda\nu}\int_0^{\delta-t^2}\left(\int_{g_0(\varepsilon)}^{z} f(y,t)\,dy\right)^2\frac{d}{dz}\left[-\exp\left(2\lambda\psi^{-\nu}\right)\right]dz\\
&\quad\le\frac{C}{\lambda}\Bigg\{-\exp\left(2\lambda\left(\xi+\delta\right)^{-\nu}\right)\left(\int_0^{\delta-t^2} f(y,t)\,dy\right)^2\\
&\qquad\qquad+2\int_0^{\delta-t^2}\varphi^2 f(z,t)\int_{g_0(\varepsilon)}^{z} f(y,t)\,dydz\Bigg\}\\
&\quad\le\frac{C}{\lambda}\int_0^{\delta-t^2}\varphi^2 f(z,t)\int_{g_0(\varepsilon)}^{z} f(y,t)\,dydz.
\end{aligned}$$

Hence, we have obtained that

$$\int_0^{\delta-t^2}\left(\int_{g_0(\varepsilon)}^{z} f(y,t)\,dy\right)^2\varphi^2 dz\le\frac{C}{\lambda}\int_0^{\delta-t^2}\varphi^2 f(z,t)\int_{g_0(\varepsilon)}^{z} f(y,t)\,dydz. \tag{4.53}$$

By the Cauchy–Schwarz inequality

$$\begin{aligned}
&\frac{C}{\lambda}\int_0^{\delta-t^2}\varphi^2 f(z,t)\int_{g_0(\varepsilon)}^{z} f(y,t)\,dydz\\
&\le\frac{C}{\lambda}\left[\int_0^{\delta-t^2} f^2(z,t)\,\varphi^2 dz\right]^{1/2}\left[\int_0^{\delta-t^2}\left(\int_{g_0(\varepsilon)}^{z} f(y,t)\,dy\right)^2\varphi^2 dz\right]^{1/2}.
\end{aligned}$$

Substituting the latter into (4.53), we obtain

$$\left[\int_0^{\delta-t^2}\left(\int_{g_0(\varepsilon)}^{z} f(y,t)\,dy\right)^2\varphi^2 dz\right]^{1/2}\le\frac{C}{\lambda}\left[\int_0^{\delta-t^2} f^2(z,t)\,\varphi^2 dz\right]^{1/2}.$$

Squaring both sides of this inequality, we obtain the target estimate of this lemma. $\square$

LEMMA 4. *The following estimate holds for all real valued functions $f \in L_2(K_\delta)$:*

$$\int_{K_\delta}\left(\int_{g_0(\varepsilon)}^{z}\int_0^t f(y,t)\,d\tau dy\right)^2\varphi^2 dzdt \le \frac{C}{\lambda^3}\int_{K_\delta} f^2(z,t)\,\varphi^2 dzdt \quad \forall\lambda>1.$$

Proof. Denote

$$F(y,t)=\int_0^t f(y,t)\,d\tau.$$

Applying sequentially Lemmata 3 and 2, we obtain

$$\begin{aligned}&\int_{K_\delta}\left(\int_{g_0(\varepsilon)}^{z}\int_0^t f(y,t)\,d\tau dy\right)^2\varphi^2 dzdt\\ &=\int_{K_\delta}\left(\int_{g_0(\varepsilon)}^{z}F(y,t)dy\right)^2\varphi^2 dzdt \;\le\; \frac{C}{\lambda^2}\int_{K_\delta}F^2(z,t)\,\varphi^2 dzdt\\ &\le\frac{C}{\lambda^3}\int_{K_\delta} f^2(z,t)\,\varphi^2 dzdt. \qquad\square\end{aligned}$$

4.4. Finishing the proof of Theorem 1. Square both sides of the inequality (4.43), multiply by the function φ^2, integrate over the domain K_δ, and apply (4.50) and (4.51) to the left-hand side using Gauss's formula and (4.45)–(4.48). Also, apply Lemmata 2–4 to the right-hand side. We obtain

$$\begin{aligned}&\frac{C}{\lambda}\int_{K_\delta}\left(p_t^2+p_{zz}^2\right)\varphi^2 dzdt + C\lambda\int_{K_\delta}\left(p_z^2+\lambda^2p^2\right)\varphi^2 dzdt\\ &\le M\frac{\gamma^2}{\lambda}\int_{K_\delta}p_{zz}^2\varphi^2 dzdt+\frac{M}{\lambda^3}\int_{K_\delta}p_{zz}^2\varphi^2 dzdt+M\int_{K_\delta}\left(p_z^2+p^2\right)\varphi^2 dzdt\\ &\quad + C\lambda\exp\left[2\lambda\left(\xi+\delta\right)^{-\nu}\right]\int_{\partial_2K_\delta}\left(p_t^2+p_z^2+\lambda^2p^2\right)dS \quad \forall\lambda>1.\end{aligned}$$

Since constants C and M are independent of γ, we choose γ so small that $M\gamma^2<C/4$. Next, we choose $\lambda_0>1$ so large that $M/\lambda_0^2<C/4$ and $M<C\lambda_0/2$. Then we obtain with a new constant C

$$\begin{aligned}&\frac{1}{\lambda}\int_{K_\delta}\left(p_t^2+p_{zz}^2\right)\varphi^2 dzdt+\lambda\int_{K_\delta}\left(p_z^2+\lambda^2p^2\right)\varphi^2 dzdt\\ &\le C\lambda\exp\left[2\lambda\left(\xi+\delta\right)^{-\nu}\right]\int_{\partial_2K_\delta}\left(p_t^2+p_z^2+\lambda^2p^2\right)dS \quad \forall\lambda\ge\lambda_0.\end{aligned}\tag{4.54}$$

Consider a number $\delta'\in(0,\delta)$. Since $\varphi^2\ge\exp[2\lambda(\xi+\delta')^{-\nu}]$ in $K_{\delta'}$ and $K_{\delta'}\subset K_\delta$, we obtain from (4.54)

$$\begin{aligned}&\exp\left[2\lambda\left(\xi+\delta'\right)^{-\nu}\right]\int_{K_{\delta'}}p^2dzdt\\ &\le\frac{C}{\lambda^2}\exp\left[2\lambda\left(\xi+\delta\right)^{-\nu}\right]\int_{\partial_2K_\delta}\left(p_t^2+p_z^2+\lambda^2p^2\right)dS \quad \forall\lambda\ge\lambda_0.\end{aligned}$$

Dividing this inequality by $\exp[2\lambda(\xi+\delta')^{-\nu}]$, we obtain

$$\begin{aligned}&\int_{K_{\delta'}} p^2 dzdt\\ &\le \frac{C}{\lambda^2}\exp\left\{-2\lambda\left[(\xi+\delta')^{-\nu}-(\xi+\delta)^{-\nu}\right]\right\}\int_{\partial_2 K_\delta}\left(p_t^2+p_z^2+\lambda^2p^2\right)dS \quad \forall\lambda\ge\lambda_0.\end{aligned}$$

Note that $(\xi+\delta')^{-\nu}-(\xi+\delta)^{-\nu}>0$. Hence, letting $\lambda\to\infty$, we obtain

$$\int_{K_{\delta'}} p^2 dzdt = 0.$$

Hence, $p=0$ in $K_{\delta'}$. Since δ' is an arbitrary number from the interval $(0,\delta)$, $p=0$ in K_δ. By (4.38), the function $q=0$ in K_δ. Hence, (4.16) together with (4.27) implies that

$$\widetilde{k}(z)=0 \quad \text{ for } z\in\left(\frac{g_0\left(\varepsilon\right)}{\sqrt{\gamma}},\frac{g_0\left(\varepsilon\right)}{\sqrt{\gamma}}+\delta\right).$$

Dropping $\widetilde{k}(z)$ in (4.16) for $z\in(\frac{g_0(\varepsilon)}{\sqrt{\gamma}},\frac{g_0(\varepsilon)}{\sqrt{\gamma}}+\delta)$, we obtain a parabolic equation

$$q_t-h_1\left(z,t\right)q_{zz}-h_2\left(z,t\right)q_z=0, \quad (z,t)\in\left(\frac{g_0\left(\varepsilon\right)}{\sqrt{\gamma}},\frac{g_0\left(\varepsilon\right)}{\sqrt{\gamma}}+\delta\right)\times\left(-\frac{\varepsilon}{\gamma},\frac{\varepsilon}{\gamma}\right)$$

with the Cauchy data at $\{z=\frac{g_0(\varepsilon)}{\sqrt{\gamma}}\}$,

$$q\left(\frac{g_0\left(\varepsilon\right)}{\sqrt{\gamma}},t\right)=q_z\left(\frac{g_0\left(\varepsilon\right)}{\sqrt{\gamma}},t\right)=0, \quad t\in\left(-\frac{\varepsilon}{\gamma},\frac{\varepsilon}{\gamma}\right).$$

Hence, the above-mentioned unique continuation theorem implies that $q(z,t)=0$ for $(z,t)\in(\frac{g_0(\varepsilon)}{\sqrt{\gamma}},\frac{g_0(\varepsilon)}{\sqrt{\gamma}}+\delta)\times(-\frac{\varepsilon}{\gamma},\frac{\varepsilon}{\gamma})$. Therefore, we can now "shift" the left boundary $\{z=\frac{g_0(\varepsilon)}{\sqrt{\gamma}}\}$ of the rectangle R' to the right by δ via replacing R' with the rectangle

$$R'_\delta=\left(\frac{g_0\left(\varepsilon\right)}{\sqrt{\gamma}}+\delta,\frac{g_0\left(\varepsilon\right)}{\sqrt{\gamma}}+2\delta\right)\times\left(-\frac{\varepsilon}{\gamma},\frac{\varepsilon}{\gamma}\right).$$

Next, we can repeat the above process. This way we arrive at target equalities (4.28) and (4.29).

5. Application examples.

5.1. A diffusion model in population dynamics. In this section we discuss the assumptions of Theorem 1 for an example from population dynamics, given in the form (2.4): Aronson in [1] proposes the diffusion model

$$v_t=(\phi(v)v)_{xx} \tag{5.1}$$

in the absence of drift, where $v(x,t)$ is the population density at location x and time t and the diffusion coefficient $\phi(v)$ is the population density dependent limit (as the minimal individual step length tends to zero) of the second moment of the transition probability between different locations. The function ϕ plays the role of k in the setting of Theorem 1. With $u(x,t) = \int_0^x v(\xi,t)\,d\xi + f_0(t)$ and an integration with respect to the space variable this can be rewritten as

$$u_t - (\phi(u_x)u_x)_x = c, \tag{5.2}$$

with c depending on time only, which without loss of generality we can set to zero (as an inspection of the proof of Theorem 1 shows), which yields

$$u_t = (\phi(u_x)u_x)_x \tag{5.3}$$

so that with $k = \phi$ we get the PDE considered in Theorem 1. The boundary and initial data as well as the conditions imposed on them have the following interpretation in the context of this example:

- Conditions (2.7), (3.1) are natural assumptions according to [1]. Condition (3.6) can be guaranteed by imposing nonvanishing population densities at the boundary, which seems to be natural as well.
- $u(x,0) = r(x)$; i.e., $v(x,0) = r'(x)$ means that the population density is known everywhere at time $t = 0$, e.g., from a census at that instance of time.
- $u(0,t) = f_0(t)$ is satisfied by our setting of the integration constants.
- $u_x(0,t) = v(0,t) = g_0(t)$ with $g' \geq 0$: The population density at location $x = 0$ is observed for all time instances and increases with time.
- $u_x(L,t) = v(L,t) = g_1(t) = \tilde{g}$ and $[g_0(\varepsilon), \tilde{g}]$ is the interval on which k can be identified according to Theorem 1: The population density at location $x = L$ is observed for all time instances and is constant in time, where this constant should be as large as possible, e.g., equal to some saturation value.
- $u_{xx} = v_x \geq \alpha > 0$: The population density increases from left to right.

5.2. Nonlinear magnetics. Quasi-static magnetic fields can be described by a subset of Maxwell's equations, more precisely, Ampère's law in the quasi-static case

$$\nabla \times \mathbf{H} = \mathbf{J}$$

and Faraday's law

$$\nabla \times \mathbf{E} = -\mathbf{B}_t\,,$$

combined with the constitutive relations

$$\mathbf{J} = \gamma \mathbf{E} + \mathbf{J}^{imp}\,, \quad \mathbf{H} = \nu \mathbf{B},$$

where $\mathbf{H}$ is the magnetic field intensity, $\mathbf{B}$ the magnetic flux density, $\mathbf{E}$ the electric field, γ the electric conductivity, ν the magnetic reluctivity (i.e., the reciprocal of the magnetic permeability μ), and J_{imp} the impressed current density; see, e.g., [6], [10], [16]. Using the fact that $\mathbf{B}$ is solenoidal,

$$\nabla \cdot \mathbf{B} = 0\,,$$

we can make use of a magnetic vector potential $\mathbf{A}$ satisfying

$$\mathbf{B} = \nabla \times \mathbf{A}\,,$$

which leads to the system of PDEs

$$\gamma \mathbf{A}_t + \nabla \times (\nu \nabla \times \mathbf{A}) = J_{imp} \tag{5.4}$$

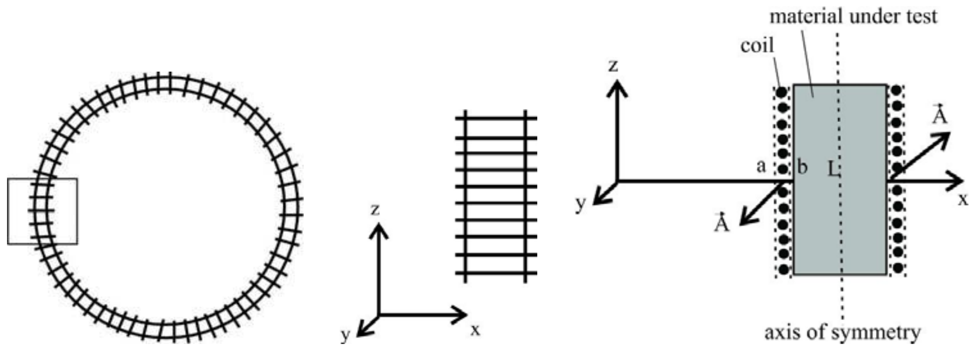

FIG. 5.1. *Schematic of probe with coil (left), quasi-straight detail (middle), and cut along x-z plane (right).*

for the vector field $\mathbf{A}$. In the situation of high magnetic fields, the parameter ν is not constant but depends on the magnetic flux density, i.e.,

$$\mathbf{H} = \nu(\mathbf{B})\mathbf{B}\,. \tag{5.5}$$

By an appropriate experimental setup, this can be reduced to the spatially one-dimensional case: Consider a ring-shaped probe entwined with an excitation/measurement coil according to Figure 5.1 (left) with a large interior radius so that the curvature can be neglected (see Figure 5.1 (middle)), and the magnetic flux density points into the z direction but does not vary in the z direction. Moreover, we consider a cut along the x-z plane (see Figure 5.1 (right)), in which $\mathbf{A}$ must be parallel to the y axis and dependence of $\mathbf{A}$, $\mathbf{B}$ on y can be neglected, so that altogether

$$\mathbf{B}(x, y, z) = (0, 0, B^z(x))^T,$$

or equivalently

$$\mathbf{A}(x, y, z) = (0, A^y(x), 0)^T.$$

With $u(x) := A^y(x)$ the system (5.4) becomes the spatially one-dimensional model problem

$$\gamma u_t - (\nu(u_x)u_x)_x = 0 \quad \text{in } (b, L) \times (0, T);$$

i.e., with $k = \frac{1}{\gamma}\nu$ we arrive at the PDE considered in Theorem 1. An interpretation of the conditions of Theorem 1 in the context of this example can be made as follows:

- Conditions (2.7), (3.1) are natural conditions on the coefficient also in the context of magnetics, unless very special materials are considered. Also, the assumption of knowledge of the coefficient on a short interval $(g_0(-c), g_0(\varepsilon))$ according to (3.7) is not restrictive: Note that to resolve the full range of the B-H curve, one will typically choose g_0 small and $\widetilde{g}$ large, i.e., close to the saturation value. Hence (3.7) means that the coefficient is known for small magnetic fields, which is actually the case, since for moderate amplitudes of the fields, ν is a constant that is either known or can be determined from simpler measurements. It therefore also makes sense to exclude zero magnetic flux density from the range of measurements according to (3.6).

- Neumann boundary data $u_x(0,t) = g_0(t)$, $u_x(L,t) = g_1(t)$ here have the meaning of a magnetic flux density, which can be extracted from measurements of the magnetic flux through two coils positioned on both sides of the material strip. The magnetic flux can be controlled via the impressed current through these coils such that it is monotonically nondecreasing (and small) at the left endpoint as well as constant (and large) at the right endpoint to achieve $g_0' \geq 0$, $g_1' = 0$, and a wide interval (a, b).
- Via the relation $\mathbf{u}_t = \mathbf{E}$ with $\mathbf{E}$ the electric field, one can obtain the initial and boundary data of u by time integration of electric field measurements.

The conventional measurement setup for determining ν consists of just an excitation (and measurement) coil wound around the probe and does not enable us to collect all the data required from the point of view of our uniqueness theorem (especially not electric field measurements inside the probe which would be required for giving initial data for u). In this sense, there is a gap between theory and practice. Still, the model problem considered in this paper gives important insight, since the correct form of the PDE with a coefficient depending on the space derivative of u is considered. For more details on a PDE-based approach for nonlinearity identification in magnetics, we refer the reader to [17].

6. Numerical results. In this section, we briefly outline a numerical method for determining the coefficient k in (2.1) and provide some computational results.

A method for forward magnetic field computations in the nonlinear case that has recently attracted considerable interest is the so-called harmonic balancing finite element method (cf., e.g., [2], [9], [25]). It is based on the idea of making a multiharmonic ansatz in time to capture the higher harmonics physically arising due to nonlinearity. Mathematically speaking, one makes use of a special time discretization based on trigonometric polynomials; i.e., in a complex valued setting, time harmonic functions $t \mapsto \exp(\imath nt)$, where $\imath = \sqrt{-1}$. An idea for using this approach in parameter identification was presented in [15] for a hyperbolic PDE. Here we will derive such a multiharmonic parameter identification method in the original context of magnetics, i.e., a parabolic PDE.

Thinking of the boundary data as extended periodically and sufficiently smoothly to the larger interval $[0, \bar{T}] = [0, T + T_1]$ with some $T_1 > 0$, we make an ansatz

$$u(x,t) \approx u^N(x,t) := \sum_{n=-N}^{N} \exp(\imath n\omega t)\hat{u}_n(x)\,, \tag{6.1}$$

with $\omega = 2\pi/\bar{T}$. (Note that continuation of the boundary values beyond T by the causality of the problem does not influence u for $t < T$.) Inserting into the PDE, we get

$$\sum_{j=-N}^{N} e^{\imath j\omega t} \left(\imath\omega j \hat{u}_j - \left(k \left(\sum_{n=-N}^{N} e^{\imath n\omega t} \hat{u}_{n\,x} \right) \hat{u}_{j\,x} \right)_x \right) = 0\,.$$

Testing this with the functions

$$t \mapsto \frac{1}{\bar{T}} e^{-\imath l\omega t}$$

and using the orthonormality

$$\frac{1}{\bar{T}} \int_0^{\bar{T}} e^{-\imath l\omega t} e^{\imath j\omega t}\, dt = \delta_{lj}, \tag{6.2}$$

where δ_{lj} is the Kronecker symbol, yields

$$\imath\omega l\hat{u}_l - \frac{1}{\bar{T}}\int_0^{\bar{T}} \sum_{j=-N}^{N} e^{\imath(j-l)\omega t}\left(k\left(\sum_{n=-N}^{N} e^{\imath n\omega t}\hat{u}_{n\,x}\right)\hat{u}_{j\,x}\right)_x dt \ = 0 \quad \forall l \in \{-N,\dots,N\}\,. \tag{6.3}$$

To eliminate the time integral, we use an appropriate approximation for k that enables us to take advantage of the orthogonality (6.2). For this purpose we make use of a polynomial ansatz

$$k(z) \approx \sum_{p=0}^{P} \alpha_p z^p\,,$$

which is justified by the fact that in the applications we have in mind, k is typically a smooth function. Since the multinomial theorem yields

$$\left(\sum_{n=-N}^{N} e^{\imath n\omega t}\hat{u}_{n\,x}\right)^p = \sum_{\substack{\mathbf{p}=(p_{-N},\dots,p_N)\in\mathbb{N}_0^{2N+1}\\ \sum_{n=-N}^{N} p_n = p}} \begin{pmatrix} p \\ \mathbf{p}\end{pmatrix} \prod_{m=-N}^{N}\left(e^{\imath m\omega t}\hat{u}_{m\,x}\right)^{p_m}\,,$$

with the multinomial coefficients

$$\begin{pmatrix} p \\ (p_{-N},\dots,p_N)\end{pmatrix} = \frac{p!}{p_{-N}!\cdots p_N!}\,,$$

by (6.2) one arrives at a system of space dependent PDEs

$$\imath\omega l\hat{u}_l - \left(\sum_{n=-N}^{N}\sum_{p=0}^{P}\alpha_p \vec{c}^{\,p}_{l-n}\hat{u}_{n\,x}\right)_x = 0, \quad l \in \{-N,\dots,N\}\,, \tag{6.4}$$

where

$$\vec{c}^{\,p}_s = \sum_{\mathbf{p}\in\mathcal{I}(p,s)} \begin{pmatrix} p \\ \mathbf{p}\end{pmatrix} \prod_{m=-N}^{N}(\hat{u}_{m\,x})^{p_m}\,,$$

$$\mathcal{I}(p,s) = \left\{\mathbf{p}=(p_{-N},\dots,p_N)\subseteq\mathbb{N}_0^{2N+1} \;\middle|\; \sum_{n=-N}^{N} p_n = p \;\wedge\; \sum_{n=-N}^{N} np_n = s\right\};$$

i.e., the coefficients $\vec{c}^{\,p}_{l-n}$ depend nonlinearly on $(\hat{u}_{-N\,x},\dots,\hat{u}_{N\,x})$. The boundary conditions and measurements become

$$\hat{u}_{l\,x}(0) = \hat{g}_{0\,l},\ \hat{u}_{l\,x}(L) = \hat{g}_{1\,l}, \quad l \in \{-N,\dots,N\}, \tag{6.5}$$

$$\hat{u}_l(0) = \hat{f}_{0\,l},\ \hat{u}_l(L) = \hat{f}_{1\,l}, \quad l \in \{-N,\dots,N\}, \tag{6.6}$$

with

$$\hat{f}_{i\,l} = \frac{1}{\bar{T}}\int_0^{\bar{T}} \exp(-\imath l\omega\tau) f_i(\tau)\ d\tau\,,$$

and analogously for g_i, $i = 0, 1$. Note that we consider the Neumann data as boundary conditions (and the Dirichlet data as measurement) in our numerical tests below in order to be able to directly prescribe g_0 monotonically increasing on the subinterval $[0, T]$ and g_1 constant. To avoid singularity of the system due to the elliptic Neumann problem for index $l = 0$, we make the additional normalization assumption $\hat{u}_0 = \frac{1}{\bar{T}} \int_0^{\bar{T}} u^N(\cdot, t)\, dt = 0$. Physically, this corresponds to the fact that in experiments only *higher* harmonics (i.e., multiples $n\omega$ with $|n| \geq 1$ of the basic frequency ω) appear. From a mathematical point of view this normalization corresponds to a $\bar{T}$ periodicity assumption on the antiderivative of u^N, while the multiharmonic ansatz implies periodicity of u^N itself. To keep compatibility, we add this assumption of a vanishing time integral also to the conditions imposed on the periodic extension of the boundary values f_0, f_1, g_0, g_1.

If k is real valued, we expect to get a real valued solution and therefore additionally stipulate

$$\hat{u}_{-n} = \overline{\hat{u}_n}\,. \tag{6.7}$$

We refer the reader to [15] for more details in the context of a hyperbolic model problem and to [2] for a well-posedness proof of the forward problem in this form under the conditions we have made here for the coefficient function k. The inverse problem of reconstructing k from boundary measurements of u in this kind of discretization amounts to determining the vector of polynomial coefficients $\underline{\alpha} = (\alpha_0, \ldots, \alpha_p)$ from boundary data of $\hat{u}_l$, $l = 0, \ldots, N$; cf. [15]. Written as a system of equations

$$F_N^P(\underline{\alpha}) = y_N\,, \tag{6.8}$$

where $F_N^P : \underline{\alpha} \mapsto (\hat{u}_n(0), \hat{u}_n(L))_{n=0}^N$ with $(\hat{u}_n)_{n=0}^N$ solving (6.4), (6.5), (6.7), this can be viewed as the projected version of an operator equation

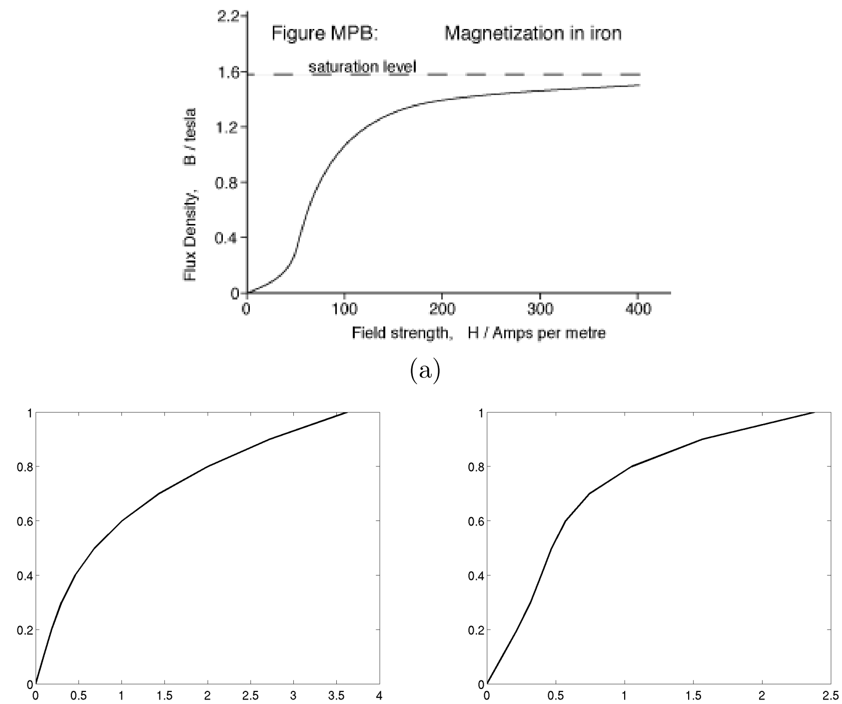
$$F^P(\underline{\alpha}) = y \tag{6.9}$$

resulting from replacing N by ∞ in (6.1), i.e., taking the full expansion of u into account. More precisely, our special time discretization corresponds to an L^2 projection in data space to the subspace spanned by the first $2N + 1$ trigonometric polynomials. These L^2 projections converge pointwise to the identity due to the fact that $\{t \mapsto \frac{1}{\sqrt{\bar{T}}} e^{\imath j \omega t} \mid j \in \mathbb{Z}\}$ forms a complete orthonormal system in $L^2_{\mathbb{C}}(0, \bar{T})$. Keeping in mind the fact that the original infinite-dimensional inverse problem of recovering k is ill-posed in the sense of instability, here we rely on the regularizing effect of discretization. As a matter of fact, we can combine the approximation error estimates from [2] with Theorem 1 in [14] to conclude that (6.8) is a regularization method for the solution of (6.9) with N acting as a regularization parameter. Since the convergence and stability properties of this method hold independently of the polynomial degree P, this can be regarded as a regularization method for the original problem of determining k from boundary measurements of u.

We can apply Newton's method to (6.8),

$$\underline{\alpha}^{m+1} = \underline{\alpha}^m + \theta \underline{\beta} \quad \text{with } F_N^{P'}(\underline{\alpha}^m)\underline{\beta} = y - F_N^P(\underline{\alpha}^m),$$

to iteratively recover $\underline{\alpha}$. Here θ is an appropriately chosen stepsize that guarantees strictly monotone decrease of the residual. To fully discretize this method it remains



(a) (b) (c)

FIG. 6.1. *Typical B-H curve for iron ((a), schematic) and two synthetic test examples ((b), (c)).*

to define a space discretization of the space dependent functions $\hat{u}_l$, which we do by using finite elements on a uniform grid.

The application we have in mind here is nonlinear magnetics (cf. subsection 5.2), where the nonlinearity is usually considered in terms of the so-called B-H curves, i.e., a plot of the magnetic flux density $\mathbf{B}$ over the magnetic field intensity $\mathbf{H}$. By the relation (5.5), in our context this translates into plotting the function a, where $a^{-1}(z) = k(z)z$. A typical B-H curve for iron is displayed in Figure 6.1(a), where the ratio between the slope at $B = 0$ and the slope at the saturation level $B = B_{sat}$ amounts to the relative reluctivity $\nu_{rel} \sim \frac{1}{5000}$. For testing the proposed method, we constructed two test problems with similar behavior. Upon renormalization to $B_{sat}^{norm} = 1$, $\nu_{rel}^{norm} = \frac{1}{10}$, the values $H_{sat}^{norm} = 3.6$ and $H_{sat}^{norm} = 2.4$ as they appear in the synthetic test examples in Figure 6.1(b), (c) indeed turn out to be in a realistic range.

For the first test example (i.e., Figure 6.1(b)), Figure 6.2 shows the iteration history of the proposed method for exact and for randomly perturbed data with a noise level of 1 percent, as compared to the true curve a_{ex} in black. In our inverse computations, we used $N = 5$ higher harmonics. To avoid an inverse crime, we generated the data with a larger number N in the multiharmonic ansatz. Figure 6.3 shows the development of the residuals during the Newton iteration in the exact and noisy case, respectively. In Figures 6.4 and 6.5 we give another example of such a B-H curve, namely the one corresponding to Figure 6.1(c). This example exhibits a changing sign of curvature as typical for some materials; see, e.g., Figure 6.1(a). The proposed method is able to also satisfactorily reproduce this more complicated behavior. Note that in each of these tests, the starting value for k is just a constant

function, corresponding to the fact that in practice the constant reluctivity coefficient for small magnetic fields is typically known.

LOW REGULARITY LOCAL WELL-POSEDNESS OF THE DERIVATIVE NONLINEAR SCHRÖDINGER EQUATION WITH PERIODIC INITIAL DATA*

AXEL GRÜNROCK† AND SEBASTIAN HERR‡

Abstract. The Cauchy problem for the derivative nonlinear Schrödinger equation with periodic boundary condition is considered. Local well-posedness for data u_0 in the space $\widehat{H}^s_r(\mathbb{T})$, defined by the norms $\|u_0\|_{\widehat{H}^s_r(\mathbb{T})} = \|\langle\xi\rangle^s \widehat{u}_0\|_{\ell^{r'}_\xi}$, is shown in the parameter range $s \geq \frac{1}{2}$, $2 > r > \frac{4}{3}$. The proof is based on an adaptation of the gauge transform to the periodic setting and an appropriate variant of the Fourier restriction norm method.

Key words. local well-posedness, derivative nonlinear Schrödinger equation, periodic functions, sharp multilinear estimates, gauge transformation, generalized Fourier restriction norm method

AMS subject classification. 35Q55

1. Introduction and main result. The Cauchy problem for the derivative nonlinear Schrödinger equation

$$\text{(DNLS)} \qquad \begin{aligned} i\partial_t u + \partial_x^2 u &= i\partial_x(|u|^2 u), \\ u(0,x) &= u_0(x) \end{aligned}$$

describes the propagation of nonlinear waves arising in plasma physics, nonlinear optics, and other disciplines. For initial data u_0 in the classical Sobolev spaces $H^s(\mathbb{R})$ of functions defined on the real line, (DNLS) is known to be locally well-posed for $s \geq \frac{1}{2}$. This was shown by Takaoka in [25], where he improved the earlier $H^1(\mathbb{R})$-result of Hayashi and Ozawa [16, 17] and Hayashi [15]. His method of proof combines the gauge transform already used by Hayashi and Ozawa with Bourgain's Fourier restriction norm method. Global well-posedness in $H^s(\mathbb{R})$ for $s > \frac{1}{2}$ is derived by Colliander et al. in [7, 8]. A counterexample of Biagioni and Linares [2] shows the optimality of Takaoka's local result on the $H^s(\mathbb{R})$-scale of data spaces: For $s < \frac{1}{2}$ the Cauchy problem (DNLS) is ill-posed in the C^0-uniform sense, although the standard scaling argument suggests only local ill-posedness for $s < 0$. This gap of $1/2$ derivative between the scaling prediction and Takaoka's result can be closed by leaving the $H^s(\mathbb{R})$-scale and considering data in the spaces $\widehat{H}^s_r(\mathbb{R})$ defined by the norms

$$\|u_0\|_{\widehat{H}^s_r(\mathbb{R})} = \|\langle\xi\rangle^s \widehat{u}_0\|_{L^{r'}_\xi}, \qquad \langle\xi\rangle = (1+\xi^2)^{\frac{1}{2}}, \qquad \frac{1}{r} + \frac{1}{r'} = 1.$$

We remark that these spaces coincide with $B_{r',k}$ (with weight $k(\xi) = \langle\xi\rangle^s$), introduced by Hörmander; cf. [20, section 10.1]. The idea to consider them as data spaces for nonlinear Schrödinger equations goes back to the work of Cazenave, Vega, and

Vilela [4], where corresponding weak norms are used. Yet another alternative class of data spaces has been considered by Vargas and Vega in [26].

Concerning the (DNLS) equation on the real line, it was shown by the first author in [13] that local well-posedness holds for data in $\widehat{H}^s_r(\mathbb{R})$, provided $s \geq \frac{1}{2}$ and $2 \geq r > 1$. This generalization of Takaoka's result almost reaches the case $(s,r) = (\frac{1}{2}, 1)$, which is critical with respect to the scaling symmetry. The proof uses the gauge transform again and an appropriate variant of the Fourier restriction norm method, which was developed in [12]. Furthermore, it relies heavily on certain smoothing properties of the Schrödinger group, expressed in terms of bi- and trilinear estimates for free solutions.

On the other hand, it could be shown by the second author in [18] that Takaoka's result concerning the real line can be carried over to the periodic case *with the same lower bound* $s \geq \frac{1}{2}$ on the Sobolev regularity. This is remarkable, since there is a number of nonlinear Schrödinger and Korteweg–de Vries-type equations, which are—due to a lack of smoothing properties—strictly worse behaved in the periodic setting than in the continuous case. To prove the result concerning the one-dimensional torus, the gauge transform had to be adjusted to the periodic case; see [18, section 2]. The transformed equation is then treated by the Fourier restriction norm method. Here, the L^4 Strichartz estimate [27, 3] turned out to be a central tool in the derivation of the nonlinear estimates.

Now it is natural to ask for a synthesis of the two last-mentioned results, i.e., to consider the Cauchy problem (DNLS) with u_0 in the following two parameter scale of data spaces.

DEFINITION 1.1. *Let $s \in \mathbb{R}$, $1 \leq r \leq \infty$, and $\frac{1}{r} + \frac{1}{r'} = 1$. Define $\widehat{H}^s_r(\mathbb{T})$ as the completion of all trigonometric polynomials with respect to the norm*

$$\|f\|_{\widehat{H}^s_r} := \|\widehat{J^s f}\|_{\ell^{r'}_\xi}, \tag{1}$$

where J^s is the Bessel potential operator of order $-s$ given by $\widehat{J^s f}(\xi) = \langle \xi \rangle^s \widehat{f}(\xi)$.

Remark 1. In contrast to the nonperiodic case the continuous embedding $\widehat{H}^s_q(\mathbb{T}) \subset \widehat{H}^s_r(\mathbb{T})$ holds true for any $1 \leq r \leq q \leq \infty$. Moreover, we have $H^s_2(\mathbb{T}) = \widehat{H}^s_2(\mathbb{T})$ and, more generally, $H^s_r(\mathbb{T}) \subset \widehat{H}^s_r(\mathbb{T})$ for $1 \leq r \leq 2$ by the Hausdorff–Young inequality, where $H^s_r(\mathbb{T})$ denotes the Bessel potential space of all u such that $J^s u \in L^r(\mathbb{T})$. If $r = 2$, we will usually omit the index r.

The main result of this paper is local well-posedness of (DNLS) in these data spaces in the parameter range[1] $s \geq \frac{1}{2}$ and $2 > r > \frac{4}{3}$. More precisely, the following theorem will be shown.

THEOREM 1.2. *Let $\frac{4}{3} < q \leq r \leq 2$. For every*

$$u_0 \in B_R := \left\{ u_0 \in \widehat{H}^{\frac{1}{2}}_r(\mathbb{T}) \mid \|u_0\|_{\widehat{H}^{\frac{1}{2}}_q} < R \right\}$$

and $T \lesssim R^{-2q'-}$ there exists a solution $u \in C([-T,T], \widehat{H}^{\frac{1}{2}}_r(\mathbb{T}))$ of the Cauchy problem (DNLS). *This solution is the unique limit of smooth solutions, and the map*

$$\left(B_R, \|\cdot\|_{\widehat{H}^{\frac{1}{2}}_r}\right) \longrightarrow C([-T,T], \widehat{H}^{\frac{1}{2}}_r(\mathbb{T})): \quad u_0 \mapsto u$$

[1] For the sake of clearness of the exposition we state the main results only for the most interesting case $s = \frac{1}{2}$, but standard arguments also provide persistence of higher regularity.

is continuous but not locally uniformly continuous. However, on subsets of B_R with fixed L^2-norm it is locally Lipschitz continuous.

Remark 2.

1. The uniqueness statement in the theorem above can be sharpened; see Remark 5.

2. Our methods rely on the L^2 conservation law, but not on the complete integrability of (DNLS) (see [21]), and also apply to nonlinearities with (say) additional polynomial terms of type $|u|^k u$.

3. Solution always means solution of the corresponding integral equation

$$u(t) = e^{it\partial_x^2} u_0 + i \int_0^t e^{i(t-t')\partial_x^2} \partial_x (|u|^2 u)(t') dt', \quad t \in (-T, T).$$

4. On any level of regularity the flow map is not uniformly continuous. This is precisely due to the influence of a translation; see Lemma 6.3. However, our arguments imply that the map $u_0 \mapsto u(t, x - \frac{t}{\pi}\|u\|_{L^2}^2)$ is real analytic for any $s \geq \frac{1}{2}$; see also [19, Theorem 3.1.5]. In view of the counterexamples in [18, Theorem 5.3], and [19, Theorem 3.1.5] for the corresponding modified equation, which are essentially of the same kind as the one already given in [25, Proposition 3.3], we cannot expect any positive result with smooth dependence (modulo the translation specified above) for $s < \frac{1}{2}$. Observe that the examples concerning the periodic case are monochromatic waves and thus do not distinguish between an ℓ^2_ξ- and an $\ell^{r'}_\xi$-norm. Concerning the second parameter r, we must leave open the question whether or not there is local well-posedness for $r \leq \frac{4}{3}$. Nonetheless, we will show below that our result is optimal within the framework we use.

Before we turn to details, let us point out that in the periodic case almost nothing is known about Cauchy problems with data in the $\widehat{H}^s_r(\mathbb{T})$ spaces. The only result we are aware of is due to Christ [6, 5], who considers the following modification of the cubic nonlinear Schrödinger equation on the one-dimensional torus:

$$\text{(NLS*)} \qquad i\partial_t u + \partial_x^2 u = \left(|u|^2 - 2 \fint_0^{2\pi} |u|^2 dx \right) u,$$

with initial condition $u(0) = u_0 \in \widehat{H}^s_r(\mathbb{T})$. He shows that for $s \geq 0$ and $r > 1$ the solution map

$$S : H^\sigma(\mathbb{T}) \longrightarrow C([0,\infty), H^\sigma(\mathbb{T})) \cap C^1([0,\infty), H^{\sigma-2}(\mathbb{T}))$$

(σ sufficiently large) "extends by continuity to a uniformly continuous mapping from the ball centered at 0 of [arbitrary] radius R in" $\widehat{H}^s_r(\mathbb{T})$ to $C([0,\tau], \widehat{H}^s_r(\mathbb{T}))$, where τ depends on R; see [6, Theorem 6.1.1].[2] This result is shown by a *new method of solution*, which is developed in [6]; a summary of this method is given in section 6.1.5 of that paper. The positive result in [6] is supplemented in [5] by a statement of nonuniqueness: For $2 > r > 1$ there exists a nonvanishing weak solution[3] $u \in C([0,1], \widehat{H}^0_r(\mathbb{T}))$ of (NLS*) with initial value $u_0 \equiv 0$; see [5, Theorem 2.3].

Using the function spaces $X^{s,b}_r$, defined by the norms

$$\|u\|_{X^{s,b}_r} = \|\langle \xi \rangle^s \langle \tau + \xi^2 \rangle^b \widehat{u}\|_{\ell^{r'}_\xi L^{r'}_\tau},$$

[2] In [6] the data spaces are denoted as $\mathcal{F}L^{s,p}(\mathbb{T})$, which corresponds to $\widehat{H}^s_{p'}(\mathbb{T})$ in our terms.

[3] A precise definition of a weak solution is given in [5, section 2.1].

where $\frac{1}{r} + \frac{1}{r'} = 1$ (cf. [12, section 2]), we can actually show local *well-posedness* of the initial value problem associated with (NLS*) with data $u_0 \in \widehat{H}^0_r(\mathbb{T})$, $2 > r > 1$, thus giving an alternative proof (based on the contraction mapping principle) of Christ's result from [6]. The argument also provides uniqueness of the solution in the restriction norm space based on $X^{0,b}_r$; see [12, formulas (2.37) and (2.38)]. It was the starting point for our investigations concerning the (DNLS) equation and already exhibits some of the main arguments; so let us sketch this proof.

We define the trilinear operator C_1 by its partial Fourier transform (in the space variable only)

$$\widehat{C_1(u_1, u_2, u_3)}(\xi) = (2\pi)^{-1} \sum_{\substack{\xi = \xi_1 + \xi_2 + \xi_3 \\ \xi_1 \neq \xi,\, \xi_2 \neq \xi}} \widehat{u}_1(\xi_1)\widehat{u}_2(\xi_2)\widehat{\overline{u}}_3(\xi_3),$$

so that the (partial) Fourier transform of the nonlinearity in (NLS*) becomes

$$\widehat{C_1(u, u, u)}(\xi) - (2\pi)^{-1}\widehat{u}^2(\xi)\widehat{\overline{u}}(-\xi).$$

By [12, Theorem 2.3] it is sufficient to estimate the latter appropriately in $X^{0,b}_r$-norms. Here, the second contribution turns out to be harmless; cf. the end of the proof of Theorem 2.4 below. So matters essentially reduce to show the following estimate.

PROPOSITION 1.3. *Let $r > 1$, $\varepsilon > 0$, and $b > \frac{1}{r}$. Then*

$$\|C_1(u_1, u_2, u_3)\|_{X^{0,-\varepsilon}_r} \lesssim \prod_{i=1}^{3} \|u_i\|_{X^{0,b}_r}.$$

Proof. Choosing $f_i \in \ell^{r'}_\xi L^{r'}_\tau$ such that $\|f_i\|_{\ell^{r'}_\xi L^{r'}_\tau} = \|u_i\|_{X^{0,b}_r}$ the above estimate can be rewritten as

$$\left\| \langle\sigma_0\rangle^{-\varepsilon} \sum_{\substack{\xi = \xi_1 + \xi_2 + \xi_3 \\ \xi_1 \neq \xi,\, \xi_2 \neq \xi}} \int_{\tau = \tau_1 + \tau_2 + \tau_3} \prod_{i=1}^{3} \frac{f_i(\xi_i, \tau_i)}{\langle\sigma_i\rangle^b} \, d\tau_1 d\tau_2 \right\|_{\ell^{r'}_\xi L^{r'}_\tau} \lesssim \prod_{i=1}^{3} \|f_i\|_{\ell^{r'}_\xi L^{r'}_\tau}, \tag{2}$$

where $\sigma_0 = \tau + \xi^2$, $\sigma_i = \tau_i + \xi_i^2$ $(i = 1, 2)$, and $\sigma_3 = \tau_3 - \xi_3^2$. By Hölder's inequality and Fubini's theorem, (2) can be deduced from

$$\sup_{\xi,\tau} \langle\sigma_0\rangle^{-r\varepsilon} \sum_{\substack{\xi = \xi_1 + \xi_2 + \xi_3 \\ \xi_1 \neq \xi,\, \xi_2 \neq \xi}} \int_{\tau = \tau_1 + \tau_2 + \tau_3} \prod_{i=1}^{3} \langle\sigma_i\rangle^{-rb} \, d\tau_1 d\tau_2 < \infty. \tag{3}$$

Using the resonance relation

$$2|\xi_1\xi_2 + \xi\xi_3| = 2|\xi - \xi_1||\xi - \xi_2| \leq \sum_{i=0}^{3} \langle\sigma_i\rangle \leq \prod_{i=0}^{3} \langle\sigma_i\rangle \tag{4}$$

the left-hand side of (3) is bounded by

$$\begin{aligned} &\sum_{\substack{\xi = \xi_1 + \xi_2 + \xi_3 \\ \xi_1 \neq \xi,\, \xi_2 \neq \xi}} \langle\xi - \xi_1\rangle^{0-}\langle\xi - \xi_2\rangle^{0-} \int_{\tau = \tau_1 + \tau_2 + \tau_3} d\tau_1 d\tau_2 \prod_{i=1}^{3} \langle\sigma_i\rangle^{-1-} \\ \lesssim &\sum_{\substack{\xi = \xi_1 + \xi_2 + \xi_3 \\ \xi_1 \neq \xi,\, \xi_2 \neq \xi}} \langle\xi - \xi_1\rangle^{0-}\langle\xi - \xi_2\rangle^{0-}\langle\tau + \xi^2 - 2(\xi - \xi_1)(\xi - \xi_2)\rangle^{-1-}, \end{aligned}$$

where in the last step we have used Lemma 4.1 twice. Setting $\mathbb{Z}^* = \mathbb{Z}\setminus\{0\}$, $n_i = \xi - \xi_i$ for $i = 1, 2$, and $r = n_1 n_2$ the last sum can be rewritten as

$$\sum_{r\in\mathbb{Z}^*} \langle \tau + \xi^2 - 2r\rangle^{-1-} \langle r\rangle^{0-} \sum_{\substack{n_1,n_2\in\mathbb{Z}^*\\ r=n_1n_2}} 1,$$

which is bounded by a constant independent of ξ and τ, since the number of divisors of $r \in \mathbb{N}$ can be estimated by $c_\varepsilon r^\varepsilon$ for any positive ε. □

Three aspects of the preceding are worth being emphasized in view of our investigations here.

Necessity of cancellations and correction terms. For $r < 2$ the above argument breaks down completely without the restrictions $\xi \neq \xi_1$ and $\xi \neq \xi_2$ in the sum over the Fourier coefficients. As was pointed out already by Christ, this cancellation comes from the correction term $2 \fint_0^{2\pi} |u|^2 dx u$ subtracted in the nonlinearity, and for any other coefficient in front of this term one cannot obtain continuous dependence; see [6, last sentence of section 6.1.3 and the remark before (6.2.6)]. A very similar cancellation turns out to be fundamental in our analysis of the (DNLS) equation, but here *the corresponding correction term comes from the gauge transform* in its periodic variant, which is discussed in Remark 4 in section 6. In fact, the main contribution to the cubic part of the transformed equation is given by $T^*(u, u, u)$, where

$$T^*(\widehat{u_1, u_2}, u_3)(\xi) = (2\pi)^{-1} \sum_{\substack{\xi=\xi_1+\xi_2+\xi_3\\ \xi_1\neq\xi,\, \xi_2\neq\xi}} \widehat{u}_1(\xi_1)\widehat{u}_2(\xi_2) i\xi_3 \widehat{\overline{u}}_3(\xi_3).$$

Again, our argument would not work without the restrictions $\xi \neq \xi_1$, $\xi \neq \xi_2$.

Modification of the norms. If we try to estimate the term $T^*(u_1, u_2, u_3)$ in an $X_r^{s,b}$-norm in a similar manner as in the proof of Proposition 1.3, we have to get control over a whole derivative, that is, on the Fourier side, over the factor ξ_3. The complete absence of smoothing effects (gaining derivatives) in the periodic case forces us to get this control from the resonance relation (4) only, which is the same for (DNLS) as for (NLS*). This means that we have to choose the b-parameters equal to $-\frac{1}{2}$ on the left-hand side and to $+\frac{1}{2}$ on the right-hand side of the estimate. Now, the necessity to cancel the ξ_3-factor and the resonance relation lead to the consideration of eight cases—some of them being symmetric—depending on which of the σ's is maximal and on whether or not $|\xi\xi_3| \lesssim |\xi_1\xi_2|$; see the table in the proof of Theorem 2.4 below. Picking out the (relatively harmless) subcase, where $|\xi\xi_3| \lesssim |\xi_1\xi_2|$ and σ_0 is maximal, so that $\prod_{i=1}^3 \langle\sigma_i\rangle^{\frac{1}{6}} \leq \langle\sigma_0\rangle^{\frac{1}{2}}$, we are in the situation of the above proof, with a half derivative on each factor (as desired) but with a b-parameter on the right of at most $\frac{2}{3}$, which means that we end up with the nonoptimal restriction $r > \frac{3}{2}$. This leads us to *introduce a fourth parameter* p in the $X_r^{s,b}$-norms, which is the Hölder exponent concerning the τ-integration and may differ from r; see Definition 2.1 below. In our application here we choose $p = 2$, thus going back to some extent to the meanwhile classical $X^{s,b}$-spaces.

Number of divisor estimate. The number of divisor argument at the end of the proof of Proposition 1.3 has already been used in Christ's work and can be seen as a substitute for Bourgain's L^6 Strichartz estimate for the periodic case, which itself was shown by the aid of this argument; see [3, Proposition 2.36]. We will need a refined version thereof, which is shown by elementary geometric considerations in section 3. Here, we use arguments similar to those of De Silva et al. [10, section 4].

Concerning the organization of the paper the following should be added: In section 2 we introduce the relevant function spaces and state all the nonlinear estimates needed as well as a sharpness result. The crucial trilinear estimates and a counterexample are derived in section 4, which is very much in the spirit of [22]. Section 5 deals with the quintilinear estimate. In both cases we have made some effort to extract the correct lifespan from the nonlinear estimates and to obtain persistence of higher regularity.[4] By this we mean that the lifespan of a solution with $\widehat{H}^{\frac{1}{2}}_r(\mathbb{T})$-data depends only on the smaller $\widehat{H}^{\frac{1}{2}}_q(\mathbb{T})$-norm of the initial value, where $2 \geq r > q > \frac{4}{3}$. Finally, in section 7, the contraction mapping principle is invoked to prove local well-posedness for the transformed equation (49); see Theorem 7.2. Our main result, Theorem 1.2, is then a consequence of Lemma 6.4 on the gauge transform.

We close this section by fixing some notational conventions.

- The Fourier transform with respect to the space variable (periodic) is

$$\mathcal{F}_x f(\xi) = \widehat{f}(\xi) = \frac{1}{\sqrt{2\pi}} \int_0^{2\pi} f(x) e^{-ix\xi} dx \quad (f \in L^1(\mathbb{T})).$$

- The Fourier transform with respect to the time variable (nonperiodic) is

$$\mathcal{F}_t f(\tau) = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} f(t) e^{-it\tau} dt \quad (f \in L^1(\mathbb{R})).$$

- The Fourier transform with respect to time and space variables is $\mathcal{F} = \mathcal{F}_t \mathcal{F}_x$.
- For the mean value integral we write

$$⨍_0^{2\pi} f(x) dx = \frac{1}{2\pi} \int_0^{2\pi} f(x) dx \quad (f \in L^1(\mathbb{T})).$$

- Let $a \in \mathbb{R}$. The expressions $a\pm$ denote numbers $a \pm \varepsilon$ for sufficiently small $\varepsilon > 0$ (in the case $a = \infty$ the expression $a-$ denotes a sufficiently large real number). The implicit constraint on ε may involve the corresponding expressions in the same line and the lines before in a natural way, and eventually ε is chosen small enough such that it also fulfills the constraints imposed in what follows.
- For a given set of parameters (typically a subset of $\varepsilon, \delta, \nu, p, q, r, s$) the statement $A \lesssim B$ means that there exists a constant $C > 0$ which depends only on these parameters such that $A \leq CB$. This is equivalent to $B \gtrsim A$. We may write $A \ll B$ if it is possible to choose $0 < C < \frac{1}{4}$.
- For all parameters $1 \leq p \leq \infty$ the number $1 \leq p' \leq \infty$ is defined to be the dual parameter satisfying $\frac{1}{p} + \frac{1}{p'} = 1$.

2. Function spaces and main estimates. Let $\mathcal{S}(\mathbb{R} \times \mathbb{T})$ be the linear space of all C^∞-functions $f : \mathbb{R}^2 \to \mathbb{C}$ such that

$$f(t,x) = f(t, x + 2\pi), \qquad \sup_{(t,x)\in\mathbb{R}^2} |t^\alpha \partial_t^\beta \partial_x^\gamma f(t,x)| < \infty, \quad \alpha, \beta, \gamma \in \mathbb{N}_0.$$

[4]We refer the reader to [24, Theorem 2, part V] for the corresponding notion if data in the H^s-scale are considered. In the H^s-case this property usually is a simple consequence of the convolution constraint; see again [24, Remark 2 below Theorem 3]. We cannot see that a similar argument should work in our setting.

DEFINITION 2.1. *Let $s, b \in \mathbb{R}$, $1 \le r, p \le \infty$, and $\frac{1}{r} + \frac{1}{r'} = 1 = \frac{1}{p} + \frac{1}{p'}$. Define the space $X^{s,b}_{r,p}$ as the completion of $\mathcal{S}(\mathbb{R} \times \mathbb{T})$ with respect to the norm*

$$\|u\|_{X^{s,b}_{r,p}} = \|\langle \tau + \xi^2 \rangle^b \langle \xi \rangle^s \mathcal{F} u\|_{\ell^{r'}_\xi L^{p'}_\tau}. \tag{5}$$

In the case where $r = p = 2$ we write $X^{s,b}_{r,p} = X^{s,b}$ as usual.

LEMMA 2.2. *Let $s, b_1, b_2 \in \mathbb{R}$, $1 \le r \le \infty$, and $b_1 > b_2 + \frac{1}{2}$. The following embeddings are continuous:*

$$X^{s,b_1}_{r,2} \subset X^{s,b_2}_{r,\infty}, \tag{6}$$

$$X^{s,0}_{r,\infty} \subset C(\mathbb{R}, \widehat{H}^s_r(\mathbb{T})). \tag{7}$$

Proof. The first embedding is proved by the Cauchy–Schwarz inequality with respect to the L^1_τ-norm.

The second embedding follows from $\mathcal{F}_t^{-1} L^1(\mathbb{R}) \subset L^\infty(\mathbb{R})$. ◻

DEFINITION 2.3. *Let $s \in \mathbb{R}$ and $1 \le r \le \infty$. We define*

$$Z^s_r := X^{s,\frac{1}{2}}_{r,2} \cap X^{s,0}_{r,\infty}$$

and for $0 < T \le 1$ the restriction space $Z^s_r(T)$ of all $v = w\,|_{[-T,T]}$ for some $w \in Z^s_r$ with norm

$$\|v\|_{Z^{\frac{1}{2}}_r(T)} := \inf \left\{ \|w\|_{Z^{\frac{1}{2}}_r} | w \in Z^{\frac{1}{2}}_r : w\,|_{[-T,T]} = v \right\}.$$

A main ingredient for the proof of Theorem 1.2 is an estimate on the trilinear operator (suppressing the t dependence):

$$\begin{aligned} \widehat{T(u_1, u_2, u_3)}(\xi) = (2\pi)^{-1} &\sum_{\substack{\xi = \xi_1 + \xi_2 + \xi_3 \\ \xi_1 \ne \xi,\, \xi_2 \ne \xi}} \widehat{u}_1(\xi_1) \widehat{u}_2(\xi_2) i\xi_3 \widehat{\overline{u}}_3(\xi_3) \\ &+ (2\pi)^{-1} \widehat{u}_1(\xi) \widehat{u}_2(\xi) i\xi \widehat{\overline{u}}_3(-\xi). \end{aligned} \tag{8}$$

THEOREM 2.4. *Let $\frac{4}{3} < q \le r \le 2$ and $0 \le \delta < \frac{1}{q'}$. Then*

$$\|T(u_1, u_2, u_3)\|_{X^{\frac{1}{2},-\frac{1}{2}}_{r,2}} \lesssim T^\delta \|u_1\|_{X^{\frac{1}{2},\frac{1}{2}}_{q,2}} \|u_2\|_{X^{\frac{1}{2},\frac{1}{2}}_{q,2}} \|u_3\|_{X^{\frac{1}{2},\frac{1}{2}}_{r,2}} \tag{9}$$

if $\operatorname{supp}(u_i) \subset \{(t, x) \mid |t| \le T\}$, $0 < T \le 1$.

Additionally, we will need the following estimate on $T(u_1, u_2, u_3)$.

THEOREM 2.5. *Let $\frac{4}{3} < q \le r \le 2$ and $0 \le \delta < \frac{1}{q'}$. Then*

$$\|T(u_1, u_2, u_3)\|_{X^{\frac{1}{2},-1}_{r,\infty}} \lesssim T^\delta \|u_1\|_{X^{\frac{1}{2},\frac{1}{2}}_{q,2}} \|u_2\|_{X^{\frac{1}{2},\frac{1}{2}}_{q,2}} \|u_3\|_{X^{\frac{1}{2},\frac{1}{2}}_{r,2}} \tag{10}$$

if $\operatorname{supp}(u_i) \subset \{(t, x) \mid |t| \le T\}$, $0 < T \le 1$.

The above estimates are sharp with respect to the lower threshold on r within the full scale of spaces $X^{\frac{1}{2},\frac{1}{2}}_{r,p}$. Note that in particular the estimates fail to hold in the endpoint case $r = \frac{4}{3}$.

Remark 3. For all $b \le 0$, $1 \le r \le \frac{4}{3}$, and $1 \le p, q \le \infty$ the estimate

$$\|T(u_1, u_2, u_3)\|_{X^{\frac{1}{2},b}_{r,p}} \lesssim \prod_{i=1}^{3} \|u_i\|_{X^{\frac{1}{2},\frac{1}{2}}_{r,q}} \tag{11}$$

is false.

We also consider the quintilinear expression defined as

$$\widehat{Q(u_1,\dots,u_5)}(\xi) = (2\pi)^{-2} \sum_{**} \widehat{u_1}(\xi_1)\widehat{\overline{u_2}}(\xi_2)\widehat{u_3}(\xi_3)\widehat{\overline{u_4}}(\xi_4)\widehat{u_5}(\xi_5), \tag{12}$$

where we suppressed the t dependence and $**$ is shorthand for summation over the subset of $\mathbb{Z}^5$ given by the restrictions

$$\xi = \xi_1 + \cdots + \xi_5; \quad \xi_1 + \cdots + \xi_4 \neq 0; \quad \xi_1 + \xi_2 \neq 0; \quad \xi_3 + \xi_4 \neq 0.$$

THEOREM 2.6. *Let* $\frac{4}{3} < q \leq r \leq 2$ *and* $b > \frac{1}{6} + \frac{1}{3q}$. *Then*

$$\|u_1\overline{u}_2u_3\overline{u}_4u_5\|_{X^{\frac{1}{2},-b}_{r,2}} \lesssim \sum_{k=1}^{5} \|u_k\|_{X^{\frac{1}{2},b}_{r,2}} \prod_{\substack{1\leq i\leq 5\\ i\neq k}} \|u_i\|_{X^{\frac{1}{2},b}_{q,2}}. \tag{13}$$

Additionally assume that for $0 < T \leq 1$ *we have* $\operatorname{supp}(u_i) \subset \{(t,x) \mid |t| \leq T\}$ *and* $0 \leq \delta < \frac{2}{q'}$. *Then*

$$\|u_1\overline{u}_2u_3\overline{u}_4u_5\|_{X^{\frac{1}{2},-\frac{1}{2}}_{r,2} \cap X^{\frac{1}{2},-1}_{r,\infty}} \lesssim T^{\delta} \sum_{k=1}^{5} \|u_k\|_{X^{\frac{1}{2},\frac{1}{2}}_{r,2}} \prod_{\substack{1\leq i\leq 5\\ i\neq k}} \|u_i\|_{X^{\frac{1}{2},\frac{1}{2}}_{q,2}} \tag{14}$$

and

$$\|Q(u_1,u_2,u_3,u_4,u_5)\|_{X^{\frac{1}{2},-\frac{1}{2}}_{r,2} \cap X^{\frac{1}{2},-1}_{r,\infty}} \lesssim T^{\delta} \sum_{k=1}^{5} \|u_k\|_{X^{\frac{1}{2},\frac{1}{2}}_{r,2}} \prod_{\substack{1\leq i\leq 5\\ i\neq k}} \|u_i\|_{X^{\frac{1}{2},\frac{1}{2}}_{q,2}}. \tag{15}$$

3. Number of divisor estimates and consequences. The next lemma contains estimates on the number of divisors of a given natural number r. Part 1 is well known; see Hardy and Wright [14, Theorem 315]. The approach used to prove part 2 of Lemma 3.1 is motivated by [10, Lemma 4.4].

LEMMA 3.1.

1. *Let* $\varepsilon > 0$. *There exists* $c_\varepsilon > 0$ *such that for all* $r \in \mathbb{N}$

$$\#\left\{(n_1,n_2) \in \mathbb{N}^2 \mid n_1n_2 = r\right\} \leq c_\varepsilon r^{\varepsilon}. \tag{16}$$

2. *For all* $r \in \mathbb{N}$

$$\#\left\{(n_1,n_2) \in \mathbb{N}^2 \mid n_1n_2 = r, \quad 3|n_1 - n_2| \leq r^{\frac{1}{6}}\right\} \leq 2. \tag{17}$$

Proof of part 2. Let $r \in \mathbb{N}$. Assume that there are three lattice points contained in the above set. Then these points form a triangle of area $\mu \geq \frac{1}{2}$; see Figure 1. This triangle is located

(i) in the strip

$$S = \left\{(x_1,x_2) \in \mathbb{R}^2 \mid \sqrt{r} - \delta \leq x_1 \leq \sqrt{r} + \delta\right\},$$

where $\delta = \frac{1}{3}r^{\frac{1}{6}}$, because $|n_1 - \sqrt{r}| \leq |n_1 - n_2| \leq \delta$;

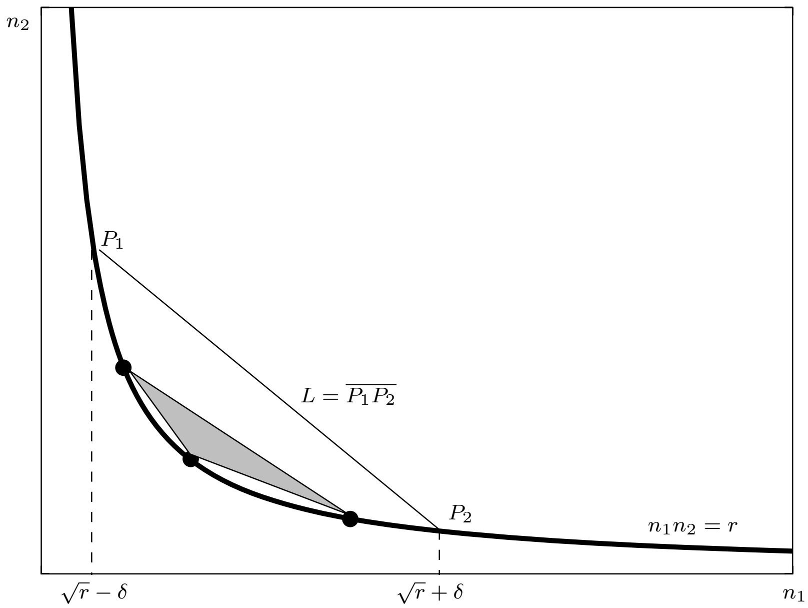

FIG. 1. *The notional triangle from the proof of Lemma* 3.1.

(ii) below the line $L = \overline{P_1P_2}$ which connects the points

$$P_1 = \left(\sqrt{r}-\delta, \frac{r}{\sqrt{r}-\delta}\right), \qquad P_2 = \left(\sqrt{r}+\delta, \frac{r}{\sqrt{r}+\delta}\right);$$

(iii) above the hyperbola

$$H = \left\{(x_1, x_2) \in (0,\infty)^2 \mid x_1x_2 = r\right\}$$

because the function $x \mapsto \frac{r}{x}$ is convex for $x > 0$.

Now, the area μ of the triangle is bounded from above by the area of the region in the strip S below L and above H; hence

$$\begin{aligned}
\mu &\le r\delta\left(\frac{1}{\sqrt{r}-\delta}+\frac{1}{\sqrt{r}+\delta}\right) - \int_{\sqrt{r}-\delta}^{\sqrt{r}+\delta} \frac{r}{x}\,dx \\
&= r\left(\frac{2\sqrt{r}\delta}{r-\delta^2} - \ln\left(1+\frac{2\delta}{\sqrt{r}-\delta}\right)\right) \\
&\le r\left(\frac{2\sqrt{r}\delta}{r-\delta^2} - \frac{2\delta}{\sqrt{r}-\delta} + \frac{2\delta^2}{(\sqrt{r}-\delta)^2}\right) = \frac{4r\delta^3}{(\sqrt{r}-\delta)^2(\sqrt{r}+\delta)} \\
&\le \frac{4\sqrt{r}\delta^3}{(\sqrt{r}-\delta)^2} \le \frac{4}{27}\frac{r}{(\sqrt{r}-\delta)^2} \le \frac{1}{3},
\end{aligned}$$

which contradicts $\mu \ge \frac{1}{2}$. $\square$

Now, we use Lemma 3.1 to prove the following.

COROLLARY 3.2. *Fix* $\varepsilon > 0$.

1. *There exists* $C_\varepsilon > 0$ *such that for all* $\xi \in \mathbb{Z}$ *and* $a \in \mathbb{R}$

$$\sum_{\substack{\xi_1,\xi_2\in\mathbb{Z} \\ \xi_1,\xi_2\neq\xi}} \langle \xi-\xi_1\rangle^{-\varepsilon}\langle \xi-\xi_2\rangle^{-\varepsilon}\langle a+2(\xi-\xi_1)(\xi-\xi_2)\rangle^{-1-\varepsilon} \le C_\varepsilon. \tag{18}$$

2. *There exists $C_\varepsilon > 0$ such that for all $\xi_1 \in \mathbb{Z}$ and $a \in \mathbb{R}$*

$$\sum_{\substack{\xi,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \langle \xi-\xi_1\rangle^{-\varepsilon}\langle \xi-\xi_2\rangle^{-\varepsilon}\langle a+2(\xi-\xi_1)(\xi-\xi_2)\rangle^{-1-\varepsilon} \le C_\varepsilon. \tag{19}$$

3. *There exists $C_\varepsilon > 0$ such that for all $\xi \in \mathbb{Z}$ and $a \in \mathbb{R}$*

$$\sum_{\substack{\xi_1,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \langle \xi_1\rangle^{-\varepsilon}\langle \xi_2\rangle^{-\varepsilon}\langle a+2(\xi-\xi_1)(\xi-\xi_2)\rangle^{-1-\varepsilon} \le C_\varepsilon. \tag{20}$$

4. *There exists $C_\varepsilon > 0$ such that for all $\xi_1 \in \mathbb{Z}$ and $a \in \mathbb{R}$*

$$\langle \xi_1\rangle^{-\varepsilon}\sum_{\substack{\xi,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \langle \xi_2\rangle^{-\varepsilon}\langle a+2(\xi-\xi_1)(\xi-\xi_2)\rangle^{-1-\varepsilon} \le C_\varepsilon. \tag{21}$$

Proof. The first and second part follow from the standard number of divisors estimate (16) as follows: By the change of variables $n_1 = \xi-\xi_1$, $n_2 = \xi-\xi_2$ the sums in (18) and (19) are equal to

$$\sum_{n_1,n_2\in\mathbb{Z}^*} \langle n_1\rangle^{-\varepsilon}\langle n_2\rangle^{-\varepsilon}\langle a+2n_1n_2\rangle^{-1-\varepsilon}.$$

This can be written as

$$\begin{aligned}
&\sum_{r\in\mathbb{Z}^*}\sum_{\substack{n_1,n_2\in\mathbb{Z}^*\\ n_1n_2=r}} \langle n_1\rangle^{-\varepsilon}\langle n_2\rangle^{-\varepsilon}\langle a+2n_1n_2\rangle^{-1-\varepsilon}\\
&\le \sum_{r\in\mathbb{Z}^*}\langle a+2r\rangle^{-1-\varepsilon}\langle r\rangle^{-\varepsilon}\#\left\{(n_1,n_2)\in(\mathbb{Z}^*)^2 \mid n_1n_2=r\right\}\\
&\le c_\varepsilon\sum_{r\in\mathbb{Z}^*}\langle a+2r\rangle^{-1-\varepsilon}
\end{aligned}$$

for some $c_\varepsilon > 1$. We write $a = 2b+\delta$, $b\in\mathbb{Z}$, $\delta\in[0,2)$, and

$$\sum_{r\in\mathbb{Z}^*}\langle a+2r\rangle^{-1-\varepsilon} \le \sum_{r\in\mathbb{Z}}\langle r+\delta\rangle^{-1-\varepsilon} \le 3+2\sum_{r\in\mathbb{N}}\langle r\rangle^{-1-\varepsilon} =: s_\varepsilon.$$

Now, the estimates (18) and (19) hold with $C_\varepsilon := s_\varepsilon c_\varepsilon$. In order to show formula (20) of the third part we use the same change of variables as above and obtain

$$\sum_{r\in\mathbb{Z}^*}\langle a+2r\rangle^{-1-\varepsilon}\sum_{\substack{n_1,n_2\in\mathbb{Z}^*\\ n_1n_2=r}}\langle \xi-n_1\rangle^{-\varepsilon}\langle \xi-n_2\rangle^{-\varepsilon}.$$

Let $M(r) = \{(n_1,n_2)\in(\mathbb{Z}^*)^2 \mid n_1n_2 = r\}$. Now, we split the inner sum into two parts. Let

$$M_1(r) = \left\{(n_1,n_2)\in M(r) \mid 6|\xi-n_1| \ge |r|^{\frac16} \text{ or } 6|\xi-n_2| \ge |r|^{\frac16}\right\}$$

and

$$M_2(r) = \left\{(n_1,n_2)\in M(r) \mid 6|\xi-n_1| \le |r|^{\frac16} \text{ and } 6|\xi-n_2| \le |r|^{\frac16}\right\}.$$

Obviously we have $M(r) = M_1(r) \cup M_2(r)$. By part 1 of Lemma 3.1 there exists $c_\varepsilon > 1$ such that

$$\# M_1(r) \leq 2\,\# \left\{(n_1, n_2) \in \mathbb{N}^2 \mid n_1 n_2 = r\right\} \leq c_\varepsilon |r|^{\frac{\varepsilon}{6}},$$

and it follows that

$$\sum_{(n_1,n_2)\in M_1(r)} \langle \xi - n_1\rangle^{-\varepsilon}\langle \xi - n_2\rangle^{-\varepsilon} \leq 6^\varepsilon |r|^{-\frac{\varepsilon}{6}} \# M_1(r) \leq 6^\varepsilon c_\varepsilon.$$

For $(n_1, n_2) \in M_2(r)$ it holds that $3|n_1 - n_2| \leq |r|^{\frac{1}{6}}$. An application of part 2 of Lemma 3.1 shows that

$$\sum_{(n_1,n_2)\in M_2(r)} \langle \xi - n_1\rangle^{-\varepsilon}\langle \xi - n_2\rangle^{-\varepsilon} \leq \# M_2(r) \leq 4.$$

Therefore, we see that

$$\sum_{\substack{\xi_1,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \langle \xi_1\rangle^{-\varepsilon}\langle \xi_2\rangle^{-\varepsilon}\langle a + 2(\xi-\xi_1)(\xi-\xi_2)\rangle^{-1-\varepsilon} \leq (6^\varepsilon c_\varepsilon + 4)\sum_{r\in\mathbb{Z}^*}\langle a + 2r\rangle^{-1-\varepsilon},$$

and the third part is proved with constant $C_\varepsilon = s_\varepsilon(6^\varepsilon c_\varepsilon + 4)$. Concerning the fourth part we proceed similarly. After changing variables

$$\begin{aligned}
&\langle \xi_1\rangle^{-\varepsilon} \sum_{\substack{\xi,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \langle \xi_2\rangle^{-\varepsilon}\langle a + 2(\xi-\xi_1)(\xi-\xi_2)\rangle^{-1-\varepsilon}\\
&= \langle \xi_1\rangle^{-\varepsilon}\sum_{r\in\mathbb{Z}^*}\langle a+2r\rangle^{-1-\varepsilon}\sum_{\substack{n_1,n_2\in\mathbb{Z}^*\\ n_1 n_2 = r}}\langle \xi_1 + n_1 - n_2\rangle^{-\varepsilon}
\end{aligned}$$

we consider two subregions of summation. In the case where $|r|^{\frac{1}{6}} \leq 6|\xi_1|$ or $|r|^{\frac{1}{6}} \leq 6|\xi_1 + n_1 - n_2|$ we apply estimate (16) from the first part of Lemma 3.1, while in the remaining case it holds that $3|n_1 - n_2| \leq |r|^{\frac{1}{6}}$, and we utilize estimate (17) from the second part of Lemma 3.1. $\square$

4. The proof of the trilinear estimates. In this section we prove Theorems 2.4 and 2.5. We will frequently use the following well-known tool; see, e.g., [11, Lemma 4.2].

Lemma 4.1. *Let $0 \leq \alpha \leq \beta$ such that $\alpha + \beta > 1$ and $\varepsilon > 0$. Then*

$$\int_{\mathbb{R}} \langle s-a\rangle^{-\alpha}\langle s-b\rangle^{-\beta} ds \lesssim \langle a-b\rangle^{-\gamma}, \quad \gamma = \begin{cases}\alpha+\beta-1, & \beta<1,\\ \alpha-\varepsilon, & \beta=1,\\ \alpha, & \beta>1.\end{cases}$$

We write $T = T^* + T^{**}$, where

$$\begin{aligned}
T^*\widehat{(u_1,u_2},u_3)(\xi) &= (2\pi)^{-1}\sum_{\substack{\xi=\xi_1+\xi_2+\xi_3\\ \xi_1\neq\xi,\ \xi_2\neq\xi}} \widehat{u}_1(\xi_1)\widehat{u}_2(\xi_2) i\xi_3 \widehat{\overline{u}}_3(\xi_3),\\
T^{**}\widehat{(u_1,u_2},u_3)(\xi) &= (2\pi)^{-1}\widehat{u}_1(\xi)\widehat{u}_2(\xi) i\xi\widehat{\overline{u}}_3(-\xi).
\end{aligned}$$

Proof of Theorem 2.4. To fix notation, let $\sigma_0 = \tau + \xi^2$, $\sigma_j = \tau_j + \xi_j^2$, $j = 1, 2$, and $\sigma_3 = \tau_3 - \xi_3^2$. Throughout the proof the quantities ξ_3, τ_3 are defined as $\xi_3 = \xi - \xi_1 - \xi_2$ and $\tau_3 = \tau - \tau_1 - \tau_2$, respectively. Let us denote $\mu = (\tau, \xi)$, $\mu_i = (\tau_i, \xi_i)$, $i = 1, 2, 3$, for brevity. By the definition of the norms we may assume that $\widehat{u}_j \geq 0$. Then

$$\|T(u_1, u_2, u_3)\|_{X^{\frac{1}{2},-\frac{1}{2}}_{r,2}} \leq \|T^*(u_1, u_2, u_3)\|_{X^{\frac{1}{2},-\frac{1}{2}}_{r,2}} + \|T^{**}(u_1, u_2, u_3)\|_{X^{\frac{1}{2},-\frac{1}{2}}_{r,2}},$$

and we consider the contribution from T^* first: Let m be given by

$$m(\mu, \mu_1, \mu_2) = \frac{\langle \xi \rangle^{\frac{1}{2}} i\xi_3}{\prod_{j=1}^3 \langle \xi_j \rangle^{\frac{1}{2}} \prod_{j=0}^3 \langle \sigma_j \rangle^{\frac{1}{2}}}.$$

Estimate (9) for the T^* contribution is equivalent to

$$\left\| \sum_{\substack{\xi_1,\xi_2 \in \mathbb{Z} \\ \xi_1 \neq \xi,\, \xi_2 \neq \xi}} \int m(\mu, \mu_1, \mu_2) f_1(\mu_1) f_2(\mu_2) f_3(\mu_3) d\tau_1 d\tau_2 \right\|_{\ell^{r'}_\xi L^2_\tau} \tag{22}$$
$$\lesssim T^\delta \|f_1\|_{\ell^{q'}_\xi L^2_\tau} \|f_2\|_{\ell^{q'}_\xi L^2_\tau} \|f_3\|_{\ell^{r'}_\xi L^2_\tau},$$

where we may assume that $f_3(\tau_3, 0) = 0$. The resonance relation

$$\sigma_0 - \sigma_1 - \sigma_2 - \sigma_3 = 2(\xi - \xi_1)(\xi - \xi_2) = 2(\xi_1\xi_2 + \xi\xi_3) \tag{23}$$

holds true; cf. [25, 13, 18]. Let us first consider the subregion where $\langle \xi_1 \rangle \langle \xi_2 \rangle \ll \langle \xi \rangle \langle \xi_3 \rangle$. Then

$$\langle \xi \rangle^{\frac{1}{2}} \langle \xi_3 \rangle^{\frac{1}{2}} \lesssim \sum_{k=0}^3 \langle \sigma_k \rangle^{\frac{1}{2}}, \tag{24}$$

and in this subregion we control $|m|$ by the sum of all

$$m_{k,1}(\mu, \mu_1, \mu_2) = \frac{1}{\langle \xi_1 \rangle^{\frac{1}{2}} \langle \xi_2 \rangle^{\frac{1}{2}} \prod_{j=0,\, j\neq k}^3 \langle \sigma_j \rangle^{\frac{1}{2}}}$$

for $k = 0, \ldots, 3$. Second, in the subregion where $\langle \xi \rangle \langle \xi_3 \rangle \lesssim \langle \xi_1 \rangle \langle \xi_2 \rangle$ (note that $\xi_1 \neq \xi$, $\xi_2 \neq \xi$ within the domain of summation) it holds that

$$\langle \xi - \xi_1 \rangle^{\frac{1}{2}} \langle \xi - \xi_2 \rangle^{\frac{1}{2}} \lesssim \sum_{k=0}^3 \langle \sigma_k \rangle^{\frac{1}{2}}, \tag{25}$$

and in this subregion we control $|m|$ by the sum of all

$$m_{k,2}(\mu, \mu_1, \mu_2) = \frac{1}{\langle \xi - \xi_1 \rangle^{\frac{1}{2}} \langle \xi - \xi_2 \rangle^{\frac{1}{2}} \prod_{j=0,\, j\neq k}^3 \langle \sigma_j \rangle^{\frac{1}{2}}}$$

for $k = 0, \ldots, 3$. According to these multipliers we subdivide the proof into several cases summarized in Table 1. For technical reasons, we will prove the slightly stronger

Table 1

Summary of cases (with a preview of the lower bound on q for each subcase obtained by our arguments below).

	$\sigma_0 = \max$	$\sigma_1 = \max$	$\sigma_2 = \max$	$\sigma_3 = \max$
$\langle\xi_1\rangle\langle\xi_2\rangle \ll \langle\xi\rangle\langle\xi_3\rangle$	Case 0.1: $q > 1$	Case 1.1: $q > 4/3$	Case 2.1: $q > 4/3$	Case 3.1: $q > 4/3$
$\langle\xi\rangle\langle\xi_3\rangle \lesssim \langle\xi_1\rangle\langle\xi_2\rangle$	Case 0.2: $q > 1$	Case 1.2: $q > 4/3$	Case 2.2: $q > 4/3$	Case 3.2: $q > 4/3$

estimates

$$\left\| \sum_{\substack{\xi_1,\xi_2\in\mathbb{Z}\\ \xi_1\neq\xi,\,\xi_2\neq\xi}} \int m_{k,j,\nu}(\mu,\mu_1,\mu_2) f_1(\mu_1) f_2(\mu_2) f_3(\mu_3) d\tau_1 d\tau_2 \right\|_{\ell^{r'}_\xi L^2_\tau} \tag{26}$$
$$\lesssim \|f_1\|_{\ell^{q'}_\xi L^2_\tau} \|f_2\|_{\ell^{q'}_\xi L^2_\tau} \|f_3\|_{\ell^{r'}_\xi L^2_\tau}$$

for any $0 \le \nu < \frac{1}{3q'}$, $k = 0,\dots,3$, and $j = 1,2$, where

$$m_{k,1,\nu}(\mu,\mu_1,\mu_2) = \frac{1}{\langle\xi_1\rangle^{\frac12}\langle\xi_2\rangle^{\frac12}\prod_{j=0,\,j\neq k}^{3}\langle\sigma_j\rangle^{\frac12-\nu}},$$
$$m_{k,2,\nu}(\mu,\mu_1,\mu_2) = \frac{1}{\langle\xi-\xi_1\rangle^{\frac12}\langle\xi-\xi_2\rangle^{\frac12}\prod_{j=0,\,j\neq k}^{3}\langle\sigma_j\rangle^{\frac12-\nu}}$$

for $k = 0,\dots,3$. Clearly, (26) implies (22) with $\delta = 3\nu$ because

$$\left\|\langle\sigma_j\rangle^{-\nu} f_j\right\|_{\ell^{p'}_\xi L^2_\tau} \lesssim T^\nu \|f_j\|_{\ell^{p'}_\xi L^2_\tau}, \quad 1 \le p \le \infty. \tag{27}$$

Case 0.1. We consider the contribution

$$t_{0,1} := \left\| \sum_{\substack{\xi_1,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \int \frac{f_1(\mu_1)}{\langle\xi_1\rangle^{\frac12}\langle\sigma_1\rangle^{\frac12-\nu}} \frac{f_2(\mu_2)}{\langle\xi_2\rangle^{\frac12}\langle\sigma_2\rangle^{\frac12-\nu}} \frac{f_3(\mu_3)}{\langle\sigma_3\rangle^{\frac12-\nu}} d\tau_1 d\tau_2 \right\|_{\ell^{r'}_\xi L^2_\tau}$$
$$\lesssim \left\| \sum_{\substack{\xi_1,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \langle\xi_1\rangle^{-\frac12}\langle\xi_2\rangle^{-\frac12} I(\mu,\mu_1,\mu_2) \left(\int f_1^2 f_2^2 f_3^2 d\tau_1 d\tau_2\right)^{\frac12} \right\|_{\ell^{r'}_\xi L^2_\tau},$$

where

$$I(\mu,\mu_1,\mu_2) := \left(\int \frac{d\tau_1 d\tau_2}{(\langle\sigma_1\rangle\langle\sigma_2\rangle\langle\sigma_3\rangle)^{1-2\nu}}\right)^{\frac12} \lesssim \langle\sigma^{(0)}_{res}\rangle^{\frac{1}{q'}-\frac12-}$$

with $\sigma^{(0)}_{res} = \tau + \xi^2 - 2(\xi-\xi_1)(\xi-\xi_2)$ by two applications of Lemma 4.1. Hölder's inequality in ξ_1,ξ_2 leads to[5]

$$t_{0,1} \lesssim \left\| \Sigma_{0,1}(\mu) \left(\sum_{\xi_1,\xi_2\in\mathbb{Z}} \left(\int \frac{f_1^2(\mu_1)}{\langle\xi_1\rangle^{1-}} \frac{f_2^2(\mu_2)}{\langle\xi_2\rangle^{1-}} f_3^2(\mu_3) d\tau_1 d\tau_2 \right)^{\frac{\varrho}{2}} \right)^{\frac{1}{\varrho}} \right\|_{\ell^{r'}_\xi L^2_\tau},$$

[5]Note that here the exponents of $\langle\xi_1\rangle$ and $\langle\xi_2\rangle$ may be chosen arbitrarily close to 1, independently of the implicit constraints on ϱ and ϱ'.

where

$$\Sigma_{0,1}(\mu) := \left(\sum_{\substack{\xi_1,\xi_2\in\mathbb{Z} \\ \xi_1,\xi_2\neq\xi}} \langle\xi_1\rangle^{0-}\langle\xi_2\rangle^{0-}\langle\sigma_{res}^{(0)}\rangle^{-1-} \right)^{\frac{1}{\varrho'}}$$

for $\varrho = \frac{2q'}{q'+2}+$ and $\varrho' = \frac{2q'}{q'-2}-$. The sum $\Sigma_{0,1}(\mu)$ is uniformly bounded due to Corollary 3.2, estimate (20). Hence,

$$t_{0,1} \lesssim \left\| \left(\sum_{\xi_1,\xi_2\in\mathbb{Z}} \frac{\|f_1(\cdot,\xi_1)\|_{L^2}^{\varrho}}{\langle\xi_1\rangle^{\frac{\varrho}{2}-}} \frac{\|f_2(\cdot,\xi_2)\|_{L^2}^{\varrho}}{\langle\xi_2\rangle^{\frac{\varrho}{2}-}} \|f_3(\cdot,\xi_3)\|_{L^2}^{\varrho} \right)^{\frac{1}{\varrho}} \right\|_{\ell_\xi^{r'}}$$

by Minkowski's inequality because $\varrho \le 2$. Now, we apply Hölder's inequality to obtain

$$t_{0,1} \lesssim \left\| \left(\sum_{\xi_1,\xi_2\in\mathbb{Z}} \frac{\|f_1(\cdot,\xi_1)\|_{L^2}^{r'}}{\langle\xi_1\rangle^{1-\frac{r'}{q'}+}} \frac{\|f_2(\cdot,\xi_2)\|_{L^2}^{r'}}{\langle\xi_2\rangle^{1-\frac{r'}{q'}+}} \|f_3(\cdot,\xi_3)\|_{L^2}^{r'} \right)^{\frac{1}{r'}} \right\|_{\ell_\xi^{r'}}. \tag{28}$$

Hölder's inequality shows that

$$\left(\sum_{\xi_i\in\mathbb{Z}} \|f_i(\cdot,\xi_i)\|_{L^2}^{r'} \langle\xi_i\rangle^{\frac{r'}{q'}-1-} \right)^{\frac{1}{r'}} \lesssim \|f_i\|_{\ell_\xi^{q'}L_\tau^2}, \quad i=1,2.$$

Hence, Fubini's theorem provides

$$t_{0,1} \lesssim \|f_1\|_{\ell_\xi^{q'}L_\tau^2}\|f_2\|_{\ell_\xi^{q'}L_\tau^2}\|f_3\|_{\ell_\xi^{r'}L_\tau^2}$$

for any $1 < q \le r \le 2$, as desired.

Case 0.2. We consider the contribution

$$t_{0,2} := \left\| \sum_{\substack{\xi_1,\xi_2\in\mathbb{Z} \\ \xi_1,\xi_2\neq\xi}} \int \frac{f_1(\mu_1)}{\langle\xi-\xi_1\rangle^{\frac{1}{2}}\langle\sigma_1\rangle^{\frac{1}{2}-\nu}} \frac{f_2(\mu_2)}{\langle\xi-\xi_2\rangle^{\frac{1}{2}}\langle\sigma_2\rangle^{\frac{1}{2}-\nu}} \frac{f_3(\mu_3)}{\langle\sigma_3\rangle^{\frac{1}{2}-\nu}} d\tau_1 d\tau_2 \right\|_{\ell_\xi^{r'}L_\tau^2}.$$

By replacing the weight $\langle\xi_1\rangle^{-\frac{1}{2}}\langle\xi_2\rangle^{-\frac{1}{2}}$ by $\langle\xi-\xi_1\rangle^{-\frac{1}{2}}\langle\xi-\xi_2\rangle^{-\frac{1}{2}}$ in the expression $t_{0,1}$, the same arguments as in the previous case lead to

$$t_{0,2} \lesssim \left\| \left(\sum_{\xi_1,\xi_2\in\mathbb{Z}} \frac{\|f_1(\cdot,\xi_1)\|_{L^2}^{r'}}{\langle\xi-\xi_1\rangle^{1-\frac{r'}{q'}+}} \frac{\|f_2(\cdot,\xi_2)\|_{L^2}^{r'}}{\langle\xi-\xi_2\rangle^{1-\frac{r'}{q'}+}} \|f_3(\cdot,\xi_3)\|_{L^2}^{r'} \right)^{\frac{1}{r'}} \right\|_{\ell_\xi^{r'}}$$

instead of (28), where we used Corollary 3.2, estimate (18) to bound the sum

$$\Sigma_{0,2}(\mu) := \left(\sum_{\substack{\xi_1,\xi_2\in\mathbb{Z} \\ \xi_1,\xi_2\neq\xi}} \langle\xi-\xi_1\rangle^{0-}\langle\xi-\xi_2\rangle^{0-}\langle\sigma_{res}^{(0)}\rangle^{-1-} \right)^{\frac{1}{\varrho'}}.$$

By the change of variables $\xi \mapsto \xi - \xi_1 - \xi_2$ we obtain

$$t_{0,2} \lesssim \left(\sum_{\xi,\xi_1,\xi_2 \in \mathbb{Z}} \frac{\|f_1(\cdot,\xi_1)\|_{L^2}^{r'}}{\langle \xi+\xi_1\rangle^{1-\frac{r'}{q'}+}} \frac{\|f_2(\cdot,\xi_2)\|_{L^2}^{r'}}{\langle \xi+\xi_2\rangle^{1-\frac{r'}{q'}+}} \|f_3(\cdot,\xi)\|_{L^2}^{r'} \right)^{\frac{1}{r'}}.$$

Now, we sum first in ξ_1, ξ_2 and use

$$\sup_{\xi \in \mathbb{Z}} \left(\sum_{\xi_i \in \mathbb{Z}} \|f_i(\cdot,\xi_i)\|_{L^2}^{r'} \langle \xi+\xi_i\rangle^{\frac{r'}{q'}-1-} \right)^{\frac{1}{r'}} \lesssim \|f_i\|_{\ell_\xi^{q'} L_\tau^2}, \quad i=1,2, \tag{29}$$

to obtain

$$t_{0,2} \lesssim \|f_1\|_{\ell_\xi^{q'} L_\tau^2} \|f_2\|_{\ell_\xi^{q'} L_\tau^2} \|f_3\|_{\ell_\xi^{r'} L_\tau^2}$$

similarly as above.

Case 1.1. From now on we have to restrict ourselves to $2 \le q' < 4$, which is mainly due to various applications of Young's inequality. We use duality and consider for $\varphi \in \ell_\xi^r L_\tau^2$ the quantity $t_{1,1}$ defined by

$$\begin{aligned} &\sum_{\xi \in \mathbb{Z}} \int \frac{\varphi(\mu)}{\langle \sigma_0\rangle^{\frac12-\nu}} \sum_{\substack{\xi_1,\xi_2 \in \mathbb{Z} \\ \xi_1,\xi_2 \neq \xi}} \int \frac{f_1(\mu_1)}{\langle \xi_1\rangle^{\frac12}} \frac{f_2(\mu_2)}{\langle \xi_2\rangle^{\frac12}\langle \sigma_2\rangle^{\frac12-\nu}} \frac{f_3(\mu_3)}{\langle \sigma_3\rangle^{\frac12-\nu}} d\tau_1 d\tau_2 d\tau \\ =& \sum_{\xi_1 \in \mathbb{Z}} \int f_1(\mu_1) \sum_{\substack{\xi,\xi_2 \in \mathbb{Z} \\ \xi_1,\xi_2 \neq \xi}} \int \frac{\varphi(\mu)}{\langle \sigma_0\rangle^{\frac12-\nu}} \frac{f_2(\mu_2)}{\langle \xi_2\rangle^{\frac12}\langle \sigma_2\rangle^{\frac12-\nu}} \frac{f_3(\mu_3)}{\langle \xi_1\rangle^{\frac12}\langle \sigma_3\rangle^{\frac12-\nu}} d\tau d\tau_2 d\tau_1. \end{aligned}$$

The Cauchy–Schwarz inequality in τ, τ_2 and two applications of Lemma 4.1 show that

$$t_{1,1} \lesssim \sum_{\xi_1 \in \mathbb{Z}} \int f_1(\mu_1) \sum_{\substack{\xi,\xi_2 \in \mathbb{Z} \\ \xi_1,\xi_2 \neq \xi}} \langle \sigma_{res}^{(1)}\rangle^{\frac{1}{q'}-\frac12-} \left(\int \frac{\varphi^2(\mu) f_2^2(\mu_2) f_3^2(\mu_3)}{\langle \xi_1\rangle\langle \xi_2\rangle} d\tau d\tau_2 \right)^{\frac12} d\tau_1,$$

where with $\sigma_{res}^{(1)} = \tau_1 + \xi_1^2 + 2(\xi-\xi_1)(\xi-\xi_2)$ Hölder's inequality in ξ, ξ_2 leads to

$$t_{1,1} \lesssim \sum_{\xi_1 \in \mathbb{Z}} \int f_1(\mu_1) \Sigma_{1,1}(\mu_1) \left(\sum_{\xi,\xi_2 \in \mathbb{Z}} \left(\int \frac{\varphi^2(\mu) f_2^2(\mu_2) f_3^2(\mu_3)}{\langle \xi_1\rangle^{1-}\langle \xi_2\rangle^{1-}} d\tau d\tau_2 \right)^{\frac{\varrho}{2}} \right)^{\frac{1}{\varrho}} d\tau_1$$

for $\varrho = \frac{2q'}{q'+2}+$ and $\varrho' = \frac{2q'}{q'-2}-$, where

$$\Sigma_{1,1}(\mu_1) := \left(\langle \xi_1\rangle^{0-} \sum_{\substack{\xi,\xi_2 \in \mathbb{Z} \\ \xi_1,\xi_2 \neq \xi}} \langle \xi_2\rangle^{0-} \langle \sigma_{res}^{(1)}\rangle^{-1-} \right)^{\frac{1}{\varrho'}}.$$

This is bounded by Corollary 3.2, estimate (21). The Cauchy–Schwarz inequality in τ_1 and Minkowski's inequality provide

$$t_{1,1} \lesssim \sum_{\xi_1 \in \mathbb{Z}} \|f_1(\cdot,\xi_1)\|_{L_\tau^2} \left(\sum_{\xi,\xi_2} \frac{\|\varphi(\cdot,\xi)\|_{L_\tau^2}^{\varrho} \|f_2(\cdot,\xi_2)\|_{L_\tau^2}^{\varrho} \|f_3(\cdot,\xi_3)\|_{L_\tau^2}^{\varrho}}{\langle \xi_1\rangle^{\frac{\varrho}{2}-}\langle \xi_2\rangle^{\frac{\varrho}{2}-}} \right)^{\frac{1}{\varrho}}. \tag{30}$$

Now, we use Hölder's inequality in ξ_1 to obtain

$$t_{1,1} \lesssim \|f_1\|_{\ell^{q'}_\xi L^2_\tau} \left\| \left(\sum_{\xi,\xi_2} \frac{\|f_2(\cdot,\xi_2)\|^\varrho_{L^2_\tau} \|f_3(\cdot,\xi_3)\|^\varrho_{L^2_\tau} \|\varphi(\cdot,\xi)\|^\varrho_{L^2_\tau}}{\langle \xi_2 \rangle^{\frac{\varrho}{2}-}} \right)^{\frac{1}{\varrho}} \right\|_{\ell^{\varrho'}_{\xi_1}} . \tag{31}$$

By the change of variables $\xi_2 \mapsto -\xi_2$, $\xi \mapsto \xi$ the second factor equals

$$\left\| \sum_{\xi,\xi_2} \frac{\|\tilde{f}_2(\cdot,\xi_2)\|^\varrho_{L^2_\tau}}{\langle \xi_2 \rangle^{\frac{\varrho}{2}-}} \|\varphi(\cdot,\xi)\|^\varrho_{L^2_\tau} \|\tilde{f}_3(\cdot,\xi_1-\xi_2-\xi)\|^\varrho_{L^2_\tau} \right\|^{\frac{1}{\varrho}}_{\ell^{\frac{\varrho'}{\varrho}}_{\xi_1}},$$

where $\tilde{f}_j = f_j(-\cdot,-\cdot)$, $j=2,3$. This convolution is bounded by

$$\left\| \frac{\tilde{f}_2}{\langle \xi_2 \rangle^{\frac{1}{2}-}} \right\|_{\ell^\varrho_{\xi_2} L^2_\tau} \|\varphi\|_{\ell^r_\xi L^2_\tau} \|\tilde{f}_3\|_{\ell^{r'}_\xi L^2_\tau}$$

due to Young's inequality, because

$$2 + \frac{\varrho}{\varrho'} = 1 + \frac{\varrho}{r} + \frac{\varrho}{r'}.$$

Another application of Hölder's inequality with respect to f_2 yields

$$t_{1,1} \lesssim \|\varphi\|_{\ell^r_\xi L^2_\tau} \|f_1\|_{\ell^{q'}_\xi L^2_\tau} \|f_2\|_{\ell^{q'}_\xi L^2_\tau} \|f_3\|_{\ell^{r'}_\xi L^2_\tau}$$

for $4/3 < q \le r \le 2$.

Case 1.2. For the contribution $t_{1,2}$ the same approach as above leads to

$$t_{1,2} \lesssim \sum_{\xi_1 \in \mathbb{Z}} \|f_1(\cdot,\xi_1)\|_{L^2_\tau} \left(\sum_{\xi,\xi_2} \frac{\|\varphi(\cdot,\xi)\|^\varrho_{L^2_\tau} \|f_2(\cdot,\xi_2)\|^\varrho_{L^2_\tau} \|f_3(\cdot,\xi_3)\|^\varrho_{L^2_\tau}}{\langle \xi-\xi_1 \rangle^{\frac{\varrho}{2}-} \langle \xi-\xi_2 \rangle^{\frac{\varrho}{2}-}} \right)^{\frac{1}{\varrho}}$$

instead of (30) by replacing $\langle \xi_1 \rangle$, $\langle \xi_2 \rangle$ in $t_{1,1}$ by $\langle \xi-\xi_1 \rangle$, $\langle \xi-\xi_2 \rangle$, respectively. The only difference is the use of Corollary 3.2, estimate (19) to bound the sum

$$\Sigma_{1,2}(\mu_1) := \left(\sum_{\substack{\xi,\xi_2 \in \mathbb{Z} \\ \xi_1,\xi_2 \neq \xi}} \langle \xi-\xi_1 \rangle^{0-} \langle \xi-\xi_2 \rangle^{0-} \langle \sigma^{(1)}_{res} \rangle^{-1-} \right)^{\frac{1}{\varrho'}} .$$

Hölder's inequality in ξ_1 and then in ξ,ξ_2 provides

$$\begin{aligned} t_{1,2} &\lesssim \|f_1\|_{\ell^{q'}_\xi L^2_\tau} \left\| \left(\sum_{\xi,\xi_2} \frac{\|f_2(\cdot,\xi_2)\|^\varrho_{L^2_\tau} \|f_3(\cdot,\xi_3)\|^\varrho_{L^2_\tau} \|\varphi(\cdot,\xi)\|^\varrho_{L^2_\tau}}{\langle \xi-\xi_1 \rangle^{\frac{\varrho}{2}-} \langle \xi-\xi_2 \rangle^{\frac{\varrho}{2}-}} \right)^{\frac{1}{\varrho}} \right\|_{\ell^q_{\xi_1}} \\ &\lesssim \|f_1\|_{\ell^{q'}_\xi L^2_\tau} \left(\sum_{\xi,\xi_1,\xi_2 \in \mathbb{Z}} \frac{\|\varphi(\cdot,\xi)\|^q_{L^2}}{\langle \xi-\xi_1 \rangle^{1-\frac{q}{q'}+}} \frac{\|f_2(\cdot,\xi_2)\|^q_{L^2}}{\langle \xi-\xi_2 \rangle^{1-\frac{q}{q'}+}} \|f_3(\cdot,\xi_3)\|^q_{L^2} \right)^{\frac{1}{q}} . \end{aligned}$$

Now, Hölder's inequality in ξ and the change of variables $\xi_1 \mapsto \xi - \xi_1$ give

$$\left(\sum_{\xi,\xi_1,\xi_2 \in \mathbb{Z}} \frac{\|\varphi(\cdot,\xi)\|_{L^2}^q}{\langle \xi - \xi_1 \rangle^{1-\frac{q}{q'}+}} \frac{\|f_2(\cdot,\xi_2)\|_{L^2}^q}{\langle \xi - \xi_2 \rangle^{1-\frac{q}{q'}+}} \|f_3(\cdot,\xi_3)\|_{L^2}^q \right)^{\frac{1}{q}}$$
$$\lesssim \|\varphi\|_{\ell_\xi^r L_\tau^2} \left\| \sum_{\xi_2 \in \mathbb{Z}} \frac{\|f_2(\cdot,\xi_2)\|_{L^2}^q}{\langle \xi - \xi_2 \rangle^{1-\frac{q}{q'}+}} \sum_{\xi_1 \in \mathbb{Z}} \frac{\|f_3(\cdot,\xi_1-\xi_2)\|_{L^2}^q}{\langle \xi_1 \rangle^{1-\frac{q}{q'}+}} \right\|_{\ell_\xi^{\frac{r}{r-q}}}^{\frac{1}{q}}.$$

Let us define

$$\psi(\xi_2) = \sum_{\xi_1 \in \mathbb{Z}} \frac{\|f_3(\cdot,\xi_1-\xi_2)\|_{L^2}^q}{\langle \xi_1 \rangle^{1-\frac{q}{q'}+}}.$$

Young's inequality shows that

$$\|\psi\|_{\ell^{\frac{r}{r-q}}} \lesssim \|f_3\|_{\ell_\xi^{r'} L_\tau^2}^q$$

and therefore

$$\left\| \sum_{\xi_2 \in \mathbb{Z}} \frac{\|f_2(\cdot,\xi_2)\|_{L^2}^q}{\langle \xi - \xi_2 \rangle^{1-\frac{q}{q'}+}} \psi(\xi_2) \right\|_{\ell_\xi^{\frac{r}{r-q}}}^{\frac{1}{q}} \lesssim \|f_3\|_{\ell_\xi^{r'} L_\tau^2} \left\| \sum_{\xi_2 \in \mathbb{Z}} \frac{\|f_2(\cdot,\xi_2)\|_{L^2}^r}{\langle \xi - \xi_2 \rangle^{\frac{r}{q}-\frac{r}{q'}+}} \right\|_{\ell_\xi^{\frac{q}{r-q}}}^{\frac{1}{r}}$$

by Hölder's inequality in ξ_2. Due to the fact that

$$1 + \frac{r-q}{q} = \frac{r}{q'} + \frac{r}{q} - \frac{r}{q'},$$

Young's inequality shows that

$$t_{1,2} \lesssim \|\varphi\|_{\ell_\xi^r L_\tau^2} \|f_1\|_{\ell_\xi^{q'} L_\tau^2} \|f_2\|_{\ell_\xi^{q'} L_\tau^2} \|f_3\|_{\ell_\xi^{r'} L_\tau^2}$$

for all $4/3 < q \leq r \leq 2$.

Case 2.1. To control the contribution from $m_{2,1,\nu}$ we exchange the roles of f_1 and f_2, and the arguments from Case 1.1 apply.

Case 2.2. To control the contribution from $m_{2,2,\nu}$ we exchange the roles of f_1 and f_2, and the arguments from Case 1.2 apply.

Case 3.1. Fix $2 \leq q' < 4$ and $0 \leq \nu < \frac{1}{3q'}$. By the change of variables

$$\mu_1 \mapsto -\mu_1,\ \mu_2 \mapsto -\mu_2,\ \mu \mapsto \mu - \mu_1 - \mu_2 \tag{32}$$

we obtain for the contribution $t_{3,1}$ the identity

$$\sum_{\xi \in \mathbb{Z}} \int \frac{\varphi(\mu)}{\langle \sigma_0 \rangle^{\frac{1}{2}-\nu}} \sum_{\substack{\xi_1,\xi_2 \in \mathbb{Z} \\ \xi_1,\xi_2 \neq \xi}} \iint \frac{f_1(\mu_1)}{\langle \xi_1 \rangle^{\frac{1}{2}} \langle \sigma_1 \rangle^{\frac{1}{2}-\nu}} \frac{f_2(\mu_2)}{\langle \xi_2 \rangle^{\frac{1}{2}} \langle \sigma_2 \rangle^{\frac{1}{2}-\nu}} f_3(\mu_3) d\tau_1 d\tau_2 d\tau$$
$$= \sum_{\xi \in \mathbb{Z}} \int f_3(\mu) \sum_{\substack{\xi_1,\xi_2 \in \mathbb{Z} \\ \xi_1,\xi_2 \neq \xi}} \iint \frac{\tilde{f}_1(\mu_1)}{\langle \xi_1 \rangle^{\frac{1}{2}} \langle \tilde{\sigma}_1 \rangle^{\frac{1}{2}-\nu}} \frac{\tilde{f}_2(\mu_2)}{\langle \xi_2 \rangle^{\frac{1}{2}} \langle \tilde{\sigma}_2 \rangle^{\frac{1}{2}-\nu}} \frac{\varphi(\mu_3)}{\langle \tilde{\sigma}_3 \rangle^{\frac{1}{2}-\nu}} d\tau_1 d\tau_2 d\tau,$$

where $\tilde{\sigma}_1 = \tau_1 - \xi_1^2$, $\tilde{\sigma}_2 = \tau_2 - \xi_2^2$, $\tilde{\sigma}_3 = \tau - \tau_1 - \tau_2 + (\xi - \xi_1 - \xi_2)^2$, and $\tilde{f}_j = f_j(-\cdot, -\cdot)$, $j = 1, 2$. Using the Cauchy–Schwarz inequality in τ_1, τ_2 and Lemma 4.1, the quantity $t_{3,1}$ is bounded by

$$\sum_{\xi\in\mathbb{Z}} \int f_3(\mu) \sum_{\substack{\xi_1,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \langle \sigma_{res}^{(3)} \rangle^{\frac{1}{q'}-\frac{1}{2}-} \left(\iint \frac{\tilde{f}_1^2(\mu_1)\tilde{f}_2^2(\mu_2)\varphi^2(\mu_3)}{\langle \xi_1\rangle\langle\xi_2\rangle} d\tau_1 d\tau_2 \right)^{\frac{1}{2}} d\tau,$$

where $\sigma_{res}^{(3)} = \tau - \xi^2 + 2(\xi - \xi_1)(\xi - \xi_2)$. Hölder's inequality leads to

$$\sum_{\xi\in\mathbb{Z}} \int f_3(\mu)\Sigma_{3,1}(\mu) \left(\sum_{\substack{\xi_1,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \left(\iint \frac{\tilde{f}_1^2(\mu_1)\tilde{f}_2^2(\mu_2)\varphi^2(\mu_3)}{\langle \xi_1\rangle^{1-}\langle\xi_2\rangle^{1-}} d\tau_1 d\tau_2 \right)^{\frac{\varrho}{2}} \right)^{\frac{1}{\varrho}} d\tau$$

as an upper bound for $t_{3,1}$ with

$$\Sigma_{3,1}(\mu) = \left(\sum_{\substack{\xi_1,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \langle\xi_1\rangle^{0-}\langle\xi_2\rangle^{0-}\langle\sigma_{res}^{(3)}\rangle^{-1-} \right)^{\frac{1}{\varrho'}}$$

which is uniformly bounded by Corollary 3.2, estimate (20). By the Cauchy–Schwarz inequality in τ and Minkowski's inequality $t_{3,1}$ is dominated by

$$\sum_{\xi\in\mathbb{Z}} \|f_3(\cdot,\xi)\|_{L^2_\tau} \left(\sum_{\substack{\xi_1,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \frac{\|\tilde{f}_1(\cdot,\xi_1)\|_{L^2_\tau}^{\varrho} \|\tilde{f}_2(\cdot,\xi_2)\|_{L^2_\tau}^{\varrho} \|\varphi(\cdot,\xi_3)\|_{L^2_\tau}^{\varrho}}{\langle\xi_1\rangle^{\frac{\varrho}{2}-}\langle\xi_2\rangle^{\frac{\varrho}{2}-}} \right)^{\frac{1}{\varrho}}.$$

Now, we recall that $r \geq \varrho$ for all $4/3 < q \leq r \leq 2$ and apply Hölder's inequality and Fubini's theorem to obtain

$$\begin{aligned} t_{3,1} &\lesssim \|f_3\|_{\ell^{r'}_\xi L^2_\tau} \left\| \left(\sum_{\substack{\xi_1,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \frac{\|\tilde{f}_1(\cdot,\xi_1)\|_{L^2_\tau}^{\varrho} \|\tilde{f}_2(\cdot,\xi_2)\|_{L^2_\tau}^{\varrho} \|\varphi(\cdot,\xi_3)\|_{L^2_\tau}^{\varrho}}{\langle\xi_1\rangle^{\frac{\varrho}{2}-}\langle\xi_2\rangle^{\frac{\varrho}{2}-}} \right)^{\frac{1}{\varrho}} \right\|_{\ell^r_\xi} \\ &\lesssim \|f_3\|_{\ell^{r'}_\xi L^2_\tau} \left(\sum_{\substack{\xi,\xi_1,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \frac{\|\tilde{f}_1(\cdot,\xi_1)\|_{L^2_\tau}^{r} \|\tilde{f}_2(\cdot,\xi_2)\|_{L^2_\tau}^{r} \|\varphi(\cdot,\xi_3)\|_{L^2_\tau}^{r}}{\langle\xi_1\rangle^{1-\frac{r}{q'}+}\langle\xi_2\rangle^{1-\frac{r}{q'}+}} \right)^{\frac{1}{r}}. \end{aligned} \tag{33}$$

Again, Hölder's inequality shows that

$$\left(\sum_{\xi_i\in\mathbb{Z}} \|\tilde{f}_i(\cdot,\xi_i)\|_{L^2}^r \langle\xi_i\rangle^{\frac{r}{q'}-1-} \right)^{\frac{1}{r}} \lesssim \|f_i\|_{\ell^{q'}_\xi L^2_\tau}, \quad i = 1, 2.$$

Hence,

$$t_{3,1} \lesssim \|f_1\|_{\ell^{q'}_\xi L^2_\tau} \|f_2\|_{\ell^{q'}_\xi L^2_\tau} \|f_3\|_{\ell^{r'}_\xi L^2_\tau} \|\varphi\|_{\ell^r_\xi L^2_\tau}$$

for $4/3 < q \le r \le 2$, as desired.

Case 3.2. To obtain the contribution $t_{3,2}$ we replace $\langle \xi_1 \rangle$ and $\langle \xi_2 \rangle$ in $t_{3,1}$ by $\langle \xi - \xi_1 \rangle$ and $\langle \xi - \xi_2 \rangle$, respectively. The change of variables (32) transforms $\langle \xi - \xi_1 \rangle$ into $\langle \xi - \xi_2 \rangle$ and vice versa, and we follow the arguments above to obtain

$$t_{3,2} \lesssim \|f_3\|_{\ell_\xi^{r'} L_\tau^2} \left(\sum_{\substack{\xi,\xi_1,\xi_2 \in \mathbb{Z} \\ \xi_1,\xi_2 \neq \xi}} \frac{\|\tilde{f}_1(\cdot,\xi_1)\|_{L_\tau^2}^r \|\tilde{f}_2(\cdot,\xi_2)\|_{L_\tau^2}^r \|\varphi(\cdot,\xi_3)\|_{L_\tau^2}^r}{\langle \xi - \xi_1 \rangle^{1-\frac{r}{q'}+} \langle \xi - \xi_2 \rangle^{1-\frac{r}{q'}+}} \right)^{\frac{1}{r}}$$

instead of (33), with the only exception that

$$\Sigma_{3,2}(\mu) := \left(\sum_{\substack{\xi_1,\xi_2 \in \mathbb{Z} \\ \xi_1,\xi_2 \neq \xi}} \langle \xi - \xi_1 \rangle^{0-} \langle \xi - \xi_2 \rangle^{0-} \langle \sigma_{res}^{(3)} \rangle^{-1-} \right)^{\frac{1}{\varrho'}}$$

is controlled by Corollary 3.2, estimate (18). Similar to Case 0.2, the change of variables $\xi \mapsto \xi - \xi_1 - \xi_2$ and Hölder's inequality

$$\sup_{\xi \in \mathbb{Z}} \left(\sum_{\xi_i \in \mathbb{Z}} \|f_i(\cdot,\xi_i)\|_{L^2}^r \langle \xi + \xi_i \rangle^{\frac{r}{q'}-1-} \right)^{\frac{1}{r}} \lesssim \|f_i\|_{\ell_\xi^{q'} L_\tau^2}, \quad i = 1,2,$$

yield

$$t_{3,2} \lesssim \|f_1\|_{\ell_\xi^{q'} L_\tau^2} \|f_2\|_{\ell_\xi^{q'} L_\tau^2} \|f_3\|_{\ell_\xi^{r'} L_\tau^2} \|\varphi\|_{\ell_\xi^{r} L_\tau^2},$$

and the estimate for T^* is done. Finally, we consider the harmless contribution from T^{**} and show the much stronger estimate

$$\|T^{**}(u_1,u_2,u_3)\|_{X_{r,2}^{\frac{1}{2},0}} \lesssim \|u_1\|_{X_{1,2}^{\frac{1}{2},\frac{1}{3}+}} \|u_2\|_{X_{1,2}^{\frac{1}{2},\frac{1}{3}+}} \|u_3\|_{X_{r,2}^{\frac{1}{2},\frac{1}{3}+}}, \tag{34}$$

which immediately yields the desired estimate by trivial embeddings and (27). Indeed, Young's and Hölder's inequalities provide

$$\begin{aligned} &\left\| \langle \xi \rangle^{\frac{1}{2}} \xi \int \frac{f_1(\tau_1,\xi)}{\langle \xi \rangle^{\frac{1}{2}} \langle \tau_1 + \xi^2 \rangle^{\frac{1}{3}+}} \frac{f_2(\tau_2,\xi)}{\langle \xi \rangle^{\frac{1}{2}} \langle \tau_2 + \xi^2 \rangle^{\frac{1}{3}+}} \frac{f_3(\tau_3,-\xi)}{\langle \xi \rangle^{\frac{1}{2}} \langle \tau_3 - \xi^2 \rangle^{\frac{1}{3}+}} d\tau_1 d\tau_2 \right\|_{\ell_\xi^{r'} L_\tau^2} \\ \lesssim &\left\| \left\| \frac{f_1(\tau_1,\xi)}{\langle \tau_1 + \xi^2 \rangle^{\frac{1}{3}+}} \right\|_{L_{\tau_1}^{\frac{6}{5}}} \left\| \frac{f_2(\tau_2,\xi)}{\langle \tau_2 + \xi^2 \rangle^{\frac{1}{3}+}} \right\|_{L_{\tau_2}^{\frac{6}{5}}} \left\| \frac{f_3(\tau_3,-\xi)}{\langle \tau_3 - \xi^2 \rangle^{\frac{1}{3}+}} \right\|_{L_{\tau_3}^{\frac{6}{5}}} \right\|_{\ell_\xi^{r'}} \\ \lesssim &\|f_1\|_{\ell_\xi^\infty L_\tau^2} \|f_2\|_{\ell_\xi^\infty L_\tau^2} \|f_3\|_{\ell_\xi^{r'} L_\tau^2}. \end{aligned}$$

This concludes the proof of Theorem 2.4. ☐

Proof of Theorem 2.5. Due to the emdedding (6) the estimate for T^{**} is already covered by (34). With the same notation as above, the estimate (10) for the contribution T^* is equivalent to

$$\begin{aligned} &\left\| \sum_{\substack{\xi_1,\xi_2 \in \mathbb{Z} \\ \xi_1 \neq \xi,\, \xi_2 \neq \xi}} \int n(\mu,\mu_1,\mu_2) f_1(\mu_1) f_2(\mu_2) f_3(\mu_3) d\tau_1 d\tau_2 \right\|_{\ell_\xi^{r'} L_\tau^1} \\ &\lesssim T^\delta \|f_1\|_{\ell_\xi^{q'} L_\tau^2} \|f_2\|_{\ell_\xi^{q'} L_\tau^2} \|f_3\|_{\ell_\xi^{r'} L_\tau^2}, \end{aligned} \tag{35}$$

where $n = \langle\sigma_0\rangle^{-\frac{1}{2}} m$. We decompose $n_{k,j} = \langle\sigma_0\rangle^{-\frac{1}{2}} m_{k,j}$ as above. Again, due to the embedding (6) the stronger estimate (26) already proves estimate (35) for n replaced by $n_{k,j,\nu}$ with $k = 1,2,3$, $j = 1,2$, corresponding to Cases 1–3 above. Hence, it is enough to consider the case $k = 0$, where $\langle\sigma_0\rangle$ is the maximal modulation.

Case 0.1. Let us fix $1 < q \le r \le 2$ and $0 \le \delta < \frac{1}{q'}$. We proceed similarly to the Case 0.1 in the proof of Theorem 2.4:

$$\widetilde{t_{0,1}} := \left\| \langle\sigma_0\rangle^{-\frac{1}{2}} \sum_{\substack{\xi_1,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \int \frac{f_1(\mu_1)}{\langle\xi_1\rangle^{\frac{1}{2}}\langle\sigma_1\rangle^{\frac{1}{2}-\nu}} \frac{f_2(\mu_2)}{\langle\xi_2\rangle^{\frac{1}{2}}\langle\sigma_2\rangle^{\frac{1}{2}-\nu}} \frac{f_3(\mu_3)}{\langle\sigma_3\rangle^{\frac{1}{2}-\nu}} d\tau_1 d\tau_2 \right\|_{\ell^{r'}_\xi L^1_\tau}$$
$$\lesssim \left\| \sum_{\substack{\xi_1,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \int \frac{g_1(\mu_1)}{\langle\xi_1\rangle^{\frac{1}{2}}\langle\sigma_1\rangle^{\frac{1}{2}-\nu-}} \frac{g_2(\mu_2)}{\langle\xi_2\rangle^{\frac{1}{2}}\langle\sigma_2\rangle^{\frac{1}{2}-\nu-}} \frac{g_3(\mu_3)}{\langle\sigma_3\rangle^{\frac{1}{2}-\nu-}} d\tau_1 d\tau_2 \right\|_{\ell^{r'}_\xi L^p_\tau}$$

for any $p = 2-$, where we define $g_j = \langle\sigma_j\rangle^{0-} f_j$ such that

$$\|g_j\|_{\ell^{q'}_\xi L^p_\tau} \lesssim \|f_j\|_{\ell^{q'}_\xi L^2_\tau}. \tag{36}$$

Now, by Hölder's inequality and two applications of Lemma 4.1 we get

$$\widetilde{t_{0,1}} \lesssim \left\| \sum_{\substack{\xi_1,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \langle\xi_1\rangle^{-\frac{1}{2}}\langle\xi_2\rangle^{-\frac{1}{2}}\langle\sigma^{(0)}_{res}\rangle^{\frac{1}{q'}-\frac{1}{2}-} \left(\int g_1^p g_2^p g_3^p d\tau_1 d\tau_2\right)^{\frac{1}{p}} \right\|_{\ell^{r'}_\xi L^p_\tau}$$

with $\sigma^{(0)}_{res} = \tau + \xi^2 - 2(\xi-\xi_1)(\xi-\xi_2)$. Hölder's inequality in ξ_1, ξ_2 leads to

$$\widetilde{t_{0,1}} \lesssim \left\| \widetilde{\Sigma_{0,1}}(\mu) \left(\sum_{\xi_1,\xi_2\in\mathbb{Z}} \left(\int \frac{g_1^p(\mu_1)}{\langle\xi_1\rangle^{1-}} \frac{g_2^p(\mu_2)}{\langle\xi_2\rangle^{1-}} g_3^p(\mu_3) d\tau_1 d\tau_2 \right)^{\frac{\varrho}{p}} \right)^{\frac{1}{\varrho}} \right\|_{\ell^{r'}_\xi L^p_\tau},$$

where

$$\widetilde{\Sigma_{0,1}}(\mu) := \left(\sum_{\substack{\xi_1,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \langle\xi_1\rangle^{0-}\langle\xi_2\rangle^{0-}\langle\sigma^{(0)}_{res}\rangle^{-1-} \right)^{\frac{1}{\varrho'}}$$

for $\varrho = \frac{2q'}{q'+2}+$ and $\varrho' = \frac{2q'}{q'-2}-$. The sum $\widetilde{\Sigma_{0,1}}(\mu)$ is uniformly bounded due to Corollary 3.2, estimate (20). Hence,

$$\widetilde{t_{0,1}} \lesssim \left\| \left(\sum_{\xi_1,\xi_2\in\mathbb{Z}} \frac{\|g_1(\cdot,\xi_1)\|^\varrho_{L^p}}{\langle\xi_1\rangle^{\frac{\varrho}{2}-}} \frac{\|g_2(\cdot,\xi_2)\|^\varrho_{L^p}}{\langle\xi_2\rangle^{\frac{\varrho}{2}-}} \|g_3(\cdot,\xi_3)\|^\varrho_{L^p} \right)^{\frac{1}{\varrho}} \right\|_{\ell^{r'}_\xi}$$

by Minkowski's inequality because $\varrho \le p$. Now, we apply Hölder's inequality and Fubini's theorem as in Case 0.1 of the proof of Theorem 2.4 and obtain

$$\widetilde{t_{0,1}} \lesssim \|g_1\|_{\ell^{q'}_\xi L^p_\tau}\|g_2\|_{\ell^{q'}_\xi L^p_\tau}\|g_3\|_{\ell^{r'}_\xi L^p_\tau}$$

for any $1 < q \le r \le 2$. Finally, (36) proves the desired estimate.

Case 0.2. We consider $\widetilde{t_{0,2}}$ defined as

$$\left\| \langle\sigma_0\rangle^{-\frac{1}{2}} \sum_{\substack{\xi_1,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \int \frac{f_1(\mu_1)}{\langle\xi-\xi_1\rangle^{\frac{1}{2}}\langle\sigma_1\rangle^{\frac{1}{2}-\nu}} \frac{f_2(\mu_2)}{\langle\xi-\xi_2\rangle^{\frac{1}{2}}\langle\sigma_2\rangle^{\frac{1}{2}-\nu}} \frac{f_3(\mu_3)}{\langle\sigma_3\rangle^{\frac{1}{2}-\nu}} d\tau_1 d\tau_2 \right\|_{\ell^{r'}_\xi L^1_\tau}.$$

The same arguments as in the previous case lead to

$$\widetilde{t_{0,2}} \lesssim \left\| \left(\sum_{\xi_1,\xi_2\in\mathbb{Z}} \frac{\|g_1(\cdot,\xi_1)\|^{\varrho}_{L^p}}{\langle\xi-\xi_1\rangle^{\frac{\varrho}{2}-}} \frac{\|g_2(\cdot,\xi_2)\|^{\varrho}_{L^p}}{\langle\xi-\xi_2\rangle^{\frac{\varrho}{2}-}} \|g_3(\cdot,\xi_3)\|^{\varrho}_{L^p} \right)^{\frac{1}{\varrho}} \right\|_{\ell^{r'}_\xi},$$

where we used Corollary 3.2, estimate (18) to bound the sum

$$\widetilde{\Sigma_{0,2}}(\mu) := \left(\sum_{\substack{\xi_1,\xi_2\in\mathbb{Z}\\ \xi_1,\xi_2\neq\xi}} \langle\xi-\xi_1\rangle^{0-}\langle\xi-\xi_2\rangle^{0-}\langle\sigma^{(0)}_{res}\rangle^{-1-} \right)^{\frac{1}{\varrho'}}.$$

By the change of variables $\xi \mapsto \xi-\xi_1-\xi_2$ we obtain

$$\widetilde{t_{0,2}} \lesssim \left(\sum_{\xi,\xi_1,\xi_2\in\mathbb{Z}} \frac{\|g_1(\cdot,\xi_1)\|^{r'}_{L^p}}{\langle\xi+\xi_1\rangle^{1-\frac{r'}{q'}+}} \frac{\|g_2(\cdot,\xi_2)\|^{r'}_{L^p}}{\langle\xi+\xi_2\rangle^{1-\frac{r'}{q'}+}} \|g_3(\cdot,\xi)\|^{r'}_{L^p} \right)^{\frac{1}{r'}}.$$

Now, we sum first in ξ_1,ξ_2 and use the analogue of (29) for $\|g_i\|_{L^p_\tau}$ $(i=1,2)$ to obtain

$$\widetilde{t_{0,2}} \lesssim \|g_1\|_{\ell^{q'}_\xi L^p_\tau}\|g_2\|_{\ell^{q'}_\xi L^p_\tau}\|g_3\|_{\ell^{r'}_\xi L^p_\tau}$$

and recall the property (36) of g_j. ◻

Proof of Remark 3. Assume that the estimate (11) is valid for some $b \le 0$, $1 \le r \le \frac{4}{3}$, and $1 \le p,q \le \infty$. Then for all $f_i \in \ell^{r'}_\xi L^{q'}_\tau$ $(1 \le i \le 3)$ and $f_0 \in \ell^r_\xi L^p_\tau$ we have

$$\sum_{\substack{\xi,\xi_1,\xi_2\in\mathbb{Z}\\ \xi_1\neq\xi,\ \xi_2\neq\xi}} \int \frac{\langle\xi\rangle^{\frac{1}{2}} f_0(\mu) f_1(\mu_1) f_2(\mu_2)|\xi_3| f_3(\mu_3)}{\langle\sigma_0\rangle^{-b}\langle\xi_1\rangle^{\frac{1}{2}}\langle\sigma_1\rangle^{\frac{1}{2}}\langle\xi_2\rangle^{\frac{1}{2}}\langle\sigma_2\rangle^{\frac{1}{2}}\langle\xi_3\rangle^{\frac{1}{2}}\langle\sigma_3\rangle^{\frac{1}{2}}} d\tau d\tau_1 d\tau_2 < \infty. \tag{37}$$

We choose

$$\begin{aligned}
f_0(0,\tau) &= \chi(\tau) \text{ and } f_0(\xi,\tau) = 0 \quad \text{for } \xi \neq 0,\\
f_2(1,\tau_2) &= \chi(\tau_2) \text{ and } f_2(\xi_2,\tau_2) = 0 \quad \text{for } \xi_2 \neq 1,\\
f_1(0,\tau_1) &= 0 \text{ and } f_1(\xi_1,\tau_1) = \frac{\chi(\tau_1+(\xi_1+1)^2)}{\langle\xi_1\rangle^{\frac{1}{4}}\ln^{\frac{1}{3}}(\langle\xi_1\rangle)} \quad \text{for } \xi_1 \neq 0,\\
f_3(0,\tau_3) &= 0 \text{ and } f_3(\xi_3,\tau_3) = \frac{\chi(\tau_3-\xi_3^2)}{\langle\xi_3\rangle^{\frac{1}{4}}\ln^{\frac{1}{3}}(\langle\xi_3\rangle)} \quad \text{for } \xi_3 \neq 0,
\end{aligned}$$

where χ denotes the characteristic function of $[-1,1]$. Then $f_0 \in \ell^r_\xi L^p_\tau$ and $f_2 \in \ell^{r'}_\xi L^{q'}_\tau$ for all $1 \le r,p,q \le \infty$ and $f_1, f_3 \in \ell^{r'}_\xi L^{q'}_\tau$ for all $r' \ge 4$ and $1 \le q \le \infty$. Let $I(\xi_1)$ be defined as

$$
\begin{aligned}
&\int \chi(\tau)\chi(\tau_1 + (\xi_1+1)^2)\chi(\tau_2)\chi(\tau - \tau_1 - \tau_2 - (\xi_1+1)^2)d\tau d\tau_1 d\tau_2 \\
\gtrsim &\int \chi(\tau)\chi(\tau_1 + (\xi_1+1)^2)\chi(\tau - \tau_1 - (\xi_1+1)^2)d\tau_1 d\tau \\
\gtrsim &\int \chi(\tau_1 + (\xi_1+1)^2)d\tau_1 \gtrsim 1.
\end{aligned}
$$

Due to $\langle\sigma_1\rangle^{\frac12} \lesssim \langle\xi_1\rangle^{\frac12}$, the left-hand side of (37) becomes

$$
\sum_{|\xi_1|\ge 1} \frac{I(\xi_1)}{\langle\xi_1\rangle \ln^{\frac23}(\langle\xi_1\rangle)} \gtrsim \sum_{|\xi_1|\ge 1} \frac{1}{\langle\xi_1\rangle \ln^{\frac23}(\langle\xi_1\rangle)} = \infty,
$$

which contradicts (37). ☐

5. The proof of the quintilinear estimate. Before we start with the proof of Theorem 2.6 we show the following trilinear refinement of the L^6 Strichartz-type estimate; see [3, Proposition 2.36]. The major point is that for one of the factors the loss of ε derivatives can be avoided. In fact, this refinement also follows by carefully using the decomposition arguments and the Galilean transformation in [3, section 5]. However, we decided to present a proof based on the representation $\|u\|^3_{L^6_{xt}} = \|u^2\overline{u}\|_{L^2_{xt}}$ which we learned from [23], in combination with the estimates from section 3. Similar arguments were already used in [10, Proposition 4.6 and its proof].

LEMMA 5.1. *For $\frac13 < b < \frac12$ and $s > 3(\frac12 - b)$ the estimate*

$$
\|u_1 u_2 \overline{u}_3\|_{L^2_{xt}} \lesssim \|u_1\|_{X^{s,b}} \|u_2\|_{X^{s,b}} \|u_3\|_{X^{0,b}} \tag{38}
$$

holds true.

Proof. We rewrite $u_1 u_2 \overline{u}_3 = C_1(u_1,u_2,u_3) + C_2(u_1,u_2,u_3)$ for

$$
\begin{aligned}
\widehat{C_1(u_1,u_2,u_3)}(\xi) &= (2\pi)^{-1} \sum_{\substack{\xi=\xi_1+\xi_2+\xi_3 \\ \xi_1\neq\xi,\, \xi_2\neq\xi}} \widehat{u}_1(\xi_1)\widehat{u}_2(\xi_2)\widehat{\overline{u}}_3(\xi_3), \\
\widehat{C_2(u_1,u_2,u_3)}(\xi) &= (2\pi)^{-1} \sum_{\substack{\xi=\xi_1+\xi_2+\xi_3 \\ \xi_1=\xi \text{ or } \xi_2=\xi}} \widehat{u}_1(\xi_1)\widehat{u}_2(\xi_2)\widehat{\overline{u}}_3(\xi_3),
\end{aligned}
$$

where we suppressed the t dependence. By Plancherel's identity we observe that

$$
C_2(u_1,u_2,u_3) = u_1 \fint_0^{2\pi} u_2\overline{u}_3 dy + u_2 \fint_0^{2\pi} u_1 \overline{u}_3 dy - u_1 * u_2 * \overline{u}_3,
$$

where $*$ denotes convolution with respect to normalized Lebesgue measure on $[0,2\pi]$. Clearly,

$$
\|C_2(u_1,u_2,u_3)\|_{L^2_t L^2_x} \lesssim \prod_{1\le k\le 3} \|u_k\|_{L^6_t L^2_x} \lesssim \prod_{1\le k\le 3} \|u_k\|_{X^{0,\frac13}}
$$

by Sobolev estimates in the time variable. For the convolution term we also used Young's inequality. So it remains to prove (38) with $\|u_1 u_2 \overline{u}_3\|_{L^2_{xt}}$ on the left-hand side replaced by $\|C_1(u_1,u_2,u_3)\|_{L^2_{xt}}$. Now by the Cauchy–Schwarz inequality and Fubini's theorem (cf. the arguments in the previous section), matters reduce to show that

$$\sup_{\xi,\tau} \Sigma(\xi,\tau) < \infty,$$

where $\Sigma(\xi,\tau)$ is defined as

$$\sum_{\substack{\xi=\xi_1+\xi_2+\xi_3\\ \xi_1\neq\xi,\,\xi_2\neq\xi}} \langle\xi_1\rangle^{-2s}\langle\xi_2\rangle^{-2s}\int \langle\tau_1+\xi_1^2\rangle^{-2b}\langle\tau_2+\xi_2^2\rangle^{-2b}\langle\tau_3-\xi_3^2\rangle^{-2b}d\tau_1 d\tau_2.$$

Using Lemma 4.1 twice, we see that

$$\begin{aligned}\Sigma(\xi,\tau) &\lesssim \sum_{\substack{\xi=\xi_1+\xi_2+\xi_3\\ \xi_1\neq\xi,\,\xi_2\neq\xi}} \langle\xi_1\rangle^{-2s}\langle\xi_2\rangle^{-2s}\langle\tau+\xi^2-2(\xi-\xi_1)(\xi-\xi_2)\rangle^{2-6b}\\ &\lesssim \left(\sum_{\substack{\xi=\xi_1+\xi_2+\xi_3\\ \xi_1\neq\xi,\,\xi_2\neq\xi}} \langle\xi_1\rangle^{0-}\langle\xi_2\rangle^{0-}\langle\tau+\xi^2-2(\xi-\xi_1)(\xi-\xi_2)\rangle^{\frac{2-6b}{1-2s}-}\right)^{(1-2s)+}\end{aligned}$$

by Hölder's inequality. Since by assumption $\frac{2-6b}{1-2s}<-1$, a final application of Corollary 3.2, part 3, completes the proof. $\square$

In the L^2_{xt}-norm on the left-hand side of (38) we may, of course, replace any single factor by its complex conjugate. Especially we have

$$\|u_1u_2\overline{u}_3\|_{L^2_{xt}} \lesssim \|u_1\|_{X^{0,b}}\|u_2\|_{X^{s,b}}\|u_3\|_{X^{s,b}}. \tag{39}$$

Fixing u_2 and u_3 and considering the linear operator

$$X^{0,b}\to L^2_{xt}: \quad u_1\mapsto u_1u_2\overline{u}_3$$

we obtain by duality the estimate

$$\|v\overline{u}_2u_3\|_{X^{0,-b}} \lesssim \|v\|_{L^2_{xt}}\|u_2\|_{X^{s,b}}\|u_3\|_{X^{s,b}}. \tag{40}$$

Choosing $v=u_1\overline{u}_4u_5$ and applying (39) (and (38), respectively) again, we have shown the following quintilinear estimate.

Corollary 5.2. *Set $i=1$ or $i=4$. For $\frac{1}{3}<b_0<\frac{1}{2}$ and $s_0>3(\frac{1}{2}-b_0)$ the estimate*

$$\|u_1\overline{u}_2u_3\overline{u}_4u_5\|_{X^{0,-b_0}} \lesssim \|u_i\|_{X^{0,b_0}}\prod_{\substack{k=1\\k\neq i}}^{5}\|u_k\|_{X^{s_0,b_0}} \tag{41}$$

is valid.

In order to prove Theorem 2.6 we shall rely on the interpolation properties of our scale of spaces obtained by the complex method.

Lemma 5.3. *Let $s_i,b_i\in\mathbb{R}$, $1<r_i,p_i<\infty$ for $i=1,2$. Then*

$$(X^{s_0,b_0}_{r_0,p_0},X^{s_1,b_1}_{r_1,p_1})_{[\theta]} = X^{s,b}_{r,p} \qquad (0<\theta<1),$$

where

$$s = (1-\theta)s_0 + \theta s_1, \quad b = (1-\theta)b_0 + \theta b_1,$$
$$\frac{1}{r} = \frac{1-\theta}{r_0} + \frac{\theta}{r_1}, \quad \frac{1}{p} = \frac{1-\theta}{p_0} + \frac{\theta}{p_1}.$$

Proof. The map

$$\mathcal{F} \circ e^{-it\partial_x^2} : X^{s,b}_{r,p} \to \ell^{r'}_\xi(\langle\xi\rangle^s; L^{p'}_\tau(\langle\tau\rangle^b))$$

is an isometric isomorphism. Here, the image space is the space of sequences in $\ell^{r'}_\xi$ with weight $\langle\xi\rangle^s$, taking values in $L^{p'}_\tau$ with weight $\langle\tau\rangle^b$ (with the natural norm). Now, arguing as in [1, Theorem 5.6.3] (replacing 2^k by k) and using [1, Theorem 5.5.3] the claim follows. ∎

Proof of Theorem 2.6. By Sobolev-type embeddings and Young's inequality, we see that for $r_1, q_1 > 1$, $s_1 > \frac{1}{q_1}$, $b_1 > \frac{1}{3}$, and an auxiliary exponent p with $b_1 + \frac{1}{2} > \frac{1}{p} > 5(\frac{1}{2} - b_1)$

$$\begin{aligned} \|u_1\overline{u}_2u_3\overline{u}_4u_5\|_{X^{0,-b_1}_{r_1,2}} &\lesssim \|u_1\overline{u}_2u_3\overline{u}_4u_5\|_{X^{0,0}_{r_1,p}} \\ &\leq \|u_1\|_{X^{0,0}_{r_1,5p}} \prod_{i=2}^{5} \|u_i\|_{X^{0,0}_{\infty,5p}} \\ &\lesssim \|u_1\|_{X^{0,b_1}_{r_1,2}} \prod_{i=2}^{5} \|u_i\|_{X^{s_1,b_1}_{q_1,2}}. \end{aligned} \tag{42}$$

Now fix $\frac{4}{3} < q \leq r \leq 2$ and $b > \frac{1}{6} + \frac{1}{3q}$. We will use complex multilinear[6] interpolation [1, Theorem 4.4.1] between (41) and (42) with interpolation parameter $\theta = \frac{1}{2}$. To do so, we choose

$$s_0 = \frac{3}{2} - \frac{2}{q} - \varepsilon, \quad b_0 = \frac{2}{3q} + \varepsilon$$

in the endpoint (41) and

$$\frac{1}{r_1} = \frac{2}{r} - \frac{1}{2}, \quad \frac{1}{q_1} = \frac{2}{q} - \frac{1}{2}, \quad s_1 = \frac{2}{q} - \frac{1}{2} + \varepsilon, \quad b_1 = \frac{1}{3} + \varepsilon$$

in the endpoint (42), where $\varepsilon := b - \frac{1}{6} - \frac{1}{3q} > 0$, and we use Lemma 5.3. As a result,

$$\|u_1\overline{u}_2u_3\overline{u}_4u_5\|_{X^{0,-b}_{r,2}} \lesssim \|u_1\|_{X^{0,b}_{r,2}} \prod_{i=2}^{5} \|u_i\|_{X^{\frac{1}{2},b}_{q,2}},$$

where in the last line of (42) as well as in the last expression we may exchange u_1 and u_4. Now our first claim (13) follows from $\langle\xi\rangle \leq \sum_{1\leq i\leq 5}\langle\xi_i\rangle$. We use (6) of Lemma 2.2, that is, $X^{\frac{1}{2},-\frac{1}{2}+}_{r,2} \subset X^{\frac{1}{2},-1}_{r,\infty}$, and apply (27) with $\nu = \frac{1}{3q'}-$ to all six norms appearing, which gives a factor $T^{\frac{2}{q'}-}$. Finally, (15) follows from (14), and the proof of Theorem 2.6 is complete. ∎

---

[6] Due to the fact that $\|\langle\xi\rangle^s\langle\tau+\xi^2\rangle^b\widehat{\overline{u}}\|_{\ell^r_\xi L^p_\tau} = \|\langle\xi\rangle^s\langle\tau-\xi^2\rangle^b\widehat{u}\|_{\ell^r_\xi L^p_\tau}$ it is equivalent to remove the complex conjugate on the second and fourth functions at the expense of changing signs in the weight of the respective norm. Of course, the analogue of Lemma 5.3 for the corresponding spaces is valid. With this modification the estimate becomes complex linear in each factor.

6. The gauge transform. In this subsection we study a nonlinear transformation which turned out to be a key ingredient to the well-posedness theory of (DNLS). This type of transformation for (DNLS) was already used by Hayashi and Ozawa [16, 17] and Hayashi [15], and later by Takaoka [25], in the nonperiodic case and then adapted to the periodic setting by the second author in [18, 19]. Let us define for $u \in C([-T,T], L^2(\mathbb{T}))$

$$\mathcal{G}_0 u := \exp\left(-i\mathcal{I}u\right) u, \tag{43}$$

where

$$\mathcal{I}u(t,x) := \fint_0^{2\pi} \int_\theta^x \left(|u(t,y)|^2 - \fint_0^{2\pi} |u(t,z)|^2 dz \right) dy d\theta \tag{44}$$

is the unique primitive of

$$x \mapsto |u(t,x)|^2 - \fint_0^{2\pi} |u(t,z)|^2 dz$$

with vanishing mean value.

Before we study the mapping properties of this transformation let us recall the Sobolev multiplication law in our setting.

LEMMA 6.1. *Let $1 < r < \infty$, $0 \le s \le s_1$, and $s_1 > \frac{1}{r}$. Then*

$$\|u_1 u_2\|_{\widehat{H}^s_r} \lesssim \|u_1\|_{\widehat{H}^{s_1}_r} \|u_2\|_{\widehat{H}^s_r}. \tag{45}$$

In particular, for $1 < r < \infty$, $s > \frac{1}{r}$ we have

$$\|u_1 u_2\|_{\widehat{H}^s_r} \lesssim \|u_1\|_{\widehat{H}^s_r} \|u_2\|_{\widehat{H}^s_r}. \tag{46}$$

Proof. We have $\langle \xi \rangle^s \lesssim \langle \xi - \xi_1 \rangle^s + \langle \xi_1 \rangle^{s_1} \langle \xi - \xi_1 \rangle^{s - s_1}$, and by Young's inequality

$$\begin{aligned}
\|u_1 u_2\|_{\widehat{H}^s_r} &\lesssim \|\widehat{u}_1\|_{\ell^1} \|\langle \xi \rangle^s \widehat{u}_2\|_{\ell^{r'}} + \|\langle \xi \rangle^{s_1} \widehat{u}_1\|_{\ell^{r'}} \|\langle \xi \rangle^{s-s_1} \widehat{u}_2\|_{\ell^1} \\
&\lesssim \|u_1\|_{\widehat{H}^{s_1}_r} \|u_2\|_{\widehat{H}^s_r}
\end{aligned}$$

because $\|\langle \xi \rangle^{-s_1} \widehat{u}_i\|_{\ell^1} \lesssim \|\widehat{u}_i\|_{\ell^{r'}}$, $i = 1, 2$. ∎

LEMMA 6.2. *Let $1 < r \le 2$ and $s > \frac{1}{r} - \frac{1}{2}$ or $r = 2$ and $s \ge 0$. Then*

$$\mathcal{G}_0 : C([-T,T], \widehat{H}^s_r(\mathbb{T})) \to C([-T,T], \widehat{H}^s_r(\mathbb{T}))$$

is a locally bi-Lipschitz homeomorphism with inverse $\mathcal{G}_0^{-1} u = \exp\left(i\mathcal{I}u\right) u$.

Proof. We will transfer the ideas from the proof of [18, Lemma 2.3] (where the claim is shown in the L^2 setting) to the case $1 < r < 2$ and $s > \frac{1}{r} - \frac{1}{2}$. Obviously, it suffices to prove

$$\begin{aligned}
&\|(\exp(\pm i\mathcal{I}f) - \exp(\pm i\mathcal{I}g))\, h\|_{\widehat{H}^s_r} \\
&\lesssim \exp(c\|f\|^2_{\widehat{H}^s_r} + c\|g\|^2_{\widehat{H}^s_r}) \|f - g\|_{\widehat{H}^s_r} \|h\|_{\widehat{H}^s_r}
\end{aligned} \tag{47}$$

for smooth $f, g, h \in \widehat{H}^s_r$. By the series expansion of the exponential and (45) we infer that the left-hand side of (47) is bounded by

$$\|h\|_{\widehat{H}^s_r} \|\mathcal{I}f - \mathcal{I}g\|_{\widehat{H}^{s_1}_r} \sum_{n=1}^\infty \frac{c^n}{n!} \sum_{k=0}^{n-1} \|\mathcal{I}f\|^k_{\widehat{H}^{s_1}_r} \|\mathcal{I}g\|^{n-1-k}_{\widehat{H}^{s_1}_r}$$

for $s_1 = \max\{\frac{1}{r}+, s\}$. By the definition of $\mathcal{I}$ it follows that

$$\|\mathcal{I}f - \mathcal{I}g\|_{\widehat{H}_r^{s_1}} \lesssim \||f|^2 - |g|^2\|_{\widehat{H}_r^{s_1-1}}.$$

In the case $s \le \frac{1}{r}$ we have

$$\||f|^2 - |g|^2\|_{\widehat{H}_r^{s_1-1}} \lesssim (\|\widehat{f}\|_{\ell^{2-}} + \|\widehat{g}\|_{\ell^{2-}})\|\widehat{f} - \widehat{g}\|_{\ell^{2-}}.$$

Because $s > \frac{1}{r} - \frac{1}{2}$ we find

$$\|\mathcal{I}f - \mathcal{I}g\|_{\widehat{H}_r^{s_1}} \lesssim \left(\|f\|_{\widehat{H}_r^s} + \|g\|_{\widehat{H}_r^s}\right)\|f - g\|_{\widehat{H}_r^s}.$$

In the case $s > \frac{1}{r}$ we use (46) to deduce

$$\||f|^2 - |g|^2\|_{\widehat{H}_r^{s_1-1}} \lesssim \|f - g\|_{\widehat{H}_r^s}(\|f\|_{\widehat{H}_r^s} + \|g\|_{\widehat{H}_r^s}),$$

and the estimate (47) follows. $\square$

The following lemma is contained in [19] in the $r = 2$ case.

LEMMA 6.3. *Let $1 < r \le 2$ and $s > \frac{1}{r} - \frac{1}{2}$ or $r = 2$ and $s \ge 0$. The translation operators*

$$\tau^{\mp} : C([-T,T], \widehat{H}_r^s(\mathbb{T})) \to C([-T,T], \widehat{H}_r^s(\mathbb{T})),$$
$$\tau^{\mp}u(t,x) := u\left(t, x \mp 2t \fint_0^{2\pi} |u(t,y)|^2 dy\right)$$

are continuous. However, their restrictions to arbitrarily small balls are not uniformly continuous.

Proof. We sketch only the main ideas and refer the reader to [19, Propositions 3.2.1 and 3.2.2] for details in the H^s case which easily carry over to the $\widehat{H}_r^s$ setting: Because the embedding $\widehat{H}_r^s \subset L^2$ is continuous, the continuity statement follows from the continuity of the map

$$\tau : \mathbb{R} \times C([-T,T], \widehat{H}_r^s(\mathbb{T})) \to C([-T,T], \widehat{H}_r^s(\mathbb{T})),$$
$$\tau(h,u)(t,x) := u(t, x + ht).$$

If we fix the time variable, the map

$$\mathbb{R} \times \widehat{H}_r^s(\mathbb{T}) \to \widehat{H}_r^s(\mathbb{T}), \quad (h,f) \mapsto f(\cdot + h)$$

is continuous. This follows from the fact that a translation by a fixed amount is an isometry in $\widehat{H}_r^s(\mathbb{T})$ combined with $e^{i\xi h} \to e^{i\xi h_0}$ for $h \to h_0$ and the dominated convergence theorem. Now, because $[-T,T]$ is compact, we may approximate $u \in C([-T,T], \widehat{H}_r^s(\mathbb{T}))$ uniformly by a piecewise constant (in time) function and apply the result for t fixed.

For $r > 0$, the sequences of functions

$$u_{n,j}(t,x) = u_{n,j}(x) = rn^{-s}e^{inx} + c_{n,j}, \quad n \in \mathbb{N},\ j = 1,2,$$

with $c_{n,1} = \frac{1}{\sqrt{n}}$ and $c_{n,2} = 0$ provide a counterexample to the uniform continuity on balls. $\square$

As in [18, 19] we define $\mathcal{G} = \mathcal{G}_0 \circ \tau^-$, i.e.,

$$\mathcal{G}u(t,x) = (\mathcal{G}_0 u)\left(t, x - 2t \fint_0^{2\pi} |u(t,y)|^2 dy\right). \tag{48}$$

LEMMA 6.4. *Let $u, v \in C([-T,T], H^2) \cap C^1((-T,T), L^2)$ such that $v = \mathcal{G}u$. Then u solves* (DNLS) *if and only if v solves*

$$\begin{aligned} i\partial_t v(t) + \partial_x^2 v(t) &= -i\mathcal{T}(v)(t) - \tfrac{1}{2}\mathcal{Q}(v)(t), \quad t \in (-T,T), \\ v(0) &= \mathcal{G}u(0), \end{aligned} \tag{49}$$

where

$$\mathcal{T}(v) = v^2 \partial_x \bar{v} - 2i \fint_0^{2\pi} \mathrm{Im}\,(v\partial_x \bar{v})\, dx\, v \tag{50}$$

and

$$\mathcal{Q}(v) = \left(|v|^4 - \fint_0^{2\pi} |v|^4 dx\right) v - 2\fint_0^{2\pi} |v|^2 dx \left(|v|^2 - \fint_0^{2\pi} |v|^2 dx\right) v, \tag{51}$$

i.e., $\mathcal{T}(v) = T(v,v,v)$ and $\mathcal{Q}(v) = Q(v,v,v,v,v)$ for T and Q defined in (8) *and* (12)*, respectively. Moreover, the map*

$$\mathcal{G} : C([-T,T], \widehat{H}^s_r(\mathbb{T})) \to C([-T,T], \widehat{H}^s_r(\mathbb{T}))$$

is a homeomorphism with inverse $\mathcal{G}^{-1} = \tau^+ \circ \mathcal{G}_0^{-1}$. The restrictions of $\mathcal{G}$ and $\mathcal{G}^{-1}$ to arbitrarily small balls fail to be uniformly continuous. However, $\mathcal{G}$ is locally bi-Lipschitz on subsets of functions with prescribed L^2-norm.

Proof. To see the equivalence of (DNLS) and (49) the calculations for the periodic case may be found in [18, section 2]. The fact that we may represent $\mathcal{T}$ and $\mathcal{Q}$ via convolution operators on the Fourier side where certain frequency interactions are cancelled out was remarked in [19, Remark 3.2.7]. The verification of the precise formulas are straightforward, using (suppressing the t dependence)

$$\begin{aligned} (2\pi)^{-1} \widehat{v} * \widehat{\partial_x \overline{v}}(0) &= i \fint_0^{2\pi} \mathrm{Im}\,(v\partial_x \overline{v})\, dx, \\ (2\pi)^{-1} \widehat{v} * \widehat{\overline{v}}(0) &= \fint_0^{2\pi} |v|^2\, dx, \\ (2\pi)^{-2} \widehat{v} * \widehat{\overline{v}} * \widehat{v} * \widehat{\overline{v}}(0) &= \fint_0^{2\pi} |v|^4\, dx. \end{aligned}$$

The mapping properties follow from Lemma 6.2. ∎

Remark 4. The cancellation of certain frequency interactions due to the term

$$2\fint_0^{2\pi} \mathrm{Im}\,(v\partial_x \overline{v})\, dx v,$$

which is crucial for our arguments (cf. (8)), is an important feature of the gauge transformation. We observe as well that this expression itself is not well defined in $\widehat{H}^{\frac{1}{2}}_r(\mathbb{T})$ for $1 < r < 2$.

7. Proof of well-posedness. Now, we show that the Cauchy problem (49) is well-posed. Let $\chi \in C_0^\infty(\mathbb{R})$ be nonnegative and symmetric such that $\chi(t) = 0$ for $|t| \geq 2$ and $\chi(t) = 1$ for $|t| \leq 1$. Recall that $Z_r^s := X_{r,2}^{s,\frac{1}{2}} \cap X_{r,\infty}^{s,0}$. We have, similar to the L^2 case, the following linear estimates.

LEMMA 7.1. *Let $s \in \mathbb{R}$, $1 < r < \infty$.*

$$\|\chi S u_0\|_{Z_r^s} \lesssim \|u_0\|_{\widehat{H}_r^s}, \tag{52}$$

$$\left\| \chi \int_0^t S(t-t')u(t')dt' \right\|_{Z_r^s} \lesssim \|u\|_{X_{r,2}^{s,-\frac{1}{2}}} + \|u\|_{X_{r,\infty}^{s,-1}}. \tag{53}$$

Proof. We use the approach from [9, Lemma 3.1]. Let $u_0 \in C^\infty(\mathbb{R})$ be periodic. We calculate $\mathcal{F}(\chi S u_0)(\tau,\xi) = \mathcal{F}_t\chi(\tau+\xi^2)\mathcal{F}_x u_0(\xi)$, and (52) follows because $\mathcal{F}_t\chi$ is rapidly decreasing. It suffices to consider smooth u with $\operatorname{supp}(u) \subset \{(t,x) \mid |t| \leq 2\}$. We rewrite

$$\chi(t) \int_0^t S(t-t')f(t')\,dt' = F_1(t) + F_2(t),$$

where

$$F_1(t) = \frac{1}{2}\chi(t)S(t)\int_{\mathbb{R}} \varphi(t')S(-t')u(t')\,dt',$$
$$F_2(t) = \frac{1}{2}\chi(t)\int_{\mathbb{R}} \varphi(t-t')S(t-t')u(t')\,dt',$$

and $\varphi(t') = \chi(t'/10)\operatorname{sign}(t')$. Concerning φ we have

$$|\mathcal{F}_t\varphi(\tau)| \lesssim \langle\tau\rangle^{-1}. \tag{54}$$

Estimate (52) yields

$$\|F_1\|_{Z_r^s} \lesssim \left\| \int_{\mathbb{R}} \varphi(t')S(-t')u(t')\,dt' \right\|_{\widehat{H}_r^s}.$$

Parseval's equality implies that

$$\mathcal{F}_x\left(\int_{\mathbb{R}} \varphi(t')S(-t')u(t')\,dt'\right)(\xi) = \int_{\mathbb{R}} \overline{\mathcal{F}_t\varphi}(\tau+\xi^2)\mathcal{F}u(\tau,\xi)\,d\tau,$$

which gives

$$\left\| \int_{\mathbb{R}} \varphi(t')S(-t')u(t')\,dt' \right\|_{\widehat{H}_r^s} \lesssim \|u\|_{X_{r,\infty}^{s,-1}}$$

by (54). Now, let us consider F_2. Due to Young's inequality, we may remove the cutoff function χ in front of the integral. The Fourier transform of the remainder is given by

$$\mathcal{F}\left(\int_{\mathbb{R}} \varphi(t-t')S(t-t')u(t')\,dt'\right)(\tau,\xi) = \mathcal{F}_t\varphi(\tau+\xi^2)\mathcal{F}u(\tau,\xi).$$

Estimate (54) proves (53). ∎

A standard application of the fixed point argument gives the following.

THEOREM 7.2. *Let $\frac{4}{3} < q \leq r \leq 2$. Then for every*

$$v_0 \in B_R := \left\{ v_0 \in \widehat{H}^{\frac{1}{2}}_r(\mathbb{T}) \mid \|v_0\|_{\widehat{H}^{\frac{1}{2}}_q} < R \right\}$$

and $T \lesssim R^{-2q'-}$ there exists a solution

$$v \in Z^{\frac{1}{2}}_r(T) \subset C([-T,T], \widehat{H}^{\frac{1}{2}}_r(\mathbb{T}))$$

of the Cauchy problem (49)*. This solution is unique in the space $Z^{\frac{1}{2}}_q(T)$, and the map*

$$\left(B_R, \|\cdot\|_{\widehat{H}^{\frac{1}{2}}_r} \right) \longrightarrow C([-T,T], \widehat{H}^{\frac{1}{2}}_r(\mathbb{T})) : \quad v_0 \mapsto v$$

is locally Lipschitz continuous. Moreover, it is real analytic.

Sketch of proof. As a consequence of the estimates (53), (9), (10), and (15),

$$\Phi(v)(t) := \int_0^t e^{i(t-t')\partial_x^2} \left(-\tfrac{1}{2}\mathcal{Q} - i\mathcal{T}\right) v(t')\, dt'$$

extends to a continuous map $\Phi : Z^{\frac{1}{2}}_r(T) \to Z^{\frac{1}{2}}_r(T)$ for $\frac{4}{3} < r \leq 2$ along with the estimate

$$\begin{aligned} \|\Phi(v_1) - \Phi(v_2)\|_{Z^{\frac{1}{2}}_r(T)} \lesssim{}& T^{\frac{1}{r'}-} \left(\|v_1\|_{Z^{\frac{1}{2}}_r(T)} + \|v_2\|_{Z^{\frac{1}{2}}_r(T)} \right)^2 \|v_1 - v_2\|_{Z^{\frac{1}{2}}_r(T)} \\ &+ T^{\frac{2}{r'}-} \left(\|v_1\|_{Z^{\frac{1}{2}}_r(T)} + \|v_2\|_{Z^{\frac{1}{2}}_r(T)} \right)^4 \|v_1 - v_2\|_{Z^{\frac{1}{2}}_r(T)}, \end{aligned} \tag{55}$$

and with (52) we also have

$$\|e^{it\partial_x^2} v_0 + \Phi(v)\|_{Z^{\frac{1}{2}}_r(T)} \lesssim \|v_0\|_{\widehat{H}^{\frac{1}{2}}_{r_1}} + T^{\frac{1}{r'}-} \|v\|^3_{Z^{\frac{1}{2}}_r(T)} + T^{\frac{2}{r'}-} \|v\|^5_{Z^{\frac{1}{2}}_r(T)}.$$

Hence, for fixed v_0 the operator $e^{it\partial_x^2} v_0 + \Phi : D \to D$ is a strict contraction in some closed ball $D \subset Z^{\frac{1}{2}}_r(T)$ for small enough T. By the contraction mapping principle we find a fixed point $v \in Z^{\frac{1}{2}}_r(T)$ which is a solution of (49) for small times. Similarly, the implicit function theorem shows that the map $v_0 \mapsto v$ is real analytic, hence locally Lipschitz. Uniqueness in $Z^{\frac{1}{2}}_q(T)$ follows by contradiction: A translation in time reduces matters to uniqueness for an arbitrarily short time interval which follows from the estimate (55) with $r = q$. The lower bound on the maximal time of existence is a consequence of the mixed estimate

$$\|v\|_{Z^{\frac{1}{2}}_r(T)} \lesssim \|v(0)\|_{\widehat{H}^{\frac{1}{2}}_r} + T^{\frac{1}{q'}-} \|v\|^2_{Z^{\frac{1}{2}}_q(T)} \|v\|_{Z^{\frac{1}{2}}_r(T)} + T^{\frac{2}{q'}-} \|v\|^4_{Z^{\frac{1}{2}}_q(T)} \|v\|_{Z^{\frac{1}{2}}_r(T)}$$

for solutions v and an iteration argument. □

By combining Theorem 7.2 with Lemma 6.4 and some approximation arguments, Theorem 1.2 follows (this is carried out in detail in [13] for the nonperiodic case). In particular, the claim concerning the nonuniform continuity is a consequence of the properties of $\mathcal{G}$ and of the flow map of (49).

Remark 5. In fact, our estimates also imply uniqueness of solutions of (49) in a restriction space based on the $X_{q,2}^{\frac{1}{2},\frac{1}{2}}$ component only. Hence, the optimal uniqueness statement concerning solutions of (DNLS) provided by our methods is the following: Let $4/3 < q \leq 2$ and $u_1, u_2 \in C([-T,T], \widehat{H}_q^{\frac{1}{2}}(\mathbb{T}))$ be solutions of (DNLS) with $u_1(0) = u_2(0)$. If additionally $\mathcal{G}u_1, \mathcal{G}u_2 \in X_{q,2}^{\frac{1}{2},\frac{1}{2}}$, which also satisfy (49), then $u_1 = u_2$.

Acknowledgment. The authors would like to thank the anonymous referees for their valuable comments.

LOWER SEMICONTINUITY OF QUASI-CONVEX BULK ENERGIES IN SBV AND INTEGRAL REPRESENTATION IN DIMENSION REDUCTION*

JEAN-FRANÇOIS BABADJIAN†

Abstract. A result of Larsen concerning the structure of the approximate gradient of certain sequences of functions with bounded variation is used to present a short proof of Ambrosio's lower semicontinuity theorem for quasi-convex bulk energies in SBV. It enables us to generalize to the SBV setting the decomposition lemma for scaled gradients in dimension reduction and also to show that, from the point of view of bulk energies, SBV dimensional reduction problems can be reduced to analog ones in the Sobolev spaces framework.

Key words. dimension reduction, Γ-convergence, functions of bounded variation, free discontinuity problems, quasi convexity, equi-integrability

1. Introduction. Since the pioneering work [22], the modeling of thin films through dimensional reduction techniques and Γ-convergence analysis has become one of the main issues in the field of the calculus of variations. In the membrane theory framework in nonlinear elasticity, the problem rests on the study of the (scaled) elastic energy

$$\frac{1}{\varepsilon}\int_{\Omega_\varepsilon} W(\varepsilon)(y,\nabla v)\,dy$$

of such bodies. Here $\Omega_\varepsilon := \omega \times (-\varepsilon/2, \varepsilon/2)$, where ω is a bounded open subset of $\mathbb{R}^2$ and $\varepsilon > 0$, stands for the reference configuration of a nonlinear elastic thin film, $v : \Omega_\varepsilon \to \mathbb{R}^3$ is the deformation field which maps the reference configuration into a deformed configuration, and $W(\varepsilon) : \Omega_\varepsilon \times \mathbb{R}^{3\times 3} \to [0,+\infty)$ is the stored energy density of the body which is a Carathéodory function satisfying uniform p-growth and p-coercivity conditions (with $1 < p < \infty$). From a mathematical point of view, the previous energy is well defined, provided v is a Sobolev function in $W^{1,p}(\Omega_\varepsilon;\mathbb{R}^3)$.

To study the limit problem as the thickness $\varepsilon \to 0$, it will be useful to recast the energy functional over the varying set Ω_ε into a functional with a fixed domain of integration $\Omega := \omega \times (-1/2, 1/2)$. To this end, denoting by $x_\alpha := (x_1, x_2)$ the in-plane variable, we set $u(x_\alpha, x_3) := v(x_\alpha, \varepsilon\, x_3)$ so that, after the (now standard) change of variables

$$x_\alpha = y_\alpha, \quad x_3 = \frac{y_3}{\varepsilon},$$

we are equivalently led to study the following rescaled functional:

$$\int_\Omega W_\varepsilon\left(x, \nabla_\alpha u \Big| \frac{1}{\varepsilon}\nabla_3 u\right) dx, \quad u \in W^{1,p}(\Omega;\mathbb{R}^3), \tag{1.1}$$

where $W_\varepsilon : \Omega \times \mathbb{R}^{3\times 3} \to [0, +\infty)$ is the rescaled stored energy density expressed in the new variables and defined by $W_\varepsilon(x_\alpha, x_3, \xi) := W(\varepsilon)(x_\alpha, \varepsilon\, x_3, \xi)$. From now on, ∇_α (resp., ∇_3) will stand for the (approximate) gradient with respect to x_α (resp., x_3), $\xi = (\xi_\alpha|\xi_3)$ for some matrix $\xi \in \mathbb{R}^{3\times 3}$, and $z = (z_\alpha|z_3)$ for some vector $z \in \mathbb{R}^3$. Thus in view of the p-growth of the energy, it is important to understand the structure of what we call the scaled gradient of u, i.e.,

$$\left(\nabla_\alpha u \Big| \frac{1}{\varepsilon}\nabla_3 u\right). \tag{1.2}$$

In particular, if $\{u_\varepsilon\} \subset W^{1,p}(\Omega; \mathbb{R}^3)$ is a minimizing sequence uniformly bounded in energy, up to a subsequence, there always exist $u \in W^{1,p}(\Omega; \mathbb{R}^3)$ such that $D_3 u = 0$ in the sense of distributions and $b \in L^p(\Omega; \mathbb{R}^3)$ such that $u_\varepsilon \rightharpoonup u$ in $W^{1,p}(\Omega; \mathbb{R}^3)$ and $(1/\varepsilon)\nabla_3 u_\varepsilon \rightharpoonup b$ in $L^p(\Omega; \mathbb{R}^3)$. The limit function u is nothing but the deformation of the midplane, while b is called the *Cosserat vector*. It thus seems natural to expect a limit model depending on the pair (u, b). Unfortunately, this is still out of reach, and we refer the reader to [19] for a more detailed discussion on the subject. However, in [9] (see also [7]) a simplified model has been considered taking into account the *bending moment* $\bar{b} \in L^p(\omega; \mathbb{R}^3)$, i.e., the average in the transverse direction x_3 of b, instead of the full Cosserat vector field.

In the framework of fracture mechanics, one usually adds a surface energy term, penalizing the presence of the crack. The simplest case consists of just penalizing its area leading to the so-called Griffith surface energy. Thus, for a given crack, one should study the energy given by the competing sum of the bulk and the surface energies. Such fracture mechanics problems belong (among others) to the class of free discontinuity problems, that is, variational problems where the unknown is not only a function but a pair set/function. Based on the idea that the deformation may be discontinuous across the crack, it is convenient to study the weak formulation, replacing the crack by the jump set of the deformation and leading to a variational problem stated in the space of (special) functions with bounded variation. Now the energy in which we are interested is

$$\frac{1}{\varepsilon}\int_{\Omega_\varepsilon} W(\varepsilon)(y, \nabla v)\, dy + \frac{1}{\varepsilon}\mathcal{H}^2(S_v), \quad v \in SBV^p(\Omega_\varepsilon; \mathbb{R}^3),$$

where ∇v is intended as the approximate gradient of v, S_v is the jump set of v, and $\mathcal{H}^2$ stands for the 2-dimensional Hausdorff measure. Writing as before, this energy in the rescaled variables yields

$$\int_\Omega W_\varepsilon\left(x, \nabla_\alpha u \Big| \frac{1}{\varepsilon}\nabla_3 u\right) dx + \int_{S_u} \left|\left((\nu_u)_\alpha \Big| \frac{1}{\varepsilon}(\nu_u)_3\right)\right| d\mathcal{H}^2, \quad u \in SBV^p(\Omega; \mathbb{R}^3), \tag{1.3}$$

where ν_u is the generalized normal to S_u and (1.2) is now referred to as the approximate scaled gradient of u.

The aim of this paper is to study the connections between variational problems (1.1) and (1.3), possibly taking into account the presence of the bending moment vector field. To this end, we will use Theorem 4.1 as the main ingredient, which extends the decomposition lemma for scaled gradients (see [8, Theorem 1.1] or [13, Theorem 3.1]) to the SBV setting. It states that any SBV sequence with bounded rescaled bulk energy and whose derivative's singular part behaves asymptotically well can be energetically replaced, up to a set of vanishing Lebesgue measure, by a sequence of Lipschitz maps whose scaled gradient is p-equi-integrable. Thus it reduces the free discontinuity problem to a usual dimensional reduction one in the framework of Sobolev spaces. This result is nothing but a rescaled version of [21, Lemma 2.1] (see also Theorem 3.1 below). Using this structure theorem, we are able to show two integral representation theorems in SBV (Theorems 6.1 and 7.3) which say that, up to a subsequence, the functional (1.3) Γ-converges (in an appropriate topology) to a functional of the same kind, i.e., the sum of a bulk and a surface energy. Moreover, the surface energy is still of Griffith's type, while the bulk energy is exactly the same as that obtained in the analog Sobolev spaces analysis. The main importance of these representation theorems relies on the fact that results on dimension reduction in Sobolev spaces can now be extended to SBV (see [5, 6, 7, 9, 22]).

Note that an integral representation result for dimensional reduction problems in SBV already exists (see [11, Theorem 2.1] and also [10]). Even if this reference may seem more general from the point of view of the hypothesis, it does not contain as a special case our results because the authors made strong use of the fact that their surface energy had to grow linearly with respect to the deformation jump. This assumption was essential in order to get compactness in $BV(\Omega;\mathbb{R}^3)$ of minimizing sequences. However, they suggested a way to remove that constraint by singular perturbation [11, Remark 2.2]. In our study we use a direct argument based on a trick introduced in [18] and which was already used in [4] in the framework of dimensional reduction. It consists of defining an artificial functional exactly as we usually do for the Γ-$\liminf$, except that we impose the minimizing sequences to be uniformly bounded in $L^\infty(\Omega;\mathbb{R}^3)$. Thanks to a truncation argument (see Lemma 6.2) we show that it actually coincides with the Γ-$\liminf$ for deformations $u \in L^\infty(\Omega;\mathbb{R}^3)$, and the advantage is that now minimizing sequences turn out to be relatively compact in $SBV(\Omega;\mathbb{R}^3)$ thanks to Ambrosio's compactness theorem. We refer the reader to [4] for a deeper insight on that subject.

To close this introduction, we wish to stress that in this paper, we are mostly interested in representation of effective bulk energies arising in 3D-2D dimensional reduction problems stated in SBV. For this reason we will consider a large class for such bulk energies, while surface energies will be restricted to the simplified case of a Griffith-type one. However, we are convinced that the results presented here could be generalized to a larger class of surface energies.

The overall plan of the paper is as follows: after recalling some useful notations in section 2, and in order to show the technique in a more transparent way, we present in section 3 a short proof of Ambrosio's lower semicontinuity result for quasi-convex integrands using [21, Lemma 2.1]. Then in section 4 we prove our main tool, Theorem 4.1, thanks to a slicing argument together with [21, Lemma 2.1]. To reach our goal, we need to prove a general integral representation for the Γ-limit of (1.1) in $W^{1,p}(\Omega;\mathbb{R}^3) \times L^p(\omega;\mathbb{R}^3)$ as a function of the deformation and the bending moment. This is the purpose of Theorem 5.1 in section 5 which contains as particular cases [9, Theorem 3.1] (with $W_\varepsilon(x,\xi) = W(\xi)$) and [7, Theorem 3.4] (with $W_\varepsilon(x,\xi) = W(x,\xi)$). In section 6, we refine the analysis of section 3, adding the difficulties of dimension reduction. From the integral representation in Sobolev spaces, Theorem 5.1, we deduce an analog result in SBV, Theorem 6.1, which says that the Γ-limit of (1.3) in $BV(\Omega;\mathbb{R}^3) \times L^p(\omega;\mathbb{R}^3)$ also has an integral representation and that the bulk energy density is exactly the same one as that obtained in the $W^{1,p}$ analysis. This will be achieved thanks to Theorem 4.1 and a blow-up method which enables us to reduce the problem to affine deformations and constant bending moments. Finally, we deduce a similar result in section 7 without the presence of the bending moment.

2. Notations and preliminaries. If $\Omega \subset \mathbb{R}^N$ is an open set, we consider the Lebesgue spaces $L^p(\Omega;\mathbb{R}^d)$ and the Sobolev spaces $W^{1,p}(\Omega;\mathbb{R}^d)$ in the usual way. When needed, we will make precise what topology the space $L^p(\Omega;\mathbb{R}^d)$ will be endowed. In particular we will denote by $L^p_s(\Omega;\mathbb{R}^d)$ (resp., $L^p_w(\Omega;\mathbb{R}^d)$) the space $L^p(\Omega;\mathbb{R}^d)$ endowed with the strong (resp., weak) topology. Strong convergence will always be denoted by $\to$, while weak (resp., weak*) convergence will be denoted by $\rightharpoonup$ (resp., $\overset{*}{\rightharpoonup}$).

We denote by $\mathcal{M}(\Omega;\mathbb{R}^d)$ the space of vector valued finite Radon measures. If $\mu \in \mathcal{M}(\Omega;\mathbb{R}^d)$ and E is a Borel subset of Ω, we will write $\mu \llcorner E$ for the restriction of μ to E; that is, for every Borel subset F of Ω, $\mu \llcorner E\,(F) = \mu(E \cap F)$. The Lebesgue measure in $\mathbb{R}^N$ will be denoted by $\mathcal{L}^N$, while $\mathcal{H}^{N-1}$ is the $(N-1)$-dimensional Hausdorff measure. We will denote by B the unit ball of $\mathbb{R}^N$ and by $\omega_N := \mathcal{L}^N(B)$ its Lebesgue measure. If $x_0 \in \mathbb{R}^N$ and $\rho > 0$, $B(x_0,\rho) := x_0 + \rho\, B$ is the ball centered at x_0 with radius ρ. The notation $-\!\!\!\!\!\!\int_A$ stands for the average $\mathcal{L}^N(A)^{-1}\int_A$.

The space of functions of bounded variation is denoted by $BV(\Omega;\mathbb{R}^d)$, and we refer the reader to [3] for standard theory of BV functions. We recall here a few facts: if $u \in BV(\Omega;\mathbb{R}^d)$, then its distributional derivative $Du \in \mathcal{M}(\Omega;\mathbb{R}^{d\times N})$, and thanks to Lebesgue's decomposition theorem, we can write $Du = D^a u + D^s u$, where $D^a u$ and $D^s u$ stand for, respectively, the absolutely continuous and singular part of Du with respect to the Lebesgue measure $\mathcal{L}^N$. Let S_u be the complementary of Lebesgue points of u. We say that u is a special function of bounded variation, and we write $u \in SBV(\Omega;\mathbb{R}^d)$, if

$$Du = \nabla u\, \mathcal{L}^N + (u^+ - u^-) \otimes \nu_u\, \mathcal{H}^{N-1} \llcorner S_u,$$

where ∇u is the approximate gradient of u, ν_u is the generalized normal to S_u, and $u^\pm$ are the traces of u on both sides of S_u. If $E \subset \Omega$, we say that E has finite perimeter in Ω, provided $\chi_E \in SBV(\Omega)$. We denote by $\partial^* E$ (resp., $\partial_* E$) the reduced (resp., essential) boundary of E. When $p > 1$, we define

$$SBV^p(\Omega;\mathbb{R}^d) := \Big\{ u \in SBV(\Omega;\mathbb{R}^d) : \nabla u \in L^p(\Omega;\mathbb{R}^{d\times N}) \text{ and } \mathcal{H}^{N-1}(S_u \cap \Omega) < +\infty \Big\}.$$

We say that a sequence $\{u_n\} \subset SBV^p(\Omega;\mathbb{R}^d)$ converges weakly to $u \in SBV^p(\Omega;\mathbb{R}^d)$, and we write $u_n \rightharpoonup u$ in $SBV^p(\Omega;\mathbb{R}^d)$, if

$$\begin{cases} u_n \to u \quad \text{in } L^1(\Omega;\mathbb{R}^d), \\ \nabla u_n \rightharpoonup \nabla u \quad \text{in } L^p(\Omega;\mathbb{R}^{d\times N}), \\ (u_n^+ - u_n^-) \otimes \nu_{u_n} \mathcal{H}^{N-1} \llcorner S_{u_n} \overset{*}{\rightharpoonup} (u^+ - u^-) \otimes \nu_u \mathcal{H}^{N-1} \llcorner S_u \quad \text{in } \mathcal{M}(\Omega;\mathbb{R}^{d\times N}). \end{cases}$$

If $\Omega := \omega \times I$, where ω is a bounded open subset of $\mathbb{R}^2$ and $I := (-1/2, 1/2)$, we will identify the spaces $L^p(\omega;\mathbb{R}^3)$, $W^{1,p}(\omega;\mathbb{R}^3)$, or $SBV^p(\omega;\mathbb{R}^3)$ with the space of functions $v \in L^p(\Omega;\mathbb{R}^3)$, $W^{1,p}(\Omega;\mathbb{R}^3)$, or $SBV^p(\Omega;\mathbb{R}^3)$ such that $D_3 v = 0$ in the sense of distributions.

By $\mathcal{A}(\omega)$ we mean the family all open subsets of ω, while $\mathcal{R}(\omega)$ stands for the countable subfamily of $\mathcal{A}(\omega)$ obtained by taking all finite unions of open cubes contained in ω, centered at rational points and with rational edge length.

In what follows, we will denote by $Q' := (-1/2, 1/2)^2$ the unit cube of $\mathbb{R}^2$ and by $Q'(x_0,\rho) := x_0 + \rho\, Q'$ the cube centered at $x_0 \in \mathbb{R}^2$ and side length $\rho > 0$. Similarly $B' := \{x_\alpha \in \mathbb{R}^2 : |x_\alpha| < 1\}$ stands for the unit ball in $\mathbb{R}^2$, and $B'(x_0,\rho) := x_0 + \rho\, B'$ denotes the ball of $\mathbb{R}^2$ centered at $x_0 \in \mathbb{R}^2$ and of radius $\rho > 0$.

3. Lower semicontinuity of quasi-convex bulk energies in $\boldsymbol{SBV}$. This section is devoted to give a short proof of Ambrosio's lower semicontinuity result for quasi-convex bulk energies in SBV using the following theorem proved in [21, Lemma 2.1].

THEOREM 3.1. *Let $\Omega \subset \mathbb{R}^N$ be a bounded open set with Lipschitz boundary and let $\{u_n\} \subset BV(\Omega;\mathbb{R}^d)$ be such that*

$$\begin{cases} \sup_{n\in\mathbb{N}} \|u_n\|_{BV(\Omega;\mathbb{R}^d)} < +\infty, \\ \sup_{n\in\mathbb{N}} \|\nabla u_n\|_{L^p(\Omega;\mathbb{R}^{d\times N})} < +\infty \quad \text{for some } p>1, \\ |D^s u_n|(\Omega) \to 0. \end{cases}$$

Then there exists a subsequence $\{n_k\} \nearrow +\infty$ and a sequence $\{w_k\} \subset W^{1,\infty}(\Omega;\mathbb{R}^d)$ such that

$$\begin{cases} \sup_{k\in\mathbb{N}} \|w_k\|_{W^{1,p}(\Omega;\mathbb{R}^d)} < +\infty, \\ \{|\nabla w_k|^p\} \text{ is equi-integrable}, \\ \mathcal{L}^N(\{w_k \neq u_{n_k}\} \cup \{\nabla w_k \neq \nabla u_{n_k}\}) \to 0. \end{cases}$$

This theorem is nothing but the BV counterpart of the decomposition lemma, [20, Lemma 1.2], in Sobolev spaces. We now use the previous result to give a short proof of Ambrosio's lower semicontinuity result for quasi-convex bulk energies in SBV (see [2, Theorem 4.3] or [3, Proposition 5.29]). This will enable us to emphasize the techniques used in this paper, occulting the difficulties of dimension reduction. The same kind of arguments will be used in section 6 to prove the lower bound of Theorem 6.1.

THEOREM 3.2. *Let Ω be bounded open subset of $\mathbb{R}^N$ and $f : \Omega \times \mathbb{R}^d \times \mathbb{R}^{d\times N} \to [0,+\infty)$ be a Carathéodory function satisfying, for all $(s,\xi) \in \mathbb{R}^d \times \mathbb{R}^{d\times N}$ and a.e. $x \in \Omega$,*

$$c|\xi|^p \le f(x,s,\xi) \le a(x) + \psi(|s|)(1+|\xi|^p) \tag{3.1}$$

for some $p > 1$, $c > 0$, $a \in L^1(\Omega)$ and some increasing function $\psi : [0,+\infty) \to [0,+\infty)$. If $\xi \mapsto f(x,s,\xi)$ is quasi-convex for every $s \in \mathbb{R}^d$ and a.e. $x \in \Omega$, then

$$\liminf_{n\to+\infty} \int_\Omega f(x,u_n,\nabla u_n)\,dx \ge \int_\Omega f(x,u,\nabla u)\,dx$$

for any sequence $\{u_n\} \subset SBV(\Omega;\mathbb{R}^d)$ converging in $L^1(\Omega;\mathbb{R}^d)$ to $u \in SBV(\Omega;\mathbb{R}^d)$ and satisfying $\sup_n \mathcal{H}^{N-1}(S_{u_n}) < +\infty$.

Proof. The proof is divided into three steps. We first apply the blow-up method to reduce the study to an affine limit function. Then we prove that the resulting sequence can be modified, without increasing the energy too much, into another one uniformly bounded in L^∞. Finally, we apply Theorem 3.1 to replace this last sequence of SBV functions by a sequence of Sobolev functions.

Step 1. Up to a subsequence, there is no loss of generality to assume the existence of nonnegative and finite Radon measures λ and $\mu \in \mathcal{M}(\Omega)$ such that $f(\cdot,u_n,\nabla u_n)\,\mathcal{L}^N \xrightarrow{*} \lambda$ and $\mathcal{H}^{N-1} \llcorner S_{u_n} \xrightarrow{*} \mu$ in $\mathcal{M}(\Omega)$. To prove Theorem 3.2 it is enough to check that

$$\lambda(\Omega) \ge \int_\Omega f(x,u,\nabla u)\,dx,$$

and thanks to Lebesgue's differentiation theorem, it suffices to show that

$$\frac{d\lambda}{d\mathcal{L}^N}(x_0) \geq f(x_0, u(x_0), \nabla u(x_0))$$

for $\mathcal{L}^N$-a.e. $x_0 \in \Omega$. Select $x_0 \in \Omega$ such that

(a) x_0 is a Lebesgue point of u and a and a point of approximate differentiability of u;

(b) the Radon–Nikodým derivative of λ with respect to $\mathcal{L}^N$ exists and is finite;

(c) the following limit exists and

$$\lim_{\rho \to 0^+} \frac{\mu(B(x_0, \rho))}{\omega_{N-1}\rho^{N-1}} = 0; \tag{3.2}$$

(d) for any sequence $\{\rho_i\} \searrow 0^+$ there exist a subsequence $\{\rho_{i(k)}\}$ and a $\mathcal{L}^N$-negligible set $E \subset B$ such that

$$\lim_{k \to +\infty} f(x_0 + \rho_{i(k)} y, u(x_0) + \rho_{i(k)} s, \xi) = f(x_0, u(x_0), \xi) \tag{3.3}$$

locally uniformly in $\mathbb{R}^d \times \mathbb{R}^{d \times N}$ for any $y \in B \setminus E$.

Note that $\mathcal{L}^N$-a.e. points x_0 in Ω satisfy these properties. Items (a) and (b) are immediate, while item (d) is a consequence of [3, Lemma 5.38]. Concerning item (c), we remark that, setting

$$\Theta(x) := \limsup_{\rho \to 0^+} \frac{\mu(B(x, \rho))}{\omega_{N-1}\rho^{N-1}},$$

then $\{\Theta > 0\} = \bigcup_{h=1}^{+\infty} \{\Theta \geq 1/h\}$, and using [3, Theorem 2.56], we get that $\mathcal{H}^{N-1}(\{\Theta \geq 1/h\}) \leq h\mu(\{\Theta \geq 1/h\}) < +\infty$. Thus $\mathcal{L}^N(\{\Theta \geq 1/h\}) = 0$ and consequently $\mathcal{L}^N(\{\Theta > 0\}) = 0$.

Consider a sequence $\{\rho_k\} \searrow 0^+$ such that $0 < \rho_k < 1$, $\mu(\partial B(x_0, \rho_k)) = 0$, and $\lambda(\partial B(x_0, \rho_k)) = 0$ for every $k \in \mathbb{N}$, and (3.3) holds with ρ_k in place of $\rho_{i(k)}$. Then

$$\begin{aligned}
\frac{d\lambda}{d\mathcal{L}^N}(x_0) &= \lim_{k \to +\infty} \frac{\lambda(B(x_0, \rho_k))}{\omega_N \rho_k^N} \\
&= \lim_{k \to +\infty} \lim_{n \to +\infty} \frac{1}{\omega_N \rho_k^N} \int_{B(x_0, \rho_k)} f(x, u_n, \nabla u_n)\, dx \\
&= \lim_{k \to +\infty} \lim_{n \to +\infty} \frac{1}{\omega_N} \int_B f(x_0 + \rho_k y, u(x_0) + \rho_k u_{n,k}, \nabla u_{n,k})\, dy, \qquad (3.4)
\end{aligned}$$

where we set $u_{n,k}(y) = [u_n(x_0 + \rho_k\, y) - u(x_0)]/\rho_k$. Since x_0 is a point of approximate differentiability of u, it follows that

$$\lim_{k \to +\infty} \lim_{n \to +\infty} \|u_{n,k} - w_0\|_{L^1(B;\mathbb{R}^d)} = 0, \tag{3.5}$$

where $w_0(y) := \nabla u(x_0)\, y$. Moreover, by (3.2) we get that

$$\begin{aligned}
\lim_{k \to +\infty} \lim_{n \to +\infty} \mathcal{H}^{N-1}(S_{u_{n,k}} \cap B) &= \lim_{k \to +\infty} \lim_{n \to +\infty} \frac{\mathcal{H}^{N-1}(S_{u_n} \cap B(x_0, \rho_k))}{\rho_k^{N-1}} \\
&= \lim_{k \to +\infty} \frac{\mu(B(x_0, \rho_k))}{\rho_k^{N-1}} = 0. \qquad (3.6)
\end{aligned}$$

From (3.4), (3.5), and (3.6), one can find a sequence $n(k) \nearrow +\infty$ such that, setting $v_k := u_{n(k),k}$, then $v_k \to w_0$ in $L^1(B;\mathbb{R}^d)$, $\mathcal{H}^{N-1}(S_{v_k} \cap B) \to 0$, and

$$\frac{d\lambda}{d\mathcal{L}^N}(x_0) = \lim_{k\to+\infty} \frac{1}{\omega_N} \int_B f(x_0 + \rho_k y, u(x_0) + \rho_k v_k, \nabla v_k)\, dy. \tag{3.7}$$

From now on, all the integrals will be restricted to the unit ball B.

Step 2. We now use the same truncation argument as in the proof of [3, Proposition 5.37]. Define $\hat{v}_k := (\sqrt{1+|v_k - w_0|^2} - 2)^+$ so that by Theorem 3.96 and Proposition 3.64(c) in [3], $\hat{v}_k \in SBV(B)$, $|\nabla \hat{v}_k| \le |\nabla v_k - \nabla w_0|$ $\mathcal{L}^N$-a.e. in B, and $S_{\hat{v}_k} \subset S_{v_k}$. According to the coarea formula in BV [3, Theorem 3.40], we have that

$$\begin{aligned}\int_0^1 \mathcal{H}^{N-1}\big(\partial^*\{\hat{v}_k > t\} \cap (B \setminus S_{\hat{v}_k})\big)\, dt \le |D\hat{v}_k|(B \setminus S_{\hat{v}_k}) = \int_B |\nabla \hat{v}_k|\, dx \\ \le \int_{B\cap\{|v_k - w_0| > \sqrt{3}\}} |\nabla v_k - \nabla w_0|\, dx,\end{aligned}$$

where we have used the fact that $\nabla \hat{v}_k = 0$ $\mathcal{L}^N$-a.e. in $B \cap \{|v_k - w_0| \le \sqrt{3}\}$. From (3.7) and the p-coercivity condition (3.1), the sequence $\{\nabla v_k\}$ is uniformly bounded in $L^p(B;\mathbb{R}^{d\times N})$, and since $p > 1$, it is equi-integrable. Using the fact that $\mathcal{L}^N(B \cap \{|v_k - w_0| > \sqrt{3}\}) \to 0$ we obtain that the right-hand side of the previous relation tends to zero as $k \to +\infty$. Consequently, one can find $t_k \in (0,1)$ such that $A_k := \{\hat{v}_k > t_k\}$ has finite perimeter in B and

$$\lim_{k\to+\infty} \mathcal{H}^{N-1}(B \cap \partial^* A_k \setminus S_{\hat{v}_k}) = 0. \tag{3.8}$$

Define $\tilde{v}_k := v_k \chi_{B\setminus A_k} + w_0 \chi_{B\cap A_k}$ so that $\tilde{v}_k \to w_0$ in $L^1(B;\mathbb{R}^d)$. As $|\hat{v}_k| \le t_k < 1$ in $B \setminus A_k$ it follows that $|v_k - w_0| \le 2\sqrt{2}$ in $B \setminus A_k$ and thus

$$\|\tilde{v}_k\|_{L^\infty(B;\mathbb{R}^d)} \le \|v_k\|_{L^\infty(B\setminus A_k;\mathbb{R}^d)} + \|w_0\|_{L^\infty(B;\mathbb{R}^d)} \le M, \tag{3.9}$$

where $M > 0$ is independent of k. Denoting by v_k^- the exterior trace of v_k on $\partial^* A_k \cap B$ oriented by the inner normal of A_k, [3, Remark 3.85] implies that $|v_k^-(x)| \le M$ for $\mathcal{H}^{N-1}$-a.e. $x \in \partial^* A_k \cap B$ and thus

$$\int_{\partial^* A_k \cap B} |v_k^-|\, d\mathcal{H}^{N-1} \le M \mathcal{H}^{N-1}(\partial^* A_k \cap B) < +\infty$$

so that [3, Theorem 3.84] ensures that $\tilde{v}_k \in SBV(B;\mathbb{R}^d)$. Since $S_{\tilde{v}_k} \subset S_{v_k} \cup \partial_* A_k$, by (3.8) we get that

$$\begin{aligned}\mathcal{H}^{N-1}(B \cap S_{\tilde{v}_k}) &\le \mathcal{H}^{N-1}(B \cap S_{v_k}) + \mathcal{H}^{N-1}(B \cap \partial_* A_k \setminus S_{v_k}) \\ &\le \mathcal{H}^{N-1}(B \cap S_{v_k}) + \mathcal{H}^{N-1}(B \cap \partial^* A_k \setminus S_{\hat{v}_k}) \to 0,\end{aligned}$$

where we used the fact that $S_{\hat{v}_k} \subset S_{v_k}$ and $\mathcal{H}^{N-1}(B \cap \partial_* A_k \setminus \partial^* A_k) = 0$. Using the locality of approximate gradients and the p-growth condition (3.1), we get that

$$\begin{aligned}\int_B & f(x_0+\rho_k y, u(x_0)+\rho_k \tilde v_k, \nabla \tilde v_k)\, dy\\ &= \int_{B\setminus A_k} f(x_0+\rho_k y, u(x_0)+\rho_k v_k, \nabla v_k)\, dy\\ &\qquad + \int_{B\cap A_k} f(x_0+\rho_k y, u(x_0)+\rho_k w_0, \nabla u(x_0))\, dy\\ &\le \int_B f(x_0+\rho_k y, u(x_0)+\rho_k v_k, \nabla v_k)\, dy\\ &\qquad + \int_{B\cap A_k} [a(x_0+\rho_k y)+\psi(|u(x_0)+\rho_k w_0|)(1+|\nabla u(x_0)|^p)]\, dy.\end{aligned}$$

By the choice of x_0, the sequence $\{a(x_0+\rho_k\cdot)\}$ is strongly converging in $L^1(B)$ to $a(x_0)$, and thus it is equi-integrable. Hence as $\mathcal{L}^N(A_k)\le \mathcal{L}^N(\{|v_k-w_0|\ge\sqrt{3}\})\to 0$ we deduce that the second term on the right-hand side of the previous relation tends to zero as $k\to+\infty$, and thanks to (3.7) it follows that

$$\frac{d\lambda}{d\mathcal{L}^N}(x_0)\ge \limsup_{k\to+\infty}\frac{1}{\omega_N}\int_B f(x_0+\rho_k y, u(x_0)+\rho_k\tilde v_k, \nabla\tilde v_k)\, dy. \tag{3.10}$$

Step 3. By (3.9) we have that $|D^s\tilde v_k|(B)\le 2M\mathcal{H}^{N-1}(S_{\tilde v_k}\cap B)\to 0$, while the p-coercivity condition (3.1) and item (b) imply that

$$\sup_{k\in\mathbb{N}}\|\nabla\tilde v_k\|_{L^p(B;\mathbb{R}^{d\times N})}<+\infty.$$

Consequently the sequence $\{\tilde v_k\}$ fulfills the assumptions of Theorem 3.1 so that considering a suitable (not relabeled) subsequence, there exist a Lebesgue measurable set $E_k\subset B$ and a sequence $\{w_k\}\subset W^{1,\infty}(B;\mathbb{R}^d)$ such that $\{|\nabla w_k|^p\}$ is equi-integrable, $w_k=\tilde v_k$ on $B\setminus E_k$, and $\mathcal{L}^N(E_k)\to 0$. From the proof of [21, Lemma 2.1], it can also be checked that $\sup_k\|w_k\|_{L^\infty(B;\mathbb{R}^d)}\le M$. As

$$\int_B |w_k-w_0|\, dy\le \int_{B\setminus E_k}|\tilde v_k-w_0|\, dy+2M\mathcal{L}^N(E_k)\to 0$$

it follows that $w_k\to w_0$ in $L^1(B;\mathbb{R}^d)$, and defining the set $B_k^t:=\{x\in B: |\nabla w_k(x)|\le t\}$, relation (3.10) leads to

$$\frac{d\lambda}{d\mathcal{L}^N}(x_0)\ge \limsup_{t\to+\infty}\limsup_{k\to+\infty}\frac{1}{\omega_N}\int_{B_k^t\setminus E_k} f(x_0+\rho_k y, u(x_0)+\rho_k w_k, \nabla w_k)\, dy.$$

Now using (3.3) with $\rho_{i(k)}=\rho_k$, we obtain that

$$\lim_{k\to+\infty}\int_{B_k^t\setminus E_k}|f(x_0+\rho_k y, u(x_0)+\rho_k w_k, \nabla w_k)-f(x_0,u(x_0),\nabla w_k)|\, dy=0$$

for each $t>0$, implying that

$$\frac{d\lambda}{d\mathcal{L}^N}(x_0)\ge \limsup_{t\to+\infty}\limsup_{k\to+\infty}\frac{1}{\omega_N}\int_{B_k^t\setminus E_k} f(x_0,u(x_0),\nabla w_k)\, dy. \tag{3.11}$$

Since $\mathcal{L}^N(E_k) \to 0$, according to the p-growth condition (3.1) we get that for every $t > 0$,

$$\int_{E_k \cap B_k^t} f(x_0, u(x_0), \nabla w_k)\, dy \leq \big(a(x_0) + \psi(|u(x_0)|)(1+t^p)\big)\mathcal{L}^N(E_k) \xrightarrow[k\to+\infty]{} 0. \tag{3.12}$$

On the other hand, Chebyshev's inequality ensures the existence of a constant $c > 0$ (independent of k and t) such that $\mathcal{L}^N(B \setminus B_k^t) \leq c/t^p \to 0$ as $t \to +\infty$, so that the equi-integrability of $\{|\nabla w_k|^p\}$ yields

$$\begin{aligned} &\sup_{k\in\mathbb{N}} \int_{B\setminus B_k^t} f(x_0, u(x_0), \nabla w_k)\, dy \\ &\leq \sup_{k\in\mathbb{N}} \int_{B\setminus B_k^t} \big(a(x_0) + \psi(|u(x_0)|)(1 + |\nabla w_k|^p)\big)\, dy \xrightarrow[t\to+\infty]{} 0. \end{aligned} \tag{3.13}$$

Gathering (3.11), (3.12), and (3.13), we deduce that

$$\frac{d\lambda}{d\mathcal{L}^N}(x_0) \geq \limsup_{k\to+\infty} \frac{1}{\omega_N} \int_B f(x_0, u(x_0), \nabla w_k)\, dy,$$

and since $w_k \rightharpoonup w_0$ in $W^{1,p}(B;\mathbb{R}^d)$, we can apply [1, Theorem II-4] to conclude that

$$\frac{d\lambda}{d\mathcal{L}^N}(x_0) \geq f(x_0, u(x_0), \nabla u(x_0)),$$

which yields the desired result. ∎

4. Structure of approximate scaled gradients. In this section we prove the following theorem, Theorem 4.1, which is a result similar to Theorem 3.1 in the context of dimension reduction. Note that it generalizes [8, Theorem 1.1] and [13, Theorem 3.1] (with obvious changes for nD-$(n-k)$D dimensional reduction). Its proof relies on a slicing argument similar to that used in [13, Theorem 3.1]. It will be instrumental in section 6 to prove Theorem 6.1 because it will enable us to replace SBV minimizing sequences by Lipschitz ones without increasing the energy.

From now on, $\Omega := \omega \times I$, where ω is a bounded open subset of $\mathbb{R}^2$ and $I := (-1/2, 1/2)$.

THEOREM 4.1. *Assume that ω has a Lipschitz boundary and $p > 1$. Let $\{\varepsilon_n\} \searrow 0^+$ and $\{u_n\} \subset SBV^p(\Omega;\mathbb{R}^3)$ be such that*

$$\sup_{n\in\mathbb{N}} \left\{ \|u_n\|_{L^\infty(\Omega;\mathbb{R}^3)} + \int_\Omega \left| \left(\nabla_\alpha u_n \Big| \frac{1}{\varepsilon_n} \nabla_3 u_n \right) \right|^p dx \right\} < +\infty, \tag{4.1}$$

$$\int_{S_{u_n}} \left| \left(\big(\nu_{u_n}\big)_\alpha \Big| \frac{1}{\varepsilon_n} \big(\nu_{u_n}\big)_3 \right) \right| d\mathcal{H}^2 \to 0 \tag{4.2}$$

and that $u_n \rightharpoonup u$ in $SBV^p(\Omega;\mathbb{R}^3)$, $(1/\varepsilon_n)\nabla_3 u_n \rightharpoonup b$ in $L^p(\Omega;\mathbb{R}^3)$ for some $u \in W^{1,p}(\omega;\mathbb{R}^3)$, and $b \in L^p(\Omega;\mathbb{R}^3)$. Then there exist a subsequence $\{\varepsilon_{n_k}\} \subset \{\varepsilon_n\}$ and a sequence $\{z_k\} \subset W^{1,\infty}(\Omega;\mathbb{R}^3)$ such that $z_k \rightharpoonup u$ in $W^{1,p}(\Omega;\mathbb{R}^3)$, $(1/\varepsilon_{n_k})\nabla_3 z_k \rightharpoonup b$ in $L^p(\Omega;\mathbb{R}^3)$, the sequence $\big\{\big|\big(\nabla_\alpha z_k | \frac{1}{\varepsilon_{n_k}} \nabla_3 z_k\big)\big|^p\big\}$ is equi-integrable, and

$$\mathcal{L}^3(\{z_k \neq u_{n_k}\} \cup \{\nabla z_k \neq \nabla u_{n_k}\}) \to 0.$$

Proof. The proof is based on a slicing argument. We first come back to the nonrescaled cylinder $\Omega_{\varepsilon_n} = \omega \times (-\varepsilon_n/2, \varepsilon_n/2)$ of thickness ε_n setting $v_n(x_\alpha, x_3) := u_n(x_\alpha, x_3/\varepsilon_n)$. It follows that for each $n \in \mathbb{N}$, $v_n \in SBV^p(\Omega_{\varepsilon_n}; \mathbb{R}^3)$, and changing variables in (4.1) we get that

$$\sup_{n\in\mathbb{N}} \left\{ \|v_n\|_{L^\infty(\Omega_{\varepsilon_n};\mathbb{R}^3)} + \frac{1}{\varepsilon_n} \int_{\Omega_{\varepsilon_n}} |\nabla v_n|^p \, dx \right\} < +\infty \tag{4.3}$$

and

$$\mathcal{H}^2(S_{v_n}) = \varepsilon_n \int_{S_{u_n}} \left| \left((\nu_{u_n})_\alpha \Big| \frac{1}{\varepsilon_n} (\nu_{u_n})_3 \right) \right| d\mathcal{H}^2. \tag{4.4}$$

We now periodize the functions v_n in the transverse direction defining

$$\hat{v}_n(x_\alpha, x_3) := \begin{cases} v_n(x_\alpha, -\varepsilon_n - x_3) & \text{if } \ -\varepsilon_n < x_3 \le -\frac{\varepsilon_n}{2}, \\ v_n(x_\alpha, x_3) & \text{if } \ -\frac{\varepsilon_n}{2} < x_3 < \frac{\varepsilon_n}{2}, \\ v_n(x_\alpha, \varepsilon_n - x_3) & \text{if } \ \frac{\varepsilon_n}{2} \le x_3 < \varepsilon_n. \end{cases}$$

Then $\hat{v}_n \in SBV^p\big(\omega \times (-\varepsilon_n, \varepsilon_n); \mathbb{R}^3\big)$ for each $n \in \mathbb{N}$, and from (4.3) and (4.4) it follows that

$$\sup_{n\in\mathbb{N}} \left\{ \|\hat{v}_n\|_{L^\infty(\omega\times(-\varepsilon_n,\varepsilon_n);\mathbb{R}^3)} + \frac{1}{\varepsilon_n} \int_{\omega\times(-\varepsilon_n,\varepsilon_n)} |\nabla \hat{v}_n|^p \, dx \right\} < +\infty \tag{4.5}$$

and

$$\mathcal{H}^2(S_{\hat{v}_n}) = 2\varepsilon_n \int_{S_{u_n}} \left| \left((\nu_{u_n})_\alpha \Big| \frac{1}{\varepsilon_n} (\nu_{u_n})_3 \right) \right| d\mathcal{H}^2. \tag{4.6}$$

We are now in a position to extend $\hat{v}_n$ by periodicity in the x_3 direction. Note that we do not create any additional jump set because periodicity ensures continuity at the interface of each slice. Let

$$N_n := \begin{cases} \dfrac{1}{4\varepsilon_n} - \dfrac{1}{2} & \text{if } \ \dfrac{1}{4\varepsilon_n} - \dfrac{1}{2} \in \mathbb{N}, \\ \left[\dfrac{1}{4\varepsilon_n} + \dfrac{1}{2} \right] & \text{otherwise}, \end{cases}$$

where $[t]$ denotes the integer part of t. For every $i \in \{-N_n, \dots, N_n\}$, we set $I_{i,n} := \big((2i-1)\varepsilon_n, (2i+1)\varepsilon_n\big)$ and $\Omega_{i,n} := \omega \times I_{i,n}$. Note that N_n is the largest integer such that $\Omega \cap \Omega_{i,n} \neq \emptyset$ for every $i \in \{-N_n, \dots, N_n\}$. We define the function $\tilde{v}_n$ on $\Omega(n) := \omega \times (-(2N_n+1)\varepsilon_n, (2N_n+1)\varepsilon_n)$ by extending $\hat{v}_n$ by periodicity in the x_3 direction on $\Omega(n)$:

$$\tilde{v}_n(x_\alpha, x_3) = \hat{v}_n(x_\alpha, x_3 - 2i\varepsilon_n) \quad \text{if } x_3 \in I_{i,n}.$$

Since $\Omega \subset \Omega(n)$, $\tilde{v}_n \in SBV^p(\Omega; \mathbb{R}^3)$ and thanks to (4.5) and the definition of N_n, we have that

$$\sup_{n\in\mathbb{N}} \left\{ \|\tilde{v}_n\|_{L^\infty(\Omega;\mathbb{R}^3)} + \int_\Omega |\nabla \tilde{v}_n|^p \, dx \right\} < +\infty, \tag{4.7}$$

while (4.6), together with (4.2), implies that

$$\mathcal{H}^2(S_{\tilde{v}_n}) \le c \int_{S_{u_n}} \left| \left((\nu_{u_n})_\alpha \Big| \frac{1}{\varepsilon_n} (\nu_{u_n})_3 \right) \right| d\mathcal{H}^2 \to 0. \tag{4.8}$$

As a consequence of (4.7) and (4.8), the sequence $\{\tilde{v}_n\}$ fulfills the assumptions of Theorem 3.1. Hence there exist a subsequence $\{\varepsilon_{n_k}\} \subset \{\varepsilon_n\}$ and a sequence $\{w_k\} \subset W^{1,\infty}(\Omega;\mathbb{R}^3)$ such that

$$\begin{cases} \sup_{k\in\mathbb{N}} \|w_k\|_{W^{1,p}(\Omega;\mathbb{R}^3)} < +\infty, \\ \{|\nabla w_k|^p\} \text{ is equi-integrable}, \\ \mathcal{L}^3(\{\tilde{v}_{n_k} \neq w_k\} \cup \{\nabla \tilde{v}_{n_k} \neq \nabla w_k\}) \to 0. \end{cases}$$

From de La Vallée Poussin's criterion, one can find an increasing and continuous function $\vartheta : [0,+\infty) \to [0,+\infty]$ such that $\vartheta(t)/t \to +\infty$ as $t \to +\infty$ and

$$\sup_{k\in\mathbb{N}} \int_\Omega \vartheta(|\nabla w_k|^p)\, dx < +\infty.$$

We claim that for at least half of the indexes $i \in \{-N_{n_k}+1, \dots, N_{n_k}-1\}$, there holds that

$$\begin{aligned} \frac{2N_{n_k}-1}{2} \int_{\Omega_{i,n_k}} &\left[\vartheta(|\nabla w_k|^p) + |w_k|^p + |\nabla w_k|^p\right] dx \\ &\le \int_\Omega \left[\vartheta(|\nabla w_k|^p) + |w_k|^p + |\nabla w_k|^p\right] dx. \end{aligned} \tag{4.9}$$

If not, define J_k to be the set of indexes $i \in \{-N_{n_k}+1, \dots, N_{n_k}-1\}$ such that (4.9) does not hold. Then it would imply that $\#(J_k) > (2N_{n_k}-1)/2$ and

$$\begin{aligned} \int_\Omega &\left[\vartheta(|\nabla w_k|^p) + |w_k|^p + |\nabla w_k|^p\right] dx \\ &\ge \sum_{i\in J_k} \int_{\Omega_{i,n_k}} \left[\vartheta(|\nabla w_k|^p) + |w_k|^p + |\nabla w_k|^p\right] dx \\ &> \frac{2}{2N_{n_k}-1} \#(J_k) \int_\Omega \left[\vartheta(|\nabla w_k|^p) + |w_k|^p + |\nabla w_k|^p\right] dx, \end{aligned}$$

which is absurd. Similarly, one can show that for at least half of the indexes satisfying (4.9), we have that

$$\begin{aligned} \frac{2N_{n_k}-1}{4} &\mathcal{L}^3 \llcorner \Omega_{i,n_k}(\{\tilde{v}_{n_k} \neq w_k\} \cup \{\nabla \tilde{v}_{n_k} \neq \nabla w_k\}) \\ &\le \mathcal{L}^3(\{\tilde{v}_{n_k} \neq w_k\} \cup \{\nabla \tilde{v}_{n_k} \neq \nabla w_k\}). \end{aligned} \tag{4.10}$$

Let $i_k \in \{-N_{n_k}+1, \dots, N_{n_k}-1\}$ be such that (4.9) and (4.10) hold at the same time. Now define $z_k(x_\alpha, x_3) := w_k(x_\alpha, \varepsilon_{n_k} x_3 + 2\varepsilon_{n_k} i_k)$. Changing variables in (4.9) and (4.10) and using the construction of $\tilde{v}_{n_k}$ from u_{n_k} we get that

$$\begin{aligned} \varepsilon_{n_k} \frac{2N_{n_k}-1}{2} \int_\Omega &\left[\vartheta\left(\left|\left(\nabla_\alpha z_k \Big| \frac{1}{\varepsilon_{n_k}} \nabla_3 z_k\right)\right|^p\right) + |z_k|^p + \left|\left(\nabla_\alpha z_k \Big| \frac{1}{\varepsilon_{n_k}} \nabla_3 z_k\right)\right|^p\right] dx \\ &\le \int_\Omega \left[\vartheta(|\nabla w_k|^p) + |w_k|^p + |\nabla w_k|^p\right] dx \end{aligned}$$

and

$$\varepsilon_{n_k} \frac{2N_{n_k}-1}{4} \mathcal{L}^3 \llcorner \Omega \left(\{u_{n_k} \neq z_k\} \cup \{\nabla u_{n_k} \neq \nabla z_k\}\right)$$
$$\leq \mathcal{L}^3(\{\tilde{v}_{n_k} \neq w_k\} \cup \{\nabla \tilde{v}_{n_k} \neq \nabla w_k\}).$$

Since $\varepsilon_{n_k}(2N_{n_k}-1) \geq 1/4$ for k large enough, it follows that

$$\begin{cases} \displaystyle\sup_{k\in\mathbb{N}} \int_\Omega \left[\vartheta\left(\left|\left(\nabla_\alpha z_k \Big| \frac{1}{\varepsilon_{n_k}}\nabla_3 z_k\right)\right|^p\right) + |z_k|^p + \left|\left(\nabla_\alpha z_k \Big| \frac{1}{\varepsilon_{n_k}}\nabla_3 z_k\right)\right|^p\right] dx < +\infty, \\ \mathcal{L}^3(\{u_{n_k} \neq z_k\} \cup \{\nabla u_{n_k} \neq \nabla z_k\}) \to 0, \end{cases}$$

and the equi-integrability of $\left\{\left|\left(\nabla_\alpha z_k \big| \frac{1}{\varepsilon_{n_k}}\nabla_3 z_k\right)\right|^p\right\}$ follows from de La Vallée Poussin's criterion.

It remains to prove the weak convergence of z_k and $(1/\varepsilon_{n_k})\nabla_3 z_k$. Let $v \in L^{p'}(\Omega;\mathbb{R}^3)$ with $1/p + 1/p' = 1$; then

$$\int_\Omega (z_k - u)\cdot v\,dx = \int_{\{z_k = u_{n_k}\}} (u_{n_k} - u)\cdot v\,dx + \int_{\{z_k \neq u_{n_k}\}} (z_k - u)\cdot v\,dx.$$

As $\mathcal{L}^3(\{z_k \neq u_{n_k}\}) \to 0$, it follows that $v\chi_{\{z_k = u_{n_k}\}} \to v$ in $L^{p'}(\Omega;\mathbb{R}^3)$. Then, using Hölder's inequality, the fact that $\{z_k\}$ is uniformly bounded in $L^p(\Omega;\mathbb{R}^3)$, and the fact that $u_{n_k} \rightharpoonup u$ in $L^p(\Omega;\mathbb{R}^3)$, we obtain that

$$\lim_{k\to+\infty} \left|\int_\Omega (z_k - u)\cdot v\,dx\right| \leq \lim_{k\to+\infty} \left|\int_\Omega (u_{n_k} - u)\cdot v\chi_{\{z_k = u_{n_k}\}}\,dx\right|$$
$$+ \lim_{k\to+\infty} \|z_k - u\|_{L^p(\Omega;\mathbb{R}^3)} \|v\chi_{\{z_k \neq u_{n_k}\}}\|_{L^{p'}(\Omega;\mathbb{R}^3)} = 0.$$

Similarly we may show that $\nabla z_k \rightharpoonup \nabla u$ in $L^p(\Omega;\mathbb{R}^{3\times 3})$ and that $(1/\varepsilon_{n_k})\nabla_3 z_k \rightharpoonup b$ in $L^p(\Omega;\mathbb{R}^3)$. ◻

5. Integral representation for dimension reduction problems in Sobolev spaces involving the bending moment.

Consider a Carathéodory function $W_\varepsilon : \Omega \times \mathbb{R}^{3\times 3} \to [0,+\infty)$ satisfying uniform p-growth and p-coercivity conditions: there exist $0 < \beta' \leq \beta < +\infty$ and $1 < p < +\infty$ such that

$$\beta'|\xi|^p \leq W_\varepsilon(x,\xi) \leq \beta(1 + |\xi|^p) \tag{5.1}$$

for a.e. $x \in \Omega$ and all $\xi \in \mathbb{R}^{3\times 3}$. Define $\mathcal{J}_\varepsilon : L^p(\Omega;\mathbb{R}^3) \times L^p(\omega;\mathbb{R}^3) \times \mathcal{A}(\omega) \to [0,+\infty]$ by

$$\mathcal{J}_\varepsilon(u,\overline{b},A) := \begin{cases} \displaystyle\int_{A\times I} W_\varepsilon\left(x, \nabla_\alpha u \Big| \frac{1}{\varepsilon}\nabla_3 u\right) dx & \text{if } \begin{cases} u \in W^{1,p}(A\times I;\mathbb{R}^3), \\ \overline{b} = \frac{1}{\varepsilon}\int_I \nabla_3 u(\cdot,x_3)\,dx_3, \end{cases} \\ +\infty & \text{otherwise.} \end{cases}$$

We prove the following integral representation for the Γ-limit.

THEOREM 5.1. *For every sequence $\{\varepsilon_n\} \searrow 0^+$, there exist a subsequence (not relabeled) and a Carathéodory function $W^* : \omega \times \mathbb{R}^{3\times 2} \times \mathbb{R}^3 \to [0,+\infty)$ (depending on* *the subsequence) such that for every $A \in \mathcal{A}(\omega)$, the sequence $\mathcal{J}_{\varepsilon_n}(\cdot,\cdot,A)$ Γ-converges in $L^p_s(A\times I;\mathbb{R}^3)\times L^p_w(A;\mathbb{R}^3)$ to $\mathcal{J}(\cdot,\cdot,A)$, where*

$$\mathcal{J}(u,\overline{b},A) = \begin{cases} \displaystyle\int_A W^*(x_\alpha, \nabla_\alpha u(x_\alpha)|\overline{b}(x_\alpha))\,dx_\alpha & \text{if } u \in W^{1,p}(A;\mathbb{R}^3),\\ +\infty & \text{otherwise.}\end{cases}$$

Proof. For every $\{\varepsilon_n\} \searrow 0^+$, $u \in L^p(\Omega;\mathbb{R}^3)$, $\overline{b} \in L^p(\omega;\mathbb{R}^3)$, and $A \in \mathcal{A}(\omega)$, let

$$\mathcal{J}(u,\overline{b},A) := \inf_{\{u_n,\overline{b}_n\}} \Big\{ \liminf_{n\to+\infty} \mathcal{J}_{\varepsilon_n}(u_n,\overline{b}_n,A) : u_n \to u \text{ in } L^p(A\times I;\mathbb{R}^3) \text{ and } \overline{b}_n \rightharpoonup \overline{b} \text{ in } L^p(A;\mathbb{R}^3)\Big\}.$$

Repeating word for word the (standard) proof of [9, Lemma 2.1] one can show that there exists a subsequence, still labeled $\{\varepsilon_n\}$, such that for any $A \in \mathcal{A}(\omega)$, $\mathcal{J}(\cdot,\cdot,A)$ is the Γ-limit in $L^p_s(A\times I;\mathbb{R}^3)\times L^p_w(A;\mathbb{R}^3)$ of $\mathcal{J}_{\varepsilon_n}(\cdot,\cdot,A)$, that $\mathcal{J}(u,\overline{b},A) = +\infty$ if $u \in L^p(\Omega;\mathbb{R}^3)\setminus W^{1,p}(A;\mathbb{R}^3)$, and that for every $(u,\overline{b}) \in W^{1,p}(\omega;\mathbb{R}^3)\times L^p(\omega;\mathbb{R}^3)$, the set function $\mathcal{J}(u,\overline{b},\cdot)$ is the restriction to $\mathcal{A}(\omega)$ of a Radon measure absolutely continuous with respect to the Lebesgue measure $\mathcal{L}^2$. The remainder of the proof is very close to that of [14, Theorem 1.1]; thus we will point out only the main changes. Let $\overline{\xi} \in \mathbb{R}^{3\times 2}$, $z \in \mathbb{R}^3$, and $x_0 \in \omega$ and define

$$W^*(x_0,\overline{\xi}|z) := \limsup_{\rho\to 0^+} \frac{\mathcal{J}(u_{\overline{\xi}},\overline{b}_z,Q'(x_0,\rho))}{\rho^2},$$

where we have denoted $u_{\overline{\xi}}(x_\alpha) := \overline{\xi}\,x_\alpha$ and $\overline{b}_z(x_\alpha) := z$. Since $\mathcal{J}(u_{\overline{\xi}},\overline{b}_z,\cdot)$ is (the restriction of) a Radon measure absolutely continuous with respect to $\mathcal{L}^2$, we have for every $A \in \mathcal{A}(\omega)$,

$$\mathcal{J}(u_{\overline{\xi}},\overline{b}_z,A) = \int_A W^*(x_\alpha,\overline{\xi}|z)\,dx_\alpha = \int_A W^*(x_\alpha,\nabla_\alpha u_{\overline{\xi}}|\overline{b}_z)\,dx_\alpha. \tag{5.2}$$

By additivity, it is clear that

$$\mathcal{J}(u,\overline{b},A) = \int_A W^*(x_\alpha,\nabla_\alpha u|\overline{b})\,dx_\alpha \tag{5.3}$$

holds whenever u is piecewise affine and $\overline{b}$ is piecewise constant in A and we wish to extend (5.3) to arbitrary functions $u \in W^{1,p}(A;\mathbb{R}^3)$ and $\overline{b} \in L^p(A;\mathbb{R}^3)$.

Using the lower semicontinuity of $\mathcal{J}$ and a suitable choice of sequence, one can show as in [14, Theorem 1.1] that $\overline{\xi} \mapsto W^*(x_0,\overline{\xi}|z)$ is rank one convex. We claim that $z \mapsto W^*(x_0,\overline{\xi}|z)$ is convex. To see this let $\theta \in [0,1]$, z_1, $z_2 \in \mathbb{R}^3$, and $\overline{\xi} \in \mathbb{R}^{3\times 2}$. Fix $x_0 \in \omega$, $\rho > 0$ and take an open set $A \subset Q'(x_0,\rho)$ such that $\mathcal{L}^2(\partial A) = 0$ and $\mathcal{L}^2(A) = \theta\rho^2$ (take, e.g., $A = Q'(x_0,\sqrt{\theta}\rho)$). Define

$$\overline{b}_n(x_\alpha) := z_1\chi(nx_\alpha) + z_2(1-\chi(nx_\alpha)),$$

where χ is the characteristic function of A in $Q'(x_0,\rho)$ which has been extended to $\mathbb{R}^2$ by ρ-periodicity. The Riemann–Lebesgue lemma asserts that $\overline{b}_n \rightharpoonup \overline{b}_{\theta z_1+(1-\theta)z_2}$ in

$L^p(Q'(x_0,\rho);\mathbb{R}^3)$, and since $\mathcal{J}(u_{\overline{\xi}},\cdot,Q'(x_0,\rho))$ is sequentially weakly lower semicontinuous in $L^p(Q'(x_0,\rho);\mathbb{R}^3)$, it follows that

$$\begin{aligned}
&\mathcal{J}(u_{\overline{\xi}},\overline{b}_{\theta z_1+(1-\theta)z_2},Q'(x_0,\rho))\\
&\qquad\le \liminf_{n\to+\infty}\mathcal{J}(u_{\overline{\xi}},\overline{b}_n,Q'(x_0,\rho))\\
&\qquad= \liminf_{n\to+\infty}\left\{\mathcal{J}(u_{\overline{\xi}},\overline{b}_{z_1},A_n)+\mathcal{J}(u_{\overline{\xi}},\overline{b}_{z_2},Q'(x_0,\rho)\setminus\overline{A}_n)\right\},
\end{aligned}\tag{5.4}$$

where $A_n:=\{x_\alpha\in Q'(x_0,\rho):\chi(nx_\alpha)=1\}$ is an open set. Note that in the last equality, we have used the fact that since $\mathcal{L}^2(\partial A_n)=0$, then $\mathcal{J}(u_{\overline{\xi}},\overline{b}_n,\partial A_n)=0$ as well, and that $\mathcal{J}$ is local on open sets. Using once more the Riemann–Lebesgue lemma together with (5.2), we get that

$$\begin{aligned}
\lim_{n\to+\infty}\mathcal{J}(u_{\overline{\xi}},\overline{b}_{z_1},A_n)&=\lim_{n\to+\infty}\int_{Q'(x_0,\rho)}\chi(nx_\alpha)W^*(x_\alpha,\overline{\xi}|z_1)\,dx_\alpha\\
&=\theta\int_{Q'(x_0,\rho)}W^*(x_\alpha,\overline{\xi}|z_1)\,dx_\alpha\\
&=\theta\mathcal{J}(u_{\overline{\xi}},\overline{b}_{z_1},Q'(x_0,\rho))
\end{aligned}$$

and similarly for the second term of (5.4). Hence we deduce that

$$\mathcal{J}(u_{\overline{\xi}},\overline{b}_{\theta z_1+(1-\theta)z_2},Q'(x_0,\rho))\le\theta\mathcal{J}(u_{\overline{\xi}},\overline{b}_{z_1},Q'(x_0,\rho))+(1-\theta)\mathcal{J}(u_{\overline{\xi}},\overline{b}_{z_2},Q'(x_0,\rho)),$$

and the convexity of $W^*(x_0,\overline{\xi}|\cdot)$ arises after dividing the previous inequality by ρ^2 and taking the lim sup as ρ tends to zero. It follows that $(\overline{\xi}|z)\mapsto W^*(x_0,\overline{\xi}|z)$ is separately convex for a.e. $x_0\in\omega$, and since the following p-growth and p-coercivity conditions hold,

$$\beta'(|\overline{\xi}|^p+|z|^p)\le W^*(x_0,\overline{\xi}|z)\le\beta(1+|\overline{\xi}|^p+|z|^p),\tag{5.5}$$

for a.e. $x_0\in\omega$ and all $(\overline{\xi},z)\in\mathbb{R}^{3\times2}\times\mathbb{R}^3$, we conclude that $(\overline{\xi}|z)\mapsto W^*(x_0,\overline{\xi}|z)$ is continuous for a.e. $x_0\in\omega$, which proves that W^* is a Carathéodory function.

We now prove that (5.3) holds for any $(u,\overline{b})\in W^{1,p}(A;\mathbb{R}^3)\times L^p(A;\mathbb{R}^3)$. By approximation and thanks to the lower semicontinuity of $\mathcal{J}(\cdot,\cdot,A)$ for the strong $W^{1,p}(A;\mathbb{R}^3)\times L^p(A;\mathbb{R}^3)$ topology, there holds that

$$\mathcal{J}(u,\overline{b},A)\le\int_A W^*(x_\alpha,\nabla_\alpha u|\overline{b})\,dx_\alpha$$

for any $(u,\overline{b})\in W^{1,p}(A;\mathbb{R}^3)\times L^p(A;\mathbb{R}^3)$, and it remains to prove the converse inequality. This is achieved exactly as in the final step of the proof of [14, Theorem 1.1], by considering the translated functional

$$\widetilde{\mathcal{J}}(v,\overline{c},A):=\mathcal{J}(u+v,\overline{b}+\overline{c},A),$$

where $(u,\overline{b})$ are arbitrary functions in $W^{1,p}(A;\mathbb{R}^3)\times L^p(A;\mathbb{R}^3)$. □

We refer the reader to [8, 9] for more explicit formulas for the integrand W^* in particular cases.

The following technical proposition states some kind of blow-up result for functionals through Γ-convergence. It will be of use in the proof of the lower bound in Theorem 6.1 because at some point, we will need to get rid of small residual terms occurring inside the integrand W_ε. In [5, 6, 7], this difficulty was treated thanks to a decoupling variable method which consisted of replacing the function W_ε by a much more regular one thanks to the Scorza–Dragoni and the Tietze extension theorems, and the set where these two integrands did not match was controlled thanks to the equi-integrability result [8, Theorem 1.1]. This method was quite powerful in that context since the manner on which W_ε was depending on ε was completely known. However, in the generalized framework considered here, it no longer applies since we have no information on the way W_ε depends on ε. The following blow-up result, together with a diagonalization argument (see Remark 5.3 below), will enable us to overcome that problem.

PROPOSITION 5.2. *There exists a set $N \subset \omega$ with $\mathcal{L}^2(N) = 0$ such that for every $\{\rho_k\} \searrow 0^+$ and every $x_0 \in \omega \setminus N$, the functional $J_k : L^p(B' \times I;\mathbb{R}^3) \times L^p(B';\mathbb{R}^3) \to [0,+\infty]$ defined by*

$$J_k(u,\bar{b}) = \begin{cases} \displaystyle\int_{B'} W^*(x_0 + \rho_k x_\alpha, \nabla_\alpha u(x_\alpha)|\bar{b}(x_\alpha))\, dx_\alpha & \text{if } u \in W^{1,p}(B';\mathbb{R}^3), \\ +\infty & \text{otherwise} \end{cases}$$

Γ-converges in $L^p_s(B' \times I;\mathbb{R}^3) \times L^p_w(B';\mathbb{R}^3)$ to $J : L^p(B' \times I;\mathbb{R}^3) \times L^p(B';\mathbb{R}^3) \to [0,+\infty]$, where

$$J(u,\bar{b}) = \begin{cases} \displaystyle\int_{B'} W^*(x_0, \nabla_\alpha u(x_\alpha)|\bar{b}(x_\alpha))\, dx_\alpha & \text{if } u \in W^{1,p}(B';\mathbb{R}^3), \\ +\infty & \text{otherwise.} \end{cases}$$

Proof. The proof relies on the Scorza–Dragoni theorem (see, e.g., [17, Chapter VIII]). For any $q \in \mathbb{N}$, there exists a compact set $K_q \subset \omega$ with $\mathcal{L}^2(\omega \setminus K_q) < 1/q$ and such that W^* is continuous on $K_q \times \mathbb{R}^{3\times 2} \times \mathbb{R}^3$. Let $N := \omega \setminus \bigcup_q K_q^*$, where

$$K_q^* := \left\{ x \in K_q : \lim_{\rho \to 0} \frac{\mathcal{L}^2(B'(x_0,\rho) \setminus K_q)}{\mathcal{L}^2(B'(x_0,\rho))} = 0 \right\}. \tag{5.6}$$

Since $\mathcal{L}^2(K_q \setminus K_q^*) = 0$, then $\mathcal{L}^2(N) \le \mathcal{L}^2(\omega \setminus K_q^*) = \mathcal{L}^2(\omega \setminus K_q) < 1/q \to 0$. Select a point $x_0 \in \omega \setminus N$, so that $x_0 \in K_q^*$ for some $q \in \mathbb{N}$.

The upper bound. Assume first that $u \in W^{1,\infty}(B';\mathbb{R}^3)$ and $\bar{b} \in L^\infty(B';\mathbb{R}^3)$ and set $M := \|(\nabla_\alpha u|\bar{b})\|_{L^\infty(B';\mathbb{R}^{3\times 3})}$. Then according to the p-growth condition (5.5)

$$\begin{aligned} J_k(u,\bar{b}) &= \int_{B'} W^*(x_0 + \rho_k x_\alpha, \nabla_\alpha u|\bar{b})\, dx_\alpha \\ &\le \int_{B' \cap \left(\frac{K_q - x_0}{\rho_k}\right)} W^*(x_0 + \rho_k x_\alpha, \nabla_\alpha u|\bar{b})\, dx_\alpha \\ &\quad + \beta(1 + M^p)\mathcal{L}^2\left(B' \setminus \left(\frac{K_q - x_0}{\rho_k}\right)\right). \end{aligned} \tag{5.7}$$

As W^* is uniformly continuous on $K_q \times B(0,M)$, there exists a continuous and increasing function $\eta : [0,+\infty) \to [0,+\infty)$ such that $\eta(0) = 0$ and

$$\int_{B' \cap \left(\frac{K_q - x_0}{\rho_k}\right)} |W^*(x_0 + \rho_k x_\alpha, \nabla_\alpha u|\bar{b}) - W^*(x_0, \nabla_\alpha u|\bar{b})|\, dx_\alpha \leq \eta(\rho_k). \tag{5.8}$$

Gathering (5.6), (5.7), and (5.8) and passing to the limit as $k \to +\infty$ yields

$$\Gamma\text{-}\limsup_{k\to+\infty} J_k(u,\bar{b}) \leq \limsup_{k\to+\infty} J_k(u,\bar{b}) \leq J(u,\bar{b}).$$

The general case follows from the density of the space $W^{1,\infty}(B';\mathbb{R}^3) \times L^\infty(B';\mathbb{R}^3)$ in $W^{1,p}(B';\mathbb{R}^3) \times L^p(B';\mathbb{R}^3)$, the lower continuity of the Γ-limsup, and the continuity of J for the strong $W^{1,p}(B';\mathbb{R}^3) \times L^p(B';\mathbb{R}^3)$-topology.

The lower bound. Let $(u,\bar{b}) \in L^p(B' \times I;\mathbb{R}^3) \times L^p(B';\mathbb{R}^3)$ and $\{(u_k,\bar{b}_k)\} \subset L^p(B' \times I;\mathbb{R}^3) \times L^p(B';\mathbb{R}^3)$ such that $u_k \to u$ in $L^p(B' \times I;\mathbb{R}^3)$, $\bar{b}_k \rightharpoonup \bar{b}$ in $L^p(B';\mathbb{R}^3)$, and

$$\liminf_{k\to+\infty} J_k(u_k,\bar{b}_k) < +\infty.$$

Up to a subsequence (not relabeled) we can suppose that u and $u_k \in W^{1,p}(B';\mathbb{R}^3)$ for each $k \in \mathbb{N}$ and that $u_k \rightharpoonup u$ in $W^{1,p}(B';\mathbb{R}^3)$. According to the decomposition lemma [20, Lemma 1.2] and Chacon's biting lemma [3, Lemma 5.32], there is no loss of generality to assume that $\{|\nabla_\alpha u_k|^p\}$ and $\{|\bar{b}_k|^p\}$ are equi-integrable. Define the set $A_k^t := \left\{x_\alpha \in B' : |(\nabla_\alpha u_k(x_\alpha)|\bar{b}_k(x_\alpha))| \leq t\right\}$. From Chebyshev's inequality we have that $\mathcal{L}^2(B' \setminus A_k^t) \leq c/t^p$ for some constant $c > 0$ independent of t and k, and arguing exactly as in the proof of the upper bound, one can show that for each $t > 0$,

$$\liminf_{k\to+\infty} J_k(u_k,\bar{b}_k) \geq \liminf_{k\to+\infty} \int_{A_k^t \cap \left(\frac{K_q - x_0}{\rho_k}\right)} W^*(x_0, \nabla_\alpha u_k|\bar{b}_k)\, dx_\alpha. \tag{5.9}$$

According to the p-growth condition (5.5) and (5.6),

$$\begin{aligned} &\int_{A_k^t \setminus \left(\frac{K_q - x_0}{\rho_k}\right)} W^*(x_0, \nabla_\alpha u_k|\bar{b}_k)\, dx_\alpha \\ &\qquad \leq \beta(1+t^p)\mathcal{L}^2\left(B' \setminus \left(\frac{K_q - x_0}{\rho_k}\right)\right) \xrightarrow[k\to+\infty]{} 0, \end{aligned} \tag{5.10}$$

while the equi-integrability of $\{|\nabla_\alpha u_k|^p\}$ and $\{|\bar{b}_k|^p\}$ and the fact that $\mathcal{L}^2(B' \setminus A_k^t) \to 0$ as $t \to +\infty$ imply that

$$\begin{aligned} &\sup_{k\in\mathbb{N}} \int_{B' \setminus A_k^t} W^*(x_0, \nabla_\alpha u_k|\bar{b}_k)\, dx_\alpha \\ &\qquad \leq \beta \sup_{k\in\mathbb{N}} \int_{B' \setminus A_k^t} (1 + |\nabla_\alpha u_k|^p + |\bar{b}_k)|^p)\, dx_\alpha \xrightarrow[t\to+\infty]{} 0. \end{aligned} \tag{5.11}$$

Hence gathering (5.9), (5.10), and (5.11) yields

$$\liminf_{k\to+\infty} J_k(u_k,\bar{b}_k) \geq \liminf_{k\to+\infty} J(u_k,\bar{b}_k) \geq J(u,\bar{b}),$$

where the last inequality holds because J is sequentially weakly lower semicontinuous in $W^{1,p}(B';\mathbb{R}^3) \times L^p(B';\mathbb{R}^3)$. ◻

Remark 5.3. One can show that in Theorem 5.1, the value of $\mathcal{J}$ does not change when replacing W_{ε_n} by its quasi-convexification QW_{ε_n} defined by

$$QW_{\varepsilon_n}(x,\xi) := \inf_{\varphi \in W_0^{1,\infty}((0,1)^3;\mathbb{R}^3)} \int_{(0,1)^3} W_{\varepsilon_n}(x, \xi + \nabla\varphi(y))\, dy \tag{5.12}$$

for all $\xi \in \mathbb{R}^{3\times 3}$ and a.e. $x \in \Omega$. Hence there is no loss of generality to assume in Theorem 5.1 that W_ε is quasi-convex. Since the weak topology on every normed bounded subset of $L^p(B';\mathbb{R}^3)$ is metrizable, it follows from a diagonalization argument, Theorem 5.1, Proposition 5.2, and the fact that Γ-convergence of coercive and lower semicontinuous functionals on a metric space is metrizable (see [16, Theorem 10.22(a)]) that for every $M > 0$ and every sequence $\{\rho_k\} \searrow 0^+$, there exists a subsequence $n(k) \nearrow +\infty$ such that $\varepsilon_{n(k)}/\rho_k \to 0$ and for every $(u,\bar{b}) \in L^p(B' \times I;\mathbb{R}^3) \times L^p(B';\mathbb{R}^3)$ with $\|\bar{b}\|_{L^p(B';\mathbb{R}^3)} \le M$, the Γ-limit in $L^p_s(B' \times I;\mathbb{R}^3) \times L^p_w(B';\mathbb{R}^3)$ of

$$\begin{cases} \displaystyle\int_{B'\times I} W_{\varepsilon_{n(k)}}\left(x_0 + \rho_k x_\alpha, x_3, \nabla_\alpha u \Big| \frac{\rho_k}{\varepsilon_{n(k)}} \nabla_3 u\right) dx & \text{if } \begin{cases} u \in W^{1,p}(B' \times I;\mathbb{R}^3), \\ \bar{b} = \frac{\rho_k}{\varepsilon_{n(k)}} \int_I \nabla_3 u(\cdot, x_3)\, dx_3, \end{cases} \\ +\infty & \text{otherwise} \end{cases}$$

coincides with

$$\begin{cases} \displaystyle\int_{B'} W^*(x_0, \nabla_\alpha u|\bar{b})\, dx_\alpha & \text{if } u \in W^{1,p}(B';\mathbb{R}^3), \\ +\infty & \text{otherwise} \end{cases}$$

for every $x_0 \in \omega \setminus N$, where $N \subset \omega$ is the same exceptional set as in Proposition 5.2.

6. Integral representation for dimension reduction problems in *SBV* involving the bending moment. We now come to the heart of this study, that is, dealing with a similar problem to that in Theorem 5.1 but in the framework of special functions with bounded variation, adding a surface energy term. Let us define $\mathcal{G}_\varepsilon : BV(\Omega;\mathbb{R}^3) \times L^p(\omega;\mathbb{R}^3) \to [0,+\infty]$ by

$$\mathcal{G}_\varepsilon(u,\bar{b}) := \begin{cases} \displaystyle\int_\Omega W_\varepsilon\left(x, \nabla_\alpha u \Big| \frac{1}{\varepsilon}\nabla_3 u\right) dx & \\ \displaystyle\qquad + \int_{S_u} \left| \left((\nu_u)_\alpha \,\Big|\, \frac{1}{\varepsilon}\,(\nu_u)_3 \right) \right| d\mathcal{H}^2 & \text{if } \begin{cases} u \in SBV^p(\Omega;\mathbb{R}^3), \\ \bar{b} = \frac{1}{\varepsilon} \int_I \nabla_3 u(\cdot, x_3)\, dx_3, \end{cases} \\ +\infty & \text{otherwise.} \end{cases}$$

Then the following Γ-convergence result holds.

THEOREM 6.1. *For every sequence $\{\varepsilon_n\} \searrow 0^+$, there exists a subsequence, still labeled $\{\varepsilon_n\}$, such that $\mathcal{G}_{\varepsilon_n}$ Γ-converges in $L^1_s(\Omega;\mathbb{R}^3) \times L^p_w(\omega;\mathbb{R}^3)$ to $\mathcal{G} : BV(\Omega;\mathbb{R}^3) \times L^p(\omega;\mathbb{R}^3) \to [0,+\infty]$ defined by*

$$\mathcal{G}(u,\bar{b}) := \begin{cases} \displaystyle\int_\omega W^*(x_\alpha, \nabla_\alpha u|\bar{b})\, dx_\alpha + \mathcal{H}^1(S_u) & \textit{if } u \in SBV^p(\omega;\mathbb{R}^3), \\ +\infty & \textit{otherwise,} \end{cases}$$

where W^* is given by Theorem 5.1.

The remainder of this section is devoted to proving Theorem 6.1. We will first localize the functional $\mathcal{G}_\varepsilon$ on $\mathcal{A}(\omega)$, and noticing that minimizing sequences are not necessarily weakly relatively compact in BV, we will use the same truncation argument as in [4] (see also [18]), introducing an artificial functional. Then we will show that it actually coincides with the Γ-limit whenever $u \in BV(\Omega;\mathbb{R}^3) \cap L^\infty(\Omega;\mathbb{R}^3)$ (see Lemma 6.2 and Remark 6.3), and it will enable us to show that for such u's the Γ-limit is a measure absolutely continuous with respect to $\mathcal{L}^2 + \mathcal{H}^1 \llcorner S_u$ (see Lemma 6.6). Together with a blow-up argument, this property will be useful to prove the upper bound in section 6.3, while the lower bound, in section 6.4, will be obtained thanks to Theorem 4.1 and a suitable diagonalization argument (see Remark 5.3).

6.1. Localization. We start by localizing our functional on $\mathcal{A}(\omega)$, defining $\mathcal{G}_\varepsilon : BV(\Omega;\mathbb{R}^3) \times L^p(\omega;\mathbb{R}^3) \times \mathcal{A}(\omega) \to [0,+\infty]$ by

$$\mathcal{G}_\varepsilon(u,\bar{b},A) := \begin{cases} \displaystyle\int_{A\times I} W_\varepsilon\left(x, \nabla_\alpha u \Big| \frac{1}{\varepsilon}\nabla_3 u\right) dx & \\ \displaystyle\quad + \int_{S_u \cap (A\times I)} \left| \left((\nu_u)_\alpha \,\Big|\, \frac{1}{\varepsilon}\,(\nu_u)_3 \right) \right| d\mathcal{H}^2 & \text{if } \begin{cases} u \in SBV^p(A\times I;\mathbb{R}^3), \\ \bar{b} = \frac{1}{\varepsilon}\int_I \nabla_3 u(\cdot,x_3)\,dx_3, \end{cases} \\ +\infty & \text{otherwise.} \end{cases}$$

For every sequence $\{\varepsilon_n\} \searrow 0^+$ and all $(u,\bar{b},A) \in BV(\Omega;\mathbb{R}^3) \times L^p(\omega;\mathbb{R}^3) \times \mathcal{A}(\omega)$, we define

$$\mathcal{E}(u,\bar{b},A) := \inf_{\{u_n,\bar{b}_n\}} \Big\{ \liminf_{n\to+\infty} \mathcal{G}_{\varepsilon_n}(u_n,\bar{b}_n,A) : u_n \to u \text{ in } L^1(A\times I;\mathbb{R}^3)$$

$$\text{and } \bar{b}_n \rightharpoonup \bar{b} \text{ in } L^p(A;\mathbb{R}^3) \Big\}. \tag{6.1}$$

Theorem 8.5 and Corollary 8.12 in [16] together with a diagonalization argument imply the existence of a subsequence, still denoted $\{\varepsilon_n\}$, such that, for any $A \in \mathcal{R}(\omega)$ (or $A = \omega$), $\mathcal{E}(\cdot,\cdot,A)$ is the Γ-limit of $\mathcal{G}_{\varepsilon_n}(\cdot,\cdot,A)$ in $L^1_s(A\times I;\mathbb{R}^3) \times L^p_w(A;\mathbb{R}^3)$. Extracting if necessary a further subsequence, one may assume that $\{\varepsilon_n\}$ is chosen so that Theorem 5.1 holds. To prove Theorem 6.1, it is enough to show that $\mathcal{E}(u,\bar{b},\omega) = \mathcal{G}(u,\bar{b})$.

6.2. A truncation argument. As pointed out in [4], the main problem with the definition of $\mathcal{E}$ in (6.1) is that minimizing sequences are not necessarily bounded in $BV(\Omega;\mathbb{R}^3)$ and thus not necessarily weakly convergent in this space. Following [4], we define for all $(u,\bar{b},A) \in BV(\Omega;\mathbb{R}^3) \times L^p(\omega;\mathbb{R}^3) \times \mathcal{A}(\omega)$

$$\mathcal{E}_\infty(u,\bar{b},A) := \inf_{\{u_n,\bar{b}_n\}} \Big\{ \liminf_{n\to+\infty} \mathcal{G}_{\varepsilon_n}(u_n,\bar{b}_n,A) : u_n \to u \text{ in } L^1(A\times I;\mathbb{R}^3),$$

$$\bar{b}_n \rightharpoonup \bar{b} \text{ in } L^p(A;\mathbb{R}^3) \text{ and } \sup_{n\in\mathbb{N}} \|u_n\|_{L^\infty(A\times I;\mathbb{R}^3)} < +\infty \Big\}.$$

It is immediate that $\mathcal{E}(u,\bar{b},A) \le \mathcal{E}_\infty(u,\bar{b},A)$, while we will show that equality holds when u belongs to $BV(\Omega;\mathbb{R}^3) \cap L^\infty(\Omega;\mathbb{R}^3)$. This will be obtained as a consequence of Lemma 6.2. It means that for such deformation fields $u \in BV(\Omega;\mathbb{R}^3) \cap L^\infty(\Omega;\mathbb{R}^3)$, strong $L^1(\Omega;\mathbb{R}^3)$-convergence and weak $BV(\Omega;\mathbb{R}^3)$-convergence are, in a sense, equivalent for the computation of the Γ-limit.

LEMMA 6.2. *Let $A \in \mathcal{A}(\omega)$, $u \in BV(\Omega;\mathbb{R}^3) \cap L^\infty(\Omega;\mathbb{R}^3)$, and $\overline{b} \in L^p(\omega;\mathbb{R}^3)$. If $\{u_n\} \subset SBV^p(A \times I;\mathbb{R}^3)$ is such that $u_n \to u$ in $L^1(A \times I;\mathbb{R}^3)$, $\frac{1}{\varepsilon_n}\int_I \nabla_3 u_n(\cdot,x_3)\, dx_3 \rightharpoonup \overline{b}$ in $L^p(A;\mathbb{R}^3)$ and the limit*

$$L := \lim_{n\to+\infty} \mathcal{G}_{\varepsilon_n}\left(u_n, \frac{1}{\varepsilon_n}\int_I \nabla_3 u_n(\cdot,x_3)\, dx_3, A\right)$$

exists and is finite. Then for any $\eta > 0$ one can find $C > 0$ and $\{w_n\} \subset SBV^p(A \times I;\mathbb{R}^3)$ such that $w_n \to u$ in $L^1(A \times I;\mathbb{R}^3)$, $\frac{1}{\varepsilon_n}\int_I \nabla_3 w_n(\cdot,x_3)\, dx_3 \rightharpoonup \overline{b}$ in $L^p(A;\mathbb{R}^3)$, $\sup_n \|w_n\|_{L^\infty(A\times I;\mathbb{R}^3)} \le C$, and

$$L \ge \limsup_{n\to+\infty} \mathcal{G}_{\varepsilon_n}\left(w_n, \frac{1}{\varepsilon_n}\int_I \nabla_3 w_n(\cdot,x_3)\, dx_3, A\right) - \eta.$$

Proof. Let us define a smooth truncation function $\varphi_i \in \mathcal{C}^1_c(\mathbb{R}^3;\mathbb{R}^3)$ satisfying

$$\varphi_i(s) = \begin{cases} s & \text{if} \quad |s| < e^i, \\ 0 & \text{if} \quad |s| \ge e^{i+1} \end{cases} \qquad \text{and} \qquad |\nabla\varphi_i(s)| \le 2. \tag{6.2}$$

Let $w_{n,i} := \varphi_i(u_n)$, thanks to the chain rule formula [3, Theorem 3.96], $w_{n,i} \in SBV^p(A \times I;\mathbb{R}^3)$, and

$$\begin{cases} \|w_{n,i}\|_{L^\infty(A\times I;\mathbb{R}^3)} \le e^{i+1}, \\ S_{w_{n,i}} \subset S_{u_n}, \\ \nabla w_{n,i} = \nabla\varphi_i(u_n)\nabla u_n \quad \mathcal{L}^3\text{-a.e. in } A \times I. \end{cases} \tag{6.3}$$

Since $u \in L^\infty(\Omega;\mathbb{R}^3)$, we can choose i large enough ($i \ge m := [\ln(\|u\|_{L^\infty(\Omega;\mathbb{R}^3)})] + 1$) so that $u = \varphi_i(u)$ and thus according to (6.2)

$$\|w_{n,i} - u\|_{L^1(A\times I;\mathbb{R}^3)} = \|\varphi_i(u_n) - \varphi_i(u)\|_{L^1(A\times I;\mathbb{R}^3)} \le 2\|u_n - u\|_{L^1(A\times I;\mathbb{R}^3)}. \tag{6.4}$$

Since (a subsequence of) $u_n \to u$ a.e. in $A \times I$ and $\nabla\varphi_i$ is continuous, it follows that $\nabla\varphi_i(u_n) \to \nabla\varphi_i(u) = \mathrm{Id}$ a.e. in $A \times I$ as $n \to +\infty$. Take $v \in L^{p'}(A;\mathbb{R}^3)$, where $1/p + 1/p' = 1$; as $|\nabla\varphi_i(u_n)^T v| \le 2|v| \in L^{p'}(A)$, the dominated convergence theorem implies that $\nabla\varphi_i(u_n)^T v \to v$ in $L^{p'}(A \times I;\mathbb{R}^3)$ and thus

$$\lim_{n\to+\infty} \int_A \left(\frac{1}{\varepsilon_n}\int_I \nabla_3 w_{n,i}(x_\alpha,x_3)\, dx_3\right) \cdot v(x_\alpha)\, dx_\alpha$$

$$= \lim_{n\to+\infty} \int_{A\times I} \frac{1}{\varepsilon_n}\nabla_3 u_n \cdot \left(\nabla\varphi_i(u_n)^T v\right)\, dx = \int_A \overline{b} \cdot v\, dx_\alpha,$$

where we used the fact that $(1/\varepsilon_n)\nabla_3 u_n \rightharpoonup b$ in $L^p(A \times I;\mathbb{R}^3)$ and $\overline{b} = \int_I b(\cdot,x_3)\, dx_3$. Hence

$$\frac{1}{\varepsilon_n}\int_I \nabla_3 w_{n,i}(\cdot,x_3)\, dx_3 \xrightharpoonup[n\to+\infty]{} \overline{b} \text{ in } L^p(A;\mathbb{R}^3) \quad \text{for all } i \ge m. \tag{6.5}$$

The growth condition (5.1), (6.2), and (6.3) imply that

$$\begin{aligned}
&\int_{A\times I} W_{\varepsilon_n}\left(x, \nabla_\alpha w_{n,i}\Big|\frac{1}{\varepsilon_n}\nabla_3 w_{n,i}\right)dx \\
&\qquad\le \int_{\{|u_n|<e^i\}} W_{\varepsilon_n}\left(x, \nabla_\alpha u_n\Big|\frac{1}{\varepsilon_n}\nabla_3 u_n\right)dx + \beta\mathcal{L}^3(\{|u_n|\ge e^{i+1}\}) \\
&\qquad\quad + \int_{\{e^i\le|u_n|<e^{i+1}\}} W_{\varepsilon_n}\left(x, \nabla\varphi_i(u_n)\nabla_\alpha u_n\Big|\frac{1}{\varepsilon_n}\nabla\varphi_i(u_n)\nabla_3 u_n\right)dx \\
&\qquad\le \int_{A\times I} W_{\varepsilon_n}\left(x, \nabla_\alpha u_n\Big|\frac{1}{\varepsilon_n}\nabla_3 u_n\right)dx + \beta\, e^{-i}\,\|u_n\|_{L^1(A\times I;\mathbb{R}^3)} \\
&\qquad\quad + 2^p\beta\int_{\{e^i\le|u_n|<e^{i+1}\}}\left|\left(\nabla_\alpha u_n\Big|\frac{1}{\varepsilon_n}\nabla_3 u_n\right)\right|^p dx,
\end{aligned}\tag{6.6}$$

where we have used Chebyshev's inequality. Since $\nu_{w_{n,i}}(x) = \pm\nu_{u_n}(x)$ for $\mathcal{H}^2$-a.e. $x\in S_{w_{n,i}}$, (6.3) yields

$$\begin{aligned}
&\int_{S_{w_{n,i}}\cap(A\times I)}\left|\left(\left(\nu_{w_{n,i}}\right)_\alpha\Big|\frac{1}{\varepsilon_n}\left(\nu_{w_{n,i}}\right)_3\right)\right|d\mathcal{H}^2 \\
&\qquad\qquad\le \int_{S_{u_n}\cap(A\times I)}\left|\left(\left(\nu_{u_n}\right)_\alpha\Big|\frac{1}{\varepsilon_n}\left(\nu_{u_n}\right)_3\right)\right|d\mathcal{H}^2.
\end{aligned}\tag{6.7}$$

Let $M\in\mathbb{N}$; from (6.6) and (6.7), a summation for $i=m$ to M implies that

$$\begin{aligned}
&\frac{1}{M-m+1}\sum_{i=m}^{M}\left[\int_{A\times I} W_{\varepsilon_n}\left(x, \nabla_\alpha w_{n,i}\Big|\frac{1}{\varepsilon_n}\nabla_3 w_{n,i}\right)dx\right. \\
&\qquad\qquad\left. + \int_{S_{w_{n,i}}\cap(A\times I)}\left|\left(\left(\nu_{w_{n,i}}\right)_\alpha\Big|\frac{1}{\varepsilon_n}\left(\nu_{w_{n,i}}\right)_3\right)\right|d\mathcal{H}^2\right] \\
&\quad\le \int_{A\times I} W_{\varepsilon_n}\left(x, \nabla_\alpha u_n\Big|\frac{1}{\varepsilon_n}\nabla_3 u_n\right)dx + \int_{S_{u_n}\cap(A\times I)}\left|\left(\left(\nu_{u_n}\right)_\alpha\Big|\frac{1}{\varepsilon_n}\left(\nu_{u_n}\right)_3\right)\right|d\mathcal{H}^2 \\
&\qquad\qquad + \frac{c}{M-m+1},
\end{aligned}$$

where $0<c<+\infty$ is given by

$$c = \beta\sup_{n\in\mathbb{N}}\|u_n\|_{L^1(A\times I;\mathbb{R}^3)}\sum_{i\ge1}e^{-i} + 2^p\beta\sup_{n\in\mathbb{N}}\left\|\left(\nabla_\alpha u_n\Big|\frac{1}{\varepsilon_n}\nabla_3 u_n\right)\right\|^p_{L^p(A\times I;\mathbb{R}^{3\times3})}.$$

We may find some $i_n\in\{m,\dots,M\}$ such that, setting $w_n := w_{n,i_n}$, then

$$\begin{aligned}
&\int_{A\times I} W_{\varepsilon_n}\left(x, \nabla_\alpha w_n\Big|\frac{1}{\varepsilon_n}\nabla_3 w_n\right)dx + \int_{S_{w_n}\cap(A\times I)}\left|\left(\left(\nu_{w_n}\right)_\alpha\Big|\frac{1}{\varepsilon_n}\left(\nu_{w_n}\right)_3\right)\right|d\mathcal{H}^2 \\
&\quad\le \int_{A\times I} W_{\varepsilon_n}\left(x, \nabla_\alpha u_n\Big|\frac{1}{\varepsilon_n}\nabla_3 u_n\right)dx + \int_{S_{u_n}\cap(A\times I)}\left|\left(\left(\nu_{u_n}\right)_\alpha\Big|\frac{1}{\varepsilon_n}\left(\nu_{u_n}\right)_3\right)\right|d\mathcal{H}^2 \\
&\qquad\qquad + \frac{c}{M-m+1}.
\end{aligned}\tag{6.8}$$

Moreover, in view of (6.4) and (6.5), $w_n \to u$ in $L^1(A \times I; \mathbb{R}^3)$, $\frac{1}{\varepsilon_n} \int_I \nabla_3 w_n(\cdot, x_3)\, dx_3 \rightharpoonup \overline{b}$ in $L^p(A; \mathbb{R}^3)$, and (6.3) implies that $\|w_n\|_{L^\infty(A \times I; \mathbb{R}^3)} \le e^{i_n+1} \le e^{M+1} =: C$. The proof is achieved passing to the limit as n tends to $+\infty$ in (6.8) and choosing M large enough so that $c/(M - m + 1) \le \eta$. ∎

Remark 6.3. As a consequence of Lemma 6.2, we get that for any $A \in \mathcal{R}(\omega)$ (or $A = \omega$), every $u \in BV(\Omega; \mathbb{R}^3) \cap L^\infty(\Omega; \mathbb{R}^3)$, and every $\overline{b} \in L^p(\omega; \mathbb{R}^3)$, then $\mathcal{E}(u, \overline{b}, A) = \mathcal{E}_\infty(u, \overline{b}, A)$.

Remark 6.4. A similar statement of Lemma 6.2 can be proved in the framework of Sobolev spaces, replacing $\mathcal{G}_{\varepsilon_n}$ by $\mathcal{J}_{\varepsilon_n}$.

Remark 6.5. Using a relaxation argument as in the proof of [4, Lemma 3.4] and Lemma 6.2, one can show that if $u \in SBV^p(\omega; \mathbb{R}^3) \cap L^\infty(\omega; \mathbb{R}^3)$ and if $\overline{b} \in L^p(\omega; \mathbb{R}^3)$, the value of $\mathcal{E}_\infty$ does not change when replacing W_{ε_n} by its quasi-convexification QW_{ε_n} defined in (5.12). The main point is that the diagonalization argument can still be used despite the weak $L^p(\omega; \mathbb{R}^3)$-convergence of the bending moment since the dual of $L^p(\omega; \mathbb{R}^3)$ is separable. Hence we may assume without loss of generality that W_ε is quasi-convex. In particular (see [15, Lemma 2.2, Chapter 4]), the following p-Lipschitz condition holds:

$$|W_\varepsilon(x, \xi_1) - W_\varepsilon(x, \xi_2)| \le c(1 + |\xi_1|^{p-1} + |\xi_2|^{p-1})|\xi_1 - \xi_2| \tag{6.9}$$

for all $\xi_1,\ \xi_2 \in \mathbb{R}^{3\times 3}$ and a.e. $x \in \Omega$.

Lemma 6.2 and Remark 6.3 are essential for the proof of the following result because they allow us to replace strong $L^1(\Omega; \mathbb{R}^3)$-convergence of any minimizing sequence by strong $L^p(\Omega; \mathbb{R}^3)$-convergence.

LEMMA 6.6. *For all $u \in SBV^p(\omega; \mathbb{R}^3) \cap L^\infty(\omega; \mathbb{R}^3)$ and all $\overline{b} \in L^p(\omega; \mathbb{R}^3)$, $\mathcal{E}_\infty(u, \overline{b}, \cdot)$ is the restriction to $\mathcal{A}(\omega)$ of a Radon measure absolutely continuous with respect to $\mathcal{L}^2 + \mathcal{H}^1 \llcorner S_u$.*

Proof. Let $u \in SBV^p(\omega; \mathbb{R}^3) \cap L^\infty(\omega; \mathbb{R}^3)$, $A \in \mathcal{A}(\omega)$ and assume first that $\overline{b}$ is smooth. Then taking $u_n(x_\alpha, x_3) := u(x_\alpha) + \varepsilon_n x_3 \overline{b}(x_\alpha)$ and $\overline{b}_n(x_\alpha) := \overline{b}(x_\alpha)$ as test functions for $\mathcal{E}_\infty(u, \overline{b}, A)$ and using the p-growth condition (5.1), we get that

$$\mathcal{E}_\infty(u, \overline{b}, A) \le \beta \int_A (1 + |\nabla_\alpha u|^p + |\overline{b}|^p)\, dx_\alpha + \mathcal{H}^1(S_u \cap A). \tag{6.10}$$

The same inequality holds for arbitrary functions $\overline{b} \in L^p(\omega; \mathbb{R}^3)$ thanks to the density of smooth maps into $L^p(\omega; \mathbb{R}^3)$ and the sequential weak lower semicontinuity of $\mathcal{E}_\infty(u, \cdot, A)$ in $L^p(A; \mathbb{R}^3)$. The remainder of the proof is very classical and is essentially the same as that of [4, Lemma 3.6]. As usual, the most delicate point is to prove the subadditivity of $\mathcal{E}_\infty(u, \overline{b}, \cdot)$, and this is done by gluing together suitable minimizing sequences by means of a cut-off function. The argument still works with the presence of the bending moment since the cut-off function is chosen independently of x_3. One should once more be careful when applying a diagonalization argument because of the weak convergence in L^p. As already mentioned in Remark 6.5, it is still allowed in the case where we include the bending moment since the dual of L^p is separable. ∎

As a consequence of Lemma 6.6 and Lebesgue's decomposition theorem, there exists a $\mathcal{L}^2$-measurable function f and a $\mathcal{H}^1 \llcorner S_u$-measurable function g such that for every $A \in \mathcal{A}(\omega)$,

$$\mathcal{E}_\infty(u, \overline{b}, A) = \int_A f\, d\mathcal{L}^2 + \int_{A \cap S_u} g\, d\mathcal{H}^1. \tag{6.11}$$

Since the measures $\mathcal{L}^2$ and $\mathcal{H}^1 \llcorner S_u$ are mutually singular, f is the Radon–Nikodým derivative of $\mathcal{E}_\infty(u,\bar{b},\cdot)$ with respect to $\mathcal{L}^2$,

$$f(x_0) = \lim_{\rho\to 0} \frac{\mathcal{E}_\infty(u,\bar{b},B'(x_0,\rho))}{\mathcal{L}^2(B'(x_0,\rho))} \quad \text{for } \mathcal{L}^2\text{-a.e. } x_0 \in \omega,$$

and g is the Radon–Nikodým derivative of $\mathcal{E}_\infty(u,\bar{b},\cdot)$ with respect to $\mathcal{H}^1 \llcorner S_u$,

$$g(x_0) = \lim_{\rho\to 0} \frac{\mathcal{E}_\infty(u,\bar{b},B'(x_0,\rho))}{\mathcal{H}^1(S_u \cap B'(x_0,\rho))} \quad \text{for } \mathcal{H}^1\text{-a.e. } x_0 \in S_u.$$

6.3. The upper bound. We first show the upper bound. To this end, we will use the locality property of the Γ-limit proved in the previous subsection when $u \in BV(\Omega;\mathbb{R}^3) \cap L^\infty(\Omega;\mathbb{R}^3)$ and the analog Γ-convergence result in Sobolev spaces (Theorem 5.1).

LEMMA 6.7. *For all $u \in BV(\Omega;\mathbb{R}^3)$ and all $\bar{b} \in L^p(\omega;\mathbb{R}^3)$, $\mathcal{E}(u,\bar{b},\omega) \le \mathcal{G}(u,\bar{b})$.*

Proof. It is enough to consider the case where $\mathcal{G}(u,\bar{b}) < +\infty$ and thus $u \in SBV^p(\omega;\mathbb{R}^3)$. In fact, we will first restrict ourselves to the case where $u \in L^\infty(\omega;\mathbb{R}^3) \cap SBV^p(\omega;\mathbb{R}^3)$ because, thanks to Remark 6.3, it allows us to replace $\mathcal{E}$ by $\mathcal{E}_\infty$. According to (6.11) and the definition of $\mathcal{G}$, we must show that $g(x_0) \le 1$ for $\mathcal{H}^1$-a.e. $x_0 \in S_u$ and $f(x_0) \le W^*(x_0, \nabla_\alpha u(x_0)|\bar{b}(x_0))$ for $\mathcal{L}^2$-a.e. $x_0 \in \omega$.

Let us first treat the surface term. By virtue of (6.10) with $A = B'(x_0,\rho)$, we have that for $\mathcal{H}^1$-a.e. $x_0 \in S_u$,

$$\begin{aligned} g(x_0) &= \lim_{\rho\to 0} \frac{\mathcal{E}_\infty(u,\bar{b},B'(x_0,\rho))}{\mathcal{H}^1(S_u \cap B'(x_0,\rho))} \\ &\le \limsup_{\rho\to 0} \frac{1}{\mathcal{H}^1(S_u \cap B'(x_0,\rho))} \Bigg\{ \beta \int_{B'(x_0,\rho)} (1 + |\nabla_\alpha u|^p + |\bar{b}|^p)\, dx_\alpha \\ &\qquad\qquad + \mathcal{H}^1(S_u \cap B'(x_0,\rho)) \Bigg\} \\ &= \limsup_{\rho\to 0} \frac{\mu(B'(x_0,\rho))}{\mathcal{H}^1(S_u \cap B'(x_0,\rho))} + 1, \end{aligned}$$

where we set $\mu := \beta(1 + |\nabla_\alpha u|^p + |\bar{b}|^p)\mathcal{L}^2$. But since μ and $\mathcal{H}^1 \llcorner S_u$ are mutually singular, we have for $\mathcal{H}^1$-a.e. $x_0 \in S_u$

$$\lim_{\rho\to 0} \frac{\mu(B'(x_0,\rho))}{\mathcal{H}^1(S_u \cap B'(x_0,\rho))} = 0,$$

which shows that $g(x_0) \le 1$ for $\mathcal{H}^1$-a.e. $x_0 \in S_u$.

Concerning the bulk term, choose $x_0 \in \omega$ to be a Lebesgue point of u, $\nabla_\alpha u$, $\bar{b}$, and $W^*(\cdot,\nabla_\alpha u(\cdot)|\bar{b}(\cdot))$ and such that

$$\lim_{\rho\to 0} \frac{\mathcal{H}^1(S_u \cap B'(x_0,\rho))}{\mathcal{L}^2(B'(x_0,\rho))} = 0. \tag{6.12}$$

Remark that $\mathcal{L}^2$-a.e. points x_0 in ω satisfy these properties and set $u_0(x_\alpha) := \nabla_\alpha u(x_0)\, x_\alpha$ and $\bar{b}_0(x_\alpha) := \bar{b}(x_0)$. For every $\rho > 0$, Theorem 5.1 implies the existence of a sequence $\{v_n^\rho\} \subset W^{1,p}(B'(x_0,\rho)\times I;\mathbb{R}^3)$ such that $v_n^\rho \to u_0$ in $L^p(B'(x_0,\rho)\times I;\mathbb{R}^3)$

(thus in $L^1(B'(x_0,\rho)\times I;\mathbb{R}^3)$ as well), $\frac{1}{\varepsilon_n}\int_I \nabla_3 v_n^\rho(\cdot,x_3)\,dx_3 \rightharpoonup \bar b_0$ in $L^p(B'(x_0,\rho);\mathbb{R}^3)$, and

$$\lim_{n\to+\infty}\int_{B'(x_0,\rho)\times I} W_{\varepsilon_n}\left(x,\nabla_\alpha v_n^\rho\Big|\frac{1}{\varepsilon_n}\nabla_3 v_n^\rho\right)dx = \int_{B'(x_0,\rho)} W^*(x_\alpha,\nabla_\alpha u(x_0)|\bar b(x_0))\,dx_\alpha.$$

Since $u_0\in L^\infty(\omega;\mathbb{R}^3)$, by Lemma 6.2 and Remark 6.4, for any $\eta>0$ we can find a sequence $\{w_n^\rho\}\subset W^{1,p}(B'(x_0,\rho)\times I;\mathbb{R}^3)$ and $C_\rho>0$ such that

$$\sup_{n\in\mathbb{N}}\|w_n^\rho\|_{L^\infty(B'(x_0,\rho)\times I;\mathbb{R}^3)}\le C_\rho,$$

$w_n^\rho\to u_0$ in $L^p(B'(x_0,\rho)\times I;\mathbb{R}^3)$, $\frac{1}{\varepsilon_n}\int_I\nabla_3 w_n^\rho(\cdot,x_3)\,dx_3\rightharpoonup \bar b_0$ in $L^p(B'(x_0,\rho);\mathbb{R}^3)$, and

$$\limsup_{n\to+\infty}\int_{B'(x_0,\rho)\times I} W_{\varepsilon_n}\left(x,\nabla_\alpha w_n^\rho\Big|\frac{1}{\varepsilon_n}\nabla_3 w_n^\rho\right)dx \le \int_{B'(x_0,\rho)} W^*(x_\alpha,\nabla_\alpha u(x_0)|\bar b(x_0))\,dx_\alpha + \mathcal{L}^2(B'(x_0,\rho))\eta.$$

Thanks to (5.5) and the separately convex character of $W^*(x_0,\cdot|\cdot)$ (see the proof of Theorem 5.1), it follows that $W^*(x_0,\cdot|\cdot)$ is p-Lipschitz. Thus our choice of x_0 implies that

$$\limsup_{\rho\to 0}\limsup_{n\to+\infty}⨍_{B'(x_0,\rho)\times I} W_{\varepsilon_n}\left(x,\nabla_\alpha w_n^\rho\Big|\frac{1}{\varepsilon_n}\nabla_3 w_n^\rho\right)dx \le W^*(x_0,\nabla_\alpha u(x_0)|\bar b(x_0))+\eta, \tag{6.13}$$

and from the coercivity condition (5.1), we get

$$\sup_{\rho>0,\,n\in\mathbb{N}}⨍_{B'(x_0,\rho)\times I}\left|\left(\nabla_\alpha w_n^\rho\Big|\frac{1}{\varepsilon_n}\nabla_3 w_n^\rho\right)\right|^p dx<+\infty. \tag{6.14}$$

Let $\bar b_k\in\mathcal{C}_c^\infty(\omega;\mathbb{R}^3)$ be such that $\bar b_k\to\bar b$ in $L^p(\omega;\mathbb{R}^3)$ and define

$$u_{n,k}^\rho(x) := u(x_\alpha)+\varepsilon_n x_3(\bar b_k(x_\alpha)-\bar b(x_0))+w_n^\rho(x_\alpha,x_3)-\nabla_\alpha u(x_0)\,x_\alpha.$$

Then we have that $u_{n,k}^\rho\to u$ in $L^1(B'(x_0,\rho)\times I;\mathbb{R}^3)$, $\frac{1}{\varepsilon_n}\int_I\nabla_3 u_{n,k}^\rho(\cdot,x_3)\,dx_3\rightharpoonup\bar b_k$ in $L^p(B'(x_0,\rho);\mathbb{R}^3)$ as $n\to+\infty$, and $\sup_n\|u_{n,k}^\rho\|_{L^\infty(B'(x_0,\rho)\times I;\mathbb{R}^3)}<+\infty$. Thus, since $S_{u_{n,k}^\rho}\cap(B'(x_0,\rho)\times I)=(S_u\cap B'(x_0,\rho))\times I$, we get that

$$\begin{aligned}\mathcal{E}_\infty(u,\bar b_k,B'(x_0,\rho)) &\le \liminf_{n\to+\infty}\left\{\int_{B'(x_0,\rho)\times I} W_{\varepsilon_n}\left(x,\nabla_\alpha u_{n,k}^\rho\Big|\frac{1}{\varepsilon_n}\nabla_3 u_{n,k}^\rho\right)dx\right.\\ &\qquad\left.+\int_{S_{u_{n,k}^\rho}\cap(B'(x_0,\rho)\times I)}\left|\left(\left(\nu_{u_{n,k}^\rho}\right)_\alpha\Big|\frac{1}{\varepsilon_n}\left(\nu_{u_{n,k}^\rho}\right)_3\right)\right|d\mathcal{H}^2\right\}\\ &\le \liminf_{n\to+\infty}\int_{B'(x_0,\rho)\times I} W_{\varepsilon_n}\Big(x,\nabla_\alpha u(x_\alpha)-\nabla_\alpha u(x_0)+\nabla_\alpha w_n^\rho(x)\\ &\qquad+\varepsilon_n x_3\nabla_\alpha\bar b_k(x_\alpha)\Big|\frac{1}{\varepsilon_n}\nabla_3 w_n^\rho(x)+\bar b_k(x_\alpha)-\bar b(x_0)\Big)\,dx\\ &\qquad+\mathcal{H}^1(S_u\cap B'(x_0,\rho)).\end{aligned}$$

Thus from (6.12), we obtain

$$f(x_0) \leq \liminf_{\rho\to 0} \liminf_{k\to+\infty} \liminf_{n\to+\infty} \fint_{B'(x_0,\rho)\times I} W_{\varepsilon_n}\Big(x, \nabla_\alpha u(x_\alpha) - \nabla_\alpha u(x_0) + \nabla_\alpha w_n^\rho(x) + \varepsilon_n x_3 \nabla_\alpha \bar{b}_k(x_\alpha)\Big| \frac{1}{\varepsilon_n}\nabla_3 w_n^\rho(x) + \bar{b}_k(x_\alpha) - \bar{b}(x_0)\Big)\, dx.$$

Relations (6.9), (6.13), (6.14), and Hölder's inequality yield

$$\begin{aligned} f(x_0) \leq \liminf_{\rho\to 0} \liminf_{k\to+\infty} \liminf_{n\to+\infty} \Bigg\{ & \fint_{B'(x_0,\rho)\times I} W_{\varepsilon_n}\left(x, \nabla_\alpha w_n^\rho \Big| \frac{1}{\varepsilon_n}\nabla_3 w_n^\rho\right) dx \\ & + c \fint_{B'(x_0,\rho)\times I} \Big(1 + |\nabla_\alpha u(x_\alpha) - \nabla_\alpha u(x_0)|^{p-1} + |\bar{b}_k(x_\alpha) - \bar{b}(x_0)|^{p-1} \\ & + \left|\left(\nabla_\alpha w_n^\rho(x)\Big|\frac{1}{\varepsilon_n}\nabla_3 w_n^\rho(x)\right)\right|^{p-1} + \varepsilon_n^{p-1}|\nabla_\alpha \bar{b}_k(x_\alpha)|^{p-1}\Big) \\ & \times\Big(|\nabla_\alpha u(x_\alpha) - \nabla_\alpha u(x_0)| + \varepsilon_n|\nabla_\alpha \bar{b}_k(x_\alpha)| + |\bar{b}_k(x_\alpha) - \bar{b}(x_0)|\Big)\, dx \Bigg\} \\ \leq{} & W^*(x_0, \nabla_\alpha u(x_0)|\bar{b}(x_0)) + \eta \\ & + c \limsup_{\rho\to 0} \left\{ \fint_{B'(x_0,\rho)} \left(1 + |\nabla_\alpha u - \nabla_\alpha u(x_0)|^p + |\bar{b} - \bar{b}(x_0)|^p\right) dx_\alpha \right\}^{(p-1)/p} \\ & \times \left\{ \fint_{B'(x_0,\rho)} \left(|\nabla_\alpha u - \nabla_\alpha u(x_0)|^p + |\bar{b} - \bar{b}(x_0)|^p\right) dx_\alpha \right\}^{1/p}. \end{aligned}$$

Thanks to our choice of x_0 and letting $\eta \to 0$, we conclude that

$$f(x_0) \leq W^*(x_0, \nabla_\alpha u(x_0)|\bar{b}(x_0))$$

for $\mathcal{L}^2$-a.e. $x_0 \in \omega$, which completes the proof in the case where $u \in L^\infty(\omega;\mathbb{R}^3) \cap SBV^p(\omega;\mathbb{R}^3)$. The general case can in turn be treated by approximation exactly as in the proof of [4, Lemma 3.8]. □

6.4. The lower bound. Let us now prove the lower bound. The proof is essentially based on Theorem 4.1 and a blow-up argument.

LEMMA 6.8. *For all $u \in BV(\Omega;\mathbb{R}^3)$ and all $\bar{b} \in L^p(\omega;\mathbb{R}^3)$, $\mathcal{E}(u,\bar{b},\omega) \geq \mathcal{G}(u,\bar{b})$.*

Proof. It is not restrictive to assume that $\mathcal{E}(u,\bar{b},\omega) < +\infty$. By Γ-convergence, there exists a recovery sequence $\{u_n\} \subset SBV^p(\Omega;\mathbb{R}^3)$ such that $u_n \to u$ in $L^1(\Omega;\mathbb{R}^3)$, $\frac{1}{\varepsilon_n}\int_I \nabla_3 u_n(\cdot,x_3)\,dx_3 \rightharpoonup \bar{b}$ in $L^p(\omega;\mathbb{R}^3)$, and

$$\lim_{n\to+\infty}\left[\int_\Omega W_{\varepsilon_n}\left(x, \nabla_\alpha u_n \Big| \frac{1}{\varepsilon_n}\nabla_3 u_n\right) dx + \int_{S_{u_n}} \left|\left(\left(\nu_{u_n}\right)_\alpha \Big| \frac{1}{\varepsilon_n}\left(\nu_{u_n}\right)_3\right)\right| d\mathcal{H}^2\right] = \mathcal{E}(u,\bar{b},\omega). \tag{6.15}$$

Arguing exactly as in the proof of [4, Lemma 3.9], we can actually show that $u \in SBV^p(\omega;\mathbb{R}^3)$ and that $u_n \rightharpoonup u$ in $SBV^p(\Omega;\mathbb{R}^3)$. Now for every Borel set $E \subset \omega$, define the following sequences of Radon measures:

$$\lambda_n(E) := W_{\varepsilon_n}\left(\cdot, \nabla_\alpha u_n \Big| \frac{1}{\varepsilon_n}\nabla_3 u_n\right)\mathcal{L}^3 \llcorner (E \times I) \\ + \left|\left(\left(\nu_{u_n}\right)_\alpha \Big| \frac{1}{\varepsilon_n}\left(\nu_{u_n}\right)_3\right)\right| \mathcal{H}^2 \llcorner (S_{u_n} \cap (E \times I))$$

and

$$\mu_n(E) := \left|\left(\left(\nu_{u_n}\right)_\alpha \Big| \frac{1}{\varepsilon_n}\left(\nu_{u_n}\right)_3\right)\right| \mathcal{H}^2 \llcorner (S_{u_n} \cap (E \times I)).$$

Then for a subsequence (not relabeled), there exist nonnegative and finite Radon measures λ and $\mu \in \mathcal{M}(\omega)$ such that $\lambda_n \overset{*}{\rightharpoonup} \lambda$ and $\mu_n \overset{*}{\rightharpoonup} \mu$ in $\mathcal{M}(\omega)$. By the Besicovitch differentiation theorem [3, Theorem 2.22], one can find three mutually singular nonnegative Radon measures λ^a, λ^j, and λ^c such that $\lambda = \lambda^a + \lambda^j + \lambda^c$, where $\lambda^a \ll \mathcal{L}^2$ and $\lambda^j \ll \mathcal{H}^1 \llcorner S_u$. It is enough to check that

$$\frac{d\lambda^j}{d\mathcal{H}^1 \llcorner S_u}(x_0) \geq 1 \quad \text{for } \mathcal{H}^1\text{-a.e. } x_0 \in S_u \tag{6.16}$$

and

$$\frac{d\lambda^a}{d\mathcal{L}^2}(x_0) \geq W^*(x_0, \nabla_\alpha u(x_0)|\bar{b}(x_0)) \quad \text{for } \mathcal{L}^2\text{-a.e. } x_0 \in \omega. \tag{6.17}$$

Indeed, if (6.16) and (6.17) hold, we obtain from (6.15) that

$$\begin{aligned} \mathcal{E}(u, \bar{b}, \omega) &\geq \lambda(\omega) = \lambda^a(\omega) + \lambda^j(\omega) + \lambda^c(\omega) \\ &\geq \int_\omega W^*(x_\alpha, \nabla_\alpha u|\bar{b})\, dx_\alpha + \mathcal{H}^1(S_u) = \mathcal{G}(u, \bar{b}). \end{aligned}$$

We first prove (6.16). Fix a point $x_0 \in S_u$ such that

$$\frac{d\lambda^j}{d\mathcal{H}^1 \llcorner S_u}(x_0) = \frac{d\lambda}{d\mathcal{H}^1 \llcorner S_u}(x_0)$$

exists and is finite and remark that $\mathcal{H}^1$-a.e. points in S_u satisfy this property. Let $\{\rho_k\} \searrow 0^+$ be such that $\lambda(\partial B'(x_0, \rho_k)) = 0$ for each $k \in \mathbb{N}$. Then

$$\begin{aligned} \frac{d\lambda}{d\mathcal{H}^1 \llcorner S_u}(x_0) &= \lim_{k\to+\infty} \frac{\lambda(B'(x_0,\rho_k))}{\mathcal{H}^1(S_u \cap B'(x_0,\rho_k))} \\ &= \lim_{k\to+\infty} \lim_{n\to+\infty} \frac{\lambda_n(B'(x_0,\rho_k))}{\mathcal{H}^1(S_u \cap B'(x_0,\rho_k))} \\ &\geq \liminf_{k\to+\infty} \liminf_{n\to+\infty} \frac{\mathcal{H}^2(S_{u_n} \cap (B'(x_0,\rho_k) \times I))}{\mathcal{H}^1(S_u \cap B'(x_0,\rho_k))}. \end{aligned}$$

By [3, Theorem 4.36], we have that

$$\liminf_{n\to+\infty} \mathcal{H}^2(S_{u_n} \cap (B'(x_0,\rho_k) \times I)) \geq \mathcal{H}^1(S_u \cap B'(x_0,\rho_k));$$

hence we obtain (6.16).

Let us prove that (6.17) holds at every point $x_0 \in \omega \setminus N$ (where $N \subset \omega$ is the exceptional set introduced in Proposition 5.2) which is a Lebesgue point of both $\nabla_\alpha u$ and $\bar{b}$, a point of approximate differentiability of u such that

$$\frac{d\lambda^a}{d\mathcal{L}^2}(x_0) = \frac{d\lambda}{d\mathcal{L}^2}(x_0)$$

exists and is finite and which satisfies

$$\lim_{\rho \to 0} \frac{\mu(B'(x_0,\rho))}{2\rho} = 0. \tag{6.18}$$

It turns out that $\mathcal{L}^2$-a.e. points x_0 in ω satisfy these properties. Indeed, the verification of (6.18) is similar to the one of (3.2) used in the proof of Theorem 3.2. As before, let $\{\rho_k\} \searrow 0^+$ be such that $\lambda(\partial B'(x_0,\rho_k)) = 0$ for every $k \in \mathbb{N}$; then

$$\begin{aligned}
\frac{d\lambda}{d\mathcal{L}^2}(x_0) &= \lim_{k\to+\infty} \frac{\lambda(B'(x_0,\rho_k))}{\mathcal{L}^2(B'(x_0,\rho_k))} \\
&= \lim_{k\to+\infty} \lim_{n\to+\infty} \frac{\lambda_n(B'(x_0,\rho_k))}{\mathcal{L}^2(B'(x_0,\rho_k))} \\
&\geq \limsup_{k\to+\infty} \limsup_{n\to+\infty} \fint_{B'(x_0,\rho_k)\times I} W_{\varepsilon_n}\left(x, \nabla_\alpha u_n \middle| \frac{1}{\varepsilon_n}\nabla_3 u_n\right) dx \\
&= \limsup_{k\to+\infty} \limsup_{n\to+\infty} \fint_{B'\times I} W_{\varepsilon_n}\left(x_0+\rho_k x_\alpha, x_3, \nabla_\alpha u_{n,k} \middle| \frac{\rho_k}{\varepsilon_n}\nabla_3 u_{n,k}\right) dx, \qquad (6.19)
\end{aligned}$$

where $u_{n,k}(x_\alpha,x_3) = [u_n(x_0+\rho_k x_\alpha, x_3) - u(x_0)]/\rho_k$. Since x_0 is a point of approximate differentiability of u, we have that

$$\lim_{k\to+\infty} \lim_{n\to+\infty} \int_{B'\times I} |u_{n,k}(x) - \nabla_\alpha u(x_0) x_\alpha|\, dx = 0, \tag{6.20}$$

and using the fact that x_0 is a Lebesgue point of $\bar{b}$, for every $v \in L^{p'}(B';\mathbb{R}^3)$ we get that

$$\lim_{k\to+\infty} \lim_{n\to+\infty} \int_{B'} \left(\frac{\rho_k}{\varepsilon_n}\int_I \nabla_3 u_{n,k}(x_\alpha,x_3)\, dx_3\right)\cdot v(x_\alpha)\, dx_\alpha = \int_{B'} \bar{b}(x_0)\cdot v\, dx_\alpha. \tag{6.21}$$

Changing variables in the surface term and thanks to (6.18), it yields

$$\begin{aligned}
&\limsup_{k\to+\infty} \limsup_{n\to+\infty} \int_{S_{u_{n,k}}\cap(B'\times I)} \left| \left(\left(\nu_{u_{n,k}}\right)_\alpha \middle| \frac{\rho_k}{\varepsilon_n}\left(\nu_{u_{n,k}}\right)_3 \right) \right| d\mathcal{H}^2 \\
&\quad = \limsup_{k\to+\infty} \limsup_{n\to+\infty} \frac{1}{\rho_k} \int_{S_{u_n}\cap(B'(x_0,\rho_k)\times I)} \left| \left(\left(\nu_{u_n}\right)_\alpha \middle| \frac{1}{\varepsilon_n}\left(\nu_{u_n}\right)_3 \right) \right| d\mathcal{H}^2 \\
&\quad \leq \limsup_{k\to+\infty} \limsup_{n\to+\infty} \frac{\mu_n(\overline{B'(x_0,\rho_k)})}{\rho_k} \leq \limsup_{k\to+\infty} \frac{\mu(\overline{B'(x_0,\rho_k)})}{\rho_k} = 0 \qquad (6.22)
\end{aligned}$$

because $\mu(\partial B'(x_0,\rho_k)) \le \lambda(\partial B'(x_0,\rho_k)) = 0$. Set

$$M := \max\left\{\left(\frac{\mathcal{L}^2(B')}{\beta'}\left(\left|\frac{d\lambda}{d\mathcal{L}^2}(x_0)\right|+1\right)\right)^{1/p}, |\bar{b}(x_0)|\mathcal{L}^2(B')^{1/p}\right\} < +\infty. \tag{6.23}$$

From (6.19)–(6.22), using a diagonalization argument, the fact that $L^{p'}(B';\mathbb{R}^3)$ is separable, and Remark 5.3, we can find a sequence $n(k) \nearrow +\infty$ such that, setting $\delta_k := \varepsilon_{n(k)}/\rho_k$, $v_k := u_{n(k),k}$, $u_0(x_\alpha) := \nabla u(x_0)\,x_\alpha$, and $\bar{b}_0(x_\alpha) := \bar{b}(x_0)$, then $\delta_k \to 0$, $v_k \to u_0$ in $L^1(B'\times I;\mathbb{R}^3)$, $\frac{1}{\delta_k}\int_I \nabla_3 v_k(\cdot,x_3)\,dx_3 \rightharpoonup \bar{b}_0$ in $L^p(B';\mathbb{R}^3)$,

$$\lim_{k\to+\infty}\int_{S_{v_k}}\left|\left((\nu_{v_k})_\alpha\Big|\frac{1}{\delta_k}(\nu_{v_k})_3\right)\right|d\mathcal{H}^2 = 0, \tag{6.24}$$

$$\frac{d\lambda}{d\mathcal{L}^2}(x_0) \ge \limsup_{k\to+\infty}\frac{1}{\mathcal{L}^2(B')}\int_{B'\times I} W_{\varepsilon_{n(k)}}\left(x_0+\rho_k x_\alpha, x_3, \nabla_\alpha v_k\Big|\frac{1}{\delta_k}\nabla_3 v_k\right)dx, \tag{6.25}$$

and for every $(u,\bar{b}) \in L^p(B'\times I;\mathbb{R}^3)\times L^p(B';\mathbb{R}^3)$ with $\|\bar{b}\|_{L^p(B';\mathbb{R}^3)} \le M$, the Γ-limit in $L^p_s(B'\times I;\mathbb{R}^3)\times L^p_w(B';\mathbb{R}^3)$ of

$$\begin{cases} \displaystyle\int_{B'\times I} W_{\varepsilon_{n(k)}}\left(x_0+\rho_k x_\alpha, x_3, \nabla_\alpha u\Big|\frac{1}{\delta_k}\nabla_3 u\right)dx & \text{if } \begin{cases} u \in W^{1,p}(B'\times I;\mathbb{R}^3),\\ \bar{b} = \frac{1}{\delta_k}\int_I \nabla_3 u(\cdot,x_3)\,dx_3, \end{cases}\\ +\infty & \text{otherwise} \end{cases}$$

coincides with

$$\begin{cases} \displaystyle\int_{B'} W^*(x_0,\nabla_\alpha u|\bar{b})\,dx_\alpha & \text{if } u \in W^{1,p}(B';\mathbb{R}^3),\\ +\infty & \text{otherwise.} \end{cases}$$

From (6.24), (6.25), and (a slight variant of) Lemma 6.2, for any $0<\eta<1$, there exist a constant $C>0$ and $\{w_k\}\subset SBV^p(B'\times I;\mathbb{R}^3)$ such that $w_k \to u_0$ in $L^1(B'\times I;\mathbb{R}^3)$, $\frac{1}{\delta_k}\int_I \nabla_3 w_k(\cdot,x_3)\,dx_3 \rightharpoonup \bar{b}_0$ in $L^p(B';\mathbb{R}^3)$, $\sup_k \|w_k\|_{L^\infty(B'\times I;\mathbb{R}^3)} \le C$,

$$\lim_{k\to+\infty}\int_{S_{w_k}}\left|\left((\nu_{w_k})_\alpha\Big|\frac{1}{\delta_k}(\nu_{w_k})_3\right)\right|d\mathcal{H}^2 = 0,$$

and

$$\frac{d\lambda}{d\mathcal{L}^2}(x_0) \ge \limsup_{k\to+\infty}\frac{1}{\mathcal{L}^2(B')}\int_{B'\times I} W_{\varepsilon_{n(k)}}\left(x_0+\rho_k x_\alpha, x_3, \nabla_\alpha w_k\Big|\frac{1}{\delta_k}\nabla_3 w_k\right)dx - \eta.$$

From the p-coercivity condition (5.1) and [3, Theorem 4.36], the sequence $\{w_k\}$ converges weakly to u in $SBV^p(\Omega;\mathbb{R}^3)$, and it fulfills the assumptions of Theorem 4.1. Thus, for a not relabeled subsequence, one can find another sequence $\{z_k\}\subset W^{1,\infty}(B'\times I;\mathbb{R}^3)$ such that $z_k \rightharpoonup u_0$ in $W^{1,p}(B'\times I;\mathbb{R}^3)$, $\frac{1}{\delta_k}\int_I \nabla_3 z_k(\cdot,x_3)\,dx_3 \rightharpoonup \bar{b}_0$ in $L^p(B';\mathbb{R}^3)$, $\left\{\left|\left(\nabla_\alpha z_k|\frac{1}{\delta_k}\nabla_3 z_k\right)\right|^p\right\}$ is equi-integrable, and $\mathcal{L}^3(\{z_k \ne w_k\}\cup\{\nabla z_k \ne \nabla w_k\}) \to 0$. Hence

$$\frac{d\lambda}{d\mathcal{L}^2}(x_0) \ge \limsup_{k\to+\infty}\frac{1}{\mathcal{L}^2(B')}\int_{\{w_k=z_k\}} W_{\varepsilon_{n(k)}}\left(x_0+\rho_k x_\alpha, x_3, \nabla_\alpha z_k\Big|\frac{1}{\delta_k}\nabla_3 z_k\right)dx - \eta,$$

and using the p-growth condition (5.1), the fact that $\left\{\left|\left(\nabla_\alpha z_k\middle|\frac{1}{\delta_k}\nabla_3 z_k\right)\right|^p\right\}$ is equi-integrable, and the fact that $\mathcal{L}^3(\{z_k \neq w_k\}) \to 0$ we get that

$$\limsup_{k\to+\infty} \int_{\{w_k\neq z_k\}} W_{\varepsilon_{n(k)}}\left(x_0+\rho_k x_\alpha, x_3, \nabla_\alpha z_k\middle|\frac{1}{\delta_k}\nabla_3 z_k\right)dx = 0.$$

As a consequence

$$\frac{d\lambda}{d\mathcal{L}^2}(x_0) \geq \limsup_{k\to+\infty} \frac{1}{\mathcal{L}^2(B')}\int_{B'\times I} W_{\varepsilon_{n(k)}}\left(x_0+\rho_k x_\alpha, x_3, \nabla_\alpha z_k\middle|\frac{1}{\delta_k}\nabla_3 z_k\right)dx - \eta,$$

and by the p-coercivity condition (5.1) and (6.23),

$$\left\|\frac{1}{\delta_k}\int_I \nabla_3 z_k(\cdot,x_3)\,dx_3\right\|_{L^p(B';\mathbb{R}^3)} \leq M, \quad \|\bar{b}_0\|_{L^p(B';\mathbb{R}^3)} \leq M.$$

Thus by our choice of the subsequence $n(k)$ and Remark 5.3, we get that

$$\frac{d\lambda}{d\mathcal{L}^2}(x_0) \geq W^*(x_0, \nabla_\alpha u(x_0)|\bar{b}(x_0)) - \eta.$$

Letting η tend to zero completes the proof of (6.17). □

Remark 6.9. Note that it seems difficult to think of applying the decoupling variable method introduced in [7] and further developed in [5, 6]. Indeed, this generalized framework has the drawback that we have no information on the way that W_ε depends on ε, and it requires application of such abstract results as metrizability of Γ-convergence. Remark also that the same kind of blow-up argument considered here could have been used in [5, 6, 7] in place of the decoupling variable method, in order to treat the presence of the spatial variable.

7. Case without bending moment. In this last section, we deduce from Theorem 6.1 a similar result without the presence of the bending moment. Define $\mathcal{I}_\varepsilon : L^p(\Omega;\mathbb{R}^3) \to [0,+\infty]$ by

$$\mathcal{I}_\varepsilon(u) := \begin{cases} \displaystyle\int_\Omega W_\varepsilon\left(x, \nabla_\alpha u\middle|\frac{1}{\varepsilon}\nabla_3 u\right)dx & \text{if } u \in W^{1,p}(\Omega;\mathbb{R}^3), \\ +\infty & \text{otherwise.} \end{cases}$$

In [12, Theorem 2.5], the following integral representation result has been proved.

THEOREM 7.1. *For every sequence* $\{\varepsilon_n\} \searrow 0^+$, *there exist a subsequence (not relabeled) and a Carathéodory function* $\widehat{W} : \omega \times \mathbb{R}^{3\times 2} \to [0,+\infty)$ *(depending on the subsequence) such that the sequence* $\mathcal{I}_{\varepsilon_n}$ Γ*-converges in* $L^p_s(\Omega;\mathbb{R}^3)$ *to* $\mathcal{I}$, *where*

$$\mathcal{I}(u) = \begin{cases} \displaystyle\int_\omega \widehat{W}(x_\alpha, \nabla_\alpha u)\,dx_\alpha & \textit{if } u \in W^{1,p}(\omega;\mathbb{R}^3), \\ +\infty & \textit{otherwise.} \end{cases}$$

We refer the reader to [22, 12, 7, 5, 6] for more explicit formulas in particular cases.

Remark 7.2. As it has been pointed out in [7] in the case where W_ε was independent of ε (see also [9]), it can still be seen here that

$$\widehat{W}(x_0,\bar{\xi}) = \min_{z\in\mathbb{R}^3} W^*(x_0,\bar{\xi}|z)$$

for all $\bar{\xi} \in \mathbb{R}^{3\times 2}$ and a.e. $x_0 \in \omega$.

Now define $\mathcal{F}_\varepsilon : BV(\Omega;\mathbb{R}^3) \to [0,+\infty]$ by

$$\mathcal{F}_\varepsilon(u) := \begin{cases} \displaystyle\int_\Omega W_\varepsilon\left(x, \nabla_\alpha u \Big| \frac{1}{\varepsilon}\nabla_3 u\right) dx & \\ \qquad\qquad + \displaystyle\int_{S_u} \left| \left((\nu_u)_\alpha \left| \frac{1}{\varepsilon} (\nu_u)_3 \right.\right) \right| d\mathcal{H}^2 & \text{if } u \in SBV^p(\Omega;\mathbb{R}^3), \\ +\infty & \text{otherwise.} \end{cases}$$

As a consequence of Theorem 6.1, Theorem 7.1, Remark 7.2, and a standard measurability selection criterion (see, e.g., [17, Theorem 1.2, Chapter VIII]) we get the following integral representation result for dimension reduction problems in SBV without bending moment.

THEOREM 7.3. *For every sequence $\{\varepsilon_n\} \searrow 0^+$, there exists a subsequence, still labeled $\{\varepsilon_n\}$, such that $\mathcal{F}_{\varepsilon_n}$ Γ-converges in $L^1_s(\Omega;\mathbb{R}^3)$ to $\mathcal{F} : BV(\Omega;\mathbb{R}^3) \to [0,+\infty]$ defined by*

$$\mathcal{F}(u) := \begin{cases} \displaystyle\int_\omega \widehat{W}(x_\alpha, \nabla_\alpha u)\, dx_\alpha + \mathcal{H}^1(S_u) & \textit{if } u \in SBV^p(\omega;\mathbb{R}^3), \\ +\infty & \textit{otherwise,} \end{cases}$$

where $\widehat{W}$ is given by Theorem 7.1.

Acknowledgments. The author wishes to thank Irene Fonseca and Gilles Francfort for having drawn this problem to his attention.

LONG TAILS IN THE LONG-TIME ASYMPTOTICS OF QUASI-LINEAR HYPERBOLIC-PARABOLIC SYSTEMS OF CONSERVATION LAWS*

GUILLAUME VAN BAALEN†, NIKOLA POPOVIĆ†, AND C. EUGENE WAYNE†

Abstract. The long-time behavior of solutions of systems of conservation laws has been extensively studied. In particular, Liu and Zeng [*Mem. Amer. Math. Soc.*, 125 (1997), pp. viii–120] have given a detailed exposition of the leading order asymptotics of solutions close to a constant background state. In this paper, we extend the analysis of Liu and Zeng by examining higher order terms in the asymptotics in the framework of the so-called two-dimensional *p-system*, though we believe that our methods and results also apply to more general systems. We give a constructive procedure for obtaining these terms, and we show that their structure is determined by the interplay of the parabolic and hyperbolic parts of the problem. In particular, we prove that the corresponding solutions develop *long tails*.

Key words. long-time asymptotics, long tails, hyberbolic-parabolic conservation laws, p-system

DOI. 10.1137/070684835

1. Introduction.

In this paper, we consider the long-time behavior of solutions of systems of viscous conservation laws. This topic has been extensively studied. In particular, for the case of solutions close to a constant background state, [6] (building on work of [2]) contains a detailed exposition of the leading order long-time behavior of such solutions. More precisely, it is shown in [6] that the leading order asymptotics are given as a sum of contributions moving with the characteristic speeds of the undamped system of conservation laws and that each contribution evolves either as a Gaussian solution of the heat equation or as a self-similar solution of the viscous Burger's equation. Thus, with the exception of the translation along characteristics, these leading order terms reflect primarily the dissipative aspects of the problem.

In this paper, in an effort to better understand the interplay between the hyperbolic and parabolic aspects of the problem, we examine higher order terms in the asymptotics. We work with a specific two-dimensional system of equations–the *p-system*, but we believe that its behavior is prototypical. In particular, we think that our methods and results would extend to more complicated systems such as the "full gas dynamics" and the equations of magnetohydrodynamics (MHD) as considered in [6].

The specific set of equations we consider is the following:

$$\begin{aligned} &\partial_t a = c_1 \partial_x b, && a(x,0) = a_0(x), \\ &\partial_t b = c_2 \partial_x a + \partial_x g(a,b) + \alpha \left(\partial_x^2 b + \partial_x (f(a,b) \partial_x b) \right), && b(x,0) = b_0(x). \end{aligned} \tag{1.1}$$

We will make precise the assumptions on the nonlinear terms f and g below, but in order to describe our results informally, we basically assume that $|g(a,b)| \sim \mathcal{O}((|a| +$

$|b|)^2)$ and $|f(a,b)| \sim \mathcal{O}((|a|+|b|))$. We also note that, without loss of generality, we can set $c_1 = c_2 = 1$ and $\alpha = 2$ in (1.1), which can be achieved by appropriate scalings of space, time and the dependent variables, and possible redefinition of the functions f and g.

Physically, (1.1) is a model for compressible, constant entropy flow, where a represents the volume fraction (i.e., the reciprocal of the density) and b is the fluid velocity. The first of the two equations in (1.1) is the consistency relation between these two physical quantities. In particular, it would not be physically reasonable to include a dissipative term in this equation, whereas such a term arises naturally in the second equation which is essentially Newton's law, in which internal frictional forces are often present. As a consequence of the form of the dissipation the damping here is not "diagonalizable" in the terminology of [6].

Next, we note that, with the scaling $c_1 = c_2 = 1$ and $\alpha = 2$ in (1.1), the characteristic speeds are ± 1. If the initial conditions a_0 and b_0 in (1.1) decay sufficiently fast as $|x| \to \infty$, Liu and Zeng [6] showed that $a(x,t) \pm b(x,t) = \frac{1}{\sqrt{1+t}} g_0^{\pm}(\frac{x \pm t}{\sqrt{1+t}}) + \mathcal{O}((1+t)^{-\frac{3}{4}})$, where $g_0^{\pm}$ are self-similar solutions either of the heat equation or of Burger's equation, depending on the detailed form of the nonlinear terms. In this paper we derive similar expressions for the higher order terms in the asymptotics through a constructive procedure that can be carried out to arbitrary order.

More precisely, we show that, for any $N \geq 1$, there exist (universal) functions $\{g_n^{\pm}\}_{n=1}^N$ and constants $\{d_n^{\pm}\}_{n=1}^N$ determined by the initial conditions such that

$$\begin{aligned} a(x,t) + b(x,t) &= \frac{1}{\sqrt{1+t}} g_0^+ \left(\frac{x+t}{\sqrt{1+t}} \right) + \sum_{n=1}^N \frac{1}{(1+t)^{\delta_n}} d_n^+ g_n^+ \left(\frac{x+t}{\sqrt{1+t}} \right) \\ &\quad + \mathcal{O}\left(\frac{1}{(1+t)^{\delta_{N+1}}} \right), \\ a(x,t) - b(x,t) &= \frac{1}{\sqrt{1+t}} g_0^- \left(\frac{x-t}{\sqrt{1+t}} \right) + \sum_{n=1}^N \frac{1}{(1+t)^{\delta_n}} d_n^- g_n^- \left(\frac{x-t}{\sqrt{1+t}} \right) \\ &\quad + \mathcal{O}\left(\frac{1}{(1+t)^{\delta_{N+1}}} \right), \end{aligned} \tag{1.2}$$

where

$$\delta_n = 1 - \frac{1}{2^{n+1}}.$$

We give explicit expressions for the functions $g_n^{\pm}$ below, but focusing for the moment on the case $N = 1$ and the variable a, we have

$$\begin{aligned} a(x,t) = &\frac{1}{2\sqrt{1+t}} \left(g_0^+ \left(\frac{x+t}{\sqrt{1+t}} \right) + g_0^- \left(\frac{x-t}{\sqrt{1+t}} \right) \right) \\ &+ \frac{1}{2(1+t)^{\frac{3}{4}}} \left(d_1^+ g_1^+ \left(\frac{x+t}{\sqrt{1+t}} \right) + d_1^- g_1^- \left(\frac{x-t}{\sqrt{1+t}} \right) \right) + \mathcal{O}\left(\frac{1}{(1+t)^{\frac{7}{8}}} \right), \end{aligned}$$

where the functions $g_0^{\pm}(z)$ and $g_1^{\pm}(z)$ are solutions of the following ordinary differential equations:

$$\partial_z^2 g_0^{\pm}(z) + \frac{1}{2} z \partial_z g_0^{\pm}(z) + \frac{1}{2} g_0^{\pm}(z) + c_{\pm} \partial_z (g_0^{\pm}(z)^2) = 0, \tag{1.3}$$

$$\partial_z^2 g_1^{\pm}(z) + \frac{1}{2} z \partial_z g_1^{\pm}(z) + \frac{3}{4} g_1^{\pm}(z) + 2c_{\pm} \partial_z (g_0^{\pm}(z) g_1^{\pm}(z)) = 0. \tag{1.4}$$

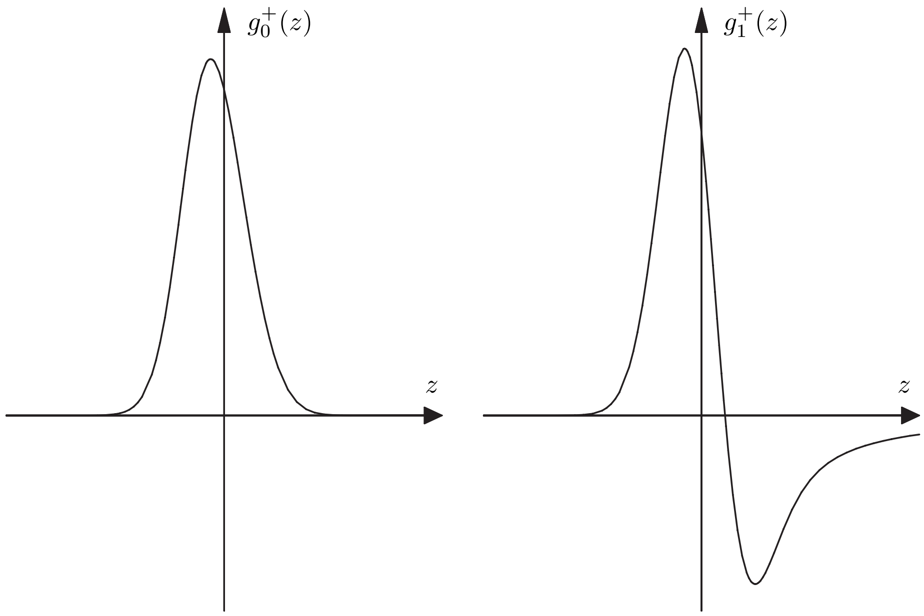

FIG. 1. *Graphs of the functions g_0^+ (left panel) and g_1^+ (right panel). Note the* long tail *of g_1^+ as $z \to \infty$.*

Here $c_\pm$ are constants that depend on the Hessian matrix of $g(a, b)$ at $a = b = 0$ and that will be specified in the course of our analysis. We will prove that, while all solutions of (1.3) have Gaussian decay as $|x| \to \infty$, general solutions of the *linear* equation (1.4) are linear combinations of two functions $g_{1,\pm}(z)$, where $g_{1,\pm}(z)$ decays like a Gaussian as $z \to \mp\infty$ but only like $|z|^{-\frac{3}{2}}$ as $z \to \pm\infty$; see also [5]. The graphs of the functions $g_0^+(z)$ and $g_1^+(z)$ are presented in Figure 1.

Thus, the higher order terms in the asymptotics develop *long tails*. These tails are a manifestation of the hyperbolic part of the problem (or perhaps more precisely of the interplay between the parabolic and hyperbolic parts). Were we to consider just the asymptotic behavior of the viscous Burger's equation which gives the leading order behavior of the solutions, we would find that, if the initial data are well-localized, the higher order terms in the long-time asymptotics decay rapidly in space and have temporal decay rates given by half-integers.

We also note one additional fact about the expansion in (1.2). Prior research [3, 9] has shown that for both parabolic equations and damped wave equations the eigenfunctions of the operator

$$\mathcal{L}u(z) = \partial_z^2 u + \frac{1}{2} z \partial_z u$$

play an important role for the asymptotics. In particular, on appropriate function spaces this operator has a sequence of isolated eigenvalues whose associated eigenfunctions can be used to construct an expansion for the long-time asymptotics. In this connection we prove that the functions $g_n^\pm$ are closely approximated by eigenfunctions of $\mathcal{L}$ with eigenvalues $\lambda_n = -\frac{1}{2} + 2^{-(n+1)}$; more precisely, the functions $g_n^\pm$ are eigenfunctions of a compact perturbation of $\mathcal{L}$; see, e.g., (1.4). However, so far we have not succeeded in finding a function space which both contains these eigenfunctions (the functions $g_n^\pm$ decay slowly as $z \to \pm\infty$) and in which the corresponding eigenvalues are isolated points in the spectrum. We plan to investigate this point further in future research.

Before moving to a precise statement of our results, we note that our approach makes no use of Kawashima's energy estimates for hyperbolic-parabolic conservation laws [4]. Instead we prove existence by directly studying the integral form of (1.1).

We now state our results on the Cauchy problem (1.1). We begin by stating the precise assumptions we make on the nonlinearities f and g in (1.1).

DEFINITION 1. *The maps* $f, g : \mathbf{R}^2 \to \mathbf{R}$ *are admissible nonlinearities for* (1.1) *if there is a quadratic map* $g_0 : \mathbf{R}^2 \to \mathbf{R}$ *and a constant* C *such that, for all* $|\mathbf{z}|$, $|\mathbf{z}_1|$, *and* $|\mathbf{z}_2|$ *small enough,*

$$
\begin{aligned}
|g(\mathbf{z})| &\le C|\mathbf{z}|^2, & |g(\mathbf{z}_1) - g(\mathbf{z}_2)| &\le C|\mathbf{z}_1 - \mathbf{z}_2|(|\mathbf{z}_1| + |\mathbf{z}_2|),\\
|\Delta g(\mathbf{z})| &\le C|\mathbf{z}|^3, & |\Delta g(\mathbf{z}_1) - \Delta g(\mathbf{z}_2)| &\le C|\mathbf{z}_1 - \mathbf{z}_2|(|\mathbf{z}_1| + |\mathbf{z}_2|)^2,\\
|f(\mathbf{z})| &\le C|\mathbf{z}|, \quad \textit{and} & |f(\mathbf{z}_1) - f(\mathbf{z}_2)| &\le C|\mathbf{z}_1 - \mathbf{z}_2|,
\end{aligned}
$$

where $\Delta g(\mathbf{z}) \equiv g(\mathbf{z}) - g_0(\mathbf{z})$.

The main result of this paper can be formulated as follows.

THEOREM 2. *Fix* $N > 0$. *There exists* $\epsilon_0 > 0$ *sufficiently small such that if*

(i) $|a_0|_{\mathrm{H}^1(\mathbb{R})} + |a_0|_{\mathrm{L}^1(\mathbb{R})} < \epsilon_0$ *and* $|b_0|_{\mathrm{H}^2(\mathbb{R})} + |b_0|_{\mathrm{L}^1(\mathbb{R})} < \epsilon_0$,

(ii) $|x^2 a_0|_{\mathrm{L}^2(\mathbb{R})} + |x^2 b_0|_{\mathrm{L}^2(\mathbb{R})} < \infty$,

then (1.1) *has a unique (mild) solution with initial conditions* a_0 *and* b_0. *Moreover, there exist functions* $\{g_n^\pm\}_{n=0}^N$ *(independent of initial conditions for* $n \ge 1$*) and constants* C_N, $\{d_n^\pm\}_{n=1}^N$ *determined by the initial conditions such that*

$$
\begin{aligned}
a(x,t) + b(x,t) &= \frac{1}{\sqrt{1+t}} g_0^+\left(\frac{x+t}{\sqrt{1+t}}\right) + \sum_{n=1}^N \frac{1}{(1+t)^{1-\frac{1}{2^{n+1}}}} d_n^+ g_n^+\left(\frac{x+t}{\sqrt{1+t}}\right) + R_u^N(x,t),\\
a(x,t) - b(x,t) &= \frac{1}{\sqrt{1+t}} g_0^-\left(\frac{x-t}{\sqrt{1+t}}\right) + \sum_{n=1}^N \frac{1}{(1+t)^{1-\frac{1}{2^{n+1}}}} d_n^- g_n^-\left(\frac{x-t}{\sqrt{1+t}}\right) + R_v^N(x,t),
\end{aligned}
\tag{1.5}
$$

where the remainders R_u^N *and* R_v^N *satisfy the estimates*

$$
\begin{aligned}
\sup_{t\ge0}(1+t)^{\frac34 - \frac{1}{2^{N+2}}} \|R^N_{\{u,v\}}(\cdot,t)\|_{\mathrm{L}^2(\mathbb{R})} &\le C_N,\\
\sup_{t\ge0}(1+t)^{\frac54 - \frac{1}{2^{N+2}}} \|\partial_x R^N_{\{u,v\}}(\cdot,t)\|_{\mathrm{L}^2(\mathbb{R})} &\le C_N.
\end{aligned}
\tag{1.6}
$$

Furthermore, for $n \ge 1$, *the functions* $g_n^\pm$ *satisfy* $g_n^\pm(z) \sim |z|^{-2+\frac{1}{2^n}}$ *as* $z \to \pm\infty$.

There is a slight incongruity in this result in that the norm in which we estimate the remainder term is weaker than the one we use on the initial data; namely, we do not give estimates for the remainder in $\mathrm{H}^2(\mathbb{R})$ or in the localization norms $\mathrm{L}^1(\mathbb{R})$ and the weighted $\mathrm{L}^2(\mathbb{R})$-norm (on that aspect of the problem, see Remark 3 below). Theorem 2 actually holds for slightly more general initial conditions than those satisfying (i)–(ii). Furthermore, we will prove that the estimates (1.6) hold for all initial conditions (a_0, b_0) in a subset $\mathcal{D}_2 \subset \mathrm{H}_1 \times \mathrm{H}_2$ that is *positively invariant* under the flow of (1.1). However, since the topology used to define the subset $\mathcal{D}_2$ is somewhat nonstandard, we have chosen to state the result initially in this slightly weaker, but hopefully more comprehensible, form to keep the introduction as simple as possible.

Remark 3. It is interesting to note (see Proposition 7 below) that $\|x^2 a(\cdot,t)\|_{\mathrm{L}^2(\mathbb{R})} + \|x^2 b(\cdot,t)\|_{\mathrm{L}^2(\mathbb{R})}$ is finite for all finite $t > 0$ but that the terms with $n \ge 1$ in the asymptotic expansion do not satisfy this property due to the long tails of the functions $g_n^{\pm}$.

Remark 4. As the asymmetry in the degree of x derivatives in (1.1) suggests, we require more spatial regularity from the second component (the b variable) than from the first (the a variable). It is then natural to expect that R_u^N or R_v^N are not necessarily in H^2 but that only their difference is.

We conclude this section with a few remarks. Define $u_{\pm}(x,t) = a(x,t) \pm b(x,t)$. Then the asymptotics of the solutions of (1.1) in the variables $u_{\pm}$ are the same as those of the two-dimensional (generalized) Burger's equation

$$\begin{aligned} \partial_t u_+ &= \partial_x^2 u_+ + \partial_x u_+ + \partial_x (c_+ u_+^2 - c_- u_-^2), \\ \partial_t u_- &= \partial_x^2 u_- - \partial_x u_- + \partial_x (c_- u_-^2 - c_+ u_+^2), \end{aligned} \tag{1.7}$$

where the constants $c_{\pm}$ are determined by the Hessian of $g(a,b)$ at $a = b = 0$ through

$$c_{\pm} = \pm \frac{1}{8} (1, \pm 1) \cdot \begin{pmatrix} \partial_a^2 g & \partial_a \partial_b g \\ \partial_a \partial_b g & \partial_b^2 g \end{pmatrix}\bigg|_{a=b=0} \cdot \begin{pmatrix} 1 \\ \pm 1 \end{pmatrix}.$$

We will show that the hyperbolic effects manifest themselves through the "source" terms $-c_- u_-^2$ (respectively, $c_+ u_+^2$) in the first (respectively, second) equation in (1.7). In particular, none of the terms $g_n^{\pm}$, with $n \geq 1$, would be present in the asymptotic expansion if those terms were absent.

Finally, note that we have chosen to state Theorem 2 for finite N. As it turns out, the sums appearing in (1.5) converge in the limit as $N \to \infty$, in which case the estimates (1.6) hold with time weights replaced by $(1+t)^{\frac{3}{4}} \ln(2+t)^{-1}$ and $(1+t)^{\frac{5}{4}} \ln(2+t)^{-1}$. The proof can easily be done with the techniques used in this paper and is left to the reader.

The remainder of the paper is organized as follows: In section 2, we discuss the well-posedness of the Cauchy problem (1.1) in an appropriately defined topology. In section 3, we explain our strategy for proving our main result (Theorem 2) on the long-time asymptotics of solutions of (1.1). Namely, we decompose that proof into a series of simpler subproblems which are then tackled in subsequent sections: In sections 4 and 5, we investigate properties of solutions of Burger-type equations (respectively, of inhomogeneous heat equations) as they occur naturally in the asymptotic analysis. In section 6, we collect some estimates that are used in the proof of the well-posedness of (1.1). Finally, in section 7, we specify the sense in which the semigroup of the linearization of (1.1) is close to heat kernels translating along the characteristics, and we give estimates on the remainder terms occurring in Theorem 2.

2. Cauchy problem. To motivate our technical treatment of the problem and in particular our choice of function spaces, we first note that, upon taking the Fourier transform of the linearization of (1.1), it follows that

$$\partial_t \begin{pmatrix} a \\ b \end{pmatrix} = \mathrm{L} \begin{pmatrix} a \\ b \end{pmatrix} \equiv \begin{pmatrix} 0 & ik \\ ik & -2k^2 \end{pmatrix} \begin{pmatrix} a \\ b \end{pmatrix}. \tag{2.1}$$

We then find that the (Fourier transform of) the semigroup associated with (2.1) is

$$\mathrm{e}^{\mathrm{L}t} = \mathrm{e}^{-k^2 t} \begin{pmatrix} \cos(kt\Delta) + \frac{k}{\Delta} \sin(kt\Delta) & \frac{i}{\Delta} \sin(kt\Delta) \\ \frac{i}{\Delta} \sin(kt\Delta) & \cos(kt\Delta) - \frac{k}{\Delta} \sin(kt\Delta) \end{pmatrix}, \tag{2.2}$$

where $\Delta = \sqrt{1-k^2}$. The most important fact about the semigroup $\mathrm{e}^{\mathrm{L}t}$ is that it is close to $\mathrm{e}^{\mathrm{L}_0 t}$, the semigroup associated with the problem

$$\partial_t \begin{pmatrix} u \\ v \end{pmatrix} = \mathrm{L}_0 \begin{pmatrix} u \\ v \end{pmatrix} \equiv \begin{pmatrix} \partial_x^2 + \partial_x & 0 \\ 0 & \partial_x^2 - \partial_x \end{pmatrix} \begin{pmatrix} u \\ v \end{pmatrix}. \tag{2.3}$$

Formally, $\mathrm{e}^{\mathrm{L}_0 t}$ can be obtained by setting $\Delta = 1$ in $\mathrm{e}^{\mathrm{L}t}$ and by conjugating with the matrix

$$\mathcal{S} \equiv \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}. \tag{2.4}$$

These two operations correspond to a long wavelength expansion and a change of dependent variables to quantities that move along the characteristics. More precisely, we will prove that $\mathrm{e}^{\mathrm{L}t}$ satisfies the intertwining property

$$\mathcal{S}\mathrm{e}^{\mathrm{L}t} \approx \mathrm{e}^{\mathrm{L}_0 t}\mathcal{S},$$

where the symbol $\approx$ means that the action of these two operators is the same in the large-scale—long-time limit; see Lemma 19 at the beginning of section 7 for details.

Furthermore, $\mathrm{e}^{\mathrm{L}t}$ satisfies paraboliclike estimates

$$|\mathrm{e}^{\mathrm{L}t}| \le C\mathrm{e}^{-\min(k^2,1)\frac{t}{4}} \begin{pmatrix} 1 & \frac{1}{\sqrt{1+k^2}} \\ \frac{1}{\sqrt{1+k^2}} & 1 \end{pmatrix}, \tag{2.5}$$

$$\left| \mathrm{e}^{\mathrm{L}t} \begin{pmatrix} 0 \\ ik \end{pmatrix} \right| \le C \frac{\mathrm{e}^{-\min(k^2,1)\frac{t}{4}}}{\sqrt{t}} \begin{pmatrix} 1 \\ \frac{1}{\sqrt{1+k^2}} \end{pmatrix} \tag{2.6}$$

uniformly in $t \ge 0$ and $k \in \mathbf{R}$.

Hence, to summarize, $\mathrm{e}^{\mathrm{L}t}$ behaves like a superposition of heat kernels translating along the characteristics of the underlying hyperbolic problem. In view of the above observations as well as of classical techniques for parabolic PDEs (see, e.g., [7, 1]), we will consider (1.1) in the following (somewhat nonstandard) topology (cf. also [8]).

Definition 5. *We define $\mathcal{B}_0$ (respectively, $\mathcal{B}$) as the closure of $\mathcal{C}_0^\infty(\mathbf{R}, \mathbf{R}^2)$ (respectively, $\mathcal{C}_0^\infty(\mathbf{R} \times [0,\infty), \mathbf{R}^2)$) under the norm $|\cdot|$ (respectively, $\|\cdot\|$), where, for $\mathbf{z}_0 = (a_0, b_0) : \mathbf{R} \to \mathbf{R}^2$ and $\mathbf{z} = (a,b) : \mathbf{R} \times [0,\infty) \to \mathbf{R}^2$, we define*

$$|\mathbf{z}_0| = \|\widehat{\mathbf{z}}_0\|_\infty + \|\mathbf{z}_0\|_2 + \|\mathrm{D}\mathbf{z}_0\|_2 + \|\mathrm{D}^2 b_0\|_2,$$
$$\|\mathbf{z}\| = \|\hat{\mathbf{z}}\|_{\infty,0} + \|\mathbf{z}\|_{2,\frac{1}{4}} + \|\mathrm{D}\mathbf{z}\|_{2,\frac{3}{4}} + \|\mathrm{D}^2 b\|_{2,\frac{5}{4}\star}.$$

Here $(Da)(x,t) \equiv \partial_x a(x,t)$, $\hat{a}(k,t)$ is the Fourier transform of $a(x,t)$,

$$\|f\|_{p,q} = \sup_{t\ge 0}(1+t)^q \|f(\cdot,t)\|_p, \qquad \|f\|_{p,q^\star} = \sup_{t\ge 0} \frac{(1+t)^q}{\ln(2+t)} \|f(\cdot,t)\|_p,$$

and $\|\cdot\|_p$ is the standard $\mathrm{L}^p(\mathbf{R})$-norm.

Before turning to the Cauchy problem with initial data in $\mathcal{B}_0$, we collect a few comments on our choice of function spaces.

Consider first the requirements on the initial conditions in (1.1). While the use of H^1 space is quite natural in this context, we choose to replace the L^1-norm by the (weaker) control of the L^∞-norm in Fourier space. This has the great advantage that all estimates can then be done in Fourier space, where the semigroup $\mathrm{e}^{\mathrm{L}t}$ has the simple, explicit, form (2.2).

In turn, our choice of q-exponents in the norm $\|\cdot\|$ is motivated by the fact that these are the highest possible exponents for which the $\|\cdot\|$-norm of the leading order asymptotic term $\frac{1}{\sqrt{1+t}}g_0^{\pm}(\frac{x\pm t}{\sqrt{1+t}})$ is bounded. Note also that, for the linear evolution (2.1), we have

$$\|\mathrm{e}^{\mathrm{L}t}\mathbf{z}_0\| \leq C|\mathbf{z}_0|, \tag{2.7}$$

since $\hat{j}(k,t) = \mathrm{e}^{-\min(k^2,1)t}u_0(k)$ satisfies

$$\|\mathrm{D}^n j(\cdot,t)\|_2 \leq C\Big(\mathrm{e}^{-t}\|\mathrm{D}^n u_0\|_2 + \min\Big(t^{-\frac{1}{4}-\frac{n}{2}}\|\hat{u}_0\|_\infty, \|D^n u_0\|_2\Big)\Big)$$

for all $n = 0, 1, \ldots$.

Finally, we note that, for admissible nonlinearities in the sense of Definition 1, the map $h(a,b) = f(a,b)\partial_x b + g(a,b) = h(\mathbf{z})$ satisfies

$$\|h(\mathbf{z})\|_{1,\frac{1}{2}} + \|h(\mathbf{z})\|_{2,\frac{3}{4}} + \|Dh(\mathbf{z})\|_{2,\frac{5}{4}} \leq C\|\mathbf{z}\|^2, \tag{2.8}$$

$$\|h(\mathbf{z}_1) - h(\mathbf{z}_2)\|_{1,\frac{1}{2}} + \|h(\mathbf{z}_1) - h(\mathbf{z}_2)\|_{2,\frac{3}{4}} \leq C\|\mathbf{z}_1 - \mathbf{z}_2\|(\|\mathbf{z}_1\| + \|\mathbf{z}_2\|), \tag{2.9}$$

$$\|D(h(\mathbf{z}_1) - h(\mathbf{z}_2))\|_{2,\frac{5}{4}} \leq C\|\mathbf{z}_1 - \mathbf{z}_2\|(\|\mathbf{z}_1\| + \|\mathbf{z}_2\|). \tag{2.10}$$

We are now fully equipped to study the Cauchy problem (1.1) in $\mathcal{B}$.

THEOREM 6. *For all $\mathbf{z}_0 \in \mathcal{B}_0$ with $|\mathbf{z}_0| = |(a_0, b_0)| \leq \epsilon_0$ small enough, the Cauchy problem* (1.1) *is (locally) well posed in $\mathcal{B}$ if the nonlinearities are admissible in the sense of Definition* 1*. In particular, the solution satisfies $\|\mathbf{z}\| \leq c\epsilon_0$ for some $c > 1$ and is unique among functions in $\mathcal{B}$ satisfying this bound.*

Proof. Upon taking the Fourier transform of (1.1), we get

$$\partial_t\begin{pmatrix} a \\ b \end{pmatrix} = \begin{pmatrix} 0 & ik \\ ik & -2k^2 \end{pmatrix}\begin{pmatrix} a \\ b \end{pmatrix} + \begin{pmatrix} 0 \\ ikh \end{pmatrix}, \tag{2.11}$$

which gives the following representation for the solution:

$$\mathbf{z}(t) \equiv \begin{pmatrix} a(t) \\ b(t) \end{pmatrix} = \mathrm{e}^{\mathrm{L}t}\begin{pmatrix} a_0 \\ b_0 \end{pmatrix} + \int_0^t \mathrm{d}s\ \mathrm{e}^{\mathrm{L}(t-s)}\begin{pmatrix} 0 \\ \partial_x h(\mathbf{z}(s)) \end{pmatrix} \equiv \mathrm{e}^{\mathrm{L}t}\mathbf{z}_0 + \mathcal{N}[\mathbf{z}](t). \tag{2.12}$$

We will prove below that for all $\mathbf{z}_i \in \mathcal{B}$, $i = 1, 2$, we have

$$\|\mathcal{N}[\mathbf{z}]\| \leq C\|\mathbf{z}\|^2 \quad \text{and} \quad \|\mathcal{N}[\mathbf{z_1}] - \mathcal{N}[\mathbf{z_2}]\| \leq C\|\mathbf{z}_1 - \mathbf{z}_2\|(\|\mathbf{z}_1\| + \|\mathbf{z}_2\|) \tag{2.13}$$

for some constant C. The proof of Theorem 6 then follows from the fact that, for all $\mathbf{z}_0 \in \mathcal{B}_0$ with $|\mathbf{z}_0| \leq \epsilon_0$ small enough and $c > 1$, the right-hand side (r.h.s.) of (2.12) defines a contraction map from some (small) ball of radius $c\epsilon_0$ in $\mathcal{B}$ onto itself.

The general rule for proving the various estimates involved in (2.13) is to split the integration interval into two parts, with $s \in \mathcal{I}_1 \equiv [0, \frac{t}{2}]$ and $s \in \mathcal{I}_2 \equiv [\frac{t}{2}, t]$. In $\mathcal{I}_1$, we place as many derivatives (or, equivalently, factors of k) as possible on the semigroup $\mathrm{e}^{\mathrm{L}(t-s)}$, while on $\mathcal{I}_2$, (most of) these derivatives need to act on h, since the integral would otherwise be divergent at $s = t$.

Additional difficulties arise from the fact that $\mathrm{e}^{\mathrm{L}t}$ has very few smoothing properties (slow or no decay in k as $|k| \to \infty$), so that in some cases we need to consider separately the large-k part and the small-k part of the L^2-norm, say. This is done through the use of $\mathbb{P}$, defined as the Fourier multiplier with the characteristic function on $[-1, 1]$.

We decompose the proof of $\|\mathcal{N}[\mathbf{z}]\| \leq C\|\mathbf{z}\|^2$ into that of

$$\begin{aligned}\|\mathcal{N}[\mathbf{z}]\| \leq{}& \|\widehat{\mathcal{N}[\mathbf{z}]}\|_{\infty,0} + \|\mathcal{N}[\mathbf{z}]\|_{2,\frac{1}{4}} + \|\mathbb{P}\mathrm{D}\mathcal{N}[\mathbf{z}]\|_{2,\frac{3}{4}} + \|(1-\mathbb{P})\mathrm{D}\mathcal{N}[\mathbf{z}]\|_{2,\frac{3}{4}}\\ &+ \|(1-\mathbb{P})\mathrm{D}^2\mathcal{N}[\mathbf{z}]_2\|_{2,\frac{5}{4}^\star} + \|(1-\mathbb{Q})\mathbb{P}\mathrm{D}^2\mathcal{N}[\mathbf{z}]_2\|_{2,\frac{5}{4}^\star} + \|\mathbb{Q}\mathbb{P}\mathrm{D}^2\mathcal{N}[\mathbf{z}]_2\|_{2,\frac{5}{4}^\star}\\ \leq{}& C\|\mathbf{z}\|^2, \end{aligned} \tag{2.14}$$

where $\mathbb{Q}$ is the characteristic function for $t \geq 1$ and $\mathcal{N}[\mathbf{z}]_2$ denotes the second component of $\mathcal{N}[\mathbf{z}]$.

We now consider $\|\mathbb{P}\mathrm{D}\mathcal{N}[\mathbf{z}]\|_{2,\frac{3}{4}}$ as an example of the way we prove the above estimates. We have

$$\begin{aligned}\|\mathbb{P}\mathrm{D}\mathcal{N}[\mathbf{z}](\cdot,t)\|_2 \leq{}& \|h(\mathbf{z})\|_{2,\frac{3}{4}} \left(\sup_{|k|\leq 1,\tau\geq 0} |k|\sqrt{\tau}\mathrm{e}^{-\frac{k^2\tau}{4}}\right)\int_0^{\frac{t}{2}} \mathrm{d}s\ \frac{(1+s)^{-\frac{3}{4}}}{t-s}\\ &+ \|\mathrm{D}h(\mathbf{z})\|_{2,\frac{5}{4}}\left(\sup_{|k|\leq 1,\tau\geq 0} \mathrm{e}^{-\frac{k^2\tau}{4}}\right)\int_{\frac{t}{2}}^t \mathrm{d}s\ \frac{(1+s)^{-\frac{5}{4}}}{\sqrt{t-s}}\\ \leq{}& C\|\mathbf{z}\|^2\left(\frac{2}{t}\int_0^{\frac{t}{2}}\frac{\mathrm{d}s}{(1+s)^{\frac{3}{4}}} + \frac{1}{(1+\frac{t}{2})^{\frac{5}{4}}}\int_{\frac{t}{2}}^t\frac{\mathrm{d}s}{\sqrt{t-s}}\right)\\ \leq{}& C\|\mathbf{z}\|^2(1+t)^{-\frac{3}{4}}\end{aligned} \tag{2.15}$$

for all $t \geq 0$, which shows that $\|\mathbb{P}\mathrm{D}\mathcal{N}[\mathbf{z}]\|_{2,\frac{3}{4}} \leq C\|\mathbf{z}\|^2$. All other estimates in (2.14) can be done similarly; we postpone their proof to section 6 below.

Finally, we note that the Lipschitz-type estimate in (2.13) can be obtained in the same manner, mutatis mutandis, due to the similarity between (2.9) and (2.10) with (2.8); we omit the details. ∎

We can now turn to the question of the asymptotic structure of the solutions of (1.1) provided by Theorem 6. Note that already if we wanted to prove that $\mathrm{e}^{\mathrm{L}t}\mathbf{z}_0$ satisfies "Gaussian asymptotics" we would need more localization properties on $\mathbf{z}_0$ than those provided by the $\mathcal{B}_0$-topology. It will turn out to be sufficient to require $\mathbf{z}_0 \in \mathcal{B}_0 \cap \mathrm{L}^2(\mathbb{R}, x^m\mathrm{d}x)$ for (some) $m \geq 2$. We now prove that this requirement is *forward invariant* under the flow of (1.1).

PROPOSITION 7. *Let* $\rho_m(x) = |x|^m$, *and define*

$$\mathcal{D}_m = \left\{ \mathbf{z}_0 \in \mathcal{B}_0 \textit{ such that } |\mathbf{z}_0| + \|\rho_m\mathbf{z}_0\|_2 < \infty \right\}.$$

If $\mathbf{z}_0 \in \mathcal{D}_m$ *and* $|\mathbf{z}_0| \leq \epsilon_0$ *such that Theorem* 6 *holds, then the corresponding solution* $\mathbf{z}(t)$ *of* (1.1) *satisfies* $\mathbf{z}(t) \in \mathcal{D}_m$ *for all finite* $t > 0$. *Furthermore, there holds* $|\mathbf{z}(t)| \leq (1+\delta)\epsilon_0$ *for some (small) constant* δ.

Proof. Note first that, by Theorem 6, $|\mathbf{z}(t)| \leq \|\mathbf{z}\| \leq (1+\delta)\epsilon_0$ since $\mathbf{z}_0 \in \mathcal{B}_0$ and $|\mathbf{z}_0| \leq \epsilon_0$. Then fix $m \in \mathbf{N}$, $m \geq 1$. The proof of Theorem 6 can easily be adapted to show that (1.1) is *locally* (in time) well posed in $\mathcal{D}_m$. Global existence then follows from the fact that the quantity

$$N(t) = \frac{1}{2}\|\rho_m\mathbf{z}(\cdot,t)\|^2 = \frac{1}{2}\int_{-\infty}^{\infty}\mathrm{d}x\ |x|^m(a(x,t)^2 + b(x,t)^2)$$

grows *at most exponentially* as $t \to \infty$. Namely, we have

$$\begin{aligned}
\partial_t N(t) &= \int_{-\infty}^{\infty} \mathrm{d}x\ |x|^m \Big(\partial_x(ab) + 2b\partial_x^2 b + b\partial_x\Big(f(a,b)\partial_x b + g(a,b)\Big)\Big) \\
&= -\int_{-\infty}^{\infty} \mathrm{d}x\ m|x|^{m-1}\mathrm{sign}(x)\Big(b(a+g(a,b)) + (2+f(a,b))b\partial_x b\Big) \\
&\quad - \int_{-\infty}^{\infty} \mathrm{d}x\ |x|^m(\partial_x b)^2\Big(2+f(a,b)\Big) \\
&\le \int_{-\infty}^{\infty} \mathrm{d}x\ \Big((m-1)^{m-1} + |x|^m\Big)\Big|\ b(a+g(a,b)) + (2+f(a,b))b\partial_x b\ \Big| \\
&\quad - \int_{-\infty}^{\infty} \mathrm{d}x\ |x|^m(\partial_x b)^2\Big(2+f(a,b)\Big) \\
&\le \int_{-\infty}^{\infty} \mathrm{d}x\ \Big((m-1)^{m-1} + |x|^m\Big)\Big(|b(a+g(a,b))| + 2^{-1}|2+f(a,b)|b^2\Big) \\
&\le C_1(m,\epsilon_0) + C_2(\epsilon_0)N(t),
\end{aligned}$$

due to the estimates $\|f(a,b)\|_\infty \le C\epsilon_0 \ll 2$ and $\|\frac{g(a,b)}{\sqrt{a^2+b^2}}\|_\infty \le C\epsilon_0$. $\square$

3. Asymptotic structure—proof of Theorem 2. We can now state our main result on the asymptotic structure of solutions of (1.1) in a definitive manner.

THEOREM 8. *Let $\mathcal{D}_m$ be as in Proposition 7 with $m \ge 2$, let $\mathbf{z}_0 \in \mathcal{D}_m$ with $|\mathbf{z}_0| \le \epsilon_0$ such that Theorem 6 holds, and write $\mathbf{z}(t) = (a(t), b(t))$ for the corresponding solution of* (1.1)*. Then there exist functions $\{g_n^\pm\}_{n=0}^N$ (independent of $\mathbf{z}_0$ for $n \ge 1$) and constants C_N, $\{d_n^\pm\}_{n=1}^N$ determined by $\mathbf{z}_0$ such that*

$$\begin{aligned}
a(x,t) + b(x,t) &= \frac{1}{\sqrt{1+t}} g_0^+\left(\frac{x+t}{\sqrt{1+t}}\right) + \sum_{n=1}^N \frac{1}{(1+t)^{1-\frac{1}{2^{n+1}}}} d_n^+ g_n^+\left(\frac{x+t}{\sqrt{1+t}}\right) + R_u^N(x,t), \\
a(x,t) - b(x,t) &= \frac{1}{\sqrt{1+t}} g_0^-\left(\frac{x-t}{\sqrt{1+t}}\right) + \sum_{n=1}^N \frac{1}{(1+t)^{1-\frac{1}{2^{n+1}}}} d_n^- g_n^-\left(\frac{x-t}{\sqrt{1+t}}\right) + R_v^N(x,t),
\end{aligned} \tag{3.1}$$

where the remainders R_u^N and R_v^N satisfy the estimates

$$\begin{aligned}
\sup_{t\ge0}(1+t)^{\frac{3}{4}-\frac{1}{2^{N+2}}}\|R_{\{u,v\}}^N(\cdot,t)\|_{\mathrm{L}^2(\mathbb{R})} &\le C_N, \\
\sup_{t\ge0}(1+t)^{\frac{5}{4}-\frac{1}{2^{N+2}}}\|\partial_x R_{\{u,v\}}^N(\cdot,t)\|_{\mathrm{L}^2(\mathbb{R})} &\le C_N.
\end{aligned} \tag{3.2}$$

Furthermore, for $n \ge 1$, the functions $g_n^\pm$ satisfy $g_n^\pm(z) \sim |z|^{-2+\frac{1}{2^n}}$ as $z \to \pm\infty$.

Remark 9. As will be apparent from the proof of Theorem 8, any hyperbolic-parabolic system of the form

$$\partial_t \mathbf{z} + f(\mathbf{z})_x = (B(\mathbf{z})\mathbf{z}_x)_x$$

with admissible nonlinearities in the sense of (the natural extension of) Definition 1 gives rise to solutions having the same asymptotic structure as those of the p-system as long as the following two conditions are satisfied:

1. There exist two matrices $\mathcal{S}$ and A, with $\mathcal{S}$ nonsingular and A diagonal having eigenvalues of multiplicity 1 for which $\mathcal{S}\mathrm{e}^{\mathrm{L}t} \approx \mathrm{e}^{\mathrm{L}_0 t}\mathcal{S}$ in the sense of Lemma 19 (see section 7), where $\mathrm{L}_0 = \partial_x^2 + \mathrm{A}\partial_x$ and $\mathrm{L} = B(0)\partial_x^2 - f'(0)\partial_x$.

2. The Cauchy problem with the initial condition in the corresponding function space (the natural extension of $\mathcal{B}_0$ to the problem considered) is well-posed and satisfies the analogues of Theorem 6 and Proposition 7.

We now briefly comment on the above assumptions for specific systems such as the "full gas dynamics" and the MHD system. The intertwining property of item 1 above is proved in [6] for quite general systems, though not in exactly the same topology as that used in Lemma 19. As for item 2, local well posedness for initial data in $\mathcal{B}_0$ is certainly not an issue; the only difficulty is to prove that the various norms of Definition 5 exhibit "paraboliclike" decay as $t \to \infty$. This is very likely to hold, particularly for systems satisfying item 1.

While the variables (a, b) are adapted to the study of the Cauchy problem because of the inherent asymmetry of spatial regularity in (1.1), they are not the best framework for studying the asymptotic structure of the solutions to (1.1). It turns out to be more convenient to change variables to quantities that move along the characteristics. We thus define

$$\begin{pmatrix} u(x,t) \\ v(x,t) \end{pmatrix} \equiv \begin{pmatrix} \mathcal{T}^{-1} & 0 \\ 0 & \mathcal{T} \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \begin{pmatrix} a(x,t) \\ b(x,t) \end{pmatrix} \equiv \begin{pmatrix} \mathcal{T}^{-1} & 0 \\ 0 & \mathcal{T} \end{pmatrix} \mathcal{S}\mathbf{z}(x,t),$$

where $\mathcal{T}$ is the translation operator defined by

$$(\mathcal{T}f)(x,t) = f(x+t,t) \quad \text{or, equivalently, by} \quad \widehat{\mathcal{T}f}(k,t) = \mathrm{e}^{ikt}\hat{f}(k,t). \tag{3.3}$$

Note in passing that

$$a(x,t) = \frac{1}{2}\Big(u(x+t,t) + v(x-t,t)\Big) \quad \text{and} \quad b(x,t) = \frac{1}{2}\Big(u(x+t,t) - v(x-t,t)\Big).$$

We then use the fact that $\mathbf{z}$ satisfies the integral equation

$$\begin{aligned} \mathcal{S}\mathbf{z}(t) &= \mathcal{S}\mathrm{e}^{\mathrm{L}t}\mathbf{z}_0 + \int_0^t \mathrm{d}s\; \mathcal{S}\mathrm{e}^{\mathrm{L}(t-s)} \begin{pmatrix} 0 \\ \partial_x h(\mathbf{z}(s)) \end{pmatrix} \\ &= \mathrm{e}^{\mathrm{L}_0 t}\mathcal{S}\mathbf{z}_0 + \int_0^t \mathrm{d}s\; \mathrm{e}^{\mathrm{L}_0(t-s)}\mathcal{S} \begin{pmatrix} 0 \\ \partial_x g_0(\mathbf{z}(s)) \end{pmatrix} + \mathcal{R}[\mathbf{z}](t), \end{aligned} \tag{3.4}$$

where

$$\begin{aligned} \mathcal{R}[\mathbf{z}](t) =& \Big(\mathcal{S}\mathrm{e}^{\mathrm{L}t} - \mathrm{e}^{\mathrm{L}_0 t}\mathcal{S}\Big)\mathbf{z}_0 \\ &+ \int_0^t \mathrm{d}s\; \left[\mathcal{S}\mathrm{e}^{\mathrm{L}(t-s)} \begin{pmatrix} 0 \\ \partial_x h(\mathbf{z}(s)) \end{pmatrix} - \mathrm{e}^{\mathrm{L}_0(t-s)}\mathcal{S} \begin{pmatrix} 0 \\ \partial_x g_0(\mathbf{z}(s)) \end{pmatrix} \right]. \end{aligned}$$

To justify the notation, which suggests that $\mathcal{R}[\mathbf{z}] = (\mathcal{R}_u[\mathbf{z}], \mathcal{R}_v[\mathbf{z}])$ is a remainder term, we will prove in section 7 that it satisfies the improved decay rates

$$\|\mathcal{R}_{\{u,v\}}[\mathbf{z}]\|_{2,\frac{3}{4}^\star} + \|\mathrm{D}\mathcal{R}_{\{u,v\}}[\mathbf{z}]\|_{2,\frac{5}{4}^\star} \le C\epsilon_0, \tag{3.5}$$

because of the intertwining relation $\mathcal{S}\mathrm{e}^{\mathrm{L}t} \approx \mathrm{e}^{\mathrm{L}_0 t}\mathcal{S}$ (see Lemma 19) and the fact that $h(\mathbf{z}) = g_0(\mathbf{z}) + \text{h.o.t.}$

Recalling that g_0 is quadratic (cf. Definition 1), we will write

$$\begin{aligned} g_0(\mathbf{z}) &= c_+(a+b)^2 - c_-(a-b)^2 + c_3(a+b)(a-b) \\ &= c_+(\mathcal{T}u)^2 - c_-(\mathcal{T}^{-1}v)^2 + c_3(\mathcal{T}u)(\mathcal{T}^{-1}v) \end{aligned}$$

for $\mathbf{z}=(a,b)$. We thus find from (3.4) that u and v satisfy

$$\begin{aligned} u(t) &= \mathrm{e}^{\partial_x^2 t}(a_0+b_0) + \partial_x \int_0^t \mathrm{d}s\ \mathrm{e}^{\partial_x^2(t-s)}\Big(c_+u(s)^2 - c_-\mathcal{T}^{-2}v(s)^2\Big) \\ &\qquad + \mathcal{T}^{-1}\mathcal{R}_u[\mathbf{z}](t) + c_3\partial_x \int_0^t \mathrm{d}s\ \mathrm{e}^{\partial_x^2(t-s)}\mathcal{T}^{-1}\Big((\mathcal{T}u(s))(\mathcal{T}^{-1}v(s))\Big), \end{aligned} \tag{3.6}$$

$$\begin{aligned} v(t) &= \mathrm{e}^{\partial_x^2 t}(a_0-b_0) + \partial_x \int_0^t \mathrm{d}s\ \mathrm{e}^{\partial_x^2(t-s)}\Big(c_-v(s)^2 - c_+\mathcal{T}^{2}u(s)^2\Big) \\ &\qquad + \mathcal{T}\mathcal{R}_v[\mathbf{z}](t) - c_3\partial_x \int_0^t \mathrm{d}s\ \mathrm{e}^{\partial_x^2(t-s)}\mathcal{T}\Big((\mathcal{T}u(s))(\mathcal{T}^{-1}v(s))\Big). \end{aligned} \tag{3.7}$$

Note that, but for the presence of the second lines in (3.6) and (3.7), these expressions are precisely Duhamel's formula for the solution of the model problem (1.7), written in terms of $u=\mathcal{T}^{-1}u_+$ and $v=\mathcal{T}u_-$. The next step is to write

$$u = u_\star + R_u^N = u_0 + u_1 + R_u^N \quad \text{and} \quad v = v_\star + R_v^N = v_0 + v_1 + R_v^N,$$

considering R_u^N and R_v^N as new "unknowns" and

$$\begin{aligned} u_0(x,t) &= \frac{1}{\sqrt{1+t}} g_0^+\left(\frac{x}{\sqrt{1+t}}\right), & u_1(x,t) &= \sum_{n=1}^N \frac{1}{(1+t)^{1-\frac{1}{2^{n+1}}}} d_n^+ g_n^+\left(\frac{x}{\sqrt{1+t}}\right), \\ v_0(x,t) &= \frac{1}{\sqrt{1+t}} g_0^-\left(\frac{x}{\sqrt{1+t}}\right), \quad \text{and} & v_1(x,t) &= \sum_{n=1}^N \frac{1}{(1+t)^{1-\frac{1}{2^{n+1}}}} d_n^- g_n^-\left(\frac{x}{\sqrt{1+t}}\right) \end{aligned} \tag{3.8}$$

for some coefficients $\{d_n^\pm\}_{n=1}^N$ and functions $\{g_n^\pm\}_{n=0}^N$ to be determined later.

We now use

$$\begin{aligned} u^2 &= (u-u_\star)(u+u_\star) + u_\star^2 = R_u^N(u+u_\star) + u_1^2 + 2u_0u_1 + u_0^2, \\ v^2 &= (v-v_\star)(v+v_\star) + v_\star^2 = R_v^N(v+v_\star) + v_1^2 + 2v_0v_1 + v_0^2, \\ (\mathcal{T}u)(\mathcal{T}^{-1}v) &= (\mathcal{T}R_u^N)\mathcal{T}^{-1}\Big(\frac{v+v_\star}{2}\Big) + (\mathcal{T}^{-1}R_v^N)\mathcal{T}\Big(\frac{u+u_\star}{2}\Big) + (\mathcal{T}u_\star)(\mathcal{T}^{-1}v_\star). \end{aligned}$$

Since

$$\begin{aligned} g_0^+(x) &= u_0(x,0), & u_1(x,0) &= \sum_{n=1}^N d_n^+ g_n^+(x), \\ g_0^-(x) &= v_0(x,0), \quad \text{and} & v_1(x,0) &= \sum_{n=1}^N d_n^- g_n^-(x), \end{aligned}$$

we find that R_u^N and R_v^N satisfy

$$
\begin{aligned}
R_u^N(t) &= \mathrm{e}^{\partial_x^2 t}(a_0+b_0-g_0^+) \\
&\quad + \left[\mathrm{e}^{\partial_x^2 t} u_0(0) + c_+\partial_x \int_0^t \mathrm{d}s\ \mathrm{e}^{\partial_x^2(t-s)} u_0(s)^2 \right] - u_0(t) \\
&\quad + \left[\mathrm{e}^{\partial_x^2 t} u_1(0) + 2c_+\partial_x \int_0^t \mathrm{d}s\ \mathrm{e}^{\partial_x^2(t-s)} u_0(s)u_1(s) \right] - u_1(t) \\
&\quad - c_-\left[\partial_x \int_0^t \mathrm{d}s\ \mathrm{e}^{\partial_x^2(t-s)} \mathcal{T}^{-2}\Big((v_0(s)^2 + 2v_0(s)v_1(s)) \Big) \right] - \sum_{n=1}^N \mathrm{e}^{\partial_x^2 t} d_n^+ g_n^+ \\
&\quad + \widetilde{\mathcal{R}}_u[\mathbf{z},\mathbf{R}^N](t) + \mathcal{T}^{-1}\mathcal{R}_u[\mathbf{z}](t),
\end{aligned} \tag{3.9}
$$

$$
\begin{aligned}
R_v^N(t) &= \mathrm{e}^{\partial_x^2 t}(a_0-b_0-g_0^-) \\
&\quad + \left[\mathrm{e}^{\partial_x^2 t} v_0(0) + c_-\partial_x \int_0^t \mathrm{d}s\ \mathrm{e}^{\partial_x^2(t-s)} v_0(s)^2 \right] - v_0(t) \\
&\quad + \left[\mathrm{e}^{\partial_x^2 t} v_1(0) + 2c_-\partial_x \int_0^t \mathrm{d}s\ \mathrm{e}^{\partial_x^2(t-s)} v_0(s)v_1(s) \right] - v_1(t) \\
&\quad - c_+\left[\partial_x \int_0^t \mathrm{d}s\ \mathrm{e}^{\partial_x^2(t-s)} \mathcal{T}^{2}\Big((u_0(s)^2 + 2u_0(s)u_1(s)) \Big) \right] - \sum_{n=1}^N \mathrm{e}^{\partial_x^2 t} d_n^- g_n^- \\
&\quad + \widetilde{\mathcal{R}}_v[\mathbf{z},\mathbf{R}^N](t) + \mathcal{T}\mathcal{R}_v[\mathbf{z}](t),
\end{aligned} \tag{3.10}
$$

where

$$
\begin{aligned}
\widetilde{\mathcal{R}}_u[\mathbf{z},\mathbf{R}^N](t) &= c_+\mathrm{E}_0[h_{1,u}+h_{3,u}](t) - c_-\mathrm{E}_{-2}[h_{1,v}+h_{3,v}](t) + c_3\mathrm{E}_{-1}[h_2+h_4](t), \\
\widetilde{\mathcal{R}}_v[\mathbf{z},\mathbf{R}^N](t) &= c_-\mathrm{E}_0[h_{1,v}+h_{3,v}](t) - c_+\mathrm{E}_2[h_{1,u}+h_{3,u}](t) - c_3\mathrm{E}_1[h_2+h_4](t),
\end{aligned}
$$

with $\mathbf{R}^N = (R_u^N, R_v^N)$, $h_{1,u} = R_u^N(u+u_\star)$, $h_{3,u} = u_1^2$, $h_{1,v} = R_v^N(v+v_\star)$, $h_{3,v} = v_1^2$, $h_4 = (\mathcal{T}u_\star)(\mathcal{T}^{-1}v_\star)$, and

$$
\begin{aligned}
h_2 &= (\mathcal{T}R_u^N)\mathcal{T}^{-1}\Big(\frac{v+v_\star}{2}\Big) + (\mathcal{T}^{-1}R_v^N)\mathcal{T}\Big(\frac{u+u_\star}{2}\Big), \\
\mathrm{E}_\sigma[h](t) &= \partial_x \int_0^t \mathrm{d}s\ \mathrm{e}^{\partial_x^2(t-s)}\ \mathcal{T}^\sigma h(s).
\end{aligned}
$$

Note that we can write (3.9) and (3.10) as $\mathbf{R}^N = \mathcal{F}[\mathbf{z},\mathbf{R}^N]$. If we now consider $\mathbf{z}$ fixed, we can interpret $\mathbf{R}^N = \mathcal{F}[\mathbf{z},\mathbf{R}^N]$ as an equation for $\mathbf{R}^N$ which can be solved via a contraction-mapping argument. Namely, we will prove that, if $\|\mathbf{z}\| \le C\epsilon_0$, $\mathbf{R}^N \mapsto \mathcal{F}[\mathbf{z},\mathbf{R}^N]$ defines a contraction map inside the ball

$$
\|R_u^N\|_{2,\frac{3}{4}-\epsilon} + \|\mathrm{D}R_u^N\|_{2,\frac{5}{4}-\epsilon} + \|R_v^N\|_{2,\frac{3}{4}-\epsilon} + \|\mathrm{D}R_v^N\|_{2,\frac{5}{4}-\epsilon} \le C \tag{3.11}
$$

for $\epsilon = 2^{-N-2}$, provided $\{g_n^\pm\}_{n=0}^N$ and $\{d_n^\pm\}_{n=1}^N$ are appropriately chosen.

Basically, we will choose u_0, v_0, u_1, and v_1 in such a way that the second and third lines of (3.9) and (3.10) vanish. Note that if, for instance, we set the second (respectively, third) lines of (3.9) and (3.10) equal to zero, the resulting equalities are nothing but Duhamel's formulas for Burger's equations for u_0 and v_0 (respectively, for linearized Burger's equations for u_1 and v_1). Properties of solutions to these types of equations are studied in detail in section 4 below.

Once u_0, v_0, u_1, and v_1 are fixed, the time convolutions in the fourth lines of (3.9) and (3.10) can then be viewed as the solution of inhomogeneous heat equations with very specific inhomogeneous terms. Properties of solutions to this type of equation are studied in detail in section 5 below.

Assuming all results of sections 4 and 5, we now explain how to proceed to prove that $\mathcal{F}[\mathbf{z}, \mathbf{R}^N]$ defines a contraction map.

Obviously, the requirement on $\{g_n^\pm\}_{n=0}^N$ and $\{d_n^\pm\}_{n=1}^N$ is that the first four lines in (3.9) and (3.10) satisfy (3.11). This is achieved in the following way:

1. The first line of (3.9) (respectively, of (3.10)) satisfies (3.11) for any $g_0^\pm$ such that the total mass of $g_0^\pm$ is equal to that of $a_0 \pm b_0$, provided $a_0 \pm b_0$ and $g_0^\pm$ satisfy $\| x^2(a_0 \pm b_0)\|_2 < \infty$ and $\| x^2 g_0^\pm\|_2 < \infty$. This fixes the total mass of $g_0^\pm$. Note also that we need the estimate $\| x^2(a_0 \pm b_0)\|_2 < \infty$. There is no smallness assumption here, which is to be expected since generically $\| x^2(a(\cdot,t) \pm b(\cdot,t))\|_2$ will grow as $t \to \infty$. Note, on the other hand, that Proposition 7 shows that $\| x^2(a(\cdot,t) \pm b(\cdot,t))\|_2$ remains finite for all $t < \infty$, so requiring $\| x^2(a_0 \pm b_0)\|_2 < \infty$ is acceptable.
2. We can set the second lines in (3.9) and (3.10) equal to zero by picking for u_0 and v_0 any solution of Burger's equations
$$\partial_t u_0 = \partial_x^2 u_0 + c_+ \partial_x (u_0)^2 \quad \text{and} \quad \partial_t v_0 = \partial_x^2 v_0 + c_- \partial_x (v_0)^2$$
(or of the corresponding heat equations if either c_+ or c_- happen to be zero). In Proposition 12, we will prove that there exist unique functions u_0 and v_0 of the form given in (3.8) that satisfy the conditions of item 1 above (total mass and decay properties). This uniquely determines u_0 and v_0.
3. We can also set the third lines in (3.9) and (3.10) equal to zero, by picking any solutions u_1 and v_1 of linearized Burger's equations
$$\partial_t u_1 = \partial_x^2 u_1 + 2c_+ \partial_x (u_0 u_1) \quad \text{and} \quad \partial_t v_1 = \partial_x^2 v_1 + 2c_- \partial_x (v_0 v_1). \tag{3.12}$$
In Proposition 12, we will also prove that there is a choice of functions $\{g_n^\pm\}_{n=1}^N$ such that u_1 and v_1 in (3.8) satisfy (3.12) for any choice of the coefficients $\{d_n^\pm\}_{n=1}^N$. Furthermore, in Proposition 12, we will prove that the choice of functions can be made in such a way that $g_n^\pm(x)$ have Gaussian tails as $x \to \mp\infty$ and algebraic tails as $x \to \pm\infty$. This actually completely determines $g_n^\pm(x)$ up to multiplicative constants (this last indeterminacy will be removed when the coefficients $\{d_n^\pm\}_{n=1}^N$ are fixed).
4. We then further decompose the terms involving $g_n^\pm$ in the fourth lines in (3.9) and (3.10) as $g_n^\pm(x) = f_n(\mp x) + R_n^\pm(x)$. The definition and properties of $f_n(x)$ are given in Lemma 10. In particular, in Proposition 12, we will prove that $R_n^\pm(x)$ have zero total mass and Gaussian tails as $|x| \to \infty$, which implies that $\mathrm{e}^{\partial_x^2 t} R_n^\pm$ also satisfy (3.11).
5. Finally, in section 5, we will prove that the time convolution part of the fourth lines in (3.9) and (3.10) can be split into linear combinations of $\mathrm{e}^{\partial_x^2 t} f_n(\mp x)$, with $n = 1 \dots N+1$ plus a remainder that satisfies (3.11). The coefficients $\{d_n^\pm\}_{n=1}^N$ can then be set recursively by requiring that all of the terms with $n = 1 \dots N$ coming from the time convolution are canceled by those coming from item 4 above. This can always be done because the coefficient of $\mathrm{e}^{\partial_x^2 t} f_m(\mp x)$ in the time convolution part of the fourth lines in (3.9) and (3.10) depends only on $g_0^\pm$ if $m = 1$ and on $d_{m-1}^\pm$ if $m > 1$. The only term that cannot be set

to zero is the last term in the linear combination (the one with $n = N+1$), which is the one that "drives" the equations and fixes $\epsilon = 2^{-N-2}$.

The procedure outlined in 1–5 takes care of the first four lines in (3.9) and (3.10). We will then prove in section 7 that the terms $\mathcal{R}_{\{u,v\}}[\mathbf{z}]$ satisfy (3.11) and that

$$\sum_{\alpha=0}^{1} \|\mathrm{D}^\alpha \widetilde{\mathcal{R}}_{\{u,v\}}[\mathbf{z}, \mathbf{R}^N]\|_{2,\frac{3}{4}+\frac{\alpha}{2}-\epsilon} \le C\epsilon_0 \sum_{\alpha=0}^{1} \|\mathrm{D}^\alpha \mathbf{R}^N\|_{2,\frac{3}{4}+\frac{\alpha}{2}-\epsilon} + C, \tag{3.13}$$

$$\sum_{\alpha=0}^{1} \|\mathrm{D}^\alpha (\Delta\widetilde{\mathcal{R}}_{\{u,v\}})\|_{2,\frac{3}{4}+\frac{\alpha}{2}-\epsilon} \le C\epsilon_0 \sum_{\alpha=0}^{1} \|\mathrm{D}^\alpha (\Delta\mathbf{R}^N)\|_{2,\frac{3}{4}+\frac{\alpha}{2}-\epsilon}, \tag{3.14}$$

where $\Delta\widetilde{\mathcal{R}}_{\{u,v\}} = \widetilde{\mathcal{R}}_{\{u,v\}}[\mathbf{z}, \mathbf{R}_1^N] - \widetilde{\mathcal{R}}_{\{u,v\}}[\mathbf{z}, \mathbf{R}_2^N]$ and $\Delta\mathbf{R} = \mathbf{R}_1^N - \mathbf{R}_2^N$. This finally proves that $\mathcal{F}[\mathbf{z}, \mathbf{R}^N]$ defines a contraction map and that the solution of $\mathbf{R}^N = \mathcal{F}[\mathbf{z}, \mathbf{R}^N]$ satisfies (3.11), which completes the proof of Theorems 2 and 8. ∎

4. Burger-type equations. In this section, we consider particular solutions of Burger-type equations

$$\partial_t u_0 = \partial_x^2 u_0 + \gamma \partial_x u_0^2, \tag{4.1}$$

$$\partial_t u_n^\pm = \partial_x^2 u_n^\pm + 2\gamma \partial_x (u_0 u_n^\pm) \tag{4.2}$$

of the form

$$u_0(x,t) = \frac{1}{\sqrt{1+t}} g_0\left(\frac{x}{\sqrt{1+t}}\right) \quad \text{and} \quad u_n^\pm(x,t) = \frac{1}{(1+t)^{1-\frac{1}{2^{n+1}}}} g_n^\pm\left(\frac{x}{\sqrt{1+t}}\right). \tag{4.3}$$

We will show that for fixed $\mathrm{M}(u_0) = \int_{-\infty}^{\infty} \mathrm{d}x\ u_0(x,t) = \int_{-\infty}^{\infty} \mathrm{d}x\ g_0(x)$ small enough, there is a unique choice of g_0 and $g_n^\pm$ such that $g_n^\pm(x) = f_n(\mp x) + R_n^\pm(x)$, where

$$f_n(z) = \int_z^\infty \mathrm{d}\xi\ \frac{\xi \mathrm{e}^{-\frac{\xi^2}{4}}}{(\xi - z)^{1-\frac{1}{2^n}}} \tag{4.4}$$

and $R_n^\pm$ has zero mean and Gaussian tails as $|x| \to \infty$. In particular, $g_n^\pm(x)$ decays algebraically as $x \to \pm\infty$, as is apparent from (4.4).

Before proceeding to our study of (4.1) and (4.2), we prove key properties of the functions f_n.

LEMMA 10. *Fix $1 \le n < \infty$. The function f_n is the unique solution of*

$$\begin{aligned} &\partial_z^2 f_n(z) + \frac{1}{2} z \partial_z f_n(z) + \left(1 - \frac{1}{2^{n+1}}\right) f_n(z) = 0, \qquad \textit{with} \\ &f_n(0) = 2^{\frac{1}{2^n}} \Gamma\left(\frac{1+2^{-n}}{2}\right) \qquad \textit{and} \qquad \lim_{z\to\infty} z^{-1+\frac{1}{2^n}} \mathrm{e}^{\frac{z^2}{4}} f_n(z) < \infty. \end{aligned} \tag{4.5}$$

It satisfies $\int_{-\infty}^{\infty} \mathrm{d}z\ f_n(z) = 0$, and there exists a constant $C(n)$ such that

$$\begin{aligned} &\sup_{z\in\mathbf{R}} \sum_{m=0}^{2} \rho_{\frac{1}{2^n}-m, 1+m-\frac{1}{2^n}}(z) \left|\partial_z^m\Big(z f_n(z) + 2\partial_z f_n(z)\Big)\right| \le C(n), \\ &\qquad\qquad \sup_{z\in\mathbf{R}} \sum_{m=0}^{3} \rho_{\frac{1}{2^n}-1-m, 2+m-\frac{1}{2^n}}(z) |\partial_z^m f_n(z)| \le C(n), \end{aligned} \tag{4.6}$$

where

$$\rho_{p,q}(z) = \begin{cases} (1+z^2)^{\frac{p}{2}} \mathrm{e}^{\frac{z^2}{4}} & \text{if } z \geq 0, \\ (1+z^2)^{\frac{q}{2}} & \text{if } z \leq 0. \end{cases}$$

Proof. We first note that f_n can be written as

$$f_n(z) = \int_0^\infty \mathrm{d}\xi \; \frac{(\xi+z)\mathrm{e}^{-\frac{(\xi+z)^2}{4}}}{\xi^{1-\frac{1}{2^n}}} = -2 \int_0^\infty \mathrm{d}\xi \; \xi^{\frac{1}{2^n}-1} \partial_\xi \Big(\mathrm{e}^{-\frac{(z+\xi)^2}{4}} \Big). \tag{4.7}$$

This shows that f_n solves (4.5) since, by defining $\mathcal{L}f \equiv \partial_z^2 f + \frac{1}{2} z \partial_z f + (1 - \frac{1}{2^{n+1}}) f$, we find

$$\mathcal{L}f_n(z) = \int_0^\infty \mathrm{d}\xi \; \Big[\xi^{\frac{1}{2^n}} \partial_\xi^2 \Big(\mathrm{e}^{-\frac{(z+\xi)^2}{4}} \Big) - \frac{1}{2^{n+1}} (-2) \xi^{\frac{1}{2^n}-1} \partial_\xi \Big(\mathrm{e}^{-\frac{(z+\xi)^2}{4}} \Big) \Big] = 0.$$

Obviously, $f_n(z)$ is finite for all finite z, so we need only to prove that f_n satisfies the correct decay properties as $|z| \to \infty$ so that (4.6) holds. It is apparent from (4.4) that f_n decays like a (modified) Gaussian as $z \to \infty$ and algebraically as $z \to -\infty$. Furthermore, substituting $f(z) = C|z|^{p_1}$ and $f(z) = C|z|^{p_2} \mathrm{e}^{-\frac{z^2}{4}}$ into $\mathcal{L}f = 0$ shows that the only decay rates compatible with $\mathcal{L}f = 0$ are $p_1 = -2 + \frac{1}{2^n}$ and $p_2 = 1 - \frac{1}{2^n}$.

We now complete the proof of the decay estimates (4.6). Let $F_{n,m}(\xi, z) = \partial_z^m ((\xi + z)\mathrm{e}^{-\frac{(\xi+z)^2}{4}})$ and $G_{n,m}(\xi, z) = \partial_z^m (z F_n(\xi, z) + 2 \partial_z F_n(\xi, z))$.

We first consider the case $z > 0$ and note that $F_{n,m}$ and $G_{n,m}$ satisfy

$$|F_{n,m}(\xi, z)| \leq |F_{n,m}(0, z)| \quad \text{and} \quad |G_{n,m}(\xi, z)| \leq |G_{n,m}(0, z)|,$$

respectively, for all $\xi \geq 0$ if $z \geq z_0$ for some z_0 large enough. We thus get, e.g.,

$$\begin{aligned} |f_n(z)| &= \Big| \int_0^\infty \mathrm{d}\xi \; F_{n,0}(\xi, z) \xi^{\frac{1}{2^n}-1} \Big| \\ &\leq |F_{n,0}(0, z)| \int_0^{z^{-1}} \mathrm{d}\xi \; \xi^{\frac{1}{2^n}-1} + z^{1-\frac{1}{2^n}} \int_{z^{-1}}^\infty \mathrm{d}\xi \; |F_{n,0}(\xi, z)| \leq C z^{1-\frac{1}{2^n}} \mathrm{e}^{-\frac{z^2}{4}}. \end{aligned}$$

The estimates on $|\partial_z^m (z f_n(z) + 2\partial_z f_n(z))|$ and $|\partial_z^{1+m} f_n(z)|$ when $z > 0$ and $m \geq 1$ can be done in exactly the same way; hence we omit the details.

We now consider the case $z < 0$ and note that $F_{n,m}$ and $G_{n,m}$ satisfy

$$|F_{n,m}(\xi, z)| \leq \Big| F_{n,m}\Big(-\frac{z}{2}, z\Big) \Big| \quad \text{and} \quad |G_{n,m}(\xi, z)| \leq \Big| G_{n,m}\Big(-\frac{z}{2}, z\Big) \Big|,$$

respectively, for all $0 \leq \xi \leq -\frac{z}{2}$ if $z \leq -z_0$ for some z_0 large enough. We thus find (integrating by parts in the second integral below)

$$\begin{aligned} |f_n(z)| &= \Big| \int_0^\infty \mathrm{d}\xi \; F_{n,0}(\xi, z) \xi^{\frac{1}{2^n}-1} \Big| \\ &\leq \Big| F_{n,0}\Big(-\frac{z}{2}, z\Big) \Big| \int_0^{-\frac{z}{2}} \mathrm{d}\xi \; \xi^{\frac{1}{2^n}-1} + \Big| \int_{-\frac{z}{2}}^\infty \mathrm{d}\xi \; F_{n,0}(\xi, z) \xi^{\frac{1}{2^n}-1} \Big| \\ &\leq C|z|^{\frac{1}{2^n}-1} \mathrm{e}^{-\frac{z^2}{16}} + 2\Big(1 - \frac{1}{2^n}\Big) \int_{-\frac{z}{2}}^\infty \mathrm{d}\xi \; \mathrm{e}^{-\frac{(\xi+z)^2}{4}} \xi^{\frac{1}{2^n}-2} \leq C|z|^{\frac{1}{2^n}-2}. \end{aligned}$$

Since the remaining estimates can again be done in exactly the same way, we omit the details. It remains only to show that $f_n(z)$ has zero total mass. This follows from

$$\int_{-\infty}^{\infty} \mathrm{d}z\ f_n(z) = \left(\frac{1}{2} - \frac{1}{2^{n+1}}\right)^{-1} \int_{-\infty}^{\infty} \mathrm{d}z\ \mathcal{L} f_n(z) = 0,$$

since $\partial_z^2 f_n, z\partial_z f_n$ and f_n are all integrable over $\mathbf{R}$. ∎

Remark 11. By using the representation (4.7), splitting the integration interval into $[0, 2^{-\frac{n}{2}})$ and $[2^{-\frac{n}{2}}, \infty)$, integrating by parts, and letting $n \to \infty$, one can prove that

$$\lim_{n\to\infty} 2^{-n} f_n(z) = z\mathrm{e}^{-\frac{z^2}{4}},$$

which shows that the constant $C(n)$ in (4.6) grows at most like 2^n.

We can now study in detail the solutions of (4.1) and (4.2) that are of the form (4.3).

PROPOSITION 12. *Fix $1 \le n < \infty$. For all $\alpha, \gamma \in \mathbf{R}$ with $|\alpha\gamma|$ small enough, there exist unique functions u_0 and $u_n^{\pm}$ of the form* (4.3) *that solve* (4.1) *and* (4.2), *with g_0 satisfying*

$$\int_{-\infty}^{\infty} \mathrm{d}z\ g_0(z) = \alpha, \qquad \sum_{m=0}^{3} \frac{\mathrm{e}^{\frac{z^2}{4}}}{(\sqrt{1+z^2})^m} |\partial_z^m g_0(z)| \le C|\alpha|$$

and with $g_n^{\pm}(z) = f_n(\mp z) + R_n^{\pm}(z)$, where $R_n^{\pm}$ satisfy

$$\int_{-\infty}^{\infty} \mathrm{d}z\ R_n^{\pm}(z) = 0 \quad \textit{and} \quad \sup_{z\in\mathbf{R}} \sum_{m=0}^{3} \frac{\mathrm{e}^{\frac{z^2}{4}}}{(\sqrt{1+z^2})^{1+m-\frac{1}{2^n}}} |\partial_z^m R_n^{\pm}(z)| \le C|\alpha\gamma|.$$

Proof. The (unique) solution of (4.1) of the form $u_0(x,t) = \frac{1}{\sqrt{1+t}} g_0(\frac{x}{\sqrt{1+t}})$ satisfying $\int_{-\infty}^{\infty} \mathrm{d}z\ g_0(z) = \alpha$ is given by

$$g_0(z) = \frac{\tanh(\frac{\alpha\gamma}{2})\mathrm{e}^{-\frac{z^2}{4}}}{\gamma\sqrt{\pi}(1 + \tanh(\frac{\alpha\gamma}{2})\mathrm{erf}(\frac{z}{2}))}.$$

In particular, we have

$$\sum_{m=0}^{3} \frac{\mathrm{e}^{\frac{z^2}{4}}}{(\sqrt{1+z^2})^m} |\partial_z^m g_0(z)| \le C|\alpha|. \tag{4.8}$$

We next note that substituting (4.3) into (4.2) gives

$$\begin{aligned} 0 &= \partial_z^2 g_n^{\pm}(z) + \frac{1}{2} z\partial_z g_n^{\pm}(z) + \left(1 - \frac{1}{2^{n+1}}\right) g_n^{\pm}(z) + 2\gamma\partial_z(g_0(z) g_n^{\pm}(z)) \\ &\equiv \mathcal{L} g_n^{\pm}(z) + 2\gamma\partial_z(u_0(z) g_n^{\pm}(z)). \end{aligned} \tag{4.9}$$

We formally have (using integration by parts)

$$\int_{-\infty}^{\infty} \mathrm{d}z\ g_n^{\pm}(z) = \left(\frac{1}{2} - \frac{1}{2^{n+1}}\right)^{-1} \int_{-\infty}^{\infty} \mathrm{d}z\ \mathcal{L} g_n^{\pm}(z) + 2\gamma\partial_z(u_0(z) g_n^{\pm}(z)) = 0, \tag{4.10}$$

which shows that $g_n^\pm$ have zero total mass, *provided the formal manipulations above are justified*, i.e., provided $g_n^\pm$ and its derivatives decay fast enough so that the integrals are convergent.

As is easily seen, $f_n(z)$ and $f_n(-z)$ are two linearly independent solutions of $\mathcal{L}f = 0$, whose general solution can thus be written as $c_1 f_n(z) + c_2 f_n(-z)$. By using the variation of constants formula, we get that the solution of (4.9) satisfies the integral equation

$$g_n^\pm(z) = f_n(z)\biggl(c_1^\pm + 2\gamma \int_0^z \mathrm{d}\xi \; \frac{f_n(-\xi)\partial_\xi(g_0(\xi)g_n^\pm(\xi))}{W(\xi)}\biggr) + f_n(-z)\biggl(c_2^\pm - 2\gamma \int_0^z \mathrm{d}\xi \; \frac{f_n(\xi)\partial_\xi(g_0(\xi)g_n^\pm(\xi))}{W(\xi)}\biggr),$$

where the Wronskian $W(z)$ is given by $W(z) = f_n(z)\partial_z f_n(-z) - f_n(-z)\partial_z f_n(z)$ and $c_1^\pm$ and $c_2^\pm$ are free parameters. Note that $W(z)$ satisfies $\partial_z W(z) = -\frac{z}{2}W(z)$ and hence $W(z) = W(0)\mathrm{e}^{-\frac{z^2}{4}}$ for some $W(0) \neq 0$. We now set $c_1^\pm$ and $c_2^\pm$ in such a way that (after integration by parts) we have

$$\begin{aligned} g_n^\pm(z) &= f_n(\mp z) + R[g_n^\pm](z), \\ R[g_n^\pm](z) &= \frac{\gamma}{W(0)} f_n(z) \int_{-\infty}^z \mathrm{d}\xi \; \mathrm{e}^{\frac{\xi^2}{4}}(\xi f_n(-\xi) + 2\partial_\xi f_n(-\xi))g_0(\xi)g_n^\pm(\xi) \\ &\quad + \frac{\gamma}{W(0)} f_n(-z) \int_z^\infty \mathrm{d}\xi \; \mathrm{e}^{\frac{\xi^2}{4}}(\xi f_n(\xi) + 2\partial_\xi f_n(\xi))g_0(\xi)g_n^\pm(\xi). \end{aligned} \tag{4.11}$$

By using Lemma 10 and (4.8), it is then easy to show that, for $|\alpha\gamma|$ small enough, (4.11) defines a contraction map in the norm

$$|f|_{2-\frac{1}{2^n}} \equiv \sup_{z\in\mathbf{R}} (\sqrt{1+z^2})^{2-\frac{1}{2^n}} |f(z)|.$$

Namely, we have the improved decay rates

$$\sup_{z\in\mathbf{R}} \sum_{m=0}^{1} \frac{\mathrm{e}^{\frac{z^2}{4}}}{(\sqrt{1+z^2})^{1+m-\frac{1}{2^n}}} |\partial_z^m R[g_n^\pm](z)| \leq C|\alpha\gamma| \; |g_n^\pm|_{2-\frac{1}{2^n}}.$$

This shows that (4.11) has a (locally) unique solution among functions with $|f|_{2-\frac{1}{2^n}} \leq c_0$ if $|\alpha\gamma|$ is small enough. In particular, there holds

$$\sup_{z\in\mathbf{R}} \sum_{m=0}^{1} \frac{\mathrm{e}^{\frac{z^2}{4}}}{(\sqrt{1+z^2})^{1+m-\frac{1}{2^n}}} |\partial_z^m R[g_n^\pm](z)| \leq C|\alpha\gamma|,$$

from which we deduce, by using again (4.11) and Lemma 10, that $|\mathrm{D}g_n^\pm|_{3-\frac{1}{2^n}} \leq c_1$ and thus

$$\sup_{z\in\mathbf{R}} \frac{\mathrm{e}^{\frac{z^2}{4}}}{(\sqrt{1+z^2})^{3-\frac{1}{2^n}}} |\partial_z^2 R[g_n^\pm](z)| \leq C|\alpha\gamma|.$$

Iterating this procedure shows that $|\mathrm{D}^m g_n^\pm|_{2+m-\frac{1}{2^n}} \leq c_m$ and that

$$\sup_{z\in\mathbf{R}} \sum_{m=0}^{3} \frac{\mathrm{e}^{\frac{z^2}{4}}}{(\sqrt{1+z^2})^{1+m-\frac{1}{2^n}}} |\partial_z^m R[g_n^\pm](z)| \leq C|\alpha\gamma|$$

as claimed. In turn, this proves that the formal manipulations in (4.10) are justified, so that the functions $g_n^{\pm}(z)$ have zero total mass, which shows that the remainders $R[g_n^{\pm}](z)$ have zero total mass as claimed, since $R[g_n^{\pm}](z) = g_n^{\pm}(z) - f_n(\pm z)$ and since both $g_n^{\pm}(z)$ and $f_n(z)$ have zero total mass. $\square$

5. Inhomogeneous heat equations. In this section, we consider solutions of inhomogeneous heat equations of the form

$$\partial_t u = \partial_x^2 u + \partial_x \left((1+t)^{\frac{1}{2^n} - \frac{3}{2}} f\left(\frac{x - 2\sigma t}{\sqrt{1+t}} \right) \right), \qquad u(x,0) = 0, \tag{5.1}$$

where f is a regular function having Gaussian decay at infinity. Solutions of (5.1) satisfy the following theorem.

THEOREM 13. *Let* $1 \leq n < \infty$, $\sigma = \pm 1$, $\Xi(x) = \mathrm{e}^{\frac{x^2}{8}}$, $\mathrm{M}(f) = \int_{-\infty}^{\infty} \mathrm{d}z\ f(z)$, *and*

$$u_n(x,t) = \frac{\sigma}{(1+t)^{1 - \frac{1}{2^{n+1}}}} \frac{2^{-1-\frac{1}{2^n}}}{\sqrt{4\pi}} f_n\left(\frac{-\sigma x}{\sqrt{1+t}} \right), \quad \textit{with} \quad f_n(z) = \int_z^{\infty} \mathrm{d}\xi\ \frac{\xi \mathrm{e}^{-\frac{\xi^2}{4}}}{(\xi - z)^{1 - \frac{1}{2^n}}}. \tag{5.2}$$

The solution u *of* (5.1) *satisfies*

$$\|u - \mathrm{M}(f)\, u_n\|_{2,\frac{3}{4}^\star} + \|\mathrm{D}(u - \mathrm{M}(f)\, u_n)\|_{2,\frac{5}{4}^\star} \leq C \sum_{m=0}^{2} \|\Xi \mathrm{D}^m f\|_\infty \tag{5.3}$$

for all f *such that the r.h.s. of* (5.3) *is finite.*

Remark 14. Note that, while $u \to \mathrm{M}(f) u_n$ as $t \to \infty$ in the Sobolev norm (5.3), it does not do so in spatially weighted norms such as $\mathrm{L}^2(\mathbf{R}, x^2 \mathrm{d}x)$, as u_n has infinite spatial moments for all times, while all moments of u are bounded for finite time.

Proof. We first define

$$F(\xi) = \int_{-\infty}^{\xi} \mathrm{d}z \left(f(z) - \mathrm{M}(f)\, \frac{\mathrm{e}^{-\frac{z^2}{4}}}{\sqrt{4\pi}} \right), \qquad \text{with} \qquad \mathrm{M}(f) = \int_{-\infty}^{\infty} \mathrm{d}z\ f(z), \tag{5.4}$$

and note that F satisfies

$$\|\mathrm{D}^3 F\|_1 + \sum_{m=0}^{2} \|\rho \mathrm{D}^m F\|_1 + \sum_{m=1}^{2} \|\mathrm{D}^m F\|_2 \leq C \sum_{m=0}^{2} \|\Xi \mathrm{D}^m f\|_\infty, \tag{5.5}$$

where $\rho(x) = \sqrt{1+x^2}$. Namely, we first note that $\|\rho F\|_1 \leq \|\hat{F}\|_2 + \|\hat{F}''\|_2$ and $\hat{F}(k) = (ik)^{-1}(\hat{f}(k) - \hat{f}(0)\mathrm{e}^{-k^2})$. Then, since $\|\Xi f\|_\infty < \infty$ implies that $\hat{f}$ is analytic, $\hat{F}$ is regular near $k = 0$. The proof of (5.5) now follows from elementary arguments.

We finally note that it follows from (5.4) that

$$\begin{aligned} (1+t)^{\frac{1}{2^n} - \frac{3}{2}} f\left(\frac{x - 2\sigma t}{\sqrt{1+t}} \right) &= \mathrm{M}(f) A(x,t) + \partial_x B(x,t), \qquad \text{where} \\ A(x,t) &= \frac{(1+t)^{\frac{1}{2^n} - \frac{3}{2}}}{\sqrt{4\pi}} \mathrm{e}^{-\frac{(x - 2\sigma t)^2}{4(1+t)}}, \\ B(x,t) &= (1+t)^{\frac{1}{2^n} - 1} \partial_x F\left(\frac{x - 2\sigma t}{\sqrt{1+t}} \right). \end{aligned} \tag{5.6}$$

The proof of (5.3) is then completed by considering separately the solutions of heat equations with inhomogeneous terms given by $\partial_x A(x,t)$ and $\partial_x^2 B(x,t)$. This is done in Propositions 15 and 16 below. ∎

PROPOSITION 15. *Let $\sigma = \pm 1$, $1 \le n < \infty$, and let u_n be defined as in* (5.2). *The solution u of*

$$\partial_t u = \partial_x^2 u + \partial_x A, \qquad u(x,0) = 0, \tag{5.7}$$

with A defined in (5.6), *satisfies*

$$\|u - u_n\|_{2,\frac{3}{4}} + \|\mathrm{D}(u - u_n)\|_{2,\frac{5}{4}} \le C. \tag{5.8}$$

Proof. The solution of (5.7) is given by

$$u(x,t) = \partial_x \int_0^t \mathrm{d}s \int_{-\infty}^{\infty} \mathrm{d}y \frac{\mathrm{e}^{-\frac{(x-y)^2}{4(t-s)}}}{\sqrt{4\pi(t-s)}} \frac{\mathrm{e}^{-\frac{(y-2\sigma s)^2}{4(1+s)}}}{\sqrt{4\pi}(1+s)^{\frac{3}{2}-\frac{1}{2^n}}}. \tag{5.9}$$

To motivate our result, we note that performing the y-integration and changing variables from s to $\xi \equiv \frac{2s - \sigma x}{\sqrt{1+t}}$ in (5.9) leads to

$$\begin{aligned}\lim_{t\to\infty}(1+t)^{1-\frac{1}{2^{n+1}}} u(-\sigma z\sqrt{1+t}, t) &= \lim_{t\to\infty} \frac{\sigma 2^{-1-\frac{1}{2^n}}}{\sqrt{4\pi}} \int_z^{\frac{2t}{\sqrt{1+t}}+z} \mathrm{d}\xi \; \frac{\xi \mathrm{e}^{-\frac{\xi^2}{4}}}{(\xi - z + \frac{2}{\sqrt{1+t}})^{1-\frac{1}{2^n}}} \\ &= \frac{\sigma 2^{-1-\frac{1}{2^n}}}{\sqrt{4\pi}} f_n(z).\end{aligned}$$

More formally, taking the Fourier transform of (5.9) gives

$$\hat{u}(k,t) = ik\mathrm{e}^{-k^2(1+t)} \int_0^t \mathrm{d}s \; \frac{\mathrm{e}^{2ik\sigma s}}{(1+s)^{1-\frac{1}{2^n}}}.$$

We now use that

$$\begin{aligned}\left| \int_0^t \mathrm{d}s \; \frac{\mathrm{e}^{2ik\sigma s}}{(1+s)^{1-\frac{1}{2^n}}} - \int_0^t \mathrm{d}s \; \frac{\mathrm{e}^{2ik\sigma s}}{s^{1-\frac{1}{2^n}}} \right| &\le C(n), \\ \int_0^t \mathrm{d}s \; \frac{\mathrm{e}^{2ik\sigma s}}{s^{1-\frac{1}{2^n}}} &= |k|^{-\frac{1}{2^n}} \Big(\theta(\sigma k) J_n(|k|t) + \theta(-\sigma k) \overline{J_n(|k|t)} \Big),\end{aligned}$$

where $\theta(k)$ is the Heaviside step function and we defined

$$J_n(z) = \int_0^z \mathrm{d}s \; \frac{\mathrm{e}^{2is}}{s^{1-\frac{1}{2^n}}}$$

for $z \ge 0$. This function satisfies

$$\sup_{z\ge 0} z^{1-\frac{1}{2^n}} |J_n(z) - J_{n,\infty}| \le \frac{1}{2} \quad \text{for} \quad J_{n,\infty} = \lim_{z\to\infty} J_n(z).$$

Now define

$$\widehat{u_n}(k,t) = ik\mathrm{e}^{-k^2(1+t)} |k|^{-\frac{1}{2^n}} \Big(\theta(\sigma k) J_{n,\infty} + \theta(-\sigma k) \overline{J_{n,\infty}} \Big). \tag{5.10}$$

We have

$$|\hat{u}(k,t) - \widehat{u_n}(k,t)| \le (C(n)|k| + t^{-1+\frac{1}{2^n}})\mathrm{e}^{-k^2(1+t)} \le \frac{\tilde{C}(n)}{\sqrt{t}}\mathrm{e}^{-\frac{k^2(1+t)}{2}}, \tag{5.11}$$

from which (5.8) follows by direct integration. We complete the proof by showing that the inverse Fourier transform of the function $\widehat{u_n}(k,t)$ defined in (5.10) satisfies

$$u_n(x,t) = \frac{\sigma}{(1+t)^{1-\frac{1}{2^{n+1}}}} \frac{2^{-1-\frac{1}{2^n}}}{\sqrt{4\pi}} f_n\left(\frac{-\sigma x}{\sqrt{1+t}}\right) \quad \text{for} \quad f_n(z) = \int_z^\infty \mathrm{d}\xi\; \frac{\xi \mathrm{e}^{-\frac{\xi^2}{4}}}{(\xi - z)^{1-\frac{1}{2^n}}}. \tag{5.12}$$

This follows easily from the fact that

$$\widehat{u_n}(k,t) = (1+t)^{-\frac{1}{2}+\frac{1}{2^{n+1}}} \widehat{u_n}(k\sqrt{1+t}, 0)$$

and that, since

$$f_n(z) = \int_0^\infty \mathrm{d}\xi\; \frac{(z+\xi)\mathrm{e}^{-\frac{(z+\xi)^2}{4}}}{\xi^{1-\frac{1}{2^n}}},$$

we get

$$\begin{aligned}\frac{\sigma 2^{-1-\frac{1}{2^n}}}{\sqrt{4\pi}} \widehat{f_n}(-\sigma k) &= 2^{-\frac{1}{2^n}} ik\mathrm{e}^{-k^2} \int_0^\infty \mathrm{d}\xi\; \frac{\mathrm{e}^{ik\sigma\xi}}{\xi^{1-\frac{1}{2^n}}} = ik\mathrm{e}^{-k^2}|k|^{-\frac{1}{2^n}} \int_0^\infty \mathrm{d}\xi\; \frac{\mathrm{e}^{2i\mathrm{sign}(k\sigma)\xi}}{\xi^{1-\frac{1}{2^n}}} \\ &= ik\mathrm{e}^{-k^2}|k|^{-\frac{1}{2^n}}\Big(\theta(k\sigma)J_{n,\infty} + \theta(-k\sigma)\overline{J_{n,\infty}}\Big) = \widehat{u_n}(k,0)\end{aligned}$$

as claimed. ◻

Proposition 16. *Let $\sigma = \pm 1$, $1 \le n < \infty$, and $\rho(x) = \sqrt{1+x^2}$. The solution u of*

$$\partial_t u = \partial_x^2 u + \partial_x^2 B, \qquad u(x,0) = 0, \tag{5.13}$$

with B defined in (5.6), *satisfies*

$$\|u\|_{2,\frac{3}{4}\star} + \|\mathrm{D}u\|_{2,\frac{5}{4}\star} \le C \left(\|\mathrm{D}^3 F\|_1 + \sum_{m=0}^{2} \|\rho \mathrm{D}^m F\|_1 + \sum_{m=1}^{2} \|\mathrm{D}^m F\|_2\right) \tag{5.14}$$

for all F for which the r.h.s. of (5.14) *is finite.*

Proof. We first note that the Fourier transform of u is given by

$$\hat{u}(k,t) = -k^2 \int_0^t \mathrm{d}s\; \mathrm{e}^{-k^2(t-s)-2ik\sigma s} \hat{F}(k\sqrt{1+s})(1+s)^{\frac{1}{2^n}-\frac{1}{2}},$$

which implies that

$$\|(1-\mathbb{Q})u\|_{2,\frac{3}{4}} + \|(1-\mathbb{Q})\mathrm{D}u\|_{2,\frac{5}{4}} \le C\Big(\|\mathrm{D}F\|_2 + \|\mathrm{D}^2 F\|_2\Big) \sup_{0\le t\le 1} \int_0^t \frac{\mathrm{d}s}{\sqrt{t-s}}.$$

Here $\mathbb{Q}$ is again defined as the characteristic function for $t \ge 1$. Next, by integrating by parts, we find

$$\hat{u}(k,t) = \frac{ik\hat{F}(k)\mathrm{e}^{-k^2 t}}{2\sigma} - \frac{ik\hat{F}(k\sqrt{1+t})\mathrm{e}^{-2ik\sigma t}}{2\sigma(1+t)^{\frac{1}{2}-\frac{1}{2^n}}} + \hat{N}(k,t),$$

$$\text{where}\qquad \hat{N}(k,t) = \frac{ik}{2\sigma}\int_0^t \mathrm{d}s\ \mathrm{e}^{-k^2(t-s)-2ik\sigma s}\Big(k^2+\partial_s\Big)\left(\frac{\hat{F}(k\sqrt{1+s})}{(1+s)^{\frac12-\frac{1}{2^n}}}\right).$$

We then note that

$$\|u-N\|_{2,\frac34}+\|\mathrm{D}(u-N)\|_{2,\frac54}\le C\Big(\|F\|_1+\|\mathrm{D}F\|_2+\|\mathrm{D}^2F\|_2\Big)$$

and that, by defining $\hat{G}(k)=\frac12\partial_k\hat{F}(k)$, we have $\hat{N}(k,t)=\hat{N}_0(k,t)+\hat{N}_1(k,t)+\hat{N}_2(k,t)$, where

$$\begin{aligned}
\hat{N}_0(k,t) &= \frac{ik^3}{2\sigma}\int_0^t \mathrm{d}s\ \mathrm{e}^{-k^2(t-s)-2ik\sigma s}\left(\frac{\hat{F}(k\sqrt{1+s})}{(1+s)^{\frac12-\frac{1}{2^n}}}\right),\\
\hat{N}_1(k,t) &= \frac{ik^2}{2\sigma}\int_0^t \mathrm{d}s\ \mathrm{e}^{-k^2(t-s)-2ik\sigma s}\left(\frac{\hat{G}(k\sqrt{1+s})}{(1+s)^{1-\frac{1}{2^n}}}\right),\\
\hat{N}_2(k,t) &= \frac{ik}{2\sigma}\left(\frac{1}{2^n}-\frac12\right)\int_0^t \mathrm{d}s\ \mathrm{e}^{-k^2(t-s)-2ik\sigma s}\left(\frac{\hat{F}(k\sqrt{1+s})}{(1+s)^{\frac32-\frac{1}{2^n}}}\right).
\end{aligned}$$

The procedure is now similar to that outlined in the proof of Theorem 6: Split the integration intervals into $[0,\frac{t}{2}]$ and $[\frac{t}{2},t]$, and distribute the derivatives (k-factors) either on the functions F and G or on the Gaussian. By introducing the notation

$$B_1\Big[\begin{smallmatrix}p_1,q_1\\ p_2,q_2\end{smallmatrix}\Big](t)\equiv\int_0^{\frac{t}{2}}\mathrm{d}s\ \frac{(1+s)^{-q_1}}{(t-s)^{p_1}}+\int_{\frac{t}{2}}^t\mathrm{d}s\ \frac{(1+s)^{-q_2}}{(t-s)^{p_2}}, \tag{5.15}$$

we then find that

$$\begin{aligned}
\|\mathbb{Q}\mathrm{D}^\alpha N_0\|_{2,\frac34+\frac{\alpha}{2}} &\le C(\|F\|_1+\|\mathrm{D}^{2+\alpha}F\|_1)\sup_{t\ge1}t^{\frac34+\frac{\alpha}{2}}\ B_1\Big[\begin{smallmatrix}\frac74+\frac{\alpha}{2},0\\ \frac34,1+\frac{\alpha}{2}\end{smallmatrix}\Big](t),\\
\|\mathbb{Q}\mathrm{D}^\alpha N_1\|_{2,\frac34+\frac{\alpha}{2}} &\le C(\|G\|_1+\|\mathrm{D}^{1+\alpha}G\|_1)\sup_{t\ge1}t^{\frac34+\frac{\alpha}{2}}\ B_1\Big[\begin{smallmatrix}\frac54+\frac{\alpha}{2},\frac12\\ \frac34,1+\frac{\alpha}{2}\end{smallmatrix}\Big](t),\\
\|\mathbb{Q}\mathrm{D}^\alpha N_2\|_{2,\frac34+\frac{\alpha}{2}\star} &\le C(\|F\|_1+\|\mathrm{D}^{\alpha}F\|_1)\sup_{t\ge1}\frac{t^{\frac34+\frac{\alpha}{2}}}{\ln(2+t)}\ B_1\Big[\begin{smallmatrix}\frac34+\frac{\alpha}{2},1\\ \frac34,1+\frac{\alpha}{2}\end{smallmatrix}\Big](t)
\end{aligned}$$

for $\alpha=0,1$. The proof is completed by a straightforward application of Lemma 18 below, where we consider generalizations of the function B_1 in (5.15), since those will occur later on in sections 6 and 7 (see Definition 17 below). ∎

6. Proof of Theorem 6, continued. In view of the estimates (2.6) and (2.8) on $\mathrm{e}^{\mathrm{L}t}$ and h, respectively, the estimates needed to conclude the proof of Theorem 6 will naturally involve the functions B_0 and B, which are defined as follows.

DEFINITION 17. *We define*

$$B_0[q](t)=\int_0^t\mathrm{d}s\frac{\mathrm{e}^{-\frac{t-s}{8}}}{\sqrt{t-s}(1+s)^q},$$

$$B\Big[\begin{smallmatrix}p_1,q_1,r_1\\ p_2,q_2,r_2,r_3\end{smallmatrix}\Big](t)=\int_0^{\frac{t}{2}}\mathrm{d}s\ \frac{(1+s)^{-q_1}}{(t-s)^{p_1}(t-1+s)^{r_1}}+\int_{\frac{t}{2}}^t\mathrm{d}s\ \frac{(1+s)^{-q_2}\ln(2+s)^{r_3}}{(t-s)^{p_2}(t-1+s)^{r_2}}. \tag{6.1}$$

These functions satisfy the following estimates.

LEMMA 18. *Let $0 \le p_2 < 1$, $0 \le r_2 \le 1 - p_2$, $p_1, q_1, q_2, r_1 \ge 0$, and $r_3 \in \{0, 1\}$. There exists a constant C such that for all $t \ge 0$ there holds*

$$B_0[q_1](t) \le C(1+t)^{-q_1},$$

$$B\Big[{}^{p_1,q_1,r_1}_{p_2,q_2,r_2,r_3}\Big](t) \le C \ \ln(2+t)^{\alpha} \begin{cases} \frac{1}{(1+t)^{\beta}} & \text{if} \quad 0 \le p_1 \le 1, \\ \frac{1}{t^{p_1-1}\ (1+t)^{\beta-p_1+1}} & \text{if} \quad p_1 > 1, \end{cases} \tag{6.2}$$

where $\beta = \min(p_1 + \min(q_1 - 1, 0) + r_1, p_2 + q_2 + r_2 - 1)$, $\alpha = \max(\delta_{q_1,1}, \delta_{p_2+r_2,1} + r_3)$, and $\delta_{i,j}$ is the Kronecker delta. Furthermore, since

$$B_1\Big[{}^{p_1,q_1}_{p_2,q_2}\Big](t) = B\Big[{}^{p_1,q_1,0}_{p_2,q_2,0,0}\Big](t),$$

the estimate in (6.2) *applies for B_1 as well.*

Proof. The proof follows immediately from

$$B_0[q_1](t) \le \mathrm{e}^{-\frac{t}{16}} \int_0^{\frac{t}{2}} \frac{\mathrm{d}s}{\sqrt{t-s}} + \frac{1}{(\frac{t}{2}+1)^{q_1}} \int_0^{\frac{t}{2}} \mathrm{d}s\ \frac{\mathrm{e}^{-\frac{s}{8}}}{\sqrt{s}},$$

$$B\Big[{}^{p_1,q_1,r_1}_{p_2,q_2,r_2,r_3}\Big](t) \le \frac{1}{(\frac{t}{2})^{p_1}(\frac{t}{2}+1)^{r_1}} \int_0^{\frac{t}{2}} \frac{\mathrm{d}s}{(1+s)^{q_1}} + \frac{\ln(2+t)^{r_3}}{(\frac{t}{2}+1)^{q_2}} \int_0^{\frac{t}{2}} \frac{\mathrm{d}s}{s^{p_2}(1+s)^{r_2}},$$

and straightforward integrations. ☐

We can now complete the proof of Theorem 6.

Proof of Theorem 6 *continued*. First, we recall that our goal is to prove that the map $\mathcal{N}$ defined by

$$\mathcal{N}[\mathbf{z}](t) = \int_0^t \mathrm{d}s\ \mathrm{e}^{\mathrm{L}(t-s)} \begin{pmatrix} 0 \\ \partial_x h(\mathbf{z}(s)) \end{pmatrix} \tag{6.3}$$

satisfies $\|\mathcal{N}[\mathbf{z}]\| \le C$ for all $\mathbf{z} \in \mathcal{B}$ with $\|\mathbf{z}\| = 1$. The estimate $\|\mathbb{P}\mathrm{D}\mathcal{N}[\mathbf{z}]\|_{2,\frac{3}{4}} \le C$ has already been proved. The other necessary estimates are done as follows:

$$\begin{aligned}
\|\widehat{\mathcal{N}[\mathbf{z}]}\|_{\infty,0} &\le C \sup_{t\ge 0} B_1\Big[{}^{\frac{1}{2},\frac{1}{2}}_{\frac{1}{2},\frac{1}{2}}\Big](t) \le C, \\
\|\mathcal{N}[\mathbf{z}]\|_{2,\frac{1}{4}} &\le C \sup_{t\ge 0} (1+t)^{\frac{1}{4}} B_1\Big[{}^{\frac{1}{2},\frac{3}{4}}_{\frac{1}{2},\frac{3}{4}}\Big](t) \le C, \\
\|\mathbb{P}\mathrm{D}\mathcal{N}[\mathbf{z}]\|_{2,\frac{3}{4}} &\le C \sup_{t\ge 0} (1+t)^{\frac{3}{4}} B_1\Big[{}^{1,\frac{3}{4}}_{\frac{1}{2},\frac{5}{4}}\Big](t) \le C, \\
\|(1-\mathbb{P})\mathrm{D}\mathcal{N}[\mathbf{z}]\|_{2,\frac{3}{4}} &\le \sup_{t\ge 0} (1+t)^{\frac{3}{4}} B_0[\tfrac{5}{4}](t) \le C, \\
\|(1-\mathbb{Q})\mathbb{P}\mathrm{D}^2\mathcal{N}[\mathbf{z}]_2\|_{2,\frac{5}{4}^\star} &\le C \|(1-\mathbb{Q})\mathbb{P}\mathrm{D}\mathcal{N}[\mathbf{z}]_2\|_{2,\frac{3}{4}} \\
&\le C \|\mathbb{P}\mathrm{D}\mathcal{N}[\mathbf{z}]_2\|_{2,\frac{3}{4}} \le C, && (6.4) \\
\|\mathbb{Q}\mathbb{P}\mathrm{D}^2\mathcal{N}[\mathbf{z}]_2\|_{2,\frac{5}{4}^\star} &\le C \sup_{t\ge 1} \frac{(1+t)^{\frac{5}{4}}}{\ln(2+t)}\ B\Big[{}^{\frac{3}{2},\frac{3}{4},0}_{\frac{1}{2},\frac{5}{4},\frac{1}{2},0}\Big](t) \le C, && (6.5) \\
\|(1-\mathbb{P})\mathrm{D}^2\mathcal{N}[\mathbf{z}]_2\|_{2,\frac{5}{4}^\star} &\le \sup_{t\ge 0} (1+t)^{\frac{5}{4}} B_0[\tfrac{5}{4}](t) \le C. && (6.6)
\end{aligned}$$

In (6.4), we used the obvious estimates $\|\mathbb{P}\mathrm{D}f\|_2 \le \|\mathbb{P}f\|_2$ and $\|(1-\mathbb{Q})f\|_{2,p} \le 2^{p-q}\|(1-\mathbb{Q})f\|_{2,q}$ if $q < p$, while in (6.5), we made use of $\sup_{|k|\le 1, t\ge 0}|k|\sqrt{1+t}\mathrm{e}^{-k^2 t} \le$

1, and finally in (6.6) we used $\sup_{k\in\mathbf{R}} |k|(1+k^2)^{-\frac{1}{2}} = 1$. Incidentally, (6.6) is the only place in the above estimates where the (crucial) presence of the extra factor $(1+k^2)^{-\frac{1}{2}}$ in the second component of the r.h.s. of (2.6) is used. This concludes the proof of Theorem 6. $\square$

7. Remainder estimates. We now make precise the sense in which the semigroup $\mathrm{e}^{\mathrm{L}t}$ is *close* to that of (2.3), whose Fourier transform is given by

$$\mathrm{e}^{\mathrm{L}_0 t} \equiv \begin{pmatrix} \mathrm{e}^{-k^2t+ikt} & 0 \\ 0 & \mathrm{e}^{-k^2t-ikt} \end{pmatrix}. \tag{7.1}$$

LEMMA 19. *Let $\mathbb{P}$ be the Fourier multiplier with the characteristic function on $[-1,1]$, and let $\mathrm{e}^{\mathrm{L}t}$ (respectively, $\mathrm{e}^{\mathrm{L}_0 t}$) be as in* (2.2) *(respectively,* (7.1)*) and $\mathcal{S}$ be as in* (2.4)*. Then one has the estimates*

$$\sup_{t\geq 0, k\in\mathbf{R}} \sqrt{1+t}\,\mathrm{e}^{\frac{k^2t}{2}} \left| \left(\mathbb{P}\mathcal{S}\mathrm{e}^{\mathrm{L}t} - \mathrm{e}^{\mathrm{L}_0 t}\mathcal{S}\right)_{i,j} \right| \leq C, \tag{7.2}$$

where $(\mathbb{P}\mathcal{S}\mathrm{e}^{\mathrm{L}t} - \mathrm{e}^{\mathrm{L}_0 t}\mathcal{S})_{i,j}$ denotes the (i,j)-entry in the matrix $\mathbb{P}\mathcal{S}\mathrm{e}^{\mathrm{L}t} - \mathrm{e}^{\mathrm{L}_0 t}\mathcal{S}$.

Proof. The proof follows by considering separately $|k| \leq 1$ and $|k| > 1$. We first rewrite

$$\mathbb{P}\mathcal{S}\mathrm{e}^{\mathrm{L}t} - \mathrm{e}^{\mathrm{L}_0 t}\mathcal{S} = \mathbb{P}\Big(\mathcal{S}\mathrm{e}^{\mathrm{L}t} - \mathrm{e}^{\mathrm{L}_0 t}\mathcal{S}\Big) + (1-\mathbb{P})\mathrm{e}^{\mathrm{L}_0 t}\mathcal{S}.$$

We then have

$$\sup_{t\geq 0, k\in\mathbf{R}} \sqrt{1+t}\,\mathrm{e}^{\frac{k^2t}{2}} \left| \left((1-\mathbb{P})\mathrm{e}^{\mathrm{L}_0 t}\mathcal{S}\right)_{i,j} \right| \leq \sup_{t\geq 0, |k|\geq 1} \sqrt{1+t}\,\mathrm{e}^{-\frac{k^2t}{2}} \leq C.$$

For $|k| \leq 1$, we first compute

$$\mathrm{e}^{\mathrm{L}_0 t}\mathcal{S} = \mathrm{e}^{-k^2t}\begin{pmatrix} \mathrm{e}^{ikt} & \mathrm{e}^{ikt} \\ \mathrm{e}^{-ikt} & -\mathrm{e}^{-ikt} \end{pmatrix},$$
$$\mathcal{S}\mathrm{e}^{\mathrm{L}t} = \mathrm{e}^{-k^2t}\begin{pmatrix} \cos(kt\Delta) + \frac{1-ik}{\Delta}\, i\sin(kt\Delta) & \cos(kt\Delta) + \frac{1+ik}{\Delta}\, i\sin(kt\Delta) \\ \cos(kt\Delta) - \frac{1+ik}{\Delta}\, i\sin(kt\Delta) & -(\cos(kt\Delta) - \frac{1-ik}{\Delta}\, i\sin(kt\Delta)) \end{pmatrix},$$

where we recall that $\Delta = \sqrt{1-k^2}$. We next note that

$$\begin{aligned}
\mathbb{P}|\sin(kt\Delta) - \sin(kt)| &\leq \mathbb{P}|\cos(kt(\Delta-1)) - 1| + \mathbb{P}|\sin(kt(\Delta-1))| \\
&\leq \mathbb{P}|\sqrt{1-k^2} - 1|\ |k|t \leq \mathbb{P}|k|^3 t, \\
\mathbb{P}|\cos(kt\Delta) - \cos(kt)| &\leq \mathbb{P}|\cos(kt(\Delta-1)) - 1| + \mathbb{P}|\sin(kt(\Delta-1))| \\
&\leq \mathbb{P}|\sqrt{1-k^2} - 1|\ |k|t \leq \mathbb{P}|k|^3 t, \\
\mathbb{P}\left|\left(\frac{1}{\Delta} - 1\right)\sin(kt\Delta)\right| &\leq \mathbb{P}|\sqrt{1-k^2} - 1|\ |k|t \leq \mathbb{P}|k|^3 t.
\end{aligned}$$

The proof is completed noting that

$$\sup_{|k|\leq 1, t\geq 0} t^{\frac{m}{2}} |k|^n \mathrm{e}^{-\frac{k^2t}{2}} \leq C(n)$$

for any (finite) $0 \leq m \leq n$. $\square$

We are now in a position to prove that the remainder

$$\mathcal{R}[\mathbf{z}](t) = \Big(\mathcal{S}\mathrm{e}^{\mathrm{L}t} - \mathrm{e}^{\mathrm{L}_0 t}\mathcal{S}\Big)\mathbf{z}_0 + \int_0^t \mathrm{d}s \;\left[\; \mathcal{S}\mathrm{e}^{\mathrm{L}(t-s)}\begin{pmatrix} 0 \\ \partial_x h(\mathbf{z}(s)) \end{pmatrix} - \mathrm{e}^{\mathrm{L}_0(t-s)}\mathcal{S}\begin{pmatrix} 0 \\ \partial_x g_0(\mathbf{z}(s)) \end{pmatrix} \right]$$

satisfies improved estimates as stated in (3.5).

THEOREM 20. *Let ϵ_0 be again the (small) constant provided by Theorem 6. Then for all $\mathbf{z}_0 \in \mathcal{B}_0$ with $|\mathbf{z}_0| \le \epsilon_0$, the solution $\mathbf{z}$ of (1.1) satisfies*

$$\|\mathcal{R}[\mathbf{z}]\|_{2,\frac{3}{4}^\star} + \|\mathrm{D}\mathcal{R}[\mathbf{z}]\|_{2,\frac{5}{4}^\star} \le C\epsilon_0. \tag{7.3}$$

Proof. We first note that

$$\Big(\mathcal{S}\mathrm{e}^{\mathrm{L}t} - \mathrm{e}^{\mathrm{L}_0 t}\mathcal{S}\Big)\mathbf{z}_0 = \Big(\mathcal{S}\mathbb{P}\mathrm{e}^{\mathrm{L}t} - \mathrm{e}^{\mathrm{L}_0 t}\mathcal{S}\Big)\mathbf{z}_0 + \mathcal{S}(1-\mathbb{P})\mathrm{e}^{\mathrm{L}t}\mathbf{z}_0 \equiv L_1[\mathbf{z}_0](t) + L_2[\mathbf{z}_0](t)$$

and then use the fact that by Lemma 19 we have

$$\|\mathrm{D}^\alpha L_1[\mathbf{z}_0]\|_{2,\frac{3}{4}+\frac{\alpha}{2}} \le C \sup_{t\ge 0}(1+t)^{\frac{1}{4}+\frac{\alpha}{2}} \min\Big(\|\mathrm{D}^\alpha \mathbf{z}_0\|_2,\; t^{-\frac{1}{4}-\frac{\alpha}{2}}\|\widehat{z_0}\|_\infty\Big) \le C|\mathbf{z}_0|$$

for $\alpha = 0, 1$, and finally

$$\|L_2[\mathbf{z}_0]\|_{2,\frac{3}{4}} + \|\mathrm{D}L_2[\mathbf{z}_0]\|_{2,\frac{5}{4}} \le C(\|\mathbf{z}_0\|_2 + \|\mathrm{D}\mathbf{z}_0\|_2) \sup_{t\ge 0}(1+t)^{\frac{5}{4}}\mathrm{e}^{-\frac{t}{4}} \le C|\mathbf{z}_0|.$$

This proves

$$\Big\|\Big(\mathcal{S}\mathrm{e}^{\mathrm{L}t} - \mathrm{e}^{\mathrm{L}_0 t}\mathcal{S}\Big)\mathbf{z}_0\Big\|_{2,\frac{3}{4}} + \Big\|\mathrm{D}\Big(\mathcal{S}\mathrm{e}^{\mathrm{L}t} - \mathrm{e}^{\mathrm{L}_0 t}\mathcal{S}\Big)\mathbf{z}_0\Big\|_{2,\frac{5}{4}} \le C|\mathbf{z}_0|$$

for all $\mathbf{z}_0 \in \mathcal{B}_0$. We then show that

$$\Big\|\mathcal{R}[\mathbf{z}](t) - \Big(\mathcal{S}\mathrm{e}^{\mathrm{L}t} - \mathrm{e}^{\mathrm{L}_0 t}\mathcal{S}\Big)\mathbf{z}_0\Big\|_{2,\frac{3}{4}^\star} + \Big\|\mathrm{D}\Big(\mathcal{R}[\mathbf{z}](t) - \Big(\mathcal{S}\mathrm{e}^{\mathrm{L}t} - \mathrm{e}^{\mathrm{L}_0 t}\mathcal{S}\Big)\mathbf{z}_0\Big)\Big\|_{2,\frac{5}{4}^\star} \le C\|\mathbf{z}\|^2$$

for all $\mathbf{z} \in \mathcal{B}$. We need only to prove the estimates for $\|\mathbf{z}\| = 1$. We first decompose

$$\mathcal{R}[\mathbf{z}](t) - \Big(\mathcal{S}\mathrm{e}^{\mathrm{L}t} - \mathrm{e}^{\mathrm{L}_0 t}\mathcal{S}\Big)\mathbf{z}_0 = \mathcal{S}\mathcal{N}_1[\mathbf{z}](t) + \mathcal{S}\mathcal{N}_2[\mathbf{z}](t) + \mathcal{N}_3[\mathbf{z}](t), \tag{7.4}$$

where

$$\mathcal{N}_1[\mathbf{z}](t) = (1-\mathbb{P})\int_0^t \mathrm{d}s\; \mathrm{e}^{\mathrm{L}(t-s)}\begin{pmatrix} 0 \\ \partial_x h(\mathbf{z}(s)) \end{pmatrix},$$

$$\mathcal{N}_2[\mathbf{z}](t) = \mathbb{P}\int_0^t \mathrm{d}s\; \mathrm{e}^{\mathrm{L}(t-s)}\begin{pmatrix} 0 \\ \partial_x h(\mathbf{z}(s)) - \partial_x g_0(\mathbf{z}(s)) \end{pmatrix},$$

$$\mathcal{N}_3[\mathbf{z}](t) = \int_0^t \mathrm{d}s\; \Big(\mathbb{P}\mathcal{S}\mathrm{e}^{\mathrm{L}(t-s)} - \mathrm{e}^{\mathrm{L}_0(t-s)}\mathcal{S}\Big)\begin{pmatrix} 0 \\ \partial_x g_0(\mathbf{z}(s)) \end{pmatrix}.$$

We then recall that $h(\mathbf{z})$ satisfies

$$\|h(\mathbf{z})\|_{2,\frac{3}{4}} + \|\mathrm{D}h(\mathbf{z})\|_{2,\frac{5}{4}} \le C\|\mathbf{z}\|^2,$$

which implies that

$$\|\mathcal{N}_1[\mathbf{z}]\|_{2,\frac{3}{4}} \leq C \sup_{t\geq 0}(1+t)^{\frac{3}{4}} B_0[\tfrac{3}{4}](t) \leq C, \quad \|\mathrm{D}\mathcal{N}_1[\mathbf{z}]\|_{2,\frac{5}{4}} \leq C \sup_{t\geq 0}(1+t)^{\frac{5}{4}} B_0[\tfrac{5}{4}](t) \leq C.$$

Moreover $h_0(a,b) \equiv f(a,b)\partial_x b + g(a,b) - g_0(a,b)$ satisfies

$$\|h_0(\mathbf{z})\|_{1,1} + \|\mathrm{D}h_0(\mathbf{z})\|_{1,\frac{3}{2}^\star} \leq C\|\mathbf{z}\|^2.$$

Here we need to consider separately $t \in [0,1]$ and $t \geq 1$ when estimating $\|\mathbb{P}\mathrm{D}\mathcal{N}_2[\mathbf{z}]\|_{2,\frac{5}{4}^\star}$. By writing again $\mathbb{Q}$ for the characteristic function for $t \geq 1$, we find that

$$\begin{aligned}
\|\mathbb{P}\mathcal{N}_2[\mathbf{z}]\|_{2,\frac{3}{4}^\star} &\leq C \sup_{t\geq 0} \frac{(1+t)^{\frac{3}{4}}}{\ln(2+t)} B_1\Big[\begin{smallmatrix}\frac{3}{4},1\\ \frac{3}{4},1\end{smallmatrix}\Big](t) \leq C,\\
\|(1-\mathbb{Q})\mathbb{P}\mathrm{D}\mathcal{N}_2[\mathbf{z}]\|_{2,\frac{5}{4}^\star} &\leq C \sup_{0\leq t\leq 1} (1+t)^{\frac{5}{4}}\ B_1\Big[\begin{smallmatrix}\frac{3}{4},\frac{3}{2}\\ \frac{3}{4},\frac{3}{2}\end{smallmatrix}\Big](t) \leq C,\\
\|\mathbb{Q}\mathbb{P}\mathrm{D}\mathcal{N}_2[\mathbf{z}]\|_{2,\frac{5}{4}^\star} &\leq C \sup_{t\geq 1} \frac{(1+t)^{\frac{5}{4}}}{\ln(2+t)}\ B\Big[\begin{smallmatrix}\frac{5}{4},1,0\\ \frac{3}{4},\frac{3}{2},0,1\end{smallmatrix}\Big](t) \leq C.
\end{aligned}$$

We finally note that

$$\|g_0(\mathbf{z})\|_{2,\frac{3}{4}} + \|\mathrm{D}g_0(\mathbf{z})\|_{2,\frac{5}{4}} \leq C\|\mathbf{z}\|^2,$$

and so, by using Lemma 19, we find

$$\begin{aligned}
\|\mathcal{N}_3[\mathbf{z}]\|_{2,\frac{3}{4}^\star} &\leq \sup_{t\geq 0} \frac{(1+t)^{\frac{3}{4}}}{\ln(2+t)}\ B\Big[\begin{smallmatrix}\frac{1}{2},\frac{3}{4},\frac{1}{2}\\ \frac{1}{2},\frac{3}{4},\frac{1}{2},0\end{smallmatrix}\Big](t) \leq C,\\
\|\mathrm{D}\mathcal{N}_3[\mathbf{z}]\|_{2,\frac{5}{4}^\star} &\leq \sup_{t\geq 0} \frac{(1+t)^{\frac{5}{4}}}{\ln(2+t)}\ B\Big[\begin{smallmatrix}1,\frac{3}{4},\frac{1}{2}\\ \frac{1}{2},\frac{5}{4},\frac{1}{2},0\end{smallmatrix}\Big](t) \leq C.
\end{aligned}$$

This completes the proof. ∎

It now remains only to prove the estimates (3.13) and (3.14) on the maps $\widetilde{\mathcal{R}}_{\{u,v\}}$, where we recall that

$$\begin{aligned}
\widetilde{\mathcal{R}}_u[\mathbf{z},\mathbf{R}^N](t) &= c_+\mathrm{E}_0[h_{1,u}+h_{3,u}](t) - c_-\mathrm{E}_{-2}[h_{1,v}+h_{3,v}](t) + c_3\mathrm{E}_{-1}[h_2+h_4](t),\\
\widetilde{\mathcal{R}}_v[\mathbf{z},\mathbf{R}^N](t) &= c_-\mathrm{E}_0[h_{1,v}+h_{3,v}](t) - c_+\mathrm{E}_2[h_{1,u}+h_{3,u}](t) - c_3\mathrm{E}_1[h_2+h_4](t),
\end{aligned}$$

with $h_{1,u} = R_u^N(u+u_\star)$, $h_{3,u} = u_1^2$, $h_{1,v} = R_v^N(v+v_\star)$, $h_{3,v} = v_1^2$, $h_4 = (\mathcal{T}u_\star)(\mathcal{T}^{-1}v_\star)$, and

$$\begin{aligned}
h_2 &= (\mathcal{T}R_u^N)\mathcal{T}^{-1}\Big(\frac{v+v_\star}{2}\Big) + (\mathcal{T}^{-1}R_v^N)\mathcal{T}\Big(\frac{u+u_\star}{2}\Big),\\
\mathrm{E}_\sigma[h](t) &= \partial_x \int_0^t \mathrm{d}s\ \mathrm{e}^{\partial_x^2(t-s)}\ \mathcal{T}^\sigma h(s).
\end{aligned}$$

Here we will prove only that

$$\sum_{\alpha=0}^{1} \|\mathrm{D}^\alpha \widetilde{\mathcal{R}}_{\{u,v\}}[\mathbf{z},\mathbf{R}^N]\|_{2,\frac{3}{4}+\frac{\alpha}{2}-\epsilon} \leq C\epsilon_0 \sum_{\alpha=0}^{1} \|\mathrm{D}^\alpha \mathbf{R}^N\|_{2,\frac{3}{4}+\frac{\alpha}{2}-\epsilon} + C. \tag{7.5}$$

It is then straightforward to show (3.14), namely, that the maps $\widetilde{\mathcal{R}}_{\{u,v\}}$ are Lipschitz in their second argument; we omit the details.

To prove (7.5), we first need estimates on $\mathbf{h}_1 = (h_{1,u}, h_{1,v})$, h_2, $\mathbf{h}_3 = (h_{3,u}, h_{3,v})$, and h_4. We note that $\mathbf{u}_0 = (u_0, v_0)$ and $\mathbf{u}_1 = (u_1, v_1)$ satisfy

$$\|\mathbf{u}_0\|_{1,0} + \|\mathbf{u}_1\|_{1,0} + \|\mathrm{D}\mathbf{u}_0\|_{1,\frac{1}{2}} + \|\mathrm{D}\mathbf{u}_1\|_{1,\frac{1}{2}} \le C,$$
$$\sup_{t\ge 0}(1+t)^{\frac{3}{2}}\Big(|\mathbf{u}_0(\pm t,t)| + |\mathbf{u}_1(\pm t,t)|\Big) + (1+t)^2\Big(|\mathrm{D}\mathbf{u}_0(\pm t,t)| + |\mathrm{D}\mathbf{u}_1(\pm t,t)|\Big) \le C$$

for some constant C; see Proposition 12. We thus find that

$$\begin{aligned}
\|\mathbf{h}_1\|_{1,1-\epsilon} + \|\mathrm{D}\mathbf{h}_1\|_{1,\frac{3}{2}-\epsilon} &\le C\epsilon_0 \sum_{\alpha=0}^{1} \|\mathrm{D}^\alpha \mathbf{R}^N\|_{2,\frac{3}{4}+\frac{\alpha}{2}-\epsilon},\\
\|h_2\|_{1,1-\epsilon} + \|\mathrm{D}h_2\|_{1,\frac{3}{2}-\epsilon} &\le C\epsilon_0 \sum_{\alpha=0}^{1} \|\mathrm{D}^\alpha \mathbf{R}^N\|_{2,\frac{3}{4}+\frac{\alpha}{2}-\epsilon},\\
\|\mathbf{h}_3\|_{1,1} + \|\mathrm{D}\mathbf{h}_3\|_{1,\frac{3}{2}} + \|h_4\|_{1,\frac{3}{2}} + \|\mathrm{D}h_4\|_{2,2} &\le C.
\end{aligned}\tag{7.6}$$

The proof of (7.5) then follows from Proposition 21, which implies that

$$\sum_{\alpha=0}^{1} \|\mathrm{D}^\alpha \mathrm{E}_\sigma[\mathbf{h}_1]\|_{2,\frac{3}{4}+\frac{\alpha}{2}-\epsilon} + \|\mathrm{D}^\alpha \mathrm{E}_\sigma[h_2]\|_{2,\frac{3}{4}+\frac{\alpha}{2}-\epsilon} \le C\epsilon_0 \sum_{\alpha=0}^{1} \|\mathrm{D}^\alpha \mathbf{R}^N\|_{2,\frac{3}{4}+\frac{\alpha}{2}-\epsilon},$$
$$\sum_{\alpha=0}^{1} \|\mathrm{D}^\alpha \mathrm{E}_\sigma[\mathbf{h}_3]\|_{2,\frac{3}{4}+\frac{\alpha}{2}^\star} + \|\mathrm{D}^\alpha \mathrm{E}_\sigma[h_4]\|_{2,\frac{3}{4}+\frac{\alpha}{2}^\star} \le C$$

for any $\sigma \in \{-2,-1,0,1,2\}$ if the estimates in (7.6) are satisfied.

PROPOSITION 21. *Let $\epsilon > 0$ and $\sigma \in \{-2,-1,0,1,2\}$. Then there holds*

$$\sum_{\alpha=0}^{1} \|\mathrm{D}^\alpha \mathrm{E}_\sigma[h_1]\|_{2,\frac{3}{4}+\frac{\alpha}{2}-\epsilon} \le C \sum_{\alpha=0}^{1} \|\mathrm{D}^\alpha h_1\|_{1,1+\frac{\alpha}{2}-\epsilon},$$
$$\sum_{\alpha=0}^{1} \|\mathrm{D}^\alpha \mathrm{E}_\sigma[h_2]\|_{2,\frac{3}{4}+\frac{\alpha}{2}^\star} \le C \sum_{\alpha=0}^{1} \|\mathrm{D}^\alpha h_2\|_{1,1+\frac{\alpha}{2}}.$$

Proof. Let $u_i = \mathrm{E}_\sigma[h_i]$. By taking the Fourier transform, we find that

$$\widehat{u_i}(k,t) = ik\int_0^t \mathrm{d}s\, \mathrm{e}^{-k^2(t-s)+i\sigma k s}\widehat{h_i}(k,s).$$

We can restrict ourselves to $\sum_{\alpha=0}^{1} \|\mathrm{D}^\alpha h_1\|_{1,1+\frac{\alpha}{2}-\epsilon} = 1$ and $\sum_{\alpha=0}^{1} \|\mathrm{D}^\alpha h_2\|_{1,1+\frac{\alpha}{2}} = 1$. Then it follows that

$$\|\mathrm{D}^\alpha u_1\|_{2,\frac{3}{4}+\frac{\alpha}{2}-\epsilon} \le C\sup_{t\ge 0}(1+t)^{\frac{3}{4}+\frac{\alpha}{2}-\epsilon}\, B_1\Big[\begin{smallmatrix}\frac{3}{4}+\frac{\alpha}{2},1-\epsilon\\ \frac{3}{4},1+\frac{\alpha}{2}-\epsilon\end{smallmatrix}\Big](t) \le C,$$
$$\|\mathrm{D}^\alpha u_2\|_{2,\frac{3}{4}+\frac{\alpha}{2}^\star} \le C\sup_{t\ge 0}\frac{(1+t)^{\frac{3}{4}+\frac{\alpha}{2}}}{\ln(2+t)}\, B_1\Big[\begin{smallmatrix}\frac{3}{4}+\frac{\alpha}{2},1\\ \frac{3}{4},1+\frac{\alpha}{2}\end{smallmatrix}\Big](t) \le C$$

for $\alpha = 0, 1$ as claimed. $\square$

LARGE TIME BEHAVIOR OF RADIALLY SYMMETRIC SURFACES IN THE MEAN CURVATURE FLOW*

MITSUNORI NARA†

Abstract. The large time behavior of radially symmetric surfaces in $\mathbb{R}^{n+1}$ moving by the mean curvature flow is studied. By studying a Cauchy problem, we deal with moving surfaces represented by entire graphs on a hyperplane. Here an initial surface is given by a function that is bounded and radially symmetric. It is proved that the solution converges uniformly to the solution of the Cauchy problem of the heat equation with the same initial value. The difference is of order $O(t^{-1/2})$ as time goes to infinity. The proof is based on the construction of the Green's function and the decay estimates for the derivatives of the solution. By virtue of the stability results for the heat equation, our result gives the sufficient and necessary conditions on the asymptotic stability of constant functions that represent stationary hyperplanes in the mean curvature flow.

Key words. large time behavior, mean curvature flow, heat equation, radially symmetric solution

1. Introduction.

In this paper, we study *the mean curvature flow* in $\mathbb{R}^{n+1}$. Especially we study the large time behavior of the solution to the Cauchy problem of a scalar parabolic equation

$$\frac{u_t}{\sqrt{1+|\nabla u|^2}} = \operatorname{div}\left(\frac{\nabla u}{\sqrt{1+|\nabla u|^2}}\right), \quad x \in \mathbb{R}^n,\ t > 0, \tag{1}$$

$$u(x,0) = u_0(x), \qquad x \in \mathbb{R}^n. \tag{2}$$

Here we assume that $n \geq 2$ and that the initial value $u_0(x)$ is bounded and radially symmetric. Throughout this paper, we say that a function $f(x)$ is *radially symmetric* when it depends only on $r = |x|$.

The mean curvature flow is a mathematical model that describes motion of oriented hypersurfaces. Let $S(t)$ be a moving hypersurface in $\mathbb{R}^{n+1}$. We are interested in the dynamics of $S(t)$ given by $V = -\kappa$, where V and κ are the outward normal velocity and the mean curvature of $S(t)$, respectively. This model appears in several fields. For example, this describes the motion of phase boundaries in the Allen–Cahn equation [2] and also in the reaction-diffusion systems of a competition type [7].

The mean curvature flow of compact surfaces is extensively studied. It is well known that a compact surface $S(t)$ in $\mathbb{R}^{n+1}$ shrinks to a single point when $n = 1$ or $S(0)$ is convex. This fact has been proved by Gage and Hamilton [11], Grayson [12], and Huisken [13]. When $n \geq 2$, smooth initial surfaces may develop geometric singularities. Evans and Spruck [9] and Chen, Giga, and Goto [1] developed a level set approach for handling such geometric singularities.

On the other hand, some researchers focus on the mean curvature flow of *graphical surfaces*. In this case, an initial surface $S(0)$ is given by a scalar function $y = u_0(x), x \in$

$\mathbb{R}^n$, and a moving surface $S(t), t > 0$, is expressed by a scalar function $y = u(x,t), x \in \mathbb{R}^n, t > 0$. Under these assumptions, the mean curvature flow $V = -\kappa$ is rewritten as the Cauchy problem (1)–(2).

A pioneering work for the mean curvature flow of graphical surfaces is given by Ecker and Huisken [6]. They showed the existence of expanding self-similar solutions and the large time behavior of solutions. It is proved that a graphical solution $u(x,t)$ of (1)–(2) converges to an expanding self-similar solution, if an unbounded initial graph $u_0(x)$ satisfies linear growth and additional assumptions. Ishimura [14] also studied the same problem in detail.

Our aim in this paper is to study the large time behavior of graphical surfaces with bounded initial graphs, i.e., the large time behavior of the solution $u(x,t)$ to the Cauchy problem (1)–(2) with bounded initial values $u_0(x)$. The major interest is the asymptotic stability of the hyperplane $u(x,t) = 0$, which is the simplest stationary surface in the mean curvature flow.

Now we briefly mention the stability results for the heat equation. For the Cauchy problem of the heat equation

$$H_t = \Delta H, \qquad x \in \mathbb{R}^n,\ t > 0, \tag{3}$$

$$H(x,0) = \Phi(x), \quad x \in \mathbb{R}^n, \tag{4}$$

the necessary and sufficient conditions for the asymptotic stability of $H(x,t) = 0$ are obtained as follows. This result is shown in [5, 8, 15, 18], for example.

Proposition 1.1. *Let $\Phi(x)$ be a bounded function. Then the solution $H(x,t)$ of (3)–(4) satisfies $\lim_{t\to\infty} H(0,t) = 0$ if and only if $\Phi(x)$ satisfies*

$$\lim_{R\to\infty} \frac{1}{(2R)^n} \int_{y\in V_R} \Phi(y)\, dy = 0.$$

Moreover it satisfies $\lim_{t\to\infty} \sup_{x\in\mathbb{R}^n} |H(x,t)| = 0$ if and only if $\Phi(x)$ satisfies

$$\lim_{R\to\infty} \sup_{x\in\mathbb{R}} \frac{1}{(2R)^n} \left| \int_{y\in V_R} \Phi(y-x)\, dy \right| = 0,$$

where V_R is the cube with the center at the origin and the side $2R$.

Here we note that an initial value $\Phi(x)$ does not need to decay to zero as $|x| \to \infty$. It may oscillate with some amplitude. Collet and Eckmann [4] showed a remarkable example where an initial value does not satisfy the criterion for the asymptotic stability of $H(x,t) = 0$ and the solution $H(x,t)$ does not converge to any fixed constant as $t \to \infty$.

Proposition 1.2 (see [4]). *Let $H(x,t)$ be the solution of the Cauchy problem of the heat equation*

$$\begin{aligned} &H_t = H_{xx}, && x \in \mathbb{R},\ t > 0, \\ &H(x,0) = \Phi^*(x), && x \in \mathbb{R}. \end{aligned}$$

Suppose that $\Phi^*(x)$ is a smooth even function that satisfies $|\Phi^*(x)| \le 1$ for $x \in \mathbb{R}$ and

$$\Phi^*(x) = (-1)^m, \quad x \in [\, m! + 2^m,\ (m+1)! - 2^{m+1}\,]$$

for $m \ge 5$. Then it holds that

$$\liminf_{t\to\infty} H(0,t) = -1, \quad \limsup_{t\to\infty} H(0,t) = 1.$$

This implies that the solution $H(x,t)$ oscillates forever as $t \to \infty$ with an amplitude of 2. Here the initial value $\Phi^*(x)$ does not decay but oscillates slower and slower as $|x| \to \infty$. This example shows the difficulty in considering the asymptotic stability of the zero solution for spatially nondecaying initial values.

In the case of $n = 1$, the asymptotic stability of $u(x,t) = 0$ of the problem (1)–(2) with bounded initial values is obtained in [17]. In this case, the problem (1)–(2) is rewritten as follows:

$$u_t = \frac{u_{xx}}{1+u_x^2}, \qquad x \in \mathbb{R},\ t > 0, \tag{5}$$

$$u(x,0) = u_0(x), \quad x \in \mathbb{R}. \tag{6}$$

This describes the motion of curves in $\mathbb{R}^2$ expressed by the function $y = u(x,t), x \in \mathbb{R}, t > 0$. The constant solution $u(x,t) = 0$ means the stationary line in $\mathbb{R}^2$. Equation (5) is rewritten as $u_t = (\arctan u_x)_x = u_{xx} - (u_x - \arctan u_x)_x = u_{xx} + F_x(x,t)$, which is considered to be the heat equation with the flux $F_x(x,t)$. Then $u(x,t)$ is given by

$$u(x,t) = \int_{\mathbb{R}} \Gamma(x-y,t)\, u_0(y)\, dy + \int_0^t \int_{\mathbb{R}} \Gamma(x-y,t-s)\, F_y(y,s)\, dy\, ds,$$

where $\Gamma(\xi,\tau)$ is the heat kernel. In [17], under the assumption of $u_0 \in C^{2+\alpha}(\mathbb{R})$, it is proved that

$$\left| \int_0^t \int_{\mathbb{R}} \Gamma(x-y,t-s)\, F_y(y,s)\, dy\, ds \right| \le C\, t^{-\frac{1}{2}}, \quad t > 0.$$

This means that the contribution of the flux F_x can be ignored as $t \to \infty$, and the large time behavior of $u(x,t)$ of (5)–(6) is derived directly from that of the Cauchy problem of the heat equation with the same initial value $u_0(x)$. Here the initial value $u_0(x)$ does not need to decay to zero as $|x| \to \infty$. Consequently, the asymptotic stability of the stationary line $u(x,t) = 0$ of (5)–(6) is obtained as in Proposition 1.1. In addition, a similar result to Proposition 1.2 holds true for the problem (5)–(6). We briefly mention why such a result holds true. One reason is that the mean value of $F_x(x,t)$ is zero at each $t \ge 0$ when $|u_x|$ is bounded. Thus Proposition 1.1 gives that, for each $s \ge 0$,

$$\lim_{t\to\infty} \int_{\mathbb{R}} \Gamma(x-y,t-s)\, F_y(y,s)\, dy = 0.$$

This means that the contribution of the flux $F_y(y,s)$ at each $s \ge 0$ may be ignored as $t \to \infty$. Another reason is that the flux $F_y(y,s)$ itself decays fast enough as $s \to \infty$. Then the whole contribution of the flux may be neglected in considering the large time behavior.

Our motivation in this paper is to answer the question of whether similar results hold true for the problem (1)–(2) with $n \ge 2$. The following is the main result in this paper.

THEOREM 1.3. *Suppose that $n \ge 2$ and that $u_0 \in C(\mathbb{R}^n) \cap W^{1,\infty}(\mathbb{R}^n)$ is radially symmetric. Then there exists a classical solution $u(x,t)$ to the Cauchy problem* (1)–(2) *up to $t = +\infty$. Moreover it satisfies*

$$\sup_{x\in\mathbb{R}^n} \left| u(x,t) - \int_{\mathbb{R}^n} \Gamma(x-y,t)\, u_0(y)\, dy \right| \le C\, t^{-\frac{1}{2}}, \quad t \ge 2,$$

for a constant $C > 0$ depending only on n and u_0. Here $\Gamma(\xi, \tau)$ is the heat kernel given by $\Gamma(\xi, \tau) = 1/(4\pi\tau)^{n/2} \exp(-|\xi|^2/(4\tau))$.

Thus the large time behavior of the solution of (1)–(2) with $n \geq 2$ is also derived directly from that of the Cauchy problem of the heat equation with the same initial value $u_0(x)$ if it is radially symmetric. The difference is of order $O(t^{-1/2})$. We also note that the initial value $u_0(x)$ does not need to decay to zero as $|x| \to \infty$ and that it does not need to converge to any fixed constant as $|x| \to \infty$. It may oscillate with some amplitude.

From Proposition 1.1 and Theorem 1.3, we obtain the necessary and sufficient conditions for the asymptotic stability of the hyperplane $u(x, t) = 0$ of (1)–(2) with radially symmetric initial values as follows.

COROLLARY 1.4. *Suppose that $n \geq 2$ and that $u_0 \in C(\mathbb{R}^n) \cap W^{1,\infty}(\mathbb{R}^n)$ is radially symmetric. Then the solution $u(x, t)$ to the Cauchy problem* (1)–(2) *satisfies* $\lim_{t\to\infty} u(0, t) = 0$ *if and only if $u_0(x)$ satisfies*

$$\lim_{R\to\infty} \frac{1}{(2R)^n} \int_{y\in V_R} u_0(y)\, dy = 0. \tag{7}$$

Moreover it satisfies $\lim_{t\to\infty} \sup_{x\in\mathbb{R}^n} |u(x, t)| = 0$ *if and only if $u_0(x)$ satisfies*

$$\lim_{R\to\infty} \sup_{x\in\mathbb{R}} \frac{1}{(2R)^n} \left| \int_{y\in V_R} u_0(y - x)\, dy \right| = 0, \tag{8}$$

where V_R is the cube with the center at the origin and the side $2R$.

To prove Theorem 1.3, we will extend the idea given by [17] to the case where an initial value is radially symmetric and $n \geq 2$. If the initial value is radially symmetric, the solution of (1)–(2) is also radially symmetric and satisfies

$$u_t = \frac{u_{rr}}{1 + u_r^2} + \frac{n-1}{r} u_r = u_{rr} + \frac{n-1}{r} u_r + F_r(r, t), \quad r > 0,\ t > 0,$$

where $r = |x|$ and $F_r(r, t) = -(u_r - \arctan u_r)_r$. An extra difficulty in most of the radial problems is to handle a singularity appearing at the origin properly. Our idea in this paper is to construct the Green's function $Z^{(n)}$ of the equation $u_t = u_{rr} + (n - 1)u_r/r$, which is the heat equation for radially symmetric solutions. In section 3, we give an explicit expression for the Green's function $Z^{(n)}$ and its estimates. Once we obtain the Green's function $Z^{(n)}$, we will have the expression

$$u(r, t) = \int_0^\infty Z^{(n)}(r, \xi, t)\, u_0(\xi)\, d\xi + \int_0^t \int_0^\infty Z^{(n)}(r, \xi, t - s)\, F_\xi(\xi, s)\, d\xi\, ds. \tag{9}$$

The first term of the right-hand side is the radially symmetric solution of the heat equation with the same initial value. The remaining problem is to estimate $F_r(r, t)$. For this purpose, we show the decay estimates for the derivatives of $u(r, t)$ in section 4. In section 5, we give the proof of Theorem 1.3. We estimate the second term of the right-hand side of (9) by making use of the estimates for the Green's function $Z^{(n)}$ and the derivatives of $u(r, t)$ obtained in sections 3 and 4, respectively.

Here we introduce the notation. $L^\infty(\mathbb{R}^n)$ and $W^{1,\infty}(\mathbb{R}^n)$ denote the Lebesgue and the Sobolev spaces, respectively. For $\alpha \in (0, 1)$, $C^\alpha(\mathbb{R}^n)$ denotes the Hölder space, that is, the space of functions that are bounded and uniformly Hölder continuous with exponent α on $\mathbb{R}^n$. $C^{2+\alpha}(\mathbb{R}^n)$ means the space of functions with $u, u_{x_i}, u_{x_i x_j} \in$

$C^\alpha(\mathbb{R}^n)$. For a domain $R_T = \mathbb{R}^n \times [0,T]$, $C^{\alpha,\alpha/2}(R_T)$ denotes the space of functions that are bounded and uniformly Hölder continuous with exponent α and $\alpha/2$ with respect to x_i and t, respectively, on R_T. $C^{2+\alpha,1+\alpha/2}(R_T)$ means the space of functions that satisfy $u, u_{x_i}, u_{x_i x_j}, u_t \in C^{\alpha,\alpha/2}(R_T)$. The norm in the space $C^{2+\alpha,1+\alpha/2}(R_T)$ is denoted by $\|\cdot\|_{C^{2+\alpha,1+\alpha/2}(R_T)}$.

2. Preliminaries. Before proving our results for large time behavior, we briefly mention the existence and some estimates of the solutions $u(x,t)$ to the problem (1)–(2). Throughout this paper, we always assume that $n \geq 2$ and that an initial value belongs to $C(\mathbb{R}^n) \cap W^{1,\infty}(\mathbb{R}^n)$ even if it is not mentioned specifically. First we introduce the existence result given by Ecker and Huisken [6].

PROPOSITION 2.1 (see [6]). *Suppose that $u_0(x)$ is uniform Lipschitz continuous on $\mathbb{R}^n$. Then there exists a solution $u(x,t)$ of (1)–(2) globally in time. Moreover it satisfies*

$$|\nabla u(x,t)| \leq \|\nabla u_0\|_{L^\infty(\mathbb{R}^n)}, \quad x \in \mathbb{R}^n,\ t > 0. \tag{10}$$

They assumed only uniform Lipschitz continuity of initial surfaces to study the large time behavior of solutions with linear growth. In the present paper, we focus on the large time behavior of bounded solutions and assume that $u_0 \in C(\mathbb{R}^n) \cap W^{1,\infty}(\mathbb{R}^n)$. In this case, the existence of the solution follows directly from Proposition 2.1. In addition, the following estimate holds true.

PROPOSITION 2.2. *Suppose that $u_0(x)$ belongs to $C(\mathbb{R}^n) \cap W^{1,\infty}(\mathbb{R}^n)$. Then there exists a solution $u(x,t)$ of (1)–(2) globally in time. Moreover it belongs to $C^{2+\alpha,1+\alpha/2}(\mathbb{R}^n \times [1,T])$ for any $T > 0$ and satisfies the estimate*

$$\|u\|_{C^{2+\alpha,1+\alpha/2}(\mathbb{R}^n \times [1,T])} \leq C_1, \tag{11}$$

where $C_1 > 0$ is a constant that depends only on n and u_0 and is independent of $T > 0$.

Proof. Proposition 2.1 implies that the solution exists globally in time, and the estimate (10) holds true. The estimate (10) implies that (1) is considered to be a uniformly parabolic equation, and hence the comparison principle is valid. Thus the L^∞-bound for u is obtained, since the constants $\pm\|u_0\|_{L^\infty(\mathbb{R}^n)}$ are both stationary solutions of (1)–(2). The L^∞-bound for u and the estimate (10) imply that

$$\|u_{x_i}\|_{C^{\alpha,\alpha/2}(\mathbb{R}^n \times [1,T])} \leq C \quad \text{for } 1 \leq i \leq n,$$

where $C > 0$ is a constant that depends only on n and u_0 and is independent of $T > 0$. This fact follows from the general theory for quasi-linear parabolic equations. See Chapter XII of [16], for instance. Finally we apply the Schauder theory of linear parabolic equations and hence obtain (11). Thus the proof is completed. ∎

All discussions in this paper will construct on the basis of Propositions 2.1 and 2.2. The existence of solutions to the problem (1)–(2) is obtained also in other papers. For example, Chou and Kwong [3] proved the existence of solutions for smooth initial values without the restriction of growth order.

3. Green's function for radially symmetric solutions. As is mentioned in the introduction, our idea in this paper is to express radially symmetric solutions of (1)–(2) by using the Green's function of the heat equation for radially symmetric solutions. For this purpose, we begin with the Cauchy problem of the heat equation

$$\begin{aligned} &H_t = \Delta H, && x \in \mathbb{R}^n,\ t > 0, \\ &H(x,0) = \Phi(x), && x \in \mathbb{R}^n. \end{aligned}$$

It is well known that the solution $H(x,t)$ is expressed by the heat kernel as follows:

$$H(x,t) = \int_{\mathbb{R}^n} \frac{1}{(4\pi\, t)^{n/2}} \exp\left(-\frac{|x-y|^2}{4t}\right) \Phi(y)\, dy. \tag{12}$$

When the initial value $\Phi(x)$ is radially symmetric, the solution $H(x,t)$ is also radially symmetric. Here we denote $H(x,t)$ and $\Phi(x)$ by $h(r,t)$ and $\varphi(r)$ for $r = |x|$, respectively. Then we have the initial value problem of the heat equation for radially symmetric solutions, that is,

$$h_t = h_{rr} + \frac{n-1}{r} h_r, \quad r > 0,\ t > 0, \tag{13}$$

$$h(r,0) = \varphi(r), \qquad r > 0. \tag{14}$$

By changing the variables in (12) to the polar coordinate system, we obtain an explicit expression for $h(r,t)$, which is useful to our discussions. We give the following proposition.

PROPOSITION 3.1. *The solution $h(r,t)$ of* (13)–(14) *is given by*

$$h(r,t) = \int_0^\infty Z^{(n)}(r,\xi,t)\, \varphi(\xi)\, d\xi, \tag{15}$$

where $Z^{(n)}(r,\xi,t)$ is the function defined by

$$Z^{(n)}(r,\xi,t) = \frac{K_n\, \xi^{n-1}}{(4\pi\, t)^{n/2}} \int_0^\pi \exp\left(-\frac{(r-\xi\cos\theta)^2 + (\xi\sin\theta)^2}{4t}\right) \sin^{n-2}\theta\, d\theta. \tag{16}$$

The constant K_n is given by $K_2 = 2$, $K_3 = 2\pi$, and

$$K_n = \frac{2(2\pi)^{m+1}}{1\cdot 3\cdot 5 \ldots (2m+1)} \qquad \text{if} \quad n = 2m+4 \geq 4, \tag{17}$$

$$K_n = \frac{(2\pi)^{m+2}}{2\cdot 4\cdot 6 \ldots 2(m+1)} \qquad \text{if} \quad n = 2m+5 \geq 5. \tag{18}$$

Proof. First we consider the case of $n = 2$. In this case, we use the polar coordinate system with $x_1 = r\cos\Theta, x_2 = r\sin\Theta$ and denote $H(x,t)$ and $\Phi(x)$ by $\widetilde{H}(r,\Theta,t)$ and $\widetilde{\Phi}(r,\Theta)$, respectively. Then by changing the variables in (12), we have

$$\widetilde{H}(r,\Theta,t) = \int_0^\infty \int_0^{2\pi} \frac{1}{4\pi\, t} \exp\left(-\frac{d(r,\Theta,\xi,\theta)}{4t}\right) \widetilde{\Phi}(\xi,\theta)\, \xi\, d\theta\, d\xi, \tag{19}$$

where $d(r,\Theta,\xi,\theta) = (r\cos\Theta - \xi\cos\theta)^2 + (r\sin\Theta - \xi\sin\theta)^2$. If the initial value $\widetilde{\Phi}(r,\Theta)$ is radially symmetric, the solution $\widetilde{H}(r,\Theta,t)$ is also radially symmetric; that is, $\widetilde{H}(r,\Theta,t)$ is independent of Θ. Thus the solution $h(r,t)$ of (13)–(14) is given by $h(r,t) = \widetilde{H}(r,0,t)$, for example. By setting $\Theta = 0$ in (19), we obtain

$$\begin{aligned} h(r,t) = \widetilde{H}(r,0,t) &= \int_0^\infty \int_0^{2\pi} \frac{1}{4\pi\, t} \exp\left(-\frac{(r-\xi\cos\theta)^2 + (\xi\sin\theta)^2}{4t}\right) \varphi(\xi)\, \xi\, d\theta\, d\xi \\ &= \int_0^\infty \frac{\xi}{2\pi\, t} \int_0^\pi \exp\left(-\frac{(r-\xi\cos\theta)^2 + (\xi\sin\theta)^2}{4t}\right) d\theta\ \varphi(\xi)\, d\xi. \end{aligned}$$

This implies (15)–(16) with $K_2 = 2$. Thus the proof for the case $n = 2$ is completed.

Next we consider the case of $n \geq 3$. In this case, we use the polar coordinate system with

$$\begin{aligned} x_1 &= r\cos\Theta_1, \\ x_2 &= r\sin\Theta_1\cos\Theta_2, \\ x_3 &= r\sin\Theta_1\sin\Theta_2\cos\Theta_3, \\ &\cdots \\ x_{n-1} &= r\sin\Theta_1\sin\Theta_2\ldots\sin\Theta_{n-2}\cos\Theta_{n-1}, \\ x_n &= r\sin\Theta_1\sin\Theta_2\ldots\sin\Theta_{n-2}\sin\Theta_{n-1}, \end{aligned}$$

where

$$(r, \Theta_1, \ldots, \Theta_{n-2}, \Theta_{n-1}) \in [0,\infty) \times [0,\pi] \times \cdots \times [0,\pi] \times [0,2\pi].$$

We denote $H(x,t)$ and $\Phi(x)$ by $\widetilde{H}(r,\mathbf{\Theta},t)$ and $\widetilde{\Phi}(r,\mathbf{\Theta})$ with $\mathbf{\Theta} = (\Theta_1,\ldots,\Theta_{n-1})$, respectively. Then by changing the variables in (12), we have

$$\begin{aligned} \widetilde{H}(r,\mathbf{\Theta},t) = \int_0^\infty \int_0^{2\pi} \int_0^\pi \cdots \int_0^\pi & \frac{1}{(4\pi\, t)^{n/2}} \exp\left(-\frac{d(r,\mathbf{\Theta},\xi,\boldsymbol{\theta})}{4t}\right) \widetilde{\Phi}(\xi,\boldsymbol{\theta}) \\ & \times \xi^{n-1} \sin^{n-2}\theta_1 \,\ldots\, \sin\theta_{n-2}\;\; d\theta_1 \,\ldots\, d\theta_{n-1}\, d\xi, \end{aligned}$$

where $\boldsymbol{\theta} = (\theta_1,\ldots,\theta_{n-1})$ and the function $d(r,\mathbf{\Theta},\xi,\boldsymbol{\theta})$ is given by

$$\begin{aligned} d(r,\mathbf{\Theta},\xi,\boldsymbol{\theta}) = {} & (r\cos\Theta_1 - \xi\cos\theta_1)^2 \\ & + (r\sin\Theta_1\cos\Theta_2 - \xi\sin\theta_1\cos\theta_2)^2 \\ & + \cdots \\ & + (r\sin\Theta_1\ldots\sin\Theta_{n-2}\cos\Theta_{n-1} - \xi\sin\theta_1\ldots\sin\theta_{n-2}\cos\theta_{n-1})^2 \\ & + (r\sin\Theta_1\ldots\sin\Theta_{n-2}\sin\Theta_{n-1} - \xi\sin\theta_1\ldots\sin\theta_{n-2}\sin\theta_{n-1})^2. \end{aligned}$$

Similarly to the case of $n = 2$, the solution $h(r,t)$ of (13)–(14) is given by $h(r,t) = \widetilde{H}(r,\mathbf{0},t)$, with $\mathbf{0} = (0,\ldots,0)$. By setting $\mathbf{\Theta} = \mathbf{0}$, we have

$$\begin{aligned} d(r,\mathbf{0},\xi,\boldsymbol{\theta}) &= (r - \xi\cos\theta_1)^2 + (\xi\sin\theta_1\cos\theta_2)^2 \\ & \quad + \cdots \\ & \quad + (\xi\sin\theta_1\ldots\sin\theta_{n-2}\cos\theta_{n-1})^2 + (\xi\sin\theta_1\ldots\sin\theta_{n-2}\sin\theta_{n-1})^2 \\ &= (r - \xi\cos\theta_1)^2 + (\xi\sin\theta_1)^2. \end{aligned}$$

Thus $h(r,t)$ is given as follows:

$$\begin{aligned} h(r,t) &= \int_0^\infty \int_0^\pi \frac{1}{(4\pi\, t)^{n/2}} \exp\left(-\frac{d_0(r,\xi,\theta_1)}{4t}\right) \varphi(\xi)\, \xi^{n-1} \sin^{n-2}\theta_1\, d\theta_1\, d\xi \\ & \quad \times \int_0^\pi \sin^{n-3}\theta_2\, d\theta_2 \times \cdots \times \int_0^\pi \sin\theta_{n-2}\, d\theta_{n-2} \times \int_0^{2\pi} d\theta_{n-1} \\ &= \int_0^\infty \frac{\xi^{n-1}}{(4\pi\, t)^{n/2}} \int_0^\pi \exp\left(-\frac{d_0(r,\xi,\theta_1)}{4t}\right) \sin^{n-2}\theta_1\, d\theta_1\, \varphi(\xi)\, d\xi \\ & \quad \times \prod_{i=1}^{n-3} \int_0^\pi \sin^i\theta\, d\theta \times 2\pi, \end{aligned}$$

where $d_0(r,\xi,\theta_1) = (r-\xi\cos\theta_1)^2 + (\xi\sin\theta_1)^2$. By setting $K_n = 2\pi\prod_{i=1}^{n-3}\int_0^\pi \sin^i\theta\,d\theta$ for $n \geq 4$ and $K_3 = 2\pi$, we obtain (15)–(16). Here K_n for $n \geq 4$ is given by (17)–(18), since we have

$$\int_0^\pi \sin^i\theta\,d\theta = \pi\cdot\frac{1\cdot 3\cdot 5\ldots(2m-1)}{2\cdot 4\cdot 6\ldots 2m} \quad \text{for} \quad i = 2m,$$
$$\int_0^\pi \sin^i\theta\,d\theta = 2\cdot\frac{2\cdot 4\cdot 6\ldots 2m}{1\cdot 3\cdot 5\ldots(2m+1)} \quad \text{for} \quad i = 2m+1.$$

This completes the proof. $\square$

For later discussions, we need some properties of the Green's function $Z^{(n)}(r,\xi,t)$. These properties look like that of the usual heat kernel.

LEMMA 3.2. *The function $Z^{(n)}(r,\xi,r)$ defined in Proposition 3.1 has the following properties:*

(i) *For every $r \geq 0$, it satisfies*

$$\int_0^\infty |Z^{(n)}(r,\xi,t)|\,d\xi = \int_0^\infty Z^{(n)}(r,\xi,t)\,d\xi = 1, \quad t > 0.$$

(ii) *For every $r \geq 0$, it satisfies*

$$\int_0^\infty |Z_\xi^{(n)}(r,\xi,t)|\,d\xi \leq C_2\,t^{-\frac{1}{2}}, \quad t > 0.$$

(iii) *For every ξ with $0 \leq \xi \leq 1$, it satisfies*

$$\sup_{r\geq 2}|Z^{(n)}(r,\xi,t)| \leq C_3\,(1+t)^{-\frac{n}{2}}, \quad t > 0,$$

where $C_2 > 0$ and $C_3 > 0$ are constants depending only on n.

Proof. First we show property (i). By the definition of $Z^{(n)}$, it is obvious that

$$\int_0^\infty Z^{(n)}(r,\xi,t)\,d\xi = \int_{\mathbb{R}^n}\frac{1}{(4\pi\,t)^{n/2}}\exp\left(-\frac{|x-y|^2}{4t}\right)dy = 1, \quad t > 0,$$

holds true for $|x| = r$. In addition, $Z^{(n)}(r,\xi,t) > 0$ also holds true. Thus we obtain property (i).

Next we show property (iii). By the definition of $Z^{(n)}$, we have

$$|Z^{(n)}(r,\xi,t)| \leq \frac{K_n}{(4\pi\,t)^{n/2}}\int_0^\pi \exp\left(-\frac{1}{4t}\right)\sin^{n-2}\theta\,d\theta, \quad t > 0,$$

for $0 \leq \xi \leq 1$ and $r \geq 2$. This implies that

$$\sup_{r\geq 2}|Z^{(n)}(r,\xi,t)| \leq \min\left\{\frac{K_n}{(4\pi\,t)^{n/2}},\ C\right\}, \quad t > 0,$$

for every ξ with $0 \leq \xi \leq 1$, where C is a constant depending only on n. Thus we obtained property (iii).

Finally we show property (ii). For simplicity, we define a function $E^{(n)}$ as

$$E^{(n)}(r,\xi,\theta,t) = \frac{K_n}{(4\pi\,t)^{n/2}}\exp\left(-\frac{(r-\xi\cos\theta)^2+(\xi\sin\theta)^2}{4t}\right).$$

Then by definition, we have

$$\int_0^\infty |Z_\xi^{(n)}|\,d\xi \le \int_0^\infty \int_0^\pi \left| \left(\xi^{n-1} E^{(n)} \sin^{n-2}\theta\right)_\xi \right| d\xi\, d\theta$$
$$\le \int_0^\pi \int_0^\infty \left[(n-1)\xi^{n-2}E^{(n)} + \xi^{n-1}|E_\xi^{(n)}|\right] \sin^{n-2}\theta\, d\xi\, d\theta.$$

Noting that $E_\xi^{(n)} = (r\cos\theta - \xi)/2t \cdot E^{(n)}$ and $E^{(n)} > 0$, we divide it into four terms as follows:

$$\int_0^\infty |Z_\xi^{(n)}|\,d\xi \le \int_0^\pi \int_0^\infty (n-1)\xi^{n-2}E^{(n)} \sin^{n-2}\theta\, d\xi\, d\theta$$
$$+ \left(-\int_{\frac{\pi}{2}}^\pi \int_0^\infty - \int_0^{\frac{\pi}{2}} \int_{r\cos\theta}^\infty + \int_0^{\frac{\pi}{2}} \int_0^{r\cos\theta} \right) \xi^{n-1} E_\xi^{(n)} \sin^{n-2}\theta\, d\xi\, d\theta$$
$$= \int_0^\pi \int_0^\infty (n-1)\xi^{n-2}E^{(n)} \sin^{n-2}\theta\, d\xi\, d\theta + J_1 + J_2 + J_3.$$

By integrating by parts, we have

$$J_1 = \int_{\frac{\pi}{2}}^\pi \int_0^\infty (n-1)\, \xi^{n-2} E^{(n)} \sin^{n-2}\theta\, d\xi\, d\theta,$$
$$J_2 = \int_0^{\frac{\pi}{2}} \left[\xi^{n-1}E^{(n)}\right]_{\xi = r\cos\theta} \sin^{n-2}\theta\, d\theta + \int_0^{\frac{\pi}{2}} \int_{r\cos\theta}^\infty (n-1)\, \xi^{n-2} E^{(n)} \sin^{n-2}\theta\, d\xi\, d\theta,$$
$$J_3 = \int_0^{\frac{\pi}{2}} \left[\xi^{n-1}E^{(n)}\right]_{\xi = r\cos\theta} \sin^{n-2}\theta\, d\theta - \int_0^{\frac{\pi}{2}} \int_0^{r\cos\theta} (n-1)\, \xi^{n-2} E^{(n)} \sin^{n-2}\theta\, d\xi\, d\theta.$$

By combining these results, we have

$$\int_0^\infty |Z_\xi^{(n)}|\,d\xi \le 2 \int_0^{\frac{\pi}{2}} \left[\xi^{n-1}E^{(n)}\right]_{\xi = r\cos\theta} \sin^{n-2}\theta\, d\theta$$
$$+ 2 \int_0^\pi \int_0^\infty (n-1)\xi^{n-2}E^{(n)} \sin^{n-2}\theta\, d\xi\, d\theta = J_4 + J_5.$$

Here J_4 is estimated as

$$J_4 = 2\int_0^{\frac{\pi}{2}} (r\cos\theta)^{n-1} \frac{K_n}{(4\pi\, t)^{n/2}} \exp\left(-\frac{(r\sin\theta)^2}{4t}\right) \sin^{n-2}\theta\, d\theta$$
$$\le \frac{K_n}{\pi^{n/2}} \cdot t^{-\frac{1}{2}} \int_0^\infty z^{n-2} \exp\left(-z^2\right) dz = C\, t^{-\frac{1}{2}},$$

where C is a constant depending only on n. For J_5, we have

$$J_5 = \frac{2\,K_n}{\sqrt{4\pi t}\, K_{n-1}} \int_0^\pi \int_0^\infty (n-1)\xi^{n-2}E^{(n-1)} \sin^{n-2}\theta\, d\xi\, d\theta$$
$$= \widehat{C}\, t^{-\frac{1}{2}} \int_0^\pi \int_0^\infty \xi^{n-2} E^{(n-1)} \sin^{n-3}\theta \cdot \sin\theta\, d\xi\, d\theta$$
$$\le \widehat{C}\, t^{-\frac{1}{2}} \int_0^\infty Z^{(n-1)}\, d\xi = \widehat{C}\, t^{-\frac{1}{2}} \quad \text{if } n \ge 3.$$

If $n = 2$, we have

$$\begin{aligned} J_5 &= 2\int_0^{\pi}\int_0^{\infty} E^{(2)}\,d\xi\,d\theta = 2\int_0^{\pi}\int_0^{\infty} \frac{K_2}{4\pi\,t}\exp\left(-\frac{(r-\xi\cos\theta)^2+(\xi\sin\theta)^2}{4t}\right)d\xi\,d\theta \\ &\le \int_0^{\pi}\int_0^{\infty}\frac{K_2}{2\pi\,t}\exp\left(-\frac{(\xi-r\cos\theta)^2}{4t}\right)d\xi\,d\theta \\ &= \frac{K_2}{\pi}\,t^{-\frac{1}{2}}\int_0^{\pi}\int_{-\infty}^{\infty}\exp\left(-z^2\right)\,dz\,d\theta = \widetilde{C}\,t^{-\frac{1}{2}}, \end{aligned}$$

where $\widetilde{C}$ is a constant depending only on n. Thus we obtain property (ii). This completes the proof. ∎

Finally we give an expression for radially symmetric solutions of (1)–(2) by using the Green's function $Z^{(n)}(r,\xi,t)$ obtained above. This expression plays an essential role in our discussion.

Lemma 3.3. *Let $u(r,t)$ be the solution to the initial value problem of the form*

$$u_t = \frac{u_{rr}}{1+u_r^2} + \frac{n-1}{r}u_r, \quad r>0,\ t>0, \tag{20}$$

$$u(r,0) = u_0(r), \qquad r>0. \tag{21}$$

Then the solution $u(r,t)$ of (20)–(21) *is expressed by*

$$u(r,t) = \int_0^{\infty} Z^{(n)}(r,\xi,t)\,u_0(\xi)\,d\xi - \int_0^t\int_0^{\infty} Z^{(n)}(r,\xi,t-s)\,\frac{u_{\xi\xi}\,u_\xi^2}{1+u_\xi^2}\,d\xi\,ds, \tag{22}$$

where the function $Z^{(n)}(r,\xi,t)$ is defined as in Proposition 3.1.

Proof. Since (1) is rewritten as

$$u_t = \Delta u - \sum_{i,j=1}^{n}\frac{u_{x_i}u_{x_j}u_{x_ix_j}}{1+|\nabla u|^2},$$

we have the expression

$$\begin{aligned} u(x,t) &= \int_{\mathbb{R}^n}\frac{1}{(4\pi\,t)^{n/2}}\exp\left(-\frac{|x-y|^2}{4t}\right)u_0(y)\,dy \\ &\quad - \sum_{i,j=1}^{n}\int_0^t\int_{\mathbb{R}^n}\frac{1}{(4\pi(t-s))^{n/2}}\exp\left(-\frac{|x-y|^2}{4(t-s)}\right)\frac{u_{y_i}u_{y_j}u_{y_iy_j}}{1+|\nabla u|^2}\,dy\,ds. \end{aligned}$$

If the solution $u(x,t)$ is radially symmetric, we have $\partial/\partial x_i = x_i/r\cdot\partial/\partial r$ and hence obtain

$$\sum_{i,j=1}^{n}\frac{u_{x_i}u_{x_j}u_{x_ix_j}}{1+|\nabla u|^2} = \frac{u_{rr}u_r^2}{1+u_r^2}.$$

Thus we obtain (22) by changing the variables to the polar coordinate system similarly to the proof of Proposition 3.1. This completes the proof. ∎

4. Decay estimates for the derivatives. In this section, we show the decay estimates for derivatives of radially symmetric solutions of (1)–(2). When we consider radially symmetric solutions, the problem (1)–(2) is rewritten as follows:

$$u_t = \frac{u_{rr}}{1+u_r^2} + \frac{n-1}{r}u_r, \qquad r>0,\ t>0, \tag{23}$$

$$u(r,0) = u_0(r), \qquad r>0, \tag{24}$$

$$u_r(0,t)=0,\ u_{tr}(0,t)=0, \quad t>0, \tag{25}$$

where $r=|x|$. The boundary condition (25) is necessary to derive the decay estimates for the derivatives. In what follows, we focus on this problem to study the large time behavior of radially symmetric solutions.

First we prepare maximum principles. In Chapter 2 of [10], the maximum principle for the Cauchy problem of usual parabolic equations is given. As a modification of discussions in [10], we provide the maximum principles on the half-space with the Neumann boundary condition. We need to take care of the coefficient $(n-1)/r$ in (23).

LEMMA 4.1. *Let $g=g(r,t)$ be a continuous and bounded function for $r\ge 0$ and $t\ge 0$. Suppose that a function $w=w(r,t)$ is continuous and bounded for $r\ge 0$ and $t\ge 0$, has continuous derivatives w_t, w_r, w_{rr} for $r\ge 0$ and $t>0$, and satisfies*

$$\begin{aligned} &L[w] = w_t - \frac{w_{rr}}{1+g^2} - \frac{n-1}{r}w_r \le 0, \quad && r>0,\ t>0,\\ &w_r(0,t)=0, && t>0. \end{aligned}$$

Then $w(r,t)$ satisfies

$$\sup_{r>0,\ t>0} w(r,t) \le \|w(r,0)\|_{L^\infty(0,\infty)}.$$

Proof. We define a function

$$E(r,t) = \exp\left(\frac{r^2}{1-\mu t}+\nu t\right) \quad \text{on } R_0 = [0,\infty)\times\left[0,\frac{1}{2\mu}\right].$$

By taking constants $\mu=16$ and $\nu>4n$, we have $L[E]/E>0$ on R_0. Indeed, because of $1/2\le 1-\mu t\le 1$, it follows that

$$\begin{aligned} \frac{L[E]}{E} &= \frac{1}{E}\left(E_t - \frac{E_{rr}}{1+g^2} - \frac{n-1}{r}E_r\right)\\ &= \frac{\mu r^2}{(1-\mu t)^2} + \nu - \frac{1}{1+g^2}\left(\frac{2}{1-\mu t}+\frac{4r^2}{(1-\mu t)^2}\right) - \frac{n-1}{r}\cdot\frac{2r}{1-\mu t}\\ &\ge \mu r^2 + \nu - (4+16r^2) - 4(n-1) = \nu - 4n. \end{aligned}$$

For the constant $M=\|w(r,0)\|_{L^\infty(0,\infty)}$, we consider the function $v=(w-M)/E$ on R_0. Then v satisfies

$$v_t - \frac{v_{rr}}{1+g^2} - \frac{n-1}{r}v_r - \frac{2E_r}{E(1+g^2)}v_r + \frac{L[E]}{E}v \le 0, \tag{26}$$

$$v(r,0)\le 0. \tag{27}$$

Moreover $\lim_{r\to\infty} v(r,t)=0$ holds true for $0\le t\le 1/2\mu$, since w is bounded by the assumption. Thus the inequality (27) implies that v satisfies one of the following:

(i) v takes the positive maximum on R_0 at a point $(0, t_0)$ with $0 < t_0 \leq 1/2\mu$.

(ii) v takes the positive maximum on R_0 at a point (r_0, t_0) with $r_0 > 0$ and $0 < t_0 \leq 1/2\mu$.

(iii) $v(x, t) \leq 0$ on R_0.

Case (i) cannot happen. Indeed, by passing to the limit as $r \to 0$ in (26), we have

$$v_t(0,t) - \left(\frac{1}{1+g^2} + (n-1)\right) v_{rr}(0,t) + \frac{L[E]}{E} v(0,t) \leq 0, \tag{28}$$

by the boundary condition $v_r(0,t) = 0$. On the other hand, we have $v_t(0, t_0) \geq 0$, $v_{rr}(0, t_0) \leq 0$, and $v(0, t_0) > 0$, since $v(0, t_0)$ is the positive maximum. Because of $L[E]/E > 0$, these values do not satisfy (28). This is a contradiction.

Case (ii) also leads to a contradiction. Indeed, for any $R > 0$, v takes the positive maximum on $[r_0/2, r_0 + R] \times [0, 1/2\mu]$ at the interior point (r_0, t_0). Thus the strong maximum principle implies that v is positive and constant on $[r_0/2, r_0 + R] \times [0, 1/2\mu]$. Since $R > 0$ is arbitrary, this contradicts $\lim_{r\to\infty} v(r,t) = 0$.

Consequently, case (iii) holds true. Namely, we have $v = (w - M)/E \leq 0$ on R_0. Since E is positive, this implies that $w \leq M$ on R_0. By repeating a similar argument for $t \geq 1/2\mu$, we obtain $w \leq M$ for $r \geq 0$ and $t \geq 0$. This completes the proof. ∎

Similarly to the above, we obtain the following lemma. Here the equation differs slightly from that of Lemma 4.1.

LEMMA 4.2. *Let $g = g(r, t)$ be a given function such that g and g_r are continuous and bounded for $r \geq 0$ and $t \geq 0$. Suppose that a function $w = w(r, t)$ is continuous and bounded for $r \geq 0$ and $t \geq 0$, has continuous derivatives w_t, w_r, w_{rr} for $r \geq 0$ and $t > 0$, and satisfies*

$$\begin{aligned} &L[w] = w_t - \left(\frac{w_r}{1+g^2}\right)_r - \frac{n-1}{r} w_r \leq 0, && r > 0,\ t > 0, \\ &w_r(0,t) = 0, && t > 0. \end{aligned}$$

Then $w(r,t)$ satisfies

$$\sup_{r>0,\, t>0} w(r,t) \leq \|w(r,0)\|_{L^\infty(0,\infty)}.$$

Proof. We define a function

$$E(r,t) = \exp\left(\frac{r^2}{1-\mu t} + \nu t\right) \quad \text{on } R_0 = [0,\infty) \times \left[0, \frac{1}{2\mu}\right].$$

By taking constants $\mu \geq 16 + 8\|gg_r\|_{L^\infty((0,\infty)\times(0,\infty))}$ and $\nu > 4n + 8\|gg_r\|_{L^\infty((0,\infty)\times(0,\infty))}$, we have $L[E]/E > 0$ on R_0. Indeed, because of $1/2 \leq 1 - \mu t \leq 1$, we have

$$\begin{aligned} \frac{L[E]}{E} &= \frac{1}{E}\left(E_t - \left(\frac{E_r}{1+g^2}\right)_r - \frac{n-1}{r}E_r\right) \\ &= \frac{\mu r^2}{(1-\mu t)^2} + \nu - \frac{1}{1+g^2}\left(\frac{2}{1-\mu t} + \frac{4r^2}{(1-\mu t)^2}\right) + \frac{2gg_r}{(1+g^2)^2}\frac{2r}{1-\mu t} - \frac{n-1}{r}\frac{2r}{1-\mu t} \\ &\geq \mu r^2 + \nu - (4 + 16r^2) - 8\|gg_r\|_{L^\infty((0,\infty)\times(0,\infty))} \cdot r - 4(n-1) \\ &\geq \left(\mu - 16 - 8\|gg_r\|_{L^\infty((0,\infty)\times(0,\infty))}\right) r^2 + \nu - 4n - 8\|gg_r\|_{L^\infty((0,\infty)\times(0,\infty))}. \end{aligned}$$

For the constant $M = \|w(r,0)\|_{L^\infty(0,\infty)}$, we consider the function $v = (w-M)/E$ on R_0. Then v satisfies

$$\begin{aligned}&v_t - \left(\frac{v_r}{1+g^2}\right)_r - \frac{n-1}{r}v_r - \frac{2E_r}{E(1+g^2)}v_r + \frac{L[E]}{E}v \le 0,\\ &v(r,0) \le 0.\end{aligned}$$

Moreover $\lim_{r\to\infty} v(r,t) = 0$ holds true for $0 \le t \le 1/2\mu$. Thus, similarly to the proof of Lemma 4.1, we obtain $w \le M$ on R_0. By repeating a similar argument for $t \ge 1/2\mu$, we obtain $w \le M$ for $r \ge 0$ and $t \ge 0$. This completes the proof. □

Now we show the decay estimates for derivatives of the solution of (23)–(25). The following estimate for $|u_t|$ is derived by using the idea of Ecker and Huisken [6].

PROPOSITION 4.3. *The solution $u(r,t)$ of (23)–(25) satisfies the following estimate:*

$$\sup_{r>0} |u_t(r,t)| \le C_4\, t^{-\frac{1}{2}}, \quad t \ge 1, \tag{29}$$

where $C_4 > 0$ is a constant depending only on n and u_0.

Proof. For the solution $u(r,t)$ of (23)–(25), we define an operator L as follows:

$$L[w] = w_t - \left(\frac{w_r}{1+u_r^2}\right)_r - \frac{n-1}{r}w_r.$$

We consider a function $V(r,t)$ defined by

$$V(r,t) = u_r^2 + \frac{t}{n-1}u_t^2.$$

Here we note that $V(r,t)$ is continuous and bounded for $r \ge 0$ and $t \ge 1$ by virtue of the estimate (11) in Proposition 2.2. Then we obtain

$$L[V] = L[u_r^2] + \frac{1}{n-1}\,u_t^2 + \frac{t}{n-1}\,L[u_t^2] \le -\frac{u_t^2}{n-1} + \frac{1}{n-1}u_t^2 = 0.$$

Indeed, we have

$$\begin{aligned}L[u_r^2] &= -\frac{2u_{rr}^2}{1+u_r^2} - \frac{2(n-1)}{r^2}u_r^2 \le -\frac{2}{n-1}\left[\left(\frac{u_{rr}}{1+u_r^2}\right)^2 + \left(\frac{n-1}{r}u_r\right)^2\right]\\ &\le -\frac{1}{n-1}\left(\frac{u_{rr}}{1+u_r^2} + \frac{n-1}{r}u_r\right)^2 = -\frac{u_t^2}{n-1},\\ L[u_t^2] &= -\frac{2u_{rt}^2}{1+u_r^2} \le 0.\end{aligned}$$

Since the boundary condition (25) gives

$$V_r(0,t) = \left.\left(2u_r u_{rr} + \frac{2t}{n-1}u_t u_{tr}\right)\right|_{r=0} = 0, \quad t > 0,$$

we can apply Lemma 4.2 and hence obtain

$$\sup_{r>0} V(r,t) = \sup_{r>0}\left(u_r^2 + \frac{t}{n-1}u_t^2\right) \le \|V(r,1)\|_{L^\infty(0,\infty)}.$$

The estimate (11) in Proposition 2.2 implies that $\|V(r,1)\|_{L^\infty(0,\infty)}$ depends only on n and u_0. Thus the decay estimate (29) follows. This completes the proof. $\square$

Next we use a similar technique for deriving the decay estimate for $|u_r|$. Note that the definition of the operator L differs slightly from that in Proposition 4.3.

Proposition 4.4. *The solution $u(r,t)$ of (23)–(25) satisfies the following estimate:*

$$\sup_{r>0} |u_r(r,t)| \le C_5\,(1+t)^{-\frac{1}{2}}, \quad t \ge 0, \tag{30}$$

where $C_5 > 0$ is a constant depending only on $\|u_0\|_{W^{1,\infty}(0,\infty)}$.

Proof. For the solution $u(r,t)$ of (23)–(25), we define an operator L as follows:

$$L[w] = w_t - \frac{w_{rr}}{1+u_r^2} - \frac{n-1}{r} w_r.$$

We denote the derivative of $u_0(r)$ with respect to r by $u_0'(r)$. For the constant $M = \|u_0'\|_{L^\infty(0,\infty)}$, we consider a function $V(r,t)$ defined by

$$V(r,t) = u^2 + \frac{1+t}{1+M^2} u_r^2.$$

Since Proposition 2.1 gives $|u_r| \le M$, we have

$$L[V] = L[u^2] + \frac{1}{1+M^2}\, u_r^2 + \frac{1+t}{1+M^2}\, L[u_r^2] \le -\frac{2u_r^2}{1+u_r^2} + \frac{1}{1+M^2} u_r^2 \le 0.$$

Indeed, we have

$$L[u^2] = -\frac{2u_r^2}{1+u_r^2} \quad \text{and} \quad L[u_r^2] = -\frac{4u_r^2 u_{rr}^2}{(1+u_r^2)^2} - \frac{2(n-1)}{r^2} u_r^2 - \frac{2u_{rr}^2}{1+u_r^2} \le 0.$$

Noting that

$$V_r(0,t) = \left(2uu_r + \frac{2(1+t)}{1+M^2} u_r u_{rr}\right)\bigg|_{r=0} = 0, \quad t > 0,$$

we apply Lemma 4.1 and hence obtain

$$\sup_{r>0} V(r,t) = \sup_{r>0} \left(u^2 + \frac{1+t}{1+M^2} u_r^2\right) \le \|u_0\|^2_{L^\infty(0,\infty)} + \frac{\|u_0'\|^2_{L^\infty(0,\infty)}}{1+M^2}, \quad t \ge 0.$$

This implies the estimate (30). This completes the proof. $\square$

Now we give the decay estimate for $|u_{rr}|$ by combining the estimates established above. The following estimate may have room for improvement. But this suffices to prove Theorem 1.3.

Proposition 4.5. *The solution $u(r,t)$ of (23)–(25) satisfies the following estimate:*

$$|u_{rr}(r,t)| \le C_6 \cdot \min\left\{1, \frac{1}{r}\, t^{-\frac{1}{2}}\right\}, \quad r > 0,\ t \ge 1, \tag{31}$$

where $C_6 > 0$ is a constant depending only on n and u_0.

Proof. The estimate (11) in Proposition 2.2 implies that $|u_{rr}|$ is bounded uniformly for $t \ge 1$. On the other hand, by substituting the decay estimates for $|u_t|$ and

$|u_r|$ to (23), we find that $|u_{rr}|$ decays with the rate of $1/r \times t^{-1/2}$. Thus we obtain the estimate (31). ∎

Theorem 1.3 will be proved in section 5 by using the decay estimates for $|u_r|$ and $|u_{rr}|$ given by Propositions 4.4 and 4.5. Finally, we modify the proof of Proposition 4.3 and improve the estimate for $|u_t|$ which, however, will not be used in the later discussions.

Proposition 4.6. *The solution $u(r,t)$ of (23)–(25) satisfies the following estimate:*

$$\sup_{r>0} |u_t(r,t)| \le C_7\, t^{-1}\sqrt{\log t}, \quad t > e^2, \tag{32}$$

where $C_7 > 0$ is a constant depending only on n and u_0.

Proof. Similarly to the proof of Proposition 4.3, we define an operator L as follows:

$$L[w] = w_t - \left(\frac{w_r}{1+u_r^2}\right)_r - \frac{n-1}{r} w_r.$$

Let σ be any constant with $0 < \sigma < 1/2$. We consider a function $V(r,t)$ defined by

$$V(r,t) = t^{1-\sigma} u_r^2 + \frac{t^{2-\sigma}}{(2-\sigma)(n-1)} u_t^2,$$

where $V(r,t)$ is continuous and bounded for $r \ge 0$ and $t \ge 1$ from Proposition 2.2. By noting that the inequalities $L[u_r^2] \le -u_t^2/(n-1)$ and $L[u_t^2] \le 0$ hold true as in the proof of Proposition 4.3, we have

$$\begin{aligned} L[V] &= (1-\sigma)\, t^{-\sigma} u_r^2 + t^{1-\sigma} L[u_r^2] + \frac{t^{1-\sigma}}{n-1}\, u_t^2 + \frac{t^{2-\sigma}}{(2-\sigma)(n-1)}\, L[u_t^2] \\ &\le (1-\sigma)\, t^{-\sigma} u_r^2. \end{aligned}$$

By substituting the decay estimate for $|u_r|$ established in Proposition 4.4, we have

$$L[V] \le C(1-\sigma)\, t^{-(1+\sigma)},$$

where $C > 0$ is a constant depending only on u_0. Now we define

$$P(t) = \|V(r,1)\|_{L^\infty(0,\infty)} + \frac{C(1-\sigma)}{\sigma}\left(1 - t^{-\sigma}\right)$$

for $t \ge 1$. Then we find that $\widehat{V}(r,t) = V(r,t) - P(t)$ satisfies $L[\widehat{V}] \le 0$ and $\widehat{V}(r,1) \le 0$. Thus Lemma 4.2 gives $\widehat{V}(r,t) \le 0$ for $t \ge 1$, and thus

$$V(r,t) \le P(t) \le P(\infty) = \|V(r,1)\|_{L^\infty(0,\infty)} + \frac{C(1-\sigma)}{\sigma}, \quad t \ge 1.$$

Since $0 < \sigma < 1/2$ by the definition, this implies that

$$\begin{aligned} t^{2-\sigma} u_t^2 &\le (2-\sigma)(n-1)\left(\|V(r,1)\|_{L^\infty(0,\infty)} + \frac{C(1-\sigma)}{\sigma}\right) \\ &\le \frac{2(n-1)}{\sigma}\left(\|V(r,1)\|_{L^\infty(0,\infty)} + C\right), \quad t \ge 1. \end{aligned}$$

Here $\|V(r,1)\|_{L^\infty(0,\infty)}$ depends only on n and u_0 from Proposition 2.2. Consequently, there exists a constant $\widetilde{C} > 0$ depending only on n and u_0 such that, for any constant $0 < \sigma < 1/2$, it holds that

$$|u_t| \le \frac{\widetilde{C}}{\sqrt{\sigma}}\, t^{-1+\frac{\sigma}{2}}, \quad t \ge 1.$$

Now we set $\sigma = 1/\log t$ for each $t \ge 1$. Here we assume that $t > e^2$ for $\sigma < 1/2$. Then we have

$$|u_t| \le \frac{\widetilde{C}}{\sqrt{\sigma}} \cdot t^{-1} \exp\left(\log t \cdot \frac{\sigma}{2}\right) = \widetilde{C}\sqrt{\log t} \cdot t^{-1}\sqrt{e}, \quad t > e^2.$$

This implies the estimate (32). The proof is completed. ∎

5. Proof of Theorem 1.3. In this section, we give a proof of Theorem 1.3. We analyze the expression for $u(r,t)$ obtained in Lemma 3.3 by using the properties of the Green's function $Z^{(n)}(r,\xi,r)$ and the decay estimates for the derivatives u_r and u_{rr}.

Proof of Theorem 1.3. Proposition 2.1 gives the existence of the solution globally in time. It suffices to show large time behavior of the solution. In this proof, we always write C or $\widetilde{C}$ for positive constants depending only on n and u_0, which may take a different value in each context. From Lemma 3.3, the solution $u(r,t)$ of (23)–(25) is given by

$$\begin{aligned} u(r,t) &= \int_0^\infty Z^{(n)}(r,\xi,t)\, u_0(\xi)\, d\xi - \int_0^t \int_0^\infty Z^{(n)}(r,\xi,t-s)\, \frac{u_{\xi\xi}u_\xi^2}{1+u_\xi^2}\, d\xi\, ds \\ &= h(r,t) - \int_0^t \int_0^\infty Z^{(n)}(r,\xi,t-s)\, \frac{u_{\xi\xi}u_\xi^2}{1+u_\xi^2}\, d\xi\, ds. \end{aligned}$$

Since the function $h(r,t)$ is the solution of the Cauchy problem of the heat equation, it suffices to show the decay estimate for the second term of the right-hand side. For this purpose, we divide it into two terms and define I, I_1, and I_2 as follows:

$$I = -\left(\int_0^{t/2} + \int_{t/2}^t\right) \int_0^\infty Z^{(n)}(r,\xi,t-s)\, \frac{u_{\xi\xi}u_\xi^2}{1+u_\xi^2}\, d\xi\, ds = -(I_1 + I_2).$$

First we evaluate I_1. By noting that $u_{\xi\xi}u_\xi^2/(1+u_\xi^2) = (u_\xi - \arctan u_\xi)_\xi$ and integrating I_1 by parts, we have

$$|I_1| \le \int_0^{t/2} \int_0^\infty |Z_\xi^{(n)}|\, |u_\xi - \arctan u_\xi|\, d\xi\, ds.$$

Here the Taylor expansion for $f(p) = \arctan p$ implies that

$$\begin{aligned} |p - f(p)| &= \left| p - \left(f(0) + f'(0)\,p + \frac{f''(0)}{2}\, p^2 + \frac{f'''(\delta p)}{3!}\, p^3 \right) \right| \\ &= \left| \frac{3(\delta p)^2 - 1}{3(1+(\delta p)^2)^3}\, p^3 \right| \le |p|^3 \end{aligned}$$

for a constant δ with $0<\delta<1$. Thus by virtue of property (ii) of $Z^{(n)}$ in Lemma 3.2 and the decay estimate for $|u_r|$ in Proposition 4.4, we obtain

$$\begin{aligned}|I_1| &\le \int_0^{t/2}\int_0^\infty |Z_\xi^{(n)}|\,|u_\xi|^3\,d\xi\,ds \le C\int_0^{t/2}(t-s)^{-\frac12}(1+s)^{-\frac32}\,ds\\ &\le \sqrt{2}\,C\,t^{-\frac12}\int_0^{t/2}(1+s)^{-\frac32}\,ds \le 2\sqrt{2}\,C\,t^{-\frac12},\quad t>0.\end{aligned}$$

Next we evaluate $|I_2|$. We divide I_2 into three terms as follows:

$$\begin{aligned}I_2 &= -\int_{t/2}^t\left(\int_0^{s^{-\frac12}}+\int_{s^{-\frac12}}^1+\int_1^\infty\right)Z^{(n)}(r,\xi,t-s)\,\frac{u_{\xi\xi}u_\xi^2}{1+u_\xi^2}\,d\xi\,ds\\ &= -(I_{21}+I_{22}+I_{23}).\end{aligned}$$

Here we assume that $t\ge 2$ for $s^{-1/2}\le 1$. To evaluate I_{21}, we use the decay estimate for $|u_r|$ given by Proposition 4.4 and the L^∞-bounds for $Z^{(n)}$ and $|u_{rr}|$ given by property (iii) of Lemma 3.2 and Proposition 4.5. Then, for $r\ge 2$, we have

$$\begin{aligned}|I_{21}| &\le \int_{t/2}^t\int_0^{s^{-\frac12}}\left|Z^{(n)}(r,\xi,t-s)\right|\left|\frac{u_{\xi\xi}u_\xi^2}{1+u_\xi^2}\right|d\xi\,ds \le C\int_{t/2}^t\int_0^{s^{-\frac12}} s^{-1}\,d\xi\,ds\\ &= C\int_{t/2}^t s^{-\frac32}\,ds \le 2\sqrt{2}\,C\,t^{-\frac12},\quad t\ge 2.\end{aligned}$$

Next, for I_{22}, we use property (iii) of $Z^{(n)}$ and the decay estimates for $|u_{rr}|$ and $|u_r|$. Then, for $r\ge 2$, we have

$$\begin{aligned}|I_{22}| &\le \int_{t/2}^t\int_{s^{-\frac12}}^1\left|Z^{(n)}(r,\xi,t-s)\right|\left|\frac{u_{\xi\xi}u_\xi^2}{1+u_\xi^2}\right|d\xi\,ds\\ &\le C\int_{t/2}^t\int_{s^{-\frac12}}^1(1+t-s)^{-\frac n2}\cdot\frac{1}{\xi}\,s^{-\frac32}\,d\xi\,ds\\ &\le \frac{C}{2}\int_{t/2}^t(1+t-s)^{-\frac n2}\,s^{-\frac32}\,\log s\,ds\\ &\le \sqrt{2}\,C\,t^{-\frac32}\,\log t\int_{t/2}^t(1+t-s)^{-\frac n2}\,ds\\ &\le \sqrt{2}\,C\,t^{-1}\int_{t/2}^t(1+t-s)^{-\frac n2}\,ds \le \widetilde{C}\,t^{-\frac12},\quad t\ge 2.\end{aligned}$$

Finally, for I_{23}, we use property (i) of $Z^{(n)}$ and the decay estimates for $|u_{rr}|$ and $|u_r|$. Then we have

$$|I_{23}| \le C\int_{t/2}^t\int_1^\infty\left|Z^{(n)}(r,\xi,t-s)\right|s^{-\frac32}\,d\xi\,ds \le C\int_{t/2}^t s^{-\frac32}\,ds \le 2\sqrt{2}\,C\,t^{-\frac12}$$

for $t\ge 2$. By combining all estimates established above, we obtain the following estimate:

$$\sup_{r\ge 2}|u(r,t)-h(r,t)| \le C\,t^{-\frac12},\quad t\ge 2.$$

Thus it remains to show the large time behavior of $u(r,t)$ for $r \in [0,2]$. If $0 \le r \le 2$, we have

$$|u(r,t) - h(r,t)| \le |u(r,t) - u(2,t)| + |u(2,t) - h(2,t)| + |h(2,t) - h(r,t)|$$
$$\le 2 \sup_{r>0} |u_r(r,t)| + 2 \sup_{r>0} |h_r(r,t)| + C\, t^{-\frac{1}{2}}, \quad t \ge 2.$$

For the heat equation, it is well known that $\sup_{r>0} |h_r(r,t)| \le t^{-\frac{1}{2}} \|u_0'\|_{L^\infty(0,\infty)}$ for $t > 0$. By this fact and the decay estimate for $|u_r|$ in Proposition 4.4, we obtain the estimate

$$\sup_{r>0} |u(r,t) - h(r,t)| \le C\, t^{-\frac{1}{2}}, \quad t \ge 2.$$

This completes the proof of Theorem 1.3. $\square$

Acknowledgment. The author thanks Prof. Masaharu Taniguchi at Tokyo Institute of Technology who gave me valuable comments and suggestions.

THE DERRIDA–LEBOWITZ–SPEER–SPOHN EQUATION: EXISTENCE, NONUNIQUENESS, AND DECAY RATES OF THE SOLUTIONS*

ANSGAR JÜNGEL† AND DANIEL MATTHES‡

Abstract. The logarithmic fourth-order equation $\partial_t u + \frac{1}{2}\sum_{i,j=1}^d \partial_{ij}^2(u\partial_{ij}^2 \log u) = 0$, called the Derrida–Lebowitz–Speer–Spohn equation, with periodic boundary conditions is analyzed. The global-in-time existence of weak nonnegative solutions in space dimensions $d \leq 3$ is shown. Furthermore, a family of entropy-entropy dissipation inequalities is derived in arbitrary space dimensions, and rates of the exponential decay of the weak solutions to the homogeneous steady state are estimated. The proofs are based on the algorithmic entropy construction method developed by the authors and on an exponential variable transformation. Finally, an example for nonuniqueness of the solution is provided.

Key words. logarithmic fourth-order equation, entropy-entropy dissipation method, existence of weak solutions, long-time behavior of solutions, decay rates, nonuniqueness of solutions

1. Introduction.

The logarithmic fourth-order equation

$$\partial_t u + \frac{1}{2}\partial_{ij}^2(u\partial_{ij}^2 \log u) = 0, \quad u(0,\cdot) = u_0 \geq 0, \tag{1.1}$$

appears in various places in mathematical physics (notice that we employed the summation convention). It has been first derived by Derrida, Lebowitz, Speer, and Spohn [10, 11], and we shall therefore refer to (1.1) as the *DLSS equation*. Derrida et al. studied in [10, 11] interface fluctuations in a two-dimensional spin system, the so-called (time-discrete) Toom model. In a suitable scaling limit, a random variable u related to the deviation of the interface from a straight line satisfies the one-dimensional equation (1.1). The multidimensional DLSS equation appears in quantum semiconductor modeling as the zero-temperature, zero-field limit of the quantum drift-diffusion model [18]. The variable u describes the electron density in a microelectronic device or in a quantum plasma. In both applications, the variable u is a nonnegative quantity.

In fact, the proof of positivity or nonnegativity of solutions constitutes the main analytical difficulty in rigorous studies of (1.1). There is generally no maximum principle available for fourth-order equations, which would allow to conclude from $u_0 \geq 0$ that also $u(t,\cdot) \geq 0$ at later times $t > 0$. Consequently, one has to rely on suitable regularization techniques and a priori estimates. The latter are difficult to

obtain because of the highly nonlinear structure of the equation. We remark that similar difficulties appear in studies of the thin-film equation

$$\partial_t u + \operatorname{div}(u^\alpha \nabla \Delta u) = 0, \quad u(0,\cdot) = u_0 \geq 0.$$

For this equation it is well known that preservation of positivity strongly depends on the parameter $\alpha > 0$. For a certain range of α's, there are solutions which are strictly positive initially, but which vanish at certain points after finite time [2].

In the present paper, we prove global-in-time existence of nonnegative weak solutions to (1.1) on the d-dimensional torus $\mathbb{T}^d$, and we calculate rates for the exponential decay of the solutions to the homogeneous steady state. Moreover, we provide a family of initial data u_0 for which there exist at least two solutions. These results are new in the literature (also see below). Our method of proof is based on the entropy construction method recently developed in [16] to derive a priori estimates and an exponential transformation of variables to prove the nonnegativity of solutions.

The first mathematically rigorous treatment of (1.1) is due to [4]. There, *local-in-time* existence of classical solutions for strictly positive $W^{1,p}(\mathbb{T}^d)$ initial data with $p > d$ was proven. The existence result is obtained by means of classical semigroup theory applied to the equation

$$2\partial_t \sqrt{u} + \Delta^2 \sqrt{u} - \frac{(\Delta\sqrt{u})^2}{\sqrt{u}} = 0, \quad \sqrt{u}(0,x) = \sqrt{u_0(x)} > 0, \quad x \in \mathbb{T}^d,$$

which is equivalent to (1.1) as long as u remains bounded away from zero. Lacking suitable a priori estimates, existence was proven only locally in time (for $d > 1$), even for strictly positive solutions.

More information is available in dimension $d = 1$ because (1.1) is then well posed in H^1. The *Fisher information*

$$F = \int_{\mathbb{T}} (\sqrt{u})_x^2 dx$$

is a Lyapunov functional, $dF/dt \leq 0$, which allows to relate global existence of solutions to strict positivity: if a classical solution breaks down at $t = t^*$, then the limit profile $\lim_{t \nearrow t^*} u(t,x)$ is still in H^1 but vanishes at some point $x \in \mathbb{T}$.

This observation has motivated the study on *nonnegative weak* solutions instead of positive classical solutions. In [17] global existence for the one-dimensional DLSS equation was shown in the class of functions with finite generalized entropy, $\widetilde{E}_0 = \int_{\mathbb{T}} (u - \log u) dx < \infty$ and with physically motivated boundary conditions. The key ingredient in the proof is the observation that $\widetilde{E}_0$ constitutes another Lyapunov functional for (1.1), providing nonnegativity of the solutions. The restriction to one spatial dimension is essential, since $\widetilde{E}_0$ is seemingly *not* a Lyapunov functional in dimensions $d > 1$.

In the following years, the one-dimensional DLSS equation with (mainly) periodic boundary conditions was extensively studied in the context of entropy-entropy production methods, and the exponentially fast decay of the solutions to the steady state has been proved [6, 7, 12, 14, 16, 19]. A numerical study of the long-time asymptotics for various boundary conditions can be found in [8].

Concerning the multidimensional problem, we remark that an independent investigation of (generalizations to) the DLSS equation has been just finished [13]. There, it is proven that (1.1) constitutes the gradient flow for the Fisher information with respect to the Wasserstein distance. The resulting existence theorem is more general than ours as it also holds in the nonphysical dimensions $d \geq 4$ and on unbounded domains. Clearly, the treatment of the DLSS equation as a gradient flow promotes a deeper understanding of its nature. Our approach in the present note is complementary as it is very direct and much simpler (and also much shorter). Furthermore, we point out that the decay estimates derived by our methods are slightly sharper than those of [13], and we are able to present an example of nonuniqueness of solutions.

In the following we describe our results in more detail. The global existence result is based on the fact that the *physical entropy*

$$\widetilde{E}_1 = \int_{\mathbb{T}^d} u \log\left(\frac{u}{\int u dx}\right) dx \geq 0 \tag{1.2}$$

is a Lyapunov functional in any space dimension $d \geq 1$. In fact, multiplying (1.1) formally by $\log u$, integrating over $\mathbb{T}^d$, and integrating by parts lead to

$$\frac{d\widetilde{E}_1}{dt} + \frac{1}{2}\int_{\mathbb{T}^d} u\|\nabla^2 \log u\|^2 dx = 0,$$

where $\nabla^2 \log u$ is the Hessian of $\log u$ and $\|\cdot\|$ is the Euclidean norm. We call the above integral the *entropy production*. Since there is no lower bound for u available, this does not yield an H^2 bound on $\log u$. However, we are able to show that, for periodic functions with positive lower bound,

$$\frac{1}{4}\int_{\mathbb{T}^d} u\|\nabla^2 \log u\|^2 dx \geq \kappa_1 \int_{\mathbb{T}^d} \|\nabla^2\sqrt{u}\|^2 dx, \quad \text{where } \kappa_1 = \frac{4d-1}{d(d+2)}, \tag{1.3}$$

leading to an H^2 bound for $\sqrt{u}$. This inequality was proved independently in [13, equation (1.82)]; we will show a more general version below (see Lemma 2.2). This motivates rewriting the nonlinearity in (1.1) in terms of $\sqrt{u}$, yielding the following (formally) equivalent equation:

$$\partial_t u + \partial^2_{ij}\big(\sqrt{u}\partial^2_{ij}\sqrt{u} - \partial_i\sqrt{u}\partial_j\sqrt{u}\big) = 0, \quad x \in \mathbb{T}^d,\ t > 0, \tag{1.4}$$

$$u(0,x) = u_0(x), \quad x \in \mathbb{T}^d. \tag{1.5}$$

The other crucial idea, which eventually provides nonnegativity of u, is an exponential variable transformation. To be more precise, for the fixed-point argument leading to the existence result, we also work in the original formulation (1.1),

$$\partial_t u + \frac{1}{2}\partial^2_{ij}(u\partial^2_{ij} y) = 0$$

with the exponential variable $y = \log u$. In a suitable regularization regime, y is bounded in modulus, and hence $u = \exp(y)$ is strictly positive.

Our proof of the crucial inequality (1.3) and its generalizations presented below is inspired by the algorithmic entropy construction method of [16]; there, the task of deriving inequalities like (1.3) is reformulated as a decision problem for polynomial systems. The latter can be solved (at least in principle) by computer algebra systems. The solution of the decision problem determines how to perform integration by parts in a way which leads to the desired inequality. By this method, the proof of (1.3) becomes quite short and elementary. Positivity of u is needed to make the computer-aided manipulations mathematically rigorous.

Our existence result reads as follows.

THEOREM 1.1. *Let $T > 0$ and $d \leq 3$. Furthermore, let u_0 be a nonnegative measurable function on $\mathbb{T}^d$ with finite physical entropy $E_1(u_0) = \int_T (u_0(\log u_0 - 1) + 1)dx < +\infty$. Then there exists a weak solution u to (1.4)–(1.5) satisfying*

$$u(t,\cdot) \geq 0 \ a.e., \quad u \in W^{1,1}(0,T;H^{-2}(\mathbb{T}^d)), \quad \sqrt{u} \in L^2(0,T;H^2(\mathbb{T}^d)),$$

and for all $z \in L^\infty(0,T;H^2(\mathbb{T}^d))$,

$$\int_0^T \langle \partial_t u, z\rangle_{H^{-2},H^2} dt + \int_0^T \int_{\mathbb{T}^d} \big(\sqrt{u}\partial_{ij}^2 \sqrt{u} - \partial_i \sqrt{u}\partial_j \sqrt{u}\big)\partial_{ij}^2 z dx = 0.$$

The theorem is valid in the physically relevant dimensions $d \leq 3$. This restriction is related to the lack of certain Sobolev embeddings in higher dimensions $d \geq 4$. Most prominently, the fixed-point argument exploits the continuous embedding $H^2(\mathbb{T}^d) \hookrightarrow L^\infty(\mathbb{T}^d)$ to conclude absolute boundedness of y and hence strict positivity of $u = \exp(y)$. We have chosen periodic boundary conditions in order to avoid boundary integrals. For the treatment of nonhomogeneous boundary conditions of Dirichlet–Neumann-type in one space dimension, we refer the reader to [14].

Our second result concerns the long-time behavior of weak solutions to the homogeneous steady state u_∞, and generally the systematic investigation of Lyapunov functionals. More specifically, we determine a range of parameters $\gamma > 0$, for which the *entropies*

$$\widetilde{E}_\gamma = \frac{1}{\gamma(\gamma-1)} \int_{\mathbb{T}^d} \big(u(t,\cdot)^\gamma - u_\infty^\gamma\big) dx$$

monotonically decay to zero. (Recall that $\widetilde{E}_1$ is the physical entropy from (1.2).) Starting from the results of [4], Lyapunov functionals of this (and more general) type have been investigated for $d = 1$. Here, we extend the entropy construction method developed in [16] to the multidimensional case.

To prove entropy decay, we multiply (1.4) formally by $v^{2(\gamma-1)}/(\gamma-1)$, where $v = \sqrt{u}$, integrate over the torus, and integrate by parts. This leads to

$$\frac{d\widetilde{E}_\gamma}{dt} + \frac{1}{\gamma-1} \int_{\mathbb{T}^d} v^2 \partial_{ij}^2(\log v)\partial_{ij}^2(v^{2(\gamma-1)}) dx = 0.$$

Next, we need to relate the entropy production to the entropy itself. For this, inequality (1.3) is generalized. We show, by using the method of [16], that if $0 < \gamma < 2(d+1)/(d+2)$, then

$$\frac{1}{2(\gamma-1)} \int_{\mathbb{T}^d} v^2 \partial_{ij}^2(\log v)\partial_{ij}^2(v^{2(\gamma-1)}) dx \geq \kappa_\gamma \int_{\mathbb{T}^d} (\Delta v^\gamma)^2 dx, \tag{1.6}$$

where

$$\kappa_\gamma = \frac{-(d+2)^2\gamma^2 + 2(d+1)(d+2)\gamma - (d-1)^2}{\gamma^2(-(d+2)^2\gamma^2 + 2(d+1)(d+2)\gamma)}.$$

The constant κ_γ is positive if and only if $(\sqrt{d}-1)^2/(d+2) < \gamma < (\sqrt{d}+1)^2/(d+2)$. By a Beckner-type inequality, we can relate the integral of Δv^γ to the entropy itself, giving $d\widetilde{E}_\gamma/dt + c\widetilde{E}_\gamma \leq 0$ for some $c > 0$. A similar strategy works for the physical entropy, $\gamma = 1$. Eventually, Gronwall's lemma yields the following exponential decay estimates.

THEOREM 1.2. *Assume that u is either a positive classical solution to* (1.4)–(1.5) *or the weak solution constructed in the proof of Theorem* 1.1. *Let*

$$u_\infty \equiv \mathrm{meas}(\mathbb{T}^d)^{-1}\int_{\mathbb{T}^d} u_0\,dx > 0.$$

Then the entropies decay exponentially fast,

$$\widetilde{E}_\gamma(u(t,\cdot)) \le \widetilde{E}_\gamma(u_0)\exp(-16\pi^4\gamma^2\kappa_\gamma t) \quad \textit{for} \quad 1 \le \gamma < \frac{(\sqrt{d}+1)^2}{d+2},$$

and the solution itself decays exponentially in the L^1 norm,

$$\|u(t,\cdot)-u_\infty\|_{L^1(\mathbb{T}^d)} \le (2\widetilde{E}_1(u_0))^{1/2}\exp(-8\pi^4\kappa_1 t).$$

In order to make the above inequalities rigorous, we consider a regularized semidiscrete version of (1.4) for which we obtain positive H^2 solutions. Since the fourth-order differential operator in (1.1) is not strictly elliptic in $y = \log u$ ($u = 0$ may be possible), we add the regularization $-\varepsilon(\Delta^2 y + y)$ for $\varepsilon > 0$ to the right-hand side of (1.1). Unfortunately, this regularization destroys the dissipative structure of the DLSS equation, and we cannot prove anymore the entropy-entropy production inequality for $\gamma \neq 1$. To cure this problem, we need to add the expression

$$\varepsilon\mathrm{div}(|\nabla \log\max\{v,\mu\}|^2\nabla y) \quad \text{for some } \mu > 0.$$

The third main result of this paper concerns the nonuniqueness of solutions. We show that, for a family of particular initial data, there exist at least two solutions to (1.4)–(1.5) in the class of nonnegative functions in $L^1(0,T;H^2(\mathbb{T}^d))$ with finite physical entropy $\widetilde{E}_1$. Recall that uniqueness holds in the class of positive smooth functions [4]. Here, the initial data are chosen in such a way that they vanish on a set of measure zero and that they represent classical solutions to the stationary and, hence, to the transient equation. On the other hand, our existence result provides a solution which converges to the homogeneous positive steady state u_∞. Therefore, this solution is not equal to the first one. This observation may give a criterium how to choose the physically relevant solution: it should dissipate the physical entropy.

Throughout this paper, we make the following simplification. Due to the scaling invariance of (1.5) with respect to $x \to \xi x$, $t \to \xi^4 t$, and $u \to \eta u$ for ξ, $\eta > 0$, we may assume that the torus $\mathbb{T}^d$ is normalized, $\mathbb{T}^d \cong [0,1]^d$. We further assume that the initial datum has unit mass, $\int_{\mathbb{T}^d} u_0 dx = 1$; notice that the DLSS equation is mass preserving.

The paper is organized as follows. In section 2 we show some inequalities needed for the analysis of the DLSS equation. In particular we prove (1.3) and (1.6). Theorem 1.2 is proved in section 3 for smooth positive solutions. Then the existence of solutions is shown in section 4. Section 5 is devoted to the proof of Theorem 1.2 for weak solutions. Finally, in section 6 the nonuniqueness result is presented.

2. Some inequalities. We collect some inequalities which are needed in the following sections. We start with a lower bound on the Euclidean norm of a matrix. Let $A = (a_{ij}) \in \mathbb{R}^{d\times d}$ be a matrix and let $a \in \mathbb{R}^d$ be a vector. We define the Euclidean norm of A and a, respectively, by $\|A\|^2 = \sum_{i,j} a_{ij}^2$ and $\|a\|^2 = \sum_j a_j^2$. Furthermore, $\mathrm{tr}\, A = \sum_j a_{jj}$ is the trace of A and

$$A : (a)^2 = \sum_{i,j=1}^d a_{ij}a_i a_j.$$

LEMMA 2.1. *Let $A \in \mathbb{R}^{d\times d}$ be a real symmetric matrix and let $a \in \mathbb{R}^d$ be a nonzero vector. Then*

$$\|A\|^2 \geq \frac{1}{d}(\operatorname{tr} A)^2 + \frac{d}{d-1}\left(\frac{A:(a)^2}{\|a\|^2} - \frac{\operatorname{tr} A}{d}\right)^2. \tag{2.1}$$

Proof. Since A is real and symmetric, one can assume (by the spectral theorem), without loss of generality, that A is a diagonal matrix, $A = \operatorname{diag}(\lambda_1, \dots, \lambda_d)$; recall that norms and traces are invariant under orthogonal transformations. Furthermore, one can also assume, by homogeneity of (2.1), that $a = (a_1, \dots, a_d)^\top$ is a unit vector, $\sum_j a_j^2 = 1$. Thus, inequality (2.1) becomes

$$\frac{1}{d}\sum_{j=1}^d \lambda_j^2 - \left(\frac{1}{d}\sum_{j=1}^d \lambda_j\right)^2 \geq \frac{1}{d-1}\left(\sum_{j=1}^d \lambda_j a_j^2 - \frac{1}{d}\sum_{j=1}^d \lambda_j\right)^2. \tag{2.2}$$

Set $\sigma = \sum_{j=1}^d \lambda_j/d$ and $\rho_j = \lambda_j - \sigma$. Then (2.2) is equivalent to

$$\frac{1}{d}\sum_{j=1}^d \rho_j^2 \geq \frac{1}{d-1}\left(\sum_{j=1}^d \rho_j a_j^2\right)^2, \tag{2.3}$$

where $\sum_{j=1}^d \rho_j = 0$. Without loss of generality, we assume that ρ_d is the term with maximal modulus. We employ the identity $\sum_{j=1}^{d-1}\rho_j = -\rho_d$ and the elementary inequalities

$$\sum_{j=1}^{d-1}\rho_j^2 \geq \frac{1}{d-1}\left(\sum_{j=1}^{d-1}\rho_j\right)^2 \quad \text{and} \quad \rho_d^2 \geq \left(\sum_{j=1}^d \rho_j a_j^2\right)^2$$

to obtain

$$\begin{aligned}\frac{1}{d}\sum_{j=1}^d \rho_j^2 &= \frac{1}{d}\rho_d^2 + \frac{1}{d}\sum_{j=1}^{d-1}\rho_j^2 \geq \frac{1}{d}\rho_d^2 + \frac{1}{d(d-1)}\left(\sum_{j=1}^{d-1}\rho_j\right)^2 \\ &= \frac{1}{d}\rho_d^2 + \frac{1}{d(d-1)}\rho_d^2 = \frac{1}{d-1}\rho_d^2 \geq \frac{1}{d-1}\left(\sum_{j=1}^d \rho_j a_j^2\right)^2.\end{aligned}$$

This shows (2.3) and finishes the proof. $\square$

The main result of this section is the following inequality.

LEMMA 2.2. *Let $v \in H^2(\mathbb{T}^d) \cap W^{1,4}(\mathbb{T}^d) \cap L^\infty(\mathbb{T}^d)$ in dimension $d \geq 2$, and assume that $\inf_{\mathbb{T}^d} v > 0$. Then, for any $0 < \gamma < 2(d+1)/(d+2)$,*

$$\frac{1}{2(\gamma-1)}\int_{\mathbb{T}^d} v^2 \partial_{ij}^2(\log v)\partial_{ij}^2(v^{2(\gamma-1)})dx \geq \kappa_\gamma \int_{\mathbb{T}^d}(\Delta v^\gamma)^2 dx \tag{2.4}$$

if $\gamma \neq 1$, or

$$\int_{\mathbb{T}^d} v^2 \partial_{ij}^2(\log v)^2 dx \geq \kappa_1 \int_{\mathbb{T}^d}(\Delta v)^2 dx \tag{2.5}$$

if $\gamma = 1$*, respectively, where*

$$\kappa_\gamma = \frac{p(\gamma)}{\gamma^2(p(\gamma)-p(0))} \quad \textit{and} \quad p(\gamma) = -\gamma^2 + \frac{2(d+1)}{d+2}\gamma - \Big(\frac{d-1}{d+2}\Big)^2. \tag{2.6}$$

The function $\nabla^2 v$ denotes the Hessian of v. By Sobolev embedding, it is sufficient to assume $v \in H^2(\mathbb{T}^d)$ in space dimensions $d \le 3$. The condition $0 < \gamma < 2(d+1)/(d+2)$ ensures that $p(\gamma) > p(0)$ so that κ_γ is well defined; if the stronger condition $(\sqrt{d}-1)^2/(d+2) < \gamma < (\sqrt{d}+1)^2/(d+2)$ holds, then $\kappa_\gamma > 0$. Finally, we remark that the method of [16] directly applies to the one-dimensional situation, yielding (2.4) and (2.5), respectively, for $0 \le \gamma \le \frac{3}{2}$, with $\kappa_\gamma = \min(\gamma, 12-8\gamma)/\gamma^3$.

Proof. In order to simplify the computations, we introduce the functions θ, λ, and μ, respectively, by (recall that $v > 0$)

$$\theta = \frac{|\nabla v|}{v}, \quad \lambda = \frac{1}{d}\frac{\Delta v}{v}, \quad (\lambda+\mu)\theta^2 = \frac{1}{v^3}\nabla^2 v : (\nabla v)^2,$$

and $\rho \ge 0$ by

$$\|\nabla^2 v\|^2 = \Big(d\lambda^2 + \frac{d}{d-1}\mu^2 + \rho^2\Big)v^2.$$

We need to show that ρ is well defined. But this is clear since

$$\|\nabla^2 v\|^2 \ge \Big(d\lambda^2 + \frac{d}{d-1}\mu^2\Big)v^2$$

follows directly from (2.1) after taking $A = \nabla^2 v$ and $a = \nabla v$.

We compute the left-hand side of (2.4),

$$\begin{aligned} J &= \frac{1}{2(\gamma-1)}\int_{\mathbb{T}^d} v^2 \partial_{ij}^2(\log v)\partial_{ij}^2(v^{2(\gamma-1)})dx \\ &= \frac{1}{2(\gamma-1)}\int_{\mathbb{T}^d} (v\partial_{ij}^2 v - \partial_i v \partial_j v)\partial_{ij}^2(v^{2(\gamma-1)})dx \\ &= \int_{\mathbb{T}^d} (v\partial_{ij}^2 v - \partial_i v\partial_j v)v^{2(\gamma-2)}\big(v\partial_{ij}^2 v + (2\gamma-3)\partial_i v\partial_j v\big)dx \\ &= \int_{\mathbb{T}^d} v^{2\gamma}\left(\frac{\|\nabla^2 v\|^2}{v^2} - 2(2-\gamma)\frac{\nabla^2 v}{v^2} : \Big(\frac{\nabla v}{v}\Big)^2 + (3-2\gamma)\frac{|\nabla v|^4}{v^4}\right)dx, \end{aligned}$$

and express it in terms of the functions θ, λ, μ, and ρ defined above,

$$J = \int_{\mathbb{T}^d} v^{2\gamma}\Big(d\lambda^2 + \frac{d}{d-1}\mu^2 + \rho^2 - 2(2-\gamma)(\lambda+\mu)\theta^2 + (3-2\gamma)\theta^4\Big)dx.$$

This integral is compared to

$$\begin{aligned} K &= \frac{1}{\gamma^2}\int_{\mathbb{T}^d}(\Delta v^\gamma)^2 dx = \int_{\mathbb{T}^d} v^{2(\gamma-2)}\big(v\Delta v + (\gamma-1)|\nabla v|^2\big)^2 dx \\ &= \int_{\mathbb{T}^d} v^{2\gamma}\big(d\lambda + (\gamma-1)\theta^2\big)^2 dx. \end{aligned}$$

More precisely, we shall determine a constant $c_0 > 0$ independent of v such that $J - c_0 K \ge 0$ for all (positive) functions v. Our strategy is an adaption of the method developed in [16]. We formally perform integration by parts in the expression $J - c_0K$ by adding a linear combination of certain "dummy" integrals—which are actually zero and hence do not change the value of $J - c_0K$. The coefficients in the linear combination are determined in such a way that makes the resulting integrand pointwise nonnegative. The latter is a decision problem from real algebraic geometry, and it is solved with computer aid.

We shall rely on the following two "dummy" integral expressions:

$$J_1 = \int_{\mathbb{T}^d} \operatorname{div}\big(v^{2\gamma-2}(\nabla^2 v - \Delta v \mathbb{I}) \cdot \nabla v\big)dx,$$
$$J_2 = \int_{\mathbb{T}^d} \operatorname{div}\big(v^{2\gamma-3}|\nabla v|^2 \nabla v\big)dx,$$

where $\mathbb{I}$ is the unit matrix in $\mathbb{R}^{d\times d}$. Clearly, in view of the periodic boundary conditions, $J_1 = J_2 = 0$. The goal is to find constants c_0, c_1, and c_2 such that $J - c_0K = J - c_0K + c_1J_1 + c_2J_2 \geq 0$; moreover, c_0 should be as large as possible. Since, with the above notations,

$$\begin{aligned} J_1 &= \int_{\mathbb{T}^d} v^{2(\gamma-2)}\big(v^2(\|\nabla^2 v\|^2 - (\Delta v)^2) + 2(\gamma-1)v(\nabla^2 v - \Delta v\mathbb{I}) : (\nabla v)^2\big)dx \\ &= \int_{\mathbb{T}^d} v^{2\gamma}\Big(- d(d-1)\lambda^2 + \frac{d}{d-1}\mu^2 + \rho^2 + 2(\gamma-1)(-(d-1)\lambda\theta^2 + \mu\theta^2)\Big)dx \end{aligned}$$

and

$$\begin{aligned} J_2 &= \int_{\mathbb{T}^d} v^{2(\gamma-2)}\big((2\nabla^2 v + \Delta v\mathbb{I}) : (\nabla v)^2 + (2\gamma-3)|\nabla v|^4\big)dx \\ &= \int_{\mathbb{T}^d} v^{2\gamma}\big((d+2)\lambda\theta^2 + 2\mu\theta^2 + (2\gamma-3)\theta^4\big)dx, \end{aligned}$$

we obtain

$$\begin{aligned} J - c_0K + c_1J_1 + c_2J_2 = \int_{\mathbb{T}^d} & v^{2\gamma}\big\{d\lambda^2\big[1 - dc_0 - (d-1)c_1\big] \\ & + \lambda\theta^2\big[2(\gamma-1)(1 - dc_0 - (d-1)c_1) + (d+2)c_2 - 2\big] + Q(\theta,\mu,\rho)\big\}dx, \end{aligned} \tag{2.7}$$

where Q is a polynomial in θ, μ, and ρ with coefficients depending on c_0, c_1, and c_2 but not on λ. We choose to eliminate λ from the above integrand by defining c_1 and c_2 appropriately. The linear system

$$\begin{aligned} 1 - dc_0 - (d-1)c_1 &= 0, \\ 2(\gamma-1)(1 - dc_0 - (d-1)c_1) + (d+2)c_2 - 2 &= 0 \end{aligned}$$

has the solution $c_1 = (1 - dc_0)/(d-1)$ and $c_2 = 2/(d+2)$. With this choice, the polynomial Q in (2.7) reads as

$$Q(\theta,\mu,\rho) = \frac{1}{(d-1)^2(d+2)}\big(b_1\mu^2 + 2b_2\mu\theta^2 + b_3\theta^4 + b_4\rho^2\big),$$

where

$$\begin{aligned} b_1 &= d^2(d+2)(1-c_0), \\ b_2 &= d(d-1)\big((d+2)(\gamma + c_0(1-\gamma)) - 2d - 1\big), \\ b_3 &= (d-1)^2\big(d(3-2\gamma) - c_0(d+2)(\gamma-1)^2\big), \\ b_4 &= d(d+2)(d-1)(1-c_0). \end{aligned}$$

If $c_0 \le 1$, then $b_4 \ge 0$. We wish to choose $c_0 \le 1$ in such a way that the remaining sum $b_1\mu^2 + 2b_2\mu\theta^2 + b_3\theta^4$ is nonnegative as well for any μ and θ. This is the case if (i) $b_1 > 0$ and (ii) $b_1 b_3 - b_2^2 \ge 0$. Condition (ii) is equivalent to

$$\begin{aligned} 0 &\le (1-c_0)(d+2)\big(2(d+1)\gamma - (d+2)\gamma^2\big) - (d-1)^2 \\ &= (1-c_0)(d+2)^2(p(\gamma)-p(0)) - (d-1)^2, \end{aligned}$$

which is further equivalent to (recall that $p(\gamma) > p(0)$ on the considered range of γ's)

$$c_0 \le \frac{p(\gamma)}{p(\gamma)-p(0)}.$$

The best choice for c_0 is obviously to make it equal to the right-hand side. As $p(0) < 0$, one has in particular that $c_0 < 1$, so condition (i) is satisfied as well. Thus we have found constants c_0, c_1, and c_2 for which the expression $J - c_0 K + c_1 J_1 + c_2 J_2$ is nonnegative. With $\kappa_\gamma = c_0/\gamma^2$, Lemma 2.2 is proven. ∎

Remark 2.3. Elimination of λ from the integrand in (2.7) is clearly not the only strategy to initiate the polynomial reduction process. However, from numerical studies of the multivariate polynomial, there is strong evidence that this strategy leads to the optimal values for c_0, at least for γ close to one.

As a consequence of Lemma 2.2 for $v = \sqrt{u}$ and $\gamma = 1$, we obtain inequality (1.3) which connects the entropy production of (1.4) to the smoothness of its solution.

LEMMA 2.4. *For all $d \ge 1$ and all strictly positive functions u such that $\sqrt{u} \in H^2(\mathbb{T}^d) \cap L^\infty(\mathbb{T}^d)$ it holds that*

$$\frac{1}{4}\int_{\mathbb{T}^d} u\|\nabla^2 \log u\|^2 dx \ge \kappa_1 \int_{\mathbb{T}^d} \|\nabla^2\sqrt{u}\|^2 dx, \quad \textit{where } \kappa_1 = \frac{4d-1}{d(d+2)}.$$

We also need the following generalized convex Sobolev inequalities.

LEMMA 2.5. *Let $f \in H^2(\mathbb{T}^d)$ be nonnegative. Then, for $1 < p \le 2$,*

$$\frac{p}{p-1}\left(\int_{\mathbb{T}^d} f^2 dx - \left(\int_{\mathbb{T}^d} f^{2/p} dx\right)^p\right) \le \frac{1}{8\pi^4}\int_{\mathbb{T}^d} (\Delta f)^2 dx. \tag{2.8}$$

Furthermore,

$$\int_{\mathbb{T}^d} f^2 \log\big(f^2/\|f\|_{L^2}^2\big) dx \le \frac{1}{8\pi^4}\int_{\mathbb{T}^d} (\Delta f)^2 dx. \tag{2.9}$$

Inequality (2.9) represents the limit of (2.8) as $p \searrow 1$. Unfortunately, (2.8) does seemingly *not* generalize for parameters $0 < p < 1$ in dimensions $d > 1$. The reason is that the functional on the left-hand side is convex in f only if $1 \le p \le 2$; see the discussion in [5]. This limits our decay estimates to entropies E_γ with $\gamma \ge 1$.

Proof. We only prove inequality (2.8) as (2.9) follows in a completely analogous manner. The estimate is a consequence of the Beckner-type inequality and the Poincaré inequality. For the one-dimensional torus $\mathbb{T}$, the former reads as (see [3])

$$\frac{p}{p-1}\left(\int_{\mathbb{T}} f^2 dx_j - \left(\int_{\mathbb{T}} f^{2/p} dx_j\right)^p\right) \le \frac{1}{2\pi^2}\int_{\mathbb{T}} |\partial_j f|^2 dx_j$$

(see, e.g., [12] for an easy proof). In several space dimensions, we obtain the same result since the above inequality *tensorizes*. Indeed, by employing the relation

$$\int_{\mathbb{T}^d} f^2 dx - \left(\int_{\mathbb{T}^d} f^{2/p} dx\right)^p \le \sum_{j=1}^d \int_{\mathbb{T}^d}\left(\int_0^1 f^2 dx_j - \left(\int_0^1 f^{2/p} dx_j\right)^p\right) dx$$

from Proposition 4.1 in [21], it follows that

$$\frac{p}{p-1}\left(\int_{\mathbb{T}^d} f^2 dx - \left(\int_{\mathbb{T}^d} f^{2/p} dx\right)^p\right) \le \frac{1}{2\pi^2}\sum_{j=1}^d \int_{\mathbb{T}^d}\left(\int_0^1 (\partial_j f)^2 dx_j\right) dx$$
$$= \frac{1}{2\pi^2}\int_{\mathbb{T}^d} |\nabla f|^2 dx.$$

Now, Poincaré's inequality for multiperiodic functions with zero mean,

$$\int_{\mathbb{T}^d} |\nabla f|^2 dx \le \frac{1}{4\pi^2}\int_{\mathbb{T}^d} \|\nabla^2 f\|^2 dx = \frac{1}{4\pi^2}\int_{\mathbb{T}^d} (\Delta f)^2 dx,$$

gives the assertion. ◻

In section 4 we frequently refer to the Gagliardo–Nirenberg inequalities which we recall for convenience [15].

Lemma 2.6. *Let m, $k \in \mathbb{N}_0$ with $0 \le k \le m$, $0 \le \theta < 1$, and $1 \le p, q, r \le \infty$. If both*

$$k - \frac{d}{p} \le \theta\left(m - \frac{d}{q}\right) + (1-\theta)\left(-\frac{d}{r}\right) \quad \text{and} \quad \frac{1}{p} \le \frac{\theta}{q} + \frac{1-\theta}{r},$$

then any function $f \in W^{m,q}(\mathbb{T}^d) \cap L^r(\mathbb{T}^d)$ belongs to $W^{k,p}(\mathbb{T}^d)$, and there exists a constant $C > 0$ independent of f such that

$$\|f\|_{W^{k,p}} \le C\|f\|_{W^{m,q}}^{\theta}\|f\|_{L^r}^{1-\theta}. \tag{2.10}$$

If additionally $k \ge 1$, we conclude from (2.10) that

$$\|\nabla^k f\|_{L^p} \le C\|\nabla^m f\|_{L^q}^{\theta}\|f\|_{L^r}^{1-\theta} \tag{2.11}$$

by means of the Poincaré inequality.

3. Decay rates for smooth positive solutions. We show Theorem 1.2 first for smooth positive solutions by using Lemmas 2.2 and 2.5. The proof for weak solutions is based on estimates for the semidiscrete, regularized problem and is therefore presented later in section 5. Both proofs are identical in their structure, but the proof for smooth solutions is stripped of the technicalities that are introduced by the regularization process.

The essential tool to derive the a priori estimates are the so-called *relative entropies*, as introduced in [1],

$$E_\gamma(u_1|u_2) = \int_{\mathbb{T}^d} \phi_\gamma\Big(\frac{u_1}{u_2}\Big) u_2 dx, \quad \gamma \notin \{0,1\},$$

where u_1 and u_2 are nonnegative functions on $\mathbb{T}^d$ with unit mean value, and ϕ_γ is given by

$$\phi_\gamma(s) = \frac{1}{\gamma(\gamma-1)}\big(s^\gamma - \gamma s + \gamma - 1\big), \quad s \ge 0. \tag{3.1}$$

The natural continuation for $\gamma = 1$ is $\phi_1(s) = s(\log s - 1) + 1$; the functional E_1 corresponds to the physical entropy. The functions ϕ_γ are nonnegative and convex and attain their minimal value at $s = 1$. Consequently, E_γ is nonnegative (possibly $+\infty$) and vanishes if and only if $u_1 = u_2$.

To obtain the a priori estimates (and the decay rates), we consider entropies of solutions $u_1 = u$ relative to the spatial homogeneous steady state $u_2 \equiv 1$:

$$E_\gamma(u(t,\cdot)) = \frac{1}{\gamma(\gamma-1)}\left(\int_{\mathbb{T}^d} u(t,x)^\gamma dx - 1\right), \quad \gamma \geq 1. \tag{3.2}$$

We obtain the following entropy-entropy production estimate.

PROPOSITION 3.1. *Assume that* u *is a smooth positive solution to* (1.4)–(1.5) *in dimensions* $d \geq 2$. *Then*

$$\frac{dE_\gamma}{dt} + 2\kappa_\gamma \int_{\mathbb{T}^d} (\Delta u^{\gamma/2})^2 dx \leq 0 \quad \textit{for} \quad 0 < \gamma < \frac{2(d+1)}{d+2}, \tag{3.3}$$

where $\kappa_\gamma > 0$ *is defined in* (2.6).

Proof. For convenience, we work with the function $v = \sqrt{u}$ instead of u. If $\gamma \neq 1$, we integrate the DLSS equation (1.4) against the test function $v^{2(\gamma-1)}/2(\gamma-1)$. Then we obtain for the time derivative

$$\frac{1}{2(\gamma-1)}\int_{\mathbb{T}^d} \partial_t(v^2)v^{2(\gamma-1)}dx = \frac{1}{2\gamma(\gamma-1)}\int_{\mathbb{T}^d}\partial_t(v^{2\gamma})dx = \frac{1}{2}\,\frac{dE_\gamma}{dt}.$$

In combination with Lemma 2.2,

$$\frac{1}{2}\,\frac{dE_\gamma}{dt} = -\frac{1}{2(\gamma-1)}\int_{\mathbb{T}^d} v^2\partial_{ij}^2(\log v)\partial_{ij}^2(v^{2(\gamma-1)})dx \leq -\kappa_\gamma\int_{\mathbb{T}^d}(\Delta v^\gamma)^2 dx.$$

If $\gamma = 1$, we use the test function $\log v$ instead. $\square$

Remark 3.2. As pointed out before, the coefficient function κ_γ follows a different law in dimension $d = 1$; see the remarks after Lemma 2.2. In conclusion, the entropy production is estimated as

$$\frac{dE_\gamma}{dt} + \frac{2\mu_\gamma}{\gamma^2}\int_{\mathbb{T}} |(u^{\gamma/2})_{xx}|^2 dx \leq 0,$$

where

$$\mu_\gamma = \begin{cases} 1 & \text{for } 0 < \gamma < 4/3, \\ 12/\gamma - 8 & \text{for } 4/3 < \gamma < 3/2. \end{cases}$$

Estimates for the limiting case $\gamma = 0$ are also available (see Theorem 3 in [7]).

The proof of Theorem 1.2 in the case of smooth positive solutions is immediate: applying Lemma 2.5 to $f = u^{\gamma/2}$ with $p = \gamma$ and taking into account that u has unit mass, we obtain from Proposition 3.1

$$\frac{dE_\gamma}{dt} + (2\pi)^4\gamma^2\kappa_\gamma E_\gamma \leq 0.$$

Gronwall's lemma shows the entropy decay. The decay in the L^1 norm is a straightforward consequence of the Csiszár–Kullback inequality [9, 20].

The values of κ_γ as a function of γ are plotted in Figure 3.1 (left). For $\gamma \geq 1$, these correspond to exponential decay rates of the respective entropy E_γ. (There is no immediate interpretation of κ_γ for $0 < \gamma < 1$.) The right figure shows the decay

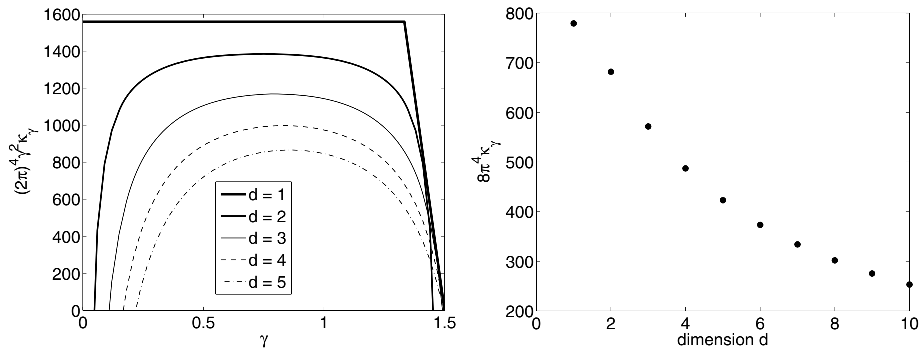

FIG. 3.1. *Decay rates for the entropy E_γ (left) and in the L^1 norm for $\gamma = 1$ (right) depending on the dimension d.*

rate $8\pi^4\kappa_1$ in the L^1 norm for $\gamma = 1$ as a function of the dimension d. This rate is given by

$$8\pi^4\kappa_1 = 8\pi^4\frac{4d-1}{d(d+2)};$$

this is slightly better than the rate obtained in [13], which amounts to $24\pi^4/(d+2)$ for (1.1).

4. Existence of solutions. In this section we prove Theorem 1.1. The proof is divided into a series of lemmas. We continue to use $v = \sqrt{u}$ for easier notation.

4.1. Existence of a time-discrete solution. Let $T > 0$ be a terminal time and $\tau > 0$ a time step. Let w be a given function. We wish to find a solution $v \in H^2(\mathbb{T}^d)$ to the semidiscrete equation

$$\frac{1}{\tau}(v^2 - w^2) = -\partial_{ij}^2\big(v\partial_{ij}^2 v - \partial_i v\partial_j v\big). \tag{4.1}$$

LEMMA 4.1. *Let $d \le 3$. Assume that w is a nonnegative measurable function on $\mathbb{T}^d$ with finite entropy $E_1(w^2) < +\infty$ and unit mass $\int_{\mathbb{T}^d} w^2 dx = 1$. Then there exists a nonnegative weak solution $v \in H^2(\mathbb{T}^d)$ to (4.1). Furthermore, v^2 has unit mass, the physical entropy is dissipated in the sense*

$$E_1(v^2) + 2\tau\kappa_1\int_{\mathbb{T}^d}\|\nabla^2 v\|^2 dx \le E_1(w^2), \tag{4.2}$$

and the entropies $E_\gamma(v^2)$ and $E_\gamma(w^2)$ are related by

$$(1 + 16\pi^4\tau\gamma^2\kappa_\gamma)E_\gamma(v^2) \le E_\gamma(w^2), \tag{4.3}$$

where $1 \le \gamma < (\sqrt{d}+1)^2/(d+2)$ and κ_γ is defined in (2.6).

Proof.

Step 1. Definition of the regularized problem. The solution to (4.1) is obtained as the limit of solutions to a regularized problem. For this, recall that (1.4) can be written as

$$\partial_t(v^2) = -\frac{1}{2}\partial_{ij}^2(v^2\partial_{ij}^2 y) \quad \text{with } y = \log(v^2).$$

We regularize (4.1) in the above formulation by adding a strongly elliptic operator in y:

$$\frac{1}{\tau}(v^2 - w^2) = -\frac{1}{2}\partial_{ij}^2(v^2\partial_{ij}^2 y) - \varepsilon(\Delta^2 y + y) + \varepsilon\mathrm{div}\big(|\nabla \log[v]_\mu|^2\nabla y\big), \tag{4.4}$$

where ε, $\mu > 0$ are regularization parameters and $[v]_\mu = \max\{v, \mu\}$. The fourth-order operator $\varepsilon(\Delta^2 y + y)$ guarantees coercivity of the above right-hand side with respect to y. The nonlinear second-order operator allows to derive the a priori estimates for the general entropy E_γ.

Step 2. Solution of the regularized problem. In order to solve (4.4) we employ the Leray–Schauder fixed-point theorem (see Theorem B.5 in [23]). Let $\sigma \in [0,1]$ and $\bar{v} \in W^{1,4}(\mathbb{T}^d) \hookrightarrow L^\infty(\mathbb{T}^d)$, and introduce for y, $z \in H^2(\mathbb{T}^d)$,

$$\begin{aligned} a(y,z) &= \frac{1}{2}\int_{\mathbb{T}^d} \bar{v}^2\partial_{ij}^2 y\partial_{ij}^2 z dx + \varepsilon\int_{\mathbb{T}^d}(\Delta y\Delta z + yz + |\nabla \log[\bar{v}]_\mu|^2\nabla y\cdot\nabla z)dx, \\ f(z) &= \frac{\sigma}{\tau}\langle \bar{v}^2 - w^2, z\rangle_{H^{-2},H^2}. \end{aligned}$$

Since $\bar{v} \in W^{1,4}(\mathbb{T}^d)$, also $\log[\bar{v}]_\mu \in W^{1,4}(\mathbb{T}^d)$, hence $|\nabla \log[\bar{v}]_\mu|^2\nabla y\cdot\nabla z$ is integrable. The bilinear form a is continuous and coercive since, by the Gagliardo–Nirenberg inequality (2.11),

$$a(y,y) \ge \varepsilon\int_{\mathbb{T}^d}\big((\Delta y)^2 + y^2\big)dx \ge C\varepsilon\|y\|_{H^2}^2. \tag{4.5}$$

Moreover, w^2 has finite physical entropy, so $w^2 \in L^1(\mathbb{T}^d) \hookrightarrow H^{-2}(\mathbb{T}^d)$ in space dimensions $d \le 3$, yielding continuity of the linear form f. Consequently, Lax–Milgram's lemma provides the existence of a unique solution to

$$-a(y,z) = f(z) \quad \text{for all } z \in H^2(\mathbb{T}^d).$$

Define the fixed-point operator $S : W^{1,4}(\mathbb{T}^d)\times[0,1] \to W^{1,4}(\mathbb{T}^d)$ by $S(\bar{v},\sigma) := v = e^{y/2}$. Since $y \in H^2(\mathbb{T}^d) \hookrightarrow L^\infty(\mathbb{T}^d)$, we have indeed that $v \in H^2(\mathbb{T}^d) \hookrightarrow W^{1,4}(\mathbb{T}^d)$.

We shall now verify the hypotheses of the Leray–Schauder theorem; the latter provides a solution v of $S(v,1) = v$. The operator S is constant at $\sigma = 0$, $S(\bar{v},0) = 1$. By standard results for elliptic equations, S is continuous and compact since the embedding $H^2(\mathbb{T}^d) \hookrightarrow W^{1,4}(\mathbb{T}^d)$ is compact. It remains to show a uniform bound for all fixed points of $S(\cdot,\sigma)$. This bound is obtained from the production of the physical entropy and Lemma 2.4.

Let $v \in H^2(\mathbb{T}^d)$ be a fixed point of $S(\cdot,\sigma)$ for some $\sigma \in [0,1]$. Then v is a solution to (4.4) with σ/τ instead of $1/\tau$, and with $v = e^{y/2} > 0$, $y \in H^2(\mathbb{T}^d)$. Since $\phi(s) = s(\log s - 1) + 1$ is convex, $\phi(s_1) - \phi(s_2) \le \phi'(s_1)(s_1 - s_2)$ for all s_1, $s_2 \ge 0$. Hence,

$$\begin{aligned} \frac{\sigma}{\tau}(E_1(v^2) - E_1(w^2)) &= \frac{\sigma}{\tau}\int_{\mathbb{T}^d}(\phi(v^2) - \phi(w^2))dx \\ &\le \frac{\sigma}{2\tau}\int_{\mathbb{T}^d}(v^2 - w^2)\log(v^2)dx = -a(y,y) \\ &\le -\frac{1}{2}\int_{\mathbb{T}^d} v^2\|\nabla^2\log(v^2)\|^2 dx - \varepsilon\int_{\mathbb{T}^d}((\Delta y)^2 + y^2)dx. \end{aligned} \tag{4.6}$$

The estimate of Lemma 2.4 shows that

$$\frac{\sigma}{\tau}(E_1(v^2)-E_1(w^2))+2\kappa_1\int_{\mathbb{T}^d}\|\nabla^2 v\|^2dx\le 0.$$

As a consequence,

$$E_1(v^2)\le E_1(w^2)\quad\text{and}\quad \|\nabla^2 v\|_{L^2}^2\le\frac{1}{2\tau\kappa_1}E_1(w^2).$$

In particular, $\nabla^2 v$ is uniformly bounded in $L^2(\mathbb{T}^d)$. Together with the elementary inequality $s\le\phi(s)+(e-1)$ for all $s\ge 0$, we obtain

$$\|v\|_{L^2}^2\le\int_{\mathbb{T}^d}(\phi(v^2)+e-1)dx=E_1(v^2)+e-1.$$

This means that v is uniformly bounded in $L^2(\mathbb{T}^d)$. Then the Gagliardo–Nirenberg inequality gives the desired uniform bound for v:

$$\|v\|_{H^2}^2\le C(\|\nabla^2 v\|_{L^2}^2+\|v\|_{L^2}^2)\le C\Big(1+\frac{1}{2\tau\kappa_1}\Big)E_1(w^2)+2C. \tag{4.7}$$

The Leray–Schauder fixed-point theorem provides a solution v to $S(v,1)=v$, which we denote by v_ε. Obviously, v_ε satisfies (4.4).

Step 3. Lower bound for v_ε. By construction of v_ε, there exists $y_\varepsilon\in H^2(\mathbb{T}^d)$ such that $v_\varepsilon=e^{y_\varepsilon/2}$. Going back to (4.6), we see that

$$\frac{1}{2\tau}(E_1(v_\varepsilon^2)-E_1(w^2))\le-\varepsilon\int_{\mathbb{T}^d}((\Delta y_\varepsilon)^2+y_\varepsilon^2)dx\le-\varepsilon C\|y_\varepsilon\|_{H^2}^2,$$

using the Gagliardo–Nirenberg inequality. Hence,

$$\|y_\varepsilon\|_{H^2}\le\left(\frac{E_1(w^2)}{2\varepsilon\tau C}\right)^{1/2}\le c\varepsilon^{-1/2}, \tag{4.8}$$

where $c>0$ is, here and in the following, a generic constant independent of ε. In combination with the embedding $H^2(\mathbb{T}^d)\hookrightarrow L^\infty(\mathbb{T}^d)$, this gives $\|y_\varepsilon\|_{L^\infty}\le c\varepsilon^{-1/2}$. Consequently, v_ε is strictly positive:

$$v_\varepsilon=\exp\Big(\frac{y_\varepsilon}{2}\Big)\ge\exp\Big(-\frac{c}{2\varepsilon^{1/2}}\Big)=\mu(\varepsilon)>0.$$

Thus, with $\mu:=\mu(\varepsilon)$, it holds that $[v_\varepsilon]_\mu=v_\varepsilon$, and the respective fixed point $v_\varepsilon\in H^2(\mathbb{T}^d)$ satisfies

$$\begin{aligned}\frac{1}{\tau}(v_\varepsilon^2-w^2)&=-\partial_{ij}^2(v_\varepsilon\partial_{ij}^2v_\varepsilon-\partial_i v_\varepsilon\partial_j v_\varepsilon)\\&\quad-\varepsilon(\Delta^2\log v_\varepsilon+\log v_\varepsilon)+\varepsilon\operatorname{div}(|\nabla\log v_\varepsilon|^2\nabla\log v_\varepsilon).\end{aligned} \tag{4.9}$$

Step 4. The limit $\varepsilon\to 0$. The estimate (4.7) shows that the sequence (v_ε) is bounded in $H^2(\mathbb{T}^d)$. Thus, for a subsequence which is not relabeled, $v_\varepsilon\rightharpoonup v$ weakly in $H^2(\mathbb{T}^d)$ and $v_\varepsilon\to v$ strongly in $W^{1,4}(\mathbb{T}^d)$ and $L^\infty(\mathbb{T}^d)$ as $\varepsilon\to 0$ for some $v\in H^2(\mathbb{T}^d)$. For the first expression on the right-hand side in (4.9), we thus obtain

$$v_\varepsilon\partial_{ij}^2v_\varepsilon-\partial_i v_\varepsilon\partial_j v_\varepsilon\rightharpoonup v\partial_{ij}^2v-\partial_i v\partial_j v\quad\text{weakly in }L^2(\mathbb{T}^d).$$

In order to prove that v is indeed a solution to (4.1), we verify that the expressions involving the factor ε vanish as $\varepsilon \to 0$. From the refined coercivity estimate

$$a(y_\varepsilon, y_\varepsilon) \geq \varepsilon(c\|y_\varepsilon\|_{H^2}^2 + \|\nabla y_\varepsilon\|_{L^4}^4),$$

we learn that

$$\|\nabla y_\varepsilon\|_{L^4} \leq c\varepsilon^{-1/4}.$$

In combination with (4.8), this gives

$$\begin{aligned}
&\big|\big\langle \varepsilon\big(\Delta^2 \log v_\varepsilon + \log v_\varepsilon - \operatorname{div}(|\nabla \log v_\varepsilon|^2 \nabla \log v_\varepsilon)\big), z\big\rangle_{H^{-2},H^2}\big| \\
&\quad \leq \varepsilon\big(\|\log v_\varepsilon\|_{H^2}\|z\|_{H^2} + \|\log v_\varepsilon\|_{L^2}\|z\|_{L^2} + \|\nabla \log v_\varepsilon\|_{L^4}^3\|z\|_{W^{1,4}}\big) \\
&\quad \leq c(\varepsilon^{1/2} + \varepsilon^{1/4})\|z\|_{H^2}
\end{aligned}$$

for any test function $z \in H^2(\mathbb{T}^d)$. Therefore,

$$\varepsilon\big(\Delta^2 \log v_\varepsilon + \log v_\varepsilon - \operatorname{div}(|\nabla \log v_\varepsilon|^2 \nabla \log v_\varepsilon)\big) \rightharpoonup 0 \quad \text{weakly in } H^{-2}(\mathbb{T}^d),$$

so v satisfies (4.1).

Step 5. Verification of (4.2) and (4.3). Conservation of mass follows from the weak formulation of (4.1) by using $z \equiv 1$ as a test function. From (4.6) and Lemma 2.4 it follows that

$$E_1(v_\varepsilon^2) + 2\tau\kappa_1 \int_{\mathbb{T}^d} \|\nabla^2 v_\varepsilon\|^2 dx \leq E_1(w^2).$$

In the limit $\varepsilon \to 0$, this inequality gives (4.2) since (a subsequence of) v_ε converges weakly to v in $H^2(\mathbb{T}^d)$ and the L^2 norm of the Hessian of v_ε constitutes a weakly lower semicontinuous functional on $H^2(\mathbb{T}^d)$.

Next, we prove (4.3). Recall that the solutions v_ε of the regularized equation (4.4) are strictly positive and bounded in modulus. Hence $\log v_\varepsilon$ and v_ε^p, for arbitrary exponents $p \in \mathbb{R}$, are well-defined functions in $H^2(\mathbb{T}^d)$. Using the test function $\phi_\gamma'(v_\varepsilon)/2 = (v_\varepsilon^{2(\gamma-1)} - 1)/2(\gamma-1)$ in (4.9) gives (see (3.1) for the definition of ϕ_γ)

$$\begin{aligned}
\frac{1}{2\tau}&(E_\gamma(v_\varepsilon^2) - E_\gamma(w^2)) = \frac{1}{2\tau}\int_{\mathbb{T}^d} \big(\phi_\gamma(v_\varepsilon^2) - \phi_\gamma(w^2)\big)dx \\
&\leq \frac{1}{2\tau}\int_{\mathbb{T}^d} \phi_\gamma'(v_\varepsilon^2)(v_\varepsilon^2 - w^2)dx = \frac{1}{2(\gamma-1)\tau}\int_{\mathbb{T}^d}(v_\varepsilon^2 - w^2)\partial_{ij}^2(v_\varepsilon^{2(\gamma-1)})dx \\
&= -\frac{1}{2(\gamma-1)}\int_{\mathbb{T}^d}(v_\varepsilon\partial_{ij}^2 v_\varepsilon - \partial_i v_\varepsilon \partial_j v_\varepsilon)\partial_{ij}^2(v_\varepsilon^{2(\gamma-1)})dx \\
&\quad - \frac{\varepsilon}{\gamma-1}\int_{\mathbb{T}^d}\big(\Delta(v_\varepsilon^{2(\gamma-1)})\Delta(\log v_\varepsilon) + |\nabla \log v_\varepsilon|^2 \nabla(\log v_\varepsilon)\cdot\nabla(v_\varepsilon^{2(\gamma-1)})\big)dx \\
&\quad - \frac{\varepsilon}{2(\gamma-1)}\int_{\mathbb{T}^d} v_\varepsilon^{\gamma-1}\log v_\varepsilon dx \\
&= A_1 - \varepsilon A_2 - \varepsilon A_3.
\end{aligned}$$

Now, by Lemma 2.2,

$$A_1 \leq -\kappa_\gamma \int_{\mathbb{T}^d} (\Delta u^{\gamma/2})^2 dx.$$

Furthermore, by Lemma 2.5, applied to $f = u^{\gamma/2}$ and $p = \gamma$, and since u has unit mass, we obtain

$$\frac{\gamma}{\gamma-1}\left(\int_{\mathbb{T}^d} u^\gamma dx - 1\right) \le \frac{1}{8\pi^4}\int_{\mathbb{T}^d}(\Delta u^{\gamma/2})^2 dx,$$

so finally,

$$A_1 \le -\frac{8\pi^4\gamma\kappa_\gamma}{\gamma-1}\left(\int_{\mathbb{T}^d} u^\gamma dx - 1\right) = -8\pi^4\gamma^2\kappa_\gamma E_\gamma(v_\varepsilon^2).$$

Now, we show that A_2 and A_3 are bounded from below, uniformly in $\varepsilon > 0$. This is clear for A_3 since $\gamma > 1$. The remaining integral can be written as

$$\begin{aligned} A_2 &= 2\int_{\mathbb{T}^d} v_\varepsilon^{2(\gamma-1)}\Big(\Big(\frac{\Delta v_\varepsilon}{v_\varepsilon}\Big)^2 - 2(2-\gamma)\frac{\Delta v_\varepsilon}{v_\varepsilon}\Big|\frac{\nabla v_\varepsilon}{v_\varepsilon}\Big|^2 + 2(2-\gamma)\Big|\frac{\nabla v_\varepsilon}{v_\varepsilon}\Big|^4\Big)dx \\ &= 2\int_{\mathbb{T}^d} v_\varepsilon^{2(\gamma-1)}\Big(\Big(\frac{\Delta v_\varepsilon}{v_\varepsilon} - (2-\gamma)\Big|\frac{\nabla v_\varepsilon}{v_\varepsilon}\Big|^2\Big)^2 + \gamma(2-\gamma)\Big|\frac{\nabla v_\varepsilon}{v_\varepsilon}\Big|^4\Big)dx \\ &\ge 0 \end{aligned}$$

since $\gamma < (\sqrt{d}+1)^2/(d+2) \le 3/2$. These estimates give

$$\frac{1}{\tau}(E_1(v_\varepsilon^2) - E_1(w^2)) \le -16\pi^4\gamma^2\kappa_\gamma E_\gamma(v_\varepsilon^2).$$

We pass to the limit $\varepsilon \to 0$ in this inequality. As $v_\varepsilon \to v$ strongly in $L^\infty(\mathbb{T}^d)$, integration and limit commute and we conclude that

$$\frac{1}{\tau}(E_\gamma(v^2) - E_\gamma(w^2)) \le -16\pi^4\gamma^2\kappa_\gamma E_\gamma(v^2)$$

from which (4.3) follows. This finishes the proof. ◻

4.2. A priori estimates. Let an arbitrary terminal time $T > 0$ be fixed in the following. Define the step function $v^{(\tau)} : [0,T) \to L^2(\mathbb{T}^d)$ recursively as follows. Let $v_0 = \sqrt{u_0}$, and for given $k \in \mathbb{N}$, let $v_k \in H^2(\mathbb{T}^d)$ be the nonnegative solution (according to Lemma 4.1) to (4.1) with $w = v_{k-1}$. Now define $v^{(\tau)}(t) := v_k$ for $(k-1)\tau < t \le k\tau$. Then $v^{(\tau)}$ satisfies

$$\frac{1}{\tau}\big((v^{(\tau)})^2 - (\sigma_\tau v^{(\tau)})^2\big) = -\partial_{ij}^2\big(v^{(\tau)}\partial_{ij}^2 v^{(\tau)} - \partial_i v^{(\tau)}\partial_j v^{(\tau)}\big), \tag{4.10}$$

where σ_τ denotes the shift operator $(\sigma_\tau v^{(\tau)})(t) = v^{(\tau)}(t-\tau)$ for $\tau \le t < T$. In order to pass to the continuum limit $\tau \to 0$ in (4.10), we need the following a priori estimate.

LEMMA 4.2. *The function $v^{(\tau)}$ satisfies*

$$\|(v^{(\tau)})^2\|_{L^{11/10}(0,T;H^2(\mathbb{T}^d))} + \tau^{-1}\|(v^{(\tau)})^2 - (\sigma_\tau v^{(\tau)})^2\|_{L^{11/10}(0,T;H^{-2}(\mathbb{T}^d))} \le c, \tag{4.11}$$

where the constant $c > 0$ is independent of τ.

Proof. From Lemma 4.1 we know that

$$\|v^{(\tau)}\|_{L^\infty(0,T;L^2(\mathbb{T}^d))} = \|u_0\|_{L^1(\mathbb{T}^d)}^{1/2} = 1, \quad \|\nabla^2 v^{(\tau)}\|_{L^2(0,T;L^2(\mathbb{T}^d))} \le c.$$

In order to derive (4.11), we employ the Gagliardo–Nirenberg and Hölder inequalities. The former inequality shows that

$$
\begin{aligned}
\|v^{(\tau)}\|^{8/3}_{L^{8/3}(0,T;L^\infty(\mathbb{T}^d))} &\le C\int_0^T \|v^{(\tau)}(t,\cdot)\|^{8\theta/3}_{H^2}\|v^{(\tau)}(t,\cdot)\|^{8(1-\theta)/3}_{L^2}dt \\
&\le C\|v^{(\tau)}\|^{8(1-\theta)/3}_{L^\infty(0,T;L^2(\mathbb{T}^d))}\int_0^T \|v^{(\tau)}(t,\cdot)\|^{8\theta/3}_{H^2}dt,
\end{aligned}
\tag{4.12}
$$

where $\theta = d/4$. Since $8\theta/3 = 2d/3 \le 2$ in dimensions $d \le 3$, the right-hand side is uniformly bounded. Applying Hölder's inequality with respect to t, for $p = 9/5$ and $p' = 9/4$, we infer that

$$
\begin{aligned}
\|v^{(\tau)}\partial^2_{ij}v^{(\tau)}\|^{11/10}_{L^{11/10}(0,T;L^2(\mathbb{T}^d))} &\le C\int_0^T \|v^{(\tau)}(t,\cdot)\|^{11/10}_{H^2}\|v^{(\tau)}(t,\cdot)\|^{11/10}_{L^\infty}dt \\
&\le C\|v^{(\tau)}\|^{11/10}_{L^{11p/10}(0,T;H^2(\mathbb{T}^d))}\|v^{(\tau)}\|^{11/10}_{L^{11p'/10}(0,T;L^\infty(\mathbb{T}^d))}.
\end{aligned}
\tag{4.13}
$$

Since $11p/10 = 99/50 \le 2$ and $11p'/10 = 99/40 \le 8/3$, the right-hand side is uniformly bounded in view of the boundedness of $v^{(\tau)}$ in $L^{8/3}(0,T;L^\infty(\mathbb{T}^d))$. On the other hand, by the Gagliardo–Nirenberg inequality,

$$
\begin{aligned}
\|v^{(\tau)}\|^{16/7}_{L^{16/7}(0,T;W^{1,4}(\mathbb{T}^d))} &\le C\int_0^T \|v^{(\tau)}(t,\cdot)\|^{16\theta/7}_{H^2}\|v^{(\tau)}(t,\cdot)\|^{16(1-\theta)/7}_{L^2}dt \\
&\le C\|v^{(\tau)}\|^{16(1-\theta)/7}_{L^\infty(0,T;L^2(\mathbb{T}^d))}\|v^{(\tau)}\|^{16\theta/7}_{L^{16\theta/7}(0,T;H^2(\mathbb{T}^d))},
\end{aligned}
\tag{4.14}
$$

where $\theta = (d+4)/8$. As $16\theta/7 = 2(d+4)/7 \le 2$ in dimensions $d \le 3$, $v^{(\tau)}$ is uniformly bounded in $L^{16/7}(0,T;W^{1,4}(\mathbb{T}^d))$. As a straightforward conclusion,

$$
\begin{aligned}
\|\partial_i v^{(\tau)}\partial_j v^{(\tau)}\|^{11/10}_{L^{11/10}(0,T;L^2(\mathbb{T}^d))} &\le \int_0^T \|\nabla v^{(\tau)}(t,\cdot)\|^{22/10}_{L^4}dt \\
&\le \|v^{(\tau)}\|^{22/10}_{L^{22/10}(0,T;W^{1,4}(\mathbb{T}^d))} \le c,
\end{aligned}
\tag{4.15}
$$

since $22/10 < 16/7$. Estimates (4.13) and (4.15) together yield

$$
\begin{aligned}
&\|\nabla^2(v^{(\tau)})^2\|_{L^{11/10}(0,T;L^2(\mathbb{T}^d))} \\
&\qquad\le 2\sum_{i,j=1}^d \|v^{(\tau)}\partial_{ij}v^{(\tau)} + \partial_i v^{(\tau)}\partial_j v^{(\tau)}\|_{L^{11/10}(0,T;L^2(\mathbb{T}^d))} \le c.
\end{aligned}
$$

Moreover, by (4.12) and (4.14), since $22/10 < 8/3$ and $22/10 < 16/7$,

$$
\|\nabla(v^{(\tau)})^2\|_{L^{11/10}(0,T;L^2(\mathbb{T}^d))} \le 2\|v^{(\tau)}\|_{L^{22/10}(0,T;L^4(\mathbb{T}^d))}\|\nabla v^{(\tau)}\|_{L^{22/10}(0,T;L^4(\mathbb{T}^d))}.
$$

The right-hand side is bounded by the considerations above. This estimates the first term in (4.11). To obtain a uniform bound on the second term in (4.11), we combine again (4.13) and (4.15):

$$
\begin{aligned}
&\frac{1}{\tau}\|(v^{(\tau)})^2 - (\sigma_\tau v^{(\tau)})^2\|_{L^{11/10}(0,T;H^{-2}(\mathbb{T}^d))} \\
&\quad\le \sum_{i,j=1}^d \Big(\|v^{(\tau)}\partial^2_{ij}v^{(\tau)}\|_{L^{11/10}(0,T;L^2(\mathbb{T}^d))} + \|\partial_i v^{(\tau)}\partial_j v^{(\tau)}\|_{L^{11/10}(0,T;L^2(\mathbb{T}^d))}\Big) \le c. \qquad \square
\end{aligned}
$$

4.3. The limit $\tau \to 0$. The a priori estimates of the previous subsection are sufficient to pass to the limit $\tau \to 0$.

LEMMA 4.3. *There exists some nonnegative function $u \in W^{1,1}(0,T;H^{-2}(\mathbb{T}^d))$ with $\sqrt{u} \in L^2(0,T;H^2(\mathbb{T}^d))$ such that, for a subsequence of $(v^{(\tau)})$, which is not relabeled, as $\tau \to 0$,*

$$\begin{aligned} \frac{1}{\tau}\left((v^{(\tau)})^2 - \sigma_\tau(v^{(\tau)})^2\right) &\rightharpoonup \partial_t u \quad \textit{weakly in } L^{11/10}(0,T;H^{-2}(\mathbb{T}^d)),\\ v^{(\tau)}\partial_{ij}^2 v^{(\tau)} &\rightharpoonup \sqrt{u}\partial_{ij}^2\sqrt{u} \quad \textit{weakly in } L^1(0,T;L^2(\mathbb{T}^d)),\\ \partial_i v^{(\tau)}\partial_j v^{(\tau)} &\rightharpoonup \partial_i\sqrt{u}\partial_j\sqrt{u} \quad \textit{weakly in } L^1(0,T;L^2(\mathbb{T}^d)). \end{aligned}$$

Moreover, u is a weak solution to (1.4)–(1.5).

Proof. Estimate (4.11) allows to apply the Aubin lemma [22], showing that, up to a subsequence, $(v^{(\tau)})^2 \to u$ in $L^{11/10}(0,T;L^\infty(\mathbb{T}^d))$ as $\tau \to 0$ for some limit function u. Here, we have used that $H^2(\mathbb{T}^d)$ embeds compactly into $L^\infty(\mathbb{T}^d)$ in dimensions $d \le 3$. In particular, $(v^{(\tau)})$ converges pointwise a.e. Since obviously, $(v^{(\tau)})^2$ is nonnegative, so is u, and we can define $\sqrt{u} \in L^{22/10}(0,T;L^\infty(\mathbb{T}^d))$; note that $v^{(\tau)}$ converges strongly to $\sqrt{u}$ in this space.

Now, the first claim follows directly from (4.11) and the construction of $v^{(\tau)}$. Estimate (4.11) further yields weak convergence of $v^{(\tau)}$ in $L^2(0,T;H^2(\mathbb{T}^d))$. The weak limit necessarily coincides with $\sqrt{u}$, the strong limit from above.

By Hölder's inequality,

$$\begin{aligned} \|v^{(\tau)} - \sqrt{u}\|^2_{L^2(0,T;L^\infty(\mathbb{T}^d)} &\le \|(v^{(\tau)} - \sqrt{u})^2\|_{L^{11/10}(0,T;L^\infty(\mathbb{T}^d))} \cdot T^{1/11}\\ &\le \|(v^{(\tau)})^2 - u\|_{L^{11/10}(0,T;L^\infty(\mathbb{T}^d))} \cdot T^{1/11}. \end{aligned} \tag{4.16}$$

In the last step, we have used that $(a-b)^2 \le |a^2 - b^2|$ for arbitrary nonnegative $a, b \in \mathbb{R}$. Now, by the Gagliardo–Nirenberg and Hölder inequalities,

$$\begin{aligned} &\|\nabla(v^{(\tau)} - \sqrt{u})\|^2_{L^2(0,T;L^4(\mathbb{T}^d))}\\ &\qquad \le C\|v^{(\tau)} - \sqrt{u}\|_{L^2(0,T;H^2(\mathbb{T}^d))}\|v^{(\tau)} - \sqrt{u}\|_{L^2(0,T;L^\infty(\mathbb{T}^d))}. \end{aligned}$$

The first term in the product is bounded (cf. estimate (4.2)); the second term converges to zero by (4.16) above. Thus $v^{(\tau)} \to \sqrt{u}$ strongly in $L^2(0,T;W^{1,4}(\mathbb{T}^d))$ and

$$\partial_i v^{(\tau)}\partial_j v^{(\tau)} \rightharpoonup \partial_i\sqrt{u}\partial_j\sqrt{u} \quad \text{weakly in } L^1(0,T;L^2(\mathbb{T}^d)).$$

The remaining limit follows from (4.16) and weak convergence of $v^{(\tau)}$ to $\sqrt{u}$ in $L^2(0,T;H^2(\mathbb{T}^d))$. Finally, since $L^2(0,T;H^2(\mathbb{T}^d)) \hookrightarrow L^2(0,T;L^\infty(\mathbb{T}^d))$, one verifies that $u = \sqrt{u}\cdot\sqrt{u} \in L^1(0,T;H^2(\mathbb{T}^d))$ by the Hölder and Gagliardo–Nirenberg estimates. ∎

5. Decay rates for nonnegative weak solutions. We prove Theorem 1.2 for the solutions constructed in the previous section.

First, we show that $\kappa_\gamma > 0$ for $1 \le \gamma < (\sqrt{d}+1)^2/(d+2)$. Indeed, by definition, $\kappa_\gamma > 0$ if $p(\gamma) > 0$, with the quadratic polynomial $p(\gamma)$ given in (2.6). But $p(\gamma) > 0$ if and only if $\gamma_- < \gamma < \gamma_+$ where $\gamma_\pm$ are the two roots of p. Now, a computation yields $\gamma_\pm = (\sqrt{d} \pm 1)^2/(d+2)$, and it is immediately seen that $\gamma_- < 1 < \gamma_+$.

Next, set $t_n = n\tau$ for $n = 0, \dots, M$. From (4.3) we know that

$$E_\gamma\big(v^{(\tau)}(t_{n+1},\cdot)^2\big) - E_\gamma\big(v^{(\tau)}(t_n,\cdot)^2\big) \le -(2\pi)^4\tau\gamma^2\kappa_\gamma E_\gamma\big(v^{(\tau)}(t_{n+1},\cdot)^2\big).$$

Summation over $n = 0, \dots, M-1$ gives

$$\begin{aligned} E_\gamma\big(v^{(\tau)}(t_M,\cdot)^2\big) - E_\gamma(u_0) &\le -(2\pi)^4\tau\gamma^2\kappa_\gamma \sum_{j=1}^{M} E_\gamma\big(v^{(\tau)}(t_j,\cdot)^2\big) \\ &\le -(2\pi)^4\tau\gamma^2\kappa_\gamma \int_\tau^{t_M} E_\gamma\big(v^{(\tau)}(s,\cdot)^2\big)ds. \end{aligned}$$

Keep t fixed; perform the limits $\tau \to 0$ and $M \to \infty$ such that $t_M = M\tau \to t$. Since $v^{(\tau)} \to \sqrt{u}$ strongly in $L^2(0,T;L^\infty(\mathbb{T}^d))$ as $\tau \to 0$,

$$E_\gamma\big(u(t,\cdot)\big) \le E_\gamma(u_0) - (2\pi)^4\tau\gamma^2\kappa_\gamma \int_0^t E_\gamma\big(u(s,\cdot)\big)ds.$$

Gronwall's lemma leads to the desired decay estimate. Decay in the L^1 norm follows immediately from the Csiszár–Kullback inequality. This finishes the proof of Theorem 1.2.

6. Nonuniqueness of solutions. In dimensions $d \le 3$, we provide a family of initial conditions for which the DLSS equation (1.4)–(1.5) has at least two solutions in the class $L^1(0,T;H^2(\mathbb{T}^d))$ for all $T > 0$. Namely, for arbitrary integers $n_1, \dots, n_d$, let

$$\hat{u}(t,x) = \cos^2(n_1\pi x_1)\cdots\cos^2(n_d\pi x_d), \quad x = (x_1,\dots,x_n)^\top \in \mathbb{T}^d.$$

This function is C^∞ smooth, time-independent, spatially multiperiodic, and has finite physical entropy, $\int_{\mathbb{T}^d}(\hat{u}(\log\hat{u}-1)+1)dx < +\infty$. Moreover, a simple calculation shows that the distribution

$$\partial^2_{ij}\big(\sqrt{\hat{u}}\partial^2_{ij}\sqrt{\hat{u}} - \partial_i\sqrt{\hat{u}}\partial_j\sqrt{\hat{u}}\big)$$

is identically zero. In other words, $\hat{u}$ is a weak solution of the stationary and, hence, also of the transient equation. This time-independent function is clearly not physical: it does not converge to the homogeneous steady state and it does not dissipate the physical (or any other) entropy.

On the other hand, Theorems 1.1 and 1.2 provide the existence of a weak solution $u(t,\cdot)$ to (1.4) with initial datum $u_0(x) = \hat{u}(0,x)$ which converges to the constant steady state as $t \to \infty$. Thus, $u \ne \hat{u}$. Hence, we have found two weak solutions to (1.4)–(1.5) in the class of nonnegative functions in $L^1(0,T;H^2(\mathbb{T}^d))$.

Moreover, the above observation makes clear that one cannot expect strict positivity of weak solutions for $t > 0$ if the initial conditions attain zero somewhere. On the other hand, numerical experiments (see, e.g., [8]) lead to the conjecture that for strictly positive initial data, the solutions are also strictly positive.

We remark that the stationary solution $\hat{u}$ does *not* have the regularity stated in the conclusions of Theorem 1.1: observe that $\sqrt{\hat{u}} \notin L^2(0,T;H^2(\mathbb{T}^d))$. Whether the condition $\sqrt{u} \in L^2(0,T;H^2(\mathbb{T}^d))$ is sufficient to obtain entropy-dissipative solutions (or perhaps even uniqueness and positivity) remains an open question.

Acknowledgment. The authors thank the anonymous referee for a simplification of the proof of Lemma 2.1.

A FLUID DYNAMIC MODEL FOR T-JUNCTIONS*

ALESSIA MARIGO† AND BENEDETTO PICCOLI†

Abstract. Motivated by real road junctions, we consider a new fluid dynamic model for traffic flow on networks. In particular at T-junctions, beside some flows distribution and/or merging, there happen some interactions of cars coming from different roads and going to different destinations. After determining some rules to uniquely solve Riemann problems, we prove existence of solutions on complete networks for initial data with bounded variation (and their limits in L^1_{loc}).

Key words. traffic flow on networks, conservation laws, T-junctions

AMS subject classifications. 90B20, 35L65

DOI. 10.1137/060673060

1. Introduction.

In recent years, many authors contributed to the development of fluid dynamic theory for flows on networks, see [4, 6, 7, 10, 11, 13, 14, 15, 16, 19]. The most important applications are in urban car traffic [5, 12], telecommunication data networks [9, 21, 22], gas pipelines [2], supply chains [1], and others.

The main approach used for car traffic is based on the idea of a junction (corresponding to the nodes of the network), with no particular relationships between incoming and outgoing roads. Then, real crossings are modeled splitting them into many junctions of lower complexity; see, e.g., [6, 13]. This means that the traffic flow from incoming roads distributes to outgoing roads according to certain preferences, which in [7] were modeled by a traffic distribution matrix. Then, in general, to solve uniquely Riemann problems, i.e., Cauchy problems with constant initial data on each road, one also needs to impose the maximization of a functional, e.g., the total flux.

In this paper we consider a different point of view for junctions, inspired by modeling need. To illustrate our approach, let us focus on a simple example of T-junction, represented in Figure 1. Here we have three roads with both directions of traffic. Then we can individuate the incoming flows, denoted by 1, 2, and 3, and the outgoing ones, denoted by A, B, and C. Each incoming flux at the junction splits into two parts depending on the final destination. Thus flux 1 is split into fluxes $1B$ and $1C$ (assuming that U-turns are not possible). As Figure 1 shows, there are many interactions among the various fluxes at the junction. However, not all such interactions can be considered in the same way. In fact, for instance, fluxes $1B$ and $3B$ must flow to the same final direction, thus clearly their sum cannot exceed the possible outgoing flow towards B. On the contrary, fluxes $1B$ and $3A$ share conflicting trajectories, but they do not share the same final destination, thus their sum is bounded only by the junction capacity.

To capture this situation, we model the T-junction as in Figure 2. More precisely, to encompass the whole dynamic happening at the T-junction, we use nine virtual junctions denoted by letters G, H, and K. The three junctions G are formed by an

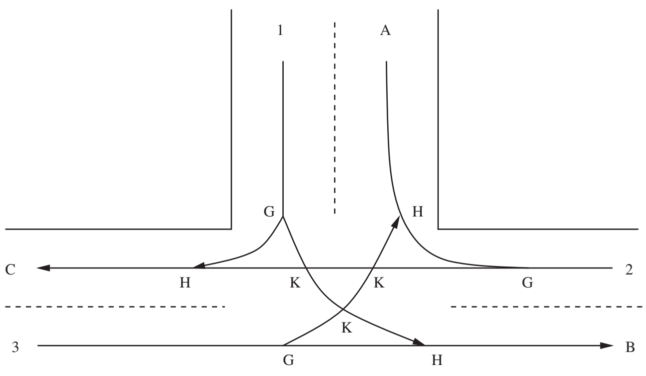

Fig. 2. *The model for a T-junction.*

incoming road and two outgoing roads, thus the described phenomenon is simply a flux split. Such junctions were already modeled in [7].

Instead, the three junctions H are formed by two incoming and one outgoing roads. In this case, clearly some right of way or yielding rule should show up to describe the traffic distribution. This is in fact the case and the theory was first developed in [6].

The junctions K have a quite different meaning. In this case there are two incoming and two outgoing roads. However, the traffic from each incoming road goes to a precise outgoing road, while sharing the junction space. Our main aim is then to model these new types of junctions. Let us illustrate the mathematical counterpart of this example.

We use the Lighthill–Whitham–Richards model (see [20, 23]), which consists of a single conservation law:

$$\rho_t + f(\rho)_x = 0, \tag{1.1}$$

where $\rho \in [0, \rho_{\max}]$ is the car density and $f(\rho) = \rho v(\rho)$ is the flux with $v(\rho)$ the average velocity. A junction J is called a crossing junction if it has the same characteristic of junctions K above. Thus J has n incoming roads, denoted for simplicity by $I_1, \dots, I_n$, and n outgoing roads, denoted by $I_{n+1}, \dots, I_{2n}$. Also, we denote by $\rho_i(t,x)$, $i = 1, \dots, n$, and $\rho_j(t,x)$, $j = n+1, \dots, 2n$, the traffic densities, respectively, on the incoming roads and the outgoing ones. To describe the dynamics at J, we assume the following.

(1) The flux from road I_i is the same of the corresponding exiting road I_{n+i}.

(2) The total flux through J does not exceed its maximum capacity Γ_J.

(3) The total flux through J is maximal respecting rules (1) and (2).

In case of high traffic, rules (1), (2), and (3) are not enough to isolate a unique solution to Riemann problems at J. This need of a new rule is not at all surprising, since such rules were used in car traffic for junctions with more incoming than outgoing roads, see [6], and also for telecommunication networks; see [9].

Therefore, we introduce a *flux proportion rule*, which is active only when the maximal incoming fluxes overcome the maximal junction capacity Γ_J. More precisely, we assume that there exist ideal equilibrium flux proportions among incoming roads. Thus, there exist coefficients $\bar{r}_i$ so that the following holds.

(FPR) The flux from road I_{i+1} is $\bar{r}_i$ times the flux from road I_i, for $i = 1, \dots, n-1$.

The rule (FPR) well captures the situation in the example of the T-junction above. Indeed, for instance, the flux $3A$ must yield to the flux $2C$, thus the corresponding flux proportion coefficient will be less than 1. While, usually the flux $1B$ must give precedence to the flux $3A$, unless yielding signs are deciding the contrary.

Let us further illustrate the role of rule (FPR), for simplicity restricting to the case of two incoming and two outgoing roads. First, (FPR) is used only if the sum of incoming maximal fluxes exceeds Γ_J. Then, to respect (FPR), we should set the incoming fluxes γ_1 and γ_2 so that $\gamma_2 = \bar{r}_1\gamma_1$. However, this may be in contrast with (3) (if, for example, $\bar{r}_1 = 1$, the maximal flux $\gamma_1^{\max}$ from road 1 exceeds Γ_J and the maximal flux from road 2 is less than $\Gamma_J/2$). In the latter case, we set the proportion between incoming fluxes so to respect rule (3) (i.e., summing up to Γ_J) and be as close as possible to the value prescribed by (FPR).

We first show how to define the solution to Riemann problems for the new type of junctions: the *crossing junctions*. The procedure to define the solution is based on rules (1), (2), (3), and (FPR). The obtained solution effectively defines a Riemann solver with consistency properties; see Proposition 2.

Then we provide estimates on the total variation of the flux for a wave interacting with a crossing junction, having two incoming and two outgoing roads. Such estimates are the key point to prove bounded variation (BV) estimates on the flux along wave front tracking approximate solutions.

More precisely, a wave front tracking algorithm is defined as in [7], i.e., approximating initial data with a piecewise constant function and solving Riemann problems (RPs) for interactions between waves and of waves with junctions. To provide a well-defined construction, estimates on the number of waves and interactions are in order. The latter are obtained with a careful analysis based on the special properties of the introduced Riemann solver. Then, to pass to the limit, BV estimates on the flux are used, together with standard weak compactness arguments. The final result is existence of solutions to Cauchy problems on networks.

The paper is organized as follows. Section 2 provides the basic definitions and results from previous papers, while in section 2.1 we describe the Riemann solver for crossing junctions. Section 3 contains flux variation estimates for waves interacting with crossing junctions. Finally, in section 4, we prove existence of solutions on the whole network for L^1_{loc} initial data, which can be approximated by BV functions with uniformly bounded variation.

2. Basic definitions. We use the same approach as in [16, 7, 11]. For reader convenience, we recall the main notation and results.

We consider a network formed by a collection $\mathcal{I}$ of unidirectional roads I_i, modeled by real (possibly unbounded) intervals $[a_i, b_i]$, whose natural order respects the direction of the road. Roads meet at junctions: each junction J is given by a collection of incoming roads and outgoing roads, and we indicate by $\mathcal{J}$ the collection of junctions. Thus the network can be identified with a directed graph. On each road the evolution is given by (1.1) and we assume

(F) The flux f is a smooth, strictly concave function (with $f(0) = f(\rho_{\max}) = 0$), thus there exists a unique $\sigma \in [0, \rho_{\max}]$ such that $f'(\sigma) = 0$ and it is the maximum of f over $[0, \rho_{\max}]$.

For notational simplicity, we assume that $\rho_{\max} = 1$.

DEFINITION 1. *We let $\tau : [0, 1] \to [0, 1]$ be the map such that $f(\rho) = f(\tau(\rho))$ and $\tau(\rho) \neq \rho$ if $\rho \neq \sigma$. Thus τ sends ρ to the other density value with the same flux (and $\tau(\sigma) = \sigma$).*

We restrict to crossing junctions as explained in the introduction. Then each junction J has $n = n(J)$ incoming roads and n outgoing roads.

Let us fix now a junction J and for simplicity assume that the incoming roads are $I_1, \ldots, I_n$ and the outgoing roads are $I_{n+1}, \ldots, I_{2n}$. A Riemann problem for system (1.1), on the real line, is a Cauchy problem with Heaviside-type initial data. We define a Riemann problem at J to be a Cauchy problem with initial datum constant on each road. Thus let us fix an initial condition $\rho_0 = (\rho_{1,0}, \ldots, \rho_{2n,0})$. We look for centered self-similar solutions (as it is natural for conservation laws, see [3]), thus we want to determine a $(2n)$-tuple $\hat{\rho} = (\hat{\rho}_1, \ldots, \hat{\rho}_{2n}) \in [0, 1]^{2n}$, so that the following holds. On each incoming road I_i, $i = 1, \ldots, n$, the solution consists of the single wave solution to the Riemann problem $(\rho_{i,0}, \hat{\rho}_i)$, while on each outgoing road I_j, $j = n + 1, \ldots, 2n$, the solution consists of the single wave $(\hat{\rho}_j, \rho_{j,0})$.

We consider waves with negative speed on incoming roads and positive on outgoing ones, thus

$$\hat{\rho}_i \in \begin{cases} \{\rho_{i,0}\} \cup \,]\tau(\rho_{i,0}), 1] & \text{if } 0 \leq \rho_{i,0} \leq \sigma, \\ [\sigma, 1] & \text{if } \sigma \leq \rho_{i,0} \leq 1, \end{cases} \tag{2.1}$$

$i = 1, \ldots, n$, and

$$\hat{\rho}_j \in \begin{cases} [0, \sigma] & \text{if } 0 \leq \rho_{j,0} \leq \sigma, \\ \{\rho_{j,0}\} \cup [0, \tau(\rho_{j,0})[& \text{if } \sigma \leq \rho_{j,0} \leq 1, \end{cases} \tag{2.2}$$

$j = n + 1, \ldots, 2n$. As a consequence, not every flux can be obtained on each road. More precisely, we define

$$\gamma_i^{\max} = \begin{cases} f(\rho_{i,0}) & \text{if } \rho_{i,0} \in [0, \sigma], \\ f(\sigma) & \text{if } \rho_{i,0} \in \,]\sigma, 1], \end{cases} \quad i = 1, \ldots, n, \tag{2.3}$$

and

$$\gamma_j^{\max} = \begin{cases} f(\sigma) & \text{if } \rho_{j,0} \in [0, \sigma], \\ f(\rho_{j,0}) & \text{if } \rho_{j,0} \in \,]\sigma, 1], \end{cases} \quad j = n + 1, \ldots, 2n. \tag{2.4}$$

The quantities $\gamma_i^{\max}$ and $\gamma_j^{\max}$ represent the maximum flux that can be obtained by a single wave solution on each road.

Remark 1. We may consider waves with zero speed on incoming or outgoing roads. However, this would generate shocks which stay at the intersection, without entering roads. Since solutions are usually considered in L^1, such shocks are not part of the solution on roads (because they affect the value only at one point).

Remark 2. The maximum fluxes on incoming and outgoing roads can be interpreted as maximal demands and supplies, according to the theory introduced by Lebacque; see [17, 18, 11]. Notice that for each road I_i and possible flux $\hat{\gamma}_i$, there exists a unique $\hat{\rho}_i$, satisfying (2.1) or (2.2), such that $f(\hat{\rho}_i) = \hat{\gamma}_i$. Moreover, by rule (1), outgoing fluxes are obtained once incoming fluxes are fixed. Then we obtain the following.

PROPOSITION 1. *To solve a Riemann problem at a crossing junction J, it is enough to determine the fluxes on incoming roads.*

We aim at finding a systematic way of solving RP at junctions as described by next definition.

DEFINITION 2. *Given a crossing junction J, we call Riemann solver for J a map $RS : [0,1]^n \times [0,1]^n \to [0,1]^n \times [0,1]^n$ that associates with Riemann data $\rho_0 = (\rho_{1,0}, \ldots, \rho_{2n,0})$ at J a vector $\hat{\rho} = (\hat{\rho}_1, \ldots, \hat{\rho}_{2n})$ so that the solution on an incoming road I_i, $i = 1, \ldots, n$, is given by the wave $(\rho_{i,0}, \hat{\rho}_i)$ and on an outgoing one I_j, $j = n+1, \ldots, 2n$, is given by the wave $(\rho_{j,0}, \hat{\rho}_j)$. We require the consistency condition:*

(CC) $RS\,(RS\,(\rho_0)) = RS\,(\rho_0)$.

Once a Riemann solver is introduced for every junction J, we can define the concept of solution on the network as in [11].

2.1. Riemann solver at crossing junctions. The aim of this section is to describe the solution to a Riemann problem at a crossing junction J, using rules (1), (2), (3), and (FPR).

Fix a crossing junction J with n incoming roads, $I_1, \ldots, I_n$ and n outgoing roads $I_{n+1}, \ldots, I_{2n}$. We denote by $\rho_i(t,x)$, $i = 1, \ldots, n$, and $\rho_j(t,x)$, $j = n+1, \ldots, 2n$, the traffic densities, respectively, on the incoming roads and the outgoing ones and by $(\rho_{i,0}, \rho_{j,0})$ the initial data of a Riemann problem. The rules (1), (2), and (3) can be rewritten as

(1) $f(\hat{\rho}_i) = f(\hat{\rho}_{n+i})$ for each $i = 1, \ldots, n$,

(2) $\sum_i f(\hat{\rho}_i) \le \Gamma_J$,

(3) $\sum_i f(\hat{\rho}_i)$ is maximal respecting rules (1) and (2).

The rules (1) and (2) alone do not give a unique solution $(\hat{\rho}_1, \ldots, \hat{\rho}_{2n})$. Moreover, since the solution $(\hat{\rho}_1, \ldots, \hat{\rho}_{2n})$ must satisfy conditions (1) and (2), we denote by Ω the admissible region for the fluxes $\gamma_i = f(\rho_i)$

$$\Omega = \{(\gamma_1, \ldots, \gamma_n) : \sum \gamma_i \le \Gamma_J, 0 \le \gamma_i \le \gamma_i^\wedge, i = 1, \ldots, n\},$$

where $\gamma_i^\wedge = \min\{\gamma_i^{\max}, \gamma_{n+i}^{\max}\}$.

Let us now quantify rule (FPR). We can rewrite the rule as

(FPR) $\bar{r}_i$ is the ratio among the fluxes on two successive roads $f(\hat{\rho}_i)$ and $f(\hat{\rho}_{i+1})$.

Now, we want to determine a unique solution to the Riemann problem using rules (1), (2), (3), and (FPR). More precisely, we try to fit rule (FPR) as much as possible respecting rules (1), (2), and (3).

Recall that, by Proposition 1, to solve the Riemann problem, it is enough to determine the fluxes $\hat{\gamma}_i = f(\hat{\rho}_i), i = 1, \ldots, n$. (Then $\hat{\gamma}_{n+i} = f(\hat{\rho}_i), i = 1, \ldots, n$.)

Then, let us determine $\hat{\gamma}_i, i = 1, \ldots, n$. We denote $\Gamma = \sum_i \gamma_i^\wedge$. We have to distinguish two cases:

(I) $\Gamma \le \Gamma_J$,

(II) $\Gamma > \Gamma_J$.

In the first case we set $\hat{\gamma}_i = \gamma_i^{\wedge},\ i = 1, \dots, n$. Let us analyze the second case in which we use the flux proportion coefficients $\bar{r}_1, \dots, \bar{r}_{n-1}$.

Consider the space $(\gamma_1, \dots, \gamma_n)$ and denote by γ_r the point that satisfy the following system of equations:

$$\begin{cases} \sum_i \gamma_i = \Gamma_J, \\ \gamma_{i+1} = \bar{r}_i \gamma_i. \end{cases} \tag{2.5}$$

Recall that the final fluxes should belong to Ω. We distinguish two cases:

(a) γ_r belongs to Ω,

(b) γ_r is outside Ω.

In the first case the solution is $\hat{\gamma} = \gamma_r$, which, by direct computations, is given by

$$\begin{aligned} \hat{\gamma}_1 &= \hat{\gamma}_{n+1} = \frac{1}{p(r)} \Gamma_J, \\ \hat{\gamma}_2 &= \hat{\gamma}_{n+2} = \frac{\bar{r}_1}{p(r)} \Gamma_J, \\ \hat{\gamma}_3 &= \hat{\gamma}_{n+3} = \frac{\bar{r}_1 \bar{r}_2^{\min}}{p(r)} \Gamma_J, \\ &\vdots \\ \hat{\gamma}_n &= \hat{\gamma}_{2n} = \frac{\bar{r}_1 \bar{r}_2 \cdots \bar{r}_{n-1}}{p(r)} \Gamma_J, \end{aligned} \tag{2.6}$$

where $p(r) = 1 + \bar{r}_1 + \bar{r}_1 \bar{r}_2 + \dots + \bar{r}_1 \bar{r}_2 \cdots \bar{r}_{n-1}$.

In the second case, we project γ_r on the admissible region. More precisely, for the case of two incoming and outgoing roads, i.e., for $n = 2$, the solution is as follows. If $\gamma_{r1} > \gamma_1^{\wedge}$, we set

$$\begin{aligned} \hat{\gamma}_1 &= \hat{\gamma}_3 = \gamma_1^{\wedge}, \\ \hat{\gamma}_2 &= \hat{\gamma}_4 = \Gamma_J - \gamma_1^{\wedge}. \end{aligned}$$

If otherwise $\gamma_{r2} > \gamma_2^{\wedge}$, we set

$$\begin{aligned} \hat{\gamma}_2 &= \hat{\gamma}_4 = \gamma_2^{\wedge}, \\ \hat{\gamma}_1 &= \hat{\gamma}_3 = \Gamma_J - \gamma_2^{\wedge}. \end{aligned}$$

For reader convenience, we illustrate the cases I, IIa, and IIb for the case of $n = 2$ in Figure 3.

For $n > 2$ we chose $\hat{\gamma}$ to be the projection $pr_{\widehat{\Omega}}(\gamma_r)$ on the convex set $\widehat{\Omega} = \Omega \cap \{\gamma : \sum_{i=1}^n \gamma_i = \Gamma_J\}$. (Notice that γ_r already belongs to the hyperplane $\{\gamma : \sum_{i=1}^n \gamma_i = \Gamma_J\}$.)

For future convenience we make a little abuse of notation as follows.

Notation. We define

$$\tilde{\Omega} = \{(\gamma_1, \dots, \gamma_n) : 0 \leq \gamma_i \leq \gamma_i^{\wedge}, i = 1, \dots, n\}$$

and denote by Case IIa the case where $\gamma_r \in \mathrm{Int}(\tilde{\Omega})$ and by Case IIb the case where $\gamma_r \notin \mathrm{Int}(\tilde{\Omega})$.

Roughly speaking, the case of γ_r belonging to the boundary of $\tilde{\Omega}$ is included in Case IIb, in fact this corresponds to have equality constraints on some flux solutions, as it will be more clear later.

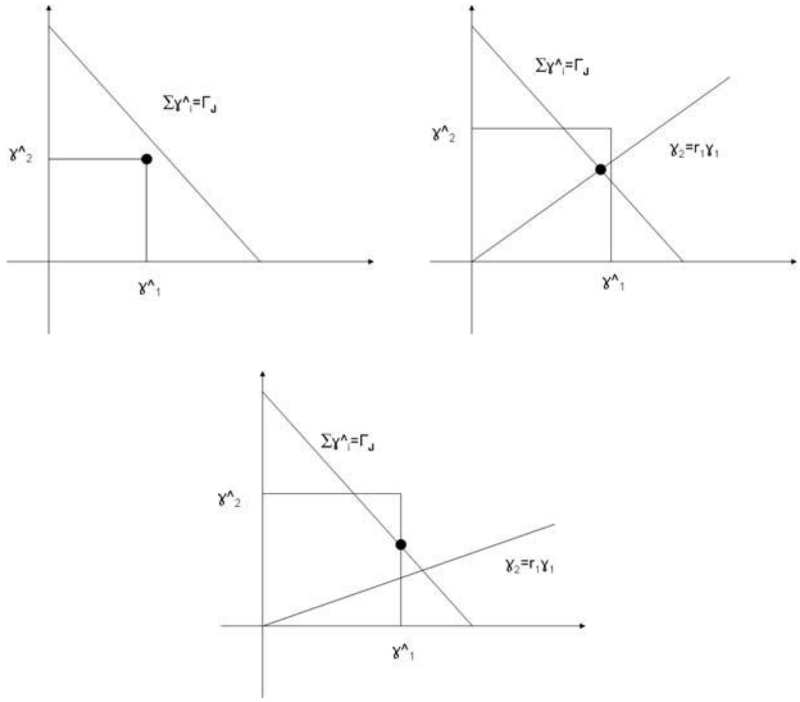

FIG. 3. *Solutions at junctions for $n = 2$: Case* I *(top), Case* IIa *(centre), Case* IIb *(bottom). The bold point represents the values of the fluxes in the solution to the Riemann problem.*

Moreover, we introduce the following.

Notation. For all $i \in \{1, \dots, n\}$ we denote

Case H0. $\rho_i \in [0, \sigma]$ and $\rho_{n+i} \in [\sigma, 1]$.

Case H1. $\rho_i \in [0, \sigma[$ and $\rho_{n+i} \in [0, \sigma[$.

Case H2. $\rho_i \in]\sigma, 1]$ and $\rho_{n+i} \in]\sigma, 1]$.

Case H3. $\rho_i \in]\sigma, 1]$ and $\rho_{n+i} \in [0, \sigma[$.

PROPOSITION 2. *Given an initial condition $(\rho_{i,0}, \rho_{j,0})$, there exists a unique $(\hat{\rho}_1, \dots, \hat{\rho}_{2n})$ satisfying rules* (1), (2), (3), *and* (FPR). *Such solution uniquely defines a Riemann solver at J, which respects the compatibility condition* (CC).

Proof. Assume first that $\Gamma \le \Gamma_J$, i.e., we are in Case I, then (2) is automatically satisfied. From (1) and (3), the solution to the RP is the point with coordinates $\hat{\gamma}_i = \hat{\gamma}_{n+i} = \min\{\gamma_i^{\max}, \gamma_{n+i}^{\max}\}$. Then there is no need to apply rule (FPR). The following situations represent an equilibrium point for the RP, i.e., $RS(\rho_0) = \rho_0$.

(i) Case H0 with $\rho_{n+i,0} = \tau(\rho_{i,0})$. Indeed $\hat{\gamma}_i = \hat{\gamma}_{n+i} = \gamma_i^{\wedge}$ and the unique solution $\hat{\rho}_i$ that satisfies $f(\hat{\rho}_i) = \hat{\gamma}_i$ and (2.1) is $\hat{\rho}_i = \rho_{i,0}$. The same can be said for $\hat{\rho}_{n+i}$.

(ii) Case H1 with $\rho_{i,0} = \rho_{n+i,0}$. Indeed $\hat{\gamma}_i = \hat{\gamma}_{n+i} = \gamma_1^{\max}$ and, as for Case H0, we have $\hat{\rho}_i = \rho_{i,0}$, while the unique $\hat{\rho}_{n+i}$, such that $f(\hat{\rho}_{n+i}) = \gamma_1^{\max}$, is $\hat{\rho}_{n+i} = \rho_{n+i,0}$.

(iii) Case H2 with $\rho_{i,0} = \rho_{n+i,0}$. This case is the opposite of (ii) and we reason in the same way.

Now the following cases may happen, for $i = 1, \dots, n$.

- If $\gamma_i^{\max} = \gamma_{n+i}^{\max}$ and the initial condition is described by Case H0, then we are in case (i).

- If $\gamma_i^{\max} = \gamma_{n+i}^{\max}$ and $(\rho_{i,0}, \rho_{n+i,0})$ is described by Case H3, then $f(\hat{\rho}_i) = \hat{\gamma}_i = \gamma_i^{\max} = f(\sigma)$ and $f(\hat{\rho}_{n+i}) = \hat{\gamma}_{n+i} = \gamma_{n+i}^{\max} = f(\sigma)$. Then the solution to the RP is given by $\hat{\rho}_i = \hat{\rho}_{n+i} = \sigma$, thus falling in (i).
- If $\gamma_i^{\max} < \gamma_{n+i}^{\max}$, then it must be $\rho_{i,0} \in [0, \sigma[$ and $\rho_{n+i,0} \in [0, \tau(\rho_{i,0})[$. Thus $f(\hat{\rho}_i) = \hat{\gamma}_i = \gamma_i^{\max} = f(\rho_{i,0})$, hence $\hat{\rho}_i = \rho_{i,0}$, and $f(\hat{\rho}_{n+i}) = \hat{\gamma}_i = \gamma_i^{\max} = f(\rho_{i,0})$ and $\hat{\rho}_{n+i,0} = \hat{\rho}_i$ since this is the unique solution that satisfies (2.2). The solution to the RP falls in case (ii).
- If $\gamma_i^{\max} > \gamma_{n+i}^{\max}$, then, reasoning as in the previous case, the solution falls in case (iii).

Finally, we proved that, for every ρ_0 satisfying Case I, $RS(\rho_0)$ is an equilibrium, therefore condition (CC) is satisfied.

Assume now Case IIa occurs, which means $\Gamma > \Gamma_J$ and γ_r, obtained by solving (2.5), belongs to $\mathrm{Int}(\tilde{\Omega})$. Then this is the only point satisfying all rules. Thus the solution is given by $\hat{\gamma} = \gamma_r$ (see (2.6)). The following situations represent an equilibrium point for the RP, i.e., $RS(\rho_0) = \rho_0$.

(iv) Case H3 with $\rho_{n+i,0} = \tau(\rho_{i,0})$ and $f(\rho_{i,0}) = \gamma_{r,i}$. Indeed $\hat{\gamma}_i = \hat{\gamma}_{n+i} = \gamma_{r,i}$ and the unique solution $(\hat{\rho}_i, \hat{\rho}_{n+i})$ such that $f(\hat{\rho}_i) = f(\hat{\rho}_{n+i}) = \gamma_{r,i}$ and (2.1) and (2.2) are satisfied is $(\rho_{i,0}, \rho_{n+i,0})$.

Now $\hat{\gamma} \in \tilde{\Omega}$ by assumption hence for $i = 1, \ldots, n$, it holds that $\hat{\gamma}_i < \gamma_i^{\wedge}$. Moreover, the unique solution $(\hat{\rho}_i, \hat{\rho}_{n+i})$ such that $f(\hat{\rho}_i) = f(\hat{\rho}_{n+i}) = \hat{\gamma}_i$ and (2.1) and (2.2) are satisfied is $\hat{\rho}_{n+i} = \tau(\hat{\rho}_i) \in [0, \sigma[$. This new point is described by case (iv).

Again, condition (CC) is satisfied.

Finally, assume that Case IIb holds true, i.e., $\Gamma > \Gamma_J$ and $\gamma_r \notin \mathrm{Int}(\tilde{\Omega})$. Then the solution given by $pr_{\widehat{\Omega}}(\gamma_r)$ maximizes the flux from each road, while respecting rules (1), (2), (3), and (FPR) (if not in contrast with previous rules). For $i = 1, \ldots, n$ we have either $\hat{\gamma}_i = \hat{\gamma}_{n+1} = \gamma_i^{\wedge}$ or $\hat{\gamma}_i = \hat{\gamma}_{n+i} < \gamma_1^{\wedge}$. In the first case we have the same analysis as for Case I, while in the second case we have the same analysis as for Case IIa.

Then condition (CC) is again satisfied and we are done. □

3. Interaction estimates for 2 × 2 crossing junctions. The aim of this section is to obtain estimates for the flux variation in case of interactions of a wave with a 2×2 junction J, i.e., a junction with two incoming and two outgoing roads.

For simplicity, we assume that the incoming roads are I_1 and I_2, while the outgoing roads are I_3 and I_4. We use the superscript "$-$" to indicate all quantities before the interaction and "$+$" to indicate all quantities after the interaction. Thus, for example, the initial data are given by $(\rho_1^-, \ldots, \rho_4^-)$, while the solution after the interaction is $(\rho_1^+, \ldots, \rho_4^+)$. We have four possible situations for the initial data:

Case I: $\Gamma \leq \Gamma_J$.

Case IIa: $\Gamma > \Gamma_J$ and $\gamma_r \in \mathrm{Int}(\tilde{\Omega})$.

Case IIb1: $\Gamma > \Gamma_J$, $\gamma_r \notin \mathrm{Int}(\tilde{\Omega})$, and $\gamma_{r1} \geq \gamma_1^{\wedge}$.

Case IIb2: $\Gamma > \Gamma_J$, $\gamma_r \notin \mathrm{Int}(\tilde{\Omega})$, and $\gamma_{r2} \geq \gamma_2^{\wedge}$.

We assume that the interaction with J happens for a wave (ρ_1, ρ_1^-) coming from road I_1, being the other cases entirely similar. In next sections, we provide estimates on the flux variation in the different cases.

3.1. Case I. We consider first the case $\Gamma \leq \Gamma_J$. As explained in the proof of Proposition 2, at the equilibrium before the interaction, for roads I_1 and I_3, and for roads I_2 and I_4 the following cases may happen: (i), (ii), and (iii). Now we describe the equilibrium type after the interaction of the wave (ρ_1, ρ_1^-) in the different cases.

Case i. We have that $\rho_1^- = \tau(\rho_3^-) \le \sigma$. Now ρ_1 is such that the speed of the wave (ρ_1, ρ_1^-) is positive then it must be $\rho_1 \in [0,\sigma] \setminus \{\rho_1^-\}$.

- If $\rho_1 \in [0, \rho_1^-[$, then $\gamma_1^{\max} < \gamma_1^{\max,-} = \gamma_3^{\max,-}$. We fall in Case I.H1 with $\rho_3^+ = \rho_1^+$ where $\rho_1^+ = \rho_1$ since $f(\rho_1^+) = \gamma_1^{\max}$. The new equilibrium is then $(\rho_1, \rho_2^-, \rho_1, \rho_4^-)$.
- If otherwise $\rho_1 \in]\rho_1^-, \sigma]$, then $\gamma_1^{\max} > \gamma_1^{\max,-} = \gamma_3^{\max,-}$. We therefore fall in Case I.H2 with the equilibrium $\rho_1^+ = \rho_3^+ = \rho_3^-$. The new equilibrium is $(\tau(\rho_1^-), \rho_2^-, \rho_3^-, \rho_4^-)$.

Case ii. In this case we have $\rho_1^- \in [0,\sigma]$ and $\rho_3^- = \rho_1^-$. Again, since the wave (ρ_1, ρ_1^-) must have positive speed, ρ_1 must satisfy $\rho_1 \in [0,\sigma] \setminus \{\rho_1^-\}$. Different cases may arise. To distinguish among them we denote by $\rho_1^{\lim}$ the density for which $f(\rho_1^{\lim}) + \gamma_2^{\wedge,-} = \Gamma_J$. Notice that, since we are in the situation $\Gamma_J \ge \Gamma^-$, it must be $\rho_1^{\lim} \ge \rho_1^-$.

- $\rho_1 \in [0, \rho_1^-[$. Thus $\gamma_1^{\max} < \gamma_1^{\max,-} < \gamma_3^{\max,-}$. This is the case denoted by Case I.H1 with $\rho_3^+ = \rho_1^+$ and $\rho_1^+ = \rho_1$. The new equilibrium is then given by $(\rho_1, \rho_2^-, \rho_1, \rho_4^-)$.
- $\rho_1 \in]\rho_1^-, \rho_1^{\lim}]$. Thus $\gamma_3^{\max,-} = f(\sigma) \ge \gamma_1^{\max} > \gamma_1^{\max,-}$ and $\gamma_1^{\max} = \gamma_1^{\wedge} \le \Gamma_J - \gamma_2^{\wedge,-}$. We fall in Case I.H1 with $\rho_3^+ = \rho_1^+ = \rho_1$ and the new equilibrium is given by $(\rho_1, \rho_2^-, \rho_1, \rho_4^-)$.
- If $\rho_1 \in]\rho_1^{\lim}, \sigma]$, then $\gamma_3^{\max,-} = f(\sigma) \ge \gamma_1^{\max} > \gamma_1^{\max,-}$ and $\gamma_1^{\max} = \gamma_1^{\wedge} > \Gamma_J - \gamma_2^{\wedge,-}$. This situation is described by the following cases:
  - if $\gamma_1^{\max} \le \gamma_{r1}$ and $\gamma_2^{\wedge,-} > \gamma_{r2}$, then we fall in Case IIb1.H1. The new equilibrium is $(\rho_1, \rho_2^+, \rho_1, \rho_4^+)$, where $f(\rho_2^+) = f(\rho_4^+) = \Gamma_J - f(\rho_1)$. Notice that $f(\rho_2^+) = f(\rho_4^+) < \gamma_2^{\wedge,-}$ therefore, for roads I_2 and I_4 we are in Case H3;
  - if $\gamma_1^{\max} > \gamma_{r1}$ and $\gamma_2^{\wedge,-} \le \gamma_{r2}$, then we fall in Case IIb2.H3. The new equilibrium is $(\rho_1^+, \rho_2^-, \rho_3^+, \rho_4^-)$ with $f(\rho_1^+) = f(\rho_3^+) = \Gamma_J - \gamma_2^{\wedge}$;
  - if $\gamma_1^{\max} > \gamma_{r1}$ and $\gamma_2^{\wedge,-} > \gamma_{r2}$, then we fall in Case IIa.H3 and then the new equilibrium is $(\rho_1^+, \rho_2^+, \rho_1^+, \rho_4^+)$, where $f(\rho_1^+) = \gamma_{r1}$ and $f(\rho_2^+) = f(\rho_4^+) = \Gamma_J - f(\rho_1^+) = \gamma_{r2}$. Roads I_2 and I_4 also fall in the situation described by Case H3.

Case iii. We have that $\rho_1^- = \rho_3^- > \sigma$. Since ρ_1 is such that the speed of wave (ρ_1, ρ_1^-) is positive, it must be $\rho_1 \in [0, \tau(\rho_3^-)[$. Thus $\gamma_1^{\max} < \gamma_3^{\max,-}$ and we fall in Case H1 with new equilibrium $(\rho_1, \rho_2^-, \rho_1, \rho_4^-)$.

In Case i, Case ii with $0 \le \rho_1 \le \rho_1^{\lim}$, and Case iii we have that $\rho_2^+ = \rho_2^-$ and $\rho_4^+ = \rho_4^-$ hence the variation of the flux at the junction is given only by the variation of the flux in roads I_1 and I_3. Only in Case ii with $\rho_1^{\lim} < \rho_1 \le \sigma$ we may have that $\rho_2^+ \ne \rho_2^-$ and $\rho_4^+ \ne \rho_4^-$. In this case, it holds that

$$f(\rho_2^+) = f(\rho_4^+) = \Gamma_J - f(\rho_1^+).$$

Then for the flux variation we have

$$0 \le f(\rho_2^-) - f(\rho_2^+) = f(\rho_2^-) - \Gamma_J + f(\rho_1^+) \le f(\rho_1^+) - f(\rho_1^-) \le f(\rho_1) - f(\rho_1^-),$$

and similarly for road I_4.

3.2. Case IIa. Assume now that $\Gamma > \Gamma_J$ with $\gamma_r \in \mathrm{Int}(\tilde{\Omega})$. Then at the equilibrium we are in Case iv.

We have $\rho_1^- = \tau(\rho_3^-) \in]\sigma, 1]$. Then it must be $\rho_1 \in [0, \tau(\rho_1^-)[$ for the wave (ρ_1, ρ_1^-) to have positive speed. In this case we get that $\gamma_1^{\max} < f(\sigma) = \gamma_1^{\max,-} = \gamma_3^{\max,-}$. Define again $\rho_1^{\lim}$ by $f(\rho_1^{\lim}) + \gamma_2^{\wedge,-} = \Gamma_J$, then we may have the following:

- $\rho_1 < \rho_1^{\lim}$, then $\gamma_1^{\max} < \gamma_1^{\max,-} = \gamma_3^{\max,-}$ and $\Gamma \le \Gamma_J$. Then we fall in Case I.H1 and the equilibrium is given by $(\rho_1, \rho_2^+, \rho_1, \rho_4^+)$ with $f(\rho_2^+) = \gamma_2^{\wedge,-}$. The situation in the roads I_2 and I_4 falls in one among Case H0, Case H1, and Case H2. For the flux variation on roads I_2 and I_4 we have

$$f(\rho_2^+) = \gamma_2^{\wedge,-} = \Gamma_J - f(\rho_1^{\lim}) < \Gamma_J - f(\rho_1)$$

and $f(\rho_2^-) = \Gamma_J - f(\rho_1^-)$. Thus

$$f(\rho_2^+) - f(\rho_2^-) < f(\rho_1^-) - f(\rho_1).$$

- $\rho_1 = \rho_1^{\lim}$. This case is similar to the previous one: we fall in Case I.H1 with equilibrium $(\rho_1, \rho_2^+, \rho_1, \rho_4^+)$, with $f(\rho_2^+) = f(\rho_4^+) = \gamma_2^{\wedge,-} = \Gamma_J - f(\rho_1)$ and the flux variation on roads I_2 and I_4 is

$$f(\rho_2^+) - f(\rho_2^-) = f(\rho_1^-) - f(\rho_1).$$

- $\rho_1^{\lim} < \rho_1 < \gamma_{r1}$, then we fall in Case IIb1.H1 with equilibrium $(\rho_1, \rho_2^+, \rho_1, \rho_4^+)$ where $f(\rho_2^+) = f(\rho_4^+) = \Gamma_J - f(\rho_1)$. The situation in roads I_2 and I_4 remains in Case H3 and the flux variation is

$$f(\rho_2^+) - f(\rho_2^-) = \Gamma_J - f(\rho_1) - (\Gamma_J - f(\rho_1^-)) = f(\rho_1^-) - f(\rho_1).$$

- $\gamma_{r1} \le \rho_1 < \tau(\rho_1^-)$, then we remain in Case IIa.H3 with equilibrium $(\rho_1^-, \rho_2^-, \rho_3^-, \rho_4^-)$ and no flux variation occurs.

3.3. Case IIb1. Assume finally that $\Gamma > \Gamma_J$ with $\gamma_{r1} \ge \gamma_1^{\wedge,-}$. Then roads I_1 and I_3 are in one among Case i, Case ii, and Case iii, while roads I_2 and I_4 are in Case iv. Let us consider now the equilibrium after the interaction of a wave (ρ_1, ρ_1^-).

Case i. In this case $\rho_1^- \in [0, \sigma]$ and $\rho_3^- = \tau(\rho_1^-)$. Then since (ρ_1, ρ_1^-) must have positive speed, $\rho_1 \in [0, \sigma]$.

- If $\rho_1 \in [0, \rho_1^-[$, we have $\gamma_1^{\max} < \gamma_1^{\max,-} = \gamma_3^{\max,-}$ and we have to distinguish among $\rho_1 < \rho_1^{\lim}$, $\rho_1 = \rho_1^{\lim}$, and $\rho_1 > \rho_1^{\lim}$. In all cases the new equilibrium is given by $(\rho_1, \rho_2^+, \rho_1, \rho_4^+)$ with $f(\rho_2^+) = f(\rho_4^+) = \Gamma_J - f(\rho_1)$ or $f(\rho_2^+) = f(\rho_4^+) = \gamma_2^{\wedge,-}$ and, since $f(\rho_2^-) = \Gamma_J - f(\rho_1^-)$, the flux variation satisfies

$$f(\rho_2^+) - f(\rho_2^-) \le f(\rho_1^-) - f(\rho_1).$$

- If $\rho_1 \in]\rho_1^-, \sigma]$, then $\gamma_1^{\max} > \gamma_1^{\max,-} = \gamma_3^{\max,-}$. This is Case IIb1.H2 and the new equilibrium is given by $(\tau(\rho_1^-), \rho_2^-, \rho_3^-, \rho_4^-)$.

Case ii. Now $\rho_1^- \in [0, \sigma[$ and $\rho_3^- = \rho_1^-$. Then it must be $\rho_1 \in [0, \sigma]$.

- If $\rho_1 \in [0, \rho_1^-[\cup]\rho_1^-, f^{-1}(\gamma_{r1})]$, then we distinguish among the cases $\rho_1 < \rho_1^{\lim}$, $\rho_1 = \rho_1^{\lim}$, and $\rho_1 > \rho_1^{\lim}$. The new equilibrium is $(\rho_1, \rho_2^+, \rho_1, \rho_4^+))$ with $f(\rho_2^+) = f(\rho_4^+) = \Gamma_J - f(\rho_1)$ or $f(\rho_2^+) = f(\rho_4^+) = \gamma_2^{\wedge,-}$. For the flux variation we have

$$f(\rho_2^+) - f(\rho_2^-) \le f(\rho_1^-) - f(\rho_1).$$

- If $\rho_1 \in]f^{-1}(\gamma_{r1}), \sigma]$, then we fall in Case IIa.H3 and the new equilibrium is $(\rho_1^+, \rho_2^+, \tau(\rho_1^+), \tau(\rho_2^+))$ with $f(\rho_1^+) = \gamma_{r1}$ and $f(\rho_2^+) = \Gamma_J - f(\rho_1^+) = \gamma_{r1}$. Since $\rho_1 > \rho_1^+$, then $f(\rho_1) > f(\rho_1^+)$ and the flux variation is

$$f(\rho_2^-) - f(\rho_2^+) = f(\rho_1^+) - f(\rho_1^-) < f(\rho_1) - f(\rho_1^-).$$

Case iii. In this case we have that $\rho_1^- \in]\sigma, 1]$ and $\rho_3^- = \rho_1^-$. Then it must be $\rho_1 \in [0, \tau(\rho_1^-)]$ with $\gamma_1^{\max} < \gamma_3^{\max,-}$. We may have the following cases:

- $\rho_1^{\lim} \leq \rho_1 \leq \tau(\rho_1^-)$. Then we fall in Case IIb1.H1 and the new equilibrium is $(\rho_1, \rho_2^+, \rho_1, \rho_4^+))$ with $f(\rho_2^+) = f(\rho_4^+) = \Gamma_J - f(\rho_1)$. The flux variation is given by

$$f(\rho_2^+) - f(\rho_2^-) = f(\rho_1^-) - f(\rho_1).$$

- $0 \leq \rho_1 \leq \rho_1^{\lim}$. This is the situation described by Case I.H1 with equilibrium $(\rho_1, \rho_2^+, \rho_1, \rho_4^+))$ with $f(\rho_2^+) = f(\rho_4^+) = \gamma_2^{\wedge,-}$. Then the flux variation is

$$f(\rho_2^+) - f(\rho_2^-) = \gamma_2^{\wedge,-} - f(\rho_2^-) = -f(\rho_1^{\lim}) + f(\rho_1^-) < f(\rho_1^-) - f(\rho_1).$$

3.4. Case IIb2. Assume finally that $\Gamma > \Gamma_J$ with $\gamma_{r2} \geq \gamma_2^{\wedge,-}$. Then roads I_2 and I_4 are in one among Case i, Case ii, and Case iii while roads I_1 and I_3 are in Case iv. Let us consider now the equilibrium after the interaction of a wave (ρ_1, ρ_1^-). We have $\rho_1^- = \tau(\rho_3^-) \in]\sigma, 1]$ then it must be $\rho_1 \in [0, \tau(\rho_1^-)[$. In this case, since $f(\rho_1^-) = \Gamma_J - \gamma_2^{\wedge,-}$, $\gamma_1^{\max} + \gamma_2^{\wedge,-} < \Gamma_J$ and we fall in Case I.H1 with equilibrium $(\rho_1, \rho_2^-, \rho_1, \rho_4^-)$. No flux variation occurs on roads I_2 and I_4.

3.5. Interaction estimates. By the analysis of previous subsections, we have the following. Define $\mathcal{I}(\gamma, \gamma')$ to be the closed interval with extreme points γ and γ', then we have the following.

PROPOSITION 3. *For the interaction of a wave (ρ_1, ρ_1^-) with the junction J, we get $f(\rho_1^+) \in \mathcal{I}(f(\rho_1^-), f(\rho_1))$. Moreover, $|f(\rho_2^+) - f(\rho_2^-)| \leq |f(\rho_1) - f(\rho_1^-)|$.*

Let us denote by $TV_{1,3}^{\pm}(f)$ the sum of flux variations on roads I_1 and I_3 before and after the interaction and define similarly $TV_{2,4}^{\pm}(f)$. Then

$$TV_{1,3}^-(f) = f(\rho_1) - f(\rho_1^-).$$

Recalling that $f(\rho_3^{\pm}) = f(\rho_1^{\pm})$,

$$TV_{1,3}^+(f) = |f(\rho_1) - f(\rho_1^+)| + |f(\rho_3^+) - f(\rho_3^-)| = |f(\rho_1) - f(\rho_1^+)| + |f(\rho_1^+) - f(\rho_1^-)|.$$

Now, from Proposition 3, it follows that

$$TV_{1,3}^+(f) = TV_{1,3}^-(f).$$

Moreover, for the total variation of f on roads I_2 and I_4, we have

$$TV_{2,4}^+(f) = 2|f(\rho_2^+) - f(\rho_2^-)| \leq 2|f(\rho_1) - f(\rho_1^-)| = 2TV_{1,3}^-(f).$$

Finally, we get the following.

PROPOSITION 4. *The total variation of the flux on the whole junction satisfies*

$$TV(f)^+ = TV_{1,3}^+(f) + TV_{2,4}^+(f) \leq 3TV_{1,3}^-(f) = 3TV(f)^-.$$

4. Existence of solutions. The aim of this section is to prove the existence of solutions for networks with only crossing junction having (at most) two incoming and two outgoing roads. The existence is obtained via wave-front tracking algorithm.

Fix a decreasing sequence $\delta_\nu > 0$ such that $\delta_\nu \to 0$ as $\nu \to \infty$. Given an initial data $\rho_{i,0}$ on each road $I_i \in \mathcal{I}$ with bounded total variation, one approximates $\rho_{i,0}$ by a piecewise constant function with smaller total variation. Then one solves the

Riemann problems on the roads and at junctions, using Proposition 2. Moreover, rarefaction waves are replaced by rarefaction fans, i.e., collection of small shocks of size $\leq \delta_\nu$ traveling with the speed of the right state. When two waves interact inside a road, or a wave interact with a junction, then one solves a new Riemann problem and so on. The obtained weak solution ρ_ν is called a wave-front tracking approximate solution. See [3, 11] for further details.

For the wave-front tracking algorithm to work we need three basic estimates:

(i) bound on the number of waves;

(ii) bound on the number of interactions among waves and of waves with junctions;

(iii) bound on the total variation of ρ_ν.

The first two estimates are necessary to construct the wave-front tracking approximation, while the third is necessary to pass to the limit in ν and obtain a solution on the network ρ.

Therefore one has to prove (i), (ii), and (iii) for networks with crossing junctions having two incoming (and two outgoing roads). From now on, we fix a wave-front tracking approximate solution $\rho = \rho_\nu$ and provide estimates on it. Notice that (i), (ii), and (iii) hold on each road if no wave is generated by the junction J. In fact the total variation decreases in time. Thus the crucial point is to estimate the number of interactions with junctions and total variation increase due to such interactions.

4.1. Estimates on number of waves and interactions. The first estimate is achieved via a series of lemmas: the obtained results permits to avoid explosions in the number of interactions with a junction and thus on the number of waves.

We first need to recall some results from [11].

THEOREM 1. *Consider a network $(\mathcal{I}, \mathcal{J})$, and a Riemann solver RS_J, assigned for every $J \in \mathcal{J}$. Let ρ_0 be a piecewise constant (taking a finite number of values) initial datum and assume:*

(H*) *For every vertex J, consider a network formed by only the vertex J, replacing incoming and outgoing edges by infinite length ones. Then there exists a constant C_J such that, using the corresponding Riemann solver RS_J, the following holds. For every wave-front tracking approximate solution, denoting by M the number of waves in the initial datum, at most $C_J M$ waves are produced by the vertex J and there are at most $C_J M$ interactions of waves with the vertex J.*

Then, for every $T > 0$, we can construct a wave-front tracking approximate solution on $[0, T]$.

Theorem 1 essentially says that it is enough to consider each junction separately. In fact, via finite speed of waves, the interactions of waves with different junctions may happen only in a time interval whose length is bounded below.

Then for the rest of the section, we fix a network formed by a single junction J with two incoming roads with infinite length, namely I_1 and I_2, and two outgoing roads I_3 and I_4 with infinite length: our aim is to prove (H*).

Again, we recall some definitions and results from [11].

DEFINITION 3. *A wave (ρ_-, ρ_+) is a* big shock *if $\rho_- < \rho_+$ and*

$$sgn(\rho_- - \sigma) \cdot sgn(\rho_+ - \sigma) < 0.$$

DEFINITION 4. *We say that an incoming road I_i has a* good datum *at J at time $t > 0$ if*

$$\rho_i(t, b_i-) \in [\sigma, 1]$$

and a bad datum *otherwise. We say that an outgoing road I_j has a* good datum *at J at time $t > 0$ if*

$$\rho_j(t, a_j+) \in [0, \sigma]$$

and a bad datum *otherwise.*

DEFINITION 5. *For every road I_i, $i = 1, \ldots, 4$, we indicate by*

$$(\rho_-^\theta, \rho_+^\theta), \quad \theta \in \Theta = \Theta(\rho, t, i), \quad \Theta \text{ finite set,}$$

the discontinuities on road I_i at time t and by $x^\theta(t)$, $\lambda^\theta(t)$, $\theta \in \Theta$, respectively, their positions and velocities at time t. We also refer to the wave θ to indicate the discontinuity $(\rho_-^\theta, \rho_+^\theta)$.

For each discontinuity $(\rho_-^\theta, \rho_+^\theta)$ at time $\bar{t}$ on road I_i, we call $y^\theta(t)$, $t \in [\bar{t}, t_\theta]$, the trace of the wave so defined. We start with $y^\theta(\bar{t}) = x^\theta(\bar{t})$ and we continue up to the first interaction with another wave or a junction. If at time $\tilde{t}$ an interaction with a wave or a junction occurs, then either a single new wave $(\rho_-^{\tilde{\theta}}, \rho_+^{\tilde{\theta}})$ on road I_i is produced or no wave is produced. In the latter case we set $t_\theta = \tilde{t}$, otherwise we set $y^\theta(\tilde{t}) = x^{\tilde{\theta}}(\tilde{t})$ and follow $x^{\tilde{\theta}}(t)$ for $t \geq t^{\tilde{\theta}}$ up to next interaction and so on.

We have the following lemma whose proof can be found in [11, Lemma A.1.1, page 122].

LEMMA 1. *Consider a trace of a wave y^θ such that*

(a) *y^θ is generated at time $\bar{t}$ from J,*

(b) *y^θ interacts at time $\tilde{t} > \bar{t}$ with J,*

(c) *y^θ does not interact with the junction J on the interval $]\bar{t}, \tilde{t}[$.*

Then

(i) *$y^\theta(t)$ is a big shock for some $t \in]\bar{t}, \tilde{t}[$,*

(ii) *if $y^\theta(\bar{t})$ is generated on an incoming road and $y^\theta(\tilde{t}) = (\rho_l, \rho_r)$, then ρ_l is a bad datum and $f(\rho_l) < f(\rho_r)$; for outgoing roads, ρ_r is a bad datum and it holds that $f(\rho_l) > f(\rho_r)$.*

The previous lemma essentially tells us that waves produced by the junction J can come back only if they are big shocks. Now we need two additional results describing the effect of a big shock interacting back with a junction.

LEMMA 2. *Let $(\rho_{1,0}, \ldots, \rho_{4,0})$ be an equilibrium at J and $(\rho_i, \rho_{i,0})$ a wave interacting from road I_i, $i \in \{1, 3\}$, such that $f(\rho_i) < f(\rho_{i,0})$ $(f(\rho_i) > f(\rho_{i,0}))$. Call $\hat{\rho}$ the solution after the interaction, then $f(\hat{\rho}_j) \geq f(\rho_{j,0})$ $(f(\hat{\rho}_j) \leq f(\rho_{j,0}))$ for $j = 2, 4$.*

The same conclusion holds for roads I_i, $i \in \{1, 3\}$, if the wave interacts from a road I_j, $j \in \{2, 4\}$.

Proof. It is enough to reason on the space of incoming fluxes γ_i $(i = 1, 2)$. At interaction time, we move from the equilibrium $(\gamma_{1,0}, \gamma_{2,0})$ to a new equilibrium $(\hat{\gamma}_1, \hat{\gamma}_2)$. Both equilibria can be in one of the Cases I, IIa, or IIb. However, notice that the new equilibrium is always obtained from the old one either moving along the line $\sum_i \gamma_i = \Gamma_J$ or along the line $\gamma_2 = \gamma_2^\wedge$. In both cases a decrease in the flux on roads I_1 and I_3 produces an increase of the flux on roads I_2 and I_4, and vice versa. Thus the conclusion follows. ∎

LEMMA 3. *If either on road I_1 or road I_3 there is a bad datum, then nothing can happen on such roads when a big shock comes back to J from roads I_2 and I_4.*

The same conclusion holds for roads I_2 and I_4.

Proof. Assume, to fix the notation, that ρ_1 is a bad datum and a big shock $(\bar{\rho}_2, \rho_2)$ interacts back to J. From Lemma 1, $f(\bar{\rho}_2) < f(\rho_2)$. Moreover, from Lemma 2, on roads I_1 and I_3 there is an increase of the flux. However, a bad datum can give rise only to a wave decreasing the flux; see formulas (2.1), (2.2). Thus no wave can be produced on roads I_1 and I_3. ☐

LEMMA 4. *Assumption* (H*) *holds true.*

Proof. We can reason in the following way. The increase in the number of waves may happen only by interactions with the junction J.

Let y^θ, $\theta \in \Theta_0$, be the traces of waves in the initial data and every road, thus the trace ends at the first time of interaction with J. Let $t' < t''$ be an interval between two consecutive interactions of traces y^θ with J or with waves produced by J. Our aim is to estimate the number of waves in the time interval $[t', t'']$.

First, by Lemma 1, an interaction with J may happen only with a big shock coming back to J. Assume, for instance, that the first of such interactions happens for a big shock coming from road I_1 at time t_1 with $t' \leq t_1 < t''$. Then the datum on road I_1 is bad after the interaction and no wave produced by J on road I_1. Nothing can happen on road I_1, unless a big shock interacts from road I_3, say at time t_3 with $t_1 < t_3 < t''$. In this case, a bad datum is on road I_3, after time t_3, and a big shock may be produced on road I_1. After time t_3, and before time t'', by Lemma 3 no wave is produced from J on roads I_1 and I_3. In particular, the (possible) big shock on road I_1 cannot interact with any wave produced by J and also with any wave of the initial data by definition of t''. Notice that at most four new waves on roads I_2 and I_4 are produced in this way and there are at most four interactions of waves with J.

The same reasoning can be done for roads I_2 and I_4.

Finally, in the time interval $[t', t'']$ at most four new waves are produced.

Since the estimate is valid on each interval of the type $[t', t'']$, we can bound the total number of waves by $4 \cdot \#(\Theta_0)$, where $\#(\Theta_0)$ indicates the cardinality of Θ_0, i.e., the number of waves in the initial data. Similarly, the number of interactions is bounded again by $5 \cdot \#(\Theta_0)$, thus the proof is finished. ☐

4.2. BV estimates. Reasoning as for Theorem 1, it is enough to consider every junction one at a time.

So, first we consider a network formed by a single junction J with two incoming roads with infinite length, namely I_1 and I_2, and two outgoing roads I_3 and I_4 with infinite length. Then we can prove the following.

LEMMA 5. *For every wave-front tracking approximate solution ρ, we have*

$$TV(f(\rho(t))) \leq 3TV(f(\rho(0))) + 2f(\sigma). \tag{4.1}$$

Proof. First notice that only interactions with J may increase the total variation of the flux.

We need to reason on waves coming back to J. So let t_1 be the first time in which a wave generated by J comes back to J, say from road I_1. On the time interval $[0, t_1]$, waves may interact with J only from one road; otherwise to have interaction from two different roads, at least one wave should have come back to J. Then, using Proposition 4, we have

$$TV(f(\rho(t_1))) \leq 3TV(f(\rho(0))).$$

Now, necessarily on road I_1, we have a bad datum at time t_1. By Lemma 3, road I_1 does not change its status because of interactions with J of waves from roads I_2 and I_4. If a wave interacts with J from I_1, then I_1 still has a bad datum (because of the positive velocity of the wave). If a wave interacts with J from I_3, then the following happens. If the wave increases the flux, then it is simply reflected back. While a wave decreasing the flux, again because of the velocity, necessarily brings road I_3 to a bad datum. Then, we proved that after time t_1, at least one of the two roads I_1 or I_3 has a bad datum. Then, again by Lemma 3, the interactions with J from roads I_2 and I_4 can only decrease the flux variation.

On the other side, interactions with J from I_1 and I_3 can only decrease the flux, because at least one road has a bad datum. Thus, by Lemma 2, the total variation produced on roads I_2 and I_4, after time t_1, is bounded by $2f(\sigma)$. Then we conclude. $\square$

Let us now pass to the case of a complete network.

PROPOSITION 5. *Consider a network $(\mathcal{I}, \mathcal{J})$ and a wave-front tracking approximate solution ρ. Let $\delta = \min\{b_i - a_i : I_i \in \mathcal{I}\}$, i.e., the minimum length of a road, and let $\bar\lambda = \max\{|f'(0)|, |f'(\rho_{\max})|\}$, i.e., the maximum velocity of a wave. For $t \in [(n-1)\ \delta/\bar\lambda,\ n\ \delta/\bar\lambda[$, it holds that*

$$TV(f(\rho(t))) \le 3^n\ TV(f(\rho(0))) + \sum_{\ell=1}^{n} 3^\ell\ 2\ f(\sigma).$$

Proof. On a time interval of length $\Delta t = \delta/\bar\lambda$, no wave generated from a junction may interact with another junction. Thus we can reason as if junctions were isolated, and so apply Lemma 5. Then defining $TV_k = TV(f(\rho(k\Delta t)))$, we get

$$TV_k \le 3\, TV_{k-1} + 2f(\sigma),$$

and the desired estimate is readily obtained. $\square$

Remark 3. Notice that Proposition 5 says that the increase in the flux total variation is exponential in time, we can in fact rewrite the estimate as

$$TV(f(\rho(t))) \sim e^{\frac{\bar\lambda t}{\delta}\ln(3)} \left(TV(f(\rho(0))) + \frac{\bar\lambda t}{\delta} 2f(\sigma) \right).$$

4.3. Existence of solutions. Once an estimate on the flux variation is obtained, we can prove existence of solutions by the same technique of [11].

DEFINITION 6. *Consider a road network $(\mathcal{I}, \mathcal{J})$ and consider an approximate wave-front tracking solution ρ. For every road I_i, we define two curves $Y_-^{i,\rho}(t)$, $Y_+^{i,\rho}(t)$, called boundary of external flux, briefly BEF, in the following way. We set the initial condition $Y_-^{i,\rho}(0) = a_i$, $Y_+^{i,\rho}(0) = b_i$ (if $a_i = -\infty$, then $Y_-^{i,\rho} \equiv -\infty$ and if $b_i = +\infty$, then $Y_+^{i,\rho} \equiv +\infty$). We let $Y_\pm^{i,\rho}(t)$ follow the generalized characteristic as defined in* [8]*, letting $Y_-^{i,\rho}(t) = a_i$ (resp., $Y_+^{i,\rho}(t) = b_i$) if the generalized characteristic reaches the boundary and $f'(\rho(t, a_i)) < 0$ (resp., $f'(\rho(t, b_i)) > 0$). (In this way $Y_\pm^{i,\rho}(t)$ may coincide with a_i or b_i for some time intervals.) Let $\bar t$ be the first time $\bar t$ such that $Y_-^{i,\rho}(\bar t) = Y_+^{i,\rho}(\bar t)$ (possibly $\bar t = +\infty$), then we let $Y_\pm^{i,\rho}$ be defined on $[0, \bar t]$. Finally, we define the sets*

$$D_1^i(\rho) = \left\{(t,x) : t \in [0, \bar t) : Y_-^{i,\rho}(t) \le x \le Y_+^{i,\rho}(t)\right\}$$

and

$$D_2^i(\rho) = [0, +\infty) \times [a_i, b_i] \setminus D_1^i(\rho).$$

Clearly $Y_\pm^i(t)$ bound the set on which the datum is not influenced by the other roads through the junctions.

LEMMA 6. *The curves $t \mapsto Y_{\pm}^i(t)$ are uniformly Lipschitz.*

Proof. The curves $Y_{\pm}^i$ are generalized characteristics, thus their velocity is uniformly bounded by $\max\{f'(0), |f'(1)|\}$. ∎

LEMMA 7. *For every $t \geq 0$, there exist at most two big waves on*

$$\left\{x : (t,x) \in D_2^i(\rho)\right\} \subseteq [a_i, b_i].$$

Proof. A big wave can originate at time t on road I_i from J only if road I_i has a bad datum at J at time t. If this happens, then road I_i does not have a bad datum at J up to the time in which a big wave is absorbed from I_i. Then we reach the conclusion. ∎

We are able to state and prove the main result.

THEOREM 2. *Fix a road network $(\mathcal{I}, \mathcal{J})$. Given $C > 0$ and $T > 0$, there exists an admissible solution defined on $[0,T]$ for every initial data $\bar{\rho} \in \mathrm{cl}\{\rho : TV(\rho) \leq C\}$, where* cl *indicates the closure in L^1_{loc}.*

Proof. We fix a sequence of initial data $\bar{\rho}_\nu$ piecewise constant such that $TV(\bar{\rho}_\nu) \leq C$ for every $\nu \geq 0$ and $\bar{\rho}_\nu \to \bar{\rho}$ in L^1_{loc} as $\nu \to +\infty$. For each $\bar{\rho}_\nu$ we consider an approximate wave-front tracking solution ρ_ν such that $\rho_\nu(0,x) = \bar{\rho}_\nu(x)$ and rarefactions are split in rarefaction shocks of size $\frac{1}{\nu}$.

For every road I_i, we notice that on $D_1^i(\rho_\nu)$, ρ_ν is not influenced by other roads and so the estimates of [3] hold. Since the curves $Y_{\pm}^{i,\rho_\nu}$ are uniformly Lipschitz continuous, they converge uniformly in time, up to a subsequence, to a limit curve. Therefore the regions $D_1^i(\rho_\nu)$ converge in measure to a limit region D_1^i. More precisely, we have the estimate

$$\mathrm{meas}(D_1^i(\rho_{\nu+1}) \Delta D_1^i(\rho_\nu)) \leq T \cdot \|Y_{\pm}^{i,\nu+1} - Y_{\pm}^{i,\nu}\|_{L^\infty},$$

where Δ is the symmetric difference of sets, namely $A \Delta B = (A \setminus B) \cup (B \setminus A)$. Then $\rho_\nu \to \rho$ in L^1_{loc} on D_1^i with ρ admissible solution to the Cauchy problem.

On $D_2^i := [0, +\infty[\times[a_i, b_i] \setminus D_1^i$, we have that, up to a subsequence, $\rho_\nu \rightharpoonup^* \rho$ weak* on L^1 and, using Proposition 5, $f(\rho_\nu) \to \bar{f}$ in L^1 for some $\bar{f}$. By Lemma 7, there are at most two big waves on D_2^i for every time, hence, splitting the domain D_2^i into a finite number of pieces where we can invert the function f, getting $\rho_\nu \to f^{-1}(\bar{f})$ in L^1. Together with $\rho_\nu \rightharpoonup^* \rho$ weak* on L^1, we conclude that $\rho_\nu \to \rho$ strongly in L^1.

The other requirements of the definition of admissible solution are clearly satisfied. ∎

5. Summary. We considered a fluid dynamic model for traffic flow on networks. On each road we used the established Lighthill–Witham–Richards model, while special type of junctions, called crossing junctions, are treated, coming from modeling of real junctions of T type.

We first defined a Riemann solver at crossing junctions, taking into account the maximal load of the junction and equilibrium flux proportions among incoming roads. Then we established existence of solutions on the whole network by a wave-front tracking algorithm.

Since the flux variation is not conserved for interactions of waves with junctions (see Proposition 4), we cannot expect Lipschitz continuous dependence of solutions; see [11, section 5.4, page 111].

HOPF BIFURCATION FROM VISCOUS SHOCK WAVES*

BJÖRN SANDSTEDE† AND ARND SCHEEL‡

Abstract. Using spatial dynamics, we prove a Hopf bifurcation theorem for viscous Lax shocks in viscous conservation laws. The bifurcating viscous shocks are unique (up to time and space translation), exponentially localized in space, periodic in time, and their speed satisfies the Rankine–Hugoniot condition. We also prove an "exchange of spectral stability" result for super- and subcritical bifurcations and outline how our proofs can be extended to cover degenerate, over-, and undercompressive viscous shocks.

Key words. viscous conservation law, Lax shock, Hopf bifurcation

AMS subject classifications. 35L65, 35B32, 35L67

1. Introduction. The purpose of this paper is to study Hopf bifurcation from viscous shock waves. While Hopf bifurcations from equilibria are well understood in ordinary differential equations (ODEs) and in dissipative partial differential equations (PDEs) on bounded domains, a variety of new phenomena and difficulties arise when studying Hopf bifurcations for PDEs on unbounded domains.

In particular, Hopf bifurcations from travelling waves are complicated by the presence of a neutral mode at the origin which is induced by spatial translation. If the essential spectrum of the linearization around the travelling wave is bounded away from the imaginary axis, appropriate center-manifold reductions and equivariant parametrizations as in [4, 6, 17] show that the bifurcation problem reduces to a standard Hopf bifurcation, and standard results on bifurcation and exchange of stability [2] immediately carry over to this setting [15, section 2]; the only effect of the translation mode is an adjustment of the wave speed. When the Hopf instability is caused by essential spectrum that crosses the imaginary axis, a variety of interesting new phenomena can occur, including failure of bifurcation [15] and bifurcation of multiple solution branches [16, section 2.3]. The situation becomes more involved when the instability caused by the essential spectrum is stationary, as the wave will then typically decay only algebraically at onset which leads to significant complications in the analysis [16, sections 2.1, 2.2, and 3].

From the preceding list, one can easily envision yet another possible scenario where the complex Hopf eigenvalues belong to the point spectrum, whilst the translation mode is embedded in the continuous spectrum. This situation arises, for instance, when the primary wave is not spatially localized, but the Hopf eigenfunctions are localized: Examples are Hopf bifurcations from coherent structures such as sources and sinks in one spatial dimension, and spiral waves in two dimensions. A model problem in higher space dimensions, but with a space-dependent potential, has recently been analyzed in [1]. Viscous shock waves provide another prominent example where the translation mode is embedded into the continuous spectrum. In fact, conservation

laws can often be derived formally and rigorously in spatially extended systems where the primary pattern breaks the underlying continuous symmetry [3, 7].

In this article, we investigate Hopf bifurcations from viscous shock waves using the spatial-dynamics techniques we developed in [13, 14, 15] for Hopf bifurcations from fronts and pulses in reaction-diffusion systems. Our paper is strongly motivated by recent work of Texier and Zumbrun [19, 20] in which they analyzed oscillatory instabilities of viscous shocks using delicate estimates for the temporal period map of the linearized semigroup. Texier and Zumbrun proved the existence of a continuous branch of oscillatory viscous shocks with a $1/x$ decay estimate at spatial infinity. In a personal communication, Zumbrun asked us whether spatial-dynamics techniques can be used to obtain the same or stronger results than those in [19, 20]. We demonstrate here that the spatial-dynamics approach yields indeed sharper results, while simplifying the analysis and adding geometric insight into the problem: We show that the bifurcating oscillatory shocks are unique, exponentially localized, and depend smoothly on the bifurcation parameter, and we calculate the spectra of the linearization about the bifurcating oscillating shock waves, thereby confirming the expected exchange of stability. Instead of analyzing the temporal semigroup whose linearization has essential spectrum up to the imaginary axis, we consider the spatial evolution of temporally periodic functions for which we gain compactness of the resolvent due to the imposed time periodicity. While this method may appear nonintuitive, it is completely analogous to the usual phase-plane analysis used to prove existence of viscous shocks and to study their stationary bifurcations. After this paper was completed, Texier and Zumbrun were able to extend their approach to prove in [21] exponential localization of the bifurcating solutions for compressible Navier–Stokes and magnetohydrodynamics.

Outline. In section 2, we state our main result on bifurcation and spectral stability of modulated shocks. The bifurcation result is proved in section 3. In section 4, we review the precise characterization of spectra and prove stability and instability in the case of super- and subcritical bifurcations, respectively. We conclude with a discussion of several extensions and generalizations in section 5.

2. Setup and main results. Consider the viscous conservation law

$$u_t + f(u)_y = u_{yy}, \qquad y \in \mathbb{R},\ u \in \mathbb{R}^n, \tag{2.1}$$

where f is a smooth flux function. We are interested in viscous shocks $q^0(y - c^0 t)$ which connect the constant rest states $u^0_\pm$ at $y = \pm\infty$ so that

$$\lim_{x\to\pm\infty} q^0(x) = u^0_\pm.$$

Viscous shocks are stationary solutions in the moving reference frame $x = y - ct$ in which (2.1) becomes

$$u_t = \partial_x \left[u_x + cu - f(u)\right], \qquad x \in \mathbb{R},\ u \in \mathbb{R}^n, \tag{2.2}$$

and they therefore satisfy the integrated steady state equation

$$u_x = [f(u) - f(u^0_-)] - c[u - u^0_-], \tag{2.3}$$

where the speed c is given necessarily by the Rankine–Hugoniot condition

$$c = \frac{f_j(u^0_+) - f_j(u^0_-)}{u^0_{+,j} - u^0_{-,j}}, \qquad j = 1, \ldots, n. \tag{2.4}$$

In particular, $q^0(x)$ lies in the intersection of the unstable manifold $\widetilde{W}^{\mathrm{u}}_-$ of u^0_- and the stable manifold $\widetilde{W}^{\mathrm{s}}_+$ of u^0_+ for (2.3).

The most common viscous shocks are Lax shocks for which $u^0_\pm$ are hyperbolic equilibria of (2.3) with $\dim \widetilde{W}^{\mathrm{u}}_- = p+1$ and $\dim \widetilde{W}^{\mathrm{s}}_+ = n-p$ for some $p \in \{0, \dots, n-1\}$. We assume that the intersection of $\widetilde{W}^{\mathrm{u}}_-$ and $\widetilde{W}^{\mathrm{s}}_+$ is transverse along q^0 and that the Jacobian $f_u(u^0_\pm)$ has only real and distinct eigenvalues. If $u^\varepsilon_\pm$ are smooth curves that depend on a real parameter $\varepsilon \approx 0$, then we find a smooth family of Lax shocks $q^\varepsilon(x)$ with a smooth speed relation $c = c^\varepsilon$ given by the Rankine–Hugoniot condition. Since the eigenvalues of $f_u(u)$ are the characteristic speeds of propagation at u, the condition on the dimensions of $\widetilde{W}^{\mathrm{s,u}}_\pm$ merely states that $p+1$ characteristics enter the shock from the left and $n-p$ characteristics enter from the right.

We are interested in the scenario where the Lax shocks undergo a Hopf instability upon increasing ε through zero. We therefore consider the linearization at the shock which is given by the linear operator

$$\mathcal{L}^\varepsilon := \partial_x \left[\partial_x + c^\varepsilon - f_u(q^\varepsilon(x)) \right],$$

which we view as a closed unbounded operator on $L^2(\mathbb{R}, \mathbb{R}^n)$. Its essential spectrum is readily seen to be contained in the closed left half-plane, touching the imaginary axis only at the origin with a quadratic tangency. We assume that the point spectrum lies in the open left half-plane, bounded away from the imaginary axis, except for an isolated pair $\lambda(\varepsilon)$ and $\overline{\lambda(\varepsilon)}$ of simple complex eigenvalues with

$$\lambda(0) = \mathrm{i}\omega_0 \neq 0, \qquad \operatorname{Re} \lambda_\varepsilon(0) > 0. \tag{2.5}$$

THEOREM 2.1 (bifurcation). *Under the above assumptions, there are positive constants K, η, and δ and a smooth function*

$$\begin{aligned} [0, \delta) &\longrightarrow \mathcal{C}^2_{\mathrm{unif}}(\mathbb{R} \times S^1, \mathbb{R}^n) \times \mathbb{R} \times \mathbb{R}, \\ a &\longmapsto (q^*(a), \varepsilon(a), \omega(a)), \end{aligned}$$

so that $u^*(x,t;a) := q^*(x, \omega(a)t; a)$ satisfies (2.2) with $c = c^{\varepsilon(a)}$ for all a,

$$|q^*(x,\tau;a) - u^{\varepsilon(a)}_\pm| \leq K \mathrm{e}^{-\eta|x|}, \qquad q^*(x,\tau;0) = q^0(x), \qquad \omega(0) = \omega_0,$$

and $q^*(x,\cdot;a)$ has minimal period 2π in τ for each $a > 0$. Furthermore, any non-stationary time-periodic solution $u(x,t)$ of (2.2), which is pointwise close to $q^0(x)$ and converges to $u^\varepsilon_\pm$ as $x \to \pm\infty$, is in fact an appropriate space and time translation of u^*.

Note that $u^*(x,t;a)$ and $q^{\varepsilon(a)}(x)$ have the same asymptotic rest states and travel with the same (average) wave speed. Theorem 2.1 remains true if $f = f(u;\varepsilon)$ depends smoothly on the parameter ε.

Spectral stability of the modulated shocks $u^*(x,t;a)$ is determined by the Floquet spectrum

$$\Sigma = \{\lambda \in \mathbb{C};\ \mathrm{e}^{\lambda T} \in \text{ spectrum of } \Phi_T\},$$

where $T = 2\pi/\omega$ is the temporal period of u^*, and Φ_t is the evolution operator of the linearization

$$v_t = \partial_x[\partial_x + c^{\varepsilon(a)} - f_u(u^*(x,t;a))]v$$

of (2.2) about u^* on L^2 or $\mathcal{C}^0_{\mathrm{unif}}$.

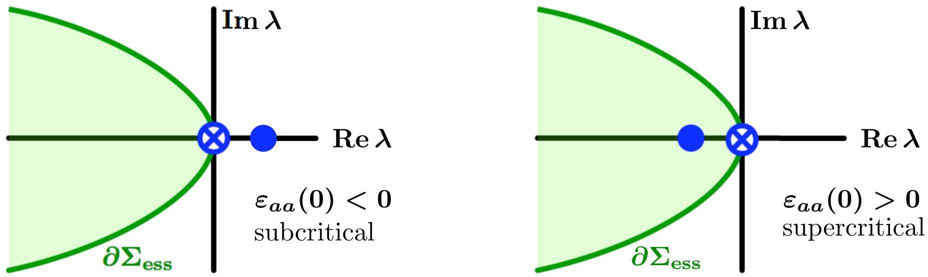

FIG. 1. *The Floquet spectra of the oscillatory shocks u^* from Theorem* 2.1 *is shown for $a > 0$: $\lambda = 0$ has geometric and algebraic multiplicity two, while the location of the remaining simple Floquet exponent near the origin depends on the sign of $\varepsilon_{aa}(0)$.*

THEOREM 2.2 (stability). *Assume that the hypotheses of Theorem* 2.1 *are met and that the Evans function associated with q^0 has a simple zero at the origin (see section* 4 *for details). If $\varepsilon_{aa}(0) \neq 0$, then the Floquet spectrum Σ of the oscillatory shock u^* given in Theorem* 2.1 *is as indicated in Figure* 1*.*

We refer the reader to [5, section 3.4] and [23, sections 9, 10] for explicit conditions which imply that the Evans function of q^0 has a simple zero at the origin.

3. Existence of modulated viscous shocks. In this section, we prove Theorem 2.1.

3.1. Preparations. We begin by collecting some properties of the linearization

$$\mathcal{L}^\varepsilon = \partial_x \left[\partial_x + c^\varepsilon - f_u(q^\varepsilon(x))\right]$$

about the viscous shocks that we need later on. Since we assumed in (2.5) that the Hopf eigenvalues $\lambda(0) = \mathrm{i}\omega_0 \neq 0$ and $\overline{\lambda(0)}$ of $\mathcal{L}^0$ are simple, we know that there are nonzero L^2-functions v_j and ψ_j for $j = 1, 2$ that form a basis of the eigenspaces of $\mathcal{L}^0$ and its adjoint $[\mathcal{L}^0]^*$, respectively, associated with these Hopf eigenvalues. We can choose these functions so that

$$\begin{aligned} \langle \psi_i, v_j\rangle_{L^2} = \langle \psi_i, \psi_j\rangle_{L^2} &= \delta_{ij}, \\ \mathcal{L}^0 v_1 = -\omega_0 v_2, \qquad \mathcal{L}^0 v_2 &= \omega_0 v_1. \end{aligned} \tag{3.1}$$

The result [10, Theorem 5.4 in Chapter II] gives the characterization

$$\mathrm{Re}\,\lambda_\varepsilon(0) = \frac{1}{2}\sum_{j=1}^{2} \langle \psi_j, \partial_\varepsilon \mathcal{L}^\varepsilon|_{\varepsilon=0} v_j\rangle_{L^2} \tag{3.2}$$

of the derivative $\mathrm{Re}\,\lambda_\varepsilon(0)$ which we assumed in (2.5) to be positive.

3.2. Spatial dynamics. To find time-periodic solutions of (2.2), we rescale time $\tau := \omega t$ to get

$$\omega\partial_\tau u + f(u)_x - cu_x = u_{xx},$$

which we then cast as the first-order system

$$\begin{pmatrix} u_x \\ v_x \end{pmatrix} = \begin{pmatrix} v \\ \omega\partial_\tau u + f(u)_x - cv \end{pmatrix} = \begin{pmatrix} v \\ \omega\partial_\tau u + f_u(u)v - cv \end{pmatrix}. \tag{3.3}$$

We view (3.3) as an equation for $U = (u, v)$ in $Y = H^1(S^1) \times H^{1/2}(S^1)$ with $S^1 = [0, 2\pi]/\sim$. The space Y is natural for various reasons: First, we wish to work on spaces of time-periodic functions and shall see later in (3.13), see also [13, section 3], that the spaces $H^{s+1/2}(S^1) \times H^s(S^1)$ for $s \geq 0$ are the only spaces compatible with the linear leading-order part of (3.3). We choose $s = 1/2$ since $H^1(S^1)$ embeds into $C^0(S^1)$ which guarantees that the nonlinearity $f_u(u)$ in (3.3) is well defined and differentiable on Y. Finally, we remark that we shall often use, for convenience, the scalar product

$$\langle U, V\rangle_X := \frac{1}{2\pi}\int_0^{2\pi} \langle U(\tau), V(\tau)\rangle_{\mathbb{R}^{2n}}\, \mathrm{d}\tau$$

of the space $X = L^2(S^1) \times L^2(S^1)$ to define complements and compute adjoints; this scalar product is also an inner product on Y as Y embeds continuously into X.

The system (3.3) is invariant under the S^1-action

$$\Gamma : S^1 \longrightarrow L(Y, Y), \qquad \sigma \longmapsto \Gamma_\sigma, \qquad [\Gamma_\sigma U](\tau) = U(\tau - \sigma). \tag{3.4}$$

We record that the fixed-point space $\operatorname{Fix}\Gamma \cong \mathbb{R}^n \times \mathbb{R}^n$ of this action consists precisely of all time-independent functions, and (3.3) restricted to $\operatorname{Fix}\Gamma$ becomes the usual travelling-wave ODE

$$\begin{pmatrix} u_x \\ v_x \end{pmatrix} = \begin{pmatrix} v \\ f_u(u)v - cv \end{pmatrix} \tag{3.5}$$

which is equivalent to (2.3). Equation (3.5) possesses the equilibria $U_{\mathrm{eq}} = (u, 0)$ for $u \in \mathbb{R}^n$ and the heteroclinic orbits $Q^\varepsilon(x) := (q^\varepsilon, q^\varepsilon_x)(x)$ for $c = c^\varepsilon$: $Q^\varepsilon(x)$ connects $U^-_{\mathrm{eq}}(\varepsilon) = (u^\varepsilon_-, 0)$ to $U^+_{\mathrm{eq}}(\varepsilon) = (u^\varepsilon_+, 0)$ with

$$T_{Q^\varepsilon(x)} W^{\mathrm{u}}_- + T_{Q^\varepsilon(x)} W^{\mathrm{cs}}_+ = \mathbb{R}^{2n}, \tag{3.6}$$

where $W^j_\pm := W^j(U^\pm_{\mathrm{eq}}(\varepsilon))$. The transversality of the intersection in (3.6) is a consequence of the following dimension count for $\varepsilon = 0$. Since $\dim W^{\mathrm{u}}_- = p + 1$ and $\dim W^{\mathrm{cs}}_+ = 2n - p$, it suffices to show that the only nontrivial elements in the intersection of the tangent spaces are multiples of $Q^0_x(x)$. This, in turn, can be seen as follows. Starting with any nontrivial bounded solution $(u, v)(x)$ of the variational equation

$$\begin{pmatrix} u_x \\ v_x \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ f_{uu}(q^0)[q^0_x, \cdot] & f_u(q^0) - c^0 \end{pmatrix} \begin{pmatrix} u \\ v \end{pmatrix} \tag{3.7}$$

of (3.5) about $Q^0 = (q^0, q^0_x)$, we find that its first component $u(x)$ is a nontrivial bounded solution of

$$u_{xx} = [(f_u(q^0) - c^0)u]_x. \tag{3.8}$$

If a nontrivial bounded solution $(u, v)(x)$ of (3.7) lies, in addition, in $T_{Q^\varepsilon(x)} W^{\mathrm{u}}_-$, then $u(x)$ decays exponentially at $x = -\infty$ and is therefore also a nontrivial bounded solution of the variational equation

$$u_x = [f_u(q^0) - c^0]u \tag{3.9}$$

of (2.3) about q^0 since we can integrate (3.8) once, starting at $x=-\infty$. To complete the argument, we recall our assumption that q^0 lies in the transverse intersection of the unstable and stable manifolds of the hyperbolic rest states $u^0_\pm$ of (2.3); this hypothesis implies that each nontrivial bounded solution of (3.9) is necessarily exponentially localized and must, in fact, be a multiple of q^0_x as claimed.

Next, we linearize the full system (3.3) in the solution $Q^0=(q^0,q^0_x)$ for $\omega=\omega_0$ to get

$$V_x=\begin{pmatrix} 0 & 1 \\ \omega_0\partial_\tau+f_{uu}(q^0)[q^0_x,\cdot] & f_u(q^0)-c^0 \end{pmatrix}V, \qquad V\in Y. \tag{3.10}$$

For $x\to\pm\infty$, we obtain the asymptotic systems

$$V_x=\begin{pmatrix} 0 & 1 \\ \omega_0\partial_\tau & f_u(u^0_\pm)-c^0 \end{pmatrix}V, \qquad V\in Y, \tag{3.11}$$

whose properties we discuss first. Equations (3.10) and (3.11) leave each subspace $Y_k:=\{\mathrm{e}^{\mathrm{i}k\tau}\hat V;\ \hat V\in\mathbb{C}^{2n}\}$ invariant for $k\in\mathbb{Z}$. If we restrict (3.11) to Y_k, we obtain the system

$$\hat V_x=\begin{pmatrix} 0 & 1 \\ \mathrm{i}k\omega_0 & f_u(u^0_\pm)-c^0 \end{pmatrix}\hat V, \qquad \hat V\in\mathbb{C}^{2n}, \tag{3.12}$$

where $V=\mathrm{e}^{\mathrm{i}k\tau}\hat V$. For $k\neq 0$, the matrices in (3.12) are hyperbolic: $\nu=\mathrm{i}\kappa$ is an eigenvalue if and only if $\det[-\kappa^2-\mathrm{i}\kappa(f_u(u^0_\pm)-c^0)-\mathrm{i}k\omega_0]=0$, which is excluded since $f_u(u^0_\pm)$ was assumed to have only real eigenvalues.[1] For $|k|\to\infty$, the eigenvalues of the matrices in (3.12) are

$$\nu_j=\pm\sqrt{\mathrm{i}\omega_0 k}(1+\mathrm{O}(|k|^{-1/2})) \qquad \text{with eigenfunction } \begin{pmatrix}\nu_j e_j\\ e_j\end{pmatrix}, \tag{3.13}$$

where e_j denotes the canonical basis in $\mathbb{R}^n$. In particular, the stable and unstable eigenspaces have a uniform angle in $H^1(S^1)\times H^{1/2}(S^1)$ as $|k|\to\infty$, and therefore for all $k\neq 0$; see also [13, Lemma 3.3]. Thus, we can apply the results in [11, 13] to conclude that (3.11) restricted to $Y_\mathrm{h}:=\overline{\bigoplus_{k\neq 0}Y_k}$ has exponential dichotomies $\Phi^{\mathrm{s,u}}_{\pm,\mathrm{h}}(x,y)$ on $\mathbb{R}^\pm$ since the perturbation

$$\begin{pmatrix} 0 & 0 \\ f_{uu}(q^0(x))[q^0_x(x),\cdot] & f_u(q^0(x))-f_u(u^0_\pm) \end{pmatrix}: H^1\times H^{1/2}\longrightarrow H^1\times H^{1/2}$$

is bounded independently of x and converges to zero as $|x|\to\infty$. We define

$$\nu^\mathrm{s}_\pm:=-\frac{1}{2}\sup\left\{\mathrm{Re}\,\nu_j;\ \mathrm{Re}\,\nu_j<0,\ \nu_j \text{ is an eigenvalue of } (3.12)_\pm \text{ for some } k\in\mathbb{Z}\right\},$$
$$\nu^\mathrm{u}_\pm:=\frac{1}{2}\inf\left\{\mathrm{Re}\,\nu_j;\ \mathrm{Re}\,\nu_j>0,\ \nu_j \text{ is an eigenvalue of } (3.12)_\pm \text{ for some } k\in\mathbb{Z}\right\},$$

---

[1] Purely imaginary spatial eigenvalues $\nu=\mathrm{i}\kappa$ are actually equivalent to essential spectrum at $\lambda=\mathrm{i}\omega_0 k$ so that, for more general viscosity matrices and fluxes, the analysis goes through provided the Hopf eigenvalue $\mathrm{i}\omega_0$ is *not resonant* with essential spectrum on the imaginary axis.

and observe that $\nu^{\mathrm{s}}_{\pm}, \nu^{\mathrm{u}}_{\pm} > 0$ due to (3.13). The spaces

$$E^{\mathrm{cs}}_{+} = \left\{ V_0 \in Y;\ \exists \text{ solution } V(x) \text{ of (3.10) on } \mathbb{R}^+ \text{ with } V(0) = V_0,\ \sup_{x\geq 0} |V(x)| < \infty \right\},$$

$$E^{\mathrm{u}}_{-} = \left\{ V_0 \in Y;\ \exists \text{ solution } V(x) \text{ of (3.10) on } \mathbb{R}^- \text{ with } V(0) = V_0, \right.$$
$$\left. \sup_{x\leq 0} |V(x)| \mathrm{e}^{\nu^{\mathrm{u}}_{-}|x|} < \infty \right\}$$

are closed subspaces of Y.

CLAIM. *We have*

$$E^{\mathrm{cs}}_{+} \cap E^{\mathrm{u}}_{-} = \mathbb{R}Q^0_x(0) \oplus \mathbb{R}V_1(0) \oplus \mathbb{R}V_2(0), \tag{3.14}$$
$$Y = [E^{\mathrm{cs}}_{+} + E^{\mathrm{u}}_{-}] \oplus \mathbb{R}\Psi_1(0) \oplus \mathbb{R}\Psi_2(0), \tag{3.15}$$

where, using the definitions of v_j and ψ_j from section 3.1*,*

$$\begin{aligned} V_1(x) &:= \cos\tau \begin{pmatrix} v_1 \\ \partial_x v_1 \end{pmatrix}(x) + \sin\tau \begin{pmatrix} v_2 \\ \partial_x v_2 \end{pmatrix}(x), \\ V_2(x) &:= -\sin\tau \begin{pmatrix} v_1 \\ \partial_x v_1 \end{pmatrix}(x) + \cos\tau \begin{pmatrix} v_2 \\ \partial_x v_2 \end{pmatrix}(x) \end{aligned} \tag{3.16}$$

and

$$\begin{aligned} \Psi_1(x) &:= \cos\tau \begin{pmatrix} \widetilde{\psi}_1 \\ \psi_1 \end{pmatrix}(x) + \sin\tau \begin{pmatrix} \widetilde{\psi}_2 \\ \psi_2 \end{pmatrix}(x), \\ \Psi_2(x) &:= -\sin\tau \begin{pmatrix} \widetilde{\psi}_1 \\ \psi_1 \end{pmatrix}(x) + \cos\tau \begin{pmatrix} \widetilde{\psi}_2 \\ \psi_2 \end{pmatrix}(x) \end{aligned} \tag{3.17}$$

with $\widetilde{\psi}_j := -\partial_x \psi_j - [f_u^T(q^0) - c^0]\psi_j$ for $j = 1, 2$.

Proof. The characterization of E^{cs}_{+} and E^{u}_{-} is a consequence of the existence of exponential dichotomies on Y_{h} and the dynamics of the travelling-wave ODE (3.5). First, recall that the dynamics on the Fourier subspaces Y_k decouple, so that we can write

$$E^{\mathrm{cs}}_{+} = \bigoplus_{k\in\mathbb{Z}} (E^{\mathrm{cs}}_{+} \cap Y_k), \qquad E^{\mathrm{u}}_{-} = \bigoplus_{k\in\mathbb{Z}} (E^{\mathrm{u}}_{-} \cap Y_k).$$

We know that the strong unstable manifold $W^{\mathrm{u}}(U^{-}_{\mathrm{eq}}(0))$ and the center-stable manifold $W^{\mathrm{cs}}(U^{+}_{\mathrm{eq}}(0))$ of (3.5) intersect transversely along $Q^0(x)$; see (3.6). Thus,

$$\operatorname{span} Q^0_x(0) = E^{\mathrm{cs}}_{+} \cap E^{\mathrm{u}}_{-} \cap Y_0.$$

Next, $V_0 \in Y_{\mathrm{h}}$, the subspace of nonzero Fourier modes $k \neq 0$, lies in $E^{\mathrm{cs}}_{+} \cap E^{\mathrm{u}}_{-}$ if and only if $V(x)$ satisfies (3.11) on $\mathbb{R}$ with $V(x) \to 0$ exponentially as $|x| \to \infty$. Since (3.11) on Y decouples, we find that such a solution can be taken in the form $V(x) = \mathrm{e}^{\mathrm{i}k\tau}(v, v_x)(x)$ for some integer $k \neq 0$. In particular, $v(x)$ satisfies

$$\mathcal{L}^0 v = \mathrm{i}k\omega_0 v,$$

and is therefore an L^2-eigenfunction of $\mathcal{L}^0$ to the eigenvalue $\lambda = \mathrm{i}k\omega_0$. Inspecting our hypotheses on $\mathcal{L}^0$, (3.14) follows. To prove (3.15), we consider the adjoint equation

$$\Psi_x = -\begin{pmatrix} 0 & -\omega_0\partial_\tau + f_{uu}^T(q^0)[q_x^0,\cdot] \\ 1 & f_u^T(q^0) - c^0 \end{pmatrix}\Psi, \qquad \Psi \in Y, \tag{3.18}$$

of (3.11), taken with respect to the inner product in the space $X = L^2(S^1) \times L^2(S^1)$. We note that the functions $\Psi_j(x)$ from (3.17) satisfy (3.18). A calculation shows that

$$\frac{\mathrm{d}}{\mathrm{d}x}\langle V(x), \Psi(x)\rangle_X = 0 \qquad \text{for all } x \in \mathbb{R}$$

for solutions $V(x)$ of (3.11) and $\Psi(x)$ of (3.18); see [14] for similar arguments. Using the relation between (3.18) and $[\mathcal{L}^0]^*$, we conclude that (3.15) is met. □

Note that the direction $Q_x^0(0) \in E_+^{\mathrm{cs}} \cap E_-^{\mathrm{u}}$ corresponds to the flow direction. To remove it, we shall later use the hyperplane

$$\mathcal{S} := [\mathbb{R}Q_x^0(0)]^\perp \subset Y. \tag{3.19}$$

We are now ready to discuss the nonlinear equation (3.3) near the orbit $Q^0(x)$ for ω close to ω_0 and ε close to zero. It is convenient to set

$$\omega = \omega_0 + \Omega$$

and to consider

$$\begin{pmatrix} u_x \\ v_x \end{pmatrix} = \begin{pmatrix} v \\ (\omega_0 + \Omega)\partial_\tau u + f_u(u)v - c^\varepsilon v \end{pmatrix} \tag{3.20}$$

near the orbit $Q^0 = (q^0, q_x^0)$ for (ε, Ω) close to zero. We employ the smooth coordinate change

$$z = x\sqrt{\omega_0 + \Omega}, \qquad (\widetilde{u}, \widetilde{v}) = \left(u, v/\sqrt{\omega_0 + \Omega}\right)$$

which transforms (3.20) into the equation

$$\begin{pmatrix} \widetilde{u}_z \\ \widetilde{v}_z \end{pmatrix} = \begin{pmatrix} \widetilde{v} \\ \partial_\tau \widetilde{u} + (\omega_0 + \Omega)^{-1/2}[f_u(\widetilde{u}) - c^\varepsilon]\widetilde{v} \end{pmatrix}. \tag{3.21}$$

The advantage of (3.21) over (3.20) is that the Ω-dependent part of the right-hand side of (3.21) is a smooth mapping from Y into itself which depends smoothly on (ε, Ω) for (ε, Ω) near zero; in contrast, the dependence on Ω of the right-hand side of (3.20) is through the term $u \mapsto \Omega\partial_\tau u$ which is not even bounded from H^1 into $H^{1/2}$. Using the fact that the linearized equation (3.10) can be solved using exponential dichotomies (whose existence we established above), we can proceed as in [13, section 3.5] and [22] to prove the existence of unstable and center-stable manifolds for (3.21), and therefore for (3.20), near the viscous shock. More precisely, there exist constants $\delta > 0$ and $K > 0$ such that

$$\begin{aligned} \mathcal{W}^{\mathrm{u}}_{\varepsilon,\Omega} := \{&U_0 \in Y;\ \exists \text{ solution } U(x) \text{ of (3.20) on } \mathbb{R}^- :\ U(0) = U_0,\ |U_0 - Q^0(0)| < \delta, \\ &|U(x) - U_{\mathrm{eq}}^-(\varepsilon)| \le K\mathrm{e}^{-\nu_-^{\mathrm{u}}|x|} \text{ for } x \le 0\}, \\ \mathcal{W}^{\mathrm{cs}}_{\varepsilon,\Omega} := \{&U_0 \in Y;\ \exists \text{ solution } U(x) \text{ of (3.20) on } \mathbb{R}^+ :\ U(0) = U_0,\ |U_0 - Q^0(0)| < \delta, \\ &\exists U_{\mathrm{eq}}^+ \in Y_0 \text{ with } |U_{\mathrm{eq}}^+ - U_{\mathrm{eq}}^+(0)| < \delta \text{ so that } |U(x) - U_{\mathrm{eq}}^+| \le K\mathrm{e}^{-\nu_+^{\mathrm{s}}|x|} \\ &\text{for } x \ge 0\} \end{aligned}$$

are smooth manifolds that are invariant under the action of the group Γ defined in (3.4) and that depend smoothly on (ε, Ω) near zero (smoothness with respect to the parameters follows from [22] since the right-hand side of the rescaled equation (3.21) is smooth in the parameters). Moreover, $Q^\varepsilon(0) \in \mathcal{W}^{\mathrm{u}}_{\varepsilon,\Omega} \cap \mathcal{W}^{\mathrm{cs}}_{\varepsilon,\Omega}$, and the tangent spaces of the invariant manifolds at this point of intersection are given by

$$T_{Q^0(0)}\mathcal{W}^{\mathrm{u}}_{0,0} = E^{\mathrm{u}}_{-}, \qquad T_{Q^0(0)}\mathcal{W}^{\mathrm{cs}}_{0,0} = E^{\mathrm{cs}}_{+}.$$

Note that the center-stable manifold $\mathcal{W}^{\mathrm{cs}}_{\varepsilon,\Omega}$ is in effect given as the union of stable manifolds to the manifold $\{U^+_{\mathrm{eq}} = (u, 0);\ u \in \mathbb{R}^n\}$ of asymptotic states, and therefore unique.

Finding solutions of (2.2), with temporal frequency ω near ω_0, that converge asymptotically to constants as $x \to \pm\infty$ is therefore equivalent to finding elements U_0 in the intersection

$$\mathcal{W}^{\mathrm{u}}_{\varepsilon,\Omega} \cap \mathcal{W}^{\mathrm{cs}}_{\varepsilon,\Omega} \cap \left[Q^0(0) + \mathcal{S}\right] \tag{3.22}$$

for Ω close to zero, with $\mathcal{S}$ as in (3.19). Note that U_0 will have nontrivial time-τ dependence if and only if U_0 has a nonzero Y_{h}-component. The minimal period will be $2\pi/\omega$ if the component of U_0 in Y_1 does not vanish. We use Lyapunov–Schmidt reduction to determine the intersection (3.22). To this end, we write

$$E^{\mathrm{cs}}_{+} \cap \mathcal{S} = \widetilde{E}^{\mathrm{cs}}_{+} \oplus \mathrm{span}\{V_1(0), V_2(0)\}, \qquad E^{\mathrm{u}}_{-} \cap \mathcal{S} = \widetilde{E}^{\mathrm{u}}_{-} \oplus \mathrm{span}\{V_1(0), V_2(0)\}.$$

There are then unique smooth maps

$$\begin{aligned} G^{\mathrm{cs}}(\cdot;\varepsilon,\Omega):&\quad \widetilde{E}^{\mathrm{cs}}_{+} \oplus \mathrm{span}\{V_1(0), V_2(0)\} \longrightarrow \widetilde{E}^{\mathrm{u}}_{-} \oplus \mathrm{span}\{\Psi_1(0), \Psi_2(0)\},\\ G^{\mathrm{u}}(\cdot;\varepsilon,\Omega):&\quad \widetilde{E}^{\mathrm{u}}_{-} \oplus \mathrm{span}\{V_1(0), V_2(0)\} \longrightarrow \widetilde{E}^{\mathrm{cs}}_{+} \oplus \mathrm{span}\{\Psi_1(0), \Psi_2(0)\} \end{aligned}$$

with

$$Q^\varepsilon(0) + \mathrm{graph}\, G^j(\cdot;\varepsilon,\Omega) = \mathcal{W}^j_{\varepsilon,\Omega} \cap [Q^0(0) + \mathcal{S}], \qquad j = \mathrm{cs}, \mathrm{u},$$

and $D_U G^j(0;0,0) = 0$ for $j = \mathrm{cs}, \mathrm{u}$. In particular, both maps are equivariant under the S^1-action Γ. Thus, intersections of $\mathcal{W}^{\mathrm{u}}_{\varepsilon,\Omega}$ and $\mathcal{W}^{\mathrm{cs}}_{\varepsilon,\Omega}$ in $Q^0(0) + \mathcal{S}$ are in one-to-one correspondence with the zeroes of the mapping

$$\begin{aligned} G(\cdot;\varepsilon,\Omega):&\quad \mathbb{R} \times \widetilde{E}^{\mathrm{u}}_{-} \times \widetilde{E}^{\mathrm{cs}}_{+} \longrightarrow \widetilde{E}^{\mathrm{u}}_{-} \oplus \widetilde{E}^{\mathrm{cs}}_{+} \oplus \mathrm{span}\{\Psi_1(0), \Psi_2(0)\},\\ &(a, w^{\mathrm{u}}, w^{\mathrm{cs}}) \longmapsto w^{\mathrm{u}} + G^{\mathrm{u}}(w^{\mathrm{u}} + aV_1(0);\varepsilon,\Omega) - [w^{\mathrm{cs}} + G^{\mathrm{cs}}(w^{\mathrm{cs}} + aV_1(0);\varepsilon,\Omega)], \end{aligned}$$

where we factored out the nontrivial S^1-action on $\mathrm{span}\{V_1(0), V_2(0)\}$. Lyapunov–Schmidt reduction shows that there is a unique map

$$W: \quad U_\delta(0) \subset \mathbb{R}^3 \longrightarrow \widetilde{E}^{\mathrm{u}}_{-} \times \widetilde{E}^{\mathrm{cs}}_{+}, \quad (a,\varepsilon,\Omega) \longmapsto (W^{\mathrm{u}}(a,\varepsilon,\Omega), W^{\mathrm{cs}}(a,\varepsilon,\Omega)),$$

so that $G(a, w^{\mathrm{u}}, w^{\mathrm{cs}};\varepsilon,\Omega) = 0$ if and only if

$$\langle \Psi_j(0), G(a, W(a,\varepsilon,\Omega);\varepsilon,\Omega)\rangle_X = 0 \qquad \text{for } j = 1, 2.$$

Furthermore, W is smooth in (a,ε,Ω) and we have $D_{(a,\varepsilon,\Omega)}W(0,0,0) = 0$. In fact, since $G(0,0,0;\varepsilon,\Omega) \equiv 0$ due to $Q^\varepsilon(0) \in \mathcal{W}^{\mathrm{u}}_{\varepsilon,\Omega} \cap \mathcal{W}^{\mathrm{cs}}_{\varepsilon,\Omega}$ for all (ε,Ω), we have in addition that $W(0,\varepsilon,\Omega) = 0$ for all small (ε,Ω), so that

$$W(a,\varepsilon,\Omega) = a\mathrm{O}(|a| + |\varepsilon| + |\Omega|). \tag{3.23}$$

It suffices therefore to solve the reduced equations

$$\langle \Psi_j(0), G(a, W(a,\varepsilon,\Omega);\varepsilon,\Omega)\rangle_X = 0 \qquad \text{for } j = 1,2. \tag{3.24}$$

To derive an expression for (3.24), we write (3.20) as

$$U_x = F(U,\varepsilon,\Omega). \tag{3.25}$$

Using the coordinates $U = Q^\varepsilon + \widetilde{U}$, we find that $\widetilde{U}$ satisfies

$$\widetilde{U}_x = F_U(Q^0,0,0)\widetilde{U} + \mathcal{N}(\widetilde{U},\varepsilon,\Omega,x), \tag{3.26}$$

where

$$\begin{aligned} \mathcal{N}(\widetilde{U},\varepsilon,\Omega,x) &:= F(Q^\varepsilon + \widetilde{U},\varepsilon,\Omega) - F(Q^\varepsilon,\varepsilon,\Omega) - F_U(Q^0,0,0)\widetilde{U} \\ &= \mathrm{O}(|\widetilde{U}|(|\widetilde{U}| + |\varepsilon| + |\Omega|)). \end{aligned} \tag{3.27}$$

Using the variation-of-constant formula that captures unstable and center-stable manifolds (see, e.g., [22] or [13, Proposition 3.13]) and the fact that $\Psi_j(x)$ satisfies (3.18) together with [14, Lemma 5.1], we find that (3.24) is given by

$$\int_{-\infty}^{\infty} \left\langle \Psi_j(x), \mathcal{N}(\widetilde{U}^\pm(x),\varepsilon,\Omega,x)\right\rangle_X \mathrm{d}x = 0, \qquad j = 1,2, \tag{3.28}$$

where $\widetilde{U}^\pm(x)$ satisfies (3.26) on $\mathbb{R}^\pm$ with $\widetilde{U}^-(0) = aV_1(0) + W^{\mathrm{u}}(a,\varepsilon,\Omega)$ and $\widetilde{U}^+(0) = aV_1(0) + W^{\mathrm{cs}}(a,\varepsilon,\Omega)$. If we write (3.28) as $\Pi(a,\varepsilon,\Omega) = 0$, then we know from the preceding discussion that $\Pi(0,\varepsilon,\Omega) = 0$ for all (ε,Ω): this solution corresponds to the persisting Lax shocks in $\operatorname{Fix}\Gamma$. To obtain genuinely time-periodic solutions corresponding to $a \neq 0$, we write

$$\Pi(a,\varepsilon,\Omega) = a\widetilde{\Pi}(a,\varepsilon,\Omega) \tag{3.29}$$

and consider $\widetilde{\Pi}(a,\varepsilon,\Omega) = 0$, which can be solved by the implicit function theorem provided the 2×2 matrix $D_{(\varepsilon,\Omega)}\widetilde{\Pi}(0,0,0)$ is invertible. Equations (3.29) and (3.28) show that

$$\begin{aligned} D_{(\varepsilon,\Omega)}\widetilde{\Pi}(0,0,0) &= D_a D_{(\varepsilon,\Omega)}\Pi(0,0,0) \\ &= \left[D_a D_{(\varepsilon,\Omega)} \int_{-\infty}^{\infty} \langle \Psi_j(x), \mathcal{N}(\widetilde{U}^\pm(x),\varepsilon,\Omega,x)\rangle_X \,\mathrm{d}x \Big|_{(a,\varepsilon,\Omega)=0} \right]_{j=1,2} \end{aligned} \tag{3.30}$$

which we now compute. We know that

$$\widetilde{U}^+(x) = aV_1(x) + W^{\mathrm{cs}}(a,\varepsilon,\Omega)(x), \qquad \widetilde{U}^-(x) = aV_1(x) + W^{\mathrm{u}}(a,\varepsilon,\Omega)(x)$$

which we rewrite as

$$\widetilde{U}^\pm(x) = a[V_1(x) + \widetilde{W}^\pm(x;a,\varepsilon,\Omega)] \tag{3.31}$$

with

$$\begin{aligned} \widetilde{W}^-(x;a,\varepsilon,\Omega) &:= \frac{1}{a} W^{\mathrm{u}}(a,\varepsilon,\Omega)(x) = \mathrm{O}(|a| + |\varepsilon| + |\Omega|), \qquad x \in \mathbb{R}^-, \\ \widetilde{W}^+(x;a,\varepsilon,\Omega) &:= \frac{1}{a} W^{\mathrm{cs}}(a,\varepsilon,\Omega)(x) = \mathrm{O}(|a| + |\varepsilon| + |\Omega|), \qquad x \in \mathbb{R}^+, \end{aligned} \tag{3.32}$$

due to the estimate (3.23). Thus,

$$\frac{\mathrm{d}^2}{\mathrm{d}(\varepsilon,\Omega)\mathrm{d}a}\mathcal{N}(\widetilde{U}^{\pm}(x),\varepsilon,\Omega,x)|_{(a,\varepsilon,\Omega)=0} = D_{(\varepsilon,\Omega)}F_U(Q^{\varepsilon}(x),\varepsilon,\Omega)|_{(a,\varepsilon,\Omega)=0}V_1(x).$$

Upon comparing (3.25) with (3.20), we see that

$$\begin{aligned}\frac{\mathrm{d}^2}{\mathrm{d}\Omega\mathrm{d}a}\mathcal{N}|_{(a,\varepsilon,\Omega)=0} &= \begin{pmatrix} 0 & 0 \\ \partial_\tau & 0 \end{pmatrix} V_1,\\ \frac{\mathrm{d}^2}{\mathrm{d}\varepsilon\mathrm{d}a}\mathcal{N}|_{(a,\varepsilon,\Omega)=0} &= \begin{pmatrix} 0 & 0 \\ \partial_\varepsilon(f_{uu}(q^\varepsilon)[q_x^\varepsilon,\cdot])|_{\varepsilon=0} & \partial_\varepsilon[f_u(q^\varepsilon)-c^\varepsilon]|_{\varepsilon=0} \end{pmatrix} V_1.\end{aligned}$$

Substituting the expressions (3.16) and (3.17) for V_1 and Ψ_j and using the normalization (3.1), we obtain

$$\left[\frac{\mathrm{d}^2}{\mathrm{d}\Omega\mathrm{d}a}\int_{-\infty}^{\infty}\left\langle \Psi_j(x),\mathcal{N}(\widetilde{U}^{\pm}(x),\varepsilon,\Omega,x)\right\rangle_X \mathrm{d}x\Big|_{(\varepsilon,\Omega)=0}\right]_{j=1,2} = \begin{pmatrix} 0 \\ 1 \end{pmatrix} \in \mathbb{R}^2. \tag{3.33}$$

An analogous computation for the derivative with respect to ε gives

$$\begin{aligned}&\left[\frac{\mathrm{d}^2}{\mathrm{d}\varepsilon\mathrm{d}a}\int_{-\infty}^{\infty}\left\langle \Psi_1(x),\mathcal{N}(\widetilde{U}^{\pm}(x),\varepsilon,\Omega,x)\right\rangle_X \mathrm{d}x\Big|_{(\varepsilon,\Omega)=0}\right]\\ &= \frac{1}{2}\sum_{j=1}^{2}\left\langle \psi_j, \partial_\varepsilon\partial_x\left[f_u(q^\varepsilon)v_j - c^\varepsilon v_j\right]_{\varepsilon=0}\right\rangle_{L^2}\\ &= -\frac{1}{2}\sum_{j=1}^{2}\langle \psi_j, \partial_\varepsilon\mathcal{L}^\varepsilon|_{\varepsilon=0}v_j\rangle_{L^2}\\ &= -\operatorname{Re}\lambda_\varepsilon(0),\end{aligned}$$

where we used (3.2) to obtain the last step. Hence, we find that the Jacobian in (3.30) is given by

$$D_{(\varepsilon,\Omega)}\widetilde{\Pi}(0,0,0) = \begin{pmatrix} -\operatorname{Re}\lambda_\varepsilon(0) & 0 \\ \star & 1 \end{pmatrix} \tag{3.34}$$

which is invertible due to our hypothesis on the transverse crossing of the Hopf eigenvalues.

Upon applying the implicit function theorem to solve $\widetilde{\Pi}(a,\varepsilon,\Omega)=0$, we conclude that there exist unique functions $(\varepsilon_*,\Omega_*)(a)\in\mathbb{R}^2$ and $Q^*(0;a)\in Y$, defined for $|a|<\delta$, so that

$$Q^*(0;a)\in\mathcal{W}^{\mathrm{u}}_{(\varepsilon_*,\Omega_*)(a)}\cap\mathcal{W}^{\mathrm{cs}}_{(\varepsilon_*,\Omega_*)(a)}\cap\left[Q^0(0)+\mathcal{S}\right].$$

These functions are smooth and satisfy $\partial_a(\varepsilon_*,\Omega_*)|_{a=0}=0$, $Q^*(0;0)=Q^0(0)$, and

$$\begin{aligned}Q^*(x;a) &= Q^{\varepsilon_*(a)}(x) + a[V_1(x)+\widetilde{W}^{\pm}(x;a,\epsilon_*(a),\Omega_*(a))]\\ &=: Q^{\varepsilon_*(a)}(x) + a\widetilde{Q}^*(x;a).\end{aligned} \tag{3.35}$$

By construction, we have $Q^*(x;a)\to U^-_{\mathrm{eq}}(\varepsilon_*(a))$ as $x\to-\infty$. Furthermore, we have $Q^*(x;a)\in\mathcal{W}^{\mathrm{cs}}_{(\varepsilon_*,\Omega_*)(a)}$ from which we infer that there exists a $U^+_*(a)\in\mathbb{R}^n$ with

$|U_*^+(a) - U_{\rm eq}^+(\varepsilon_*(a))| < \delta$, so that $Q^*(x;a) \to U_*^+(a)$ exponentially as $x \to \infty$ with rate $\nu_+^{\rm s}$. We claim that $U_*^+(a) = U_{\rm eq}^+(\varepsilon_*(a))$. To prove this claim, consider the smooth functional

$$\mathcal{E}: \quad Y \longrightarrow \mathbb{R}^n, \quad (u,v) \longmapsto \int_0^{2\pi} [v - f(u) + cu]\,\mathrm{d}\tau. \tag{3.36}$$

This functional is conserved under the evolution of (3.3). If $U(x) = (u,v)(x) \in Y$ is a solution of (3.3), then $v = u_x$ and

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}\mathcal{E}(U(x)) &= \frac{\mathrm{d}}{\mathrm{d}x}\int_0^{2\pi} [v - f(u) + cu]\,\mathrm{d}\tau \\ &= \int_0^{2\pi} [v_x - f_u(u)v + cv]\,\mathrm{d}\tau \\ &\overset{(3.3)}{=} \int_0^{2\pi} \omega u_\tau\,\mathrm{d}\tau = 0 \end{aligned} \tag{3.37}$$

since u is 2π-periodic in τ. Furthermore, for $U = (u_0, v_0) \in \operatorname{Fix}\Gamma \subset Y$, we have

$$D_U\mathcal{E}(u_0,v_0)\begin{pmatrix}\widetilde{u}\\ \widetilde{v}\end{pmatrix} = \int_0^{2\pi} [\widetilde{v} - f_u(u_0)\widetilde{u} + c\widetilde{u}]\,\mathrm{d}\tau = \widetilde{v}_0 - f_u(u_0)\widetilde{u}_0 + c\widetilde{u}_0 \in \mathbb{R}^n.$$

In particular, $D_U\mathcal{E}(u_\pm^0, 0)$ restricted to $\mathbb{R}^n \times \{0\} \subset Y_0$ is invertible, since we assumed that none of the characteristic speeds vanishes in the frame that moves with speed c^0. Since $Q^{\varepsilon_*(a)}(x)$ connects $U_{\rm eq}^-(\varepsilon_*(a))$ to $U_{\rm eq}^+(\varepsilon_*(a))$, they have the same $\mathcal{E}$-values, and the preceding argument shows that there is no other equilibrium $U_{\rm eq}^+$ near $U_{\rm eq}^+(\varepsilon_*(a))$ with the $\mathcal{E}$-value of $U_{\rm eq}^+(\varepsilon_*(a))$. Therefore, $Q^*(x;a) \to U_{\rm eq}^\pm(\varepsilon_*(a))$ for $x \to \pm\infty$.

This completes the existence proof of the bifurcating oscillatory viscous shock waves. The uniqueness statement in Theorem 2.1 is a consequence of our construction which captures all solutions that lie in the intersection of $\mathcal{W}_{\varepsilon,\Omega}^{\rm u}$ and $\mathcal{W}_{\varepsilon,\Omega}^{\rm cs}$. We remark that (3.37) also shows that any time-periodic localized travelling viscous shock wave satisfies the Rankine–Hugoniot condition (2.4).

To prepare the ground for the following spectral stability proof, we derive an expression for $\varepsilon_{aa}(0)$. First, we set $(\varepsilon, \Omega) = 0$ and compute the derivatives

$$\frac{\mathrm{d}^j}{\mathrm{d}a^j}\Pi_i(a,0,0) = \frac{\mathrm{d}^j}{\mathrm{d}a^j}\int_{-\infty}^{\infty} \left\langle \Psi_i(x), \mathcal{N}(\widetilde{U}^\pm(x),0,0,x)\right\rangle_X \mathrm{d}x$$

at $a = 0$ for $i = 1,2$. Using the expressions (3.27) for $\mathcal{N}$ and (3.31) for $\widetilde{U}^\pm$ together with the estimate (3.32) for $\widetilde{W}(x;a,0,0)$, we easily find that the first and second derivatives vanish at $a = 0$ for $i = 1,2$, while

$$\begin{aligned} \kappa_3 :=& \frac{\mathrm{d}^3}{\mathrm{d}a^3}\Pi_1(a,0,0) \\ =& \int_{-\infty}^{\infty} \Big\langle \Psi_1(x), F_{UUU}(Q^0(x),0,0)[V_1(x)]^3 + \\ & \qquad + 3F_{UU}(Q^0(x),0,0)[V_1(x), \widetilde{W}_a(x;0,0,0)]\Big\rangle_X \mathrm{d}x. \end{aligned} \tag{3.38}$$

A straightforward calculation using (3.34) then shows that

$$\varepsilon_{aa}(0) = \frac{\kappa_3}{3\operatorname{Re}\lambda_\varepsilon(0)}. \tag{3.39}$$

4. Stability of the bifurcating modulated viscous shocks. This section is devoted to the proof of Theorem 2.2. Our goal is to determine the Floquet spectrum

$$\Sigma = \{\lambda \in \mathbb{C};\ \mathrm{e}^{2\pi\lambda} \in \text{ spectrum of } \Phi_{2\pi}\}$$

associated with the evolution Φ_t of the linearization

$$\omega v_\tau = \partial_x[\partial_x + c - f_u(q^*(x,\tau;a))]v$$

of (2.2) about q^* on $\mathcal{C}^0_{\mathrm{unif}}$. Note that (ε,ω) and q^* depend smoothly on the parameter a introduced in section 3, and so do the wave speed $c = c^\varepsilon$ and the asymptotic rest states $u^\varepsilon_\pm$ through $\varepsilon = \varepsilon_*(a)$; we will suppress this dependence for most of the proof.

The Floquet spectrum Σ is the disjoint union of the essential spectrum Σ_{ess} and the point spectrum Σ_{pt}, which consists, by definition, of all isolated eigenvalues with finite multiplicity. Since the modulated shock $q^*(x,\tau;a)$ converges exponentially to the constants $u^\varepsilon_\pm$ as $x \to \pm\infty$, uniformly in τ, the set Σ_{ess} is bounded to the right by the essential spectra

$$\Sigma^\pm_{\mathrm{ess}} = \{\lambda \in \mathbb{C};\ \det(k^2 + \mathrm{i}k[f_u(u^\varepsilon_\pm) - c^\varepsilon] + \lambda) = 0 \text{ for some } k \in \mathbb{R}\}$$

of $u^\varepsilon_\pm$ (see, for instance, [14, Proposition 2.10]), which touch the imaginary axis at $\lambda = 0$ and lie otherwise in the open left half-plane due to our hypothesis that the eigenvalues of $f_u(u^\varepsilon_\pm)$ are real and simple.

It therefore suffices to locate point spectrum, that is, isolated Floquet exponents λ which are captured, via the ansatz $v(x,\tau) = \mathrm{e}^{\lambda\tau}u(x,\tau)$ with $u(x,\tau+2\pi) = u(x,\tau)$ for all τ, by the equation

$$\omega_*(a)u_\tau + \lambda u = \partial_x[\partial_x + c^{\varepsilon_*(a)} - f_u(q^*(x,\tau;a))]u$$

which we rewrite as

$$\begin{aligned} V_x &= \begin{pmatrix} 0 & 1 \\ \omega\partial_\tau + \lambda + f_{uu}(q^*)[q^*_x,\cdot] & f_u(q^*) - c \end{pmatrix} V \\ &= [F_U(Q^*(x;a), \epsilon_*(a), \Omega_*(a)) + \lambda\mathcal{B}]V, \qquad V \in Y, \end{aligned} \tag{4.1}$$

with $Q^*(x;a) = (q^*, q^*_x)(x,\cdot;a)$ from (3.35).

Since we assumed spectral stability for $\epsilon = 0$ except for the Hopf eigenvalues and the translational eigenvalue at the origin (which all contribute to the Floquet exponent $\lambda = 0$), it suffices to find all isolated Floquet exponents of (4.1) in a fixed small neighborhood of the origin. We choose an open set $\Omega \subset \mathbb{C}$ as indicated in Figure 2. Standard theory implies that $\lambda \in \Omega$ is a Floquet exponent if and only if (4.1) has a nontrivial exponentially decaying solution on $\mathbb{R}$. Taking the limit $x \to \pm\infty$ in (4.1), we obtain the asymptotic operators

$$\begin{pmatrix} 0 & 1 \\ \omega\partial_\tau + \lambda & f_u(u_\pm) - c \end{pmatrix}. \tag{4.2}$$

We denote the eigenvectors and eigenvalues of $[f_u(u_\pm) - c]$ by $r^\pm_j$ and $\nu^\pm_j$, respectively. As discussed in section 3, the operators in (4.2) are hyperbolic for $\lambda = 0$ except for the n-fold eigenvalue $\mathcal{V} = 0$ with eigenvectors $(r^\pm_j, 0) \in Y_0$. This eigenvalue and the associated eigenvectors become

$$\mathcal{V}^\pm_j = -\frac{\lambda}{\nu^\pm_j} + \mathrm{O}(\lambda^2), \qquad R^\pm_j = \begin{pmatrix} r^\pm_j \\ \mathcal{V}^\pm_j r^\pm_j \end{pmatrix}, \qquad j = 1,\dots,n, \tag{4.3}$$

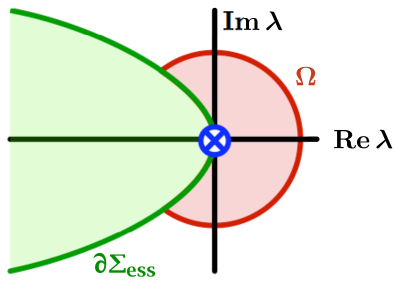

FIG. 2. *The definition of the open set $\Omega \subset \mathbb{C}$ in the complex Floquet plane is shown. The embedded Floquet exponent at the origin has multiplicity at least equal to two with eigenfunctions q_x^* and q_τ^*.*

for λ near zero. For $\lambda \in \Omega$, the unstable eigenspace $E_-^\infty(\lambda, a)$ at $x = -\infty$ and the stable eigenspace $E_+^\infty(\lambda, a)$ at $x = \infty$ are therefore given by

$$E_+^\infty := E_+^{\mathrm{s}} \oplus \mathcal{R}_+, \qquad E_-^\infty := E_-^{\mathrm{u}} \oplus \mathcal{R}_-, \qquad \mathcal{R}_\pm = \mathrm{span}\{R_j^\pm;\ \nu_j^\pm \gtrless 0\},$$

and these spaces depend smoothly on a and are analytic in λ for λ near zero. Note that $\dim \mathcal{R}^+ = p$ and $\dim \mathcal{R}^- = n - p - 1$ with p as in section 2.

LEMMA 4.1. *There are unique closed subspaces $E_\pm(\lambda, a)$ of Y, defined and analytic in λ near zero and smooth in $a \geq 0$, such that $V(x)$ is a bounded solution of (4.1) on $\mathbb{R}^\pm$ for some $\lambda \in \Omega$ if and only if $V(0) \in E_\pm(\lambda, a)$.*

Proof. We begin by considering (4.1) with Q^* replaced by Q^ε. In this case, (4.1) decouples on each Fourier space Y_k, and the claimed statement holds for Q^ε due to the Gap lemma [5, 9] applied in Y_0 and exponential dichotomy theory together with estimates as in [13, Lemma 3.3] in the other Fourier spaces. Since the difference of Q^ε and Q^* is small for all x and decays to zero exponentially as $|x| \to \infty$, these results carry over to (4.1) using, for instance, the integral formulation in [12, (4.12) in section 4.3]; see also [18, section 7.6] for a slightly different proof. ∎

Lemma 4.1 shows that Floquet exponents in Ω can be found by seeking nontrivial intersections of $E_-(\lambda, a)$ and $E_+(\lambda, a)$. To determine their intersections, we first set $(\lambda, a) = 0$ to see what these spaces look like at onset and then use perturbation theory to analyze the case when $(\lambda, a) \neq 0$.

Hence, let $\lambda = 0$, then (4.1) is simply the variational equation

$$V_x = F_U(Q^*(x; a), \epsilon_*(a), \Omega_*(a))V, \qquad V \in Y, \tag{4.4}$$

of the modulated wave Q^*. When $a = 0$, we have $Q^* = Q^0$, and (4.4) describes Floquet exponents at $\lambda = 0$ of the unperturbed viscous shock q^0. In particular, (4.4) decouples on each Fourier space Y_k, and our hypotheses on the Evans function and the spectral properties of the viscous shock imply that

$$\begin{aligned} E_+(0,0) \cap E_-(0,0) &= \mathrm{span}\{Q_x^0(0), V_1(0), V_2(0)\}, \\ [E_+(0,0) + E_-(0,0)]^\perp &= \mathrm{span}\{\Psi_0, \Psi_1(0), \Psi_2(0)\} \end{aligned} \tag{4.5}$$

for an appropriate nonzero vector $\Psi_0 \in Y_0$. Next, consider (4.4) for an arbitrary a near zero. First, note that the gradient of the jth component $\mathcal{E}_j$ of the conserved quantity $\mathcal{E}$ from (3.36), computed in the $X = L^2(S^1) \times L^2(S^1)$ scalar product, is given by

$$\nabla \mathcal{E}_j(u, v) = \nabla \langle \mathcal{E}(u, v), e_j \rangle_{\mathbb{R}^n} = \begin{pmatrix} -[f_u^T(u) - c]e_j \\ e_j \end{pmatrix}, \qquad j = 1, \dots, n, \tag{4.6}$$

where e_j denotes the jth canonical basis vector in $\mathbb{R}^n$. Our analysis of $\mathcal{E}$ in section 3 implies that these n gradients are linearly independent for $a = 0$, and we therefore have $\dim E^*(a) = n$ for all small a where

$$E^*(a) := \mathrm{span}\,\{\nabla\langle\mathcal{E}(Q^*(0;a)), e_j\rangle_{\mathbb{R}^n};\ j = 1, \ldots, n\}\,.$$

The gradients in (4.6) also satisfy the adjoint equation of (4.4), again computed in X, which shows that

$$\frac{\mathrm{d}}{\mathrm{d}x}\langle\nabla\langle\mathcal{E}(Q^*(x;a)), e_j\rangle_{\mathbb{R}^n}, V(x)\rangle_X \equiv 0, \qquad j = 1, \ldots, n, \tag{4.7}$$

for each solution $V(x)$ of (4.4); this can also be verified directly by evaluating (4.7). We denote by $\ell_j^{\pm}(a)$ the smooth eigenvectors of $[f_u^T(u_{\pm}^{\varepsilon}) - c^{\varepsilon}]$ at $\varepsilon_*(a)$ associated with the eigenvalues $\nu_j^{\pm}$ and define

$$E_{\pm}^*(a) = \mathrm{span}\left\{\nabla\langle\mathcal{E}(Q^*(0;a)), \ell_j^{\pm}(a)\rangle_{\mathbb{R}^n};\ \nu_j^{\pm} \lessgtr 0\right\} \subset E^*(a). \tag{4.8}$$

Set $a = 0$, then $\dim E_+^*(0) = n - p$ and $\dim E_-^*(0) = p + 1$. Equations (4.3), (4.6), and (4.7) imply that $E_{\pm}^*(0) \perp_X E_{\pm}(0,0)$ and, in fact, that $E_{\pm}^*(0)$ are perpendicular to each solution of (4.4) at $a = 0$ that decays exponentially at $x = -\infty$ or $x = \infty$. Equation (4.5) implies then that $E_+^*(0) \cap E_-^*(0) = \mathrm{span}\{\Psi_0\}$, and therefore $\dim[E_+^*(0) + E_-^*(0)] = n$. Since $E_{\pm}^*(a) \subset E^*(a)$ for all a, and the latter space is n-dimensional for all a, we conclude that $E_+^*(a) + E_-^*(a) = E^*(a)$, and the dimensions of the sum and intersection of $E_{\pm}^*(a)$ cannot change for a close to zero. Hence, we can choose a nonzero basis vector $\Psi_0^*(0;a)$ in the one-dimensional intersection $E_+^*(a) \cap E_-^*(a)$ that depends smoothly on a as well as linearly independent smooth elements $\Psi_j^{\pm}(0;a) \in E_{\pm}^*(a)$, with $j = 1, \ldots, n-p-1$ for the $+$ sign and $j = 1, \ldots, p$ for the $-$ sign, so that $\Psi_j^{\pm}(0;a) \perp_X \Psi_0^*(0;a)$ for all j. Using (4.3), (4.6), and (4.8), we see that

$$\Psi_j^{\pm}(0;a) \perp_X E_{\pm}(0,a), \qquad \Psi_0^*(0;a) \perp_X [E_+(0,a) + E_-(0,a)] \tag{4.9}$$

for all a. Lastly, we define

$$\Psi_{1,2}^*(0;a) := [1 - P(a)]\Psi_{1,2}(0;a), \tag{4.10}$$

where $P(a)$ is the orthogonal projection in X onto $E_+^*(a) + E_-^*(a)$.

Having prepared the ground for the forthcoming analysis, we now return to the full eigenvalue problem (4.1)

$$V_x = [F_U(Q^*(x;a), \epsilon_*(a), \Omega_*(a)) + \lambda\mathcal{B}]V.$$

We seek solutions $V^{\pm}(x)$ on $\mathbb{R}^{\pm}$ of the form

$$V^{\pm}(x) = b_0 Q_x^*(x;a) + b_1 V_1(x) + b_2 \widetilde{Q}_\tau^*(x;a) + \widetilde{V}^{\pm}(x;\lambda,a)b \tag{4.11}$$

with $b = (b_0, b_1, b_2)$, $Q^* = Q^{\varepsilon} + a\widetilde{Q}^*$ as in (3.35), and

$$\widetilde{V}^{\pm}(0;\lambda,a)b \perp \mathrm{span}\{Q_x^*(0;a), V_1(0), \widetilde{Q}_\tau^*(0;a)\} \tag{4.12}$$

for all b, so that

$$V^+(0) - V^-(0) \in \mathrm{span}\{\Psi_j^*(0;a);\ j = 0, 1, 2\}, \tag{4.13}$$

$$\mathrm{dist}\left(\frac{1}{|V^{\pm}(x)|_X}V^{\pm}(x), E_{\pm}^{\infty}(\lambda,a)\right) \to 0 \text{ as } x \to \pm\infty. \tag{4.14}$$

Using exponential dichotomies as in section 3, we can then easily show that the system (4.1), (4.11)–(4.14) has unique solutions for each $b \in \mathbb{R}^3$ and (λ, a) near zero and that these solutions depend analytically on λ and smoothly on a. In particular, $E_+(\lambda, a) \cap E_-(\lambda, a) \neq \{0\}$ if and only if $\det \mathcal{D}(\lambda, a) = 0$ where

$$\mathcal{D}(\lambda, a): \quad \mathbb{R}^3 \longrightarrow \mathbb{R}^3, \quad b \longmapsto \mathcal{D}(\lambda, a)b = \big(\langle \Psi_j^*(0; a), V^+(0) - V^-(0)\rangle_X\big)_{j=0,1,2}.$$

We will now compute the Taylor expansion of $\mathcal{D}$ to solve $\det \mathcal{D}(\lambda, a) = 0$.

First, we set $a = 0$ so that $Q^* = Q^0$, $Q_x^0 =: V_0$, and $\widetilde{Q}_\tau^* = V_2$. A calculation similar to the derivation of (3.28) gives

$$\begin{aligned} \partial_\lambda \mathcal{D}(0,0) &= \left(\int_{\mathbb{R}} \langle \Psi_i^*(x; 0), \mathcal{B}V_j(x)\rangle_X \, \mathrm{d}x \right)_{i,j=0,1,2} \\ &= \operatorname{diag}\left(\int_{\mathbb{R}} \langle \Psi_j(x), \mathcal{B}V_j(x)\rangle_X \, \mathrm{d}x \right) \\ &= \operatorname{diag}(M_0, 1, 1), \end{aligned}$$

where we used the normalization (3.1). Our hypothesis that $\lambda = 0$ is a simple zero of the Evans function of the viscous shock at $\varepsilon = 0$ implies that $M_0 \neq 0$.

Next, we set $\lambda = 0$ and compute derivatives with respect to a. Since $\lambda = 0$, the eigenvalue problem reduces to the variational equation (4.4). In particular, both $\partial_x Q^*(x; a)$ and $\partial_\tau \widetilde{Q}^*(x; a)$ are solutions of (4.4) that satisfy (4.14), and we can set $b_0 = b_2 = 0$ as they make no contribution to $\mathcal{D}(0, a)$. We focus therefore on $V^\pm(x) = V_1(x) + \widetilde{V}^\pm(x; 0, a)$ for which (4.9) and (4.14) together imply

$$\langle \Psi_0^*(0; a), V^+(0) - V^-(0)\rangle_X = 0 \tag{4.15}$$

for all a. The equation for $\widetilde{V}$ is

$$\begin{aligned} \widetilde{V}_x &= F_U(Q^0(x), 0, 0)\widetilde{V} \\ &\quad + [F_U(Q^*(x; a), \varepsilon_*(a), \Omega_*(a)) - F_U(Q^0(x), 0, 0)](V_1(x) + \widetilde{V}) \end{aligned} \tag{4.16}$$

and, proceeding as before and using (3.35), we obtain

$$\begin{aligned} &\frac{\mathrm{d}}{\mathrm{d}a} \left\langle \Psi_j^*(0; a), \widetilde{V}^+(0; 0, a) - \widetilde{V}^-(0; 0, a) \right\rangle_X \Big|_{a=0} \\ &= \int_{\mathbb{R}} \left\langle \Psi_j(x), F_{UU}(Q^0(x), 0, 0)[V_1(x), V_1(x)] \right\rangle_X \, \mathrm{d}x \end{aligned}$$

for $j = 1, 2$. Inspecting (3.16) and (3.17), we see that the integrands vanish pointwise for each x. Summarizing the findings obtained so far, we have

$$\mathcal{D}(\lambda, a) = \begin{pmatrix} M_0\lambda & 0 & 0 \\ 0 & \lambda + \mathrm{O}(a^2) & 0 \\ 0 & \mathrm{O}(a^2) & \lambda \end{pmatrix} + \mathrm{O}(|\lambda|(|\lambda + |a|)).$$

Thus, it remains to compute the diagonal $\mathrm{O}(a^2)$ term. Expanding (4.16), we see that the second derivative with respect to a of this diagonal term is given by

$$\begin{aligned}\partial_a^2\mathcal{D}_{22}(0,0) &= \int_{-\infty}^{\infty}\langle\Psi_1(x), F_{UUU}(Q^0(x),0,0)[V_1(x)]^3\\ &\quad + 3F_{UU}(Q^0(x),0,0)[V_1(x),\partial_a\widetilde{V}(x;0,0)]\\ &\quad + \varepsilon_{aa}(0)D_\varepsilon(F_U(Q^\varepsilon(x),\varepsilon,0))|_{\varepsilon=0}V_1(x)\\ &\quad + \Omega_{aa}(0)\partial_\Omega F_U(Q^0(x),0,0)V_1\rangle_X\,\mathrm{d}x\\ &= \int_{-\infty}^{\infty}\langle\Psi_1(x), F_{UUU}(Q^0(x),0,0)[V_1(x)]^3\\ &\quad + 3F_{UU}(Q^0(x),0,0)[V_1(x),\partial_a\widetilde{V}(x;0,0)]\rangle_X\,\mathrm{d}x - \varepsilon_{aa}(0)\operatorname{Re}\lambda_\varepsilon(0),\end{aligned}$$

where the term involving Ω vanishes for the same reason that shows that the first component in (3.33) is zero. Comparing the integral term in the above expression with (3.38), we see that they coincide provided $\partial_a\widetilde{V}(x;0,0) = \partial_a\widetilde{W}(x;0,0,0)$. The following lemma, whose proof we postpone until after we finished the discussion of $\mathcal{D}(\lambda,a)$, states that this identity indeed holds.

LEMMA 4.2. *We have* $\partial_a\widetilde{V}(x;0,0) = \partial_a\widetilde{W}(x;0,0,0)$.

Thus, we can conclude that

$$\partial_a^2\mathcal{D}_{22}(0,0) = \kappa_3 - \varepsilon_{aa}(0)\operatorname{Re}\lambda_\varepsilon(0) \overset{(3.39)}{=} 2\varepsilon_{aa}(0)\operatorname{Re}\lambda_\varepsilon(0)$$

and consequently

$$\mathcal{D}(\lambda,a) = \begin{pmatrix} M_0\lambda & 0 & 0\\ 0 & \lambda+\varepsilon_{aa}(0)\operatorname{Re}\lambda_\varepsilon(0)a^2+\mathrm{O}(a^3) & 0\\ 0 & \mathrm{O}(a^2) & \lambda\end{pmatrix} + \mathrm{O}(|\lambda|(|\lambda+|a|)).$$

The equation $\det\mathcal{D}(\lambda,a) = 0$ has therefore precisely three solutions, counted with multiplicity, near zero which are given by $\lambda = 0$ with multiplicity two and a simple zero at

$$\lambda_*(a) = -\varepsilon_{aa}(0)\operatorname{Re}\lambda_\varepsilon(0)a^2 + \mathrm{O}(a^3),$$

so that $\lambda_*(a)$ and $\varepsilon_*(a)$ have opposite signs since we assumed that $\operatorname{Re}\lambda_\varepsilon(0) > 0$. Subject to establishing Lemma 4.2, this completes the proof of Theorem 2.2.

Proof of Lemma 4.2. Expanding the relevant equations for $\widetilde{V}$ and $\widetilde{W}$, we find that both $\partial_a\widetilde{V}^\pm(x;0,0)$ and $\partial_a\widetilde{W}^\pm(x;0,0,0)$ satisfy the linear inhomogeneous differential equation

$$V_x = F_U(Q^0(x),0,0)V + F_{UU}(Q^0(x),0,0)[V_1(x),V_1(x)].$$

The asymptotic boundary conditions in the hyperbolic directions coincide for both functions, but differ for the center directions. We shall show that the center components of $\partial_a\widetilde{V}^\pm(0;0,0)$ and $\partial_a\widetilde{W}^\pm(0;0,0,0)$ are equal to each other from which we can infer that the two solutions coincide as claimed.

We begin by discussing $\widetilde{V}^\pm(x;0,0)$. Equation (4.15) implies that the $\Psi_0^*(0;a)$ components of $\widetilde{V}^\pm(0;0,a)$ coincide for all a. Since $\Psi_j^\pm(0;a)$ is perpendicular to the space on the right-hand side of (4.12), we also have

$$\langle\Psi_j^\pm(0;a), \widetilde{V}^+(0;0,a) - \widetilde{V}^-(0;0,a)\rangle_X = 0$$

for all j and all a, and we conclude that the center components of $\widetilde{V}^{\pm}(0;0,a)$ coincide for all a. Since $V^{\pm}(0) \in E_{\pm}(0,a)$ for all a, (4.9) gives

$$\langle \Psi_j^{\pm}(0;a), V^{\pm}(0)\rangle_X = 0, \qquad \langle \Psi_0^{*}(0;a), V^{\pm}(0)\rangle_X = 0$$

for all a, and a Taylor expansion gives

$$\begin{aligned} &\langle \partial_a \Psi_j^{\pm}(0;0), V_1(0)\rangle_X + \langle \Psi_j^{\pm}(0;0), \partial_a \widetilde{V}^{\pm}(0;0,0)\rangle_X = 0 \qquad \text{for all } j,\\ &\langle \partial_a \Psi_0^{*}(0;0), V_1(0)\rangle_X + \langle \Psi_0^{*}(0;0), \partial_a \widetilde{V}^{\pm}(0;0,0)\rangle_X = 0. \end{aligned} \tag{4.17}$$

We now turn to $\partial_a \widetilde{W}^{\pm}(0;0,0,0)$. We set $(\varepsilon,\Omega)=0$ and consider the solution pieces

$$U^{\pm}(x) = Q^0(x) + a[V_1(x) + \widetilde{W}^{\pm}(x;a,0,0)]$$

from section 3. By construction, we have $U^{\pm}(x) \in \mathcal{W}^{\mathrm{u}}_{0,0}$, and the conserved quantity $\mathcal{E}(U^-(x))$ does, therefore, not depend on a. Its derivative with respect to a is given by

$$\begin{aligned} 0 &= \frac{\mathrm{d}}{\mathrm{d}a}\mathcal{E}(Q^0(0) + a[V_1(0) + \widetilde{W}^-(0;a,0,0)])\\ &= \langle \nabla\mathcal{E}(Q^0(0) + a[V_1(0) + \widetilde{W}^-(0;a,0,0)]), V_1(0) + \widetilde{W}(0;a,0,0)\rangle_X\\ &= \langle \nabla\mathcal{E}(Q^0(0) + a[V_1(0) + \mathrm{O}(a)]), V_1(0) + a\widetilde{W}_a^-(0;0,0,0) + \mathrm{O}(a^2)\rangle_X\\ &= a\left[\left\langle \frac{\mathrm{d}}{\mathrm{d}a}\nabla\mathcal{E}(Q^0(0) + aV_1(0))|_{a=0}, V_1(0)\right\rangle_X + \langle \nabla\mathcal{E}(Q^0(0)), \widetilde{W}_a^-(0;0,0,0)\rangle_X\right]\\ &\quad + \mathrm{O}(a^2). \end{aligned}$$

Thus, we get

$$\begin{aligned} &\langle \partial_a \Psi_j^{\pm}(0;0), V_1(0)\rangle_X + \langle \Psi_j^{\pm}(0;0), \widetilde{W}_a^-(0;0,0,0)\rangle_X = 0,\\ &\langle \partial_a \Psi_0^{*}(0;0), V_1(0)\rangle_X + \langle \Psi_0^{*}(0;0), \widetilde{W}_a^-(0;0,0,0)\rangle_X = 0. \end{aligned} \tag{4.18}$$

We can proceed as before to show continuity of $\widetilde{W}_a^{\pm}(0;0,0,0)$ in the center components. This fact, together with the continuity of $\widetilde{V}_a(0;0,0)$ in the center directions and (4.17) and (4.18), shows that the center components of $\partial_a \widetilde{V}^{\pm}(0;0,0)$ and $\partial_a \widetilde{W}^{\pm}(0;0,0,0)$ are indeed equal to each other as claimed. ∎

5. Discussion. There are numerous possible generalizations and extensions of our results. The crucial ingredient is the existence of the evolution operators $\Phi_{\pm}^{\mathrm{s,u}}$ for the spatial dynamical system, which requires some hyperbolicity in the spatial dynamics. The results are clearly not dependent on the particular form of the viscosity matrix: *nonlinear viscosity* $B(u)u_{xx}$ is allowed as long as the essential spectrum is nonresonant with the Hopf eigenvalue (uniform positivity is typically sufficient). We can also allow *parameter-dependent fluxes*: the parameter ε may appear explicitly in the viscosity matrix and the flux $f = f(u;\varepsilon)$.

Under- and overcompressive shocks can be treated similarly. All viscous shocks can be viewed as heteroclinic orbits in the travelling-wave ODE (3.5)

$$\begin{pmatrix} u_x \\ v_x \end{pmatrix} = \begin{pmatrix} v \\ f_u(u)v - cv \end{pmatrix} \tag{5.1}$$

which connect families of equilibria at $x = \pm\infty$. To set up the problem, we can, for instance, prescribe the values of u on ingoing characteristics. Choose manifolds $\mathcal{S}_\pm$ of $\mathbb{R}^n$ so that $T_{u^0_\pm}\mathcal{S}_\pm \oplus \mathcal{I}_\pm = \mathbb{R}^n$, where $\mathcal{I}_\pm$ is the eigenspace belonging to eigenvalues $\nu^\pm \lessgtr 0$ of $f_u(u^0_\pm) - c^0$. We then seek viscous shock waves in the intersection of $\mathcal{W}^{\mathrm{u}}(\mathcal{S}_-)$ and $\mathcal{W}^{\mathrm{s}}(\mathcal{S}_+)$, where we regard $\mathcal{S}_\pm$ as subsets of the manifold $\mathbb{R}^n \times \{0\} \subset Y_0$ of equilibria of (5.1). Both manifolds are n-dimensional, and we will assume that their intersection along the viscous shock is transverse in the parameter c; this is equivalent to the assumption that $\lambda = 0$ is a simple root of the Evans function associated with the PDE linearization at the shock [5, 8, 23]. One can now vary $\mathcal{S}_\pm = \mathcal{S}^\varepsilon_\pm$ and continue the transverse intersection provided the speed $c = c^\varepsilon$ is adjusted appropriately. If a pair of complex eigenvalues crosses the imaginary axis at $\varepsilon = 0$, the analysis in this paper can be adapted easily to show that there is a unique family of oscillatory under- or overcompressive shocks bifurcating from the primary viscous shock. As for Lax shocks, the bifurcating oscillatory shocks converge exponentially to time-independent rest states as $|x| \to \infty$ due to the presence of the n conservation laws (3.36). We remark that undercompressive shocks occur as weak denotations in combustion, which makes them interesting from an applied viewpoint.

The analysis extends also to the case of *degenerate shock waves*, where we allow for an additional center direction within the travelling-wave ODE in $\mathrm{Fix}\,\Gamma$ at either u^0_- or u^0_+. Again, suitable transversality conditions on the intersections of $\mathcal{W}^{\mathrm{u}}_-$ and $\mathcal{W}^{\mathrm{s}}_+$ together with appropriate assumptions on the nonlinear behavior of the zero characteristic speed near the shock are needed.

Problems posed in *infinite cylinders*,

$$u_t = \Delta u + \sum_j \partial_{x_j} f_j(u), \qquad x \in \mathbb{R} \times \Omega,$$

for bounded cross sections $\Omega \subset \mathbb{R}^N$ and with Neumann boundary conditions on $\mathbb{R}\times\partial\Omega$, say, can also be treated. The existence of exponential dichotomies for this problem follows from [11, 14].

The major open problem that we did not address in this paper is nonlinear stability of the bifurcating oscillatory viscous shocks. It should be possible to establish nonlinear stability using a combination of the approach via pointwise estimates developed by Howard and Zumbrun in [8, 23] and our spatial-dynamics technique which can be used to obtain the necessary estimates for the Green's function; this will be pursued elsewhere.
