NONLINEAR INSTABILITY OF A CRITICAL TRAVELING WAVE IN THE GENERALIZED KORTEWEG–DE VRIES EQUATION*

ANDREW COMECH†, SCIPIO CUCCAGNA‡, AND DMITRY E. PELINOVSKY§

Abstract. We prove the instability of a "critical" solitary wave of the generalized Korteweg–de Vries equation, the one with the speed at the border between the stability and instability regions. The instability mechanism involved is "purely nonlinear" in the sense that the linearization at a critical soliton does not have eigenvalues with positive real part. We prove that critical solitons correspond generally to the saddle-node bifurcation of two branches of solitons.

Key words. Korteweg–de Vries equation, critical soliton, dynamic instability, orbital stability

1. Introduction and main results.

We consider the generalized Korteweg–de Vries (KdV) equation in one dimension,

$$\partial_t \boldsymbol{u} = \partial_x \left(-\partial_x^2 \boldsymbol{u} + f(\boldsymbol{u})\right), \qquad \boldsymbol{u} = \boldsymbol{u}(x,t) \in \mathbb{R}, \quad x \in \mathbb{R}, \tag{1.1}$$

where $f \in C^\infty(\mathbb{R})$ is a real-valued function that satisfies

$$f(0) = f'(0) = 0. \tag{1.2}$$

Depending on the nonlinearity f, (1.1) may admit solitary wave solutions, or solitons, of the form $\boldsymbol{u}(x,t) = \boldsymbol{\phi}_c(x - ct)$. Generically, solitons exist for speeds c from (finite or infinite) intervals of a real line. For a particular nonlinearity f, solitons with certain speeds are (orbitally) stable with respect to the perturbations of the initial data, while others are linearly (and also dynamically) unstable. We will study the stability of the critical solitons, the ones with speeds c on the border of stability and instability regions. These solitons are no longer linearly unstable. Still, we will prove their instability, which is the consequence of the higher algebraic multiplicity of the zero eigenvalue of the linearized system.

When $f(\boldsymbol{u}) = -3\boldsymbol{u}^2$, (1.1) turns into the classical KdV equation

$$\partial_t \boldsymbol{u} + \partial_x^3 \boldsymbol{u} + 6\boldsymbol{u}\partial_x \boldsymbol{u} = 0, \tag{1.3}$$

which is well known to have solitons

$$\boldsymbol{u}_c(x,t) = \boldsymbol{\phi}_c(x - ct) = \frac{c}{2\cosh^2\left(\frac{\sqrt{c}}{2}(x - ct)\right)}, \qquad c > 0.$$

For $f(\boldsymbol{u}) = -\boldsymbol{u}^p$, $p > 1$, we obtain the family of generalized KdV equations (also known as gKdV-k with $k = p - 1$) that have the form

$$\partial_t \boldsymbol{u} + \partial_x^3 \boldsymbol{u} + \partial_x(\boldsymbol{u}^p) = 0. \tag{1.4}$$

They also have solitary wave solutions. All solitary waves of the classical KdV equation and of the subcritical generalized KdV equations ($1 < p < 5$) are orbitally stable; see [Ben72, Bon75, Wei87, ABH87]. Orbital stability is defined in the following sense.

DEFINITION 1.1. *The traveling wave $\boldsymbol{\phi}_c(x - ct)$ is said to be orbitally stable if for any $\epsilon > 0$ there exists $\delta > 0$ so that for any $\boldsymbol{u}_0$ with $\|\boldsymbol{u}_0 - \boldsymbol{\phi}_c\|_{H^1} \le \delta$ there is a solution $\boldsymbol{u}(t)$ with $\boldsymbol{u}(0) = \boldsymbol{u}_0$, defined for all $t \ge 0$, such that*

$$\sup_{t\ge 0} \inf_{s\in\mathbb{R}} \|\boldsymbol{u}(x,t) - \boldsymbol{\phi}(x - s)\|_{H^1} < \epsilon,$$

where $H^1 = H^1(\mathbb{R})$ is the standard Sobolev space. Otherwise the traveling wave is said to be unstable.

Equation (1.1) is a Hamiltonian system, with the Hamiltonian functional

$$E(\boldsymbol{u}) = \int_{\mathbb{R}} \left(\frac{1}{2}(\partial_x \boldsymbol{u})^2 + F(\boldsymbol{u}) \right) dx, \tag{1.5}$$

with $F(\boldsymbol{u})$ the antiderivative of $f(\boldsymbol{u})$ such that $F(0) = 0$. There are two more invariants of motion: the mass

$$I(\boldsymbol{u}) = \int_{\mathbb{R}} \boldsymbol{u}\, dx \tag{1.6}$$

and the momentum

$$\mathscr{N}(\boldsymbol{u}) = \int_{\mathbb{R}} \frac{1}{2}\boldsymbol{u}^2\, dx. \tag{1.7}$$

Assumption 1. There is an open set $\Sigma \subset \mathbb{R}_+$ so that for $c \in \Sigma$ the equation $-c\boldsymbol{\phi}_c = -\boldsymbol{\phi}_c'' + f(\boldsymbol{\phi}_c)$ has a unique solution $\boldsymbol{\phi}_c(x) \in H^\infty(\mathbb{R})$ such that $\boldsymbol{\phi}_c(x) > 0$, $\boldsymbol{\phi}_c(-x) = \boldsymbol{\phi}_c(x)$, $\lim_{|x|\to\infty} \boldsymbol{\phi}_c(x) = 0$. The map $c \mapsto \boldsymbol{\phi}_c \in H^s(\mathbb{R})$ is C^∞ for $c \in \Sigma$ and for any s. Consequently, (1.1) admits traveling wave solutions

$$\boldsymbol{u}(x,t) = \boldsymbol{\phi}_c(x - ct), \qquad c \in \Sigma. \tag{1.8}$$

In Appendix A we specify conditions under which Assumption 1 is satisfied.

Let $\mathscr{N}_c$ and I_c denote $\mathscr{N}(\boldsymbol{\phi}_c)$ and $I(\boldsymbol{\phi}_c)$, respectively. By Assumption 1, $\mathscr{N}_c$ and I_c are C^∞ functions of $c \in \Sigma$. For the general KdV equation (1.1) with smooth $f(\boldsymbol{u})$, Bona, Souganidis, and Strauss [BSS87] show that the traveling wave $\boldsymbol{\phi}_c(x - ct)$ is orbitally stable if

$$\mathscr{N}_c' = \frac{d}{dc}\mathscr{N}_c = \frac{d}{dc}\mathscr{N}(\boldsymbol{\phi}_c) > 0 \tag{1.9}$$

and unstable if instead $\mathscr{N}_c' < 0$. See Figure 1. The criterion (1.9) coincides with the stability condition obtained in [GSS87] in the context of abstract Hamiltonian systems with $\mathbf{U}(1)$ symmetry (the theory developed there does not apply to the generalized KdV equation).

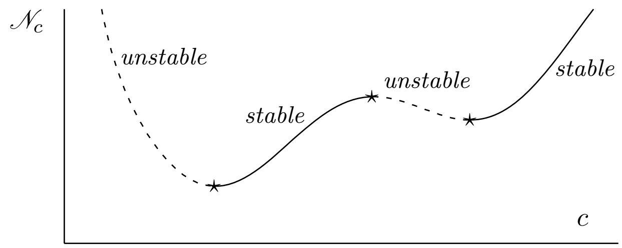

FIG. 1. *Stable and unstable regions on a possible graph of $\mathscr{N}_c$ vs. c. Three critical solitary waves are denoted by stars.*

Remark 1.2. Note that, as one can readily show, the amplitude of solitary waves is monotonically increasing with their speed c, while the momentum $\mathscr{N}_c$ does not have to.

Remark 1.3. For the generalized KdV equations (1.4), the soliton profiles satisfy the scaling relation $\boldsymbol{\phi}_c(x) = c^{\frac{1}{p-1}}\boldsymbol{\phi}_1(c^{\frac{1}{2}}x)$. The values of the momentum functional that correspond to solitons with different speeds c are given by $\mathscr{N}(\boldsymbol{\phi}_c) = \text{const}\, c^{\frac{2}{p-1}-\frac{1}{2}} = \text{const}\, c^{\frac{5-p}{2(p-1)}}$, so that $\frac{d}{dc}\mathscr{N}(\boldsymbol{\phi}_c) > 0$ for $p < 5$, in agreement with the stability criterion (1.9) derived in [BSS87].

In [BSS87] it is stated that critical traveling waves $\boldsymbol{\phi}_{c_\star}(x)$, that is, $c_\star$ such that $\mathscr{N}'_{c_\star} = 0$, are unstable as a consequence of the claim that the set $\{c\colon \boldsymbol{\phi}_c \text{ is stable}\}$ is open. This claim, however, is left unproved in [BSS87]. Moreover, this is not true in general. (This is demonstrated by the dynamical system in $\mathbb{R}^2$ described in the polar coordinates by $\dot\theta = \sin\theta$, $\dot r = 0$. The set of stationary states is the line $y = 0$; the subset of stable stationary points, $x \le 0$, is closed.) The question of stability of critical traveling waves has been left open. We address this question in this paper, proving the instability under certain rather generic assumptions. This result is the analogue of [CP03] for the generalized KdV equation (1.1).

Remark 1.4. We will not consider the L^2-critical KdV equation given by (1.4) with $p = 5$, when $\mathscr{N}_c = \text{const}$. In this case, the solitons are not only unstable but also exhibit a blow-up behavior. This blow-up is considered in a series of papers by Martel and Merle [Mer01, MM01b, MM02a, MM02b].

The analysis of the instability of critical solitary waves (with no linear instability) requires better control of the growth of a particular perturbation. We achieve this by employing the asymptotic stability methods. Pego and Weinstein [PW94] proved that the traveling wave solutions to (1.4) for the subcritical values $p = 2, 3, 4$, and also $p \in (2,5)\backslash E$ with E a finite and possibly empty set, are asymptotically stable in the weighted spaces. Their approach was extended in [Miz01]. For other deep results of stability see [MM01a, MM05]. The proofs extend, under certain spectral hypotheses, to solitary solutions to a generalized KdV equation (1.1) with c such that $\mathscr{N}'_c > 0$.

Substituting $\boldsymbol{u}(x,t) = \boldsymbol{\phi}_c(x-ct) + \boldsymbol{\rho}(x-ct,t)$ into (1.1) and discarding terms nonlinear in $\boldsymbol{\rho}$, we get the linearization at $\boldsymbol{\phi}_c$:

$$\partial_t \boldsymbol{\rho} = \partial_x\big(-\partial_x^2\boldsymbol{\rho} + f'(\boldsymbol{\phi}_c)\boldsymbol{\rho} + c\boldsymbol{\rho}\big) \equiv J\mathcal{H}_c\boldsymbol{\rho}, \tag{1.10}$$

where

$$J = \partial_x, \qquad \mathcal{H}_c = -\partial_x^2 + f'(\boldsymbol{\phi}_c) + c. \tag{1.11}$$

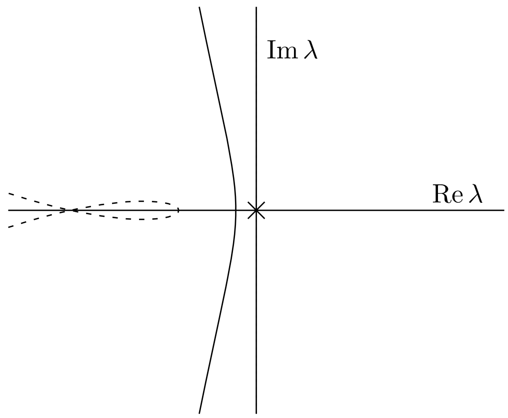

FIG. 2. *Essential spectrum of $J\mathcal{H}_c$, $c = 1$, in the exponentially weighted space $L^2_\mu(\mathbb{R})$ for $\mu = 0.1 < \sqrt{c/3}$ (solid line) and $\mu = 0.65 > \sqrt{c/3}$ (dashed line).*

In (1.10), both $\boldsymbol{\phi}_c(\cdot)$ and $\boldsymbol{\rho}(\cdot, t)$ are evaluated at $x - ct$, but we change the variable and write x instead.

The essential spectrum of $J\mathcal{H}_c$ in $L^2(\mathbb{R})$ coincides with the imaginary axis. $\lambda = 0$ is an eigenvalue (with $\partial_x \boldsymbol{\phi}_c$ being the corresponding eigenvector). To use the asymptotic stability methods from [PW94], we will consider the action of $J\mathcal{H}_c$ in the exponentially weighted spaces. For $s \in \mathbb{R}$ and $\mu \geq 0$, we define

$$H^s_\mu(\mathbb{R}) = \{\boldsymbol{\psi} \in H^s_{loc}(\mathbb{R})\colon\, e^{\mu x}\boldsymbol{\psi}(x) \in H^s(\mathbb{R})\}\,, \qquad \mu \geq 0, \tag{1.12}$$

where $H^s(\mathbb{R})$ is the standard Sobolev space of order s. We also denote $L^2_\mu(\mathbb{R}) = H^0_\mu(\mathbb{R})$. We define the operator $A^\mu_c = e^{\mu x} \circ J\mathcal{H}_c \circ e^{-\mu x}$, where $e^{\pm \mu x}$ are understood as the operators of multiplication by the corresponding functions, so that the action of $J\mathcal{H}_c$ in $L^2_\mu(\mathbb{R})$ corresponds to the action of A^μ_c in $L^2(\mathbb{R})$. The explicit form of A^μ_c is

$$A^\mu_c = e^{\mu x} \circ J\mathcal{H}_c \circ e^{-\mu x} = (\partial_x - \mu)\big[-(\partial_x - \mu)^2 + c - f'(\boldsymbol{\phi}_c)\big]. \tag{1.13}$$

The domain of A^μ_c is given by $D(A^\mu_c) = H^3(\mathbb{R})$. Since the operator $[\partial_x - \mu] f'(\boldsymbol{\phi}_c)$ is relatively compact with respect to $\mathscr{A}^\mu_c = -(\partial_x - \mu)^3 + c(\partial_x - \mu)$, the essential spectrum of A^μ_c coincides with that of $\mathscr{A}^\mu_c$ and thus is given by

$$\sigma_{\mathrm{e}}(A^\mu_c) = \big\{\lambda \in \mathbb{C}\colon\, \lambda = \lambda_{\mathrm{cont}}(k) = (\mu - ik)^3 - c(\mu - ik), \quad k \in \mathbb{R}\big\}\,. \tag{1.14}$$

The essential spectrum of $\mathscr{A}^\mu_c$ is located in the left half-plane for $0 < \mu < \sqrt{c}$ and is simply connected for $0 < \mu < \sqrt{c/3}$; see Figure 2.

We need assumptions about the existence and properties of a critical wave.

Assumption 2. There exists $c_\star \in \Sigma \backslash \partial\Sigma$, $c_\star > 0$, such that $\mathscr{N}'_{c_\star} = 0$.

Remark 1.5. Let us give examples of the nonlinearities that lead to the existence of critical solitary waves. Take $f_-(z) = -Az^p + Bz^q$, with $2 < p < q$, $A > 0$, $B > 0$, or $f_+(z) = Az^p - Bz^q + Cz^r$, with $2 < p < q < r$, $A > 0$, $B > 0$, $C > 0$. In the case of f_+, we require that B be sufficiently large so that $f_+(z)$ takes negative values on a nonempty interval $I \subset \mathbb{R}_+$. Then there will be traveling wave solutions $\boldsymbol{\phi}_c(x - ct)$ with $c \in (0, c_1)$ (also with $c = 0$ in the case of f_+) for some $c_1 > 0$.[1] Elementary

[1] The value of c_1 is determined from the system $f(z_1) + c_1 z_1 = 0$, $F(z_1) + c_1 z_1^2/2 = 0$, with F the primitive of f such that $F(0) = 0$. See Appendix A or [BL83] for more details.

computations show that the value of the momentum $\mathscr{N}_c$ goes to infinity as $c \nearrow c_1$. It also goes to infinity as $c \searrow 0$ if $p > 5$ (also if $p = 5$ in the case of f_+), so that there is a global minimum of $\mathscr{N}_c$ at some point $c_\star \in (0, c_1)$.

Assumption 3. There exists $\mu_0 \in (0, \sqrt{c_\star}/2)$ such that for $0 \le \mu \le \mu_0$ the operator $A^\mu_{c_\star}$ has no L^2-eigenvalues except $\lambda = 0$.

Remark 1.6. We require that $\mu \le \sqrt{c_\star}/2$ so that the inequality $\mu < \sqrt{c/3}$ (needed in the condition of Lemma 4.2) is satisfied for c from an open neighborhood of $c_\star$.

Assumption 4. At the critical value $c_\star$, the nondegeneracy condition $I'_{c_\star} \ne 0$ is satisfied. Here $I_c = I(\boldsymbol{\phi}_c)$ is the value of the mass functional (1.6) on the traveling wave $\boldsymbol{\phi}_c$.

Remark 1.7. If $I'_{c_\star} = 0$, then the eigenvalue $\lambda = 0$ of $J\mathcal{H}_{c_\star}$ corresponds to a Jordan block larger than 3×3. We will not consider this situation.

Our main result is that the critical traveling wave $\boldsymbol{\phi}_{c_\star}(x)$ of the generalized KdV equation (1.1) is (nonlinearly) unstable.

THEOREM 1 (main theorem). *Let Assumptions* 1, 2, 3, *and* 4 *be satisfied, and assume that $\boldsymbol{\phi}_{c_\star}$ is a critical soliton. Assume that there exists an open neighborhood $\mathcal{O}(c_\star) \subset \Sigma$ of $c_\star$ so that $\mathscr{N}'_c$ is strictly negative and nonincreasing for $c \in \mathcal{O}(c_\star)$, $c > c_\star$ (or strictly negative and nondecreasing for $c < c_\star$, or both). Then the critical traveling wave $\boldsymbol{\phi}_{c_\star}(x)$ is orbitally unstable. More precisely, there exists $\epsilon > 0$ such that for any $\delta > 0$ there exists $\boldsymbol{u}_0 \in H^1(\mathbb{R})$ with $\|\boldsymbol{u}_0 - \boldsymbol{\phi}_{c_\star}\|_{H^1} < \delta$ and $t > 0$ so that*

$$\inf_{s\in\mathbb{R}} \|\boldsymbol{u}(\cdot, t) - \boldsymbol{\phi}_{c_\star}(\cdot - s)\|_{H^1} = \epsilon. \tag{1.15}$$

Remark 1.8. For definiteness, we consider the case when $\mathscr{N}'_c$ is strictly negative and nonincreasing for $c > c_\star$, $c \in \mathcal{O}(c_\star)$. The proof for the case when $\mathscr{N}'_c$ is strictly negative and nondecreasing for $c < c_\star$, $c \in \mathcal{O}(c_\star)$, is the same.

Thus, we assume that there exists $\eta_1 > 0$ such that

$$[c_\star, c_\star + \eta_1] \subset \Sigma, \qquad \mathscr{N}'_c < 0 \quad \text{for } c \in (c_\star, c_\star + \eta_1] \subset \Sigma. \tag{1.16}$$

Strategy of the proof and the structure of the paper. In our proof, we develop the method of Pego and Weinstein [PW94] and derive the nonlinear bounds relating the energy estimate and the dissipative estimate. We follow a center manifold approach; that is, we reduce the infinite-dimensional Hamiltonian system to a finite-dimensional system which contains the main features of the dynamics. Specifically, we consider the spectral decomposition near the zero eigenvalue in section 2, and a center manifold reduction is considered in section 3, this part being similar to the approach in [CP03]. Estimates in the energy space and in the weighted space for the error terms are in sections 4 and 5. In this part of our argument we develop the approach of [PW94]. In section 6, we complete the proof of Theorem 1. In section 7, we give an alternative approach to the instability of the critical traveling wave $\boldsymbol{\phi}_{c_\star}(x)$ by a normal form argument [Car81, IA98], under the additional hypothesis that the critical point $c_\star$ of $\mathscr{N}_c$ is nondegenerate:

$$\mathscr{N}''_{c_\star} = \frac{d^2\,\mathscr{N}(\boldsymbol{\phi}_c)}{dc^2}\Big|_{c=c_\star} \ne 0. \tag{1.17}$$

The construction of traveling waves is considered in Appendix A. The details on the Fredholm alternative for $\mathcal{H}_c$ are in Appendix B. An auxiliary technical result is proved in Appendix C.

2. Spectral decomposition in $L^2_\mu(\mathbb{R})$ near $\lambda = 0$. First, we observe that for any $c \in \Sigma$ (see Assumption 1), the linearization operator $J\mathcal{H}_c$ given by (1.11) satisfies the following relations:

$$\mathcal{H}_c \boldsymbol{e}_{1,c} = 0, \qquad \text{where } \boldsymbol{e}_{1,c} = -\partial_x \boldsymbol{\phi}_c(x), \tag{2.1}$$

$$J\mathcal{H}_c \boldsymbol{e}_{2,c} = \boldsymbol{e}_{1,c}, \qquad \text{where } \boldsymbol{e}_{2,c} = \partial_c \boldsymbol{\phi}_c(x). \tag{2.2}$$

Let $\mathscr{S}(\mathbb{R})$ denote the Schwarz space of functions.

Definition 2.1. *Let $\chi_+ \in C^\infty(\mathbb{R})$ be such that $0 \le \chi_+ \le 1$, $\chi_+|_{(-\infty,-1]} = 0$, $\chi_+|_{[0,\infty)} \equiv 1$. Define $\mathscr{S}_{+,m}(\mathbb{R})$, $m \ge 0$, to be the set of functions $u \in C^\infty(\mathbb{R})$ such that $\chi_+ u \in \mathscr{S}(\mathbb{R})$ and for any $N \in \mathbb{Z}$, $N \ge 0$, there exists $C_N > 0$ such that*

$$|u^{(N)}(x)| \le C_N (1 + |x|)^m.$$

Note that for any $m \ge 0$, $\mathrm{Image}(J\mathcal{H}_c|_{\mathbb{S}_{+,m}(\mathbb{R})}) \subset \mathscr{S}_{+,m}(\mathbb{R})$. The algebraic multiplicity of zero eigenvalue of the operator $J\mathcal{H}_c$ considered in $\mathscr{S}_{+,m}(\mathbb{R})$ depends on the values of $\mathscr{N}_c'$ and I_c' as follows.

Proposition 2.2. *Fix $m \ge 0$, and consider the operator $J\mathcal{H}_c$ in $\mathscr{S}_{+,m}(\mathbb{R})$.*

(i) *The eigenvalue $\lambda = 0$ is of geometric multiplicity one, with the kernel generated by $\boldsymbol{e}_{1,c}$.*
(ii) *Assume that $c \in \Sigma$ is such that $\mathscr{N}_c' \ne 0$. Then the eigenvalue $\lambda = 0$ is of algebraic multiplicity two.*
(iii) *Assume that $c_\star \in \Sigma$ is such that $\mathscr{N}_{c_\star}' = 0$, $I_{c_\star}' \ne 0$. Then the eigenvalue $\lambda = 0$ is of algebraic multiplicity three.*

Proof. First of all we claim that in $\mathscr{S}_{+,m}(\mathbb{R})$ we have $\dim\ker J\mathcal{H}_c = 1$.

The differential equation $\mathcal{H}_c \boldsymbol{\psi} = 0$ has two linearly independent solutions. According to (2.1), one of them is $\boldsymbol{e}_{1,c}$, which is odd and exponentially decaying at infinity. The other solution is even and exponentially growing as $|x| \to \infty$ and hence does not belong to $\mathscr{S}_{+,m}(\mathbb{R})$; we denote this solution by $\boldsymbol{\Xi}_c(x)$.

Observe that if $\boldsymbol{v} \in \ker J\mathcal{H}_c$, then $\mathcal{H}_c \boldsymbol{v} = K$, $\boldsymbol{v} \in C^\infty(\mathbb{R})$. Set $\boldsymbol{v} = \frac{K}{c} + \boldsymbol{w}$. Then $\mathcal{H}_c \boldsymbol{w} = -\frac{K}{c} f'(\boldsymbol{\phi}_c)$. Since $\langle f'(\boldsymbol{\phi}_c), \boldsymbol{e}_{1,c} \rangle = 0$, by Lemma B.1 there exists a function $\boldsymbol{w}_0 \in \mathscr{S}_{+,m}(\mathbb{R})$ such that $\mathcal{H}_c \boldsymbol{w}_0 = -\frac{K}{c} f'(\boldsymbol{\phi}_c)$. So $\boldsymbol{w} = \boldsymbol{w}_0 + A\partial_x \boldsymbol{\phi}_c + B\boldsymbol{\Xi}_c$, with A and B constants. Since

$$\boldsymbol{v} = \frac{K}{c} + \boldsymbol{w} = \frac{K}{c} + \boldsymbol{w}_0 + A\partial_x \boldsymbol{\phi}_c + B\boldsymbol{\Xi}_c \in \mathscr{S}_{+,m}(\mathbb{R}),$$

we need $\boldsymbol{v}(x) \to 0$ for $x \to +\infty$, and therefore $B = 0$ and $K = 0$. Hence, $\boldsymbol{v} \in \ker \mathcal{H}_c$, proving that $\ker J\mathcal{H}_c = \ker \mathcal{H}_c$. This proves Proposition 2.2 (i).

Let us introduce the function

$$\boldsymbol{\Theta}_c(x) = \int_{+\infty}^{x} \partial_c \boldsymbol{\phi}_c(y)\, dy. \tag{2.3}$$

Then $\partial_x \boldsymbol{\Theta}_c(x) = \partial_c \boldsymbol{\phi}_c(x)$, $\lim_{x\to-\infty} \boldsymbol{\Theta}_c(x) = -I_c'$; hence $\Theta_c \in \mathscr{S}_{+,0}(\mathbb{R})$. If $\boldsymbol{v}$ satisfies

$$J\mathcal{H}_c \boldsymbol{v} = \partial_c \boldsymbol{\phi}_c(x), \qquad \lim_{x\to+\infty} \boldsymbol{v}(x) = 0, \tag{2.4}$$

then $\boldsymbol{v}(x)$ is the only solution to the problem

$$\mathcal{H}_c \boldsymbol{v} = \boldsymbol{\Theta}_c(x), \qquad \lim_{x\to+\infty} \boldsymbol{v}(x) = 0. \tag{2.5}$$

According to Lemma B.1 (see Appendix B), if $\langle \boldsymbol{e}_{1,c}, \boldsymbol{\Theta}_c\rangle = \langle \boldsymbol{\phi}_c, \partial_c \boldsymbol{\phi}_c\rangle = \mathscr{N}_c' \ne 0$, then $\boldsymbol{v}(x)$ has exponential growth as $x \to -\infty$,

$$\boldsymbol{v}(x) \propto e^{\sqrt{c}|x|}, \qquad x \to -\infty, \tag{2.6}$$

and therefore does not belong to $\mathscr{S}_{+,m}(\mathbb{R})$. This finishes the proof of Proposition 2.2 (ii).

Let us now assume that $\mathscr{N}_{c_\star}' = 0$ for some $c_\star \in \Sigma$. Then, again by Lemma B.1 with $m = 0$, there exists $\boldsymbol{e}_{3,c_\star}(x) \in \mathscr{S}_{+,0}(\mathbb{R})$ such that

$$\mathcal{H}_{c_\star} \boldsymbol{e}_{3,c_\star} = \boldsymbol{\Theta}_{c_\star}(x), \qquad \lim_{x\to+\infty} \boldsymbol{e}_{3,c_\star}(x) = 0. \tag{2.7}$$

Now let us consider $\boldsymbol{w} \in C^\infty(\mathbb{R})$ such that

$$J\mathcal{H}_{c_\star} \boldsymbol{w} = \boldsymbol{e}_{3,c_\star}, \qquad \lim_{x\to+\infty} \boldsymbol{w}(x) = 0. \tag{2.8}$$

Let $\boldsymbol{E}(x) = \int_{+\infty}^x \boldsymbol{e}_{3,c_\star}(y)\,dy$; the function $\boldsymbol{w}(x)$ satisfies $\mathcal{H}_{c_\star}\boldsymbol{w} = \boldsymbol{E}$. Taking the pairing of $\boldsymbol{E}$ with $\boldsymbol{e}_{1,c_\star}$, we get

$$\begin{aligned} \langle \boldsymbol{e}_{1,c_\star}, \boldsymbol{E}\rangle &= -\langle \boldsymbol{\phi}_{c_\star}, \boldsymbol{e}_{3,c_\star}\rangle = \langle \mathcal{H}_{c_\star}\partial_c\boldsymbol{\phi}_{c_\star}, \boldsymbol{e}_{3,c_\star}\rangle = \langle \partial_c\boldsymbol{\phi}_{c_\star}, \mathcal{H}_{c_\star}\boldsymbol{e}_{3,c_\star}\rangle \\ &= \langle \partial_x \boldsymbol{\Theta}_{c_\star}, \boldsymbol{\Theta}_{c_\star}\rangle = \frac{\boldsymbol{\Theta}_{c_\star}^2}{2}\bigg|_{-\infty}^{+\infty} = -\lim_{x\to-\infty}\frac{\boldsymbol{\Theta}_{c_\star}^2(x)}{2} = -\frac{(I_{c_\star}')^2}{2} < 0. \end{aligned} \tag{2.9}$$

(In the first equality, the boundary term does not appear because when $x \to \pm\infty$ the function $\boldsymbol{E}(x)$ grows at most algebraically while $\boldsymbol{\phi}_c$ decays exponentially.) By Lemma B.1, since $\langle \boldsymbol{e}_{1,c_\star}, \boldsymbol{E}\rangle$ is nonzero, $\boldsymbol{w}(x)$ grows exponentially as $x \to -\infty$. This proves that the algebraic multiplicity of the eigenvalue $\lambda = 0$ is exactly three. ◻

Now we would like to consider $J\mathcal{H}_c$ in the weighted space $L^2_\mu(\mathbb{R})$, $\mu > 0$. This is equivalent to considering $A_c^\mu = e^{\mu x} \circ J\mathcal{H}_c \circ e^{-\mu x}$ in $L^2(\mathbb{R})$. In what follows, we always require that

$$0 < \mu < \min(\mu_0, \mu_1), \tag{2.10}$$

with μ_0 from Assumption 3 and μ_1 from Lemma C.1.

We define

$$\boldsymbol{e}_{j,c}^\mu = e^{\mu x}\boldsymbol{e}_{j,c}, \quad j = 1, 2; \qquad \boldsymbol{e}_{3,c_\star}^\mu = e^{\mu x}\boldsymbol{e}_{3,c_\star}. \tag{2.11}$$

From Proposition 2.2, we obtain the following statement.

Corollary 2.3.

(i) *If $\mathscr{N}_c' \ne 0$, then the basis for the generalized kernel of A_c^μ in $L^2(\mathbb{R})$ is formed by the generalized eigenvectors $\{\boldsymbol{e}_{1,c}^\mu, \boldsymbol{e}_{2,c}^\mu\}$.*

(ii) *At $c_\star$ where $\mathscr{N}_{c_\star}' = 0$, $I_{c_\star}' \ne 0$, the basis for the generalized kernel of $A_{c_\star}^\mu$ in $L^2(\mathbb{R})$ is formed by the generalized eigenvectors $\{\boldsymbol{e}_{1,c_\star}^\mu, \boldsymbol{e}_{2,c_\star}^\mu, \boldsymbol{e}_{3,c_\star}^\mu\}$.*

Proof. As follows from Lemma A.1 in Appendix A,

$$|\boldsymbol{e}_{1,c}(x)| \le \mathrm{const}\, e^{-\sqrt{c}|x|}, \qquad x \in \mathbb{R}. \tag{2.12}$$

Applying Lemma A.2 to (2.2) (for both $x \ge 0$ and $x \le 0$), we also see that

$$|\boldsymbol{e}_{2,c}(x)| \le \mathrm{const}(1 + |x|)e^{-\sqrt{c}|x|}, \qquad x \in \mathbb{R}. \tag{2.13}$$

It follows that $\boldsymbol{e}^\mu_{1,c}$, $\boldsymbol{e}^\mu_{2,c} \in L^2(\mathbb{R})$.

If $\mathscr{N}_c' \neq 0$, then by (2.6) $e^{\mu x}\boldsymbol{v}(x) \neq L^2(\mathbb{R})$.

If $\mathscr{N}_c' = 0$ at $c = c_\star$, then $\boldsymbol{e}_{3,c_\star} \in \mathscr{S}_{+,0}(\mathbb{R})$ (belongs to $\mathscr{S}$ for $x \geq 0$ and remains bounded for $x \leq 0$). Moreover, applying Lemma A.2 to (2.7), we see that

$$|\boldsymbol{e}_{3,c_\star}(x)| \leq \mathrm{const}(1+|x|)e^{-\sqrt{c_\star}\,x}, \qquad x \geq 0. \tag{2.14}$$

It follows that $\boldsymbol{e}^\mu_{3,c_\star} \in L^2(\mathbb{R})$. As follows from Proposition 2.2, the function $e^{\mu x}\boldsymbol{w}(x)$ in (2.8) does not belong to $L^2(\mathbb{R})$, so the algebraic multiplicity of $\lambda = 0$ is precisely three. ◻

Lemma 2.4.

(i) *Let $c \in (c_\star, c_\star + \eta_1]$. Then there exists a simple positive eigenvalue λ_c of A^μ_c. This eigenvalue does not depend on μ.*

(ii) *λ_c is a simple eigenvalue of the operator $J\mathcal{H}_c$ considered in $L^2(\mathbb{R})$.*

(iii) *There exists a C^∞ extension of $\boldsymbol{e}_{3,c_\star}$ into an interval $[c_\star, c_\star + \eta_1]$,*

$$c \mapsto \boldsymbol{e}_{3,c} \in H^\infty_\mu(\mathbb{R}), \qquad c \in [c_\star, c_\star + \eta_1],$$

so that the frame

$$\{\boldsymbol{e}^\mu_{j,c} = e^{\mu x}\boldsymbol{e}_{j,c} \in H^\infty(\mathbb{R})\colon j = 1,2,3\}, \qquad c \in [c_\star, c_\star + \eta_1],$$

depends smoothly on c (in L^2), $X^\mu_c = \mathrm{span}\langle \boldsymbol{e}^\mu_{1,c}, \boldsymbol{e}^\mu_{2,c}, \boldsymbol{e}^\mu_{3,c}\rangle$ is the invariant subspace of A^μ_c, and $A^\mu_c|_{X^\mu_c}$ is represented in the frame $\{\boldsymbol{e}^\mu_{j,c}\}$ by the following matrix:

$$A^\mu_c|_{X^\mu_c} = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & \lambda_c \end{bmatrix}, \tag{2.15}$$

where λ_c equals

$$\lambda_c = -\frac{\mathscr{N}_c'}{\langle \boldsymbol{\phi}_c, \boldsymbol{e}_{3,c}\rangle}, \tag{2.16}$$

with $\langle \boldsymbol{\phi}_c, \boldsymbol{e}_{3,c}\rangle > 0$ for $c \in [c_\star, c_\star + \eta_1]$.

Proof. Due to the restriction (2.10) on μ, the essential spectrum of A^μ_c for $c \geq c_\star$ is given by (1.14) and is located strictly to the left of the imaginary axis. By Assumption 3, the discrete spectrum of $A^\mu_{c_\star}$ consists of the isolated eigenvalue $\lambda = 0$, which is of algebraic multiplicity three by Corollary 2.3. We choose a closed contour $\gamma \subset \rho(A^\mu_{c_\star})$ in $\mathbb{C}^1$ so that the interval $[0, \Lambda]$ of the real axis is strictly inside γ, where

$$\Lambda = \sup_{c \in \Sigma} \sup_{x \in \mathbb{R}} |f''(\boldsymbol{\phi}_c(x))\boldsymbol{\phi}_c'(x)|. \tag{2.17}$$

Remark 2.5. The value of Λ is chosen so that all point eigenvalues of the operator $J\mathcal{H}_c$, $c \in \Sigma$, are bounded by Λ. Indeed, if $\boldsymbol{\psi}$ satisfies $J\mathcal{H}_c\boldsymbol{\psi} = \lambda\boldsymbol{\psi}$ with $\lambda \in \mathbb{R}$, then $\boldsymbol{\psi} \in H^\infty(\mathbb{R})$ and can be assumed to be real-valued. Therefore, we have

$$\begin{aligned}\lambda\langle \boldsymbol{\psi}, \boldsymbol{\psi}\rangle &= \langle \boldsymbol{\psi}, \partial_x(-\partial_x^2 + f'(\boldsymbol{\phi}_c) + c)\boldsymbol{\psi}\rangle \\ &= -\langle \boldsymbol{\psi}', f'(\boldsymbol{\phi}_c)\boldsymbol{\psi}\rangle = -\langle \boldsymbol{\psi}\boldsymbol{\psi}', f'(\boldsymbol{\phi}_c)\rangle = \frac{1}{2}\int_{\mathbb{R}} \boldsymbol{\psi}^2 \partial_x f'(\boldsymbol{\phi}_c)\,dx,\end{aligned}$$

so that $|\lambda| \le \sup_{x\in\mathbb{R}} |f''(\boldsymbol{\phi}_c(x))\boldsymbol{\phi}_c'(x)|/2$.

We notice that for c from an open neighborhood of $c_\star$, γ belongs to the resolvent set $\rho(A_c^\mu)$. Indeed, we have

$$\frac{1}{A_c^\mu - z} = \frac{1}{A_{c_\star}^\mu - z + (A_c^\mu - A_{c_\star}^\mu)} = \frac{1}{(A_{c_\star}^\mu - z)} \frac{1}{(1 + (A_{c_\star}^\mu - z)^{-1}(A_c^\mu - A_{c_\star}^\mu))}. \tag{2.18}$$

Since $A_{c_\star}^\mu - z$, $z \in \gamma$, is invertible in L^2 and is smoothing of order three, while $A_c^\mu - A_{c_\star}^\mu$ depends continuously on c as a differential operator of order 1, the operator $(A_{c_\star}^\mu - z)^{-1}(A_c^\mu - A_{c_\star}^\mu)$ is bounded by $1/2$ as an operator in L^2 for all $z \in \gamma$ and for all c sufficiently close to $c_\star$. We assume that $\eta_1 > 0$ is small enough so that

$$\gamma \in \rho(A_c^\mu) \quad \text{for} \quad c \in [c_\star, c_\star + \eta_1]. \tag{2.19}$$

Integrating $(A_c^\mu - z)^{-1}$ along γ, we get a projection

$$P_c^\mu = -\frac{1}{2\pi i} \oint_\gamma \frac{dz}{A_c^\mu - z}, \qquad c \in [c_\star, c_\star + \eta_1]. \tag{2.20}$$

Since $\operatorname{rank} P_{c_\star}^\mu = 3$, we also have

$$\operatorname{rank} P_c^\mu = 3, \qquad c \in [c_\star, c_\star + \eta_1].$$

The three-dimensional spectral subspace $\operatorname{Range} P_{c_\star}^\mu$ corresponds to the eigenvalue $\lambda = 0$ that has algebraic multiplicity three. According to Corollary 2.3, when $\mathscr{N}_c' \ne 0$, $\lambda = 0$ is of algebraic multiplicity two, and therefore $X_c^\mu \equiv \operatorname{Range} P_c^\mu$ splits into a two-dimensional spectral subspace of A_c^μ corresponding to $\lambda = 0$ (it is spanned by $\{\boldsymbol{e}_{1,c}^\mu, \boldsymbol{e}_{2,c}^\mu\}$) and a one-dimensional subspace that corresponds to a nonzero eigenvalue.

For $c \in [c_\star, c_\star + \eta_1]$, we define

$$\tilde{\boldsymbol{e}}_{3,c}^\mu = P_c^\mu \boldsymbol{e}_{3,c_\star}^\mu, \qquad c \in [c_\star, c_\star + \eta_1]. \tag{2.21}$$

Note that $\tilde{\boldsymbol{e}}_{3,c}^\mu \in L^2(\mathbb{R})$ since P_c^μ is continuous in L^2. In the frame $\{\boldsymbol{e}_{1,c}^\mu, \boldsymbol{e}_{2,c}^\mu, \tilde{\boldsymbol{e}}_{3,c}^\mu\}$ we can write

$$A_c^\mu \tilde{\boldsymbol{e}}_{3,c}^\mu = a_c \boldsymbol{e}_{1,c}^\mu + b_c \boldsymbol{e}_{2,c}^\mu + \lambda_c \tilde{\boldsymbol{e}}_{3,c}^\mu. \tag{2.22}$$

Since the frame $\{\boldsymbol{e}_{1,c}^\mu, \boldsymbol{e}_{2,c}^\mu, \tilde{\boldsymbol{e}}_{3,c}^\mu\}$ and also $A_c^\mu \tilde{\boldsymbol{e}}_{3,c}^\mu$ depend smoothly on c (as functions from $[c_\star, c_\star + \eta_1]$ to $L^2(\mathbb{R})$; recall that f is smooth), the coefficients a_c, b_c, and λ_c are smooth functions of c for $c \in [c_\star, c_\star + \eta_1]$. It is also important to point out that a_c, b_c, and λ_c do not depend on $\mu > 0$, since if the relation (2.22) holds for certain values of a_c, b_c, and λ_c for a particular value $\mu > 0$, then, by the definition of A_c^μ, $\boldsymbol{e}_{1,c}^\mu$, $\boldsymbol{e}_{2,c}^\mu$, and $\tilde{\boldsymbol{e}}_{3,c}^\mu$, the relation (2.22) also holds for μ' from an open neighborhood of μ.

According to the construction of $\boldsymbol{e}_{3,c_\star}$ in Proposition 2.2, $a_{c_\star} = \lambda_{c_\star} = 0$ and $b_{c_\star} = 1$. We define

$$\boldsymbol{e}_{3,c}^\mu = \frac{1}{b_c + a_c \lambda_c} (\tilde{\boldsymbol{e}}_{3,c}^\mu - a_c \boldsymbol{e}_{2,c}^\mu).$$

Then $\boldsymbol{e}_{3,c}^\mu \in L^2(\mathbb{R})$ for $c \in [c_\star, c_\star + \eta_1]$. We compute

$$A_c^\mu \boldsymbol{e}_{3,c}^\mu = \boldsymbol{e}_{2,c}^\mu + \lambda_c \boldsymbol{e}_{3,c}^\mu. \tag{2.23}$$

Thus, in the frame $\{\boldsymbol{e}^\mu_{j,c}\colon\ j=1,2,3\}$ the operator $A^\mu_c|_{\mathrm{Range}\,P^\mu_c}$ has the desired matrix form (2.15). Conjugating by means of $e^{\mu x}$ we get a corresponding frame $\{\boldsymbol{e}_{j,c}\colon j=1,2,3\}$ in L^2_μ, with $\boldsymbol{e}_{3,c}$ satisfying

$$J\mathcal{H}_c\boldsymbol{e}_{3,c}=\boldsymbol{e}_{2,c}+\lambda_c\boldsymbol{e}_{3,c},\qquad \boldsymbol{e}_{3,c}\in L^2_\mu(\mathbb{R}). \tag{2.24}$$

For $c\in[c_\star,c_\star+\eta_1]$ and $z\notin\sigma(A^\mu_c)$, $R^\mu_c(z)=(A^\mu_c-z)^{-1}$ is a pseudodifferential operator of order -3, and hence P^μ_c is smoothing of order three in the Sobolev spaces $H^s(\mathbb{R})$. The bootstrapping argument applied to the relations $\boldsymbol{e}^\mu_{j,c}=P^\mu_c\boldsymbol{e}^\mu_{j,c}$ shows that $\boldsymbol{e}^\mu_{j,c}\in H^\infty(\mathbb{R})$. By definition (1.12), this means that

$$\boldsymbol{e}_{j,c}\in H^\infty_\mu(\mathbb{R}),\qquad j=1,2,3,\quad c\in[c_\star,c_\star+\eta_1]. \tag{2.25}$$

Using (2.24), we compute

$$\begin{aligned}0&=\langle\mathcal{H}_c\boldsymbol{e}_{1,c},\boldsymbol{e}_{3,c}\rangle=-\langle\mathcal{H}_cJ\boldsymbol{\phi}_c,\boldsymbol{e}_{3,c}\rangle\\&=\langle\boldsymbol{\phi}_c,J\mathcal{H}_c\boldsymbol{e}_{3,c}\rangle=\langle\boldsymbol{\phi}_c,\boldsymbol{e}_{2,c}\rangle+\lambda_c\langle\boldsymbol{\phi}_c,\boldsymbol{e}_{3,c}\rangle,\quad c\in[c_\star,c_\star+\eta_1].\end{aligned}$$

We conclude that

$$\lambda_c=-\frac{\langle\boldsymbol{\phi}_c,\boldsymbol{e}_{2,c}\rangle}{\langle\boldsymbol{\phi}_c,\boldsymbol{e}_{3,c}\rangle},\qquad c\in[c_\star,c_\star+\eta_1],$$

where $\langle\boldsymbol{\phi}_c,\boldsymbol{e}_{2,c}\rangle=\langle\boldsymbol{\phi}_c,\partial_c\boldsymbol{\phi}_c\rangle=\mathcal{N}_c'<0$. Note that $\langle\boldsymbol{\phi}_c,\boldsymbol{e}_{3,c}\rangle>0$ for $c_\star<c\le c_\star+\eta_1$, since $\langle\boldsymbol{\phi}_{c_\star},\boldsymbol{e}_{3,c_\star}\rangle>0$ by (2.9) and $\langle\boldsymbol{\phi}_c,\boldsymbol{e}_{3,c}\rangle$ does not change sign for $c_\star<c\le c_\star+\eta_1$ (this follows from the inequality $|\langle\boldsymbol{\phi}_c,\boldsymbol{e}_{3,c}\rangle|>|\mathcal{N}_c'|/\Lambda>0$; see Remark 2.5). This finishes the proof of the lemma. ∎

Remark 2.6. According to Assumption 3, we may assume that η_1 is small enough so that for $c\in[c_\star,c_\star+\eta_1]$ and $0\le\mu\le\mu_0$ there is no discrete spectrum of A^μ_c except $\lambda=0$ and $\lambda=\lambda_c$. It follows that P^μ_c is the spectral projector that corresponds to the discrete spectrum of A^μ_c.

LEMMA 2.7. *If $\lambda_c>0$, then $\boldsymbol{e}_{3,c}\in H^\infty(\mathbb{R})$.*

Proof. By Lemma 2.4, $\lambda_c>0$ is a simple eigenvalue of $J\mathcal{H}_c$ considered in $L^2(\mathbb{R})$. By (2.1), (2.2), and (2.24),

$$\boldsymbol{\psi}_c=\boldsymbol{e}_{c,1}+\lambda_c\boldsymbol{e}_{c,2}+\lambda_c^2\boldsymbol{e}_{c,3}\in C^\infty(\mathbb{R}) \tag{2.26}$$

satisfies $J\mathcal{H}_c\boldsymbol{\psi}_c=\lambda_c\boldsymbol{\psi}_c$, and also $\lim_{x\to+\infty}\boldsymbol{\psi}_c(x)=0$. Thus, $\boldsymbol{\psi}_c$ coincides with an L^2 eigenvector of $J\mathcal{H}_c\boldsymbol{\psi}_c$ that corresponds to λ_c. Therefore, $\boldsymbol{\psi}_c\in H^\infty(\mathbb{R})$. Since $\boldsymbol{e}_{c,1},\boldsymbol{e}_{c,2}\in H^1(\mathbb{R})$ and $\lambda_c\ne0$, the statement of the lemma follows from the relation (2.26). ∎

Let us also introduce the dual basis that consists of eigenvectors of the adjoint operator $(J\mathcal{H}_c)^*=-\mathcal{H}_cJ=-\mathcal{H}_c\partial_x$ which we consider in the weighted space

$$L^2_{-\mu}(\mathbb{R})=\left\{\boldsymbol{\psi}\in L^2_{loc}(\mathbb{R})\colon e^{-\mu x}\boldsymbol{\psi}(x)\in L^2(\mathbb{R})\right\},\quad \mu>0. \tag{2.27}$$

For any $c\in\Sigma$, the generalized kernel of $(J\mathcal{H}_c)^*$ contains at least two linearly independent vectors:

$$-\mathcal{H}_c\partial_x\boldsymbol{g}_{1,c}=0,\qquad -\mathcal{H}_c\partial_x\boldsymbol{g}_{2,c}=\boldsymbol{g}_{1,c}, \tag{2.28}$$

where

$$\boldsymbol{g}_{1,c}(x) = -\int_{-\infty}^{x} \boldsymbol{e}_{1,c}(y,c)\,dy = \boldsymbol{\phi}_c(x), \tag{2.29}$$

$$\boldsymbol{g}_{2,c}(x) = \int_{-\infty}^{x} \boldsymbol{e}_{2,c}(y,c)\,dy = \int_{-\infty}^{x} \partial_c \boldsymbol{\phi}_c(y)\,dy. \tag{2.30}$$

The lower limit of integration ensures that $\lim_{x\to-\infty} \boldsymbol{g}_{2,c}(x) = 0$, so that $\boldsymbol{g}_{2,c} \in L^2_{-\mu}(\mathbb{R})$.

PROPOSITION 2.8. *Assume that $c_\star \in \Sigma$ is such that $\mathscr{N}'_{c_\star} = 0$, $I'_{c_\star} \neq 0$. The eigenvalue $\lambda = 0$ of the operator $-\mathcal{H}_{c_\star}\partial_x$ is of algebraic multiplicity three in $L^2_{-\mu}(\mathbb{R})$, and there exists $\boldsymbol{g}_{3,c_\star} \in H^\infty_{-\mu}(\mathbb{R})$ such that*

$$-\mathcal{H}_{c_\star}\partial_x \boldsymbol{g}_{3,c_\star} = \boldsymbol{g}_{2,c_\star}.$$

Proof. The argument repeats the steps of the proof of Proposition 2.2. The function $\boldsymbol{g}_{3,c_\star}$ is given by

$$\boldsymbol{g}_{3,c_\star}(x) = -\int_{-\infty}^{x} \tilde{\boldsymbol{e}}_{3,c_\star}(y)dy, \tag{2.31}$$

where $\tilde{\boldsymbol{e}}_{3,c_\star}(x)$ satisfies

$$\mathcal{H}_{c_\star}\tilde{\boldsymbol{e}}_{3,c_\star} = \int_{-\infty}^{x} \boldsymbol{e}_{2,c_\star}(y)\,dy, \qquad \lim_{x\to-\infty} \tilde{\boldsymbol{e}}_{3,c_\star}(x) = 0. \tag{2.32}$$

Since $\int_{-\infty}^{x} \boldsymbol{e}_{2,c_\star}(y)\,dy$ remains bounded as $x \to +\infty$, while $\langle \boldsymbol{g}_{2,c_\star}, \boldsymbol{\phi}_{c_\star}\rangle = 0$, the function $\tilde{\boldsymbol{e}}_{3,c_\star}(x)$ remains bounded as $x \to +\infty$. This follows from Lemma B.1 of Appendix B (after the reflection $x \to -x$). Therefore, $\boldsymbol{g}_{3,c_\star}(x)$ has a linear growth as $x \to +\infty$; $\boldsymbol{g}_{3,c_\star} \in \mathscr{S}_{-,1}(\mathbb{R})$ (defined similarly to $\mathscr{S}_{+,1}$ in Definition 2.1). □

As in Lemma 2.4, one can show that there is an extension of $\boldsymbol{g}_{3,c_\star}$ into an interval $[c_\star, c_\star + \eta_1]$,

$$c \mapsto \boldsymbol{g}_{3,c} \in H^\infty_{-\mu}(\mathbb{R}), \qquad c \in [c_\star, c_\star + \eta_1],$$

so that, similarly to (2.24) and (2.25),

$$-\mathcal{H}_c\partial_x \boldsymbol{g}_{3,c} = \boldsymbol{g}_{2,c}(x) + \lambda_c \boldsymbol{g}_{3,c}, \qquad \boldsymbol{g}_{3,c} \in H^\infty_{-\mu}(\mathbb{R}), \quad c \in [c_\star, c_\star + \eta_1]. \tag{2.33}$$

Using the bases $\{\boldsymbol{e}_{j,c} \in H^\infty_{\mu}(\mathbb{R})\colon\ j = 1,2,3\}$, $\{\boldsymbol{g}_{j,c} \in H^\infty_{-\mu}(\mathbb{R})\colon\ j = 1,2,3\}$, we can write the projection operator $e^{-\mu x} \circ P^\mu_c \circ e^{\mu x}$ that corresponds to the discrete spectrum of $J\mathcal{H}_c$ in the form

$$(e^{-\mu x} \circ P^\mu_c \circ e^{\mu x})\boldsymbol{\psi} = \sum_{j,k=1}^{3} \mathcal{T}^{jk}_c \langle \boldsymbol{g}_{k,c}, \boldsymbol{\psi}\rangle \boldsymbol{e}_{j,c}, \tag{2.34}$$

with $\mathcal{T}^{jk}_c$ being the inverse of the matrix

$$\mathcal{T}_c = \{\mathcal{T}_{jk,c}\}, \quad \mathcal{T}_{jk,c} = \langle \boldsymbol{g}_{j,c}, \boldsymbol{e}_{k,c}\rangle, \quad c \in [c_\star, c_\star + \eta_1], \quad 1 \le j,k \le 3. \tag{2.35}$$

Let us introduce the functions

$$\alpha_c = \langle \boldsymbol{g}_{1,c}, \boldsymbol{e}_{3,c}\rangle, \qquad \beta_c = \langle \boldsymbol{g}_{2,c}, \boldsymbol{e}_{3,c}\rangle, \qquad \gamma_c = \langle \boldsymbol{g}_{3,c}, \boldsymbol{e}_{3,c}\rangle. \tag{2.36}$$

Since $\boldsymbol{e}_{j,c} \in L^2_\mu(\mathbb{R})$ and $\boldsymbol{g}_{j,c} \in L^2_{-\mu}(\mathbb{R})$, α_c, β_c, and γ_c are continuous functions of c for $c \in [c_\star, c_\star + \eta_1]$. Recalling that $\langle \boldsymbol{g}_{2,c}, \boldsymbol{e}_{1,c}\rangle = \langle \boldsymbol{g}_{2,c}, J\mathcal{H}_c \boldsymbol{e}_{2,c}\rangle = -\langle \mathcal{H}_c J \boldsymbol{g}_{2,c}, \boldsymbol{e}_{2,c}\rangle = \langle \boldsymbol{g}_{1,c}, \boldsymbol{e}_{2,c}\rangle = \langle \boldsymbol{\phi}_c, \partial_c \boldsymbol{\phi}_c\rangle = \mathscr{N}_c'$, $\langle \boldsymbol{g}_{1,c}, \boldsymbol{e}_{1,c}\rangle = -\langle \boldsymbol{\phi}_c, \partial_x \boldsymbol{\phi}_c\rangle = 0$, we may write the matrix $\mathcal{T}$ in the following form:

$$\mathcal{T}_c = \begin{bmatrix} 0 & \mathscr{N}_c' & \alpha_c \\ \mathscr{N}_c' & \frac{1}{2}(I_c')^2 & \beta_c \\ \alpha_c & \beta_c & \gamma_c \end{bmatrix}. \tag{2.37}$$

Note that $\mathcal{T}_{c_\star}$ is nondegenerate, because $\mathscr{N}_{c_\star}' = 0$ by the choice of $c_\star$, while $\alpha_{c_\star} = \langle \boldsymbol{g}_{1,c_\star}, \boldsymbol{e}_{3,c_\star}\rangle = \langle \boldsymbol{\phi}_{c_\star}, \boldsymbol{e}_{3,c_\star}\rangle = \frac{1}{2}(I_{c_\star}')^2 > 0$ by (2.9).

3. Center manifold reduction. We first discuss the existence of a solution $\boldsymbol{u}(t)$ that corresponds to perturbed initial data. We will rely on the well-posedness results due to T. Kato.

LEMMA 3.1. *For any $\mu > 0$, $s \geq 2$, and $\boldsymbol{u}_0 \in H^s(\mathbb{R}) \cap L^2_{2\mu}(\mathbb{R})$ with $\|\boldsymbol{u}_0\|_{H^1} < 2\|\boldsymbol{\phi}_{c_\star}\|_{H^1}$, there exists a function*

$$\boldsymbol{u}(t) \in C([0,\infty), H^s(\mathbb{R}) \cap L^2_{2\mu}(\mathbb{R})), \qquad \boldsymbol{u}(0) = \boldsymbol{u}_0, \tag{3.1}$$

which solves (1.1) *for $0 \leq t < t_1$, where t_1 is finite or infinite, defined by*

$$t_1 = \sup\{t \geq 0 : \ \|\boldsymbol{u}(t)\|_{H^1} < 2\|\boldsymbol{\phi}_{c_\star}\|_{H^1}\}. \tag{3.2}$$

Proof. According to [Kat83, Theorem 10.1], equation (1.1) is globally well-posed in $H^s(\mathbb{R}) \cap L^2_{2\mu}(\mathbb{R})$ for any $s \geq 2$, $\mu > 0$ (for the initial data with arbitrarily large norm) if f satisfies

$$\lim_{|z|\to\infty} |z|^{-4} f'(z) \geq 0. \tag{3.3}$$

We modify the nonlinearity $f(z)$ for $|z| > 2\|\boldsymbol{\phi}_{c_\star}\|_{H^1}$ so that (3.3) is satisfied; let us call this modified nonlinearity $\tilde{f}(z)$. Thus, for any $\boldsymbol{u}_0 \in H^s(\mathbb{R}) \cap L^2_{2\mu}(\mathbb{R})$ with $\|\boldsymbol{u}_0\|_{H^1} < 2\|\boldsymbol{\phi}_{c_\star}\|_{H^1}$, there exists a function

$$\boldsymbol{u}(t) \in C([0,\infty), H^s(\mathbb{R}) \cap L^2_{2\mu}(\mathbb{R})), \qquad \boldsymbol{u}(0) = \boldsymbol{u}_0, \tag{3.4}$$

that solves the equation with the modified nonlinearity

$$\partial_t \boldsymbol{u} = \partial_x\big(-\partial_x^2 \boldsymbol{u} + \tilde{f}(\boldsymbol{u})\big). \tag{3.5}$$

For $0 \leq t < t_1$, with t_1 defined by (3.2), one has $\|\boldsymbol{u}(t)\|_{L^\infty} \leq \|\boldsymbol{u}(t)\|_{H^1} < 2\|\boldsymbol{\phi}_{c_\star}\|_{H^1}$. Therefore, for $0 \leq t < t_1$, $\boldsymbol{u}(t)$ solves both (3.5) and (1.1) since $\tilde{f}(z) = f(z)$ for $|z| \leq 2\|\boldsymbol{\phi}_{c_\star}\|_{H^1}$. $\square$

We fix μ satisfying (2.10). For the initial data $\boldsymbol{u}_0 \in H^2(\mathbb{R}) \cap L^2_{2\mu}(\mathbb{R})$ with $\|\boldsymbol{u}_0\|_{H^1} < 2\|\boldsymbol{\phi}_{c_\star}\|_{H^1}$ there is a function $\boldsymbol{u} \in C([0,\infty), H^2(\mathbb{R}) \cap L^2_{2\mu}(\mathbb{R}))$ that solves (1.1) for $0 \leq t < t_1$, with t_1 from (3.2). We will approximate the solution $\boldsymbol{u}(x,t)$ by a traveling wave $\boldsymbol{\phi}_c$ moving with the variable speed $c = c(t)$. Thus, we decompose the solution $\boldsymbol{u}(x,t)$ into the traveling wave $\boldsymbol{\phi}_c(x)$ and the perturbation $\boldsymbol{\rho}(x,t)$ as follows:

$$\boldsymbol{u}(x,t) = \boldsymbol{\phi}_{c(t)}\left(x - \xi(t) - \int_0^t c(t')\,dt'\right) + \boldsymbol{\rho}\left(x - \xi(t) - \int_0^t c(t')\,dt',\, t\right). \tag{3.6}$$

The functions $\xi(t)$ and $c(t)$ are yet to be chosen.

Using (3.6), we rewrite the generalized KdV equation (1.1) as an equation on $\boldsymbol{\rho}$:

$$\dot{\boldsymbol{\rho}} - J\mathcal{H}_c\boldsymbol{\rho} = -\dot{\xi}\boldsymbol{e}_{1,c} - \dot{c}\boldsymbol{e}_{2,c} + \dot{\xi}\partial_x\boldsymbol{\rho} + J\boldsymbol{N}, \tag{3.7}$$

with $\mathcal{H}_c$ given by (1.11) and with $J\boldsymbol{N}$ given by

$$J\boldsymbol{N} = \partial_x\left[f(\boldsymbol{\phi}_c + \boldsymbol{\rho}) - f(\boldsymbol{\phi}_c) - \boldsymbol{\rho}f'(\boldsymbol{\phi}_c)\right], \tag{3.8}$$

where we changed coordinates, denoting $y = x - \xi(t) - \int_0^t c(t')\,dt'$ by x. By Proposition 2.2 (iii), the eigenvalue $\lambda = 0$ of operator $J\mathcal{H}_{c_\star}$ in $L^2_\mu(\mathbb{R})$ has algebraic multiplicity three. We decompose the perturbation $\boldsymbol{\rho}(x,t)$ as follows:

$$\boldsymbol{\rho}(x,t) = \zeta(t)\boldsymbol{e}_{3,c(t)}(x) + \boldsymbol{v}(x,t), \tag{3.9}$$

where $\boldsymbol{e}_{3,c}$ is constructed in Lemma 2.4. The inclusions $\boldsymbol{\phi}_c \in H^2(\mathbb{R})\cap L^2_{2\mu}(\mathbb{R}) \subset H^1_\mu(\mathbb{R})$ and $\boldsymbol{e}_{3,c} \in H^1_\mu(\mathbb{R})$ show that $\boldsymbol{v}(\cdot,t) \in H^1_\mu(\mathbb{R})$.

We would like to choose $\xi(t)$, $c(t) = c_\star + \eta(t)$, and $\zeta(t)$ so that

$$\boldsymbol{v}(x,t) = \boldsymbol{u}\left(x + \xi(t) + \int_0^t (c_\star + \eta(t'))\,dt',\, t\right) - \boldsymbol{\phi}_{c_\star+\eta(t)}(x) - \zeta(t)\boldsymbol{e}_{3,c_\star+\eta(t)}(x) \tag{3.10}$$

represents the part of the perturbation that corresponds to the continuous spectrum of $J\mathcal{H}_c$.

Proposition 3.2. *There exist $\eta_1 > 0$, $\zeta_1 > 0$, and $\delta_1 > 0$ such that if η_0 and ζ_0 satisfy*

$$|\eta_0| < \eta_1, \qquad |\zeta_0| < \zeta_1, \qquad \|\boldsymbol{\phi}_{c_\star+\eta_0} + \zeta_0\boldsymbol{e}_{3,c_\star+\eta_0} - \boldsymbol{\phi}_{c_\star}\|_{H^1} < \|\boldsymbol{\phi}_{c_\star}\|_{H^1}, \tag{3.11}$$

then there is $T_1 \in \mathbb{R}_+ \cup \{+\infty\}$ such that the following hold:

(i) *There exists $\boldsymbol{u} \in C([0,\infty), H^2(\mathbb{R}) \cap L^2_{2\mu}(\mathbb{R}))$ so that*

$$\boldsymbol{u}(0) = \boldsymbol{\phi}_{c_\star+\eta_0} + \zeta_0\boldsymbol{e}_{3,c_\star+\eta_0} \tag{3.12}$$

and $\boldsymbol{u}(t)$ solves (1.1) for $0 \le t < T_1$.

(ii) *There exist functions*

$$\xi, \eta, \zeta \in C([0,\infty)), \qquad \xi(0) = 0, \quad \eta(0) = \eta_0, \quad \zeta(0) = \zeta_0, \tag{3.13}$$

such that the function $\boldsymbol{v}(t)$ defined by (3.10) satisfies

$$e^{\mu x}\boldsymbol{v}(x,t) \in \ker P^\mu_{c_\star+\eta(t)}, \qquad 0 \le t < T_1. \tag{3.14}$$

(iii) *The following inequalities hold for $0 \le t < T_1$:*

$$\|\boldsymbol{u}(t)\|_{H^1} < 2\|\boldsymbol{\phi}_{c_\star}\|_{H^1}, \quad |\eta(t)| < \eta_1, \quad |\zeta(t)| < \zeta_1, \quad \|\boldsymbol{v}(t)\|_{H^1_\mu} < \delta_1. \tag{3.15}$$

(iv) *If one cannot choose $T_1 = \infty$, then at least one of the inequalities in (3.15) turns into an equality at $t = T_1$.*

Proof. Since $\boldsymbol{u}_0 = \boldsymbol{\phi}_{c_\star+\eta_0} + \zeta_0\boldsymbol{e}_{3,c_\star+\eta_0} \in H^2(\mathbb{R})\cap L^2_{2\mu}(\mathbb{R})$ and the conditions (3.11) are satisfied, by Lemma 3.1, there is a function $\boldsymbol{u}(t) \in C([0,\infty), H^2(\mathbb{R})\cap L^2_{2\mu}(\mathbb{R}))$ and $t_1 \in \mathbb{R}_+ \cup \{+\infty\}$ such that $\boldsymbol{u}(t)$ solves (1.1) for $0 \le t < t_1$ and, if $t_1 < \infty$, then

$\|\boldsymbol{u}(t_1)\|_{H^1} = 2\|\boldsymbol{\phi}_{c_\star}\|_{H^1}$. We thus need to construct $\xi(t)$, $\eta(t)$, and $\zeta(t)$ so that $\boldsymbol{v}(x,t)$ defined by (3.10) satisfies the constraints

$$\langle \boldsymbol{g}_{1,c_\star+\eta(t)}, \boldsymbol{v}(t)\rangle = \langle \boldsymbol{g}_{2,c_\star+\eta(t)}, \boldsymbol{v}(t)\rangle = \langle \boldsymbol{g}_{3,c_\star+\eta(t)}, \boldsymbol{v}(t)\rangle = 0. \tag{3.16}$$

Let us note that $\boldsymbol{v}(0) = 0$ by (3.10), (3.12), and (3.13). Since $J\mathcal{H}_c\boldsymbol{e}_{3,c} = \lambda_c\boldsymbol{e}_{3,c} + \boldsymbol{e}_{2,c}$,

$$\partial_t(\zeta\boldsymbol{e}_{3,c}) - J\mathcal{H}_c(\zeta\boldsymbol{e}_{3,c}) = \dot\zeta\boldsymbol{e}_{3,c} + \dot\eta\zeta\partial_c\boldsymbol{e}_{3,c} - \zeta(\lambda_c\boldsymbol{e}_{3,c} + \boldsymbol{e}_{2,c}). \tag{3.17}$$

Therefore, (3.7) can be written as the following equation on $\boldsymbol{v}(t) = \boldsymbol{\rho} - \zeta\boldsymbol{e}_{3,c}$:

$$\dot{\boldsymbol{v}} - J\mathcal{H}_c\boldsymbol{v} = -\dot\xi\boldsymbol{e}_{1,c} - (\dot\eta - \zeta)\,\boldsymbol{e}_{2,c} - (\dot\zeta - \lambda_c\zeta)\boldsymbol{e}_{3,c} - \dot\eta\zeta\partial_c\boldsymbol{e}_{3,c} + \dot\xi\partial_x\boldsymbol{\rho} + J\boldsymbol{N}. \tag{3.18}$$

Differentiating the constraints (3.16) and using the evolution equation (3.18), we derive the center manifold reduction,

$$\mathcal{T}_c\begin{bmatrix}\dot\xi\\ \dot\eta-\zeta\\ \dot\zeta-\lambda_c\zeta\end{bmatrix} - \dot\eta\begin{bmatrix}\langle\partial_c\boldsymbol{g}_{1,c},\boldsymbol{v}\rangle\\ \langle\partial_c\boldsymbol{g}_{2,c},\boldsymbol{v}\rangle\\ \langle\partial_c\boldsymbol{g}_{3,c},\boldsymbol{v}\rangle\end{bmatrix} = -\dot\eta\zeta\begin{bmatrix}\langle\boldsymbol{g}_{1,c},\partial_c\boldsymbol{e}_{3,c}\rangle\\ \langle\boldsymbol{g}_{2,c},\partial_c\boldsymbol{e}_{3,c}\rangle\\ \langle\boldsymbol{g}_{3,c},\partial_c\boldsymbol{e}_{3,c}\rangle\end{bmatrix} + \dot\xi\begin{bmatrix}\langle\boldsymbol{g}_{1,c},\partial_x\boldsymbol{\rho}\rangle\\ \langle\boldsymbol{g}_{2,c},\partial_x\boldsymbol{\rho}\rangle\\ \langle\boldsymbol{g}_{3,c},\partial_x\boldsymbol{\rho}\rangle\end{bmatrix} + \begin{bmatrix}\langle\boldsymbol{g}_{1,c},J\boldsymbol{N}\rangle\\ \langle\boldsymbol{g}_{2,c},J\boldsymbol{N}\rangle\\ \langle\boldsymbol{g}_{3,c},J\boldsymbol{N}\rangle\end{bmatrix}, \tag{3.19}$$

where the matrix $\mathcal{T}_c$ is given by (2.35). The above can be rewritten as

$$\mathcal{S}\begin{bmatrix}\dot\xi\\ \dot\eta-\zeta\\ \dot\zeta-\lambda_c\zeta\end{bmatrix} = \begin{bmatrix}-\zeta^2\langle\boldsymbol{g}_{1,c},\partial_c\boldsymbol{e}_{3,c}\rangle + \zeta\langle\partial_c\boldsymbol{g}_{1,c},\boldsymbol{v}\rangle + \langle\boldsymbol{g}_{1,c},J\boldsymbol{N}\rangle\\ -\zeta^2\langle\boldsymbol{g}_{2,c},\partial_c\boldsymbol{e}_{3,c}\rangle + \zeta\langle\partial_c\boldsymbol{g}_{2,c},\boldsymbol{v}\rangle + \langle\boldsymbol{g}_{2,c},J\boldsymbol{N}\rangle\\ -\zeta^2\langle\boldsymbol{g}_{3,c},\partial_c\boldsymbol{e}_{3,c}\rangle + \zeta\langle\partial_c\boldsymbol{g}_{3,c},\boldsymbol{v}\rangle + \langle\boldsymbol{g}_{3,c},J\boldsymbol{N}\rangle\end{bmatrix}, \tag{3.20}$$

where $c = c_\star + \eta$ and

$$\mathcal{S}(\eta,\zeta,\boldsymbol{v}) = \mathcal{T}_c + \begin{bmatrix}-\langle\boldsymbol{g}_{1,c},\partial_x(\zeta\boldsymbol{e}_{3,c}+\boldsymbol{v})\rangle & \zeta\langle\boldsymbol{g}_{1,c},\partial_c\boldsymbol{e}_{3,c}\rangle - \langle\partial_c\boldsymbol{g}_{1,c},\boldsymbol{v}\rangle & 0\\ -\langle\boldsymbol{g}_{2,c},\partial_x(\zeta\boldsymbol{e}_{3,c}+\boldsymbol{v})\rangle & \zeta\langle\boldsymbol{g}_{2,c},\partial_c\boldsymbol{e}_{3,c}\rangle - \langle\partial_c\boldsymbol{g}_{2,c},\boldsymbol{v}\rangle & 0\\ -\langle\boldsymbol{g}_{3,c},\partial_x(\zeta\boldsymbol{e}_{3,c}+\boldsymbol{v})\rangle & \zeta\langle\boldsymbol{g}_{3,c},\partial_c\boldsymbol{e}_{3,c}\rangle - \langle\partial_c\boldsymbol{g}_{3,c},\boldsymbol{v}\rangle & 0\end{bmatrix}. \tag{3.21}$$

Note that the matrix $\mathcal{S}(\eta,\zeta,\boldsymbol{v})$ depends continuously on $(\eta,\zeta,\boldsymbol{v}) \in \mathbb{R}^2 \times H^1_\mu(\mathbb{R})$. Since the matrix $\mathcal{T}_{c_\star}$ is nonsingular (see (2.37)), the matrix $\mathcal{S}(\eta,\zeta,\boldsymbol{v})$ is invertible for sufficiently small values of $|\eta|$, $|\zeta|$, and $\|\boldsymbol{v}\|_{H^1_\mu}$.

Thus, there exist $\eta_1 > 0$, $\zeta_1 > 0$, and $\delta_1 > 0$ so that the matrix $\mathcal{S}(\eta,\zeta,\boldsymbol{v})$ is invertible if

$$|\eta| \le 2\eta_1, \qquad |\zeta| \le 2\zeta_1, \qquad \|\boldsymbol{v}\|_{H^1_\mu} \le 2\delta_1. \tag{3.22}$$

For such η, ζ, and $\boldsymbol{v}$, we can write

$$\begin{bmatrix}\dot\xi\\ \dot\eta-\zeta\\ \dot\zeta-\lambda_c\zeta\end{bmatrix} = \begin{bmatrix}R_1(\eta,\zeta,\boldsymbol{v})\\ R_2(\eta,\zeta,\boldsymbol{v})\\ R_3(\eta,\zeta,\boldsymbol{v})\end{bmatrix}, \tag{3.23}$$

where the right-hand side is given by

$$\begin{bmatrix}R_1(\eta,\zeta,\boldsymbol{v})\\ R_2(\eta,\zeta,\boldsymbol{v})\\ R_3(\eta,\zeta,\boldsymbol{v})\end{bmatrix} = \mathcal{S}(\eta,\zeta,\boldsymbol{v})^{-1}\begin{bmatrix}-\zeta^2\langle\boldsymbol{g}_{1,c},\partial_c\boldsymbol{e}_{3,c}\rangle + \zeta\langle\partial_c\boldsymbol{g}_{1,c},\boldsymbol{v}\rangle + \langle\boldsymbol{g}_{1,c},J\boldsymbol{N}\rangle\\ -\zeta^2\langle\boldsymbol{g}_{2,c},\partial_c\boldsymbol{e}_{3,c}\rangle + \zeta\langle\partial_c\boldsymbol{g}_{2,c},\boldsymbol{v}\rangle + \langle\boldsymbol{g}_{2,c},J\boldsymbol{N}\rangle\\ -\zeta^2\langle\boldsymbol{g}_{3,c},\partial_c\boldsymbol{e}_{3,c}\rangle + \zeta\langle\partial_c\boldsymbol{g}_{3,c},\boldsymbol{v}\rangle + \langle\boldsymbol{g}_{3,c},J\boldsymbol{N}\rangle\end{bmatrix}. \tag{3.24}$$

Assume that η_0 and ζ_0 are such that the conditions (3.11) are satisfied. Let $\varrho_0 \in C^\infty_{comp}(\mathbb{R})$ be such that $0 \le \varrho_0(s) \le 1$, $\varrho_0(s) \equiv 1$ for $|s| \le 1$, and $\varrho_0(s) \equiv 0$ for $|s| \ge 2$. Define a continuous matrix-valued function $\tilde{\mathcal{S}} : \mathbb{R}^2 \times H^1_\mu \to GL(3)$ by

$$\tilde{\mathcal{S}}(\eta, \zeta, \boldsymbol{v}) = \mathcal{S}(\varrho\eta, \varrho\zeta, \varrho\boldsymbol{v}), \qquad \text{where} \quad \varrho = \varrho_0(\eta/\eta_1)\varrho_0(\zeta/\zeta_1)\varrho_0(\|\boldsymbol{v}\|_{H^1_\mu}/\delta_1).$$

This function coincides with $\mathcal{S}$ (defined in (3.21)) for $|\eta| < \eta_1$, $|\zeta| < \zeta_1$, and $\|\boldsymbol{v}\|_{H^1_\mu} < \delta_1$, and has uniformly bounded inverse. The system (3.23) with the right-hand side as in (3.24) but with $\tilde{\mathcal{S}}$ instead of $\mathcal{S}$, and with $\boldsymbol{v}$ given by the ansatz (3.10), defines differentiable functions $\xi(t)$, $\eta(t)$, and $\zeta(t)$ for all $t \ge 0$. Note that $\boldsymbol{v}(t)$ defined by (3.10) is a continuous function of time and is valued in $H^1_\mu(\mathbb{R})$, since so are $\boldsymbol{u}$, $\boldsymbol{\phi}_c$, and $\boldsymbol{e}_{3,c}$. Define $t_2 \in \mathbb{R}_+ \cup \{+\infty\}$ by

$$t_2 = \sup\{t \ge 0\colon |\eta(t)| < \eta_1,\ |\zeta(t)| < \zeta_1,\ \|\boldsymbol{v}(\cdot,t)\|_{H^1_\mu} < \delta_1\}. \tag{3.25}$$

For $t \in (0, t_2)$, the solution $(\xi(t), \eta(t), \zeta(t))$ also solves (3.23), since the inequalities $|\eta(t)| < \eta_1$, $|\zeta(t)| < \zeta_1$, and $\|\boldsymbol{v}(\cdot,t)\|_{H^1_\mu} < \delta_1$ ensure that $\tilde{\mathcal{S}}$ coincides with $\mathcal{S}$. Thus, Proposition 3.2 is proved with

$$T_1 = \min(t_1, t_2) \in \mathbb{R}_+ \cup \{+\infty\}, \tag{3.26}$$

where t_1, t_2 are from (3.2) and (3.25). ∎

4. Energy and dissipative estimates. We adapt the analysis from [PW94]. In this section, we formulate two lemmas that are the analogue of [PW94, Proposition 6.1]. Lemma 4.1 is based on the energy conservation and allows us to control $\|\boldsymbol{\rho}\|_{H^1}$ in terms of $\|\boldsymbol{v}\|_{H^1_\mu}$. Lemma 4.3 bounds $\|\boldsymbol{v}\|_{H^1_\mu}$ in terms of $\|\boldsymbol{\rho}\|_{H^1}$ and is based on dissipative estimates on the semigroup generated by A^μ_c (see Lemma 4.2).

Let $\eta_1 > 0$, $\zeta_1 > 0$, and $\delta_1 > 0$ not be larger than in Proposition 3.2, and assume that δ_1 satisfies

$$\delta_1 < \frac{\min(1, c_\star)}{4\sup_{|z|\le 2\|\boldsymbol{\phi}_{c_\star}\|_{H^1}} |f''(z)|}. \tag{4.1}$$

Let $\eta_0 > 0$ and ζ_0 be such that the conditions (3.11) are satisfied. According to Proposition 3.2, there exists $T_1 \in \mathbb{R}_+ \cup \{+\infty\}$ such that there is a solution $\boldsymbol{u} \in C((0, T_1), H^2(\mathbb{R}) \cap L^2_{2\mu}(\mathbb{R}))$ to (1.1) with the initial data

$$\boldsymbol{u}(0) = \boldsymbol{u}_0 := \boldsymbol{\phi}_{c_\star+\eta_0} + \zeta_0 \boldsymbol{e}_{3,c_\star+\eta_0},$$

and functions $\xi(t)$, $\eta(t)$, and $\zeta(t)$ and $\boldsymbol{v}(t)$ (given by (3.10)), defined for $0 \le t < T_1$, such that (3.14) and (3.15) are satisfied. For given η_0 and ζ_0, define the following function of η:

$$\mathscr{Y}(\eta) = \|\boldsymbol{\rho}_0\|_{H^1} + \|\boldsymbol{\rho}_0\|_{H^1}^{1/2}|\eta - \eta_0|^{1/2} + |\mathscr{N}_{c_\star+\eta} - \mathscr{N}_{c_\star+\eta_0}|^{1/2}, \tag{4.2}$$

where $\boldsymbol{\rho}_0 \equiv \zeta_0 \boldsymbol{e}_{3,c_\star+\eta_0}$.

Lemma 4.1. *There exists $C_1 > 0$ such that if at some moment $0 \le t < T_1$,*

$$\|\boldsymbol{\rho}(t)\|_{H^1} \le \delta_1,$$

then

$$\|\boldsymbol{\rho}(t)\|_{H^1} \le C_1 \left(\mathscr{Y}(\eta(t)) + |\zeta(t)| + \|\boldsymbol{v}(t)\|_{H^1_\mu}\right), \tag{4.3}$$

where $\mathscr{Y}(\eta)$ *is given by* (4.2).

Proof. Let us introduce the effective Hamiltonian $\mathscr{L}_c$:

$$\mathscr{L}_c(\boldsymbol{u}) = E(\boldsymbol{u}) + c\mathscr{N}(\boldsymbol{u}), \quad \mathscr{L}_c'(\boldsymbol{\phi}_c) = E'(\boldsymbol{\phi}_c) + c\mathscr{N}'(\boldsymbol{\phi}_c) = 0, \quad \mathscr{L}_c''(\boldsymbol{\phi}_c) = \mathcal{H}_c, \tag{4.4}$$

where E and $\mathscr{N}$ are the energy and momentum functionals defined in (1.5) and (1.7). Using the Taylor series expansion for $\mathscr{L}_c$ at $\boldsymbol{\phi}_c$, we have

$$\begin{aligned} \mathscr{L}_c(\boldsymbol{u}(t)) &= \mathscr{L}_c(\boldsymbol{\phi}_c) + \frac{1}{2}\langle \boldsymbol{\rho}, \mathcal{H}_c\boldsymbol{\rho}\rangle + \int_{\mathbb{R}} g(\boldsymbol{\phi}_c, \boldsymbol{\rho})\boldsymbol{\rho}^3\,dx \\ &= \mathscr{L}_c(\boldsymbol{\phi}_c) + \frac{1}{2}\langle \boldsymbol{\rho}, (-\partial_x^2 + c)\boldsymbol{\rho}\rangle + \frac{1}{2}\langle \boldsymbol{\rho}, f'(\boldsymbol{\phi}_c)\boldsymbol{\rho}\rangle + \int_{\mathbb{R}} g(\boldsymbol{\phi}_c, \boldsymbol{\rho})\boldsymbol{\rho}^3\,dx, \end{aligned} \tag{4.5}$$

where

$$g(\boldsymbol{\phi}_c, \boldsymbol{\rho}) = \frac{1}{2}\int_0^1 (1-s)^2 f''(\boldsymbol{\phi}_c + s\boldsymbol{\rho})\,ds. \tag{4.6}$$

For the second term in (4.5), there is the following bound from below:

$$\frac{1}{2}\int_{\mathbb{R}} \left((\partial_x\boldsymbol{\rho})^2 + c\boldsymbol{\rho}^2\right)dx \geq m\|\boldsymbol{\rho}\|_{H^1}^2, \qquad m = \frac{1}{2}\min(1, c_\star) > 0. \tag{4.7}$$

The bound for the third term in the right-hand side of (4.5) follows from the inequalities

$$\int_{\mathbb{R}} |f'(\boldsymbol{\phi}_c)|\boldsymbol{\rho}^2\,dx \leq \|e^{-2\mu x} f'(\boldsymbol{\phi}_c)\|_{L^\infty}\|\boldsymbol{\rho}\|_{L^2_\mu}^2 \leq b\left[|\zeta|\|\boldsymbol{e}_{3,c}\|_{L^2_\mu} + \|\boldsymbol{v}(t)\|_{L^2_\mu}\right]^2, \tag{4.8}$$

where $b = \sup_{c\in[c_\star, c_\star+\eta_1]}\|e^{-2\mu x} f'(\boldsymbol{\phi}_c)\|_{L^\infty} < \infty$ due to (2.10), the assumption (1.2) that $f'(0) = 0$, and due to Lemma A.1 from Appendix A. We bound the last term in (4.5) by

$$\int_{\mathbb{R}} |g(\boldsymbol{\phi}_c, \boldsymbol{\rho})\boldsymbol{\rho}^3|\,dx \leq \|g(\boldsymbol{\phi}_c, \boldsymbol{\rho})\|_{L^\infty}\|\boldsymbol{\rho}\|_{H^1}^3 \leq \delta_1\|g(\boldsymbol{\phi}_c, \boldsymbol{\rho})\|_{L^\infty}\|\boldsymbol{\rho}\|_{H^1}^2. \tag{4.9}$$

According to (4.1), g from (4.6) satisfies $\delta_1\|g(\boldsymbol{\phi}_c, \boldsymbol{\rho})\|_{L^\infty} < \frac{\min(1,c_\star)}{4} = \frac{m}{2}$, and this leads to

$$\int_{\mathbb{R}} |g(\boldsymbol{\phi}_c, \boldsymbol{\rho})\boldsymbol{\rho}^3|\,dx \leq \frac{m}{2}\|\boldsymbol{\rho}\|_{H^1}^2. \tag{4.10}$$

Combining (4.5) with the bounds (4.7), (4.8), and (4.10), we obtain

$$\frac{m}{2}\|\boldsymbol{\rho}\|_{H^1}^2 \leq |\mathscr{L}_c(\boldsymbol{u}) - \mathscr{L}_c(\boldsymbol{\phi}_c)| + \frac{b}{2}\left[|\zeta|\|\boldsymbol{e}_{3,c}\|_{L^2_\mu} + \|\boldsymbol{v}\|_{H^1_\mu}\right]^2,$$

so that, for some $C > 0$,

$$\|\boldsymbol{\rho}\|_{H^1} \leq C\left[|\mathscr{L}_c(\boldsymbol{u}) - \mathscr{L}_c(\boldsymbol{\phi}_c)|^{1/2} + |\zeta| + \|\boldsymbol{v}\|_{H^1_\mu}\right]. \tag{4.11}$$

Now let us estimate $|\mathscr{L}_c(\boldsymbol{u}(t)) - \mathscr{L}_c(\boldsymbol{\phi}_c)|$. Note that $\mathscr{L}_c(\boldsymbol{u}(t)) = \mathscr{L}_c(\boldsymbol{u}_0)$ since the value of the energy functional E given by (1.5) and the value of the momentum functional $\mathscr{N}$ given by (1.7) are conserved along the trajectories of (1.1). Thus, we can write

$$|\mathscr{L}_c(\boldsymbol{u}(t)) - \mathscr{L}_c(\boldsymbol{\phi}_c)| \le |\mathscr{L}_c(\boldsymbol{u}_0) - \mathscr{L}_c(\boldsymbol{\phi}_{c_0})| + |\mathscr{L}_c(\boldsymbol{\phi}_c) - \mathscr{L}_c(\boldsymbol{\phi}_{c_0})|. \tag{4.12}$$

Using the definition (4.4) of the functional $\mathscr{L}_c$, we express the first term in the right-hand side of (4.12) as

$$\mathscr{L}_c(\boldsymbol{u}_0) - \mathscr{L}_c(\boldsymbol{\phi}_{c_0}) = \mathscr{L}_{c_0}(\boldsymbol{u}_0) - \mathscr{L}_{c_0}(\boldsymbol{\phi}_{c_0}) + (\eta - \eta_0)(\mathscr{N}(\boldsymbol{u}_0) - \mathscr{N}(\boldsymbol{\phi}_{c_0})). \tag{4.13}$$

Since $\mathscr{L}'_{c_0}(\boldsymbol{\phi}_{c_0}) = 0$, there exists $k > 0$ such that $|\mathscr{L}_{c_0}(\boldsymbol{u}_0) - \mathscr{L}_{c_0}(\boldsymbol{\phi}_{c_0})| \le k\|\boldsymbol{\rho}_0\|^2_{H^1}$, where $\boldsymbol{\rho}_0 = \boldsymbol{u}_0 - \boldsymbol{\phi}_{c_0}$; this allows us to bound (4.13) by

$$|\mathscr{L}_c(\boldsymbol{u}_0) - \mathscr{L}_c(\boldsymbol{\phi}_{c_0})| \le \mathrm{const}(\|\boldsymbol{\rho}_0\|^2_{H^1} + |\eta - \eta_0|\|\boldsymbol{\rho}_0\|_{H^1}). \tag{4.14}$$

For the second term in the right-hand side of (4.12), we have

$$|\mathscr{L}_c(\boldsymbol{\phi}_c) - \mathscr{L}_c(\boldsymbol{\phi}_{c_0})| \le |E_c - E_{c_0}| + c|\mathscr{N}_c - \mathscr{N}_{c_0}|.$$

From the relation

$$\frac{d}{dc}E_c = -c\frac{d}{dc}\mathscr{N}_c$$

we conclude that $|E_c - E_{c_0}| \le \max(c, c_0)|\mathscr{N}_c - \mathscr{N}_{c_0}|$, since $\mathscr{N}_c'$ is sign-definite for $c_\star < c \le c_\star + \eta_1$ by (1.16). Therefore, there is the following bound for the second term in the right-hand side of (4.12):

$$|\mathscr{L}_c(\boldsymbol{\phi}_c) - \mathscr{L}_c(\boldsymbol{\phi}_{c_0})| \le 2\max(c, c_0)|\mathscr{N}_c - \mathscr{N}_{c_0}|. \tag{4.15}$$

Using the bounds (4.14) and (4.15) in (4.12), we obtain

$$|\mathscr{L}_c(\boldsymbol{u}(t)) - \mathscr{L}_c(\boldsymbol{\phi}_c)| \le \mathrm{const}\left(\|\boldsymbol{\rho}_0\|^2_{H^1} + |\eta - \eta_0|\|\boldsymbol{\rho}_0\|_{H^1} + |\mathscr{N}_c - \mathscr{N}_{c_0}|\right).$$

Substituting this result into (4.11), we obtain the bound (4.3). ◻

LEMMA 4.2 (see [PW94]). *Let Assumption* 3 *be satisfied, and pick* $\mu \in (0, \sqrt{c/3})$. *Let* $Q_c^\mu = I - P_c^\mu$, *where* P_c^μ *introduced in* (2.20) *is the spectral projection that corresponds to the discrete spectrum of* A_c^μ *(see Remark* 2.6*). Then* A_c^μ *is the generator of a strongly continuous linear semigroup on* $H^s(\mathbb{R})$ *for any real* s, *and there exist constants* $a > 0$ *and* $b > 0$ *such that for all* $\boldsymbol{v} \in L^2(\mathbb{R})$ *and* $t > 0$ *the following estimate is satisfied:*

$$\|e^{A_c^\mu t} Q_c^\mu \boldsymbol{v}\|_{H^1} \le a t^{-1/2} e^{-bt} \|\boldsymbol{v}\|_{L^2}. \tag{4.16}$$

We require that η_1 be small enough, so that

$$\eta_1 \sup_{c \in [c_\star, c_\star + \eta_1]} \|\partial_c Q_c^\mu\|_{H^1 \to H^1} \le \frac{1}{2}. \tag{4.17}$$

LEMMA 4.3. *There exists* $C_2 > 0$ *such that if*

$$\eta_1 + \zeta_1 + \delta_1 < C_2 \tag{4.18}$$

and

$$\sup_{s\in[0,t]}|\eta(s)|\le\eta_1,\quad \sup_{s\in[0,t]}|\zeta(s)|\le\zeta_1,\quad \sup_{s\in[0,t]}\|\boldsymbol{\rho}(s)\|_{H^1}\le\delta_1,\quad \sup_{s\in[0,t]}\|\boldsymbol{v}(s)\|_{H^1_\mu}\le\delta_1, \tag{4.19}$$

then

$$\|\boldsymbol{v}(t)\|_{H^1_\mu}\le C_2\sup_{s\in[0,t]}\left[\zeta^2(s)+|\zeta(s)|\|\boldsymbol{\rho}(s)\|_{H^1}\right]. \tag{4.20}$$

Proof. Using the center manifold reduction (3.23), we rewrite the evolution equation (3.18) in the following form:

$$\dot{\boldsymbol{v}}-J\mathcal{H}_c\boldsymbol{v}=-\sum_{j=1}^{3}R_j\boldsymbol{e}_{j,c}-\zeta(\zeta+R_2)\partial_c\boldsymbol{e}_{3,c}+R_1\partial_x(\zeta\boldsymbol{e}_{3,c}+\boldsymbol{v})+J\boldsymbol{N}, \tag{4.21}$$

where $c=c(t)=c_\star+\eta(t)$, $\zeta=\zeta(t)$, and the nonlinear terms $R_j(t)$ are given by (3.24). We set

$$\boldsymbol{\omega}(x,t)=e^{\mu x}\boldsymbol{v}(x,t),\qquad \boldsymbol{e}^\mu_{j,c}(x)=e^{\mu x}\boldsymbol{e}_{j,c}(x),\qquad c\in[c_\star,c_\star+\eta_1],\quad j=1,2,3,$$

and consider A^μ_c given by (1.13). Equation (4.21) takes the following form:

$$\dot{\boldsymbol{\omega}}-A^\mu_c\boldsymbol{\omega}=\boldsymbol{G}, \tag{4.22}$$

where

$$\boldsymbol{G}(x,t)=-\sum_{j=1}^{3}R_j\boldsymbol{e}^\mu_{j,c}-\zeta(\zeta+R_2)\partial_c\boldsymbol{e}^\mu_{3,c}+R_1(\partial_x-\mu)(\zeta\boldsymbol{e}^\mu_{3,c}+\boldsymbol{\omega})+e^{\mu x}J\boldsymbol{N}. \tag{4.23}$$

As follows from (4.22),

$$\partial_t(Q^\mu_{c_\star}\boldsymbol{\omega})=Q^\mu_{c_\star}\dot{\boldsymbol{\omega}}=Q^\mu_{c_\star}\left(A^\mu_c\boldsymbol{\omega}+\boldsymbol{G}\right)=A^\mu_{c_\star}Q^\mu_{c_\star}\boldsymbol{\omega}+Q^\mu_{c_\star}(A^\mu_c-A^\mu_{c_\star})\boldsymbol{\omega}+Q^\mu_{c_\star}\boldsymbol{G}.$$

We may write $Q^\mu_{c_\star}\boldsymbol{\omega}$ as follows:

$$Q^\mu_{c_\star}\boldsymbol{\omega}(t)=\int_0^t e^{A^\mu_{c_\star}(t-s)}\mathfrak{G}(s)\,ds, \tag{4.24}$$

where

$$\mathfrak{G}(x,t)=Q^\mu_{c_\star}(A^\mu_c-A^\mu_{c_\star})\boldsymbol{\omega}(x,t)+Q^\mu_{c_\star}\boldsymbol{G}(x,t). \tag{4.25}$$

Using the dissipative estimate given by (4.16), we get

$$\|Q^\mu_{c_\star}\boldsymbol{\omega}(t)\|_{H^1}\le C\int_0^t(t-s)^{-1/2}e^{-b(t-s)}\|\mathfrak{G}(s)\|_{L^2}\,ds \tag{4.26}$$

$$\le Ce^{-bt/2}\sup_{s\in[0,t]}e^{bs/2}\|\mathfrak{G}(s)\|_{L^2}\int_0^t(t-s)^{-1/2}e^{-b(t-s)/2}\,ds \tag{4.27}$$

$$\le C\sup_{s\in[0,t]}e^{bs/2}\|\mathfrak{G}(s)\|_{L^2}. \tag{4.28}$$

Since $\boldsymbol{\omega} = Q^\mu_c \boldsymbol{\omega} = Q^\mu_{c_\star}\boldsymbol{\omega} + (Q^\mu_c - Q^\mu_{c_\star})\boldsymbol{\omega}$, we have

$$\|\boldsymbol{\omega}\|_{H^1} \le \|Q^\mu_{c_\star}\boldsymbol{\omega}\|_{H^1} + |\eta| \sup_{c\in[c_\star, c_\star+\eta_1]} \|\partial_c Q^\mu_c\|_{H^1\to H^1}\|\boldsymbol{\omega}\|_{H^1} \le \|Q^\mu_{c_\star}\boldsymbol{\omega}\|_{H^1} + \frac{1}{2}\|\boldsymbol{\omega}\|_{H^1},$$

where we used (4.17). It follows that $\|\boldsymbol{\omega}\|_{H^1} \le 2\|Q^\mu_{c_\star}\boldsymbol{\omega}\|_{H^1}$. Hence, we have

$$\|\boldsymbol{\omega}(t)\|_{H^1} \le Ce^{-bt/2} \sup_{s\in[0,t]} e^{bs/2}\|\mathfrak{G}(s)\|_{L^2}. \tag{4.29}$$

We now need the bound on $\|\mathfrak{G}\|_{L^2}$. We start with

$$\|\mathfrak{G}\|_{L^2} \le \|Q^\mu_{c_\star}(A^\mu_c - A^\mu_{c_\star})\boldsymbol{\omega}\|_{L^2} + \|Q^\mu_{c_\star}\boldsymbol{G}\|_{L^2}. \tag{4.30}$$

We estimate the first term in the right-hand side of (4.30) as follows:

$$\|Q^\mu_{c_\star}(A^\mu_c - A^\mu_{c_\star})\boldsymbol{\omega}(t)\|_{L^2} \le \|Q^\mu_{c_\star}(A^\mu_c - A^\mu_{c_\star})\|_{H^1\text{-}L^2}\|\boldsymbol{\omega}(t)\|_{H^1} \le C|\eta|\|\boldsymbol{\omega}(t)\|_{H^1}. \tag{4.31}$$

Since $\boldsymbol{e}^\mu_{j,c}$, $1\le j\le 3$, depend continuously on c while $Q^\mu_{c_\star}\boldsymbol{e}^\mu_{j,c_\star} = 0$, there are bounds $\|Q^\mu_{c_\star}\boldsymbol{e}^\mu_{j,c}\|_{H^1} \le C|\eta|$. This allows us to derive the following bound for the second term in the right-hand side of (4.30):

$$\begin{aligned}\|Q^\mu_{c_\star}\boldsymbol{G}\|_{L^2} &\le C\left(|\eta| \sup_{1\le j\le 3}|R_j| + |\zeta||\zeta+R_2| + |R_1|(|\zeta| + \|\boldsymbol{\omega}\|_{H^1}) + \|J\boldsymbol{N}\|_{L^2_\mu}\right)\\ &\le C\left(\zeta^2 + (|\eta| + |\zeta| + \|\boldsymbol{\omega}\|_{H^1})\sup_{1\le j\le 3}|R_j| + \|J\boldsymbol{N}\|_{L^2_\mu}\right).\end{aligned}$$

Using the representation (3.24) and the inclusions $\partial_c\boldsymbol{e}_{3,c} \in H^\infty_\mu(\mathbb{R})$, $\boldsymbol{g}_i \in H^\infty_{-\mu}(\mathbb{R})$, $\partial_c\boldsymbol{g}_i \in H^\infty_{-\mu}(\mathbb{R})$, we obtain the following estimates on R_j:

$$|R_j(\eta,\zeta,\boldsymbol{v})| \le C\left(\zeta^2 + |\zeta|\|\boldsymbol{v}\|_{H^1_\mu} + \|J\boldsymbol{N}\|_{L^2_\mu}\right), \qquad j = 1,2,3. \tag{4.32}$$

Taking into account (4.32), we get

$$\begin{aligned}\|Q^\mu_{c_\star}\boldsymbol{G}\|_{L^2_\mu} &\le C\left(\zeta^2 + (|\eta| + |\zeta| + \|\boldsymbol{\omega}\|_{H^1})(\zeta^2 + |\zeta|\|\boldsymbol{\omega}\|_{H^1} + \|J\boldsymbol{N}\|_{L^2_\mu}) + \|J\boldsymbol{N}\|_{L^2_\mu}\right)\\ &\le C\left(\zeta^2 + (|\eta| + \|\boldsymbol{\omega}\|_{H^1})|\zeta|\|\boldsymbol{\omega}\|_{H^1} + \|J\boldsymbol{N}\|_{L^2_\mu}\right).\end{aligned} \tag{4.33}$$

In the last inequality, we used the uniform boundedness of $|\eta|$, $|\zeta|$, and $\|\boldsymbol{\omega}\|_{H^1}$ that follows from (4.19).

Summing up (4.31) and (4.33), we obtain the following bound on $\|\mathfrak{G}\|_{L^2_\mu}$:

$$\|\mathfrak{G}\|_{L^2_\mu} \le C\left[\zeta^2 + (|\eta| + |\zeta|)\|\boldsymbol{\omega}\|_{H^1} + \|J\boldsymbol{N}\|_{L^2_\mu}\right]. \tag{4.34}$$

Using the integral representation for the nonlinearity (3.8),

$$J\boldsymbol{N} = \partial_x[f(\boldsymbol{\phi}_c + \boldsymbol{\rho}) - f(\boldsymbol{\phi}_c) - f'(\boldsymbol{\phi}_c)\boldsymbol{\rho}] = \partial_x\left[\frac{\boldsymbol{\rho}^2}{2}\int_0^1 (1-s)^2 f''(\boldsymbol{\phi}_c + s\boldsymbol{\rho})\,ds\right], \tag{4.35}$$

we obtain the bound

$$\|J\boldsymbol{N}\|_{L^2_\mu} \le C\|\boldsymbol{\rho}\|_{H^1_\mu}\|\boldsymbol{\rho}\|_{H^1} \le C\left(|\zeta|\|\boldsymbol{e}_{3,c}\|_{H^1_\mu} + \|\boldsymbol{v}\|_{H^1_\mu}\right)\|\boldsymbol{\rho}\|_{H^1},$$

with the constant C that depends on $\|\boldsymbol{\phi}_c\|_{H^1}$ and on the bounds on $f''(z)$ and $f'''(z)$ for $|z| \leq \|\boldsymbol{u}\|_{L^\infty}$, which is bounded by $2\|\boldsymbol{\phi}_{c_\star}\|_{H^1}$. This bound allows us to rewrite (4.34) as

(4.36)
$$\|\mathfrak{G}\|_{L^2_\mu} \leq C\left[\zeta^2 + (|\eta| + |\zeta| + \|\boldsymbol{\rho}\|_{H^1})\|\boldsymbol{\omega}\|_{H^1} + |\zeta|\|\boldsymbol{\rho}\|_{H^1}\right] \leq C\left[g_0 + g_1\|\boldsymbol{\omega}\|_{H^1}\right],$$

where

$$g_0(t) = \zeta^2(t) + |\zeta(t)|\|\boldsymbol{\rho}(t)\|_{H^1}, \qquad g_1(t) = |\eta(t)| + |\zeta(t)| + \|\boldsymbol{\rho}(t)\|_{H^1}. \tag{4.37}$$

Thus, (4.29) could be written as

$$2e^{bt/2}\|\boldsymbol{\omega}(t)\|_{H^1} \leq C_2 \sup_{s\in[0,t]} e^{bs/2}\left[g_0(s) + g_1(s)\|\boldsymbol{\omega}(s)\|_{H^1}\right] \tag{4.38}$$

for some $C_2 > 0$. Since the right-hand side is monotonically increasing with t, we also have

$$\sup_{s\in[0,t]} 2e^{bs/2}\|\boldsymbol{\omega}(s)\|_{H^1} \leq C_2 \sup_{s\in[0,t]} e^{bs/2}\left[g_0(s) + g_1(s)\|\boldsymbol{\omega}(s)\|_{H^1}\right]. \tag{4.39}$$

The function g_1 from (4.37) satisfies $C_2 \sup_{s\in[0,t]} g_1(s) < 1$ (this follows from the assumptions (4.18) and (4.19)), and therefore

$$\|\boldsymbol{\omega}(t)\|_{H^1} \leq C_2 e^{-bt/2} \sup_{s\in[0,t]} e^{bs/2} g_0(s) \leq C_2 \sup_{s\in[0,t]} \left[\zeta^2(s) + |\zeta(s)|\|\boldsymbol{\rho}(s)\|_{H^1}\right].$$

Since $\boldsymbol{\omega} = e^{\mu x}\boldsymbol{v}$, the last inequality yields (4.20). ◻

5. Nonlinear estimates. Now we close the estimates using the bounds on $\|\boldsymbol{\rho}\|_{H^1}$ (Lemma 4.1) and on $\|\boldsymbol{v}\|_{H^1_\mu}$ (Lemma 4.3) from the previous section.

We assume that $\eta_1 > 0$, $\zeta_1 > 0$, and $\delta_1 > 0$ are sufficiently small: not larger than in Proposition 3.2, satisfy the bounds (4.1), (4.17), and (4.18), and also that ζ_1 satisfies

$$\zeta_1 < \frac{1}{3\max(1, C_1)C_2}. \tag{5.1}$$

Define

$$C_3 = 2C_1, \qquad C_4 = 2C_2\max(1, C_3), \tag{5.2}$$

with C_1 and C_2 as in Lemmas 4.1 and 4.3. Choosing smaller values of η_1 and ζ_1 if necessary, we may assume that

$$C_3\left(\zeta_1 + 2\eta_1 + (\mathscr{N}_{c_\star+\eta_1} - \mathscr{N}_{c_\star})^{1/2}\right) < \delta_1, \tag{5.3}$$

$$C_4\left(\zeta_1^2 + 2\eta_1\zeta_1 + \zeta_1(\mathscr{N}_{c_\star+\eta_1} - \mathscr{N}_{c_\star})^{1/2}\right) < \delta_1. \tag{5.4}$$

Define

$$\eta_M(t) = \sup_{0\leq s\leq t} \eta(s), \tag{5.5}$$

$$\zeta_M(t) = \sup_{0\leq s\leq t} |\zeta(s)|. \tag{5.6}$$

PROPOSITION 5.1. *Assume that the initial data $\eta_0 > 0$ and ζ_0 are such that the following inequalities are satisfied:*

$$\eta_0 \in (0, \eta_1), \qquad |\zeta_0| < \zeta_1, \qquad \|\boldsymbol{\rho}_0\|_{H^1} < \min(\eta_1, \delta_1). \tag{5.7}$$

Then for $0 \le t < T_1$ the functions $\boldsymbol{\rho}(t)$, $\boldsymbol{v}(t)$ satisfy the bounds

$$\|\boldsymbol{\rho}(t)\|_{H^1} \le C_3 \left[\zeta_M(t) + \mathscr{Y}(\eta_M(t))\right], \tag{5.8}$$

$$\|\boldsymbol{v}(t)\|_{H^1_\mu} \le C_4 \left[\zeta_M(t)^2 + \zeta_M(t)\mathscr{Y}(\eta_M(t))\right], \tag{5.9}$$

where C_3, C_4 are defined by (5.2), *$\mathscr{Y}(\eta) = \|\boldsymbol{\rho}_0\|_{H^1} + \|\boldsymbol{\rho}_0\|_{H^1}^{1/2}|\eta - \eta_0|^{1/2} + |\mathscr{N}_{c_\star+\eta} - \mathscr{N}_{c_\star+\eta_0}|^{1/2}$ is introduced in* (4.2), *and η_M, ζ_M are defined in* (5.5) *and* (5.6).

Proof. Let

$$S = \{t \in [0, T_1)\colon \|\boldsymbol{\rho}(t)\|_{H^1} < \delta_1\}.$$

S is nonempty since $\|\boldsymbol{\rho}(0)\|_{H^1} < \delta_1$ by (5.7). According to Proposition 3.2 and representation (3.6), $\|\boldsymbol{\rho}(t)\|_{H^1}$ is a continuous function of t. Since the inequality in the definition of S is sharp, S is an open subset of $[0, T_1)$. Let us assume that $T_2 \in (0, T_1)$ is such that

$$\|\boldsymbol{\rho}(t)\|_{H^1} < \delta_1, \qquad 0 \le t < T_2. \tag{5.10}$$

It is enough to prove that $T_2 \in S$ (then the connected subset of S that contains $t = 0$ is both open and closed in $[0, T_1)$ and hence coincides with $[0, T_1)$). Since $\|\boldsymbol{v}(t)\|_{H^1_\mu} < \delta_1$ for $0 \le t < T_1$, Lemmas 4.1 and 4.3 are both applicable for $t \le T_2$. The estimate (4.3) on $\|\boldsymbol{\rho}(t)\|_{H^1}$ together with the estimate (4.20) on $\|\boldsymbol{v}(t)\|_{H^1_\mu}$ give

$$\begin{aligned}\|\boldsymbol{\rho}(t)\|_{H^1} &\le C_1\Big(\mathscr{Y}(\eta(t)) + |\zeta(t)| + \|\boldsymbol{v}(t)\|_{H^1_\mu}\Big)\\ &\le C_1\Big(\mathscr{Y}(t) + |\zeta(t)| + C_2 \sup_{s\in[0,t]}\left[\zeta^2 + |\zeta|\|\boldsymbol{\rho}\|_{H^1}\right]\Big).\end{aligned}$$

For $0 \le t \le T_2$, define $M(t) = \sup_{s\in[0,t]} \|\boldsymbol{\rho}(s)\|_{H^1}$. We have

$$M(t) \le C_1\Big(\sup_{s\in[0,t]}(\mathscr{Y}(\eta(s)) + |\zeta(s)|) + C_2 \sup_{s\in[0,t]}\left[\zeta^2(s) + |\zeta(s)|M(t)\right]\Big).$$

We carry the term $C_1C_2|\zeta|M(t)$ to the left-hand side of the inequality, taking into account that $C_1C_2|\zeta(t)| \le C_1C_2\zeta_1 \le \frac{1}{3}$ for all $0 \le t < T_1$ by (5.1). This results in the following relation:

$$\|\boldsymbol{\rho}(t)\|_{H^1} \le M(t) \le \frac{3}{2}C_1\Big(\sup_{s\in[0,t]}(\mathscr{Y}(\eta(s)) + |\zeta(s)|) + C_2\sup_{s\in[0,t]}\zeta^2(s)\Big).$$

Since $C_2\zeta^2 \le C_2\zeta_1|\zeta| \le |\zeta|/3$ by (5.1), we obtain

$$\|\boldsymbol{\rho}(t)\|_{H^1} \le \frac{3}{2}C_1 \sup_{s\in[0,t]}\left(\mathscr{Y}(\eta(s)) + \frac{4}{3}|\zeta(s)|\right) \le C_3 \sup_{s\in[0,t]}\left(\mathscr{Y}(\eta(s)) + |\zeta(s)|\right), \quad t \in [0, T_2],$$

with $C_3 = 2C_1$. This proves (5.8) for $t \in [0, T_2]$. It then follows that

$$\|\boldsymbol{\rho}(T_2)\|_{H^1} \le C_3\left[\zeta_1 + \mathscr{Y}(\eta_1)\right] \le C_3\left[\zeta_1 + 2\eta_1 + \left(\mathscr{N}_{c_\star+\eta_1} - \mathscr{N}_{c_\star}\right)^{1/2}\right] < \delta_1,$$

where we took into account the definition of $\mathscr{Y}(\eta)$ in (4.2), the bound $\|\boldsymbol{\rho}_0\|_{H^1} < \eta_1$ from (5.7), and inequality (5.3). Hence, $T_2 \in S$. It follows that S coincides with $[0, T_1)$.

Using the bound (5.8) in (4.20) and recalling the definition of C_4 in (5.2), we derive the bound (5.9) on $\|\boldsymbol{v}(t)\|_{H^1_\mu}$. ◻

COROLLARY 5.2. *Assume that the conditions of Proposition* 5.1 *are satisfied. If* $\eta_1 > 0$ *and* $\zeta_1 > 0$ *were chosen sufficiently small, then there exists a constant* $C_5 > 0$ *so that for* $0 \le t < T_1$ *the function* $\boldsymbol{v}(t)$ *satisfies the bound*

$$\|\boldsymbol{v}(t)\|_{H^1_{\mu/2}} \le C_5 \left[\zeta_M^2(t) + \zeta_M(t)\mathscr{Y}(\eta_M(t))\right], \tag{5.11}$$

where η_M, ζ_M *are defined in* (5.5), (5.6).

Proof. The bound (5.11) is proved in the same way as (5.9). We may need to take smaller values of η_1 and ζ_1 so that Lemmas 4.1 and 4.3 become applicable for the new exponential weight. Note that the exponential weight does not enter the definition (4.2) of the function $\mathscr{Y}(\eta)$. ◻

LEMMA 5.3. *Assume that the bounds* (5.9) *and* (5.11) *are satisfied for* $0 \le t < T_1$. *Then there exists* $C_6 > 0$ *so that the terms* R_2 *and* R_3 *defined in* (3.24) *satisfy for* $0 \le t < T_1$ *the bounds*

$$|R_j(\eta, \zeta, \boldsymbol{v})| \le C_6 \zeta_M^2, \qquad j = 2, 3. \tag{5.12}$$

Proof. By (4.32),

$$|R_j(\eta, \zeta, \boldsymbol{v})| \le C\left(\zeta^2 + |\zeta|\|\boldsymbol{v}\|_{H^1_\mu} + \|J\boldsymbol{N}\|_{L^2_\mu}\right), \qquad j = 2, 3. \tag{5.13}$$

According to (5.9), the second term in the right-hand side of (5.13) is bounded by $C\zeta^2$ as long as $\eta \in (0, \eta_1)$ and $|\zeta| \le \zeta_1$. We now need a bound on $\|J\boldsymbol{N}\|_{L^2_\mu}$. Using the representation (4.35) for the nonlinearity, we obtain the bounds

$$\|J\boldsymbol{N}\|_{L^2_\mu} \le C\|\boldsymbol{\rho}\|^2_{H^1_{\mu/2}} \le C\left(\zeta^2\|\boldsymbol{e}_{3,c}\|^2_{H^1_{\mu/2}} + \|\boldsymbol{v}\|^2_{H^1_{\mu/2}}\right). \tag{5.14}$$

The constant depends on $\|\boldsymbol{\phi}_c\|_{H^1}$ and on the bounds on $f''(z)$ and $f'''(z)$ for $|z| \le \|\boldsymbol{u}\|_{L^\infty}$, which is bounded by $2\|\boldsymbol{\phi}_{c_\star}\|_{H^1}$. As follows from (5.11),

$$\|\boldsymbol{v}(t)\|_{H^1_{\mu/2}} \le C_5(\zeta_1 + \mathscr{Y}(\eta_1))\zeta_M(t). \tag{5.15}$$

Using this bound in (5.14), we get $\|J\boldsymbol{N}\|_{L^2_\mu} \le C\zeta_M^2$. The bound (5.12) follows. ◻

6. Choosing the initial perturbation. In this section, we show how to choose the initial perturbation that indeed leads to the instability and conclude the proof of Theorem 1.

We choose $\eta_1 > 0$, $\zeta_1 > 0$, and $\delta_1 > 0$ small enough so that (4.1), (4.17), (4.18) are satisfied, and so that Lemmas 4.1 and 4.3 apply to both exponential weights μ and $\mu/2$. Taking $\eta_1 > 0$, $\zeta_1 > 0$ smaller if necessary, we may assume that the conditions (5.1), (5.3), and (5.4) are satisfied, and moreover that

$$C_6 \zeta_1 < 1/2, \tag{6.1}$$

where $C_6 > 0$ is from Lemma 5.3.

Let

$$\lambda(\eta)=\lambda_{c_\star+\eta},\qquad \Lambda(\eta)=\int_0^\eta \lambda(\eta')\,d\eta'. \tag{6.2}$$

Let us recall that, according to (1.16), we assume that there exists $\eta_1>0$ so that $\mathscr{N}_c'<0$ and is nonincreasing for $c_\star<c\le c_\star+\eta_1$. Thus, we assume that $\lambda(\eta)>0$ for $0<\eta\le\eta_1$ (according to (2.16), $\mathscr{N}_c'$ and λ_c are of opposite sign).

LEMMA 6.1. *One can choose $\eta_1>0$ sufficiently small so that for $0<\eta\le\eta_1$ one has*

$$3C_6e^{2C_6\eta}\Lambda(\eta)<\lambda(\eta). \tag{6.3}$$

Proof. By (2.16), $\lambda_c=-\frac{\mathrm{N}_c'}{B_c}$, where

$$B_c=\langle\boldsymbol{\phi}_c,\boldsymbol{e}_{3,c}\rangle. \tag{6.4}$$

Since $B_{c_\star}>0$ by (2.9), we may assume that $\eta_1>0$ is small enough so that

$$B_{c_\star}/2\le B_c\le 2B_{c_\star},\qquad c\in[c_\star,c_\star+\eta_1]. \tag{6.5}$$

According to Theorem 1, $\mathscr{N}_c'<0$ and is nonincreasing for $c\in(c_\star,c_\star+\eta_1)$. Therefore, using inequalities (6.5), we obtain

$$\Lambda(\eta)=\int_{c_\star}^{c_\star+\eta}\lambda_c\,dc=\int_{c_\star}^{c_\star+\eta}\frac{-\mathscr{N}_c'}{B_c}\,dc\le-\frac{2\eta\mathscr{N}_{c_\star+\eta}'}{B_{c_\star}}\le 4\eta\lambda(\eta),\qquad 0\le\eta\le\eta_1,$$

where $\lambda(\eta)>0$ for $0<\eta\le\eta_1$. We take $\eta_1>0$ so small that $12\,\eta_1C_6e^{2C_6\eta_1}<1$; then (6.3) is satisfied. □

Taking $\eta_1>0$ smaller if necessary, we may assume that Lemma C.1 is satisfied and that

$$\lambda(\eta)/C_6<\zeta_1. \tag{6.6}$$

Remark 6.2. Inequality (6.6) ensures that $\eta(t)$ reaches η_1 prior to $\zeta(t)$ reaching ζ_1 (see Lemma 6.4 and Figure 3).

Since $\Lambda(\eta)=\mathrm{o}(\eta)$, we may also assume that $\eta_1>0$ is small enough so that

$$K_1\Lambda(\eta_1)\le\kappa\eta_1/2, \tag{6.7}$$

where $K_1=K_1(\eta_1,\zeta_1)$ is defined below in (6.26) and $\kappa>0$ is from Lemma C.1.

LEMMA 6.3. *For any $\delta\in(0,\min(\eta_1,\delta_1))$, one can choose the initial data $\eta_0\in(0,\eta_1)$, $\zeta_0\in(0,\zeta_1)$ so that the following estimates are satisfied:*

$$\|\zeta_0\boldsymbol{e}_{3,c_\star+\eta_0}\|_{H^1}<\min(\eta_1,\delta_1), \tag{6.8}$$

$$\|(\boldsymbol{\phi}_{c_\star+\eta_0}+\zeta_0\boldsymbol{e}_{3,c_\star+\eta_0})-\boldsymbol{\phi}_{c_\star}\|_{H^1\cap H^1_\mu}<\delta<\min(\eta_1,\delta_1), \tag{6.9}$$

$$\zeta_0<\Lambda(\eta_0). \tag{6.10}$$

Proof. Pick $\eta_0\in(0,\eta_1)$ so that

$$\|\boldsymbol{\phi}_{c_\star+\eta_0}-\boldsymbol{\phi}_{c_\star}\|_{H^1\cap H^1_\mu}<\delta/2. \tag{6.11}$$

For given $\eta_0 > 0$, we take $\zeta_0 \in (0, \zeta_1)$ small enough so that

$$\zeta_0 \|\boldsymbol{e}_{3,c_\star+\eta_0}\|_{H^1 \cap H^1_\mu} < \delta/2. \tag{6.12}$$

Note that $\|\boldsymbol{e}_{3,c_\star+\eta_0}\|_{H^1}$ for $\eta_0 > 0$ is finite by Lemma 2.7. Inequality (6.12) implies that (6.8) is satisfied. Together with (6.11), it also guarantees that (6.9) holds. We then require that $\zeta_0 > 0$ be small enough so that (6.10) takes place. ∎

We rewrite the last two equations from the system (3.23):

$$\begin{cases} \dot\eta = \zeta + R_2(\eta, \zeta, \boldsymbol{v}), \\ \dot\zeta = \lambda(\eta)\zeta + R_3(\eta, \zeta, \boldsymbol{v}). \end{cases} \tag{6.13}$$

LEMMA 6.4. *For $0 \le t < T_1$, with $T_1 > 0$ as in Proposition 3.2,*

$$\dot\eta \ge \zeta_0/2, \qquad \dot\zeta \ge 0, \tag{6.14}$$

$$\zeta_0 \le \zeta(t) < 3e^{2C_6\eta(t)}\Lambda(\eta(t)). \tag{6.15}$$

Proof. According to Proposition 3.2, the trajectory $(\eta(t), \zeta(t))$ that starts at (η_0, ζ_0) satisfies the inequalities $\eta(t) < \eta_1$ and $\zeta(t) < \zeta_1$ for $0 \le t < T_1$. We define the region $\Omega \subset \mathbb{R}_+ \times \mathbb{R}_+$ by

$$\Omega = \{(\eta, \zeta)\colon \zeta_0 \le \zeta \le \lambda(\eta)/C_6,\ \eta_0 \le \eta \le \eta_1\}. \tag{6.16}$$

Define $T_\Omega \in \mathbb{R}_+ \cup \{+\infty\}$ by

$$T_\Omega = \sup\{\, t \in [0, T_1)\colon\ (\eta(t), \zeta(t)) \in \Omega, \quad \dot\zeta(t) \ge 0\,\}. \tag{6.17}$$

Let us argue that $T_\Omega > 0$. At $t = 0$, $(\eta(0), \zeta(0)) = (\eta_0, \zeta_0) \in \Omega$. From (6.13), we compute $\dot\eta(0) \ge \zeta_0 - C_6\zeta_0^2 > 0$, where we applied the bounds (5.12) and the inequality $C_6\zeta_0 < 1/2$ that follows from (6.1) and the choice $\zeta_0 < \zeta_1$. Similarly, $\dot\zeta(0) \ge \lambda(\eta_0)\zeta_0 - C_6\zeta_0^2 > 0$ due to the inequality $C_6\zeta_0 < \lambda(\eta_0)$ that follows from (6.10) and (6.3). Therefore, $(\eta(t), \zeta(t)) \in \Omega$ and $\dot\zeta(t) > 0$ for times $t > 0$ from a certain open neighborhood of $t = 0$, proving that $T_\Omega > 0$.

The monotonicity of $\zeta(t)$ for $t < T_\Omega$ implies that $\zeta_M(t) := \sup_{s\in(0,t)} |\zeta(s)| = \zeta(t)$ for $0 \le t < T_\Omega$, and (5.12) takes the form

$$|R_j(\eta, \zeta, \boldsymbol{v})| \le C_6\zeta^2, \qquad j = 2, 3, \qquad 0 \le t < T_\Omega. \tag{6.18}$$

Using (6.13) and (6.18), and taking into account (6.1) and monotonicity of $\zeta(t)$ for $0 \le t < T_\Omega$, we compute

$$\dot\eta(t) = \zeta(t) + R_2 \ge \zeta(t) - C_6\zeta^2(t) = \zeta(t)(1 - C_6\zeta(t)) > \zeta_0/2, \tag{6.19}$$

which is valid for $0 \le t < T_\Omega$. This allows us to consider ζ as a function of η (as long as $0 \le t < T_\Omega$). By (6.13), (6.18), and (6.1),

$$\frac{d\zeta}{d\eta} = \frac{\lambda(\eta)\zeta + R_3}{\zeta + R_2} \le \frac{\lambda(\eta)\zeta + C_6\zeta^2}{\zeta - C_6\zeta^2} = \frac{\lambda(\eta) + C_6\zeta}{1 - C_6\zeta} \le 2(\lambda(\eta) + C_6\zeta), \tag{6.20}$$

which is valid for $0 \le t < T_\Omega$. Thus, $\frac{d\zeta}{d\eta} - 2C_6\zeta < 2\lambda(\eta)$ for $0 \le t < T_\Omega$. Multiplying both sides of this relation by $e^{-2C_6\eta}$ and integrating, we get Gronwall's inequality:

$$\int_{\eta_0}^{\eta} \frac{d}{d\eta'}\left(e^{-2C_6\eta'}\zeta(\eta')\right) d\eta' < 2\int_{\eta_0}^{\eta} e^{-2C_6\eta'}\lambda(\eta')\, d\eta' \le 2e^{-2C_6\eta_0}\Lambda(\eta), \tag{6.21}$$

$$\zeta < e^{2C_6\eta}\Big(2e^{-2C_6\eta_0}\Lambda(\eta) + e^{-2C_6\eta_0}\zeta_0\Big) < 3e^{2C_6\eta}\Lambda(\eta), \qquad 0 \le t < T_\Omega. \tag{6.22}$$

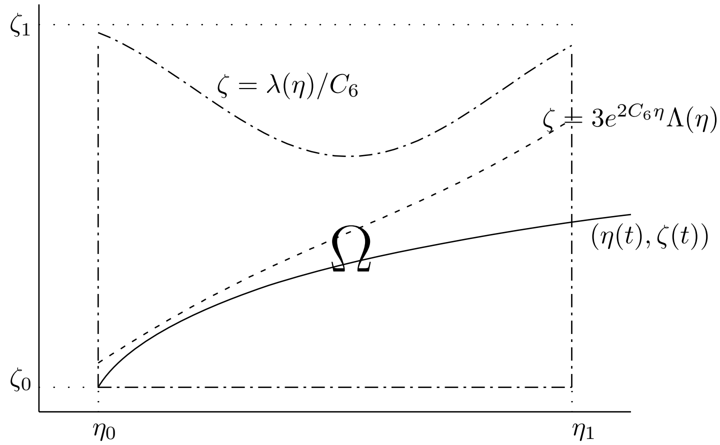

FIG. 3. *The trajectory $(\eta(t), \zeta(t))$ (the solid line) stays in the part of the region Ω below the dashed line $\zeta = 3e^{2C_6\eta}\Lambda(\eta)$.*

See Figure 3. We used the inequality $\zeta_0 < \Lambda(\eta_0) \le \Lambda(\eta)$ that follows from (6.10) and monotonicity of $\Lambda(\eta)$.

Now let us argue that $T_\Omega = T_1$. If $T_\Omega = \infty$, we are done; therefore we only need to consider the case $T_\Omega < \infty$. By (6.17), the moment T_Ω is characterized by

$$\text{either} \quad T_\Omega = T_1 \quad \text{or} \quad (\eta(T_\Omega), \zeta(T_\Omega)) \in \partial\Omega \quad \text{or} \quad \dot{\eta}(T_\Omega) = 0, \tag{6.23}$$

or any combination of these three conditions. By continuity, the bound (6.22) is also valid at T_Ω (the last inequality in (6.22) remains strict); therefore,

$$\zeta(T_\Omega) < 3e^{2C_6\eta(T_\Omega)}\Lambda(\eta(T_\Omega)) < \lambda(\eta(T_\Omega))/C_6. \tag{6.24}$$

In the last inequality, we used Lemma 6.1. Inequality (6.24) also leads to

$$\dot{\zeta} = \lambda(\eta)\zeta + R_3 \ge \zeta(\lambda(\eta) - C_6\zeta) > 0, \qquad 0 \le t \le T_\Omega. \tag{6.25}$$

Using (6.24) and (6.25) in (6.23), we conclude that either $T_\Omega = T_1$ or $\eta(T_\Omega) = \eta_1$, and hence again $T_\Omega = T_1$ (by (3.15), $\eta(t) < \eta_1$ for $0 \le t < T_1$). The bounds (6.14) and (6.15) for $0 \le t < T_\Omega = T_1$ follow from (6.19) and (6.22) (note that $\dot{\zeta} \ge 0$ for $0 \le t < T_\Omega = T_1$ by (6.17)). $\square$

LEMMA 6.5. *Assume that $\|\boldsymbol{\rho}_0\|_{H^1} < \eta_1$. There exists $C_7 > 0$ so that*

$$\|\boldsymbol{\rho}(t)\|_{L^2_\mu} \le C_7\Lambda(\eta), \qquad 0 \le t < T_1.$$

Proof. Using the estimate (6.15) from Lemma 6.4 and the estimate (5.9) from Proposition 5.1 (where $\eta_M(t) = \eta(t)$ and $\zeta_M(t) = \zeta(t)$ due to (6.14) and positivity of η_0 and ζ_0), we obtain

$$\|\boldsymbol{\rho}(t)\|_{L^2_\mu} \le |\zeta|\|\boldsymbol{e}_{3,c}\|_{L^2_\mu} + \|\boldsymbol{v}\|_{L^2_\mu} \le |\zeta|\left(\|\boldsymbol{e}_{3,c}\|_{L^2_\mu} + C_4[\zeta + \mathscr{Y}(\eta)]\right).$$

Now the statement of the lemma follows from the bound (6.15). The value of C_7 could be taken equal to $K_1 = K_1(\eta_1, \zeta_1)$, which we define by

$$K_1 = 3e^{2C_6\eta_1}\left(\sup_{c\in[c_\star, c_\star+\eta_1]} \|\boldsymbol{e}_{3,c}\|_{L^2_\mu} + C_4\big[\zeta_1 + \big\{2\eta_1 + |\mathscr{N}_{c_\star+\eta_1} - \mathscr{N}_{c_\star}|^{\frac{1}{2}}\big\}\big]\right). \tag{6.26}$$

Note that the term in the braces dominates $\mathscr{Y}(\eta)$, which was defined in (4.2) (when estimating $\mathscr{Y}(\eta)$, we used the bound $\|\boldsymbol{\rho}_0\|_{H^1} < \eta_1$). ∎

Conclusion of the proof of Theorem 1. In Theorem 1, let us take

$$\epsilon = \min(\kappa\eta_1/2, \|\boldsymbol{\phi}_{c_\star}\|_{H^1}) > 0. \tag{6.27}$$

Pick $\delta > 0$ arbitrarily small. To comply with the requirements of Lemmas 6.3 and 6.5, we may assume that δ is smaller than $\min(\eta_1, \delta_1)$. Fix $\mu \in (0, \min(\mu_0, \mu_1))$, with μ_0 from Assumption 3 and μ_1 as in Lemma C.1. Let η_0 and ζ_0 satisfy all the inequalities in Lemma 6.3; then the conditions (3.11) of Proposition 3.2 are satisfied. Let

$$\boldsymbol{u}_0 = \boldsymbol{\phi}_{c_\star+\eta_0} + \zeta_0 \boldsymbol{e}_{3,c_\star+\eta_0},$$

so that $\boldsymbol{u}_0 \in H^2(\mathbb{R}) \cap L^2_{2\mu}(\mathbb{R})$ by (2.25) and $\|\boldsymbol{u}_0 - \boldsymbol{\phi}_{c_\star}\|_{H^1} < \delta$ by (6.9). Proposition 3.2 states that there exist $T_1 \in \mathbb{R}_+ \cup \{+\infty\}$ and a function $\boldsymbol{u}(t) \in C([0,\infty), H^2(\mathbb{R}) \cap L^2_{2\mu}(\mathbb{R}))$, $\boldsymbol{u}(0) = \boldsymbol{u}_0$, so that for $0 \le t < T_1$ the function $\boldsymbol{u}(t)$ solves (1.1) and all the inequalities (3.15) are satisfied.

LEMMA 6.6. *In Proposition* 3.2*, one can only take $T_1 < \infty$.*

Proof. If we had $T_1 = +\infty$, then $\dot\eta \ge \zeta_0/2$ for $t \in \mathbb{R}_+$ by Lemma 6.4; hence $\eta(t)$ would reach η_1 in finite time, contradicting the bound $\eta(t) < \eta_1$ for $0 \le t < T_1$ from Proposition 3.2 (iii). ∎

Since $T_1 < \infty$, Proposition 3.2 (iv) states that at least one of the inequalities in (3.15) turns into an equality at $t = T_1$. As follows from the bound (5.9) and inequality (5.4), $\|\boldsymbol{v}(T_1)\|_{H^1_\mu} < \delta_1$. Also, by (6.15) (where the bound from above does not have to be strict at T_1),

$$\zeta(T_1) \le 3e^{2C_6\eta_1}\Lambda(\eta(T_1)) \le 3e^{2C_6\eta_1}\Lambda(\eta_1) < \lambda(\eta)/C_6 < \zeta_1. \tag{6.28}$$

We took into account the monotonicity of $\Lambda(\eta)$ and inequalities (6.3) and (6.6). Therefore, either $\|\boldsymbol{u}(T_1)\|_{H^1} = 2\|\boldsymbol{\phi}_{c_\star}\|_{H^1}$ or $\eta(T_1) = \eta_1$ (or both). In the first case,

$$\inf_{s\in\mathbb{R}} \|\boldsymbol{u}(\cdot, T_1) - \boldsymbol{\phi}_{c_\star}(\cdot - s)\|_{H^1} \ge \|\boldsymbol{u}(\cdot, T_1)\|_{H^1} - \|\boldsymbol{\phi}_{c_\star}\|_{H^1} \ge \|\boldsymbol{\phi}_{c_\star}\|_{H^1} \ge \epsilon; \tag{6.29}$$

hence the instability of $\boldsymbol{\phi}_{c_\star}$ follows. We are left to consider the case $\eta(T_1) = \eta_1$. According to (3.6),

$$\begin{aligned}\inf_{s\in\mathbb{R}} \|\boldsymbol{u}(\cdot, t) - \boldsymbol{\phi}_{c_\star}(\cdot - s)\|_{L^2} &\ge \inf_{s\in\mathbb{R}} \|\boldsymbol{u}(\cdot, t) - \boldsymbol{\phi}_{c_\star}(\cdot - s)\|_{L^2(\mathbb{R}, \min(1, e^{\mu x})\,dx)} \\ &\ge \inf_{s\in\mathbb{R}} \|\boldsymbol{\phi}_{c(t)}(\cdot) - \boldsymbol{\phi}_{c_\star}(\cdot - s)\|_{L^2(\mathbb{R}, \min(1, e^{\mu x})\,dx)} - \|\boldsymbol{\rho}(t)\|_{L^2_\mu}.\end{aligned} \tag{6.30}$$

Applying Lemmas C.1 and 6.5 to the two terms in the right-hand side of (6.30), we see that

$$\inf_{s\in\mathbb{R}} \|\boldsymbol{u}(\cdot, t) - \boldsymbol{\phi}_{c_\star}(\cdot - s)\|_{L^2} \ge \kappa\eta - C_7\Lambda(\eta), \qquad 0 \le t < T_1, \quad \kappa > 0. \tag{6.31}$$

Since $C_7\Lambda(\eta_1) \le \kappa\eta_1/2$ by (6.7),

$$\inf_{s\in\mathbb{R}} \|\boldsymbol{u}(\cdot, T_1) - \boldsymbol{\phi}_{c_\star}(\cdot - s)\|_{L^2} \ge \kappa\eta_1/2 \ge \epsilon, \tag{6.32}$$

and again the instability of $\boldsymbol{\phi}_{c_\star}$ follows.

This completes the proof of Theorem 1.

7. Nondegenerate case: Normal form. In this section, we prove that the critical soliton with speed $c_\star$ generally corresponds to the saddle-node bifurcation of two branches of noncritical solitons. We assume for simplicity that $c_\star$ is a nondegenerate critical point of $\mathscr{N}_c$, in the sense that

$$\mathscr{N}'_{c_\star} = 0, \qquad \mathscr{N}''_{c_\star} \neq 0. \tag{7.1}$$

We rewrite the last two equations from system (3.23):

$$\begin{bmatrix} \dot\eta \\ \dot\zeta \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ 0 & \lambda_c \end{bmatrix} \begin{bmatrix} \eta \\ \zeta \end{bmatrix} + \begin{bmatrix} R_2(\eta,\zeta,\boldsymbol{v}) \\ R_3(\eta,\zeta,\boldsymbol{v}) \end{bmatrix}. \tag{7.2}$$

As follows from (2.9) and (2.16),

$$\lambda_c = \lambda_{c_\star+\eta} = \lambda'_{c_\star}\eta + \mathrm{O}(\eta^2), \qquad \lambda'_{c_\star} = -\frac{2\mathscr{N}''_{c_\star}}{(I'_{c_\star})^2}, \tag{7.3}$$

where $\lambda'_{c_\star} \neq 0$ by (7.1). System (7.2) has the nonlinear terms $R_j(\eta,\zeta,\boldsymbol{v})$, $j = 2, 3$, estimated in Lemma 5.3 for monotonically increasing functions $\eta(t)$, $|\zeta(t)|$ on a local existence interval $0 < t < T_1$. It follows from (3.24) that

$$R_2(0,0,0) = R_3(0,0,0) = 0,$$

so that the point $(\eta,\zeta) = (0,0)$ is a critical point of (7.2) when $\boldsymbol{v} = 0$. This critical point corresponds to the critical traveling wave $\boldsymbol{\phi}_{c_\star}(x)$ itself. The following result establishes a local equivalence between system (7.2) and the truncated system $\ddot\eta = \lambda'_{c_\star}\eta\dot\eta$, thus guaranteeing the instability of the critical point $(\eta,\zeta) = (0,0)$.

Proposition 7.1. *Assume that conditions* (7.1) *are satisfied. Consider the subset of trajectories* $(\eta(t),\zeta(t))$ *of system* (7.2) *that lie inside the* ϵ*-neighborhood* $\mathcal{D}_\epsilon \subset \mathbb{R}^2$ *of the origin and satisfy the condition that both functions* $\eta(t)$ *and* $|\zeta(t)|$ *are monotonically increasing. For sufficiently small* $\epsilon > 0$ *this subset of the trajectories is topologically equivalent to a subset of the trajectories of the truncated normal form,*

$$\dot x = \frac{1}{2}\lambda'_{c_\star} x^2 + E_1, \tag{7.4}$$

where E_1 *is constant.*

Proof. Since $\zeta = \dot\eta - R_2(\eta,\zeta,\boldsymbol{v})$, we can rewrite system (7.2) in the equivalent form

$$\frac{d}{dt}\left(\dot\eta - \frac{1}{2}\lambda'_{c_\star}\eta^2 - R_2(\eta,\zeta,\boldsymbol{v})\right) = R(\eta,\zeta,\boldsymbol{v}), \tag{7.5}$$

where

$$R(\eta,\zeta,\boldsymbol{v}) \equiv R_3(\eta,\zeta,\boldsymbol{v}) - \lambda_c R_2(\eta,\zeta,\boldsymbol{v})) + (\lambda_c - \lambda'_{c_\star}\eta)\zeta.$$

It follows from Lemma 5.3 and (7.3) that there exists a constant $C > 0$ such that $|R| \le C(\zeta^2 + \eta^2|\zeta|)$. The integral form of (7.5) is

$$\dot\eta - \frac{1}{2}\lambda'_{c_\star}\eta^2 - E_1 = \tilde R(t), \tag{7.6}$$

where

$$\tilde{R}(t) \equiv R_2(\eta(t), \zeta(t), \boldsymbol{v}(t)) + \int_0^t R(\eta(t'), \zeta(t'), \boldsymbol{v}(t'))\, dt'$$

and E_1 is the constant of integration. Using Lemma 5.3, the bound $|\zeta| \le \dot{\eta} + C_6\zeta^2$, and integration by parts, we obtain that

$$\int_0^t \zeta^2\, dt' \le \eta|\zeta| + C_6 \int_0^t |\zeta|^3\, dt' \le \eta|\zeta| + C_6\eta|\zeta|^2 + C_6^2 \int_0^t |\zeta|^4\, dt' \le \cdots \le \frac{\eta|\zeta|}{1 - C_6|\zeta|}$$

and

$$\int_0^t \eta^2|\zeta|\, dt' \le \frac{\eta^3}{3} + C_6 \int_0^t \eta^2\zeta^2\, dt' \le \cdots \le \frac{\eta^3}{3(1 - C_6|\zeta|)}.$$

Thus, if $|\zeta|$ is sufficiently small, there exists a constant $\tilde{C} > 0$ such that $|\tilde{R}| \le \tilde{C}(\zeta^2 + |\zeta|\eta + \eta^3)$. The topological equivalence of (7.6) with the above estimate on $|\tilde{R}|$ in the disk $(\eta, \zeta) \in \mathcal{D}_\epsilon$ to the truncated normal form (7.4) with sufficiently small E_1 is proved in [Kuz98, Lemma 3.1]. By definition, two systems are said to be topologically equivalent if there exists a homeomorphism between solutions of these systems. We note that this equivalence holds for a family of trajectories which corresponds to monotonically increasing functions $\eta(t)$, $|\zeta(t)|$ in a subset of the small disk near $(\eta, \zeta) = (0, 0)$. □

Corollary 7.2. *The critical point* $(0, 0)$ *of system* (7.2) *is unstable in the sense that there exists* $\epsilon > 0$ *such that for any* $\delta > 0$ *there are* $(\eta(0), \zeta(0)) \in \mathcal{D}_\delta$ *and* $t_* = t_*(\delta, \epsilon) < \infty$ *such that* $(\eta(t_*), \zeta(t_*)) \notin \mathcal{D}_\epsilon$.

Proof. The normal form equation (7.4) shows that the critical point $x = 0$ is semistable at $E_1 = 0$, such that the trajectory with any $x(0) \neq 0$ of the same sign as $\lambda'_{c_\star}$ escapes the local neighborhood of the point $x = 0$ in a local time $t \in [0, T]$. By Proposition 7.1, local dynamics of (7.4) for $x(t)$ is equivalent to local dynamics of (7.2) for (η, ζ). □

Remark 7.3. The truncated normal form (7.4) is rewritten for $c = c_\star + x$:

$$\dot{c} = \frac{1}{2}\lambda'_{c_\star}(c - c_\star)^2 + E_1. \tag{7.7}$$

The normal form (7.7) corresponds to the standard saddle-node bifurcation. It was derived and studied in [PG96] by using the asymptotic multiscale expansion method. When $E = 0$, the critical point $c = c_\star$ is a degenerate saddle point, which is nonlinearly unstable. Assume for definiteness that $\lambda'_{c_\star} > 0$ (which implies that $\mathscr{N}''_{c_\star} < 0$). Then there are no fixed points for $E_1 > 0$ and two fixed points for $E_1 < 0$ in the normal form equation (7.7). Therefore, there exist initial perturbations (with $E_1 > 0$ and any c_0 or with $E_1 = 0$ and $c_0 > c_\star$) which are arbitrarily close to the traveling wave with $c = c_\star$, but the norm $|c - c_\star|$ exceeds some a priori fixed value at $t = t_* > 0$. Two fixed points exist for $E_1 < 0$:

$$c = c_E^\pm = c_\star \pm \sqrt{\frac{E_1}{\mathscr{N}''_{c_\star}}}|I'_{c_\star}|, \tag{7.8}$$

so that $c = c_E^+$ is an unstable saddle point and $c = c_E^-$ is a stable node. The two fixed points correspond to two branches of traveling waves with $\mathscr{N}_c < \mathscr{N}_{\max}$, where

$\mathscr{N}_{\max} = \mathscr{N}(\boldsymbol{\phi}_{c_\star})$. The left branch with $c_E^- < c_\star$ corresponds to $\mathscr{N}'_{c_E^-} > 0$ and the right branch with $c_E^+ > c_\star$ corresponds to $\mathscr{N}'_{c_E^+} < 0$. According to the stability theory for traveling waves [PW92], the left branch is orbitally stable, while the right branch is linearly unstable.

Appendix A. Existence of solitary waves. Let us discuss the existence of standing waves. We assume that f is smooth. Let F denote the primitive of f such that $F(0) = 0$. Thus, by (1.2),

$$F(0) = F'(0) = F''(0) = 0. \tag{A.1}$$

The wave profile $\boldsymbol{\phi}_c$ is to satisfy the equation

$$u'' - cu = f(u), \qquad c > 0.$$

Multiplying the above relation by u' and integrating, and taking into account that we need $\lim_{|x|\to\infty} u(x) = 0$, we get

$$\frac{du(x)}{dx} = \pm\sqrt{cu^2 + 2F(u)}. \tag{A.2}$$

There will be a strictly positive continuous solution exponentially decaying at infinity if there exists $\boldsymbol{\xi}_c > 0$ such that $c\frac{u^2}{2} + F(u) > 0$ for $0 < u < \boldsymbol{\xi}_c$, and also

$$c\frac{\boldsymbol{\xi}_c^2}{2} + F(\boldsymbol{\xi}_c) = 0, \qquad c\boldsymbol{\xi}_c + f(\boldsymbol{\xi}_c) < 0.$$

The last two conditions imply that the map $c \mapsto \boldsymbol{\xi}_c$ is invertible and smooth (as F is). One immediately sees that $\boldsymbol{\phi}_c \in C^\infty(\mathbb{R})$ and, due to the exponential decay at infinity, $\boldsymbol{\phi}_c \in H^\infty(\mathbb{R})$. For each c, the solution $\boldsymbol{\phi}_c$ is unique (up to translations of the origin) and (after a suitable translation of the origin) satisfies the following properties: it is strictly positive, symmetric, and monotonically decreasing (strictly) away from the origin. This result follows from the implicit representation

$$x = \pm\int_{\boldsymbol{\phi}_c}^{\boldsymbol{\xi}_c} \frac{du}{\sqrt{cu^2 + 2F(u)}}. \tag{A.3}$$

See [BL83, section 6] for the exhaustive treatment of this subject.

LEMMA A.1. *There exist positive constants C_1, C_2, C_1', and C_2' such that*

$$C_1 e^{-\sqrt{c}|x|} \le |\boldsymbol{\phi}_c(x)| \le C_2 e^{-\sqrt{c}|x|}, \qquad x \in \mathbb{R}, \tag{A.4}$$

$$C_1' e^{-\sqrt{c}|x|} \le |\partial_x \boldsymbol{\phi}_c(x)| \le C_2' e^{-\sqrt{c}|x|}, \qquad |x| \ge 1. \tag{A.5}$$

Proof. Since $\lim_{|x|\to\infty} \boldsymbol{\phi}_c(x) = 0$, there exists $x_1 > 0$ so that $\frac{|F(\boldsymbol{\phi}_c(x))|}{\boldsymbol{\phi}_c^2(x)} < \frac{c}{4}$ for $|x| \ge x_1$. Then, for $x > x_1$, we get from (A.3)

$$x - x_1 = \int_{\boldsymbol{\phi}_c(x)}^{\boldsymbol{\phi}_c(x_1)} \frac{du}{\sqrt{cu^2 + 2F(u)}}.$$

It follows that

$$\begin{aligned} \int_{\boldsymbol{\phi}_c(x)}^{\boldsymbol{\phi}_c(x_1)} \frac{du}{c^{1/2}u} - \int_{\boldsymbol{\phi}_c(x)}^{\boldsymbol{\phi}_c(x_1)} \frac{|F(u)|}{c^{3/2}u^3}\,du \le x - x_1 \\ \le \int_{\boldsymbol{\phi}_c(x)}^{\boldsymbol{\phi}_c(x_1)} \frac{du}{c^{1/2}u} + \int_{\boldsymbol{\phi}_c(x)}^{\boldsymbol{\phi}_c(x_1)} \frac{|F(u)|}{c^{3/2}u^3}\,du. \end{aligned} \tag{A.6}$$

By (A.1), $|F(u)|/u^3$ is bounded for u small, and we conclude from (A.6) that

$$\ln \boldsymbol{\phi}_c(x) - C_3 \le c^{1/2}(x - x_1) \le \ln \boldsymbol{\phi}_c(x) + C_3, \tag{A.7}$$

where $C_3 = c^{-1} \int_0^{\boldsymbol{\phi}_c(x_1)} |F(u)| u^{-3}\, du$. Inequalities (A.7) immediately prove (A.4). Bounds (A.5) immediately follow from (A.2). □

We also need the following result that gives the rate of decay of $\boldsymbol{e}_{2,c} = \partial_c \boldsymbol{\phi}_c$ and $\boldsymbol{e}_{3,c_\star}$ at infinity.

Lemma A.2. *Let $R \in C^\infty(\mathbb{R})$ satisfy the bound $|R(x)| \le C_1 e^{-\sqrt{c}|x|}$ for $x \ge 0$ for some $c > 0$, $C_1 > 0$. Let $u \in C^\infty(\mathbb{R})$ satisfy*

$$u'' - cu = R, \qquad \lim_{x\to+\infty} u(x) = 0. \tag{A.8}$$

Then there exists $C_2 > 0$ (that depends on c, C_1, and u) such that

$$|u(x)| \le C_2(1 + |x|)e^{-\sqrt{c}|x|}, \qquad x \ge 0. \tag{A.9}$$

Remark A.3. C_2 depends not only on c and C_1 but also on u because the solution to (A.8) is defined up to $\mathrm{const}\, e^{-\sqrt{c}\,x}$.

Proof. First, we notice that if $P \in C^\infty(\mathbb{R})$, $P(x) \ge 0$ for $x \ge 0$, and if $v \in C^\infty(\mathbb{R})$ solves

$$v'' - cv = P(x), \qquad v(0) = 0, \qquad \lim_{x\to+\infty} v(x) = 0, \tag{A.10}$$

then $v(x) \le 0$ for $x \ge 0$. (The existence of a point $x_0 > 0$ where u assumes a positive maximum contradicts the equation in (A.10).)

Now we consider the functions u_- and u_+ that satisfy

$$u_\pm''(x) - cu_\pm = \pm C_1 e^{-\sqrt{c}|x|}, \qquad u_\pm(0) = u(0), \qquad \lim_{x\to+\infty} u_\pm(x) = 0. \tag{A.11}$$

Both $u_\pm$ can be written explicitly; they satisfy (A.9). Since $v = u - u_-$ and $v = u_+ - u$ satisfy (A.10) with $P(x) = C_1 e^{-\sqrt{c}|x|} + R(x)$ and $P(x) = C_1 e^{-\sqrt{c}|x|} - R(x)$, respectively, we conclude that $u_+(x) \le u(x) \le u_-(x)$ for $x \ge 0$, and hence u also satisfies (A.9). □

Appendix B. Fredholm alternative for $\boldsymbol{\mathcal{H}_c}$.

Lemma B.1 (Fredholm alternative). *Let $R(x) \in \mathscr{S}_{+,m}(\mathbb{R})$, $m \ge 0$ (see Definition* 2.1*). If*

$$\int_{\mathbb{R}} \boldsymbol{e}_{1,c}(x) R(x)\, dx = 0, \tag{B.1}$$

then the equation

$$\mathcal{H}_c u = R \tag{B.2}$$

has a solution $u \in \mathscr{S}_{+,m}(\mathbb{R})$. (This solution is unique if we impose the constraint $\langle \boldsymbol{e}_{1,c}, u\rangle = 0$.) Otherwise, any solution $u(x)$ to (B.2) *such that $\lim_{x\to+\infty} u(x) = 0$ grows exponentially at $-\infty$:*

$$\lim_{x\to-\infty} e^{-\sqrt{c}|x|} u(x) \ne 0.$$

Proof. Let us pick an even function $R_+ \in H^\infty(\mathbb{R})$ so that $R_+(x) = R(x)$ for $x \ge 1$. Since R_+ is even and therefore orthogonal to the kernel of the operator $\mathcal{H}_c$, there is a solution $u_+ \in H^\infty(\mathbb{R})$ to the equation

$$\mathcal{H}_c u_+ = R_+. \tag{B.3}$$

Denote by u the solution to the ordinary differential equation

$$\mathcal{H}_c u \equiv -u'' + (f'(\boldsymbol{\phi}_c) + c)u = R \tag{B.4}$$

such that $u|_{x=1} = u_+|_{x=1}$, $u'|_{x=1} = u'_+|_{x=1}$. Then $u \in C^\infty(\mathbb{R})$ coincides with u_+ for $x \ge 1$ and thus satisfies

$$\lim_{x\to+\infty} u(x) = 0. \tag{B.5}$$

We take the pairing of (B.4) with $\boldsymbol{e}_{1,c}$:

$$\int_x^\infty \boldsymbol{e}_{1,c}(y)\mathcal{H}_c u(y)\,dy = \int_x^\infty \boldsymbol{e}_{1,c}(y)R(y)\,dy \equiv r(x), \qquad x \in \mathbb{R}. \tag{B.6}$$

Since

$$\boldsymbol{e}_{1,c}\mathcal{H}_c u = u\mathcal{H}_c\boldsymbol{e}_{1,c} - \boldsymbol{e}_{1,c}\partial_x^2 u + u\partial_x^2\boldsymbol{e}_{1,c} = -\partial_x(\boldsymbol{e}_{1,c}u') + \partial_x(u\partial_x\boldsymbol{e}_{1,c}),$$

where we took into account that $\mathcal{H}_c\boldsymbol{e}_{1,c} = 0$, we obtain from (B.6) the relation

$$\boldsymbol{e}_{1,c}(x)u'(x) - u(x)\partial_x\boldsymbol{e}_{1,c}(x) = r(x). \tag{B.7}$$

The boundary term at $x = +\infty$ does not contribute into (B.7) due to the limit (B.5). We will use this relation to find the behavior of $u(x)$ as $x \to -\infty$. For $x \le -1$, we divide the relation (B.7) by $\boldsymbol{e}_{1,c}^2$ (we can do this since $\boldsymbol{e}_{1,c}(x) = -\partial_x\boldsymbol{\phi}_c(x) \ne 0$ for $x \ne 0$), getting

$$\partial_x\left(\frac{u(x)}{\boldsymbol{e}_{1,c}(x)}\right) = \frac{r(x)}{\boldsymbol{e}_{1,c}^2(x)}. \tag{B.8}$$

Therefore, for $x \le -1$,

$$u(x) - \boldsymbol{e}_{1,c}(x)\frac{u(-1)}{\boldsymbol{e}_{1,c}(-1)} = \boldsymbol{e}_{1,c}(x)\int_{-1}^x \frac{(r(y) - r_-) + r_-}{\boldsymbol{e}_{1,c}^2(y)}\,dy, \tag{B.9}$$

where $r_- = \lim_{x\to-\infty} r(x)$.

Since $R \in \mathscr{S}_{+,m}(\mathbb{R})$, $|R(x)| \le C(1+|x|)^m$, $m \in \mathbb{Z}$, $m \ge 0$. Using Lemma A.1, we see that

$$|r(x) - r_-| = \left|\int_{-\infty}^x R(y)\boldsymbol{e}_{1,c}(y)\,dy\right| \le \mathrm{const}\, e^{-\sqrt{c}|x|}(1+|x|)^m, \quad x \le -1. \tag{B.10}$$

At the same time, Lemma A.1 also shows that

$$\int_{-1}^x \frac{dy}{\boldsymbol{e}_{1,c}^2(y)} \ge \mathrm{const}\, e^{2\sqrt{c}|x|}, \qquad x \le -1. \tag{B.11}$$

Therefore, if $r_- \neq 0$, the right-hand side of (B.9) grows exponentially as $x \to -\infty$. The same is true for $u(x)$, since the second term in the left-hand side of (B.9) decays exponentially when $|x| \to \infty$ by Lemma A.1. If instead $r_- = 0$, Lemma A.1 and the bound (B.10) show that the right-hand side of (B.9) is bounded by $\mathrm{const}(1+|x|)^m$, proving a similar bound for $u(x)$. Using (B.4) to get the bounds on the derivatives $u^{(N)}$, we conclude that $u \in \mathscr{S}_{+,m}(\mathbb{R})$. ◻

Appendix C. Nondegeneracy of $\inf_{s\in\mathbb{R}} \|\boldsymbol{\phi}_c(\cdot) - \boldsymbol{\phi}_{c_\star}(\cdot - s)\|$ at $c_\star$.

LEMMA C.1. *If $\eta_1 > 0$ is sufficiently small, there exist $\mu_1 > 0$ and $\kappa > 0$ so that*

$$\inf_{s\in\mathbb{R}} \|\boldsymbol{\phi}_c(\cdot) - \boldsymbol{\phi}_{c_\star}(\cdot - s)\|_{L^2(\mathbb{R},\min(1,e^{\mu x})\,dx)} \geq \kappa|c - c_\star|, \quad c \in [c_\star, c_\star + \eta_1], \quad \mu \in [0, \mu_1].$$

Proof. Consider the function

$$g_\mu(c,s) = \|\boldsymbol{\phi}_c(\cdot) - \boldsymbol{\phi}_{c_\star}(\cdot - s)\|^2_{L^2(\mathbb{R},\min(1,e^{\mu x})\,dx)}. \tag{C.1}$$

It is a smooth nonnegative function of c and s for $c \in [c_\star, c_\star + \eta_1]$ and $s \in \mathbb{R}$. It also depends smoothly on the parameter $\mu \geq 0$. Zero is its absolute minimum, achieved at the point $(c,s) = (c_\star, 0)$. We also note that the point $(c_\star, 0)$ is nondegenerate when $\mu = 0$:

$$\partial_c^2 g_0(c,s)|_{(c_\star,0)} = 2\|\partial_c \boldsymbol{\phi}_c|_{c=c_\star}\|^2_{L^2} > 0, \qquad \partial_s^2 g_0(c,s)|_{(c_\star,0)} = 2\|\partial_x \boldsymbol{\phi}_{c_\star}\|^2_{L^2} > 0,$$
$$\partial_c \partial_s g_0(c,s)|_{(c_\star,0)} = -2(\partial_c \boldsymbol{\phi}_c|_{c=c_\star}, \partial_x \boldsymbol{\phi}_{c_\star}) = 0.$$

By continuity, the quadratic form $g''_\mu|_{(c_\star,0)}$ is nondegenerate for $0 \leq \mu \leq \mu_1$, with some $\mu_1 > 0$. Therefore, there exist $\kappa > 0$ and an open neighborhood $\Omega \subset \mathbb{R}^2$ of the point $(c_\star, 0)$ such that

$$g_\mu(c,s) \geq \kappa^2((c - c_\star)^2 + s^2), \qquad (c,s) \in \Omega, \qquad 0 \leq \mu \leq \mu_1. \tag{C.2}$$

Moreover, we claim that

$$\mathit{\Gamma} \equiv \inf_{\mu\in(0,\mu_1)} \inf_{(c,s)\in[c_\star,c_\star+\eta_1]\times\mathbb{R})\backslash\Omega} g_\mu(c,s) > 0. \tag{C.3}$$

To prove (C.3), we only need to note that $(c_\star, 0)$ is the only point where $g_\mu(c,s)$ takes the zero value and that $\lim_{|s|\to\infty} g_\mu(c,s) \geq \inf_{c\in[c_\star,c_\star+\eta_1]} \|\boldsymbol{\phi}_c\|^2_{L^2(\mathbb{R},\min(1,e^{\mu_1 x})\,dx)} > 0$.

Now, we assume that $\eta_1 > 0$ is small enough so that $\kappa^2\eta_1^2 < \mathit{\Gamma}$. Then, by (C.2) (valid for $(c,s) \in \Omega$) and (C.3) (valid for $(c,s) \in ([c_\star, c_\star + \eta_1] \times \mathbb{R})\backslash\Omega$), we conclude that

$$\inf_{s\in\mathbb{R}} g_\mu(c,s) \geq \kappa^2(c - c_\star)^2, \qquad c \in [c_\star, c_\star + \eta_1], \quad \mu \in [0, \mu_1]. \tag{C.4}$$

This proves the lemma. ◻

ON THE BLOWUP FOR THE L^2-CRITICAL FOCUSING NONLINEAR SCHRÖDINGER EQUATION IN HIGHER DIMENSIONS BELOW THE ENERGY CLASS*

MONICA VISAN† AND XIAOYI ZHANG‡

Abstract. We consider the focusing mass-critical nonlinear Schrödinger equation and prove that blowup solutions to this equation with initial data in $H^s(\mathbb{R}^d)$, $s > s_0(d)$ and $d \geq 3$, concentrate at least the mass of the ground state at the blowup time. This extends recent work by Colliander et al. [*Math. Res. Lett.*, 12 (2005), pp. 357–375], Hmidi and Keraani [*Remarks on the Blowup for the L^2-Critical Nonlinear Schrödinger Equations*, preprint], and Tzirakis [*SIAM J. Math. Anal.*, 37 (2006), pp. 1923–1946] on the blowup of the two-dimensional and one-dimensional mass-critical focusing nonlinear Schrödinger equation below the energy space to all dimensions $d \geq 3$.

Key words. nonlinear Schrödinger equation, blowup, I-method.

1. Introduction.

We consider the initial value problem for the focusing L_x^2-critical nonlinear Schrödinger equation

$$\begin{cases} iu_t + \Delta u = -|u|^{\frac{4}{d}}u, \\ u(0,x) = u_0(x) \in H^s(\mathbb{R}^d),\ s \geq 0, \end{cases} \tag{1.1}$$

where $u(t,x)$ is a complex-valued function in spacetime $\mathbb{R} \times \mathbb{R}^d$, $d \geq 3$.

It is well known (see, for example, [6]) that the Cauchy problem (1.1) is locally well posed in $H^s(\mathbb{R}^d)$ for $s \geq 0$. Moreover, the unique solution obeys conservation of *mass*:

$$M(u(t)) := \int_{\mathbb{R}^d} |u(t,x)|^2\,dx = M(u_0).$$

If $s \geq 1$, the *energy* is also finite and conserved:

$$E(u(t)) := \int_{\mathbb{R}^d} \left(\frac{1}{2}|\nabla u(t,x)|^2 - \frac{d}{2(d+2)}|u(t,x)|^{2+\frac{4}{d}} \right) dx = E(u_0).$$

This equation has a natural scaling. More precisely, the map

$$u(t,x) \mapsto u_\lambda(t,x) := \lambda^{\frac{d}{2}} u(\lambda^2 t, \lambda x) \tag{1.2}$$

maps a solution to (1.1) to another solution to (1.1). The reason why this equation is called L_x^2-critical (or mass-critical) is because the scaling (1.2) also leaves the mass invariant.

Equation (1.1) is subcritical for $s > 0$. In this case, (1.1) is well posed in $H^s(\mathbb{R}^d)$ and the life span of the local solution depends only on the H_x^s-norm of the initial data

(see [6]). Denote by $T^* > 0$ the maximal forward time of existence. As a consequence of the local well-posedness theory, we have the following blowup criterion:

$$\text{either} \quad T^* = \infty \quad \text{or} \quad T^* < \infty \quad \text{and} \quad \lim_{t \to T^*} \|u(t)\|_{H^s_x} = \infty.$$

The blowup behavior for solutions from H^1_x initial data has received a lot of attention. The results are closely related to the ground state Q which is the unique positive radial solution to the elliptic equation

$$\Delta Q - Q + |Q|^{\frac{4}{d}} Q = 0.$$

Using the sharp Gagliardo–Nirenberg inequality (see [39]),

$$\|u\|^{\frac{4}{d}+2}_{L_x^{\frac{4}{d}+2}} \leq C_d \|u\|^{\frac{4}{d}}_{L^2_x} \|\nabla u\|^2_{L^2_x} \quad \text{with } C_d := \frac{d+2}{d\,\|Q\|^{\frac{4}{d}}_{L^2_x}}, \tag{1.3}$$

it is not hard to see that the mass of the ground state is the minimal mass required for the solution to develop a singularity. Indeed, in the case $\|u_0\|_{L^2_x} < \|Q\|_{L^2_x}$, (1.3) combined with the conservation of energy implies that the solution to (1.1) is global. This is sharp since the pseudoconformal invariance of (1.1) allows us to build a solution with mass equal to that of the ground state that blows up at time T^*:

$$u(t,x) := |T^* - t|^{-\frac{d}{2}} e^{[i(T^*-t)^{-1} - i|x|^2(T^*-t)^{-1}]} Q\Big(\frac{x}{T^* - t}\Big).$$

Moreover, Merle [28] showed that up to the symmetries of (1.1), this is the only blowup solution with minimal mass. Furthermore, any blowup solution must concentrate at least the mass of the ground state at the blowup time; more precisely, as shown in [31], there exists $x(t) \in \mathbb{R}^d$ such that

$$\forall R > 0, \; \lim_{t \to T^*} \int_{|x - x(t)| \leq R} |u(t,x)|^2 dx \geq \int_{\mathbb{R}^d} Q^2 dx. \tag{1.4}$$

Of course, the goal is to establish all these properties for blowup solutions from data in L^2_x rather than H^1_x. Unfortunately, all the methods used in the H^1_x setting break down at the L^2_x level. Moreover, as (1.1) is L^2_x-critical, even the local well-posedness theory in L^2_x is substantially different from that in H^s_x for $s > 0$. Specifically, the life span of the local solution depends on the profile of the initial data, rather than on its L^2_x-norm (see [6]). In particular, this leads to the following blowup criterion:

$$\text{either} \quad T^* = \infty \quad \text{or} \quad T^* < \infty \quad \text{and} \quad \|u\|_{L^{2+\frac{4}{d}}_{t,x}([0,T^*) \times \mathbb{R}^d)} = \infty.$$

From the global theory for small data (see [6]), we know that if the mass of the initial data is sufficiently small, then there exists a unique global solution to (1.1). However, for large (but finite) mass initial data, which is also sufficiently smooth and decaying, the viriel identity guarantees that finite time blowup occurs; see [18, 42].

The first blowup result for general L^2_x initial data belongs to Bourgain [2], who proved the following parabolic concentration of mass at the blowup time:

$$\lim_{t \nearrow T^*} \sup_{\substack{\text{cubes } I \subset \mathbb{R}^2 \\ \text{side}(I) < (T^* - t)^{\frac{1}{2}}}} \Big(\int_I |u(t,x)|^2 \, dx \Big)^{\frac{1}{2}} \geq c(\|u_0\|_{L^2_x}) > 0, \tag{1.5}$$

where $c(\|u_0\|_{L^2_x})$ is a small constant depending on the mass of the initial data. This result was extended to dimension $d = 1$ by Keraani [25], and to dimensions $d \geq 3$ by Begout and Vargas [1]. The conjecture is that rather than $c(\|u_0\|_{L^2_x})$ on the right-hand side of (1.5), one should have the mass of the ground state as in (1.4); however, this appears to be a very difficult problem.

The goal of this paper is to reproduce as much of the H^1_x theory as we can at lower regularity (but, unfortunately, well above L^2_x) in dimensions three and higher. In two dimensions, this was pursued by Colliander et al. [13]; using the *I-method* (introduced by Colliander et al. [10]), they established a mass concentration property (at the blowup time) for radial blowup solutions from initial data in $H^s(\mathbb{R}^2)$ with $s > \frac{1+\sqrt{11}}{5}$:

$$\limsup_{t \nearrow T^*} \|u\|_{L^2(|x|<(T^*-t)^{\frac{s}{2}}\gamma(T^*-t))} \geq \|Q\|_{L^2_x}, \tag{1.6}$$

where $\gamma(r) \to \infty$ arbitrarily slowly as $r \to 0$. While the right-hand side in (1.6) is the conjectured one, we should remark that the width of concentration, that is, $(T^*-t)^{\frac{s}{2}-}$, is larger than the expected concentration width, $(T^*-t)^{\frac{1}{2}-}$. Moreover, the lim sup in (1.6) is not present in the H^1_x theory (see (1.4)); the reason for its appearance is basically the lack of information on the blowup rate of the H^s_x-norm.

Hmidi and Keraani [21] removed the radial assumption used in [13]. Moreover, they showed that, up to symmetries of the equation, the ground state Q is the profile for blowup solutions with minimal mass and initial data in $H^s(\mathbb{R}^2)$ with $s > \frac{1+\sqrt{11}}{5}$. We will make use of the key innovation of their work, namely, Lemma 2.11 below.

In one dimension, recent work by Tzirakis [36] established the analogue of (1.6) for arbitrary initial data in $H^s(\mathbb{R})$, $s > \frac{10}{11}$.

Our contribution is to treat (nonradial) data in $H^s(\mathbb{R}^d)$ for $s > s_0(d)$, where

$$s_0(d) := \begin{cases} \dfrac{1+\sqrt{13}}{5} & \text{for } d = 3, \\ \dfrac{8-d+\sqrt{9d^2+64d+64}}{2(d+10)} & \text{for } d \geq 4. \end{cases} \tag{1.7}$$

We prove the following theorem.

THEOREM 1.1. *Assume $d \geq 3$ and $s > s_0(d)$. Let $u_0 \in H^s(\mathbb{R}^d)$ such that the corresponding solution u to* (1.1) *blows up at time $0 < T^* < \infty$. Then there exists a function $V \in H^1_x$ such that $\|V\|_2 \geq \|Q\|_2$ and there exist sequences $\{t_n, \rho_n, x_n\}_{n\geq 1} \subset \mathbb{R}_+ \times \mathbb{R}_+^* \times \mathbb{R}^d$ satisfying*

$$t_n \nearrow T^* \text{ as } n \to \infty \quad \text{and} \quad \rho_n \lesssim (T^*-t_n)^{\frac{s}{2}} \quad \forall\, n \geq 1$$

such that

$$\rho_n^{\frac{d}{2}} u(t_n, \rho_n \cdot + x_n) \rightharpoonup V \quad \text{weakly as } n \to \infty.$$

As a consequence of Theorem 1.1, we establish the following mass concentration property for blowup solutions.

THEOREM 1.2. *Assume $d \geq 3$ and $s > s_0(d)$. Let $u_0 \in H^s(\mathbb{R}^d)$ such that the corresponding solution u to* (1.1) *blows up at time $0 < T^* < \infty$. Let $\alpha(t) > 0$ be such that*

$$\lim_{t \nearrow T^*} \frac{(T^*-t)^{\frac{s}{2}}}{\alpha(t)} = 0.$$

Then there exists $x(t) \in \mathbb{R}^d$ *such that*

$$\limsup_{t \nearrow T^*} \int_{|x-x(t)| \leq \alpha(t)} |u(x,t)|^2 dx \geq \int_{\mathbb{R}^d} Q^2 dx.$$

Under the additional hypothesis that the mass of the initial data equals the mass of the ground state, we may upgrade Theorem 1.1 to the following.

THEOREM 1.3. *Assume* $d \geq 3$ *and* $s > s_0(d)$. *Let* $u_0 \in H^s(\mathbb{R}^d)$ *with* $\|u_0\|_2 = \|Q\|_2$ *such that the corresponding solution* u *to* (1.1) *blows up at time* $0 < T^* < \infty$. *Then there exist sequences* $\{t_n, \theta_n, \rho_n, x_n\}_{n \geq 1} \subset \mathbb{R}_+ \times S^1 \times \mathbb{R}_+^* \times \mathbb{R}^d$ *satisfying*

$$t_n \nearrow T^* \text{ as } n \to \infty \quad \text{and} \quad \rho_n \lesssim (T^* - t_n)^{\frac{s}{2}} \quad \forall\, n \geq 1$$

such that

$$\rho_n^{\frac{d}{2}} e^{i\theta_n} u(t_n, \rho_n x + x_n) \to Q \quad \text{strongly in } H_x^{\tilde{s}-},$$

where

$$\tilde{s} := \frac{2d + 8s + s^2 d(2 - \min\{1, \frac{4}{d}\})}{4d + 16s - s^2(d \min\{1, \frac{4}{d}\} + 8)}.$$

In a nutshell, Theorem 1.3 says that up to the symmetries for (1.1), the ground state is the profile for blowup solutions with minimal mass and initial data in H_x^s, $s > s_0(d)$. Alas, we only show that this is true along a sequence of times.

To prove Theorems 1.1 through 1.3, we will rely on the *I*-method and Lemma 2.11. The idea behind the *I*-method is to smooth out the initial data in order to access the theory available at H_x^1 regularity. To this end, one introduces the Fourier multiplier I, which is the identity on low frequencies and behaves like a fractional integral operator of order $1 - s$ on high frequencies. Thus, the operator I maps H_x^s to H_x^1. However, even though we do have energy conservation for (1.1), Iu is not a solution to (1.1), and hence we expect an energy increment. The key is to prove that on intervals of local well-posedness, the modified energy $E(Iu)$ is an "almost conserved" quantity and grows much slower than the modified kinetic energy $\|\nabla Iu\|_{L_x^2}^2$. This requires delicate estimates on the commutator between I and the nonlinearity. In dimensions one and two, the nonlinearity is algebraic and one can write the commutator explicitly using the Fourier transform and control it by multilinear analysis and bilinear estimates (see [13, 36]). However, in dimensions $d \geq 3$ this method fails. Instead, we will have to rely on more rudimentary tools such as Strichartz and fractional chain rule estimates in order to control the commutator.

The remainder of this paper is organized as follows: In section 2, we introduce notation and prove some lemmas that will be useful. In section 3, we revisit the H_x^s local well-posedness theory for (1.1). Section 4 is devoted to controlling the modified energy increment. In sections 5 through 7 we prove Theorems 1.1 through 1.3.

After this work was submitted, we were informed of an independent paper attacking the same problem [14]. However, there appear to be several gaps in their argument, for example, in estimating (4.19). While it seems possible to remedy their errors, this would result in a larger value for $s_0(d)$ than that claimed in their paper, which is already inferior to that given here. We contend that all overlap between this paper and [14] can be attributed to the precursors [13] and [21].

2. Preliminaries. We will often use the notation $X \lesssim Y$ whenever there exists some constant C so that $X \leq CY$. Similarly, we will use $X \sim Y$ if $X \lesssim Y \lesssim X$. We use $X \ll Y$ if $X \leq cY$ for some small constant c. The derivative operator ∇ refers to the space variable only. We use $A\pm$ to denote $A \pm \varepsilon$ for any sufficiently small $\varepsilon > 0$; the implicit constant in an inequality involving this notation is permitted to depend on ε.

We use $L^r_x(\mathbb{R}^d)$ to denote the Banach space of functions $f : \mathbb{R}^d \to \mathbb{C}$ whose norm

$$\|f\|_r := \Big(\int_{\mathbb{R}^d} |f(x)|^r dx \Big)^{\frac{1}{r}}$$

is finite, with the usual modifications when $r = \infty$.

We use $L^q_t L^r_x$ to denote the spacetime norm

$$\|u\|_{q,r} := \|u\|_{L^q_t L^r_x(\mathbb{R}\times\mathbb{R}^d)} := \Big(\int_{\mathbb{R}} \Big(\int_{\mathbb{R}^d} |u(t,x)|^r dx \Big)^{q/r} dt \Big)^{1/q},$$

with the usual modifications when either q or r are infinity, or when the domain $\mathbb{R}\times\mathbb{R}^d$ is replaced by some smaller spacetime region. When $q = r$ we abbreviate $L^q_t L^r_x$ by $L^q_{t,x}$.

We define the Fourier transform on $\mathbb{R}^d$ to be

$$\hat{f}(\xi) := \int_{\mathbb{R}^d} e^{-2\pi i x\cdot\xi} f(x) dx.$$

We will make use of the fractional differentiation operators $|\nabla|^s$ defined by

$$\widehat{|\nabla|^s f}(\xi) := |\xi|^s \hat{f}(\xi).$$

These define the homogeneous Sobolev norms

$$\|f\|_{\dot{H}^s_x} := \||\nabla|^s f\|_{L^2_x}$$

and the more common inhomogeneous Sobolev norms

$$\|f\|_{H^{s,p}_x} := \|\langle\nabla\rangle^s f\|_{L^p_x}, \quad \text{where } \langle\nabla\rangle := (1 + |\nabla|^2)^{\frac{1}{2}}.$$

We will often denote $H^{s,2}_x$ by H^s_x.

Let $F(z) := -|z|^{\frac{4}{d}} z$ be the function that defines the nonlinearity in (1.1). Then

$$F_z(z) := \frac{\partial F}{\partial z}(z) = -\frac{2+d}{d}|z|^{\frac{4}{d}} \quad \text{and} \quad F_{\bar{z}}(z) := \frac{\partial F}{\partial \bar{z}}(z) = -\frac{2}{d}|z|^{\frac{4}{d}} \frac{z}{\bar{z}}.$$

We write F' for the vector $(F_z, F_{\bar{z}})$ and adopt the notation

$$w \cdot F'(z) := wF_z(z) + \bar{w}F_{\bar{z}}(z).$$

In particular, we observe the chain rule

$$\nabla F(u) = \nabla u \cdot F'(u).$$

Clearly $F'(z) = O(|z|^{\frac{4}{d}})$ and we have the Hölder continuity estimate

$$|F'(z) - F'(w)| \lesssim |z - w|^{\min\{1,\frac{4}{d}\}}(|z| + |w|)^{\frac{4}{d}-\min\{1,\frac{4}{d}\}} \tag{2.1}$$

for all $z, w \in \mathbb{C}$. By the fundamental theorem of calculus,

$$F(z+w) - F(z) = \int_0^1 w \cdot F'(z+\theta w) d\theta$$

and hence

$$F(z+w) = F(z) + O(|w||z|^{\frac{4}{d}}) + O(|w|^{\frac{4+d}{d}})$$

for all complex values z and w.

Let $e^{it\Delta}$ be the free Schrödinger propagator. In physical space this is given by the formula

$$e^{it\Delta} f(x) = \frac{1}{(4\pi it)^{d/2}} \int_{\mathbb{R}^d} e^{i|x-y|^2/4t} f(y) dy$$

for $t \neq 0$ (using a suitable branch cut to define $(4\pi it)^{d/2}$), while in frequency space one can write this as

$$\widehat{e^{it\Delta} f}(\xi) = e^{-4\pi^2 it|\xi|^2} \hat{f}(\xi). \tag{2.2}$$

In particular, the propagator obeys the *dispersive inequality*

$$\|e^{it\Delta} f\|_{L_x^\infty} \lesssim |t|^{-\frac{d}{2}} \|f\|_{L_x^1} \tag{2.3}$$

for all times $t \neq 0$.

We also recall *Duhamel's formula*

$$u(t) = e^{i(t-t_0)\Delta} u(t_0) - i \int_{t_0}^t e^{i(t-s)\Delta} (iu_t + \Delta u)(s) ds. \tag{2.4}$$

Definition 2.1. *A pair of exponents (q, r) is called Schrödinger-admissible if*

$$\frac{2}{q} + \frac{d}{r} = \frac{d}{2}, \quad 2 \leq q, r \leq \infty, \quad \textit{and} \quad (q, r, d) \neq (2, \infty, 2).$$

Throughout this paper we will use the following admissible pairs:

$$\left(2, \frac{2d}{d-2}\right) \quad \text{and} \quad (\gamma, \rho) := \left(\frac{2(d+2)}{d-2s}, \frac{2d(d+2)}{d^2+4s}\right) \quad \text{with } 0 < s < 1.$$

Let $\rho^* := \frac{2(d+2)}{d-2s}$. Using Hölder and Sobolev embedding, on any spacetime slab $I \times \mathbb{R}^d$ we estimate

$$\|F(u)\|_{\gamma', \rho'} \lesssim |I|^{\frac{2s}{d}} \|u\|_{\gamma,\rho} \|u\|_{\gamma,\rho^*}^{\frac{4}{d}} \lesssim |I|^{\frac{2s}{d}} \|\langle \nabla \rangle^s u\|_{\gamma,\rho}^{1+\frac{4}{d}}. \tag{2.5}$$

Let $I \times \mathbb{R}^d$ be a spacetime slab; we define the Strichartz norm

$$\|u\|_{S^0(I)} := \sup_{(q,r) \text{ admissible}} \|u\|_{L_t^q L_x^r (I \times \mathbb{R}^d)}.$$

We define the Strichartz space $S^0(I)$ to be the closure of all test functions under the Strichartz norm $\|\cdot\|_{S^0(I)}$. We use $N^0(I)$ to denote the dual space of $S^0(I)$.

We record the standard Strichartz estimates which we will invoke repeatedly throughout this paper (see [33, 17] for (q,r) admissible with $q>2$ and [24] for the endpoint $(2,\frac{2d}{d-2})$).

LEMMA 2.2. *Let I be a compact time interval, $t_0\in I$, $s\geq 0$, and let u be a solution to the forced Schrödinger equation*

$$iu_t+\Delta u=\sum_{i=1}^m F_i$$

for some functions $F_1,\ldots,F_m$. Then

$$\||\nabla|^s u\|_{S^0(I)}\lesssim\|u(t_0)\|_{\dot H^s(\mathbb{R}^d)}+\sum_{i=1}^m\||\nabla|^s F_i\|_{L_t^{q_i'}L_x^{r_i'}(I\times\mathbb{R}^d)} \tag{2.6}$$

for any admissible pairs (q_i,r_i), $1\leq i\leq m$.

We will also need some Littlewood–Paley theory. Specifically, let $\varphi(\xi)$ be a smooth bump supported in the ball $|\xi|\leq 2$ and equaling one on the ball $|\xi|\leq 1$. For each dyadic number $N\in 2^{\mathbb{Z}}$ we define the Littlewood–Paley operators

$$\begin{aligned}\widehat{P_{\leq N}f}(\xi)&:=\varphi(\xi/N)\hat f(\xi),\\ \widehat{P_{>N}f}(\xi)&:=[1-\varphi(\xi/N)]\hat f(\xi),\\ \widehat{P_N f}(\xi)&:=[\varphi(\xi/N)-\varphi(2\xi/N)]\hat f(\xi).\end{aligned}$$

Similarly we can define $P_{<N}$, $P_{\geq N}$, and $P_{M<\cdot\leq N}:=P_{\leq N}-P_{\leq M}$ whenever M and N are dyadic numbers. We will frequently write $f_{\leq N}$ for $P_{\leq N}f$ and similarly for the other operators. We recall the following standard Bernstein- and Sobolev-type inequalities.

LEMMA 2.3. *For any $1\leq p\leq q\leq\infty$ and $s>0$, we have*

$$\begin{aligned}\|P_{\geq N}f\|_{L_x^p}&\lesssim N^{-s}\||\nabla|^s P_{\geq N}f\|_{L_x^p},\\ \||\nabla|^s P_{\leq N}f\|_{L_x^p}&\lesssim N^s\|P_{\leq N}f\|_{L_x^p},\\ \||\nabla|^{\pm s}P_N f\|_{L_x^p}&\sim N^{\pm s}\|P_N f\|_{L_x^p},\\ \|P_{\leq N}f\|_{L_x^q}&\lesssim N^{\frac{d}{p}-\frac{d}{q}}\|P_{\leq N}f\|_{L_x^p},\\ \|P_N f\|_{L_x^q}&\lesssim N^{\frac{d}{p}-\frac{d}{q}}\|P_N f\|_{L_x^p}.\end{aligned}$$

For $N>1$, we define the Fourier multiplier I_N (cf. [10]) by

$$\widehat{I_N u}(\xi):=m_N(\xi)\hat u(\xi),$$

where m_N is a smooth radial decreasing function such that

$$m_N(\xi)=\begin{cases}1 & \text{if}\quad |\xi|\leq N,\\ \bigl(\frac{|\xi|}{N}\bigr)^{s-1} & \text{if}\quad |\xi|\geq 2N.\end{cases}$$

Thus, I_N is the identity operator on frequencies $|\xi|\leq N$ and behaves like a fractional integral operator of order $1-s$ on higher frequencies. In particular, I_N maps H_x^s to H_x^1; this allows us to access the theory available for H_x^1 data. We collect the basic properties of I_N into the following lemma.

LEMMA 2.4. *Let $1 < p < \infty$ and $0 \le \sigma \le s < 1$. Then*

$$\|I_N f\|_p \lesssim \|f\|_p, \tag{2.7}$$

$$\||\nabla|^\sigma P_{>N} f\|_p \lesssim N^{\sigma-1}\|\nabla I_N f\|_p, \tag{2.8}$$

$$\|f\|_{H^s_x} \lesssim \|I_N f\|_{H^1_x} \lesssim N^{1-s}\|f\|_{H^s_x}. \tag{2.9}$$

Proof. The estimate (2.7) is a direct consequence of the multiplier theorem.

To prove (2.8), we write

$$\||\nabla|^\sigma P_{>N} f\|_p = \|P_{>N}|\nabla|^\sigma(\nabla I_N)^{-1}\nabla I_N f\|_p.$$

The claim follows again from the multiplier theorem.

Now we turn to (2.9). By the definition of the operator I_N and (2.8),

$$\begin{aligned}\|f\|_{H^s_x} &\lesssim \|P_{\le N} f\|_{H^s_x} + \|P_{>N} f\|_2 + \||\nabla|^s P_{>N} f\|_2\\ &\lesssim \|P_{\le N} I_N f\|_{H^1_x} + N^{-1}\|\nabla I_N f\|_2 + N^{s-1}\|\nabla I_N f\|_2\\ &\lesssim \|I_N f\|_{H^1_x}.\end{aligned}$$

On the other hand, since the operator I_N commutes with $\langle\nabla\rangle^s$, we get

$$\|I_N f\|_{H^1_x} = \|\langle\nabla\rangle^{1-s} I_N \langle\nabla\rangle^s f\|_2 \lesssim N^{1-s}\|\langle\nabla\rangle^s f\|_2 \lesssim N^{1-s}\|f\|_{H^s_x},$$

which proves the last inequality in (2.9). Note that a similar argument also yields

$$\|I_N f\|_{\dot H^1_x} \lesssim N^{1-s}\|f\|_{\dot H^s_x}. \qquad \square \tag{2.10}$$

The estimate (2.8) shows that we can control the high frequencies of a function f in the Sobolev space $H^{\sigma,p}_x$ by the smoother function $I_N f$ in a space with a loss of derivative but a gain of negative power of N. This fact is crucial in extracting the negative power of N when estimating the increment of the modified Hamiltonian.

In one and two dimensions, one can use multilinear analysis to understand commutator expressions like $F(I_N u) - I_N F(u)$; on the Fourier side, one can expand this commutator into a product of Fourier transforms of u and $I_N u$ and carefully measure the frequency interactions to derive an estimate (see, for example, [13, 36]). However, this is not possible in dimensions $d \ge 3$. Instead, we will have to rely on the following rougher (weaker, but more robust) lemma.

LEMMA 2.5. *Let $1 < r, r_1, r_2 < \infty$ be such that $\frac{1}{r} = \frac{1}{r_1} + \frac{1}{r_2}$ and let $0 < \nu < s$. Then*

$$\|I_N(fg) - (I_N f)g\|_r \lesssim N^{-(1-s+\nu)}\|I_N f\|_{r_1}\|\langle\nabla\rangle^{1-s+\nu} g\|_{r_2}. \tag{2.11}$$

Proof. Applying a Littlewood–Paley decomposition to f and g, we write

$$\begin{aligned}I_N(fg) - (I_N f)g = I_N(f g_{\le 1}) - (I_N f) g_{\le 1} &+ \sum_{1<M\in 2^{\mathbb{Z}}}\big[I_N(f_{\lesssim M} g_M) - (I_N f_{\lesssim M}) g_M\big]\\ &+ \sum_{1<M\in 2^{\mathbb{Z}}}\big[I_N(f_{\gg M} g_M) - (I_N f_{\gg M}) g_M\big]\end{aligned}$$

$$
\begin{aligned}
&= I_N(f_{\gtrsim N} g_{\leq 1}) - (I_N f_{\gtrsim N}) g_{\leq 1} + \sum_{N \lesssim M \in 2^{\mathbb{Z}}} \big[I_N(f_{\lesssim M} g_M) - (I_N f_{\lesssim M}) g_M \big] \\
&\quad + \sum_{1 < M \in 2^{\mathbb{Z}}} \big[I_N(f_{\gg M} g_M) - (I_N f_{\gg M}) g_M \big] \\
&= I + II + III. \qquad (2.12)
\end{aligned}
$$

The second equality above follows from the fact that the operator I_N is the identity operator on frequencies $|\xi| \leq N$; thus,

$$
I_N(f_{\ll N} g_{\leq 1}) = (I_N f_{\ll N}) g_{\leq 1} \quad \text{and} \quad I_N(f_{\lesssim M} g_M) = (I_N f_{\lesssim M}) g_M \quad \forall\, M \ll N.
$$

We first consider II. Dropping the operator I_N, by Hölder and Bernstein we estimate

$$
\begin{aligned}
\| I_N(f_{\lesssim M} g_M) - (I_N f_{\lesssim M}) g_M \|_r &\lesssim \| f_{\lesssim M} \|_{r_1} \| g_M \|_{r_2} \\
&\lesssim \Big(\frac{M}{N} \Big)^{1-s} \| I_N f \|_{r_1} \| g_M \|_{r_2} \\
&\lesssim M^{-\nu} N^{-(1-s)} \| I_N f \|_{r_1} \| |\nabla|^{1-s+\nu} g \|_{r_2}.
\end{aligned}
$$

Summing over all M such that $N \lesssim M \in 2^{\mathbb{Z}}$, we get

$$
II \lesssim N^{-(1-s+\nu)} \| I_N f \|_{r_1} \| |\nabla|^{1-s+\nu} g \|_{r_2}. \qquad (2.13)
$$

We turn now towards III. Applying a Littlewood–Paley decomposition to f, we write each term in III as

$$
\begin{aligned}
I_N(f_{\gg M} g_M) - (I_N f_{\gg M}) g_M &= \sum_{1 \ll k \in \mathbb{N}} \big[I_N(f_{2^k M} g_M) - (I_N f_{2^k M}) g_M \big] \\
&= \sum_{\substack{1 \ll k \in \mathbb{N} \\ N \lesssim 2^k M}} \big[I_N(f_{2^k M} g_M) - (I_N f_{2^k M}) g_M \big].
\end{aligned}
$$

To derive the second inequality, we used again the fact that the operator I_N is the identity on frequencies $|\xi| \leq N$.

We write

$$
\big[I_N(f_{2^k M} g_M) - (I_N f_{2^k M}) g_M \big]\widehat{\ }(\xi) = \int_{\xi = \xi_1 + \xi_2} (m_N(\xi_1 + \xi_2) - m_N(\xi_1)) \widehat{f_{2^k M}}(\xi_1) \widehat{g_M}(\xi_2).
$$

For $|\xi_1| \sim 2^k M$, $k \gg 1$, and $|\xi_2| \sim M$, the fundamental theorem of calculus implies

$$
|m_N(\xi_1 + \xi_2) - m_N(\xi_1)| \lesssim 2^{-k} \Big(\frac{2^k M}{N} \Big)^{s-1}.
$$

By the Coifman–Meyer multilinear multiplier theorem [8, 9] and by Bernstein, we get

$$
\begin{aligned}
\| I_N(f_{2^k M} g_M) - (I_N f_{2^k M}) g_M \|_r &\lesssim 2^{-k} \Big(\frac{2^k M}{N} \Big)^{s-1} \| f_{2^k M} \|_{r_1} \| g_M \|_{r_2} \\
&\lesssim 2^{-k} M^{-(1-s+\nu)} \| I_N f \|_{r_1} \| |\nabla|^{1-s+\nu} g \|_{r_2}.
\end{aligned}
$$

Summing over M and k such that $N \lesssim 2^k M$, and recalling that $0 < \nu < s$, we get

$$III \lesssim N^{-(1-s+\nu)} \|I_N f\|_{r_1} \||\nabla|^{1-s+\nu} g\|_{r_2}. \tag{2.14}$$

To estimate I, we apply the same argument as for III. We get

$$\begin{aligned} I = \|I_N(f_{\gtrsim N} g_{\leq 1}) - (I_N f_{\gtrsim N}) g_{\leq 1}\|_r &\lesssim \sum_{k\in\mathbb{N}, 2^k \gtrsim N} \|I_N(f_{2^k} g_{\leq 1}) - (I_N f_{2^k}) g_{\leq 1}\|_r \\ &\lesssim \sum_{k\in\mathbb{N}, 2^k \gtrsim N} 2^{-k} \|I_N f\|_{r_1} \|g\|_{r_2} \\ &\lesssim N^{-1} \|I_N f\|_{r_1} \|g\|_{r_2}. \end{aligned} \tag{2.15}$$

Putting together (2.12) through (2.15), we derive (2.11). ◻

As an application of Lemma 2.5 we have the following commutator estimate.

LEMMA 2.6. *Let $1 < r, r_1, r_2 < \infty$ be such that $\frac{1}{r} = \frac{1}{r_1} + \frac{1}{r_2}$. Then for any $0 < \nu < s$ we have*

$$\|\nabla I_N F(u) - (I_N \nabla u) F'(u)\|_r \lesssim N^{-1+s-\nu} \|\nabla I_N u\|_{r_1} \|\langle\nabla\rangle^{1-s+\nu} F'(u)\|_{r_2}, \tag{2.16}$$

$$\|\nabla I_N F(u)\|_r \lesssim \|\nabla I_N u\|_{r_1} \|F'(u)\|_{r_2} + N^{-1+s-\nu} \|\nabla I_N u\|_{r_1} \|\langle\nabla\rangle^{1-s+\nu} F'(u)\|_{r_2}. \tag{2.17}$$

Proof. As

$$\nabla F(u) = \nabla u \cdot F'(u),$$

the estimate (2.16) follows immediately from Lemma 2.5 with $f := \nabla u$ and $g := F'(u)$. The estimate (2.17) is a consequence of (2.16) and the triangle inequality. ◻

Since we work at regularity $0 < s < 1$, we will need the following fractional chain rules to estimate our nonlinearity in H^s_x.

LEMMA 2.7 (fractional chain rule for a C^1 function). *Suppose that $F \in C^1(\mathbb{C})$, $\sigma \in (0,1)$, and $1 < r, r_1, r_2 < \infty$ such that $\frac{1}{r} = \frac{1}{r_1} + \frac{1}{r_2}$. Then*

$$\||\nabla|^\sigma F(u)\|_r \lesssim \|F'(u)\|_{r_1} \||\nabla|^\sigma u\|_{r_2}.$$

LEMMA 2.8 (fractional chain rule for a Lipschitz function). *Let F be a Lipschitz function, $\sigma \in (0,1)$, and $1 < r < \infty$. Then*

$$\||\nabla|^\sigma F(u)\|_r \lesssim \|F'\|_\infty \||\nabla|^\sigma u\|_r.$$

LEMMA 2.9 (fractional derivatives for fractional powers). *Let F be a Hölder continuous function of order $0 < \alpha < 1$. Then for every $0 < \sigma < \alpha$, $1 < r < \infty$, and $\frac{\sigma}{\alpha} < \delta < 1$ we have*

$$\big\||\nabla|^\sigma F(u)\big\|_r \lesssim \big\||u|^{\alpha - \frac{\sigma}{\delta}}\big\|_{r_1} \big\||\nabla|^\delta u\big\|^{\frac{\sigma}{\delta}}_{\frac{\sigma}{\delta} r_2}, \tag{2.18}$$

provided $\frac{1}{r} = \frac{1}{r_1} + \frac{1}{r_2}$ and $(1 - \frac{\sigma}{\alpha\delta}) r_1 > 1$.

The first two results originate in [7] and [32]; for a textbook treatment see [35]. The third result can be found in Appendix A of [38]. Using the chain rule estimates in these lemmas, we can upgrade the pointwise-in-time commutator estimate in Lemma 2.6 to a spacetime estimate.

Lemma 2.10. *Let I be a compact time interval and let $\frac{1}{1+\min\{1,\frac{4}{d}\}} < s < 1$. Then*

$$\|(I_N\nabla u)F'(u) - \nabla I_N F(u)\|_{L_t^2 L_x^{\frac{2d}{d+2}}(I\times\mathbb{R}^d)} \lesssim N^{-\min\{1,\frac{4}{d}\}s+}\|\langle\nabla\rangle I_N u\|_{S^0(I)}^{1+\frac{4}{d}}, \tag{2.19}$$

$$\|\langle\nabla\rangle I_N F(u)\|_{N^0(I)} \lesssim |I|^{\frac{2s}{d}}\|\langle\nabla\rangle I_N u\|_{S^0(I)}^{1+\frac{4}{d}} + N^{-\min\{1,\frac{4}{d}\}s+}\|\langle\nabla\rangle I_N u\|_{S^0(I)}^{1+\frac{4}{d}}. \tag{2.20}$$

Proof. Throughout the proof, all spacetime norms will be taken on the slab $I\times\mathbb{R}^d$.

As by hypothesis $s > \frac{1}{1+\min\{1,\frac{4}{d}\}}$, there exists $\varepsilon_0 > 0$ such that for any $0<\varepsilon<\varepsilon_0$ we have $s > \frac{1+\varepsilon}{1+\min\{1,\frac{4}{d}\}}$. Let $\nu := \min\{1,\frac{4}{d}\}s - (1-s) - \varepsilon$ with $0<\varepsilon<\varepsilon_0$. It is easy to check that $0<\nu<s$. Applying Lemma 2.6 with this value of ν, we get

$$\begin{aligned}\|(\nabla I_N u)F'(u) - &\nabla I_N F(u)\|_{2,\frac{2d}{d+2}}\\ &\lesssim N^{-\min\{1,\frac{4}{d}\}s+\varepsilon}\|\nabla I_N u\|_{2,\frac{2d}{d-2}}\|\langle\nabla\rangle^{\min\{1,\frac{4}{d}\}s-\varepsilon}F'(u)\|_{\infty,\frac{d}{2}}.\end{aligned}$$

The claim (2.19) will follow immediately from the estimate above, provided we show

$$\|\langle\nabla\rangle^{\min\{1,\frac{4}{d}\}s-\varepsilon}F'(u)\|_{\infty,\frac{d}{2}} \lesssim \|\langle\nabla\rangle I_N u\|_{\infty,2}^{\frac{4}{d}}. \tag{2.21}$$

We start by observing that for any (q,r) admissible pair,

$$\|\langle\nabla\rangle^s u\|_{q,r} \lesssim \|\langle\nabla\rangle I_N u\|_{q,r}. \tag{2.22}$$

Indeed, decomposing $u := u_{\leq N} + u_{>N}$ and using Lemma 2.4 and the fact that I_N is the identity operator on frequencies $|\xi|\leq N$, we get

$$\begin{aligned}\|u\|_{q,r} &\leq \|u_{\leq N}\|_{q,r} + \|u_{>N}\|_{q,r}\\ &\lesssim \|I_N u_{\leq N}\|_{q,r} + N^{-1}\|\nabla I_N u_{>N}\|_{q,r}\\ &\lesssim \|\langle\nabla\rangle I_N u\|_{q,r}.\end{aligned}$$

Similarly, we estimate

$$\begin{aligned}\||\nabla|^s u\|_{q,r} &\leq \||\nabla|^s u_{\leq N}\|_{q,r} + \||\nabla|^s u_{>N}\|_{q,r}\\ &\lesssim \||\nabla|^s I_N u_{\leq N}\|_{q,r} + N^{s-1}\|\nabla I_N u\|_{q,r}\\ &\lesssim \|\langle\nabla\rangle I_N u\|_{q,r},\end{aligned}$$

and the estimate (2.22) follows.

As $F'(u) = O(|u|^{\frac{4}{d}})$, by (2.22) we get

$$\|F'(u)\|_{\infty,\frac{d}{2}} \lesssim \|\langle\nabla\rangle I_N u\|_{\infty,2}^{\frac{4}{d}}. \tag{2.23}$$

We first prove (2.21) for $d\leq 4$. By (2.23), we estimate

$$\begin{aligned}\|\langle\nabla\rangle^{\min\{1,\frac{4}{d}\}s-\varepsilon}F'(u)\|_{\infty,\frac{d}{2}} &= \|\langle\nabla\rangle^{s-\varepsilon}F'(u)\|_{\infty,\frac{d}{2}}\\ &\lesssim \|\langle\nabla\rangle^s F'(u)\|_{\infty,\frac{d}{2}}\\ &\lesssim \|F'(u)\|_{\infty,\frac{d}{2}} + \||\nabla|^s F'(u)\|_{\infty,\frac{d}{2}}\\ &\lesssim \|\langle\nabla\rangle I_N u\|_{\infty,2}^{\frac{4}{d}} + \||\nabla|^s F'(u)\|_{\infty,\frac{d}{2}}.\end{aligned}$$

Using Lemmas 2.7 (for $d = 3$) and 2.8 (for $d = 4$) together with (2.22), we estimate

$$\||\nabla|^s F'(u)\|_{\infty,\frac{d}{2}} \lesssim \||\nabla|^s u\|_{\infty,2} \|u\|_{\infty,2}^{\frac{4}{d}-1} \lesssim \|\langle\nabla\rangle I_N u\|_{\infty,2}^{\frac{4}{d}}.$$

Thus, (2.21) holds for $d \leq 4$.

If $d > 4$, using Lemma 2.9 (with $\alpha := \frac{4}{d}$, $\sigma := \frac{4s}{d} - \varepsilon$, and $\delta := s$) and (2.22), we get

$$\begin{aligned}\||\nabla|^{\min\{1,\frac{4}{d}\}s-\varepsilon} F'(u)\|_{\infty,\frac{d}{2}} = \||\nabla|^{\frac{4s}{d}-\varepsilon} F'(u)\|_{\infty,\frac{d}{2}} &\lesssim \|u\|_{\infty,2}^{\frac{\varepsilon}{s}} \||\nabla|^s u\|_{\infty,2}^{\frac{4}{d}-\frac{\varepsilon}{s}} \\ &\lesssim \|\langle\nabla\rangle I_N u\|_{\infty,2}^{\frac{4}{d}}.\end{aligned}$$

From this and (2.23) we derive (2.21) in the case $d > 4$. The claim (2.19) follows.

We now consider (2.20). Using (2.5), (2.7), and (2.22), we obtain

$$\|I_N F(u)\|_{N^0(I)} \lesssim \|F(u)\|_{\gamma',\rho'} \lesssim |I|^{\frac{2s}{d}} \|\langle\nabla\rangle^s u\|_{\gamma,\rho}^{1+\frac{4}{d}} \lesssim |I|^{\frac{2s}{d}} \|\langle\nabla\rangle I_N u\|_{\gamma,\rho}^{1+\frac{4}{d}}.$$

Similarly, by Hölder and (2.22),

$$\begin{aligned}\|(I_N \nabla u) F'(u)\|_{N^0(I)} &\lesssim \|(I_N \nabla u) F'(u)\|_{\gamma',\rho'} \\ &\lesssim |I|^{\frac{2s}{d}} \|I_N \nabla u\|_{\gamma,\rho} \|u\|_{\gamma,\rho^*}^{\frac{4}{d}} \\ &\lesssim |I|^{\frac{2s}{d}} \|I_N \nabla u\|_{\gamma,\rho} \|\langle\nabla\rangle^s u\|_{\gamma,\rho}^{\frac{4}{d}} \\ &\lesssim |I|^{\frac{2s}{d}} \|\langle\nabla\rangle I_N u\|_{\gamma,\rho}^{1+\frac{4}{d}}.\end{aligned}$$

The estimate (2.20) follows from the estimates above, from (2.19), and from the triangle inequality. $\square$

We end this section with the following concentration-compactness lemma.

LEMMA 2.11 (concentration-compactness [20]). *Let $\{v_n\}_{n\geq 1}$ be a bounded sequence in $H^1(\mathbb{R}^d)$ such that*

$$\limsup_{n\to\infty} \|\nabla v_n\|_2 \leq M < \infty$$

and

$$\limsup_{n\to\infty} \|v_n\|_{2+\frac{4}{d}} \geq m > 0.$$

Then there exists $\{x_n\}_{n\geq 1} \subset \mathbb{R}^d$ such that, up to a subsequence,

$$v_n(\cdot + x_n) \rightharpoonup V \quad \textit{weakly in } H_x^1 \textit{ as } n \to \infty$$

with $\|V\|_2 \geq \sqrt{\frac{d}{d+2}\frac{m^{\frac{2}{d}+1}}{M}} \|Q\|_2$.

3. Local H_x^s theory. In this section, we review the local H_x^s theory for (1.1) as described in [6].

PROPOSITION 3.1 (local well-posedness in H_x^s [6]). *Let $0 < s < 1$ and $u_0 \in H^s(\mathbb{R}^d)$. Then (1.1) is well posed on $[0, T_{lwp}]$ with*

$$T_{lwp} = C_0 \|\langle\nabla\rangle^s u_0\|_2^{-\frac{2}{s}}.$$

Moreover, the unique solution u enjoys the following estimate:

$$\|\langle\nabla\rangle^s u\|_{S^0([0,T_{lwp}])} \lesssim \|\langle\nabla\rangle^s u_0\|_2.$$

Here, C_0 and the implicit constant depend only on dimension d and regularity s.

As a direct consequence of the H^s_x local well-posedness result, we have the following lower bound on the blowup rate of the H^s_x-norm.

COROLLARY 3.2 (blowup criterion [6]). *Let $0 < s < 1$ and $u_0 \in H^s_x$. Assume that the unique solution u to (1.1) blows up at time $0 < T^* < \infty$. Then there exists a constant C depending only on d and s such that*

$$\|u(t)\|_{H^s_x} \geq C(T^* - t)^{-\frac{s}{2}}.$$

As a variation of Proposition 3.1, we have the following.

PROPOSITION 3.3 ("modified" local well-posedness). *Let $\frac{\frac{4}{d}+1}{1+\min\{1,\frac{4}{d}\}+\frac{4}{d}} < s < 1$ and $u_0 \in H^s_x$. Let also*

$$N \gg \|u_0\|_{H^s_x}^{\frac{4}{\min\{4,d\}s-(4+d)(1-s)-d\varepsilon}} \quad \textit{for any } \varepsilon > 0 \textit{ sufficiently small,} \tag{3.1}$$

$$\tilde{T}_{lwp} := c_0\|\langle\nabla\rangle I_N u_0\|_2^{-\frac{2}{s}} \quad \textit{for a small constant } c_0 = c_0(d,s). \tag{3.2}$$

Then (1.1) is well posed on $[0,\tilde{T}_{lwp}]$, and moreover

$$\|\langle\nabla\rangle I_N u\|_{S^0([0,\tilde{T}_{lwp}])} \lesssim \|\langle\nabla\rangle I_N u_0\|_2. \tag{3.3}$$

Proof. As by Lemma 2.4,

$$\|u_0\|_{H^s_x} \lesssim \|\langle\nabla\rangle I_N u_0\|_2,$$

choosing c_0 sufficiently small, we get

$$\tilde{T}_{lwp} \leq T_{lwp}.$$

Thus, (1.1) is well posed in H^s_x on $[0,\tilde{T}_{lwp}]$. Let u be the unique solution; by Proposition 3.1 we have

$$\|\langle\nabla\rangle^s u\|_{S^0([0,\tilde{T}_{lwp}])} \lesssim \|u_0\|_{H^s_x}. \tag{3.4}$$

On the other hand, by Strichartz, for any $t \leq \tilde{T}_{lwp}$ we estimate

$$\|\langle\nabla\rangle I_N u\|_{S^0([0,t])} \lesssim \|\langle\nabla\rangle I_N u_0\|_2 + \|\langle\nabla\rangle I_N F(u)\|_{N^0([0,t])}.$$

As by hypothesis, $s > \frac{\frac{4}{d}+1}{1+\min\{1,\frac{4}{d}\}+\frac{4}{d}} > \frac{1}{1+\min\{1,\frac{4}{d}\}}$, by Lemma 2.10 we get

$$\begin{aligned}\|\langle\nabla\rangle I_N u\|_{S^0([0,t])} \lesssim{}& \|\langle\nabla\rangle I_N u_0\|_2 + t^{\frac{2s}{d}}\|\langle\nabla\rangle I_N u\|_{S^0([0,t])}^{1+\frac{4}{d}} \\ &+ N^{-\min\{1,\frac{4}{d}\}s+\varepsilon}\|\langle\nabla\rangle I_N u\|_{S^0([0,t])}^{1+\frac{4}{d}}\end{aligned} \tag{3.5}$$

for any $\varepsilon > 0$ sufficiently small. For N satisfying (3.1), we use Lemma 2.4 and (3.4) to estimate

$$
\begin{aligned}
N^{-\min\{1,\frac{4}{d}\}s+\varepsilon}&\|\langle\nabla\rangle I_N u\|_{S^0([0,t])}^{1+\frac{4}{d}}\\
&\lesssim N^{-\min\{1,\frac{4}{d}\}s+\varepsilon}N^{(1+\frac{4}{d})(1-s)}\|\langle\nabla\rangle^s u\|_{S^0([0,t])}^{1+\frac{4}{d}}\\
&\ll \|u_0\|_{H_x^s}^{\frac{4}{\min\{4,d\}s-(4+d)(1-s)-d\varepsilon}\times[-\min\{1,\frac{4}{d}\}s+\varepsilon+(1+\frac{4}{d})(1-s)]}\|u_0\|_{H_x^s}^{1+\frac{4}{d}}\\
&\lesssim \|u_0\|_{H_x^s}^{-\frac{4}{d}}\|u_0\|_{H_x^s}^{1+\frac{4}{d}}\lesssim \|\langle\nabla\rangle I_N u_0\|_2.
\end{aligned}
$$

Here, we have used the fact that $s > \frac{\frac{4}{d}+1}{1+\min\{1,\frac{4}{d}\}+\frac{4}{d}}$ implies that there exists $\varepsilon_1 > 0$ sufficiently small such that for any $0 < \varepsilon < \varepsilon_1$ we have $s > \frac{\frac{4}{d}+1+\varepsilon}{1+\min\{1,\frac{4}{d}\}+\frac{4}{d}}$; thus the power of N in the estimates above is negative for $0 < \varepsilon < \varepsilon_1$.

Returning to (3.5), we conclude that

$$\|\langle\nabla\rangle I_N u\|_{S^0([0,t])} \lesssim \|\langle\nabla\rangle I_N u_0\|_2 + t^{\frac{2s}{d}}\|\langle\nabla\rangle I_N u\|_{S^0([0,t])}^{1+\frac{4}{d}}.$$

Standard arguments yield (3.3), provided

$$t \le \tilde{T}_{lwp} = c_0(d,s)\|\langle\nabla\rangle I_N u_0\|_2^{-\frac{2}{s}}. \qquad \square$$

4. Modified energy increment. The main purpose of this section is to prove that the modified energy of u, $E(I_N u)$, grows much slower than the modified kinetic energy of u, $\|\nabla I_N u\|_2^2$. As will be shown later, this result is crucial in establishing the main theorems.

Before stating the result, we need to introduce more notation. We define

$$\Lambda(t) := \sup_{0\le\tau\le t}\|u(\tau)\|_{H_x^s} \quad \text{and} \quad \Sigma(t) := \sup_{0\le\tau\le t}\|I_N u(\tau)\|_{H_x^1}.$$

With this notation we have the following.

PROPOSITION 4.1 (increment of the modified energy). *Let $s_0(d) < s < 1$ and let $u_0 \in H_x^s$ such that the corresponding solution u to* (1.1) *blows up at time $0 < T^* < \infty$. Let $0 < T < T^*$. Then for*

$$N(T) := C\Lambda(T)^{\frac{p(s)}{2(1-s)}}, \tag{4.1}$$

we have

$$|E(I_{N(T)}u(T))| \lesssim \Lambda(T)^{p(s)}.$$

Here, C and the implicit constant depend only on s, T^*, and $\|u_0\|_{H_x^s}$, and $p(s)$ is given by

$$p(s) := \frac{2(2+\frac{2}{s}+\frac{8}{d})(1-s)}{\min\{1,\frac{4}{d}\}s-(\frac{2}{s}+\frac{8}{d})(1-s)-}.$$

Note that by Lemma 2.4, $\Lambda(T) \lesssim \Sigma(T)$. Thus, if the solution blows up at time T^*, the modified energy $E(I_{N(T)}u(T))$ is at most $O(\Sigma(T)^{p(s)})$, which is much smaller than the modified kinetic energy, $\|\nabla I_{N(T)}u(T)\|_2^2 = O(\Sigma(T)^2)$ for $s > s_0(d)$.

We prove Proposition 4.1 in two steps. The first step is to control the increment of the modified energy of u on intervals of local well-posedness $[0,\tilde{T}_{lwp}]$. The second step is to divide the interval $[0,T]$ into finitely many subintervals of local well-posedness, control the increment of the modified energy of u on each of these subintervals, and sum these bounds.

We start with the following.

LEMMA 4.2 (local increment of the modified energy). *Let* $\frac{1+\frac{4}{d}}{1+\frac{4}{d}+\min\{1,\frac{4}{d}\}} < s < 1$ *and let* $u_0 \in H_x^s$. *Assume that* N *and* $\tilde{T}_{lwp}$ *satisfy* (3.1) *and* (3.2), *respectively, that is,*

$$N \gg \|u_0\|_{H_x^s}^{\frac{4}{\min\{4,d\}s-(4+d)(1-s)-}},$$
$$\tilde{T}_{lwp} := c_0 \|\langle\nabla\rangle I_N u_0\|_2^{-\frac{2}{s}} \quad \text{for a small constant } c_0 = c_0(d,s).$$

Then

$$\sup_{t\in[0,\tilde{T}_{lwp}]} |E(I_N u(t))| \leq |E(I_N u_0)| + CN^{-\min\{1,\frac{4}{d}\}s+}(\|I_N\langle\nabla\rangle u_0\|_2^{2+\frac{4}{d}} + \|I_N\langle\nabla\rangle u_0\|_2^{2+\frac{8}{d}}).$$

Here, the constant C *depends on* s, T^*, *and* $\|u_0\|_{H_x^s}$.

Proof. Note that by Proposition 3.3, (1.1) is well posed on $[0,\tilde{T}_{lwp}]$. Furthermore, the unique solution u to (1.1) on $[0,\tilde{T}_{lwp}]$ satisfies

$$\|\langle\nabla\rangle I_N u\|_{S^0([0,\tilde{T}_{lwp}])} \lesssim \|\langle\nabla\rangle I_N u_0\|_2. \tag{4.2}$$

Let $0 < t \leq \tilde{T}_{lwp}$; throughout the rest of the proof, all spacetime norms will be taken on $[0,t]\times\mathbb{R}^d$. By the fundamental theorem of calculus, we can write the modified energy increment as

$$\begin{aligned} E(I_N u(t)) - E(I_N u_0) &= \int_0^t \frac{\partial}{\partial s} E(I_N u(s))\, ds \\ &= \mathrm{Re} \int_0^t \int_{\mathbb{R}^d} \overline{I_N u_t}(-\Delta I_N u + F(I_N u))\, dx\, ds. \end{aligned}$$

As $I_N u_t = i\Delta I_N u - iI_N F(u)$, we have

$$\mathrm{Re} \int_0^t \int_{\mathbb{R}^d} \overline{I_N u_t}(-\Delta I_N u + I_N F(u))\, dx\, ds = 0.$$

Thus, after an integration by parts,

$$E(I_N u(t)) - E(I_N u_0) = \mathrm{Re} \int_0^t \int_{\mathbb{R}^d} \overline{I_N u_t}[F(I_N u) - I_N F(u)]\, dx\, ds$$
$$= -\mathrm{Im} \int_0^t \int_{\mathbb{R}^d} \overline{\nabla I_N u} \cdot \nabla[F(I_N u) - I_N F(u)]\, dx\, ds \tag{4.3}$$
$$- \mathrm{Im} \int_0^t \int_{\mathbb{R}^d} \overline{I_N F(u)} \cdot [F(I_N u) - I_N F(u)]\, dx\, ds. \tag{4.4}$$

Consider the contribution from (4.3). By the triangle inequality,

$$\begin{aligned} \|\nabla[F(I_N u) - I_N F(u)]\|_{2,\frac{2d}{d+2}} &\lesssim \|(\nabla I_N u)[F'(I_N u) - F'(u)]\|_{2,\frac{2d}{d+2}} \\ &\quad + \|(\nabla I_N u)F'(u) - \nabla I_N F(u)\|_{2,\frac{2d}{d+2}}. \end{aligned}$$

By Hölder, (2.1), (2.8), and (2.22), we estimate

$$\begin{aligned}
&\|(\nabla I_N u)[F'(I_N u) - F'(u)]\|_{2,\frac{2d}{d+2}} \\
&\qquad \lesssim \|\nabla I_N u\|_{2,\frac{2d}{d-2}} \|F'(I_N u) - F'(u)\|_{\infty,\frac{d}{2}} \\
&\qquad \lesssim \|\langle\nabla\rangle I_N u\|_{S^0([0,t])} \big\| |I_N u - u|^{\min\{1,\frac{4}{d}\}} (|I_N u| + |u|)^{\frac{4}{d}-\min\{1,\frac{4}{d}\}} \big\|_{\infty,\frac{d}{2}} \\
&\qquad \lesssim \|\langle\nabla\rangle I_N u\|_{S^0([0,t])} \|P_{>N} u\|_{\infty,2}^{\min\{1,\frac{4}{d}\}} \|u\|_{\infty,2}^{\frac{4}{d}-\min\{1,\frac{4}{d}\}} \\
&\qquad \lesssim N^{-\min\{1,\frac{4}{d}\}} \|\langle\nabla\rangle I_N u\|_{S^0([0,t])}^{1+\frac{4}{d}}.
\end{aligned}$$

Combining this with (2.19), we get

$$\|\nabla[F(I_N u) - I_N F(u)]\|_{2,\frac{2d}{d+2}} \lesssim N^{-\min\{1,\frac{4}{d}\}s+} \|\langle\nabla\rangle I_N u\|_{S^0([0,t])}^{1+\frac{4}{d}}. \tag{4.5}$$

Therefore

$$\begin{aligned}
|(4.3)| &\lesssim \|\nabla I_N u\|_{2,\frac{2d}{d-2}} \|\nabla[F(I_N u) - I_N F(u)]\|_{2,\frac{2d}{d+2}} \\
&\lesssim N^{-\min\{1,\frac{4}{d}\}s+} \|\langle\nabla\rangle I_N u\|_{S^0([0,t])}^{2+\frac{4}{d}}. \qquad (4.6)
\end{aligned}$$

We turn now toward (4.4). By (4.5) and Sobolev embedding, we estimate

$$\begin{aligned}
|(4.4)| &\lesssim \|\nabla[F(I_N u) - I_N F(u)]\|_{2,\frac{2d}{d+2}} \||\nabla|^{-1} I_N F(u)\|_{2,\frac{2d}{d-2}} \\
&\lesssim N^{-\min\{1,\frac{4}{d}\}s+} \|\langle\nabla\rangle I_N u\|_{S^0([0,t])}^{1+\frac{4}{d}} \|I_N F(u)\|_{2,2}. \qquad (4.7)
\end{aligned}$$

To estimate the last factor in (4.7), we drop the operator I_N and use Sobolev embedding to obtain

$$\|I_N F(u)\|_{2,2} \lesssim \|u\|_{\frac{2(d+4)}{d},\frac{2(d+4)}{d}}^{1+\frac{4}{d}} \lesssim \||\nabla|^{\frac{d}{d+4}} u\|_{\frac{2(d+4)}{d},\frac{2(d+4)}{d+2}}^{1+\frac{4}{d}}.$$

Note that $(\frac{2(d+4)}{d}, \frac{2(d+4)}{d+2})$ is a Schrödinger-admissible pair. Decompose $u := u_{\leq N} + u_{>N}$. To estimate the low frequencies, we use the fact that I_N is the identity on frequencies $|\xi| \leq N$:

$$\||\nabla|^{\frac{d}{d+4}} u_{\leq N}\|_{\frac{2(d+4)}{d},\frac{2(d+4)}{d+2}} \lesssim \|\langle\nabla\rangle I_N u\|_{S^0([0,t])}.$$

For the high frequencies, we use Lemma 2.4 to get

$$\||\nabla|^{\frac{d}{d+4}} u_{>N}\|_{\frac{2(d+4)}{d},\frac{2(d+4)}{d+2}} \lesssim N^{-\frac{4}{d+4}} \|\nabla I_N u_{>N}\|_{S^0([0,t])},$$

provided $s > \frac{d}{d+4}$; this condition is satisfied since by assumption,

$$s > \frac{1+\frac{4}{d}}{1+\frac{4}{d}+\min\{1,\frac{4}{d}\}} > \frac{d}{d+4}.$$

Therefore,

$$\|I_N F(u)\|_{2,2} \lesssim \|\langle\nabla\rangle I_N u\|_{S^0([0,t])}^{1+\frac{4}{d}}. \tag{4.8}$$

By (4.7) and (4.8), we obtain

$$|(4.4)| \lesssim N^{-\min\{1,\frac{4}{d}\}s+} \|\langle\nabla\rangle I_N u\|_{S^0([0,t])}^{2+\frac{8}{d}}. \tag{4.9}$$

Collecting (4.2), (4.6), and (4.9), we get

$$|E(I_N u(t)) - E(I_N u_0)| \lesssim N^{-\min\{1,\frac{4}{d}\}s+} (\|\langle\nabla\rangle I_N u_0\|_2^{2+\frac{4}{d}} + \|\langle\nabla\rangle I_N u_0\|_2^{2+\frac{8}{d}}).$$

This proves Lemma 4.2. ☐

Next, we use Lemma 4.2 to prove Proposition 4.1.

Let $T < T^*$ and $\Lambda(T)$ and $\Sigma(T)$ be defined as in the beginning of this section. By Proposition 3.3, if we take

$$\begin{cases} N(T) \gg \Lambda(T)^{\frac{4}{\min\{4,d\}s-(4+d)(1-s)-}}, \\ \delta := c_0 \Sigma(T)^{-\frac{2}{s}}, \end{cases} \tag{4.10}$$

then the solution u satisfies the estimate

$$\|\langle\nabla\rangle I_{N(T)} u\|_{S^0([t,t+\delta])} \lesssim \|\langle\nabla\rangle I_{N(T)} u(t)\|_2 \lesssim \Sigma(T),$$

uniformly in t, provided $[t, t+\delta] \subset [0,T]$. Thus, splitting $[0,T]$ into $O(\frac{T}{\delta})$ subintervals and applying Lemma 4.2 on each of these subintervals, we get

$$\begin{aligned} \sup_{t\in[0,T]} |E(I_{N(T)} u(t))| &\lesssim |E(I_{N(T)} u_0)| + \frac{T}{\delta} N(T)^{-\min\{1,\frac{4}{d}\}s+} \Sigma(T)^{2+\frac{4}{d}} \\ &\quad + \frac{T}{\delta} N(T)^{-\min\{1,\frac{4}{d}\}s+} \Sigma(T)^{2+\frac{8}{d}} \\ &\lesssim |E(I_{N(T)} u_0)| + N(T)^{-\min\{1,\frac{4}{d}\}s+} \Sigma(T)^{2+\frac{4}{d}+\frac{2}{s}} \\ &\quad + N(T)^{-\min\{1,\frac{4}{d}\}s+} \Sigma(T)^{2+\frac{8}{d}+\frac{2}{s}}. \end{aligned} \tag{4.11}$$

Using interpolation, Sobolev embedding, and Lemma 2.4, we estimate

$$\begin{aligned} |E(I_{N(T)} u_0)| &\lesssim \|\nabla I_N u_0\|_2^2 + \|I_N u_0\|_{2+\frac{4}{d}}^{2+\frac{4}{d}} \\ &\lesssim N^{2(1-s)} \|u_0\|_{H_x^s}^2 + \|I_N u_0\|_2^{\frac{4}{d}} \|\nabla I_N u_0\|_2^2 \\ &\lesssim N^{2(1-s)} \big(\|u_0\|_{H_x^s}^2 + \|u_0\|_{H_x^s}^{2+\frac{4}{d}} \big) \\ &\lesssim N^{2(1-s)}. \end{aligned} \tag{4.12}$$

Moreover, by Lemma 2.4, we also have

$$\Sigma(T) \lesssim N(T)^{1-s} \Lambda(T). \tag{4.13}$$

Substituting (4.12) and (4.13) into (4.11), we obtain

$$\begin{aligned} \sup_{t\in[0,T]} |E(I_{N(T)} u(t))| &\lesssim N(T)^{2(1-s)} + N(T)^{-\min\{1,\frac{4}{d}\}s+(2+\frac{4}{d}+\frac{2}{s})(1-s)+} \Lambda(T)^{2+\frac{4}{d}+\frac{2}{s}} \\ &\quad + N(T)^{-\min\{1,\frac{4}{d}\}s+(2+\frac{8}{d}+\frac{2}{s})(1-s)+} \Lambda(T)^{2+\frac{8}{d}+\frac{2}{s}}. \end{aligned} \tag{4.14}$$

Optimizing (4.14), we observe that if

$$N(T) \sim \Lambda(T)^{\frac{2+\frac{8}{d}+\frac{2}{s}}{\min\{1,\frac{4}{d}\}s-(1-s)(\frac{8}{d}+\frac{2}{s})-}}, \tag{4.15}$$

then $N(T)$ satisfies the assumption (4.10), and moreover

$$\sup_{t\in[0,T]} |E(I_{N(T)}u(t))| \lesssim N(T)^{2(1-s)}$$
$$\lesssim \Lambda(T)^{\frac{2(2+\frac{8}{d}+\frac{2}{s})(1-s)}{\min\{1,\frac{4}{d}\}s-(1-s)(\frac{8}{d}+\frac{2}{s})-}}.$$

Let

$$p(s) := \frac{2(2+\frac{8}{d}+\frac{2}{s})(1-s)}{\min\{1,\frac{4}{d}\}s-(1-s)(\frac{8}{d}+\frac{2}{s})-}.$$

Then a little work shows that the condition $0 < p(s) < 2$ leads to the restriction

$$s > s_0(d).$$

Thus, for $N(T)$ defined in (4.15) and $s > s_0(d)$, we have $0 < p(s) < 2$ and

$$\sup_{t\in[0,T]} |E(I_{N(T)}u)(t)| \lesssim \Lambda(T)^{p(s)}.$$

This proves Proposition 4.1.

5. Proof of Theorem 1.1. In this section, we use Proposition 4.1 together with Lemma 2.11 to prove Theorem 1.1.

We choose a sequence of times $\{t_n\}_{n\geq 1}$, such that $t_n \to T^*$ as $n \to \infty$ and

$$\|u(t_n)\|_{H_x^s} = \Lambda(t_n).$$

As the solution u blows up at time T^*, we must have $\Lambda(t_n) \to \infty$ as $n \to \infty$.

Set

$$\psi_n(x) := \rho_n^{\frac{d}{2}}(I_{N(t_n)}u)(t_n, \rho_n x),$$

where $N(t_n)$ is given by (4.1) with $T := t_n$ and the parameter ρ_n is given by

$$\rho_n := \frac{\|\nabla Q\|_2}{\|\nabla I_{N(t_n)}u(t_n)\|_2}.$$

By Lemma 2.4 and Corollary 3.2, we get

$$\rho_n \lesssim \frac{1}{\|u(t_n)\|_{H_x^s}} \lesssim (T^* - t_n)^{\frac{s}{2}}.$$

Basic calculations show that $\{\psi_n\}_{n\geq 1}$ is a bounded sequence in H_x^1. Indeed,

$$\begin{aligned} \|\psi_n\|_2 &= \|I_{N(t_n)}u(t_n)\|_2 \leq \|u(t_n)\|_2 = \|u_0\|_2, \\ \|\nabla\psi_n\|_2 &= \rho_n\|I_{N(t_n)}\nabla u(t_n)\|_2 = \|\nabla Q\|_2. \end{aligned} \tag{5.1}$$

By Proposition 4.1 (with $T = t_n$), we can estimate the energy of ψ_n as follows:

$$E(\psi_n) = \rho_n^2 E(I_{N(t_n)}u(t_n)) \lesssim \rho_n^2\Lambda(t_n)^{p(s)} \lesssim \|u(t_n)\|_{H_x^s}^{p(s)-2}.$$

Thus, as $p(s) < 2$ for $s > s_0(d)$,

$$E(\psi_n) \to 0 \quad \text{as} \quad n \to \infty,$$

which by the definition of the energy and (5.1) implies

$$\|\psi_n\|_{2+\frac{4}{d}}^{2+\frac{4}{d}} \to \frac{d+2}{d}\|\nabla Q\|_2^2 \quad \text{as } n\to\infty. \tag{5.2}$$

Applying Lemma 2.11 to the sequence $\{\psi_n\}_{n\geq 1}$ (with $M := \|\nabla Q\|_2$ and $m := (\frac{d+2}{d}\|\nabla Q\|_2^2)^{\frac{d}{2d+4}}$), we derive the existence of a sequence $\{x_n\}_{n\geq 1}\subset \mathbb{R}^d$ and of a function $V\in H^1(\mathbb{R}^d)$ such that $\|V\|_2 \geq \|Q\|_2$ and, up to a subsequence,

$$\psi_n(\cdot + x_n) \rightharpoonup V \quad \text{weakly in } H_x^1 \quad \text{as } n\to\infty,$$

that is,

$$\rho_n^{\frac{d}{2}}(I_{N(t_n)}u)(t_n, \rho_n\cdot + x_n) \rightharpoonup V \quad \text{weakly in } H_x^1 \quad \text{as } n\to\infty. \tag{5.3}$$

To prove Theorem 1.1, we have to eliminate the smoothing operator $I_{N(t_n)}$ from (5.3). We do so at the expense of trading the weak convergence in H_x^1 for convergence in the sense of distributions. Indeed, for any $\sigma < s$ we have

$$\begin{aligned}
\|\rho_n^{\frac{d}{2}}\big(u(t_n) - I_{N(t_n)}u(t_n)\big)(\rho_n\cdot + x_n)\|_{\dot H_x^\sigma} &= \rho_n^\sigma \|P_{\geq N(t_n)}u(t_n)\|_{\dot H_x^\sigma}\\
&\lesssim \rho_n^\sigma N(t_n)^{\sigma - s}\|P_{\geq N(t_n)}u(t_n)\|_{\dot H_x^s}\\
&\lesssim \Lambda(t_n)^{-\sigma}\Lambda(t_n)^{\frac{(\sigma-s)p(s)}{2(1-s)}}\|P_{\geq N(t_n)}u(t_n)\|_{H_x^s}\\
&\lesssim \Lambda(t_n)^{1-\sigma+\frac{(\sigma-s)p(s)}{2(1-s)}}.
\end{aligned}\tag{5.4}$$

Plugging the explicit expression for $p(s)$ into the above computation, we find that for

$$\sigma < \tilde s := \frac{2d+8s+s^2 d(2-\min\{1,\frac{4}{d}\})}{4d+16s - s^2(d\min\{1,\frac{4}{d}\}+8)},$$

the exponent of $\Lambda(t_n)$ in (5.4) is negative. Hence,

$$\|\rho_n^{\frac{d}{2}}\big(u(t_n) - I_{N(t_n)}u(t_n)\big)(\rho_n\cdot + x_n)\|_{H_x^{\tilde s -}} \to 0 \quad \text{as } n\to\infty. \tag{5.5}$$

Combining (5.3) and (5.5) finishes the proof of Theorem 1.1.

6. Proof of Theorem 1.2. By Theorem 1.1, there exists a blowup profile $V\in H_x^1$, with $\|V\|_2\geq \|Q\|_2$, and there exist sequences $\{t_n,\rho_n,x_n\}_{n\geq1}\subset \mathbb{R}_+\times\mathbb{R}_+^*\times\mathbb{R}^d$ such that $t_n\to T^*$,

$$\frac{\rho_n}{(T^*-t_n)^{\frac{s}{2}}} \lesssim 1 \quad \forall\, n\geq 1, \tag{6.1}$$

and

$$\rho_n^{\frac{d}{2}} u(t_n, \rho_n\cdot + x_n) \rightharpoonup V \quad \text{weakly as } n\to\infty. \tag{6.2}$$

From (6.2) it follows that for any $R>0$ we have

$$\liminf_{n\to\infty} \rho_n^d \int_{|x|\leq R} |u(t_n,\rho_n x + x_n)|^2 \geq \int_{|x|\leq R} |V|^2 dx,$$

which, by a change of variables, yields

$$\liminf_{n\to\infty}\sup_{y\in\mathbb{R}^d}\int_{|x-y|\le R\rho_n}|u(t_n,x)|^2dx\ge\int_{|x|\le R}|V|^2dx.$$

As by hypothesis $\frac{(T^*-t_n)^{\frac{s}{2}}}{\alpha(t_n)}\to 0$ as $n\to\infty$, (6.1) implies that $\frac{\rho_n}{\alpha(t_n)}\to 0$ as $n\to\infty$. Therefore,

$$\liminf_{n\to\infty}\sup_{y\in\mathbb{R}^d}\int_{|x-y|\le\alpha(t_n)}|u(t_n,x)|^2dx\ge\int_{|x|\le R}|V|^2dx.$$

Letting $R\to\infty$, we obtain

$$\liminf_{n\to\infty}\sup_{y\in\mathbb{R}^d}\int_{|x-y|\le\alpha(t_n)}|u(t_n,x)|^2dx\ge\|V\|_2^2.$$

As $\|V\|_2\ge\|Q\|_2$, this implies

$$\limsup_{t\to T^*}\sup_{y\in\mathbb{R}^d}\int_{|x-y|\le\alpha(t)}|u(t,x)|^2dx\ge\|Q\|_2^2.$$

As for any fixed time t, the map $y\to\int_{|x-y|\le\alpha(t)}|u(t,x)|^2dx$ is continuous and goes to zero as $y\to\infty$, and there exists $x(t)\in\mathbb{R}^d$ such that

$$\sup_{y\in\mathbb{R}^d}\int_{|x-y|\le\alpha(t)}|u(t,x)|^2dx=\int_{|x-x(t)|\le\alpha(t)}|u(t,x)|^2dx.$$

This finally implies

$$\limsup_{t\to T^*}\int_{|x-x(t)|\le\alpha(t)}|u(t,x)|^2dx\ge\|Q\|_2^2,$$

which proves Theorem 1.2.

7. Proof of Theorem 1.3. In this section, we upgrade Theorem 1.1 to Theorem 1.3 under the additional assumption $\|u_0\|_2=\|Q\|_2$.

With the notation used in the proof of Theorem 1.1, we have

$$\|\psi_n\|_2\le\|u_0\|_2=\|Q\|_2\le\|V\|_2.$$

On the other hand, using the semicontinuity of weak convergence,

$$\|V\|_2\le\liminf_{n\to\infty}\|\psi_n\|_2\le\|Q\|_2.$$

Therefore,

$$\|V\|_2=\|Q\|_2=\lim_{n\to\infty}\|\psi_n\|_2.$$

Thus, as $\psi_n(\cdot+x_n)\rightharpoonup V$ weakly in L^2_x (up to a subsequence which we still denote by $\psi_n(\cdot+x_n)$), we conclude that

$$\psi_n(\cdot+x_n)\to V\ \text{ strongly in } L^2_x.$$

Moreover, by the Gagliardo–Nirenberg inequality and the boundedness of $\{\psi_n\}_{n\geq 1}$ in H^1_x, we have

$$\psi_n(\cdot + x_n) \to V \quad \text{in } L_x^{2+\frac{4}{d}}.$$

Combining this with (5.2) and the sharp Gagliardo–Nirenberg inequality, we obtain

$$\|\nabla Q\|_2 \leq \|\nabla V\|_2.$$

By the semicontinuity of weak convergence, we also have

$$\|\nabla V\|_2 \leq \liminf_{n\to\infty} \|\nabla \psi_n\|_2 = \|\nabla Q\|_2,$$

and so

$$\|\nabla V\|_2 = \|\nabla Q\|_2 = \lim_{n\to\infty} \|\nabla \psi_n\|_2.$$

Thus, as $\psi_n(\cdot + x_n) \rightharpoonup V$ in H^1_x, we conclude that

$$\psi_n(\cdot + x_n) \to V \quad \text{strongly in } H^1_x.$$

In particular, this implies

$$E(V) = 0.$$

Collecting the properties of V, we find

$$V \in H^1_x, \quad \|V\|_2 = \|Q\|_2, \quad \|\nabla V\|_2 = \|\nabla Q\|_2, \quad \text{and} \quad E(V) = 0.$$

The variational characterization of the ground state [39] implies that

$$V(x) = e^{i\theta} Q(x + x_0)$$

for some $(e^{i\theta}, x_0) \in (S^1 \times \mathbb{R}^d)$. Thus,

$$\rho_n^{\frac{d}{2}} (I_{N(t_n)} u)(t_n, \rho_n x + x_n) \to e^{i\theta} Q(x + x_0) \quad \text{strongly in } H^1_x \text{ as } n \to \infty. \tag{7.1}$$

Theorem 1.3 follows from (5.5) and (7.1).

INVERSE SOURCE PROBLEMS IN TRANSPORT EQUATIONS*

GUILLAUME BAL† AND ALEXANDRU TAMASAN‡

Abstract. This paper proposes an iterative technique to reconstruct the source term in transport equations, which account for scattering effects, from boundary measurements. In the two-dimensional setting, the full outgoing distribution in the phase space (position and direction) needs to be measured. In three space dimensions, we show that measurements for angles that are orthogonal to a given direction are sufficient. In both cases, the derivation is based on a perturbation of the inversion of the two-dimensional attenuated Radon transform and requires that (the anisotropic part of) scattering be sufficiently small. We present an explicit iterative procedure, which converges to the source term we want to reconstruct. Applications of the inversion procedure include optical molecular imaging, an increasingly popular medical imaging modality.

Key words. attenuated Radon transform, scattering, optical molecular imaging

1. Introduction.

Optical molecular imaging (OMI) is being increasingly studied as a powerful detection method in medical imaging. New biochemical markers are currently being engineered to attach to specific molecules and thus be used to detect faulty genes and other molecular processes, which precede the development of certain diseases. This makes possible the detection of such diseases long before phenotypical symptoms appear. In OMI, the markers are light-emitting molecules, such as fluorophores or luminophores. Compared to other molecular imaging techniques, such as single photon emission tomography (SPECT) or positron emission tomography (PET), optical markers emit low-energy near-infrared photons that are relatively harmless to the human body. Other advantages are their high sensitivity to oxygen levels, metal ion concentrations, pH, and lipid composition, for instance; see [31, 32, 40, 41] for recent references in the biomedical literature.

The inverse problem consists of reconstructing the spatial distribution of the markers from measurements of light intensities at the boundary of the object we wish to image. Two main types of markers are used in OMI, namely, bioluminescent and fluorescent markers. In both cases, the propagation in human tissues of the photons emitted by the markers can quite satisfactorily be modeled as inverse source problems of time-harmonic and steady-state radiative transfer equations [11, 21, 42]. To simplify the presentation, we consider only the steady-state problem here, for which relatively few results exist in the mathematical literature.

Our main result consists in providing an explicit (and converging) iterative technique to reconstruct the source term from boundary measurements of the photon intensity in the phase space, i.e., as a function of position and angular direction. We consider the two-dimensional and the three-dimensional settings. In both cases,

we have to assume that the *anisotropic part* of scattering is sufficiently regular and small (in the sense that a certain operator linear in the anisotropic part of the scattering term must have a norm bounded by one in appropriate spaces). In three dimensions, we show that measurements of the photon intensity for directions orthogonal to an arbitrary given vector are sufficient. Both results are based on perturbations of the Novikov inversion formula to invert the attenuated Radon transform (see [3, 7, 9, 19, 14, 15, 20, 26, 29, 30] for some references on that problem), and we thus show that the Novikov inversion formula is stable under perturbations by a scattering operator. How small scattering has to be in terms of the absorbing and geometric properties of the domain is somewhat characterized in Corollary 3.7.

Several imaging techniques such as SPECT and PET are based on the inversion of the Radon transform or the attenuated Radon transform. Because optical markers emit low-energy light, the photons scatter before they are measured. This renders the inversion more difficult than in the higher-energy methods SPECT and PET and necessitates the use of transport equations that account for scattering effects.

For earlier works on the inverse source problem of transport equations based on different methods, we refer the reader to [2, 22, 33, 35, 37, 1]. A more general geometric setting than is presented here can be found in [35] (see also [36]), where particles may travel along the geodesics of a general Riemannian manifold. For a fixed domain Ω the main assumption in the uniqueness and stability result in [35] imposes a smallness condition on a, even in the absence of scattering. This constraint is not needed here.

In this paper, we are interested only in the source reconstruction and assume that the absorption and scattering coefficients are known; see [4, 5, 6, 12, 18, 23, 24, 38, 39] for references on the determination of these parameters.

The iterative procedure presented here will not work in the highly scattering regime (unless that scattering is fully isotropic), in which case the diffusion approximation should be used [4]. It should be mostly effective in situations where scattering needs to be accounted for to obtain a desired accuracy in the reconstruction and yet is not too strong for a method based on a perturbation of a nonscattering inversion technique to converge. Practically, we expect this situation to arise in OMI in small domains (on the order of 5–10 mean free paths), such as small animals, and in SPECT and PET, where moderate scattering is accounted for.

The rest of the paper is organized as follows. Section 2 introduces the inverse source problem in transport equations and presents our main results. The derivation of the results is postponed to section 3 for the two-dimensional case and section 4 for the three-dimensional extension.

2. An inverse source problem. The distribution of photons emitted by the markers is denoted by $f(\mathbf{x})$, where position $\mathbf{x} \in \Omega \subset \mathbb{R}^d$. Here Ω is a bounded open convex domain and $d = 2, 3$ is the space dimension. We normalize the light speed to unity and denote by $\boldsymbol{\theta} \in S^{d-1}$ the direction of the photons. Notice that $d = 3$ is the physical model, whereas $d = 2$ is not physical as photons are allowed to travel only in a two-dimensional plane.

Let $u(\mathbf{x}, \boldsymbol{\theta})$ be the density of photons at position x moving in the direction $\boldsymbol{\theta}$, and let

$$\Gamma_\pm \equiv \Gamma_\pm(\Omega) = \{(\mathbf{x}, \boldsymbol{\theta}) \in \partial\Omega \times S^{d-1}, \quad \pm\boldsymbol{\theta} \cdot \mathbf{n}(\mathbf{x}) > 0\} \tag{1}$$

denote the boundary spaces. Here $\mathbf{n}(\mathbf{x})$ is the outward normal to Ω at $\mathbf{x} \in \partial\Omega$. The density of particles satisfies the radiation transfer (transport) equation

$$\begin{aligned} &\boldsymbol{\theta} \cdot \nabla_{\mathbf{x}} u(\mathbf{x}, \boldsymbol{\theta}) + a(\mathbf{x}) u(\mathbf{x}, \boldsymbol{\theta}) = K u(\mathbf{x}, \boldsymbol{\theta}) + f(\mathbf{x}) \quad \text{in } \Omega \times S^{d-1}, \\ &u(\mathbf{x}, \boldsymbol{\theta}) = 0 \quad \text{on } \Gamma_-, \end{aligned} \tag{2}$$

where the measure $d\boldsymbol{\theta}$ is the usual surface measure on the unit sphere normalized such that $\int_{S^{d-1}} d\boldsymbol{\theta} = 1$. Photon interaction with the underlying medium is modeled by an absorption parameter $a(\mathbf{x})$ and a scattering operator

$$Ku(\mathbf{x}, \boldsymbol{\theta}) = \int_{S^{d-1}} k(\mathbf{x}, \boldsymbol{\theta} \cdot \boldsymbol{\theta}') u(\mathbf{x}, \boldsymbol{\theta}') d\boldsymbol{\theta}', \tag{3}$$

where $k(\mathbf{x}, \mu)$ is the scattering coefficient.

Throughout this paper, the absorption a and the scattering k are nonnegative smooth functions which satisfy the subcritical inequality

$$a(\mathbf{x}) - \int_{S^{d-1}} k(\mathbf{x}, \boldsymbol{\theta} \cdot \boldsymbol{\theta}') d\boldsymbol{\theta}' \geq 0, \tag{4}$$

pointwise in $\mathbf{x} \in \Omega$. We assume that the absorption coefficient $a \in C^2(\Omega)$ and it is of compact support. The smoothness of the scattering coefficient k will be stated in the theorems. The subcritical assumption (4) defines the forward operator, which maps the source f to the distribution u and is bounded from $L^2(\Omega)$ to $L^2(\Omega \times S^{d-1})$. Since $\overline{\Omega}$ is compact, it is shown in [25] that the operator norm of the forward operator is bounded independently of the scattering kernel k in (4).

Moreover, the outgoing photon distribution, defined as the trace of $u(\mathbf{x}, \boldsymbol{\theta})$ on Γ_+, is well defined and belongs to $L^2_{\boldsymbol{\theta} \cdot \mathbf{n}}(\Gamma_+)$, in the sense that $\int_{\Gamma_+} \boldsymbol{\theta} \cdot \mathbf{n}\, u^2(\mathbf{x}, \boldsymbol{\theta}) d\sigma(\mathbf{x}) d\boldsymbol{\theta} < \infty$, where $d\sigma$ is the surface measure on $\partial\Omega$. For additional references on the mathematical theory of the transport equation (2), see, for instance, [10, 13, 25].

We remark that for the inverse problem under consideration, the fact that a has compact support is not an essential restriction. Indeed, we can extend a to a larger domain $\tilde{\Omega} \supset \Omega$ by preserving its C^2 smoothness and such that it vanishes near the boundary. The scattering is extended by zero outside Ω. Now we can consider the boundary value problem in the larger domain $\tilde{\Omega}$. The operator norm of the forward operator may increase, but its bound is still independent of the scattering coefficient on Ω. Since scattering vanishes on $\tilde{\Omega} \backslash \Omega$, the values of the transport solution at the boundary of the extended domain $\tilde{\Omega}$ on $\Gamma_{\pm}(\tilde{\Omega})$ can easily be related to the values of the transport solution at the boundary of the initial domain Ω on $\Gamma_{\pm}(\Omega)$ by a bijective transformation.

It is convenient in the analysis to have unbounded spatial domains. We extended $f(\mathbf{x})$, $k(\mathbf{x}, \mu)$, and $a(\mathbf{x})$ by 0 on $\mathbb{R}^d \backslash \Omega$. The transport equation is now recast as

$$\begin{aligned} &\boldsymbol{\theta} \cdot \nabla_{\mathbf{x}} u(\mathbf{x}, \boldsymbol{\theta}) + a(\mathbf{x}) u(\mathbf{x}, \boldsymbol{\theta}) = K u(\mathbf{x}, \boldsymbol{\theta}) + f(\mathbf{x}) \quad \text{in } \mathbb{R}^d \times S^{d-1}, \\ &\lim_{t \to \infty} u(\mathbf{x} - t\boldsymbol{\theta}, \boldsymbol{\theta}) = 0 \quad \text{on } \mathbb{R}^d \times S^{d-1}. \end{aligned} \tag{5}$$

The restriction of the above solution on $\Omega \times S^{d-1}$ solves (2).

Our main results are that in dimension $d = 2$, knowledge of

$$m(s, \boldsymbol{\theta}) = \lim_{t \to \infty} u(t\boldsymbol{\theta} + s\boldsymbol{\theta}^{\perp}, \boldsymbol{\theta}) \tag{6}$$

on $\mathbb{R} \times S^1$, with u the unique solution of (5), uniquely determines $f(\mathbf{x})$ compactly supported on the bounded domain Ω provided that the scattering kernel $k(\mathbf{x}, \mu)$ is sufficiently small. Moreover, the reconstruction is explicit, in the sense that $f(\mathbf{x})$ is obtained as the limit of a converging Neumann series expansion. Note that $u(t\boldsymbol{\theta} + s\boldsymbol{\theta}^{\perp}, \boldsymbol{\theta})$ is independent of t for t sufficiently large.

In three dimensions, $d = 3$, the above result generalizes as follows. Let an arbitrary vector in $\mathbb{R}^3$ be given, which after possible rotation of Ω we denote by $\mathbf{e}_z$. For $\boldsymbol{\theta} = (\cos\theta, \sin\theta, 0)$, we define $\boldsymbol{\theta}^{\perp} = (-\sin\theta, \cos\theta, 0)$. Then knowledge of

$$m(z, s, \theta) = \lim_{t\to\infty} u(t\boldsymbol{\theta} + s\boldsymbol{\theta}^{\perp} + z\mathbf{e}_z, \boldsymbol{\theta}) \tag{7}$$

for $(z, s, \theta) \in \mathbb{R} \times \mathbb{R} \times (0, 2\pi)$ uniquely determines $f(\mathbf{x})$ compactly supported on the bounded domain Ω. This result also requires that $k(\mathbf{x}, \mu)$ be sufficiently small in an appropriate sense and the reconstruction is explicit in the sense mentioned above. This implies that the outgoing measurements are known only for directions orthogonal to $\mathbf{e}_z$. Note that in both cases, the problem is formally determined since both the measurements as well as the unknown source term are d-dimensional.

To state the regularity and smallness assumption of the scattering, we introduce the following notation. When $d = 2$, we identify $k(\mathbf{x}, \boldsymbol{\theta}\cdot\boldsymbol{\theta}') = k(\mathbf{x}, \cos(\theta - \theta')) = \tilde{k}(\mathbf{x}, \theta - \theta')$ and define the Fourier coefficients $k_n(\mathbf{x})$ by

$$k_n(\mathbf{x}) = \frac{1}{2\pi}\int_0^{2\pi} \tilde{k}(\mathbf{x}, \theta) e^{-in\theta} d\theta. \tag{8}$$

By $\hat{k}_n(\boldsymbol{\xi})$, we mean its Fourier transform $\hat{k}_n(\boldsymbol{\xi}) = \int_{\mathbb{R}^2} e^{-i\boldsymbol{\xi}\cdot\mathbf{x}} k_n(\mathbf{x}) d\mathbf{x}$.

When $d = 3$, we use the Legendre polynomials expansion in $L^2[-1, 1]$:

$$k(\mathbf{x}, t) = \sum_{n=0}^{\infty} k_n(\mathbf{x}) P_n(t). \tag{9}$$

By $\hat{k}_n(\boldsymbol{\xi}', z)$, we mean the restricted Fourier transform to the horizontal plane $\hat{k}_n(\boldsymbol{\xi}, z) = \int_{\mathbb{R}^2} e^{-i\mathbf{x}'\cdot\boldsymbol{\xi}'} k_n(\mathbf{x}', z) d\mathbf{x}'$. For $\boldsymbol{\theta} = (\cos\theta\sin\phi, \sin\theta\sin\phi, \cos\phi) \in S^2$, $0 \le \theta < 2\pi$, $0 \le \phi < \pi$, let

$$Y_{nm}(\boldsymbol{\theta}) = C_{nm}^{1/2} e^{im\theta} P_n^m(\cos\phi) \tag{10}$$

denote the spherical harmonics on the sphere S^2. Here, P_n^m are the associated Legendre polynomials and $C_{nm} = (2n+1)(n-m)!/(n+m)!$; see [17] for details. We need only to consider horizontal directions

$$\boldsymbol{\theta} \in S_H^2 = \{\boldsymbol{\theta} \in S^2 : \boldsymbol{\theta}\cdot e_z = 0\}. \tag{11}$$

We are ready to formulate our main results, whose proof is postponed to the following sections. The decay uses the usual notation $\langle n\rangle = (1 + |n|^2)^{1/2}$.

THEOREM 2.1 (two-dimensional case). *Let $f(\mathbf{x}) \in L^2(\mathbb{R}^2)$ be a source term of compact support in Ω and $a \in C_0^2(\Omega)$ an absorption coefficient of compact support. Then there exists $\epsilon > 0$ depending on the size of the support and on the smoothness of a such that, for a scattering coefficient k with*

$$\max_{n\in\mathbb{Z}} \langle n\rangle^{\alpha} \|\hat{k}_n\|^2_{L^1(\mathbb{R}^2)} < \epsilon \tag{12}$$

for some $\alpha > 1$, the measurements $m(s, \theta)$ in (6) uniquely determine the source term $f(\mathbf{x})$. Moreover, the source term $f(\mathbf{x})$ can be obtained as the limit of the explicit *convergent Neumann series in* (44) *below; see also Remark* 3.12. *A more explicit expression for* ϵ *in* (12) *can be found in Corollary* 3.7 *below.*

THEOREM 2.2 (three-dimensional case). *Let* $f(\mathbf{x}) \in L^2(\mathbb{R}^3)$ *be a source term of compact support and* $a \in C_0^2(\Omega)$ *an absorption coefficient of compact support. Then there exists an* $\epsilon > 0$ *depending on the size of the support and on the smoothness of* a *such that, for a scattering kernel* k *with*

$$\max_{n\in\mathbb{N}} \left(\langle n \rangle^{\alpha-1} \max_{|m|\le n} \max_{\boldsymbol{\theta}\in S_H^2} |Y_{nm}(\boldsymbol{\theta})|^2 \int_{\mathbb{R}} \|\hat{k}_n(\cdot,z)\|^2_{L^1(\mathbb{R}^2)} dz \right) \le \epsilon \tag{13}$$

for some $\alpha > 1$, *the measurements* $m(z,s,\theta)$ *in* (7) *uniquely determine the source term* $f(\mathbf{x})$. *Moreover, the source term* $f(\mathbf{x})$ *can be obtained as the limit of the convergent Neumann series expansion in* (66) *below.*

Note that each theorem requires smallness as well as (weak) smoothness on the scattering kernel k. That k is not arbitrary is already apparent in the existence theory for the forward problem, where we have assumed (4). The L^1-norm in the Fourier variables implies continuity of the scattering in the horizontal plane. The Sobolev-type decay property implies smoothness in the angular variable. For instance, $\alpha > 2$ in (12) already implies continuity of k in θ. The size of ϵ depends on the (operator) norm of the operator N_K introduced below and is not explicit. This restriction is the price to pay to obtain a reconstruction as a perturbation of the inversion of the attenuated Radon transform, where there is no scattering.

Let us conclude this section by noting, as was mentioned in the introduction, that only the *anisotropic* part of the scattering need be small.

COROLLARY 2.3. *The results stated in Theorems* 2.1 *and* 2.2 *are still valid when* (12) *and* (13), *respectively, hold only for* $n \neq 0$.

Proof. Indeed, let us decompose $K = K_0 + K_1$, where $K_0u(\mathbf{x}) = k_0(\mathbf{x}) \int_{S^{d-1}} u(\mathbf{x}, \boldsymbol{\theta}')$ $\cdot d\boldsymbol{\theta}'$ is the isotropic part of K, and $K_1 = K - K_0$ the anisotropic part. We define the source term

$$F(\mathbf{x}) = f(\mathbf{x}) + K_0u(\mathbf{x}), \tag{14}$$

where $u(\mathbf{x}, \boldsymbol{\theta})$ is the solution to (5). We then verify that the following equation also holds:

$$\begin{aligned} &\boldsymbol{\theta} \cdot \nabla_{\mathbf{x}} u(\mathbf{x}, \boldsymbol{\theta}) + a(\mathbf{x}) u(\mathbf{x}, \boldsymbol{\theta}) = K_1 u(\mathbf{x}, \boldsymbol{\theta}) + F(\mathbf{x}) \quad \text{in } \mathbb{R}^d \times S^{d-1}, \\ &\lim_{t\to\infty} u(\mathbf{x} - t\boldsymbol{\theta}, \boldsymbol{\theta}) = 0 \quad \text{on } \mathbb{R}^d \times S^{d-1}. \end{aligned} \tag{15}$$

We can then apply Theorem 2.1 or 2.2, depending on dimension d, based on the smallness assumptions on K_1, and conclude that $F(\mathbf{x})$ can be reconstructed from the boundary measurements. Once $F(\mathbf{x})$ is known, we can solve for u in (15) and thus calculate $K_0u(\mathbf{x})$. It remains to identify $f(\mathbf{x}) = F(\mathbf{x}) - K_0u(\mathbf{x})$ to conclude the proof of the corollary. ∎

3. Derivation in two space dimensions. This section is devoted to the derivation of the inversion procedure in two space dimensions and on the proof of Theorem 2.1. For any unit vector $\boldsymbol{\theta} \in S^1$, we introduce the representation $\boldsymbol{\theta} = (\cos\theta, \sin\theta)$ for $0 \le \theta < 2\pi$ and identify any function $f(\boldsymbol{\theta}) \equiv f(\theta)$.

We define the classical beam transform S and the symmetrized beam transform

D (independently of the spatial dimension d) as

$$Sa(\mathbf{x}, \boldsymbol{\theta}) = \int_{-\infty}^{0} a(\mathbf{x} + s\boldsymbol{\theta}) ds, \tag{16}$$

$$Da(\mathbf{x}, \boldsymbol{\theta}) = \frac{1}{2}\Big(\int_{-\infty}^{0} a(\mathbf{x} + s\boldsymbol{\theta}) ds - \int_{0}^{\infty} a(\mathbf{x} + s\boldsymbol{\theta}) ds \Big). \tag{17}$$

Since $a(\mathbf{x}) \in C_0^2(\Omega)$ then $Da(\mathbf{x}, \theta)$ and $(e^{Da})(\mathbf{x}, \theta)$ are well defined C^2-smooth functions. Notice that e^{Da} is an integrating factor for (5) (since $(\boldsymbol{\theta} \cdot \nabla) e^{Da} = a e^{Da}$) and so it is more convenient to consider the equation for

$$w(\mathbf{x}, \theta) = (e^{Da} u)(\mathbf{x}, \theta). \tag{18}$$

Next we multiply (5) by the integrating factor e^{Da} and integrate in the direction of $\boldsymbol{\theta}$ to see that w solves the equivalent integral equation [13, 25]

$$w(\mathbf{x}, \theta) = S e^{Da} K e^{-Da} w(\mathbf{x}, \theta) + S e^{Da} f(\mathbf{x}, \theta). \tag{19}$$

Under the subcritical assumption (4) the equation above is uniquely solvable [25] and the operator

$$T := [I - S e^{Da} K e^{-Da}]^{-1} S e^{Da} \tag{20}$$

is bounded from $L^2(\Omega)$ to $L^2(\mathbb{R}^2 \times S^1)$. Moreover, the operator norm can be bounded independently of the scattering operator K provided that (4) holds; see [25] for the details.

We have then

$$w(\mathbf{x}, \theta) = Tf(\mathbf{x}, \theta) = S e^{Da} f + S e^{Da} K e^{-Da} T f. \tag{21}$$

Let us introduce the operator L acting on functions $w(\mathbf{x}, \theta)$ as

$$Lw(s, \theta) = \lim_{t \to \infty} w(t\boldsymbol{\theta} + s\boldsymbol{\theta}^{\perp}, \theta). \tag{22}$$

The product LS is the usual Radon transform

$$Rf(s, \theta) = LSf(s, \theta). \tag{23}$$

It is convenient to work with slightly modified measurements. Let us introduce

$$g(s, \theta) = Lw(s, \theta) = \lim_{t \to \infty} (e^{Da} u)(t\boldsymbol{\theta} + s\boldsymbol{\theta}^{\perp}, \theta) = e^{\frac{1}{2} Ra}(s, \theta) m(s, \theta), \tag{24}$$

where $m(s, \theta)$ was defined in (6). Since a is known, then so are the new "measurements" $g(s, \theta)$.

Let us finally introduce the attenuated X-ray transform operator

$$R_a f(s, \theta) = LS e^{Da} f(s, \theta). \tag{25}$$

Applying L to (19), we deduce that the measurements $g(s, \theta)$ are given by

$$g(s, \theta) = R_a f(s, \theta) + R e^{Da} K e^{-Da} T f(s, \theta). \tag{26}$$

An inversion for R_a was recently obtained in [29]; see also [3, 7, 9, 19, 26, 30] for recent works on the attenuated X-ray transform. We define the inversion operator N, acting on functions $g(s,\theta)$ defined on $\mathbb{R}\times S^1$, by

$$Ng(\mathbf{x}) = \frac{1}{4\pi}\int_0^{2\pi} \boldsymbol{\theta}^{\perp}\cdot\nabla_{\mathbf{x}}(R^*_{-a,\theta}H_a g)(\mathbf{x},\theta)d\theta, \tag{27}$$

where

$$\begin{aligned} R^*_{a,\theta}g(\mathbf{x}) &= e^{D_\theta a(\mathbf{x})}g(\mathbf{x}\cdot\boldsymbol{\theta}^{\perp}), \\ H_a &= C_cHC_c + C_sHC_s, & Hu(t) &= \frac{1}{\pi}\int_{\mathbb{R}}\frac{u(s)}{t-s}ds, \\ C_cg(s,\theta) &= g(s,\theta)\cos\left(\frac{HRa(s,\theta)}{2}\right), & C_sg(s,\theta) &= g(s,\theta)\sin\left(\frac{HRa(s,\theta)}{2}\right). \end{aligned} \tag{28}$$

The integral in the Hilbert transform H, which acts in C_c and in C_s on the s variable, has to be understood in the principal value sense. Note that $H_a = H$ in the absence of absorption ($a \equiv 0$) and that the above formula then becomes the usual inversion of the Radon transform [27].

We thus formally apply the operator N to (26) and obtain the equation for $f(\mathbf{x})$:

$$Ng(\mathbf{x}) = f(\mathbf{x}) + NRe^{Da}Ke^{-Da}Tf(\mathbf{x}). \tag{29}$$

Let $\chi(\mathbf{x})$ be a cut-off function supported on Ω and such that $\chi\equiv 1$ on the support of f. The equation above is recast as

$$\chi(\mathbf{x})Ng(\mathbf{x}) = f(\mathbf{x}) + \chi NRe^{Da}Ke^{-Da}Tf(\mathbf{x}) =: (I-N_K)f(\mathbf{x}), \tag{30}$$

where we have introduced the operator $N_K = -\chi NRe^{Da}Ke^{-Da}T$. This equation is of Fredholm type since K has a smoothing property which makes $Ke^{-Da}T : L^2(\Omega)\hookrightarrow L^2(\Omega\times S^{d-1})$ compact; see [25]. We do not use the compactness property in Theorems 2.1 and 2.2. Our reconstruction results are based on a smallness assumption on N_K. Note, however, that, more generally, our results show that the source term $f(\mathbf{x})$ can be reconstructed from the measured data provided that 1 is not an eigenvalue of the compact operator N_K.

The proof of Theorem 2.1 is based on the following result.

THEOREM 3.1. *The operator N_K defined above is bounded from $L^2(\Omega)$ to $L^2(\Omega)$.*

We study first the mapping properties of the scattering operator K. For this we introduce the functional spaces

$$L^{\hat{2}}(\mathbb{R}^2;C^0(S^1)) = \Big\{u(\mathbf{x},\boldsymbol{\theta}) \text{ s.t. } \hat{u}(\boldsymbol{\xi},\boldsymbol{\theta})\in L^2(\mathbb{R}^2;C^0(S^1))\Big\}, \tag{31}$$

$$L^{\hat{2}}(\Omega;C^0(S^1)) = \Big\{u\in L^{\hat{2}}(\mathbb{R}^2;C^0(S^1)) \text{ s.t. supp } u(\cdot,\theta)\subseteq\Omega\Big\}, \tag{32}$$

endowed with the norm

$$\|u\|^2_{\hat{2},\infty} = \|\hat{u}\|^2_{L^2(\mathbb{R}^2;C^0(S^1))} = \int_{\mathbb{R}^2}\max_{\boldsymbol{\theta}\in S^1}|\hat{u}(\boldsymbol{\xi},\boldsymbol{\theta})|^2 d\boldsymbol{\xi}.$$

Since K is a convolution in the angular variable, it is decomposed as

$$Ku(\mathbf{x},\boldsymbol{\theta}) = \sum_{n=-\infty}^{\infty} k_n(\mathbf{x})u_n(\mathbf{x})e^{in\theta}. \tag{33}$$

LEMMA 3.2. *Assume that* supp $k(\cdot,\theta)\subset\Omega$ *and that* $\max_{n\in\mathbb{Z}}\langle n\rangle^\alpha\|k_n\|^2_{L^1(\mathbb{R}^2)}<C$ *for some* $\alpha>1$. *Then the operator* K *maps* $L^2(\mathbb{R}^2\times S^1)$ *to* $L^{\hat{2}}(\Omega;C^0(S^1))$.

Proof. Taking the Fourier transform in the space variable in (33), we get

$$|\widehat{Ku}(\xi,\boldsymbol{\theta})|^2=\left|\sum_{-\infty}^{\infty}(\widehat{k_n}*\widehat{u_n})(\xi)e^{in\theta}\right|^2\le\left(\sum_{-\infty}^{\infty}\left|\widehat{k}_n*\widehat{u}_n\right|(\boldsymbol{\xi})\right)^2$$
$$\le\left(\sum_{-\infty}^{\infty}\frac{1}{\langle n\rangle^\alpha}\right)\left(\sum_{-\infty}^{\infty}\langle n\rangle^\alpha|\hat{k}_n*\hat{u}_n|^2(\boldsymbol{\xi})\right).$$

Now we take the maximum over $\boldsymbol{\theta}\in S^1$ on both sides and integrate in $\xi\in\mathbb{R}^2$ to get

$$\|Ku\|^2_{L^{\hat{2}}(\mathbb{R}^2;C^0(S^1))}\le\left(\sum_{-\infty}^{\infty}\frac{1}{\langle n\rangle^\alpha}\right)\sum_{-\infty}^{\infty}\langle n\rangle^\alpha\|\hat{k}_n*\hat{u}_n\|^2_{L^2(\mathbb{R}^2)}$$
$$\le\left(\sum_{-\infty}^{\infty}\frac{1}{\langle n\rangle^\alpha}\right)\sum_{-\infty}^{\infty}\langle n\rangle^\alpha\|\hat{k}_n\|^2_{L^1(\mathbb{R}^2)}\|\hat{u}_n\|^2_{L^2(\mathbb{R}^2)}$$
$$\le\left(\sum_{-\infty}^{\infty}\frac{1}{\langle n\rangle^\alpha}\right)\max_{n\in\mathbb{N}}\langle n\rangle^\alpha\|\hat{k}_n\|^2_{L^1(\mathbb{R}^2)}\sum_{-\infty}^{\infty}\|\hat{u}_n\|^2_{L^2(\mathbb{R}^2)}$$
$$\le C\left(\sum_{-\infty}^{\infty}\frac{1}{\langle n\rangle^\alpha}\right)\|u\|^2_{L^2(\mathbb{R}^2\times S^1)}.\qquad\square$$

LEMMA 3.3. *Let* $h:\mathbb{R}^2\times S^1\to\mathbb{R}$ *be a smooth map such that*

$$\int_{\mathbb{R}^2}\max_{\boldsymbol{\theta}}|\hat{h}(\xi,\boldsymbol{\theta})|d\xi<\infty.$$

Then the operator M_h *of multiplication by* h *is bounded from* $L^{\hat{2}}(\Omega;C^0(S^1))$ *to itself.*

Proof.

$$\|M_hf\|^2_{\hat{2},\infty}=\|hf\|^2_{\hat{2},\infty}=\int_{\mathbb{R}^2}\max_{\boldsymbol{\theta}\in S^1}|\widehat{hf}|^2(\xi,\boldsymbol{\theta})d\xi=\int_{\mathbb{R}^2}\max_{\theta\in S^1}|\hat{h}*_\xi\hat{f}|^2(\xi,\theta)d\xi$$
$$\le\left\|\max_{\boldsymbol{\theta}\in S^1}|\hat{h}|*\max_{\boldsymbol{\theta}\in S^1}|\hat{f}|\right\|^2_{L^2}\le\left\|\max_{\boldsymbol{\theta}\in S^1}|\hat{h}|\right\|^2_{L^1}\|f\|^2_{\hat{2},\infty}.\qquad\square\tag{34}$$

Recall that, when acting on maps $f(x,\boldsymbol{\theta})$, R denotes the Radon transform in $x\in\mathbb{R}^2$. The following smoothing property holds.

LEMMA 3.4. *The operator* $R:L^{\hat{2},\infty}(\Omega\times S^1)\to H^{1/2}(\mathbb{R};L^2(S^1))$ *is bounded; more precisely,*

$$\int_{S^1}\int_{\mathbb{R}}\left|\widehat{Rg}(\rho,\theta)\right|^2(1+|\rho|)d\rho d\theta\le(4\pi|\Omega|^2+3)\|g\|^2_{\hat{2},\infty},$$

where $|\Omega|$ *denotes the volume of* Ω.

Proof. Notice first that the Fourier slice theorem $\widehat{Rg}(\rho,\theta)=\hat{g}(\rho\boldsymbol{\theta}^\perp,\theta)$ holds. On the right-hand side the Fourier transform is taken with respect to the space variable only. The following inequalities hold:

$$\begin{aligned}\int_0^{2\pi}\int_0^\infty \left|\widehat{Rg}(\rho,\theta)\right|^2 \rho d\rho d\theta &= \int_0^{2\pi}\int_0^\infty \left|\hat{g}(\rho\boldsymbol{\theta}^\perp,\theta)\right|^2 \rho d\rho d\theta\\ &\le \int_0^{2\pi}\int_0^\infty \max_{\nu\in S^1}\left|\hat{g}(\rho\boldsymbol{\theta}^\perp,\nu)\right|^2 \rho d\rho d\theta = \|g\|^2_{\hat{2},\infty},\\ \int_0^{2\pi}\int_{-\infty}^0 \left|\widehat{Rg}(\rho,\theta)\right|^2 |\rho| d\rho d\theta &= \int_0^{2\pi}\int_0^\infty \left|\hat{g}(-\rho\boldsymbol{\theta}^\perp,\theta)\right|^2 \rho d\rho d\theta\\ &\le \int_0^{2\pi}\int_0^\infty \max_{\nu\in S^1}\left|\hat{g}(-\rho\boldsymbol{\theta}^\perp,\nu)\right|^2 \rho d\rho d\theta = \|g\|^2_{\hat{2},\infty}.\end{aligned}$$

We also have

$$\int_0^{2\pi}\int_0^\infty |\widehat{Rg}(\rho,\theta)|^2 d\rho d\theta \le \int_0^{2\pi}\int_0^1 |\hat{g}(\rho\boldsymbol{\theta}^\perp,\theta)|^2 d\rho d\theta + \int_0^{2\pi}\int_0^\infty |\widehat{Rg}(\rho,\theta)|^2 \rho d\rho d\theta$$

and

$$\int_0^{2\pi}\int_0^1 |\hat{g}(\rho\boldsymbol{\theta}^\perp,\theta)|^2 d\rho d\theta \le \int_0^{2\pi}\int_0^1 \max_{\nu\in S^1}|\hat{g}(\rho\boldsymbol{\theta}^\perp,\nu)|^2 d\rho d\theta \le 2\pi \max_{|\boldsymbol{\xi}|\le 1}|\hat{g}(\boldsymbol{\xi},\nu_0)|^2,$$

where to simplify notation we have defined

$$|\hat{g}(\boldsymbol{\xi},\nu_0)| = \max_{\nu\in S^1}|\hat{g}(\boldsymbol{\xi},\nu)|.$$

Let $\{\chi_n(\mathbf{x})\}_{n\ge 1}$ be a sequence of smooth cut-off functions equal to 1 on Ω, the support of g, and equal to 0 at $\mathbf{x}$ such that $d(\mathbf{x},\Omega) > n^{-1}$; and let $\chi_n(\mathbf{x};\boldsymbol{\xi}) = e^{i\mathbf{x}\cdot\boldsymbol{\xi}}\chi_n(\mathbf{x})$. Then we verify that

$$\hat{g}(\boldsymbol{\xi},\nu_0) = \int_{\mathbb{R}^2} e^{-i\mathbf{x}\cdot\boldsymbol{\xi}}\chi_n(\mathbf{x})g(\mathbf{x},\nu_0)d\mathbf{x} = \int_{\mathbb{R}^2}\overline{\chi_n(\mathbf{x};\boldsymbol{\xi})}g(\mathbf{x},\nu_0)d\mathbf{x} = \int_{\mathbb{R}^2}\overline{\hat{\chi_n}(\boldsymbol{\eta};\boldsymbol{\xi})}\hat{g}(\boldsymbol{\eta},\nu_0)d\boldsymbol{\eta},$$

from which we deduce the following bound:

$$|\hat{g}(\boldsymbol{\xi},\nu_0)| \le \inf_n ||\hat{\chi_n}(\cdot;\xi)||_{L^2}||\hat{g}(\cdot,\nu_0)||_{L^2} = \inf_n ||\chi_n||_{L^2}\|g\|_{\hat{2},\infty} \le |\Omega|\|g\|_{\hat{2},\infty}. \tag{35}$$

Similarly, we have

$$\int_0^{2\pi}\int_{-\infty}^0 |\widehat{Rg}(\rho,\theta)|^2 d\rho d\theta \le 2\pi|\Omega|^2\|g\|^2_{\hat{2},\infty} + \int_0^{2\pi}\int_{-\infty}^0 |\widehat{Rg}(\rho,\theta)|^2|\rho| d\rho d\theta.$$

This concludes the proof of the lemma. ∎

LEMMA 3.5. *Let $f\in H^{1/2}(\mathbb{R};L^2(S^1))$ and $\phi(\mathbf{x},\theta)$ be a smooth function such that*

$$\int_{\mathbb{R}^2}\max_{\nu\in S^1}|\hat{\phi}(\boldsymbol{\xi};\nu)|^2(1+|\boldsymbol{\xi}|^2)d\boldsymbol{\xi} < \infty. \tag{36}$$

Then the map $(\mathbf{x},\theta)\to\phi(\mathbf{x},\theta)f(\mathbf{x}\cdot\boldsymbol{\theta}^\perp,\boldsymbol{\theta})$ is in $H^{1/2}(\mathbb{R}^2;L^2(S^1))$.

Proof. We have the following sequence of inequalities:

$$
\begin{aligned}
&\int_0^{2\pi}\int_{\mathbb{R}^2}(1+|\boldsymbol{\xi}|^2)^{\frac12}|\widehat{\phi f}(\boldsymbol{\xi},\theta)|^2 d\boldsymbol{\xi} d\theta\\
&= \int_0^{2\pi}\int_{\mathbb{R}^2}(1+|\boldsymbol{\xi}|^2)^{\frac12}\left|\int_{\mathbb{R}}\hat\phi(\boldsymbol{\xi}\cdot\boldsymbol{\theta},t;\theta)\hat f(\boldsymbol{\xi}\cdot\boldsymbol{\theta}^\perp-t,\theta)dt\right|^2 d\boldsymbol{\xi} d\theta\\
&\le \int_0^{2\pi}\left\{\int_{\mathbb{R}}\left[\int_{\mathbb{R}^2}(1+|\boldsymbol{\xi}|^2)^{\frac12}|\hat\phi(\xi_1,t;\theta)|^2|\hat f(\xi_2-t;\theta)|^2 d\xi_1 d\xi_2\right]^{\frac12}dt\right\}^2 d\theta\\
&\le \int_0^{2\pi}\left\{\int_{\mathbb{R}}\left[\int_{\mathbb{R}^2}(1+|\xi_1|^2)^{\frac12}(1+|\xi_2|^2)^{\frac12}|\hat\phi(\xi_1,t;\theta)|^2|\hat f(\xi_2-t;\theta)|^2 d\xi_1 d\xi_2\right]^{\frac12}dt\right\}^2 d\theta\\
&= \int_0^{2\pi}\left\{\int_{\mathbb{R}}(1+t^2)^{\frac14}\Big[\int_{\mathbb{R}^2}(1+|\xi_1|^2)^{\frac12}|\hat\phi(\xi_1,t;\theta)|^2\left(\frac{1+|\xi_2+t|^2}{1+|t|^2}\right)^{\frac12}\right.\\
&\qquad\qquad\left.\cdot|\hat f(\xi_2;\theta)|^2 d\xi_1 d\xi_2\Big]^{\frac12}dt\right\}^2 d\theta\\
&\le \int_0^{2\pi}\left\{\int_{\mathbb{R}}(1+t^2)^{\frac14}\Big[\int_{\mathbb{R}^2}(1+|\xi_1|^2)^{\frac12}|\hat\phi(\xi_1,t;\theta)|^2(1+|\xi_2|^2)^{\frac12}\right.\\
&\qquad\qquad\left.\cdot|\hat f(\xi_2;\theta)|^2 d\xi_1 d\xi_2\Big]^{\frac12}dt\right\}^2 d\theta\\
&= \int_0^{2\pi}\int_{\mathbb{R}}(1+|\xi_2|^2)^{\frac12}|\hat f(\xi_2;\theta)|^2 d\xi_2\left\{\int_{\mathbb{R}}(1+t^2)^{\frac14}\right.\\
&\qquad\qquad\left.\cdot\left[\int_{\mathbb{R}}(1+|\xi_1|^2)^{\frac12}|\hat\phi(\xi_1,t;\theta)|^2 d\xi_1\right]^{\frac12}dt\right\}^2 d\theta\\
&\le \int_0^{2\pi}\left(\int_{\mathbb{R}}(1+|\xi_2|^2)^{\frac12}|\hat f(\xi_2;\theta)|^2 d\xi_2\int_{\mathbb{R}^2}(1+t^2)^{\frac12}(1+|\xi_1|^2)^{\frac12}\max_{\nu\in S^1}|\hat\phi(\xi_1,t;\nu)|^2 dt\xi_1\right)d\theta\\
&\le \int_0^{2\pi}\int_{\mathbb{R}}(1+|\xi_2|^2)^{\frac12}|\hat f(\xi_2;\theta)|^2 d\xi_2 d\theta\int_{\mathbb{R}^2}(1+|\boldsymbol{\xi}|^2)\max_{\nu\in S^1}|\hat\phi(\boldsymbol{\xi};\nu)|^2 d\boldsymbol{\xi},
\end{aligned}
$$

where we have used the Minkowsky and Cauchy inequalities. From the second line onward, we have used the θ dependent coordinates $\xi_1=\boldsymbol{\xi}\cdot\boldsymbol{\theta}$ and $\xi_2=\boldsymbol{\xi}\cdot\boldsymbol{\theta}^\perp$. □

Recall that $\chi(\mathbf{x})$ defined before (29) is a smooth cut-off function supported in Ω. To simplify notation, let

$$
\begin{aligned}
f_1(\mathbf{x},\theta)&=e^{Da}(\mathbf{x},\theta)\mathrm{trig}(HRa(\mathbf{x}\cdot\boldsymbol{\theta}^\perp,\theta)/2),\\
f_2(s,\theta)&=\mathrm{trig}(HRa(s,\theta)/2),\\
f_3(\mathbf{x},\theta)&=\chi(\mathbf{x})(\boldsymbol{\theta}^\perp\cdot\nabla_{\mathbf{x}})f_1(\mathbf{x},\theta)
\end{aligned}
$$

be smooth functions depending on the attenuation a only, where trig stands for either sin or cos. The composition operator χNR becomes

$$
\chi NRw(\mathbf{x})=\frac{\chi(\mathbf{x})}{4\pi}\int_0^{2\pi}\boldsymbol{\theta}^\perp\cdot\nabla\Big(f_1(\mathbf{x},\theta)H[f_2(s,\theta)R[w](s,\theta)](\mathbf{x}\cdot\boldsymbol{\theta}^\perp,\theta)\Big)d\theta,
$$

where the above is understood as a sum over the values that the functions trig can take in f_1 and f_2. We now follow ideas from [6], though we need to derive some of the estimates in the Fourier domain to characterize the norm of the operator. Let $\phi_n(\mathbf{x})$, $n = 1, 2, \dots$, be an orthonormal basis of $L^2(\Omega)$ and let

$$\chi(\mathbf{x})f_1(\mathbf{x},\theta) = \sum_{n=1}^{\infty} \alpha_n(\theta)\phi_n(\mathbf{x}), \qquad \alpha_n(\theta) = \int_\Omega \chi(\mathbf{x})f_1(\mathbf{x},\theta)\phi_n(\mathbf{x})d\mathbf{x}. \tag{37}$$

PROPOSITION 3.6. *The composition operator χNR maps $L^{\hat{2}}(\Omega; C^0(S^1))$ to $L^2(\Omega)$. Moreover, we have the more explicit characterization*

$$\begin{aligned}\|\chi NRw\|_{L^2} \le \|w\|_{\hat{2},\infty} \int_{\mathbb{R}^2} \max_{\boldsymbol{\theta}} |\widehat{e^{Da}}(\boldsymbol{\xi},\boldsymbol{\theta})|d\boldsymbol{\xi} \Bigg[\int_{\mathbb{R}^2} \max_{\nu\in S^1} |\hat{f}_3(\boldsymbol{\xi};\nu)|^2(1+|\boldsymbol{\xi}|^2)d\boldsymbol{\xi} \\ +2\left(\sum_{n=1}^{\infty} \max_{\nu\in S^1} |\alpha_n(\nu)|^2\right)^{\frac{1}{2}} \int_{-\infty}^{\infty} |\hat{f}_2(s,\nu_0)|(2+4\pi|\Omega|s^2)ds\Bigg].\end{aligned} \tag{38}$$

Proof. Using Lemma 3.4 we obtain that $Rw \in H^{1/2}(\mathbb{R}; L^2(S^1))$. Since $a \in C_0^2(\Omega)$ it is easy to check that $\chi(\mathbf{x})(\boldsymbol{\theta}^\perp \cdot \nabla_x f_1(\mathbf{x},\theta))$ satisfies the smoothness condition (36). From Lemma 3.5 we get that the map

$$(\mathbf{x},\theta) \to \chi(\mathbf{x}) \left(\boldsymbol{\theta}^\perp \cdot \nabla_x f_1(\mathbf{x},\theta)\right) H[f_2(s,\theta)R[w](s,\theta)](\mathbf{x}\cdot\boldsymbol{\theta}^\perp,\theta)$$

is in $H^{1/2}(\mathbb{R}^2; L^2(S^1))$.

Next we show that the operator M defined by

$$Mw(\mathbf{x}) = \int_0^{2\pi} \chi(\mathbf{x})f_1(\mathbf{x},\theta) \left(\boldsymbol{\theta}^\perp \cdot \nabla_x\right) H[f_2(s,\theta)R(w)(s,\theta)](\mathbf{x}\cdot\boldsymbol{\theta}^\perp,\theta)d\theta$$

is bounded from $L^{\hat{2}}(\Omega; C^0(S^1))$ in $L^2(\Omega)$. We have

$$\begin{aligned}&\left\| \int_0^{2\pi} \sum_{n=1}^{\infty} \alpha_n(\theta)\phi_n(\mathbf{x})(\boldsymbol{\theta}^\perp \cdot \nabla)H(f_2Rw(s,\theta))(\mathbf{x}\cdot\boldsymbol{\theta}^\perp,\theta)d\theta \right\|_{L_x^2}^2 \\ &= \sum_{n=1}^{\infty} \left\langle \phi_n; \int_0^{2\pi} \alpha_n(\theta)(\boldsymbol{\theta}^\perp \cdot \nabla)H(f_2Rw(s,\theta)(\mathbf{x}\cdot\boldsymbol{\theta}^\perp,\theta))d\theta \right\rangle_{L_x^2}^2 \\ &\le \sum_{n=1}^{\infty} \left\| \int_0^{2\pi} \alpha_n(\theta)(\boldsymbol{\theta}^\perp \cdot \nabla)H(f_2Rw(s,\theta))(\mathbf{x}\cdot\boldsymbol{\theta}^\perp,\theta)d\theta \right\|_{L_x^2}^2 \\ &\le \sum_{n=1}^{\infty} \left\| F_{\mathbf{x}\to\boldsymbol{\xi}} \left\{ \int_0^{2\pi} \alpha_n(\theta)(\boldsymbol{\theta}^\perp \cdot \nabla)H(f_2Rw(s,\theta))(\mathbf{x}\cdot\boldsymbol{\theta}^\perp,\theta)d\theta \right\}(\boldsymbol{\xi}) \right\|_{L_\xi^2}^2 \\ &= \sum_{n=1}^{\infty} \left\| \alpha_n(\xi_-)\widehat{f_2Rw}(-|\boldsymbol{\xi}|,\xi_-) + \alpha_n(\xi_+)\widehat{f_2Rw}(|\boldsymbol{\xi}|,\xi_+) \right\|_{L_\xi^2}^2 \\ &\le \left(\sum_{n=1}^{\infty} \max_{\nu\in S^1} |\alpha_n(\nu)|^2\right) \left(\|\widehat{f_2Rw}(-|\boldsymbol{\xi}|,\xi_-)\|_{L_\xi^2}^2 + \|\widehat{f_2Rw}(|\boldsymbol{\xi}|,\xi_+)\|_{L_\xi^2}^2 \right).\end{aligned}$$

In the above expressions, $F_{\mathbf{x}\to\boldsymbol{\xi}}$ represents the two-dimensional Fourier transform in the $\mathbf{x}$ variable, while $\hat{\cdot}$ represents the one-dimensional Fourier transform. The angles

$\xi_\pm$ are defined by $\boldsymbol{\xi}\cdot\boldsymbol{\theta}=0$. The estimate above uses the fact that, for any $f\in H^{1/2}(\mathbb{R})$, $F_{\mathbf{x}\to\boldsymbol{\xi}}[\boldsymbol{\theta}^\perp\cdot\nabla Hf(\mathbf{x}\cdot\boldsymbol{\theta}^\perp)]=\hat f(\boldsymbol{\xi}\cdot\boldsymbol{\theta}^\perp)\delta(\boldsymbol{\theta}\cdot\frac{\boldsymbol{\xi}}{|\boldsymbol{\xi}|})$; see [7, pp. 413, 415] for the details. By the Fourier slice theorem we verify that

$$\widehat{f_2Rw}(|\boldsymbol{\xi}|,\xi_+)=\int_{\mathbb{R}}\hat f_2(|\boldsymbol{\xi}|-s,\xi_+)\hat w\left(s\frac{\xi}{|\xi|},\xi_+\right)ds.$$

Let us now define ν_0 and ν_1 as the values of the angles where $\max_{\nu\in S^1}|\hat f_2(\rho,\nu)|$ and $\max_{\nu\in S^1}|\hat w(\rho,\nu)|$ are achieved, respectively. We compute

$$\begin{aligned}
(39)\qquad &\left\{\int_{\mathbb{R}^2}|\widehat{f_2Rw}(|\boldsymbol{\xi}|,\xi_+)|^2d\boldsymbol{\xi}\right\}^{\frac12}=\left\{\int_0^{2\pi}\int_0^\infty|\widehat{f_2Rw}(r,-\boldsymbol{\theta}^\perp)|^2rdrd\theta\right\}^{\frac12}\\
&=\left\{\int_0^{2\pi}\int_0^\infty\left|\int_{\mathbb{R}}\hat f_2(s,-\boldsymbol{\theta}^\perp)\hat w((r-s)\boldsymbol{\theta},-\boldsymbol{\theta}^\perp)|ds\right|^2rdrd\theta\right\}^{\frac12}\\
&\le\left\{\int_0^{2\pi}\int_0^\infty\left(\int_{\mathbb{R}}\max_{\nu\in S^1}|\hat f_2(s,\nu)|\max_{\nu\in S^1}|\hat w((r-s)\boldsymbol{\theta},\nu)|ds\right)^2rdrd\theta\right\}^{\frac12}\\
&=\left\{\int_0^{2\pi}\int_0^\infty\left(\int_{\mathbb{R}}|\hat f_2(s,\nu_0)||\hat w((r-s)\boldsymbol{\theta},\nu_1)|ds\right)^2rdrd\theta\right\}^{\frac12}\\
&\le\int_{\mathbb{R}}\left\{\int_0^{2\pi}\int_0^\infty|\hat f_2(s,\nu_0)|^2|\hat w((r-s)\boldsymbol{\theta},\nu_1)|^2rdrd\theta\right\}^{\frac12}ds\\
&=\int_{\mathbb{R}}|\hat f_2(s,\nu_0)|\left\{\int_0^{2\pi}\int_0^\infty|\hat w((r-s)\boldsymbol{\theta},\nu_1)|^2rdrd\theta\right\}^{\frac12}ds.
\end{aligned}$$

We evaluate the last term by splitting the integral $\int_0^\infty(\dots)ds+\int_{-\infty}^0(\dots)ds$. To estimate

$$\int_0^\infty|\hat f_2(s,\nu_0)|\left\{\int_0^{2\pi}\int_0^\infty|\hat w((r-s)\boldsymbol{\theta},\nu_1)|^2rdrd\theta\right\}^{\frac12}ds,$$

we further split the inner integral into $\int_0^{2s}(\dots)drd\theta+\int_{2s}^\infty(\dots)drd\theta$. We obtain that

$$\begin{aligned}
\int_0^{2\pi}\int_{2s}^\infty|\hat w((r-s)\boldsymbol{\theta},\nu_1)|^2rdrd\theta&\le2\int_0^{2\pi}\int_{2s}^\infty|\hat w((r-s)\boldsymbol{\theta},\nu_1)|^2(r-s)drd\theta\\
&=2\int_{|\boldsymbol{\xi}|\ge s}|\hat w(\boldsymbol{\xi},\nu_1)|^2d\boldsymbol{\xi},
\end{aligned}$$

and

$$\begin{aligned}
\int_0^{2\pi}\int_0^{2s}|\hat w((r-s)\boldsymbol{\theta},\nu_1)|^2rdrd\theta&=\int_0^{2\pi}\int_{-s}^s|\hat w(t\boldsymbol{\theta},\nu_1)|^2(t+s)dtd\theta\\
&=2\int_{|\boldsymbol{\xi}|\le s}|\hat w(\boldsymbol{\xi},\nu_1)|^2d\boldsymbol{\xi}+2s\int_0^{2\pi}\int_0^s|\hat w(t\boldsymbol{\theta},\nu_1)|^2dtd\theta\\
&\le2\int_{|\boldsymbol{\xi}|\le s}|\hat w(\boldsymbol{\xi},\nu_1)|^2d\boldsymbol{\xi}+4\pi s^2\max_{|\boldsymbol{\xi}|\le s}|\hat w(\boldsymbol{\xi},\nu_1)|^2\\
&\le2\int_{|\boldsymbol{\xi}|\le s}|\hat w(\boldsymbol{\xi},\nu_1)|^2d\boldsymbol{\xi}+4\pi s^2|\Omega|\|\hat w(\boldsymbol{\xi},\nu_1)\|^2_{L^2_\xi}.
\end{aligned}$$

The last inequality uses in a crucial way the estimate (35) and the fact that w is compactly supported. We have obtained so far that

$$\int_0^\infty |\hat{f}_2(s,\nu_0)| \left\{ \int_0^{2\pi} \int_0^\infty |\hat{w}((r-s)\boldsymbol{\theta},\nu_1)|^2 r dr d\theta \right\}^{\frac{1}{2}} ds \\ \leq \|w\|_{\hat{2},\infty} \int_0^\infty |\hat{f}_2(s,\nu_0)(2+4\pi|\Omega|s^2) ds.$$

The other contribution is handled similarly:

$$\begin{aligned}
&\int_{-\infty}^0 |\hat{f}_2(s,\nu_0)| \left\{ \int_0^{2\pi} \int_0^\infty |\hat{w}((r-s)\boldsymbol{\theta},\nu_1)|^2 r dr d\theta \right\}^{\frac{1}{2}} ds \\
&\quad = \int_0^\infty |\hat{f}_2(-s,\nu_0)| \left\{ \int_0^{2\pi} \int_0^\infty |\hat{w}((r+s)\boldsymbol{\theta},\nu_1)|^2 r dr d\theta \right\}^{\frac{1}{2}} ds \\
&\quad \leq \int_0^\infty |\hat{f}_2(-s,\nu_0)| \left\{ \int_0^{2\pi} \int_0^\infty |\hat{w}((r+s)\boldsymbol{\theta},\nu_1)|^2 (r+s) dr d\theta \right\}^{\frac{1}{2}} ds \\
&\quad = \|w\|_{\hat{2},\infty} \int_0^\infty |\hat{f}_2(-s,\nu_0)| ds = \|w\|_{\hat{2},\infty} \int_{-\infty}^0 |\hat{f}_2(s,\nu_0)| ds.
\end{aligned}$$

Combined with the estimate in (39), we have obtained that

$$\left\{ \int_{\mathbb{R}^2} |\widehat{f_2 Rw}|(|\boldsymbol{\xi}|,\xi_+)|^2 d\boldsymbol{\xi} \right\}^{\frac{1}{2}} \leq \|w\|_{\hat{2},\infty} \int_{-\infty}^\infty |\hat{f}_2(s,\nu_0)|(2+4\pi|\Omega|s^2) ds. \tag{40}$$

A similar calculation shows that

$$\left\{ \int_{\mathbb{R}^2} |\widehat{f_2 Rw}(-|\boldsymbol{\xi}|,\xi_-)|^2 d\boldsymbol{\xi} \right\}^{\frac{1}{2}} \leq \|w\|_{\hat{2},\infty} \int_{-\infty}^\infty |\hat{f}_2(s,\nu_0)|(2+4\pi|\Omega|s^2) ds. \tag{41}$$

In summary, we have obtained the following estimate for the operator M:

$$\|Mw\|_{L^2} \leq 2\|w\|_{\hat{2},\infty} \left(\sum_{n=1}^\infty \max_{\nu\in S^1} |\alpha_n(\nu)|^2 \right)^{\frac{1}{2}} \int_{-\infty}^\infty |\hat{f}_2(s,\nu_0)|(2+4\pi|\Omega|s^2) ds. \tag{42}$$

This concludes the proof of the proposition. ◻

Note that N has range in $L^2_{\text{loc}}(\mathbb{R}^2)$ and not necessarily in $L^2(\mathbb{R}^2)$. This is where the assumption of the compactness of the support of the source term $f(\mathbf{x})$, which is natural in practice, comes into play. The above estimate shows the role played by the size of the support of the source term.

The proof of Theorem 3.1 follows from the preceding lemmas and proposition. As we have seen, T maps $L^2(\mathbb{R}^2)$ to $L^2(\mathbb{R}^2)$, and let $|||T|||_{L^2\to L^2}$ denote its operator norm. The preceding calculations allow us to obtain the following more explicit version of Theorem 3.1.

Corollary 3.7. *Assume that K is such that $\max_n \langle n\rangle^{\alpha/2}\|\hat{k}_n\|_{L^1(\mathbb{R}^2)} \leq C_\alpha$ for some $\alpha > 1$. Then the operator norm $|||N_K|||_{L^2\to L^2}$ is bounded by the following* *expression:*

$$\begin{aligned}
(43)\qquad &\Bigg[\int_{\mathbb{R}^2}\max_{\nu\in S^1}|\hat f_3(\boldsymbol{\xi};\nu)|^2(1+|\boldsymbol{\xi}|^2)d\xi \\
&+2\left(\sum_{n=1}^{\infty}\max_{\nu\in S^1}|\alpha_n(\nu)|^2\right)^{\frac12}\int_{-\infty}^{\infty}|\hat f_2(s,\nu_0)|(2+4\pi|\Omega|s^2)ds\Bigg] \\
&\times C_\alpha\left(\sum_{-\infty}^{\infty}\frac{1}{\langle n\rangle^\alpha}\right)^{\frac12}\left(\int_{\mathbb{R}^2}\max_{\boldsymbol{\theta}}|\widehat{e^{Da}}(\xi,\boldsymbol{\theta})|d\xi\right)\|e^{-Da}\|_{L^\infty(\mathbb{R}^2\times S^1)}|||T|||_{L^2\to L^2}.
\end{aligned}$$

From [25] we know that the operator norm $|||T|||$ can be bounded independently of the scattering k. Since all the other terms in (43) are independent of k, for C_α small enough, the operator norm of N_K is bounded by a constant less than one. This proves the first part of Theorem 2.1. Note that the constraint on the norm of N_K is only sufficient to solve (30) and by no means necessary. Reconstructions based on (30) thus have a larger domain of validity than what we consider in Theorem 2.1. The reconstruction procedure is based on the fact that the Neumann series

$$f(\mathbf{x})=\sum_{n=0}^{\infty}N_K^nNg(\mathbf{x}) \tag{44}$$

converges in $L^2(\Omega)$ to the solution $f(\mathbf{x})$. This provides us with an explicit reconstruction formula to recover $f(\mathbf{x})$ from the measurements

$$m(s,\theta)=e^{-\frac12 Ra}(s,\theta)g(s,\theta)$$

and concludes the proof of Theorem 2.1. Let us conclude this section with a few remarks.

Remark 3.8. The measurements $m(s,\theta)$ for $s\in\mathbb{R}$ and $0\le\theta<2\pi$ are redundant. Indeed in the case $a\equiv 0$ and $k\equiv 0$, the measurements satisfy $m(s,\theta)=m(-s,\theta+\pi)$ so that the source term can be reconstructed from knowledge of $m(s,\theta)$ on $Z=\mathbb{R}\times(0,\pi)$. When $a\neq 0$, such a redundancy still exists, although it is harder to characterize. Under certain smallness assumptions on $a(\mathbf{x})$, an explicit procedure to reconstruct the source term from m on Z when $k=0$ was proposed in [7] and implemented in [8]. That measurements on Z suffice to determine the source term was recently obtained in [34]; see also [28] in the case of constant absorption. The explicit procedure proposed in [7] can be extended to the case of scattering kernels so that, provided that k is sufficiently small, the source term is uniquely determined by $m(s,\theta)$ on Z.

Remark 3.9. We could have considered more general scattering kernels of the form $k(\mathbf{x},\boldsymbol{\theta},\boldsymbol{\theta}')$ so long as the smoothing of the scattering kernel K imposed in Lemma 3.2 still holds. The description of this smoothing effect in terms of the scattering coefficients is simplified for kernels of the form $k(\mathbf{x},\boldsymbol{\theta}\cdot\boldsymbol{\theta}')$. However, this is the only place where the specific structure of the kernel has been used (except for the subcriticality condition (4), which should hold with $k(\mathbf{x},\boldsymbol{\theta}\cdot\boldsymbol{\theta}')$ replaced by both $k(\mathbf{x},\boldsymbol{\theta},\boldsymbol{\theta}')$ and $k(\mathbf{x},\boldsymbol{\theta}',\boldsymbol{\theta})$; see [13]).

Remark 3.10. The smoothing effect of the scattering kernel described in Lemma 3.2 is rendered necessary (at least some sort of smoothing is) by the behavior of the Radon transform and the inversion operator N. Although NR maps functions in $L^2(\Omega)$ to functions in $L^2(\Omega)$ (since the operator NR is then identity), this is no longer the case for functions in $L^2(\Omega\times S^1)$ that depend nontrivially on θ. We need to map functions from the smaller space $L^{\hat{2}}(\mathbb{R}^2; C^0(S^1))$, which is made possible by the regularizing effect of K.

Remark 3.11. Under appropriate assumptions on the scattering kernel K, (29) is indeed of Fredholm type as the operator N_K can be shown to be compact. Indeed NR is a bounded operator, whereas the operator KT (as well as $Ke^{-Da}T$ for smooth absorption $a(\mathbf{x})$) can be shown to be compact under general assumptions. We refer the reader to [25] for such results and to [16] for connected results on averaging lemmas.

Remark 3.12. The reconstruction of the source term can be obtained by the following iterative scheme. We consider the setting of Corollary 2.3. Let $g(s,\theta) = e^{Ra/2}m(s,\theta)$ be the measurements. We initialize the algorithm as

$$F^{(0)}(\mathbf{x}) = Ng(\mathbf{x}). \tag{45}$$

Provided that $F^{(k)}(\mathbf{x})$ is known, we solve for $u^{(k)}$ in

$$\begin{aligned} &\boldsymbol{\theta}\cdot\nabla_{\mathbf{x}}u^{(k)}(\mathbf{x},\theta) + a(\mathbf{x})u^{(k)}(\mathbf{x},\theta) = K_1u^{(k)}(\mathbf{x},\theta) + F^{(k)}(\mathbf{x}) \quad \text{in } \mathbb{R}^2\times S^1,\\ &\lim_{t\to\infty} u^{(k)}(\mathbf{x}-t\boldsymbol{\theta},\theta) = 0 \quad \text{on } \mathbb{R}^2\times S^1. \end{aligned} \tag{46}$$

We next solve for $v^{(k)}(\mathbf{x},\theta)$ in

$$\begin{aligned} &\boldsymbol{\theta}\cdot\nabla_{\mathbf{x}}v^{(k)}(\mathbf{x},\theta) + a(\mathbf{x})v^{(k)}(\mathbf{x},\theta) = K_1u^{(k)}(\mathbf{x},\theta) \quad \text{in } \mathbb{R}^2\times S^1,\\ &\lim_{t\to\infty} v^{(k)}(\mathbf{x}-t\boldsymbol{\theta},\theta) = 0 \quad \text{on } \mathbb{R}^2\times S^1. \end{aligned} \tag{47}$$

We then compute the new data

$$g^{(k)}(s,\theta) = e^{Ra/2}R_av^{(k)}(s,\theta). \tag{48}$$

Finally, we set the new source term

$$F^{(k+1)}(\mathbf{x}) = N(g-g^{(k)})(\mathbf{x}). \tag{49}$$

We verify that $F^{(k)}(\mathbf{x})$ converges to $F(\mathbf{x}) = K_0u(\mathbf{x}) + f(\mathbf{x})$ in $L^2(\Omega)$ as the above algorithm is equivalent to the Neumann series expansion (44). We then solve for $u(\mathbf{x},\theta)$ and reconstruct the source term $f(\mathbf{x}) = F(\mathbf{x}) - K_0u(\mathbf{x})$.

4. Derivation in three space dimensions. The derivation in the three-dimensional case is very similar to that of the preceding section. The main observation is that the inversion of the X-ray transform can be performed "slice by slice," i.e., "z by z," using outgoing information for angles perpendicular to $\mathbf{e}_z$ only. The inversion with scattering coefficient is again considered as a perturbation of the inversion of the X-ray transform. Mathematically, the main novelty compared to the two-dimensional case is that we need to control the number of photons scattered into the directions orthogonal to $\mathbf{e}_z$.

Upon defining $w(\mathbf{x},\boldsymbol{\theta}) = (e^{Da}u)(\mathbf{x},\boldsymbol{\theta})$, we still obtain that

$$w(\mathbf{x},\boldsymbol{\theta}) = Se^{Da}Ke^{-Da}w(\mathbf{x},\boldsymbol{\theta}) + Se^{Da}f(\mathbf{x},\boldsymbol{\theta}). \tag{50}$$

We define now the trace operator P onto the horizontal directions S^2_H defined in (11). More precisely, P takes functions on $\Omega\times S^2$ onto a function on $\Omega\times S^2_H$ as follows. For $\boldsymbol{\theta} = (\cos\theta\sin\phi, \sin\theta\sin\phi, \cos\phi)$,

$$P[w(\mathbf{x},\boldsymbol{\theta})] = w(\mathbf{x},(\cos\theta,\sin\theta,0)). \tag{51}$$

For $\boldsymbol{\theta} \in S^2_H$, we define the orthogonal vector $\boldsymbol{\theta}^\perp = (-\sin\theta, \cos\theta, 0)$ and the transversal X-ray transform

$$Rf(z, s, \theta) = LSf(z, s, \theta), \tag{52}$$

where the trace operator at infinity is defined by

$$Lw(z, s, \theta) = \lim_{t\to\infty} w(t\boldsymbol{\theta} + s\boldsymbol{\theta}^\perp + z\mathbf{e}_z, \boldsymbol{\theta}). \tag{53}$$

Finally, the transversal attenuated X-ray transform is defined by

$$R_a f(z, s, \theta) = Re^{Da} f(z, s, \theta). \tag{54}$$

Note that

$$R = LS = LPS = LSP = RP, \quad \text{ and } \quad Pe^{Da} = (Pe^{Da})P,$$

so that the rescaled measurements are given by

$$g(z, s, \theta) = e^{\frac{1}{2}Ra}(z, s, \theta)m(z, s, \theta) = R_a f(z, s, \theta) + Re^{Da}PKe^{-Da}Tf(z, s, \theta). \tag{55}$$

Now the operator $R_a f(z, s, \theta)$ can be inverted at each fixed z by using the Novikov formula. Namely, for $\mathbf{x} = (\mathbf{x}', z)$, we define

$$N_3 g(\mathbf{x}) = N[g(z, \cdot, \cdot)](\mathbf{x}'), \tag{56}$$

by applying the two-dimensional operator N to $(s, \theta) \to g(s, \theta, z)$ for each $z \in \mathbb{R}$. We verify that $N_3 R_a = Id$ on functions of $\mathbf{x} \in \mathbb{R}^3$. As in the two-dimensional case, however, $N_3 R_a$ is no longer identity when applied to functions that depend on the variable $\boldsymbol{\theta}$. Thus formally applying the operator N_3 to (55), we obtain that

$$N_3 g(\mathbf{x}) = f(\mathbf{x}) + N_3 Re^{Da}PKe^{-Da}Tf(\mathbf{x}) = (I - N_K)f(\mathbf{x}), \tag{57}$$

where now $N_K = -N_3 Re^{Da}PKe^{-Da}T$. The results of section 3 extend as follows.

PROPOSITION 4.1. *The operator N_K defined above is bounded from $L^2(\Omega)$ to $L^2(\Omega)$.*

Similarly to the planar case, let $\hat{u}(\boldsymbol{\xi}', z, \theta) = \int_{\mathbb{R}^2} e^{-i\mathbf{x}'\cdot\boldsymbol{\xi}'} u(\mathbf{x}', z, \theta) d\mathbf{x}'$ denote the Fourier transform in the first two components of the spatial variable only. We work with the functional space

$$L^{\hat{2}}(\mathbb{R}^2_{\mathbf{x}'} \times \mathbb{R}_z; C^0(S^1)) = \Big\{ u(\mathbf{x}', z, \theta) \text{ s.t. } \hat{u}(\boldsymbol{\xi}', z, \theta) \in L^2(\mathbb{R}^2_{\boldsymbol{\xi}'} \times \mathbb{R}_z; C^0(S^1)) \Big\}, \tag{58}$$

where $L^2(\mathbb{R}^2_{\boldsymbol{\xi}'} \times \mathbb{R}_z; C^0(S^1))$ is endowed with the norm

$$\|\hat{u}\|^2_{L^2(\mathbb{R}^2_{\boldsymbol{\xi}'} \times \mathbb{R}_z; C^0(S^1))} = \int_{\mathbb{R}^3} \max_{\boldsymbol{\theta}\in S^1} |\hat{u}(\boldsymbol{\xi}', z, \theta)|^2 d\boldsymbol{\xi}' dz.$$

The proposition is based on the following lemmas.

LEMMA 4.2. *Consider the decomposition of $k(\mathbf{x}, \cdot) \in L^2[-1, 1]$ in Legendre polynomials*

$$k(\mathbf{x}, t) = \sum_{n=0}^{\infty} k_n(\mathbf{x}) P_n(t), \tag{59}$$

and assume that, for some $\alpha > 1$,

$$\max_{n\in\mathbb{N}}\left(\langle n\rangle^{\alpha-1}\max_{|m|\le n}\max_{\boldsymbol{\theta}\in S_z^2}|Y_{nm}(\boldsymbol{\theta})|^2\int_{\mathbb{R}}\|\hat{k}_n(\cdot,z)\|^2_{L^1(\mathbb{R}^2)}dz\right)\le C. \tag{60}$$

Then the operator PK maps $L^2(\mathbb{R}^3\times S^2)$ to $L^{\hat{2}}(\mathbb{R}^2_{\mathbf{x}'}\times\mathbb{R}_z;C^0(S^1))$.

Proof. Using the summation formula $P_n(\boldsymbol{\theta}\cdot\boldsymbol{\theta}')=\frac{1}{2n+1}\sum_{m=-n}^n Y_{nm}(\boldsymbol{\theta})Y^*_{nm}(\boldsymbol{\theta}')$ (see [17], for instance), we get the following decomposition of the scattering operator:

$$Ku(\mathbf{x},\boldsymbol{\theta})=\int_{S^2}k(\mathbf{x},\boldsymbol{\theta}\cdot\boldsymbol{\theta}')u(\mathbf{x},\boldsymbol{\theta}')d\boldsymbol{\theta}'=\sum_{n=0}^{\infty}\sum_{m=-n}^{n}\frac{1}{2n+1}k_n(\mathbf{x})u_{nm}(\mathbf{x})Y_{nm}(\boldsymbol{\theta}), \tag{61}$$

where

$$u_{nm}(\mathbf{x})=\int_{S^2}u(\mathbf{x},\boldsymbol{\theta}')\overline{Y_{nm}(\boldsymbol{\theta}')}d\boldsymbol{\theta}'. \tag{62}$$

The Plancherel identity for the spherical harmonics gives

$$\|u\|^2_{L^2(\mathbb{R}^3\times S^2)}=\sum_{n=0}^{\infty}\sum_{m=-n}^{n}\|u_{nm}\|^2_{L^2(\mathbb{R}^3)}. \tag{63}$$

In what follows we consider $\boldsymbol{\theta}\in S^2_H$, i.e., only horizontal directions. To simplify the notation, we denote

$$\beta_n=\max_{|m|\le n}\max_{\boldsymbol{\theta}\in S_H^2}|Y_{nm}(\boldsymbol{\theta})|. \tag{64}$$

Taking the Fourier transform with respect to the horizontal variables in (61), we obtain

$$\begin{aligned}|\widehat{Ku}(\boldsymbol{\xi},z,\boldsymbol{\theta})|^2&=\left|\sum_{n=0}^{\infty}\sum_{m=-n}^{n}\frac{1}{2n+1}(\hat{k}_n*_{\boldsymbol{\xi}}\hat{u}_{nm})(\boldsymbol{\xi},z)Y_{nm}(\boldsymbol{\theta})\right|^2\\&\le\left(\sum_{n=0}^{\infty}\sum_{m=-n}^{n}\frac{\beta_n}{2n+1}\left|(\hat{k}_n*\hat{u}_{nm})(\boldsymbol{\xi},z)\right|\right)^2\\&\le\left(\sum_{n=0}^{\infty}\sum_{m=-n}^{n}\frac{1}{\langle n\rangle^{\alpha}(2n+1)}\right)\left(\sum_{n=0}^{\infty}\sum_{m=-n}^{n}\frac{\langle n\rangle^{\alpha}\beta_n^2}{2n+1}\left|(\hat{k}_n*\hat{u}_{nm})(\boldsymbol{\xi},z)\right|^2\right).\end{aligned}$$

We now take the maximum in $\boldsymbol{\theta}\in S_z^2$ and then integrate in $\boldsymbol{\xi}\in\mathbb{R}^2$. We deduce that

$$\begin{aligned}\int_{\mathbb{R}^2}\max_{\boldsymbol{\theta}\in S_z^2}|\widehat{Ku}(\boldsymbol{\xi},z,\boldsymbol{\theta})|^2d\boldsymbol{\xi}&\le\left(\sum_{n=0}^{\infty}\frac{1}{\langle n\rangle^{\alpha}}\right)\left(\sum_{n=0}^{\infty}\sum_{m=-n}^{n}\frac{\beta_n^2\langle n\rangle^{\alpha}}{2n+1}\|\hat{k}_n*\hat{u}_{nm}(\cdot,z)\|^2_{L^2(\mathbb{R}^2)}\right)\\&\le\left(\sum_{n=0}^{\infty}\frac{1}{\langle n\rangle^{\alpha}}\right)\left(\sum_{n=0}^{\infty}\sum_{m=-n}^{n}\frac{\beta_n^2\langle n\rangle^{\alpha}}{2n+1}\|\hat{k}_n(\cdot,z)\|^2_{L^1(\mathbb{R}^2)}\|\hat{u}_{nm}(\cdot,z)\|^2_{L^2(\mathbb{R}^2)}\right)\\&\le\left(\max_{n\in\mathbb{N}}\frac{\beta_n^2\langle n\rangle^{\alpha}}{2n+1}\|\hat{k}_n(\cdot,z)\|^2_{L^1(\mathbb{R}^2)}\right)\left(\sum_{n=0}^{\infty}\frac{1}{\langle n\rangle^{\alpha}}\right)\left(\sum_{n=0}^{\infty}\sum_{m=-n}^{n}\|\hat{u}_{nm}(\cdot,z)\|^2_{L^2(\mathbb{R}^2)}\right).\end{aligned}$$

It remains to integrate in $z \in \mathbb{R}$ to obtain that

$$||Ku||^2_{L^{\hat{2}}(\mathbb{R}^2_{\mathbf{x}'}\times\mathbb{R}_z;C^0(S^1))} \leq \left(\max_{n\in\mathbb{N}} \frac{\beta_n^2\langle n\rangle^\alpha}{2n+1}\int_{\mathbb{R}}\|\hat{k}_n(\cdot,z)\|^2_{L^1(\mathbb{R}^2)}dz\right) \cdot \left(\sum_{n=0}^\infty \frac{1}{\langle n\rangle^\alpha}\right)||u||^2_{L^2(\mathbb{R}^3\times S^2)}.$$

This concludes the proof of the lemma. □

LEMMA 4.3. *The operator* N_3R *maps* $L^{\hat{2}}(\mathbb{R}^2_{\mathbf{x}'}\times\mathbb{R}_z;C^0(S^1))$ *to* $L^2(\Omega)$.

Proof. This is a direct consequence of Lemma 3.6:

$$\|N_3Rf\|^2_{L^2(\Omega)} = \int_{\mathbb{R}}\int_{\mathbb{R}^2}|N_3Rf(\mathbf{x}',z)|^2\,d\mathbf{x}'dz = \int_{\mathbb{R}}\int_{\mathbb{R}^2}|[NRf(\cdot,\cdot,z)](\mathbf{x}')|^2\,d\mathbf{x}'dz$$

$$\leq C\int_{\mathbb{R}}dz\left\{\int_{\mathbb{R}^2}\max_{\boldsymbol{\theta}\in S_z^2}\left|\hat{f}(\boldsymbol{\xi},\boldsymbol{\theta},z)\right|^2 d\boldsymbol{\xi}\right\} = \|f\|^2_{L^{\hat{2}}(\mathbb{R}^2_{\mathbf{x}'}\times\mathbb{R}_z;C^0(S^1))}. \tag{65}$$

□

The rest of the proof of Theorem 2.2 is similar to that of Theorem 2.1. Provided that scattering is sufficiently small, the Neumann series expansion

$$f(\mathbf{x}) = \sum_{n=0}^\infty N_K^n N_3 g(\mathbf{x}) \tag{66}$$

converges in $L^2(\Omega)$ strongly to the solution $f(\mathbf{x})$.

The remarks at the end of section 3 still hold in the three-dimensional setting. The main difference between the two-dimensional and three-dimensional theories is that the scattering operator is required to be more regularizing in three dimensions than in two dimensions. This is so because the three-dimensional reconstruction is based on measurements of the outgoing distribution for directions that are orthogonal to the vertical axis $\mathbf{e}_z$. The influence of the geometry on the norm of N_K could be characterized in the three-dimensional setting as we have done for the two-dimensional setting in Corollary 3.7, although we shall not do so here.

Acknowledgments. We thank the referees for valuable comments and suggestions. This work was completed in part while both authors visited the Institute for Pure and Applied Mathematics at UCLA during the program on Inverse Problems and Gunther Uhlmann at the University of Washington. We would like to thank both organizations for their hospitality.

INTERACTION OF A BULK AND A SURFACE ENERGY WITH A GEOMETRICAL CONSTRAINT*

ANTONIN CHAMBOLLE† AND MARGHERITA SOLCI‡

Abstract. This study is an attempt to generalize in dimension higher than two the mathematical results in [E. Bonnetier and A. Chambolle, *SIAM J. Appl. Math.*, 62 (2002), pp. 1093–1121]. It is the study of a physical system whose equilibrium is the result of a competition between an elastic energy inside a domain and a surface tension, proportional to the perimeter of the domain. The domain is constrained to remain a subgraph. It is shown by Bonnetier and Chambolle that several phenomena appear at various scales as a result of this competition. In this paper, we focus on establishing a sound mathematical framework for this problem in a higher dimension. We also provide an approximation, based on a phase-field representation of the domain.

Key words. epitaxial growth, surface tension, phase-field approximation, diffuse interface, Γ-convergence

1. Introduction.

In this paper, we seek to extend to a higher dimension the results of Bonnetier and Chambolle in [9]. There, the authors modelize the physical system which consists of a thin film of atoms deposited on a substrate, made of a different crystal. Such systems are common in the engineering of devices such as electronic chips, which are obtained by growing epitaxial films on flat surfaces.

In such a situation, the misfit between the crystalline lattices of the substrate and the film induces strains in the film. To release the elastic energy due to these strains, the atoms of the free surface of the film may diffuse and a reorganization occurs in the film. The result of this mechanism is a competition between the surface energy of the crystal and the bulk elastic energy. The former is roughly proportional to the free surface of the crystal and therefore favors flat configurations. The bulk energy, on the contrary, is best released if oscillatory patterns develop. We refer to [9] and the former study [11] for a more complete explanation of the phenomenon and for references on "stress driven rearrangement instabilities" and epitaxial growth.

Here, we restrict our study to the mathematical model which is proposed in [9] in dimension two. We extend to a higher dimension the relaxation result (implicitly contained in Lemma 2.1 and Theorem 2.2 in [9]) and show the correctness of the phase-field approximation, extending [9, Thm. 3.1]. Observe, however, that in that paper the bulk energy is a linearized elasticity energy that involves the symmetrized gradient of the displacement. It seems that up to now, the theory of "special bounded deformation" functions [6, 8] is not developed well enough to make possible the generalization of our results to that case so that we only work with $W^{1,p}$-coercive bulk energies. Alternatively, we could have decided to impose an additional (artificial) L^∞ constraint to the displacements, in which case the extension to linearized elasticity energies would have been relatively easy (see, for instance, [16]).

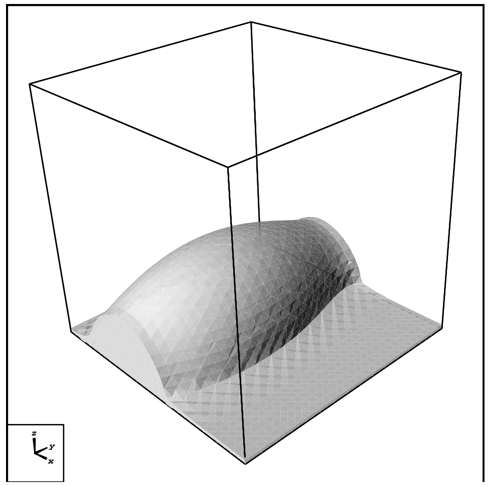

FIG. 1. *Example of an "island."*

Numerical experiments conducted by Jouve and Bonnetier [10] show that the phase-field energy introduced in section 5, in dimension three, yields results similar to the two-dimensional (2D) plots in [9]. See Figure 1 which shows how an island is formed, as a result of the competition between the surface energy and the strains in the material. Here the stretch (the lattice misfit) along the x-direction is stronger than in the y-direction, explaining the shape of the island. (In this example, the bulk energy is a linearized elasticity energy.)

To be precise, we consider in this paper a displacement in a material domain which is the subgraph of an unknown nonnegative function h. Assuming h is defined on an open Lipschitz set $\omega \subset \mathbb{R}^{N-1}$, the displacement u will be defined on the subgraph $\Omega_h := \{x = (x', x_N) \in \omega \times (0, +\infty) \,:\, x_N < h(x')\}$ of h. We will consider energies of the form

$$F(u,h) = \int_{\Omega_h} W(\nabla u)\,dx + \int_\omega \sqrt{1+|\nabla h|^2}\,dx',$$

where u sastisfies a prescribed boundary condition on the boundary $\omega \times \{0\}$. In this paper, ω will be the $(N-1)$-dimensional torus and the boundary condition of u on "$\partial\omega$" will be of periodic type, as in [9] (however, adaption to other situations will not be difficult as long as $\partial\omega$ is Lipschitz).

The goal of our paper is to show that the relaxed functional of F can be written

$$\overline{F}(u,h) = \int_{\Omega_h} W(\nabla u)\,dx + \mathcal{H}^{N-1}(\partial_*\Omega_h) + 2\mathcal{H}^{N-1}(\Sigma),$$

where Σ, the "internal" discontinuity set of u "inside" the subgraph Ω_h of h (which is now a function of bounded variation (BV)), will be a "vertical" rectifiable set so that $\Omega_h \cup \Sigma$ can be viewed as a generalized subgraph.

In an article written almost simultaneously by Braides and the authors of the present paper [13], a similar problem is studied, without the constraint that the domain is the subgraph of a function. Although this may seem more general, showing that "recovery" sequences can be built, so that $\overline{F}$ is not only a lower bound but also an upper bound for the l.s.c. envelope of F, is considerably more difficult in our setting, since the sequence which is found must satisfy the constraint, and therefore has to be built in a constructive way (and not using some general existence result). This construction follows the discretization/reinterpolation technique introduced in [15, 16]. On the other hand, the lower bound in this work is almost a straightforward consequence of [13].

Finally, the last section in this paper deals with the phase-field approximation of $\overline{F}$, using the same approach as in [9].

2. Setting of the problem and statement of the result.

2.1. Functions of bounded variation. We start by recalling some definitions and results, useful in this paper, concerning functions of bounded variation; for this topic, we refer essentially to [7].

Let Ω be an open subset of $\mathbb{R}^N$. Given $u \in L^1(\Omega)$, its total variation is defined as

$$\sup \left\{ \int_\Omega u \operatorname{div} \psi \, dx \ : \ \psi \in C_c^\infty(\Omega; \mathbb{R}^N), \ |\psi(x)| \le 1 \ \forall x \in \Omega \right\} .$$

One may check that it is finite if and only if the distributional derivative Du of u is a bounded Radon measure in Ω. In this case, the total variation of u is equal to the total variation of the measure Du and is classically denoted by $|Du|(\Omega)$.

At each $x \in \Omega$, one can define upper and lower values of u as follows: The upper value is

$$u_+x(u_+(x)) \ = \ \inf \left\{ t \in [-\infty, +\infty] \ : \ \limsup_{\rho \to 0} \frac{|\{y \in \Omega \ : \ u(y) > t\}| \cap B_\rho(x)}{|B_\rho(x)|} = 0 \right\} ,$$

where $B_\rho(x)$ is the ball of radius ρ centered at x. The lower value is simply $-(-u)_+$. Defining the "jump set" of u as $S_u := \{x \in \Omega : u_-(x) < u_+(x)\}$, one can show that if $u \in BV(\Omega)$, S_u is a $(\mathcal{H}^{N-1}, N-1)$-rectifiable set (in the sense of Federer [19]) so that it admits a normal $\nu_u(x)$ at $\mathcal{H}^{N-1}$-a.e. $x \in S_u$, and Du decomposes as

$$Du \ = \ \nabla u(x) \, dx \ + \ (u_+(x) - u_-(x)) \nu_u(x) \, d\mathcal{H}^{N-1} \llcorner S_u(x) \ + \ D^c u,$$

where $D^c u$, the "Cantor part," is singular with respect to the Lebesgue measure and vanishes on any set with finite $(N-1)$-dimensional Hausdorff measure. The Radon–Nikodym derivative of Du with respect to the Lebesgue measure dx, denoted by $\nabla u(x)$, is a.e. the "approximate gradient" of u at x; see [7]. Of course, if $u \in W^{1,1}(\Omega)$, it coincides with the weak gradient.

Up to now, we have considered real-valued functions. If $u \colon \Omega \to \mathbb{R}^d$ is vector-valued, S_u will be the union of the jump sets of the d components of u. One shows, then, that when two of these jump sets intersect, the corresponding normals coincide $\mathcal{H}^{N-1}$-everywhere in the intersection up to a change of sign. The jump part of the derivative Du is given by $(u_+ - u_-) \otimes \nu_u \, d\mathcal{H}^{N-1} \llcorner S_u$, where now u_+ and u_- are not the "upper" and "lower" values (since there is no natural order in $\mathbb{R}^d$) but the orientation depends on the choice of the direction of the normal ν_u (the triple (u_-, u_+, ν_u) being equivalent to $(u_+, u_-, -\nu_u)$).

The space $SBV(\Omega)$ is defined as the subset of $BV(\Omega)$ of functions u such that $D^c u = 0$, that is, Du is absolutely continuous with respect to $dx + \mathcal{H}^{N-1} \llcorner S_u$. Then, for $p > 1$, we say that a function $u \colon \Omega \to \mathbb{R}$ belongs to the space $SBV_p(\Omega)$ if $u \in SBV(\Omega)$, $\nabla u \in L^p(\Omega; \mathbb{R}^N)$, and $\mathcal{H}^{N-1}(S_u) < +\infty$.

We say that a function $u \in L^1(\Omega)$ is a *generalized function of bounded variation* ($u \in GBV(\Omega)$) if $u^T := (-T) \vee u \wedge T$ belongs to $BV(\Omega)$ for every $T \geq 0$. If $u \in GBV(\Omega)$, setting $S_u = \bigcup_{T>0} S_{u^T}$, a truncation argument allows to define the traces $u_-(x)$ and $u_+(x)$ for a.e. $x \in S_u$. Defining, for $u \in GBV(\Omega)$, the Cantor part of the derivative as $|D^c u| = \sup_{T>0} |D^c u^T|$, we say that a function u in $GBV(\Omega)$ belongs to $GSBV(\Omega)$ if $|D^c u| = 0$, and moreover u in $GSBV(\Omega)$ belongs to $GSBV_p(\Omega)$ for $p > 1$ if $\nabla u \in L^p(\Omega; \mathbb{R}^N)$ and $\mathcal{H}^{N-1}(S_u) < +\infty$.

The following compactness result for SBV is proven in [3, 5] (see also [7, Thm. 4.8]).

THEOREM 2.1 (compactness in SBV). *Let $(u_n)_n \subset SBV(\Omega)$ satisfy*

$$\sup_n \left\{ \int_\Omega |\nabla u_n|^p \, dx + \mathcal{H}^{N-1}(S_{u_n}) \right\} < +\infty,$$

with u_n uniformly bounded in $L^\infty(\Omega)$. Then, there exist a subsequence $(u_{n_k})_k$ and $u \in SBV_p(\Omega)$ such that $u_{n_k} \to u$ a.e. in Ω, $\nabla u_{n_k} \rightharpoonup \nabla u$ in $L^p(\Omega; \mathbb{R}^N)$, and

$$\mathcal{H}^{N-1}(S_u) \leq \liminf_{k\to\infty} \mathcal{H}^{N-1}(S_{u_{n_k}}).$$

If u_n is bounded only in $L^1(\Omega)$, one shows easily by truncation that the results still hold, with $u \in GSBV_p(\Omega)$.

2.2. Subgraphs of finite perimeter. In this paper, to simplify, ω is the torus $(\mathbb{R}/\mathbb{Z})^{N-1}$; however, the extension of our results to the case of a Lipschitz bounded open subset of $\mathbb{R}^{N-1}$ does not raise any difficulties. A generic point $x \in \omega \times \mathbb{R}$ will be denoted by (x', x_N), $x' = (x_1, \ldots, x_{N-1}) \in \omega$, $x_N \in \mathbb{R}$. For $h : \omega \to \mathbb{R}_+$ measurable, we consider

$$\Omega_h = \{x \in \omega \times (-1, +\infty) \;:\; x_N < h(x')\} \quad \text{and}$$

$$\Omega_h^+ = \{x \in \omega \times (0, +\infty) \;:\; x_N < h(x')\} = \Omega_h \cap (\omega \times (0, +\infty)).$$

If $h \in BV(\omega; \mathbb{R}_+)$, the set Ω_h has a finite perimeter in the sense of Caccioppoli in $\omega \times (-1, +\infty)$ (that is, $|D\chi_{\Omega_h}|(\omega \times (-1, +\infty)) \leq |\omega| + |Dh|(\omega) < +\infty$, so that $\chi_{\Omega_h} \in BV(\omega \times (-1, +\infty))$). At each point $\xi \in \omega$ one can define the upper and lower values $h_+(\xi)$ and $h_-(\xi)$ as in the previous section. As before, it is known that $h_+ = h_-$ a.e. in ω and the set of points where $h_- < h_+$, called the jump set of h, is denoted by S_h. Then, if $x = (x', x_N) \in \omega \times (-1, +\infty)$, $x_N < h_-(x') \Rightarrow x \in \Omega_h^1$ (the set of points where Ω_h has Lebesgue density 1), $x_N > h_+(x') \Rightarrow x \in \Omega_h^0$ (the set of points where it has density 0), and $\partial_* \Omega_h = \omega \times (-1, +\infty) \setminus (\Omega_h^0 \cup \Omega_h^1)$, the measure-theoretical boundary is a subset of (and $\mathcal{H}^{N-1}$-a.e. equal to) $\bigcup_{\xi \in \omega} \{\xi\} \times [h_-(\xi), h_+(\xi)]$. It is known that the measure-theoretical boundary is $\mathcal{H}^{N-1}$-a.e. equal to a subset $\partial^* \Omega_h$ called the "reduced boundary" of De Giorgi, which contains only points x where the blowups $(\Omega_h - x)/\rho$ converge as $\rho \to 0$ (in $L^1_{\mathrm{loc}}(\mathbb{R}^N)$) to a half-space of outer normal $\nu_{\Omega_h}(x)$ (hence, Ω_h has density exactly $1/2$ at x).

Let us emphasize the fact that the boundaries $\partial \Omega_f$, $\partial_* \Omega_h$ will always, in this paper, be intended as boundaries *inside* $\omega \times (-1, +\infty)$, that is, they do not contain $\omega \times \{-1\}$.

2.3. The relaxation result. Let $W \colon M^{d\times N} \to [0, +\infty)$, with $d \geq 1$, be a continuous and quasi-convex function satisfying a p-growth condition. Let $u^0 \in W^{1,p}(\omega \times (-1, 0); \mathbb{R}^d)$.

For $h \in C^1(\omega;[0,+\infty))$ and $u \in W^{1,p}(\Omega_h^+;\mathbb{R}^d)$, with $u = u^0$ in $\omega \times \{0\}$, we set

$$F(u,h) = \int_{\Omega_h^+} W(\nabla u)\,dx + \int_\omega \sqrt{1+|\nabla h|^2}\,dx';$$

clearly, the same definition can be given for $u \in L^1(\omega \times (0,+\infty);\mathbb{R}^d)$ such that the restriction to Ω_h^+ satisfies the previous properties. Moreover, we define $F(u,h) = +\infty$ otherwise in $L^1(\omega \times (0,+\infty);\mathbb{R}^d) \times BV(\omega;[0,+\infty))$.

It is clear that equivalently one can write that $u \in W^{1,p}(\Omega_h;\mathbb{R}^d)$, with $u = u^0$ in $\omega \times (-1,0)$.

The main result of this paper is the proof of the following relaxation result for the functional F, here written in the case $d = 1$ (for the general case, see the fourth remark in section 2.4).

THEOREM 2.2. *The l.s.c. envelope of the functional F, with respect to the $L^1(\omega \times (0,+\infty)) \times L^1(\omega)$ topology, is the functional $\overline{F}\colon L^1(\omega \times (0,+\infty)) \times L^1(\omega) \to [0,+\infty]$ defined as*

$$\overline{F}(u,h) = \begin{cases} \displaystyle\int_{\Omega_h^+} W(\nabla u)\,dx + \mathcal{H}^{N-1}(\partial_*\Omega_h) + 2\mathcal{H}^{N-1}(S'_u \cap \Omega_h^1) & \\ \qquad \text{if } \ h \in BV(\omega;[0,+\infty)) \ \text{ and } \ u\chi_{\Omega_h^+} \in GSBV(\omega \times (0,+\infty)), & \\ +\infty \qquad \text{otherwise,} & \end{cases}$$

where

$$S'_u \;=\; \{(x', x_N + t) \,:\, x \in S_u\,, t \geq 0\}\;.$$

Observe that, denoting $\Sigma = S'_u \cap \Omega_h^1$, Σ is a "vertical" rectifiable set, and we will sometimes write $\Gamma = \partial_*\Omega_h \cup \Sigma$, the "generalized" interface.

The proof of Theorem 2.2 will be given by showing a lower and an upper bound, respectively, in section 3 (Proposition 3.1) and in section 4 (Proposition 4.1); the thesis of Theorem 2.2 immediately follows from these results.

2.4. Some remarks.

1. In [13], a similar result is shown with mainly two differences, which both follow from the constraint that the set where u is defined is a subgraph: In the lim inf inequality, we have to keep track of the vertical parts of the boundary (S'_u) that might not be in the jump set of u (that is, one might have $(S'_u \setminus S_u) \cap \Omega_h^1 \neq \emptyset$). In the lim sup inequality, one needs to build a recovery sequence which remains a subgraph, leading to a much more complex proof than in [13].

2. In [9], one also considers the case where the surface tension for the substrate (of boundary $\omega \times \{0\}$), σ_S, can be different from the surface tension σ_C of the crystal (of boundary $\partial\Omega_h \cap (\omega \times (0,+\infty))$ if h is smooth). In this case, two different phenomena occur, depending on the fact that $\sigma_S \leq \sigma_C$ or $\sigma_C < \sigma_S$. In the latter case, it is always energetically convenient to cover (or "wet") all the surface of the substrate with an infinitesimal layer of crystal, so that the global surface tension in the relaxed energy is σ_C. In case σ_S is less than σ_C, then parts of the substrate might remain uncovered by the crystal, and the surface energy in the relaxed functional will be given by

$$\sigma_C(\mathcal{H}^{N-1}(\partial_*\Omega_h \cap (\omega \times (0,+\infty))) \,+\, 2\mathcal{H}^{N-1}(S'_u \cap \Omega_h^1)) \\ \qquad\qquad + \,\sigma_S\mathcal{H}^{N-1}(\{x' \in \omega \,:\, h(x') = 0\})\,.$$

We do not prove this result here; we fear it would make the paper harder to read, mostly because of the notation. See also Remark 4.4.

3. Still in [9], the (2D) functional F is minimized with an additional volume constraint ($\int_\omega h\,dx = 1$). It is easy to show that the relaxed functional $\overline{F}$ does not change under this constraint—see Remark 4.2 below.

4. In what follows, we will assume that $d = 1$, u is scalar, and hence W is convex. In the vectorial case, one has to assume that W is a continuous, quasi-convex function of ∇u with growth p (that is, bounded from below and above by functions of the form $a + b|\nabla u|^p$, with $b > 0$). Then, the lower bound (Proposition 3.1) remains the same thanks to results of semicontinuity for quasi-convex integrands, due to Ambrosio [4] in the SBV case (see also [7]), and to Kristensen [23] in the general case). The proof of the upper bound (Proposition 4.1, in which W does not appear) can be written with a scalar or vectorial u without any change. Then, its generalization to the Lagrangian W follows from the continuity and p-growth assumptions, as in the scalar case.

5. In [9] and the problem mentioned in the introduction, it is not u but $u - x_1$ which is 1-periodic in the first variable. Here, to simplify, everything is written with $u \in GSBV_p(\omega \times (-1, +\infty))$; that is, u is periodic in the $(N-1)$ first directions (we recall ω is the $(N-1)$-dimensional torus). Adapting the results to extend them to the case where, for instance, $u - \alpha(x_1, 0, \dots, 0) \in GSBV_p(\omega \times (-1, +\infty))$, $\alpha > 0$, would not be difficult.

3. A lower bound for the relaxed envelope of *F*. In this section we obtain a lower bound for the relaxed functional $\overline{F}$ by proving the following proposition.

PROPOSITION 3.1. *For every sequence $(u_n, h_n) \in W^{1,p}(\Omega_{h_n}) \times C^1(\omega; [0, +\infty))$, with $u_n = u_0$ in $\omega \times (-1, 0)$, such that*

$$\sup_n F(u_n, h_n) < +\infty,$$

there exist $h \in BV(\omega; [0, +\infty))$ and $u \in GSBV(\omega \times (0, +\infty))$ (with $u = 0$ out of Ω_h) such that $\chi_{\Omega_{h_n}} u_n \to u$ in $L^1(\omega \times (0, +\infty))$, $h_n \to h$ in $L^1(\omega)$,

$$\int_{\Omega_h^+} |\nabla u(x)|^p\,dx \le \liminf_{n\to\infty} \int_{\Omega_{h_n}^+} |\nabla u_n(x)|^p\,dx\,, \tag{1}$$

and

$$\mathcal{H}^{N-1}(\partial_* \Omega_h) + 2\mathcal{H}^{N-1}(S'_u \cap \Omega_h^1) \le \liminf_{n\to\infty} \int_\omega \sqrt{1 + |\nabla h_n(x')|^2}\,dx'\,. \tag{2}$$

This proposition implies immediately the lower bound for the relaxed envelope of F, that is, the first part of the proof of Theorem 2.2. Indeed, we obtain in the proof that the sequence $(u_n)_n$ converges in fact weakly in the $W^{1,p}$-topology, and since the function W is l.s.c. and convex, with growth p, the functional $G(u) = \int_{\Omega_h^+} W(\nabla u)\,dx$ is weakly l.s.c. in $W^{1,p}$; then, in the same hypothesis, we get the inequality

$$\begin{aligned} &\int_{\Omega_h^+} W(\nabla u(x))\,dx + \mathcal{H}^{N-1}(\partial_* \Omega_h) + 2\mathcal{H}^{N-1}(S'_u \cap \Omega_h^1) \\ &\qquad \le \liminf_{n\to\infty} \int_{\Omega_{h_n}^+} W(\nabla u_n(x))\,dx + \int_\omega \sqrt{1 + |\nabla h_n(x')|^2}\,dx'\,. \end{aligned} \tag{3}$$

Let us consider a sequence (u_n, h_n) such that

$$\sup_{n\ge 1} F(u_n, h_n) < +\infty\,;$$

we show that, up to a subsequence, $u_n \to u$ in $L^1(\omega \times (0, +\infty))$ and $h_n \to h$ in $L^1(\omega)$, with

$$\overline{F}(u, h) \le \liminf_{n\to\infty} F(u_n, h_n). \tag{4}$$

To prove the lower inequality, it is sufficient to consider sequences (u_n, h_n) with $h_n \in C^\infty(\omega; [0, +\infty))$ and $u_n \in W^{1,p}(\Omega^+_{h_n})$, and $u_n = u^0$ on $\omega \times \{0\}$; however, this compactness property, as well as inequality (4), will still hold if we just assume that $h_n \in W^{1,1}(\omega)$ and $u_n \in SBV_p(\omega \times (-1, +\infty))$ with $u_n = u^0$ in $\omega \times (-1, 0)$, $u_n(x) = 0$ a.e. in $\{x_N > h_n(x')\}$, and $S_u \tilde{\subset} \partial_* \Omega_{h_n}$ (where $A \tilde{\subset} B$ means $\mathcal{H}^{N-1}(A \setminus B) = 0$).

Let us consider first the compactness and l.s.c. of the jump term, and for this we will use a special notion of convergence for a jump set of SBV_p functions.

3.1. Jump set convegence. The following notion of jump set convergence is introduced by Dal Maso, Francfort, and Toader [18, Def. 4.1] and [17, Def. 3.1]. It is called "σ^p-convergence." A variant, which is independent on the exponent $p > 1$, has been introduced more recently by Giacomini and Ponsiglione; see [21].

In what follows, we denote equality and inclusion up to a $\mathcal{H}^{N-1}$-negligible set by the symbols $\tilde{=}$ and $\tilde{\subset}$, respectively.

Definition 3.2. *Let Ω be an open set in $\mathbb{R}^N$, and let $p \in (1, +\infty)$. We say that a sequence $(\Gamma_n)_{n\in\mathbb{N}}$ of subsets of Ω σ^p-converges to Γ if and only if $\sup_{n\in\mathbb{N}} \mathcal{H}^{N-1}(\Gamma_n) < +\infty$ and*

(i) *for any sequence $(v_n)_n$ of functions in $SBV_p(\Omega)$, with $S_{v_n} \tilde{\subset} \Gamma_n$, if the subsequence v_{n_k} goes to v weakly in $SBV_p(\Omega)$ as $k \to \infty$ then $S_v \tilde{\subset} \Gamma$;*

(ii) *there exists a function $v \in SBV_p(\Omega)$ and sequence $(v_n)_n$ of functions in $SBV_p(\Omega)$ converging to v such that $S_{v_n} \tilde{\subset} \Gamma_n$ for each n and $S_v = \Gamma$.*

The following compactness theorem is proven in [18, Thm. 4.7]

Theorem 3.3. *Every sequence $\Gamma_n \subset \Omega$, with $\mathcal{H}^{N-1}(\Gamma_n)$ uniformly bounded, has a σ^p-convergent subsequence.*

The proof of this theorem is based on the following lemma (cf. [18, Lem. 4.5]).

Lemma 3.4. *Let $(v_i)_{i=1}^\infty$ be a sequence in $SBV_p(\Omega) \cap L^\infty(\Omega)$, and let us assume $\mathcal{H}^{N-1}(\bigcup_{i=1}^\infty S_{v_i}) < +\infty$. Then there exist real numbers $c_i > 0$ with $\sum_{i=1}^\infty c_i < +\infty$ such that $v := \sum_{i=1}^\infty c_i v_i \in SBV_p(\Omega) \cap L^\infty(\Omega)$ and $S_v \tilde{=} \bigcup_{i=1}^\infty S_{v_i}$.*

Let us mention the following variant of the proof of Theorem 3.3, still based on Lemma 3.4: Given $\Gamma \subset \Omega$, we introduce

$$X(\Gamma) \;=\; \left\{ v \in SBV_p(\Omega; [-1, 1]) \,:\, S_v \tilde{\subset} \Gamma\,,\; \int_\Omega |\nabla v|^p \, dx \le 1 \right\}.$$

Then, if $\mathcal{H}^{N-1}(\Gamma) < +\infty$, by Ambrosio's compactness theorem, Theorem 2.1, $X(\Gamma)$ is compact in $L^1_{\mathrm{loc}}(\Omega)$ (which is metrizable). If $(\Gamma_n)_n$ is a sequence of jump sets with $L = \sup_n \mathcal{H}^{N-1}(\Gamma_n) < +\infty$, then the sets $X(\Gamma_n)$ all belong to

$$X_L \;=\; \left\{ v \in SBV_p(\Omega; [-1, 1]) \,:\, \mathcal{H}^{N-1}(S_v) \le L,\; \int_\Omega |\nabla v|^p \, dx \le 1 \right\}$$

which is also compact in $L^1_{\mathrm{loc}}(\Omega)$. Hence, a subsequence $(X(\Gamma_{n_k}))_k$ converges in the Hausdorff sense (with the Hausdorff distance in $L^1_{\mathrm{loc}}(\Omega)$ induced by a distance in $L^1_{\mathrm{loc}}(\Omega)$) to a compact $K \subset X_L$. We show that $K \subseteq X(\Gamma)$ for some Γ.

Let $(v_i)_{i=1}^\infty$ be a dense sequence in the compact set K. We first observe that, since K is convex, given any v, v' in K there exists w (given by $\theta v + (1-\theta)v'$ for an appropriate choice of θ, see, for instance, [20]) such that $S_w \tilde{=} S_v \cup S_{v'}$; hence, $\mathcal{H}^{N-1}(S_v \cup S_{v'}) \le L$. In particular, we deduce that $\mathcal{H}^{N-1}(\bigcup_{i=1}^k S_{v_i}) \le L$ for any $k \ge 1$ and, passing to the limit, that $\mathcal{H}^{N-1}(\Gamma) \le L < +\infty$, where we have let $\Gamma = \bigcup_{i=1}^\infty S_{v_i}$. Using Lemma 3.4, we deduce that there exists $v \in K$ with $\Gamma \tilde{=} S_v$. Hence Γ satisfies axiom (ii) in Definition 3.2. On the other hand, any $v \in K$ is the limit of an appropriate subsequence $v_{i(k)}$, $k \ge 1$, with $S_{v_{i(k)}} \tilde{\subset} \Gamma$, and a consequence of Ambrosio's compactness theorem is that $S_v \tilde{\subset} \Gamma$, so that axiom (i) in Definition 3.2 is also satisfied. Hence Γ_{n_k} σ^p-converges to Γ. ∎

We observe that an obvious consequence of Ambrosio's theorem is that, if Γ_n σ^p-converges to Γ,

$$\mathcal{H}^{N-1}(\Gamma) \le \liminf_{n\to\infty} \mathcal{H}^{N-1}(\Gamma_n)\,. \tag{5}$$

3.2. Proof of the lower inequality. Let $\Gamma_n = \partial\Omega_{h_n} = \{x \in \omega \times (-1,+\infty) : x_N = h_n(x')\}$ be the graph of the function h_n. Up to a subsequence, we know by Theorem 3.3 that Γ_n σ^p-converges to some Γ as $n \to \infty$. Since h_n is uniformly bounded in $W^{1,1}(\omega)$, possibly extracting another subsequence, $h_n \to h$ in $L^1(\omega)$. Equivalently, the sets Ω_{h_n} converge to Ω_h in the $L^1(\omega \times (0,+\infty))$ topology for the characteristic functions.

Clearly, $\partial_*\Omega_h \subseteq \Gamma$; indeed, if we take in Definition 3.2 the sequence $v_n = \chi_{\Omega_{h_n}}$, we find that $v_n \to \chi_{\Omega_h}$, whose jump set is $\partial_*\Omega_h$.

Let us decompose Γ in the three parts $\partial_*\Omega_h$, $\Sigma = \Gamma \cap \Omega_h^1$, and $\Sigma^0 = \Gamma \cap \Omega_h^0$. The part Σ^0 is irrelevant in our study since the functions u, limits of converging subsequences of (u_n), will all vanish outside of Ω_h.

We show that Σ is vertical: That is, for any $x = (x', x_N) \in \Sigma$, $(x', x_N + t) \in \Sigma \cup (\mathbb{R}^N \setminus \Omega_h^1)$ for any $t \ge 0$. Indeed, let $v \in SBV_p(\omega \times (-1,+\infty))$ be such that $S_v \tilde{=} \Gamma$, and let v_n be a sequence weakly converging to v in $SBV_p(\omega \times (-1,+\infty))$ with $S_{v_n} \tilde{\subset} \Gamma_n$. Consider the functions $x \mapsto v_n(x', x_N - t)\chi_{\Omega_{h_n}}(x)$, with $t < 1$, extended in an appropriate way in $\omega \times (-1, -1+t)$. These functions will converge to $x \mapsto v(x', x_N - t)\chi_{\Omega_h}(x)$, showing that $(S_v + te_N) \cap \Omega_h^1 \subset \Gamma$, which shows our claim. In particular, we deduce that $\mathcal{H}^{N-1}$-a.e. in Σ, $\nu_\Sigma \cdot e_N = 0$.

By (5), we have $\mathcal{H}^{N-1}(\partial_*\Omega_h) + \mathcal{H}^{N-1}(\Sigma) \le \liminf_{n\to\infty} \mathcal{H}^{N-1}(\Gamma_n)$. We claim that, in addition,

$$\mathcal{H}^{N-1}(\partial_*\Omega_h) + 2\mathcal{H}^{N-1}(\Sigma) \le \liminf_{n\to\infty} \mathcal{H}^{N-1}(\Gamma_n).$$

This follows from [13] and the definition of σ^p-convergence. Indeed, it is a consequence of the lim inf-inequality in [13], applied to a sequence $(v_n)_{n\ge1}$ with $S_{v_n} \tilde{\subset} \Gamma_n$, weakly converging in $SBV_p(\omega \times (-1,+\infty))$ to a v such that $\Sigma \tilde{\subset} S_v$.

Let us now conclude. If $F(u_n, h_n)$ is uniformly bounded, then by integration along vertical segments we easily check that (u_n) is uniformly bounded in $L^p_{\mathrm{loc}}(\omega \times (-1,+\infty))$. Then, it is a consequence of Ambrosio's theorem, Theorem 2.1, that there exists $u \in GSBV_p(\omega \times (-1,+\infty))$ such that $u_n(x) \to u(x)$ a.e., and $\nabla u_n \rightharpoonup \nabla u$ in $L^p(\omega \times (-1,+\infty); \mathbb{R}^N)$ so that the inequality (1) holds. Clearly, u vanishes out of Ω_h. By point (i) in Definition 3.2, which is easily generalized to $GSBV_p$ functions (see [18, Prop. 4.6]), we have that $S_u \tilde{\subset} \Sigma \cup \partial_*\Omega_h$. In particular, since Σ is vertical, $S'_u \cap \Omega_h^1 \subset \Sigma$. We deduce (2). Clearly, the inequality (4) follows from (1) and (2). ∎

4. An upper bound for the relaxed envelope of *F*. We now get the upper bound for the relaxed envelope of the functional F by proving the following proposition.

Proposition 4.1. *For any u, h, with $\overline{F}(u,h) < +\infty$, there exist (u_n, h_n) with $h_n \in C^1(\omega; [0,+\infty))$, $u_n \in W^{1,p}(\Omega_{h_n})$, and $u_n = u^0$ in $\omega \times (-1, 0)$ such that $h_n \to h$ in $L^1(\omega)$, $u_n \chi_{\Omega^+_{h_n}} \to u\chi_{\Omega^+_h}$ in $L^1(\omega \times (0,+\infty))$,*

$$\limsup_{n\to\infty} \int_{\Omega^+_{h_n}} |\nabla u_n(x)|^p\,dx = \int_{\Omega^+_h} |\nabla u(x)|^p\,dx, \tag{6}$$

and

$$\limsup_{n\to\infty} \int_\omega \sqrt{1+|\nabla h_n(x')|^2}\,dx' \le \mathcal{H}^{N-1}(\partial_*\Omega_h) + 2\mathcal{H}^{N-1}(S'_u \cap \Omega^1_h). \tag{7}$$

We note that the proposition completes the proof of Theorem 2.2. Indeed, if we find a sequence $(u_n)_n$ satisfying (6), we can deduce the strong convergence $\nabla u_n \chi_{\Omega^+_{h_n}} \to \nabla u \chi_{\Omega^+_h}$ in L^p; the continuity of W (together with (6) and the growth condition of W) gives the general result

$$\begin{aligned} &\limsup_{n\to\infty} \int_{\Omega^+_{h_n}} W(\nabla u_n(x))\,dx + \int_\omega \sqrt{1+|\nabla h_n(x')|^2}\,dx' \\ &\quad\le \int_{\Omega^+_h} W(\nabla u(x))\,dx + \mathcal{H}^{N-1}(\partial_*\Omega_h) + 2\mathcal{H}^{N-1}(S'_u\cap\Omega^1_h), \end{aligned} \tag{8}$$

which is the $\limsup$ inequality for the functional F.

Remark 4.2. In case one adds in the definition of functional F a volume constraint (that is, $F(u,h) = +\infty$ if $\int_\omega h\,dx \neq V$, where $V > 0$ is a fixed volume), then it is easy to show that Proposition 4.1 still holds, with the sequence (h_n) satisfying the same volume constraint as the limit h. Indeed, given the sequence (h_n) provided by the proposition (without volume constraint), one clearly has $r_n = \int_\omega h_n\,dx / \int_\omega h\,dx \to 1$ as $n \to \infty$, and an appropriate scaling (of the form $x \mapsto (x', x_N/r_n)$) of the functions and the domain will provide new sequences (u_n, h_n) with $\int_\omega h_n\,dx = \int_\omega h\,dx$, still satisfying (6) and (7).

We first state the following lemma, which shows that any BV, nonnegative subgraph with an *essentially closed* boundary can be approximated from below by the subgraph of a smooth, nonnegative function.

Lemma 4.3. *Let $g \in BV(\omega; \mathbb{R}_+)$, and assume $\partial_*\Omega_g$ is essentially closed, that is, $\mathcal{H}^{N-1}(\overline{\partial_*\Omega_g} \setminus \partial_*\Omega_g) = 0$. Then, for any $\varepsilon > 0$, there exists $f \in C^\infty(\omega; \mathbb{R}_+)$ such that $0 \le f \le g$ a.e. in ω, $\|f - g\|_{L^1(\omega)} \le \varepsilon$ and*

$$\left| \int_\omega \sqrt{1+|\nabla f|^2}\,dx \;-\; \mathcal{H}^{N-1}(\partial_*\Omega_g) \right| \;\le\; \varepsilon\,.$$

Proof. Consider first the distance function $d(x) = \mathrm{dist}(x, \partial_*\Omega_g)$ in $\omega \times (-1, +\infty)$. By results on the Minkowski contents [7, 19], we have (because of our assumption of essential closedness)

$$\lim_{\varepsilon\to 0} \frac{|\{x \in \omega\times(-1,+\infty) \,:\, d(x) \le \varepsilon\}|}{2\varepsilon} \;=\; \mathcal{H}^{N-1}(\partial_*\Omega_g)\,.$$

From the BV-coarea formula (and since $|\nabla d| = 1$ a.e.),

$$\frac{|\{x \,:\, d(x)\le\varepsilon\}|}{2\varepsilon} \;=\; \frac{1}{2\varepsilon}\int_{\{d\le\varepsilon\}} |\nabla d(x)|\,dx \;=\; \frac{1}{2\varepsilon}\int_0^\varepsilon \mathcal{H}^{N-1}(\partial\{d\le s\})\,ds\,.$$

We deduce the convergence of the average values,

$$\lim_{\varepsilon\to 0} \fint_0^{\varepsilon} \frac{1}{2}\mathcal{H}^{N-1}(\partial\{d\le s\})\,ds \;=\; \mathcal{H}^{N-1}(\partial_*\Omega_g)\,,$$

so that we can find a sequence $(\varepsilon_k)_{k\ge 1}$ with $\varepsilon_k\downarrow 0$ such that

$$\lim_{k\to\infty} \frac{1}{2}\mathcal{H}^{N-1}(\partial\{d\le \varepsilon_k\}) \;=\; \mathcal{H}^{N-1}(\partial_*\Omega_g) \tag{9}$$

(without loss of generality we also may assume that the boundary $\partial\{d\le\varepsilon_k\}$ is Lipschitz).

Now, the boundary of $\{d\le\varepsilon_k\}$ is the disjoint union of the boundaries of $\{x\in\omega\times(-1,+\infty) : \mathrm{dist}(x,\Omega_g)\le\varepsilon_k\}$ and $\{x\in\Omega_g : d(x)>\varepsilon_k\}$, and both of these sets converge (in $L^1(\omega\times(-1,+\infty))$) to Ω_g so that the lim inf of their perimeter is greater or equal to $\mathcal{H}^{N-1}(\partial_*\Omega_g)$. Together with (9) it shows that these perimeters go to $\mathcal{H}^{N-1}(\partial_*\Omega_g)$, in particular,

$$\lim_{k\to\infty} \mathcal{H}^{N-1}(\partial\{x\in\Omega_g\,:\,d(x)>\varepsilon_k\}) \;=\; \mathcal{H}^{N-1}(\partial_*\Omega_g)\,.$$

This set $\{x\in\Omega_g \,:\, d(x)>\varepsilon_k\}$ is the subgraph in $\omega\times(-1,+\infty)$ of a function $g_k\in BV(\omega;[-\varepsilon_k,+\infty))$, with $g_k\le g-\varepsilon_k$ a.e. in ω. We consider $g_k^+ = g_k\vee 0$: We have $0\le g_k^+$ and

$$\mathcal{H}^{N-1}(\partial\Omega_{g_k^+}) \;\le\; \mathcal{H}^{N-1}(\partial\Omega_{g_k})$$

(since $\partial\Omega_{g_k^+}\cap(\omega\times\{0\})$ is the orthogonal projection onto $\omega\times\{0\}$ of $\partial\Omega_{g_k}\cap(\omega\times(-1,0]))$. Hence, we still have

$$\lim_{k\to\infty}\mathcal{H}^{N-1}(\partial\Omega_{g_k^+}) \;=\; \mathcal{H}^{N-1}(\partial_*\Omega_g)\,.$$

By convolution, we can build from g_k^+ a sequence of smooth functions f_k that are still nonnegative, that go to g in $L^1(\omega)$, and such that

$$\lim_{k\to\infty}\int_\omega \sqrt{1+|\nabla f_k(x')|^2}\,dx' \;=\; \mathcal{H}^{N-1}(\partial_*\Omega_g)\,.$$

Let $x'\in\omega$. By construction of g_k we have $g_k(y')\le g_+(x')$ a.e. in $\{y'\in\omega : |y'-x'|\le\varepsilon_k\}$ (where $g_+=g$ a.e. is the precise representative defined in section 2.1). Since $g\ge 0$ a.e., we also have $g_k^+(y')\le g_+(x')$ a.e. in $\{y'\in\omega : |y'-x'|\le\varepsilon_k\}$. This shows that if for each k the size of the support of the convolution kernel is chosen small enough (for instance, of diameter less than $\varepsilon_k/2$), we also have $f_k\le g_+$. This proves Lemma 4.3. □

Proof of Proposition 4.1. Let us consider, now, u and h such that $\overline{F}(u,h)<+\infty$. We divide this proof into two steps.

Step 1 (approximation of (most of) the graph). We show that we can approximate a "generalized graph" $(\partial_*\Omega_h,\Sigma)$, where $\Sigma\subset\Omega_h^1\cap(\omega\times(0,+\infty))$ is vertical in the sense that $x\in\Sigma\Rightarrow(x',x_N+t)\in\Sigma$ for any $t\ge 0$ as long as $(x',x_N+t)\in\Omega_h^1$, with the graph of a smooth function $f:\omega\to\mathbb{R}_+$, with $\Omega_f\subset\Omega_h\setminus\Sigma$ up to a small part, and with a good approximation of the total surface energy $\mathcal{H}^{N-1}(\partial_*\Omega_h)+2\mathcal{H}^{N-1}(\Sigma)$ (by the surface of the smooth graph $\int_\omega\sqrt{1+|\nabla f|^2}\,dx$).

Let us first assume that $\Sigma = \emptyset$: We claim that for any $h \in BV(\omega;\mathbb{R}_+)$ and $\varepsilon > 0$, there exists $f \in C^\infty(\omega;\mathbb{R}_+)$ such that

$$\|f-h\|_{L^1(\omega)} \;+\; \mathcal{H}^{N-1}(\partial_*\Omega_h \cap \Omega_f) \;\le\; \varepsilon \tag{10}$$

and

$$\left| \int_\omega \sqrt{1+|\nabla f(x)|^2}\,dx \;-\; \mathcal{H}^{N-1}(\partial_*\Omega_h) \right| \;\le\; \varepsilon\,. \tag{11}$$

We fix $\varepsilon > 0$. Let us consider a mollifying kernel $\rho \in C_c^\infty(\mathbb{R}^N)$, with support in the unit ball, and for any $\eta > 0$ let $\rho_\eta(x) = (1/\eta)^N \rho(x/\eta)$. For $n \ge 1$ we consider the function $w_n = \rho_{1/n} * \chi_{\Omega_h} : \omega \times \mathbb{R} \to [0,1]$. It is well known not only that $w_n \to \chi_{\Omega_h}$ strongly in L^1 but also that $\int_{\omega\times(-1,+\infty)} |\nabla w_n(x)|\,dx \;\to\; |D\chi_{\Omega_h}|(\omega\times(-1,+\infty)) \;=\; \mathcal{H}^{N-1}(\partial_*\Omega_h)$ as $n \to +\infty$.

One has, for every $x \in \Omega_h^1 \cup \partial^*\Omega_h \cup \Omega_h^0$ (hence, $\mathcal{H}^{N-1}$-a.e. $x \in \omega\times(-1,+\infty)$),

$$\lim_{n\to\infty} w_n(x) \;=\; \begin{cases} 1 & \text{if } x \in \Omega_h^1\,,\\ \frac{1}{2} & \text{if } x \in \partial^*\Omega_h\,,\\ 0 & \text{if } x \in \Omega_h^0\,. \end{cases} \tag{12}$$

The same properties are true for the sequence of (l.s.c.) functions $(\tilde{w}_n)_{n\ge1}$ defined by

$$\tilde{w}_n(x) \;=\; \begin{cases} w_n(x) & \text{if } x \in \omega\times[0,+\infty)\,,\\ 1 & \text{if } x \in \omega\times(-1,0)\,. \end{cases}$$

Indeed, using the coarea formula, one sees that

$$\begin{aligned} |D\tilde{w}_n|(\omega\times(-1,+\infty)) \;&=\; \int_0^1 \mathcal{H}^{N-1}(\partial\{\tilde{w}_n > s\})\,ds \\ &\le\; \int_0^1 \mathcal{H}^{N-1}(\partial\{w_n > s\})\,ds \;=\; \int_{\omega\times(0,+\infty)} |\nabla w_n(x)|\,dx \end{aligned}$$

since $\mathcal{H}^{N-1}(\partial\{w_n > s\} \cap (\omega\times(-1,0))) \ge \mathcal{H}^{N-1}(\{x' \in \omega : w_n(x',0) \le s\}) = \mathcal{H}^{N-1}(\partial\{\tilde{w}_n > s\} \cap (\omega\times(-1,0)))$, the second set being the projection onto $\omega\times\{0\}$ of the first one. We deduce that $\limsup_{n\to\infty} |D\tilde{w}_n|(\omega\times(-1,+\infty)) \le \mathcal{H}^{N-1}(\partial_*\Omega_h)$, but since $\tilde{w}_n \to \chi_{\Omega_h}$, it yields $\lim_{n\to\infty} |D\tilde{w}_n|(\omega\times(-1,+\infty)) = \mathcal{H}^{N-1}(\partial_*\Omega_h)$. Clearly, (12) is also true for $\tilde{w}$ since $\Omega_h^1 \supset \omega\times(-1,0)$. We drop the tilde in the sequel and just write w_n instead of $\tilde{w}_n$.

For a.e. $s \in (0,1)$, one also checks that $\lim_{n\to\infty} |\{w_n > s\}\triangle\Omega_h| = 0$, and using Fatou's lemma and the coarea formula, that for a.e. $s \in (0,1)$, $\{w_n > s\}$ is an open set such that $\liminf_{n\to\infty} \mathcal{H}^{N-1}(\partial\{w_n > s\}) = \mathcal{H}^{N-1}(\partial_*\Omega_h)$. Thus, up to a subsequence (possibly depending on s), we may assume $\lim_{n\to\infty} \mathcal{H}^{N-1}(\partial\{w_n > s\}) = \mathcal{H}^{N-1}(\partial_*\Omega_h)$. Let us consider $s^* \in (2/3, 3/4)$ and an appropriate subsequence such that this property is true, and let us consider the corresponding sequence of sets $\{x \in \omega\times(-1,+\infty) : w_n(x) > s^*\}$. We have that $\mathcal{H}^{N-1}(\partial_*\Omega_h \cap \{w_n > s^*\}) = \int_{\partial_*\Omega_h} \chi_{\{w_n > s^*\}}(x)\,d\mathcal{H}^{N-1}(x)$, and since by (12), $\chi_{\{w_n > s^*\}}(x) \to 0$ $\mathcal{H}^{N-1}$-a.e. in $\partial_*\Omega_h$, we find $\mathcal{H}^{N-1}(\partial_*\Omega_h \cap \{w_n > s^*\}) \to 0$ as $n \to \infty$. We fix n large such that

$$\begin{gathered} |\{w_n > s^*\}\triangle\Omega_h| \;+\; \mathcal{H}^{N-1}(\partial_*\Omega_h \cap \{w_n > s^*\}) \;\le\; \frac{\varepsilon}{2}\,, \\ \left|\mathcal{H}^{N-1}(\partial\{w_n > s^*\}) \;-\; \mathcal{H}^{N-1}(\partial_*\Omega_h)\right| \;\le\; \frac{\varepsilon}{2}\,. \end{gathered}$$

It is clear that there exists $g : \omega \to [0, +\infty)$ a BV function such that $\{w_n > s^*\} = \{x_N < g(x')\}$. By Lemma 4.3 applied to g, we find a smooth function $f \le g$, $f \ge 0$, satisfying both (10) and (11).

Now, assume $\Sigma \neq \emptyset$. First, possibly replacing h by $h \wedge (M-1) = \min\{h, M-1\}$, $M > 1$ large, we may assume without loss of generality that h is bounded by $M-1$. Let us then define Σ' by $\Sigma' = \bigcup_{x\in\Sigma}\{x'\}\times[x_N, M]$ and recall that by assumption $\Sigma' \cap \Omega_h^1 = \Sigma$. We may also assume without loss of generality that $\mathcal{H}^{N-1}(\Sigma' \cap (\omega \times [0, M])) < +\infty$, possibly replacing (in a preliminary step) h with $h_\delta = (h-\delta)^+$, $\delta > 0$ small, and Σ with $\Sigma_\delta = \Sigma \cap \Omega_{h_\delta}$: Indeed, one will have that $\Sigma'_\delta \cap \{h_\delta(x') \le x_N \le h_\delta(x') + \delta\} \subseteq \Sigma$ so that $\mathcal{H}^{N-1}(\Sigma'_\delta \cap (\omega \times [0, M])) \le (M/\delta)\mathcal{H}^{N-1}(\Sigma) < +\infty$. Now, let $K \subseteq \Sigma'$ be a compact set such that $\mathcal{H}^{N-1}(\Sigma' \setminus K) \le \varepsilon/10$. Observe that, if K' is defined as Σ', also $\mathcal{H}^{N-1}(\Sigma' \setminus K') \le \varepsilon/10$, and K' is compact.

Let us build the sequence of l.s.c. functions $(w_n)_{n\ge1}$ and find a level $s^* \in (2/3, 3/4)$, as previously. By (12), we have that $\chi_{\{w_n > s^*\}}$ converges to 1 in Ω_h^1, while it tends to 0 $\mathcal{H}^{N-1}$-a.e. outside. In particular, $\mathcal{H}^{N-1}(K' \cap \{w_n > s^*\}) \to \mathcal{H}^{N-1}(K' \cap \Omega_h^1)$ as $n \to \infty$, and this limit satifies $\mathcal{H}^{N-1}(\Sigma) - \varepsilon/10 \le \mathcal{H}^{N-1}(K' \cap \Omega_h^1) \le \mathcal{H}^{N-1}(\Sigma)$. We can hence choose n such that

$$|\{w_n > s^*\} \triangle \Omega_h| \ + \ \mathcal{H}^{N-1}(\partial_* \Omega_h \cap \{w_n \ge s^*\}) \ \le \ \frac{\varepsilon}{4}\,,$$

$$\left|\mathcal{H}^{N-1}(\partial\{w_n > s^*\}) \ - \ \mathcal{H}^{N-1}(\partial_*\Omega_h)\right| \ \le \ \frac{\varepsilon}{4}\,,$$

and

$$\left|\mathcal{H}^{N-1}(K' \cap \{w_n > s^*\}) \ - \ \mathcal{H}^{N-1}(\Sigma)\right| \ \le \ \frac{\varepsilon}{8}\,.$$

Observe now that since the set K' is compact, its Minkowski content $|\{\mathrm{dist}(\cdot, K') < s\}|/(2s)$ converges to $\mathcal{H}^{N-1}(K')$ as $s \to 0$ (see [7, 19]). As in the proof of Lemma 4.3, we deduce that there exists a sequence $(s_k)_{k\ge1}$ such that

$$\lim_{k\to\infty} \mathcal{H}^{N-1}(\partial\{\mathrm{dist}(\cdot, K') > s_k\}) \ = \ 2\mathcal{H}^{N-1}(K')\,. \tag{13}$$

We introduce the measures $\mu_k = \mathcal{H}^{N-1} \llcorner \partial\{\mathrm{dist}(\cdot, K') > s_k\}$. Up to a subsequence, we may assume that they converge (weakly-$*$) to a measure μ supported on K'. A consequence of the lim inf inequality in [13] is that $\mu(A) \ge 2\mathcal{H}^{N-1}(K' \cap A)$ for any open set $A \subset \omega \times (0, +\infty)$. (In this simple case, it can be shown directly by a slicing argument; see, for instance, [12, Lem. 2]). Together with (13), it shows that $\mu = 2\mathcal{H}^{N-1} \llcorner K'$. In particular, if k is large enough and provided we have chosen s^* such that $\mathcal{H}^{N-1}(K' \cap \partial\{w_n > s^*\}) = 0$ (almost any choice suits, since $\mathcal{H}^{N-1}(K' \cap (\omega \times \{0\})) = 0$—otherwise $\mathcal{H}^{N-1}(\Sigma')$ would be infinite), we have

$$\left|\mathcal{H}^{N-1}(\partial\{\mathrm{dist}(\cdot, K') > s_k\} \cap \{w_n > s^*\}) \ - \ 2\mathcal{H}^{N-1}(\Sigma)\right| \ \le \ \frac{\varepsilon}{2}\,,$$

while $|\{\mathrm{dist}(\cdot, K') \le s_k\}| \le \varepsilon/4$ and $\mathcal{H}^{N-1}(\partial\{w_n > s^*\} \cap \{\mathrm{dist}(\cdot, K') \le s_k\}) \le \varepsilon/8$.

For such values of k, the open set $\{\mathrm{dist}(\cdot, K') > s_k\} \cap \{w_n > s^*\} \cap (\omega \times (-1, +\infty))$ (with piecewise Lipschitz boundary if s_k was properly chosen) is the subgraph Ω_g of a nonnegative BV function g with $\|g - h\|_{L^1(\omega)} \le \varepsilon/2$, $\mathcal{H}^{N-1}(\partial\Omega_g \setminus \partial_*\Omega_g) = 0$,

$$\mathcal{H}^{N-1}((\partial_*\Omega_h \cup \Sigma) \cap \Omega_g) \ \le \ \frac{\varepsilon}{2},$$

and $\partial\Omega_g = (\partial\{\mathrm{dist}(\cdot, K') > s_k\} \cap \{w_n > s^*\}) \cup (\partial\{w_n > s^*\} \cap \{\mathrm{dist}(\cdot, K') > s_k\})$, so that

$$\left|\mathcal{H}^{N-1}(\partial\Omega_g) - (\mathcal{H}^{N-1}(\partial_*\Omega_h) + 2\mathcal{H}^{N-1}(\Sigma))\right| \le \frac{3\varepsilon}{4}.$$

Then, invoking again Lemma 4.3, we find a smooth function $f \le g$, $f \ge 0$, with $\|f - h\|_{L^1(\omega)} \le \varepsilon$,

$$\mathcal{H}^{N-1}((\partial_*\Omega_h \cup \Sigma) \cap \Omega_f) \le \varepsilon \tag{14}$$

and

$$\left|\int_\omega \sqrt{1 + |\nabla f(x)|^2}\, dx - (\mathcal{H}^{N-1}(\partial_*\Omega_h) + 2\mathcal{H}^{N-1}(\Sigma))\right| \le \varepsilon\,. \tag{15}$$

Remark 4.4. We have, in addition,

$$\lim_{\varepsilon\to 0} \mathcal{H}^{N-1}(\{x' \in \omega : f_\varepsilon(x') = 0\}) = \mathcal{H}^{N-1}(\{x' \in \omega : h(x') = 0\})$$

(f_ε denoting the f obtained for a particular $\varepsilon > 0$). Indeed, for $\eta > 0$, there exist $k > 1$ such that $\mathcal{H}^{N-1}(\{h < 1/k\}) \le \mathcal{H}^{N-1}(\{h = 0\}) + \eta$ and $K \subset \omega$ with $\mathcal{H}^{N-1}(K) \le \eta$ such that $f_\varepsilon \to h$ uniformly in $\omega \setminus K$. Then, if ε is small enough, $h(x') \ge 1/k$ and $x' \notin K$ will yield $f_\varepsilon(x') \ge 1/(2k)$; hence, $\{f_\varepsilon = 0\} \subset K \cup \{h < 1/k\}$ so that $\mathcal{H}^{N-1}(\{f_\varepsilon = 0\}) \le \mathcal{H}^{N-1}(\{h = 0\}) + 2\eta$. We deduce that $\limsup_{\varepsilon\to 0} \mathcal{H}^{N-1}(\{f_\varepsilon = 0\}) \le \mathcal{H}^{N-1}(\{h = 0\})$. On the other hand, since $\mathcal{H}^{N-1}(\partial_*\Omega_h \cap \Omega_{f_\varepsilon}) \to 0$, we see that $\mathcal{H}^{N-1}(\{h = 0\} \cap \{f_\varepsilon > 0\}) \to 0$ so that $\mathcal{H}^{N-1}(\{h = 0\} \cap \{f_\varepsilon = 0\}) \to \mathcal{H}^{N-1}(\{h = 0\})$; hence, $\mathcal{H}^{N-1}(\{h = 0\}) \le \liminf_{\varepsilon\to 0} \mathcal{H}^{N-1}(\{f_\varepsilon = 0\})$.

A consequence is that in case (as in [9]) the "substrate" $\{x_N \le 0\}$ has a superficial tension σ_S less than the superficial tension σ_C of the crystal, that is, the surface energy of $(\partial_*\Omega_h, \Sigma)$ is

$$\sigma_S \mathcal{H}^{N-1}(\{h = 0\}) + \sigma_C(\mathcal{H}^{N-1}(\partial_*\Omega_h \cap (\omega \times (0, +\infty))) + 2\mathcal{H}^{N-1}(\Sigma))\,,$$

then f can fulfill the additional requirement

$$\begin{aligned}\Big|\sigma_S \mathcal{H}^{N-1}(\{f = 0\}) + \sigma_C \int_{\{f>0\}} \sqrt{1 + |\nabla f|^2}\, dx \\ - \left(\sigma_S \mathcal{H}^{N-1}(\{h = 0\}) + \sigma_C(\mathcal{H}^{N-1}(\partial_*\Omega_h \cap (\omega \times (0, +\infty))) + 2\mathcal{H}^{N-1}(\Sigma))\right)\Big| \le \varepsilon.\end{aligned}$$

If on the other hand $\sigma_C < \sigma_S$, this is not optimal (in terms of relaxation, approximating (h, Σ) with $(h + \delta, \Sigma + \delta e_N)$, δ small, will reduce the energy).

Step 2. (approximation of both the graph and the displacement). We now show that if $u \in GSBV_p(\omega \times (-1, +\infty))$ is given, with $S_u \subseteq \partial_*\Omega_h \cup \Sigma$, $u = 0$ out of Ω_h, and $u = u^0$ on $\omega \times (-1, 0)$ (where $u^0 \in W^{1,p}(\omega \times (-1, 0))$, $\Sigma \subset \Omega_h^1 \cap (\omega \times (0, +\infty))$ vertical), then there exists $(u_n, h_n)_{n\ge 1}$, with $h_n \in C^\infty(\omega; \mathbb{R}_+)$, $u_n \in W^{1,p}(\Omega_{h_n})$, and $u_n = u^0$ in $\omega \times (-1, 0)$, such that as $n \to \infty$, $h_n \to h$ in $L^1(\omega)$, and (extending both u_n and ∇u_n with zero out of Ω_{h_n}) $u_n \to u$ in $L^1(\omega \times (-1, +\infty))$, $\nabla u_n \to \nabla u$ strongly in $L^p(\omega \times (-1, +\infty); \mathbb{R}^N)$,

$$\lim_{n\to\infty} \int_\omega \sqrt{1 + |\nabla h_n(x)|^2}\, dx = \mathcal{H}^{N-1}(\partial_*\Omega_h) + 2\mathcal{H}^{N-1}(\Sigma)\,.$$

Before entering the proof of this second step, which is very technical, let us give a rough idea of how it goes. It follows a discretization/reinterpolation argument introduced in [15, 16]. We first discretize the function u in $\omega \times (-1, +\infty)$ on a regular square grid (of the form $\eta\mathbb{Z}^N$ with η small). Then, we reinterpolate this discretization into a piecewise continuous function u^η. All this is done in a way that ensures that some suitable volume energy of u^η is controlled by the same energy of u and converges in the limit $\eta \to 0$. On the other hand, the jump set of this approximation u^η is "close" in some sense to the jump set of u, but a drawback of this technique is that we can control only its total surface by $C \times (\mathcal{H}^{N-1}(\partial_*\Omega_h) + 2\mathcal{H}^{N-1}(\Sigma))$ (with C a large constant depending on the dimension N).

To overcome this difficulty, we have to use the approximation f provided by the previous step: Instead of doing the construction in the whole set $\omega \times (-1, +\infty)$, we work in the smooth set Ω_f, where f is such that the jump of u in Ω_f has a surface of order ε (and satisfies (15)). In this way, the jump set of u^η in Ω_f is now controlled by $C\varepsilon$, and after extending u^η to $\omega \times (-1, +\infty)$ by zero above the graph of f, we get a couple (u^η, h^η) with total surface energy controlled by $\mathcal{H}^{N-1}(\partial_*\Omega_h) + 2\mathcal{H}^{N-1}(\Sigma) + (C+1)\varepsilon$, as required.

Let us now enter the details. We fix $\varepsilon > 0$. By Step 1, there exists $f \in C^\infty(\omega)$ with $\|f - h\|_{L^1(\omega)} \le \varepsilon$, such that both (14) and (15) hold. (In particular, (14) states that f is "almost" below h (and Σ) in the sense that very little of $\partial_*\Omega_h \cup \Sigma$ lies below f.) We denote by v the $GSBV_p$ function that is equal to u in Ω_f, to 0 in $(\omega \times (0, +\infty)) \setminus \Omega_f$, and to u^0 in $\omega \times (-1, 0)$. Possibly choosing f closer to h, we may assume, also, that $\|v - u\|_{L^1(\omega \times (-1,+\infty))} \le \varepsilon$. Eventually, we also extend v (by symmetry) slightly below $\omega \times \{-1\}$ to the set $\omega \times (-1-\delta, -1)$, $0 < \delta < 1$.

Let us define, for $\xi \in \mathbb{R}^N$, the anisotropic potential

$$W_p(\xi) \ := \ \sum_{i=1}^N |\xi_i|^p \,.$$

Clearly, $v \in GSBV_p(\omega \times (-1-\delta, +\infty))$, and one has, if δ is small enough,

$$\begin{aligned} \int_{\Omega_f^\delta} W_p(\nabla v(x))\,dx \ &= \ \int_{\omega\times(-1-\delta,+\infty)} W_p(\nabla v(x))\,dx \\ &\le \ \int_{\omega\times(-1,+\infty)} W_p(\nabla u(x))\,dx + \varepsilon, \end{aligned} \tag{16}$$

where $\Omega_f^\delta = \{x \in \omega \times (-1-\delta, +\infty) \,:\, x_N < f(x')\}$. The jump set of v satisfies $S_v \subset \partial\Omega_f \cup ((\partial_*\Omega_h \cup \Sigma) \cap \Omega_f)$; its surface energy is estimated by (14) and (15).

For $n \ge 1$, let $\eta = 1/n$ be a discretization step. Given $y \in (0,1)^N$, we introduce a discretization of v by setting $v_k^{y,\eta} = v(y\eta + k\eta)$, with $(k_1, \dots, k_{N-1}) \in (\mathbb{Z}/n\mathbb{Z})^{N-1}$ and $k_N \in \mathbb{Z} \cap [-(1+\delta)/\eta - y_N, +\infty)$ (so that only points in $\omega \times (-1-\delta, +\infty)$ are considered).

We also define a "discrete jump" of $v^{y,\eta}$: We let, for $i = 1, \dots, N$, and y, k as above, $l_k^{i,y,\eta} = 0$ if $(\partial_*\Omega_h \cup \Sigma) \cap [y\eta + k\eta, y\eta + (k+e_i)\eta] = \emptyset$ and $l_k^{i,y,\eta} = 1$ otherwise. We have that $l^{i,y,\eta} = \chi_{S_\eta^i}(y\eta + k\eta)$, where the set S_η^i is given by

$$S_\eta^i \ = \ (\partial_*\Omega_h \cup \Sigma) \, + \, [-\eta e_i, 0] \,.$$

Here $(e_1, \dots, e_N)$ is the canonical basis of $\mathbb{R}^N$, and as usual the sum of two sets A, B is $A + B = \{a + b \,:\, a \in A, b \in B\}$.

The discrete energy of $(v_k^{y,\eta},(l_k^{i,y,\eta})_{i=1}^N)_k$ is defined by

$$D_\eta^y \;=\; \sum_{i=1}^N D_\eta^{i,y} \;\text{ with }\; D_\eta^{i,y}=\eta^N\sum_k (1-l_k^{i,y,\eta})\frac{|v_{k+e_i}^{y,\eta}-v_k^{y,\eta}|^p}{\eta^p}+\alpha\frac{l_k^{i,y,\eta}}{\eta}\,,$$

where the sum is taken on all k such that the segment $[y\eta+k\eta, y\eta+(k+e_i)\eta]$ lies inside the subgraph Ω_f^δ. The parameter $\alpha>0$ will be fixed later on.

Let us compute the average $\int_{y\in(0,1)^N} D_\eta^y\,dy$. For each i, one has (using the change of variable $(y,k)\mapsto x=(y+k)\eta$)

$$\text{(17)}\qquad \int_{(0,1)^N} D_\eta^{i,y}\,dy \;=\; \int_{\mathcal{O}_\eta^i}(1-\chi_{S_\eta^i})(x)\frac{|v(x+\eta e_i)-v(x)|^p}{\eta^p}\;+\;\alpha\frac{\chi_{S_\eta^i}(x)}{\eta}\,dx\,,$$

where the domain of integration is

$$\mathcal{O}_\eta^i=\left\{x\in\omega\times(-1-\delta,+\infty)\;:\;x_N<\min_{0\le t\le 1} f(x'+t\eta e_i)\right\}\quad\text{if } i\le N-1,\ \text{and}$$
$$\mathcal{O}_\eta^N=\{x\in\omega\times(-1-\delta,+\infty)\;:\;x_N<f(x')-\eta\}\;.$$

We now use a slicing technique introduced by Gobbino [22] (based on the slicing properties of $GSBV$ functions [7] and applied in a similar setting in [2, 15, 16]). The second integral in (17) is decomposed into an integral on $e_i^\perp$ and an integral along the direction e_i, as follows:

$$\int_{(0,1)^N} D_\eta^{i,y}\,dy \;=\; \int_{e_i^\perp} d\mathcal{H}^{N-1}(z)\int_{\{s:z+se_i\in\mathcal{O}_\eta^i\}}(1-\chi_{S_\eta^i})(z+se_i)\frac{|v(z+(s+\eta)e_i)-v(z+se_i)|^p}{\eta^p}\;+\;\alpha\frac{\chi_{S_\eta^i}(z+se_i)}{\eta}\,ds\,.$$

For $\mathcal{H}^{N-1}$-a.e. $z\in e_i^\perp$, from the definition of S_η^i there is no jump of v between $z+se_i$ and $z+(s+\eta)e_i$ (for a.e. s) when $(1-\chi_{S_\eta^i})(z+se_i)\neq 0$, so that in this case

$$|v(z+(s+\eta)e_i)-v(z+se_i)|^p \;=\; \left|\int_0^\eta \frac{\partial v}{\partial x_i}(z+(s+t)e_i)\,dt\right|^p \;\le\; \eta^{p-1}\int_0^\eta\left|\frac{\partial v}{\partial x_i}(z+(s+t)e_i)\right|^p\,dt\,.$$

We deduce

$$\text{(18)}\qquad \int_{e_i^\perp} d\mathcal{H}^{N-1}(z)\int_{\{s:z+se_i\in\mathcal{O}_\eta^i\}}(1-\chi_{S_\eta^i})(z+se_i)\frac{|v(z+(s+\eta)e_i)-v(z+se_i)|^p}{\eta^p} \;\le\; \int_{\Omega_f^\delta}\left|\frac{\partial v}{\partial x_i}(x)\right|^p\,dx\,.$$

On the other hand, for $\mathcal{H}^{N-1}$-a.e. z, we have (from the definition of S_η^i)

$$\left|\{s:z+se_i\in\mathcal{O}_\eta^i\cap S_\eta^i\}\right| \;\le\; \eta\mathcal{H}^0\left(\{s:z+se_i\in\mathcal{O}_\eta^i\cap(\partial_*\Omega_h\cup\Sigma)\}\right)$$

so that

$$
\int_{e_i^\perp} d\mathcal{H}^{N-1}(z) \int_{\{s: z+se_i \in \mathcal{O}_\eta^i\}} \frac{\chi_{S_\eta^i}(z+se_i)}{\eta}\, ds \le \int_{(\partial_*\Omega_h \cup \Sigma)\cap\Omega_f} |e_i\cdot\nu(x)|\, d\mathcal{H}^{N-1}(x)\,, \tag{19}
$$

where ν is the normal to $\partial_*\Omega_h \cup \Sigma$, defined $\mathcal{H}^{N-1}$-a.e. (up to a change of sign which is not relevant here). Collecting (18) and (19), we get

$$
\int_{(0,1)^N} D_\eta^{i,y}\, dy \;\le\; \int_{\Omega_f^\delta} \left|\frac{\partial v}{\partial x_i}(x)\right|^p dx \;+\; \alpha \int_{(\partial_*\Omega_h\cup\Sigma)\cap\Omega_f} |e_i\cdot\nu(x)|\, d\mathcal{H}^{N-1}(x)\,.
$$

By construction, we have $\mathcal{H}^{N-1}((\partial_*\Omega_h \cup \Sigma)\cap\Omega_f) \le \varepsilon$ (see (14)); hence,

$$
D_\eta^y \;=\; \sum_{i=1}^N \int_{(0,1)^N} D_\eta^{i,y} \;\le\; \int_{\Omega_f^\delta} W_p(\nabla v(x))\, dx \;+\; \alpha\sqrt{N}\varepsilon\,. \tag{20}
$$

Now, for any y and $\eta > 0$ (small), we introduce the interpolate (known as "Q1" in finite elements theory) of $(v_k^{y,\eta})_k$:

$$
v^{y,\eta}(x) \;=\; \sum_{k\in(\mathbb{Z}/n\mathbb{Z})^{N-1}\times\mathbb{Z}} v_k^{y,\eta}\Delta\left(\frac{x}{\eta} - (k+y)\right)\,, \quad x \in \omega\times\mathbb{R}\,,
$$

where (as before $a^+ = a \vee 0 = \max\{a, 0\}$)

$$
\Delta(x) \;=\; \prod_{i=1}^N (1-|x_i|)^+\,. \tag{21}
$$

It is classical [2, 14] that there exists a sequence $(\eta_l)_{l\ge1}$ such that $v^{y,\eta} \to v$ in $L^1(\omega\times(-1,+\infty))$ as $l\to\infty$ for a.e. $y\in(0,1)^N$. Then, possibly extracting a subsequence, we deduce from (20) that there exists $y\in(0,1)^N$ such that both

$$
\lim_{l\to\infty} D_{\eta_l}^y \;\le\; \int_{\omega\times(-1-\delta,+\infty)} W_p(\nabla v)\, dx \;+\; \alpha\sqrt{N}\varepsilon \tag{22}
$$

and $\|v^{y,\eta_l} - v\|_{L^1} \to 0$ as $l\to\infty$. In what follows, we fix y to this value and drop the corresponding superscript.

Consider now a cube $C_k = (y+k)\eta_l + (0,\eta_l)^N$ such that $C_k \subset \Omega_f^\delta$. We say that C_k is a "regular cube" if $\partial_*\Omega_h \cup \Sigma$ does not cross any edge of C_k, that is, when $l_{\hat{k}}^{i,\eta_l} = 0$ for any i and $\hat{k} \in k + \{0,1\}^N$ with $\hat{k}_i = k_i$. On the other hand, if $\partial_*\Omega_h\cup\Sigma$ crosses at least one of the edges of C_k, we say the cube is a "jump cube." Notice that in the latter case, since $\partial_*\Omega_h\cup\Sigma$ is a generalized subgraph, all cubes "above" C_k are also jump cubes as long as they intersect Ω_h: Precisely, every other cube $C' = C_{k',k_N+m}$, $m\ge1$, with $C'\subset\Omega_f^\delta$ has at least one edge that crosses $\partial_*\Omega_h\cup\Sigma$ unless $C'\subset\Omega_f\setminus\Omega_h^1$ (in which case $v=0$ and $v^{\eta_l}=0$ a.e. in C'). We denote by $\mathcal{J}$ the union of all jump cubes and of all cubes in Ω_f^δ that lie above a jump cube (i.e., either jump cubes or regular cubes where v vanishes) and by $\mathcal{R}$ the union of all the other regular cubes (the regular cubes that lie below $\partial_*\Omega_h\cup\Sigma$) so that $\mathcal{C}_f = \mathcal{R}\cup\mathcal{J}$ is the union of all cubes $C_k\subset\Omega_f^\delta$ (see Figure 2).

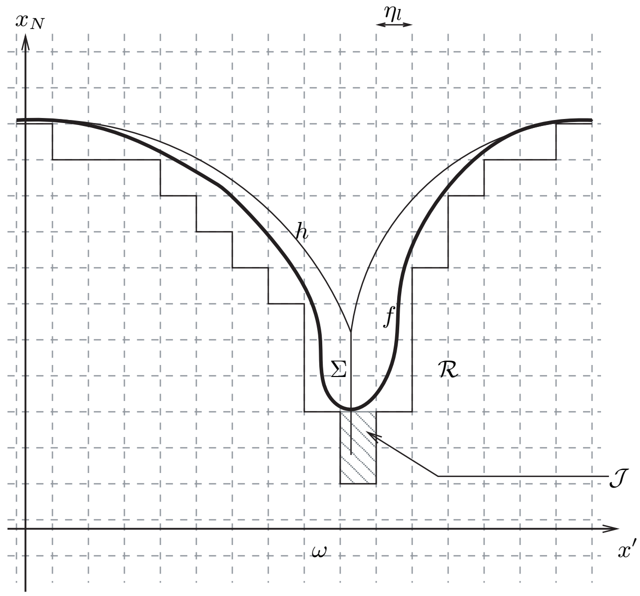

FIG. 2. *The cubes below f are grouped into two regions: a region $\mathcal{R}$ where the total bulk energy of v^{η_l} is estimated by the "bulk" part of D_{η_l} and a region $\mathcal{J}$ whose common boundary with $\mathcal{R}$ is estimated by the "surface term," or order ε, of D_{η_l}.*

Since each edge $[(y+k)\eta_l,(y+k+e_i)\eta_l]$ (for any i) is shared by at most 2^{N-1} cubes, one can decompose the energy D_{η_l} as a sum of contributions of the cubes in the following way:

$$D_{\eta_l} \;\geq\; \sum_{C_k \text{ "regular"}} (\eta_l)^N \frac{1}{2^{N-1}} \sum_{i=1}^{N} \sum_{\substack{\hat{k}\in k+\{0,1\}^N \\ \hat{k}_i=k_i}} \frac{\left| v^{\eta_l}_{\hat{k}+e_i} - v^{\eta_l}_{\hat{k}} \right|^p}{(\eta_l)^p}$$
$$+\; \alpha\left(\frac{\eta_l}{2}\right)^{N-1} \times (\text{number of "jump cubes"})$$

(this is a very rough estimate since only one edge of each jump cube is taken into account even if many edges cross $\partial_*\Omega_h \cup \Sigma$). In particular, from (20) we find that the number of the jump cubes is bounded by a constant times η_l^{1-N}, so that their total Lebesgue measure is $O(\eta_l)$.

By inequality (36) in Lemma A.1, the term in the sum over regular cubes is larger or equal to $\int_{C_k} W_p(\nabla v^{\eta_l}(x))\,dx$; on the other hand, the term involving the jump cubes bounds the measure of the boundary of these cubes since clearly $\alpha(\eta_l/2)^{N-1} = \alpha\mathcal{H}^{N-1}(\partial C_k)/(N2^N)$. In particular, we have

$$D_{\eta_l} \;\geq\; \int_{\mathcal{R}} W_p(\nabla v^{\eta_l}(x))\,dx \;+\; \frac{\alpha}{N2^N}\mathcal{H}^{N-1}(\partial\mathcal{J}\cap\partial\mathcal{R})\,. \tag{23}$$

Now, we will "move" $\mathcal{C}_f = \mathcal{R}\cup\mathcal{J}$ upwards (in the direction x_N) in order to cover Ω_f (we will then translate v^{η_l} accordingly): Let $\kappa = 1+\sqrt{N}\max_{\xi\in\omega}|\nabla f(\xi)|$; this constant is such that

$$\mathcal{C}_f + \kappa\eta_l e_N \;\supset\; \Omega_f$$

as soon as l is large enough (so that $x_N > -1$ yields $x_N - \kappa\eta_l > -1 - \delta + \eta_l$ which clearly holds as soon as $\eta_l \le \delta/(1+\kappa)$).

We then define, for any l (large enough), the function $f_l \in BV(\omega)$ by $f_l(x') = \sup\{x_N < f(x') : (x', x_N - \kappa\eta_l) \in \mathcal{R}\}$, and for any $x \in \omega \times (-1,+\infty)$, we also define $v_l(x)$ by

$$v_l(x) \;=\; \begin{cases} v^{\eta_l}(x', x_N - \kappa\eta_l) & \text{if } -1 < x_N < f_l(x'), \\ 0 & \text{otherwise.} \end{cases}$$

By construction, the boundary of Ω_{f_l} (in $\omega \times (-1,+\infty)$) is a piecewise smooth compact set made of two parts: One part is contained in the (smooth) graph of f, $\partial\Omega_f$, and the rest, $\partial\Omega_{f_l} \cap \Omega_f$, is a subset of $(\partial\mathcal{J} \cap \partial\mathcal{R}) + \kappa\eta_l e_N$, which is a finite union of facets of hypercubes. On the other hand, $v_l \in W^{1,p}(\Omega_{f_l})$, with as a consequence of (23),

$$\int_{\Omega_{f_l}} W_p(\nabla v_l(x))\,dx \;+\; \frac{\alpha}{N2^N}\mathcal{H}^{N-1}(\partial\Omega_{f_l} \cap \Omega_f) \;\le\; D_{\eta_l}\,. \tag{24}$$

We fix $\alpha = N2^N$ and make the observation that $v_l = v^{\eta_l}(\cdot - \kappa\eta_l e_N)$ except on a set of measure $O(\eta_l)$ (the union of the cubes of $\mathcal{J}$ such that $\partial_*\Omega_h \cup \Sigma$ crosses an edge of the cube). Therefore, $v_l \to v$ as $l \to \infty$ in $L^1(\omega \times (-1,+\infty))$ (and, as well, $f_l \to f$). We can now fix l large enough so that $\|f_l - f\|_{L^1(\omega)} + \|v_l - v\|_{L^1(\omega\times(-1,+\infty))} < \varepsilon$ and

$$\begin{aligned}\int_{\Omega_{f_l}} W_p(\nabla v_l(x))\,dx \;+\; \mathcal{H}^{N-1}(\partial\Omega_{f_l}) \;&\le\; D_{\eta_l} \;+\; \mathcal{H}^{N-1}(\partial\Omega_f)\\ &\le\; \int_{\omega\times(-1,+\infty)} W_p(\nabla u(x))\,dx \;+\; \mathcal{H}^{N-1}(\partial_*\Omega_h) \;+\; 2\mathcal{H}^{N-1}(\Sigma) \;+\; (3 + 2^N N\sqrt{N})\varepsilon\,,\end{aligned}$$

where we have used (15), (16), (22), and (24). Observe eventually that if l is large enough, we also have (since $\liminf_{l\to\infty} \mathcal{H}^{N-1}(\partial\Omega_{f_l}) \ge \mathcal{H}^{N-1}(\partial\Omega_f)$ and using (15))

$$\mathcal{H}^{N-1}(\partial\Omega_{f_l}) \;\ge\; \mathcal{H}^{N-1}(\partial_*\Omega_h) \;+\; 2\mathcal{H}^{N-1}(\Sigma)) \;-\; 2\varepsilon\,.$$

Using now Lemma 4.3, we can find a smooth $f' \in C^\infty(\omega;\mathbb{R}^N)$ with $f' \le f_l$, close enough to f_l, in such a way that if $v' = v_l$ in Ω'_f and 0 in $(\omega \times (-1,+\infty)) \setminus \Omega'_f$, one has $\|f' - f\|_{L^1(\omega)} + \|v' - v\|_{L^1(\omega\times(-1,+\infty))} < 2\varepsilon$; hence, both $\|f' - h\|_{L^1(\omega)} < 3\varepsilon$ and $\|v' - u\|_{L^1(\omega\times(-1,+\infty))} < 3\varepsilon$, and

$$\begin{aligned}&\int_{\Omega_{f'}} W_p(\nabla v'))\,dx \;+\; \mathcal{H}^{N-1}(\partial\Omega_{f'})\\ &\qquad\le\; \int_{\omega\times(-1,+\infty)} W_p(\nabla u(x))\,dx \;+\; \mathcal{H}^{N-1}(\partial_*\Omega_h) \;+\; 2\mathcal{H}^{N-1}(\Sigma) \;+\; \beta\varepsilon,\end{aligned}$$

where $\beta = 4 + 2^N N\sqrt{N}$ is a constant and, as well,

$$\mathcal{H}^{N-1}(\partial\Omega_{f'}) \;\ge\; \mathcal{H}^{N-1}(\partial_*\Omega_h) \;+\; 2\mathcal{H}^{N-1}(\Sigma)) \;-\; 3\varepsilon\,.$$

Performing this construction for $\varepsilon = 1/n$, $n \ge 1$, yields the existence of two sequences $(f_n)_{n\ge1}$, $(u_n)_{n\ge1}$, with $f_n \in C^\infty(\omega)$, $u_n \in W^{1,p}(\Omega_{f_n})$, $f_n \to h$ in $L^1(\omega)$,

$u_n \to u$ in $L^1(\omega \times (-1,+\infty))$,

$$\limsup_{n\to\infty} \int_{\Omega_{f_n}} W_p(\nabla u_n(x))\,dx + \int_\omega \sqrt{1+|\nabla f_n(x)|^2}\,dx \\ \le \int_{\omega\times(-1,+\infty)} W_p(\nabla u(x))\,dx + \mathcal{H}^{N-1}(\partial_*\Omega_h) + 2\mathcal{H}^{N-1}(\Sigma)\,, \tag{25}$$

and

$$\mathcal{H}^{N-1}(\partial_*\Omega_h) + 2\mathcal{H}^{N-1}(\Sigma) \le \liminf_{n\to\infty} \int_\omega \sqrt{1+|\nabla f_n(x)|^2}\,dx\,. \tag{26}$$

The function u_n, extended with 0 out of Ω_{f_n}, is in $GSBV(\omega \times (-1,+\infty))$, and its gradient is ∇u_n in Ω_{f_n} and 0 outside. Invoking now Ambrosio's compactness theorem for $GSBV$ functions, we find that $\nabla u_n \rightharpoonup \nabla u$ in $L^p(\omega\times(-1,+\infty);\mathbb{R}^N)$, so that

$$\int_{\omega\times(-1,+\infty)} W_p(\nabla u(x))\,dx \le \liminf_{n\to\infty} \int_{\omega\times(-1,+\infty)} W_p(\nabla u_n(x))\,dx\,,$$

which, combined with (25) and (26), yields that

$$\lim_{n\to\infty} \int_{\omega\times(-1,+\infty)} W_p(\nabla u_n(x))\,dx = \int_{\omega\times(-1,+\infty)} W_p(\nabla u(x))\,dx\,, \tag{27}$$

$$\lim_{n\to\infty} \int_\omega \sqrt{1+|\nabla f_n(x)|^2}\,dx = \mathcal{H}^{N-1}(\partial_*\Omega_h) + 2\mathcal{H}^{N-1}(\Sigma))\,. \tag{28}$$

In particular, we deduce from (27) (since $1<p<+\infty$) that ∇u_n goes strongly to ∇u in $L^p(\omega\times(-1,+\infty);\mathbb{R}^N)$. We also find that $u_n \to u^0$ strongly in $W^{1,p}(\omega\times(-1,0))$. Modifying u_n in order to ensure that $u_n \equiv u^0$ in $\omega\times(-1,0)$ is now not difficult. A simple way is as follows: We choose a continuous extension operator from $W^{1,p}(\omega\times(-1,0))$ to $W^{1,p}(\omega\times(-1,+\infty))$ and define, for all n, a function w_n as the extension of $(u_n|_{\omega\times(-1,0)} - u^0)$. Clearly, $w_n \to 0$ strongly in $W^{1,p}(\omega\times(-1,+\infty))$. The sequence u_n is then modified in the following way: We replace u_n with $u_n - w_n$ in Ω_{f_n}, letting it keep the value 0 outside. This new u_n satisfies the same properties as before, but additionally, $u_n = u^0$ a.e. in $\omega\times(-1,0)$. This shows the thesis. ◻

5. An approximation result. We introduce in this section, as in [9], a phase-field approximation of the functional $\overline{F}$. The idea is to represent the subgraph $\Omega_h\setminus\Sigma$ by a field v that will be an approximation of the characteristic function of this set, at a scale of order ε. Then, numerically, the minimization of our new functional will provide an approximation of (u,h) minimizing $\overline{F}$. Our approximated functional is the following:

$$F_\varepsilon(u,v) = \int_{\omega\times(0,+\infty)} (\eta_\varepsilon + v^2(x)) W(\nabla u(x))\,dx \\ + c_V\left(\frac{\varepsilon}{2}\int_{\omega\times(0,+\infty)} |\nabla v(x)|^2\,dx + \frac{1}{\varepsilon}\int_{\omega\times(0,+\infty)} V(v(x))\,dx\right) \tag{29}$$

if $u \in W^{1,p}(\omega\times(0,+\infty))$, with $u=u^0$ on $\omega\times\{0\}$, and $v\in H^1(\omega\times(0,+\infty))$, with $v=1$ on $\omega\times\{0\}$ and $\partial_N v \le 0$ a.e. in $\omega\times(0,+\infty)$. Otherwise, for all other $u,v \in L^1(\omega\times(0,+\infty))$, we let $F_\varepsilon(u,v)=+\infty$. Here the potential V is a two-wells potential with $V(t) > 0$ except if $t \in \{0,1\}$, $V(0) = V(1) = 0$, and $c_V^{-1} = \int_0^1 \sqrt{2V(t)}\,dt$. The parameter η_ε is any function of ε with $\eta_\varepsilon/(\varepsilon^{p-1}) \to 0$ as $\varepsilon \to 0$. The function u^0 is assumed to be the trace of a function in $W^{1,p}(\omega\times(-1,0))$, still denoted by u^0, and for technical reasons we also have to assume that it is bounded: $u^0 \in L^\infty(\omega\times(-1,0))$. The following results generalize in arbitrary dimension Theorem 3.1 of [9]. However, its proof also owes a lot to [13, sect. 5.2], where a similar approximation is studied.

THEOREM 5.1. *Let $(\varepsilon_j)_{j\geq 1}$ be a decreasing sequence of positive numbers, going to* 0. *Then the following hold.*

(i) *For any (u_j, v_j), if $\limsup_{j\to\infty} F_{\varepsilon_j}(u_j, v_j) < +\infty$, then up to a subsequence there exist u, v such that $v_j \to v$ in $L^1(\omega\times(0,+\infty))$ and $u_j(x) \to u(x)$ a.e. in $\{v = 1\}$, and there exists $h \in BV(\omega;\mathbb{R}_+)$ such that $\{v = 1\} = \Omega_h$ and*

$$\overline{F}(u,h) \ \leq\ \liminf_{j\to\infty} F_{\varepsilon_j}(u_j, v_j)\,. \tag{30}$$

(ii) *For any $h \in BV(\omega;\mathbb{R}_+)$ and $u \in GSBV_p(\omega\times(-1,+\infty))$ with $u = u^0$ in $\omega\times(-1,0)$ and $u(x) = 0$ a.e. in $\{x_N > h(x')\}$, there exists (u_j, v_j) such that $u_j \to u$ and $v_j \to \chi_{\Omega_h}$ in $L^1(\omega\times(0,+\infty))$ and*

$$\limsup_{j\to\infty} F_{\varepsilon_j}(u_j, v_j) \ \leq\ \overline{F}(u,h)\,. \tag{31}$$

This is almost a Γ-convergence result. We deduce, in particular, that if for all j, (u_j, v_j) is a minimizer of F_{ε_j}, then up to a subsequence, $v_j \to \chi_{\Omega_h}$ and $u_j \to u$ a.e. in Ω_h, where (u,h) minimize the relaxed functional $\overline{F}$.

Remark 5.2. The thesis of the theorem is still valid if (as in [9, Thm. 3.1]) the set Ω_h must satisfy a volume constraint $|\Omega_h| = V > 0$ (which is imposed in the approximation by a constraint on v_j: $\int_{\omega\times(0,+\infty)} v_j(x)\,dx = V$). The adaption of the proofs is easy; see Remark 4.2 above.

Proof of Theorem 5.1. We first show the first point. Let (u_j, v_j) be as in (i). Since $F_{\varepsilon_j}(u_j, v_j)$ is finite, v_j must be nondecreasing in x_N. Now, if we replace v_j by $\tilde v_j(x) = 0 \vee ((v_j(x) - \delta_j x_N)\wedge 1)$ and if δ_j is small enough, one can ensure that $F_{\varepsilon_j}(u_j, v_j) = F_{\varepsilon_j}(u_j, \tilde v_j) + O(1/j)$, and $\tilde v_j$ is strictly decreasing.

Assume first that v_j is smooth, so that $\tilde v_j$ is smooth in $\{0 < \tilde v_j < 1\}$. For any $s \in (0,1)$, let $h_j^s : \omega \to \mathbb{R}_+$ be the function such that $\tilde v_j(x', h_j^s(x')) = s$ for any $x' \in \omega$; then clearly, h_j^s is in $C^1(\omega)$, with

$$|\nabla' h_j^s(x')| \ =\ \frac{|\nabla'\tilde v_j(x', h_j^s(x'))|}{|\partial_N \tilde v_j(x', h_j^s(x'))|} \ \leq\ \frac{1}{\delta_j}|\nabla'\tilde v_j(x', h_j^s(x'))|$$

for any $x' \in \omega$. Now, we deduce that

$$\begin{aligned}
\int_\omega |\nabla' h_j^s(x')|^2\,dx' \ &\leq\ \frac{1}{\delta_j}\int_\omega \frac{|\nabla'\tilde v_j(x', h_j^s(x'))|^2}{|\partial_N \tilde v_j(x', h_j^s(x'))|}\,dx' \\
&\leq\ \frac{1}{\delta_j}\int_\omega |\nabla'\tilde v_j(x', h_j^s(x'))|^2 \left(\frac{\sqrt{1 + |\nabla' h_j^s(x')|^2}}{|\nabla \tilde v_j(x', h_j^s(x'))|}\right) dx' \\
&=\ \frac{1}{\delta_j}\int_{\partial\{\tilde v_j > s\}} \frac{|\nabla'\tilde v_j(x)|^2}{|\nabla\tilde v_j(x)|}\,d\mathcal{H}^{N-1}(x)\,.
\end{aligned}$$

Using the coarea formula, we find that

$$\int_0^1 \left(\int_\omega |\nabla' h_j^s(x')|^2 \, dx' \right) ds \;\le\; \frac{1}{\delta_j} \int_{\{1>\tilde v_j>0\}} |\nabla' \tilde v_j(x)|^2 \, dx \;<\; +\infty \,.$$

By approximation, we easily deduce that this remains true when v_j is just in $H^1(\omega \times (0,+\infty))$: We get that for a.e. level $s \in (0,1)$, the set $\{\tilde v_j > s\}$ can be represented as the subgraph of a function $h_j^s \in H^1(\omega)$. We may also assume that this is true for all $j \ge 1$.

Now, we notice that (using $a^2 + b^2 \ge 2ab$ and the coarea formula)

$$\begin{aligned}(32)\quad \frac{\varepsilon_j}{2} \int_{\omega\times(0,+\infty)} |\nabla \tilde v_j(x)|^2 \, dx \;+\; \frac{1}{\varepsilon_j} \int_{\omega\times(0,+\infty)} V(\tilde v_j(x)) \, dx \\ \ge \int_{\omega\times(0,+\infty)} \sqrt{2V(\tilde v_j(x))} |\nabla \tilde v_j(x)| \, dx \\ \ge \int_0^1 \sqrt{2V(s)} \left(\int_\omega \sqrt{1 + |\nabla' h_j^s(x')|^2} \, dx' \right)\end{aligned}$$

and, in particular, using Fatou's lemma, we see that

$$\begin{aligned}\int_0^1 \sqrt{2V(s)} \left(\liminf_{j\to\infty} \int_\omega \sqrt{1 + |\nabla' h_j^s(x')|^2} \, dx' \right) \\ \le \liminf_{j\to\infty} \left(\frac{\varepsilon_j}{2} \int_{\omega\times(0,+\infty)} |\nabla \tilde v_j(x)|^2 \, dx \;+\; \frac{1}{\varepsilon_j} \int_{\omega\times(0,+\infty)} V(\tilde v_j(x)) \, dx \right).\end{aligned}$$

In particular, for a.e. $s \in (0,1)$, $h_j^s \in H^1(\omega)$ for all $j \ge 1$, and in addition, $\liminf_{j\to\infty} \sqrt{1 + |\nabla' h_j^s|^2}$ is finite.

By a diagonal argument, we can find a subsequence (still denoted by (ε_j)) and a decreasing sequence $(s_n)_{n\ge1}$ of real numbers in $(0,1)$ with $\lim_{n\to\infty} s_n = 0$ and such that, for each n,

$$\lim_{j\to\infty} \int_\omega \sqrt{1 + |\nabla' h_j^{s_n}(x')|^2} \, dx' \;=\; \liminf_{j\to\infty} \int_\omega \sqrt{1 + |\nabla' h_j^{s_n}(x')|^2} \, dx' \;<\; +\infty \,.$$

We can also assume that, for each n, $h_j^{s_n}$ converges in $L^1(\omega)$ to some function h^{s_n}, and since it is then clear (since $V(\tilde v_j(x)) \to 0$ a.e. in $\omega \times (0,+\infty)$) that $\tilde v_j(x) \to 0$ for a.e. x with $x_N > h^{s_n}(x')$ and $\tilde v_j(x) \to 1$ for a.e. x with $x_N < h^{s_n}(x')$, this function is independent on n and will be denoted simply by h.

For any $n \ge 1$, let us denote by u_j^n the function given by $u_j(x)$ if $x_N < h_j^{s_n}(x')$ and by 0 otherwise; let us show that $(u_j^n)_{j\ge1}$ is compact in $GSBV(\omega \times (-1,+\infty))$. One has $u_j^n \in W^{1,p}(\{x \,:\, -1 < x_N < h_j^{s_n}(x')\})$; hence, $u_j^n \in GSBV(\omega \times (-1,+\infty))$ with $S_{u_j^n} \subseteq \{(x', h_j^{s_n}(x')) \,:\, x' \in \omega\}$. In particular,

$$\mathcal{H}^{N-1}(S_{u_j^n}) \;\le\; \int_\omega \sqrt{1 + |\nabla' h_j^{s_n}(x')|^2} \, dx'$$

is uniformly bounded (in j). On the other hand,

$$F_{\varepsilon_j}(u_j, \tilde v_j) \;\ge\; (\eta_{\varepsilon_j} + s_n^2) \int_{\omega\times(0,+\infty)} W(\nabla u_j^n(x)) \, dx$$

showing that ∇u_j^n is uniformly bounded in $L^p(\omega \times (-1,+\infty); \mathbb{R}^N)$.

Now, for any $x' \in \omega$, if we denote by $\hat{u}_j^n$ the function $u_j^n - u^0$ (where u^0 is appropriately extended to a function in $W^{1,p}(\omega \times (-1,+\infty))$ that vanishes for $x_N \geq 1$), one sees that, for any x with $x_N < h_j^{s_n}(x')$,

$$|\hat{u}_j^n(x)| \;\leq\; \int_0^{x_N} |\partial_N \hat{u}_j^n(x',s)|\,ds \;\leq\; x_N^{1-1/p} \left(\int_0^{x_N} |\partial_N \hat{u}_j^n(x',s)|^p\,ds\right)^{1/p}$$

so that, for any $M > 0$ and a.e. $x' \in \omega$,

$$\int_0^{M\wedge h_j^{s_n}(x')} |\hat{u}_j^n(x',s)|\,ds \;\leq\; \frac{M^{2-1/p}}{2^{1-1/p}} \left(\int_0^{h_j^{s_n}(x')} |\partial_N \hat{u}_j^n(x',s)|^p\,ds\right)^{1/p}.$$

We get

$$\|\hat{u}_j^n\|_{L^1(\omega\times(-1,M))} \;\leq\; C(M)\|\partial_N \hat{u}_j^n\|_{L^p(\omega\times(-1,+\infty))}.$$

Therefore, $u_j^n = \hat{u}_j^n + u^0$ is uniformly bounded in $L^1_{\text{loc}}(\omega \times (-1,+\infty))$. By Ambrosio's compactness theorem we deduce that there exists $u^n \in GSBV_p(\omega\times(-1,+\infty))$ such that $u_j^n(x) \to u^n(x)$ a.e. in $\omega \times (-1,+\infty)$, up to a subsequence.

By a diagonal argument, we can extract a subsequence (still denoted by $(\varepsilon_j)_{j\geq 1}$) such that for each $n \geq 0$, $u_j^n(x) \to u^n(x)$ a.e. as $\varepsilon_j \to 0$. Now, by construction we have that if $n' \geq n$, then $u_j^{n'}(x) = u_j^n(x)$ a.e. in $\{x_N < h_j^n(x')\}$. From this we deduce that $u^{n'}(x) = u^n(x)$ a.e. in $\{x_N < h(x')\}$, and since moreover one checks easily that both functions vanish a.e. in $\{x_N > h(x')\}$, one deduces that u^n, which is simply denoted by u in the following, is independent on n.

We have shown the first assertion of point (i) of Theorem 5.1: Indeed, if we let $v = \chi_{\Omega_h}$, one sees that $\tilde{v}_j(x) \to v(x)$ a.e., and by construction also $v_j(x) \to v(x)$ a.e. in $\omega \times (0,+\infty)$. Moreover, $u_j(x) \to u(x)$ a.e. in $\{x \in \omega\times(-1,+\infty) \,:\, x_N < h(x)\}$, with $u = u^0$ in $\omega \times (-1,0)$. The function u is in $GSBV_p(\omega\times(-1,+\infty))$ and vanishes above the graph of h.

Let us now show (30). We follow a similar proof as that in [13]. We have

$$\begin{aligned}\int_{\omega\times(0,+\infty)} (\eta_{\varepsilon_j} + \tilde{v}_j^2(x)) W(\nabla u_j(x))\,dx \;&\geq\; \int_{\omega\times(0,+\infty)} \left(2\int_0^{\tilde{v}_j(x)} s\,ds\right) W(\nabla u_j(x))\,dx \\ &\geq\; \int_0^1 2s \left(\int_{\{\tilde{v}_j(x)>s\}} W(\nabla u_j(x))\,dx\right) ds\,.\end{aligned}$$

This inequality, together with (32), yields

$$\begin{aligned}&F_{\varepsilon_j}(u_j,\tilde{v}_j) \;\geq \\ &\qquad \int_0^1 \left(2s\int_{\{\tilde{v}_j(x)>s\}} W(\nabla u_j(x))\,dx \,+\, c_V\sqrt{2V(s)}\int_\omega \sqrt{1+|\nabla' h_j^s(x')|^2}\,dx'\right) ds\,.\end{aligned}$$

By Fatou's lemma, we deduce that

$$\begin{aligned}&\int_0^1 \liminf_{j\to\infty} \left(2s\int_{\{\tilde{v}_j(x)>s\}} W(\nabla u_j(x))\,dx \,+\, c_V\sqrt{2V(s)}\int_\omega \sqrt{1+|\nabla' h_j^s(x')|^2}\,dx'\right) ds \\ &\qquad\qquad \leq\; \liminf_{j\to\infty} F_{\varepsilon_j}(u_j,\tilde{v}_j) \;<\; +\infty\,.\end{aligned} \tag{33}$$

Therefore, for a.e. $s \in (0,1)$,

$$\liminf_{j\to\infty}\ 2s\int_{\{\tilde v_j(x)>s\}} W(\nabla u_j(x))\,dx \,+\, c_V\sqrt{2V(s)}\int_\omega \sqrt{1+|\nabla' h_j^s(x')|^2}\,dx' \ <\ +\infty\,.$$

Let us choose such an s, with additionally $h_j^s \in H^1(\omega)$ for all $j \ge 1$, and let us consider a subsequence $(j_k)_{k\ge1}$ such that

$$\begin{aligned}\lim_{k\to\infty} 2s\int_{\{\tilde v_{j_k}(x)>s\}} & W(\nabla u_{j_k}(x))\,dx \,+\, c_V\sqrt{2V(s)}\int_\omega \sqrt{1+|\nabla' h_{j_k}^s(x')|^2}\,dx' \\ &= \liminf_{j\to\infty}\ 2s\int_{\{\tilde v_j(x)>s\}} W(\nabla u_j(x))\,dx \,+\, c_V\sqrt{2V(s)}\int_\omega \sqrt{1+|\nabla' h_j^s(x')|^2}\,dx'\,.\end{aligned}$$

As above, let us introduce the sequence of functions $u_{j_k}^s \in GSBV_p(\omega\times(-1,+\infty))$ such that $u_{j_k}^s(x) = u_{j_k}(x)$ if $x_N < h_{j_k}^s(x')$ and 0 otherwise. By compactness, we easily check that $u_{j_k}^s(x) \to u(x)$ a.e. in $\omega\times(-1,+\infty)$, while $h_{j_k}^s \to h$ in $L^1(\omega)$. By the l.s.c. property (P1), we deduce

$$\begin{aligned} 2s\int_{\Omega_h^+} & W(\nabla u) \,+\, c_V\sqrt{2V(s)}(\mathcal{H}^{N-1}(\partial_*\Omega_h) + 2\mathcal{H}^{N-1}(S'_u\cap\Omega_h^1)) \\ &\le \lim_{k\to\infty} 2s\int_{\{\tilde v_{j_k}(x)>s\}} W(\nabla u_{j_k}(x))\,dx \,+\, c_V\sqrt{2V(s)}\int_\omega \sqrt{1+|\nabla' h_{j_k}^s(x')|^2}\,dx'\,.\end{aligned}$$

Integrating (33) on $(0,1)$ and recalling that by construction $F_{\varepsilon_j}(u_j,\tilde v_j) = F_{\varepsilon_j}(u_j,v_j) + o(1)$, we deduce (30).

Let us now show point (ii) of Theorem 5.1. The proof follows the same lines as in [9], where the same inequality is shown in the 2D case, and we will only sketch it.

Let $h \in BV(\omega;\mathbb{R}_+)$, and let $u \in GSBV_p(\omega\times(-1,+\infty))$, with $u = u^0$ in $\omega\times(-1,0)$ and $u(x) = 0$ a.e. in $\{x_N > h(x')\}$, with $\overline{F}(u,h) < +\infty$. By Theorem 2.2, there exist h_n in $C^1(\omega;\mathbb{R}_+)$ and $u^n \in W^{1,p}(\Omega_h;\mathbb{R})$, with $u^n = u^0$ in $\omega\times(-1,0)$, $h_n \to h$ in $L^1(\omega)$, and $u^n \to u$ a.e. in $\omega\times(0,+\infty)$, with

$$\limsup_{n\to\infty} F(u^n,h_n) = \overline{F}(u,h)\,.$$

By construction (since we have assumed $u^0 \in L^\infty(\omega\times(-1,0))$), one also has that $u^n \in L^\infty(\omega\times(0,+\infty))$. Now, we construct sequences $(u_j^n)_j$ and $(v_j^n)_j$ with $u_j^n \to u^n$ in $L^1(\omega\times(0,+\infty))$ and $v_j^n \to \chi_{\Omega_{h_n}}$ in $L^1(\omega\times(0,+\infty))$ such that

$$\limsup_{j\to\infty} F_{\varepsilon_j}(u_j^n,v_j^n) \le F(u^n,h_n). \tag{34}$$

Let us condider the sequence of functionals

$$H_\varepsilon(v) = \frac{\varepsilon}{2}\int_{\omega\times(0,+\infty)} |\nabla v(x)|^2\,dx + \frac{1}{\varepsilon}\int_{\omega\times(0,+\infty)} V(v(x))\,dx;$$

the celebrated Γ-convergence result of Modica and Mortola for such functionals (see [1]) allows us to find, for each n, a sequence $(v_j^n)_j$ converging to the characteristic function $\chi_{\Omega_{h_n}}$ such that

$$\begin{aligned}\limsup_{j\to\infty} H_{\varepsilon_j}(v_j^n) &= \int_0^1 \sqrt{2V(s)}\,ds\ \mathcal{H}^{N-1}(S_{\chi_{\Omega_{h_n}}}\cap\omega\times(0,+\infty)) \\ &= c_V^{-1}\mathcal{H}^{N-1}(\partial\Omega_{h_n}).\end{aligned}$$

We recall that the explicit construction of the recovery sequence $(v_j^n)_j$ can be obtained in the following way: One considers γ_j solution of the Euler's equation of the functional with appropriate boundary conditions, namely,

$$\begin{cases} -\gamma_j'' + V'(\gamma_j) = 0, \\ \gamma_j(0) = 1, \quad \gamma_j\Big(\dfrac{1}{\sqrt{\varepsilon_j}}\Big) = 0\,. \end{cases}$$

This function is extended by 0 beyond $1/\sqrt{\varepsilon_j}$. One then lets

$$v_j^n(x) = \gamma_j\Big(\frac{\operatorname{dist}(x,\Omega_{h_n}^+)}{\varepsilon_j}\Big).$$

Then, the sequence $(u_j^n)_j$ is constructed by translating u_n and multiplying by an appropriate cut-off function, as in [9]. We first choose $c_n \geq \max\{1, \|\nabla h_n\|_{L^\infty(\omega)}\}$, and let $w_j^n(x) := v_j^n(x', x_N - c_n\sqrt{2\varepsilon_j})$. This function is 1 on the support of v_j^n and vanishes shortly beyond. Then, we let $u_j^n(x) = u^n(x', x_N - 2c_n\sqrt{2\varepsilon_j})w_j^n(x)$. (As in the end of the proof of Proposition 4.1, we have to modify slightly u_j^n in order to ensure $u_j^n = u^0$ in $\omega\times(-1,0)$; however, this is easily done, and one checks that this modified u_j^n satisfies a uniform (in j) L^∞ bound.) In order to show that (34) holds, we just need to check

$$\limsup_{j\to\infty} \int_{\omega\times(0,+\infty)} (\eta_{\varepsilon_j} + (v_j^n(x))^2) W(\nabla u_j^n(x))\,dx \;\leq\; \int_{\Omega_{h_n}^+} W(\nabla u^n(x))\,dx\,. \tag{35}$$

Since $\nabla u_j^n(x) = w_j^n(x)\nabla u^n(x', x_N - 2c_n\sqrt{2\varepsilon_j}) + u^n(x', x_N - 2c_n\sqrt{2\varepsilon_j})\nabla w_j^n(x)$, this inequality is clear as soon as we have established that

$$\limsup_{j\to\infty}\ \eta_{\varepsilon_j} \int_{\omega\times(0,+\infty)} |u^n(x', x_N - 2c_n\sqrt{2\varepsilon_j})\nabla w_j^n(x)|^p\,dx = 0,$$

and since u^n is bounded in L^∞, we need to show

$$\limsup_{j\to\infty}\ \eta_{\varepsilon_j} \int_{\omega\times(0,+\infty)} |\nabla w_j^n(x)|^p\,dx = 0\,.$$

This integral is bounded by

$$\begin{aligned}
&\int_{\{0<\operatorname{dist}(x,\Omega_{h_n}^+)<\sqrt{\varepsilon_j}\}} \frac{|\gamma_j'|^p\,\big(\operatorname{dist}(x,\Omega_{h_n}^+)/\varepsilon_j\big)}{\varepsilon_j^p}\,dx \\
&\qquad = \int_0^{\sqrt{\varepsilon_j}} \frac{|\gamma_j'|^p(s/\varepsilon_j)}{\varepsilon_j^p}\mathcal{H}^{N-1}(\{\operatorname{dist}(\cdot,\Omega_{h_n}^+) = s\})\,ds \\
&\qquad\qquad = \frac{1}{\varepsilon_j^{p-1}} \int_0^{1/\sqrt{\varepsilon_j}} |\gamma_j'|^p(s)\mathcal{H}^{N-1}(\{\operatorname{dist}(\cdot,\Omega_{h_n}^+) = \varepsilon_j s\})\,ds\,.
\end{aligned}$$

Now, one can show that

$$\int_0^{1/\sqrt{\varepsilon_j}} |\gamma_j'|^p(s)\mathcal{H}^{N-1}(\{\operatorname{dist}(\cdot,\Omega_{h_n}^+) = \varepsilon_j s\})\,ds \to \mathcal{H}^{N-1}(\partial\Omega_{h_n}^+)\int_0^1 \sqrt{2V(t)}^{\,p-1}\,dt$$

as $j \to \infty$; hence, since we have assumed $\eta_\varepsilon/\varepsilon^{p-1} \to 0$ as $\varepsilon \to 0$, we deduce (35) and (34).

Since (34) holds, a standard diagonal extraction argument allows us to find subsequences $(u^{n_k}_{j_k})_k$, $(v^{n_k}_{j_k})_k$ satisfying point (ii) of Theorem 5.1, and this completes the proof of the theorem.

Appendix A. A simple inequality.

LEMMA A.1. *Let $w \in C^1([0,1]^N)$ satisfy, for any $x \in [0,1]^N$,*

$$w(x) \;=\; \sum_{k\in\{0,1\}^N} w(k)\Delta(x-k),$$

where Δ is defined in (21)*. Then, for any $p \geq 1$,*

$$\int_{(0,1)^N} W_p(\nabla w(x))\,dx \;\leq\; \frac{1}{2^{N-1}}\sum_{i=1}^{N}\sum_{\substack{k\in\{0,1\}^N\\ k_i=0}} |w(k+e_i)-w(k)|^p. \tag{36}$$

Proof. We show that, for each i,

$$\int_{(0,1)^N}\left|\frac{\partial w}{\partial x_i}(x)\right|^p dx \;\leq\; \frac{1}{2^{N-1}}\sum_{\substack{k\in\{0,1\}^N\\ k_i=0}} |w(k+e_i)-w(k)|^p\,.$$

We will show this inequality for $i = N$. Let us denote, for $x' = (x_1,\dots,x_{N-1})$,

$$\Delta_{N-1}(x') \;=\; \prod_{i=1}^{N-1}(1-|x_i|)^+\,.$$

Then, for any $x \in (0,1)^N$,

$$\begin{aligned} w(x) \;&=\; \sum_{k\in\{0,1\}^N} w(k)\Delta(x-k)\\ &=\; \sum_{k'\in\{0,1\}^{N-1}} \Delta_{N-1}(x'-k')(w_{k',0}(1-x_N)+w_{k',1}x_N) \end{aligned}$$

so that

$$\frac{\partial w}{\partial x_N}(x) \;=\; \sum_{k'\in\{0,1\}^{N-1}} \Delta_{N-1}(x'-k')(w_{k',1}-w_{k',0})\,.$$

Now, at any x, we have $\sum_{k'\in\{0,1\}^{N-1}} \Delta_{N-1}(x'-k') = 1$ so that this is a convex combination of $(w_{k',1}-w_{k',0})_{k'\in\{0,1\}^{N-1}}$. Hence, by convexity of the function $|\cdot|^p$,

$$\int_{(0,1)^N}\left|\frac{\partial w}{\partial x_N}(x)\right|^p dx \;\leq\; \int_{(0,1)^N}\sum_{k'\in\{0,1\}^{N-1}} \Delta_{N-1}(x'-k')|w_{k',1}-w_{k',0}|^p\,dx\,.$$

We deduce (36) by simply observing that, for any $k' \in \{0,1\}^{N-1}$,

$$\int_{(0,1)^N}\Delta_{N-1}(x'-k')\,dx \;=\; \int_0^1 dx_N \times \prod_{i=1}^{N-1}\int_0^1 (1-|x_i-k_i|)^+\,dx_i \;=\; \frac{1}{2^{N-1}}\,. \qquad \square$$

TRAVELING WAVEFRONTS IN A DELAYED FOOD-LIMITED POPULATION MODEL*

CHUNHUA OU† AND JIANHONG WU‡

Abstract. In this paper we develop a new method to establish the existence of traveling wavefronts for a food-limited population model with nonmonotone delayed nonlocal effects. Our approach is based on a combination of perturbation methods, the Fredholm theory, and the Banach fixed point theorem. We also develop and theoretically justify Canosa's asymptotic method for the wavefronts with large wave speeds. Numerical simulations are provided to show that there exists a prominent hump when the delay is large.

Key words. traveling wave fronts, nonmonotone, nonlocal, food-limited

1. Introduction.

There has been some success in establishing the existence of traveling wavefronts for the reaction-diffusion equation with nonlocal delayed nonlinearity. When the nonlinearity is monotone, the existence of traveling wavefronts can be obtained by extension of the methods of the super/subsolution pair [1], [7], [29], homotopy [3], and Leray-Schauder degree [28]. Unfortunately, when the delayed nonlinearity is no longer monotone, very little has been achieved (except for the work in [9]). While one suspects that the method developed by Wu and Zou [29] and based on a nonstandard ordering could be applicable, the construction of a supersolution and subsolution pair is nontrivial, and it is almost as difficult as solving the original given equations. In this paper we develop a new approach to establish the existence of traveling wavefronts in the case when the delayed nonlinearity is nonmonotone. We shall demonstrate this approach by considering the following food-limited reaction-diffusion equation

$$\frac{\partial u}{\partial t}(t,x) = \frac{\partial^2 u}{\partial x^2}(t,x) + u(t,x)\frac{1-(f*u)(t,x)}{1+\gamma(f*u)(t,x)}, \tag{1.1}$$

where the parameter $\gamma > 0$, and the spatiotemporal convolution $f*u$ is defined by

$$f*u = \int_{-\infty}^{t}\int_{-\infty}^{\infty} f(t,s,x,y)u(s,y)dyds, \tag{1.2}$$

with the kernel $f(t,s,x,y)$ satisfying the normalization condition

$$\int_{-\infty}^{t}\int_{-\infty}^{\infty} f(t,s,x,y)dyds = 1.$$

The simplest version of (1.1) without diffusion is the following ODE:

$$\frac{du}{dt} = ru(t)\frac{K - u(t)}{K + \gamma u(t)}, \tag{1.3}$$

where r, K, and γ are positive constants. This equation was first proposed by Smith [25] as a mathematical model for population of *Daphnia* (water flea), and a derivation of this equation is given in [23]. The equation can also be used to study the effects of environmental toxicants on aquatic populations [16].

The delayed food-limited model

$$\frac{du}{dt} = ru(t)\frac{K - u(t-\tau)}{K + \gamma u(t-\tau)}, \quad \tau > 0, \tag{1.4}$$

has been studied recently by several authors; see [13], [17], [27], [18], and [8]. It seems that the best result for the local stability of the positive equilibrium $u = K$ is given in [27]. For the first time, the global stability of the positive equilibrium was established in [18]; see also [8] for further generalizations.

Equation (1.3) incorporating spatial dispersal was investigated by Feng and Lu [11]. They considered both the reaction-diffusion equation without time delay

$$\frac{\partial u}{\partial t} - Au(t,x) = r(x)u(t,x)\frac{K(x) - u(t,x)}{K(x) + \gamma(x)u(t,x)} \tag{1.5}$$

and the corresponding time-delay model

$$\frac{\partial u}{\partial t} - Au(t,x) = r(x)u(t,x)\frac{K(x) - au(t,x) - bu(t-\tau,x)}{K(x) + a\gamma(x)u(t,x) + b\gamma(x)u(t-\tau,x)}, \tag{1.6}$$

where $x = (x_1, x_2, \ldots, x_n) \in \Omega \subseteq R^n$, with Ω bounded and the operator A, given by

$$A = \sum_{i,j=1}^{n} a_{ij}(x)\frac{\partial^2}{\partial x_i \partial x_j} + \sum_{j=1}^{n} \beta_j(x)\frac{\partial}{\partial x_j},$$

is uniformly strongly elliptic and has coefficient functions that are uniformly Hölder continuous in $\bar{\Omega}$. Feng and Lu studied the above problems subject to general boundary conditions that include both the zero-Dirichlet and zero-Neumann cases, and they established a global convergence result for the nonzero steady state.

We are here concerned about the general case (1.1), and we first note that this includes various types of special cases by choosing the kernel function f.

(i) If the kernel f is taken to be

$$f(t,s,x,y) = \delta(t-s)\delta(x-y),$$

(1.1) becomes the reaction-diffusion equation without delay

$$\frac{\partial u}{\partial t}(t,x) = \frac{\partial^2 u}{\partial x^2}(t,x) + u(t,x)\frac{1 - u(t,x)}{1 + \gamma u(t,x)}, \tag{1.7}$$

which is a special case of (1.5).

(ii) If the kernel function f has a discrete time lag τ and spatial averaging, that is,

$$f(t,s,x,y) = \frac{1}{\sqrt{4\pi(t-s)}}e^{-(x-y)^2/4(t-s)}\delta(t-s-\tau),$$

then (1.1) becomes

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + u\frac{1 - \int_{-\infty}^{\infty} \frac{e^{-(x-y)^2/4\tau}}{\sqrt{4\pi\tau}} u(t-\tau, y)dy}{1 + \gamma \int_{-\infty}^{\infty} \frac{e^{-(x-y)^2/4\tau}}{\sqrt{4\pi\tau}} u(t-\tau, y)dy}. \tag{1.8}$$

A derivation of this type of model, using probabilistic arguments, was given in [4]. In this model, the movement of individuals to their present positions from where they have been at previous times is accounted for by a spatial convolution with a kernel that spreads normally with a dependence on the delay.

(iii) If $f(t, s, x, y) = \delta(x - y)G(t - s)$, where

$$G(t) = \frac{1}{\tau}e^{-t/\tau} \quad \text{or} \quad G(t) = \frac{t}{\tau^2}e^{-t/\tau}, \tag{1.9}$$

(1.1) becomes a model of reaction diffusion equation with distributed delay:

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + u\frac{1 - \int_{-\infty}^{t} G(t-\eta)u(\eta, x)d\eta}{1 + \gamma \int_{-\infty}^{t} G(t-\eta)u(\eta, x)d\eta}. \tag{1.10}$$

The parameter τ measures time delay and is comparable to the discrete delay τ in (1.8). The two kernel functions G in (1.9) are used frequently in the literature on delay differential equations. The first of the two functions G is sometimes called the "weak" generic kernel because it implies that the importance of events in the past decreases exponentially. The second kernel (the "strong" generic case) is different because it implies that a particular time in the past, namely, τ time units ago, is more important than any other since this kernel achieves its unique maximum when $t = \tau$. This kernel can be viewed as a smoothed out version of the case $G(t) = \delta(t-\tau)$, which gives rise to the discrete delay model.

(iv) If the kernel f is taken to be

$$f(t, s, x, y) = \frac{1}{\sqrt{4\pi(t-s)}}e^{-(x-y)^2/4(t-s)}G(t-s),$$

then (1.1) is a reaction diffusion equation with both distributed delay and spatial averaging. In the distributed delay case with $G(t) = \frac{1}{\tau}e^{-t/\tau}$, a formal asymptotic expansion of traveling wavefront to (1.1) when τ is small was found recently by Gourley and Chaplain by using the so-called linear chain techniques; see [14], [15]. But the convergence of this series or the proof of validity of this expansion has been absent. The central idea of this trick is to recast the traveling wave equation into a higher dimensional system of ODEs without delay. When τ is small, Fenichel's geometrical singular perturbation theory (see [12] or part two of [2]) is applicable. As mentioned in [14], if $G(t) = \frac{t}{\tau^2}e^{-t/\tau}$, linear chain techniques are still applicable, but the system of traveling wave profile equation is six-dimensional. While the trick remains to be effective theoretically, it will be much more difficult in practice. Apparently, it is well known that the drawback of this method is that it is applicable only for models with the special distributed delays. One cannot extend this technique to the discrete case. Another disadvantage of this approach is that if the unperturbed system ($\tau = 0$) is a higher dimensional system, the construction of a traveling wavefront is extraordinarily difficult.

As mentioned in section 3 of [14], traveling wave solutions to (1.1) in the discrete case are much more difficult to study than in the distributed case with specific kernels, because we are no longer able to recast the wave profile equation of (1.8) into a nondelay equation, and thus Fenichel's geometrical singular perturbation theory cannot be directly used to find a heteroclinic connection in a finite dimensional manifold. Generally, it is well known that in this case the search for traveling wavefronts becomes a much more difficult task.

The purpose of this paper is to develop a completely new approach suitable for all of the aforementioned cases for the existence of traveling wavefronts. The principal result can be stated as follows.

THEOREM 1.1. *For any fixed constant* $c \geq 2$, *there exists a real number* $\delta = \delta(c) > 0$ *so that for* $\tau \in [0, \delta]$, (1.1) *possesses a traveling wavefront* $u(t, x) = U(x - ct)$ *satisfying* $U(-\infty) = 1$ *and* $U(\infty) = 0$.

We should remark that our approach here can be developed to study more general equations including

$$\frac{\partial u}{\partial t}(t,x) = \frac{\partial^2 u}{\partial t^2}(t,x) + u(t,x)H((f * u)(t,x)),$$

with $H(\cdot)$ a decreasing function; we refer to [20] for this development.

Although the main result should be of interest, we wish to emphasize the novelty of the approach that we develop. This approach is based on a combination of the perturbation analysis, the Fredholm operator theory, and the fixed point theorems and is expected to find applications in other models as well. A detailed proof is given for case (ii) and is sketched to emphasize the key differences for cases (iii) and (iv). This approach does not work when the delay is not small. In the case where the delay is arbitrary, we develop in section 5 Faria, Huang, and Wu's perturbation method [9] for traveling wavefronts with large wave speeds. We shall provide both theoretical justifications and numerical simulations for this method.

2. The discrete-delay and spatial-averaging case. In the discrete-delay and spatial-averaging case, i.e., the case when the delayed term involves an evaluation of the dependence exactly time τ ago and a convolution in space to account for the movement of individuals to their present positions from their past positions at previous times, (1.1) becomes

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + u(t,x)\left(\frac{1 - \int_{-\infty}^{\infty} 1/\sqrt{4\pi\tau}e^{-(x-y)^2/(4\tau)}u(t-\tau,y)dy}{1 + \gamma\int_{-\infty}^{\infty} 1/\sqrt{4\pi\tau}e^{-(x-y)^2/(4\tau)}u(t-\tau,y)dy}\right). \tag{2.1}$$

Our intention here is to establish the existence of traveling waves to (2.1) connecting the two uniform steady states $u = 0$ and $u = 1$. For this purpose, we first show the existence of such wavefronts when the delay τ is zero.

Letting $\tau \to 0^+$, we arrive at the following nondelay version of the food-limited model:

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + u\frac{1-u}{1+\gamma u}, \tag{2.2}$$

which is actually a modified version of the well-known Fisher's equation. Obviously, (2.2) has two uniform steady-state solutions $u = 0$ and $u = 1$. Considering the traveling wavefront form by setting $u(t, x) = U_0(z) = U_0(x - ct)$ in (2.2), we obtain the following second-order ODE for $U_0(z)$:

$$U_0'' + cU_0' + U_0\frac{1-U_0}{1+\gamma U_0} = 0 \tag{2.3}$$

or equivalently the following first-order coupled system

$$\begin{cases} U_0' = V_0, \\ V_0' = -cV_0 - U_0 \frac{1-U_0}{1+\gamma U_0}. \end{cases} \tag{2.4}$$

The existence of traveling wavefronts to (2.4) can be established by using the standard phase-plane techniques. Here we present only the result below.

THEOREM 2.1. *If $c \geq 2$, then in the (U_0, V_0) phase plane, a heteroclinic connection exists between the critical points $(U_0, V_0) = (1, 0)$ and $(0, 0)$. Furthermore, the traveling front $U_0(z)$ is strictly monotonically decreasing.*

It is easy to see that the equilibrium $(1, 0)$ is a saddle and the origin $(0, 0)$ is a stable node.

To obtain an extension when $\tau > 0$, we need the following estimate on the derivative of the wave profile U_0.

THEOREM 2.2. *Let U_0 be a traveling wavefront solution to* (2.3). *Then*

$$-\frac{1}{2\sqrt{\gamma}} < U_0'(z) \leq 0 \ \textit{ for all } z \in (-\infty, \infty). \tag{2.5}$$

Proof. Since U_0 is strictly monotonically decreasing, it is obvious that $U_0'(z) \leq 0$. It remains to prove that $U_0'(z) > -1/(2\sqrt{\gamma})$. Note that (2.3) can be rewritten as

$$U_0'' + cU_0' \ - \frac{1}{\gamma} U_0 + \left(1 + \frac{1}{\gamma}\right) \frac{U_0}{1 + \gamma U_0} = 0. \tag{2.6}$$

Let

$$\lambda_1 = \frac{-c - \sqrt{c^2 + 4/\gamma}}{2} < 0, \quad \lambda_2 = \frac{-c + \sqrt{c^2 + 4/\gamma}}{2} > 0.$$

Then it follows from (2.6) that

$$U_0(z) = \frac{(1 + \frac{1}{\gamma})}{\lambda_2 - \lambda_1} \left[\int_{-\infty}^{z} e^{\lambda_1 (z-s)} \frac{U_0}{1 + \gamma U_0} ds + \int_{z}^{\infty} e^{\lambda_2 (z-s)} \ \frac{U_0}{1 + \gamma U_0} ds \right],$$

and hence using the fact that $0 < U_0 < 1$, we have

$$\begin{aligned} U_0'(z) &= \frac{(1 + \frac{1}{\gamma})}{\lambda_2 - \lambda_1} \left[\lambda_1 \int_{-\infty}^{z} e^{\lambda_1 (z-s)} \frac{U_0}{1 + \gamma U_0} ds + \lambda_2 \int_{z}^{\infty} e^{\lambda_2 (z-s)} \frac{U_0}{1 + \gamma U_0} ds \right] \\ &> \frac{(1 + \frac{1}{\gamma})\lambda_1}{\lambda_2 - \lambda_1} \int_{-\infty}^{z} e^{\lambda_1 (z-s)} \frac{U_0}{1 + \gamma U_0} ds \\ &\geq \frac{(1 + \frac{1}{\gamma})\lambda_1}{\lambda_2 - \lambda_1} \max \left(\frac{U_0}{1 + \gamma U_0} \right) \int_{-\infty}^{z} e^{\lambda_1 (z-s)} ds \\ &= -\frac{(1 + \frac{1}{\gamma})}{(1 + \gamma)\sqrt{c^2 + 4/\gamma}} \geq -\frac{1}{2\sqrt{\gamma}}. \end{aligned}$$

The proof is complete. $\square$

Now we are in a position to establish the existence of traveling wavefronts to (2.1). We will show that the traveling fronts to (2.1) can be approximated by the corresponding wavefronts $U_0(z)$ of (2.3) when τ is small. First, we introduce some notations. Let $C(R,R)$ be the Banach space of continuous and bounded functions from R to R equipped with the standard norm $||\phi||_C = \sup\{|\phi(t)|, t \in R\}$. Let $C^1 = C^1(R,R) = \{\phi \in C : \phi' \in C\}$, $C^2 = \{\phi \in C : \phi'' \in C\}$, $C_0 = \{\phi \in C : \lim_{t\to\pm\infty} \phi = 0\}$, and $C_0^1 = \{\phi \in C_0 : \phi' \in C_0\}$, where the corresponding norms are defined by

$$||\phi||_{C_0} = ||\phi||_C,\ ||\phi||_{C^1} = ||\phi||_{C_0^1} = ||\phi||_C + ||\phi'||_C,$$

and

$$||\phi||_{C^2} = ||\phi||_C + ||\phi'||_C + ||\phi''||_C.$$

Set $u(t,x) = U(z) = U(x-ct)$ in (2.1). Then $U(z)$ satisfies the profile equation

$$-cU' = U'' + \ U\frac{1-H(U)(z)}{1+\gamma H(U)(z)}, \tag{2.7}$$

where

$$H(U)(z) = \int_{-\infty}^{\infty} \frac{1}{\sqrt{4\pi\tau}} e^{-y^2/(4\tau)} U(z-y+c\tau)dy.$$

We suppose that U can be approximated by U_0 and hence assume that $U = U_0 + W$. Then an equation for W is given by

$$-cW' = W'' \ + (U_0+W)\frac{1-H(U_0+W)(z)}{1+\gamma H(U_0+W)(z)} - \ U_0\frac{1-U_0(z)}{1+\gamma U_0(z)}\ . \tag{2.8}$$

Applying Taylor's expansions to

$$(U_0+W)\frac{1-H(U_0+W)(z)}{1+\gamma H(U_0+W)(z)}$$

yields

$$\begin{aligned}(U_0+W)\frac{1-H(U_0+W)(z)}{1+\gamma H(U_0+W)(z)} = \ & U_0\frac{1-H(U_0)}{1+\gamma H(U_0)}\\ &+W\frac{1-H(U_0)}{1+\gamma H(U_0)} - \frac{(1+\gamma)U_0}{(1+\gamma H(U_0))^2}H(W)\\ &+R_1(z,\tau,W),\end{aligned} \tag{2.9}$$

where $R_1(z,\tau,W)$ is the remainder (higher order terms) of this expansion, and for the time being we write it as

$$\begin{aligned}R_1(z,\tau,W) = & (U_0+W)\frac{1-H(U_0+W)(z)}{1+\gamma H(U_0+W)(z)}\\ &-U_0\frac{1-H(U_0)}{1+\gamma H(U_0)}\\ &-W\frac{1-H(U_0)}{1+\gamma H(U_0)} + \frac{(1+\gamma)U_0}{(1+\gamma H(U_0))^2}H(W).\end{aligned} \tag{2.10}$$

Let $g(x) = x\frac{1-x}{1+\gamma x}$. Then we have

$$g'(x) = \frac{1-x}{1+\gamma x} - \frac{(1+\gamma)x}{(1+\gamma x)^2}.$$

Therefore, by (2.9), (2.8) becomes

$$\begin{aligned}(2.11)\qquad -cW' &= W'' + g'(U_0(z))W(z)\\ &\quad + R_1(z,\tau,W) + R_2(z,\tau) + R_3(z,\tau,W),\end{aligned}$$

where

$$R_2(z,\tau) = U_0\frac{1-H(U_0)}{1+\gamma H(U_0)} - g(U_0),$$

and

$$R_3(z,\tau,W) = W\frac{1-H(U_0)}{1+\gamma H(U_0)} - \frac{(1+\gamma)U_0}{(1+\gamma H(U_0))^2}H(W) - g'(U_0(z))W(z).$$

Next we transform (2.11) into an integral equation as follows. Recall that the equation

$$W'' + cW' - W = 0$$

has the characteristic equation

$$\lambda^2 + c\lambda - 1 = 0$$

that has two real roots

$$\lambda_1 = \frac{-c-\sqrt{c^2+4}}{2} < 0, \quad \lambda_2 = \frac{-c+\sqrt{c^2+4}}{2} > 0.$$

Thus (2.11) is equivalent to the following integral equation:

$$(2.12)\quad W = \frac{1}{\lambda_2-\lambda_1}\left(\begin{array}{c}\int_{-\infty}^{z} e^{\lambda_1(z-s)}\left[(1+g'(U_0(s)))W(s) + R_1 + R_2 + R_3\right]ds\\ +\int_{z}^{\infty} e^{\lambda_2(z-s)}\left[(1+g'(U_0(s)))W(s) + R_1 + R_2 + R_3\right]ds\end{array}\right).$$

We will study the existence of a solution $W \in C_0$ to (2.12). For this purpose, we define a linear operator $L : C_0 \to C_0$ by

$$\begin{aligned}L(W)(z) = W &- \frac{\int_{-\infty}^{z} e^{\lambda_1(z-s)}(1+g'(U_0(s)))W(s)ds}{\lambda_2-\lambda_1}\\ &- \frac{\int_{z}^{\infty} e^{\lambda_2(z-s)}(1+g'(U_0(s)))W(s)ds}{\lambda_2-\lambda_1}.\end{aligned}$$

It is obvious that $L(W) \in C_0$ if $W \in C_0$. In order to verify the existence of a solution $W \in C_0$ to (2.12), we need to establish some estimates for the terms in the right-hand side of (2.12) when $W \in C_0$. We have the following.

LEMMA 2.3. *For each $\delta > 0$, there is a $\sigma > 0$ such that*

$$(2.13)\qquad ||R_1(z,\tau,\phi) - R_1(z,\tau,\varphi)||_{C_0} \le \delta||\phi-\varphi||_{C_0}$$

and

$$\int_{-\infty}^{z} e^{\lambda_1(z-s)}|R_1(s,\tau,\phi) - R_1(s,\tau,\varphi)|ds + \int_{z}^{\infty} e^{\lambda_2(z-s)}|R_1(s,\tau,\phi) - R_1(s,\tau,\varphi)|ds$$
$$\le \delta||\phi-\varphi||_{C_0}$$

(2.14)

for all finite τ and all $\phi, \varphi \in B(\sigma)$, where $B(\sigma)$ is the ball in C_0 with radius σ and the center at the origin.

Proof. Since R_1 is the remainder of Taylor's expansion and $||H\phi|| \le ||\phi||$ for any $\phi \in C$, we have

$$||R_1(\cdot,\tau,\phi)|| = O(||\phi||^2_{C_0}) \text{ as } ||\phi||_{C_0} \to 0, \tag{2.15}$$

uniformly for all finite τ. Obviously $R_1(\cdot,\tau,\phi)$, $(R_1)_\phi(\cdot,\tau,\phi)$ (the derivative of R_1 with respect to ϕ), and $(R_1)_{\phi\phi}(\cdot,\tau,\phi)$ (the second derivative of R_1 with respect to ϕ) are continuous for ϕ in a neighborhood of the origin in C_0, and $\tau \in [0,\tau_0]$, where τ_0 is a positive number. Therefore, (2.13) and (2.14) follow from (2.15). □

LEMMA 2.4. *As $\tau \to 0$, we have*

$$\left|\int_{-\infty}^{z} e^{\lambda_1(z-s)}R_2(s,\tau)ds + \int_z^\infty e^{\lambda_2(z-s)}R_2(s,\tau)ds\right| = O(\sqrt{\tau})$$

uniformly for all $z \in (-\infty,\infty)$.

Proof. Since

$$\begin{aligned} R_2(z,\tau) &= U_0\frac{1-H(U_0)}{1+\gamma H(U_0)} - g(U_0)\\ &= U_0\frac{1-H(U_0)}{1+\gamma H(U_0)} - U_0\frac{1-U_0}{1+\gamma U_0}, \end{aligned}$$

we need to show only that when τ is small, the following:

$$\int_{-\infty}^{z} e^{\lambda_1(z-s)}\,|H(U_0)(s)-U_0(s)|\,ds = O(\sqrt{\tau}) \tag{2.16}$$

and

$$\int_z^\infty e^{\lambda_1(z-s)}\,|H(U_0)(s)-U_0(s)|\,ds = O(\sqrt{\tau}) \tag{2.17}$$

hold. In fact, we have

$$\begin{aligned} &\int_{-\infty}^{z} e^{\lambda_1(z-s)}\,|H(U_0)(s)-U_0(s)|\,ds\\ =&\int_{-\infty}^{z} e^{\lambda_1(z-s)}\left|\int_{-\infty}^{\infty}\frac{1}{\sqrt{4\pi\tau}}e^{-y^2/4\tau}U_0(s-y+c\tau)dy - U_0(s)\right|ds\\ =&\int_{-\infty}^{z} e^{\lambda_1(z-s)}\left|\int_{-\infty}^{\infty}\frac{1}{\sqrt{4\pi\tau}}e^{-y^2/4\tau}\left[U_0(s-y+c\tau)-U_0(s)\right]dy\right|ds\\ \le&\int_{-\infty}^{z} e^{\lambda_1(z-s)}\int_{-\infty}^{\infty}\frac{1}{\sqrt{4\pi\tau}}e^{-y^2/4\tau}(|y|+c\tau)dyds||U_0'||\\ =&\ O(\sqrt{\tau}). \end{aligned}$$

Similarly we can show (2.17). □

LEMMA 2.5. *There exists an $M_0 > 0$ such that for all $W \in C_0$, the following inequality:*

$$\left|\int_{-\infty}^{z} e^{\lambda_1(z-s)}R_3(s,\tau,W)ds + \int_z^\infty e^{\lambda_2(z-s)}R_3(s,\tau,W)ds\right| \le \sqrt{\tau}M_0||W||_{C_0} \tag{2.18}$$

holds. Furthermore for any two elements ϕ and φ in C_0, we have

$$\left|\int_{-\infty}^{z} e^{\lambda_1(z-s)}(R_3(s,\tau,\phi)-R_3(s,\tau,\varphi))ds+\int_{z}^{\infty} e^{\lambda_2(z-s)}(R_3(s,\tau,\phi)-R_3(s,\tau,\varphi))ds\right|$$
$$=O(\sqrt{\tau})||\phi-\varphi||_{C_0}. \tag{2.19}$$

Proof. We rewrite R_3 as

$$\begin{aligned} R_3(z,\tau,W)= {} & W\left(\frac{1-H(U_0)}{1+\gamma H(U_0)}-\frac{1-U_0}{1+\gamma U_0}\right)\\ & -H(W)\left(\frac{(1+\gamma)U_0}{(1+\gamma H(U_0))^2}-\frac{(1+\gamma)U_0}{(1+\gamma U_0)^2}\right)\\ & -\frac{(1+\gamma)U_0}{(1+\gamma U_0)^2}\left(H(W)-W\right). \end{aligned} \tag{2.20}$$

Therefore, for the integrations of the first and the second lines on the right-hand side of (2.20), we have from (2.16) the following estimates:

$$\left|\int_{-\infty}^{z} e^{\lambda_1(z-s)}W\left(\frac{1-H(U_0)}{1+\gamma H(U_0)}-\frac{1-U_0}{1+\gamma U_0}\right)ds\right|=O(\sqrt{\tau}||W||), \tag{2.21}$$

and

$$\left|\int_{-\infty}^{z} e^{\lambda_1(z-s)}H(W)\left(\frac{(1+\gamma)U_0}{(1+\gamma H(U_0))^2}-\frac{(1+\gamma)U_0}{(1+\gamma U_0)^2}\right)ds\right|=O(\sqrt{\tau}||W||), \tag{2.22}$$

due to the fact $||H(W)||\le||W||$. For the integration of the function in the last line of (2.20), if $W\in C_0^1$, by exchanging the order of integration and integration by parts, we have

$$\begin{aligned} & \int_{-\infty}^{z} e^{\lambda_1(z-s)}\frac{(1+\gamma)U_0}{(1+\gamma U_0)^2}\left(H(W)-W\right)ds\\ ={} & \int_{-\infty}^{z} e^{\lambda_1(z-s)}\;\frac{(1+\gamma)U_0}{(1+\gamma U_0)^2}\int_{-\infty}^{\infty}\frac{1}{\sqrt{4\pi\tau}}e^{-y^2/(4\tau)}\left(W(s-y+c\tau)-W(s)\right)dyds\\ ={} & \int_{-\infty}^{z} e^{\lambda_1(z-s)}\frac{(1+\gamma)U_0}{(1+\gamma U_0)^2}\int_{-\infty}^{\infty}\frac{1}{\sqrt{4\pi\tau}}e^{-y^2/(4\tau)}\int_0^{-y+c\tau}W'(s+\eta)d\eta dyds\\ ={} & \int_{-\infty}^{\infty}\frac{1}{\sqrt{4\pi\tau}}e^{-y^2/(4\tau)}\int_0^{-y+c\tau}\int_{-\infty}^{z} e^{\lambda_1(z-s)}\frac{(1+\gamma)U_0}{(1+\gamma U_0)^2}W'(s+\eta)dsd\eta dy\\ ={} & \frac{(1+\gamma)U_0(z)}{(1+\gamma U_0(z))^2}\int_{-\infty}^{\infty}\frac{1}{\sqrt{4\pi\tau}}e^{-y^2/(4\tau)}\int_0^{-y+c\tau}W(z+\eta)d\eta dy\\ & -\int_{-\infty}^{\infty}\frac{1}{\sqrt{4\pi\tau}}e^{-y^2/(4\tau)}\int_0^{-y+c\tau}\int_{-\infty}^{z}W(s+\eta)\left[e^{\lambda_1(z-s)}\frac{(1+\gamma)U_0}{(1+\gamma U_0)^2}\right]'dsd\eta dy\\ ={} & O(\sqrt{\tau}||W||). \end{aligned} \tag{2.23}$$

To obtain the above result, we have used the fact that

$$\int_{-\infty}^{z}\left|\frac{d}{ds}\left[e^{\lambda_1(z-s)}\frac{(1+\gamma)U_0(s)}{(1+\gamma U_0(s))^2}\right]\right|ds$$

is uniformly bounded for all $z \in (-\infty, \infty)$. Therefore, from (2.21), (2.22), and (2.23) it follows that there exists a constant M_1 such that

$$\left| \int_{-\infty}^{z} e^{\lambda_1 (z-s)} R_3(s, \tau, W) ds \right| \leq \sqrt{\tau} M_1 ||W||_{C_0}. \tag{2.24}$$

Similarly, we can prove that there exists a constant M_2 so that

$$\left| \int_{z}^{\infty} e^{\lambda_2 (z-s)} R_3(s, \tau, W) ds \right| \leq \sqrt{\tau} M_2 ||W||_{C_0}. \tag{2.25}$$

Therefore, it follows from (2.24) and (2.25) that for any $W \in C_0^1$, we have

$$\left| \int_{-\infty}^{z} e^{\lambda_1 (z-s)} R_3(s, \tau, W) ds + \int_{z}^{\infty} e^{\lambda_2 (z-s)} R_3(s, \tau, W) ds \right| \leq \sqrt{\tau} M_0 ||W||_{C_0},$$

with

$$M_0 = \sum_{j=1}^{2} M_j.$$

Since C_0^1 is dense in C_0, the inequality (2.18) holds for all $W \in C_0$. Thus (2.19) is satisfied due to the fact that $R_3(s, \tau, W)$ is a linear functional of W.

We should mention that for each $\tau > 0$ and $W \in C_0$, we have R_1, R_2, and $R_3 \in C_0$ and hence

$$\int_{-\infty}^{z} e^{\lambda_1 (z-s)} (R_1 + R_2 + R_3) ds + \int_{z}^{\infty} e^{\lambda_2 (z-s)} \left[R_1 + R_2 + R_3 \right] ds \in C_0.$$

Now we are ready to prove our main result. □

THEOREM 2.6. *For any $c \geq 2$, there exists a constant $\delta = \delta(c) > 0$ so that for any $\tau \in [0, \delta]$,* (2.1) *possesses a traveling wavefront $u(t, x) = U(x - ct)$ satisfying $U(-\infty) = 1$ and $U(\infty) = 0$.*

Proof. Define an operator $T : \Psi \in C^2 \to C$ from the homogeneous part of (2.11) as follows:

$$T\Psi(z) = c\Psi'(z) + \Psi''(z) + g'(U_0(z))\Psi(z). \tag{2.26}$$

The formal adjoint equation of $T\Psi = 0$ is given by

$$-c\Phi'(z) + \Phi''(z) + g'(U_0(z))\Phi(z) = 0, \quad z \in R. \tag{2.27}$$

We now divide our proof into five steps.

Step 1. We claim that if $\Phi \in C$ is a solution of (2.27) and Φ is C^2-smooth, then $\Phi = 0$. Moreover, we have $\Re(T) = C$, where $\Re(T)$ is the range space of T.

Indeed, when $z \to \infty$, $U_0(z) \to 0$ and $g'(U_0(z)) \to 1$. Then (2.27) tends asymptotically to an equation with constant coefficients

$$-c\Phi'(z) + \Phi''(z) + \Phi(z) = 0. \tag{2.28}$$

The corresponding characteristic equation of (2.28) is

$$\lambda^2 - c\lambda + 1 = 0. \tag{2.29}$$

Both roots of (2.29) have a positive real part as $c \geq 2$, and thus we can conclude that any bounded solution to (2.28) must be the zero solution. So as $z \to \infty$, any solution to (2.27) other than the zero solution must grow exponentially for large z. Then the only solution satisfying $\Phi(\pm\infty) = 0$ is the zero solution. By the Fredholm theory (see Lemma 4.2 in [22]) we have that $\Re(T) = C$.

Step 2. Let $\Theta \in C_0$ be given. We conclude that if Ψ is a bounded solution of $T\Psi = \Theta$, then we have $\lim_{z\to\pm\infty} \Psi(z) = 0$.

In fact when $z \to \infty$, the equation

$$c\Psi'(z) + \Psi''(z) + g'(U_0(z))\Psi(z) = \Theta \tag{2.30}$$

tends asymptotically to

$$c\Psi'(z) + \Psi''(z) + \Psi(z) = 0. \tag{2.31}$$

Note for (2.31), the ω-limit set of every bounded solution is just the critical point $\Psi = 0$. Using Theorem 1.8 from [19], we find that every bounded solution of (2.30) also satisfies

$$\lim_{z\to\infty} \Psi(z) = 0.$$

When $z \to -\infty$, (2.30) tends asymptotically to

$$c\Psi'(z) + \Psi''(z) + g'(1)\Psi(z) = 0. \tag{2.32}$$

Since $g'(1) = -1$, the characteristic equation of (2.32) has two eigenvalues: $\bar{\lambda}_1 < 0$ and $\bar{\lambda}_2 > 0$. Thus every bounded solution of (2.32) must satisfy

$$\lim_{z\to-\infty} \Psi(z) = 0.$$

Inverting the time from z to $-z$ and using the result in [19] again, we know that any bounded solution to (2.30) satisfies $\lim_{z\to-\infty} \Psi(z) = 0$. Hence the claim of Step 2 holds.

Step 3. For a linear operator $L : C_0 \to C_0$ defined by

$$L(W)(z) = W - \frac{1}{\lambda_2 - \lambda_1} \begin{pmatrix} \int_{-\infty}^{z} e^{\lambda_1(z-s)}(1 + g'(U_0(s)))W(s)ds \\ + \int_{z}^{\infty} e^{\lambda_2(z-s)}(1 + g'(U_0(s)))W(s)ds \end{pmatrix},$$

we want to prove that $\Re(L) = C_0$; that is, for each $Z \in C_0$, we have a $W \in C_0$ so that

$$W - \frac{1}{\lambda_2 - \lambda_1} \begin{pmatrix} \int_{-\infty}^{z} e^{\lambda_1(z-s)}(1 + g'(U_0(s)))W(s)ds \\ + \int_{z}^{\infty} e^{\lambda_2(z-s)}(1 + g'(U_0(s))W(s))ds \end{pmatrix} = Z(z).$$

To see this, we assume that $\xi(z) = W(z) - Z(z)$ and obtain an equation for ξ as follows:

$$\begin{aligned} \xi(z) = {} & \frac{1}{\lambda_2 - \lambda_1} \begin{pmatrix} \int_{-\infty}^{z} e^{\lambda_1(z-s)}(1 + g'(U_0(s)))\xi(s)ds \\ + \int_{z}^{\infty} e^{\lambda_2(z-s)}(1 + g'(U_0(s)))\xi(s)ds \end{pmatrix} \\ & + \frac{1}{\lambda_2 - \lambda_1} \begin{pmatrix} \int_{-\infty}^{z} e^{\lambda_1(z-s)}(1 + g'(U_0(s)))Z(s)ds \\ + \int_{z}^{\infty} e^{\lambda_2(z-s)}(1 + g'(U_0(s)))Z(s)ds \end{pmatrix}. \end{aligned}$$

Differentiating both sides twice yields

$$-c\xi' - \xi''(z) - g'(U_0(z))\xi(z) = (1 + g'(U_0(z)))Z(z). \tag{2.33}$$

Using the results that $\Re(T) = C$ in Step 1 and $Z \in C_0$, we obtain by Step 2 that there exists a solution $\xi(z)$ satisfying (2.33) and $\xi(\pm\infty) = 0$. Returning to the variable W, we have $W = \xi + Z \in C_0$.

Step 4. Let $N(L)$ be the null space of operator L. By Lemma 5.1 in [9], there is a subspace $N^{\perp}(L)$ in C_0 so that

$$C_0 = N^{\perp}(L) \oplus N(L);$$

see also [10]. It is clear that $N^{\perp}(L)$ is a Banach space. If we let $S = L|_{N^{\perp}(L)}$ be the restriction of L to $N^{\perp}(L)$, then $S : N^{\perp}(L) \to C_0$ is one-to-one and onto. By the well-known Banach inverse operator theorem, we have that $S^{-1} : C_0 \to N^{\perp}(L)$ is a linear bounded operator.

Step 5. When L is restricted to $N^{\perp}(L)$, (2.12) can be written as

$$S(W)(z) = \frac{1}{\lambda_2 - \lambda_1} \begin{pmatrix} \int_{-\infty}^{z} e^{\lambda_1(z-s)} \left[R_1 + R_2 + R_3\right] ds \\ + \int_{z}^{\infty} e^{\lambda_2(z-s)} \left[R_1 + R_2 + R_3\right] ds \end{pmatrix}.$$

Since the norm $||S^{-1}||$ is independent of τ, it follows from Lemmas 2.3, 2.4, and 2.5 that there exist $\sigma > 0, \delta > 0$, and $0 < \rho < 1$ such that for all $\tau \in (0, \delta]$ and $W, \varphi, \psi \in B(\sigma) \cap N^{\perp}(L)$,

$$||F(z, W)\ || \le \frac{1}{3}\left(||W|| + \sigma\right)$$

and

$$||F(z, \varphi) - F(z, \psi)||\ \le \rho||\varphi - \psi||,$$

where

$$F(z, W) = \frac{1}{\lambda_2 - \lambda_1} S^{-1} \begin{pmatrix} \int_{-\infty}^{z} e^{\lambda_1(z-s)} \left[R_1 + R_2 + R_3(\tau, s, W)\right] ds \\ + \int_{z}^{\infty} e^{\lambda_2(z-s)} \left[R_1 + R_2 + R_3(\tau, s, W)\right] ds \end{pmatrix}.$$

It is easy to know that for any $W \in B(\sigma) \cap N^{\perp}(L)$, we have

$$||F(z, W)\ || \le \frac{1}{3}\left(||W|| + \sigma\right) \le \sigma.$$

Hence $F(z, \varphi)$ is a uniform contractive mapping for $W \in N^{\perp}(L) \cap B(\sigma)$. By using the Banach contraction principle, it follows that for $\tau \in [0, \delta]$, equation (2.12) has a unique solution $W \in N^{\perp}(L)$. Returning to the original variable, $W + U_0$ is a heteroclinic connection between the two equilibria 1 and 0. This completes the proof. $\square$

3. The distributed delay case. In this section we consider (1.1) with the kernel function

$$f(t, s, x, y) = G(t - s)\delta(x - y),$$

where

$$G(t) = \frac{1}{\tau} e^{-t/\tau} \quad \text{or} \quad G(t) = \frac{t}{\tau^2} e^{-t/\tau}. \tag{3.1}$$

We shall focus on the following equation

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + u \frac{1 - \int_{-\infty}^{t} \frac{t-\eta}{\tau^2} e^{-(t-\eta)/\tau} u(\eta, x) d\eta}{1 + \gamma \int_{-\infty}^{t} \frac{t-\eta}{\tau^2} e^{-(t-\eta)/\tau} u(\eta, x) d\eta} \tag{3.2}$$

since the corresponding analysis for the weak kernel $G(t) = \frac{1}{\tau} e^{-t/\tau}$ is much easier. Instead of using the linear chain trick which is valid only for the kernels in (3.1), we shall use the approach in section 2 to prove rigorously that traveling fronts exist when τ is small.

As in section 2, assume that $u(t, x) = U(z)$, $z = x - ct$, where $c \geq 2$. Substituting $u = U(z)$ into (3.2), we have a wave equation for U

$$-cU' = U'' + U \frac{1 - \int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} U(z + c\eta) d\eta}{1 + \gamma \int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} U(z + c\eta) d\eta}.$$

Let $U = U_0 + W$, where U_0 is the traveling fronts for (2.4). Then we have an equation for W of the form

$$-cW' = W'' - W + (U_0 + W) h[U_0 + W] - U_0 \frac{1 - U_0}{1 + \gamma U_0}, \tag{3.3}$$

where the functional h is defined by

$$h[U](z) = \frac{1 - \int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} U(z + c\eta) d\eta}{1 + \gamma \int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} U(z + c\eta) d\eta}.$$

Applying Taylor's expansion to $h[U_0 + W]$, we have

$$\begin{aligned} h[U_0 + W](z) &= \frac{1 - \int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} [U_0(z + c\eta) + W(z + c\eta] dy d\eta}{1 + \gamma \int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} [U_0(z + c\eta) + W(z + c\eta] dy d\eta} \\ &= h[U_0](z) - \frac{(1 + \gamma)}{\left(1 + \gamma \int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} U_0(z + c\eta) d\eta\right)^2} \int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} W(z + c\eta) d\eta + \cdots . \end{aligned}$$

Thus (3.3) becomes

$$\begin{aligned} -cW' &= W'' + g'(U_0(z)) W(z) \\ &\quad + R_1(z, \tau, W) + R_2(z, \tau) + R_3(z, \tau, W), \end{aligned} \tag{3.4}$$

where

$$\begin{aligned} R_1(z, \tau, W) = {} & (U_0 + W) h[U_0 + W](z) - U_0 h[U_0](z) \\ & + U_0 \frac{(1 + \gamma)}{\left(1 + \gamma \int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} U_0(z + c\eta) d\eta\right)^2} \int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} W(z + c\eta) d\eta \\ & - h[U_0] W, \end{aligned} \tag{3.5}$$

$$R_2(z, \tau) = U_0 h[U_0](z) - U_0 \frac{1 - U_0}{1 + \gamma U_0}, \tag{3.6}$$

and

$$R_3(z,\tau,W) = \frac{(1+\gamma)\ U_0 \int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} W(z+c\eta)d\eta}{\left(1+\gamma\int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} U_0(z+c\eta)d\eta\right)^2} \tag{3.7}$$
$$+h[U_0]W(z) - g'(U_0(z))W(z).$$

To obtain the existence of the traveling fronts when τ is small, we need to prove that Lemmas 2.3, 2.4, and 2.5 hold. The proofs are quite similar to those in the discrete case, so we shall prove only Lemma 2.5 as an illustration and leave the proofs of Lemmas 2.3 and 2.4 to interested readers.

Proof of Lemma 2.5 *in the case of distributed delay.* Note that

$$g'(U_0(z)) = \frac{1-U_0}{1+\gamma U_0} - \frac{(1+\gamma)U_0}{(1+\gamma U_0)^2}.$$

So

$$\begin{aligned} R_3(z,\tau,W) = {} & \bar{F}(U_0)(z)\left(\int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} W(z+c\eta)d\eta - W(z)\right) \\ & - \left(\frac{(1+\gamma)\ U_0}{\left(1+\gamma\int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} U_0(z+c\eta)d\eta\right)^2} - \frac{(1+\gamma)U_0}{(1+\gamma U_0)^2}\right) W \\ & + \left(h[U_0] - \frac{1-U_0}{1+\gamma U_0}\right) W, \end{aligned}$$

where

$$\bar{F}(U_0)(z) = -\frac{(1+\gamma)U_0}{\left(1+\gamma\int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} U_0(z+c\eta)d\eta\right)^2}.$$

We note that when τ is small,

$$\int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} U_0(z+c\eta)d\eta - U_0(z) = O(\tau)$$

holds uniformly for any $z \in (-\infty, \infty)$. Therefore, we have

$$\begin{aligned} & \int_{-\infty}^z e^{\lambda_1(z-s)} \left(\frac{(1+\gamma)\ U_0}{\left(1+\gamma\int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} U_0(s+c\eta)d\eta\right)^2} - \frac{(1+\gamma)U_0}{(1+\gamma U_0)^2}\right) W(s)ds \\ & = O(\tau\|W\|) \end{aligned}$$

and

$$\int_{-\infty}^z e^{\lambda_1(z-s)} \left(h[U_0] - \frac{1-U_0}{1+\gamma U_0}\right) W(s)ds = O(\tau\|W\|).$$

We now prove that

$$\int_{-\infty}^z e^{\lambda_1(z-s)} \bar{F}(U_0)(s) \left(\int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} \left(W(s+c\eta) - W(s)\right) d\eta\right) ds = O(\tau\|W\|).$$

Using the fact that

$$\bar{F}(U_0)(s) = O(1)$$

for any $s \in (-\infty, \infty)$, we need only prove that

$$\int_{-\infty}^{z} e^{\lambda_1(z-s)} \left(\int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} \left(W(s+c\eta) - W(s) \right) d\eta \right) ds = O(\tau ||W||).$$

Indeed, when $W \in C_0^1$, we have

$$W(s+c\eta) - W(s) = \int_0^{c\eta} W'(s+v) dv.$$

Exchanging the order of integration and using the integration by parts, we obtain

$$\begin{aligned} &\int_{-\infty}^{z} e^{\lambda_1(z-s)} \left(\int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} \left(W(s+c\eta) - W(s) \right) d\eta \right) ds \\ &= \int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} \left(\int_0^{c\eta} \int_{-\infty}^{z} e^{\lambda_1(z-s)} W'(s+v) ds dv \right) d\eta \\ &= O(\tau ||W||_{C_0}). \end{aligned}$$

Continuing the process as in section 2, we can show that Lemma 2.5 remains true, and so does the result in Theorem 2.6 for (3.2).

Similarly, we can prove that Theorem 2.6 is true if the kernel function is replaced by

$$f(t,s,x,y) = \frac{1}{\tau} e^{-(t-s)} \delta(x-y). \qquad \square$$

4. The distributed delay and spatial-averaging case. In this section, we consider (1.1) with the distributed delay and spatial averaging. Namely, we study the following equation:

(4.1)
$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + u(t,x) \left(\frac{1 - \int_{-\infty}^0 \frac{t-\eta}{\tau^2} e^{-(t-\eta)/\tau} \int_{-\infty}^\infty \frac{\exp(-(x-y)^2/(4(t-\eta)))}{\sqrt{4\pi(t-\eta)}} u(\eta,y) dy d\eta}{1 + \int_{-\infty}^0 \frac{t-\eta}{\tau^2} e^{-(t-\eta)/\tau} \int_{-\infty}^\infty \frac{\exp(-(x-y)^2/(4(t-\eta)))}{\sqrt{4\pi(t-\eta)}} u(\eta,y) dy d\eta} \right).$$

As before, by a traveling wavefront, we mean a solution $u(t,x) = U(z) = U(-ct+x)$, where $c > 0$ is the wave speed. Thus this specific kind of solution satisfies the following second-order ODE:

$$-cU' = U'' + U \frac{1 - H_1(U)(z)}{1 + \gamma H_1(U)(z)}, \tag{4.2}$$

where

$$H_1(U)(z) = \int_0^\infty \frac{\eta}{\tau^2} e^{-\eta/\tau} \int_{-\infty}^\infty \frac{1}{\sqrt{4\pi\eta}} e^{-y^2/4\eta} U(z-y+c\eta) dy d\eta.$$

We suppose that U can be approximated by U_0 and hence assume that $U = U_0 + W$. Then we obtain the equation for W as follows:

$$-cW' = W'' + (U_0 + W) \frac{1 - H_1(U_0+W)(z)}{1 + \gamma H_1(U_0+W)(z)} - U_0 \frac{1 - U_0(z)}{1 + \gamma U_0(z)}. \tag{4.3}$$

Applying Taylor's expansions to

$$(U_0+W)\frac{1-H_1(U_0+W)(z)}{1+\gamma H_1(U_0+W)(z)},$$

we have

$$\begin{aligned}(U_0+W)\frac{1-H_1(U_0+W)(z)}{1+\gamma H_1(U_0+W)(z)} = {} & U_0\frac{1-H_1(U_0)}{1+\gamma H_1(U_0)}\\ & +W\frac{1-H_1(U_0)}{1+\gamma H_1(U_0)}-\frac{(1+\gamma)\ U_0}{(1+\gamma H_1(U_0))^2}H_1(W)\\ & +R_1(z,\tau,W),\end{aligned} \tag{4.4}$$

where $R_1(z,\tau,W)$ is the remainder (higher order terms) of this expansion, and this can be rewritten as

$$\begin{aligned}R_1(z,\tau,W) = {} & (U_0+W)\frac{1-H_1(U_0+W)(z)}{1+\gamma H_1(U_0+W)(z)}\\ & -U_0\frac{1-H_1(U_0)}{1+\gamma H_1(U_0)}\\ & -W\frac{1-H_1(U_0)}{1+\gamma H_1(U_0)}+\frac{(1+\gamma)U_0}{(1+\gamma H_1(U_0))^2}H_1(W).\end{aligned} \tag{4.5}$$

Recall that

$$g(x)=x\frac{1-x}{1+\gamma x}\ \text{ and } g'(x)=\frac{1-x}{1+\gamma x}-\frac{(1+\gamma)x}{(1+\gamma x)^2}.$$

Therefore, in view of (4.4), (4.3) becomes

$$\begin{aligned}-cW' = {} & W''+g'(U_0(z))W(z)\\ & +\ R_1(z,\tau,W)+R_2(z,\tau)+R_3(z,\tau,W),\end{aligned} \tag{4.6}$$

where

$$R_2(z,\tau)=U_0\frac{1-H_1(U_0)}{1+\gamma H_1(U_0)}-\ g(U_0)$$

and

$$R_3(z,\tau,W)=\ W\frac{1-H_1(U_0)}{1+\gamma H_1(U_0)}-\frac{(1+\gamma)U_0}{(1+\gamma H_1(U_0))^2}H_1(W)-g'(U_0(z))W(z).$$

As before, we transform (4.6) into the following integral equation

$$W=\frac{1}{\lambda_2-\lambda_1}\begin{pmatrix}\int_{-\infty}^{z}e^{\lambda_1(z-s)}\left[(1+g'(U_0(s)))W(s)+R_1+R_2+R_3\right]ds\\ +\int_{z}^{\infty}e^{\lambda_2(z-s)}\left[(1+g'(U_0(s)))W(s)+R_1+R_2+R_3\right]ds\end{pmatrix}. \tag{4.7}$$

Now the above argument can be repeated to show that Theorem 2.6 holds for (4.1).

Similarly, we can prove Theorem 2.6 for (1.1) with the kernel function

$$f(t,s,x,y)=\frac{1}{\tau}e^{-(t-s)}\frac{1}{\sqrt{4\pi(t-s)}}e^{-(x-y)^2/(4(t-s))}. \tag{4.8}$$

5. Traveling wavefronts with large wave speed. In section 2, we obtained a traveling wavefront for our model by assuming that the maturation time τ is small. In this section we utilize the idea of Canosa [6] to investigate the existence of traveling wavefront for (2.1) without the smallness requirement of τ. Although the method is originally a formal asymptotic analysis as the front speed approaches infinity, it is known that for Fisher's equation the method generates a solution that is accurate within a few percent of the true solution, even at the minimum speed. The method has also been applied to other reaction-diffusion equations, including coupled systems, with a very good accuracy; see [21] and [24]. The main purpose here is to give a theoretical justification of the method for our food-limited model by showing the fact that when the wave speed tends to infinity, our traveling wavefront approaches a heteroclinic solution (the leading term of Canosa's expansions) of the original model without diffusion. The main idea of this section is from [9], except that we use some known results of global stability of the positive equilibrium instead of applying Smith and Thieme's order preserving semiflows theory [26].

Linearizing (2.7) for U far ahead of the front, where $U \to 0$, gives

$$-cU'(z) = U''(z) - U(z).$$

To ensure that we are studying ecologically realistic fronts that are positive for all values of z, we assume, as in Fisher's equation, that the wave speed $c \geq 2$. Following Canosa's approach, we introduce the small parameter

$$\varepsilon = 1/c^2 \leq \frac{1}{4}$$

and seek a solution of the form

$$U(z) = G(\zeta), \quad \zeta = \sqrt{\varepsilon} z.$$

Equation (2.7) becomes

$$\varepsilon G'' + G' + G \frac{1 - \int_{-\infty}^{\infty} \frac{1}{\sqrt{4\pi\tau}} e^{-y^2/4\tau} G(\zeta - \sqrt{\varepsilon} y + \tau) dy}{1 + \gamma \int_{-\infty}^{\infty} \frac{1}{\sqrt{4\pi\tau}} e^{-y^2/4\tau} G(\zeta - \sqrt{\varepsilon} y + \tau) dy} = 0. \tag{5.1}$$

When $\varepsilon = 0$, (5.1) reduces to

$$G' + G \frac{1 - G(\zeta + \tau)}{1 + \gamma G(\zeta + \tau)} = 0. \tag{5.2}$$

For (5.2), we have the following result concerning the heteroclinic orbit connecting the two equilibria $G = 0$ and $G = 1$.

THEOREM 5.1. *Assume $\tau/(1+\gamma) < \frac{3}{2}$. Then* (5.2) *has a heteroclinic orbit $g_0(\zeta)$ connecting the two equilibria $G = 1$ and $G = 0$.*

Proof. When $\varepsilon = 0$, we set $g_0(\zeta) = G(-\zeta)$ to invert (5.2) into a delay differential equation

$$g_0' = g_0 \frac{1 - g_0(\zeta - \tau)}{1 + \gamma g_0(\zeta - \tau)}. \tag{5.3}$$

By the result in [18] or [8], we know that the equilibrium $g_0 = 1$ is a global attractor as long as the initial value $g_0(s) = \phi(s)$, $s \in [-\tau, 0]$, satisfies

$$\phi(0) > 0 \text{ and } \phi(s) \geq 0 \text{ for s} \in [-\tau, 0].$$

Linearizing (5.3) around $g_0 = 0$, we have

$$g_0' = g_0. \tag{5.4}$$

Therefore, the unstable space E_u of the trivial solution in the usual phase space $C_\tau = C([-\tau, 0]; R)$ of continuous functions equipped with the sup-norm $||\cdot||$ is spanned by $\chi(s) = e^s, s \in [-\tau, 0]$. Let E_s be the subspace in C_τ so that $C_\tau = E_s \oplus E_u$; then there exists $\epsilon_0 > 0$ and a C^1-map $w : E_u \to E_s$, with $w(0) = 0$ and $Dw(0) = 0$ so that a local unstable manifold of $g_0 = 0$ is given by $\epsilon\chi + w(\epsilon\chi)$ for $\epsilon \in (-\epsilon_0, \epsilon_0)$. Choose $\epsilon_0 > 0$ sufficiently small so that the operator norm $||Dw(\epsilon\chi)|| < e^{-\tau}$ for $\epsilon \in (0, \epsilon_0)$. Then pick up $\epsilon \in (0, \epsilon_0)$ and consider $\phi = \epsilon\chi + w(\epsilon\chi)$. We have

$$\phi(s) = \epsilon e^s + w(\epsilon\chi)(s) > \epsilon e^s - e^{-\tau}\epsilon||\chi|| \geq \epsilon(e^{-\tau} - e^{-\tau}) \geq 0.$$

So the solution from the point ϕ on the local unstable manifold of $g_0 = 0$ is positive and tends to 1 due to the global attractivity of the positive equilibrium $g_0 = 1$. Returning to the original variable, we have an orbit G connecting the two equilibria $G = 1$ and $G = 0$. This completes the proof. ∎

For (5.3), the positive equilibrium 1 is a node, and all of the conditions in Theorem 1.1 in [9] are satisfied. Thus direct application of this result gives the following.

THEOREM 5.2. *Assume $\tau/(1+\gamma) < \frac{3}{2}$. There is a constant $c^* > 0$ such that for any $c > c^*$,* (5.1) *has a traveling wave solution $G(x - ct)$ connecting the two equilibria* 0 *and* 1. *When the wave speed $c \to \infty$, the wave profile $G(\xi)$ converges to a solution to* (5.2).

Although the result is a consequence of Theorem 1.1 in [9], for the completeness of this paper and the convenience of readers, we outline the proof of this theorem as follows.

For (5.1), set $\bar{G}(\zeta) = G(-\zeta)$. Then $\bar{G}$ satisfies the equation

$$\varepsilon\bar{G}'' - \bar{G}' + \bar{G}\frac{1 - \int_{-\infty}^{\infty}\frac{1}{\sqrt{4\pi\tau}}e^{-y^2/4\tau}\bar{G}(\zeta + \sqrt{\varepsilon}y - \tau)dy}{1 + \gamma\int_{-\infty}^{\infty}\frac{1}{\sqrt{4\pi\tau}}e^{-y^2/4\tau}\bar{G}(\zeta + \sqrt{\varepsilon}y - \tau)dy} = 0.$$

Now when ε is small, we use g_0 to approximate the wavefront $\bar{G}(\zeta)$ in (5.1). Let $\bar{G} = g_0 + W$. Then we have an equation for W

$$W' = \varepsilon W'' + \varepsilon g_0'' + (g_0 + W)\frac{1 - h_1(g_0 + W)}{1 + \gamma h_1(g_0 + W)} - g_0\frac{1 - g_0(\zeta - \tau)}{1 + \gamma g_0(\zeta - \tau)}, \tag{5.5}$$

where the functional h_1 is given by

$$h_1[U](\zeta) = \int_{-\infty}^{\infty}\frac{1}{\sqrt{4\pi\tau}}e^{-\eta^2/4\tau}U(\zeta + \sqrt{\varepsilon}\eta - \tau)d\eta. \tag{5.6}$$

By means of Taylor's expansion, we have

$$\begin{aligned}(g_0 + W)\frac{1 - h_1(g_0 + W)(\zeta)}{1 + \gamma h_1(g_0 + W)(\zeta)} = \;& g_0\frac{1 - h_1(g_0)}{1 + \gamma h_1(g_0)} \\ & + W\frac{1 - h_1(g_0)}{1 + \gamma h_1(g_0)} - \frac{(1+\gamma)g_0}{(1 + \gamma h_1(g_0))^2}h_1(W) \\ & + R_1(\zeta, \tau, W),\end{aligned} \tag{5.7}$$

where $R_1(\zeta,\tau,W)$ is the remainder (higher order terms) of this expansion. Therefore by (5.7), (5.5) becomes

$$W' = \varepsilon W'' + P^0 W(z) + R_1(\zeta,\tau,W) + R_2(\zeta,\tau) + R_3(\zeta,\tau,W), \tag{5.8}$$

where the linear operator $P^0 : C \to C$ is defined by

$$\begin{aligned}
P^0 W(\zeta) &= \frac{1-g_0(\zeta-\tau)}{1+\gamma g_0(\zeta-\tau)} W(\zeta) - g_0 \frac{(1+\gamma)}{(1+\gamma g_0(\zeta-\tau))^2} W(\zeta-\tau),\\
R_2(\zeta,\tau) &= g_0 \frac{1-h_1(g_0)}{1+\gamma h_1(g_0)} - g_0 \frac{1-g_0(\zeta-\tau)}{1+\gamma g_0(\zeta-\tau)} + \varepsilon g_0'',
\end{aligned}$$

and

$$\begin{aligned}
R_3(\zeta,\tau,W) = {} & W \frac{1-h_1(g_0)}{1+\gamma h_1(g_0)} - g_0 \frac{(1+\gamma)}{(1+\gamma h_1(g_0))^2} h_1(W)\\
& - W \frac{1-g_0(\zeta-\tau)}{1+\gamma g_0(\zeta-\tau)} + g_0 \frac{(1+\gamma)}{(1+\gamma g_0(\zeta-\tau))^2} h_1(W).
\end{aligned}$$

Now we prove that there exists a $W \in C_0$ satisfying (5.8) when ε is small. Equation (5.8) can be transformed into an integral equation as follows. We first write (5.8) as

$$\varepsilon W'' - W' - W = -W - P^0 W - R_1 - R_2 - R_3. \tag{5.9}$$

Since the equation

$$\varepsilon \lambda^2 - \lambda - 1 = 0$$

has two real zeros λ_1 and λ_2, with

$$\lambda_1 = \frac{1-\sqrt{1+4\varepsilon}}{2\varepsilon} < 0, \quad \lambda_2 = \frac{1+\sqrt{1+4\varepsilon}}{2\varepsilon} > 0, \tag{5.10}$$

(5.9) is equivalent to the integral equation

$$\begin{aligned}
W(\zeta) = {} & \frac{1}{\sqrt{1+4\varepsilon}} \int_{-\infty}^{\zeta} e^{\lambda_1(\zeta-t)} [W(t) + P^0 W(t)] dt\\
& + \frac{1}{\sqrt{1+4\varepsilon}} \int_{\zeta}^{\infty} e^{\lambda_2(\zeta-t)} [W(t) + P^0 W(t)] dt\\
& + \frac{1}{\sqrt{1+4\varepsilon}} \int_{-\infty}^{\zeta} e^{\lambda_1(\zeta-t)} [R_1 + R_2 + R_3] dt\\
& + \frac{1}{\sqrt{1+4\varepsilon}} \int_{\zeta}^{\infty} e^{\lambda_2(\zeta-t)} [R_1 + R_2 + R_3] dt.
\end{aligned} \tag{5.11}$$

It is easy to show that

$$\lim_{\varepsilon \to 0^+} \lambda_1 = -1, \quad \lim_{\varepsilon \to 0^+} \lambda_2 = +\infty.$$

Thus we have, from (5.11), that

$$
\begin{aligned}
&W(\zeta) - \int_{-\infty}^{\zeta} e^{-(\zeta-t)}[W(t) + P^0W(t)]dt \\
&= \int_{-\infty}^{\zeta} \left[\frac{e^{\lambda_1(\zeta-t)}}{\sqrt{1+4\varepsilon}} - e^{-(\zeta-t)}\right][W(t) + P^0W(t)]dt \\
&\quad + \frac{1}{\sqrt{1+4\varepsilon}} \int_{\zeta}^{\infty} e^{\lambda_2(\zeta-t)}[W(t) + P^0W(t)]dt \\
&\quad + \frac{1}{\sqrt{1+4\varepsilon}} \int_{-\infty}^{\zeta} e^{\lambda_1(\zeta-t)}[R_1 + R_2 + R_3\ ]dt \\
&\quad + \frac{1}{\sqrt{1+4\varepsilon}} \int_{\zeta}^{\infty} e^{\lambda_2(\zeta-t)}[R_1 + R_2 + R_3]dt. \qquad (5.12)
\end{aligned}
$$

For the right-hand side of (5.12), in a similar manner as in section 2, we can prove that

$$\int_{-\infty}^{\zeta} \left[\frac{e^{\lambda_1(\zeta-t)}}{\sqrt{1+4\varepsilon}} - e^{-(\zeta-t)}\right][W(t) + P^0W(t)]dt = O(\sqrt{\varepsilon}||W||_{C_0}),$$

$$\frac{1}{\sqrt{1+4\varepsilon}} \int_{\zeta}^{\infty} e^{\lambda_2(\zeta-t)}[W(t) + P^0W(t)]dt = O(\sqrt{\varepsilon}||W||_{C_0}),$$

$$\frac{1}{\sqrt{1+4\varepsilon}} \left(\int_{-\infty}^{\zeta} e^{\lambda_1(\zeta-t)}R_1\ dt + \int_{\zeta}^{\infty} e^{\lambda_2(\zeta-t)}R_1 dt\right) = O(||W||^2),$$

$$\frac{1}{\sqrt{1+4\varepsilon}} \left(\int_{-\infty}^{\zeta} e^{\lambda_1(\zeta-t)}R_2\ dt + \int_{\zeta}^{\infty} e^{\lambda_2(\zeta-t)}R_2 dt\right) = O(\sqrt{\varepsilon}),$$

and

$$\frac{1}{\sqrt{1+4\varepsilon}} \left(\int_{-\infty}^{\zeta} e^{\lambda_1(\zeta-t)}R_3\ dt + \int_{\zeta}^{\infty} e^{\lambda_2(\zeta-t)}R_3 dt\right) = O(\sqrt{\varepsilon}||W||_{C_0}).$$

Let L be the linear operator defined by the left-hand side of (5.12), namely,

$$[LW](\zeta) = W(\zeta) - \int_{-\infty}^{\zeta} e^{-(\zeta-t)}[W(t) + P^0W(t)]dt.$$

It is obvious that if $W \in C_0$, then $LW \in C_0$. In order to use the argument in section 2 to prove our result, we need to prove that $\Re(L) = C_0$, where $\Re(L)$ is the range space of L; that is, for each $u \in C_0$, we need to show that equation $LW = u$ or, equivalently,

$$W(\zeta) - \int_{-\infty}^{\zeta} e^{-(\zeta-t)}[W(t) + P^0W(t)]dt = u(\zeta), \quad \zeta \in (-\infty, \infty)$$

has a solution in C_0. For this purpose, we set $w = W - u$. Upon substitution, we have an equation for w :

$$w' = P^0w(\zeta) + u(\zeta) + P^0u(\zeta). \tag{5.13}$$

Define an operator $T : C_0^1 \to C_0$ by

$$[Tw](\zeta) = w'(\zeta) - P^0w(\zeta)$$

and the formal adjoint equation of $Tw = 0$ by

$$\phi'(t) = -\frac{1 - g_0(t-\tau)}{1+\gamma g_0(t-\tau)}\phi(t) + \frac{g_0(1+\gamma)}{(1+\gamma g_0(t-\tau))^2}\phi\,(t+\tau)\,,\ t \in (-\infty, \infty). \tag{5.14}$$

When $t \to \infty$, (5.14) tends asymptotically to

$$\phi'(t) = \frac{1}{1+\gamma}\phi(t+\tau).$$

When $\tau/(1+\gamma) < \frac{\pi}{2}$, it is easy to see that if ϕ is a bounded solution to (5.14), then $\phi = 0$. From p. 7 of Chow, Lin, and Mallet-Paret [5], we see that T is Fredholm and $\Re(T) = C_0$. Therefore, (5.13) has a solution $w \in C_0$. From now on we can use the same argument as in sections 4 and 5 in [9] to verify that (5.12) has a solution $W \in C_0$.

6. Summary and simulations. In this paper we have studied the existence of traveling wavefronts for the food-limited population model that involves nonmonotone delayed nonlocal response. The classical phase-plane approach or super/subsolution technique does not work for this type of model due to the lack of monotonicity. Hence, we develop a perturbation argument based on some analytical tools such as the contraction mapping principle and the Fredholm theory to establish the existence of traveling wavefronts. We consider three cases with spatiotemporal averaging when the delay is small. In the general case where the smallness condition on the delay is no longer required, we also developed Canosa's method to establish traveling wavefronts with large wave speeds.

Our work shows how our perturbation analyses based on some analytical tools are particularly useful for models with small delay or for wavefronts with large wave speeds. We believe the smallness condition on τ and the largeness condition on the wave speed can be removed by a certain homotopy argument, and this remains to be a subject for future study.

We should emphasize the difficulty caused by the nonmonotonicity of the delayed nonlocal response. In particular, we note that the traveling wavefronts obtained have prominent humps as the following two numerical simulations show.

The first numerical simulation, reported in Figure 1, is for (2.1), carried out by using Matlab on a spatial domain $-L_0 \le x \le L_0$ (for some $L_0 > 0$) with homogeneous Neumann boundary conditions at both ends. For initial data, we set a nonzero steady state value 1 at the left side and zero elsewhere for all $t \in [-\tau, 0]$. The solution stabilizes to a wavefront when time t goes on. For τ sufficiently small, the resulting traveling fronts appear to be strictly monotone. Increasing the value τ, we find that the monotonicity is lost and a prominent hump is exhibited. When $\gamma = 1$ and $\tau = 2$, the solutions at two different times are shown in Figure 1.

The second numerical simulation is about (4.1) with the kernel given by (4.8). Set

$$v(t,x) = \int_{-\infty}^{t} \frac{1}{\tau}e^{-(t-s)} \int_{-\infty}^{\infty} \frac{1}{\sqrt{4\pi(t-s)}} e^{-(x-y)^2/(4(t-s))} u(s,y)dyds.$$

Then it is easy to recast (1.1) into the form

$$\begin{cases} u_t = u_{xx} + u\frac{1-v}{1+\gamma v} \\ v_t = v_{xx} + \frac{1}{\tau}(u-v). \end{cases}$$

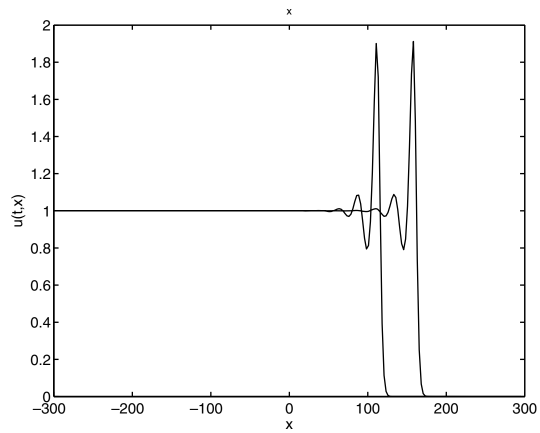

FIG. 1. $\gamma = 1, \tau = 2$. *There exists a prominent hump in the front.*

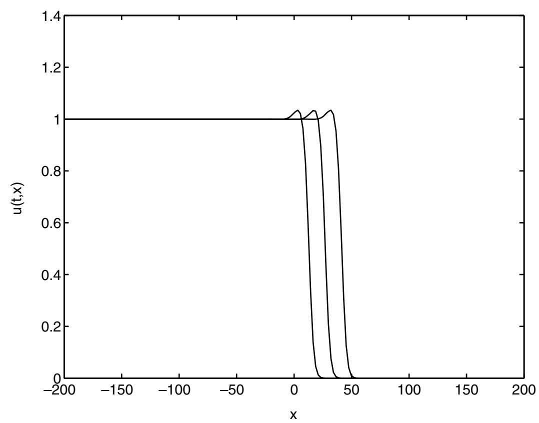

FIG. 2. $\gamma = 1, \tau = 1$. *There exists a prominent hump in the front.*

Using the method of lines, we find again the solution to the above equations with step initial functions and the Neumann boundary conditions stabilizes to a wavefront with a hump. The solution pattern at three different times with $\gamma = 1, \tau = 1$ are shown in Figure 2.

Acknowledgment. We thank the reviewers whose constructive comments lead to a significant improvement of the manuscript.

EXISTENCE, UNIQUENESS, AND REGULARITY OF OPTIMAL TRANSPORT MAPS*

ALESSIO FIGALLI†

Abstract. Adapting some techniques and ideas of McCann [*Duke Math. J.*, 80 (1995), pp. 309–323], we extend a recent result with Fathi [*Optimal Transportation on Manifolds*, preprint] to yield existence and uniqueness of a unique transport map in very general situations, without any integrability assumption on the cost function. In particular this result applies for the optimal transportation problem on an n-dimensional noncompact manifold M with a cost function induced by a C^2-Lagrangian, provided that the source measure vanishes on sets with σ-finite $(n-1)$-dimensional Hausdorff measure. Moreover we prove that in the case $c(x, y) = d^2(x, y)$, the transport map is approximatively differentiable a.e. with respect to the volume measure, and we extend some results of [D. Cordero-Erasquin, R. J. McCann, and M. Schmuckenschlager, *Invent. Math.*, 146 (2001), pp. 219–257] about concavity estimates and displacement convexity.

Key words. optimal transportation, existence, uniqueness, approximate differentiability, concavity estimate, displacement convexity

1. Introduction and main result.

Let M be an n-dimensional manifold (Hausdorff and with a countable basis), N a Polish space, $c : M \times N \to \mathbb{R}$ a cost function, and μ and ν two probability measures on M and N, respectively.

In a recent work with Fathi [6], we proved, under general assumption on the cost function, existence and uniqueness of optimal transport maps for the Monge–Kantorovich problem. More precisely, the result is as follows.

THEOREM 1.1. *Assume that $c : M \times N \to \mathbb{R}$ is lower semicontinuous, bounded from below, and such that*

$$\int_{M\times N} c(x, y)\, d\mu(x)\, d\nu(y) < +\infty.$$

If

(i) *$x \mapsto c(x, y) = c_y(x)$ is locally semiconcave in x locally uniformly in y;*
(ii) *$\frac{\partial c}{\partial x}(x, \cdot)$ is injective on its domain of definition;*
(iii) *and the measure μ gives zero mass to sets with σ-finite $(n-1)$-dimensional Hausdorff measure,*

then there exists a measurable map $T : M \to N$ such that any plan γ optimal for the cost c is concentrated on the graph of T.

More precisely, there exists a sequence of Borel subsets $B_n \subset M$, with $B_n \subset B_{n+1}$, $\mu(B_n) \nearrow 1$, and a sequence of locally semiconcave functions $\varphi_n : M \to \mathbb{R}$, where φ_n is differentiable on B_n, such that, thanks to assumption (ii)*, the map $T : M \to N$ is uniquely defined on B_n by*

$$\frac{\partial c}{\partial x}(x, T(x)) = d_x\varphi_n. \tag{1}$$

This implies both existence of an optimal transport map and uniqueness for the Monge problem.

Now we want to generalize this existence and uniqueness result for optimal transport maps without any integrability assumption on the cost function, adapting the ideas of [8]. We observe that, without the hypothesis

$$\int_{M\times N} c(x,y)\,d\mu(x)\,d\nu(y) < +\infty,$$

denoting with $\Pi(\mu,\nu)$ the set of probability measures on $M\times N$ whose marginals are μ and ν, in general the minimization problem

$$C(\mu,\nu) := \inf_{\gamma\in\Pi(\mu,\nu)} \left\{ \int_{M\times N} c(x,y)\,d\gamma(x,y) \right\} \tag{2}$$

is ill-posed, as it may happen that $C(\mu,\nu) = +\infty$. However, it is known that the optimality of a transport plan γ is equivalent to the c-cyclical monotonicity of the measure-theoretic support of γ whenever $C(\mu,\nu) < +\infty$ (see [2], [11], [13]), and so one may ask whether the fact that the measure-theoretic support of γ is c-cyclically monotone implies that γ is supported on a graph. Moreover one can also ask whether this graph is unique, that is, it does not depend on γ, which is the case when the cost is $\mu\otimes\nu$ integrable, as Theorem 1.1 tells us. In that case, uniqueness follows by the fact that the functions φ_n are constructed using a pair of functions (φ,ψ) which is optimal for the dual problem, and so they are independent of γ (see [6] for more details). The result we now want to prove is the following.

THEOREM 1.2. *Assume that $c : M\times N \to \mathbb{R}$ is lower semicontinuous and bounded from below, and let γ be a plan concentrated on a c-cyclically monotone set. If*

(i) *the family of maps $x \mapsto c(x,y) = c_y(x)$ is locally semiconcave in x locally uniformly in y;*
(ii) *$\frac{\partial c}{\partial x}(x,\cdot)$ is injective on its domain of definition;*
(iii) *and the measure μ gives zero mass to sets with σ-finite $(n-1)$-dimensional Hausdorff measure,*

then γ is concentrated on the graph of a measurable map $T : M \to N$ (existence). Moreover, if $\tilde\gamma$ is another plan concentrated on a c-cyclically monotone set, then $\tilde\gamma$ is concentrated on the same graph (uniqueness).

Once the above result is proven, the uniqueness of the Wasserstein geodesic between absolutely continuous measures will follow as a simple corollary (see section 3). Finally, in subsection 3.1, we will prove that in the particular case $c(x,y) = \frac{1}{2}d^2(x,y)$, the optimal transport map is approximatively differentiable a.e. with respect to the volume measure, and we will obtain a concavity estimate on the Jacobian of the optimal transport map, which will allows us to generalize to noncompact manifolds a displacement convexity result proven in [4].

2. Proof of Theorem 1.2.

Existence. We want to prove that γ is concentrated on a graph. First we recall that since γ is concentrated on a c-cyclically monotone set, there exists a pair of functions (φ,ψ), with φ μ-measurable and ψ ν-measurable, such that

$$\varphi(x) = \inf_{y\in N} \psi(y) + c(x,y) \quad \forall x\in M,$$

which implies

$$\varphi(x) - \psi(y) \le c(x,y) \quad \forall (x,y)\in M\times N.$$

Moreover we have

$$\varphi(x) - \psi(y) = c(x,y) \quad \gamma\text{-a.e.} \tag{3}$$

and there exists a point $x_0 \in M$ such that $\varphi(x_0) = 0$ (see [13, Theorem 5.9]). In particular, this implies

$$\psi(y) \geq -c(x_0,y) > -\infty \quad \forall y \in N.$$

So, we can argue as in [6]. More precisely, given a suitable increasing sequence of compact sets $(K_n) \subset N$ such that $\nu(K_n) \nearrow 1$ and $\psi \geq -n$ on K_n (it suffices to take an increasing sequence of compact sets $K_n \subset \{\psi \geq -n\}$ such that $\nu(\{\psi \geq -n\} \setminus K_n) \leq \frac{1}{n}$), we consider the locally semiconcave function

$$\varphi_n(x) := \inf_{y \in K_n} \psi(y) + c(x,y). \tag{4}$$

Then, thanks to (3), it is possible to find an increasing sequence of Borel sets $D_n \subset \operatorname{supp}(\mu)$, with $\mu(D_n) \nearrow 1$, such that φ_n is differentiable on D_n, $\varphi_n \equiv \varphi$ on D_n, the set $\{\varphi_n = \varphi\}$ has μ-density 1 at all the points of D_n, and γ is concentrated on the graph of the map T uniquely determined on D_n by

$$\frac{\partial c}{\partial x}(x, T(x)) = d_x\varphi_n \quad \text{for } x \in D_n.$$

Moreover one has

$$\varphi(x) = \psi(T(x)) + c(x, T(x)) \quad \forall x \in \bigcup_n D_n \tag{5}$$

(see [6] for more details).

Uniqueness. As we observed before, the difference here with the case of Theorem 1.1 is that the function φ_n depends on the pair (φ, ψ), which in this case depends on γ. Let $(\tilde{\varphi}, \tilde{\psi})$ be a pair associated to $\tilde{\gamma}$ as above, and let $\tilde{\varphi}_n$ and $\tilde{D}_n$ be such that $\tilde{\gamma}$ is concentrated on the graph of the map $\tilde{T}$ determined on $\tilde{D}_n$ by

$$\frac{\partial c}{\partial x}(x, \tilde{T}(x)) = d_x\tilde{\varphi}_n \quad \text{for } x \in \tilde{D}_n.$$

We need to prove that $T = \tilde{T}$ μ-a.e.

Let us define $C_n := D_n \cap \tilde{D}_n$. Then $\mu(C_n) \nearrow 1$. We want to prove that if x is a μ-density point of C_n for a certain n, then $T(x) = \tilde{T}(x)$ (we recall that since $\mu(\cup_n C_n) = 1$, the union of the μ-density points of C_n is also of full μ-measure; see, for example, [5, Chapter 1.7]).

Let us assume by contradiction that $T(x) \neq \tilde{T}(x)$, that is,

$$d_x\varphi_n \neq d_x\tilde{\varphi}_n.$$

Since $x \in \operatorname{supp}(\mu)$, each ball around x must have positive measure under μ. Moreover, the fact that the sets $\{\varphi_n = \varphi\}$ and $\{\tilde{\varphi}_n = \tilde{\varphi}\}$ have μ-density 1 in x implies that the set

$$\{\varphi = \tilde{\varphi}\}$$

has μ-density 0 in x. In fact, as φ_n and $\tilde{\varphi}_n$ are locally semiconcave, up to adding a C^1 function they are concave in a neighborhood of x and their gradients differ at x. So we can apply the nonsmooth version of the implicit function theorem proven in [8], which tells us that $\{\varphi_n = \tilde{\varphi}_n\}$ is a set with finite $(n-1)$-dimensional Hausdorff measure in a neighborhood of x (see [8, Theorem 17 and Corollary 19]). So we have

$$\limsup_{r\to 0} \frac{\mu(\{\varphi = \tilde{\varphi}\} \cap B_r(x))}{\mu(B_r(x))} \le \limsup_{r\to 0} \Bigg[\frac{\mu(\{\varphi \ne \varphi_n\} \cap B_r(x))}{\mu(B_r(x))} + \frac{\mu(\{\varphi_n = \tilde{\varphi}_n\} \cap B_r(x))}{\mu(B_r(x))} + \frac{\mu(\{\tilde{\varphi}_n \ne \tilde{\varphi}\} \cap B_r(x))}{\mu(B_r(x))} \Bigg] = 0.$$

Therefore, exchanging φ with $\tilde{\varphi}$ if necessary, we may assume that

$$\mu(\{\varphi < \tilde{\varphi}\} \cap B_r(x)) \ge \frac{1}{4}\mu(B_r(x)) \quad \text{for } r > 0 \text{ sufficiently small.} \tag{6}$$

Let us define $A := \{\varphi < \tilde{\varphi}\}$, $A_n := \{\varphi_n < \tilde{\varphi}_n\}$, $E_n := A \cap A_n \cap C_n$. Since the sets $\{\varphi_n = \varphi\}$ and $\{\tilde{\varphi}_n = \tilde{\varphi}\}$ have μ-density 1 in x, and x is a μ-density point of C_n, we have

$$\lim_{r\to 0} \frac{\mu((A \setminus E_n) \cap B_r(x))}{\mu(B_r(x))} = 0,$$

and so, by (6), we get

$$\mu(E_n \cap B_r(x)) \ge \frac{1}{5}\mu(B_r(x)) \quad \text{for } r > 0 \text{ sufficiently small.} \tag{7}$$

Now, arguing as in the proof of Aleksandrov's lemma (see [8, Lemma 13]), we can prove that

$$X := \tilde{T}^{-1}(T(A)) \subset A$$

and $X \cap E_n$ lies a positive distance from x. In fact let us assume, without loss of generality, that

$$\varphi(x) = \varphi_n(x) = \tilde{\varphi}(x) = \tilde{\varphi}_n(x) = 0, \quad d_x\varphi_n \ne d_x\tilde{\varphi}_n = 0.$$

To obtain the inclusion $X \subset A$, let $z \in X$ and $y := \tilde{T}(z)$. Then $y = T(m)$ for a certain $m \in A$. For any $w \in M$, recalling (5), we have

$$\varphi(w) \le c(w, y) - c(m, y) + \varphi(m),$$

$$\tilde{\varphi}(m) \le c(m, y) - c(z, y) + \tilde{\varphi}(z).$$

Since $\varphi(m) < \tilde{\varphi}(m)$ we get

$$\varphi(w) < c(w, \tilde{T}(z)) - c(z, \tilde{T}(z)) + \tilde{\varphi}(z) \quad \forall w \in M.$$

In particular, taking $w = z$, we obtain $z \in A$, which proves the inclusion $X \subset A$.

Let us suppose now, by contradiction, that there exists a sequence $(z_k) \subset X \cap E_n$ such that $z_k \to x$. Again there exists m_k such that $\tilde{T}(z_k) = T(m_k)$. As $d_x\tilde{\varphi}_n = 0$, the closure of the superdifferential of a semiconcave function implies that $d_{z_k}\tilde{\varphi}_n \to 0$. We now observe that, arguing exactly as above with φ_n and $\tilde{\varphi}_n$ instead of φ and $\tilde{\varphi}$, by using (4), (5), and the fact that $\varphi = \varphi_n$ and $\tilde{\varphi} = \tilde{\varphi}_n$ on C_n, one obtains

$$\varphi_n(w) < c(w, \tilde{T}(z_k)) - c(z_k, \tilde{T}(z_k)) + \tilde{\varphi}_n(z_k) \quad \forall w \in M.$$

Taking w sufficiently near to x, we can assume that we are in $\mathbb{R}^n \times N$. We now remark that since $z_k \in E_n \subset \tilde{D}_n$, $\tilde{T}(z_k)$ vary in a compact subset of N (this follows by the construction of $\tilde{T}$). So, by hypothesis (i) on c, we can find a common modulus of continuity ω in a neighborhood of x for the family of uniformly semiconcave functions $z \mapsto c(z, \tilde{T}(z_k))$. Then we get

$$\begin{aligned}\varphi_n(w) &< \frac{\partial c}{\partial x}(z_k, \tilde{T}(z_k))(w - z_k) + \omega(|w - z_k|)|w - z_k| + \tilde{\varphi}_n(z_k) \\ &= d_{z_k}\tilde{\varphi}_n(w - z_k) + \omega(|w - z_k|)|w - z_k| + \tilde{\varphi}_n(z_k).\end{aligned}$$

Letting $k \to \infty$ and recalling that $d_{z_k}\tilde{\varphi}_n \to 0$ and $\tilde{\varphi}_n(x) = \varphi_n(x) = 0$, we obtain

$$\varphi_n(w) - \varphi_n(x) \le \omega(|w - x|)|w - x| \Rightarrow d_x\varphi_n = 0,$$

which is absurd.

Thus there exists $r > 0$ such that $B_r(x) \cap E_n$ and $X \cap E_n$ are disjoint, and (7) holds. Defining now $Y := T(A)$, by (7) we obtain

$$\begin{aligned}\nu(Y) = \mu(T^{-1}(Y)) \ge \mu(A) = \mu(E_n) + \mu(A \setminus E_n) \ge \mu(B_r(x) \cap E_n) \\ + \mu(X \cap E_n) + \mu(X \setminus E_n) = \mu(B_r(x) \cap E_n) + \mu(X) \ge \frac{1}{5}\mu(B_r(x)) + \nu(Y),\end{aligned}$$

which is absurd. □

Let us now consider the special case $N = M$, with M a complete manifold. As shown in [6], this theorem applies in the following cases:

1. $c : M \times M \to \mathbb{R}$ is defined by

$$c(x, y) := \inf_{\gamma(0)=x,\ \gamma(1)=y} \int_0^1 L(\gamma(t), \dot{\gamma}(t))\, dt,$$

where the infimum is taken over all the continuous piecewise C^1 curves, and the Lagrangian $L(x, v) \in C^2(TM, \mathbb{R})$ is C^2-strictly convex and uniform superlinear in v, and verifies a uniform boundedness in the fibers.

2. $c(x, y) = d^p(x, y)$ for any $p \in (1, +\infty)$, where $d(x, y)$ denotes a complete Riemannian distance on M.

Moreover, in the cases above, the following important fact holds.

Remark 2.1. For μ-a.e. x, there exists a unique curve from x to $T(x)$ that minimizes the action. In fact, since $\frac{\partial c}{\partial x}(x, y)$ exists at $y = T(x)$ for μ-a.e. x, the fact that $\frac{\partial c}{\partial x}(x, \cdot)$ is injective on its domain of definition tells us that its velocity at time 0 is μ-a.e. uniquely determined (see [6]).

Let us recall the following definition; see [1, Definition 5.5.1, p. 129].

DEFINITION 2.2 (approximate differential). *We say that $f : M \to \mathbb{R}^m$ has an approximate differential at $x \in M$ if there exists a function $h : M \to \mathbb{R}^m$ differentiable at x such that the set $\{f = h\}$ has density 1 at x with respect to the Lebesgue measure (this just means that the density is 1 in the charts). In this case, the approximate* *value of f at x is defined as $\tilde{f}(x) = h(x)$, and the approximate differential of f at x is defined as $\tilde{d}_x f = d_x h$. It is not difficult to show that this definition makes sense. In fact, neither $h(x)$ nor $d_x h$ depend on the choice of h, provided x is a density point of the set $\{f = h\}$ for the Lebesgue measure.*

We recall that many standard properties of the differential still hold for the approximate differential, such as linearity and additivity. In particular, it is simple to check that the property of being approximatively differentiable is stable by right composition with smooth maps (say C^1), and in this case the standard chain rule formula for the differentials holds. Moreover we remark that it makes sense to speak of approximate differential for maps between manifolds.

In [6], the following formula is proven: In the particular case $c(x, y) = d^2(x, y)$, if μ is absolutely continuous with respect to the Lebesgue measure, then the optimal transport map is given by

$$T(x) = \exp_x[-\tilde{\nabla}_x \varphi],$$

where $\tilde{\nabla}_x \varphi$ denotes the approximate gradient of φ at x, which simply corresponds to the element of $T_x M$ obtained from $\tilde{d}_x \varphi$ using the isomorphism with $T_x^* M$ induced by the Riemannian metric (the above formula generalizes the one found by McCann on compact manifolds; see [10]).

3. The Wasserstein space W_2. Let (M, g) be a smooth complete Riemannian manifold, equipped with its geodesic distance d and its volume measure vol. We denote with $P(M)$ the set of probability measures on M. The space $P(M)$ can be endowed with the so-called Wasserstein distance W_2:

$$W_2(\mu_0, \mu_1)^2 := \min_{\gamma \in \Pi(\mu_0, \mu_1)} \left\{ \int_{M \times M} d^2(x, y)\, d\gamma(x, y) \right\}.$$

The quantity $W_2(\mu_0, \mu_1)$ will be called the *Wasserstein distance of order* 2 between μ_0 and μ_1. It is well known that it defines a metric on $P(M)$ (not necessarily finite), and so one can speak about geodesic in the metric space $(P(M), W_2)$. This space turns out, indeed, to be a length space (see, for example, [12], [13]). Now, whenever $W_2(\mu_0, \mu_1) < +\infty$, we know that any optimal transport plan is supported on a c-cyclical monotone set (see, for example, [2], [11], [13]). We denote with $P^{ac}(M)$ the subset of $P(M)$ that consists of the Borel probability measures on M that are absolutely continuous with respect to vol. Thus, if $\mu_0, \mu_1 \in P^{ac}(M)$ and $W_2(\mu_0, \mu_1) < +\infty$, we know that there exists a unique transport map between μ_0 and μ_1.

PROPOSITION 3.1. *$P^{ac}(M)$ is a geodesically convex subset of $P(M)$. Moreover, if $\mu_0, \mu_1 \in P^{ac}(M)$ and $W_2(\mu_0, \mu_1) < +\infty$, then there is a unique Wasserstein geodesic $\{\mu_t\}_{t \in [0,1]}$ joining μ_0 to μ_1, which is given by*

$$\mu_t = (T_t)_\sharp \mu_0 := (\exp[-t\tilde{\nabla}\varphi])_\sharp \mu_0,$$

where $T(x) = \exp_x[-\tilde{\nabla}_x \varphi]$ is the unique transport map from μ_0 to μ_1, which is optimal for the cost $\frac{1}{2} d^2(x, y)$ (and so also optimal for the cost $d^2(x, y)$). Moreover,

1. *T_t is the unique optimal transport map from μ_0 to μ_t for all $t \in [0, 1]$;*
2. *T_t^{-1} is the unique optimal transport map from μ_t to μ_0 for all $t \in [0, 1]$ (and, if $t \in [0, 1)$, it is countably Lipschitz);*
3. *$T \circ T_t^{-1}$ is the unique optimal transport map from μ_t to μ_1 for all $t \in [0, 1]$ (and, if $t \in (0, 1]$, it is countably Lipschitz).*

Proof. Regarding the fact that $\mu_t \in P^{ac}(M)$ (which corresponds to saying that $P^{ac}(M)$ is geodesically convex) and the countably Lipschitz regularity of the transport maps (i.e., there exists a countable partition of M such that the map is Lipschitz on each set), they follow from the results in [6].

Thanks to the results proved in the last section, the proof of the rest of the proposition is quite standard. In fact, a basic representation theorem (see [13, Corollary 7.20]) states that any Wasserstein geodesic curve necessarily takes the form $\mu_t = (e_t)_{\#}\Pi$, where Π is a probability measure on the set Γ of minimizing geodesics $[0,1] \to M$, and $e_t : \Gamma \to M$ is the evaluation at time t: $e_t(\gamma) := \gamma(t)$. Thus the thesis follows from Remark 2.1. □

The above result tells us that also $(P^{ac}(M), W_2)$ is a length space.

3.1. Regularity, concavity estimate, and a displacement convexity result. We now consider the cost function $c(x,y) = \frac{1}{2}d^2(x,y)$. Let $\mu, \nu \in P^{ac}(M)$ with $W_2(\mu,\nu) < +\infty$, and let us denote with f and g their respective densities with respect to vol. Let

$$T(x) = \exp_x[-\tilde{\nabla}_x \varphi]$$

be the unique optimal transport map from μ to ν.

We recall that locally semiconcave functions with linear modulus admit vol-a.e. a second order Taylor expansion (see [3], [4]). Let us recall the definition of approximate hessian.

Definition 3.2 (approximate hessian). *We say that $f : M \to \mathbb{R}^m$ has a approximate hessian at $x \in M$ if there exists a function $h : M \to \mathbb{R}$ such that the set $\{f = h\}$ has density 1 at x with respect to the Lebesgue measure and h admits a second order Taylor expansion at x, that is, there exists a self-adjoint operator $H : T_xM \to T_xM$ such that*

$$h(\exp_x w) = h(x) + \langle \nabla_x h, w\rangle + \frac{1}{2}\langle Hw, w\rangle + o(\|w\|_x^2).$$

In this case the approximate hessian is defined as $\tilde{\nabla}_x^2 f := H$.

As in the case of the approximate differential, it is not difficult to show that this definition makes sense.

Observing that $d^2(x,y)$ is locally semiconcave with linear modulus (see [6, Appendix]), we get that φ_n is locally semiconcave with linear modulus for each n. Thus we can define μ-a.e. an approximate hessian for φ (see Definition 3.2):

$$\tilde{\nabla}_x^2 \varphi := \nabla_x^2 \varphi_n \quad \text{for } x \in D_n \cap E_n,$$

where D_n was defined in the proof of Theorem 1.2, E_n denotes the full μ-measure set of points where φ_n admits a second order Taylor expansion, and $\nabla_x^2 \varphi_n$ denotes the self-adjoint operator on T_xM that appears in the Taylor expansion on φ_n at x. Let us now consider, for each set $F_n := D_n \cap E_n$, an increasing sequence of compact sets $K_m^n \subset F_n$ such that $\mu(F_n \setminus \cup_m K_m^n) = 0$. We now define the measures $\mu_m^n := \mu \llcorner K_m^n$ and $\nu_m^n := T_\sharp \mu_m^n = (\exp[-\nabla\varphi_n])_\sharp \mu_m^n$, and we renormalize them in order to obtain two probability measures:

$$\hat{\mu}_m^n := \frac{\mu_m^n}{\mu_m^n(M)} \in P_2^{ac}(M), \quad \hat{\nu}_m^n := \frac{\nu_m^n}{\nu_m^n(M)} = \frac{\nu_m^n}{\mu_m^n(M)} \in P_2^{ac}(M).$$

We now observe that T is still optimal. In fact, if this were not the case, we would have

$$\int_{M\times M} c(x,S(x))\,d\hat{\mu}_m^n(x) < \int_{M\times M} c(x,T(x))\,d\hat{\mu}_m^n(x)$$

for a certain S transport map from $\hat{\mu}_m^n$ to $\hat{\nu}_m^n$. This would imply that

$$\int_{M\times M} c(x,S(x))\,d\mu_m^n(x) < \int_{M\times M} c(x,T(x))\,d\mu_m^n(x),$$

and so the transport map

$$\tilde{S}(x) := \begin{cases} S(x) & \text{if } x\in K_m^n, \\ T(x) & \text{if } x\in M\setminus K_m^n \end{cases}$$

would have a cost strictly less than the cost of T, which would contradict the optimality of T.

We will now apply the results of [4] to the compactly supported measures $\hat{\mu}_m^n$ and $\hat{\nu}_m^n$ in order to get information on the transport problem from μ to ν. In what follows we will denote by $\nabla_x d_y^2$ and by $\nabla_x^2 d_y^2$, respectively, the gradient and the hessian with respect to x of $d^2(x,y)$, and by $d_x\exp$ and $d(\exp_x)_v$ the two components of the differential of the map $TM\ni(x,v)\mapsto\exp_x[v]\in M$ (whenever they exist). By [4, Theorem 4.2], we get the following.

THEOREM 3.3 (Jacobian identity a.e.). *There exists a subset $E\subset M$ such that $\mu(E)=1$ and, for each $x\in E$, $Y(x):=d(\exp_x)_{-\tilde{\nabla}_x\varphi}$ and $H(x):=\frac{1}{2}\nabla_x^2 d_{T(x)}^2$ both exist and we have*

$$f(x)=g(T(x))\det[Y(x)(H(x)-\tilde{\nabla}_x^2\varphi)]\neq 0.$$

Proof. It suffices to observe that [4, Theorem 4.2] applied to $\hat{\mu}_m^n$ and $\hat{\nu}_m^n$ gives that, for μ-a.e. $x\in K_m^n$,

$$\frac{f(x)}{\mu_m^n(M)}=\frac{g(T(x))}{\mu_m^n(M)}\det[Y(x)(H(x)-\nabla_x^2\varphi_n)]\neq 0,$$

which implies

$$f(x)=g(T(x))\det[Y(x)(H(x)-\tilde{\nabla}_x^2\varphi)]\neq 0 \quad \text{for } \mu\text{-a.e. } x\in K_m^n.$$

Passing to the limit as $m,n\to+\infty$ we get the result. □

We can thus define μ-a.e. the (weak) differential of the transport map at x as

$$d_xT := Y(x)\big(H(x)-\tilde{\nabla}_x^2\varphi\big).$$

Let us prove now that, indeed, $T(x)$ is approximately differentiable μ-a.e., and that the above differential coincides with the approximate differential of T. In order to prove this fact, let us first make a formal computation. Observe that since the map $x\mapsto\exp_x[-\frac{1}{2}\nabla_x d_y^2]=y$ is constant, we have

$$0=d_x(\exp_x[-\tfrac{1}{2}\nabla_x d_y^2])=d_x\exp[-\tfrac{1}{2}\nabla_x d_y^2]-d(\exp_x)_{-\frac{1}{2}\nabla_x d_y^2}\big(\tfrac{1}{2}\nabla_x^2 d_y^2\big)\quad\forall y\in M,$$

By differentiating (in the approximate sense) the equality $T(x) = \exp[-\tilde{\nabla}_x\varphi]$ and recalling the equality $\tilde{\nabla}_x\varphi = \frac{1}{2}\nabla_x d^2_{T(x)}$, we obtain

$$\begin{aligned}\tilde{d}_x T &= d(\exp_x)_{-\tilde{\nabla}_x\varphi}\big(-\tilde{\nabla}^2_x\varphi\big) + d_x \exp[-\tilde{\nabla}_x\varphi]\\ &= d(\exp_x)_{-\tilde{\nabla}_x\varphi}\big(-\tilde{\nabla}^2_x\varphi\big) + d(\exp_x)_{-\frac{1}{2}\nabla_x d^2_{T(x)}}\big(\tfrac{1}{2}\nabla^2_x d^2_{T(x)}\big)\\ &= d(\exp_x)_{-\tilde{\nabla}_x\varphi}\big(H(x) - \tilde{\nabla}^2_x\varphi\big),\end{aligned}$$

as wanted. In order to make the above proof rigorous, it suffices to observe that for μ-a.e. x, $T(x) \notin cut(x)$, where $cut(x)$ is defined as the set of points $z \in M$ which cannot be linked to x by an extendable minimizing geodesic. Indeed we recall that the square of the distance fails to be semiconvex at the cut locus, that is, if $x \in cut(y)$, then

$$\inf_{0<\|v\|_x<1} \frac{d^2_y(\exp_x[v]) - 2d^2_y(x) + d^2_y(\exp_x[-v])}{|v|^2} = -\infty$$

(see [4, Proposition 2.5]). Now fix $x \in F_n$. Since we know that $\frac{1}{2}d^2(z, T(x)) \geq \varphi_n(z) - \psi(T(x))$ with equality for $z = x$, we obtain a bound from below of the hessian of $d^2_{T(x)}$ at x in terms of the hessian of φ_n at x (see the proof of [4, Proposition 4.1(a)]). Thus, since each φ_n admits vol-a.e. a second order Taylor expansion, we obtain that, for μ-a.e. x,

$$x \notin cut(T(x)), \quad \text{or equivalently} \quad T(x) \notin cut(x).$$

This implies that all the computations we made above in order to prove the formula for $\tilde{d}_x T$ are correct. Indeed the exponential map $(x, v) \mapsto \exp_x[v]$ is smooth if $\exp_x[v] \notin cut(x)$, the function d^2_y is smooth around any $x \notin cut(y)$ (see [4, Paragraph 2]), and $\tilde{\nabla}_x\varphi$ is approximatively differentiable μ-a.e. Thus, recalling that, once we consider the right composition of an approximatively differentiable map with a smooth map, the standard chain rule holds (see the remarks after Definition 2.2), we have proved the following regularity result for the transport map.

Proposition 3.4 (approximate differentiability of the transport map). *The transport map is approximatively differentiable for μ-a.e. x, and its approximate differential is given by the formula*

$$\tilde{d}_x T = Y(x)\big(H(x) - \tilde{\nabla}^2_x\varphi\big),$$

where Y and H are defined in Theorem 3.3.

To prove our displacement convexity result, the following change of variables formula will be useful.

Proposition 3.5 (change of variables for optimal maps). *If $A : [0 + \infty) \to \mathbb{R}$ is a Borel function such that $A(0) = 0$, then*

$$\int_M A(g(y))\, d\,\mathrm{vol}(y) = \int_E A\left(\frac{f(x)}{J(x)}\right) J(x)\, d\,\mathrm{vol}(x),$$

where $J(x) := \det[Y(x)(H(x) - \tilde{\nabla}^2_x\varphi)] = \det[\tilde{d}_x T]$ (*either both integrals are undefined or both take the same value in* $\overline{\mathbb{R}}$).

The proof follows by the Jacobian identity proved in Theorem 3.3, exactly as in [4, Corollary 4.7].

Let us now define for $t \in [0,1]$ the measure $\mu_t := (T_t)_\sharp \mu$, where

$$T_t(x) = \exp_x[-t\tilde{\nabla}_x \varphi].$$

By the results in [6] and Proposition 3.1, we know that T_t coincides with the unique optimal map pushing μ forward to μ_t, and that μ_t is absolutely continuous with respect to vol for any $t \in [0,1]$.

Given $x, y \in M$, following [4], we define for $t \in [0,1]$

$$Z_t(x,y) := \{z \in M \mid d(x,z) = td(x,y) \text{ and } d(z,y) = (1-t)d(x,y)\}.$$

If N is now a subset of M, we set

$$Z_t(x,N) := \cup_{y \in N} Z_t(x,y).$$

Letting $B_r(y) \subset M$ denote the open ball of radius $r > 0$ centered at $y \in M$, for $t \in (0,1]$ we define

$$v_t(x,y) := \lim_{r \to 0} \frac{\mathrm{vol}(Z_t(x, B_r(y)))}{\mathrm{vol}(B_{tr}(y))} > 0$$

(the above limit always exists, though it will be infinite when x and y are conjugate points; see [4]). Arguing as in the proof of Theorem 3.3, by [4, Lemma 6.1] we get the following.

THEOREM 3.6 (Jacobian inequality). *Let E be the set of full μ-measure given by Theorem* 3.3. *Then for each $x \in E$, $Y_t(x) := d(\exp_x)_{-t\tilde{\nabla}_x \varphi}$ and $H_t(x) := \frac{1}{2}\nabla_x^2 d^2_{T_t(x)}$ both exist for all $t \in [0,1]$ and the Jacobian determinant*

$$J_t(x) := \det[Y_t(x)(H_t(x) - t\tilde{\nabla}_x^2 \varphi)] \tag{8}$$

satisfies

$$J_t^{\frac{1}{n}}(x) \geq (1-t)\,[v_{1-t}(T(x),x)]^{\frac{1}{n}} + t\,[v_t(x,T(x))]^{\frac{1}{n}}\, J_1^{\frac{1}{n}}(x).$$

We now consider as source measure $\mu_0 = \rho_0\, d\,\mathrm{vol}(x) \in P^{ac}(M)$ and as target measure $\mu_1 = \rho_1\, d\,\mathrm{vol}(x) \in P^{ac}(M)$, and we assume as before that $W_2(\mu_0, \mu_1) < +\infty$. By Proposition 3.1 we have

$$\mu_t = (T_t)_\sharp[\rho_0\, d\,\mathrm{vol}] = \rho_t\, d\,\mathrm{vol} \in P_2^{ac}(M)$$

for a certain $\rho_t \in L^1(M, d\,\mathrm{vol})$.

We now want to consider the behavior of the functional

$$U(\rho) := \int_M A(\rho(x))\, d\,\mathrm{vol}(x)$$

along the path $t \mapsto \rho_t$. In Euclidean spaces, this path is called *displacement interpolation* and the functional U is said to be *displacement convex* if

$$[0,1] \ni t \mapsto U(\rho_t) \quad \text{is convex for every } \rho_0, \rho_1.$$

A sufficient condition for the displacement convexity of U in $\mathbb{R}^n$ is that $A : [0,+\infty) \to \mathbb{R} \cup \{+\infty\}$ satisfy

$$(0,+\infty) \in s \mapsto s^n A(s^{-n}) \text{ is convex and nonincreasing, with } A(0) = 0 \tag{9}$$

(see [7], [9]). Typical examples include the entropy $A(\rho) = \rho \log \rho$ and the L^q-norm $A(\rho) = \frac{1}{q-1}\rho^q$ for $q \geq \frac{n-1}{n}$.

By all the results collected above, arguing as in the proof of [4, Theorem 6.2], we can prove that the displacement convexity of U is still true on Ricci nonnegative manifolds under the assumption (9).

THEOREM 3.7 (displacement convexity on Ricci nonnegative manifolds). *If* Ric $\geq$ 0 *and A satisfies* (9)*, then U is displacement convex.*

Proof. As we remarked above, T_t is the optimal transport map from μ_0 to μ_t. So, by Theorem 3.3 and Proposition 3.5, we get

$$U(\rho_t) = \int_M A(\rho_t(x))\, d\,\mathrm{vol}(x) = \int_{E_t} A\left(\frac{\rho_0(x)}{\left(J_t^{\frac{1}{n}}(x)\right)^n}\right)\left(J_t^{\frac{1}{n}}(x)\right)^n d\,\mathrm{vol}(x), \tag{10}$$

where E_t is the set of full μ_0-measure given by Theorem 3.3 and $J_t(x) \neq 0$ is defined in (8). Since Ric ≥ 0, we know that $v_t(x, y) \geq 1$ for every $x, y \in M$ (see [4, Corollary 2.2]). Thus, for fixed $x \in E_1$, Theorem 3.6 yields the concavity of the map

$$[0, 1] \ni t \mapsto J_t^{\frac{1}{n}}(x).$$

Composing this function with the convex nonincreasing function $s \mapsto s^n A(s^{-n})$ we get the convexity of the integrand in (10). The only problem we run into in trying to conclude the displacement convexity of U is that the domain of integration appears to depend on t. But, since by Theorem 3.3 E_t is a set of full μ_0-measure for any $t \in [0, 1]$, we obtain that, for fixed $t, t', s \in [0, 1]$,

$$U(\rho_{(1-s)t+st'}) \leq (1 - s)U(\rho_t) + sU(\rho_{t'}),$$

simply by computing each of the three integrals above on the full measure set $E_t \cap E_{t'} \cap E_{(1-s)t+st'}$. $\square$

Acknowledgment. I wish to thank Cédric Villani for fruitful discussions on this subject.

ASYMPTOTIC STABILITY OF TRAVELING WAVE FRONTS IN THE BUFFERED BISTABLE SYSTEM*

JE-CHIANG TSAI†

Abstract. In this paper, we study a model which describes the propagation of increased calcium concentration wave front in excitable systems with the diffusing species being buffered. Our goal is to prove the global exponential stability of the unique traveling wave front. Comparing with the unbuffered system, we conclude that multiple stationary buffers (buffers do not diffuse) cannot prevent the existence of a global asymptotic stable traveling wave front, or cannot eliminate propagated waves in the buffered bistable equation. Concerning the method of the proof, we will present a method in which only the comparison principle and suitably constructed supersolutions (subsolutions) are involved. The feature of the method is to avoid calculating the spectrum of the associated linear operator.

Key words. calcium, reaction-diffusion equations, traveling wave front, bistable equation, FitzHugh–Nagumo equations, asymptotic stability

1. Introduction.

Wave propagations have been observed in a wide array of biological and chemical systems (e.g., the FitzHugh–Nagumo model and Belousov–Zhabotinskii reaction), and have been an interesting subject of mathematical studies for many years. Recently, waves of increased calcium concentration that travel within cells have been studied in depth, both by experimentalists and theoreticians [13, 2, 26, 6, 33, 11]. Although their precise physiological function is not always clear, it has been known for some time that they are important ways in which cells can transmit an intracellular signal. Among them, the fertilization calcium (Ca^{2+}) wave in *Xenopus laevis* oocytes (eggs) has attracted much attention. This may be due to the interesting fact that the cell divisions that initiate development of *Xenopus* begin only after the fertilization calcium wave has traveled across the whole cell (see [31, 17]).

Existing experimental evidence suggests the following mechanism for calcium waves in cells [3, 41, 2, 24, 19, 18, 16, 39, 17, 36, 14]. Binding of an agonist (e.g., a hormone) to the receptors in the plasma membrane results in the production of IP_3. Then the IP_3 diffuses rapidly into the interior of the cell, where it can bind to IP_3R (which is the IP_3 receptor and acts as a calcium channel) on the membrane of the internal calcium store ER (endoplasmic reticulum) and activate the IP_3R. It turns out that calcium can be released from ER into cytosol through the IP_3R. Note that the IP_3R is regulated by both IP_3 and calcium. Therefore if the released calcium through the IP_3 receptor diffuses to neighboring IP_3R, then it will initiate further calcium release from there (we assume that the concentration of the released calcium is large enough). This is the so-called calcium-induced calcium release. Repetition of this process can then generate an advancing wave front of high calcium concentration.

Before stating the model for calcium waves, we make some comments on ER. First, in addition to the calcium flux through IP_3R, there are two other components of the calcium flux across the ER membrane. More precisely, they are direct leak through the membrane and calcium uptake by molecular pumps. Second, compared with the calcium concentration in cytosol, the calcium concentration in ER is huge and can be treated as a constant. Finally, we will assume that the ER is a homogeneous, continuous medium, and that the dynamics of calcium in cytosol are much slower than the gating variable for calcium inactivation of the IP_3R (see [15, 39, 31]).

Now we can present the model for the calcium waves. Indeed, by taking calcium diffusion into account [1, 15], the above discussion leads to the following equation:

$$\frac{\partial u}{\partial t} = D\frac{\partial^2 u}{\partial x^2} + f(u), \tag{1.1}$$

where u denotes the concentration of free cytosolic calcium, $D > 0$ is the diffusion coefficient of the free cytosolic calcium, and $f(u) = J_{\text{channel}} + J_{\text{pump}} + J_{\text{leak}}$ is the calcium fluxes through the IP_3R, pumps, and the passive leak, respectively. Regarding the form of the function f, we shall choose the well-known *bistable* nonlinearity. More precisely, f is a function in $C^1[a_0, a_2]$ such that $f(a_0) = f(a_1) = f(a_2) = 0$ for some $0 < a_0 < a_1 < a_2$ and the following condition holds:

$$f(u) < 0 \text{ in } (a_0, a_1),\ f(u) > 0 \text{ in } (a_1, a_2),\ f'(a_0) < 0,\ f'(a_2) < 0.$$

The reason for choosing such a nonlinearity is not only because it can maintain stable self-sustained waves [17, 10], but it is also thought to be essential in the fertilization calcium waves of *Xenopus laevis* oocytes (see [39, 24, 4, 9]). According to the discussion of Smith, Pearson, and Keizer [31], the state a_0 represents a stable resting state which is the basal calcium concentration in cytosol, the state a_2 is a stable resting point at high calcium concentration in cytosol, while the state a_1 is unstable and corresponds to a threshold for calcium-induced calcium release (see [31, 17]). For simplicity, in this paper we shall only consider the typical *bistable* nonlinearity, i.e.,

$$f(u) = u(1-u)(u-a)$$

for some $a \in (0, 1)$. However, since we shall only concern the existence and stability of traveling calcium waves, it will not lose any information that we want.

At first glance, the study of calcium waves is similar to the simplified version of the well-known FitzHugh–Nagumo model, which was originally designed for studying the action potential. However, there are still some crucial differences for the study of calcium waves. Among them, the calcium buffers are the most important. Calcium buffers are large proteins that act as the binding sites for calcium (see [26]). Typical examples are calsequestrin and calbindin. The importance of studying buffers lies in two facts. First, if we want to observe the waves in cells, we need to put the indicator dyes (e.g., Ca^{2+}-green dextran, BAPTA, and fura-2) into the cells. The dye is one kind of (exogeneous) buffer. Therefore, if the buffers cannot preserve the existence of the stable traveling calcium waves, then we may not be able to observe the traveling calcium waves in the laboratory. Second, a large fraction of cytosolic calcium (at least 99%) is bound to calcium (endogenous) buffers. Not only do these buffers restrict the diffusion of free calcium, they also affect the kinetics of calcium release and uptake, and thus they would be expected to have an important effect on the properties of calcium traveling waves (see [35, 17, 31]).

A widely used way to model buffering is to assume that calcium reacts with buffers according to the following reaction scheme (see Wagner and Keizer [38]):

$$\mathrm{Ca}^{2+} + \mathrm{B}_i \underset{k_-^i}{\overset{k_+^i}{\rightleftarrows}} \mathrm{Ca}^{2+}\mathrm{B}_i, \ \ i = 1, \dots, n, \tag{1.2}$$

where B_i denotes the ith buffer in its unbound form, and $\mathrm{Ca}^{2+}\mathrm{B}_i$ denotes the ith buffer that is bound to calcium. Let v_i denote the concentration $[\mathrm{B}_i]$ of the ith buffer and b_0^i denote the total amount of the ith buffer. Also note that $b_0^i = [\mathrm{B}_i] + [\mathrm{Ca}^{2+}\mathrm{B}_i]$. We shall assume that b_0^i is a constant. Then it follows from the law of mass action and (1.2) that the rate of change of u due to buffering is given by

$$\frac{du}{dt} = \sum_{i=1}^{n} [k_-^i(b_0^i - v_i) - k_+^i u v_i],$$

where k_+^i and k_-^i denote the forward and reverse rate constants of the ith reaction (1.2), respectively. Combining this with (1.1), we obtain the following buffered bistable system:

$$\frac{\partial u}{\partial t} = D\frac{\partial^2 u}{\partial x^2} + f(u) + \sum_{i=1}^{n} [k_-^i(b_0^i - v_i) - k_+^i u v_i], \tag{1.3}$$

$$\frac{\partial v_i}{\partial t} = k_-^i(b_0^i - v_i) - k_+^i u v_i, \ (x,t) \in \mathbf{R} \times (0,\infty), \ i = 1, \dots, n, \tag{1.4}$$

with the initial data

$$u(x,0) = \phi(x), \ v_i(x,0) = \psi_i(x), \ x \in \mathbf{R}, \ i = 1, \dots, n. \tag{1.5}$$

Note that we assume that buffers are stationary (buffers do not diffuse). Hence, mathematically, we also obtain an excitable system with the diffusing species being buffered (see [14, 17]). Thus we will not be restricted to the case for the fertilization calcium traveling wave in *Xenopus* eggs only, it may be applied to other cell types.

There have been a large number of numerical studies on the biological models including calcium buffers (see [8, 15, 23, 27]). Regarding the analytical studies, the assumption that the buffer has fast kinetics with respect to the other reactions in the model is always made. Under this assumption, the well-known *rapid buffering approximation* (see Wagner and Keizer [38]) can be applied, and the full model can be reduced to a single quasilinear equation, in which the effective diffusion coefficient of calcium now depends on the calcium concentration (see [20, 21, 22, 29, 30]). Using this reduction and assuming that there is only one buffer, Sneyd, Dale, and Duffy [34] have proved the existence of traveling waves of the reduced system and Tsai and Sneyd [36] have considered the uniqueness and stability of waves. Both Sneyd, Dale, and Duffy [34] and Slepchenko, Schaff, and Choi [28] also did many interesting simulations on the relation between the wave speed and the parameters k_-, k_+, b_0, and D. However, these previous studies left open the question of whether or not multiple buffers, not necessarily having fast kinetics, could eliminate wave propagation, and the stability is also unknown. Thus, in order to get a deeper understanding of how buffers affect the calcium traveling waves in the model (1.1), we shall not assume that the buffers have lower affinity and fast kinetics with respect to the other reactions in the model (1.3)–(1.4). Hence we need to consider the whole system (1.3)–(1.4) instead of the reduced equation.

Since we are concerned with how stationary buffers (buffers do not diffuse) affect wave activity, we briefly review the results of traveling wave solutions for the case of (1.3)–(1.4) without buffers, i.e., we consider the well-known *bistable* equation (1.1),

$$\frac{\partial u}{\partial t} = D\frac{\partial^2 u}{\partial x^2} + f(u).$$

A nonnegative function $U(\xi) \in C^2(\mathbf{R})$ is said to be a traveling wave solution of (1.1), if for some $c \in \mathbf{R}$, (U, c) satisfies that $u(x,t) = U(x - ct)$ is a solution of (1.1) and

$$U(+\infty) = 1, \;\; U(-\infty) = 0.$$

Note that c is the so-called wave speed associated with the profile of the traveling wave front U. Fife and Mcleod [10] have shown that for any given $a \in (0, 1/2)$, there exists a unique $c := c(a) < 0$ such that there is a unique (up to a translation) traveling wave solution U of (1.1) with wave speed c. Moreover, the profile of the front U is monotone increasing on $\mathbf{R}$. Furthermore, they have also considered the asymptotic stability for this traveling wave front $U(\xi)$. More precisely, let $u(x,t)$ be the solution of (1.1) with the initial data $u(x, 0) = \phi(x)$ satisfying $\phi \in [0, 1]$ on $\mathbf{R}$. Then $u(x,t)$ approaches a translate of U uniformly in x and exponentially fast in time if $\limsup_{x\to-\infty} \phi(x) > 0$ and $1 - \liminf_{x\to+\infty} \phi(x) > 0$ are sufficiently small.

Next we turn to the system (1.3)–(1.4). First, we set up some notation:

$$\begin{aligned}
&\kappa_i(u) := k_-^i b_0^i/(k_+^i u + k_-^i) \;\text{ for }\; i = 1, \ldots, n,\\
&\mathbf{b}_0 = (b_0^1, \ldots, b_0^n) := (\kappa_1(0), \ldots, \kappa_n(0)),\\
&\mathbf{b}_1 = (b_1^1, \ldots, b_1^n) := (\kappa_1(a), \ldots, \kappa_n(a)),\\
&\mathbf{b}_2 = (b_2^1, \ldots, b_2^n) := (\kappa_1(1), \ldots, \kappa_n(1)),\\
&\mathbf{v}(x,t) := (v_1(x,t), \ldots, v_n(x,t)).
\end{aligned}$$

We are interested in traveling wave solutions of (1.3)–(1.4) that connect the two equilibria $(0, \mathbf{b}_0)$ and $(1, \mathbf{b}_2)$. More precisely, a set of nonnegative functions $(\mathcal{U}(\xi), \mathbf{\Pi}(\xi)) = (\mathcal{U}(\xi), \Pi_1(\xi), \ldots, \Pi_n(\xi)) \in \mathbf{C}^2(\mathbf{R}) \times \mathbf{C}^1(\mathbf{R}) \times \cdots \times \mathbf{C}^1(\mathbf{R})$ are said to be a traveling wave solution of (1.3)–(1.4), if for some $c < 0$, $(\mathcal{U}(\xi), \mathbf{\Pi}(\xi), c)$ satisfies that $(u(x,t), \mathbf{v}(x,t)) = (\mathcal{U}(x - ct), \mathbf{\Pi}(x - ct))$ is a solution of (1.3)–(1.4) and

$$\mathcal{U}(+\infty) = 1, \; \mathbf{\Pi}(+\infty) = \mathbf{b}_2, \; \mathcal{U}(-\infty) = 0, \; \mathbf{\Pi}(-\infty) = \mathbf{b}_0. \tag{1.6}$$

As before, c is the so-called wave speed associated with the profile of the traveling wave front $(\mathcal{U}, \mathbf{\Pi})$. Therefore, $(\mathcal{U}(\xi), \mathbf{\Pi}(\xi))$ satisfies the following ordinary differential equations:

$$\begin{aligned}
&D\ddot{\mathcal{U}} + c\,\dot{\mathcal{U}} + f(\mathcal{U}) + \sum_{i=1}^{n}\Big[k_-^i(b_0^i - \Pi_i) - k_+^i \mathcal{U}\Pi_i\Big] = 0,\\
&c\dot{\Pi}_i + k_-^i(b_0^i - \Pi_i) - k_+^i \mathcal{U}\Pi_i = 0, \; \xi = x - ct \in \mathbf{R}, \; i = 1, \ldots, n,
\end{aligned} \tag{1.7}$$

where $\cdot$ denotes $d/d\xi$. In [35], we have proved that for any given $a \in (0, 1/2)$, there exists a unique $c := c(a) < 0$ such that there exists a unique (up to a translation) traveling wave solution $(\mathcal{U}, \mathbf{\Pi})$ of the buffered bistable equations (1.3)–(1.4) with wave speed c. Moreover, $(\mathcal{U}, \mathbf{\Pi})$ satisfies that $\dot{\mathcal{U}} > 0$ and $\dot{\Pi}_i < 0$, $i = 1, \ldots, n$, on $\mathbf{R}$. Throughout the remainder of this paper, $(\mathcal{U}, \mathbf{\Pi})$ will denote the unique traveling wave solution of (1.3)–(1.4) with speed c and $\mathcal{U}(0) = 1/2$.

In [35], the stability of this traveling wave solution of (1.3)–(1.4) was established under the following technical constraint on the initial values. Let $a \in (0, 1/2)$ and $(u(x,t), \mathbf{v}(x,t))$ be the solution of (1.3)–(1.4) with the initial data $(u(\cdot,0), \mathbf{v}(\cdot,0))$ satisfying the following conditions:

(1) $u(\cdot,0)$, $v_i(\cdot,0)$ are sufficiently smooth and $u_x(x,0) \geq 0$, $v_{i,x}(\cdot,0) \leq 0$ on $\mathbf{R}$ for $i = 1,\ldots,n$;
(2) $\tilde{u}_t(x,0) \geq 0$ and $\tilde{v}_{i,t}(x,0) \leq 0$ for all $x \in \mathbf{R}$ and $i = 1,\ldots,n$;
(3) $\sup_{x\in\mathbf{R}} |u(x,0)| + \sup_{x\in\mathbf{R}} |u_x(x,0)| + \sup_{x\in\mathbf{R}} |u_{xx}(x,0)| + \sup_{x\in\mathbf{R}} |u_{xxx}(x,0)| < +\infty$;
(4) $u(\cdot,0)$, $v_i(\cdot,0)$, $i = 1,\ldots,n$, are in $[0,1]$ and $[b_2^i, b_0^i]$, respectively;
(5) $1 - \phi_2 > 0$, $\psi_{2i} - b_2^i > 0$, $\phi_0 > 0$ and $b_0^i - \psi_{0i} > 0$ are sufficiently small for $i = 1,\ldots,n$,

where $v_{i,x} = \partial v_i/\partial x$, $\tilde{v}_{i,t} = \partial \tilde{v}_i/\partial t$,

$$\phi_2 = \lim_{x\to+\infty} u(x,0),\ \psi_{2i} = \lim_{x\to+\infty} v_i(x,0),\ \phi_0 = \lim_{x\to-\infty} u(x,0),$$
$$\text{and}\ \ \psi_{0i} = \lim_{x\to-\infty} v_i(x,0),$$

and $(\tilde{u}(x,t), \tilde{\mathbf{v}}(x,t)) = (u(x+ct,t), \mathbf{v}(x+ct,t))$ on $\mathbf{R}\times\mathbf{R}^+$. Then there exists $x_0 \in \mathbf{R}$ such that

$$\lim_{t\to+\infty} |u(x,t) - \mathcal{U}(x-ct+x_0)| = 0,\ \ \lim_{t\to+\infty} |v_i(x,t) - \Pi_i(x-ct+x_0)| = 0,\ i = 1,\ldots,n,$$

uniformly with respect to $x \in \mathbf{R}$. Roughly speaking, this implies that a solution of (1.3)–(1.4) which vaguely resembles a traveling front $(\mathcal{U}, \mathbf{\Pi})$ at initial time will develop into a translation of such a traveling front as $t \to +\infty$.

It is obvious that the conditions (1), (2), and (3) in our previous stability result are technical. Moreover, the condition (5) also implies that the previous result is only "local stability." Therefore, the goal of this paper is to remove these conditions and our main result is the following theorem which is global exponential stability.

THEOREM 1. *Let $a \in (0,1/2)$ and $(u(x,t), \mathbf{v}(x,t))$ be the solution of* (1.3)–(1.4) *with the initial data $(u(\cdot,0), \mathbf{v}(\cdot,0))$ satisfying the following conditions:*

(1) *$u(\cdot,0)$, $v_i(\cdot,0)$, are uniformly Hölder continuous in $\mathbf{R}$ with exponent α for some $\alpha \in (0,1)$ and for $i = 1,\ldots,n$;*
(2) *$u(\cdot,0)$, $v_i(\cdot,0)$, $i = 1,\ldots,n$, are in $[0,1]$ and $[b_2^i, b_0^i]$, respectively;*
(3)

$$\liminf_{x\to+\infty} u(x,0) > a,\ \limsup_{x\to+\infty} v_i(x,0) < b_1^i,\ \limsup_{x\to-\infty} u(x,0) < a,\ \liminf_{x\to-\infty} v_i(x,0) > b_1^i$$

for $i = 1,\ldots,n$.

Then there exists a positive constant κ which is independent of the initial data $(u(\cdot,0), \mathbf{v}(\cdot,0))$ such that

$$\sup_{x\in\mathbf{R}} |u(x,t) - \mathcal{U}(x-ct+\xi^*)| \leq Ke^{-\kappa t},\quad \sup_{x\in\mathbf{R}} |v_i(x,t) - \Pi_i(x-ct+\xi^*)| \leq Ke^{-\kappa t},$$

for $i = 1,\ldots,n$, and for some constants ξ^* and K which may depend on $(u(\cdot,0), \mathbf{v}(\cdot,0))$.

Note that the condition (3) is weaker than the previous one.

Comparing this result with the one of the unbuffered equation (1.1), we may conclude that *physiologically, a unique asymptotic stable traveling wave front exists as long as it exists in the absence of buffers.* Hence, our results complete the picture of how stationary buffers affect wave activity in the bistable equation. This may suggest that the same result is true for more complex and realistic models of calcium wave propagation (see [17, 31, 35]).

We conclude the introduction with some comments on the method of our proof. In general, the key step of the commonly used method for proving the asymptotic exponential stability of a traveling wave solution is to study the spectrum of the linear operator associated with the traveling wave solution under study, which is sometimes bothersome (see [10, 25, 40, 37] and references therein). Here, to avoid the spectrum analysis, we shall use a method involving only comparison principle and suitably constructed supersolutions (subsolutions) to establish our result. In fact, we shall extend the method of Chen [5] to prove our result, where the author studied the existence, uniqueness, and stability of a single nonlocal equation. However, since our problem is a system of differential equations (not a single equation), this method cannot be carried along the whole way and much modification is needed. In fact, for each crucial part (except the very final argument) in [5], we need to find the counterpart for our problem.

This paper is organized as follows. In section 2, we shall state some properties of (1.3)–(1.4) and derive the comparison principle for the subsolution and supersolution of (1.3)–(1.4). Then in section 3, we will prove Theorem 1.

2. Preliminaries. First, for simplicity we set up some notation. For each $i = 1, \ldots, n$, we set

$$F(u, \mathbf{v}) := f(u) + \sum_{i=1}^{n} G_i(u, \mathbf{v}),$$

$$G_i(u, \mathbf{v}) := k_-^i b_0^i - (k_+^i u + k_-^i) v_i, \ i = 1, \ldots, n.$$

Then we can rewrite (1.3)–(1.4) as the following system:

$$\frac{\partial u}{\partial t} = L_1[u, \mathbf{v}] := D\frac{\partial^2 u}{\partial x^2} + F(u, \mathbf{v}), \tag{2.1}$$

$$\frac{\partial v_i}{\partial t} = L_{2i}[u, \mathbf{v}] := G_i(u, \mathbf{v}), \ (x, t) \in \mathbf{R} \times \mathbf{R}^+ \ (\mathbf{R}^+ := (0, \infty)), \ i = 1, \ldots, n. \tag{2.2}$$

Note that $G_i(u, \mathbf{v}) = 0$ if and only if $v_i = \kappa_i(u)$. Furthermore, we have that

$$F_u(u, \mathbf{v}) = f'(u) - \sum_{i=1}^{n} k_+^i v_i, \quad F_{v_i}(u, \mathbf{v}) = -(k_+^i u + k_-^i) < 0,$$

$$G_{i,u}(u, \mathbf{v}) = -k_+^i v_i \le 0, \quad G_{i,v_i}(u, \mathbf{v}) = -(k_+^i u + k_-^i) < 0$$

for all $u \in [-\min_{j=1,\ldots,n}\{1, k_-^j/(2k_+^j)\}, 2]$ and $v_i \in [0, \infty)$, $i = 1, \ldots, n$. Finally, for two vectors $\mathbf{c} = (c_1, \ldots, c_n)$ and $\mathbf{d} = (d_1, \ldots, d_n)$, the symbol $\mathbf{c} < \mathbf{d}$ means $c_i < d_i$ for $i = 1, \ldots, n$, and $\mathbf{c} \le \mathbf{d}$ means $c_i \le d_i$ for $i = 1, \ldots, n$.

We shall investigate the asymptotic behavior as $t \to +\infty$ of the solution of (2.1)–(2.2) with the initial data $(u(\cdot, 0), \mathbf{v}(\cdot, 0))$. For this we briefly discuss the existence of the global solution $(u, \mathbf{v})$ of (2.1)–(2.2) with the initial data $(u(\cdot, 0), \mathbf{v}(\cdot, 0))$ (also see [14]). Suppose that $u(\cdot, 0)$ and $v_i(\cdot, 0)$, $i = 1, \ldots, n$, are uniformly Hölder continuous in $\mathbf{R}$ with exponent α for some $\alpha \in (0, 1)$ and that $0 \le u(x, 0) \le 1$ and $b_2^i \le v_i(x, 0) \le b_0^i$ for all $x \in \mathbf{R}$. Then by using an iteration method of Evans and Shenk [7], a regularity theory of parabolic equations (cf. [12]), and an invariance region theory [32, Theorem 14.11 on p. 203], we can prove that there is a unique solution $(u,\mathbf{v})$ defined for all $t>0$ such that $u\in C^{2,1}(\mathbf{R}\times\mathbf{R}^+)\cap C^0(\mathbf{R}\times[0,\infty))$, $v_i\in C^0(\mathbf{R}\times\mathbf{R}^+)$, and $v_{i,t}\in C^0(\mathbf{R}\times\mathbf{R}^+)$ for $i=1,\dots,n$, where the set $C^{2,1}(\mathbf{R}\times\mathbf{R}^+)$ consists of all functions that are once continuously differentiable in t and twice continuously differentiable in x for all $(x,t)\in\mathbf{R}\times\mathbf{R}^+$, and the set $C^0(\mathbf{R}\times[0,\infty))$ consists of continuous functions in $\mathbf{R}\times[0,\infty)$. Moreover, we recall from [35, Lemma 4.1] the following proposition of invariance regions.

PROPOSITION 1 (invariance region). *Let $(u,\mathbf{v})$ be a global solution of* (2.1)–(2.2) *with $0\le u(x,0)\le 1$ and $\mathbf{b}_2\le\mathbf{v}(x,0)\le\mathbf{b}_0$ for all $x\in\mathbf{R}$. Then we have $0\le u(x,t)\le 1$ and $\mathbf{b}_2\le\mathbf{v}(x,t)\le\mathbf{b}_0$ for all $(x,t)\in\mathbf{R}\times\mathbf{R}^+$.*

Therefore, except otherwise stated, we shall assume that the initial data $u(\cdot,0)$ and $v_i(\cdot,0)$, $i=1,\dots,n$, are uniformly Hölder continuous in $\mathbf{R}$ with exponent α for some $\alpha\in(0,1)$ and satisfy that $u(\cdot,0)$ and $v_i(\cdot,0)$ are in $[0,1]$ and $[b_2^i,b_0^i]$, respectively.

Since we will frequently use the notion of supersolutions (subsolutions) of (2.1)–(2.2) and the comparison principle, we state the definition of supersolutions (subsolutions) as follows.

DEFINITION 1. *A set of functions $(u,\mathbf{v})$ is called a subsolution of* (2.1)–(2.2) *in $\mathbf{R}\times\mathbf{R}^+$ if $u,v_i\in C^{2,1}(\mathbf{R}\times\mathbf{R}^+)$ satisfies that $u_t\le L_1[u,\mathbf{v}]$, $v_{i,t}\ge L_{2i}[u,\mathbf{v}]$, that $|u_t-L_1[u,\mathbf{v}]|$, $|v_{i,t}-L_{2i}[u,\mathbf{v}]|$ are bounded on $\mathbf{R}\times\mathbf{R}^+$, and that*

$$-\min_{j=1,\dots,n}\{1,k_-^j/(2k_+^j)\}\le u(x,t)\le 2,\quad b_2^i/2\le v_i(x,t)\le 2b_0^i \tag{2.3}$$

on $\mathbf{R}\times\mathbf{R}^+$ for $i=1,\dots,n$. Supersolution is defined by reversing the inequalities with (2.3) *held.*

The next proposition is a comparison theorem for the system (2.1)–(2.2) and the idea of the proof is based on [35, Lemma 5.3]. We remark that Proposition 2 essentially is a comparison principle for cooperative systems. Note that (2.1)–(2.2) is a competitive type. In general, a competition system with three or more equations cannot be transformed into cooperative ones, but it works for (2.1)–(2.2) due to its special structure.

PROPOSITION 2 (comparison principle). *Let $(u_1,\mathbf{v}_1)$ and $(u_2,\mathbf{v}_2)$ be a subsolution and a supersolution of* (2.1)–(2.2) *on $\mathbf{R}\times\mathbf{R}^+$, respectively, with $u_1(x,0)\le u_2(x,0)$ and $\mathbf{v}_2(x,0)\le\mathbf{v}_1(x,0)$ for all $x\in\mathbf{R}$. Then we have $u_1(x,t)\le u_2(x,t)$ and $\mathbf{v}_2(x,t)\le\mathbf{v}_1(x,t)$ for all $(x,t)\in\mathbf{R}\times\mathbf{R}^+$.*

Proof. Set $\mathbf{v}_1=(v_{11},\dots,v_{1n})$, $\mathbf{v}_2=(v_{21},\dots,v_{2n})$, and $(\tilde u,\tilde{\mathbf{v}})=(u_1-u_2,\mathbf{v}_2-\mathbf{v}_1)$. Then $(\tilde u,\tilde{\mathbf{v}})$ satisfies

$$\begin{aligned} u_t-Du_{xx} &= F(u_1,\mathbf{v}_1)-F(u_2,\mathbf{v}_2)+N_1(z,t)\\ &:=\left[f_1(x,t)\tilde u-\sum_{i=1}^n f_{1i}(x,t)\tilde v_i\right]+N_1(z,t), \end{aligned}\tag{2.4}$$

$$\begin{aligned} v_{i,t} &= G_i(u_2,\mathbf{v}_2)-G_i(u_1,\mathbf{v}_1)+N_{2i}(z,t)\\ &:=[-g_{2i}(x,t)\tilde u+\tilde g_{2i}(x,t)\tilde v_i]+N_{2i}(z,t) \end{aligned}\tag{2.5}$$

for $i=1,\dots,n$, together with the initial data

$$\tilde u(x,0)=u_1(x,0)-u_2(x,0),\ \tilde v_i(x,0)=v_{2i}(x,0)-v_{1i}(x,0),\ i=1,\dots,n,$$

where $N_1(z,t)$ and $N_{2i}(z,t)$ are nonpositive bounded smooth functions on $\mathbf{R}\times[0,+\infty)$,

and

$$
\begin{aligned}
f_1(x,t) &= F_u(\theta_1 u_1 + (1-\theta_1)u_2, \theta_1 \mathbf{v}_1 + (1-\theta_1)\mathbf{v}_2)(x,t),\\
f_{1i}(x,t) &= F_{v_i}(\theta_1 u_1 + (1-\theta_1)u_2, \theta_1 \mathbf{v}_1 + (1-\theta_1)\mathbf{v}_2)(x,t),\\
g_{2i}(x,t) &= G_{i,u}(\theta_{2i} u_1 + (1-\theta_{2i})u_2, \theta_{2i} \mathbf{v}_1 + (1-\theta_{2i})\mathbf{v}_2)(x,t),\\
\tilde{g}_{2i}(x,t) &= G_{i,v_i}(\theta_{2i} u_1 + (1-\theta_{2i})u_2, \theta_{2i} \mathbf{v}_1 + (1-\theta_{2i})\mathbf{v}_2)(x,t),
\end{aligned}
$$

for some $\theta_1 = \theta_1(u_1, \mathbf{v}_1, u_2, \mathbf{v}_2) \in (0,1)$, $\theta_{2i} = \theta_{2i}(u_1, \mathbf{v}_1, u_2, \mathbf{v}_2) \in (0,1)$ and $i = 1, \ldots, n$.

We claim that the region $\{\tilde{u} \le 0, \tilde{v}_i \le 0, i = 1, \ldots, n\}$ is invariant under the flow (2.4)–(2.5). Indeed, from (2.3) and the definitions of F and G_i, it follows that

$$f_{1i}(x,t) < 0 \text{ and } g_{2i}(x,t) < 0 \text{ for all } (x,t) \in \mathbf{R} \times [0, +\infty) \text{ and } i = 1, \ldots, n.$$

Note that $\tilde{u}(x,0) \le 0$ and $\tilde{\mathbf{v}}(x,0) \le \mathbf{0}$ for all $x \in \mathbf{R}$. Therefore, by [32, Theorem 14.11 on p. 203], we have $\tilde{u}(x,t) \le 0$ and $\tilde{\mathbf{v}}(x,t) \le \mathbf{0}$ for all $(x,t) \in \mathbf{R} \times \mathbf{R}^+$. The proof is completed. ◻

3. Asymptotic behavior of traveling wave fronts.

3.1. Several auxiliary lemmas. Before proving our main results, we need some auxiliary lemmas. First, we use the traveling waves $(\mathcal{U}, \mathbf{\Pi})$ to construct supersolutions (subsolutions) of (2.1)–(2.2) whose proof can be found in [35, Lemma 3.7].

LEMMA 3.1. *There exist positive constants d_0, μ_0, and k_{0i}, $i = 1, \ldots, n$, which are independent of $(\mathcal{U}, \mathbf{\Pi}, c)$, and a positive constant ν, which depends on $(\mathcal{U}, \mathbf{\Pi}, c)$, such that, for any $d \in (0, d_0]$ and $\xi_0 \in \mathbf{R}$, the functions $(w^+, \mathbf{p}^+)$ and $(w^-, \mathbf{p}^-)$ defined by*

$$
\begin{aligned}
w^{\pm}(x,t) &:= \mathcal{U}(x - ct + \xi_0 \pm \nu d(1 - e^{-\mu_0 t})) \pm d e^{-\mu_0 t},\\
p_i^{\pm}(x,t) &:= \Pi_i(x - ct + \xi_0 \pm \nu d(1 - e^{-\mu_0 t})) \mp d k_{0i} e^{-\mu_0 t},\ i = 1, \ldots, n,
\end{aligned}
\tag{3.1}
$$

are a supersolution and a subsolution of (2.1)–(2.2)*, respectively. In what follows, we will retain the notation: d_0, μ_0, ν, and k_{0i}.*

Next, we will show that under the assumption of Theorem 1, the solution $(u, \mathbf{v})$ of (2.1)–(2.2) will eventually get trapped between two translates of the traveling wave. For this, we will construct a set of supersolution and subsolution of (2.1)–(2.2). First, we define $\zeta \in C^\infty(\mathbf{R})$ as follows:

$$
\begin{aligned}
&\zeta(s) = 0 \ \text{ if } \ s \le 0, \quad \zeta(s) = 1 \ \text{ if } \ s \ge 2,\\
&0 < \zeta'(s) < 1,\ |\zeta''(s)| \le 1 \ \text{ if } \ s \in (0,2).
\end{aligned}
$$

LEMMA 3.2. *There exist a small positive constant $\hat{d} \in (0, \min\{a/2, (1-a)/2\})$, and functions $\epsilon(\cdot)$, $\sigma(\cdot)$, and $C(\cdot)$ defined on $[0, \hat{d}]$, such that for every $d \in (0, \hat{d}]$ and $\xi \in \mathbf{R}$, the functions $(\hat{w}^+(x,t), \hat{\mathbf{p}}^+(x,t))$ and $(\hat{w}^-(x,t), \hat{\mathbf{p}}^-(x,t))$ defined by*

$$
\begin{aligned}
\hat{w}^+(x,t) = \hat{w}^+(x,t;\xi) &:= (1+d) - [1 - (a - 2d)e^{-\epsilon t}]\zeta(-\epsilon(x - \xi + Ct)),\\
\hat{p}_i^+(x,t) = \hat{p}_i^+(x,t;\xi) &:= \kappa_i(\hat{w}^+(x,t)) - \sigma,\ i = 1, \ldots, n,
\end{aligned}
$$

and

$$
\begin{aligned}
\hat{w}^-(x,t) = \hat{w}^-(x,t;\xi) &:= -d + [1 - (1 - a - 2d)e^{-\epsilon t}]\zeta(\epsilon(x - \xi - Ct)),\\
\hat{p}_i^-(x,t) = \hat{p}_i^-(x,t;\xi) &:= \kappa_i(\hat{w}^-(x,t)) + \sigma,\ i = 1, \ldots, n,
\end{aligned}
$$

are a supersolution and a subsolution of (2.1)–(2.2)*, respectively.*

Proof. Let (and then fix) $\hat{d} \in (0, \min\{a/2, (1-a)/2\})$ be sufficiently small such that $(\hat{w}^+, \hat{\mathbf{p}}^+)$ and $(\hat{w}^-, \hat{\mathbf{p}}^-)$ satisfy (2.3) on $\mathbf{R} \times \mathbf{R}^+$. Next, for each fixed $d \in (0, \hat{d}]$, we will only prove that the conclusion of this lemma holds for $(\hat{w}^+, \hat{\mathbf{p}}^+)$ since the case for $(\hat{w}^-, \hat{\mathbf{p}}^-)$ follows by analogous arguments. Without loss of generality, we may assume that $\xi = 0$. Also by (2.3), there exist positive constants C_1 and C_2, which depend only on k_+^i, k_-^i, b_0^i, and D, such that for all $C > 0$, the inequalities

$$|D[1-(a-2d)e^{-\epsilon t}]\zeta''(-\epsilon(x+Ct))| \le C_1$$

and

$$C_2 \le \sum_{i=1}^n (k_+^i \hat{w}^+(x,t) + k_-^i),\ -\kappa_i'(\hat{w}^+(x,t)) \le C_1$$

hold for all $(x,t) \in \mathbf{R} \times \mathbf{R}^+$. Finally, we set

$$\sigma = \sigma(d) := \min\left\{ d/2, -\frac{f(1+d/2)}{2C_1}, \frac{\min_{u\in[d,a-\frac{d}{2}]}(-f(u))}{2C_1} \right\}.$$

Recalling that $\hat{p}_i^+(x,t) = \kappa_i(\hat{w}^+(x,t)) - \sigma$ and $\kappa_i(u) := k_-^i b_0^i/(k_+^i u + k_-^i)$, we have

$$\begin{aligned}
&k_-^i b_0^i - (k_+^i \hat{w}^+(x,t) + k_-^i)\hat{p}_i^+(x,t) \\
&= \left[k_-^i b_0^i - (k_+^i \hat{w}^+(x,t) + k_-^i)\kappa_i(\hat{w}^+(x,t))\right] + (k_+^i \hat{w}^+(x,t) + k_-^i)\sigma \\
&= (k_+^i \hat{w}^+(x,t) + k_-^i)\sigma
\end{aligned}$$

for $i = 1, \ldots, n$ and $(x,t) \in \mathbf{R} \times \mathbf{R}^+$. Hence for each $i = 1, \ldots, n$, and all $(x,t) \in \mathbf{R} \times \mathbf{R}^+$, we have the following inequalities:

$$\begin{aligned}
\hat{w}_t^+(x,t) - L_1[\hat{w}^+, \hat{\mathbf{p}}^+](x,t) &= C\epsilon[1-(a-2d)e^{-\epsilon t}]\zeta' - \epsilon(a-2d)e^{-\epsilon t}\zeta \\
&\quad + D\epsilon^2[1-(a-2d)e^{-\epsilon t}]\zeta'' \\
&\quad - f(\hat{w}^+(x,t)) - \sum_{i=1}^n \left[k_-^i b_0^i - (k_+^i \hat{w}^+(x,t) + k_-^i)\hat{p}_i^+(x,t)\right] \\
&\ge C\epsilon(1-a)\zeta' - a\epsilon - C_1\epsilon^2 - f(\hat{w}^+(x,t)) \\
&\quad - \sum_{i=1}^n (k_+^i \hat{w}^+(x,t) + k_-^i)\sigma \\
&\ge C\epsilon(1-a)\zeta' - a\epsilon - C_1\epsilon^2 - f(\hat{w}^+(x,t)) - C_1\sigma,
\end{aligned} \tag{3.2}$$

and

$$\begin{aligned}
\hat{p}_{i,t}^+(x,t) - L_{2i}[\hat{w}^+, \hat{\mathbf{p}}^+](x,t) &= \kappa_i'(\hat{w}^+(x,t))\left[C\epsilon(1-(a-2d)e^{-\epsilon t})\zeta' - \epsilon(a-2d)e^{-\epsilon t}\zeta\right] \\
&\quad - \left[k_-^i b_0^i - (k_+^i \hat{w}^+(x,t) + k_-^i)\hat{p}_i^+(x,t)\right] \\
&\le -CC_2\epsilon(1-a)\zeta' + C_1 a\epsilon - C_2\sigma,
\end{aligned} \tag{3.3}$$

where, for simplicity, we have denoted $\zeta(-\epsilon(x-\xi+Ct))$ by ζ. In order to find ϵ and C satisfying that the right-hand sides of (3.2) and (3.3) are nonnegative and nonpositive, respectively, we consider the following three cases:

(i) $\zeta < d/2$,
(ii) $\zeta > 1 - d/2$,
(iii) $\zeta \in [d/2, 1-d/2]$.

For case (i), we have $\hat{w}^+ > 1 + d/2$, and so $-f(\hat{w}^+) > -f(1 + d/2)$. Choose a sufficiently small ϵ satisfying that

$$\epsilon \le \min\left\{d, \frac{C_2\sigma}{C_1 a}\right\} \quad \text{and} \quad -a\epsilon - C_1\epsilon^2 - \frac{f(1 + d/2)}{2} > 0. \tag{3.4}$$

Noting that $\zeta' \ge 0$ and using (3.4) and the definition of σ, it follows that the right-hand sides of (3.2) and (3.3) are nonnegative and nonpositive, respectively.

For case (ii), we have

$$d \le \hat{w}^+ \le (1 + d) - [1 - (a - 2d)](1 - d/2) < a - d/2.$$

Hence if we choose ϵ satisfying both (3.4) and the inequality

$$-a\epsilon - C_1\epsilon^2 + \frac{\min_{u\in[d,a-d/2]}(-f(u))}{2} > 0,$$

then by the definition of σ, the right-hand sides of (3.2) and (3.3) in both cases (i) and (ii) are nonnegative and nonpositive, respectively. In the remaining proof, we fix such ϵ.

Finally, for case (iii), we have a positive lower bound for ζ'. Note that $|f(\hat{w}^+)|$ has an upper bound which depends only on k_+^i, k_-^i, b_0^i, and D. Hence we can choose a sufficiently large $C = C(d, \epsilon)$ to make the right-hand sides of (3.2) and (3.3) nonnegative and nonpositive, respectively. This completes the proof. ◻

With the use of $(\hat{w}^\pm, \hat{\mathbf{p}}^\pm)$, we can obtain the long time behavior of $(u(x,t), \mathbf{v}(x,t))$ for sufficiently large $|x|$, which implies that $(u(\cdot,t), \mathbf{v}(\cdot,t))$ will eventually get trapped between two translates of the traveling wave. We have the following lemma.

Lemma 3.3. *Under the assumption of Theorem* 1, *the solution* $(u, \mathbf{v})$ *of* (2.1)–(2.2) *satisfies that*

$$\lim_{t\to+\infty}\left(\liminf_{x\to+\infty} u(x,t)\right) = 1, \quad \lim_{t\to+\infty}\left(\limsup_{x\to+\infty} v_i(x,t)\right) = b_2^i,$$
$$\lim_{t\to+\infty}\left(\limsup_{x\to-\infty} u(x,t)\right) = 0, \quad \lim_{t\to+\infty}\left(\liminf_{x\to-\infty} v_i(x,t)\right) = b_0^i,\ i = 1, \dots, n.$$

Proof. We only prove that $\lim_{t\to+\infty}(\liminf_{x\to+\infty} u(x,t)) = 1, \lim_{t\to+\infty}(\limsup_{x\to+\infty} v_i(x,t)) = b_2^i$ for $i = 1, \dots, n$, since the remaining part follows in a similar way. Let $\hat{d}$ be defined in Lemma 3.2. By the assumption of Theorem 1, we may choose $\bar{d} \in (0, \hat{d})$ and M_1 such that

$$u(x,0) \ge a + \bar{d} \quad \text{and} \quad v_i(x,0) \le \kappa_i(a) - \frac{k_+^i k_-^i b_0^i}{(k_+^i a + k_-^i)^2}\bar{d} \quad \text{for all} \quad x \ge M_1 \tag{3.5}$$

and $i = 1, \dots, n$. Now for any fixed $d \in (0, \bar{d})$, recall from Lemma 3.2 that $(\hat{w}^-, \hat{\mathbf{p}}^-)$ satisfies

$$\hat{w}^-(x,0) = -d \ \text{ if } \ x \le \xi, \ \ \hat{w}^-(x,0) \le a + d \ \text{ for all } x \in \mathbf{R}, \ \text{ and}$$
$$\hat{p}_i^-(x,0) \ge \kappa_i(-d) \ \text{ if } \ x \le \xi, \ \ \hat{p}_i^-(x,0) \ge \kappa_i(a + d) \ \text{ for all } x \in \mathbf{R}$$

for any $\xi \in \mathbf{R}$ and $i = 1, \dots, n$. Set $\xi = M_1$. *Then we claim that* $u(x,0) \ge \hat{w}^-(x,0)$ *and* $v_i(x,0) \le \hat{p}_i^-(x,0)$ *for all* $x \in \mathbf{R}$. Indeed, it follows from (3.5) that for all $x \ge M_1$

and $i = 1, \ldots, n$, $u(x, 0) \geq \hat{w}^-(x, 0)$ and

$$\begin{aligned} v_i(x,0) &\leq \kappa_i(a) - \frac{k_+^i k_-^i b_0^i}{(k_+^i a + k_-^i)^2} d \\ &\leq \kappa_i(a+d) \\ &\leq \hat{p}_i^-(x,0), \end{aligned}$$

where, in the second inequality, we have used the mean-value theorem and the fact that $\kappa_i'(u) = -k_+^i k_-^i b_0^i/(k_+^i u + k_-^i)^2$. Now we turn to the case $x \leq M_1$. Since $u(\cdot, t) \geq 0$ and $v_i(\cdot, t) \leq b_0^i$, $i = 1, \ldots, n$, it follows from the definition of $(\hat{w}^-, \hat{\mathbf{p}}^-)$ that $u(x, 0) \geq \hat{w}^-(x, 0)$ and $v_i(x, 0) \leq \hat{p}_i^-(x, 0)$ for all $x \leq M_1$. Hence the assertion of this claim follows.

From the definition of $(\hat{w}^-, \hat{\mathbf{p}}^-)$ and the above claim, it follows that for each $i = 1, \ldots, n$, and $d \in (0, \bar{d})$, we have

$$u(x,t) \geq 1 - d - (1 - a - 2d)e^{-\epsilon(d)t}$$

and

$$v_i(x,t) \leq \kappa_i(1 - d - (1 - a - 2d)e^{-\epsilon(d)t}) + \sigma(d)$$

for all $x \geq M_1 + C(d)t + 2/\epsilon(d)$ and $t > 0$. Since d can be taken arbitrary small and $\epsilon(d), \sigma(d) < d$, the assertion of the lemma follows from taking the limit in the above inequalities. This completes the proof. ∎

The following technical lemma is one of the crucial tools, with which we can extend Chen's method [5] to the system (1.3)–(1.4), or, more generally, a system of parabolic equations.

Lemma 3.4. *There exists a positive function $\eta(m)$ defined on $[1, +\infty)$ such that if $(u_1, \mathbf{v}_1)$, $(u_2, \mathbf{v}_2)$ are the supersolution and subsolution of* (2.1)–(2.2)*, respectively, with $u_1(\cdot, 0) \geq u_2(\cdot, 0)$ and $\mathbf{v}_1(\cdot, 0) \leq \mathbf{v}_2(\cdot, 0)$ on $\mathbf{R}$, then for all $m \geq 1$ and $i = 1, \ldots, n$, the following hold:*

$$\min_{x\in[-m,m]} \{u_1(x,1) - u_2(x,1)\} \geq \eta(m) \left[\int_0^1 (u_1(\xi,0) - u_2(\xi,0))d\xi + \sum_{i=1}^n \int_0^1 (v_{2i}(\xi,0) - v_{1i}(\xi,0))d\xi \right],$$

$$\min_{x\in[-m,m]} \{v_{2i}(x,1) - v_{1i}(x,1)\} \geq \eta(m) \left[\int_0^1 (u_1(\xi,0) - u_2(\xi,0))d\xi + \sum_{i=1}^n \int_0^1 (v_{2i}(\xi,0) - v_{1i}(\xi,0))d\xi \right].$$

Proof. First, we set

$$\hat{u} := u_1 - u_2, \quad \hat{\mathbf{v}} = (\hat{v}_1, \ldots, \hat{v}_n) := (v_{21} - v_{11}, \ldots, v_{2n} - v_{1n}),$$

and

$$\begin{aligned} r(x,t) &:= (u_{1,t}(x,t) - L_1[u_1, \mathbf{v}_1](x,t)) - (u_{2,t}(x,t) - L_1[u_2, \mathbf{v}_2](x,t)), \\ s_i(x,t) &:= (v_{2i,t}(x,t) - L_{2i}[u_2, \mathbf{v}_2](x,t)) - (v_{1i,t}(x,t) - L_{2i}[u_1, \mathbf{v}_1](x,t)) \end{aligned}$$

for $i = 1, \ldots, n$. Then $r(x,t)$, $s_i(x,t)$ are nonnegative bounded continuous functions and the following hold:

$$\begin{aligned}\hat{u}_t &= L_1[u_1, \mathbf{v}_1] - L_1[u_2, \mathbf{v}_2] + r(x,t)\\ &= D\hat{u}_{xx} + \hat{b}(x,t)\hat{u} + \sum_{i=1}^{n}[(k_+^i u_2 + k_-^i)\hat{v}_i] + r(x,t)\\ &:= D\hat{u}_{xx} + \hat{b}(x,t)\hat{u} + \sum_{i=1}^{n}(k_-^i \hat{v}_i) + \bar{r}(x,t), \end{aligned}\tag{3.6}$$

$$\hat{v}_{i,t} = -(k_+^i u_2 + k_-^i)\hat{v}_i + (k_+^i \hat{u} v_{1i} + s_i)(x,t),\tag{3.7}$$

where

$$\hat{b}(x,t) := \int_0^1 \frac{df}{du}(\tau u_1(x,t) + (1-\tau)u_2(x,t))d\tau - \sum_{i=1}^{n} k_+^i v_{1i}(x,t)$$

and $\bar{r}(x,t)$ is a nonnegative bounded continuous function. Note that $\hat{u} \geq 0$ and $\hat{\mathbf{v}} \geq \mathbf{0}$ on $\mathbf{R} \times \mathbf{R}^+$, by Proposition 2.

Now we will prove that the conclusion holds for $u_1 - u_2$. Indeed, by the definitions of supersolution and subsolution of (2.1)–(2.2), there exists a positive constant M, which is independent of u_1, u_2, and $\mathbf{v}_1$, such that for all $(x,t) \in \mathbf{R} \times [0, +\infty)$, we have

$$|\hat{b}(x,t)| \leq M.$$

Let $\bar{u}(x,t) := e^{Mt}\hat{u}(x,t)$ on $\mathbf{R} \times [0, +\infty)$. Then $\bar{u}$ satisfies the following equation:

$$\bar{u}_t = D\bar{u}_{xx} + (M + \hat{b}(x,t))\bar{u} + e^{Mt}\sum_{i=1}^{n}(k_-^i \hat{v}_i) + e^{Mt}\bar{r}(x,t),$$

and so $\bar{u}$ can be represented by

$$\begin{aligned}\bar{u}(x,t) = &\int_{\mathbf{R}} \Gamma(x,t,\xi,0)\bar{u}(\xi,0)d\xi\\ &+ \int_0^t \int_{\mathbf{R}} \Gamma(x,t,\xi,\tau)\left[e^{M\tau}\sum_{i=1}^{n}(k_-^i \hat{v}_i(\xi,\tau))\right] d\xi d\tau\\ &+ \int_0^t \int_{\mathbf{R}} \Gamma(x,t,\xi,\tau)\left[(M + \hat{b}(\xi,\tau))\bar{u}(\xi,\tau) + e^{M\tau}\bar{r}(\xi,\tau)\right] d\xi d\tau,\end{aligned}\tag{3.8}$$

where

$$\Gamma(x,t,\xi,\tau) = \frac{\exp[-\frac{(x-\xi)^2}{4D(t-\tau)}]}{2\sqrt{\pi D(t-\tau)}}.$$

Solving (3.7), we obtain

$$\begin{aligned}\hat{v}_i(x,t) &= \hat{v}_i(x,0)\exp\left[-\int_0^t (k_+^i u_2(x,\sigma) + k_-^i)d\sigma\right]\\ &\quad + \int_0^t \exp\left[-\int_\sigma^t (k_+^i u_2(x,\tau) + k_-^i)d\tau\right](k_+^i \hat{u} v_{1i} + s_i)(x,\sigma)d\sigma\\ &\geq \hat{v}_i(x,0)\exp\left[-\int_0^t (k_+^i u_2(x,\sigma) + k_-^i)d\sigma\right]\\ &\geq \hat{v}_i(x,0)\exp[-\tilde{C}_1 t],\end{aligned}\tag{3.9}$$

where $\tilde{C}_1$ is a positive constant depending only on k_+^i, k_-^i, and b_0^i. Note that by the definitions of M, $\hat{b}$, and $\bar{r}$, the third term in (3.8) is nonnegative. Combining this with (3.8)–(3.9), there exist positive constants C_1 and $\hat{C}_1$, which depend only on D, k_+^i, k_-^i, and b_0^i, such that for all $(x,t) \in \mathbf{R} \times \mathbf{R}^+$, the following holds:

$$
\begin{aligned}
\bar{u}(x,t) \geq\ & \frac{C_1}{\sqrt{t}} \int_{\mathbf{R}} \exp\Big[-\hat{C}_1 \frac{(x-\xi)^2}{t} \Big] \bar{u}(\xi,0) d\xi \\
& + C_1 \sum_{i=1}^n \int_0^t \int_{\mathbf{R}} \frac{\exp(-\hat{C}_1 \frac{(x-\xi)^2}{t-\tau})}{\sqrt{t-\tau}} \Big[\exp(M\tau) \hat{v}_i(\xi,\tau) \Big] d\xi d\tau \\
\geq\ & \frac{C_1}{\sqrt{t}} \int_{\mathbf{R}} \exp\Big[-\hat{C}_1 \frac{(x-\xi)^2}{t} \Big] \bar{u}(\xi,0) d\xi \\
& + C_1 \sum_{i=1}^n \int_0^t \int_{\mathbf{R}} \frac{\exp(-\hat{C}_1 \frac{(x-\xi)^2}{t-\tau})}{\sqrt{t-\tau}} \Big[\exp((M-\tilde{C}_1)\tau) \hat{v}_i(\xi,0) \Big] d\xi d\tau.
\end{aligned}
$$

Hence for each $m \geq 1$ and $t > 0$, we have

(3.10)

$$
\begin{aligned}
\min_{x \in [-m,m]} \hat{u}(x,t) \geq\ & C_1 \frac{\exp[-Mt - \hat{C}_1 (m+1)^2/t]}{\sqrt{t}} \int_0^1 \hat{u}(\xi,0) d\xi \\
& + C_1 \sum_{i=1}^n \left(\int_0^t \frac{\exp[-Mt - \hat{C}_1 \frac{(m+1)^2}{t-\tau} + (M-\tilde{C}_1)\tau]}{\sqrt{t-\tau}} d\tau \right) \int_0^1 \hat{v}_i(\xi,0) d\xi \\
:=\ & A(t) \int_0^1 \hat{u}(\xi,0) d\xi + B(t) \sum_{i=1}^n \int_0^1 \hat{v}_i(\xi,0) d\xi.
\end{aligned}
$$

Finally, by setting

$$\eta_1(m) := \min\{A(1), B(1)\}$$

and using (3.10), our conclusion for $u_1 - u_2$ follows. However, we will replace $\eta_1(m)$ by a smaller quantity, $\eta(m)$, later.

Next, we will show that the conclusion holds for $v_2 - v_1$. Indeed, by the definitions of supersolution and subsolution of (2.1)–(2.2), there exist positive constants C_2 and $\hat{C}_2$, which depend only on k_+^i, k_-^i, and b_0^i, such that for each $i = 1, \ldots, n$, the following holds:

$$k_+^i u_2 + k_-^i \leq \hat{C}_2, \quad k_+^i v_{1i} \geq C_2 \quad \text{on} \quad \mathbf{R} \times [0, +\infty).$$

Using this inequality and the fact that $\hat{v}_i, s_i \geq 0$ on $\mathbf{R} \times [0, +\infty)$, and solving (3.7), we obtain that for $t = 1$ and $x \in [-m, m]$ with $m \geq 1$, there holds

$$
\begin{aligned}
\hat{v}_i(x,1) =\ & \hat{v}_i(x,0) \exp\left[-\int_0^1 (k_+^i u_2(x,\sigma) + k_-^i) d\sigma \right] \\
& + \int_0^1 \exp\left[-\int_\sigma^1 (k_+^i u_2(x,\tau) + k_-^i) d\tau \right] (k_+^i \hat{u} v_{1i} + s_i)(x,\sigma) d\sigma \\
\geq\ & \int_0^1 \exp\left[-\int_\sigma^1 (k_+^i u_2(x,\tau) + k_-^i) d\tau \right] (k_+^i \hat{u}(x,\sigma) v_{1i}(x,\sigma)) d\sigma \\
\geq\ & C_2 \int_0^1 \exp\left[-\int_\sigma^1 \hat{C}_2 d\tau \right] A(\sigma) d\sigma \cdot \int_0^1 \hat{u}(\xi,0) d\xi \\
& + C_2 \int_0^1 \exp\left[-\int_\sigma^1 \hat{C}_2 d\tau \right] B(\sigma) d\sigma \cdot \sum_{i=1}^n \int_0^1 \hat{v}_i(\xi,0) d\xi,
\end{aligned}
$$

where, in the last inequality, we have used (3.10). Finally, by setting

$$\eta(m) := \min\left\{\eta_1(m), C_2\int_0^1 \exp\left[-\int_\sigma^1 \hat{C}_2 d\tau\right] A(\sigma)d\sigma, C_2\int_0^1 \exp\left[-\int_\sigma^1 \hat{C}_2 d\tau\right] B(\sigma)d\sigma\right\},$$

and using the above inequality and (3.10), the assertion of this lemma follows. This completes the proof. ∎

The following lemma is the main tool for the iteration process in the proof of Theorem 1. We will modify the method of [5, Lemma 3.3] to prove it (see also [36]).

LEMMA 3.5. *Suppose that the assumptions of Theorem* 1 *hold. Then for each* $h_0 > 0$*, there exists a small positive constant* $\epsilon^* = \epsilon^*(h_0) \in (0, \min\{1/(2\nu), d_0/2\})$*, which is independent of* $(u(\cdot,0), \mathbf{v}(\cdot,0))$*, such that if, for some* $\tau \geq 0$*,* $\xi \in \mathbf{R}$*,* $d \in (0, \min\{1/\nu, d_0/2\}]$*, and* $h \in [0, h_0]$*, the following holds:*

$$\mathcal{U}(x - c\tau + \xi) - d \leq u(x,t) \leq \mathcal{U}(x - c\tau + \xi + h) + d, \tag{3.11}$$

$$\Pi_i(x - c\tau + \xi + h) - dk_{0i} \leq v_i(x,t) \leq \Pi_i(x - c\tau + \xi) + dk_{0i} \tag{3.12}$$

for all $x \in \mathbf{R}$ *and* $i = 1, \ldots, n$*, then for every* $t > \tau + 1$*, there exist* $\hat{\xi}(t)$*,* $\hat{d}(t)$*, and* $\hat{h}(t)$ *satisfying*

$$\begin{aligned}
&\hat{\xi}(t) \in [\xi - \nu d, \xi + \min\{h, 1\} + \nu d]\\
&\hat{d}(t) \leq e^{-\mu_0(t-\tau-1)}[d + \epsilon^*(h_0)\min\{h, 1\}],\\
&\hat{h}(t) \leq [h - \nu\epsilon^*(h_0)\min\{h, 1\}] + 2\nu d,
\end{aligned}$$

such that (3.11)–(3.12) *hold with* (τ, ξ, d, h) *replaced by* $(t, \hat{\xi}(t), \hat{d}(t), \hat{h}(t))$*. In the remainder of this paper, we will retain the notation* $\epsilon^*(h_0)$*.*

Proof. If necessary, by a shift of time, we may assume that $\tau = 0$. Now by comparing $(u, \mathbf{v})$ with $(w^\pm, \mathbf{p}^\pm)$ in Lemma 3.1 (with $\xi_0 = \xi$ for $(w^-, \mathbf{p}^-)$ and $\xi_0 = \xi + h$ for $(w^+, \mathbf{p}^+)$), we have that for all $(x,t) \in \mathbf{R} \times \mathbf{R}^+$ and $i = 1, \ldots, n$, there holds

$$\begin{aligned}
\mathcal{U}(x - ct + \xi - \nu d(1 - e^{-\mu_0 t})) - de^{-\mu_0 t} &\leq u(x,t)\\
&\leq \mathcal{U}(x - ct + \xi + h + \nu d(1 - e^{-\mu_0 t})) + de^{-\mu_0 t},
\end{aligned} \tag{3.13}$$

$$\begin{aligned}
\Pi_i(x - ct + \xi + h + \nu d(1 - e^{-\mu_0 t})) - dk_{0i}e^{-\mu_0 t} &\leq v_i(x,t)\\
&\leq \Pi_i(x - ct + \xi - \nu d(1 - e^{-\mu_0 t})) + dk_{0i}e^{-\mu_0 t}.
\end{aligned} \tag{3.14}$$

Fix a number x_0 with the property

$$0 \leq x_0 + \xi < \frac{1}{2}.$$

Since $\lim_{|s|\to\infty}(\mathcal{U}'(s), \mathbf{\Pi}'(s)) = (0, \mathbf{0})$, we can fix a sufficiently large constant $M > h_0$ such that for all $|s| \geq M$ and $i = 1, \ldots, n$, we have

$$\mathcal{U}'(s) \leq \frac{1}{2\nu} \quad \text{and} \quad -\Pi_i'(s) \leq \frac{\min\{1, k_{0i}\}}{2\nu}. \tag{3.15}$$

Set

$$\bar{h} = \min\{h, 1\} \ \text{ and } \ \epsilon_1 := \frac{(n+1)}{2} \min_{s\in[0,3], 1\leq i\leq n} \left\{\mathcal{U}'(s), -\Pi_i'(s)\right\}.$$

Then by using the mean-value theorem, we have

$$\int_0^1 \Big(\mathcal{U}(y+x_0+\xi+\bar{h}) - \mathcal{U}(y+x_0+\xi)\Big)dy + \sum_{i=1}^n \int_0^1 \Big(\Pi_i(y+x_0+\xi) - \Pi_i(y+x_0+\xi+\bar{h})\Big)dy \geq 2\epsilon_1\bar{h},$$

and so, at least one of the following holds:

$$\text{(i)} \int_0^1 \Big(\mathcal{U}(y+x_0+\xi+\bar{h}) - u(y+x_0,0)\Big)dy + \sum_{i=1}^n \int_0^1 \Big(v_i(y+x_0,0) - \Pi_i(y+x_0+\xi+\bar{h})\Big)dy \geq \epsilon_1\bar{h},$$

$$\text{(ii)} \int_0^1 \Big(u(y+x_0,0) - \mathcal{U}(y+x_0+\xi)\Big)dy + \sum_{i=1}^n \int_0^1 \Big(\Pi_i(y+x_0+\xi) - v_i(y+x_0,0)\Big)dy \geq \epsilon_1\bar{h}.$$

In what follows, we will consider case (i) since case (ii) follows by analogous arguments. Set $\xi_1 := c - \nu d(1-e^{-\mu_0})$. Note that $|\xi_1| \leq |c|+1$, since $\nu d \leq 1$. By using (3.13)–(3.14) and Lemma 3.4, we obtain that for $\eta = \eta(2(M+|c|+1))$, every x with $x+x_0+\xi+h-\xi_1 \in [-2(M+|c|+1), 2(M+|c|+1)]$, and each $i = 1,\ldots,n$, there holds

$$\begin{aligned}
&[\mathcal{U}(x+x_0+\xi+h-\xi_1) + de^{-\mu_0}] - u(x+x_0,1) \\
&\geq \eta\left[\int_0^1 \Big([\mathcal{U}(y+x_0+\xi+\bar{h}) + d] - u(y+x_0,0)\Big)dy \right.\\
&\quad \left. + \sum_{i=1}^n \int_0^1 \Big(v_i(y+x_0,0) - [\Pi_i(y+x_0+\xi+\bar{h}) - dk_{0i}]\Big)dy\right] \\
&\geq \eta\epsilon_1\bar{h}, \\
&v_i(x+x_0,1) - [\Pi_i(x+x_0+\xi+h-\xi_1) - dk_{0i}e^{-\mu_0}] \\
&\geq \eta\left[\int_0^1 \Big([\mathcal{U}(y+x_0+\xi+\bar{h}) + d] - u(y+x_0,0)\Big)dy \right.\\
&\quad \left. + \sum_{i=1}^n \int_0^1 \Big(v_i(y+x_0,0) - [\Pi_i(y+x_0+\xi+\bar{h}) - dk_{0i}]\Big)dy\right] \\
&\geq \eta\epsilon_1\bar{h},
\end{aligned} \tag{3.16}$$

where we have used the facts that $\mathcal{U}$, $-\Pi_i$ are monotone increasing and $h \geq \bar{h}$. Define

$$\epsilon^* = \epsilon^*(h_0) := \min_{i=1,\ldots,n}\Big\{\frac{d_0}{2}, \frac{1}{2\nu}, \min_{|x|\leq 2(M+|c|+1)} \frac{\eta\epsilon_1}{2\nu\mathcal{U}'(x)}, \min_{|x|\leq 2(M+|c|+1)} \frac{\eta\epsilon_1}{-2\nu\Pi_i'(x)}\Big\}.$$

Let the set A_1 defined by

$$A_1 = \{x \in \mathbf{R} \mid -2(M+|c|+1) \leq x+x_0+\xi-\xi_1 \leq (M+|c|+1)\}.$$

Recall that $h \in (0, M)$ and $2\nu\epsilon^*(h_0) \in (0,1)$. Therefore for all $x \in A_1$ and $\theta \in (0,1)$, there holds

$$|x + x_0 + \xi + h - \xi_1| \leq 2(M + |c| + 1),$$
$$|x + x_0 + \xi + h - \xi_1 - 2\nu\theta\epsilon^*(h_0)\bar{h})| \leq 2(M + |c| + 1).$$

Hence by the mean-value theorem and the choice of $\epsilon^*(h_0)$, we can choose $\theta_i \in (0,1)$, $i = 0, 1, \dots, n$, such that for all $x \in A_1$ and $i = 1, \dots, n$, the following holds:

$$\begin{aligned}
&\mathcal{U}(x + x_0 + \xi + h - \xi_1 - 2\nu\epsilon^*(h_0)\bar{h}) - \mathcal{U}(x + x_0 + \xi + h - \xi_1)\\
&= \mathcal{U}'(x + x_0 + \xi + h - \xi_1 - 2\theta_0\nu\epsilon^*(h_0)\bar{h})(-2\nu\epsilon^*(h_0)\bar{h})\\
&\geq -\eta\epsilon_1\bar{h},\\
&\Pi_i(x + x_0 + \xi + h - \xi_1 - 2\nu\epsilon^*(h_0)\bar{h}) - \Pi_i(x + x_0 + \xi + h - \xi_1)\\
&= \Pi_i'(x + x_0 + \xi + h - \xi_1 - 2\theta_i\nu\epsilon^*(h_0)\bar{h})(-2\nu\epsilon^*(h_0)\bar{h})\\
&\leq \eta\epsilon_1\bar{h}.
\end{aligned}$$

Combining these two inequalities with (3.16), it follows that for all $x \in A_1$ and $i = 1, \dots, n$, we have

$$\begin{aligned}
u(x + x_0, 1) &\leq \mathcal{U}(x + x_0 + \xi + h - \xi_1 - 2\nu\epsilon^*(h_0)\bar{h}) + de^{-\mu_0},\\
v_i(x + x_0, 1) &\geq \Pi_i(x + x_0 + \xi + h - \xi_1 - 2\nu\epsilon^*(h_0)\bar{h}) - dk_{0i}e^{-\mu_0}.
\end{aligned} \tag{3.17}$$

Next, we turn to consider the set $A_2 := \mathbf{R} \setminus A_1$. By using the properties of h_0 and $\epsilon^*(h_0)$ again, we can conclude that for all $x \in A_2$ and $\theta \in (0,1)$, there holds

$$|x + x_0 + \xi + h - \xi_1| \geq M + |c| + 1,$$
$$|x + x_0 + \xi + h - \xi_1 - 2\nu\theta\epsilon^*(h_0)\bar{h})| \geq M + |c| + 1.$$

Therefore by using the mean-value theorem, the last inequalities, (3.15), and the second inequality of (3.13) and the first inequality of (3.14) with $t = 1$, we can conclude that there exist $\theta_i \in (0,1)$, $i = 0, 1, \dots, n$, such that for all $x \in A_2$ and $i = 1, \dots, n$, there holds

$$\begin{aligned}
&\mathcal{U}(x + x_0 + \xi + h - \xi_1 - 2\nu\epsilon^*(h_0)\bar{h})\\
&\quad = \mathcal{U}(x + x_0 + \xi + h - \xi_1)\\
&\quad\quad + \mathcal{U}'(x + x_0 + \xi + h - \xi_1 - 2\theta_0\nu\epsilon^*(h_0)\bar{h})(-2\nu\epsilon^*(h_0)\bar{h})\\
&\quad \geq \mathcal{U}(x + x_0 + \xi + h - \xi_1) - \epsilon^*(h_0)\bar{h}\\
&\quad \geq u(x + x_0, 1) - [de^{-\mu_0} + \epsilon^*(h_0)\bar{h}],\\
&\Pi_i(x + x_0 + \xi + h - \xi_1 - 2\nu\epsilon^*(h_0)\bar{h})\\
&\quad = \Pi(x + x_0 + \xi + h - \xi_1)\\
&\quad\quad + \Pi'(x + x_0 + \xi + h - \xi_1 - 2\theta_i\nu\epsilon^*(h_0)\bar{h})(-2\nu\epsilon^*(h_0)\bar{h})\\
&\quad \leq \Pi(x + x_0 + \xi + h - \xi_1) + \epsilon^*(h_0)\bar{h}k_{0i}\\
&\quad \leq v(x + x_0, 1) + [de^{-\mu_0} + \epsilon^*(h_0)\bar{h}]k_{0i},
\end{aligned}$$

which together with (3.17), implies that for all $x \in \mathbf{R}$ and $i = 1, \dots, n$, we have

$$\begin{aligned}
u(x, 1) &\leq \mathcal{U}(x + \xi + h - \xi_1 - 2\nu\epsilon^*(h_0)\bar{h}) + [de^{-\mu_0} + \epsilon^*(h_0)\bar{h}],\\
v_i(x, 1) &\geq \Pi_i(x + \xi + h - \xi_1 - 2\nu\epsilon^*(h_0)\bar{h}) - [de^{-\mu_0} + \epsilon^*(h_0)\bar{h}]k_{0i}.
\end{aligned}$$

Now set $q := de^{-\mu_0} + \epsilon^*(h_0)\bar{h}$. Note that q is not bigger than d_0 by the choice of $\epsilon^*(h_0)$. Also recall that $\xi_1 = c - \nu d(1 - e^{-\mu_0})$. Hence by comparing $(u(x, 1 + t'), \mathbf{v}(x, 1 + t'))$ with $(\mathcal{U}(\xi_2) + qe^{-\mu_0 t'}, \mathbf{\Pi}(\xi_2) - \mathbf{k}_0 qe^{-\mu_0 t'})$ (with $\xi_2 = x - ct' + \xi + h - \xi_1 - 2\nu\epsilon^*(h_0)\bar{h} + \nu q(1 - e^{-\mu_0 t'})$ and $\mathbf{k}_0 = (k_{01}, \ldots, k_{0n})$), we can conclude that for all $(x, t') \in \mathbf{R} \times \mathbf{R}^+$ and $i = 1, \ldots, n$, there holds

$$\begin{aligned} u(x, 1 + t') &\leq \mathcal{U}(x - ct' + \xi + h - \xi_1 - 2\nu\epsilon^*(h_0)\bar{h} + \nu q(1 - e^{-\mu_0 t'})) + qe^{-\mu_0 t'} \\ &\leq \mathcal{U}(x - c(1 + t') + \xi - \nu d + [h - \nu\epsilon^*(h_0)\bar{h} + 2\nu d]) + (d + \epsilon^*(h_0)\bar{h})e^{-\mu_0 t'} \end{aligned}$$

and

$$\begin{aligned} &v_i(x, 1 + t') \\ &\quad \geq \Pi_i(x - ct' + \xi + h - \xi_1 - 2\nu\epsilon^*(h_0)\bar{h} + \nu q(1 - e^{-\mu_0 t'})) - qk_{0i}e^{-\mu_0 t'} \\ &\quad \geq \Pi_i(x - c(1 + t') + \xi - \nu d + [h - \nu\epsilon^*(h_0)\bar{h} + 2\nu d]) - (d + \epsilon^*(h_0)\bar{h})k_{0i}e^{-\mu_0 t'}. \end{aligned}$$

Set

$$t = 1 + t', \ \hat{\xi}(t) = \xi - \nu d, \ \hat{h}(t) = h - \nu\epsilon^*(h_0)\bar{h} + 2\nu d, \ \text{and} \ \hat{d}(t) = (d + \epsilon^*(h_0)\bar{h})e^{-\mu_0(t-1)}.$$

It then follows that for all $(x, t) \in \mathbf{R} \times \mathbf{R}^+$ with $t > 1$ and $i = 1, \ldots, n$, we have

$$\begin{aligned} u(x, t) &\leq \mathcal{U}(x - ct + \hat{\xi}(t) + \hat{h}(t)) + \hat{d}(t), \\ v_i(x, t) &\geq \Pi_i(x - ct + \hat{\xi}(t) + \hat{h}(t)) - \hat{d}(t)k_{0i}. \end{aligned} \tag{3.18}$$

Finally, it remains to be seen whether the first inequality of (3.11) and the second inequality of (3.12) hold with (τ, ξ, d, h) replaced by $(t, \hat{\xi}(t), \hat{d}(t), \hat{h}(t))$. In fact, by using (3.13)–(3.14) and the monotonicity of $(\mathcal{U}, \mathbf{\Pi})$, we can conclude that for all $(x, t) \in \mathbf{R} \times \mathbf{R}^+$ and $i = 1, \ldots, n$, there holds

$$\begin{aligned} u(x, t) &\geq \mathcal{U}(x - ct + \xi - \nu d(1 - e^{-\mu_0 t})) - de^{-\mu_0 t} \\ &\geq \mathcal{U}(x - ct + \xi - \nu d) - (d + \epsilon^*(h_0)\bar{h})e^{-\mu_0(t-1)} \\ &= \mathcal{U}(x - ct + \hat{\xi}(t)) - \hat{d}(t), \end{aligned} \tag{3.19}$$

and

$$\begin{aligned} v_i(x, t) &\leq \Pi_i(x - ct + \xi - \nu d(1 - e^{-\mu_0 t})) + dk_{0i}e^{-\mu_0 t} \\ &\leq \Pi_i(x - ct + \xi - \nu d) + (d + \epsilon^*(h_0)\bar{h})k_{0i}e^{-\mu_0(t-1)} \\ &= \Pi_i(x - ct + \hat{\xi}(t)) + \hat{d}(t)k_{0i}. \end{aligned} \tag{3.20}$$

Therefore (3.18), (3.19), and (3.20) imply the assertion of this lemma. The proof is completed. □

3.2. The proof of Theorem 1. Now we have every necessary tool at hand to prove our main theorem. Note that it may take a long time for the solution $(u, \mathbf{v})$ of (2.1)–(2.2) with the initial data satisfying the condition of Theorem 1 to be trapped between two translates of the wave whose difference of phase shifts is less than 1. Therefore, the proof will consist of two main steps. First, we will use the squeezing method [5, pp. 139–140] with minor modification to prove that the assertion of Theorem 1 holds, but the rate constant of convergence $\widehat{\kappa}$ may depend on the initial data $(u(\cdot, 0), \mathbf{v}(\cdot, 0))$ (see Lemma 3.6). Next, we will show that the exponent constant

$\widehat{\kappa}$ can be replaced with a universal constant κ. We remark that the presentation of this subsection is similar to that in [36] where we study a single quasilinear diffusion-advection equation. But for completeness and reader's convenience, we would like to include it here.

LEMMA 3.6. *Under the assumption of Theorem* 1, *there exists a positive constant* $\widehat{\kappa}$ *which may depend on the initial data* $(u(\cdot,0),\mathbf{v}(\cdot,0))$ *such that*

$$\sup_{x\in\mathbf{R}}|u(x,t)-\mathcal{U}(x-ct+\xi^*)|\le Ke^{-\widehat{\kappa}t},\quad \sup_{x\in\mathbf{R}}|v_i(x,t)-\Pi_i(x-ct+\xi^*)|\le Ke^{-\widehat{\kappa}t},$$

for $i=1,\dots,n$, *and for some constants* ξ^* *and* K *which may depend on* $(u(\cdot,0),\mathbf{v}(\cdot,0))$.

Proof. The proof consists of four steps.

Step 1. Define the quantity

$$\tilde{d}^*:=\min\{1/(2\nu),d_0/2\}.$$

For this $\tilde{d}^*$, by Lemma 3.3 and the fact that $(\mathcal{U}(+\infty),\mathbf{\Pi}(+\infty))=(1,\mathbf{b}_2)$, $(\mathcal{U}(-\infty),\mathbf{\Pi}(-\infty))=(0,\mathbf{b}_0)$, there exist sufficiently large constants $h_0>2$ and $\tilde{T}_0$ such that the following holds:

$$\mathcal{U}(x-c\tilde{T}_0-h_0/4)-\tilde{d}^*\le u(x,\tilde{T}_0)\le\mathcal{U}(x-c\tilde{T}_0-h_0/4+h_0/2)+\tilde{d}^*, \tag{3.21}$$
$$\Pi(x-c\tilde{T}_0-h_0/4+h_0/2)-\tilde{d}^*k_{0i}\le v(x,\tilde{T}_0)\le\Pi(x-c\tilde{T}_0-h_0/4)+\tilde{d}^*k_{0i} \tag{3.22}$$

for all $x\in\mathbf{R}$ and $i=1,\dots,n$. Therefore (3.11)–(3.12) holds with $\tau=\tilde{T}_0$, $\xi=-h_0/4$, $h=h_0/2$, and $d=\tilde{d}^*$. Let $\epsilon^*(h_0)$ be defined as in the proof of Lemma 3.5, and set

$$d_0^*:=\epsilon^*(h_0)/4,\quad \kappa_0^*:=\nu\epsilon^*(h_0)/2<1/4.$$

Note that $\epsilon^*(h_0)\le\tilde{d}^*$ by the definition of $\epsilon^*(h_0)$. Therefore we can fix a sufficiently large constant $t_0^*\ge 2$ with the property that

$$e^{-\mu_0(t_0^*-1)}(\tilde{d}^*+\epsilon^*(h_0))\le d_0^*\ \text{ and }\ e^{-\mu_0(t_0^*-1)}(1+\epsilon^*(h_0)/d_0^*)\le 1-\kappa_0^*.$$

Now by (3.21)–(3.22) and Lemma 3.5, we can conclude that (3.11)–(3.12) hold for $\tau=\tilde{T}_0+t_0^*$, some $\hat{\xi}\in[-h_0/4-\nu\tilde{d}^*,-h_0/4+1+\nu\tilde{d}^*]$, $h=\hat{h}(\tilde{T}_0+t_0^*)$, and $d=\hat{d}(\tilde{T}_0+t_0^*)$. By the associated definitions, we can estimate $\hat{h}(\tilde{T}_0+t_0^*)$ and $\hat{d}(\tilde{T}_0+t_0^*)$ as follows:

$$\begin{aligned}\hat{h}(\tilde{T}_0+t_0^*)&\le\frac{h_0}{2}-\nu\epsilon^*(h_0)+2\nu\tilde{d}^*<\frac{h_0}{2}+1<h_0,\\ \hat{d}(\tilde{T}_0+t_0^*)&\le e^{-\mu_0(t_0^*-1)}(\tilde{d}^*+\epsilon^*(h_0))\le d_0^*.\end{aligned}$$

Together with the monotonicity of $(\mathcal{U},\mathbf{\Pi})$, the above discussion leads to

$$\mathcal{U}(x-c(\tilde{T}_0+t_0^*)+\hat{\xi})-d_0^*\le u(x,\tilde{T}_0+t_0^*)\le\mathcal{U}(x-c(\tilde{T}_0+t_0^*)+\hat{\xi}+h_0)+d_0^*, \tag{3.23}$$
$$\begin{aligned}\Pi_i(x-c(\tilde{T}_0+t_0^*)+\hat{\xi}+h_0)-d_0^*k_{0i}&\le v_i(x,\tilde{T}_0+t_0^*)\\ &\le\Pi_i(x-c(\tilde{T}_0+t_0^*)+\hat{\xi})+d_0^*k_{0i}\end{aligned} \tag{3.24}$$

for all $x\in\mathbf{R}$ and $i=1,\dots,n$. Therefore (3.11)–(3.12) hold for $\tau=T_0:=\tilde{T}_0+t_0^*$, some $\hat{\xi}\in[-h_0/4-\nu\tilde{d}^*,-h_0/4+1+\nu\tilde{d}^*]$, $h=h_0$, and $d=d_0^*$. Although the remainder of the proof is almost identical to [5, pp. 139–140], for completeness and the later use, we include it here.

Step 2. *Now we claim that there exists a finite time $T_1 > T_0$ such that* (3.11)–(3.12) *hold for $\tau = T_1$, $h = 1$, $d = d_0^*$, and some $\xi \in \mathbf{R}$.* Recall that $h_0 > 2$. Let N be the unique positive integer such that $h_0 \in [1 + (N-1)\kappa_0^*, 1 + N\kappa_0^*)$. Now by (3.23)–(3.24) and Lemma 3.5, it follows that (3.11)–(3.12) hold for $\tau = T_0 + t_0^*$, some $\xi \in [\hat{\xi} - \nu d_0^*, \hat{\xi} + 1 + \nu d_0^*]$, $h = \hat{h}(T_0 + t_0^*)$, and $d = \hat{d}(T_0 + t_0^*)$. As before, $\hat{h}(T_0 + t_0^*)$ and $\hat{d}(T_0 + t_0^*)$ can be estimated as follows:

$$\hat{h}(T_0+t_0^*) \le h_0 - \nu\epsilon^*(h_0) + 2\nu d_0^* = h_0 - \kappa_0^*, \quad \hat{d}(T_0+t_0^*) \le e^{-\mu_0(t_0^*-1)}(d_0^* + \epsilon^*(h_0)) \le d_0^*.$$

Combined with the monotonicity of $(\mathcal{U}, \mathbf{\Pi})$, it follows that (3.11)–(3.12) hold for $\tau = T_0 + t_0^*$, some $\xi \in [\hat{\xi} - \nu d_0^*, \hat{\xi} + 1 + \nu d_0^*]$, $h = h_0 - \kappa_0^*$, and $d = d_0^*$. Repeating the same process N times, it yields that (3.11)–(3.12) hold for $\tau = T_1 := T_0 + Nt_0^*$, some $\xi^0 \in \mathbf{R}$, $h = h_0 - N\kappa_0^*$, and $d = d_0^*$. Finally, by the monotonicity of $(\mathcal{U}, \mathbf{\Pi})$ again, the assertion of this claim follows.

Step 3. *Now we claim that for each $k \in \mathbf{N} \cup \{0\}$,* (3.11)–(3.12) *hold for some $\xi = \xi^k \in \mathbf{R}$ and*

$$\tau = T^k := T_1 + kt_0^*, \quad h = h^k := (1 - \kappa_0^*)^k, \quad d = d^k := (1-\kappa_0^*)^k d_0^*.$$

Moreover, we have

$$|\xi^{k+1} - \xi^k| \le (1 + \nu d_0^*)(1-\kappa_0^*)^k \text{ for all } k \in \mathbf{N} \cup \{0\}. \tag{3.25}$$

Indeed, *Step* 2 implies that the claim holds for $k = 0$. Now we assume that the claim holds for some $k = m \ge 0$. Applying Lemma 3.5 with $(\tau, \xi, h, d) = (T^m, \xi^m, h^m, d^m)$, we then obtain that (3.11)–(3.12) hold for $(\tau, \xi, h, d) = (T^m + t_0^*, \hat{\xi}(T^m + t_0^*), \hat{h}(T^m + t_0^*), \hat{d}(T^m + t_0^*))$ which satisfies the following:

$$\begin{aligned}
\xi^{m+1} &:= \hat{\xi}(T^m + t_0^*) \in [\xi^m - \nu d^m, \xi^m + \nu d^m + h^m],\\
\hat{h}(T^m + t_0^*) &\le h^m - \nu\epsilon^*(h_0)h^m + 2\nu d^m\\
&= (1-\kappa_0^*)^{m+1},\\
\hat{d}(T^m + t_0^*) &\le e^{-\mu_0(t_0^*-1)}(d^m + \epsilon^*(h_0)h^m)\\
&= (1-\kappa_0^*)^m d_0^* e^{-\mu_0(t_0^*-1)}(1 + \epsilon^*(h_0)/d_0^*)\\
&\le (1-\kappa_0^*)^{m+1} d_0^*.
\end{aligned}$$

Using this and the monotonicity of $(\mathcal{U}, \mathbf{\Pi})$, we can conclude that (3.11)–(3.12) hold for $(\tau, \xi, h, d) = (T^{m+1}, \xi^{m+1}, h^{m+1}, d^{m+1})$. This completes the proof of the first part of this claim.

Finally, noting that $|\xi^{k+1} - \xi^k| \le \nu d^k + h^k$ and using the definitions of h^k and d^k, (3.25) follows.

Step 4. *Finally, we will prove the assertion of the lemma.* For each $k \in \mathbf{N} \cup \{0\}$, recall that (3.11)–(3.12) hold for $(\tau, \xi, h, d) = (T^k, \xi^k, h^k, d^k)$. Hence from (3.13)–(3.14) and the monotonicity of $(\mathcal{U}, \mathbf{\Pi})$, it follows that (3.11)–(3.12) hold for $\tau \in [T^k, \infty)$, $d = d^k$, $h = h^k + 2\nu d^k$, and $\xi = \xi^k - \nu d^k$. Hence, if we define $\xi(t) = \xi^k - \nu d^k$, $h(t) = h^k + 2\nu d^k$, and $d(t) = d^k$ for all $t \in [T^k, T^{k+1})$, then it follows that for all $(x, t) \in \mathbf{R} \times [T_1, +\infty)$ and $i = 1, \ldots, n$, there holds

$$\mathcal{U}(x - ct + \xi(t)) - d(t) \le u(x,t) \le \mathcal{U}(x - ct + \xi(t) + h(t)) + d(t), \tag{3.26}$$

$$\Pi_i(x - ct + \xi(t) + h(t)) - d(t)k_{0i} \le v_i(x,t) \le \Pi_i(x - ct + \xi(t)) + d(t)k_{0i}. \tag{3.27}$$

Next, for each $t \in [T_1, +\infty)$, there exists a unique nonnegative integer $m = m(t)$ which is the largest integer not greater than $(t - T_1)/t_0^*$. Then we have $t \in [T^m, T^{m+1})$, and from the definitions of $h(t)$ and $d(t)$, it follows that for all $t \geq T_1$, there holds

$$h(t) = h^m + 2\nu d^m \leq (1 + 2\nu d_0^*) \exp\left[\Big(\frac{t - T_1}{t_0^*} - 1\Big) \ln(1 - \kappa_0^*)\right], \tag{3.28}$$

$$d(t) = d^m \leq d_0^* \exp\left[\Big(\frac{t - T_1}{t_0^*} - 1\Big) \ln(1 - \kappa_0^*)\right]. \tag{3.29}$$

Now we will show that $\xi(\infty) := \lim_{t \to +\infty} \xi(t)$ exists. Indeed, for any $\tau \geq t \geq T_1$, there exist nonnegative integers l and p such that $\tau \in [T^l, T^{l+1})$ and $t \in [T^p, T^{p+1})$. Then by the definitions of $\xi(t)$ and (3.25), we can estimate $|\xi(\tau) - \xi(t)|$ as follows:

$$\begin{aligned}
|\xi(\tau) - \xi(t)| &= |(\xi^l - \nu d^l) - (\xi^p - \nu d^p)| \\
&\leq \sum_{i=p}^{l-1} |\xi^{i+1} - \xi^i| + \nu |d^l - d^p| \\
&= \Big(\frac{1 + \nu d_0^*}{\kappa_0^*} + \nu d_0^*\Big) |(1 - \kappa_0^*)^p - (1 - \kappa_0^*)^l)|,
\end{aligned}$$

which tends to zero as $\tau, t \to +\infty$. Hence $\xi(\infty)$ exists. Moreover, we have

$$|\xi(t) - \xi(\infty)| \leq \Big(\frac{1 + \nu d_0^*}{\kappa_0^*} + \nu d_0^*\Big) \exp\left[\Big(\frac{t - T_1}{t_0^*} - 1\Big) \ln(1 - \kappa_0^*)\right] \tag{3.30}$$

for all $t \geq T_1$. Now set

$$\widehat{\kappa} := -\ln(1 - \kappa_0^*)/t_0^*,$$

which may depend on the initial data $(u(\cdot, 0), \mathbf{v}(\cdot, 0))$. Finally, combining (3.26)–(3.30) with the mean-value theorem, we obtain the assertion of this lemma. This completes the proof. $\square$

Final Proof of Theorem 1. With this preparation, we are ready to complete the proof of Theorem 1. Note that it remains to be seen whether the exponent constant $\hat{\kappa}$ can be replaced with a universal constant κ.

First, we define the following two quantities:

$$d^* := \frac{\epsilon^*(1)}{4} \quad \text{and} \quad \kappa^* := \frac{\nu \epsilon^*(1)}{2} < \frac{1}{4},$$

where $\epsilon^*(1)$ is defined in the proof of Lemma 3.5. We then fix a sufficiently large constant $t^* \geq 2$ with the property that

$$e^{-\mu_0 (t^* - 1)} (1 + \epsilon^*(1)/d^*) \leq 1 - \kappa^*.$$

Let ξ^* be defined in Lemma 3.6. Next, by Lemma 3.6, there exists a positive constant T such that there holds

$$\begin{aligned}
&\mathcal{U}(x - cT + \xi^*) - d^* \leq u(x, T) \leq \mathcal{U}(x - cT + \xi^*) + d^*, \\
&\Pi_i(x - cT + \xi^*) - d^* k_{0i} \leq v_i(x, T) \leq \Pi_i(x - cT + \xi^*) + d^* k_{0i}
\end{aligned}$$

for all $x \in \mathbf{R}$ and $i = 1, \ldots, n$. Define

$$\kappa := -\ln(1 - \kappa^*)/t^*,$$

which is independent of the initial data $(u(\cdot,0),\mathbf{v}(\cdot,0))$. Finally, by using a similar argument of Step 3–Step 4 in the proof of Lemma 3.6, we can conclude that

$$\sup_{x\in\mathbf{R}}|u(x,t)-\mathcal{U}(x-ct+\xi^*)|\le Ke^{-\kappa t},\quad \sup_{x\in\mathbf{R}}|v_i(x,t)-\Pi_i(x-ct+\xi^*)|\le Ke^{-\kappa t}$$

hold for all $t>0$ and $i=1,\dots,n$, and for some constant K. This completes the proof. ∎

Acknowledgements. This work was initiated during the visit at the Mathematical Biosciences Institute of The Ohio State University. The author thanks Professor Xinfu Chen for his valuable discussion and careful reading of the manuscript. The author also thanks Professor James Sneyd for his valuable discussion. EXISTENCE OF SOLUTIONS FOR SUPPLY CHAIN MODELS BASED ON PARTIAL DIFFERENTIAL EQUATIONS*

M. HERTY†, A. KLAR†, AND B. PICCOLI‡

Abstract. We consider a model for supply chains governed by partial differential equations. The mathematical properties of a continuous model are discussed and existence and uniqueness are proven. Moreover, Lipschitz continuous dependence on the initial data is proven. We make use of the front tracking method to construct approximate solutions. The obtained results extend the preliminary work of [S. Göttlich, M. Herty, and A. Klar, *Commun. Math. Sci.*, 3 (2005), pp. 545–559].

Key words. supply chains, networks, front tracking

1. Introduction.

Supply chain modeling is characterized by different mathematical approaches: on one hand, there are discrete event simulations based on considerations of individual parts; on the other hand, continuous models like [1, 2, 3] using partial differential equations have been introduced. We consider supply chain modeling based on the latter—the continuous models. Recently those models based on scalar conservation laws have been reformulated in the framework of network models where the dynamics on the arcs is governed by a partial differential equation; see [12]. This approach is inspired by other recent discussions on networks; see, e.g., [4, 8, 13, 14].

We recall the basic supply chain model under consideration: a supply chain network consists of connected suppliers which are going to process parts. Further, each supplier consists of a processor for assembling and construction and a buffer for unprocessed parts, called a queue. We have the following definition.

Definition 1.1 (network definition). *A supply chain network is a finite, connected, directed graph consisting of a finite set of arcs $\mathcal{J}$ and a finite set of vertices $\mathcal{V}$. Each supplier j is modeled by an arc j, which is again parameterized by an interval $[a_j, b_j]$.*

Each processor is characterized by a maximum processing capacity μ_j, its length L_j, and the processing time T_j. The rate L_j/T_j describes the processing velocity and we assume for simplicity that $L_j/T_j = 1$ for all j. To model the evolution of parts inside the processor we introduce the function $\rho_j(x,t)$, i.e., the density of parts in processor j at point x and time t. Now, the dynamics of each processor on an arc j are governed by an advection equation as in [2]:

$$\partial_t \rho_j(x,t) + \partial_x \min\left\{\mu_j, \frac{L_j}{T_j}\rho_j(x,t)\right\} = 0 \quad \forall x \in [a_j, b_j],\ t \in \mathbb{R}^+, \tag{1.1a}$$

$$\rho_j(x,0) = \rho_{j,0}(x) \quad \forall x \in [a_j, b_j]. \tag{1.1b}$$

Equation (1.1) can be derived from a discrete event simulation [2] and allows for the following interpretation: The parts are processed with velocity L_j/T_j but with a maximal flux of μ_j. The dynamical behavior of the queues is discussed in detail in the following sections. Roughly speaking, if the inflow is greater than the maximum possible outflow, then the queue increases proportionally to the difference of the two, while it decreases in the opposite case.

First, in section 2, we consider a chain-like network geometry as in Figure 1 for which the discussion below simplifies. Then, in the following section, we turn to the situation of arbitrary networks—in particular, those with vertices having more than two connected arcs.

Our main achievement is the extension of results proposed in [12]. The correct space to be considered is that of couples (ρ_j, q_j): density of parts and queue buffer occupancy. We prove existence and uniqueness of weak solutions for a general network of supply chains and bounded variation (BV) initial data. The densities ρ_j are Lipschitz continuous in time w.r.t. the L^1 metric, while the queue's buffer occupancies q_j are absolutely continuous.

Moreover, we prove Lipschitz continuous dependence on the initial data. This, in turn, permits us to extend the corresponding semigroup trajectories to L^∞ initial data.

The main idea of the proof is to construct approximated solutions by wave front tracking [5] and derive bounds on the total variation by a careful estimate of the interactions at the vertices of the network. The proof of Lipschitz dependence uses the approach as in [6].

2. Consecutive processors. In this section we recall the supply chain network model introduced and investigated in [12] and extend the existence results obtained therein.

First, we consider the case where each vertex is connected to exactly to one incoming arc and one outgoing arc and we assume that the arcs are consecutively labeled, i.e., arc j is connected to arc $j+1$, and that $b_j = a_{j-1}$; see also Figure 1.

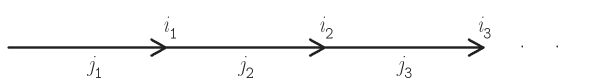

FIG. 1. *Example of a simple network structure.*

2.1. Modeling and previous results. As in the introduction, the supplier j is defined by a queue j and a processor j. Physically, the queue is located in front of each processor, i.e., at $x = a_j$. To avoid technical difficulties, we assume that the first supplier consists of a processor only and the last has infinite length, so $a_1 = -\infty$ and $b_N = +\infty$ for the first and, respectively, the last supplier in the supply chain.

In addition to (1.1), the queue buffer occupancy in front of each processor is modeled as time-dependent function $t \to q_j(t)$. If the capacity of processor $j-1$ and the demand of processor j are not equal, the queue q_j increases or decreases its buffer. Mathematically, this implies that each queue q_j satisfies the following equation:

$$\partial_t q_j(t) = f_{j-1}(\rho_{j-1}(b_{j-1}, t)) - f_j(\rho_j(a_j, t)), \quad j = 2, \ldots, N. \tag{2.1}$$

Last, a reasonable mathematical condition for the boundary values for outgoing arcs

j is given by (see [12])

$$f_j(\rho_j(a_j,t)) = \begin{cases} \min\{f_{j-1}(\rho_{j-1}(b_{j-1},t)),\mu_j\}, & q_j(t)=0, \\ \mu_j, & q_j(t)>0. \end{cases} \tag{2.2}$$

This allows for the following interpretation: If the outgoing buffer is empty, we process as many parts as possible but at most μ_j. If the buffering queue contains parts, then we process at the maximal possible rate, namely, again μ_j. Finally, the supply chain model is a coupled system of partial and ordinary differential equations on a network given by (1.1), (2.1), and (2.2).

We recall some preliminary facts from [12].

Note that due to the very special flux function

$$f_j(x) := \min\{\mu_j; L_j/T_j\rho\}, \tag{2.3}$$

a Riemann problem for (1.1) and $(x,t)\in\mathbb{R}\times\mathbb{R}^+$ admits one of the following two solutions. Let $\rho_{j,0}(x)=\rho_l$ for $x<0$ and $\rho_{j,0}=\rho_r$ for $x\geq 0$. If $\rho_l<\rho_r$, then the solution ρ_j is given by

$$\rho_j(x,t) = \begin{cases} \rho_l, & -\infty < \frac{x}{t} \leq \frac{f_j(\rho_r)-f_j(\rho_l)}{\rho_r-\rho_l}, \\ \rho_r, & \frac{f_j(\rho_r)-f_j(\rho_l)}{\rho_r-\rho_l} < \frac{x}{t} < \infty. \end{cases} \tag{2.4}$$

If, on the contrary, $\rho_l>\rho_r$, then the following happens. If either $\rho_l\leq\mu_j$ or $\rho_r\geq\mu_j$, then the solution is given by (2.4). Otherwise (i.e., if $\rho_r<\mu_j<\rho_l$), we obtain the solution given by

$$\rho(x,t) = \begin{cases} \rho_l, & -\infty < \frac{x}{t} \leq \frac{f_j(\rho_l)-\mu_j}{\rho_l-\mu_j}, \\ \mu_j, & \frac{f_j(\rho_l)-\mu_j}{\rho_l-\mu_j} < \frac{x}{t} \leq \frac{\mu_j-f_j(\rho_r)}{\mu_j-\rho_r}, \\ \rho_r, & \frac{\mu_j-f_j(\rho_r)}{\mu_j-\rho_r} < \frac{x}{t} < \infty. \end{cases} \tag{2.5}$$

Notice that the right-hand side (RHS) of the first two inequalities is always 0 or 1.

We can introduce the following definition.

Definition 2.1 (network solution). *A family of functions $\{\rho_j,q_j\}_{j\in\mathcal{J}}$ is called an* admissible *solution for a network as in Figure* 1 *if, for all j, ρ_j is a weak entropic solution* [16] *to* (1.1)*, q_j is absolutely continuous, and, in the sense of traces for ρ_js,* (2.1) *and* (2.2) *hold for a.e. t.*

For the particular situation of a single vertex $v\in\mathcal{V}$ with incoming arc $j=1$ and outgoing arc $j=2$ and constant initial data $\rho_{j,0}(x)\leq\mu_j$, there exists an admissible solution $\{\rho_1,\rho_2,q_2\}$. The solution has the explicit form

$$\rho_1(x,t)=\rho_{1,0}, \tag{2.6a}$$

$$\rho_2(x,t) = \begin{cases} f_1(\rho_{1,0})<\mu_2 & \begin{cases} \rho_{1,0}, & 0\leq (x-t_0)/t<1=\frac{f_2(\mu_2)-f_2(\rho_{1,0})}{\mu_2-\rho_{1,0}}, \\ \mu_2, & 1\leq (x-t_0)/t \text{ and } x/t<1, \\ \rho_{2,0}, & 1\leq x/t<\infty, \end{cases} \\ f_1(\rho_{1,0})\geq\mu_2 & \begin{cases} \mu_2, & 0\leq x/t<1=\frac{f_2(\mu_2)-f_2(\rho_{2,0})}{\mu_2-\rho_{2,0}}, \\ \rho_{2,0}, & 1\leq x/t<\infty, \end{cases} \end{cases} \tag{2.6b}$$

$$q_2(t)=q_{2,0}+\int_0^t f_1(\rho_{1,0})-f_2(\rho_2(a_2+,\tau))d\tau, \tag{2.6c}$$

wherein $t_0 = q_{2,0}/(\mu_2 - f_1(\rho_{1,0}))$. For a network as in Figure 1, for initial data $\{\rho_{j,0}(x)\}_j$ where each $\rho_{j,0}$ is a step function, and for initial values $q_j(0) = 0$, there exists an admissible solution $\{\rho_j, q_j\}_j$ to the network problem (1.1), (2.1), (2.2); see [12]. The construction of the solution is based on wave or front tracking (see below and in [9, 5, 15]). For applications of this method in the context of network problems we also refer the reader to [14, 8].

2.2. Wave front tracking approximations. To start, we introduce a equidistant grid $(i\delta)_{i0}^{N_x}$ such that $0 \leq (i\delta) \leq \max\{\mu_j : j \in \mathcal{J}\}$ and such that $\forall j \exists i_j : i\delta\mu_j$. Here, it is implicitly assumed that μ_i/μ_j is rational. We approximate the initial data by step functions $\rho_{j,0}^\delta$ taking values in the set $\{i\delta : i0, \ldots, N_x\}$. Then each Riemann problem inside an arc or at a vertex is solved, obtaining various traveling discontinuities. If discontinuities collide, then the collision can be resolved either by solving a Riemann problem inside the arc j (see (2.4),(2.5)) or as a collision with a vertex (see (2.6)). In both cases we obtain new discontinuities propagating until the next collision.

At the same time, an evolution of the queue's buffers q_j is automatically defined when solving the Riemann problems at vertices.

This construction guarantees that the solution on arcs takes values only in the set $\{i\delta : i = 0, \ldots, N_x\}$ and we obtain a wave front tracking approximate solution (denoted by $(\rho^\delta, q^\delta) := \{(\rho_j^\delta, q_j^\delta)\}_j$) consisting of a set of moving discontinuities along the intervals $[a_j, b_j]$ and the queue's buffers' evolutions.

As usual [5, 10], to guarantee the good definition of wave front tracking approximate solutions and, passing to the limit, prove existence of solutions in the sense of Definition 2.1, three basic estimates are in order:

1. the estimate on the number of waves;
2. the estimate on the number of interactions (between waves and of waves with queues); and
3. the estimate on total variation of solutions for ρ_j.

Moreover, in our case, we need to prove some compactness of the sequence q_j^δ in an appropriate space.

It is easy to check that every collision inside an arc decreases the number of waves, while the interactions with a vertex may produce two new waves; cf. (2.6). Also, since the characteristic velocity of waves is always positive and is bounded from above, then the first two estimates are readily obtained; see [12]. Therefore the construction of wave front tracking approximations is well-defined up to any given time T.

2.3. Total variation estimates on densities. Here, we provide total variation estimates on ρ_j^δ (i.e., along wave front tracking approximate solutions). This will imply the existence of an admissible solution for BV initial data $\rho_{j,0}$.

First, we discuss the case of initial data $\rho_{j,0}$ additionally satisfying the following assumption (K).

(K) For every j the initial datum satisfies $\rho_{j,0} \leq \mu_j$.

The above construction guarantees that (K) remains valid for every time along wave front tracking approximate solutions.

Each $\rho_j^\delta(x,t)$ is a piecewise constant function in x and thus will define a number of constant states $\rho_{j,i}^\delta, i = 1, \ldots, N_j$, where we assume that $\rho_j^\delta(a_j, \cdot) = \rho_{j,1}^\delta$, and so forth. We define the total variation of the flux on the network as

$$T.V.(f(\rho^\delta)) = \sum_{j\in\mathcal{J}} T.V.(f_j(\rho_j^\delta(\cdot,t))) = \sum_{j\in\mathcal{J}} \sum_{i1}^{N_j-1} |f_j(\rho_{j,i}^\delta) - f_j(\rho_{j,i+1}^\delta)|. \tag{2.7}$$

Note that, thanks to assumption (K), a bound on $T.V.(f_j(\rho_j^\delta(\cdot,t)))$ provides also a bound on $T.V.(\rho_j^\delta(\cdot,t))$, since $\rho_{j,i}^\delta \leq \mu_j$ for all j,i. Furthermore, $T.V.(f(\rho^\delta))$ does not increase when discontinuities collide *inside* an arc j; see [5]. Next, we discuss the collision of a discontinuity with a vertex.

LEMMA 2.2. *Assume a single vertex with incoming arc $j=1$ and outgoing arc $j=2$. Furthermore, assume constant states $\rho_{j,0}$, $j=1,2$, at the vertex and consider a discontinuity colliding at time t_0. Denote the new solution at the vertex after the collision by $\bar\rho_j$. Assume no more collision of discontinuities happens until t^*. Then, for all $t_0 < t < t^*$,*

$$\sum_{j=1}^{2} T.V.(f_j(\rho_j(\cdot,t))) + |\partial_t q_2(t)| \leq \sum_{j=1}^{2} T.V.(f_j(\rho_j(\cdot,t_0))) + |\partial_t q_2(t_0)|. \tag{2.8}$$

Proof. By construction the colliding discontinuity has to arrive from arc $j=1$, and therefore the total variation of the flux on this arc decreases by $|f_1(\bar\rho_1) - f_1(\rho_{1,0})|$. On the outgoing arc $j=2$ we distinguish two cases. First, assume that $f_2(\rho_{2,0}) = f_1(\rho_{1,0})$. Then, due to (2.1) we have $\partial_t q_2(t_0) = 0$. If $f_1(\bar\rho_1) \leq \mu_2$, then $f_2(\bar\rho_2) = f_1(\bar\rho_1)$ and (2.8) holds. If, on the other hand, $f_1(\bar\rho_1) > \mu_2$, then due to (2.2), $f_2(\bar\rho_2) = \mu_2$ and again (2.8) holds, since for $t > t_0$

$$\begin{aligned} |f_1(\bar\rho_1) - f_1(\rho_{1,0})| &= |\mu_2 - f_1(\rho_{1,0})| + |f_1(\bar\rho_1) - \mu_2| \\ &= |f_2(\bar\rho_2) - f_2(\rho_{2,0})| + |\partial_t q_2(t)|. \end{aligned}$$

In the second case, we assume $f_2(\rho_{2,0}) = \mu_2$. Then,

$$|\partial_t q_2(t_0)| = |f_1(\rho_{1,0}) - \mu_2|$$

and we distinguish two more subcases depending on whether the queue is increasing or decreasing after the collisions. First, assume $f_1(\bar\rho_1) \geq \mu_2$, i.e., the queue q_2 is increasing with

$$|\partial_t q_2(t)| = f_1(\bar\rho_1) - \mu_2$$

and

$$f_2(\bar\rho_2) = f_2(\rho_{2,0}) = \mu_2. \tag{2.9}$$

Inequality (2.8) still holds, since

$$|f_1(\rho_{1,0}) - f_1(\bar\rho_1)| + |\partial_t q_2(t_0)| \geq |\partial_t q_2(t)|$$

for $t > t_0$. Second, assume $f_1(\bar\rho_1) < \mu_2$, i.e., the queue q_2 is decreasing. Let $\bar t$ be such that $q_2(\bar t) = 0$. Then (2.8) holds since for $t < \min\{\bar t, t^*\}$

$$T.V.(f_2(\bar\rho_2(\cdot,t))) = 0$$

and

$$\begin{aligned} |f_1(\bar\rho_1) - f_1(\rho_{1,0})| + |f_1(\rho_{1,0}) - \mu_2| &\geq |\mu_2 - f_1(\bar\rho_1)| \\ &= |\partial_t q_2(t)|. \end{aligned}$$

If $\bar{t} < t^*$ we obtain a new traveling discontinuity on the outgoing arc $j = 2$ for times $t > \bar{t}$ when the queue q_2 becomes empty: $f_2(\bar{\rho}_2(a_2+, t)) = f_1(\bar{\rho}_1)$ and $\partial_t q(t) = 0$ for $t > \bar{t}$. Then, (2.8) still holds, since

$$T.V.(f_2(\rho_2(\cdot, t))) + |\partial_t q_2(t)|$$

is constant for this interaction. This finishes the proof. ∎

Summarizing, we conclude that for all $\delta > 0$ the following holds for all $t > 0$:

$$\sum_{j=1}^{N} T.V.(\rho_j^\delta(\cdot, t)) + \sum_{j=2}^{N} |\partial_t q_j^\delta(t)| \le \sum_{j=1}^{N} T.V.(\rho_{j,0}^\delta(\cdot)) + \sum_{j=2}^{N} |\partial_t q_j^\delta(0)| \tag{2.10a}$$

$$\text{and } \rho_j^\delta(x, t) \le \max_j \mu_j \ \forall j, x. \tag{2.10b}$$

2.4. Total variation estimates on queues buffers. Let us now estimate the total variation of $\partial_t q_j$.

LEMMA 2.3. *Assume we have a single vertex with incoming arc $j = 1$ and outgoing arc $j = 2$ (of infinite length). Furthermore, assume we have constant states $\rho_{j,0}, j = 1, 2$, at the vertex and consider a discontinuity collision at time t_0. Denote the new solution at the vertex after the collision by $\bar{\rho}_j$. Assume no more collisions of discontinuities happen until t^*. Then, for all $t_0 < t < t^*$,*

$$T.V.(\partial_t q_2, [t_0, t]) \le 2\ |f_1(\bar{\rho}_1) - f_1(\rho_{1,0})| + |\partial_t q_2(t_0)|. \tag{2.11}$$

Proof. The interactions are clearly the same examined in Lemma 2.2.

First, assume that $f_2(\rho_{2,0}) = f_1(\rho_{1,0})$. Then, due to (2.1) we have $\partial_t q_2(t_0) = 0$. If $f_1(\bar{\rho}_1) \le \mu_2$, then $f_2(\bar{\rho}_2) = f_1(\bar{\rho}_1)$ and $\partial_t q_2(t) = 0$; thus (2.11) holds because the left-hand side vanishes.

If on the other hand, $f_1(\bar{\rho}_1) > \mu_2$, then

$$|f_1(\bar{\rho}_1) - f_1(\rho_{1,0})| = |f_2(\bar{\rho}_2) - f_2(\rho_{2,0})| + |\partial_t q_2(t)| \ge |\partial_t q_2(t)|;$$

thus (2.11) holds because $\partial_t q_2(t_0) = 0$.

In the second case, we assume $f_2(\rho_{2,0}) = \mu_2$. Then,

$$\partial_t q_2(t_0) = f_1(\rho_{1,0}) - \mu_2, \quad \partial_t q_2(t_0+) = f_1(\bar{\rho}_1) - \mu_2. \tag{2.12}$$

If the queue is increasing after the interaction, then

$$T.V.(\partial_t q_2(t), [t_0, t]) = |f_1(\rho_{1,0}) - \mu_2 - (f_1(\bar{\rho}_1) - \mu_2)| = |f_1(\rho_{1,0}) - f_1(\bar{\rho}_1)|. \tag{2.13}$$

Second, assume $f_1(\bar{\rho}_1) < \mu_2$, i.e., the queue q_2 is decreasing. Let $\bar{t}$ be such that $q_2(\bar{t}) = 0$. For $t < \min\{\bar{t}, t^*\}$, (2.13) still holds; thus we conclude the case $t^* \le \bar{t}$. If, on the contrary, $\bar{t} < t^*$, we obtain a new traveling discontinuity on the outgoing arc $j = 2$ for times $t > \bar{t}$ when the queue q_2 becomes empty: $f_2(\bar{\rho}_2(a_2+, t)) = f_1(\bar{\rho}_1)$ and $\partial_t q_2(t) = 0$ for $t > \bar{t}$. Then,

$$\begin{aligned} T.V.(\partial_t q_2(t), [t_0, t]) &= |\partial_t q_2(t_0) - \partial_t q_2(t_0+)| + |\partial_t q_2(t_0+) - \partial_t q_2(t)| \\ &\le |f_1(\rho_{1,0}) - f_1(\bar{\rho}_1)| + |f_1(\bar{\rho}_1) - \mu_2| \\ &\le 2\ |f_1(\rho_{1,0}) - f_1(\bar{\rho}_1)| + |\partial_t q_2(t_0)|. \end{aligned}$$

∎

We can now reason as follows. Define

$$\eta = \min_j |b_j - a_j|$$

as the minimum length of a supplier and set

$$TV_j^k = T.V.(f_j(\rho_j^\delta(\cdot, k\eta))), \qquad q_j^k = \partial_t q_j^\delta(k\eta).$$

Then by Lemmas 2.2 and 2.3, we get

$$T.V.(\partial_t q_j^\delta, [k\eta, (k+1)\eta]) \le 2\, TV_{j-1}^k + q_j^k,$$

$$q_j^k + TV_{j-1}^k + TV_j^k \le q_j^{k-1} + TV_{j-1}^{k-1} + TV_j^{k-1}.$$

Moreover, defining by $\widetilde{TV}_N^k$ the variation in the flux produced on the last supplier by the queue q_N^δ on the time interval $[k\eta, (k+1)\eta]$, we get

$$TV_1^k \le TV_1^0, \quad q_N^k + TV_{N-1}^k + \widetilde{TV}_N^k \le q_N^{k-1} + TV_{N-1}^{k-1} + \widetilde{TV}_N^{k-1}.$$

Therefore, summing up on j and k we get the following:

$$\sum_{j=2}^{N} T.V.(\partial_t q_j^\delta, [0, K\eta]) = \sum_{j=2}^{N} \sum_{k=0}^{K-1} T.V.(\partial_t q_j^\delta, [k\eta, (k+1)\eta])$$

$$\le \sum_{j=2}^{N} \sum_{k=0}^{K-1} \left(2\, TV_{j-1}^k + q_j^k\right) \le K \sum_{j=2}^{N} \left(2\, TV_{j-1}^0 + q_j^0\right).$$

Restating, we have

$$\sum_{j=2}^{N} T.V.(\partial_t q_j^\delta, [0, K\eta]) \le K \sum_{j=2}^{N} \left(2\ T.V.(\rho_{j-1,0}^\delta(\cdot)) + |\partial_t q_j^\delta(0)|\right)\ \forall t. \tag{2.14}$$

2.5. Existence of a network solution for BV initial data. For existence of solutions, we consider the space the space of data (ρ, q) on the supply chain with the norm

$$\|(\rho, q)\| = \sum_j \|\rho_j\|_{L^1} + \sum_j |q_j|. \tag{2.15}$$

Then, we want to find a solution in the space $Lip([0,T], L^1((a_j, b_j)))$ for the ρ components and in the space $W^{1,1}([0,T])$ for the q components.

Due to the special flux function, we obtain discontinuities traveling with speed v at most equal to 1. Therefore, we have for $t_1 < t_2$ and every j

$$\int_{a_j}^{b_j} |\rho_j^\delta(x, t_1) - \rho_j^\delta(x, t_2)| dx \le T.V.(\rho_j^\delta(\cdot, t_1))|t_1 - t_2| + \int_{t_1}^{t_2} |f(\rho_j^\delta(a_j, t))|\, dt. \tag{2.16}$$

The estimate (2.16) guarantees Lipschitz dependence w.r.t. time in L^1, while (2.10) ensures uniform BV bounds. Therefore, by using standard techniques [5, 17], one can show that for $\delta \to 0$ a subsequence of ρ^δ converges in L^1 provided that $T.V.(\rho_{j,0}(x))$ is bounded. Furthermore, the limit solution ρ^* is a weak entropic solution for (1.1).

Concerning q_j, we observe that $\partial_t q_j$ are of bounded variation. Again by BV compactness, we have that $\partial_t q_j$ converges by subsequences in BV, in particular, almost everywhere and strongly in L^1. Thus q_j converges uniformly. Finally q_j converges by subsequences in $W^{1,1}$.

Remark 2.4. Notice that we can pass to the limit using the uniform Lipschitz continuities of q_j. In fact, by definition, $Lip_t(q_j) \leq \max\{\mu_{j-1}, \mu_j\}$. Thus we can pass to the limit obtaining Lipschitz continuous functions with the same bound on the Lipschitz constant.

Also, we can pass to the limit using estimate (2.10) and the Ascoli–Arzelá theorem, but in that case we cannot guarantee that $\partial_t q_j$ is in BV and that q_j is in $W^{1,1}$.

Consider now the case in which (K) is violated. For every j, the data entering the supplier from a_j satisfies (K). Consider the generalized characteristic $\pi_j(t)$ starting from a_j at time 0 and let τ_j (possibly $+\infty$) be the time in which it reaches b_j. We can divide the supplier into two regions:

$$A_j = \{(t,x) : x \leq \pi_j(t)\}, \qquad B_j = \{(t,x) : x > \pi_j(t)\};$$

see Figure 2.

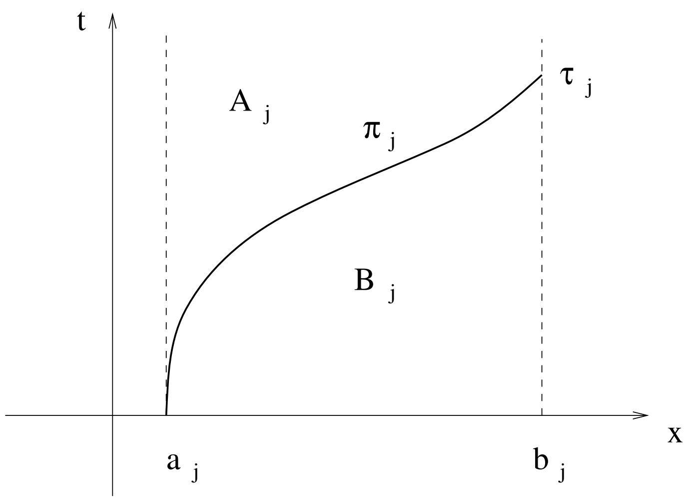

FIG. 2. *Regions A_j and B_j.*

A_j is the region influenced by the incoming flux from a_j, while B_j is the region where ρ depends only on the initial datum $\rho_{j,0}$. Notice that for $t \geq \tau_j$, $B_j \cap \{(t,x) : a_j \leq x \leq b_j\} = \emptyset$. On A_j, (K) holds true; thus the estimate (2.10) also holds. On B_j the solution is the same as the solution to a scalar problem; thus the total variation is decreasing. We thus again reach compactness in BV and the existence of a solution.

Finally, we get the following.

PROPOSITION 2.5. *If $T.V.(\rho_{j,0}(x)) \leq C$ for some $C > 0$, then there exists a solution (ρ, q) on the network such that $(\rho, q) \in Lip([0,T], L^1((a_j,b_j))) \times W^{1,1}([0,T])$, ρ is BV for every time, and $\partial_t q_j$ is in BV.*

2.6. Uniqueness and Lipschitz continuous dependence. We want to prove uniqueness and Lipschitz continuous dependence on the space of data (ρ, q) on the supply chain with the norm (2.15). We use the same approach of [6, 10] and thus consider a Riemannian metric on this space where the tangent vectors are considered only for ρ_j piecewise constant functions.

Let us first focus on the ρ_j's: a "generalized tangent vector" consists of two components (v, ξ), where $v \in L^1$ describes the L^1 infinitesimal displacement, while $\xi \in \mathbb{R}^n$ describes the infinitesimal displacement of discontinuities. A family of piecewise constant functions $\theta \to \rho^\theta$, $\theta \in [0,1]$, with the same number of jumps, say, at the points $x_1^\theta < \cdots < x_M^\theta$, admits a tangent vector in the following functions is well defined (see Figure 3):

$$L^1 \ni v^\theta(x) \doteq \lim_{h \to 0} \frac{\rho^{\theta+h}(x) - \rho^\theta(x)}{h},$$

and also the numbers

$$\xi_\beta^\theta \doteq \lim_{h \to 0} \frac{x_\beta^{\theta+h} - x_\beta^\theta}{h}, \qquad \beta = 1, \ldots, M.$$

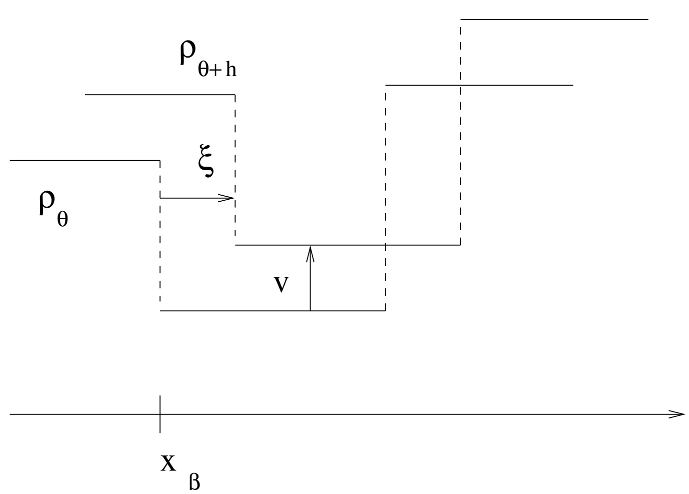

FIG. 3. *Construction of "generalized tangent vectors."*

Notice that the path $\theta \to \rho^\theta$ is not differentiable w.r.t. the usual differential structure of L^1; in fact, if $\xi_\beta^\theta \neq 0$, as $h \to 0$ the ratio $\left[\rho^{\theta+h}(x) - \rho^\theta(x)\right]/h$ does not converge to any limit in L^1.

The L^1 length of the path $\gamma : \theta \to \rho^\theta$ is given by

$$\|\gamma\|_{L^1} = \int_0^1 \left\|v^\theta\right\|_{L^1} d\theta + \sum_{\beta=1}^{M} \int_0^1 \left|\rho^\theta(x_\beta+) - \rho^\theta(x_\beta-)\right| \left|\xi_\beta^\theta\right| d\theta. \tag{2.17}$$

According to (2.17), the L^1 length of a path γ is the integral of the norm of its tangent vector, defined as follows:

$$\|(v, \xi)\| \doteq \|v\|_{L^1} + \sum_{\beta=1}^{M} |\Delta\rho_\beta| \, |\xi_\beta| \,,$$

where $\Delta\rho_\beta = \rho(x_\beta+) - \rho(x_\beta-)$ is the jump across the discontinuity x_β.

Now, given two piecewise constant functions ρ and ρ', call $\Omega(u, u')$ the family of all "differentiable" paths $\gamma : [0, 1] \to \gamma(t)$ with $\gamma(0) = u$, $\gamma(1) = u'$. The Riemannian distance between u and u' is given by

$$d(u, u') \doteq \inf \left\{ \|\gamma\|_{L^1}, \gamma \in \Omega(u, u') \right\}.$$

To define d on all L^1, for given $u, u' \in L^1$ we set

$$\begin{aligned} d(u, u') \doteq \inf \{ &\|\gamma\|_{L^1} + \|u - \tilde{u}\|_{L^1} + \|u' - \tilde{u}'\|_{L^1} : \\ &\tilde{u}, \tilde{u}' \text{ piecewise constant functions, } \gamma \in \Omega(u, u') \}. \end{aligned}$$

It is easy to check that this distance coincides with the distance of L^1.

To estimate the L^1 distance among wave front tracking approximate solutions we proceed as follows. Take ρ, ρ' piecewise constant initial data and let $\gamma_0(\vartheta) = u^\vartheta$ be a regular path joining $\rho = \rho^0$ with $\rho' = \rho^1$. Define $\rho^\vartheta(t, x)$ to be a wave front tracking approximate solution with initial data ρ^ϑ and let $\gamma_t(\vartheta) = \rho^\vartheta(t, \cdot)$. Then for every $t \geq 0$, γ_t is a differentiable path. If we can prove that

$$\|\gamma_t\|_{L^1} \leq \|\gamma_0\|_{L^1} \tag{2.18}$$

for every $t \geq 0$, then

$$\|\rho(t, \cdot) - \rho'(t, \cdot)\|_{L^1} \leq \inf_{\gamma_t} \|\gamma_t\|_{L^1} \leq \inf_{\gamma_0} \|\gamma_0\|_{L^1} = \|\rho(0, \cdot) - \rho'(0, \cdot)\|_{L^1}. \tag{2.19}$$

Now, to obtain (2.18), and hence (2.19), it is enough to prove that, for every tangent vector $(v, \xi)(t)$ to any regular path γ_t, one has

$$\|(v, \xi)(t)\| \leq \|(v, \xi)(0)\|; \tag{2.20}$$

i.e., the norm of a tangent vector does not increase in time. Moreover, if (2.19) is established, then uniqueness and Lipschitz continuous dependence of solutions to Cauchy problems are straightforwardly achieved passing to the limit on the wave front tracking approximate solutions.

Remark 2.6. Since the Riemannian distance d is equivalent to the L^1 metric, the reader could think that the whole framework is not so useful. On the contrary, the different differential structure permits one to rely on tangent vectors, whose norm can be easily controlled. This would not be possible using the tangent vectors of the usual differential structure of L^1, i.e., having only the v component.

Also, while for systems of conservation laws it is possible to find a decreasing functional (see [7]), this is not the case for networks (see [10]), even for a scalar conservation law.

Let us now turn to the supply chains case. It is easy to see that all paths in L^1 connecting piecewise constant functions can be realized using only the ξ component of the tangent vector; see [5, 6]. Therefore, indicating by $x_{\beta_i^j}$ the positions of discontinuities, $j = 1, \ldots, N$, $i = 1, \ldots, M_j$, a tangent vector to a function defined on the network is given by

$$(\xi_{\beta_i^j}, \eta_j),$$

where $\xi_{\beta_i^j}$ is the shift of the discontinuity $x_{\beta_i^j}$, while η_j is the shift of the queue buffer occupancy q_j. The norm of a tangent vector is given by

$$\|(\xi_{\beta_i^j}, \eta_j)\| = \sum_{j,i} |\xi_{\beta_i^j}| |\Delta\rho_{\beta_i^j}| + \sum_j |\eta_j|.$$

Again, to control the distance among solutions it is enough to control the evolution of norms of tangent vectors. Finally, we have the following lemma.

LEMMA 2.7. *The norm of tangent vectors are decreasing along wave front tracking approximations.*

Proof. The norm of tangent vectors changes only at interaction times or if a wave is generated (see [6]); thus we have to consider three cases.

(i) Two waves interact on a supplier.
(ii) A wave interacts with a vertex.
(iii) One queue empties down.

Case (i) is the same as the classical case; see [5, 6].

Consider case (ii) and assume that the interaction happens with vertex j at time t. Let us indicate by $f_j^{\pm}$ the value of the flux at a_j before and after the interaction and, similarly, by $f_{j-1}^{\pm}$ the value of the flux at b_{j-1}. In general we use the symbols $+$ and $-$ to indicate quantities before and after the interaction, respectively.

Assume first that $q_j(t) = 0$; then $f_{j-1}^- = f_j^- < \mu_j$. If $f_{j-1}^+ \leq \mu_j$, then the queue remains empty, a ρ wave is generated on supplier j, and the tangent vector norm remains unchanged. If $f_{j-1}^+ > \mu_j$, then $\xi^+ = \xi^-$, $\Delta\rho^+ = \mu_j - f_j^-$, and $\eta^+ = \eta^- + \xi^-(f_{j-1}^+ - \mu_j)$. Since $\Delta\rho^- = f_{j-1}^+ - f_{j-1}^- = f_{j-1}^+ - f_j^-$, the norm is conserved.

Assume now that $q_j(t) > 0$; then $f_j^- = f_j^+ = \mu_j$. No ρ wave is produced, $\eta^+ = \eta^- + \xi^-\Delta\rho^-$, and again we conclude.

Let us pass to case (iii) and use the same notation of case (ii). Then $f_j^- = \mu_j$ and $f_j^+ = f_{j-1}^- = f_{j-1}^+ < \mu_j$. We get $\Delta\rho^+ = \mu_j - f_{j-1}^-$, $\xi^+ = \eta^-/(\mu_j - f_{j-1}^-)$, and $\eta^+ = 0$; thus we are finished. $\square$

2.7. Existence for L^1 initial data. Since we proved Lipschitz continuous dependence, by an approximation argument, we also get existence for L^1 initial data. More precisely, we get the following theorem.

THEOREM 2.8. *There exists a Lipschitz continuous semigroup S_t defined on the domain $\mathcal{D} = \{(\rho_j, q_j) : \rho_j \in L^\infty, q_j \in \mathbb{R}\}$. Moreover, for every initial datum (ρ_j, q_j) with ρ_j of bounded variation, the semigroup trajectory $t \mapsto S_t(\rho_j, q_j)$ is a network solution.*

We point out that assumption (K) guarantees the existence of a solution on the network, while this is not granted in the general case, as shown by the following example.

Example 2.9. Consider a simple network formed by only one vertex connecting an incoming arc $j = 1$ and an outgoing arc $j = 2$ and initial data

$$\rho_1(0, x) = \mu_1 = \mu_2, \qquad \rho_2(0, x) = \mu_2 + \sin^2\left(\frac{1}{x - a_2}\right), \qquad q_2(0) > 0.$$

Clearly on the outgoing arc $j = 2$ the solution takes values in the flat part of the flux; thus it is constant in time. In particular, $\rho_2(t, x)$ has no trace as $x \to a_2$ for any value of t.

Remark 2.10. Notice that (2.2) still makes sense for Example 2.9 if we interpret the relation to hold for every limit $\lim_n \rho_2(t, x_n)$ with $x_n \to a_2$. On the other side, we can make oscillations in ρ_2 arbitrarily large if we put no constraints on the possible values of ρ_2.

3. General networks. Now, we turn to the case of more general networks as, for example, depicted in Figure 4.

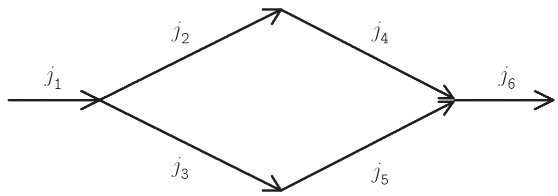

FIG. 4. *Network geometry for a supply chain.*

3.1. Modeling. We consider general vertices $v \in \mathcal{V}$ with m_v incoming and n_v outgoing arcs. The set of arc indices of incoming (outgoing) arcs is denoted by δ_v^- (δ_v^+). If we have more than one outgoing arc, we need to define the distribution of the goods from the incoming arcs. Similar to [8], we model this as follows. We assume that for each single vertex v a matrix $A_v := A(\alpha_{ij})_{i,j} \in \mathbb{R}^{m_v \times n_v}$ is given and that the total flux willing to go to arc $j \in \delta_v^+$ is given by

$$\sum_{i \in \delta_v^-} \alpha_{ij} f_i(\rho_i(b_i-, t)).$$

Therefore, we assume that the matrix A satisfies for all $i \in \delta_v^-, j \in \delta_v^+ : 0 \leq \alpha_{ij} \leq 1$ and $\sum_{j \in \delta_v^+} \alpha_{ij} = 1$. Then, the supply chain network model is given by (1.1) and for each junction v by the equations for the queues (see also [11])

$$\forall j \in \delta_v^+ : \partial_t q_j(t) = \sum_{i \in \delta_v^-} \alpha_{ij} f_i(\rho_i(b_i-, t)) - f_j(\rho_j(a_j+, t)), \tag{3.1}$$

and the boundary values $\forall j \in \delta_v^+$,

$$f_j(\rho_j(a_j+, t)) = \begin{cases} \min\{\sum_{i \in \delta_v^-} \alpha_{ij} f_i(\rho_i(b_i-, t)); \mu_j\}, & q_j(t) = 0, \\ \mu_j, & q_j(t) > 0. \end{cases} \tag{3.2}$$

Note that due to the positive velocity of the occurring waves the boundary conditions are well defined. In particular, and in contrast to [8, 14], no additional maximization problem near the vertex has to be solved. Moreover, due to (3.1) and the assumption on A, we conserve the total flux at each vertex v for all times $t > 0$:

$$\sum_{j \in \delta_v^+} (\partial_t q_j(t) + f_j(\rho_j(a_j+, t))) = \sum_{i \in \delta_v^-} f_i(\rho_i(b_i-, t)).$$

Now, the construction of a solution to the network problem (1.1), (3.1), (3.2) is as before. In particular, the results of [12] extend to problem (1.1), (3.1), (3.2) on the network $(\mathcal{J}, \mathcal{V})$. It is enough to control the number of waves and interactions: Let $\eta = \min_j(b_j - a_j)$ be the minimum length of a supplier. Since all waves move at positive velocity at most equal to 1, two interactions with vertices of the same wave can happen at most every η units of time. If N is the number of suppliers, then there is at most a multiplication by N every η unit of time; thus we control the number of waves and interactions.

Therefore, for given piecewise constant initial data $\rho_{j,0}^\delta$ on a network, a solution (ρ^δ, q^δ) can be defined by the wave tracking method up to any time T. Next, we extend Lemma 2.2 to the more general situation of a vertex v above.

3.2. Existence, uniqueness, and Lipschitz continuous dependence of a weak solution. We can get again BV estimates.

LEMMA 3.1. *Assume we have a single vertex with incoming arcs* $\delta^- = \{1, \dots, m\}$ *and outgoing arcs* $\delta^+ = \{m+1, \dots, m+n\}$*. Furthermore, assume we have constant states* $\rho_{j,0}, j \in \delta^- \cup \delta^+$*, at the vertex and consider a discontinuity collision at time* t_0*. Denote the new solution at the vertex after the collision by* $\bar{\rho}_j$*. Assume that there are no more collision of discontinuities until* t^**. Then, for all* $t_0 < t < t^*$*,*

$$\begin{aligned}\sum_{j\in\delta^-\cup\delta^+} T.V.(f_j(\rho_j(\cdot,t))) + \sum_{j\in\delta^+} |\partial_t q_j(t)| \\ \le \sum_{j\in\delta^-\cup\delta^+} T.V.(f_j(\rho_j(\cdot,t_0))) + \sum_{j\in\delta^+} |\partial_t q_j(t_0)|.\end{aligned} \tag{3.3}$$

Proof. The proof is very similar to the proof of Lemma 2.2. The colliding discontinuity has to arrive on an arc $i \in \delta^-$ and we assume $i = 1$. The total variation on the incoming arc $i = 1$ therefore decreases by

$$|f_1(\bar{\rho}_1) - f_1(\rho_{1,0})| = \sum_{j\in\delta^+} |\alpha_{1j} f_1(\bar{\rho}_1) - \alpha_{1j} f_1(\rho_{1,0})|.$$

Hence, it suffices to prove that for any fixed outgoing arc $j \in \delta^+$ and for all $t > t_0$ the following inequality holds:

$$|\alpha_{1j} f_1(\bar{\rho}_1) - \alpha_{1j} f_1(\rho_{1,0})| + |\partial_t q_j(t_0)| \ge T.V.(f_j(\rho_j(\cdot,t))) + |\partial_t q_j(t)|. \tag{3.4}$$

Fix $j \in \delta^+$. With the other cases being similar we discuss only the (most interesting) case: Assume

$$\sum_{i\in\delta^-} \alpha_{ij} f_i(\rho_{i,0}) > f_j(\rho_{j,0})$$

and

$$\alpha_{1j} f_1(\bar{\rho}_1) + \sum_{i,i\ne1} f_i(\rho_{i,0}) < \mu_j.$$

Then, the queue q_j is decreasing after the collision at time t_0, and we denote again by $\bar{t}$ the time when $q_j(\bar{t})0$. Then for $t < \min\{\bar{t}, t^*\}$ we obtain $T.V.(f_j(\bar{\rho}_j(\cdot,t))) = 0$ and $|\alpha_{1j} f_1(\bar{\rho}_1) - \alpha_{1j} f_1(\rho_{1,0})| + |\partial_t q_j(t_0)| \ge \mu_j - \sum_{i,i\ne1} \alpha_{ij} f_i(\rho_{i,0}) - \alpha_{1j} f_1(\bar{\rho}_1) = |\partial_t q_j(t)|$. If $\bar{t} < t^*$, then a new discontinuity is generated since the queue q_j empties. By (3.2) we have

$$f_j(\bar{\rho}_j(a_j+,t)) = \sum_{i,i\ne1} \alpha_{ij} f_j(\rho_{j,0}) + \alpha_{1j} f_1(\bar{\rho}_1),$$

and therefore

$$|\partial_t q(\bar{t})| T.V.(f_j(\rho_j(\cdot,t)))$$

for $t > \bar{t}$. Hence, (3.4) holds for all $t > t_0$. This finishes the proof. ∎

Therefore, we again obtain the estimate (2.10), where the sum now should run over all arcs and nodes of the network. Moreover, the estimates on $\partial_t q_j$ work in the same way.

The same arguments as above give existence and uniqueness of a weak solution as well as the Lipschitz continuous dependence on the data in the general case for BV initial data. Finally, Theorem 2.8 holds for a general network.

4. Summary. We have proven existence, uniqueness, and Lipschitz continuous dependence of a weak solution to a network model for supply chains. The model consists of a scalar hyperbolic equation governing the dynamics of a supplier and an ordinary differential equation for describing the behavior of the queues. The proof of existence relies on the front tracking approximations and estimates on the total variation.

BIFURCATION FOR A FREE BOUNDARY PROBLEM MODELING TUMOR GROWTH BY STOKES EQUATION*

AVNER FRIEDMAN† AND BEI HU‡

Abstract. We consider a free boundary problem modeling tumor growth in fluid-like tissue. The model equations include a diffusion equation for the nutrient concentration, and the Stokes equation with a source which represents the proliferation density of the tumor cells. The proliferation rate μ and the cell-to-cell adhesiveness γ which keeps the tumor intact are two parameters which characterize the "aggressiveness" of the tumor. For any positive radius R there exists a unique radially symmetric stationary solution with radius $r = R$. We prove that for a sequence $\mu/\gamma = M_n(R)$ there exist symmetry-breaking bifurcation branches of solutions with free boundary $r = R + \varepsilon Y_{n,0}(\theta) + O(\varepsilon^2)$ (n even ≥ 2) for small $|\varepsilon|$, where $Y_{n,0}$ is the spherical harmonic of mode $(n, 0)$. Furthermore, the smallest $M_n(R)$, say, $M_{n_*}(R)$, is such that $n_* = n_*(R) \to \infty$ as $R \to \infty$. The biological implications of this result are discussed at the end of the paper.

Key words. free boundary problems, stationary solution, stability, instability, bifurcation, symmetry-breaking, tumor growth

1. Introduction.

Mathematical models of solid tumor growth, which consider the tumor tissue as a density of proliferating cells, have been developed and studied in many papers; see [1, 2, 3, 4, 7, 9, 10, 18, 20, 21, 23, 27, 28, 30, 31] and the references given there. Most of the models discuss the case of radially symmetric tumors.

Tumors grown in vitro have a nearly spherical shape, but tumors in vivo may develop all kinds of protrusions. It is therefore interesting to explore the existence of nonspherical solutions of tumor models.

Let $\Omega(t)$ denote the tumor domain at time t, and p the pressure within the tumor resulting from proliferation of the tumor cells. The density of the cells, c, depends on the concentration of nutrients, σ, and, assuming that this dependence is linear, we simply identify c with σ. We also assume a linear dependence of the proliferation rate S on σ, that is,

$$S = \mu(\sigma - \widetilde{\sigma}),$$

where $\widetilde{\sigma} > 0$ is a threshold concentration and μ is a positive parameter. If the consumption rate of nutrients by tumor cells is proportional to the concentration of the nutrients, then σ satisfies

$$\beta\sigma_t - \Delta\sigma + \sigma = 0 \quad \text{in } \Omega(t), \qquad \sigma = \overline{\sigma} \quad \text{on } \partial\Omega(t). \tag{1.1}$$

Most tumor models assume that the tissue has the structure of a porous medium for which Darcy's law holds. If we denote by p the pressure within the tumor resulting

from the proliferation of tumor cells, then p is related to the velocity $\vec{v}$ by which the cells move, by Darcy's law $\vec{v} = -\nabla p$. Since by conservation of mass

$$\operatorname{div} \vec{v} = S = \mu(\sigma - \widetilde{\sigma}), \tag{1.2}$$

we obtain for the pressure p the equation

$$\Delta p = -\mu(\sigma - \widetilde{\sigma}) \quad \text{in } \Omega(t). \tag{1.3}$$

There are, however, tumors for which the tissue is more naturally modeled as fluid. For example, in early stages of breast cancer the tumor is confined to the duct of a mammary gland, which consists of epithelial cells, a meshwork of proteins, and extracellular fluid. Several recent papers on ductal carcinoma in the breast use the Stokes equation in their mathematical models [15, 16, 17]. If we denote the fluid velocity by $\vec{v} = (v_1, v_2, v_3)$ and the fluid pressure by p, then the constitutive law is $\sigma_{ij} = -p\delta_{ij} + 2\nu(e_{ij} - \frac{1}{3}\overline{\Delta}\,\delta_{ij})$, where σ_{ij} is the stress tensor, $p = -\frac{1}{3}\sigma_{kk}$, $e_{ij} = \frac{1}{2}(\frac{\partial v_i}{\partial x_j} + \frac{\partial v_j}{\partial x_i})$ is the strain tensor, $\overline{\Delta} = e_{kk} = \operatorname{div}\vec{v}$ is the dilation, and ν is the viscosity coefficient. If there are no body forces, then $\frac{\partial \sigma_{ij}}{\partial x_j} = 0$.

We can rewrite this equation as the Stokes equation

$$-\nu\Delta\vec{v} + \nabla p - (\nu/3)\nabla \operatorname{div}\vec{v} = 0 \quad \text{in } \Omega(t), \quad t > 0. \tag{1.4}$$

We now turn to the boundary conditions at the boundary $\Gamma(t)$ of $\Omega(t)$. We assume that the tumor is held together by the forces of cell-to-cell adhesion with constant γ; the role of γ is discussed in [5, 6, 8]. Introducing the stress tensor $Q = \nu(\nabla\vec{v} + (\nabla\vec{v})^T) - (p + \frac{2}{3}\nu \operatorname{div}\vec{v})I$ with components $Q_{ij} = \nu(\frac{\partial v_i}{\partial x_j} + \frac{\partial v_j}{\partial x_i}) - \delta_{ij}(p + \frac{2\nu}{3}\operatorname{div}\vec{v})$, we then have $Q\vec{n} = -\gamma\kappa\vec{n}$ on $\Gamma(t)$, where $\vec{n}$ is the outward normal and κ is the mean curvature ($\kappa > 0$ if $\Gamma(t)$ is the surface of a convex body). Noting that $\frac{2\nu}{3}\operatorname{div}\vec{v} = \frac{2\nu}{3}\mu(\overline{\sigma} - \widetilde{\sigma})$ on $\Gamma(t)$, this boundary condition can be written in the form

$$T\vec{n} = \big\{-\gamma\kappa + (2\nu/3)\mu(\overline{\sigma} - \widetilde{\sigma})\big\}\vec{n} \quad \text{on } \Gamma(t), \quad t > 0, \tag{1.5}$$

where $T_{ij} = \nu(\frac{\partial v_i}{\partial x_j} + \frac{\partial v_j}{\partial x_i}) - \delta_{ij}p$.

We also assume the kinematic condition $\vec{v}\cdot\vec{n} = V_n$ on $\Gamma(t)$, $t > 0$.

The system (1.2), (1.4), and (1.5) has six-dimensional kernel V_0 consisting of rigid motions $\vec{v}_0 = \vec{a} + \vec{b} \times \vec{x}$. We must therefore add six scalar constraints. These constraints can be written in the form $\int_{\Omega(t)} \vec{v}\, dx = \vec{A}(t)$, $\int_{\Omega(t)} \vec{v} \times \vec{x}\, dx = \vec{B}(t)$, where $\vec{A}(t)$, $\vec{B}(t)$ are prescribed functions. Finally, we prescribe the initial condition

$$\Omega(t)\Big|_{t=0} = \Omega_0, \qquad \sigma\Big|_{t=0} = \sigma_0(x) \quad \text{in } \Omega_0. \tag{1.6}$$

Local existence and uniqueness of solutions for the system (1.4)–(1.6) for a general domain were recently proved by Friedman [19].

In this paper we are interested in discovering a nonspherical stationary solution to the tumor model based on the Stokes equation. For the case of Darcy's law it was proved in Friedman and Reitich [23] that if $\widetilde{\sigma} < \overline{\sigma}$ then there exists a unique stationary spherical solution with radius $R = R_S$ which is determined by $\widetilde{\sigma}/\overline{\sigma}$. It was further proved in Fontelos and Friedman [13] that there exists a family of symmetry-breaking bifurcation branches of stationary solutions with free boundary

$$r = R_S + \varepsilon Y_{n,0} + O(\varepsilon^2) \qquad (n \geq 2) \tag{1.7}$$

with μ, γ such that

$$\frac{\mu}{\gamma} = M_n(R_S) + O(\varepsilon), \quad M_n(R) = \frac{(n-1)n(n+2)}{2R^5 P_0(R)[P_1(R) - P_n(R)]}, \tag{1.8}$$

where $Y_{n,0}$ is the spherical harmonic of order $(n, 0)$, $P_n(R) = I_{n+3/2}(R)/[RI_{n+1/2}(R)]$, and $I_m(r)$ is the modified Bessel function of order m; furthermore, $M_n(R) < M_{n+1}(R)$. For dimension 2, such a result was proved earlier in Friedman and Reitich [24].

The purpose of the present paper is to establish the existence of symmetry-breaking bifurcation branches of stationary solutions in the case where we replace Darcy's law by the Stokes equation and maintain the conservation law (1.2).

By scaling we may assume that $\nu = 1$ and $\overline{\sigma} = 1$. We also take $\vec{A} = 0$, $\vec{B} = 0$ in the constraints. Then the stationary problem becomes

$$-\Delta\sigma + \sigma = 0 \quad \text{in } \Omega, \qquad \sigma = 1 \quad \text{on } \partial\Omega, \tag{1.9}$$

$$-\Delta\vec{v} + \nabla p = (\mu/3)\nabla(\sigma - \widetilde{\sigma}) \quad \text{in } \Omega, \tag{1.10}$$

$$\operatorname{div}\vec{v} = \mu(\sigma - \widetilde{\sigma}) \quad \text{in } \Omega \quad (\widetilde{\sigma} < 1), \tag{1.11}$$

$$T(\vec{v}, p)\vec{n} = \Big(-\gamma\kappa + \frac{2\nu}{3}\mu(1 - \widetilde{\sigma})\Big)\vec{n} \quad \text{on } \partial\Omega, \tag{1.12}$$

$$\vec{v} \cdot \vec{n} = 0 \quad \text{on } \partial\Omega, \tag{1.13}$$

$$\int_\Omega \vec{v}\, dx = 0, \qquad \int_\Omega \vec{v} \times \vec{x}\, dx = 0, \tag{1.14}$$

where $T(\vec{v}, p) = (\nabla\vec{v})^T + \nabla\vec{v} - p\, I$, $I = (\delta_{ij})_{i,j=1}^3$.

In this paper, we shall prove that there exists a family of symmetry-breaking bifurcation branches of stationary solutions of (1.9)–(1.14) with free boundary as (1.7) for n even ≥ 2, where

$$\frac{\mu}{\gamma} = M_n(R_S) + O(\varepsilon),\ M_n(R) = \frac{n(n+2)(2n+1)}{4(n+1)(2n+3)} \frac{1}{R^3 P_0(R)[P_1(R) - P_n(R)]} \tag{1.15}$$

instead of (1.8). In an interesting contrast to the situation for (1.8), the present sequence $M_n(R_S)$ is generally not monotone increasing for all $n \geq 2$. Instead, it is monotone increasing beginning only from some $n = \overline{n}(R_S)$; furthermore, if $M_{n_*(R_S)}(R_S) = \min\{M_n(R_S);\ n = 2, 3, 4, \dots\}$, then $n_*(R_S) \to \infty$ if $R_S \to \infty$. The biological implications of this result will be discussed in the concluding section of this paper. For the reader's convenience, some important formulas on vector spherical harmonics and on Bessel functions are collected in Appendices A and B.

2. Radially symmetric stationary spherical solution. The only radially symmetric solution of (1.9) is

$$\sigma_S(r) = \frac{R_S}{\sinh R_S}\frac{\sinh r}{r} = \frac{R_S^{1/2}}{I_{1/2}(R_S)}\frac{I_{1/2}(r)}{r^{1/2}} \quad \text{in } \{r < R_S\}, \tag{2.1}$$

where R_S is uniquely determined by integrating (1.11) over $\{r < R_S\}$ and using the relation (1.13), $\int_0^{R_S} \mu(\sigma_S - \widetilde{\sigma})r^2 dr = 0$, or (cf. [23])

$$P_0(R_S) \equiv (R_S \coth R_S - 1)/R_S^2 = \widetilde{\sigma}/3. \tag{2.2}$$

We shall show that the pressure and velocity corresponding to σ_S are

$$p_S(r) = \overline{p} + \frac{4\mu}{3}\sigma_S(r), \quad \vec{v}_S = \mu G(r) r \vec{e}_r, \quad G(r) = \frac{R^{1/2}}{I_{1/2}(R)} \frac{I_{3/2}(r)}{r^{3/2}} - P_0(R), \tag{2.3}$$

where $R = R_S$, and the constant $\overline{p}$ in (2.3) is determined by

$$p_S(R) \;=\; \frac{\gamma}{R} + \frac{4\mu}{3}(1 - \widetilde{\sigma}) \;\equiv\; \frac{\gamma}{R} + \frac{4\mu}{3}(1 - 3P_0(R)). \tag{2.4}$$

In fact, from (B.14) with $n = 0$ we get $G(R) = 0$, so that (1.13) is satisfied. Using various properties of the Bessel functions we verify

$$RG'(R) = 1 - 3P_0(R) = \sigma_S(R) - \widetilde{\sigma}, \tag{2.5}$$

$$4G'(r) + rG''(r) = (\sigma_S)_r(r) = \frac{R^{1/2}}{I_{1/2}(R)} \frac{I_{3/2}(r)}{r^{1/2}}, \tag{2.6}$$

$$\Big(\frac{\partial}{\partial x_i}(G(r)x_j) + \frac{\partial}{\partial x_j}(G(r)x_i)\Big)\Big|_{r=R} = 2G'(R)\frac{x_i x_j}{R}\Big|_{r=R}, \tag{2.7}$$

from which we deduce that (1.10)–(1.12) are satisfied. Finally, the constraints in (1.14) are obviously satisfied. From now on we set $R = R_S$.

3. The bifurcation problem. Consider a family of domains with boundaries $\partial\Omega_\varepsilon : r = R_S + \widetilde{R}(\theta, \phi)$, where $\widetilde{R}(\theta, \phi) = \varepsilon S(\theta, \phi)$. Let $(\sigma, \vec{v}, p)$ be the solution of (1.9)–(1.12) with the constraints (1.14). We define a function F by

$$F(\widetilde{R}, \mu) = \vec{v} \cdot \vec{n}. \tag{3.1}$$

Then $(\sigma, \vec{v}, p, R_S + \widetilde{R})$ is a stationary solution if and only if $F(\widetilde{R}, \mu) = 0$.

The function $S(\theta, \phi)$ may be viewed as a function defined on the unit sphere $\Sigma = \{x;\ |x| = 1\}$. We shall later assume that $S(\theta, \phi)$ is in $C^{m+\alpha}(\Sigma)$, that is, S is $C^{m+\alpha}$ as a function defined on Σ; note that this does not mean that $S(\theta, \phi)$ is in $C^{m+\alpha}$ in the variable (θ, ϕ). We shall see in sections 4–6 that F maps the space $C^{m+\alpha}(\Sigma) \times \mathbb{R}$ into the space $C^{m+\alpha-1}(\Sigma)$. In section 4 we shall formally compute the Fréchet derivatives of F. Since F is smooth (as will be shown in section 6), the formal derivation will be rigorously justified.

In order to compute the Fréchet derivatives of F, we need the expansion of $(\sigma, \vec{v}, p)$ of order ε. Note that the normal vector $\vec{n}$ is given by

$$\vec{n} = \vec{e}_r - \varepsilon \frac{S_\theta}{R} \vec{e}_\theta - \varepsilon \frac{S_\phi}{R \sin\theta} \vec{e}_\phi + O(\varepsilon^2) = \vec{e}_r - \frac{\varepsilon}{R} \nabla_\omega S + O(\varepsilon^2). \tag{3.2}$$

We can formally write, for any fixed value of the positive parameter μ,

$$\sigma = \sigma_S + \varepsilon\sigma_1 + O(\varepsilon^2), \quad p = p_S + \varepsilon p_1 + O(\varepsilon^2), \quad \vec{v} = \vec{v}_S + \varepsilon \vec{v}_1 + O(\varepsilon^2), \tag{3.3}$$

$$\partial\Omega_\varepsilon : r = R + \varepsilon S(\theta, \phi). \tag{3.4}$$

Since $\vec{v}_S(R) = 0$, $F(\varepsilon S, \mu) = \varepsilon(\vec{v}_1 + S \frac{\partial}{\partial r} \vec{v}_S)|_{r=R} \cdot \vec{e}_r + O(\varepsilon^2)$. Using the relation $S(\theta, \phi) \frac{\partial}{\partial r} \vec{v}_S|_{r=R} \cdot \vec{e}_r = \mu G'(R) R\, S(\theta, \phi)$ and (2.5), the Fréchet derivative is given by

$$[F_{\widetilde{R}}(0, \mu)]S = \Big(\vec{v}_1 + S \frac{\partial}{\partial r} \vec{v}_S\Big)\Big|_{r=R} \cdot \vec{e}_r = \vec{v}_1\Big|_{r=R} \cdot \vec{e}_r + \mu(1 - 3P_0(R))\, S(\theta, \phi). \tag{3.5}$$

Without the constraint (1.14), the velocity $\vec{v}_1$ is determined only up to an additive vector of the form $\vec{a}+\vec{b}\times\vec{x}$. In section 4 we shall compute this Fréchet derivative, and in section 5 we shall prove that this derivative satisfies the conditions of the bifurcation theorem of Crandall and Rabinowitz for a sequence of parameters M_n, thus allowing us to conclude the existence of symmetry-breaking bifurcations initiating from M_n.

4. Computation of Fréchet derivative. In this section we shall compute the Fréchet derivative $[F_{\widetilde{R}}(0,\mu)]S$. For clarity we shall first perform the computation in a formal way; namely, we assume that the asymptotic formulas (3.3) are valid and that these relations may be differentiated several times; we also drop all the $O(\varepsilon^2)$ terms. All these formal computations will be made rigorous in section 6.

LEMMA 4.1.

$$[F_{\widetilde{R}}(0,\mu)]Y_{l,0} = \Big\{\mu R^2 P_0(R)[P_1(R)-P_l(R)]\Big(1+\frac{l}{(2l^2+4l+3)}\Big) - \frac{\gamma(l+2)(2l+1)l}{4R(2l^2+4l+3)}\Big\}Y_{l,0} \quad \textit{for } l\neq 1, \tag{4.1}$$

$$[F_{\widetilde{R}}(0,\mu)]Y_{1,0}=0 \quad \textit{for } l=1. \tag{4.2}$$

The rigorous proof of this lemma will be given in section 5.

Since we will not impose in this section the constraints of (1.14), $\vec{v}$ and $\vec{v}_1$ are determined only up to additive vectors $\vec{a}+\vec{b}\times\vec{x}$. In the next section we shall impose the constraints (1.14) for $\vec{v}$ and then determine $\vec{v}_1$ in a unique way in the form $\vec{v}_1 = \vec{v}_{1*}+\vec{a}+\vec{b}\times\vec{x}$, where $\vec{v}_{1*}$ is a special solution satisfying (1.9)–(1.13) and $\vec{a},\vec{b}$ are such that (1.14) is satisfied.

4.1. Computation of $\boldsymbol{\sigma_1}$. Formally, $s_1|_{\partial B_R} = \sigma_1|_{\partial\Omega_\varepsilon}+O(\varepsilon)$, so that

$$\varepsilon\sigma_1\Big|_{\partial B_R} = \varepsilon\sigma_1\Big|_{\partial\Omega_\varepsilon}+O(\varepsilon^2) = -\varepsilon(\sigma_S)_r(R)S+O(\varepsilon^2). \tag{4.3}$$

Substituting (3.3) and (4.3) into (1.9), we find that σ_1 satisfies

$$-\Delta\sigma_1+\sigma_1=0 \quad \text{in } B_R, \qquad \sigma_1=-(\sigma_S)_r(R)S(\theta,\phi) \quad \text{on } \partial B_R. \tag{4.4}$$

Hence, we have the following lemma.

LEMMA 4.2. *If $S=Y_{l,m}$, then*

$$\sigma_1 = -(\sigma_S)_r(R)\frac{I_{l+1/2}(r)}{r^{1/2}}\,\frac{R^{1/2}}{I_{l+1/2}(R)}Y_{l,m}(\theta,\phi). \tag{4.5}$$

Remark 4.1. Lemma 4.2 is understood in the sense that it holds for the real and imaginary parts of $Y_{l,m}$ separately. The same interpretation will be used in subsequent computations.

4.2. Computation of $\boldsymbol{\vec{v}_1}$ and $\boldsymbol{p_1}$. Substituting (3.3) into (1.10), (1.11), we get

$$-\Delta\vec{v}_1+\nabla p_1=(\mu/3)\nabla\sigma_1 \quad \text{in } B_R, \tag{4.6}$$

$$\operatorname{div}\vec{v}_1=\mu\sigma_1 \quad \text{in } B_R. \tag{4.7}$$

By taking the divergence in (4.6) and using (4.7), we also have

$$\Delta\big(p_1-(4\mu/3)\sigma_1\big)=0 \quad \text{in } B_R. \tag{4.8}$$

Using (4.4), we can rewrite (4.6) in the form

$$\Delta\big(\vec{v}_1 - \mu\nabla\sigma_1\big) = \nabla\big(p_1 - (4\mu/3)\sigma_1\big) \quad \text{in } B_R. \tag{4.9}$$

In the special case $S = Y_{l,m}$, we look for a solution $(\vec{v}_1, p_1)$ of the form

$$\vec{v}_1 = \vec{a} + \vec{b} \times \vec{x} + \mu\nabla\sigma_1 + v_{l,m}(r)\vec{V}_{l,m} + x_{l,m}(r)\vec{X}_{l,m} + w_{l,m}(r)\vec{W}_{l,m}, \tag{4.10}$$

$$p_1 = \frac{4\mu}{3}\sigma_1 + p_{l,m}(r)Y_{l,m}, \tag{4.11}$$

where $\vec{V}_{l,m}$, $\vec{X}_{l,m}$, and $\vec{W}_{l,m}$ are vector spherical harmonics; see (A.10)–(A.12) for their expressions.

Then by (A.15)

$$\begin{aligned} \nabla\Big(p_1 - \frac{4\mu}{3}\sigma_1\Big) \;=\; & \Big(\frac{l+1}{2l+1}\Big)^{1/2}\Big[-\frac{\partial}{\partial r}p_{l,m} + \frac{l}{r}p_{l,m}\Big]\vec{V}_{l,m} \\ & + \Big(\frac{l}{2l+1}\Big)^{1/2}\Big[\frac{\partial}{\partial r}p_{l,m} + \frac{l+1}{r}p_{l,m}\Big]\vec{W}_{l,m}. \end{aligned} \tag{4.12}$$

Applying (A.15) to $I_{l+1/2}(r)/r^{1/2}$ and using (B.9) and (B.10), we obtain

$$\begin{aligned} \nabla\sigma_1 \;=\; & -(\sigma_S)_r(R)\frac{R^{1/2}}{I_{l+1/2}(R)}\Big\{-\Big(\frac{l+1}{2l+1}\Big)^{1/2}\frac{I_{l+3/2}(r)}{r^{1/2}}\vec{V}_{l,m} \\ & + \Big(\frac{l}{2l+1}\Big)^{1/2}\frac{I_{l-1/2}(r)}{r^{1/2}}\vec{W}_{l,m}\Big\}. \end{aligned} \tag{4.13}$$

Taking the divergence in (4.10) and using (4.4) and (A.16)–(A.18), we find that

$$\begin{aligned} \operatorname{div}\vec{v}_1 \;=\; & \mu\sigma_1 - \Big(\frac{l+1}{2l+1}\Big)^{1/2}\Big[\frac{dv_{l,m}}{dr} + \frac{l+2}{r}v_{l,m}\Big]Y_{l,m} \\ & + \Big(\frac{l}{2l+1}\Big)^{1/2}\Big[\frac{dw_{l,m}}{dr} - \frac{l-1}{r}w_{l,m}\Big]Y_{l,m}. \end{aligned} \tag{4.14}$$

Similarly, taking the Laplacian in (4.10) and using (A.20)–(A.22), we obtain

$$\Delta\big(\vec{v}_1 - \mu\nabla\sigma_1\big) = L_{l+1}(v_{l,m})\vec{V}_{l,m} + L_l(x_{l,m})\vec{X}_{l,m} + L_{l-1}(w_{l,m})\vec{W}_{l,m}. \tag{4.15}$$

Then the system (4.7), (4.6) reduces to four ODEs:

$$-\Big(\frac{l+1}{2l+1}\Big)^{1/2}\Big[\frac{dv_{l,m}}{dr} + \frac{l+2}{r}v_{l,m}\Big] + \Big(\frac{l}{2l+1}\Big)^{1/2}\Big[\frac{dw_{l,m}}{dr} - \frac{l-1}{r}w_{l,m}\Big] = 0, \tag{4.16}$$

$$L_{l+1}(v_{l,m}) = \Big(\frac{l+1}{2l+1}\Big)^{1/2}\Big[-\frac{\partial}{\partial r}p_{l,m} + \frac{l}{r}p_{l,m}\Big], \tag{4.17}$$

$$L_l(x_{l,m}) = 0, \tag{4.18}$$

$$L_{l-1}(w_{l,m}) = \Big(\frac{l}{2l+1}\Big)^{1/2}\Big[\frac{\partial}{\partial r}p_{l,m} + \frac{l+1}{r}p_{l,m}\Big]. \tag{4.19}$$

LEMMA 4.3. *The solutions of the system* (4.16)–(4.19) *have the form*

$$p_{l,m}(r) = 2A_1(2l+3)r^l, \tag{4.20}$$

$$v_{l,m}(r) = \frac{2lA_1}{2l+1}\Big(\frac{2l+1}{l+1}\Big)^{1/2}r^{l+1}, \tag{4.21}$$

$$x_{l,m}(r) = B_1 r^l, \tag{4.22}$$

$$w_{l,m}(r) = C_1 l\Big(\frac{2l+1}{l}\Big)^{1/2}r^{l-1} + \frac{A_1(2l+3)l}{(2l+1)}\Big(\frac{2l+1}{l}\Big)^{1/2}r^{l+1}, \tag{4.23}$$

where A_1, B_1, C_1 are arbitrary constants.

Proof. From (4.8), (4.11), and (A.19), we have $L_l(p_{l,m}) = 0$. This equation has two linearly independent solutions, r^l and r^{-l-1}. Since $p_{l,m}$ is not singular at $r = 0$, we have $p_{l,m}(r) = D_1 r^l$ for some constant D_1. Hence (4.17) is reduced to $L_{l+1}(v_{l,m}) = 0$. This equation has linearly independent solutions r^{l+1} and r^{-l-2}. Since $v_{l,m}(r)$ is not singular at $r = 0$, it must be equal to const $\cdot\, r^{l+1}$, which, for convenience in future computations, we write in the form (4.21).

Similarly, $x_{l,m}(r)$ has the form (4.22). Finally, (4.19) is reduced to

$$L_{l-1}(w_{l,m}) = D_1\Big(\frac{l}{2l+1}\Big)^{1/2}(2l+1)r^{l-1}; \tag{4.24}$$

the general solution of this equation which is not singular at $r = 0$ is of the form

$$w_{l,m}(r) = C_1 l\Big(\frac{2l+1}{l}\Big)^{1/2} r^{l-1} + \frac{D_1}{2}\Big(\frac{l}{2l+1}\Big)^{1/2} r^{l+1}, \tag{4.25}$$

where C_1 is an arbitrary constant. A direct computation shows that (4.16) holds if and only if

$$-\frac{2lA_1}{2l+1}(2l+3) + \Big(\frac{l}{2l+1}\Big)^{1/2} D_1 \Big(\frac{l}{2l+1}\Big)^{1/2} = 0. \tag{4.26}$$

Therefore, $w_{l,m}(r)$ is given by (4.23). ∎

4.3. The boundary condition for $\vec{v}_1$ and p_1. We need three equations to determine the constants A_1, B_1, C_1. They should come from the boundary conditions for $\vec{v}_1$ and p_1. By [23], the curvature κ for the surface $r = R_S + \varepsilon S$ is given by

$$\kappa = \frac{1}{R} - \frac{\varepsilon}{R^2}\Big(S + \frac{1}{2}\Delta_\omega S\Big) + O(\varepsilon^2). \tag{4.27}$$

Thus, by (3.2),

$$\kappa\vec{n} = \frac{1}{R}\vec{e}_r - \frac{\varepsilon}{R^2}\Big\{\nabla_\omega S + \Big(S + \frac{1}{2}\Delta_\omega S\Big)\vec{e}_r\Big\} + O(\varepsilon^2). \tag{4.28}$$

A direct computation shows that

$$\begin{aligned} T(\vec{v},p)\vec{n}\Big|_{\partial\Omega_\varepsilon} &= \Big(T(\vec{v}_S,p_S)\Big|_{\partial\Omega_\varepsilon} + \varepsilon T(\vec{v}_1,p_1)\Big|_{\partial\Omega_\varepsilon}\Big)\Big(\vec{e}_r - \frac{\varepsilon}{R}\nabla_\omega S\Big) + O(\varepsilon^2) \\ &= T(\vec{v}_S,p_S)\Big|_{\partial B_R}\vec{e}_r + \varepsilon\Big\{\Big(T(\vec{v}_1,p_1)\Big|_{\partial B_R} + S\frac{\partial}{\partial r}T(\vec{v}_S,p_S)\Big|_{\partial B_R}\Big)\vec{e}_r \\ &\quad - \frac{1}{R}T(\vec{v}_S,p_S)\Big|_{\partial B_R}\nabla_\omega S\Big\} + O(\varepsilon^2), \end{aligned} \tag{4.29}$$

where $T(\vec{v}_1,p_1) = \nu(\nabla\vec{v}_1 + (\nabla\vec{v}_1)^T) - p_1 I$. Thus the boundary condition for $\vec{v}$ becomes

$$T(\vec{v}_1,p_1)\Big|_{\partial B_R}\vec{e}_r = \vec{\Phi}_1, \tag{4.30}$$

where

$$\begin{aligned} \vec{\Phi}_1 \;&=\; \frac{\gamma}{R^2}\Big\{\nabla_\omega S + \Big(S + \frac{1}{2}\Delta_\omega S\Big)\vec{e}_r\Big\} - S\frac{\partial}{\partial r}T(\vec{v}_S,p_S)\Big|_{\partial B_R}\vec{e}_r \\ &\quad + \Big(\frac{1}{R}T(\vec{v}_S,p_S)\Big|_{\partial B_R} - \frac{2\mu}{3R}(1-\widetilde{\sigma})\Big)\nabla_\omega S. \end{aligned} \tag{4.31}$$

For a (column) vector $\vec{Z}$, ∇Z denotes the matrix with components $(\nabla\vec{Z})_{ij} = \partial_{x_i} Z_j$, so that for any vector $\vec{U}$, we have $\nabla\vec{Z}\cdot\vec{U} = (\partial_{x_1}\vec{Z}^T\cdot\vec{U},\, \partial_{x_2}\vec{Z}^T\cdot\vec{U},\, \partial_{x_3}\vec{Z}^T\cdot\vec{U})^T$. Since $\vec{v}_S = \mu G(r) r\vec{e}_r$ and $r\nabla\vec{e}_r = I - \vec{e}_r\vec{e}_r^{\,T}$, for any vector $\vec{U}$

$$\begin{aligned}\nabla\vec{v}_S\cdot\vec{U} &= \Big[\frac{\partial}{\partial r}\Big(\mu G(r) r\Big)\vec{e}_r\Big]\vec{e}_r^{\,T}\cdot\vec{U} + \mu G(r) r\nabla\vec{e}_r\cdot\vec{U}\\ &= \frac{\partial}{\partial r}\Big(\mu G(r) r\Big)(\vec{U}\cdot\vec{e}_r)\vec{e}_r + \mu G(r)\Big(\vec{U} - (\vec{U}\cdot\vec{e}_r)\vec{e}_r\Big)\\ &= \Big\{-\mu G(r) + \frac{\partial}{\partial r}\Big(\mu G(r) r\Big)\Big\}(\vec{U}\cdot\vec{e}_r)\vec{e}_r + \mu G(r)\vec{U}.\end{aligned} \tag{4.32}$$

Since $\nabla_\omega S\cdot\vec{e}_r = 0$, if we apply (4.32) to $\vec{U} = \nabla_\omega S$, the right-hand side of (4.32) will vanish at $r = R$. The same is true if we replace ∇v_S by $(\nabla v_S)^T$ in (4.32), since ∇v_S is symmetric (cf. (2.7)). Hence

$$\begin{aligned}\Big(T(\vec{v}_S, p_S)\Big|_{\partial B_R} - \frac{2\mu}{3}(1-\widetilde{\sigma})\Big)\nabla_\omega S &= \Big(-p_S(R) - \frac{2\mu}{3}(1-\widetilde{\sigma})\Big)\nabla_\omega S\\ &= -\Big(\frac{\gamma}{R} + 2\mu(1 - 3P_0(R))\Big)\nabla_\omega S,\end{aligned} \tag{4.33}$$

where in the last equality we used (2.2), (2.4). Similarly, taking $\vec{U} = \vec{e}_r$ and differentiating in r, we get

$$\begin{aligned}\frac{\partial}{\partial r}T(\vec{v}_S, p_S)\Big|_{\partial B_R}\vec{e}_r &= \Big[2\frac{\partial^2}{\partial r^2}\Big(\mu G(r) r\Big) - \frac{\partial p_S(r)}{\partial r}\Big]_{r=R}\vec{e}_r\\ &= -2\mu\Big[\frac{2}{R}(1 - 3P_0(R)) - \frac{1}{3}RP_0(R)\Big]\vec{e}_r,\end{aligned}$$

where in the last equality we used (2.5) and (2.6). Substituting this and (4.33) into (4.31), we find that, in the special case $S = Y_{l,m}$,

$$\begin{aligned}\vec{\Phi}_1 \;=\; & -\frac{2\mu}{R}(1 - 3P_0(R))\nabla_\omega Y_{l,m} + \Big\{\frac{\gamma}{R^2}\Big(1 - \frac{l(l+1)}{2}\Big)\\ & + \frac{4\mu}{R}(1 - 3P_0(R)) - \frac{2\mu}{3}RP_0(R)\Big\}Y_{l,m}\vec{e}_r.\end{aligned} \tag{4.34}$$

Using (A.13), (A.14), we then obtain the orthogonality relation

$$\langle\vec{\Phi}_1, \vec{X}_{l,m}\rangle = 0. \tag{4.35}$$

According to Lemma 4.1 of [26], if $T(\vec{v}_1, p_1)\vec{e}_r = \vec{\Phi}_1 = M_1\vec{V}_{l,m} + M_2\vec{X}_{l,m} + M_3\vec{W}_{l,m}$, where $\vec{v}_1$, p_1 are as in (4.10), (4.11) with $\vec{a} = 0$, $\vec{b} = 0$, $\nabla\sigma_1 = 0$, then $x_{l,m}$ satisfies

$$\frac{\partial x_{l,m}}{\partial r} - \frac{1}{r}x_{l,m} = M_2 \quad \text{at } r = R. \tag{4.36}$$

The same is true if σ_1 is as in (4.5) since, by (4.13), the introduction of σ_1 does not change M_2 (i.e., $\langle\nabla\sigma_1, \vec{X}_{l,m}\rangle = 0$); the same is true if the constant vectors are not equal to zero since $T(\vec{v}_1, p_1) = T(\vec{v}_1 - \vec{a} - \vec{b}\times\vec{x}, p_1)$. In the present case $M_2 = 0$ (by (4.34) and (A.13), (A.14)), so that, by (4.22), equation (4.36) reduces to

$$B_1\Big(lR^{l-1} - \frac{R^l}{R}\Big) = 0, \tag{4.37}$$

and, since $l \geq 2$, $B_1 = 0$.

Using Lemma 4.3 with $B_1 = 0$, and (4.5), one can verify that

$$\vec{v}_1 = \vec{a} + \vec{b} \times \vec{x} + H_1(r) Y_{l,m} \vec{e}_r + H_2(r) \nabla_\omega Y_{l,m}, \tag{4.38}$$

where

$$\begin{aligned} H_1(r) \;=\; & \Big\{ -\mu R P_0(R) \frac{R^{1/2}}{I_{l+1/2}(R)} \Big(\frac{I_{l+3/2}(r)}{r^{1/2}} + \frac{l}{r^{3/2}} I_{l+1/2}(r) \Big) \\ & + A_1 l\, r^{l+1} + C_1 l\, r^{l-1} \Big\}, \end{aligned} \tag{4.39}$$

$$H_2(r) \;=\; -\mu R P_0(R) \frac{R^{1/2}}{I_{l+1/2}(R)} \frac{I_{l+1/2}(r)}{r^{3/2}} + A_1 \frac{(l+3)}{(l+1)} r^{l+1} + C_1 r^{l-1}. \tag{4.40}$$

Also, by (4.11), (4.5), and the equality $(\sigma_S)_r(R) = R P_0(R)$,

$$p_1\Big|_{r=R} = \Big(-\frac{4\mu}{3} R P_0(R) + 2A_1(2l+3) R^l \Big) Y_{l,m}. \tag{4.41}$$

Lemma 4.4. *For any function $H(r)$, there hold*

$$\nabla\Big(H(r) Y_{l,m} \vec{e}_r\Big) \cdot \vec{e}_r = \nabla\Big(H(r) Y_{l,m}\Big) = H'(r) Y_{l,m} \vec{e}_r + r^{-1} H(r) \nabla_\omega Y_{l,m}, \tag{4.42}$$

$$\Big(\nabla\Big(H(r) Y_{l,m} \vec{e}_r\Big)\Big)^T \cdot \vec{e}_r = H'(r) Y_{l,m} \vec{e}_r, \tag{4.43}$$

$$\nabla\Big(H(r) \nabla_\omega Y_{l,m}\Big) \cdot \vec{e}_r = -r^{-1} H(r)\, \nabla_\omega Y_{l,m}, \tag{4.44}$$

$$\Big(\nabla\Big(H(r) \nabla_\omega Y_{l,m}\Big)\Big)^T \cdot \vec{e}_r = H'(r) \nabla_\omega Y_{l,m}. \tag{4.45}$$

Proof. As in the proof of Lemma 4.1 of [26], the following relations hold for any vectors $\vec{U}, \vec{Z}$ and scalar Ψ:

$$\nabla(\Psi \vec{Z}) \cdot \vec{e}_r = \Psi \nabla \vec{Z} \cdot \vec{e}_r + (\vec{Z} \cdot \vec{e}_r) \nabla \Psi, \tag{4.46}$$

$$(\nabla \vec{Z})^T \vec{U} = (\nabla \vec{Z}) \vec{U} - \vec{U} \times (\nabla \times \vec{Z}), \tag{4.47}$$

$$(\nabla \vec{Z}) \cdot \vec{U} = \nabla(\vec{Z} \cdot \vec{U}) - \nabla \vec{U} \cdot \vec{Z}, \tag{4.48}$$

$$\nabla \vec{e}_r \cdot \vec{Z} = r^{-1} \Big(\vec{Z} - (\vec{Z} \cdot \vec{e}_r) \vec{e}_r \Big). \tag{4.49}$$

Using (4.46) with $\Psi = H(r) Y_{l,m}$ and $\vec{Z} = \vec{e}_r$, and then also recalling (4.49), we obtain (4.42).

Using (A.4)–(A.5), we can directly compute $\nabla \times (H(r) Y_{l,m} \vec{e}_r)$. If we now apply (4.47) with $\vec{U} = \vec{e}_r$, $Z = H(r) Y_{l,m} \vec{e}_r$ and use (4.42), we obtain the assertion (4.43).

Similarly, $\nabla(H(r) \nabla_\omega Y_{l,m}) \cdot \vec{e}_r = H(r) \nabla(\nabla_\omega Y_{l,m}) \cdot \vec{e}_r$, since $\nabla_\omega Y_{l,m} \cdot \vec{e}_r = 0$. Using (4.48) with $\vec{Z} = \nabla_\omega Y_{l,m}$, $\vec{U} = \vec{e}_r$, we derive $\nabla(\nabla_\omega Y_{l,m}) \cdot \vec{e}_r = -\nabla \vec{e}_r \cdot \nabla_\omega Y_{l,m}$, and using (4.49), the inequality (4.44) follows.

Finally, using (A.4)–(A.7) and (A.10)–(A.14), one can verify directly that, for some function $\widetilde{Q}$,

$$\begin{aligned} \nabla \times (H(r) \nabla_\omega Y_{l,m}) \;=\; & H'(r) \Big(\vec{e}_\phi \partial_\theta Y_{l,m} - \frac{\vec{e}_\theta}{\sin\theta} \partial_\phi Y_{l,m} \Big) + \widetilde{Q} \vec{e}_r \\ & + r^{-1} H(r) \Big(\vec{e}_\phi (\partial_\theta Y_{l,m}) - \frac{\vec{e}_\theta}{\sin\theta} (\partial_\phi Y_{l,m}) \Big). \end{aligned} \tag{4.50}$$

Taking the vector product with $\vec{e}_r$ and using (4.44), (4.47), we obtain (4.45). ∎

By Lemma 4.4,

$$\begin{aligned}&\Big((\nabla\vec{v}_1)+(\nabla\vec{v}_1)^T\Big)\Big|_{r=R}\cdot\vec{e}_r\\&=2H_1'(r)\Big|_{r=R}Y_{l,m}\vec{e}_r+\Big(r^{-1}H_1(r)-r^{-1}H_2(r)+H_2'(r)\Big)\Big|_{r=R}\nabla_\omega Y_{l,m}.\end{aligned}$$

A direct computation shows that

$$2H_1'(r)\Big|_{r=R}=-2\mu RP_0(R)\Big(1-2P_l(R)+\frac{l(l-1)}{R^2}\Big)+2A_1l(l+1)R^l+2C_1l(l-1)R^{l-2},$$

and

$$\begin{aligned}&\Big(r^{-1}H_1(r)-r^{-1}H_2(r)+H_2'(r)\Big)\Big|_{r=R}\\&=-2\mu RP_0(R)\Big(P_l(R)+\frac{l-1}{R^2}\Big)+2A_1\frac{l(l+2)}{(l+1)}R^l+2C_1(l-1)R^{l-2}.\end{aligned}$$

Recalling (4.34), one can verify that the boundary condition (4.30) reduces to the two equations

$$\begin{aligned}&2A_1\frac{l(l+2)}{(l+1)}R^l+2C_1(l-1)R^{l-2}\\&=-\frac{2\mu}{R}(1-3P_0(R))+2\mu RP_0(R)\Big(P_l(R)+\frac{l-1}{R^2}\Big)\end{aligned}\tag{4.51}$$

and

$$\begin{aligned}&2A_1R^l(l^2-l-3)+2C_1R^{l-2}l(l-1)\\&=\frac{\gamma}{R^2}\Big(1-\frac{l(l+1)}{2}\Big)+\frac{4\mu}{R}(1-3P_0(R))\\&\quad-4\mu RP_0(R)P_l(R)+2\mu RP_0(R)\frac{l(l-1)}{R^2}.\end{aligned}\tag{4.52}$$

In order to compute the Fréchet derivative in (3.5), we need only to compute the linear combination $A_1R^{l+1}+C_1R^{l-1}$, since they always appear in this form. To do that, note that the combination $3(l+1)R\times(4.51)+(2l+1)R\times(4.52)$ gives

$$\begin{aligned}&2(l-1)(2l^2+4l+3)\Big(A_1R^{l+1}+C_1R^{l-1}\Big)y\\&=-\gamma\frac{(l-1)(l+2)}{2R}(2l+1)+2\mu(1-3P_0(R))(l-1)\\&\quad-2\mu R^2P_0(R)P_l(R)(l-1)+2\mu P_0(R)(l-1)(2l^2+4l+3).\end{aligned}\tag{4.53}$$

If $l\neq 1$, then

$$\begin{aligned}A_1R^{l+1}+C_1R^{l-1}=\mu P_0(R)+\frac{1}{2(2l^2+4l+3)}\Big\{&-\gamma\frac{(l+2)}{2R}(2l+1)\\&+2\mu(1-3P_0(R))-2\mu R^2P_0(R)P_l(R)\Big\},\end{aligned}$$

so that by (4.39), (4.40),

$$\Big(\vec{v}_1 - \vec{a} - \vec{b}\times\vec{x}\Big)\cdot\vec{e}_r\Big|_{r=R} = \Big\{-\mu R P_0(R)\Big(RP_l(R) + \frac{l}{R}\Big) + A_1 l R^{l+1} + C_1 l R^{l-1}\Big\} Y_{l,m}$$
$$= \Big\{-\mu R^2 P_0(R) P_l(R) + \frac{l}{2(2l^2+4l+3)}\Big(-\gamma\frac{(l+2)}{2R}(2l+1) + 2\mu(1-3P_0(R)) - 2\mu R^2 P_0(R)P_l(R)\Big)\Big\} Y_{l,m}.$$

Recalling that $1 - 3P_0(R) = R^2 P_0(R) P_1(R)$ (cf. (B.16) with $n = 0$), we obtain

$$\begin{aligned}&\Big(\vec{v}_1 - \vec{a} - \vec{b}\times\vec{x}\Big)\cdot\vec{e}_r\Big|_{r=R} + \mu(1-3P_0(R))\, Y_{l,m}\\ &= \Big\{\mu R^2 P_0(R)[P_1(R) - P_l(R)]\Big(1 + \frac{l}{(2l^2+4l+3)}\Big) - \frac{\gamma(l+2)(2l+1)l}{4R(2l^2+4l+3)}\Big\} Y_{l,m}.\end{aligned} \tag{4.54}$$

From (3.5) and the fact that $(\vec{b}\times\vec{x})\cdot\vec{e}_r = 0$ we then get

$$\begin{aligned}[F_{\widetilde{R}}(0,\mu)]Y_{l,m} \;=\; &\Big\{\mu R^2 P_0(R)[P_1(R) - P_l(R)]\Big(1 + \frac{l}{(2l^2+4l+3)}\Big)\\ &- \frac{\gamma(l+2)(2l+1)l}{4R(2l^2+4l+3)}\Big\} Y_{l,m} + \vec{a}\cdot\vec{e}_r.\end{aligned} \tag{4.55}$$

Note that we have not yet implemented the constraints (1.14). This will be done in the next section, where we shall prove that (1.14) for $l \geq 2$ is satisfied with $\vec{a} = 0$ and some vector $\vec{b}$.

Hence, for $l \geq 2$, $\vec{a} = 0$ in (4.55). Therefore, the expression in (4.55) vanishes if and only if $\mu/\gamma = M_l(R)$, where

$$M_l(R) = \frac{k(l)}{R^3 P_0(R)[P_1(R) - P_l(R)]}, \quad k(l) = \frac{l(l+2)(2l+1)}{4(l+1)(2l+3)}, \quad l \geq 2. \tag{4.56}$$

So far we have assumed that the Fréchet derivative exists and we computed it at $S = Y_{l,m}$. Since the Fréchet derivative is a linear operator, the formula (4.55) formally extends to any $S = \sum_l a_l Y_{l,0}(\theta)$.

5. Constraints in (1.14).

Proof of Lemma 4.1. When we computed the Fréchet derivative in (4.54) we assumed that $(\sigma, \vec{v}, p)$ is a solution of (1.9)–(1.13), but we have not yet imposed the constraints in (1.14). If we impose these constraints on $\vec{v}$, then we obtain similar constraints on $\vec{v}_1$:

$$\int_{B_R} \vec{v}_1\, dx = 0, \qquad \int_{B_R} \vec{v}_1 \times \vec{x}\, dx = 0. \tag{5.1}$$

Writing v_1 in the form (4.38), namely, $\vec{v}_1 = \vec{a} + \vec{b}\times\vec{x} + \vec{v}_{1*}$, where

$$\vec{v}_{1*} = H_1(r) Y_{l,m}\vec{e}_r + H_2(r)\nabla_\omega Y_{l,m} \tag{5.2}$$

and H_1, H_2 are given by (4.39)–(4.40), we then need to determine $\vec{a}, \vec{b}$ such that

$$\int_{B_R} (\vec{a} + \vec{b}\times\vec{x}) dx = -\int_{B_R} \vec{v}_{1*}\, dx, \quad \int_{B_R} (\vec{a} + \vec{b}\times\vec{x})\times\vec{x}\, dx = -\int_{B_R} \vec{v}_{1*}\times\vec{x}\, dx, \tag{5.3}$$

by (5.1). By a direct computation using (A.1), (5.3) is reduced to

$$\int_{B_R} \vec{v}_{1*}\, dx = -\frac{4\pi}{3} R^3 \vec{a}, \qquad \int_{B_R} \vec{v}_{1*} \times \vec{x}\, dx = \frac{8\pi}{15} R^5 \vec{b}. \tag{5.4}$$

The case $l \geq 2$. Since $Y_{l,0}$ is orthogonal to $Y_{1,0}$ for $l \neq 1$,

$$\int_0^\pi Y_{l,0}(\theta)\cos\theta\, \vec{e}_3(\sin\theta d\theta) = \int_0^\pi Y_{l,0}(\theta) 2\sqrt{\frac{\pi}{3}} Y_{1,0}(\theta)\, \vec{e}_3(\sin\theta d\theta) = 0, \tag{5.5}$$

and using (A.1), (5.5), we obtain

$$\int_0^{2\pi} \Big(\int_0^\pi Y_{l,0}(\theta)\vec{e}_r \sin\theta d\theta\Big) d\phi = 2\pi \int_0^\pi Y_{l,0}(\theta)\cos\theta\, \vec{e}_3 \sin\theta d\theta = 0; \tag{5.6}$$

similarly, by integration by parts,

$$\int_0^{2\pi} \Big(\int_0^\pi \nabla_\omega Y_{l,0}(\theta)\sin\theta d\theta\Big) d\phi = 4\pi \int_0^\pi Y_{l,0}(\theta)\cos\theta\, \vec{e}_3 \sin\theta d\theta \;=\; 0. \tag{5.7}$$

If we substitute (5.2) into the left-hand side of (5.4) and then use (5.6), (5.7), we get $\int_{B_R} \vec{v}_{1*}\, dx = 0$ if $l \neq 1$; hence

$$\vec{a} = 0 \quad \text{ if } l \neq 1. \tag{5.8}$$

We can solve $\vec{b}$ by (5.4), but since $(\vec{b}\times\vec{x})\cdot\vec{e}_r = r(\vec{b}\times\vec{e}_r)\cdot\vec{e}_r = 0$, the extra term from $\vec{b}\times\vec{x}$ does not contribute anything to the Fréchet derivative (cf. (3.5), (4.54)), and hence Lemma 4.1 holds in this case.

In the derivation of some of the formulas above we have assumed $l \geq 2$. So the cases $l = 0$ and $l = 1$ have to be treated separately.

The case $l = 0$. Since $Y_{0,0}$ is a constant, if we perturb the system by $R + \varepsilon Y_{0,0}$, the system remains radially symmetric, and in fact, as easily verified,

$$\sigma_1 = -Y_{0,0}(\sigma_S)_r(R)\frac{I_{1/2}(r)}{r^{1/2}}\frac{R^{1/2}}{I_{1/2}(R)} = -Y_{0,0}(\sigma_S)_r(R)\sigma_S(r), \tag{5.9}$$

$$\vec{v}_1 = \mu\nabla\sigma_1 = \mu(\sigma_1)_r(r)\vec{e}_r, \qquad p_1 = \overline{p}_1 + \frac{4\mu}{3}\sigma_1, \tag{5.10}$$

where $\overline{p}_1$ is a uniquely determined constant. Thus

$$\vec{v}_1\Big|_{r=R} \cdot \vec{e}_r = \mu(\sigma_1)_r(R) = -\mu Y_{0,0}[(\sigma_S)_r(R)]^2 = -\mu Y_{0,0} R^2 P_0^2(R).$$

By (3.5) and the relation $1 - 3P_0(R) = R^2 P_0(R) P_1(R)$ (by (B.16)), we then obtain

$$[F_{\tilde{R}}(0,\mu)]Y_{0,0} = -\mu Y_{0,0} R^2 P_0(R)[P_0(R) - P_1(R)]. \tag{5.11}$$

Thus (4.1) is valid also for $l = 0$. □

The case $l = 1$. The case $l = 1$ has to be treated in a special way. In this case, if we follow the proof for $l \geq 2$ we find that the constants C_1 and B_1 in (4.22) and (4.23) are not determined by the boundary conditions, so some changes need to be made. However, it is easier to compute the Fréchet derivative in a different and more illuminating way. We shall write the spherically symmetric solution $(\sigma_S, \vec{v}_S, p_S)$

on $B_{R_S}(0) = \{|x| < R_S\}$ in the form $(\sigma_S(x), \vec{v}_S(x), p_S(x))$. Let $\vec{x}_0 = \frac{3}{\sqrt{4\pi}}\vec{e}_3$. Then the translated functions $(\sigma_S(x - \varepsilon x_0),\ \vec{v}_S(x - \varepsilon x_0),\ p_S(x - \varepsilon x_0))$ form a solution on $B_{R_S}(\varepsilon x_0) = \{|x - \varepsilon x_0| < R_S\}$. We can rewrite the boundary $|x - \varepsilon x_0| = R_S$ as

$$r = |x| = R_S + \varepsilon r \vec{e}_r \frac{3}{\sqrt{4\pi}}\vec{e}_3 + O(\varepsilon^2) \ = \ R_S + \varepsilon Y_{1,0}(\theta) + O(\varepsilon^2).$$

This means that when the perturbation is given by $\varepsilon Y_{1,0}$, we have the explicit translated solution up to an error of order $O(\varepsilon^2)$. Thus $v_S(x - \varepsilon x_0) = O(\varepsilon^2)$ on $r = R_S + \varepsilon Y_{1,0}(\theta)$ and, by (3.1), $F(\varepsilon Y_{10}, \mu) = O(\varepsilon^2)$. It follows that

$$[F_{\widetilde{R}}(0, \mu)]Y_{1,0} = 0 \quad \text{ for any } \mu > 0. \qquad \square \tag{5.12}$$

6. Rigorous justification. For $S \in C^{k+\alpha}(\Sigma)$, $k \geq 3$, we set $\Omega_\varepsilon = \{r < R + \varepsilon S\}$, and define σ_1 by (4.4) and $(p_1, \vec{v}_1)$ by (4.6)–(4.7), (4.30)–(4.31), and (5.1).

Note that $(\sigma, p, \vec{v})$ is defined only on Ω_ε, while $(\sigma_S, p_S, \vec{v}_S)$ is defined on whole $\mathbb{R}^3$ and $(\sigma_1, p_1, \vec{v}_1)$ is defined on B_R. We need to transform all these functions to the same domain Ω_ε and shall do it by the Hanzawa transformation, which is a diffeomorphism defined by $(r, \theta, \phi) = H_\varepsilon(r', \theta', \phi') \equiv (r' + \chi(R - r')\varepsilon S(\theta', \phi'), \theta', \phi')$, where $\chi \in C^\infty$, $\chi(z) = 0$ if $|z| \geq 3\delta_0/4$, and $\chi(z) = 1$ if $|z| < \delta_0/4$. Observe that H_ε maps B_R onto Ω_ε while keeping the ball $\{r < R - (3\delta_0/4)\}$ fixed. The inverse Hanzawa transformation H_ε^{-1} maps Ω_ε onto B_R. Note that $H_\varepsilon = I + \varepsilon N$, where N is a C^∞ operator.

It was rigorously proved in [22, Lemma 3.2] that

$$\|\sigma - (\sigma_S + \varepsilon\sigma_1(H_\varepsilon^{-1}\cdot))\|_{C^{k+\alpha}(\Omega_\varepsilon)} \leq C|\varepsilon|^2 \|S\|_{C^{k+\alpha}(\Omega_\varepsilon)} \tag{6.1}$$

for $k = 3$; the proof extends to all $k \geq 2$.

From (6.1), it follows that the formal expansion for σ is rigorous. We now proceed to rigorously justify the expansion used in section 5 for p and $\vec{v}$ in the same manner as was done in [22], using estimates derived for the (inhomogeneous) Stokes equation instead of the parabolic equation of [22].

By (4.6)–(4.7), (4.30)–(4.31), and (5.1), we can apply the estimates for the Stokes equation [32, Proposition 2] to obtain

$$\|\vec{v}_1\|_{C^{k-1+\alpha}(B_R)} + \|p_1\|_{C^{k-2+\alpha}(B_R)} \leq C\|\vec{\Phi}_1\|_{C^{k-2+\alpha}(\Sigma)} \leq C\|S\|_{C^{k+\alpha}(\Sigma)}. \tag{6.2}$$

Using (4.6), (4.7) and (6.1), (6.2), we can rewrite (1.10)–(1.11) in the form

$$-\Delta\Big(\vec{v} - \vec{v}_S - \varepsilon\vec{v}_1(H_\varepsilon^{-1}x)\Big) + \nabla\Big(p - p_S - \varepsilon p_1(H_\varepsilon^{-1}x)\Big) = \varepsilon^2 \widetilde{f} \quad \text{ in } \Omega_\varepsilon, \tag{6.3}$$

$$\operatorname{div}\Big(\vec{v} - \vec{v}_S - \varepsilon\vec{v}_1(H_\varepsilon^{-1}x)\Big) = \varepsilon^2 \widetilde{g} \quad \text{ in } \Omega_\varepsilon, \tag{6.4}$$

where

$$\|\widetilde{f}\|_{C^{k-3+\alpha}(\overline{\Omega}_\varepsilon)} + \|\widetilde{g}\|_{C^{k-2+\alpha}(\overline{\Omega}_\varepsilon)} \leq C\|S\|_{C^{k+\alpha}(\Sigma)}. \tag{6.5}$$

In order to derive estimates for the expansion of $(\vec{v}, p)$, we also need to estimate the boundary conditions. By the proof of [25, Theorem 8.1],

$$\big\|\kappa - R^{-1} + \varepsilon R^{-2}\big(S + \Delta_\omega S/2\big)\big\|_{C^{k-2+\alpha}(\Sigma)} \leq C|\varepsilon|^2 \|S\|_{C^{k+\alpha}(\Sigma)}. \tag{6.6}$$

We also have, from (3.2),

$$\big\|\vec{n} - \big(\vec{e}_r - \varepsilon R^{-1}\nabla_\omega S\big)\big\|_{C^{k+\alpha}(\Sigma)} \leq C|\varepsilon|^2 \|S\|_{C^{k+1+\alpha}(\Sigma)}. \tag{6.7}$$

By essentially repeating all the formal computations of section 4 while keeping track of the error terms (using (6.6) and (6.7)), we find that

$$\|T[\vec{v} - \vec{v}_S - \varepsilon \vec{v}_1(H_\varepsilon^{-1}x), p - p_S - \varepsilon p_1(H_\varepsilon^{-1}x)] \cdot \vec{n}\|_{C^{k-2+\alpha}(\Sigma)} \le C|\varepsilon|^2 \|S\|_{C^{k+\alpha}(\Sigma)}.$$

The constraints in (1.14) imposed on $\vec{v}_1$ ensure that

$$\left|\int_{\Omega_\varepsilon} \Big(\vec{v} - \vec{v}_S - \varepsilon \vec{v}_1(H_\varepsilon^{-1}x)\Big) dx\right| + \left|\int_{\Omega_\varepsilon} \Big(\vec{v} - \vec{v}_S - \varepsilon \vec{v}_1(H_\varepsilon^{-1}x)\Big) \times \vec{x}\, dx\right| \le C|\varepsilon|^2. \tag{6.8}$$

We can then apply again the estimates from [32] for the Stokes equation to obtain

$$\|\vec{v} - \vec{v}_S - \varepsilon \vec{v}_1(H_\varepsilon^{-1}\cdot)\|_{C^{k-1+\alpha}(\overline{\Omega}_\varepsilon)} \le C|\varepsilon|^2 \|S\|_{C^{k+\alpha}(\Sigma)}, \tag{6.9}$$

$$\|p - p_S - \varepsilon p_1(H_\varepsilon^{-1}\cdot)\|_{C^{k-2+\alpha}(\overline{\Omega}_\varepsilon)} \le C|\varepsilon|^2 \|S\|_{C^{k+\alpha}(\Sigma)}. \tag{6.10}$$

These estimates combined with (6.1) ensure that the expansion in the computations of the Fréchet derivative are rigorous, that is,

$$\|F(\widetilde{R}, \mu) - F(0, \mu) - \varepsilon F_{\widetilde{R}}(0, \mu) S\|_{C^{k-1+\alpha}} \le \text{const} \cdot |\varepsilon|\, \|\widetilde{R}\|_{C^{k+\alpha}(\Sigma)}, \quad \widetilde{R} = \varepsilon S,$$

where $S \to F_{\widetilde{R}}(0, \mu) S$ is the linear operator defined by (4.1), (4.2).

7. Monotonicity of $M_n(R)$. In the model with Darcy's law (1.2), it was proved in [13] that $M_n(R) < M_{n+1}(R)$ for all $n \ge 2$ and all $R > 0$.

For the present model (1.9)–(1.14) we have a different result:

$$M_n(R) \text{ is monotone increasing beginning only from some } n = \overline{n}(R); \tag{7.1}$$

furthermore, if $M_{n_*(R)}(R) = \min\{M_n(R);\, n = 2, 3, 4, \dots\}$, then

$$n_*(R) \to \infty \quad \text{if } R \to \infty, \tag{7.2}$$

whereas

$$\text{for } R \text{ small, } n_*(R) = 3, \text{ and } M_3(R) < M_2(R) < M_4(R). \tag{7.3}$$

It is clear from (4.56) that $k(n) = n/4 + O(n^{-1})$. Using this in (4.56), we obtain the assertion (7.1). We next establish the assertion (7.2).

THEOREM 7.1. (i) *For every $n > m \ge 2$, there exists an $R_*(n, m)$ such that*

$$M_n(R) < M_m(R) \quad \textit{for } R > R_*(n, m); \tag{7.4}$$

(ii) (7.2) *holds.*

Proof. By (B.21), $P_n(R) = \frac{1}{R} - \frac{n+1}{R^2} + O(\frac{n^2}{R^3})$, so that

$$M_n(R) = \frac{k(n)}{(n-1)RP_0(R)}\Big[1 + O\Big(\frac{n^2}{R}\Big)\Big]. \tag{7.5}$$

Clearly $\frac{k(n)}{n-1} = \frac{1}{4}(1 + \frac{2n^2+4n+3}{(n^2-1)(2n+3)}) = \frac{1}{4}(1 + \frac{2}{2n+3} + \frac{4n+5}{(n^2-1)(2n+3)})$ and the sequence $\frac{2}{2n+3}$ is monotone decreasing. Since also, for $x > 2$, the function $f(x) = \frac{4x+5}{(x^2-1)(2x+3)}$ satisfies $f'(x) < 0$, the assertion (7.4) follows.

To prove (7.2) note that if $n_*(R_j)$ remains bounded for a sequence of $R_j \to \infty$, then (7.5) is valid uniformly for $R = R_j$. By taking a subsequence, we may assume that $n_*(R_j)$ is a number n_* independent of j. By the previous analysis, if $n > n_*$ and R_j is large enough, then $M_n(R_j) < M_{n_*}(R_j)$, which is a contradiction. ∎

We next state (7.3) more precisely.

THEOREM 7.2. *If* $0 < R < R^\#$, *where* $R^\# \approx 2.601086$, *then* $M_n(R)$ *is monotone increasing for* $n \geq 4$, *and*

$$M_3(R) < M_2(R) < M_4(R) \quad \textit{for } 0 < R < R^\#. \tag{7.6}$$

Proof. The inequality (7.6) can be verified numerically with $R^\#$ uniquely determined by the equation $M_2(R^\#) = M_4(R^\#)$. The monotonicity of $M_n(R)$ for $0 < R < R^\#$ and $n \geq 4$ can be rigorously established using (B.16), (B.20), and (B.22); the details are omitted. ∎

8. Bifurcation. We shall apply the following Crandall–Rabinowitz theorem.

THEOREM 8.1 (see [11, Theorem 1.7]). *Let* X, Y *be real Banach spaces and* $F(x,\mu)$ *a* C^p *map,* $p \geq 3$, *of a neighborhood* $(0,\mu_0)$ *in* $X \times \mathbb{R}$ *into* Y. *Suppose*

(i) $F(0,\mu) = 0$ *for all* μ *in a neighborhood of* μ_0.
(ii) $\ker F_x(0,\mu_0)$ *is one dimensional space, spanned by* x_0.
(iii) $\operatorname{Im} F_x(0,\mu_0) = Y_1$ *has codimension* 1.
(iv) $F_{\mu x}(0,\mu_0)x_0 \notin Y_1$.

Then $(0,\mu_0)$ *is a bifurcation point of the equation* $F(x,\mu) = 0$ *in the following sense: In a neighborhood of* $(0,\mu_0)$ *the set of solutions of* $F(x,\mu) = 0$ *consists of two* C^{p-2} *smooth curves* Γ_1 *and* Γ_2 *which intersect only at the point* $(0,\mu_0)$; Γ_1 *is the curve* $(0,\mu)$ *and* Γ_2 *can be parameterized as follows:*

$$\Gamma_2 : (x(\varepsilon), \mu(\varepsilon)),\ |\varepsilon| \textit{ small}, \qquad (x(0),\mu(0)) = (0,\mu_0),\ x'(0) = x_0.$$

As in [13] we introduce the Banach spaces: for $k \geq 3$,

$$\begin{aligned}
X^{k+\alpha} &= \left\{\widetilde{R} \in C^{k+\alpha}(\Sigma),\ \widetilde{R} \text{ is } \pi\text{-periodic in } \theta,\ 2\pi\text{-periodic in } \phi\right\},\\
X_1^{k+\alpha} &= \text{closure of the linear space spanned by } \{Y_{j,0}(\theta),\ j = 0,1,2,\dots\} \text{ in } X^{k+\alpha},\\
X_2^{k+\alpha} &= \text{closure of the linear space spanned by } \{Y_{j,0}(\theta),\ j = 0,2,4,\dots\} \text{ in } X^{k+\alpha}.
\end{aligned}$$

Notice that (A.8) implies that $Y_{j,0}(\pi-\theta) = Y_{j,0}(\theta)$ if and only if j is even. Thus $X_2^{k+\alpha}$ coincides with the subspace of the $C^{k+\alpha}(\Sigma)$-closure of the smooth functions consisting of those functions u that are independent of ϕ and satisfies $u(\theta) = u(\pi-\theta)$. This property ensures that F defined by (3.1) satisfies $F : X_2^{k+\alpha} \to X_2^{k-1+\alpha}$.

We shall take $X = X_2^{k+\alpha}$ and $Y = X_2^{k-1+\alpha}$ and define F by (3.1) for any $\widetilde{R} \in X_2^{k+\alpha}$. It is clear that

$$\ker[F_{\widetilde{R}}(0,\mu)] = \{0\} \quad \text{if } \mu/\gamma \neq M_2, M_4, M_6, \dots. \tag{8.1}$$

If, for some $R > 0$ and some even integer $n \geq 2$,

$$M_n(R) \neq M_{2m}(R) \quad \text{for all } 2m \neq n, \tag{8.2}$$

then $\ker[F_{\widetilde{R}}(0,\mu)] = \operatorname{span}\{Y_{n,0}\}$. Since $[F_{\widetilde{R}}(0,M_n)]Y_{2m,0} = f(2m,n)Y_{2m,0}$, where $f(2m,n) \neq 0$ for $2m \neq n$, we have

$$\operatorname{Im}[F_{\widetilde{R}}(0,M_n)] \oplus \operatorname{span}\{Y_{n,0}\} = Y,$$

so that the codimension of $Y_1 = \mathrm{Im}[F_{\widetilde{R}}(0, M_n)]$ is 1. From Lemma 4.1 we also have

$$[F_{\mu\widetilde{R}}(0, M_n)]Y_{n,0} = R^2 P_0(R)[P_1(R) - P_n(R)]\Big(1 + \frac{n}{2n^2+4n+3}\Big)Y_{n,0} \notin Y_1.$$

Thus all the assumptions of Theorem 8.1 are satisfied and we obtain the following theorem.

THEOREM 8.2. *For even $n \geq 2$, if $R = R_S$ is such that* (8.2) *is satisfied, then the point* $(0, M_n)$ *is a bifurcation point for the problem* (1.9)–(1.14)*, and the corresponding branch of solutions has free boundaries of the form $r = R + \varepsilon Y_{l,0}(\theta) + O(\varepsilon^2)$.*

Remark 8.1. From Theorems 7.1 and 7.2 it follows that for any n, m larger than 3, there exists at least one R such that $M_n(R) = M_m(R)$. Therefore, the assumption (8.2) for $R = R_S$ cannot be dropped. On the other hand, for any given $n \geq 2$, (8.2) is satisfied for all R with the exception of a discrete sequence.

Remark 8.2. The choice of $X_2^{k+\alpha}$ is necessary in order to be able to use the Crandall–Rabinowitz theorem (this choice is also necessary in the proof of [14, Theorem 2] in order to apply the Crandall–Rabinowitz theorem). Indeed, if we replace $X_2^{k+\alpha}$ by $X_1^{k+\alpha}$, then, for $n \geq 2$, the subspace $\ker[F_{\widetilde{R}}(0, \mu)] = \mathrm{span}\{Y_{n,0}, Y_{1,0}\}$ is of dimension 2, so that the condition (ii) in Theorem 8.1 is not satisfied. Note that $Y_{1,0}$ is the kernel element which corresponds to translation.

Remark 8.3. Theorem 8.2 establishes bifurcation only for even integer $n \geq 2$. One can probably also establish bifurcation for any odd integer $n \geq 3$ by the method of expansion into the power series of ε as done in [13]. However, we should be able to establish bifurcation for any odd $n \geq 3$ also by applying the Crandall–Rabinowitz theorem in a more delicate manner, working with the space

$$M^{k+\alpha} = \text{closure of the linear space spanned by } \{Y_{j,0}(\theta),\ j = 0, 2, 3, 4, \dots\} \text{ in } X^{k+\alpha}$$

for $k \geq 3$. Here we face the problem that F does not map $M^{k+\alpha}$ into $M^{k-1+\alpha}$, but we propose to shift the center of the system in order to eliminate the mode of $Y_{1,0}$ and so that the modified F will map $M^{k+\alpha}$ into $M^{k-1+\alpha}$. Since the image of the shift is of higher order than $\varepsilon Y_{1,0}$, we should be able to use a fixed point theorem in order to make a shift which will eliminate the term with mode $(1, 0)$. The mapping $\widetilde{F}$ composed of F followed by this shift of the origin will map $M^{k+\alpha}$ onto $M^{k-1+\alpha}$, and the Crandall–Rabinowitz theorem could then be applied to $\widetilde{F}$. Indeed, a similar argument was carried out in [21].

9. Conclusion: Biological interpretation. Although the tumor model analyzed in this paper is quite simple, we may nevertheless draw some interesting biological conclusions from the mathematical results. Tumors grown in culture are typically spherical. However, tumors in vivo can have a variety of shapes. In particular, invasion of tumors into their surrounding stroma is associated with growth of protrusions, or "fingers." In our model, these protrusions are expressed by the shape $r = R_S + \varepsilon Y_{n,0}(\theta) + O(\varepsilon^2)$ of the free boundary; the number of protrusions is proportional to n.

The aggressiveness of a tumor is measured by two parameters, μ and γ. The parameter μ is the proliferation rate; the larger the μ is the more aggressive the tumor is. The parameter γ is the cell-to-cell adhesiveness; it plays an important role in keeping the tumor cohesive (see [5, 6, 8]). A smaller value of γ enables the tumor to develop fingers more easily and thus be more prone to invasion. In our model the two parameters appear as a quotient μ/γ. As this parameter increases, the tumor will lose its spherical shape, develop fingers, and become invasive.

The ability of a tumor to invade the surrounding tissue depends also on the material properties of its surroundings. If the tissue is a porous medium, then, according to [13], the smallest value of μ/γ which generates protrusions is $M_2(R_S)$, at which time the tumor will have just three protrusions, no matter how large the radius R_S is. In contrast, in fluid-like tissue as in the present paper, the smallest value of μ/γ which generates protrusions is $M_{n_*}(R_S)$, where $n_* \to \infty$ as $R_S \to \infty$. Thus, when a large spherical tumor develops protrusions, it does so right away with a large number of protrusions, namely, with a number proportional to $n_*(R_S)$. This makes the tumor invasion more hazardous, since it increases the probability that one or several of the many invasive protrusions will reach a blood vessel and lead to metastasis.

Appendix A. Vector spherical harmonics. We use the notation $\vec{e}_r$, $\vec{e}_\theta$, $\vec{e}_\phi$ for the unit normal vectors in the r, θ, ϕ directions, respectively; here $0 \le r < \infty$, $0 \le \theta \le \pi$, $0 \le \phi \le 2\pi$. Then, written in the Cartesian coordinates in $\mathbb{R}^3$,

$$\vec{e}_r = \sin\theta\cos\phi\,\vec{e}_1 + \sin\theta\sin\phi\,\vec{e}_2 + \cos\theta\,\vec{e}_3, \tag{A.1}$$

$$\vec{e}_\theta = \cos\theta\cos\phi\,\vec{e}_1 + \cos\theta\sin\phi\,\vec{e}_2 - \sin\theta\,\vec{e}_3, \tag{A.2}$$

$$\vec{e}_\phi = -\sin\phi\,\vec{e}_1 + \cos\phi\,\vec{e}_2, \tag{A.3}$$

where $(\vec{e}_1, \vec{e}_2, \vec{e}_3)$ is the standard basis in $\mathbb{R}^3$ in Cartesian coordinates, i.e., $\vec{e}_1 = (1,0,0)^T$, $\vec{e}_2 = (0,1,0)^T$, $\vec{e}_3 = (0,0,1)^T$. The gradient is given by

$$\nabla_x = \vec{e}_r\,\partial_r + \vec{e}_\theta\,r^{-1}\,\partial_\theta + \vec{e}_\phi\,(r\sin\theta)^{-1}\,\partial_\phi \equiv \vec{e}_r\,\partial_r + r^{-1}\nabla_\omega,$$

and

$$\vec{e}_r \times \vec{e}_\theta = \vec{e}_\phi, \quad \vec{e}_\phi \times \vec{e}_r = \vec{e}_\theta, \quad \vec{e}_\theta \times \vec{e}_\phi = \vec{e}_r, \tag{A.4}$$

$$\partial_r\vec{e}_r = 0, \quad \partial_r\vec{e}_\theta = 0, \quad \partial_r\vec{e}_\phi = 0, \tag{A.5}$$

$$\partial_\theta\vec{e}_r = \vec{e}_\theta, \quad \partial_\theta\vec{e}_\theta = -\vec{e}_r, \quad \partial_\theta\vec{e}_\phi = 0, \tag{A.6}$$

$$\partial_\phi\vec{e}_r = \sin\theta\,\vec{e}_\phi, \quad \partial_\phi\vec{e}_\theta = \cos\theta\,\vec{e}_\phi, \quad \partial_\phi\vec{e}_\phi = -\sin\theta\,\vec{e}_r - \cos\theta\,\vec{e}_\theta. \tag{A.7}$$

The spherical harmonic $Y_{l,m}(\theta,\phi)$ is defined by

$$Y_{l,m}(\theta,\phi) = (-1)^m\sqrt{\frac{(2l+1)(l-m)!}{2(l+m)!}}\,P_l^m(\cos\theta)\frac{e^{im\phi}}{\sqrt{2\pi}} \quad (m = -l,\dots,l), \tag{A.8}$$

where $P_l^m(z) = \frac{1}{2^l l!}(1-z^2)^{m/2}\frac{d^{l+m}}{dz^{l+m}}(z^2-1)^l$. The family of functions $\{Y_{l,m}\}$ forms a complete orthonormal basis for $L^2(\Sigma)$, where Σ is the unit sphere, and

$$\Delta_\omega Y_{l,m} = -l(l+1)Y_{l,m}, \tag{A.9}$$

where $\Delta_\omega = \frac{1}{\sin\theta}\frac{\partial}{\partial\theta}(\sin\theta\frac{\partial}{\partial\theta}) + \frac{1}{\sin^2\theta}\frac{\partial^2}{\partial\phi^2}$ is the Laplace operator on Σ. The vector spherical harmonics are defined by

$$\begin{aligned}\vec{V}_{l,m} = \vec{e}_r\Big\{-\Big(\frac{l+1}{2l+1}\Big)^{1/2}Y_{l,m}\Big\} + \vec{e}_\theta\Big\{\frac{1}{[(l+1)(2l+1)]^{1/2}}\frac{\partial Y_{l,m}}{\partial\theta}\Big\}\\ + \vec{e}_\phi\Big\{\frac{imY_{l,m}}{[(l+1)(2l+1)]^{1/2}\sin\theta}\Big\},\end{aligned} \tag{A.10}$$

$$\vec{X}_{l,m} = \vec{e}_\theta\Big\{\frac{-mY_{l,m}}{[l(l+1)]^{1/2}\sin\theta}\Big\} + \vec{e}_\phi\Big\{\frac{-i}{l(l+1)]^{1/2}}\frac{\partial Y_{l,m}}{\partial\theta}\Big\}, \tag{A.11}$$

$$\vec{W}_{l,m} = \vec{e}_r\Big\{\Big(\frac{l}{2l+1}\Big)^{1/2} Y_{l,m}\Big\} + \vec{e}_\theta\Big\{\frac{1}{[l(2l+1)]^{1/2}}\frac{\partial Y_{l,m}}{\partial\theta}\Big\} + \vec{e}_\phi\Big\{\frac{imY_{l,m}}{[l(2l+1)]^{1/2}\sin\theta}\Big\}. \tag{A.12}$$

The family of vector spherical harmonics $\{\vec{V}_{l,m}, \vec{X}_{l,m}, \vec{W}_{l,m}\}$ forms a complete orthonormal basis for $(L^2(\Sigma))^3$. We shall need the well-known formulas (see [29] or [26])

$$\nabla Y_{l,m} = \frac{1}{r}\nabla_\omega Y_{l,m} \;=\; \frac{l}{r}\Big(\frac{l+1}{2l+1}\Big)^{1/2}\vec{V}_{l,m} + \frac{l+1}{r}\Big(\frac{l}{2l+1}\Big)^{1/2}\vec{W}_{l,m}, \tag{A.13}$$

$$\vec{e}_r Y_{l,m} = -\Big(\frac{l+1}{2l+1}\Big)^{1/2}\vec{V}_{l,m} + \Big(\frac{l}{2l+1}\Big)^{1/2}\vec{W}_{l,m}; \tag{A.14}$$

for any function $H(r)$,

$$\nabla[H(r)Y_{l,m}] = \Big(\frac{l+1}{2l+1}\Big)^{1/2}\Big[-\frac{dH}{dr} + \frac{l}{r}H\Big]\vec{V}_{l,m} + \Big(\frac{l}{2l+1}\Big)^{1/2}\Big[\frac{dH}{dr} + \frac{l+1}{r}H\Big]\vec{W}_{l,m}, \tag{A.15}$$

$$\operatorname{div}[H(r)\vec{V}_{l,m}] = -\Big(\frac{l+1}{2l+1}\Big)^{1/2}\Big[\frac{dH}{dr} + \frac{l+2}{r}H\Big]Y_{l,m}, \tag{A.16}$$

$$\operatorname{div}[H(r)\vec{X}_{l,m}] = 0, \tag{A.17}$$

$$\operatorname{div}[H(r)\vec{W}_{l,m}] = \Big(\frac{l}{2l+1}\Big)^{1/2}\Big[\frac{dH}{dr} - \frac{l-1}{r}H\Big]Y_{l,m}, \tag{A.18}$$

and

$$\Delta[H(r)Y_{l,m}] = L_l(H)Y_{l,m}, \tag{A.19}$$

$$\Delta[H(r)\vec{V}_{l,m}] = L_{l+1}(H)\vec{V}_{l,m}, \tag{A.20}$$

$$\Delta[H(r)\vec{X}_{l,m}] = L_l(H)\vec{X}_{l,m}, \tag{A.21}$$

$$\Delta[H(r)\vec{W}_{l,m}] = L_{l-1}(H)\vec{W}_{l,m}, \tag{A.22}$$

where

$$L_l = \frac{\partial^2}{\partial r^2} + \frac{2}{r}\frac{\partial}{\partial r} - \frac{l(l+1)}{r^2}. \tag{A.23}$$

Appendix B. Bessel functions. We introduce the Bessel functions (see [12])

$$I_l(\xi) = \Big(\frac{\xi}{2}\Big)^l \sum_{k=0}^{\infty} \frac{1}{k!\Gamma(l+k+1)}\Big(\frac{\xi}{2}\Big)^{2k} \tag{B.1}$$

and recall some well-known properties:

$$I_{1/2}(\xi) = \sqrt{2/(\pi\xi)}\;\sinh\xi, \tag{B.2}$$

$$I_{3/2}(\xi) = \sqrt{2/(\pi\xi)}\;\big(-\xi^{-1}\sinh\xi + \cosh\xi\big), \tag{B.3}$$

$$I_{5/2}(\xi) = \sqrt{2/(\pi\xi)}\;\big\{(3\xi^{-2}+1)\sinh\xi - 3\xi^{-1}\cosh\xi\big\}, \tag{B.4}$$

$$I_l''(\xi) + \xi^{-1}I_l'(\xi) - \big(1 + l^2\xi^{-2}\big)I_l(\xi) = 0, \tag{B.5}$$

$$I_l'(\xi) + l\xi^{-1}I_l(\xi) = I_{l-1}(\xi),\ \ l \ge 1, \tag{B.6}$$

$$I_l'(\xi) - l\xi^{-1}I_l(\xi) = I_{l+1}(\xi),\ \ l \ge 0, \tag{B.7}$$

$$I_{l-1}(\xi) - I_{l+1}(\xi) = 2l\xi^{-1}I_l(\xi),\ \ l \ge 1. \tag{B.8}$$

From (B.6) and (B.7) we obtain

$$\text{(B.9)} \qquad \Big(\frac{d}{dr} - \frac{l}{r}\Big)\frac{I_{l+1/2}(r)}{r^{1/2}} = \frac{I_{l+3/2}(r)}{r^{1/2}},$$

$$\text{(B.10)} \qquad \Big(\frac{d}{dr} + \frac{l+1}{r}\Big)\frac{I_{l+1/2}(r)}{r^{1/2}} = \frac{I_{l-1/2}(r)}{r^{1/2}}.$$

One can also easily verify that, for the operator L_l given in (A.23),

$$\text{(B.11)} \qquad L_l\big(I_{l+1/2}(r)/r^{1/2}\big) = I_{l+1/2}(r)/r^{1/2}.$$

From (B.7) we derive, for any complex number s,

$$\text{(B.12)} \qquad \frac{d}{dr}\Big[\frac{I_{l+1/2}(r\sqrt{s+1}\,)}{r^{1/2}}\Big] = \frac{l}{r^{3/2}}I_{l+1/2}(r\sqrt{s+1}\,) + \frac{\sqrt{s+1}}{r^{1/2}}I_{l+3/2}(r\sqrt{s+1}\,).$$

By differentiating (B.12) in r and using (B.6) and (B.7), we obtain

$$\text{(B.13)} \qquad \begin{aligned} \frac{d^2}{dr^2}\Big[\frac{I_{l+1/2}(r\sqrt{s+1}\,)}{r^{1/2}}\Big] \quad = \quad & \Big(\frac{s+1}{r^{1/2}} + \frac{l(l-1)}{r^{5/2}}\Big)I_{l+1/2}(r\sqrt{s+1}\,) \\ & - \frac{2\sqrt{s+1}}{r^{3/2}}I_{l+3/2}(r\sqrt{s+1}\,). \end{aligned}$$

We next introduce the functions

$$\text{(B.14)} \qquad P_n(\xi) = \frac{I_{n+3/2}(\xi)}{\xi I_{n+1/2}(\xi)}, \qquad n = 0, 1, 2, 3, \ldots.$$

From the preceding properties of the Bessel functions we can derive the following relations (see [20]). For ξ complex,

$$\text{(B.15)} \qquad P_0(\xi) = \xi^{-1}\coth\xi - \xi^{-2}, \qquad P_1(\xi) = (\xi\coth\xi - 1)^{-1} - 3\xi^{-2},$$

$$\text{(B.16)} \qquad P_n(\xi) = 1/\{\xi^2 P_{n+1}(\xi) + (2n+3)\}, \qquad P_n(0) = 1/(2n+3),$$

$$\text{(B.17)} \qquad (d/d\xi)P_n(\xi) = \xi^{-1} - (2n+3)\xi^{-1}P_n(\xi) - \xi P_n^2(\xi),$$

$$\text{(B.18)} \qquad |P_n(\xi)| \le \sqrt{2}P_n(|\xi|) \le \sqrt{2}/(2n+3) \quad \text{for } |\arg(\xi)| \le \pi/4,$$

and, for $r > 0$,

$$\text{(B.19)} \qquad P_n(r) > P_{n+1}(r), \ n \ge 0,$$

$$\text{(B.20)} \qquad \frac{2n+5}{r^2 + (2n+3)(2n+5)} < P_n(r) < \frac{r^2 + (2n+5)(2n+7)}{2(2n+5)r^2 + (2n+3)(2n+5)(2n+7)},$$

$$\text{(B.21)} \qquad \frac{1}{r} - \frac{n+1}{r^2} < P_n(r) < \frac{1}{r} - \frac{n+1}{r^2} + \frac{n^2+n+1}{2r^3},$$

$$\text{(B.22)} \qquad \frac{d}{dr}P_n(r) < 0.$$

SINGULAR PERTURBATION AS A SELECTION CRITERION FOR YOUNG-MEASURE SOLUTIONS*

M. LILLI†, T. J. HEALEY‡, AND H. KIELHÖFER†

Abstract. We prove existence of Young-measure solutions of an Euler–Lagrange equation arising from a one-dimensional nonconvex variational problem in nonlinear elasticity. In particular, we consider a physically reasonable stored-energy density W such that $W(x, \mu)$ goes to infinity for $\mu \searrow 0$ and $\mu \to \infty$. The selection criterion for the Young measure is a singular perturbation in form of an interfacial energy with capillarity coefficient ε. We first establish uniform a priori bounds on all solutions of the Euler–Lagrange equation, before passing to the limit for $\varepsilon \searrow 0$. Moreover, the singular perturbation allows us to characterize the support of the Young measure.

Key words. Young-measure solution, nonlinear elasticity, singular limits

1. Introduction.

This paper is motivated to a large extent by results presented in [11]. There we consider a two-phase model for an elastic solid in the presence of live-body forcing and interfacial or higher-gradient effects, the latter characterized by a small capillarity coefficient $\varepsilon > 0$. The existence of families of equilibria is routine, and the main goal in [11] is the analysis of those solutions in the limit $\varepsilon \searrow 0$. Assuming that the loading is bounded and everywhere nonnegative, we obtain uniform a priori bounds on solutions via maximum-principle arguments. An important by-product of that analysis is a certain monotonicity property for all solutions. In the end we obtain global weak solutions that satisfy the Maxwell condition.

In this work we pursue precisely the same question without presuming that the live-body forcing is bounded or satisfies a sign condition, the latter obviating any apparent maximum principle. Instead we impose very general, physically reasonable growth conditions on both the stored-energy function (double-well) and the body force function. Also in contrast to [11], we impose the pointwise unilateral constraint ensuring that all deformations of the bar are injective (with the concomitant infinite growth of the stored energy).

The outline of this work is as follows: After presenting our formulation in section 2, we obtain uniform a priori bounds on solutions of the regularized ($\varepsilon > 0$) problem in section 3. There we pay careful attention to the injectivity constraint and show that the strains are uniformly (pointwise) positive. The existence of solutions is fairly routine, which we summarize in section 4. In section 5 we examine the limit $\varepsilon \searrow 0$. We demonstrate strong convergence to a continuous displacement field and weak* convergence to a stress field and a strain field, the latter two of which are each

characterized by the family of Young measures generated by the sequence of strains. The limiting strain is generally incompatible with the displacement field. Remarkably the limiting stress has a C^1 representation (within its equivalence class) that satisfies the force-balance equilibrium equation classically. Finally, we show that the family of Young measures reduces to a family of "Dirac" masses in stress field regimes where the stress is an injective function of strain (for "large enough" compressive and tensile stresses). In particular, within those regimes our limiting fields reduce to classical solutions.

L. C. Young first employed (what is now called) the Young measure in the study of problems from the calculus of variations for which a classical minimizer does not exist [23]. Since that time Young measures have become an important tool for characterizing highly oscillatory sequences of functions. Tartar was the first to introduce them in the context of measure-valued solutions of conservation laws (see [20]), and their use in the study of evolutionary PDEs is now well known, e.g., [7], [8], [16]. Existence of Young-measure solutions was proven for PDEs (see, e.g., [9], [19], [21]) and the Young measure serves also as an important tool to prove existence of classical solutions for quasilinear PDEs (see, e.g., [12], [14]). The original ideas of Young have also found great application in the "sharp interface" energetic theory of martensitic phase transformations, e.g., [3], [4]. Our motivation here is similar. However, we focus instead on the behavior of sequences of equilibrium solutions (of a regularized theory), albeit in the context of a simple model problem. In particular, our limiting stress field satisfies equilibrium (pointwise), which is typically not the case for minimizing sequences.

2. Formulation. We consider a one-dimensional elastic bar placed in a soft loading device. We follow the reasoning of [13]; see also [5] and [10].

Let $[0, 1]$ be the reference configuration in the undeformed state and let

$$u(x) \text{ be the placement of the bar;}$$

i.e., $u(x)$ is the position of the material point occupying position x in the undeformed state; $\mu \equiv u'$ is the stretch ratio. The bar is presumed elastic and inhomogeneous, which is reflected by an explicit dependence of the *stored-energy function* $W \in C^2([0, 1] \times \mathbb{R}^+)$ upon the spatial variable x in the interval $[0, 1]$. We assume the function $W(x, \cdot)$ to be a double-well potential. We also require

$$\lim_{\mu \searrow 0} W(x, \mu) = \infty, \quad \lim_{\mu \to \infty} W(x, \mu) = \infty. \tag{2.1}$$

The first condition reflects the fact that an infinite amount of energy is required to compress any finite segment of the bar to zero length, while the second accounts for the fact that an infinite amount of energy is needed to stretch any finite segment of the bar to infinite length.

The bar is presumed "stable" in the undeformed state; i.e., for every $x \in [0, 1]$,

$$W(x, 1) = W_\mu(x, 1) = 0 \text{ and } W_{\mu\mu}(x, 1) > 0. \tag{2.2}$$

The *stress* is defined by $\sigma(x, \mu) := W_\mu(x, \mu)$. Moreover, we impose the following assumptions on W: For arbitrary $x \in [0, 1]$ we have

$$W(x, \mu) \geq W(x, 1) = 0 \text{ for every } \mu \in \mathbb{R}^+. \tag{2.3}$$

Furthermore, there exist for every $x \in [0,1]$ numbers $c_1(x), c_2(x) \in \mathbb{R}$ with $c_j \in C^1(0,1)$ for $j = 1, 2$ such that

$$W_{\mu\mu}(x,\mu) \begin{cases} < 0 \text{ for } \mu \in (c_1(x), c_2(x)), \\ > 0 \text{ otherwise.} \end{cases} \tag{2.4}$$

Let $B : \mathbb{R}_0^+ \times [0,1] \to \mathbb{R}$ denote a loading potential delivering a live-body force

$$-\frac{\partial B}{\partial u}(u,x) =: b(u,x),$$

where

$$b \in C(\mathbb{R}_0^+ \times [0,1]).$$

We require the following growth conditions for σ and b:

(i) We assume for all $x \in [0,1]$

$$\lim_{\mu\to\infty} \frac{W_\mu(x,\mu)\mu}{\mu^{p+1}} \geq K > 0, \tag{2.5}$$

where K is independent of x, $p \in \mathbb{N}$, and

(ii)

$$|b(u,x)| \leq c_3 |u|^r + c_4 \tag{2.6}$$

for some $0 < r < p$, c_3, $c_4 \geq 0$. Moreover, both constants can be chosen independently of x, u.

The left end of the bar is fixed, viz., $u(0) = 0$. The free end of the bar is subjected to a concentrated force τ. The total *potential energy* of the bar is given by

$$\begin{aligned} J(u) &:= \int_0^1 [W(x,u') + B(u,x)]\, dx - \tau u(1), \\ u(0) &= 0. \end{aligned} \tag{2.7}$$

The corresponding Euler–Lagrange equation is

$$\begin{aligned} &\frac{d}{dx}[\sigma(x,u')] + b(u,x) = 0, \\ &u(0) = 0, \quad \text{and} \quad \sigma(1,u'(1)) = \tau. \end{aligned} \tag{2.8}$$

Note that (2.7) has no global minimizer, in general, due to the fact that W is non-convex in u'. In particular, existence of a global minimizer of problem (2.7) cannot be guaranteed by the direct methods of the calculus of variations (see [6] for details). For the same reason, the boundary value problem (2.8) is singular, obviating any systematic solution strategy.

Instead we introduce a "relaxed" variational problem by adding an additional strain gradient term, intended to model interfacial energy:

$$\begin{aligned} J_\varepsilon(u) &:= \int_0^1 \left(\frac{\varepsilon}{2}u''^2 + W(x,u') + B(u,x)\right) dx - \tau u(1), \\ u(0) &= 0, \end{aligned} \tag{2.9}$$

where $\varepsilon > 0$ is a small parameter. The Euler–Lagrange equation of equilibrium is the fourth-order equation

$$-\varepsilon u^{(4)} + \frac{d}{dx}\left[\sigma(x,u')\right] + b(u,x) = 0 \tag{2.10}$$

with boundary conditions

$$u(0) = u''(0) = u''(1) = 0, \qquad \varepsilon u'''(1) = \sigma(1,u'(1)) - \tau. \tag{2.11}$$

Integration of (2.10) yields the system

$$\begin{aligned} &u' = z, \\ &-\varepsilon z'' + \sigma(x,z) = \int_x^1 b(u(\eta),\eta)d\eta + \tau, \\ &u(0) = z'(0) = z'(1) = 0. \end{aligned} \tag{2.12}$$

In contrast to (2.7) and (2.8), (2.9) and (2.12) are amenable to fairly standard existence methods for each $\varepsilon > 0$, which we quote in section 4.

3. A priori bounds. In this section we prove some a priori bounds for solutions of (2.12) (provided they exist) which hold independently of ε. Our first result states that the derivative of all solutions of (2.12) is uniformly bounded away from the singularity of W, namely, 0, which generalizes in a certain sense a result of Antman and Brezis; see [1].

THEOREM 1. *Let W and b satisfy the growth conditions* (2.1), (2.5), *and* (2.6). *Let (u_ε) be a solution of* (2.12) *and set $z_\varepsilon := u'_\varepsilon$. Then there exists some $\delta > 0$ such that for every $\varepsilon > 0$ we have*

$$z_\varepsilon(x) > \delta$$

for all $x \in [0,1]$.

Proof. We prove by contradiction and therefore we assume sequences $(\varepsilon_n)_n$, $(x_n)_n \in [0,1]$, and $(z_{\varepsilon_n})_n := (z_n)_n$ with

$$\varepsilon_n \searrow 0, \quad z_n(x_n) \searrow 0.$$

We separate the proof into several steps.

Step 1. We claim $||z_n||_{L^{p+1}(0,1)} \to \infty$. Without loss of generality we assume that x_n is a location of the global minimum of z_n and hence $z''_n(x_n) \geq 0$ for every $n \in \mathbb{N}$. Equation (2.12) and the property (2.1) yield

$$\int_{x_n}^1 b(u_n(\eta),\eta)d\eta + \tau \leq \sigma(x_n, z_n(x_n)) \to -\infty. \tag{3.1}$$

Assumption (2.6) with $c_3 > 0$ then yields

$$||u_n||_{L^r(0,1)} \to \infty.$$

(If $c_3 = 0$ in (2.6), then (3.1) is a contradiction and Theorem 1 is proved.) By the fundamental theorem of calculus and with Hölder's inequality, $r < p$, we obtain the assertion.

Step 2. We define

$$A_n := \{x \in [0,1] \mid z_n(x) > 1\} := \bigcup_{j=1}^{k(n)} (x_1^j(n), x_2^j(n)).$$

Observe that z_n is monotonically increasing at $x_1^j(n)$ and monotonically decreasing at $x_2^j(n)$ for every $j = 1, \dots, k(n)$ and $z_n'(0) = z_n'(1) = 0$, which yields

$$z_n'(x_1^j(n)) \geq 0, \quad z_n'(x_2^j(n)) \leq 0 \tag{3.2}$$

for all j. Multiplying (2.12) by z_n and integrating over A_n give

$$\int_{A_n} \varepsilon_n (z_n')^2 dx - \sum_j \varepsilon_n z_n z_n' |_{x_1^j}^{x_2^j} = \int_{A_n} \left(-\sigma(x, z_n) + \int_x^1 b(u_n(\eta), \eta) d\eta + \tau \right) z_n dx. \tag{3.3}$$

Note that the left-hand side of (3.3) is nonnegative by (3.2), and hence

$$\int_{A_n} \sigma(x, z_n) z_n dx \leq \int_{A_n} \left[\int_x^1 \left(b(u_n(\eta), \eta) d\eta + \tau \right) z_n \right] dx \tag{3.4}$$

for every $n \in \mathbb{N}$.

Step 3. From Step 1 we deduce

$$||z_n||_{L^{p+1}(A_n)} \to \infty. \tag{3.5}$$

Multiplying (3.4) by $\frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}}$ we obtain for every $n \in \mathbb{N}$

$$\begin{aligned} &\frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}} \int_{A_n} \sigma(x, z_n) z_n \, dx \\ &\qquad \leq \frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}} \int_{A_n} \left(\int_x^1 b(u_n(\eta), \eta) d\eta + \tau \right) z_n dx. \end{aligned} \tag{3.6}$$

We claim the following.

(a) *The right side of* (3.6) *converges to* 0 *for* $n \to \infty$. By assumption (2.6) and Hölder's inequality we obtain

$$\begin{aligned} &\left| \int_{A_n} \left(\int_x^1 b(u_n(\eta), \eta) d\eta z_n \right) dx \right| \leq \int_{A_n} \int_x^1 |b(u_n(\eta), \eta)| \, d\eta \, |z_n| \, dx \\ &\leq \int_0^1 |b(u_n(\eta), \eta)| \, d\eta \int_{A_n} |z_n| \, dx \leq \int_0^1 (c_3 |u_n|^r + c_4) \, d\eta \, ||z_n||_{L^1(A_n)} . \end{aligned}$$

Due to the continuous imbedding $L^{p+1}(0,1) \hookrightarrow L^r(0,1)$, the inequality $||u_n||_{L^r(0,1)} \leq ||z_n||_{L^r(0,1)}$, and $z_{n|(0,1)\setminus A_n} < 1$, the following holds:

$$\begin{aligned} &\int_0^1 (c_3 |u_n|^r + c_4) \, d\eta \, ||z_n||_{L^1(A_n)} \leq \left(c_3 \, ||z_n||^r_{L^{p+1}(0,1)} + c_4 \right) ||z_n||_{L^{p+1}(A_n)} \\ &\leq \left(c_3 + c_3 \, ||z_n||^r_{L^{p+1}(A_n)} + c_4 \right) ||z_n||_{L^{p+1}(A_n)} \\ &\leq c_3 \, ||z_n||^{r+1}_{L^{p+1}(A_n)} + (c_3 + c_4) \, ||z_n||_{L^{p+1}(A_n)} . \end{aligned}$$

In view of $r < p$ and (3.5), we see that assertion (a) is proved.

(b) *We have*

$$\lim_{n\to\infty} \frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}} \int_{A_n} \sigma(x, z_n) z_n \, dx \geq K > 0 \tag{3.7}$$

with K given in (2.5). For any $\varrho > 0$, (2.5) implies the existence of $t_o = t_o(\varrho)$ such that

$$\sigma(x, t)t - K\, |t|^{p+1} > -\frac{\varrho}{2}\, |t|^{p+1} \tag{3.8}$$

for every $t > t_o$. Due to (3.8) we get for an arbitrary $n \in \mathbb{N}$ and for all $x \in [0, 1]$ with $z_n(x) > t_o$ the estimate

$$\frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}} \Big(\sigma(x, z_n(x))z_n(x) - K\, |z_n(x)|^{p+1}\Big) > -\frac{\varrho}{2} \frac{|z_n(x)|^{p+1}}{||z_n||^{p+1}_{L^{p+1}(A_n)}}. \tag{3.9}$$

Furthermore, we have by the continuity of $\sigma(x, \cdot)$ for every $x \in [0, 1]$ with $z_n(x) \in [1, t_o]$

$$\frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}} \Big|\sigma(x, z_n(x))z_n(x) - K\, |z_n(x)|^{p+1}\Big| \leq \frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}} C.$$

Note that the constant C depends only on ϱ. Hence we deduce the existence of $n_1 = n_1(\varrho)$ such that for every $n > n_1$ we have

$$\frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}} \Big(\sigma(x, z_n(x))z_n(x) - K\, |z_n(x)|^{p+1}\Big) > -\frac{\varrho}{2} \tag{3.10}$$

for every $x \in [0, 1]$ with $z_n(x) \in [1, t_o]$. We define

$$B_n := \{x \in [0, 1] \mid z_n(x) > t_o\}.$$

Then we obtain by virtue of (3.9) and (3.10)

$$\begin{aligned}
&\frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}} \int_{A_n} (\sigma(x, z_n)z_n \, dx - K \\
&= \frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}} \left(\int_{A_n} (\sigma(x, z_n)z_n - K\, |z_n(x)|^{p+1}) \, dx\right) \\
&= \frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}} \left[\left(\int_{A_n\cap B_n} + \int_{A_n\cap B_n^c}\right) \Big(\sigma(x, z_n)z_n - K\, |z_n|^{p+1}\Big) \, dx\right] \\
&\geq -\frac{\varrho}{2} \frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}} ||z_n||^{p+1}_{L^{p+1}(A_n)} - \frac{\varrho}{2} = -\varrho.
\end{aligned} \tag{3.11}$$

Because $\varrho > 0$ was chosen arbitrarily, (3.7) holds.

Now by virtue of (3.6) we get

$$\begin{aligned}
0 < K &\leq \lim_{n\to\infty} \left(\frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}} \int_{A_n} \sigma(x, z_n)z_n \, dx\right) \\
&\leq \lim_{n\to\infty} \left(\frac{1}{||z_n||^{p+1}_{L^{p+1}(A_n)}} \int_{A_n} \left(\int_x^1 b(u_n(\eta), \eta)d\eta + \tau\right) z_n \, dx\right) = 0,
\end{aligned} \tag{3.12}$$

which is obviously a contradiction, and the proof is complete. ∎

In what follows we will always assume the growth conditions (2.5), (2.6). Next we consider an *arbitrary* sequence of solutions of (2.12) $(\varepsilon_n, u_n)_{n\in\mathbb{N}}$, $\varepsilon_n \searrow 0$ and we define $z_n := u_n'$. We now show that the sequence $(z_n)_{n\in\mathbb{N}}$ is uniformly bounded (in some appropriate function space).

LEMMA 2. *Let σ and b satisfy the above-mentioned growth conditions and let $(u_n)_{n\in\mathbb{N}}$ be a sequence of solutions of (2.12) for corresponding ε_n as $\varepsilon_n \searrow 0$. Then there exists a constant $C > 0$ independent of $n \in \mathbb{N}$ such that*

$$||z_n||_{L^{p+1}} \leq C. \tag{3.13}$$

Proof. Let $(u_n)_{n\in\mathbb{N}}$ be a solution of (2.12) and $z_n = u_n'$. We assume

$$||z_n||_{L^{p+1}(0,1)} \to \infty. \tag{3.14}$$

As in the proof of Theorem 1, we obtain

$$\begin{aligned} &\frac{1}{||z_n||^{p+1}_{L^{p+1}(0,1)}} \int_0^1 \sigma(x, z_n) z_n \, dx \\ &\qquad \leq \frac{1}{||z_n||^{p+1}_{L^{p+1}(0,1)}} \int_0^1 \left(\int_x^1 b(u_n(\eta), \eta) d\eta + \tau \right) z_n dx. \end{aligned} \tag{3.15}$$

In particular, as in Step 3 of the proof of Theorem 1 we have on the one hand that the right side of (3.15) converges to 0 for $n \to \infty$ and, on the other hand,

$$\lim_{n\to\infty} \frac{1}{||z_n||^{p+1}_{L^{p+1}(0,1)}} \int_0^1 \sigma(x, z_n) z_n \, dx \geq K > 0$$

with K given in (2.5), which is a contradiction. $\square$

We can actually prove a stronger result, which seems to be limited to the one-dimensional case.

LEMMA 3. *Let $(z_n)_{n\in\mathbb{N}}$ be a sequence as in Lemma 2. Then we obtain the following: The sequence $(z_n)_{n\in\mathbb{N}}$ is uniformly bounded in $C^0([0,1])$.*

Proof. Let $(z_n)_{n\in\mathbb{N}}$ be a sequence as in Lemma 2 and assume for any constant $K > 0$ the existence of a certain $x \in [0,1]$ and $n \in \mathbb{N}$ such that $z_n(x) > K$. In particular, we obtain $x_m \in [0,1]$ and n_m such that $z_{n_m}(x_m) > m$ for every $m \in \mathbb{N}$.

By the continuity of z_{n_m} we know that

$$x \mapsto z_{n_m}(x) \text{ has a global maximum in } [0,1],$$

and without loss of generality, we assume this maximum is at $x = x_m$. By properties (2.5) we deduce

$$\lim_{m\to\infty} \sigma(x_m, z_{n_m}(x_m)) = \infty. \tag{3.16}$$

Moreover, we have for every $m \in \mathbb{N}$

$$-\varepsilon_{n_m} z''_{n_m}(x_m) + \sigma(x_m, z_{n_m}(x_m)) = \int_{x_m}^1 b(u_{n_m}(\eta), \eta) d\eta + \tau. \tag{3.17}$$

The growth conditions (2.6) together with (3.13) imply for every $m \in \mathbb{N}$

$$\left| \int_{x_m}^1 b(u_{n_m}(\eta), \eta) d\eta \right| \leq c_3 \, ||u_{n_m}||^r_\infty + c_4 \leq c_3 \, ||u_{n_m}||^r_{1,p+1} + c_4 \leq c_5.$$

Therefore, we have by (3.16)

$$\varepsilon_{n_m} z''_{n_m}(x_m) \geq \sigma(x_m, z_{n_m}(x_m)) - c_5 \to \infty$$

for $m \to \infty$, and, in particular, we get $z''_{n_m}(x_m) > 0$ for m sufficiently large. On the other hand, we have $z'_{n_m}(x_m) = 0$ for every $m \in \mathbb{N}$ (note that this is also true if $x_m = 0$ or $x_m = 1$ by our boundary conditions). Hence x_m cannot be a maximum, which contradicts our assumption. ∎

LEMMA 4. *Let $(z_n)_{n\in\mathbb{N}}$ be a sequence as in Lemma 2. Then there exists a subsequence of $(z_n)_{n\in\mathbb{N}}$, not relabeled, such that $\varepsilon_n z''_n \rightharpoonup^* 0$ in $L^\infty(0,1)$.*

Proof. Let $(z_n)_{n\in\mathbb{N}}$ be a sequence with the above-mentioned property. To prove the assertion, we multiply (2.12) by z_n, integrate the equation over the unit interval, and integrate by parts to find

$$\int_0^1 \varepsilon_n (z'_n)^2 dx = \int_0^1 \left(\int_x^1 b(u_n(\eta), \eta) d\eta + \tau - \sigma(x, z_n) \right) z_n \, dx,$$

which proves immediately that

$$(\sqrt{\varepsilon_n} z'_n)_{n\in\mathbb{N}} \text{ is bounded in } L^2(0,1). \tag{3.18}$$

Let $\varphi \in C_0^\infty(0,1)$; then integration by parts and (3.18) yield

$$\left| \int_0^1 \varepsilon_n z''_n \varphi dx \right| \leq \sqrt{\varepsilon_n} \int_0^1 |\sqrt{\varepsilon_n} z'_n \varphi'| \, dx \leq \sqrt{\varepsilon_n} \, ||\sqrt{\varepsilon_n} z'_n||_{L^2} \, ||\varphi'||_{L^2} \to 0$$

for $n \to \infty$. Because φ was chosen arbitrarily, we have $\varepsilon_n z''_n \rightharpoonup 0$ in $L^1(0,1)$. Since $(\varepsilon_n z''_n)_n$ is also uniformly bounded in $L^\infty(0,1)$ by (2.12) and Lemma 3, the assertion follows. ∎

4. Critical points of the singular perturbed Euler–Lagrange equation. We have now established various properties of solutions of (2.12) presuming the latter exist. There are at least two well-known approaches to existence, each of which we now briefly discuss. First we may examine the energy functional (2.9), which is readily seen to be weakly lower semicontinuous and coercive over $W^{2,2}(0,1)$. Hence the existence of a minimizer is ensured. That the minimizer also satisfies the weak form of the Euler–Lagrange equation requires a rather delicate argument [1], associated with the pointwise constraint $\mu = u' > 0$, accompanied by the growth condition (2.1). A standard bootstrap argument then shows that the minimizer is actually a classical solution. However, in the context of our problem, the methods of [1] do not provide a uniform bound as in Theorem 1.

Another approach to existence follows along the lines of [11]. We first embed the loading "b" within a one-parameter family and then obtain global branches of solutions. The only difference here is our pointwise restriction $u' > 0$, which does not alter the arguments in [11] in view of Theorem 1.

5. Generalized solutions. In this section we consider a sequence $(z_n)_{n\in\mathbb{N}}$, where $z_n = u'_n$ and u_n is a solution of (2.12) for corresponding ε_n, with $\varepsilon_n \searrow 0$. By virtue of Lemma 3, the sequence $(z_n)_{n\in\mathbb{N}}$ is uniformly bounded in $L^\infty(0,1)$. As such it has a weak* limit, say, z. The uniform boundedness also yields the existence of a family of probability measures, called Young measures,

$$\nu : [0,1] \to \text{Prob}(\mathbb{R}),$$

such that

$$z(x) = \langle \nu_x, Id \rangle \equiv \int_{\mathbb{R}} \rho \, d\nu_x(\rho) \tag{5.1}$$

for a.e. $x \in [0,1]$ (see [2] for details). Recall from Theorem 1 that $z_n(x) > \delta > 0$ for all $x \in [0,1]$ and every n, from which we conclude that

$$z(x) \geq \delta \quad \text{a.e.}$$

In view of Lemma 2 we see that the sequence $(u_n)_{n\in\mathbb{N}}$ is uniformly bounded in $W^{1,p+1}([0,1])$. Thus, by compact imbedding $(u_n)_{n\in\mathbb{N}}$ has a subsequence that converges uniformly to some $u \in C^0([0,1])$. We now prove the following theorem.

THEOREM 5. *Let ν be the Young measure generated by a sequence $(z_n)_{n\in\mathbb{N}}$, where z_n is a solution of* (2.12) *for corresponding ε_n. Then ν satisfies the equation*

$$\langle \nu_x, \sigma(x,\cdot)\rangle = \int_{\mathbb{R}^+} \sigma(x,\rho) d\nu_x(\rho) = \int_x^1 b(u(\eta),\eta)d\eta + \tau \tag{5.2}$$

for a.e. $x \in [0,1]$, where $u \in W^{1,\infty}(0,1) \cap \{v \mid v(0) = 0\}$ is the limit of $(u_n)_{n\in\mathbb{N}}$—in particular, the function

$$x \mapsto \langle \nu_x, \sigma(x,\cdot)\rangle \in C^1(0,1). \tag{5.3}$$

Proof. We consider a sequence $(u_n, z_n)_{n\in\mathbb{N}}$ of solutions of (2.12) for corresponding ε_n with $\varepsilon_n \searrow 0$. Accordingly, for every $n \in \mathbb{N}$ we have

$$-\varepsilon_n z_n'' + \sigma(x, z_n) = \int_x^1 b(u_n(\eta),\eta)d\eta + \tau.$$

By Theorem 1, Lemma 3, and the smoothness of $\sigma(\cdot)$, we see that the sequence of stresses $(\sigma(\cdot, z_n))_{n\in\mathbb{N}}$ is also uniformly bounded in $L^\infty(0,1)$. Accordingly, it too possesses a weak limit, which, by the fundamental theorem for Young measures (cf. [2], [17]), has the following characterization:

$$\sigma(x, z_n) \rightharpoonup^* \langle \nu_x, \sigma(x,\cdot)\rangle \quad \text{in } L^\infty(0,1).$$

Also,

$$\int_x^1 b(u_n(\eta),\eta)d\eta \to \int_x^1 b(u(\eta),\eta)d\eta$$

uniformly. Taking into account Lemma 4, we arrive at (5.2). Finally, the continuity of both $b(\cdot)$ and u shows there is a C^1 member within the equivalence class $\langle \nu_x, \sigma(x,\cdot)\rangle$. $\square$

In summary, our selection procedure delivers a displacement field

$$u_n \to u \quad \text{in } C^0([0,1]),$$

a strain field

$$u_n' \rightharpoonup^* z = \langle \nu_x, Id\rangle \quad \text{in } L^\infty(0,1),$$

and a stress field

$$\sigma(x, z_n) \rightharpoonup^* \tilde{\sigma} := \langle \nu_x, \sigma(x, \cdot) \rangle \quad \text{in } L^\infty(0,1),$$

where ν_x is the family of Young measures generated by the sequence $(z_n)_n$. Equation (5.2) expresses force balance at $x \in [0,1]$. Observe by (5.3) that (5.2) may even be differentiated:

$$\frac{d}{dx} \langle \nu_x, \sigma(x, \cdot) \rangle = b(u(x), x) \quad \text{in } (0,1).$$

We call the pair (u, ν_x) a *Young-measure solution* of (2.12). Note that we recover classical elasticity in the special case when the Young measure reduces to a Dirac mass, viz., $\nu_x = \delta_{z(x)}$ a.e. In particular, (5.2) then expresses the usual stress-strain relation $\tilde{\sigma}(x) = \sigma(x, z(x))$.

Remark 6. Under more specific assumptions on the sign change of b one can prove that the Young-measure solution is a Dirac mass a.e. (see [15]).

Next we show that the Young measures ν_x reduce to a Dirac mass in the "regions" where the stress function is monotonic. Following the approach in [22], the key ingredient here is the following inequality.

LEMMA 7. *Let $\varphi \in C^1([0,1] \times \mathbb{R}_0^+, \mathbb{R})$ be an arbitrary function with $\varphi_z(x,z) \geq 0$ for every $x \in [0,1]$. Then we deduce the inequality*

$$\int_0^1 \langle \nu_x, \sigma(x,\rho)\varphi(x,\rho) \rangle \, dx \leq \int_0^1 \langle \nu_x, \sigma(x,\rho) \rangle \langle \nu_x, \varphi(x,\rho) \rangle \, dx, \tag{5.4}$$

where ν is the Young measure generated by a sequence $(z_n)_{n \in \mathbb{N}}$ of solutions of (2.12) *for corresponding ε_n, $\varepsilon_n \searrow 0$.*

Proof. Multiplying (2.12) by φ and integrating over the unit interval yield

$$\int_0^1 (-\varepsilon z'' \varphi(x,z) + \sigma(x,z)\varphi(x,z)) \, dx = \int_0^1 \left(\int_x^1 b(u(\eta), \eta) d\eta + \tau \right) \varphi(x,z) dx.$$

Integration by parts, taking the boundary conditions and the assumption on φ into account, yields

$$\begin{aligned} &\int_0^1 \sigma(x,z)\varphi(x,z) dx \\ &= \int_0^1 \left(-\varepsilon z' \varphi_x(x,z) - \varepsilon z'^2 \varphi_z(x,z) + \left(\int_x^1 b(u(\eta),\eta) d\eta + \tau \right) \varphi(x,z) \right) dx \\ &\leq \int_0^1 \left(-\varepsilon z' \varphi_x(x,z) + \left(\int_x^1 b(u(\eta),\eta) d\eta + \tau \right) \varphi(x,z) \right) dx. \end{aligned} \tag{5.5}$$

Consider a sequence $(\varepsilon_n, z_n)_{n \in \mathbb{N}}$ with $\varepsilon_n \searrow 0$ and z_n a solution of (2.12) for corresponding ε_n. Let ν be the Young measure generated by $(z_n)_{n \in \mathbb{N}}$. It is easy to see that

$$\lim_{n \to \infty} \int_0^1 -\varepsilon_n z_n' \varphi_x(x, z_n(x)) dx = 0,$$

and (5.5) implies

$$\int_0^1 \langle \nu_x(\rho), \sigma(x,\rho)\varphi(x,\rho) \rangle \, dx \leq \int_0^1 \left[\left(\int_x^1 b(u(\eta),\eta) d\eta + \tau \right) \langle \nu_x(\rho), \varphi(x,\rho) \rangle \right] dx,$$

which together with Theorem 5 immediately implies (5.4). $\square$

Similar to the treatment in [22], we now consider an estimate which is more convenient for our forthcoming analysis. Therefore, we consider the product measure $\tilde{\nu} := \nu \otimes \nu$ over $\mathbb{R} \times \mathbb{R}$.

LEMMA 8. *Let φ be a test function as in Lemma 7 and let ν be a Young measure generated by a sequence $(z_n)_{n\in\mathbb{N}}$. Then*

$$\int_0^1 \left[\int_{\mathbb{R}^2} \big(\varphi(x,\rho) - \varphi(x,\tau)\big)\big(\sigma(x,\rho) - \sigma(x,\tau)\big) d\big(\nu_x(\rho) \otimes \nu_x(\tau)\big) \right] dx \leq 0. \tag{5.6}$$

Proof. Let $\tilde{\nu} := \nu \otimes \nu$ and let ν be the Young measure generated by a sequence of solutions of (2.12). Furthermore, let $(\rho, \tau) \in \mathbb{R}^2$ and φ be an arbitrary test function as the one considered in Lemma 7. Then we obtain by Fubini's theorem

$$\begin{aligned} &\langle \nu_x, \sigma \rangle \langle \nu_x, \varphi \rangle \\ &= \frac{1}{2} \left[\int_{\mathbb{R}} \sigma(x,\rho) d\nu_x(\rho) \int_{\mathbb{R}} \varphi(x,\tau) d\nu_x(\tau) + \int_{\mathbb{R}} \sigma(x,\tau) d\nu_x(\tau) \int_{\mathbb{R}} \varphi(x,\rho) d\nu_x(\rho) \right] \\ &= \frac{1}{2} \left[\int_{\mathbb{R}^2} (\sigma(x,\rho)\varphi(x,\tau) + \sigma(x,\tau)\varphi(x,\rho))\, d(\tilde{\nu}_x(\rho,\tau)) \right]. \end{aligned} \tag{5.7}$$

On the other hand, due to the fact that ν_x is a probability measure for a.e. $x \in [0,1]$, we have

$$\int_{\mathbb{R}} \sigma(x,\rho)\varphi(x,\rho) d\nu_x(\rho) = \frac{1}{2} \left[\int_{\mathbb{R}^2} (\sigma(x,\rho)\varphi(x,\rho) + \sigma(x,\tau)\varphi(x,\tau))\, d(\tilde{\nu}_x(\rho,\tau)) \right]. \tag{5.8}$$

By (5.7) and (5.8) we conclude that

$$\begin{aligned} &\langle \nu_x, \sigma\varphi \rangle - \langle \nu_x, \sigma \rangle \langle \nu_x, \varphi \rangle \\ &\qquad = \frac{1}{2} \left[\int_{\mathbb{R}^2} (\sigma(x,\rho) - \sigma(x,\tau))\, (\varphi(x,\rho) - \varphi(x,\tau))\, d(\tilde{\nu}_x(\rho,\tau)) \right], \end{aligned}$$

and Lemma 7 gives the result. $\square$

We introduce certain functions

$$\begin{aligned} r_a(x) &:= \min \left\{ r \in \mathbb{R}^+ \mid \sigma(x,r) = \sigma(x, c_2(x)) \right\}, \\ r_b(x) &:= \max \left\{ r \in \mathbb{R}^+ \mid \sigma(x,r) = \sigma(x, c_1(x)) \right\}, \end{aligned}$$

where $c_1(x), c_2(x)$ are defined as in (2.4). Furthermore,

$$\sigma \in C^1([0,1] \times \mathbb{R}^+, \mathbb{R}),$$

which implies that $r_a, r_b \in C^1([0,1])$. Note that $\sigma(x,\rho)$ is injective for $\rho \in (-\infty, r_a(x)) \cup (r_b(x), \infty)$. We define

$$T(x) := \mathbb{R} \backslash [\sigma(x, c_2(x)), \sigma(x, c_1(x))],$$

and, furthermore, for some $u \in C^0(0,1) \cap \{v \mid v(0) = 0\}$, let

$$A(u) := \left\{ x \in [0,1] \mid \int_x^1 b(u(\eta),\eta) d\eta + \tau \in T(x) \right\}. \tag{5.9}$$

Note that $A(u)$ is an open subset of $[0,1]$ by the continuity of $x \mapsto \int_x^1 b(u(\eta),\eta) d\eta$ and by the assumptions on W. Now we can prove the following.

THEOREM 9. *Let* $(z_n)_n$ *be a sequence of solutions of* (2.12) *for corresponding* ε_n, $\varepsilon_n \searrow 0$, *let* z *be the weak limit of the sequence, and let* $u(x) = \int_0^x z(s)ds$. *Furthermore, let* ν *be the Young measure generated by this sequence. Then we obtain for a.e.* $x \in A(u)$

$$\nu_x = \delta_{z(x)}. \tag{5.10}$$

In particular, there exists a subsequence, not relabeled, of $(z_n)_{n\in\mathbb{N}}$ *such that* $z_n(x) \to z(x)$ *for a.e.* $x \in A(u)$.

Remark 10. Note that the last assertion is clear by (5.10) (see [17, p. 118]).

Proof. Let $(z_n)_{n\in\mathbb{N}}$ be a sequence of solutions of (2.12) for corresponding ε_n with $\varepsilon_n \searrow 0$ and let ν be the Young measure generated by this sequence. Let u be the limit of the corresponding sequence $(u_n)_{n\in\mathbb{N}}$.

To deduce the result we define a test function $\varphi \in C^1([0,1] \times \mathbb{R}_0^+, \mathbb{R})$ with the following properties:

(i) $\varphi(x,\cdot)_{|\mathbb{R}_0^+\setminus[r_a(x),r_b(x)]}$ is strictly monotonically increasing for every $x \in [0,1]$,

(ii) $\varphi(x,\cdot)_{|[r_a(x),r_b(x)]} \equiv$ const for every $x \in [0,1]$.

Moreover, we define

$$f(x,\rho,\tau) := (\sigma(x,\rho) - \sigma(x,\tau))\,(\varphi(x,\rho) - \varphi(x,\tau))\,,$$
$$f : [0,1] \times \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R},$$

and by the properties of φ we obtain for every $x \in [0,1]$

$$f(x,\rho,\tau) \begin{cases} > 0 & \text{if } (\varrho,\tau) \notin [r_a(x), r_b(x)]^2 \text{ and } \rho \neq \tau, \\ = 0 & \text{elsewhere.} \end{cases} \tag{5.11}$$

By virtue of (5.6) and (5.11), we deduce

$$\int_{\mathbb{R}^2} f(x,\rho,\tau)\, d(\nu_x(\rho) \otimes \nu_x(\tau)) = 0 \text{ for a.e. } x \in [0,1].$$

Hence, we have

$$\operatorname{supp}(\nu_x \otimes \nu_x) \subseteq \left\{(\rho,\tau) \in \mathbb{R}^2 \mid f(x,\rho,\tau) = 0\right\} \text{ for a.e. } x \in [0,1]. \tag{5.12}$$

We now show that if $\operatorname{supp}\nu_x$ consists of at least two points, then $x \notin A(u)$. Assume $\operatorname{supp}\nu_x \supset \{c(x), d(x)\}$; then

$$\{c(x), d(x)\} \times \{c(x), d(x)\} \in \operatorname{supp}(\nu_x \otimes \nu_x).$$

Because of (5.11) and (5.12) we deduce $\{c(x), d(x)\} \in [r_a(x), r_b(x)]$. Thus we obtain

$$\operatorname{supp}\nu_x \subseteq [r_a(x), r_b(x)], \tag{5.13}$$

which, in view of Theorem 5, implies

$$\int_x^1 b(u(\eta),\eta)d\eta + \tau = \langle \nu_x, \sigma\rangle \in [\sigma(x, c_2(x)), \sigma(x, c_1(x))].$$

We conclude immediately that $x \notin A(u)$. This yields the desired result. ∎

In the same way one can prove the following corollary just using $z(x) = \langle \nu_x, Id \rangle$ for a.e. $x \in [0,1]$, where z is the weak limit of $(z_n)_{n\in\mathbb{N}}$ and ν is the Young measure generated by $(z_n)_{n\in\mathbb{N}}$.

COROLLARY 11. *Let $(z_n)_{n\in\mathbb{N}}$ and ν be as in Theorem 9, and let z be the weak limit of $(z_n)_{n\in\mathbb{N}}$. Then for a.e. $x \in [0,1]$ with $z(x) \in \mathbb{R}^+ \setminus [r_a(x), r_b(x)]$ we obtain $\nu_x = \delta_{z(x)}$. Moreover, we have the following: If $\operatorname{supp} \nu_x \subseteq (-\infty, r_a(x)) \cup (r_b(x), \infty)$ is valid, then we also get $\nu_x = \delta_{z(x)}$.*

Another immediate consequence of (5.13) is the following corollary.

COROLLARY 12. *Let the assumptions be as in Corollary 11 and define $u(x) := \int_0^x z(s)ds$. Then for a.e. $x \in [0,1] \setminus A(u)$ we have*

$$\operatorname{supp} \nu_x \subseteq [r_a(x), r_b(x)].$$

Proof. We assume some $x \in [0,1] \setminus A(u)$ such that

$$c \notin [r_a(x), r_b(x)] \text{ and } \{c\} \in \operatorname{supp} \nu_x. \tag{5.14}$$

Without loss of generality we assume $c < r_a(x)$, and hence

$$\sigma(x,c) < \int_x^1 b(u(\eta),\eta)d\eta + \tau = \langle \nu_x, \sigma \rangle \in [\sigma(x, c_2(x)), \sigma(x, c_1(x))].$$

In particular, $\operatorname{supp} \nu_x$ consists of at least two points $\{c, d\}$ with $d > c$. By the same procedure as in Theorem 9, we obtain (see (5.13))

$$\{c, d\} \subseteq [r_a(x), r_b(x)],$$

contradicting (5.14). □

Remark 13. By Theorem 9 and Corollary 12 we conclude the following: Let $(z_n)_{n\in\mathbb{N}}$ be a sequence of solutions of (2.12) for corresponding ε_n, $\varepsilon_n \searrow 0$. By virtue of Theorem 1 there exists $\delta > 0$ with $z_n(x) > \delta > 0$ for every $n \in \mathbb{N}$ and $x \in [0,1]$. Let ν be the Young measure generated by $(z_n)_{n\in\mathbb{N}}$ and let $\{c\} \in \operatorname{supp} \nu_x$. Then $c \geq \delta$.

6. Concluding remarks. (i) The Young measure $\nu = (\nu_x)_{x\in\Omega}$ generated by a sequence $(v_n)_{n\in\mathbb{N}}$, where $v_n : \Omega \mapsto \mathbb{R}^N$, Ω denotes some open set, has the following interpretation: The measure ν_{x_0} can be thought of as the limiting probability of values of $(v_n)_{n\in\mathbb{N}}$ in a small neighborhood of $x_0 \in \Omega$. In order to be mathematically more precise we have the following: First we define

$$\mu_{x_0,\delta,v_n}(C) := \frac{|\{x \in B_\delta(x_0) \mid v_n(x) \in C\}|}{|B_\delta(x_0)|},$$

where $B_\delta(x_0)$ is an open ball with center x_0 and radius δ, C denotes some measurable set in $\mathbb{R}^N$, and $|\cdot|$ denotes the Lebesgue measure. Then we have for every $f \in C_0(\mathbb{R}^N)$

$$\lim_{\delta \searrow 0} \lim_{n\to\infty} \langle \mu_{x_0,\delta,v_n}, f \rangle = \langle \nu_{x_0}, f \rangle .$$

Hence we obtain the following by Theorem 9: Let $u(x) := \int_0^x z(s)ds$, where z is the weak limit of the generating sequence $(z_n)_{n\in\mathbb{N}}$. If $\int_x^1 b(u(\eta),\eta)d\eta + \tau \in A(u)$, where $A(u)$ is defined by (5.9), then the limit of the generating sequence $(z_n)_{n\in\mathbb{N}}$ is determined, because the resulting Young measure ν is a Dirac measure for a.e. $x \in A(u)$. In particular, we have by the Vitalis theorem

$$\lim_{n\to\infty} z_{n|A(u)} = z_{|A(u)} \quad \text{in } L^1(A).$$

On the other hand, if $x \notin A(u)$, then ν_x is not necessarily a Dirac measure, indicating the possibility of strongly oscillatory behavior of the sequence $(z_n)_{n\in\mathbb{N}}$ in this region. However, by virtue of Corollary 12, the values attained by $(z_n)_{n\in\mathbb{N}}$ in $[0,1] \setminus A(u)$ are in the interval $[r_a(x) - \theta, r_b(x) + \theta]$ for arbitrary $\theta > 0$ and for $n = n(\theta)$ sufficiently large. Thus the amplitude of the possible oscillation is restricted by these two values.

(ii) Note that

$$\begin{aligned} &\int_0^1 (\langle \nu_x, W\rangle + B(u,x))\,dx - \tau u(1),\\ &u(0) = 0, \quad u'(x) = \langle \nu_x, Id\rangle\,,\\ &\int_0^1 \int_{\mathbb{R}} ||s||^{p+1}\,d\nu_x(s)dx < \infty \end{aligned} \tag{6.1}$$

possesses a global minimizer in the space of Young measures (see [18]). Since we do not know if $\int_0^1 \varepsilon(z_\varepsilon')^2\,dx \searrow 0$ as $\varepsilon \searrow 0$, it is unclear if the Young-measure solution ν obtained here is the global minimizer of (6.1)—even in the case when the family of critical points corresponds to the global minimizers of (2.9).

(iii) Problem (2.10) with Dirichlet boundary conditions seems to be more difficult than problem (2.10), (2.11). Indeed the latter is statically determinate, a by-product of which is the reformulation (2.12). In particular, it is unclear if Theorem 1 and Lemma 2 hold for the Dirichlet problem.

(iv) In higher-dimensional problems, we consider a nonconvex $W : \Omega \times \mathbb{R}^{N\times M} \to \mathbb{R}$ ($\Omega \subseteq \mathbb{R}^N$ is some bounded smooth domain) with the usual polynomial growth conditions and some subcritical $B : \Omega \times \mathbb{R}^M \to \mathbb{R}$; then by similar techniques to those presented here, we can prove the existence of Young-measure solutions of the corresponding nonelliptic Euler–Lagrange system of the variational problem

$$\begin{aligned} &\int_\Omega W(x, Du(x)) + B(u(x), x)\,dx,\\ &u_{|\Gamma} = 0, \end{aligned}$$

where $\Gamma \subseteq \partial\Omega$ and the $(n-1)$-dimensional Hausdorff measure of Γ is positive. In addition, if we require the analogue of (2.1), namely, $W = W(x, F, \det F)$, where $F \in \mathbb{R}^{N\times N}$ with

$$\lim_{\det F \searrow 0} W(x, F, \det F) = \infty$$

for a.e. $x \in \Omega$, then proving a version of Theorem 1 is an open problem.

BIFURCATION ANALYSIS OF AN ELLIPTIC FREE BOUNDARY PROBLEM MODELLING THE GROWTH OF AVASCULAR TUMORS*

SHANGBIN CUI† AND JOACHIM ESCHER‡

Abstract. We study bifurcations from radially symmetric solutions of a free boundary problem modelling the dormant state of nonnecrotic avascular tumors. This problem consists of two semilinear elliptic equations with a Dirichlet and a Neumann boundary condition, respectively, and a third boundary condition coupling surface tension effects on the free interface to the internal pressure. By reducing the full problem to an abstract bifurcation equation in terms of the free boundary only and by characterizing the linearization as a Fourier multiplication operator, we carry out a precise analysis of local bifurcations of this problem.

Key words. free boundary problem, elliptic equations, bifurcation, tumor growth, surface tension

1. Introduction.

In this paper we consider the following free boundary problem:

$$
\left\{
\begin{array}{rcll}
\Delta\sigma & = & f(\sigma) & \text{in} \quad \Omega, \\
\Delta p & = & -g(\sigma) & \text{in} \quad \Omega, \\
\sigma & = & \bar{\sigma} & \text{on} \quad \partial\Omega, \\
\frac{\partial p}{\partial\nu} & = & 0 & \text{on} \quad \partial\Omega, \\
p & = & \gamma\kappa & \text{on} \quad \partial\Omega,
\end{array}
\right.
\tag{1.1}
$$

where σ, p are unknown functions defined on an a priori unknown domain Ω. Furthermore, f and g are given functions defined on $[0,\infty)$, satisfying suitable conditions $(A1)$–$(A3)$ on the following page, $\bar{\sigma}$ is a positive constant, $\partial/\partial\nu$ denotes the derivative in the direction of outward normal ν of the free boundary $\partial\Omega$, γ is a positive parameter, and κ is the mean curvature of the free boundary $\partial\Omega$. The manner of determining the sign of κ is such that $\kappa \geq 0$ at points where $\partial\Omega$ is (locally) convex.

The above problem is a mathematical model describing the dormant state of a nonnecrotic avascular tumor. In this model Ω is the domain occupied by the tumor, σ denotes the concentration of nutrient within the tumor, p is the tumor's tissue pressure, and f and g are the nutrient consumption rate function and the tumor-cell proliferation rate function, respectively. It is assumed that all tumor cells are alive and dividable and that their density is constant. This explains why f and g are independent of the cell density. Typical examples of f and g are as follows:

$$
f(\sigma) = \sigma, \quad g(\sigma) = \mu(\sigma - \tilde{\sigma}),
\tag{1.2}
$$

where μ and $\tilde{\sigma}$ are positive constants (see Byrne and Chaplain [2]) and

$$g(\sigma) = \mu(\sigma) - \nu(\sigma) \equiv \frac{A\sigma^{m_1}}{\sigma_c^{m_1} + \sigma^{m_1}} - B\left(1 - \frac{\delta\sigma^{m_2}}{\sigma_d^{m_2} + \sigma^{m_2}}\right),$$
$$f(\sigma) = \beta\mu(\sigma) + h(\sigma), \tag{1.3}$$

where A, B, β, δ, m_1, m_2, σ_c, and σ_d are positive constants, and $h(u)$ is a nonnegative increasing function (see Ward and King [12]). In this paper we shall assume that f, g are general functions satisfying the following condition (A):

(A_1) $\quad f \in C^\infty[0,\infty)$ and $g \in C^\infty[0,\infty)$,

(A_2) $\quad f'(\sigma) > 0$ for $\sigma \geq 0$ and $f(0) = 0$,

(A_3) $\quad g'(\sigma) > 0$ for $\sigma \geq 0$ and $g(\tilde{\sigma}) = 0$ for some $\tilde{\sigma} > 0$,

(A_4) $\quad \tilde{\sigma} < \bar{\sigma}$.

Note that the positive value $\tilde{\sigma}$ in (A_3) plays the role of a threshold in the sense that $g(\sigma) < 0$ for $0 \leq \sigma < \tilde{\sigma}$ and $g(\sigma) > 0$ for $\sigma > \tilde{\sigma}$. Moreover, using the maximum principle and Green's formula, one can easily prove that (1.1) does not have any solution if $\tilde{\sigma} \geq \bar{\sigma}$. Thus it is reasonable to assume that (A_4) holds true.

A basic result is that under the above assumptions (A), the problem (1.1) has a radially symmetric solution, which is unique up to translation and rotation (see section 2). Moreover, it can be shown that this solution is globally asymptotically stable under radially symmetric perturbations, namely, if we consider the corresponding evolutionary problem and regard the solution of (1.1) as a stationary solution of the corresponding evolutionary problem, then all radially symmetric transient solutions converge to this radially symmetric stationary solution as time goes to infinity. A natural and very interesting question is whether the problem (1.1) admits nonradial solutions. This question has the following obvious implication: If (1.1) has a nonradial solution, then we cannot expect that the radially symmetric solution is globally asymptotically stable under nonradially symmetric perturbations.

In the particular case that f and g have the simple form given in (1.2), this question has been answered by Friedman and Reitich [8] in the two-dimensional case, and by Fontelos and Friedman [7] in the three-dimensional case. They considered (1.1) as a bifurcation problem with γ being the bifurcation parameter and used the power series method suggested by the work of Greenspan [11] and Byrne [1] to prove that there exists a sequence of positive numbers γ_k, such that in a neighborhood of each γ_k there exists a bifurcation branch $(\sigma_\varepsilon, p_\varepsilon, \Omega_\varepsilon, \gamma_\varepsilon)$, with ε being a small parameter (bifurcation parameter) of nonradial solutions which bifurcates from the radially symmetric solution at γ_k. This power series method has also been used by Friedman and Reitich [9] to consider the symmetry-breaking bifurcation of some other related free boundary problems. Recently, Borisovich and Friedman [3] used a different approach to reconsider all of those free boundary problems. By this new approach, these problems were reduced to bifurcation problems treatable by the standard bifurcation theory developed, e.g., by Crandall and Rabinowitz [4], and Krasnoselskii.

In this paper we study the problem (1.1) for general nonlinear functions f and g satisfying the condition (A) and for star shaped domains Ω. As in [3, 4, 5, 6, 7, 8, 9], we shall also regard (1.1) as a bifurcation problem with γ being the bifurcation parameter. However, we shall not use the power series method, because in the general situation f, g are not necessarily analytic functions, and therefore this approach is certainly not applicable. Instead, we shall solve the first four equations in terms of an unknown function η describing the free boundary and substitute the solution into the last equation, reducing the problem (1.1) in that way into a bifurcation problem of the following form:

$$A(\eta) + c = \gamma B(\eta), \tag{1.4}$$

where η, c are the unknowns and A, B are nonlinear operators mapping a hypersurface $\mathcal{M}$ of a suitable Banach space X into another Banach space Y. In our application it turns out that X is compactly embedded into Y and that (A, B) is smooth. The key step of our approach is to show that for each eigenvalue γ_k of the linearized problem of (1.4), there exist corresponding closed subspaces X_k of X and Y_k of Y, such that X_k is compactly embedded into Y_k, $A : X_k \cap \mathcal{M} \to X_k$ and $B : X_k \cap \mathcal{M} \to Y_k$, and when restricted to X_k, the linearized problem possesses γ_k as a simple eigenvalue so that the well-known Crandall–Rabinowitz theorem is applicable.

The main result of this paper is the following theorem.

THEOREM 1.1. *Assume that condition* (A) *holds true. Then there exist a null sequence of numbers* $\{\gamma_k\}_{k\geq 2}$ *and an integer* $k^* \geq 2$ *such that in a neighborhood of each* γ_k *with* $k \geq k^*$*, the problem* (1.1) *has a branch of nonradial solutions bifurcating from the radially symmetric solution. If* $\gamma \neq \gamma_k$ *for all* $k \geq 2$*, then* γ *is not a bifurcation point.*

It is worthwhile to note that our proof of Theorem 1.1 yields an asymptotic expansion of the bifurcation branch with respect to the bifurcation parameter; cf. section 5. This expansion particularly shows that the domains corresponding to the above bifurcation solutions are always star shaped perturbations of round spheres.

We also remark that the proof of Theorem 1.1 shows that all mutually distinct γ_k are bifurcation points and that k^* is the smallest number such that all γ_k with $k \geq k^*$ are distinct. It is known that in the linear case (1.2) this threshold value k^* is minimal, i.e., $k^* = 2$ and all γ_k are bifurcation points; cf. [7]. For general nonlinearities f and g this seems to be in unknown. However, it can be shown that if f and g are real analytic functions, then, excluding at most a discrete set of boundary concentrations $\overline{\sigma}$, all γ_k are distinct and thus bifurcation points. We are indebted to one of the referees for bringing this point to our attention.

The structure of this paper is as follows. In section 2 we study the existence and uniqueness of radially symmetric solutions to problem (1.1). The linearization of (1.1) at radially symmetric solutions is determined in section 3, where we also calculate the eigenvalues of the linearized problem. In section 4 we reduce the problem (1.1) into the abstract form (1.4), and we show that if $\gamma \neq \gamma_k$, then no bifurcation occurs at γ. In the last section we prove the local bifurcation result.

2. Radially symmetric solutions. In this section we study the existence and uniqueness of radially symmetric solutions to the system (1.1). Obviously, this problem is equivalent to the study of the following free boundary value problem:

$$\left\{ \begin{array}{rcll} \sigma_0''(r) + \frac{n-1}{r}\sigma_0'(r) & = & f(\sigma_0(r)), & 0 < r < R, \\ p_0''(r) + \frac{n-1}{r}p_0'(r) & = & -g(\sigma_0(r)), & 0 < r < R, \\ \sigma_0, p_0 \in C^1[0,R] & \cap & C^2(0,R), & \\ \sigma_0(R) & = & \bar{\sigma}, & \\ p_0'(R) & = & 0, & \\ p_0(R) & = & \frac{\gamma}{R}. & \end{array} \right. \tag{2.1}$$

That is, if (σ_0, p_0, R) is a solution of (2.1) then, letting $\Omega_0 = \{x \in \mathbb{R}^n : |x| < R\}$, the triple $(\sigma_0(|x|), p_0(|x|), \Omega_0)$ is a radially symmetric solution of (1.1) and vice versa.

Given any $c > 0$, it can be shown by ODE techniques that the first equation in (2.1) has a unique local solution $\sigma_0 \in C^\infty[0, \delta]$ such that $\sigma_0(0) = c$. We extend this local solution to a solution which is not further extendable, and let $[0, R^*)$ be the maximal interval of existence, where $0 < R^* \leq \infty$. We claim that

$$\sigma_0'(r) > 0 \quad \text{for } \; 0 < r < R^*. \tag{2.2}$$

Indeed, it is not difficult to see that $\sigma_0'(0) = 0$. Since $\sigma_0(0) = c > 0$, we infer from the first equation in (2.1) that $\sigma_0''(0) = f(c)/n > 0$. Hence there is a $\delta > 0$ such that $\sigma_0'(r) > 0$ for $0 < r < \delta$. If $\sigma_0'(r) > 0$ does not hold for some $0 < r < R^*$, then for the first positive zero r_0 of $\sigma_0'(r)$ we have $\sigma_0''(r_0) \leq 0$. On the other hand, the first equation in (2.1) shows that $\sigma_0''(r_0) = f(\sigma_0(r_0)) > f(c) > 0$, which is a contradiction. Hence (2.2) holds.

From the just-established relation (2.2), it is clear that if $R^* < \infty$, then

$$\lim_{r \to R^*} \sigma_0(r) = \infty. \tag{2.3}$$

We claim that even if $R^* = \infty$, then (2.3) still holds true. Indeed, by (2.2) we know that $\sigma_0(r) \geq \sigma_0(0) = c$ for all $0 < r < R^* = \infty$. Further, the first equation of (2.1) shows that

$$\sigma_0'(r) = \frac{1}{r^{n-1}} \int_0^r f(\sigma_0(\rho))\rho^{n-1} d\rho \geq \frac{1}{r^{n-1}} \int_0^r f(c)\rho^{n-1} d\rho = \frac{1}{n} f(c) r, \tag{2.4}$$

which implies $\lim_{r \to \infty} \sigma_0(r) = \infty$.

Given $c \in (0, \bar{\sigma})$, it follows from (2.2) and (2.3) that there exists a unique $R_c > 0$ such that

$$\sigma_0(R_c) = \bar{\sigma}.$$

Since $\sigma_0(r)$ is clearly increasing in c and smooth we conclude that R_c is a smooth and decreasing function of c on $0 < c < \bar{\sigma}$. Moreover, it is also clear that

$$\lim_{c \to 0^+} R_c = \infty, \qquad \lim_{c \to \bar{\sigma}^-} R_c = 0.$$

Hence, given $R > 0$, there exists a unique $0 < c < \bar{\sigma}$ such that $R_c = R$. Thus, we have shown that for any given $R > 0$, the problem

$$\sigma_0''(r) + \frac{n-1}{r} \sigma_0'(r) = f(\sigma_0(r)), \qquad \sigma_0(R) = \bar{\sigma}, \tag{2.5}$$

has a unique solution, which we denote by $\sigma_0(r, R)$.

In the following, we shall derive a further representation of $\sigma_0(r, R)$. To this end we consider the following parameter-dependent problem:

$$\begin{cases} \dfrac{\partial^2 U(r,\lambda)}{\partial r^2} + \dfrac{n-1}{r} \dfrac{\partial U(r,\lambda)}{\partial r} = \lambda f(U(r,\lambda)), \quad 0 < r < 1, \\ \dfrac{\partial U}{\partial r}\Big|_{r=0} = 0, \quad U\Big|_{r=1} = \bar{\sigma}, \end{cases} \tag{2.6}$$

where λ is a positive parameter. By a similar argument, as used previously, we see that for every $\lambda > 0$ this problem has a unique solution $U(r, \lambda)$. Clearly, $U(r, \lambda)$ is smooth in both variables r and λ. We have

$$\frac{\partial U(r,\lambda)}{\partial r} > 0, \quad \frac{\partial U(r,\lambda)}{\partial \lambda} < 0 \quad \text{for } 0 < r < 1, \ \ \lambda > 0, \tag{2.7}$$

and

$$\lim_{\lambda \to 0^+} U(r,\lambda) = \bar{\sigma}, \quad \lim_{\lambda \to \infty} U(r,\lambda) = 0 \quad \text{for } 0 \le r < 1. \tag{2.8}$$

Indeed, the first inequality in (2.7) is obvious. The second inequality follows from the maximum principle applied to the equation satisfied by $\partial U(r, \lambda)/\partial\lambda$. Concerning (2.8), the first relation is also obvious, because if $\lambda = 0$ in (2.6), then we get the trivial solution $U = \bar{\sigma}$. To prove the second relation, we apply Lebesgue's dominated convergence theorem to the integral representation of $U(r, \lambda)$ in terms of $f(U(r, \lambda))$ to get $\lim_{\lambda\to\infty} U(r, \lambda) = 0$; cf. also [5], where a similar argument is used. By uniqueness of the solution of the problem (2.5), one can easily verify that

$$\sigma_0(r,R) = U\Big(\frac{r}{R}, R^2\Big) \quad \text{for } 0 \le r \le R. \tag{2.9}$$

Next let us consider the second equation in (2.1), where $\sigma_0(r) = \sigma_0(r, R)$. Clearly this equation has a unique local solution $\bar{p}_0(r)$ satisfying the following initial conditions:

$$\bar{p}_0(0) = 0, \quad \bar{p}_0'(0) = 0;$$

cf. [6]. Since the ODE for $\bar{p}$ is linear and regular on $r > 0$, its solution $\bar{p}_0(r)$ can be extended to the whole interval $[0, R^*)$. Moreover, we have

$$\bar{p}_0'(R) = -\frac{1}{R^{n-1}} \int_0^R g(\sigma_0(r,R)) r^{n-1} dr = -R \int_0^1 g(U(\rho,R^2))\rho^{n-1} d\rho.$$

Consider next the auxiliary function

$$\psi(R) = \int_0^1 g(U(\rho,R^2))\rho^{n-1} d\rho, \quad R > 0.$$

Since $g' > 0$ and $\partial U(r, \lambda)/\partial\lambda < 0$, it is clear that ψ is strictly decreasing. Recalling (2.8) and (A_3), (A_4), we have

$$\lim_{R\to 0^+} \psi(R) = \frac{1}{n} g(\bar{\sigma}) > 0, \qquad \lim_{R\to\infty} \psi(R) = \frac{1}{n} g(0) < 0.$$

Hence, there exists a unique $R > 0$ such that $\psi(R) = 0$, showing that $\bar{p}_0'(R) = 0$. Summarizing, we have constructed a unique solution to the first five equations of (2.1) under the additional condition $\bar{p}_0(0) = 0$. The solution of the full system (2.1) is now obtained by replacing $\bar{p}_0(r)$ with

$$p(r) = \frac{\gamma}{R} + \bar{p}_0(r) - \bar{p}_0(R),$$

which is clearly the unique solution of this problem.

For later purposes we shall derive the following property of $p(r)$:

$$p'(r) > 0 \quad \text{for } 0 < r < R, \qquad p'(r) < 0 \quad \text{for } R < r < R^*. \tag{2.10}$$

The proof is simple: We have

$$\begin{aligned}\frac{d}{dr}\Big(\frac{p'(r)}{r}\Big) &= -\frac{d}{dr}\Big(\frac{1}{r^n}\int_0^r g(\sigma_0(\rho))\rho^{n-1}d\rho\Big) = -\frac{d}{dr}\int_0^1 g\Big(U\Big(\frac{r\rho}{R},R^2\Big)\Big)\rho^{n-1}d\rho\\ &= -\frac{1}{R}\int_0^1 g'\Big(U\Big(\frac{r\rho}{R},R^2\Big)\Big)\frac{\partial U}{\partial r}\Big(\frac{r\rho}{R},R^2\Big)\rho^n d\rho < 0.\end{aligned}$$

Both the relation and the fact that $p'(R)=0$ obviously implies (2.10).

We summarize the above considerations in the following theorem.

THEOREM 2.1. *Under the assumption* (*A*)*, the problem* (1.1) *has a unique radially symmetric solution* $(\sigma_0(r),p_0(r),\Omega_0)$*, where* $\Omega_0=\{x\in\mathbb{R}^n:\ r=|x|<R\}$*. Moreover, the functions* $\sigma_0(r)$ *and* $p_0(r)$ *can be extended to a maximal interval* $[0,R^*)$*, where* $0<R^*\le\infty$*, such that* $\sigma_0(r)$, $p_0(r)\in C^\infty[0,R^*)$*. In addition, the properties* (2.2)*,* (2.3)*, and* (2.10) *hold true.*

As pointed out in section 1, the radially symmetric solution is globally asymptotically stable under radially symmetric perturbations. This means that if we consider the corresponding time-dependent problem, then all radially symmetric transient solutions converge to the solution of (2.1) obtained above. A proof of this fact in the three-dimensional case is given in [5]; the proof for higher dimensional problems is similar.

3. Linearization. In this section we determine the linearization of the problem (1.1) at the unique radially symmetric solution constructed in the previous section. We also provide conditions which imply that the linearized problem has nontrivial solutions.

Consider perturbations of the radially symmetric solution $(\sigma_0(r),p_0(r),\Omega_0)$ of the form

$$\sigma(x)=\sigma_0(r)+\varepsilon\varphi(r,\omega),\quad p(x)=p_0(r)+\varepsilon\psi(r,\omega),\quad \Omega=\{x\in\mathbb{R}^n:\ r<R+\varepsilon\eta(\omega)\},$$

where $r=|x|$ and $\omega=x/|x|$. Moreover, ε is a small parameter and φ, ψ, η are new unknown functions. Let Δ_ω be the Laplace–Beltrami operator on the sphere $\mathbb{S}^{n-1}$. Using the corresponding equations of (2.1), one can easily verify that the linearization of the first two equations of (1.1) is given by

$$\frac{\partial^2\varphi}{\partial r^2}+\frac{n-1}{r}\frac{\partial\varphi}{\partial r}+\frac{1}{r^2}\Delta_\omega\varphi=f'(\sigma_0(r))\varphi, \tag{3.1}$$

$$\frac{\partial^2\psi}{\partial r^2}+\frac{n-1}{r}\frac{\partial\psi}{\partial r}+\frac{1}{r^2}\Delta_\omega\psi=-g'(\sigma_0(r))\varphi. \tag{3.2}$$

Besides, it is also immediate to see that the linearization of the first boundary condition in (1.1) is given by

$$\varphi(R,\omega)+\sigma_0'(R)\eta(\omega)=0. \tag{3.3}$$

To find the linearization of the second boundary condition of (1.1), we first compute the outward normal of $\partial\Omega$:

$$\nu=\frac{\omega-\varepsilon\nabla_\omega\eta(\omega)}{|\omega-\varepsilon\nabla_\omega\eta(\omega)|}=\omega-\varepsilon\nabla_\omega\eta(\omega)+o(\varepsilon),$$

where ∇_ω denotes the tangent mapping on the sphere $\mathbb{S}^{n-1}$, or the orthogonal projection of the gradient ∇ to the tangent space $T_\omega(\mathbb{S}^{n-1})$, when regarding a function in $\omega \in \mathbb{S}^{n-1}$ as a function in $x \in \mathbb{R}^n$ with $\omega = x/|x|$, so that $\omega \cdot \nabla_\omega = 0$. Thus

$$\begin{aligned}\frac{\partial p}{\partial \nu} &= \nu \cdot \nabla p|_{r=R+\varepsilon\eta} = [\omega - \varepsilon \nabla_\omega \eta(\omega) + o(\varepsilon)] \cdot \Big(\frac{\partial p}{\partial r}\omega + \nabla_\omega p\Big)\Big|_{r=R+\varepsilon\eta} \\ &= \frac{\partial p}{\partial r}(R,\omega) + \varepsilon\Big(\frac{\partial^2 p}{\partial r^2}(R,\omega)\eta(\omega) - \nabla_\omega \eta(\omega)\cdot\nabla_\omega p(R,\omega)\Big) + o(\varepsilon) \\ &= p_0'(R) + \varepsilon\Big(\frac{\partial \psi}{\partial r}(R,\omega) + p_0''(R)\eta(\omega)\Big) + o(\varepsilon).\end{aligned}$$

Since $p_0'(R) = 0$ and $p_0''(R) = -g(\bar\sigma)$, we see that the desired linearization is given by

$$\frac{\partial \psi}{\partial r}(R,\omega) - g(\bar\sigma)\eta(\omega) = 0. \tag{3.4}$$

Finally, we have the following formula for the mean curvature of the hypersurface given by $r = R + \varepsilon\eta(\omega)$ (see [9]):

$$\kappa = \frac{1}{R} - \frac{\varepsilon}{R^2}\left[\eta(\omega) + \frac{1}{n-1}\Delta_\omega \eta(\omega)\right] + o(\varepsilon).$$

Therefore the linearization of the last equation in (1.1) reads as

$$\psi(R,\omega) + \frac{\gamma}{R^2}\left[\eta(\omega) + \frac{1}{n-1}\Delta_\omega\eta(\omega)\right] = 0. \tag{3.5}$$

Summarizing, we have the following lemma.

LEMMA 3.1. *The linearization of the problem* (1.1) *at the radially symmetric solution* $(\sigma_0(|x|), p_0(|x|), \Omega_0)$ *is given by the problem* (3.1)–(3.5).

We now investigate the question of whether there exists $\gamma > 0$ such that the problem (3.1)–(3.5) has nontrivial solutions. For this purpose we first note that standard results for second order elliptic partial differential equations imply that all solutions φ, ψ, η are smooth, namely, $\varphi, \psi \in C^\infty(\overline{B}_R) \subseteq C^\infty([0,R], C^\infty(\mathbb{S}^{n-1}))$, and $\eta \in C^\infty(\mathbb{S}^{n-1})$. Thus these functions can be expanded in the following way:

$$\begin{cases} \varphi(r,\omega) = \displaystyle\sum_{k=1}^{\infty}\sum_{l=1}^{d_k} u_{kl}(r) Y_{kl}(\omega), \\ \psi(r,\omega) = \displaystyle\sum_{k=1}^{\infty}\sum_{l=1}^{d_k} v_{kl}(r) Y_{kl}(\omega), \\ \eta(\omega) = \displaystyle\sum_{k=1}^{\infty}\sum_{l=1}^{d_k} c_{kl} Y_{kl}(\omega), \end{cases} \tag{3.6}$$

where we denote by $Y_{kl}(\omega)$ $(l = 1, 2, \ldots, d_k)$ the normalized orthogonal basis of all spherical harmonics of degree k. Note that

$$d_1 = n, \quad d_k = \binom{n+k-1}{k} - \binom{n+k-3}{k-2} \ (k \geq 2).$$

The coefficients $u_{kl}(r)$, $v_{kl}(r)$, c_{kl} satisfy the following estimates: Given positive integers N, k, and $1 \leq l \leq d_k$, we have

$$|u_{kl}(r)| \leq C_N(1+k)^{-N}, \quad |v_{kl}(r)| \leq C_N(1+k)^{-N}, \quad |c_{kl}| \leq C_N(1+k)^{-N}.$$

Substituting (3.6) into (3.1)–(3.5), using the relation

$$\Delta_\omega Y_{kl}(\omega) = -\lambda_k Y_{kl}(\omega), \quad \lambda_k = k^2 + (n-2)k \ \ (k = 1, 2, \dots),$$

and comparing coefficients of every $Y_{kl}(\omega)$, we get

$$u''_{kl}(r) + \frac{n-1}{r} u'_{kl}(r) - \frac{\lambda_k}{r^2} u_{kl}(r) = f'(\sigma_0(r)) u_{kl}(r), \tag{3.7}$$

$$v''_{kl}(r) + \frac{n-1}{r} v'_{kl}(r) - \frac{\lambda_k}{r^2} v_{kl}(r) = -g'(\sigma_0(r)) u_{kl}(r), \tag{3.8}$$

$$u_{kl}(R) + \sigma'_0(R) c_{kl} = 0, \tag{3.9}$$

$$v'_{kl}(R) - g(\bar\sigma) c_{kl} = 0, \tag{3.10}$$

$$v_{kl}(R) + \frac{\gamma}{R^2}\Big(1 - \frac{\lambda_k}{n-1}\Big) c_{kl} = 0. \tag{3.11}$$

Solutions of (1.1) are innately nonunique: Any translation or rotation of a solution is again a solution. This nonuniqueness of solutions to (1.1) causes, correspondingly, a nonuniqueness of solutions to (3.1)–(3.5). To eliminate this nonuniqueness we assume that

$$c_{1l} = 0, \quad u_{1l}(r) = 0, \quad v_{1l}(r) = 0, \quad l = 1, 2, \dots, n. \tag{3.12}$$

Observe that, given $k \ge 2$, we have

$$(n-1) - \lambda_k = (n-1) - k^2 - (n-2)k \le -n - 1 < 0.$$

Using this fact it is not difficult to see that any solution of (3.7) is given by

$$u_{kl}(r) = \alpha_{kl} r^{\mu_k} \bar u_k(r), \tag{3.13}$$

where α_{kl} is an arbitrary constant,

$$\mu_k = \frac{1}{2}\Big[\sqrt{(n-2)^2 + 4\lambda_k} - (n-2)\Big] = k \ge 2, \tag{3.14}$$

and $\bar u_k(r)$ is the unique solution of the problem

$$\begin{cases} \bar u''_k(r) + \dfrac{a_k}{r} \bar u'_k(r) = f'(\sigma_0(r)) \bar u_k(r), \\ \bar u_k(0) = 1, \quad \bar u'_k(0) = 0, \end{cases} \tag{3.15}$$

where

$$a_k = 2\mu_k + n - 1 = 2k + n - 1 \ge n + 3. \tag{3.16}$$

Note that (3.15) is a linear equation, which is regular on $r > 0$. Hence the maximal existence interval of $\bar u_k(r)$, and, consequently, also that of $u_{kl}(r)$, is the same as that for $\sigma_0(r)$, namely, $[0, R^*)$. Besides, since $\sigma_0 \in C^\infty[0, R^*)$ and $a_k > 0$, we have

$\bar{u}_k \in C^\infty[0, R^*)$; cf. [6]. Substituting (3.13) into the right-hand side of (3.8) we infer that solutions of (3.8) are given by

$$v_{kl}(r) = \alpha_{kl} r^{\mu_k} \bar{v}_k(r) + \beta_{kl} r^{\mu_k}, \tag{3.17}$$

where α_{kl} is as before, β_{kl} is an arbitrary constant proportional to α_{kl}, i.e., $\beta_{kl} = c\alpha_{kl}$ for an arbitrary constant c, and $\bar{v}_k$ is the unique solution of the problem

$$\begin{cases} \bar{v}_k''(r) + \dfrac{a_k}{r}\bar{v}_k'(r) = -g'(\sigma_0(r))\bar{u}_k(r), \\ \bar{v}_k(0) = 0, \quad \bar{v}_k'(0) = 0. \end{cases} \tag{3.18}$$

Note that $\bar{v}_k(r)$, and, consequently, also $v_k(r)$, is defined for all $0 \le r < R^*$, and $\bar{v}_k \in C^\infty[0, R^*)$. Substituting (3.13) and (3.17) into (3.9)–(3.11) we get the following equations for α_{kl}, β_{kl}, and c_{kl}:

$$\begin{cases} R^{\mu_k}\bar{u}_k(R)\alpha_{kl} + \sigma_0'(R)c_{kl} = 0, \\ [R^{\mu_k}\bar{v}_k'(R) + \mu_k R^{\mu_k-1}\bar{v}_k(R)]\alpha_{kl} + \mu_k R^{\mu_k-1}\beta_{kl} - g(\bar{\sigma})c_{kl} = 0, \\ R^{\mu_k}\bar{v}_k(R)\alpha_{kl} + R^{\mu_k}\beta_{kl} + \dfrac{\gamma}{R^2}\Big(1 - \dfrac{\lambda_k}{n-1}\Big)c_{kl} = 0. \end{cases} \tag{3.19}$$

Hence, (3.1)–(3.5) has a nontrivial solution if and only if there exists $k \ge 2$ such that (3.19) has a nontrivial solution. In the following, we provide conditions on γ which guarantee that (3.19) has a nontrivial solution.

LEMMA 3.2. *The system* (3.19) *has a nontrivial solution if and only if* $\gamma = \gamma_k$, *where*

$$\gamma_k = \frac{(n-1)R^3}{(\lambda_k - n+1)\mu_k}\left[g(\bar{\sigma}) - \frac{\sigma_0'(R)}{\bar{u}_k(R)R^{a_k}}\int_0^R g'(\sigma_0(\rho))\bar{u}_k(\rho)\rho^{a_k}\,d\rho\right], \quad k \ge 2. \tag{3.20}$$

In this case the nontrivial solutions of (3.19) *are unique up to a constant factor. Moreover,* $\gamma_k > 0$ *for all* $k \ge 2$ *and there exists a* $k^* = k^*(f, g, R, n)$ *such that*

$$\gamma_{k+1} < \gamma_k \quad \forall \quad k \ge k^*. \tag{3.21}$$

Finally, $\lim_{k\to\infty}\gamma_k = 0$.

Proof. A simple computation shows that the determinant of the coefficient matrix of (3.19) is equal to the product of $R^{2\mu_k-1}\mu_k\bar{u}_k(R)$ with

$$\frac{R}{\mu_k}\left[g(\bar{\sigma}) + \frac{\bar{v}_k'(R)\sigma_0'(R)}{\bar{u}_k(R)}\right] + \frac{\gamma}{R^2}\left(1 - \frac{\lambda_k}{n-1}\right) \equiv D_k(\gamma).$$

Hence, (3.19) has a nontrivial solution if and only if $D_k(\gamma) = 0$, or

$$\gamma = \gamma_k \equiv \frac{(n-1)R^3}{(\lambda_k - n+1)\mu_k}\left[g(\bar{\sigma}) + \frac{\bar{v}_k'(R)\sigma_0'(R)}{\bar{u}_k(R)}\right].$$

From (3.18) we further infer that

$$\bar{v}_k'(r) = -\frac{1}{r^{a_k}}\int_0^r g'(\sigma_0(\rho))\bar{u}_k(\rho)\rho^{a_k}\,d\rho, \quad r \in [0, R^*), \tag{3.22}$$

which shows that γ_k is given by (3.20). If $\gamma = \gamma_k$, then clearly solutions of (3.19) are unique up to a constant factor. To prove $\gamma_k > 0$, we need only to show that

$$g(\bar{\sigma}) > \frac{\sigma_0'(R)}{\bar{u}_k(R)R^{a_k}} \int_0^R g'(\sigma_0(\rho))\bar{u}_k(\rho)\rho^{a_k}\,d\rho. \tag{3.23}$$

Since $a_k = 2\mu_k + n - 1$ (see (3.16)), we infer that $\rho^{a_k} \le R^{\mu_k - 1}\rho^{\mu_k + n}$ for $0 < \rho \le R$. Thus

$$\begin{aligned}\frac{\sigma_0'(R)}{\bar{u}_k(R)R^{a_k}} \int_0^R g'(\sigma_0(\rho))\bar{u}_k(\rho)\rho^{a_k}\,d\rho &\le \frac{\sigma_0'(R)}{\bar{u}_k(R)R^{\mu_k+n}} \int_0^R g'(\sigma_0(\rho))\bar{u}_k(\rho)\rho^{\mu_k+n}\,d\rho \\ &= \frac{1}{R^n}\int_0^R g'(\sigma_0(\rho))w(\rho)\rho^n\,d\rho,\end{aligned}$$

where $w(r) = \frac{\sigma_0'(R)r^{\mu_k}\bar{u}_k(r)}{R^{\mu_k}\bar{u}_k(R)}$. But (A_2) implies that $\bar{u}_k(r) > 0$, and we conclude that

$$w''(r) + \frac{n-1}{r}w'(r) - \frac{n-1}{r^2}w(r) \ge w''(r) + \frac{n-1}{r}w'(r) - \frac{\lambda_k}{r^2}w(r) = f'(\sigma_0(r))w(r),$$

and

$$w(0) = 0, \quad w(R) = \sigma_0'(R).$$

This implies, by comparison, that $w(r) < \sigma_0'(r)$ for $0 < r < R$, since by differentiating the first equation of (2.1) we get that

$$\sigma_0'''(r) + \frac{n-1}{r}\sigma_0''(r) - \frac{n-1}{r^2}\sigma_0'(r) = f'(\sigma_0(r))\sigma_0'(r),$$

and we know that $\sigma_0'(0) = 0$. Hence

$$\begin{aligned}\frac{1}{R^n}\int_0^R g'(\sigma_0(\rho))w(\rho)\rho^n\,d\rho &< \frac{1}{R^n}\int_0^R g'(\sigma_0(\rho))\sigma_0'(\rho)\rho^n\,d\rho \\ &= g(\sigma_0(R)) - \frac{n}{R^n}\int_0^R g(\sigma_0(\rho))\rho^{n-1}\,d\rho \\ &= g(\bar{\sigma}) + \frac{n}{R}p_0'(R) = g(\bar{\sigma}).\end{aligned}$$

This proves (3.23). Hence, $\gamma_k > 0$ for $k \ge 2$.

To verify (3.21), we first observe that (3.15) implies that

$$\bar{u}_k'(r) = \frac{1}{r^{a_k}}\int_0^r f'(\sigma_0(\rho))\bar{u}_k(\rho)\rho^{a_k}\,d\rho, \quad r \in [0, R^*).$$

Hence $\bar{u}_k$ is increasing. Let us introduce the notation

$$\delta_k := \frac{\sigma_0'(R)}{\bar{u}_k(R)R^{a_k}} \int_0^R g'(\sigma_0(\rho))\bar{u}_k(\rho)\rho^{a_k}\,d\rho.$$

Integration by parts shows that

$$\begin{aligned}\delta_k &= \frac{R\sigma_0'(R)g'(\bar\sigma)}{a_k+1} - \frac{\sigma_0'(R)}{(a_k+1)\bar u_k(R)R^{a_k}}\int_0^R g''(\sigma_0(\rho))\sigma_0'(\rho)\bar u_k(\rho)\rho^{a_k+1}d\rho\\ &\quad -\frac{\sigma_0'(R)}{(a_k+1)\bar u_k(R)R^{a_k}}\int_0^R g'(\sigma_0(\rho))\bar u_k'(\rho)\rho^{a_k+1}d\rho\\ &= \frac{R\sigma_0'(R)g'(\bar\sigma)}{a_k+1} - \frac{\sigma_0'(R)}{(a_k+1)\bar u_k(R)R^{a_k}}\int_0^R g''(\sigma_0(\rho))\sigma_0'(\rho)\bar u_k(\rho)\rho^{a_k+1}d\rho\\ &\quad -\frac{\sigma_0'(R)}{(a_k+1)\bar u_k(R)R^{a_k}}\int_0^R\int_0^\rho g'(\sigma_0(\rho))\rho f'(\sigma_0(\eta))\bar u_k(\eta)\eta^{a_k}d\eta d\rho\\ &\equiv \frac{R\sigma_0'(R)g'(\bar\sigma)}{a_k+1} - \frac{\sigma_0'(R)}{(a_k+1)}\varepsilon_k(R).\end{aligned}$$

Since $\bar u_k$ is increasing, we have $0 \le \bar u_k(\rho)\rho^{a_k}/\bar u_k(R)R^{a_k} \le (\rho/R)^{a_k}$ for $0 \le \rho \le R$, which implies that $\lim_{k\to\infty}\bar u_k(\rho)\rho^{a_k}/\bar u_k(R)R^{a_k} = 0$ for $0 \le \rho < R$. Hence, by dominated convergence, we see that $\lim_{k\to\infty}\varepsilon_k(R) = 0$, or

$$\delta_k = \frac{R\sigma_0'(R)g'(\bar\sigma)}{a_k+1}(1+o(1)) \quad \text{as } k\to\infty.$$

Substituting this expression into (3.20), we deduce that

$$\gamma_{k+1}-\gamma_k = -\frac{3(n-1)R^3g(\bar\sigma)}{k^4}(1+o(1)) \quad \text{as } k\to\infty,$$

so that γ_k is strictly decreasing for k sufficiently large. This completes the proof of (3.21). Finally, $\lim_{k\to\infty}c_k = \infty$ implies that (γ_k) is a null sequence. □

Remark 3.1. We note that

$$D_1(\gamma) = 0 \quad \text{for any } \gamma > 0.$$

Indeed, letting $c = \frac{n}{f(\sigma_0(0))}$, it is easy to verify that $\bar u_1(r) = c\frac{\sigma_0'(r)}{r}$ solves (3.15) in the case $k=1$. Thus using (3.22) we get

$$\begin{aligned}D_1(\gamma) &= R\Big[g(\bar\sigma) + \frac{\bar v_1'(R)\sigma_0'(R)}{\bar u_1(R)}\Big] = R[g(\bar\sigma)+c^{-1}R\bar v_1'(R)]\\ &= R\left[g(\bar\sigma) - \frac{1}{R^n}\int_0^R g'(\sigma_0(\rho))\sigma_0'(\rho)\rho^n d\rho\right] = \frac{n}{R}p_0'(R) = 0.\end{aligned}$$

This implies that for $k=1$, the system (3.19) has nontrivial solutions for any $\gamma > 0$. This nonuniqueness is a consequence of the fact that the system (1.1) is invariant under translations of Ω.

We now summarize the main result of this section.

THEOREM 3.3. *The system of* (3.1)–(3.5) *has a nontrivial solution if and only if* $\gamma = \gamma_k$ *for some* $k \ge 2$.

In the succeeding section we shall express (1.1) as a bifurcation problem in a suitable function space which can be treated by standard bifurcation theory in Banach spaces. We shall see that Theorem 3.3 implies that $\gamma_k's$ are bifurcation points of the full system (1.1), provided $k \ge k^*$.

4. Nonbifurcation at $\gamma \neq \gamma_k$. In this section we shall reduce the system of equations (1.1) into the form (1.4), and use the reduced equation and the implicit function theorem to prove that if $\gamma \neq \gamma_k$ $(k \geq 2)$, then no bifurcation occurs at γ.

For a given $R > 0$, we denote by B_R the open ball in $\mathbb{R}^n$ centered at the origin with radius R, and for a given function $\eta \in C(\mathbb{S}^{n-1})$ satisfying

$$\max_{\omega \in \mathbb{S}^{n-1}} |\eta(\omega)| < R,$$

we denote

$$\Omega_\eta = \{x \in \mathbb{R}^n :\ x = r\omega,\ 0 \leq r < R + \eta(\omega),\ \omega \in \mathbb{S}^{n-1}\}.$$

Given two Banach spaces X and Y, we denote by $L(X, Y)$ the Banach space of all bounded linear mappings from X into Y, by $C(X, Y)$ the Fréchet space of all continuous mappings from X into Y, and by $C^1(X, Y)$ the Fréchet space of all continuously Fréchet differentiable mappings from X to Y. We shall use both $DF(u)$ and $F'(u)$ to denote the Fréchet derivative. For a positive integer m, we denote by $C^m(X, Y)$ the Fréchet space of all m-times continuously Fréchet differentiable mappings from X into Y, and we write $C^\infty(X, Y) = \cap_{m\geq 1} C^m(X, Y)$. Given $0 < \mu < 1$, a positive integer m, and two open sets $\Omega_1, \Omega_2 \subseteq \mathbb{R}^n$, we denote by $\mathrm{Diff}^{m+\mu}(\overline{\Omega}_1, \overline{\Omega}_2)$ the set of all $C^{m+\mu}$-diffeomorphisms from $\overline{\Omega}_1$ onto $\overline{\Omega}_2$. We also set $\mathrm{Diff}^\infty(\overline{\Omega}_1, \overline{\Omega}_2) = \cap_{m\geq 1} \mathrm{Diff}^m(\overline{\Omega}_1, \overline{\Omega}_2)$.

We now use the so-called *Hanzawa transformation* to convert the original problem (1.1) into a nonlinear problem on the fixed reference domain B_R. For this purpose pick a function $\phi \in C^\infty[0, \infty)$ such that

$$\phi(t) = 0 \quad \text{for} \ \ 0 \leq t \leq \frac{1}{2}, \qquad \phi(1) = 1, \tag{4.1}$$

and

$$0 \leq \phi'(t) \leq C_0 \quad \text{for} \ \ t \geq 0, \qquad \phi''(t) \geq 0 \quad \text{for} \ \ 0 \leq t \leq 1. \tag{4.2}$$

By the mean value theorem we have $C_0 > 2$. Given a number $R > 0$ and a function $\eta \in C(\mathbb{S}^{n-1})$ satisfying

$$\max_{\omega \in \mathbb{S}^{n-1}} |\eta(\omega)| < \frac{R}{C_0 - 1}, \tag{4.3}$$

we consider the mapping $\Psi_\eta :\ \mathbb{R}^n \to \mathbb{R}^n$ defined by

$$\Psi_\eta(x) = x - \eta(\omega)\phi\left(\frac{|x|}{R + \eta(\omega)}\right)\omega, \quad x \in \mathbb{R}^n,$$

where $\omega = \frac{x}{|x|}$ for $x \neq 0$. Using (4.1)–(4.3), one can easily verify that if $\eta \in C^{m+\mu}(\mathbb{S}^{n-1})$ for some $m \in \mathbb{N}$ and $0 \leq \mu < 1$, then

$$\Psi_\eta \in \mathrm{Diff}^{m+\mu}(\mathbb{R}^n, \mathbb{R}^n) \bigcap \mathrm{Diff}^{m+\mu}(\overline{\Omega}_\eta, \overline{B}_R).$$

As usual we denote by Ψ_η^* and $(\Psi_\eta)_*$ the pullback and push-forward operators, respectively, induced by Ψ_η, i.e.,

$$\Psi_\eta^* u = u \circ \Psi_\eta \quad \text{for} \ \ u \in C(\overline{B}_R), \qquad (\Psi_\eta)_* v = v \circ \Psi_\eta^{-1} \quad \text{for} \ \ v \in C(\overline{\Omega}_\eta).$$

Clearly, if $\eta \in C^{m+\mu}(\mathbb{S}^{n-1})$ for some $m \in \mathbb{N}$ and $0 \le \mu < 1$, then

$$\Psi_\eta^* \in L(C^{m+\mu}(\overline{B}_R), C^{m+\mu}(\overline{\Omega}_\eta)), \quad (\Psi_\eta)_* \in L(C^{m+\mu}(\overline{\Omega}_\eta), C^{m+\mu}(\overline{B}_R)).$$

We denote by Ψ, Ψ^*, and Ψ_*, respectively, the three mappings

$$\eta \mapsto \Psi_\eta, \quad \eta \mapsto \Psi_\eta^*, \quad \eta \mapsto (\Psi_\eta)_*.$$

Since $\phi \in C^\infty[0,\infty)$, we also have

$$\Psi \in C^\infty(C^{m+\mu}(\mathbb{S}^{n-1}) \cap M(R, C_0), \mathrm{Diff}^{m+\mu}(\overline{\Omega}_\eta, \overline{B}_R)),$$

where

$$M(R, C_0) = \left\{ \eta \in C(\mathbb{S}^{n-1}) : \max_{\omega \in \mathbb{S}^{n-1}} |\eta(\omega)| < \frac{R}{C_0 - 1} \right\}.$$

Similar mapping properties of Ψ^* and Ψ_* can easily be formulated.

Given $\eta \in C^{2+\mu}(\mathbb{S}^{n-1}) \cap M(R, C_0)$, we define operators $L(\eta): C^{2+\mu}(\overline{B}_R) \to C^\mu(\overline{B}_R)$ and $N(\eta): C^{2+\mu}(\overline{B}_R) \to C^{1+\mu}(\partial B_R)$ by

$$L(\eta) = (\Psi_\eta)_* \circ \Delta \circ \Psi_\eta^*, \qquad N(\eta) = (\Psi_\eta|_{\partial\Omega_\eta})_* \circ \frac{\partial}{\partial \nu} \circ \Psi_\eta^*,$$

where $\partial/\partial\nu$ denotes the outward normal derivative operator on $\partial\Omega_\eta$, and $\Psi_\eta|_{\partial\Omega_\eta}$ denotes the restriction of Ψ_η on $\partial\Omega_\eta$. Clearly, if $\eta \in C^{m+\mu}(\mathbb{S}^{n-1})$ $(m \ge 2)$, then

$$L(\eta) \in L(C^{m+\mu}(\overline{B}_R), C^{m+\mu-2}(\overline{B}_R)), \quad N(\eta) \in L(C^{m+\mu}(\overline{B}_R), C^{m+\mu-1}(\partial B_R)).$$

Moreover, the mappings $\eta \mapsto L(\eta)$ and $\eta \mapsto N(\eta)$ are smooth on $C^{m+\mu}(\mathbb{S}^{n-1}) \cap M(R, C_0)$. In order to handle the right-hand sides of (1.1), we define the operators $F, G : C^{m+\mu}(\overline{B}_R) \to C^{m+\mu}(\overline{B}_R)$ and $\Gamma_0 : C^{m+\mu}(\overline{B}_R) \to C^{m+\mu}(\partial B_R)$ by

$$F(u) = f \circ u, \quad G(u) = g \circ u, \quad \Gamma_0 u = u|_{\partial B_R}$$

for $u \in C^{m+\mu}(\overline{B}_R)$, as well as $B : C^{m+2+\mu}(\mathbb{S}^{n-1}) \to C^{m+\mu}(\partial B_R)$, where

$$\begin{aligned} B(\eta)(R\omega) \;=\;& \text{the mean curvature of the hypersurface } r = R + \eta(\omega) \\ & \text{at the point } x = (R + \eta(\omega))\omega \end{aligned}$$

for $\eta \in C^{m+2+\mu}(\mathbb{S}^{n-1})$. Again it is not difficult to verify that these mappings depend smoothly on their argument.

With the above notations we can now transform the problem (1.1) into the following system: Find $(u, v, \eta) \in C^{2+\mu}(\overline{B}_R) \times C^{2+\mu}(\overline{B}_R) \times C^{2+\mu}(\mathbb{S}^{n-1})$, such that

$$L(\eta)u = F(u), \tag{4.4}$$
$$\Gamma_0 u = \bar{\sigma}, \tag{4.5}$$
$$L(\eta)v = -G(u), \tag{4.6}$$
$$N(\eta)v = 0, \tag{4.7}$$
$$\Gamma_0 v = \gamma B(\eta). \tag{4.8}$$

Fix $m \in \mathbb{N}$ with $m \ge 2$ and $0 < \mu < 1$. Given $\eta \in C^{m+\mu}(\mathbb{S}^{n-1})$, it follows from Theorems 9.5 and 12.8 in [10] that the problem (4.4), (4.5) has a unique solution

$u \in C^{m+\mu}(\overline{B}_R)$, satisfying $0 < u(x) \le \bar{\sigma}$ for $x \in \overline{B}_R$. We define a mapping $A_1 : C^{m+\mu}(\mathbb{S}^{n-1}) \to C^{m+\mu}(\overline{B}_R)$ by setting $A_1(\eta) = u$.

Next, let us introduce the functional Φ on $C^{m+\mu}(\mathbb{S}^{n-1})$ by setting

$$\Phi(\eta) = \int_{B_R} G(A_1(\eta))(x) J_\eta(x) dx \qquad \text{for } \eta \in C^{m+\mu}(\mathbb{S}^{n-1}), \tag{4.9}$$

where $J_\eta(x)$ is the determinant of the Jacobian of the transformation $x \mapsto \Psi_\eta^{-1}(x)$. Substituting $u = A_1(\eta)$ into (4.6) and using the Fredholm property of (4.6) (4.7), we see that $\Phi(\eta) = 0$ is a necessary (and sufficient) condition for the solvability of problem (4.6), (4.7). Later we shall see that $\Phi \in C^\infty(C^{m+\mu}(\mathbb{S}^{n-1}) \cap M(R, C_0), \mathbb{R})$, and that $\Phi'(0) \ne 0$. Therefore, $\mathcal{M} := \Phi^{-1}(0)$ is a C^∞ Banach submanifold of codimension 1 in a small neighborhood of the origin of $C^{m+\mu}(\mathbb{S}^{n-1})$. By elliptic Schauder theory, given any $\eta \in \mathcal{M}$, the problem (4.6), (4.7) has a solution $v \in C^{m+\mu}(\overline{B}_R)$, which is unique up to a constant. Let us denote by v the particular solution which is zero at the origin, and define a mapping $A_2 : \mathcal{M} \to C^{m+\mu}(\overline{B}_R)$ by setting $A_2(\eta) = v$. Finally, we set $A = \Gamma_0 \circ A_2$. Then, clearly, $A : \mathcal{M} \to C^{m+\mu}(\partial B_R)$.

With the above notations, it is not difficult to verify that the problem (4.4)–(4.8) reduces to the following problem: Find $\eta \in C^{m+\mu}(\mathbb{S}^{n-1})$ and $c \in \mathbb{R}$ such that

$$\begin{cases} A(\eta) + c = \gamma B(\eta), \\ \Phi(\eta) = 0. \end{cases} \tag{4.10}$$

We summarize with the following lemma.

LEMMA 4.1. *The problem* (1.1) *is equivalent to the system of* (4.10). *More precisely, if* (σ, p, Ω), *where* $\sigma \in C^{m+\mu}(\overline{\Omega})$, $p \in C^{m+\mu}(\overline{\Omega})$, $\Omega = \{x \in R^n : r < \eta(\omega), r = |x|, \omega = x/|x|\}$, *and* $\eta \in C^{m+\mu}(\mathbb{S}^{n-1})$ *is a solution of* (1.1), *then there exists a unique real number c such that* (η, c) *is a solution of* (4.10). *Conversely, if* $(\eta, c) \in C^{m+\mu}(\mathbb{S}^{n-1}) \times \mathbb{R}$ *is a solution of* (4.10), *then there exists a unique pair of functions* $(\sigma, p) \in C^{m+\mu}(\overline{\Omega}) \times C^{m+\mu}(\overline{\Omega})$, *such that* (σ, p, Ω), *with* Ω *as above, is a solution of* (1.1).

Remark. Using the above equivalence and a standard bootstrapping argument, one can easily show that if (σ, p, Ω) is a solution of (1.1)–(1.5), then $\eta \in C^\infty(\mathbb{S}^{n-1})$ and, consequently, also $\sigma \in C^\infty(\overline{\Omega})$, $p \in C^\infty(\overline{\Omega})$. Besides, if (σ, p, Ω) is a solution of (1.1), then the value of c in (5.20) is clearly equal to $p(0)$.

We now prove the following preliminary result.

LEMMA 4.2. *Let* $m \in \mathbb{N} \cup \{\infty\}$ *with* $m \ge 2$ *and* $0 < \mu < 1$ *be given. Then we have the following assertions:*

(i) $\Phi \in C^\infty(C^{m+\mu}(\mathbb{S}^{n-1}) \cap M(R, C_0), \mathbb{R})$ *with* $\Phi'(0)\mathbf{1} < 0$, *where* $\mathbf{1}$ *represents the function on* $\mathbb{S}^{n-1}$ *taking identically the value* 1.

(ii) *There exists a neighborhood* $\mathcal{N}$ *of* 0 *in* $C^{m+\mu}(\mathbb{S}^{n-1})$ *such that* $\mathcal{M} := \Phi^{-1}(0) \cap \mathcal{N}$ *is a* C^∞*-Banach submanifold of codimension* 1. *Moreover, we have*

$$A \in C^\infty(\mathcal{M}, C^{m+\mu}(\partial B_R)). \tag{4.11}$$

Proof. We define a mapping

$$\mathcal{F} : (C^{m+\mu}(\mathbb{S}^{n-1}) \cap M(R, C_0)) \times C^{m+\mu}(\overline{B}_R) \to C^{m+\mu-2}(\overline{B}_R) \times C^{m+\mu}(\partial B_R)$$

by setting

$$\mathcal{F}(\eta, u) := (L(\eta)u - F(u), \Gamma_0 u - \bar{\sigma}).$$

Clearly, $\mathcal{F}$ is smooth and the system (4.4), (4.5) is equivalent to $\mathcal{F}(\eta, u) = 0$. Thus, by the definition of A_1, given any $\eta \in C^{m+\mu}(\mathbb{S}^{n-1}) \cap M(R, C_0)$, this equation has a unique solution $u = A_1(\eta)$. Consider the partial Fréchet derivative $D_u\mathcal{F}(\eta, u)$ of $\mathcal{F}(\eta, u)$ in u. An easy computation reveals that

$$D_u\mathcal{F}(\eta, u)v = (L(\eta)v - F'(u)v, \Gamma_0 v) = (L(\eta)v - f'(u)v, \Gamma_0 v) \quad \forall v \in C^{m+\mu}(\overline{B}_R).$$

Given any $(\eta, u) \in (C^{m+\mu}(\mathbb{S}^{n-1}) \cap M(R, C_0)) \times C^{m+\mu}(\overline{B}_R)$, we have that $L(\eta)$ is a uniformly elliptic operator in divergence form without the zero order term and $f'(u) \geq 0$. Hence standard elliptic theory implies that for any $(w, z) \in C^{m+\mu-2}(\overline{B}_R) \times C^{m+\mu}(\partial B_R))$, the elliptic boundary value problem $L(\eta)v - f'(u)v = w, \quad \Gamma_0 v = z$ has a unique solution $v \in C^{m+\mu}(\overline{B}_R)$. This means that the mapping $D_u\mathcal{F}(\eta, u) : C^{m+\mu}(\overline{B}_R) \to C^{m+\mu-2}(\overline{B}_R) \times C^{m+\mu}(\partial B_R)$ is an isomorphism. It follows by the Banach inverse mapping theorem that its inverse is also bounded. Thus, by the implicit function theorem we conclude that A_1 is smooth with

$$A_1'(\eta) = -(D_u\mathcal{F}(\eta, A_1(\eta)))^{-1} \circ D_\eta\mathcal{F}(\eta, A_1(\eta)).$$

Since $G \in C^\infty(C^{m+\mu}(\overline{B}_R), C^{m+\mu}(\overline{B}_R))$ and since it is obvious that the mapping $\eta \mapsto J_\eta$ belongs to $C^\infty(C^{m+\mu}(\mathbb{S}^{n-1}) \cap M(R, C_0), C^{m+\mu-1}(\overline{B}_R))$, we immediately conclude that $\Phi \in C^\infty(C^{m+\mu}(\mathbb{S}^{n-1}) \cap M(R, C_0), \mathbb{R})$.

Next, we compute $\Phi'(0)\mathbf{1}$. The change of variables $x \mapsto \Psi_\eta(x)$ in the integral on the right-hand side of (4.9) shows that

$$\Phi(\eta) = \int_{\Omega_\eta} g(\sigma_\eta(x))dx,$$

where σ_η denotes the solution of the boundary value problem

$$\Delta\sigma_\eta = f(\sigma_\eta) \quad \text{in } \Omega_\eta, \qquad \sigma_\eta = \bar{\sigma} \quad \text{on } \partial\Omega_\eta.$$

In the case $\eta = \varepsilon\mathbf{1}$, we simply denote $\sigma_{\varepsilon\mathbf{1}}$ by σ_ε, so that $\Phi(\varepsilon\mathbf{1}) = \int_{B_{R+\varepsilon}} g(\sigma_\varepsilon(x))dx$. It follows that

$$\begin{aligned}
\Phi'(0)\mathbf{1} &= \frac{d}{d\varepsilon}\Phi(\varepsilon\mathbf{1})\Big|_{\varepsilon=0} = g(\bar{\sigma})\frac{d}{d\varepsilon}|B_{R+\varepsilon}|\Big|_{\varepsilon=0} + \int_{B_R} g'(\sigma_0(|x|))\frac{d}{d\varepsilon}\sigma_\varepsilon(x)\Big|_{\varepsilon=0}dx \\
&= c_n R^{n-1}g(\bar{\sigma}) + c_n\int_0^R g'(\sigma_0(r))v_0(r)r^{n-1}dr,
\end{aligned}$$

where c_n denotes the surface measure of $\mathbb{S}^{n-1}$, and where v_0 is the solution of the boundary value problem

$$\begin{cases} v_0''(r) + \dfrac{n-1}{r}v_0'(r) = f'(\sigma_0(r))v_0(r) \quad \text{for } 0 < r < R, \\ v_0'(0) = 0, \quad v_0(R) = -\sigma_0'(R). \end{cases}$$

Using the maximum principle, one can easily show that $v_0(r) < -\sigma'(r)$ for $0 < r < R$. Hence

$$\begin{aligned}
\Phi'(0)\mathbf{1} &< c_n R^{n-1}g(\bar{\sigma}) - c_n\int_0^R g'(\sigma_0(r))\sigma_0'(r)r^{n-1}dr \\
&= \frac{c_n}{R}\int_0^R g'(\sigma_0(r))\sigma_0'(r)r^n dr - c_n\int_0^R g'(\sigma_0(r))\sigma_0'(r)r^{n-1}dr < 0.
\end{aligned}$$

Here we use the fact that

$$g(\bar{\sigma}) - \frac{1}{R^n}\int_0^R g'(\sigma_0(r))\sigma_0'(r)r^n dr = \frac{n}{R}p_0'(R) = 0.$$

This proves assertion (i).

(ii) By continuity of Φ', we infer that there exists a neighborhood $\mathcal{N}$ of 0 in $C^{m+\mu}(\mathbb{S}^{n-1})$ such that $\Phi'(\eta)\mathbf{1} \neq 0$ for all $\eta \in \mathcal{N}$. It follows that $\mathcal{M} = \Phi^{-1}(0) \cap \mathcal{N}$ is a C^∞ Banach submanifold of codimension 1 in $C^{m+\mu}(\mathbb{S}^{n-1})$. Based on the implicit function theorem one sees that, similarly as for A_1, that A_2 is smooth. Hence $A = \Gamma_0 \circ A_2 \in C^\infty(\mathcal{M}, C^{m+\mu}(\partial B_R))$. This completes the proof. □

Recall that $D_1(\gamma) = 0$ for all $\gamma > 0$; see Remark 3.1. This implies that the operator $(\eta, c) \mapsto A'(0)\eta + c - \gamma B'(0)\eta$, $(\eta, c) \in C^{m+\mu}(\mathbb{S}^{n+1}) \times \mathbb{R}$, is not injective for any $\gamma > 0$. For this reason we shall restrict the operators A, B on the subspace $C_2^{m+\mu}(\mathbb{S}^{n-1})$ of $C^{m+\mu}(\mathbb{S}^{n+1})$, which is defined as follows: We first let

$$H_1(\mathbb{S}^{n-1}) = \text{the span of all spherical harmonics of degree } 1,$$

and then set

$$C_2^{m+\mu}(\mathbb{S}^{n-1}) = \{\eta \in C^{m+\mu}(\mathbb{S}^{n-1}) :\ \eta \text{ is orthogonal to } H_1(\mathbb{S}^{n-1}) \text{ in } L^2(\mathbb{S}^{n-1})\}.$$

It can be easily shown that

$$C^{m+\mu}(\mathbb{S}^{n-1}) = H_1(\mathbb{S}^{n-1}) \oplus C_2^{m+\mu}(\mathbb{S}^{n-1}).$$

Given a point $x_0 \in \mathbb{R}$, we denote by S_{x_0} the translation on $\mathbb{R}^n$ induced by x_0, i.e., $S_{x_0}(x) = x + x_0$ for $x \in \mathbb{R}^n$. Further, let $r_0 = |x_0|$, $\omega_0 = x_0/|x_0|$, and assume that $r_0 \in (0, R/4)$. Given $\eta \in C(\mathbb{S}^{n-1})$ such that

$$\|\eta\|_{L^\infty(\mathbb{S}^{n-1})} < \min\left\{\frac{R}{C_0 - 1}, \frac{R}{4}\right\},$$

consider the image of the hypersurface $r = R + \eta(\omega)$ under the translation S_{x_0}. Clearly, this hypersurface has the equation $r = R + \tilde{\eta}(\omega)$, where $\tilde{\eta}$ is uniquely determined by η and x_0. We use the notation

$$\tilde{\eta} = S_{x_0}^*(\eta).$$

An explicit expression of $S_{x_0}^*$ is given by

$$\tilde{\eta}(\omega') = \sqrt{[R + \eta(\omega)]^2 + r_0^2 + 2r_0[R + \eta(\omega)]\omega \cdot \omega_0} - R,$$

where $\omega' \in \mathbb{S}^{n-1}$ and $\omega \in \mathbb{S}^{n-1}$ are connected by the relation

$$\omega' = \frac{[R + \eta(\omega)]\omega + r_0\omega_0}{\sqrt{[R + \eta(\omega)]^2 + r_0^2 + 2r_0[R + \eta(\omega)]\omega \cdot \omega_0}}.$$

Now, since the problem (1.1) is invariant under translations, we see that if η is a solution of (4.10), then for any $x \in \mathbb{R}^n$ with $|x|$ sufficiently small, $\tilde{\eta} = S_x^*(\eta)$ is also a solution of (4.10). This shows that if we denote by $B_\varepsilon(0)$ the ball in $\mathbb{R}^n$ with radius ε, and assume that η is a solution of (5.20), then for $\varepsilon > 0$ small enough we have

$$\left\{\begin{array}{l} A(S_x^*(\eta)) + c = \gamma B(S_x^*(\eta)) \\ \Phi(S_x^*(\eta)) = 0 \end{array}\right. \qquad \text{for any } \; x \in B_\varepsilon(0). \tag{4.12}$$

Hence, for any solution η of (4.10) which lies in $C_2^{m+\mu}(\mathbb{S}^{n-1})$, we get a new solution of (4.10) by applying S_x^* to η for any $x \in B_\varepsilon(0)$. The following lemma shows that the converse is also true, i.e., any small solution of (4.10) can be obtained by a suitable translation of a solution belonging to $C_2^{m+\mu}(\mathbb{S}^{n-1})$.

LEMMA 4.3. *For $\varepsilon > 0$ sufficiently small, let $\mathcal{B}_\varepsilon$ be the ball in $C^{m+\mu}(\mathbb{S}^{n-1})$ with radius ε. Then for any $\eta \in \mathcal{B}_\varepsilon$, there exists a unique $\xi \in C_2^{m+\mu}(\mathbb{S}^{n-1})$ and a unique $x \in B_\varepsilon$ such that $S_x^*(\xi) = \eta$.*

Proof. We introduce a mapping $F : \mathcal{B}_\varepsilon \times B_\varepsilon \to \mathbb{R}^n$ by defining the jth component of $F(\eta, x)$ to be

$$F_j(\eta, x) = nc_n^{-1} \int_{\mathbb{S}^{n-1}} S_{-x}^*(\eta)(\omega)\omega_j d\omega, \quad j = 1, 2, \dots, n,$$

where c_n denotes the surface measure of $\mathbb{S}^{n-1}$, and $d\omega$ represents the volume element on $\mathbb{S}^{n-1}$. It can be easily shown that $F \in C^{m+\mu}(\mathcal{B}_\varepsilon \times B_\varepsilon, \mathbb{R}^n)$. Besides, it is clear that $F(0,0) = 0$, and a simple calculation shows that $D_x F(0,0) = -id$. Hence, by the implicit function theorem, we infer that there exist a small neighborhood $\mathcal{O}$ of the origin of $C^{m+\mu}(\mathbb{S}^{n-1})$ and a C^m-mapping $\varphi : \mathcal{O} \to B_\varepsilon$ such that $\varphi(0) = 0$, $F(\eta, \varphi(\eta)) = 0$ for all $\eta \in \mathcal{O}$, and $x = \varphi(\eta)$ is the unique solution of the equation $F(\eta, x) = 0$ in B_ε for every fixed $\eta \in \mathcal{B}_\varepsilon$. Let $\xi = S_{-x}^*(\eta) = S_{-\varphi(\eta)}^*(\eta)$. Then, clearly, $\xi \in C^{m+\mu}(\mathbb{S}^{n-1})$, $S_x^*(\xi) = \eta$, and the condition $F(\eta, x) = 0$ implies that ξ is orthogonal to all first order spherical harmonics in $L^2(\mathbb{S}^{n-1})$, so that $\xi \in C_2^{m+\mu}(\mathbb{S}^{n-1})$, as desired. ∎

Based on Lemma 4.3, we may assume without restriction that

$$\eta \in C_2^{m+\mu}(\mathbb{S}^{n-1}). \tag{4.13}$$

Let R and $\overline{p}_0(r)$ be as in section 2. We know that R, $\overline{p}_0$ are independent of γ. By the definition of A, B it is clear that

$$A(0) = \overline{p}_0(R), \quad B(0) = \frac{1}{R}. \tag{4.14}$$

We now set

$$c_\gamma = \frac{\gamma}{R} - \overline{p}_0(R) \quad \text{for } \; \gamma > 0,$$

and remark that given any $\gamma > 0$, the pair $(\eta, c) = (0, c_\gamma)$ is a solution of (4.10).

LEMMA 4.4. *Let $\gamma_0 > 0$. If $\gamma_0 \neq \gamma_k$, $k = 2, 3, \dots,$ then there exists $\varepsilon > 0$ such that for any $\gamma \in (\gamma_0 - \varepsilon, \gamma_0 + \varepsilon)$ the pair $(0, c_\gamma)$ is the only solution of* (4.10)*, i.e., γ_0 is not a bifurcation point of* (4.10).

Proof. We set

$$X = (\mathcal{M} \cap C_2^{m+\mu}(\mathbb{S}^{n-1})) \times \mathbb{R}, \quad Y = C^{m-2+\mu}(\mathbb{S}^{n-1}),$$

and define a mapping $F : X \times \mathbb{R} \to Y$ by

$$F(\zeta, \gamma) = A(\eta) + c - \gamma B(\eta), \quad \zeta = (\eta, c) \in X, \ \ \gamma \in \mathbb{R}.$$

Here we regard X as a smooth Banach submanifold of $C_2^{m+\mu}(\mathbb{S}^{n-1}) \times \mathbb{R}$. Clearly, $F \in C^\infty(X, Y)$ and (4.10) is equivalent to

$$F(\zeta, \gamma) = 0. \tag{4.15}$$

We already know that given $\gamma > 0$, this equation has the solution $\zeta = \zeta_\gamma \equiv (0, c_\gamma)$. Thus, by the Banach inverse mapping theorem and the implicit function theorem, it suffices to prove that for any $\gamma \neq \gamma_k$, $k = 2, 3, \ldots$, the operator $D_\zeta F(\zeta_\gamma, \gamma) : T_{\zeta_\gamma}(X) \to T_0(Y)$ is an isomorphism. Here $T_{\zeta_\gamma}(X)$ denotes the tangent space of X at ζ_γ. Observe that

$$T_{\zeta_\gamma}(X) = T_0(\mathcal{M} \cap C_2^{m+\mu}(\mathbb{S}^{n-1})) \times \mathbb{R},$$

and, given $\zeta = (\eta, c) \in T_{\zeta_\gamma}(X)$, we have

$$D_\zeta F(\zeta_\gamma, \gamma)\zeta = A'(0)\eta + c - \gamma B'(0)\eta.$$

Hence, for any $\xi \in T_0(Y) = Y$, the equation $D_\zeta F(\zeta_\gamma, \gamma)\zeta = \xi$ is equivalent to the system

$$\begin{cases} A'(0)\eta + c - \gamma B'(0)\eta = \xi, \\ \Phi'(0)\eta = 0, \quad \eta \in C_2^{m+\mu}(\mathbb{S}^{n-1}). \end{cases} \tag{4.16}$$

In particular, $D_\zeta F(\zeta_\gamma, \gamma)\zeta = 0$ is equivalent to the system

$$\begin{cases} A'(0)\eta + c - \gamma B'(0)\eta = 0, \\ \Phi'(0)\eta = 0, \quad \eta \in C_2^{m+\mu}(\mathbb{S}^{n-1}). \end{cases} \tag{4.17}$$

Since (4.17) is the linearization of (4.10) with the constraint $\eta \in C_2^{m+\mu}(\mathbb{S}^{n-1})$, and (4.10) is equivalent to (1.1), whose linearization is (3.1)–(3.5), we see that (4.17) is equivalent to (3.1)–(3.5) subject to the constraint $\eta \in C_2^{m+\mu}(\mathbb{S}^{n-1})$. By Theorem 3.3, we know that if $\gamma \neq \gamma_k$, $k = 2, 3, \ldots$, then (3.1)–(3.5) does not have nontrivial solutions in $C_2^{m+\mu}(\mathbb{S}^{n-1})$. Hence, if $\gamma \neq \gamma_k$, $k = 1, 2, \ldots$, then the pair $(0, c_\gamma)$ is the only solution to (4.17), i.e., $D_\zeta F(\zeta_\gamma, \gamma)$ is injective.

Next, by assertion (i) of Lemma 4.2 we see that the curve in $C^{m+\mu}(\mathbb{S}^{n-1})$ starting from $0 \in \mathcal{M}$ with tangent $\mathbf{1}$: $t \mapsto t\mathbf{1}$ is transverse to $\mathcal{M}$. Since $\mathcal{M}$ is of codimension 1 in $C^{m+\mu}(\mathbb{S}^{n-1})$, it follows that $C^{m+\mu}(\mathbb{S}^{n-1}) = T_0(\mathcal{M}) \oplus \mathbb{R}\mathbf{1}$, and the mapping $\zeta = (\eta, c) \to \eta + c\mathbf{1}$ is an isomorphism from $T_{\zeta_\gamma}(\mathcal{M} \times \mathbb{R}) = T_0(\mathcal{M}) \times \mathbb{R}$ to $C^{m+\mu}(\mathbb{S}^{n-1})$. For $\overline{\eta} \in C^{m+\mu}(\mathbb{S}^{n-1})$, let $\overline{\eta} = \eta + c\mathbf{1}$, where $\eta \in T_0(\mathcal{M})$ and $c \in \mathbb{R}$. The above argument implies that (η, c) is uniquely determined by $\overline{\eta}$. Clearly,

$$B'(0)\overline{\eta} = B'(0)\eta - \frac{c}{R^2}.$$

We define a bounded linear operator $L_\gamma : \ C^{m+\mu}(\mathbb{S}^{n-1}) \to C^{m+\mu}(\mathbb{S}^{n-1})$ by

$$L_\gamma \overline{\eta} = A'(0)\eta + c - \frac{\gamma c}{R^2}.$$

Then (4.16) is equivalent to

$$L_\gamma \overline{\eta} - \gamma B'(0)\overline{\eta} = \xi, \quad \text{with } \ \overline{\eta} \in C_2^{m+\mu}(\mathbb{S}^{n-1}).$$

Note that $B'(0)$ is a linear second order elliptic differential operator on $\mathbb{S}^{n-1}$. Hence the well-known Fredholm theory for elliptic operators implies that, given any $\xi \in C^{m-2+\mu}(\mathbb{S}^{n-1})$, the solvability of the above equation is equivalent to the uniqueness of solutions of the corresponding homogeneous equation. Thus, by the uniqueness assertion we have just proved, it follows that if $\gamma \neq \gamma_k$, then for any given $\xi \in C^{m-2+\mu}(\mathbb{S}^{n-1})$ this equation has a solution $\overline{\eta} \in C_2^{m+\mu}(\mathbb{S}^{n-1})$. Hence, (4.16) is solvable for any $\xi \in C^{m-2+\mu}(\mathbb{S}^{n-1})$, implying that the operator $D_\zeta F(\zeta_\gamma, \gamma)$ is surjective. This completes the proof. □

By combining Lemmas 4.1 and 4.4 we get the following theorem.

THEOREM 4.5. *If $\gamma \neq \gamma_k$, $k = 2, 3, \ldots$, then γ is not a bifurcation point of the problem* (1.1).

5. Bifurcation at $\boldsymbol{\gamma_k}$. In this section we prove that γ_k is a bifurcation point, provided $k \geq k^*$; cf. Lemma 3.2. We first tackle the case $n = 2$ in some detail and then indicate how to treat the general case $n \geq 3$.

5.1. The case $\boldsymbol{n = 2}$. Throughout this subsection we use (r, θ) to indicate polar coordinates in $\mathbb{R}^2$. We shall also frequently identify a 2π-periodic function η on $\mathbb{R}$ with the function $\psi^*(\eta) = \eta \circ \psi$ on $\mathbb{S}^1$, where $\psi : \mathbb{S}^1 \to \mathbb{R}$, $\psi(\cos\theta, \sin\theta) = \theta$ for $\theta \in [0, 2\pi)$. The Banach space of all 2π-periodic functions on $\mathbb{R}$ of class $C^{m+\mu}$ is denoted by $C_{2\pi}^{m+\mu}$. Given a positive integer l, we also introduce the space

$$C_{2\pi,l}^\infty = \Big\{\eta(\theta) = a_0 + \sum_{k=1}^\infty [a_k \cos(kl\theta) + b_k \sin(kl\theta)] : \ a_0, a_k, b_k \in \mathbb{R}, \text{ and } \forall\, N > 0 \ \exists\, C_N \geq 0 : \ |a_k| + |b_k| \leq C_N (1+k)^{-N}, \ k = 1, 2, \cdots \Big\}.$$

It is well known that $C_{2\pi}^\infty = C_{2\pi,l=1}^\infty$. Furthermore, by writing $C_{2\pi,l,0}^\infty$ and $C_{2\pi,l,1}^\infty$ for the spaces obtained from $C_{2\pi,l}^\infty$ by letting $b_k = 0$ and $a_k = 0$, respectively, it is clear that $C_{2\pi,l}^\infty$, $C_{2\pi,l,0}^\infty$, $C_{2\pi,l,1}^\infty$ are closed subspaces of $C_{2\pi}^\infty$ and that

$$C_{2\pi,l}^\infty = C_{2\pi,l,0}^\infty \oplus C_{2\pi,l,1}^\infty.$$

Further, given integers $m \geq 0$, $l \geq 1$, and a number $0 \leq \mu < 1$, let

$$C_{2\pi,l}^{m+\mu} = \text{the closure of } \ C_{2\pi,l}^\infty \ \text{ in } \ C_{2\pi}^{m+\mu}.$$

The spaces $C_{2\pi,l,i}^{m+\mu}$ for $i = 0$, 1 are defined similarly.

We now collect some properties of the above spaces, which we need in what follows.

LEMMA 5.1. *The following assertions hold:*

(1) $\frac{\partial}{\partial\theta} \in L(C_{2\pi,l,0}^{m+\mu}, C_{2\pi,l,1}^{m+\mu-1}) \cap L(C_{2\pi,l,1}^{m+\mu}, C_{2\pi,l,0}^{m+\mu-1})$.

(2) $\frac{\partial^2}{\partial\theta^2} \in L(C_{2\pi,l,0}^{m+\mu}, C_{2\pi,l,0}^{m+\mu-2}) \cap L(C_{2\pi,l,1}^{m+\mu}, C_{2\pi,l,1}^{m+\mu-2})$.

(3) *If $\eta_1, \eta_2 \in C_{2\pi,l,0}^{m+\mu}$, then $\eta_1\eta_2 \in C_{2\pi,l,0}^{m+\mu}$; if $\zeta_1, \zeta_2 \in C_{2\pi,l,1}^{m+\mu}$, then $\zeta_1\zeta_2 \in C_{2\pi,l,0}^{m+\mu}$; if $\eta \in C_{2\pi,l,0}^{m+\mu}$ and $\zeta \in C_{2\pi,l,1}^{m+\mu}$, then $\eta\zeta \in C_{2\pi,l,1}^{m+\mu}$.*

(4) *If $f \in C^\infty(\mathbb{R})$, then $f \circ \eta \in C_{2\pi,l,0}^{m+\mu}$ for $\eta \in C_{2\pi,l,0}^{m+\mu}$, and $f \circ \eta \in C_{2\pi,l}^{m+\mu}$ for $\eta \in C_{2\pi,l}^{m+\mu}$.*

Proof. The first three assertions are immediate. Assertion (4) follows from the Stone–Weierstrass theorem and (3). □

In the following, we write $\overline{B}_R$ for the closed ball in $\mathbb{R}^2$ centered at 0 with radius R. We often regard a given function u defined on $\overline{B}_R$ as a mapping from $[0, R]$ to the set of 2π-periodic functions on $\mathbb{R}$ by identifying u with the mapping $r \mapsto u(r\cos\theta, r\sin\theta)$. We further set

$$C^{m+\mu}_{2\pi,l}(\overline{B}_R) = \text{the closure of } C^\infty(\overline{B}_R) \cap C^\infty([0,R], C^\infty_{2\pi,l}(\mathbb{R})) \text{ in } C^{m+\mu}(\overline{B}_R).$$

The spaces $C^{m+\mu}_{2\pi,l,i}(\overline{B}_R)$ for $i = 0$, 1 are defined similarly.

Given $\eta \in C^{m+\mu}_{2\pi}$, the mean curvature of the surface $r = R + \eta(\theta)$ is given by

$$\kappa = \frac{2[\eta'(\theta)]^2 - [R+\eta(\theta)]\eta''(\theta) + [R+\eta(\theta)]^2}{\{[R+\eta(\theta)]^2 + [\eta'(\theta)]^2\}^{\frac{3}{2}}},$$

and the outward normal derivative can be expressed as

$$\frac{\partial}{\partial\nu} = \frac{R+\eta(\theta)}{\{[R+\eta(\theta)]^2 + [\eta'(\theta)]^2\}^{\frac{1}{2}}}\left\{\frac{\partial}{\partial r} - \frac{\eta'(\theta)}{[R+\eta(\theta)]^2}\frac{\partial}{\partial\theta}\right\}.$$

Finally, shrinking $\mathcal{M}$ we may assume that $\max|\eta| \le R/(C_0 - 1)$ for all $\eta \in \mathcal{M}$. Using these notations, we prove the following properties of the operators A and B appearing in (4.10).

LEMMA 5.2. *For any integers $m \ge 2$, $l \ge 1$, and any $0 \le \mu < 1$ we have*

$$A \in C^\infty(C^{m+\mu}_{2\pi,l,0} \cap \mathcal{M}, C^{m+\mu}_{2\pi,l,0}) \cap C^\infty(C^{m+\mu}_{2\pi,l} \cap \mathcal{M}, C^{m+\mu}_{2\pi,l}),$$

$$B \in C^\infty(C^{m+\mu}_{2\pi,l,0} \cap \mathcal{M}, C^{m+\mu-2}_{2\pi,l,0}) \cap C^\infty(C^{m+\mu}_{2\pi,l} \cap \mathcal{M}, C^{m+\mu-2}_{2\pi,l}).$$

Proof. The assertion for B is an immediate consequence of Lemma 5.1. In what follows we give the proof of the assertion for A.

We first prove that A maps $C^{m+\mu}_{2\pi,l,0} \cap \mathcal{M}$ into $C^{m+\mu}_{2\pi,l,0}$. Given $\eta \in C^{m+\mu}_{2\pi,l,0} \cap \mathcal{M}$, there exists a sequence $\{\eta_j\}_{j=1}^\infty \subseteq C^\infty_{2\pi,l,0} \cap \mathcal{M}$ such that $\eta_j \to \eta$ in $C^{m+\mu}_{2\pi}$. By the continuity of $A:\ \mathcal{M} \to C^{m+\mu}_{2\pi}$, we have $A(\eta_j) \to A(\eta)$ in $C^{m+\mu}_{2\pi}$. If we can prove that $A(\eta_j) \in C^\infty_{2\pi,l,0}$, then $A(\eta) \in C^{m+\mu}_{2\pi,l,0}$ by definition of $C^{m+\mu}_{2\pi,l,0}$. Hence it suffices to prove that if $\eta \in C^\infty_{2\pi,l,0} \cap \mathcal{M}$, then $A(\eta) \in C^\infty_{2\pi,l,0}$. Let $\eta \in C^\infty_{2\pi,l,0} \cap \mathcal{M}$ and set $u = A_1(\eta)$, i.e., u is the unique solution of (4.4) and (4.5). Since $\eta \in C^\infty_{2\pi}$, we have that $u \in C^\infty(\overline{B}_R) \subseteq C^\infty([0,R], C^\infty_{2\pi}(\mathbb{R}))$. Consequently, $u(r,\theta)$ has the Fourier expansion

$$u(r,\theta) = a_0(r) + \sum_{k=1}^\infty [a_k(r)\cos(k\theta) + b_k(r)\sin(k\theta)],$$

with coefficients satisfying the following conditions: $a_0, a_k, b_k \in C^\infty[0,R]$ $(k \ge 1)$, and for any integer $m \ge 0$ and any $N > 0$ there exists a constant $C_{m,N} > 0$ such that

$$|a_k^{(m)}(r)| + |b_k^{(m)}(r)| \le C_{m,N}(1+k)^{-N}, \quad r \in [0,R], \quad k = 1, 2, \ldots .$$

We now prove that all b_k's are zero, and if k is not proportional to l, then a_k is also zero. To this end we let $H^1_{2\pi}$ be the usual $H^1(\mathbb{R})$ Sobolev spaces of 2π-periodic functions on $\mathbb{R}$. We also write $H^1_{2\pi,l,0}$ and $H^1_{2\pi,l,0}$, respectively, for the closed subspaces of $H^1_{2\pi}$ consisting of all functions having the Fourier expansions

$$\zeta(\theta) = a_0 + \sum_{k=1}^\infty a_{kl}\cos(kl\theta) \qquad \text{and} \qquad \zeta(\theta) = \sum_{k=1}^\infty b_{kl}\sin(kl\theta),$$

respectively, and let $H^1_{2\pi,l} = H^1_{2\pi,l,0} \oplus H^1_{2\pi,l,1}$. Then, clearly,

$$H^1_{2\pi} = H^1_{2\pi,l,0} \oplus H^1_{2\pi,l,1} \oplus (H^1_{2\pi,l})^{\perp}.$$

Next, we introduce an analogous splitting of the usual Sobolev space $H^1(B_R)$. Let $H^1_{l,0}(B_R)$ and $H^1_{l,1}(B_R)$ be the closed subspaces of $H^1(B_R)$ defined by

$$H^1_{l,0}(B_R) = \left\{ w \in H^1(B_R) : \ w(r,\theta) = a_0(r) + \sum_{k=1}^{\infty} a_{kl}(r)\cos(kl\theta) \right\}$$

and

$$H^1_{l,1}(B_R) = \left\{ w \in H^1(B_R) : \ w(r,\theta) = \sum_{k=1}^{\infty} b_{kl}(r)\cos(kl\theta) \right\},$$

respectively, and set $H^1_l(B_R) = H^1_{l,0}(B_R) \oplus H^1_{l,1}(B_R)$. Then, clearly,

$$H^1(B_R) = H^1_{l,0}(B_R) \oplus H^1_{l,1}(B_R) \oplus (H^1_l(B_R))^{\perp}.$$

Given $\eta \in C^{\infty}_{2\pi,l,0} \cap \mathcal{M}$, let Ψ_η be the Hanzawa transformation introduced in section 4, and define

$$\Lambda_\eta = (\Psi_\eta)_* \circ \nabla \circ \Psi^*_\eta.$$

Further, let f_1 be an antiderivative of f, i.e., $f_1' = f$. Without loss of generality, we may assume that f is asymptotically linear at infinity, because the solution of (4.4) and (4.5) satisfies $0 < u \leq \bar{\sigma}$, so that changing values of f in the interval $(\bar{\sigma}, \infty)$ without changing its monotonicity and smoothness does not change the solution. We now consider the functional I on $H^1_{l,0}(B_R) \cap H^1_0(B_R)$ defined by

$$I(w) = \frac{1}{2}\int_{B_R} |\Lambda_\eta w(y)|^2 J_\eta(y)dy + \int_{B_R} f_1(\bar{\sigma} + w(y))J_\eta(y)dy.$$

Using a standard argument, we can easily prove that I has a local minimum in $H^1_{l,0}(B_R) \cap H^1_0(B_R)$, which we denote by u_0. Since both η and f are smooth, we actually have $u_0 \in C^\infty(\overline{B}_R) \cap C^\infty([0,R], C^\infty_{2\pi,l,0})$. In what follows we prove that $u = \bar{\sigma} + u_0$.

First, since u_0 is the minimum point of I, we have

$$0 = I'(u_0)w = \int_{B_R} \Lambda_\eta u_0(y) \cdot \Lambda_\eta w(y) J_\eta(y)dy + \int_{B_R} f(\bar{\sigma} + u_0(y))w(y)J_\eta(y)dy \tag{5.1}$$

for any $w \in H^1_{l,0}(B_R) \cap H^1_0(B_R)$. Next, we set $\rho = |y|$ and write $r = r(\rho, \eta)$ for the inverse function of

$$\rho = r - \eta\phi\left(\frac{r}{R+\eta}\right)$$

for any fixed $|\eta| < R/(C_0 - 1)$. Then a simple computation shows that

$$J_\eta(y) = \frac{r(\rho,\eta(\theta))}{\rho}\frac{\partial r(\rho,\eta(\theta))}{\partial\rho}. \tag{5.2}$$

This expression, Lemma 5.1, and $\eta \in C^\infty_{2\pi,l,0} \cap M(R, C_0)$ show that $J_\eta \in C^\infty(\overline{B}_R) \cap C^\infty([0,R], C^\infty_{2\pi,l,0})$. Note that $u_0 \in C^\infty(\overline{B}_R) \cap C^\infty([0,R], C^\infty_{2\pi,l,0})$ and Lemma 5.1 also imply that $f(\bar\sigma + u_0(y)) \in C^\infty(\overline{B}_R) \cap C^\infty([0,R], C^\infty_{2\pi,l,0})$. Hence we conclude that $f(\bar\sigma + u_0(y))J_\eta(y) \in C^\infty(\overline{B}_R) \cap C^\infty([0,R], C^\infty_{2\pi,l,0}) \subseteq H^1_{l,0}(B_R)$. Therefore, given any $v \in H^1_{l,1}(B_R) \oplus (H^1_l(B_R))^\perp = (H^1_{l,0}(B_R))^\perp$, we have

$$\int_{B_R} f(\bar\sigma + u_0(y))v(y)J_\eta(y)dy = 0. \tag{5.3}$$

Finally, denoting

$$a(\rho,\eta) = 1 - \frac{\eta}{R+\eta}\phi'\Big(\frac{r}{R+\eta}\Big) \quad \text{and} \quad b(\rho,\eta) = \frac{\eta}{(R+\eta)^2}\phi'\Big(\frac{r}{R+\eta}\Big) - \phi\Big(\frac{r}{R+\eta}\Big),$$

a simple computation shows that

$$\begin{aligned} \Lambda_\eta u_0(y)\cdot\Lambda_\eta v(y) = \quad & \left[a^2(\rho,\eta) + \frac{b^2(\rho,\eta)}{r^2(\rho,\eta)}(\eta')^2\right]\frac{\partial u_0}{\partial\rho}\frac{\partial v}{\partial\rho} \\ & + \frac{b(\rho,\eta)}{r^2(\rho,\eta)}\left[\frac{\partial u_0}{\partial\rho}\frac{\partial v}{\partial\theta}\eta' + \frac{\partial v}{\partial\rho}\frac{\partial u_0}{\partial\theta}\eta'\right] + \frac{1}{r^2(\rho,\eta)}\frac{\partial u_0}{\partial\theta}\frac{\partial v}{\partial\theta}. \end{aligned} \tag{5.4}$$

From (5.2), (5.4), and a similar argument as above, we can easily deduce that

$$\int_{B_R} \Lambda_\eta u_0(y)\cdot\Lambda_\eta v(y)J_\eta(y)dy = 0 \tag{5.5}$$

for any $v \in H^1_{l,1}(B_R) \oplus (H^1_l(B_R))^\perp = (H^1_{l,0}(B_R))^\perp$. Invoking (5.1), (5.3), and (5.5), we conclude that

$$\int_{B_R} \Lambda_\eta u_0(y)\cdot\Lambda_\eta v(y)J_\eta(y)dy + \int_{B_R} f(\bar\sigma + u_0(y))v(y)J_\eta(y)dy = 0$$

for any $v \in H^1_0(B_R)$. This shows that if we use the same formula to redefine I as a functional on the larger space $H^1_0(B_R)$, then u_0 is also a critical point of this functional; see (5.1). But it is well known that the Euler–Lagrange equations of the variational problem of this redefined functional I are given by (4.4) and (4.5). Hence, $\bar\sigma + u_0$ is a solution of (4.4) and (4.5). By uniqueness, we conclude that $u = \bar\sigma + u_0$, so that $u \in C^\infty(\overline{B}_R) \cap C^\infty([0,R], C^\infty_{2\pi,l,0})$.

Now, substituting $u = A_1(\eta)$ into (4.6) and using a similar argument, we deduce that $v = A_2(\eta) \in C^\infty(\overline{B}_R) \cap C^\infty([0,R], C^\infty_{2\pi,l,0})$. This readily implies that $A(\eta) \in C^\infty_{2\pi,l,0}$, as desired.

A similar argument shows that A also maps $C^{m+\mu}_{2\pi,l} \cap \mathcal{M}$ into $C^{m+\mu}_{2\pi,l}$, so that the proof is completed. ∎

Let $\mathcal{M}_{l,0} = C^{m+\mu}_{2\pi,l,0} \cap \mathcal{M}$. It is not difficult to see that $\mathcal{M}_{l,0}$ is a smooth submanifold of $C^{m+\mu}_{2\pi,l,0}$ of codimension 1. We denote by $A_{l,0}$ and $B_{l,0}$ the restrictions of A and B to $\mathcal{M}_{l,0}$ and study the abstract problem

$$A_{l,0}(\eta) + \tilde c = \gamma B_{l,0}(\eta). \tag{5.6}$$

Clearly, (5.6) is not equivalent to (4.10), but any solution of (5.6) is of course a solution of (4.10).

Given $\varepsilon > 0$, let

$$\mathcal{N}_{l,0,\varepsilon} = \{\overline{\eta} \in C^{m+\mu}_{2\pi,l,0} \;:\; \overline{\eta} = \eta + c,\, \Phi_{l,0}(\eta) = 0,\, \|\eta\|_{C^{m+\mu}_{2\pi,l,0}(\mathbb{R})} < \varepsilon,\, c \in \mathbb{R},\, |c| < \varepsilon\}.$$

Then it is not difficult to see that the mapping $(\eta, c) \mapsto \eta + c$ is a C^∞-diffeomorphism from $\mathcal{M}_{l,0} \times (-\varepsilon, \varepsilon)$ onto $\mathcal{N}_{l,0,\varepsilon}$.

We define mappings $\overline{A}(\cdot, \gamma) : \mathcal{N}_{l,0,\varepsilon} \to C^{m+\mu}_{2\pi,l,0}$ and $\overline{B} : \mathcal{N}_{l,0,\varepsilon} \to C^{m+\mu-2}_{2\pi,l,0}$ by

$$\overline{A}(\overline{\eta}, \gamma) = A_{l,0}(\eta) + c + c_\gamma - \frac{c\gamma}{R^2}, \qquad \overline{B}(\overline{\eta}) = B_{l,0}(\eta) - \frac{c}{R^2},$$

where c_γ is as in section 4 and $\bar{\eta} = \eta + c \in \mathcal{N}_{l,0,\varepsilon}$. These mappings allow a reduction of the system (5.6) to

$$\overline{A}(\overline{\eta}, \gamma) = \gamma \overline{B}(\overline{\eta}), \tag{5.7}$$

with $\tilde{c} = c + c_\gamma$. Observe that

$$\overline{B}'(0)\overline{\eta} = B'_{l,0}(0)\eta - \frac{c}{R^2} = -\frac{1}{R^2}(\eta'' + \eta) - \frac{c}{R^2} = -\frac{1}{R^2}(\overline{\eta}'' + \overline{\eta}).$$

Since $l \geq 2$ the operator $\overline{\eta} \to \overline{\eta}'' + \overline{\eta}$ is an isomorphism mapping $C^{m+\mu}_{2\pi,l,0}$ onto $C^{m-2+\mu}_{2\pi,l,0}$, so that $\overline{B}'(0)$ is also is an isomorphism as well. We now define the mapping $F : C^{m-2+\mu}_{2\pi,l,0} \times (0,\infty) \to C^{m-2+\mu}_{2\pi,l,0}$ by

$$F(\xi, \gamma) = \overline{A}(\overline{B}'(0)^{-1}\xi, \gamma) - \gamma \overline{B}(\overline{B}'(0)^{-1}\xi), \quad \xi \in C^{m-2+\mu}_{2\pi,l,0}, \;\; \gamma > 0.$$

Setting $\overline{\eta} = \overline{B}'(0)^{-1}\xi$, (5.7) is equivalent to

$$F(\xi, \gamma) = 0. \tag{5.8}$$

Clearly, $F \in C^\infty(C^{m-2+\mu}_{2\pi,l,0} \times (0,\infty), C^{m-2+\mu}_{2\pi,l,0})$ and

$$F(0, \gamma) = 0, \quad D_\xi F(0, \gamma)\xi = K(\gamma)\xi - \gamma\xi,$$

where

$$K(\gamma)\xi = D_{\overline{\eta}}\overline{A}(0, \gamma)\overline{B}'(0)^{-1}\xi, \quad \xi \in C^{m-2+\mu}_{2\pi,l,0}.$$

Obviously, the operator $K(\gamma) \colon C^{m-2+\mu}_{2\pi,l,0} \to C^{m-2+\mu}_{2\pi,l,0}$ is compact, so that $D_\xi F(0, \gamma)$ is a Fredholm operator of index zero on $C^{m-2+\mu}_{2\pi,l,0}$. We claim that

$$\dim \mathrm{Ker} D_\xi F(0, \gamma) = 1 \quad \text{if } \; \gamma = \gamma_l. \tag{5.9}$$

Indeed, using the variable transformation $\xi = \overline{B}'(0)\overline{\eta}$, we see that $D_\xi F(0, \gamma)\xi = 0$ is equivalent to $D_{\overline{\eta}}\overline{A}(0, \gamma)\overline{\eta} = \gamma \overline{B}'(0)\overline{\eta}$. Letting $\overline{\eta} = \eta + c$ as before, this equation is equivalent to

$$A'_{l,0}(0)\eta + c = \gamma B'_{l,0}(0)\eta. \tag{5.10}$$

It follows from the discussion in section 3, in particular from Lemma 3.2, that, if $\gamma = \gamma_l$ with $l \geq k^*$, then (5.10) has nontrivial solutions, given by $\overline{\eta} = C(\cos(l\theta) + c_l)$, with $C \in \mathbb{R}$ and where c_l is a real constant uniquely determined by l. This proves

(5.9). Moreover, letting $\xi_k := \overline{B}'(0)(\cos(k\theta) + c_k)$ for $k \in \mathbb{N}$, the deduction in section 3 also yields

$$D_\xi F(0,\gamma_l)\xi_k = \frac{(\gamma_k - \gamma_l)}{R^2} k^2 \cos(k\theta), \quad k \in \mathbb{N}.$$

Furthermore, a direct calculation shows that

$$D_\gamma D_\xi F(0,\gamma_l)\xi_l = \frac{\gamma_l}{R^2}(1 - l^2)\cos(l\theta).$$

Hence we conclude that

$$\mathbb{R} \cdot D_\gamma D_\xi F(0,\gamma_l)\xi_l \oplus \operatorname{im} D_\xi F(0,\gamma_l) = C^{m-2+\mu}_{2\pi,l,0}.$$

This observation implies the nondegeneration condition in the Crandall–Rabinowitz theorem on bifurcation from simple eigenvalues; cf. [4]. From the latter result we conclude that $(\xi,\gamma) = (0,\gamma_l)$ is a bifurcation point for (5.8). The corresponding bifurcation branch of solutions is of the form

$$\xi = \frac{\varepsilon(l^2 - 1)}{R^2}\cos(l\theta) + O(\varepsilon^2), \quad \gamma = \gamma_l + O(|\varepsilon|)$$

for a small real parameter ε. Returning to the original problem, we get the result stated in Theorem 1.1 in the case $n = 2$.

5.2. The case $n \geq 3$. Let us briefly indicate how the general n-dimensional case can be treated. In polar coordinates the Laplacian Δ on $\mathbb{R}^n$ is given by

$$\Delta u = \frac{1}{r^{n-1}}\frac{\partial}{\partial r}\Big(r^{n-1}\frac{\partial u}{\partial r}\Big) + \frac{1}{r^2}\Delta_\omega u,$$

where Δ_ω represents the Laplace–Beltrami operator on $\mathbb{S}^{n-1}$. In the following, we identify a point $\omega = (\omega_1, \omega_2, \ldots, \omega_{n-1}, \omega_n)$ on $\mathbb{S}^{n-1}$ with

$$(\theta_1, \theta_2, \ldots, \theta_{n-2}, \theta_{n-1}) \in [0,\pi] \times [0,\pi] \times \cdots [0,\pi] \times [0,2\pi)$$

via the spherical coordinates

$$\begin{cases} \omega_1 = \cos\theta_1, \\ \omega_2 = \sin\theta_1 \cos\theta_2, \\ \vdots \\ \omega_{n-1} = \sin\theta_1 \sin\theta_2 \cdots \sin\theta_{n-2}\cos\theta_{n-1}, \\ \omega_n = \sin\theta_1 \sin\theta_2 \cdots \sin\theta_{n-2}\sin\theta_{n-1}. \end{cases}$$

Let $\xi = (\xi_1, \xi_2, \ldots, \xi_{n-1})$ be the point on $\mathbb{S}^{n-2}$ related to ω, i.e.,

$$\omega_2 = \xi_1 \sin\theta_1, \;\; \omega_3 = \xi_2 \sin\theta_1, \ldots, \omega_n = \xi_{n-1}\sin\theta_1,$$

and denote by Δ_ξ the Laplace–Beltrami operator on $\mathbb{S}^{n-2}$. Then

$$\Delta_\omega = \frac{1}{\sin^{n-2}\theta_1}\frac{\partial}{\partial\theta_1}\Big(\sin^{n-2}\theta_1 \frac{\partial u}{\partial\theta_1}\Big) + \frac{1}{\sin^2\theta_1}\Delta_\xi u. \tag{5.11}$$

To reduce the notation we omit the subscript of θ_1 and simply write θ.

Given a closed surface in the form $r = R + \eta(\theta)$, where R is a positive constant and $\eta \in C^2[0,\pi]$ with $\eta'(0) = \eta'(\pi) = 0$, the mean curvature of this surface is given by

$$\kappa = \frac{1}{n-1}\left\{\frac{(n-1)[R+\eta(\theta)]^2 + n[\eta'(\theta)]^2 - [R+\eta(\theta)]\eta''(\theta)}{\{[R+\eta(\theta)]^2+[\eta'(\theta)]^2\}^{\frac{3}{2}}} - \frac{(n-2)\eta'(\theta)\cot\theta}{[R+\eta(\theta)]\{[R+\eta(\theta)]^2+[\eta'(\theta)]^2\}^{\frac{1}{2}}}\right\}.$$

Now let $Z_k^n(\omega)$ denote the zonal spherical harmonics of degree k with pole $e = (1,0,\dots,0)$, i.e.,

$$Z_k^n(\omega) = c_{nk}C_k^{\frac{n}{2}-1}(\omega\cdot e) = c_{nk}C_k^{\frac{n}{2}-1}(\cos\theta),$$

where C_k^λ represents the ultraspherical (or Gegenbauer) polynomial of degree k and index λ, i.e.,

$$C_0^\lambda(t) = 1, \quad C_k^\lambda(t) = \frac{1}{\Gamma(\lambda)}\sum_{j=0}^{\left[\frac{k}{2}\right]}(-1)^j\frac{\Gamma(\lambda+k-j)}{j!(k-2j)!}(2t)^{k-2j} \quad (k\ge 1),$$

and c_{nk} is the normalization factor. Using (6.18) and

$$(1-t^2)(C_k^\lambda(t))'' - (n-1)t(C_k^\lambda(t))' + k(k+n-2)C_k^\lambda(t) = 0,$$

one can easily verify that $Z_k^{(n)}(\theta)$ satisfies

$$\Delta_\omega Z_k^n(\omega) = -k(k+n-2)Z_k^n(\omega).$$

We next introduce

$$P_{zon}(\mathbb{S}^{n-1}) = \text{the span of } \{Z_k^n(\omega),\, k = 0,1,2,\dots\},$$

and for any nonnegative integer m and any $0\le\mu<1$ we define

$$C_{zon}^{m+\mu}(\mathbb{S}^{n-1}) = \text{the closure of } P_{zon}(\mathbb{S}^{n-1}) \text{ in } C^{m+\mu}(\mathbb{S}^{n-1}).$$

A significant difference between the cases $n\ge 3$ and $n = 2$ is that in the latter the closure of the linear space spanned by all $Z_{kl}^2(\theta) = \cos(kl\theta)$, $k = 0,1,2,\dots$, in $C^{m+\mu}(\mathbb{S}^1)$ is an algebra for any $l\ge 2$. In the case $n\ge 3$ this is not true for $l\ge 3$. However, we have the following result. We omit the details of the proof.

Lemma 5.3. *The following assertions hold:*

(1) *If* $\eta\in C_{zon}^{m+\mu}(\mathbb{S}^{n-1})$, *then* $\frac{\partial^2\eta}{\partial\theta^2}\in C_{zon}^{m-2+\mu}(\mathbb{S}^{n-1})$ *for* $m\ge 2$.
(2) *If* $\eta\in C_{zon}^{m+\mu}(\mathbb{S}^{n-1})$, *then* $\frac{\partial\eta}{\partial\theta}\cot\theta\in C_{zon}^{m-2+\mu}(\mathbb{S}^{n-1})$ *for* $m\ge 2$.
(3) *If* η_1, $\eta_2\in C_{zon}^{m+\mu}(\mathbb{S}^{n-1})$, *then* $\eta_1\eta_2\in C_{zon}^{m+\mu}(\mathbb{S}^{n-1})$.
(4) *If* η_1, $\eta_2\in C_{zon}^{m+\mu}(\mathbb{S}^{n-1})$, *then* $\frac{\partial\eta_1}{\partial\theta}\frac{\partial\eta_2}{\partial\theta}\in C_{zon}^{m-1+\mu}(\mathbb{S}^{n-1})$ *for* $m\ge 1$.
(5) *If* $\eta\in C_{zon}^{m+\mu}(\mathbb{S}^{n-1})$, *then* $f\circ\eta\in C_{zon}^{m+\mu}(\mathbb{S}^{n-1})$ *for any* $f\in C^\infty(R)$.

Based on Lemma 5.3 one can show the following analogue to Lemma 5.2.

Lemma 5.4. *Let* A, B *be the operators defined in section* 4. *For any integer* $m\ge 2$ *and any* $0\le\mu<1$, *we have the following assertions:*

$$A\in C^\infty(C_{zon}^{m+\mu}(\mathbb{S}^{n-1})\cap\mathcal{M}, C_{zon}^{m+\mu}(\mathbb{S}^{n-1})),$$

$$B \in C^\infty(C_{zon}^{m+\mu}(\mathbb{S}^{n-1}) \cap M(R, C_0), C_{zon}^{m+\mu-2}(\mathbb{S}^{n-1})).$$

Due to Lemma 5.4, we can now slightly modify the deduction in section 5.1 to prove that every γ_k with $k \geq k^*$ is a bifurcation point. Indeed, in the present case we have to replace the space $C_{2\pi,l,0}^{m+\mu}$ by the space $C_{zon}^{m+\mu}(\mathbb{S}^{n-1})$. Since for every $k \geq k^*$ the kernel in $C_{zon}^{m+\mu}(\mathbb{S}^{n-1}) \cap C_2^{m+\mu}(\mathbb{S}^{n-1})$ of the operator $(\eta, c) \mapsto A'(0)\eta + c - \gamma_k B'(0)\eta$ is given by $\mathbb{R} \cdot (\cos(k\theta), c_k)$, we get the result after a Lyapunov–Schmidt reduction. We omit the details.

Acknowledgments. We are grateful to the anonymous referees for helpful suggestions.

HOMOGENIZATION IN VISCOPLASTICITY*

SERGIY NESENENKO†

Abstract. In this work we present the justification of the formally derived homogenized problem for the quasi-static initial boundary value problem with internal variables, which models the deformation behavior of viscoplastic materials with a periodic microstructure.

Key words. homogenization, plasticity, viscoplasticity, two-scale convergence, maximal monotone operator, microstructure

AMS subject classifications. 74Q15, 74C05, 74C10, 74D10, 35J25, 34G20, 34G25, 47H04, 47H05

DOI. 10.1137/060655092

1. Introduction and statement of results. During the last few decades, the rigorous mathematical investigation of homogenization has brought appreciable success in determining the macroscopic behavior from the knowledge of the microstructure in many problems from different sciences. Among them are problems from the linear and nonlinear theory of elasticity, linear viscoelasticity and electrodynamics, hydrodynamics, and porous media; see, for example, [5], [7], [9], [10], [19], [22], [23], [24], [25], [28], [29], [31]. The only rigorous results of homogenization related to problems from the theory of plasticity or viscoplasticity known to the author are [4] and [17]. This is in contrast to the importance of homogenization in solid mechanics. This circumstance motivated the further study of these problems.

In this work I deal with the homogenization of the initial boundary value problem describing the deformation behavior of inelastic materials with a periodic microstructure, in particular for plastic and viscoplastic materials. The formulation of the problem is based on the assumption that only small strains occur: Let Ω be an open bounded set, the set of material points of the body, with C^1-boundary $\partial\Omega$. T_e denotes a positive number (time of existence) and for $0 \leq t \leq T_e$

$$\Omega_t = \Omega \times (0,t).$$

Let $\mathcal{S}^3$ denote the set of symmetric 3×3 matrices, and let $u(x,t) \in \mathbb{R}^3$ be the unknown displacement of the material point x at time t; $T(x,t) \in \mathcal{S}^3$ is the unknown Cauchy stress tensor, and $z(x,t) \in \mathbb{R}^N$ denotes the unknown vector of internal variables. The model equations of the problem (a microscopic problem) are

$$-\mathrm{div}_x T(x,t) = b(x,t), \tag{1}$$

$$T(x,t) = \mathcal{D}\left[\frac{x}{\eta}\right](\varepsilon(\nabla_x u(x,t)) - Bz(x,t)), \tag{2}$$

$$\begin{aligned} \frac{\partial}{\partial t} z(x,t) &\in g\left(\frac{x}{\eta}, -\nabla_z \psi\left(\frac{x}{\eta}, \varepsilon(\nabla_x u(x,t)), z(x,t)\right)\right) \\ &= g\left(\frac{x}{\eta}, B^T T(x,t) - L\left[\frac{x}{\eta}\right] z(x,t)\right), \end{aligned} \tag{3}$$

which must hold for $x \in \Omega$ and $t \in [0, \infty)$. The initial value for $z(x,t)$ is taken in the form

$$z(x,0) = z^{(0)}\left(x, \frac{x}{\eta}\right), \tag{4}$$

which must hold for $x \in \Omega$. We consider the Dirichlet boundary condition

$$u(x,t) = \gamma(x,t), \tag{5}$$

which must be satisfied for $(x,t) \in \partial\Omega \times [0, \infty)$.

Here

$$\varepsilon(\nabla_x u(x,t)) = \frac{1}{2}(\nabla_x u(x,t) + (\nabla_x u(x,t))^T) \in \mathcal{S}^3$$

is the strain tensor, and $B : \mathbb{R}^N \to \mathcal{S}^3$ is a linear mapping, which assigns to the vector $z(x,t)$ the plastic strain tensor $\varepsilon_p(x,t) = Bz(x,t)$. For every $y \in \mathbb{R}^3$ we denote by $\mathcal{D}[y] : \mathcal{S}^3 \to \mathcal{S}^3$ a linear, symmetric, positive definite mapping, the elasticity tensor. The mapping $y \to \mathcal{D}[y]$ is assumed to be measurable and periodic with a periodicity cell $Y \subset \mathbb{R}^3$. Suppose that there exist two positive constants $0 < \alpha \leq \beta$ satisfying

$$\alpha|\xi|^2 \leq \mathcal{D}_{ijkl}[y]\xi_{kl}\xi_{ij} \leq \beta|\xi|^2 \quad \text{for any } \xi \in \mathcal{S}^3.$$

The function $b : \Omega \times [0, \infty) \to \mathbb{R}^3$ is the volume force, and $z^{(0)} : \Omega \times \mathbb{R}^3 \to \mathbb{R}^N$ is the initial value of the vector of internal variables, periodic in y with the same periodicity cell Y. The positive semidefinite quadratic form

$$\psi(y, \varepsilon, z) = \frac{1}{2}\mathcal{D}[y](\varepsilon - Bz) \cdot (\varepsilon - Bz) + \frac{1}{2}(L[y]z) \cdot z \tag{6}$$

represents the free energy (see [1, Appendix]), and for all $y \in \mathbb{R}^3$ the function $z \to g(y,z) : \mathbb{R}^N \to 2^{\mathbb{R}^N}$ is monotone satisfying $0 \in g(y,0)$; $y \to g(y,z)$ is periodic with the periodicity cell $Y \subset \mathbb{R}^3$. The positive semidefinite $N \times N$ matrix $L[y]$ is measurable and periodic with the same periodicity cell Y.

A function $g : D(g) \subseteq \mathbb{R}^N \mapsto 2^{\mathbb{R}^N}$ is called *monotone* if

$$(z_1 - z_2, y_1 - y_2) \geq 0$$

for any $y_i \in g(z_i)$ and any $z_i \in D(g),\ i = 1, 2$. A monotone function is said to be *maximal monotone* if it has no monotone extension. In other words, g is *maximal monotone* if and only if the inequality

$$(z_1 - z_2, y_1 - y_2) \geq 0 \quad \forall\, y_1 \in g(z_1)$$

implies $y_2 \in g(z_2)$.

The number $\eta > 0$ is the scaling parameter of the microstructure.

The differential inclusion (3) with the given function g and (2) together define the material behavior. They are the constitutive relations which model the inelastic response of the body, whereas (1) is the conservation law of linear momentum. The differential inclusion (3) is called a constitutive relation (or equation) of monotone type which was first introduced in [1]. The class of constitutive relations of monotone type naturally generalizes the class of constitutive relations of generalized standard materials defined by B. Halphen and N. Q. Son, because in the last case the function

g is the gradient or the subdifferential of a convex function. For examples of models from engineering, and for the study of whether they are of monotone type, we refer the reader to [1]. It must be said here that the classical models like the Prandtl–Reuss and the Norton–Hoff laws belong to the class of constitutive equations of monotone type. However, this class is still too small to include all models used in engineering. Namely, most models describing the deformation behavior of inelastic bodies with infinitesimal strains can be written in the form (3), but often the function g is not monotone.[1]

The existence and uniqueness theory for (1)–(3) is well understood under additional assumptions: If the free energy is not only positive semidefinite but positive definite (equivalently, if the $N \times N$ matrix L is positive definite), and, additionally, if the mapping $z \to g(y, z)$ is maximal monotone for all $y \in \mathbb{R}^3$, then the initial boundary value problem has a unique solution denoted by (u_η, T_η, z_η); see [3] or [1]. We want to point out that in many cases the free energy is not positive definite but positive semidefinite. For example, the Prandtl–Reuss and Norton–Hoff laws are constitutive equations with positive semidefinite free energy, whereas models with linear hardening have positive definite free energy. For problems with semidefinite free energy, to the author's knowledge there have been no general existence results until now. But for some models with a particular choice of the function g the existence and uniqueness theory is already available; see, for example, [15], [14], [13], [30], and the literature cited there concerning this side of the investigation.

To study the asymptotic behavior of (u_η, T_η, z_η) as η tends to 0 we postulate that this function is close to the function $(\hat{u}_\eta, \hat{T}_\eta, \hat{z}_\eta)$ defined by

$$\begin{aligned}
\hat{u}_\eta(x,t) &= u_0(x,t) + \eta u_1\left(x, \frac{x}{\eta}, t\right), \\
\hat{T}_\eta(x,t) &= T_0\left(x, \frac{x}{\eta}, t\right), \\
\hat{z}_\eta(x,t) &= z_0\left(x, \frac{x}{\eta}, t\right),
\end{aligned}$$

where (u_0, u_1, T_0, z_0) solves the homogenized initial boundary value problem (see [2]):

$$-\mathrm{div}_x T_\infty(x,t) = b(x,t), \tag{7}$$

$$T_\infty(x,t) = \frac{1}{|Y|}\int_Y T_0(x,y,t)dy, \tag{8}$$

$$-\mathrm{div}_y T_0(x,y,t) = 0, \tag{9}$$

$$\begin{aligned} T_0(x,y,t) = \mathcal{D}[y](\varepsilon(\nabla_y u_1(x,y,t)) &- Bz_0(x,y,t) \\ &+\varepsilon(\nabla_x u_0(x,t))), \end{aligned} \tag{10}$$

$$\frac{\partial}{\partial t} z_0(x,y,t) \in g(y, B^T T_0(x,y,t) - L[y] z_0(x,y,t)), \tag{11}$$

$$z_0(x,y,0) = z_0^{(0)}(x,y), \tag{12}$$

[1]To the author's knowledge all models proposed in engineering sciences belong to the problems of premonotone type. The problem (1)–(3) is of a premonotone type if the multifunction g in (3) satisfies the inequality

$$\forall\ z \in D(g),\ \forall\ z^* \in g(z) \quad z^* \cdot z \geq 0.$$

which must hold for $(x, y, t) \in \Omega \times Y \times [0, \infty)$,

$$u_0(x,t) = \gamma(x,t), \quad (x,t) \in \partial\Omega \times [0,\infty). \tag{13}$$

Note. For fixed x, (9)–(12) together with the periodicity assumption on $y \mapsto (u_1, T_0)(x, y, t)$, which can be considered to be a boundary condition, define an initial boundary problem, the cell problem, in $Y \times [0, \infty)$. u_0, u_1 can be interpreted as macro- and microdisplacement, T_0 as a microstress; the macrostress T_∞ is obtained by averaging of T_0 over the representative volume element. In Theorem 2 in [4] it was shown that under some additional assumptions on the function g the homogenized initial boundary value problem (7)–(13) has a unique solution,

$$(u_0, u_1, T_\infty) \in L^2(0, T_e; H^1(\Omega, \mathbb{R}^3)) \times L^2(\Omega_{T_e}, H^1(Y, \mathbb{R}^3)) \times L^2(\Omega_{T_e}, \mathcal{S}^3)$$

$$(T_0, z_0) \in L^2((\Omega \times Y)_{T_e}, \mathcal{S}^3) \times C([0, T_e]; L^2(\Omega \times Y, \mathbb{R}^N)).$$

The main goal of this work is to prove that the solution of the microscopic problem (u_η, T_η, z_η) has as the asymptotics the function $(\hat{u}_\eta, \hat{T}_\eta, \hat{z}_\eta)$. The justification uses methods from the established homogenization theory for linear problems, but several difficulties arise not present in this theory.

First, the existence and uniqueness theory for the homogenized initial boundary value problem as well as the justification procedure are more complicated due to the impossibility of decoupling the homogenized problem (the first equation) and the so-called cell problem (the last three equations with the periodicity assumption, which can be considered as a boundary condition), unlike in linear elasticity, where the homogenized and the cell problem can be decoupled. This difficulty was successfully solved in [4].

Second, difficulties arise which are based on the fact that the solution of the homogenized problem is of low regularity because of the nonlinearity of the constitutive equation. One of the difficulties resulting from the low regularity of the solution of the homogenized problem is that the mapping $x \mapsto (T_0, z_0)(x, x/\eta, t)$ is not well defined because $x \mapsto (x, x/\eta)$ maps Ω onto a three-dimensional subspace of a six-dimensional space $\Omega \times \mathbb{R}^3$.

Indeed, $x \mapsto (x, x/\eta)$ maps Ω onto a three-dimensional subspace of $\Omega \times \mathbb{R}^3$ (see Figure 1) and by virtue of Theorem 5.2.2 in [12] the mapping $x \mapsto (T_0, z_0)(x, x/\eta, t)$ is not well defined. In other words, the function $(T_0, z_0)(t) \in L^2(\Omega \times Y, \mathcal{S}^3) \times L^2(\Omega \times Y, \mathbb{R}^N)$ has no trace on a three-dimensional subspace of a six-dimensional space.

In [4] this difficulty is overcome by imposing higher regularity on the given data in such a way that the solution of the homogenized problem becomes smoother and the existence of the trace for $(T_0(t), z_0(t))$ on the three-dimensional subspace is an easy consequence of this obtained smoothness. The higher regularity of the solution of the homogenized problem plays an essential role in that work also at another place: in order to apply the energy method of Tartar[2] (see [27, 34]) in the justification, the author needs $\partial_t \mathrm{div}_x T_0(x, y, t) \mid_{y=x/\eta}$ and $\partial_t \mathrm{rot}_x \nabla_y u_1(x, y, t) \mid_{y=x/\eta}$ to belong to a compact subset of H^{-1}_{loc}. This is provided by the smoothness of $(T_0, u_1)(x, y, t)$. Unfortunately, one cannot expect that the solution is of this higher regularity globally in time. Instead, after a certain finite time the solution is only of lower regularity. Therefore in [4] the justification of the homogenized problem is only possible locally

[2]It is also called the *oscillating test function method*.

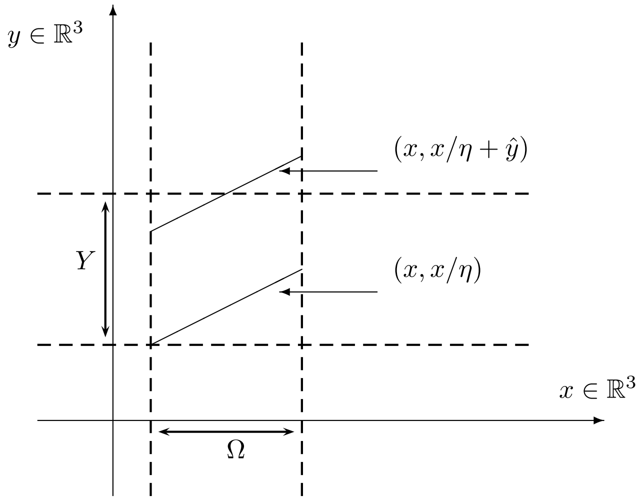

FIG. 1.

in time. In contrast, here we can justify the homogenized problem globally in time without imposing additional smoothness on the data.

To avoid the difficulty with the trace I, follow an idea,[3] proposed in [2], of introducing an additional fast variable y, which is plugged into (1)–(5):

$$-\mathrm{div}_x T(x,y,t) = b(x,t), \tag{14}$$

$$T(x,y,t) = \mathcal{D}\left[\frac{x}{\eta}+y\right](\varepsilon(\nabla_x u(x,y,t)) - Bz(x,y,t)), \tag{15}$$

$$\frac{\partial}{\partial t} z(x,y,t) \in g\left(\frac{x}{\eta}+y, B^T T(x,y,t) - L\left[\frac{x}{\eta}+y\right] z(x,y,t)\right), \tag{16}$$

$$z(x,y,0) = z^{(0)}\left(x, \frac{x}{\eta}+y\right), \tag{17}$$

which hold for $(x,y) \in \Omega \times Y$ and $t \in [0,\infty)$, and of the Dirichlet boundary condition

$$u(x,y,t) = \gamma(x,t), \tag{18}$$

which holds for $(x,y) \in \partial\Omega \times Y$ and $t \in [0,\infty)$. The function $(u_\eta, T_\eta, z_\eta)(x,y,t)$ is periodic in y.

We give the definition of a solution of the initial boundary value problem (14)–(18). $\eta > 0$ is fixed.

DEFINITION 1.1. *Let*

$$(u_\eta, T_\eta, z_\eta) : \Omega \times \mathbb{R}^3 \times \mathbb{R}^+ \mapsto \mathbb{R}^3 \times \mathcal{S}^3 \times \mathbb{R}^N$$

be a function which satisfies the initial condition (17) *for a.e.* $(x,y) \in \Omega \times \mathbb{R}^3$ *and for which the function* $(x,y) \mapsto (u_\eta, T_\eta, z_\eta)(x,y,t)$ *is a solution of* (14)–(18) *for almost*

[3]The idea of considering the family of shifted problems was also used in [16] to show that for some linear and nonlinear problems the averaging over the shifting y eliminates the rapid oscillations in the solution. For details we refer the reader to this work.

all $y \in \mathbb{R}^3$. *Then* (u_η, T_η, z_η) *is called a* family of solutions *of the initial boundary value problem* (14)–(18) *depending on the fast variable* y.

We assume now that for all $0 < \eta < \eta_0$ such a solution family (u_η, T_η, z_η) of the initial boundary value problem depending on the fast variable y exists and is close to

$$\hat{u}_\eta(x, y, t) = u_0(x, t) + \eta u_1 \left(x, \frac{x}{\eta} + y, t \right), \tag{19}$$

$$\hat{T}_\eta(x, y, t) = T_0 \left(x, \frac{x}{\eta} + y, t \right), \tag{20}$$

$$\hat{z}_\eta(x, y, t) = z_0 \left(x, \frac{x}{\eta} + y, t \right). \tag{21}$$

The functions $u_0(x,t), u_1(x,y,t), T_0(x,y,t), z_0(x,y,t)$, which are assumed to be periodic with respect to the y-argument with a periodicity cell $Y \subset \mathbb{R}^3$, solve the problem (7)–(13).

Notation. Banach spaces $W^{m,p}(\Omega, \mathbb{R}^N)$ are endowed with the norm $\| \cdot \|_{m,p,\Omega}$. $H^m(\Omega, \mathbb{R}^N) = W^{m,2}(\Omega, \mathbb{R}^N)$ are Hilbert spaces with the usual scalar product on them and the norm $\| \cdot \|_{m,\Omega}$, $\| \cdot \|_\Omega = \| \cdot \|_{0,\Omega}$.

Define the space

$$W(Y) = \left\{ v \in H^1(Y) \mid \frac{1}{|Y|} \int_Y v(y) dy = 0 \right\},$$

which becomes a Banach space due to the Poincaré–Wirtinger inequality (see [18, Proposition 3.38]) for the norm $\|u\|_{W(Y)} = \|\nabla u\|_Y$.

The symbols $\mathcal{D}_\eta$ and L_η denote the mappings $\mathcal{D}[x/\eta + y]$ and $L[x/\eta + y]$, respectively, i.e., $\mathcal{D}_\eta := \mathcal{D}[x/\eta + y]$, $L_\eta := L[x/\eta + y]$.

Now we can formulate the main result of this work.

THEOREM 1.2. *Let* $T_e > 0$. *Assume that the matrix* $L \in L^\infty(Y, \mathbb{R}^{N \times N})$ *in* (6) *is uniformly positive definite and that the mapping* $g : \mathbb{R}^3 \times \mathbb{R}^N \to 2^{\mathbb{R}^N}$ *satisfies the following three conditions:*

- $0 \in g(y, 0)$ *for almost all* $y \in Y$,
- $z \mapsto g(y, z)$ *is maximal monotone for almost all* $y \in Y$,
- *the mapping* $y \mapsto j_\lambda(y, z) : \mathbb{R}^3 \to \mathbb{R}^N$ *is measurable for all* $\lambda > 0$, *where* $j_\lambda(y, z)$ *is the inverse of* $z \mapsto z + \lambda g(y, z)$.[4]

Suppose that $b \in W^{2,1}(0, T_e; L^2(\Omega, \mathbb{R}^3))$ *and* $\gamma \in W^{2,1}(0, T_e; H^1(\Omega, \mathbb{R}^3))$. *Assume that* $z^{(0)} \in L^2(\Omega \times Y, \mathbb{R}^N)$ *and there exists* $\zeta \in L^2(\Omega \times Y, \mathbb{R}^N)$ *such that*

$$\zeta(x, y) \in g(y, B^T T^{(0)}(x, y) - L[y] z^{(0)}(x, y)) \quad \text{a.e. in } \Omega \times Y,$$

where $(u^{(0)}, T^{(0)})$ *is a weak solution of the problem of linear elasticity theory* (25)–(27) *to the data* $\hat{b} = b(0)$, $\hat{\varepsilon}_p = B z^{(0)}$, $\hat{\gamma} = \gamma(0)$.

Assume further that there exists a positive function $h \in L^2(\Omega \times Y, \mathbb{R}^N)$ *such that the inequality*

$$| \, g_\lambda(x/\eta + y, B^T T^{(0)} - L[x/\eta + y] z^{(0)})| \le C h(x, y) \tag{22}$$

[4]The mapping $z \mapsto j_\lambda(y, z)$ is single valued and well defined, since $z \mapsto g(y, z)$ is assumed to be maximal monotone.

with a constant $C = C(\lambda)$ independent of η holds, where g_λ is the Yosida approximation of g.

Then the solution (u_η, T_η, z_η) of the microscopic problem (14)–(18) with parameter y satisfies for all $0 \le t \le T_e$,

$$\lim_{\eta\to 0}(\|u_0(t) - u_\eta(t)\|_{\Omega\times Y} + \|\hat{T}_\eta(t) - T_\eta(t)\|_{\Omega\times Y} + \|\hat{z}_\eta(t) - z_\eta(t)\|_{\Omega\times Y}) = 0. \tag{23}$$

Note. We note that the inequality (22) is easily satisfied in practice. Let us take, for example, the model of Melan–Prager with the Prandtl–Reuss flow rule, i.e.,

$$g(z) = \partial I_K\left(T - k\left(\frac{\cdot}{\eta}\right)z\right),$$

where $k : \mathbb{R}^3 \to \mathbb{R}^+$ is a material function with $k(y) \ge C > 0$, and I_K is the indicator function of a closed convex set $K = \{\sigma \in \mathcal{S}^3 |\ \sigma^D \cdot \sigma^D \le c\}$ specified by the von Mises yield criterion. Here σ^D is the deviator of σ and $c > 0$ is a given constant. We assume that c is independent of η. Then the Yosida approximation of g is (see [11, p. 46])

$$g_\lambda(z) = \frac{1}{\lambda}\left(T - k\left(\frac{\cdot}{\eta}\right)z - \mathrm{proj}_K\left(T - k\left(\frac{\cdot}{\eta}\right)z\right)\right).$$

If $k \in L^\infty(Y, \mathbb{R}^+)$, then (22) is satisfied for $h = |T + \|k\|_{L^\infty(Y,\mathbb{R}^+)}z| + \|\mathrm{proj}_K(T - k(\frac{\cdot}{\eta})z)\|_{L^\infty(\Omega\times Y,\mathcal{S}^3)}$. Note that (22) is fulfilled for $k(y) \ge 0$ as well, but in this case the existence theory fails. In a similar way one gets that the inequality (22) holds for the model of Melan–Prager with the Norton–Hoff flow rule.

Note. For future use we need an estimate obtained in Theorem 2 in [4] for the time derivative of z_0. Define a function $h = -(B^T\mathcal{D}QB + L)z_0 + B^T\sigma_0$, where the operator Q is a projector in $L^2(\Omega\times Y, \mathcal{S}^3)$, and the function σ_0 solves the usual linear elasticity problem. Then the function h satisfies the inequality

$$\left\|\frac{\partial}{\partial t}h(t)\right\|_{\Omega\times Y} \le |Ch(0)| + ||B^T\sigma_{0,t}(0)||_{\Omega\times Y} + \int_0^t ||B^T\sigma_{0,tt}(s)||_{\Omega\times Y}ds, \tag{24}$$

with $|C\zeta| = \inf\{\|(B^T\mathcal{D}QB + L)\xi\|_{\Omega\times Y} \mid \xi(x, y) \in g(y, \zeta(x, y)) \text{ a.e.}\}$.
See [4] for more details.

2. Justification of the homogenized model.

2.1. Preliminaries. In this section we deal with a boundary value problem, a linear problem of elasticity theory with a parameter y, formed by the following equations:

$$-\mathrm{div}_x T(x, y) = \hat{b}(x), \tag{25}$$

$$T(x, y) = \mathcal{D}\left[\frac{x}{\eta} + y\right](\varepsilon(\nabla_x u(x, y)) - \hat{\varepsilon}_p(x, y)), \tag{26}$$

$$u(x, y) = \hat{\gamma}(x), \qquad x \in \partial\Omega. \tag{27}$$

The solution of this problem is understood in the following sense: A function $(u, T) \in L^2(Y, H^1(\Omega, \mathbb{R}^3)) \times L^2(\Omega\times Y, \mathcal{S}^3)$ is a solution of (25)–(27), if (26) is satisfied, and if for $\hat{b} \in L^2(\Omega, \mathbb{R}^3)$, $\hat{\gamma} \in H^1(\Omega, \mathbb{R}^3)$, $\hat{\varepsilon}_p \in L^2(\Omega\times Y, \mathcal{S}^3)$ and for a.e. $y \in Y$, the following identity

$$\left(\mathcal{D}\left[\frac{\cdot}{\eta} + y\right](\varepsilon(\nabla_x u(\cdot, y)) - \hat{\varepsilon}_p(\cdot, y)), \varepsilon(\nabla_x v(\cdot))\right)_\Omega = (\hat{b}, v)_\Omega \tag{28}$$

holds for all $v \in H_0^1(\Omega, \mathbb{R}^3)$, and if u can be represented in the form $u = \hat{\gamma} + w$ with $w \in L^2(Y, H_0^1(\Omega, \mathbb{R}^3))$.

By the well-known theory for elliptic boundary value problems (see [35]) one gets immediately that to $\hat{b} \in L^2(\Omega, \mathbb{R}^3)$, $\hat{\gamma} \in H^1(\Omega, \mathbb{R}^3)$, $\hat{\varepsilon}_p \in L^2(\Omega \times Y, \mathcal{S}^3)$ and for a fixed $\eta > 0$ there is a unique weak solution (u, T) satisfying

$$\|u\|_{L^2(Y,H^1(\Omega,\mathbb{R}^3))} + \|T\|_{\Omega\times Y} \leq C(\|\hat{b}\|_\Omega + \|\hat{\varepsilon}_p\|_{\Omega\times Y} + \|\hat{\gamma}\|_{1,\Omega}), \tag{29}$$

with a constant C independent of η.

In the following we need a special projection operator.

DEFINITION 2.1. *For every $\hat{\varepsilon}_p \in L^2(\Omega \times Y, \mathcal{S}^3)$ a linear operator $P_\eta : L^2(\Omega \times Y, \mathcal{S}^3) \mapsto L^2(\Omega \times Y, \mathcal{S}^3)$ is defined by*

$$P_\eta \hat{\varepsilon}_p = \varepsilon(\nabla_x u),$$

where (u, T) is a unique solution of (25)–(27) *to $\hat{b} = \hat{\gamma} = 0$. Furthermore, we define a linear operator $Q_\eta = I - P_\eta$. Here I is an identity operator.*

It is immediately seen from the estimate (29) that the operator P_η is uniformly bounded. Other properties of P_η and Q_η are delivered by the following lemma.

LEMMA 2.2. (i) *The operators P_η and Q_η are orthogonal projectors with respect to the scalar product $[\xi, \zeta]_{\Omega\times Y} = (\mathcal{D}_\eta \xi, \zeta)_{\Omega\times Y}$ on $L^2(\Omega \times Y, \mathcal{S}^3)$.*

(ii) *The operator $B^T \mathcal{D}_\eta Q_\eta B : L^2(\Omega \times Y, \mathbb{R}^N) \mapsto L^2(\Omega \times Y, \mathbb{R}^N)$ is selfajoint and nonnegative with respect to the scalar product $(\xi, \zeta)_{\Omega\times Y}$. Moreover, there exists a constant $C > 0$ such that*

$$\|B^T \mathcal{D}_\eta Q_\eta B \xi\|_{\Omega\times Y} \leq C\|\xi\|_{\Omega\times Y} \tag{30}$$

for all $\eta > 0$.

Proof. See Lemma 2.5 in [3]. ∎

Since L_η is uniformly positive definite, it follows from Lemma 2.2 that the operator $L_\eta + B^T \mathcal{D}_\eta Q_\eta B$ is uniformly positive definite and bounded. This implies that

$$\langle \xi, \zeta \rangle_{\Omega\times Y,\eta} = ((L_\eta + B^T \mathcal{D}_\eta Q_\eta B)\xi, \zeta)_{\Omega\times Y}$$

defines a scalar product on $L^2(\Omega\times Y, \mathbb{R}^N)$. Furthermore, the associated norm $||\xi||_{\Omega\times Y,\eta} = \langle \xi, \xi \rangle_{\Omega\times Y,\eta}^{1/2}$ is equivalent to the norm $|| \cdot ||_{\Omega\times Y}$.

2.2. Reduction to an evolution equation. The preparations made in the previous section enable us to reduce the initial boundary value problem (14)–(18) to an evolution equation with a monotone operator.

Note that (15) yields

$$B^T T_\eta - L_\eta z_\eta = B^T \mathcal{D}_\eta(\varepsilon(\nabla_x u_\eta) - B z_\eta) - L_\eta z_\eta. \tag{31}$$

Let (u_η, T_η, z_η) be a solution of the initial boundary value problem (14)–(18). Now we fix t. If $z(t)$ is known, then (14), (15), (18) is a boundary value problem for the components $u_\eta(t), T_\eta(t)$ of the solution, the problem from the linear elasticity theory with a parameter y. Due to linearity of these problems the functions are obtained in the form

$$(u_\eta(t), T_\eta(t)) = (\tilde{u}_\eta(t), \tilde{T}_\eta(t)) + (v_\eta(t), \sigma_\eta(t)),$$

with a solution $(v_\eta(t), \sigma_\eta(t))$ of the Dirichlet boundary value problem (25)–(27) to the data $\hat{b} = b(t)$, $\hat{\gamma} = \gamma(t)$, $\hat{\varepsilon}_p = 0$, and with a solution $(\tilde{u}_\eta(t), \tilde{T}_\eta(t))$ of the problem (25)–(27) to the data $\hat{b} = \hat{\gamma} = 0$, $\hat{\varepsilon}_p = Bz_\eta(t)$. Thus one obtains

$$\varepsilon((\nabla_x u_\eta)(t)) - Bz_\eta(t) = (P_\eta - I)Bz_\eta(t) + \varepsilon((\nabla_x v_\eta)(t)).$$

We insert this equation into (31) and obtain that (16) can be rewritten in the following form:

$$\frac{\partial}{\partial t} z_\eta(t) \in G_\eta(-(B^T \mathcal{D}_\eta Q_\eta B + L_\eta) z_\eta(t) + B^T \sigma_\eta(t)), \tag{32}$$

with the mapping $G_\eta : L^2(\Omega \times Y, \mathbb{R}^N) \mapsto 2^{L^2(\Omega\times Y,\mathbb{R}^N)}$ defined by

$$G_\eta(\xi) = \{\zeta \in L^2(\Omega \times Y, \mathbb{R}^N) | \zeta(x, y) \in g(x/\eta + y, \xi(x, y)) \text{ a.e.}\}.$$

The function σ_η can be determined from the boundary value problem (25)–(27) to the given data b, γ, $\hat{\varepsilon}_p = 0$ and can be considered as known.

The evolution equation (32) for z_η can be rewritten as a nonautonomous evolution equation in $L^2(\Omega \times Y, \mathbb{R}^N)$

$$\frac{\partial}{\partial t} z_\eta(t) + A_\eta(t) z_\eta(t) \ni 0, \tag{33}$$

with the operator

$$A_\eta(t)z(t) = -G_\eta(-(B^T \mathcal{D}_\eta Q_\eta B + L_\eta) z_\eta(t) + B^T \sigma_\eta(t)).$$

It turns out that the operator $A_\eta(t)$ is maximal monotone as the next lemma shows.

Lemma 2.3. *Operator $A_\eta(t)$ is maximal monotone on $L^2(\Omega\times Y, \mathbb{R}^N)$ with respect to the scalar product $\langle \xi, \zeta \rangle_{\Omega\times Y,\eta}$.*

Proof. Set for simplicity $M_\eta = B^T \mathcal{D}_\eta Q_\eta B + L_\eta$.

Monotonicity of $A_\eta(t)$ for all t and η with respect to the scalar product $\langle \xi, \zeta \rangle_{\Omega\times Y,\eta}$ is shown in Theorem 3.3 in [3].

Now we prove that the mapping $G_\eta : L^2(\Omega \times Y, \mathbb{R}^N) \mapsto 2^{L^2(\Omega\times Y,\mathbb{R}^N)}$, defined through the maximal monotone function $g : Y \times \mathbb{R}^N \mapsto 2^{\mathbb{R}^N}$ with $g(y, 0) \ni 0$, is maximal monotone with respect to the scalar product $(\xi, \zeta)_{\Omega\times Y}$.

It is well known that G_η is maximal monotone if and only if $I + G_\eta$ is surjective. To show the surjectivity, we must prove that for every $q \in L^2(\Omega\times Y, \mathbb{R}^N)$ the equation

$$q \in z + G_\eta z \tag{34}$$

has a solution $z \in L^2(\Omega \times Y, \mathbb{R}^N)$. Since g is maximal monotone, for a.e. (x, y) the mapping $(\cdot \ + g(x/\eta + y, \cdot)) : \mathbb{R}^N \mapsto 2^{\mathbb{R}^N}$ has an inverse $j(x/\eta + y, \cdot) : \mathbb{R}^N \mapsto \mathbb{R}^N$, which satisfies for a.e. (x, y) the inequality $|j(x/\eta + y, \xi) - j(x/\eta + y, \zeta)| \leq |\xi - \zeta|$ for all $\xi, \zeta \in \mathbb{R}^N$. This Lipschitz continuity, together with the measurability of j with respect to the first argument, yields that the function $j(x/\eta+y, q)$ is of Caratheodory type. Thus one can prove that the mapping $(x, y) \mapsto j(x/\eta+y, q(x, y))$ is measurable. From $g(\cdot, 0) \ni 0$ it follows that $j(x/\eta + y, 0) = 0$, whence

$$|j(x/\eta + y, \xi)| = |j(x/\eta + y, \xi) - j(x/\eta + y, 0)| \leq |\xi|. \tag{35}$$

For $q \in L^2(\Omega \times Y, \mathbb{R}^N)$ we define $z(x, y) = j(x/\eta + y, q(x, y))$ for all $(x, y) \in \Omega \times Y$. Obviously, such defined z solves (34) if $z \in L^2(\Omega \times Y, \mathbb{R}^N)$. Yet, (35) yields that indeed $z \in L^2(\Omega \times Y, \mathbb{R}^N)$ and therefore we conclude that $I + G_\eta$ is surjective. Hence G_η is maximal monotone.

With this result it is easy to prove that $A_\eta(t)$ is maximal monotone for all t. In other words we have to show that for all $[z, \xi] \in L^2(\Omega \times Y, \mathbb{R}^N) \times L^2(\Omega \times Y, \mathbb{R}^N)$ and all $[\hat{z}, \hat{\xi}] \in GrA_\eta(t)$ such that

$$\langle z - \hat{z}, \xi - \hat{\xi} \rangle_{\Omega \times Y, \eta} \geq 0,$$

it follows that $[z, \xi] \in GrA_\eta(t)$.

Indeed,

$$\langle z - \hat{z}, \xi - \hat{\xi} \rangle_{\Omega \times Y, \eta} = ((-M_\eta z + B^T \sigma) - (-M_\eta \hat{z} + B^T \sigma), (-\xi) + \hat{\xi})_{\Omega \times Y} \geq 0.$$

Since G_η is maximal monotone, $[-M_\eta z + B^T \sigma, -\xi] \in GrG_\eta$, which means that $[z, \xi] \in GrA_\eta(t)$. $\square$

2.3. Beginning of the justification. Now we can prove the main result of this work, Theorem 1.2.

The approximate solution $(u_0, \hat{T}_\eta, \hat{z}_\eta)(x, y, t)$, determined from the homogenized problem, solves the same initial boundary value problem as the exact solution, however, with a special right-hand side. Observing (7)–(13) we get by a simple computation that $(u_0, \hat{T}_\eta, \hat{z}_\eta)$ satisfies the equations (a special microscopic problem)

$$-\operatorname{div}_x \hat{T}_\eta = -\operatorname{div}_x T_0(x, \xi, t)|_{\xi = \frac{x}{\eta} + y}, \tag{36}$$

$$\hat{T}_\eta = \mathcal{D}\left[\frac{x}{\eta} + y\right](\varepsilon(\nabla_x u_0) - B\hat{z}_\eta + \varepsilon(\nabla_\xi u_1(x, \xi, t))|_{\xi = \frac{x}{\eta} + y}), \tag{37}$$

$$\frac{\partial}{\partial t}\hat{z}_\eta \in g\left(\frac{x}{\eta} + y, B^T \hat{T}_\eta - L\left[\frac{x}{\eta} + y\right]\hat{z}_\eta\right), \tag{38}$$

$$\hat{z}_\eta(x, y, 0) = z_0^{(0)}\left(x, \frac{x}{\eta} + y\right), \qquad (x, y) \in \Omega \times Y, \tag{39}$$

$$u_0(x, t) = \gamma(x, t) \qquad (x, t) \in \partial\Omega \times [0, \infty). \tag{40}$$

Since these equations have the same structure as the equations of the microscopic problem with a parameter y, we can again employ the procedure from the last section and obtain that if $(\hat{v}_\eta(t), \hat{\sigma}_\eta(t))$ is the solution of the linear boundary value problem (25)–(27) to the data

$$\hat{b}(x) = -\operatorname{div}_x T_0(x, \xi, t)|_{\xi = x/\eta + y}, \tag{41}$$

$$\hat{\varepsilon}_p(x) = -\varepsilon(\nabla_\xi u_1(x, \xi, t))|_{\xi = x/\eta + y}, \tag{42}$$

$$\hat{\gamma}(x) = \gamma(x, t), \tag{43}$$

then the special microscopic problem is equivalent to a nonautonomous evolution equation

$$\frac{\partial}{\partial t}\hat{z}_\eta(t) + \hat{A}_\eta(t)\hat{z}_\eta(t) \ni 0, \tag{44}$$

where

$$\hat{A}_\eta(t)v = -g\left(\frac{x}{\eta} + y, -(B^T \mathcal{D}_\eta Q_\eta B + L_\eta)v + B^T \hat{\sigma}_\eta\right).$$

It turns out that the operator $\hat{A}_\eta(t)$ is maximal monotone, as we will see in the following lemma.

Lemma 2.4. *The operator $\hat{A}_\eta(t)$ is maximal monotone on $L^2(\Omega \times Y, \mathbb{R}^N)$ with respect to the scalar product $\langle \xi, \xi \rangle_{\Omega \times Y, \eta}$.*

Proof. The proof is the same as for $A_\eta(t)$ (Lemma 2.3). □

We are going to use the results of Lemmas 2.3 and 2.4 and a special distance between two maximal monotone operators to estimate the difference of solutions of the evolution inclusions (33), (44) by the norm of a function, which solves a linear elasticity problem to a special data. This is a crucial step in the justification of the homogenized model because we are able to employ classical results from homogenization theory for linear problems. In the next section this estimate is given.

2.4. Main estimate. We define a special distance between two maximal monotone operators due to [35]. With its help we obtain an important estimate in the justification procedure of the homogenized model.

Let H be a Hilbert space.

Definition 2.5. *The distance between two maximal monotone operators on H is defined as*

$$\operatorname{dis}(A_1, A_2) = \sup \left\{ \frac{(y_1 - y_2, x_2 - x_1)}{\|y_1\| + \|y_2\| + 1} \mid x_i \in D(A_i),\ y_i \in A_i x_i,\ i = 1, 2 \right\}$$

with the value possibly equal to $+\infty$.

The distance dis is not a metric because in a general case the triangle inequality is not fulfilled.

Concerning properties and applications to the study of evolution equations in a Hilbert space, the reader is referred to the original work [35].

The following lemma plays an important role in the proof of the convergence result, since it reduces the convergence problem for the nonlinear evolution equation to the convergence problem for a linear system of elasticity.

Lemma 2.6. *For the functions $\hat{z}_\eta(t)$ and $z_\eta(t)$, the following estimate with a constant C independent of η holds:*

$$\|\hat{z}_\eta(t) - z_\eta(t)\|^2_{\Omega \times Y} \le C \int_0^t \|\hat{\sigma}_\eta(s) - \sigma_\eta(s)\|_{\Omega \times Y} ds. \tag{45}$$

Proof. We use the operator distance introduced in Definition 2.5:

$$\operatorname{dis}(\hat{A}_\eta(t), A_\eta(t)) = \sup_{\substack{z_1 \in D(\hat{A}_\eta),\ z_2 \in D(A_\eta) \\ y_1 \in \hat{A}_\eta z_1,\ y_2 \in A_\eta z_2}} \frac{\langle y_1 - y_2, z_2 - z_1 \rangle_{\Omega \times Y, \eta}}{1 + \|y_1\|_{\Omega \times Y, \eta} + \|y_2\|_{\Omega \times Y, \eta}},$$

which is well defined, since $\hat{A}_\eta$ and A_η are maximal monotone operators.

We get

$$\begin{aligned}
&\langle y_1 - y_2, z_2 - z_1 \rangle_{\Omega \times Y, \eta} = (M_\eta(y_1 - y_2), z_2 - z_1)_{\Omega \times Y} \\
&= -(-y_2 + y_1, (-M_\eta z_2 + B^T \sigma_\eta(t)) - (-M_\eta z_1 + B^T \hat{\sigma}_\eta(t)))_{\Omega \times Y} \\
&\quad -(y_2 - y_1, B^T \sigma_\eta(t) - B^T \hat{\sigma}_\eta(t))_{\Omega \times Y} \\
&\le -(y_2 - y_1, B^T(\sigma_\eta(t) - \hat{\sigma}_\eta(t)))_{\Omega \times Y},
\end{aligned}$$

since the inclusion $-y_2 + y_1 \in G_\eta(-M_\eta z_2 + B^T\sigma_\eta(t)) - G_\eta(-M_\eta z_1 + B^T\hat{\sigma}_\eta(t))$ holds and the operator G_η is monotone.

Then we have

$$\operatorname{dis}(\hat{A}_\eta(t), A_\eta(t)) \leq \sup_{\substack{z_1\in D(\hat{A}_\eta),\ z_2\in D(A_\eta)\\ y_1\in\hat{A}_\eta z_1,\ y_2\in A_\eta z_2}} \frac{|(y_2-y_1, B^T(\sigma_\eta(t)-\hat{\sigma}_\eta(t)))_{\Omega\times Y}|}{1+\|y_1\|_{\Omega\times Y,\eta}+\|y_2\|_{\Omega\times Y,\eta}}$$

$$\leq \sup_{\substack{z_1\in D(\hat{A}_\eta),\ z_2\in D(A_\eta)\\ y_1\in\hat{A}_\eta z_1,\ y_2\in A_\eta z_2}} \frac{(\|y_2\|_{\Omega\times Y,\eta}+\|y_1\|_{\Omega\times Y,\eta})\|B^T(\sigma_\eta(t)-\hat{\sigma}_\eta(t))\|_{\Omega\times Y}}{1+\|y_1\|_{\Omega\times Y,\eta}+\|y_2\|_{\Omega\times Y,\eta}}$$

$$\leq \|B^T(\sigma_\eta(t)-\hat{\sigma}_\eta(t))\|_{\Omega\times Y} \leq C_1\|\sigma_\eta(t)-\hat{\sigma}_\eta(t)\|_{\Omega\times Y}.$$

Now we use the last inequality to obtain the main estimate. If $\hat{z}_\eta(t)$ and $z_\eta(t)$ are, respectively, absolutely continuous solutions of the monotone evolution equations (33) and (44) with the same initial conditions, then one easily gets

$$\frac{d}{dt}\|\hat{z}_\eta(t)-z_\eta(t)\|^2_{\Omega\times Y,\eta} = 2\langle \hat{z}_{\eta,t}(t)-z_{\eta,t}(t), \hat{z}_\eta(t)-z_\eta(t)\rangle_{\Omega\times Y,\eta}$$

$$= 2\frac{\langle \hat{z}_{\eta,t}(t)-z_{\eta,t}(t), \hat{z}_\eta(t)-z_\eta(t)\rangle_{\Omega\times Y,\eta}}{1+\|\hat{z}_{\eta,t}(t)\|_{\Omega\times Y,\eta}+\|z_{\eta,t}(t)\|_{\Omega\times Y,\eta}}(1+\|\hat{z}_{\eta,t}(t)\|_{\Omega\times Y,\eta}+\|z_{\eta,t}(t)\|_{\Omega\times Y,\eta})$$

$$\leq 2\ \operatorname{dis}(\hat{A}_\eta(t), A_\eta(t))(1+\|\hat{z}_{\eta,t}(t)\|_{\Omega\times Y,\eta}+\|z_{\eta,t}(t)\|_{\Omega\times Y,\eta})$$

$$\leq 2C_1\|\bar{\sigma}_\eta(t)\|_{\Omega\times Y}(1+\|\hat{z}_{\eta,t}(t)\|_{\Omega\times Y}+\|z_{\eta,t}(t)\|_{\Omega\times Y}),$$

since $-\hat{z}_{\eta,t}(t)\in\hat{A}_\eta\hat{z}_\eta(t)$, $-z_{\eta,t}(t)\in A_\eta z_\eta(t)$ a.e. Here $\bar{\sigma}_\eta(t)=\sigma_\eta(t)-\hat{\sigma}_\eta(t)$.

As a result of all calculations:

$$\|\hat{z}_\eta(T_e)-z_\eta(T_e)\|^2_{\Omega\times Y} \leq 2C_1\int_0^{T_e}\|\bar{\sigma}_\eta(t)\|_{\Omega\times Y}(1+\|\hat{z}_{\eta,t}(t)\|_{\Omega\times Y}+\|z_{\eta,t}(t)\|_{\Omega\times Y})dt.$$

We have to show that $\|\hat{z}_{\eta,t}(t)\|_{\Omega\times Y}$ and $\|z_{\eta,t}(t)\|_{\Omega\times Y}$ are uniformly bounded with respect to η.

We can transform (33) into an autonomous equation by inserting

$$h_\eta = -(B^T\mathcal{D}_\eta Q_\eta B + L_\eta)z_\eta + B^T\sigma_\eta$$

into (32). This autonomous equation is

$$\frac{d}{dt}h_\eta(t) + C_\eta h(t) \ni B^T\sigma_{\eta,t}(t)$$

with the operator $C_\eta : L^2(\Omega\times Y,\mathbb{R}^N) \to 2^{L^2(\Omega\times Y,\mathbb{R}^N)}$ defined by $C_\eta = (B^T\mathcal{D}_\eta Q_\eta B + L_\eta)G_\eta$. The operator C_η is maximal monotone (see Theorem 3.3 in [3]).

The estimate (79) then implies

$$\left\|\frac{\partial}{\partial t}h_\eta(t)\right\|_{\Omega\times Y} \leq ||G_\lambda h(0)||_{\Omega\times Y} + ||B^T\sigma_{\eta,t}(0)||_{\Omega\times Y} + \int_0^t ||B^T\sigma_{\eta,tt}(s)||_{\Omega\times Y}ds.$$

From the estimate (29) with $\hat{\varepsilon}_p = 0$ we conclude that the $L^2(\Omega\times Y)$-norm of σ_η is uniformly bounded with respect to η. By virtue of the assumptions made on b, γ, we can differentiate (25)–(27) with respect to t and apply the existence theory for elliptic problems to the obtained system. It results in the inequality

$$\|v_{\eta,t}\|_{L^2(Y,H^1(\Omega,\mathbb{R}^3))} + \|\sigma_{\eta,t}\|_{\Omega\times Y} \le C(\|\hat{b}_t\|_\Omega + \|\hat{\gamma}_t\|_{1,\Omega}), \tag{46}$$

with a constant C independent of η. Equation (46) yields that the $L^2(\Omega\times Y)$-norm of $\sigma_{\eta,t}$ is uniformly bounded with respect to η. Similarly, we conclude the same result for $\sigma_{\eta,tt}$. From (22) it follows that $||G_\lambda h(0)||_{\Omega\times Y}$ is also uniformly bounded with respect to η (G_λ is the Yosida approximation of G). These conclusions imply that the function $z_{\eta,t}$ is uniformly bounded.[5]

We notice that $\|\hat{z}_{\eta,t}\|_{\Omega\times Y} = \|z_{0,t}\|_{\Omega\times Y}$, where $z_0(t)$ is a solution of the homogenized problem. Thus the required result is obtained from the estimate (24). This completes the proof of the lemma. ∎

Note. Using the special distance between two maximal monotone operators, the difference of solutions of the evolution inclusions can be estimated by the norm of a function which solves a linear elasticity problem for special data. It is a crucial step in the justification of the homogenized model. Instead of treating evolution equations (inclusions) with, in general, nonlinear multivalued operators, the problem is reduced to the linear elasticity case. It allows us the possibility of using standard methods which work perfectly for linear problems.

2.5. End of the justification. Thus, we can estimate $\hat{z}_\eta - z_\eta$ by the difference $\sigma_\eta - \hat{\sigma}_\eta$. In the next section we present an estimate for the function $\sigma_\eta - \hat{\sigma}_\eta$. Both, σ_η and $\hat{\sigma}_\eta$ solve the same boundary value problem, the problem of linear elasticity theory, but for different data. Here we only state the estimate and refer to the next section for the proof.

LEMMA 2.7. *Let $(v_\eta(t), \sigma_\eta(t))$ be a solution of the boundary value problem* (25)–(27) *for the data*

$$\hat{b} = b(t), \qquad \hat{\varepsilon}_p = 0, \qquad \hat{\gamma} = \gamma(t),$$

and let $(\hat{v}_\eta(t), \hat{\sigma}_\eta(t))$ be a solution of the problem (25)–(27) *for the data*

$$\hat{b} = -\mathrm{div}_x T_0\left(x, \frac{x}{\eta} + y, t\right), \qquad \hat{\varepsilon}_p = -\varepsilon\left(\nabla_y u_1\left(x, \frac{x}{\eta} + y, t\right)\right), \qquad \hat{\gamma} = \gamma(t).$$

Then for all $t \in [0, T_e]$

$$\|v_\eta(t) - \hat{v}_\eta(t)\|_{\Omega\times Y} + \|\sigma_\eta(t) - \hat{\sigma}_\eta(t)\|_{\Omega\times Y} \to 0 \qquad \text{as } \eta \to 0. \tag{47}$$

Moreover, there exists a constant C independent of η such that for all $t \in [0, T_e]$ and all $\eta > 0$,

$$\|\sigma_\eta(t) - \hat{\sigma}_\eta(t)\|_{\Omega\times Y} \le C. \tag{48}$$

With this lemma the proof of Theorem 1.2 can be finished.

Proof of Theorem 1.2. Lemma 2.7 and the inequality (45) yield, together with Lebesgue's convergence theorem, that for all $t \in [0, T_e]$,

$$\lim_{\eta\to 0} \|\hat{z}_\eta(t) - z_\eta(t)\|_{\Omega\times Y} = 0. \tag{49}$$

[5] Remember also that the operator $(B^T \mathcal{D}_\eta Q_\eta B + L_\eta)$ is uniformly bounded and invertible.

We observe also that (14), (15), (18) form the boundary value problem for (u_η, T_η) and (36), (37), (40) form a boundary value problem for $(u_0, \hat{T}_\eta)$. Definition 2.1 of P_η and the definitions of $(\hat{v}_\eta(t), \hat{\sigma}_\eta(t))$ and $(v_\eta(t), \sigma_\eta(t))$ thus yield the decomposition

$$u_\eta = w_\eta + v_\eta, \quad T_\eta = \mathcal{D}\left[\frac{\cdot}{\eta} + y\right](P_\eta - I)Bz_\eta + \sigma_\eta,$$
$$u_0 = \hat{w}_\eta + \hat{v}_\eta, \quad \hat{T}_\eta = \mathcal{D}\left[\frac{\cdot}{\eta} + y\right](P_\eta - I)B\hat{z}_\eta + \hat{\sigma}_\eta,$$

where $w_\eta(t), \hat{w}_\eta(t) \in L^2(Y, H_0^1(\Omega, \mathbb{R}^3))$ are the unique functions from Definition 2.1 which satisfy $\varepsilon(\nabla_x w_\eta(t)) = P_\eta B z_\eta(t)$ and $\varepsilon(\nabla_x \hat{w}_\eta(t)) = P_\eta B \hat{z}_\eta(t)$. We thus have

$$\varepsilon(\nabla_x(w_\eta - \hat{w}_\eta)) = P_\eta B(z_\eta - \hat{z}_\eta), \tag{50}$$

$$T_\eta - \hat{T}_\eta = -\mathcal{D}\left[\frac{\cdot}{\eta} + y\right] Q_\eta B(z_\eta - \hat{z}_\eta) + (\sigma_\eta - \hat{\sigma}_\eta), \tag{51}$$

$$u_0 - u_\eta = (w_\eta - \hat{w}_\eta) + (v_\eta - \hat{v}_\eta). \tag{52}$$

From Lemma 2.7, (49), (51), and the uniform boundedness of $\mathcal{D}_\eta Q_\eta B$, we infer that

$$\lim_{\eta\to 0} \|\hat{T}_\eta(t) - T_\eta(t)\|_{\Omega\times Y} = 0.$$

Since for a.e. $y \in Y$ the function $(w_\eta - \hat{w}_\eta)$ belongs to $H_0^1(\Omega, \mathbb{R}^3)$, we conclude from the first Korn's inequality that the inequality $\|(w_\eta - \hat{w}_\eta)(t,y)\|_{1,\Omega} \le C\|\varepsilon(\nabla_x(w_\eta - \hat{w}_\eta)(t,y))\|_\Omega$ holds for a.e. y and from (49), (50) that $\|w_\eta(t) - \hat{w}_\eta(t)\|_{\Omega\times Y} \to 0$ as $\eta \to 0$; from Lemma 2.7 and (52) we thus conclude that

$$\lim_{\eta\to 0} \|u_0(t) - u_\eta(t)\|_{\Omega\times Y} = 0$$

for all $t \in [0, T_e]$. These two relations and (49) together yield

$$\lim_{\eta\to 0}(\|u_0(t) - u_\eta(t)\|_{\Omega\times Y} + \|\hat{T}_\eta(t) - T_\eta(t)\|_{\Omega\times Y} + \|\hat{z}_\eta(t) - z_\eta(t)\|_{\Omega\times Y}) = 0.$$

This completes the proof of Theorem 1.2. $\square$

To finish the proof of Theorem 1.2 it thus remains to verify Lemma 2.7. The next section is devoted to the proof of this lemma.

3. Convergence results based on the two-scale convergence method. In this section we present the convergence result stated in Lemma 2.7. To do this an auxiliary function is taken into consideration. We define it to be a solution of a Dirichlet boundary value problem of the linear elasticity theory for special data. These data are chosen to be smooth enough so the two-scale convergence method can be applied. The direct application of the method seems impossible to the author because of the low regularity of the functions $T_0(x,y,t)$ and $u_1(x,y,t)$, the solutions of the homogenized problem, which are now considered as the data for the elasticity problem.

Now we give the definition of the so-called two-scale converged sequence.

We assume that $|Y| = 1$.

Definition 3.1. *A sequence of functions u_η in $L^2(\Omega, \mathbb{R}^3)$ is said to two-scale converge to a limit $u_0(x,y)$ belonging to $L^2(\Omega\times Y, \mathbb{R}^3)$ if, for any test function $\psi(x,y)$ in $L^2(\Omega, C(Y, \mathbb{R}^3))$, one has*

$$\lim_{\eta\to 0} \int_\Omega u_\eta(x)\psi\left(x, \frac{x}{\eta}\right) dx = \int_\Omega \int_Y u_0(x,y)\psi(x,y)\,dxdy. \tag{53}$$

Note. This definition makes sense for every bounded sequence u_η in $L^2(\Omega, \mathbb{R}^3)$. As it is shown in Theorem 1.2 in [6] for such a sequence u_η there exists a limit $u_0 \in L^2(\Omega \times Y, \mathbb{R}^3)$ such that, with possible expanse of extracting a subsequence, $u_\eta(x)$ two-scale converges to $u_0(x, y)$.

Note. The two-scale convergence method [27], [6] is an alternative to the energy method of Tartar [26], applied for partial differential equations with periodically oscillating coefficients. We refer the reader to [6] for main properties of two-scale converged sequences.

Let the boundary value problem be given:

$$-\mathrm{div}_x T(x, y) = \hat{b}(x), \tag{54}$$

$$T(x, y) = \mathcal{D}\left[\frac{x}{\eta} + y\right](\varepsilon(\nabla_x u(x, y)) - \hat{\varepsilon}_p(x, y)), \tag{55}$$

$$u(x, y) = \hat{\gamma}(x), \qquad x \in \partial\Omega, \tag{56}$$

with given functions $\hat{b} : \Omega \mapsto \mathbb{R}^3$, $\hat{\gamma} : \partial\Omega \mapsto \mathbb{R}^3$, $\hat{\varepsilon}_p : \Omega \mapsto \mathcal{S}^3$, a given number $\eta > 0$, and fixed $y \in Y$. This is the linear problem of elasticity with a parameter y.

We recall that for a.e. $y \in Y$ the function $(v_\eta(t), \sigma_\eta(t))$ solves the boundary value problem (54)–(56) to the data

$$\hat{b} = b(t), \qquad \hat{\varepsilon}_p = 0, \qquad \hat{\gamma} = \gamma(t),$$

and $(\hat{v}_\eta(t), \hat{\sigma}_\eta(t))$ solves the problem (54)–(56) to

$$\hat{b} = -\mathrm{div}_x T_0\left(x, \frac{x}{\eta} + y, t\right), \qquad \hat{\varepsilon}_p = -\varepsilon\left(\nabla_y u_1\left(x, \frac{x}{\eta} + y, t\right)\right), \qquad \hat{\gamma} = \gamma(t).$$

My goal now is to show that for almost all $y \in Y$ and all $t \in [0, T_e]$,

$$\lim_{\eta \to 0} \|v_\eta(\cdot, y, t) - \hat{v}_\eta(\cdot, y, t)\|_\Omega = 0,$$
$$\lim_{\eta \to 0} \|\sigma_\eta(\cdot, y, t) - \hat{\sigma}_\eta(\cdot, y, t)\|_\Omega = 0.$$

These relations follow from two auxiliary lemmas proved in the next section.

3.1. Two auxiliary lemmas.

LEMMA 3.2. *Let the function $\tau \in L^2(\Omega \times Y, \mathcal{S}^3)$ have the property $\mathrm{div}_y \tau(x, y) = 0$, and let the family $\{\tau_{\eta,n}(x) = \tau_n(x, x/\eta)\}_{\eta,n}$ with $\tau_n \in L^2(\Omega, C(Y, \mathcal{S}^3))$ be such that the sequence $\tau_n(x, y)$ converges strongly to $\tau(x, y)$ in $L^2(\Omega \times Y, \mathcal{S}^3)$. Denote*

$$\tau_{n,\infty}(x) := \frac{1}{|Y|}\int_Y \tau_n(x, y)dy \quad \text{and} \quad \tau_\infty(x) = \frac{1}{|Y|}\int_Y \tau(x, y)dy.$$

Then $\tau_{n,\infty}(x)$ converges strongly to $\tau_\infty(x)$ in $L^2(\Omega, \mathcal{S}^3)$.

Let $(v_{\eta,n}, \sigma_{\eta,n}) \in H_0^1(\Omega, \mathbb{R}^3) \times L^2(\Omega, \mathcal{S}^3)$ be a weak solution of the boundary value problem formed by the equations

$$-\mathrm{div}\ \sigma_{\eta,n} = b + \mathrm{div}_x \tau_{\eta,n}, \qquad x \in \Omega, \tag{57}$$

$$\sigma_{\eta,n} = \mathcal{D}\left[\frac{\cdot}{\eta}\right]\ \varepsilon(\nabla_x v_{\eta,n}), \qquad x \in \Omega. \tag{58}$$

If, additionally, the function τ_∞ satisfies

$$-\mathrm{div}\tau_\infty = b$$

for $b \in L^2(\Omega, \mathbb{R}^3)$, *then*

$$\lim_{n\to\infty} \lim_{\eta\to 0} (\|v_{\eta,n}\|_\Omega + \|\sigma_{\eta,n}\|_\Omega) = 0.$$

Proof. First, we observe that the symmetry of the matrices $\sigma_{\eta,n}$, $\tau_{\eta,n}$ and (57)–(58) yields

$$\begin{aligned} c\|\sigma_{\eta,n}\|_\Omega^2 &\le \int_\Omega \mathcal{D}^{-1}\left[\frac{x}{\eta}\right] \ \sigma_{\eta,n}(x)\cdot\sigma_{\eta,n}(x)dx = \int_\Omega \varepsilon(\nabla_x v_{\eta,n}(x))\cdot\sigma_{\eta,n}(x)dx \\ &= (v_{\eta,n}, b)_\Omega + \left(\operatorname{div}_x \tau_n\left(\cdot, \frac{\cdot}{\eta}\right), v_{\eta,n}\right)_\Omega \\ &= (v_{\eta,n}, b)_\Omega - \left(\tau_n\left(\cdot, \frac{\cdot}{\eta}\right), \nabla_x v_{\eta,n}\right)_\Omega . \end{aligned} \tag{59}$$

Now we notice that for a fixed n the function $\tau_n(x, x/\eta)$ can be considered as a test function in the definition of the two-scale convergence (see Definition 3.1), and by properties of these functions

$$\|\psi\left(\cdot, \frac{\cdot}{\eta}\right)\|_\Omega \le \|\psi(\cdot,\cdot)\|_{L^2(\Omega, C(Y,\mathbb{R}^3))} \equiv \left(\int_\Omega \sup_{y\in Y} |\psi(x,y)|^2 dx\right)^{1/2}, \tag{60}$$

we can easily conclude using the standard estimates for elliptic boundary value problems that the sequence $v_{\eta,n}$ is uniformly bounded in $H_0^1(\Omega,\mathbb{R}^3)$ for a fixed n. Then by virtue of the property (i) of Proposition 1.14 in [6], one gets the following result:

$$\begin{aligned} &(v_{\eta,n}, b)_\Omega - \left(\tau_n\left(\cdot, \frac{\cdot}{\eta}\right), \nabla_x v_{\eta,n}\right)_\Omega \to (v_{0,n}, b)_\Omega \\ &\qquad - \int_{\Omega\times Y} \tau_n(x,y)\cdot\nabla_x v_{0,n}(x)dxdy - \int_{\Omega\times Y} \tau_n(x,y)\cdot\nabla_y w_{1,n}(x,y)dxdy \\ &= (v_{0,n}, b)_\Omega - (\tau_{n,\infty}, \nabla_x v_{0,n})_\Omega - \int_{\Omega\times Y} \tau_n(x,y)\cdot\nabla_y w_{1,n}(x,y)dydx, \end{aligned} \tag{61}$$

where the function $(v_{0,n}, w_{1,n}) \in H_0^1(\Omega,\mathbb{R}^3)\times L^2(\Omega, W(Y,\mathbb{R}^3))$ solves the problem written in the variational form

$$\begin{aligned} &\int_Y\int_\Omega \mathcal{D}[y]\varepsilon(\nabla v_{0,n}(x) + \nabla_y w_{1,n}(x,y))\varepsilon(\nabla\psi(x) + \nabla_y\psi_1(x,y))dxdy \\ &\qquad = (b + \operatorname{div}_x \tau_{n,\infty}, \psi)_\Omega \end{aligned} \tag{62}$$

with a function $(\psi,\psi_1) \in H_0^1(\Omega,\mathbb{R}^3)\times L^2(\Omega, W(Y,\mathbb{R}^3))$. Here $v_{0,n}(x)$ is a weak limit of $v_{\eta,n}(x)$ in $H_0^1(\Omega,\mathbb{R}^3)$. Equation (62) is obtained in the same way as (89) in the proof of Theorem 4.2.

The existence and uniqueness of the solution for this problem is obtained in Theorem 4.2. If in (62) we choose $\psi = v_{0,n}$ and $\psi_1 = w_{1,n}$, then we easily obtain the following estimate for $(v_{0,n}(x), w_{1,n}(x,y))$ with constants C, C_1 independent of n:

$$\|v_{0,n}\|_{1,\Omega}^2 + \|w_{1,n}\|_{L^2(\Omega, W(Y,\mathbb{R}^3))}^2 \le C(\|b\|_\Omega + \|\tau_{n,\infty}\|_\Omega) \le C_1. \tag{63}$$

As a consequence of the last estimate, one can extract subsequences of $v_{0,n}(x)$ and $w_{1,n}(x,y)$, which converge weakly to $v_{0,\infty}(x)$ in $H_0^1(\Omega,\mathbb{R}^3)$ and to $w_{1,\infty}(x,y)$ in $L^2(\Omega, W(Y,\mathbb{R}^3))$, respectively. Taking into account this fact and the properties of τ_∞ and τ we finally obtain after the passage to the limit in (62) as $n\to\infty$ that

$$(v_{0,\infty},b)_\Omega-(\tau_\infty,\nabla_x v_{0,\infty})_\Omega-(\tau,\nabla_y w_{1,\infty})_{\Omega\times Y}$$

$$=(b+\mathrm{div}_x\tau_\infty,v_{0,\infty})_\Omega+(\mathrm{div}_y\tau,w_{1,\infty})_{\Omega\times Y}=0.$$

This means that $\|\sigma_{\eta,n}\|_\Omega\to 0$ as $\eta\to 0$ and $n\to\infty$. Together with Korn's inequality it follows that

$$\lim_{n\to\infty}\lim_{\eta\to 0}(\|\sigma_{\eta,n}\|_\Omega+\|v_{\eta,n}\|_\Omega)=0.$$

This ends the proof of Lemma 3.2. $\square$

LEMMA 3.3. *Let $\kappa_\eta(x):=\kappa(x,x/\eta)$ be a sequence of functions in $L^2(\Omega,\mathbb{R}^{3\times3})$, where $\kappa\in L^2(\Omega,C(Y,\mathbb{R}^{3\times3}))$ satisfies the relation $\kappa=\nabla_y\vartheta$ with a suitable Y-periodic in y function $\vartheta(x,y)$. Suppose that $(v_\eta,\sigma_\eta)\in H_0^1(\Omega,\mathbb{R}^3)\times L^2(\Omega,\mathcal{S}^3)$ is a weak solution of the boundary value problem formed by the equations*

$$-\mathrm{div}\ \sigma_\eta=0,\qquad x\in\Omega,\tag{64}$$

$$\sigma_\eta=\mathcal{D}\left[\frac{\cdot}{\eta}\right]\ (\varepsilon(\nabla_x v_\eta)+\varepsilon(\kappa_\eta)),\qquad x\in\Omega.\tag{65}$$

Then

$$\lim_{\eta\to 0}(\|v_\eta\|_\Omega+\|\sigma_\eta\|_\Omega)=0.$$

Proof. Similarly as in the proof of Lemma 3.2, the symmetry of σ_η and (64)–(65) yields

$$c\|\sigma_\eta\|_\Omega^2\le\int_\Omega\kappa\left(x,\frac{x}{\eta}\right)\cdot\sigma_\eta(x)dx+\int_\Omega\nabla_x v_\eta\cdot\sigma_\eta(x)dx=(\kappa_\eta,\sigma_\eta)_\Omega.\tag{66}$$

Notice that due to the regularity assumption on the function $\kappa(x,x/\eta)$ it can be taken as a test function in the sense of the definition of two-scale convergence (see Definition 3.1). Moreover, from the estimate

$$\left\|\psi\left(x,\frac{x}{\eta}\right)\right\|_{L^2(\Omega,\mathbb{R}^{3\times3})}\le\|\psi(x,y)\|_{L^2(\Omega,C(Y,\mathbb{R}^{3\times3}))},$$

which holds for every $\psi\in L^2(\Omega,C(Y,\mathbb{R}^{3\times3}))$ and from (66) we obtain

$$c\|\sigma_\eta\|_\Omega^2\le\|\kappa_\eta\|_{L^2(\Omega,C(Y,\mathbb{R}^{3\times3}))}\ \|\sigma_\eta\|_\Omega,$$

which implies that $\sigma_\eta(x)$ is uniformly bounded in $L^2(\Omega,\mathcal{S}^3)$. Simultaneously, one gets a uniform bound for v_η in $H_0^1(\Omega,\mathbb{R}^3)$. The boundness of σ_η allows us to pass to the limit in the inequality (66) as $\eta\to 0$. Using the property (iii) of Proposition 1.14 in [6] we obtain

$$\int_\Omega\kappa\left(x,\frac{x}{\eta}\right)\cdot\sigma_\eta(x)dx\to\int_{\Omega\times Y}\kappa(x,y)\cdot\sigma_0(x,y)dxdy=-(\vartheta,\mathrm{div}_y\sigma_0)_{\Omega\times Y}=0,$$

where $\sigma_0(x,y)$ is a two-scale limit of the sequence $\sigma_\eta(x)$. From the last limit relation and the inequality (66) we can conclude that σ_η converges strongly to 0 in $L^2(\Omega,\mathcal{S}^3)$.

Now we observe that the uniform boundness of v_η in $H^1_0(\Omega,\mathbb{R}^3)$ gives us the possibility of extracting a subsequence, which converges weakly to a function v_0 in $H^1_0(\Omega,\mathbb{R}^3)$, or, by the compactness result, converges strongly to the same function v_0 in $L^2(\Omega,\mathbb{R}^3)$. To finish the proof of Lemma 3.3 we have to show that $v_0(x)=0$. Notice first that well-known properties[6] of functions from $L^2(\Omega,C(Y,\mathbb{R}^{3\times 3}))$ yield the weak convergence of κ_η to 0 in $L^2(\Omega,\mathbb{R}^{3\times 3})$. Indeed, from the weak convergence of $\kappa(\cdot,\cdot/\eta)$ and periodicity of $\vartheta(x,y)$ with respect to the second variable it follows that for $\psi\in L^2(\Omega,\mathbb{R}^{3\times 3})$,

$$\int_\Omega \kappa\left(x,\frac{x}{\eta}\right)\cdot\psi(x)dx \to \int_\Omega\int_Y \nabla_y\vartheta(x,y)dy\ \psi(x)dx = 0.$$

Taking into account the last result we get from the equality

$$(\varepsilon(\nabla_x v_\eta),\psi)_\Omega + (\kappa_\eta,\psi)_\Omega = \int_\Omega \mathcal{D}^{-1}\left[\frac{x}{\eta}\right]\sigma_\eta(x)\cdot\psi(x)dx,$$

where $\psi\in L^2(\Omega,\mathcal{S}^3)$, that $\varepsilon(\nabla_x v_\eta(x))$ weakly converges to 0 in $L^2(\Omega,\mathcal{S}^3)$.[7]

Since $\nabla_x v_\eta \rightharpoonup \nabla_x v_0$ in $L^2(\Omega,\mathbb{R}^{3\times 3})$ it follows that $\varepsilon(\nabla_x v_0(x))=0$. Using that $v_0\in H^1_0(\Omega,\mathbb{R}^3)$ we conclude from the first Korn's inequality that $v_0(x)=0$.

Therefore

$$\|\sigma_\eta\|_\Omega + \|v_\eta\|_\Omega \to 0 \qquad \text{as} \quad \eta\to 0.$$

This completes the proof of Lemma 3.3. ∎

3.2. Proof of Lemma 2.7. Now we are well prepared to prove Lemma 2.7. The crucial point in the proof of Lemma 2.7 is to introduce an auxiliary function, which solves a linear elasticity problem to smoothed data. These smoothed data satisfy all requirements of Lemmas 3.2 and 3.3. The rest of the proof is the consequence of these two lemmas.

Proof. Let $T_{0,n}(x,y,t)$ be a sequence of smooth functions in $C_0^\infty(\Omega,C(Y,\mathcal{S}^3))$ that converges strongly to $T_0(x,y,t)$ in $L^2(\Omega\times Y,\mathcal{S}^3)$ for all t, and let $u_{1,n}(t)$ be another sequence of smooth functions in $C_0^\infty(\Omega,C(Y,\mathbb{R}^3))$ that converges strongly to $u_1(t)$ in $L^2(\Omega,H^1(Y,\mathbb{R}^3))$ for all t. We notice that an approximation sequence for $T_\infty(t)$ in the strong topology of $L^2(\Omega,\mathcal{S}^3)$ necessarily has to be of the form $T_{\infty,n}(x,t)=\int_Y T_{0,n}(x,y,t)dy$.

Now we fix t and introduce an auxiliary function[8] $(v_{\eta,n},\sigma_{\eta,n})$. We define it as a unique solution of an elasticity problem to the data determined by the smooth functions $T_{0,n}(x,y,t)$ and $u_{1,n}(x,y,t)$:

$$-\mathrm{div}\sigma_{\eta,n}(x) = -\mathrm{div}_x T_{0,n}\left(x,\frac{x}{\eta}+y,t\right), \tag{67}$$

[6]We use the fact (Lemma 9.1 of [18]) that for any $\psi\in L^2(\Omega,C(Y,\mathbb{R}^{3\times 3}))$ the sequence

$$\psi\left(\cdot,\frac{\cdot}{\eta}\right) \rightharpoonup \int_Y \psi(\cdot,y)dy \quad \text{weakly in } L^2(\Omega,\mathbb{R}^{3\times 3}).$$

[7]From the strong convergence of σ_η to 0 and the inequality $\|\mathcal{D}^{-1}[\cdot/\eta]\sigma_\eta\|_\Omega \le C\|\sigma_\eta\|_\Omega$, we conclude that the sequence $\mathcal{D}^{-1}[\cdot/\eta]\sigma_\eta$ also converges strongly to 0 in $L^2(\Omega,\mathcal{S}^3)$. The constant C is independent of η.

[8]A similar idea was used in [8].

$$\sigma_{\eta,n}(x) = \mathcal{D}\left[\frac{x}{\eta}+y\right]\left(\varepsilon(\nabla_x v_{\eta,n}(x)) + \varepsilon\left(\nabla_y u_{1,n}\left(x, \frac{x}{\eta}+y, t\right)\right)\right), \tag{68}$$

$$v_{\eta,n}(x) = \gamma(x,t), \qquad x \in \partial\Omega. \tag{69}$$

The existence and uniqueness of the function $(v_{\eta,n}, \sigma_{\eta,n})$ as a solution of the boundary value problem (67)–(69) can be obtained by the well-known theory for elliptic problems. Details are omitted.

We obviously have that

$$\sigma_\eta(x,t) - \hat{\sigma}_\eta(x,t) = (\sigma_\eta(x,t) - \sigma_{\eta,n}(x)) + (\sigma_{\eta,n}(x) - \hat{\sigma}_\eta(x,t)),$$

$$v_\eta(x,t) - \hat{v}_\eta(x,t) = (v_\eta(x,t) - v_{\eta,n}(x)) + (v_{\eta,n}(x) - \hat{v}_\eta(x,t)).$$

The proof of the convergence result will be separated into two steps. In the first step we show that the sequences $(\bar{v}_{\eta,n}(x),\, \bar{\sigma}_{\eta,n}(x))$ with $\bar{\sigma}_{\eta,n}(x) := \sigma_\eta(x,t) - \sigma_{\eta,n}(x)$ and $\bar{v}_{\eta,n}(x) := v_\eta(x,t) - v_{\eta,n}(x)$ converge to 0 in appropriate strong topologies. Then the same result will be shown for sequences $(\hat{v}_{\eta,n}(x),\, \hat{\sigma}_{\eta,n}(x))$, where $\hat{\sigma}_{\eta,n}(x) := \sigma_{\eta,n}(x) - \hat{\sigma}_\eta(x,t)$ and $\hat{v}_{\eta,n}(x) := v_{\eta,n}(x) - \hat{v}_\eta(x,t)$.

First step. By definition, $(\bar{v}_{\eta,n}(x),\, \bar{\sigma}_{\eta,n}(x))$ is a weak solution of the boundary value problem (54)–(56) to the data

$$\hat{b}(x) = b(x,t) + \mathrm{div}_x T_{0,n}\left(x, \frac{x}{\eta}+y, t\right), \tag{70}$$

$$\hat{\varepsilon}_p(x,y) = \varepsilon\left(\nabla_y u_{1,n}\left(x, \frac{x}{\eta}+y, t\right)\right), \tag{71}$$

$$\hat{\gamma}(x) = 0. \tag{72}$$

By linearity of the problem (54)–(56) to the data (70)–(72) the required convergence of $(\bar{v}_{\eta,n}(x),\, \bar{\sigma}_{\eta,n}(x))$ is an easy consequence of Lemmas 3.2 and 3.3, which are applied for a.e. value $y = \hat{y} \in Y$.

Indeed, to see that we set for fixed t and a.e. $\hat{y}$,

$$\tau_{\eta,n}(x) = T_{0,n}\left(x, \frac{x}{\eta}+\hat{y}, t\right), \quad \tau(x,y) = T_0(x, y+\hat{y}, t), \quad \tau_\infty(x) = T_\infty(x,t),$$
$$\kappa_{\eta,n}(x) = -\nabla_y u_{1,n}\left(x, \frac{x}{\eta}+\hat{y}, t\right), \quad \tau_{\infty,n}(x) = T_{\infty,n}(x,t), \quad b = b(t).$$

Note first that the periodicity of $T_{0,n}, T_0$ and the choice of $T_{0,n}$ yield

$$\int_{\Omega\times Y} (T_{0,n}(x, y+\hat{y}, t) - T_0(x, y+\hat{y}, t))^2 dxdy$$
$$= \int_{\Omega\times Y} (T_{0,n}(x,y,t) - T_0(x,y,t))^2 dxdy \to 0 \ \text{ as } n \to \infty.$$

From (9) one immediately gets

$$\mathrm{div}_y \tau(x,y) = \mathrm{div}_y T_0(x, y+\hat{y}, t) = 0$$

and

$$\mathrm{div}_x \tau_{\eta,n}(x) = \mathrm{div}_x T_{0,n}\left(x, \frac{x}{\eta}+\hat{y}, t\right).$$

Due to the periodicity of $T_0(x, y, t)$ we obtain also that

$$\int_Y T_0(x, y + \hat{y}, t)dy = \int_Y T_0(x, y, t)dy = T_\infty(x, t) = \tau_\infty(x),$$

and from the strong convergence of $T_{0,n}$ to T_0 we deduce that the sequence $\tau_{\infty,n}(x) = T_{\infty,n}(x, t)$ converges strongly to $\tau_\infty(x) = T_\infty(x, t)$ in $L^2(\Omega, \mathcal{S}^3)$. One needs to apply Hölder's inequality.

Moreover, (7) implies that

$$b + \operatorname{div}_x \tau_\infty(x) = b(t) + \operatorname{div}_x T_\infty(t) = 0.$$

Since by definition $(\bar{v}_{\eta,n}(x), \bar{\sigma}_{\eta,n}(x))$ is a weak solution of the boundary value problem (54)–(56) to the data

$$\begin{aligned}
\hat{b}(x) &= b(x, t) + \operatorname{div}_x T_{0,n}\left(x, \frac{x}{\eta} + \hat{y}, t\right) = b + \operatorname{div}_x \tau_{\eta,n},\\
\hat{\varepsilon}_p(x) &= \varepsilon(\nabla_y u_{1,n}(x, y, t))|_{y=\frac{x}{\eta}+\hat{y}} = -\varepsilon(\kappa_\eta)\\
\hat{\gamma}(x) &= 0,
\end{aligned}$$

we can use the linearity of the problem (54)–(56) to write the function $(\bar{v}_{\eta,n}(x), \bar{\sigma}_{\eta,n}(x))$ as a sum of two functions

$$(\bar{v}_{\eta,n}, \bar{\sigma}_{\eta,n})(x) = (\bar{v}, \bar{\sigma})(x) + (\hat{v}, \hat{\sigma})(x),$$

where the function $(\bar{v}, \bar{\sigma})(x)$ solves the boundary problem (57)–(58) and the function $(\hat{v}, \hat{\sigma})(x)$ solves the problem (64)–(65). Then the application of Lemmas 3.2 and 3.3 to $(\bar{v}, \bar{\sigma})$ and $(\hat{v}, \hat{\sigma})$ gives, for every t and a.e. $\hat{y} \in Y$,

$$\lim_{n\to\infty} \lim_{\eta\to 0} (\|\bar{v}_{\eta,n}(\cdot, \hat{y}, t)\|_\Omega + \|\bar{\sigma}_{\eta,n}(\cdot, \hat{y}, t)\|_\Omega) = 0. \tag{73}$$

Second step. We fix t and y. The function $(\hat{v}_{\eta,n}(x), \hat{\sigma}_{\eta,n}(x))$ is a weak solution of the boundary value problem (54)–(56) to the data

$$\hat{b}(x) = -\operatorname{div}_x \left(T_{0,n}\left(x, \frac{x}{\eta} + y, t\right) - T_0\left(x, \frac{x}{\eta} + y, t\right)\right) \tag{74}$$

$$\hat{\varepsilon}_p(x) = -\varepsilon\left(\nabla_y\left(u_{1,n}\left(x, \frac{x}{\eta} + y, t\right) - u_1\left(x, \frac{x}{\eta} + y, t\right)\right)\right), \tag{75}$$

$$\hat{\gamma}(x) = 0. \tag{76}$$

Using the properties of $\mathcal{D}_\eta$, we obtain an elliptic theory applied to the boundary value problem (54)–(56) to the data (74)–(76), observing that $\hat{b} \in H^{-1}(\Omega, \mathbb{R}^3)$, $\hat{\varepsilon}_p \in L^2(\Omega, \mathcal{S}^3)$, $\hat{\gamma} \in H^1(\Omega, \mathbb{R}^3)$, and $\eta > 0$, $y \in Y$, and that there is a constant C independent of η, y, t, and n, such that

$$\begin{aligned}
\|\hat{\sigma}_{\eta,n}(t)\|_\Omega^2 \le C \Bigg[&\left\| T_{0,n}\left(\cdot, \frac{\cdot}{\eta} + y, t\right) - T_0\left(\cdot, \frac{\cdot}{\eta} + y, t\right)\right\|_\Omega^2\\
&+ \left\| \nabla_y u_{1,n}\left(\cdot, \frac{\cdot}{\eta} + y, t\right) - \nabla_y u_1\left(\cdot, \frac{\cdot}{\eta} + y, t\right)\right\|_\Omega^2 \Bigg].
\end{aligned}$$

We integrate the right-hand side of this inequality with respect to the parameter y over Y. As a result we have

$$\int_\Omega \int_Y \left| T_{0,n}\left(x, \frac{x}{\eta} + y, t\right) - T_0\left(x, \frac{x}{\eta} + y, t\right) \right|^2$$

$$+ \left| \nabla_y u_{1,n}\left(x, \frac{x}{\eta} + y, t\right) - \nabla_y u_1\left(x, \frac{x}{\eta} + y, t\right) \right|^2 dydx$$

$$= \int_\Omega \int_{\frac{x}{\eta}+Y} |T_{0,n}(x,y,t) - T_0(x,y,t)|^2$$

$$+ |\nabla_y u_{1,n}(x,y,t) - \nabla_y u_1(x,y,t)|^2 \, dydx$$

$$= \|T_{0,n}(t) - T_0(t)\|^2_{\Omega\times Y} + \|\nabla_y u_{1,n}(t) - \nabla_y u_1(t)\|^2_{\Omega\times Y}.$$

Thus the function $\sigma_\eta(t) - \hat{\sigma}_\eta(t)$ must satisfy the following inequality:

$$\|\sigma_\eta(t) - \hat{\sigma}_\eta(t)\|^2_{\Omega\times Y} \le C \left(\int_Y \|\bar{\sigma}_{\eta,n}(y,t)\|^2_\Omega dy \right.$$

$$\left. + \|T_{0,n}(t) - T_0(t)\|^2_{\Omega\times Y} + \|\nabla_y u_{1,n}(t) - \nabla_y u_1(t)\|^2_{\Omega\times Y} \right).$$

We notice that the $L^2(\Omega)$-norm of $\bar{\sigma}_{\eta,n}$ is uniformly bounded with respect to η and y. Indeed, $(\bar{v}_{\eta,n}(x), \bar{\sigma}_{\eta,n}(x))$ is the solution of (54)–(56) to the data (70)–(72). Applying the standard existence theory for linear elliptic problems we obtain that

$$\|\bar{\sigma}_{\eta,n}(y,t)\|_\Omega \le C \left(\|b(t)\|_\Omega + \left\| T_{0,n}\left(\cdot, \frac{\cdot}{\eta} + y, t\right) \right\|_\Omega + \left\| \nabla_y u_{1,n}\left(\cdot, \frac{\cdot}{\eta} + y, t\right) \right\|_\Omega \right).$$

The functions $T_{0,n}$, $\nabla_y u_{1,n}$ can be considered as an "admissible" test function in the definition of the two-scale convergence. By the properties of these functions we get that

$$\|\bar{\sigma}_{\eta,n}(y,t)\|_\Omega \le C \, (\|b(t)\|_\Omega + \|T_{0,n}(t)\|_{L^2(\Omega, C(Y, \mathcal{S}^3))}$$
$$+ \|\nabla_y u_{1,n}(t)\|_{L^2(\Omega, C(Y, \mathbb{R}^{3\times 3}))}).$$

Thus we can use Lebesgue's convergence theorem to interchange the passage to the limit and the integration in the lines below.

Let us now pass to the limit as $\eta \to 0$:

$$\lim_{\eta\to 0} \|\sigma_\eta(t) - \hat{\sigma}_\eta(t)\|^2_{\Omega\times Y} \le C \quad \lim_{\eta\to 0} \left(\int_Y \|\bar{\sigma}_{\eta,n}(y,t)\|^2_\Omega dy \right.$$

$$\left. + \|T_{0,n}(t) - T_0(t)\|^2_{\Omega\times Y} + \|\nabla_y u_{1,n}(t) - \nabla_y u_1(t)\|^2_{\Omega\times Y} \right)$$

$$= C \left(\int_Y \lim_{\eta\to 0} \|\bar{\sigma}_{\eta,n}(y,t)\|^2_\Omega dy + \|T_{0,n}(t) - T_0(t)\|^2_{\Omega\times Y} \right.$$

$$\left. + \|\nabla_y u_{1,n}(t) - \nabla_y u_1(t)\|^2_{\Omega\times Y} \right).$$

Lemmas 3.2 and 3.3 imply, if we set $\tau_{\eta,n}(x) = T_{0,n}(x, x/\eta + y, t)$ and $\kappa_{\eta,n}(x) = -\nabla_y u_{1,n}(x, x/\eta + y, t)$, that the function $\lim_{\eta\to 0} \|\bar{\sigma}_{\eta,n}(y,t)\|^2_\Omega$ is uniformly bounded with respect to n and y. It follows from (59), (62), and (63) and we can now pass to the limit as $n \to \infty$:

$$\begin{aligned}
&\lim_{\eta\to 0} \|\sigma_\eta(t) - \hat{\sigma}_\eta(t)\|^2_{\Omega\times Y} \le \lim_{n\to\infty} C \left(\int_Y \lim_{\eta\to 0} \|\bar{\sigma}_{\eta,n}(y,t)\|^2_{2,\Omega} dy \right. \\
&\left. + \lim_{n\to\infty} \|T_{0,n}(t) - T_0(t)\|^2_{\Omega\times Y} + \lim_{n\to\infty} \|\nabla_y u_{1,n}(t) - \nabla_y u_1(t)\|^2_{\Omega\times Y} \right) \\
&= C \left(\int_Y \lim_{n\to\infty} \lim_{\eta\to 0} \|\bar{\sigma}_{\eta,n}(y,t)\|^2_{2,\Omega} dy + \lim_{n\to\infty} \|T_{0,n}(t) - T_0(t)\|^2_{\Omega\times Y} \right. \\
&\left. + \lim_{n\to\infty} \|\nabla_y u_{1,n}(t) - \nabla_y u_1(t)\|^2_{\Omega\times Y} \right) = 0.
\end{aligned}$$

In exactly the same way we get

$$\begin{aligned}
&\lim_{\eta\to 0} \|v_\eta(t) - \hat{v}_\eta(t)\|^2_{\Omega\times Y} \le C \left(\int_Y \lim_{n\to\infty} \lim_{\eta\to 0} \|\bar{v}_{\eta,n}(y)\|^2_{2,\Omega} dy \right. \\
&\left. + \lim_{n\to\infty} \|T_{0,n}(t) - T_0(t)\|^2_{\Omega\times Y} + \lim_{n\to\infty} \|\nabla_y u_{1,n}(t) - \nabla_y u_1(t)\|^2_{\Omega\times Y} \right) = 0.
\end{aligned}$$

This ends the proof of Lemma 2.7. ∎

4. Appendix.

4.1. Existence of solutions for the reduced equation. In this subsection we are going to show the existence result[9] in a Hilbert space H for the following Cauchy problem:

$$\frac{d}{dt} u(t) + A(u(t)) \ni f(t), \tag{77}$$

$$u(0) = u_0 \tag{78}$$

with $A = MG$, where M is a linear, bounded, positive definite, selfadjoint operator, and G is a maximal monotone operator with respect to the usual scalar product $(\cdot,\cdot)$. It is already shown in Theorem 3.3 in [3] that A is maximal monotone with respect to the scalar product $\langle\cdot,\cdot\rangle = (M^{-1}\cdot,\cdot)$.

THEOREM 4.1. *Let G_λ be a Yosida approximation of G. Assume that $u_0 \in D(A)$ and $f \in W^{1,1}(0,T_e;H)$. Then the Cauchy problem has a unique solution $u \in W^{1,\infty}(0,T_e;H)$. The solution satisfies the inequality*

$$\left\| \frac{d}{dt} u(t) \right\|_H \le C \|G_\lambda u_0\|_H + \|f(0)\|_H + \int_0^t \|f'(s)\|_H ds \tag{79}$$

with a constant C independent of λ.

[9] Actually in [11], [32] it is already shown that the problem (77) has a unique solution, but in one place in the justification proof we need other estimates for solutions than this theory delivers. We slightly modify the classical proof in order to obtain the mentioned estimates. More details can be found in [11], [32].

Proof. The uniqueness follows directly from the monotonicity of A.

For each $\lambda > 0$ let u_λ be the solution of

$$\frac{d}{dt}u_\lambda(t) + A_\lambda(u_\lambda(t)) \ni f(t), \tag{80}$$

$$u_\lambda(0) = u_0 \tag{81}$$

with a maximal monotone (with respect to $\langle\cdot,\cdot\rangle = (M^{-1}\cdot,\cdot)$) operator $A_\lambda = MG_\lambda$.

Then similarly as in Theorem IV.4.1 in [32] we get the estimate for $u_\lambda^{'}$,

$$\begin{aligned}\|u_\lambda^{'}(t)\|_H &\le \|A_\lambda u_0\|_H + \|f(0)\|_H + \int_0^t \|f^{'}(s)\|_H ds \\ &\le C\|G_\lambda u_0\|_H + \|f(0)\|_H + \int_0^t \|f^{'}(s)\|_H ds \\ &\le C|G^0 u_0| + \|f(0)\|_H + \int_0^t \|f^{'}(s)\|_H ds. \end{aligned} \tag{82}$$

From (80) and (82) it follows that $u_\lambda^{'}$, u_λ, and $A_\lambda u_\lambda$ are uniformly bounded in $C([0,T_e],H)$.

u_λ is a Cauchy sequence in $C([0,T_e],H)$. To see that, let $\lambda,\mu > 0$ and use (80) to obtain

$$\frac{1}{2}\frac{d}{dt}\|u_\lambda(t) - u_\mu(t)\|^2 = -\langle A_\lambda(u_\lambda(t)) - A_\mu(u_\mu(t)), u_\lambda(t) - u_\mu(t)\rangle.$$

With $u_\lambda = \lambda G_\lambda u_\lambda + J_\lambda u_\lambda$ and $u_\mu = \mu G_\mu u_\mu + J_\mu u_\mu$ (J_λ is a resolvent of G) we obtain as in Theorem IV.4.1 in [32]

$$\|u_\lambda(t) - u_\mu(t)\|^2 \le \frac{\lambda+\mu}{2}K^2, \qquad 0 \le t \le T_e,$$

where $K = \sup\{\|G_\lambda(u_\lambda(t))\| \mid 0 \le t \le T_e,\ \lambda > 0\}$, so u_λ is a Cauchy sequence in $C([0,T_e],H)$ with

$$\|u_\lambda(t) - u(t)\|_H \le \sqrt{\frac{\lambda}{2}}C\left(|G^0 u_0| + \|f(0)\|_H + \|f\|_{C([0,T_e],H)} + \int_0^{T_e} \|f^{'}(s)\|_H ds\right). \tag{83}$$

The proof ends similarly as in Theorem IV.4.1 in [32]. □

4.2. Homogenization of linear elasticity systems. Now we show how to apply the two-scale convergence method to the homogenization of linear elasticity systems with periodically oscillating coefficients. This example is of great importance in the rigorous justification procedure because of the frequent use of estimates obtained for the sequence of solutions of the linear elasticity problem as well as of its homogenized problem. Therefore the proof, actually a rephrasing of Theorem 2.3 in [6] for the case of linear elasticity with a slight modification, is given in detail.

Consider the following problem:

$$-\mathrm{div}\ \mathcal{D}\left[\frac{x}{\eta}\right]\varepsilon\left(\nabla_x u(x)\right) = b(x), \quad x \in \Omega, \tag{84}$$

$$u(x) = 0, \qquad x \in \partial\Omega, \tag{85}$$

with a given function $b \in L^2(\Omega, \mathbb{R}^3)$ and a Y-periodic linear positive definite mapping $\mathcal{D}[y] : \mathcal{S}^3 \mapsto \mathcal{S}^3$, the elasticity tensor. $\mathcal{D}[y]$ is such that there exist two positive constants $0 < \alpha \leq \beta$ satisfying

$$\alpha|\xi|^2 \leq \mathcal{D}_{ijkl}[y]\xi_{kl}\xi_{ij} \leq \beta|\xi|^2 \quad \text{for any } \xi \in \mathcal{S}^3. \tag{86}$$

The last assumption (86) implies that the mapping $\mathcal{D}[y]$ belongs to $L^\infty(Y, \mathcal{S}^3)$ and, consequently, by virtue of the first Korn's inequality (see, for example, [28]) that the problem (84)–(85) admits a unique solution u_η in $H^1_0(\Omega, \mathbb{R}^3)$, which satisfies the estimate

$$\|u_\eta\|_{1,\Omega} \leq C\|b\|_2, \tag{87}$$

where C is a positive constant that depends on Ω and α and not on η.

THEOREM 4.2. *The sequence u_η of solutions of the problem* (84)–(85) *converges weakly to $u(x)$ in $H^1_0(\Omega, \mathbb{R}^3)$, and the sequence ∇u_η two-scale converges to $\nabla u(x) + \nabla_y u_1(x, y)$, where $(u, u_1) \in H^1_0(\Omega, \mathbb{R}^3) \times L^2(\Omega, W(Y, \mathbb{R}^3))$ is the unique solution of the following two-scale homogenized system:*

$$\begin{aligned} -\operatorname{div}_y[\mathcal{D}[y]\varepsilon(\nabla u(x) + \nabla_y u_1(x, y))] &= 0 \quad \textit{in } \Omega \times Y, \\ -\operatorname{div}_x\left[\int_Y \mathcal{D}[y]\varepsilon(\nabla u(x) + \nabla_y u_1(x, y))dy\right] &= b(x) \quad \textit{in } \Omega, \\ y \mapsto u_1(x, y) &\quad Y\textit{-periodic.} \end{aligned}$$

Proof. By virtue of the estimate (87) and Proposition 1.14 in [6], the sequence u_η and the sequence of its gradient ∇u_η, up to a subsequence, have the weak limit $u \in H^1_0(\Omega, \mathbb{R}^3)$ and the two-scale limit $\nabla u(x) + \nabla_y u_1(x, y)$, respectively, with $u_1 \in L^2(\Omega, W(Y, \mathbb{R}^3))$.

Multiply (84) by a test function $\psi(x) + \eta\psi_1(x, x/\eta)$, with $\psi \in C^\infty_0(\Omega, \mathbb{R}^3)$ and $\psi_1 \in C^\infty_0(\Omega, C^\infty(Y, \mathbb{R}^3))$. Integration by parts of the resulting equation and some rewriting imply

$$\begin{aligned} &\int_\Omega \nabla u_\eta(x)\mathcal{D}\left[\frac{x}{\eta}\right]\varepsilon\left[\nabla\psi(x) + \nabla_y\psi_1\left(x, \frac{x}{\eta}\right)\right]dx \\ &+\eta\int_\Omega \mathcal{D}\left[\frac{x}{\eta}\right]\varepsilon(\nabla u_\eta(x))\varepsilon\left(\nabla_x\psi_1\left(x, \frac{x}{\eta}\right)\right)dx = \int_\Omega b(x)\left(\psi(x) + \eta\psi_1\left(x, \frac{x}{\eta}\right)\right)dx. \end{aligned} \tag{88}$$

Here the symmetry of $\mathcal{D}$ was used in the first term.

It is easily seen now that applying consecutively the limit relation in the definition of the admissible test functions and Theorem 1.8 in [6] justifies the passage to the two-scale limit in (88):

$$\begin{aligned} &\int_Y\int_\Omega \mathcal{D}[y]\varepsilon(\nabla u(x) + \nabla_y u_1(x, y))\varepsilon(\nabla\psi(x) + \nabla_y\psi_1(x, y))dxdy \\ &= \int_\Omega b(x)\psi(x)dx. \end{aligned} \tag{89}$$

Equation (89) holds true for any function $(\psi, \psi_1) \in H^1_0(\Omega, \mathbb{R}^3) \times L^2(\Omega, W(Y, \mathbb{R}^3))$. Equation (89) is the variational formulation associated with the two-scale homogenized problem stated above. Due to the first Korn's inequality and to the Korn's inequality for periodic functions (see [28]), the Hilbert space $\mathcal{H} = H_0^1(\Omega,\mathbb{R}^3)\times L^2(\Omega, W(Y,\mathbb{R}^3))$ can be endowed with the following norm:

$$\|\Psi\|_{\mathcal{H}}^2 = \|\psi\|_{1,\Omega}^2 + \|\varepsilon(\nabla_y\psi_1)\|_{\Omega\times Y}^2.$$

Then the application of the Lax–Milgram lemma shows that there exists a unique solution of the two-scale homogenized problem. Consequently, the entire sequences $u_\eta(x)$ and $\nabla u_\eta(x)$ converge to $u(x)$ and $\nabla u(x) + \nabla_y u_1(x,y)$. ∎

4.3. Homogenization of the second order elliptic operators with nonuniformly oscillating coefficients. For another interesting application of a parameter y consider the following problem with nonuniformly oscillating coefficients (Chapter 1, section 6 in [9]):

$$-\mathrm{div}\, \mathcal{D}\left[x, \frac{x}{\eta}\right](\nabla_x u_\eta(x)) = b(x), \quad x\in\Omega, \tag{90}$$

$$u_\eta(x) = 0, \qquad x\in\partial\Omega, \tag{91}$$

with a given $b\in L^2(\Omega)$ and with a Y-periodic in y matrix $\mathcal{D}[x,y]$. We assume that there exist two positive constants $0<\alpha\le\beta$ such that the matrix $\mathcal{D}[x,y]$ satisfies

$$\alpha|\xi|^2 \le \mathcal{D}_{ij}[x,y]\xi_i\xi_j \le \beta|\xi|^2 \quad \text{for any } \xi\in\mathbb{R}^N. \tag{92}$$

The last assumption (92) implies that the mapping $\mathcal{D}[x,y]$ belongs to $L^\infty(\Omega\times Y,\mathbb{R}^{N\times N})$. But it is not enough to ensure that the mapping $x\mapsto\mathcal{D}[x,x/\eta]$ is measurable, so in [9] it is assumed that $\mathcal{D}\in C(\Omega, L^\infty(Y,\mathbb{R}^{N\times N}))$ to obtain a solution of (90)–(91). Instead of increasing the regularity of $\mathcal{D}[x,y]$ we consider a family of shifted problems

$$-\mathrm{div}_x\, \mathcal{D}\left[x, \frac{x}{\eta}+y\right](\nabla_x u_\eta(x,y)) = b(x), \qquad (x,y)\in\Omega\times Y, \tag{93}$$

$$u_\eta(x,y) = 0, \qquad (x,y)\in\partial\Omega\times Y. \tag{94}$$

Now the problem (93)–(94) admits a unique solution u_η in $L^2(Y, H_0^1(\Omega))$, which satisfies the estimate

$$\|u_\eta\|_{L^2(Y,H_0^1(\Omega))} \le C\|b\|_\Omega,$$

where C is a positive constant independent of η. For a.e. fixed $y\in Y$ the existence of the solution is provided by the well-known result for second order elliptic operators and the integrability with respect to y is then the easy consequence of it.

It is convenient now to write (93)–(94) in the form

$$-\mathrm{div}_x\sigma_\eta(x,y) = b(x), \qquad (x,y)\in\Omega\times Y, \tag{95}$$

$$\sigma_\eta(x,y) = \mathcal{D}\left[x, \frac{x}{\eta}+y\right](\nabla_x u_\eta(x,y)), \quad (x,y)\in\Omega\times Y, \tag{96}$$

$$u_\eta(x,y) = 0, \qquad (x,y)\in\partial\Omega\times Y. \tag{97}$$

Now the solution of (95)–(97) is a function $(u_\eta,\sigma_\eta)\in L^2(Y,H_0^1(\Omega))\times L^2(\Omega\times Y,\mathbb{R}^N)$.

Then inserting the formal ansatz for the solution u_η

$$\hat{u}_\eta(x,y) = u_0(x) + \eta u_1\left(x, \frac{x}{\eta}+y\right) + \eta^2 u_2\left(x,\frac{x}{\eta}+y\right) + \cdots$$

into the boundary problem (93)–(94) and identifying powers of η lead to the homogenized problem

$$\begin{aligned}
-\mathrm{div}_x \sigma_\infty(x) &= b(x), \\
\sigma_\infty(x) &= \frac{1}{|Y|}\int_Y \sigma_0(x,y)dy, \\
-\mathrm{div}_y \sigma_0(x,y) &= 0, \\
\sigma_0(x,y,t) &= \mathcal{D}[x,y](\nabla_y u_1(x,y) + \nabla_x u_0(x)),
\end{aligned}$$

which must hold for $(x,y) \in \Omega \times Y$,

$$u_0(x) = 0,$$

which must hold for $x \in \partial\Omega$. This form of the homogenized problem is equivalent to the already obtained one in [9]. A slight modification of the proof of Lemma 2.7 yields the following convergence result:

$$\lim_{\eta\to 0}(\|u_0 - u_\eta\|_{\Omega\times Y} + \|\sigma_0 - \sigma_\eta\|_{\Omega\times Y}) = 0, \tag{98}$$

where (u_0, u_1, σ_0) is the solution of the homogenized problem and (u_η, σ_η) is the solution of the problem (95)–(97) with a parameter y.

Equation (98) holds without imposing additional regularity on $\mathcal{D}[x,y], b(x)$, and $\partial\Omega$.

Acknowledgment. The author thanks Hans-Dieter Alber for helpful suggestions.

FLUX OF SUPERCONDUCTING VORTICES THROUGH A DOMAIN*

S. N. ANTONTSEV† AND N. V. CHEMETOV‡

Abstract. This article addresses the mathematical study of a mean-field model of superconducting vortices in a II-type superconductor, previously introduced in [S. J. Chapman, *SIAM J. Appl. Math.*, 55 (1995), pp. 1259–1279]. We investigate a hyperbolic-elliptic type system of PDEs in a given domain. Motivated by physical experiments, we consider nonzero and nonconstant boundary conditions, which describe a flux of superconducting vortices through the domain. We prove the existence of the regular solutions of a parabolic-elliptic approximated system and establish a uniform L_∞-bound for the vorticity and the convergence to the initial system. Finally, we analyze the regularity of weak solutions.

Key words. mean-field model, superconducting vortices, flux, solvability

1. The statement of the problem.

Certain materials, when cooled through a critical temperature, exhibit a superconducting state in which they have the ability to conduct electric currents without resistance. Many models have been proposed to describe the behavior of superconductors: the microscopic theory of Bardeen, Cooper, and Schrieffer, the mesoscopic theories of London, Ginzburg, and Landau, and the macroscopic critical state theories, like the Bean model. For the description and relationship of these models we refer to the excellent works of Chapman [3], [4]. In this paper we investigate a mean-field model of superconducting vortices in a II-type superconductor, formulated in [5]. In 1-D and 2-D cases the following system describes the evolution of the vorticity ω and the average magnetic field h of the superconducting sample:

$$\omega_t + \operatorname{div}(\omega\vec{v}) = 0, \quad (\vec{x},t) \in \Omega_T := \Omega \times (0,T), \tag{1.1}$$

$$-\Delta h + h = \omega, \qquad (\vec{x},t) \in \Omega_T, \tag{1.2}$$

$$\vec{v} = -\nabla h, \qquad (\vec{x},t) \in \Omega_T, \tag{1.3}$$

with the following boundary conditions:

$$\vec{v}\,\vec{n} = a(\vec{x},t), \quad (\vec{x},t) \in \Gamma_T := \Gamma \times (0,T), \tag{1.4}$$

$$\omega = b(\vec{x},t), \quad (\vec{x},t) \in \Gamma_T^- := \Gamma^- \times (0,T) \tag{1.5}$$

and the initial conditions

$$\omega(\vec{x},0) = \omega_0(\vec{x}), \quad \vec{x} \in \Omega. \tag{1.6}$$

Here $\vec{n}$ denotes the outward normal to the $C^{2+\gamma}$-smooth boundary $\Gamma = \Gamma^+ \cup \Gamma^0 \cup \Gamma^-$ of the bounded domain $\Omega \subset \mathbb{R}^n$, with some $\gamma > 0$; Γ^+ is the part of the boundary Γ, where $\vec{v}\,\vec{n} = a > 0$; Γ^0 is the part of Γ, where $\vec{v}\,\vec{n} = a = 0$; Γ^- is the part of Γ, where $\vec{v}\,\vec{n} = a < 0$ and $meas(\Gamma^+) \neq 0$, $meas(\Gamma^-) \neq 0$. Let us note that the physical statement of the system is valid just for $n = 1$ and $n = 2$, but in this article we shall consider the common case, when $n \geq 1$. Note that the system (1.1)–(1.3) is of hyperbolic-elliptic type for unknown functions $\{\omega, h\}$.

Many articles on (1.1)–(1.3) have been written in the last ten years. The problem has been studied through various approaches ranging from asymptotic analysis, numerical simulations, and rigorous mathematical analysis. As we know that the first positive existence result for the system (1.1)–(1.3), (1.6) was obtained by Huang and Svobodny [12] in the case of the Cauchy problem for the domain $\Omega = \mathbb{R}^2$, using the method of characteristics and potentials. In the articles [2], [17], the system (1.1)–(1.3), (1.6) was considered in the case of a bounded domain Ω with boundary conditions

$$
\begin{aligned}
h(\vec{x}, t) &= a, \quad (\vec{x}, t) \in \Gamma_T, \\
\omega(\vec{x}, t) &= b, \quad (\vec{x}, t) \in \Gamma_T^-,
\end{aligned} \tag{1.7}
$$

where a, b are given *constants*. In [17] the existence of a weak solution of (1.1)–(1.3), (1.6)–(1.7) for $b = 0$ was deduced by an approach based on a parabolic-elliptic approximation. In the 1-D case the authors have shown the uniqueness of the solution. Also in this work and in [6] the existence of a steady state solution $\{\omega, h\}$ of (1.1)–(1.3), (1.6)–(1.7) was demonstrated. In [9] the solvability of (1.1)–(1.3), (1.6)–(1.7) with an additional curvature term in (1.1) was shown. In [10], the case of flux pinning and boundary nucleation of vorticity (i.e., the *constants* $a, b > 0$) was considered, where existence and uniqueness of a solution in the 1-D case were proved. The discretization, the convergence of discretizated solutions, and numerical simulations of (1.1)–(1.3) were extensively studied in articles [7], [11], [19], [2]. In all mentioned works the boundary conditions (1.7) were taken as *zero or constant* valued. The evolution of vortices arises under penetration of the magnetic field into superconducting bodies and due to it the vortices are generated *only at the boundary*, hence the question of the boundary conditions is important in the modelling of the motion of the vortices. Chapman discussed this question in many articles (see, for instance, [3], [4], [5]). One of the possible boundary conditions suggested by him is to define the value of the vorticity ω on Γ^- as a nonlinear combination of the current $\nabla^\perp h$,

$$
\omega = \alpha \max\{|\nabla^\perp h| - J, \quad 0\} \qquad \text{on } \Gamma_T^-, \tag{1.8}
$$

where α, J are physical constants. The physical meaning of the condition (1.8) is that the nucleation of the vortices at the boundary provided the magnitude of current is larger than the *so-called* nucleation current J. The nucleation of the vorticity is a consequence of the behavior of the current $\nabla^\perp h$, i.e., the case of nonzero or nonconstant boundary conditions is really physical.

In this article we assume that the nucleation of the vorticity can be measured by a physical experiment, which is possible (we refer to the Web site: http://www.fys.uio.no/super/results/sv/index.html), that is, the normal component of the velocity $\vec{v}$ and the vorticity ω on the boundary Γ are defined by (1.4) and (1.5), respectively. The system (1.1)–(1.6) exhibits a transport effect, which plays an important role in understanding the behavior of the vortices *after the nucleation*.

In this article, we consider the problem (1.1)–(1.6) for the general case, when $a(\vec{x},t)$, $b(\vec{x},t)$ are *arbitrary* given functions of the conditions (1.4)–(1.5). We prove the existence of solution $\{\omega, h\}$ with a natural smooth restriction on the data of the problem.

1.1. Terminology and notations. In accordance with the notations introduced in the books [14], [15], we shall use Sobolev's spaces $L_q(\Omega)$, $W_q^l(\Omega)$, $W_q^{l,\,m}(\Omega_T)$, $W_q^l(\Gamma)$, $W_q^{l,\,m}(\Gamma_T)$ for $l,q \geq 1$, $m \geq 0$ and the Hölder spaces $C^l(\Omega)$, $C^{l,\,m}(\Omega_T)$, $C^{l,\,m}(\Gamma_T)$ for $l,m \geq 0$, where the index l corresponds to the variable $\vec{x}$ and m to the variable t (l,q,m are integer or noninteger).

Let B be a given Banach space. We denote by $C(0,T;B)$ the space of continuous functions from $[0,T]$ into the Banach space B with the norm

$$||u||_{C(0,T;\ B)} = \max_{t\in[0,T]} ||u(t)||_B$$

and by $L_p(0,T;B)$ for any $1 \leq p \leq \infty$, the space of measurable functions from $[0,T]$ into the Banach space B with pth power summable on $[0,T]$, with the norm

$$||u||_{L_p(0,T;\ B)} = \left(\int_0^T ||u(t)||_B^p dt\right)^{\frac{1}{p}} \qquad \Big(= ess \sup_{0<t<T} ||u(t)||_B \text{ if } p=\infty\Big).$$

We also introduce the space $V_2^{1,0}(\Omega_T)$ with the norm

$$||u||_{V_2^{1,0}(\Omega_T)} = \max_{t\in[0,T]} ||u(x,t)||_{L_2(\Omega)} + ||u_x(x,t)||_{L_2(\Omega_T)}.$$

1.2. Regularity of data. We assume that the datum a satisfies the condition

$$a \in C^{\eta,\,\theta}(\Gamma_T) \quad \text{for some } \eta,\, \theta \in (0,1) \tag{1.9}$$

and the data $b,\ \omega_0$ admit an extension $\breve{\omega}$, defined on the domain $\overline{\Omega}_T$, such that

$$\breve{\omega}(\vec{x},t) = b(\vec{x},t), \quad (\vec{x},t) \in \Gamma_T^-; \qquad \breve{\omega}(\vec{x},0) = \omega_0(\vec{x}), \quad \vec{x} \in \Omega; \tag{1.10}$$

and $\breve{\omega}$ satisfies

$$0 \leq \breve{\omega}(\vec{x},t) \leq \aleph \quad \text{for a.e. } (\vec{x},t) \in \overline{\Omega}_T, \tag{1.11}$$

$$(||\partial_t\breve{\omega}(\cdot,t)||_{L_1(\Omega)} + || \triangle \breve{\omega}(\cdot,t)||_{L_1(\Omega)} + || \bigtriangledown \breve{\omega}(\cdot,t)||_{L_\infty(\Omega)}) \in L_1(0,T), \tag{1.12}$$

where $\aleph$ is a constant.

Remark 1. The assumption (1.11) implies that the functions ω_0 and b are positive and bounded above by the constant $\aleph$ on $\overline{\Omega}$ and Γ_T^-, respectively. In section 6 we give sufficient conditions on the data $b,\ \omega_0$ that permit the existence of an extension $\breve{\omega}$ on the domain $\overline{\Omega}_T$, satisfying the conditions (1.10)–(1.12).

Let us give the definition of the weak solution of our problem.

Definition 1. *A pair of functions $\{\omega, h\}$ is said to be a weak solution of the problem* (1.1)–(1.6)*, if $\omega \in L_\infty(\Omega_T)$, $h \in L_\infty(0,T;\ C^{1+\alpha}(\overline{\Omega})) \cap L_2(0,T;\ W_2^2(\Omega'))$ for some $\alpha \in (0,1)$ and for any subdomain Ω' of Ω such that $\overline{\Omega'} \subset \Omega$ and the following equalities*:

$$\int_{\Omega_T} \omega(\psi_t + \vec{v}\,\nabla\psi)\, d\vec{x}dt + \int_\Omega \omega_0\ \psi(\vec{x},0)\ d\vec{x} = -\int_{\Gamma_T^-} a\ b\ \psi\ d\vec{x}dt, \tag{1.13}$$

$$-\Delta h + h = \omega \qquad a.e.\ in\ \Omega_T, \tag{1.14}$$

$$\vec{v} = -\nabla h \qquad a.e.\ in\ \Omega_T, \tag{1.15}$$

$$-\nabla h\,\vec{n} = a \qquad a.e.\ on\ \Gamma_T \tag{1.16}$$

hold for an arbitrary function $\psi \in H^1(\Omega_T)$, *such that*

$$\psi(\vec{x},T) = 0 \text{ for } \vec{x} \in \Omega \quad \text{and} \quad \psi(\vec{x},t) = 0 \text{ for } (\vec{x},t) \in \Gamma_T^+ \cup \Gamma_T^0. \tag{1.17}$$

Our main result in this work is the following theorem.

THEOREM 1. *If the data* a, b, ω_0 *satisfy* (1.9)–(1.12), *then there exists at least one weak solution* $\{\omega, h\}$ *of the problem* (1.1)–(1.6). *Moreover, we have*

$$\omega \in L_\infty(\Omega_T),\ \partial_t\omega \in L_\infty(0,T;H^{-1}(\Omega)) \tag{1.18}$$

and

$$\begin{gathered} h \in L_\infty(0,T;\, C^{1+\eta}(\overline{\Omega})) \cap L_\infty(0,T;\, W_q^2(\overline{\Omega'})),\\ h,\ \bigtriangledown h \in C^{0,\,\theta}(\overline{\Omega'} \times [0,T]) \end{gathered} \tag{1.19}$$

for any $q \in (1,\infty)$ *and for any* Ω', *such that* $\overline{\Omega'} \subset \Omega$.

Remark 2. A similar result is valid for both Dirichlet and Robin boundary conditions (in accordance with "www.wikipedia.org" terminology), instead of (1.16), on the function h. For simplicity, we prove this theorem for the dimension $n \geq 2$.

We divide the proof of this theorem into four steps:

Step 1: In section 2, we remember well-known results from the theory of elliptic equations that will be very useful in what follows.

Step 2: In section 3, we show that an approximate problem of (1.1)–(1.6), which is of parabolic-elliptic type, is solvable, if the initial and boundary conditions are smooth; the reasoning is based on the Schauder fixed point theorem.

Step 3: In section 4, by using the principle of maximum-minimum and the results of potential theory for elliptic equations, mentioned in section 2, we deduce L_∞-estimates and some additional a priori estimates for the solutions of the approximate problem of (1.1)–(1.6).

Step 4: In section 5, we use a compactness argument to establish the existence of a solution for the original problem.

2. Auxiliary assertions. The elliptic boundary value problem. In this section, for the convenience of the reader, we give well-known results on elliptic equations.

According to the potential theory for elliptic equations [20], the solution of the problem

$$\begin{cases} -\Delta h_1 + h_1 = F, & \vec{x} \in \Omega, \\ -\nabla h_1\, \vec{n} = 0, & \vec{x} \in \Gamma \end{cases} \tag{2.1}$$

can be written in the form $h_1(\vec{x}) = (K_1 * F)(\vec{x}) := \int_\Omega K_1(\vec{x},\vec{y})\ F(\vec{y})\ d\vec{y}$, and the solution of the problem

$$\begin{cases} -\Delta h_2 + h_2 = 0, & \vec{x} \in \Omega, \\ -\nabla h_2\, \vec{n} = g, & \vec{x} \in \Gamma \end{cases} \tag{2.2}$$

can be written in the form $h_2 = (K_2 * g)(\vec{x}) := \int_\Gamma K_2(\vec{x},\vec{y}) g(\vec{y})\ d\vec{y}$. Since Γ is $C^{2+\gamma}$-smooth, the kernels $K_1,\ K_2$ satisfy the inequalities

$$\begin{aligned} |K_i(\vec{x},\vec{y})| &\leq C|x-y|^{2-n}, \\ |\nabla_{\vec{x}} K_i(\vec{x},\vec{y})| &\leq C|x-y|^{1-n}, \quad i=1,2, \qquad \text{for any } \vec{x},\vec{y} \in \Omega \end{aligned}$$

in the n-dimensional case with $n > 2$ and

$$|K_i(\vec{x},\vec{y})| \le C|ln|x-y||,$$
$$|\nabla_{\vec{x}} K_i(\vec{x},\vec{y})| \le C|x-y|^{-1}, \quad i = 1,2, \qquad \text{for any } \vec{x},\vec{y} \in \Omega$$

in the 2-D case.

According to the theory of elliptic equations [15, pp. 169–193], the embedding theorem of Sobolev, $W_p^1(\Omega) \subset C^{\alpha}(\overline{\Omega})$ with $\alpha = 1 - \frac{n}{p}$ if $n < p < \infty$ (see, for instance, [14, p. 61]), and the potential theory [13, p. 191, Lemma 1.4], [8, p. 88, Lemma 10.1]; [16, p. 100, Theorem 3.4 and Remark], the operators $F \to K_1 * F$, $g \to K_2 * g$ possess the following properties.

Lemma 1. *For any n-dimensional case with $n \ge 2$*

(1) *the function $h_1 = K_1 * F$ satisfies the following estimates*:

$$h_1 \ge 0 \ \text{ in } \ \Omega \qquad \text{if } F \ge 0 \ \text{a.e. in } \Omega, \tag{2.3}$$

$$||h_1||_{W_p^2(\Omega)} \le C||F||_{L_p(\Omega)} \qquad \text{if } 1 < p < \infty, \tag{2.4}$$

$$||h_1||_{C^{1+\alpha}(\overline{\Omega})} \le C||F||_{L_p(\Omega)} \quad \alpha = 1 - \frac{n}{p} \quad \text{if } n < p < \infty, \tag{2.5}$$

$$||h_1||_{C^{1+\alpha}(\overline{\Omega})} \le C||F||_{L_\infty(\Omega)} \ \ \forall\, \alpha \in (0,1), \tag{2.6}$$

$$||h_1||_{W_1^1(\Omega)} \le C||F||_{L_1(\Omega)}. \tag{2.7}$$

(2) *the function $h_2 = K_2 * g$ satisfies the following estimates*:

$$||h_2||_{C^{1+\alpha}(\overline{\Omega})} \le C||g||_{C^{\alpha}(\Gamma)} \qquad \text{if } \ 0 < \alpha < 1, \tag{2.8}$$

$$||h_2||_{C^{l}(\overline{\Omega}')} \le C||g||_{L_1(\Gamma)}, \tag{2.9}$$

for any Ω', such that $\overline{\Omega}' \subset \Omega$ and any $l \ge 0$.

3. Construction of approximate solutions. Let $\breve{\omega}^{\varepsilon}$, a^{ε} for $\varepsilon > 0$ be smooth approximations of the functions $\breve{\omega}$, a, such that

$$\begin{aligned} 0 \le & \breve{\omega}^{\varepsilon}(\vec{x},t) \le \aleph && \text{for} \quad (\vec{x},t) \in \overline{\Omega}_T, \\ 0 < & a^{\varepsilon}(\vec{x},t) && \text{for} \quad (\vec{x},t) \in \Gamma_T^{+}, \\ 0 = & a^{\varepsilon}(\vec{x},t) && \text{for} \quad (\vec{x},t) \in \Gamma_T^{0}, \\ & a^{\varepsilon}(\vec{x},t) < 0 && \text{for} \quad (\vec{x},t) \in \Gamma_T^{-}. \end{aligned} \tag{3.1}$$

We require also that

$$\begin{cases} \breve{\omega}^{\varepsilon}(\vec{x},t) \underset{\varepsilon \to 0}{\longrightarrow} \breve{\omega}(\vec{x},t) & \text{a.e. in } \overline{\Omega}_T, \\ \\ ||a^{\varepsilon} - a\,||_{C^{\eta,\theta}(\Gamma_T)} \underset{\varepsilon \to 0}{\longrightarrow} 0 \end{cases} \tag{3.2}$$

and

$$\begin{aligned} \int_0^T \{ & ||\partial_t(\breve{\omega}^{\varepsilon} - \breve{\omega})||_{L_1(\Omega)} + ||\triangle\,(\breve{\omega}^{\varepsilon} - \breve{\omega})||_{L_1(\Omega)} \\ & + ||\bigtriangledown(\breve{\omega}^{\varepsilon} - \breve{\omega})||_{L_\infty(\Omega)}\}\, dt \underset{\varepsilon \to 0}{\longrightarrow} 0. \end{aligned} \tag{3.3}$$

Let us fix a positive number R. Next we construct the pair $\{\omega_{\varepsilon,R}, h_{\varepsilon,R}\}$ as a solution of auxiliary **Problem $\mathbf{P}_{\varepsilon,\mathbf{R}}$**. For the sake of simplicity, in this section we suppress the dependence $\omega_{\varepsilon,R}, h_{\varepsilon,R}$ on ε, R and write ω and h.

Let us consider the problem which is a coupling of the following two systems.

Problem $\mathbf{P}_{\varepsilon,\mathbf{R}}$. *Find $\omega \in W_2^{2,1}(\Omega_T)$, satisfying the system*

$$(3.4)\quad \begin{cases} \omega_t + \operatorname{div}(\omega\vec{v}) = \varepsilon\Delta\omega \quad \text{and} \quad \vec{v} = -\nabla h \qquad \text{for} \quad (\vec{x},t) \in \Omega_T, \\ \omega(\vec{x},t) = \breve{\omega}^{\varepsilon}(\vec{x},t),\ (\vec{x},t) \in \Gamma_T, \qquad \omega(\vec{x},0) = \breve{\omega}^{\varepsilon}(\vec{x},0),\ \vec{x} \in \Omega \end{cases}$$

and find $h \in W_2^2(\Omega)$, satisfying the system

$$(3.5)\quad \begin{cases} -\Delta h + h = [\omega]_R, \quad (\vec{x},t) \in \Omega_T, \\ -\nabla h\,\vec{n} = a^{\varepsilon}(\vec{x},t), \quad (\vec{x},t) \in \Gamma_T, \end{cases}$$

where $[\cdot]_R$ is the cut-off function defined as $[\phi]_R := \max\{0,\ \min\{R,\phi\}\}$.

To prove the solvability of **Problem $\mathbf{P}_{\varepsilon,\mathbf{R}}$** we use the Schauder fixed point argument. Let us introduce the class of functions

$$(3.6)\qquad \mathcal{M} = \{\omega(\vec{x},t) \in C(0,T;\ L_2(\Omega)) : ||\omega||_{C(0,T;\ L_2(\Omega))} \le M\},$$

where an exact value of M will be determined below. First we define the operator T_1, which transforms a "fixed" vorticity into the corresponding superconductive field

$$(3.7)\qquad \mathcal{M} \ni \widetilde{\omega} \mapsto T_1[\widetilde{\omega}] = h$$

as the solution of (3.5), where instead of ω we put the chosen $\widetilde{\omega}$. By (2.1), (2.2) the solution h can be represented in the form

$$(3.8)\qquad h(\vec{x},t) = (K_1 * [\widetilde{\omega}]_R)(\vec{x},t) + (K_2 * a^{\varepsilon})(\vec{x},t)$$

for a.e. $(\vec{x},t) \in \Omega_T$, and by (2.5), (2.8) of Lemma 1 we derive the estimate

$$(3.9)\qquad \begin{aligned} ||h||_{L_\infty(0,T;\ C^1(\overline{\Omega}))} &\le C(||\,[\widetilde{\omega}]_R\,||_{L_\infty(\Omega_T)} + ||a^{\varepsilon}||_{L_\infty(0,T;\ C^{\eta}(\Gamma))}) \\ &\le C(R+1), \end{aligned}$$

where the constant C depends on the datum a^{ε} being independent of ε, R. The second operator T_2 describes the evolution of the vorticity

$$(3.10)\qquad \vec{v} = -\nabla h \mapsto T_2[h] = \omega,$$

where ω is the solution of (3.4) for the found "superconductive field" h in (3.7). Taking into account (3.9) and the results of [14, Theorem 4.1, p. 153 and Theorem 4.2, p. 160], there exists a unique weak solution ω of (3.4) such that

$$(3.11)\qquad ||\omega||_{V_2^{1,0}(\Omega_T)} \le C_*,$$

$$(3.12)\qquad ||\omega(\cdot,t_1) - \omega(\cdot,t_2)||_{L_2(\Omega)} \le \phi_*(|t_1 - t_2|) \quad \forall t_1, t_2 \in [0,T],$$

where the constant C_* and the function $\phi_* = \phi_*(t) \in C([0,T]),\ \phi_*(0) = 0$ depend on ε, R and the data $\breve{\omega}^{\varepsilon},\ a^{\varepsilon}$. Setting $M := C_*$ in (3.6) and $T = T_2 \circ T_1$, by (3.6), (3.11), (3.12), we see that T maps the bounded set $\mathcal{M}$ into a compact subset of $\mathcal{M}$.

In order to apply the Schauder fixed point theorem we need to prove that the operator T is continuous. Let $\widetilde{\omega}_n, \widetilde{\omega} \in \mathcal{M}$ and $\widetilde{\omega}_n \to \widetilde{\omega}$ in $C(0,T;\ L_2(\Omega))$. From (3.8) and (2.5) of Lemma 1, it follows that for any $p > n$

$$\begin{aligned} ||\nabla h_n - \nabla h||_{C^{\alpha}(\overline{\Omega})} &\le C||[\widetilde{\omega}_n]_R - [\widetilde{\omega}]_R||_{L_p(\Omega)} \\ \le C\cdot(2R)^{\frac{p-2}{p}}\,||[\widetilde{\omega}_n]_R - [\widetilde{\omega}]_R||^{2/p}_{L_2(\Omega)} &\le C(R)||\widetilde{\omega}_n - \widetilde{\omega}||^{2/p}_{L_2(\Omega)} \overset{n\to\infty}{\longrightarrow} 0, \end{aligned}$$

where the constant $C(R)$ depends on R being independent of ε and the index n. Hence

$$||\nabla h_n - \nabla h||_{C(0,T;\, C^\alpha(\overline{\Omega}))} \to 0, \tag{3.13}$$

where h_n and h are the solutions of (3.5) with ω replaced by $\widetilde{\omega}_n$ and $\widetilde{\omega}$, respectively. Next we consider $\omega_n = T[\widetilde{\omega}_n]$ and $\omega = T[\widetilde{\omega}_n]$. Using (3.13) and the results of [14] we conclude that

$$\max_{t\in[0,T]} ||\omega_n(\cdot,t) - \omega(\cdot,t)||_{L_2(\Omega)} + ||\nabla(\omega_n - \omega)||_{L_2(\Omega_T)} \to 0.$$

Therefore we conclude that the sequence ω_n itself converges to ω and the continuity of the operator T is proved.

Hence there exists a fixed point ω, such that $\omega = T[\omega]$. We now show the following lemma.

Lemma 2. *There exists at least one solution* $\{\omega, h\}$ *of the systems* (3.4)–(3.5)*, such that for some* $\alpha \in (0,1)$

$$\omega \in W_2^{1,0}(\Omega_T) \cap C(0,T;\, L_2(\Omega)), \qquad h \in C(0,T;\, C^{1+\alpha}(\overline{\Omega})).$$

By the theory of parabolic and elliptic equations the constructed functions ω, h have a better regularity. In fact we deduce the following result.

Theorem 2. *For fixed* $\varepsilon, R > 0$*, there exists a unique pair of functions*

$$\omega \in W_2^{2,1}(\Omega_T) \cap C^{\alpha,\alpha/2}(\Omega_T), \qquad h \in C^{2+\alpha,\alpha/2}(\Omega_T) \tag{3.14}$$

for some $\alpha \in (0,1)$*, which is the solution of* ***Problem*** $\mathbf{P}_{\varepsilon,\mathbf{R}}$.

Proof. Because of (3.1), the function $\breve{\omega}^\varepsilon$ is bounded in $\overline{\Omega}_T$ by the constant $\aleph$. Applying Theorem 7.1, p. 181 of [14], we have

$$||\omega||_{L_\infty(\Omega_T)} \le C(R,\varepsilon)\,\aleph, \tag{3.15}$$

where the constant $C(R,\varepsilon)$ depends on R, ε. Hence ω is the solution of the equation

$$\omega_t - \varepsilon\Delta\omega = \mathcal{F}(\vec{x},t), \quad (\vec{x},t) \in \Omega_T$$

with $\mathcal{F} = -\nabla\omega\,\vec{v} - \omega([\omega]_R - h) \in L_2(\Omega_T)$ by (3.9), (3.11), (3.15). Using Theorem 6.1, p. 178 of [14], we deduce $\omega(\vec{x},t) \in W_2^{2,1}(\Omega_T)$ and also by Theorem 10.1, p. 204 of [14], we have $\omega \in C^{\alpha,\alpha/2}(\Omega_T)$ for some $\alpha \in (0,1)$. Moreover, by the theory of elliptic equations [15], we conclude that $h \in C^{2+\alpha,\alpha/2}(\Omega_T)$.

The uniqueness of the solution $\{\omega, h\}$ for **Problem** $\mathbf{P}_{\varepsilon,\mathbf{R}}$ follows in the usual way. Let $\omega_i, h_i, i = 1,2$, be different solutions of **Problem** $\mathbf{P}_{\varepsilon,\mathbf{R}}$ and $\omega = \omega_1 - \omega_2, h = h_1 - h_2$. Then the pair $\{\omega, h\}$ satisfies

$$\begin{cases} \omega_t - \varepsilon\Delta\omega = \operatorname{div}(\nabla h_1 \omega + \omega_2 \nabla h), & (\vec{x},t) \in \Omega_T, \\ \omega(\vec{x},t) = 0, \ \ (\vec{x},t) \in \Gamma_T, & \omega(\vec{x},0) = 0, \ \ \vec{x} \in \Omega, \end{cases}$$

$$\begin{cases} -\Delta h + h = [\omega_1]_R - [\omega_2]_R, & (\vec{x},t) \in \Omega_T, \\ -\nabla h\, \vec{n} = 0, & (\vec{x},t) \in \Gamma_T. \end{cases}$$

Multiplying the first equation by ω, the second one by h, and integrating them over Ω, we obtain the following relations:

$$\frac{1}{2}\frac{d}{dt}\int_\Omega \omega^2\, d\vec{x} + \varepsilon\int_\Omega |\nabla\omega|^2\, d\vec{x} = -\int_\Omega (\nabla h_1\omega + \omega_2\nabla h)\,\nabla\omega\, d\vec{x},$$
$$\int_\Omega \left(|\nabla h|^2 + |h|^2\right)\, d\vec{x} = \int_\Omega ([\omega_1]_R - [\omega_2]_R)\, h\, d\vec{x}.$$

Applying the property of *the cut-off function*, that $|[\omega_1]_R - [\omega_2]_R| \le |\omega_1 - \omega_2|$, and Cauchy's inequality, we come to the inequality

$$\frac{d}{dt}\int_\Omega \omega^2\, d\vec{x} + \varepsilon\int_\Omega |\nabla\omega|^2\, d\vec{x} \le C\int_\Omega \omega^2\, d\vec{x} \quad \text{and} \quad \int_\Omega \omega^2(\vec{x},0)\, d\vec{x} = 0$$

with some constant $C = C(\varepsilon, \|\nabla h_1\|_{L_\infty(\Omega_T)}, \|\omega_2\|_{L_\infty(\Omega_T)})$. Application of the standard Gronwall inequality completes the proof of the uniqueness of solution. □

4. A priori estimates independent of $\boldsymbol{\varepsilon, R}$. In this section we derive a priori estimates of the solution $\{\omega_{\varepsilon,R},\ h_{\varepsilon,R}\}$ for **Problem $\mathbf{P}_{\varepsilon,\mathbf{R}}$**, which do not depend on ε, R.

In sections 4, 5, and 6, all constants C, which are used in a priori estimates, do not depend on ε and R.

4.1. Maximum-minimum principle for $\boldsymbol{\omega}$ and $\boldsymbol{h}$. In this section, we show that the solution $\{\omega_{\varepsilon,R},\ h_{\varepsilon,R}\}$ is bounded in $L_\infty(\Omega_T)$, independently of ε, R. Throughout the section, for simplicity of presentation, we continue to suppress the dependence of $\omega_{\varepsilon,R}$ and $h_{\varepsilon,R}$ on ε, R and write ω and h.

The proof of boundedness of the functions ω, h is divided into a few lemmas. First let us show the positivity of ω.

LEMMA 3. *For all $(\vec{x},t) \in \Omega_T$*

$$\omega(\vec{x},t) \ge 0. \tag{4.1}$$

Proof. By (3.14) we have

$$\sup_{\vec{x}\in\Omega}\left|\operatorname{div}\vec{v}(\vec{x},t)\right| \le \lambda(t) = \max_{\vec{x}\in\Omega}\left|[\omega(\vec{x},t)]_R - h(\vec{x},t)\right| \in C(0,T). \tag{4.2}$$

Let us denote $\omega_- = \min(\omega, 0)$. Then using (3.1), the first equation of (3.4), and the boundary condition $\omega_-(\vec{x},t) = 0$ for all $(\vec{x},t) \in \Gamma_T$, it is easy to verify that the function ω_- satisfies the inequality

$$\frac{d}{dt}\int_\Omega \omega_-^2\, d\vec{x} + \varepsilon\int_\Omega \left|\nabla\omega_-\right|^2\, d\vec{x} = -\int_\Omega \operatorname{div}\vec{v}\,\omega_-^2\, d\vec{x} \le \lambda(t)\int_\Omega \omega_-^2\, d\vec{x}.$$

Since $\omega_-(\vec{x},0) = 0$ for all $\vec{x} \in \Omega$, from the Gronwall inequality we have $\omega_- = 0$ for all $(x,t) \in \Omega_T$, which implies (4.1). □

Now we show that ω is bounded in the space $L_1(\Omega)$.

LEMMA 4. *There exists a constant Υ_0, independent of R, ε, such that*

$$||\omega(\cdot,t)||_{L_1(\Omega)} \le \Upsilon_0 \quad \forall t \in [0,T]. \tag{4.3}$$

Proof. The function $z = \omega - \breve{\omega}^\varepsilon$ satisfies the problem

$$\begin{cases} z_t + \operatorname{div}(z\vec{v}) = \varepsilon\Delta z + F, & (\vec{x},t) \in \Omega_T, \\ z|_{\Gamma_T} = 0,\ (\vec{x},t) \in \Gamma_T, & z|_{t=0} = 0,\ \vec{x} \in \Omega \end{cases} \tag{4.4}$$

with

$$F = \varepsilon \triangle \breve{\omega}^\varepsilon - \partial_t \breve{\omega}^\varepsilon - \operatorname{div}(\vec{v}\,\breve{\omega}^\varepsilon). \tag{4.5}$$

By (3.1)–(3.3) and (3.5), we have

$$\begin{aligned} &||\operatorname{div}(\vec{v}\,\breve{\omega}^\varepsilon)(\cdot,t)||_{L_1(\Omega)} \le ||\breve{\omega}^\varepsilon||_{L_\infty(\Omega_T)}\,||[\omega]_R - h||_{L_1(\Omega)} \\ &+||\nabla\breve{\omega}^\varepsilon(\cdot,t)||_{L_\infty(\Omega)}\,||\vec{v}||_{L_1(\Omega)} \le \lambda(t)(||[\omega]_R - h||_{L_1(\Omega)} + ||\vec{v}||_{L_1(\Omega)}) \end{aligned} \tag{4.6}$$

with $\lambda(t) \in L_1(0,T)$. Using (3.8) and the estimates (2.7), (2.8) of Lemma 1, we derive that for a.e. $t \in [0,T]$,

$$\begin{aligned} &\left.\begin{matrix} ||h(\cdot,t)||_{L_1(\Omega)} \\ \\ ||\vec{v}(\cdot,t)||_{L_1(\Omega)} \end{matrix}\right\} \le C(||\omega(\cdot,t)||_{L_1(\Omega)} + ||a^\varepsilon(\cdot,t)||_{C^\eta(\Gamma)}) \\ &\qquad\qquad\qquad\qquad \le C||z(\cdot,t)||_{L_1(\Omega)} + C. \end{aligned} \tag{4.7}$$

Therefore, according to (3.2), (3.3), we deduce that

$$||F(\cdot,t)||_{L_1(\Omega)} \le \lambda(t)\left(||z(\cdot,t)||_{L_1(\Omega)} + 1\right) \quad \text{with} \quad \lambda(t) \in L_1(0,T), \tag{4.8}$$

where $\lambda(t)$ does not depend on ε, R. Multiplying (4.4) by $sgn_\delta z := \frac{z}{\sqrt{z^2+\delta}}$ with some $\delta \in (0,1)$, we obtain that

$$\begin{aligned} &\partial_t((z^2+\delta)^{1/2}) + \operatorname{div}(\vec{v}\,(z^2+\delta)^{1/2}) - \frac{\delta}{(z^2+\delta)^{1/2}}\operatorname{div}\vec{v} \\ &= \varepsilon \operatorname{div}\left(\nabla z \frac{z}{(z^2+\delta)^{1/2}}\right) - \varepsilon\delta \frac{|\nabla z|^2}{(z^2+\delta)^{3/2}} + F\, sgn_\delta z. \end{aligned} \tag{4.9}$$

Taking into account that $z = 0$ on Γ_T and integrating this equality over Ω, we have

$$\frac{d}{dt}\left(||\sqrt{z^2+\delta}||_{L_1(\Omega)}\right) + I_\delta(t) \le \lambda(t)\ \left(||z||_{L_1(\Omega)} + 1\right) \text{ for a.e. } t \in [0,T],$$

with $I_\delta(t) = \int_\Omega [\operatorname{div}(\vec{v}\sqrt{z^2+\delta}) - \frac{\delta}{(z^2+\delta)^{1/2}}\operatorname{div}\vec{v}]\,d\vec{x}$. Since

$$|I_\delta| \le \delta^{1/2}\left\{\int_\Omega (|\omega| + |h|)\,d\vec{x} + \left|\int_\Gamma a^\varepsilon\,d\vec{x}\right|\right\} \underset{\delta\to 0}{\longrightarrow} 0,$$

we deduce the inequality

$$\frac{d}{dt}||z||_{L_1(\Omega)} \le \lambda(t)\,(||z||_{L_1(\Omega)} + 1), \text{ a.e. } t \in [0,T],$$

where the function $\lambda(t)$ does not depend on ε, R. Hence applying the Gronwall inequality, we obtain $||z(\cdot,t)||_{L_1(\Omega)} \le C$ for $t \in [0,T]$ with the constant C independent of ε, R. This immediately implies the estimate (4.3). □

Now we prove an auxiliary lemma.

LEMMA 5. *There exists a positive constant R_*, such that*

$$\max_{\overline{\Omega}_T} \omega(\vec{x},t) \le \max\left\{\max_{\overline{\Omega}_T} h(\vec{x},t),\ \aleph\right\} \tag{4.10}$$

for any fixed $R \geq R_*$. The constant R_* depends on $\Upsilon_0, \Gamma, \Omega, ||a||_{L_\infty(0;T;\, C^\eta(\Gamma))}$ and $\aleph$ being independent of ε.

Proof. (A) If ω attains its maximum on the parabolic boundary Γ_T, then (4.10) is obvious.

(B) If ω attains a positive maximum $\overline{\omega} = \omega(\vec{x}_0, t_0)$ inside Ω_T, then we come to the relation

$$0 \leq \omega_t(\vec{x}_0, t_0) - \varepsilon \bigtriangleup \omega(\vec{x}_0, t_0) = \overline{\omega}(h(\vec{x}_0, t_0) - [\overline{\omega}]_R) \tag{4.11}$$

and hence

$$[\overline{\omega}]_R = \min\{R, \overline{\omega}\} \leq \max_{\overline{\Omega}_T} h(\vec{x}, t).$$

Let us consider two possibilities.

(B.1) If $\overline{\omega} \leq R$, we have $[\overline{\omega}]_R = \overline{\omega} \leq \max_{\overline{\Omega}_T} h(\vec{x}, t)$, and therefore (4.10) is proved.

(B.2) If $\overline{\omega} > R$, we have

$$R \leq \max_{\overline{\Omega}_T} h(\vec{x}, t). \tag{4.12}$$

Let us prove that this case is impossible for large enough R. Using the representation (3.8), Lemma 4, and (2.3), (2.5), (2.8) of Lemma 1, we have

$$\begin{aligned}
\max_{\overline{\Omega}} |h| &\leq \max_{\overline{\Omega}} |K_1 * ([\omega]_R{}^{1/q}[\omega]_R{}^{1-1/q})| \;+\; \max_{\overline{\Omega}} |h_2| \\
&\leq C(q, \Omega)\; ||\omega||_{L_1(\Omega)}\; R^{1-1/q} \;+\; C(\Gamma)||a^\varepsilon||_{C^\eta(\Gamma)} \\
&\leq C(q, \Omega)\; \Upsilon_0\; R^{1-1/q} \;+\; C(\Gamma)||a^\varepsilon||_{C^\eta(\Gamma)}
\end{aligned}$$

with $n < q < \infty$. The previous inequality implies that

$$\max_{\overline{\Omega}_T} |h| \leq C_* \left(\max_{\overline{\Omega}_T} R^{1-1/q} + 1 \right)$$

with some constant $C_* = C(q, \Omega, \Gamma, \Upsilon_0, ||a||_{L_\infty(0;T;\, C^\eta(\Gamma))})$, which does not depend on ε, R. Since $0 < 1 - 1/q < 1$, there exists a constant R_*, depending on C_*, such that $C_*(\, R^{1-1/q} + 1) \leq \frac{R}{2}$ for any $R \geq R_*$. Therefore we conclude that

$$\max_{\overline{\Omega}_T} |h| \leq \frac{R}{2} \quad \text{for any} \quad R \geq R_*.$$

But this inequality contradicts with (4.12). □

Remark 3. Let us note that if we consider that the system (3.4)–(3.5) with the right side of (3.5) equals ω, instead of $[\omega]_R$, then the desired assertion of Lemma 5 follows immediately from an analog of the relation (4.11),

$$0 \leq \omega_t(\vec{x}_0, t_0) - \varepsilon \bigtriangleup \omega(\vec{x}_0, t_0) = \overline{\omega}(h(\vec{x}_0, t_0) - \overline{\omega}). \tag{4.13}$$

Now we are able to show the boundedness of $\{\omega, h\}$ in $L_\infty(\Omega_T)$.

LEMMA 6. *There exist constants Υ_1, Υ_2 depending on the data $\breve{\omega}$, a, but independent of R, ε, such that*

$$||\omega||_{L_\infty(\Omega_T)} \leq \Upsilon_1, \tag{4.14}$$

$$||h||_{L_\infty(\Omega_T)},\; ||\nabla h||_{L_\infty(\Omega_T)} \leq \Upsilon_2. \tag{4.15}$$

Proof. Using the representation (3.8), Lemma 4, and (2.3), (2.5), (2.8) of Lemma 1, we have

$$\max_{\overline{\Omega}} |h| \le \max_{\overline{\Omega}} |K_1 * ([\omega]_R{}^{1/q}[\omega]_R{}^{1-1/q})| \; + \; \max_{\overline{\Omega}} |h_2|$$
$$\le C(q,\Omega)\ \Upsilon_0\ \max_{\overline{\Omega}}\ \omega^{1-1/q} \; + \; C(\Gamma)||a^\varepsilon||_{C^\eta(\Gamma)}$$

with $n < q < \infty$. The previous inequality implies that

$$\max_{\overline{\Omega}_T} |h| \le C\left(\max_{\overline{\Omega}_T} \omega^{1-1/q} + ||a||_{L_\infty(0,T;\ C^\eta(\Gamma))}\right) \tag{4.16}$$

with some constant $C = C(q,\Omega,\Gamma,\Upsilon_0)$, which does not depend on ε, R. Joining (4.10) and (4.16), we obtain the inequality

$$\max_{\overline{\Omega}_T} \omega \le C \max\left\{\max_{\overline{\Omega}_T} \omega^{1-1/q} + ||a||_{L_\infty(0,T;\ C^\eta(\Gamma))},\ \aleph\right\}, \tag{4.17}$$

which leads to (4.14), because $0 < 1-1/q < 1$. The estimates (4.15) follow immediately from (2.5), (2.8) of Lemma 1. This completes the proof. □

Choosing $R := \max\{R_*, \Upsilon_1\}$ in (3.5), we see that the cut-off function $[\cdot]_R$ in (3.5) can be omitted. In the following, we consider the solution of (3.4), (3.5) as ω_ε, h_ε, depending only on ε (not R).

4.2. Estimates of derivatives. From this section we shall write ω_ε, h_ε, and $\vec{v}_\varepsilon = -\bigtriangledown h_\varepsilon$. Let us show the following lemma.

LEMMA 7. *There exist constants C independent of ε, such that*

$$||\sqrt{\varepsilon}\nabla\omega_\varepsilon||_{L_2(\Omega_T)} \le C, \tag{4.18}$$
$$||\partial_t(\omega_\varepsilon)||_{L_2(0,T;\ H^{-1}(\Omega))} \le C, \tag{4.19}$$
$$||h_\varepsilon||_{L_\infty(0,T;\ C^{1+\eta}(\overline{\Omega}))} \le C, \tag{4.20}$$
$$||h_\varepsilon(\cdot,t)||_{L_\infty(0,T;\ W^2_p(\overline{\Omega'}))} \le C, \tag{4.21}$$

for any $p \in [1,\infty)$ and for any Ω', such that $\overline{\Omega'} \subset \Omega$.

Proof. According to Lemma 6, we have that

$$||h_\varepsilon||_{L_\infty(\Omega_T)},\ ||\nabla h_\varepsilon||_{L_\infty(\Omega_T)},\ ||\omega_\varepsilon||_{L_\infty(\Omega_T)} \le \Upsilon_3, \tag{4.22}$$

where Υ_3 is independent of ε. Multiplying (4.4) by $z_\varepsilon = \omega_\varepsilon - \breve{\omega}^\varepsilon$ and using (3.1), (4.22), $\operatorname{div}\vec{v}_\varepsilon = \omega_\varepsilon - h_\varepsilon$, we easily get

$$\frac{1}{2}\frac{d}{dt}||z_\varepsilon||^2_{L_2(\Omega)} + \varepsilon||\nabla z_\varepsilon||_{L_2(\Omega)}$$
$$\le -\int_\Omega \operatorname{div}\vec{v}_\varepsilon \frac{z_\varepsilon^2}{2}\, d\vec{x} + \int_\Omega F_\varepsilon\ z_\varepsilon\ d\vec{x} \le C + C||F_\varepsilon||_{L_1(\Omega)}.$$

Integrating on $(0,T)$ and taking into account (1.12), (3.3), we have

$$||\sqrt{\varepsilon}\nabla z_\varepsilon||_{L_2(\Omega_T)} \le C, \tag{4.23}$$

which implies (4.18).

Let us choose an arbitrary function $\phi \in H^1(\Omega_T)$, such that $\phi(\vec{x},T) = \phi(\vec{x},0) = 0$ for all $\vec{x} \in \Omega$ and $\phi(\vec{x},t) = 0,\ (\vec{x},t) \in \Gamma_T$. Multiplying the first equation in (3.4) by ϕ and integrating it over Ω_T, from (4.22)–(4.23) we obtain

$$\left| \int\limits_{\Omega_T} \omega_\varepsilon\, \phi_t\ d\vec{x}dt \right| \leq C\, \|\phi\|_{L_2(0,T;\ H_0^1(\Omega))},$$

which gives (4.19).

Taking into account the representation (3.8), we have

$$h_\varepsilon(\vec{x},t) = (K_1 * \omega_\varepsilon)(\vec{x},t) + (K_2 * a^\varepsilon)(\vec{x},t). \tag{4.24}$$

Hence by (2.6), (2.8) of Lemma 1 we have for all $t \in (0,T)$,

$$||h_\varepsilon(\cdot,t)||_{C^{1+\eta}(\overline{\Omega})} \leq C\left(||\omega_\varepsilon(\cdot,t)||_{L_\infty(\Omega)} + ||a^\varepsilon(\cdot,t)||_{C^\eta(\Gamma)}\right)$$

and by (2.4), (2.9) of Lemma 1

$$||h_\varepsilon(\cdot,t)||_{W_p^2(\overline{\Omega'})} \leq C\left(||\omega_\varepsilon(\cdot,t)||_{L_\infty(\Omega)} + ||a^\varepsilon(\cdot,t)||_{L_1(\Gamma)}\right)$$

for all $p \in [1,\infty)$ and for any Ω' such that $\overline{\Omega'} \subset \Omega$. With the help of (1.9), (3.2), and (4.22), we derive the assertions (4.20), (4.21). $\square$

5. Limit transition. In this section we prove Theorem 2.

From (4.21), (4.22) we conclude that there exists a subsequence of $\{\omega_\varepsilon, h_\varepsilon\}$ such that

$$\begin{aligned} h_\varepsilon &\rightharpoonup h \text{ weakly} - * \text{ in } L_\infty(\Omega_T) \cap L_\infty(0,T;\, W_p^2(\overline{\Omega'})), \\ \nabla h_\varepsilon &\rightharpoonup \nabla h \text{ weakly} - * \text{ in } L_\infty(\Omega_T), \end{aligned} \tag{5.1}$$

for any $p \in (1,\infty)$ and for any Ω', such that $\overline{\Omega}' \subset \Omega$. By results obtained in [1], [18], the compact embedding of $L_2(\Omega)$ in $H^{-1}(\Omega)$ and (4.19) imply

$$\omega_\varepsilon \to \omega \quad \text{strongly in} \quad L_2(0,T;\ H^{-1}(\Omega)). \tag{5.2}$$

In view of (4.18), (4.22), we have

$$\begin{aligned} \omega_\varepsilon &\rightharpoonup \omega \quad \text{weakly} - * \quad \text{in } L_\infty(\Omega_T), \\ \varepsilon\nabla\omega_\varepsilon &\rightharpoonup 0 \quad \text{weakly} \qquad \text{in } L_2(\Omega_T). \end{aligned} \tag{5.3}$$

With the help of (3.2), (5.1), (5.3), the limit transition in the representation (4.24) on $\varepsilon \to 0$ yields

$$h(\vec{x},t) = (K_1 * \omega)(\vec{x},t) + (K_2 * a)(\vec{x},t) \quad \text{for a.e. } (\vec{x},t) \in \Omega_T. \tag{5.4}$$

From the elliptic theory [15], [20] and (2.6), (2.8) of Lemma 1, the function h satisfies (1.14) with the boundary conditions (1.16), such that

$$h \in L_\infty(0,T;\, C^{1+\eta}(\overline{\Omega})). \tag{5.5}$$

Definition 2. *Let the distance between any given point $\vec{x} \in \mathbb{R}^n$ and any subset $A \subseteq \mathbb{R}^n$ be defined by $d(\vec{x},A) := \inf_{\vec{y}\in A}|\vec{x}-\vec{y}|$. Let $d = d(\vec{x})$ be the distance function on Γ, defined by*

$$d(\vec{x}) := d(\vec{x}, \mathbb{R}^n \backslash \Omega) - d(\vec{x},\Omega) \quad \textit{for any } \vec{x} \in \mathbb{R}^n.$$

Let A be an arbitrary subdomain of Ω. We also introduce the distance between A and the boundary Γ by $d(A,\Gamma) := inf_{\vec{y}\in A} d(\vec{y})$.

The set of all points of $\overline{\Omega}$, whose distance to Γ (respectively, to Γ^- and to Γ^+) is less than σ, is denoted by $U_\sigma(\Gamma)$ (respectively, $U_\sigma(\Gamma^-)$ and $U_\sigma(\Gamma^+)$). Since $\Gamma \in C^{2+\gamma}$, the function $d = d(\vec{x})$ belongs to C^2 in a neighborhood $U_{\sigma_0}(\Gamma)$ of Γ for some $\sigma_0 > 0$. For $0 < 2\sigma < \sigma_0$, we introduce the approximation of the unit function for all $\vec{x} \in \overline{\Omega}$ by

$$\mathbf{1}_\sigma(\vec{x}) := \begin{cases} 1 & \text{if } \vec{x} \in \Omega \backslash U_{2\sigma}(\Gamma), \\ \frac{d-\sigma}{\sigma} & \text{if } \sigma < d(\vec{x}) < 2\sigma, \\ 0 & \text{if } 0 \le d(\vec{x}) < \sigma. \end{cases} \tag{5.6}$$

Now we show an auxiliary lemma, playing the crucial role in the proof that the function ω satisfies the boundary condition (1.5) in the sense of the equality (1.13).

LEMMA 8. *For any positive $\psi \in C^{1,1}(\Omega_T)$, such that* $\operatorname{supp}(\psi) \subset \Omega_T \cup \Gamma_T^-$, *and $\psi(\vec{x},T) = 0,\ \vec{x} \in \Omega$, we have*

$$\lim_{\sigma\to 0} \left(\overline{\lim_{\varepsilon\to 0}} \frac{1}{\sigma} \int_0^T \int_{[\sigma<d<2\sigma]} |\omega_\varepsilon - \breve{\omega}_\varepsilon|\ \vec{v}_\varepsilon \bigtriangledown d\ \psi\ d\vec{x}dt \right) = 0. \tag{5.7}$$

Proof. Taking into account that $z_\varepsilon = \omega_\varepsilon - \breve{\omega}_\varepsilon = 0$ on Γ_T and multiplying the equality (4.9) by an arbitrary nonnegative function $\eta \in H^1(\Omega_T)$ with $\eta(\vec{x},T) = 0$, $\vec{x} \in \Omega$, we derive that

$$\begin{aligned} -\int\int_{\Omega_T} \eta_t (z_\varepsilon^2+\delta)^{1/2}\, d\vec{x}dt + \int_\Omega \eta(\vec{x},0)(z_\varepsilon^2(\vec{x},0)+\delta)^{1/2}\, d\vec{x} \\ + \int_{\Gamma_T} a^\varepsilon \sqrt{\delta}\,\eta\, d\vec{x}dt - \int\int_{\Omega_T} (z_\varepsilon^2+\delta)^{1/2}\, \vec{v}_\varepsilon \nabla\eta\, d\vec{x}dt \\ -\int\int_{\Omega_T} \frac{\delta}{(z_\varepsilon^2+\delta)^{1/2}}\,(\omega_\varepsilon - h_\varepsilon)\eta\, d\vec{x}dt = -\varepsilon \int\int_{\Omega_T} \nabla z_\varepsilon \nabla\eta\, \frac{z_\varepsilon}{(z_\varepsilon^2+\delta)^{1/2}}\, d\vec{x}dt \\ -\varepsilon\delta \int\int_{\Omega_T} \frac{|\nabla z_\varepsilon|^2}{(z_\varepsilon^2+\delta)^{3/2}}\,\eta\, d\vec{x}dt + \int\int_{\Omega_T} F_\varepsilon\, sgn_\delta z_\varepsilon\, \eta\, d\vec{x}dt. \end{aligned}$$

Let us denote $G_\varepsilon := |\partial_t \breve{\omega}^\varepsilon| + |\bigtriangledown \breve{\omega}^\varepsilon|$ and $G := |\partial_t \breve{\omega}| + |\bigtriangledown \breve{\omega}|$. Since the functions $\{z_\varepsilon, \omega_\varepsilon, h_\varepsilon\}$ and a^ε are uniformly bounded with respect to ε in $L_\infty(\Omega_T)$ and in $L_\infty(\Gamma_T)$, using (4.5) and (4.18), we obtain

$$\begin{aligned} -\int\int_{\Omega_T} (z_\varepsilon^2+\delta)^{1/2}\, \vec{v}_\varepsilon \nabla\eta\, d\vec{x}dt \le C \int\int_{\Omega_T} (|\eta_t| + |\eta| + |\eta|\,|G_\varepsilon|)\, d\vec{x}dt \\ + C\int_\Omega |\eta(\vec{x},0)|\, d\vec{x} + C\sqrt{\delta} \int_{\Gamma_T} |\eta|\, d\vec{x}dt + C\sqrt{\varepsilon}||\nabla\eta||_{L_2(\Omega_T)}. \end{aligned}$$

Taking $\delta \to 0$, we get

$$\begin{aligned} -\int\int_{\Omega_T} |z_\varepsilon|\ \vec{v}_\varepsilon \nabla\eta\, d\vec{x}dt \le C \int\int_{\Omega_T} (|\eta_t| + |\eta| + |\eta|\,|G_\varepsilon|)\, d\vec{x}dt \\ + C\int_\Omega |\eta(\vec{x},0)|\, d\vec{x} + C\sqrt{\varepsilon}||\nabla\eta||_{L_2(\Omega_T)}. \end{aligned} \tag{5.8}$$

Let us choose an arbitrary function $\psi \in C^{1,1}(\Omega_T)$, satisfying the conditions of the present lemma and take the test function in (5.8). As $\eta_\sigma = (1-\mathbf{1}_\sigma)\,\psi$, we derive that

$$\int\int_{\Omega_T} |z_\varepsilon|\,\psi\,\frac{\vec{v}_\varepsilon \nabla d}{\sigma}\,\chi_{[\sigma<d<2\sigma]}\;d\vec{x}dt$$
$$\leq C\int\int_{\Omega_T}(|\partial_t\eta_\sigma| + |\eta_\sigma| + |\eta_\sigma|\,|G_\varepsilon| + (1-\mathbf{1}_\sigma)|\nabla\psi|)\;d\vec{x}dt$$
$$+\,C\int_\Omega |\eta_\sigma(\vec{x},0)|\;d\vec{x} + C\sqrt{\varepsilon}||\nabla\eta_\sigma||_{L_2(\Omega_T)}.$$

By (4.20) the set $\{\vec{v}_\varepsilon(\cdot,t)\}$ is uniformly continuous on $\overline{\Omega}$, independent of ε and $t \in [0,T]$. Also we have that the function $d(\vec{x}) \in C^2$ in the neighborhood $U_{\sigma_0}(\Gamma)$ and $\bigtriangledown d = -\vec{n}$ on Γ. Hence there exists $\sigma_1 < \sigma_0$, independent of ε and $t \in [0,T]$, such that

$$\left\{\psi\;\vec{v}_\varepsilon \bigtriangledown d\right\}(\vec{x},t) = \begin{cases} >0 & \text{if } (\vec{x},t) \in U_{\sigma_1}(\Gamma^-)\times[0,T], \\ 0 & \text{if } (\vec{x},t)\in U_{\sigma_1}(\Gamma^+\cup\Gamma^0)\times[0,T]. \end{cases} \tag{5.9}$$

Therefore for any $2\sigma \in (0,\sigma_1)$, according to (3.3), we have

$$0 \leq \overline{\lim_{\varepsilon\to 0}}\,\frac{1}{\sigma}\int_0^T\int_{[\sigma<d<2\sigma]}\psi\;|z_\varepsilon|\,\vec{v}_\varepsilon\nabla d\;d\vec{x}dt \leq C\int_\Omega|\eta_\sigma(\vec{x},0)|\;d\vec{x}$$
$$+\,C\int\int_{\Omega_T}(|\partial_t\eta_\sigma| + |\eta_\sigma| + |\eta_\sigma|\,|G| + (1-\mathbf{1}_\sigma)|\nabla\psi|)\;d\vec{x}dt\;d\vec{x}.$$

This implies the property (5.7), since $\eta_\sigma = (1-\mathbf{1}_\sigma)\psi$, $\partial_t\eta_\sigma = (1-\mathbf{1}_\sigma)\psi_t$, and $(1-\mathbf{1}_\sigma) \to 0$ in Ω_T, when $\sigma \to 0$. $\square$

Now we are able to prove that the pair $\{\omega, h\}$ satisfies (1.13). For any $2\sigma \in (0,\sigma_1)$, we put $\eta_\sigma = \mathbf{1}_\sigma\,\psi$, where ψ is an arbitrary function, satisfying the conditions of Lemma 8. Clearly, $\eta_\sigma \in H^1(\Omega_T),\ \eta_\sigma(\vec{x},T) = 0$ for $\vec{x}\in\Omega$, and $\eta_\sigma = 0$ on Γ_T. Multiplying the first equation in (3.4) by η_σ and integrating it over Ω_T, we derive that

$$0 = \left\{\int_{\Omega_T}[\omega_\varepsilon(\psi_t + \vec{v}_\varepsilon\nabla\psi)]\mathbf{1}_\sigma - \varepsilon\nabla\omega_\varepsilon\nabla\eta_\sigma\;d\vec{x}dt + \int_\Omega \breve{\omega}^\varepsilon(\vec{x},0)\,\eta_\sigma(\vec{x},0)\;d\vec{x}\right\}$$
$$+\,\frac{1}{\sigma}\int_0^T\int_{[\sigma<d<2\sigma]}\omega_\varepsilon\,(\vec{v}_\varepsilon\nabla d)\,\psi\;d\vec{x}dt = I^{\varepsilon,\sigma} + J^{\varepsilon,\sigma}. \tag{5.10}$$

Using (5.1), (5.2) and $\vec{v}_\varepsilon\nabla\psi\,\mathbf{1}_\sigma \underset{\varepsilon\to 0}{\rightharpoonup} \vec{v}\nabla\psi\,\mathbf{1}_\sigma$ weakly in $L_2(0,T;\ H_0^1(\Omega))$ with $\vec{v} = -\nabla h$, we have

$$\lim_{\varepsilon\to 0}\int_{\Omega_T}\omega_\varepsilon\,\vec{v}_\varepsilon\nabla\psi\,\mathbf{1}_\sigma\;d\vec{x}dt = \int_{\Omega_T}\omega\,\vec{v}\nabla\psi\,\mathbf{1}_\sigma\;d\vec{x}dt.$$

Because $\mathbf{1}_\sigma \underset{\sigma\to 0}{\longrightarrow} 1$ in Ω_T and Ω, we get

$$\lim_{\sigma\to 0}\left(\lim_{\varepsilon\to 0} I^{\varepsilon,\sigma}\right) = \int_{\Omega_T}\omega(\psi_t + \vec{v}\nabla\psi)\;d\vec{x}dt + \int_\Omega \omega_0\psi(\vec{x},0)\;d\vec{x}.$$

Since

$$J^{\varepsilon,\sigma} = \left[\frac{1}{\sigma}\int_0^T \int_{[\sigma<d<2\sigma]} z_\varepsilon\,(\vec{v}_\varepsilon \nabla d)\,\psi\;d\vec{x}dt\right] + \left[\frac{1}{\sigma}\int_0^T \int_{[\sigma<d<2\sigma]} \breve{\omega}^\varepsilon\,(\vec{v}_\varepsilon \nabla d)\,\psi\;d\vec{x}dt\right] = J_1^{\varepsilon,\sigma} + J_2^{\varepsilon,\sigma},$$

according to Lemma 8, we have

$$\lim_{\sigma\to 0}\,\left(\overline{\lim_{\varepsilon\to 0}}|J_1^{\varepsilon,\sigma}|\right) = 0.$$

By (5.5) the set of functions $\vec{v}_\varepsilon \bigtriangledown d$ is uniformly continuous on $\overline{\Omega}$ for all $t \in [0,T]$, independent of ε, and the trace of $\vec{v}_\varepsilon \bigtriangledown d$ on Γ_T satisfies, in the usual sense,

$$\vec{v}_\varepsilon \bigtriangledown d = -a^\varepsilon \;\text{ for } (\vec{x},t) \in \Gamma_T.$$

By the standard theory of traces and (1.10), (1.12), (3.3), the function $\breve{\omega}_\varepsilon$ has a trace on the boundary Γ_T^-, which converges to b, when $\varepsilon \to 0$, in the space $L_1(0,T;\,L_q(\Gamma^-))$ for any $q \in [1,\infty)$. Therefore the convergences (3.2), (3.3) imply

$$\lim_{\sigma\to 0}\,\left(\lim_{\varepsilon\to 0}\;J_2^{\varepsilon,\sigma}\right) = -\int_0^T \int_{\Gamma_T^-} ab\,\psi\;d\vec{x}dt.$$

Therefore the pair $\{\omega,\,h\}$ satisfies (1.13) for any ψ, satisfying the conditions of Lemma 8. In view of the linearity of (1.13) with respect to ψ, we see that this equation is also fulfilled for any ψ, satisfying the conditions (1.17) of Definition 1.

Let us show that the limit functions $\omega, h, \bigtriangledown h$ admit additional regularity with respect to the time variable t.

Lemma 9. *For any Ω', such that $\overline{\Omega}' \subset \Omega$, we have*

$$\partial_t\,\omega \in L_\infty(0,T;\;H^{-1}(\Omega)), \tag{5.11}$$

$$h,\;\bigtriangledown h \in C^{0,\,\theta}(\overline{\Omega'} \times [0,T]). \tag{5.12}$$

Proof. Let us choose in (1.13) the test function $\phi(\vec{x},t) := \psi(\vec{x})\,\varphi(t)$, such that $\psi(\vec{x}) \in H_0^1(\Omega)$ and $\varphi(t) \in W_1^1([0,T]):\;\; \varphi(0) = \varphi(T) = 0$, which yields

$$\left|\int_0^T \left(\int\limits_\Omega \omega\,\psi\;d\vec{x}\right)\varphi_t dt\right| \le C\,\|\psi\|_{H_0^1(\Omega)}||\varphi||_{L_1(0,T)},$$

which is equivalent to (5.11).

Now we show the Hölder continuity of h with respect to the time $t \in [0,T]$. By the representation (5.4) this can be done for $h_1 := (K_1 * \omega)$ and $h_2 := (K_2 * a)$, separately. Let

$$\rho(s) \in C_0^\infty(\mathbb{R}) \qquad \text{with} \qquad \rho(s) := \begin{cases} 1 \text{ if } & |s| \le 1, \\ 0 \text{ if } & |s| > 2. \end{cases}$$

We introduce the functions $\rho_\sigma(\vec{x}) := \rho(|\vec{x}|/\sigma)$ and $\rho_\sigma^\Gamma(\vec{x}) := \rho(d(\vec{x})/\sigma)$ for $\sigma > 0$. Let Ω' be a subdomain of Ω, such that $\delta := \operatorname{dist}(\overline{\Omega'},\Gamma) > 0$. Then, for any fixed $\vec{x} \in \overline{\Omega'}$

and for any $\sigma < \frac{\delta}{4}$, the function $\bigtriangledown h_1$ can be written in the form

$$\begin{aligned}\nabla h_1(\vec{x},t) &= \int_\Omega \nabla_{\vec{x}} K_1(\vec{x},\vec{y})\ \omega(\vec{y},t)\ d\vec{y}\\ &= \int_\Omega \nabla_{\vec{x}} K_1(\vec{x},\vec{y})\ \rho_\sigma^\Gamma(\vec{y})\ \omega(\vec{y},t)\ d\vec{y}\\ &+ \int_\Omega \nabla_{\vec{x}} K_1(\vec{x},\vec{y})\ \rho_\sigma(\vec{x}-\vec{y})\ \omega(\vec{y},t)\ d\vec{y}\\ &+ \int_\Omega \nabla_{\vec{x}} K_1(\vec{x},\vec{y})\ (1-\rho_\sigma^\Gamma(\vec{y})-\rho_\sigma(\vec{x}-\vec{y}))\ \omega(\vec{y},t)\ d\vec{y}. \end{aligned} \tag{5.13}$$

Hence for any $t_1, t_2 \in [0,T]$ we have that

$$\nabla h_1(\vec{x},t_2) - \nabla h_1(\vec{x},t_1) = I_1 + I_2 + I_3.$$

Using $\omega \in L_\infty(\Omega_T)$, the terms $I_i,\ i = 1,2,3$ are estimated by

$$\begin{aligned}|I_1| &\le ||\rho_\sigma^\Gamma\, \nabla_{\vec{x}} K_1(\vec{x},\cdot)||_{L_1(\Omega)}\ ||\omega(\cdot,t_2)-\omega(\cdot,t_1)||_{L_\infty(\Omega)} \le C\sigma,\\ |I_2| &\le ||\rho_\sigma\, \nabla_{\vec{x}} K_1(\vec{x},\cdot)||_{L_1(\Omega)}\ ||\omega(\cdot,t_2)-\omega(\cdot,t_1)||_{L_\infty(\Omega)} \le C\sigma,\end{aligned} \tag{5.14}$$

and

$$|I_3| \le ||(1-\rho_\sigma^\Gamma-\rho_\sigma)\,\nabla_{\vec{x}} K_1(\vec{x},\cdot)||_{H_0^1(\Omega)} ||\omega(\cdot,t_2)-\omega(\cdot,t_2)||_{H^{-1}(\Omega)}. \tag{5.15}$$

Since the function $(1-\rho_\sigma^\Gamma-\rho_\sigma)\,\nabla_{\vec{x}} K_1(\vec{x},\vec{y}),\ \ \vec{y}\in\Omega$, has a singularity just at the point $\vec{x}\in\overline{\Omega'}$, we obtain

$$||(1-\rho_\sigma^\Gamma-\rho_\sigma)\,\nabla_{\vec{x}} K_1(\vec{x},\cdot)||_{H_0^1(\Omega)} \le C\,|\,ln(\sigma)| \tag{5.16}$$

and by (5.11)

$$\begin{aligned}||\,\omega(\cdot,t_2)-\omega(\cdot,t_1)||_{H^{-1}(\Omega)} &\le \left\| \int_{t_1}^{t_2} \partial_t\omega(\cdot,t)\ dt \right\|_{H^{-1}(\Omega)}\\ &\le |t_2-t_1|\ \max_{t\in[0,T]} ||\,\partial_t\omega\,||_{L_\infty(0,T;\ H^{-1}(\Omega))} \le C|t_2-t_1|.\end{aligned} \tag{5.17}$$

Therefore choosing $\sigma := |t_2-t_1|$, from (5.13)–(5.17), we derive

$$|\nabla h_1(\vec{x},t_2) - \nabla h_1(\vec{x},t_1)| \le C|t_2-t_1|\,|\,ln|t_2-t_1|\,| \tag{5.18}$$

for all $t_1,t_2\in[0,T]$. Using this approach we can deduce the same estimate for h_1.

In view of (2.9) of Lemma 1, we have

$$||h_2(\cdot,t_2)-h_2(\cdot,t_1)||_{C^1(\overline{\Omega'})} \le C||a(\cdot,t_2)-a(\cdot,t_1)||_{L_1(\Gamma)} \le C|t_2-t_1|^\theta \tag{5.19}$$

for any $t_1,t_2\in[0,T]$. Therefore, accounting for (5.18) and (5.19), we derive (5.12). This completes the proof of the lemma. ∎

6. Appendix. Let us suppose that initially the boundary and initial data $b,\ \omega_0$ of the problem (1.1)–(1.6) are known. In this section we give sufficient conditions on these data under which there exists at least one extension $\breve{\omega}$ on the domain $\overline{\Omega}_T$, satisfying the conditions (1.10)–(1.12).

Let us assume that the data $b,\ \omega_0$ admit the following regularity:

$$\omega_0 \in W_p^{(2-\frac{1}{p})}(\Omega) \cap L_\infty(\Omega), \qquad b \in W_p^{(2-\frac{1}{p})}(\Gamma_T^-) \cap L_\infty(\Gamma_T^-) \tag{6.1}$$

with some $p > n$, such that

$$\omega_0(\vec{x}) \geq 0 \text{ a.e. in } \Omega, \quad b(\vec{x}, t) \geq 0 \text{ a.e. on } \Gamma_T^-. \tag{6.2}$$

Since $\Gamma \in C^{2+\gamma}$ for $\gamma > 0$, there exists a function $\breve{b} = \breve{b}(\vec{x}, t)$, defined on the boundary Γ_T, such that

$$\breve{b} \ \in W_p^{(2-\frac{1}{p})}(\Gamma_T) \cap L_\infty(\Gamma_T) \quad \text{and} \quad \breve{b}\big|_{\Gamma_T^-} = b, \quad \breve{b} \geq 0 \ \text{ on } \ \Gamma_T \tag{6.3}$$

and

$$\begin{cases} ||\breve{b}||_{L_\infty(\Gamma_T)} & \leq \quad ||b||_{L_\infty(\Gamma_T^-)}, \\ ||\breve{b}||_{W_p^{(2-\frac{1}{p})}(\Gamma_T)} & \leq \quad ||b||_{W_p^{(2-\frac{1}{p})}(\Gamma_T^-)}. \end{cases} \tag{6.4}$$

Let $\breve{\omega}$ be the solution of the system

$$\begin{cases} \breve{\omega}_t - \Delta\breve{\omega} = 0, \quad (\vec{x}, t) \in \Omega_T, \\ \breve{\omega}\big|_{\Gamma_T} = \breve{b}; \qquad \breve{\omega}\big|_{t=0} = \omega_0(\vec{x}), \quad \vec{x} \in \Omega. \end{cases}$$

According to (6.1)–(6.4), by [14, Theorem 9.1, p. 341 and Theorem 7.1, p. 181], there exists a unique solution $\breve{\omega} \in W_p^{2,1}(\Omega_T) \cap L_\infty(\Omega_T)$, such that

$$\begin{aligned} \breve{\omega} \geq 0 \quad \text{a.e. on } \ \Omega_T, \\ ||\breve{\omega}||_{L_\infty(\Omega_T)} &\leq C(||\breve{b}||_{L_\infty(\Gamma_T)} + ||\omega_0||_{L_\infty(\Omega)}) \\ &\leq C(||b||_{L_\infty(\Gamma_T^-)} + ||\omega_0||_{L_\infty(\Omega)}) \end{aligned} \tag{6.5}$$

and

$$\begin{aligned} ||\breve{\omega}||_{W_p^{2,1}(\Omega_T)} &\leq C\left(||\breve{b}||_{W_p^{\left(2-\frac{1}{p}\right)}(\Gamma_T)} + ||\omega_0||_{W_p^{\left(2-\frac{2}{p}\right)}(\Omega)}\right) \\ &\leq C\left(||b||_{W_p^{\left(2-\frac{1}{p}\right)}(\Gamma_T^-)} + ||\omega_0||_{W_p^{\left(2-\frac{2}{p}\right)}(\Omega)}\right), \end{aligned} \tag{6.6}$$

where the constants C depend only on p and Ω. The previous inequality implies that

$$\int_0^T || \bigtriangledown \breve{\omega}(\cdot, t)||^p_{L_\infty(\Omega)} \, dt \leq C||\breve{\omega}||^p_{W_p^{2,1}(\Omega_T)}. \tag{6.7}$$

Combining the estimates (6.5)–(6.7), we see that the constructed function $\breve{\omega}$ is an extension of $b,\ \omega_0$ on the domain $\overline{\Omega}_T$, which satisfies the conditions (1.10)–(1.12).

CONVERGENCE OF SCHRÖDINGER OPERATORS*

JOHANNES F. BRASCHE† AND KATEŘINA OŽANOVÁ‡

Abstract. We prove two limit relations between Schrödinger operators perturbed by measures. First, weak convergence of finite real-valued Radon measures $\mu_n \longrightarrow m$ implies that the operators $-\Delta + \varepsilon^2\Delta^2 + \mu_n$ in $L^2(\mathbb{R}^d, dx)$ converge to $-\Delta + \varepsilon^2\Delta^2 + m$ in the norm-resolvent sense, provided $d \leq 3$. Second, for a large family, including the Kato class, of real-valued Radon measures m, the operators $-\Delta + \varepsilon^2\Delta^2 + m$ tend to the operator $-\Delta + m$ in the norm-resolvent sense as ε tends to zero. Explicit upper bounds for the rates of convergences are derived. Since one can choose point measures μ_n with mass at only finitely many points, a combination of both convergence results leads to an efficient method for the numerical computation of the eigenvalues in the discrete spectrum and corresponding eigenfunctions of Schrödinger operators.

Key words. point interaction, eigenvalue, eigenfunction, singular Schrödinger operator

AMS subject classifications. 81-08, 35P15, 47B25

DOI. 10.1137/060651598

1. Introduction. In this paper we are going to analyze convergence of Schrödinger operators perturbed by measures. It is known that weak convergence of potentials implies norm-resolvent convergence of the corresponding one-dimensional Schrödinger operators. This result from [6] may be interesting for several reasons. For instance, every finite real-valued Radon measure on $\mathbb{R}$ is the weak limit of a sequence of point measures with mass at only finitely many points. There exist efficient numerical methods for the computation of the eigenvalues and corresponding eigenfunctions of one-dimensional Schrödinger operators with a potential supported by a finite set; actually the effort for the computation grows at most linearly with the number of points of the support [9]. Since the norm-resolvent convergence implies convergence of the eigenvalues in the discrete spectra and corresponding eigenspaces, we get an efficient method for the numerical calculation of the discrete spectra of one-dimensional Schrödinger operators. Norm-resolvent convergence also has other important consequences: locally uniform convergence of the associated unitary groups and semigroups, convergence of the spectral projectors (which implies the mentioned results on the discrete spectra), etc.

Let us also mention a completely different motivation for studying the convergence of operators with point potentials. In quantum mechanics neutron scattering is often described via so-called zero-range Hamiltonians (the monograph [1] is an excellent standard reference to this research area). In a wide variety of models the positions of the neutrons are described via a family $(X_j)_{j=1}^n$ of independent random variables with joint distribution μ. Usually the number n of neutrons is large, and one is interested in the limit when n tends to infinity and the strengths of the single size potentials tend to zero. In the one-dimensional case this motivates one to investigate the limits

*Received by the editors February 6, 2006; accepted for publication (in revised form) January 4, 2007; published electronically May 22, 2007. This work is partially supported by the Marie Curie fellowship MEIF-CT-2004-009256.

of operators of the form

$$-\frac{d^2}{dx^2}+\frac{a}{n}\sum_{j=1}^{n}\delta_{X_j(\omega)}, \qquad \omega\in\Omega,$$

$a\neq 0$ being a real constant and $(\Omega,\mathcal{F},\mathbb{P})$ a probability space. By the theorem of Glivenko–Cantelli, for $\mathbb{P}$-almost all $\omega\in\Omega$ the sequence $(\frac{a}{n}\sum_{j=1}^{n}\delta_{X_j(\omega)})_{n\in\mathbb{N}}$ converges to the measure $a\mu$ weakly. By the mentioned result from [6], this implies that

$$-\frac{d^2}{dx^2}+a\mu=\lim_{n\longrightarrow\infty}\left(-\frac{d^2}{dx^2}+\frac{a}{n}\sum_{j=1}^{n}\delta_{X_j(\omega)}\right)$$

in the norm-resolvent sense $\mathbb{P}$ a.s.

It is the purpose of the present note to derive analogous results in the two- and three-dimensional cases. It was shown in [6] and [8] that one can approximate Schrödinger operators perturbed by suitable measures by a point potential Hamiltonian. However, the convergence there was in the strong resolvent sense, which is of course a weaker result than the norm-resolvent convergence.

If the dimension is higher than one, then it seems to be impossible to work directly with operators of the form $-\Delta+\mu$, μ being a point measure. In fact, while the operators $-\frac{d^2}{dx^2}+\sum_{j=1}^{n}a_j\delta_{x_j}$ can be defined in dimension one via Kato's quadratic form method as the unique lower semibounded self-adjoint operator associated to the energy form

$$\begin{aligned} D(\mathcal{E}) &:= H^1(\mathbb{R}),\\ \mathcal{E}(f,f) &:= \int |f'(x)|^2dx+\sum_{j=1}^{n}a_j|\tilde{f}(x_j)|^2, \quad f\in D(\mathcal{E}), \end{aligned}$$

$\tilde{f}$ being the unique continuous representative of $f\in H^1(\mathbb{R})$, in higher dimension $d>1$, the quadratic form

$$\begin{aligned} D(\mathcal{E}) &:= \{f\in H^1(\mathbb{R}^d) : f \text{ has a continuous representative } \tilde{f}\},\\ \mathcal{E}(f,f) &:= \int |\nabla f(x)|^2dx+\sum_{j=1}^{n}a_j|\tilde{f}(x_j)|^2, \quad f\in D(\mathcal{E}), \end{aligned}$$

is not lower semibounded and closable if at least one coefficient a_j is different from zero.

The strategy to overcome the mentioned problem in higher dimensions is based on two simple observations:

1. The lower semibounded self-adjoint operator $\Delta^2+\mu$ can be defined via Kato's quadratic form method for every real-valued finite Radon measure μ on $\mathbb{R}^d$ (if $d\in\{1,2,3\}$), including point measures.
2. $-\Delta+\varepsilon^2\Delta^2\longrightarrow-\Delta$ in the norm-resolvent sense, as $\varepsilon>0$ tends to zero.

We show the convergence claim in two steps. In section 2 we shall prove that the sequence $(-\Delta+\varepsilon^2\Delta^2+\mu_n)_{n\in\mathbb{N}}$ converges to $-\Delta+\varepsilon^2\Delta^2+m$ in the norm-resolvent sense provided $d\leq 3$, $\varepsilon>0$, and the finite real-valued Radon measures μ_n on $\mathbb{R}^d$ converge to the finite real-valued Radon measure m weakly. Then for a large class of measures m we shall prove that

$$-\Delta+\varepsilon^2\Delta^2+m\longrightarrow-\Delta+m$$

in the norm-resolvent sense as ε tends to zero; cf. section 3. Actually, we will not only prove convergence but also give explicit error estimates.

As approximating measures μ_n we can, in particular, choose point measures with mass at only finitely many points. In section 4 we will present formulas which make it possible to calculate the eigenvalues and corresponding eigenspaces of operators perturbed by a finite number point measures. Then similarly to [1, Chapter II.2], the spectral problem means to solve an implicit equation and the effort for these computations grows at most as $\mathcal{O}(n^3)$.

Putting both convergence results from sections 2 and 3 and formulas from section 4 together, we get an efficient method to calculate the eigenvalues in the discrete spectrum and corresponding eigenspaces of Schrödinger operators $-\Delta + m$ numerically.

Our method covers not only the case when m is absolutely continuous w.r.t. the $(d-1)$-dimensional volume measure of a manifold with codimension one but also a fairly large class of measures m containing the set of all finite real-valued measures belonging to the Kato class. In particular, the absolutely continuous case $dm = V dx$, where $-\Delta + m = -\Delta + V$ is a regular Schrödinger operator, is contained in our approach. We refer to [10] for related convergence results in the regular case.

Notation and auxiliary results. Let μ be a real-valued Radon measure on $\mathbb{R}^d$. By the Hahn–Jordan theorem, there exist unique positive Radon measures $\mu^{\pm}$ on $\mathbb{R}^d$ such that

$$\mu = \mu^+ - \mu^- \text{ and } \mu^+(\mathbb{R}^d \setminus B) = 0 = \mu^-(B)$$

for some suitably chosen Borel set B. We put

$$\| \mu \| := \mu^+(\mathbb{R}^d) + \mu^-(\mathbb{R}^d) \text{ and } |\mu| := \mu^+ + \mu^-.$$

If μ is finite, then we define its Fourier transform $\hat{\mu}$ as

$$\hat{\mu}(p) := (2\pi)^{-d/2} \int e^{ipx} \mu(dx), \qquad p \in \mathbb{R}^d.$$

Similarly, $\hat{f}$ also denotes the Fourier transform of $f \in L^2(dx) := L^2(\mathbb{R}^d, dx)$, dx being the Lebesgue measure.

For $s > 0$ we denote the Sobolev space of order s by $H^s(\mathbb{R}^d)$; i.e.,

$$H^s(\mathbb{R}^d) := \left\{ f \in L^2(dx) : \int (1+p^2)^s |\hat{f}(p)|^2 dp < \infty \right\},$$
$$\| f \|_{H^s} := \left(\int (1+p^2)^s |\hat{f}(p)|^2 dp \right)^{1/2}, \qquad f \in H^s(\mathbb{R}^d).$$

We shall use occasionally the abbreviations $L^2(\mu) := L^2(\mathbb{R}^d, \mu)$ and $H^s := H^s(\mathbb{R}^d)$.

$\| T \|_{\mathcal{H}_1, \mathcal{H}_2}$ denotes the operator norm of T as an operator from $\mathcal{H}_1$ to $\mathcal{H}_2$, and $\| T \|_{\mathcal{H}} := \| T \|_{\mathcal{H},\mathcal{H}}$. $\| f \|_{\mathcal{H}}$ and $(f,h)_{\mathcal{H}}$ represent the norm and the scalar product in the Hilbert $\mathcal{H}$, respectively. If the reference to a measure is missing, then we tacitly refer to the Lebesgue measure dx. For instance, "integrable" means "integrable w.r.t. dx" if not stated otherwise; $\| T \|$, (f,h), and $\| f \|$ denote the operator norm of T, the scalar product, and the norm in the Hilbert space $L^2(dx)$, respectively. We denote by $C_0^\infty(\mathbb{R}^d)$ the space of smooth functions with compact support.

For arbitrary $\varepsilon \geq 0$ ($\varepsilon = 0$ will be admitted only in section 3) let $\mathcal{E}_\varepsilon$ be the nonnegative closed quadratic form in the Hilbert space $L^2(dx)$ associated to the nonnegative self-adjoint operator $-\Delta + \varepsilon^2\Delta^2$ in $L^2(dx)$. Obviously we have

$$D(\mathcal{E}_\varepsilon) = H^2(\mathbb{R}^d),$$
$$\mathcal{E}_\varepsilon(f,f) = \varepsilon^2\,(\Delta f, \Delta f) + (\nabla f, \nabla f) \geq \varepsilon^2\,(\Delta f, \Delta f), \qquad f \in D(\mathcal{E}_\varepsilon),$$

for every $\varepsilon > 0$. Note that for $\varepsilon = 0$ the form domain is $H^1(\mathbb{R}^d)$, and $\mathcal{E}_0$ is the classical Dirichlet form. For any $\alpha > 0$ we put

$$\mathcal{E}_{\varepsilon,\alpha}(f,h) := \mathcal{E}_\varepsilon(f,h) + \alpha(f,h), \qquad f,h \in D(\mathcal{E}_\varepsilon).$$

2. Operator norm convergence. Throughout this section let $d \leq 3$, and let μ be a finite real-valued Radon measure on $\mathbb{R}^d$. Then, by Sobolev's embedding theorem, for every $s > 3/2$, and, in particular, for $s = 2$, every $f \in H^s(\mathbb{R}^d)$ has a unique continuous representative $\tilde{f}$ and

$$\| \tilde{f} \|_\infty := \sup\{|\tilde{f}(x)| : x \in \mathbb{R}^d\} \leq c_s \| f \|_{H^s}, \qquad f \in H^s(\mathbb{R}^d), \tag{1}$$

for some finite constant c_s. Note that $c_s \leq 1$ if $s = 2$. It follows that for every $\varepsilon > 0$ and every $\eta > 0$ there exists an $\alpha = \alpha(\varepsilon, \eta) < \infty$ such that

$$\| \tilde{f} \|_\infty^2 \leq \eta\, \mathcal{E}_\varepsilon(f,f) + \alpha(f,f), \qquad f \in H^2(\mathbb{R}^d). \tag{2}$$

Since μ is finite, for arbitrary $\varepsilon, \eta > 0$ and some finite α we get

$$\left| \int |\tilde{f}|^2 d\mu \right| \leq \eta \| \mu \| \mathcal{E}_\varepsilon(f,f) + \alpha \| \mu \| (f,f), \qquad f \in H^2(\mathbb{R}^d). \tag{3}$$

We put

$$D(\mathcal{E}_\varepsilon^\mu) := H^2(\mathbb{R}^d),$$
$$\mathcal{E}_\varepsilon^\mu(f,f) := \mathcal{E}_\varepsilon(f,f) + \int |\tilde{f}|^2 d\mu, \qquad f \in D(\mathcal{E}_\varepsilon^\mu).$$

By (3) and the Kato-Lax-Milgram-Nelson (KLMN) theorem [7, Theorem 1.5], $\mathcal{E}_\varepsilon^\mu$ is a lower semibounded closed quadratic form in $L^2(dx)$. We denote the lower semibounded self-adjoint operator in $L^2(dx)$ associated to $\mathcal{E}_\varepsilon^\mu$ by $-\Delta + \varepsilon^2\Delta^2 + \mu$.

Our main tool to prove convergence results will be a Krein-like formula which expresses the resolvent $(-\Delta + \varepsilon^2\Delta^2 + \mu + \alpha)^{-1}$ by means of the resolvent

$$G_{\varepsilon,\alpha} := (-\Delta + \varepsilon^2\Delta^2 + \alpha)^{-1}.$$

The operator $G_{\varepsilon,\alpha}$ has the integral kernel $g_{\varepsilon,\alpha}(x-y)$ with the Fourier transform

$$\hat{g}_{\varepsilon,\alpha}(p) := \frac{1}{\varepsilon^2 p^4 + p^2 + \alpha}, \qquad p \in \mathbb{R}^d.$$

For every $\varepsilon \geq 0$ and $\alpha > 0$, the function $g_{\varepsilon,\alpha}(x)$ is continuous on $\mathbb{R}^d \setminus \{0\}$, and, if $d = 1$ or if $d \leq 3$ and $\varepsilon > 0$, it is continuous on whole $\mathbb{R}^d$. Moreover, it is radially symmetric. Finally, $g_{0,\alpha}$ is the Green function of the free Laplacian in $\mathbb{R}^d$, and it is nonnegative. By the dominated convergence theorem,

$$\| g_{\varepsilon,\alpha} \|_{H^2}^2 = \int \frac{(1+p^2)^2}{|\varepsilon^2 p^4 + p^2 + \alpha|^2}\, dp \longrightarrow 0 \qquad \text{as } |\alpha| \longrightarrow \infty, \tag{4}$$

which, by Sobolev's inequality, implies that

$$\| g_{\varepsilon,\alpha} \|_\infty \longrightarrow 0 \qquad \text{as } |\alpha| \longrightarrow \infty. \tag{5}$$

The fact that $g_{\varepsilon,\alpha}$ is the Green function of $-\Delta + \varepsilon^2\Delta^2$ means that

$$\int g_{\varepsilon,\alpha}(x-y)(-\Delta + \varepsilon^2\Delta^2 + \alpha)h(y)dy = h(x) \qquad dx \text{ a.e.}$$

for all $h \in D(-\Delta + \varepsilon^2\Delta^2) = H^4(\mathbb{R}^d)$. The equation above not only holds almost everywhere w.r.t. the Lebesgue measure dx but even pointwise everywhere, as the following lemma states.

LEMMA 1. *Let the Green function $g_{\varepsilon,\alpha}$ and the operator $-\Delta+\varepsilon^2\Delta^2+\alpha$ be defined as above. Then one has*

$$\int g_{\varepsilon,\alpha}(x-y)(-\Delta + \varepsilon^2\Delta^2 + \alpha)h(y)dy = \tilde{h}(x), \qquad x \in \mathbb{R}^d, \tag{6}$$

for all $h \in H^4(\mathbb{R}^d)$.

Proof. In fact, we have only to show that the integral on the left-hand side is a continuous function of $x \in \mathbb{R}^d$. We choose any sequence $(f_n)_{n\in\mathbb{N}}$ of continuous functions with compact support converging to $(-\Delta + \varepsilon^2\Delta^2 + \alpha)h$ in $L^2(dx)$. By (4), $g_{\varepsilon,\alpha} \in H^2(\mathbb{R}^d) \subset L^2(dx)$; therefore, we can write

$$\int g_{\varepsilon,\alpha}(x-y)(-\Delta + \varepsilon^2\Delta^2 + \alpha)h(y)dy = \lim_{n\longrightarrow\infty} \int g_{\varepsilon,\alpha}(x-y)f_n(y)dy, \qquad x \in \mathbb{R}^d.$$

Obviously the mapping $x \mapsto \int g_{\varepsilon,\alpha}(x-y)f_n(y)dy$, $\mathbb{R}^d \longrightarrow \mathbb{C}$, is the unique continuous representative $\widetilde{G_{\varepsilon,\alpha}f_n}$ of $G_{\varepsilon,\alpha}f_n$ for every $n \in \mathbb{N}$. Since $G_{\varepsilon,\alpha}$ is a bounded operator from $L^2(dx)$ to $H^2(\mathbb{R}^d)$ (even to $H^4(\mathbb{R}^d)$), the sequence $(G_{\varepsilon,\alpha}f_n)_{n\in\mathbb{N}}$ converges in $H^2(\mathbb{R}^d)$ to $G_{\varepsilon,\alpha}(-\Delta + \varepsilon^2\Delta^2 + \alpha)h = h$. By Sobolev's inequality (1), this implies that the sequence $(\widetilde{G_{\varepsilon,\alpha}f_n})_{n\in\mathbb{N}}$ of the unique continuous representatives converges to a continuous function uniformly. By the last equality, $x \mapsto \int g_{\varepsilon,\alpha}(x-y)(-\Delta+\varepsilon^2\Delta^2+\alpha)h(y)dy$, $\mathbb{R}^d \longrightarrow \mathbb{C}$, is this continuous uniform limit, and we have proved (6). □

We introduce the following integral operator:

$$G^\mu_{\varepsilon,\alpha} f(x) := \int g_{\varepsilon,\alpha}(x-y)\tilde{f}(y)\mu(dy) \qquad dx \text{ a.e., } f \in H^2(\mathbb{R}^d).$$

We can prove several estimates of its operator norm.

LEMMA 2. *The operator $G^\mu_{\varepsilon,\alpha}$ is bounded on $H^2(\mathbb{R}^d)$, and its operator norm $\| G^\mu_{\varepsilon,\alpha} \|_{H^2}$ decays with $\alpha \longrightarrow \infty$. The operator is bounded also w.r.t. other operator norms; in particular, there are finite real numbers c_i, $i = 1, 2, 3$, such that*

$$\begin{aligned} \| G^\mu_{\varepsilon,\alpha} f \|_{H^2} &\le c_1(\alpha) \| \tilde{f} \|_\infty, \\ \| G^\mu_{\varepsilon,\alpha} f \|_{L^2} &\le c_2(\alpha) \| \tilde{f} \|_{L^2(|\mu|)}, \qquad f \in H^2(\mathbb{R}^d), \\ \| \widetilde{G^\mu_{\varepsilon,\alpha} f} \|_{L^2(|\mu|)} &\le c_3(\alpha) \| \tilde{f} \|_{L^2(|\mu|)}, \end{aligned}$$

and all three numbers c_i vanish in the limit $\alpha \longrightarrow \infty$.

Proof. Using Sobolev's inequality we have for arbitrary $f \in H^2(\mathbb{R}^d)$

$$|\widehat{\tilde{f}\mu}(p)|^2 \le (2\pi)^{-d} \| \tilde{f} \|^2_\infty \| \mu \|^2 \le (2\pi)^{-d} \| \tilde{f} \|^2_{H^2} \| \mu \|^2, \qquad p \in \mathbb{R}^d.$$

Then the convolution theorem yields

$$
\begin{aligned}
\| G^{\mu}_{\varepsilon,\alpha} f \|^2_{H^2} &= \int |(1+p^2)^2| \, |(g_{\varepsilon,\alpha} * \tilde{f}\mu)\hat{}(p)|^2 dp \\
&= (2\pi)^d \int \frac{(1+p^2)^2}{|\varepsilon^2 p^4 + p^2 + \alpha|^2} |\widehat{\tilde{f}\mu}(p)|^2 dp \\
&\leq \int \frac{(1+p^2)^2}{|\varepsilon^2 p^4 + p^2 + \alpha|^2} \ \| \tilde{f} \|^2_{\infty} \| \mu \|^2 \, dp \\
&\leq \int \frac{(1+p^2)^2}{|\varepsilon^2 p^4 + p^2 + \alpha|^2} dp \ \| \tilde{f} \|^2_{H^2} \| \mu \|^2 < \infty, \qquad f \in H^2(\mathbb{R}^d).
\end{aligned}
$$

Therefore $G^{\mu}_{\varepsilon,\alpha}$ is an everywhere defined bounded operator on $H^2(\mathbb{R}^d)$, and we get an upper bound for the norm

$$
\| G^{\mu}_{\varepsilon,\alpha} \|_{H^2,H^2} \leq \| \mu \| \left(\int \frac{(1+p^2)^2}{|\varepsilon^2 p^4 + p^2 + \alpha|^2} dp \right)^{1/2}, \tag{7}
$$

and the expression on the right-hand side (R.H.S.) is also the uniform upper bound c_1.

To determine the remaining upper bounds c_2 and c_3, we can write

$$
\begin{aligned}
& \int |G^{\mu}_{\varepsilon,\alpha} f(x)|^2 dx \\
= \ & \int \left| \int g_{\varepsilon,\alpha}(x-y)\tilde{f}(y)\mu^+(dy) - \int g_{\varepsilon,\alpha}(x-y)\tilde{f}(y)\mu^-(dy) \right|^2 dx \\
\leq \ & 2 \int \left| \int g_{\varepsilon,\alpha}(x-y)\tilde{f}(y)\mu^+(dy) \right|^2 dx + 2 \int \left| \int g_{\varepsilon,\alpha}(x-y)\tilde{f}(y)\mu^-(dy) \right|^2 dx \\
\leq \ & 2 \int \int |g_{\varepsilon,\alpha}(x-y)|^2 \mu^+(dy) \int |\tilde{f}(y)|^2 \mu^+(dy) \, dx \\
& + 2 \int \int |g_{\varepsilon,\alpha}(x-y)|^2 \mu^-(dy) \int |\tilde{f}(y)|^2 \mu^-(dy) \, dx \\
\leq \ & 2 \int |g_{\varepsilon,\alpha}(x)|^2 dx \ \| \mu \| \int |\tilde{f}(y)|^2 |\mu|(dy), \qquad f \in H^2(\mathbb{R}^d). \quad (8)
\end{aligned}
$$

In a similar way we arrive at

$$
\int |\widetilde{G^{\mu}_{\varepsilon,\alpha} f}(x)|^2 |\mu|(dx) \leq 2 \| g_{\varepsilon,\alpha} \|^2_{\infty} \| \mu \|^2 \int |\tilde{f}(y)|^2 |\mu|(dy).
$$

Finally, from (4) and (5) one concludes that all of the upper bounds of the operator norms tend to zero in the limit $\alpha \longrightarrow \infty$. □

General results of [3] (cf. also section 3 below) provide, in particular, an explicit formula for the resolvent of the operator $-\Delta + \varepsilon^2\Delta^2 + \mu$. In this resolvent formula there occur operators acting in different Hilbert spaces. This is inconvenient when we investigate the convergence of sequences of such operators, and we shall use a slightly different resolvent formula:

$$
(-\Delta + \varepsilon^2\Delta^2 + \mu + \alpha)^{-1} = G_{\varepsilon,\alpha} - G^{\mu}_{\varepsilon,\alpha}(I + G^{\mu}_{\varepsilon,\alpha})^{-1} G_{\varepsilon,\alpha}. \tag{9}
$$

For the sake of completeness we present the proof of the above Krein's formula in the appendix. According to Lemma 2, we can choose $\alpha > 0$ such that $\| G^{\mu}_{\varepsilon,\alpha} \|_{H^2,H^2} < 1$.

Then the operator $I + G^{\mu}_{\varepsilon,\alpha}$ is invertible, and its inverse is everywhere defined on $H^2(\mathbb{R}^d)$ and bounded; here I denotes the identity on $H^2(\mathbb{R}^d)$. By (3), we can choose $\alpha > 0$ such that, in addition,

$$\mathcal{E}^{\mu}_{\varepsilon,\alpha}(f,f) := \mathcal{E}^{\mu}_{\varepsilon}(f,f) + \alpha(f,f) \geq (f,f), \quad f \in D(\mathcal{E}^{\mu}_{\varepsilon}). \tag{10}$$

We are now prepared for the proof of the main theorem of this section.

THEOREM 3. *Let m and μ_n, $n \in \mathbb{N}$, be finite real-valued Radon measures on $\mathbb{R}^d$. Suppose that the sequence $(\mu_n)_{n\in\mathbb{N}}$ converges to m weakly and* $\sup_{n\in\mathbb{N}} \| \mu_n \| < \infty$. *Let $\varepsilon, \alpha > 0$ and $d \in \{1,2,3\}$. Then the operators $-\Delta + \varepsilon^2\Delta^2 + \mu_n$ converge to $-\Delta + \varepsilon^2\Delta^2 + m$ in the norm-resolvent sense.*

Proof. Let $\varepsilon > 0$ be arbitrary. We choose $0 < c < 1$ and $\alpha > 0$ such that

$$\| \mu_n \|^2 \int \frac{(1+p^2)^2}{|\varepsilon^2 p^4 + p^2 + \alpha|^2}\, dp \leq c^2, \quad n \in \mathbb{N}, \tag{11}$$

and

$$\| m \|^2 \int \frac{(1+p^2)^2}{|\varepsilon^2 p^4 + p^2 + \alpha|^2}\, dp \leq c^2. \tag{12}$$

According to (3), we can choose $\alpha > 0$ such that, in addition,

$$\mathcal{E}^{\mu_n}_{\varepsilon,\alpha}(f,f) \geq (f,f), \qquad f \in H^2(\mathbb{R}^d), \quad n \in \mathbb{N}. \tag{13}$$

Since $(\mu_n)_{n\in\mathbb{N}}$ converges to m weakly, (13) also holds when we replace μ_n by m. By Lemma 2, in particular estimate (7), inequalities (11) and (12) yield

$$\begin{aligned}
&\| G^{\mu_n}_{\varepsilon,\alpha} \|_{H^2,H^2} \leq c, \qquad n \in \mathbb{N},\\
&\| G^{m}_{\varepsilon,\alpha} \|_{H^2,H^2} \leq c,\\
&\| G^{m}_{\varepsilon,\alpha} f \|_{H^2} \leq c \, \| \tilde{f} \|_{\infty}, \qquad f \in H^2(\mathbb{R}^d).
\end{aligned} \tag{14}$$

Hence the resolvent formula (9) is valid both for $\mu = m$ and for $\mu = \mu_n$, $n \in \mathbb{N}$. By Lemma 2, we can choose α sufficiently large so that also

$$\int |G^m_{\varepsilon,\alpha} h(x)|^2 dx \leq c^2 \int |\tilde{h}|^2 d|m| \text{ and } \int |\widetilde{G^m_{\varepsilon,\alpha} h}(x)|^2 |m|(dx) \leq c^2 \int |\tilde{h}|^2 d|m| \tag{15}$$

for every $h \in H^2(\mathbb{R}^d)$.

For notational brevity we put

$$g_0 := g_{0,1}, \quad g := g_{\varepsilon,\alpha}, \quad G := G_{\varepsilon,\alpha}, \quad G^{\mu_n} := G^{\mu_n}_{\varepsilon,\alpha}, \quad \text{and} \quad G^m := G^m_{\varepsilon,\alpha}.$$

With this notation we have

$$\begin{aligned}
&(-\Delta + \varepsilon^2\Delta^2 + \mu_n + \alpha)^{-1} - (-\Delta + \varepsilon^2\Delta^2 + m + \alpha)^{-1}\\
&\quad = G^m[I + G^m]^{-1}G - G^{\mu_n}[I + G^{\mu_n}]^{-1}G\\
&\quad = (G^m - G^{\mu_n})[I + G^m]^{-1}G + (G^{\mu_n} - G^m)[I + G^m]^{-1}(G^{\mu_n} - G^m)[I + G^{\mu_n}]^{-1}G\\
&\qquad + G^m[I + G^m]^{-1}(G^{\mu_n} - G^m)[I + G^{\mu_n}]^{-1}G.
\end{aligned}$$

Since G is a bounded operator from $L^2(dx)$ to $H^2(\mathbb{R}^d)$, we have only to show that

$$\| G^m - G^{\mu_n} \|_{H^2,L^2(dx)} \longrightarrow 0 \qquad \text{as } n \longrightarrow \infty, \tag{16}$$

$$\| G^m[I + G^m]^{-1}(G^m - G^{\mu_n}) \|_{H^2,L^2(dx)} \longrightarrow 0 \qquad \text{as } n \longrightarrow \infty. \tag{17}$$

We introduce

$$\nu_n := m - \mu_n,$$
$$\nu_{nx}(dy) := g(x-y)\,\nu_n(dy), \qquad x \in \mathbb{R}^d, \quad n \in \mathbb{N}.$$

As $d \leq 3$, the function

$$y \mapsto \int g_0(y-a)\, f(a)\, da$$

is continuous and bounded for every $f \in L^2(dx)$; this well-known fact can be proved in the same way as (6). Since the function g is bounded and g_0 is nonnegative, it follows that

$$\left| \int |g(x-y)| \int |g_0(y-a)|\, |(-\Delta+1)h(a)|\, da\, \nu_n^{\pm}(dy) \right| < \infty$$

for all $x \in \mathbb{R}^d$ and $h \in H^2(\mathbb{R}^d)$. Hence by Fubini's theorem, the function $k_{\nu_{nx}} : \mathbb{R}^d \longrightarrow \mathbb{R}$, defined by

$$k_{\nu_{nx}}(a) := \begin{cases} \int g_0(y-a)\, g(x-y)\, \nu_n(dy) & \text{if defined,} \\ 0 & \text{otherwise,} \end{cases}$$

is Borel measurable, the integral on the R.H.S. is defined and finite for almost all $a \in \mathbb{R}^d$ (almost all w.r.t. the Lebesgue measure) and

$$\begin{aligned} |(G^{\nu_n} \tilde{h})(x)|^2 &= \left| \int g(x-y)\, h(y)\, \nu_n(dy) \right|^2 \\ &= \left| \int g(x-y) \int g_0(y-a)(-\Delta+1)h(a)\, da\, \nu_n(dy) \right|^2 \\ &\leq \int |k_{\nu_{nx}}(a)|^2 da \cdot \int |(-\Delta+1)h(a)|^2 da \\ &\leq 2 \parallel h \parallel_{H^2}^2 \int |k_{\nu_{nx}}(a)|^2 da, \qquad h \in H^2(\mathbb{R}^d),\ n \in \mathbb{N}. \end{aligned} \tag{18}$$

Thus in order to prove (16) we have only to show that

$$\int \int |k_{\nu_{nx}}(a)|^2 da\, dx \longrightarrow 0 \qquad \text{as } n \longrightarrow \infty. \tag{19}$$

We have

$$\begin{aligned} &\int \int |k_{\nu_{nx}}(a)|^2 da\, dx = (2\pi)^d \int \int |\widehat{g_0}(p)|^2 |\widehat{\nu_{nx}}(p)|^2 dp\, dx \\ &= \int \int \frac{1}{|1+p^2|^2} \int e^{ipy} g(x-y)\, \nu_n(dy) \int e^{-ipz} g(x-z) \nu_n(dz)\, dp\, dx. \end{aligned} \tag{20}$$

Since $|1+p^2|^{-2}$ and g are integrable w.r.t. the Lebesgue measure, g is bounded, and the Radon measures ν_n are finite, we can change the order of integration. Let us rewrite (20) as

$$\int f(y,z)\, h(y,z)\, \nu_n \otimes \nu_n(dy\, dz).$$

The function

$$f(y,z) := \int e^{ipy} e^{-ipz} \frac{1}{|1+p^2|^2}\, dp, \qquad y,z \in \mathbb{R}^d,$$

is bounded and continuous. It follows from the fact that it is (up to multiplication by $(2\pi)^{d/2}$) the inverse Fourier transform of the integrable function $|1+p^2|^{-2}$ at the point $z-y$.

Also the function

$$h(y,z) := \int g(x-y)\, g(x-z)\, dx$$

is bounded and continuous for $y,z \in \mathbb{R}^d$. This can be shown using the following observation. Let $y \in \mathbb{R}^d$ and K be any compact neighborhood of y. Since $|x|^j g_{\varepsilon,\alpha}(x) \longrightarrow 0$ for every $j \in N$ as $|x| \longrightarrow \infty$, there exists a constant $a < \infty$ such that

$$|g(x-y)\, g(x-z)| \le a \parallel g \parallel_\infty \mathrm{dist}(x,K)^{-4}, \qquad x \in \mathbb{R}^d \setminus K, \quad z \in \mathbb{R}^d, \quad y \in K.$$

By the Stone–Weierstrass theorem, the set of functions of the form $\sum_{j=1}^N f_j(x) g_j(y)$, $N \in \mathbb{N}$, where f_j, g_j are bounded and continuous, is dense in the space of bounded continuous functions w.r.t. the supremum norm. Since the measures ν_n tend to zero weakly and $\sup_{n\in\mathbb{N}} \parallel \nu_n \parallel < \infty$, this implies that the product measures $\nu_n \otimes \nu_n$ tend to zero weakly, too. Hence by (20), we have proved (19) and therefore also (16).

It only remains to prove (17). For this purpose we first note that

$$c_n := \int\int |k_{\nu_{nx}}(a)|^2\, da\, |m|(dx) \longrightarrow 0 \qquad \text{as } n \longrightarrow \infty.$$

This can be shown by mimicking the proof of (19). By (18), it follows that

$$\int |(G^{\nu_n} h\tilde{)}(x)|^2\, |m|(dx) \le 2c_n \parallel h \parallel_{H^2}^2, \qquad h \in H^2(\mathbb{R}^d).$$

Thus, in order to prove (17), we have only to show that there exists a finite constant C such that

$$\parallel G^m (I+G^m)^{-1} h \parallel_{L^2(dx)} \le C \left(\int |\tilde{h}|^2 d|m| \right)^{1/2}, \qquad h \in H^2(\mathbb{R}^d). \tag{21}$$

Using the estimates (14), we have

$$G^m (I+G^m)^{-1} = -\sum_{j=1}^{\infty} (-G^m)^j. \tag{22}$$

According to (15),

$$\parallel (G^m)^{j+1} h \parallel_{L^2(dx)} \le c \left(\int |\widetilde{(G^m)^j h}|^2 d|m| \right)^{1/2} \le c \cdot c^j \left(\int |\tilde{h}|^2 d|m| \right)^{1/2}$$

for every $j \in \mathbb{N}$, and hence

$$\left\| \sum_{j=1}^{\infty} (-G^m)^j h \right\|_{L^2(dx)} \le \sum_{j=1}^{\infty} c^j \left(\int |\tilde{h}|^2 d|m| \right)^{1/2} = \frac{c}{1-c} \left(\int |\tilde{h}|^2 d|m| \right)^{1/2}.$$

By (22), this implies (21) and the proof of the theorem is complete. □

Remark 4. We have shown that

$$
\begin{aligned}
&\| (-\Delta + \varepsilon^2\Delta^2 + \mu_n + \alpha)^{-1} - (-\Delta + \varepsilon^2\Delta^2 + m + \alpha)^{-1} \|^2 \\
\leq \quad & C_1 \int\int \left| \int g_{0,1}(y-a) g_{\varepsilon,\alpha}(x-y)(m-\mu_n)(dy) \right|^2 da\, dx \\
&+ C_2 \int\int \left| \int g_{0,1}(y-a) g_{\varepsilon,\alpha}(x-y)(m-\mu_n)(dy) \right|^2 da\, |m|(dx)
\end{aligned}
$$

for some finite constants $C_j = C_j(\varepsilon,\alpha)$, $j = 1, 2$, which can be computed with the aid of the proof of Theorem 3. Thus the proof provides explicit upper bounds for the error one makes when one replaces the operator $-\Delta+\varepsilon^2\Delta^2+m$ by $-\Delta+\varepsilon^2\Delta^2+\mu_n$.

Remark 5. The essential spectrum of $-\Delta + \varepsilon^2\Delta^2 + m$ remains the same for any finite real-valued Radon measure m on $\mathbb{R}^d$; i.e.,

$$
\sigma_{ess}(-\Delta + \varepsilon^2\Delta^2 + m) = \sigma_{ess}(-\Delta + \varepsilon^2\Delta^2) = [0,\infty). \tag{23}
$$

By Sobolev's inequality and [4, Lemma 19], the mapping $f \mapsto \tilde{f}$ from $H^2(\mathbb{R}^d)$ to $L^2(|m|)$ is compact. Therefore using estimate (8), one may conclude that $G^{\mu}_{\varepsilon,\alpha}$ is compact if regarded as an operator from $H^2(\mathbb{R}^d)$ to $L^2(dx)$. According to the resolvent formula (9), this implies that the resolvent difference $G^m_{\varepsilon,\alpha} - G_{\varepsilon,\alpha}$ is compact, and hence the corresponding essential spectra coincide.

3. Dependence on the coupling constant. In this section we are going to prove that

$$
-\Delta + \varepsilon^2\Delta^2 + m \longrightarrow -\Delta + m \qquad \text{as } \varepsilon \downarrow 0, \tag{24}
$$

in the norm-resolvent sense. Here m denotes a real-valued Radon measure on $\mathbb{R}^d$, and we assume, in addition, that for every $\eta > 0$ there exists a $\beta_\eta < \infty$ such that

$$
\int |f|^2 d|m| \leq \eta \left(\int |\nabla f|^2 dx + \beta_\eta \int |f|^2 dx \right), \qquad f \in C_0^\infty(\mathbb{R}^d). \tag{25}
$$

Note that we neither require that m is finite nor that $d \leq 3$. On the other hand, the condition (25) implies that $m(B) = 0$ for every Borel set B with classical capacity zero, and, for instance, it is excluded that m is a point measure if $d > 1$.

The inequality (25) holds, in particular, provided m belongs to the Kato class; i.e.,

$$
\begin{aligned}
\sup_{n\in\mathbb{Z}} |m|([n,n+1]) < \infty, &\qquad d = 1, \\
\lim_{\varepsilon\to 0} \sup_{x\in\mathbb{R}^2} \int_{B(x,\varepsilon)} |\log(|x-y|)|\, |m|(dy) = 0, &\qquad d = 2, \\
\lim_{\varepsilon\to 0} \sup_{x\in\mathbb{R}^3} \int_{B(x,\varepsilon)} \frac{1}{|x-y|}\, |m|(dy) = 0, &\qquad d = 3,
\end{aligned}
$$

with $B(x,\varepsilon)$ denoting the ball of radius ε centered at x (cf. [11, Theorem 3.1]). We refer to [7, Chapter 1.2] for additional examples of measures satisfying (25).

In general, the elements f in the form domain of $-\Delta$ do not possess a continuous representative $\tilde{f}$. Therefore we shall give a definition of $\mathcal{E}^m_\varepsilon$ different from the one in section 2 so that it works for all $\varepsilon \geq 0$. Of course, both definitions are equivalent in the special case of positive ε.

Since the space $C_0^\infty(\mathbb{R}^d)$ of smooth functions with compact support is dense in the Sobolev space $H^1(\mathbb{R}^d)$, there exists a unique bounded linear mapping $J_m : H^1(\mathbb{R}^d) \longrightarrow L^2(|m|)$ satisfying

$$J_m f = f, \qquad f \in C_0^\infty(\mathbb{R}^d)$$

(strictly speaking J_m maps the dx-equivalence class of the continuous function $\tilde{f} \in C_0^\infty(\mathbb{R}^d)$ to the $|m|$-equivalence class of $\tilde{f}$). We put

$$\begin{aligned} D(\mathcal{E}_\varepsilon^m) &:= D(\mathcal{E}_\varepsilon), \\ \mathcal{E}_\varepsilon^m(f,f) &:= \mathcal{E}_\varepsilon(f,f) + (A_m J_m f, J_m f)_{L^2(|m|)}, \qquad f \in D(\mathcal{E}_\varepsilon^m), \end{aligned}$$

where $D(\mathcal{E}_\varepsilon) = H^1(\mathbb{R}^d)$ for $\varepsilon = 0$, $D(\mathcal{E}_\varepsilon) = H^2(\mathbb{R}^d)$ otherwise, and

$$A_m h(x) := \begin{cases} h(x), & x \in B, \\ -h(x), & x \in \mathbb{R}^d \setminus B, \end{cases} \qquad h \in L^2(|m|),$$

with B being any Borel set such that $m^+(\mathbb{R}^d \setminus B) = 0 = m^-(B)$. By (25) and the KLMN theorem, the quadratic form $\mathcal{E}_\varepsilon^m$ in $L^2(dx)$ is lower semibounded and closed, and

$$\mathcal{E}_{\varepsilon,\beta_1}^m(f,f) \geq 0, \qquad f \in D(\mathcal{E}_\varepsilon^m).$$

Again, $-\Delta + \varepsilon^2\Delta^2 + m$ denotes the lower semibounded self-adjoint operator associated to $\mathcal{E}_\varepsilon^m$, and we put

$$R_{\varepsilon,\alpha}^m := (-\Delta + \varepsilon^2\Delta^2 + m + \alpha)^{-1},$$

provided the inverse operator exists. $G_{\varepsilon,\alpha}$ is defined the same way as in section 2.

One key for the proof of the convergence result (24) is the observation that one can decompose

$$\hat{g}_{\varepsilon,\alpha}(p) = \frac{c(\varepsilon)}{p^2 + \alpha(\varepsilon)} - \frac{c(\varepsilon)}{p^2 + \beta(\varepsilon)},$$

whenever $c(\varepsilon)$ is defined. The coefficients $-\alpha(\varepsilon)$ and $-\beta(\varepsilon)$ are the roots of the polynomial $\varepsilon^2 x^2 + x + \alpha$; a simple calculation yields

$$\begin{aligned} c(\varepsilon) &:= \frac{1}{\sqrt{1 - 4\varepsilon^2\alpha}} && \longrightarrow 1 \qquad \text{as } \varepsilon \downarrow 0, \\ \alpha(\varepsilon) &:= \frac{2\alpha}{1 + \sqrt{1 - 4\varepsilon^2\alpha}} && \longrightarrow \alpha \qquad \text{as } \varepsilon \downarrow 0, \\ \beta(\varepsilon) &:= \frac{1 + \sqrt{1 - 4\varepsilon^2\alpha}}{2\varepsilon^2} && \longrightarrow \infty \qquad \text{as } \varepsilon \downarrow 0. \end{aligned} \tag{26}$$

Using the parameters introduced above, we arrive at

$$G_{\varepsilon,\alpha} = c(\varepsilon) G_{0,\alpha(\varepsilon)} - c(\varepsilon) G_{0,\beta(\varepsilon)}. \tag{27}$$

In the proof of the convergence result (24) we will use again a Krein-like resolvent formula, this time using the one from [3]; cf. (29) below. First we need some preparation. Let $\alpha > 0$ and $\varepsilon \geq 0$. We introduce the operator $J_{m,\varepsilon,\alpha}$ from the Hilbert space $(D(\mathcal{E}_\varepsilon), \mathcal{E}_{\varepsilon,\alpha})$ to $L^2(|m|)$ as follows:

$$\begin{aligned} D(J_{m,\varepsilon,\alpha}) &:= D(\mathcal{E}_\varepsilon), \\ J_{m,\varepsilon,\alpha} f &:= J_m f, \qquad f \in D(J_{m,\varepsilon,\alpha}). \end{aligned}$$

By (25), the operator norm of $J_{m,\varepsilon,\alpha}$ is less than or equal to η provided $\alpha \geq \beta_\eta$. Thus we can choose $\alpha_0 > 0$ and $c < 1$ such that

$$\| J_{m,\varepsilon,\alpha} \|_{(D(\mathcal{E}_\varepsilon),\mathcal{E}_{\varepsilon,\alpha}),L^2(|m|)} \leq \sqrt{c}, \qquad \alpha \geq \alpha_0. \tag{28}$$

Due to (28), the hypothesis of Theorem 3 in [3] is satisfied, and the theorem implies that $-\alpha$ belongs to the resolvent set of $-\Delta + \varepsilon^2\Delta^2 + m$ and

$$R^m_{\varepsilon,\alpha} = G_{\varepsilon,\alpha} - (J_{m,\varepsilon,\alpha})^* A_m (1 + J_m J^*_{m,\varepsilon,\alpha} A_m)^{-1} J_m G_{\varepsilon,\alpha}, \qquad \alpha \geq \alpha_0. \tag{29}$$

In fact, we can write

$$J^*_{m,\varepsilon,\alpha'} = (J_m G_{\varepsilon,\alpha'})^*, \qquad \alpha' > 0, \tag{30}$$

since we have

$$(J^*_{m,\varepsilon,\alpha'} f, h) = \mathcal{E}_{\varepsilon,\alpha'}(J^*_{m,\varepsilon,\alpha'} f, G_{\varepsilon,\alpha'} h) = (f, J_{m,\varepsilon,\alpha'} G_{\varepsilon,\alpha'} h)_{L^2(|m|)} = ((J_m G_{\varepsilon,\alpha'})^* f, h)$$

for every $h \in L^2(dx)$, $\varepsilon \geq 0$, and $\alpha' > 0$.

THEOREM 6. *Let m be a real-valued Radon measure on $\mathbb{R}^d$ satisfying* (25)*. Then the operators $-\Delta + \varepsilon^2\Delta^2 + m$ converge to $-\Delta + m$ in the norm-resolvent sense as $\varepsilon \downarrow 0$.*

Proof. Both resolvents are written by means of Krein's formula (29), so we can compare the first and second terms separately. To see that $\| G_{\varepsilon,\alpha} - G_{0,\alpha} \|_{L^2(dx)}$ vanishes in the limit $\varepsilon \downarrow 0$ is simple. It is enough to use the first resolvent formula

$$G_{0,\alpha(\varepsilon)} - G_{0,\alpha} = (\alpha - \alpha(\varepsilon)) G_{0,\alpha} G_{0,\alpha(\varepsilon)} \tag{31}$$

and the fact that

$$\| G_{0,\alpha'} \|^2_{L^2(dx),H^1} \leq k(\alpha'), \qquad \alpha' > 0,$$

for some continuous function k vanishing at infinity (actually, $k(x) = 1/x^2$ for $x \leq 2$ and $k(x) = 1/(4(x-1))$ for $x > 2$). Then the decomposition (27) of $G_{\varepsilon,\alpha}$ and the asymptotic behavior (26) of $\alpha(\varepsilon), \beta(\varepsilon)$, and $c(\varepsilon)$ finish the argument.

The proof that the difference of second terms in Krein's formula also tends to zero as $\varepsilon \to 0$ can be reduced into two tasks

$$\begin{aligned} \| J_m G_{\varepsilon,\alpha} - J_m G_{0,\alpha} \|_{L^2(dx),L^2(|m|)} &\longrightarrow 0 \qquad \text{as } \varepsilon \downarrow 0, \\ \| (1 + J_m J^*_{m,\varepsilon,\alpha} A_m)^{-1} - (1 + J_m J^*_{m,0,\alpha} A_m)^{-1} \|_{L^2(|m|)} &\longrightarrow 0 \qquad \text{as } \varepsilon \downarrow 0. \end{aligned}$$

The argument for the first line is similar to the one we have presented above for $G_{\varepsilon,\alpha} - G_{0,\alpha}$; we only have to add that, by hypothesis (25), it follows that

$$\| J_m G_{0,\alpha'} \|^2_{L^2(dx),L^2(|m|)} \leq \max(1, \beta_1) k(\alpha'), \qquad \alpha' > 0, \tag{32}$$

where the function $k(\alpha')$ is defined as above.

To show the second line we choose any $\alpha > \alpha_0$; then from (28) we get

$$\| (1 + J_m J^*_{m,\varepsilon,\alpha} A_m)^{-1} \|_{L^2(|m|)} \leq \frac{1}{1-c}, \qquad \varepsilon \geq 0.$$

By the second resolvent identity

$$(1+A)^{-1} - (1+B)^{-1} = (1+A)^{-1}(B-A)(1+B)^{-1},$$

it is sufficient to prove that

$$\| J_m J_{m,\varepsilon,\alpha}^* - J_m J_{m,0,\alpha}^* \|_{L^2(|m|)} \longrightarrow 0 \qquad \text{as } \varepsilon \downarrow 0. \tag{33}$$

From (27) and (30) follows that

$$J_m J_{m,\varepsilon,\alpha}^* = c(\varepsilon) J_m (J_m G_{0,\alpha(\varepsilon)})^* - c(\varepsilon) J_m (J_m G_{0,\beta(\varepsilon)})^*;$$

note that $c(\varepsilon)$ is real for sufficiently small ε. Using this expression and (31) and (30), we get

$$\begin{aligned} &\| J_m J_{m,\varepsilon,\alpha}^* - J_m J_{m,0,\alpha}^* \|_{L^2(|m|)} \\ &\le \| (c(\varepsilon)-1) J_m (J_m G_{0,\alpha(\varepsilon)})^* \|_{L^2(|m|)} + \| J_m (J_m G_{0,\alpha(\varepsilon)})^* - J_m (J_m G_{0,\alpha})^* \|_{L^2(|m|)} \\ &\qquad + \| c(\varepsilon) J_m (J_m G_{0,\beta(\varepsilon)})^* \|_{L^2(|m|)} \\ &= \| (c(\varepsilon)-1) J_{m,0,\alpha(\varepsilon)} J_{m,0,\alpha(\varepsilon)}^* \|_{L^2(|m|)} + \| (\alpha - \alpha(\varepsilon)) J_m G_{0,\alpha} (J_m G_{0,\alpha(\varepsilon)})^* \|_{L^2(|m|)} \\ &\qquad + \| c(\varepsilon) J_{m,0,\beta(\varepsilon)} J_{m,0,\beta(\varepsilon)}^* \|_{L^2(|m|)}, \qquad \varepsilon > 0. \end{aligned}$$

According to (25), the mapping $\| J_{m,0,\alpha} J_{m,0,\alpha}^* \|_{L^2(|m|)}$ is locally bounded for $\alpha \in (0,\infty)$ and tends to zero as α tends to infinity. Since $\alpha(\varepsilon) \longrightarrow \alpha$, $c(\varepsilon) \longrightarrow 1$, and $\beta(\varepsilon) \longrightarrow \infty$ as $\varepsilon \downarrow 0$, this implies, in conjunction with (32), that (33) holds. □

Remark 7. By the proof above, $\| G_{\varepsilon,\alpha}^m - G_{0,\alpha}^m \|$ is upper bounded by an expression of the form $c \cdot (\varepsilon^2 + \eta(m,\varepsilon))$, where the finite constant c can be extracted from the proof and $\eta(m,\varepsilon)$ has to be chosen (and can be chosen) such that (25) holds with η and β replaced by $\eta(m,\varepsilon)$ and $\beta(\varepsilon)$, respectively.

4. Eigenvalues and eigenspaces of the approximating operators. In this section let $d \le 3$, and let m be a finite real-valued Radon measure satisfying (25) (e.g., let m be from the Kato class). By the two preceding convergence results, we can approximate the operator $-\Delta + m$ in $L^2(\mathbb{R}^d, dx)$ by operators of the form $-\Delta + \varepsilon^2 \Delta^2 + \mu$, where $\varepsilon > 0$ and μ is a point measure with mass at only finitely many points. Since the convergence is in the norm-resolvent sense, we can thus approximate the negative eigenvalues and corresponding eigenspaces of the former operator by the corresponding eigenvalues and eigenfunctions of the latter one. Note that we know from (23) and [5, Theorem 3.1] that the essential spectra coincide.

The following theorem shows how to compute the eigenvalues and corresponding eigenspaces of the approximating operators.

THEOREM 8. *Let $d \le 3$ and $\varepsilon > 0$. Let $\mu = \sum_{j=1}^N c_j \delta_{x_j}$, where $N \in \mathbb{N}$, $x_1, \dots, x_N$ are N distinct points in $\mathbb{R}^d$, and $c_1, \dots, c_N$ are real numbers different from zero. Then the following holds:*

(a) *The real number $-\alpha < 0$ is an eigenvalue of $-\Delta + \varepsilon^2 \Delta^2 + \mu$ if and only if*

$$\det \left(\frac{\delta_{jk}}{c_k} + g_{\varepsilon,\alpha}(x_j - x_k) \right)_{1 \le j,k \le N} = 0.$$

(b) *For every eigenvalue $-\alpha < 0$ the corresponding eigenfunctions have the following form:*

$$\sum_{k=1}^N h_k g_{\varepsilon,\alpha}(\cdot - x_k), \qquad (h_k)_{1 \le k \le N}^T \in \ker \left(\frac{\delta_{jk}}{c_k} + g_{\varepsilon,\alpha}(x_j - x_k) \right)_{1 \le j,k \le N}.$$

Proof. Since $D(\mathcal{E}_\varepsilon) = H^2(\mathbb{R}^d)$, the mapping J_μ can be understood as

$$J_\mu f := \tilde{f} \qquad |\mu| \text{ a.e.}, \quad f \in H^2(\mathbb{R}^d).$$

By (6), $\int g_{\varepsilon,\alpha}(\cdot - y)f(y)dy$ is the unique continuous representative of $G_{\varepsilon,\alpha}f$. Hence $J_\mu G_{\varepsilon,\alpha}$ is the integral operator from $L^2(dx)$ to $L^2(|\mu|)$ with kernel $g_{\varepsilon,\alpha}(x-y)$, and its inverse operator $(J_\mu G_{\varepsilon,\alpha})^*$ is the integral operator from $L^2(|\mu|)$ to $L^2(dx)$ with the same kernel. Thus we get

$$J_\mu(J_\mu G_{\varepsilon,\alpha})^* A_\mu h(x_j) = \sum_{k=1}^{N} c_k g_{\varepsilon,\alpha}(x_j - x_k)h(x_k), \qquad 1 \le j \le N, \tag{34}$$

for every $h \in L^2(|\mu|)$.

Due to Krein's formula (29), $-\alpha < 0$ belongs to the resolvent set of $(-\Delta+\varepsilon^2\Delta^2+\mu)$ provided $1 + J_\mu(J_\mu G_{\varepsilon,\alpha})^* A_\mu$ is bijective. Since $L^2(|\mu|)$ is finite-dimensional and we have expression (34), that is true if and only if

$$\lambda(\alpha) := \det(\delta_{jk} + c_k g_{\varepsilon,\alpha}(x_j - x_k))_{1\le j,k\le N} \neq 0,$$

with $\delta_{j,k}$ being the Kronecker delta. As $g_{\varepsilon,\alpha}(x)$ is a real analytic function of $\alpha \in (0,\infty)$ for every $x \in \mathbb{R}^d$, the function $\lambda(\alpha)$ is also real analytic on $(0,\infty)$. By (5), it is different from zero for all sufficiently large α. Thus the set of zeros on $(0,\infty)$ of this function is discrete.

Since $J_\mu G_{\varepsilon,\alpha}$ is surjective and $(J_\mu G_{\varepsilon,\alpha})^* A_\mu$ injective, the resolvent formula (29) implies that any $\alpha_0 > 0$ satisfying $\lambda(\alpha_0) = 0$ is a pole of $R^\mu_{\varepsilon,\alpha}$. Thus we have proved that $-\alpha_0$ is an eigenvalue of $-\Delta + \varepsilon^2\Delta^2 + \mu$ if and only if $\lambda(\alpha_0) = 0$. Finally, the expression

$$\det(\delta_{jk} + c_k g_{\varepsilon,\alpha}(x_j - x_k))_{1\le j,k\le N} = \Pi_{k=1}^N c_k \cdot \det(\delta_{jk}/c_k + g_{\varepsilon,\alpha}(x_j - x_k))_{1\le j,k\le N}$$

implies assertion (a).

By the preceding considerations and [3, Lemma 1],

$$h \mapsto (J_\mu G_{\varepsilon,\alpha})^* A_\mu h$$

is a linear bijective mapping from $\ker(1+J_\mu(J_\mu G_{\varepsilon,\alpha})^* A_\mu)$ onto $\ker(-\Delta+\varepsilon^2\Delta^2+\mu+\alpha)$. Assertion (b) follows from a simple algebraic calculation. □

Remark 9. Since the Hilbert space $L^2(|\mu|)$ is N-dimensional with $N < \infty$, the resolvent formula (29) implies that the difference $G^\mu_{\varepsilon,\alpha} - G_{\varepsilon,\alpha}$ is a finite rank operator with rank less than or equal to N. Thus the number, counting multiplicity, of negative eigenvalues of $-\Delta + \varepsilon^2\Delta^2 + \mu$ is less than or equal to N.

Let us illustrate the approximation by point measures on a simple example in dimension two. Suppose that measure m is a minus length measure supported by a circle of radius R; i.e., m is a constant and negative measure. This makes the choice of approximating point measures very simple: We spread equidistantly N points along the circle, and all of the points have the same coupling constant c:

$$c = -\frac{\gamma 2\pi R}{N}.$$

Due to the symmetry, the spectrum of $-\Delta+m$ is known; it consists of the essential spectrum $[0,\infty)$ and a finite number of negative eigenvalues, which are all except the

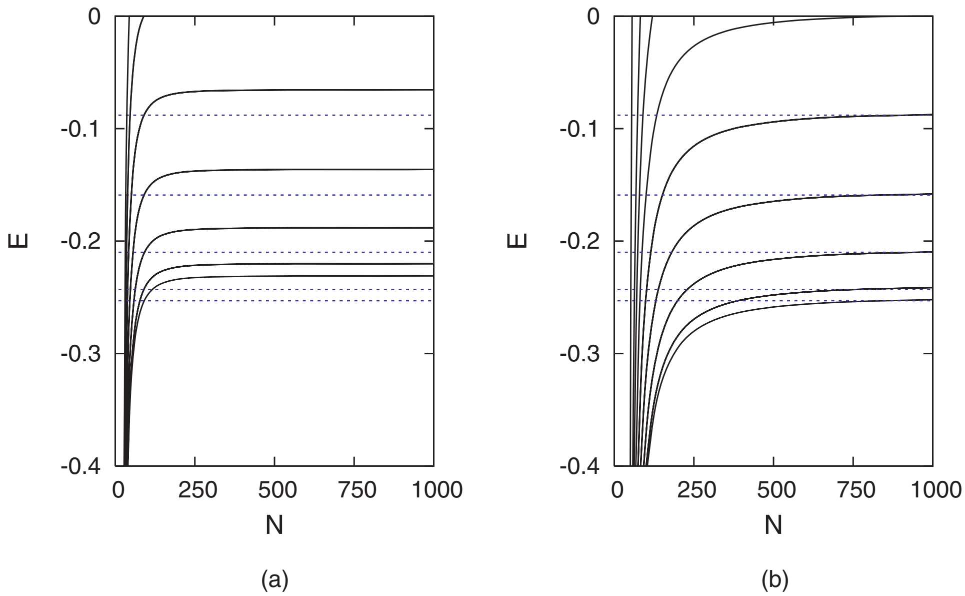

FIG. 1. *The dependence of the approximate eigenvalues on the number of point potentials for a circle with* $R = 10$ *and* $\varepsilon = 0.1$ (a), $\varepsilon = 0.01$ (b). *The dashed lines represent the exact eigenvalues of* $-\Delta + m$.

lowest one twice degenerate; see [2]. To find the eigenvalues, one has to decompose $L^2(\mathbb{R}^2)$ into angular momentum subspaces and then to look for solutions of an implicit equation in each of the subspaces. Therefore we can compute and compare both exact and approximate eigenvalues.

Each approximation is characterized by a pair of numbers, $\varepsilon > 0$ and $N \in \mathbb{N}$. In numerical calculations we fix ε, and we let N grow. The results for one chosen radius and two different parameters ε are depicted in Figure 1; cases (a) and (b) correspond to $\varepsilon = 0.1$ and $\varepsilon = 0.01$, respectively. We observe that below some threshold number of points the approximate discrete spectrum has no resemblance to the exact spectrum. The approximate eigenvalues may be very large negative, and their number may be much higher than the number of exact eigenvalues (in Figure 1, we have not even plotted all of the eigenvalues which exist only for small N).

It appears that, for larger ε, we get a fast convergence of eigenvalues; however, they are all shifted from the exact ones. The reason is that, since we work with fixed ε, the limit operator is, in fact, $-\Delta + \varepsilon^2\Delta^2 + m$ instead of $-\Delta + m$. On the contrary, small ε means that one needs more points to obtain a qualitatively correct spectrum, but then for a large number of points one gets much closer to the exact spectrum.

We can also compare this approximation to [8], where approximating operators were Laplacians with point potentials. Those point potentials are, of course, different: They are not defined via a quadratic form and cannot be understood as a special case $\varepsilon = 0$ of section 2; instead boundary conditons on wave functions are used; see [1]. Figure 2 presents the eigenvalues of Laplacians perturbed by point potentials which converge to $-\Delta + m$ with the same measure m as above. We have already mentioned in the introduction that, here, we obtain a stronger convergence result than the one in [8]. Moreover, comparing both Figures 1 and 2, we see that employing fourth-order differential operators in the approximation may improve significantly the spectral convergence.

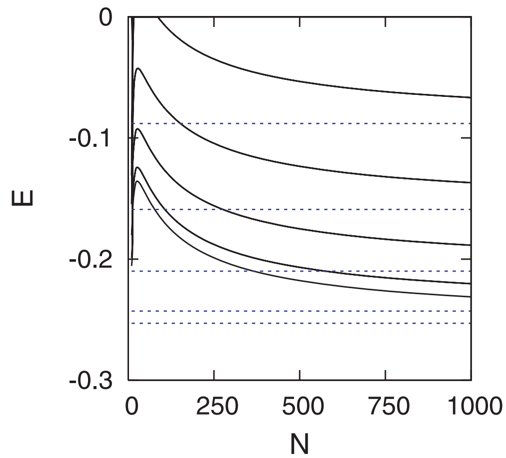

FIG. 2. *The dependence of the approximate eigenvalues on the number of point potentials for $R = 10$, using the standard two-dimensional point potentials. The dashed lines represent the exact eigenvalues of $-\Delta + m$.*

Appendix. In section 2 we have employed Krein's formula (9). Various forms of this formula can be found in the literature. Let us prove here the one we have used.

Let $f \in L^2(dx)$. Since $\mathcal{E}_\varepsilon$ and $\mathcal{E}_\varepsilon^\mu$ are associated to $-\Delta+\varepsilon^2\Delta^2$ and $-\Delta+\varepsilon^2\Delta^2+\mu$, respectively, it follows from Kato's representation theorem that

$$\mathcal{E}_{\varepsilon,\alpha}(G_{\varepsilon,\alpha}f, h) = (f, h) = \mathcal{E}^\mu_{\varepsilon,\alpha}((-\Delta + \varepsilon^2\Delta^2 + \mu + \alpha)^{-1}f, h) \tag{35}$$

for any $h \in H^2(\mathbb{R}^d)$ and $f \in L^2(\mathbb{R}^d)$. Moreover we have

$$\begin{aligned} \mathcal{E}_{\varepsilon,\alpha}(G^\mu_{\varepsilon,\alpha}\psi, h) &= (G^\mu_{\varepsilon,\alpha}\psi, (-\Delta + \varepsilon^2\Delta^2 + \alpha)h) \\ &= \int\int g_{\varepsilon,\alpha}(x-y)\bar{\tilde{\psi}}(y)\mu(dy)(-\Delta + \varepsilon^2\Delta^2 + \alpha)h(x)\,dx \\ &= \int\int g_{\varepsilon,\alpha}(x-y)(-\Delta + \varepsilon^2\Delta^2 + \alpha)h(x)\,dx\,\bar{\tilde{\psi}}(y)\mu(dy) \\ &= \int \tilde{h}\bar{\tilde{\psi}}\,\mu(dy), \qquad \psi \in H^2(\mathbb{R}^d), \quad h \in D(-\Delta + \varepsilon^2\Delta^2). \end{aligned} \tag{36}$$

We could change the order of integration in the second step. In fact, as $\mu^\pm$ are finite Radon measures and $g_{\varepsilon,\alpha}$ is square integrable w.r.t. the Lebesgue measure dx, the mappings $x \mapsto \int |g_{\varepsilon,\alpha}(x-y)|\mu^\pm(dy)$, $\mathbb{R}^d \longrightarrow \mathbb{R}$, are square integrable w.r.t. dx. Since $\tilde{\psi}$ is bounded and $(-\Delta + \varepsilon^2\Delta^2 + \alpha)h \in L^2(dx)$, it follows that

$$\int\int |g_{\varepsilon,\alpha}(x-y)\bar{\tilde{\psi}}(y)|\mu^\pm(dy)|(-\Delta + \varepsilon^2\Delta^2 + \alpha)h(x)|dx < \infty,$$

and, by Fubini's theorem, we could change the order of integration in the second step. In the last step we have used (6). Employing Sobolev's inequality and the fact that $D(-\Delta + \varepsilon^2\Delta^2)$ is dense in $(D(\mathcal{E}_\varepsilon), \mathcal{E}_{\varepsilon,\alpha})$, we can extend (36) to all functions ψ, $h \in D(\mathcal{E}_\varepsilon)$.

Put

$$\phi := G_{\varepsilon,\alpha}f - G^\mu_{\varepsilon,\alpha}(I + G^\mu_{\varepsilon,\alpha})^{-1}G_{\varepsilon,\alpha}f.$$

Then $\phi \in H^2(\mathbb{R}^d) = D(\mathcal{E}^\mu_\varepsilon)$, and (35) and extended (36) yield

$$\begin{aligned}\mathcal{E}^\mu_{\varepsilon,\alpha}(\phi,h) &= \mathcal{E}_{\varepsilon,\alpha}(G_{\varepsilon,\alpha}f,h) - \mathcal{E}_{\varepsilon,\alpha}(G^\mu_{\varepsilon,\alpha}(I+G^\mu_{\varepsilon,\alpha})^{-1}G_{\varepsilon,\alpha}f,h) \\ &\quad + \int [G_{\varepsilon,\alpha}f - G^\mu_{\varepsilon,\alpha}(I+G^\mu_{\varepsilon,\alpha})^{-1}G_{\varepsilon,\alpha}\tilde{\tilde{f}}]\tilde{h}\,d\mu \\ &= (f,h) - \int [(I+G^\mu_{\varepsilon,\alpha})^{-1}G_{\varepsilon,\alpha}\tilde{\tilde{f}}]\tilde{h}\,d\mu \\ &\quad + \int [(I+G^\mu_{\varepsilon,\alpha})(I+G^\mu_{\varepsilon,\alpha})^{-1}G_{\varepsilon,\alpha}f - G^\mu_{\varepsilon,\alpha}(I+G^\mu_{\varepsilon,\alpha})^{-1}G_{\varepsilon,\alpha}\tilde{\tilde{f}}]\tilde{h}\,d\mu \\ &= (f,h), \qquad h \in H^2(\mathbb{R}^d).\end{aligned}$$

Due to (10), $\mathcal{E}^\mu_{\varepsilon,\alpha}$ is a scalar product on $D(\mathcal{E}^\mu_{\varepsilon,\alpha}) = H^2(\mathbb{R}^d)$. Thus (35) and the calculation above imply that $\phi = (-\Delta + \varepsilon^2\Delta^2 + \mu + \alpha)^{-1}f$.

OPTIMALLY SPARSE MULTIDIMENSIONAL REPRESENTATION USING SHEARLETS*

KANGHUI GUO† AND DEMETRIO LABATE‡

Abstract. In this paper we show that shearlets, an affine-like system of functions recently introduced by the authors and their collaborators, are essentially optimal in representing 2-dimensional functions f which are C^2 except for discontinuities along C^2 curves. More specifically, if f_N^S is the N-term reconstruction of f obtained by using the N largest coefficients in the shearlet representation, then the asymptotic approximation error decays as $\|f - f_N^S\|_2^2 \asymp N^{-2} (\log N)^3$, $N \to \infty$, which is essentially optimal, and greatly outperforms the corresponding asymptotic approximation rate N^{-1} associated with wavelet approximations. Unlike curvelets, which have similar sparsity properties, shearlets form an affine-like system and have a simpler mathematical structure. In fact, the elements of this system form a Parseval frame and are generated by applying dilations, shear transformations, and translations to a single well-localized window function.

1. Introduction.

The notion of efficient representation of data plays an increasingly important role in areas across applied mathematics, science, and engineering. Over the past few years, there has been a rapidly increasing pressure to handle ever larger and higher-dimensional data sets, with the challenge of providing representations of these data that are sparse (that is, "very" few terms of the representation are sufficient to accurately approximate the data) and computationally fast. Sparse representations have implications reaching beyond data compression. Understanding the compression problem for a given data type entails a precise knowledge of the modeling and approximation of that data type. This in turn is useful for many other important tasks, including classification, denoising, interpolation, and segmentation [13].

Multiscale techniques based on wavelets have emerged over the last two decades as the most successful methods for the efficient representation of data, as attested, for example, by their use in the new FBI fingerprint database [3] and in JPEG2000, the new standard for image compression [4, 19]. Indeed, wavelets are optimally efficient in representing functions with pointwise singularities [27, Chap. 9].

More specifically, consider the wavelet representation (using a "nice" wavelet basis) of a function f of a *single variable* that is smooth apart from a point discontinuity. Because the elements of the wavelet basis are well localized (i.e., they have very fast decay both in the spatial and in the frequency domain), very few of them interact significantly with the singularity, and thus very few elements of the wavelet expansion are sufficient to provide an accurate approximation. This contrasts sharply with the

Fourier representation, for which the discontinuity interacts extensively with the elements of the Fourier basis. Denoting by f_N the approximation obtained by using the largest N coefficients in the wavelet expansion, the asymptotic approximation error satisfies

$$\|f - f_N\|_2^2 \asymp N^{-2}, \qquad N \to \infty.$$

This is the optimal approximation rate for this type of function [10], and outperforms the corresponding Fourier approximation error rate N^{-1} [13, 27]. In addition, the multiresolution analysis (MRA) associated with wavelets provides very fast numerical algorithms for computing the wavelet coefficients [27].

However, despite their remarkable success in applications, wavelets are far from optimal in dimensions larger than one. Indeed wavelets are very efficient in dealing with pointwise singularities *only*. In higher dimensions other types of singularities are usually present or even dominant, and wavelets are unable to handle them very efficiently. Consider, for example, the wavelet representation of a 2-dimensional (2-D) function that is C^2 away from a discontinuity along a curve of finite length (a reasonable model for an image containing an edge). Because the discontinuity is spatially distributed, it interacts extensively with the elements of the wavelet basis. As a consequence, the wavelet coefficients have a slow decay, and the approximation error $\|f - f_N\|_2^2$ decays at most as fast as $O(N^{-1})$ [27]. This is better than the rate of the Fourier approximation error $N^{-1/2}$, but far from the optimal theoretical approximation rate (cf. [12])

$$\|f - f_N\|_2^2 \asymp N^{-2}, \qquad N \to \infty. \tag{1.1}$$

There is, therefore, large room for improvements, and several attempts have been made in this direction both in the mathematical and engineering communities in recent years. Those include *contourlets*, *complex wavelets* and other "directional wavelets" in the filter bank literature [1, 2, 11, 22, 26, 28], as well as *brushlets* [8], *ridgelets* [5], *curvelets* [7], and *bandelets* [24].

The most successful approach so far are the curvelets of Candès and Donoho. This is the first and so far the only construction providing an essentially optimal approximation property for 2-D piecewise smooth functions with discontinuities along C^2 curves [7]. The main idea in the curvelet approach is that, in order to approximate functions with edges accurately, one has to exploit their geometric regularity much more efficiently than traditional wavelets. This is achieved by constructing an appropriate tight frame of well-localized functions at various scales, positions, and directions. We refer to [6, 7] for more details about this construction.

The main goal of this paper is to show that shearlets, a construction based on the theory of composite wavelets, also provides an essentially optimal approximation property for 2-D piecewise C^2 functions with discontinuities along C^2 curves. We will show that the approximation error associated with the N-term reconstruction f_N^S obtained by taking the N largest coefficients in the shearlet expansion satisfies

$$\|f - f_N^S\|_2^2 \asymp N^{-2}(\log N)^3, \qquad N \to \infty. \tag{1.2}$$

This is exactly the approximation rate obtained using curvelets. The proof of our result adapts several ideas from the corresponding sparsity result of the curvelets [7] and follows the general architecture of that proof, but does not follow directly from the curvelets construction. Indeed, as we will argue in the following, our alternative approach based on shearlets has some mathematical advantages with respect to curvelets, including a simplified construction that provides the framework for a simpler mathematical analysis and fast algorithmic implementation (see also [9, 14]).

The theory of composite wavelets, recently proposed by the authors and their collaborators [16, 17, 18], provides a most general setting for the construction of truly multidimensional, efficient, multiscale representations. Unlike the curvelets, this approach takes full advantage of the theory of affine systems on $\mathbb{R}^n$. Specifically, the *affine systems with composite dilations* are the systems

$$\mathcal{A}_{AB}(\psi) = \{\psi_{j,\ell,k}(x) = |\det A|^{j/2}\,\psi(B^\ell A^j x - k) : \, j,\ell \in \mathbb{Z}, k \in \mathbb{Z}^n\}, \tag{1.3}$$

where A, B are $n \times n$ invertible matrices and $|\det B| = 1$. The elements of this system are called *composite wavelets* if $\mathcal{A}_{AB}(\psi)$ forms a *Parseval frame* (also called a tight frame) for $L^2(\mathbb{R}^n)$; that is,

$$\sum_{j,\ell,k} |\langle f, \psi_{j,\ell,k}\rangle|^2 = \|f\|^2$$

for all $f \in L^2(\mathbb{R}^n)$. The shearlets, which will be considered in this paper, are a special class of composite wavelets where A is an anisotropic dilation and B is a shear matrix. Details for this construction will be given in section 1.2. These representations have fully controllable geometrical features, such as orientations, scales, and shapes, which set them apart from traditional wavelets as well as complex and directional wavelets. In addition, thanks to their mathematical structure, there is a multiresolution analysis naturally associated with composite wavelets. This is particularly useful for the development of fast algorithmic implementations of these transformations [23, 25].

Observe that curvelets are not of the form (1.3), and, unlike the shearlets, are not generated from the action of a family of operators on a single or finite family of functions.

1.1. Notation. Throughout this paper, we shall consider the points $x \in \mathbb{R}^n$ to be column vectors, i.e.,

$$x = \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix},$$

and the points $\xi \in \widehat{\mathbb{R}}^n$ (the frequency domain) to be row vectors, i.e., $\xi = (\xi_1, \dots, \xi_n)$. A vector x multiplying a matrix $a \in GL_n(\mathbb{R})$ on the right is understood to be a column vector, while a vector ξ multiplying a on the left is a row vector. Thus, $ax \in \mathbb{R}^n$ and $\xi a \in \widehat{\mathbb{R}}^n$. The Fourier transform is defined as

$$\hat{f}(\xi) = \int_{\mathbb{R}^n} f(x)\, e^{-2\pi i \xi x}\, dx,$$

where $\xi \in \widehat{\mathbb{R}}^n$, and the inverse Fourier transform is

$$\check{f}(x) = \int_{\widehat{\mathbb{R}}^n} f(\xi)\, e^{2\pi i \xi x}\, d\xi.$$

1.2. Shearlets. The collection of shearlets that we are going to define in this section is a special example of composite wavelets in $L^2(\mathbb{R}^2)$, of the form (1.3), where

$$A = \begin{pmatrix} 4 & 0 \\ 0 & 2 \end{pmatrix}, \quad B = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}, \tag{1.4}$$

and ψ will be defined in the following. It is useful to observe that, by applying the Fourier transform to the elements $\psi_{j,\ell,k}$ in (1.3), we obtain

$$\hat{\psi}_{j,\ell,k}(\xi) = |\det A|^{-j/2}\,\psi(\xi A^{-j} B^{-\ell})\, e^{2\pi i \xi A^{-j} B^{-\ell} k}.$$

For any $\xi = (\xi_1, \xi_2) \in \widehat{\mathbb{R}}^2$, $\xi_1 \neq 0$, let ψ be given by

$$\hat{\psi}(\xi) = \hat{\psi}(\xi_1, \xi_2) = \hat{\psi}_1(\xi_1)\,\hat{\psi}_2\left(\frac{\xi_2}{\xi_1}\right), \tag{1.5}$$

where $\hat{\psi}_1, \hat{\psi}_2 \in C^\infty(\widehat{\mathbb{R}})$, $\operatorname{supp}\hat{\psi}_1 \subset [-\frac{1}{2}, -\frac{1}{16}] \cup [\frac{1}{16}, \frac{1}{2}]$, and $\operatorname{supp}\hat{\psi}_2 \subset [-1, 1]$. We assume that

$$\sum_{j \geq 0} |\hat{\psi}_1(2^{-2j}\omega)|^2 = 1 \quad \text{for } |\omega| \geq \frac{1}{8} \tag{1.6}$$

and

$$|\hat{\psi}_2(\omega - 1)|^2 + |\hat{\psi}_2(\omega)|^2 + |\hat{\psi}_2(\omega + 1)|^2 = 1 \quad \text{for } |\omega| \leq 1. \tag{1.7}$$

It follows from the last equation that, for any $j \geq 0$,

$$\sum_{\ell=-2^j}^{2^j} |\hat{\psi}_2(2^j\,\omega + \ell)|^2 = 1 \quad \text{for } |\omega| \leq 1. \tag{1.8}$$

It also follows from our assumptions that $\hat{\psi} \in C_0^\infty(\widehat{\mathbb{R}}^2)$, with $\operatorname{supp}\hat{\psi} \subset [-\frac{1}{2}, \frac{1}{2}]^2$. There are several examples of functions ψ_1, ψ_2 satisfying the properties described above (see the appendix).

Observe that $(\xi_1, \xi_2)\, A^{-j} B^{-\ell} = (2^{-2j}\xi_1, -\ell 2^{-2j}\xi_1 + 2^{-j}\xi_2)$. Using (1.6) and (1.8), it is easy to see that

$$\begin{aligned}\sum_{j \geq 0} \sum_{\ell=-2^j}^{2^j} |\hat{\psi}(\xi\, A^{-j} B^{-\ell})|^2 &= \sum_{j \geq 0} \sum_{\ell=-2^j}^{2^j} |\hat{\psi}_1(2^{-2j}\,\xi_1)|^2 \left|\hat{\psi}_2\left(2^j\,\frac{\xi_2}{\xi_1} - \ell\right)\right|^2 \\ &= \sum_{j \geq 0} |\hat{\psi}_1(2^{-2j}\,\xi_1)|^2 \sum_{\ell=-2^j}^{2^j} \left|\hat{\psi}_2\left(2^j\,\frac{\xi_2}{\xi_1} - \ell\right)\right|^2 = 1\end{aligned}$$

for $(\xi_1, \xi_2) \in \mathcal{D}_C$, where $\mathcal{D}_C = \{(\xi_1, \xi_2) \in \widehat{\mathbb{R}}^2 : |\xi_1| \geq \frac{1}{8}, |\frac{\xi_2}{\xi_1}| \leq 1\}$. This equation, together with the fact that $\hat{\psi}$ is supported inside $[-\frac{1}{2}, \frac{1}{2}]^2$, implies that the collection of *shearlets*,

$$\mathcal{SH}(\psi) = \left\{\psi_{j,\ell,k}(x) = 2^{\frac{3j}{2}}\,\psi(B^\ell A^j x - k) : j \geq 0, -2^j \leq \ell \leq 2^j, k \in \mathbb{Z}^2\right\}, \tag{1.9}$$

is a Parseval frame for $L^2(\mathcal{D}_C)^\vee = \{f \in L^2(\mathbb{R}^2) : \operatorname{supp}\hat{f} \subset \mathcal{D}_C\}$. Details about the argument that this system is a Parseval frame can be found in [18, sect. 5.2.1].

To obtain a Parseval frame for $L^2(\mathbb{R}^2)$, one can construct a second system of shearlets which form a Parseval frame for the functions with frequency support in the vertical cone $\mathcal{D}_{\widetilde{C}} = \{(\xi_1, \xi_2) \in \widehat{\mathbb{R}}^2 : |\xi_2| \geq \frac{1}{8}, |\frac{\xi_1}{\xi_2}| \leq 1\}$. Finally, one can easily

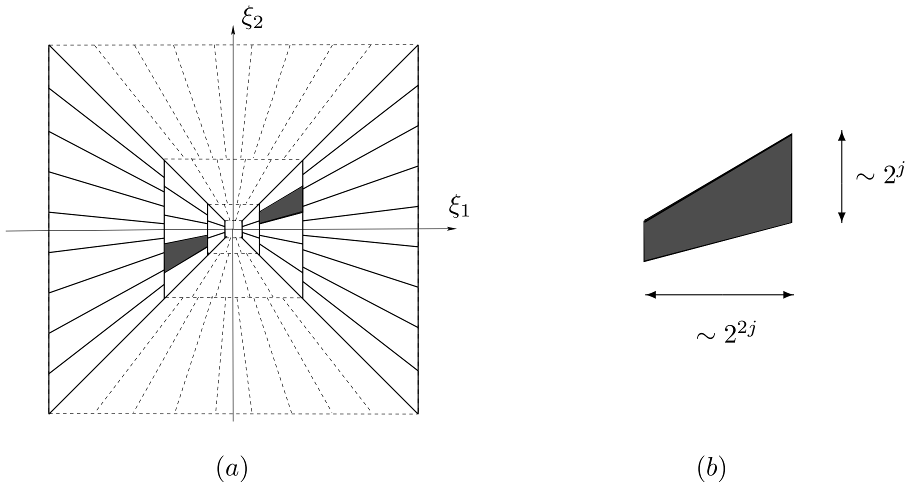

FIG. 1.1. (a) *The tiling of the frequency plane* $\widehat{\mathbb{R}}^2$ *induced by the shearlets.* (b) *Frequency support of the shearlet* $\psi_{j,\ell,k}$*, for* $\xi_1 > 0$*. The other half of the support, for* $\xi_1 < 0$*, is symmetrical.*

construct a Parseval frame (or an orthonormal basis) for $L^2([-\frac{1}{8}, \frac{1}{8}]^2)^\vee$. Then any function in $L^2(\mathbb{R}^2)$ can be expressed as a sum $f = P_C f + P_{\widetilde{C}} f + P_0 f$, where each component corresponds to the orthogonal projection of f into one of the three subspaces of $L^2(\mathbb{R}^2)$ described above. The tiling of the frequency plane $\widehat{\mathbb{R}}^2$ induced by this system is illustrated in Figure 1.1(a). The above construction was first introduced in [15].

The conditions on the support of $\hat{\psi}_1$ and $\hat{\psi}_2$ imply that the functions $\hat{\psi}_{j,\ell,k}$ have frequency support:

$$\operatorname{supp} \hat{\psi}_{j,\ell,k} \subset \left\{ (\xi_1, \xi_2) : \xi_1 \in [-2^{2j-1}, -2^{2j-4}] \cup [2^{2j-4}, 2^{2j-1}], \left| \frac{\xi_2}{\xi_1} - \ell\, 2^{-j} \right| \leq 2^{-j} \right\}.$$

Thus, the system $\mathcal{SH}(\psi)$, given by (1.9), is a Parseval frame exhibiting the following properties:

(i) *Time-frequency localization.* Since $\hat{\psi} \in C_0^\infty(\widehat{\mathbb{R}}^2)$, then $|\psi(x)| \leq C_N\,(1+|x|)^{-N}$ for any $N \in \mathbb{N}$, and thus the elements $\psi_{j,\ell,k}$ are well localized.

(ii) *Parabolic scaling.* Each element $\hat{\psi}_{j,\ell,k}$ has support on a pair of trapezoids, each one contained in a box of size approximately $2^{2j} \times 2^j$ (see Figure 1.1(b)). Because the shearlets are well localized, each $\psi_{j,\ell,k}$ is essentially supported on a box of size $2^{-2j} \times 2^{-j}$. Thus, their supports become increasingly thin as $j \to \infty$.

(iii) *Directional sensitivity.* The elements $\hat{\psi}_{j,\ell,k}$ are oriented along lines with slope given by $\ell\, 2^{-j}$. As a consequence, the corresponding elements $\psi_{j,\ell,k}$ are oriented along lines with slope $-\ell\, 2^{-j}$. The number of orientations (approximately) doubles at each finer scale.

(iv) *Spatial localization.* For any fixed scale and orientation, the shearlets are obtained by translations on the lattice $\mathbb{Z}^2$.

(v) *Oscillatory behavior.* The shearlets $\psi_{j,\ell,k}$ are nonoscillatory along the orientation axis of slope $-\ell\, 2^{-j}$, and oscillatory across this axis.

Observe that the curvelets of Candès and Donoho also satisfy similar properties, with the following main differences. Concerning property (iii), the number of orientations in the curvelet constructions doubles at every other scale. Concerning property (iv), the curvelets are not associated with a *fixed* translation lattice. However, for a given scale parameter j and orientation θ, they are obtained by translations on a grid that depends on j and θ. In fact, as we mentioned before, unlike the shearlets, the curvelets are not generated from the action of a family of operators on a single or finite family of functions.

1.3. Main results. One major feature of shearlets is that, if f is a compactly supported function which is C^2 away from a C^2 curve, then the sequence of shearlet coefficients $\{\langle f, \psi_{j,\ell,k}\rangle\}$ has (essentially) optimally fast decay. As a consequence, if f_N^S is the N-term approximation of f obtained from the N largest coefficients of its shearlet expansion, then the approximation error is essentially optimal.

Before stating the main theorems, let us define more precisely the class of functions we are interested in. We follow [7] and introduce $STAR^2(A)$, a class of indicator functions of sets B with C^2 boundaries ∂B. In polar coordinates, let $\rho(\theta) : [0, 2\pi) \to [0, 1]^2$ be a radius function, and define B by $x \in B$ if and only if $|x| \leq \rho(\theta)$. In particular, the boundary ∂B is given by the curve in $\mathbb{R}^2$:

$$\beta(\theta) = \begin{pmatrix} \rho(\theta)\,\cos(\theta) \\ \rho(\theta)\,\sin(\theta) \end{pmatrix}. \tag{1.10}$$

The class of boundaries of interest to us is defined by

$$\sup|\rho''(\theta)| \leq A, \quad \rho \leq \rho_0 < 1. \tag{1.11}$$

We say that a set $B \in STAR^2(A)$ if $B \subset [0, 1]^2$ and B is a translate of a set obeying (1.10) and (1.11). In addition, we set $C_0^2([0, 1]^2)$ to be the collection of twice differentiable functions supported inside $[0, 1]^2$.

Finally, we define the set $\mathcal{E}^2(A)$ of *functions which are* C^2 *away from a* C^2 *edge* as the collection of functions of the form

$$f = f_0 + f_1\,\chi_B,$$

where $f_0, f_1 \in C_0^2([0, 1]^2)$, $B \in STAR^2(A)$, and $\|f\|_{C^2} = \sum_{|\alpha|\leq 2}\|D^\alpha f\|_\infty \leq 1$.

Let M be the set of indices $\{(j, \ell, k) : j \geq 0, -2^j \leq \ell \leq 2^j, k \in \mathbb{Z}^2\}$, and let $\{\psi_\mu\}_{\mu\in M}$ be the Parseval frame of shearlets given by (1.9). The *shearlet coefficients* of a given function f are the elements of the sequence $\{s_\mu(f) = \langle f, \psi_\mu\rangle : \mu \in M\}$. We denote by $|s(f)|_{(N)}$ the Nth largest entry in this sequence. We can now state the following results.

THEOREM 1.1. *Let $f \in \mathcal{E}^2(A)$, and let $\{s_\mu(f) = \langle f, \psi_\mu\rangle : \mu \in M\}$ be the sequence of shearlet coefficients associated with f. Then*

$$\sup_{f\in\mathcal{E}^2(A)} |s(f)|_{(N)} \leq C\,N^{-3/2}\,(\log N)^{3/2}. \tag{1.12}$$

Let f_N^S be the N-term approximation of f obtained from the N largest coefficients of its shearlet expansion, namely,

$$f_N^S = \sum_{\mu\in I_N} \langle f, \psi_\mu\rangle\,\psi_\mu,$$

where $I_N \subset M$ is the set of indices corresponding to the N largest entries of the sequence $\{|\langle f, \psi_\mu\rangle|^2 : \mu \in M\}$. Then the approximation error satisfies

$$\|f - f_N^S\|_2^2 \leq \sum_{m>N} |s(f)|_{(m)}^2.$$

Therefore, from (1.12) we immediately have the following.

THEOREM 1.2. *Let $f \in \mathcal{E}^2(A)$ and f_N^S be the approximation to f defined above. Then*

$$\|f - f_N^S\|_2^2 \le C\, N^{-2}\, (\log N)^3.$$

1.4. Analysis of the shearlet coefficients. The argument that will be used to prove Theorem 1.1 follows essentially the architecture of the proofs in [7]. In order to measure the sparsity of the shearlet coefficients $\{\langle f, \psi_\mu \rangle : \mu \in M\}$, we will use the *weak-$\ell^p$ quasi-norm* $\|\cdot\|_{w\ell^p}$ defined as follows. Let $|s_\mu|_{(N)}$ be the Nth largest entry in the sequence $\{s_\mu\}$. Then

$$\|s_\mu\|_{w\ell^p} = \sup_{N>0} N^{\frac{1}{p}}\, |s_\mu|_{(N)}.$$

One can show (cf. [29, sect. 5.3]) that this definition is equivalent to

$$\|s_\mu\|_{w\ell^p} = \left(\sup_{\epsilon>0} \#\{\mu : |s_\mu| > \epsilon\}\, \epsilon^p \right)^{\frac{1}{p}}.$$

To analyze the decay properties of the shearlet coefficients $\{\langle f, \psi_\mu \rangle\}$ at a given scale 2^{-j}, we will smoothly localize the function f near dyadic squares. Fix the scale parameter $j \ge 0$. For this j fixed, let $M_j = \{(j,\ell,k) : -2^j \le \ell \le 2^j, k \in \mathbb{Z}^2\}$ and $\mathcal{Q}_j$ be the collection of dyadic cubes of the form $Q = [\frac{k_1}{2^j}, \frac{k_1+1}{2^j}] \times [\frac{k_2}{2^j}, \frac{k_2+1}{2^j}]$, with $k_1, k_2 \in \mathbb{Z}$. For w a nonnegative C^∞ function with support in $[-1,1]^2$, we define a smooth partition of unity

$$\sum_{Q \in \mathcal{Q}_j} w_Q(x) = 1, \quad x \in \mathbb{R}^2,$$

where, for each dyadic square $Q \in \mathcal{Q}_j$, $w_Q(x) = w(2^j x_1 - k_1, 2^j x_2 - k_2)$. We will then examine the shearlet coefficients of the localized function $f_Q = f\, w_Q$, i.e., $\{\langle f_Q, \psi_\mu \rangle : \mu \in M_j\}$.

For $f \in \mathcal{E}^2(A)$, the decay properties of the coefficients $\{\langle f_Q, \psi_\mu \rangle : \mu \in M_j\}$ will exhibit a very different behavior depending on whether the edge curve intersects the support of w_Q or not. Let $\mathcal{Q}_j = \mathcal{Q}_j^0 \cup \mathcal{Q}_j^1$, where the union is disjoint and $\mathcal{Q}_j^0$ is the collection of those dyadic cubes $Q \in \mathcal{Q}_j$ such that the edge curve intersects the support of w_Q. Since each Q has sidelength $2 \cdot 2^{-j}$, then $\mathcal{Q}_j^0$ has cardinality $|\mathcal{Q}_j^0| \le C_0\, 2^j$, where C_0 is independent of j. Similarly, since f is compactly supported in $[0,1]^2$, $|\mathcal{Q}_j^1| \le 2^{2j} + 4 \cdot 2^j$.

We have the following results, which will be proved in section 2.

THEOREM 1.3. *Let $f \in \mathcal{E}^2(A)$. For $Q \in \mathcal{Q}_j^0$, with $j \ge 0$ fixed, the sequence of shearlet coefficients $\{\langle f_Q, \psi_\mu \rangle : \mu \in M_j\}$ obeys*

$$\|\langle f_Q, \psi_\mu \rangle\|_{w\ell^{2/3}} \le C\, 2^{-\frac{3j}{2}}$$

for some constant C independent of Q and j.

THEOREM 1.4. *Let $f \in \mathcal{E}^2(A)$. For $Q \in \mathcal{Q}_j^1$, with $j \ge 0$ fixed, the sequence of shearlet coefficients $\{\langle f_Q, \psi_\mu \rangle : \mu \in M_j\}$ obeys*

$$\|\langle f_Q, \psi_\mu \rangle\|_{w\ell^{2/3}} \le C\, 2^{-3j}$$

for some constant C independent of Q and j.

As a consequence of these two theorems, we have the following.

COROLLARY 1.5. *Let $f \in \mathcal{E}^2(A)$ and, for $j \geq 0$, let $s_j(f)$ be the sequence $s_j(f) = \{\langle f, \psi_\mu \rangle : \mu \in M_j\}$. Then*

$$\|s_j(f)\|_{w\ell^{2/3}} \leq C$$

for some C independent of j.

Proof. Using Theorems 1.3 and 1.4, by the p-triangle inequality for weak ℓ^p spaces, $p \leq 1$, we have

$$\begin{aligned} \|s_j(f)\|_{w\ell^{2/3}}^{2/3} &\leq \sum_{Q \in \mathcal{Q}_j} \|\langle f_Q, \psi_\mu \rangle\|_{w\ell^{2/3}}^{2/3} \\ &= \sum_{Q \in \mathcal{Q}_j^0} \|\langle f_Q, \psi_\mu \rangle\|_{w\ell^{2/3}}^{2/3} + \sum_{Q \in \mathcal{Q}_j^1} \|\langle f_Q, \psi_\mu \rangle\|_{w\ell^{2/3}}^{2/3} \\ &\leq C\,|\mathcal{Q}_j^0|\,2^{-j} + C\,|\mathcal{Q}_j^1|\,2^{-2j}. \end{aligned}$$

The proof is completed by observing that $|\mathcal{Q}_j^0| \leq C_0\, 2^j$, where C_0 is independent of j, and $|\mathcal{Q}_j^1| \leq 2^{2j} + 4 \cdot 2^j$. ☐

We can now prove Theorem 1.1.

Proof of Theorem 1.1. By Corollary 1.5, we have that

$$R(j, \epsilon) = \#\{\mu \in M_j : |\langle f, \psi_\mu \rangle| > \epsilon\} \leq C\, \epsilon^{-2/3}. \tag{1.13}$$

Also, observe that, since $\hat{\psi} \in C_0^\infty(\mathbb{R}^2)$, then

$$\begin{aligned} |\langle f, \psi_\mu \rangle| &= \left| \int_{\mathbb{R}^2} f(x)\, 2^{3j/2}\, \psi(B^\ell A^j x - k)\, dx \right| \\ &\leq 2^{3j/2}\, \|f\|_\infty \int_{\mathbb{R}^2} |\psi(B^\ell A^j x - k)|\, dx \\ &= 2^{-3j/2}\, \|f\|_\infty \int_{\mathbb{R}^2} |\psi(y)|\, dy < C'\, 2^{-3j/2}. \end{aligned} \tag{1.14}$$

As a consequence, there is a scale j_ϵ such that $|\langle f, \psi_\mu \rangle| < \epsilon$ for each $j \geq j_\epsilon$. Specifically, it follows from (1.14) that $R(j, \epsilon) = 0$ for $j > \frac{2}{3}\,(\log_2(\epsilon^{-1}) + \log_2(C')) > \frac{2}{3}\, \log_2(\epsilon^{-1})$. Thus, using (1.13), we have that

$$\#\{\mu \in M : |\langle f, \psi_\mu \rangle| > \epsilon\} \leq \sum_{j \geq 0} R(j, \epsilon) \leq C\, \epsilon^{-2/3}\, \log_2(\epsilon^{-1}),$$

and this implies (1.12). ☐

2. Proofs. This section contains the constructions and proofs needed for the theorems in section 1.4.

2.1. Proof of Theorem 1.3. Suppose that a function in $\mathcal{E}^2(A)$ contains a C^2 edge. Following the approach in [7], we suppose that, for $j > j_0$, the scale 2^{-j} is small enough so that over the square $-2^{-j} \leq x_1, x_2 \leq 2^{-j}$ the edge curve may be parametrized as $\binom{E(x_2)}{x_2}$ or $\binom{x_1}{E(x_1)}$. (The case where $j \leq j_0$ is small requires a much simpler analysis and will be discussed in section 2.3.) Without loss of generality, let

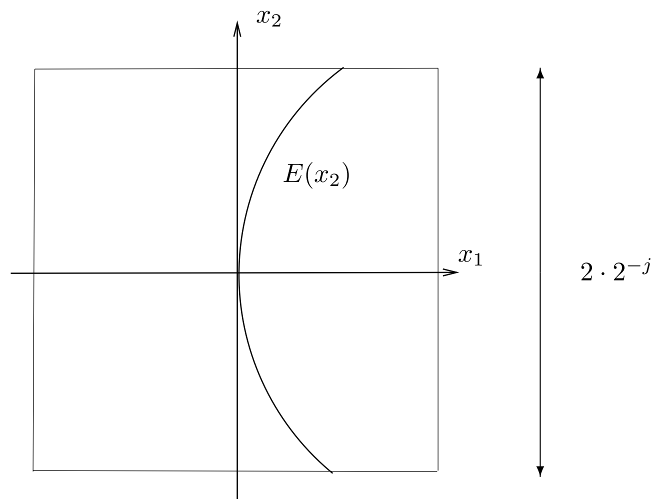

Fig. 2.1. *Representation of an edge fragment.*

us assume that the first parametrization holds. Then an *edge fragment* is a function of the form

$$f(x_1, x_2) = w(2^j x_1, 2^j x_2)\, g(x_1, x_2)\, \chi_{\{x_1 \geq E(x_2)\}},$$

where $g \in C_0^2((0,1)^2)$. For simplicity, let us assume that the edge goes through the origin and, at this point, its tangent is vertical (see Figure 2.1). Then, using the regularity of the edge curve, we have that

(i) $E(0) = 0$, $E'(0) = 0$;

(ii) $\sup_{|x_2| \leq 2^{-j}} |E(x_2)| \leq \frac{1}{2} \sup_{|x_2| \leq 2^{-j}} 2^{-2j} |E''(x_2)|$.

That means that, for $|x_2| \leq 2^{-j}$, the edge curve is almost straight. Observe that any arbitrary edge fragment is obtained by rotating and translating the one above. Since the analysis of the edge fragment that will be presented in the following is not affected by these transformations, there is no loss of generality in considering this case only.

In order to quantify the decay properties of the shearlet coefficients, we first need to analyze the decay of the Fourier transform of the edge fragment along radial lines in the region $\mathcal{D}_C \subset \widehat{\mathbb{R}}^2$, defined in section 1.2. It will be convenient to introduce polar coordinates. Let $\xi = (\xi_1, \xi_2) \in \mathcal{D}_C$. Using polar coordinates, we have

$$\xi_1 = \lambda \cos\theta,\ \xi_2 = \lambda \sin\theta, \quad \text{with } |\theta| \leq \frac{\pi}{4},\ \lambda \in \mathbb{R},\ |\xi_1| \geq \frac{1}{8}.$$

Using this notation, the radial lines have the form $(\lambda\cos\theta, \lambda\sin\theta)$, $\lambda \in \mathbb{R}$, $|\theta| \leq \frac{\pi}{4}$.

For $\xi = (\xi_1, \xi_2) \in \mathcal{D}_C$, $j \geq 0$, $-2^j \leq \ell \leq 2^j$, we introduce the notation

$$\Gamma_{j,\ell}(\xi) = \hat{\psi}_1\big(2^{-2j}\, \xi_1\big)\ \hat{\psi}_2\left(2^j\, \frac{\xi_2}{\xi_1} - \ell\right). \tag{2.1}$$

We have the following claim.

Proposition 2.1. *Let f be an edge fragment and $\Gamma_{j,\ell}$ be given by* (2.1). *Then*

$$\int_{\mathbb{R}^2} |\hat{f}(\xi)|^2\, |\Gamma_{j,\ell}(\xi)|^2\, d\xi \leq C\, 2^{-3j}\, (1 + |\ell|)^{-5}.$$

In order to prove this proposition, we need to recall the following result [7, Thm. 6.1].

THEOREM 2.2. *Let f be an edge fragment and I_j a dyadic interval* $[2^{2j-\alpha}, 2^{2j+\beta}]$ *with* $\alpha \in \{0,1,2,3,4\}$, $\beta \in \{0,1,2\}$. *Then, for all* θ,

$$\int_{|\lambda|\in I_j} |\hat{f}(\lambda\cos\theta, \lambda\sin\theta)|^2 \, d\lambda \le C\, 2^{-3j} \left(1 + 2^j |\sin\theta|\right)^{-5}.$$

Proof of Proposition 2.1. The assumptions on the support of $\hat{\psi}_1$ and $\hat{\psi}_2$ imply that

$$\operatorname{supp} \hat{\psi}_1(2^{-2j}\xi_1) \subset \left\{\xi_1 \in [-2^{2j-1}, -2^{2j-4}] \cup [2^{2j-4}, 2^{2j-1}]\right\} \tag{2.2}$$

and

$$\operatorname{supp} \hat{\psi}_2\left(2^j \frac{\xi_2}{\xi_1} - \ell\right) \subset \left\{(\xi_1, \xi_2) : \left|2^j \frac{\xi_2}{\xi_1} - \ell\right| \le 1\right\}.$$

Since $\tan\theta = \frac{\xi_2}{\xi_1}$, the last expression can be written as

$$\operatorname{supp} \hat{\psi}_2\left(2^j \frac{\xi_2}{\xi_1} - \ell\right) \subset \left\{(\lambda, \theta) :\, 2^{-j}(\ell - 1) \le \tan\theta \le 2^{-j}(\ell + 1)\right\}. \tag{2.3}$$

Since $\lambda^2 = \xi_1^2 + \xi_2^2 = \xi_1^2\,(1 + (\tan\theta)^2)$ and $|\ell| \le 2^j$, then, using (2.2) and (2.3), we have

$$|\lambda| \le 2^{2j-1}\left(1 + 2^{-2j}(1 + |\ell|)^2\right)^{\frac{1}{2}} \le 2^{2j-1}\left(1 + 2^{-2j}(1 + 2^j)^2\right)^{\frac{1}{2}} \le 2^{2j+1}$$

and

$$|\lambda| \ge 2^{2j-4}\left(1 + 2^{-2j}(|\ell| - 1)^2\right)^{\frac{1}{2}} \ge 2^{2j-4}.$$

Thus, the support of $\Gamma_{j,\ell}$ is contained in

$$W_{j,\ell} = \{(\lambda, \theta) :\, 2^{2j-4} \le |\lambda| \le 2^{2j+1},\ \arctan(2^{-j}(\ell - 1)) \le \theta \le \arctan(2^{-j}(\ell + 1))\}.$$

Observe that, in particular, $|\theta| \le \arctan 2$. Since, for $|\theta| \le 2$, we have that[1] $\tan\theta \approx \sin\theta$, it follows from (2.3) that, on $W_{j,\ell}$,

$$2^j\,|\sin\theta| \approx 2^j\,(2^{-j}\,|\ell|) = |\ell|. \tag{2.4}$$

Thus, using (2.4) and Theorem 2.2, we have that

$$\begin{aligned}
\int_{\widehat{\mathbb{R}}^2} |\hat{f}(\xi)|^2\,|\Gamma_{j,\ell}(\xi)|^2\,d\xi &\le C \int_{W_{j,\ell}} |\hat{f}(\lambda\cos\theta, \lambda\sin\theta)|^2\,\lambda\,d\lambda\,d\theta \\
&\le C \int_{\arctan(2^{-j}(\ell-1))}^{\arctan(2^{-j}(\ell+1))} \int_{2^{2j-4}}^{2^{2j+1}} |\hat{f}(\lambda\cos\theta, \lambda\sin\theta)|^2\,|\lambda|\,d\lambda\,d\theta \\
&\le C\,2^{2j+1} \int_{\arctan(2^{-j}(\ell-1))}^{\arctan(2^{-j}(\ell+1))} 2^{-4j}\left(1 + 2^j|\sin\theta|\right)^{-5} d\theta \\
&\le C\,2^{-2j}\,(1 + |\ell|)^{-5}\left(\arctan(2^{-j}(\ell - 1)) - \arctan(2^{-j}(\ell + 1))\right) \\
&= C\,2^{-3j}\,(1 + |\ell|)^{-5}. \qquad \square
\end{aligned}$$

[1] We use the notation $f(x) \approx g(x)$, $x \in D$, to mean that there are constants $C_1, C_2 > 0$ such that $C_1\,g(x) \le f(x) \le C_2\,g(x)$ for all $x \in D$.

The following proposition provides a similar estimate for the partial derivatives of the Fourier transform of the edge fragment.

PROPOSITION 2.3. *Let f be an edge fragment, $\Gamma_{j,\ell}$ be given by* (2.1), *and L be the differential operator*

$$L = \left(I - \left(\frac{2^{2j}}{2\pi\,(1+|\ell|)}\right)^2 \frac{\partial^2}{\partial \xi_1^2}\right) \left(1 - \left(\frac{2^j}{2\pi}\right)^2 \frac{\partial^2}{\partial \xi_2^2}\right).$$

Then

$$\int_{\widehat{\mathbb{R}}^2} \left| L\left(\hat{f}(\xi)\,\Gamma_{j,\ell}(\xi)\right)\right|^2 d\xi \le C\, 2^{-3j}\,(1+|\ell|)^{-5}.$$

In order to prove this proposition, we need to recall the following result [7, Cor. 6.6].

COROLLARY 2.4. *Let f be an edge fragment and I_j a dyadic interval $[2^{2j-\alpha}, 2^{2j+\beta}]$ with $\alpha \in \{0,1,2,3,4\}$, $\beta \in \{0,1,2\}$. Then, for each $m = (m_1, m_2) \in \overline{\mathbb{N}} \times \overline{\mathbb{N}}$ and for each θ,*

$$\begin{aligned}\int_{|\lambda|\in I_j} &\left| \frac{\partial^{m_1}}{\partial \xi_1^{m_1}} \frac{\partial^{m_2}}{\partial \xi_2^{m_2}} \hat{f}(\lambda\cos\theta, \lambda\sin\theta)\right|^2 d\lambda \\ &\le C_m\, 2^{-2j|m|}\left(2^{-(4+2m_1)j}\,(1+2^j|\sin\theta|)^{-5} + 2^{-10j}\right),\end{aligned}$$

where C_m is independent of j and ℓ and $\overline{\mathbb{N}} = \mathbb{N}\cup\{0\}$.

We also need the following lemma, which follows from a direct computation.

LEMMA 2.5. *Let $\Gamma_{j,\ell}$ be given by* (2.1). *Then, for each $m = (m_1, m_2) \in \overline{\mathbb{N}} \times \overline{\mathbb{N}}$, $m_1, m_2 \in \{0,1,2\}$,*

$$\left| \frac{\partial^{m_1}}{\partial \xi_1^{m_1}} \frac{\partial^{m_2}}{\partial \xi_2^{m_2}} \Gamma_{j,\ell}(\xi_1,\xi_2)\right| \le C_m\, 2^{-(2m_1+m_2)j}\,(1+|\ell|)^{m_1},$$

where $|m| = m_1 + m_2$ and C_m is independent of j and ℓ.

We can now prove Proposition 2.3.

Proof of Proposition 2.3. From Corollary 2.4, using (2.4), we have

$$\int_{2^{2j-4}}^{2^{2j+1}} \left| \frac{\partial^2}{\partial \xi_1^2}\hat{f}(\lambda\cos\theta,\lambda\sin\theta)\right|^2 d\lambda \le C\,2^{-4j}\left(2^{-8j}\,(1+|\ell|)^{-5} + 2^{-10j}\right).$$

Thus, using the same idea as in the proof of Proposition 2.1,

$$\begin{aligned}\int_{\widehat{\mathbb{R}}^2} &\left| \left(\frac{\partial^2}{\partial \xi_1^2}\hat{f}(\xi)\right)\,\Gamma_{j,\ell}(\xi)\right|^2 d\xi \\ &\le C \int_{\arctan(2^{-j}(\ell-1))}^{\arctan(2^{-j}(\ell+1))} \int_{2^{2j-4}}^{2^{2j+1}} \left| \frac{\partial^2}{\partial \xi_1^2}\hat{f}(\lambda\cos\theta,\lambda\sin\theta)\right|^2 |\lambda|\,d\lambda\,d\theta \\ &\le C\,2^{-3j}\left(2^{-8j}\,(1+|\ell|)^{-5} + 2^{-10j}\right). \qquad (2.5)\end{aligned}$$

Similarly, using Corollary 2.4 and Lemma 2.5, we have

$$\begin{aligned}
&\int_{\widehat{\mathbb{R}}^2} \left| \left(\frac{\partial}{\partial \xi_1} \hat{f}(\xi) \right) \left(\frac{\partial}{\partial \xi_1} \Gamma_{j,\ell}(\xi) \right) \right|^2 d\xi \\
&\quad \le C\, 2^{-4j} (1+|\ell|)^2 \int_{\arctan(2^{-j}(\ell-1))}^{\arctan(2^{-j}(\ell+1))} \int_{2^{2j-4}}^{2^{2j+1}} \left| \frac{\partial}{\partial \xi_1} \hat{f}(\lambda\cos\theta, \lambda\sin\theta) \right|^2 |\lambda| \, d\lambda \, d\theta \\
&\quad \le C\, 2^{-4j} (1+|\ell|)^2\, 2^{-j} \Big(2^{-6j} (1+|\ell|)^{-5} + 2^{-10j} \Big) \\
&\quad = C\ 2^{-5j} (1+|\ell|)^2 \Big(2^{-6j} (1+|\ell|)^{-5} + 2^{-10j} \Big) \qquad (2.6)
\end{aligned}$$

and

$$\begin{aligned}
&\int_{\widehat{\mathbb{R}}^2} \left| \hat{f}(\xi) \left(\frac{\partial^2}{\partial \xi_1^2} \Gamma_{j,\ell}(\xi) \right) \right|^2 d\xi \\
&\quad \le C\, 2^{-8j} (1+|\ell|)^4 \int_{\arctan(2^{-j}(\ell-1))}^{\arctan(2^{-j}(\ell+1))} \int_{2^{2j-4}}^{2^{2j+1}} \left| \hat{f}(\lambda\cos\theta, \lambda\sin\theta) \right|^2 |\lambda| \, d\lambda \, d\theta \\
&\quad \le C\, 2^{-8j} (1+|\ell|)^4\, 2^{-3j} (1+|\ell|)^{-5} = C\, 2^{-11j} (1+|\ell|)^{-1}. \qquad (2.7)
\end{aligned}$$

Finally, combining (2.5), (2.6), (2.7), and using the fact that $|\ell| \le 2^j$, we have that

$$\int_{\widehat{\mathbb{R}}^2} \left| \left(\frac{2^{2j}}{2\pi(1+|\ell|)} \right)^2 \frac{\partial^2}{\partial \xi_1^2} \Big(\hat{f}(\xi)\, \Gamma_{j,\ell}(\xi) \Big) \right|^2 d\xi \le C\, 2^{-3j} (1+|\ell|)^{-5}. \qquad (2.8)$$

Similarly for the derivatives with respect to ξ_2 we have

$$\int_{\widehat{\mathbb{R}}^2} \left| \left(\frac{\partial^2}{\partial \xi_2^2} \hat{f}(\xi) \right) \Gamma_{j,\ell}(\xi) \right|^2 d\xi \le C\, 2^{-3j} \Big(2^{-4j} (1+|\ell|)^{-5} + 2^{-10j} \Big), \qquad (2.9)$$

$$\int_{\widehat{\mathbb{R}}^2} \left| \left(\frac{\partial}{\partial \xi_2} \hat{f}(\xi) \right) \left(\frac{\partial}{\partial \xi_2} \Gamma_{j,\ell}(\xi) \right) \right|^2 d\xi \le C\, 2^{-3j} \Big(2^{-4j} (1+|\ell|)^{-5} + 2^{-10j} \Big), \qquad (2.10)$$

$$\int_{\widehat{\mathbb{R}}^2} \left| \hat{f}(\xi) \left(\frac{\partial^2}{\partial \xi_2^2} \Gamma_{j,\ell}(\xi) \right) \right|^2 d\xi \le C\, 2^{-7j} (1+|\ell|)^{-5}. \qquad (2.11)$$

Combining (2.9), (2.10), (2.11), and using again the fact that $|\ell| \le 2^j$, we have that

$$\int_{\widehat{\mathbb{R}}^2} \left| \left(\frac{2^j}{2\pi} \right)^2 \frac{\partial^2}{\partial \xi_2^2} \Big(\hat{f}(\xi)\, \Gamma_{j,\ell}(\xi) \Big) \right|^2 d\xi \le C\, 2^{-3j} (1+|\ell|)^{-5}. \qquad (2.12)$$

Similarly, one can show that

$$\int_{\widehat{\mathbb{R}}^2} \left| \frac{2^{3j}}{(1+|\ell|)(2\pi)^2} \frac{\partial^2}{\partial \xi_2^2} \frac{\partial^2}{\partial \xi_1^2} \Big(\hat{f}(\xi)\, \Gamma_{j,\ell}(\xi) \Big) \right|^2 d\xi \le C\, 2^{-3j} (1+|\ell|)^{-5}. \qquad (2.13)$$

The proof is completed using (2.8), (2.12), (2.13), and Lemma 2.5. ∎

We can now prove Theorem 1.3. The following proof adapts some ideas from [7].

Proof of Theorem 1.3. Fix $j \geq 0$ and, for simplicity of notation, let $f = f_Q$. For $\mu \in M_j$, the shearlet coefficient of f is

$$\langle f, \psi_\mu \rangle = \langle f, \psi_{j,\ell,k} \rangle = |\det A|^{-j/2} \int_{\widehat{\mathbb{R}}^2} \hat{f}(\xi)\, \Gamma_{j,\ell}(\xi)\, e^{2\pi i \xi A^{-j} B^{-\ell} k}\, d\xi,$$

where $\Gamma_{j,\ell}(\xi)$ is given by (2.1) and A, B are given by (1.4). Observe that

$$\begin{aligned} 2\pi i \xi A^{-j} B^{-\ell} k &= 2\pi i \begin{pmatrix} \xi_1 & \xi_2 \end{pmatrix} \begin{pmatrix} 2^{-2j} & 0 \\ 0 & 2^{-j} \end{pmatrix} \begin{pmatrix} 1 & -\ell \\ 0 & 1 \end{pmatrix} \begin{pmatrix} k_1 \\ k_2 \end{pmatrix} \\ &= 2\pi i \left((k_1 - k_2 \ell) 2^{-2j} \xi_1 + k_2 2^{-j} \xi_2 \right). \end{aligned} \tag{2.14}$$

Using (2.14), a direct computation shows that

$$\frac{\partial^2}{\partial \xi_1^2} \left(2\pi \xi A^{-j} B^{-\ell} k \right) = -(2\pi)^2 2^{-4j} (k_1 - k_2 \ell)^2 = \begin{cases} -(2\pi)^2\, \ell^2\, 2^{-4j} (\frac{k_1}{\ell} - k_2)^2 & \text{if } \ell \neq 0, \\ -(2\pi)^2\, 2^{-4j} k_1^2 & \text{if } \ell = 0, \end{cases}$$

$$\frac{\partial^2}{\partial \xi_2^2} \left(2\pi \xi A^{-j} B^{-\ell} k \right) = -(2\pi)^2\, 2^{-2j} k_2^2. \tag{2.15}$$

By the equivalent definition of weak ℓ^p norm, the theorem is proved, provided we show that

$$\#\{\mu \in M_j : |\langle f, \psi_\mu \rangle| > \epsilon\} \leq C\, 2^{-j}\, \epsilon^{-\frac{2}{3}}. \tag{2.16}$$

Let L be the second order differential operator defined in Proposition 2.3. Using (2.14) and (2.15), it follows that

$$L\big(e^{2\pi i \xi A^{-j} B^{-\ell} k}\big) = \begin{cases} \left(1 + \left(\frac{\ell}{(1+|\ell|)} \right)^2 \left(\frac{k_1}{\ell} - k_2 \right)^2 \right) (1 + k_2^2)\, e^{2\pi i \xi A^{-j} B^{-\ell} k} & \text{if } \ell \neq 0, \\ (1 + k_1^2)(1 + k_2^2)\, e^{2\pi i \xi A^{-j} B^{-\ell} k} & \text{if } \ell = 0. \end{cases} \tag{2.17}$$

Integration by parts gives

$$\langle f, \psi_\mu \rangle = |\det A|^{-j/2} \int_{\widehat{\mathbb{R}}^2} L \left(\hat{f}(\xi)\, \Gamma_{j,\ell}(\xi) \right)\, L^{-1} \left(e^{2\pi i \xi A^{-j} B^{-\ell} k} \right)\, d\xi.$$

Let us consider first the case $\ell \neq 0$. In this case, from (2.17) we have that

$$L^{-1}\big(e^{2\pi i \xi A^{-j} B^{-\ell} k}\big) = G(k, \ell)^{-1}\, e^{2\pi i \xi A^{-j} B^{-\ell} k}, \tag{2.18}$$

where $G(k, \ell) = \big(1 + \big(\frac{\ell}{(1+|\ell|)}\big)^2 \big(\frac{k_1}{\ell} - k_2\big)^2\big)(1 + k_2^2)$. Thus

$$\langle f, \psi_\mu \rangle = |\det A|^{-j/2}\, G(k, \ell)^{-1} \int_{\widehat{\mathbb{R}}^2} L \left(\hat{f}(\xi)\, \Gamma_{j,\ell}(\xi) \right)\, e^{2\pi i \xi A^{-j} B^{-\ell} k}\, d\xi,$$

or, equivalently,

$$G(k, \ell)\, \langle f, \psi_\mu \rangle = |\det A|^{-j/2} \int_{\widehat{\mathbb{R}}^2} L \left(\hat{f}(\xi)\, \Gamma_{j,\ell}(\xi) \right)\, e^{2\pi i \xi A^{-j} B^{-\ell} k}\, d\xi.$$

Let $K = (K_1, K_2) \in \mathbb{Z}^2$, and define $R_K = \{k = (k_1, k_2) \in \mathbb{Z}^2 : \frac{k_1}{\ell} \in [K_1, K_1 + 1],\ k_2 = K_2\}$. Since, for j, ℓ fixed, the set $\{|\det A|^{-j/2}\, e^{2\pi i \xi A^{-j} B^{-\ell} k} : k \in \mathbb{Z}^2\}$ is an orthonormal basis for the L^2 functions on $[-\frac{1}{2}, \frac{1}{2}]A^j B^\ell$, and the function $\Gamma_{j,\ell}(\xi)$ is supported on this set, then

$$\sum_{k \in R_K} |\langle G(k,\ell)\, f, \psi_\mu \rangle|^2 \le \int_{\widehat{\mathbb{R}}^2} \left| L\left(\hat{f}(\xi)\, \Gamma_{j,\ell}(\xi)\right)\right|^2 \, d\xi.$$

From the definition of R_K it follows that

$$\sum_{k \in R_K} |\langle f, \psi_\mu \rangle|^2 \le C\, \left(1 + (K_1 - K_2)^2\right)^{-2} (1 + K_2)^{-2} \int_{\widehat{\mathbb{R}}^2} \left| L\left(\hat{f}(\xi)\, \Gamma_{j,\ell}(\xi)\right)\right|^2 \, d\xi.$$

By Proposition 2.3,

$$\sum_{k \in R_K} |\langle f, \psi_\mu \rangle|^2 \le C\, L_K^{-2}\, 2^{-3j} (1 + |\ell|)^{-5}, \tag{2.19}$$

where $L_K = (1 + (K_1 - K_2)^2)(1 + K_2^2)$. For j, ℓ fixed, let $N_{j,\ell,K}(\epsilon) = \#\{k \in R_K : |\psi_{j,\ell,k}| > \epsilon\}$. Then it is clear that $N_{j,\ell,K}(\epsilon) \le C\,(|\ell| + 1)$, and (2.19) implies that

$$N_{j,\ell,K}(\epsilon) \le C\, L_K^{-2}\, 2^{-3j}\, \epsilon^{-2} (1 + |\ell|)^{-5}.$$

Thus

$$N_{j,\ell,K}(\epsilon) \le C\, \min\left(|\ell| + 1, L_K^{-2}\, 2^{-3j}\, \epsilon^{-2} (1 + |\ell|)^{-5}\right). \tag{2.20}$$

Using (2.20), we will now show that

$$\sum_{\ell = -2^j}^{2^j} N_{j,\ell,K}(\epsilon) \le C\, L_K^{-\frac{2}{3}}\, 2^{-j}\, \epsilon^{-\frac{2}{3}}. \tag{2.21}$$

In fact, let ℓ^* be defined by $(\ell^* + 1) = L_K^{-2}\, 2^{-3j}\, \epsilon^{-2} (1 + \ell^*)^{-5}$. That is, $\ell^* + 1 = L_K^{-1/3}\, 2^{-j/2}\, \epsilon^{-1/3}$. Then

$$\begin{aligned}
\sum_{\ell = -2^j}^{2^j} N_{j,\ell,K}(\epsilon) &\le \sum_{|\ell| \le (\ell^* + 1)} N_{j,\ell,K}(\epsilon) + \sum_{|\ell| > (\ell^* + 1)} N_{j,\ell,K}(\epsilon) \\
&\le \sum_{|\ell| \le (\ell^* + 1)} (|\ell| + 1) + \sum_{|\ell| > (\ell^* + 1)} L_K^{-2}\, 2^{-3j}\, \epsilon^{-2} (1 + |\ell|)^{-5} \\
&\le (\ell^* + 1)^2 + C\, L_K^{-2}\, 2^{-3j}\, \epsilon^{-2} (1 + \ell^*)^{-4} \le C\, (\ell^* + 1)^2,
\end{aligned}$$

which gives (2.21).

Since $\sum_{K \in \mathbb{Z}^2} L_K^{-2/3} < \infty$, using (2.21) we then have that

$$\#\{\mu \in M_j : |\langle f, \psi_\mu \rangle| > \epsilon\} \le \sum_{K \in \mathbb{Z}^2} \sum_{\ell = -2^j}^{2^j} N_{j,\ell,K}(\epsilon) \le C\, 2^{-j}\, \epsilon^{-\frac{2}{3}} \sum_{K \in \mathbb{Z}^2} L_K^{-\frac{2}{3}} \le C\, 2^{-j}\, \epsilon^{-\frac{2}{3}},$$

and, thus (2.16) holds.

The case $\ell = 0$ is similar. Indeed, in this case

$$L^{-1}\left(e^{2\pi i \xi A^{-j} B^{-\ell} k}\right) = (1 + k_1^2)^{-1} (1 + k_2^2)^{-1}\, e^{2\pi i \xi A^{-j} B^{-\ell} k},$$

and we can proceed as in the case $\ell \neq 0$, with $L_K = (1 + K_1^2)\,(1 + K_2^2)$. It is clear that also in this case $\sum_{K \in \mathbb{Z}^2} L_K^{-2/3} < \infty$. This completes the proof of the theorem. □

2.2. Proof of Theorem 1.4. In order to prove Theorem 1.4, the following lemmata will be useful.

LEMMA 2.6. *Let $f = g\, w_Q$, where $g \in \mathcal{E}^2(A)$ and $Q \in \mathcal{Q}_j^1$. Then*

$$\int_{W_{j,\ell}} |\hat{f}(\xi)|^2 \, d\xi \le C\, 2^{-10j}. \tag{2.22}$$

Proof. The proof follows [7, Lem. 8.1] and is reported here for completeness.

The function f belongs to $C_0^2(\mathbb{R}^2)$, and its second partial derivative with respect to x_1 is

$$\frac{\partial^2 f}{\partial x_1^2} = \frac{\partial^2 g}{\partial x_1^2}\, w_Q + 2\, \frac{\partial\, g}{\partial x_1}\, \frac{\partial\, w_Q}{\partial x_1} + f\, \frac{\partial^2 w_Q}{\partial x_1^2} = h_1 + h_2 + h_3.$$

Using the fact that w_Q is supported in a square of sidelength $2 \cdot 2^{-j}$, we have

$$\int_{\widehat{\mathbb{R}}^2} |\hat{h}_1(\xi)|^2 \, d\xi = \int_{\mathbb{R}^2} |h_1(x)|^2 \; dx \le C\, 2^{-2j}.$$

Next, observe that $\|\frac{\partial}{\partial x_1} h_2\|_\infty \le C\, 2^{2j}$. Using again the condition on the support of w_Q, it follows that

$$\int_{\widehat{\mathbb{R}}^2} |2\pi\xi_1\, \hat{h}_2(\xi)|^2 \, d\xi = \int_{\mathbb{R}^2} \left| \frac{\partial}{\partial x_1} h_2(x) \right|^2 \; dx \le C\, 2^{2j},$$

and thus, for $\xi \in W_{j,\ell}$ (hence $\xi_1 \approx 2^{2j}$),

$$\int_{W_{j,\ell}} |\hat{h}_2(\xi)|^2 \, d\xi \le C\, 2^{-2j}.$$

Finally, observing that $\|\frac{\partial^2}{\partial x_1^2} h_3\|_\infty \le C\, 2^{4j}$, a computation similar to the one above shows that

$$\int_{W_{j,\ell}} |\hat{h}_3(\xi)|^2 \, d\xi \le C\, 2^{-2j}.$$

Since $-(2\pi)^2\, \xi_1^2\, \hat{f}(\xi) = \hat{h}_1(\xi) + \hat{h}_2(\xi) + \hat{h}_3(\xi)$, it follows from the estimates above that

$$\int_{W_{j,\ell}} |\hat{f}(\xi)|^2 \, d\xi \le C\, 2^{-10j}.$$

This completes the proof. □

LEMMA 2.7. *Let $m = (m_1, m_2) \in \overline{\mathbb{N}} \times \overline{\mathbb{N}}$, $\xi = (\xi_1, \xi_2) \in \widehat{\mathbb{R}}^2$, and $\Gamma_{j,\ell}$ be given by (2.1). Then*

$$\sum_{\ell=-2^j}^{2^j} \left| \frac{\partial^{m_1}}{\partial \xi_1^{m_1}}\, \frac{\partial^{m_2}}{\partial \xi_2^{m_2}}\, \Gamma_{j,\ell}(\xi) \right|^2 \le C_m\, 2^{-2|m|j},$$

where C_m is independent of j and ξ and $|m| = m_1 + m_2$.

Proof. Observe that $W_{j,\ell} \cap W_{j,\ell+\ell'} = \emptyset$ whenever $|\ell'| \ge 3$. Since $|\ell| \le 2^j$, the lemma then follows from Lemma 2.5. □

LEMMA 2.8. *Let $f = g\, w_Q$, where $g \in \mathcal{E}^2(A)$ and $Q \in \mathcal{Q}_j^1$. Define*

$$T = \left(I - \frac{2^j}{(2\pi)^2}\,\Delta\right), \tag{2.23}$$

where $\Delta = \frac{\partial^2}{\partial \xi_1^2} + \frac{\partial^2}{\partial \xi_2^2}$. Then

$$\int_{\widehat{\mathbb{R}}^2} \sum_{\ell=-2^j}^{2^j} \left| T^2 \left(\hat f\, \Gamma_{j,\ell}\right)(\xi)\right|^2 d\xi \le C\, 2^{-10j}.$$

Proof. Observe that, for $N \in \overline{\mathbb{N}}$,

$$\Delta^N \left(\hat f\, \Gamma_{j,\ell}\right) = \sum_{|\alpha|+|\beta|=2N} C_{\alpha,\beta} \left(\frac{\partial^{\alpha_1}}{\partial \xi_1^{\alpha_1}}\, \frac{\partial^{\alpha_2}}{\partial \xi_2^{\alpha_2}}\, \hat f\right) \left(\frac{\partial^{\beta_1}}{\partial \xi_1^{\beta_1}}\, \frac{\partial^{\beta_2}}{\partial \xi_2^{\beta_2}}\, \Gamma_{j,\ell}\right).$$

Then, using Lemma 2.7, we have that

$$\begin{aligned}\int_{\widehat{\mathbb{R}}^2} \sum_{\ell=-2^j}^{2^j} &\left|\frac{\partial^{\alpha_1}}{\partial \xi_1^{\alpha_1}}\, \frac{\partial^{\alpha_2}}{\partial \xi_2^{\alpha_2}}\, \hat f(\xi)\right|^2 \left|\frac{\partial^{\beta_1}}{\partial \xi_1^{\beta_1}}\, \frac{\partial^{\beta_2}}{\partial \xi_2^{\beta_2}}\, \Gamma_{j,\ell}(\xi)\right|^2 d\xi \\ &\le C_\beta\, 2^{-2|\beta| j} \int_{W_{j,\ell}} \left|\frac{\partial^{\alpha_1}}{\partial \xi_1^{\alpha_1}}\, \frac{\partial^{\alpha_2}}{\partial \xi_2^{\alpha_2}}\, \hat f(\xi)\right|^2 d\xi.\end{aligned}$$

Recall that $f(x)$ is of the form $g(x)\, w(2^j x)$. It follows that $x^\alpha f(x) = 2^{-j|\alpha|}\, g(x)\, w_\alpha(2^j x)$, where $w_\alpha(x) = x^\alpha w(x)$. By Lemma 2.6, $g(x)\, w_\alpha(2^j x)$ obeys the estimate (2.22). Thus, observing that $\frac{\partial^{\alpha_1}}{\partial \xi_1^{\alpha_1}}\, \frac{\partial^{\alpha_2}}{\partial \xi_2^{\alpha_2}}\, \hat f(\xi)$ is the Fourier transform of $(-2\pi i x)^\alpha f(x)$, we have that

$$\int_{W_{j,\ell}} \left|\frac{\partial^{\alpha_1}}{\partial \xi_1^{\alpha_1}}\, \frac{\partial^{\alpha_2}}{\partial \xi_2^{\alpha_2}}\, \hat f(\xi)\right|^2 d\xi \le C_\alpha\, 2^{-2j|\alpha|}\, 2^{-10j}.$$

Combining the estimates above, we have that, for each α, β with $|\alpha| + |\beta| = 2N$,

$$\int_{\widehat{\mathbb{R}}^2} \sum_{\ell=-2^j}^{2^j} \left|\frac{\partial^{\alpha_1}}{\partial \xi_1^{\alpha_1}}\, \frac{\partial^{\alpha_2}}{\partial \xi_2^{\alpha_2}}\, \hat f(\xi)\right|^2 \left|\frac{\partial^{\beta_1}}{\partial \xi_1^{\beta_1}}\, \frac{\partial^{\beta_2}}{\partial \xi_2^{\beta_2}}\, \Gamma_{j,\ell}(\xi)\right|^2 d\xi \le C_{\alpha,\beta}\, 2^{-10j}\, 2^{-4jN}. \tag{2.24}$$

Since $T^2 = 1 - 2\,\frac{2^j}{(2\pi)^2}\,\Delta + \frac{2^{2j}}{(2\pi)^4}\,\Delta^2$, the lemma now follows from (2.24) and Lemma 2.7. $\square$

We can now prove Theorem 1.4.

Proof of Theorem 1.4. Using (2.15), for T given by (2.23), we have that

$$T\left(e^{2\pi i \xi A^{-j} B^{-\ell} k}\right) = \left(1 + 2^{-2j}(k_1 - k_2\,\ell)^2 + k_2^2\right)\, e^{2\pi i \xi A^{-j} B^{-\ell} k}. \tag{2.25}$$

Fix $j \ge 0$ and let $f = f_Q$. Then, using integration by parts as in the proof of Theorem 1.3, from (2.25) it follows that

$$\langle f, \psi_\mu\rangle = |\det A|^{-j} \left(1 + 2^{-2j}(k_1 - k_2\,\ell)^2 + k_2^2\right)^{-2} \int_{\widehat{\mathbb{R}}^2} T^2 \left(\hat f\, \Gamma_{j,\ell}\right)(\xi)\, e^{2\pi i \xi A^{-j} B^{-\ell} k}\, d\xi.$$

Let $K = (K_1, K_2) \in \mathbb{Z}^2$ and R_K be the set $\{(k_1, k_2) \in \mathbb{Z}^2 : k_2 = K_2, 2^{-j}(k_1 - K_2\ell) \in [K_1, K_1 + 1]\}$. Observing that, for each K, there are only $1 + 2^j$ choices for k_1 in R_K, it follows that the number of terms in R_K is bounded by $1 + 2^j$. Thus, arguing again as in the proof of Theorem 1.3, we have that

$$\sum_{k \in R_K} |\langle f, \psi_\mu \rangle|^2 \le C \, \left(1 + K_1^2 + K_2^2\right)^{-4} \int_{\widehat{\mathbb{R}}^2} \left| T^2 \left(\hat{f} \, \Gamma_{j,\ell} \right)(\xi) \right|^2 \, d\xi.$$

From this inequality, using Lemma 2.8, we have that

$$\begin{aligned} \sum_{\ell=-2^j}^{2^j} \sum_{k \in R_K} |\langle f, \psi_\mu \rangle|^2 &\le C \, (1 + K^2)^{-4} \int_{\widehat{\mathbb{R}}^2} \sum_{\ell=-2^j}^{2^j} \left| T^2 \left(\hat{f} \, \Gamma_{j,\ell} \right)(\xi) \right|^2 \, d\xi \\ &\le C \, (1 + K^2)^{-4} \, 2^{-10j}. \end{aligned} \tag{2.26}$$

For any $N \in \mathbb{N}$, provided $\frac{1}{2} < p < 2$, the Hölder inequality yields

$$\sum_{m=1}^{N} |a_m|^p \le \left(\sum_{m=1}^{N} |a_m|^2 \right)^{\frac{p}{2}} \, N^{\left(1 - \frac{p}{2}\right)}. \tag{2.27}$$

Since the cardinality of R_K is bounded by $1 + 2^j$, it follows from (2.26) and (2.27) that, for $\frac{1}{2} < p < 2$,

$$\sum_{\ell=-2^j}^{2^j} \sum_{k \in R_K} |\langle f, \psi_\mu \rangle|^p \le C \, \left(2^{2j}\right)^{(1 - \frac{p}{2})} \, (1 + K^2)^{-2p} \, 2^{-5pj}.$$

Thus, since $p > \frac{1}{2}$,

$$\sum_{\mu \in M_j} |\langle f, \psi_\mu \rangle|^p \le C \, 2^{\left(2j(1 - \frac{p}{2}) - 5pj\right)} \sum_{K \in \mathbb{Z}^2} (1 + K^2)^{-2p} \le C \, 2^{(2-3p)j},$$

and, in particular,

$$\|\langle f, \psi_\mu \rangle\|_{\ell^{2/3}} \le C \, 2^{-3j}. \qquad \square$$

2.3. Coarse scale analysis. In section 2.1, we assumed that the scale parameter j was large enough. The situation where j is small can be treated in a much simpler way. In fact, if f_Q is an edge fragment, then a trivial estimate shows that

$$\|f_Q\|_2 = \left(\int_{\operatorname{supp} w_Q} |f_Q(x)|^2 \, dx \right)^{1/2} \le C \, |\operatorname{supp} w_Q| = C \, 2^{-j}.$$

It follows that $\|\langle f_Q, \psi_\mu \rangle\|_{\ell^2} \le C \, 2^{-j}$, and thus, by the Hölder inequality,

$$\|\langle f_Q, \psi_\mu \rangle\|_{\ell^{2/3}} \le C \, 2^{j}.$$

This satisfies Theorem 1.3 for j small.

2.4. Additional remarks.

- In order to define the collection of shearlets, in section 1.2 we have constructed a function $\hat{\psi} \in C_0^\infty$. This property allows us to obtain a collection of elements that are well localized. Observe, however, that we need only $\hat{\psi} \in C_0^2$ in order to prove all the results presented in this paper.
- In this paper, we have considered the representation of functions containing a discontinuity along a C^2 curve. More generally, we can consider the situation where a function f contains many edge curves of this type, exhibiting finitely many junctions or corners between them. In this setting, the discontinuity curve is not globally C^2 but only piecewise C^2. The results reported in this paper, namely Theorems 1.1 and 1.2, extend to this setting as well. We refer to [7] for a similar discussion in the case of curvelets.
- The assumption we made about the regularity of the discontinuity curve plays a critical role in our construction. If the discontinuity curve is in C^α, with $\alpha > 2$, then our argument still works and we can still prove Theorem 1.2. This result, however, is not (essentially) optimal as in the case $\alpha = 2$. On the other hand, if the discontinuity curve is in C^α, with $\alpha < 2$, then the estimate given by Theorem 1.2 does not hold, and the estimate could be worse in general. We refer to [24] for additional observations about this fact, and for an alternative approach, based on an adaptive construction, to the sparse representation of functions with edges.
- There are natural ways of extending the shearlets to dimensions larger than 2. We refer to [18] for a discussion of these extensions, as well as the extensions of the shear transformations to the general multidimensional setting. For example, in dimension 3, let $A = \left(\begin{smallmatrix} 4 & 0 \\ 0 & 2\,I_2 \end{smallmatrix}\right)$; define the shear matrices $\{S_k = \left(\begin{smallmatrix} 1 & k \\ 0 & I_2 \end{smallmatrix}\right) : k \in \mathbb{Z}^2\}$, where I_2 is the 2×2 identity matrix, $0 = \left(\begin{smallmatrix} 0 \\ 0 \end{smallmatrix}\right)$; and, for $\xi = (\xi_1, \xi_2, \xi_3) \in \mathbb{R}^3$, define ψ by

$$\hat{\psi}(\xi) = \hat{\psi}_1(\xi_1)\, \hat{\psi}_2\left(\frac{\xi_2}{\xi_1}\right)\, \hat{\psi}_2\left(\frac{\xi_3}{\xi_1}\right),$$

where ψ_1 and ψ_2 are given as in the 2-D case. Then, similarly to their 2-D counterpart, one can construct a Parseval frame of well-localized 3-D shearlets

$$\{\psi_{j,\ell,k} = |\det A|^{-j/2}\, \psi(S_\ell\, A^{-j} x - k) : \, j \in \mathbb{Z}, \ell \in \mathbb{Z}^2, k \in \mathbb{Z}^2\},$$

with frequency support on a parallelepiped of approximate size $2^{2j} \times 2^j \times 2^j$, at various scales j, with orientations controlled by the 2-D index ℓ and spatial location k. Then, using a heuristic argument, one can argue that these systems provide sparse representations for 3-D functions f that are smooth away from "nice" surface discontinuities of finite area. In fact, thanks to their frequency support and their localization properties, the elements $\psi_{j,\ell,k}$, at scale j, are essentially supported on a parallelepiped of size $2^{-2j} \times 2^{-j} \times 2^{-j}$, with location controlled by k and orientation controlled by ℓ. Thus, there are at most $O(2^{2j})$ significant shearlet coefficients $\mathcal{SH}_{j,\ell,k}(f) = \langle f, \psi_{j,\ell,k} \rangle$, and they are bounded by $C\, 2^{-2j}$. This implies that the Nth largest 3-D shearlet coefficient $|\mathcal{SH}_N(f)|$ is bounded by $O(N^{-1})$, and thus, if f is approximated by taking the N largest coefficients in the 3-D shearlets expansion, the L^2-error would approximately obey

$$\|f - f_N^S\|_{L^2}^2 \le \sum_{\ell > N} |\mathcal{SH}_\ell(f)|^2 \le C\, N^{-1},$$

up to lower order factors. A rigorous proof of this fact will be presented elsewhere.

Appendix. Construction of $\boldsymbol{\psi_1, \psi_2}$. In this section we show how to construct examples of functions ψ_1, ψ_2 satisfying the properties described in section 1.2.

In order to construct ψ_1, let $h(t)$ be an even C_0^∞ function, with support in $(-\frac{1}{6}, \frac{1}{6})$, satisfying $\int_{\mathbb{R}} h(t)\,dt = \frac{\pi}{2}$, and define $\theta(\omega) = \int_{-\infty}^{\omega} h(t)\,dt$. Then one can construct a smooth bell function as

$$b(\omega) = \begin{cases} \sin\left(\theta\left(|\omega| - \frac{1}{2}\right)\right) & \text{if } \frac{1}{3} \le |\omega| \le \frac{2}{3}, \\ \sin\left(\frac{\pi}{2} - \theta\left(\frac{|\omega|}{2} - \frac{1}{2}\right)\right) & \text{if } \frac{2}{3} < |\omega| \le \frac{4}{3}, \\ 0 & \text{otherwise.} \end{cases}$$

It follows from our assumptions (cf. [20, sect. 1.4]) that

$$\sum_{j=-1}^{\infty} b^2(2^{-j}\omega) = 1 \quad \text{for } |\omega| \ge \frac{1}{3}.$$

Now letting $u^2(\omega) = b^2(2\omega) + b^2(\omega)$, it follows that

$$\sum_{j\ge 0}^{\infty} u^2(2^{-2j}\omega) = \sum_{j=-1}^{\infty} b^2(2^{-j}\omega) = 1 \quad \text{for } |\omega| \ge \frac{1}{3}.$$

Finally, let ψ_1 be defined by $\hat{\psi}_1(\omega) = u(\frac{8}{3}\omega)$. Then $\operatorname{supp}\hat{\psi}_1 \subset [-\frac{1}{2}, -\frac{1}{16}] \cup [\frac{1}{16}, \frac{1}{2}]$, and (1.6) is satisfied. This construction is illustrated in Figure A.1(a).

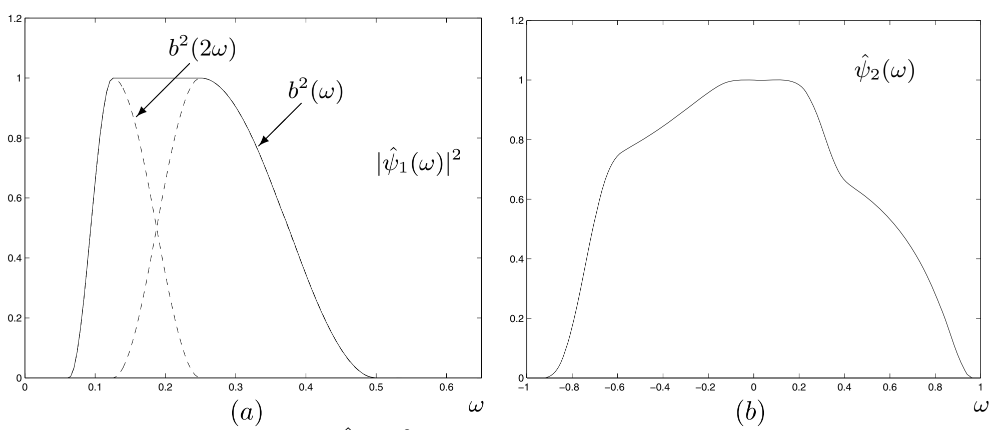

FIG. A.1. (a) *The function* $|\hat{\psi}_1(\omega)|^2$ *(solid line), for* $\omega > 0$*; the negative side is symmetrical. This function is obtained, after rescaling, from the sum of the window functions* $b^2(\omega) + b^2(2\omega)$ *(dashed lines).* (b) *The function* $\hat{\psi}_2(\omega)$.

For the construction of ψ_2, we start by considering a smooth bump function $f_1 \in C_0^\infty(-1,\ 1)$ such that $0 \le f_1 \le 1$ on $(-1, 1)$ and $f_1 = 1$ on $[-\frac{1}{2}, \frac{1}{2}]$ (cf. [21, sect. 1.4]). Next, let $f_2(t) = \sqrt{1 - \exp(1/t)}$. Then (in the left limit sense) $f_2(0) = 1$, $f_2^{(k)}(0) = 0$ for $k \ge 1$ and $0 < f_2 < 1$ on $(-1, 0)$. Define $f(t) = f_1(t) f_2(t)$ for $t \in [-1, 0]$. It is then easy to see that $f^{(k)}(-1) = 0$ for $k \ge 0$, and $f(0) = 1$, $f^{(k)}(0) = 0$ for $k \ge 1$.

Since $g(t) = \exp\left(\frac{1}{2(t-1)}\right)$ for $t \in (\frac{1}{2}, 1)$, it follows that $\lim_{t\to 1-} g^{(k)}(t) = 0$ for $k \geq 0$. Finally, we define

$$\hat{\psi}_2(\omega) = \begin{cases} f(\omega) & \text{if } \omega \in [-1, 0), \\ g(\omega) & \text{if } \omega \in [0, 1], \\ 0 & \text{otherwise.} \end{cases}$$

Then $\hat{\psi}_2 \in C_0^\infty(\mathbb{R})$, with $\operatorname{supp} \hat{\psi}_2 \subset [-1, 1]$, and

$$\hat{\psi_2}^2(\omega) + \hat{\psi_2}^2(\omega - 1) = 1, \quad \omega \in [0, 1].$$

The last equality implies (1.7). The function $\hat{\psi}_2$ is illustrated in Figure A.1(b).

TRAVELING FRONTS OF PYRAMIDAL SHAPES IN THE ALLEN–CAHN EQUATIONS*

MASAHARU TANIGUCHI†

Abstract. This paper studies pyramidal traveling fronts in the Allen–Cahn equation or in the Nagumo equation. For the nonlinearity we are concerned mainly with the bistable reaction term with unbalanced energy density. Two-dimensional V-form waves and cylindrically symmetric waves in higher dimensions have been recently studied. Our aim in this paper is to construct truly three-dimensional traveling waves. For a pyramid that satisfies a condition, we construct a traveling front for which the contour line has a pyramidal shape. We also construct generalized pyramidal fronts and traveling waves of a hybrid type between pyramidal waves and planar V-form waves. We use the comparison principles and construct traveling fronts between supersolutions and subsolutions.

Key words. pyramidal traveling wave, Allen–Cahn equation, bistable

AMS subject classification. 35K57

DOI. 10.1137/060661788

1. Introduction.

In this paper we consider the following equation:

$$\frac{\partial u}{\partial t} = \Delta u + f(u) \quad \text{in } \mathbb{R}^3, \quad t > 0,$$
$$u\big|_{t=0} = u_0 \quad \text{in } \mathbb{R}^3.$$

Here a given function u_0 is bounded and of class C^1. The Laplacian Δ stands for $\partial^2/\partial x^2 + \partial^2/\partial y^2 + \partial^2/\partial z^2$. If the nonlinearity f is cubic, it is called the Allen–Cahn equation or the Nagumo equation. We study general nonlinear terms of a bistable type including cubic ones.

In the one-dimensional space, let $\Phi(x - kt)$ be a traveling wave that connects two stable equilibrium states ± 1 with speed k. By putting $\mu = x - kt$, Φ satisfies

$$(1) \qquad \begin{gathered} -\Phi''(\mu) - k\Phi'(\mu) - f(\Phi(\mu)) = 0 \quad -\infty < \mu < \infty, \\ \Phi(-\infty) = 1, \quad \Phi(\infty) = -1. \end{gathered}$$

To fix the phase we set $\Phi(0) = 0$. Such one-dimensional traveling waves have been studied in many works. See Fife and McLeod [5], Aronson and Weinberger [1], Kanel' [10, 11], Chen [2], and Terman [18], for instance. We state equations for the unbalanced nonlinearity and the balanced one.

The unbalanced case is as follows. The following are the assumptions on f in this paper:

(A1) f is of class $C^1[-1, 1]$, with $f(\pm 1) = 0$ and $f'(\pm 1) < 0$.
(A2) $\int_{-1}^{1} f > 0$ holds true.
(A3) There exists $\Phi(\mu)$ that satisfies (1) for some $k \in \mathbb{R}$.

The assumption (A1) implies that f is bistable and that (A2) means that it is unbalanced. Note that (A2) implies $k > 0$. Under (A1), $(k, \Phi(\mu))$ is uniquely

determined if it exists. For the proof of this uniqueness, see [5] or [2]. We show simple examples for f here.

Example 1. If f satisfies $f'(\beta) > 0$ and

$$\begin{aligned} f(s) > 0 \quad &\text{for } \beta < s < 1, \\ f(s) < 0 \quad &\text{for } -1 < s < \beta, \end{aligned}$$

with some $\beta \in (-1, 1)$ in addition to (A1), then it is well known that (A3) is valid. See [5] or [2]. Especially, $f(u) = -(u+1)(u+a)(u-1)$ has a one-dimensional traveling wave $\Phi(\mu) = -\tanh(\mu/\sqrt{2})$ with speed $k = \sqrt{2}a$ for every $a \in [0, 1)$. This traveling wave is sometimes called the Huxley solution. See Nagumo, Yoshizawa, and Arimoto [14].

Example 2 (Fife and McLeod [5, Theorem 2.7]). Assume f satisfies (A1) and (A2). For $-1 < \lambda < 1$ assume that there exists (c_L, Φ_L) to

$$\begin{gathered} -\Phi_L''(\mu) - k\Phi_L'(\mu) - f(\Phi_L(\mu)) = 0 \quad -\infty < \mu < \infty, \\ \Phi_L(-\infty) = 1, \quad \Phi_L(\infty) = \lambda, \end{gathered}$$

and there exists (c_R, Φ_R) to

$$\begin{gathered} -\Phi_R''(\mu) - k\Phi_R'(\mu) - f(\Phi_R(\mu)) = 0 \quad -\infty < \mu < \infty, \\ \Phi_R(-\infty) = \lambda, \quad \Phi_R(\infty) = -1. \end{gathered}$$

If $c_L > c_R$, then (A3) holds true. If $c_L \le c_R$, there exists no solution to (1).

Example 3. For G with (B1) and (B2) below, we define

$$f(u) = -G'(u) + k\sqrt{2G(u)}$$

for $k > 0$. Then $\Phi_0(\mu)$ given by (3) is a solution to (1) for $k > 0$. If k is small enough, $f(u)$ satisfies (A1), (A2), and (A3).

We note that (A1) and (A2) do not always imply (A3), because we can construct such f with $c_L \le c_R$ in Example 2. If it exists, it is always monotone in μ as in Lemma 1. See [5, Lemma 2.1] for the proof of the monotony of one-dimensional fronts. We use this monotony and the comparison principles in this paper.

The balanced case is as follows:

$$\begin{aligned} \frac{\partial u}{\partial t} &= \Delta u - G'(u) \quad \text{in } \mathbb{R}^3, \quad t > 0, \\ u|_{t=0} &= u_0 \quad \text{in } \mathbb{R}^3. \end{aligned} \tag{2}$$

The assumptions on G are as follows:

(B1) G is of class $C^2[-1, 1]$, with $G'(\pm 1) = 0$, $G''(\pm 1) > 0$.

(B2) $G(1) = 0$ and $G(s) > 0$ for $-1 < s < 1$.

Under (B1) and (B2), (2) has a standing wave solution $\Phi_0(x)$ to

$$\begin{gathered} -\Phi_0''(\mu) + G'(\Phi_0(x)) = 0 \quad -\infty < \mu < \infty, \\ \Phi_0(-\infty) = 1, \quad \Phi_0(\infty) = -1. \end{gathered}$$

Φ_0 is given by

$$x = -\int_0^{\Phi_0} \frac{dv}{\sqrt{2G(v)}}. \tag{3}$$

The condition $G(1) = 0$ means that a potential density term G has minimizers with an equal depth. If G takes a negative value or zero in $(-1, 1)$, there exists no standing wave. Thus (B2) is the condition for the existence of a standing wave solution Φ_0. A typical balanced nonlinearity term is $-G'(u) = u - u^3$, with $G(u) = (1/4)(1 - u^2)^2$.

First we study traveling waves for the unbalanced nonlinearity. We adopt the moving coordinate of speed c toward the z-axis without loss of generality. We put $s = z - ct$ and $u(x, y, z, t) = w(x, y, s, t)$. We denote $w(x, y, s, t)$ by $w(x, y, z, t)$ for simplicity. Then we obtain

$$\begin{aligned} w_t - w_{xx} - w_{yy} - w_{zz} - cw_z - f(w) = 0 \quad &\text{in } \mathbb{R}^3, \quad t > 0, \\ w|_{t=0} = u_0 \quad &\text{in } \mathbb{R}^3. \end{aligned} \tag{4}$$

Here w_t stands for $\partial w/\partial t$ and so on. We write the solution as $w(x, y, z, t; u_0)$. If v is a traveling wave with speed c, it satisfies

$$\mathcal{L}[v] \overset{\text{def}}{=} -v_{xx} - v_{yy} - v_{zz} - cv_z - f(v) = 0 \quad \text{in } \mathbb{R}^3. \tag{5}$$

We assume

$$c > k$$

throughout this paper. There exist many traveling waves in this situation, because k is the speed of a planar traveling wave, and the curvature effect often accelerates the speed.

In the two-dimensional plane there exists the following V-form wave.

THEOREM 1 (see [15]). *Under the assumptions* $c > k$, (A1), (A2), *and* (A3), *there exists* $v_*(x, y)$, *with*

$$-(v_*)_{xx} - (v_*)_{yy} - c(v_*)_y - f(v_*) = 0 \qquad \text{for } (x, y) \in \mathbb{R}^2,$$
$$\lim_{R\to\infty} \sup_{x^2+y^2>R^2} \left| v_*(x, y) - \Phi\left(\frac{k}{c}\left(y - \frac{\sqrt{c^2 - k^2}}{k}|x|\right)\right)\right| = 0.$$

Under these two equalities $v_*(x, y)$ *is uniquely determined.*

See also Hamel, Monneau, and Roquejoffre [8, 9] for V-form waves in the Allen–Cahn equation. Recently Haragus and Scheel [13] studied V-form waves in reaction-diffusion systems including the Allen–Cahn equation by using the bifurcation theory when the angle $\arctan(\sqrt{c^2 - k^2}/k)$ is small enough. Such a bifurcation technique is applicable to the cases where a one-dimensional traveling front loses its monotony.

For three- or higher-dimensional cases with cylindrical symmetry, Hamel, Monneau, and Roquejoffre [8, 9] studied conical traveling waves for unbalanced bistable nonlinearity. The proof is based on the results for bounded cylinders, and a passage to the limit gives the existence of a conical front in the whole domain.

Now we study three-dimensional traveling waves, and our aim is to search truly three-dimensional traveling waves that have pyramidal structures and are neither cylindrically symmetric nor reducible to two-dimensional traveling waves. For this purpose, we construct pyramidal traveling waves to (5). We apply the method of Ninomiya and Taniguchi [15, 16]. A supersolution for the V-form wave is constructed in [15] as follows. In the moving coordinate we put an almost flat planar front above the shape "V." This curve is almost flat, and then the real solution goes downwards with speed $c - k > 0$, since we are using a moving coordinate. This means that an almost flat stationary planar front is a supersolution. This method is based on the monotony of a one-dimensional traveling front and the comparison methods. The application of this method is restricted to equations for which the comparison principle holds true. In this paper, we put a mollified pyramid above a pyramid in $\mathbb{R}^3$ and construct a supersolution carefully, because a pyramidal wave is everywhere apart from a pyramid near the edges.

Let $n \geq 3$ be a given integer. We put

$$\tau \stackrel{\text{def}}{=} \frac{\sqrt{c^2 - k^2}}{k} > 0. \tag{6}$$

Assume $(A_j, B_j) \in \mathbb{R}^2$ satisfies

$$A_j^2 + B_j^2 = 1 \qquad \text{for all } j = 1, \ldots, n \tag{7}$$

and

$$\begin{gathered} A_j B_{j+1} - A_{j+1} B_j > 0, \qquad 1 \leq j \leq n-1, \\ A_n B_1 - A_1 B_n > 0. \end{gathered} \tag{8}$$

We assume $(A_{j_1}, B_{j_1}) \neq (A_{j_2}, B_{j_2})$ if $j_1 \neq j_2$. Now $(-\tau A_j, -\tau B_j, 1)$ is the normal vector of a surface $\{z = \tau(A_j x + B_j y)\}$. We put

$$\begin{aligned} h_j(x,y) &\stackrel{\text{def}}{=} \tau \left(A_j x + B_j y\right), \\ h(x,y) &\stackrel{\text{def}}{=} \max_{1 \leq j \leq n} h_j(x,y) = \tau \max_{1 \leq j \leq n} \left(A_j x + B_j y\right). \end{aligned} \tag{9}$$

Then $z = h(x,y)$ represents a pyramid in $\mathbb{R}^3$. We set

$$\Omega_j = \{(x,y) \,|\, h(x,y) = h_j(x,y)\}$$

and obtain

$$\mathbb{R}^2 = \cup_{j=1}^n \Omega_j.$$

We locate $\Omega_1, \Omega_2, \ldots, \Omega_n$ counterclockwise as in Figure 1. To ensure this location we assumed (8). We set

$$E \stackrel{\text{def}}{=} \cup_{j=1}^n \partial\Omega_j \subset \mathbb{R}^2.$$

Now the lateral surfaces of a pyramid are given by

$$S_j = \{(x,y,z) \in \mathbb{R}^3 \,|\, z = h_j(x,y), \quad (x,y) \in \Omega_j\}$$

for $j = 1, \ldots, n$. We put

$$\Gamma_j \stackrel{\text{def}}{=} \begin{cases} S_j \cap S_{j+1} & \text{if } 1 \leq j \leq n-1, \\ S_n \cap S_1 & \text{if } j = n. \end{cases}$$

Then Γ_j represents an edge of a pyramid. Also

$$\Gamma \stackrel{\text{def}}{=} \cup_{j=1}^n \Gamma_j$$

represents the set of all edges.

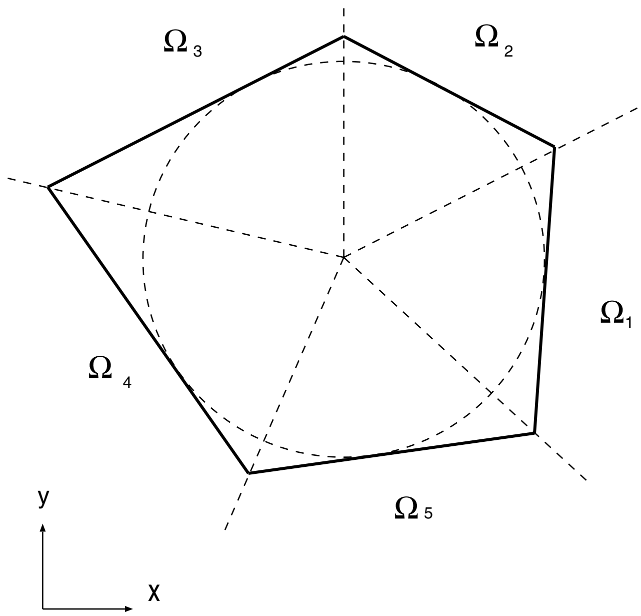

FIG. 1. *The decomposition of the x-y plane by Ω_j for $n = 5$.*

For every (A_j, B_j) with (7), (5) has a solution $\Phi\left((k/c)(z - h_j(x,y))\right)$, which is called a planar wave. Now we have

$$\Phi\left(\frac{k}{c}(z - h(x,y))\right) = \max_{1\le j\le n} \Phi\left(\frac{k}{c}(z - h_j(x,y))\right) = \max_{1\le j\le n} \Phi\left(\frac{k}{c}(z - a_j x - b_j y)\right).$$

This becomes a subsolution to (5). We define

$$D(\gamma) \stackrel{\text{def}}{=} \{(x,y,z) \in \mathbb{R}^3 \mid \operatorname{dist}((x,y,z), \mathit{\Gamma}) > \gamma\} \tag{10}$$

for $\gamma > 0$. We will construct a supersolution that is larger than this subsolution and obtain a traveling wave between them.

The following theorem is the main assertion in this paper.

THEOREM 2. *Let $c > k$, and let $h(x,y)$ be given by* (9). *Under the assumptions* (A1), (A2), *and* (A3), *there exists a solution $V(x,y,z)$ to* (5) *with*

$$\Phi\left(\frac{k}{c}(z - h(x,y))\right) < V(x,y,z) < 1 \qquad \text{in } \mathbb{R}^3$$

and

$$\lim_{\gamma\to+\infty} \sup_{(x,y,z)\in D(\gamma)} \left| V(x,y,z) - \Phi\left(\frac{k}{c}(z - h(x,y))\right)\right| = 0, \tag{11}$$

$$V_z(x,y,z) < 0 \qquad \text{for all } (x,y,z) \in \mathbb{R}^3. \tag{12}$$

We state the proof of this theorem in section 3. A domain $D(\gamma)$ is a complement of a neighborhood of the edges. The property (11) implies that the geometric shape of V can be approximated by a combination of n planar waves except on a neighborhood of the edges (see Figure 2). We conjecture that the geometric shape of V

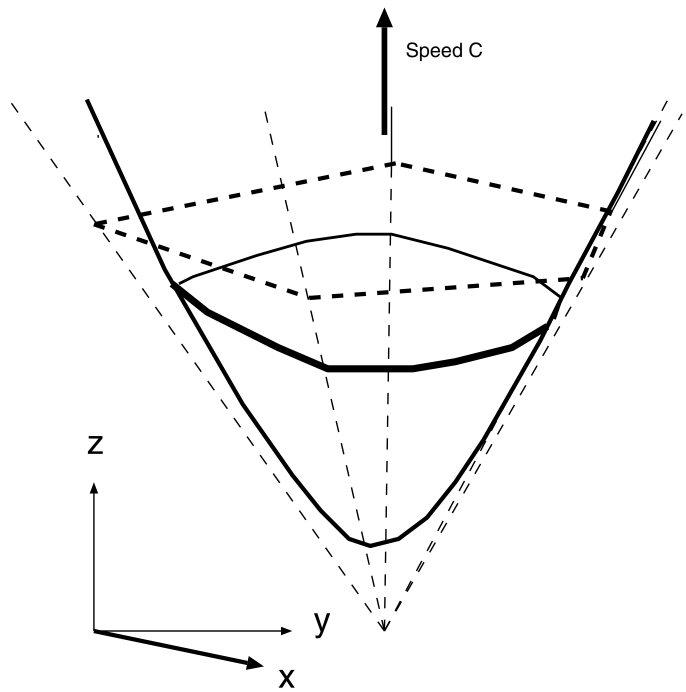

FIG. 2. *A pyramidal traveling wave.*

can be approximated by two-dimensional V-form waves on the edges and that V is a combination of planar waves and two-dimensional V-form waves. The uniqueness and the stability of V is yet to be proved.

Section 4 is devoted to applications of Theorem 2. A two-dimensional V-form wave in Theorem 1 immediately gives a three-dimensional wave $v_*(x,z)$. We call this wave a planar V-form wave. It is natural to search for a combination of a pyramidal wave and a planar V-form wave. In section 4 we study a traveling wave of a hybrid type between pyramidal waves and planar V-form waves as a special case of Theorem 2.

We studied pyramids whose lateral surfaces contain the origin in $\mathbb{R}^3$ in Theorem 2. We consider the case where the surfaces do not have a common point in section 5. Even in that case a combination of n planar waves gives three-dimensional traveling waves, and we construct generalized pyramidal traveling waves when the zero level sets of planar waves have no common point.

We study traveling waves for the balanced nonlinearity in section 6. For any given $c > 0$ we study

$$\mathcal{L}_0[v] \stackrel{\text{def}}{=} -v_{xx} - v_{yy} - v_{zz} - cv_z + G'(v) = 0 \quad \text{in } \mathbb{R}^3. \tag{13}$$

We call $-G'(u)$ in Example 3 a balanced nonlinearity. Cylindrically symmetric traveling waves for balanced nonlinearity have been studied in Chen et al [3] for two or higher dimensions. The limit of traveling waves for unbalanced nonlinearity terms when the difference of energy density goes to zero gives a traveling wave in (13). Pyramidal traveling waves for unbalanced nonlinear terms converge to traveling waves for a balanced nonlinearity term as the difference of the energy density goes to zero. Up to now the profile of the limit traveling wave is unknown and is yet to be studied.

The characterization and classification of all traveling waves for unbalanced and balanced nonlinearities will give interesting problems and are left for further studies.

2. Pyramids and mollified pyramids. In this section we make preparations. We state known results for one-dimensional traveling waves and construct mollified pyramids

LEMMA 1 (Fife and McLeod [5]). *Under the assumptions* (A1) *and* (A3), $\Phi(\mu)$ *as in* (1) *satisfies*

$$\Phi'(\mu) < 0 \qquad \text{for all } \mu \in \mathbb{R},$$
$$\max\{|\Phi'(\mu)|, |\Phi''(\mu)|, |\mu\Phi'(\mu)|\} \leq K_0 \exp(-\kappa_0|\mu|).$$

Here K_0, κ_0 are positive constants.

There exists a positive constant δ_* $(0 < \delta_* < 1/4)$, with

$$-f'(s) > \kappa_1 \qquad \text{if } |s+1| < 2\delta_* \text{ or } |s-1| < 2\delta_*,$$

where

$$\kappa_1 \stackrel{\text{def}}{=} \frac{1}{2}\min\{-f'(-1), -f'(1)\} > 0.$$

We construct mollified pyramids. Let $\widetilde{\rho}(r) \in C^\infty[0,\infty)$ be a function with the following properties:

$$\widetilde{\rho}(r) > 0, \quad \widetilde{\rho}_r(r) \leq 0 \qquad \text{for } r \geq 0,$$
$$\widetilde{\rho}(r) \equiv 1 \qquad \text{if } 0 \leq r \leq \tfrac{1}{2},$$
$$\widetilde{\rho}(r) = e^{-r} \qquad \text{if } r > 0 \text{ is large enough},$$
$$2\pi \int_0^\infty r\widetilde{\rho}(r)dr = 1.$$

Then $\rho(x,y) \stackrel{\text{def}}{=} \widetilde{\rho}(\sqrt{x^2+y^2})$ belongs to $C^\infty(\mathbb{R}^2)$ and satisfies $\int_{\mathbb{R}^2} \rho = 1$. For a pyramid $z = h(x,y)$ we define a mollified pyramid $z = \varphi(x,y)$ as $\varphi(x,y) \stackrel{\text{def}}{=} \rho * h$, which means

$$\varphi(x,y) = \int_{\mathbb{R}^2} \rho(x-x', y-y')h(x', y')dx'dy' = \int_{\mathbb{R}^2} \rho(x', y')h(x-x', y-y')dx'dy'. \tag{14}$$

We set $(a_j, b_j) \stackrel{\text{def}}{=} \tau(A_j, B_j)$. Then $(a_j, b_j) \in \mathbb{R}^2$ satisfies

$$\frac{c}{\sqrt{1+a_j^2+b_j^2}} = k \qquad \text{for all } j = 1, \ldots, n. \tag{15}$$

We put

$$S(x,y) \stackrel{\text{def}}{=} \frac{c}{\sqrt{1+\varphi_x(x,y)^2+\varphi_y(x,y)^2}} - k. \tag{16}$$

Then we have the following lemma.

LEMMA 2. *Let φ and S be as in* (14) *and* (16), *respectively. Then one has*

$$\sup_{(x,y)\in\mathbb{R}^2} |D_x^{i_1} D_y^{i_2} \varphi(x,y)| < +\infty$$

for all integers $i_1 \geq 0$, $i_2 \geq 0$, *and*

$$\begin{aligned} h(x,y) < \varphi(x,y) \leq h(x,y) + 2\pi\tau \int_0^\infty r^2 \widetilde{\rho}(r)\, dr \\ |(\nabla\varphi)(x,y)| < \tau, \quad 0 < S(x,y) < c \end{aligned} \tag{17}$$

for all $(x,y) \in \mathbb{R}^2$.

Proof. Now ρ satisfies $|D_x^{i_1} D_y^{i_2} \rho(x,y)| \leq (\text{const}) e^{-\sqrt{x^2+y^2}}$ for large $\sqrt{x^2+y^2} > 0$. We get the first estimate from $D_x^{i_1} D_y^{i_2}(\rho * g_j) = (D_x^{i_1} D_y^{i_2} \rho) * g_j$. Note that $\rho * h_j = h_j$. Using $\rho > 0$, $h_j(x,y) \leq h(x,y)$, and $h_j(x,y) \not\equiv h(x,y)$, we have a strict inequality $h_j(x,y) < \varphi(x,y)$. Thus we get $h(x,y) = \max_{1 \leq j \leq n}(h_j(x,y)) < \varphi(x,y)$. Now

$$|h_j(x',y') - h_j(x,y)| \leq \tau\sqrt{(x'-x)^2 + (y'-y)^2}$$

gives

$$|h(x',y') - h(x,y)| \leq \tau\sqrt{(x'-x)^2 + (y'-y)^2}.$$

Thus we obtain

$$\varphi - h \leq \int_{\mathbb{R}^2} |h(x-x', y-y') - h(x,y)|\, \rho(x',y') dx'dy' \leq \tau \int_{\mathbb{R}^2} \sqrt{x^2+y^2}\rho(x,y) dxdy$$

and prove the first inequality. We have

$$(\nabla\varphi)(x) = \int_{\mathbb{R}^2} \rho(x',y')(\nabla h)(x-x', y-y')\, dx'dy'.$$

Here ∇h is a constant vector in each Ω_j, and at least two of these vectors are linearly independent. Thus we get a strict inequality

$$|(\nabla\varphi)(x)| < \int_{\mathbb{R}^2} \rho(x',y')|(\nabla h)(x-x', y-y')|\, dx'dy'.$$

The right-hand side equals

$$\int_{\mathbb{R}^2} \sqrt{a_j^2 + b_j^2}\, \rho(x',y')\, dx'dy' = \tau.$$

Clearly $S < c$ is valid, and $S > 0$ follows from $|\nabla\varphi| < \tau$. This completes the proof. □

The following proposition plays a key role in this paper.

Proposition 1. *For every integer* $i_1 \geq 0$, $i_2 \geq 0$, *with* $2 \leq i_1 + i_2 \leq 3$,

$$\sup_{(x,y)\in\mathbb{R}^2} \frac{|(D_x^{i_1} D_y^{i_2}\varphi)(x,y)|}{S(x,y)} < +\infty$$

holds true.

The proof of this proposition is given at the end of this section.

We study the difference of a mollified pyramid and the original pyramid, that is, $\varphi(x,y) - h(x,y)$. We put

$$\widetilde{\varphi}_j(x,y) \stackrel{\text{def}}{=} \varphi(x,y) - h_j(x,y) = \varphi(x,y) - a_j x - b_j y. \tag{18}$$

Then we have $\varphi(x,y) - h(x,y) = \widetilde{\varphi}_j(x,y)$ in Ω_j. It suffices to study $\widetilde{\varphi}_j(x,y)$ in each Ω_j for studying $\varphi(x,y) - h(x,y)$ in $\mathbb{R}^2$. To do this we study here the simplest case. For

$$q(x,y) \stackrel{\text{def}}{=} \max\{x,0\} = \begin{cases} -x & x < 0, \\ 0 & x \geq 0, \end{cases}$$

we define

$$\begin{aligned} P(x) &\stackrel{\text{def}}{=} \int_{\mathbb{R}^2} \rho(x',y') q(x-x', y-y')\, dx'dy' \\ &= -\int_{-\infty}^{\infty} \left(\int_x^{\infty} \rho(x',y')(x-x')\, dx' \right) dy' > 0. \end{aligned} \tag{19}$$

This $P(x)$ is a mollified function for $q(x,y)$. We use it to estimate $\varphi(x,y) - h(x,y)$ because it stands for the influence of a lateral surface when we construct a mollified pyramid from the original pyramid. Then we have

$$\begin{aligned} P'(x) &= -\int_{-\infty}^{\infty} \left(\int_x^{\infty} \rho(x',y)\, dx' \right) dy < 0, \\ P''(x) &= \int_{-\infty}^{\infty} \rho(x,y)\, dy = \int_{-\infty}^{\infty} \widetilde{\rho}(\sqrt{x^2+y^2})\, dy > 0, \\ P^{(3)}(x) &= \int_{-\infty}^{\infty} \frac{x}{\sqrt{x^2+y^2}} \widetilde{\rho}_r(\sqrt{x^2+y^2})\, dy \leq 0. \end{aligned}$$

Especially we have

$$P''(x) = \int_{-\infty}^{\infty} e^{-\sqrt{x^2+y^2}}\, dy, \quad P^{(3)}(x) = -\int_{-\infty}^{\infty} \frac{x}{\sqrt{x^2+y^2}} e^{-\sqrt{x^2+y^2}}\, dy,$$

if $x > 0$ is large enough. Now we have the following lemma.

LEMMA 3. *Let $P(x)$ be as in* (19). *Then it satisfies*

$$\lim_{x\to\infty} \frac{P(x)}{\sqrt{2\pi x} e^{-x}} = 1$$

and

$$\lim_{x\to\infty} \frac{|P^{(i)}(x)|}{P(x)} = 1, \quad 0 < \inf_{x\geq 1} \frac{|P^{(i)}(x)|}{P(x)} \leq \sup_{x\geq 1} \frac{|P^{(i)}(x)|}{P(x)} < +\infty$$

for all i with $1 \leq i \leq 3$.

Proof. For $x > 0$ we use $y = \sqrt{s^2 + 2sx}$ and obtain

$$2\int_0^{\infty} e^{-\sqrt{x^2+y^2}}\, dy = 2e^{-x} \int_0^{\infty} e^{-s} \frac{s+x}{\sqrt{s^2+2sx}}\, ds = \sqrt{2x} e^{-x} Q(x).$$

Here

$$Q(x) \stackrel{\text{def}}{=} \int_0^{\infty} \frac{1}{\sqrt{s}} e^{-s} \left(1 + \frac{s}{x}\right) \left(1 + \frac{s}{2x}\right)^{-\frac{1}{2}}\, ds.$$

By Lebesgue's convergence theorem we have

$$\lim_{x\to\infty} Q(x) = \int_0^{\infty} \frac{1}{\sqrt{s}} e^{-s}\, ds = \sqrt{\pi}.$$

Thus we have

$$P''(x) = \sqrt{2\pi x} e^{-x}(1+o(1)) \qquad \text{as } x \to \infty. \tag{20}$$

Similarly we get

$$\begin{aligned} &2\int_0^\infty \frac{x}{\sqrt{x^2+y^2}} e^{-\sqrt{x^2+y^2}}\, dy = \sqrt{2x} e^{-x} \int_0^\infty e^{-s} \sqrt{\frac{2x}{s^2+2sx}}\, ds \\ &= \sqrt{2x} e^{-x} \int_0^\infty e^{-s} \frac{1}{\sqrt{s}} \left(1+\frac{s}{2x}\right)^{-\frac{1}{2}} ds = \sqrt{2\pi x} e^{-x} \left(1+o(1)\right) \qquad \text{as } x \to \infty. \end{aligned}$$

Thus we obtain

$$\lim_{x\to\infty} \frac{-P^{(3)}(x)}{P''(x)} = 1.$$

Now the Cauchy mean value theorem gives

$$\frac{P''(x)}{P'(x)} = \frac{P^{(3)}(x')}{P''(x')}$$

for some $x' > x$. This yields

$$\lim_{x\to\infty} \frac{P''(x)}{-P'(x)} = 1.$$

Similarly we have

$$\lim_{x\to\infty} \frac{-P'(x)}{P(x)} = \lim_{x\to\infty} \frac{P''(x)}{-P'(x)} = 1.$$

Thus we obtain

$$\lim_{x\to\infty} \frac{-P'(x)}{P(x)} = \lim_{x\to\infty} \frac{P''(x)}{-P'(x)} = \lim_{x\to\infty} \frac{-P^{(3)}(x)}{P''(x)} = 1.$$

This completes the proof. □

Now we come back to study

$$\widetilde{\varphi}_j(x,y) = \varphi(x,y) - h_j(x,y) = \left(\rho * (h-h_j)\right)(x,y)$$

in Ω_j. Hereafter we assume $(x,y) \in \Omega_j$. We write

$$\boldsymbol{a}_j = (a_j, b_j) \qquad (1 \le j \le n).$$

Then we get

$$0 < \tau^2 - |\nabla\varphi|^2 = -2\boldsymbol{a}_j \cdot \nabla\widetilde{\varphi}_j - |\nabla\widetilde{\varphi}_j|^2. \tag{21}$$

We have

$$h(x,y) - h_j(x,y) = \begin{cases} (a_{j+1}-a_j)x + (b_{j+1}-b_j)y & \text{in } \Omega_{j+1}, \\ (a_{j-1}-a_j)x + (b_{j-1}-b_j)y & \text{in } \Omega_{j-1}. \end{cases}$$

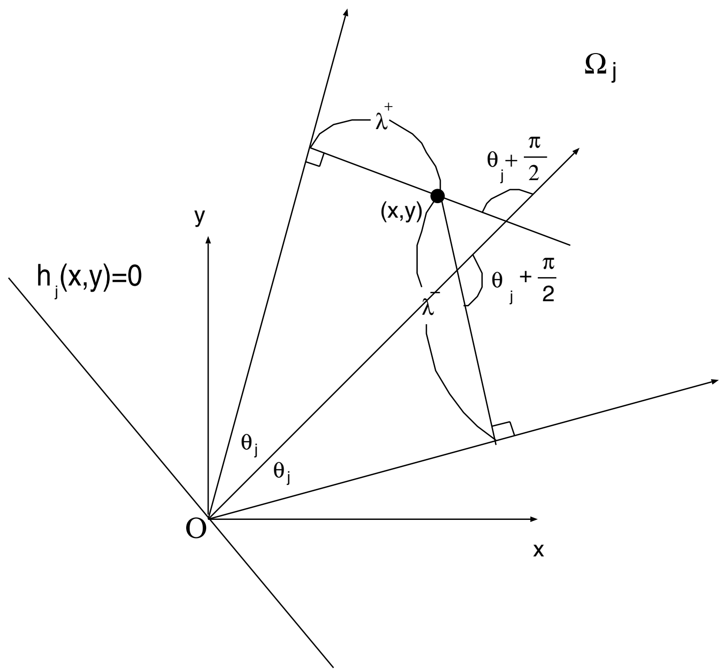

FIG. 3. *The definition of* $\lambda^{\pm}$.

Now

$$m_j^+ \stackrel{\text{def}}{=} \sqrt{(a_{j+1}-a_j)^2+(b_{j+1}-b_j)^2}, \quad m_j^- \stackrel{\text{def}}{=} \sqrt{(a_{j-1}-a_j)^2+(b_{j-1}-b_j)^2} \tag{22}$$

give the gradients of the adjacent surfaces S_{j+1} and S_{j-1} from a surface S_j, respectively. Let the angle of Ω_j be denoted by $2\theta_j$, with $\theta_j \in (0, \pi/2)$ for $j = 1, \ldots, n$ as in Figure 3. For $(x, y) \in \Omega_j$, let λ^+ and λ^- be the lengths of the perpendiculars onto $\partial\Omega_j$. We have

$$\lambda^+ = \frac{(a_j - a_{j+1})x + (b_j - b_{j+1})y}{m_j^+}, \quad \lambda^- = \frac{(a_j - a_{j-1})x + (b_j - b_{j-1})y}{m_j^-}. \tag{23}$$

We study $\widetilde{\varphi}_j(x, y)$ and its derivatives in Ω_j when $\sqrt{x^2+y^2}$ is large enough. The number of the nearest latent surfaces for $(x, y) \in \Omega_j$ is at most two. This fact suggests that $\widetilde{\varphi}_j(x, y)$ can be approximated by $m^+P(\lambda^+) + m^-P(\lambda^-)$ in Ω_j if $\sqrt{x^2+y^2} \to \infty$ up to the derivatives. We have

$$\widetilde{\varphi}_j = \rho * (\max\{h_{j+1} - h_j, 0\}) + \rho * (\max\{h_{j-1} - h_j, 0\}) + \rho * g_j,$$

where

$$g_j \stackrel{\text{def}}{=} h - h_j - \max\{h_{j+1} - h_j, 0\} - \max\{h_{j-1} - h_j, 0\}.$$

Using P, we write the first and the second terms as

$$(\rho * (\max\{h_{j+1} - h_j, 0\}))(x, y) = m_j^+ P(\lambda^+),$$
$$(\rho * (\max\{h_{j-1} - h_j, 0\}))(x, y) = m_j^- P(\lambda^-),$$

respectively. We estimate the third term. We have

$$g_j \equiv 0 \quad \text{on } \Omega_{j-1} \cup \Omega_j \cup \Omega_{j+1}$$

and

$$h_j(x,y) \geq 0 \qquad \text{for all } (x,y) \in \Omega_j.$$

The distance between (x,y) and a line $\{(x,y) \mid h_j(x,y)=0\}$ is $(1/\tau)h_j(x,y)$. The gradients of the planes h_j $(1 \leq j \leq n)$ are at most τ. We put $\Lambda^+ = \mathrm{dist}((x,y), \Omega_{j+2})$ and $\Lambda^- = \mathrm{dist}((x,y), \Omega_{j-2})$. We have $0 < \sin\theta_j < 1$ and $\min\{\lambda^+, \lambda^-\} \leq (h_j(x,y)/\tau)\sin\theta_j$. There exists $\gamma_0 > 1$ such that we have

$$\gamma_0 \min\{\lambda^+, \lambda^-\} \leq \min\left\{\Lambda^+, \Lambda^-, \frac{1}{\tau}h_j(x,y)\right\}.$$

The following lemma is useful to estimate $\rho * g_j$ and $\varphi(x,y) - h(x,y)$.

Lemma 4. *For every j $(1 \leq j \leq n)$, one has*

$$\varphi(x,y) - h(x,y) = m_j^+ P(\lambda^+) + m_j^- P(\lambda^-) + (\rho * g_j)(x,y) \qquad \text{for all } (x,y) \in \Omega_j,$$

where $m_j^{\pm}$, $\lambda^{\pm}$ are given by (22) *and* (23), *respectively. For all nonnegative integers i_1, i_2, with $0 \leq i_1 + i_2 \leq 3$, one has*

$$\left|D_x^{i_1} D_y^{i_2} (\rho * g_j)(x,y)\right| \leq K \left(\gamma_0 \min\{\lambda^+, \lambda^-\}\right)^{\frac{1}{2}} \exp\left(-\gamma_0 \min\{\lambda^+, \lambda^-\}\right)$$

for $(x,y) \in \Omega_j$ and $x^2 + y^2 \geq 1$. Here $K > 0$ and $\gamma_0 > 1$ are constants independent of j, i_1, and i_2. In particular one has

$$\lim_{\lambda\to\infty} \sup\left\{S(x,y) \mid (x,y) \in \mathbb{R}^2, \mathrm{dist}((x,y), E) \geq \lambda\right\} = 0,$$
$$\lim_{\lambda\to\infty} \sup\left\{\varphi(x,y) - h(x,y) \mid (x,y) \in \mathbb{R}^2, \mathrm{dist}((x,y), E) \geq \lambda\right\} = 0.$$

Proof. We already obtained the first equality. We decompose g_j as

$$g_j = g_j \chi_{\{h_{j+2}-h_{j+1}>0\}} + g_j \chi_{\{h_{j-2}-h_{j-1}>0\}} + g_j \chi_{\{h_{j+2}-h_{j+1}\leq 0, h_{j-2}-h_{j-1}\leq 0\}},$$

where $\chi_{\{h_{j+2}-h_{j+1}>0\}}$ is the characteristic function of $\{h_{j+2} - h_{j+1} > 0\}$ and so on. For all nonnegative integers i_1, i_2, with $0 \leq i_1 + i_2 \leq 3$, we take $\gamma_1 > 0$ so large to get $|D_x^{i_1} D_y^{i_2} \rho(x,y)| \leq \gamma_1 \rho(x,y)$ for all $(x,y) \in \mathbb{R}^2$. Then applying Lemma 3 we obtain

$$|(D_x^{i_1} D_y^{i_2} \rho) * g_j(x,y)| \leq 6\tau\gamma_1 P(\Lambda^+) + 6\tau\gamma_1 P(\Lambda^-) + 6\tau\gamma_1 P\left(-\frac{1}{\tau}h_j(x,y)\right)$$

for all $(x,y) \in \mathbb{R}^2$. Using $D_x^{i_1} D_y^{i_2}(\rho * g_j) = (D_x^{i_1} D_y^{i_2} \rho) * g_j$, we get the desired inequality. The last two equalities follow from this inequality. $\square$

We have

$$\widetilde{\varphi}_j(x,y) = m_j^+ P(\lambda^+) + m_j^- P(\lambda^-) + (\rho * g_j)(x,y).$$

Using Lemma 4 we obtain

$$\lim_{\sqrt{x^2+y^2}\to\infty} \frac{\widetilde{\varphi}_j(x,y)}{m_j^+ P(\lambda^+) + m_j^- P(\lambda^-)} = 1,$$
$$\lim_{\sqrt{x^2+y^2}\to\infty} \frac{\boldsymbol{a}_j \cdot (\nabla\widetilde{\varphi}_j)(x,y)}{-\tau m_j^+ P'(\lambda^+)\cos(\theta_j + \frac{\pi}{2}) - \tau m_j^- P'(\lambda^-)\cos(\theta_j + \frac{\pi}{2})} = 1.$$

For all integers $i_1 \geq 0$, $i_2 \geq 0$, with $2 \leq i_1 + i_2 \leq 3$, we can estimate $|D_x^{i_1} D_y^{i_2} \widetilde{\varphi}_j(x,y)|$ by

$$\left|P^{''}(\lambda^+)\right| + \left|P^{(3)}(\lambda^+)\right| + \left|P^{''}(\lambda^-)\right| + \left|P^{(3)}(\lambda^-)\right|.$$

From Lemma 4 there exists a constant $M > 0$, with

$$|D_x^{i_1} D_y^{i_2} \widetilde{\varphi}_j(x,y)| \leq M\left(P(\lambda^+) + P(\lambda^-)\right) \qquad \text{in } \Omega_j \tag{24}$$

for every j $(1 \leq j \leq n)$ and all integers $i_1 \geq 0$, $i_2 \geq 0$, with $0 \leq i_1 + i_2 \leq 3$.

The definition of $S(x,y)$ and (21) give

$$\frac{k^3}{2c^2}\left(-2\boldsymbol{a}_j \cdot \nabla\widetilde{\varphi}_j - |\nabla\widetilde{\varphi}_j|^2\right) < S(x,y) < \frac{k^2}{c+k}\left(-2\boldsymbol{a}_j \cdot \nabla\widetilde{\varphi}_j - |\nabla\widetilde{\varphi}_j|^2\right). \tag{25}$$

Lemma 5. *For any given $\omega > 0$*

$$0 < \inf\left\{S(x,y) \mid \operatorname{dist}((x,y), E) \leq \omega\right\}$$

holds true.

Proof. It suffices to prove the lemma assuming $(x,y) \in \Omega_j$ and $\operatorname{dist}((x,y), \partial\Omega_j) \leq \omega$. We have

$$\begin{aligned}
&-2(\boldsymbol{a}_j, \nabla(m_j^+ P(\lambda^+))) - \left|\nabla(m_j^+ P(\lambda^+))\right|^2 \\
&= -P'(\lambda^+)\left(2(\boldsymbol{a}_j, \boldsymbol{a}_j - \boldsymbol{a}_{j+1}) + P'(\lambda^+)|\boldsymbol{a}_{j+1} - \boldsymbol{a}_j|^2\right) \\
&\geq -P'(\lambda^+)\left(2(\boldsymbol{a}_j, \boldsymbol{a}_j - \boldsymbol{a}_{j+1}) - \frac{1}{2}|\boldsymbol{a}_{j+1} - \boldsymbol{a}_j|^2\right) = -P'(\lambda^+)\left(|\boldsymbol{a}_j|^2 - (\boldsymbol{a}_j, \boldsymbol{a}_{j+1})\right) > 0.
\end{aligned}$$

As $\sqrt{x^2+y^2} \to \infty$, we can assume λ^+ remains finite and $\lambda^- \to \infty$ without loss of generality. Then the inequality stated above implies

$$\lim_{r\to\infty} \inf\left\{S(x,y) \,|\, (x,y) \in \Omega_j, \operatorname{dist}((x,y), \partial\Omega_j) \leq \omega, x^2 + y^2 \geq r^2\right\} > 0.$$

This completes the proof. □

Now we prove the following lemma.

Lemma 6. *There exists positive constants ν_1, ν_2 so that*

$$0 < \nu_1 \leq \frac{\varphi(x,y) - h(x,y)}{S(x,y)} \leq \nu_2$$

holds true for $(x,y) \in \mathbb{R}^2$.

Proof. We note that $(\varphi(x,y) - h(x,y))/S(x,y)$ is a positive function in $\mathbb{R}^2$. Without loss of generality, we assume (x,y) lies in Ω_j. Due to Lemma 5 it suffices to prove that it remains no less than a positive constant as $\sqrt{x^2+y^2} \to \infty$ under the condition $|\nabla\widetilde{\varphi}_j| \to 0$. We have

$$\limsup_{\sqrt{x^2+y^2}\to\infty} \left|\frac{\widetilde{\varphi}_j(x,y)}{-\boldsymbol{a}_j \cdot (\nabla\widetilde{\varphi}_j)(x,y)}\right| = \frac{1}{\tau\sin\theta_j} \limsup_{\sqrt{x^2+y^2}\to\infty} \left|\frac{m_j^+ P(\lambda^+) + m_j^- P(\lambda^-)}{-m_j^+ P'(\lambda^+) - m_j^- P'(\lambda^-)}\right|.$$

The right-hand side takes a positive bounded value. Using Lemma 5, (25), and this fact, we complete the proof. □

Proof of Proposition 1. Without loss of generality we can assume $(x, y) \in \Omega_j$ for some j. By Lemma 5 it suffices to prove

$$\sup_{(x,y)\in\Omega_j} \frac{|(D_x^{i_1} D_y^{i_2} \widetilde{\varphi}_j)(x,y)|}{S(x,y)} < +\infty \tag{26}$$

for each $i_1 \geq 0$, $i_2 \geq 0$, with $2 \leq i_1 + i_2 \leq 3$, under the condition $|\nabla \widetilde{\varphi}_j| \to 0$. From (24) we obtain

$$\lim_{\sqrt{x^2+y^2}\to\infty} \left| \frac{(D_x^{i_1} D_y^{i_2} \widetilde{\varphi}_j)(x,y)}{-\boldsymbol{a}_j \cdot (\nabla \widetilde{\varphi}_j)(x,y)} \right| \leq \frac{M'}{\tau \sin\theta_j} \lim_{\sqrt{x^2+y^2}\to\infty} \left| \frac{m_j^+ P(\lambda^+) + m_j^- P(\lambda^-)}{-m_j^+ P'(\lambda^+) - m_j^- P'(\lambda^-)} \right|.$$

Here $M' > 0$ is a constant. The right-hand side is bounded. Using this estimate, (25), and (21), we obtain (26). This completes the proof. □

3. Proof of Theorem 2. In this section we prove Theorem 2 by constructing a supersolution and a subsolution and by finding a pyramidal traveling wave between them.

For $\alpha \in (0, 1)$ we consider the graph of

$$z = \frac{1}{\alpha}\varphi(\alpha x, \alpha y). \tag{27}$$

Later we will choose α to be small enough. We use this function as a mollified pyramid. We note that

$$\frac{1}{\alpha} h(\alpha x, \alpha y) = h(x, y).$$

We use a rescaled coordinate (ξ, η, ζ) as

$$\xi = \alpha x, \quad \eta = \alpha y, \quad \zeta = \alpha z$$

and write (27) as $\zeta = \varphi(\xi, \eta)$.

For $(x_0, y_0) \in \mathbb{R}^2$, the tangent plane of (27) at $(x_0, y_0, \alpha^{-1}\varphi(\alpha x_0, \alpha y_0))$ is expressed by

$$-\varphi_\xi(\xi_0, \eta_0)(x - x_0) - \varphi_\eta(\xi_0, \eta_0)(y - y_0) + z - \frac{1}{\alpha}\varphi(\xi_0, \eta_0) = 0,$$

where $\xi_0 = \alpha x_0$, $\eta_0 = \alpha y_0$. The length of the perpendicular from (x_0, y_0, z_0) onto the tangent plane is

$$\frac{\left| z_0 - \frac{1}{\alpha}\varphi(\xi_0, \eta_0) \right|}{\sqrt{1 + \varphi_\xi(\xi_0, \eta_0)^2 + \varphi_\eta(\xi_0, \eta_0)^2}}.$$

We define

$$\widehat{\mu} \stackrel{\text{def}}{=} \frac{z - \frac{1}{\alpha}\varphi(\alpha x, \alpha y)}{\sqrt{1 + \varphi_\xi(\alpha x, \alpha y)^2 + \varphi_\eta(\alpha x, \alpha y)^2}} = \frac{1}{\alpha} \frac{\zeta - \varphi(\xi, \eta)}{\sqrt{1 + \varphi_\xi(\xi, \eta)^2 + \varphi_\eta(\xi, \eta)^2}}. \tag{28}$$

Then we have

$$\widehat{\mu}_z = \frac{1}{\sqrt{1 + \varphi_\xi^2 + \varphi_\eta^2}}, \qquad \widehat{\mu}_{zz} = 0.$$

Also we get

$$\widehat{\mu}_x = -\frac{\varphi_\xi}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}} + \alpha\widehat{\mu}F_1(\xi,\eta), \qquad \widehat{\mu}_{xx} = \alpha G_{11}(\xi,\eta) + \alpha^2\widehat{\mu}H_{11}(\xi,\eta),$$

where

$$\begin{aligned}
F_1(\xi,\eta) &\stackrel{\text{def}}{=} \sqrt{1+\varphi_\xi^2+\varphi_\eta^2}\left(\frac{1}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}}\right)_\xi, \\
G_{11}(\xi,\eta) &\stackrel{\text{def}}{=} -\left(\frac{\varphi_\xi}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}}\right)_\xi - \varphi_\xi\left(\frac{1}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}}\right)_\xi \\
&= \frac{(-1+\varphi_\xi^2-\varphi_\eta^2)\varphi_{\xi\xi} + (2\varphi_\xi^2+2\varphi_\xi\varphi_\eta)\varphi_{\xi\eta}}{(1+\varphi_\xi^2+\varphi_\eta^2)^{\frac{3}{2}}}, \\
H_{11}(\xi,\eta) &\stackrel{\text{def}}{=} (F_1(\xi,\eta))_\xi + F_1(\xi,\eta)^2.
\end{aligned}$$

Similarly we obtain

$$\widehat{\mu}_{xy} = \alpha G_{12}(\xi,\eta) + \alpha^2\widehat{\mu}H_{12}(\xi,\eta),$$

where

$$\begin{aligned}
G_{12}(\xi,\eta) &\stackrel{\text{def}}{=} -\left(\frac{\varphi_\xi}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}}\right)_\eta - \varphi_\eta\left(\frac{1}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}}\right)_\xi, \\
H_{12}(\xi,\eta) &\stackrel{\text{def}}{=} (F_1(\xi,\eta))_\eta + F_1(\xi,\eta)F_2(\xi,\eta).
\end{aligned}$$

We get

$$\widehat{\mu}_y = -\frac{\varphi_\eta}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}} + \alpha\widehat{\mu}F_2(\xi,\eta), \qquad \widehat{\mu}_{yy} = \alpha G_{22}(\xi,\eta) + \alpha^2\widehat{\mu}H_{22}(\xi,\eta),$$

where

$$\begin{aligned}
F_2(\xi,\eta) &\stackrel{\text{def}}{=} \sqrt{1+\varphi_\xi^2+\varphi_\eta^2}\left(\frac{1}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}}\right)_\eta, \\
G_{22}(\xi,\eta) &\stackrel{\text{def}}{=} -\left(\frac{\varphi_\eta}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}}\right)_\eta - \varphi_\eta\left(\frac{1}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}}\right)_\eta, \\
H_{22}(\xi,\eta) &\stackrel{\text{def}}{=} (F_2(\xi,\eta))_\eta + F_2(\xi,\eta)^2.
\end{aligned}$$

We define

$$U(x,y,z) = \Phi(\widehat{\mu}) + \sigma(x,y), \tag{29}$$

where $\widehat{\mu}$ is as in (28) and

$$\sigma(x,y) \stackrel{\text{def}}{=} \varepsilon S(\alpha x, \alpha y).$$

Here we will fix $\varepsilon > 0$ later. We have

$$U_z = \frac{1}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}}\Phi'(\widehat{\mu}), \quad U_{zz} = \frac{1}{1+\varphi_\xi^2+\varphi_\eta^2}\Phi''(\widehat{\mu}),$$

and

$$U_{xx}+U_{yy} = \Phi^{'}(\widehat{\mu})(\widehat{\mu}_{xx}+\widehat{\mu}_{yy}) + \Phi^{''}(\widehat{\mu})(\widehat{\mu}_x^2+\widehat{\mu}_y^2) + \sigma_{xx}+\sigma_{yy}.$$

Thus we get

$$\begin{aligned} U_{xx}+U_{yy} = {}& \alpha\Phi^{'}(\widehat{\mu})(G_{11}(\xi,\eta)+G_{22}(\xi,\eta)) + \alpha^2\widehat{\mu}\Phi^{'}(\widehat{\mu})(H_{11}(\xi,\eta)+H_{22}(\xi,\eta)) \\ & + \Phi^{''}(\widehat{\mu})\frac{\varphi_\xi^2+\varphi_\eta^2}{1+\varphi_\xi^2+\varphi_\eta^2} - 2\alpha\widehat{\mu}\Phi^{''}(\widehat{\mu})\frac{\varphi_\xi(\xi,\eta)F_1(\xi,\eta)+\varphi_\eta(\xi,\eta)F_2(\xi,\eta)}{\sqrt{1+\varphi_\xi(\xi,\eta)^2+\varphi_\eta(\xi,\eta)^2}} \\ & + \alpha^2\widehat{\mu}^2\Phi^{''}(\widehat{\mu})(F_1(\xi,\eta)^2+F_2(\xi,\eta)^2) + \sigma_{xx}+\sigma_{yy}. \end{aligned}$$

We calculate $\mathcal{L}[U]$ as

$$\begin{aligned} \mathcal{L}[U] = {}& -\Phi^{''}(\widehat{\mu}) - \frac{c}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}}\Phi^{'}(\widehat{\mu}) - f(\Phi+\sigma) \\ & - \alpha\Phi^{'}(\widehat{\mu})(G_{11}(\xi,\eta)+G_{22}(\xi,\eta)) - \alpha^2\widehat{\mu}\Phi^{'}(\widehat{\mu})(H_{11}(\xi,\eta)+H_{22}(\xi,\eta)) \\ & + 2\alpha\widehat{\mu}\Phi^{''}(\widehat{\mu})\frac{\varphi_\xi(\xi,\eta)F_1(\xi,\eta)+\varphi_\eta(\xi,\eta)F_2(\xi,\eta)}{\sqrt{1+\varphi_\xi(\xi,\eta)^2+\varphi_\eta(\xi,\eta)^2}} \\ & - \alpha^2\widehat{\mu}^2\Phi^{''}(\widehat{\mu})(F_1(\xi,\eta)^2+F_2(\xi,\eta)^2) - \varepsilon\alpha^2(S_{\xi\xi}+S_{\eta\eta}). \end{aligned}$$

We have

$$S_{\xi\xi}(\xi,\eta)+S_{\eta\eta}(\xi,\eta) = \left(\frac{c}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}}\right)_{\xi\xi} + \left(\frac{c}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}}\right)_{\eta\eta}$$

and define

$$\begin{aligned} R(\xi,\eta,\mu;\varepsilon,\alpha) \overset{\text{def}}{=} {}& -\Phi^{'}(\mu)(G_{11}(\xi,\eta)+G_{22}(\xi,\eta)) - \alpha\mu\Phi^{'}(\mu)(H_{11}(\xi,\eta)+H_{22}(\xi,\eta)) \\ & + 2\mu\Phi^{''}(\mu)\frac{\varphi_\xi(\xi,\eta)F_1(\xi,\eta)+\varphi_\eta(\xi,\eta)F_2(\xi,\eta)}{\sqrt{1+\varphi_\xi(\xi,\eta)^2+\varphi_\eta(\xi,\eta)^2}} \\ & - \alpha\mu^2\Phi^{''}(\mu)(F_1(\xi,\eta)^2+F_2(\xi,\eta)^2) - \varepsilon\alpha\left(S_{\xi\xi}(\xi,\eta)+S_{\eta\eta}(\xi,\eta)\right). \end{aligned}$$

Thus we get

$$\mathcal{L}[U] = -\Phi^{''}(\widehat{\mu}) - \frac{c}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}}\Phi^{'}(\widehat{\mu}) - f(\Phi+\sigma) + \alpha R(\xi,\eta,\widehat{\mu};\varepsilon,\alpha).$$

Using $-\Phi^{''}(\mu) - k\Phi^{'}(\mu) - f(\Phi) = 0$, we obtain

$$\mathcal{L}[U] = -\Phi^{'}(\widehat{\mu})S(\xi,\eta) - \sigma\int_0^1 f^{'}(\Phi(\widehat{\mu})+s\sigma)ds + \alpha R(\xi,\eta,\widehat{\mu};\varepsilon,\alpha).$$

We estimate $|R(\xi,\eta,\mu;\varepsilon,\alpha)|$ using

$$\begin{aligned}&|R(\xi,\eta,\mu;\varepsilon,\alpha)| \leq \max\left\{|\Phi^{'}(\mu)|, |\mu\Phi^{'}(\mu)|, |\mu\Phi^{''}(\mu)|, |\mu^2\Phi^{''}(\mu)|\right\}\\&\times (|G_{11}(\xi,\eta)| + |G_{22}(\xi,\eta)| + |H_{11}(\xi,\eta)| + |H_{22}(\xi,\eta)| + 2|F_1(\xi,\eta) + F_2(\xi,\eta)|\\&\quad +|F_1(\xi,\eta)|^2 + |F_2(\xi,\eta)|^2 + |S_{\xi\xi}(\xi,\eta)| + |S_{\eta\eta}(\xi,\eta)|)\end{aligned}$$

if $0 < \alpha < 1$. The first term $|G_{11}(\xi,\eta)|$ includes the second derivatives of φ as in the definition of G_{11}. Other terms also include the second or third derivatives of φ. Using Lemmas 1 and 2, we estimate all terms and obtain

$$\begin{aligned}&|G_{11}(\xi,\eta)| + |G_{22}(\xi,\eta)| + |H_{11}(\xi,\eta)| + |H_{22}(\xi,\eta)| + 2|F_1(\xi,\eta) + F_2(\xi,\eta)|\\&+|F_1(\xi,\eta)|^2 + |F_2(\xi,\eta)|^2 + |S_{\xi\xi}(\xi,\eta)| + |S_{\eta\eta}(\xi,\eta)|\\&\leq A' \sum_{2\leq i_1+i_2\leq 3} |(D_\xi^{i_1} D_\eta^{i_2}\varphi)(\xi,\eta)| \qquad \text{for all } (\xi,\eta)\in\mathbb{R}^2\end{aligned}$$

with a constant A'. Using Proposition 1 we find a constant A so that

$$\frac{|R(\xi,\eta,\mu;\varepsilon,\alpha)|}{S(\xi,\eta)} < A$$

holds true for all $(\xi,\eta)\in\mathbb{R}^2$, $\mu\in\mathbb{R}$, $\varepsilon\in(0,1)$, and $\alpha\in(0,1)$. Constants A' and A depend only on f and c. We continue to calculate $\mathcal{L}[U]$ as

$$\mathcal{L}[U] = S(\xi,\eta)\left(-\Phi^{'}(\widehat{\mu}) - \varepsilon\int_0^1 f^{'}(\Phi(\widehat{\mu}) + s\sigma)ds + \alpha\frac{R(\xi,\eta,\widehat{\mu};\varepsilon,\alpha)}{S(\xi,\eta)}\right).$$

Thus we get

$$\mathcal{L}[U] \geq S(\xi,\eta)\left(-\Phi^{'}(\widehat{\mu}) - \varepsilon\int_0^1 f^{'}(\Phi(\widehat{\mu}) + s\sigma)ds - \alpha A\right). \tag{30}$$

Now we choose ε and α as was mentioned before. We take ε small enough to get

$$0 < \varepsilon < \min\left\{\frac{1}{2}, \frac{\delta_*}{c}, \frac{2K_0}{c}, \frac{\min_{-1+\delta_*\leq\Phi(p)\leq 1-\delta_*}(-\Phi^{'}(p))}{4\max_{|s|\leq 1+\delta_*}|f^{'}(s)|}\right\}. \tag{31}$$

Then we choose α small enough to get

$$0 < \alpha < \min\left\{\frac{1}{2}, \frac{\varepsilon\kappa_1}{2A}, \frac{\min_{-1+\delta_*\leq\Phi(p)\leq 1-\delta_*}(-\Phi^{'}(p))}{4A}, \frac{k\kappa_0\nu_1}{\log\left(\frac{2K_0}{c\varepsilon}\right)}\right\}. \tag{32}$$

Now we show that U is a supersolution and is larger than the maximum of planar solutions.

Lemma 7. *Assume ε and α satisfy* (31) *and* (32)*, respectively. Let U be as in* (29)*. Then*

$$\mathcal{L}[U] > 0 \qquad \text{in } \mathbb{R}^3$$

holds true. Moreover

$$\Phi\left(\frac{k}{c}(z - h(x,y))\right) < U(x,y,z) \qquad \text{in } \mathbb{R}^3$$

holds true.

Proof. If $\Phi(\widehat{\mu}) < -1+\delta_*$ or $\Phi(\widehat{\mu}) > 1-\delta_*$, we have $|s\varepsilon S| \leq s\varepsilon c \leq \delta_*$ for $0 \leq s \leq 1$ in view of Lemma 2. We get $\Phi(\widehat{\mu}) + s\varepsilon S < -1 + 2\delta_*$ or $\Phi(\widehat{\mu}) + s\varepsilon S > 1 - 2\delta_*$. Combining $-\Phi'(\widehat{\mu}) > 0$ and (30), we obtain

$$\mathcal{L}[U] \geq S(\xi,\eta)\,(\varepsilon\kappa_1 - \alpha A) > 0.$$

If $-1+\delta_* \leq \Phi(\widehat{\mu}) \leq 1-\delta_*$, then we have

$$\mathcal{L}[U] \geq S(\xi,\eta)\left(\min_{-1+\delta_*\leq\Phi(p)\leq 1-\delta_*}(-\Phi^{'}(p)) - \varepsilon\max_{|s|\leq 1+\delta_*}|f^{'}(s)| - \alpha A\right) > 0.$$

In both cases we proved that U is a supersolution.

We use a similar argument as in [15] to prove the latter statement. It suffices to prove

$$\Phi\left(\frac{k}{c}(z - a_j x - b_j y)\right) < U(x,y,z) \tag{33}$$

for fixed j. Temporarily we denote a_j, b_j simply by a, b to prove (33). If

$$\widehat{\mu} \leq \frac{k}{c}(z - ax - by),$$

we get

$$U(x,y,z) > \Phi(\widehat{\mu}) \geq \Phi\left(\frac{k}{c}(z - ax - by)\right).$$

Thus it suffices to prove (33) by assuming

$$\widehat{\mu} > \frac{k}{c}(z - ax - by).$$

Substituting the definition of $\widehat{\mu}$ into this inequality, we obtain

$$\frac{z - ax - by + \left(ax + by - \frac{1}{\alpha}\varphi(\xi,\eta)\right)}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}} > \frac{k}{c}(z - ax - by),$$

which is equivalent to

$$\left(\frac{c}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}} - k\right)(z - ax - by) \geq \frac{c}{\alpha}\;\frac{\varphi(\xi,\eta) - a\xi - b\eta}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}}.$$

Combining this inequality with the definition of $S(\xi,\eta)$, we get

$$z - ax - by \geq \frac{c\nu_1}{\alpha\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}} \geq \frac{k\nu_1}{\alpha}. \tag{34}$$

Using $\alpha(ax+by) = a\xi + b\eta \le \varphi(\xi,\eta)$, we obtain

$$
\begin{aligned}
U(x,y,z) &- \Phi\left(\frac{k}{c}(z-ax-by)\right) \\
&\ge \Phi\left(\frac{z-ax-by}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}}\right) - \Phi\left(\frac{k}{c}(z-ax-by)\right) + \varepsilon S(\xi,\eta) \\
= \frac{(z-ax-by)S(\xi,\eta)}{c} &\int_0^1 \Phi'\left(\left(\frac{\theta}{\sqrt{1+\varphi_\xi^2+\varphi_\eta^2}} + \frac{k}{c}(1-\theta)\right)(z-ax-by)\right) d\theta \\
&\qquad + \varepsilon S(\xi,\eta) \\
&\qquad\qquad \ge S(\xi,\eta)\left(\varepsilon - \frac{1}{c}\sup_{|\mu|\ge\frac{k\nu_1}{\alpha}}\left|\mu\Phi'\left(\frac{k}{c}\mu\right)\right|\right).
\end{aligned}
$$

By virtue of Lemma 1 and (32) we have

$$
\frac{1}{c}\sup_{|\mu|\ge\frac{k\nu_1}{\alpha}}\left|\mu\Phi'\left(\frac{k}{c}\mu\right)\right| < \frac{\varepsilon}{2}
$$

and obtain

$$
U(x,y,z) - \Phi\left(\frac{k}{c}(z-ax-by)\right) > \frac{\varepsilon}{2}S(\xi,\eta) > 0,
$$

which yields (33). This completes the proof. ∎

Thus U is a supersolution to (5). Now we prove the main assertion.

Proof of Theorem 2. We put

$$
\underline{v}(x,y,z) = \Phi\left(\frac{k}{c}(z-h(x,y))\right) \tag{35}
$$

and consider solutions of (4) given by $w(x,y,z,t;\underline{v})$ and $w(x,y,z,t;U)$. Since U is a supersolution and $\underline{v}$ is a subsolution, we have

$$
\underline{v} \le w(x,y,z,t;\underline{v}) \le w(x,y,z,t;U) \le U
$$

for $(x,y,z)\in\mathbb{R}^3$ and $t\ge 0$ by using [17, Theorem 3.4]. Then

$$
V(x,y,z) \stackrel{\text{def}}{=} \lim_{t\to\infty} w(x,y,z,t;\underline{v}) \tag{36}
$$

exists in $L^\infty(\mathbb{R}^3)$, with

$$
\underline{v}(x,y,z) < V(x,y,z) < U(x,y,z) \qquad \text{in } \mathbb{R}^3.
$$

This $V(x,y,z)$ is a solution of (5). See Sattinger [17, Theorem 3.6] for detailed arguments. Now we have

$$
\underline{v}(x,y,z) < V(x,y,z) < \Phi(\widehat{\mu}) + \varepsilon S.
$$

Now we prove (11). Let ε be arbitrarily given. Let U be as in (29). It suffices to prove

$$\sup_{(x,y,z)\in D(\gamma)} \left(U(x,y,z) - \Phi\left(\frac{k}{c}(z-h(x,y))\right)\right) < 2\varepsilon \tag{37}$$

if $\gamma > 0$ is large enough. Assume the contrary. Then there exists (γ_n) such that we have

$$\lim_{n\to\infty} \gamma_n = \infty, \quad (x_n, y_n, z_n) \in D(\gamma_n), \tag{38}$$

and

$$\left| \Phi(\widehat{\mu}_n) - \Phi\left(\frac{k}{c}(z_n - h(x_n, y_n))\right)\right| \geq \varepsilon. \tag{39}$$

Here we put $\xi_n = \alpha x_n$, $\eta_n = \alpha y_n$, $\zeta_n = \alpha z_n$, and

$$\widehat{\mu}_n = \frac{1}{\alpha} \frac{\zeta_n - \varphi(\xi_n, \eta_n)}{\sqrt{1 + \varphi_\xi(\xi_n,\eta_n)^2 + \varphi_\eta(\xi_n,\eta_n)^2}} = \frac{z_n - h(x_n,y_n) - \frac{1}{\alpha}(\varphi(\xi_n,\eta_n) - h(\xi_n,\eta_n))}{\sqrt{1 + \varphi_\xi(\xi_n,\eta_n)^2 + \varphi_\eta(\xi_n,\eta_n)^2}}.$$

If we have $\lim_{n\to\infty} \operatorname{dist}((\xi_n,\eta_n), E) = \infty$, then we obtain $\lim_{n\to\infty} |\varphi(\xi_n,\eta_n) - h(\xi_n,\eta_n)| = 0$ and $\lim_{n\to\infty} S(\xi_n,\eta_n) = 0$ by applying Lemma 4. Recall $E \stackrel{\text{def}}{=} \cup_{j=1}^n \partial\Omega_j \subset \mathbb{R}^2$. Then we get

$$\lim_{n\to\infty} \left| \widehat{\mu}_n - \frac{k}{c}(z_n - h(x_n,y_n))\right| = 0.$$

This contradicts (39). If $\operatorname{dist}((\xi_n,\eta_n), E)$ remains finite uniformly in n, then (38) implies that $\lim_{n\to\infty}(z_n - h(x_n,y_n)) = \pm\infty$ and $\lim_{n\to\infty} \widehat{\mu}_n = \pm\infty$, respectively. This contradicts (39). This completes the proof of Theorem 2. ∎

4. Application of Theorem 2. In this section we state applications of Theorem 2. Traveling waves in Theorem 2 have a contour line of a pyramidal shape if the normal vectors of lateral surfaces are linearly independent. What is the shape of traveling waves in Theorem 2 if lateral surfaces are linearly dependent? In this section we show an example of such a traveling wave.

LEMMA 8. *Let $h(x,y)$ be given by (9) with (7) and (8). Assume that $h(-x,y) = h(x,y)$ and that at least one A_j is positive. For any fixed y, assume that $h(x,y)$ is nondecreasing for $x > 0$. Then V in Theorem 2 satisfies*

$$V(-x,y,z) = V(x,y,z) \qquad \text{in } \mathbb{R}^3,$$
$$V_x(x,y,z) > 0 \qquad \text{for } x > 0.$$

The same statement holds for y.

Proof. We have $\underline{v}(-x,y,z) = \underline{v}(x,y,z)$ and thus $w(-x,y,z,t;\underline{v}) = w(x,y,z,t;\underline{v})$. Then V given by (36) satisfies $V(-x,y,z) = V(x,y,z)$. We have $(\underline{v})_x(x,y,z) \geq 0$ for $x > 0$. Now $w_x(x,y,z,t;\underline{v})$ satisfies the derivative of (4) by x in $\{(x,y,z)\in\mathbb{R}^3 \mid x > 0\}$ with the Neumann boundary condition $w_x(x,y,z,t;\underline{v}) = 0$ on $\{(x,y,z)\in\mathbb{R}^3 \mid x = 0\}$. Then the comparison principle gives $w_x \geq 0$ and thus $V_x \geq 0$ for $x > 0$. From Theorem 2, $V_x \not\equiv 0$, and thus we get $V_x > 0$. ∎

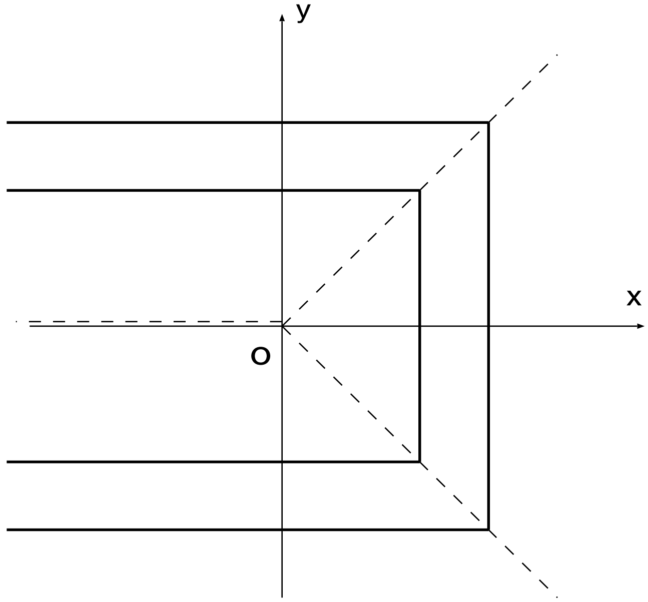

FIG. 4. *The contour lines of* $\tau \max\{x, |y|\}$.

We consider

$$h_1(x, y) = \tau y, \quad h_2(x, y) = -\tau y,$$

and thus $h(x, y) = \tau|y|$. Theorem 2 and its proof are applicable to this case. Then $V(x, y, z)$ as in Theorem 2 equals $v_*(y, z)$, where v_* is as in Theorem 1. The uniqueness follows from that of Theorem 1 in this case. We call this a planar V-form wave.

As an application of Theorem 2 we consider the following example:

$$h_1(x, y) = \tau x, \quad h_2(x, y) = \tau y, \quad h_3(x, y) = -\tau y,$$

and thus

$$h(x, y) = \max_{1 \leq j \leq 3} h_j(x, y) = \tau \max\{x, |y|\}. \tag{40}$$

See Figure 4. The edge lines are given by

$$\begin{aligned} \Gamma_1 &= \{(x, y, z) \,|\, x = y = z, z \geq 0\}, \\ \Gamma_2 &= \{(x, y, z) \,|\, x = -y = z, z \geq 0\}, \\ \Gamma_3 &= \{(x, 0, 0) \,|\, x \leq 0\}. \end{aligned}$$

We have $\Gamma = \cup_{j=1}^{3} \Gamma_j$ and $D(\gamma)$ as in (10).

PROPOSITION 2. *Assume* $c > k$, (A1), (A2), *and* (A3). *Let* $V_1(x, y, z)$ *be a solution of* (5) *as in Theorem* 2 *for* (40). *Then* $V_1(x, y, z)$ *satisfies* $V_1(x, -y, z) = V_1(x, y, z)$ *and*

$$\begin{gathered} 0 \leq V_1(x, 0, 0) \qquad \textit{for all } x \leq 0, \\ (V_1)_z(x, y, z) < 0, \quad (V_1)_x(x, y, z) > 0 \qquad \textit{in } \mathbb{R}^3, \\ (V_1)_y(x, y, z) > 0 \qquad \textit{if } (x, y, z) \in \mathbb{R}^3,\ y > 0. \end{gathered}$$

Proof. We put $v_1^-(x,y,z) \stackrel{\text{def}}{=} \Phi\left((k/c)(z-\tau\max\{x,|y|\})\right)$. It suffices to prove $(V_1)_x > 0$. We have $(v_1^-)_x \geq 0$ in $\mathbb{R}^3$. The comparison principle yields

$$w_x(x,y,z,t;v_1^-) \geq 0, \quad (V_1)_x \geq 0 \qquad \text{in } \mathbb{R}^3.$$

The maximum principle gives $(V_1)_x > 0$. $(V_1)_y > 0$ follows from Lemma 8 for $y > 0$. This completes the proof. ∎

From Theorem 2, $V_1(x,y,z)$ satisfies

$$\lim_{\gamma\to\infty} \sup_{(x,y,z)\in D(\gamma)} \left| V_1(x,y,z) - \Phi\left(\frac{k}{c}(z-\tau\max\{x,|y|\})\right)\right| = 0.$$

If $x < 0$ and $|x|$ is large enough, V_1 has a profile of the planar V-form wave. If $x > 0$ is large, V_1 has a profile of a pyramidal wave. Thus V_1 is a hybrid of them.

5. Generalized pyramidal traveling waves. The lateral surfaces of a pyramid have a common point. As a combination of planar traveling waves associated with the surfaces, we construct a pyramidal traveling wave in Theorem 2. How about if the surfaces have no common point? In this section we treat planes that have no common point and construct a generalized pyramidal traveling wave from a combination of planar traveling waves.

We introduce the following example:

$$\begin{aligned} h_1(x,y) &= \tau x, & h_2(x,y) &= \tau y, \\ h_3(x,y) &= -\tau x, & h_4(x,y) &= -\tau y. \end{aligned}$$

Then we have

$$h(x,y) = \tau\max\{|x|,|y|\}. \tag{41}$$

Let V_2 be a solution as in Theorem 2 for (41). Then Lemma 8 gives

$$\begin{aligned} (V_2)_x(x,y,z) &> 0 \qquad \text{for } x > 0, \\ (V_2)_y(x,y,z) &> 0 \qquad \text{for } y > 0. \end{aligned}$$

Let $U_2(x,y,z)$ be a supersolution as in Lemma 7 for (41). For any given $a \geq 0$, we define

$$\begin{aligned} \widetilde{h}_1(x,y) &= \tau(x-a), & \widetilde{h}_2(x,y) &= \tau y, \\ \widetilde{h}_3(x,y) &= -\tau(x+a), & \widetilde{h}_4(x,y) &= -\tau y, \end{aligned}$$

and

$$\widetilde{h}(x,y;a) \stackrel{\text{def}}{=} \max_{1\leq j\leq 4} \widetilde{h}_j(x,y;a) = \tau\max\{|y|,|x|-a\}. \tag{42}$$

The edges of a pyramid $z = \widetilde{h}(x,y;a)$ are given by

$$\begin{aligned} \widetilde{\Gamma}_1 &= \{(x,y,z) \mid z = \tau(x-a), x-a = y, z \geq 0\}, \\ \widetilde{\Gamma}_2 &= \{(x,y,z) \mid z = \tau y, y = -x-a, z \geq 0\}, \\ \widetilde{\Gamma}_3 &= \{(x,y,z) \mid z = -\tau(x+a), x+a = y, z \geq 0\}, \\ \widetilde{\Gamma}_4 &= \{(x,y,z) \mid z = -\tau y, -y = x-a, z \geq 0\}. \end{aligned}$$

We put $\widetilde{\Gamma} = \cup_{j=1}^4 \widetilde{\Gamma}_j$ and

$$\widetilde{D}(\gamma) \stackrel{\text{def}}{=} \left\{ (x,y,z) \in \mathbb{R}^3 \mid \operatorname{dist}((x,y,z), \widetilde{\Gamma}) > \gamma \right\}.$$

We set

$$v_2^-(x,y,z) \stackrel{\text{def}}{=} \Phi\left(\frac{k}{c}(z - \widetilde{h}(x,y;a))\right) = \max_{1\le j\le 4} \Phi\left(\frac{k}{c}(z - \widetilde{h}_j(x,y;a))\right).$$

Let $w(x,y,z,t;v_2^-)$ be the solution of (4) with an initial condition $w|_{t=0} = v_2^-$. From the comparison principle we obtain

$$v_2^-(x,y,z) < w(x,y,z,t;v_2^-) < U_2(x-x_0,y,z) \tag{43}$$

for any x_0 with $|x_0| \le a$. Thus we get

$$v_2^-(x,y,z) < w(x,y,z,t;v_2^-) \le \inf_{-a\le x_0\le a} U_2(x-x_0,y,z).$$

Then we get the limit function

$$\widetilde{V}(x,y,z) \stackrel{\text{def}}{=} \lim_{t\to\infty} w(x,y,z,t;v_2^-) \qquad \text{in } C^2_{\text{loc}}(\mathbb{R}^3).$$

This satisfies (5). See Sattinger [17] for the general arguments. For every $x_0 \in [-a,a]$ we have

$$\widetilde{h}(x,y;a) \le \tau \max\{|y|, |x-x_0|\}$$

and thus

$$v_2^-(x,y,z) \le \Phi\left(\frac{k}{c}(z - \tau\max\{|y|,|x-x_0|\})\right).$$

We consider each side as an initial function of (4) and send $t \to \infty$. Then we get

$$\Phi\left(\frac{k}{c}(z - \tau\max\{|y|,|x|-a\})\right) < \widetilde{V}(x,y,z) < V_2(x-x_0,y,z).$$

The strict inequality follows from the strong maximum principle. See Figure 5.

THEOREM 3. *Assume $c > k$, (A1), (A2), and (A3). Let V_2 be the solution of (5) in Theorem 2 for $h(x,y) = \tau\max\{|x|,|y|\}$. There exists a solution $\widetilde{V}(x,y,z)$ to (5) with*

$$\Phi\left(\frac{k}{c}(z - \tau\max\{|y|,|x|-a\})\right) < \widetilde{V}(x,y,z) < \inf_{-a\le x_0\le a} V_2(x-x_0,y,z)$$

and

$$(\widetilde{V})_z(x,y,z) < 0 \qquad \text{in } \mathbb{R}^3.$$

$\widetilde{V}$ satisfies $\widetilde{V}(-x,y,z) = \widetilde{V}(x,y,z)$, $\widetilde{V}(x,-y,z) = \widetilde{V}(x,y,z)$, and

$$(\widetilde{V})_x(x,y,z) > 0 \qquad \text{for } x > 0,$$
$$(\widetilde{V})_y(x,y,z) > 0 \qquad \text{for } y > 0.$$

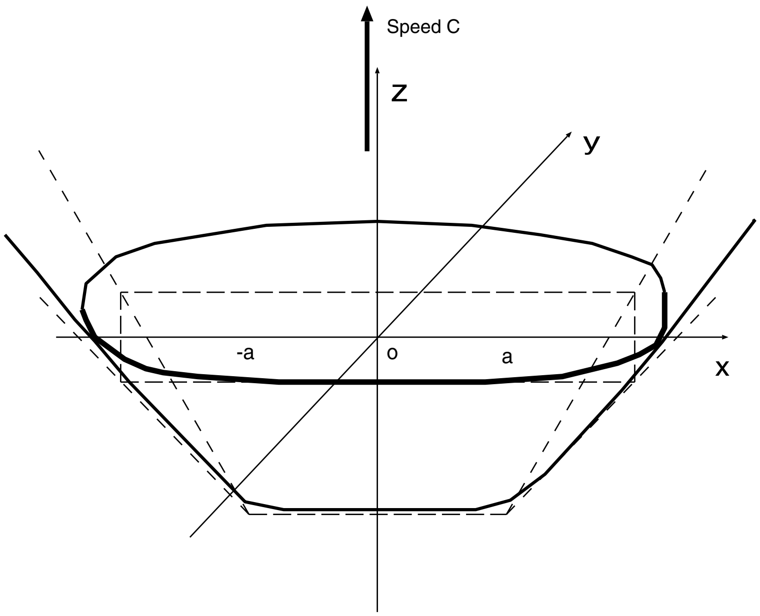

FIG. 5. *A generalized pyramidal traveling wave.*

Moreover

$$\lim_{\gamma\to\infty} \sup_{(x,y,z)\in D(\gamma)} \left| \widetilde{V}(x,y,z) - \Phi\left(\frac{k}{c}(z - \widetilde{h}(x,y;a))\right) \right| = 0$$

holds true.

Proof. Since $(v_2^-)_z \le 0$, we get $w_z(x,y,z,t;v_2^-) \le 0$ and also get $(\widetilde{V})_z < 0$. Lemma 8 and the proof are applicable to $\widetilde{h}(x,y;a)$. Thus we get $(\widetilde{V})_x > 0$ for $x > 0$ and $(\widetilde{V})_y > 0$ for $y > 0$. The asymptotic property of $\widetilde{V}(x,y,z)$ follows from that of V_2 in Theorem 2. ◻

This $\widetilde{V}(x,y,z)$ is a generalized pyramidal traveling wave. The method of this section might be applicable to a general case. The classification of all generalized pyramidal waves will give interesting problems.

6. Traveling fronts for balanced bistable nonlinearity. In this section we study traveling waves for balanced nonlinearity. Recently Chen et al. [3] constructed two-dimensional traveling waves and n-dimensional cylindrically symmetric traveling waves for balanced nonlinearity. They constructed such traveling waves as the limit of traveling waves for an unbalanced nonlinearity term when the difference of the energy density goes to zero.

Now we construct traveling waves for balanced nonlinearity by taking the limit of pyramidal traveling waves for unbalanced nonlinearity terms when the difference of the energy density goes to zero.

We consider (2) with a balanced nonlinear term $-G'(u)$. Let $c > 0$ be arbitrarily fixed. We study (13) in section 1. We define

(44) $$\mathcal{L}_\delta[v] \stackrel{\text{def}}{=} -v_{xx} - v_{yy} - v_{zz} - cv_z - f_\delta(v) = 0 \quad \text{in } \mathbb{R}^3$$

for any δ with $0 < \delta < 1$, where

$$f_\delta(v) \stackrel{\text{def}}{=} -G'(v) + \delta c\sqrt{2G(v)}.$$

Putting $k = \delta c$, we see that $\Phi_0(\mu)$ given by (3) satisfies (1). Let $V_\delta(x,y,z)$ be a solution of (44) as in Theorem 2 for

$$h_\delta(x,y) = \frac{\sqrt{1-\delta^2}}{\delta}\max\{|x|,|y|\}.$$

We fix $\lambda_1 \in (-1,1)$, with $G'(\lambda_1) < 0$. Let $z_1(\delta)$ be defined by

$$V_\delta(0,0,z_1(\delta)) = \lambda_1. \tag{45}$$

We construct a solution of (13) as the limit of $V_\delta(x,y,z+z_1(\delta))$.

PROPOSITION 3. *Assume* (B1) *and* (B2). *Let $c > 0$ be arbitrarily fixed. Let $V_\delta(x,y,z)$ be a solution of* (44) *as in Theorem* 2 *for $h_\delta(x,y) = (\sqrt{1-\delta^2}/\delta)\max\{|x|,|y|\}$. There exists $1 > \delta_1 > \delta_2 > \cdots > \delta_i > \cdots \to 0$ so that one has*

$$\lim_{i\to\infty} V_{\delta_i}(x,y,z+z_1(\delta_i)) = V_*(x,y,z) \quad \text{in } C^2_{\text{loc}}(\mathbb{R}^3).$$

This solution V_* satisfies $V_*(0,0,0) = \lambda_1$ and

$$\mathcal{L}_0[V_*] = 0, \quad (V_*)_z < 0 \qquad \text{in } \mathbb{R}^3.$$

Proof. We denote $V_{\delta_i}(x,y,z+z_1(\delta_i))$ simply by $v_i(x,y,z)$. Let $B(N)$ be a closed ball defined by

$$B(N) \stackrel{\text{def}}{=} \left\{(x,y,z) \mid \sqrt{x^2+y^2+z^2} \le N\right\}$$

for $N \in \mathbb{N}$. For any fixed N, $v_i(x,y,z)$ satisfies

$$\mathcal{L}[v_i] = 0, \quad -1 < v_i < 1 \qquad \text{in } B(N).$$

For any $p > 1$, (v_i) is bounded in $L^p(B(N))$. The Schauder interior estimates [6, Theorem 9.11] imply that

$$\sup_i \|v_i\|_{W^{2,p}(B(N))} < \infty.$$

We take p so large as to get $1 - 3/p > \beta > 0$. Then $W^{2,p}(B(N))$ is compactly embedded in $C^{1,\beta}(\overline{B(N)})$. By taking a subsequence (v_i) converges in $C^{1,\beta}(\overline{B(N)})$ as $i \to \infty$. Applying the Schauder interior estimates [6, Corollary 6.3] again, we find that (v_i) converges in $C^{2,\beta}(\overline{B(N)})$. By the diagonal argument we find a subsequence (v_i) that converges in $C^{2,\beta}_{\text{loc}}(\mathbb{R}^3)$. Let V_* be the limit function. Then it satisfies (13). Since $(v_i)_z < 0$ in $\mathbb{R}^3$, we have $(V_*)_z \le 0$ in $\mathbb{R}^3$. From Lemma 8 we have $(v_i)_{xx}(0,0,0) \ge 0$ and $(v_i)_{yy}(0,0,0) \ge 0$ and thus $(V_*)_{xx}(0,0,0) \ge 0$ and $(V_*)_{yy}(0,0,0) \ge 0$. If $(V_*)_z \equiv 0$, we obtain a contradiction by $G'(\lambda_1) < 0$ and $\mathcal{L}_0[V_*] = 0$ at the origin. By the strong maximum principle, we get $(V_*)_z < 0$ in $\mathbb{R}^3$. ∎

This V_* might inherit pyramidal structures, or it might not. This problem is yet to be studied. If we replace $h_\delta(x,y)$ by $(\sqrt{1-\delta^2}/\delta)\max_{1\le j\le n}(A_jx + B_jy)$ with (7) and (8), we get the associated limit traveling waves from the argument stated above and also find interesting open problems. The classification and the stability of all traveling waves for unbalanced and balanced nonlinearity have a wide variety of unknown problems and are left for further studies.

Acknowledgments. The author thanks Professor Hirokazu Ninomiya of Ryukoku University for many stimulating and valuable discussions. Special thanks go to the referees, who carefully read the manuscript and gave important and useful comments and suggestions.

SELF-SIMILAR SOLUTIONS TO THE OORT–HULST–SAFRONOV COAGULATION EQUATION*

VÉRONIQUE BAGLAND† AND PHILIPPE LAURENÇOT‡

Abstract. The existence of self-similar solutions with a finite first moment is established for the Oort–Hulst–Safronov coagulation equation when the coagulation kernel is given by $a(y, y_*) = y^\lambda + y_*^\lambda$ for some $\lambda \in (0, 1)$. The corresponding self-similar profiles are compactly supported and have a discontinuity at the edge of their support.

Key words. coagulation equation, Oort–Hulst–Safronov model, self-similar solution, compact support

1. Introduction.

Coagulation models provide a mean-field description of particle growth, the particles increasing their size as a consequence of successive binary mergers. Assuming the particles to be fully identified by their size, the resulting equations determine the dynamics of the size distribution function $g(t, v) \geq 0$ of particles of size $v \in \mathbb{R}_+ := (0, \infty)$ at time $t \geq 0$. Of particular interest are the predictions concerning the large time behavior of the size distribution of the particles which can be drawn from these models. It is actually commonly expected that, for coagulation kernels with a moderate growth for large sizes, the size distribution function g should approach a mass-conserving self-similar function g_s for large times; that is,

$$g(t, v) \sim g_s(t, v) = \frac{1}{s(t)^2}\, \xi\left(\frac{v}{s(t)}\right) \quad \text{as} \quad t \to \infty, \tag{1.1}$$

where $s(t)$ denotes the mean particle size at time $t > 0$ and ξ is a nonnegative function in $L^1(\mathbb{R}_+, vdv)$ (see the extensive discussion in [4, 19] for Smoluchowski's coagulation equation [24, 25]). However, the validity of the dynamical scaling hypothesis (1.1) has up to now mainly been checked by numerical simulations [7, 14, 18] and is not yet established rigorously (except in a few particular cases, [2, 13, 16, 17, 20]). The first difficulty encountered is actually the existence of the profile ξ, and such a result has been obtained only recently for Smoluchowski's coagulation equation [6, 8]. The aim of the present paper is to investigate the existence of self-similar solutions for another coagulation equation which has been proposed in astrophysics by Oort and van de Hulst [21] and Safronov [22] in order to describe the aggregation of stellar objects.

More precisely, the Oort–Hulst–Safronov (OHS) equation reads

$$\partial_t g = Q_{OHS}(g), \quad (t,v) \in (0,\infty)^2, \tag{1.2}$$

$$Q_{OHS}(g)(v) := -\partial_v \left(\int_0^v v_*\ a(v,v_*)\ g(v_*)\ dv_*\ g(v) \right)$$

$$- \int_v^\infty a(v,v_*)\ g(v_*)\ dv_*\ g(v), \tag{1.3}$$

$$g(0) = g_0, \tag{1.4}$$

where the coagulation kernel a is a nonnegative and symmetric function. On one hand, the first term on the right-hand side of (1.3) describes the formation of clusters of size v from smaller clusters with the growth rate

$$\int_0^v v_*\ a(v,v_*)\ g(v_*)\ dv_*$$

which does not depend on the sizes of the clusters involved in the coagulation reaction but on the size distribution of the small clusters. On the other hand, the second term on the right-hand side of (1.3) accounts for the disappearance of clusters of size v by "sedimentation" on larger clusters. Let us mention at this point that a solution to (1.2), (1.4) is expected to satisfy the conservation of mass

$$\int_0^\infty v\ g(t,v)\ dv = \int_0^\infty v\ g_0(v)\ dv \quad \text{for} \quad t \geq 0, \tag{1.5}$$

a property which holds true if a does not grow too fast for large values of v and v_*. For the coagulation kernels we consider in this paper, the weak solutions constructed in [15] enjoy the mass conservation property.

For a homogeneous coagulation kernel satisfying

$$a(uv, uv_*) = u^\lambda a(v,v_*), \qquad (u,v,v_*) \in (0,\infty)^3,$$

for some $\lambda \in (-\infty, 1)$, it is rather natural to expect that the self-similar function g_s is in fact a self-similar solution to (1.2). Inserting the self-similar ansatz (1.1) in (1.2), we obtain $s(t) := (w(1-\lambda)t)^{1/(1-\lambda)}$, while ξ satisfies

$$w\,[y\,\partial_y \xi(y) + 2\,\xi(y)] + Q_{OHS}(\xi)(y) = 0, \qquad y \in (0,\infty), \tag{1.6}$$

for some positive constant w. In addition, in view of (1.5), we require that $\xi \in L^1(0,\infty; y\,dy)$ with

$$\int_0^\infty \xi(y)\,y\,dy = \varrho \tag{1.7}$$

for some positive constant ϱ. We first observe that, if ξ is a solution to (1.6), (1.7) for the parameters (w,ϱ), then the function $\xi_{A,B}$ defined by $\xi_{A,B}(y) = A\ \xi(B\,y)$, $A > 0$, $B > 0$, is a solution to (1.6), (1.7) for $\left(w\ A\ B^{-(1+\lambda)}, \varrho\ A\ B^{-2}\right)$. Choosing

$$A = \frac{1}{\varrho}\ \left(\frac{\varrho}{w\,(1-\lambda)}\right)^{2/(1-\lambda)}, \qquad B = \left(\frac{\varrho}{w\,(1-\lambda)}\right)^{1/(1-\lambda)},$$

then the function $\xi_{A,B}$ is a solution to (1.6), (1.7) for $(1/(1-\lambda), 1)$. We therefore may assume without loss of generality that

$$w = \gamma := 1/(1-\lambda) \qquad \text{and} \qquad \varrho = 1.$$

From now on, we assume further that the coagulation kernel is given by

$$a(y,y_*) = y^\lambda + y_*^\lambda, \quad (y,y_*) \in (0,\infty)^2, \tag{1.8}$$

for some $\lambda \in (0,1)$ and prove the following result.

Theorem 1.1. *There exists a nonnegative function $\xi \in L^1(0,\infty;(y+y^\lambda)\ dy)$, $y_0 \in (0,\infty)$, and $q \in (0,\infty)$ such that*

$$\int_0^\infty y\ \xi(y)\ dy = 1, \quad M_\lambda := \int_0^\infty y^\lambda\ \xi(y)\ dy \in (1,\gamma), \tag{1.9}$$

$$\xi \in \mathcal{C}((0,\infty)\setminus\{y_0\}) \quad \textit{with} \quad \mathrm{Supp}\ \xi = [0,y_0] \quad \textit{and} \quad \xi(y_0-) > 0, \tag{1.10}$$

$$\lim_{y\to 0} y^\tau\ \xi(y) = q \quad \textit{with} \quad \tau := 2 - \frac{M_\lambda}{\gamma} \in (1,1+\lambda) \quad \textit{and} \quad \gamma = \frac{1}{1-\lambda}, \tag{1.11}$$

and satisfying

$$\left(\gamma\ y - \int_0^y \left(y^\lambda + y_*^\lambda\right)\ y_*\ \xi(y_*)\ dy_*\right)\ \xi(y) = \left(\gamma - \int_y^\infty y_*^\lambda\ \xi(y_*)\ dy_*\right)\ \int_y^\infty \xi(y_*)\ dy_* \tag{1.12}$$

for $y \in (0,y_0)$.

We first note that (1.12) is in fact a weak formulation of (1.6) but that ξ satisfies (1.6) in $(0,y_0)$ and (y_0,∞). Next, on one hand, we point out that the profile ξ has a singularity at $y=0$ and is actually not integrable near $y=0$ by (1.11): a similar property is enjoyed by the profile of self-similar solutions to Smoluchowski's coagulation equation (see [4, 19] for formal arguments and [5, 9] for a rigorous proof). By the way, the exponent of the singularity of ξ can be predicted by formal computations similar to the ones done for the Smoluchowski coagulation equation [4, 19]. On the other hand, a striking difference between the profiles of self-similar solutions to the OHS and Smoluchowski coagulation equations is that the former are compactly supported with a discontinuity at the edge of the support while the latter belong to $\mathcal{C}^1((0,\infty))$ with infinite support [9]. Such a difference had already been noticed for the constant coagulation kernel ($a \equiv 1$), for which self-similar profiles to Smoluchowski's coagulation equation are explicitly given by $y \mapsto (4/\varrho)\ e^{-2y/\varrho}$ [4, 19], while self-similar profiles to (1.2) are also explicit and given by $y \mapsto (2/\varrho)\mathbf{1}_{[0,\varrho]}(y)$ [16].

The function ξ constructed in Theorem 1.1 allows us to construct a self-similar solution to (1.2) (in a weak sense).

Corollary 1.2. *Let ξ be the function constructed in Theorem* 1.1 *and put*

$$g_s(t,v) := t^{-2\gamma}\ \xi\left(vt^{-\gamma}\right), \qquad (t,v) \in (0,\infty)^2.$$

Then g_s is a weak solution to (1.2)*, that is,*

$$\begin{aligned}&\frac{d}{dt}\int_0^\infty g_s(t,v)\ \vartheta(v)\ dv \\ &\quad = \int_0^\infty \int_0^v \left(v_*\ \partial_v\vartheta(v) - \vartheta(v_*)\right)\ \left(v^\lambda + v_*^\lambda\right)\ g_s(t,v_*)\ g_s(t,v)\ dv_* dv\end{aligned}$$

for every $t \in (0,\infty)$ and $\vartheta \in \mathcal{C}_0^\infty((0,\infty))$. In addition, for $t > 0$,

$$\int_0^\infty v\ g_s(t,v)\ dv = \int_0^\infty v\ \xi(v)\ dv = 1.$$

Remark 1.3. More generally, given $w > 0$ and $\varrho > 0$, the function

$$(t,v) \longmapsto \frac{1}{s_w(t)^2}\ A\ \xi\left(\frac{B\ v}{s_w(t)}\right)$$

with

$$s_w(t) := (w(1-\lambda)t)^{1/(1-\lambda)}, \quad A := \varrho\ \left(\frac{w(1-\lambda)}{\varrho}\right)^{2/(1-\lambda)}, \quad B = \left(\frac{w(1-\lambda)}{\varrho}\right)^{1/(1-\lambda)},$$

is also a weak (self-similar) solution to (1.2) in the sense of Corollary 1.2 with a first moment equal to ϱ for each $t > 0$. Observe that all the profiles $y \mapsto A\xi(By)$ of these self-similar solutions have the same singular behavior as $y \to 0$. In particular, it does not depend on the parameter ϱ.

Owing to the nonintegrability of ξ, $v \longmapsto g_s(t,v)$ does not belong to $L^1(\mathbb{R}_+)$ for $t > 0$ and actually solves (1.2) in a weaker sense than the solutions constructed in [15]. Since $g_s(t)$ has a finite moment of order λ for each $t > 0$, the above formulation actually makes sense for any test function $\vartheta \in \mathcal{C}^1(\mathbb{R}_+)$ such that $|\partial_v\vartheta(v)| \le C\ v^{\lambda-1}$ and $\vartheta(0) = 0$. In fact, in view of the well-posedness results obtained recently for the Smoluchowski coagulation equation [10], it is likely that the existence of (weak) solutions can be shown for nonnegative initial data in $L^1(\mathbb{R}_+, v^\lambda dv)$.

To prove Theorem 1.1, we use a dynamical approach as in [6, 8, 11] relying on the fact that finding profiles ξ that satisfy (1.6), (1.7) amounts to finding steady states to

$$\partial_t f = \gamma\ \ (y\ \partial_y f + 2\ f) + Q_{OHS}(f), \quad (t,y) \in \mathbb{R}_+^2. \tag{1.13}$$

To this aim, we recall the following result.

THEOREM 1.4. *Let X be a locally convex topological vector space and K be a nonempty compact and convex subset of X. If $\mathcal{F}\ : [0,\infty)\times K \to X$ is a semiflow on X for which $\mathcal{F}(t,K) \subset K$ for each $t \ge 0$, then there is $x_0 \in K$ such that $\mathcal{F}(t,x_0) = x_0$ for each $t \ge 0$. In other words, x_0 is a steady state for the semiflow $\mathcal{F}$ in K.*

The proof of Theorem 1.4 relies on the Tychonov–Schauder fixed point theorem (or Brouwer fixed point theorem if $\dim X < \infty$) [1, 6, 11]. For the sake of completeness, the proof of Theorem 1.4 is given in Appendix A.

Applying Theorem 1.4 thus requires finding a functional setting in which (1.13) is well-posed and possesses a compact and convex invariant set as well. The existence of mass-conserving weak solutions to (1.2), (1.4) in $L^1(\mathbb{R}_+, (1+v)\ dv)$ has been established in [15]: noting that, if f is a solution to (1.13), (1.4), then

$$g(t,v) = \frac{1}{(1+t)^{2\gamma}}\ f\left(\ln(1+t), \frac{v}{(1+t)^\gamma}\right)$$

is a solution to (1.2), (1.4), we thus also obtain weak solutions to (1.13), (1.4) in the same functional setting. However, since the function ξ constructed in Theorem 1.1 does not belong to $L^1(\mathbb{R}_+)$, and g_s defined in Corollary 1.2 is not a weak solution to (1.2) in the sense of [15], we thus have to find a more appropriate functional setting. Furthermore, as far as uniqueness and continuous dependence are concerned, it turns out that it is more convenient to construct a semiflow in $L^1(\mathbb{R}_+)$ for the cumulative distribution function F defined by

$$F(t,y) = \int_y^\infty f(t,y_*)\,dy_*, \qquad (t,y) \in \mathbb{R}_+^2.$$

But at this point another serious difficulty to be bypassed arises: indeed, for each $r > 0$, $\gamma\ r^{-\lambda}\ \delta_{y=r}$ is a measure-valued stationary solution to (1.13), $\delta_{y=r}$ denoting the Dirac measure at $y = r$. A consequence of this remark and Theorem 1.1 is that (1.12) has singular (measure-valued) and "regular" solutions. As the singular ones are explicit, our aim is to construct a "regular" solution, and thus the functional setting to be used must exclude the singular solutions. Unfortunately, we have been unable to find a suitable functional framework for either f or F in which the application of Theorem 1.4 warrants the existence of a "regular" solution to (1.12).

One difference between the singular solutions $\gamma\ r^{-\lambda}\ \delta_{y=r}$, $r > 0$ and the "regular" solutions we are looking for is that the latter are expected to have an invertible primitive while the primitive of the former has only a generalized inverse. This property leads us to study the inverse function $\Phi(t,.)$ of $F(t,.)$, hoping that a similar difficulty will not show up with this alternative formulation. Formally, Φ is a solution to

$$\begin{aligned}\partial_t\Phi(t,x) &= -\gamma\ \left(x\ \partial_x\Phi(t,x)+\Phi(t,x)\right)+x\ \left(\int_0^x \Phi(t,x_*)^\lambda\ dx_*\right)\ \partial_x\Phi(t,x)\\ &\quad+\int_x^\infty \left(\Phi(t,x)^\lambda+\Phi(t,x_*)^\lambda\right)\ \Phi(t,x_*)\ dx_*. \end{aligned}\tag{1.14}$$

A weak stationary solution Ψ to (1.14) then solves

$$x\ \left(\gamma-\int_0^x \Psi(x_*)^\lambda\ dx_*\right)\ \Psi(x)=\int_x^\infty\int_0^x \left(\Psi(x_*)^\lambda+\Psi(x')^\lambda\right)\ \Psi(x_*)\ dx'dx_*$$

for $x > 0$ and this equation has no solution of the form $A\ \mathbf{1}_{[0,B]}$.

A natural functional setting for the well-posedness of (1.14) is the set

$$K_R := \left\{\begin{array}{l} U\ \in\ L^1(0,\infty) \text{ is a nonnegative and nonincreasing function such that}\\ \|U\|_1=1,\ \|U\|_\infty\le R \text{ and } \|U^\lambda\|_1\le R \end{array}\right\},$$

which is also invariant for sufficiently large R. Unfortunately, K_R is not convex since $\lambda \in (0,1)$. Therefore we cannot use Theorem 1.4, and this leads us to introduce the following modified equation:

$$\begin{aligned}\partial_t\Phi(t,x) &= -\gamma\ \left(x\ \partial_x\Phi(t,x)+\Phi(t,x)\right)+x\ \left(\int_0^x \Phi(t,x_*)^\lambda\ dx_*+\delta x\right)\ \partial_x\Phi(t,x)\\ &\quad+\int_x^\infty \left(\Phi(t,x)^\lambda+\Phi(t,x_*)^\lambda+2\delta\right)\ \Phi(t,x_*)\ dx_*, \end{aligned}\tag{1.15}$$

where $\delta \in (0,1)$. Let us mention at this point that (1.15) can be obtained from (1.13) with the coagulation kernel $a_\delta(y,y_*) = y^\lambda + y_*^\lambda + 2\delta$ by the same procedure as (1.14). We then investigate the existence of steady states to (1.15). For that purpose, we first study in section 2 the well-posedness of (1.15) supplemented with the initial condition

$$\Phi(0,x)=\Phi_0(x).\tag{1.16}$$

We then determine in section 3 a compact and convex set which is left invariant by the semiflow induced by (1.15), (1.16). The existence of a stationary solution to (1.15) then follows by applying Theorem 1.4. We obtain a stationary solution to (1.14) by letting $\delta \to 0$. Section 4 is then devoted to the analysis of the smoothness of this stationary solution. The proof of Theorem 1.1 is carried out in section 5.

Remark 1.5. As a final comment, let us point out that Theorem 1.1 and Corollary 1.2 are only a first step towards the study of the validity of the *dynamical scaling hypothesis* (1.1). Indeed, our analysis shows the existence of at least one self-similar solution with a first moment being constant through time evolution and equal to ϱ for each $\varrho > 0$ (see Remark 1.3) but we do not have any clue concerning the stability of this solution. A related open question is the uniqueness of the profile ξ given by Theorem 1.1 (in the class of functions).

Finally, we introduce some notations: for any $u, v \in \mathbb{R}$, we define

$$\begin{aligned} u \wedge v &= \min\{u,v\}, \qquad u \vee v = \max\{u,v\}, \\ u_+ &= \max\{u,0\}, \qquad \operatorname{sign}_+(u) = \operatorname{sign}(u_+). \end{aligned}$$

For any $p \in [1,\infty]$ and $\zeta \in L^p(0,\infty)$, we set

$$\|\zeta\|_p = \|\zeta\|_{L^p(0,\infty)}.$$

2. Well-posedness of (1.15), (1.16). In this section we prove the following theorem.

THEOREM 2.1. *Assume that*

$$\begin{cases} \Phi_0 \in L^\infty(\mathbb{R}_+) \text{ is a nonnegative and nonincreasing compactly supported function} \\ \text{such that } Supp\ \Phi_0 \subset [0,R_0] \text{ for some } R_0 > 0. \end{cases} \tag{2.1}$$

Then there is a unique function $\Phi \in \mathcal{C}([0,\infty); L^1(0,\infty))$ such that

- *$\Phi(t,.)$ is nonnegative and nonincreasing with compact support in $[0, e^{\gamma t} R_0]$,*
- *$\|\Phi(t)\|_1 = \|\Phi_0\|_1$ and $\Phi \in L^\infty((0,t)\times(0,\infty))$,*

and Φ satisfies (1.15) *in the following weak sense:*

$$\begin{aligned} &\frac{d}{dt}\int_0^\infty \Phi(t,y)\ \vartheta(y)\ dy \\ &\quad = \int_0^\infty \partial_y\vartheta(y)\ \left(\gamma\ y - \delta\ y^2 - y\int_0^y \Phi(t,y_*)^\lambda\ dy_*\right)\ \Phi(t,y)\ dy \\ &\quad - \int_0^\infty \partial_y\vartheta(y)\ \int_y^\infty\int_0^y \left(\Phi(t,y_*)^\lambda + \Phi(t,y')^\lambda + 2\delta\right)\ \Phi(t,y_*)\ dy' dy_*\ dy \end{aligned} \tag{2.2}$$

for every $t \geq 0$ and $\vartheta \in \mathcal{C}_0^\infty((0,\infty))$.

Before proving Theorem 2.1, we first observe that, if φ is a weak solution to

$$\begin{aligned} \partial_t\varphi(t,x) &= x\ \left(\int_0^x \varphi(t,x_*)^\lambda\ dx_* + \delta x(1+t)^{\lambda\gamma}\right)\ \partial_x\varphi(t,x) \\ &\quad + \int_x^\infty \left(\varphi(t,x)^\lambda + \varphi(t,x_*)^\lambda + 2\delta(1+t)^{\lambda\gamma}\right)\ \varphi(t,x_*)\ dx_*, \end{aligned} \tag{2.3}$$

$$\varphi(0,x) = \Phi_0(x), \tag{2.4}$$

then the function Φ defined by

$$\Phi(t,x) = e^{-\gamma t}\varphi(e^t - 1, e^{-\gamma t}x), \qquad (t,x) \in (0,\infty)^2, \tag{2.5}$$

is a weak solution to (1.15), (1.16).

We now consider the existence part of Theorem 2.1 and show that there exists a weak solution to (2.3), (2.4). It then implies the existence of a weak solution to (1.15), (1.16) by (2.5).

Remark 2.2. Formally, if Φ is the solution to (1.15), (1.16) given by Theorem 2.1, then $\tilde{f}(t,.) = -\frac{d}{dy}\Phi(t,.)^{-1}$ is a solution to (1.13) with coagulation kernel $a_\delta(y,y_*) = y^\lambda + y_*^\lambda + 2\delta$ and vice versa. A rigorous justification of this fact does not seem to be obvious and prevents us from using [15] to prove the existence part of Theorem 2.1.

2.1. The regularized problem. We first investigate a regularized problem and prove the existence of a solution by the method of characteristics. Let $\varepsilon > 0$, $R > 1$, and $\chi_R \in \mathcal{C}^1(\mathbb{R}_+)$ be such that

$$\chi_R(x) = \begin{cases} x & \text{if} \quad x \le R+1, \\ 2R & \text{if} \quad x \ge 4R, \end{cases}$$

and

$$0 \le \chi_R(x) \le 2R, \qquad 0 \le \chi_R'(x) \le 1 \qquad \text{for} \quad x \ge 0.$$

We consider the following equation:

$$\begin{aligned} \partial_t\varphi(t,x) = {} & x \left(\int_0^x \mathcal{R}_\varepsilon(\varphi(t,x_*))\, dx_* + \delta\,(1+t)^{\lambda\gamma}\chi_{R_0}(x) \right) \partial_x\varphi(t,x) \\ & + \int_x^\infty \left(\mathcal{R}_\varepsilon(\varphi(t,x)) + \mathcal{R}_\varepsilon(\varphi(t,x_*)) + 2\,\delta\,(1+t)^{\lambda\gamma} \right) \varphi(t,x_*)\, dx_*, \end{aligned} \tag{2.6}$$

$$\varphi(0,x) = \Phi_0(x), \tag{2.7}$$

where the initial condition Φ_0 fulfills (2.1) (R_0 is given in (2.1)) and

$$\mathcal{R}_\varepsilon(z) := (\varepsilon + z)^\lambda - \varepsilon^\lambda, \qquad z \in \mathbb{R}_+$$

is a $\mathcal{C}^1$-smooth approximation of $z \mapsto z^\lambda$. In particular, $\mathcal{R}_\varepsilon$ enjoys the following properties:

$$0 \le \mathcal{R}_\varepsilon(z) \le \left(\lambda\,\varepsilon^{\lambda-1}\,z\right) \wedge z^\lambda, \qquad |\mathcal{R}_\varepsilon(z) - \mathcal{R}_\varepsilon(z_*)| \le \lambda\,\varepsilon^{\lambda-1}|z-z_*|, \quad (z,z_*) \in \mathbb{R}_+^2. \tag{2.8}$$

We now establish the existence of a solution to (2.6), (2.7) by a fixed point method. Let M, C_1, L_1, and T_ε be four positive real numbers, the values of which we will specify later. We denote by $\mathcal{H}_\varepsilon$ the set of nonnegative functions $h \in \mathcal{C}([0,T_\varepsilon]; L^1(0,\infty))$ such that, for every $t \in [0,T_\varepsilon]$,

- $h(t,.)$ is nonincreasing with compact support $\operatorname{Supp} h(t,.) \subset [0,R_0]$,
- $\|h(t)\|_\infty \le M$, $\|h(t)\|_1 \le C_1$, and $|h(t,x) - h(t,x_*)| \le L_1|x-x_*|$ for every $(x,x_*) \in \mathbb{R}_+^2$.

For $h \in \mathcal{H}_\varepsilon$, we consider the following transport equation:

$$\partial_t\varphi(t,x) + A_h(t,x)\,\partial_x\varphi(t,x) = B_h(t,x), \tag{2.9}$$

where

$$\begin{aligned} A_h(t,x) &= -x \int_0^x \mathcal{R}_\varepsilon(h(t,x_*))\, dx_* - \delta\, x\,(1+t)^{\lambda\gamma}\chi_{R_0}(x), \\ B_h(t,x) &= \int_x^\infty \left(\mathcal{R}_\varepsilon(h(t,x)) + \mathcal{R}_\varepsilon(h(t,x_*)) + 2\,\delta\,(1+t)^{\lambda\gamma} \right) h(t,x_*)\, dx_*. \end{aligned}$$

Since $h(t,.)$ is nonincreasing for every $t \in [0,T_\varepsilon]$, we have

$$x\,h(t,x) \le \int_0^x h(t,x_*)\,dx_*, \qquad (t,x) \in [0,T_\varepsilon] \times (0,\infty). \tag{2.10}$$

Owing to (2.8) and (2.10), A_h and B_h enjoy the following properties.

LEMMA 2.3. *For $h \in \mathcal{H}_\varepsilon$, A_h is continuous on $[0,T_\varepsilon]\times[0,\infty)$ and, for every $(t,x)\in[0,T_\varepsilon]\times[0,\infty)$, we have*

$$-x\,\lambda\,\varepsilon^{\lambda-1}\,C_1 - 2\,\delta\,R_0\,x\,(1+T_\varepsilon)^{\lambda\gamma} \le\ A_h(t,x)\ \le 0,$$
$$-2\,\lambda\varepsilon^{\lambda-1}C_1 - 6\,\delta\,R_0\,(1+T_\varepsilon)^{\lambda\gamma} \le \partial_x A_h(t,x) \le 0.$$

Moreover, $B_h(t,.)$ is a nonincreasing function with compact support in $[0,R_0]$ for every $t\in[0,T_\varepsilon]$ and

$$0\ \le\ B_h(t,x) \le 2\,\left(M^\lambda + \delta\,(1+T_\varepsilon)^{\lambda\gamma}\right)\,C_1, \qquad (t,x)\in[0,T_\varepsilon]\times[0,\infty).$$

We then construct the characteristic curves associated with (2.9): for $h\in\mathcal{H}_\varepsilon$, $t\in[0,T_\varepsilon]$, and $x\in[0,\infty)$, it follows from the continuity of A_h and the boundedness of $\partial_x A_h$ established in Lemma 2.3 and the Cauchy–Lipschitz theorem that the ordinary differential equation

$$\frac{dX}{ds}(s;t,x) = A_h(s,X(s;t,x)), \tag{2.11}$$
$$X(t;t,x) = x, \tag{2.12}$$

has a unique global solution $X(.;t,x)\in\mathcal{C}^1([0,T_\varepsilon];\mathbb{R})$. Furthermore, Lemma 2.3 warrants that

$$x\,e^{-(\lambda\varepsilon^{\lambda-1}C_1+2\,\delta\,R_0\,(1+T_\varepsilon)^{\lambda\gamma})(s-t)} \le X(s;t,x)\le x \quad \text{for} \quad s\in[t,T_\varepsilon], \tag{2.13}$$
$$x\le X(s;t,x)\le x\,e^{(\lambda\varepsilon^{\lambda-1}C_1+2\,\delta\,R_0\,(1+T_\varepsilon)^{\lambda\gamma})(t-s)} \quad \text{for} \quad s\in[0,t]. \tag{2.14}$$

PROPOSITION 2.4. *Consider $\Phi_0\in W^{1,\infty}(\mathbb{R}_+)$ satisfying* (2.1) *and $h\in\mathcal{H}_\varepsilon$. Setting*

$$\varphi(t,x) = \Phi_0(X(0;t,x)) + \int_0^t B_h(s,X(s;t,x))\,ds, \qquad (t,x)\in[0,T_\varepsilon]\times[0,\infty), \tag{2.15}$$

then φ is the unique weak solution to (2.9) *with initial condition Φ_0. In addition, $\varphi(t,.)$ is nonincreasing and* Supp $\varphi(t,.)\subset[0,R_0]$ *for each $t\in[0,T_\varepsilon]$. Moreover, if $\varepsilon\in(0,\lambda^\gamma)$, $M=1+2\|\Phi_0\|_\infty$, $C_1=2\|\Phi_0\|_1$, $L_1=4(\|\partial_x\Phi_0\|_\infty+M+(M^2/C_1))$, and*

$$T_\varepsilon = \min\left(2^{1/(\lambda\gamma)}-1,\ \frac{1}{8\,\lambda\,\varepsilon^{\lambda-1}\,\|\Phi_0\|_1 + 24\,\delta\,R_0}\right),$$

then $\varphi\in\mathcal{H}_\varepsilon$.

Proof. The first assertion of Proposition 2.4 is classical and the compactness of the support of $\varphi(t,.)$ follows from that of Φ_0 and B_h (see Lemma 2.3). We next investigate the behavior of the L^∞- and L^1-norms of φ. We deduce from Lemma 2.3 that

$$0\le\varphi(t,x)\le\|\Phi_0\|_\infty + 2\left(M^\lambda+\delta\,(1+T_\varepsilon)^{\lambda\gamma}\right)C_1\;T_\varepsilon \tag{2.16}$$

for every $(t,x)\in[0,T_\varepsilon]\times[0,\infty)$. Next, the change of variables $x_*=X(s;t,x)$ is a diffeomorphism for every $(s,t)\in[0,T_\varepsilon]^2$ and we have $x=X(t;s,x_*)$ with

$$\partial_x X(t;s,x_*) = \exp\left(\int_s^t \partial_x A_h(\sigma,X(\sigma;s,x_*))\,d\sigma\right). \tag{2.17}$$

Consequently, we deduce from (2.13), (2.14), and (2.15) that

$$\begin{aligned}\int_0^\infty \varphi(t,x)\,dx &= \int_0^\infty \Phi_0(x_*) \exp\left(\int_0^t \partial_x A_h(\sigma, X(\sigma;0,x_*))\,d\sigma\right)\,dx_* \\ &\quad + \int_0^t \int_0^\infty B_h(s,x_*) \exp\left(\int_s^t \partial_x A_h(\sigma, X(\sigma;s,x_*))\,d\sigma\right)\,dx_*\,ds.\end{aligned}$$

The nonpositivity of $\partial_x A_h$ (see Lemma 2.3) implies that

$$\int_0^\infty \varphi(t,x)\,dx \le \int_0^\infty \Phi_0(x_*)\,dx_* + \int_0^t \int_0^\infty B_h(s,x_*)\,dx_*\,ds.$$

But, by (2.8), we get the following equation by the monotonicity and the compactness of the support of $h(s,.)$ for $s \in [0,T_\varepsilon]$:

$$\begin{aligned}\int_0^t \int_0^\infty B_h(s,x_*)\,dx_*\,ds &\le 2\,\lambda\,\varepsilon^{\lambda-1} \int_0^t \int_0^\infty h(s,x_*) \int_{x_*}^\infty h(s,x)\,dx\,dx_*\,ds \\ &\quad + 2\,\delta(1+T_\varepsilon)^{\lambda\gamma} \int_0^t \int_0^{R_0} \int_{x_*}^{R_0} h(s,x)\,dx\,dx_*\,ds \\ &\le \lambda\,\varepsilon^{\lambda-1}\,T_\varepsilon\,C_1^2 + 2\,\delta\,R_0\,C_1\,T_\varepsilon\,(1+T_\varepsilon)^{\lambda\gamma}.\end{aligned}$$

Thus,

$$\|\varphi(t)\|_1 \le \|\Phi_0\|_1 + 2\,C_1\,T_\varepsilon\left(\lambda\,\varepsilon^{\lambda-1}\,C_1 + \delta\,R_0\,(1+T_\varepsilon)^{\lambda\gamma}\right), \qquad t \in [0,T_\varepsilon]. \tag{2.18}$$

We next turn to the Lipschitz property and put $L_0 := \|\partial_x \Phi_0\|_\infty$. For every $(x,x_*) \in (0,\infty)^2$, we have

$$\begin{aligned}|\varphi(t,x) - \varphi(t,x_*)| &\le |\Phi_0(X(0;t,x)) - \Phi_0(X(0;t,x_*))| \\ &\quad + \int_0^t |B_h(s,X(s;t,x)) - B_h(s,X(s;t,x_*))|\,ds.\end{aligned}$$

But, by (2.8),

$$\begin{aligned}&|B_h(s,X(s;t,x)) - B_h(s,X(s;t,x_*))| \\ &\quad \le 2\,M\left(\lambda\,\varepsilon^{\lambda-1} M + \delta\,(1+T_\varepsilon)^{\lambda\gamma}\right)|X(s;t,x) - X(s;t,x_*)| \\ &\quad + \lambda\,\varepsilon^{\lambda-1}\,C_1\,|h(s,X(s;t,x)) - h(s,X(s;t,x_*))|.\end{aligned}$$

Consequently,

$$\begin{aligned}|\varphi(t,x) - \varphi(t,x_*)| &\le L_0\,|X(0;t,x) - X(0;t,x_*)| \\ &\quad + \left(\lambda\,\varepsilon^{\lambda-1}(L_1\,C_1 + 2M^2) + 2\,\delta\,M\,(1+T_\varepsilon)^{\lambda\gamma}\right) \int_0^t |X(s;t,x) - X(s;t,x_*)|\,ds.\end{aligned}$$

We next deduce from (2.17) and Lemma 2.3 that, for $s \in [0,t]$,

$$|X(s;t,x) - X(s;t,x_*)| \le \exp\left(\left(2\,\lambda\,\varepsilon^{\lambda-1} C_1 + 6\,\delta\,R_0\,(1+T_\varepsilon)^{\lambda\gamma}\right)(t-s)\right)|x - x_*|.$$

Consequently,

$$
\begin{aligned}
&|\varphi(t,x)-\varphi(t,x_*)| \\
&\quad \le |x-x_*| \Bigg[\left(L_0 + \frac{M^2}{C_1} + \frac{M}{3\,R_0} \right) \exp\left\{ (2\lambda\,\varepsilon^{\lambda-1}\,C_1 + 6\,\delta\,R_0\,(1+T_\varepsilon)^{\lambda\gamma})\,T_\varepsilon \right\} \\
&\quad + \frac{L_1}{2} \left(\exp\left\{ (2\lambda\,\varepsilon^{\lambda-1}\,C_1 + 6\,\delta\,R_0\,(1+T_\varepsilon)^{\lambda\gamma})\,T_\varepsilon \right\} - 1 \right) \Bigg].
\end{aligned} \tag{2.19}
$$

Moreover, (2.17) implies that the function $x \mapsto X(s;t,x)$ is nondecreasing for every $(s,t) \in [0,T_\varepsilon]^2$. It thus follows from the monotonicity of Φ_0 and $B_h(s,.)$ (see Lemma 2.3) that $x \mapsto \varphi(t,x)$ is a nonincreasing function.

Finally, if $\varepsilon \in (0,\lambda^\gamma)$, we put $M = 1 + 2\|\Phi_0\|_\infty$, $C_1 = 2\|\Phi_0\|_1$,

$$
L_1 = 4\left(L_0 + \frac{M^2}{C_1} + M \right), \qquad T_\varepsilon = \min\left(2^{1/(\lambda\gamma)} - 1,\ \frac{1}{4\,\lambda\,\varepsilon^{\lambda-1}\,C_1 + 24\,\delta\,R_0} \right),
$$

and notice that $C_1 \le R_0 M$. It then readily follows from (2.16), (2.18), and (2.19) that φ belongs to $\mathcal{H}_\varepsilon$. ∎

THEOREM 2.5. *Consider $\varepsilon \in (0,\lambda^\gamma)$ and $\Phi_0 \in W^{1,\infty}(\mathbb{R}_+)$ satisfying* (2.1)*. Then there exists a nonnegative weak solution $\varphi^\varepsilon \in \mathcal{C}([0,\infty);L^1(0,\infty))$ to* (2.6)*,* (2.7) *such that $\varphi^\varepsilon(t,.)$ is a nonincreasing function for every $t \ge 0$ and φ^ε satisfies*

$$
\mathrm{Supp}\ \varphi^\varepsilon(t,.) \subset [0,R_0], \qquad \|\varphi^\varepsilon(t)\|_1 = \|\Phi_0\|_1, \qquad t \in (0,\infty).
$$

To prove the existence of a weak solution to (2.6), (2.7), we need a preliminary lemma.

LEMMA 2.6. *Consider $\varepsilon \in (0,\lambda^\gamma)$ and $\Phi_0 \in W^{1,\infty}(\mathbb{R}_+)$ satisfying* (2.1)*. Assume that the parameters M, C_1, L_1, and T_ε are given by Proposition* 2.4*. Let h_1 and h_2 be two functions in $\mathcal{H}_\varepsilon$ and denote by X_1 and X_2 the associated characteristic curves. Setting $z := X_1 - X_2$, we have*

$$
|z(s;t,x)| \le \lambda\,\varepsilon^{\lambda-1}\,T_\varepsilon\,\|h_1-h_2\|_{\mathcal{C}([0,T_\varepsilon];L^1(0,\infty))}\,X_i(s;t,x)\,\exp\left(2\,T_\varepsilon\,(\lambda\,\varepsilon^{\lambda-1}\,C_1+6\,\delta\,R_0)\right), \tag{2.20}
$$

for $0 \le s \le t \le T_\varepsilon$, $x \in [0,\infty)$ and $i = 1,2$.

Proof. By (2.11), for $s \le t$, we have

$$
\begin{aligned}
|z(s;t,x)| \le {} & \int_s^t |A_{h_1}(\sigma,X_1(\sigma;t,x)) - A_{h_1}(\sigma,X_2(\sigma;t,x))|\,d\sigma \\
& + \int_s^t |(A_{h_1}-A_{h_2})(\sigma,X_2(\sigma;t,x))|\,d\sigma.
\end{aligned}
$$

Since $(1+T_\varepsilon)^{\lambda\gamma} \le 2$, it follows from Lemma 2.3 that

$$
\begin{aligned}
|z(s;t,x)| \le {} & 2\,(\lambda\,\varepsilon^{\lambda-1}\,C_1 + 6\,\delta\,R_0) \int_s^t |z(\sigma;t,x)|\,d\sigma \\
& + \int_s^t X_2(\sigma;t,x) \int_0^{X_2(\sigma;t,x)} |\mathcal{R}_\varepsilon(h_1(\sigma,x_*)) - \mathcal{R}_\varepsilon(h_2(\sigma,x_*))|\,dx_*\,d\sigma.
\end{aligned}
$$

For $s \le t$, (2.8) thus leads to

$$|z(s;t,x)| \le 2\,(\lambda\,\varepsilon^{\lambda-1}\,C_1 + 6\,\delta\,R_0) \int_s^t |z(\sigma;t,x)|\,d\sigma \\ + \lambda\,\varepsilon^{\lambda-1}\,\|h_1 - h_2\|_{\mathcal{C}([0,T_\varepsilon];L^1(0,\infty))} \int_s^t X_2(\sigma;t,x)\,d\sigma.$$

The Gronwall lemma and the monotonicity of $X_2(.;t,x)$ then imply that, for $s \le t$, (2.20) holds for $i=2$. By symmetry of X_1 and X_2, we infer that (2.20) also holds for $i=1$. $\square$

Proof of Theorem 2.5. Let M, C_1, L_1, and T_ε be the four parameters given by Proposition 2.4. We consider the map $\mathcal{T} : \mathcal{H}_\varepsilon \longrightarrow \mathcal{H}_\varepsilon$ defined by $\mathcal{T}(h) = \varphi$, where φ is given by (2.15). Let us check that $\mathcal{T}$ is continuous and compact for the topology of $\mathcal{C}([0,T_\varepsilon];L^1(0,\infty))$.

Continuity of $\mathcal{T}$

Let $(h_n)_{n\ge1}$ be a sequence in $\mathcal{H}_\varepsilon$ that converges to $h \in \mathcal{H}_\varepsilon$. Let X_n and X be the characteristic curves defined by (2.11), (2.12) associated to A_{h_n} and A_h, respectively. We set $z_n = X_n - X$, $\varphi_n = \mathcal{T}(h_n)$ and $\varphi = \mathcal{T}(h)$ for $n \ge 1$. Then,

$$\|\varphi_n(t) - \varphi(t)\|_1 \le \int_0^\infty |\Phi_0(X_n(0;t,x)) - \Phi_0(X(0;t,x))|\,dx \quad (=: J_1(t)) \\ + \int_0^\infty\!\!\int_0^t |B_{h_n}(s,X_n(s;t,x)) - B_h(s,X_n(s;t,x))|\,ds\,dx \quad (=: J_2(t)) \\ + \int_0^\infty\!\!\int_0^t |B_h(s,X_n(s;t,x)) - B_h(s,X(s;t,x))|\,ds\,dx \quad (=: J_3(t)).$$

Owing to the compactness of the support of Φ_0, we have

$$J_1(t) = \int_0^{R_0} |\Phi_0(X_n(0;t,x)) - \Phi_0(X(0;t,x))|\,dx \le \|\partial_x\Phi_0\|_\infty \int_0^{R_0} |z_n(0;t,x)|\,dx,$$

and we deduce from (2.14) and (2.20) that

$$J_1(t) \le \frac{1}{2}\,\lambda\,\varepsilon^{\lambda-1}\,T_\varepsilon\,\|\partial_x\Phi_0\|_\infty\,R_0^2\,\exp\left(T_\varepsilon\,(3\,\lambda\,\varepsilon^{\lambda-1}\,C_1 + 16\,\delta\,R_0)\right)\|h_n - h\|_{\mathcal{C}([0,T_\varepsilon];L^1(0,\infty))}. \tag{2.21}$$

Let us now consider $J_2(t)$. A change of variables yields

$$J_2(t) = \int_0^t\int_0^\infty |B_{h_n}(s,x_*) - B_h(s,x_*)|\ \partial_x X_n(t;s,x_*)\ dx_* ds \\ \le \int_0^t\int_0^\infty |B_{h_n}(s,x) - B_h(s,x)|\ dx ds,$$

the last inequality being a consequence of the nonpositivity of $\partial_x A_{h_n}$ and (2.17). Since both $h(s,.)$ and $h_n(s,.)$ are nonincreasing and compactly supported for $s \in [0,T_\varepsilon]$, we obtain

$$J_2(t) \le \int_0^t\int_0^\infty |\mathcal{R}_\varepsilon(h_n(s,x)) - \mathcal{R}_\varepsilon(h(s,x))| \int_x^\infty h_n(s,x_*)\,dx_*\,dx\,ds \\ + 2\int_0^t\int_0^{R_0} \left(\mathcal{R}_\varepsilon(h(s,x)) + \delta\,(1+s)^{\lambda\gamma}\right) \int_x^\infty |(h_n - h)(s,x_*)|\ dx_*\,dx\,ds \\ + \int_0^t\int_0^\infty h_n(s,x) \int_x^\infty |\mathcal{R}_\varepsilon(h_n(s,x_*)) - \mathcal{R}_\varepsilon(h(s,x_*))|\,dx_*\,dx\,ds.$$

By (2.8), we get

$$\begin{aligned} J_2(t) &\le \lambda\,\varepsilon^{\lambda-1}\,C_1 \int_0^t\int_0^\infty |(h_n-h)(s,x)|\,dx\,ds \\ &\quad + 2\,\delta\,R_0\,T_\varepsilon\,(1+T_\varepsilon)^{\lambda\gamma}\,\|h_n-h\|_{\mathcal{C}([0,T_\varepsilon];L^1(0,\infty))} \\ &\quad + \lambda\,\varepsilon^{\lambda-1}\,\|h_n-h\|_{\mathcal{C}([0,T_\varepsilon];L^1(0,\infty))} \int_0^t\int_0^{R_0} (2h(s,x)+h_n(s,x))\,dx\,ds, \end{aligned}$$

from whence

$$J_2(t) \le 4\,T_\varepsilon\big(\lambda\,\varepsilon^{\lambda-1}\,C_1 + \delta\,R_0\big)\,\|h_n-h\|_{\mathcal{C}([0,T_\varepsilon];L^1(0,\infty))}. \tag{2.22}$$

It remains to handle $J_3(t)$. By the compactness of the support of $h(s,.)$ for $s\in[0,T_\varepsilon]$, we have

$$\begin{aligned} &J_3(t) \\ &\le \int_0^t\int_0^{R_0} |\mathcal{R}_\varepsilon(h(s,X_n(s;t,x))) - \mathcal{R}_\varepsilon(h(s,X(s;t,x)))| \int_{X_n(s;t,x)}^\infty h(s,x_*)\,dx_*\,dx\,ds \\ &+ \int_0^t\int_0^{R_0} \big(\mathcal{R}_\varepsilon(h(s,X(s;t,x))) + 2\,\delta\,(1+s)^{\lambda\gamma}\big) \left| \int_{X_n(s;t,x)}^{X(s;t,x)} h(s,x_*)\,dx_* \right| dx\,ds \\ &+ \int_0^t\int_0^{R_0} \left| \int_{X_n(s;t,x)}^{X(s;t,x)} h(s,x_*)\,\mathcal{R}_\varepsilon(h(s,x_*))\,dx_* \right| dx\,ds. \end{aligned}$$

Thanks to (2.8), we obtain

$$\begin{aligned} J_3(t) &\le \lambda\,\varepsilon^{\lambda-1}\,C_1 \int_0^t\int_0^{R_0} |h(s,X_n(s;t,x)) - h(s,X(s;t,x))|\,dx\,ds \\ &\quad + 2\,M\,\big(\lambda\,\varepsilon^{\lambda-1}\,M + \delta\,(1+T_\varepsilon)^{\lambda\gamma}\big) \int_0^t\int_0^{R_0} |z_n(s;t,x)|\,dx\,ds. \end{aligned}$$

The Lipschitz continuity of h, (2.14) and (2.20) then imply that

$$\begin{aligned} J_3(t) &\le \left(\lambda\,\varepsilon^{\lambda-1}\,M^2 + 2\,\delta\,M + \frac{1}{2}\,\lambda\,\varepsilon^{\lambda-1}\,C_1\,L_1\right)\lambda\,\varepsilon^{\lambda-1}\,T_\varepsilon^2\,R_0^2 \\ &\quad \times \exp\big(T_\varepsilon\,(3\,\lambda\,\varepsilon^{\lambda-1}\,C_1 + 16\,\delta\,R_0)\big)\,\|h_n-h\|_{\mathcal{C}([0,T_\varepsilon];L^1(0,\infty))}. \end{aligned} \tag{2.23}$$

Finally, since

$$\|\varphi_n(t)-\varphi(t)\|_1 \le J_1(t)+J_2(t)+J_3(t),$$

we infer from (2.21), (2.22), and (2.23) that $\mathcal{T}$ is continuous.

COMPACTNESS OF $\mathcal{T}$

Let $(h_n)_{n\ge1}$ be a sequence in $\mathcal{H}_\varepsilon$ and put $\varphi_n = \mathcal{T}(h_n)$ for $n\ge1$. On one hand, since φ_n belongs to $\mathcal{H}_\varepsilon$ for each $n\ge1$, the sequence $(\varphi_n)_{n\ge1}$ is bounded in $L^\infty(0,T_\varepsilon;W^{1,\infty}(0,R_0))$. On the other hand, we have $\partial_t\varphi_n = -A_{h_n}\,\partial_x\varphi_n + B_{h_n}$ by Lemma 2.3 and Proposition 2.4, from which we readily conclude that $(\partial_t\varphi_n)_{n\ge1}$ is bounded in $L^\infty((0,T_\varepsilon)\times(0,R_0))$. By the Arzelà–Ascoli theorem, $(\varphi_n)_{n\ge1}$ is then relatively compact in $\mathcal{C}([0,T_\varepsilon]\times[0,R_0])$, from whence $\mathcal{C}([0,T_\varepsilon];L^1(0,\infty))$ thanks to the compactness of the support of $\varphi_n(t,.)$ for each $t\in[0,T_\varepsilon]$ and $n\ge1$.

Therefore, $\mathcal{H}_\varepsilon$ is a nonempty, convex, closed, and bounded subset of $\mathcal{C}([0,T_\varepsilon];L^1(0,\infty))$, and $\mathcal{T}$ is a compact and continuous map from $\mathcal{H}_\varepsilon$ into $\mathcal{H}_\varepsilon$. The Schauder fixed point theorem ensures the existence of a fixed point of $\mathcal{T}$ that is a weak solution $\varphi^{\varepsilon,1}\in\mathcal{C}([0,T_\varepsilon];L^1(0,\infty))$ to (2.6), (2.7) such that $\varphi^{\varepsilon,1}(t,.)$ is nonnegative and nonincreasing with compact support in $[0,R_0]$ for each $t\in[0,T_\varepsilon]$.

Now, since Supp $\varphi^{\varepsilon,1}(t,.)\subset[0,R_0]$ for $t\in[0,T_\varepsilon]$ and $\chi_{R_0}(x)=x$ for $x\le R_0+1$, we deduce from (2.6) that

$$\frac{d}{dt}\int_0^\infty \varphi^{\varepsilon,1}(t,x)\,dx=0,$$

from whence $\|\varphi^{\varepsilon,1}(t)\|_1=\|\Phi_0\|_1$ for $t\in[0,T_\varepsilon]$. Observing that T_ε depends only on R_0 and $\|\Phi_0\|_1$, we may thus proceed as before with $\varphi^{\varepsilon,1}(T_\varepsilon)$ instead of Φ_0 and deduce the existence of a solution $\varphi^{\varepsilon,2}\in\mathcal{C}([0,T_\varepsilon];L^1(0,\infty))$ to (2.6) with initial condition $\varphi^{\varepsilon,1}(T_\varepsilon)$. Repeating this argument yields the existence of a solution $\varphi^\varepsilon\in\mathcal{C}([0,\infty);L^1(0,\infty))$ to (2.6), (2.7) that satisfies the desired properties. ∎

The next task is to pass to the limit as $\varepsilon\to0$. For that purpose, we need the following estimates.

PROPOSITION 2.7. *Let $\varepsilon\in(0,\lambda^\gamma)$ and $\Phi_0\in W^{1,\infty}(0,\infty)$ satisfy* (2.1). *The weak solution φ^ε to* (2.6), (2.7) *given by Theorem* 2.5 *is nonnegative, $\varphi^\varepsilon(t,.)$ is nonincreasing with compact support in* $[0,R_0]$, *and*

$$\|\varphi^\varepsilon(t)\|_1=\|\Phi_0\|_1, \tag{2.24}$$

$$\|\varphi^\varepsilon(t)\|_\infty\le(1+\|\Phi_0\|_\infty)\,e^{2\|\Phi_0\|_1t\,(1+\delta\,(1+t)^{\lambda\gamma})}, \tag{2.25}$$

for every $t\ge0$.

Proof. All statements of Proposition 2.7 are actually a consequence of Theorem 2.5, except the L^∞-bound which we establish now. Let $p>2$. Multiplying (2.6) by $p\,\varphi^\varepsilon(t,x)^{p-1}$ and recalling that Supp $\varphi^\varepsilon(t,.)\subset[0,R_0]$ for $t\ge0$, we get

$$\begin{aligned}
&\frac{d}{dt}\int_0^\infty \varphi^\varepsilon(t,x)^p\,dx\\
&\quad= -\int_0^\infty \varphi^\varepsilon(t,x)^p\left(\int_0^x \mathcal{R}_\varepsilon(\varphi^\varepsilon(t,x_*))\,dx_*+\delta\,(1+t)^{\lambda\gamma}x\right)dx\\
&\quad- \int_0^\infty \varphi^\varepsilon(t,x)^p\left(x\,\mathcal{R}_\varepsilon(\varphi^\varepsilon(t,x))+\delta\,(1+t)^{\lambda\gamma}\,x\right)\,dx\\
&\quad+\ p\int_0^\infty \varphi^\varepsilon(t,x)\int_0^x \varphi^\varepsilon(t,x_*)^{p-1}\,\mathcal{R}_\varepsilon(\varphi^\varepsilon(t,x_*))\,dx_*\,dx\\
&\quad+\ p\int_0^\infty \left(\mathcal{R}_\varepsilon(\varphi^\varepsilon(t,x))+2\,\delta\,(1+t)^{\lambda\gamma}\right)\,\varphi^\varepsilon(t,x)\int_0^x \varphi^\varepsilon(t,x_*)^{p-1}\,dx_*\,dx.
\end{aligned}$$

By (2.8), it follows from the nonnegativity and the monotonicity of φ^ε that, for

$t \in [0,T]$,

$$\begin{aligned}
&\frac{d}{dt}\int_0^\infty \varphi^\varepsilon(t,x)^p\,dx \\
&\quad\le 2p\int_0^\infty \varphi^\varepsilon(t,x)\int_0^x \left(\varphi^\varepsilon(t,x_*)^{p+\lambda-1} + \delta\,(1+t)^{\lambda\gamma}\,\varphi^\varepsilon(t,x_*)^{p-1}\right)\,dx_*\,dx \\
&\quad\le 2p\,\|\Phi_0\|_1\left[\int_0^\infty \varphi^\varepsilon(t,x_*)^{p(p+\lambda-2)/(p-1)}\,\varphi^\varepsilon(t,x_*)^{(1-\lambda)/(p-1)}\,dx_*\right. \\
&\quad\left. +\,\delta\,(1+t)^{\lambda\gamma}\int_0^\infty \varphi^\varepsilon(t,x_*)^{p(p-2)/(p-1)}\,\varphi^\varepsilon(t,x_*)^{1/(p-1)}\,dx_*\right].
\end{aligned}$$

Since $p>2$, the Young inequality implies that

$$\frac{d}{dt}\int_0^\infty \varphi^\varepsilon(t,x)^p\,dx \le 2p\,\|\Phi_0\|_1(1+\delta\,(1+t)^{\lambda\gamma})\left[\int_0^\infty \varphi^\varepsilon(t,x)^p\,dx + \|\Phi_0\|_1\right].$$

Thus, we infer from the Gronwall lemma that

$$\|\varphi^\varepsilon(t)\|_p^p \;\le\; (\|\Phi_0\|_p^p + \|\Phi_0\|_1)\,e^{2p\|\Phi_0\|_1 t\,(1+\delta\,(1+t)^{\lambda\gamma})}.$$

Hence,

$$\|\varphi^\varepsilon(t)\|_p \;\le\; (\|\Phi_0\|_p + \|\Phi_0\|_1^{1/p})\,e^{2\|\Phi_0\|_1 t\,(1+\delta\,(1+t)^{\lambda\gamma})}.$$

Letting $p \longrightarrow \infty$ leads to (2.25). □

2.2. Proof of Theorem 2.1. The existence part of Theorem 2.1 is a straightforward consequence of (2.5) and the following proposition.

PROPOSITION 2.8. *Let $\Phi_0 \in L^\infty(0,\infty)$ satisfy* (2.1)*. Then, there exists a weak solution $\varphi \in \mathcal{C}([0,\infty);L^1(0,\infty))$ to* (2.3), (2.4) *such that $\varphi(t,.)$ is nonnegative and nonincreasing with compact support in* $[0,R_0]$,

$$\|\varphi(t)\|_1 = \|\Phi_0\|_1 \qquad \textit{and} \qquad \sup_{0\le s\le t}\|\varphi(s)\|_\infty < \infty,$$

for every $t \ge 0$.

Proof. We fix $k_0 \ge 1$ such that $k_0 > \lambda^{-\gamma}$ and $T>0$. Let $(\Phi_0^k)_{k\ge k_0}$ be a sequence of functions from $W^{1,\infty}(\mathbb{R}_+)$ such that Φ_0^k is nonnegative and nonincreasing with compact support in $[0,R_0]$, $\Phi_0^k(x) \le 2\Phi_0(x)$ a.e., and $(\Phi_0^k)_{k\ge k_0}$ converges towards Φ_0 in $L^1(\mathbb{R}_+)$.

For all $k \ge k_0$, we set $\varepsilon_k = 1/k < \lambda^\gamma$ and denote by $\varphi^k = \varphi^{\varepsilon_k}$ the solution to (2.6) with initial condition Φ_0^k given by Theorem 2.5. It follows from (2.6) and Proposition 2.7 that

$$\begin{aligned}
&(\varphi^k)_{k\ge k_0}\text{is bounded in } L^\infty((0,T)\times(0,R_0)) \cap L^\infty(0,T;BV(0,R_0)), \\
&(\partial_t\varphi^k)_{k\ge k_0}\text{is bounded in } L^\infty(0,T;W^{1,1}(0,R_0)').
\end{aligned}$$

Since $L^\infty(0,R_0)\cap BV(0,R_0)$ is compactly embedded in $L^1(0,R_0)$ [12] and $L^1(0,R_0)$ is continuously embedded in $W^{1,1}(0,R_0)'$, we infer from [23, Corollary 4] that $(\varphi^k)_{k\ge k_0}$ is relatively compact in $\mathcal{C}([0,T];L^1(0,R_0))$, from whence in $\mathcal{C}([0,T];L^1(0,\infty))$ since φ^k identically vanishes in $(0,\infty)\times(R_0,\infty)$ for each $k \ge k_0$. Consequently, there exists

$\varphi \in \mathcal{C}([0,T];L^1(0,\infty))$ such that, up to an extraction, (φ^k) converges towards φ in $\mathcal{C}([0,T];L^1(0,\infty))$ and a.e. on $[0,T]\times(0,\infty)$.

Let $\vartheta \in \mathcal{C}_0^\infty((0,\infty))$. Then, recalling that $\mathrm{Supp}\,\varphi^k(t,.) \subset [0,R_0]$ and $\chi_{R_0}(x)=x$ for $x \le R_0+1$, we deduce from (2.6) that, for every $t\in[0,T]$,

$$
\begin{aligned}
&\int_0^\infty \varphi^k(t,x)\,\vartheta(x)\,dx - \int_0^\infty \Phi_0^k(x)\,\vartheta(x)\,dx \\
&= -\int_0^t\int_0^\infty \varphi^k(s,x)\,\partial_x\vartheta(x)\,x\left(\int_0^x \mathcal{R}_{\varepsilon_k}(\varphi^k(s,x_*))\,dx_* + \delta\,x\,(1+s)^{\lambda\gamma}\right)dx\,ds \\
&- \int_0^t\int_0^\infty \varphi^k(s,x)\,\vartheta(x)\left(\int_0^x \mathcal{R}_{\varepsilon_k}(\varphi^k(s,x_*))\,dx_* + x\,\mathcal{R}_{\varepsilon_k}(\varphi^k(s,x)) + 2\,\delta\,x\,(1+s)^{\lambda\gamma}\right)dx\,ds \\
&+ \int_0^t\int_0^\infty \vartheta(x)\int_x^\infty \varphi^k(s,x_*)\,\left(\mathcal{R}_{\varepsilon_k}(\varphi^k(s,x)) + \mathcal{R}_{\varepsilon_k}(\varphi^k(s,x_*)) + 2\,\delta\,(1+s)^{\lambda\gamma}\right)\,dx_*\,dx\,ds.
\end{aligned}
$$

Thanks to the dominated convergence theorem, we let $k\to\infty$ and get that φ is a weak solution to (2.3), (2.4). The properties satisfied by φ follow easily from Proposition 2.7. $\square$

The uniqueness assertion of Theorem 2.1 is actually a consequence of the following result.

Proposition 2.9. *Consider two functions Φ_0 and $\hat{\Phi}_0$ fulfilling the assumptions* (2.1). *If Φ and $\hat{\Phi}$ are weak solutions to* (1.15), (1.16) *with initial data Φ_0 and $\hat{\Phi}_0$, respectively, and $T>0$, then there exists $C(T)$ depending only on λ, $\|\Phi_0\|_\infty$, $\|\hat{\Phi}_0\|_\infty$, R_0, and T such that*

$$\left\|\Phi(t)-\hat{\Phi}(t)\right\|_1 \le C(T)\ \left\|\Phi_0-\hat{\Phi}_0\right\|_1 \quad \textit{for} \quad t\in[0,T]. \tag{2.26}$$

Proof. Let $T>0$. By Proposition 2.8 and (2.5), the support of $\Phi(t,.)$ and $\hat{\Phi}(t,.)$ is contained in $[0,R_0\ e^{\gamma t}]$ for each $t\in[0,T]$ and both Φ and $\hat{\Phi}$ belong to $L^\infty((0,T)\times(0,\infty))$. Consequently, we have

$$\Lambda := \sup_{t\in[0,T]}\left\{\left\|\Phi(t)^\lambda\right\|_1 \vee \left\|\hat{\Phi}(t)^\lambda\right\|_1\right\} \le R_0\ e^{\gamma T}\ \sup_{t\in[0,T]}\left\{\|\Phi(t)\|_\infty^\lambda \vee \left\|\hat{\Phi}(t)\right\|_\infty^\lambda\right\} < \infty,$$

and notice that the monotonicity of Φ and $\hat{\Phi}$ imply that

$$x\ \Phi(t,x)^\lambda \le \int_0^x \Phi(t,x_*)^\lambda\ dx_* \le \Lambda \quad\text{and}\quad x\ \hat{\Phi}(t,x)^\lambda \le \int_0^x \hat{\Phi}(t,x_*)^\lambda\ dx_* \le \Lambda \tag{2.27}$$

for $x>0$. We put $E:=\Phi-\hat{\Phi}$ and $\sigma = \ \mathrm{sign}(E)$ and give only a formal proof of (2.26) below as both Φ and $\hat{\Phi}$ do not have the required smoothness to justify the forthcoming computations. Nevertheless, a rigorous proof can be performed by approximation arguments as in [3]. We infer from (1.15) that

$$
\begin{aligned}
\frac{d}{dt}\|E(t)\|_1 = & -\gamma \int_0^\infty \left(x\ \partial_x|E(t,x)| + |E(t,x)|\right)\ dx \\
& + \delta \int_0^\infty x^2\ \partial_x|E(t,x)|\ dx + 2\delta \int_0^\infty \sigma(t,x) \int_x^\infty E(t,x_*)\ dx_* dx \\
& + \frac{1}{2} \int_0^\infty x \left(\int_0^x \left(\Phi^\lambda + \hat{\Phi}^\lambda \right)(t,x_*)\ dx_* \right)\ \partial_x|E(t,x)|\ dx \\
& + \frac{1}{2} \int_0^\infty x\ \sigma(t,x) \left(\int_0^x \left(\Phi^\lambda - \hat{\Phi}^\lambda \right)(t,x_*)\ dx_* \right)\ \partial_x \left(\Phi + \hat{\Phi} \right)(t,x)\ dx \\
& + \int_0^\infty \sigma(t,x) \int_x^\infty \left(\Phi(t,x)^\lambda\ \Phi(t,x_*) - \hat{\Phi}(t,x)^\lambda\ \hat{\Phi}(t,x_*) \right)\ dx_* dx \\
& + \int_0^\infty \sigma(t,x) \int_x^\infty \left(\Phi^{1+\lambda} - \hat{\Phi}^{1+\lambda} \right)(t,x_*)\ dx_* dx.
\end{aligned}
$$

Integrating by parts the first, third, and fifth terms of the right-hand side of the above equality and using the fact that $|\sigma(t,x)| \le 1$, we obtain

$$
\begin{aligned}
\frac{d}{dt}\|E(t)\|_1 \le & \left[(-\gamma\ x + \delta\ x^2)\ |E(t,x)| \right]_0^\infty \\
& + \frac{1}{2} \left[x \left(\int_0^x \left(\Phi(t,x_*)^\lambda + \hat{\Phi}(t,x_*)^\lambda \right)\ dx_* \right)\ |E(t,x)| \right]_0^\infty \\
& + 2\delta \int_0^\infty \int_x^\infty |E(t,x_*)|\ dx_* dx - 2\delta \int_0^\infty x\ |E(t,x)|\ dx \quad (=: -I_1(t)) \\
& - \frac{1}{2} \int_0^\infty \int_0^x \left(\Phi^\lambda + \hat{\Phi}^\lambda \right)(t,x_*)\ dx_*\ |E(t,x)|\ dx \quad (=: -I_2(t)) \\
& - \frac{1}{2} \int_0^\infty x \left(\Phi^\lambda + \hat{\Phi}^\lambda \right)(t,x)\ |E(t,x)|\ dx \quad (=: -I_3(t)) \\
& + \frac{1}{2} \int_0^\infty x \left(\int_0^x \left| \Phi^\lambda - \hat{\Phi}^\lambda \right|(t,x_*)\ dx_* \right) \left| \partial_x \left(\Phi + \hat{\Phi} \right)(t,x) \right|\ dx \quad (=: I_4(t)) \\
& + \int_0^\infty \int_x^\infty \left| \Phi(t,x)^\lambda\ \Phi(t,x_*) - \hat{\Phi}(t,x)^\lambda\ \hat{\Phi}(t,x_*) \right|\ dx_* dx \quad (=: I_5(t)) \\
& + \int_0^\infty \int_x^\infty \left| \Phi^{1+\lambda} - \hat{\Phi}^{1+\lambda} \right|(t,x_*)\ dx_* dx. \quad (=: I_6(t)).
\end{aligned}
$$

Owing to the compactness of the support of $\Phi(t,.)$ and $\hat{\Phi}(t,.)$, the boundary terms in the previous inequality vanish. Also, we clearly have $I_1(t) \ge 0$ by the Fubini theorem. Consequently,

$$
\frac{d}{dt}\|E(t)\|_1 \le -I_2(t) - I_3(t) + I_4(t) + I_5(t) + I_6(t). \tag{2.28}
$$

Thanks to the monotonicity of $\Phi(t,.)$ and $\hat{\Phi}(t,.)$ with respect to x, $I_4(t)$ also reads

$$\begin{aligned}
2\ I_4(t) &= -\int_0^\infty x\ \left(\int_0^x \left|\Phi^\lambda - \hat{\Phi}^\lambda\right|(t,x_*)\ dx_*\right)\ \partial_x \left(\Phi+\hat{\Phi}\right)(t,x)\ dx \\
&= -\left[x\ \left(\int_0^x \left|\Phi^\lambda - \hat{\Phi}^\lambda\right|(t,x_*)\ dx_*\right)\ \left(\Phi+\hat{\Phi}\right)(t,x)\right]_0^\infty \\
&+ \int_0^\infty x\ \left|\Phi^\lambda - \hat{\Phi}^\lambda\right|(t,x)\ \left(\Phi+\hat{\Phi}\right)(t,x)\ dx \\
&+ \int_0^\infty \int_0^x \left|\Phi^\lambda - \hat{\Phi}^\lambda\right|(t,x_*)\ dx_*\ \left(\Phi+\hat{\Phi}\right)(t,x)\ dx.
\end{aligned}$$

As in the above computation, the boundary terms vanish. Since

$$(\Phi+\hat{\Phi})(t,x) = 2\ \left(\Phi\wedge\hat{\Phi}\right)(t,x) + |E(t,x)|, \tag{2.29}$$

we infer from the mean value theorem that

$$\begin{aligned}
2\ I_4(t) &\le 2\lambda\ \int_0^\infty x\ \left(\Phi\wedge\hat{\Phi}\right)^\lambda(t,x)\ |E(t,x)|\ dx \\
&+ \int_0^\infty x\ \left|\Phi^\lambda - \hat{\Phi}^\lambda\right|(t,x)\ |E(t,x)|\ dx \\
&+ 2\lambda\ \int_0^\infty \int_0^x \left(\Phi\wedge\hat{\Phi}\right)^{\lambda-1}(t,x_*)\ |E(t,x_*)|\ dx_*\ \left(\Phi\wedge\hat{\Phi}\right)(t,x)\ dx \\
&+ \int_0^\infty \int_0^x \left|\Phi^\lambda - \hat{\Phi}^\lambda\right|(t,x_*)\ dx_*\ |E(t,x)|\ dx.
\end{aligned}$$

Using the monotonicity of $\Phi(t,.)$ and $\hat{\Phi}(t,.)$ with respect to x and (2.27), we further obtain

$$\begin{aligned}
2\ I_4(t) &\le 2\lambda\ \Lambda\ \|E(t)\|_1 + 2\ \Lambda\ \|E(t)\|_1 \\
&+ 2\lambda\ \int_0^\infty \int_0^x \left(\Phi\wedge\hat{\Phi}\right)^{\lambda-1}(t,x)\ |E(t,x_*)|\ dx_*\ \left(\Phi\wedge\hat{\Phi}\right)(t,x)\ dx \\
&+ 2\ \Lambda\ \|E(t)\|_1 \\
&\le 2(\lambda+2)\ \Lambda\ \|E(t)\|_1 + 2\lambda\ \int_0^\infty \int_{x_*}^\infty \left(\Phi\wedge\hat{\Phi}\right)^\lambda(t,x)\ dx\ |E(t,x_*)|\ dx_*
\end{aligned}$$

$$I_4(t) \le 2(\lambda+1)\ \Lambda\ \|E(t)\|_1. \tag{2.30}$$

Next, by (2.29), the Fubini theorem and the mean value theorem, we have

$$\begin{aligned}
I_5(t) \leq & \frac{1}{2} \int_0^\infty \int_x^\infty \left(\Phi^\lambda + \hat{\Phi}^\lambda\right)(t,x) \ |E(t,x_*)| \ dx_* dx \\
& + \frac{1}{2} \int_0^\infty \int_x^\infty \left(\Phi + \hat{\Phi}\right)(t,x_*) \ \left|\Phi^\lambda - \hat{\Phi}^\lambda\right|(t,x) \ dx_* dx \\
\leq & \frac{1}{2} \int_0^\infty \int_0^x \left(\Phi^\lambda + \hat{\Phi}^\lambda\right)(t,x_*) \ dx_* \ |E(t,x)| \ dx \\
& + \lambda \int_0^\infty \int_x^\infty \left(\Phi \wedge \hat{\Phi}\right)(t,x_*) \ \left(\Phi \wedge \hat{\Phi}\right)^{\lambda-1}(t,x) \ |E(t,x)| \ dx_* dx \\
& + \frac{1}{2} \int_0^\infty \int_x^\infty \left|\Phi^\lambda - \hat{\Phi}^\lambda\right|(t,x) \ |E(t,x_*)| \ dx_* dx \\
\leq & I_2(t) + \lambda \int_0^\infty \int_x^\infty \left(\Phi \wedge \hat{\Phi}\right)^\lambda (t,x_*) \ |E(t,x)| \ dx_* dx + \Lambda \ \|E(t)\|_1,
\end{aligned}$$

the last inequality resulting from the monotonicity of $\Phi(t,.)$ and $\hat{\Phi}(t,.)$ with respect to x. We therefore end up with

$$I_5(t) \leq I_2(t) + (\lambda+1) \ \Lambda \ \|E(t)\|_1. \tag{2.31}$$

Next, using once more the monotonicity of $\Phi(t,.)$ and $\hat{\Phi}(t,.)$ with respect to x and the mean value theorem, we obtain

$$\begin{aligned}
I_6(t) & \leq (1+\lambda) \int_0^\infty \int_x^\infty \left(\Phi(t,x_*) \vee \hat{\Phi}(t,x_*)\right)^\lambda \ |E(t,x_*)| \ dx_* dx \\
& \leq (1+\lambda) \int_0^\infty \left(\Phi(t,x) \vee \hat{\Phi}(t,x)\right)^\lambda \int_x^\infty |E(t,x_*)| \ dx_* dx \\
& \leq 2 \ (1+\lambda) \ \Lambda \ \|E(t)\|_1. \qquad (2.32)
\end{aligned}$$

Since I_3 is nonnegative, we infer from (2.28), (2.30), (2.31), and (2.32) that

$$\frac{d}{dt}\|E(t)\|_1 \leq 5 \ (1+\lambda) \ \Lambda \ \|E(t)\|_1$$

for $t \in [0,T]$, from whence (2.26). $\square$

3. Stationary solutions to (1.14). To establish the existence of a steady state Ψ to (1.14) satisfying $\|\Psi\|_1 = 1$, we proceed in two steps and first show that, for each $\delta \in (0,1)$, there is a stationary solution Ψ_δ to (1.15) such that $\|\Psi_\delta\|_1 = 1$. We next prove that the family $(\Psi_\delta)_{\delta\in(0,1)}$ belongs to a compact subset of $L^1(0,\infty)$ and that the cluster points of $(\Psi_\delta)_{\delta\in(0,1)}$ are stationary solutions to (1.14) satisfying the required L^1-constraint.

In order to apply Theorem 1.4 to the semiflow associated to (1.15), (1.16), we have to identify a compact and convex subset of $L^1(0,\infty)$ which is left invariant by the semiflow. We first recall that when Φ_0 satisfies (2.1), then $\Phi(t,.)$ is compactly supported with Supp $\Phi(t,.) \subset [0, R_0 \ e^{\gamma t}]$ and

$$\int_0^\infty \Phi(t,x) \ dx = 1 := \int_0^\infty \Phi_0(x) \ dx \quad \text{for} \quad t \geq 0. \tag{3.1}$$

We next investigate the time evolution of the L^∞-norm.

Lemma 3.1. *Consider $\delta \in (0,1)$ and assume that Φ_0 satisfies* (2.1). *Denoting by Φ the corresponding solution to* (1.15), (1.16), *we have*

$$\|\Phi(t)\|_\infty \le m(t), \quad t \ge 0, \tag{3.2}$$

where m is the solution to

$$\frac{dm}{dt}(t) = 2\left(m(t)^\lambda + \delta\right) - \gamma\, m(t), \quad m(0) = \|\Phi_0\|_\infty. \tag{3.3}$$

Proof. We fix $T > 0$ and recall that $\operatorname{Supp}\Phi(t,.) \subset [0, x_T]$ for $t \in [0,T]$ with $x_T := R_0\, e^{\gamma T}$. For $t \in [0,T]$, it follows from (1.15), (3.1) and the monotonicity and nonnegativity of Φ that

$$\begin{aligned}
&\frac{d}{dt}\int_0^\infty (\Phi(t,x)-m(t))_+\ dx = \frac{d}{dt}\int_0^{x_T} (\Phi(t,x)-m(t))_+\ dx \\
&\quad \le \gamma \int_0^{x_T} \operatorname{sign}_+(\Phi(t,x)-m(t))\ (\Phi(t,x)-m(t)-\Phi(t,x))\ dx \\
&\quad - 2\delta \int_0^{x_T} x\ (\Phi(t,x)-m(t))_+\ dx \\
&\quad + 2\delta \int_0^{x_T} \operatorname{sign}_+(\Phi(t,x)-m(t)) \int_x^\infty \Phi(t,x_*)\ dx_* dx \\
&\quad + \int_0^{x_T} \operatorname{sign}_+(\Phi(t,x)-m(t)) \int_x^\infty \Phi(t,x_*)\ \left(\Phi(t,x)^\lambda + \Phi(t,x_*)^\lambda\right)\ dx_* dx \\
&\quad - \int_0^{x_T} \operatorname{sign}_+(\Phi(t,x)-m(t))\ \frac{dm}{dt}(t)\ dx \\
&\quad \le \int_0^{x_T} \operatorname{sign}_+(\Phi(t,x)-m(t))\ \left(2\delta - \gamma\, m(t) - \frac{dm}{dt}(t)\right)\ dx \\
&\quad + 2\int_0^{x_T} \operatorname{sign}_+(\Phi(t,x)-m(t))\ \Phi(t,x)^\lambda\ dx.
\end{aligned}$$

By (3.3), we have the lower bound $m(t) \ge m(0)\ e^{-\gamma t} \ge m(0)\ e^{-\gamma T}$, and we obtain

$$\begin{aligned}
\frac{d}{dt}\int_0^\infty (\Phi(t,x)-m(t))_+\ dx &\le 2\int_0^{x_T} \operatorname{sign}_+(\Phi(t,x)-m(t))\ \left(\Phi(t,x)^\lambda - m(t)^\lambda\right)\ dx \\
&\le 2\ \lambda\ m(t)^{\lambda-1} \int_0^{x_T} (\Phi(t,x)-m(t))_+\ dx \\
&\le 2\ \lambda\ m(0)^{\lambda-1}\ e^T \int_0^{x_T} (\Phi(t,x)-m(t))_+\ dx \\
&\le 2\ \lambda\ m(0)^{\lambda-1}\ e^T \int_0^\infty (\Phi(t,x)-m(t))_+\ dx.
\end{aligned}$$

Consequently,

$$\int_0^\infty (\Phi(t,x)-m(t))_+\ dx \le C(T) \int_0^\infty (\Phi_0(x)-m(0))_+\ dx = 0,$$

from which the inequality (3.2) readily follows for $t \in [0,T]$. Since T was arbitrarily chosen, we obtain the expected result. ∎

Having excluded the occurrence of large values of Φ throughout time evolution, we next turn to a refined estimate on the propagation of the support of Φ.

LEMMA 3.2. *Consider* $\delta \in (0,1)$ *and assume that* Φ_0 *satisfies* (2.1). *Denoting by* Φ *the corresponding solution to* (1.15), (1.16), *we have*

$$\text{Supp}\ \Phi(t,.) \subset [0,R(t)], \quad t \geq 0, \tag{3.4}$$

where R *is the solution to*

$$\frac{dR}{dt}(t) = \gamma\ R(t) - \delta\ R(t)^2, \quad R(0) = R_0. \tag{3.5}$$

Proof. For $t \in (0,\infty)$, it follows from (1.15) and the Fubini theorem that

$$\begin{aligned}
&\frac{d}{dt}\int_{R(t)}^\infty \Phi(t,x)\ dx \\
&= -\frac{dR}{dt}(t)\ \Phi(t,R(t)) - \gamma\ \Big[x\ \Phi(t,x)\Big]_{R(t)}^\infty \\
&+ \left[x\ \Phi(t,x)\left(\delta\ x + \int_0^x \Phi(t,x_*)^\lambda\ dx_*\right)\right]_{R(t)}^\infty \\
&- \int_{R(t)}^\infty \left(\delta\ x + \int_0^x \Phi(t,x_*)^\lambda\ dx_*\right)\ \Phi(t,x)\ dx \\
&- \int_{R(t)}^\infty x\ \left(\delta + \Phi(t,x)^\lambda\right)\ \Phi(t,x)\ dx \\
&+ \int_{R(t)}^\infty \int_{R(t)}^x \left(\Phi(t,x)^\lambda + \Phi(t,x_*)^\lambda + 2\delta\right)\ \Phi(t,x)\ dx_* dx \\
&= \left(-\frac{dR}{dt}(t) + \gamma\ R(t) - \delta\ R(t)^2 - R(t)\ \int_0^{R(t)} \Phi(t,x_*)^\lambda\ dx_*\right)\Phi(t,R(t)) \\
&- \int_{R(t)}^\infty \int_0^x \left(2\delta + \Phi(t,x)^\lambda + \Phi(t,x_*)^\lambda\right)\ \Phi(t,x)\ dx_* dx \\
&+ \int_{R(t)}^\infty \int_{R(t)}^x \left(\Phi(t,x)^\lambda + \Phi(t,x_*)^\lambda + 2\delta\right)\ \Phi(t,x)\ dx_* dx \\
&\leq 0,
\end{aligned}$$

from which we deduce (3.4) by integration. □

Observe that the estimate on the expansion on the support of Φ obtained in the previous lemma heavily depends on δ and will thus not be useful to pass to the limit as $\delta \to 0$. For that purpose, a control on the behavior of Φ for large x which does not depend on δ is obtained in the next lemma.

LEMMA 3.3. *Consider* $\delta \in (0,1)$ *and assume that* Φ_0 *satisfies* (2.1). *Denoting by* Φ *the corresponding solution to* (1.15), (1.16), *we have*

$$\mathcal{L}(t) := \int_0^\infty x^{(1-\lambda)/\lambda}\ \Phi(t,x)\ dx \leq \ell(t), \quad t \geq 0, \tag{3.6}$$

where

$$\frac{d\ell}{dt}(t) = \frac{1}{\lambda}\ \ell(t) - \frac{1-\lambda}{(1+\lambda)\lambda^{1+\lambda}}\ \ell(t)^{1+\lambda}, \quad \ell(0) = \mathcal{L}(0) = \int_0^\infty x^{(1-\lambda)/\lambda}\ \Phi_0(x)\ dx.$$

Proof. For $t \in (0,\infty)$, it follows from (1.15), the compactness of the support of $\Phi(t,.)$ and the Fubini theorem that

$$\begin{aligned}
\frac{d\mathcal{L}}{dt}(t) &= \frac{\mathcal{L}(t)}{\lambda} - \frac{1}{\lambda} \int_0^\infty x^{(1-\lambda)/\lambda} \left(\delta\ x + \int_0^x \Phi(t,x_*)^\lambda\ dx_*\right)\ \Phi(t,x)\ dx \\
&\quad - \int_0^\infty x^{1/\lambda} \left(\delta + \Phi(t,x)^\lambda\right) \Phi(t,x)\ dx \\
&\quad + \int_0^\infty \int_0^x x_*^{(1-\lambda)/\lambda} \left(2\delta + \Phi(t,x)^\lambda + \Phi(t,x_*)^\lambda\right)\ \Phi(t,x)\ dx_* dx \\
&= \frac{\mathcal{L}(t)}{\lambda} + \left(2\lambda - 1 - \frac{1}{\lambda}\right)\ \delta \int_0^\infty x^{1/\lambda}\ \Phi(t,x)\ dx \\
&\quad + \int_0^\infty \int_0^x \left(x_*^{(1-\lambda)/\lambda} - \frac{x^{(1-\lambda)/\lambda}}{\lambda}\right)\ \Phi(t,x_*)^\lambda\ \Phi(t,x)\ dx_* dx \\
&\quad - (1-\lambda) \int_0^\infty x^{1/\lambda}\ \Phi(t,x)^{1+\lambda}\ dx.
\end{aligned}$$

Since $\lambda \in (0,1)$, we end up with

$$\frac{d\mathcal{L}}{dt}(t) \le \frac{\mathcal{L}(t)}{\lambda} - \frac{1-\lambda}{\lambda} \int_0^\infty x^{(1-\lambda)/\lambda} \int_0^x \Phi(t,x_*)^\lambda\ dx_*\ \Phi(t,x)\ dx.$$

Using Lemma B.1, we further obtain

$$\begin{aligned}
\frac{d\mathcal{L}}{dt}(t) &\le \frac{\mathcal{L}(t)}{\lambda} - \frac{1-\lambda}{\lambda^{1+\lambda}} \int_0^\infty x^{(1-\lambda)/\lambda}\ \Phi(t,x) \left(\int_0^x x_*^{(1-\lambda)/\lambda}\ \Phi(t,x_*)\ dx_*\right)^\lambda\ dx \\
&\le \frac{\mathcal{L}(t)}{\lambda} - \frac{1-\lambda}{(1+\lambda)\lambda^{1+\lambda}}\ \mathcal{L}(t)^{1+\lambda},
\end{aligned}$$

from whence (3.6) by the comparison principle. ∎

We are now in a position to construct stationary solutions to (1.15).

PROPOSITION 3.4. *Given $\delta \in (0,1)$, there exists a nonnegative and nonincreasing function $\Psi_\delta \in L^1(0,\infty) \cap L^\infty(0,\infty)$ such that* $\text{Supp}\ \Psi_\delta \subset [0,\gamma/\delta]$,

$$\|\Psi_\delta\|_1 = 1, \quad \|\Psi_\delta\|_\infty \le A(\lambda) + 2\ \delta, \quad \int_0^\infty x^{(1-\lambda)/\lambda}\ \Psi_\delta(x)\ dx \le B(\lambda), \tag{3.7}$$

and

$$\begin{aligned}
& x \left(\gamma - \delta\ x - \int_0^x \Psi_\delta(x_*)^\lambda\ dx_*\right)\ \Psi_\delta(x) \\
&\qquad = \int_x^\infty \int_0^x \left(\Psi_\delta(x_*)^\lambda + \Psi_\delta(x')^\lambda + 2\delta\right)\ \Psi_\delta(x_*)\ dx' dx_*
\end{aligned} \tag{3.8}$$

for almost every $x \in (0,\gamma/\delta)$. The parameters $A(\lambda)$ and $B(\lambda)$ are given by

$$A(\lambda) := \left(\frac{2}{\gamma}\right)^\gamma, \quad B(\lambda) := \lambda\ \left(\frac{1+\lambda}{1-\lambda}\right)^{1/\lambda}.$$

Proof. Given $\delta \in (0,1)$, we introduce the set $\mathcal{K}_\delta$ defined by

$$\mathcal{K}_\delta := \left\{ \begin{array}{l} U \in L^1(0,\infty) \text{ is a nonnegative and nonincreasing compactly sup-} \\ \text{ported function such that } \text{Supp}\ U \subset [0,\gamma/\delta],\ \|U\|_1 = 1,\ \|U\|_\infty \le \\ z(\delta) \text{ and } \displaystyle\int_0^\infty x^{(1-\lambda)/\lambda}\ U(x)\ dx \le B(\lambda) \end{array} \right\},$$

where $z(\delta)$ is the unique positive zero of $z \longmapsto 2(\delta + z^\lambda) - \gamma z$. We note that

$$z(0) = A(\lambda) \le z(\delta) \le A(\lambda) + 2\delta. \tag{3.9}$$

Then, $\mathcal{K}_\delta$ is a closed convex subset of $L^1(0,\infty)$. In addition, if $(U_n)_{n\ge1}$ is a sequence in $\mathcal{K}_\delta$, then $(U_n)_{n\ge1}$ is bounded in $BV(0,\infty)$ and there is a subsequence of $(U_n)_{n\ge1}$ (not relabeled) and a function U such that $(U_n(x))$ converges towards $U(x)$ for almost every $x \in (0,\infty)$ as $n \to \infty$ [12]. On one hand, this convergence and the Fatou lemma imply that U is a nonnegative and nonincreasing function with compact support in $[0,\gamma/\delta]$ and satisfies

$$\|U\|_\infty \le z(\delta) \quad \text{and} \quad \int_0^\infty x^{(1-\lambda)/\lambda}\ U(x)\ dx \le B(\lambda).$$

On the other hand, since $(U_n)_{n\ge1}$ is bounded in $L^\infty(0,\infty)$ with $\text{Supp}\ U_n \subset [0,\gamma/\delta]$, we deduce from the Lebesgue dominated convergence theorem that (U_n) converges towards U in $L^1(0,\infty)$, from whence $\|U\|_1 = 1$. Therefore, $U \in \mathcal{K}_\delta$, and we have thus shown that $\mathcal{K}_\delta$ is a closed convex and compact subset of $L^1(0,\infty)$.

We now claim that, if $\Phi_0 \in \mathcal{K}_\delta$, then $\Phi(t,.) \in \mathcal{K}_\delta$ for each $t \ge 0$, Φ being the corresponding solution to (1.15), (1.16). Indeed, consider $\Phi_0 \in \mathcal{K}_\delta$. From the analysis of the previous section and (3.1), we know that $\Phi(t,.)$ is a nonnegative and nonincreasing function in $L^1(0,\infty)$ with $\|\Phi(t)\|_1 = \|\Phi_0\|_1 = 1$ for $t \ge 0$. Next, it readily follows from (3.3) that $m(t) \le \|\Phi_0\|_\infty \vee z(\delta)$, from whence $\|\Phi(t)\|_\infty \le z(\delta)$ for $t \ge 0$ by Lemma 3.1. Similarly, as $\text{Supp}\ \Phi_0 \subset [0,\gamma/\delta]$, the function R defined by (3.5) is bounded from above by $R(0) \vee (\gamma/\delta) = \gamma/\delta$ and we infer from Lemma 3.2 that $\text{Supp}\ \Phi(t,.) \subset [0,\gamma/\delta]$ for $t \ge 0$. Finally, Lemma 3.3 implies that

$$\int_0^\infty x^{(1-\lambda)/\lambda}\ \Phi(t,x)\ dx \le \left(\int_0^\infty x^{(1-\lambda)/\lambda}\ \Phi_0(x)\ dx \right) \vee B(\lambda) = B(\lambda), \quad t \ge 0.$$

Consequently, $\mathcal{K}_\delta$ is a closed convex and compact subset of $L^1(0,\infty)$ which is left invariant by the semiflow associated to (1.15), (1.16). Applying Theorem 1.4 with $X = L^1(0,\infty)$ and $K = \mathcal{K}_\delta$, we obtain the existence of a stationary solution Ψ_δ to (1.15) which belongs to $\mathcal{K}_\delta$. This last property and (3.9) yield the bounds (3.7) while (3.8) follows from (2.2). ∎

We are thus left to pass to the limit as $\delta \to 0$ to construct a stationary solution to (1.14) and this is the purpose of the next proposition.

PROPOSITION 3.5. *There exists a nonnegative and nonincreasing function* $\Psi \in L^1(0,\infty) \cap L^\infty(0,\infty)$ *such that*

$$\|\Psi\|_1 = 1, \quad \|\Psi\|_\infty \le A(\lambda), \quad \int_0^\infty x^{(1-\lambda)/\lambda}\ \Psi(x)\ dx \le B(\lambda), \tag{3.10}$$

and

$$x\ \left(\gamma - \int_0^x \Psi(x_*)^\lambda\ dx_* \right)\ \Psi(x) = \int_x^\infty \int_0^x \left(\Psi(x_*)^\lambda + \Psi(x')^\lambda \right)\ \Psi(x_*)\ dx' dx_* \tag{3.11}$$

for almost every $x \in (0,\infty)$*, the parameters* $A(\lambda)$ *and* $B(\lambda)$ *being defined in Proposition* 3.4.

Proof. For $\delta \in (0,1)$, let Ψ_δ be a stationary solution to (1.15) given by Proposition 3.4. We infer from Proposition 3.4 that $(\Psi_\delta)_{\delta\in(0,1)}$ is bounded in $BV(0,\infty) \cap$

$L^1(0,\infty;x^{(1-\lambda)/\lambda}\,dx)\cap L^\infty(0,\infty)$ which is clearly compactly embedded in $L^1(0,\infty)$ as $(1-\lambda)/\lambda>0$. Consequently, there is a sequence $(\delta_n)_{n\geq 1}$, $\delta_n\to 0$, and $\Psi\in L^1(0,\infty)$ such that Ψ_{δ_n} converges to Ψ in $L^1(0,\infty)$ and a.e. in $(0,\infty)$. Passing to the limit as $\delta_n\to 0$ in (3.7), we obtain (3.10) (with the help of the Fatou lemma for the moment estimate and a weak convergence argument for the L^∞-bound). Owing to the boundedness of (Ψ_{δ_n}) and the convergence of (Ψ_{δ_n}) towards Ψ in $L^1(0,\infty)$ and a.e., it is straightforward to pass to the limit as $\delta_n\to 0$ in (3.8) and obtain (3.11). □

4. Properties of stationary solutions to (1.14). We next turn to the study of properties of stationary solutions Ψ to (1.14) given by Proposition 3.5. We first establish their $\mathcal{C}^1$-smoothness on $[0,\infty)$.

PROPOSITION 4.1. *Let Ψ be a stationary solution to* (1.14) *given by Proposition* 3.5. *Then, $\Psi\in\mathcal{C}^1([0,\infty))$ and $\Psi^\lambda\in L^1(0,\infty)$ with*

$$L_\lambda := \|\Psi^\lambda\|_1 < \gamma. \tag{4.1}$$

Proof. We first observe that, since $\Psi\in L^\infty(0,\infty)$, we have

$$x_0 := \sup\left\{x\geq 0 \ \text{ such that } \ \int_0^x \Psi(x_*)^\lambda\ dx_* < \gamma\right\}\in(0,\infty].$$

It then clearly follows from (3.10) and (3.11) that $\Psi\in\mathcal{C}^1((0,x_0))$ with

$$\begin{aligned} & x\ \left(\gamma-\int_0^x \Psi(x_*)^\lambda\ dx_*\right)\ \frac{d\Psi}{dx}(x) \\ & = -\gamma\ \Psi(x)+\int_x^\infty \Psi(x_*)^{\lambda+1}\ dx_* + \Psi(x)^\lambda\ \int_x^\infty \Psi(x_*)\ dx_* \end{aligned} \tag{4.2}$$

for $x\in(0,x_0)$.

Assume for contradiction that $x_0<\infty$. Then

$$\int_0^{x_0}\Psi(x_*)^\lambda\ dx_* = \gamma \tag{4.3}$$

and the nonnegativity of Ψ and (3.11) imply that $\Psi(x)=0$ for $x>x_0$. It next follows from (4.2) and the monotonicity of Ψ that, if $x\in(0,x_0)$, we have

$$\begin{aligned} x\ \left(\gamma-\int_0^x \Psi(x_*)^\lambda\ dx_*\right)\ \frac{d\Psi}{dx}(x) & \leq -\gamma\ \Psi(x)+2\ \Psi(x)\ \int_x^{x_0}\Psi(x_*)^\lambda\ dx_* \\ & \leq -\gamma\ \Psi(x)+2\ \Psi(x)\ \left(\gamma-\int_0^x \Psi(x_*)^\lambda\ dx_*\right), \end{aligned}$$

from whence

$$x\ \frac{d\Psi}{dx}(x)\leq -\gamma\ \Psi(x)\ \left(\gamma-\int_0^x\Psi(x_*)^\lambda\ dx_*\right)^{-1}+2\ \Psi(x).$$

Therefore

$$\begin{aligned} \frac{d}{dx}\left\{x\ \Psi(x)^\lambda\right\} & = \Psi(x)^\lambda+\lambda\ x\ \Psi(x)^{\lambda-1}\ \frac{d\Psi}{dx}(x) \\ & \leq \Psi(x)^\lambda-\gamma\ \lambda\ \Psi(x)^\lambda\ \left(\gamma-\int_0^x\Psi(x_*)^\lambda\ dx_*\right)^{-1}+2\ \lambda\ \Psi(x)^\lambda \\ & \leq \frac{d}{dx}\left\{-(1+2\lambda)\ \int_x^{x_0}\Psi(x_*)^\lambda\ dx_*+\lambda\ \gamma\ \log\left(\gamma-\int_0^x\Psi(x_*)^\lambda\ dx_*\right)\right\}, \end{aligned}$$

from which we deduce after integration over $(0,x)$, $x\in(0,x_0)$ that

$$\begin{aligned} & x\ \Psi(x)^\lambda + (1+2\lambda)\ \int_x^{x_0} \Psi(x_*)^\lambda\ dx_* - \lambda\ \gamma\ \log\left(\gamma - \int_0^x \Psi(x_*)^\lambda\ dx_*\right) \\ & \le (1+2\lambda)\ \int_0^{x_0} \Psi(x_*)^\lambda\ dx_* - \lambda\ \gamma\ \log\gamma \\ & \le (1+2\lambda)\ \gamma - \lambda\ \gamma\ \log\gamma. \end{aligned} \tag{4.4}$$

But the right-hand side of (4.4) is finite while the left-hand side of (4.4) diverges to infinity as $x\to x_0$ by (4.3) and a contradiction. Therefore, $x_0=\infty$, $\Psi\in\mathcal{C}^1((0,\infty))$ and

$$\int_0^x \Psi(x_*)^\lambda\ dx_* < \gamma \quad \text{for each} \quad x\in(0,\infty).$$

In particular, $\Psi^\lambda\in L^1(0,\infty)$ and $L_\lambda=\|\Psi^\lambda\|_1\le\gamma$.

Suppose now for contradiction that $\|\Psi^\lambda\|_1=\gamma$. Arguing as before, we realize that (4.4) is valid for every $x\in(0,\infty)$. Then, letting $x\to\infty$ in (4.4) yields that the left-hand side of (4.4) diverges to infinity while the right-hand side is finite, from whence a contradiction. We have thus shown that $L_\lambda<\gamma$, from whence the claim (4.1).

We next turn to the regularity of Ψ at $x=0$. Since Ψ is a nonincreasing and bounded function, the limit $\Psi(0+)$ of $\Psi(x)$ as $x\to0$ exists and is finite and we may actually set $\Psi(0)=\Psi(0+)$. Then $\Psi\in\mathcal{C}([0,\infty))$. In addition, since $\|\Psi\|_1=1>0$, Ψ is not identically equal to zero and thus $\Psi(0)>0$ by the monotonicity of Ψ. Since the identity (3.11) also reads

$$\left(\gamma - \int_0^x \Psi(x_*)^\lambda\ dx_*\right)\ \Psi(x) = \int_x^\infty \Psi(x_*)^{\lambda+1}\ dx_* + \frac{1}{x}\ \int_0^x \Psi(x_*)^\lambda\, dx_*\ \int_x^\infty \Psi(x_*)\, dx_*,$$

we may let $x\to0$ in the previous inequality and obtain

$$\gamma\ \Psi(0) = \int_0^\infty \Psi(x_*)^{\lambda+1}\ dx_* + \Psi(0)^\lambda. \tag{4.5}$$

It follows from (3.11), (4.5) and the monotonicity of Ψ that

$$\begin{aligned} \gamma\ (\Psi(0)-\Psi(x)) &= \int_0^x \Psi(x_*)^{1+\lambda}\ dx_* - \Psi(x)\ \int_0^x \Psi(x_*)^\lambda\ dx_* \\ &\quad + \Psi(0)^\lambda - \frac{1}{x}\ \int_0^x \Psi(x_*)^\lambda\ dx_*\ \int_x^\infty \Psi(x_*)\ dx_* \\ &\le 2\ x\ \Psi(0)^{1+\lambda} + \left(\Psi(0)^\lambda - \frac{1}{x}\ \int_0^x \Psi(x_*)^\lambda\ dx_*\right) \\ &\le 2\ x\ \Psi(0)^{1+\lambda} + \left(\Psi(0)^\lambda - \Psi(x)^\lambda\right) \\ &\le 2\ x\ \Psi(0)^{1+\lambda} + \lambda\ \Psi(x)^{\lambda-1}\ (\Psi(0)-\Psi(x)), \end{aligned}$$

from whence

$$\left(\gamma - \lambda\ \Psi(x)^{\lambda-1}\right)\ \frac{\Psi(0)-\Psi(x)}{x} \le 2\ \Psi(0)^{1+\lambda}.$$

As $\lambda \in (0,1)$ and $\gamma \ge \Psi(0)^{\lambda-1}$ by (4.5), we have $\gamma > \lambda\ \Psi(0)^{\lambda-1}$ and we infer from the continuity of Ψ at $x=0$ that there are $\delta_1 > 0$ and $x_1 > 0$ such that

$$\gamma - \lambda\ \Psi(x)^{\lambda-1} \ge \delta_1 \quad \text{for} \quad x \in (0,x_1).$$

Combining the above two inequalities and the monotonicity of Ψ yields

$$0 \le \frac{\Psi(0)-\Psi(x)}{x} \le \frac{2}{\delta_1}\ \Psi(0)^{1+\lambda} \quad \text{for} \quad x \in (0,x_1), \tag{4.6}$$

so that $x \longmapsto (\Psi(0)-\Psi(x))/x$ belongs to $L^\infty(0,x_1)$.

Another consequence of (4.5) is that we may pass to the limit as $x \to 0$ in (4.2) to deduce that

$$\lim_{x\to 0} x\ \frac{d\Psi}{dx}(x) = 0. \tag{4.7}$$

Using once more (4.5), the identity (4.2) also reads

$$\begin{aligned}\gamma\ x\ \frac{d\Psi}{dx}(x) &= x \int_0^x \Psi(x_*)^\lambda\ dx_*\ \frac{d\Psi}{dx}(x) - \gamma\ (\Psi(x)-\Psi(0)) - \int_0^x \Psi(x_*)^{1+\lambda}\ dx_* \\ &\quad + \left(\Psi(x)^\lambda - \Psi(0)^\lambda\right) - \Psi(x)^\lambda \int_0^x \Psi(x_*)\ dx_*,\end{aligned}$$

from which we deduce that

$$\begin{aligned}&\gamma\ \frac{d\Psi}{dx}(x) + \left(\gamma - \lambda\ \Psi(0)^{\lambda-1}\right)\ \frac{\Psi(x)-\Psi(0)}{x} \\ &= \left(\frac{1}{x}\int_0^x \Psi(x_*)^\lambda\ dx_*\right)\left(x\ \frac{d\Psi}{dx}(x)\right) - \frac{1}{x}\int_0^x \Psi(x_*)^{1+\lambda}\ dx_* - \frac{\Psi(x)^\lambda}{x}\int_0^x \Psi(x_*)\ dx_* \\ &+ \frac{1}{x}\ \left(\Psi(x)^\lambda - \Psi(0)^\lambda - \lambda\ \Psi(0)^{\lambda-1}(\Psi(x)-\Psi(0))\right),\end{aligned}$$

On one hand, by (4.7) and the continuity of Ψ at $x=0$, we have

$$\begin{aligned}&\lim_{x\to 0}\left(\frac{1}{x}\int_0^x \Psi(x_*)^\lambda\ dx_*\right)\left(x\ \frac{d\Psi}{dx}(x)\right) = 0, \\ &\lim_{x\to 0}\frac{1}{x}\int_0^x \Psi(x_*)^{1+\lambda}\ dx_* = \lim_{x\to 0}\frac{\Psi(x)^\lambda}{x}\int_0^x \Psi(x_*)\ dx_* = \Psi(0)^{1+\lambda}.\end{aligned}$$

On the other hand, it follows from the concavity of $r \mapsto r^\lambda$, the monotonicity of Ψ, and (4.6) that, if $x \in (0,x_1)$, then

$$\begin{aligned}&\left|\frac{1}{x}\ \left(\Psi(x)^\lambda - \Psi(0)^\lambda - \lambda\ \Psi(0)^{\lambda-1}(\Psi(x)-\Psi(0))\right)\right| \\ &\quad = \frac{1}{x}\ \left(\Psi(0)^\lambda - \Psi(x)^\lambda - \lambda\ \Psi(0)^{\lambda-1}(\Psi(0)-\Psi(x))\right) \\ &\quad \le \frac{\lambda}{x}\ \left(\Psi(x)^{\lambda-1} - \Psi(0)^{\lambda-1}\right)\ (\Psi(0)-\Psi(x)) \\ &\quad \le \lambda \sup_{x_*\in(0,x_1)}\left(\frac{\Psi(0)-\Psi(x_*)}{x_*}\right)\ \left(\Psi(x)^{\lambda-1} - \Psi(0)^{\lambda-1}\right) \\ &\quad \le \frac{2\ \lambda}{\delta_1}\ \Psi(0)^{1+\lambda}\ \left(\Psi(x)^{\lambda-1} - \Psi(0)^{\lambda-1}\right) \underset{x\to 0}{\longrightarrow} 0\end{aligned}$$

by the continuity of Ψ at $x=0$. Consequently,

$$\lim_{x\to 0}\left\{\gamma\ \frac{d\Psi}{dx}(x)+\left(\gamma-\lambda\ \Psi(0)^{\lambda-1}\right)\ \frac{\Psi(x)-\Psi(0)}{x}\right\}=-2\ \Psi(0)^{1+\lambda}. \tag{4.8}$$

Introducing $\omega:=1-\lambda\ \Psi(0)^{\lambda-1}\ \gamma^{-1}$, we have $\omega>0$ by (4.5) and the previous limit also reads

$$\lim_{x\to 0}\left\{x^{-\omega}\ \frac{d}{dx}\left(x^{\omega}\ (\Psi(x)-\Psi(0))\right)\right\}=-\frac{2\ \Psi(0)^{1+\lambda}}{\gamma},$$

from whence, by integration,

$$\lim_{x\to 0}\frac{\Psi(x)-\Psi(0)}{x}=-\frac{2\ \Psi(0)^{1+\lambda}}{\gamma\ (\omega+1)}.$$

Therefore, Ψ is differentiable at $x=0$ with

$$\frac{d\Psi}{dx}(0)=-\frac{2\ \Psi(0)^{1+\lambda}}{2\ \gamma-\lambda\ \Psi(0)^{\lambda-1}}<0, \tag{4.9}$$

and (4.8) ensures the continuity of $d\Psi/dx$ at $x=0$. ∎

We next turn to the positivity and monotonicity properties of stationary solutions to (1.14).

PROPOSITION 4.2. *Let Ψ be a stationary solution to* (1.14) *given by Proposition* 3.5. *Then*

$$\Psi(x)>0\quad \text{and}\quad \frac{d\Psi}{dx}(x)<0\quad \text{for}\quad x\ge 0. \tag{4.10}$$

Proof. Recalling that $L_\lambda:=\|\Psi^\lambda\|_1<\gamma$ by Proposition 4.1, we have for $\delta>0$ and $x\ge\delta$

$$\delta\ (\gamma-L_\lambda)\le x\ \left(\gamma-\int_0^x \Psi(x_*)^\lambda\ dx_*\right).$$

We then infer from (4.2) and the nonpositivity of $d\Psi/dx\le 0$ that

$$\delta\ (\gamma-L_\lambda)\ \frac{d\Psi}{dx}(x)\ge -\gamma\ \Psi(x),\quad x\ge\delta.$$

Therefore,

$$\Psi(x)\ge\Psi(\delta)\ \exp\left\{\frac{\gamma\ (\delta-x)}{\delta\ (\gamma-L_\lambda)}\right\},\quad x\ge\delta.$$

Owing to the continuity of Ψ at $x=0$ and the positivity of $\Psi(0)$, we also have $\Psi(\delta)>0$ for δ sufficiently small, which, together with the above lower bound for Ψ, entail the positivity of Ψ in $[0,\infty)$. Similarly, it follows from (4.2) that Ψ is twice differentiable in $(0,\infty)$ with

$$\begin{aligned}
&x\ \left(\gamma-\int_0^x \Psi(x_*)^\lambda\ dx_*\right)\ \frac{d^2\Psi}{dx^2}(x)\\
&=\left(x\ \Psi(x)^\lambda+\lambda\ \Psi(x)^{\lambda-1}\ \int_x^\infty \Psi(x_*)\ dx_*+\int_0^x \Psi(x_*)^\lambda\ dx_*-2\ \gamma\right)\ \frac{d\Psi}{dx}(x)\\
&-2\ \Psi(x)^{1+\lambda}\\
&\le -2\ \gamma\ \frac{d\Psi}{dx}(x),
\end{aligned}$$

the last inequality being a consequence of the positivity and monotonicity of Ψ. Consequently, if $\delta > 0$ and $x \geq \delta$,

$$\begin{aligned}\frac{d^2\Psi}{dx^2}(x) &\leq -\frac{2\,\gamma}{x}\,\frac{d\Psi}{dx}(x)\,\left(\gamma - \int_0^x \Psi(x_*)^\lambda\,dx_*\right)^{-1}\\ &\leq -\frac{2\,\gamma}{\delta\,(\gamma - L_\lambda)}\,\frac{d\Psi}{dx}(x),\end{aligned}$$

from whence

$$\frac{d\Psi}{dx}(x) \leq \frac{d\Psi}{dx}(\delta)\,\exp\left\{\frac{2\,\gamma\,(\delta - x)}{\delta\,(\gamma - L_\lambda)}\right\}, \quad x \geq \delta.$$

Recalling that $d\Psi/dx \in \mathcal{C}([0,\infty))$ with $d\Psi(0)/dx < 0$ by (4.9), we easily deduce from the previous inequality that $d\Psi(x)/dx < 0$ for $x \geq 0$. □

We finally identify the behavior of Ψ as $x \to \infty$.

PROPOSITION 4.3. *Let Ψ be a stationary solution to* (1.14) *given by Proposition* 3.5. *Then $L_\lambda := \left\|\Psi^\lambda\right\|_1 > 1$ and there is a positive constant $b > 0$ such that*

$$\lim_{x\to\infty} x^\alpha\,\Psi(x) = b \quad \textit{and} \quad \lim_{x\to\infty} x^{1+\alpha}\,\frac{d\Psi}{dx}(x) = -\alpha\,b, \tag{4.11}$$

with $\alpha := \gamma/(\gamma - L_\lambda) > 0$.

Proof. We first establish that

$$L_\lambda = \left\|\Psi^\lambda\right\|_1 > 1. \tag{4.12}$$

Indeed, since $\Psi(x) > 0$ for $x \geq 0$, we multiply (4.2) by $\lambda\,\Psi(x)^{\lambda-1}$ and integrate over $(0,\infty)$ to obtain

$$\begin{aligned}&\left[x\,\left(\gamma - \int_0^x \Psi(x_*)^\lambda\,dx_*\right)\,\Psi(x)^\lambda\right]_0^\infty\\ &\qquad - \int_0^\infty \Psi(x)^\lambda\,\left(\gamma - \int_0^x \Psi(x_*)^\lambda\,dx_* - x\,\Psi(x)^\lambda\right)\,dx\\ &\qquad = -\lambda\,\gamma\,L_\lambda + \lambda\,\int_0^\infty \int_x^\infty \left(\Psi(x)^{\lambda-1}\,\Psi(x_*)^{\lambda+1} + \Psi(x)^{2\lambda-1}\,\Psi(x_*)\right)\,dx_* dx\\ &\qquad = -\lambda\,\gamma\,L_\lambda + \lambda\,\int_0^\infty \int_0^x \left(\Psi(x)^{\lambda+1}\,\Psi(x_*)^{\lambda-1} + \Psi(x)\,\Psi(x_*)^{2\lambda-1}\right)\,dx_* dx.\end{aligned}$$

Since Ψ is nonincreasing and $\Psi^\lambda \in L^1(0,\infty)$, the boundary terms vanish and we end up with

$$\begin{aligned}(1-\lambda)\,\gamma\,L_\lambda &= \int_0^\infty \int_0^x \left(\Psi(x)^\lambda\,\Psi(x_*)^\lambda + \Psi(x)^{2\lambda}\right)\,dx_* dx\\ &\quad - \lambda\,\int_0^\infty \int_0^x \left(\Psi(x)^{\lambda+1}\,\Psi(x_*)^{\lambda-1} + \Psi(x)\,\Psi(x_*)^{2\lambda-1}\right)\,dx_* dx,\end{aligned}$$

$$L_\lambda = \int_0^\infty \int_0^x \left(\Psi(x)^\lambda + \Psi(x_*)^\lambda\right)\,\left(\Psi(x)^{\lambda-1} - \lambda\,\Psi(x_*)^{\lambda-1}\right)\,\Psi(x)\,dx_* dx.$$

Since $\Psi(x) \le \Psi(x_*)$ for $x_* \in (0,x)$, it follows from Lemma B.2 and the elementary inequality $\Psi(x)^\lambda + \Psi(x_*)^\lambda \le 2^{1-\lambda}\ (\Psi(x)+\Psi(x_*))^\lambda$ that

$$L_\lambda \le 2^{1-\lambda} \int_0^\infty \int_0^x \Psi(x)^\lambda\ \Psi(x_*)^\lambda dx_* dx = 2^{-\lambda}\ L_\lambda^2.$$

Therefore, $L_\lambda \ge 2^\lambda > 1$ which completes the proof of (4.12).

We next infer from (4.2) and the positivity and monotonicity of Ψ that

$$x\ (\gamma - L_\lambda)\ \frac{d\Psi}{dx}(x) \ge x\ \left(\gamma - \int_0^x \Psi(x_*)^\lambda\ dx_*\right)\ \frac{d\Psi}{dx}(x) \ge -\gamma\ \Psi(x),$$

from whence

$$x\ \left|\frac{d\Psi}{dx}(x)\right| \le \frac{\gamma}{\gamma - L_\lambda}\ \Psi(x),$$

and

$$(\gamma - L_\lambda)\ x\ \frac{d\Psi}{dx}(x) + \gamma\ \Psi(x) \le \left(2\ \Psi(x) + x\ \left|\frac{d\Psi}{dx}(x)\right|\right)\ \int_x^\infty \Psi(x_*)^\lambda\ dx_*$$

for $x > 0$. We combine the previous inequalities to obtain

$$(\gamma - L_\lambda)\ x\ \frac{d\Psi}{dx}(x) + \gamma\ \Psi(x) \le \left(2 + \frac{\gamma}{\gamma - L_\lambda}\right)\ \Psi(x)\ \int_x^\infty \Psi(x_*)^\lambda\ dx_*.$$

Recall that $\alpha = \gamma/(\gamma - L_\lambda) > 0$ and fix $\varepsilon \in (0,\alpha)$. Since $\Psi^\lambda \in L^1(0,\infty)$, there is $x_\varepsilon > 0$ such that

$$\int_x^\infty \Psi(x_*)^\lambda\ dx_* \le \frac{\gamma - L_\lambda}{2+\alpha}\ \varepsilon \quad \text{for} \quad x \ge x_\varepsilon.$$

Therefore, for $x \ge x_\varepsilon$, we have

$$x\ \frac{d\Psi}{dx}(x) + \alpha\ \Psi(x) \le \varepsilon\ \Psi(x),$$

from which we deduce by integration that

$$\Psi(x) \le \frac{x_\varepsilon^{\alpha-\varepsilon}\ \Psi(x_\varepsilon)}{x^{\alpha-\varepsilon}} \quad \text{for} \quad x \ge x_\varepsilon.$$

Recalling that $\Psi \in L^\infty(0,\infty)$, we have thus established that, for each $\varepsilon \in (0,\alpha)$, there is $\kappa_\varepsilon > 0$ such that

$$\Psi(x) \le \kappa_\varepsilon\ x^{-\alpha+\varepsilon} \quad \text{for} \quad x > 0. \tag{4.13}$$

Once more we use (4.2) to obtain that

$$\begin{aligned}(\gamma - L_\lambda)\ \frac{d}{dx}\left\{x^\alpha\ \Psi(x)\right\} &= (\gamma - L_\lambda)\ x^\alpha\ \frac{d\Psi(x)}{dx} + \gamma\ x^{\alpha-1}\ \Psi(x) \\ &= x^{\alpha-1}\ \left(\int_x^\infty \Psi(x_*)^{1+\lambda}\ dx_* + \Psi(x)^\lambda\ \int_x^\infty \Psi(x_*)\ dx_*\right) \\ &\quad - x^\alpha\ \frac{d\Psi}{dx}(x)\ \int_x^\infty \Psi(x_*)^\lambda\ dx_*. \end{aligned} \tag{4.14}$$

Now, since $L_\lambda > 1$ by (4.12), we have $\alpha > \lambda\alpha > 1$ and there exists $\varepsilon \in (0, \alpha - 1)$ such that $\lambda\alpha > 1 + (1+\lambda)\varepsilon$. Then, on one hand, by the monotonicity of Ψ and (4.13), an integration by parts yields

$$\begin{aligned}
0 &\le -\int_1^\infty x^\alpha \ \frac{d\Psi}{dx}(x) \ \int_x^\infty \Psi(x_*)^\lambda \ dx_* dx \\
&\le \Psi(1) \int_1^\infty \Psi(x_*)^\lambda \ dx_* + \int_1^\infty \Psi(x) \ \left(\alpha \ x^{\alpha-1} \ \int_x^\infty \Psi(x_*)^\lambda \ dx_* - x^\alpha \ \Psi(x)^\lambda \right) \ dx \\
&\le C + \frac{\alpha \ \kappa_\varepsilon^{1+\lambda}}{\lambda\alpha - 1 - \lambda\varepsilon} \ \int_1^\infty x^{(1+\lambda)\varepsilon - \lambda\alpha} \ dx \\
&\le C(\varepsilon).
\end{aligned}$$

On the other hand, it follows from the monotonicity of Ψ and (4.13) that

$$\begin{aligned}
&\int_1^\infty x^{\alpha-1} \ \left(\int_x^\infty \Psi(x_*)^{1+\lambda} \ dx_* + \Psi(x)^\lambda \ \int_x^\infty \Psi(x_*) \ dx_* \right) \ dx \\
&\le 2 \ \frac{\kappa_\varepsilon^{1+\lambda}}{\alpha - 1 - \varepsilon} \ \int_1^\infty x^{(1+\lambda)\varepsilon - \lambda\alpha} \ dx \le C(\varepsilon).
\end{aligned}$$

Consequently, the right-hand side of (4.14) belongs to $L^1(1,\infty)$ and is positive, from which we conclude that $x \longmapsto x^\alpha \ \Psi(x)$ has a positive limit b as $x \to \infty$. We have thus proved the first assertion in (4.11).

As for $d\Psi/dx$, we note that the large x-behavior of Ψ ensures that there is x_∞ large enough such that $x^\alpha \ \Psi(x) \le 2b$ for $x \ge x_\infty$. Consequently, for $x \ge x_\infty$, we have

$$\begin{aligned}
x^\alpha \ \left(\int_x^\infty \Psi(x_*)^{\lambda+1} \ dx_* + \Psi(x)^\lambda \ \int_x^\infty \Psi(x_*) \ dx_* \right) &\le 2 \ x^\alpha \ \Psi(x)^\lambda \ \int_x^\infty \Psi(x_*) \ dx_* \\
&\le 2 \ (2b)^{\lambda+1} \ x^{(1-\lambda)\alpha} \int_x^\infty x_*^{-\alpha} \ dx_* \\
&\le \frac{2 \ (2b)^{\lambda+1}}{\alpha - 1} \ x^{1-\lambda\alpha}.
\end{aligned}$$

Recalling that $\lambda\alpha > 1$ by (4.12), we conclude that

$$\lim_{x\to\infty} x^\alpha \ \left(\int_x^\infty \Psi(x_*)^{\lambda+1} \ dx_* + \Psi(x)^\lambda \ \int_x^\infty \Psi(x_*) \ dx_* \right) = 0.$$

We now multiply (4.2) by x^α and let $x \to \infty$ in the resulting identity with the help of the previous limit and the first statement in (4.11) to complete the proof of (4.11). $\square$

5. Proofs of Theorem 1.1 and Corollary 1.2. By Proposition 3.5 there exists a nonnegative function $\Psi \in L^1(0,\infty)$ satisfying (3.10) and (3.11). In addition, $\Psi \in \mathcal{C}^1([0,\infty))$ is a positive and decreasing function from $[0,\infty)$ onto $(0, y_0]$ with $y_0 := \Psi(0)$ by Propositions 4.1 and 4.2. We then denote its inverse function by $\Xi : (0, y_0] \longrightarrow [0,\infty)$ which is also a decreasing and nonnegative function in $\mathcal{C}^1((0,y_0])$ and put $\xi := -d\Xi/dy > 0$. We extend Ξ and ξ to (y_0,∞) by setting $\Xi(y) = \xi(y) = 0$ for $y > y_0$. Then $\xi \in \mathcal{C}((0,\infty) \setminus \{y_0\})$ with $\xi(y_0-) = -(d\Psi/dx(0))^{-1} > 0$ by (4.9) and $\xi(y_0+) = 0$. Also, since $\Xi(y) \longrightarrow \infty$ as $y \to 0$, we infer from Propositions 4.1 and 4.3 that

$$\lim_{y\to 0}\ y\ \Xi(y)^{\gamma/(\gamma-L_\lambda)} = b, \quad \lim_{y\to 0}\ -\frac{\Xi(y)^{1+(\gamma/(\gamma-L_\lambda))}}{\xi(y)} = -\frac{\gamma\ b}{\gamma - L_\lambda}$$

with $L_\lambda := \left\|\Psi^\lambda\right\|_1 \in (1,\gamma)$, from whence

$$\lim_{y\to 0}\ y^{2-(L_\lambda/\gamma)}\ \xi(y) = \frac{\gamma - L_\lambda}{\gamma}\ b^{1-L_\lambda/\gamma} > 0.$$

In addition, Ξ being a $\mathcal{C}^1$-diffeomorphism from $(0,y_0]$ onto $[0,\infty)$, a simple change of variables yields

$$\int_0^\infty y\ \xi(y)\ dy = \|\Psi\|_1 = 1 \quad \text{and} \quad \int_0^\infty y^\lambda\ \xi(y)\ dy = \left\|\Psi^\lambda\right\|_1 = L_\lambda.$$

We have thus shown that ξ enjoys all the properties (1.9), (1.10), and (1.11) listed in Theorem 1.1. To check (1.12), we consider $y \in (0,y_0)$ and take $x = \Xi(y)$ in (4.2) to obtain

$$-\left(\gamma - \int_0^{\Xi(y)} \Psi(x_*)^\lambda\ dx_*\right)\ \frac{\Xi(y)}{\xi(y)} = -\gamma\ y + \int_{\Xi(y)}^\infty \left(\Psi(x_*)^{\lambda+1} + y^\lambda\ \Psi(x_*)\right)\ dx_*,$$

from whence (1.12) after performing the change of variables $x_* = \Xi(y_*)$ in the integrals. The proof of Theorem 1.1 is now complete and we show that Corollary 1.2 follows. Let $t \in (0,\infty)$ and $\vartheta \in \mathcal{C}_0^\infty((0,\infty))$. Then

$$\begin{aligned}
&\frac{d}{dt}\int_0^\infty g_s(t,y)\ \vartheta(y)\ dy \\
&\quad = \frac{d}{dt}\left(\frac{1}{t^{2\gamma}}\ \int_0^\infty \xi\left(\frac{y}{t^\gamma}\right)\ \vartheta(y)\ dy\right) \\
&\quad = \frac{d}{dt}\left(\frac{1}{t^{\gamma}}\ \int_0^\infty \xi(y)\ \vartheta\left(y\ t^\gamma\right)\ dy\right) \\
&\quad = -\frac{\gamma}{t^{1+\gamma}}\ \int_0^\infty \xi(y)\ \vartheta\left(y\ t^\gamma\right)\ dy + \frac{\gamma}{t}\ \int_0^\infty y\ \xi(y)\ \partial_y\vartheta\left(y\ t^\gamma\right)\ dy \\
&\quad = \frac{\gamma}{t}\int_0^\infty y\ \xi(y)\ \partial_y\vartheta\left(y\ t^\gamma\right)\ dy - \frac{\gamma}{t}\int_0^\infty \xi(y)\ \int_0^y \partial_y\vartheta\left(y_*\ t^\gamma\right)\ dy_* dy,
\end{aligned}$$

from whence

$$t\ \frac{d}{dt}\int_0^\infty g_s(t,y)\ \vartheta(y)\ dy = \gamma\ \int_0^\infty \left(y\ \xi(y) - \int_y^\infty \xi(y_*)\ dy_*\right)\partial_y\vartheta\left(y\ t^\gamma\right)\ dy_* dy.$$

Using (1.12), we deduce that

$$
\begin{aligned}
t\ \frac{d}{dt}\int_0^\infty & g_s(t,y)\ \vartheta(y)\ dy \\
&= \int_0^\infty \partial_y\vartheta\left(y\ t^\gamma\right)\ \int_0^y \left(y^\lambda + y_*^\lambda\right)\ y_*\ \xi(y_*)\ dy_*\ \xi(y)\ dy \\
&- \int_0^\infty \partial_y\vartheta\left(y\ t^\gamma\right)\ \left(\int_y^\infty y_*^\lambda\ \xi(y_*)\ dy_*\right)\ \left(\int_y^\infty \xi(y')\ dy'\right)\ dy \\
&= \frac{1}{t^{(3+\lambda)\gamma}}\ \int_0^\infty \partial_y\vartheta(y)\ \int_0^y \left(y^\lambda + y_*^\lambda\right)\ y_*\ \xi\left(\frac{y_*}{t^\gamma}\right)\ dy_*\ \xi\left(\frac{y}{t^\gamma}\right)\ dy \\
&- \frac{1}{t^\gamma}\ \int_0^\infty \vartheta\left(y\ t^\gamma\right)\ \int_y^\infty \left(y^\lambda + y_*^\lambda\right)\ \xi(y_*)\ \xi(y)\ dy_* dy \\
&= t^{(1-\lambda)\gamma}\ \int_0^\infty \partial_y\vartheta(y)\ \int_0^y \left(y^\lambda + y_*^\lambda\right)\ y_*\ g_s(t,y_*)\ g_s(t,y)\ dy_* dy \\
&- t^{(1-\lambda)\gamma}\ \int_0^\infty \vartheta(y)\ \int_y^\infty \left(y^\lambda + y_*^\lambda\right)\ g_s(t,y_*)\ g_s(t,y)\ dy_* dy \\
&= t\int_0^\infty \int_0^y \left(y_*\,\partial_y\vartheta(y) - \vartheta(y_*)\right)\ \left(y^\lambda + y_*^\lambda\right)\ g_s(t,y_*)\, g_s(t,y)\, dy_* dy,
\end{aligned}
$$

since $\gamma = 1/(1-\lambda)$. Dividing the above equality by t yields that g_s is a weak solution to (1.2) and completes the proof of Corollary 1.2. ∎

Appendix A. Proof of Theorem 1.4.

We first recall the definition of a semiflow.

DEFINITION A.1. *Let X be a topological vector space. A semiflow $\mathcal{F} : [0,\infty) \times X \to X$ is a continuous mapping such that $\mathcal{F}(0,x) = x$ and $\mathcal{F}(t,\mathcal{F}(s,x)) = \mathcal{F}(t+s,x)$ for every $(s,t,x) \in [0,\infty)^2 \times X$.*

We first need a preliminary result.

PROPOSITION A.2. *Let X be a topological vector space and $\mathcal{F}$ a semiflow on X. For $T > 0$, we denote the set of T-periodic orbits by K_T, that is,*

$$K_T := \{x \in X, \quad \mathcal{F}(T,x) = x\}.$$

If there is $T > 0$ such that

$$K_T \text{ is compact} \qquad \text{and} \qquad K_{T2^{-k}} \neq \emptyset \qquad \text{for every } k \in \mathbb{N},$$

then $K := \{x \in X \text{ such that } \mathcal{F}(t,x) = x \text{ for all } t \geq 0\}$ is a nonempty compact subset of X and $K = \cap_{k\geq 0} K_{T2^{-k}}$.

Proof. Let $k \geq 0$. If $x \in K_{T2^{-(k+1)}}$, then, by definition of a semiflow,

$$
\begin{aligned}
\mathcal{F}(T2^{-k},x) &= \mathcal{F}(T2^{-(k+1)},\mathcal{F}(T2^{-(k+1)},x)) \\
&= \mathcal{F}(T2^{-(k+1)},x) = x,
\end{aligned}
$$

from whence $K_{T2^{-(k+1)}} \subset K_{T2^{-k}}$. Moreover, $K_t = (Id - \mathcal{F}(t,.))^{-1}(\{0\})$ is a closed set for every $t \geq 0$ and $K_{T2^{-k}}$ is thus compact for every $k \geq 0$. Therefore $K_{stat} := \cap_{k\geq 0} K_{T2^{-k}}$ is a nonempty compact subset of X.

Consider now $x \in K_{stat}$ for which we have

$$\mathcal{F}(T2^{-k},x) = x \quad \text{for every} \quad k \in \mathbb{N}.$$

Let $t \in [0,T]$. For every $k \geq 1$, there is $i_k \in \{0,\dots,2^k-1\}$ such that

$$\frac{i_k}{2^k} \leq \frac{t}{T} < \frac{1+i_k}{2^k} \qquad \text{and} \qquad \lim_{k\to\infty} \frac{i_k}{2^k} = \frac{t}{T}.$$

But, by induction,

$$\mathcal{F}\left(\frac{Ti_k}{2^k}, x\right) = \mathcal{F}\left(\frac{T(i_k-1)}{2^k}, \mathcal{F}\left(\frac{T}{2^k}, x\right)\right) = x,$$

and the continuity of $\mathcal{F}$ leads to $\mathcal{F}(t,x) = x$. We may then extend this result to (T,∞) by the semiflow property. We have thus shown that $K_{stat} = K$. ◻

We are now in a position to prove Theorem 1.4.

Proof of Theorem 1.4. Let $T > 0$. Since X is a locally convex topological vector space and $\mathcal{F}(T,.) : K \to K$ is continuous, the Tychonov–Schauder fixed point theorem ensures the existence of $x_T \in K$ such that

$$\mathcal{F}(T, x_T) = x_T.$$

Then, with the notations introduced in Proposition A.2, K_T is a nonempty closed subset of K and K_T is consequently compact. We thus conclude thanks to Proposition A.2. ◻

Appendix B. Two inequalities.

Lemma B.1. *Consider $\vartheta \in (0,1)$ and a nonnegative and nonincreasing measurable function U such that $U^\vartheta \in L^\infty(0,\infty)$. Then*

$$\int_0^x x_*^{(1-\vartheta)/\vartheta}\ U(x_*)\ dx_* \leq \vartheta\ \left(\int_0^x U(x_*)^\vartheta\ dx_*\right)^{1/\vartheta} \tag{B.1}$$

for $x \in (0,\infty)$. Furthermore, if $U^\vartheta \in L^1(0,\infty)$, then $U \in L^1(0,\infty; x^{(1-\vartheta)/\vartheta}\ dx)$ and

$$\int_0^\infty x^{(1-\vartheta)/\vartheta}\ U(x)\ dx \leq \vartheta\ \left(\int_0^\infty U(x)^\vartheta\ dx\right)^{1/\vartheta}. \tag{B.2}$$

Proof. Consider $x \in (0,\infty)$ and $x_* \in (0,x)$. By the monotonicity of U, we have

$$x_*\ U(x_*)^\vartheta \leq \int_0^{x_*} U(y)^\vartheta\ dy,$$

from whence

$$x_*^{1/\vartheta}\ U(x_*) \leq \left(\int_0^{x_*} U(y)^\vartheta\ dy\right)^{1/\vartheta}.$$

Consequently,

$$\begin{aligned}\int_0^x x_*^{(1-\vartheta)/\vartheta}\ U(x_*)\ dx_* &= \int_0^x x_*^{(1-\vartheta)/\vartheta}\ U(x_*)^{1-\vartheta}\ U(x_*)^\vartheta\ dx_* \\ &\leq \int_0^x U(x_*)^\vartheta\ \left(\int_0^{x_*} U(y)^\vartheta\ dy\right)^{(1-\vartheta)/\vartheta}\ dx_* \\ &= \vartheta\ \left(\int_0^x U(x_*)^\vartheta\ dx_*\right)^{1/\vartheta},\end{aligned}$$

from whence (B.1). Next, if $U^\vartheta \in L^1(0,\infty)$, we may let $x \to \infty$ in (B.1) to obtain (B.2) and thus complete the proof of Lemma B.1. ∎

LEMMA B.2. *Consider $\lambda \in [0,1]$, $r > 0$, and $r_* \in (0,r)$. Then*

$$(1-\lambda)\ 2^\lambda\ \frac{r^\lambda\ r_*^{\lambda-1}}{(r+r_*)^\lambda} \le r_*^{\lambda-1} - \lambda\ r^{\lambda-1} \le \frac{r^\lambda\ r_*^{\lambda-1}}{(r+r_*)^\lambda}. \tag{B.3}$$

Proof. The inequalities (B.3) being obvious for $\lambda \in \{0,1\}$, we restrict ourselves to $\lambda \in (0,1)$ and put

$$p(z) := (1+z)^\lambda\ \left(1 - \lambda\ z^{1-\lambda}\right), \quad q(z) := z^\lambda - z - (1-\lambda)$$

for $z \in (0,1)$. Then

$$p'(z) = \frac{\lambda}{z^\lambda\ (1+z)^{1-\lambda}}\ q(z), \quad q'(z) = \lambda\ z^{\lambda-1} - 1,$$

from which we deduce that $q(z) \le q\left(\lambda^\gamma\right)$ for $z \in (0,1)$. Since $q\left(\lambda^\gamma\right) = \left(\lambda^{\lambda\gamma} - 1\right)\ (1-\lambda) < 0$, we conclude that $p'(z) \le 0$ for $z \in (0,1)$. Consequently, $p(1) \le p(z) \le p(0)$ for $z \in (0,1)$, from whence

$$(1-\lambda)\ 2^\lambda \le p(z) \le 1 \quad \text{for} \quad z \in (0,1).$$

We next consider $r > 0$ and $r_* \in (0,r)$ and take $z = r_*/r$ in the previous inequality to obtain (B.3). ∎

L_P-THEORY FOR A CLASS OF NON-NEWTONIAN FLUIDS*

DIETER BOTHE† AND JAN PRÜSS‡

Abstract. Local-in-time well-posedness of the initial-boundary value problem for a class of non-Newtonian Navier–Stokes problems on domains with compact C^{3-}-boundary is proven in an L_p-setting for any space dimension $n \geq 2$. The stress tensor is assumed to be of the generalized Newtonian type, i.e., $\mathcal{S} = 2\mu(|\mathcal{E}|_2^2)\mathcal{E} - \pi I$, $\mathcal{E} = \frac{1}{2}(\nabla u + \nabla u^{\mathsf{T}})$, where $|\mathcal{E}|_2^2 = \sum_{i,j=1}^n \varepsilon_{ij}^2$ denotes the Hilbert–Schmidt norm of the rate of strain tensor $\mathcal{E}$. The viscosity function $\mu \in C^{2-}(\mathbb{R}_+)$ is subject only to the condition $\mu(s) > 0$, $\mu(s) + 2s\mu'(s) > 0$, $s \geq 0$, which for the standard power-law–like function $\mu(s) = \mu_0(1+s)^{\frac{d-2}{2}}$ merely means $\mu_0 > 0$ and $d \geq 1$. This result is based on maximal regularity theory for a suitable linear problem and a contraction argument.

Key words. maximal regularity, non-Newtonian fluids, L_p-theory, $\mathcal{R}$-boundedness, initial boundary value problems, power-law–like fluids, strong ellipticity, Lopatinskii–Shapiro condition

DOI. 10.1137/060663635

1. Introduction. In this paper, we study boundary value problems for the Navier–Stokes system of non-Newtonian fluids. By this we mean the following problem:

$$
\begin{aligned}
&\partial_t(\rho u) + \operatorname{div}(\rho u \otimes u) = \operatorname{div} \mathcal{S},\\
&\mathcal{S} = \mu[\nabla u + (\nabla u)^{\mathsf{T}}] - \pi I,\\
&\operatorname{div} u = 0, \quad t > 0,\ x \in G,\\
&u(0,x) = u_0(x), \quad x \in G.
\end{aligned}
\tag{1.1}
$$

Here $G \subset \mathbb{R}^n$, $n \geq 2$, denotes the domain occupied by the fluid, and $\Gamma = \partial G$ means the boundary of G. We assume that Γ is compact and of class C^{3-}. Throughout, $u(t,x)$ means the velocity field of the fluid, $\pi(t,x)$ the pressure, and $\mathcal{S}(t,x)$ the stress tensor. The numbers $\rho > 0$, $\mu > 0$ represent the density and viscosity of the fluid, respectively. We assume that $\rho > 0$ is constant, and without loss of generality (w.l.o.g.) $\rho = 1$.

On the other hand, the (nonconstant) viscosity μ will be taken of *generalized Newtonian type*, i.e.,

$$
\mu = \mu(|\mathcal{E}|_2^2), \quad \mathcal{E} = \frac{1}{2}\,[\nabla u + (\nabla u)^{\mathsf{T}}]. \tag{1.2}
$$

Here $\mathcal{E} = (\varepsilon_{ij})$ denotes the rate of strain tensor and

$$
|\mathcal{E}|_2^2 = \sum_{i,j=1}^n \varepsilon_{ij}^2
$$

its Hilbert–Schmidt norm. Note that the first invariant of $\mathcal{E}$, namely $\operatorname{tr}\mathcal{E} = \operatorname{div} u$, is zero, and hence the Hilbert–Schmidt norm of $\mathcal{E}$ coincides with the second invariant of $\mathcal{E}$ up to a constant factor. It is believed that many *isotropic* fluids which are not subject to viscoelastic memory effects can be described by such a material law. A prominent example is the *power-law fluid* of Ostwald and de Waele,

$$\mu(s) = ms^{d/2-1},$$

where $d \geq 1$ and $m > 0$. Due to the obvious defect of this constitutive equation at $s = 0$, it is common practice to use modified power-laws like the truncated power law of Spriggs, the Eyring model, the Carreau model, etc.; see Chapter 5 of [2].

A standard model in the mathematical literature is

$$\mu(s) = \mu_0(1+s)^{(d-2)/2}, \quad s \geq 0,$$

where $d \geq 1$ and $\mu_0 > 0$. The case $d = 2$ corresponds to the Newtonian case.

At this point it should be observed that such constitutive laws are just the most basic ones beyond the Newtonian case. Such simple stress-strain relations cannot account for many exciting phenomena observed in the world of non-Newtonian fluids; they can only be considered as a starting point. Nevertheless, there has been—and there still is—considerable interest in generalized Newtonian fluids, in the mathematical as well as in the engineering communities, since a nonconstant viscosity that depends on the shear rate covers the most important deviation from the linear behavior for many macromolecular fluids; see [2].

Three natural boundary conditions are of interest, namely the nonslip condition

$$u(t,x) = 0, \quad t > 0,\ x \in \Gamma_0,$$

the pure slip case

$$\mathcal{S}\nu - (\nu|\mathcal{S}\nu)\nu = 0, \qquad (u|\nu) = 0, \quad t > 0,\ x \in \Gamma_s,$$

and the pure Neumann condition

$$\mathcal{S}\nu = 0, \quad x \in \Gamma_n.$$

Here we decompose $\Gamma = \partial G$ disjointly as $\Gamma = \Gamma_0 \cup \Gamma_s \cup \Gamma_n$, where each set Γ_j is open and closed in Γ. The outer normal of G at $x \in \Gamma$ is denoted by $\nu = \nu(x)$. We emphasize that each Γ_j may be empty.

Already in 1890, Schwedoff realized a nonlinearity in the torque-angular velocity relationship for colloidal gelatin solutions in a Couette device; cf. [24] for further historical information about rheology. It was Ladyzhenskaya who in 1964 suggested studying the partial differential equations for incompressible flows of non-Newtonian fluids in a mathematically rigorous way. Due to her also are the first results on weak solutions, dating back to 1969 [14]. More recently, this problem has been studied intensively by the group around Nečas, leading to many interesting results. This group employs various notions of weak solutions, which have a number of advantages in requiring less regularity of the data or allowing one to handle certain degenerate or singular viscosities; they also yield results that hold globally in time and for large data. We do not want to comment on all of the literature here, but concerning weak solutions we refer to the survey article by Málek and Rajagopal [17], and to the papers [6, 8, 9, 12, 13, 16, 18, 19, 20]. However, in any of the papers in the literature there are some restrictions on the exponent d. In space dimension 3, the least restrictive condition we are aware of is $d > 7/5$; this concerns local-in-time existence and uniqueness of strong solutions. This covers the case of *shear-thickening* fluids well, but is quite restrictive or even does not apply in the *shear-thinning* case $d < 2$. From the engineering literature one can infer that $d \geq 1$ is the range of physical interest. A first step toward a larger range of admissible exponents has been achieved in Wielage [25] for the full-space case $G = \mathbb{R}^n$.

We also want to mention that for small initial values u_0 there are well-posedness results for very general stress-strain relations (cf. [1]), and even analyticity of strong solutions has been proved recently; cf. [7]. For such initial values it has already been shown in [1] that for bounded domains unique strong solutions exist which are global in time.

In this paper we show that, in fact, for $d \geq 1$ the problem is well-posed, locally in time, in *any* space dimension without restriction on the size of the initial velocity u_0.

Another aspect are the boundary conditions. Mainly Dirichlet conditions or periodic boundary conditions have been employed in the non-Newtonian case, so far. One exception is [8], where slip boundary conditions are treated. In the engineering literature, in the non-Newtonian case the no-slip condition is no longer well accepted, as the extensive and thorough discussion in [15] shows.

The consideration of pure slip conditions at the boundary requires a more careful inspection of the form of the proper linearization of the Navier–Stokes system, which is a key point of our analysis. In the end, it is this analysis which allows us to generalize previous results to the situation $d \geq 1$ in all space dimensions.

Our tools will be results on maximal L_p-regularity of the following linear problem, which we call the *generalized Stokes problem*:

$$
\begin{aligned}
\partial_t v + \mathcal{A}(x,D)v + \nabla q &= f(t,x), \quad t > 0,\ x \in G,\\
\operatorname{div} v &= g(t,x), \quad t > 0,\ x \in G,\\
\mathcal{B}_j(x,D)v &= h_j(t,x), \quad t > 0,\ x \in \Gamma_j,\ j = 0, s, n,\\
v(0,x) &= v_0(x), \quad x \in G.
\end{aligned}
\tag{1.3}
$$

Here $\mathcal{A}(x,D)$ is a second order differential operator with continuous top order coefficients acting on $\mathbb{C}^n$-valued functions; $\mathcal{B}_j(x,D)$ denote boundary operators of order zero or one, which correspond to the boundary conditions described above; and the data f, g, h_j, u_0 are given. Assuming *strong normal ellipticity* (cf. section 3) of the initial-boundary value problem without pressure and divergence condition, we show that (1.3) is well-posed and has maximal regularity in L_p as well.

It should be mentioned here that, recently, this problem has also been investigated by Solonnikov [23]. However, in his paper only Dirichlet conditions are considered, and—more importantly—only sufficient conditions for solvability are presented. Moreover, additional regularity assumptions on the coefficients a_{ij}^{kl} are imposed, which are too limiting for solving the nonlinear problem.

Based on our maximal regularity result for the generalized Stokes problem, we are able to prove local well-posedness for the nonlinear problem (1.1) by a contraction argument. This way we are able to extend results in the literature for the L_2 case to L_p, and at the same time we improve the conditions on μ in (1.2) to

$$
\mu(s) > 0 \quad \text{and} \quad \mu(s) + 2s\mu'(s) > 0 \quad \text{for all } s \geq 0. \tag{1.4}
$$

In particular, for the model $\mu(s) = \mu_0(1+s)^{(d-2)/2}$ this follows by $\mu_0 > 0$ and $d \geq 1$. Note that the second condition in (1.4) means that the function $s \mapsto \mu(s)\sqrt{s}$ is strictly increasing. Physically, this is a natural assumption, meaning that the viscous stress given by

$$|S_0|_2 = \mu(|\mathcal{E}|_2^2)|\mathcal{E}|_2$$

is increasing with increasing rate of strain $|\mathcal{E}|_2$.

The linear generalized Stokes problem (1.3) is taken here in a fairly general form. Therefore our approach can also be applied to constitutive laws more general than the generalized Newtonian law considered here, in particular to nonisotropic ones. The only restriction we impose is strong normal ellipticity of the proper linearization, which implies parabolicity of the nonlinear problem. More precisely, we can easily generalize our results to the case

$$\mathcal{S}_{ij} = -\pi\delta_{ij} + \partial_{\varepsilon_{ij}}\psi(u,\mathcal{E}),$$

where $\psi : \mathbb{R}^n \times \mathcal{S}ym(n) \to \mathbb{R}$ is of class C^2 and $\mathcal{S}ym(n)$ is the space of real-valued symmetric matrices of dimension n, provided that $a_{ij}^{kl} = \partial_{\varepsilon_{ik}}\partial_{\varepsilon_{jl}}\psi(u,\mathcal{E})$ is strongly normally elliptic as defined in section 3. Roughly speaking, this means that the scalar function ψ is uniformly convex in its second variable.

The boundary conditions considered here seem to be the most interesting ones, but still generalizations are possible. First, an engineer might be confronted with a fast flow through a tube in direction of coordinate z. Then he would of course require the condition $(u|\nu) = 0$, but he would also neglect circumferential convection at the boundary, i.e., $u_\phi = 0$. However, because of fast flow he would omit friction in the axial direction z, i.e., $\partial_z u_z = 0$. Such boundary conditions are covered by our analysis as well, but we will not discuss them here. Secondly, there might be tangential friction which leads to a boundary condition of the form

$$S\nu - (S\nu|\nu)\nu = -\gamma(u - (u|\nu)\nu),$$

where $\gamma \geq 0$ is an empirical constant. This is known as the *Navier condition* in the literature; cf. [15]. We will not deal with it here since the additional term is a lower order perturbation, which even stabilizes to some extent but does not affect the analysis of local well-posedness and regularity.

The plan for this paper is as follows. Section 2 contains the statement of the main result of this paper, namely well-posedness in the L_p-sense. The discussion of normal ellipticity of the linearized problem in section 3 leads to the condition (1.4) on the function $\mu(s)$. The main result on the generalized Stokes problem is presented in section 4. Sections 5 and 6 deal with constant coefficient generalized Stokes problems on $\mathbb{R}^n$ and on the half-space $\mathbb{R}^n_+$, respectively. By means of localization and straightening of the boundary, these results are extended to general domains with compact C^{3-}-boundary in section 7. The contraction argument is carried out in section 8 for the homogeneous slip and nonslip cases, and in section 9 for general inhomogeneous boundary conditions. In an appendix (section 10), we summarize some auxiliary results on optimal regularity for parabolic systems used in previous sections.

2. Main results. With the definition of $\mathcal{S} := \mathcal{S}_0 - \pi I$ we have $\mathcal{S}_0 = 2\mu(|\mathcal{E}|_2^2)\mathcal{E}$,

$$\begin{aligned}[\operatorname{div}\mathcal{S}_0]_i &= \mu(|\mathcal{E}|_2^2)\sum_{k=1}^{n}(\partial_k^2 u_i + \partial_i\partial_k u_k) + 4\mu'(|\mathcal{E}|_2^2)\sum_{j,k,l=1}^{n}\varepsilon_{ij}\varepsilon_{kl}\partial_j\varepsilon_{kl}\\ &= \mu(|\mathcal{E}|_2^2)\sum_{k=1}^{n}(\partial_k^2 u_i + \partial_i\partial_k u_k) + 4\mu'(|\mathcal{E}|_2^2)\sum_{j,k,l=1}^{n}\varepsilon_{ik}(u)\varepsilon_{jl}(u)\partial_k\partial_l u_j\\ &= \sum_{j,k,l=1}^{n} a_{ij}^{kl}(u)\partial_k\partial_l u_j.\end{aligned}$$

Here we have set

$$a_{ij}^{kl}(u) = \mu(|\mathcal{E}|_2^2)(\delta_{kl}\delta_{ij} + \delta_{il}\delta_{jk}) + 4\mu'(|\mathcal{E}|_2^2)\varepsilon_{ik}(u)\varepsilon_{jl}(u). \tag{2.1}$$

Observe that $a_{ij}^{kl}(u)$ are real and that the symmetries $a_{ij}^{kl} = a_{ji}^{lk} = a_{kl}^{ij} = a_{kj}^{il} = a_{il}^{kj}$ are valid.

Define the quasi-linear differential operator $\mathcal{A}(u, D)$ as

$$\mathcal{A}(u, D) = \sum_{k,l=1}^{n} a_{ij}^{kl}(u) D_k D_l,$$

where $D_k = -i\partial_k$. If the function $u \in W_p^{2-2/p}(G;\mathbb{R}^n)$ is known and $p > n+2$, then by the Sobolev embedding $W_p^{2-2/p}(G;\mathbb{R}^n) \hookrightarrow BUC^1(G;\mathbb{R}^n)$ the coefficients of the differential operator $\mathcal{A}(x, D) = \mathcal{A}(u(x), D)$ are uniformly continuous and

$$[\mathcal{A}(\infty, D)v]_i = -\mu(0)\sum_{k=1}^{n}(\partial_k^2 v_i + \partial_i\partial_k v_k)$$

in case G is unbounded, since $|Du(x)| \to 0$ as $|x| \to \infty$. Denoting the boundary operators on Γ_j by $\mathcal{B}_j(u, D)$, problem (1.1), complemented by the boundary conditions discussed above, can be rewritten as

$$\begin{aligned}\partial_t u + \mathcal{A}(u, D)u + \nabla\pi = f(u), &\quad t \in J,\ x \in G,\\ \operatorname{div} u = 0, &\quad t \in J,\ x \in G,\\ \mathcal{B}_j(u, D)u = 0, &\quad t \in J,\ x \in \Gamma_j,\ j = 0, s, n,\\ u|_{t=0} = u_0. &\end{aligned} \tag{2.2}$$

Here the boundary operators $\mathcal{B}_j$ will be $\mathcal{B}_0(u, D)u = u$ on Γ_0, while on Γ_n they will be $S\nu = 0$, i.e.,

$$\mathcal{B}_n(u, D)(u, \pi) = 2\mu(|\mathcal{E}|_2^2)\mathcal{E}\nu - \pi\nu.$$

Similarly, on Γ_s we obtain

$$\mathcal{B}_s(u, D)u = ((u|\nu), 2\mu(|\mathcal{E}|_2^2)[\mathcal{E}\nu - (\mathcal{E}\nu|\nu)\nu]).$$

The nonlinearity $f(u)$ is the convective term $f(u) = -u \cdot \nabla u$.

It is convenient to introduce the projection $\mathcal{P}$ defined by

$$\mathcal{P}w(x) = w(x) - (w(x)|\nu(x))\nu(x), \quad x \in \Gamma,$$

which projects a vector field w on the boundary Γ of G to its tangential part. $\mathcal{P}$ preserves $W^s_p(\Gamma;\mathbb{R}^n)$ for each $s\in[0,2]$, since G is assumed to be of class C^{3-}, and hence $\nu\in C^{2-}(\Gamma;\mathbb{R}^n)$; here a domain is said to be of class C^{k-} if its boundary is locally parameterized by functions which are in C^{k-1} with a Lipschitz continuous $(k-1)$th derivative. Obtaining this property for $\mathcal{P}$ is the main reason that we impose this particular regularity of the boundary. In what follows, we as usual let $\dot H^1_p(G)$ denote the completion of $H^1_p(G)$ w.r.t. the L_p-gradient norm, and $\frac{1}{p}+\frac{1}{p'}=1$.

Our main result is the following.

THEOREM 2.1. *Let $G\subset\mathbb{R}^n$ be a domain with compact boundary $\Gamma=\partial G$ of class C^{3-}, where $\Gamma=\Gamma_0\cup\Gamma_s\cup\Gamma_n$ with disjoint, open and closed Γ_j; let $n+2<p<\infty$; and assume that $\mu\in C^{2-}(\mathbb{R}_+)$ is such that*

$$\mu(s)>0 \quad \textit{and} \quad \mu(s)+2s\mu'(s)>0 \quad \textit{for all } s\geq 0. \tag{2.3}$$

Then for each $u_0\in W^{2-2/p}_p(G;\mathbb{R}^n)$ satisfying the compatibility conditions

$$\operatorname{div} u_0|_G=0,\quad u_0|_{\Gamma_0}=0,\quad (u_0|\nu)|_{\Gamma_s}=0,\quad \mathcal{P}\mathcal{E}(u_0)\nu|_{\Gamma_s\cup\Gamma_n}=0, \tag{2.4}$$

there is a unique solution (u,π) of (2.2) on a maximal time interval $[0,t^*(u_0))$. The solution is in the maximal regularity class

$$u\in H^1_p(J,L_p(G;\mathbb{R}^n))\cap L_p(J,H^2_p(G;\mathbb{R}^n)),\quad \pi\in L_p(J;\dot H^1_p(G)),$$

additionally with

$$\pi|_{\Gamma_n}\in W^{1/2-1/2p}_p(J;L_p(\Gamma_n))\cap L_p(J;W^{1-1/p}_p(\Gamma_n)),$$

for each interval $J=[0,a]$ with $a<t^*(u_0)$. The maximal time $t^*(u_0)$ is characterized by the property

$$\textit{if } t^*(u_0)<\infty, \quad \textit{then} \quad \lim_{t\to t^*(u_0)} u(t) \ \textit{ does not exist in } \ W^{2-2/p}_p(G;\mathbb{R}^n).$$

The solution map $u_0\mapsto u$ generates a local semiflow on

$$X_{pc}:=\{v\in W^{2-2/p}_p(G;\mathbb{R}^n):\ v \textit{ satisfies } (2.4)\},$$

the natural phase space for the problem in the L_p-setting.

Note that in case $\Gamma_n=\emptyset$ uniqueness of π means uniqueness up to a constant. The remainder of this paper deals with the proof of this result. In fact, in section 9 we will even prove well-posedness for the completely inhomogeneous problem.

3. Linearization and strong normal ellipticity. Consider the differential operator $\mathcal{A}(x,D)$ acting on $\mathbb{C}^n$-valued functions as

$$[\mathcal{A}(x,D)v(x)]_i=\sum_{j,k,l=1}^n a^{kl}_{ij}(x)D_kD_lv_j(x),\quad x\in G.$$

Its symbol is defined as the matrix

$$\mathcal{A}(x,\xi)=\sum_{k,l=1}^n a^{kl}_{ij}(x)\xi_k\xi_l.$$

Such a second order differential operator is called *normally elliptic* if the spectrum $\sigma(\mathcal{A}(x,\xi))$ of the matrix $\mathcal{A}(x,\xi)$ is entirely contained in the open right half-plane $\mathbb{C}_+$ for each $x \in \overline{G}$, $\xi \in \mathbb{R}^n$, $|\xi| = 1$; cf. the appendix. It is called *strongly elliptic* if the numerical range of $\mathcal{A}(x,\xi)$ is a subset of $\mathbb{C}_+$ for each $x \in \overline{G}$, $\xi \in \mathbb{R}^n$, $|\xi| = 1$. Thus strongly elliptic means that there is a constant $c > 0$ such that

$$\operatorname{Re}(\mathcal{A}(x,\xi)\eta|\eta) \geq c \quad \text{ for all } \xi \in \mathbb{R}^n,\ \eta \in \mathbb{C}^n,\ |\xi| = |\eta| = 1,\ x \in G.$$

Here $(\cdot|\cdot)$ denotes the inner product on $\mathbb{C}^n$. Obviously, a strongly elliptic differential operator $\mathcal{A}(x,D)$ is also normally elliptic, but the converse is false, in general.

Let us check what this means in our situation, where $\mathcal{A}(x,D) := \mathcal{A}(u,D)$ is defined as in section 2, with a given function $u \in W_p^{2-2/p}(G;\mathbb{R}^n)$. A simple computation shows for $\xi \in \mathbb{R}^n$, $\eta \in \mathbb{C}^n$, $|\xi| = |\eta| = 1$, by the definition of a_{ij}^{kl} in (2.1) and using the sum convention,

$$a_{ij}^{kl}\xi_l\eta_j = \mu(\xi_k\eta_i + \xi_i\eta_k) + 4\mu'\varepsilon_{ik}\varepsilon_{jl}\xi_l\eta_j.$$

Using the symmetry of $\mathcal{E}(u)$, this yields

$$a_{ij}^{kl}\xi_l\eta_j = 2\mu c_{ik} + 4\mu'\varepsilon_{ik}\overline{((\mathcal{E}|\mathcal{C}))},$$

where $\mathcal{C} = (c_{ik}) = \frac{1}{2}(\xi\otimes\eta + \eta\otimes\xi)$ and $((\cdot|\cdot))$ means the inner product in $\mathbb{C}^{n\times n}$. Next observe that this matrix is symmetric; hence we obtain

$$\begin{aligned}(\mathcal{A}(x,\xi)\eta|\eta) &= a_{ij}^{kl}\xi_l\eta_j\xi_k\overline{\eta}_i \\ &= 2\mu c_{ik}\xi_k\overline{\eta}_i + 4\mu'\varepsilon_{ik}\xi_k\overline{\eta}_i\overline{((\mathcal{E}|\mathcal{C}))} \\ &= 2\mu|\mathcal{C}|_2^2 + 4\mu'|((\mathcal{E}|\mathcal{C}))|^2 \\ &= \mu(|\xi|^2|\eta|^2 + |(\xi|\eta)|^2) + 4\mu'|(\mathcal{E}\xi|\eta)|^2.\end{aligned}$$

Notice that $(\mathcal{A}(x,\xi)\eta|\eta)$ is real, for each $x \in G$, $\xi \in \mathbb{R}^n$, $\eta \in \mathbb{C}^n$. To obtain a necessary condition for strong ellipticity, choose ξ as an eigenvector of $\mathcal{E}$ and η perpendicular to ξ. This shows that the condition $\mu(s) > 0$ for each $s \geq 0$ is necessary for strong ellipticity. Obviously this condition is also sufficient in the case $\mu'(|\mathcal{E}|_2^2) \geq 0$. So suppose that $\mu'(|\mathcal{E}|_2^2) < 0$. Then the Cauchy–Schwarz inequality implies

$$(\mathcal{A}(x,\xi)\eta|\eta) \geq 2\mu|\mathcal{C}|_2^2 + 4\mu'|\mathcal{E}|_2^2|\mathcal{C}|_2^2 \geq c|\mathcal{C}|_2^2,$$

provided that we have

$$\mu(s) > 0 \quad \text{ and } \quad \mu(s) + 2s\mu'(s) > 0 \quad \text{ for all } s \geq 0.$$

If $|\mathcal{C}|_2 = 0$, then $(\mathcal{C}\xi|\xi) = 0$, which means $2|\xi|^2(\eta|\xi) = 0$; hence $(\eta|\xi) = 0$ since $|\xi| = 1$ by assumption. But this in turn yields $2\mathcal{C}\xi = \eta|\xi|^2$, and hence the contradiction $\eta = 0$. Thus strong ellipticity is implied by (2.3), independently of the choice of $u \in W_p^{2-2/p}(G;\mathbb{R}^n)$.

We note that the condition $\mu(s) + 2s\mu'(s) > 0$ for $s > 0$ is also necessary, if one allows for *all* symmetric $\mathcal{E}$; choose, e.g., $\mathcal{E} = \operatorname{diag}(\sqrt{s}, 0, \ldots, 0)$ to see this.

Let us next discuss the Lopatinskii–Shapiro condition for the parabolic problem without pressure and incompressibility. For this purpose let $\xi \in \mathbb{R}^n$, $\nu \in \mathbb{R}^n$, $|\nu| = 1$, $(\xi|\nu) = 0$, $\operatorname{Re}\lambda \geq 0$. For convenience, we drop the x-dependence. Consider the linear ode-problem with constant coefficients

$$\lambda w(y) + \mathcal{A}(\xi - \nu D_y)w(y) = 0, \quad y > 0, \quad \mathcal{B}(\xi - \nu D_y)w(0) = 0.$$

The Lopatinskii–Shapiro condition requires that any solution $w \in C_0(\mathbb{R}_+;\mathbb{C}^n)$ of this problem be zero; cf. the appendix. Note that strong ellipticity already implies $w \in H^2_2(\mathbb{R}_+;\mathbb{C}^n)$.

To verify the Lopatinskii–Shapiro condition, we form the inner product of the equation with a solution w, integrate over $\mathbb{R}_+$, and integrate by parts to obtain the result

$$\begin{aligned}
0 &= \lambda|w|_2^2 + \int_0^\infty (\mathcal{A}(\xi - \nu D_y)w(y)|w(y))dy \\
&= \lambda|w|_2^2 + \int_0^\infty \sum_{i,j,k,l=1}^n a_{ij}^{kl}(\xi_l - \nu_l D_y)w_j(y)\overline{(\xi_k - \nu_k D_y)w_i(y)}dy \\
&\quad - i \sum_{i,j,k,l=1}^n \nu_k a_{ij}^{kl}(\xi_l - \nu_l D_y)w_j(0)\overline{w_i(0)} \\
&= \lambda|w|_2^2 + \int_0^\infty \sum_{i,j,k,l=1}^n a_{ij}^{kl}(\xi_l - \nu_l D_y)w_j(y)\overline{(\xi_k - \nu_k D_y)w_i(y)}dy,
\end{aligned}$$

provided that the boundary term vanishes. This is, of course, the case if w is subject to Dirichlet conditions, i.e., on Γ_0, or in case of Neumann conditions on Γ_n,

$$[\mathcal{B}(\xi - \nu D_y)w]_i(0) = \sum_{j,k,l=1}^n \nu_k a_{ij}^{kl}(\xi_l - \nu_l D_y)w_j(0) = 0.$$

But it is also true in the case $(w|\nu) = 0$ and

$$\mathcal{B}(\xi - \nu D_y)w(0) - (\mathcal{B}(\xi - \nu D_y)w(0)|\nu)\nu = 0,$$

which corresponds to the pure slip case, i.e., to Γ_s.

Next consider the generalized Stokes problem (1.3). The same arguments yield

$$\begin{aligned}
0 &= \lambda|w|_2^2 + \int_0^\infty (\mathcal{A}(\xi - \nu D_y)w(y)|w(y))dy + \int_0^\infty ((i\xi - \nu\partial_y)\pi(y)|w(y))dy \\
&= \lambda|w|_2^2 + \int_0^\infty \sum_{i,j,k,l=1}^n [a_{ij}^{kl}(\xi_l - \nu_l D_y)w_j\overline{(\xi_k - \nu_k D_y)w_i} + \pi((i\xi + \nu\partial_y)|w)]dy \\
&\quad - i \sum_{i,j,k,l=1}^n [\nu_k a_{ij}^{kl}(\xi_l - \nu_l D_y)w_j(0) + i\nu_i\pi(0)]\overline{w_i(0)} \\
&= \lambda|w|_2^2 + \int_0^\infty \sum_{i,j,k,l=1}^n a_{ij}^{kl}(\xi_l - \nu_l D_y)w_j(y)\overline{(\xi_k - \nu_k D_y)w_i(y)}dy,
\end{aligned}$$

provided that the boundary term vanishes again, and since $((i\xi + \nu\partial_y)|w) = 0$. Once more, this is certainly true if w is subject to Dirichlet conditions on Γ_0, or in case of the relevant Neumann condition for this situation on Γ_n,

$$\mathcal{B}(\xi - \nu D_y)(w(0), \pi(0)) = \left(\sum_{j,k,l=1}^n \nu_k a_{ij}^{kl}(\xi_l - \nu_l D_y)w_j(0) + i\pi(0)\nu_i \right)_{i=1}^n = 0.$$

However, as before, it is also true in the case $(w|\nu) = 0$ and

$$\mathcal{B}(\xi - \nu D_y)w(0) - (\mathcal{B}(\xi - \nu D_y)w(0)|\nu)\nu = 0,$$

i.e., for the pure slip case on Γ_s.

Thus in all cases we have the identity

$$0 = \lambda|w|_2^2 + \int_0^\infty \sum_{i,j,k,l=1}^n a_{ij}^{kl}(\xi_l - \nu_l D_y)w_j(y)\overline{(\xi_k - \nu_k D_y)w_i(y)}dy. \tag{3.1}$$

To satisfy the Lopatinskii–Shapiro condition, we would like to conclude from this identity that $w \equiv 0$. For this purpose we introduce the following notation.

Definition 3.1. *$\mathcal{A}(D)$ is called* strongly normally elliptic *if it is strongly elliptic and*

$$\mathrm{Re} \sum_{i,j,k,l=1}^n a_{ij}^{kl}(\xi_l u_j - \nu_l v_j)\overline{(\xi_k u_i - \nu_k v_i)} > 0$$

for all $\xi, \nu \in \mathbb{R}^n$, $|\xi| = |\nu| = 1$, $(\xi|\nu) = 0$, $u, v \in \mathbb{C}^n$, $\mathrm{Im}\,(u|v) \neq 0$.

Let us show that this condition implies $w \equiv 0$, for each $w \in H_2^1(\mathbb{R}_+; \mathbb{C}^n)$ satisfying (3.1) with $\mathrm{Re}\,\lambda \geq 0$. In fact, taking real parts in (3.1), we obtain

$$\int_0^\infty \mathrm{Re} \sum_{i,j,k,l=1}^n a_{ij}^{kl}(\xi_l w_j(y) - \nu_l D_y w_j(y))\overline{(\xi_k w_i(y) - \nu_k D_y w_i)(y)}dy = 0,$$

and hence

$$\frac{d}{dy}|w(y)|^2 = 2\,\mathrm{Re}\left(\frac{d}{dy}w(y)|w(y)\right) = -2\,\mathrm{Im}\,(D_y w(y)|w(y)) = 0, \quad y > 0.$$

However, this implies that $|w(y)|$ is constant on $\mathbb{R}_+$, and hence $w(y) = 0$ on $\mathbb{R}_+$. So strong normal ellipticity implies the Lopatinskii–Shapiro condition for all three types of boundary operators introduced above.

Let us check what strong normal ellipticity means for the generalized Stokes problem with a_{ij}^{kl} from (2.1). With $\mathcal{D} = \xi \otimes u + \nu \otimes v$, $\mathcal{C} = \frac{1}{2}(\mathcal{D} + \mathcal{D}^T)$, and using sum convention again, we have

$$a_{ij}^{kl} d_{lj} = \mu(d_{ik} + d_{ki}) + 4\mu' \varepsilon_{ik}\varepsilon_{jl} d_{lj} = 2\mu c_{ik} + 4\mu' \varepsilon_{ik}\overline{((\mathcal{E}|\mathcal{C}))},$$

by symmetry of $\mathcal{E}$. Note that the resulting matrix is symmetric. This yields

$$a_{ij}^{kl} d_{lj}\overline{d}_{ki} = 2\mu|\mathcal{C}|_2^2 + 4\mu'|((\mathcal{E}|\mathcal{C}))|^2;$$

hence this expression is real and

$$a_{ij}^{kl} d_{lj}\overline{d}_{ki} \geq 2\min\{\mu, \mu + 2\mu'|\mathcal{E}|_2^2\}|\mathcal{C}|_2^2.$$

Condition (2.3) implies $a_{ij}^{kl} d_{lj}\overline{d_{ki}} \geq 0$, and $\mathcal{C} = 0$ in case of equality. This yields $\mathcal{C}\xi = 0$ as well as $\mathcal{C}\nu = 0$, and leads to the relations

$$u + (v|\xi)\nu + (u|\xi)\xi = v + (v|\nu)\nu + (u|\nu)\xi = 0.$$

Taking the inner product with ξ (resp., ν), we obtain $(u|\xi) = (v|\nu) = 0$ and $(u|\nu) + (v|\xi) = 0$. We may then conclude

$$u = \alpha\nu, \quad v = -\alpha\xi,$$

and in particular $(u|v) = 0$.

Thus, the Lopatinskii–Shapiro condition also holds for the generalized Stokes problem, as far as $\xi \neq 0$. We want to stress that $\pi = 0$ follows from the equations as long as $\xi \neq 0$. However, if $\xi = 0$, then we obtain $\pi = 0$ from the Neumann boundary condition, but only $\pi = const$ in case of slip or no-slip conditions. This reflects the nonuniqueness of the pressure for no-slip and slip conditions.

4. The generalized Stokes problem on domains. Let $G \subset \mathbb{R}^n$ be a domain with compact boundary $\Gamma = \partial G$, and $J = [0, a]$. We decompose Γ disjointly as $\Gamma = \Gamma_0 \cup \Gamma_s \cup \Gamma_n$, where Γ_j is open and closed in Γ. In this section we consider the fully inhomogeneous initial-boundary value problem

$$\begin{aligned} \partial_t v + \mathcal{A}(t,x,D)v + \nabla q &= f, \quad t \in J,\ x \in G, \\ \operatorname{div} v &= g, \quad t \in J,\ x \in G, \\ \mathcal{B}_j(t,x,D)v &= h_j, \quad t \in J,\ x \in \Gamma_j,\ j = 0, s, n, \\ v|_{t=0} &= v_0. \end{aligned} \tag{4.1}$$

Here $\mathcal{A}(t,x,D) = \sum_{k,l=1}^n \mathcal{A}^{kl}(t,x) D_k D_l$ denotes a strongly normally elliptic differential operator, and the boundary operator $\mathcal{B}_j(t,x,D)$ is $\mathcal{B}_0(t,x,D)v = v$ on Γ_0, while on Γ_n it is given by

$$[\mathcal{B}_n(t,x,D)(v,q)]_i = \sum_{j,k,l=1}^n a_{ij}^{kl}(t,x)\nu_k D_l v_j + iq\nu_i,$$

and on Γ_s it is

$$[\mathcal{B}_s(t,x,D)v]_i = \left((v|\nu),\ \sum_{j,k,l=1}^n a_{ij}^{kl}(t,x)\nu_k D_l v_j - \left[\sum_{r,j,k,l=1}^n a_{rj}^{kl}(t,x)\nu_k\nu_r D_l v_j \right] \nu_i \right).$$

We suppose that the coefficients $\mathcal{A}^{kl}(t,x)$ of $\mathcal{A}(t,x,D)$ are continuous on $J \times \overline{G}$ and have limits $\mathcal{A}^{kl}(t,\infty)$ at $x = \infty$, uniformly in $t \in J$, in case G is unbounded, and that $\mathcal{A}(t,\infty,D)$ is strongly elliptic as well. In addition, we assume

$$a_{ij}^{kl} \in W_s^{1/2-1/2p}(J; L_r(\Gamma_s \cup \Gamma_n)) \cap L_s(J; W_r^{1-1/p}(\Gamma_s \cup \Gamma_n)),$$

for some $r, s \geq p$ such that $\frac{1}{s} + \frac{n-1}{2r} < 1 - \frac{1}{p}$.

Suppose that (4.1) has a solution in the class

$$v \in H_p^1(J; L_p(G;\mathbb{C}^n)) \cap L_p(J; H_p^2(G;\mathbb{C}^n)), \quad q \in L_p(J; \dot{H}_p^1(G)).$$

Then, following the paper of Denk, Hieber, and Prüss [5], we may conclude $f \in L_p(J \times G;\mathbb{C}^n)$, $g \in L_p(J; H_p^1(G))$, $v_0 \in W_p^{2-2/p}(G;\mathbb{C}^n)$, and the compatibility $\operatorname{div} v_0 = g|_{t=0}$. Furthermore,

$$v|_\Gamma \in W_p^{1-1/2p}(J; L_p(\Gamma;\mathbb{C}^n)) \cap L_p(J; W_p^{2-1/p}(\Gamma;\mathbb{C}^n))$$

and

$$\nabla v|_\Gamma \in W_p^{1/2-1/2p}(J;L_p(\Gamma;\mathbb{C}^{n\times n}))\cap L_p(J;W_p^{1-1/p}(\Gamma;\mathbb{C}^{n\times n})).$$

This implies

$$\begin{aligned} h_0 &\in W_p^{1-1/2p}(J;L_p(\Gamma_0;\mathbb{C}^n))\cap L_p(J;W_p^{2-1/p}(\Gamma_0;\mathbb{C}^n)),\\ h_s &\in W_p^{1/2-1/2p}(J;L_p(\Gamma_s;\mathbb{C}^n))\cap L_p(J;W_p^{1-1/p}(\Gamma_s;\mathbb{C}^n)),\\ h_{j2} := (u|\nu) &\in W_p^{1-1/2p}(J;L_p(\Gamma_j))\cap L_p(J;W_p^{2-1/p}(\Gamma_j)), \qquad j=0,s,\\ h_n &\in W_p^{1/2-1/2p}(J;L_p(\Gamma_n;\mathbb{C}^n))\cap L_p(J;W_p^{1-1/p}(\Gamma_n;\mathbb{C}^n)),\end{aligned}$$

and with $h_{s1} := \mathcal{P}h_s$ the compatibility conditions $h_0|_{t=0} = v_0|_{\Gamma_0}$ in case $p>3/2$, $h_{s1}|_{t=0} = \mathcal{P}a_{ij}^{kl}(0,x)\nu_k D_l u_{0j}|_{\Gamma_s}$ in case $p>3$, $h_{s2}|_{t=0} = (v_0|\nu)|_{\Gamma_s}$, and $\mathcal{P}h_n|_{t=0} = \mathcal{P}a_{ij}^{kl}(0,x)\nu_k D_l v_{0j}|_{\Gamma_s}$ in case $p>3$. Note that ν is of class C^{2-} since Γ is assumed to be C^{3-}.

But in addition to these natural conditions on the data, there is a more involved structural property which is due to the divergence equation. To see this, take the L_2-inner product of a function $\phi\in H^1_{p'}(G)$ with the equation $\operatorname{div} v = g$, and integrate to the result

$$\int_G (\operatorname{div} v)\,\phi\,dx - \int_\Gamma (v|\nu)\phi\,d\sigma = -\int_G (v|\nabla\phi)dx.$$

Replacing $\operatorname{div} v$ by g and $(v|\nu)$ by h_ν, this yields

$$\langle F_{g,h_\nu}|\phi\rangle := \int_G g\phi\,dx - \int_\Gamma h_\nu\phi\,d\sigma = -\int_G (v|\nabla\phi)dx.$$

Differentiating w.r.t. t, we get

$$\frac{d}{dt}\langle F_{g,h_\nu}|\phi\rangle = -\int_G (\partial_t v|\nabla\phi)dx.$$

Define $\dot H^1_{p,\Gamma_n}(G)$ as

$$\dot H^1_{p,\Gamma_n}(G) = \{v\in H^1_{p,loc}(G):\ \nabla v\in L_p(G;\mathbb{C}^n), v|_{\Gamma_n}=0\},$$

and set

$$\dot H^{-1}_{p,\Gamma_n}(G) = (\dot H^1_{p',\Gamma_n}(G)/constants)^*.$$

Then we may conclude $F_{g,h_\nu}\in H^1_p(J;\dot H^{-1}_{p,\Gamma_n}(G))$. For this property, we write briefly $(g,h_\nu)\in H^1_p(J;\dot H^{-1}_{p,\Gamma_n}(G))$. Summarizing, we obtain the following necessary conditions on the data.

(D) *Assumptions on the data.*

(a) $f\in L_p(J\times G;\mathbb{C}^n)$.

(b1) $g\in L_p(J;H^1_p(G))$.

(b2) $(g,h_\nu)\in H^1_p(J;\dot H^{-1}_{p,\Gamma_n}(G))$, where $h_\nu = h_{j2}$ on Γ_j, $j=0,s$.

(c) $v_0\in W_p^{2-2/p}(G;\mathbb{C}^n)$ and $\operatorname{div} v_0 = g|_{t=0}$, $h_\nu|_{t=0} = (v_0|\nu)|_{\Gamma_j}$, $j=0,s$.

(d0) $h_0\in W_p^{1-1/2p}(J;L_p(\Gamma_0;\mathbb{C}^n))\cap L_p(J;W_p^{2-1/p}(\Gamma_0;\mathbb{C}^n))$;

$h_0|_{t=0} = v_0|_{\Gamma_0}$ in case $p > 3/2$.

(ds) $h_s \in W_p^{1/2-1/2p}(J; L_p(\Gamma_s; \mathbb{C}^n)) \cap L_p(J; W_p^{1-1/p}(\Gamma_s; \mathbb{C}^n))$,
$h_{s2} \in W_p^{1-1/2p}(J; L_p(\Gamma_0)) \cap L_p(J; W_p^{2-1/p}(\Gamma_0))$;
$h_{s1}|_{t=0} = \mathcal{P}a_{ij}^{kl}(0,x)\nu_k D_l v_{0j}|_{\Gamma_s}$ in case $p > 3$.

(dn) $h_n \in W_p^{1/2-1/2p}(J; L_p(\Gamma_n; \mathbb{C}^n)) \cap L_p(J; W_p^{1-1/p}(\Gamma_n; \mathbb{C}^n))$;
$\mathcal{P}h_n|_{t=0} = \mathcal{P}a_{ij}^{kl}(0,x)\nu_k D_l v_{0j}|_{\Gamma_s}$ in case $p > 3$.

Note that in case G is bounded and $\Gamma_n = \emptyset$, the natural compatibility condition

$$\int_G g\,dx - \int_\Gamma h_\nu\, d\sigma = 0$$

is included in (b2).

Based on the results for problem (4.1) on $G = \mathbb{R}^n$ and $G = \mathbb{R}^n_+$, by means of localization and straightening of the boundary of G, we can prove also the sufficiency of these conditions, which yields the following result.

THEOREM 4.1. *Let G and $\mathcal{A}(t,x,D)$ be as above, and let $1 < p < \infty$, $p \neq 3/2, 3$. Then* (4.1) *has maximal L_p-regularity in the following sense. There is a unique solution (v,q) of* (4.1) *in the class*

$$v \in H_p^1(J; L_p(G; \mathbb{C}^n)) \cap L_p(J; H_p^2(G; \mathbb{C}^n)), \quad q \in L_p(J; \dot{H}_p^1(G)),$$

such that $q \in W_p^{1/2-1/2p}(J; L_p(\Gamma_n)) \cap L_p(J; W_p^{1-1/p}(\Gamma_n))$ if and only if the data f, g, v_0, h_j satisfy conditions (D). *The solution (v,q) depends continuously on the data in the corresponding spaces. For $f \equiv g \equiv h \equiv 0$ and a_{ij}^{kl} independent of t the solutions u generate a semiflow in*

$$X_{pc} = \{v \in W_p^{2-2/p}(G; \mathbb{C}^n) : \operatorname{div} v = 0,\ v|_{\Gamma_0} = (v|\nu)|_{\Gamma_s} = \mathcal{P}a_{ij}^{kl}\nu_k D_l v|_{\Gamma_s \cup \Gamma_n} = 0\},$$

the natural phase space for (4.1) *in the L_p-setting.*

The proof of this result is given in section 7.

It is sometimes convenient to reduce the data to $v_0 = g = h_\nu = 0$. For this we have the following result.

PROPOSITION 4.2. *Let v_0, g, h_ν satisfying the relevant conditions in* (D) *be given. Then there is a function $v_* \in H_p^1(J; L_p(G; \mathbb{C}^n)) \cap L_p(J; H_p^2(G; \mathbb{C}^n))$ such that*

$$\operatorname{div} v_* = g, \quad v_*|_{t=0} = v_0, \quad (v_*|\nu)|_{\Gamma_0 \cup \Gamma_s} = h_\nu,$$

and v_* depends continuously on (v_0, g, h_ν) in the corresponding spaces.

Proof. Since $\nabla : \dot{H}_{p'}^1(G)/constants \to L_{p'}(G; \mathbb{C}^n)$ is injective and has closed range, its dual $\nabla^* := -\mathrm{div} : L_p(G; \mathbb{C}^n) \to \dot{H}_p^{-1}(G)$ is surjective. Choose a bounded right inverse R of ∇^*, which exists since the kernel of ∇^* is complemented in $L_p(G; \mathbb{C}^n)$. This assertion follows from the boundedness of the corresponding Helmholtz projection; cf. [22]. Then $Rg \in H_p^1(J; L_p(G; \mathbb{C}^n))$. Next, solve the parabolic problem

$$\begin{aligned}
(\partial_t - \Delta)w &= \partial_t Rg - \nabla g, \quad t \in J,\ x \in G,\\
w|_{t=0} &= v_0, \quad x \in G,\\
\operatorname{div} w &= g, \quad t \in J,\ x \in \Gamma,\\
\mathcal{P}w &= e^{\Delta_\Gamma t}(\mathcal{P}v_0|_\Gamma),
\end{aligned} \tag{4.2}$$

where Δ_Γ denotes the Laplace–Beltrami operator on Γ. Note that the right-hand side $f = \partial_t Rg - \nabla g$ belongs to $L_p(J \times G)$, $v_0 \in W_p^{2-2/p}(G; \mathbb{C}^n)$ by assumption; hence

$\mathcal{P}v_0|_\Gamma \in W_p^{2-3/p}(\Gamma;\mathbb{C}^n)$, and so the boundary function $h(t) = e^{\Delta_\Gamma t}(\mathcal{P}v_0|_\Gamma)$ belongs to $W_p^{1-1/2p}(J; L_p(\Gamma;\mathbb{C}^n)) \cap L_p(J; W_p^{2-1/p}(\Gamma;\mathbb{C}^n))$, by parabolic regularity theory, and the compatibility condition $\mathcal{P}h|_{t=0} = \mathcal{P}v_0|_\Gamma$ is valid. Similarly, taking traces, $g|_\Gamma$ belongs to $W_p^{1/2-1/2p}(J; L_p(\Gamma;\mathbb{C}^n)) \cap L_p(J; W_p^{1-1/p}(\Gamma;\mathbb{C}^n))$ by assumption and fulfills the compatibility condition $\operatorname{div} v_0 = g|_{t=0}$. Moreover, the Lopatinskii–Shapiro condition is easily seen to be valid (cf. the appendix), and hence problem (4.2) admits a unique solution w in the maximal class of L_p, by Theorem 10.1. Now set $\phi = \operatorname{div} w - g$. Then we see that ϕ solves the problem

$$\begin{aligned} (\partial_t - \Delta)\phi &= 0, \quad t \in J,\ x \in G, \\ \phi|_{t=0} &= 0, \quad x \in G, \\ \phi &= 0, \quad t \in J,\ x \in \Gamma; \end{aligned} \tag{4.3}$$

i.e., $\phi = 0$ by uniqueness of the parabolic problems. Thus the first two conditions in the proposition are valid for w. To obtain v_* we have to modify w in the following way. Solve the problem

$$\begin{aligned} \Delta\psi &= 0, \quad t \in J,\ x \in G, \\ \partial_\nu\psi &= h_\nu - (w|\nu), \quad t \in J,\ x \in \Gamma_0 \cup \Gamma_s, \\ \psi &= 0, \quad t \in J,\ x \in \Gamma_n, \end{aligned} \tag{4.4}$$

and set $v_* = w + \nabla\psi$. This function has the desired properties since for the boundary datum we have $h_\nu \in H_p^1(J; \dot{W}_p^{-1/p}(\Gamma_0 \cup \Gamma_s)) \cap L_p(J; W_p^{2-1/p}(\Gamma_0 \cup \Gamma_s))$, by assumption (b2). Here we once more used $\Gamma \in C^{3-}$. Note that the time trace of $h_\nu - (w|\nu)$ at $t = 0$ is zero by construction, and hence v_* has the right initial condition $v_*(0) = v_0$. ☐

5. The generalized Stokes problem on $\mathbb{R}^n$. Let $J = [0,T]$ be a compact interval, and consider the problem

$$\begin{aligned} \partial_t u + \mathcal{A}(D)u + \nabla\pi &= f(t,x), \quad t \in J,\ x \in \mathbb{R}^n, \\ \operatorname{div} u &= g(t,x), \quad t \in J,\ x \in \mathbb{R}^n, \\ u(0,x) &= u_0(x), \quad x \in \mathbb{R}^n. \end{aligned} \tag{5.1}$$

Here $\mathcal{A}(D) = \sum_{k,l=1}^n \mathcal{A}^{kl} D_k D_l$ denotes a differential operator with constant coefficient matrices $\mathcal{A}^{kl}$ acting on $\mathbb{C}^n$-valued functions. We assume that $\mathcal{A}(D)$ is *strongly elliptic*. This implies (cf. the appendix) that the problem

$$\begin{aligned} \partial_t u + \mathcal{A}(D)u &= f(t,x), \quad t \in J,\ x \in \mathbb{R}^n, \\ u(0,x) &= u_0(x), \quad x \in \mathbb{R}^n, \end{aligned} \tag{5.2}$$

has maximal L_p-regularity, $1 < p < \infty$. In particular, for each $f \in L_p(J \times \mathbb{R}^n; \mathbb{C}^n)$, $u_0 \in W_p^{2-2/p}(\mathbb{R}^n;\mathbb{C}^n)$ there is a unique solution u of (5.2) in the class

$$u \in H_p^1(J; L_p(\mathbb{R}^n;\mathbb{C}^n)) \cap L_p(J; H_p^2(\mathbb{R}^n;\mathbb{C}^n)) \hookrightarrow C(J; W_p^{2-2/p}(\mathbb{R}^n;\mathbb{C}^n)).$$

We want to show that a similar assertion is valid for the generalized Stokes problem (5.1). More precisely, with the definition of

$$\dot{H}_p^{-1}(\mathbb{R}^n) = (\dot{H}_{p'}^1(\mathbb{R}^n)/\mathit{constants})^* = \{f \in \mathcal{S}'(\mathbb{R}^n) : \mathcal{F}^{-1}|\xi|^{-1}\mathcal{F}f \in L_p(\mathbb{R}^n)\},$$

where $\mathcal{F}$ denotes Fourier transform, we have the following result.

THEOREM 5.1. *Let $1 < p < \infty$, and assume that $\mathcal{A}(D) = \sum_{k,l=1}^{n} \mathcal{A}^{kl} D_k D_l$ is strongly elliptic. Then* (5.1) *has maximal L_p-regularity in the following sense. There is a unique solution (u, π) of* (5.1) *in the class*

$$u \in H^1_p(J; L_p(\mathbb{R}^n; \mathbb{C}^n)) \cap L_p(J; H^2_p(\mathbb{R}^n; \mathbb{C}^n)), \quad \pi \in L_p(J; \dot{H}^1_p(\mathbb{R}^n)),$$

if and only if the data f, g, u_0 satisfy the following conditions:

(a) $f \in L_p(J \times \mathbb{R}^n; \mathbb{C}^n)$;

(b) $g \in H^1_p(J; \dot{H}^{-1}_p(\mathbb{R}^n)) \cap L_p(J; H^1_p(\mathbb{R}^n))$;

(c) $u_0 \in W^{2-2/p}_p(\mathbb{R}^n; \mathbb{C}^n)$ *and* $\mathrm{div}\, u_0 = g|_{t=0}$.

The solution (u, π) depends continuously on the data in the corresponding spaces. For $f \equiv g \equiv 0$ the solutions generate a semiflow in

$$X_p = \{v \in W^{2-2/p}_p(\mathbb{R}^n; \mathbb{C}^n) : \ \mathrm{div}\, u = 0\},$$

the natural phase space for (5.1) *in the L_p-setting.*

Proof. To prove sufficiency of the conditions, note that by the open mapping theorem, the continuity assertion follows as soon as the solvability assertion is proved. So let data f, g, u_0 be given, which are subject to conditions (a), (b), and (c). We first solve the parabolic problem

$$\partial_t v + \mathcal{A}(D)v = f, \quad v(0) = u_0,$$

with maximal L_p-regularity, applying the main result of Denk, Hieber, and Prüss [4, section 5]; cf. section 10, Theorem 10.1. Then $w = u - v$ must be a solution of the system

$$\partial_t w + \mathcal{A}(D)w + \nabla \pi = 0, \quad \mathrm{div}\, w = g_0, \quad w(0) = 0,$$

where $g_0 = g - \mathrm{div}\, v$ has the same regularity as g and trace 0 at time $t = 0$.

Suppose that the pressure π is already known. Taking Fourier transform in the space variables and Laplace transform in the time variable, we obtain the system

$$\begin{aligned} \lambda \hat{w} + \mathcal{A}(\xi)\hat{w} &= -i\xi\hat{\pi}, \\ i(\hat{w}|\xi) &= \hat{g}_0. \end{aligned} \tag{5.3}$$

Solving for $\hat{w}$, this yields

$$\hat{w} = -i(\lambda + \mathcal{A}(\xi))^{-1}\xi\hat{\pi},$$

and inserting this relation into the second equation of (5.3), we obtain

$$\hat{g}_0 = ((\lambda + \mathcal{A}(\xi))^{-1}\xi|\xi)\hat{\pi}.$$

Set $\eta = (\lambda + \mathcal{A}(\xi))^{-1}\xi$; then $\eta \neq 0$ unless $\xi = 0$, and

$$\alpha(\lambda, \xi) := ((\lambda + \mathcal{A}(\xi))^{-1}\xi|\xi) = \overline{\lambda}|\eta|^2 + (\eta|\mathcal{A}(\xi)\eta).$$

Hence strong ellipticity of $\mathcal{A}(D)$ implies $\alpha(\lambda, \xi) \neq 0$ for all $\xi \in \mathbb{R}^n$, $\lambda \in \Sigma_\theta$ with $|\xi| + |\lambda| \neq 0$, provided that $\theta > \pi/2$ is sufficiently close to $\pi/2$. We may now solve for $\hat{\pi}$ to the result

$$\hat{\pi} = \frac{\hat{g}_0}{\alpha(\lambda, \xi)},$$

and for $\hat{w}$ we get

$$\hat{w} = -i\frac{(\lambda + \mathcal{A}(\xi))^{-1}\xi}{\alpha(\lambda,\xi)}\hat{g}_0.$$

Choose

$$v_0 \in {}_0H^1_p(J; L_p(\mathbb{R}^n;\mathbb{C}^n)) \cap L_p(J; H^2_p(\mathbb{R}^n;\mathbb{C}^n)), \quad \text{div } v_0 = g_0;$$

this is possible by assumption (b) on the function g. In fact, setting

$$g_1 = (-\Delta)^{-1/2}\partial_t g_0 + (-\Delta)^{1/2} g_0,$$

we obtain $g_0 = -\text{div } R(\partial_t - \Delta)^{-1} g_1$, where R denotes the Riesz transform defined by the symbol $i\xi/|\xi|$; i.e., we may choose $v_0 = -R(\partial_t - \Delta)^{-1} g_1$. Therefore

$$(\partial_t - \Delta)w = T_1(\partial_t - \Delta)v_0, \quad \nabla\pi = T_2(\partial_t - \Delta)v_0,$$

where T_j are defined by means of their Fourier–Laplace symbols

$$\hat{T}_1(\lambda,\xi) = \frac{(\lambda + \mathcal{A}(\xi))^{-1}\xi\otimes\xi}{\alpha(\lambda,\xi)}, \quad \hat{T}_2(\lambda,\xi) = -\frac{\xi\otimes\xi}{(\lambda + |\xi|^2)\alpha(\lambda,\xi)}.$$

Thus, to prove the theorem, it is enough to show that the operators T_j are bounded in L_p.

This in turn will follow by an application of the Kalton–Weis theorem and $\mathcal{R}$-boundedness of families of Fourier multipliers. By the scaling $\mu = \lambda/|\xi|^2$, $\zeta = \xi/|\xi|$, we may rewrite the symbols as

$$\hat{T}_1(\lambda,\xi) = \frac{(\mu + \mathcal{A}(\zeta))^{-1}\zeta\otimes\zeta}{\alpha(\mu,\zeta)}, \quad \hat{T}_2(\lambda,\xi) = -\frac{\zeta\otimes\zeta}{(1+\mu)\alpha(\mu,\zeta)}.$$

By strong ellipticity, we already know $\alpha(\mu,\zeta) \neq 0$ for all $\zeta \in \mathbb{R}^n$, $|\zeta| = 1$, and $\mu \in \Sigma_\phi$, for some $\phi > \pi/2$. As $|\mu| \to \infty$ we have $\mu\alpha(\mu,\zeta) \to 1$, while $\alpha(\mu,\zeta) \to \alpha(0,\zeta) = (\mathcal{A}(\zeta)^{-1}\zeta|\zeta) \neq 0$ as $\mu \to 0$. Therefore, by compactness, $|(1+\mu)\alpha(\mu,\zeta)| \geq \alpha_0 > 0$ for all such ζ and μ, where α_0 denotes a constant. This implies boundedness of the symbols $\hat{T}_j(\mu|\xi|^2,\xi)$, uniformly in ξ and μ. Furthermore, $\hat{T}_j(\mu|\xi|^2,\xi)$ are homogeneous in ξ of degree 0, and so $|\xi|^{|\beta|}D^\beta_\xi \hat{T}_j(\mu|\xi|^2,\xi)$ are also uniformly bounded in ξ and μ, for each multi-index $\beta \in \mathbb{N}^n_0$. The classical Mikhlin multiplier theorem then implies that these symbols are Fourier multipliers in $L_p(\mathbb{R}^n;\mathbb{C}^n)$ w.r.t. ξ, which yields a holomorphic uniformly bounded family $\{T_j(\mu)\}_{\mu\in\Sigma_\phi} \subset \mathcal{B}(L_p(\mathbb{R}^n;E_j))$ for $j = 1,2$, where $E_1 = \mathbb{C}^n$, $E_2 = \mathbb{C}$. Theorem 3.2 of Girardi and Weis [10] shows that this family is also $\mathcal{R}$-bounded in $L_p(\mathbb{R}^n;E_j)$, and hence in $L_p(J;L_p(\mathbb{R}^n;E_j))$ as well. Since the operator $L := \partial_t(-\Delta)^{-1}$ admits an $\mathcal{H}^\infty$-calculus in $L_p(J;L_p(\mathbb{R}^n;E_j))$ of angle $\pi/2$, the Kalton–Weis theorem [11] implies boundedness of $T_j(L)$ in $L_p(J;L_p(\mathbb{R}^n;E_j))$. This completes the proof of Theorem 5.1. ∎

We can easily extend Theorem 5.1 to the case of variable coefficients with small deviation from constant ones. To see this, let $\mathcal{A}(t,x,D) = \mathcal{A}_0(D) + \mathcal{A}_1(t,x,D)$, where

$$\sup\{|a^{kl}_{1,ij}| : k,l,i,j = 1,\ldots,n,\ t\in J,\ x\in\mathbb{R}^n\} \leq \eta.$$

Let S denote the solution operator of the generalized Stokes problem (5.1) from Theorem 5.1 for $\mathcal{A}_0(D)$, and T that of the perturbed problem. Then we obtain the identity

$$T = S + SBT, \qquad \text{where} \qquad B = \begin{bmatrix} -\mathcal{A}_1(t,x,D) & 0 \\ 0 & 0 \end{bmatrix}.$$

The norm of B as an operator from the maximal regularity space into $L_p(J\times\mathbb{R}^n;\mathbb{C}^n)$ is bounded by $C\eta$, where $C>0$ denotes a constant independent of η. Let $|S|$ stand for the norm of the solution operator from the data space to the maximal regularity space. If $|S|C\eta<1$, then a Neumann series argument shows that $T=(I-SB)^{-1}S$ in fact exists and is bounded as a map from the data space to the maximal regularity space as well. Let us record this as the following result.

Corollary 5.2. *The assertions of Theorem* 5.1 *remain valid in the case of variable coefficients* $\mathcal{A}(t,x,D)=\mathcal{A}_0(D)+\mathcal{A}_1(t,x,D)$, *provided that*

$$\sup\{|a^{kl}_{1,ij}(t,x)| : k,l,i,j=1,\dots,n,\ t\in J,\ x\in\mathbb{R}^n\}\le\eta,$$

for some sufficiently small $\eta>0$.

In section 7 we will need a certain decomposition of the solution operator. For this purpose observe that from the proof of Theorem 5.1 we have the representations

$$\hat u=[I-(\lambda+\mathcal{A}(\xi))^{-1}\xi\otimes\xi](\lambda+\mathcal{A}(\xi))^{-1}\hat f-i\alpha^{-1}(\lambda+\mathcal{A}(\xi))^{-1}\xi\hat g$$

and

$$\hat\pi=-i\alpha^{-1}((\lambda+\mathcal{A}(\xi))^{-1}\hat f|\xi)+\frac{\hat g}{\alpha}.$$

Here we have assumed $u_0=0$ for simplicity. Let us have a closer look at the term $1/\alpha(\lambda,\xi)$. We may write

$$\begin{aligned}\frac{1}{\alpha(\lambda,\xi)}&=(\mu+1)\frac{1}{(\mu+1)((\mu+\mathcal{A}(\zeta))^{-1}\zeta|\zeta)}\\&=\mu+1+(\mu+1)\left[\frac{1}{(\mu+1)((\mu+\mathcal{A}(\zeta))^{-1}\zeta|\zeta)}-1\right]\\&=\mu+1+\frac{(\mu+1)[(\mu+\mathcal{A}(\zeta))-(\mu+1)]((\mu+\mathcal{A}(\zeta))^{-1}\zeta|\zeta)}{(\mu+1)((\mu+\mathcal{A}(\zeta))^{-1}\zeta|\zeta)}\\&=\mu+1+\frac{[\mathcal{A}(\zeta)-1](\mu+1)((\mu+\mathcal{A}(\zeta))^{-1}\zeta|\zeta)}{(\mu+1)((\mu+\mathcal{A}(\zeta))^{-1}\zeta|\zeta)}\\&=\frac{\lambda}{|\xi|^2}+1+M_{22}(\lambda,\xi),\end{aligned}$$

where we again used the notation $\mu=\lambda/|\xi|^2$ and $\zeta=\xi/|\xi|$. As in the proof of Theorem 5.1, $\xi\mapsto M_{22}(\mu|\xi|^2,\xi)$ is homogeneous of degree 0 and bounded, uniformly in $\xi\in\mathbb{R}^n$ and $\lambda\in\Sigma_\phi$. The arguments given there apply again to the result that there is an $L_p(J\times\mathbb{R}^n)$-bounded operator S_{22} with symbol $\hat S_{22}=M_{22}$. In a similar way we decompose

$$-i\alpha^{-1}(\lambda+\mathcal{A}(\xi))^{-1}\xi=\frac{-i\xi}{|\xi|^2}+(\lambda+|\xi|^2)^{-1}|\xi|M_{21}(\lambda,\xi),$$

where M_{21} is the symbol of an L_p-bounded operator S_{21}, as well as

$$-i((\lambda+\mathcal{A}(\xi))^{-1}\cdot|\xi)=-i(\xi/|\xi|^2|\cdot)+(\lambda+|\xi|^2)^{-1}|\xi|M_{12}(\lambda,\xi),$$

and M_{12} is the symbol of an L_p-bounded operator S_{12}. Last but not least, in the same way we obtain the decomposition

$$[I-(\lambda+\mathcal{A}(\xi))^{-1}\xi\otimes\xi](\lambda+\mathcal{A}(\xi))^{-1}=(\lambda+|\xi|^2)^{-1}+(\lambda+|\xi|^2)^2|\xi|^{-2}M_{11}(\lambda,\xi),$$

with M_{11} the symbol of an L_p-bounded operator S_{11}. Thus the solution operator S of the generalized Stokes problem splits as $S = S_0 + S_1$, where the symbols of S_j are given by

$$\hat{S}_0 = \begin{bmatrix} (\lambda + |\xi|^2)^{-1} & -i\xi/|\xi|^2 \\ -i(\xi/|\xi|^2|\cdot) & (\lambda + |\xi|^2)/|\xi|^2 \end{bmatrix} \tag{5.4}$$

and

$$\hat{S}_1 = \begin{bmatrix} (\lambda + |\xi|^2)^{-2}|\xi|^2 M_{11}(\lambda,\xi) & (\lambda + |\xi|^2)^{-1}|\xi| M_{12}(\lambda,\xi) \\ (\lambda + |\xi|^2)^{-1}|\xi| M_{21}(\lambda,\xi) & M_{22}(\lambda,\xi) \end{bmatrix}. \tag{5.5}$$

It is important that S_0 is independent of the coefficients of $\mathcal{A}(D)$, and that S_1 factors as

$$\hat{S}_1 = \begin{bmatrix} \frac{1}{\lambda+|\xi|^2} & 0 \\ 0 & \frac{1}{|\xi|} \end{bmatrix} \begin{bmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{bmatrix} \begin{bmatrix} \frac{|\xi|^2}{\lambda+|\xi|^2} & 0 \\ 0 & |\xi| \end{bmatrix}.$$

Here $M = [M_{ij}]$ is the symbol of an L_p-bounded operator. It is a remarkable fact that such a decomposition remains valid in the variable coefficient case of Corollary 5.2. This can be seen as follows. We have the Neumann series for T which reads

$$T = S + \sum_{n\geq 1} (SB)^n S = S_0 + S_1 + \sum_{n\geq 1} (SB)^n S.$$

By induction we obtain

$$(SB)^n = \begin{bmatrix} (S_{11}\mathcal{A}_1)^n & 0 \\ S_{21}\mathcal{A}_1(S_{11}\mathcal{A}_1)^{n-1} & 0 \end{bmatrix}$$

and

$$(SB)^n S = \begin{bmatrix} (S_{11}\mathcal{A}_1)^n S_{11} & (S_{11}\mathcal{A}_1)^n S_{12} \\ S_{21}\mathcal{A}_1(S_{11}\mathcal{A}_1)^{n-1} S_{11} & S_{21}\mathcal{A}_1(S_{11}\mathcal{A}_1)^{n-1} S_{12} \end{bmatrix}.$$

In symbolic notation, using the factorization of S, this yields for the first entry

$$(S_{11}\mathcal{A}_1)^n S_{11} = \frac{1}{\lambda + |\xi|^2}\left(1 + \frac{|\xi|^2}{\lambda + |\xi|^2} M_{11}\right)(A_1 S_{11})^{n-1}\mathcal{A}\left(1 + \frac{|\xi|^2}{\lambda + |\xi|^2} M_{11}\right)\frac{|\xi|^2}{\lambda + |\xi|^2}.$$

Similarly, for the second entry we get

$$(S_{11}\mathcal{A}_1)^n S_{12} = \frac{1}{\lambda + |\xi|^2}\left(1 + \frac{|\xi|^2}{\lambda + |\xi|^2} M_{11}\right)(A_1 S_{11})^{n-1}\mathcal{A}_1(\zeta)\left(\frac{-i\xi}{|\xi|} + \frac{|\xi|^2}{\lambda + |\xi|^2} M_{12}\right)|\xi|.$$

In the same way the third entry becomes

$$S_{21}(\mathcal{A}_1 S_{11})^n = \frac{1}{|\xi|}\left(\frac{-i\xi}{|\xi|} + \frac{|\xi|^2}{\lambda + |\xi|^2} M_{21}\right)(A_1 S_{11})^{n-1}\mathcal{A}_1(\zeta)\left(1 + \frac{|\xi|^2}{\lambda + |\xi|^2} M_{11}\right)\frac{|\xi|^2}{\lambda + |\xi|^2},$$

and finally the last entry is

$$\begin{aligned} &S_{21}\mathcal{A}_1(S_{11}\mathcal{A}_1)^{n-1} S_{12} \\ &\quad = \frac{1}{|\xi|}\left(\frac{-i\xi}{|\xi|} + \frac{|\xi|^2}{\lambda + |\xi|^2} M_{12}\right)(A_1 S_{11})^{n-1}\mathcal{A}_1\left(\frac{-i\xi}{|\xi|} + \frac{|\xi|^2}{\lambda + |\xi|^2} M_{12}\right)|\xi|. \end{aligned}$$

This proves the assertion.

6. The generalized Stokes problem on $\mathbb{R}^n_+$. In this section we consider the generalized Stokes problem in $\mathbb{R}^n_+ = \mathbb{R}^{n-1} \times \mathbb{R}_+$ with any one of the three boundary conditions mentioned above. Thus we consider the problem

$$\begin{aligned} \partial_t u + \mathcal{A}(D)u + \nabla\pi &= f(t,x), \quad t \in J,\ x \in \mathbb{R}^n_+, \\ \operatorname{div} u &= g(t,x), \quad t \in J,\ x \in \mathbb{R}^n_+, \\ u(0,x) &= u_0(x), \quad x \in \mathbb{R}^n_+. \end{aligned} \tag{6.1}$$

Here, as in section 5, $\mathcal{A}(D) = \sum_{k,l=1}^n \mathcal{A}^{kl} D_k D_l$ denotes a strongly elliptic differential operator with constant coefficients acting on $\mathbb{C}^n$-valued functions. The boundary conditions are either

$$u(t,x) = h_0(t,x), \quad t \in J,\ x \in \partial\mathbb{R}^n_+, \tag{6.2}$$

or

$$u_n = h_{sn}(t,x),\ \left[\sum_{l=1}^n \mathcal{A}^{nl} D_l u\right]_k = h_{sk}(t,x) \quad t \in J,\ x \in \partial\mathbb{R}^n_+,\ k = 1,\dots,n-1, \tag{6.3}$$

or

$$\sum_{l=1}^n \mathcal{A}^{nl} D_l u + i\pi e_n = h_n(t,x), \quad t \in J,\ x \in \partial\mathbb{R}^n_+. \tag{6.4}$$

Of course, appropriate compatibility conditions have to be satisfied. Assuming strong normal ellipticity, we already verified that the parabolic problem without pressure and divergence condition satisfies the Lopatinskii–Shapiro condition for these boundary conditions, and hence is well-posed and has maximal L_p-regularity for $1 < p < \infty$. The main result of this section states that these properties carry over to the generalized Stokes problem. But before we state the theorem let us specify conditions (D) for the half-space case.

Using the notation introduced in section 4, we define ${}_0\dot{H}_p^{-1}(\mathbb{R}^n_+)$ as the dual of $\dot{H}^1_{p,\partial\mathbb{R}^n_+}(\mathbb{R}^n_+)$, and $\dot{H}_p^{-1}(\mathbb{R}^n_+)$ as the dual of $\dot{H}^1_{p,\emptyset}(\mathbb{R}^n_+)/constants$. Observe that the space ${}_0\dot{H}_p^{-1}(\mathbb{R}^n_+)$ consists solely of distributions in $\mathbb{R}^n_+$, but $\dot{H}_p^{-1}(\mathbb{R}^n_+)$ does not have this property. It should also be observed that $(0,h) \in \dot{H}_p^{-1}(\mathbb{R}^n_+)$ is equivalent to $h \in \dot{W}_p^{-1/p}(\mathbb{R}^{n-1})$.

The conditions for right-hand side f and for the initial value u_0 do not change; they become the following:

(a) $f \in L_p(J \times \mathbb{R}^n_+; \mathbb{C}^n)$, $u_0 \in W_p^{2-2/p}(\mathbb{R}^n_+; \mathbb{C}^n)$.

For g, part of the conditions are

(b) $g \in H^1_p(J; {}_0\dot{H}_p^{-1}(\mathbb{R}^n_+)) \cap L_p(J; H^1_p(\mathbb{R}^n_+))$, $\operatorname{div} u_0 = g|_{t=0}$.

The main part of the Dirichlet boundary condition is the same as well.

(d0) for Dirichlet boundary conditions:
$h_0 \in W_p^{1-1/2p}(J; L_p(\partial\mathbb{R}^n_+; \mathbb{C}^n)) \cap L_p(J; W_p^{2-1/p}(\partial\mathbb{R}^n_+; \mathbb{C}^n))$ and for $p > 3/2$ in addition $h(0,x) = u_0(x)$;

Similarly, we have

(ds) for slip boundary conditions:
$h_{sn} \in W_p^{1-1/2p}(J; L_p(\partial\mathbb{R}^n_+; \mathbb{C}^n)) \cap L_p(J; W_p^{2-1/p}(\partial\mathbb{R}^n_+; \mathbb{C}^n))$;
$h_{sk} \in W_p^{1/2-1/2p}(J; L_p(\partial\mathbb{R}^n_+)) \cap L_p(J; W_p^{1-1/p}(\partial\mathbb{R}^n_+))$ and, if $p > 3$,

$[\sum_{l=1}^n \mathcal{A}^{nl} D_l u_0]_k = h_{sk}(0,x)$ for $x \in \partial\mathbb{R}^n_+$, $k = 1, \dots, n-1$;

and

(dn) for Neumann boundary conditions:
$h_n \in W_p^{1/2-1/2p}(J; L_p(\partial\mathbb{R}^n_+; \mathbb{C}^n)) \cap L_p(J; W_p^{1-1/p}(\partial\mathbb{R}^n_+; \mathbb{C}^n))$ and, if $p > 3$,
$[h_n(0,x)]_k = [\sum_{l=1}^n \mathcal{A}^{nl} D_l u_0(x)]_k$ for $x \in \partial\mathbb{R}^n_+$, $k = 1, \dots, n-1$.

In case of Neumann conditions these are all requirements. In case of slip or Dirichlet conditions we have the additional property

(e) $(g, h_{jn}) \in H^1_p(J; \dot{H}_p^{-1}(\mathbb{R}^n_+))$ and $h_{jn}(0,x) = u_{0n}(x,0)$, $x \in \mathbb{R}^{n-1}$, $j = 0, s$.

After these preliminaries we can state the main result of this section.

THEOREM 6.1. *Let* $1 < p < \infty$, *and assume that* $\mathcal{A}(D) = \sum_{k,l=1}^n \mathcal{A}^{kl} D_k D_l$ *is strongly normally elliptic. Then* (6.1) *with boundary conditions* (6.2), (6.3), *or* (6.4) *has maximal* L_p*-regularity in the following sense. There is a unique solution* (u, π) *of* (6.1) *in the class*

$$u \in H^1_p(J; L_p(\mathbb{R}^n_+; \mathbb{C}^n)) \cap L_p(J; H^2_p(\mathbb{R}^n_+; \mathbb{C}^n)), \quad \pi \in L_p(J; \dot{H}^1_p(\mathbb{R}^n_+)),$$

satisfying the corresponding boundary condition with $\pi \in W_p^{1/2-1/2p}(J; L_p(\partial\mathbb{R}^n_+))$ *in case of boundary condition* (6.4), *if and only if the data* f, g, u_0, h *satisfy the conditions* (D). *The solution* u *depends continuously on the data in the corresponding spaces.*

Proof. According to the discussion above, we need to show only the sufficiency part. Let data f, g, u_0 and boundary data h with the corresponding regularity be given. Without loss of generality we may assume $f \equiv g \equiv u_0 \equiv 0$ and trace 0 of h at $t = 0$ in case it exists. This can be seen as follows. First we solve the parabolic initial-boundary value problem without pressure and divergence condition; this gives a function u_1 in the right regularity class. Then $u_2 := u - u_1$, and π should solve the full problem with $f \equiv h \equiv u_0 \equiv 0$ and g replaced by $g_1 := g - \operatorname{div} u_1$, which belongs to the same regularity class but has trace 0 at $t = 0$. Extend g_1 evenly in x_n to all of $J \times \mathbb{R}^n$, and solve the full-space generalized Stokes problem (5.1) with $f = u_0 = 0$ to obtain a pair (u_3, π_3) in the right regularity class. Then the pair (u_4, π_4) defined by $u_4 := u_2 - u_3$, $\pi_4 := \pi - \pi_3$ should solve (6.1) with the boundary condition in question, where $f \equiv g \equiv u_0 \equiv 0$ and $h = -\mathcal{B}(D)(u_3, \pi_3)$; here $\mathcal{B}(D)$ denotes the boundary operator under consideration. Note that the new boundary data h belongs to the right regularity class and has trace 0 at $t = 0$ whenever it exists.

So we have to solve the homogeneous problem (6.1) with one of the inhomogeneous boundary conditions. It is convenient to split the spatial variables as $x = (x', y)$, where $x' \in \mathbb{R}^{n-1}$ and $y > 0$; recall that $\nu = -e_n$. Similarly we decompose $u = (v, w)$, with $v \in \mathbb{R}^{n-1}$ the tangential and $w \in \mathbb{R}$ the normal velocity. Taking Fourier transform in the tangential space directions, Laplace transform in t, we obtain the parameter-dependent ode-problem

$$\begin{aligned}
(\lambda + \mathcal{A}_{11}(\xi + e_n D_y))\hat{v} + \mathcal{A}_{12}(\xi + e_n D_y)\hat{w} + i\xi\hat{\pi} = 0, \quad y > 0,\\
\mathcal{A}_{21}(\xi + e_n D_y)\hat{v} + (\lambda + \mathcal{A}_{22}(\xi + e_n D_y))\hat{w} + \partial_y\hat{\pi} = 0, \quad y > 0,\\
i\xi^{\mathsf{T}}\hat{v} + iD_y\hat{w} = 0, \quad y > 0,\\
\mathcal{B}_{11}(\xi + e_n D_y)v(0) + \mathcal{B}_{12}(\xi + e_n D_y)w(0) = \hat{h}_v,\\
\mathcal{B}_{21}(\xi + e_n D_y)v(0) + \mathcal{B}_{22}(\xi + e_n D_y)w(0) + \mathcal{B}_{23}\pi(0) = \hat{h}_w,
\end{aligned} \tag{6.5}$$

where $\mathcal{B}$ is defined by one of the boundary conditions (6.2), (6.3), or (6.4). The parameters ξ and λ satisfy $(\xi, \lambda) \in \mathbb{R}^n \times \Sigma_\phi$ for some $\phi > \pi/2$ and $\xi_n = 0$. Here and below we identify $\xi \in \mathbb{R}^{n-1}$ with $(\xi, 0) \in \mathbb{R}^n$. Introducing the vector

$$x = [\hat{v}, \hat{w}, \partial_y \hat{v}, \partial_y \hat{w}, \hat{\pi}]^{\mathsf{T}},$$

we rewrite this problem as the first order system

$$E\partial_y x + Ax = 0, \quad y > 0, \quad Bx(0) = \hat{h}, \tag{6.6}$$

where the dependence on (λ, ξ) has been dropped. Here the $(2n+1)$-dimensional square matrix E is defined as

$$E = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & A^0_{11} & A^0_{12} & 0 \\ 0 & 0 & A^0_{21} & A^0_{22} & -1 \\ 0 & 1 & 0 & 0 & 0 \end{bmatrix}$$

and A by

$$A = \begin{bmatrix} 0 & 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 \\ -(\lambda + A^2_{11}) & -A^2_{12} & A^1_{11} & A^1_{12} & -i\xi \\ -A^2_{21} & -(\lambda + A^2_{22}) & A^1_{21} & A^1_{22} & 0 \\ i\xi^{\mathsf{T}} & 0 & 0 & 0 & 0 \end{bmatrix}.$$

Here we have used the abbreviations

$$A^2 = (\mathcal{A}^{kl}\xi_k\xi_l), \quad A^1 = i(\mathcal{A}^{kl}\nu_k\xi_l + \mathcal{A}^{kl}\nu_l\xi_k), \quad A^0 = (\mathcal{A}^{kl}\nu_k\nu_l);$$

remember the summation convention. Observe that A^k are homogeneous in ξ of order k; in particular, A^0 is constant and invertible by ellipticity. Also note that E depends neither on λ nor on ξ. The boundary matrices B are

$$B = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \end{bmatrix}$$

in the case of Dirichlet conditions,

$$B = \begin{bmatrix} B^1_{11} & B^1_{12} & B^0_{11} & B^0_{12} & 0 \\ 0 & 1 & 0 & 0 & 0 \end{bmatrix}$$

for slip conditions, and

$$B = \begin{bmatrix} B^1_{11} & B^1_{12} & B^0_{11} & B^0_{12} & 0 \\ B^1_{21} & B^1_{22} & B^0_{21} & B^0_{22} & -1 \end{bmatrix}$$

in the case of Neumann conditions. Here B^k are homogeneous of order k in ξ, and $B^0 = A^0$. Recall that the Lopatinskii–Shapiro condition means that system (6.6) admits at most one solution $x \in C_0(\mathbb{R}_+; \mathbb{C}^{2n+1})$, for each $\hat{h} \in \mathbb{C}^n$ and $\xi \in \mathbb{R}^{n-1}$, $\operatorname{Re}\lambda \geq 0$, $\xi \neq 0$.

It is our purpose to derive a representation formula of the function x in terms of the given data $\hat{h}$, which is accessible to inversion of the Fourier and Laplace transform.

(i) Assume $x \in C_0(\mathbb{R}_+; \mathbb{C}^{2n+1})$ to be a solution of (6.6). Taking Laplace transform $\mathcal{L}$ in y, this yields

$$(zE + A)\mathcal{L}x(z) = Ex^0, \quad \operatorname{Re} z > 0, \quad Bx^0 = \hat{h},$$

where $x^0 = x(0)$ denotes the initial value of x. To obtain a representation of x we have to study the operator pencil $zE + A$. To this end note that E is not invertible but its kernel $N(E)$ is one-dimensional, and $N(E^2) = N(E)$; hence $N(E) \oplus R(E) = \mathbb{C}^{2n+1}$. Therefore, (6.6) is a differential-algebraic system of index ≥ 1. This implies that the characteristic polynomial $p(z) = \det(zE + A)$ has at most order $2n$. Let us show that it is precisely of order $2n$, i.e., that the index is 1. This can be seen as follows. Expand $\det(zE + A)$ first w.r.t. the last column and the last row and then w.r.t. the second row. This yields up to a sign

$$p(z) = z^2 \det \begin{bmatrix} z & -1 \\ -(\lambda + A_{11}^2) & zA_{11}^0 + A_{11}^1 \end{bmatrix} + q(z),$$

where $q(z)$ is of order less than $2n$. Asymptotically this yields for large z

$$p(z) \sim z^2 \det \begin{bmatrix} z & 0 \\ 0 & zA_{11}^0 \end{bmatrix} = z^{2n} \det A_{11}^0,$$

and $\det A_{11}^0 \neq 0$ by strong ellipticity. Therefore $p(z)$ is of order $2n$. Ellipticity shows also that $p(z)$ has no zeros on the imaginary axis for $\xi \neq 0$. Now consider the case $\xi = 0$. Then we see by the same procedure that $p(z)$ is in fact a function of z^2; i.e., if z_0 is a zero of p, then $-z_0$ is one as well. Unfortunately, $z = 0$ is a solution in case $\xi = 0$; this is the degeneracy of the Stokes problem. We have to look at this zero more closely.

The eigenvalue problem for these small zeros $z(\xi)$ for small ξ (or large λ) becomes

$$(A(z,\xi) - \lambda) \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} i\xi \\ z \end{bmatrix}, \quad (i\xi | x_1) + z x_2 = 0,$$

where

$$A(z,\xi) = z^2 A^0 + zA^1(\xi) - A^2(\xi).$$

Since by $\lambda \neq 0$ we have invertibility of $A(z,\xi) - \lambda$, this implies the condition

$$\left(\begin{bmatrix} i\xi \\ z \end{bmatrix} \middle| (A(z,\xi) - \lambda)^{-1} \begin{bmatrix} i\xi \\ z \end{bmatrix} \right) = 0$$

for the small eigenvalues. Writing $(A(z,\xi) - \lambda)^{-1}$ as a Neumann series, this condition becomes

$$z^2 - |\xi|^2 + O((|\xi| + |z|)^4) = 0,$$

which shows that $z = \pm|\xi| + O(|\xi|^2)$ near $\xi = 0$. Therefore the double zero $z(0) = 0$ for $\xi = 0$ splits into two simple real zeros, which behave like $z_1^{\pm}(\xi) \sim \pm|\xi|$ near $\xi = 0$.

Now varying ξ, we may conclude that $p(z)$ has exactly n roots with positive real parts, counting with multiplicity, for each $\xi \in \mathbb{R}^{n-1}$, $\operatorname{Re} \lambda > 0$, $\xi \neq 0$, since none of them can cross the imaginary axis by ellipticity.

We may now write

$$\mathcal{L}x(z) = (zE + A)^{-1}Ex^0, \quad Bx^0 = \hat{h},$$

for the Laplace transform of x. The initial value x^0 thus must be chosen in such a way that $\mathcal{L}x(z)$ has no poles in the right half-plane, and $Bx^0 = \hat{h}$ holds.

Define the projection P^+ by means of

$$P^+ = \frac{1}{2\pi i}\int_{\Gamma_+} (zE + A)^{-1}Edz,$$

where Γ_+ denotes a closed simple contour in the right half-plane surrounding the poles of $(zE + A)^{-1}$, i.e., the zeros of $p(z)$ in the right half-plane. Let z_k, $k = 1, \dots, m^+$ denote the zeros of $p(z)$ in the right and for $k = -m^-, \dots, -1$ in the left half-plane. Set

$$P_k = \frac{1}{2\pi i}\int_{|z-z_k|=r} (zE + A)^{-1}Edz.$$

These operators are mutually disjoint projections, and by Cauchy's theorem we have

$$P^+ = \sum_{k=1}^{m^+} P_k.$$

It can be seen, e.g., by Cramer's rule, that $(zE + A)^{-1}$ is a rational function which is bounded at ∞ and hence admits a limit as $|z| \to \infty$. Therefore

$$z(zE + A)^{-1}E = I - (zE + A)^{-1}A$$

is bounded at ∞ as well and admits the limit

$$Q_0 = \lim_{z\to\infty} z(zE + A)^{-1}E,$$

which is a projection, too. We set $P_0 = I - Q_0$. Obviously, $Q_0x = 0$ for each $x \in N(E)$, and, on the other hand, we have

$$EQ_0 = \lim_{z\to\infty} zE(zE + A)^{-1}E = \lim_{z\to\infty}(E - A(zE + A)^{-1}E) = E.$$

This implies that P_0 projects onto the kernel of E. Moreover,

$$\sum_k P_k = P_0 + \lim_{R\to\infty}\frac{1}{2\pi i}\int_{|z|=R}(zE + A)^{-1}Edz = P_0 + Q_0 = I,$$

which also shows that $P_0P_k = P_kP_0 = 0$ for all $k \neq 0$. Linear algebra implies further that the dimension of the range of P_k is m_k, and hence P^+ has dimension n. Since

$$x^0 = x(0) = \lim_{t\to 0+} x(t) = \lim_{\mathbb{R}\ni z\to\infty} z\mathcal{L}x(z) = \lim_{z\to\infty} z(zE + A)^{-1}Ex^0 = Q_0x^0,$$

we must have $P_0x^0 = 0$. It is not difficult to compute the projection P_0; it is given by

$$P_0x = \frac{x_4 + (i\xi|x_1)}{\alpha_0}\begin{bmatrix} 0 \\ A^{0^{-1}}\left[\begin{smallmatrix} 0 \\ -1 \end{smallmatrix}\right] \\ 1 \end{bmatrix},$$

where

$$\alpha_0 := \left(\begin{bmatrix} 0 \\ 1 \end{bmatrix} | A^{0^{-1}} \begin{bmatrix} 0 \\ 1 \end{bmatrix} \right)$$

is nonzero by ellipticity. Observe that

$$P_0 x^0 = 0 \quad \Leftrightarrow \quad x_4^0 + (i\xi | x_1^0) = 0.$$

For later purposes we also compute the projection $P_1^{\pm}$ corresponding to the small eigenvalue $z_1^{\pm}(\xi) \sim \pm|\xi|$ for small ξ. The analysis of $z_1^{\pm}$ given above shows that an eigenvector is given by

$$e_1^{\pm} = \left[(A(z_1^{\pm}) - \lambda)^{-1} \begin{bmatrix} i\xi \\ z_1^{\pm} \end{bmatrix}, z_1^{\pm}(A(z_1^{\pm}) - \lambda)^{-1} \begin{bmatrix} i\xi \\ z_1^{\pm} \end{bmatrix}, 1 \right]^{\mathsf{T}} \sim \left[\frac{1}{\lambda} \begin{bmatrix} -i\xi \\ \mp|\xi| \end{bmatrix}, 0, 1 \right]^{\mathsf{T}}.$$

For a dual eigenvector we get similarly

$$e_1^{*\pm} = \left[(z_1^{\pm} A^0 + A^1)^{\mathsf{T}} (A(z_1^{\pm})^{\mathsf{T}} - \lambda)^{-1} \begin{bmatrix} i\xi \\ z_1^{\pm} \end{bmatrix}, (A(z_1^{\pm})^{\mathsf{T}} - \lambda)^{-1} \begin{bmatrix} i\xi \\ z_1^{\pm} \end{bmatrix}, -1 \right]^{\mathsf{T}},$$

and hence

$$e_1^{*\pm} \sim \left[0, \frac{1}{\lambda} \begin{bmatrix} -i\xi \\ \mp|\xi| \end{bmatrix}, -1 \right]^{\mathsf{T}}.$$

The projections are then $P_1^{\pm} x = \frac{(e_1^{*\pm}|Ex)}{(e_1^{*\pm}|Ee_1^{\pm})} e_1^{\pm}$. Note that $(e_1^{*\pm}|Ee_1^{\pm}) \sim \pm 2|\xi|/\lambda$ for small ξ, and the asymptotics of $z_1^{\pm}$, $e_1^{\pm}$, and $e_1^{*\pm}$ do not depend on the coefficients a_{ij}^{kl}. Note also that

$$P_1^{+} x^0 = 0 \quad \Leftrightarrow \quad (e_1^{*+}|Ex^0) = 0,$$

which asymptotically yields the condition

$$x_5^0 - \frac{\lambda}{|\xi|} x_2^0 \sim \left(\begin{bmatrix} i\xi/|\xi| \\ 1 \end{bmatrix} | A^0 \begin{bmatrix} x_3^0 \\ x_4^0 \end{bmatrix} \right).$$

(ii) To determine the initial value x^0 we therefore have to solve the linear system

$$Bx^0 = \hat{h}, \quad P^+ x^0 = 0, \quad P_0 x^0 = 0. \tag{6.7}$$

The Lopatinskii–Shapiro condition is equivalent to the uniqueness of the solution x^0 of this system, for $\xi \neq 0$. To see that it is solvable for each $\hat{h} \in \mathbb{C}^n$, observe that the kernel N of $P^+ + P_0$ has dimension n. $B : N \to \mathbb{C}^n$ is injective, and hence the rank theorem implies that it is also surjective. Thus there is a linear operator $M = M(\lambda, \xi)$ such that $x^0 = M(\lambda, \xi)\hat{h}$ gives the unique solution of (6.7). We have the explicit representation

$$x^0 = (B^* B + (P^+)^* P^+ + P_0^* P_0)^{-1} B^* \hat{h},$$

which shows that $M(\lambda, \xi)$ is holomorphic since B and P^+ have this property. By homogeneity, λ can even be taken from a sector Σ_ϕ for some $\phi > \pi/2$, but $\xi \neq 0$ in general.

Therefore, we have to look more closely at $\xi = 0$. Note that the projections $P_1^\pm$ are not holomorphic at $\xi = 0$. However, $P_1^0 := P_1^+ + P_1^-$ does have this property. A simple calculation shows that for $\xi = 0$ we have

$$P_1^0 x = x_2 \begin{bmatrix} 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix} + (x_5 - A_{21}^0 x_3 - A_{22}^0 x_4) \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 1 \end{bmatrix}.$$

Therefore it is convenient to decompose $x^0 = y^0 + \alpha e_1^-$, with $\alpha \in \mathbb{C}$ and $P_1^- y^0 = 0$. Setting $P = P_0 + P^+ + P_1^-$, we therefore have to solve the system

$$By^0 + \alpha B e_1^- = \hat{h}, \quad Py^0 = 0.$$

From $Py^0 = 0$ we obtain $y_2^0 = 0$, $y_4^0 = 0$, and $y_5^0 = A_{21}^0 y_3^0$. Solving the system $(zE + A)x = Ex^0$, we obtain with $e_1^- = [0,0,0,0,1]^\mathsf{T}$ and $x_2^0 = y_2^0 = x_4^0 = y_4^0 = 0$ the relations $x_2 = x_4 = 0$ and

$$(z^2 A_{11}^0 - \lambda) x_1 = A_{11}^0 (x_3^0 + z x_1^0), \quad x_3 = z x_1 - x_1^0, \quad x_5 = A_{21}^0 x_3 + \frac{\alpha}{z},$$

since $x_5^0 - A_{21}^0 x_3^0 = \alpha + y_5^0 - A_{21}^0 y_3^0 = \alpha$. By strong ellipticity, A_{11}^0 is invertible and has spectrum in the open right half-plane, and hence we may compute further

$$\begin{aligned} x_1(z) = {}& \frac{1}{2}(z + \sqrt{\lambda}(A_{11}^0)^{-1/2})^{-1} \left(y_1^0 + (A_{11}^0)^{1/2} \frac{y_3^0}{\sqrt{\lambda}} \right) \\ & + \frac{1}{2}(z - \sqrt{\lambda}(A_{11}^0)^{-1/2})^{-1} \left(y_1^0 - (A_{11}^0)^{1/2} \frac{y_3^0}{\sqrt{\lambda}} \right). \end{aligned}$$

Now, $x_1(z)$ must be holomorphic in the right half-plane, which means that necessarily we have $y_3^0 = -\sqrt{\lambda}(A_{11}^0)^{-1/2} y_1^0$. The boundary condition yields in the Dirichlet case $x_1^0 = y_1^0 = \hat{h}_1$, and in the slip or Neumann case $x_3^0 = y_3^0 = (A_{11}^0)^{-1}\hat{h}_3$. Note that in the Neumann case, $\alpha = -\hat{h}_4$ is uniquely determined, in contrast to the Dirichlet or slip case, where α is not unique. In fact, the function $\alpha(\lambda, \xi)$ is discontinuous at $\xi = 0$ for the latter, but holomorphic in the Neumann case.

Now, for $\xi \neq 0$ small, we may parametrize the kernel of P by a holomorphic map

$$y \mapsto R(\lambda,\xi)y := [y, 0, -\sqrt{\lambda}(A_{11}^0)^{-1/2} y, 0, -A_{21}^0 \sqrt{\lambda}(A_{11}^0)^{-1/2} y]^\mathsf{T} + R^1(\lambda,\xi)y,$$

where $R^1 = O(|\xi|)$ near $\xi = 0$, with $y \in \mathbb{C}^{n-1}$. Then we have to solve the equation $BRy + \alpha B e_1^- = \hat{h}$. For the pure Neumann case it then follows that y and α are uniquely determined and holomorphic near $\xi = 0$; hence $M(\lambda, \xi)$ is holomorphic also at $\xi = 0$. However, in the other cases things are more involved. We begin with the Dirichlet case. Then the system becomes

$$y - \frac{i\alpha\xi}{\lambda} = \hat{h}_1 + O(|\xi|)y + O(|\xi|^2)\alpha, \quad \frac{\alpha|\xi|}{\lambda} = \hat{h}_2 + O(|\xi|)y + O(|\xi|^2)\alpha,$$

and hence

$$\alpha \sim \frac{\lambda}{|\xi|}\hat{h}_2, \quad y \sim \hat{h}_1 + \frac{i\xi}{|\xi|}\hat{h}_2.$$

In the case of slip conditions we have similarly

$$-\sqrt{\lambda}{A_{11}^0}^{1/2}y - \alpha A_{11}^0\frac{i\xi}{\sqrt{\lambda}} = \hat{h}_3 + O(|\xi|)y + O(|\xi|^2)\alpha, \quad \frac{\alpha|\xi|}{\lambda} = \hat{h}_2 + O(|\xi|)y + O(|\xi|^2)\alpha,$$

and so

$$\alpha \sim \frac{\lambda}{|\xi|}\hat{h}_2, \quad y \sim -{A_{11}^0}^{1/2}\frac{{A_{11}^0}^{-1}\hat{h}_3 + \frac{i\xi}{|\xi|}\hat{h}_2}{\sqrt{\lambda}}.$$

Thus there are holomorphic functions $M_0(\lambda,\xi)$ and $\alpha_0(\lambda,\xi)$ such that

$$M(\lambda,\xi)\hat{h} = M_0(\lambda,\xi)\hat{h} + \left[\frac{\lambda}{|\xi|}\hat{h}_2 + (\alpha_0(\lambda,\xi)|\hat{h})\right]e_1^-,$$

where $\hat{h}_2$ denotes the normal component of u at the boundary $\partial\mathbb{R}^n_+$.

(iii) We may now write the following representation of the solution $x(y) = x(y,\lambda,\xi)$ of (6.6):

$$x(y,\lambda,\xi) = \frac{1}{2\pi i}\int_{\Gamma_-} e^{zy}(zE + A(\lambda,\xi))^{-1}EM(\lambda,\xi)\hat{h}(\lambda,\xi)dz, \tag{6.8}$$

where Γ_- denotes a closed simple contour in the open left half-plane surrounding the zeros of $p(z) = p(z,\lambda,\xi)$ in the left half-plane. Employing residue calculus, this representation can be rewritten as

$$x(y,\lambda,\xi) = \sum_{\mathrm{Re} z_k<0} \mathrm{Res}_{z=z_k(\lambda,\xi)}[e^{zy}(zE + A(\lambda,\xi))^{-1}E]M(\lambda,\xi)\hat{h}(\lambda,\xi);$$

hence it is an exponential polynomial in y.

Note that the zeros z_k of $p(z) = p(z,\lambda,\xi)$ depend on ξ and λ, and hence the integration path in (6.8) cannot be chosen independently of ξ and λ. To remove this defect a scaling argument will help. With $\rho = \sqrt{\lambda + |\xi|^2}$, the standard parabolic symbol, and $\sigma = \lambda/\rho^2$, $\zeta = \xi/\rho$, the pair (σ,ζ) belongs to a compact subset of $\mathbb{C}^n \setminus \{0\}$. Replace $\hat{\pi}(y)$ by $\hat{\pi}(\rho y)/\rho$, $x(y)$ by $x(\rho y)$, Neumann data $\hat{h}_k$ by $\hat{h}_k/\rho$, and leave Dirichlet data unchanged. Then homogeneity of $\mathcal{A}$ and $\mathcal{B}$ yield the modified representation formula

$$x(y,\lambda,\xi) = \frac{1}{2\pi i}\int_{\Gamma_-} e^{\rho zy}(zE + A(\sigma,\zeta))^{-1}EM(\sigma,\zeta)\hat{h}(\lambda,\xi)dz. \tag{6.9}$$

Since the poles of $(zE + A(\sigma,\zeta))^{-1}$ stay in a compact set in the left half-plane we may now choose the contour Γ_- independently of (σ,ζ). This argument parallels the scaling employed in section 6 of Denk, Hieber, and Prüss [4] for the parabolic case.

Observe that the scaling of h induces

$$h \in Y := {}_0W_p^{1-1/2p}(J; L_p(\mathbb{R}^{n-1};\mathbb{C}^n)) \cap L_p(J; W_p^{2-1/p}(\mathbb{R}^{n-1};\mathbb{C}^n)),$$

which is independent of the choice of the boundary conditions. Let $L := (\partial_t - \Delta_x)^{1/2}$ with natural domain

$$D(L) = {}_0H_p^{1/2}(J; L_p(\mathbb{R}^{n-1};\mathbb{C}^n)) \cap L_p(J; H_p^1(\mathbb{R}^{n-1};\mathbb{C}^n)).$$

Then $Y = D_L(2-1/p,p)$; hence if $h \in Y$, then $e^{-L\cdot}h \in D(L^2)$; i.e.,

$$g(\cdot) = L^2 e^{-L\cdot} h \in L_p(J \times \mathbb{R}^n_+; \mathbb{C}^n).$$

The symbol of L is $\sqrt{\lambda + |\xi|^2}$, which is precisely ρ. By means of the identity

$$\hat{h} = \int_0^\infty 2\rho e^{-2\rho\bar{y}} \hat{h} d\bar{y} = \frac{2}{\rho} \int_0^\infty e^{-\rho\bar{y}} \hat{g}(\bar{y}) d\bar{y},$$

we may rewrite the representation of $x(y)$ in the following way:

$$x(y,\lambda,\xi) = \operatorname{diag}\left[\frac{1}{\rho^2}, \frac{1}{\rho^2}, \frac{1}{\rho^2}, \frac{1}{\rho^2}, \frac{1}{\rho|\xi|}\right] \int_0^\infty \hat{k}(y,\bar{y},\lambda,\xi)\hat{g}(\bar{y},\lambda,\xi)d\bar{y}, \tag{6.10}$$

where the Fourier–Laplace transform of k is given by

$$\hat{k}(y,\bar{y},\lambda,\xi) = \frac{1}{i\pi}\int_{\Gamma_-} e^{\rho(yz-\bar{y})} D(\rho,|\xi|)(zE + A(\sigma,\zeta))^{-1} EM(\sigma,\zeta)dz, \tag{6.11}$$

where $D(\rho,|\xi|) = \operatorname{diag}[\rho,\rho,\rho,\rho,|\xi|]$.

It remains to be shown that the integral operator with operator-valued kernel $K(y,\bar{y})$ is bounded from $L_p(J \times \mathbb{R}^n_+; \mathbb{C}^n)$ to $L_p(J \times \mathbb{R}^n_+; \mathbb{C}^{2n+1})$, where the symbol of $K(y,\bar{y})$ is $\hat{k}(y,\bar{y},\lambda,\xi)$ from (6.11). This then implies that u belongs to the maximal regularity space, and the remaining regularity statements concerning the pressure π follow from the equations.

(iv) However, due to the presence of the small eigenvalues $z_1^\pm(\xi)$ introduced above, there are problems at $\zeta = 0$. We have to deal with the cases $|\zeta| \le \eta$ and $|\zeta| > \eta$ for some small $\eta > 0$ separately. For this purpose we introduce a cut-off function $\chi(|\zeta|^2)$, where χ belongs to C^∞ and is 1 in $B_\eta(0)$, 0 outside of $B_{2\eta}(0)$, and between 0 and 1 elsewhere. Then we may decompose $\hat{k}(y,\bar{y},\lambda,\xi)$ as $\hat{k} = \hat{k}_S + \hat{k}_R$, where

(6.12)
$$\hat{k}_R(y,\bar{y},\lambda,\xi) = \frac{1}{2\pi i}\int_{\Gamma_-} (1-\chi(\zeta))D(\rho,|\xi|)e^{\rho(zy-\bar{y})}(zE + A(\sigma,\zeta))^{-1} EM(\sigma,\zeta)dz.$$

Let us first deal with $\hat{k}_R$ and invert the Fourier transform via Mikhlin's theorem. Since Γ_- is compact and contained in the open left half-plane, for $|\zeta| > \eta$, (σ,ζ) runs through a compact subset of $\mathbb{C}^n$, and

$$\operatorname{Re}\rho \le |\rho| \le c_\phi \operatorname{Re}\rho,$$

we obtain

$$|\hat{k}_R(y,\bar{y},\lambda,\xi)| \le C|\rho|e^{-c|\rho|(y+\bar{y})} \le \frac{C}{y+\bar{y}}, \quad y,\bar{y} > 0,$$

where $C, c > 0$ are independent of $y, \bar{y}$, λ, and ξ. This is already sufficient in case $p = 2$, by Plancherel's theorem. For the case of general $p \in (1,\infty)$, note first that

$$|\xi|\left|\frac{1}{\rho}\partial_{\xi_k}\rho\right| = |\xi|\left|\frac{\xi_k}{\rho^2}\right| \le \frac{|\xi|^2}{\rho^2} \le 1,$$

and similarly we have by induction $|\xi|^{|\alpha|}|D^\alpha_\xi \rho| \le M_\alpha$, for each multi-index $\alpha \in \mathbb{N}_0^{n-1}$. Next,

$$|\xi||\partial_{\xi_k}\zeta_j| = |\xi|\left|\frac{\delta_{kj}}{\rho} - \frac{\zeta_j \partial_{\xi_k}\rho}{\rho^2}\right| \le M_1,$$

and similarly for higher derivatives, by induction. The relation $\sigma = 1 - |\xi|^2/\rho^2$ shows that also $|\xi|^{|\alpha|}|D^\alpha_\xi \sigma|$ is uniformly bounded for each α. Next

$$|\xi||\partial_{\xi_k} e^{\rho(yz-\bar{y})}| \le |\xi|\left|\frac{\partial_{\xi_k}\rho}{\rho^2}\right| |\rho^2(yz-\bar{y})e^{\rho(yz-\bar{y})}| \le C|\rho|e^{-c|\rho|(y+\bar{y})} \le \frac{C}{y+\bar{y}},$$

and similarly by induction also for all higher derivatives. Therefore we may conclude that

$$|\xi|^{|\alpha|}|D^\alpha_\xi \hat{k}_R(y,\bar{y},\lambda,\xi)| \le \frac{M_\alpha}{y+\bar{y}}, \quad y,\bar{y} > 0,$$

for each multi-index α, where M_α is independent of $y, \bar{y}$, λ, and ξ. Mikhlin's theorem implies that there is a family of operators $k_R(y,\bar{y},\lambda)$ from $L_p(\mathbb{R}^{n-1};\mathbb{C}^n)$ to $L_p(\mathbb{R}^{n-1};\mathbb{C}^{2n+1})$ with norms bounded by

$$||k_R(y,\bar{y},\lambda)|| \le \frac{c}{y+\bar{y}}, \quad y,\bar{y} > 0,\ \lambda \in \Sigma_\phi.$$

Because of uniformity of the "Mikhlin bounds," Theorem 3.2 of Girardi and Weis [10] implies that the family $\{(y+\bar{y})k(y,\bar{y},\lambda) :\ y,\bar{y} > 0,\ \lambda \in \Sigma_\phi\}$ is also $\mathcal{R}$-bounded in $\mathcal{B}(L_p(J \times \mathbb{R}^n;\mathbb{C}^{(2n+1)\times n}))$.

(v) Now we deal with the other part of $\hat{k}$. Since we have enough information about the small eigenvalue $z_1(\xi)$ we may use residue calculus to decompose $\hat{k}_S = \hat{k}_{S0} + \hat{k}_{S1}$, where

$$\hat{k}_{S1}(y,\bar{y},\lambda,\xi) = \frac{1}{i\pi}\int_{\Gamma_-} \chi(\zeta)e^{\rho(yz-\bar{y})}D(\rho,|\xi|)(zE + A(\sigma,\zeta))^{-1}E(I-P_1^-)M(\sigma,\zeta)dz,$$

with a fixed contour Γ_- contained in the open left half-plane. The part $\hat{k}_{S1}$ can then be treated as above.

The essential part is $\hat{k}_{S0}$, which is given by

$$\hat{k}_{S0}(y,\bar{y},\lambda,\xi) = \chi(\zeta)e^{\rho(z_1^-(\sigma,\zeta)y-\bar{y})}D(\rho,|\xi|)P_1^-(\sigma,\zeta)M(\sigma,\zeta).$$

Using the decomposition $x^0 = y^0 + \alpha e_1^-$ as above, this yields

$$\hat{k}_{S0}(y,\bar{y},\lambda,\xi) = \chi(\zeta)|\xi|e^{\rho(z_1^-(\sigma,\zeta)y-\bar{y})}D(\rho/|\xi|,1)e_1^-(\lambda,\xi)\otimes\alpha(\lambda,\xi).$$

In the Neumann case α is holomorphic, and

$$D(\rho/|\xi|,1)e_1^-(\lambda,\xi) = \left[0,0,-i\xi^{\mathsf{T}}\frac{\rho}{\lambda}, \frac{-|\xi|\rho}{\lambda}, 1\right]^{\mathsf{T}}$$

is bounded and satisfies the Mikhlin condition. Since $z_1^- \sim -|\xi|$ we obtain as above an estimate of the form

$$|\xi|^{|\alpha|}|D^\alpha_\xi \hat{k}_{S0}(y,\bar{y},\lambda,\xi)| \le \frac{M_\alpha}{y+\bar{y}},$$

where M_α is independent of $y, \bar{y}$, ξ and λ. Therefore we may argue as above to obtain

$$||k_{S0}(y,\bar{y},\lambda)|| \le \frac{c}{y+\bar{y}}, \quad y,\bar{y}>0,\ \lambda\in\Sigma_\phi.$$

The argument is more involved in the case of Dirichlet or slip conditions; it is here where the extra time regularity of the normal velocity h_2 comes in. As shown above, α decomposes as

$$\alpha(\lambda,\xi) = \alpha_0(\lambda,\xi) + \frac{\lambda}{|\xi|}\begin{bmatrix} 0 \\ 1 \end{bmatrix},$$

where $\alpha_0(\lambda,\xi)$ is holomorphic. Since the term containing α_0 can be treated as before, we concentrate on the extra term. This yields the kernel k_{S00}, defined by

$$\hat{k}_{S00}(y,\bar{y},\lambda,\xi) = \chi(\zeta)|\xi|e^{\rho(z_1^-(\sigma,\zeta)y-\bar{y})}D(\rho/|\xi|,1)e_1^-(\lambda,\xi)\frac{\lambda}{|\xi|}\begin{bmatrix} 0 \\ 1 \end{bmatrix}.$$

Since, by assumption, $\hat{h}_2$ is the Fourier–Laplace transform of a function of the class ${}_0H^1_p(J;\dot{W}_p^{-1/p}(\mathbb{R}^{n-1}))$, we see that $\lambda\hat{h}_2/|\xi|$ is the Fourier–Laplace transform of a function in $L_p(J;\dot{W}_p^{1-1/p}(\mathbb{R}^{n-1}))$. Thus we obtain $g\in L_p(J\times\mathbb{R}^n_+)$ such that

$$\hat{g}(\bar{y},\lambda,\xi) = e^{-|\xi|\bar{y}}\hat{h}_2(\lambda,\xi)\frac{\lambda}{|\xi|}.$$

Writing

$$\frac{\lambda}{|\xi|}\hat{h}_2 = 2\int_0^\infty |\xi|e^{-2|\xi|\bar{y}}\frac{\lambda}{|\xi|}\hat{h}_2 d\bar{y} = 2\int_0^\infty e^{-|\xi|\bar{y}}g(\bar{y})d\bar{y},$$

we have

$$|\xi|e^{\rho z_1^- y}D(\rho/|\xi|,1)e_1^-\frac{\lambda}{|\xi|}\hat{h}_2 = \int_0^\infty |\xi|e^{\rho z_1^- y-|\xi|\bar{y}}D(\rho/|\xi|,1)e_1^-\hat{g}(\bar{y},\lambda,\xi)d\bar{y},$$

and the kernel of this representation can be treated as before.

(vi) Summarizing, we have obtained a family

$$k(y,\bar{y},\lambda)\subset\mathcal{B}(L_p(J\times\mathbb{R}^{n-1};\mathbb{C}^{(2n+1)\times n}))$$

such that the family $\{(y+\bar{y})k(y,\bar{y},\lambda) : y,\bar{y}>0,\lambda\in\Sigma_\phi\}$ is also $\mathcal{R}$-bounded in $\mathcal{B}(L_p(J\times\mathbb{R}^{n-1};\mathbb{C}^{(2n+1)\times n}))$. In addition, $\hat{k}$ is holomorphic in $\lambda\in\Sigma_\phi$, and so the operator family $\{k(y,\bar{y},\lambda)\}_{\lambda\in\Sigma_\phi}$ also has this property; i.e.,

$$k(y,\bar{y},\cdot)\in\mathcal{H}^\infty(\Sigma_\phi;\mathcal{B}(L_p(J\times\mathbb{R}^{n-1};\mathbb{C}^{(2n+1)\times n}))),$$

with $\mathcal{H}^\infty$-norm less than $c/(y+\bar{y})$.

The operator ∂_t in $L_p(J;X)$ with natural domain ${}_0H^1_p(J;X)$ admits a bounded $\mathcal{H}^\infty$-calculus with $\mathcal{H}^\infty$-angle $\pi/2$, where $X=L_p(\mathbb{R}^{n-1};\mathbb{C}^{(2n+1)\times n})$. Therefore, by the Kalton–Weis theorem, $K(y,\bar{y}):=k_R(y,\bar{y},\partial_t)$ is bounded in $L_p(J;X)$ with bound

$$|K(y,\bar{y})|_{\mathcal{B}(L_p(J;X))}\le\frac{M}{y+\bar{y}}, \quad y,\bar{y}>0.$$

This shows that the integral operator in $L_p(\mathbb{R}_+; L_p(J;X))$ with operator-valued kernel $K(y,\bar{y})$ is dominated pointwise by the kernel $\kappa(y,\bar{y}) = \frac{1}{y+\bar{y}}$ of the one-sided Hilbert transform, which is well known to be bounded in $L_p(\mathbb{R}_+; Z)$, for any Banach space Z, provided $1 < p < \infty$.

This completes the proof of Theorem 6.1. □

We can easily extend Theorem 6.1 to the case of variable coefficients with small deviation from constant ones. To see this, let $\mathcal{A}(t,x,D) = \mathcal{A}_0(D) + \mathcal{A}_1(t,x,D)$, where

$$\sup\{|a_{1,ij}^{kl}| : k,l,i,j = 1,\ldots,n,\ t \in J,\ x \in \mathbb{R}^n\} \le \eta$$

and

$$a_{1,ij}^{kl} \in W_s^{1/2-1/2p}(J; L_r(\Gamma_s \cup \Gamma_n)) \cap L_s(J; W_r^{1-1/p}(\Gamma_s \cup \Gamma_n)),$$

for some $r, s \ge p$ such that $\frac{1}{s} + \frac{n-1}{2r} < 1 - \frac{1}{p}$. Let S denote the solution operator of the generalized Stokes problem (4.1) from Theorem 6.1 for $\mathcal{A}_0(D)$, and T that of the perturbed problem. Then we obtain the identity

$$T = S + SBT, \qquad \text{where} \qquad B = \begin{bmatrix} -\mathcal{A}_1(t,x,D) & 0 \\ 0 & 0 \\ -\mathcal{B}_1(t,x,D) & 0 \end{bmatrix},$$

in the case of slip or Neumann condition. Here $\mathcal{B}_1$ has the obvious meaning of the corresponding boundary operator generated by the perturbation $\mathcal{A}_1$. The norm of the first component of B as an operator from the maximal regularity space Z into $L_p(J \times \mathbb{R}^n; \mathbb{C}^n)$ is bounded by $C\eta$, where $C > 0$ denotes a constant independent of η, and the norm of its third component in the boundary space X_∂ is estimated by

$$|B_3 v|_{X_\partial} \le C\eta |v|_Z + C \max_{i,j,k,l} |a_{1,ij}^{kl}|_{W_s^{1/2-1/2p}(L_r) \cap L_s(W_r^{1-1/p})} |v|_Z^{\alpha} |v|_{L_p}^{1-\alpha}$$

for some $\alpha \in (0,1)$, due to the Gagliardo–Nirenberg inequality and the restriction on r and s. Then, as in the previous section, a Neumann series argument shows that $T = (I - SB)^{-1} S$ in fact exists and is bounded as a map from the data space to the maximal regularity space as well. Let us state this as follows.

Corollary 6.2. *The assertions of Theorem* 6.1 *remain valid in the case of variable coefficients* $\mathcal{A}(t,x,D) = \mathcal{A}_0(D) + \mathcal{A}_1(t,x,D)$, *provided*

$$\sup\{|a_{1,ij}^{kl}(t,x)| : k,l,i,j = 1,\ldots,n,\ t \in J,\ x \in \mathbb{R}^n\} \le \eta,$$

for some sufficiently small $\eta > 0$, *and*

$$a_{1,ij}^{kl} \in W_s^{1/2-1/2p}(J; L_r(\Gamma_s \cup \Gamma_n)) \cap L_s(J; W_r^{1-1/p}(\Gamma_s \cup \Gamma_n)),$$

for some $r, s \ge p$ *such that* $\frac{1}{s} + \frac{n-1}{2r} < 1 - \frac{1}{p}$.

7. Proof of Theorem 4.1: Localization.

Step 1. We first deal with the case $G = \mathbb{R}^n$, i.e., the problem without boundary conditions. Note that the generalized Stokes problems with coefficients frozen at any $t \in J$, $x \in \mathbb{R}^n \cup \{\infty\}$ have maximal L_p-regularity according to Theorem 4.1. Because of uniform continuity of the coefficients on $J \times (\mathbb{R}^n \cup \{\infty\})$ the maximal regularity constant is uniform as well, as are the norms of the solution operators S_j. Given

$\eta > 0$, cut the interval $J = [0, a]$ into pieces $J_i = [i\delta, i\delta + \delta]$ of equal length $\delta = a/l$ such that the coefficients $a(t, x)$ appearing in $\mathcal{A}(t, x, D)$ satisfy

$$\sup\{|a(t,x) - a(s,x)| : x \in \mathbb{R}^n,\ t, s \in J,\ |t-s| \le \delta\} \le \eta.$$

We then solve the problem successively on the intervals J_i, $i = 0, \ldots, l$, so w.l.o.g. it is enough to treat the first interval $J_0 = [0, \delta]$. The number $\delta > 0$ will be chosen later.

By Theorem 10.1, we may assume $v_0 = f = 0$. Choose a large ball $B_R(0)$ such that

$$\sup\{|a(t,x) - a(0,\infty)| : |x| \ge R,\ t \in J_0\} \le \eta.$$

Cover the ball $\bar{B}_R(0)$ by finitely many balls $B_r(x_k)$, $k = 1, \ldots, N$, such that

$$\sup\{|a(t,x) - a(0,x_k)| : x \in B_r(x_k),\ t \in J_0\} \le \eta.$$

Fix a C^∞-partition of unity ϕ_k, which is subordinate to the covering $\bigcup_{k=1}^N B_r(x_k) \cup \bar{B}_R(0)^c$ of $\mathbb{R}^n$. The index $k = 0$ corresponds to the chart at infinity. Define local operators $\mathcal{A}_k(D) = \mathcal{A}(t, x, D)$ for each chart $B_r(x_k)$, $k = 1, \ldots, N$, and $\mathcal{A}_0(D) = \mathcal{A}(t, x, D)$; extend these coefficients to all of $J \times \mathbb{R}^n$ by, say, reflection at the boundary of the corresponding ball. Corollary 5.2 shows that each of these operators has maximal regularity, provided that $\eta > 0$ and $\delta > 0$ are sufficiently small.

Suppose (v, q) is a solution of (4.1) with $G = \mathbb{R}^n$. In what follows we normalize the pressure by $\int_{B_{2R}(0)} q(t,x)dx = 0$. Setting $v_k = \phi_k v$, $q_k = \phi_k q$, $g_k = \phi_k g$, we obtain the following problem for the functions v_k and q_k:

$$\begin{aligned} \partial_t v_k + \mathcal{A}_k(D)v_k + \nabla q_k &= (\nabla\phi_k)q + [\mathcal{A}, \phi_k]v, \\ \operatorname{div} v_k &= g_k + (\nabla\phi_k|v), \quad t \in J_0,\ x \in \mathbb{R}^n, \\ v_k|_{t=0} &= 0, \end{aligned} \tag{7.1}$$

where $[\mathcal{A}, \phi_k]v = \mathcal{A}(\phi_k v) - \phi_k \mathcal{A}v$ means the commutator of $\mathcal{A}$ and ϕ_k. Denote the solution operator of the generalized Stokes problem for $\mathcal{A}_k$ by S^k. Then we have the representation

$$\begin{bmatrix} v_k \\ q_k \end{bmatrix} = S^k \begin{bmatrix} (\nabla\phi_k)q + [\mathcal{A}, \phi_k]v \\ g_k + (\nabla\phi_k|v) \end{bmatrix}.$$

Summing over all charts k, we deduce

$$\begin{bmatrix} v \\ q \end{bmatrix} = \sum_{k=0}^N \begin{bmatrix} v_k \\ q_k \end{bmatrix} = \sum_{k=0}^N S^k \begin{bmatrix} (\nabla\phi_k)q + [\mathcal{A}, \phi_k]v \\ g_k + (\nabla\phi_k|v) \end{bmatrix}.$$

We decompose this representation of the solution as

$$\begin{bmatrix} v \\ q \end{bmatrix} = \sum_{k=0}^N S^k \begin{bmatrix} 0 \\ g_k \end{bmatrix} + T \begin{bmatrix} q \\ v \end{bmatrix} + Rv,$$

where

$$T = \sum_{k=0}^N S^k \nabla\phi_k \quad \text{and} \quad R = \sum_{k=0}^N S^k \begin{bmatrix} [\mathcal{A}, \phi_k] \\ 0 \end{bmatrix}.$$

We estimate T and R separately. For this purpose, we define the spaces

$$Z = [H_p^1(J_0; L_p(\mathbb{R}^n;\mathbb{C}^n)) \cap L_p(J_0; H_p^2(\mathbb{R}^n;\mathbb{C}^n))] \times L_p(J_0; \dot{H}_p^1(\mathbb{R}^n))$$

and

$$X = L_p(J_0 \times \mathbb{R}^n;\mathbb{C}^n), \quad X_p = W_p^{2-2/p}(\mathbb{R}^n;\mathbb{C}^n),$$

as well as

$$Y = H_p^1(J_0; \dot{H}_p^{-1}(\mathbb{R}^n)) \cap L_p(J_0; H_p^1(\mathbb{R}^n)).$$

To begin with T, recall that each S^k splits into $S^k = S_0 + S_1^k$, with the same S_0 for each k, since the latter does not depend on the coefficients of $\mathcal{A}_k$. Hence

$$T = \sum_{k=0}^N S^k \nabla\phi_k = \sum_{k=0}^N S_1^k \nabla\phi_k + S_0 \nabla \sum_{k=0}^N \phi_k = \sum_{k=0}^N S_1^k \nabla\phi_k,$$

since ϕ_k forms a partition of unity. Let us decompose T into its components, employing the factorization of S_1 obtained in section 5. We have

$$\begin{aligned}
T_{11}q &= (\partial_t - \Delta)^{-1} \sum_k S_{11}^k (-\Delta)(\partial_t - \Delta)^{-1}(q\nabla\phi_k),\\
T_{21}q &= (-\Delta)^{-1/2} \sum_k S_{21}^k (-\Delta)(\partial_t - \Delta)^{-1}(q\nabla\phi_k),\\
T_{12}v &= (\partial_t - \Delta)^{-1} \sum_k S_{12}^k (-\Delta)^{1/2}(\nabla\phi_k|v),\\
T_{22}v &= (-\Delta)^{-1/2} \sum_k S_{22}^k (-\Delta)^{1/2}(\nabla\phi_k|v).
\end{aligned}$$

Since $\nabla\phi_k$ has compact support also for $k = 0$, we see that $(\nabla\phi_k)q$ belongs to $L_p(J_0; H_p^1(\mathbb{R}^n))$, and

$$|(-\Delta)^{1/2}(q\nabla\phi_k)|_{L_p(J_0\times\mathbb{R}^n)} \le C|\nabla q|_{L_p(J_0\times\mathbb{R}^n)}$$

holds with some constant $C > 0$; recall the normalization of the pressure

$$\int_{B_{2R}(0)} q(t,x)dx = 0;$$

hence Poincaré's inequality is valid. Therefore

$$|(-\Delta)(\partial_t - \Delta)^{-1}(\nabla\phi_k q)|_{H_p^{1/2}(J_0;L_p(\mathbb{R}^n))} \le C|\nabla q|_{L_p(J_0\times\mathbb{R}^n)}.$$

Since $H_p^{1/2} \hookrightarrow L_{2p}$, this implies that the norm of $(-\Delta)(\partial_t - \Delta)^{-1}(\nabla\phi_k q)$ in $L_p(J_0\times\mathbb{R}^n)$ is dominated by $C\delta^{1/2p}|\nabla q|_{L_p(J_0\times\mathbb{R}^n)}$, and the constant $C\delta^{1/2p}$ can be made small by choice of $\delta > 0$.

Similarly, $\nabla\phi_k$ is a multiplier for the space $H_p^s(\mathbb{R}^n)$, and hence there is a constant $C > 0$ such that

$$|(-\Delta)^{1/2}(\nabla\phi_k|v)|_{H_p^{1/2}(J_0;L_p(\mathbb{R}^n))} \le C|(\partial_t - \Delta)v|_{L_p(J_0\times\mathbb{R}^n)}.$$

By this estimate we may conclude as before that the norm of $(-\Delta)^{1/2}(\nabla\phi_k v)$ in $L_p(J_0\times\mathbb{R}^n;\mathbb{C}^n)$ is dominated by $C\delta^{1/2p}|(\partial_t-\Delta)v|_{L_p(J_0\times\mathbb{R}^n;\mathbb{C}^n)}$. As a consequence, the operator T satisfies

$$\left|T\begin{bmatrix} q\\ v\end{bmatrix}\right|_Z \le C\delta^{1/2p}\left|\begin{bmatrix} v\\ q\end{bmatrix}\right|_Z.$$

Next, R is given by

$$R=\sum_k S^k\begin{bmatrix} [\mathcal{A},\phi_k]v\\ 0\end{bmatrix}.$$

The commutator $[\mathcal{A},\phi_k]$ is a differential operator of first order, and hence we see that

$$[\mathcal{A},\phi_k]v\in H^{1/2}_p(J_0;L_p(\mathbb{R}^n;\mathbb{C}^n))\cap L_p(J_0;H^1_p(\mathbb{R}^n;\mathbb{C}^n)).$$

Therefore, we obtain

$$\begin{aligned}|Rv|_Z&\le C\max_k|[\mathcal{A},\phi_k]v|_{L_p(J_0\times\mathbb{R}^n;\mathbb{C}^n)}\\ &\le C\delta^{1/2p}\max_k|[\mathcal{A},\phi_k]v|_{L_{2p}(J;L_p(\mathbb{R}^n;\mathbb{C}^n))}\le C\delta^{1/2p}|v|_Z;\end{aligned}$$

i.e., the norm of R in Z is also bounded by $C\delta^{1/2p}$, which becomes small by the smallness of $\delta>0$.

The above arguments show that, choosing first $\eta>0$ and then $\delta>0$ small enough, there is a constant $C>0$ such that the estimate

$$|(v,q)|_Z\le C[|f|_X+|g|_Y+|v_0|_{X_p}] \tag{7.2}$$

holds for each solution (v,q) on J_0 for given data $v_0\in X_p$, $f\in X$, $g\in Y$. Therefore, the generalized Stokes operator $L\in\mathcal{B}(Z;X\times Y\times X_p)$ defined by the first lines of the left-hand side of (4.1) is injective and has closed range; hence it is semi-Fredholm for each set of coefficients which are continuous on $J_0\times\mathbb{R}^n$, admit uniform limits as $|x|\to\infty$, and are strongly elliptic, uniformly on $J_0\times(\mathbb{R}^n\cup\{\infty\})$. Define the family $\mathcal{A}_\tau=\tau\mathcal{A}+(1-\tau)(-\Delta)$; we then may conclude that for each $\tau\in[0,1]$, the corresponding generalized Stokes operator L_τ is injective and has closed range. By the continuity of the Fredholm index, it must be constant; i.e., the index is zero for all $\tau\in[0,1]$ since L_0 is bijective by Theorem 4.1. This shows that $L=L_1$ is also surjective, and hence the proof is complete in case $G=\mathbb{R}^n$.

Step 2. Next we consider the case of a half-space, i.e., $G=\mathbb{R}^n_+$. We extend the coefficients $a^{kl}_{ij}(t,x)$ of $\mathcal{A}(t,x,D)$ by symmetry to $J\times\mathbb{R}^n$. According to Proposition 4.2 we may assume $v_0=g=0$, and also $h_\nu=0$ in the case of Dirichlet or slip conditions. We localize as in Step 1 to obtain

$$\begin{aligned}\partial_t v_k+\mathcal{A}_k(D)v_k+\nabla q_k&=f_k+(\nabla\phi_k)q+[\mathcal{A},\phi_k]v,\\ \operatorname{div}v_k&=(\nabla\phi_k|v),\quad t\in J_0,\ x\in\mathbb{R}^n,\\ v_k|_{t=0}&=0,\end{aligned}\tag{7.3}$$

for charts which are interior to $\mathbb{R}^n_+$ (according to Step 1 only one such chart is sufficient), and

$$\begin{aligned}\partial_t v_k+\mathcal{A}_k(D)v_k+\nabla q_k&=f_k+(\nabla\phi_k)q+[\mathcal{A},\phi_k]v,\\ \operatorname{div}v_k&=(\nabla\phi_k|v),\quad t\in J_0,\ x\in\mathbb{R}^n_+,\\ v_k|_{t=0}&=0,\\ \mathcal{B}_k(D)(v_k,q_k)&=h_k+[\mathcal{B},\phi_k]v\end{aligned}\tag{7.4}$$

for charts intersecting the boundary. We concentrate now on the charts intersecting the boundary; the interior chart is treated as in Step 1. Decompose $v_k = \nabla\psi_k + v_k^2 + v_k^3$, $q_k = q_k^2 + q_k^3$ as follows. For Dirichlet or slip conditions, ψ_k is taken as the solution of the problem

$$\Delta\psi_k = (\nabla\phi_k|v),\ x \in \mathbb{R}^n_+, \quad \partial_\nu\psi_k = 0,\ x \in \partial\mathbb{R}^n_+.$$

Thus, $\psi_k \in {}_0H^1_p(J; \dot{H}^2_p(\mathbb{R}^n_+)) \cap L_p(J; \dot{H}^4_p(\mathbb{R}^n_+))$; hence $\nabla\psi_k = R_0(\nabla\phi_j v)$ belongs to ${}_0H^1_p(J; \dot{H}^1_p(\mathbb{R}^n_+)) \cap L_p(J; \dot{H}^3_p(\mathbb{R}^n_+))$, and $\sum_k \nabla\psi_k = R_0 \sum_k \nabla\phi_k v = 0$. On the other hand, for $\theta \in \dot{H}^1_{p'}(\mathbb{R}^n_+)$ we have

$$\int_{\mathbb{R}^n_+} (\nabla\phi_k) v\theta dx = -\int_{\mathbb{R}^n_+} \phi_k v \nabla\theta dx,$$

since div $v = (v|\nu) = 0$; hence $\nabla\phi_k v \in {}_0H^1_p(J; \dot{H}^{-1}_p(\mathbb{R}^n_+))$, and consequently $\nabla\psi_k \in {}_0H^1_p(J; L_p(\mathbb{R}^n_+))$. Therefore, we see $\nabla\psi_k \in {}_0H^1_p(J; H^1_p(\mathbb{R}^n_+)) \cap L_p(J; H^3_p(\mathbb{R}^n_+))$. In case of Neumann boundary conditions we use instead

$$\Delta\psi_k = (\nabla\phi_k|v),\ x \in \mathbb{R}^n_+, \quad \psi_k = 0,\ x \in \partial\mathbb{R}^n_+.$$

Next (v_k^2, q_k^2) denotes the full-space solution of the problem

$$\begin{aligned} \partial_t v_k^2 + \mathcal{A}_k(D) v_k^2 + \nabla q_k^2 &= f_k + \nabla\phi_k q + [\mathcal{A}, \phi_k] v - (\partial_t + \mathcal{A}_k(D))\nabla\psi_j, \\ \operatorname{div} v_k &= 0, \quad t \in J_0,\ x \in \mathbb{R}^n, \\ v_k|_{t=0} &= 0. \end{aligned} \tag{7.5}$$

With the same notation as in Step 1 we then obtain

$$\begin{bmatrix} v^2 \\ q^2 \end{bmatrix} = \sum_{k=0}^N \begin{bmatrix} v_k^2 \\ q_k^2 \end{bmatrix} = \sum_{k=0}^N S^k \begin{bmatrix} f_k - (\partial_t + \mathcal{A}_k(D))\nabla\psi_k + \nabla\phi_k q + [\mathcal{A}, \phi_k] v \\ 0 \end{bmatrix}.$$

Since $(\partial_t + \mathcal{A}_k(D))\nabla\psi_k \in L_p(J; H^1_p(\mathbb{R}^n_+))$ we may argue as in Step 1 to estimate (v^2, q^2).

Thus it remains to estimate (v^3, q^3), which is a solution of the problem

$$\begin{aligned} \partial_t v_k^3 + \mathcal{A}_k(D) v_k^3 + \nabla q_k^3 &= 0, \\ \operatorname{div} v_k^3 &= 0, \quad t \in J_0,\ x \in \mathbb{R}^n_+, \\ v_k^3|_{t=0} &= 0, \\ \mathcal{B}_k(D)(v_k^3, q_k^3) &= h_k + [\mathcal{B}, \phi_k] v - \mathcal{B}_k(D)(\nabla\psi_k + v_k^2, q_k^2). \end{aligned} \tag{7.6}$$

To achieve this, note that the commutator $[\mathcal{B}, \phi_k]$ is either zero in the case of Dirichlet conditions or an operator of order zero and hence gains time regularity. Since $\nabla\psi_k$ belongs to the space ${}_0H^1_p(J; H^1_p(\mathbb{R}^n_+)) \cap L_p(J; H^3_p(\mathbb{R}^n_+))$, the term $\mathcal{B}_k(D)\nabla\psi_k$ has also more time regularity than required by the boundary space for h. Next (v_k^2, q_k^2) splits into

$$(v_k^2, q_k^2) = S^k f_k + S_0 \bar{f}_k + S_1^k \bar{f}_k,$$

where

$$\bar{f}_k = [\mathcal{A}, \phi_k] v + (\nabla\phi_k) q - (\partial_t + \mathcal{A}_k(D))\nabla\psi_k$$

belongs to $L_p(J;H^1_p(\mathbb{R}^n_+))$. S_0 maps this space into ${}_0H^1_p(J;H^1_p(\mathbb{R}^n))\cap L_p(J;H^3_p(\mathbb{R}^n))$, and hence $\mathcal{B}_k(D)S_0f_k$ also gains extra regularity in time. Due to the factorization of S_1^j, the term $\mathcal{B}_k(D)S_1^kf_k$ will be small, as in Step 1.

Thus, as in Step 1, we obtain an a priori estimate of the form

$$|(v,q)|_Z \le C[|f|_X + |g|_Y + |v_0|_{X_p} + |h|_{Y_\partial}], \tag{7.7}$$

by choosing first $\eta>0$ and then $\delta>0$ small enough. Here Y_∂ denotes the relevant boundary space. The Fredholm argument at the end of Step 1 again completes the proof for the half-space case.

Step 3. The localization procedure for general domains with compact boundary of class C^{3-} follows the lines of Step 2. The only difference concerns that the charts intersecting the boundary cannot be handled by Theorem 6.1 directly, since they lead to problems in perturbed half-spaces. Therefore we show in this step how to transfer Theorem 6.1 to perturbed half spaces.

For this purpose, consider a graph ρ over $\mathbb{R}^{n-1}$, and let G be the corresponding epigraph

$$G=\{x=(x',x_n)\in\mathbb{R}^n:\, x_n>\rho(x')\}.$$

We may assume that ρ is of class C^{3-} and has compact support, and $|\nabla\rho|_{L^\infty}\le\eta$, where $\eta>0$ is sufficiently small. Suppose that (u,π) is a solution in the maximal regularity class of the generalized Stokes problem (4.1) with given data f, g, h, u_0 subject to (D). According to Proposition 4.2 we may assume $u_0=g=h_\nu=0$. Introduce the pull back (v,q) defined on $\mathbb{R}^n_+$ by

$$v(t,x)=u(t,x+\rho(x')e_n),\quad q(t,x)=\pi(t,x+\rho(x')e_n),$$

where $t\in J$, $x=(x',x_n)$, $x'\in\mathbb{R}^{n-1}$, and $x_n>0$. Then (v,q) satisfies the perturbed problem

$$\begin{aligned}\partial_t v+\mathcal{A}(D)v+\nabla q &= f+\mathcal{A}_\rho(D)v+(\nabla\rho)\partial_n q,\\ \operatorname{div} v &= (\nabla\rho|\partial_n v),\quad t\in J,\ x\in\mathbb{R}^n_+,\\ \mathcal{B}(D)(v,q) &= \mathcal{B}_\rho(D)v+h,\quad t\in J,\ x=(x',0),\ x'\in\mathbb{R}^{n-1},\\ v_{|t=0} &= 0,\quad x\in\mathbb{R}^n_+.\end{aligned} \tag{7.8}$$

Here, f and h also denote the transformed data, which belong to the right regularity class, since $\rho\in C^{3-}$. The operator $\mathcal{A}_\rho(D)$ is given by

$$\mathcal{A}_\rho(D)=a^{kl}_{ij}[\partial_k\rho D_lD_n+\partial_l\rho D_kD_n+\partial_k\rho\partial_l\rho D_n^2+i\partial_k\partial_l\rho D_n].$$

Since the second order derivatives in $\mathcal{A}_\rho(D)$ carry the factor $\nabla\rho$, they are small by the condition $|\nabla\rho|_{L^\infty}\le\eta$, as is $(\nabla\rho)\partial_n q$. Next, for the same reason, the term $(\nabla\rho|\partial_n v)$ in the divergence equation is also small in $L_p(J;H^1_p(\mathbb{R}^n_+))$.

The normal ν at ∂G is given by

$$\nu(x+\rho(x')e_n)=\begin{bmatrix}\nabla_{x'}\rho\\ -1\end{bmatrix}\frac{1}{\sqrt{1+|\nabla_{x'}\rho|^2}};$$

therefore the condition $(u|\nu)=0$ transforms to $(v|-e_n)=-(\nabla\rho|v)$. Thus we have to verify that the pair $((\nabla\rho|\partial_n v),-(\nabla\rho|v)_{|x_n=0})$ is small in $H^1_p(J;\dot H^{-1}_p(\mathbb{R}^n_+))$. For this purpose, let $\phi\in\dot H^1_{p'}(\mathbb{R}^n_+)$; then

$$\int_{\mathbb{R}^n_+}\phi(\partial_n v|\nabla\rho)dx-\int_{\partial\mathbb{R}^n_+}-\phi(\nabla\rho|v)dx'=-\int_{\mathbb{R}^n_+}(v|\nabla\rho)\partial_n\phi dx,$$

and hence

$$|((\nabla\rho|\partial_n v), -(\nabla\rho|v)_{|x_n=0})|_{H^1_p(\dot H^{-1}_p)} \le |\nabla\rho|_{L^\infty}|v|_{H^1_p(L_p)},$$

thereby showing the smallness of this term.

Finally, we show smallness of the boundary perturbation $\mathcal{B}_\rho(D)$. We have

$$a^{kl}_{ij}\nu_k D_l u_j = \frac{1}{\sqrt{1+|\nabla\rho|^2}} a^{kl}_{ij}(\partial_k\rho - \delta_{kn})(D_l v - \partial_l\rho D_n v);$$

hence

$$\mathcal{B}_\rho(D) = \left(1 - \frac{1}{\sqrt{1+|\nabla\rho|^2}}\right) a^{nl}_{ij} D_l + \frac{1}{\sqrt{1+|\nabla\rho|^2}}[a^{nl}_{ij}\partial_l\rho D_n + a^{kl}_{ij}\partial_k\rho(D_l - \partial_l D_n)]$$

in the case of Neumann conditions, and a similar expression in the slip case. Since

$$1 - \frac{1}{\sqrt{1+|\nabla\rho|^2}} = \frac{|\nabla\rho|^2}{(1+\sqrt{1+|\nabla\rho|^2})\sqrt{1+|\nabla\rho|^2}},$$

each term in $\mathcal{B}_\rho(D)$ carries a factor $\nabla\rho$; hence, as at the end of section 6, we have an estimate of the form

$$|\mathcal{B}_\rho(D)v|_{W^{1/2-1/2p}_p(L_p)\cap L_p(W^{1-1/p}_p)} \le C|\nabla\rho|_{L_\infty}|v|_Z + C|\nabla^2\rho|_{L_\infty}|v|^\alpha_Z|v|^{1-\alpha}_{L_p},$$

for some $\alpha \in (0,1)$. This shows that the boundary operator $\mathcal{B}_\rho(D)$ is also small, provided that $\eta > 0$ is small enough.

Therefore, we may apply once more a Neumann series argument to conclude from Theorem 6.1 that this result is also valid in perturbed half-spaces. This completes the proof of Theorem 4.1. □

8. The nonlinear problem with homogeneous slip and nonslip conditions. The nonlinear problem with $\Gamma_n = \emptyset$ will be solved by means of an abstract result which is essentially due to Clément and Li [3]. This is possible since in this case the involved boundary conditions are actually linear and homogeneous. We describe a version of the abstract result proved in Prüss [21].

Let X_0, X_1 be Banach spaces with norms $|\cdot|_0$, $|\cdot|_1$, $X_1 \hookrightarrow X_0$ densely, $J = [0,a]$, $J_0 = [0,a_0]$, and let $1 < p < \infty$. Consider the quasi-linear problem

$$\dot u(t) + A(u(t))u(t) = F(u(t)), \quad t \in J,\ u(0) = u_0. \tag{8.1}$$

Here $u_0 \in X_p := (X_0, X_1)_{1-1/p,p}$, $A : X_p \to \mathcal{B}(X_1, X_0)$ is continuous, and $F : X_p \to X_0$ is continuous. Moreover, we assume the following conditions on the Lipschitz continuity of A and F:

(A) For each $R > 0$ there is a constant $L(R) > 0$ such that

$$|A(u)v - A(\bar u)v|_0 \le L(R)|u-\bar u|_p|v|_1, \qquad u,\bar u \in X_p, |u|_p, |\bar u|_p \le R,\ v \in X_1.$$

(F) For each $R > 0$ there is a constant $l(R)$ such that

$$|F(u) - F(\bar u)|_0 \le l(R)|u-\bar u|_p, \quad u,\bar u \in X_p, |u|_p, |\bar u|_p \le R.$$

In the situation described above we have the following theorem.

THEOREM 8.1. *Suppose that the assumptions* (A) *and* (F) *are satisfied, and assume that $A(u)$ has the property of maximal L_p-regularity for each $u \in X_p$.*

Then (8.1) *admits a unique solution u on a maximal time interval $J(u_0) = [0, t_+(u_0))$ in the maximal regularity class*

$$u \in H^1_p(J; X_0) \cap L_p(J; X_1) \quad \textit{for each } a < t_+(u_0).$$

In case $t_+(u_0) < a_0$, the maximal time $t_+(u_0)$ is characterized by the equivalent conditions

$$\int_{J(u_0)} [|u(t)|_1^p + |\dot{u}(t)|_0^p] dt = \infty$$

and

$$\lim_{t \to t^+(u_0)-} u(t) \quad \textit{does not exist in } X_p.$$

The map $u_0 \mapsto u(t)$ defines a local semiflow on the natural phase space X_p.

Now we apply this result directly to the problem (2.2) under consideration, for a proof of Theorem 2.1 in case $\Gamma_n = \emptyset$. For this purpose we let

$$X_0 = \{u \in L_p(G, \mathbb{R}^n) :\ \operatorname{div} u = 0\},$$

$$X_1 = \{u \in H^2_p(G) \cap X_0 :\ u|_{\Gamma_0} = (u|\nu)|_{\Gamma_s} = 0,\ \mathcal{PE}(u)|_{\Gamma_s} = 0\}.$$

The operator family $A(u)$ will be defined by $A(u) = P\mathcal{A}(u, D)$ with $\mathcal{A}(u, D)$ as in section 2; here P denotes the standard Helmholtz projection. Theorem 4.1 implies that for each $u \in X_p \hookrightarrow W^{2-2/p}_p(G)$ the operator $A(u)$ has maximal L_p-regularity. Note that the involved boundary conditions are actually linear and homogeneous. This is obvious for the Dirichlet conditions $u|_{\Gamma_0} = (u|\nu)|_{\Gamma_s} = 0$, but is also true for the seemingly nonlinear condition $\mathcal{S}\nu - (\mathcal{S}\nu|\nu)\nu = 0$. In fact, the latter is equivalent to $\mathcal{E}\nu - (\mathcal{E}\nu|\nu)\nu = 0$, which is linear.

It is easy to check by Sobolev embedding that condition (A) holds, provided $p > n + 2$. Finally, we set $F(u) = -P(u \cdot \nabla u)$ and check, once more by Sobolev embedding, that condition (F) is satisfied as well. Thus we may apply Theorem 8.1 to prove Theorem 2.1 in the case $\Gamma_n = \emptyset$. We want to emphasize that this approach works as long as the boundary conditions are homogeneous and linear, so it does not apply for the Neumann problem since this one involves a truly nonlinear boundary condition.

9. The nonlinear problem with general boundary conditions. We now consider the nonlinear problem with general inhomogeneous boundary conditions, i.e.,

$$\begin{aligned}
&\partial_t u + \operatorname{div}\,(u \otimes u) = \operatorname{div}\, S + f,\\
&S = \mu[\nabla u + (\nabla u)^{\mathsf{T}}] - \pi I,\\
&\operatorname{div}\, u = g, \quad t > 0,\ x \in G,\\
&u(t,x) = h_0, \quad t > 0,\ x \in \Gamma_0,\\
&S\nu - (S\nu|\nu)\nu = h_s,\ (u|\nu) = h_\nu, \quad t > 0,\ x \in \Gamma_s,\\
&S\nu = h_n, \quad x \in \Gamma_n,\\
&u(0,x) = u_0(x),\ x \in G.
\end{aligned} \tag{9.1}$$

Assume $p > n+2$ in what follows, and let $\mu \in C^{2-}(\mathbb{R}_+)$ be a function subject to (2.3). Fix a time interval $J_0 = [0, a_0]$ and let $J_a = [0, a]$ for $a \le a_0$. We define the maximal regularity spaces

$$Z(a) := H_p^1(J_a; L_p(G; \mathbb{R}^n)) \cap L_p(J_a; H_p^2(G; \mathbb{R}^n))$$

and set $Z(0) = Z(a_0)$. We further set

$$X(a) := L_p(J_a; L_p(G; \mathbb{R}^n)), \quad X_p := W_p^{2-2/p}(G; \mathbb{R}^n),$$
$$Y_j(a) := W_p^{1/2-1/2p}(J_a; L_p(\Gamma_j; \mathbb{R}^n)) \cap L_p(J_a; W_p^{1-1/p}(\Gamma_j; \mathbb{R}^n)),$$

and $X_0 = X(a_0)$, $Y_{j0} = Y(j(a_0)$. Note that we have the embedding

$$Z(a) \hookrightarrow C(J_a; X_p)$$

since X_p is the time-trace space of Z_a. However, the embedding constant blows up as $a \to 0+$. This unpleasant fact can be removed if one restricts attention to functions with time trace 0 at $t = 0$. Therefore we let

$${}_0Z(a) = \{u \in Z(a) : u|_{t=0} = 0\}, \quad {}_0Y_j(a) = \{u \in Y_j(a) : u|_{t=0} = 0\}.$$

We also have the embedding

$$Y_j(a) \hookrightarrow C(J_a; W_p^{1-3/p}(\Gamma_j; \mathbb{R}^n)), \quad j = s, n,$$

where the embedding constant is uniform in a if the embedding is restricted to ${}_0Y_j(a)$. In particular, since $p > n+2$ by assumption, we have

$$Z_0 \hookrightarrow C(J_0; C^1(\overline{G}; \mathbb{R}^n)).$$

Now suppose that $u_0 \in X_p$, $f \in X_0$, $g \in L_p(J_0; H_p^1(G))$, $h_j \in Y_{j0}$, and $(g, h_\nu) \in H_p^1(J_0; H_{p,\Gamma_n}^{-1}(G))$ are given such that the compatibility conditions

$$\operatorname{div} u_0 = g|_{t=0}, \quad u|_{\Gamma_0} = h_0, \quad (u_0|\nu)|_{\Gamma_s} = h_\nu,$$

and

$$(h_s|\nu) = 0, \quad 2\mu(|\mathcal{E}(u_0)|_2^2)\mathcal{P}\mathcal{E}(u_0)\nu = \mathcal{P}h_j|_{t=0}, \quad j = s, n,$$

are valid, where as before $\mathcal{E}(u) = \frac{1}{2}(\nabla u + \nabla u)^{\mathsf{T}}$. To achieve reduction to time traces 0 at $t = 0$, first choose extensions h_{*j} of $2(1 - \mu(|\mathcal{E}(u_0)|_2^2))\mathcal{E}(u_0)\nu$ in Y_{j0}, which is possible since $u_0 \in W_p^{1-3/p}(\Gamma; \mathbb{R}^n)$. Then solve the classical Stokes equation with $\mu = 1$, with initial value $u_*|_{t=0} = u_0$, right-hand sides f, $\operatorname{div} u_* = g$, Dirichlet conditions $u_*|_{\Gamma_0} = h_0$ on Γ_0, slip conditions $(u_*|\nu) = h_\nu$, $2\mathcal{P}\mathcal{E}(u_*)\nu = h_s + \mathcal{P}h_{*s}$ on Γ_s, and Neumann condition $2\mathcal{E}(u_*)\nu - \pi_*\nu = h_n + h_{*n}$. Note that the map

$$(u_0, f, g, h_0, h_\nu, h_s, h_n) \mapsto (u_*, \pi_*)$$

is bounded linear; i.e., (u_*, π_*) depends continuously on the data in the correct spaces, by Theorem 4.1.

Suppose that (u,π) is a solution of (1.1) in the maximal regularity class of type L_p on an interval J_a. Set $u_1 = u - u_*$ and $\pi_1 = \pi - \pi_*$. Then the time-traces of u_1 and $\pi|_{\Gamma_n}$ are zero, and the pair (u_1,π_1) is a solution of the quasi-linear problem

$$
\begin{aligned}
&\partial_t u + \mathcal{A}(t,x,D)u + \nabla\pi = \bar f(t,x) + F(u),\\
&\operatorname{div} u = 0, \quad t \in J_a,\ x \in G,\\
&u|_{\Gamma_0} = (u|\nu)|_{\Gamma_s} = u|_{t=0} = 0,\\
&\mathcal{P}[\nu_k \mathcal{A}^{kl}(t,x)D_l u] = \mathcal{P}\bar h_s + \mathcal{P}H(u) \quad \text{ on } J_a \times \Gamma_s,\\
&\nu_k \mathcal{A}^{kl}(t,x)D_l u - \pi\nu = \bar h_n + H(u) \quad \text{ on } J_a \times \Gamma_n,
\end{aligned}
\tag{9.2}
$$

where we have once more used the sum convention and $\mathcal{A}(t,x,D) = \mathcal{A}^{kl}(t,x)D_k D_l$. Here $\mathcal{A}^{kl}(t,x) = \mathcal{A}^{kl}(u_*(t,x)) = a^{kl}_{ij}(u_*(t,x))$ denote the matrices

$$\mathcal{A}^{kl}(u) = \mu(|\mathcal{E}(u)|_2^2)(\delta_{kl}\delta_{ij} + \delta_{il}\delta_{jk}) + 4\mu'(|\mathcal{E}(u)|_2^2)\varepsilon_{ik}(u)\varepsilon_{jl}(u),$$

as introduced in (2.1). Since $\nabla u_* \in H_p^{1/2}(J_0; L_p(G;\mathbb{R}^n)) \cap L_p(J_0; H_p^1(G;\mathbb{R}^n))$ and this space embeds into $C(J_0 \times \overline{G})$, we see that the coefficients are continuous on $J_0 \times \overline{G}$ and strongly normally elliptic; see section 3. Moreover, $\nabla u_* \in Y_0$, and since $\mu \in C^2(\mathbb{R}_+)$ we also see that the coefficients of the first order boundary operators belong to $W_p^{1/2-1/2p}(J_0; L_p(\Gamma)) \cap L_p(J_0; W_p^{1-1/p}(\Gamma))$. Therefore Theorem 4.1 implies maximal regularity of the linear initial-boundary value problem defined by (4.1).

Next the function $\bar f$ is defined by

$$\bar f = -\Delta u_* - \sum_{k,l=1}^n \mathcal{A}^{kl} D_k D_l u_* - u_* \cdot \nabla u_*,$$

which belongs to $X_0 = L_p(J_0 \times G)$, and $F : {}_0Z_a \to X_a$ is given by

$$F(v) = [\mathcal{A}(u_*, D) - \mathcal{A}(u_* + v, D)](u_* + v) - [u_* \cdot \nabla v + v \cdot \nabla u_* + v \cdot \nabla v].$$

We decompose $F(v) = F_1(v) - F_2(v)$, indicated by the bracketing. The functions $\bar h_j$ read

$$\bar h_j = h_j + p_*\nu - 2\mu(|\mathcal{E}(u_*)|_2^2)\mathcal{E}(u_*)\nu, \quad j = s, n,$$

which belong to ${}_0Y_{j0}$ by the regularity of u_* and the choice of h_*. Finally, $H(v)$ is given by

$$H(v) = H_1(v) - H_2(v),$$

with

$$H_1(v) = 2[\mu(|\mathcal{E}(u_*)|_2^2) - \mu(|\mathcal{E}(u_* + v)|_2^2)]\mathcal{E}(v)\nu$$

and

$$H_2(v) = 2[\mu(|\mathcal{E}(u_* + v)|_2^2) - \mu(|\mathcal{E}(u_*)|_2^2) + 2\mu'(|\mathcal{E}(u_*)|_2^2)((\mathcal{E}(u_*)|\mathcal{E}(v)))]\mathcal{E}(u_*)\nu.$$

As a consequence, by maximal regularity we may rewrite (9.2) as the fixed point problem in ${}_0Z(a)$,

$$v = Tv := L(\bar f + F(v)) + L_s(\bar h_s + \mathcal{P}H(v)) + L_n(\bar h_n + H(v)), \quad v \in {}_0Z(a), \tag{9.3}$$

where $L \in \mathcal{B}(X(a); {}_0Z(a))$ and $L_j \in \mathcal{B}({}_0Y_j(a); {}_0Z(a))$ are causal bounded linear operators with bounds independent of $a \in (0, a_0]$. We denote this common bound by C_M in what follows.

To carry out the contraction argument, fix $r \in (0, 1]$ and consider the closed ball $\mathbb{B} := B_r(0) \subset {}_0Z(a)$. The numbers $a > 0$ and r will be chosen later small enough so that T becomes a contraction in ${}_0Z(a)$. We have $F_k(0) = H_k(0) = 0$ by definition. By uniform embedding, there is a constant $C_E > 0$ such that

$$|v|_\infty + |\nabla v|_\infty \le C_E |v|_{Z(a)}, \quad v \in {}_0Z(a).$$

Let $m := \sup\{|\mu(s)| + |\mu'(s)| + |\mu''(s)| : s \in [0, R]\}$. We first choose $a > 0$ so small that $|L\bar{f} + L_s\bar{h}_s + L_n\bar{h}_n|_{Z_a} \le r/4$.

For arbitrary $v, w \in \mathbb{B}$ we obtain

$$\begin{aligned} F_1(v) - F_1(w) = {} & [\mathcal{A}(u_*, D) - \mathcal{A}(u_* + v, D)](v - w) \\ & + [\mathcal{A}(u_* + v, D) - \mathcal{A}(u_* + w, D)](u_* + w), \end{aligned}$$

and hence

$$\begin{aligned} |F_1(v) - F_1(w)|_{X_a} \le {} & \sup_{J_a \times G} |\mathcal{A}(u_*, D) - \mathcal{A}(u_* + v, D)||v - w|_{Z(a)} \\ & + \sup_{J_a \times G} |\mathcal{A}(u_* + v, D) - \mathcal{A}(u_* + w, D)||u_* + w|_{Z(a)} \\ \le {} & C|v - w|_{Z(a)}[|v|_\infty + |\nabla v|_\infty] \\ & + C[|u_*|_{Z(a)} + r][|v - w|_\infty + |\nabla (v - w)|_\infty] \\ \le {} & C|v - w|_{Z(a)}[|u_*|_{Z(a)} + r] \le \frac{1}{8C_M}|v - w|_{Z(a)}, \end{aligned}$$

provided that $a > 0$ and $r \in (0, 1]$ are chosen small enough. Here the constants $C > 0$ differ from line to line but depend only linearly on C_E and m.

In a similar, even simpler, way we estimate F_2. Since

$$Z(a) \hookrightarrow L_p(J_a; H^1_{2p}(G; \mathbb{R}^n)),$$

with embedding constant uniform in a, we obtain

$$|F_2(v) - F_2(w)|_{X(a)} \le C(|u^*|_{Z(a)} + r)|v - w|_{Z(a)} \le \frac{1}{8C_M}|v - w|_{Z(a)},$$

provided that $a > 0$ and $r \in (0, 1]$ are small enough. This takes care of the nonlinear term containing F in the definition of T.

The estimates for H are more complicated since they involve fractional Sobolev spaces, but they are still elementary. While we do not claim that the arguments below are new, we include them for the sake of completeness. Recall that a norm for $W^s_p(\Sigma)$, Σ a compact C^1-manifold in $\mathbb{R}^n$, is given by

$$|a|_{W^s_p(\Sigma)} = |a|_p + \left[\int_\Sigma \int_\Sigma \frac{|a(x) - a(y)|^p}{|x - y|^{sp+n}} d\sigma(x) d\sigma(y)\right]^{1/p},$$

where $d\sigma$ denotes the surface measure on Σ.

There are two fundamental estimates for fractional Sobolev spaces that one should keep in mind. The first concerns products and reads as

$$|ab|_{W^s_p} \le |a|_\infty |b|_{W^s_p} + |b|_\infty |a|_{W^s_p},$$

valid for all functions $a, b \in W_p^s \cap L_\infty,\ s \in (0,1)$. The second concerns substitution operators in W_p^s of the form $\phi(a)$, where $\phi \in C^2$. Based on the identity

$$\begin{aligned}
&[\phi(a(x)) - \phi(b(x))] - [\phi(a(y)) - \phi(b(y))] \\
&= \int_0^1 \int_0^1 \partial_t \partial_s \phi(s[ta(x) + (1-t)b(x)] + (1-s)[ta(y) + (1-t)b(y)]) dsdt \\
&= \int_0^1 \int_0^1 \phi'(\xi(t,s))([a(x) - b(x)] - [a(y) - b(y)]) dsdt \\
&+ \int_0^1 \int_0^1 \phi''(\xi(t,s))([ta(x) + (1-t)b(x)] - [ta(y) + (1-t)b(y)]) \\
&\qquad\qquad \cdot (s[a(x) - b(x)] + (1-s)[a(y) - b(y)]) dtds,
\end{aligned}$$

we obtain

$$\begin{aligned}
&|[\phi(a(x)) - \phi(b(x))] - [\phi(a(y) - \phi(b(y)]| \le |\phi'|_\infty |(a(x) - b(x)) - (a(y) - b(y))| \\
&+ |\phi''|_\infty \{ |(a(x) - b(x)) - (a(y) - b(y))| \\
&\qquad \cdot (3|a - b|_\infty + |b(x) - b(y)|) + |a - b|_\infty |b(x) - b(y)| \}.
\end{aligned}$$

This implies

$$|\phi(a) - \phi(b)|_{W_p^s(\Sigma)} \le |\phi|_{BUC^2} [|a - b|_{W_p^s(\Sigma)} (1 + 3|a - b|_\infty + |b|_{W_p^s}) + |a - b|_\infty |b|_{W_p^s}].$$

Using these two inequalities, we obtain for H_1 the Lipschitz estimate

$$|H_1(v) - H_1(w)|_{Y_j(a)} \le Cr|v - w|_{Z(a)},$$

with some constant C which depends only on L and embedding constants that are uniform in a. In a similar way, skipping the details, we also get

$$|H_2(v) - H_2(w)|_{Y_j(a)} \le C(r + |u_*|_{Z(a)})|v - w|_{Z(a)}.$$

Thus, choosing $a > 0$ and $r \in (0,1]$ small enough, we obtain

$$|H(v) - H(w)|_{Y_j(a)} \le \frac{1}{8C_M} |v - w|_{Z(a)}.$$

Therefore $T : \mathbb{B} \to \mathbb{B}$ is a strict contraction and hence, by the contraction mapping principle, admits a unique fixed point in $Z(a)$.

Thus we have shown unique solvability of (9.1) on a probably small interval $J_a = [0, a]$ in the maximal regularity class. Now, we may repeat the above arguments to obtain successively solutions in the maximal regularity class on intervals $[t_i, t_{i+1}]$. Either after finitely many steps we reach a_0, or we have an infinite strictly increasing sequence which converges to some $t_* = t_*(u_0) \le a_0$. In case $\lim_{i\to\infty} u(t_i) =: u(t_*)$ exists in X_p, we may continue the process, which shows that the maximal time is characterized by the property that this limit does not exist in X_p. The continuous dependence of the solution on the data is obvious, and therefore the semiflow property claimed in Theorem 2.1 follows as well. This completes the proof of Theorem 2.1. ∎

10. Appendix: Normally elliptic boundary value problems. Above, we employed results on maximal regularity of completely inhomogeneous vector-valued parabolic initial value problems of the form

$$\begin{aligned}
\partial_t u + \mathcal{A}(t,x,D)u &= f(t,x), \quad t \in J,\ x \in G, \\
\mathcal{B}_j(t,x,D)u &= g_j(t,x), \quad t \in J,\ x \in \partial G,\ j = 1, \dots, m, \\
u(0,x) &= u_0(x), \quad x \in G.
\end{aligned} \tag{10.1}$$

Here $J = [0, T]$ for some $T > 0$, and $G \subset \mathbb{R}^n$ is an open connected set with compact boundary ∂G. The operator $\mathcal{A}(t, x, D)$ is a partial differential operator of order $2m$, and $\mathcal{B}_j(t, x, D)$ are partial boundary differential operators of order $m_j < 2m$. More precisely, let E be a Banach space and $m, m_1, \ldots, m_m$ be natural numbers with $m_j < 2m$ for $j = 1, \ldots, m$, and let

$$\mathcal{A}(t,x,D) = \sum_{|\alpha| \le 2m} a_\alpha(t,x) D^\alpha,$$
$$\mathcal{B}_j(t,x,D) = \sum_{|\beta| \le m_j} b_{j\beta}(t,x) D^\beta,$$

where a_α and $b_{j\beta}$ are $\mathcal{B}(E)$-valued variable coefficients. Here and in the following, we use the standard multi-index notation $D^\alpha = (-i)^{|\alpha|} \partial_{x_1}^{\alpha_1} \cdots \partial_{x_n}^{\alpha_n}$ with $\partial_{x_i} = \frac{\partial}{\partial x_i}$ and, later on, $\xi^\alpha = \xi_1^{\alpha_1} \cdots \xi_n^{\alpha_n}$. Note that the boundary operators have to be interpreted as $\mathcal{B}_j(t,x,D)u = \sum_{|\beta| \le m_j} b_{j\beta}(t,x) \gamma_0 D^\beta u$, where $\gamma_0 v$ denotes the trace of the function v on the boundary ∂G (given sufficient smoothness of v and ∂G); we will often omit γ_0 in the notation. In particular, the coefficients $b_{j\beta}$ are defined on ∂G only.

We are interested in maximal L_p-regularity of (10.1) for $1 < p < \infty$, which means that we are looking for solutions in the class

$$u \in H_p^1(J; L_p(G; E)) \cap L_p(J; H_p^{2m}(G; E)). \tag{10.2}$$

Trace theorems show that, for this regularity of the solution, the given data have to satisfy the following conditions:

(D) *Assumptions on the data.*

(i) $f \in L_p(J \times G; E)$,

(ii) $g_j \in W_p^{\kappa_j}(J; L_p(\partial G; E)) \cap L_p(J; W_p^{2m\kappa_j}(\partial G; E))$ with $\kappa_j := (2m - m_j - 1/p)/(2m)$,

(iii) $u_0 \in W_p^{2m(1-1/p)}(G; E)$,

(iv) if $\kappa_j > 1/p$, then $B_j(0,x)u_0(x) = g_j(0,x)$ for $x \in \partial G$.

The assumptions on the coefficients needed are of two types, namely smoothness of the coefficients and ellipticity. We start with ellipticity. For this, we denote the principal part of a partial differential operator $\mathcal{A}$ by $\mathcal{A}_\#$. The outer normal of ∂G at $x \in \partial G$ is as before $\nu(x)$, and we set $\mathbb{C}_+ := \{z \in \mathbb{C} : \Re z > 0\}$.

(E) *Ellipticity of the interior symbol.* For all $t \in J$, $x \in \overline{G}$ and $\xi \in \mathbb{R}^n$, $|\xi| = 1$ we have

$$\sigma(\mathcal{A}_\#(t,x,\xi)) \subset \mathbb{C}_+;$$

i.e., $\mathcal{A}(t,x,D)$ is *normally elliptic.*

(LS) *Lopatinskii–Shapiro condition.* For all $t \in J$, $x \in \partial G$, all $\xi \in \mathbb{R}^n$ with $(\xi|\nu(x)) = 0$, all $h \in E^m$, and all $\lambda \in \overline{\mathbb{C}}_+$ with $|\xi| + |\lambda| \neq 0$, the ordinary differential equation system in $\mathbb{R}_+$

$$\begin{aligned} \lambda v(y) + \mathcal{A}_\#(t,x,\xi - \nu(x)D_y)v(y) &= 0, \quad y > 0, \\ \mathcal{B}_{j,\#}(t,x,\xi - \nu(x)D_y)v(0) &= h_j, \quad j = 1,\ldots,m, \end{aligned} \tag{10.3}$$

admits a unique solution $v \in C_0(\mathbb{R}_+; E)$.

Now we turn to smoothness assumptions on the coefficients of $\mathcal{A}$ and $\mathcal{B}_j$.

(SD) There are $r_k, s_k \geq p$ with $\frac{1}{s_k} + \frac{n}{2mr_k} < 1 - \frac{k}{2m}$ such that

$$a_\alpha \in L_{s_k}(J; (L_{r_k} + L_\infty)(G; \mathcal{B}(E))), \quad |\alpha| = k < 2m,$$
$$a_\alpha \in C(J \times \overline{G}; \mathcal{B}(E)), \quad |\alpha| = 2m.$$

If G is unbounded, the limits $a_\alpha(t, \infty) := \lim_{|x| \to \infty, x \in G} a_\alpha(t, x)$ exist uniformly in $t \in J$, $|\alpha| = 2m$.

(SB) There are $s_{jk}, r_{jk} \geq p$ with $\frac{1}{s_{jk}} + \frac{n-1}{2mr_{jk}} < \kappa_j + \frac{m_j - k}{2m}$ such that

$$b_{j\beta} \in W^{\kappa_j}_{s_{jk}}(J; L_{r_{jk}}(\partial G; \mathcal{B}(E))) \cap L_{s_{jk}}(J; W^{2m\kappa_j}_{r_{jk}}(\partial G; E)), \qquad |\beta| = k \leq m_j.$$

The main result of this appendix states that, under the assumptions made so far, the initial boundary value problem (10.1) admits maximal regularity. This result is taken from Denk, Hieber, and Prüss [5].

THEOREM 10.1. *Let $G \subset \mathbb{R}^n$ be open and connected with compact boundary ∂G of class C^{2m}. Let the Banach space E be of class $\mathcal{HT}$, suppose assumptions* (E), (LS), (SD), *and* (SB) *are satisfied, and let $1 < p < \infty$. Then problem* (10.1) *admits a unique solution*

$$u \in H^1_p(J; L_p(G; E)) \cap L_p(J; H^{2m}_p(G; E))$$

if and only if the data are subject to conditions (D).

It should be observed that, assuming the regularity assumptions (SD) and (SB), normal ellipticity (E) and the Lopatinskii–Shapiro condition (LS) are *necessary* for this result. These facts are also proved in Denk, Hieber, and Prüss [5].

Also important, as used in this paper in the slip case, it is possible to extend this result to situations where the boundary conditions do not have fixed order. So, for example, we may split boundary condition j as follows. Suppose $E = E_1 \oplus E_2$, and let

$$\mathcal{B}_j(t, x, D)u = (\mathcal{B}_{j1}(t, x, D)u, \mathcal{B}_{j2}(t, x, D)u),$$

where the coefficients are in $\mathcal{B}(E, E_k)$, $k = 1, 2$. Then the same results are valid in case the orders m_{jk} of $\mathcal{B}_{jk}$ differ; of course, the boundary spaces have to be adjusted accordingly.

VORTEX DYNAMICS IN A TWO-DIMENSIONAL DOMAIN WITH HOLES AND THE SMALL OBSTACLE LIMIT*

M. C. LOPES FILHO†

Abstract. In this work we examine the asymptotic behavior of solutions of the incompressible two-dimensional Euler equations on a domain with several holes, when one of the holes becomes small. We show that the limit flow satisfies a modified Euler system in the domain with the small hole removed. In vorticity form, the limit system is the usual equation for transport of vorticity, coupled with a modified Biot–Savart law which includes a point vortex at the point where the small hole disappears, together with the appropriate correction for the harmonic part of the flow. This work extends results by Iftimie, Lopes Filho, and Nussenzveig Lopes, obtained in the context of the exterior of a single small obstacle in the plane; see [*Comm. Partial Differential Equations*, 28 (2003), pp. 349–379]. The main difficulty in the present situation lies in controlling the behavior of the harmonic part of the flow, which is not an exact conserved quantity. As part of our analysis we develop a new description of two-dimensional vortex dynamics in a general domain with holes.

1. Introduction.

In this article we consider incompressible two-dimensional (2D) ideal flow in a bounded smooth domain with k holes and study its asymptotic behavior when one of the holes becomes small. This research is a natural outgrowth of the work done in [3], where the authors studied the asymptotic behavior for ideal 2D flow in the exterior of a single small obstacle in the plane.

Although treating a similar problem, the present work requires an entirely new approach. In [3], a family of conformal transformations between the exterior of the small obstacle and the exterior of the unit disk played a crucial role, allowing the use of explicit formulas for basic harmonic fields and the Biot–Savart law. This approach makes it convenient to assume that the obstacle is vanishing in a self-similar fashion. For the present work, it is not possible to work with explicit formulas, and the conformal mapping technique has to be substituted by qualitative analysis using elliptic techniques, including variational methods and the maximum principle. One consequence of this new approach is that the self-similarity hypothesis, used in [3], could be removed altogether.

One important distinction between 2D ideal flow in the exterior of a single obstacle and in a bounded domain with several holes is the behavior of the harmonic part of the flow. In the single obstacle case, the harmonic part is constant in time and determined by the initial data, so no topological difficulties in reducing 2D ideal flow to vortex dynamics exist. In contrast, there was no reduction available of flow in domains with multiple holes to vortex dynamics (see, for example, [5] for an ad hoc formulation of vortex dynamics in the exterior of two identical disks). Our point of departure is a new formulation of 2D ideal flow using vorticity alone as the dynamical variable.

We refer to the system obtained by rewriting the 2D Euler equations using vorticity as the unknown as the vortex dynamics formulation of the 2D Euler equations. The main ingredient in this new formulation is an expression for the harmonic part of the flow in terms of vorticity.

The remainder of this work is divided into five sections. In section 2 we derive an expression for the harmonic part of 2D ideal flow on a bounded domain with holes in terms of vorticity, and deduce a vortex dynamics formulation for the incompressible 2D Euler equations. In section 3 we formulate the small obstacle problem and study limits for quantities that depend on the domain alone. In section 4 we introduce the dynamical problem and obtain uniform estimates for the solution of the 2D Euler system on the domain with one small hole. In section 5 we put together the estimates in sections 3 and 4 to obtain a limit equation. We draw conclusions and discuss some extensions and open problems in section 6.

2. Vortex dynamics on a domain with holes. Let Ω be a bounded connected domain in the plane whose boundary $\partial\Omega$ is the disjoint union of a finite number of smooth Jordan curves Γ_i, $i = 0, 1, \ldots, k$. We assume that Ω is the bounded region with boundary Γ_0, with the regions bounded by Γ_i, $i = 1, \ldots, k$, removed. We require basic terminology and results from DeRham cohomology and Hodge theory, in the particularly easy setting of bounded domains with holes in the plane. We refer the reader to [11] for this material.

A vector field in Ω is called *harmonic* if it is both divergence- and curl-free. We identify one-forms with vector fields by $adx_1 + bdx_2 \mapsto (a, b)$. The one-dimensional (1D) deRham cohomology of Ω is the k-dimensional real vector space $H^1_{DR}(\Omega)$. It is a consequence of Hodge's theorem that the vector space $H^1_{DR}(\Omega)$ has a basis consisting of harmonic vector fields. There is a unique family of harmonic vector fields $\{X_1, X_2, \ldots, X_k\}$ satisfying the period conditions

$$\oint_{\Gamma_j} X_i \cdot ds = \delta_{ij}, \qquad \text{with } i = 1, \ldots, k \text{ and } j = 0, 1, \ldots, k, \tag{1}$$

which are a basis for $H^1_{DR}(\Omega)$.

Let $V(\Omega)$ denote the vector space of smooth divergence-free vector fields tangent to $\partial\Omega$, and $H(\Omega)$ be the subspace of $V(\Omega)$ consisting of irrotational vector fields. For each $i = 0, 1, \ldots, k$, we introduce the function ϕ_i as the unique solution to the Dirichlet problem

$$\begin{cases} \Delta\phi_i = 0, \\ \phi_i = 0 \quad \text{on } \Gamma_j, j \neq i, \\ \phi_i = 1 \quad \text{on } \Gamma_i. \end{cases} \tag{2}$$

Given $\omega \in C^\infty(\overline{\Omega})$, let ψ be the solution of the Poisson problem

$$\begin{cases} \Delta\psi = \omega, \\ \psi = 0 \quad \text{on } \partial\Omega. \end{cases} \tag{3}$$

Denote $(a, b)^\perp = (-b, a)$. We define the Biot–Savart operator

$$K_\Omega[\omega] \equiv \nabla^\perp\psi.$$

Clearly, $K_\Omega[\omega] \in V(\Omega)$ for any $\omega \in C^\infty(\overline{\Omega})$. The Biot–Savart operator is an integral operator with kernel given by $\nabla_x^\perp G_\Omega(x, y)$, where G_Ω is the Green function of the Dirichlet Laplacian in Ω.

Fix $u \in V(\Omega)$ and let $\omega \equiv$ curl u. The Hodge–Kodaïra decomposition theorem (see [2, section 7]) implies that u can be decomposed in a unique manner in the form $u = \nabla^\perp \psi + H$, with ψ smooth, vanishing on $\partial\Omega$ and $H \in H(\Omega)$. This decomposition is orthogonal with respect to the L^2 inner product.

Taking the curl of this decomposition, using the uniqueness of solutions to (3), and expanding H, we get

$$u = K_\Omega[\omega] + \sum_{j=1}^{k} \alpha_j X^j, \tag{4}$$

for some $\alpha_j \in \mathbb{R}$.

Our first result is an identity that expresses the components of the irrotational part of u in a useful manner.

PROPOSITION 1. *For each $i = 1, \dots, k$ we have*

$$\alpha_i = \int_\Omega \phi_i \omega dx + \oint_{\Gamma_i} u \cdot ds.$$

Proof. First we integrate by parts to get

$$\mathcal{I}_i \equiv \int_\Omega \phi_i \omega dx = \int_\Omega \phi_i \text{ curl } u dx = -\int_\Omega \phi_i \text{ div } u^\perp dx$$

$$= \int_\Omega \nabla\phi_i \cdot u^\perp dx - \int_{\partial\Omega} \phi_i u^\perp \cdot \widehat{n} ds = -\int_\Omega \nabla^\perp \phi_i \cdot u dx - \int_{\Gamma_i} u^\perp \cdot \widehat{n} ds.$$

We note that $\widehat{n}$ is the outward normal of Ω at Γ_i, and hence

$$\int_{\Gamma_i} u^\perp \cdot \widehat{n} ds = -\int_{\Gamma_i} u \cdot \widehat{n}^\perp ds = \int_{\Gamma_i} u \cdot \widehat{\tau} ds,$$

where $\widehat{\tau}$ is the unit counterclockwise tangent vector to Γ_i. Therefore,

$$\int_{\Gamma_i} u^\perp \cdot \widehat{n} ds = \oint_{\Gamma_i} u \cdot ds. \tag{5}$$

Next we use (4) to obtain

$$\int_\Omega \nabla^\perp \phi_i \cdot u dx = \int_\Omega \nabla^\perp \phi_i \left(K_\Omega[\omega] + \sum_{j=1}^{k} \alpha_i X^i \right) dx$$

$$= \int_\Omega \nabla \phi_i \cdot \nabla \psi dx + \sum_{j=1}^{k} \alpha_j \int_\Omega \nabla^\perp \phi_i \cdot X^j dx$$

$$= -\int_\Omega \psi \Delta \phi_i dx + \int_{\partial\Omega} \psi \nabla \phi_i \cdot \widehat{n} ds + \sum_{j=1}^{k} \alpha_j \int_\Omega \nabla^\perp \phi_i \cdot X^j dx.$$

The two first terms above vanish because $\Delta\phi_i = 0$ in Ω and $\psi = 0$ on $\partial\Omega$. Therefore,

$$\int_\Omega \nabla^\perp \phi_i \cdot u dx = \sum_{j=1}^k \alpha_j \int_\Omega \nabla^\perp \phi_i \cdot X^j dx. \tag{6}$$

Putting together the calculation done on I_i, (5), and (6), we get

$$I_i = -\sum_{j=1}^k \alpha_j \int_\Omega \nabla^\perp \phi_i \cdot X^j dx - \oint_{\Gamma_i} u \cdot ds. \tag{7}$$

Next, we use (4) on (7) to isolate and collect terms with α_i to obtain

$$\int_\Omega \phi_i \omega dx + \oint_{\Gamma_i} K_\Omega[\omega] \cdot ds = \sum_{j=1}^k \alpha_j \left\{ -\int_\Omega \nabla^\perp \phi_i \cdot X^j dx - \oint_{\Gamma_i} X^j \right\}. \tag{8}$$

We note that ω and each α_j can be chosen independently when one chooses u. The left-hand side of (8) and each of the expressions in brackets on the right-hand side of (8) do not depend on the α_j's, and therefore identity (8) implies both that

$$\int_\Omega \phi_i \omega dx + \oint_{\Gamma_i} K_\Omega[\omega] \cdot ds = 0, \tag{9}$$

and that for each $j = 1, \ldots, k$,

$$\int_\Omega \nabla^\perp \phi_i \cdot X^j dx = -\oint_{\Gamma_i} X^j = -\delta_{ij}, \tag{10}$$

by (1). Using (10) back on (7), we get

$$I_i = \alpha_i - \oint_{\Gamma_i} u \cdot ds,$$

which concludes the proof. $\square$

The initial-boundary value problem for the incompressible 2D Euler equations in Ω and in the time interval $[0, T)$ has the form

$$\begin{cases} u_t + u \cdot \nabla u = -\nabla p & \text{in } \Omega \times (0, T), \\ \text{div } u = 0 & \text{in } \Omega \times \{t\}, \text{ for } 0 \le t < T, \\ u \cdot \widehat{n} = 0 & \text{on } \partial\Omega \times [0, T), \\ u(x, 0) = u_0(x) & \text{in } \Omega \times \{t = 0\}, \end{cases} \tag{11}$$

where the velocity u and the scalar pressure p are unknowns, u_0 is the initial data, and $\widehat{n}$ is the unit exterior normal to $\partial\Omega$. Well-posedness for this problem when u_0 is sufficiently smooth is due to Kato (see [6]), and existence of weak solutions for $u_0 \in L^2$, with $\omega_0 \equiv$ curl $u_0 \in L^1 + \mathcal{BM}^+$, is part of Delort's existence result; see [1, 10]. Vortex dynamics is an approach to the problem above where the dynamic variables u and p are replaced by the vorticity $\omega =$ curl u. Formulating problem (11) in terms of vorticity alone becomes complicated by the topology of the domain and can be accomplished only by using Proposition 1 as follows.

Let $u = u(x,t)$ be a smooth solution of (11) with $\omega = \omega(x,t) \equiv \operatorname{curl} u(x,t)$. We can write

$$u = K_\Omega[\omega] + \sum_{j=1}^{k} \alpha_j(t) X_j,$$

and Proposition 1 gives that for each $j = 1, \dots, k$

$$\alpha_j(t) = \int_\Omega \phi_j(x)\omega(x,t)dx + \oint_{\Gamma_j} u(x,t) \cdot ds.$$

By Kelvin's circulation theorem, the circulations $\oint_{\Gamma_j} u(x,t) \cdot ds$ are conserved in time, so that, if $\omega_0 = \operatorname{curl} u_0$, we have

$$\oint_{\Gamma_j} u(x,t) \cdot ds = \oint_{\Gamma_j} u(x,0) \cdot ds = \alpha_j(0) - \int_\Omega \phi_j \omega_0 dx.$$

Therefore, taking the curl of the momentum equations in (11), we can write the following initial value problem, with only ω as unknown, equivalent to (11) for classical solutions:

$$\text{(12)} \qquad \begin{cases} \omega_t + u \cdot \nabla\omega = 0 \quad \text{in } \Omega \times (0,T), \\ u = K_\Omega[\omega] + \sum_{j=1}^{k} \alpha_j(t) X_j \quad \text{in } \Omega \times \{t\}, \text{ for } 0 \le t < T, \\ \alpha_j(t) = \int_\Omega \phi_j \omega dx + \alpha_{j,0} - \int_\Omega \phi_j \omega_0 dx \quad \text{in } [0,T), \\ \omega(x,0) = \omega_0(x) \quad \text{and} \quad \alpha_j(0) = \alpha_{j,0} \quad \text{in } \Omega \times \{t = 0\}. \end{cases}$$

The initial data for problem (12) is the initial vorticity ω_0 and the initial coefficients for the harmonic part of the velocity, $\alpha_{j,0}$. Clearly, assigning this data is equivalent to choosing an initial velocity u_0. System (12) is the vortex dynamics formulation of (11).

3. Harmonic fields. Next we introduce the small obstacle problem. Let us consider a family of bounded connected domains Ω_δ, $0 \le \delta \le \delta_0$, which, for each fixed δ, has its boundary made up of curves Γ_i, $i = 0, 1, \dots, k$, arranged as in section 2. We assume that for each $i = 0, 1, \dots, k-1$, Γ_i is independent of δ, and that $\Gamma_k = \Gamma_k^\delta$ is contained on a ball of radius δ centered at some fixed point $P \in \Omega_\delta$. We declare Ω to be the original set Ω_{δ_0} union with the closure of the bounded side of $\Gamma_k^{\delta_0}$.

Fix $\omega_0 \in C_c^\infty(\Omega_{\delta_0})$, and assume that the support of ω_0 does not intercept $\{|x| \le \delta_0\}$. This implies that $\omega_0 \in C_c^\infty(\Omega_\delta)$ for any $0 \le \delta < \delta_0$. Let $X_\delta^1, \dots, X_\delta^k$ be the basis of $H(\Omega_\delta)$ satisfying condition (1). Define $\phi_{i,\delta}$ solutions of (2) in Ω_δ. Fix $\alpha_{1,0}, \dots, \alpha_{k,0}$ real numbers and define

$$u_{\delta,0} \equiv K_{\Omega_\delta}[\omega_0] + \sum_{j=1}^{k} \alpha_{j,0} X_\delta^j.$$

By Proposition 1 we have that

$$\alpha_{i,0} = \int_{\Omega_\delta} \omega_0 \phi_{i,\delta} + \oint_{\Gamma_i} u_{\delta,0} \cdot ds.$$

We begin our study of the small obstacle limit by exploring the behavior of $\phi_{i,\delta}$ as $\delta \to 0$. This is an exercise in elementary PDE, which we summarize in the following result.

LEMMA 1. *Let ϕ_i, $i = 1, \ldots, k-1$, be the solutions of* (2) *in the unperturbed domain Ω. For any $i = 1, \ldots, k$, $\phi_{i,\delta}$ is uniformly bounded. For $i = 1, \ldots, k-1$, $\phi_{i,\delta}$ converges uniformly to ϕ_i as $\delta \to 0$, uniformly outside any neighborhood of P, and $\phi_{k,\delta}$ converges uniformly to* 0 *outside any neighborhood of P when $\delta \to 0$. Furthermore, there exists a constant $C > 0$ such that $\|\nabla \phi_{i,\delta}\|_{L^2(\Omega_\delta)} \leq C$.*

Proof. First note that, by the maximum principle, $0 \leq \phi_{i,\delta}(x) \leq 1$ for all $x \in \Omega_\delta$, which proves uniform boundedness.

Next, we consider the behavior of $\phi_{k,\delta}$. Let $R > 0$ be such that $\Omega_{\delta_0} \subseteq \{|x - P| \leq R\}$. The function

$$\Psi_\delta(x) \equiv \frac{\log(R/|x-P|)}{\log(R/\delta)}$$

is the unique solution of

$$\begin{cases} \Delta \Psi_\delta = 0 & \text{in } \delta < |x-P| < R, \\ \Psi_\delta = 1 & \text{on } |x-P| = \delta, \\ \Psi_\delta = 0 & \text{on } |x-P| = R. \end{cases}$$

We consider the domain $\widetilde{\Omega}_\delta$ consisting of the domain Ω_δ with the disk $|x - P| < \delta$ removed. It is easy to see that $\phi_{k,\delta} \leq \Psi_\delta$ on $\partial\widetilde{\Omega}_\delta$, as this boundary consists of the union of the curves Γ_i, $i = 0, \ldots, k-1$ (where $\phi_{k,\delta}$ vanishes and $\Psi_\delta > 0$) with $\{|x - P| = \delta\}$, where $\Psi_\delta = 1$ and $\phi_{k,\delta} \leq 1$. Therefore, by the maximum principle, $0 \leq \phi_{k,\delta} \leq \Psi_\delta$ in $\widetilde{\Omega}_\delta$. Next we observe that if $|\log \delta|^{-1} \leq |x - P| \leq R$,

$$\Psi_\delta(x) \leq \frac{\log R + \log|\log \delta|}{\log R - \log \delta} \to 0 \quad \text{as } \delta \to 0,$$

which proves our assertion regarding $\phi_{k,\delta}$.

Next fix $i < k$ and consider $\Phi_\delta \equiv \phi_i - \phi_{i,\delta}$. The function Φ_δ is harmonic in Ω_δ and vanishes on all boundary components except Γ_k^δ, where it is bounded between 0 and 1. Therefore, the same argument used above for $\phi_{k,\delta}$ applies to Φ_δ as well, which proves the statement regarding $\phi_{k,\delta}$.

Finally, to show the L^2 estimate on derivatives, we begin with the case $j \neq k$. We claim that $\|\nabla \phi_{j,\delta}\|_{L^2(\Omega_\delta)}$ is monotonically decreasing as $\delta \to 0$. Indeed, let $0 < \delta_2 < \delta_1$ and consider $E\phi_{j,\delta_1}$ the extension of ϕ_{j,δ_1} to Ω_{δ_2} obtained by setting $E\phi_{j,\delta_1}(x) = 0$ for $x \in \Omega_{\delta_2} \setminus \Omega_{\delta_1}$. The function $E\phi_{j,\delta_1}$ is defined in Ω_{δ_2} and satisfies the same Dirichlet data as ϕ_{j,δ_2}. However, ϕ_{j,δ_2} is harmonic and hence minimizes energy among functions with the same boundary data. Therefore,

$$\|\phi_{j,\delta_2}\|_{L^2(\Omega_{\delta_2})} \leq \|E\phi_{j,\delta_1}\|_{L^2(\Omega_{\delta_2})} = \|\phi_{j,\delta_1}\|_{L^2(\Omega_{\delta_1})}.$$

This estimate implies the L^2 bound for $j = 1, \ldots, k-1$. Next, let $\phi_{0,\delta}$ be defined by 2 in Ω_δ. The variational argument above applies to this function as well, so that $\|\nabla \phi_{0,\delta}\|_{L^2(\Omega_\delta)}$ is also monotonically increasing in δ and therefore bounded as $\delta \to 0$. We observe that $\sum_{i=0}^k \phi_{i,\delta}$ is a harmonic function in Ω_δ which is identically equal to 1 on $\partial\Omega_\delta$. Therefore, $\sum_{i=0}^k \phi_{i,\delta} \equiv 1$ and

$$\nabla \phi_{k,\delta} = -\sum_{i=0}^{k-1} \nabla \phi_{i,\delta},$$

and since all summands are uniformly bounded in L^2 by the argument above, this identity concludes the proof. ◻

Remark. Note that the variational argument used in the proof of the L^2 estimate on derivatives given above assumed implicitly that $\Omega_{\delta_1} \subset \Omega_{\delta_2}$ if $\delta_2 < \delta_1$. It is easy to modify the argument to remove this implicit assumption, by comparing the L^2 norm of $\nabla\phi_{i,\delta}$ with the L^2 norm of $E\nabla\phi_{\delta_0}$, where ϕ_{δ_0} is harmonic in $\Omega \setminus \{|x-P| < \delta_0\}$, with $\phi_{\delta_0} = \phi_{i,\delta}$ on $\partial\Omega$ and $\phi_{\delta_0} = 0$ on $|x-P| = \delta_0$. If the obstacles are not nested, the quantity $\|\nabla\phi_{\delta,j}\|_{L^2}$ may not be monotonic in δ, but the L^2 bound is still valid.

Next we study the asymptotic behavior of X^j_δ and $\delta \to 0$. For each $j = 1, \ldots, k$, we denote by EX^j_δ the extension of the vector field X^j_δ from Ω_δ to Ω, obtained by setting it to vanish inside Γ^k_δ. Regarding EX^j_δ we have the following result.

LEMMA 2. *For each $j = 1, \ldots, k$ and $\delta > 0$, the vector field EX^j_δ is divergence-free, in the sense of distributions, and its curl $\mu^j_\delta \equiv$ curl EX^j_δ is a measure supported on Γ^k_δ with density given by the tangential component of X^j_δ. Moreover, $\mu^j_\delta \rightharpoonup 0$ for $j = 1, \ldots, k-1$ and $\mu^k_\delta \rightharpoonup \delta(x-P)$ weak-$*$ bounded measures when $\delta \to 0$.*

Proof. First we observe that EX^j_δ is divergence-free, in the sense of distributions. The vector field EX^j_δ is divergence-free both in Ω_δ, by construction, and in $\Omega \setminus \overline{\Omega_\delta}$ because EX^j_δ vanishes there. To show that a vector field is divergence-free as a distribution it suffices to show that its integral against the gradient of an arbitrary test function vanishes. Indeed, given that $\phi \in C^\infty_c(\Omega)$ is a test function, we can compute

$$\int_\Omega \nabla\phi \cdot EX^j_\delta dx = \int_{\Omega_\delta} \nabla\phi \cdot X^j_\delta dx = \int_{\Gamma^k_\delta} \phi(x) X^j_\delta(x) \cdot \widehat{n} dS(x) = 0,$$

since X^j_δ is tangent to Γ^k_δ.

A similar calculation, integrating EX^j_δ against $\nabla^\perp\phi$ and using the divergence theorem proves that the curl of EX^j_δ is a Dirac with smooth density supported on the curve Γ^k_δ. More precisely, let $\mu^j_\delta =$ curl EX^j_δ as a distribution. If $z_\delta = z_\delta(s)$ is a parametrization by arc length of Γ^k_δ, with $0 \le s \le L_\delta$ and $\phi \in C^\infty_c(\Omega)$, we have

$$\langle \mu_\delta, \phi \rangle = \int_0^{L_\delta} \phi(z_\delta(s))(X^j_\delta \cdot \widehat{\tau})(z_\delta(s) ds,$$

where $\widehat{\tau}$ is the counterclockwise unit tangent vector to Γ^k_δ. In other words, μ^j_δ is a Dirac supported on the curve Γ^k_δ with smooth density $X^j_\delta \cdot \widehat{\tau}$.

Next we use an adaptation of the variational argument used in Proposition 1 to show that $\|X^j_\delta\|_{L^2(\Omega_\delta)}$ is nondecreasing in δ and therefore bounded when $\delta \to 0$ for all $j = 1, \ldots, k-1$. Take $0 < \delta_2 < \delta_1$, and observe that $EX^j_{\delta_1}$ has the same circulation as $X^j_{\delta_2}$ in all boundary components. By the orthogonality of the Hodge decomposition, the harmonic vector field minimizes energy in its cohomology class, which implies that

$$\|X^j_{\delta_2}\|_{L^2(\Omega_{\delta_2})} \le \|EX^j_{\delta_1}\|_{L^2(\Omega_{\delta_2})} \|X^j_{\delta_1}\|_{L^2(\Omega_{\delta_1})}.$$

As observed in the remark following the proof of Lemma 1, the argument above makes the implicit assumption that $\Omega_{\delta_1} \subset \Omega_{\delta_2}$, but this assumption may easily be removed.

Repeating the argument done for EX^j_δ in the beginning of the proof, we see that $E\nabla^\perp\phi_{i,\delta}$ is divergence-free in Ω, and we define curl $E\nabla^\perp\phi_{i,\delta} = \nu^i_\delta$, which are also smooth measures supported on Γ_δ^k. The density of these measures is given by $\nabla^\perp \phi_{i,\delta} \cdot \widehat{\tau} = -\nabla \phi_{i,\delta} \cdot \widehat{n}$, in contrast with EX_δ^j. However, there is one important difference between the μ and the ν measures. We have that $0 \leq \phi_{i,\delta} \leq 1$ by the maximum principle, and therefore $\nu_\delta^i \leq 0$ for $i = 1, \ldots, k-1$ and $\nu_\delta^k \geq 0$. The distinguished sign obtained above, together with the fact that $\nabla^\perp \phi_{i,\delta}$ is bounded in L^2 and the fact that the support of ν_δ^i is contained in a ball of radius δ implies that ν_δ^i converges strongly as a bounded measure to zero for all $i = 1, \ldots, k$; see [1].

For each $i, j = 1, \ldots, k$, let a_δ^{ij} be defined by

$$EX_\delta^j = \sum_{i=1}^{k} a_\delta^{ij} E \nabla^\perp \phi_{i,\delta}. \tag{13}$$

Taking the scalar product with EX_δ^l, integrating in Ω, and using (10), it follows that

$$a_\delta^{ij} = -\int_{\Omega_\delta} X_\delta^i \cdot X_\delta^j dx.$$

By the L^2 estimate of X_δ^j for $j = 1, \ldots, k-1$ and using the Cauchy–Schwarz inequality, we conclude that $|a_\delta^{ij}|$ is bounded if $1 \leq i, j \leq k-1$. Fix $j = 1, \ldots, k-1$ and take the curl of (13) to obtain

$$\mu_\delta^j = \sum_{i=1}^{k-1} a_\delta^{ij} \nu_\delta^i + a_\delta^{kj} \nu_\delta^k.$$

This identity implies that μ_δ^j is the sum of a measure that converges strongly to zero, given by the summation above, with a distinguished sign measure, which may be positive or negative depending on the sign of a_δ^{kj}. This, together with the fact that $\mu_\delta^j(\Omega) = 0$, implies both that $|\mu_\delta^j| \to 0$ and that $|a_\delta^{kj}| \nu_\delta^k \to 0$. We use the fact that $\nu_\delta^k = -\sum_{i=0}^{k-1} \nu_\delta^i$ to conclude that $a_\delta^{kj} \nu_\delta^j = a_\delta^{jk} \nu_\delta^j$ also converges to zero in bounded measures for all $j = 1, \ldots, k-1$. Finally, we write

$$\mu_\delta^k = \sum_{j=1}^{k-1} a_\delta^{jk} \nu_\delta^j + a^k k_\delta \nu_\delta^k.$$

As before, the summation converges to zero in bounded measures, so μ_δ^k is asymptotically distinguished signed and therefore the total mass converges to the total variation, which concludes the proof. $\square$

For $j = 1, \ldots, k-1$, we denote by X^j the unique vector field in $H(\Omega)$ with vanishing circulation around Γ_i, $i \neq j$, and unit circulation around Γ_j.

LEMMA 3. *We have that for any* $1 \leq p < 2$,

$$EX_\delta^j \to X^j,$$

and

$$EX_\delta^k \to K_\Omega[\delta(x-P)] + \sum_{j=1}^{k-1} \phi_j(P) X^j,$$

strongly in $L^p(\Omega)$ *as* $\delta \to 0$.

Proof. We can write

$$X_\delta^j = K_\Omega[\mu_j^\delta] + \sum_{l=1}^{k-1} h_\delta^{lj} X^j.$$

By Lemma 2, we have that $\mu_k^\delta \to \delta(x-P)$ weak-$*$ bounded measures. By Proposition 1 and the fact that the circulation of X_δ^k vanishes around each Γ_l, $l = 1, \ldots, k-1$, we have

$$h_\delta^{lk} = \int_\Omega \phi_l \mu_k^\delta dx \to \phi_j(P) \quad \text{as } \delta \to 0.$$

For each $1 \le p < 2$, $\mathcal{BM} \hookrightarrow W^{-1,p}$ compactly, and therefore, $\mu^\delta \to \delta(x-P)$ strongly in $W^{-1,p}$. Elliptic regularity implies that $K_\Omega[\mu^\delta] \to K_\Omega[\delta(x-P)]$ strongly in L^p, which concludes the proof of the case $j = k$.

For $j = 1, \ldots, k-1$, we have that $\mu_j^\delta \to 0$ weak-$*$ bounded measures, and therefore, using Proposition 1 and repeating the argument above concludes the argument. □

4. The time-dependent problem. The results obtained thus far have been exclusively about divergence-free vector fields in a multiply connected domain, without dynamics. In this section we restrict our attention to solutions of the incompressible 2D Euler equations and derive the required a priori estimates.

For $0 \le \delta \le \delta_0$, let Ω_δ be as before, a multiply connected domain with one of the holes small. Fix $\omega_0 \in C_c^\infty(\Omega_{\delta_0})$ and $\alpha_0 = (\alpha_{1,0}, \ldots, \alpha_{k,0}) \in \mathbb{R}^k$ and let $u_\delta = u_\delta(x,t)$ be the solution of the problem (11) with initial velocity $u_{\delta,0} = K_{\Omega_\delta}[\omega_0] + \sum_{j=1}^k \alpha_{j,0} X_\delta^j$. As we noted before, existence and uniqueness of the smooth solution u_δ is due to Kato in [6]. Let $\omega_\delta = \operatorname{curl} u_\delta$ be the vorticity, and $\alpha_{\delta,j} = \alpha_{\delta,j}(t)$ be defined by the identity

$$u_\delta = K_{\Omega_\delta}[\omega_\delta] + \sum \alpha_{\delta,j} X_\delta^j. \tag{14}$$

System (12) takes the form

$$\begin{cases} \partial_t \omega_\delta + u_\delta \cdot \nabla \omega_\delta = 0 \quad \text{in } \Omega_\delta \times (0,T), \\[2ex] u_\delta = K_{\Omega_\delta}[\omega_\delta] + \sum_{j=1}^k \alpha_{\delta,j}(t) X_\delta^j \quad \text{in } \Omega_\delta \times \{t\}, \text{ for } 0 \le t < T, \\[2ex] \alpha_{\delta,j}(t) = \int_{\Omega_\delta} \phi_{\delta,j} \omega_\delta dx + \alpha_{j,0} - \int_{\Omega_\delta} \phi_{\delta,j} \omega_0 dx \quad \text{in } [0,T), \\[2ex] \omega_\delta(x,0) = \omega_0(x) \quad \text{and} \quad \alpha_{\delta,j}(0) = \alpha_{j,0} \quad \text{in } \Omega_\delta \times \{t=0\}, \end{cases} \tag{15}$$

It follows from the transport equation for vorticity in (15) and the fact that u_δ is divergence-free that

$$\|\omega_\delta(\cdot,t)\|_{L^p(\Omega_\delta)} = \|\omega_0\|_{L^p(\Omega_\delta)} = \|\omega_0\|_{L^p(\Omega)}. \tag{16}$$

Beyond the a priori estimate given by (16), we require velocity estimates in order to study the $\delta \to 0$ asymptotics. We have the following result.

LEMMA 4. *There exists a constant* $C = C(\omega_0, \Omega)$ *such that*

$$\|K_{\Omega_\delta}[\omega_\delta](\cdot,t)\|_{L^2(\Omega_\delta)} \le C.$$

Moreover, for any $1 \le p < 2$,

$$\|K_{\Omega_\delta}[\omega_\delta](\cdot,t) - K_\Omega[\omega_\delta](\cdot,t)\|_{L^p(\Omega_\delta)} \to 0,$$

as $\delta \to 0$.

Proof. We write $K_{\Omega_\delta}[\omega_\delta] = \nabla^\perp \psi_\delta$, with ψ_δ the unique solution of

$$\begin{cases} \Delta\psi_\delta = \omega_\delta & \text{in } \Omega_\delta, \\ \psi_\delta = 0 & \text{on } \partial\Omega_\delta. \end{cases}$$

Multiply this equation by ψ_δ and integrate by parts to obtain the energy identity

$$\int_{\Omega_\delta} |\nabla\psi_\delta|^2 dx = -\int_{\Omega_\delta} \psi_\delta \omega_\delta dx. \tag{17}$$

Next we consider ψ_0, the unique solution of

$$\begin{cases} \Delta\psi_0 = |\omega_\delta| & \text{in } \Omega, \\ \psi_0 = 0 & \text{on } \partial\Omega. \end{cases}$$

We note that ψ_0 is nonpositive in Ω, and, in particular, in Ω_δ as well. The functions $\psi_0 - \psi_\delta$ and $\psi_0 + \psi_\delta$ are both nonpositive on $\partial\Omega_\delta$ and have nonnegative laplacians in Ω_δ. By the maximum principle, they are both nonpositive in Ω_δ, which implies that $|\psi_\delta| \le -\psi_0$, which, by elliptic regularity and Sobolev imbeddings, implies that

$$\|\psi_\delta\|_{L^\infty(\Omega_\delta)} \le C\|\omega_0\|_{L^p}, \tag{18}$$

for any $p > 2$. We go back to (17) using (18) and Hölder's inequality to conclude the proof of the first assertion.

For the second assertion, let ϕ_δ be the unique solution of

$$\begin{cases} \Delta\phi_\delta = \omega_\delta & \text{in } \Omega, \\ \phi_\delta = 0 & \text{on } \partial\Omega. \end{cases}$$

We have that $K_\Omega[\omega_\delta] = \nabla^\perp\phi_\delta$. Let $W_\delta = \psi_\delta - \phi_\delta$, which satisfies the system

$$\begin{cases} \Delta W_\delta = 0 & \text{in } \Omega_\delta, \\ W_\delta = 0 & \text{on } \partial\Omega, \\ W_\delta = -\phi_\delta & \text{on } \Gamma_\delta^k. \end{cases}$$

By elliptic regularity, $\|\phi_\delta\|_{W^{2,p}} \le \|\omega_0\|_{L^p}$, and therefore ϕ_δ is bounded in Γ_δ^k. Using the argument in Lemma 1, we see that $W_\delta \to 0$ uniformly away from P. Let $\Phi \in C^\infty(\Omega)$ be such that $\Phi = 0$ in a neighborhood U_0 of P and $\Phi = 1$ outside a larger neighborhood of U_1 of P. We can write

$$\operatorname{div}(\Phi\nabla W_\delta) = \nabla\Phi \cdot \nabla W_\delta \quad \text{in } \Omega_\delta,$$

multiplying this identity by W_δ, integrating in Ω_δ, and integrating by parts leads to

$$\int_{\Omega_\delta} \Phi|\nabla W_\delta| dx = (1/2)\int_{\Omega_\delta} (\Delta\Phi)|W_\delta|^2 dx,$$

which in turn leads to the estimate:

$$\|\nabla W_\delta\|^2_{L^2(\Omega_\delta\setminus U_1)} \le C\|W_\delta\|_{L^2(\Omega_\delta\setminus U_0)} \to 0 \quad \text{as } \delta\to 0.$$

The family $\{\nabla W_\delta\}$ is bounded in $L^2(\Omega)$ since $K_\Omega[\omega_\delta]$ is trivially bounded in L^2, and we have established earlier in this proof that $K_\Omega[\omega_\delta]$ is bounded in L^2 as well. For any $p>2$, given $\varepsilon>0$, we can choose $r>0$ such that $\|\nabla W^\delta\|_{L^p((B(P,r))}<\varepsilon/2$, by using the boundedness of ∇W^ε in L^2 and the Hölder equality. Next we choose δ sufficiently small so that $\|\nabla W^\delta\|_{L^p(\Omega\setminus B(P;r))}\le\varepsilon/2$, which is possible by the convergence in L^2 outside the compacts proved above. This concludes the proof. ∎

Remark. We observe that the proof above also yields the estimate

$$\|K_{\Omega_\delta}[\omega]\|_{L^2} \le C\|\omega\|^2_{L^p},$$

for any $\omega\in L^p(\Omega_\delta)$, $p>2$.

5. Passage to the limit. We now state and prove the main result of this article.

THEOREM 1. *Fix $1\le p<2$. There exists a subsequence δ_k such that ω_{δ_k} converges weak-$*$ to ω in $L^\infty((0,T);L^{p'}(\Omega))$, which satisfies (in a weak sense) the system*

$$\left\{\begin{array}{l}\omega_t+v\cdot\nabla\omega=0,\\[2ex] v=K_\Omega[\omega+\alpha_{k,0}\delta(x-P)]+\sum_{j=1}^{k-1}(\beta_j(t)+\alpha_{k,0}\phi_j(P))X^j,\\[2ex] \beta_j(t)=\int_\Omega\phi_j(x)\omega(x,t)dx+\alpha_{j,0}-\int_\Omega\phi_j(x)\omega_0(x)dx,\quad j=1,\dots,k-1,\\[2ex] \omega(x,0)=\omega_0(x)\quad \text{and}\quad \beta_j(0)=\alpha_{j,0}.\end{array}\right. \tag{19}$$

Here, P marks the location where the small obstacle disappeared, $\alpha_{k,0}$ is the circulation of the harmonic part of the initial velocity around the small obstacle, and ϕ_j is the harmonic function in Ω such that $\phi_j=1$ on the boundary component Γ_j and $\phi_j=0$ on $\partial\Omega\setminus\Gamma_j$.

Proof. Since $\{\omega_\delta\}$ is bounded in $L^{p'}(\Omega)$ by (16), we use Alaoglu's theorem to extract a subsequence, which we will not rename, which converges weak-$*$ to $\omega\in L^\infty((0,T);L^{p'}(\Omega))$.

The bulk of the proof is to pass to the limit in u^δ. We have

$$u^\delta=K_{\Omega_\delta}[\omega_\delta]+\sum_{j=1}^k\alpha_{\delta,j}(t)X^j_\delta,$$

with

$$\alpha_{\delta,j}(t)=\int_{\Omega_\delta}\phi_{\delta,j}\omega_\delta dx+\alpha_{j,0}-\int_{\Omega_\delta}\phi_{\delta,j}\omega_0 dx.$$

First, by Lemma 4 we have

$$\begin{aligned}\|K_{\Omega_\delta}[\omega_\delta]-K_\Omega[\omega]\|_{L^p(\Omega)} &\le \|K_{\Omega_\delta}[\omega_\delta]-K_\Omega[\omega_\delta]\|_{L^p(\Omega)}+\|K_\Omega[\omega_\delta]-K_\Omega[\omega]\|_{L^p(\Omega)}\\ &\le \|K_\Omega[\omega_\delta]-K_\Omega[\omega]\|_{L^p(\Omega)}+o(1).\end{aligned}$$

Next we observe that the operator K_Ω maps $L^{p'}$ continuously into $W^{1,p'}$, which is compactly embedded in L^p for any $1 \le p < 2$. Therefore, $K_\Omega[\omega_\delta] \to K_\Omega[\omega]$ strongly in L^p, and hence

$$K_{\Omega_\delta}[\omega_\delta] \to K_\Omega[\omega] \quad \text{strongly in } L^p(\Omega) \text{ as } \delta \to 0 \tag{20}$$

Next we need to study the behavior of the harmonic part of u_δ. Extending ω_δ and $\phi_{\delta,j}$ to Ω by setting them to vanish in $\Omega \setminus \Omega_\delta$, we have

$$\int_{\Omega_\delta} \phi_{\delta,j}\omega_\delta dx = \int_\Omega \phi_{\delta,j}\omega_\delta dx.$$

By Lemma 1, $\phi_{\delta,j}$ is uniformly bounded in L^∞ and converges to ϕ_j uniformly in compacts which exclude P for $j = 1, \dots, k-1$, and converges to zero uniformly in compacts which exclude P for $j = k$. For each $\varepsilon > 0$ we have

$$\|\phi_{\delta,k}\|_{L^p(B(P,r))} \le Cr^{2/p} < \frac{\varepsilon}{2}$$

if we choose $r = r(\varepsilon)$ sufficiently small. By the uniform convergence of $\phi_{\delta,k}$ outside $B(P,r)$ we may choose $\delta = \delta(\varepsilon)$ such that $\|\phi_{\delta,k}\|_{L^p(\Omega\setminus B(P,r)} \le \varepsilon/2$. This implies that $\phi_{\delta,k} \to 0$ strongly in $L^p(\Omega)$. The same argument applied to $\phi_{\delta,j} - \phi_j$, for $j = 1, \dots, k-1$, implies that $\phi_{\delta,j} \to \phi_j$ strongly in $L^p(\Omega)$. Now, ω_δ and $\phi_{\delta,k}$ form a weak-strong pair, so that we have

$$\int_\Omega \phi_{\delta,k}\omega_\delta dx \to 0 \text{ as } \delta \to 0.$$

Furthermore, ω_δ and $\phi_{\delta,j} - \phi_j$ also form a weak-strong pair, so that

$$\int_\Omega \phi_{\delta,j}\omega_\delta dx \to \int_\Omega \phi_j \omega dx \quad \text{as } \delta \to 0 \quad \text{for } j = 1, \dots, k-1.$$

Clearly, the same convergence is true replacing ω_δ by ω_0, and therefore

$$\alpha_{\delta,j} \to \int_\Omega \phi_j \omega dx + \alpha_{j,0} - \int_\Omega \phi_j \omega_0 dx \quad \text{as } \delta \to 0, \text{ for } j = 1, \dots, k-1, \tag{21}$$

and

$$\alpha_{\delta,k} \to \alpha_{k,0} \quad \text{as } \delta \to 0. \tag{22}$$

For each $j = 1, \dots, k-1$ we define

$$\beta_j = \beta_j(t) \equiv \int_\Omega \phi_j \omega dx + \alpha_{j,0} - \int_\Omega \phi_j \omega_0 dx,$$

so that (21) reads simply $\alpha_{\delta,j} \to \beta_j$ as $\delta \to 0$.

By Lemma 3 and (21) we have

$$\sum_{j=1}^{k-1} \alpha_{\delta,j} X_\delta^j \to \sum_{j=1}^{k-1} \beta_j X^j \tag{23}$$

strongly in L^2, and therefore in L^p, $1 \leq p < 2$.

By Lemma 3 and (22) we have

$$\alpha_{\delta,k} X_\delta^k \to \alpha_{k,0} \left(K_\Omega[\delta(x-P)] + \sum_{j=1}^{k-1} \phi_j(P) X^j \right), \tag{24}$$

strongly in L^p, for $1 \leq p < 2$.

Putting together (20), (23), and (24), we conclude that $u^\delta \to v$ strongly in $L^\infty((0,T); L^p(\Omega))$, with v given by

$$v(x,t) = K_\Omega[\omega + \alpha_{k,0}] + \sum_{j=1}^{k-1} (\beta_j + \phi_j(P)) X^j.$$

With v and β_j defined above, the initial conditions and the modified Biot–Savart relation on the limit system (19) are satisfied, pointwise in time. The equation for the propagation of vorticity is satisfied in a weak sense, because the weak convergence of the vorticities is enough to pass to the limit in the time-derivative term, whereas, after integration by parts, the convergence of the nonlinear term is conditioned by the behavior of the product $u^\delta \omega^\delta$. Our argument above made this product into a weak-strong pair, which therefore converges to $v\omega$ in $L^\infty((0,T); L^1(\Omega))$. This concludes the proof. $\square$

Remark. Note that the asymptotic correction due to the presence of the small obstacle not only adds a point vortex at the limit point, but it also adds a correction to the remaining harmonic components of the flow. As an illustration, let us look at the special case $\omega_0 = 0$. Harmonic vector fields are stationary solutions of the Euler equations, and one may look specifically at the asymptotic behavior of the vector field X_δ^k. Its circulation is 1 around Γ_k and zero around Γ_j, $j = 1, \dots, k-1$. By Lemma 3, this vector field converges in L^p, $1 \leq p < 2$, to $H \equiv K_\Omega[\delta(x-P)] + \sum_{j=1}^{k-1} \phi_j(P) X^j$. If we formally apply Proposition 1 to H, we find

$$\phi_j(P) = \int_\Omega \delta(x-P)\phi_j(P)dx + \oint_{\Gamma_j} H \cdot ds,$$

which implies that

$$\oint H \cdot ds = 0,$$

preserving the circulation around Γ_j of the approximations X_δ^k, as would be desired. In other words, the correction to the harmonic part of the flow exists to compensate for an imbalance of circulation around the remaining components of the boundary that appears when the flow around the small boundary component becomes that induced by a point vortex.

Remark. Theorem 1 is a compactness result, and it implies convergence for the full family of approximations only if we have uniqueness for the limit problem. This is available only in the case $\alpha_{k,0} = 0$, because then the limit problem is the standard 2D Euler equations, and Kato's theorem includes uniqueness, even at the level of weak solutions, provided that the initial data is sufficiently smooth. As in [3], uniqueness for problem (19) with smooth initial data and $\alpha_{k,0} \neq 0$ is an interesting open problem.

6. Conclusion. It is natural to ask at this point whether our analysis can be extended to the exterior domain, i.e., the full plane with k-holes instead of a bounded domain with k-holes. This is specially desirable if we wish to compare the result obtained here with that in [3], where we studied the asymptotic behavior of ideal flow in the exterior of a single small hole in the plane. First, the exterior domain version of Kato's well-posedness result is available. It is due to Kikuchi; see [7]. Therefore, the small obstacle limit for the exterior flow around multiple holes is a reasonable problem to pose.

We chose to work on a bounded domain because this greatly simplifies the problem, allowing us to focus the analysis on the small obstacle and not on infinity. Our analysis relies on the boundedness of the domain in many ways, most notably on arguments using the maximum principle. To extend our argument to exterior domains would require detailed knowledge of the asymptotic behavior of the velocity at infinity, something which we had to work hard for in the case of a single obstacle - by conformally mapping the exterior domain to the exterior of a disk and working explicitly there. With flows on the exterior of three or more holes there is no convenient symmetric domain conformally equivalent to the original one, so the work would become even more complicated. Exterior flow with two holes is conformally equivalent to an annulus, a well-known fact (see [9] and references therein), so that perhaps that case could be done by adapting the argument on [3] more directly, using the estimates for the conformal map developed in [9] when one of the holes becomes small. In the end, extending the present work to the exterior domain is an arduous technical challenge, and it will probably lead to precisely the same result.

Another natural question is what happens if one wishes to make two or more holes small. This is a trivial extension of our work, because the treatment used here shows that the asymptotics when two holes become small independently commute with each other. Therefore, two holes may be taken small in either order or simultaneously, leading to the same behavior. Also, this work extends naturally to compactly supported initial vorticities in L^p, $p > 2$. Finally, we leave open the formulation of a viscous version of the present result. A small obstacle result for viscous flow in the exterior of a single obstacle was obtained in [4], and it is natural to ask whether such an extension could be obtained for several obstacles as well, since this is the physically meaningful case.

Finally, one natural extension of the small obstacle problem with many small obstacles is the homogenization problem, where one looks for an effective equation obtained from flow outside a large number of small holes. Such a problem has been recently addressed by Lions and Masmoudi in [8]. The problem itself, as formulated in [8], has very little to do with the problem we treated here, in large part due to scaling. In their problem, both the velocity and the viscosity scale in such a way as to enforce strict two-scale asymptotic behavior. Consequently, there is no limit flow, but a generalized limit flow depending, independently and simultaneously, on the slow and fast variables and satisfying an appropriate PDE in this extended domain. In particular, the topological complications live in the microscopic (fast) scale. It should be noted, however, that some of the difficulties involved in our analysis also appear in the homogenization problem studied by Lions and Masmoudi. In their two-scale analysis, the harmonic part of the flow becomes a new unknown, of the form $\sum_i a_i(x,t)H_i(y)$, where x is the slow (physical) variable, y is the fast variable, $\{H_i\}$ is a basis for the harmonic vector fields in a microscopic periodic cell, and a_i are the components of the harmonic part. Part of their problem is to formulate an appropriate evolution equation for a_i and study its limit. The equation for the evolution of $\widehat{v}$ in [8], equation (38), is related to the equation for β in (19), with one important distinction—without Proposition 1, Lions and Masmoudi have an equation for the temporal evolution of the harmonic part, instead of a formula for it in terms of present time vorticity. It would be interesting to reformulate the analysis in [8] in terms of vortex dynamics, using Proposition 1.

Acknowledgments. The author would like to thank D. Iftimie, N. Masmoudi, H. Nussenzveig Lopes, and M. O. de Souza for many fruitful discussions.

SHARP ESTIMATES ON MINIMUM TRAVELLING WAVE SPEED OF REACTION DIFFUSION SYSTEMS MODELLING AUTOCATALYSIS*

XINFU CHEN† AND YUANWEI QI‡

Abstract. This article studies propagating wave fronts in an isothermal chemical reaction $A + 2B \to 3B$ involving two chemical species, a reactant A and an autocatalyst B, whose diffusion coefficients, D_A and D_B, are unequal due to different molecular weights and/or sizes. Explicit bounds v_* and v^* that depend on D_B/D_A are derived such that there is a unique travelling wave of every speed $v \geq v^*$ and there does not exist any travelling wave of speed $v < v_*$. New to the literature, it is shown that $v_* \propto v^* \propto D_B/D_A$ when $D_B \leq D_A$. Furthermore, when $D_A \leq D_B$, it is shown rigorously that there exists a $v_{\min}$ such that there is a travelling wave of speed v if and only $v \geq v_{\min}$. Estimates on $v_{\min}$ significantly improve those of early works. The framework is built upon general isothermal autocatalytic chemical reactions $A + nB \to (n+1)B$ of arbitrary order $n \geq 1$.

Key words. cubic autocatalysis, travelling wave, minimum speed, reaction diffusion

AMS subject classifications. 34C20, 34C25, 92E20

DOI. 10.1137/060665749

1. Introduction.

In this paper we consider an isothermal autocatalytic chemical reaction step governed by the cubic reaction relation

$$A + 2B \to 3B \qquad \text{with rate} \quad kab^2.$$

Here, $k > 0$ is the reaction rate, and a and b are the concentrations of reactant A and autocatalyst B, respectively. Well documented in the literature, the cubic reaction relation has appeared in several important models of real chemical reactions, e.g., almost isothermal flames in the carbon-sulphide-oxygen reaction (Voronkov and Semenov [22]), iodate-arsenous acid reactions (Saul and Showwalter [19]), hydroxylamine-nitrate reactions (Gowland and Stedman [10]), as well as other applications (Aris, Gray, and Scott [1] and Sel'kov [20]).

Experimental observations demonstrate the existence of propagating chemical wave fronts in chemical systems for which cubic catalysis forms a key step [11, 12, 13, 24]. These wave fronts, or travelling waves, arise due to the interaction of reaction and diffusion. Quite often when a quantity of autocatalyst is added locally into an expanse of reactant which is initially at uniform concentration, the ensuing reaction is observed to generate wave fronts which propagate outward from the initial reaction zone, consuming fresh reactant ahead of the wave front as it propagates. This is the phenomenon to be addressed in this paper.

For this purpose, we consider a one-dimensional slab geometry and the following partial differential equations (PDEs) that govern mass concentration and molecular

diffusion for the cubic reaction scheme:

$$\frac{\partial a}{\partial t} = D_A \frac{\partial^2 a}{\partial x^2} - kab^2, \qquad \frac{\partial b}{\partial t} = D_B \frac{\partial^2 b}{\partial x^2} + kab^2,$$

where D_A and D_B are the constant diffusion rates of A and B, respectively. Initial conditions, in accordance with the observed experiments, are

$$a(x,0) = a_0, \quad b(x,0) = g(x) \qquad \forall\, x \in \mathbf{R},$$

where a_0 is a positive constant representing the initial uniform distribution of A and $g(x)$ is a nonnegative function with compact support. It is not very difficult to derive from the PDEs that the solution has the following behavior at $x = \pm\infty$:

$$a(x,t) \to a_0, \quad b(x,t) \to 0 \qquad \text{as } |x| \to \infty \qquad \forall\, t \geq 0.$$

Introducing dimensionless parameters, dependent and independent variables

$$D = \frac{D_B}{D_A}, \quad \bar{a} = \frac{a}{a_0}, \quad \bar{b} = \frac{b}{a_0}, \quad \bar{t} = ka_0^2 t, \quad \bar{x} = x\sqrt{\frac{ka_0^2}{D_A}}, \qquad \bar{g} := \frac{g}{a_0},$$

and dropping the bars, the initial value problem takes the dimensionless form

$$\tag{1.1} \begin{cases} \dfrac{\partial a}{\partial t} = \dfrac{\partial^2 a}{\partial x^2} - ab^2, & x \in \mathbf{R}, t > 0, \\[2ex] \dfrac{\partial b}{\partial t} = D\dfrac{\partial^2 b}{\partial x^2} + ab^2, & x \in \mathbf{R}, t > 0, \\[2ex] a(x,0) = 1, \quad b(x,0) = g(x), & x \in \mathbf{R}, t = 0. \end{cases}$$

Here D measures the rate of diffusion of the autocatalyst relative to that of the reactant.

In the special case $D = 1$, the function $a + b$ satisfies a linear heat equation and can be solved explicitly; thus the system is reduced to a single nonlinear equation. For scalar equations, significant results are established and rich theories are available; see, for example, the works of Aronson and Weinberger [2], Chen and Guo [7], Fife and McLeod [8], and Sattinger [18] and the excellent review paper by Xin [23] for detailed information on single equations. The primary concern of the present paper is the case $D \neq 1$, which arises when the chemical species involved have different molecular weights and/or sizes. In particular, enzyme reactions may involve large enzyme molecules and smaller substrate molecules, leading to significantly different rates of diffusion. The system (1.1) also arises in epidemiology (Bailey [3]), where a represents the population density of healthy individuals and b the population density of infected individuals; again, when healthy individuals are significantly more or less mobile than the infected, D is far away from unity.

The wave front propagating phenomenon corresponds to the following behavior of solutions to (1.1): After a certain time of initiation, there are two wave fronts expanding towards $x = \pm\infty$ at a certain speed v. In between the two fronts, the reactant is consumed and thus $a \approx 0$; since each unit of reactant consumed produces exactly one unit of autocatalyst, one can expect that $b \approx 1$ inside the wave front. Outside the wave front, the reactant mixture is basically unstirred; thus $a \approx 1$ and $b \approx$

0. Focusing on the right-hand front, one expects that $(a(x,t), b(x,t)) = (\alpha(z), \beta(z))$, where $z = x - vt$ and (α, β) solves the following system:

$$
(1.2) \qquad \begin{cases} \alpha_{zz} + v\alpha_z = \alpha\beta^2, & \alpha \geq 0 \qquad \forall\, z \in \mathbf{R}, \\ D\beta_{zz} + v\beta_z = -\alpha\beta^2, & \beta \geq 0 \qquad \forall\, z \in \mathbf{R}, \\ \lim_{z\to\infty}(\ \alpha(z), \beta(z)\ ) = (1, 0), \\ \lim_{z\to-\infty}(\ \alpha(z), \beta(z)\ ) = (0, 1). \end{cases}
$$

Here $v > 0$ is the constant travelling speed.

The Travelling Wave Problem. Given $v > 0$, find $(\alpha, \beta) \in [C^2(\mathbf{R})]^2$ that satisfies (1.2).

In this paper we study the existence and nonexistence of the travelling waves, which can be generated from the initial value problem (1.1) as just described. One of the most important questions in the study of (1.2) is the existence of a minimum speed travelling wave and the estimate of the minimum speed v_{min}. In particular, for what range of v, in relation to D, does a travelling wave solution exist?

For quadratic autocatalytic ($A + B \to 2B$), namely, for the travelling wave problem related to the dynamics

$$
\frac{\partial\alpha}{\partial t} = \frac{\partial^2\alpha}{\partial x^2} - \alpha\beta, \qquad \frac{\partial\beta}{\partial t} = D\frac{\partial^2\beta}{\partial x^2} + \alpha\beta,
$$

Billingham and Needham proved that there is a travelling wave if and only if $v \geq 2\sqrt{D}$; namely, the minimum wave speed is exactly $2\sqrt{D}$ (see also the works of Billingham, Merkin, and Needham [4, 5, 14, 15, 16]). Focant and Gallay [9] investigated the existence and stability of travelling waves when both the quadratic and cubic nonlinearities are present in the system.

For the cubic autocatalysis, i.e., for (1.2), the answer is far from complete. Based on an invariant region argument, it was shown in [4] that a travelling wave exists if its speed $v \geq 2\sqrt{D}$. A more recent work [17] by one of the authors improved the result of [4] to the following: for (1.2),

(a) there exists a solution if $\quad v \geq \begin{cases} \sqrt{2D-1} & \text{when } D \geq 1, \\ \sqrt{D} & \text{when } D < 1; \end{cases}$

(b) no solution exists if $\quad v \leq \begin{cases} \sqrt{D/6} & \text{when } D \geq 1, \\ D/\sqrt{6} & \text{when } D < 1. \end{cases}$

This result, which comes out of a much more delicate analysis than that in [4], supplied both upper and lower bounds on minimum wave speed; nevertheless, it is still far from answering the key question of providing a good estimate of minimum speed. In particular, it falls short of providing an accurate order of $v_{\min}$ in terms of small D. Numerical simulation by the authors of [4] suggests that $v_{\min} \propto D$ when $D \ll 1$. Furthermore, it is well known that $v_{min} = 1/\sqrt{2}$ when $D = 1$, but neither the results in [4] nor the results in [17] recover this special case from their results of the general case. In this paper we shall provide affirmative answers to these questions and fill in the gap between the general case and the special case of $D = 1$.

THEOREM 1. *Suppose $D < 1$. For the travelling wave problem* (1.2),

(i) *there exists a unique (up to translation) solution if* $\quad v \geq \dfrac{4D}{\sqrt{1+4D}}$;

(ii) *there does not exist any solution if* $\quad v < \dfrac{D}{\sqrt{2}}.$

Clearly the above result provides a pretty satisfying bound on the range of wave speeds. In particular, it shows that $v_{\min}(D) \propto D$ for small D.

One of the important issues in discussing existence and nonexistence of a travelling wave solution is whether the set of v of the speed for which existence holds is a single interval. While there are heuristic and numerical arguments in [4] demonstrating that the set of admissible wave speed is an interval $[v_{\min}, \infty)$, for the moment we can only supply a rigorous proof for the case $D \geq 1$.

THEOREM 2. *Suppose $D \geq 1$. There exists a positive constant $v_{\min}$ such that* (1.2) *admits a solution if and only if $v \geq v_{\min}$. In addition, $v_{\min}$ satisfies the estimate*

$$\sqrt{\frac{D}{2}} \leq v_{\min} \leq \sqrt{\frac{D}{1+1/D}}.$$

It is clear from Theorem 2 that in the special case of $D = 1$, (1.2) admits a solution if and only if $v \geq 1/\sqrt{2}$.

The general nth order isothermal autocatalytic chemical reaction step is governed by the chemical reaction relation

$$A + nB \rightarrow (n+1)B \qquad \text{with rate} \quad kab^n.$$

We can use the same idea developed in this paper to establish lower bounds for the existence of a travelling wave solution and upper bounds for nonexistence. For this general case, the governing equations are, after proper scaling,

$$\frac{\partial a}{\partial t} = \frac{\partial^2 \alpha}{\partial x^2} - ab^n, \qquad \frac{\partial b}{\partial t} = D\frac{\partial^2 b}{\partial x^2} + ab^n,$$

where $D = D_B/D_A$ and the initial value is the same as that in (1.1). The corresponding travelling wave problem is to solve

$$(1.3) \qquad \begin{cases} \alpha_{zz} + v\alpha_z = \alpha\beta^n, & \alpha \geq 0 \qquad \forall\, z \in \mathbf{R}, \\ D\beta_{zz} + v\beta_z = -\alpha\beta^n, & \beta \geq 0 \qquad \forall\, z \in \mathbf{R}, \\ \lim_{z\to\infty}(\ \alpha(z), \beta(z)\ ) = (1,0), \\ \lim_{z\to-\infty}(\ \alpha(z), \beta(z)\ ) = (0,1). \end{cases}$$

THEOREM 3. *Suppose $D < 1$ and $n \geq 2$. A unique (up to translation) travelling wave solution exists for* (1.3) *if $v \geq 4D/\sqrt{1+4D}$. On the other hand, there exists no solution for* (1.3) *if $v \leq D/\sqrt{K(n)}$, where $K(n)$ is a constant which increases with n. In particular, $K(1) = 1/4$, $K(2) = 2$.*

THEOREM 4. *Suppose $D \geq 1$ and $n \geq 1$. There exists a positive constant $v_{\min}$ such that* (1.3) *admits a travelling wave if and only if $v \geq v_{\min}$. In addition, $v_{\min}$ is bounded by*

$$\sqrt{\frac{D}{K(n)}} \leq v_{\min} \leq \sqrt{\frac{D}{K(n)}}\ \frac{1}{\sqrt{1-(1-\frac{1}{D})\frac{\sqrt{4K(n)+1}-1}{\sqrt{4K(n)+1}+1}}},$$

where $K(n)$ is the same constant as in Theorem 3.

We note in passing the recent works to study the spatiotemporal profiles of L^1 initial values by Bricmont, Kupiainen, and Xin [6] and the steady-state solutions by Shi and Wang [21].

The organization of this paper is as follows. Section 2 contains preliminary analysis and an outline of our approach. The case $D \geq 1$ is discussed in section 3, and the case $D < 1$ in section 4.

2. Preliminary.

2.1. A scalar equation. First we review the existence of a travelling wave solution of unit speed to the equation

$$u_{zz} + u_z = ku(1-u)^n, \quad 0 \leq u \leq 1 \quad \text{on } \mathbf{R}, \qquad u(-\infty) = 0, \quad u(\infty) = 1. \tag{2.1}$$

Here $n \geq 1$ is a parameter, and k is a positive constant. We seek upper bounds on k for the existence of a solution. Since a solution, if it exists, satisfies $u_z > 0$ on $\mathbf{R}$, we can write $u' = Q(u)$ and work on the (u, Q) phase plane. The resulting equation on the phase plane is

$$\begin{cases} QQ' + Q = ku(1-u)^n & \forall\, u \in [0,1], \\ Q(0) = 0, \quad Q > 0 \text{ on } (0,1). \end{cases} \tag{2.2}$$

There is a one-to-one correspondence between solutions to (2.1) and solutions to (2.2) satisfying the additional requirement $Q(1) = 0$.

LEMMA 2.1. *For each $n \geq 1$ and $k > 0$, there exists a unique solution $Q = Q(n, k; \cdot)$ to (2.2). In addition, there exists a positive constant $K(n)$ such that $Q(n, k; 1) = 0$ if $k \in (0, K(n)]$ and $Q(n, K; 1) > 0$ if $k \in (K(n), \infty)$. Consequently, (2.2) admits a solution if and only if $k \in (0, K(n)]$.*

In addition, $K(n)$ is a strictly increasing function of n and $K(1) = \frac{1}{4}, K(2) = 2$.

Proof. The existence of Q and K follows by the comparison principle. The exact value of $K(1)$ is calculated by a known fact that the function $K(1)u(1-u)$ is concave, and thus the minimum wave speed $v = 1$ satisfies $1 = 2\sqrt{K(1)}$; hence $K(1) = 1/4$. In the case $n = 2$, the exact solution is given by $Q = u(1-u)$; thus $K(2) = 2$. We omit details, because it is a standard argument. ∎

2.2. Basic properties of travelling waves. Suppose (v, α, β) solves (1.3). Then $[\alpha_z + v\alpha + D\beta_z + v\beta]_z = 0$, so that $\alpha_z + D\beta_z + v(\alpha + \beta)$ is a constant function. Using the boundary conditions, we find that

$$\alpha_z + D\beta_z + v(\alpha + \beta - 1) = 0 \qquad \text{on } \mathbf{R}.$$

With the new variable $w = \beta_z$, (1.3) is equivalent to the following third order ODE system

$$\begin{cases} \alpha_z = v(1 - \alpha - \beta) - Dw, \\ \beta_z = w, \\ w_z = -D^{-1}(\alpha\beta^n + vw), \\ \lim_{z\to\infty}(\alpha(z), \beta(z), w(z)) = (1, 0, 0), \\ \lim_{z\to-\infty}(\alpha(z), \beta(z), w(z)) = (0, 1, 0). \end{cases} \tag{2.3}$$

It is clear that in the (α, β, w) phase space, there are two equilibrium points: $(0, 1, 0)$ and $(1, 0, 0)$. The following are a few basic properties of travelling wave solutions.

PROPOSITION 1. *The systems* (1.3) *and* (2.3) *are equivalent. Any solution* (α, β) *to* (1.3) *or* (α, β, w) *to* (2.3) *has the following properties:*

(1) $\alpha_z > 0 > \beta_z$ *on* $\mathbf{R}$.
(2) $\alpha + \beta < 1$ *on* $\mathbf{R}$ *if* $D < 1$, $\alpha + \beta \equiv 1$ *if* $D = 1$, *and* $\alpha + \beta > 0$ *if* $D > 1$.
(3) $v = \int_{-\infty}^{\infty} \alpha(z)\beta^n(z)\,dz > 0$.
(4) *The equilibrium point* $(0, 1, 0)$ *of* (2.3) *is a saddle with a two-dimensional stable manifold and a one-dimensional unstable manifold. The eigenvalues and associated eigenvectors are*

$$\begin{aligned} \lambda_1 &= -vD^{-1}, & \mathbf{e}_{\lambda_1} &= (0, -1, -\lambda_1)^T, \\ \lambda_2 &= -\tfrac{1}{2}(\sqrt{v^2+4} + v), & \mathbf{e}_{\lambda_2} &= (\lambda_2(D\lambda_2 + v), -1, -\lambda_2)^T, \\ \lambda_3 &= \tfrac{1}{2}(\sqrt{v^2+4} - v), & \mathbf{e}_{\lambda_3} &= (\lambda_3(D\lambda_3 + v), -1, -\lambda_3)^T. \end{aligned}$$

(5) *When* $n > 1$, *the equilibrium point* $(1, 0, 0)$ *is degenerate; it has a two-dimensional stable manifold and a one-dimensional center manifold. The eigenvalues and associated eigenvectors are*

$$\begin{aligned} \mu_1 &= -v, & \mathbf{e}_{\nu_1} &= (1, 0, 0)^T, \\ \mu_2 &= -vD^{-1}, & \mathbf{e}_{\nu_2} &= (0, -1, -vD^{-1})^T, \\ \mu_3 &= 0, & \mathbf{e}_{\nu_3} &= (1, -1, 0)^T. \end{aligned}$$

All items except (3) were proved in [4]. The equation in property (3) is obtained by integrating the equation involving α_{zz} in (1.3) with the boundary conditions $\alpha(\infty) = 1$ and $\alpha(-\infty) = 0$.

The third property in the proposition demonstrates that $v > 0$. The fourth property clearly tells us that the travelling wave we are looking for is indeed the one-dimensional unstable manifold associated with the equilibrium $(0, 1, 0)$. Hence, given $v > 0$, a travelling wave of speed v, if it exists, is unique up to a translation.

2.3. New setting—A nonautonomous 2×2 system. Unlike in earlier works [4, 17], here we shall use a transformation to turn the third order autonomous system (2.3) into a second order nonautonomous system, using $u := 1 - \beta$ as the independent variable. This is allowed since for the solution of interest, $\beta_z < 0$, and thus $z \to 1 - \beta(z)$ has an inverse. To make the resulting system as simple as possible, we also scale the other variables. Hence, we introduce

$$u = 1 - \beta, \qquad A = \frac{D\alpha}{v^2}, \qquad y = \frac{vz}{D}, \qquad \kappa := \frac{D}{v}.$$

The system of differential equations (1.3) becomes

$$\begin{cases} u_{yy} + u_y = A(1-u)^n & \text{on } \mathbf{R}, \\ A_y = \kappa^2(u + u_y) - DA & \text{on } \mathbf{R}. \end{cases}$$

Since $u_y > 0$ for the solution of interest, we can use u as the independent variable. Introducing $P(u) = u_y$, we have an equivalent system of second order nonautonomous (singular) ODEs:

$$\begin{cases} PP' = A[1-u]^n - P & \forall u \in [0, 1], \\ PA' = \kappa^2[P + u] - DA & \forall u \in [0, 1], \\ P(u) > 0, \ A(u) > 0 & \forall\, u \in (0, 1), \\ P(0) = 0, \ A(0) = 0. \end{cases} \tag{2.4}$$

LEMMA 2.2. *For every $D > 0$ and $\kappa > 0$, (2.4) admits a unique solution. In addition,*

$$P(u) = \lambda\, u + O(u^2), \quad A(u) = \lambda(1+\lambda)u + O(u^2) \qquad \text{as } u \searrow 0, \tag{2.5}$$

where

$$\lambda := \tfrac{1}{2}(\sqrt{4\kappa^2 + D^2} - D) \qquad (\text{the only positive root to } \lambda(\lambda + D) = \kappa^2).$$

Furthermore, $A'(u) > 0$ for all $u \in [0, 1)$, and there are only two possible cases:

(a) $P(1) > 0$*: there does not exist any travelling wave solution to* (1.3)*.*

(b) $P(1) = 0$*: there exists a travelling wave solution to* (1.3)*, unique up to translation.*

Proof. We divide the proof into several steps.

1. A solution to (2.4) corresponds exactly to the part of the one-dimensional unstable manifold associated with the equilibrium point $(0, 1, 0)$ of the autonomous system (2.3) that has the property $\alpha,\ \beta > 0$ and $w < 0$. Hence, for some $\delta \in (0, 1]$, (2.4) admits a unique solution in $[0, \delta)$. The solution satisfies the asymptotic expansion (2.5) and can be extended as long as $P > 0$.

2. It is easy to see that A cannot hit zero before P does, since otherwise, $PA' = \kappa^2(p + u) > 0$ at $A = 0$ and $P > 0$, which is impossible. If $\lim_{u\nearrow\delta} P(u) = 0$ at some $\delta \in (0, 1)$, then $\liminf_{u\nearrow\delta} P(u)P'(u) \le 0$, and thus $A(\delta) := \lim_{u\nearrow\delta} A(u) = 0$. But the equation for A gives $PA' > \kappa^2\delta/2 > 0$ for all u sufficiently close to δ from below, which contradicts $A(\delta) = 0$. Since the system has at most a linear growth in P and A, the solution can be uniquely extended to $[0, 1)$ and $P > 0,\ A > 0$ in $(0, 1)$.

3. Now we show that $A' > 0$ on $[0, 1)$. From the asymptotic behavior (2.5), $A \in C^1([0, 1))$ and $A'(0) = \lambda(\lambda + 1) > 0$. Also a combination of the two equations in (2.4) yields

$$P[\kappa^2(P + u) - DA]' = -D[\kappa^2(P + u) - DA] + \kappa^2 A(1 - u)^n.$$

Gronwall's inequality then gives $\kappa^2(P + u) - DA > 0$ in $(0, 1)$. Thus,

$$0 < A < D^{-1}\kappa^2(P + u) \ \text{ in } \ (0, 1), \qquad A' > 0 \text{ in } \ [0, 1).$$

4. Since $(P+u)' = A(1-u)^n/P > 0$ in $(0, 1)$, $P+u$ is strictly increasing in $(0, 1)$ so that $\lim_{u\nearrow 1} P(u)$ exists. To show that it is finite, observe that when $P \ge 1$,

$$[P + u]' \le P[P + u]' = A(1 - u)^n \le D^{-1}\kappa^2(P + u)(1 - u)^n.$$

This implies that $P + u$ is bounded uniformly in $u \in [0, 1)$; thus $P(1) := \lim_{u\nearrow 1} P(u)$ exists and is finite. Consequently, $A(1) := \lim_{u\nearrow 1} A(u)$ also exists and is finite.

5. If $P(1) > 0$, we have a classical solution of (2.4) on $[0, 1]$. Since a travelling wave is required to have $u = 1-\beta \le 1$, we see that there is no travelling wave solution to (1.3).

6. Suppose $P(1) = 0$. Since $[P+u]' > 0$ in $(0, 1)$, we have $P(u)+u < P(1)+1 = 1$; i.e., $P(u) < 1 - u$ for all $u \in [0, 1)$. Since $\kappa^2(P + u) - DA > 0$ in $(0, 1)$, we see that

$$\begin{aligned} A(1) &= \int_0^1 \frac{\kappa^2[P(u) + u] - DA(u)}{P(u)} du \\ &\ge \int_0^1 \frac{\kappa^2[P(u) + u] - DA(u)}{1 - u} du \ge \int_0^1 \frac{\kappa^2[u - 1]}{1 - u} du + \int_0^1 \frac{\kappa^2 - DA(u)}{1 - u} du. \end{aligned}$$

Since $DA(u) < DA(1) \le \kappa^2(P(1)+1) = \kappa^2$ for all $u \in (0,1)$, for the last integral to be convergent, we must have $A(1) = \kappa^2/D$. It is then easy to see that $\alpha = DA/\kappa^2 \to 1$ as $u \to 1$. Transferring back to the original variable z, we then obtain a travelling wave solution to (1.3). $\square$

In what follows, we shall estimate upper and lower bounds of A/u; thus Lemma 2.1 can be applied to generate upper and lower bounds of $v_{\min}$.

3. The case $D \ge 1$. In this section we deal with the case of $D \ge 1$.

LEMMA 3.1. *Suppose $D \ge 1$. Then $DA(u) \ge \kappa^2 u$ for all $u \in [0,1]$. Consequently, there is no travelling wave solution to* (1.3) *when $\kappa^2 > DK(n)$, i.e., when $v < \sqrt{D/K(n)}$.*

Proof. If $D = 1$, $A(u) = \kappa^2 u$ for all $u \in [0,1]$. When $D > 1$, for every $u \in (0,1)$,

$$P[DA - \kappa^2 u]' = -D[DA - \kappa^2 u] + (D-1)\kappa^2 P > -D[DA - \kappa^2 u].$$

In addition, when u is sufficiently small, $DA(u) = D(1+\lambda)\lambda\, u + O(u^2) > [D+\lambda]\lambda\, u = \kappa^2 u$. Applying Gronwall's inequality, we derive that $DA > \kappa^2 u$ on $(0,1)$.

Now suppose $\kappa^2 > DK(n)$. Let $\hat{k} \in (K(n), k^2/D)$. Then $A(u) \ge \hat{k}u$ on $[0,1]$ so that

$$PP' + P = A(1-u)^n \ge \hat{k}u(1-u)^n \quad \forall\, u \in [0,1].$$

We compare $P(u)$ and the solution $Q(n,\hat{k};u)$ given in Lemma 2.1. Using a Taylor expansion, we can show that $P(u) > Q(n,\hat{k};u)$ for all $u \in (0,\epsilon]$ for some $\epsilon > 0$. In the interval $[\epsilon,1]$ we can use the regular comparison principle to show that $P(u) > Q(n,\hat{k};u)$ for all $u \in [\epsilon,1)$. In particular, $P(1) \ge Q(n,\hat{k};1) > 0$, so that there is no travelling wave solution to (1.3). Since $\kappa = D/v$, the condition $\kappa^2 > DK(n)$ is the same as $v < \sqrt{D/K(n)}$. $\square$

LEMMA 3.2. *Suppose $D > 1$. Then,*

$$A(u) < \lambda(1+\lambda)\, u, \qquad P(u) < \lambda\, u \quad \forall\, u \in (0,1).$$

Consequently, there exists a travelling wave solution to (1.3) *when $\lambda(\lambda+1) \le K(n)$, i.e., when*

$$v \ge \sqrt{\frac{D}{K(n)}}\,\frac{1}{\sqrt{1-(1-\frac{1}{D})\frac{\sqrt{4K(n)+1}-1}{\sqrt{4K(n)+1}+1}}}.$$

Proof. A higher order Taylor expansion near $u = 0$ shows that $A < \lambda(\lambda+1)\, u$ and $P < \lambda\, u$ for all sufficient small positive u. Set

$$\hat{B} = \sup\{b \in (0,1) \mid P(u) < \lambda\, u, \qquad A(u) < \lambda(1+\lambda)u \quad \forall u \in (0,b)\}.$$

We show that $\hat{B} = 1$. Suppose on the contrary that $\hat{B} < 1$. Then either $P(\hat{B}) - \lambda\hat{B} = 0$ or $A(\hat{B}) - \lambda(1+\lambda)\hat{B} = 0$. In $(0,\hat{B}]$,

$$\begin{aligned} P[A - \lambda(1+\lambda)u]' &= \kappa^2(P+u) - DA - \lambda(1+\lambda)P \\ &= \lambda(D+\lambda)(P+u) - DA - \lambda(1+\lambda)P \\ &= -D[A - \lambda(1+\lambda)u] + \lambda(D-1)(P - \lambda u) \\ &\le -D[A - \lambda(1+\lambda)u]. \end{aligned}$$

Gronwall's inequality then implies that $A < \lambda(\lambda+1)u$ on $(0, \hat{B}]$. Similarly, for all $u \in (0, \hat{B}]$,

$$\begin{aligned} P[P-\lambda u]' &= -(1+\lambda)P + A(1-u)^n \\ &= -(1+\lambda)(P-\lambda u) - \lambda(1+\lambda)u + A(1-u)^n \\ &< -(1+\lambda)(P-\lambda u). \end{aligned}$$

Gronwall's inequality shows that $P < \lambda\, u$ on $(0, \hat{B}]$. We reach a contradiction. This proves that $\hat{B} = 1$; i.e., $P(u) < \lambda\, u$ and $A(u) < \lambda(1+\lambda)u$ for all $u \in (0,1)$.

Suppose $\lambda(1+\lambda) \le K(n)$. We can use comparison to show that $P(u) \le Q(n, K(n); u)$ for all $u \in [0,1]$ so that $P(1) = 0$. Namely, there exists a travelling wave solution to (1.3). □

Proof of Theorem 2. This is a special case of Theorem 4, by setting $n = 2$ and acknowledging that $K(2) = 2$. □

Proof of Theorem 4. The estimate of $v_{\min}$, when it exists, follows from the above two lemmas.

We notice that the set of admissible speed is a closed set. Indeed, if there is no travelling wave of speed $\hat{v} > 0$, then the solution (P, A) to (2.4) with $v = \hat{v}$ has the property that $P(1) > 0$. It then follows by continuous dependence that for any v sufficiently close to $\hat{v}$, the solution to (2.4) also satisfies $P(1) > 0$. This implies that there is no travelling wave of speed v for any v sufficiently close to $\hat{v}$. Thus the complement of the set of admissible speed is open; that is, the set of admissible speed is closed.

Hence, to show the existence of $v_{\min}$, it suffices to show that if $v_1 > v_0$ and there exists a travelling wave of speed v_0, then there also exists a travelling wave of speed v_1. For this, we denote $\kappa_i = D/v_i$ and (P_i, A_i) the solution to (2.4) with $\kappa = D/v_i$, $i = 0, 1$. The existence of a travelling wave of speed v_0 implies that $P_0(1) = 0$. To show that there exists a travelling wave of speed v_1, it is necessary and sufficient to show that $P_1(1) = 0$. For this, it suffices to show that $P_1 < P_0$ in $(0,1)$.

Notice that $\kappa_1 < \kappa_0$. Denote by λ_i the positive root to $\lambda_i(\lambda_i + D) = \kappa_i^2$. Then $\lambda_1 < \lambda_0$. The asymptotic expansion for (P, A) then implies that there exists $\epsilon > 0$ such that for $u \in (0, \epsilon]$, $P_1(u) < P_0(u)$ and $A_1(u) < A_0(u)$. In addition, for small u, the functions $\alpha_i := DA_i/\kappa_i^2$ satisfy

$$\begin{aligned} \alpha_0 - \alpha_1 &= \left\{ \frac{D\lambda_0(\lambda_0+1)}{\kappa_0^2} - \frac{D\lambda_1(\lambda_1+1)}{\kappa_1^2} \right\} u + O(u^2) \\ &= D\left\{ \frac{\lambda_0+1}{\lambda_0+D} - \frac{\lambda_1+1}{\lambda_1+D} \right\} u + O(u^2) \\ ;6pt] &= \frac{D(D-1)(\lambda_0-\lambda_1)}{(\lambda_0+D)(\lambda_1+D)} u + O(u^2) > 0 \end{aligned}$$

since $D > 1$ and $\lambda_0 > \lambda_1$. Now let

$$\hat{B} = \sup\{b \in (0,1) \mid P_1(u) < P_0(u)\ \forall\, u \in (0, b)\}.$$

We claim that $\hat{B} = 1$. Suppose the contrary, $\hat{B} < 1$. Then $P_0(\hat{B}) = P_1(\hat{B}) > 0$.

First we claim that $A_0 > A_1$ on $(0, \hat{B}]$. Suppose it is not true; then there is a $u_1 \in (0, \hat{B}]$ at which $A_0(u_1) = A_1(u_1)$. Since $\kappa_0 > k_1$, there exists $u_2 \in (0, B_1)$ such that $\alpha_0(u_2) = \alpha_1(u_2)$ and $\alpha_0(u_2)' \le \alpha_1(u_2)'$. But, at $u = u_2$,

$$[\alpha_0 - \alpha_1]' = \frac{D(u-\alpha_0)}{P_0} - \frac{D(u-\alpha_1)}{P_1} = \frac{D(\alpha_0-u)(P_0-P_1)}{P_0P_1} > 0$$

since $\alpha_0 - u = [DA_0 - \kappa_0^2 u]/\kappa_0^2 > 0$ by Lemma 3.1 and $P_0 > P_1$ in $(0, \hat{B}) \ni u_2$. Thus, we must have $A_0 > A_1$ in $[0, \hat{B}]$. Consequently, we obtain from the equation for P_i that

$$\tfrac{1}{2}[P_1^2 - P_0^2]' = [P_0 - P_1] + (A_1 - A_0)[1-u]^n < [P_0 - P_1] = \frac{P_0^2 - P_1^2}{P_0 + P_1}.$$

Gronwall's inequality on $[\epsilon, \hat{B}]$ then gives $P_1^2 - P_0^2 < 0$ on $[\epsilon, \hat{B}]$, contradicting $P_0(\hat{B}) = P_1(\hat{B})$. Hence, $\hat{B} = 1$ and $P_1 < P_0$ on $(0,1)$. This completes the proof of Theorem 4. ∎

4. The case of $D < 1$. In this section, we establish the results on the case of $D < 1$.

LEMMA 4.1. *Suppose $D < 1$. Then $A > \kappa^2 u$ on $(0,1)$. Consequently, when $\kappa^2 > K(n)$, i.e., $v < D/\sqrt{K(n)}$, there is no travelling wave solution to* (1.3).

Proof. Direct calculation shows that

$$\begin{aligned} P[A - \kappa^2 u]' &= \kappa^2(P+u) - DA - \kappa^2 P = \kappa^2(1-D)u - D(A - \kappa^2 u) \\ &> -D(A - \kappa^2 u) \quad \forall u \in (0,1). \end{aligned}$$

Since $A = \lambda(1+\lambda)u + O(u^2) > \kappa^2 u$, for all sufficiently small positive u, Gronwall's inequality gives $A > \kappa^2 u$ on $[0,1)$.

One can show that $P(u) > Q(n, k^2; u)$ for all $u \in (0,1)$ by first using an asymptotic expansion at $u = 0$ for $0 < u \leq \epsilon$ and then a comparison principle for the differential equation in $(\epsilon, 1)$.

It then follows from Lemma 2.1 that when $\kappa^2 > K(n)$, we must have $P(1) \geq Q(n, k^2; 1) > 0$; i.e., there does not exist any solution to the travelling wave problem. ∎

To establish the existence of a solution, we need to find an upper bound of A. Although there is the estimate $A < \kappa^2(u+P)/D$ available for use, we are not satisfied with such an estimate since when D is very small, it is not sufficient to show that $v_{\min} = O(D)$. Hence, we seek another bound.

LEMMA 4.2. *Suppose $D < 1$. Then $A(u)(1-u)^{n/2} \leq \lambda[P(u) + u]$ $\forall\, u \in [0,1)$.*

Proof. When $u = 0$, the two sides are equal. Computation shows that, in $(0,1]$,

$$\begin{aligned} &P[(1-u)^{n/2}A - \lambda(P+u)]' \\ &= (1-u)^{n/2}[\kappa^2(P+u) - DA] - \tfrac{1}{2}nPA(1-u)^{n/2-1} - \lambda A(1-u)^n \\ &\leq -[D + \lambda(1-u)^{n/2}][A(1-u)^{n/2} - \lambda(P+u)] + (P+u)[(\kappa^2 - \lambda^2)(1-u)^{n/2} - \lambda D] \\ &= -[D + \lambda(1-u)^{n/2}][A(1-u)^{n/2} - \lambda(P+u)] - \lambda D(P+u)[1 - (1-u)^{n/2}] \\ &\leq -[D + \lambda(1-u)^{n/2}][A(1-u)^{n/2} - \lambda(P+u)]. \end{aligned}$$

Here we have dropped the term $\frac{1}{2}nP(1-u)^{n/2-1}$ in the first inequality and used $\kappa^2 = \lambda(\lambda + D)$ in the second inequality. The assertion of the lemma thus follows from Gronwall's inequality. ∎

Proof of Theorem 3. The nonexistence follows directly from Lemma 4.1. We now prove the existence. Simple computation shows that $v \leq 4D/\sqrt{1+4D}$ is equivalent to $\lambda \leq 1/4$. We proceed to show that $P - u(1-u)/2 \leq 0$ on $(0,1)$. It is easy to verify, using the result of Lemma 4.2, that

$$
\begin{aligned}
P[2P - u(1-u)]' &= P(2u-3) + 2A(1-u)^n \\
&\le P(2u-3) + 2\lambda(P+u)(1-u)^{n/2} \\
&= [u - 3/2 + \lambda(1-u)^{n/2}][2P - u(1-u)] \\
&\qquad + u(1-u)[2\lambda(1-u)^{n/2-1} + \lambda(1-u)^{n/2} + u - 3/2] \\
&< [u - 3/2 + \lambda(1-u)^{n/2}][2P - u(1-u)],
\end{aligned}
$$

since $\lambda \le 1/4$ and $n \ge 2$ yield

$$
\begin{aligned}
&2\lambda(1-u)^{n/2-1} + \lambda(1-u)^{n/2} + u - 3/2 \\
&\le 2\lambda + \lambda(1-u) + u - 3/2 \\
&= 2\lambda - 1/2 + (\lambda - 1)(1-u) \le 0.
\end{aligned}
$$

Because $2P < u(1+u)$ for small u, Gronwall's inequality shows that $P < u(1-u)/2$ on $(0,1)$. Thus $P(1) = 0$. This proves the existence and completes the proof of the theorem. ∎

Finally, Theorem 1 is a special case of Theorem 3 with $n = 2$.

ELASTIC ENERGY STORED IN A CRYSTAL INDUCED BY SCREW DISLOCATIONS: FROM DISCRETE TO CONTINUOUS*

MARCELLO PONSIGLIONE†

Abstract. This paper deals with the passage from discrete to continuous in modeling the static elastic properties of vertical screw dislocations in a cylindrical crystal, in the setting of antiplanar linear elasticity. We study, in the framework of Γ-convergence, the asymptotic behavior of the elastic stored energy induced by dislocations as the atomic scale ε tends to zero, in the regime of dilute dislocations, i.e., rescaling the energy functionals by $1/\varepsilon^2|\log\varepsilon|$. First we consider a continuum model, where the atomic scale is introduced as an internal scale, usually called core radius. Then we focus on a purely discrete model. In both cases, we prove that the asymptotic elastic energy as $\varepsilon \to 0$ is essentially given by the number of dislocations present in the crystal. More precisely the energy per unit volume is proportional to the length of the dislocation lines, so that our result recovers in the limit as $\varepsilon \to 0$, a line tension model.

Key words. crystals, analysis of microstructure, stress concentration, calculus of variations

1. Introduction.

This paper deals with energy minimization methods to model static elastic properties of *dislocations* in crystals. We are interested in the asymptotic behavior of the elastic energy stored in a crystal, induced by a configuration of dislocations, as the atomic scale tends to zero. Our approach is completely variational and is based on Γ-*convergence*. First we consider a continuum model, where the atomic scale is introduced as an internal scale, usually called the *core radius*. Then we focus on a purely discrete model.

We consider the setting of *antiplanar* linear elasticity, so that all the physical quantities involved in our model will be defined on a domain $\Omega \subset \mathbb{R}^2$, which represents an horizontal section of an infinite cylindrical crystal. The elastic energy associated with a vertical *displacement* $u : \Omega \to \mathbb{R}$, in absence of dislocations, is given by[1]

$$E(\nabla u) := \int_\Omega |\nabla u(x)|^2\, dx.$$

Now we assume that vertical *screw dislocations* are present in the crystal. To model the presence of dislocations we follow the general theory of eigenstrains,[2] namely, to any dislocation corresponds a preexisting strain in the reference configuration. In this framework a configuration of screw dislocations in the crystal can be represented by a measure on Ω which is a finite sum of *Dirac masses* of the type $\mu := \sum_i z_i|\mathbf{b}|\,\delta_{x_i}$. Here x_i's represent the intersection of the dislocation lines with Ω, $\mathbf{b}$ is the so-called *Burgers vector*, which in this antiplanar setting is a vertical fixed vector whose modulus depends on the specific crystal lattice, and $z_i \in \mathbb{Z}$ represents the multiplicity of the dislocations. The class of admissible strains associated with a

[1]For simplicity we will assume the *shear modulus* of the crystal is equal to 1.

[2]We refer the reader to [13], [14] for an exhaustive treatment of the subject.

dislocation μ is given by the fields whose circulation around the dislocations x_i are equal to $z_i|\mathbf{b}|$. These fields by definition have a singularity at each x_i and are not in $L^2(\Omega;\mathbb{R}^2)$. To set up a variational formulation it is then convenient to introduce an internal scale ε called the core radius, which is comparable to the atomic scale, and to remove balls of radius ε around each point of singularity x_i. More precisely to any admissible strain ψ we associate the elastic energy

$$E_\varepsilon(\psi) := \int_{\Omega_\varepsilon(\mu)} |\psi(x)|^2\, dx,$$

where $\Omega_\varepsilon(\mu) := \Omega \setminus \cup_i \overline{B}_\varepsilon(x_i)$. Given a dislocation μ, the elastic energy induced by μ, in the absence of external forces, is given by minimizing $E_\varepsilon(\psi)$ among all admissible strains.

This variational formulation has been recently considered in [4] to study the limit of the elastic energy induced by a fixed configuration of dislocations as the atomic scale ε tends to zero. The authors prove in particular that the energy[3] is of the order $|\log\varepsilon|$.

In this paper we study the asymptotic behavior of the elastic energy induced by the dislocations in terms of Γ-convergence, in this regime of energies, i.e., rescaling the energy functionals by $|\log\varepsilon|$, without assuming the dislocations to be fixed, uniformly bounded in mass, or *well separated*. Let us describe our continuum model in more detail.

Given a dislocation μ, the class of admissible strains $\mathcal{AS}_\varepsilon(\mu)$ associated with μ is given (we consider for simplicity $|\mathbf{b}| = 1$) by

$$\mathcal{AS}_\varepsilon(\mu) := \Bigg\{ \psi \in L^2(\Omega_\varepsilon(\mu);\mathbb{R}^2) : \operatorname{curl}\psi = 0 \text{ in } \Omega_\varepsilon(\mu) \text{ in the sense of distributions,} \\ \int_{\partial A} \psi(s)\cdot\tau(s)\, ds = \mu(A) \\ \text{for every open set } A \subset \Omega \text{ with } \partial A \text{ smooth and with } \partial A \subset \Omega_\varepsilon(\mu) \Bigg\}.$$

Here $\tau(s)$ is the oriented tangent vector to ∂A at the point s, and the integrand $\psi(s)\cdot\tau(s)$ is intended in the sense of traces (see Theorem 2, p. 204, of [6]). The (rescaled) elastic energy associated with μ is given by

$$\mathcal{F}_\varepsilon(\mu) := \frac{1}{|\log\varepsilon|}\Big(\min_{\psi\in\mathcal{AS}_\varepsilon(\mu)} E_\varepsilon(\psi) + |\mu|(\Omega)\Big). \tag{1.1}$$

The first term in the energy represents the elastic energy far from the dislocations, where the crystal is assumed to have a linear hyperelastic behavior (see Remark 2.6 for a partial justification of the use of linear elasticity in this region far from dislocations). The second term, $|\mu|(\Omega)$, is the *total variation* of μ on Ω and represents the elastic energy stored in the region surrounding the dislocations (the introduction of this energy in the continuum model will be fully justified by our discrete model; see Remarks 2.6 and 3.2 for more details).

[3]Though the Burgers vector should be rescaled by ε, in this and in the following results the Burgers vector is kept fixed. The relevant physical case can be recovered simply by introducing a supplementary rescaling term of the order $1/\varepsilon^2$ in the energy functionals.

In Theorem 2.4 we prove that the Γ-limit of the functionals $\mathcal{F}_\varepsilon$, with respect to the *flat convergence* of the dislocations (see (2.2)), is given by the functional $\mathcal{F}$ defined by

$$\mathcal{F}(\mu) := \frac{1}{2\pi}|\mu|(\Omega). \tag{1.2}$$

The asymptotic elastic energy per unit volume is essentially proportional to the number (and hence to the length) of the screw dislocations. Then we recover in the limit as $\varepsilon \to 0$ a *line tension model*.

A similar result was obtained in [8], [9], where the authors considered a phase field model for dislocations proposed by [11]. They study the asymptotic behavior, in different rescaling regimes, of the elastic energy given by the interaction of a nonlocal $H^{1/2}$ elastic energy, a nonlinear *Peierls potential*, and a *pinning condition* under the assumption that only one *slip system* is active. In particular, in the energy regime corresponding to a rescaling of the order $1/|\log\varepsilon|$, their Γ-limit is given by the sum of a bulk term, taking into account the pinning condition, and a surface term concentrated on the dislocation lines.

More in general, energy concentration phenomena as a result of the logarithmic rescaling are nowadays classical in the theory of *Ginzburg–Landau*-type functionals, to model vortices in superfluidity and superconductivity. We refer the reader to [3], [15], [10], [1], and to the references therein.

Even if we do not assume the dislocations to be fixed, our analysis shows that, as $\varepsilon_n \to 0$, the most convenient way to approximate a dislocation μ with multiplicity $z_i \equiv 1$, is the constant sequence $\mu_n \equiv \mu$. In this respect the main point is that there is no homogenization process able to approach an energy less than $1/2\pi \liminf_{\varepsilon_n} |\mu_n(\Omega)|$. The latter term can be interpreted as the quantity usually referred to as *geometrically necessary dislocations*. We conclude that in this energy regime there is no energetic advantage for the crystal to create micropatterns of dislocations.

These considerations become trivial if one assumes a priori a uniform bound for the number of dislocations. However, sequences $\{\mu_n\}$ with uniformly bounded energy (i.e., such that $\mathcal{F}_{\varepsilon_n}(\mu_n) \le C$) are not in general bounded in mass. The main reason is that one can easily construct a *short dipole* $\mu_n := \delta_{x_n} - \delta_{y_n}$, with $|\mu_n|(\Omega) = 2$, $|x_n - y_n| \to 0$, and whose energetic contribution is vanishing. On the other hand, it is clear that the flat norm of these dipoles is also vanishing. This is the reason why we study the Γ-convergence with respect to the flat convergence instead of the weak convergence of measures. We prove that the *equicoercivity* property holds with respect to the flat convergence: sequences μ_n with uniformly bounded energy, up to a subsequence, converge with respect to the flat norm. The proof of this result represents the main difficulty in our analysis.

Our strategy is to divide the dislocations in clusters such that in each cluster the distance between the dislocations is of order ε_n^δ for some $0 < \delta < 1$. The family of clusters with *zero effective multiplicity*, namely, such that the sum of the multiplicities in the cluster is equal to 0, will play the role of short dipoles. Using the estimate $|\mu_n|(\Omega) \le E|\log\varepsilon_n|$, which follows directly from $\mathcal{F}_{\varepsilon_n}(\mu_n) \le E$ and from the second term in (1.1), we deduce that these clusters give a vanishing contribution to the flat norm, of order $|\log\varepsilon_n|^2\varepsilon_n^\delta \to 0$. We identify the remaining clusters (with nonzero effective multiplicity) with Dirac masses, obtaining a sequence of measures $\tilde{\mu}_n := \sum_i z_i\delta_{x_i}$. Assume for a while that $\tilde{\mu}_n$ is uniformly bounded in mass so that (up to a subsequence) $\tilde{\mu}_n$ weakly converges to a measure μ. We prove that $\mu_n - \tilde{\mu}_n$ has vanishing flat norm, and we deduce the convergence of μ_n to μ with respect to the flat norm.

The main point in the previous argument is that $\tilde{\mu}_n$ is uniformly bounded in mass. This will be a consequence of the key Lemma 2.5, where we prove that each cluster with nonzero effective multiplicity gives a positive energetic contribution. It is in this step that we have to prevent the possibility of a homogenization process, able to approach a vanishing energy through a sequence μ_n with nonzero geometrically necessary dislocations. This analysis will be performed through an iterative process, which will require the introduction of several meso-scales. The choice of the number of meso-scales involved in this analysis as $\varepsilon_n \to 0$ will play a fundamental role in our proof.

The last part of this paper is devoted to a purely discrete model. We consider the illustrative case of a *square lattice* of size ε with *nearest-neighbor interactions*, following along the lines of the more general theory introduced in [2].

In this framework a displacement u is a function defined on the set Ω^0_ε of points of the lattice; the strains β are defined on the bonds of the lattice, i.e., on the class Ω^1_ε of the oriented segments of the square lattice. Finally a dislocation is represented by an integer function α defined on the class Ω^2_ε of the oriented squares of the lattice.

The class of admissible strains associated with a dislocation α is given by the strains $\xi : \Omega^1_\varepsilon \to \mathbb{R}$ satisfying

$$\mathbf{d}\,\xi = \alpha, \tag{1.3}$$

where the operator $\mathbf{d}$ is defined in (3.3). The condition expressed in (1.3) means that, for every $Q \in \Omega^2_\varepsilon$, the discrete circulation of ξ on ∂Q is equal to $\alpha(Q)$. The rescaled elastic energy induced by α is given by

$$\mathcal{F}^d_\varepsilon(\alpha) := \frac{1}{|\log \varepsilon|} \min_{\xi:\Omega^1_\varepsilon \to \mathbb{R}:\, \mathbf{d}\,\xi = \alpha} E^d_\varepsilon(\xi), \tag{1.4}$$

where the discrete elastic energy $E^d_\varepsilon(\xi)$ is defined in (3.2).

Every dislocation $\alpha : \Omega^2_\varepsilon \to \mathbb{Z}$ is induced by a function $\beta : \Omega^1_\varepsilon \to \mathbb{Z}$ defined on the bonds of the lattice such that $\mathbf{d}\,\beta = \alpha$. The class of admissible strains can then be written in the equivalent form

$$\{\beta + \mathbf{d}\,u,\ u : \Omega^0_\varepsilon \to \mathbb{R}\},$$

where $\mathbf{d}\,u : \Omega^1_\varepsilon \to \mathbb{R}$ is now the discrete gradient of u defined in (3.1). In this respect β can be interpreted as a discrete eigenstrain inducing the dislocation α. If $\alpha = \mathbf{d}\,\beta = 0$, then β is a compatible strain, i.e, $\beta = \mathbf{d}\,v$ for some displacement v, and the associated stored energy is equal to 0. Therefore α measures the degree of incompatibility of the eigenstrain β.

In Theorem 3.4 we restate our Γ-convergence result given in Theorem 2.4 in this discrete setting. The proof can be obtained as an immediate consequence of the results achieved in the continuum model, introducing an interpolation procedure with suitable commutative properties with respect to the chains $u \xrightarrow{\mathbf{d}} \xi \xrightarrow{\mathbf{d}} \alpha$ and $u \xrightarrow{\nabla} \psi \xrightarrow{\mathrm{curl}} \mu$ (see Proposition 3.3).

In the discrete model the behavior of the elastic stored energy is controlled by the lattice size ε, and it is not necessary (see Remark 3.2) to introduce a supplementary internal scale, as the core radius in the continuum case, to divide the stored elastic energy into two contributions, one concentrated in a region surrounding the dislocations and the other one far away. In this respect the discrete model seems very natural and provides a theoretical justification of the continuum model.

2. The continuum model. Here we introduce our continuum model for vertical screw dislocations in an infinite cylindrical crystal, in the setting of antiplanar elasticty. We will study, in terms of Γ-convergence, the asymptotic behavior of the elastic stored energy in the crystal induced by the screw dislocations as the atomic internal scale ε tends to 0. For the definition and the basic properties of Γ-convergence, we refer the reader to [5].

2.1. Description of the continuum model. In this section we introduce the space of *screw dislocations* X and the elastic energy functionals $\mathcal{E}_\varepsilon : X \to \mathbb{R}$. We are in the setting of antiplanar elasticty, so that the physical quantities involved in the model will be defined on an horizontal section $\Omega \subset \mathbb{R}^2$ of the infinite cylindrical crystal.

2.1.1. The space X of screw dislocations. Let Ω be an open bounded subset of $\mathbb{R}^2$. For any $x \in \Omega$ we denote by δ_x the Dirac mass centered at x. Let us denote by $\mathcal{M}(\Omega)$ the class of Radon measures on Ω. The space of screw dislocations X is given by

$$X := \left\{ \mu \in \mathcal{M}(\Omega) : \mu = \sum_{i=1}^{M} z_i \delta_{x_i},\ M \in \mathbb{N},\ x_i \in \Omega,\ z_i \in \mathbb{Z} \right\}. \tag{2.1}$$

The support set of μ defined by $\mathrm{supp}(\mu) := \{x_1, \dots, x_M\}$ represents the set where the dislocations are present, while the leading coefficients z_i in (2.1) are the *multiplicities* of the dislocations at the points x_i's. We endow X with the *flat norm* [4] $\|\mu\|_f$ defined by

$$\|\mu\|_f = \inf\{|S|,\ S \in \mathcal{S} : \partial S \llcorner \Omega = \mu\} \qquad \text{for every } \mu \in X. \tag{2.2}$$

Here $\mathcal{S}$ denotes the family of the finite formal sum of oriented segments L_i in $\overline{\Omega}$, with extreme points p_i and q_i and with integer multiplicity m_i; the mass of $S = \sum_{i=1}^{M} m_i L_i$ is given by

$$|S| := \sum_{i=1}^{M} |m_i||L_i| = \sum_{i=1}^{M} |m_i||q_i - p_i|,$$

and ∂S is defined by

$$\partial S := \sum m_i (\delta_{q_i} - \delta_{p_i}). \tag{2.3}$$

We will denote by $\mu_n \xrightarrow{f} \mu$ the convergence of μ_n to μ with respect to the flat norm.

Remark 2.1. Note that for every $\mu \in X$ we can find $S \in \mathcal{S}$ such that $\partial S \llcorner \Omega = \mu$. By linearity it is enough to consider the case $\mu = \delta_x$ for some $x \in \Omega$. Let $y \in \partial\Omega$ be the point of minimal distance from x, and let S be the segment joining y to x. Clearly we have $S \in \mathcal{S}$, $\partial S = \delta_x - \delta_y$ so that $\partial S \llcorner \Omega = \delta_x$. Moreover $\|\delta_x\|_f = |S| = \mathrm{dist}(x, \partial\Omega)$. In fact by definition $\|\mu\|_f \le |S| = \mathrm{dist}(x, \partial\Omega)$. To prove the opposite inequality it is enough to check that (by triangular inequality) any $S \in \mathcal{S}$ with $\partial S = \delta_x$ satisfies $|S| \ge \mathrm{dist}(x, \partial\Omega)$.

[4] Here we are adapting the classical definition of the flat norm to our context of Dirac masses confined in an open bounded set. For the canonical definition of the flat norm and its main properties, we refer the reader to [7], [12].

2.1.2. Admissible strains. Let us fix $\varepsilon > 0$. Given $\mu \in X$, we denote

$$\Omega_\varepsilon(\mu) := \Omega \setminus \bigcup_{x_i \in \operatorname{supp}(\mu)} \overline{B}_\varepsilon(x_i),$$

where $B_\varepsilon(x_i)$ denotes the open ball of center x_i and radius ε.

The class $\mathcal{AS}_\varepsilon(\mu)$ of *admissible strains* associated with μ is given by

$$\text{(2.4)} \quad \mathcal{AS}_\varepsilon(\mu) := \Big\{ \psi \in L^2(\Omega_\varepsilon(\mu); \mathbb{R}^2) : \operatorname{curl} \psi = 0 \text{ in } \Omega_\varepsilon(\mu) \text{ in the sense of distributions, } \int_{\partial A} \psi(s) \cdot \tau(s)\, ds = \mu(A) \text{ for every open set } A \subset \Omega \text{ with } \partial A \text{ smooth and with } \partial A \subset \Omega_\varepsilon(\mu) \Big\}.$$

Here $\tau(s)$ is the oriented tangent vector to ∂A at the point s, and the integrand $\psi(s) \cdot \tau(s)$ is intended in the sense of traces (see Theorem 2, p. 204, of [6]).

Remark 2.2. Let $\psi \in \mathcal{AS}_\varepsilon(\mu)$. By the definition (2.4), we have in particular that the circulation of ψ along ∂A is equal to 0 for every $A \subset \Omega_\varepsilon(\mu)$, which is consistent with $\operatorname{curl} \psi = 0$ in $\Omega_\varepsilon(\mu)$ in the sense of distributions. Note also that to define $\Omega_\varepsilon(\mu)$ we do not require that the balls $B_\varepsilon(x_i)$ are contained in Ω. However, only the balls compactly contained in Ω give a contribution to the circulation of the admissible fields in (2.4).

2.1.3. The elastic energy. The elastic energy associated with a strain $\psi \in \mathcal{AS}_\varepsilon(\mu)$ is given by

$$E_\varepsilon(\psi) := \|\psi(x)\|^2_{L^2(\Omega_\varepsilon(\mu);\mathbb{R}^2)}.$$

The elastic energy functional $\mathcal{E}_\varepsilon : X \to \mathbb{R}$ is defined by

$$\text{(2.5)} \qquad \mathcal{E}_\varepsilon(\mu) := \min_{\psi \in \mathcal{AS}_\varepsilon(\mu)} E_\varepsilon(\psi) + |\mu|(\Omega) \qquad \text{for every } \mu \in X.$$

The first contribution to the total energy represents the elastic energy stored in a region far from the dislocations. The second contribution to the total energy is the *total variation* of μ on Ω and represents the so-called *core energy*, namely, the energy stored in the balls $B_\varepsilon(x_i)$ (see Remarks 2.6 and 3.2 for some comment on the core energy in this model).

Remark 2.3. Note that the minimum problem in (2.5) is well posed. In fact, following the *direct method of calculus of variations*, let ψ_h be a minimizing sequence. We have that $\|\psi_h\|_{L^2(\Omega_\varepsilon(\mu);\mathbb{R}^2)} \le C$ for some positive constant C. Therefore (up to a subsequence) $\psi_h \rightharpoonup \psi$ for some $\psi \in L^2(\Omega_\varepsilon(\mu); \mathbb{R}^2)$. Moreover (see Theorem 2, p. 204, of [6]) we have $\psi \in \mathcal{AS}_\varepsilon(\mu)$. By the fact that the L^2 norm is lower semicontinuous with respect to the weak convergence, we deduce that ψ is a minimum point.

2.2. The Γ-convergence result. In this section we study the asymptotic behavior, as $\varepsilon \to 0$, of the elastic energy functionals $\mathcal{E}_\varepsilon$ defined in (2.5) in terms of Γ-convergence. To this aim let us rescale the functionals $\mathcal{E}_\varepsilon$ setting

$$\text{(2.6)} \qquad \mathcal{F}_\varepsilon := \frac{1}{|\log \varepsilon|} \mathcal{E}_\varepsilon,$$

and let us introduce the candidate Γ-limit $\mathcal{F} : X \to \mathbb{R}$ defined by

$$\mathcal{F}(\mu) := \frac{1}{2\pi}|\mu|(\Omega) \qquad \text{for every } \mu \in X. \tag{2.7}$$

THEOREM 2.4. *The following* Γ*-convergence result holds.*

(i) *Equicoercivity: Let* $\varepsilon_n \to 0$*, and let* $\{\mu_n\}$ *be a sequence in* X *such that* $\mathcal{F}_{\varepsilon_n}(\mu_n) \le E$ *for some positive constant* E *independent of* n*. Then (up to a subsequence)* $\mu_n \xrightarrow{f} \mu$ *for some* $\mu \in X$*.*

(ii) Γ*-convergence: The functionals* $\mathcal{F}_{\varepsilon_n}$ Γ*-converge to* $\mathcal{F}$ *as* $\varepsilon_n \to 0$ *with respect to the flat norm, i.e., the following inequalities hold.*

Γ*-liminf inequality:* $\mathcal{F}(\mu) \le \liminf \mathcal{F}_{\varepsilon_n}(\mu_n)$ *for every* $\mu \in X$*,* $\mu_n \xrightarrow{f} \mu$ *in* X*.*

Γ*-limsup inequality: Given* $\mu \in X$*, there exists* $\{\mu_n\} \subset X$ *with* $\mu_n \xrightarrow{f} \mu$ *such that* $\limsup \mathcal{F}_{\varepsilon_n}(\mu_n) \le \mathcal{F}(\mu)$*.*

2.2.1. Equicoercivity. The proof of the equicoercivity property is quite technical and requires some preliminary result. Before giving the rigorous proof, let us recall the main steps of our strategy.

The first step is to divide the dislocations in clusters of size $r = \varepsilon_n^\delta$ for some $0 < \delta < 1$. To this aim, let us set

$$A_r(\mu_n) := \bigcup_{x \in \operatorname{supp}(\mu_n)} B_r(x). \tag{2.8}$$

Each connected component of $A_r(\mu_n)$ represents a cluster of dislocations. By construction the distance between the dislocations belonging to the same cluster is of the order $r = \varepsilon_n^\delta$. The main point is that the family of clusters of dislocations with zero *effective multiplicity*, i.e., such that the sum of the multiplicities of the dislocations in each of these clusters is equal to 0, gives a vanishing contribution to the flat norm, while the number of the remaining clusters with nonzero effective multiplicity is uniformly bounded. This latter fact is more delicate and will be done in the following key lemma, which states that each cluster with nonzero effective multiplicity gives a positive energetic contribution.

LEMMA 2.5. *Let* $0 < \delta < 1$ *be fixed. Let* $\varepsilon_n \to 0$*, and let* $\{\mu_n\}$ *be a sequence such that* $\mathcal{F}_{\varepsilon_n}(\mu_n) \le E$ *for some positive* E *independent of* n*. Moreover assume that for every* n *there exists a connected component* C_n *of* $A_{\varepsilon_n^\delta}(\mu_n)$ *(defined according to* (2.8)*) with* $C_n \subset \Omega$ *and* $\mu_n(C_n) \ne 0$*. Then*

$$\liminf_n \frac{1}{|\log \varepsilon_n|} \int_{C_n} |\psi_n(x)|^2 \, dx \ge \frac{1}{2\pi}(1-\delta) \quad \textit{for every sequence } \{\psi_n\} \subset \mathcal{AS}_{\varepsilon_n}(\mu_n).$$

Before giving the formal proof of the lemma, let us explain its main ideas. Let C_n be a cluster of dislocations with effective multiplicity equal to $\lambda \ne 0$, and let γ be a closed curve surrounding C_n, which does not intersect any other cluster of dislocations. Then the circulation of every admissible strain $\psi_n \in \mathcal{AS}_{\varepsilon_n}(\mu_n)$ on γ is equal to λ. We get an estimate of the tangential component of ψ_n on γ and, hence, of the L^2 norm of ψ_n on γ. Extending this estimate on an annular neighborhood F_n of the cluster C_n, by means of polar coordinates, we want to obtain an estimate of the elastic energy stored around C_n independently of ε_n. However, the rigorous proof will require some additional effort. The main obstruction to the previous argument is that, in general, F_n may intersect other clusters of dislocations. Our strategy is then to iterate the previous construction in subclusters of C_n. We consider a certain number of exponents $0 < \delta = s_n^0 < s_n^1 < \cdots s_n^{M_n} \leq 1$, where $M_n \to \infty$ as $\varepsilon_n \to 0$. For *almost every scale* s_n^i we find a subcluster of C_n of size $\varepsilon^{s_n^i}$ with nonzero effective multiplicity, surrounded by some annulus F_n^i, such that the sets F_n^i are pairwise disjoint and the elastic energy stored in each F_n^i is of the order $s_n^i - s_n^{i-1}$. We deduce that the elastic energy stored in C_n is at least of the order $1 - \delta$.

The starting point of our analysis is the following estimate, which easily follows by the second term in (2.5) and by (2.6):

$$\sharp\, \mathrm{supp}(\mu_n) \leq E|\log \varepsilon_n| \qquad \text{for every } n \in \mathbb{N}, \tag{2.9}$$

where $\sharp\, \mathrm{supp}(\mu_n)$ denotes the number of elements in $\mathrm{supp}(\mu_n)$.

Proof of Lemma 2.5. Let us divide the proof of the lemma into four steps.

Step 1. In this Step we introduce the exponents $0 < \delta = s_n^0 < s_n^1 < \cdots s_n^{M_n} \leq 1$, and we select the meso-scales $\varepsilon_n^{s_n^i}$ which will be involved in our analysis.

For every n, let us set

$$s_n^i := \delta + \frac{i}{H \log|\log(\varepsilon_n)|} \qquad \text{for every } 0 \leq i \leq M_n,$$

where $H > 0$ is a fixed positive constant and M_n is the integer part of $H(1 - \delta)\log|\log(\varepsilon_n)|$. For every n and for every $0 \leq i \leq M_n$, let us set

$$A_n^i := A_{\varepsilon_n^{s_n^i}}(\mu_n) \cap C_n = \bigcup_{x \in \mathrm{supp}(\mu_n) \cap C_n} B_{\varepsilon_n^{s_n^i}}(x).$$

Let $\mathcal{C}_n^i$ be the family of the connected components $C_n^{i,j}$ of A_n^i with $\mu_n(C_n^{i,j}) \neq 0$. Let us now split the indices $i \in [0, M_n)$ into two families J_n and I_n by setting $i \in J_n$ if every element in $\mathcal{C}_n^i$ contains at least two elements of $\mathcal{C}_n^{i+1}$; $i \in I_n$ otherwise. Let us prove that

$$\liminf_n \frac{\sharp\, I_n}{M_n} = 1 - o(1/H), \tag{2.10}$$

where $\sharp E$ denotes the number of elements of a set E and $o(1/H) \to 0$ as $H \to \infty$. To this aim, note that if $i \in J_n$, then $\sharp\, \mathcal{C}_n^{i+1} \geq 2 \sharp\, \mathcal{C}_n^i$, and hence, using that $\sharp\, \mathcal{C}_n^i$ is nondecreasing with respect to i and recalling that by assumption $\sharp\, \mathcal{C}_n^0 = \sharp\, \{C_n\} = 1$, we have

$$\sharp\, \mathrm{supp}(\mu_n) \geq \sharp\, \mathcal{C}_n^{M_n} \geq 2^{\sharp\, J_n} \sharp\, \mathcal{C}_n^0 = 2^{\sharp\, J_n}.$$

By (2.9) we obtain

$$E|\log \varepsilon_n| \geq \sharp\, \mathrm{supp}(\mu_n) \geq 2^{\sharp\, J_n}.$$

Therefore $\sharp\, J_n \leq C \log|\log(\varepsilon_n)|$ for some positive constant C independent of H. We deduce that

$$\limsup_n \frac{\sharp\, J_n}{M_n} \leq \limsup_n \frac{C \log|\log(\varepsilon_n)|}{H(1-\delta)\log|\log(\varepsilon_n)| - 1} = \frac{C}{H(1-\delta)},$$

which together with $\sharp\, J_n + \sharp\, I_n \equiv M_n$ gives (2.10).

Step 2. In this step we define the annular sets F_n^i.

Let $i \in I_n$. By definition there exists C_n^{i,j_i} in $\mathcal{C}_n^i$ which contains exactly one element $C_n^{i+1,k_{i+1}}$ in $\mathcal{C}_n^{i+1}$. Let $p_n^i \in C_n^{i+1,k_{i+1}}$ be chosen arbitrarily. Let us define

$$R_1^i := E|\log\varepsilon_n|\varepsilon_n^{s_n^{i+1}}, \qquad R_2^i := \frac{1}{2}\varepsilon_n^{s_n^i}.$$

Moreover, for every connected component $C_n^{i+1,l}$ of A_n^{i+1} different from $C_n^{i+1,k_{i+1}}$, let us set

$$r_1^l := \min_{x\in C_n^{i+1,l}} |x-p_n^i| - \varepsilon_n^{s_n^{i+1}}, \qquad r_2^l := \max_{x\in C_n^{i+1,l}} |x-p_n^i| + \varepsilon_n^{s_n^{i+1}}. \tag{2.11}$$

Let us set

$$L_n^i := (R_1^i, R_2^i)\setminus \bigcup_l \overline{(r_1^l, r_2^l)}, \qquad F_n^i := \{x\in\mathbb{R}^2 : |x-p_n^i| \in L_n^i\}. \tag{2.12}$$

The set L_n^i is a finite union of open intervals, and hence it can be written in the form

$$L_n^i = \bigcup_{l=1}^{N_n^i} (\varepsilon_n^{\alpha_{i,n}^l}, \varepsilon_n^{\beta_{i,n}^l}). \tag{2.13}$$

Let us claim the following properties concerning L_n^i and F_n^i.

(a) For every i, n and for every $r \in L_n^i$, we have $\mu_n(B_r(p_n^i)) \neq 0$.

(b) For every n the sets F_n^i are pairwise disjoint.

(c) For every i we have $\sum_{l=1}^{N_n^i} |\alpha_{i,n}^l - \beta_{i,n}^l| = (1+o(1/n))/\big(H\log|\log(\varepsilon_n)|\big)$, where $o(1/n)$ is a function independent of i tending to 0 as $n\to\infty$.

Step 3. Let $\psi_n \in \mathcal{AS}_{\varepsilon_n}(\mu_n)$. Using the claim, we are in position to estimate the L^2 norm of ψ_n on each F_n^i using polar coordinates.

By property (a) and by the fact that ψ_n is an admissible strain (see (2.4)), we have

$$\int_{(0,2\pi)} |\psi_n(r,\theta)| r\,d\theta \geq |\mu_n(B_r(p_n^i))| \geq 1 \qquad \text{for every } r\in L_n^i.$$

Using Jensen's inequality and property (c) above, we deduce the following estimate:

$$\begin{aligned}
\int_{F_n^i} |\psi_n(x)|^2\,dx &= 2\pi \sum_{l=1}^{N_n^i} \int_{(\varepsilon_n^{\alpha_{i,n}^l},\varepsilon_n^{\beta_{i,n}^l})} r\left(\frac{1}{2\pi}\int_{(0,2\pi)} |\psi_n(r,\theta)|^2\,d\theta\right) dr\\
&\geq 2\pi \sum_{l=1}^{N_n^i} \int_{(\varepsilon_n^{\alpha_{i,n}^l},\varepsilon_n^{\beta_{i,n}^l})} r\left(\frac{1}{2\pi}\int_{(0,2\pi)} |\psi_n(r,\theta)|\,d\theta\right)^2 dr \geq \frac{1}{2\pi}\sum_{l=1}^{N_n^i} \int_{(\varepsilon_n^{\alpha_{i,n}^l},\varepsilon_n^{\beta_{i,n}^l})} \frac{1}{r}dr\\
&= \frac{1}{2\pi}\sum_{l=1}^{N_n^i} |\alpha_{i,n}^l - \beta_{i,n}^l||\log\varepsilon_n| = \frac{1}{2\pi}\frac{1+o(1/n)}{H\log|\log(\varepsilon_n)|}|\log\varepsilon_n|.
\end{aligned}$$

Summing the previous inequality over all $i\in I_n$ and dividing by $|\log\varepsilon_n|$, in view of (2.10) and property (b) above, we deduce

$$\begin{aligned}
\liminf_n \frac{1}{|\log\varepsilon_n|}\int_{C_n} |\psi_n(x)|^2\,dx &\geq \liminf_n \frac{1}{|\log\varepsilon_n|}\sum_{i\in I_n}\int_{F_n^i} |\psi_n(x)|^2\,dx\\
&\geq \liminf_n \frac{1}{2\pi}\frac{\sharp I_n(1+o(1/n))}{H\log|\log(\varepsilon_n)|} = \liminf_n \frac{1}{2\pi}\frac{M_n(1-o(1/H))}{H\log|\log(\varepsilon_n)|}.
\end{aligned}$$

Letting $H \to \infty$ and recalling that M_n is the integer part of $H(1-\delta)\log|\log(\varepsilon_n)|$, we obtain

(2.14)
$$\liminf_n \frac{1}{|\log\varepsilon_n|}\int_{C_n}|\psi_n(x)|^2\,dx \geq \liminf_n \frac{1}{2\pi}\frac{H(1-\delta)\log|\log(\varepsilon_n)|-1}{H\log|\log(\varepsilon_n)|} = \frac{1}{2\pi}(1-\delta).$$

Step 4. In order to conclude the proof, we have to prove the claim.

Property (a) follows directly by the construction of the intervals L^i_n. More precisely one can easily check that by construction every cluster of dislocations $C^{i+1,l}_n \in A^{i+1}_n$ intersecting $B_r(p^i_n)$ is actually contained in $B_r(p^i_n)$, and since $i \in I$, then all these clusters except one have zero effective multiplicity.

Let us pass to the proof of property (b). Let i_1, $i_2 \in I_n$, with $i_1 < i_2$. We will use the notation used in the previous constructions, with i replaced by i_1, i_2, respectively. In particular let $p^{i_1}_n \in C^{i_1+1,k_{i_1+1}}_n$, $p^{i_2}_n \in C^{i_2+1,k_{i_2+1}}_n$. We divide the proof into two cases.

In the first case we assume that $p^{i_2}_n \in C^{i_1+1,k_{i_1+1}}_n$. In this case, since $|p^{i_1}_n - p^{i_2}_n| \leq \varepsilon_n^{s^{i_1+1}_n}$, we have

$$R^{i_2}_2(p^{i_2}_n) + |p^{i_1}_n - p^{i_2}_n| = \frac{1}{2}\varepsilon_n^{s^{i_2}_n} + |p^{i_1}_n - p^{i_2}_n| \leq 2\varepsilon_n^{s^{i_1+1}_n} < E|\log\varepsilon_n|\varepsilon_n^{s^{i_1+1}_n} = R^{i_1}_1(p^{i_1}_n),$$

and hence $B_{R^{i_2}_2}(p^{i_2}_n) \subset B_{R^{i_1}_1}(p^{i_1}_n)$ so that $F^{i_1}_n$ and $F^{i_2}_n$ are disjoint.

Let us consider now the case $p^{i_2}_n \notin C^{i_1+1,k_{i_1+1}}_n$. In this case we have $p^{i_2}_n \in C^{i_1+1,l}_n$ for some connected component $C^{i_1+1,l}_n$ of $A^{i_1+1}_n$ different from $C^{i_1+1,k_{i_1+1}}_n$. Therefore by (2.11), (2.12) we deduce that

$$B_{\varepsilon_n^{s^{i_1+1}_n}}(p^{i_2}_n) \cap F^{i_1} = \emptyset.$$

On the other hand

$$R^{i_2}_2 = \frac{1}{2}\varepsilon_n^{s^{i_2}_n} \leq \frac{1}{2}\varepsilon_n^{s^{i_1+1}_n}.$$

We deduce that

$$B_{R^{i_2}_2}(p^{i_2}_n) \cap F^{i_1} = \emptyset.$$

This concludes the proof of (b).

Let us pass to the proof of (c). For every i we have

$$\begin{aligned}|L^i_n| &\geq (R^i_2 - R^i_1) - \tilde{C}|\log\varepsilon_n|\varepsilon_n^{s^{i+1}_n} \geq \frac{1}{2}\varepsilon_n^{s^i_n} - C|\log\varepsilon_n|\varepsilon_n^{s^{i+1}_n} \\ &= \varepsilon_n^{s^i_n}\left(\frac{1}{2} - C|\log\varepsilon_n|\varepsilon_n^{(s^{i+1}_n - s^i_n)}\right),\end{aligned} \tag{2.15}$$

where C is a constant depending only on E. On the other hand, fixing the quantity

$$\sum_{l=1}^{N^i_n}|\varepsilon_n^{\alpha^l_{i,n}} - \varepsilon_n^{\beta^l_{i,n}}|$$

in (2.13) and maximizing $|L^i_n|$ with respect to the position of the indices $\alpha^l_{i,n}$, $\beta^l_{i,n}$, we obtain

$$|L^i_n| \leq \varepsilon_n^{s^i_n}\left(\frac{1}{2} - \varepsilon_n^{\sum_{l=1}^{N^i_n}|\alpha^l_{i,n} - \beta^l_{i,n}|}\right). \tag{2.16}$$

From (2.15) and (2.16) we deduce that

$$\varepsilon_n^{s_n^i}\left(\frac{1}{2}-\varepsilon_n^{\sum_{l=1}^{N_n^i}|\alpha_{i,n}^l-\beta_{i,n}^l|}\right)\geq \varepsilon_n^{s_n^i}\left(\frac{1}{2}-C|\log\varepsilon_n|\varepsilon_n^{(s_n^{i+1}-s_n^i)}\right).$$

Therefore

$$\varepsilon_n^{\sum_{l=1}^{N_n^i}|\alpha_{i,n}^l-\beta_{i,n}^l|}\leq C|\log\varepsilon_n|\varepsilon_n^{(s_n^{i+1}-s_n^i)}=C|\log\varepsilon_n|\varepsilon_n^{\frac{1}{H\log|\log(\varepsilon_n)|}},$$

from which (c) easily follows. □

We are now in a position to prove the equicoercivity. The idea is to identify the clusters of dislocations with nonzero effective multiplicity with Dirac masses, obtaining a sequence of measures $\tilde{\mu}_n := \sum_i z_i\delta_{x_i}$. By Lemma 2.5 we will deduce that $\tilde{\mu}_n$ is uniformly bounded in mass so that (up to a subsequence) $\tilde{\mu}_n$ weakly converges to a measure μ. We prove that $\mu_n - \tilde{\mu}_n$ has a vanishing flat norm, and we deduce the convergence of μ_n to μ with respect to the flat norm.

Proof of the equicoercivity property. Let $0 < S < T < 1$. For every $S < \delta < T$, let us consider the set $A_{\varepsilon_n^\delta}(\mu_n)$ defined as in (2.8). Let us denote by $\mathcal{C}_{\delta,n}$ the family of connected components $C_{\delta,n}^1,\dots,C_{\delta,n}^{M_{\delta,n}}$ of $A_{\varepsilon_n^\delta}(\mu_n)$ which are contained in Ω and satisfy $\mu(C_{\delta,n}^l)\neq 0$. By Lemma 2.5 we deduce that $\sharp\mathcal{C}_{\delta,n}=M_{\delta,n}$ is bounded by a constant M independent of n and δ. For every n, let us consider the finite family of indices

$$I_n := \{t_n^1,\dots,t_n^{M_n}\},\quad S\leq t_n^1<t_n^2<\cdots<t_n^{M_n}\leq T,\quad M_n\leq M,$$

given by the discontinuity points of the function $\delta\to\sharp\mathcal{C}_{\delta,n}$. Up to a subsequence, we have that the set of accumulation points of I_n is of the type

$$I_\infty := \{\delta^1,\dots,\delta^H\},\quad S\leq \delta^1<\delta^2<\cdots<\delta^H\leq T,\quad H\leq M.$$

Let

$$[\delta_1,\delta_2]\subset (S,T)\setminus I_\infty.$$

For n big enough we have that the function $\delta\to\sharp\mathcal{C}_{\delta,n}$ is constant on $[\delta_1,\delta_2]$. Since each element of $\mathcal{C}_{\delta_1,n}$ contains at least one element of $\mathcal{C}_{\delta_2,n}$, we deduce that each element $C_{\delta_1,n}^l\in\mathcal{C}_{\delta_1,n}$ actually contains exactly one element $C_{\delta_2,n}^l\in\mathcal{C}_{\delta_2,n}$.

We want to prove that for every sequence $\{H_n\}\subset\mathcal{C}_{\delta_1,n}$ we have

$$\limsup_n|\mu_n(H_n)|\leq K \tag{2.17}$$

for some positive constant K independent of n.

Let G_n be the only element of $\mathcal{C}_{\delta_2,n}$ contained in H_n. The idea, as in the proof of Lemma 2.5, is to evaluate the elastic energy of every admissible strain $\psi_n\in\mathcal{AS}_{\varepsilon_n}(\mu_n)$ stored in the region between G_n and H_n using polar coordinates. To this aim, let $p_n\in G_n$, and let us define

$$R_1 := E|\log\varepsilon_n|\varepsilon_n^{\delta_2},\qquad R_2:=\varepsilon_n^{\delta_1}.$$

Moreover, for every connected component C_n^l of $A_{\varepsilon_n^{\delta_2}}(\mu_n)$ different from G_n, let us set

$$r_1^l := \min_{x\in C_n^l}|x-p_n|-\varepsilon_n^{\delta_2},\qquad r_2^l := \max_{x\in C_n^l}|x-p_n|+\varepsilon_n^{\delta_2}.$$

Let us set

$$L_n := (R_1, R_2) \setminus \bigcup_l \overline{(r_1^l, r_2^l)}, \qquad F_n := \{x \in \mathbb{R}^2 : |x - p_n| \in L_n\}.$$

The set L_n is a finite union of open intervals, and hence it can be written in the form

$$L_n = \bigcup_{l=1}^{N_n} (\varepsilon_n^{\alpha_n^l}, \varepsilon_n^{\beta_n^l}). \tag{2.18}$$

Arguing as in the proof of properties (a) and (c), in the proof of Lemma 2.5, we deduce that the following properties hold.

(i) For every n and for every $r \in L_n$, we have $\mu_n(B_r(p_n)) = \mu_n(G_n)$.

(ii) $\sum_{l=1}^{N_n} |\alpha_n^l - \beta_n^l| = (1 + o(1/n))(\delta_2 - \delta_1)$, where $o(1/n) \to 0$ as $n \to \infty$.

Let $\psi_n \in \mathcal{AS}_{\varepsilon_n}(\mu_n)$. By the fact that ψ_n is an admissible strain and by property (i), we deduce that

$$\int_{(0,2\pi)} |\psi_n(r,\theta)| r d\theta \geq |\mu(G_n)| \qquad \text{for every } r \in L_n.$$

Using Jensen's inequality and property (ii) above we obtain

$$\begin{aligned}
&\int_{F_n} |\psi_n(x)|^2\, dx = 2\pi \sum_{l=1}^{N_n} \int_{(\varepsilon_n^{\alpha_n^l}, \varepsilon_n^{\beta_n^l})} r \left(\frac{1}{2\pi} \int_{(0,2\pi)} |\psi_n(r,\theta)|^2\, d\theta \right) dr \\
&\geq 2\pi \sum_{l=1}^{N_n} \int_{(\varepsilon_n^{\alpha_n^l}, \varepsilon_n^{\beta_n^l})} r \left(\frac{1}{2\pi} \int_{(0,2\pi)} |\psi_n(r,\theta)|\, d\theta \right)^2 dr \geq \frac{1}{2\pi} |\mu(G_n)|^2 \sum_{l=1}^{N_n} \int_{(\varepsilon_n^{\alpha_n^l}, \varepsilon_n^{\beta_n^l})} \frac{1}{r} dr \\
&= \frac{1}{2\pi} |\mu(G_n)|^2 \sum_{l=1}^{N_n} |\alpha_n^l - \beta_n^l| |\log \varepsilon_n| = \frac{1}{2\pi} |\mu(G_n)|^2 (1 + o(1/n))(\delta_2 - \delta_1) |\log \varepsilon_n|.
\end{aligned}$$

Dividing by $|\log \varepsilon_n|$ in the previous inequality and noticing that $\mu_n(G_n) = \mu_n(H_n)$, we deduce

$$E \geq \limsup_n \mathcal{F}_n(\mu_n) \geq \frac{1}{2\pi}(\delta_2 - \delta_1) \limsup_n (\mu_n(G_n))^2 = \frac{1}{2\pi}(\delta_2 - \delta_1) \limsup_n (\mu_n(H_n))^2, \tag{2.19}$$

and this concludes the proof of (2.17).

Now we construct the sequence $\{S_n\}$ of oriented segments in $\mathcal{S}$ (see (2.2)) of the form $S_n = F_n + N_n$ such that

$$\partial S_n \llcorner \Omega = \mu_n, \quad |\partial F_n| \leq 2MK, \quad |N_n| \to 0, \tag{2.20}$$

which is clearly enough to guarantee the compactness of the sequence μ_n.

To this aim, in every element $H_n^l \in \mathcal{C}_{\delta_1,n}$ fix a point p_n^l, and consider the measure

$$\tilde{\mu}_n := \sum_{l=1}^{\sharp \mathcal{C}_{\delta_1,n}} \mu(H_n^l)\delta_{p_n^l}.$$

We have that $|\tilde{\mu}_n| \le MK$, and hence we can find $F_n \in \mathcal{S}$ satisfying

$$|\partial F_n| \le 2MK, \quad \partial F_n \llcorner \Omega = \tilde{\mu}_n. \tag{2.21}$$

Now let us denote by $\mathcal{I}_n$ the union of the connected components of $A_{\varepsilon_n^{\delta_1}}(\mu_n)$ strictly contained in Ω and by $\mathcal{K}_n$ the union of the connected components of $A_{\varepsilon_n^{\delta_1}}(\mu_n)$ intersecting $\partial\Omega$. We clearly have

$$\operatorname{supp}(\mu_n) \subset \mathcal{I}_n \cup \mathcal{K}_n. \tag{2.22}$$

Moreover by construction $(\mu_n - \tilde{\mu}_n)(I_n^l) = 0$ for every $I_n^l \in \mathcal{I}_n$. Therefore, using that $\sharp \operatorname{supp}(\mu_n) \le E|\log\varepsilon_n|$ and that for every $I_n^l \in \mathcal{I}_n$ we have $\operatorname{diam}(I_n^l) \le E|\log\varepsilon_n|\varepsilon_n^{\delta_i}$, we can easily find $V_n \in \mathcal{S}$ such that

$$\partial V_n = (\mu_n - \tilde{\mu}_n)\llcorner \mathcal{I}_n, \qquad |V_n| \le \operatorname{diam}(I_n^l)\, \sharp \operatorname{supp}(\mu_n) \le \varepsilon_n^{\delta_1} E^2 |\log\varepsilon_n|^2. \tag{2.23}$$

On the other hand, since for every $x \in \operatorname{supp}(\mu_n) \cap \mathcal{K}_n$ we have $d(x,\partial\Omega) \le E|\log\varepsilon_n|\varepsilon_n^{\delta_1}$, we can also find $W_n \in \mathcal{S}$ (joining each $x \in \operatorname{supp}(\mu_n) \cap \mathcal{K}_n$ with a point of $\partial\Omega$) such that

$$\partial W_n \llcorner \Omega = \mu_n \llcorner \mathcal{K}_n, \qquad |W_n| \le \varepsilon_n^{\delta_1} E^2 |\log\varepsilon_n|^2. \tag{2.24}$$

Setting $N_n := V_n + W_n$, by (2.21), (2.22), (2.23), and (2.24) we deduce that (2.20) holds true. ∎

2.2.2. Γ-convergence. Here we prove the Γ-convergence result.

Proof of the Γ*-limsup inequality.* It is enough to prove the Γ-limsup inequality assuming that $|\mu(x)| = 1$ for every $x \in \operatorname{supp}(\mu)$. In fact the class of measures satisfying this assumption is dense in energy, and with respect to the flat convergence in X (more precisely, given $\delta > 0$ and $\tilde{\mu} \in X$), there exists $\mu \in X$ with $\|\mu - \tilde{\mu}\|_f \le \delta$ and $\mathcal{F}(\mu) = \mathcal{F}(\tilde{\mu})$, satisfying $|\mu(x)| = 1$ for every $x \in \operatorname{supp}(\mu)$.

The recovering sequence is given by the constant sequence $\mu_n \equiv \mu$. We have to construct a sequence of admissible strains $\psi_n \in \mathcal{AS}_\varepsilon(\mu)$ satisfying

$$\mathcal{F}(\mu) \ge \limsup \frac{1}{|\log\varepsilon_n|} \int_{\Omega_{\varepsilon_n}(\mu)} |\psi_n|^2. \tag{2.25}$$

To this aim, for every $x_i \in \operatorname{supp}(\mu) \cap \Omega$, we consider the field ψ_{x_i}, which in polar coordinates is defined by

$$\psi_{x_i}(r,\theta) := \frac{1}{2\pi r}\tau_i(r,\theta),$$

where $\tau_i(r,\theta)$ is the unit tangent vector to $\partial B_r(x_i)$ at the point with coordinates (r,θ).

The recovering sequence ψ_n is defined by

$$\psi_n := \sum_{x_i \in \operatorname{supp}(\mu)} \psi_{x_i} \llcorner \Omega_{\varepsilon_n}. \tag{2.26}$$

It can be easily proved that $\psi_n \in \mathcal{AS}_{\varepsilon_n}(\mu_n)$, and

$$\limsup \frac{1}{|\log \varepsilon_n|} \int_{\Omega_{\varepsilon_n}(\mu)} |\psi_n|^2 = \limsup \sum_{x_i \in \operatorname{supp}(\mu)} \frac{1}{|\log \varepsilon_n|} \int_{\Omega_{\varepsilon_n}(\mu)} |\psi_{x_i}|^2 = \mathcal{F}(\mu),$$

and this concludes the proof of (2.25). □

Proof of the Γ*-liminf inequality.* Let $\mu \in X$, and let $\mu_n \xrightarrow{f} \mu$ in X. We can assume that $\liminf \mathcal{F}_n(\mu_n) \le E < \infty$. Let us fix $0 < S < T < 1$, and let us consider the set $A_{\varepsilon_n^T}(\mu_n)$ defined as in (2.8). By Lemma 2.5 we deduce that there exists a finite number of connected component $C_n^1, \dots, C_n^{L_n}$ of $A_{\varepsilon_n^T}(\mu_n)$, with L_n uniformly bounded by a constant M independent of n such that $C_n^l \subset \Omega$ and $\mu_n(C_n^l) \neq 0$. Let us denote by $\sharp_n : (S,T) \to \{1, \dots M\}$ the function that counts the number of connected components of $A_{\varepsilon_n^s}(\mu_n)$ containing at least one C_n^l. For every n, let us consider the finite family of indices

$$I_n := \{t_n^1, \dots, t_n^{M_n}\}, \quad S \le t_n^1 < t_n^2 < \dots < t_n^{M_n} \le T, \quad M_n \le M,$$

given by the discontinuity points of $\sharp_n$. Up to a subsequence, we have that the set of accumulation points of I_n contained in (S,T) is of the type

$$I_\infty := \{\delta^1, \dots, \delta^H\}, \quad S < \delta^1 < \delta^2 < \dots < \delta^H < T, \quad H \le M.$$

Let us set $\delta^0 = S$, $\delta^{H+1} = T$, and for every $0 \le i \le H$ consider intervals (a^i, b^i) with $\delta^i < a^i < b^i < \delta^{i+1}$. For any fixed $\tau > 0$, we can always assume that

$$\sum_i (b^i - a^i) \ge T - S - \tau.$$

For every $s \in (a^i, b^i)$, we have exactly $\sharp_n(b^i)$ connected components $K_n^{s,1}, \dots, K_n^{s,\sharp_n(b^i)}$ of $A_{\varepsilon_n^s}(\mu_n)$ containing at least one C_n^l. For every $1 \le j \le \sharp_n(b^i)$ we arbitrarily fix a point $p_n^{i,j} \in K_n^{b^i,j}$. Let us define

$$R_1^{i,n} := E|\log \varepsilon_n| \varepsilon_n^{b^i}, \qquad R_2^{i,n} := \varepsilon_n^{a^i}.$$

Moreover, for every connected component $C_n^{i,l}$ of $A_{\varepsilon_n^{b^i}}(\mu_n)$ different from $K_n^{b^i,j}$, let us set

$$r_{1,n}^{i,j,l} := \min_{x \in C_n^{i,l}} |x - p_n^{i,j}| - \varepsilon_n^{b_i}, \qquad r_{2,n}^{i,j,l} := \max_{x \in C_n^{i,l}} |x - p_n^{i,j}| + \varepsilon_n^{b_i}.$$

Let us set

$$L_n^{i,j} := (R_1^{i,n}, R_2^{i,n}) \setminus \bigcup_l \overline{(r_{1,n}^{i,j,l}, r_{2,n}^{i,j,l})}, \qquad F_n^{i,j} := \{x \in \mathbb{R}^2 : |x - p_n^{i,j}| \in L_n^{i,j}\}.$$

The sets $L_n^{i,j}$ are a finite union of open intervals, and hence they can be written in the form

$$L_n^{i,j} = \bigcup_{l=1}^{N_n^{i,j}} (\varepsilon_n^{\alpha_n^{i,j,l}}, \varepsilon_n^{\beta_n^{i,j,l}}).$$

Let us denote by $\mathcal{H}_n^i$ the family of sets $F_n^{i,j}$ which are strictly contained in Ω. The following properties concerning $L_n^{i,j}$, $F_n^{i,j}$, and $\mathcal{H}_n^i$ can be readily verified by the reader.

(a) For every i, j, for n big enough, and for every $r \in L_n^{i,j}$, we have $\mu_n(B_r(p_n^{i,j})) \equiv \mu(F_n^{i,j})$.
(b) For n big enough, the sets $F_n^{i,j}$ are pairwise disjoint.
(c) For every i, $\mu_n \llcorner \big(\cup_{F_n^{i,j} \in \mathcal{H}_n^i} F_n^{i,j}\big) \xrightarrow{f} \mu$.
(d) For every i, j, $\sum_{l=1}^{N_n^{i,j}} |\alpha_n^{i,j,l} - \beta_n^{i,j,l}| = (1 + o(1/n))(b^i - a^i)$, where $o(1/n) \to 0$ as $n \to \infty$.

Arguing as in the proof of (2.19) we obtain that, for every $\psi_n \in \mathcal{AS}_{\varepsilon_n}(\mu_n)$ and for every $F_n^{i,j} \in \mathcal{H}_n^i$,

$$\frac{1}{|\log \varepsilon_n|} \int_{F_n^{i,j}} |\psi_n|^2 \, dx \geq \frac{1}{2\pi} \big(\mu_n(F_n^{i,j})\big)^2 (1 + o(1/n))(b^i - a^i).$$

Summing the previous inequality over all $F_n^{i,j} \in \mathcal{H}_n^i$, we obtain

$$\frac{1}{|\log \varepsilon_n|} \sum_{F_n^{i,j} \in \mathcal{H}_n^i} \int_{F_n^{i,j}} |\psi_n|^2 \, dx \geq \frac{1}{2\pi} (1 + o(1/n)) \sum_{F_n^{i,j} \in \mathcal{H}_n^i} |\mu_n(F_n^{i,j})|(b^i - a^i). \tag{2.27}$$

Recalling that the diameter of $F_n^{i,j}$ tends to 0 as $n \to \infty$, by property (c) we easily deduce that, for every fixed i,

$$\liminf_n \sum_{F_n^{i,j} \in \mathcal{H}_n^i} |\mu_n(F_n^{i,j})| \geq |\mu|(\Omega). \tag{2.28}$$

Letting $n \to \infty$ in (2.27) and using (2.28), we obtain

$$\begin{aligned}
\liminf_n \mathcal{F}(\mu_n) &\geq \liminf_n \frac{1}{|\log \varepsilon_n|} \int_{\Omega_{\varepsilon_n}(\mu)} |\psi_n|^2 \, dx \\
&\geq \liminf_n \frac{1}{|\log \varepsilon_n|} \sum_i \sum_{F_n^{i,j} \in \mathcal{H}_n^i} \int_{F_n^{i,j}} |\psi_n|^2 \, dx \\
&\geq \liminf_n \frac{1}{2\pi} \sum_i \sum_{F_n^{i,j} \in \mathcal{H}_n^i} |\mu_n(F_n^{i,j})|(b^i - a^i) \geq (T - S - \tau) \frac{1}{2\pi} |\mu|(\Omega).
\end{aligned}$$

Letting $S \to 0$, $T \to 1$ and $\tau \to 0$, we deduce the Γ-liminf inequality. ◻

Remark 2.6. Let $C, C' > 0$ be fixed positive constants. Here we observe that nothing changes in our Γ-convergence result if in the definition of $\Omega_\varepsilon(\mu)$ we remove balls of radius $C\varepsilon$ instead of ε and if we multiply the second term $|\mu|(\Omega)$ in (2.5) by C'. More precisely given $\mu \in X$, define

$$\Omega_\varepsilon^C(\mu) := \Omega \setminus \bigcup_{x_i \in \operatorname{supp}(\mu)} B_{C\varepsilon}(x_i). \tag{2.29}$$

Define consequently the space of admissible strains $\mathcal{AS}_\varepsilon^C(\mu)$ associated with μ as follows:

(2.30)

$$\begin{aligned}
\mathcal{AS}_\varepsilon^C(\mu) := \bigg\{ \psi \in L^2(\Omega_\varepsilon^C(\mu); \mathbb{R}^2) :\ &\operatorname{curl} \psi = 0 \text{ in } \Omega_\varepsilon^C(\mu) \text{ in the sense of distributions}, \\
&\int_{\partial A} \psi(s) \cdot \tau(s) \, ds = \mu(A) \\
&\text{for every open set } A \subset \Omega \text{ with } \partial A \text{ smooth and with } \partial A \subset \Omega_\varepsilon^C(\mu) \bigg\}.
\end{aligned}$$

Finally let $\mathcal{E}_\varepsilon^{C,C'}(\mu)$ be defined by

$$\mathcal{E}_\varepsilon^{C,C'}(\mu) := \min_{\psi \in \mathcal{AS}_\varepsilon^C(\mu)} \int_{\Omega_\varepsilon^C(\mu)} |\psi(x)|^2 \, dx + C'|\mu|(\Omega), \tag{2.31}$$

and let $\mathcal{F}_\varepsilon^{C,C'} := 1/|\log\varepsilon|\mathcal{E}_\varepsilon^{C,C'}$ be the corresponding rescaled functionals. Then Theorem 2.4 still holds true with $\mathcal{F}_\varepsilon$ replaced by $\mathcal{F}_\varepsilon^{C,C'}$.

In this respect the choice of the core radius and of the core energy does not play an essential role in the asymptotic behavior of the functionals $\mathcal{F}_\varepsilon$ as $\varepsilon \to 0$. This fact also gives a partial justification of the use of linearized elasticity in $\Omega_\varepsilon^C(\mu)$. In fact, the recovering sequence ψ_n given in (2.26) satisfies

$$\|\psi_n\|_{L^\infty(\Omega_{\varepsilon_n}^C(\mu_n);\mathbb{R}^2)} \leq \frac{1}{2\pi C\varepsilon_n} + O(n),$$

where $O(n)$ is uniformly bounded with respect to n. Recalling that the admissible strains should be rescaled by ε_n (because the Burgers vector has to be rescaled by ε_n), we deduce that the modulus of the gradient of the rescaled recovering sequence can be chosen arbitrarily small, choosing C big enough. This is our partial justification of the use of linear elasticity.

3. The discrete model. Here we give a Γ-convergence result in a discrete model for the stored energy associated with a configuration of screw dislocations, as the atomic distance ε tends to 0. The model follows the general theory of eigenstrains (we refer the reader to [13]): a dislocation in the crystal is associated with a preexisting plastic strain in the reference lattice. In the next section we will describe our discrete model, which follows the lines of the more general theory introduced in [2].

3.1. Description of the discrete model. We will consider the illustrative case of a square lattice, with nearest-neighbor interactions. Let $\Omega \subset \mathbb{R}^2$ be a horizontal section of the region occupied by the cylindrical crystal. We will assume for simplicity Ω to be polygonal. In the reference configuration, the lattice of atoms is given by the set

$$\Omega_\varepsilon^0 := \{x \in \varepsilon\mathbb{Z}^2 \cap \overline{\Omega}\}.$$

We denote by Ω_ε^1 the class of *bonds* in Ω, i.e., the class of oriented ε-segments $[x, x+\varepsilon e_i]$, where e_1, e_2 is the canonical basis of $\mathbb{R}^2$ and x, $x+\varepsilon e_i \in \Omega_\varepsilon^0$.

Given a function $u : \Omega_\varepsilon^0 \to \mathbb{R}$, let us introduce the (rescaled) *discrete gradient* of u, $\mathbf{d}\, u : \Omega_\varepsilon^1 \to \mathbb{R}$, defined by

$$\mathbf{d}\, u([x, x+\varepsilon e_i]) := u(x+\varepsilon e_i) - u(x) \qquad \text{for every } [x, x+\varepsilon e_i] \in \Omega_\varepsilon^1. \tag{3.1}$$

Given a strain $\xi : \Omega_\varepsilon^1 \to \mathbb{R}$, the elastic energy associated with ξ is given by

$$E^d(\xi) := \sum_{v \in \Omega_\varepsilon^1} a(v)(\xi(v))^2, \tag{3.2}$$

where the function $a(v) \in \{1/2, 1\}$, introduced only to simplify some interpolation procedure (see property (b) of Proposition 3.3), is defined by

$$a([x, x+\varepsilon e_i]) := \begin{cases} \frac{1}{2} & \text{if } x,\ x+\varepsilon e_i \in \partial\Omega, \\ 1 & \text{otherwise.} \end{cases}$$

The elastic energy associated with a displacement $u:\Omega^0_\varepsilon\to\mathbb{R}$, in absence of dislocations, is given by $E^d(\mathbf{d}\,u)$.

To model the presence of dislocations, following [2] we introduce the class Ω^2_ε of oriented ε-squares $[x,x+\varepsilon e_2,x+\varepsilon e_1+\varepsilon e_2]$ with $x,\ x+\varepsilon e_2,\ x+\varepsilon e_1+\varepsilon e_2, x+\varepsilon e_1\in\Omega^0_\varepsilon$. Given $Q:=[x,x+\varepsilon e_2,x+\varepsilon e_1+\varepsilon e_2]\in\Omega^2_\varepsilon$, let us denote by $\tilde Q\subset\mathbb{R}^2$ the convex envelope of $\{x,x+\varepsilon e_1,x+\varepsilon e_2,x+\varepsilon e_1+\varepsilon e_2\}$. For simplicity we will always assume that $\overline{\Omega}=\cup_{Q_i\in\Omega^2_\varepsilon}\tilde Q_i$.

In this discrete setting, a dislocation is represented by a function $\alpha:\Omega^2_\varepsilon\to\mathbb{Z}$. The squares in the support of α represent the zone where a dislocation is present, while the value of α on these squares represents the multiplicity of the dislocation.

Given $\xi:\Omega^1_\varepsilon\to\mathbb{R}$, the function $\mathbf{d}\,\xi:\Omega^2_\varepsilon\to\mathbb{R}$ is defined by

$$\begin{aligned}(3.3)\quad \mathbf{d}\,\xi([x,x+\varepsilon e_2,x+\varepsilon e_1+\varepsilon e_2]) &:= \xi([x,x+\varepsilon e_2])+\xi([x+\varepsilon e_2,x+\varepsilon e_1+\varepsilon e_2])\\ -\xi([x+\varepsilon e_1,x+\varepsilon e_1+\varepsilon e_2])-\xi([x,x+\varepsilon e_1]) &\qquad \text{for every } [x,x+\varepsilon e_2,x+\varepsilon e_1+\varepsilon e_2]\in\Omega^2_\varepsilon.\end{aligned}$$

The elastic energy associated with a dislocation $\alpha:\Omega^2_\varepsilon\to\mathbb{Z}$ is given by

$$\mathcal{E}^d_\varepsilon(\alpha):=\min_{\xi:\Omega^1_\varepsilon\to\mathbb{R}:\,\mathbf{d}\,\xi=\alpha}E^d_\varepsilon(\xi). \tag{3.4}$$

Remark 3.1. Note that if α is a dipole of the type

$$\alpha(Q):=\begin{cases}-1 & \text{if } Q=[x,x+\varepsilon e_2,x+\varepsilon(e_1+e_2)],\\ +1 & \text{if } Q=[x+\varepsilon z e_1,x+\varepsilon(e_2+ze_1),x+\varepsilon(e_1+e_2+ze_1)],\\ 0 & \text{otherwise}\end{cases}$$

for some $x\in\Omega^0_\varepsilon$, $z\in\mathbb{Z}$, then $\alpha=\mathbf{d}\,\beta$, with β defined by

$$\beta(v):=\begin{cases}1 & \text{if } v=[x+\varepsilon s e_1,x+\varepsilon(se_1+e_2)] \text{ with } s\in\{1,\dots,z\},\\ 0 & \text{otherwise.}\end{cases}$$

Actually for every $\alpha:\Omega^2_\varepsilon\to\mathbb{Z}$ we can find β with $\mathbf{d}\,\beta=\alpha$. By linearity, it is sufficient to check it in the case

$$\alpha(Q):=\begin{cases}1 & \text{if } Q=[x,x+\varepsilon e_1,x+\varepsilon(e_1+e_2)],\\ 0 & \text{otherwise.}\end{cases}$$

We have $\alpha=\mathbf{d}\,\beta$, where

$$\beta(v):=\begin{cases}1 & \text{if } v=[x-\varepsilon s\,e_1,x-\varepsilon s\,e_1+\varepsilon\,e_2] \text{ with } s\in\{0\cup\mathbb{N}\},\\ 0 & \text{otherwise.}\end{cases}$$

Note that there are many β inducing the same α (such that $\mathbf{d}\,\beta=\alpha$). More precisely if $\mathbf{d}\,\beta=\alpha$, then α is induced exactly by

$$\{\beta+\mathbf{d}\,u,\ u:\Omega^0_\varepsilon\to\mathbb{R}\}.$$

This follows by the fact that if $\xi:\Omega^1_\varepsilon\to\mathbb{R}$ is such that $\mathbf{d}\,\xi=0$, then there exists $u:\Omega^0_\varepsilon\to\mathbb{R}$ such that $\xi=\mathbf{d}\,u$ and $\mathbf{d}\,\mathbf{d}\,u(Q)=0$ for every $u:\Omega^0_\varepsilon\to\mathbb{R}$ and for every $Q\in\Omega^2_\varepsilon$.

We deduce that if $d\beta = \alpha$, then

$$\mathcal{E}^d_\varepsilon(\alpha) := \min_{u:\Omega^0_\varepsilon \to \mathbb{R}} E^d_\varepsilon(\mathbf{d}\, u - \beta).$$

Therefore β can be interpreted as an eigenstrain associated with the dislocation α. However, we stress that the energy depends on α and not on the particular choice of the eigenstrain inducing α.

3.2. The Γ-convergence result. To study the asymptotic behavior of the elastic energy functionals $\mathcal{E}^d_\varepsilon$ as $\varepsilon \to 0$ in terms of Γ-convergence, it is convenient to define a common space of configurations of dislocations independent of ε. To this aim, to every dislocation $\alpha : \Omega^2_\varepsilon \to \mathbb{Z}$ we associate the measure

$$\hat{\mu}(\alpha) := \sum_{Q \in \Omega^2_\varepsilon} \alpha(Q)\delta_{x(Q)},$$

where $x(Q)$ denotes the center of Q. Therefore, as in the continuum case, the space of dislocations is the space X defined in (2.1). Moreover we denote by X_ε the subspace of X given by the measures μ such that $\mu = \hat{\mu}(\alpha)$ for some $\alpha \in \Omega^2_\varepsilon$. Finally, given $\mu \in X_\varepsilon$, we will denote by $\tilde{\alpha}(\mu) : \Omega^2_\varepsilon \to \mathbb{Z}$ the (unique) dislocation satisfying $\hat{\mu}(\tilde{\alpha}(\mu)) = \mu$.

The class of discrete admissible strains associated with ε and $\mu \in X_\varepsilon$ is defined by

$$\mathcal{AS}^d_\varepsilon(\mu) := \{\xi : \Omega^1_\varepsilon \to \mathbb{R} : \mathbf{d}\,\xi = \tilde{\alpha}(\mu)\}.$$

The rescaled energy functionals take the form

$$\mathcal{F}^d_\varepsilon(\mu) := \begin{cases} \frac{1}{|\log \varepsilon|}\, \mathcal{E}_\varepsilon(\tilde{\alpha}(\mu)) & \text{if } \mu \in X_\varepsilon, \\ +\infty & \text{in } X \setminus X_\varepsilon. \end{cases} \tag{3.5}$$

Remark 3.2. Here we notice that in the discrete model we do not need to introduce the core energy $|\mu|(\Omega)$ as in the continuum case to obtain an estimate similar to (2.9). The term $|\mu|(\Omega)$, in the continuum model, represents the energy stored in a region surrounding the dislocations, whose diameter is comparable to the atomic distance. This interpretation is fully justified by the following easy computation: Let $\mu \in X_\varepsilon$, let $x \in \text{supp}(\mu)$, and let $Q_\varepsilon(x)$ be the ε-square centered at x. For every admissible strain $\xi \in \mathcal{AS}^d_\varepsilon(\mu)$, we have by definition

$$\sum_{v \in \partial Q_\varepsilon(x)} \xi(v) = \mu(x).$$

We deduce that

$$\sum_{v \in \partial Q_\varepsilon(x)} |\xi(v)|^2 \geq C, \tag{3.6}$$

where C is a constant independent of ε. Therefore, in the discrete model, the energy stored in the bonds near the dislocations turns out to be controlled from below by $|\mu|(\Omega)$. As observed in Remark 2.6, a sharp computation of this energy becomes unnecessary in the continuum model in the study of the asymptotic behavior of the elastic energy as $\varepsilon \to 0$.

By (3.6) we deduce (as in (2.9)) that if $\varepsilon_n \to 0$ and $\{\mu_n\}$ is a sequence in X such that, for every $n \in \mathbb{N}$, $\mathcal{F}^d{}_{\varepsilon_n}(\mu_n) \le E$ for some positive constant E, then

$$\sharp\,\mathrm{supp}(\mu_n) \le CE|\log(\varepsilon_n)| \qquad \text{for every } n \in \mathbb{N}, \tag{3.7}$$

where C is a fixed positive constant independent of ε.

The candidate Γ-limit of the functionals $\mathcal{F}^d_\varepsilon$, as in the continuum case (see (2.7)), is the functional $\mathcal{F} : X \to \mathbb{R}$ defined by

$$\mathcal{F}(\mu) := \frac{1}{2\pi}|\mu|(\Omega) \qquad \text{for every } \mu \in X. \tag{3.8}$$

Now we provide some interpolation procedures which will be used in the proof of the Γ-convergence result. Let $u : \Omega^0_\varepsilon \to \mathbb{R}$. Let us introduce its extension $\tilde{u} : \Omega \to \mathbb{R}$, defined in the following way: We divide every $Q \in \Omega^2_\varepsilon$ (more precisely, every $\tilde{Q}$ with $Q \in \Omega^2_\varepsilon$) into two triangles. In each triangle T, $\tilde{u}$ is the only affine function coinciding with u on the vertices of T. In a similar way, given a function $\xi : \Omega^1_\varepsilon \to \mathbb{R}$ we define $\tilde{\xi} : \Omega \to \mathbb{R}^2$ imposing on each triangle

$$\tilde{\xi} \equiv (\xi(v_1(T)), \xi(v_2(T))), \tag{3.9}$$

where $v_1(T)$ and $v_2(T)$ are the horizontal (parallel to e_1) and the vertical (parallel to e_2) edges of T, respectively. We collect in the following proposition some properties satisfied by the interpolated functions introduced above.

Proposition 3.3. *The following facts hold.*

(a) *For every* $u : \Omega^0_\varepsilon \to \mathbb{R}$, *we have* $\nabla\tilde{u} = \frac{1}{\varepsilon}\widetilde{\mathbf{d}u}$.

(b) *For every* $\xi : \Omega^1_\varepsilon \to \mathbb{R}$, *we have* $E^d(\xi) = \|\tilde{\xi}\|^2_{L^2(\Omega;\mathbb{R}^2)}$.

(c) *The function* $\tilde{\xi}$ *belongs to the class* $\mathcal{AS}^C_\varepsilon(\hat{\mu}(\mathbf{d}\,\xi))$ *defined in* (2.30) *for every* $C \ge 2^{1/2}$.

Now we are in a position to give our Γ-convergence result in this discrete model, for the elastic energy functionals $\mathcal{F}^d_\varepsilon$ as $\varepsilon \to 0$.

Theorem 3.4. *The following* Γ*-convergence result holds.*

(i) *Equicoercivity: Let* $\varepsilon_n \to 0$, *and let* $\{\mu_n\}$ *be a sequence in* X *such that* $\mathcal{F}^d_{\varepsilon_n}(\mu_n) \le E$ *for some positive constant* E *independent of* n. *Then (up to a subsequence)* $\mu_n \xrightarrow{f} \mu$ *for some* $\mu \in X$.

(ii) Γ*-convergence: The functionals* $\mathcal{F}^d_{\varepsilon_n}$ Γ*-converge to* $\mathcal{F}$ *as* $\varepsilon_n \to 0$ *with respect to the flat norm; i.e., the following inequalities hold.*

Γ*-liminf inequality:* $\mathcal{F}(\mu) \le \liminf \mathcal{F}^d_{\varepsilon_n}(\mu_n)$ *for every* $\mu \in X$, $\mu_n \xrightarrow{f} \mu$ *in* X.

Γ*-limsup inequality: Given* $\mu \in X$, *there exists* $\{\mu_n\} \subset X$ *with* $\mu_n \xrightarrow{f} \mu$ *such that* $\limsup \mathcal{F}^d_{\varepsilon_n}(\mu_n) \le \mathcal{F}(\mu)$.

Proof. We begin by proving the equicoercivity property.

Equicoercivity: Let $\xi_n \in \mathcal{AS}^d_{\varepsilon_n}(\mu_n)$ be such that

$$\frac{1}{|\log \varepsilon_n|} E^d_{\varepsilon_n}(\xi_n) \le E + 1.$$

Let $C \ge 2^{1/2}$. By Proposition 3.3 we have that the functions $\tilde{\xi}_n$ introduced in (3.9) are in the class $\mathcal{AS}^C_\varepsilon(\mu_n)$ defined in (2.30). By Proposition 3.3 and by (3.7) we deduce that $\mathcal{F}^{C,1}_{\varepsilon_n}(\mu_n) \le K$ for some positive constant $K > 0$. Therefore by Theorem 2.4 and Remark 2.6 we deduce that the equicoercivity property holds.

Γ-*liminf inequality:* Let $\mu_n \xrightarrow{f} \mu$ in X, and let $\xi_n \in \mathcal{AS}^d_{\varepsilon_n}(\mu_n)$ be such that

$$\liminf \frac{1}{|\log \varepsilon_n|} E^d_{\varepsilon_n}(\xi_n) = \liminf \mathcal{F}^d_{\varepsilon_n}(\mu_n).$$

By Proposition 3.3 we have that $\tilde{\xi}_n \in \mathcal{AS}^C_\varepsilon(\mu_n)$, with $C \geq 1/2$. By the Γ-liminf inequality of Theorem 2.4 and by Remark 2.6, we deduce that for every positive constant $C' > 0$ we have

$$\mathcal{F}(\mu) \leq \liminf \frac{1}{|\log \varepsilon_n|} \left(\int_{\Omega^C_{\varepsilon_n}(\mu_n)} |\tilde{\xi}_n|^2 + C'|\mu_n|(\Omega) \right).$$

By the arbitrariness of C', by Remark 3.2, and by Proposition 3.3 we deduce

$$\mathcal{F}(\mu) \leq \liminf_n \frac{1}{|\log \varepsilon_n|} \int_{\Omega^C_{\varepsilon_n}(\mu_n)} |\tilde{\xi}_n|^2 \leq \liminf_n \frac{1}{|\log \varepsilon_n|} E^d_{\varepsilon_n}(\xi_n) = \liminf_n \mathcal{F}^d_{\varepsilon_n}(\mu_n);$$

i.e., the Γ-liminf inequality holds true.

Γ-*limsup inequality:* It is enough to prove the Γ-limsup inequality assuming that $|\mu(x)| = 1$ for every $x \in \operatorname{supp}(\mu)$. In fact the class of measures satisfying this assumption is dense in energy and with respect to the flat convergence in X.

The recovering sequence is given by the constant sequence $\mu_n \equiv \mu$. We have to construct a sequence of admissible strains $\xi_n \in \mathcal{AS}^d_{\varepsilon_n}(\mu_n)$ satisfying

$$\mathcal{F}(\mu) \geq \limsup \frac{1}{|\log \varepsilon_n|} E^d_{\varepsilon_n}(\xi_n). \tag{3.10}$$

Let us fix $x_i \in \operatorname{supp}(\mu) \cap \Omega$. For every $v := [v_1, v_2] \in \Omega^1_\varepsilon$, let us denote by $T(v)$ the triangle whose vertices are x_i, v_1, and v_2 and, by $\theta_{x_i}(v) \in [0, 2\pi)$, its angle at the point x_i. We consider the field $\xi^n_{x_i} : \Omega^1_\varepsilon \to \mathbb{R}$ defined by

$$\xi^n_{x_i}(v) := \theta_{x_i}(v) o(T) \qquad \text{for every } v \in \Omega^1_{\varepsilon_n},$$

where $o(T) \in \{-1, 1\}$ is equal to 1 if the oriented segments $[x, v_1]$, $[v_1, v_2]$, $[v_2, x]$ induce a clockwise orientation to ∂T; $o(T) = -1$ otherwise.

Let us fix $0 < \delta < 1$. We set

$$A^n_i := \{x \in \Omega : \, |x - x_i| < \varepsilon_n^{1-\delta}\},$$
$$B^n_i := \Omega \setminus \overline{A}^n_i.$$

Let us consider the function $\tilde{\xi}^n_{x_i} : \Omega \to \mathbb{R}^2$ of $\mathbb{R}^n$ defined in (3.9). By construction, for n big enough, $\tilde{\xi}^n_{x_i}$ satisfies the following.

(i) For every $x \in A^n_i$,

$$|\tilde{\xi}^n_{x_i}(x)| \leq \frac{C}{\max\{|x - x_i|, \varepsilon_n\}},$$

where C is a positive constant independent of ε_n.

(ii) For every $x \in B^n_i$,

$$|\tilde{\xi}^n_{x_i}(x)| = \frac{1 + o(\varepsilon_n)}{|x - x_i|},$$

where $o(\varepsilon_n) \to 0$ as $\varepsilon_n \to 0$.

The recovering sequence ξ_n is defined by

$$\xi_n := \sum_i \xi^n_{x_i}.$$

It can be easily proved that $\xi_n \in \mathcal{AS}^d_{\varepsilon_n}(\mu_n)$. By Proposition 3.3 and by properties (i) and (ii) above it follows that

$$\begin{aligned}\lim_{\varepsilon_n \to 0} \frac{1}{|\log \varepsilon_n|} E^d_{\varepsilon_n}(\xi_n) &= \lim_{\varepsilon_n \to 0} \frac{1}{|\log \varepsilon_n|} \|\tilde{\xi}_n\|^2_{L^2(\Omega;\mathbb{R}^2)} \\ &= \frac{1}{2\pi} \sharp \operatorname{supp}(\mu)(1 + o(\delta)) = \mathcal{F}(\mu)(1 + o(\delta)),\end{aligned}$$

where $o(\delta) \to 0$ as $\delta \to 0$, and this concludes the proof of (3.10) and of the Γ-convergence result. $\square$

Acknowledgments. I wish to thank Adriana Garroni, Stefan Müller, and Michael Ortiz for interesting and fruitful discussions.

ANALYSIS OF UNIVARIATE NONSTATIONARY SUBDIVISION SCHEMES WITH APPLICATION TO GAUSSIAN-BASED INTERPOLATORY SCHEMES*

NIRA DYN†, DAVID LEVIN†, AND JUNGHO YOON‡

Abstract. This paper is concerned with nonstationary subdivision schemes. First, we derive new sufficient conditions for C^ν smoothness of such schemes. Next, a new class of interpolatory $2m$-point nonstationary subdivision schemes based on Gaussian interpolation is presented. These schemes are shown to be $C^{L+\mu}$ with $L \in \mathbb{Z}_+$ and $\mu \in (0,1)$, where L is the integer smoothness order of the known $2m$-point Deslauriers–Dubuc interpolatory schemes.

Key words. nonstationary subdivision, radial basis function, Gaussian, asymptotical equivalence, interpolation

1. Introduction.

Subdivision is a powerful tool for the fast construction of smooth curves and surfaces from a set of control points by means of iterative refinements. In this paper, we consider subdivision schemes for curves. A univariate binary uniform stationary subdivision scheme defines recursively new sets of points $P^k = \{p_j^k : j \in \mathbb{Z}\}$ at level $k > 0$ from a given set of control points at level zero $P^0 = \{p_j^0 : j \in \mathbb{Z}\}$, formally, by

$$P^{k+1} = SP^k, \quad k = 0, 1, \ldots.$$

A point of P^k is defined by a finite linear combination of points of P^{k-1} with two different rules,

$$p_j^{k+1} = \sum_{n\in\mathbb{Z}} a_{j-2n} p_n^k, \quad k \in \mathbb{Z}_+,\ j \in \mathbb{Z}.$$

Nonstationary subdivision schemes consist of recursive refinements of an initial sparse sequence with the use of rules that may vary from level to level but are the same everywhere on the same level. Therefore, in the binary case, starting with the control points $P^0 = \{p_n^0 : n \in \mathbb{Z}\}$, we define new sets of points $P^k = \{p_n^k : n \in \mathbb{Z}\}$ generated by the relation

$$p_j^{k+1} = \sum_{n\in\mathbb{Z}} a_{j-2n}^{[k]} p_n^k, \quad k \in \mathbb{Z}_+,\ j \in \mathbb{Z}, \tag{1.1}$$

where the set of coefficients $a^{[k]} := \{a_n^{[k]}\}$ is termed the mask of the rule at level k. We denote this rule by $S_{a^{[k]}}$ and the corresponding nonstationary scheme by $\{S_{a^{[k]}}\}$. It is

common to assume that for each level k, only a finite number of coefficients $a_n^{[k]} \in \mathbb{R}$ are nonzero so that changes in a control point affect only its local neighborhood. This property clearly facilitates the practical implementation of (1.1). A subdivision scheme is said to be stationary when the masks $a_n^{[k]}$ are independent of the levels; then we use the notation $a_n := a_n^{[k]}$. We denote this rule by S_a. Nonstationary subdivision schemes are useful because they can provide design flexibility, and the masks can be adapted to the geometrical configuration of the given data. Nonstationary subdivision schemes are studied in [2, 8, 10, 18], while a general treatment of stationary schemes can be found in [1, 5, 6, 7, 9].

The analysis of a subdivision scheme can be reduced to the case of initial control points in $\mathbb{R}$ since each component of the curve is a scalar function generated by the same subdivision scheme. Therefore, starting with values $f^0 = \{f_n^0 \in \mathbb{R} : n \in \mathbb{Z}\}$, we consider $f^k = \{f_n^k \in \mathbb{R} : n \in \mathbb{Z}\}$ generated by the relation

$$f_j^{k+1} = \sum_{n\in\mathbb{Z}} a_{j-2n}^{[k]} f_n^k, \quad k \in \mathbb{Z}_+. \tag{1.2}$$

DEFINITION 1.1. *A binary subdivision scheme is said to be C^ν if for the initial data $\delta = \{f_n^0 = \delta_{n,0} : n \in \mathbb{Z}\}$ there exists a limit function $\phi_0 \in C^\nu(\mathbb{R})$, $\phi_0 \not\equiv 0$, satisfying*

$$\lim_{k\to\infty} \sup_{n\in\mathbb{Z}} |f_n^k - \phi_0(2^{-k}n)| = 0. \tag{1.3}$$

Natural questions in the analysis of subdivision schemes concern the conditions for convergence and the conditions for the limit functions to be C^ν. In particular, in this study, we are interested in the class of interpolatory subdivision schemes which refine data by inserting values corresponding to intermediate points, using linear combinations of neighboring points. The general form of their refinement rules is as follows:

$$\begin{aligned} f_{2j}^{k+1} &= f_j^k, \\ f_{2j+1}^{k+1} &= \sum_{n\in\mathbb{Z}} a_{2n+1}^{[k]} f_{j-n}^k, \quad j \in \mathbb{Z},\ k \in \mathbb{Z}_+. \end{aligned}$$

Examples of such stationary schemes are the four-point scheme by Dyn, Gregory, and Levin [7] and the Deslauriers–Dubuc schemes [6], where finer level points are determined by local polynomial interpolation of the coarse level points. When the finer level points are determined by $2m$-point interpolation from a space of exponential polynomials, the resulting scheme is nonstationary and has smoothness properties, as in the $2m$-point Deslauriers–Dubuc scheme [10].

An analysis of the smoothness of nonstationary subdivision schemes is discussed in [8]; however, the conditions given in [8] are too strong. Thus, the first objective of this paper is to provide a new tool for the regularity analysis, improving the conditions in [8]. It can be applied to a wide class of nonstationary subdivision schemes, both interpolatory and noninterpolatory. Further, the results can be used directly for the smoothness analysis of nonstationary wavelet systems, which is one of the important issues in wavelet construction. Second, in this paper, we study a new class of nonstationary interpolatory subdivision schemes, where the value at the inserted point is obtained by radial basis function (RBF) interpolation to data at $2m$ points symmetric to the inserted point. Among the many possible RBFs, we employ the Gaussian function $G(x) = e^{-|x|^2/\lambda^2}$ with λ as a shape parameter. We show that the resulting $2m$-point subdivision scheme converges and has the smoothness $C^{L+\mu}$ with $L \in \mathbb{Z}_+$ and $\mu \in (0, 1)$, where L is the integer smoothness order of the $2m$-point Deslauriers–Dubuc scheme. The proof of these results is based on the new sufficient condition for smoothness of nonstationary schemes. Moreover, we will see that the scheme itself has its own advantages in view of approximation.

The paper is organized as follows. In section 2, we present known conditions for the convergence and smoothness of nonstationary schemes and derive new sufficient conditions for the smoothness of such schemes. In section 3, along with the basic setting of RBF interpolation, we present a new family of interpolatory subdivision schemes based on Gaussian interpolation. Next, we show using the results of section 2 that the new $2m$-point schemes have the same integer smoothness as the $2m$-point Deslauriers–Dubuc interpolatory scheme. Finally, in section 4, we illustrate the performance of the new interpolatory schemes by some numerical examples.

2. Sufficient conditions for smoothness of nonstationary schemes. Nonstationary subdivision schemes define recursively values $f^k := \{f_n^k : n \in \mathbb{Z}\}$ by rules depending on the level k, as in (1.2). To simplify the presentation of a subdivision scheme and its analysis, it is convenient to assign to each rule, defined by a mask $a^{[k]} = \{a_n^{[k]}\}$, the Laurent polynomial

$$a^{[k]}(z) := \sum_{n \in \mathbb{Z}} a_n^{[k]} z^n.$$

Assume here that for each level k, supp $(a^{[k]}) \subset [-N, N]$ for some integer $N > 0$. This implies that the Laurent polynomials $a^{[k]}(z)$ have a finite degree.

A stationary subdivision scheme $\{S_a\}$ has the formal relation $f^k = S_a^k f^0$. The limit function of a C^0 stationary scheme is denoted by $S_a^\infty f^0$. In particular, for the given data $\delta = \{\delta_{0,n} : n \in \mathbb{Z}\}$ at level 0, with the Kronecker delta $\delta_{n,0}$, the basic limit function of $\{S_a\}$ is defined by

$$\phi = S_a^\infty \delta.$$

For a nonstationary subdivision scheme $\{S_{a^{[k]}}\}$, we have the formal relation

$$f^k = S_{a^{[k-1]}} \cdots S_{a^{[0]}} f^0.$$

Further, for a convergent scheme $\{S_{a^{[k]}}\}$, its *basic limit function* is the function

$$\phi_0 := \lim_{k \to \infty} S_{a^{[k]}} \cdots S_{a^{[0]}} \delta.$$

It clearly follows from the linearity of (1.2) that for any initial data $f^0 = \{f_n^0 : n \in \mathbb{Z}\} \in \ell^\infty(\mathbb{Z})$, the limit function of $\{S_{a^{[k]}}\}$ can be written as

$$f^\infty = \sum_{n \in \mathbb{Z}} f_n^0 \phi_0(\cdot - n).$$

First we cite a basic result about the smoothness of stationary subdivision schemes.

THEOREM 2.1 (smoothing factors in stationary schemes [5]). *Consider a stationary subdivision scheme $\{S_a\}$ with the Laurent polynomial*

$$a(z) = \frac{1}{2}(1 + z)b(z),$$

where the subdivision scheme $\{S_b\}$ *corresponding to* $b(z)$ *is* C^γ*. Then the scheme* $\{S_a\}$ *is convergent, and its basic limit function* ϕ *is in* $C^{\gamma+1}$*.*

Now, for the analysis of the smoothness of nonstationary schemes, we adopt the notion of asymptotically equivalent schemes [8]: A nonstationary subdivision scheme $\{S_{a^{[k]}}\}$ is *asymptotically equivalent* to a stationary scheme $\{S_a\}$, $\{S_{a^{[k]}}\} \approx \{S_a\}$, if

$$\sum_{k\in\mathbb{Z}_+} \|S_{a^{[k]}} - S_a\|_\infty < \infty, \tag{2.1}$$

where

$$\|S_{a^{[k]}}\|_\infty = \max\left\{\sum_{n\in\mathbb{Z}} |a^{[k]}_{2n}|,\ \sum_{n\in\mathbb{Z}} |a^{[k]}_{1+2n}|\right\}.$$

THEOREM 2.2 (see [8]). *Let* $\{S_a\}$ *be a* C^0 *stationary subdivision scheme, and let* $\{S_{a^{[k]}}\} \approx \{S_a\}$ *with* $\operatorname{supp}(a) = \operatorname{supp}(a^{[k]})$ *for* $k \in \mathbb{Z}_+$*. Then* $\{S_{a^{[k]}}\}$ *is* C^0*, and if*

$$\|S_{a^{[k]}} - S_a\|_\infty \le c2^{-k}, \quad k \in \mathbb{Z}_+,$$

then the basic limit function ϕ_0 *of* $\{S_{a^{[k]}}\}$ *is Hölder continuous with some exponent* $\nu > 0$*.*

An analysis of the smoothness of nonstationary subdivision schemes is also discussed in [8]; however, the conditions given in [8] are too strong. Thus, the purpose of this section is to provide less restrictive sufficient conditions for the smoothness of nonstationary schemes. Specifically, we will show that a factor $(1 + r_k z)$ in the Laurent polynomials $a^{[k]}(z)$ is a smoothing factor if $|1 - r_k| \le c2^{-k}$, while in [8], r_k is required to satisfy the condition

$$r_k = e^{c2^{-k-1}}(1 + \epsilon_k) \quad \text{with} \quad \sum_{k=K}^{\infty} |\epsilon_k| 2^k < \infty.$$

Furthermore, we infer results on the smoothness of an interpolatory nonstationary scheme from the smoothness of a stationary scheme, which is asymptotically equivalent to it.

Let $a(z)$ be the Laurent polynomial associated with a stationary scheme $\{S_a\}$ with the property $a^{(\ell)}(-1) = 0$ for $\ell = 0, \dots, M-1$ and $a^{(M)}(-1) \ne 0$. Accordingly, it can be written as

$$a(z) = \sum_{n\in\mathbb{Z}} a_n z^n = 2^{-M}(1+z)^M b(z) \tag{2.2}$$

with $b(-1) \ne 0$. When a scheme $\{S_{a^{[k]}}\}$ is asymptotically equivalent to $\{S_a\}$, by definition, $|a^{[k]}_n - a_n| = o(1)$ as k tends to ∞. Hence, the Laurent polynomial $a^{[k]}(z)$ associated with $S_{a^{[k]}}$ has M-roots in the neighborhood $z = -1$ in the complex plane, and it can be written in the form of

$$a^{[k]}(z) = b^{[k]}(z) \prod_{n=1}^{M} \frac{1}{2}(1 + r_{k,n} z), \quad b^{[k]}(-1) = c + o(1), \quad c \ne 0, \tag{2.3}$$

with $r_{k,n}$ complex numbers such that $r_{k,n} \to 1$ as k tends to ∞. Moreover, since $a^{(\ell)}(-1) = 0$ for $\ell = 0, \dots, M-1$ (see (2.2)), it is easy to see that $D^\ell a^{[k]}(-1) = o(1)$

as $k \to \infty$, where D^ℓ indicates the differential operator of order ℓ. In this study, we require $D^\ell a^{[k]}(-1)$ to satisfy the following stronger condition.

CONDITION A. *A nonstationary subdivision scheme $\{S_{a^{[k]}}\}$ satisfies this condition if the corresponding Laurent polynomials $\{a^{[k]}(z)\}$ are of the form* (2.3) *and if*

$$|D^\ell a^{[k]}(-1)| \le c2^{-(M-\ell)k}, \quad \ell = 0, \dots, M-1, \quad k \in \mathbb{Z}_+.$$

In what follows, we show that if

$$a^{[k]}(z) = c^{[k]}(z) \prod_{n=1}^{L} \frac{1}{2}(1 + r_{k,n} z)$$

and if $\{S_{c^{[k]}}\}$ is $C^{N+\mu}$ with $N \in \mathbb{Z}_+$ and $\mu \in (0,1)$, then $\{S_{a^{[k]}}\}$ with Laurent polynomials of the form (2.3) satisfying Condition A has the smoothness $C^{N+L+\nu}$ with $\nu \in (0,1)$. First we show that a factor $(1 + r_k z)$ in the Laurent polynomials of a nonstationary scheme with $|1 - r_k| \le c2^{-k}$ is a smoothing factor. For this, we cite the following lemma.

LEMMA 2.3 (see [8]). *Consider a nonstationary subdivision scheme $\{S_{a^{[k]}}\}$ with Laurent polynomials of the form*

$$a^{[k]}(z) = \frac{1}{2}(1 + r_k z) b^{[k]}(z).$$

Let ϕ_a, ϕ_b, and h be the basic limit functions of $\{S_{a^{[k]}}\}$, $\{S_{b^{[k]}}\}$, and $\{S_{1+r_k z}\}$, respectively. Then

$$\phi_a = \int_{\mathbb{R}} \phi_b(\cdot - t) h(t)\, dt.$$

For the following analysis, it is necessary to remark that the basic limit function h of $\{S_{1+r_k z}\}$ is bounded and satisfies the following properties:

$$\text{(2.4)} \qquad \begin{aligned} &\text{(a)}\ \operatorname{supp} h = [0,1), \\ &\text{(b)}\ h\big((j + 2^{-1})2^{-k}\big) = r_k h(j2^{-k}), \quad k \in \mathbb{Z}_+,\ j = 0, \dots, 2^k - 1; \end{aligned}$$

see Example 2 in [8] for the details.

LEMMA 2.4. *Let ϕ_b and h be the basic limit functions of $\{S_{b^{[k]}}\}$ and $\{S_{1+r_k z}\}$, respectively. Suppose that*

$$|1 - r_k| \le c2^{-k}, \quad k \ge K \in \mathbb{Z}_+. \tag{2.5}$$

For each $k \in \mathbb{Z}_+$, define the sequence of functions

$$I_k(x) = \int_{x-1}^{x} \phi_b(t) h_k(x - t)\, dt, \tag{2.6}$$

where

$$h_k(t) = h(j2^{-k}), \quad j2^{-k} \le t < (j+1)2^{-k}, \quad j = 0, \dots, 2^k - 1. \tag{2.7}$$

If ϕ_b is Hölder continuous with some exponent $\nu > 0$, then I_k satisfies the following properties:

(a) *For any $k, \ell \geq K \in \mathbb{Z}_+$ with $\ell > k$,*

$$|I'_\ell(x) - I'_k(x)| \leq c2^{-\nu k}. \tag{2.8}$$

(b) *There exists $\delta_0 > 0$ such that for any $\delta < \delta_0$,*

$$|I'_k(x+\delta) - I'_k(x)| \leq c\delta^\mu, \quad k \geq K \in \mathbb{Z}_+,$$

for some $\mu \in (0,1)$.

Proof. (a) By (2.7), we have

$$I'_k(x) = \sum_{j=0}^{2^k-1} h(j2^{-k})[\phi_b(x - j2^{-k}) - \phi_b(x-(j+1)2^{-k})] \in C(\mathbb{R}), \tag{2.9}$$

and after some calculations, we get

$$\begin{aligned} I'_{k+1}(x) - I'_k(x) = &\sum_{j=0}^{2^k-1} [h((j+2^{-1})2^{-k}) - h(j2^{-k})] \\ &\cdot [\phi_b(x-(j+2^{-1})2^{-k}) - \phi_b(x-(j+1)2^{-k})]. \end{aligned}$$

Here, since ϕ_b is Hölder continuous with exponent $\nu > 0$,

$$|\phi_b(x-(j+2^{-1})2^{-k}) - \phi_b(x-(j+1)2^{-k})| \leq c2^{-\nu k} \tag{2.10}$$

with a constant $c > 0$ independent of j and x. Thus, in view of (2.4), (2.5), and the boundedness of h, we obtain the expression

$$|I'_{k+1}(x) - I'_k(x)| \leq c2^{-\nu k} \sum_{j=0}^{2^k-1} |(r_k - 1)h(j2^{-k})| \leq c'2^{-\nu k}. \tag{2.11}$$

It clearly induces the required result of (a).

(b) For the given Hölder exponent $\nu > 0$ and $\delta > 0$, choose $p = \frac{1}{\nu}$ and an integer $\tau > 0$ such that

$$(2^{-4p})^\tau \leq \delta \leq (2^{-2p})^\tau.$$

Note that from this inequality we can also obtain

$$\delta^{\frac{1}{2p}} \leq 2^{-\tau} \leq \delta^{\frac{1}{4p}}. \tag{2.12}$$

Then, by the triangle inequality,

$$\begin{aligned} I'_k(x+\delta) - I'_k(x)| \leq &|I'_k(x+\delta) - I'_\tau(x+\delta)| \\ &+ |I'_\tau(x+\delta) - I'_\tau(x)| + |I'_\tau(x) - I'_k(x)|. \end{aligned} \tag{2.13}$$

Assuming $k > \tau$, we apply (2.8) and (2.12) to obtain

$$|I'_\tau(x) - I'_k(x)| \leq c2^{-\tau\nu} \leq c\delta^{\frac{\nu}{4p}} \leq c\delta^{\frac{\nu^2}{4}}, \tag{2.14}$$

which estimates the first and last terms on the right-hand side of (2.13). Next, recalling that $\operatorname{supp} h = [0,1)$, the summation in (2.9) can be rewritten as follows (with k replaced by τ):

$$I'_\tau(x) = \sum_{j=0}^{2^\tau} [h(j2^{-\tau}) - h((j-1)2^{-\tau})]\phi_b(x - j2^{-\tau}).$$

Therefore,

$$|I'_\tau(x+\delta) - I'_\tau(x)| \le \sum_{j=0}^{2^\tau} |h(j2^{-\tau}) - h((j-1)2^{-\tau})||\phi_b(x+\delta-j2^{-\tau}) - \phi_b(x-j2^{-\tau})|.$$

Here, h is bounded and ϕ_b is Hölder continuous with exponent $\nu > 0$. Thus, due to (2.12) and the fact that $p = 1/\nu$, we get

$$|I'_\tau(x+\delta) - I'_\tau(x)| \le c2^\tau\delta^\nu \le c2^{-\tau} \le c\delta^{\frac{\nu}{4}}.$$

Finally, combining this bound with (2.13) and (2.14), we conclude that

$$|I'_k(x+\delta) - I'_k(x)| \le c\delta^{\frac{\nu^2}{4}}.$$

Taking $\mu := \frac{\nu^2}{4}$, we finish the proof. □

LEMMA 2.5. *Consider a nonstationary subdivision scheme* $\{S_{a^{[k]}}\}$ *with Laurent polynomials of the form*

$$a^{[k]}(z) = \frac{1}{2}(1 + r_k z)b^{[k]}(z).$$

Suppose that

$$|1 - r_k| \le c2^{-k}, \quad k \ge K \in \mathbb{Z}_+, \tag{2.15}$$

and that the scheme corresponding to $\{S_{b^{[k]}}\}$ *is* $C^{L+\nu}$ *with* $L \in \mathbb{Z}_+$ *and* $\nu \in (0,1)$. *Then* $\{S_{a^{[k]}}\}$ *is* $C^{L+1+\mu}$ *for some* $\mu \in (0,1)$.

Proof. Due to Lemma 2.3, we find that

$$\phi_a = \int_{\mathbb{R}} \phi_b(\cdot - t)h(t)\,dt,$$

where ϕ_a, ϕ_b, and h are the basic limit functions of $\{S_{a^{[k]}}\}$, $\{S_{b^{[k]}}\}$, and $\{S_{1+r_k z}\}$, respectively. Note that h is bounded and $\operatorname{supp}\{h\} = [0,1)$ [8]. It is sufficient to prove the lemma for $\ell = 0$, since

$$D^\ell\phi_a = \int_{\mathbb{R}} D^\ell\phi_b(\cdot - t)h(t)\,dt.$$

To this end, invoking the definition of the function I_k in (2.6), we find that $I_k(x) \to \phi_a(x)$ uniformly as $k \to \infty$. Further, according to Lemma 2.4(a), $\{I'_k\}$ is uniformly convergent, which means that the limit of $\{I'_k\}$ is continuous and that is ϕ'_a. Using this fact, we can conclude from Lemma 2.4(b) that ϕ'_a is Hölder continuous with exponent $\mu > 0$. It completes the proof. □

We now show that Condition A on $\{S_{a^{[k]}}\}$ implies the condition (2.15) for all the factors in the representation (2.3). To prove this we need the following two lemmas. Without loss of generality, we rearrange the set $r_{k,n}$ in (2.3) such that

$$|1-r_{k,n}| = \max\{|1-r_{k,\ell}| : \ell = n,\dots,M\}, \quad n = 1,\dots,M, \tag{2.16}$$

that is, $|1-r_{k,n}| \geq |1-r_{k,n+1}|$. The following lemma shows that if Condition A is satisfied, $|1-r_{k,n}| \leq c2^{-k}$. For this proof, we use the notation

$$\{x_k\} \asymp \{y_k\}$$

for two sequences of nonzero reals if there exist some constants $c_1, c_2 > 0$ such that $c_1 \leq |x_k\, y_k^{-1}| \leq c_2$ for all k.

LEMMA 2.6. *Suppose that Condition A holds for the scheme $\{S_{a^{[k]}}\}$. Then*

$$|1-r_{k,n}| \leq c2^{-k}, \quad k \geq K \in \mathbb{Z}_+. \tag{2.17}$$

Proof. Denote $|1-r_{k,1}| =: \omega_k$. Since $|1-r_{k,n}| \leq \omega_k$ for any $n \leq M$, it is sufficient to show that $\sup_k |2^k\omega_k| \leq c$ for a constant $c > 0$. Now, suppose that $\sup_k |2^k\omega_k| = \infty$, which means that there exists a sequence $\{k_\ell\}$ such that

$$|2^{k_\ell}\omega_{k_\ell}| \leq |2^{k_{\ell+1}}\omega_{k_{\ell+1}}| \to \infty \quad \text{as} \quad k_\ell \to \infty. \tag{2.18}$$

Then, recalling $|1-r_{k,n+1}| \leq |1-r_{k,n}|$, we will derive a contradiction by considering the following two cases.

Case 1. $\{\omega_{k_\ell}\} \asymp \{|1-r_{k_\ell,n}|\}$ for $n = 1,\dots,M$.

In this case, it is clear from (2.3) that $\{a_{k_\ell}(-1)\} \asymp \{\omega_{k_\ell}^M\}$. By Condition A, $|a_{k_\ell}(-1)| \leq c2^{-k_\ell M}$, we get the bound $|2^{k_\ell}\omega_{k_\ell}| \leq c$ for any k_ℓ, in contradiction to (2.18).

Case 2. $\{\omega_{k_\ell}\} \asymp \{|1-r_{k_\ell,n}|\}$ for $n = 1,\dots,s < M$.

That is, there exists a subsequence $\{k_j\} \subset \{k_\ell\}$ such that for any $n > s$, $|1-r_{k_j,n}|\omega_{k_j}^{-1} \to 0$ as $k_j \to \infty$, i.e.,

$$|1-r_{k_j,n}| = o(\omega_{k_j}), \quad n > s. \tag{2.19}$$

Then we use the following lemma.

LEMMA 2.7. *Let*

$$F_{k_j}(z) := \prod_{n=1}^{M} \frac{1}{2}(1+r_{k_j,n}z).$$

Under the condition of Case 2, *we have*

$$\{F_{k_j}^{(M-s)}(-1)\} \asymp \{\omega_{k_j}^s\} \quad \text{and} \quad |F_{k_j}^{(M-s-\ell)}(-1)| = o(\omega_{k_j}^{s+\ell}) \quad \forall \ell > 0.$$

Proof. For the given $s < M$, denote $I_s := \{1,2,\dots,s\}$ and let Λ_s be the collection of all subsets of $\{1,2,\dots,M\} = I_M$ with cardinality s, i.e.,

$$\Lambda_s := \{I \subset I_M \ : \ \#I = s\}.$$

Then,

$$F_{k_j}^{(M-s)}(-1) = \left(\prod_{n\in I_s}(1-r_{k_j,n}) + \sum_{I\in\Lambda_s\setminus I_s}\prod_{n\in I}(1-r_{k_j,n})\right)\left(\frac{1}{2^M}+o(1)\right). \tag{2.20}$$

Since $|1-r_{k_j,n}| \geq |1-r_{k_j,n+1}|$,

$$\left\{\prod_{n\in I_s}|1-r_{k_j,n}|\right\} \asymp \{\omega_{k_j}^s\} \quad \text{and} \quad \prod_{n\in I}|1-r_{k_j,n}| = o(\omega_{k_j}^s).$$

Thus,

$$\{F_{k_j}^{(M-s)}(-1)\} \asymp \{\omega_{k_j}^s\}.$$

In a similar way, we can prove the relation $|F_{k_j}^{(M-s-\ell)}(-1)| = o(\omega_{k_j}^{s+\ell})$ for all $\ell > 0$. ◻

Now, we turn to the proof of Lemma 2.6 in Case 2. It follows from (2.3) that for some suitable constants c_ℓ with $\ell = 0, \ldots, M-s$, we have

$$\begin{aligned}(2.21)\quad a_{k_j}^{(M-s)}(-1) &= \sum_{\ell=0}^{M-s}\binom{2m-s}{\ell} b_{k_j}^{(\ell)}(-1)F_{k_j}^{(M-s-\ell)}(-1)\\ &= b_{k_j}(-1)F_{k_j}^{(M-s)}(-1) + \sum_{\ell=1}^{M-s}\binom{2m-s}{\ell} b_{k_j}^{(\ell)}(-1)F_{k_j}^{(M-s-\ell)}(-1).\end{aligned}$$

Since $b_{k_j}(-1) = c + o(1)$ with a constant $c \neq 0$, identity (2.21) leads to $\{a_{k_j}^{(M-s)}(-1)\} \asymp \{\omega_{k_j}^s\}$ by Lemma 2.7. Also, from Condition A, $|a_{k_j}^{(M-s)}(-1)| \leq c2^{-k_j s}$, yielding $|2^{k_j}\omega_{k_j}| \leq c$ for any k_j, which is a contradiction to (2.18). (Here c is a generic constant.) ◻

We are now ready to provide the main theorem of this section.

THEOREM 2.8 (smoothing factor in nonstationary subdivision schemes). *Consider a nonstationary subdivision scheme $\{S_{a^{[k]}}\}$ satisfying Condition A. If*

$$a^{[k]}(z) = \frac{1}{2}(1+r_k z)c^{[k]}(z), \quad k > K \in \mathbb{Z}_+,$$

where $\{S_{c^{[k]}}\}$ is of compact support and $C^{L+\nu}$ with $L \in \mathbb{Z}_+$ and $\nu \in (0,1)$, then $\{S_{a^{[k]}}\}$ is $C^{L+1+\mu}$ for some $\mu \in (0,1)$.

Proof. From Lemmas 2.6 and 2.5, the proof is immediate. ◻

For interpolatory schemes, we have the stronger result.

THEOREM 2.9. *Let $\{S_{a^{[k]}}\}$ be a nonstationary interpolatory subdivision scheme satisfying Condition A. Assume that $\{S_{a^{[k]}}\}$ is asymptotically equivalent to a stationary subdivision scheme $\{S_a\}$. Then if $\{S_a\}$ is $C^{L+\nu}$ with $L \in \mathbb{Z}_+$ and $\nu \in (0,1)$, $\{S_{a^{[k]}}\}$ is $C^{L+\mu}$ for some $\mu \in (0,1)$.*

Proof. Assume that $\{S_a\}$ is $C^{L+\nu}$. Since S_a is interpolatory, $a(z) = 2^{-L}(1+z)^L c(z)$ with $\{S_c\}$ a C^ν with $\nu \in (0,1)$ [5]. From the fact that $\{S_a\}$ and $\{S_{a^{[k]}}\}$ are asymptotically equivalent, we conclude that $L < M$, and we can write

$$a^{[k]}(z) = \prod_{n=1}^{L}\frac{1}{2}(1+r_{k,n}z)c^{[k]}(z)$$

with $\{S_{c^{[k]}}\}$ asymptotically equivalent to $\{S_c\}$. By [8], the scheme $\{S_{c^{[k]}}\}$ is Hölder continuous with some positive exponent. From Condition A and Lemmas 2.5 and 2.6, we conclude that $\{S_{a^{[k]}}\}$ is $C^{L+\mu}$ with $\mu \in (0,1)$. ◻

In what follows, we use the results of this section to analyze a new family of interpolatory schemes.

3. Subdivision schemes based on Gaussian interpolation and their analysis.

3.1. Construction. Radial basis function (RBF) interpolation is a very strong and convenient tool for interpolation in the multivariate setting [4, 12, 13, 14, 15, 17]. In this section, we apply RBF interpolation in the univariate setting to construct interpolatory subdivision schemes. Given data $(x_j, f(x_j))$, $j = 1, \dots, n$, where $X := \{x_1, \dots, x_N\}$ is a subset of $\mathbb{R}$ and $f : \mathbb{R} \to \mathbb{R}$, we consider interpolants to the data of the form

$$\mathcal{R}_{f,X}(x) := \sum_{n=1}^{N} \alpha_n G(x - x_n), \tag{3.1}$$

where G is the Gaussian function

$$G(x) = e^{-|x|^2/\lambda^2},$$

with λ a parameter (λ can serve as a shape parameter in the resulting subdivision scheme). The coefficients $\alpha_1, \dots, \alpha_N$ are determined by the interpolation condition

$$\mathcal{R}_{f,X}(x_j) = f(x_j), \quad j = 1, \dots, N. \tag{3.2}$$

It is well known [13] that the linear system (3.2) is nonsingular for any choice of X consisting of distinct points. The interpolant $\mathcal{R}_{f,X}$ in (3.1) has a Lagrange-type representation:

$$\mathcal{R}_{f,X}(x) := \sum_{n=1}^{N} u_n(x) f(x_n), \quad u_n(x_\ell) = \delta_{n,\ell}, \tag{3.3}$$

where u_n are the Lagrange functions from the space $G_X := \operatorname{span}\{G(\cdot - x_1), \dots, G(\cdot - x_N)\}$. The coefficients $u_n(x)$, $n = 1, \dots, N$, can be obtained as the solution of the linear system

$$\sum_{n=1}^{N} u_n(x) G(x_n - x_\ell) = G(x - x_\ell), \quad \ell = 1, \dots, N. \tag{3.4}$$

We study interpolatory subdivision schemes based on interpolation at symmetric $2m$-points to the inserted point. By (3.4), and since $G(x) = G(-x)$, the subdivision schemes considered are nonstationary and uniform in the sense that their refinement rules depend on the level of refinement but are the same everywhere on the same level. Let

$$X_{k,j} := \{(j+n)2^{-k} : n = -m+1, \dots, m\},$$

which is the local set of symmetric $2m$-points around $(j + 2^{-1})2^{-k}$. Then, the value f_{2j+1}^{k+1} is defined by the Gaussian-based interpolation to the data $\{(j+n)2^{-k}, f_{j+n}^k) : n = -m+1, \dots, m\}$, denoted by $\mathcal{R}_{k,j}$. Thus,

$$\begin{aligned} f_{2j+1}^{k+1} &= \mathcal{R}_{k,j}(2^{-k}(j + 2^{-1})) \\ &= \sum_{n=-m+1}^{m} u_n^{[k,j]}(2^{-k}(j+2^{-1})) f^k((j+n)2^{-k}) \end{aligned}$$

with the Lagrange function $u_n^{[k,j]}$ as in (3.4). Here and in what follows, we use the notation

$$X_0 := X_{0,0} := \{-m+1, \dots, m\}. \tag{3.5}$$

It is easy to verify from (3.4) that the $u_n^{[k,j]}(2^{-k}(j+2^{-1}))$ with $n \in X_0$ are independent of the location j. Thus, we can define

$$a_{1-2n}^{[k]} := u_n^{[k,j]}(2^{-k}(j+2^{-1})), \quad j \in \mathbb{Z}, \tag{3.6}$$

and the mask at level k of the $2m$-point Gaussian-based interpolatory subdivision scheme by

$$a_{1-2n}^{[k]} := u_n^{[k,0]}(2^{-k-1}), \quad a_{2n}^{[k]} = \delta_{n,0}, \quad n \in X_0,\ k \in \mathbb{Z}_+. \tag{3.7}$$

Note that by construction,

$$\sum_{n \in X_0} a_{1-2n}^{[k]} G((n-\ell)2^{-k}) = G((2^{-1}-\ell)2^{-k}), \quad \ell \in X_0. \tag{3.8}$$

We denote the nonstationary scheme with mask defined in (3.7) by $\{S^G_{a^{[k]}}\}$. To study the convergence and smoothness of $\{S^G_{a^{[k]}}\}$, we use the results of section 2 and compare $\{S^G_{a^{[k]}}\}$ with the $2m$-point Deslauriers–Dubuc interpolatory subdivision scheme, which we denote by $\{S_a\}$.

The $2m$-point Deslauriers–Dubuc interpolatory subdivision scheme defines the values at the inserted point by using polynomial interpolation of degree $2m-1$ through the symmetric $2m$-points. Define the Lagrange polynomials on the set X_0 in (3.5) by

$$L_n(x) = \prod_{\substack{\ell \neq n \\ \ell \in X_0}} \frac{x-\ell}{n-\ell}, \quad n \in X_0. \tag{3.9}$$

It is obvious that $L_n(\ell) = \delta_{n,\ell}$ with $\ell \in X_0$. Then, the mask of the $2m$-point Deslauriers–Dubuc interpolatory subdivision scheme is given by

$$a_{2n} = \delta_{0,n}, \quad a_{1-2n} := L_n(2^{-1}), \quad n \in X_0. \tag{3.10}$$

One should keep in mind that S_a reproduces polynomials of degree $\leq 2m-1$. In particular, for any $k \in \mathbb{Z}_+$,

$$p(2^{-k-1}) = \sum_{n \in X_0} a_{1-2n} p(n2^{-k}), \quad p \in \Pi_{<2m}, \tag{3.11}$$

where $\Pi_{<n}$ stands for the space consisting of all univariate algebraic polynomials of degree less than n.

3.2. Analysis of convergence. The goal of this section is to prove that the $2m$-point Gaussian-based interpolatory subdivision scheme $\{S^G_{a^{[k]}}\}$ is asymptotically equivalent to the $2m$-point Deslauriers–Dubuc interpolatory scheme $\{S_a\}$, which implies that $\{S^G_{a^{[k]}}\}$ is convergent [8].

THEOREM 3.1. *Let $\{a_n^{[k]}\}$ be the mask at level k of $\{S^G_{a^{[k]}}\}$, and let $\{a_n\}$ be the mask of $\{S_a\}$. Then, there exists a constant $c_{2m} > 0$ such that*

$$\max_{n \in \mathbb{Z}} |a_n^{[k]} - a_n| \leq c_{2m} 2^{-2k}, \quad k \geq K \in \mathbb{Z}_+.$$

Proof. Since $a_{2n} = a^{[k]}_{2n} = \delta_{n,0}$, we need to estimate only the difference $a_{1-2n} - a^{[k]}_{1-2n}$. Recall from (3.7) that $a^{[k]}_{1-2n} = u^{[k,0]}_n(2^{-k-1})$, $n \in X_0$, with $u^{[k,0]}_n$ the Lagrange function of the Gaussian-based interpolation on $X_{k,0} = \{\ell 2^{-k} : \ell \in X_0\}$, satisfying

$$u^{[k,0]}_n(2^{-k}\ell) = \delta_{n,\ell}, \quad \ell \in X_0. \tag{3.12}$$

Further, since $u^{[k,0]}_n(x) \in \operatorname{span}\{G(\cdot - \ell 2^{-k}) : \ell \in X_0\}$, there exist constants $\alpha^{[k]}_\ell$, $\ell \in X_0$, such that

$$u_{k,n}(x) := u^{[k,0]}_n(2^{-k}x) = \sum_{\ell \in X_0} \alpha^{[k]}_\ell G(2^{-k}(x-\ell)), \tag{3.13}$$

yielding $u_{k,n}(\ell) = \delta_{n,\ell}$ for any $\ell \in X_0$. Thus, $u_{k,n}(x)$ can be considered as the RBF interpolant to the data $\{\delta_{n,\ell} : \ell \in X_0\}$ on X_0 by $G(2^{-k}\cdot)$. On the other hand, the mask of Deslauriers–Dubuc scheme is given by $a_{1-2n} = L_n(2^{-1})$, where the function $L_n(x)$ is also a polynomial interpolant to the data $\{\delta_{n,\ell} : \ell \in X_0\}$ on X_0, which means

$$u_{k,n}(\ell) = L_n(\ell) = \delta_{n,\ell}, \quad \ell \in X_0.$$

Recently, it was proved in [16] that the Gaussian interpolant of the form $u_{k,n}(x)$ converges uniformly to the polynomial interpolant $L_n(x)$ as $k \to \infty$, with the convergence rate $O(2^{-2k})$. In particular,

$$|u_{k,n}(2^{-1}) - L_n(2^{-1})| = O(2^{-2k}).$$

Thus, since $a^{[k]}_{1-2n} = u_{k,n}(2^{-1})$ and $a_{1-2n} = L_n(2^{-1})$, we arrive at the required conclusion. □

COROLLARY 3.2. *The scheme $\{S^G_{a^{[k]}}\}$ is convergent and is C^0.*

3.3. Analysis of smoothness. First, we give a simple proof of C^1 smoothness based on a result from [8].

Result A. The scheme $\{S_{a^{[k]}}\}$ is in C^γ if a scheme $\{S_a\}$ is in C^γ and

$$\sum_{k \in \mathbb{Z}_+} 2^{\gamma k} \|S_a - S_{a^{[k]}}\|_\infty < \infty. \tag{3.14}$$

THEOREM 3.3. *Let $\{S^G_{a^{[k]}}\}$ be the $2m$-point Gaussian-based interpolatory subdivision scheme. Then, if $m \geq 2$, $\{S^G_{a^{[k]}}\}$ is at least C^1.*

Proof. Let S_a be the $2m$-point Deslauriers–Dubuc interpolatory scheme; it is clear from Theorem 3.1 that

$$\sum_{k \in \mathbb{Z}_+} 2^k \|S_a - S^G_{a^{[k]}}\|_\infty < \infty.$$

Since S_a is at least C^1 for $m \geq 2$, the C^1 smoothness of $\{S^G_{a^{[k]}}\}$ is an immediate consequence of Result A. □

Next, we show that if the $2m$-point Deslauriers–Dubuc interpolatory scheme $\{S_a\}$ is $C^{L+\nu}$ with $L \in \mathbb{Z}_+$ and $\nu \in (0,1)$, then the nonstationary $2m$-point Gaussian-based interpolatory subdivision scheme $\{S^G_{a^{[k]}}\}$ is $C^{L+\mu}$ for some $\mu \in (0,1)$. It implies that both $2m$-point schemes have the same integer smoothness as the $2m$-point Deslauriers–Dubuc interpolatory scheme. This is proved by Theorem 2.9 and by verifying first that $\{S^G_{a^{[k]}}\}$ satisfies Condition A of section 2. Our proof relies on the following property of the Gaussian function [11]:

$$\det\big(G^{(\ell+n)}(0)\big) \neq 0, \quad \ell, n = 0, \ldots, 2m-1, \tag{3.15}$$

and on the three auxiliary lemmas.

LEMMA 3.4. *Let $T_{G^{(\ell)}}$ be the Taylor polynomial of $G^{(\ell)}$ of degree $2m-1$ around zero, i.e.,*

$$T_{G^{(\ell)}}(x) := \sum_{n=0}^{2m-1} \frac{x^n}{n!}\, G^{(\ell+n)}(0). \tag{3.16}$$

Then, $T_{G^{(\ell)}}$, $\ell = 0, \ldots, 2m-1$, are linearly independent.

Proof. It is sufficient to prove that for any distinct points $t_0, \ldots, t_{2m-1}$, the $2m \times 2m$ matrix $\mathbf{T}$ with entries

$$\mathbf{T}(\ell, n) = T_{G^{(\ell)}}(t_n), \quad \ell, n = 0, \ldots, 2m-1,$$

is nonsingular. We see that the matrix $\mathbf{T}$ can be decomposed as

$$\mathbf{T} = \mathbf{B} \cdot \mathbf{V},$$

where

$$\mathbf{B}(\ell, n) = G^{(\ell+n)}(0) \quad \text{and} \quad \mathbf{V}(\ell, n) = t_n^\ell / \ell!.$$

Since both matrices $\mathbf{B}$ and $\mathbf{V}$ are invertible, the nonsingularity of $\mathbf{T}$ is immediate. $\square$

To prove the next lemma, we recall that the $(n-1)$th order *divided difference* of a function $f \in C^{n-1}$ at the points $(-m+1), \ldots, (-m+n)$ is given by

$$(n-1)!f[-m+1, \ldots, -m+n] = \sum_{\alpha=1}^{n-1} c_{n,\alpha} f(-m+\alpha) = f^{(n-1)}(\xi) \tag{3.17}$$

with $\xi \in [-m+1, -m+n]$, and where

$$c_{n,\alpha} := (n-1)! \prod_{\substack{j \neq \alpha \\ j=1}}^{n} \frac{1}{\alpha - j}, \quad \alpha = 1, \ldots, n. \tag{3.18}$$

LEMMA 3.5. *Let $\mathbf{P}_k$ be the $2m \times 2m$ matrix with entries*

$$\mathbf{P}_k(\ell, n) := \mathbf{P}_{k,x}(\ell, n) := G^{(\ell)}(x - (n-m+1)2^{-k}), \tag{3.19}$$

where $\ell, n = 0, \ldots, 2m-1$. Then there exist $\eta > 0$ and $K \in \mathbb{Z}_+$ such that for any $x \in [-\eta, \eta]$,

$$\det \mathbf{P}_k = O(2^{-km(2m-1)}) \quad \textit{and} \quad \|\mathbf{P}_k^{-1}\|_\infty = O(2^{(2m-1)k}), \quad k \geq K.$$

Here $\|\mathbf{A}\|_\infty$ indicates the ∞-norm of the matrix $\mathbf{A}$.

Proof. Denote by $\mathbf{p}_n$, $n = 1, \ldots, 2m$, the column vectors of the matrix $\mathbf{P}_k$. Since the determinant of a matrix is invariant under elementary column operations, we perform the following column operations:

$$\mathbf{p}'_n := \mathbf{p}_n + \sum_{\alpha=1}^{n-1} c_{n,\alpha}\mathbf{p}_\alpha, \quad n = 2m, 2m-1, \ldots, 1,$$

with $c_{n,\alpha}$ defined as in (3.17). Defining $\mathbf{P}'_k$ to be the matrix with columns $(\mathbf{p}'_1, \ldots, \mathbf{p}'_{2m})$, we observe that $\det(\mathbf{P}_k) = \det(\mathbf{P}'_k)$. Further, applying (3.17), we get

$$\mathbf{P}'_k(\ell, n) = 2^{-nk} G^{(\ell+n)}(x - \xi_{\ell,n}2^{-k}), \tag{3.20}$$

with $0 \le \ell, n \le 2m-1$, and $\xi_{\ell,n} \in [-m+1, -m+1+n]$. Thus, from (3.15), we can deduce that there exist $\eta > 0$ and $K \in \mathbb{Z}_+$ such that $\det \mathbf{P}_k = O(2^{-km(2m-1)}) \neq 0$ for any $x \in [-\eta, \eta]$ and $k \ge K$. Further, a direct calculation from (3.20) easily leads to the estimate $\|\mathbf{P}_k^{-1}\|_\infty = O(2^{(2m-1)k})$ as $k \to \infty$. ∎

For any $\beta = 0, \ldots, 2m-1$, define the function

$$\Phi_{k,\beta}(x) := \sum_{n \in X_0} g_\beta^{[k]}(n) G(x - 2^{-k}n) \tag{3.21}$$

so that the coefficient vector $\mathbf{g}_\beta^{[k]} := (g_\beta^{[k]}(n) : n \in X_0)$ is obtained by solving the linear system

$$\Phi_{k,\beta}^{(\ell)}(2^{-k-1}) = \delta_{\beta,\ell}(-1)^\ell \ell! \tag{3.22}$$

which can be written in the matrix form

$$\mathbf{P}_k \cdot \mathbf{g}_\beta^{[k]} = \mathbf{c},$$

where $\mathbf{P}_k = \mathbf{P}_{k,2^{-k-1}}$ with $\mathbf{P}_{k,x}$ as defined in (3.19) and $\mathbf{c}(\ell) := \delta_{\beta,\ell}(-1)^\ell \ell!$ with $\ell = 0, \ldots, 2m-1$. The following estimates are central to the proof that $\{S_{a^{[k]}}^G\}$ satisfies Condition A.

LEMMA 3.6. *For all* $\beta = 0, \ldots, 2m-1$,

$$\begin{aligned} &\text{(i) } \|\mathbf{g}_\beta\|_\infty = O(2^{k(2m-1)}) \quad \textit{as} \quad k \to \infty, \\ &\text{(ii) } |\Phi_{k,\beta}^{(\ell)}(2^{-k-1})| \le c, \quad \ell = 2m, \ldots, 4m-2. \end{aligned} \tag{3.23}$$

Proof. Since $\mathbf{g}_\beta^{[k]} = \mathbf{P}_k^{-1} \cdot \mathbf{c}$, the estimate $\|\mathbf{g}_\beta^{[k]}\|_\infty = O(2^{k(2m-1)})$ follows immediately from Lemma 3.5. Next, recall that $T_{G^{(\ell)}}$ indicates the Taylor polynomial of degree $2m-1$ of $G^{(\ell)}$ around zero with $\ell = 2m, \ldots, 4m-2$. By Lemma 3.4, there exist some suitable constants $\gamma_{\ell,0}, \ldots, \gamma_{\ell,2m-1}$ such that $T_{G^{(\ell)}} =: \sum_{\alpha=0}^{2m-1} \gamma_{\ell,\alpha} T_{G^{(\alpha)}}$. Thus, we get from (3.21),

$$\begin{aligned} \Phi_{k,\beta}^{(\ell)}(2^{-k-1}) &= \sum_{n \in X_0} g_\beta^{[k]}(n) G^{(\ell)}(2^{-k-1} - n2^{-k}) \\ &= \sum_{n \in X_0} g_\beta^{[k]}(n) \big(T_{G^{(\ell)}}(2^{-k-1} - n2^{-k}) + O(2^{-2mk})\big) \\ &= \sum_{\alpha=0}^{2m-1} \gamma_{\ell,\alpha} \sum_{n \in X_0} g_\beta^{[k]}(n) \big[T_{G^{(\alpha)}}(2^{-k-1} - n2^{-k}) + O(2^{-2mk})\big]. \end{aligned}$$

Note that

$$T_{G^{(\alpha)}}(2^{-k-1} - n2^{-k}) = G^{(\alpha)}(2^{-k-1} - n2^{-k}) + O(2^{-2mk}), \quad \alpha = 0, \dots, 2m-1.$$

Applying this identity to (3.21), we get, in view of (3.23),

$$\begin{aligned}\left|\sum_{n\in X_0} g_\beta^{[k]}(n) T_{G^{(\ell)}},(2^{-k-1} - n2^{-k})\right| &\le \left|\Phi_{k,\beta}^{(\ell)}(2^{-k-1})\right| + O(2^{-k}) \\ &\le \ell! + O(2^{-k}),\end{aligned}$$

as a consequence of (3.22). Also, by (i), the property $|\Phi_{k,\beta}^{(\ell)}(2^{-k-1})| \le c$ for $\ell = 2m, \dots, 4m-2$ is obvious. ∎

Now, we are ready to prove that $\{S^G_{a^{[k]}}\}$ satisfies Condition A with $M = 2m$.

THEOREM 3.7. *Let $a^{[k]}(z) = \sum_{n\in\mathbb{Z}} a_n^{[k]} z^n$ be the Laurent polynomial at level k associated with $\{S^G_{a^{[k]}}\}$. Then, for any $\beta = 0, \dots, 2m-1$, we have*

$$|D^\beta a^{[k]}(-1)| \le c2^{-k(2m-\beta)}, \quad k \ge K,$$

for some $K \in \mathbb{Z}_+$.

Proof. Since

$$D^\beta a^{[k]}(-1) = \sum_{\ell=0}^{\beta} \gamma_{\beta,\ell} \sum_{n\in\mathbb{Z}} a_n^{[k]} n^\ell (-1)^n$$

for some constants $\gamma_{\beta,\ell}$, $\ell = 0, \dots, \beta$, it is sufficient to prove that for any $\beta = 0, \dots, 2m-1$,

$$s_\beta := \sum_{n\in\mathbb{Z}} (-1)^n n^\beta a_n^{[k]} = O(2^{-k(2m-\beta)}), \quad k \to \infty,$$

in order to conclude Condition A. Recalling that $a_{2n}^{[k]} = \delta_{n,0}$, observe that

$$2^{-\beta(k+1)} s_\beta = \delta_{\beta,0} - \sum_{n\in X_0} a_{1-2n}^{[k]} \big((-n + 2^{-1})2^{-k}\big)^\beta. \tag{3.24}$$

Invoking (3.8) and (3.22), we get

$$\delta_{\beta,0} = \Phi_{k,\beta}(2^{-k-1}) = \sum_{n\in X_0} a_{1-2n}^{[k]} \Phi_{k,\beta}(n2^{-k}). \tag{3.25}$$

This together with (3.24) lead to

$$2^{-\beta(k+1)} s_\beta = \sum_{n\in X_0} a_{1-2n}^{[k]} \bigg(\Phi_{k,\beta}(n2^{-k}) - ((-n + 2^{-1})2^{-k})^\beta\bigg). \tag{3.26}$$

In the following, we replace $\Phi_{k,\beta}(n2^{-k})$ with its Taylor polynomial of degree $4m-2$ plus the remainder term. The Taylor expansion of $\Phi_{k,\beta}$ around 2^{-k-1} of degree $4m-2$ is

$$\Phi_{k,\beta}(n2^{-k}) = \sum_{\ell=0}^{4m-2} \big((n - 2^{-1})2^{-k}\big)^\ell \frac{\Phi_{k,\beta}^{(\ell)}(2^{-k-1})}{\ell!} + R_{k,\beta,m}, \tag{3.27}$$

where the remainder $R_{k,\beta,m}$ is given by

$$R_{\Phi_\beta,4m-1} = \big((n-2^{-1})2^{-k}\big)^{4m-1}\frac{\Phi_{k,\beta}^{(4m-1)}(\xi 2^{-k})}{(4m-1)!}$$

with ξ a point between 2^{-1} and n. Noting that by (3.22)

$$\sum_{\ell=0}^{2m-1}\big((n-2^{-1})2^{-k}\big)^{\ell}\frac{\Phi_{k,\beta}^{(\ell)}(2^{-k-1})}{\ell!} = \Big((-n+2^{-1})2^{-k}\Big)^{\beta},$$

we get from (3.25) and (3.26)

$$2^{-\beta(k+1)}s_\beta = \sum_{n\in X_0} a_{1-2n}^{[k]}\left(\sum_{\ell=2m}^{4m-2}\big((n-2^{-1})2^{-k}\big)^{\ell}\frac{\Phi_{k,\beta}^{(\ell)}(2^{-k-1})}{\ell!} + R_{k,\beta,m}\right).$$

By Lemma 3.6, $|\Phi_{k,\beta}^{(\ell)}(2^{-k-1})| \le c$ for any $\ell = 2m,\dots,4m-2$. Consequently,

$$\left|\sum_{n\in\mathbb{Z}}(-1)^n n^\beta a_n^{[k]}\right| \le c2^{-k(2m-\beta)}\Big(1+2^{-k(2m-1)}\|\Phi_{k,\beta}^{(4m-1)}\|_{L_\infty[-\eta,\eta]}\Big). \tag{3.28}$$

Since $\|\mathbf{g}_\beta\|_\infty = O(2^{k(2m-1)})$ and $G^{(4m-1)}$ is bounded,

$$2^{-k(2m-1)}\|\Phi_\beta^{(4m-1)}\|_{L_\infty[-\eta,\eta]} \le c,$$

which completes the proof of the theorem. ◻

We are now ready to state and prove the main theorem of this section.

THEOREM 3.8. *If the $2m$-point Deslauriers–Dubuc interpolatory scheme $\{S_a\}$ is $C^{L+\nu}$ with $L\in\mathbb{Z}_+$ and $\nu\in(0,1)$, then the nonstationary $2m$-point Gaussian-based interpolatory subdivision scheme $\{S_{a^{[k]}}^G\}$ is $C^{L+\mu}$ for some $\mu\in(0,1)$.*

Proof. Due to Theorem 3.1, both $2m$-point schemes $\{S_{a^{[k]}}^G\}$ and $\{S_a\}$ are asymptotically equivalent. As a consequence of Theorems 3.7 and 2.9, this theorem is immediate. ◻

COROLLARY 3.9. *The nonstationary $2m$-point Gaussian-based interpolatory subdivision scheme has the same integer smoothness as the $2m$-point Deslauriers–Dubuc interpolatory scheme.*

Remark. In this section, the Gaussian function has been used. We believe that the same results can be obtained by using other smooth RBFs such as multiquadrics.

4. Examples. In this section, we illustrate the performance of the 4-point Gaussian-based interpolatory subdivision schemes with some numerical examples. Recall that the Gaussian function is of the form

$$G(x) = e^{-|x|^2/\lambda^2}, \quad \lambda > 0.$$

Here λ serves as a shape parameter. Having tried several alternatives for the parameter λ, we found out that good choices of λ are in the range $0 < \lambda^{-1} \le 1.0$. The solid curves in Figure 4.1 are generated by the 4-point Gaussian-based interpolatory subdivision scheme using the parameter $\lambda^{-1} = .5$. The dotted curves in Figure 4.1 are generated by the 4-point Deslauriers–Dubuc scheme. It is known that the 4-point Deslauriers–Dubuc scheme has the smoothness C^1. Hence, due to Theorem 3.8, the

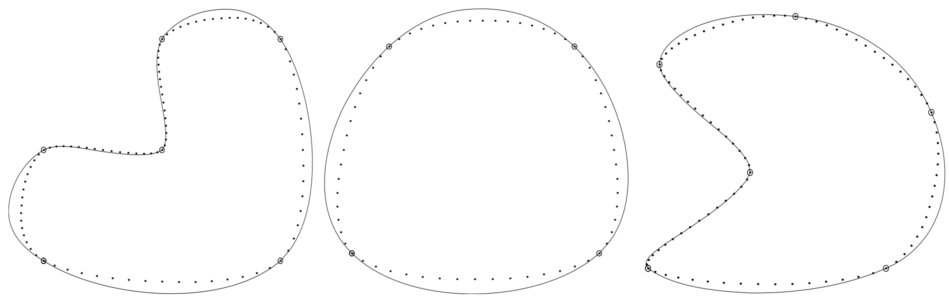

FIG. 4.1. *Interpolating curves generated by the* 4*-point Gaussian-based interpolation with* $\lambda^{-1} =$ .5 *(solid lines) and the* 4*-point DD scheme (dotted lines).*

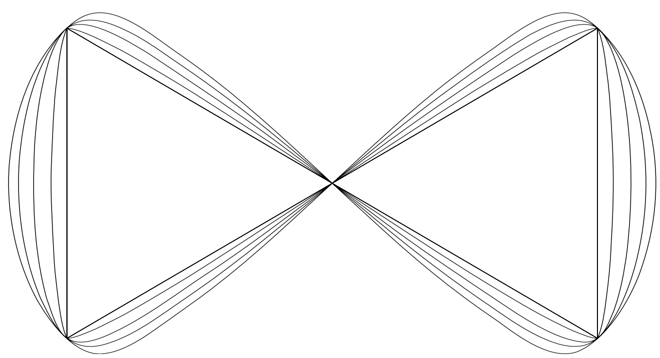

FIG. 4.2. *The effect of the tension parameters in the* 4*-point Gaussian-based scheme and the classical* 4*-point scheme.*

4-point Gaussian-based interpolatory subdivision scheme is also C^1. Also, Figure 4.2 compares the Gaussian-based 4-point scheme to the classical 4-point scheme to the mask $[-\theta, 1/2 + \theta, 1/2 + \theta, -\theta]$. In Figure 4.2, the curves, from the closer to the control polygon and outward, correspond to the values of the tension parameters $\theta = 0.03, 1/16$, and $\lambda^{-1} = 0.5, 0.8$.

In addition, the Gaussian-based schemes have an advantage over polynomial-based schemes, especially in signal processing. The following example shows the superiority of the 4-point Gaussian-based scheme over the 4-point Deslauriers–Dubuc scheme. We approximate oscillatory signals of the form [3]

$$f(t) = \cos(2\pi F t + \beta \sin(2\pi F_s t)).$$

We choose $F = 0.5$, $\beta = 5.75$, $F_s = 0.0062$ and use 311 data samples in the domain $[0, 30]$ as initial data for the subdivision. The solid curve in Figure 4.3 indicates the approximation errors by the 4-point Gaussian-based schemes as a function of λ. The dotted line is the error by the Deslauriers–Dubuc 4-point scheme. We find that by choosing a suitable parameter λ in the Gaussian $g(x) := e^{-x^2/\lambda^2}$ (around $\lambda = 2\pi$ in this example), the 4-point Gaussian-based scheme provides much better accuracy than the polynomial-based 4-point scheme. For this reason, a future project would be to find an algorithm for choosing the appropriate λ for a given signal.

We regard the study of the 4-point Gaussian-based scheme as a first step towards the design and analysis of interpolatory bivariate Gaussian-based nonstationary

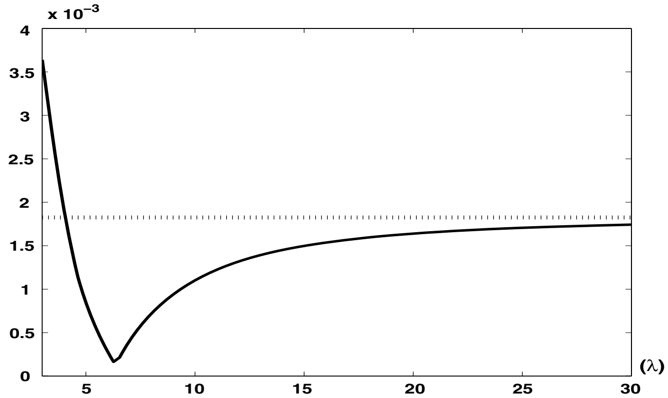

FIG. 4.3. *Approximation errors by the* 4*-point Gaussian-based scheme as a function of* λ*. The dotted line indicates the error by the* 4*-point Deslauriers–Dubuc scheme.*

schemes extending the stationary butterfly scheme. However, this requires much heavier analysis, especially at extraordinary points.

Acknowledgments. We are grateful to the anonymous referees for their helpful suggestions. The third author also would like to thank Tel-Aviv University for its hospitality during his visit as a postdoctoral research associate from October 2000 to July 2001. We also thank Yaron Lipman for suggesting a shorter proof of Lemma 2.4(b).

ELLIPTIC DIFFERENTIAL EQUATIONS WITH COEFFICIENTS MEASURABLE WITH RESPECT TO ONE VARIABLE AND VMO WITH RESPECT TO THE OTHERS*

DOYOON KIM† AND N. V. KRYLOV†

Abstract. We prove the unique solvability of second order elliptic equations in nondivergence form in Sobolev spaces. The coefficients of the second order terms are measurable in one variable and VMO in other variables. From this result, we obtain the weak uniqueness of the Martingale problem associated with the elliptic equations.

Key words. second order equations, vanishing mean oscillation, Martingale problem

1. Introduction.

We study the L_p-theory of the elliptic differential equation

$$a^{jk}(x)u_{x^jx^k}(x) + b^j(x)u_{x^j}(x) + c(x)u(x) = f(x) \quad \text{in} \quad \mathbb{R}^d, \tag{1.1}$$

where $a^{jk}(x)$ are allowed to be only measurable with respect to one coordinate, say $x^1 \in \mathbb{R}$, where $x = (x^1, x') \in \mathbb{R}^d$, $x' \in \mathbb{R}^{d-1}$.

It is well known that if the coefficients a^{jk} are only measurable, then there could not exist a *unique* solution to the above equation even in a very generalized sense (see [11, 13]). We are interested in more regular solutions. In 1967 Ural'tseva (see [7] or the original paper [17]) constructed an example of an equation in $\mathbb{R}^d$ for $d \geq 3$ with the coefficients depending only on the first two coordinates for which there is no unique solvability in W_p^2 with $p \geq d$ (for any $d \geq 3$ and $p \in (1, d)$ this was known before).

Thus in order to have the unique solvability of the equation in W_p^2, we have to impose some (regularity) conditions on the coefficients a^{jk}. The most classical case is when a^{jk} are uniformly continuous. We can also have piecewise continuous or VMO coefficients. For details, see [1, 2, 4, 6, 9, 10].

In this paper, we show that there exists a unique solution to the above equation in W_p^2, $p \in (2, \infty)$, under the assumption that $a^{jk}(x^1, x')$ are measurable in $x^1 \in \mathbb{R}$ and VMO in $x' \in \mathbb{R}^{d-1}$; see Assumptions 2.1 and 2.2. If the coefficients a^{jk} are independent of $x' \in \mathbb{R}^{d-1}$ (more generally, uniformly continuous in $x' \in \mathbb{R}^{d-1}$; see Remark 2.6), then the equation is uniquely solvable in W_2^2 as well. In addition, we show that one can easily solve the equation with the Dirichlet, Neumann, or oblique derivative boundary condition in a half space, say $\mathbb{R}^d_+ = \{(x^1, x') : x^1 > 0, x' \in \mathbb{R}^{d-1}\}$, using the results for equations in the whole space.

The class of coefficients we are dealing with is considerably more general than those previously known, as long as $p \in [2, \infty)$. It actually contains almost all types of discontinuous coefficients that have been investigated so far. For example, it contains

†School of Mathematics, University of Minnesota, 127 Vincent Hall, Minneapolis, MN 55455 (dykim@math.umn.edu, krylov@math.umn.edu).

the class of piecewise continuous coefficients investigated in [4, 8, 9]. It also contains VMO coefficients with which elliptic equations were investigated in [1, 2, 6]; see also the monograph [10], which treats elliptic and parabolic equations with discontinuous coefficients including oblique derivative problems with VMO coefficients. Although we slightly touch on the oblique derivative problem, we do not say anything about many important issues of equations with VMO coefficients, which are discussed, for instance, in [14, 15, 12].

The highlight of our assumptions on the coefficients a^{jk} would be the following: no assumptions on the regularity of the coefficients with respect to one variable as far as they are uniformly bounded and elliptic. Having only measurable coefficients (as functions of $x^1 \in \mathbb{R}$), we obtain the L_2-estimate for the equation by using the usual Fourier transforms. Based upon this estimate, we establish the L_p-estimate, $p \in (2, \infty)$, using the approach initiated by the second author of this paper (for example, see [6]). In this approach we make use of a pointwise estimate of sharp functions of second order derivatives of the solution. As noted in [6], thanks to this method, we do not need any integral representations of the solution nor commutators, which were used, for example, in [1, 2]. Especially, we deal with VMO coefficients in a rather straightforward manner.

One good motivation to consider the above equation in the whole space is to prove weak uniqueness of stochastic processes associated with the elliptic equation. As is shown in [6, 16], we can say that weak uniqueness of the processes holds true once we find a unique solution of the elliptic equation in W^2_p, $p \geq d$. More details are in [6, 16].

The paper is organized as follows. In section 2 we state our main results. The unique solvability of the equation in W^2_2 is investigated in section 3. In section 4, we present some auxiliary results which are used in section 5, where we finally prove the W^2_p-estimate $p \in (2, \infty)$ for the equation.

2. Main results. We are considering the elliptic differential equation (1.1), where the coefficients a^{jk}, b^j, and c satisfy the assumptions below.

ASSUMPTION 2.1. *The coefficients a^{jk}, b^j, and c are measurable functions defined on $\mathbb{R}^d$, $a^{jk} = a^{kj}$. There exist positive constants $\delta \in (0, 1)$ and K such that*

$$|b^j(x)| \leq K, \qquad |c(x)| \leq K,$$

$$\delta|\vartheta|^2 \leq \sum_{j,k=1}^{d} a^{jk}(x)\vartheta^j\vartheta^k \leq \delta^{-1}|\vartheta|^2$$

for any $x \in \mathbb{R}^d$ and $\vartheta \in \mathbb{R}^d$.

To state another assumption on the coefficients, especially $a = (a^{jk})$, we introduce some notations. Let $B'_r(x') = \{y' \in \mathbb{R}^{d-1} : |x' - y'| < r\}$ and $Q_r(x) = Q_r(x^1, x') = (x^1 - r, x^1 + r) \times B'_r(x')$. Denote

$$\operatorname{osc}_{x'}(a, Q_r(x)) = r^{-1}|B'_r|^{-2} \int_{x^1-r}^{x^1+r} \int_{y', z' \in B'_r(x')} |a(t, y') - a(t, z')| \, dy' \, dz' \, dt,$$

$$a^{\#(x')}_R = \sup_{x \in \mathbb{R}^d} \sup_{r \leq R} \operatorname{osc}_{x'}(a, Q_r(x)),$$

where $|B'_r|$ is the $d-1$-dimensional volume of $B'_r(0)$. We write $a \in VMO_{x'}$ if

$$\lim_{R\to 0} a_R^{\#(x')} = 0.$$

We see that $a \in VMO_{x'}$ if a is independent of x'.

Assumption 2.2. *There is a continuous function $\omega(t)$ defined on $[0,\infty)$ such that $\omega(0) = 0$ and $a_R^{\#(x')} \le \omega(R)$ for all $R \in [0,\infty)$.*

Remark 2.3. It will be seen from our proofs that in Assumption 2.2 the requirement that $\omega(0) = 0$ can be replaced with $\omega(0) \le (4N_1)^{-\nu(d+2)}$, where $N_1 = N_1(d,\delta,p)$ and $\nu = \nu(p)$ are the constants entering (5.6).

As usual, we mean by $W_p^k(\mathbb{R}^d)$, $k = 0,1,\dots$, the Sobolev spaces on $\mathbb{R}^d$. Set $W_p^k = W_p^k(\mathbb{R}^d)$, $L_p = L_p(\mathbb{R}^d)$, and

$$Lu(x) = a^{jk}(x)u_{x^jx^k}(x) + b^j(x)u_{x^j}(x) + c(x)u(x).$$

Here are our main results.

Theorem 2.4. *Let $p \in (2,\infty)$. Then there exists a constant $\lambda_0 \ge 0$, depending only on d, δ, K, p, and the function ω, such that, for any $\lambda > \lambda_0$ and $f \in L_p$, there exists a unique $u \in W_p^2$ satisfying $Lu - \lambda u = f$.*

Furthermore, there is a constant N, depending only on d, δ, K, p, and the function ω such that, for any $\lambda \ge \lambda_0$ and $u \in W_p^2$,

$$\lambda\|u\|_{L_p} + \sqrt{\lambda}\|u_x\|_{L_p} + \|u_{xx}\|_{L_p} \le N\|Lu - \lambda u\|_{L_p}.$$

This theorem obviously covers the case in which the coefficients a^{jk} are independent of $x' \in \mathbb{R}^{d-1}$. However, in that case we can allow $p = 2$, which is detailed in the theorem below. Throughout the paper, we write $N = N(d,\dots)$ if N is a constant depending only on $d,\dots$.

The following theorem can be basically found in [3]. We give it a different proof that seems to be somewhat shorter and more general.

Theorem 2.5. *Let the coefficients a^{jk} be independent of $x' \in \mathbb{R}^{d-1}$. Then there exists a constant $\lambda_0 = \lambda_0(d,\delta,K) \ge 0$ such that, for any $\lambda > \lambda_0$ and $f \in L_2$, there exists a unique $u \in W_2^2$ satisfying $Lu - \lambda u = f$.*

In addition, there is a constant $N = N(d,\delta,K)$ such that, for any $\lambda \ge \lambda_0$ and $u \in W_2^2$,

$$\lambda\|u\|_{L_2} + \sqrt{\lambda}\|u_x\|_{L_2} + \|u_{xx}\|_{L_2} \le N\|Lu - \lambda u\|_{L_2}. \tag{2.1}$$

Remark 2.6. Theorem 2.4 leads to the weak uniqueness of solutions of stochastic differential equations associated with the operator L. For details, see [16, 6]. Theorem 2.5 clearly remains true under the assumption that $a^{jk}(x^1,x')$ are uniformly continuous as functions of $x' \in \mathbb{R}^{d-1}$ uniformly in $x^1 \in \mathbb{R}$.

Three more results deal with the equation $Lu - \lambda u = f$ in the half space

$$\mathbb{R}^d_+ = \{x \in \mathbb{R}^d : x^1 > 0\}.$$

Their proofs show the advantage of having the solvability in $\mathbb{R}^d$ of equations whose coefficients are only measurable in one direction. In what follows, we denote by $\overset{o}{W}{}_p^2(\mathbb{R}^d_+)$ the collection of all $u \in W_p^2(\mathbb{R}^d_+)$ satisfying $u(0,x') \equiv 0$.

Theorem 2.7. *Let $p \in [2,\infty)$. If $p = 2$, then suppose, additionally, that the assumption in Theorem 2.5 is satisfied. Then there exists a constant $\lambda_0 =$*

$\lambda_0(d,\delta,K,p,\omega) \geq 0$ such that, for any $\lambda > \lambda_0$ and $f \in L_p(\mathbb{R}^d_+)$, there exists a unique $u \in \overset{o}{W}{}^2_p(\mathbb{R}^d_+)$ satisfying $Lu - \lambda u = f$.

Furthermore, there is a constant $N = N(d,\delta,K,p,\omega)$ such that, for any $\lambda \geq \lambda_0$ and $u \in \overset{o}{W}{}^2_p(\mathbb{R}^d_+)$,

$$\lambda\|u\|_{L_p(\mathbb{R}^d_+)} + \sqrt{\lambda}\|u_x\|_{L_p(\mathbb{R}^d_+)} + \|u_{xx}\|_{L_p(\mathbb{R}^d_+)} \leq N\|Lu - \lambda u\|_{L_p(\mathbb{R}^d_+)}. \tag{2.2}$$

Proof. We introduce a new operator $\hat{L}v = \hat{a}^{jk}v_{x^jx^k} + \hat{b}^j v_{x^j} + \hat{c}v$, the coefficients of which are as follows. First, we view the coefficients a^{jk}, b^j, and c as functions defined only on $\mathbb{R}^d_+$. Then we define $\hat{a}^{jk}$, $\hat{b}^j$, and $\hat{c}$ to be the odd or even extensions of the original coefficients. Specifically, if $j = k = 1$ or $j,k \in \{2,\dots,d\}$, then (even extension)

$$\hat{a}^{jk}(x) = \begin{cases} a^{jk}(x^1,x') & \text{if } x^1 \geq 0, \\ a^{jk}(-x^1,x') & \text{if } x^1 < 0. \end{cases}$$

If $j = 2,\dots,d$, then (odd extension)

$$\hat{a}^{1j}(x) = \hat{a}^{j1}(x) = \begin{cases} a^{1j}(x^1,x') & \text{if } x^1 \geq 0, \\ -a^{1j}(-x^1,x') & \text{if } x^1 < 0. \end{cases}$$

Similarly, the coefficient $\hat{b}^1(x)$ is the odd extension of $b^1(x)$, and the coefficients $\hat{b}^j(x)$, $j = 2,\dots,d$, and $\hat{c}(x)$ are the even extensions of $b^j(x)$ and $c(x)$, respectively.

Now we notice that the coefficients of $\hat{L}$ satisfy Assumptions 2.1 and 2.2 with $2\,\omega$. Then by Theorems 2.4 and 2.5, we can find a constant $\lambda_0 = \lambda_0(d,\delta,K,p,\omega)$ such that, for any $\lambda > \lambda_0$, there exists a unique $u \in W^2_p$ satisfying $\hat{L}u - \lambda u = \hat{f}$, where $\hat{f} \in L_p$ is the odd extension of $f \in L_p(\mathbb{R}^d_+)$. Obviously, $-u(-x^1,x') \in W^2_p$ also satisfies the same equation, so by uniqueness we have $u(x^1,x') = -u(-x^1,x')$. This implies that u, as a function defined on $\mathbb{R}^d_+$, is in the space $\overset{o}{W}{}^2_p(\mathbb{R}^d_+)$. Since $Lu - \lambda u = f$ in $\mathbb{R}^d_+$, the function u is a solution to the Dirichlet boundary problem.

To prove uniqueness and the estimate (2.2), we use the estimates in Theorems 2.4 and 2.5 and the fact that the odd extension of an element in $\overset{o}{W}{}^2_p(\mathbb{R}^d_+)$ is in W^2_p. The theorem is now proved. ∎

In the same way, only this time taking the even extension of f, one gets the solvability of the Neumann problem.

THEOREM 2.8. *Let $p \in [2,\infty)$. If $p = 2$, then suppose, additionally, that the assumption in Theorem 2.5 is satisfied. Then there exists a constant $\lambda_0 = \lambda_0(d,\delta,K,p,\omega) \geq 0$ such that, for any $\lambda > \lambda_0$ and $f \in L_p(\mathbb{R}^d_+)$, there exists a unique $u \in W^2_p(\mathbb{R}^d_+)$ satisfying $Lu - \lambda u = f$ and $u_{x^1} = 0$ on $\partial\mathbb{R}^d_+$.*

Furthermore, there is a constant $N = N(d,\delta,K,p,\omega)$ such that, for any $\lambda \geq \lambda_0$ and $u \in W^2_p(\mathbb{R}^d_+)$ satisfying $u_{x^1} = 0$ on $\partial\mathbb{R}^d_+$,

$$\lambda\|u\|_{L_p(\mathbb{R}^d_+)} + \sqrt{\lambda}\|u_x\|_{L_p(\mathbb{R}^d_+)} + \|u_{xx}\|_{L_p(\mathbb{R}^d_+)} \leq N\|Lu - \lambda u\|_{L_p(\mathbb{R}^d_+)}.$$

While the Neumann problem is solved without any effort, oblique derivative problems need some, still simple, manipulations.

Let ℓ be a constant vector field $\ell = (\ell^1,\dots,\ell^d)$, where $\ell^1 > 0$. Set $s = 1 - 1/p$ and recall that $g \in W^s_p(\mathbb{R}^{d-1})$ if

$$\|g\|_{W^s_p(\mathbb{R}^{d-1})} = \|g\|_{L_p(\mathbb{R}^{d-1})} + [g]_s < \infty,$$

where

$$[g]_s^p = \int_{\mathbb{R}^{d-1}} \int_{\mathbb{R}^{d-1}} \frac{|g(x') - g(y')|^p}{|x' - y'|^{d-1+sp}} \, dx' \, dy'.$$

THEOREM 2.9. *Let $p \in [2, \infty)$. If $p = 2$, then suppose, additionally, that the assumption in Theorem 2.5 is satisfied. Then there exists a constant $\lambda_0 = \lambda_0(d, \delta, K, p, \omega, \ell) \geq 0$ such that, for any $\lambda > \lambda_0$, $f \in L_p(\mathbb{R}^d_+)$, and $g \in W_p^{1-1/p}(\mathbb{R}^{d-1})$, there exists a unique $u \in W_p^2(\mathbb{R}^d_+)$ satisfying $Lu - \lambda u = f$ and $\ell^j \, u_{x^j} = g$ on $\partial \mathbb{R}^d_+$.*

Furthermore, there is a constant $N = N(d, \delta, K, p, \omega, \ell)$ such that, for any $\lambda \geq \lambda_0$ and $u \in W_p^2(\mathbb{R}^d_+)$,

$$\lambda \|u\|_{L_p(\mathbb{R}^d_+)} + \sqrt{\lambda} \|u_x\|_{L_p(\mathbb{R}^d_+)} + \|u_{xx}\|_{L_p(\mathbb{R}^d_+)}$$

$$\leq N \left(\|Lu - \lambda u\|_{L_p(\mathbb{R}^d_+)} + (\lambda \vee 1)^{s/2} \|g\|_{L_p(\mathbb{R}^{d-1})} + [g]_s \right), \tag{2.3}$$

where $\lambda \vee 1 = \max\{\lambda, 1\}$, $s = 1 - 1/p$, and $g(x') = \ell^j \, u_{x^j}(0, x')$.

Proof. We may assume that $\ell^1 = 1$. Then introduce new coordinates in $\mathbb{R}^d_+$ by $y^1 = x^1, y' = x' - x^1 \ell'$. It is easy to check that under this change of variables the condition $\ell^j \, u_{x^j} = g$ becomes $u_{y^1} = g$ and the operator L will be transformed into a different one but yet satisfying the same assumptions as L does (with somewhat different constants δ and K and the same ω). It follows that in the rest of the proof we may assume that $\ell = (1, 0, \ldots, 0)$ is the first unit basis vector.

Next, we reduce the case of general g to that of $g = 0$. One knows (see, for instance, Theorem 2.9.1 of [18]) that the trace operator $u(x) \to u_{x^1}(0, x')$ is a bounded operator from $W_p^2(\mathbb{R}^d_+)$ onto $W_p^s(\mathbb{R}^{d-1})$, for each $g \in W_p^s(\mathbb{R}^{d-1})$ there is a function $v \in W_p^2(\mathbb{R}^d_+)$ such that $v = 0$ and $v_{x^1} = g(x')$ on $\partial \mathbb{R}^d_+$, and for a constant N independent of g,

$$\|v\|_{W_p^2(\mathbb{R}^d_+)} \leq N \|g\|_{W_p^s(\mathbb{R}^{d-1})}. \tag{2.4}$$

It follows by using dilations $(v(x), g(x') \to v(\sqrt{\lambda} x), \sqrt{\lambda} g(\sqrt{\lambda} x'))$ that for any $g \in W_p^s(\mathbb{R}^{d-1})$ and $\lambda > 0$, we can find $v \in W_p^2(\mathbb{R}^d_+)$ satisfying $v = 0$, $v_{x^1} = g$ on $\partial \mathbb{R}^d_+$, and

$$\lambda \|v\|_{L_p(\mathbb{R}^d_+)} + \sqrt{\lambda} \|v_x\|_{L_p(\mathbb{R}^d_+)} + \|v_{xx}\|_{L_p(\mathbb{R}^d_+)} \leq N \left(\lambda^{s/2} \|g\|_{L_p(\mathbb{R}^{d-1})} + [g]_s \right), \tag{2.5}$$

where N depends only on d and p. This implies that if the first assertion of the theorem is true for $g = 0$, then by replacing f with $f - Lv + \lambda v$, finding u, and introducing $w = u + v$, we will have $w \in W_p^2(\mathbb{R}^d_+)$, $Lw - \lambda w = f$ in $\mathbb{R}^d_+$, and $w_{x^1} = g$ on $\partial \mathbb{R}^d_+$.

Furthermore, if estimate (2.3) holds true provided that $u_{x^1} = 0$ on $\partial \mathbb{R}^d_+$, then take an arbitrary $u \in W_p^2(\mathbb{R}^d_+)$, introduce $g := u_{x^1}$ on $\partial \mathbb{R}^d_+$, find v as above, but corresponding to $\lambda \vee 1$ in place of λ, and write that by the assumption

$$\|(u - v)_{xx}\|_{L_p(\mathbb{R}^d_+)} \leq N \|(L - \lambda)(u - v)\|_{L_p(\mathbb{R}^d_+)},$$

$$\|u_{xx}\|_{L_p(\mathbb{R}^d_+)} \leq N \|(L - \lambda) u\|_{L_p(\mathbb{R}^d_+)} + N \|v_{xx}\|_{L_p(\mathbb{R}^d_+)}$$

$$+N\|v_x\|_{L_p(\mathbb{R}^d_+)} + N(1+\lambda)\|v_x\|_{L_p(\mathbb{R}^d_+)}.$$

The last expression is majorated by the right-hand side of (2.3) owing to (2.5) (recall that we take there $\lambda \vee 1$ in place of λ). Similarly, one estimates the remaining terms on the left-hand side of (2.3). Thus, in the rest of the proof we may assume that $g = 0$.

In that case take the operator $\hat{L}$ from the proof of Theorem 2.7 and consider the equation

$$\hat{L}w - \lambda w = \hat{f} \tag{2.6}$$

in $\mathbb{R}^d$, where $\hat{f}(x) := f(|x^1|, x')$. Using Theorems 2.4 and 2.5, we find a unique solution $w \in W^2_p$ to (2.6) for $\lambda > \lambda_0$, where $\lambda_0 = \lambda_0(d, \delta, K, p, \omega, \ell)$ is a constant corresponding to the operator $\hat{L}$. Obviously, $v(x) = u(-x^1, x')$ is also a solution of (2.6). By uniqueness, $v = u$, $u(x) = u(-x^1, x')$ implying that $u_{x^1} = 0$ on $\partial\mathbb{R}^d_+$, and since $u \in W^2_p(\mathbb{R}^d_+)$, we have proved the existence of the desired solution.

To complete the proof, we now prove only (2.3), which implies uniqueness. As we agreed upon above we need only consider the case that $g = u_{x^1} = 0$ on $\partial\mathbb{R}^d_+$. Take such a $u \in W^2_p(\mathbb{R}^d_+)$ and set $v(x) = u(|x^1|, x')$. Since $u_{x^1} = 0$ on $\partial\mathbb{R}^d_+$, we have $v \in W^2_p$ and for $\lambda > \lambda_0 = \lambda_0(d, \delta, K, p, \omega, \ell)$, we have

$$\lambda\|v\|_{L_p} + \sqrt{\lambda}\|v_x\|_{L_p} + \|v_{xx}\|_{L_p} \le N\|f\|_{L_p},$$

where $f = \hat{L}v - \lambda v$. Obviously, $f(x) = f(|x^1|, x')$ and $v = u$ on $\mathbb{R}^d_+$. Hence, the above estimate implies (2.3) (recall that $g = 0$).

We have proved (2.3) for $\lambda > \lambda_0$. For $\lambda = \lambda_0$ we get (2.3) by continuity. □

Remark 2.10. Let $\ell(x') = (\ell^1(x'), \dots, \ell^d(x'))$ be a bounded vector field defined on $\mathbb{R}^{d-1}$ such that $\ell(x') \in C^{1-1/p+\varepsilon}(\mathbb{R}^{d-1})$, $\varepsilon > 0$, and $\ell^1(x') \ge \kappa > 0$. Then using the freezing coefficients, partition of unity, and the method of continuity, we can replace the constant vector field ℓ by $\ell(x')$ in the above theorem. Details can be found in [10].

Remark 2.11. A result similar to Theorem 2.9 holds if we replace the boundary condition $\ell^j u_{x^j} = g$ with $\ell^j u_{x^j} + \sigma u = g$, where σ is a constant. Indeed, again assuming that $\ell^1 = 1$, it is easy to find an infinitely differentiable bounded function $h(x^1)$ having bounded derivatives and bounded away from zero such that $h'(0) = -\sigma h(0)$. Then for $v = u/h$ we have $\ell^j v_{x^j} = g/h$ on $\partial\mathbb{R}^d_+$ and $Lu - \lambda u = h(\bar{L}v - \lambda v)$, where $\bar{L}\phi := h^{-1}L(h\phi)$ is an elliptic operator satisfying our hypotheses with a slightly modified K.

3. Proof of Theorem 2.5. Thanks to the method of continuity and the denseness of $C_0^\infty(\mathbb{R}^d)$ in W^2_2, it suffices to prove the a priori estimate (2.1) for $u \in C_0^\infty(\mathbb{R}^d)$ and a^{jk} that are sufficiently smooth. In addition, on the account of possibly increasing λ_0 one sees that it suffices to prove (2.1) for $b \equiv 0$, $c \equiv 0$, and $\lambda_0 = 0$. In that case set

$$f = Lu - \lambda u. \tag{3.1}$$

For functions $\phi(x^1, x')$ we denote by $\tilde{\phi}(x^1, \xi)$, $\xi \in \mathbb{R}^{d-1}$, its Fourier transform with respect to x'. By taking the Fourier transforms of both sides of (3.1), we obtain

$$\mathsf{a}\tilde{u}_{x^1x^1} + i2\mathsf{b}\tilde{u}_{x^1} - \mathsf{c}\tilde{u} = \tilde{f},$$

$$\tilde{u}_{x^1x^1} + i2\hat{\mathsf{b}}\tilde{u}_{x^1} - \hat{\mathsf{c}}\tilde{u} = \tilde{g}, \tag{3.2}$$

where $\mathrm{i} = \sqrt{-1}$ and

$$\mathsf{a}(x^1) = a^{11}(x^1), \quad \mathsf{b}(x^1,\xi) = \sum_{j=2}^{d} a^{1j}(x^1)\xi^j, \quad \hat{\mathsf{b}} = \mathsf{a}^{-1}\mathsf{b},$$

$$\mathsf{c}(x^1,\xi) = \sum_{j,k=2}^{d} a^{jk}(x^1)\xi^j\xi^k + \lambda, \quad \hat{\mathsf{c}} = \mathsf{a}^{-1}\mathsf{c}, \quad \tilde{g} = \mathsf{a}^{-1}\tilde{f}.$$

LEMMA 3.1. *We have*

$$\delta \le \mathsf{a} = a^{11} \le \delta^{-1}, \quad |\mathsf{b}(x^1,\xi)| \le \delta^{-1}|\xi|,$$

$$\delta^{-1}(|\xi|^2 + \lambda) \ge \mathsf{c}(x^1,\xi) \ge \delta|\xi|^2 + \lambda, \tag{3.3}$$

and

$$\mathsf{a}(x^1)\mathsf{c}(x^1,\xi) - \mathsf{b}^2(x^1,\xi) \ge \delta^2(|\xi|^2 + \lambda).$$

Proof. The first and last inequalities in (3.3) are obvious. The second one follows by Cauchy's inequality $(a^{jk}\eta^j\xi^k)^2 \le (a^{jk}\eta^j\eta^k)(a^{jk}\xi^j\xi^k)$, where $\xi^1 = \eta^j = 0$, $j \ge 2$, $\eta^1 = 1$. Next, from Assumption 2.1 we have

$$\delta(t^2 + |\xi|^2) \le \mathsf{a}(x^1)\,t^2 + 2\,\mathsf{b}(x^1,\xi)\,t + \mathsf{c}(x^1,\xi) - \lambda$$

for all $t \in \mathbb{R}$ and $\xi \in \mathbb{R}^{d-1}$. In particular,

$$\big(\mathsf{a}(x^1) - \delta\big)\,t^2 + 2\,\mathsf{b}(x^1,\xi)\,t + \mathsf{c}(x^1,\xi) - \delta|\xi|^2 - \lambda \ge 0.$$

This implies that

$$\mathsf{b}^2(x^1,\xi) - \big(\mathsf{a}(x^1) - \delta\big)\big(\mathsf{c}(x^1,\xi) - \delta|\xi|^2 - \lambda\big) \le 0.$$

From this and (3.3) the result follows. □

LEMMA 3.2. *For any $\xi \in \mathbb{R}^d$*

$$(|\xi|^2 + \lambda)\int_{\mathbb{R}} |\tilde{u}_{x^1}|^2\,dx^1 + (|\xi|^4 + \lambda|\xi|^2 + \lambda^2)\int_{\mathbb{R}} |\tilde{u}|^2\,dx^1 \le N(\delta)\int_{\mathbb{R}} |\tilde{f}|^2\,dx^1, \tag{3.4}$$

$$\int_{\mathbb{R}} |\tilde{u}_{x^1x^1}|^2\,dx^1 \le N(\delta)\int_{\mathbb{R}} |\tilde{f}|^2\,dx^1. \tag{3.5}$$

Proof. Estimate (3.5) is a direct consequence of (3.2) (allowing one to express $\tilde{u}_{x^1x^1}$ through $\tilde{f}$, $\tilde{u}_{x^1}$, and $\tilde{u}$), (3.3), and (3.4).

While proving (3.4) we define a function $\phi(x^1,\xi)$ by $\phi(0,\xi) = 0$ and $\phi_{x^1} = \hat{\mathsf{b}}$ and set $\rho = \tilde{u}e^{\mathrm{i}\phi}$. Then from (3.2) we see that

$$\rho_{x^1x^1} + (\hat{\mathsf{b}}^2 - \mathrm{i}\,\phi_{x^1x^1} - \hat{\mathsf{c}})\rho = \tilde{g}e^{\mathrm{i}\phi}.$$

Multiply both sides by $\bar{\rho}$ and integrate the result with respect to x^1. Integrating by parts shows that

$$-\int_{\mathbb{R}} |\rho_{x^1}|^2\,dx^1 + \int_{\mathbb{R}} (\hat{\mathsf{b}}^2 - \mathrm{i}\,\phi_{x^1x^1} - \hat{\mathsf{c}})|\tilde{u}|^2\,dx^1 = \int_{\mathbb{R}} \tilde{g}\bar{\tilde{u}}\,dx^1.$$

Taking the real parts of both sides and multiplying by $|\xi|^2+\lambda$, we have

$$\int_{\mathbb{R}}(|\xi|^2+\lambda)|\rho_{x^1}|^2\,dx^1+\int_{\mathbb{R}}(\hat{\mathsf{c}}-\hat{\mathsf{b}}^2)(|\xi|^2+\lambda)|\tilde u|^2\,dx^1$$

$$=-\int_{\mathbb{R}}(|\xi|^2+\lambda)\Re(\tilde g\bar{\tilde u})\,dx^1.$$

Note that for any $\varepsilon>0$

$$-(|\xi|^2+\lambda)\Re(\tilde g\bar{\tilde u})\le\varepsilon(|\xi|^2+\lambda)^2|\tilde u|^2+\varepsilon^{-1}|\tilde g|^2.$$

From this and Lemma 3.1 we obtain

$$\int_{\mathbb{R}}(|\xi|^2+\lambda)|\rho_{x^1}|^2\,dx^1+\int_{\mathbb{R}}(\delta^4-\varepsilon)(|\xi|^2+\lambda)^2|\tilde u|^2\,dx^1\le\varepsilon^{-1}\int_{\mathbb{R}}|\tilde g|^2\,dx^1.$$

By choosing an appropriate $\varepsilon>0$ (e.g., $\varepsilon=\delta^4/2$), we arrive at

$$\int_{\mathbb{R}}(|\xi|^2+\lambda)|\rho_{x^1}|^2\,dx^1+\int_{\mathbb{R}}(|\xi|^4+\lambda|\xi|^2+\lambda^2)|\tilde u|^2\,dx^1\le N(\delta)\int_{\mathbb{R}}|\tilde f|^2\,dx^1.$$

It only remains to observe that in light of (3.3)

$$|\tilde u_{x^1}|=|\rho_{x^1}-\mathsf{i}\mathsf{b}\mathsf{a}^{-1}\tilde u e^{i\phi}|\le|\rho_{x^1}|+N(\delta)|\xi||\tilde u|.\qquad\square$$

Now we can finish the proof of Theorem 2.5. As we pointed out in the beginning of the section, we only need to prove (2.1) for $u\in C_0^\infty(\mathbb{R}^d)$, smooth a^{ij}, $b\equiv0$, $c\equiv0$, and $\lambda_0=0$.

In that case it suffices to add (3.4) and (3.5), integrate over $\mathbb{R}^{d-1}$, and use Parseval's identity. The theorem is proved.

Remark 3.3. We have just proved that if $b^j=c=0$, then

$$\lambda\|u\|_{L_2}+\sqrt{\lambda}\|u_x\|_{L_2}+\|u_{xx}\|_{L_2}\le N\|Lu-\lambda u\|_{L_2}$$

for $u\in W_2^2$ and $\lambda\ge0$, where N depends only on δ.

4. Auxiliary results. Here we state and prove a series of observations which are needed in the proof of Theorem 2.4. First, we introduce some notation. As usual, we set $B_r(x_0)=\{x\in\mathbb{R}^d:|x-x_0|<r\}$ and $B_r=B_r(0)$. By $|B_r|$ we mean the d-dimensional volume of B_r. We denote by $|u|_0$ the supremum of $|u|$ over $\mathbb{R}^d$.

Throughout this section, we assume that

$$Lu(x)=L_0u(x)=a^{jk}(x^1)u_{x^jx^k}(x).$$

Our first auxiliary result is the following lemma.

LEMMA 4.1. *There exists $N=N(d,\delta)$ such that, for any $u\in W_2^2(B_R)$ with $u|_{\partial B_R}=0$, we have*

$$R^2\int_{B_R}|u_x|^2\,dx+\int_{B_R}|u|^2\,dx\le N\,R^4\int_{B_R}|Lu|^2\,dx.\tag{4.1}$$

Proof. Assume that (4.1) is true when $R=1$. For a given $u\in W_2^2(B_R)$ with $u|_{\partial B_R}=0$, we set

$$L_R=a^{jk}(Rx)\frac{\partial^2}{\partial x^j\partial x^k}\quad\text{and}\quad v(x)=R^{-2}u(Rx).$$

Then $v \in W_2^2(B_1)$ and $L_R v(x) = (Lu)(Rx)$ in B_1. Since L_R satisfies the same ellipticity condition as L does, we have

$$\int_{B_R} |u|^2\,dx = R^{d+4}\int_{B_1}|v|^2\,dx$$

$$\le NR^{d+4}\int_{B_1}|L_R v|^2\,dx = NR^4\int_{B_R}|Lu|^2\,dx.$$

Also

$$\int_{B_R} |u_x|^2\,dx = R^{d+2}\int_{B_1}|v_x|^2\,dx$$

$$\le NR^{d+2}\int_{B_1}|L_R v|^2\,dx = NR^2\int_{B_R}|Lu|^2\,dx.$$

This shows that we need only prove the lemma for $R = 1$.

In that case we can divide L by a^{11} and may assume that $a^{11} \equiv 1$. Then we integrate uLu over B_1 using integration by parts to find

$$\delta\int_{B_1}|u_x|^2\,dx \le \int_{B_1} a^{jk}u_{x^j}u_{x^k}\,dx = -\int_{B_1} uLu\,dx$$

$$\le \left(\int_{B_1} u^2\,dx\right)^{1/2}\left(\int_{B_1}(Lu)^2\,dx\right)^{1/2}.$$

We estimate the integral of u^2 through that of $|u_x|^2$ by using Poincaré's inequality and obtain the needed estimate for u_x. This is the only estimate we need to prove since u is estimated by u_x, again owing to Poincaré's inequality. $\square$

The following lemma is almost identical to a theorem in [5]. For completeness, we also present a proof.

LEMMA 4.2. *Let $0 < r < R$. There exists $N = N(d,\delta)$ such that, for $w \in W_2^2(B_R)$,*

$$\|w\|_{W_2^2(B_r)} \le N\left(\|Lw - w\|_{L_2(B_R)} + (R-r)^{-2}\|w\|_{L_2(B_R)}\right). \tag{4.2}$$

Proof. Set

$$R_0 = r, \quad R_m = r + (R-r)\sum_{k=1}^{m}\frac{1}{2^k}, \quad m = 1,2,\ldots,$$

$$B(m) = \{x \in \mathbb{R}^d : |x| \le R_m\}, \quad m = 0,1,\ldots.$$

Also, let $\zeta_m \in C_0^\infty(\mathbb{R}^d)$ be such that $\zeta_m(x) = 1$ in $B(m)$, $\zeta_m(x) = 0$ outside of $B(m+1)$, and

$$|(\zeta_m)_x|_0 \le N\frac{2^{m+1}}{R-r}, \quad |(\zeta_m)_{xx}|_0 \le N\frac{2^{2m+2}}{(R-r)^2},$$

where N depends only on d. To construct them take an infinitely differentiable function $g(t)$, $t \in (-\infty, \infty)$, such that $g(t) = 1$ for $t \leq 1$, $g(t) = 0$ for $t \geq 2$, and $0 \leq g \leq 1$. After this define

$$\zeta_m(x) = g(2^{m+1}(R-r)^{-1}(|x| - R_m) + 1).$$

Now we make use of the L_2-estimate of $\zeta_m w$, which is from Remark 3.3, and obtain (observe that $N2^{2m+2} = N_1 2^{2m}$ with $N_1 = 4N$)

$$\mathcal{A}_m := \|\zeta_m w\|_{W_2^2} \leq N\|(L-1)(\zeta_m w)\|_{L_2}$$

$$\leq N\mathcal{B} + N\|\zeta_{mx} w_x\|_{L_2} + N\frac{2^{2m}}{(R-r)^2}\mathcal{C}, \tag{4.3}$$

where N depends only on d and δ and

$$\mathcal{B} := \|(L-1)w\|_{L_2(B_R)} \quad \text{and} \quad \mathcal{C} := \|w\|_{L_2(B_R)}.$$

By interpolation inequalities

$$\|\zeta_{mx} w_x\|_{L_2} = \|\zeta_{mx}(\zeta_{m+1}w)_x\|_{L_2} \leq N\frac{2^m}{R-r}\|(\zeta_{m+1}w)_x\|_{L_2}$$

$$\leq \varepsilon\mathcal{A}_{m+1} + N\varepsilon^{-1}\frac{2^{2m}}{(R-r)^2}\mathcal{C},$$

where $\varepsilon > 0$ is arbitrary and N depends only on d. Thus, (4.3) yields

$$\mathcal{A}_m \leq N\mathcal{B} + \varepsilon\mathcal{A}_{m+1} + N\varepsilon^{-1}\frac{2^{2m}}{(R-r)^2}\mathcal{C}$$

with ε perhaps different from the one above but still arbitrary. We set $\varepsilon = 1/8$ and get

$$\varepsilon^m\mathcal{A}_m \leq N\varepsilon^m\mathcal{B} + \varepsilon^{m+1}\mathcal{A}_{m+1} + N\varepsilon^m\frac{2^{2m}}{(R-r)^2}\mathcal{C},$$

$$\mathcal{A}_0 + \sum_{m=1}^{\infty}\varepsilon^m\mathcal{A}_m \leq N\mathcal{B} + \sum_{m=1}^{\infty}\varepsilon^m\mathcal{A}_m + N\frac{1}{(R-r)^2}\mathcal{C}.$$

Here the series of $\varepsilon^m\mathcal{A}_m = 8^{-m}\mathcal{A}_m$ converges since

$$\mathcal{A}_m \leq N2^{2m}(R-r)^{-2}\|w\|_{W_2^2(B_R)}.$$

Therefore, after taking care of similar terms we see that $\mathcal{A}_0$ is less than the right-hand side of (4.2). Since its left-hand side is obviously less than $\mathcal{A}_0$, the lemma is proved. □

Remark 4.3. Using the dilation argument as in the proof of Lemma 4.1, we have

$$\lambda\|w\|_{L_2(B_r)} + \sqrt{\lambda}\|w_x\|_{L_2(B_r)} + \|w_{xx}\|_{L_2(B_r)}$$

$$\leq N \left(\|Lw - \lambda w\|_{L_2(B_R)} + (R-r)^{-2} \|w\|_{L_2(B_R)} \right)$$

for any $\lambda > 0$, where N depends only on d and δ. In particular, by letting $\lambda \to 0$, we have

$$\|w_{xx}\|_{L_2(B_r)} \leq N \left(\|Lw\|_{L_2(B_R)} + (R-r)^{-2} \|w\|_{L_2(B_R)} \right). \tag{4.4}$$

In the next few lemmas, we investigate some properties of a solution h of the equation $Lh = 0$. Recall that the coefficients a^{jk} of the operator L do not depend on $x' \in \mathbb{R}^{d-1}$.

LEMMA 4.4. *Let $\gamma = (\gamma^1, \dots, \gamma^d)$ be a multi-index such that $\gamma^1 = 0, 1, 2$. Also let $0 < r < R \leq 4$. If h is a sufficiently smooth function defined on B_4 such that $Lh = 0$ in B_4, then we have*

$$\int_{B_r} |D^\gamma h|^2 \, dx \leq N \int_{B_R} |h|^2 \, dx,$$

where $N = N(d, \delta, \gamma, R, r)$.

Proof. Set $\gamma' = (0, \gamma^2, \dots, \gamma^d)$ and notice that

$$L(D^{\gamma'} h) = 0, \quad \text{that is} \quad (L-1) D^{\gamma'} h = -D^{\gamma'} h \quad \text{in} \quad B_4.$$

Then by Lemma 4.2

$$\|D^\gamma h\|_{L_2(B_r)} \leq N \left(\|D^{\gamma'} h\|_{L_2(B_{r_1})} + (r_1 - r)^{-2} \|D^{\gamma'} h\|_{L_2(B_{r_1})} \right),$$

where $r < r_1 < R$. If $|\gamma'| = 0$, then we are done. Otherwise, we can consider a multi-index γ'' having at least one component less by one than the corresponding component of γ'. Then, $L(D^{\gamma''} h) = 0$ and

$$\|D^{\gamma'} h\|_{L_2(B_{r_1})} \leq N \left(\|D^{\gamma''} h\|_{L_2(B_{r_2})} + (r_2 - r_1)^{-2} \|D^{\gamma''} h\|_{L_2(B_{r_2})} \right),$$

where $r < r_1 < r_2 < R$. We repeat this argument as many times as we need. The lemma is proved. $\square$

Denote by h_x a generic derivative h_{x^j}, $j = 1, \dots, d$, and $h_{x'}$ a generic derivative h_{x^j}, $j = 2, \dots, d$. Thus, for example, $h_{xx'}$ can be $h_{x^j x^k}$, where $j \in \{1, 2, \dots, d\}$ and $k \in \{2, \dots, d\}$.

LEMMA 4.5. *Let h be a sufficiently smooth function h defined on B_4 such that $Lh = 0$ in B_4. Then we have*

$$\sup_{B_1} |h_{xxx'}|^2 \leq N \int_{B_3} |h|^2 \, dx,$$

where $N = N(d, \delta)$.

Proof. Imagine that we have

$$\sup_{B_1} |h_{xx}| \leq N(d, \delta) \|h\|_{L_2(B_{5/2})}. \tag{4.5}$$

Then, using the fact that $Lh_{x'} = 0$, we would obtain

$$\sup_{B_1} |h_{x'xx}| \leq N \|h_{x'}\|_{L_2(B_{5/2})}$$

and it would only remain to appeal to Lemma 4.4.

Therefore, it suffices to prove (4.5). To do that, we first fix an integer k such that $k-(d-1)/2>0$. Then, due to the Sobolev embedding theorem, we can find a constant N such that, for each $-1 \le x^1 \le 1$,

$$\sup_{|x'|\le 1} |h_{x'x^1x^1}(x^1,x')| \le N\|h_{x'x^1x^1}(x^1,\cdot)\|_{W_2^k(B_1')}$$

and

$$\sup_{|x'|\le 1} |h_{x'x^1}(x^1,x')| \le N\|h_{x'x^1}(x^1,\cdot)\|_{W_2^k(B_1')},$$

where $B_1' = \{x' \in \mathbb{R}^{d-1} : |x'| \le 1\}$. Set g to be either $h_{x'x^1x^1}$ or $h_{x'x^1}$. Then

$$\int_{-1}^1 \sup_{|x'|\le 1} |g(x^1,x')|^2\,dx^1 \le N\int_{-1}^1 \|g(x^1,\cdot)\|^2_{W_2^k(B_1')}\,dx^1$$

$$\le N \sum_{\substack{|\gamma|\le k+3\\ 1\le\gamma^1\le 2}} \|D^\gamma h\|^2_{L_2(B_2)}.$$

From this and Lemma 4.4 we have

$$\int_{-1}^1 \sup_{|x'|\le 1} |h_{x'x^1x^1}|^2\,dx^1 + \int_{-1}^1 \sup_{|x'|\le 1} |h_{x'x^1}|^2\,dx^1 \le N\|h\|^2_{L_2(B_{5/2})}, \tag{4.6}$$

where N depends only on d and δ. Now we notice that, for $x^1, y^1 \in [-1,1]$,

$$\sup_{|x'|\le 1} |h_{x'x^1}(x^1,x')| - \sup_{|x'|\le 1} |h_{x'x^1}(y^1,x')|$$

$$\le \sup_{|x'|\le 1} \big|h_{x'x^1}(x^1,x') - h_{x'x^1}(y^1,x')\big| \le \int_{x^1}^{y^1} \sup_{|x'|\le 1} |h_{x'x^1x^1}(t,x')|\,dt$$

$$\le |x^1-y^1|^{1/2}\left(\int_{-1}^1 \sup_{|x'|\le 1} |h_{x'x^1x^1}(t,x')|^2\,dt\right)^{1/2}.$$

This and (4.6) imply

$$\sup_{|x'|\le 1} |h_{x'x^1}(x^1,x')| \le N\|h\|_{L_2(B_{5/2})}\,|x^1-y^1|^{1/2} + \sup_{|x'|\le 1} |h_{x'x^1}(y^1,x')|.$$

Take integrals of both sides with respect to y^1, and take a supremum over x^1. Then

$$\sup_{x\in B_1} |h_{x'x^1}(x)| \le N\|h\|_{L_2(B_{5/2})} + \int_{-1}^1 \sup_{|x'|\le 1} |h_{x'x^1}(y^1,x')|\,dy^1 \le N\|h\|_{L_2(B_{5/2})},$$

where the last inequality follows from (4.6), and N depends only on d and δ. Similarly, we follow the same steps as above with $h_{x'x'x^1}$ and $h_{x'x'}$ in place of $h_{x'x^1x^1}$ and $h_{x'x^1}$, respectively. Therefore, we have

$$\sup_{x\in B_1} |h_{x'x}(x)| \le N(d,\delta)\|h\|_{L_2(B_{5/2})}.$$

Finally, using the fact that $a^{11}h_{x^1x^1} = -\sum_{jk>1} a^{jk}h_{x^jx^k}$, we finish the proof of (4.5). ◻

Denote by $(u)_{B_r(x_0)}$ the average value of a function u over $B_r(x_0)$, that is,

$$(u)_{B_r(x_0)} = \fint_{B_r(x_0)} u(x)\,dx = \frac{1}{|B_r|}\int_{B_r(x_0)} u(x)\,dx.$$

Let $u \in C_0^\infty(\mathbb{R}^d)$ and $f := Lu$. Assume that $a^{jk}(x^1)$ are infinitely differentiable as functions of $x^1 \in \mathbb{R}$. Then we can find a sufficiently smooth function h defined on B_4 such that

$$Lh = 0 \quad \text{in} \quad B_4, \quad h = u \quad \text{on} \quad \partial B_4.$$

For this solution h, we establish the following inequality.

Lemma 4.6. *There exists a constant $N = N(d,\delta)$ such that*

$$\sup_{B_1} |h_{xxx'}|^2 \le N\int_{B_4} |f|^2\,dx + N\int_{B_4} |u_{xx}|^2\,dx.$$

Proof. Define

$$\tilde{u} := u - u_{B_4} - (u_{x^i})_{B_4}x^i \quad \text{in} \quad B_4, \quad \tilde{h} := h - u_{B_4} - (u_{x^i})_{B_4}x^i \quad \text{in} \quad B_4.$$

Then

$$L\tilde{u} = f, \quad L\tilde{h} = 0 \quad \text{in} \quad B_4, \quad \text{and} \quad \tilde{h} = \tilde{u} \quad \text{on} \quad \partial B_4.$$

By Lemma 4.5 we see that

$$\sup_{B_1} |h_{xxx'}|^2 = \sup_{B_1} |\tilde{h}_{xxx'}|^2 \le N\int_{B_3} |\tilde{h}|^2\,dx.$$

Let η be a function in $C_0^\infty(\mathbb{R}^d)$ such that $\eta(x) = 0$ in B_3 and $\eta(x) = 1$ at ∂B_4. Then $\tilde{h} - \eta\tilde{u} \in W_2^2(B_4)$ and $\tilde{h} - \eta\tilde{u} = 0$ on ∂B_4. Therefore, by Lemma 4.1

$$\int_{B_3} |\tilde{h}|^2\,dx = \int_{B_3} |\tilde{h} - \eta\tilde{u}|^2\,dx \le N(d,\delta)\int_{B_4} |L(\eta\tilde{u})|^2\,dx.$$

Note that

$$L(\eta\tilde{u}) = \eta Lu + 2a^{ij}\eta_{x^i}\tilde{u}_{x^j} + \tilde{u}L\eta$$

$$= \eta f + 2a^{ij}\eta_{x^i}(u_{x^j} - (u_{x^j})_{B_4}) + (u - u_{B_4} - (u_{x^i})_{B_4}x^i)L\eta.$$

Hence we have

$$\int_{B_4} |L(\eta\tilde{u})|^2\,dx \le N\int_{B_4} (|f|^2 + |u_{x^j} - (u_{x^j})_{B_4}|^2)\,dx$$

$$+N\int_{B_4} |u - u_{B_4} - (u_{x^i})_{B_4}x^i|^2\,dx \le N\int_{B_4} |f|^2\,dx + N\int_{B_4} |u_{xx}|^2\,dx,$$

where the last inequality follows from Lemmas 3.1 and 3.2 in [6], and N depends only on d and δ. The lemma is now proved. ∎

LEMMA 4.7. *Let $\kappa \geq 4$ and $r > 0$. Also let $a^{jk}(x^1)$ be infinitely differentiable. For a given $u \in C_0^\infty(\mathbb{R}^d)$, we find a smooth function h defined on $B_{\kappa r}$ such that $Lh = 0$ in $B_{\kappa r}$ and $h = u$ on $\partial B_{\kappa r}$. Then there exists a constant $N = N(d, \delta)$ such that*

$$\fint_{B_r} |h_{xx'} - (h_{xx'})_{B_r}|^2 \, dx \leq N\kappa^{-2} \left[\left(|Lu|^2\right)_{B_{\kappa r}} + \left(|u_{xx}|^2\right)_{B_{\kappa r}} \right]. \tag{4.7}$$

Proof. Using the dilation argument as in the proof of Lemma 4.1, we see that we need to prove only the case $r = 1$. In that case we first observe that by using the same dilation argument and Lemma 4.6, we have

$$\sup_{B_{\kappa/4}} |h_{xxx'}|^2 \leq N\kappa^{-2} \left[\left(|Lu|^2\right)_{B_\kappa} + \left(|u_{xx}|^2\right)_{B_\kappa} \right],$$

where N depends only on d and δ. Now we need only observe that $\kappa/4 \geq 1$, $r = 1$, and the left-hand side of the inequality (4.7) is not greater than a constant times $\sup_{B_1} |h_{xxx'}|^2$. The lemma is now proved. ∎

Using the results obtained above, we will finally arrive at the following lemma.

LEMMA 4.8. *There exists a constant $N = N(d, \delta)$ such that, for any $\kappa \geq 4$, $r > 0$, and $u \in C_0^\infty(\mathbb{R}^d)$, we have*

$$\fint_{B_r} |u_{xx'} - (u_{xx'})_{B_r}|^2 \, dx \leq N\kappa^d \left(|Lu|^2\right)_{B_{\kappa r}} + N\kappa^{-2} \left(|u_{xx}|^2\right)_{B_{\kappa r}}. \tag{4.8}$$

Proof. We can assume that $a^{jk}(x^1)$ are infinitely differentiable. In that case, we find a sufficiently smooth h defined on $B_{\kappa r}$ such that $Lh = 0$ in $B_{\kappa r}$ and $h = u$ on $\partial B_{\kappa r}$. Note that $L(u - h) = Lu$ in $B_{\kappa r}$ and $u - h = 0$ on $\partial B_{\kappa r}$. From Lemma 4.7 we have

$$\fint_{B_r} |h_{xx'} - (h_{xx'})_{B_r}|^2 \, dx \leq N\kappa^{-2} \left[\left(|Lu|^2\right)_{B_{\kappa r}} + \left(|u_{xx}|^2\right)_{B_{\kappa r}} \right]. \tag{4.9}$$

On the other hand, from estimate (4.4) we have

$$\int_{B_r} |u_{xx'} - h_{xx'}|^2 \, dx \leq N \left(\int_{B_{\kappa r}} |Lu|^2 \, dx + r^{-4}(\kappa - 1)^{-4} \int_{B_{\kappa r}} |u - h|^2 \, dx \right).$$

Moreover, by Lemma 4.1

$$\int_{B_{\kappa r}} |u - h|^2 \, dx \leq N \, (\kappa r)^4 \int_{B_{\kappa r}} |Lu|^2 \, dx.$$

Hence

$$\fint_{B_r} |u_{xx'} - h_{xx'}|^2 \, dx \leq N\kappa^d \left(|Lu|^2\right)_{B_{\kappa r}}.$$

This and (4.9) prove the inequality (4.8) with $(h_{xx'})_{B_r}$ in place of $(u_{xx'})_{B_r}$. Now we need only notice that

$$\fint_{B_r} |u_{xx'} - (u_{xx'})_{B_r}|^2 \, dx \leq \fint_{B_r} |u_{xx'} - (h_{xx'})_{B_r}|^2 \, dx.$$

The lemma is now proved. ∎

5. Proof of Theorem 2.4. In this section we suppose that all assumptions of Theorem 2.4 are satisfied. Recall that

$$Lu(x) = a^{jk}(x)u_{x^jx^k}(x) + b^j(x)u_{x^j}(x) + c(x)u(x),$$

and introduce

$$L_0u(x) = a^{jk}(x)u_{x^jx^k}(x).$$

We use the maximal and sharp functions given by

$$Mg(x) = \sup_{r>0} \fint_{B_r(x)} |g(y)|\,dy,$$

$$g^{\#}(x) = \sup_{r>0} \fint_{B_r(x)} |g(y) - (g)_{B_r(x)}|\,dy.$$

THEOREM 5.1. *Let μ, $\nu \in (1,\infty)$, $1/\mu + 1/\nu = 1$, and $R \in (0,\infty)$. Then there exists a constant $N = N(d,\delta,\mu)$ such that, for any $u \in C_0^\infty(B_R)$, we have*

$$(u_{xx'})^{\#} \le N\left(a_R^{\#(x')}\right)^{\alpha}\left[M(|u_{xx}|^{2\mu})\right]^{\beta}$$

$$+N\left[M(|L_0u|^2)\right]^{1/(d+2)}\left[M(|u_{xx}|^2)\right]^{d/(2d+4)}, \tag{5.1}$$

where $\alpha = \nu^{-1}(d+2)^{-1}$, $\beta = 2^{-1}\mu^{-1}$.

Proof. Fix $\kappa \ge 4$, $r \in (0,\infty)$, and $x_0 = (x_0^1, x_0') \in \mathbb{R}^d$. Introduce

$$\bar a^{jk}(x^1) = \frac{1}{|B'_{\kappa r}|}\int_{B'_{\kappa r}(x'_0)} a^{jk}(x^1,y')\,dy' \quad \text{if} \quad \kappa r < R,$$

$$\bar a^{jk}(x^1) = \frac{1}{|B'_R|}\int_{B'_R} a^{jk}(x^1,y')\,dy' \quad \text{if} \quad \kappa r \ge R,$$

$$\mathcal{A} = M(|L_0u|^2)(x_0), \qquad \mathcal{B} = M(|u_{xx}|^2)(x_0), \quad \mathcal{C} = \left(M(|u_{xx}|^{2\mu})(x_0)\right)^{1/\mu}.$$

Set $\bar L_0 u = \bar a^{jk}(x^1)u_{x^jx^k}$. Then Lemma 4.8 along with the fact that $\kappa \ge 4$ allows us to obtain

$$\fint_{B_r(x_0)} |u_{xx'} - (u_{xx'})_{B_r(x_0)}|^2\,dx$$

$$\le N\kappa^d\left(|\bar L_0 u|^2\right)_{B_{\kappa r}(x_0)} + N\kappa^{-2}\left(|u_{xx}|^2\right)_{B_{\kappa r}(x_0)} \tag{5.2}$$

for $\kappa \ge 4$, where N depends only on d and δ. Note that

$$\int_{B_{\kappa r}(x_0)} |\bar L_0 u|^2\,dx \le 2\int_{B_{\kappa r}(x_0)} |\bar L_0 u - L_0 u|^2\,dx + 2\int_{B_{\kappa r}(x_0)} |L_0 u|^2\,dx \tag{5.3}$$

and

$$\int_{B_{\kappa r}(x_0)} |\bar{L}_0 u - L_0 u|^2\,dx = \int_{B_{\kappa r}(x_0)\cap B_R} |\bar{L}_0 u - L_0 u|^2\,dx$$

$$\leq \left(\int_{B_{\kappa r}(x_0)\cap B_R} |\bar{a} - a|^{2\nu}\,dx\right)^{1/\nu} \left(\int_{B_{\kappa r}(x_0)} |u_{xx}|^{2\mu}\,dx\right)^{1/\mu} := I^{1/\nu} J^{1/\mu}.$$

If $\kappa r < R$, we have

$$I \leq N \int_{x_0^1-\kappa r}^{x_0^1+\kappa r} \int_{B'_{\kappa r}(x'_0)} |\bar{a}(x^1) - a(x^1, x')|\,dx'\,dx^1$$

$$\leq N(\kappa r)^d a_{\kappa r}^{\#(x')} \leq N(\kappa r)^d a_R^{\#(x')}.$$

In case $\kappa r \geq R$

$$I \leq N \int_{-R}^{R} \int_{B'_R} |\bar{a}(x^1) - a(x^1, x')|\,dx'\,dx^1$$

$$\leq N R^d a_R^{\#(x')} \leq N(\kappa r)^d a_R^{\#(x')}.$$

Hence

$$\int_{B_{\kappa r}(x_0)} |\bar{L}_0 u - L_0 u|^2\,dx \leq N(\kappa r)^{d/\nu} \left(a_R^{\#(x')}\right)^{1/\nu} \left(\int_{B_{\kappa r}(x_0)} |u_{xx}|^{2\mu}\,dx\right)^{1/\mu}.$$

From this and (5.3) it follows that

$$\left(|\bar{L}_0 u|^2\right)_{B_{\kappa r}(x_0)} \leq N\left[\left(a_R^{\#(x')}\right)^{1/\nu} \left(|u_{xx}|^{2\mu}\right)_{B_{\kappa r}(x_0)}^{1/\mu} + \left(|L_0 u|^2\right)_{B_{\kappa r}(x_0)}\right].$$

This and (5.2) allow us to have

$$\fint_{B_r(x_0)} |u_{xx'} - (u_{xx'})_{B_r(x_0)}|^2\,dx \leq N\kappa^d \left(a_R^{\#(x')}\right)^{1/\nu} \left(|u_{xx}|^{2\mu}\right)_{B_{\kappa r}(x_0)}^{1/\mu}$$

$$+N\kappa^d \left(|L_0 u|^2\right)_{B_{\kappa r}(x_0)} + N\kappa^{-2} \left(|u_{xx}|^2\right)_{B_{\kappa r}(x_0)}$$

$$\leq N\kappa^d \left(a_R^{\#(x')}\right)^{1/\nu} \mathcal{C} + N\kappa^d \mathcal{A} + N\kappa^{-2}\mathcal{B}$$

for all $r > 0$ and $\kappa \geq 4$. In addition, the above inequality is also true for $0 < \kappa < 4$ since then

$$\fint_{B_r(x_0)} |u_{xx'} - (u_{xx'})_{B_r(x_0)}|^2\,dx \leq \fint_{B_r(x_0)} |u_{xx'}|^2\,dx \leq \mathcal{B} \leq 16\kappa^{-2}\mathcal{B}.$$

By taking the supremum with respect to $r > 0$ and then minimizing with respect to $\kappa > 0$, we have

$$\left[u^{\#}_{xx'}(x_0)\right]^2 \le N \left(\left(a_R^{\#(x')}\right)^{1/\nu} \mathcal{C} + \mathcal{A} \right)^{\frac{2}{d+2}} \mathcal{B}^{\frac{d}{d+2}}$$

$$\le N \left(a_R^{\#(x')}\right)^{\frac{2}{\nu(d+2)}} \mathcal{C}^{\frac{2}{d+2}} \mathcal{B}^{\frac{d}{d+2}} + N\, \mathcal{A}^{\frac{2}{d+2}}\, \mathcal{B}^{\frac{d}{d+2}},$$

where $N = N(d, \delta, \mu)$. Notice that $\mathcal{B} \le \mathcal{C}$. Thus, by replacing $\mathcal{B}$ with $\mathcal{C}$ in the first term on the right-hand side, we finish the proof. □

COROLLARY 5.2. *For $p > 2$, there exist constants $R = R(d, \delta, p, \omega)$ and $N = N(d, \delta, p)$ such that, for any $u \in C_0^\infty(B_R)$, we have*

$$\|u_{xx}\|_{L_p} \le N \|L_0 u\|_{L_p}. \tag{5.4}$$

Proof. Choose real numbers $\mu > 1$ such that $p > 2\mu$. Then we use the inequality (5.1) along with the Fefferman–Stein theorem on sharp functions and the Hardy–Littlewood maximal function theorem. We also use Hölder's inequality to have (note that $p/2\mu > 1$ and $p/2 > 1$)

$$\|u_{xx'}\|_{L_p} \le N \left(a_R^{\#(x')}\right)^{\frac{1}{\nu(d+2)}} \|u_{xx}\|_{L_p} + N \|L_0 u\|_{L_p}^{\frac{2}{d+2}} \|u_{xx}\|_{L_p}^{\frac{d}{d+2}}, \tag{5.5}$$

where $1/\mu + 1/\nu = 1$, and N depends only on d, δ, and p. Since

$$u_{x^1x^1} = \frac{1}{a^{11}} L_0 u - \sum_{jk>1} \frac{a^{jk}}{a^{11}} u_{x^j x^k},$$

by using (5.5) we arrive at

$$\|u_{xx}\|_{L_p} \le N_1 \left(a_R^{\#(x')}\right)^{\frac{1}{\nu(d+2)}} \|u_{xx}\|_{L_p} + N \|L_0 u\|_{L_p} + N \|L_0 u\|_{L_p}^{\frac{2}{d+2}} \|u_{xx}\|_{L_p}^{\frac{d}{d+2}}. \tag{5.6}$$

We now invoke Assumption 2.2 by which we can choose a sufficiently small R such that

$$N_1 \left(a_R^{\#(x')}\right)^{\frac{1}{\nu(d+2)}} \le 1/2.$$

Then we have

$$\frac{1}{2} \|u_{xx}\|_{L_p} \le N \|L_0 u\|_{L_p} + N \|L_0 u\|_{L_p}^{\frac{2}{d+2}} \|u_{xx}\|_{L_p}^{\frac{d}{d+2}},$$

which implies (5.4). □

Proof of Theorem 2.4. Since we have an L_p-estimate for functions with small compact support, we can just follow the standard argument, which can be found in [6]. □

Acknowledgments. The authors are sincerely grateful to Hongjie Dong who pointed out an omission in the first draft of the article and to the referees of the paper for careful reading and many useful suggestions.

A NEW CLASS OF ENTROPY SOLUTIONS OF THE BUCKLEY–LEVERETT EQUATION*

C. J. VAN DUIJN†, L. A. PELETIER‡, AND I. S. POP†

Abstract. We discuss an extension of the Buckley–Leverett (BL) equation describing two-phase flow in porous media. This extension includes a third order mixed derivatives term and models the dynamic effects in the pressure difference between the two phases. We derive existence conditions for traveling wave solutions of the extended model. This leads to admissible shocks for the original BL equation, which violate the Oleinik entropy condition and are therefore called *nonclassical*. In this way we obtain nonmonotone weak solutions of the initial-boundary value problem for the BL equation consisting of constant states separated by shocks, confirming results obtained experimentally.

Key words. conservation laws, dynamic capillarity, two-phase flows in porous media, shock waves, pseudoparabolic equations

DOI. 10.1137/05064518X

1. Introduction.

We consider the first order initial-boundary value problem

$$\text{(BL)}\begin{cases} \dfrac{\partial u}{\partial t}+\dfrac{\partial f(u)}{\partial x}=0 & \text{in} \quad Q=\{(x,t): x>0,\, t>0\},\\ u(x,0)=0 & x>0,\\ u(0,t)=u_B & t>0,\end{cases} \tag{1.1}$$

where u_B is a constant such that $0 \le u_B \le 1$. The nonlinearity $f:\mathbf{R}\to\mathbf{R}$ is given by

$$f(u)=\frac{u^2}{u^2+M(1-u)^2} \qquad \text{if} \qquad 0\le u\le 1, \tag{1.2}$$

whilst $f(u)=0$ if $u<0$ and $f(u)=1$ if $u>1$. Here, $M>0$ is a fixed constant. The function $f(u)$ is shown in Figure 1.

Equation (1.1), with the given flux function f, arises in two-phase flow in porous media, and problem (BL) models oil recovery by water-drive in one-dimensional horizontal flow. In this context, $u:\overline{Q}\to[0,1]$ denotes water saturation, f the water fractional flow function, and M the water/oil viscosity ratio. In petroleum engineering, (1.1) is known as the *Buckley–Leverett (BL) equation* [5]. It is a prototype for first order conservation laws with convex-concave flux functions.

It is well known that first order equations such as (1.1) may have solutions with discontinuities, or shocks. The value (u_ℓ) to the left of the shock, the value (u_r) to

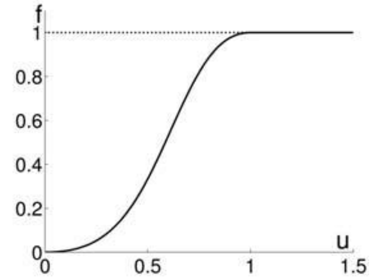

FIG. 1. *Nonlinear flux function for Buckley–Leverett ($M = 2$).*

the right, and the speed s of the shock with trace $x = x(t)$ are related through the *Rankine–Hugoniot condition*,

$$\text{(1.3)} \qquad \text{(RH)} \qquad \frac{dx}{dt} = s = \frac{f(u_\ell) - f(u_r)}{u_\ell - u_r}.$$

We will denote shocks by their values to the left and to the right: $\{u_\ell, u_r\}$.

If a function u is such that (1.1) is satisfied away from the shock curve, and the Rankine–Hugoniot condition is satisfied across the curve, then u satisfies the identity

$$\text{(1.4)} \qquad \int_Q \Big\{ u\frac{\partial \varphi}{\partial t} + f(u)\frac{\partial \varphi}{\partial x} \Big\} = 0 \qquad \text{for all} \qquad \varphi \in C_0^\infty(Q).$$

Functions $u \in L^\infty(Q)$ which satisfy (1.4) are called weak solutions of (1.1). Clearly, for any $u_B \in [0, 1]$, a weak solution of problem (BL) is given by the shock wave

$$\text{(1.5)} \qquad u(x,t) = S(x,t) \overset{\text{def}}{=} \begin{cases} u_B & \text{for} \quad x < st \\ 0 & \text{for} \quad x > st \end{cases} \qquad \text{where} \qquad s = \frac{f(u_B)}{u_B}.$$

Experiments of two-phase flow in porous media reveal complex infiltration profiles, which may involve *overshoot*; i.e., profiles may not be monotone [13]. Our main objective is to understand the shape of these profiles and to determine how the shape depends on the boundary value u_B and the flux function $f(u)$.

Equation (1.1) usually arises as the limit of a family of extended equations of the form

$$\text{(1.6)} \qquad \frac{\partial u}{\partial t} + \frac{\partial f(u)}{\partial x} = \mathcal{A}_\varepsilon(u), \qquad \varepsilon > 0,$$

in which $\mathcal{A}_\varepsilon(u)$ is a singular regularization term involving higher order derivatives. It is often referred to as a *viscosity term*. Weak solutions of problem (BL) are called *admissible* when they can be constructed as limits, as $\varepsilon \to 0$, of solutions u_ε of (1.6), i.e., for which $\mathcal{A}_\varepsilon(u_\varepsilon) \to 0$ as $\varepsilon \to 0$ in some weak sense. We return to this limit in section 6. This raises the question of which of the shock waves $S(x,t)$ defined in (1.5) are admissible. We shall see that this depends on the operator $\mathcal{A}_\varepsilon$. To obtain criteria for admissibility we shall use families of traveling wave solutions.

A classical viscosity term is

$$\mathcal{A}_\varepsilon(u) = \varepsilon \frac{\partial^2 u}{\partial x^2},$$

and with this term, (1.6) becomes

$$\frac{\partial u}{\partial t} + \frac{\partial f(u)}{\partial x} = \varepsilon \frac{\partial^2 u}{\partial x^2}. \tag{1.7}$$

Seeking a traveling wave solution, we put

$$u = u(\eta) \qquad \text{with} \qquad \eta = \frac{x - st}{\varepsilon}, \tag{1.8}$$

and we find that $u(\eta)$ satisfies the following two-point boundary value problem:

$$\begin{cases} -su' + \big(f(u)\big)' = u'' \qquad \text{in} \qquad \mathbf{R}, & \text{(1.9a)} \\ u(-\infty) = u_\ell, \qquad u(\infty) = u_r, & \text{(1.9b)} \end{cases}$$

where primes denote differentiation with respect to η. An elementary analysis shows that problem (1.9) has a solution if and only if f and the limiting values u_ℓ and u_r satisfy (i) the Rankine–Hugoniot condition (1.3), and (ii) the *Oleinik entropy condition* [29]:

$$\text{(E)} \qquad \frac{f(u_\ell) - f(u)}{u_\ell - u} \geq \frac{f(u_\ell) - f(u_r)}{u_\ell - u_r} \qquad \text{for } u \text{ between } u_\ell \text{ and } u_r. \tag{1.10}$$

Shocks $\{u_\ell, u_r\}$ which satisfy (E) are called *classical* shocks.

Note that in the limit as $\varepsilon \to 0^+$, traveling waves converge to the shock $\{u_\ell, u_r\}$.

Applying (RH) and (E) to the flux function (1.2) we find that the function $S(x,t)$ defined in (1.5) is an admissible shock wave if and only if

$$s = \frac{f(u_B)}{u_B} \quad \text{(RH)} \qquad \text{and} \qquad u_B \leq \alpha \quad \text{(E)}, \tag{1.11}$$

where α is the unique root of

$$f'(u) = \frac{f(u)}{u}.$$

It is found to be given by

$$\alpha = \sqrt{\frac{M}{M+1}} \in (0,1).$$

If $u_B > \alpha$, then the weak solution is composed of a rarefaction wave in the region where $u > \alpha$ and a shock which spans the range $0 < u < \alpha$. Thus, for any $u_B \in (0,1]$ the weak solution $u(x,t)$ is, at any given time t, a nonincreasing function of x, in contrast to the experimental data for infiltration in porous media.

For gaining a better understanding of the data, it is natural to go back to the origins of (1.1). With S_i $(i = o, w)$ being the saturations of the two phases, oil and water, conservation of mass yields

$$\phi \frac{\partial S_i}{\partial t} + \frac{\partial q_i}{\partial x} = 0, \qquad i = o, w, \tag{1.12}$$

where q_i denotes the specific discharge of oil/water and ϕ the porosity of the medium. By Darcy's law, q_i is proportional to the gradient of the phase pressure P_i:

$$q_i = -k \frac{k_{ri}(S_i)}{\mu_i} \frac{\partial P_i}{\partial x}, \tag{1.13}$$

where k denotes the absolute permeability and k_{ri} and μ_i the relative permeability and the viscosity of water, respectively, oil. The capillary pressure P_c expresses the difference in the pressures of the two phases:

$$P_c = P_o - P_w. \tag{1.14}$$

This quantity is commonly found to depend on one phase saturation, say S_w. In addition to this, studies like [28] and [30] show that P_c does not only depend on S_w, but also involves hysteretic and dynamic effects. Hassanizadeh and Gray [19, 20] have defined the dynamic capillary pressure as

$$P_c = p_c(S_w) - \phi\tau\frac{\partial S_w}{\partial t}, \tag{1.15}$$

where $p_c(S_w)$ is the *static* capillary pressure and τ a positive constant. Assuming that the medium is completely saturated,

$$S_w + S_o = 1,$$

and we obtain, upon combining (1.12)–(1.15), the single equation for the water saturation $u = S_w$:

$$\frac{\partial u}{\partial t} + \frac{\partial f(u)}{\partial x} = -\frac{\partial}{\partial x}\left\{H(u)\frac{\partial}{\partial x}\left(J(u) - \tau\frac{\partial u}{\partial t}\right)\right\}, \tag{1.16}$$

in which the functions f, H, and J are related to k_{ri} and p_c. Other noneqilibrium models are considered in [3]. Restricting, for simplicity, to linear terms on the right-hand side of (1.16), we obtain, after a suitable scaling, the pseudoparabolic equation

$$\frac{\partial u}{\partial t} + \frac{\partial f(u)}{\partial x} = \varepsilon\frac{\partial^2 u}{\partial x^2} + \varepsilon^2\tau\frac{\partial^3 u}{\partial x^2 \partial t}. \tag{1.17}$$

Thus, in addition to the classical second order term εu_{xx}, we find a third order term $\varepsilon^2\tau u_{xxt}$, its relative importance being determined by the parameter τ. We show that the value of τ is critical in determining the type of profile the solution of problem (BL) will have.

The right-hand side of (1.17) resembles the regularization $\mathcal{A}_\varepsilon(u) = \varepsilon u_{xx} + \varepsilon^2\delta u_{xxx}$, which has received considerable attention (cf. [23] and the monograph [26] and the references cited therein). We mention in particular the seminal paper [24] in which $f(u) = u^3$. There, for $\delta > 0$ an explicit function $\varphi(u;\delta)$ is derived such that the shock $\{u_\ell, u_r\}$ is admissible if and only if $u_r = \varphi(u_\ell;\delta)$. Properties of this *kinetic function* φ, such as monotonicity with respect to u_ℓ, have been studied in a series of papers (see [6] and the references cited there).

Other regularizations have been studied in [7] and [8] where a fourth order viscosity term was introduced motivated by thin film flow ($\mathcal{A}_\varepsilon(u) = -(u^3 u_{xxx})_x$, and the flux function is $f(u) = u^2 - u^3$) and in [18], where fourth order regularizations are used, motivated by problems in image processing. Traveling waves for dynamic capillarity models, but for a convex flux function, are investigated in [11].

In this paper we focus on the relation between u_ℓ and the parameter τ. With β being defined in Proposition 1.1 (see also Figure 2) we establish the existence of a function $\tau(u_\ell)$ defined for $\alpha < u_\ell < \beta$ such that (1.17) has a traveling wave solution with $u_r = 0$, if and only if $\tau = \tau(u_\ell)$. We shall show that this function is *monotone*, *continuous*, and has limits

$$\tau(u_\ell) \to \tau_* > 0 \quad \text{as} \quad u_\ell \searrow \alpha \qquad \text{and} \qquad \tau(u_\ell) \to \infty \quad \text{as} \quad u_\ell \nearrow \beta.$$

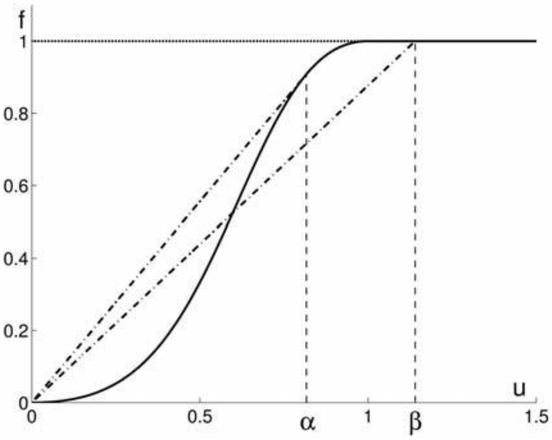

FIG. 2. *Critical values of u when $M = 2$: $\alpha \approx 0.816$ and $\beta \approx 1.147$.*

Thus τ serves as a bifurcation parameter: for $0 < \tau \leq \tau_*$ the situation will be much like in the classical case (E), but for $\tau > \tau_*$ the situation changes abruptly and new types of shock waves become admissible. Note that in the framework of [26] we have $0 = \varphi(u_\ell; \tau(u_\ell))$.

The properties of the function $\tau(u_\ell)$ will be based on three existence, uniqueness, and nonexistence theorems, Theorems 1.1, 1.2, and 1.3, for traveling waves of (1.17). Substituting (1.8) into (1.17) we obtain

$$-su' + \big(f(u)\big)' = u'' - s\tau u''' \qquad \text{in} \qquad \mathbf{R}.$$

When we integrate this equation over (η, ∞), we obtain the second order boundary value problem

$$\text{(1.18a)}\atop\text{(1.18b)} \qquad (\mathrm{TW}) \begin{cases} -s(u - u_r) + \{f(u) - f(u_r)\} = u' - s\tau u'' & \text{in} \qquad \mathbf{R}, \\ u(-\infty) = u_\ell, \qquad u(\infty) = u_r, \end{cases}$$

where $s = s(u_\ell, u_r)$ is given by the Rankine–Hugoniot condition (1.3).

We consider two cases:

$$\text{(I)} \;\; u_r = 0, \quad u_\ell > 0 \qquad \text{and} \qquad \text{(II)} \;\; u_r > u_\ell > 0.$$

Case I. $u_r = 0$. We first establish an upper bound for u_ℓ.

PROPOSITION 1.1. *Let u be a solution of problem* (TW) *such that $u_r = 0$. Then, $u_\ell < \beta$, where β is the value of u for which the equal area rule holds:*

$$\text{(1.19)} \qquad \int_0^\beta \left\{ f(u) - \frac{f(\beta)}{\beta} u \right\} du = 0.$$

In Figure 2 we indicate the different critical values of u in a graph of $f(u)$ when $M = 2$.

Proof. When we put $u_r = 0$ into (1.18a), multiply by u', and integrate over $\mathbf{R}$, we obtain the inequality

$$\int_0^{u_\ell} \left\{ f(u) - \frac{f(u_\ell)}{u_\ell} u \right\} du = -\int_{\mathbf{R}} (u')^2(\eta)\, d\eta < 0,$$

from which it readily follows that $u_\ell < \beta$. ☐

Next, we turn to the questions of existence and uniqueness. Note that if $u_\ell \in (\alpha, \beta)$, then

$$s = s(u_\ell, 0) = \frac{f(u_\ell)}{u_\ell} > f'(u_\ell) \geq f'(0) \qquad \text{for} \qquad u_\ell > \alpha,$$

and traveling waves, if they exist, lead to an admissibility condition for *fast undercompressive waves*. For convenience we write $s(u_\ell, 0) = s(u_\ell)$.

In the theorems below we first show that for each $\tau > 0$, there exists a unique value of $u_\ell \geq \alpha$, denoted by $\overline{u}(\tau)$, for which there exists a solution of problem (TW) such that $u_r = 0$.

THEOREM 1.1. *Let $M > 0$ be given. Then there exists a constant $\tau_* > 0$ such that the following hold:*

(a) *For every $0 \leq \tau \leq \tau_*$, problem* (TW) *has a unique solution with $u_\ell = \alpha$ and $u_r = 0$.*

(b) *For each $\tau > \tau_*$ there exists a unique constant $\overline{u}_\ell(\tau) \in (\alpha, \beta)$ such that problem* (TW) *has a unique solution with $u_\ell = \overline{u}_\ell(\tau)$ and $u_r = 0$.*

(c) *The function $\overline{u} : [0, \infty) \to [\alpha, \beta)$ defined by*

$$\overline{u}(\tau) = \begin{cases} \alpha & \textit{for} \quad 0 \leq \tau \leq \tau_*, \\ \overline{u}_\ell(\tau) & \textit{for} \quad \tau > \tau_* \end{cases} \tag{1.20}$$

is continuous, strictly increasing for $\tau \geq \tau_*$, and $\overline{u}(\infty) = \beta$.

The solutions in parts (a) *and* (b) *are strictly decreasing.*

We shall refer to $\overline{u} = \overline{u}(\tau)$ as the *plateau value* of u. In what follows, we shall often denote the speed $s(\overline{u})$ of the shock $\{\overline{u}, 0\}$ by $\overline{s}$.

Next, suppose that $u_\ell \neq \overline{u}(\tau)$. To deal with this case we need to introduce another critical value of u, which we denote by $\underline{u}(\tau)$.

- For $\tau \in [0, \tau_*]$ we put $\underline{u}(\tau) = \alpha$.
- For $\tau > \tau_*$ we define $\underline{u}(\tau)$ as the unique zero in the interval $(0, \overline{u}(\tau))$ of

$$f(r) - \frac{f(\overline{u})}{\overline{u}} r = 0, \qquad 0 < r < \overline{u}.$$

Plainly, if $\tau > \tau_*$, then

$$0 < \underline{u}(\tau) < \alpha < \overline{u}(\tau) < \beta \qquad \text{for} \quad \tau > \tau_*.$$

In Figure 3, we show graphs of the functions $\overline{u}(\tau)$ and $\underline{u}(\tau)$. They are computed numerically for $M = 2$ by means of a shooting technique that is explained in section 3. In this case we found

$$\tau_* \approx 0.61.$$

The following theorem states that if $u_r = 0$ and $u_\ell \in (0, \overline{u})$, then traveling waves exist if and only if $u_\ell < \underline{u}(\tau)$.

THEOREM 1.2. *Let $M > 0$ and $\tau > 0$ be given, and let $\underline{u} = \underline{u}(\tau)$ and $\overline{u} = \overline{u}(\tau)$.*

(a) *For any $u_\ell \in (0, \underline{u})$, there exists a unique solution of problem* (TW) *such that $u_r = 0$. We have $s(u_\ell) < \overline{s}$.*

(b) *Let $\tau > \tau_*$. Then for any $u_\ell \in (\underline{u}, \overline{u})$, there exists no solution of problem* (TW) *such that $u_r = 0$.*

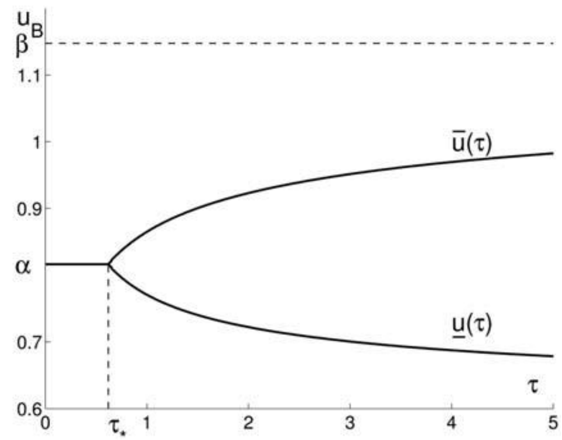

FIG. 3. *The functions $\overline{u}(\tau)$ and $\underline{u}(\tau)$ computed for $M = 2$.*

The solution in part (a) *may exhibit a damped oscillation as it tends to u_ℓ.*

Case II. $u_r > 0$. The results of Case I raise the question as to how to deal with solutions of problem (BL) when $u_B \in (\underline{u}, \overline{u})$, and by Theorem 1.2 there is no traveling wave solution with $u_r = 0$. In this situation we use two traveling waves in succession: one from u_B to the plateau value $\overline{u}$, and one from $\overline{u}$ down to $u = 0$. The existence of the latter has been established in Theorem 1.1. In the next theorem we deal with the former, in which $u_r = \overline{u}$.

THEOREM 1.3. *Let $M > 0$ and $\tau > \tau_*$ be given, and let $\underline{u} = \underline{u}(\tau)$ and $\overline{u} = \overline{u}(\tau)$.*

(a) *For any $u_\ell \in (\underline{u}, \overline{u})$, there exists a unique solution of problem* (TW) *such that $u_r = \overline{u}$. We have $s(u_\ell, \overline{u}) < \overline{s}$.*

(b) *For any $u_\ell \in (0, \underline{u})$, there exists no solution of problem* (TW) *such that $u_r = \overline{u}$.*

The solution in part (a) *may exhibit a damped oscillation as it tends to u_ℓ.*

In section 2 we show how these theorems can be used to construct weak solutions of problem (BL), i.e., weak solutions, which are admissible within the context of the regularization proposed in (1.17), and which involve shocks which may be either classical or nonclassical. In section 3 we solve the Cauchy problem for (1.17) numerically, starting from a smoothed step function, i.e., $u(x, 0) = u_B\tilde{H}(-x)$, where $\tilde{H}(x)$ is a regularized Heaviside function and $M = 2$. We find that for different values of the parameters u_B, τ, and ε the solution converges to solutions constructed in section 2 as $t \to \infty$. In sections 4 and 5 we prove Theorems 1.1, 1.2, and 1.3. The proofs rely on phase plane arguments. We conclude this paper with a discussion of the dissipation of the entropy function $u^2/2$ when u is the solution of the Cauchy problem for (1.17) (cf. section 6).

In this paper we have seen that nonmonotone traveling waves such as those observed in [13] may be explained by a regularization that takes into account properties of two-phase flow. It will be interesting to determine to what extent such results as derived in this paper for the simplified equation (1.17), continue to hold for the full equation (1.16) when realistic functions $H(u)$ and $J(u)$ are used. Such equations may be degenerate at $u = 0$ as well as at $u = 1$, and singular behavior, as in the *porous media equation* [2, 4, 27] may be expected. In this connection it is interesting to mention a numerical study of traveling waves of the original, fully nonlinear equations of this model in [14, 15].

2. Entropy solutions of problem (BL). In this section we give a classification of admissible solutions of problem (BL) based on the "extended viscosity model" (1.17), using the results about traveling wave solutions formulated in Theorems 1.1, 1.2, and 1.3. Before doing that we make a few preliminary observations, and we recall the construction based on the classical model (1.7).

Because (1.1) is a first order partial differential equation and u_B is a constant, any solution of problem (BL) depends only on the combination x/t, with shocks, constant states, and rarefaction waves as building blocks [29]. The latter are continuous solutions of the form

$$u(x,t) = r(\zeta) \qquad \text{with} \qquad \zeta = \frac{x}{t}. \tag{2.1}$$

After substitution into (1.1) this yields

$$\frac{dr}{d\zeta}\left(-\zeta + \frac{df}{du}\big(r(\zeta)\big)\right) = 0. \tag{2.2}$$

Hence, the function $r(\zeta)$ satisfies

$$\textit{either} \quad r = \text{constant} \qquad \textit{or} \qquad \frac{df}{du}\big(r(\zeta)\big) = \zeta.$$

When solving problem (BL), we will combine solutions of (2.2) with admissible shocks, i.e., shocks $\{u_\ell, u_r\}$ in which u_ℓ and u_r are such that (1.6), with the a priori selected and physically relevant viscous extension $\mathcal{A}_\varepsilon$, has a traveling wave solution $u(\eta)$ such that $u(\eta) \to u_\ell$ as $\eta \to -\infty$ and $u(\eta) \to u_r$ as $\eta \to +\infty$. Although in the physical context in which the viscous extension employed in (1.17) was derived, $0 \le u_B \le 1$, we shall drop this restriction. It will be convenient to first assume that $0 \le u_B \le \beta$. At the end of this section we discuss the case that $u_B > \beta$.

All solution graphs shown in this section and the next are numerically obtained solutions of (1.17). They are expressed in terms of the independent variable ζ and t, i.e.,

$$u(x,t) = w(\zeta, t),$$

and considered for fixed $\varepsilon > 0$ $(= 1)$ and for large times t. We return to the computational aspects in section 3.

Before discussing the implications of the viscous extension in (1.17), we recall the construction of *classical entropy solutions* of problem (BL). It uses (RH) and the entropy condition (E), which was derived for the diffusive viscous extension used in (1.8). We distinguish two cases:

$$\text{(a)} \qquad 0 \le u_B \le \alpha \qquad \text{and} \qquad \text{(b)} \qquad \alpha < u_B \le \beta.$$

Case (a). $0 \le u_B \le \alpha$. This case was discussed in the introduction, where we found that the entropy solution is given by the shock $\{u_B, 0\}$.

Case (b). $\alpha < u_B \le \beta$. In the introduction we saw that in this case, the shock $\{u_B, 0\}$ is no longer a classical entropy solution. Instead, in this case the entropy solution is a composition of three functions:

$$u(x,t) = v(\zeta) = \begin{cases} u_B & \text{for} \quad 0 \le \zeta \le \zeta_B, \\ r(\zeta) & \text{for} \quad \zeta_B \le \zeta \le \zeta_*, \\ 0 & \text{for} \quad \zeta_* \le \zeta < \infty, \end{cases} \tag{2.3}$$

where ζ_B and ζ_* are determined by

$$\zeta_B = \frac{df}{du}(u_B) \qquad \text{and} \qquad \zeta_* = \frac{df}{du}(\alpha) = \frac{f(\alpha)}{\alpha} = s(\alpha),$$

and $r : [\zeta_B, \zeta_*] \to [\alpha, u_B]$ by the relation

$$\frac{df}{du}\big(r(\zeta)\big) = \zeta \qquad \text{for} \qquad \zeta_B \le \zeta \le \zeta_*. \tag{2.4}$$

Since $f''(u) < 0$ for $u \in [\alpha, u_B]$, (2.4) has a unique solution, and hence $r(\zeta)$ is well defined. Note that if $u_B \ge 1$, then $\zeta_B = 0$, because $f'(u) = 0$ if $u \ge 1$.

Solutions corresponding to Case (b) are shown in Figure 4.

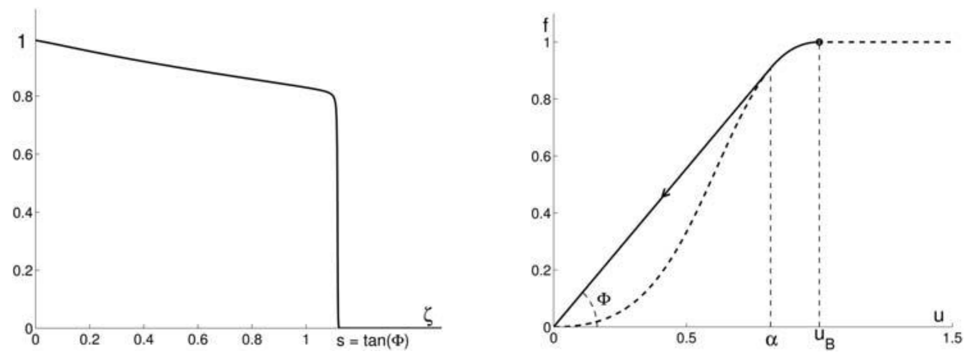

FIG. 4. *Case* (b). *Solution graph (left) and flux function with transitions from* u_B *to* α *and from* α *to* 0 *(right).*

We now turn to the pseudoparabolic equation (1.17) that arises in the context of the two-phase flow model of Hassanizadeh and Gray [19, 20]. For this problem, we define a class of nonclassical entropy solutions in which shocks are admissible if problem (TW) has a traveling wave solution with the required limit conditions.

For given $M > 0$ and $\tau > 0$, the relative values of u_B and $\overline{u}(\tau)$ and $\underline{u}(\tau)$ are now important for the type of solution we are going to get. It is easiest to represent them in the (u_B, τ)-plane. Specifically, we distinguish three regions in this plane:

$$\begin{aligned}
\mathcal{A} &= \{(u_B, \tau) : \tau > 0, \quad \overline{u}(\tau) \le u_B < \beta\},\\
\mathcal{B} &= \{(u_B, \tau) : \tau > \tau_*, \quad \underline{u}(\tau) < u_B < \overline{u}(\tau)\},\\
\mathcal{C} &= \{(u_B, \tau) : \tau > 0, \quad 0 < u_B < \underline{u}(\tau)\}.
\end{aligned}$$

These three regions are shown in Figure 5.

Case I. $(u_B, \tau) \in \mathcal{A}$. If $0 \le \tau \le \tau_*$, i.e., $(u_B, \tau) \in \mathcal{A}_1$, the construction is as in the classical case described above. After a plateau, where $u = u_B$ and $0 \le \zeta = x/t \le \zeta_B$, we find a rarefaction wave $r(\zeta)$ from u_B down to α followed by a classical shock connecting α to the initial state $u = 0$.

If $\tau > \tau_*$, i.e., $(u_B, \tau) \in \mathcal{A}_2$, the solution starts out as before, with a plateau where $u = u_B$ and $0 \le \zeta \le \zeta_B$ and a rarefaction wave $r(\zeta)$ which now takes u down from u_B to $\overline{u} > \alpha$. This takes place over the interval $\zeta_B \le \zeta \le \overline{\zeta}$. By (2.2),

$$\overline{\zeta} = \frac{df}{du}\big(\overline{u}(\tau)\big).$$

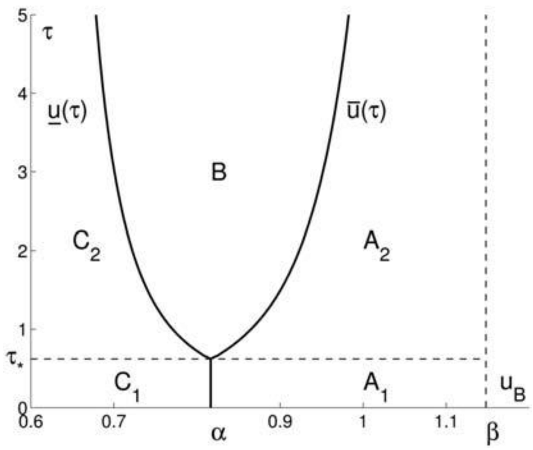

FIG. 5. *The regions $\mathcal{A}$, $\mathcal{B}$, and $\mathcal{C}$ in the (u_B, τ)-plane.*

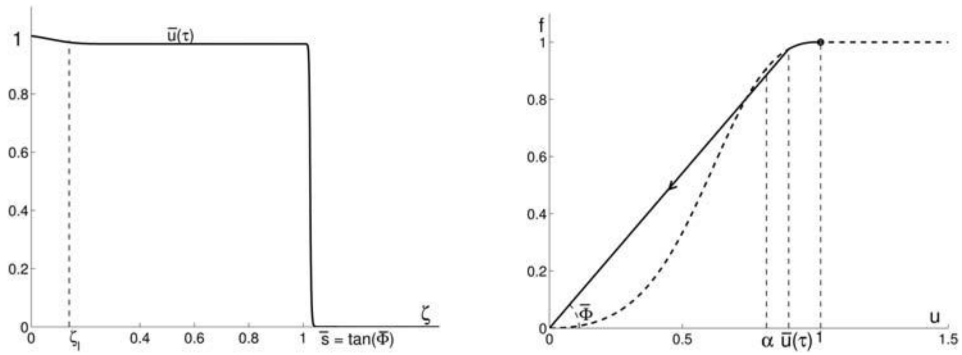

FIG. 6. *Case* I. *Solution graph (left) and flux function (right), with transitions from $u_B = 1$ to $\overline{u}(\tau)$ and from $\overline{u}(\tau)$ to* 0.

Subsequently, u drops down to the initial state $u = 0$ through a shock, $\{\overline{u}, 0\}$, which is admissible by Theorem 1.1. By (RH) the shock moves with speed

$$s = \overline{s} = \frac{f(\overline{u})}{\overline{u}} > \frac{df}{du}(\overline{u}) = \overline{\zeta},$$

because f is concave on (α, ∞). Therefore, the shock outruns the rarefaction wave and a second plateau develops between the rarefaction wave and the shock in which $u = \overline{u}$. Summarizing, we find that the (nonclassical) entropy solution has the form

$$u(x,t) = v(\zeta) = \begin{cases} u_B & \text{for} \quad 0 \le \zeta \le \zeta_B, \\ r(\zeta) & \text{for} \quad \zeta_B \le \zeta \le \overline{\zeta}, \\ \overline{u}(\tau) & \text{for} \quad \overline{\zeta} \le \zeta \le \overline{s}, \\ 0 & \text{for} \quad \overline{s} \le \zeta < \infty. \end{cases} \tag{2.5}$$

A graph of $v(\zeta)$ is given in Figure 6.

Note that if $u_B \ge 1$, then $\zeta_B = 0$. At this point v shocks to the maximum of $\overline{u}(\tau)$ and 1. If $\overline{u}(\tau) \ge 1$, then the rarefaction wave disappears and for $\zeta > 0$ the solution is continued by the shock $\{\overline{u}(\tau), 0\}$.

Case II. $(u_B, \tau) \in \mathcal{B}$. It follows from Theorem 1.2 that there are no traveling wave solutions with $u_\ell = u_B$ and $u_r = 0$, so that the shock $\{u_B, 0\}$ is now not admissible. However, in Theorem 1.3 we have shown that there does exist a traveling wave solution, and hence an admissible shock, with $u_\ell = u_B$ and $u_r = \overline{u}(\tau)$, and speed $s = s(u_B, \overline{u}(\tau))$. This shock is then followed by a second shock from $u = \overline{u}(\tau)$ down to $u = 0$, which is admissible because by Theorem 1.1 there does exist a traveling wave solution which connects $\overline{u}$ and $u = 0$ with speed $\overline{s} > s(u_B, \overline{u}(\tau))$. Thus

$$u(x,t) = v(\zeta) = \begin{cases} u_B & \text{for} \quad 0 \le \zeta \le s(u_B, \overline{u}), \\ \overline{u}(\tau) & \text{for} \quad s(u_B, \overline{u}) \le \zeta \le \overline{s}, \\ 0 & \text{for} \quad \overline{s} \le \zeta < \infty. \end{cases} \tag{2.6}$$

An example of this type of solution is shown in Figure 7. The undershoot in the solution graph is due to oscillations which are also present in the traveling waves.

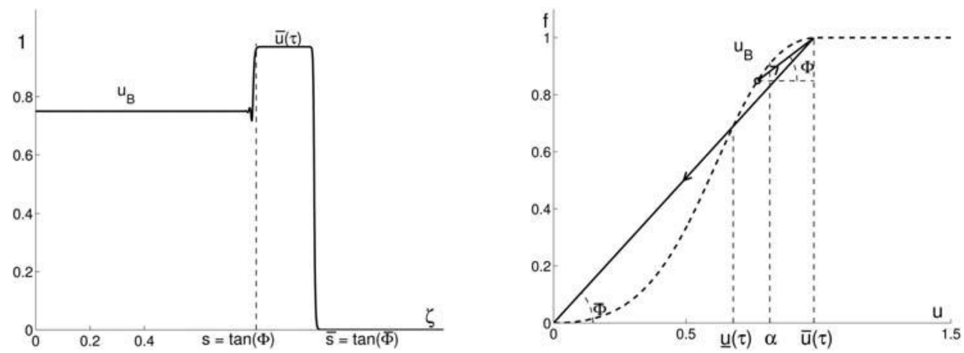

FIG. 7. *Case* II. *Solution graph (left) and flux function (right), with transitions from* $u_B = 0.75$ *to* $\overline{u}(\tau)$ *and from* $\overline{u}(\tau)$ *to* 0.

Remark 2.1. It is readily seen that

$$s(u_B, \overline{u}(\tau)) \nearrow \overline{s} \qquad \text{as} \qquad u_B \searrow \underline{u},$$

while the plateau level $\overline{u}$ remains the same. Thus, in this limit, the plateau

$$\left\{ \left(u, \frac{x}{t}\right) : u = \overline{u}(\tau),\ s(u_B, \overline{u}(\tau)) < \frac{x}{t} < \overline{s} \right\}$$

becomes thinner and thinner and eventually disappears when $u_B = \underline{u}$.

Remark 2.2. If $u_B = 1$ and $\overline{u}(\tau) > 1$, then the first shock degenerates in the sense that

$$s(u_B, \overline{u}(\tau)) = 0 \qquad \text{and} \qquad u(x,t) = \overline{u}(\tau) \quad \text{for all} \quad 0 < \frac{x}{t} < \overline{s}.$$

Case III. $(u_B, \tau) \in \mathcal{C}$. We have seen in Theorem 1.2 that in this case there exists a traveling wave solution with $u_\ell = u_B$ and $u_r = 0$. It may exhibit oscillatory behavior near $u = u_\ell$, and it leads to the classical entropy shock solution $\{u_B, 0\}$. An example of such a solution is shown in Figure 8. Note the overshoot in the solution graph, reflecting oscillations also present in the traveling waves.

We conclude with a remark about the case when $u_B > \beta$. It is readily verified that for such values of u_B the situation is completely analogous to the one for $(u_B, \tau) \in \mathcal{A}$.

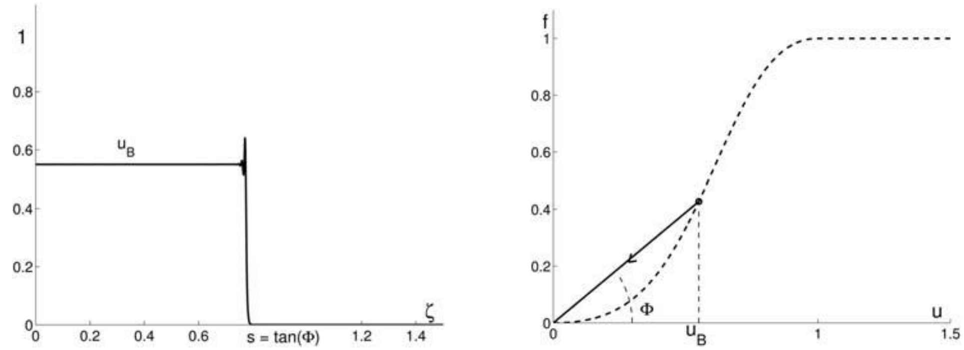

FIG. 8. *Case* III. *Solution graph (left) and flux function (right), with transition from* $u_B = 0.55$ *to* 0.

3. Numerical experiments for large times. In this section we report on the computations carried out for obtaining the numerical results presented in this paper. All computations are done for $M = 2$. We start with the calculation of the diagram in Figure 3. For determining the graphs of $\overline{u}$ and $\underline{u}$ as functions of τ we fix $u_r = 0$. Then, given a $\tau > 0$ and a left state $u_\ell \geq 0$, we look for a strictly decreasing solution $u(\eta)$ of the problem (1.18a) and (1.18b). If such a solution exists, we can invert the function $u(\eta)$ and define the new dependent variable $z(u) = -u'(\eta(u))$, which satisfies

$$s\tau zz' + z = su - f(u)$$

on the open interval $(0, u_\ell)$. Moreover, we have $z > 0$ on $(0, u_\ell)$, and $z(0) = z(u_\ell) = 0$.

Following Theorem 1.1, an $\tau_* > 0$ exists so that solutions z to the given first order equation and boundary conditions are possible for any $\tau \leq \tau_*$, and with $u_\ell = \alpha$. To compute τ_* we fix $u_\ell = \alpha$ and solve the equation in z with $z(0) = 0$. We start with a sufficiently small $\tau > 0$ and increase its value until $z(u_\ell)$ becomes strictly positive. This gives

$$\tau_* \approx 0.61.$$

Further, for $\tau > \tau_*$ there is a unique $u_\ell = \overline{u}(\tau) \in (\alpha, \beta)$ yielding a solution z with the required properties. Moreover, $\overline{u}$ is strictly increasing in τ. For finding the corresponding u_ℓ we solve numerically the equation in z with the initial value $z(0) = 0$. We repeat this procedure for different values of τ, starting close to τ_* and increasing gradually the difference between two successive values of τ as the corresponding u_ℓ approaches β. Accurate computations with different ODE solvers have led to negligible differences in the resulting diagrams. Finally, the function $\underline{u}(\tau)$ follows from a simple construction involving $f(u)$.

Nonstandard shock solutions of a hyperbolic conservation are computed numerically in [21] and [22]. The schemes considered there are applied to the hyperbolic problem, but they actually solve more accurately a regularized problem involving a ∂_{xxx} term. This term vanishes as the discretization parameters are approaching 0.

Here we consider the regularized initial value problem for (1.17) in the domain $S = \mathbf{R} \times \mathbf{R}^+$:

$$\begin{cases} \dfrac{\partial u}{\partial t} + \dfrac{\partial f(u)}{\partial x} = \varepsilon \dfrac{\partial^2 u}{\partial x^2} + \varepsilon^2 \tau \dfrac{\partial^3 u}{\partial x^2 \partial t} & \text{in} \quad S, \qquad (3.1a) \\ u(x,0) = u_B \tilde{H}(-x) & \text{for} \quad x \in \mathbf{R}. \qquad (3.1b) \end{cases}$$

Here $\tilde{H}(x)$ is a smooth monotone approximation of the Heaviside function H. We use $\tilde{H}$ instead of H because discontinuities in the initial conditions will persist for all $t > 0$, as shown in [12]. This would require an adapted and more complicated numerical approach for ensuring the continuity in flux and pressure (see, for example, [10], or [9, Chapter 3]). By the above choice we avoid this unnecessary complication.

Important parameters in this problem are M, ε, $\tau > 0$, and $u_B \in (0,1]$. The scaling

$$x \to \frac{x}{\varepsilon}, \qquad t \to \frac{t}{\varepsilon} \tag{3.2}$$

removes the parameter ε from (3.1a). Therefore, we fix $\varepsilon = 1$ and show how for different values of τ and u_B the solution $u(x,t)$ of problem (3.1) converges as $t \to \infty$ to qualitatively different final profiles.

For solving (3.1) numerically we consider a first order time stepping, combined with the finite difference discretization of the terms involving ∂_{xx}. To deal with the first order term we apply a minmod slope limiter method that is based on first order upwinding and Richtmyer's scheme. Specifically, with $k > 0$ and $h > 0$ being the discretization parameters, we define $x_i = ih$ ($i \in \mathbb{Z}$) and $t_n = nk$ ($n \in \mathbb{N}$), and let u_i^n stand for the numerical

approximation of $u(x_i, t_n)$. With

$$\Delta_{h,i}(u) := \frac{1}{h^2}\big(u_{i+1} - 2u_i + u_{i-1}\big),$$

the fully discrete counterpart of (3.1a) in (x_i, t_k) reads

$$u_i^{n+1} - u_i^n + \frac{k}{h}\big(F^n_{i+\frac{1}{2}} - F^n_{i-\frac{1}{2}}\big) = k\varepsilon\Delta_{h,i}(u^{n+1}) + \varepsilon^2\tau\Delta_{h,i}(u^{n+1} - u^n),$$

where $F^n_{i+\frac{1}{2}}$ is the numerical flux at $x_{i+\frac{1}{2}} = x_i + \frac{h}{2}$ and t_n. As mentioned above, $F^n_{i+\frac{1}{2}}$ is a convex combination of the first order upwind flux and the second order Richtmyer flux:

$$F^n_{i+\frac{1}{2}} = (1 - \Theta_i^n)F^{n,low}_{i+\frac{1}{2}} + \Theta_i^n F^{n,high}_{i+\frac{1}{2}},$$

where

$$\begin{aligned} F^{n,low}_{i+\frac{1}{2}} &= f(u_i^n), \\ F^{n,high}_{i+\frac{1}{2}} &= f(w_i^n), \qquad \text{for } w_i^n = \tfrac{u_i^n + u_{i+1}^n}{2} - \tfrac{k}{2h}\big(f(u_{i+1}^n) - f(u_i^n)\big), \end{aligned}$$

and

$$\Theta_i^n = \max(0, \min(1, \theta_i^n)), \qquad \text{for } \theta_i^n = \begin{cases} 0 & \text{if } u_i^n = u_{i+1}^n, \\ \frac{u_i^n - u_{i-1}^n}{u_{i+1}^n - u_i^n} & \text{otherwise.} \end{cases}$$

To compute the numerical solution, we restrict (3.1) to the sufficiently large spatial interval $(-1000, 5000)$, and define the artificial boundary conditions $u(-1000,t) = u_B$ and $u(5000,t) = 0.0$. The computations are performed for large times ($t > 2000$), as long as the results are not affected by the presence of the boundaries. We apply the discretization scheme mentioned above, yielding a linear tridiagonal system that is solved at each time step. A convergence proof for the numerical scheme is beyond the scope of the present work. Similar numerical schemes for problems of pseudoparabolic type are considered, for example, in [1] and [16], where also the convergence is proven.

In the figures below, we show graphs of solutions at various times t, appropriately scaled in space. Specifically, we show graphs of the function

$$w(\zeta, t) = u(x, t), \qquad \text{where} \qquad \zeta = \frac{x}{t}, \tag{3.3}$$

so that a front with speed s will be located at $\zeta = s$.

We recall that the numerical results are obtained for $M = 2$. In this case $\tau_* \approx 0.61$ (see also Figures 3 and 5). We begin with a simulation where $(u_B, \tau) = (1, 0.2) \in \mathcal{A}_1$. In Figure 9 we show the resulting solution $w(\zeta, t)$ at time $t = 1000$. It is evident that w converges to the classical entropy solution constructed in section 2.

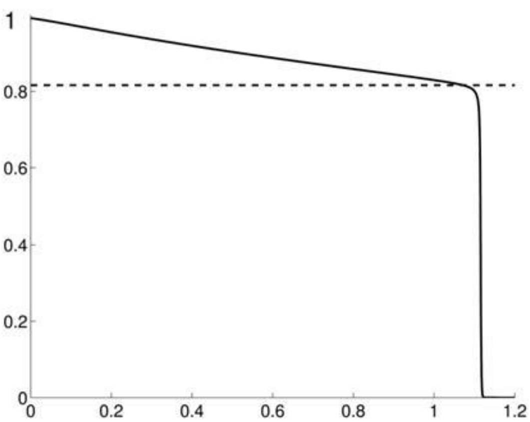

FIG. 9. *Graph of* $w(\zeta, t)$ *at* $t = 1000$ *when* $(u_B, \tau) = (1, 0.2) \in \mathcal{A}_1$. *In this case* $\overline{u}(\tau) = \alpha \approx 0.816$ *and* $s \approx 1.11$.

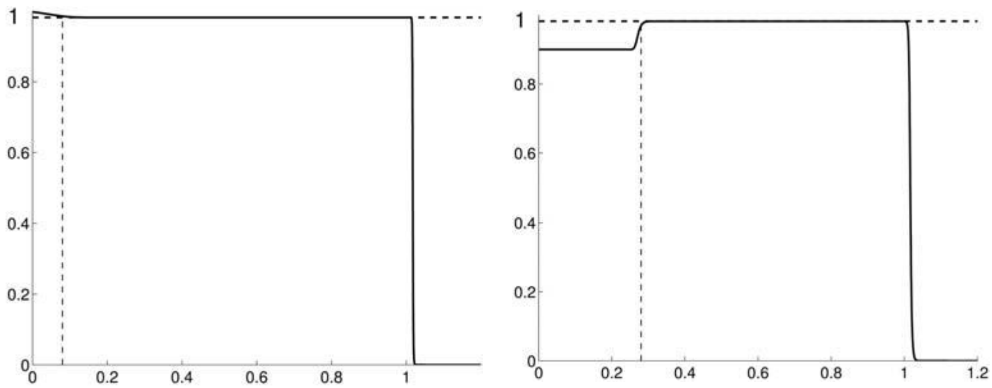
In the simulations that we present in the remainder of this section we take τ to be fixed above τ_*: $\tau = 5$. Correspondingly, by the ODE method involved in computing the diagram in Figure 3 we obtained $\overline{u}(\tau = 5) \approx 0.98$ and $\underline{u}(\tau = 5) \approx 0.68$. In the first of these experiments, in which we keep $u_B = 1$, we see that for large time the graph consists of three pieces: one in which w gradually decreases from $w = u_B = 1$ to the "plateau" value $w = \overline{u}$, one in which w is constant and equal to $\overline{u}$, and one in which it drops down to $u = 0$; see Figure 10(a). It is clear from the graph that $\overline{u} > \alpha$. The plateau value $\overline{u} \approx 0.98$ computed here is in excellent agreement with the value obtained by the ODE method; see also Figures 3 and 5.

In the next experiment we decrease u_B to $u_B = 0.9$. We are then in the region $\mathcal{B}$. For large times the solution $w(\zeta, t)$ develops two shocks, one where it jumps up from u_B to the plateau at $\overline{u} \approx 0.98$ (the same value as in the previous experiment), and one where it jumps down from $\overline{u}$ to $w = 0$; see Figure 10(b).

In the next experiments we decrease the value of u_B to values around the value $\underline{u} \approx 0.68$. The results are shown in Figure 11, where we have zoomed into the front. We see that, as u_B decreases and approaches the boundary between the regions $\mathcal{B}$ and $\mathcal{C}_2$ in Figure 5, the part of the graph where $w \approx u_B$ grows at the expense of the part where $w \approx \overline{u}$.

Finally, in Figure 12 we show the graph of $w(\zeta, t)$ when $\tau = 5$ and u_B is further



(a) $(u_B, \tau) = (1, 5) \in \mathcal{A}_2$ (b) $(u_B, \tau) = (0.9, 5) \in \mathcal{B}$

FIG. 10. *Graphs of* $w(\zeta, t)$ *at* $t = 1000$ *when* $(u_B, \tau) = (1, 5) \in \mathcal{A}_2$ *(left) and* $(u_B, \tau) = (0.9, 5) \in \mathcal{B}$ *(right). Here* $\overline{u}(\tau) \approx 0.98$ *and* $s \approx 1.02$*, while* $\zeta_\ell \approx 0.08$ *(left) and* $s_B \approx 0.28$ *(right).*

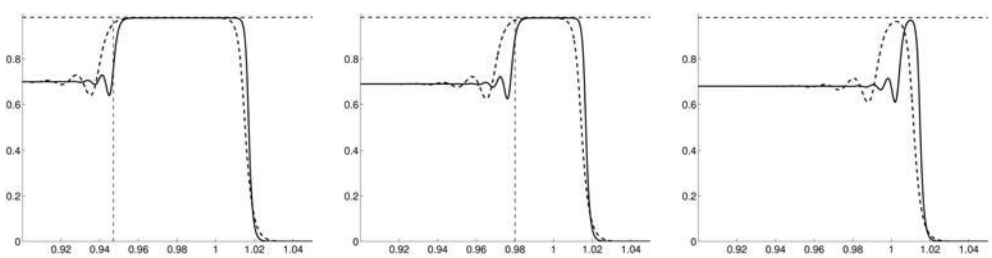


FIG. 11. *Graphs of* $w(\zeta, t)$ *with* $\tau = 5$ *at* $t = 1000$ *(dashed) and* $t = 2000$ *(solid); zoomed view:* $0.9 \leq \zeta \leq 1.05$*. Here* $\underline{u}(\tau) \approx 0.68$ *and* u_B *approaches* $\underline{u}(\tau)$ *from above through* 0.70 *(left),* 0.69 *(middle), and* 0.68 *(right). Then* s_B *increases from* 0.95 *(left) to* 0.98 *(middle) up to* 1.02 *(right). The other values are* $\overline{u}(\tau) \approx 0.98$ *and* $s \approx 1.02$*.*

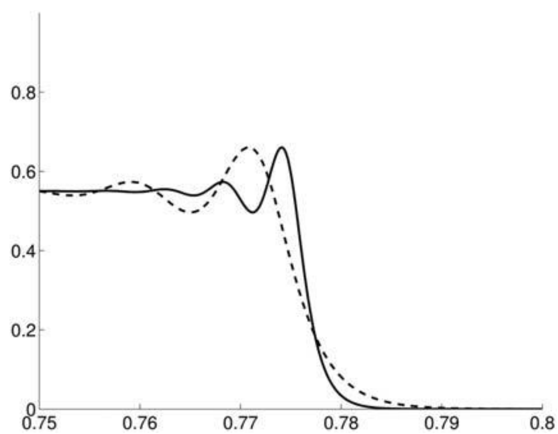

FIG. 12. *Graphs of* $w(\zeta, t)$ *at* $t = 1000$ *(dashed) and* $t = 2000$ *(solid) when* $(u_B, \tau) = (0.55, 5) \in \mathcal{C}_2$*; zoomed view:* $0.75 \leq \zeta \leq 0.8$*. Then* $s \approx 0.78$*.*

reduced to 0.55, so that we are now in $\mathcal{C}_2$. We find that the solution no longer jumps up to a higher plateau, but instead jumps right down after a small oscillation.

Note that the oscillations in Figures 11 and 12 contract around the shock as time progresses. This is due to the scaling, since we have plotted $w(\zeta, t)$ versus $\zeta = x/t$ for different values of time t.

We conclude from these simulations that the entropy solutions constructed in section 2 emerge as limiting solutions of the Cauchy problem (3.1). This suggests that these entropy solutions enjoy certain stability properties. It would be interesting to see whether these same entropy solutions would emerge if the initial value were chosen differently. We leave this question to a future study.

4. Proof of Theorem 1.1. In Theorem 1.1 we considered traveling wave solutions $u(\eta)$ of (1.17) in which the limiting conditions had been chosen so that $u(-\infty) = u_\ell \geq \alpha$ and $u(\infty) = u_r = 0$. Putting $u_r = 0$ in (1.18a) and (1.18b) we find that they are solutions of the problem

$$\text{(TW}_0\text{)}\begin{cases} s\tau u'' - u' - su + f(u) = 0 \qquad \text{for} \qquad -\infty < \eta < \infty, & \text{(4.1a)}\\ u(-\infty) = u_\ell, \qquad u(+\infty) = 0, & \text{(4.1b)}\end{cases}$$

in which the speed s is a priori determined by u_ℓ through

$$s = s(u_\ell) \stackrel{\text{def}}{=} \frac{f(u_\ell)}{u_\ell}. \tag{4.2}$$

The proof proceeds in a series of steps.

Step 1. We choose $u_\ell \in (\alpha, \beta)$ and prove that there exists a unique $\tau > 0$ for which problem (TW$_0$) has a solution, which is also unique. This defines a function $\tau = \tau(u_\ell)$ on (α, β). We then show that $\tau(u_\ell)$ is increasing, continuous, and that

$$\tau(u) \to \infty \qquad \text{if} \qquad u \to \beta.$$

Finally, we write

$$\tau_* \stackrel{\text{def}}{=} \lim_{u \to \alpha^+} \tau(u).$$

Step 2. We show that for any $\tau \in (0, \tau_*]$, problem (TW$_0$) has a solution with $u_\ell = \alpha$.

The proof is concluded by defining the function $\overline{u}_\ell(\tau)$ on (τ_*, ∞) as the inverse of the function $\tau(u_\ell)$ on the interval (α, β). The resulting function $\overline{u}(\tau)$, defined by (1.17) on $\mathbf{R}^+$, then has all the properties required in Theorem 1.1.

4.1. The function $\boldsymbol{\tau(u)}$. As a first result we prove that $\tau(u)$ is well defined on the interval (α, β).

LEMMA 4.1. *For each $u_\ell \in (\alpha, \beta)$ there exists a unique value of τ such that there exists a solution of problem* (TW$_0$). *This solution is unique and decreasing.*

Proof. It is convenient to write (4.1a) in a more conventional form, and introduce the variables

$$\xi = -\eta/\sqrt{s\tau} \qquad \text{and} \qquad \tilde{u}(\xi) = u(\eta).$$

In terms of these variables, problem (TW$_0$) becomes

$$\begin{cases} u'' + cu' - g(u) = 0 \qquad \text{in} \qquad -\infty < \xi < \infty, & \text{(4.3a)}\\ u(-\infty) = 0, \qquad u(+\infty) = u_\ell, & \text{(4.3b)}\end{cases}$$

where

$$c = \frac{1}{\sqrt{s\tau}} \qquad \text{and} \qquad g(u) = su - f(u), \tag{4.4}$$

and the tildes have been omitted. Graphs of $g(u)$ for $M = 2$ and different values of s are shown in Figure 13.

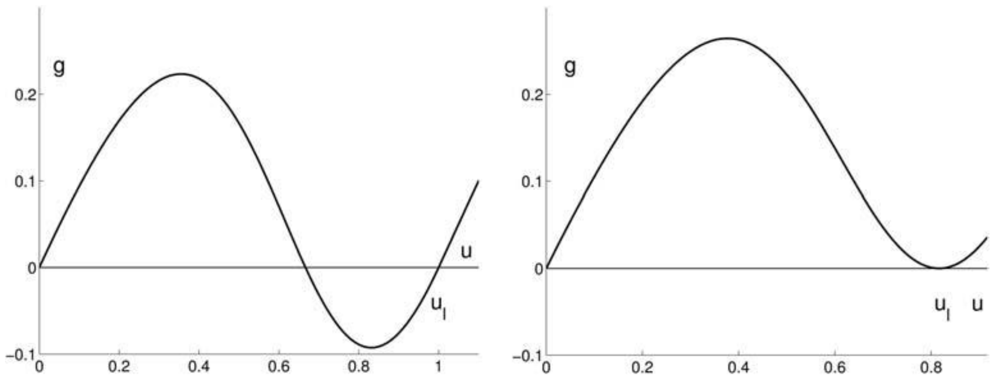

FIG. 13. *The function for $g(u)$ for $M = 2$, and $s = 0.95$ (left) and $s = s(\alpha) = 1.113$ (right).*

We study problem (4.3) in the phase plane and write (4.3a) as the first order system

$$\mathcal{P}(c,s) \begin{cases} u' = v, & (4.5a) \\ v' = -cv + g(u). & (4.5b) \end{cases}$$

For $u_\ell \in (\alpha, \beta)$ the function $g(u)$ has three distinct zeros, which we denote by u_i, $i = 0$, 1, and 2, where

$$u_0 = 0 \qquad \text{and} \qquad u_1 < \alpha < u_2 = u_\ell.$$

Plainly the points $(u, v) = (u_i, 0)$, $i = 0, 1, 2$, are the equilibrium points of (4.5) with associated eigenvalues

$$\lambda_\pm = -\frac{c}{2} \pm \frac{1}{2}\sqrt{c^2 + 4g'(u_i)}. \tag{4.6}$$

Since

$$g'(u_0) > 0, \qquad g'(u_1) < 0, \qquad \text{and} \qquad g'(u_2) > 0,$$

the outer points, $(u_0, 0)$ and $(u_2, 0)$, are saddles and $(u_1, 0)$ is either a stable node or a stable spiral.

Since we are interested in a traveling wave with $u(-\infty) = 0$ and $u(+\infty) = u_\ell$, we need to investigate orbits which connect the points $(0, 0)$ and $(u_\ell, 0)$. The existence of a unique wave speed c for which there exists such a solution of the system $\mathcal{P}(c, s)$, which is unique and decreasing, has been established in [25]; see also [17]. This allows us to define the function $c = c(u_\ell)$ for $\alpha < u_\ell < \beta$.

By definition, $c(u_\ell)$ only takes on positive values. This is consistent with the identity, obtained by multiplying (4.3a) by u' and integrating the result over $\mathbf{R}$:

$$c \int_{\mathbf{R}} \{u'(\xi)\}^2 \, d\xi = \int_{\mathbf{R}} g(u(\xi))\, u'(\xi) \, d\xi = \int_0^{u_\ell} g(t) \, dt \stackrel{\text{def}}{=} G(u_\ell), \tag{4.7}$$

because $G(u_\ell) > 0$ when $0 < u_\ell < \beta$.

Finally, by (4.2) and (4.4), we find that τ is uniquely determined by u_ℓ through the relation

$$\tau(u_\ell) = \frac{1}{s(u_\ell)c^2(u_\ell)}. \tag{4.8}$$

This completes the proof of Lemma 4.1. ∎

Lemma 4.1 allows us to define a function $\tau(u)$ on (α, β), such that if $u_\ell \in (\alpha, \beta)$, then problem ($\mathrm{TW}_0$) has a unique solution $u(\eta)$ if and only if $\tau = \tau(u_\ell)$. In the next lemma we show that the function $\tau(u)$ is strictly increasing on (α, β).

LEMMA 4.2. *Let $u_{\ell,i} = \gamma_i$ for $i = 1, 2$, where $\gamma_1 \in (\alpha, \beta)$, and let $\tau(\gamma_i) = \tau_i$. Then*

$$\gamma_1 < \gamma_2 \qquad \Longrightarrow \qquad \tau_1 < \tau_2.$$

Proof. For $i = 1, 2$ we write

$$s_i = \frac{f(\gamma_i)}{\gamma_i} \qquad \text{and} \qquad g_i(u) = s_i u - f(u).$$

Since

$$\frac{d}{du}\left(\frac{f(u)}{u}\right) = \frac{1}{u}\left(f'(u) - \frac{f(u)}{u}\right) < 0 \qquad \text{for} \qquad \alpha \le u < \beta,$$

it follows that

$$\gamma_1 < \gamma_2 \qquad \Longrightarrow \qquad s_1 > s_2 \quad \text{and} \quad g_1(u) > g_2(u) \quad \text{for} \quad u > 0. \tag{4.9}$$

To prove Lemma 4.2 we return to the formulation used in the proof of Lemma 4.1. Traveling waves correspond to heteroclinic orbits in the (u, v)-plane. Those associated with γ_1 and γ_2 we denote by Γ_1 and Γ_2. They connect the origin to $(\gamma_1, 0)$ and $(\gamma_2, 0)$, respectively.

We shall show that

$$\gamma_1 < \gamma_2 \qquad \Longrightarrow \qquad c_1 = c(\gamma_1) > c(\gamma_2) = c_2. \tag{4.10}$$

We can then conclude from (4.4) that

$$\tau_2 s_2 > \tau_1 s_1 \qquad \Longrightarrow \qquad \tau_2 > \frac{s_1}{s_2}\tau_1 > \tau_1,$$

as asserted.

Thus, suppose to the contrary that $c_1 \le c_2$. We claim that this implies that near the origin the orbit Γ_1 lies below Γ_2. Orbits of the system $\mathcal{P}(c, s)$ leave the origin along the unstable manifold under the angle θ given by

$$\theta = \theta(c, s) \stackrel{\text{def}}{=} \frac{1}{2}\left\{\sqrt{c^2 + 4s} - c\right\}. \tag{4.11}$$

An elementary computation shows that

$$\frac{\partial \theta}{\partial c} < 0 \qquad \text{and} \qquad \frac{\partial \theta}{\partial s} > 0. \tag{4.12}$$

Hence, since $s_1 > s_2$ and we assume that $c_1 \le c_2$, it follows that

$$\theta_1 = \theta(c_1, s_1) > \theta(c_2, s_2) = \theta_2,$$

and hence that the orbit Γ_1 starts out *above* Γ_2.

Since $(\gamma_2, 0)$ lies to the right of the point $(\gamma_1, 0)$ we conclude that Γ_1 and Γ_2 must intersect. Let us denote the first point of intersection by $P = (u_0, v_0)$. Then at P the slope of Γ_1 cannot exceed the slope of Γ_2. The slopes at P are given by

$$\frac{dv}{du}\Big|_{\Gamma_i} = -c_i + \frac{g_i(u_0)}{v_0}, \qquad i = 1, 2.$$

Because $g_1(u) > g_2(u)$ for $u > 0$ by (4.9), it follows that

$$\frac{dv}{du}\Big|_{\Gamma_1} > \frac{dv}{du}\Big|_{\Gamma_2} \qquad \text{at} \quad P,$$

so that, at P, the slope of Γ_1 exceeds the slope of Γ_2, a contradiction. Therefore we find that $c_1 > c_2$, as asserted. $\square$

In the next lemma we show that the function $\tau(u)$ is continuous.

LEMMA 4.3. *The function* $\tau : (\alpha, \beta) \to \mathbf{R}^+$ *is continuous.*

Proof. Because the function $s(\gamma) = \gamma^{-1} f(\gamma)$ is continuous, it suffices to show that the function $c(\gamma)$ is continuous. Since we have shown in the proof of Lemma 4.1 that $c(\gamma)$ is decreasing (cf. (4.10)), we only need to show that it cannot have any jumps.

Suppose to the contrary that it has a jump at γ_0, and let us write

$$\liminf_{\gamma \searrow \gamma_0^+} c(\gamma) = c^+ \qquad \text{and} \qquad \limsup_{\gamma \nearrow \gamma_0^-} c(\gamma) = c^-.$$

Then, since $c(\gamma)$ is decreasing, we may assume that $c^- > c^+$.

Thus, there exist sequences $\{\gamma_n^-\}$ and $\{\gamma_n^+\}$ with corresponding heteroclinic orbits $(u_n^\pm, v_n^\pm)$ and wave speeds $c_n^\pm$, such that

$$c_n^+ \searrow c^+ \qquad \text{and} \qquad c_n^- \nearrow c^- \qquad \text{as} \quad n \to \infty.$$

Since the unstable manifold at $(0, 0)$ and the stable manifold at $(\gamma, 0)$ depend continuously on c, it follows that the corresponding orbits also converge, i.e., that there exist orbits (u^+, v^+) and (u^-, v^-) such that

$$(u_n^\pm, v_n^\pm)(\xi) \to (u^\pm, v^\pm)(\xi) \qquad \text{as} \quad n \to \infty,$$

uniformly on $\mathbf{R}$. This argument yields two heteroclinic orbits, one with speed c^+ and one with speed c^-, which both connect the origin to the point $(\gamma_0, 0)$. Since by Lemma 4.1 there exists only one such orbit, we have a contradiction.

It follows that $c^- = c^+$, and continuity of the function $c(\gamma)$, and hence of $\tau(\gamma)$, has been established. $\square$

In the following lemma we prove the final assertion made in Step 1, which involves the behavior of $\tau(u)$ as $u \to \beta$.

LEMMA 4.4. *We have*

$$\tau(\gamma) \to \infty \qquad \textit{as} \qquad \gamma \to \beta^-.$$

Proof. In view of the definition (4.7) of τ, it suffices to show that $c(\gamma) \to 0$ as $\gamma \to \beta$. Proceeding as in the proof of Lemma 4.3, we find that $c(\gamma)$ and the orbit $\Gamma(c(\gamma))$ converge to c_0 and $\Gamma(c_0) = \{(u_0, v_0)(t) : t \in \mathbf{R}\}$ as $\gamma \to \beta$. Note that

$$c(\gamma) \int_{\mathbf{R}} v^2(\xi;\gamma)\, d\xi = \int_0^\gamma g(t;\gamma)\, dt,$$

where $g(t;\gamma) = s(\gamma)t - f(t)$. If we let $\gamma \to \beta$ in this identity, we obtain

$$c_0 \int_{\mathbf{R}} v_0^2(\xi)\, d\xi = \int_0^\beta g(t;\beta)\, dt = 0. \tag{4.13}$$

Because at the origin the unstable manifold points into the first quadrant when $\gamma = \beta$ (cf. (4.9)), it follows that $v_0 > 0$ on $\mathbf{R}$. Therefore, (4.13) implies that $c_0 = 0$, as asserted. ∎

4.2. Traveling waves with $u_\ell = \alpha$. In Lemmas 4.1 and 4.2 we have shown that $\tau(u)$ is an increasing function on (α, β). Since $\tau(u) > 0$ for all $u \in (\alpha, \beta)$, the limit

$$\tau_* \stackrel{\text{def}}{=} \lim_{u \to \alpha^+} \tau(u)$$

exists. In the following lemmas we show that $\tau_* > 0$ and that for all $\tau \in (0, \tau_*]$, problem (TW$_0$) has a unique solution with $u_\ell = \alpha$.

Let $\mathcal{S} \in \mathbf{R}^+$ denote the set of values of τ for which problem (TW$_0$) has a unique solution with $u_\ell = \alpha$.

LEMMA 4.5. *There exists a constant $\tau_0 > 0$ such that $(0, \tau_0) \subset \mathcal{S}$.*

Proof. We shall show that there exists a wave speed $c_0 > 0$ such that if $c > c_0$, then problem (4.5) has a heteroclinic orbit connecting the origin to the point $(\alpha, 0)$. This then yields Lemma 4.5 when we put

$$\tau_0 = \frac{1}{c_0^2 s(\alpha)}.$$

In (4.6) we saw that the origin is a saddle and that the slope of the unstable manifold is given by

$$\theta(c) = \frac{1}{2}\left\{\sqrt{c^2 + 4s} - c\right\}.$$

Note that

$$\theta(c) < \frac{1}{c} g'(0) = \frac{s}{c}.$$

Hence, near the origin the orbit lies below the isocline $\mathcal{I}_v = \{(u,v) : v = c^{-1} g(u), u \in \mathbf{R}\}$.

Since $u' > 0$ and $v' > 0$ in the lens shaped region

$$\mathcal{L} = \{(u,v) : 0 < u < \alpha,\ 0 < v < c^{-1} g(u),\ u \in \mathbf{R}\},$$

the orbit will leave $\mathcal{L}$ again. To see what happens next, we consider the triangular region Ω_m bounded by the positive u- and v-axis and the line

$$\ell_m \stackrel{\text{def}}{=} \{(u,v) : v = m(\alpha - u)\}, \qquad m > 0.$$

On the axes the vector field points into Ω_m, and on the line ℓ_m it points inwards if

$$\left.\frac{dv}{du}\right|_{\ell_m} = -c + \frac{g(u)}{m(\alpha - u)} < -m. \tag{4.14}$$

Let

$$m_0 = \inf\{m > 0 : g(u) < m(\alpha - u) \text{ on } (0, \alpha)\}.$$

Then

$$-c + \frac{g(u)}{m(\alpha - u)} < -c + \frac{m_0}{m},$$

and (4.14) will hold for values of c and m which satisfy the inequality

$$-c + \frac{m_0}{m} < -m$$

or

$$c > m + \frac{m_0}{m}.$$

To obtain the largest range of values of c for which the vector field points into Ω_m we choose m so that the right-hand side of this inequality becomes smallest; i.e., we put $m = \sqrt{m_0}$. We thus find that for

$$c > c_0 \stackrel{\text{def}}{=} 2\sqrt{m_0}$$

the region $\Omega_{\sqrt{m_0}}$ is invariant, and hence, that the orbit must tend to the point $(\alpha, 0)$. This completes the proof of Lemma 4.5. □

The next lemma gives the structure of the set $\mathcal{S}$.

LEMMA 4.6. *If* $\tau_0 \in \mathcal{S}$, *then* $(0, \tau_0] \subset \mathcal{S}$.

Proof. As in earlier lemmas we prove a related result for problem (4.5). Let $\mathcal{S}^*$ be the set of values of c for which there exists a heteroclinic orbit of problem (4.5) from $(0,0)$ to $(\alpha, 0)$. We show that if $c_0 \in \mathcal{S}^*$, then $[c_0, \infty) \subset \mathcal{S}^*$. Plainly this implies Lemma 4.6 with $\tau_0 = 1/(c_0 s^2)$.

As before, we denote the orbit emanating from the origin by $\Gamma(c)$. Suppose that $c > c_0$. Then, since $\theta'(c) < 0$ it follows that $\theta(c_0) > \theta(c)$, so that near the origin $\Gamma(c_0)$ lies above $\Gamma(c)$. We claim that $\Gamma(c_0)$ and $\Gamma(c)$ will not intersect for $u \in (0, \alpha)$. Accepting this claim for the moment, we conclude that since $\Gamma(c_0)$ tends to $(\alpha, 0)$, the orbit $\Gamma(c)$ must converge to $(\alpha, 0)$ as well.

It remains to prove the claim. Suppose that $\Gamma(c_0)$ and $\Gamma(c)$ do intersect at some $u \in (0, \alpha)$, and let (u_0, v_0) be the first point of intersection. Then

$$\left.\frac{dv}{du}\right|_{\Gamma(c)} \geq \left.\frac{dv}{du}\right|_{\Gamma(c_0)} \quad \text{at} \quad (u_0, v_0). \tag{4.15}$$

But, from the differential equations we deduce that

$$\left.\frac{dv}{du}\right|_{\Gamma(c)} = -c + \frac{g(u_0)}{v_0} < -c_0 + \frac{g(u_0)}{v_0} = \left.\frac{dv}{du}\right|_{\Gamma(c_0)} \quad \text{at} \quad (u_0, v_0),$$

which contradicts (4.15). This proves the claim and so completes the proof of Lemma 4.6. □

We conclude this section by showing that $\tau_* \in \mathcal{S}$, and hence that $\mathcal{S} = (0, \tau_*]$.

LEMMA 4.7. *We have* $\mathcal{S} = (0, \tau_*]$.

Proof. It follows from Lemmas 4.1 and 4.2 that for every $\varepsilon \in (0, \beta - \alpha)$, there exists a $\tau_\varepsilon = \tau(\alpha + \varepsilon) > 0$ such that problem (TW_0) has a unique traveling wave $u_\varepsilon(\eta)$ with speed $s_\varepsilon = s(\alpha + \varepsilon)$, such that

$$u_\varepsilon(-\infty) = \alpha + \varepsilon \qquad \text{and} \qquad u_\varepsilon(\infty) = 0.$$

This wave corresponds to a heteroclinic orbit $\Gamma_\varepsilon = \{(u_\varepsilon(\xi), v_\varepsilon(\xi)) : \xi \in \mathbf{R}\}$ of the system $\mathcal{P}(c_\varepsilon, s_\varepsilon)$, where $c_\varepsilon = 1/\sqrt{s_\varepsilon \tau_\varepsilon}$, which connects the points $(0,0)$ and $(\alpha + \varepsilon, 0)$. It leaves the origin along the stable manifold under an angle $\theta_\varepsilon = \theta(c_\varepsilon, s_\varepsilon)$ and enters the point $(\alpha + \varepsilon, 0)$ along the stable manifold under the angle

$$\psi_\varepsilon = \psi(c_\varepsilon, s_\varepsilon) = \frac{1}{2}\left\{-c_\varepsilon - \sqrt{c_\varepsilon^2 + 4g'(\alpha + \varepsilon)}\right\} \to -c_0 = -\frac{1}{\sqrt{s(\alpha)\tau_*}} \qquad \text{as} \quad \varepsilon \to 0.$$

Reversing time, i.e., replacing ξ by $-\xi$, we can view Γ_ε as the unique orbit emanating from the point $(\alpha + \varepsilon, 0)$ into the first quadrant and entering the origin as $\xi \to \infty$. In the limit, as $\varepsilon \to 0$, we find that

$$u_\varepsilon(\xi) \to u_0(\xi) \quad \text{and} \quad v_\varepsilon(\xi) \to v_0(\xi) \quad \text{as} \quad \varepsilon \to 0 \qquad \text{for} \quad -\infty < \xi \le \xi_0,$$

where ξ_0 is any finite number. We claim that

$$u_0(\xi) \to 0 \quad \text{and} \quad v_0(\xi) \to 0 \qquad \text{as} \quad \xi \to \infty;$$

i.e., $\Gamma_0 \stackrel{\text{def}}{=} \{(u_0(\xi), v_0(\xi)) : \xi \in \mathbf{R}\}$ is a heteroclinic orbit, which connects $(\alpha, 0)$ and the origin $(0,0)$.

Suppose to the contrary that Γ_0 does not enter the origin as $\xi \to \infty$ and possibly does not even exist for all $\xi \in \mathbf{R}$. Then, since

$$\frac{dv}{du} = -c_0 + \frac{g(u)}{v} > -c_0 \qquad \text{if} \qquad 0 < u < \alpha, \quad v > 0,$$

Γ_0 must leave the first quadrant in finite time, either through the u-axis or through the v-axis. This means by continuity that for ε small enough Γ_ε must also leave the first quadrant in finite time. Since Γ_ε is known to enter the origin for every $\varepsilon > 0$, and hence never to leave the first quadrant, we have a contradiction. This proves the claim that Γ_0 is a heteroclinic orbit, which connects $(\alpha, 0)$ and $(0,0)$. ∎

Remark 4.1. It is evident from Lemmas 4.6 and 4.7 that

$$\tau_* \ge \tau_0 = \frac{1}{4m_0 s(\alpha)}, \tag{4.16}$$

where m_0 was defined in (4.15). For $M = 2$, we find that $s(\alpha) \approx 1.11$, $m_0 \approx 0.70$ and hence $\tau_0 \approx 0.32$. Numerically, we find that $\tau_* \approx 0.61$.

5. Proof of Theorems 1.2 and 1.3. For the proofs of Theorems 1.2 and 1.3 we turn to the system $\mathcal{P}(c, s)$ defined in section 4. For convenience we restate it here,

$$\mathcal{P}(c,s)\begin{cases} u' = v, & \text{(5.1a)} \\ v' = -cv + g_s(u), & \text{(5.1b)} \end{cases}$$

where

$$c = \frac{1}{\sqrt{s\tau}} \qquad \text{and} \qquad g_s(u) = su - f(u).$$

Part (a) of Theorem 1.2 is readily seen to be a consequence of the following lemma.

LEMMA 5.1. *Let $\tau > \tau_*$ be given. Then for every $u_\ell \in (0, \underline{u})$, there exists a unique heteroclinic orbit of the system $\mathcal{P}(c, s)$ in which*

$$s = s_\ell = \frac{f(u_\ell)}{u_\ell} \qquad \textit{and} \qquad c = c_\ell = \frac{1}{\sqrt{s_\ell \tau}},$$

which connects $(0,0)$ and $(u_\ell, 0)$.

Proof. Let Γ_ℓ and $\overline{\Gamma}$ denote the orbits of $\mathcal{P}(c_\ell, s_\ell)$ and $\mathcal{P}(\overline{c}, \overline{s})$, where $\overline{c} = c(\overline{u})$ and $\overline{s} = s(\overline{u})$, which enter the first quadrant from the origin. They do this under the angles $\theta(c_\ell, s_\ell)$ and $\theta(\overline{c}, \overline{s})$, respectively. Since $c_\ell > \overline{c}$ and $s_\ell < \overline{s}$, it follows from (4.12) that

$$\theta(c_\ell, s_\ell) < \theta(\overline{c}, \overline{s}).$$

Hence, near the origin, Γ_ℓ lies below $\overline{\Gamma}$. Thus, Γ_ℓ enters the region Ω enclosed between $\overline{\Gamma}$ and the u-axis. Since

$$\frac{dv}{du}\bigg|_{\Gamma_\ell} = -c_\ell + \frac{s_\ell u - f(u)}{v} < -\overline{c} + \frac{\overline{s}u - f(u)}{v} = \frac{dv}{du}\bigg|_{\overline{\Gamma}},$$

it follows that Γ_ℓ cannot leave Ω though its "top" $\overline{\Gamma}$. We define the following subsets of the bottom of Ω:

$$\begin{aligned} S_1 &= \{(u, v) : 0 < u < u_\ell,\ v = 0\}, \\ S_2 &= \{(u, v) : u = u_\ell,\ v = 0\}, \\ S_3 &= \{(u, v) : u_\ell < u < \overline{u},\ v = 0\}. \end{aligned}$$

Inspection of the vector field show that orbits can only leave Ω through S_3. Note that the set S_2 consists of an equilibrium point.

There are two possibilities: *either* Γ_ℓ never leaves Ω, *or* Γ_ℓ leaves Ω, necessarily through the set S_3. In the first case Γ_ℓ is a heteroclinic orbit from $(0,0)$ to $(u_\ell, 0)$, and the proof is complete.

Thus, let us assume that Γ_ℓ leaves Ω at some point $(u, v) = (u_0, 0)$. Consider the energy function

$$\mathcal{H}(u, v) = \frac{1}{2}v^2 - G_{s_\ell}(u),$$

where G_{s_ℓ} is the primitive of g_{s_ℓ} as defined in (4.7), and write $H(\xi) = \mathcal{H}(u(\xi), v(\xi))$, when $(u(\xi), v(\xi))$ is an orbit. Then differentiation shows that

$$H'(\xi) = -c_\ell v^2(\xi) < 0.$$

Since $\mathcal{H}(0,0) = 0$, it follows that

$$\mathcal{H}(u_0, 0) = -G_{s_\ell}(u_0) < 0$$

and that

$$\mathcal{H}(u(\xi), v(\xi)) = \frac{1}{2}v^2 - G_{s_\ell}(u) < -G_{s_\ell}(u_0) \qquad \text{for} \qquad \xi > \xi_0.$$

This means that

$$G_{s_\ell}(u) > G_{s_\ell}(u_0) > 0 \qquad \text{for} \qquad \xi > \xi_0.$$

Let

$$u_1 = \inf\{s \in \mathbf{R} : G_{s_\ell}(s) > G_{s_\ell}(u_0) \text{ on } (s, u_0)\}.$$

Since $G_{s_\ell}(u_0) > 0$ it follows that $u_1 \in (0, u_\ell)$. Therefore

$$\left.\begin{array}{l} 0 < u_1 < u(x) < u_0 \\ v^2(x) < 2\{G_{s_\ell}(u_\ell) - G_{s_\ell}(u_0)\} \end{array}\right\} \qquad \text{for} \qquad x > x_0.$$

From a simple energy argument we conclude that $(u(x), v(x)) \to (u_\ell, 0)$ as $x \to \infty$. This completes the proof of Lemma 5.1. ☐

Part (b) follows from the following result.

LEMMA 5.2. *Let $\tau > \tau_*$ be given. For any $u_\ell \in (\underline{u}(\tau), \overline{u}(\tau))$ there exists no solution of the system $\mathcal{P}(c_\ell, s_\ell)$, with*

$$s_\ell = \frac{f(u_\ell)}{u_\ell} \qquad \textit{and} \qquad c_\ell = \frac{1}{\sqrt{s_\ell \tau}},$$

which connects $(0,0)$ and $(u_\ell, 0)$.

Proof. Let $\overline{\Gamma}$ denote the orbit corresponding to $\overline{c}$ and $\overline{s}$, which connects $(0,0)$ and the point $(\overline{u}, 0)$, and let Γ_ℓ denote the orbit which corresponds to c_ℓ and s_ℓ. Observe that

$$s_\ell > \overline{s} \qquad \text{and} \qquad c_\ell < \overline{c},$$

and hence

$$\theta(c_\ell, s_\ell) > \theta(\overline{c}, \overline{s}).$$

Therefore, near the origin, Γ_ℓ lies above $\overline{\Gamma}$. Hence, to reach the point $(u_\ell, 0)$, the orbit $\overline{\Gamma}_\ell$ has to cross $\overline{\Gamma}$ somewhere, and at the first point of crossing we must have

$$\left.\frac{dv}{du}\right|_{\overline{\Gamma}} \geq \left.\frac{dv}{du}\right|_{\Gamma_\ell}.$$

However, by the equations, we have

$$\left.\frac{dv}{du}\right|_{\overline{\Gamma}} = -\overline{c} + \frac{g_{\overline{s}}(u)}{u} < -c_\ell + \frac{g_{s_\ell}(u)}{u} = \left.\frac{dv}{du}\right|_{\Gamma_\ell},$$

so that we have a contradiction. ☐

This completes the proof of Theorem 1.2.

The proof of Theorem 1.3 is entirely analogous to that of Theorem 1.2, and we omit it.

6. Entropy dissipation. In this section we study the Cauchy problem

$$\text{(CP)}\begin{cases} u_t + (f(u))_x = \mathcal{A}_\varepsilon(u) & \text{in} \quad S = \mathbf{R}\times\mathbf{R}^+, & \text{(6.1a)} \\ u(\cdot,0) = u_0(\cdot) & \text{on} \quad \mathbf{R}, & \text{(6.1b)} \end{cases}$$

where

$$\mathcal{A}_\varepsilon(u) = \varepsilon u_{xx} + \varepsilon^2 \tau u_{xxt} \qquad (\varepsilon > 0). \tag{6.2}$$

With this choice (6.1a) becomes the regularized BL equation (1.17) for which we obtained traveling wave solutions in the previous sections. In (6.1a) and (6.2) we introduce subscripts to denote partial derivatives. Without further justification we assume that problem (CP) has a smooth, nonnegative, and bounded solution u^ε for each $\varepsilon > 0$, and that there exists a limit function $u : S \to [0,\infty)$ such that for each $(x,t) \in S$,

$$u^\varepsilon(x,t) \to u(x,t) \qquad \text{as} \qquad \varepsilon \to 0.$$

In addition we assume the following structural properties:

(i) $\|u^\varepsilon\|_\infty < C$ for some constant $C > 0$, and for each fixed $t > 0$,

$$u^\varepsilon(x,t) \to u_\ell \in \mathbf{R}^+ \qquad \text{as} \qquad x \to -\infty,$$
$$u^\varepsilon(x,t) \to u_r \in \mathbf{R}^+ \qquad \text{as} \qquad x \to +\infty.$$

(ii) The partial derivatives of u^ε vanish as $|x| \to \infty$.

(iii) Let $U(s) = \frac{1}{2}s^2$ for $s \geq 0$, $U_\ell = U(u_\ell)$, and $U_r = U(u_r)$. Then there exists a smooth function $\lambda_\varepsilon : [0,\infty) \to \mathbf{R}$ which is uniformly bounded with respect to $\varepsilon > 0$ in any bounded interval $(0,T)$, such that

$$\int_{\mathbf{R}} \{U(u^\varepsilon(x,t)) - G_\varepsilon(x,t)\}\, dx = 0 \qquad \text{for all} \quad t > 0,$$

where G_ε is the step function

$$G_\varepsilon(x,t) = U_\ell + (U_r - U_\ell)H(x - \lambda_\varepsilon(t)), \qquad (x,t) \in S$$

in which H denotes the Heaviside function.

Note that the traveling waves constructed in this paper all have these properties.

Remark 6.1. The question as to which conditions on u_0 would generate such a solution is left open in this paper. Clearly we need that $u_0 : \mathbf{R} \to \mathbf{R}$ satisfies (i) and (ii), and $U(u_0) - G \in L^1(\mathbf{R})$. Further we require that $u_0' \in L^2(\mathbf{R})$.

The main purpose of this section is to show that $U(u^\varepsilon)$ is an entropy for (6.1a). In doing so we borrow arguments and ideas of LeFloch [26]. For completeness we recall some definitions. We say that the term $\mathcal{A}_\varepsilon(u)$ is *conservative* if

$$\lim_{\varepsilon\to 0^+} \int_S \mathcal{A}_\varepsilon(u^\varepsilon)\varphi = 0 \qquad \text{for all} \quad \varphi \in C_0^\infty(S) \tag{6.3}$$

and we say that $\mathcal{A}_\varepsilon(u)$ is *entropy dissipative* (for an entropy U) if

$$\limsup_{\varepsilon\to 0^+} \int_S \mathcal{A}_\varepsilon(u^\varepsilon)U'(u^\varepsilon)\varphi \leq 0 \qquad \text{for all} \quad \varphi \in C_0^\infty(S), \quad \varphi \geq 0. \tag{6.4}$$

We establish the following theorem.

THEOREM 6.1. *Let u^ε be the solution of problem* (CP)*, and let u^ε satisfy* (i), (ii), *and* (iii). *Then, the regularization $\mathcal{A}_\varepsilon(u)$ defined in* (6.2) *has the following properties:*

(a) $\mathcal{A}_\varepsilon(u)$ *is conservative.*

(b) $\mathcal{A}_\varepsilon(u)$ *is entropy dissipative for the entropy* $U(u) = \frac{1}{2}u^2$.

Proof. Part (a). For any $\varphi \in C_0^\infty(S)$ we obtain after partial integration with respect to x and t,

$$\int_S \mathcal{A}_\varepsilon(u^\varepsilon)\varphi = \varepsilon \int_S u^\varepsilon \varphi_{xx} - \varepsilon^2\tau \int_S u^\varepsilon \varphi_{xxt} \to 0 \qquad \text{as} \quad \varepsilon \to 0.$$

Part (b). To simplify notation, we drop the superscript ε from u^ε. When we multiply (6.1a) by u we obtain

$$\partial_t U(u) + \partial_x F(u) = u\mathcal{A}_\varepsilon(u) = \varepsilon u u_{xx} + \varepsilon^2 \tau u u_{xxt}, \tag{6.5}$$

where

$$F(u) = \int_0^u U'(s) f'(s)\, ds = \int_0^u s f'(s)\, ds = u f(u) - \int_0^u f(s)\, ds. \tag{6.6}$$

An elementary computation shows that

$$\begin{aligned} \varepsilon u u_{xx} &= \varepsilon U_{xx} - \varepsilon u_x^2, \\ \varepsilon^2 \tau u u_{xxt} &= \varepsilon^2 \tau \left(U_{xxt} - \frac{1}{2}(u_x^2)_t - (u_x u_t)_x \right). \end{aligned}$$

Hence

$$\begin{aligned} \int_S \mathcal{A}_\varepsilon(u)\, u\varphi = \varepsilon \int_S U\varphi_{xx} - \varepsilon \int_S u_x^2 \varphi \\ - \varepsilon^2\tau \int_S U\varphi_{xxt} + \frac{1}{2}\varepsilon^2\tau \int_S u_x^2 \varphi_t + \varepsilon^2\tau \int_S u_t u_x \varphi_x. \end{aligned} \tag{6.7}$$

Plainly

$$\varepsilon \int_S U\varphi_{xx} \to 0 \quad \text{and} \quad \varepsilon^2\tau \int_S U\varphi_{xxt} \to 0 \qquad \text{as} \quad \varepsilon \to 0.$$

Since $\varphi \geq 0$, it remains to estimate the last two terms on the right-hand side of (6.7).

For this purpose we establish the following two estimates.

LEMMA 6.1. *Let $T > 0$, and let $S_T = \mathbf{R} \times (0, T]$. Then there exists a constant $C > 0$ such that for all $\varepsilon > 0$,*

$$\varepsilon \int_{S_T} u_x^2 \leq C \tag{6.8}$$

and

$$\varepsilon \int_{S_T} u_t^2 \leq C. \tag{6.9}$$

Proof of (6.8). We write (6.5) as

$$\partial_t U(u) + \partial_x F(u) = \varepsilon U_{xx} - \varepsilon u_x^2 + \varepsilon^2 \tau \left\{ U_{xxt} - \frac{1}{2}(u_x^2)_t - (u_t u_x)_x \right\}. \tag{6.10}$$

Using properties (i)–(iii) and writing $F_\ell = F(u_\ell)$, $F_r = F(u_r)$, we find that

$$\frac{d}{dt}\int_{\mathbf{R}} \{U(x,t) - G_\varepsilon(x,t)\}\,dx - \frac{d\lambda_\varepsilon}{dt}(U_r - U_\ell) \\ + (F_r - F_\ell) + \varepsilon\int_{\mathbf{R}} u_x^2 + \frac{1}{2}\varepsilon^2\tau\frac{d}{dt}\int_{\mathbf{R}} u_x^2 \le 0,$$

or, when we integrate over $(0,T)$

$$-\{\lambda_\varepsilon(t) - \lambda_\varepsilon(0)\}(U_r - U_\ell) + (F_r - F_\ell)t + \varepsilon\int_{S_T} u_x^2 + \frac{1}{2}\varepsilon^2\tau\int_{\mathbf{R}} u_x^2(t) \le \frac{1}{2}\varepsilon^2\tau\int_{\mathbf{R}}(u_0')^2,$$

from which (6.8) immediately follows. $\square$

Proof of (6.9). We multiply (6.1) by u_t. This yields

$$u_t^2 + (f(u))_x u_t = u_t\mathcal{A}_\varepsilon(u) = \varepsilon u_t u_{xx} + \varepsilon^2\tau u_t u_{xxt}. \tag{6.11}$$

Using the identities

$$u_t u_{xx} = (u_x u_t)_x - \frac{1}{2}(u_x^2)_t \qquad \text{and} \qquad u_t u_{xxt} = (u_{xt}u_t)_x - (u_{xt})^2,$$

we find that

$$u_t^2 + \frac{\varepsilon}{2}(u_x^2)_t \le -f'(u)u_t u_x + \varepsilon(u_x u_t)_x + \varepsilon^2\tau(u_{xt}u_t)_x.$$

When we integrate over $\mathbf{R}$ and use Schwarz's inequality and properties (i) and (ii), we obtain

$$\int_{\mathbf{R}} u_t^2 + \frac{\varepsilon}{2}\frac{d}{dt}\int_{\mathbf{R}} u_x^2 \le \frac{1}{2}\int_{\mathbf{R}} u_t^2 + \frac{K^2}{2}\int_{\mathbf{R}} u_x^2,$$

where $K = \max\{|f'(s)| : s > 0\}$. Hence, when we integrate over $(0,t)$,

$$\int_{S_t} u_t^2 \le \varepsilon\int_{\mathbf{R}}(u_0')^2 + K^2\int_{S_t} u_x^2.$$

In view of the first estimate this establishes (6.9) and completes the proof of Lemma 6.1. $\square$

We now return to the proof of Theorem 6.1(b). For each $\varphi \in C_0^\infty(S)$ we choose $T > 0$ so that $\operatorname{supp}\varphi \subset S_T$. Then (6.8) implies that

$$\varepsilon^2\int_{S_T} u_x^2\varphi_t \le \varepsilon^2 K_1\int_{S_T} u_x^2 \le \varepsilon K_1 C \quad \text{with} \quad K_1 = \sup|\varphi_t|, \tag{6.12}$$

and (6.8) and (6.9) together imply that

$$\varepsilon^2\int_{S_T} u_t u_x\varphi_x \le \varepsilon^2 K_2\int_{S_T}|u_t||u_x| \le \varepsilon K_2 C \quad \text{with} \quad K_2 = \sup|\varphi_x|. \tag{6.13}$$

Using (6.12) and (6.13) in (6.7) we conclude that, writing $u = u^\varepsilon$ again,

$$\limsup_{\varepsilon\searrow 0}\int_S \mathcal{A}_\varepsilon(u^\varepsilon)\,u^\varepsilon\varphi \le 0,$$

which is what was claimed in Theorem 6.1. □

It now follows from (6.5) that in the limit as $\varepsilon \to 0$,

$$\partial_t U(u) + \partial_x F(u) \leq 0 \tag{6.14}$$

holds in a weak or distributional sense. This shows that (U, F) is an entropy pair for (1.1).

The inequality in (6.14) indicates entropy dissipation. Across shocks $\{u_\ell, u_r\}$ it can be computed explicitly. Let

$$u(x,t) = \begin{cases} u_\ell & \text{for} \quad x < st, \\ u_r & \text{for} \quad x > st. \end{cases}$$

Then (6.14) implies that

$$-s(U_r - U_\ell) + (F_r - F_\ell) \leq 0.$$

Hence the entropy dissipation is given by

$$E(u_\ell, u_r) \stackrel{\text{def}}{=} -s(U_r - U_\ell) + (F_r - F_\ell). \tag{6.15}$$

We conclude by observing that if $u = u(\eta)$ is a traveling wave satisfying problem (TW), then (6.15) can be written as

$$E(u_\ell, u_r) = \int_{\mathbf{R}} \{-s(U(u))' + (F(u))'\}\, d\eta. \tag{6.16}$$

Applying (6.6) and the definition of U gives

$$E(u_\ell, u_r) = \int_{\mathbf{R}} u \left(-s + \frac{df}{du}\right) u'\, d\eta = \int_{u_\ell}^{u_r} u \left(-s + \frac{df}{du}\right) du. \tag{6.17}$$

Rewriting further

$$-s + \frac{df}{du} = \frac{d}{du}\big(-s(u - u_\ell) + f(u) - f(u_\ell)\big),$$

integrating (6.17) by parts, and using the Rankine–Hugoniot condition yields

$$E(u_\ell, u_r) = \int_{u_r}^{u_\ell} \{f(u) - f(u_\ell) - s(u - u_\ell)\}\, du.$$

In the special case when $u_r = 0$ we have $s = f(u_\ell)/u_\ell$ and thus

$$E(u_\ell, 0) = \int_0^{u_\ell} \{f(u) - su\}\, du.$$

Returning to the proof of Proposition 1.1 we observe that the integral is negative provided $u_\ell < \beta$. Thus this condition acts as an entropy condition in the sense that $E(u_\ell, 0) < 0$ only if $u_\ell < \beta$.

CONVERGENCE OF INCREASINGLY FLAT RADIAL BASIS INTERPOLANTS TO POLYNOMIAL INTERPOLANTS*

YEON JU LEE†, GANG JOON YOON‡, AND JUNGHO YOON†

Abstract. In this paper, we study the convergence behavior of interpolants by smooth radial basis functions to polynomial interpolants in $\mathbb{R}^d$ as the radial basis functions are scaled to be increasingly flat. Larsson and Fornberg [*Comput. Math. Appl.*, 49 (2005), pp. 103–130] conjectured a sufficient property for this convergence, and they also conjectured that Bessel radial functions do not satisfy this property. First, in the case of positive definite radial functions, we prove both conjectures by Larsson and Fornberg for the convergence of increasingly flat radial function interpolants. Next, we extend the results to the case of conditionally positive definite radial functions of order $m > 0$.

Key words. radial basis function, interpolation, polynomial, conditionally positive definite function

1. Introduction.

One of the most important issues in many areas of applied mathematics and applications is to construct an approximation to scattered data: Given a set X of scattered points in $\Omega \subset \mathbb{R}^d$ and values $f|_X$ of some underlying function f, the goal is to find a function $s : \Omega \to \mathbb{R}^d$ such that s approximates f in some sense. Radial basis functions (RBFs) provide well-established tools for solving the scattered data approximation or interpolation problem. In addition, they are becoming increasingly popular for the numerical solution of partial differential equations.

A function $\phi : \mathbb{R}^d \to \mathbb{R}$ is radial in the sense that $\phi(x) = \Phi(|x|)$, where $|x| := (x_1^2 + \cdots + x_d^2)^{1/2}$ stands for the usual Euclidean norm. The common choices of ϕ can be divided into two groups, piecewise smooth such as the thin plate spline $\phi(x) = |x|^2 \log |x|$ and infinitely smooth such as multiquadrics $\phi(x) = (|x|^2 + \lambda^2)^{1/2}$. In this paper, we are interested in the infinitely smooth basis functions ϕ so that each function ϕ can be expanded as

$$\phi(x) = \Phi(|x|) = \sum_{n=0}^{\infty} c_n |x|^{2n},$$

which actually means ϕ is analytic. An attractive feature of using an infinitely smooth function is that it can provide spectral approximation order [10, 11, 13, 16, 17]. Typical examples of such basis functions are given as follows: For $d \in \mathbb{N}$ and $\lambda > 0$,

- $\phi(x) := (|x|^2 + \lambda^2)^{m-d/2}$, d odd, $m - d/2 > 0$, (multiquadrics),
- $\phi(x) := (|x|^2 + \lambda^2)^{m-d/2} \log(|x|^2 + \lambda^2)^{1/2}$, $m > d/2$, d even, ('shifted' surface splines).

- $\phi(x) := (|x|^2 + \lambda^2)^{m-d/2}$, $0 < m < d/2$, (inverse multiquadrics),
- $\phi(x) := e^{-|x|^2/\lambda^2}$, (Gaussians),

These functions are considered as tempered distributions and have generalized Fourier transforms of the form

$$|\cdot|^{2m}\hat{\phi} = F \in L_\infty(\mathbb{R}^d), \quad m \geq 0, \tag{1.1}$$

where, indeed, the function F is nonnegative on $\mathbb{R}^d$ and positive at least on an open subset of $\mathbb{R}^d$. We will see in section 3 that it is an important ingredient for the convergence of increasingly flat RBF interpolants to multivariate polynomial interpolants. Further, the condition (1.1) is the major difference from the Bessel radial function ϕ_d [5], which is defined by

$$\phi_d(x) := \frac{J_{\frac{d}{2}-1}(|x|)}{|x|^{\frac{d}{2}-1}}, \quad d = 1, 2, \ldots, \tag{1.2}$$

where J_α denotes the first kind Bessel function of order α. The Fourier transform of ϕ_d is proportional to a Dirac distribution, that is, $\hat{\phi}_d \approx \delta(|\cdot| - 1)$ (see [7, p. 364]).

The RBFs can be scaled in such a way to be wider by a shape parameter $\epsilon > 0$, i.e., $\phi_\epsilon(x) := \phi(\epsilon x)$. It has been observed independently during the last decades that for smooth data, a very small value of ϵ gives very accurate results for both interpolation problems and solving elliptic partial differential equations. For this, the reader is referred to the recent papers [4, 8]; unfortunately, we have been unable to locate it in any previous references. In this case, the basis function becomes very flat and the condition number of the interpolation system grows rapidly.

In [3], Driscoll and Fornberg introduced a surprising observation that the limit of an RBF interpolant often exists and takes the form of a polynomial. Later, Fornberg, Wright, and Larsson [6] and, in parallel, Schaback [14] proved that the limiting RBF interpolant is a (multivariate) finite order polynomial interpolant, if it exists. In particular, Schaback [14] showed that interpolation with scaled Gaussians always converges to the de Boor–Ron polynomial interpolation when the Gaussian widths increase. Subsequent to carrying out this study, we became aware of another recent paper by Larsson and Fornberg [9]; they generated a matrix in (2.4) (hereafter, denoted by $\mathbf{B}_{p,K}$ with $0 \leq p \leq d$ and $K \geq 0$) from the Taylor expansion of the given RBF and proved that the nonsingularity of these matrices guarantees the convergence of the RBF interpolation to a multivariate polynomial interpolation, if it exists, as the shape parameter $\epsilon \to 0$. However, the nonsingularity of $\mathbf{B}_{p,K}$ is just conjectured and yet to be proved. Thus, the first goal of this paper is to prove this conjecture. Moreover, it is also observed in [9] that this convergence property holds for the commonly well known RBF interpolants, but some different behavior was seen for the Bessel RBF; we will see it also in section 3. There needs to be a clear discussion on the reason for the deviant behavior of the Bessel RBF interpolant. For this reason, our next aim is to provide a detailed proof and conditions which address this issue. The specific contribution of this study is given as follows:

- For any $0 \leq p \leq d$ and $K \geq 0$, the matrix $\mathbf{B}_{p,K}$ is proved to be nonsingular for all positive definite RBFs which satisfy the condition (1.1). It implies that a positive definite RBF interpolant converges to a multivariate polynomial interpolant, if it exists, as the shape parameter $\epsilon \to 0$. In fact, the existence of the limiting interpolant is guaranteed when the set X is unisolvent. However, if the set X is nonunisolvent, it is still an open problem to describe the condition under which the limit exists.

- We provide more detailed discussion on the difference between the commonly used RBFs and the Bessel RBF. It is verified that the matrix $\mathbf{B}_{p,K}$ for the Bessel RBF is singular (as is conjectured by Larsson and Fornberg in [9]) whenever $K \geq p+2$.
- The state-of-the-art studies on the limit of increasing flat RBF have considered the interpolation from the space $\mathrm{span}\{\phi(\varepsilon(x-x_j)) : x_j \in X\}$ [8, 9, 14]. However, usually, when ϕ is conditionally positive definite of order m, some suitable polynomial of degree $m-1$ is added for the construction of interpolation. Thus, this study is concerned with RBF interpolation from the augmented space $\mathrm{span}\{\phi(\varepsilon(x-x_j)) : x_j \in X\} + \Pi_{<m}$. Specifically, the matrix $\mathbf{B}_{p,K}$ is modified for conditionally positive definite RBFs of order $m > 0$ and proved to be nonsingular. Then, we show that the corresponding RBF interpolant tends to a polynomial interpolant, if it exists, as the shape parameter $\epsilon \to 0$.

We use the following notation throughout this paper. For $\alpha, \beta \in \mathbb{Z}_+^d := \{(\gamma_1, \dots, \gamma_d) \in \mathbb{Z}^d : \gamma_k \geq 0\}$, we set $\alpha! := \alpha_1! \cdots \alpha_d!$, $|\alpha|_1 := \sum_{k=1}^d \alpha_k$, and $\alpha^\beta := \alpha_1^{\beta_1} \cdots \alpha_d^{\beta_d}$. The Fourier transform of $f \in L_1(\mathbb{R}^d)$ is defined as

$$\hat{f}(\theta) := \int_{\mathbb{R}^d} f(t) \exp(-i\theta \cdot t)\, dt.$$

Also, for a function $f \in L_1(\mathbb{R}^d)$, we use the notation $f^\vee$ for the inverse Fourier transform. The Fourier transform can be uniquely extended to the space of tempered distributions on $\mathbb{R}^d$. Let $\Pi_{<K}$ denote the space of d-variate algebraic polynomials of degree $< K$ on $\mathbb{R}^d$ and denote

$$K_d := \dim \Pi_{<K+1} = \binom{K+d}{d}. \tag{1.3}$$

2. Larsson and Fornberg's conjectures. In this section, we revisit the work of Larsson and Fornberg in [9] and introduce their conjectures. For this, the multi-index definitions from [9] are introduced.

DEFINITION 2.1. *Let $\alpha =: (\alpha_1, \dots, \alpha_d)$ and $\beta =: (\beta_1, \dots, \beta_d)$ be in $\mathbb{Z}_+^d$. Then we define the following terminologies:*

(a) *The multi-indices α, β are said to have the same parity if the components α_j and β_j with $j = 1, \dots, d$ have the same parity.*

(b) *The polynomial ordering of a sequence of multi-indices is determined in the way that the index α comes before β if $|\alpha|_1 < |\beta|_1$ or if $|\alpha|_1 = |\beta|_1$, $\alpha_j = \beta_j$, $j = 1, \dots, p$, and $\alpha_{p+1} < \beta_{p+1}$.*

DEFINITION 2.2. *Let I_K, where $K \geq 0$, be the polynomially ordered sequence of all multi-indices $\alpha = (\alpha_1, \dots, \alpha_d)$ such that $|\alpha|_1 \leq K$. For $n \in \mathbb{N}$, $I_K(n)$ denotes the nth multi-index in the sequence.*

DEFINITION 2.3. *Let $I_{p,K}$, where $0 \leq p \leq d$ and $K \geq 0$, be the polynomially ordered sequence of all multi-indices $\alpha = (\alpha_1, \dots, \alpha_d)$ with $|\alpha|_1 \leq K$ such that $\alpha_1, \dots, \alpha_p$ are odd numbers, the others are even numbers. For $n \in \mathbb{N}$, $I_{p,K}(n)$ denotes the nth multi-index in the sequence.*

DEFINITION 2.4. *Let I_{2n}^α be the polynomially ordered set of all multi-indices β such that $|\alpha + \beta|_1 = 2n$, and α and β have the same parity.*

Let $X = \{x_j : j = 1, \dots, N\}$ and $(K-1)_d < N \leq K_d$ with K_d in (1.3). Let $p_1, \dots, p_N$ be N independent polynomials in $\Pi_{<K+1}$. We say X is unisolvent with respect to $\{p_j : j = 1, \dots, N\}$ if there is a unique linear combination $\sum \beta_j p_j(x)$

such that it interpolates the data over the point set X. If X is nonunisolvent with respect to any choice of N linearly independent basis functions from $\Pi_{<K+1}$, there is a smallest integer $M > K$ such that we can form a minimal nondegenerate set $\{p_j : j = 1, \ldots, N\}$ chosen from the basis in $\Pi_{<M+1}$, that is,

$$\det(p_j(x_\ell) : j, \ell = 1, \ldots, N) \neq 0.$$

Then the degree of the minimal nondegenerate basis is said to be M. With this definition in hand, we introduce the relation between polynomial interpolation and the distribution of the set X.

PROPOSITION 2.5 (see [9]). *Let $X = \{x_1, \ldots, x_N\}$ and $(K-1)_d < N \leq K_d$ with K_d in (1.3). If X is unisolvent with respect to any set of N linearly independent polynomials in $\Pi_{<K+1}$, then*

(I) *if $N = K_d$, then there is a unique interpolating polynomial of degree K for any given data on X;*

(II) *if $N < K_d$, then there is an interpolating polynomial of degree K for any given data on X, for each choice of N linearly independent basis functions.*

If X is nonunisolvent and the degree of the minimal nondegenerate basis is M, then

(III) *there is an interpolating polynomial of degree M for any given data on X, for each choice of a minimal nondegenerate basis.*

Invoking that the RBFs ϕ considered in this paper are real analytic, the Taylor expansion of $\phi(x - x_j) = \Phi(|x - x_j|)$ with respect to $|x - x_j|$ is given as

$$\phi(x - x_j) = \sum_{n=0}^{\infty} c_n |x - x_j|^{2n}. \tag{2.1}$$

Here, the coefficient of x^α in the expansion of $|x - x_j|^{2n}$ can be written by

$$|x - x_j|^{2n}\big|_{x^\alpha} = \sum_{\beta \in I_{2n}^\alpha} (-1)^{|\alpha|_1} \frac{n!}{(\frac{\alpha+\beta}{2})!} \frac{(\alpha+\beta)!}{\alpha!\beta!} x_j^\beta.$$

For the proof of this identity, the reader is referred to [15]. Combining this with (2.1), we see that the coefficient of x^α in the expansion of $\phi(x - x_j)$ is

$$\phi(x - x_j)|_{x^\alpha} = \sum_{n=|\lfloor \frac{\alpha+\vec{1}}{2} \rfloor|_1}^{\infty} c_n \sum_{\beta \in I_{2n}^\alpha} (-1)^{|\alpha|_1} \frac{n!}{(\frac{\alpha+\beta}{2})!} \frac{(\alpha+\beta)!}{\alpha!\beta!} x_j^\beta, \tag{2.2}$$

where $\vec{1} = (1, \ldots, 1) \in \mathbb{R}^d$ and for any $\gamma = (\gamma_1, \ldots, \gamma_d) \in \mathbb{Z}_+^d$, $\lfloor \gamma \rfloor := (\lfloor \gamma_1 \rfloor, \ldots, \lfloor \gamma_d \rfloor)$ with $\lfloor s \rfloor$ the greatest integer less than or equal to s. Based on this expansion of ϕ, we define the symmetric function $\mathbf{B}_n(\alpha, \beta)$ by

$$\mathbf{B}_n(\alpha, \beta) := c_n (-1)^{|\alpha|_1} \frac{n!}{(\frac{\alpha+\beta}{2})!} \frac{(\alpha+\beta)!}{\alpha!\beta!}, \qquad |\alpha + \beta|_1 = 2n, \tag{2.3}$$

where $\alpha, \beta \in \mathbb{Z}_+^d \times \mathbb{Z}_+^d$ with the same parity. Then the conjectures suggested by Larsson and Fornberg are given as follows.

Larsson–Fornberg's Conjecture I. For $0 \leq p \leq d$ and $0 \leq K$, the matrices $\mathbf{B}_{p,K}$, defined by

$$\mathbf{B}_{p,K} := \big(\mathbf{B}_n(\alpha, \beta) : \alpha, \beta \in I_{p,K}\big), \tag{2.4}$$

are nonsingular for all commonly known RBFs such as (inverse) multiquadrics and Gaussians.

It is necessary to remark that in the above conjecture, the Bessel RBF is not included. The following theorem is the main result of [9].

THEOREM 2.6 (see [9]). *Let $X = \{x_1, \dots, x_N\}$ and $(K-1)_d < N \le K_d$ with K_d in* (1.3). *Assume that Larsson–Fornberg conjecture* I *holds. Then, we have the following properties:*

(a) *If the set X is of type* (I)*, then the limit of the RBF interpolant as the shape parameter $\varepsilon \to 0$ is the unique interpolating polynomial of degree K to the given data.*

(b) *If the set X is of type* (II)*, then the limit of the RBF interpolant as the shape parameter $\varepsilon \to 0$ is a polynomial of degree K that interpolates the given data. The exact polynomial depends on the choice of RBF.*

(c) *If the set X is of type* (III)*, then the limit of the RBF interpolant as the shape parameter $\varepsilon \to 0$, if the limit exists, is a polynomial of degree M that interpolates the given data.*

Remark. It has been proved by Schaback [14] that interpolation by scaled Gaussians always converges to the de Boor–Ron polynomial interpolant when the Gaussian widths increase. However, in the cases of multiquadrics and inverse multiquadrics, there occur some cases where the interpolants diverge in the limit; for examples, see [3] and [9]. Also, for the case of type (II), the reader is referred to the same papers [3] and [9] for an example of different limit polynomials affected by different RBFs.

In [9, Example 2.4], there occurs a case where all commonly used RBFs except the Bessel RBF have the same limit which is the unique interpolating polynomial; see also section 3. Thus, it is conjectured that the expansion coefficients of the Bessel RBF do not fulfill the nonsingularity condition of $\mathbf{B}_{p,J}$ in (2.4).

Larsson–Fornberg's Conjecture II. All matrices $\mathbf{B}_{p,K}$ with $K > 1$ are singular for the expansion coefficients of the Bessel radial basis function.

In the following section, we will prove that the Larsson–Fornberg conjectures are true. Also, the difference between the commonly used RBFs and Bessel RBF will be discussed. Furthermore, we extend Theorem 2.6 up to the case of RBF interpolation from the augmented space $\operatorname{span}\{\phi(x - x_j) : x_j \in X\} + \Pi_{<m}$, using conditionally positive definite ϕ of order $m \ge 0$.

3. The main results.

3.1. Positive definite function. We first prove that Larsson–Fornberg's conjecture I is true for all positive definite functions whose Fourier transforms $\hat{\phi}$ satisfy the condition (1.1).

DEFINITION 3.1. *Let $\phi : \mathbb{R}^d \to \mathbb{R}$ be a continuous function and $\Omega \subset \mathbb{R}^d$. We say that ϕ is conditionally positive definite of order $m \in \mathbb{Z}_+ := \{0, 1, \dots\}$ if for every finite set of pairwise distinct points $X = \{x_1, \dots, x_N\} \subset \Omega$ and for every $\alpha = (\alpha_1, \dots, \alpha_N) \in \mathbb{R}^N \setminus 0$ satisfying*

$$\sum_{j=1}^{N} \alpha_j p(x_j) = 0, \quad p \in \Pi_{<m}, \tag{3.1}$$

the quadratic form

$$\sum_{i=1}^{N} \sum_{j=1}^{N} \alpha_i \alpha_j \phi(x_i - x_j)$$

is positive definite. A conditionally positive definite function of order 0 *is called a positive definite function.*

Indeed, the condition (3.1) may seem a bit technical and hard to verify in practice. However, the positive definiteness of continuous and absolutely integrable functions ϕ is guaranteed when the Fourier transform $\hat{\phi}$ satisfies the condition (1.1) with $m = 0$. We note in passing that this argument is a consequence of the simple identity

$$\sum_{j=1}^{N}\sum_{k=1}^{N} \alpha_j \alpha_k \phi(x_j - x_k) = \frac{1}{(2\pi)^d}\int_{\mathbb{R}^d} \hat{\phi}(\theta)\left|\sum_{j=1}^{N} \alpha_j e^{ix_j\cdot\theta}\right|^2 d\theta \tag{3.2}$$

for any $(\alpha_1, \ldots, \alpha_N) \in \mathbb{R}^N \setminus 0$ and the fact that the map $\theta \mapsto \sum_{j=1}^{N} \alpha_j e^{ix_j\cdot\theta}$, $\theta \in \mathbb{R}^d$, has zeros at most on a set of measure zero. This identity is also generalized to the case of conditionally positive definite functions ϕ of order $m > 0$.

Suppose that a continuous function $f : \mathbb{R}^d \to \mathbb{R}$ is known only at a set of discrete points $X := \{x_1, \ldots, x_N\}$ in $\Omega \subset \mathbb{R}^d$. A RBF interpolant to the data $(x_j, f(x_j))$, $j = 1, \ldots, N$, with a positive definite function $\phi(\varepsilon\cdot)$ is given by

$$s(x, \varepsilon) := \sum_{j=1}^{N} a_j \phi(\varepsilon(x - x_j)), \tag{3.3}$$

where the coefficients a_j $(j = 1, \ldots, N)$ are obtained by solving the linear system

$$s(x_j, \varepsilon) = f(x_j), \quad j = 1, \ldots, N. \tag{3.4}$$

LEMMA 3.2. *Let* $\mathbf{B}_n(\cdot,\cdot)$ *be the symmetric function defined as in* (2.3)*, and let* $\alpha, \beta \in \mathbb{Z}_+^d$ *with the same parity and* $|\alpha + \beta|_1 = 2n$*. Then, we have*

$$\mathbf{B}_n(\alpha, \beta) = (-1)^{|\alpha|_1} \frac{\phi^{(\alpha+\beta)}(0)}{\alpha!\beta!}.$$

Proof. Since ϕ is radially symmetric, $\phi(\cdot - x_j) = \phi(x_j - \cdot)$. Taking the Taylor expansion of $\phi(x_j - \cdot)$ around x_j yields the expression

$$\begin{aligned}
\phi(x_j - x) &= \sum_{|\alpha|_1=0}^{\infty} \phi^{(\alpha)}(x_j)\frac{(-x)^\alpha}{\alpha!}\\
&= \sum_{|\alpha|_1=0}^{\infty}\left(\sum_{|\beta|_1=0}^{\infty} \phi^{(\alpha+\beta)}(0)\frac{x_j^\beta}{\beta!}\right)\frac{(-x)^\alpha}{\alpha!}\\
&= \sum_{|\alpha|_1=0}^{\infty}\left(\sum_{n=|\lfloor\frac{\alpha+\vec{1}}{2}\rfloor|_1}^{\infty}\sum_{\beta\in I_{2n}^\alpha} \phi^{(\alpha+\beta)}(0)\frac{x_j^\beta}{\beta!}\right)\frac{(-x)^\alpha}{\alpha!};
\end{aligned}$$

where the second identity is a consequence of the Taylor expansion of $\phi^{(\alpha)}(x_j)$ around the origin. Then the coefficient of x^α in this expansion of $\phi(x_j - x)$ is denoted by

$$\phi(x - x_j)|_{x^\alpha} = \sum_{n=|\lfloor\frac{\alpha+\vec{1}}{2}\rfloor|_1}^{\infty}\sum_{\beta\in I_{2n}^\alpha} (-1)^{|\alpha|_1}\frac{\phi^{(\alpha+\beta)}(0)}{\alpha!\beta!}x_j^\beta. \tag{3.5}$$

Comparing (3.5) with (2.2), we obtain that

$$\mathbf{B}_n(\alpha,\beta) = (-1)^{|\alpha|_1} \frac{\phi^{(\alpha+\beta)}(0)}{\alpha!\beta!},$$

where $\alpha, \beta \in \mathbb{Z}_+^d$ with the same parity and $|\alpha+\beta|_1 = 2n$. ∎

The following lemma is useful for the proof of the nonsingularity of $\mathbf{B}_{p,K}$.

LEMMA 3.3. *Let ϕ be a positive definite function, and assume that ϕ satisfies the condition* (1.1) *with $m = 0$, i.e., the Fourier transform $\hat{\phi} \geq 0$ is positive on an open set in $\mathbb{R}^d$. For any integer $K > 0$, define the matrix $\mathbf{T}_\phi$ by*

$$\mathbf{T}_\phi := \mathbf{T}_{\phi,p,K} := \left((-i)^{|\alpha+\beta|_1} \frac{\phi^{(\alpha+\beta)}(0)}{\alpha!\beta!} : \alpha, \beta \in I_{p,K} \right). \tag{3.6}$$

Then $\mathbf{T}_\phi$ is positive definite, and so it is nonsingular.

Proof. Since $\alpha, \beta \in I_{p,K}$, both have the same parity and $|\alpha+\beta|_1$ is always even. It means that each entry of the matrix $\mathbf{T}_\phi$ is real. Now, let $\gamma := (\gamma_\alpha : \alpha \in I_{p,K})$ be an arbitrary nonzero vector. Then, the nonsingularity of $\mathbf{T}_\phi$ is guaranteed by showing that $\gamma \mathbf{T}_\phi \gamma^T > 0$, i.e.,

$$\gamma \mathbf{T}_\phi \gamma^T = \sum_{\beta \in I_{p,K}} \sum_{\alpha \in I_{p,K}} \gamma_\alpha \gamma_\beta (-i)^{|\alpha+\beta|_1} \frac{\phi^{(\alpha+\beta)}(0)}{\alpha!\beta!} > 0. \tag{3.7}$$

It is easy to see the identity

$$\sum_{\beta \in I_{p,K}} \sum_{\alpha \in I_{p,K}} \gamma_\alpha \gamma_\beta (-i)^{|\alpha+\beta|_1} \frac{\phi^{(\alpha+\beta)}(0)}{\alpha!\beta!} = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} \hat{\phi}(\theta) \left| \sum_{\alpha \in I_{p,K}} \gamma_\alpha \frac{\theta^\alpha}{\alpha!} \right|^2 d\theta. \tag{3.8}$$

Since the Fourier transform $\hat{\phi} \geq 0$ is nonnegative on $\mathbb{R}^d$ and positive at least on an open subset of $\mathbb{R}^d$, the above term in (3.8) is positive, which completes the proof. ∎

Remark. In fact, it is easy to check from the above proof that any symmetric matrix built from $\mathbf{B}_n(\cdot,\cdot)$ is positive definite and so are all symmetrically chosen submatrices.

We now prove Larsson–Fornberg's conjecture I.

THEOREM 3.4. *Let ϕ be a positive definite function and assume that ϕ satisfies the condition* (1.1) *with $m = 0$, i.e., the Fourier transform $\hat{\phi} \geq 0$ is positive on an open set in $\mathbb{R}^d$. Then, for any integers $p, K \geq 0$, the matrix $\mathbf{B}_{p,K}$ in* (2.4) *is nonsingular.*

Proof. Using the form of $\mathbf{B}_{p,K}$ in Lemma 3.2, we see that $\det \mathbf{T}_\phi = c \det \mathbf{B}_{p,K}$ with $|c| = 1$. Thus, by Lemma 3.3, we conclude that $\mathbf{B}_{p,K}$ is nonsingular. ∎

As a conclusion, we can get the following results, which are actually restatements of Theorem 2.6.

THEOREM 3.5. *Let $X = \{x_1, \ldots, x_N\}$ and $(K-1)_d < N \leq K_d$ with K_d in* (1.3)*. Assume that ϕ is a positive definite function and its Fourier transform $\hat{\phi} \geq 0$ is positive on an open set in $\mathbb{R}^d$. Then, we have the following properties:*

(a) *If the set X is of type* (I)*, then the limit of the RBF interpolant $s(\cdot, \varepsilon)$ as the shape parameter $\varepsilon \to 0$ is the unique interpolating polynomial of degree K to the given data.*

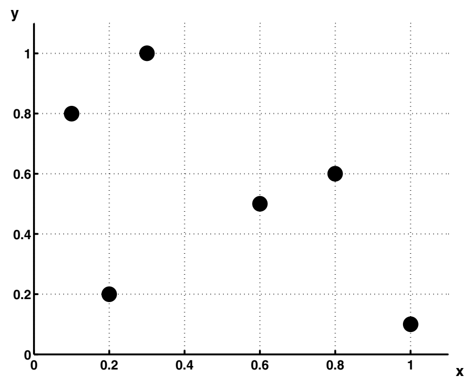

Fig. 1. *Scattered points X.*

(b) *If the set X is of type* (II)*, then the limit of the RBF interpolant $s(\cdot,\varepsilon)$ as the shape parameter $\varepsilon \to 0$ is a polynomial of degree K that interpolates the given data. The exact polynomial depends on the choice of RBFs.*

(c) *If the set X is of type* (III)*, then the limit of the RBF interpolant $s(\cdot,\varepsilon)$ as the shape parameter $\varepsilon \to 0$, if the limit exists, is a polynomial of degree M that interpolates the given data.*

An interesting example was observed in [9, Example 2.4] wherein all the well known RBF interpolants except the Bessel RBF (see (1.2)) interpolant have the same limit (as $\varepsilon \to 0$), which is the unique polynomial interpolant. We revisit this example as follows.

Example 3.6. *Let $X = \{(\frac{1}{10},\frac{4}{5}),(\frac{1}{5},\frac{1}{5}),(\frac{3}{10},1),(\frac{3}{5},\frac{1}{2}),(\frac{4}{5},\frac{3}{5})\}$ be a set of six points as in Figure* 1 *and $f(x_j) = \delta_{0,j}$ with $j = 1,\ldots,6$. These six points do not have any particular pattern. Expanding $\phi(\varepsilon(x_i - x_j))$ in powers of ε^2, the RBF interpolant $s(x,\varepsilon)$ to the given data $(x_j, f(x_j))$ can be written in the form* (see [6])

$$s(x,\varepsilon) = \frac{\varepsilon^{2r}p_{2r}(x) + \varepsilon^{2r+2}p_{2r+2}(x) + \ldots}{\varepsilon^{2q}c_{2q} + \varepsilon^{2q+2}c_{2q+2} + \ldots}, \qquad r,\, q \in \mathbb{N},$$

where c_{2n}, $n = q, q+1, \ldots,$ are some constants and $p_{2\ell}(x)$, $\ell = r, r+1, \ldots,$ are polynomials of degree (at most) 2ℓ. When $r = q$, the limit exists as $\varepsilon \to 0$ and it will be a polynomial of degree at most $2r$. Based on this expansion we programmed the limit of RBF interpolants and obtained the following results. For all the known positive definite RBFs (e.g., inverse multiquadrics and Gaussians), the interpolants converge to the same two-variable polynomial of degree 2*, that is,*

$$\lim_{\varepsilon\to 0} s(x,\varepsilon) = \frac{1}{28274}(-7711 - 81420x + 132915y + 82300x^2 - 55450xy - 91550y^2),$$

which is the unique polynomial interpolant to the given data. However, the Bessel function interpolant converges to a third order polynomial

$$\begin{aligned}\lim_{\varepsilon\to 0} s(x,\varepsilon) = \frac{1}{1017250518}(&-354545067 - 2047021330x + 4593056085y\\ &+ 255438330x^2 - 4166831700xy - 2554383300y^2\\ &- 310763000x^3 + 1319845500x^2y + 932289000xy^2 - 439948500y^3).\end{aligned}$$

It is known that the Bessel radial function ϕ_d, $d > 1$, is positive definite (see [5, Theorem 3.1]). However, its Fourier transform is proportional to a Dirac distribution, i.e., $\hat{\phi}_d \approx \delta(|\cdot| - 1)$ (see [7, p. 364]), which does not satisfy the condition (1.1). As far as we observed, this is the major difference between ϕ_d and the well known RBS. In the next theorem, we prove Larsson–Fornberg's conjecture II, that is, the matrix $\mathbf{B}_{p,K}$ of ϕ_d is singular whenever $p + 2 \leq K$. It explains the deviant behavior of ϕ_d as in Example 3.6.

THEOREM 3.7. *Let $0 \leq p \leq d$ and $p + 2 \leq K$ with $p, K \in \mathbb{N}$. Then the matrix $\mathbf{B}_{p,K}$ of the Bessel RBF ϕ_d is singular.*

Proof. Recall the following Hankel transform on $\mathbb{R}^d$ (see [2, p. 53]):

$$\phi_d(x) = \frac{1}{(2\pi)^{d/2}} \int_{|\theta|=1} e^{ix\cdot\theta} d\theta, \quad x \in \mathbb{R}^d. \tag{3.9}$$

Invoking the definition of $\mathbf{T}_{\phi_d}$ in (3.6), for an arbitrarily given $\gamma = (\gamma_\alpha : \alpha \in I_{p,K})$, we get

$$\begin{aligned}\gamma \mathbf{T}_{\phi_d} \gamma^T &= \sum_{\beta \in I_{p,K}} \sum_{\alpha \in I_{p,K}} \gamma_\alpha \gamma_\beta (-i)^{|\alpha+\beta|_1} \frac{\phi_d^{(\alpha+\beta)}(0)}{\alpha!\beta!} \\ &= \frac{1}{(2\pi)^{d/2}} \int_{|\theta|=1} \left| \sum_{\alpha \in I_{p,K}} \gamma_\alpha \frac{\theta^\alpha}{\alpha!} \right|^2 d\theta \geq 0,\end{aligned}$$

which implies that all the eigenvalues of $\mathbf{T}_{\phi_d}$ are nonnegative real numbers. In fact, since $p + 2 \leq K$, we can choose γ_α with $\alpha \in I_{p,K}$ such that

$$\left| \sum_{\alpha \in I_{p,K}} \gamma_\alpha \frac{\theta^\alpha}{\alpha!} \right|^2 = \left| \theta^{I_{p,K}(1)} [1 - (\theta_1^2 + \cdots + \theta_d^2)] \right|^2, \qquad \theta =: (\theta_1, \ldots, \theta_d),$$

where $I_{p,K}(1)$ is the first index in $I_{p,K}$. Then $\gamma \mathbf{T}_{\phi_d} \gamma^T$ becomes zero, which implies that the matrix $\mathbf{T}_{\phi_d}$ is not positive definite but semipositive definite. It leads to the conclusion that $\mathbf{T}_{\phi_d}$ has an eigenvalue of zero such that $\mathbf{T}_{\phi_d}$ is singular. Since $\det(\mathbf{T}_{\phi_d}) = c \det(\mathbf{B}_{p,K})$ with $|c| = 1$, $\mathbf{B}_{p,K}$ is singular. ∎

3.2. Conditionally positive definite function. The RBF interpolant to the data $(x_j, f(x_j))$, $j = 1, \ldots, N$, with a conditionally positive definite function ϕ of order m is given by

$$s(x, \varepsilon) := \sum_{j=1}^{N} a_j \phi(\varepsilon(x - x_j)) + \sum_{i=1}^{(m-1)_d} b_i p_i(x), \tag{3.10}$$

where $p_1, \ldots, p_{(m-1)_d}$ is a basis for the space $\Pi_{<m}$. The coefficients a_j $(j = 1, \ldots, N)$ and b_i $(i = 1, \ldots, (m-1)_d)$ are obtained by solving the linear system which can be written in a matrix form as

$$\begin{pmatrix} \mathbf{A} & \mathbf{P} \\ \mathbf{P^T} & \mathbf{0} \end{pmatrix} \begin{pmatrix} \mathbf{a} \\ \mathbf{b} \end{pmatrix} = \begin{pmatrix} \mathbf{f} \\ \mathbf{0} \end{pmatrix}, \tag{3.11}$$

where $\mathbf{A}$ and $\mathbf{P}$ are the $N \times N$ and $N \times (m-1)_d$ matrices that have the elements $\mathbf{A}_{ij} = \phi(\varepsilon(x_i - x_j))$ and $\mathbf{P}_{ij} = p_j(x_i)$, respectively. Further, $\mathbf{a} \in \mathbb{R}^N$ and $\mathbf{b} \in \mathbb{R}^{(m-1)_d}$

are the vectors of coefficients of $s(\cdot,\varepsilon)$, and the components of $\mathbf{f}$ are the data $f(x_j)$, $j=1,\ldots,N$. Here, for $m>0$, we require X to have the nondegeneracy property for $\Pi_{<m}$, i.e.,

$$q(x_j)=0, \quad 1\le j\le N \quad \text{for} \quad q\in\Pi_{<m} \quad \text{implies} \quad q=0. \tag{3.12}$$

The unique solution of the previous linear system is guaranteed when the function ϕ is conditionally positive definite of order m [12].

DEFINITION 3.8. *Let $I_{p,m,K}$, where $0\le p\le d$ and $m,K\ge 0$, be the polynomially ordered sequence of all multi-indices $\alpha=(\alpha_1,\ldots,\alpha_d)$ with $m\le|\alpha|_1\le K$ such that $\alpha_1,\ldots,\alpha_p$ are odd numbers, and the others are even numbers. For $n\in\mathbb{N}$, $I_{p,m,K}(n)$ denotes the nth multi-index in the sequence.*

Here and in what follows, assume that ϕ is conditionally positive definite of order $m\ge 0$. Recalling the Taylor expansion of ϕ, that is,

$$\phi(x-x_j)=\sum_{n=0}^{\infty}c_n|x-x_j|^{2n}, \tag{3.13}$$

and using the symmetric function $\mathbf{B}_n(\cdot,\cdot)$ in (2.3), let us define the matrix $\mathbf{B}_{p,m,K}$ corresponding to the polynomially ordered sequence $I_{p,m,K}$ by

$$\mathbf{B}_{p,m,K}:=\big(\mathbf{B}_n(\alpha,\beta):\alpha,\beta\in I_{p,m,K}\big). \tag{3.14}$$

Then, we will show that the matrix $\mathbf{B}_{p,m,K}$ is nonsingular.

THEOREM 3.9. *Let ϕ satisfy the condition* (1.1). *Then, the matrix $\mathbf{B}_{p,m,K}$ is nonsingular for any integers $p,m,K>0$.*

Proof. From Lemma 3.2, we find that

$$\mathbf{B}_{p,m,K}=\left((-1)^{|\alpha|_1}\frac{\phi^{(\alpha+\beta)}(0)}{\alpha!\beta!}:\alpha,\beta\in I_{p,m,K}\right).$$

Thus, as in Theorem 3.4, it suffices to prove the nonsingularity of the matrix $\mathbf{T}_\phi^{[m]}$ defined by

$$\mathbf{T}_\phi^{[m]}:=\mathbf{T}_{\phi,p,K}^{[m]}:=\left((-i)^{|\alpha+\beta|_1}\frac{\phi^{(\alpha+\beta)}(0)}{\alpha!\beta!}:\alpha,\beta\in I_{p,m,K}\right).$$

For this, we show $\gamma\mathbf{T}_\phi^{[m]}\gamma^T>0$ for any nonzero vector $\gamma:=(\gamma_\alpha:\alpha\in I_{p,m,K})$. Indeed, we note that this is a consequence of the following relation:

$$\begin{aligned}\gamma\mathbf{T}_\phi^{[m]}\gamma^T&=\sum_{\beta\in I_{p,m,K}}\sum_{\alpha\in I_{p,m,K}}\gamma_\alpha\gamma_\beta(-i)^{|\alpha+\beta|_1}\frac{\phi^{(\alpha+\beta)}(0)}{\alpha!\beta!}\\&=\frac{1}{(2\pi)^d}\int_{\mathbb{R}^d}\hat\phi(\theta)\left|\sum_{\alpha\in I_{p,m,K}}\gamma_\alpha\frac{\theta^\alpha}{\alpha!}\right|^2d\theta.\end{aligned} \tag{3.15}$$

Since $|\cdot|^{2m}\hat\phi=F\ge 0$ and ϕ is real analytic, we deduce that the function F decays faster than any polynomial degree around ∞. Thus, the last integral in (3.15) makes sense and is positive (see (1.1)). It completes the proof. ∎

The following theorem treats the case of conditionally positive definiteness RBFs. The proof will be given in section 4.

THEOREM 3.10. *Let ϕ be a conditionally positive definite RBF of order $m \geq 0$ with the condition* (1.1). *Let $X = \{x_1, \ldots, x_N\}$ and $(K-1)_d < N \leq K_d$, where $K_d = \dim \Pi_{<K+1}$ and $m < K$. Then, we have the following properties:*

(a) *If the set X is of type* (I)*, then the limit of the RBF interpolant* (3.10) *as the shape parameter $\varepsilon \to 0$ is the unique interpolating polynomial of degree K to the given data.*

(b) *If the set X is of type* (II)*, then the limit of the RBF interpolant* (3.10) *as the shape parameter $\varepsilon \to 0$ is a polynomial of degree K that interpolates the given data. The exact polynomial depends on the choice of RBF.*

(c) *If the set X is of type* (III)*, then the limit of the RBF interpolant* (3.10) *as the shape parameter $\varepsilon \to 0$, if the limit exists, is a polynomial of degree $2K - m$ that interpolates the given data.*

Next, we introduce some examples of RBFs which satisfy the condition (1.1).

EXAMPLE 3.11. *Let the RBF ϕ be chosen to be one of the following:*

(a) $\phi(x) := (|x|^2 + \lambda^2)^{m-d/2}$, *$m > d/2$, $m - d/2 \notin 2\mathbb{Z}$ (multiquadrics);*

(b) $\phi(x) := (|x|^2 + \lambda^2)^{m-d/2} \log(|x|^2 + \lambda^2)^{1/2}$, *$m > d/2$, d even ("shifted" surface splines);*

(c) $\phi(x) := (|x|^2 + \lambda^2)^{m-d/2}$, *$0 < m < d/2$ (inverse multiquadrics);*

(d) $\phi(x) := e^{-|x|^2/\lambda^2}$ *(Gaussians);*

where $d \in \mathbb{N}$ and $\lambda > 0$. In the sense of tempered distributions, the functions ϕ in (a)*,* (b)*, and* (c) *have generalized Fourier transforms of the form* (*see* [7])

$$\hat{\phi}(\theta) = c_{m,\lambda,d} |\theta|^{-2m} \tilde{K}_m(|\lambda\theta|), \tag{3.16}$$

where $c_{m,\lambda,d}$ is a positive constant depending on m, λ and d, and where $\tilde{K}_\nu(|t|) := |t|^\nu K_\nu(|t|)$ with $K_\nu(|t|)$ the modified Bessel function of order ν. From [1]*, we find that*

$$\begin{aligned} &\tilde{K}_\nu(|t|) \in C^{2\nu-1}(\mathbb{R}^d) \cap C^\infty(\mathbb{R}^d \setminus \{0\}), \\ &\tilde{K}_\nu(|t|) > 0, \quad \textit{and} \quad \tilde{K}_\nu(|t|) \approx e^{-|t|}(1 + |t|^{(\nu-1/2)}). \end{aligned} \tag{3.17}$$

In the case of the Gaussian RBF ϕ in (d)*, its Fourier transform is of the form*

$$\hat{\phi}(\theta) := c_0 e^{-|\theta|^2/c_1^2}, \quad c_0, c_1 > 0.$$

4. A proof of Theorem 3.10. The general technique for the proofs is similar to the method given in [9], although the interpolant has an additional polynomial term associated with the order of conditionally positive definiteness of ϕ.

The RBF $\phi(\varepsilon\cdot)$ can be written in even powers of $|x|$ as follows:

$$\phi_\varepsilon(x) := \phi(\varepsilon x) = \sum_{j=0}^{\infty} c_j \varepsilon^{2j} |x|^{2j}. \tag{4.1}$$

Then the entries of the interpolation matrix $\mathbf{A} = (\phi(\varepsilon(x_i - x_j)) : x_i, x_j \in X)$ can be expanded in even powers of ε as above. The coefficients a_j, $j = 1, \ldots, N$, and b_i, $i = 1, \ldots, (m-1)_d$ in (3.10) are obtained by Cramer's rule, and they must be rational functions of ε^2. That is, there exists an integer q such that we can write

$$a_j =: \varepsilon^{-2K} \sum_{n=-q}^{\infty} \varepsilon^{2n} a_{j,n}, \qquad b_i =: \varepsilon^{-2K} \sum_{n=-q}^{\infty} \varepsilon^{2n} b_{i,n}, \tag{4.2}$$

where at least one of $(a_{j,-q} : j = 1, \ldots, N)$ and $(b_{j,-q} : j = 1, \ldots, (m-1)_d)$ is a nonzero vector. Now, for each $n \geq -q$ and $\beta \in \mathbb{Z}_+^d$, the discrete moments of $(a_{1,n}, \ldots, a_{N,n})^T$ are defined by

$$\sigma_n^{[\beta]} := \sum_{j=1}^{N} a_{j,n} x_j^{\beta}, \quad n = -q, -q+1, \ldots. \tag{4.3}$$

Then, for the moments $\sigma_n^{[\beta]}$ with $|\beta|_1 \leq m-1$ and $n \geq -q$, we have the following estimate.

LEMMA 4.1. *Let $\beta \in \mathbb{Z}_+^d$ with $|\beta|_1 \leq m-1$. Then, $\sigma_n^{[\beta]} = 0$ for any $n \geq -q$.*

Proof. Multiplying by ε^{2n-2K} by both sides of (4.3) and summing over $n = -q, -q+1, \ldots$, we obtain from (4.2) that for any $\varepsilon > 0$

$$\begin{aligned} \varepsilon^{-2K} \sum_{n=-q}^{\infty} \varepsilon^{2n} \sigma_n^{[\beta]} &= \varepsilon^{-2K} \sum_{j=1}^{N} \sum_{n=-q}^{\infty} \varepsilon^{2n} a_{j,n} x_j^{\beta} \\ &= \sum_{j=1}^{N} a_j x_j^{\beta} = 0, \end{aligned}$$

where the last identity is a simple consequence of (3.11). Thus, from this relation, we deduce the required result $\sigma_n^{[\beta]} = 0$ with $n \geq -q$. ∎

Let S_N indicate an N-set of polynomially ordered multi-indices, i.e., $\#S_N = N$. Define the matrix $\mathbf{V}$ by

$$\mathbf{V} = (x_j^{\beta} : j = 1, \ldots, N, \ \beta \in S_N).$$

Then from (4.3), we have

$$\mathbf{s}_n = \mathbf{V}\, \mathbf{a}_n, \quad n = -q, -q+1, \ldots, \tag{4.4}$$

where $\mathbf{s}_n := (\sigma_n^{[\beta]} : \beta \in S_N)^T$ and $\mathbf{a}_n := (a_{j,n} : j = 1, \ldots, N)^T$.

Recall that the RBF interpolant with a conditionally positive definite function ϕ of order m is given by

$$s(x, \varepsilon) := \sum_{j=1}^{N} a_j \phi(\varepsilon(x - x_j)) + \sum_{i=1}^{(m-1)_d} b_i p_i(x), \tag{4.5}$$

where $p_1, \ldots, p_{(m-1)_d}$ is a basis for $\Pi_{<m}$. Due to [9, page 123], we find that

$$\sum_{j=1}^{N} a_j \phi(\varepsilon(x - x_j)) = \varepsilon^{-2K} \sum_{s=0}^{\infty} \varepsilon^{2(-q+s)} P_{-q+s}(x) \tag{4.6}$$

with

$$P_{-q+s}(x) = \sum_{\alpha \in I_{2s}} \left(\sum_{n=|\lfloor \frac{\alpha+\vec{1}}{2} \rfloor|_1}^{s} c_n \sum_{\beta \in I_{2n}^{\alpha}} (-1)^{|\alpha|} \frac{n!}{(\frac{\alpha+\beta}{2})!} \frac{(\alpha+\beta)!}{\alpha!\beta!} \sigma_{-q+s-n}^{[\beta]} \right) x^{\alpha}. \tag{4.7}$$

Applying Lemma 4.1, we note that all the coefficients of x^α with $2s-m+1 \le |\alpha|_1 \le 2s$ become zero. It follows that

$$\deg(P_{-q+s}) \le 2s - m. \tag{4.8}$$

Further, inserting (4.2) into (4.5), we obtain that

$$s(x,\varepsilon) = \varepsilon^{-2K} \sum_{s=0}^{\infty} \varepsilon^{2(-q+s)} (P_{-q+s}(x) + Q_{-q+s}(x)), \tag{4.9}$$

where

$$Q_{-q+s}(x) = \sum_{i=1}^{(m-1)_d} b_{i,-q+s} p_i(x). \tag{4.10}$$

Let $C_1 := \{1,\ldots,p\}$ and $C_i = \{i_1,\ldots,i_p : i < \cdots < i_p\}$, $i = 2,\ldots,\binom{d}{p}$, be distinct subsets of $\{1,\ldots,d\}$. Let τ_i be a permutation on $\{1,\ldots,d\}$ such that if $i_j \in C_i$, then $\tau_i(i_j) = j \in C_1$.

DEFINITION 4.2. *We define $I^i_{p,m,K}$ to be the ordered set of all multi-indices $\alpha = (\alpha_{\tau_i(1)},\ldots,\alpha_{\tau_i(d)}) \in \mathbb{Z}^d_+$ with $m \le |\alpha|_1 \le K$ such that $I^i_{p,m,K}(k)$ is a rearrangement of the components of $I^1_{p,m,K}(k)$, where $I^1_{p,m,K} = I_{p,m,K}$ and $I^i_{p,m,K}(k)$ indicates the kth element in $I^i_{p,m,K}$.*

The reader is referred to [9] for an example of such permutation. Now, from this definition, we decompose the set $\tilde{I}_{m,K} := \{\alpha \in \mathbb{Z}^d_+ : m \le |\alpha|_1 \le K\}$ into the disjoint union of $I^i_{p,m,K}$'s as follows:

$$\tilde{I}_{m,K} = \bigcup_{p,i} \left\{ I^i_{p,m,K} : p = 0,\ldots,d \text{ and } i = 1,\ldots,\binom{d}{p} \right\}.$$

For $J \ge m$ and $0 \le p \le d$, let $\alpha \in I^i_{p,m,J}$ be chosen. We investigate the coefficient of x^α in $P_{-q+s}(x)$ (hereafter, denoted by $P_{-q+s}[\alpha]$) with $2s = J + |\alpha|_1$. For this, using the definition of $\mathbf{B}_n(\cdot,\cdot)$ in (2.3), we rewrite the coefficient $P_{-q+s}[\alpha]$ in (4.7) as follows:

$$P_{-q+s}[\alpha] = \sum_{n=|\lfloor \frac{\alpha+\vec{1}}{2} \rfloor|_1}^{s} \sum_{\beta \in I^\alpha_{2n}} \mathbf{B}_n(\alpha,\beta)\sigma^{[\beta]}_{-q+s-n}. \tag{4.11}$$

Note that for any given n with $|\lfloor \frac{\alpha+\vec{1}}{2} \rfloor|_1 \le n \le s$, the index β in the second summation of the right-hand side in (4.11) has the same parity as $\alpha \in I^i_{p,m,J}$ and satisfies $|\beta|_1 \le J$ because $|\alpha+\beta|_1 = 2n \le 2s$. Also, due to Lemma 4.1, we can set $|\beta|_1 \ge m$. As a consequence, since $|\alpha|_1 = 2s - J$ and $|\alpha+\beta|_1 = 2n$, the set of all such indices β is exactly the set $I^i_{p,m,J}$ so that $P_{-q+s}[\alpha]$ can be given as

$$P_{-q+s}[\alpha] = \sum_{\beta \in I^i_{p,m,J}} \mathbf{B}_n(\alpha,\beta)\sigma^{[\beta]}_{-q+(J-|\beta|_1)/2}. \tag{4.12}$$

Next, in order to continue our argument, let us define the following two vectors:

$$\mathbf{s}^i_{p,m,J} := (\sigma^{[\beta]}_{-q+n} : \beta \in I^i_{p,m,J},\ n = (J-|\beta|_1)/2),$$
$$\mathbf{p}^i_{p,m,J} := (P_{-q+s}[\alpha] : \alpha \in I^i_{p,m,J},\ s = (J+|\alpha|_1)/2).$$

Moreover, from the definition of $\mathbf{B}(\cdot,\cdot)$ in (2.3), we see that $\mathbf{B}_n(\alpha,\beta)$ is independent of the permutation τ_i in Definition 4.2, that is,

$$\mathbf{B}_{p,m,J} = \left(\mathbf{B}_n(\alpha,\beta) : \alpha,\beta \in I^i_{p,m,J}\right), \quad i = 2,\dots,\binom{d}{p}.$$

With the matrices from Definition 3.14 and the vectors defined above, we have a sequence of systems of equations for the discrete moments,

$$\mathbf{B}_{p,m,J}\,\mathbf{s}^i_{p,m,J} = \mathbf{p}^i_{p,m,J}, \quad i = 1,2,\dots,\binom{d}{p}, \quad \text{and} \quad J = m, m+1,\dots, \tag{4.13}$$

where p and J have the same parity. By the assumption on ϕ and Theorem 3.9, the systems in (4.13) are nonsingular and we have a complete description of the relation between the discrete moments and the polynomials P_{-q+s}. From the coefficients of the polynomials, the system in (4.13) can be solved directly for determining the moments because $\mathbf{B}_{p,m,J}$ is nonsingular for $0 \le p \le d$ and $J \ge 0$.

There is a range of ε-values for which we get a well defined interpolant $s(x,\varepsilon)$ in (4.5) to the data. If we relate this to the expansion (4.9), we get the following conditions:

(4.14)
- $P_K + Q_K$ interpolates the data on the set $X = \{x_j : j = 1,\dots,N\}$,
- $P_j + Q_j$, $j \ne K$ interpolates 0 on the set X.

Note that if $P_j + Q_j$, $j \ne K$ is of degree $< m$, then the nondegeneracy property (3.12) of X on $\Pi_{<m}$ implies $P_j + Q_j = 0$.

We now introduce two useful lemmas. First, recall that at least one of $(a_{j,-q} : j = 1,\dots,N)$ and $(b_{j,-q} : j = 1,\dots,(m-1)_d)$ is a nonzero vector (see the line below (4.2)). In practice, we will see that $(a_{j,-q} : j = 1,\dots,N)$ should be a nonzero vector.

LEMMA 4.3. *If $a_{j,-q} = 0$ for $j = 1,\dots,N$, then $b_{j,-q} = 0$ for $j = 1,\dots,(m-1)_d$.*

Proof. Assume that $a_{j,-q} = 0$ for $j = 1,\dots,N$. It is clear from Lemma 4.1 that $P_{-q}(x)$ in (4.7) is a zero polynomial. Since $P_{-q} + Q_{-q} = Q_{-q}$ interpolates 0 at X, the nondegeneracy property (3.12) induces that the polynomial $Q_{-q} = 0$. The definition of Q_{-q} in (4.10) leads to the conclusion that $b_{j,-q} = 0$ with $j = 1,\dots,(m-1)_d$. ∎

LEMMA 4.4. *Let $\{p_j(x) : j = 0,\dots,K\}$ be a finite set of polynomials such that $p_0 = 0$ and $p_K \ne 0$, and denote $k := \max\{\ell \ge 0 : p_j = 0,\ j = 0,\dots,\ell\}$. Suppose that*
 (i) *$p_j = 0$ or $\deg(p_j) > K$ for any $j = 0,\dots,K-1$;*
 (ii) *$\deg(p_j) \le 2j - k - 1$ for any $j = k+1,\dots,K$.*

Then $k = K-1$ (i.e., $p_j = 0\ \forall j = 0,\dots,K-1$) and $\deg(p_K) \le K$.

Proof. Suppose, contrary to our claim, that $k < K-1$. From (ii), $\deg(p_{k+1}) \le k+1 < K$. Also, applying (i), we see that $\deg(p_{k+1}) > K$, which leads to a contradiction. Thus, we conclude that $k = K-1$ and by (ii), $\deg(p_K) \le K$. ∎

Now we are ready to prove Theorem 3.10. We consider the case when the set X is of type (I), i.e., $\#X = K_d$, where $K_d = \dim \Pi_{<K+1}$ and $K > m$, and the set X is unisolvent with respect to any basis for $\Pi_{<K+1}$. Then, the relation (4.4) holds for the basis $\{x^\alpha : \alpha \in I_K\}$. Also, due to the unisolvency of X, any polynomial of degree $\le K$ that interpolates zero at N points must be identically zero.

Proof (a) *of Theorem* 3.10. Invoking the fact $\deg(P_{-q+s}) \le 2s - m$ from (4.8), the condition (4.14) shows that at least,

$$P_{-q+j} + Q_{-q+j} = 0 \quad \forall j = 0,\dots,\left\lfloor \frac{K+m}{2} \right\rfloor - 1.$$

Let κ ($\leq K-1$) be a positive integer such that $P_{-q+j}+Q_{-q+j}=0$ for any $j=m,\ldots,\kappa$ and $P_{-q+\kappa+1}+Q_{-q+\kappa+1}\neq 0$. Then

$$P_{-q+j}[\alpha]=0 \quad \text{for} \quad j=m,\ldots,\kappa, \quad |\alpha|_1\geq m,$$

where $P_{-q+j}[\alpha]$ is the coefficient of x^α in $P_{-q+j}(x)$. From the systems (4.13), we derive that for every $J=m,\ldots,\kappa$,

$$\sigma_{-q+n}^{[\beta]}=0 \quad \forall\beta\in I_{m,J} \quad \text{and} \quad 2n=J-|\beta|_1. \tag{4.15}$$

Substituting (4.15) into (4.7), we obtain that for every $s\geq\kappa+1$, $\deg(P_{-q+s})\leq 2s-\kappa-1$, i.e., $\deg(P_{-q+s}+Q_{-q+s})\leq 2s-\kappa-1$. By applying $\{P_{-q+j}+Q_{-q+j}\}_{j=0}^{K}$ to Lemma 4.4, we have that $P_{-q+j}+Q_{-q+j}=0$ for $j=0,\ldots,K-1$ and $\deg(P_{-q+K}+Q_{-q+K})\leq K$. It clearly induces that $\deg(P_{-q+K})\leq K$ and $\deg(P_{-q+j})\leq m-1$ for $j=m,\ldots,K-1$, i.e.,

$$P_{-q+j}[\alpha]=0 \text{ for } \quad j=m,\ldots,K-1, \quad |\alpha|_1\geq m. \tag{4.16}$$

Now, we claim that

$$P_{-q+K}+Q_{-q+K}=P_K+Q_K \quad (\text{i.e., } q=0).$$

Assume, on the contrary, that $q>0$ so that $P_{-q+K}+Q_{-q+K}\neq P_K+Q_K$. Then, $P_{-q+K}+Q_{-q+K}$ interpolates zero on X and $\deg(P_{-q+K}+Q_{-q+K})\leq K$. Hence, $P_{-q+K}+Q_{-q+K}=0$. Since $\deg(Q_{-q+K})<m$ we deduce that

$$P_{-q+K}[\alpha]=0, \quad |\alpha|_1=m,\ldots,K.$$

Accordingly, together with (4.16), we solve the systems (4.13) for $J=m,\ldots,K$ to obtain

$$\sigma_{-q}^{[\beta]}=0, \quad |\beta|_1=m,\ldots,K. \tag{4.17}$$

Combining (4.17) with Lemma 4.1 and (4.4), we obtain that $a_{j,-q}=0$ for $j=1,\ldots,N$. Further, Lemma 4.3 shows that $b_{j,-q}=0$ for $j=1,\ldots,(m-1)_d$, which is impossible since not all of $a_j's$ and $b_i's$ are zeroes. Next, if $q<0$, it follows from (4.16) that $P_K[\alpha]=0$ for any $|\alpha|_1\geq m$, i.e., $\deg P_K<m$. Since $\deg Q_K<m$, $\deg(P_K+Q_K)<m$. Since X is unisolvent with respect to any set of N linearly independent polynomials in $\Pi_{<K+1}$, this is contradictory to (4.14). Thus, we arrive at the conclusion that $q=0$ and the interpolant $s(x,\varepsilon)$ in (4.9) becomes

$$s(x,\varepsilon)=P_K(x)+Q_K(x)+\varepsilon^2\sum_{\ell=1}^{\infty}\varepsilon^{2(\ell-1)}(P_{K+\ell}(x)+Q_{K+\ell}(x)).$$

Unisolvency of X to $\Pi_{<K+1}$ ensures that P_K+Q_K is the unique polynomial interpolant to the data on X. $\square$

In the case of type (II), the set X is unisolvent but the number of points does not coincide with the dimension of the polynomial space, i.e.,

$$(K-1)_d<N<K_d.$$

Thus, the condition that a polynomial $p(x)$ of degree $\leq K$ interpolates zero on X does not ensure $p(x)$ to be identically zero any more, unless its degree is less than K.

The technique for the proof of Theorem 3.10 (b) is almost the same as the method in [9, Theorem 4.2]; hence it is only sketched here.

LEMMA 4.5. *Assume that* $\deg(P_{-q+j}) < m$ *for* $j = 0, \dots, K-1$ *and* $\deg(P_{-q+K}) \le K$. *Then* P_{-q+K} *is a linear combination of* N *linearly independent polynomials of degree* $\le K$.

Proof. This lemma is immediate by applying the same analysis in the proof of [9, Theorem 4.2]. The only difference is that the matrix $\mathbf{B}_{p,K}$ in [9, Theorem 4.2] is replaced by $\mathbf{B}_{p,m,K}$ to consider the conditionally positive definite RBF ϕ of order m. $\square$

Proof (b) *of Theorem* 3.10. By applying $\{P_{-q+j} + Q_{-q+j}\}_{j=0}^{K-1}$ to Lemma 4.4, we obtain that $\deg(P_{-q+K-1}) \le K-1$ and $\deg(P_{-q+j}) \le m-1$ for $j = m, \dots, K-2$, i.e.,

$$P_{-q+j}[\alpha] = 0 \text{ for } \quad j = m, \dots, K-2, \quad |\alpha|_1 \ge m. \tag{4.18}$$

By unisolvency, we have that $P_{-q+K-1} + Q_{-q+K-1} = 0$. The systems (4.13) with $m \le J \le K-1$ yield that

$$\sigma_{-q+n}^{[\beta]} = 0 \quad \forall \beta \in I_{m,J} \quad \text{and} \quad 2n = J - |\beta|_1. \tag{4.19}$$

Then, by substituting (4.19) into (4.7) with $s = K$, we show that $\deg(P_{-q+K}) \le K$.

Now we are in a position to get $P_{-q+K} + Q_{-q+K} = P_K + Q_K$, i.e., $q = 0$. If $q < 0$, by the same method as in the proof of Theorem 3.10 (a), we can induce a contradiction. Suppose that $q > 0$ such that $P_{-q+K} + Q_{-q+K} \ne P_K + Q_K$. Then, $P_{-q+K} + Q_{-q+K}$ is a polynomial of degree $\le K$ which interpolates zero on X. Using Lemma 4.5, we find that $P_{-q+K} + Q_{-q+K} = 0$. It implies that all the coefficients of x^α with $|\alpha|_1 \ge m$ in P_{-q+i} are zero for every $i \le K$ because $\deg(Q_{-q+K}) \le m-1$. Applying (4.13) for $m \le J \le K$, we obtain that $\sigma_{-q}^{[\beta]} = 0$ for $m \le |\beta|_1 \le K$. Combining this with Lemma 4.1 and (4.4), it follows from Lemma 4.3 that $a_{j,-q} = b_{\ell,-q} = 0$, for $j = 1, \dots, N$ and $\ell = 1, \dots, (m-1)_d$, which is a contradiction to the fact that not all of $a_j's$ and $b_i's$ are zeroes. Thus, we must have $q = 0$. Hence, as $\varepsilon \to 0$, the RBF interpolant converges to the polynomial $P_K + Q_K$. $\square$

Proof (c) *of Theorem* 3.10. In this case, in order that the limit exists as $\varepsilon \to \infty$, the interpolant $s(x, \varepsilon)$ in (4.9) must be expressed as

$$s(x, \varepsilon) = P_K(x) + Q_K(x) + \varepsilon^2 (P_{K+1}(x) + Q_{K+1}(x)) + \cdots.$$

Then, the limit is $P_K(x) + Q_K(x)$ and by Lemma 4.1, $\deg(P_K + Q_K) \le 2K - m$. $\square$

EXTENDING THE RANGE OF ERROR ESTIMATES FOR RADIAL APPROXIMATION IN EUCLIDEAN SPACE AND ON SPHERES*

R. A. BROWNLEE†, E. H. GEORGOULIS†, and J. LEVESLEY†

Abstract. We adapt Schaback's error doubling trick [R. Schaback, *Math. Comp.*, 68 (1999), pp. 201–216] to give error estimates for radial interpolation of functions with smoothness lying (in some sense) between that of the usual native space and the subspace with double the smoothness. We do this for both bounded subsets of $\mathbb{R}^d$ and spheres. As a step on the way to our ultimate goal we also show convergence of pseudoderivatives of the interpolation error.

Key words. multivariate interpolation, radial basis functions, error estimates, smooth functions

1. Introduction.

In this paper we are interested in extending the range of applicability of error estimates for radial basis function interpolation in Euclidean space and on spheres. Let Ω be a subset of $\mathbb{R}^d$, or the sphere. Let $d(x, y)$ denote the distance between two points in Ω. Let $Y \subset \Omega$ be a finite set of points, and measure the *fill-distance* of Y in Ω with

$$h(Y, \Omega) := \sup_{x \in \overline{\Omega}} \min_{y \in Y} d(x, y).$$

Given a univariate function ϕ defined on either $\mathbb{R}_+$ or $[0, \pi]$, depending on whether we are in Euclidean space or on the sphere, we form an approximation

$$S_\phi^Y(x) = \sum_{y \in Y} \alpha_y \phi(d(x, y)).$$

If the coefficients α_y, $y \in Y$, are determined by the interpolation conditions

$$S_\phi^Y(y) = f(y) \qquad \text{for } y \in Y,$$

we refer to S_ϕ^Y as the ϕ-spline interpolant to f on Y.

We will be approximating functions $f \in \mathcal{H}_\phi$, a Hilbert space of functions which depends on the function ϕ—the so-called *native space*. Later we will be more explicit about this space of functions. With this Hilbert space we have an inner product $\langle \cdot, \cdot \rangle_\phi$, with associated norm $\| \cdot \|_\phi$. We will require the following useful orthogonality and consequent *Pythagorean* property; see, e.g., [11, 13].

Proposition 1.1. *Let S_ϕ^Y be the ϕ-spline interpolant to f on the point set $Y \subset \Omega$. Then, for all $f \in \mathcal{H}_\phi$,*

1. $\langle f - S_\phi^Y, S_\phi^Y \rangle_\phi = 0$;
2. $\|f\|_\phi^2 = \|f - S_\phi^Y\|_\phi^2 + \|S_\phi^Y\|_\phi^2$.

†Department of Mathematics, University of Leicester, Leicester LE1 7RH, England (r.brownlee@mcs.le.ac.uk, e.georgoulis@mcs.le.ac.uk, j.levesley@mcs.le.ac.uk). The first author was partially supported by a studentship from the Engineering and Physical Sciences Research Council.

The usual error estimate for ϕ-spline interpolants is of the form

$$|f(x) - S_\phi^Y(x)| \le P(x, Y, \phi)\|f - S_\phi^Y\|_\phi,$$

where estimation of $P(x, Y, \phi)$—the so-called *power function*—leads to error estimates for interpolation in terms of the fill-distance $h(Y, \Omega)$. For the archetypal function in $\mathcal{H}_\phi$ we can say no more than $\|f - S_\phi^Y\|_\phi \to 0$ as $h(Y, \Omega) \to 0$. However, if f has double the smoothness (in some sense to be made clear later) of the typical function, then Schaback [19] has shown how to double the convergence order of the ϕ-spline interpolant.

We show how to get improved orders of convergence when the target function, f, has less smoothness than Schaback requires, but more smoothness than the typical function. We shall be doing this on the sphere (though this can easily be generalized to other two-point homogeneous spaces) in section 2 and in Sobolev spaces on Euclidean space in section 3. An intermediate result in both cases is to prove approximation orders for pseudoderivatives of the interpolant. We will define this notation at the appropriate place in each of the following sections.

In each case we shall be concerned with the practical scenario in which Y consists of a finite number of points. Forfeiting this assumption is of theoretical interest. In particular, in Euclidean space for (perturbed) gridded data, certain improved error estimates are already known to hold for functions within the native space itself (see, e.g., [4]).

The goal in this paper is quite different from the desire to establish error estimates for functions possessing insufficient smoothness for admittance in the native space. In recent years, contributions in that direction have been provided by several authors, e.g., [16, 17, 12] for the sphere and [23, 3, 18] for the Euclidean case.

2. The sphere. Let $\mathbb{S}^d = \{x \in \mathbb{R}^{d+1} : |x| = 1\}$. Then the geodesic distance between points $x, y \in \mathbb{S}^d$ is $d(x, y) = \cos^{-1} xy$, where xy denotes the usual inner product of vectors in $\mathbb{R}^{d+1}$. We let ν denote the normalized rotationally invariant measure on the sphere and define the inner product

$$\langle f, g\rangle_{L_2(\mathbb{S}^d)} := \int_{\mathbb{S}^d} f(x)g(x)\,\mathrm{d}\nu(x).$$

Let $\|\cdot\|_{L_2(\mathbb{S}^d)} := \langle\,\cdot\,,\,\cdot\,\rangle^{1/2}_{L_2(\mathbb{S}^d)}$, and let $L_2(\mathbb{S}^d)$ denote the set of functions for which $\|\cdot\|_{L_2(\mathbb{S}^d)} < \infty$. Let P_n be the polynomials of degree n in $\mathbb{R}^{d+1}$ restricted to the sphere, and let $H_n = P_n \cap P_n^\perp$ be the space of degree n spherical harmonics. Then, $L_2(\mathbb{S}^d)$ has the decomposition

$$L_2(\mathbb{S}^d) = \bigoplus_{n\ge 0} H_n.$$

Let $Y_1^n, \dots, Y_{d_n}^n$ be an orthonormal basis for H_n.

Related to $\mathbb{S}^d$ (we will see why shortly), we have the Gegenbauer polynomials $C_n^{(\lambda)}(t)$ which are orthogonal on $[-1, 1]$ with respect to the weight $(1-t^2)^{\lambda-1/2}$. It is well known (Müller [15], for instance) that the following addition formula holds:

$$C_n^{(\lambda)}(xy) = \sum_{j=1}^{d_n} Y_j^n(x)Y_j^n(y),$$

with $\lambda = d/2-1$. The normalization of the Gegenbauer polynomials is chosen so that there is no constant in the addition theorem. It is straightforward to see that $C_n^{(\lambda)}$ is the kernel of T_n, the orthogonal projector from $L_2(\mathbb{S}^d)$ onto H_n. Thus,

$$(T_n f)(x) = \int_{\mathbb{S}^d} f(y) C_n^{(\lambda)}(xy)\,\mathrm{d}\nu(y) \qquad \text{for all } f \in L_2(\mathbb{S}^d).$$

The following lemma is a specialization of a result in [11] to the sphere.

LEMMA 2.1. *For* $n \geq 0$,

$$\|T_n f\|_{L_\infty(\mathbb{S}^d)} \leq \sqrt{d_n}\|T_n f\|_{L_2(\mathbb{S}^d)} \qquad \textit{for all } f \in L_2(\mathbb{S}^d).$$

We will be considering interpolation using kernels of the form $\phi(d(x,y))$, where $\phi : [0,\pi] \to \mathbb{R}$. We will assume that the function ϕ has an expansion

$$\phi(d(x,y)) = \sum_{n\geq 0} a_n C_n^{(\lambda)}(xy),$$

where $a_n > 0$, for $n = 0, 1, \ldots$, and

$$\sum_{n\geq 0} d_n a_n < \infty.$$

The first condition ensures that ϕ is positive definite, and the second that it is continuous. Our analysis will take place in the native space for ϕ, $\mathcal{H}_\phi$, defined by

$$\mathcal{H}_\phi := \left\{ f \in L_2(\mathbb{S}^d) : \ \|f\|_\phi := \left(\sum_{n\geq 0} a_n^{-1} \|T_n f\|^2_{L_2(\mathbb{S}^d)} \right)^{\frac{1}{2}} < \infty \right\}.$$

A pseudodifferential operator Λ on $\mathbb{S}^d$ is an operator which acts via multiplication by a constant on each eigenspace H_n:

$$\Lambda p_n = \lambda_n p_n, \qquad p_n \in H_n,\ n = 0, 1, \ldots.$$

For more information on pseudodifferential operators on spheres, see, e.g., [9, 20]. We call the sequence of numbers $\{\lambda_n\}_{n\geq 0}$ the *symbol* of Λ. Let δ_x denote the point evaluation functional at x, and, when it makes sense for the functional μ, let $\Lambda\mu(f) = \mu(\Lambda f)$. Let us denote by Y^* the span of the point evaluation functionals supported on Y. Morton and Neamtu [14] give error estimates for the collocation solution of pseudodifferential equations on spheres. Here we attempt, initially, to find errors in pseudoderivatives of solutions to the interpolation problem.

PROPOSITION 2.2. *Let* S_ϕ^Y *be the* ϕ*-spline interpolant to* $f \in \mathcal{H}_\phi$ *on the point set* $Y \subset \mathbb{S}^d$. *Let* Λ *be a pseudodifferential operator. Then, for each* $x \in \mathbb{S}^d$,

$$|\Lambda(f - S_\phi^Y)(x)| \leq \inf_{\mu\in Y^*} \sup_{\substack{v\in\mathcal{H}_\phi \\ \|v\|_\phi = 1}} |\Lambda v(x) - \mu(v)| \|f - S_\phi^Y\|_\phi.$$

Proof. Since $f(y) - S_\phi(y) = 0$, $y \in Y$, we have, for any coefficients c_y, $y \in Y$,

$$
\begin{aligned}
|\Lambda(f - S_\phi^Y)(x)| &= \left|\Lambda(f - S_\phi^Y)(x) - \sum_{y \in Y} c_y (f(y) - S_\phi^Y(y))\right| \\
&= \left|\Lambda(f - S_\phi^Y)(x) - \sum_{y \in Y} c_y (f(y) - S_\phi^Y(y))\right| \frac{\|f - S_\phi^Y\|_\phi}{\|f - S_\phi^Y\|_\phi} \\
&\le \sup_{\substack{v \in \mathcal{H}_\phi \\ \|v\|_\phi = 1}} \left|\Lambda v(x) - \sum_{y \in Y} c_y v(y)\right| \|f - S_\phi^Y\|_\phi.
\end{aligned}
$$

We now take the infimum over all functionals in Y^* to obtain the result. ∎

In what follows we will need the pseudodifferential operator Λ to satisfy the following assumption.

Assumption 2.3. For all $n \ge 0$, $\lambda_n = (n(d + n - 2))^s$, for some $s > 0$.
From Ditzian [6], if Λ satisfies Assumption 2.3, then for $p \in P_n$,

$$\|\Lambda p\|_{L_\infty(\mathbb{S}^d)} \le E\lambda_n \|p\|_{L_\infty(\mathbb{S}^d)},$$

for some E independent of n.

From [10, Lemma 7] we have the following result.

LEMMA 2.4. *Let Y be a finite set of points with fill-distance $h(Y, \mathbb{S}^d) \le 1/(2N)$, for some fixed $N \in \mathbb{Z}_+$. Then, for any linear functional γ on P_N with*

$$\sup_{\substack{p \in P_N \\ \|p\|_{L_\infty(\mathbb{S}^d)} = 1}} |\gamma p| \le 1,$$

there is a set of real numbers $\{b_y\}_{y \in Y}$, with $\sum_{y \in Y} |b_y| \le 2$, such that

$$\gamma p = \sum_{y \in Y} b_y p(y) \qquad \text{for all } p \in P_N.$$

Now, for a fixed $x \in \mathbb{S}^d$, let

$$\gamma p = \frac{\Lambda p(x)}{E\lambda_N} \qquad \text{for all } p \in P_N.$$

Then,

$$\sup_{0 \ne p \in P_N} \frac{|\gamma p|}{\|p\|_{L_\infty(\mathbb{S}^d)}} \le 1,$$

so that, by the previous lemma, there is a set of coefficients $\{b_y\}_{y \in Y}$ such that

$$\gamma p = \sum_{y \in Y} b_y p(y),$$

with $\sum_{y \in Y} |b_y| \le 2$. Thus, with $c_y = E\lambda_N b_y$, for $y \in Y$, we have

$$\Lambda p(x) = \sum_{y \in Y} c_y p(y) \qquad \text{for all } p \in P_N, \tag{2.1}$$

where

$$\sum_{y\in Y}|c_y| \le 2E\lambda_N. \tag{2.2}$$

We now arrive at the first main result of this section.

THEOREM 2.5. *Let S_ϕ^Y be the ϕ-spline interpolant to $f \in \mathcal{H}_\phi$, on the point set $Y \subset \mathbb{S}^d$, where $h(Y,\mathbb{S}^d) \le 1/(2N)$, for some fixed $N \in \mathbb{Z}_+$. Let Λ be a pseudodifferential operator with symbol $\{\lambda_n\}_{n\ge 0}$ satisfying Assumption* 2.3 *and*

$$\sum_{n\ge 0} d_n\lambda_n^2 a_n < \infty.$$

Then, for $x \in \mathbb{S}^d$,

$$|\Lambda(f - S_\phi^Y)(x)| \le (1+2E)\left(\sum_{n\ge N} d_n\lambda_n^2 a_n\right)^{\frac12} \|f - S_\phi^Y\|_\phi.$$

Proof. Let us choose $\{c_y\}_{y\in Y}$ to be the coefficients described above. Let $v \in \mathcal{H}_\phi$ with $\|v\|_\phi = 1$. Then,

$$\begin{aligned}\inf_{\mu\in Y^*}|\Lambda v(x) - \mu(v)| &\le \left|\sum_{n\ge 0}\left(\Lambda T_n v(x) - \sum_{y\in Y} c_y T_n v(y)\right)\right| \\ &= \left|\sum_{n>N}\left(\lambda_n T_n v(x) - \sum_{y\in Y} c_y T_n v(y)\right)\right|,\end{aligned}$$

by (2.1). Thus,

$$\begin{aligned}\inf_{\mu\in Y^*}|\Lambda v(x) - \mu(v)| &\le \left|\sum_{n>N}\lambda_n T_n v(x)\right| + \left|\sum_{n>N}\sum_{y\in Y} c_y T_n v(y)\right| \\ &\le \sum_{n>N}\left(\lambda_n + \sum_{y\in Y}|c_y|\right)\|T_n v\|_{L_\infty(\mathbb{S}^d)} \\ &\le \sum_{n>N}\left(\lambda_n + \sum_{y\in Y}|c_y|\right)\sqrt{d_n}\|T_n v\|_{L_2(\mathbb{S}^d)},\end{aligned}$$

using Lemma 2.1. Hence, using (2.2) and the Cauchy–Schwarz inequality,

$$\inf_{\mu\in Y^*}|\Lambda v(x) - \mu(v)| \le \left[\left(\sum_{n>N} d_n\lambda_n^2 a_n\right)^{\frac12} + 2E\lambda_N\left(\sum_{n>N} d_n a_n\right)^{\frac12}\right]\|v\|_\phi,$$

and the result follows from Proposition 2.2, since $\|v\|_\phi = 1$ and because $\{\lambda_n\}_{n\ge 0}$ is an increasing sequence. $\square$

Integrating the conclusion of the previous theorem over the sphere, we easily obtain the following result.

COROLLARY 2.6. *Under the hypotheses of Theorem* 2.5,

$$\|\Lambda(f - S_\phi^Y)\|_{L_2(\mathbb{S}^d)} \le (1 + 2E)\left(\sum_{n>N} d_n\lambda_n^2 a_n\right)^{\frac{1}{2}} \|f - S_\phi^Y\|_\phi.$$

Before we give our improved error estimate we need to define a new space $\mathcal{H}_{\Lambda\phi}$ by

$$\mathcal{H}_{\Lambda\phi} := \left\{ f \in \mathcal{H}_\phi : \ \|f\|_{\Lambda\phi} := \left(\sum_{n\ge 0}(\lambda_n a_n)^{-2}\|T_n f\|^2_{L_2(\mathbb{S}^d)}\right)^{\frac{1}{2}} < \infty \right\}.$$

THEOREM 2.7. *Let S_ϕ^Y be the ϕ-spline interpolant to $f \in \mathcal{H}_\phi$ on the point set $Y \subset \mathbb{S}^d$, where $h(Y, \mathbb{S}^d) \le 1/(2N)$, for some fixed $N \in \mathbb{Z}_+$. Let Λ be a pseudodifferential operator with symbol $\{\lambda_n\}_{n\ge 0}$ satisfying Assumption* 2.3 *and*

$$\sum_{n\ge 0} d_n\lambda_n^2 a_n < \infty.$$

Then, for $f \in \mathcal{H}_{\Lambda\phi}$ and for all $x \in \mathbb{S}^d$,

$$|f(x) - S_\phi^Y(x)| \le (1 + 2E)\left(\sum_{n>N} d_n\lambda_n^2 a_n\right)^{\frac{1}{2}}\left(\sum_{n>N} d_n a_n\right)^{\frac{1}{2}} \|f\|_{\Lambda\phi}.$$

Proof. First, using Proposition 1.1 and the Cauchy–Schwarz inequality, we have

$$\begin{aligned}
\|f - S_\phi^Y\|_\phi^2 &= \langle f - S_\phi^Y, f\rangle_\phi \\
&= \sum_{n\ge 0} a_n^{-1}\langle T_n(f - S_\phi^Y), T_n f\rangle_{L_2(\mathbb{S}^d)} \\
&\le \left(\sum_{n\ge 0}\lambda_n^2\|T_n(f - S_\phi^Y)\|^2_{L_2(\mathbb{S}^d)}\right)^{\frac{1}{2}}\left(\sum_{n\ge 0}(\lambda_n a_n)^{-2}\|T_n f\|^2_{L_2(\mathbb{S}^d)}\right)^{\frac{1}{2}} \\
&= \|\Lambda(f - S_\phi^Y)\|_{L_2(\mathbb{S}^d)}\|f\|_{\Lambda\phi} \\
&\le (1 + 2E)\left(\sum_{n>N} d_n\lambda_n^2 a_n\right)^{\frac{1}{2}}\|f - S_\phi^Y\|_\phi\|f\|_{\Lambda\phi},
\end{aligned}$$

using Corollary 2.6. Cancelling a factor of $\|f - S_\phi^Y\|_\phi$ from both sides yields

$$\|f - S_\phi^Y\|_\phi \le (1 + 2E)\left(\sum_{n>N} d_n\lambda_n^2 a_n\right)^{\frac{1}{2}}\|f\|_{\Lambda\phi}.$$

We can now employ the standard error estimate taken from Jetter, Stöckler, and Ward [10] (our Theorem 2.5 with $\lambda_n = 1$ for all n) to give the required result. ∎

3. The Euclidean case. Our attention now turns to ϕ-spline interpolants of the form

$$S_\phi^Y(x) = \sum_{y \in Y} \alpha_y \phi(|x-y|),$$

where $\phi : \mathbb{R}_+ \to \mathbb{R}$. We will conduct our analysis for positive definite basis functions $\phi \in L_1(\mathbb{R}^d)$ whose Fourier transforms satisfy, for some $s > 0$,

$$C_1(1+|x|)^{-2s} \leq \widehat{\phi}(x) \leq C_2(1+|x|)^{-2s}, \tag{3.1}$$

for some positive constants C_1 and C_2, for example, the Sobolev splines [7] or piecewise polynomial compactly supported radial functions of minimal degree [21]. The exposition contained in this section can be readily adapted to include the polyharmonic splines [8] as well. In that case, the ϕ-spline interpolant must be augmented by a polynomial p with the extra degrees of freedom taken up by the side conditions

$$\sum_{y \in Y} \alpha_y q(y) = 0,$$

where q is polynomial of the same degree (or less) as p.

For a domain $\Omega \subset \mathbb{R}^d$ let $L_2(\Omega)$ denote the usual space of square-integrable functions on Ω with inner product $\langle \cdot\,, \cdot \rangle_{L_2(\Omega)}$ and norm $\|\cdot\|_{L_2(\Omega)}$. For $k \in \mathbb{Z}_+$, the integer-order Sobolev space is defined by

$$\mathcal{H}_k := \left\{ f \in L_2(\mathbb{R}^d) : \; D^\alpha f \in L_2(\mathbb{R}^d) \text{ for all } |\alpha| \leq k \right\},$$

with D^α understood in the distributional sense, which carries the inner product

$$\langle f, g \rangle_k := \langle f, g \rangle_{L_2(\mathbb{R}^d)} + (f, g)_k,$$

where $(f, g)_k$ denotes the Sobolev semi-inner product

$$(f, g)_k := \sum_{|\alpha|=k} c_\alpha^{(k)} \int_{\mathbb{R}^d} (D^\alpha f)(x)(\overline{D^\alpha g})(x)\,\mathrm{d}x,$$

with associated seminorm $|\cdot|_k := (\,\cdot\,, \cdot\,)_k^{1/2}$. The coefficients $c_\alpha^{(k)}$ have been chosen so that

$$\sum_{|\alpha|=k} c_\alpha^{(k)} x^{2\alpha} = |x|^{2k}.$$

We can write the seminorm, using the Fourier transform, in the alternative form

$$|f|_k^2 = \int_{\mathbb{R}^d} |\widehat{f}(x)|^2 |x|^{2k}\,\mathrm{d}x,$$

which facilitates the definition of fractional-order Sobolev space, $\mathcal{H}_s$, for $s > 0$, which has the seminorm

$$|f|_s^2 := \int_{\mathbb{R}^d} |\widehat{f}(x)|^2 |x|^{2s}\,\mathrm{d}x. \tag{3.2}$$

The space $\mathcal{H}_s$ is complete with respect to

$$\|f\|_s := \begin{cases} \left(\|f\|^2_{L_2(\mathbb{R}^d)} + |f|^2_s\right)^{\frac{1}{2}} & \text{if } s \in \mathbb{Z}_+, \\ \left(\|f\|^2_{\lfloor s \rfloor} + |f|^2_s\right)^{\frac{1}{2}} & \text{otherwise,} \end{cases}$$

and, whenever we have $s > d/2$, $\mathcal{H}_s$ is continuously embedded in the continuous functions. The native space for ϕ satisfying (3.1) is equivalent to $\mathcal{H}_s$.

We now wish to make local definitions of our function spaces, which we shall denote by $\mathcal{H}_s(\Omega)$. For $s \in \mathbb{Z}_+$ the definition should be is clear. In what follows we also need the local fractional-order Sobolev spaces:

$$\mathcal{H}_s(\Omega) := \left\{ f \in \mathcal{H}_{\lfloor s \rfloor}(\Omega) : \ \|f\|_{s,\Omega} := \left(\|f\|^2_{\lfloor s \rfloor,\Omega} + |f|^2_{s,\Omega}\right)^{\frac{1}{2}} < \infty \right\},$$

where $|f|_{s,\Omega}$ is the local fractional-order Sobolev seminorm obtained by rewriting (3.2) in an equivalent direct form, i.e., not defined through the Fourier transform of f (see, e.g., Adams [1, p. 214]). For our analysis we find it more useful to exploit an equivalent wavelet representation for the local Sobolev norm [5].

To introduce this equivalent norm we stipulate that the bounded domain, Ω, admits a local multiresolution of closed subspaces $\{V_n(\Omega)\}_{n \geq 0}$ of $L_2(\Omega)$:

$$V_0(\Omega) \subset V_1(\Omega) \subset \cdots \subset L_2(\Omega), \qquad \overline{\bigcup_{n \geq 0} V_n(\Omega)} = L_2(\Omega).$$

Cohen, Dahmen, and DeVore [5] give sufficient conditions on Ω to admit such a local multiresolution. In particular, for $d = 2$, those domains whose boundaries have certain piecewise Lipschitz smoothness are admissible. The following is an incidence of [5, Theorem 4.2].

THEOREM 3.1. *Suppose that $\Omega \subset \mathbb{R}^d$ is a bounded domain that admits a local multiresolution $\{V_n(\Omega)\}_{n \geq 0}$ for $L_2(\Omega)$. For $n \geq 0$, let Q_n^Ω denote the orthogonal projection from $L_2(\Omega)$ onto $W_n(\Omega) = V_n(\Omega) \ominus V_{n-1}(\Omega)$ with the convention that $V_{-1}(\Omega) = \{0\}$. For each $s \geq 0$, let Λ_s be the pseudodifferential operator on Ω defined via*

$$\Lambda_s := \sum_{n \geq 0} 2^{ns} Q_n^\Omega.$$

Then there exist positive constants C_1 and C_2 such that, for all $f \in \mathcal{H}_s(\Omega)$,

$$C_1 \|\Lambda_s f\|_{L_2(\Omega)} \leq \|f\|_{s,\Omega} \leq C_2 \|\Lambda_s f\|_{L_2(\Omega)}.$$

Now, let us return to the task at hand. For ϕ satisfying (3.1), we will denote the ϕ-spline interpolant on the point set Y by S_ϕ^Y. The standard error estimate in this context is

$$|f(x) - S_\phi^Y(x)| \leq C h^{s-d/2} \|f - S_\phi^Y\|_s; \tag{3.3}$$

see [22]. If f is smoother (and satisfies some boundary conditions), we can get a better rate of convergence.

We will exploit the fact that $\mathcal{H}_\mu(\Omega)$, for $0 < \mu < s$, is an interpolation space lying between $L_2(\Omega)$ and $\mathcal{H}_s(\Omega)$ (see Bergh and Löfström [2, p. 131]). We can then use the standard interpolation theorem concerning the norms of operators bounded on the extreme spaces to infer a bound on the norm for the interpolation space. For further information on interpolation spaces the reader can consult, e.g., Bergh and Löfström [2]. We use the following interpolation theorem.

PROPOSITION 3.2. *Let $0 < \mu < s$. Further suppose that $T : \mathcal{H}_s(\Omega) \to L_2(\Omega)$ and that $T : \mathcal{H}_s(\Omega) \to \mathcal{H}_s(\Omega)$ is a bounded operator. Then,*

$$\|T\|_{\mathcal{H}_s(\Omega)\to\mathcal{H}_\mu(\Omega)} \le \|T\|^{1-\mu/s}_{\mathcal{H}_s(\Omega)\to L_2(\Omega)} \|T\|^{\mu/s}_{\mathcal{H}_s(\Omega)\to\mathcal{H}_s(\Omega)}.$$

Since we can write the $\mathcal{H}_s$-norm in entirely direct form, we are at liberty to utilize Duchon's localization technique [8] to enhance the standard error estimate (3.3). Therefore, if Ω is bounded and satisfies an interior cone condition, then, for $f \in \mathcal{H}_s(\Omega)$, $s > d/2$, and sufficiently small $h = h(Y, \Omega)$,

$$\|f - S^Y_\phi\|_{L_2(\Omega)} \le Ch^s \|f - S^Y_\phi\|_{s,\Omega}.$$

Writing $Tf = f - S^Y_\phi$, we see, using the last proposition, that, for $0 < \mu < s$,

$$\begin{aligned} \|f - S^Y_\phi\|_{\mu,\Omega} &\le (Ch^s \|f - S^Y_\phi\|_{s,\Omega})^{1-\mu/s} \|f - S^Y_\phi\|^{\mu/s}_{s,\Omega} \\ &= Ch^{s-\mu} \|f - S^Y_\phi\|_{s,\Omega}. \end{aligned} \tag{3.4}$$

We can now prove our main result of this section, which is a generalization of that of Schaback [19].

THEOREM 3.3. *Suppose that $\Omega \subset \mathbb{R}^d$ is bounded, satisfies an interior cone condition, and admits a local multiresolution. Let $s > d/2$, and let S^Y_ϕ be the ϕ-spline interpolant to $f \in \mathcal{H}_s$ on the point set $Y \subset \Omega$. Suppose further that $f \in \mathcal{H}_\nu$, for $s < \nu \le 2s$, and that f is compactly supported in Ω. Then there exists $C > 0$, independent of f and $h = h(Y, \Omega)$, such that for all $x \in \Omega$ and sufficiently small h,*

$$|f(x) - S^Y_\phi(x)| \le Ch^{\nu-d/2} \|f\|_{\nu,\Omega}.$$

Proof. From Proposition 1.1 we know that

$$\langle f - S^Y_\phi, S^Y_\phi\rangle_s = 0,$$

so that

$$\|f - S^Y_\phi\|^2_s = \langle f - S^Y_\phi, f\rangle_s \le C\langle f - S^Y_\phi, f\rangle_{s,\Omega},$$

where we have used the compact support of f in Ω. Now, the equivalent norm from Theorem 3.1 gives us

$$\begin{aligned} \|f - S^Y_\phi\|^2_s &\le C\langle \Lambda_s(f - S^Y_\phi), \Lambda_s f\rangle_{L_2(\Omega)} \\ &= C\sum_{n\ge 0} 4^{ns} \langle Q^\Omega_n(f - S^Y_\phi), Q^\Omega_n f\rangle_{L_2(\Omega)}, \end{aligned}$$

and successive applications of the continuous and discrete Cauchy–Schwarz inequality yield

$$\begin{aligned}
\|f - S_\phi^Y\|_s^2 &\le C \sum_{n\ge 0} \|2^{n(2s-\nu)} Q_n^\Omega (f - S_\phi^Y)\|_{L_2(\Omega)} \|2^{n\nu} Q_n^\Omega f\|_{L_2(\Omega)} \\
&\le C \left(\sum_{n\ge 0} \|2^{n(2s-\nu)} Q_n^\Omega (f - S_\phi^Y)\|_{L_2(\Omega)}^2 \right)^{\frac{1}{2}} \left(\sum_{n\ge 0} \|2^{n\nu} Q_n^\Omega f\|_{L_2(\Omega)}^2 \right)^{\frac{1}{2}} \\
&= C \|\Lambda_{2s-\nu}(f - S_\phi^Y)\|_{L_2(\Omega)} \|\Lambda_\nu f\|_{L_2(\Omega)}.
\end{aligned}$$

Thus, using the norm equivalence from Theorem 3.1 again together with (3.4), we have

$$\begin{aligned}
\|f - S_\phi^Y\|_s^2 &\le C \|f - S_\phi^Y\|_{2s-\nu,\Omega} \|f\|_{\nu,\Omega} \\
&\le C h^{\nu - s} \|f - S_\phi^Y\|_{s,\Omega} \|f\|_{\nu,\Omega} \\
&\le C h^{\nu - s} \|f - S_\phi^Y\|_s \|f\|_{\nu,\Omega},
\end{aligned}$$

and cancelling one power of $\|f - S_\phi^Y\|_s$ gives

$$\|f - S_\phi^Y\|_s \le C h^{\nu - s} \|f\|_{\nu,\Omega}.$$

The result follows by substitution into the standard error estimate (3.3). □

Acknowledgments. We are grateful to Professor Mikhail Shubin for useful input into questions of pseudodifferential operators and alternative Sobolev space seminorms.

STABLE SOLUTIONS FOR THE BILAPLACIAN WITH EXPONENTIAL NONLINEARITY*

JUAN DÁVILA†, LOUIS DUPAIGNE‡, IGNACIO GUERRA§, AND MARCELO MONTENEGRO¶

Abstract. Let $\lambda^* > 0$ denote the largest possible value of λ such that $\{\Delta^2 u = \lambda e^u$ in B, $u = \frac{\partial u}{\partial n} = 0$ on $\partial B\}$ has a solution, where B is the unit ball in $\mathbb{R}^N$ and n is the exterior unit normal vector. We show that for $\lambda = \lambda^*$ this problem possesses a unique *weak* solution u^*. We prove that u^* is smooth if $N \leq 12$ and singular when $N \geq 13$, in which case $u^*(r) = -4\log r + \log(8(N-2)(N-4)/\lambda^*) + o(1)$ as $r \to 0$. We also consider the problem with general constant Dirichlet boundary conditions.

Key words. biharmonic, singular solutions, stability

1. Introduction.

We study the fourth order problem

$$\begin{cases} \Delta^2 u = \lambda e^u & \text{in } B, \\ u = a & \text{on } \partial B, \\ \dfrac{\partial u}{\partial n} = b & \text{on } \partial B, \end{cases} \tag{1}$$

where a, $b \in \mathbb{R}$, B is the unit ball in $\mathbb{R}^N$, $N \geq 1$, n is the exterior unit normal vector, and $\lambda \geq 0$ is a parameter.

Recently higher order equations have attracted the interest of many researchers. In particular, fourth order equations with an exponential nonlinearity have been studied in four dimensions in a setting analogous to Liouville's equation in [3, 12, 24] and in higher dimensions by [1, 2, 4, 5, 13].

We shall pay special attention to (1) in the case $a = b = 0$, as it is the natural fourth order analogue of the classical Gelfand problem

$$\begin{cases} -\Delta u = \lambda e^u & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega \end{cases} \tag{2}$$

(Ω is a smooth bounded domain in $\mathbb{R}^N$) for which a vast literature exists [7, 8, 9, 10, 18, 19, 20, 21].

From the technical point of view, one of the basic tools in the analysis of (2) is the maximum principle. As pointed out in [2], in general domains the maximum principle for Δ^2 with Dirichlet boundary condition is not valid anymore. One of the reasons to study (1) in a ball is that a maximum principle holds in this situation; see [6]. In this simpler setting, though there are some similarities between the two problems, several tools that are well suited for (2) no longer seem to work for (1).

As a start, let us introduce the class of weak solutions we shall be working with: we say that $u \in H^2(B)$ is a weak solution to (1) if $e^u \in L^1(B)$, $u = a$ on ∂B, $\frac{\partial u}{\partial n} = b$ on ∂B, and

$$\int_B \Delta u \Delta \varphi = \lambda \int_B e^u \varphi \quad \forall \varphi \in C_0^\infty(B).$$

The following basic result is a straightforward adaptation of Theorem 3 in [2].

THEOREM 1.1 (see [2]). *There exists λ^* such that if $0 \le \lambda < \lambda^*$ then* (1) *has a minimal smooth solution u_λ and if $\lambda > \lambda^*$ then* (1) *has no weak solution.*

The limit $u^* = \lim_{\lambda \nearrow \lambda^*} u_\lambda$ exists pointwise, belongs to $H^2(B)$, and is a weak solution to (1). *It is called the extremal solution.*

The functions u_λ, $0 \le \lambda < \lambda^*$, and u^* are radially symmetric and radially decreasing.

The branch of minimal solutions of (1) has an important property; namely, u_λ is stable in the sense that

$$\int_B (\Delta \varphi)^2 \ge \lambda \int_B e^{u_\lambda} \varphi^2 \quad \forall \varphi \in C_0^\infty(B); \tag{3}$$

see [2, Proposition 37].

The authors in [2] pose several questions, some of which we address in this work. First we show that the extremal solution u^* is the unique solution to (1) in the class of weak solutions. Actually the statement is stronger, asserting that for $\lambda = \lambda^*$ there are no strict supersolutions.

THEOREM 1.2. *If*

$$v \in H^2(B),\ e^v \in L^1(B),\ v|_{\partial B} = a,\ \tfrac{\partial v}{\partial n}|_{\partial B} \le b, \tag{4}$$

and

$$\int_B \Delta v \Delta \varphi \ge \lambda^* \int_B e^v \varphi \quad \forall\, \varphi \in C_0^\infty(B),\ \varphi \ge 0, \tag{5}$$

then $v = u^*$. In particular, for $\lambda = \lambda^*$ problem (1) *has a unique weak solution.*

This result is analogous to the work of Martel [19] for more general versions of (2), where the exponential function is replaced by a positive, increasing, convex, and superlinear function.

Next, we discuss the regularity of the extremal solution u^*. In dimensions $N = 5, \ldots, 16$ the authors of [2] find, with a computer assisted proof, a radial singular solution U_σ to (1) with $a = b = 0$ associated to a parameter $\lambda_\sigma > 8(N-2)(N-4)$. They show that $\lambda_\sigma < \lambda^*$ if $N \le 10$ and claim to have numerical evidence that this holds for $N \le 12$. They leave open the question of whether u^* is singular in dimension $N \le 12$. We prove the following theorem.

THEOREM 1.3. *If $N \le 12$ then the extremal solution u^* of* (1) *is smooth.*

The method introduced in [10, 20] to prove the boundedness of u^* in low dimensions for (2) seems not useful for (1), thus requiring a new strategy. A first indication that the borderline dimension for the boundedness of u^* is 12 is Rellich's inequality [23], which states that if $N \ge 5$ then

$$\int_{\mathbb{R}^N} (\Delta\varphi)^2 \ge \frac{N^2(N-4)^2}{16} \int_{\mathbb{R}^N} \frac{\varphi^2}{|x|^4} \qquad \forall \varphi \in C_0^\infty(\mathbb{R}^N), \tag{6}$$

where the constant $N^2(N-4)^2/16$ is known to be optimal. The proof of Theorem 1.3 is based on the observation that if u^* is singular then $\lambda^* e^{u^*} \sim 8(N-2)(N-4)|x|^{-4}$ near the origin. But $8(N-2)(N-4) > N^2(N-4)^2/16$ if $N \le 12$, which would contradict the stability condition (3).

In view of Theorem 1.3, it is natural to ask whether u^* is singular in dimension $N \ge 13$. If $a = b = 0$, we prove the following theorem.

THEOREM 1.4. *Let $N \ge 13$ and $a = b = 0$. Then the extremal solution u^* to* (1) *is unbounded.*

For general boundary values, it seems more difficult to determine the dimensions for which the extremal solution is singular. We observe first that given any $a, b \in \mathbb{R}$, u^* is the extremal solution of (1) if and only if $u^* - a$ is the extremal solution of the same equation with boundary condition $u = 0$ on ∂B. In particular, if $\lambda^*(a, b)$ denotes the extremal parameter for problem (1), one has that $\lambda^*(a, b) = e^{-a}\lambda^*(0, b)$. So the value of a is irrelevant. But one may ask if Theorem 1.4 still holds for any $N \ge 13$ and any $b \in \mathbb{R}$. The situation turns out to be somewhat more complicated.

PROPOSITION 1.5.

(a) *Fix $N \ge 13$ and take any $a \in \mathbb{R}$. Assume $b \ge -4$. There exists a critical parameter $b^{max} > 0$, depending only on N, such that the extremal solution u^* is singular if and only if $b \le b^{max}$.*

(b) *Fix $b \ge -4$ and take any $a \in \mathbb{R}$. There exists a critical dimension $N^{min} \ge 13$, depending only on b, such that the extremal solution u^* to* (1) *is singular if $N \ge N^{min}$.*

Remark 1.6.

- We have not investigated the case $b < -4$.
- If follows from item (a) that for $b \in [-4, 0]$, the extremal solution is singular if and only if $N \ge 13$.
- It also follows from item (a) that there exist values of b for which $N^{min} > 13$. We do not know whether u^* remains bounded for $13 \le N < N^{min}$.

Our proof of Theorem 1.4 is related to an idea that Brezis and Vázquez applied to the Gelfand problem and is based on a characterization of singular *energy* solutions through linearized stability (see Theorem 3.1 in [8]). In our context we show the following.

PROPOSITION 1.7. *Assume that $u \in H^2(B)$ is an unbounded weak solution of* (1) *satisfying the stability condition*

$$\lambda \int_B e^u \varphi^2 \le \int_B (\Delta\varphi)^2 \quad \forall \varphi \in C_0^\infty(B). \tag{7}$$

Then $\lambda = \lambda^*$ and $u = u^*$.

In the proof of Theorem 1.4 we do not use Proposition 1.7 directly but some variants of it—see Lemma 2.6 and Remark 2.7—because we do not have at our disposal an explicit solution to (1). Instead, we show that it is enough to find a sufficiently good approximation to u^*. When $N \geq 32$ we are able to construct such an approximation by hand. However, for $13 \leq N \leq 31$ we resort to a computer assisted generation and verification.

Only in very few situations may one take advantage of Proposition 1.7 directly. For instance, for problem (1) with $a = 0$ and $b = -4$ we have an explicit solution

$$\bar{u}(x) = -4 \log |x|$$

associated to $\bar{\lambda} = 8(N-2)(N-4)$. Thanks to Rellich's inequality (6) the solution $\bar{u}$ satisfies condition (7) when $N \geq 13$. Therefore, by Theorem 1.3 and a direct application of Proposition 1.7 we obtain Theorem 1.4 in the case $b = -4$.

In [2] the authors say that a radial weak solution u to (1) is weakly singular if

$$\lim_{r \to 0} r u'(r) \text{ exists.}$$

For example, the singular solutions U_σ of [2] verify this condition.

As a corollary of Theorem 1.2 we show the following.

PROPOSITION 1.8. *The extremal solution u^* to* (1) *with $b \geq -4$ is always weakly singular.*

A weakly singular solution either is smooth or exhibits a log-type singularity at the origin. More precisely, if u is a nonsmooth weakly singular solution of (1) with parameter λ, then (see [2])

$$\begin{aligned} &\lim_{r \to 0} u(r) + 4 \log r = \log \frac{8(N-2)(N-4)}{\lambda}, \\ &\lim_{r \to 0} r u'(r) = -4. \end{aligned}$$

In section 2 we describe the comparison principles we use later. Section 3 is devoted to the proof of the uniqueness of u^* and Propositions 1.7 and 1.8. We prove Theorem 1.3, the boundedness of u^* in low dimensions, in section 4. The argument for Theorem 1.4 is contained in section 5 for the case $N \geq 32$ and section 6 for $13 \leq N \leq 31$. In section 7 we give the proof of Proposition 1.5.

Notation.

- B_R is the ball of radius R in $\mathbb{R}^N$ centered at the origin. $B = B_1$.
- n is the exterior unit normal vector to B_R.
- All inequalities or equalities for functions in L^p spaces are understood to be a.e.

2. Comparison principles.

LEMMA 2.1 (Boggio's principle [6]). *If $u \in C^4(\overline{B}_R)$ satisfies*

$$\begin{cases} \Delta^2 u \geq 0 & \text{in } B_R, \\ u = \dfrac{\partial u}{\partial n} = 0 & \text{on } \partial B_R, \end{cases}$$

then $u \geq 0$ in B_R.

LEMMA 2.2. *Let $u \in L^1(B_R)$ and suppose that*

$$\int_{B_R} u \Delta^2 \varphi \geq 0$$

for all $\varphi \in C^4(\overline{B}_R)$ such that $\varphi \geq 0$ in B_R, $\varphi|_{\partial B_R} = 0 = \frac{\partial \varphi}{\partial n}|_{\partial B_R}$. Then $u \geq 0$ in B_R. Moreover, $u \equiv 0$ or $u > 0$ a.e. in B_R.

For a proof see Lemma 17 in [2].

LEMMA 2.3. *If $u \in H^2(B_R)$ is radial, $\Delta^2 u \geq 0$ in B_R in the weak sense, that is,*

$$\int_{B_R} \Delta u \Delta \varphi \geq 0 \quad \forall \varphi \in C_0^\infty(B_R),\ \varphi \geq 0,$$

and $u|_{\partial B_R} \geq 0$, $\frac{\partial u}{\partial n}|_{\partial B_R} \leq 0$, then $u \geq 0$ in B_R.

Proof. We deal only with the case $R = 1$ for simplicity. Solve

$$\begin{cases} \Delta^2 u_1 = \Delta^2 u & \text{in } B_1, \\ u_1 = \dfrac{\partial u_1}{\partial n} = 0 & \text{on } \partial B_1 \end{cases}$$

in the sense $u_1 \in H_0^2(B_1)$ and $\int_{B_1} \Delta u_1 \Delta \varphi = \int_{B_1} \Delta u \Delta \varphi$ for all $\varphi \in C_0^\infty(B_1)$. Then $u_1 \geq 0$ in B_1 by Lemma 2.2.

Let $u_2 = u - u_1$ so that $\Delta^2 u_2 = 0$ in B_1. Define $f = \Delta u_2$. Then $\Delta f = 0$ in B_1 and since f is radial we find that f is constant. It follows that $u_2 = ar^2 + b$. Using the boundary conditions we deduce $a + b \geq 0$ and $a \leq 0$, which imply $u_2 \geq 0$. ☐

Similarly, we have the following lemma.

LEMMA 2.4. *If $u \in H^2(B_R)$ and $\Delta^2 u \geq 0$ in B_R in the weak sense, that is,*

$$\int_{B_R} \Delta u \Delta \varphi \geq 0 \quad \forall \varphi \in C_0^\infty(B_R),\ \varphi \geq 0,$$

and $u|_{\partial B_R} = 0$, $\frac{\partial u}{\partial n}|_{\partial B_R} \leq 0$, then $u \geq 0$ in B_R.

The next lemma is a consequence of a decomposition lemma of Moreau [22]. For a proof see [14, 15].

LEMMA 2.5. *Let $u \in H_0^2(B_R)$. Then there exist unique $w, v \in H_0^2(B_R)$ such that $u = w + v$, $w \geq 0$, $\Delta^2 v \leq 0$ in B_R and $\int_{B_R} \Delta w \Delta v = 0$.*

We need the following comparison principle.

LEMMA 2.6. *Let u_1, $u_2 \in H^2(B_R)$ with e^{u_1}, $e^{u_2} \in L^1(B_R)$. Assume that*

$$\Delta^2 u_1 \leq \lambda e^{u_1} \quad \text{in } B_R$$

in the sense that

$$\int_{B_R} \Delta u_1 \Delta \varphi \leq \lambda \int_{B_R} e^{u_1} \varphi \quad \forall \varphi \in C_0^\infty(B_R),\ \varphi \geq 0, \tag{8}$$

and $\Delta^2 u_2 \geq \lambda e^{u_2}$ in B_R in the similar weak sense. Suppose also

$$u_1|_{\partial B_R} = u_2|_{\partial B_R} \quad \text{and} \quad \frac{\partial u_1}{\partial n}|_{\partial B_R} = \frac{\partial u_2}{\partial n}|_{\partial B_R}.$$

Assume, furthermore, that u_1 is stable in the sense that

$$\lambda \int_{B_R} e^{u_1} \varphi^2 \leq \int_{B_R} (\Delta \varphi)^2 \quad \forall \varphi \in C_0^\infty(B_R). \tag{9}$$

Then

$$u_1 \leq u_2 \quad \text{in } B_R.$$

Proof. Let $u = u_1 - u_2$. By Lemma 2.5 there exist $w, v \in H_0^2(B_R)$ such that $u = w + v$, $w \geq 0$ and $\Delta^2 v \leq 0$. Observe that $v \leq 0$ so $w \geq u_1 - u_2$.

By hypothesis we have for all $\varphi \in C_0^\infty(B_R)$, $\varphi \geq 0$,

$$\int_{B_R} \Delta(u_1 - u_2)\Delta\varphi \leq \lambda \int_{B_R} (e^{u_1} - e^{u_2})\varphi \leq \lambda \int_{B_R \cap [u_1 \geq u_2]} (e^{u_1} - e^{u_2})\varphi$$

and by density this holds also for w:

$$\begin{aligned} \int_{B_R} (\Delta w)^2 &= \int_{B_R} \Delta(u_1 - u_2)\Delta w \\ &\leq \lambda \int_{B_R \cap [u_1 \geq u_2]} (e^{u_1} - e^{u_2}) w = \lambda \int_{B_R} (e^{u_1} - e^{u_2}) w, \end{aligned} \tag{10}$$

where the first equality holds because $\int_{B_R} \Delta w \Delta v = 0$. By density we deduce from (9)

$$\lambda \int_{B_R} e^{u_1} w^2 \leq \int_{B_R} (\Delta w)^2. \tag{11}$$

Combining (10) and (11), we obtain

$$\int_{B_R} e^{u_1} w^2 \leq \int_{B_R} (e^{u_1} - e^{u_2}) w.$$

Since $u_1 - u_2 \leq w$ the previous inequality implies

$$0 \leq \int_{B_R} (e^{u_1} - e^{u_2} - e^{u_1}(u_1 - u_2)) w. \tag{12}$$

But by convexity of the exponential function $e^{u_1} - e^{u_2} - e^{u_1}(u_1 - u_2) \leq 0$, and we deduce from (12) that $(e^{u_1} - e^{u_2} - e^{u_1}(u_1 - u_2))w = 0$. Recalling that $u_1 - u_2 \leq w$ we deduce that $u_1 \leq u_2$. ◻

Remark 2.7. The following variant of Lemma 2.6 also holds.

Let u_1, $u_2 \in H^2(B_R)$ be *radial* with e^{u_1}, $e^{u_2} \in L^1(B_R)$. Assume $\Delta^2 u_1 \leq \lambda e^{u_1}$ in B_R in the sense of (8) and $\Delta^2 u_2 \geq \lambda e^{u_2}$ in B_R. Suppose $u_1|_{\partial B_R} \leq u_2|_{\partial B_R}$ and $\frac{\partial u_1}{\partial n}|_{\partial B_R} \geq \frac{\partial u_2}{\partial n}|_{\partial B_R}$ and that the stability condition (9) holds. Then $u_1 \leq u_2$ in B_R.

Proof. We solve for $\tilde{u} \in H_0^2(B_R)$ such that

$$\int_{B_R} \Delta\tilde{u}\Delta\varphi = \int_{B_R} \Delta(u_1 - u_2)\Delta\varphi \quad \forall \varphi \in C_0^\infty(B_R).$$

By Lemma 2.3 it follows that $\tilde{u} \geq u_1 - u_2$. Next we apply the decomposition of Lemma 2.5 to $\tilde{u}$, that is, $\tilde{u} = w + v$ with $w, v \in H_0^2(B_R)$, $w \geq 0$, $\Delta^2 v \leq 0$ in B_R, and $\int_{B_R} \Delta w \Delta v = 0$. Then the argument follows that of Lemma 2.6. ◻

Finally, in several places we will need the method of sub- and supersolutions in the context of weak solutions.

LEMMA 2.8. *Let $\lambda > 0$ and assume that there exists $\bar{u} \in H^2(B_R)$ such that $e^{\bar{u}} \in L^1(B_R)$,*

$$\int_{B_R} \Delta\bar{u}\Delta\varphi \geq \lambda \int_{B_R} e^{\bar{u}}\varphi \quad \forall \varphi \in C_0^\infty(B_R), \varphi \geq 0,$$

and

$$\bar{u} = a, \quad \frac{\partial \bar{u}}{\partial n} \le b \quad \text{on } \partial B_1.$$

Then there exists a weak solution to (1) *such that* $u \le \bar{u}$.

The proof is similar to that of Lemma 19 in [2].

3. Uniqueness of the extremal solution: Proof of Theorem 1.2.

Proof of Theorem 1.2. Suppose that $v \in H^2(B)$ satisfies (4), (5), and $v \not\equiv u^*$. Notice that we do not need v to be radial. The idea of the proof is as follows.

Step 1. The function

$$u_0 = \frac{1}{2}(u^* + v)$$

is a supersolution to the problem

$$\begin{cases} \Delta^2 u = \lambda^* e^u + \mu \eta e^u & \text{in } B, \\ u = a & \text{on } \partial B, \\ \dfrac{\partial u}{\partial n} = b & \text{on } \partial B \end{cases} \tag{13}$$

for some $\mu = \mu_0 > 0$, where $\eta \in C_0^\infty(B)$, $0 \le \eta \le 1$, is a fixed radial cut-off function such that

$$\eta(x) = 1 \quad \text{for } |x| \le \tfrac{1}{2}, \qquad \eta(x) = 0 \quad \text{for } |x| \ge \tfrac{3}{4}.$$

Step 2. Using a solution to (13) we construct, for some $\lambda > \lambda^*$, a supersolution to (1). This provides a solution u_λ for some $\lambda > \lambda^*$, which is a contradiction.

Proof of Step 1. Observe that given $0 < R < 1$ we must have for some $c_0 = c_0(R) > 0$

$$v(x) \ge u^*(x) + c_0, \quad |x| \le R. \tag{14}$$

To prove this we recall the Green's function for Δ^2 with Dirichlet boundary conditions

$$\begin{cases} \Delta_x^2 G(x,y) = \delta_y, & x \in B, \\ G(x,y) = 0, & x \in \partial B, \\ \dfrac{\partial G}{\partial n}(x,y) = 0, & x \in \partial B, \end{cases}$$

where δ_y is the Dirac mass at $y \in B$. Boggio gave an explicit formula for $G(x,y)$ which was used in [16] to prove that in dimension $N \ge 5$ (the case $1 \le N \le 4$ can be treated similarly)

$$G(x,y) \sim |x-y|^{4-N} \min\left(1, \frac{d(x)^2 d(y)^2}{|x-y|^4}\right), \tag{15}$$

where

$$d(x) = \operatorname{dist}(x, \partial B) = 1 - |x|$$

and $a \sim b$ means that for some constant $C > 0$ we have $C^{-1}a \le b \le Ca$ (uniformly for $x, y \in B$). Formula (15) yields

$$G(x,y) \ge cd(x)^2 d(y)^2 \tag{16}$$

for some $c > 0$ and this in turn implies that for smooth functions $\tilde v$ and $\tilde u$ such that $\tilde v - \tilde u \in H_0^2(B)$ and $\Delta^2(\tilde v - \tilde u) \ge 0$,

$$\begin{aligned}\tilde v(y) - \tilde u(y) &= \int_{\partial B} \Big(\frac{\partial \Delta_x G}{\partial n_x}(x,y)(\tilde v - \tilde u) - \Delta_x G(x,y) \frac{\partial(\tilde v - \tilde u)}{\partial n} \Big)\, dx \\ &\quad + \int_B G(x,y) \Delta^2(\tilde v - \tilde u)\, dx \\ &\ge cd(y)^2 \int_B (\Delta^2 \tilde v - \Delta^2 \tilde u) d(x)^2\, dx.\end{aligned}$$

Using a standard approximation procedure, we conclude that

$$v(y) - u^*(y) \ge cd(y)^2 \lambda^* \int_B (e^v - e^{u^*}) d(x)^2\, dx.$$

Since $v \ge u^*$, $v \not\equiv u^*$ we deduce (14).

Let $u_0 = (u^* + v)/2$. Then by Taylor's theorem

$$e^v = e^{u_0} + (v - u_0)e^{u_0} + \frac{1}{2}(v-u_0)^2 e^{u_0} + \frac{1}{6}(v - u_0)^3 e^{u_0} + \frac{1}{24}(v-u_0)^4 e^{\xi_2} \tag{17}$$

for some $u_0 \le \xi_2 \le v$ and

$$e^{u^*} = e^{u_0} + (u^* - u_0)e^{u_0} + \frac{1}{2}(u^*-u_0)^2 e^{u_0} + \frac{1}{6}(u^* - u_0)^3 e^{u_0} + \frac{1}{24}(u^*-u_0)^4 e^{\xi_1} \tag{18}$$

for some $u^* \le \xi_1 \le u_0$. Adding (17) and (18) yields

$$\frac{1}{2}(e^v + e^{u^*}) \ge e^{u_0} + \frac{1}{8}(v - u^*)^2 e^{u_0}. \tag{19}$$

From (14) with $R = 3/4$ and (19) we see that $u_0 = (u^* + v)/2$ is a supersolution of (13) with $\mu_0 := c_0/8$.

Proof of Step 2. Let us show now how to obtain a weak supersolution of (1) for some $\lambda > \lambda^*$. Given $\mu > 0$, let u denote the minimal solution to (13). Define φ_1 as the solution to

$$\begin{cases} \Delta^2 \varphi_1 = \mu \eta e^u & \text{in } B, \\ \varphi_1 = 0 & \text{on } \partial B, \\ \dfrac{\partial \varphi_1}{\partial n} = 0 & \text{on } \partial B, \end{cases}$$

and φ_2 as the solution to

$$\begin{cases} \Delta^2 \varphi_2 = 0 & \text{in } B, \\ \varphi_2 = a & \text{on } \partial B, \\ \dfrac{\partial \varphi_2}{\partial n} = b & \text{on } \partial B. \end{cases}$$

If $N \geq 5$ (the case $1 \leq N \leq 4$ can be treated similarly), relation (16) yields

$$\varphi_1(x) \geq c_1 d(x)^2 \quad \forall x \in B, \tag{20}$$

for some $c_1 > 0$. But u is a radial solution of (13) and therefore it is smooth in $B \setminus B_{1/4}$. Thus

$$u(x) \leq M\varphi_1 + \varphi_2 \quad \forall x \in B_{1/2}, \tag{21}$$

for some $M > 0$. Therefore, from (20) and (21), for $\lambda > \lambda^*$ with $\lambda - \lambda^*$ sufficiently small we have

$$\left(\frac{\lambda}{\lambda^*} - 1\right) u \leq \varphi_1 + \left(\frac{\lambda}{\lambda^*} - 1\right) \varphi_2 \quad \text{in } B.$$

Let $w = \frac{\lambda}{\lambda^*} u - \varphi_1 - (\frac{\lambda}{\lambda^*} - 1)\varphi_2$. The inequality just stated guarantees that $w \leq u$. Moreover,

$$\Delta^2 w = \lambda e^u + \frac{\lambda\mu}{\lambda^*}\eta e^u - \mu\eta e^u \geq \lambda e^u \geq \lambda e^w \quad \text{in } B$$

and

$$w = a, \quad \frac{\partial w}{\partial n} = b \quad \text{on } \partial B.$$

Therefore, w is a supersolution to (1) for λ. By the method of sub- and supersolutions a solution to (1) exists for some $\lambda > \lambda^*$, which is a contradiction. ∎

Proof of Proposition 1.7. Let $\lambda > 0$ and $u \in H^2(B)$ be a weak unbounded solution of (1). If $\lambda < \lambda^*$ from Lemma 2.6 we find that $u \leq u_\lambda$, where u_λ is the minimal solution. This is impossible because u_λ is smooth and u is unbounded. If $\lambda = \lambda^*$ then necessarily $u = u^*$ by Theorem 1.2. ∎

Proof of Proposition 1.8. Let u denote the extremal solution of (1) with $b \geq -4$. If u is smooth, then the result is trivial. So we restrict our attention to the case where u is singular. By Theorem 1.3 we have, in particular, that $N \geq 13$. We may also assume that $a = 0$. If $b = -4$ by Theorem 1.2 we know that if $N \geq 13$, then $u = -4\log|x|$ so that the desired conclusion holds. Henceforth we assume $b > -4$ in this section.

For $\rho > 0$ define

$$u_\rho(r) = u(\rho r) + 4\log\rho$$

so that

$$\Delta^2 u_\rho = \lambda^* e^{u_\rho} \qquad \text{in } B_{1/\rho}.$$

Then

$$\frac{du_\rho}{d\rho}\bigg|_{\rho=1,r=1} = u'(1) + 4 > 0.$$

Hence, there is $\delta > 0$ such that

$$u_\rho(r) < u(r) \quad \forall 1 - \delta < r \leq 1,\ 1 - \delta < \rho \leq 1.$$

This implies

$$u_\rho(r) < u(r) \quad \forall 0 < r \le 1,\, 1-\delta < \rho \le 1. \tag{22}$$

Otherwise set

$$r_0 = \sup\{\, 0 < r < 1 \,|\, u_\rho(r) \ge u(r)\,\}.$$

This definition yields

$$u_\rho(r_0) = u(r_0) \quad \text{ and } \quad u_\rho'(r_0) \le u'(r_0). \tag{23}$$

Write $\alpha = u(r_0)$, $\beta = u'(r_0)$. Then u satisfies

$$\begin{cases} \Delta^2 u = \lambda e^u & \text{on } B_{r_0}, \\ u(r_0) = \alpha, \\ u'(r_0) = \beta. \end{cases} \tag{24}$$

Observe that u is an unbounded $H^2(B_{r_0})$ solution to (24), which is also stable. Thus Proposition 1.7 shows that u is the extremal solution to this problem. On the other hand, u_ρ is a supersolution to (24), since $u_\rho'(r_0) \le \beta$ by (23). We may now use Theorem 1.2 and we deduce that

$$u(r) = u_\rho(r) \quad \forall 0 < r \le r_0,$$

which in turn implies by standard ODE theory that

$$u(r) = u_\rho(r) \quad \forall 0 < r \le 1,$$

which is a contradiction to (22). This proves estimate (22).

From (22) we see that

$$\frac{du_\rho}{d\rho}\Big|_{\rho=1}(r) \ge 0 \quad \forall 0 < r \le 1. \tag{25}$$

But

$$\frac{du_\rho}{d\rho}\Big|_{\rho=1}(r) = u'(r)r + 4 \quad \forall 0 < r \le 1,$$

and this together with (25) implies

$$\frac{du_\rho}{d\rho}(r) = \frac{1}{\rho}(u'(\rho r)\rho r + 4) \ge 0 \quad \forall 0 < r \le \frac{1}{\rho},\, 0 < \rho \le 1, \tag{26}$$

which means that $u_\rho(r)$ is nondecreasing in ρ. We wish to show that $\lim_{\rho\to 0} u_\rho(r)$ exists for all $0 < r \le 1$. For this we shall show

$$u_\rho(r) \ge -4\log(r) + \log\left(\frac{8(N-2)(N-4)}{\lambda^*}\right) \quad \forall 0 < r \le \frac{1}{\rho},\, 0 < \rho \le 1. \tag{27}$$

Set

$$u_0(r) = -4\log(r) + \log\left(\frac{8(N-2)(N-4)}{\lambda^*}\right),$$

and suppose that (27) is not true for some $0 < \rho < 1$. Let

$$r_1 = \sup \{ 0 < r < 1/\rho \,|\, u_\rho(r) < u_0(r) \}.$$

Observe that

$$\lambda^* > 8(N-2)(N-4). \tag{28}$$

Otherwise $w = -4 \ln r$ would be a strict supersolution of the equation satisfied by u, which is not possible by Theorem 1.2. In particular, $r_1 < 1/\rho$ and

$$u_\rho(r_1) = u_0(r_1) \quad \text{and} \quad u_\rho'(r_1) \geq u_0'(r_1).$$

It follows that u_0 is a supersolution of

$$\begin{cases} \Delta^2 u = \lambda^* e^u & \text{in } B_{r_1}, \\ u = A & \text{on } \partial B_{r_1}, \\ \dfrac{\partial u}{\partial n} = B & \text{on } \partial B_{r_1}, \end{cases} \tag{29}$$

with $A = u_\rho(r_1)$ and $B = u_\rho'(r_1)$. Since u_ρ is a singular stable solution of (29), it is the extremal solution of the problem by Proposition 1.7. By Theorem 1.2, there is no strict supersolution of (29), and we conclude that $u_\rho \equiv u_0$ first for $0 < r < r_1$ and then for $0 < r \leq 1/\rho$. This is impossible for $\rho > 0$ because $u_\rho(1/\rho) = 4 \log \rho$ and $u_0(1/\rho) < 4 \log \rho + \log(\frac{8(N-2)(N-4)}{\lambda^*}) < u_\rho(1/\rho)$ by (28). This proves (27).

By (26) and (27) we see that

$$v(r) = \lim_{\rho \to 0} u_\rho(r) \quad \text{exists } \forall 0 < r < +\infty,$$

where the convergence is uniform (even in C^k for any k) on compact sets of $\mathbb{R}^N \setminus \{0\}$. Moreover, v satisfies

$$\Delta^2 v = \lambda^* e^v \quad \text{in } \mathbb{R}^N \setminus \{0\}. \tag{30}$$

Then for any $r > 0$

$$v(r) = \lim_{\rho \to 0} u_\rho(r) = \lim_{\rho \to 0} u(\rho r) + 4 \log(\rho r) - 4 \log(r) = v(1) - 4 \log(r).$$

Hence, using (30) we obtain

$$v(r) = -4 \log r + \log \left(\frac{8(N-2)(N-4)}{\lambda^*} \right) = u_0(r).$$

But then

$$u_\rho'(r) = u'(\rho r)\rho \to -4 \quad \text{as } \rho \to 0,$$

and therefore, with $r = 1$

$$\rho u'(\rho) \to -4 \quad \text{as } \rho \to 0. \qquad \square \tag{31}$$

4. Proof of Theorem 1.3. First we will show the following lemma.

LEMMA 4.1. *Suppose that the extremal solution u^* to* (1) *is singular. Then for any $\sigma > 0$ there exists $0 < R < 1$ such that*

$$u^*(x) \geq (1-\sigma)\log\left(\frac{1}{|x|^4}\right) \quad \forall\, |x| < R. \tag{32}$$

Proof. Assume by contradiction that (32) is false. Then there exist $\sigma > 0$ and a sequence $x_k \in B$ with $x_k \to 0$ such that

$$u^*(x_k) < (1-\sigma)\log\left(\frac{1}{|x_k|^4}\right). \tag{33}$$

Let $s_k = |x_k|$ and choose $0 < \lambda_k < \lambda^*$ such that

$$\max_{\overline{B}} u_{\lambda_k} = u_{\lambda_k}(0) = \log\left(\frac{1}{s_k^4}\right). \tag{34}$$

Note that $\lambda_k \to \lambda^*$; otherwise u_{λ_k} would remain bounded. Let

$$v_k(x) = \frac{u_{\lambda_k}(s_k x)}{\log(\frac{1}{s_k^4})}, \qquad x \in B_k \equiv \frac{1}{s_k}B.$$

Then $0 \leq v_k \leq 1$, $v_k(0) = 1$,

$$\begin{aligned}\Delta^2 v_k(x) &= \lambda_k \frac{s_k^4}{\log(\frac{1}{s_k^4})} e^{u_{\lambda_k}(s_k x)} \\ &\leq \frac{\lambda_k}{\log(\frac{1}{s_k^4})} \to 0 \quad \text{in } B_k\end{aligned}$$

by (34). By elliptic regularity $v_k \to v$ uniformly on compact sets of $\mathbb{R}^N$ to a function v satisfying $0 \leq v \leq 1$, $v(0) = 1$, $\Delta^2 v = 0$ in $\mathbb{R}^N$. By Liouville's theorem for biharmonic functions [17] we conclude that v is constant and therefore $v \equiv 1$.

Since $|x_k| = s_k$ we deduce that

$$\frac{u_{\lambda_k}(x_k)}{\log(\frac{1}{s_k^4})} \to 1,$$

which contradicts (33). ◻

Proof of Theorem 1.3. We write for simplicity $u = u^*$, $\lambda = \lambda^*$. Assume by contradiction that u^* is unbounded and $5 \leq N \leq 12$. If $N \leq 4$ the problem is subcritical, and the boundedness of u^* can be proved by other means: no singular solutions exist for positive λ (see [2]), though in dimension $N = 4$, a family of solutions (u_λ) can blow up as $\lambda \to 0$ (see [24]).

For $\varepsilon > 0$ let $\psi = |x|^{\frac{4-N}{2}+\varepsilon}$ and let $\eta \in C_0^\infty(\mathbb{R}^N)$ with $\eta \equiv 1$ in $B_{1/2}$ and $\operatorname{supp}(\eta) \subseteq$ B. Observe that

$$(\Delta\psi)^2 = (H_N + O(\varepsilon))|x|^{-N+2\varepsilon}, \quad \text{where } H_N = \frac{N^2(N-4)^2}{16}.$$

Using a standard approximation argument as in the proof of Lemma 2.6, we can use $\psi\eta$ as a test function in (9) and we obtain

$$\int_B (\Delta\psi)^2 + O(1) \geq \lambda \int_B e^u \psi^2,$$

since the contribution of the integrals outside a fixed ball around the origin remains bounded as $\varepsilon \to 0$ (here $O(1)$ denotes a bounded function as $\varepsilon \to 0$).

This implies

$$\lambda \int_B e^u |x|^{4-N+2\varepsilon} \leq (H_N + O(\varepsilon)) \int_B |x|^{-N+2\varepsilon} = \omega_N \frac{H_N}{2\varepsilon} + O(1), \tag{35}$$

where ω_N is the surface area of the unit $N-1$ dimensional sphere S^{N-1}. In particular, $\int_B e^u|x|^{4-N+2\varepsilon} < +\infty$.

For $\varepsilon > 0$ we define $\varphi = |x|^{4-N+2\varepsilon}$. Note that away from the origin

$$\Delta^2\varphi = \varepsilon k_N |x|^{-N+2\varepsilon}, \quad \text{where } k_N = 4(N-2)(N-4) + O(\varepsilon). \tag{36}$$

Let φ_j solve

$$\begin{cases} \Delta^2 \varphi_j = \varepsilon k_N \min(|x|^{-N+2\varepsilon}, j) & \text{in } B, \\ \varphi_j = \dfrac{\partial \varphi_j}{\partial n} = 0 & \text{on } \partial B. \end{cases} \tag{37}$$

Then $\varphi_j \uparrow \varphi$ as $j \to +\infty$. Using (35) and (37)

$$\begin{aligned} \varepsilon k_N \int_B u \ \min(|x|^{-N+2\varepsilon}, j) = \int_B u\Delta^2\varphi_j &= \lambda \int_B e^u \varphi_j \\ &\leq \lambda \int_B e^u \varphi \\ &\leq \omega_N \frac{H_N}{2\varepsilon} + O(1), \end{aligned}$$

where $O(1)$ is bounded as $\varepsilon \to 0$ independently of j. Letting $j \to +\infty$ yields

$$\varepsilon k_N \int_B u \ |x|^{-N+2\varepsilon} \leq \omega_N \frac{H_N}{2\varepsilon} + O(1), \tag{38}$$

showing that the integral on the left-hand side is finite. On the other hand, by (32)

$$\varepsilon k_N \int_B u \ |x|^{-N+2\varepsilon} \geq \varepsilon k_N \omega_N (1-\sigma) \int_0^1 \log\left(\frac{1}{r^4}\right) r^{-1+2\varepsilon}\, dr = k_N \omega_N (1-\sigma) \frac{1}{\varepsilon}. \tag{39}$$

Combining (38) and (39), we obtain

$$(1-\sigma) k_N \leq \frac{H_N}{2} + O(\varepsilon).$$

Letting $\varepsilon \to 0$ and then $\sigma \to 0$, we have

$$8(N-2)(N-4) \leq H_N = \frac{N^2(N-4)^2}{16}.$$

This is valid only if $N \geq 13$, which is a contradiction. □

Remark 4.2. The conclusion of Theorem 1.3 can be obtained also from Proposition 1.8. However, that proposition depends crucially on the radial symmetry of the solutions, while the argument in this section can be generalized to other domains.

5. The extremal solution is singular in large dimensions. In this section we take $a = b = 0$ and prove Theorem 1.4 for $N \geq 32$.

The idea for the proof of Theorem 1.4 is to estimate accurately from above the function $\lambda^* e^{u^*}$, and to deduce that the operator $\Delta^2 - \lambda^* e^{u^*}$ has a strictly positive first eigenvalue (in the $H_0^2(B)$ sense). Then, necessarily, u^* is singular.

Upper bounds for both λ^* and u^* are obtained by finding suitable sub- and supersolutions. For example, if for some λ_1 there exists a supersolution, then $\lambda^* \geq \lambda_1$. If for some λ_2 one can exhibit a stable singular subsolution u, then $\lambda^* \leq \lambda_2$. Otherwise, $\lambda_2 < \lambda^*$, and one can then prove that the minimal solution u_{λ_2} is above u, which is impossible. The bound for u^* also requires a stable singular subsolution.

It turns out that in dimension $N \geq 32$ we can construct the necessary subsolutions and verify their stability by hand. For dimensions $13 \leq N \leq 31$ it seems difficult to find these subsolutions explicitly. We adopt then an approach that involves a computer assisted construction of subsolutions and verification of the desired inequalities. We present this part in the next section.

LEMMA 5.1. *Assume $N \geq 13$. Then $u^* \leq \bar{u} = -4 \log |x|$ in B_1.*

Proof. Define $\bar{u}(x) = -4 \log |x|$. Then $\bar{u}$ satisfies

$$\begin{cases} \Delta^2 \bar{u} = 8(N-2)(N-4)e^{\bar{u}} & \text{in } \mathbb{R}^N, \\ \bar{u} = 0 & \text{on } \partial B_1, \\ \dfrac{\partial \bar{u}}{\partial n} = -4 & \text{on } \partial B_1. \end{cases}$$

Observe that since $\bar{u}$ is a supersolution to (1) with $a = b = 0$ we deduce immediately that $\lambda^* \geq 8(N-2)(N-4)$.

In the case $\lambda^* = 8(N-2)(N-4)$ we have $u_\lambda \leq \bar{u}$ for all $0 \leq \lambda < \lambda^*$ because $\bar{u}$ is a supersolution, and therefore $u^* \leq \bar{u}$ holds. Alternatively, one can invoke Theorem 3 in [2] to conclude that we always have $\lambda^* > 8(N-2)(N-4)$.

Suppose now that $\lambda^* > 8(N-2)(N-4)$. We prove that $u_\lambda \leq \bar{u}$ for all $8(N-2)(N-4) < \lambda < \lambda^*$. Fix such λ and assume by contradiction that $u_\lambda \leq \bar{u}$ is not true. Note that for $r < 1$ and sufficiently close to 1 we have $u_\lambda(r) < \bar{u}(r)$ because $u_\lambda'(1) = 0$ while $\bar{u}'(1) = -4$. Let

$$R_1 = \inf\{\, 0 \leq R \leq 1 \mid u_\lambda < \bar{u} \text{ in } (R, 1)\,\}.$$

Then $0 < R_1 < 1$, $u_\lambda(R_1) = \bar{u}(R_1)$, and $u_\lambda'(R_1) \leq \bar{u}'(R_1)$. So u_λ is a supersolution to the problem

$$\begin{cases} \Delta^2 u = 8(N-2)(N-4)e^{u} & \text{in } B_{R_1}, \\ u = u_\lambda(R_1) & \text{on } \partial B_{R_1}, \\ \dfrac{\partial u}{\partial n} = u_\lambda'(R_1) & \text{on } \partial B_{R_1}, \end{cases} \tag{40}$$

while $\bar{u}$ is a subsolution to (40). Moreover it is stable for this problem, since from Rellich's inequality (6) and $8(N-2)(N-4) \leq N^2(N-4)^2/16$ for $N \geq 13$, we have

$$8(N-2)(N-4)\int_{B_{R_1}} e^{\bar{u}}\varphi^2 \leq \frac{N^2(N-4)^2}{16}\int_{\mathbb{R}^N} \frac{\varphi^2}{|x|^4} \leq \int_{\mathbb{R}^N} (\Delta\varphi)^2 \quad \forall \varphi \in C_0^\infty(B_{R_1}).$$

By Remark 2.7 we deduce that $\bar{u} \leq u_\lambda$ in B_{R_1}, which is impossible. $\square$

An upper bound for λ^* is obtained by considering again a stable, singular subsolution to the problem (with another parameter, though).

LEMMA 5.2. *For $N \geq 32$ we have*

$$\lambda^* \leq 8(N-2)(N-4)e^2. \tag{41}$$

Proof. Consider $w = 2(1-r^2)$ and define

$$u = \bar{u} - w,$$

where $\bar{u}(x) = -4\log|x|$. Then

$$\begin{aligned}\Delta^2 u = 8(N-2)(N-4)\frac{1}{r^4} = 8(N-2)(N-4)e^{\bar{u}} &= 8(N-2)(N-4)e^{u+w} \\ &\leq 8(N-2)(N-4)e^2 e^u.\end{aligned}$$

Also $u(1) = u'(1) = 0$, so u is a subsolution to (1) with parameter $\lambda_0 = 8(N-2)(N-4)e^2$.

For $N \geq 32$ we have $\lambda_0 \leq N^2(N-4)^2/16$. Then by (6) u is a stable subsolution of (1) with $\lambda = \lambda_0$. If $\lambda^* > \lambda_0 = 8(N-2)(N-4)e^2$ the minimal solution u_{λ_0} to (1) with parameter λ_0 exists and is smooth. From Lemma 2.6 we find $u \leq u_{\lambda_0}$ which is impossible because u is singular and u_{λ_0} is bounded. Thus we have proved (41) for $N \geq 32$. ∎

Proof of Theorem 1.4 *in the case $N \geq 32$.* Combining Lemmas 5.1 and 5.2, we have that if $N \geq 32$ then $\lambda^* e^{u^*} \leq r^{-4}\, 8(N-2)(N-4)e^2 \leq r^{-4} N^2(N-4)^2/16$. This and (6) show that

$$\inf_{\varphi \in C_0^\infty(B)} \frac{\int_B (\Delta\varphi)^2 - \lambda^* \int_B e^{u^*}\varphi^2}{\int_B \varphi^2} > 0,$$

which is not possible if u^* is bounded. ∎

6. A computer assisted proof for dimensions $13 \leq N \leq 31$. Throughout this section we assume $a = b = 0$. As was mentioned in the previous section, the proof of Theorem 1.4 relies on precise estimates for u^* and λ^*. We present first some conditions under which it is possible to find these estimates. Later we show how to meet such conditions with a computer assisted verification.

The first lemma is analogous to Lemma 5.2.

LEMMA 6.1. *Suppose there exist $\varepsilon > 0$, $\lambda > 0$, and a radial function $u \in H^2(B) \cap W^{4,\infty}_{loc}(B \setminus \{0\})$ such that*

$$\Delta^2 u \leq \lambda e^u \quad \forall 0 < r < 1,$$

$$|u(1)| \leq \varepsilon, \quad \left|\frac{\partial u}{\partial n}(1)\right| \leq \varepsilon,$$

$$u \notin L^\infty(B),$$

$$\lambda e^\varepsilon \int_B e^u \varphi^2 \leq \int_B (\Delta\varphi)^2 \quad \forall \varphi \in C_0^\infty(B). \tag{42}$$

Then

$$\lambda^* \leq \lambda e^{2\varepsilon}.$$

Proof. Let

$$\psi(r) = \varepsilon r^2 - 2\varepsilon \tag{43}$$

so that

$$\Delta^2 \psi \equiv 0, \quad \psi(1) = -\varepsilon, \quad \psi'(1) = 2\varepsilon,$$

and

$$-2\varepsilon \le \psi(r) \le -\varepsilon \quad \forall 0 \le r \le 1.$$

It follows that

$$\Delta^2(u+\psi) \le \lambda e^u = \lambda e^{-\psi} e^{u+\psi} \le \lambda e^{2\varepsilon} e^{u+\psi}.$$

On the boundary we have $u(1) + \psi(1) \le 0$, $u'(1) + \psi'(1) \ge 0$. Thus $u + \psi$ is a singular subsolution to the equation with parameter $\lambda e^{2\varepsilon}$. Moreover, since $\psi \le -\varepsilon$ we have $\lambda e^{2\varepsilon} e^{u+\psi} \le \lambda e^{\varepsilon} e^u$, and hence, from (42) we see that $u + \psi$ is stable for the problem with parameter $\lambda e^{2\varepsilon}$. If $\lambda e^{2\varepsilon} < \lambda^*$ then the minimal solution associated to the parameter $\lambda e^{2\varepsilon}$ would be above $u + \psi$, which is impossible because u is singular. ∎

LEMMA 6.2. *Suppose we can find $\varepsilon > 0$, $\lambda > 0$, and $u \in H^2(B) \cap W^{4,\infty}_{loc}(B \setminus \{0\})$ such that*

$$\Delta^2 u \ge \lambda e^u \quad \forall 0 < r < 1,$$
$$|u(1)| \le \varepsilon, \quad \left| \frac{\partial u}{\partial n}(1) \right| \le \varepsilon.$$

Then

$$\lambda e^{-2\varepsilon} \le \lambda^*.$$

Proof. Let ψ be given by (43). Then $u - \psi$ is a supersolution to the problem with parameter $\lambda e^{-2\varepsilon}$. ∎

The next result is the main tool to guarantee that u^* is singular. The proof, as in Lemma 5.1, is based on an upper estimate of u^* by a stable singular subsolution.

LEMMA 6.3. *Suppose there exist ε_0, $\varepsilon > 0$, $\lambda_a > 0$, and a radial function $u \in H^2(B) \cap W^{4,\infty}_{loc}(B \setminus \{0\})$ such that*

$$\Delta^2 u \le (\lambda_a + \varepsilon_0) e^u \quad \forall 0 < r < 1, \tag{44}$$

$$\Delta^2 u \ge (\lambda_a - \varepsilon_0) e^u \quad \forall 0 < r < 1, \tag{45}$$

$$|u(1)| \le \varepsilon, \quad \left| \frac{\partial u}{\partial n}(1) \right| \le \varepsilon, \tag{46}$$

$$u \notin L^\infty(B), \tag{47}$$

$$\beta_0 \int_B e^u \varphi^2 \le \int_B (\Delta \varphi)^2 \quad \forall \varphi \in C_0^\infty(B), \tag{48}$$

where

$$\beta_0 = \frac{(\lambda_a + \varepsilon_0)^3}{(\lambda_a - \varepsilon_0)^2} e^{9\varepsilon}. \tag{49}$$

Then u^* is singular and

$$(\lambda_a - \varepsilon_0)e^{-2\varepsilon} \le \lambda^* \le (\lambda_a + \varepsilon_0)e^{2\varepsilon}. \tag{50}$$

Proof. By Lemmas 6.1 and 6.2 we have (50). Let

$$\delta = \log\left(\frac{\lambda_a + \varepsilon_0}{\lambda_a - \varepsilon_0}\right) + 3\varepsilon$$

and define

$$\varphi(r) = -\frac{\delta}{4}r^4 + 2\delta.$$

We claim that

$$u^* \le u + \varphi \quad \text{ in } B_1. \tag{51}$$

To prove this, we shall show that for $\lambda < \lambda^*$

$$u_\lambda \le u + \varphi \quad \text{ in } B_1. \tag{52}$$

Indeed, we have

$$\begin{aligned} &\Delta^2 \varphi = -\delta 2N(N+2),\\ &\varphi(r) \ge \delta \quad \forall 0 \le r \le 1,\\ &\varphi(1) \ge \delta \ge \varepsilon, \quad \varphi'(1) = -\delta \le -\varepsilon, \end{aligned}$$

and therefore

$$\begin{aligned} \Delta^2(u+\varphi) &\le (\lambda_a + \varepsilon_0)e^u + \Delta^2\varphi \le (\lambda_a+\varepsilon_0)e^u = (\lambda_a+\varepsilon_0)e^{-\varphi}e^{u+\varphi}\\ &\le (\lambda_a+\varepsilon_0)e^{-\delta}e^{u+\varphi}. \end{aligned} \tag{53}$$

By (50) and the choice of δ

$$(\lambda_a + \varepsilon_0)e^{-\delta} = (\lambda_a - \varepsilon_0)e^{-3\varepsilon} < \lambda^*. \tag{54}$$

To prove (52) it suffices to consider λ in the interval $(\lambda_a - \varepsilon_0)e^{-3\varepsilon} < \lambda < \lambda^*$. Fix such λ and assume that (52) is not true. Write

$$\bar{u} = u + \varphi$$

and let

$$R_1 = \sup\{\, 0 \le R \le 1 \,|\, u_\lambda(R) = \bar{u}(R)\,\}.$$

Then $0 < R_1 < 1$ and $u_\lambda(R_1) = \bar{u}(R_1)$. Since $u'_\lambda(1) = 0$ and $\bar{u}'(1) < 0$ we must have $u'_\lambda(R_1) \le \bar{u}'(R_1)$. Then u_λ is a solution to the problem

$$\begin{cases} \Delta^2 u = \lambda e^u & \text{in } B_{R_1},\\ u = u_\lambda(R_1) & \text{on } \partial B_{R_1},\\ \dfrac{\partial u}{\partial n} = u'_\lambda(R_1) & \text{on } \partial B_{R_1}, \end{cases}$$

while, thanks to (53) and (54), $\bar{u}$ is a subsolution to the same problem. Moreover, $\bar{u}$ is stable thanks to (48) since, by Lemma 6.1,

$$\lambda < \lambda^* \le (\lambda_a + \varepsilon_0)e^{2\varepsilon} \tag{55}$$

and hence

$$\lambda e^{\bar{u}} \le (\lambda_a + \varepsilon_0)e^{2\varepsilon}e^{2\delta}e^{u} \le \beta_0 e^{u}.$$

We deduce $\bar{u} \le u_\lambda$ in B_{R_1} which is impossible, since $\bar{u}$ is singular while u_λ is smooth. This establishes (51).

From (51) and (55) we have

$$\lambda^* e^{u^*} \le \beta_0 e^{-\varepsilon} e^{u}$$

and therefore

$$\inf_{\varphi \in C_0^\infty(B)} \frac{\int_B (\Delta\varphi)^2 - \lambda^* e^{u^*}\varphi^2}{\int_B \varphi^2} > 0.$$

This is not possible if u^* is a smooth solution. $\square$

For each dimension $13 \le N \le 31$ we construct u satisfying (44)–(48) of the form

$$u(r) = \begin{cases} -4\log r + \log\left(\frac{8(N-2)(N-4)}{\lambda}\right) & \text{for } 0 < r < r_0, \\ \tilde{u}(r) & \text{for } r_0 \le r \le 1, \end{cases} \tag{56}$$

where $\tilde{u}$ is explicitly given. Thus u satisfies (47) automatically.

Numerically it is better to work with the change of variables

$$w(s) = u(e^s) + 4s, \quad -\infty < s < 0,$$

which transforms the equation $\Delta^2 u = \lambda e^u$ into

$$Lw + 8(N-2)(N-4) = \lambda e^{w}, \quad -\infty < s < 0,$$

where

$$Lw = \frac{d^4 w}{ds^4} + 2(N-4)\frac{d^3 w}{ds^3} + (N^2 - 10N + 20)\frac{d^2 w}{ds^2} - 2(N-2)(N-4)\frac{dw}{ds}.$$

The boundary conditions $u(1) = 0$, $u'(1) = 0$ then yield

$$w(0) = 0, \quad w'(0) = 4.$$

Regarding the behavior of w as $s \to -\infty$, observe that

$$u(r) = -4\log r + \log\left(\frac{8(N-2)(N-4)}{\lambda}\right) \quad \text{for } r < r_0$$

if and only if

$$w(s) = \log\frac{8(N-2)(N-4)}{\lambda} \quad \forall s < \log r_0.$$

The steps we perform are the following.

(1) We fix $x_0 < 0$ and using numerical software we follow a branch of solutions to

$$\begin{cases} L\hat{w} + 8(N-2)(N-4) = \lambda e^{\hat{w}}, \quad x_0 < s < 0, \\ \hat{w}(0) = 0, \quad \hat{w}'(0) = t, \\ \hat{w}(x_0) = \log \dfrac{8(N-2)(N-4)}{\lambda}, \quad \dfrac{d^2\hat{w}}{ds^2}(x_0) = 0, \quad \dfrac{d^3\hat{w}}{ds^3}(x_0) = 0 \end{cases}$$

as t increases from 0 to 4. The numerical solution $(\hat{w}, \hat{\lambda})$ we are interested in corresponds to the case $t = 4$. The five boundary conditions are due to the fact that we are solving a fourth order equation with an unknown parameter λ.

(2) Based on $\hat{w}$, $\hat{\lambda}$ we construct a C^3 function w which is constant for $s \le x_0$ and piecewise polynomial for $x_0 \le s \le 0$. More precisely, we first divide the interval $[x_0, 0]$ into smaller intervals of length h. Then we generate a cubic spline approximation g_{fl} with floating point coefficients of $\frac{d^4\hat{w}}{ds^4}$. From g_{fl} we generate a piecewise cubic polynomial g_{ra} which uses rational coefficients and we integrate it four times to obtain w, where the constants of integration are such that $\frac{d^j w}{ds^j}(x_0) = 0$, $1 \le j \le 3$, and $w(x_0)$ is a rational approximation of $\log(8(N-2)(N-4)/\lambda)$. Thus w is a piecewise polynomial function that in each interval is of degree 7 with rational coefficients, and which is globally C^3. We also let λ be a rational approximation of $\hat{\lambda}$. With these choices note that $Lw + 8(N-2)(N-4) - \lambda e^w$ is a small constant (not necessarily 0) for $s \le x_0$.

(3) The conditions (44) and (45) we need to check for u are equivalent to the following inequalities for w:

$$Lw + 8(N-2)(N-4) - (\lambda + \varepsilon_0)e^w \le 0, \quad -\infty < s < 0, \tag{57}$$

$$Lw + 8(N-2)(N-4) - (\lambda - \varepsilon_0)e^w \ge 0, \quad -\infty < s < 0. \tag{58}$$

Using a program in Maple we verify that w satisfies (57) and (58). This is done by evaluating a second order Taylor approximation of $Lw + 8(N-2)(N-4) - (\lambda + \varepsilon_0)e^w$ at sufficiently close mesh points. All arithmetic computations are done with rational numbers and thus obtain exact results. The exponential function is approximated by a Taylor polynomial of degree 14, and the difference with the real value is controlled.

More precisely, we write

$$f(s) = Lw + 8(N-2)(N-4) - (\lambda + \varepsilon_0)e^w,$$
$$\tilde{f}(s) = Lw + 8(N-2)(N-4) - (\lambda + \varepsilon_0)T(w),$$

where T is the Taylor polynomial of order 14 of the exponential function around 0. Applying Taylor's formula to f at y_j, we have for $s \in [y_j, y_{j+h}]$

$$\begin{aligned} f(s) &\le f(y_j) + |f'(y_j)|h + \frac{1}{2}Mh^2 \\ &\le \tilde{f}(y_j) + |\tilde{f}'(y_j)|h + \frac{1}{2}Mh^2 + |f(y_j) - \tilde{f}(y_j)| + |f'(y_j) - \tilde{f}'(y_j)|h \\ &\le \tilde{f}(y_j) + |\tilde{f}'(y_j)|h + \frac{1}{2}Mh^2 + E_1 + E_2 h, \end{aligned}$$

where

M is a bound for $|f''|$ in $[y_j, y_j + h]$,
E_1 is such that $(\lambda + \varepsilon_0)|e^w - T(w)| \le E_1$ in $[y_j, y_j + h]$,
E_2 is such that $(\lambda + \varepsilon_0)|(e^w - T'(w))w'| \le E_2$ in $[y_j, y_j + h]$.

So, inequality (57) will be verified on each interval $[y_j, y_j+h]$ where w is a polynomial as soon as

$$\tilde{f}(y_j) + |\tilde{f}'(y_j)|h + \frac{1}{2}Mh^2 + E_1 + E_2 h \le 0. \tag{59}$$

When more accuracy is desired, instead of (59) one can verify that

$$\tilde{f}(x_i) + |\tilde{f}'(x_i)|\frac{h}{m} + \frac{1}{2}M\left(\frac{h}{m}\right)^2 + E_1 + E_2\frac{h}{m} \le 0,$$

where $(x_i)_{i=1\ldots m+1}$ are $m+1$ equally spaced points in $[y_j, y_j+h]$.

We obtain exact values for the upper bounds M, E_1, E_2 as follows. First note that $f'' = Lw'' - (\lambda+\varepsilon_0)e^w((w')^2 + w'')$. On $[y_j, y_j+h]$, we have $w(s) = \sum_{i=0}^7 a_i(s-y_j)^i$ and we estimate $|w(s)| \le \sum_{i=0}^7 |a_i|h^i$ for $s \in [y_j, y_j+h]$. Similarly,

$$\left|\frac{d^\ell w}{ds^\ell}(s)\right| \le \sum_{i=\ell}^{7} i(i-1)\ldots(i-\ell+1)|a_i|h^{i-\ell} \quad \forall s \in [y_j, y_j+h]. \tag{60}$$

The exponential is estimated by $e^w \le e^1 \le 3$, since our numerical data satisfies the rough bounds $-3/2 \le w \le 1$. Using this information and (60) yields a rational upper bound M. E_1 is estimated using Taylor's formula:

$$E_1 = (\lambda+\varepsilon_0)\frac{(3/2)^{15}}{15!}.$$

Similarly, $E_2 = (\lambda+\varepsilon_0)\frac{(3/2)^{14}}{14!}B_1$, where B_1 is the right-hand side of (60) when $\ell = 1$.

(4) We show that the operator $\Delta^2 - \beta e^u$ where $u(r) = w(\log r) - 4\log r$, satisfies condition (48) for some $\beta \ge \beta_0$ where β_0 is given by (49). In dimension $N \ge 13$ the operator $\Delta^2 - \beta e^u$ has indeed a positive eigenfunction in $H_0^2(B)$ with finite eigenvalue if β is not too large. The reason is that near the origin

$$\beta e^u = \frac{c}{|x|^4},$$

where c is a number close to $8(N-2)(N-4)\beta/\lambda$. If β is not too large compared to λ, then $c < N^2(N-4)^2/16$, and hence, using (6), $\Delta^2 - \beta e^u$ is coercive in $H_0^2(B_{r_0})$ (this holds under even weaker conditions; see [11]). It follows that there exists a first eigenfunction $\varphi_1 \in H_0^2(B)$ for the operator $\Delta^2 - \beta e^u$ with a finite first eigenvalue μ_1; that is,

$$\begin{aligned}
&\Delta^2\varphi_1 - \beta e^u\varphi_1 = \mu_1\varphi_1 \quad \text{in } B,\\
&\varphi_1 > 0 \quad \text{in } B,\\
&\varphi_1 \in H_0^2(B).
\end{aligned}$$

Moreover, μ_1 can be characterized as

$$\mu_1 = \inf_{\varphi\in C_0^\infty(B)} \frac{\int_B (\Delta\varphi)^2 - \beta e^u\varphi^2}{\int_B \varphi^2}$$

and is the smallest number for which a positive eigenfunction in $H_0^2(\Omega)$ exists.

Thus to prove that (48) holds it suffices to verify that $\mu_1 \geq 0$ and for this it is enough to show the existence of a nonnegative $\varphi \in H_0^2(B)$, $\varphi \not\equiv 0$, such that

$$\left\{\begin{aligned} \Delta^2\varphi - \beta e^u \varphi \geq 0 &\qquad \text{in } B,\\ \varphi = 0 &\qquad \text{on } \partial B,\\ \frac{\partial \varphi}{\partial n} \leq 0 &\qquad \text{on } \partial B. \end{aligned}\right. \tag{61}$$

Indeed, multiplication of (61) by φ_1 and integration by parts yield

$$\mu_1 \int_B \varphi\varphi_1 + \int_{\partial B} \frac{\partial\varphi}{\partial n}\Delta\varphi_1 \geq 0.$$

But $\Delta\varphi_1 \geq 0$ on ∂B and thus $\mu_1 \geq 0$. To achieve (61) we again change variables and define

$$\phi(s) = \varphi(e^s), \quad -\infty < s \leq 0.$$

Then we have to find $\phi \geq 0$, $\phi \not\equiv 0$, satisfying

$$\left\{\begin{aligned} L\phi - \beta e^w \phi \geq 0 &\quad \text{in } -\infty < s \leq 0,\\ \phi(0) = 0&,\\ \phi'(0) \leq 0&. \end{aligned}\right. \tag{62}$$

Regarding the behavior as $s \to -\infty$, we note that w is constant for $-\infty < s < x_0$, and therefore, if

$$L\phi - \beta e^w \phi \equiv 0, \quad -\infty < s \leq x_0,$$

then ϕ is a linear combination of exponential functions $e^{-\alpha s}$, where α must be a solution to

$$\alpha^4 - 2(N-4)\alpha^3 + (N^2 - 10N + 20)\alpha^2 + 2(N-2)(N-4)\alpha = \beta e^{w(x_0)},$$

where $\beta e^{w(x_0)}$ is close to $8(N-2)(N-4)\beta/\lambda$. If $N \geq 13$ the polynomial

$$\alpha^4 - 2(N-4)\alpha^3 + (N^2 - 10N + 20)\alpha^2 + 2(N-2)(N-4)\alpha - 8(N-2)(N-4)$$

has four distinct real roots, while if $N \leq 12$ there are two real roots and two complex conjugates. If $N \geq 13$ there is exactly one root in the interval $(0, (N-4)/2)$, two roots greater than $(N-4)/2$, and one negative. We know that $\varphi(r) = \phi(\log r) \sim r^{-\alpha}$ is in H^2, which forces $\alpha < (N-4)/2$. It follows that for $s < x_0$, ϕ is a combination of $e^{-\alpha_0 s}$, $e^{-\alpha_1 s}$ where $\alpha_0 > 0$, $\alpha_1 < 0$ are the two roots smaller than $\alpha < (N-4)/2$. For simplicity, however, we will look for ϕ such that $\phi(s) = Ce^{-\alpha_0 s}$ for $s < x_0$, where $C > 0$ is a constant. This restriction will mean that we will not be able to impose $\phi'(0) = 0$ at the end. This is not a problem because $\phi'(0) \leq 0$.

Notice that we need only the inequality in (62), and hence we need to choose $\alpha \in (0, N-4/2)$ such that

$$\alpha^4 - 2(N-4)\alpha^3 + (N^2 - 10N + 20)\alpha^2 + 2(N-2)(N-4)\alpha \geq \beta e^{w(x_0)}.$$

The precise choice we employed in each dimension is in a summary table at the end of this section.

To find a suitable function ϕ with the behavior $\phi(s) = Ce^{-\alpha s}$ for $s < x_0$ we set $\phi = \psi e^{-\alpha s}$ and solve the equation

$$T_\alpha \psi - \beta e^w \psi = f,$$

where the operator T_α is given by

$$\begin{aligned} T_\alpha \psi = \frac{d^4\psi}{ds^4} &+ (-4\alpha + 2(N-4))\frac{d^3\psi}{ds^3} + (6\alpha^2 - 6\alpha(N-4) + N^2 - 10N + 20)\frac{d^2 w}{ds^2} \\ &+ (-4\alpha^3 + 6\alpha^2(N-4) - 2\alpha(N^2 - 10N + 20) - 2(N-2)(N-4))\frac{d\psi}{ds} \\ &+ (\alpha^4 - 2\alpha^3(N-4) + \alpha^2(N^2 - 10N + 20) + 2\alpha(N-2)(N-4))\psi \end{aligned}$$

and f is some smooth function such that $f \geq 0$, $f \not\equiv 0$. Actually we choose $\bar\beta > \beta_0$ (where β_0 is given in (49)) and find $\bar\alpha$ satisfying approximately

$$\bar\alpha^4 - 2(N-4)\bar\alpha^3 + (N^2 - 10N + 20)\bar\alpha^2 + 2(N-2)(N-4)\bar\alpha = \bar\beta e^{w(x_0)}.$$

We solve numerically

$$\begin{aligned} T_{\bar\alpha}\hat\psi - \bar\beta e^w \hat\psi = f, &\quad x_0 < s < 0, \\ \hat\psi(x_0) = 1, &\quad \hat\psi''(x_0) = 0, \quad \hat\psi'''(x_0) = 0, \\ \hat\psi(0) = 0. & \end{aligned}$$

Using the same strategy as in (2) from the numerical approximation of $\frac{d^4\hat\psi}{ds^4}$ we compute a piecewise polynomial ψ of degree 7, which is globally C^3 and constant for $s \leq x_0$. The constant $\psi(x_0)$ is chosen so that $\psi(0) = 0$. We then use Maple to verify the inequalities

$$\begin{aligned} \psi \geq 0, &\quad x_0 \leq s \leq 0, \\ T_\alpha \psi - \beta e^w \psi \geq 0, &\quad x_0 \leq s \leq 0, \\ \psi'(0) \leq 0, & \end{aligned}$$

where $\beta_0 < \beta < \bar\beta$ and $0 < \alpha < (N-4)/2$ are suitably chosen.

At the URLs http://www.lamfa.u-picardie.fr/dupaigne/ and http://www.ime.unicamp.br/~msm/ we provide the data of the functions w and ψ defined as piecewise polynomials of degree 7 in $[x_0, 0]$ with rational coefficients for each dimension in $13 \leq N \leq 31$. We also give a rational approximation of the constants involved in the corresponding problems.

We use Maple to verify that w and ψ (with suitable extensions) are C^3 global functions and satisfy the corresponding inequalities, using only its capability to operate on arbitrary rational numbers. These operations are exact and are limited only by the memory of the computer and clearly slower than floating point operations. We chose Maple since it is a widely used software, but the reader can check the validity of our results with any other software (see, e.g., the open-source solution pari/gp).

The tests were conducted using Maple 9. See Table 1 for a summary of parameters and results.

Remark 6.4. (1) Although we work with λ rational, in Table 1 we prefer to display a decimal approximation of λ.

(2) In Table 1 we selected a "large" value of ε_0 in order to have a fast verification with Maple. By requiring more accuracy in the numerical calculations, using a

smaller value of ε_0, and using more subintervals to verify the inequalities in the Maple program, it is possible to obtain better estimates of λ^*. For instance, using formulas (50), we obtained the results in Table 2.

The verification above, however, is required to check 1500 subintervals of each of the 4500 intervals of length 0.002, which amounts to substantial computer time.

7. Proof of Proposition 1.5. Throughout this section, we restrict our attention, as permitted, to the case $a = 0$.

(a) Let u denote the extremal solution of (1) with homogeneous Dirichlet boundary condition $a = b = 0$. We extend u on its maximal interval of existence $(0, \bar{R})$.

LEMMA 7.1. *$\bar{R} < \infty$ and $u(r) \sim \log(\bar{R} - r)^{-4}$ for $r \sim \bar{R}$.*

Proof. The fact that $\bar{R} < \infty$ can be readily deduced from section 2 of [1]. We present an alternative (and more quantitative) argument. We first observe that

$$u'' - \frac{1}{r}u' > 0 \qquad \forall r \in [1, \bar{R}). \tag{63}$$

Integrate indeed (1) over a ball of radius r to conclude that

$$0 < \lambda \int_{B_r} e^u = \int_{\partial B_r} \frac{\partial}{\partial r}\Delta u = \omega_N r^{N-1}\left(u''' + \frac{N-1}{r}\left(u'' - \frac{1}{r}u'\right)\right). \tag{64}$$

If $r = 1$, since u is nonnegative in $(0, 1)$ and $u(1) = u'(1) = 0$, we must have $u''(1) \geq 0$. In fact, $u''(1) > 0$. Otherwise, we would have $u''(1) = 0$ and $u'''(1) > 0$ by (64), contradicting $u > 0$ in $(0, 1)$. So, we may define

$$R = \sup\left\{r > 1 : u''(t) - \frac{1}{t}u'(t) > 0 \;\; \forall t \in [1, r)\right\},$$

and we just need to prove that $R = \bar{R}$. Assume this is not the case; then $u''(R) - \frac{1}{R}u'(R) = 0$ and $u'''(R) = \left(u'' - \frac{1}{R}u'\right)'(R) \leq 0$. This contradicts (64) and we have just proved (63). In particular, we see that u is convex increasing on $(1, \bar{R})$.

Since u is radial, (1) reduces to

$$u^{(4)} + \frac{2(N-1)}{r}u''' + \frac{(N-1)(N-3)}{r^2}u'' - \frac{(N-1)(N-3)}{r^3}u' = \lambda e^u. \tag{65}$$

Multiply by u':

$$u^{(4)}u' + \frac{2(N-1)}{r}u'''u' + \frac{(N-1)(N-3)}{r^2}u''u' - \frac{(N-1)(N-3)}{r^3}(u')^2 = \lambda(e^u)',$$

which we rewrite as

$$\begin{aligned}[(u'''u')' - u'''u''] + 2(N-1)\left[\left(\frac{1}{r}u''u'\right)' - u''\left(\frac{1}{r}u'\right)'\right]& \\ +(N-1)(N-3)\left(\frac{(u')^2}{2r^2}\right)' &= \lambda(e^u)'.\end{aligned}$$

By (63), it follows that for $r \in [1, \bar{R})$,

$$[(u'''u')' - u'''u''] + 2(N-1)\left(\frac{1}{r}u''u'\right)' + (N-1)(N-3)\left(\frac{(u')^2}{2r^2}\right)' \geq \lambda(e^u)'.$$

Integrating, we obtain for some constant A

$$u'''u' - \frac{(u'')^2}{2} + 2(N-1)\frac{1}{r}u''u' + \frac{(N-1)(N-3)}{2}\frac{(u')^2}{r^2} \geq \lambda e^u - A.$$

We multiply again by u':

$$\begin{aligned}\left[(u''(u')^2)' - u''\left((u')^2\right)'\right] - \frac{1}{2}(u'')^2u' + 2(N-1)\frac{1}{r}u''(u')^2& \\ +\frac{(N-1)(N-3)}{2}\frac{1}{r^2}(u')^3 &\geq (\lambda e^u - Au)'.\end{aligned} \tag{66}$$

We deduce from (63) that

$$\frac{1}{r}u''(u')^2 = \frac{1}{2}\left(\frac{1}{r}(u')^3\right)' - \frac{1}{2}(u')^2\left(\frac{1}{r}u'\right)' \leq \frac{1}{2}\left(\frac{1}{r}(u')^3\right)' \quad \text{and}$$

$$\frac{1}{r^2}(u')^3 \leq \frac{1}{r}(u')^2u'' \leq \frac{1}{2}\left(\frac{1}{r}(u')^3\right)'.$$

Using this information in (66), dropping nonpositive terms, and integrating, we obtain for some constant B

$$u''(u')^2 + \frac{(N^2-1)}{4}\frac{1}{r}(u')^3 \geq \lambda e^u - Au - B.$$

Applying (63) again, it follows that for $C = \frac{N^2-1}{4} + 1$

$$Cu''(u')^2 \geq \lambda e^u - Au - B,$$

which after multiplication by u' and integration provides positive constants c, C such that

$$(u')^4 \geq c(e^u - Au^2 - Bu - C).$$

At this point, we observe that since u is convex and increasing, u converges to $+\infty$ as r approaches $\bar{R}$. Hence, for r close enough to $\bar{R}$ and for $c > 0$ perhaps smaller,

$$u' \geq c\, e^{u/4}.$$

By Gronwall's lemma, $\bar{R}$ is finite and

$$u \leq -4\log(\bar{R} - r) + C \qquad \text{for } r \text{ close to } \bar{R}.$$

It remains to prove that $u \geq -4\log(\bar{R} - r) - C$. This time, we rewrite (1) as

$$\left[r^{N-1}(\Delta u)'\right]' = \lambda r^{N-1} e^u.$$

We multiply by $r^{N-1}(\Delta u)'$ and obtain

$$\frac{1}{2}\left[r^{2N-2}((\Delta u)')^2\right]' = \lambda r^{2N-2} e^u (\Delta u)' \leq C e^u (\Delta u)' \leq C(e^u \Delta u)'.$$

Hence, for r close to $\bar{R}$ and C perhaps larger,

$$((\Delta u)')^2 \leq C e^u \Delta u,$$

and so

$$\sqrt{\Delta u}(\Delta u)' \leq C e^{u/2} \Delta u \leq C' e^{u/2} u'' \leq C'(e^{u/2} u')',$$

where we have used (63). Integrate to conclude that

$$(\Delta u)^{3/2} \leq C e^{u/2} u'.$$

Solving for Δu and multiplying by $(u')^{1/3}$, we obtain in particular that

$$(u')^{1/3} u'' \leq C e^{u/3} u'.$$

Integrating again, it follows that $(u')^{4/3} \leq C e^{u/3}$, i.e.,

$$u' \leq C e^{u/4}.$$

It then follows easily that (for r close to $\bar{R}$)

$$u \geq -4\log(\bar{R} - r) - C. \qquad \square$$

Proof of Proposition 1.5(a). Given $N \geq 13$, let b^{max} denote the supremum of all parameters $b \geq -4$ such that the corresponding extremal solution is singular. We first observe that

$$b^{max} > 0.$$

In fact, it follows from sections 5 and 6 that the extremal solution u associated to parameters $a = b = 0$ is strictly stable:

$$\inf_{\varphi \in C_0^\infty(B)} \frac{\int_B (\Delta\varphi)^2 - \lambda^* \int_B e^u \varphi^2}{\int_B \varphi^2} > 0. \tag{67}$$

Extend u as before on its maximal interval of existence $(0,\bar{R})$. Choosing $R \in (1,\bar{R})$ close to 1, we deduce that (67) still holds on the ball B_R. In particular, letting $v(x) = u(Rx) - u(R)$ for $x \in B$, we conclude that v is a singular stable solution of (1) with $a = 0$ and $b = Ru'(R) > 0$. By Proposition 1.7, we conclude that $b^{max} > 0$. We now prove that

$$b^{max} < \infty.$$

Assume this is not the case and let u_n denote the (singular) extremal solution associated to b_n, where $b_n \nearrow \infty$. We first observe that there exists $\rho_n \in (0,1)$ such that $u_n'(\rho_n) = 0$. Otherwise, u_n would remain monotone increasing on $(0,1)$ and hence bounded above by $u_n(1) = 0$. It would then follow from (1) and elliptic regularity that u_n is bounded. Let $v_n(x) = u_n(\rho_n x) - u_n(\rho_n)$ for $x \in B$ and observe that v_n solves (1) with $a = b = 0$ and some $\lambda = \lambda_n$. Clearly v_n is stable and singular. By Proposition 1.7, v_n coincides with u, the extremal solution of (1) with $a = b = 0$. By standard ODE theory, $v_n = u$ on $(0,\bar{R})$. In addition,

$$b_n = u_n'(1) = \frac{1}{\rho_n} v_n'\left(\frac{1}{\rho_n}\right) = \frac{1}{\rho_n} u'\left(\frac{1}{\rho_n}\right) \to +\infty,$$

which can happen only if $1/\rho_n \to \bar{R}$.

Now, since u_n is stable on B, $u = v_n$ is stable on B_{1/ρ_n}. Letting $n \to \infty$, we conclude that u is stable on $B_{\bar{R}}$. This clearly contradicts Lemma 7.1.

We have just proved that b^{max} is finite. It remains to prove that u^* is singular when $-4 \le b \le b^{max}$. We begin with the case $b = b^{max}$. Choose a sequence (b_n) converging to b^{max} and such that the corresponding extremal solution u_n is singular. Using the same notation as above, we find a sequence $\rho_n \in (0,1)$ such that

$$\frac{1}{\rho_n} u'\left(\frac{1}{\rho_n}\right) = b_n \to b^{max}.$$

Taking subsequences if necessary and passing to the limit as $n \to \infty$, we obtain for some $\rho \in (0,1)$

$$\frac{1}{\rho} u'\left(\frac{1}{\rho}\right) = b^{max}.$$

Furthermore, by construction of ρ_n, u is stable in B_{1/ρ_n} and hence in $B_{1/\rho}$. This implies that v defined for $x \in B$ by $v(x) = u(\frac{x}{\rho}) - u(\frac{1}{\rho})$ is a stable singular solution of (1) with $b = b^{max}$. By Proposition 1.7, we conclude that the extremal solution is singular when $b = b^{max}$.

When $b = -4$, as we have already mentioned in the introduction, u^* is singular for $N \ge 13$ as a direct consequence of Proposition 1.7 and Rellich's inequality.

So we are left with the case $-4 < b < b^{max}$. Let u_m^* denote the extremal solution when $b = b^{max}$, which is singular, and λ_m^* the corresponding parameter. For $0 < R < 1$ set

$$u_R(x) = u_m^*(Rx) - u_m^*(R).$$

Then

$$\Delta^2 u_R = \lambda_R e^{u_R}, \quad \text{where} \quad \lambda_R = \lambda_0^* R^4 e^{u_m^*(R)},$$

and $u_R = 0$ on ∂B, while

$$\frac{du_R}{dr}(1) = R\frac{du_m^*}{dr}(R).$$

By (31), note that

$$R\frac{du_m^*}{dr}(R) \to b^{max} \quad \text{as } R \to 1, \quad \text{and} \quad R\frac{du_m^*}{dr}(R) \to -4 \quad \text{as } R \to 0.$$

Thus, for any $-4 < b < b^{max}$ we have found a singular stable solution to (1) (with $a = 0$). By Proposition 1.7 the extremal solution to this problem is singular. $\square$

Proof of Proposition 1.5(b). Let $b \geq -4$. Lemma 5.1 applies also for $b \geq -4$ and yields $u^* \leq \bar{u}$, where $\bar{u}(x) = -4\log|x|$. We now modify slightly the proof of Lemma 5.2. Indeed, consider $w = (4+b)(1-r^2)/2$ and define $u = \bar{u} - w$. Then

$$\begin{aligned}\Delta^2 u &= 8(N-2)(N-4)\frac{1}{r^4} = 8(N-2)(N-4)e^{\bar{u}} = 8(N-2)(N-4)e^{u+w}\\ &\leq 8(N-2)(N-4)e^{(4+b)/2}e^u.\end{aligned}$$

Also $u(1) = 0$ and $u'(1) = b$, so u is a subsolution to (1) with parameter $\lambda_0 = 8(N-2)(N-4)e^{(4+b)/2}$.

If N is sufficiently large, depending on b, we have $\lambda_0 < N^2(N-4)^2/16$. Then by (6) u is a stable subsolution of (1) with $\lambda = \lambda_0$. As in Lemma 5.2 this implies $\lambda^* \leq \lambda_0$.

Thus for large enough N we have $\lambda^* e^{u^*} \leq r^{-4}\, 8(N-2)(N-4)e^{(4+b)/2} < r^{-4}N^2(N-4)^2/16$. This and (6) show that

$$\inf_{\varphi \in C_0^\infty(B)} \frac{\int_B (\Delta\varphi)^2 - \lambda^* \int_B e^{u^*}\varphi^2}{\int_B \varphi^2} > 0,$$

which is not possible if u^* is bounded.

Acknowledgments. Juan Dávila and Louis Dupaigne are indebted to J. Coville for useful conversations on some of the topics in the paper. The authors thank the referee for his careful reading of the manuscript.

GENERIC VALIDITY OF THE MULTIFRACTAL FORMALISM*

A. FRAYSSE†

Abstract. The multifractal formalism is a conjecture which gives the spectrum of singularities of a signal using numerically computable quantities. We prove its generic validity by showing that almost every function in a given function space is multifractal and satisfies the multifractal formalism.

Key words. Hölder regularity, multifractal analysis, prevalence, wavelet expansion

1. Introduction.

One motivation of multifractal analysis was the study of fully developed turbulent flows. Indeed, some experimental results obtained in wind tunnels showed that the regularity of the velocity of a turbulent fluid changes wildly from point to point. This quantity is therefore hard to compute. Hence, rather than measure the exponent at some point, one rather estimates the fractal dimension of sets where it takes a given value H.

The *spectrum of singularities* $d(H)$ is the function which gives the Hausdorff dimension of those sets. From its definition, it is also almost impossible to obtain numerically the spectrum of singularities.

In [9], physicists Frisch and Parisi proposed an algorithm in order to derive the spectrum of singularities from quantities that are effectively computable on a signal. They proposed using the L^p modulus of continuity of the velocity, used in the theory of turbulent flows; see [17]. This average quantity is called the *scaling* function, or scaling exponent, and is denoted by ξ_f. It is defined by $\int |f(x+l)-f(x)|^p dx \sim |l|^{\xi_f(p)}$, where $\sim$ means that $\int |f(x+l)-f(x)|^p dx$ is of the order of magnitude of $|l|^{\xi_f(p)}$ when l tends to 0 (assuming that the limit exists). Numerical estimations and further results about the scaling function and its wavelet decomposition can be found in [1, 2].

Frisch and Parisi proposed that the spectrum of singularities of a function can be obtained as follows:

$$d(H) = \inf_{p\in\mathbb{R}} (pH - \xi_f(p) + d); \tag{1}$$

see [9] for a heuristic derivation of this formula.

First, we state the mathematical framework of multifractal analysis. The main notion we need to define is the Hölder exponent.

DEFINITION 1. *Let $\alpha \geq 0$; a function $f : \mathbb{R}^d \to \mathbb{R}$ is $C^\alpha(x_0)$ if for all $x \in \mathbb{R}^d$ such that $\|x - x_0\| \leq 1$ there exist a polynomial P of degree less than $[\alpha]$ and a constant $C > 0$ such that*

$$|f(x) - P(x - x_0)| \leq C\|x - x_0\|^\alpha. \tag{2}$$

The Hölder exponent of f at x_0 is

$$h_f(x_0) = \sup\{\alpha : f \in C^\alpha(x_0)\}.$$

It was proved in [14] that for $p \geq 1$, the scaling function $\xi_f(p)$ is closely related to Sobolev or Besov smoothness. It is thus natural to replace the scaling function $\xi_f(p)$ as follows:

$$\text{If } p > 0, \quad \eta_f(p) = \sup\{s : \ f \in B_p^{s/p,\infty}\}. \tag{3}$$

So (1) applied to η_f can at most give the increasing part of the spectrum.

Defining, as in [16], an auxiliary function $s(1/p) = \eta(p)/p$, the Besov domain of a function f is the set of (q,t) such that $f \in B_{1/q}^{t,1/q}$. The boundary of the Besov domain of f is then given by the graph of $s(q)$. And by Sobolev embeddings, the Besov domain of a function is a convex set. Thus, the functions η satisfying (3) are increasing and concave. Furthermore the auxiliary function s is such that $0 \leq s'(q) \leq d$. These facts lead us to the following definition.

Definition 2. *A function η is admissible if $s(q) = q\eta(1/q)$ is concave and satisfies $0 \leq s'(q) \leq d$. Furthermore it is strongly admissible if $s(0) > 0$.*

The following important result from [16] allows us to define a metric space using admissible functions.

Proposition 3. *Any concave function s satisfying $0 \leq s'(q) \leq d$ defines the Besov domain of a distribution f.*

Thanks to Proposition 3, a metric space V can be associated to each admissible function η by taking

$$V = \bigcap_{\varepsilon>0,0<p<\infty} B_{p,loc}^{(\eta(p)-\varepsilon)/p,p}.$$

For the sake of completeness, we also recall the definition of Legendre transforms.

Definition 4. *Let f be a lower semicontinuous function defined in a normed vector space E. Then the Legendre transform of f is*

$$f^*(x) = \sup_{y\in E}(f(y) - xy). \tag{4}$$

This function is convex and lower semicontinuous.

In the present paper, we propose to study the validity of (1) for $\eta_f(p)$. An equivalent form of this heuristic formula is satisfied by a large class of invariant measures; see [4, 6, 19]. In the context of signal analysis, this conjecture is often satisfied if we add particular assumptions on f, such as self-similarity. On the other hand, there exist counterexamples to the general validity of this formula. And then, if it does not hold for every function, what is its range of validity? Our purpose here is to show that the validity of formula (1) is not an exceptional phenomenon, but it is satisfied for a large class of functions, without any additional assumption. More precisely, we study the validity of this formula for "almost every" function, i.e., in a measure-theoretic sense.

In a finite-dimensional space, the notion of "almost every" means "for the Lebesgue measure." The particular role played by this measure is justified by the fact that this is the only one which is σ-finite and invariant under translation. In a metric infinite-dimensional space no measure enjoys these properties. The following definition (see [5, 7, 11]) can thus replace the notion of the vanishing Haar measure.

Definition 5. *Let V be a complete metric vector space. A Borel set B in V is called Haar-null if there exists a probability measure μ with compact support such that*

$$\mu(B+v)=0 \quad \forall v\in V. \tag{5}$$

In this case the measure μ is said to be transverse to B.

A subset of V is called Haar-null if it is contained in a Borel Haar-null set.

The complement of a Haar-null set is called a prevalent set.

In a slight abuse of language we will say that a property is satisfied almost everywhere when it holds on a prevalent set.

Let us recall some properties of Haar-null sets; see [7, 11].

Proposition 6.

1. *If S is Haar-null, then for all $x\in V$, $x+S$ is Haar-null.*
2. *If $\dim(V)<\infty$, S is Haar-null if and only if $\mathrm{meas}(S)=0$ (where* meas *denotes the Lebesgue measure).*
3. *Prevalent sets are dense.*
4. *If S is Haar-null and $S'\subset S$, then S' is Haar-null.*
5. *The union of a countable collection of Haar-null sets is Haar-null.*
6. *If $\dim(V)=\infty$, compact subsets of V are Haar-null.*

Several kinds of measures can be used as transverse measures of a Borel set. Here, we will use only the following notion.

Definition 7. *A finite-dimensional space P is called a probe for a set $T\subset V$ if the Lebesgue measure on P is transverse to the complement of T.*

Those measures are not compactly supported probability measures. However, one immediately checks that Definition 7 is equivalent to the same one stated with the Lebesgue measure defined on the unit ball of P. Note that in this case, the support of the measure is included in the unit ball of a finite-dimensional subspace. The compactness assumption is therefore fulfilled.

The study of generic regularity for a "large" set of functions goes back to Banach [3], who gave differentiability properties of continuous functions for quasi-all functions in the Baire's categories sense. Later Hunt [12] proved the same result in the measure-theoretic sense of prevalence.

In [16], Jaffard studied properties of generic functions, in the Baire's categories sense, in Sobolev spaces. He also proved that in the sense of Baire's categories quasi-all functions in V satisfy

$$d(H)=\inf_{p\geq p_c}(pH-\eta(p)+d), \tag{6}$$

where p_c is the only critical point such that $\eta(p)=d$.

In this paper we will study the validity of the Frisch–Parisi conjecture for almost every function in the prevalence setting. The aim of this paper is to prove the following theorem.

Theorem 8. *Let η be a strongly admissible function, and let V be the space defined by*

$$V=\bigcap_{\varepsilon>0,0<p<\infty} B^{(\eta(p)-\varepsilon)/p,p}_{p,loc}; \tag{7}$$

then, in the sense of prevalence, almost every function f in V satisfies the following two conditions:

1. *For all* $p > 0$,

$$\eta_f(p) = \eta(p).$$

2. *The spectrum of singularities is defined on the interval* $[s(0), \frac{d}{p_c}]$ *and is given by*

$$d_f(H) = \inf_{p \geq p_c} (pH - \eta_f(p) + d), \tag{8}$$

where p_c *is the only critical point such that* $\eta(p_c) = d$.

REMARK 1. *We require that* η *is strongly admissible. Otherwise, according to* [8], *almost every function in* V *is nowhere locally bounded.*

In section 2 we will solve a simpler problem. We will prove that almost every function in a given intersection of a Sobolev or a Besov space and a Hölder space satisfies a slight modification of the Frisch–Parisi conjecture. We will first establish their spectrum of singularities.

THEOREM 9. *If* $\gamma > 0$ *and* $s - \frac{d}{p} < 0$, *the spectrum of singularities of almost every function in* $B_p^{s,q} \bigcap C^\gamma$ *or in* $L^{p,s} \bigcap C^\gamma$ *is given by*

$$d(H) = \begin{cases} \frac{d+(\gamma-s)p}{\gamma} H & \text{if } H \in \left[\gamma, \frac{d\gamma}{d+(\gamma-s)p}\right], \\ -\infty & \text{otherwise.} \end{cases}$$

REMARK 2. *Using the Sobolev embeddings* $B_p^{s,1} \hookrightarrow L^{p,s} \hookrightarrow B_p^{s,\infty}$, *the same result holds in Sobolev and in Besov spaces. As Besov spaces have a very simple wavelet characterization, we will prove the result in these spaces only. To obtain the Sobolev case, we only need to set* $q = \infty$ *in the following.*

In Theorem 9 we state only the spectrum of singularities of functions in the case $B_p^{s,q} \cap C^\gamma$ where $s - \frac{d}{p} < 0$. Other cases are proven in [8]. Moreover we recall the following result from [8].

PROPOSITION 10.

(i) *If* $s - d/p < 0$, *then almost every function in* $L^{p,s}$ *or in* $B_p^{s,q}$ *is nowhere locally bounded, and therefore its spectrum of singularities is not defined.*

(ii) *If* $s - d/p > 0$, *then the Hölder exponent of almost every function* f *of* $L^{p,s}$, *or of* $B_p^{s,q}$, *takes values in* $[s - d/p, s]$ *and*

$$\forall H \in [s - d/p, s], \qquad d_f(H) = Hp - sp + d; \tag{9}$$

furthermore, for almost every x, $h_f(x) = s$.

Our purpose here is to expand the result of [8] by taking an intersection of Besov spaces.

The main tool that we will use in the following is the wavelet expansion of functions. First, it yields a simple characterization of functional spaces and offers a simple condition for pointwise regularity. Let us recall some properties of the wavelet expansion.

There exist $2^d - 1$ oscillating functions $(\psi^{(i)})_{i \in \{1, \ldots, 2^d - 1\}}$ in the Schwartz class such that the functions

$$2^{dj} \psi^{(i)}(2^j x - k), \quad j \in \mathbb{Z}, \ k \in \mathbb{Z}^d,$$

form an orthonormal basis of $L^2(\mathbb{R}^d)$; see [18]. Wavelets are indexed by dyadic cubes $\lambda = (\frac{k}{2^j}; \frac{k+1}{2^j})^d$. Thus, any function $f \in L^2$ can be written as

$$f(x) = \sum c_{j,k}^{(i)} \psi^{(i)}(2^j x - k),$$

where

$$c_{j,k}^{(i)} = 2^{dj} \int f(x) \psi^{(i)}(2^j x - k) dx.$$

(Note that we use an L^∞ normalization instead of an L^2 one, which simplifies the formulas.) If $p > 1$ and $s > 0$, the Sobolev space has thus the following characterization (see [18]):

$$f \in L^{p,s} \Leftrightarrow \left(\sum_{\lambda \in \Lambda} |c_\lambda|^2 (1 + 4^{js}) \chi_\lambda(x) \right)^{1/2} \in L^p(\mathbb{R}^d), \tag{10}$$

where $\chi_\lambda(x)$ denotes the characteristic function of the cube λ and Λ is the set of all dyadics cubes. Homogeneous Besov spaces, which will also be considered, are characterized (for $p, q > 0$ and $s \in \mathbb{R}$) by

$$f \in B_p^{s,q} \iff \sum_j \left(\sum_{\lambda \in \Lambda_j} |c_\lambda|^p 2^{(sp-d)j} \right)^{q/p} \leq C, \tag{11}$$

where Λ_j denotes the set of dyadics cubes at scale j; see [18]. Note that if $p \in (0, 1)$, Besov spaces are not Banach spaces since they are not locally convex but nonetheless are separable complete metric vector spaces.

Pointwise regularity can also be expressed in terms of a condition on wavelet coefficients; see [14].

Proposition 11. *Let x be in $\mathbb{R}^d$. If f is in $C^\alpha(x)$, then there exists $c > 0$ such that for all λ,*

$$|c_\lambda| \leq c 2^{-\alpha j} (1 + |2^j x - k|)^\alpha. \tag{12}$$

In the following we will also call the "cone of influence above x_0 of width L" the set of couples (j, k) (or of cubes λ) such that

$$\left| k - 2^j x_0 \right| \leq L$$

(we use the norm on $\mathbb{R}^d$: $|x| = \sup_{i=1,\dots,d} |x_i|$).

2. Multifractal formalism in a given Besov space. The Frisch–Parisi conjecture gives the spectrum of singularities as the Legendre transform of the scaling function. We will determine the validity of this formula for measure-theoretic generic functions in a given Besov space in two steps. First we will prove Theorem 9, which gives the spectrum of singularities of almost every function. Afterwards, we will give the prevalent scaling function. This allows us to compare the spectrum obtained with the one given by formula (1) applied to the scaling function.

2.1. Proof of Theorem 9. Proposition 10 states that if $s-\frac{d}{p}<0$, almost every function in $B_p^{s,q}$ is nowhere locally bounded and the spectrum of singularities is not defined for any H. To define this spectrum, we need to assume a minimum uniform regularity. That is why, in the following, we choose $s-\frac{d}{p}<0$ and $0<\gamma<s$ and we study almost every function in $B_p^{s,q}\cap C^\gamma$.

Theorem 2.1 from [13] yields an upper bound of the spectrum of singularities.

LEMMA 12. *Let $s-\frac{d}{p}<0$. For all functions $f\in B_p^{s,q}\bigcap C^\gamma$, the Hausdorff dimension of the set $\{x : f\notin C^\alpha(x)\}$ is bounded by $\frac{d+(\gamma-s)p}{\gamma}\alpha$.*

We also need the following definition.

DEFINITION 13. *Let $\alpha\in[1,\frac{d}{d+(\gamma-s)p}]$. A point x_0 belongs to J_α if there exists an infinite sequence $(j,k)\in\mathbb{N}\times\{0,\dots,2^j-1\}^d$, $k=(k_1,\dots,k_d)$, such that for each $i=1,\dots,d$, k_i can be written as l_i2^{j-L} and*

$$\frac{1}{2^j}+\left|x_0-\frac{k}{2^j}\right|<\frac{1}{2^{\alpha L}}, \tag{13}$$

where $L:=[\frac{(d+(\gamma-s)p)j}{d}]$. We define the exponent of approximation of x as $\alpha'(x)=\sup\{\alpha : x\in J_\alpha\}$.

In [15], it is proved that the Hausdorff dimension of J_α is $\frac{d}{\alpha}$.

Let $\alpha\in[1,\frac{d}{d+(\gamma-s)p}]$, $\varepsilon>0$, and $n\in\mathbb{N}$ such that $N=2^{dn}>\frac{d}{\varepsilon\alpha}+1$ is fixed. We denote $H(\alpha)=\frac{d\gamma}{\alpha(d+(\gamma-s)p)}$ and $\beta(\alpha)=H(\alpha)+\varepsilon$. Each dyadic cube of size 2^{-dj} can be split into 2^{dn} subcubes $i(\lambda)$ with side $2^{-(j+n)}$. We define the probe P spanned by N functions g^r with the following wavelet coefficients d_λ^r:

$$d_\lambda^r=\begin{cases} j^{-2/q}2^{-\gamma j} & \text{if each } k_i \text{ is a multiple of } 2^{j-L} \text{ and } r=i(\lambda),\\ 0 & \text{elsewhere,}\end{cases} \tag{14}$$

where for each j we denote $L=[\frac{(d+(\gamma-s)p)j}{d}]$.

One can check that these functions g^r belong to $B_p^{s,q}\cap C^\gamma$; see [16].

Let $J_\alpha(i,l)=\frac{l}{2^i}+[-\frac{1}{2^{\alpha L}},\frac{1}{2^{\alpha L}}]^d$.

Let us first check that the set of points $S_c(\alpha)$ defined by

$$S_c(\alpha)=\left\{f=\sum c_\lambda\psi_\lambda\in B_p^{s,q}\cap C^\gamma :\ \exists x\in J_\alpha\ \ \forall j,k\ \ |c_\lambda|\le c2^{-\beta(\alpha)j}(1+|2^jx-k|)^{\beta(\alpha)}\right\}$$

is a Borel Haar-null set. Indeed this set can be included in the lim sup on i of the countable union over l of sets:

$$\begin{aligned} S_c(\alpha)^{i,l}=\Big\{f=\sum c_\lambda\psi_\lambda\in B_p^{s,q}\cap C^\gamma :\ \exists x\in J_\alpha(i,l)\ \ \forall j,k\ \ |c_\lambda|\\ \le c2^{-\beta(\alpha)j}(1+|2^jx-k|)^{\beta(\alpha)}\Big\}. \end{aligned} \tag{15}$$

To prove that the sets $S_c(\alpha)^{i,l}$ are closed, we pick a sequence of functions f_n in $S_c(\alpha)^{i,l}$. Suppose that f_n converges to f in $B_p^{s,q}\cap C^\gamma$. For each n, there exists x_n in $J_\alpha(i,l)$ such that f_n satisfies condition (12) at x_n. But $J_\alpha(i,l)$ is a compact set, so there exists x and a subsequence $(x_{n(i)})_{i\in\mathbb{N}}$ such that $x_{n(i)}$ converges to x. As the mapping that gives wavelet coefficients of a function is continuous, f satisfies also (12) at x. This means that $S_c(\alpha)^{i,l}$ are closed.

Let $f\in B_p^{s,q}\cap C^\gamma$ be fixed. Consider the affine subset $M=\{\delta\in\mathbb{R}^N;\ \ f+\sum\delta^ig^i\in S_c(\alpha)\}$. Let δ_1 and δ_2 be in M. There exists $x_1\in J_\alpha$ and $x_2\in J_\alpha$ such that for $l=1,2$,

$$\left|c_\lambda+\sum\delta_l^id_\lambda^i\right|\le c2^{-\beta(\alpha)j}(1+|2^jx_l-k|)^{\beta(\alpha)}\le c2^{-\alpha\beta(\alpha)L}. \tag{16}$$

Furthermore if λ is such that each k is a multiple of 2^{j-L},

$$|d^i_\lambda| > \frac{1}{j^{2/q}} 2^{-\alpha H(\alpha) L}. \tag{17}$$

So, by taking (16) and (17) we obtain

$$\|\delta_1 - \delta_2\|_{\mathbb{R}^N} \leq 2c2^{-\alpha\beta(\alpha)L} 2^{\alpha H(\alpha)L} j^{2/q} = 2cj^{2/q} 2^{-\alpha\varepsilon L}.$$

When j tends to infinity, the Lebesgue measure of $S_c(\alpha)$ tends to zero.

Now, we take the countable union over c and $\varepsilon_n \to 0$. As Haar-null sets are stable under inclusion, we obtain

$$\forall \alpha \in \left[1, \frac{d}{d+(\gamma-s)p}\right] \ \text{ a.e. in } B^{s,q}_p \cap C^\gamma \ \ \forall x \in J_\alpha \ h_f(x) \leq H(\alpha).$$

Let (α_n) be a dense sequence in $[1, \frac{d}{d+(\gamma-s)p}]$. As a countable union of Haar-null sets is still a Haar-null set, for almost every function in $B^{s,q}_p \cap C^\gamma$,

$$h_f(x) \leq H(\alpha_n) \quad \forall n \, \forall x \in J_{\alpha_n}. \tag{18}$$

Let f be a function satisfying (18) and let α be fixed. There exists a nondecreasing subsequence (α_{φ_n}) which converges to α, and the intersection of the subsets $J_{\alpha_{\varphi_n}}$ $(:= \tilde{J}_\alpha)$ contains J_α. Furthermore there exists a measure such that any set of dimension less than d/α is of measure zero. And the measure of J_α is positive. If $G_H = \{x : \ h_f(x) \leq H\}$, with Lemma 12 we have that the Hausdorff dimension of G_H is $\frac{d+(\gamma-s)p}{\gamma}H$. And the $\frac{d}{\alpha}$ Hausdorff measure of the set $\{x : \ h_f(x) < H\}$ equals zero. Thus for almost every function in $B^{s,q}_p \cap C^\gamma$,

$$d(H) = \frac{d+(\gamma-s)p}{\gamma} H \quad \text{for } H \in \left[\gamma, \frac{d\gamma}{d+(\gamma-s)p}\right].$$

2.2. The scaling function. Let us now determine the scaling function of almost every function in a given Besov space. We will now show the following result.

Proposition 14. *Let s_0 and p_0 be fixed such that $s_0 - \frac{d}{p_0} > 0$. Outside a Haar-null set in $B^{s_0,\infty}_{p_0}$, we have*

$$\eta_f(p) = \begin{cases} ps_0 & \text{if } p \leq p_0, \\ d + p(s_0 - \frac{d}{p_0}) & \text{if } p \geq p_0. \end{cases} \tag{19}$$

Let $0 < \gamma < s_0$ be fixed. If $s_0 - \frac{d}{p_0} < 0$, then outside a Haar-null set in $B^{s_0,p_0}_{p_0} \bigcap C^\gamma$,

$$\eta_f(p) = \begin{cases} ps_0 & \text{if } p \leq p_0, \\ \gamma p + p_0(s_0 - \gamma) & \text{if } p \geq p_0. \end{cases} \tag{20}$$

Proof. In each case, we can find in [20] the lower bound. Indeed, this bound is given by the Sobolev embedding.

To prove the upper bound, we will first consider the case $s_0 - \frac{d}{p_0} > 0$. Let $\varepsilon > 0$ be fixed and denote

$$\tilde{s}(p) = \begin{cases} s_0 + \varepsilon, & p \leq p_0, \\ \frac{d}{p} + (s_0 - \frac{d}{p_0}) + \varepsilon, & p \geq p_0. \end{cases}$$

Let $0 < p_0 < \infty$ be fixed. We want to show that the set of functions belonging to $B_p^{\tilde{s}(p),\infty}$ for all $0 < p < \infty$ is Haar-null. This set is clearly closed and Borel in $B_{p_0}^{s_0,\infty}$. Let $j \geq 1$ and $k \in \{0, \dots, 2^j - 1\}^d$. We define $J \leq j$ and $K \in \mathbb{Z}^d$ such that

$$\frac{K}{2^J} = \frac{k}{2^j}$$

is an irreducible fraction. Let $a > \frac{3}{p_0}$. We define a probe spanned by the function F with the following wavelet coefficients:

$$d_\lambda = j^{-a} 2^{(\frac{d}{p_0} - s_0)j} 2^{-\frac{d}{p_0}J}.$$

This function belongs to $B_{p_0}^{s_0,p_0}$.

Let f be in $B_{p_0}^{s_0,p_0}$ and consider the affine subset

$$M = \{\alpha \in \mathbb{R};\ f + \alpha F \in B_p^{\tilde{s}(p),\infty}\}.$$

Suppose that there exist α_1 and α_2 in M. We then have three cases, following the position of p.

(i) If $p = p_0$, then $\tilde{s}(p) = p_0 + \varepsilon$ and

$$\begin{aligned}
\|f + \alpha_1 F - (f + \alpha_2 F)\|_{B_p^{\tilde{s}(p),\infty}} &= \sup_j \sum_{k \in \{0,\dots,2^j-1\}^d} \left| \frac{\alpha_1 - \alpha_2}{j^a} 2^{(\tilde{s} - \frac{d}{p_0})j} 2^{(\frac{d}{p_0} - s_0)j} 2^{-\frac{d}{p_0}J} \right|^{p_0} \\
&= \sup_j \left| \frac{\alpha_1 - \alpha_2}{j^a} \right|^{p_0} 2^{p_0 \varepsilon j} \sum_{J=0}^{j} \sum_{K \in \{0,\dots,2^J-1\}^d} 2^{-dJ} \\
&= \sup_j \frac{j+1}{2} \left| \frac{\alpha_1 - \alpha_2}{j^a} \right|^{p_0} 2^{p_0 \varepsilon j}.
\end{aligned}$$

But if α_1 and α_2 belong to M, this implies that $f + \alpha_1 F - (f + \alpha_2 F)$ belong to $B_p^{\tilde{s}(p),\infty}$. This is possible only if $\alpha_1 = \alpha_2$.

(ii) If $p > p_0$, then $\tilde{s}(p) = \frac{d}{p} + (s_0 - \frac{d}{p_0}) + \varepsilon$. In this case, $f + \alpha_1 F - (f + \alpha_2 F)$ belong to $B_p^{\tilde{s}(p),\infty}$, implying that there exist $c > 0$ such that

$$\|f + \alpha_1 F - (f + \alpha_2 F)\|_{B_p^{\tilde{s}(p),\infty}} \leq \|f + \alpha_1 F\|_{B_p^{\tilde{s}(p),\infty}} + \|f + \alpha_2 F\|_{B_p^{\tilde{s}(p),\infty}} \leq c.$$

We then have the following inequalities:

$$\begin{aligned}
&\forall j > 0 \quad \sum_{k \in \{0,\dots,2^j-1\}^d} \left| \frac{\alpha_1 - \alpha_2}{j^a} 2^{(\tilde{s} - \frac{d}{p})j} 2^{(\frac{d}{p_0} - s_0)j} 2^{-\frac{d}{p_0}J} \right|^p \leq c, \\
&\forall j > 0 \quad \left| \frac{\alpha_1 - \alpha_2}{j^a} \right|^p 2^{(\tilde{s} - \frac{d}{p})pj} 2^{(\frac{d}{p_0} - s_0)pj} \sum_{J=0}^{j} \sum_{K \in \{0,\dots,2^J-1\}^d} 2^{-\frac{dp}{p_0}J} \leq c, \\
&\forall j > 0 \quad \left| \frac{\alpha_1 - \alpha_2}{j^a} \right|^p \sum_{J=0}^{j} 2^{(d - \frac{dp}{p_0})J} \leq c 2^{(-\tilde{s} + \frac{d}{p} - \frac{d}{p_0} + s_0)pj}, \\
&\forall j > 0 \quad \left| \frac{\alpha_1 - \alpha_2}{j^a} \right| \leq c 2^{(-\tilde{s} + \frac{d}{p} - \frac{d}{p_0} + s_0)j} \left| \frac{1}{1 - 2^{j(d - d\frac{p}{p_0})}} \right|^{\frac{1}{p}}.
\end{aligned} \tag{21}$$

As $p > p_0$, $1 - 2^{j(d-d\frac{p}{p_0})}$ is equivalent to 1 and (21) implies

$$|\alpha_1 - \alpha_2| \le cj^a 2^{-\varepsilon j},$$

which tends to zero when j tends to infinity.

(iii) If $p < p_0$, then $\tilde{s}(p) = s_0 + \varepsilon$ and $|1 - 2^{j(d-d\frac{p}{p_0})}|$ is equivalent to $2^{j(d-d\frac{p}{p_0})}$. Thus in (21), we obtain again

$$|\alpha_1 - \alpha_2| \le cj^a 2^{-\varepsilon j}.$$

In each case we have obtained that M is of Lebesgue measure zero. Taking a countable union over $\varepsilon \to 0$, and over p, we obtain the desired scaling exponent.

The second case, for $s_0 - \frac{d}{p_0} < 0$, can be treated the same way as for $p \le p_0$. For the case $p > p_0$ a modification is made by taking, instead of F, the function G with wavelet coefficients $d_{j,k}$ given by

$$d_{j,k} = j^{-2/q} 2^{-\gamma j} \text{ if each } k_i \text{ is a multiple of } 2^{j-L},$$

where for each j we take $L = [\frac{(d+(\gamma-s)p)j}{d}]$. □

From Theorem 9 and Proposition 14, we obtain the following Legendre transform of the scaling function of almost every function in a given Besov space.

PROPOSITION 15. *Let $s_0 > 0$ and $0 < p_0 < \infty$.*

(i) *If $s_0 - \frac{d}{p_0} > 0$, then for almost every function in $B_p^{s,q}$,*

$$\forall H \in \left[s_0 - \frac{d}{p_0}, s_0\right] \qquad \inf_{p>0}(d - \eta(p) + Hp) = d - p_0 s_0 + Hp_0. \tag{22}$$

(ii) *If $s_0 - \frac{d}{p_0} < 0$, then for almost every function in $B_p^{s,q} \bigcap C^\gamma$, we have*

$$\forall H \in [\gamma, s_0] \qquad \inf_{p>0}(d - \eta(p) + Hp) = d - p_0 s_0 + Hp_0. \tag{23}$$

This proposition shows that for $s_0 - \frac{d}{p_0} > 0$, the increasing part of the spectrum given by Frisch–Parisi conjecture is valid for almost every function. But for $s_0 - \frac{d}{p_0} < 0$, this Legendre transform does not correspond to the spectrum of singularities given by Theorem 9.

3. The Frisch–Parisi conjecture. We will now prove Theorem 8. Instead of $B_{p_0}^{s_0,q_0}$ we will now work with

$$V = \bigcap_{\varepsilon>0, 0<p<\infty} B_{p,loc}^{(\eta(p)-\varepsilon)/p,p}.$$

This set V can also be written as a countable intersection over $B_{p_n,loc}^{(\eta(p_n)-\varepsilon_n)/p_n,p_n}$.

Note that V is a topological vector space. For $p < 1$ Besov spaces are only quasi-Banach spaces; as the triangle inequality is satisfied only up to a constant, V is not a Banach space but a complete metric space. Indeed, if $p \ge 1$, we take for distance between two functions f and g in $B_p^{s,q}$

$$d(f,g) = \sum_{j\ge0} \left(\sum_{k\in\{0,\dots,2^j-1\}^d} \left|(c_{j,k} - d_{j,k}) 2^{(s-\frac{d}{p})j}\right|^p \right)^{\frac{q}{p}},$$

where $c_{j,k}$ are the wavelet coefficients of f, and $d_{j,k}$ are those of g.

If $p < 1$, Besov spaces are not Banach spaces, but complete metric spaces with the following distance:

$$d(f,g) = \left(\sum_{j\geq 0} \left(\sum_{k\in\{0,\dots,2^j-1\}^d} |(c_{j,k} - d_{j,k})2^{(s-\frac{d}{p})j}|^p \right)^{\frac{q}{p}} \right)^{\frac{\min(p,q)}{q}}.$$

Thus, we obtain a distance in V by taking

$$\forall f,g \in V \quad d(f,g) = \sum_n 2^{-n} \frac{d_n(f,g)}{1+d_n(f,g)},$$

where d_n denotes the distance in $B^{(\eta(p_n)-\varepsilon_n)/p_n,p_n}_{p_n,loc}$. With this distance, V is clearly a complete space. Note that the measure used is the Lebesgue measure on the unit ball of a probe, so this is a probability measure with compact support.

In the following subsection we prove that the spectrum of singularities of almost every function in V satisfies

$$d(H) = \inf_{p\geq p_c} (pH - \eta(p) + d).$$

3.1. Proof of Theorem 8. Let us now study the spectrum of singularities on a prevalent set of functions in V.

PROPOSITION 16. *For almost every function $f \in V$, the spectrum of singularities satisfies*

$$\forall H \in \left[s(0), \frac{d}{p_c} \right] \quad d(H) = \inf_{p\geq p_c} (Hp - \eta(p) + d). \tag{24}$$

Proof. We will first construct the probe. Denote

$$a(j,k) = \inf_p \left(\frac{d(j-J) - \eta(p)j}{p} \right)$$

and define g via its wavelet coefficients,

$$d_\lambda = \frac{1}{j^a} 2^{a(j,k)}, \tag{25}$$

where we define $a = a_j = \log j$, and $J \leq j$ is such that there exists $K \in \mathbb{Z}^d$ and $\frac{k}{2^j} = \frac{K}{2^J}$ is an irreducible form.

First, we check that g belongs to V. Let $p > 0$ be fixed. Thus we have to show that $g \in B^{\eta(p)/p,\infty}_p$. Let $s = \frac{\eta(p)}{p}$. Since $a(j,k) \leq \frac{d(j-J)}{p} - sj$, $pa(j,k) + (\eta(p) - p)j = -Jd$ and $g \in B^{\eta(p)/p,\infty}_p$. For further details on this function g, the reader is referred to [16].

DEFINITION 17. *Let α be fixed. We denote by F_α the set of α-approximable points defined by*

$$F_\alpha = \left\{ x : \exists \text{ a sequence } ((k_n,j_n))_{n\in\mathbb{N}} \ \left| x - \frac{k_n}{2^{j_n}} \right| \leq \frac{1}{2^{\alpha j_n}} \right\}. \tag{26}$$

The dyadic exponent of x is defined by $\alpha(x_0) = \sup\{\alpha : x_0$ is α-approximable by dyadics$\}$.

As stated in [16], the Hausdorff dimension of the set F_α is at least $\frac{d}{\alpha}$.

First, let $\alpha \in (1, \infty)$ be fixed, and let F_α be the set given by Definition 17. Let $\varepsilon > 0$ be fixed, and let

$$H(\alpha) = \frac{1}{\alpha} \sup_{\omega \geq \alpha} \left(\omega \sup_{q>0} \left(s(q) - d\left(1 - \frac{1}{\omega}\right) q \right)\right)$$

and $\gamma = \gamma(\alpha) = H(\alpha) + \varepsilon$.

Let $n \in \mathbb{N}$ be such that $N = 2^{dn} > \frac{d}{\varepsilon} + 1$ is fixed. The probe P is spanned by N functions g_i which are deduced from g by taking its wavelet coefficients only over some subcubes $i(\lambda)$ with size $2^{-d(j+n)}$. The aim of this part is to prove that the set of functions f such that there exists a point in F_α where f is C^γ is a Haar-null set. This set is included in the countable union over $c > 0$ of

$$S_c(\alpha) = \left\{ f = \sum c_\lambda \psi_\lambda : \ \exists x \in F_\alpha \ \forall j, k \ |c_\lambda| \leq c 2^{-\gamma(\alpha) j} (1 + |2^j x - k|)^{\gamma(\alpha)} \right\}.$$

And we have already seen that

$$H(\alpha) = \frac{1}{\alpha} \sup_{\omega \geq \alpha} \left(\omega \sup_{q>0} \left(s(q) - d\left(1 - \frac{1}{\omega}\right) q \right)\right) \geq -a(j,k)$$

for some j and k.

Let $x \in F_\alpha$ be fixed and let λ be such that $|x - \lambda| \leq A$. If $A > 2N$, for all functions g_i, the wavelet coefficients indexed by those λ satisfy

$$|d_\lambda^i| \geq \frac{c(A)}{j^a} 2^{-H(\alpha) j}. \tag{27}$$

We will now prove that the set $S_c(\alpha)$ is a Borel Haar-null set. First, this set is included in the countable union over (i, l) of

$$S_c(\alpha)^{i,l} = \left\{ f = \sum c_\lambda \psi_\lambda : \ \exists x \in F_\alpha^{i,l} \ \forall j, k \ |c_\lambda| \leq c 2^{-\gamma(\alpha) j} (1 + |2^j x - k|)^{\gamma(\alpha)} \right\},$$

where $F_\alpha^{i,l} = \{x : \ \left|x - \frac{l}{2^i}\right| \leq \frac{1}{2^{\alpha i}}\}$. This set $S_c(\alpha)^{i,l}$ is a closed set and $S_c(\alpha)$ is a Borel set. Let f be in V, and let β_1 and β_2 be such that the functions $f + \sum \beta_1^i g^i$ and $f + \sum \beta_2^i g^i$ are in $S_c(\alpha)^{i,l}$. There exist two points x_1 and x_2 in $F_\alpha^{i,l}$ such that in the cone of influence above x_1 and x_2,

$$\left| c_\lambda + \sum \beta_1^i d_\lambda^i - \left(c_\lambda + \sum \beta_2^i d_\lambda^i \right) \right| \leq 2c 2^{-\gamma(\alpha) j}.$$

However,

$$\left| c_\lambda + \sum \beta_1^i d_\lambda^i - \left(c_\lambda + \sum \beta_2^i d_\lambda^i \right) \right| = \left| \sum \beta_1^i d_\lambda^i - \beta_2^i d_\lambda^i \right|$$

and with (27),

$$\left| \sum \beta_1^i d_\lambda^i - \beta_2^i d_\lambda^i \right| \geq \left| \sum \beta_1^i - \beta_2^i \right| \frac{c(A)}{j^a} 2^{-H(\alpha) j}.$$

Thus,

$$\|\beta_1 - \beta_2\|_{\mathbb{R}^N} \leq \tilde{c} j^a 2^{-\varepsilon j}.$$

So the Lebesgue measure in $\mathbb{R}^N$ of the set of β such that $f + \beta g$ belongs to $S_c(\alpha)^{i,l}$ is bounded by $(\tilde{c} j^a)^N 2^{-N\varepsilon j}$.

The Lebesgue measure of the set of β such that $f + \sum \beta^i g^i$ belongs to $S_c(\alpha)$ vanishes. Therefore $S_c(\alpha)$ is Haar-null.

By taking a countable union over $c_n > 0$ of sets $S_c(\alpha)$, the set of functions in V with a pointwise Hölder exponent greater than $\gamma(\alpha)$ in a point of F_α is also Haar-null. If $\varepsilon_n \to 0$, then by taking the union over ε_n it follows that for all $\alpha \geq 1$ the set of functions in V with a Hölder exponent greater than $H(\alpha)$ in some point of F_α is Haar-null.

Let α_n be a dense sequence in $(1, \infty)$. By a countable intersection

$$M = \{f \in V : \forall n \ \ \forall x \in F_{\alpha_n} \ \ h_f(x) \leq H(\alpha)\} \tag{28}$$

is prevalent. Let $f \in M$ and let $\alpha \geq 1$. There exists a subsequence $\alpha_{\phi(n)}$ which is nondecreasing and tends to α. If we denote by $\tilde{F}_\alpha$ the intersection of sets F_{α_n}, then it follows that $\tilde{F}_\alpha$ contains F_α. Furthermore, the Hausdorff dimension of $\tilde{F}_\alpha$ is greater than $\frac{d}{\alpha}$ and for all $x \in \tilde{F}_\alpha$, $h_f(x) \leq H(\alpha)$.

To conclude the second point of Theorem 1, we rewrite $H(\alpha)$ in the following form:

$$H(\alpha) = \frac{1}{\alpha} \inf_{a \geq \alpha} G(a),$$

where $G(a) = \sup_q (a(-qd + s(q)) + qd) = a \sup_q (qd(-1 + \frac{1}{a}) + s(q)) = a\ s^*\left(d\left(1 - \frac{1}{a}\right)\right)$. Here s^* is the Legendre transform of s. By definition of the Legendre transform, this is a convex function. Furthermore it satisfies

$$\begin{cases} s^*(h) = +\infty & \text{if } h < s'(+\infty), \\ s^*(h) = s(0) & \text{if } h > s'(0). \end{cases} \tag{29}$$

And if s^* is twice differentiable (we refer to [10] for a general case), G is also twice differentiable and its derivative is

$$G'(a) = s^*\left(d\left(1 - \frac{1}{a}\right)\right) + \frac{d}{a}(s^*)'\left(d\left(1 - \frac{1}{a}\right)\right)$$

and

$$G''(a) \geq 0.$$

Thus G is also convex and there exists a_0 such that $G(a_0) = \inf_{a \geq 0} G(a)$, a_0 being such that $G'(a_0) = 0$. We also deduce from (29) that

$$\begin{cases} G(a) = +\infty & \text{if } a < \frac{d}{d - s'(+\infty)}, \\ G(a) = as(0) & \text{if } a > \frac{d}{d - s'(0)}. \end{cases} \tag{30}$$

By definition of s and with the hypothesis that η is an admissible function we have $0 \leq s'(q) \leq d$ for all $q > 0$. It follows from (30) that a_0 belongs to the interval $(\frac{d}{d - s'(+\infty)}, \frac{d}{d - s'(0)})$, which is included in $[0, \infty)$.

Another way to treat G is to write $G(a) = \sup_q(\tilde{s}(q))$, where $\tilde{s}(q) = a(s(q) - qd) + qd$. And if s is also twice differentiable, $\tilde{s}'(q) = -da + as'(q) + d$ and $\tilde{s}''(q) = as''(q) < 0$. Thus $\tilde{s}$ is a concave function, and there exists an upper bound q_0 which satisfies $\tilde{s}'(q_0) = -da + as'(q_0) + d = 0$, and $s'(q_0) = \frac{da-d}{a}$. The value of q_0 also depends on a, so we can now write $q_0 = q(a)$.

We can finally write $G(a) = a(-q(a)d + s(q(a))) + q(a)d$. This function is twice differentiable and its derivative satisfies

$$G'(a) = s(q(a)) - dq(a).$$

If $a = a_0$ is the lower bound of G, we obtain $G'(a_0) = s(q(a_0)) - dq(a_0) = 0$, so that $s(q(a_0)) = dq(a_0)$, that is, $q(a_0) = q_c = 1/p_c$. Furthermore, G is decreasing for $a \leq a_0$ and increasing for $a \geq a_0$. The following cases are now possible:

(i) If $\alpha \geq \frac{d}{d-s'(0)}$, then for all $a \geq \alpha$, $G(a) = as(0)$ and $H(\alpha) = s(0)$. So,

$$\dim_H(\{x:\ h_f(x) \leq s(0)\}) = d - s'(0).$$

(ii) If $1 \leq \alpha \leq a_0$, then

$$\inf_{a\geq\alpha} G(a) = G(a_0) = (a_0(-q_c d + s(q_c)) + q_c d) = dq_c.$$

The corresponding value of H is

$$H(\alpha) = \frac{1}{\alpha}\inf_{a\geq\alpha} G(a) = \frac{dq_c}{\alpha}.$$

Thus, the spectrum of singularities is defined on the interval $[\frac{dq_c}{a_0}, dq_c]$ and for almost every function, and for all $H \in [\frac{dq_c}{a_0}, dq_c]$

$$\dim_H(\{x:\ h_f(x) \leq H\}) = \frac{H}{q_c}.$$

Furthermore, we have already seen that

$$s'(q(a)) = \frac{da-d}{a},$$

which is an increasing function. As s' is decreasing, the application $a \mapsto q(a)$ is itself decreasing. So, for $\alpha \leq a_0$, $q \geq q_c = \frac{1}{p_c}$ and

$$\dim_H(\{x:\ h_f(x) \leq H\}) \leq \inf_{p\geq p_c}(pH - \eta(p) + d).$$

(iii) If $a_0 \leq \alpha \leq \frac{d}{d-s'(0)}$, which is equivalent to

$$\inf_{a\geq\alpha} G(a) = G(\alpha) = \alpha\sup_q\left(-qd + s(q) + \frac{qd}{\alpha}\right),$$

we obtain

$$H(\alpha) = \sup_q\left(-qd + s(q) + \frac{qd}{\alpha}\right).$$

So for almost every function, for all $H \in [s(0), \frac{dq_c}{a_0}]$,

$$\dim_H(\{x:\ h_f(x) \leq H\}) = \inf_{p\geq p_c}(pH - \eta(p) + d) \leq \inf_{p\geq p_c}(pH - \eta(p) + d).$$

Furthermore (see [16]), the spectrum of singularities of all functions of V satisfies

$$d(H) \leq \inf_{p \geq p_c} (pH - \eta(p) + d). \tag{31}$$

This implies that the Hausdorff dimension of the set $\{x : h_f(x) < H\}$ is strictly less than $\frac{d}{\alpha}$. As proved in [14], there exists a measure m_α such that $m_\alpha(\{x : h_f(x) \leq H\}) > 0$. But by definition of the Hausdorff dimension, $m_\alpha(\{x : h_f(x) < H\}) = 0$. Then $m_\alpha(\{x : h_f(x) = H) > 0$ and

$$d(H) \geq \inf_{p \geq p_c} (pH - \eta(p) + d). \qquad \square$$

Proposition 18. *For almost every function f in V, the scaling function of f satisfies*

$$\eta_f(p) = \eta(p) \quad \forall 0 < p < \infty.$$

Proof. As we have $V = \bigcap_{\varepsilon>0, 0<p<\infty} B^{(\eta(p)-\varepsilon)/p,p}_{p,loc}$, for any $f \in V$ the scaling function is greater than $\eta(p)$ for all p. Let $\tau > 0$ and $p > 0$ be fixed. We denote $\tau(p) = \frac{\eta(p)}{p} + \tau$. We first prove that the set

$$M(p) = \{f \in V;\ f \in B^{\tau(p),\infty}_p\}$$

is a Haar-null set. Let g be the function with wavelet coefficients given by (25), and let P be the probe spanned by g. First, we check that g does not belong to $B^{\tau(p),\infty}_p$. We write $\beta_j = d(1 - \frac{j}{J})$, where J is defined as in (25). This term β_j takes discrete values, spaced by $\frac{d}{j}$ and between 0 and d. As s is a concave function and $0 \leq s'(q) \leq d$ for all q, there exists, for j large enough, a β_j close to $s'(q)$ such that the line given by $\tau(p) + \beta_j(\frac{1}{\tilde{p}} - \frac{1}{p})$ is always above the graph of s. Thus

$$\forall \tilde{p} > 0 \quad \tau(p) + \beta_j \left(\frac{1}{\tilde{p}} - \frac{1}{p}\right) > s(1/p).$$

But $a(j,k) = j \inf_p(\frac{\beta_j}{p} - s(1/p))$, and this infimum is attained for a $p_0 \in (0,\infty)$. Therefore,

$$a(j,k) \geq j\left(\frac{\beta_j}{p} - \tau(p)\right)$$

and

$$\|g\|_{B^{\tau(p),\infty}_p} \geq \sup_j j^{-ap} 2^{\tau j p}.$$

Thus $g \notin B^{\tau(p),\infty}_p$.

Let f be in V. Suppose that there exist α_1 and α_2 such that the functions $f_1 = f + \alpha_1 g$ and $f_2 = f + \alpha_2 g$ belong to $B^{\tau(p),\infty}_p$. Then $f_1 - f_2$ also belongs to $B^{\tau(p),\infty}_p$. But

$$f_1 - f_2 = (\alpha_1 - \alpha_2)g,$$

which is possible only if $\alpha_1 = \alpha_2$. Thus $M(p)$ is Haar-null.

Taking countable unions over $\tau \to 0$ and $p > 0$, we obtain that for almost every f in V, $\eta_f(p) \leq \eta(p)$ for all $p > 0$. $\square$

CONTINUITY ESTIMATES FOR THE MONGE–AMPÈRE EQUATION*

HUAI-YU JIAN† AND XU-JIA WANG‡

Abstract. In this paper, we study the regularity of solutions to the Monge–Ampère equation. We prove the log-Lipschitz continuity for the gradient under certain assumptions. We also give a unified treatment for the continuity estimates of the second derivatives. As an application we show the local existence of continuous solutions to the semigeostrophic equation arising in meteorology.

Key words. Monge–Ampère equation, a priori estimates, semigeostrophic equation

AMS subject classifications. 35J60, 35Q35

DOI. 10.1137/060669036

1. Introduction.

In this paper we study the regularity of solutions to the Monge–Ampère equation

$$\det D^2 u = f \quad \text{in} \quad B_1(0), \tag{1.1}$$

where $B_1(0)$ is the unit ball in the Euclidean space R^n. We are mainly concerned with the log-Lipschitz continuity of the gradient Du,

$$|Du(x) - Du(y)| \le C|x-y|(1 + |\log|x-y||), \quad x, y \in B_{1/2}(0), \tag{1.2}$$

which has applications in the existence of continuous solutions to the semigeostrophic equation [E, L] or, more generally, in the optimal transportation problems [E, V]. We also study the continuity estimates of the second derivatives D^2u under appropriate conditions.

For the regularity of the Monge–Ampère equation, Caffarelli [C2] established the interior $W^{2,p}$ estimates (for any $p > 1$) for strictly convex solutions when f is positive and continuous. He also obtained the $C^{2,\alpha}$ estimate when $f > 0$, $f \in C^\alpha$, $\alpha \in (0, 1)$. In [C3] he proved the $C^{1,\alpha}$ estimate for strictly convex solutions if $C_1 \le f \le C_2$ for some positive constants C_1, C_2. By an example in [W2], the $C^{1,\alpha}$ regularity cannot be improved to $W^{2,p}$ for large p if f is not continuous.

For the Laplace equation

$$\Delta u = f, \tag{1.3}$$

the log-Lipschitz continuity of Du was established [Y] for $f \in L^\infty$; see also Theorem 3.9 in [GT]. The log-Lipschitz continuity plays a key role in the existence and uniqueness of global solutions to the 2-dimensional Euler equation [Y]. A simple proof of the log-Lipschitz continuity was recently found by the second author [W3]. Considering applications to the semigeostrophic equation [BB, C5, CuF, CRD, E, L], one wishes to

know when a solution to the Monge–Ampère equation (1.1) satisfies the log-Lipschitz continuity. By an example in [W2], the condition $C_1 \le f \le C_2$ is not enough; a stronger condition is necessary.

In this paper we first give a unified treatment for the continuity estimates of the second derivatives of solutions to the Monge–Ampère equation. Before stating our results, we first introduce the modulus of convexity for a convex function u, which is given by

$$m(t) = \inf\{u(x) - \ell_z(x) : \quad |x - z| > t\}, \tag{1.4}$$

where $t > 0$, ℓ_z is the tangent plane of u at z. Obviously m is a nonnegative function of $t > 0$. When u is strictly convex, it is a positive function.

We also denote

$$\omega_f(r) = \sup\{|f(x) - f(y)| : \quad |x - y| < r\}. \tag{1.5}$$

We say f is Dini continuous if

$$\int_0^1 \frac{\omega_f(r)}{r} dr < \infty. \tag{1.6}$$

THEOREM 1. *Let $u \in C^2$ be a strictly convex solution of* (1.1)*. Assume that f satisfies* (1.6) *and*

$$C_1 \le f \le C_2 \tag{1.7}$$

for some positive constants $C_1, C_2 > 0$. Then for all $x, y \in B_{1/2}(0)$, we have the estimate

$$|D^2u(x) - D^2u(y)| \le C\left[d + \int_0^d \frac{\omega_f(r)}{r} + d\int_d^1 \frac{\omega_f(r)}{r^2}\right], \tag{1.8}$$

where $d = |x - y|$, $C > 0$ depends only on n, m, and C_1, C_2. It follows that

(i) *if f is Dini continuous, then $u \in C^2(B_1)$;*

(ii) *if $f \in C^\alpha(B_1)$ and $\alpha \in (0, 1)$, then*

$$\|u\|_{C^{2,\alpha}(B_{1/2})} \le C\left[1 + \frac{\|f\|_{C^\alpha(B_1)}}{\alpha(1-\alpha)}\right]; \tag{1.9}$$

(iii) *if $f \in C^{0,1}(B_1)$, then*

$$|D^2u(x) - D^2u(y)| \le Cd\left[1 + \|f\|_{C^{0,1}}|\log d|\right]. \tag{1.10}$$

Note that in the estimate (1.8), the constant C depends also on $\sup_{B_1}(u - \ell_0)$, which is in turn determined by m, C_1, and C_2. Recall that if u is a convex solution of (1.1), vanishing in $\partial\Omega$, then u is strictly convex [C1]. The C^2 estimate in (i) and the $C^{2,\alpha}$ estimate in (ii) were proved in [W1] and [C2], respectively. See also section 6 of [TW]. Here we give a unified and shorter proof, using an idea from [W3], where a short and elementary proof of (1.8) for the Laplace and heat equations was given. Our argument was also inspired by the original idea of Caffarelli [C2].

The main estimate of the paper is the following log-Lipschitz continuity for the gradient Du.

THEOREM 2. *Let u be a strictly convex solution to the Monge–Ampère equation* (1.1)*, and suppose f is continuous and satisfies* (1.7)*. Then we have the estimate*

$$|Du(x) - Du(y)| \le Cd[1 + e^{-2\theta\psi(d)}] \tag{1.11}$$

for any $x, y \in B_{1/2}(0)$, where $d = |x - y|$, $C = C(n, m, C_1, C_2, \omega_f)$, θ is a positive constant, and

$$\psi(d) = -\int_d^1 \frac{\omega_{\log f}(r)}{r} dr. \tag{1.12}$$

In particular, we have $\theta < \frac{1}{2}$.

Remarks. (i) In Theorem 2 we relax the Dini continuity of f to continuity. If f is not continuous, we wouldn't obtain a log-Lipschitz continuous from (1.11) and (1.12). But we still have a related estimate; see (3.9) and Remark 3.2 below.

(ii) From (1.11) and (1.12), we see that if $\omega_{\log f}(r) \le \frac{c_0}{|\log r|}$ for some constant $c_0 \le 1/2\theta$, then Du is log-Lipschitz continuous. Our estimate $\theta < \frac{1}{2}$ implies that Du is log-Lipschitz continuous if, for small $r > 0$,

$$\omega_{\log f}(r) \le \frac{1}{|\log r|}. \tag{1.13}$$

(iii) Our estimate (1.11) should be optimal, that is, the log-Lipschitz continuity does not hold, if $\omega_{\log f}(r) \ge \frac{C}{|\log r|}$ for large C. See section 4 for discussion.

(iv) In the application to the semigeostrophic equation in section 4, it suffices to establish an estimate

$$|Du(x) - Du(y)| \le Cd[1 + \eta(d)] \tag{1.14}$$

for some positive function $\eta(t)$ satisfying

$$\int_0^{e^{-2}} \frac{1}{t\eta(t)} = \infty. \tag{1.15}$$

Examples satisfying (1.15) include the function $\eta(t) = |\log t| \log |\log t|$. However, from our argument one sees that there is not much room for inhomogeneous functions f such that Du satisfies (1.14) and (1.15) but is not log-Lipschitz continuous. This situation is similar to the Laplace equation (1.3).

Theorems 1 and 2 will be proved, respectively, in sections 2 and 3. We indicate an application of Theorem 2 on the local existence of continuous solutions to the semigeostrophic equation in section 4.

2. Proof of Theorem 1. First we collect some basic properties.

LEMMA 2.1. *Let Ω be a bounded convex domain in R^n. Then there is a unique minimum ellipsoid containing Ω, which attains the minimum volume among all ellipsoids containing Ω.*

We refer the reader to [G] for a proof. We say a convex set Ω is *normalized* if its minimum ellipsoid is a ball. When Ω is normalized, one has $B_{r/n} \subset \Omega \subset B_r$ for concentric balls $B_{r/n}$ and B_r [G].

Therefore for any bounded convex domain Ω, there is a unique unimodular linear transformation T (namely, $\det T = 1$) such that $T(\Omega)$ is normalized. Choose an appropriate coordinate system such that the minimum ellipsoid of Ω is given by $E =$

$\{\Sigma \frac{x_i^2}{a_i^2} < 1\}$, with $a_1 \geq \cdots \geq a_n$. Then T is determined by the matrix $\text{diag}(\lambda_1, \ldots, \lambda_n)$, with

$$\lambda_i = \frac{1}{a_i}(a_1 \ldots a_n)^{1/n}, 1, 2, \ldots, n.$$

Note that λ_1 and λ_n are the least and largest eigenvalues of T, respectively. For convenience we say in this paper that Ω has a *good shape* if

$$\lambda_n \leq c^* \lambda_1 \tag{2.1}$$

for some constant c^* under control. If Ω has a good shape, then there exist two concentric balls B_r and B_R, with $R \leq nc^* r$, such that $B_r \subset \Omega \subset B_R$.

Let u be a convex function defined in a bounded domain Ω. Following Caffarelli [C2], we denote, for any $y \in \Omega, h > 0$,

$$S^0_{h,u}(y) = \{x \in \Omega : \quad u(x) < \ell_y(x) + h\} \tag{2.2}$$

the level set of u and denote $S_{h,u}(y) = \partial S^0_{h,u}(y)$ its boundary, where ℓ_y is the tangent plane of u at y. When no confusion arises we will drop the subscript u, and when y is the minimum point of u, we will simply write the level set as S^0_h.

LEMMA 2.2. *Let u_i, $i = 1, 2$, be two convex solutions of* $\det D^2 u = 1$ *in $B_1(0)$. Suppose $\|u_i\|_{C^4} \leq C_0$. Then if $|u_1 - u_2| \leq \delta$ in $B_1(0)$ for some constant $\delta > 0$, we have, for $1 \leq k \leq 3$,*

$$|D^k(u_1 - u_2)| \leq C\delta \quad \text{in} \;\; B_{1/2}(0). \tag{2.3}$$

Proof. We have

$$\begin{aligned}\det D^2 u_2 - \det D^2 u_1 &= \int_0^1 \frac{d}{dt} \det[D^2 u_1 + t(D^2 u_2 - D^2 u_1)] dt \\ &= a_{ij}(x) \partial_i \partial_j (u_2 - u_1) = 0.\end{aligned}$$

Since u_i satisfies the equation det $D^2 u = 1$, it is uniformly convex by the assumption $\|u_i\|_{C^4} \leq C_0$. Hence the operator $L = a_{ij}(x)\partial_i\partial_j$ is linear and uniformly elliptic, with C^2 coefficients. By the Schauder estimates of linear elliptic equations, we obtain (2.3). □

We also need the following regularity for the Monge–Ampère equation [GT, P].

LEMMA 2.3. *Let Ω be a bounded convex domain in R^n. Let u be a convex solution of* $\det D^2 u = 1$ *in Ω, vanishing on $\partial\Omega$. If $B_r(0) \subset \Omega \subset B_R(0)$, then for any $\Omega' \subset\subset \Omega$, there is a constant $C > 0$, depending only on n, r, R, and dist$(\Omega', \partial\Omega)$, such that*

$$\|u\|_{C^4(\Omega')} \leq C. \tag{2.4}$$

From Lemma 2.3 we have the following.

LEMMA 2.4. *Let u be a convex solution of* $\det D^2 u = 1$ *in Ω which vanishes on $\partial\Omega$. Suppose u attains its minimum at the origin and $D^2 u(0)$ is the unit matrix (or uniformly bounded); then the domain Ω is of good shape.*

Indeed, if Ω does not have a good shape, one may make a unimodular linear transform $y = Tx$ to normalize Ω. Then the ratio of the largest and least eigenvalues of T will be large. By Lemma 2.3, $D^2_y u(0)$ is uniformly bounded. Hence $D^2_x u(0) = T' D^2_y(0) T$ cannot be the unit matrix (or uniformly bounded).

Proof of Theorem 1. By subtracting a linear function we suppose

$$u(0) = 0, \quad Du(0) = 0,$$

so that the origin is the minimum point of u. We consider the solution u in the level set S^0_h, where $h > 0$ is chosen small such that S^0_h is compactly supported in $B_1(0)$. By Lemma 2.1 there is a unique unimodular linear transform T_h such that $T_h(S^0_h)$ is normalized. Hence by making the change $x \to T_h x/\sqrt{h}$ and $u \to u/h$, we may suppose $h = 1$, S^0_1 is normalized, and

$$\int_0^1 \frac{\omega(r)}{r} \le \varepsilon, \tag{2.5}$$

where $\omega(r) = \omega_f(r)$, and ε can be as small as we want, provided h is sufficiently small. Note that the Monge–Ampère equation is invariant under the change $x \to Tx$ and $u \to (\det T)^{2/n} u$ for any nondegenerate linear transform T.

Let u_k, $k = 0, 1, \ldots$, be the solution of

$$\begin{aligned} \det D^2 u_k &= f(0) \quad \text{in } \ S^0_{4^{-k},u}, \\ u_k &= u \ (= 4^{-k}) \quad \text{on } \ \partial S^0_{4^{-k},u}. \end{aligned} \tag{2.6}$$

Denote

$$\begin{aligned} \nu(t) &= \sup_{z \in B_1} \{|f(x) - f(y)| : \quad x, y \in S^0_{t^2,u}(z)\}, \\ \nu_k &= \nu(2^{-k}), \end{aligned} \tag{2.7}$$

which is invariant under unimodular linear transformation of x. If $S^0_{t^2,u}$ has a good shape, then we have $\nu(t) \le \omega(Ct)$.

Since $S^0_{1,u}$ has a good shape, by Lemma 2.3, $\|u_0\|_{C^4(S^0_{3/4,u})} \le C$. Note that

$$\det D^2(1 - C\nu_0)u \le \det D^2 u_0 \le \det D^2(1 + C\nu_0)u \quad \text{in } \ S^0_{1,u}$$

for some constant C, and $u = u_0 = 1$ on the boundary. By the comparison principle, we have

$$(1 + C\nu_0)(u - 1) \le u_0 - 1 \le (1 - C\nu_0)(u - 1).$$

It follows that $|u - u_0| \le C\nu_0$. Similarly we have $|u - u_1| \le C\nu_1$. Hence we obtain $|u_1 - u_0| \le C\nu_0$. Since $S^0_{1,u}$ has a good shape, so does $S^0_{4^{-1},u}$. It follows that $\|u_1\|_{C^4(S^0_{3/16,u_1})} \le C$. Replacing the balls B_1 and $B_{1/2}$ in Lemma 2.2 by the level sets $S^0_{1/8,u_1}$ and $S^0_{1/16,u_1}$, we obtain

$$|D^k u_0(x) - D^k u_1(x)| \le C\nu_0 \tag{2.8}$$

for $x \in S^0_{4^{-2},u_1}$, where $1 \le k \le 3$. By Lemma 2.4, the estimate also implies that $S^0_{4^{-2},u_1}$ has a good shape.

By induction we assume that $S^0_{4^{-k-1},u}$ has a good shape, with the constant c^* (see (2.1)) independent of k. Hence $\nu_k \le \omega(C2^{-k})$ for some $C > 0$ independent of k (depending on c^*). Applying the same argument to $\hat{u}_0 := 4^k u_k(\frac{x}{2^k})$ and $\hat{u}_1 := 4^k u_{k+1}(\frac{x}{2^k})$, we obtain, for $x \in S^0_{4^{-k-2},u_{k+1}}$,

$$|Du_k(x) - Du_{k+1}(x)| \le C2^{-k}\nu_k, \tag{2.9a}$$

$$|D^2u_k(x) - D^2u_{k+1}(x)| \le C\nu_k, \tag{2.9b}$$

$$|D^3u_k(x) - D^3u_{k+1}(x)| \le C2^k\nu_k, \tag{2.9c}$$

where 2^k in (2.9) is the scaling constant. Hence

$$|D^2u_0(x) - D^2u_{k+1}(x)| \le C\sum_{i=0}^{k}\nu_i \le C\int_{2^{-k}}^{1}\frac{\omega(r)}{r}dr \tag{2.10}$$

for $x \in S^0_{4^{-k-2},u_{k+1}}$, where $C > 0$ is independent of k.

Estimate (2.10), together with (2.5) and Lemma 2.4, implies that $S^0_{4^{-k-2},u_{k+1}}$ has a good shape, with the constant c^* independent of k. Denote

$$\hat{u} = 4^{k+1}u\left(\frac{x}{2^{k+1}}\right), \quad \hat{u}_{k+1} = 4^{k+1}u_{k+1}\left(\frac{x}{2^{k+1}}\right). \tag{2.11}$$

Then $\hat{u}$ and $\hat{u}_{k+1}$ satisfy the equations $\det D^2\hat{u} = f(2^{-k-1}x)$ and $\det D^2\hat{u} = f(0)$, respectively. By the comparison principle,

$$|\hat{u} - \hat{u}_{k+1}| \le C\nu_{k+1}. \tag{2.12}$$

Hence $S^0_{4^{-1},\hat{u}}$ has a good shape, and so also $S^0_{4^{-k-2},u}$ has a good shape.

For any given point z near the origin,

$$\begin{aligned} |D^2u(z) - D^2u(0)| &\le I_1 + I_2 + I_3 =: \\ |D^2u_k(z) - D^2u_k(0)| &+ |D^2u_k(0) - D^2u(0)| + |D^2u(z) - D^2u_k(z)|. \end{aligned} \tag{2.13}$$

Let $k \ge 1$ such that $4^{-k-4} \le u(z) \le 4^{-k-3}$. Then by (2.9b) and recalling that $\nu(t) \le \omega(Ct)$,

$$I_2 \le C\sum_{j=k}^{\infty}\nu_j \le C\int_0^{|z|}\frac{\omega(r)}{r}. \tag{2.14}$$

We remark that in the second inequalities in (2.10) and (2.14), the integrand should be $\frac{1}{r}\omega(Cr)$ for some constant $C > 0$. But from the definition (1.5), we have $\omega(Cr) \le C\omega(r)$.

Next we estimate I_3. Let $u_{z,j}$ be the solution of

$$\begin{aligned} \det D^2u_{z,j} &= f(z) \quad \text{in } S^0_{4^{-j},u}(z), \\ u_{z,j} &= u \quad \text{on } \partial S^0_{4^{-j},u}(z). \end{aligned} \tag{2.15}$$

Let $j_k = \inf\{j : \ S^0_{4^{-j},u}(z) \subset S^0_{4^{-k},u}(0)\}$. Obviously $j_k \ge k$. We claim that $j_k \le k + l_0$ for some fixed l_0 independent of k. Indeed, by making the dilation $x \to 2^kx$ and $u \to 4^ku$, we may assume that $k = 0$ and $u(z) \le 4^{-3}$. From Caffarelli's strict convexity [C1], there exists a constant $l_0 > 0$ such that the tangent plane ℓ of u at z satisfies

$$\ell(x) \le u(x) - 4^{-l_0}$$

for any boundary point x of $S^0_{1,u}(0)$. In other words, we have $S^0_{4^{-l_0},u}(z) \subset S^0_{1,u}(0)$. Scaling back, we obtain $j_k \le k + l_0$. Note that $|u_k - u_{z,k+l_0}| \le C\nu_k$. Applying Lemma 2.2 to u_k and $u_{z,k+l_0}$ in $S^0_{4^{-k-l_0},u}(z)$, we have

$$|D^2u_k(z) - D^2u_{z,k+l_0}(z)| \le C\nu_k. \tag{2.16}$$

Similarly to (2.14) we have

$$|D^2u(z) - D^2u_{z,k+l_0}(z)| \le C \sum_{j=k+l_0}^{\infty} \nu_j \le C \int_0^{|z|} \frac{\omega(r)}{r}. \tag{2.17}$$

Combining (2.16) and (2.17), we obtain an estimate for I_3.

To estimate I_1, denote $h_j = u_j - u_{j-1}$. By (2.9c),

$$|D^2h_j(z) - D^2h_j(0)| \le C2^j\nu_j|z|. \tag{2.18}$$

Hence

$$\begin{aligned} I_1 &\le |D^2u_{k-1}(z) - D^2u_{k-1}(0)| + |D^2h_k(z) - D^2h_k(0)| \\ &\le |D^2u_0(z) - D^2u_0(0)| + \sum\nolimits_{j=1}^{k} |D^2h_j(z) - D^2h_j(0)| \\ &\le C|z|\left(1 + \sum\nolimits_{j=1}^{k} 2^j\nu_j\right) \\ &\le C|z|\left(1 + \int_{|z|}^1 \frac{\omega(r)}{r^2}\right). \end{aligned} \tag{2.19}$$

Hence we obtain (1.8). Note that (1.9) and (1.10) follow readily from (1.8). This completes the proof of Theorem 1. □

3. Proof of Theorem 2. The proof of Theorem 2 is divided into two parts. The first part is the proof of (1.11) with a large constant θ, and the second one is an estimate for θ.

The first part is a modification of the proof of Theorem 1. A difference is that in the proof of Theorem 1, due to (2.5) the level sets $S^0_{4^{-k},u}$ have a good shape for all $k > 0$, and we don't need to make linear transforms to normalize them. But in the proof of Theorem 2, due to the lack of (2.5), the level set will in general not have a good shape. Therefore we have to make linear transforms for every k to keep these level sets in good shape and estimate carefully the accumulation of all of the transforms. We also allow discontinuous f in our argument from (3.1) until (3.9).

3.1. By subtracting a linear function we suppose $u(0) = 0$, $Du(0) = 0$. By making a dilation of the axes, we may assume that $f(0) = 1$. Consider u in the level set S^0_h for some small $h > 0$ such that $S^0_h \subset\subset B_1(0)$. By making a linear transform as in section 2, we may assume that $h = 1$ and S^0_1 is normalized. Let $\nu_k = \nu(2^{-k})$ be as in (2.7). Let u_k, $k = 0, 1, \dots$, be the solution of

$$\begin{aligned} \det D^2u_k &= f_k \quad \text{in } S^0_{4^{-k},u}, \\ u_k &= u \quad \text{on } \partial S^0_{4^{-k},u}, \end{aligned} \tag{3.1}$$

where f_k is a constant:

$$f_k = \frac{1}{2}\left[\inf\{f(x) :\ x \in S^0_{4^{-k},u}\} + \sup\{f(x) :\ x \in S^0_{4^{-k},u}\}\right].$$

We choose such a special constant f_k to get a better (smaller) upper bound for the constant θ in (1.11). In this subsection we will assume $f_k = 1$ by making a dilation of the axes.

First we make a unimodular linear transform $x^{(0)} = T_0x$ such that $D^2_{x^{(0)}}u_0(0) = I$, where I denotes the unit matrix. Here and below we use D to denote derivatives in x and $D_{x^{(i)}}$ to denote derivatives in the new coordinates $x^{(i)}$. By Lemma 2.4, the level set $S^0_{\frac{1}{4},u}$ has a good shape.

We then make a unimodular linear transform $x^{(1)} = T_1 x^{(0)}$ such that $D^2_{x^{(1)}} u_1(0) = I$. Then the level set $S^0_{4^{-2},u}$ has a good shape, and estimates (2.9) (for $k = 1$) hold in the new coordinates $x^{(1)}$.

By induction we assume that $D^2_{x^{(k-1)}} u_{k-1}(0) = I$. Then by Lemma 2.4, the level set $S^0_{4^{-k+1},u_{k-1}}$ has a good shape. Hence, from the proof of Theorem 1 (see (2.11) and (2.12)), $S^0_{4^{-k+1},u}$ has a good shape. We then make a unimodular linear transform $x^{(k)} = T_k x^{(k-1)}$ such that $D^2_{x^{(k)}} u_k(0) = I$. More precisely, assume that, in the coordinates $x^{(k-1)}$, u_k has the expansion (after a rotation of axes such that $D^2_{x^{(k)}} u_k(0)$ is diagonal)

$$u_k(x) = u_k(0) + a_i x_i + \frac{1}{2} b_i x_i^2 + O(|x|^3).$$

Then the transform $x^{(k)} = T_k x^{(k-1)}$ is given by

$$T_k x = (b_1^{\frac{1}{2}} x_1, \ldots, b_n^{\frac{1}{2}} x_n),$$

so that, in $x^{(k)}$,

$$u_k(x) = u_k(0) + \frac{a_i}{b_i^{1/2}} x_i + \frac{1}{2} x_i^2 + O(|x|^3),$$

and the largest eigenvalue of T_k is

$$\lambda_{max}(T_k) = \max b_k^{1/2}. \tag{3.2}$$

Remark 3.1. Here we assume that the constant f_k in (3.1) is equal to 1, so that $\prod_{i=1}^n b_i = 1$. If $f_k \neq 1$, then T_k should be given by

$$T_k x = \frac{1}{f_k^{1/2n}} (b_1^{\frac{1}{2}} x_1, \ldots, b_n^{\frac{1}{2}} x_n),$$

so that T_k is unimodular, namely, $\det T_k = 1$.

After the transform T_k, the level set $S^0_{4^{-k},u_k}$ has a good shape, and estimates (2.9) hold in the new coordinates $x^{(k)}$. That is,

$$|D_{x^{(k)}} u_k(x) - D_{x^{(k)}} u_{k+1}(x)| \leq C 2^{-k} \nu_k, \tag{3.3a}$$

$$|D^2_{x^{(k)}} u_k(x) - D^2_{x^{(k)}} u_{k+1}(x)| \leq C \nu_k \tag{3.3b}$$

for $x \in S^0_{4^{-k-1},u_k}$.

For any given point z near the origin,

$$\begin{gathered} |Du(z) - Du(0)| \leq I_1 + I_2 + I_3 =: \\ |Du_k(z) - Du_k(0)| + |Du_k(0) - Du(0)| + |Du(z) - Du_k(z)|, \end{gathered}$$

where we choose $k = k_z \geq 1$ such that $4^{-k-4} \leq u(z) \leq 4^{-k-3}$. For the estimate of I_2, we have

$$I_2 = |Du_k(0) - Du(0)| \leq \sum_{i=k}^{\infty} |Du_i(0) - Du_{i+1}(0)|.$$

Denote $T^{(i)} = T_i \cdot T_{i-1} \ldots T_1 \cdot T_0$. Let λ_i be the largest eigenvalue of $T^{(i)}$. Then

$$|Du_i(0) - Du_{i+1}(0)| \leq \lambda_i |D_{x^{(i)}} u_i(0) - D_{x^{(i)}} u_{i+1}(0)|.$$

By (3.3a),

$$|D_{x^{(i)}}u_i(0) - D_{x^{(i)}}u_{i+1}(0)| \le C2^{-i}\nu_i.$$

It follows that

$$|Du_i(0) - Du_{i+1}(0)| \le C\lambda_i 2^{-i}\nu_i,$$

where C is independent of i. Hence we obtain

$$I_2 \le C\sum_{i=k}^{\infty} \lambda_i 2^{-i}\nu_i. \tag{3.4}$$

Similarly we have $I_3 \le C\sum_{i=k}^{\infty} \lambda_i 2^{-i}\nu_i$. To estimate I_1, by (3.3b) we have

$$|D^2_{x^{(i)}}u_i(x^{(i)}) - D^2_{x^{(i)}}u_{i+1}(x^{(i)})| \le C\nu_i$$

for any $i = 0, 1, \ldots, k$ and $x^{(i)} \in T^{(i)}(S^0_{4^{-i-2},u})$. Hence

$$|D^2u_i(x) - D^2u_{i+1}(x)| \le C\lambda_i^2\nu_i$$

for any $x \in S^0_{4^{-i-2},u}$.

Denote $h_i = u_i - u_{i-1}$. We have

$$|Dh_i(z) - Dh_i(0)| \le |D^2h_i|\,|z| \le C\lambda_i^2\nu_i|z|.$$

Hence

$$\begin{aligned} I_1 &\le |Du_{k-1}(z) - Du_{k-1}(0)| + |Dh_k(z) - Dh_k(0)| \\ &\le |Du_0(z) - Du_0(0)| + \sum\nolimits_{i=1}^{k}|Dh_i(z) - Dh_i(0)| \\ &\le |Du_0(z) - Du_0(0)| + C|z|\sum_{i=0}^{k}\lambda_i^2\nu_i \\ &\le C|z|\left[1 + \sum_{i=0}^{k}\lambda_i^2\nu_i\right]. \end{aligned} \tag{3.5}$$

We obtain

$$|Du(z) - Du(0)| \le C\sum_{i=k}^{\infty}\lambda_i 2^{-i}\nu_i + C|z|\left[1 + \sum_{i=0}^{k}\lambda_i^2\nu_i\right]. \tag{3.6}$$

Next we estimate λ_i. For a fixed i, denote

$$\hat{u} = 4^i u\left(\frac{x^{(i)}}{2^i}\right), \quad \hat{u}_i = 4^i u_i\left(\frac{x^{(i)}}{2^i}\right), \quad u^*_{i+1} = 4^i u_{i+1}\left(\frac{x^{(i)}}{2^i}\right). \tag{3.7}$$

Then $\hat{u}$, $\hat{u}_i$, and u^*_{i+1} satisfy, respectively, the equation $\det D^2\hat{u} = f(2^{-i}x^{(i)})$, f_i, and f_{i+1}. By definition, $\nu_i \ge \sup\{|f(2^{-i}x^{(i)}) - f(0)| : \ x^{(i)} \in S^0_{1,\hat{u}}\}$. Hence by the comparison principle,

$$|\hat{u} - \hat{u}_i| \le C\nu_i,$$
$$|\hat{u} - u^*_{i+1}| \le C\nu_{i+1}.$$

It follows that

$$|\hat{u}_i - u^*_{i+1}| \le C\nu_i.$$

Note that $D^2_{x^{(i)}} u_i(0) = I$. Hence by Lemma 2.2, $|D^2_{x^{(i)}} u_{i+1}(0) - I| \le C\nu_i$. We obtain

$$\lambda_{max}(T_i) \le 1 + \theta\nu_i \tag{3.8}$$

for some constant θ independent of i (but later we will give a more precise upper bound of θ for large i). Hence

$$\begin{aligned}\lambda_i &\le \prod\nolimits_{j=0}^{i} \lambda_{max}(T_j)\\ &\le \prod\nolimits_{j=0}^{i} (1 + \theta\nu_j)\\ &= e^{\sum_{j=0}^{i} \log(1+\theta\nu_j)}\\ &\le e^{\theta \sum_{j=0}^{i} \nu_j}.\end{aligned}$$

We have therefore established (recall that $Du(0) = 0$) that

$$\begin{aligned}|Du(z)| &\le C \sum_{i=k}^{\infty} 2^{-i}\nu_i e^{\theta \sum_{j=0}^{i} \nu_j} + C|z| \left[1 + \sum_{i=0}^{k} \nu_i e^{2\theta \sum_{j=0}^{i} \nu_j}\right]\\ &\le C \int_0^{2^{-k}} \nu(t) e^{\theta \int_t^1 \frac{\nu(s)}{s} ds} dt + C|z| \left[1 + \int_{2^{-k}}^1 \frac{\nu(t)}{t} e^{2\theta \int_t^1 \frac{\nu(s)}{s} ds} dt\right].\end{aligned} \tag{3.9}$$

Remark 3.2. From (3.9) we see that if $\lim_{t\to 0} \nu(t) < \varepsilon$ for some small $\varepsilon > 0$, then $u \in C^{1,\alpha}$ for some $\alpha \in (1 - 2\theta\varepsilon, 1)$, which also follows from Caffarelli's $W^{2,p}$ estimate. If, furthermore, $\int_0^1 \frac{\nu(t)}{t} < \infty$, the above estimate implies that Du is Lipschitz continuous; namely, D^2u is uniformly bounded. In the following we assume $\lim_{t\to 0} \nu(t) = 0$.

The right-hand side of (3.9) can be simplified as follows. Denote

$$\varphi(t) = -\int_t^1 \frac{\nu(s)}{s} ds.$$

Assume that $\nu(t) \to 0$ at $t \to 0$, so that $\varphi(t) = o(|\log t|)$ as $t \to 0$. The first integral on the right-hand side of (3.9) is equal to

$$\begin{aligned}\int_0^r \nu(t) e^{\theta \int_t^1 \frac{\nu(s)}{s} ds} dt &= \int_0^r t\varphi'(t) e^{-\theta\varphi(t)} dt\\ &= \frac{-r}{\theta} e^{-\theta\varphi(r)} + \frac{1}{\theta} \int_0^r e^{-\theta\varphi(t)},\end{aligned}$$

where $r = 2^{-k}$. The second integral on the right-hand side of (3.9) is equal to

$$\int_r^1 \varphi'(t) e^{-2\theta\varphi(t)} dt = \frac{1}{2\theta} [e^{-2\theta\varphi(r)} - e^{-2\theta\varphi(1)}].$$

We claim that if $\varphi(0) = -\infty$,

$$\int_0^r e^{-\theta\varphi(t)} = O(re^{-\theta\varphi(r)}) \ \text{ as } \ r \to 0.$$

Indeed, noting that $r\varphi'(r) = \nu(r) = o(1)$, we have

$$\begin{aligned}\lim_{r\to 0} \frac{\int_0^r e^{-\theta\varphi(t)}}{re^{-\theta\varphi(r)}} &= \lim_{r\to 0} \frac{(\int_0^r e^{-\theta\varphi(t)})'}{(re^{-\theta\varphi(r)})'}\\ &= \lim_{r\to 0} \frac{e^{-\theta\varphi(r)}}{e^{-\theta\varphi(r)}(1-\theta r\varphi'(r))}\\ &= 1.\end{aligned}$$

Therefore from (3.9),

$$|Du(z)| \le C2^{-k}[1 + e^{-\theta\varphi(2^{-k})}] + C|z|[1 + e^{-2\theta\varphi(2^{-k})}]. \tag{3.10}$$

Claim.

$$2^{-k}[1 + e^{-\theta\varphi(2^{-k})}] \le C|z|[1 + e^{-2\theta\varphi(2^{-k})}]. \tag{3.11}$$

Indeed, (3.11) is obvious if $2^{-k} \le |z|$. If $|z| \le 2^{-k}$, denote $h(t) = u(t\frac{z}{|z|})$, $\alpha = 2^{-k}/|z|$, $\beta = e^{-\theta\varphi(2^{-k})}$. Since $h(0) = h'(0) = 0$, by convexity, and since $u(z) \ge 4^{-k-4}$, we have

$$h'(t) \ge \frac{1}{t}[h(t) - h(0)] \ge \frac{4^{-k-4}}{|z|} = 2^{-k-8}\alpha \quad \text{at} \quad t = |z|.$$

From (3.10),

$$h'(t) \le C2^{-k}(1+\beta) + C|z|(1+\beta^2).$$

Combining the above two inequalities, we obtain

$$\alpha \le C(1+\beta) + \frac{C}{\alpha}(1+\beta^2).$$

Hence $\alpha \le C(1+\beta)$, and so

$$2^{-k}(1+\beta) = |z|\alpha(1+\beta) \le C|z|(1+\beta^2).$$

We also obtain (3.11).

We have therefore proved that

$$|Du(z) - Du(0)| \le C|z|[1 + e^{-2\theta\varphi(2^{-k})}]. \tag{3.12}$$

Note that estimate (3.12) still holds and Du is Lipschitiz continuous if $\varphi(0) > -\infty$. This is the case treated in section 2.

To obtain (1.11) from (3.12), note that, by Remark 3.2, $u \in C^{1,\alpha}$ for any α close to 1. Hence for any $\varepsilon > 0$, the level set $S^0_{t^2,u}(y)$ is contained in the ball $B_{t^{1-\varepsilon}}(y)$ provided $t > 0$ is sufficiently small. In particular, we have $2^{-k} \ge |z|^{1+\varepsilon}$ and $\nu(t) \le \omega(t^{1-\varepsilon})$. With $d = |z|$ we then obtain

$$\begin{aligned}|\varphi(2^{-k})| \le \int_{d^{1+\varepsilon}}^1 \frac{\nu(t)}{t}dt &\le \int_{d^{1+\varepsilon}}^1 \frac{\omega(t^{1-\varepsilon})}{t}dt\\ &= \frac{1}{1-\varepsilon}\int_{d^{1+\varepsilon}}^1 \frac{\omega(t^{1-\varepsilon})}{t^{1-\varepsilon}}dt^{1-\varepsilon}\\ &\le \frac{1}{1-\varepsilon}\int_{d^{1-\varepsilon^2}}^1 \frac{\omega(t)}{t}dt\\ &= \frac{1}{1-\varepsilon}|\hat\psi(d^{1-\varepsilon^2})| \le \frac{1}{1-\varepsilon}|\hat\psi(d)|,\end{aligned}$$

where

$$\hat{\psi}(d) = -\int_d^1 \frac{\omega_f(r)}{r} dr.$$

We obtain (1.11) at $y = 0$ with $\omega_{\log f}$ replaced by ω_f but under the assumption that $f(0) = 1$.

To see that estimate (1.11) is actually determined by $\omega_{\log f}$, consider $w = \frac{u}{f^{1/n}(0)}$ such that $\det D^2 w = \hat{f} =: \frac{f}{f(0)}$. We have

$$\begin{aligned} |\hat{f}(x) - \hat{f}(0)| &= \left| \frac{f(x)}{f(0)} - 1 \right| \\ &\le (1+\varepsilon) \log \frac{f(x)}{f(0)} \\ &= (1+\varepsilon)[\log f(x) - \log f(0)] \end{aligned}$$

for x near 0, namely, $\omega_{\hat{f}} \le (1+\varepsilon)\omega_{\log f}$ for some constant $\varepsilon > 0$. The constant ε can be as small as we want, provided x is sufficiently close to 0. Recall that we allow that the constant C in (1.11) depends on the upper and lower bounds of f and the modulus of continuity of f.

From (3.12) we see that if

$$\nu(t) \le \frac{1}{2\theta\,|\log t|} \tag{3.13}$$

for $t > 0$ small, then Du is log-Lipschitz continuous.

3.2. To finish the proof of Theorem 2, it remains to prove that $\theta < \frac{1}{2}$.

LEMMA 3.1. *Assume* $\lim_{x\to 0} f(x) = 1$. *For any* $\varepsilon > 0$, *there exists* $h_\varepsilon > 0$ *such that, when* $0 < h < h_\varepsilon$, $S_{h,u}(0)$ *is in the* $\varepsilon h^{\frac{1}{2}}$*-neighborhood of a sphere of radius* $(2h)^{1/2}$ *after normalization.*

This was proved in [C2, Lemma 7]. Moreover, the condition $\lim_{x\to 0} f(x) = 1$ can be relaxed to

$$\overline{\lim}_{x\to 0} |f(x) - 1| \le \delta$$

for some $\delta > 0$ depending on ε. We note that Lemma 3.1 can also be proved by a blowup argument, as a convex solution of $\det D^2 u = 1$ must be a quadratic function if its graph is complete.

LEMMA 3.2. *Let* $f(0) = 1$ *and* $\nu = osc_{S^0_{1,u}} f$. *Let* $\overline{u} \in C^4_{loc}(S^0_{1,u})$ *be the solution of*

$$\det D^2 v = \overline{f} \quad in \quad S^0_{1,u}, \quad v = 1 \quad on \quad \partial S^0_{1,u}, \tag{3.14}$$

where $\overline{f}$ *is a constant,* $\overline{f} = \frac{1}{2}(f_{min} + f_{max})$, $f_{min} = \inf\{f(x) : \ x \in S^0_{1,u}\}$, *and* $f_{max} = \sup\{f(x) : \ x \in S^0_{1,u}\}$. *Then*

$$|u - \overline{u}| \le \frac{3\nu}{8n} + C\nu^2 \quad on \ \partial S^0_{\frac{1}{4},u}. \tag{3.15}$$

Proof. Let u_{min} (u_{max}, respectively) be the solution of $\det D^2 v = f_{min}$ (f_{max}, respectively) in $S^0_{1,u}$ such that $v = 1$ on $\partial S^0_{1,u}$. Then

$$u_{max} - 1 = \left(\frac{f_{max}}{f_{min}}\right)^{\frac{1}{n}} (u_{min} - 1).$$

Observe that $\frac{f_{max}}{f_{min}} = 1 + \nu + O(\nu^2)$. We have $\left(\frac{f_{max}}{f_{min}}\right)^{\frac{1}{n}} = 1 + \frac{\nu}{n} + O(\nu^2)$. By the comparison principle,

$$u_{max} \le u \le u_{min}.$$

Hence on $S_{\frac{1}{4},u}$,

$$|u_{max}| \le |u_{min}| + \frac{3\nu}{4n} + C\nu^2. \tag{3.16}$$

By our choice, $\overline{f} = \frac{1}{2}(f_{max} + f_{min})$. Hence

$$\overline{u} = \frac{1}{2}\big(u_{min} + u_{max}\big) + O(\nu^2).$$

We obtain (3.15). Alternatively we have

$$\overline{u} - 1 = \left(\frac{\overline{f}}{f_{min}}\right)^{\frac{1}{n}} (u_{min} - 1),$$

and, similarly to (3.16), $|\overline{u}| \le |u_{min}| + \frac{3\nu}{8n} + C\nu^2$. We also obtain (3.15). ◻

Denote

$$\beta_n = \sup |D^2 u(0)|, \tag{3.17}$$

where $|D^2 u| = \max_{|\xi|=1} u_{\xi\xi}$, and the sup is taken among all harmonic functions in the unit ball $B_1(0) \subset \mathrm{R}^n$ satisfying $|u| \le 1$ on ∂B_1.

Let $\hat{u}$, $\hat{u}_i$, and u^*_{i+1} be the functions given in (3.7). Then $\hat{u}_i$ (u^*_{i+1}, respectively) satisfies

$$\det D^2 u = f_i \quad (f_{i+1}, \text{respectively}) \;\; \text{in } S^0_{1,\hat{u}} \;\; (\text{in } S^0_{\frac{1}{4},\hat{u}}, \text{respectively}),$$

where, by Lemma 3.1, the set $S^0_{\frac{r^2}{2},\hat{u}}$ is a small perturbation of a ball of radius r. As f_{i+1} may differ from f_i, we introduce a new function $\hat{v}_{i+1}$, which is the solution of

$$\det D^2 v = f_i \quad \text{in} \;\; S^0_{\frac{1}{4},\hat{u}}, \quad v = \hat{u} \quad \text{on} \;\; S_{\frac{1}{4},\hat{u}}.$$

Then

$$\hat{v}_{i+1} - \frac{1}{4} = \left(\frac{f_i}{f_{i+1}}\right)^{\frac{1}{n}} (u^*_{i+1} - \frac{1}{4}). \tag{3.18}$$

Let

$$v = \frac{\hat{u}_i - \hat{v}_{i+1}}{\|\hat{u}_i - \hat{v}_{i+1}\|_{L^\infty(S^0_{1/4,\hat{u}})}}.$$

Then v satisfies a linearized Monge–Ampère equation, that is,

$$\begin{aligned} \det D^2\hat{v}_{i+1} - \det D^2\hat{u}_i &= \int_0^1 \frac{d}{dt}\det[D^2\hat{u}_i + t(D^2\hat{v}_{i+1} - D^2\hat{u}_i)]dt \\ &= a_{ij}(x)\partial_i\partial_j(\hat{v}_{i+1} - \hat{u}_i) = 0. \end{aligned} \tag{3.19}$$

Notice that, by Lemma 3.1, both $\hat{u}_i$ and $\hat{v}_{i+1}$ converge to $\frac{1}{2}|x|^2$ as $i \to \infty$. By the regularity of the Monge–Ampère equation (Lemma 2.3), the matrix $\{a_{ij}\}$ converges to the unit matrix. Hence from (3.17),

$$|D^2 v(0)| \le 2(\beta_n + \varepsilon), \tag{3.20}$$

where $\varepsilon > 0$ can be as small as we want, provided i is large enough. The coefficient 2 is due to the fact that v_{i+1} is defined in $S^0_{\frac{1}{4},\hat{u}}$, which is a small perturbation of $B_{1/\sqrt{2}}$.

By the homogeneous equation (3.19), $\sup\{|\hat{u}_i - \hat{v}_{i+1}|(x) : \ x \in S^0_{\frac{1}{4},\hat{u}}\}$ is attained on the boundary $S_{\frac{1}{4},\hat{u}}$. Hence by Lemma 3.2,

$$\begin{aligned}\sup\{|\hat{u}_i - \hat{v}_{i+1}|(x) : \ x \in S^0_{\frac{1}{4},\hat{u}}\} &\le \sup\{|\hat{u}_i - \hat{u}|(x) : \ x \in S_{\frac{1}{4},\hat{u}}\} \\ &\le \frac{3\nu_i}{8n} + O(\nu_i^2).\end{aligned}$$

Recall that $D^2\hat{u}_i(0) = I$. Hence by (3.20),

$$|D^2\hat{v}_{i+1}(0) - I| \le (\beta_n + \varepsilon)\frac{3\nu_i}{4n} + O(\nu_i^2). \tag{3.21}$$

Note that, by (3.18),

$$D^2\hat{v}_{i+1} = \left(\frac{f_i}{f_{i+1}}\right)^{\frac{1}{n}} D^2 u^*_{i+1}.$$

Hence by a dilation $x \to \big(f_i/f_{i+1}\big)^{-1/2n}x$, we may cancel the coefficient $\big(\frac{f_i}{f_{i+1}}\big)^{\frac{1}{n}}$. It is obvious that the dilation does not affect the eigenvalues of the mapping T_i in (3.8) (because T_i is unimodular). Hence by (3.2) and (3.21),

$$\lambda_{max}(T_i) \le \left(1 + (\beta_n + \varepsilon)\frac{3\nu_i}{4n}\right)^{\frac{1}{2}}.$$

Therefore we obtain an upper bound for the constant θ in (3.8) (for large i)

$$\theta \le \frac{3\beta_n}{8n} + \varepsilon. \tag{3.22}$$

Next we give an upper bound for β_n.

Lemma 3.3. *Let β_n be given in* (3.17). *Then we have the estimate*

$$\beta_n = \frac{4(n+2)\omega_{n-1}}{\omega_n\sqrt{n}}\left(\frac{n-1}{n}\right)^{\frac{n-1}{2}}, \tag{3.23}$$

where ω_n is the area of the unit sphere $S^{n-1} \subset \mathrm{R}^n$.

Proof. For any small $\varepsilon > 0$, let u be a harmonic function satisfying

$$u_{nn}(0) \ge \sup|D^2 v(0)| - \varepsilon,$$

where the sup is taken among all harmonic functions v in the unit ball with $|v| \le 1$, and $|D^2 v|$ denotes the largest eigenvalue of the matrix $D^2 v$. By a rotation of axes we assume that $D^2u(0)$ is diagonal and $|D^2u(0)| = u_{nn}(0)$. By Green's representation,

$$u(x) = \frac{1 - |x|^2}{\omega_n}\int_{\partial B_1}\frac{g(y)}{|x - y|^n}dy,$$

where g is the boundary value of u on ∂B_1. Hence

$$u_{nn}(0)=\frac{n+2}{\omega_n}\left[\int_{\partial B_1} ny_n^2 g-\int_{\partial B_1} g\right]. \tag{3.24}$$

To compute the above integrals, we make a rearrangement of the function g, which keeps the integral $\int_{\partial B_1} g$ invariant, such that g is rotationally symmetric in $x'=(x_1,\dots,x_{n-1})$, even in x_n, and is monotone increasing in x_n for $x_n\in(0,1)$. It is easy to see that the rearrangement will increase the value $u_{nn}(0)$.

After the arrangement, g is a function of x_n. There exists a constant $t\in(0,1)$ such that $g>0$ when $x_n>t$ and $g\le 0$ when $x_n\le t$. If g is strictly positive or negative, we take $t=0$ or 1. Let h be a function on ∂B_1 which is rotationally symmetric in x', even in x_n, increasing in x_n for $x_n\in(0,1)$, and satisfies $\int_{\partial B_1} h=0$. Then $\int_{\partial B_1} y_n^2 h\ge 0$ and

$$\int_{\partial B_1} ny_n^2(g+h)-\int_{\partial B_1}(g+h)\ge\int_{\partial B_1} ny_n^2 g-\int_{\partial B_1} g.$$

Hence to compute $\sup|D^2v(0)|$, we may assume furthermore that

$$\begin{aligned} g&=1 \quad \text{when } x_n\in(t,1],\\ g&=-1 \quad \text{when } x_n\in[0,t) \end{aligned} \tag{3.25}$$

for a different $t\in(0,1)$. We have now the family of functions $\{g=g_t\}_{|t\in(0,1)}$. From the integrand in (3.24), one easily verifies that, among all of the functions $g=g_{t|t\in(0,1)}$, the sup is attained when $t=\frac{1}{\sqrt{n}}$. Therefore

$$u_{nn}(0)\le\frac{n+2}{\omega_n}\left\{\int_{S^{n-1}\cap\{|x_n|>\frac{1}{\sqrt{n}}\}}(ny_n^2-1)-\int_{S^{n-1}\cap\{|x_n|<\frac{1}{\sqrt{n}}\}}(ny_n^2-1)\right\}. \tag{3.26}$$

Notice that $u_{nn}(0)$ is invariant if we add a constant to g. Hence

$$\int_{S^{n-1}}(ny_n^2-1)=0.$$

We obtain

$$u_{nn}(0)\le\frac{2(n+2)}{\omega_n}\int_{S^{n-1}\cap\{|x_n|>\frac{1}{\sqrt{n}}\}}(ny_n^2-1).$$

Denote $r=|x'|$, $a=\sqrt{1-\frac{1}{n}}$. Then $y_n^2=1-r^2$ and

$$\int_{S^{n-1}\cap\{|x_n|>\frac{1}{\sqrt{n}}\}}(ny_n^2-1)=2\omega_{n-1}\int_0^a\frac{n(1-r^2)-1}{\sqrt{1-r^2}}r^{n-2}dr.$$

We have

$$\int_0^a\frac{r^n}{\sqrt{1-r^2}}=\frac{n-1}{n}\int_0^a\frac{r^{n-2}}{\sqrt{1-r^2}}-\frac{1}{n}a^{n-1}\sqrt{1-a^2}.$$

Hence

$$\int_0^a\frac{n(1-r^2)-1}{\sqrt{1-r^2}}r^{n-2}dr=a^{n-1}\sqrt{1-a^2}.$$

We obtain

$$\begin{aligned} u_{nn}(0) &\leq \frac{4(n+2)\omega_{n-1}}{\omega_n} a^{n-1}\sqrt{1-a^2} \\ &= \frac{4(n+2)\omega_{n-1}}{\omega_n\sqrt{n}}\left(\frac{n-1}{n}\right)^{\frac{n-1}{2}}. \end{aligned}$$

This completes the proof. ∎

The upper bound in (3.23) can be simplified.

LEMMA 3.4. *Let* β_n *be given in* (3.17). *Then* $\beta_2 = \frac{4}{\pi}$, $\beta_3 = \frac{20\sqrt{3}}{9}$, $\beta_4 = \frac{9\sqrt{3}}{\pi}$, $\beta_5 = \frac{168}{25}\sqrt{\frac{4}{5}}$, *and, for* $n \geq 6$,

$$\beta_n < n+2. \tag{3.27}$$

Proof. Since $\omega_2 = 2\pi$, $\omega_3 = 4\pi$, we have obviously $\beta_2 = \frac{4}{\pi}$, $\beta_3 = \frac{20\sqrt{3}}{9}$.

For $n \geq 4$, denote

$$\beta_n^* := \frac{\beta_n}{n+2} = \frac{4}{\sqrt{n-1}}\frac{\omega_{n-1}}{\omega_n}\left(\frac{n-1}{n}\right)^{\frac{n}{2}}. \tag{3.28}$$

We have

$$\begin{aligned} \omega_n &= 2\int_{\{|x'|<1\}} \frac{dx'}{\sqrt{1-|x'|^2}} \\ &= 2\omega_{n-1}\int_0^1 \frac{r^{n-2}}{\sqrt{1-r^2}}dr, \end{aligned}$$

where $x' = (x_1, \ldots, x_{n-1})$. Integration by parts gives

$$\int_0^1 \frac{r^{n-2}}{\sqrt{1-r^2}}dr = \frac{n-3}{n-2}\int_0^1 \frac{r^{n-4}}{\sqrt{1-r^2}}dr.$$

Hence we have

$$\int_0^1 \frac{r^{n-2}}{\sqrt{1-r^2}}dr = \frac{n-3}{n-2}\cdots\frac{2}{3} \tag{3.29}$$

if n is odd, and

$$\int_0^1 \frac{r^{n-2}}{\sqrt{1-r^2}}dr = \frac{n-3}{n-2}\cdots\frac{1}{2}\frac{\pi}{2}$$

if n is even. By direct computation, we obtain $\beta_4 = \frac{9\sqrt{3}}{\pi}$, $\beta_5 = \frac{168}{25}\sqrt{\frac{4}{5}}$, and (3.27) for $n \leq 10$. When $n > 10$, by (3.28) we have

$$\beta_n^* < \frac{4}{\sqrt{e}\sqrt{n-1}}\frac{\omega_{n-1}}{\omega_n}.$$

If $n = 2k > 10$ is even, then

$$\frac{\omega_{n-1}}{\omega_n} = \frac{1}{\pi}\frac{(n-2)(n-4)\ldots 2}{(n-3)(n-5)\ldots 1} := \frac{1}{\pi}I_n.$$

Since $\frac{k+1}{k} \le \frac{k}{k-1}$ for all k,

$$I_n < \left(\frac{n-2}{n-3}\frac{n-3}{n-4}\cdots\frac{10}{9}\frac{9}{8}\right)^{1/2}\frac{8}{7}\frac{6}{5}\frac{4}{3}\frac{2}{1} = \frac{\sqrt{n-2}}{\sqrt{8}}\frac{8}{7}\frac{6}{5}\frac{4}{3}\frac{2}{1}.$$

We obtain

$$\beta_n^* \le \sqrt{\frac{2}{e}}\frac{8}{7}\frac{6}{5}\frac{4}{3}\frac{2}{1}\frac{1}{\pi} < 1.$$

If $n = 2k+1$ is odd, then similarly

$$\beta_n^* \le \frac{2}{3\sqrt{e}}\frac{9}{8}\frac{7}{6}\frac{5}{4}\frac{3}{2} < 1.$$

This proves (3.27). $\square$

Let $\varepsilon > 0$ be sufficiently small; from (3.22) and Lemma 3.4 we have

$$\theta < \frac{1}{2} \tag{3.30}$$

in all dimensions. From (3.30) and (3.13), we see that Du is log-Lipschitz continuous when $\nu(t) \le \frac{1}{|\log t|}$. This completes the proof of Theorem 2. $\square$

4. Remarks. The log-Lipschitz continuity in Theorem 2 can be used to prove the local existence of continuous solutions to the Cauchy problem of the semigeostrophic equation, which is the transport equation

$$\partial_t \rho + \nabla(v\rho) = 0, \quad v = \nabla^{\perp} u, \tag{4.1}$$

coupled with the Monge–Ampère equation

$$\det(D^2 u + I) = \rho, \tag{4.2}$$

where $\nabla^{\perp} u = (-u_{x_2}, u_{x_1})$ in R^2 or $\nabla^{\perp} u = (-u_{x_2}, u_{x_1}, 0)$ in R^3 [BB, C5, CRD, CuF, E, L]. We assume the initial condition $\rho(\cdot, 0) = \rho_0 \in C^0(R^n)$ and the boundary condition $T_u(\mathrm{R}^n) = \Omega^*$, where $T_u(x) = Du(x) + x$ and Ω^* is a given bounded, convex domain. As in [L] we consider the periodic case. That is, for any $\vec{p} \in Z^n$, $\rho_0(x + \vec{p}) = \rho_0(x)$.

As the quasi-geostrophic equation, which is the transport equation (4.1) coupled with the equation $u = (-\Delta)^{-\frac{1}{2}}\rho$ [CF], the semigeostrophic equation has also been used as an approximation to the Euler equation [BB, C5, CRD, CuF, E, L]. Recall that for the 2-dimensional Euler equation, which can be written as a system of the transport equation (4.1) and the Poisson equation $u = (-\Delta)^{-1}\rho$, the global existence and uniqueness of smooth solutions were first derived by using the log-Lipschitz continuity for the Poisson equation [Y]. For the semigeostrophic equation, since the log-Lipschitz estimate (1.11) depends on the modulus of continuity of $\log f$, our Theorem 2 implies the local existence of continuous solutions when the initial data ρ_0 satisfies

$$\omega_{\log \rho_0}(r) < \frac{1}{|\log r|} \tag{4.3}$$

for small r. The proof is similar to that in [L], where it is assumed that f is Dini continuous. The local existence of continuous solutions was first obtained in [L] when ρ_0 is Dini continuous. We also refer the reader to [Br, C4] for the existence and regularity of solutions to the Monge–Ampère equation (4.2) subject to the boundary condition $T_u(\Omega) = \Omega^*$, where Ω is a convex domain in R^n.

Next we remark that the L^∞-oscillation $\omega_{\log f}$ in the estimate (3.9) can be replaced by the L^1-oscillation, using the following L^∞-estimate for the Monge–Ampère equation.

LEMMA 4.1. *Let u (respectively, $\overline{u}$) be a solution to the Monge–Ampère equation $\det D^2 u = f \geq 0$ (respectively, $\overline{f}$) in Ω. Suppose $u = \overline{u}$ on $\partial\Omega$. Then we have the estimate*

$$\sup_\Omega |u - \overline{u}| \leq C|f - \overline{f}|^{1/n}_{L^1(\Omega)}, \tag{4.4}$$

where C depends only on n and $\mathrm{diam}(\Omega)$.

Proof. Let φ be the convex solution to

$$\begin{aligned} \det D^2\varphi &= |f^{1/n} - \overline{f}^{1/n}|^n \quad \text{in} \quad \Omega, \\ \varphi &= 0 \quad \text{on} \quad \partial\Omega. \end{aligned}$$

Then we have the estimate

$$|\inf \varphi|^n \leq C \int_\Omega |f - \overline{f}|. \tag{4.5}$$

Estimate (4.5) can be established easily as follows. Suppose $\inf\varphi$ is attained at $x_0 \in \Omega$. Consider a convex function ψ whose graph is the convex cone with a vertex at $(x_0, \varphi(x_0))$ and a base $\partial\Omega \times \{x_{n+1} = 0\}$. Then $\psi = \varphi$ on $\partial\Omega$ and $\psi \geq \varphi$ in Ω. Denote by N_φ the normal mapping of φ [P]. Then $N_\psi(\Omega) \subset N_\varphi(\Omega)$. It follows that

$$|\inf \varphi|^n \leq C|N_\psi(\Omega)| \leq C|N_\varphi(\Omega)| = C \int_\Omega |f^{1/n} - \overline{f}^{1/n}|^n.$$

Noting that $|f^{1/n} - \overline{f}^{1/n}|^n \leq |f - \overline{f}|$, we obtain

$$|\inf \varphi|^n \leq C \int_\Omega |f - \overline{f}|,$$

where C depends only on n and $\mathrm{diam}(\Omega)$.

Next, observing that the Monge–Ampère operator $M(u) = \det^{1/n} D^2 u$ is concave, we have $M(\frac{u+v}{2}) \geq \frac{1}{2}(M(u) + M(v))$ for any convex function u, v. Hence

$$\det{}^{1/n} D^2(\overline{u} + \varphi) \geq \det{}^{1/n} D^2\overline{u} + \det{}^{1/n} D^2\varphi \geq f^{1/n}.$$

Similarly, $\det^{1/n} D^2(u + \varphi) \geq \overline{f}^{1/n}$. By the comparison principle, $|u - \overline{u}| \leq |\varphi|$. We obtain the estimate. □

Finally we would like to point out that estimate (1.11) should be optimal, in the sense that the gradient Du may not be log-Lipschitz continuous if $\omega_{\log f} \geq \frac{C}{|\log r|}$ for some large C. Indeed, consider the case when u and f are even functions in dimension two such that u and u_i (solutions of (3.1)) attain their minimum at 0. Then for an appropriate f, there is a positive constant $c_0 > 0$ independent of i such that $|\hat{u}_i - u^*_{i+1}| \geq c_0\nu_i$ and $\lambda_{max}(T_i) \geq 1 + c_0\nu_i$ (see (3.8) and the formula before it).

REMARKS ON THE MASS CONSTRAINT FOR KP-TYPE EQUATIONS*

L. MOLINET†, J. C. SAUT‡, AND N. TZVETKOV§

Abstract. For a rather general class of equations of Kadomtsev–Petviashvili type, we prove that the zero-mass (in x) constraint is satisfied at any nonzero time even if it is not satisfied at initial time zero. Our results are based on a precise analysis of the fundamental solution of the linear part and its anti-x-derivative.

Key words. Kadomtsev–Petviashvili equation, zero-mass (in x) solution, conservation laws

AMS subject classifications. 35B05, 35Q53

DOI. 10.1137/060654256

1. Introduction.

Kadomtsev–Petviashvili (KP) equations are universal for the modeling of the propagation of long weakly dispersive waves which propagate essentially in one direction with weak transverse effects. As explained in the pioneering paper of Kadomtsev and Petviashvili [7], they are (formally) obtained in the following way. We start from a one-dimensional long-wave dispersive equation which is of Korteweg–de Vries (KdV) type, i.e.,

$$u_t + u_x + uu_x - Lu_x = 0, \qquad u = u(t,x),\ x \in \mathbb{R},\ t \geq 0\,. \tag{1.1}$$

In (1.1) L is a (possibly nonlocal) operator, defined in a Fourier variable by

$$\widehat{Lf}(\xi) = c(\xi)\widehat{f}(\xi), \tag{1.2}$$

where c is a real function which is linked to the phase velocity. For instance, the case $c(\xi) = \pm\xi^2$ ($L = \mp\partial_x^2$) corresponds to the classical KdV equation. In the context of water waves, the sign of $c(\xi)$ depends on the surface tension parameter. The case $c(\xi) = |\xi|$ ($L = H\partial_x$) corresponds to the Benjamin–Ono equation, etc. We will consider here only the case of homogeneous symbols.

As observed in [7] the correction to (1.1) due to weak transverse effects is independent of the dispersion in x and is related only to the finite propagation speed properties of the transport operator $M = \partial_t + \partial_x$. Recall that M gives rise to one-directional waves moving to the right with speed one; i.e., a profile $\varphi(x)$ evolves under the flow of M as $\varphi(x-t)$. A weak transverse perturbation of $\varphi(x)$ is a two-dimensional function $\psi(x,y)$ close to $\varphi(x)$, localized in the frequency region $\left|\frac{\eta}{\xi}\right| \ll 1$, where ξ and η are the Fourier modes corresponding to x and y, respectively. We look for a two-dimensional perturbation $\widetilde{M} = \partial_t + \partial_x + \omega(D_x, D_y)$ of M such that, similarly to above, the profile of $\psi(x,y)$ does not change much when evolving under the flow of $\widetilde{M}$. Here $\omega(D_x, D_y)$

denotes the Fourier multiplier with symbol the real function $\omega(\xi,\eta)$. Natural generalizations of the flow of M in two dimensions are the flows of the wave operators $\partial_t \pm \sqrt{-\Delta}$ which enjoy the finite propagation speed property. Since

$$\xi + \frac{1}{2}\xi^{-1}\eta^2 \sim \pm\sqrt{\xi^2+\eta^2}, \quad \text{when} \quad \left|\frac{\eta}{\xi}\right| \ll 1,$$

we deduce that

$$\partial_t + \partial_x + \frac{1}{2}\partial_x^{-1}\partial_y^2 \sim \partial_t \pm \sqrt{-\Delta},$$

which leads to the correction $\omega(D_x, D_y) = \frac{1}{2}\partial_x^{-1}\partial_y^2$ in (1.1).

Of course when the transverse effects are two-dimensional, the correction is $\frac{1}{2}\partial_x^{-1}\Delta_\perp$, where $\Delta_\perp = \partial_y^2 + \partial_z^2$.

We are thus led to the following model in two dimensions:

$$u_t + u_x + uu_x - Lu_x + \partial_x^{-1}\partial_y^2 u = 0. \tag{1.3}$$

In (1.3), it is implicitly assumed that the operator $\partial_x^{-1}\partial_y^2$ is well defined, which a priori imposes a constraint on the solution u, which, in some sense, has to be an x-derivative. This is achieved, for instance, if $u \in \mathcal{S}'(\mathbb{R}^2)$ is such that

$$\xi_1^{-1}\,\xi_2^2\,\widehat{u}(t,\xi_1,\xi_2) \in \mathcal{S}'(\mathbb{R}^2)\,, \tag{1.4}$$

thus in particular if $\xi_1^{-1}\,\widehat{u}(t,\xi_1,\xi_2) \in \mathcal{S}'(\mathbb{R}^2)$. Another possibility to fulfill the constraint is to write u as

$$u(t,x,y) = \frac{\partial}{\partial x}v(t,x,y), \tag{1.5}$$

where v is a continuous function having a classical derivative with respect to x, which, for any fixed y and $t \neq 0$, vanishes when $x \to \pm\infty$. Thus one has

$$\int_{-\infty}^{\infty} u(t,x,y)dx = 0, \qquad y \in \mathbb{R}, \ \ t \neq 0, \tag{1.6}$$

in the sense of generalized Riemann integrals. Of course the differentiated version of (1.3), namely

$$(u_t + u_x + uu_x - Lu_x)_x + \partial_y^2 u = 0, \tag{1.7}$$

can make sense without any constraint of type (1.4) or (1.6) on u, and so does the Duhamel integral representation of (1.3),

$$u(t) = S(t)u_0 - \int_0^t S(t-s)(u(s)u_x(s))ds, \tag{1.8}$$

where $S(t)$ denotes the (unitary in all Sobolev spaces $H^s(\mathbb{R}^2)$) group associated with (1.3),

$$S(t) = e^{-t(\partial_x - L\partial_x + \partial_x^{-1}\partial_y^2)}\,. \tag{1.9}$$

Let us notice, at this point, that models alternative to KdV-type equations (1.1) are the equations of Benjamin–Bona–Mahony (BBM) type

$$u_t + u_x + uu_x + Lu_t = 0 \tag{1.10}$$

with corresponding two-dimensional "KP–BBM-type models" (in the case $c(\xi) \geq 0$)

$$u_t + u_x + uu_x + Lu_t + \partial_x^{-1}\partial_y^2 u = 0 \tag{1.11}$$

or

$$(u_t + u_x + uu_x + Lu_t)_x + \partial_y^2 u = 0 \tag{1.12}$$

and free group

$$S(t) = e^{-t(I+L)^{-1}[\partial_x + \partial_x^{-1}\partial_y^2]} .$$

In view of the above discussion, all the results established for the Duhamel form of KP-type equations (e.g., those of Bourgain [5] and Saut and Tzvetkov [14]) do not need any constraint on the initial data u_0. It is then possible (see, for instance, [10]) to check that the solution u will satisfy (1.7) or (1.12) in the distributional sense but not a priori the integrated forms (1.3) or (1.11).

On the other hand, a constraint has to be imposed when using the Hamiltonian formulation of the equation. In fact, the Hamiltonian for (1.7) is

$$\frac{1}{2}\int \left[-u\,Lu + (\partial_x^{-1}u_y)^2 + u^2 + \frac{u^3}{3}\right] \tag{1.13}$$

and the Hamiltonian associated with (1.12) is

$$\frac{1}{2}\int \left[(\partial_x^{-1}u_y)^2 + u^2 + \frac{u^3}{3}\right] . \tag{1.14}$$

Therefore, the global well-posedness results for KP-I obtained in [11, 8] do need that the initial data satisfy (in particular) the constraint $\partial_x^{-1}\partial_y u_0 \in L^2(\mathbb{R}^2)$, and this constraint is preserved by the flow. Actually, the global results of [11, 8] make use of the next conservation law of the KP-I equation whose quadratic part contains the L^2-norms of u_{xx}, u_y, and $\partial_x^{-2}u_{yy}$. The constraint $\partial_x^{-2}\partial_{yy}u_0 \in L^2(\mathbb{R}^2)$ is thus also clearly needed, and one can prove that it is preserved by the flow.

On the other hand, as noticed in [11] there is a serious drawback with the higher conservation laws of both KP-I and KP-II equations, starting with that involving the L^2-norm of $\partial_x^3 u$ in its quadratic part. The problem is that this conservation law contains the L^2-norm of $(\partial_x^{-1}\partial_y)u^2$, whereas this expression is meaningless for $u \in H^3(\mathbb{R}^2)$. Indeed, for $u \in H^3(\mathbb{R}^2)$, using the Lebesgue theorem it is not to hard to see that if $(\partial_x^{-1}\partial_y)u^2 \in L^2(\mathbb{R}^2)$, then the integral $\int_{\mathbb{R}} \partial_y(u^2)(x,y)\,dx = \partial_y \int_{\mathbb{R}} u^2(x,y)\,dx$ must vanish for every $y \in \mathbb{R}$. Since $u \in L^2(\mathbb{R}^2)$ this clearly forces u to be identically zero.

The goal of this paper is to investigate the behavior of a solution to the general KP-type equations (1.7), (1.12) which initially does not satisfy the zero-mass constraint. We will show that, in fact, the zero-mass constraint is satisfied at any nonzero time t.

At this point we should mention the papers [1, 3, 4] and especially [6], where the inverse scattering transform machinery is used to solve the Cauchy problem for KP-I and KP-II without the constraint. The more complete and rigorous results are obtained in [6] (see also [17]). In the present work we consider a rather general class of KP or KP–BBM equations and emphasize the key point which concerns only the linear part: the fundamental solution of KP-type equations is a x derivative of a C^1

with respect to an x-continuous function which, for fixed $t \neq 0$ and y, tends to zero as $x \to \pm\infty$. Thus its generalized Riemann integral in x vanishes for all values of the transverse variable y and of $t \neq 0$. A similar property can be established for the solution of the nonlinear problem.

The paper is organized as follows. Section 2 deals with the KP-type equations, while section 3 focuses on KP–BBM-type equations. Section 4 reviews briefly some extensions: the three-dimensional case and nonhomogeneous dispersion relations.

In what follows, different harmless numerical constants will be denoted by c.

2. KP-type equations.

2.1. The linear case. We consider two-dimensional linear KP-type equations

$$(u_t - Lu_x)_x + u_{yy} = 0, \quad u(0,x,y) = \varphi(x,y)\,, \tag{2.1}$$

where

$$\widehat{Lf}(\xi) = \varepsilon|\xi|^\alpha \widehat{f}(\xi), \quad \xi \in \mathbb{R}, \tag{2.2}$$

where $\varepsilon = 1$ (KP-II-type equations) or $\varepsilon = -1$ (KP-I-type equations). We denote by G the fundamental solution

$$G(t,x,y) = \mathcal{F}^{-1}_{(\xi,\eta)\to(x,y)}\big[e^{it(\varepsilon\xi|\xi|^\alpha - \eta^2/\xi)}\big].$$

A priori, we have only that $G(t,\cdot,\cdot) \in \mathcal{S}'(\mathbb{R}^2)$. Actually, for $t \neq 0$, $G(t,\cdot,\cdot)$ has a very particular form which is the main result of this section.

THEOREM 2.1. *Suppose that $\alpha > 1/2$ in (2.2). Then for $t \neq 0$,*

$$G(t,\cdot,\cdot) \in C(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2).$$

Moreover, for $t \neq 0$, there exists

$$A(t,\cdot,\cdot) \in C(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2) \cap C^1_x(\mathbb{R}^2)$$

($C^1_x(\mathbb{R}^2)$ denotes the space of continuous functions on $\mathbb{R}^2$ which have a continuous derivative with respect to the first variable) such that

$$G(t,x,y) = \frac{\partial A}{\partial x}(t,x,y).$$

In addition, for $t \neq 0$, $y \in \mathbb{R}$, $\varphi \in L^1(\mathbb{R}^2)$,

$$\lim_{|x|\to\infty} (A \star \varphi)(t,x,y) = 0.$$

As a consequence, the solution of (2.1) with data $\varphi \in L^1(\mathbb{R}^2)$ is given by

$$u(t,\cdot,\cdot) \equiv S(t)\varphi = G \star \varphi$$

and

$$u(t,\cdot,\cdot) = \frac{\partial}{\partial x}\big(A \star \varphi\big).$$

One therefore has

$$\int_{-\infty}^{\infty} u(t,x,y)\,dx = 0 \quad \forall y \in \mathbb{R}, \;\; \forall t \neq 0$$

in the sense of generalized Riemann integrals.

REMARK 2.1. *It is worth noticing that the result of Theorem* 2.1 *is related to the infinite speed of propagation of the KP free evolutions. Let us also notice that the assumption* $\alpha > 1/2$ *can be relaxed if we assume that a sufficient number of derivatives of* φ *belong to* L^1. *Such an assumption is, however, not natural in the context of the KP equations.*

REMARK 2.2. *In the case of the classical KP-II equation* ($\alpha = 2$, $\varepsilon = +1$), *Theorem* 2.1 *follows from an observation of Redekopp* [13]. *Namely, one has*

$$G(t,x,y) = -\frac{1}{3t}\mathrm{Ai}(\zeta)\,\mathrm{Ai}'(\zeta),$$

where Ai *is the Airy function and*

$$\zeta = c_1\frac{x}{t^{1/3}} + c_2\frac{y^2}{t^{4/3}}$$

for some real constants $c_1 > 0$ *and* $c_2 > 0$. *Thus* $G(t,x,y) = \frac{\partial}{\partial x}A(t,x,y)$ *with*

$$A(t,x,y) = -\frac{1}{6c_1 t^{2/3}}\,\mathrm{Ai}^2\Big(c_1\frac{x}{t^{1/3}} + c_2\frac{y^2}{t^{4/3}}\Big)$$

and

$$u = \frac{\partial A}{\partial x}\star\varphi = \frac{\partial}{\partial x}\big(A\star\varphi\big),$$

which proves the claim for the KP-II equation (the fact that $\lim_{|x|\to\infty} A(t,x,y) = 0$ *results from a well-known decay property of the Airy function). A similar explicit computation does not seem to be valid for the classical KP-I equation or for KP-type equations with general symbols.*

Proof of Theorem 2.1. We will consider only the case $\varepsilon = 1$ in (2.1). The analysis in the case $\varepsilon = -1$ is analogous. It is plainly sufficient to consider only the case $t > 0$. We have

$$G(t,x,y) = (2\pi)^{-2}\int_{\mathbb{R}^2} e^{i(x\xi+y\eta)+it(\xi|\xi|^\alpha-\eta^2/\xi)}d\xi d\eta\,, \tag{2.3}$$

where the last integral has the usual interpretation of a generalized Riemann integral. We first check that $G(t,x,y)$ is a continuous function of x and y. By the change of variables

$$\eta' = \frac{t^{1/2}}{|\xi|^{1/2}}\eta,$$

we obtain

$$\begin{aligned}
G(t,x,y) &= \frac{c}{t^{1/2}}\int_{\mathbb{R}_\xi}|\xi|^{1/2}\left(\int_{\mathbb{R}_\eta} e^{i(y/t^{1/2})|\xi|^{1/2}\eta - i\mathrm{sgn}(\xi)\eta^2}d\eta\right)e^{ix\xi+it\xi|\xi|^\alpha}d\xi\\
&= \frac{c}{t^{1/2}}\int_{\mathbb{R}} e^{-i(\mathrm{sgn}(\xi))\frac{\pi}{4}}\,|\xi|^{1/2}e^{iy^2\xi/4t}\,e^{ix\xi+it\xi|\xi|^\alpha}d\xi\\
&= \frac{c}{t^{1/2}}\int_{\mathbb{R}} e^{-i(\mathrm{sgn}(\xi))\frac{\pi}{4}}\,|\xi|^{1/2}e^{i\xi(x+y^2/4t)}\,e^{it\xi|\xi|^\alpha}d\xi\\
&= \frac{c}{t^{\frac12+\frac{3}{2(\alpha+1)}}}\int_{\mathbb{R}} e^{-i(\mathrm{sgn}(\xi))\frac{\pi}{4}}\,|\xi|^{1/2}\exp\left(i\xi\left(\frac{x}{t^{\frac{1}{\alpha+1}}}+\frac{y^2}{4t^{\frac{\alpha+2}{\alpha+1}}}\right)\right)e^{i\xi|\xi|^\alpha}d\xi\,.
\end{aligned}$$

Let us define

$$H(\lambda) = c\int_{\mathbb{R}} e^{-i(\mathrm{sgn}(\xi))\frac{\pi}{4}}\,|\xi|^{1/2}e^{i\lambda\xi}\,e^{i\xi|\xi|^{\alpha}}d\xi\,.$$

Then H is continuous in λ. We will consider only the worst case $\lambda \le 0$. The phase $\varphi(\xi) = i(\lambda\xi + \xi|\xi|^{\alpha})$ then has two critical points $\pm\xi_{\alpha}$, where $\xi_{\alpha} = \left(\frac{\mu}{\alpha+1}\right)^{1/\alpha}$, $\mu = -\lambda$. We write, for $\varepsilon > 0$ small enough

$$H(\lambda) = \int_{-\infty}^{-\xi_{\alpha}-\varepsilon} + \int_{-\xi_{\alpha}-\varepsilon}^{\xi_{\alpha}+\varepsilon} + \int_{\xi_{\alpha}+\varepsilon}^{\infty} := I_1(\lambda) + I_2(\lambda) + I_3(\lambda)\,.$$

Clearly $I_2(\lambda)$ is a continuous function of λ. We consider only $I_3(\lambda)$,

$$\begin{aligned} I_3(\lambda) &= c\int_{\xi_{\alpha}+\varepsilon}^{\infty} \frac{\xi^{1/2}}{\varphi'(\xi)}\,\frac{d}{d\xi}\left[e^{\varphi(\xi)}\right]d\xi \\ &= c\left[\frac{\xi^{1/2}e^{\varphi(\xi)}}{\lambda+\xi^{\alpha}(\alpha+1)}\right]_{\xi_{\alpha}+\varepsilon}^{\infty} + c\int_{\xi_{\alpha}+\varepsilon}^{\infty}\left[\frac{1}{2(\lambda+\xi^{\alpha}(\alpha+1))\xi^{1/2}} - \frac{\alpha(\alpha+1)\xi^{\alpha-1/2}}{(\lambda+(\alpha+1)\xi^{\alpha})^2}\right]e^{\varphi(\xi)}d\xi, \end{aligned}$$

which for $\alpha > 1/2$ defines a continuous function of λ. Hence the integral (2.3) is a continuous function of (x, y) which coincides with the inverse Fourier transform (in $\mathcal{S}'(\mathbb{R}^2)$) of $\exp(it(\xi|\xi|^{\alpha} - \eta^2/\xi))$.

We next set for $t > 0$

$$A(t,x,y) \equiv (2\pi)^{-2}\int_{\mathbb{R}^2}\frac{1}{i\xi}e^{i(x\xi+y\eta)+it(\xi|\xi|^{\alpha}-\eta^2/\xi)}d\xi d\eta\,.$$

The last integral is clearly not absolutely convergent not only at infinity but also for ξ near zero. Nevertheless, the oscillations involved in its definition will allow us to show that $A(t, x, y)$ is in fact a continuous function. By the change of variables

$$\eta' = \frac{t^{1/2}}{|\xi|^{1/2}}\eta,$$

we obtain

$$\begin{aligned} A(t,x,y) &= \frac{c}{t^{1/2}}\int_{\mathbb{R}_{\xi}}\frac{\mathrm{sgn}(\xi)}{|\xi|^{1/2}}\left(\int_{\mathbb{R}_{\eta}}e^{i(y/t^{1/2})|\xi|^{1/2}\eta - i\mathrm{sgn}(\xi)\eta^2}d\eta\right)e^{ix\xi+it\xi|\xi|^{\alpha}}d\xi \\ &= \frac{c}{t^{1/2}}\int_{\mathbb{R}}\frac{(\mathrm{sgn}(\xi))e^{-i(\mathrm{sgn}(\xi))\frac{\pi}{4}}}{|\xi|^{1/2}}e^{iy^2\xi/4t}\,e^{ix\xi+it\xi|\xi|^{\alpha}}d\xi \\ &= \frac{c}{t^{\frac{\alpha+2}{2(\alpha+1)}}}\int_{\mathbb{R}}\frac{(\mathrm{sgn}(\xi))e^{-i(\mathrm{sgn}(\xi))\frac{\pi}{4}}}{|\xi|^{1/2}}\exp\left(i\xi\left(\frac{x}{t^{\frac{1}{\alpha+1}}} + \frac{y^2}{4t^{\frac{\alpha+2}{\alpha+1}}}\right)\right)e^{i\xi|\xi|^{\alpha}}d\xi\,. \end{aligned}$$

We now need the following lemma.

LEMMA 2.1. *Let for $\alpha > 0$*

$$F(\lambda) = \int_{\mathbb{R}}\frac{(\mathrm{sgn}(\xi))e^{-i(\mathrm{sgn}(\xi))\frac{\pi}{4}}}{|\xi|^{1/2}}e^{i\lambda\xi+i\xi|\xi|^{\alpha}}d\xi\,.$$

Then F is a continuous function which tends to zero as $|\lambda| \to +\infty$.

Proof. Write F as

$$F(\lambda) = \int_{|\xi|\leq 1} + \int_{|\xi|\geq 1} := F_1(\lambda) + F_2(\lambda)\,.$$

Since $|\xi|^{-1/2}$ in integrable near the origin, by the Riemann–Lebesgue lemma $F_1(\lambda)$ is continuous and

$$\lim_{|\lambda|\to\infty} F_1(\lambda) = 0\,.$$

We consider two cases in the analysis of $F_2(\lambda)$.

Case 1. $\lambda \geq -1$.

After an integration by parts, we obtain that

$$\begin{aligned}(2.4)\quad F_2(\lambda) = &\frac{c\cos(\lambda+1-\frac{\pi}{4})}{\lambda+\alpha+1}\\ &+ c\int_1^\infty \cos\Big(\lambda\xi+\xi^{\alpha+1}-\frac{\pi}{4}\Big)\,\frac{\lambda+(\alpha+1)(2\alpha+1)\xi^\alpha}{\xi^{3/2}(\lambda+(\alpha+1)\xi^\alpha)^2}\,d\xi\,.\end{aligned}$$

The first term is clearly a continuous function of λ which tends to zero as $\lambda\to\infty$. Observing that

$$0 \leq \frac{\lambda+(\alpha+1)(2\alpha+1)\xi^\alpha}{\xi^{3/2}(\lambda+(\alpha+1)\xi^\alpha)^2} \leq C_\alpha \xi^{-3/2}$$

uniformly with respect to $\xi\geq 1$ and $\lambda\geq -1$, we deduce from the dominated convergence theorem that the right-hand side of (2.4) is a continuous function of λ for $\lambda\geq -1$. On the other hand, for $\lambda\geq 1$,

$$\frac{\lambda+(\alpha+1)(2\alpha+1)\xi^\alpha}{\xi^{3/2}(\lambda+(\alpha+1)\xi^\alpha)^2} \leq \frac{2\alpha+1}{\lambda\xi^{3/2}},$$

and thus the right-hand side of (2.4) tends to zero as $\lambda\to+\infty$.

Case 2. $\lambda\leq -1$.

Set $\lambda=-\mu$ with $\mu\geq 1$. In the integral over $|\xi|\geq 1$ defining $F_2(\lambda)$, we consider only the integration over $[1,+\infty[$. The integration over $]-\infty,-1]$ can be treated in a completely analogous way. We perform the changes of variables

$$\xi \longrightarrow \xi^2$$

and

$$\xi \longrightarrow \mu^{\frac{1}{2\alpha}}\xi$$

to conclude that

$$\widetilde{F_2}(\lambda) := c\int_1^\infty \frac{1}{\xi^{1/2}} e^{i\lambda\xi+i\xi|\xi|^\alpha}\,d\xi = c\mu^{\frac{1}{2\alpha}}\int_{\mu^{-\frac{1}{2\alpha}}}^\infty e^{i\mu^{1+\frac{1}{\alpha}}\left[\xi^{2(\alpha+1)}-\xi^2\right]}\,d\xi.$$

Let us set

$$\varphi(\xi) = \xi^{2(\alpha+1)} - \xi^2\,.$$

Then

$$\varphi'(\xi) = 2\xi[(\alpha+1)\xi^{2\alpha} - 1]\,.$$

Let us split

$$\widetilde{F_2}(\lambda) = c\mu^{\frac{1}{2\alpha}} \int_{\mu^{-\frac{1}{2\alpha}}}^{1} + c\mu^{\frac{1}{2\alpha}} \int_{1}^{\infty} := I_1(\mu) + I_2(\mu)\,.$$

Since $\varphi'(\xi)$ does not vanish for $\xi \geq 1$, we can integrate by parts, which gives

$$I_2(\mu) = \frac{1}{2i\mu^{1+\frac{1}{2\alpha}}} \left(\frac{c}{\alpha} + c\int_1^\infty e^{i\mu^{1+\frac{1}{\alpha}}\left[\xi^{2(\alpha+1)}-\xi^2\right]}\ \frac{(\alpha+1)(2\alpha+1)\xi^{2\alpha}-1}{\xi^2((\alpha+1)\xi^{2\alpha}-1)^2} d\xi \right),$$

which is a continuous function of $\mu \geq 1$ thanks to the dominated convergence theorem. Moreover, it clearly tends to zero as $\mu \to +\infty$.

Let us next analyze $I_1(\mu)$. We first observe that thanks to the dominated convergence theorem, $I_1(\mu)$ is a continuous function of μ. It remains to prove that $I_1(\mu) \to 0$ as $\mu \to \infty$. For $\xi \in [\mu^{-\frac{1}{2\alpha}}, 1]$, the phase φ has a critical point, and a slightly more delicate argument is needed. Compute

$$\varphi''(\xi) = 2[(\alpha+1)(2\alpha+1)\xi^{2\alpha} - 1]\,.$$

Observe that $\varphi'(\xi)$ is vanishing only at zero and

$$\xi_1(\alpha) := \left(\frac{1}{\alpha+1}\right)^{\frac{1}{2\alpha}} \quad .$$

Next, we notice that $\varphi''(\xi)$ is vanishing at

$$\xi_2(\alpha) := \left(\frac{1}{(\alpha+1)(2\alpha+1)}\right)^{\frac{1}{2\alpha}} \quad .$$

Clearly $\xi_2(\alpha) < \xi_1(\alpha) < 1$, and we choose a real number δ such that

$$\xi_2(\alpha) < \delta < \xi_1(\alpha) < 1\,.$$

For $\mu \gg 1$, we can split

$$I_1(\mu) = c\mu^{\frac{1}{2\alpha}} \int_{\mu^{-\frac{1}{2\alpha}}}^{\delta} + c\mu^{\frac{1}{2\alpha}} \int_{\delta}^{1} := J_1(\mu) + J_2(\mu)\ .$$

For $\xi \in [\mu^{-\frac{1}{2\alpha}}, \delta]$, we have the lower bound

$$|\varphi'(\xi)| \geq c\mu^{-\frac{1}{2\alpha}} > 0,$$

and an integration by parts shows that

$$J_1(\mu) = \mu^{\frac{1}{\alpha}}\,\mathcal{O}(\mu^{-1-\frac{1}{\alpha}}) \leq C\mu^{-1},$$

which clearly tends to zero as $\mu \to \infty$. For $\xi \in [\delta, 1]$, we have the minoration

$$|\varphi''(\xi)| \geq c > 0,$$

and therefore we can apply the Van der Corput lemma (see [16, Proposition 2]) to conclude that

$$J_2(\mu) = \mu^{\frac{1}{2\alpha}} \mathcal{O}(\mu^{-\frac{1}{2}-\frac{1}{2\alpha}}) \le C\mu^{-\frac{1}{2}},$$

which tends to zero as $\mu \to \infty$. This completes the proof of Lemma 2.1. ∎

It is now easy to check that $\partial_x A = G$ in the sense of distributions. Since both A and G are continuous, we deduce that A has a classical derivative with respect to x which is equal to G. Finally, since $\varphi \in L^1(\mathbb{R}^2)$, applying Lemma 2.1 and the Lebesgue theorem completes the proof of Theorem 2.1. ∎

2.2. The nonlinear case. After a change of frame we can eliminate the u_x term and reduce the Cauchy problem for (1.7) to

$$(u_t + uu_x - Lu_x)_x + u_{yy} = 0, \quad u(0,x,y) = \varphi(x,y). \tag{2.5}$$

In order to state our result concerning (2.5), for $k \in \mathbb{N}$, we denote by $H^{k,0}(\mathbb{R}^2)$ the Sobolev space of $L^2(\mathbb{R}^2)$ functions $u(x,y)$ such that $\partial_x^k u \in L^2(\mathbb{R}^2)$.

Theorem 2.2. *Assume that $\alpha > 1/2$. Let $\varphi \in L^1(\mathbb{R}^2) \cap H^{2,0}(\mathbb{R}^2)$ and*

$$u \in C([0,T]\,;\, H^{2,0}(\mathbb{R}^2)) \tag{2.6}$$

be a distributional solution of (2.5). Then, for every $t \in (0,T]$, $u(t,\cdot,\cdot)$ is a continuous function of x and y which satisfies

$$\int_{-\infty}^{\infty} u(t,x,y)dx = 0 \quad \forall y \in \mathbb{R},\ \ \forall t \in (0,T]$$

in the sense of generalized Riemann integrals. Moreover, $u(t,x,y)$ is the derivative with respect to x of a C_x^1 continuous function which vanishes as $x \to \pm\infty$ for every fixed $y \in \mathbb{R}$ and $t \in [0,T]$.

Remark 2.3. *The case $\alpha = 2$ corresponds to the classical KP-I, KP-II equations. In the case of the KP-II, we have global solutions for data in $L^1(\mathbb{R}^2) \cap H^{2,0}(\mathbb{R}^2)$ (see [5]). Thus Theorem 2.2 displays a striking smoothing effect of the KP-II equation: $u(t,\cdot,\cdot)$ becomes a continuous function of x and y (with zero mean in x) for $t \neq 0$ (note that $L^1(\mathbb{R}^2) \cap H^{2,0}(\mathbb{R}^2)$ is not included in $C^0(\mathbb{R}^2)$). A similar comment is valid for the local solutions of the KP-I equation in [10] and more especially in [12].*

Remark 2.4. *The numerical simulations in [9] display clearly the phenomena described in Theorem 2.2 in the case of the KP-I equation.*

Proof of Theorem 2.2. Under our assumption on u, one has the Duhamel representation

$$u(t) = S(t)\varphi - \int_0^t S(t-s)\big(u(s)u_x(s)\big)ds, \tag{2.7}$$

where

$$\int_0^t S(t-s)\big(u(s)u_x(s)\big)ds = \int_0^t \partial_x \left(\int_{\mathbb{R}^2} A(x-x', y-y', t-s)(uu_x)(x',y',s)dx'dy' \right) ds\,.$$

From Theorem 2.1, it suffices to consider only the integral term in the right-hand side of (2.7). Using the notations of Lemma 2.1,

$$A(x-x',y-y',t-s)=\frac{c}{(t-s)^{\frac{\alpha+2}{2(\alpha+1)}}}F\left(\frac{x-x'}{(t-s)^{\frac{1}{\alpha+1}}}+\frac{(y-y')^2}{4(t-s)^{\frac{\alpha+2}{\alpha+1}}}\right).$$

Recall that F is a continuous and bounded function on $\mathbb{R}$. Next, we set

$$I(x,y,t-s,s)\equiv\partial_x\left(\int_{\mathbb{R}^2}A(x-x',y-y',t-s)(uu_x)(x',y',s)dx'dy'\right).$$

Using the Lebesgue differentiation theorem and the assumption (2.6), we can write

$$I(x,y,t-s,s)=\int_{\mathbb{R}^2}A(x-x',y-y',t-s)\partial_x(uu_x)(x',y',s)dx'dy'.$$

Moreover, for $\alpha>0$,

$$\frac{\alpha+2}{2(\alpha+1)}<1,$$

and therefore I is integrable in s on $[0,t]$. Therefore, by the Lebesgue differentiation theorem,

$$\int_0^t\int_{\mathbb{R}^2}A(x-x',y-y',t-s)(uu_x)(x',y',s)dx'dy'ds \tag{2.8}$$

is a C_x^1 function and

$$\int_0^t S(t-s)\big(u(s)u_x(s)\big)ds$$
$$=\partial_x\left(\int_0^t\int_{\mathbb{R}^2}A(x-x',y-y',t-s)(uu_x)(x',y',s)dx'dy'ds\right).$$

Let us finally show that for fixed y and t the function (2.8) tends to zero as x tends to $\pm\infty$. For that purpose, it suffices to apply the Lebesgue dominated convergence theorem to the integral in s,x',y'. Indeed, for fixed s,x',y', the function under the integral tends to zero as x tends to $\pm\infty$ thanks to the linear analysis. On the other hand, using Lemma 2.1, we can write

$$|A(x-x',y-y',t-s)(uu_x)(x',y',s)|\le\frac{c}{(t-s)^{\frac{\alpha+2}{2(\alpha+1)}}}|(uu_x)(x',y',s)|.$$

Thanks to the assumptions on u, the right-hand side of the above inequality is integrable in s,x',y' and independent of x. Thus we can apply the Lebesgue dominated convergence theorem to conclude that the function (2.8) tends to zero as x tends to $\pm\infty$. This completes the proof of Theorem 2.2. □

REMARK 2.5. *If $\alpha>2$, the assumptions can be weakened to $\varphi\in L^1(\mathbb{R}^2)\cap H^{1,0}(\mathbb{R}^2)$ and $u\in C([0,T];H^{1,0}(\mathbb{R}^2))$. This result follows from the fact that the fundamental solution G writes*

$$G(t,x,y)=\frac{c}{t^{1/2+3/2(\alpha+1)}}B(t,x,y),$$

where $B\in L^\infty$ and $1/2+3/(2(\alpha+1))<1$ for $\alpha>2$.

3. KP–BBM-type equations.

3.1. The linear case. We consider the Cauchy problem

$$(u_t + u_x + Lu_t)_x + u_{yy} = 0, \quad u(0,x,y) = \varphi(x,y)\,, \tag{3.1}$$

where L is given by (2.2) with $\varepsilon = 1$. A simple computation shows that the fundamental solution is given by

$$G(t,x,y) = \mathcal{F}^{-1}\big[e^{-i\frac{t}{1+|\xi|^\alpha}(\xi+\eta^2/\xi)}\big]\,.$$

Due to the bad oscillatory properties of the phase, we have to modify slighty the statement of Theorem 2.1.

THEOREM 3.1. *Assume that $\alpha > 0$. Let φ be such that $(I-\partial_x^2)^{\beta/2}\varphi \in L^1(\mathbb{R}^2)$ with $\beta > (\alpha+3)/2$. Then*

$$u(t,\cdot,\cdot) \equiv S(t)\varphi = G \star \varphi$$

can be written as

$$\frac{\partial}{\partial x}\big(A \star (I-\partial_x^2)^{\beta/2}\varphi\big),$$

where

$$A = \partial_x^{-1}(I-\partial_x^2)^{-\beta/2}G$$

and

$$A(t,\cdot,\cdot) \in C(\mathbb{R}^2) \cap L^\infty(\mathbb{R}^2) \cap C_x^1(\mathbb{R}^2)\,.$$

Moreover, $(A \star (I-\partial_x^2)^{\beta/2}\varphi)(t,x,y)$ is, for fixed $t \neq 0$, continuous in x and y and satisfies

$$\lim_{|x|\to\infty}(A \star (I-\partial_x^2)^{\beta/2}\varphi)(t,x,y) = 0$$

for any $y \in \mathbb{R}$ and $t \neq 0$. Thus,

$$\int_{-\infty}^{\infty} u(t,x,y)\,dx = 0 \quad \forall y \in \mathbb{R}, \;\; \forall t \neq 0$$

in the sense of generalized Riemann integrals.

REMARK 3.1. *The assumption $(I-\partial_x^2)^{\beta/2}\varphi \in L^1(\mathbb{R}^2)$ is natural in the context of KP–BBM problems, in view of the weak dispersive properties of the BBM free evolution.*

Proof. We set

$$\tilde{G}(t,x,y) = \int_{\mathbb{R}^2} \frac{1}{(1+|\xi|^2)^{\beta/2}}\; e^{-\frac{it}{1+|\xi|^\alpha}(\xi+\eta^2/\xi)} e^{ix\xi+iy\eta} d\xi d\eta\,.$$

Setting

$$\eta' = \frac{t^{1/2}\eta}{|\xi|^{1/2}(1+|\xi|^\alpha)^{1/2}}\,,$$

we obtain

$$
\begin{aligned}
&\tilde{G}(t,x,y)\\
&= \frac{c}{t^{1/2}} \int_{\mathbb{R}_\xi} |\xi|^{1/2} \frac{(1+|\xi|^\alpha)^{1/2}}{(1+|\xi|^2)^{\beta/2}} \left(\int_{\mathbb{R}_\eta} e^{-i\operatorname{sgn}(\xi)\eta^2} e^{i(y\eta/t^{1/2})|\xi|^{1/2}(1+|\xi|^\alpha)^{1/2}} d\eta \right) e^{ix\xi - i\frac{t\xi}{1+|\xi|^\alpha}} d\xi\\
&= \frac{c}{t^{1/2}} \int_{\mathbb{R}} |\xi|^{1/2} e^{-i(\operatorname{sgn}(\xi))\frac{\pi}{4}} \frac{(1+|\xi|^\alpha)^{1/2}}{(1+|\xi|^2)^{\beta/2}} e^{-i\frac{t\xi}{1+|\xi|^\alpha}} e^{i\lambda\xi} e^{i(y^2/4t)\xi|\xi|^\alpha} d\xi\,,
\end{aligned}
$$

where $\lambda = x + y^2/4t$. Setting

$$
a_t(\xi) = |\xi|^{1/2} e^{-i(\operatorname{sgn}(\xi))\frac{\pi}{4}} \frac{(1+|\xi|^\alpha)^{1/2}}{(1+|\xi|^2)^{\beta/2}} e^{-it\frac{\xi}{1+|\xi|^\alpha}}\,,
$$

we clearly have

$$
\tilde{G}(t,x,y) = \frac{c}{t^{1/2}} \int a_t(\xi) e^{i\lambda\xi} e^{i(y^2/4t)\xi|\xi|^\alpha} d\xi\,.
$$

We have the following lemma.

Lemma 3.1. *Let us fix $y \in \mathbb{R}$ and $t > 0$. Set*

$$
F(\lambda) := \int a_t(\xi) e^{i\lambda\xi} e^{i(y^2/4t)\xi|\xi|^\alpha} d\xi\,.
$$

Then F is a continuous function such that

$$
\lim_{|\lambda|\to\infty} F(\lambda) = 0\,.
$$

Proof. It suffices to apply the Riemann–Lebesgue lemma since $a \in L^1(\mathbb{R})$ when $\beta > (\alpha+3)/2$. $\square$

Next, we set

$$
\tilde{A}(t,x,y) = -i \int_{\mathbb{R}^2} \frac{1}{\xi(1+|\xi|^2)^{\beta/2}}\ e^{-\frac{it}{1+|\xi|^\alpha}(\xi+\eta^2/\xi)} e^{ix\xi+iy\eta} d\xi d\eta\,.
$$

Similarly to above, we set

$$
\eta' = \frac{\eta t^{1/2}}{|\xi|^{1/2}(1+|\xi|^\alpha)^{1/2}}\,,
$$

and therefore

$$
\begin{aligned}
&\tilde{A}(t,x,y)\\
&= \frac{c}{t^{1/2}} \int_{\mathbb{R}_\xi} \frac{\operatorname{sgn}(\xi)}{|\xi|^{1/2}} \frac{(1+|\xi|^\alpha)^{1/2}}{(1+|\xi|^2)^{\beta/2}} \left(\int_{\mathbb{R}_\eta} e^{-i\operatorname{sgn}(\xi)\eta^2} e^{iy\eta/t^{1/2}|\xi|^{1/2}(1+|\xi|^\alpha)^{1/2}} d\eta \right) e^{ix\xi - i\frac{t\xi}{1+|\xi|^\alpha}} d\xi\\
&= \frac{c}{t^{1/2}} \int_{\mathbb{R}} \frac{\operatorname{sgn}(\xi)}{|\xi|^{1/2}} e^{-i(\operatorname{sgn}(\xi))\frac{\pi}{4}} \frac{(1+|\xi|^\alpha)^{1/2}}{(1+|\xi|^2)^{\beta/2}} e^{-it\frac{\xi}{1+|\xi|^\alpha}} e^{i\lambda\xi} e^{i(y^2/4t)\xi|\xi|^\alpha} d\xi\,,
\end{aligned}
$$

where $\lambda = x + y^2/4t$. Setting

$$
\tilde{a}_t(\xi) = \frac{\operatorname{sgn}(\xi)}{|\xi|^{1/2}} e^{-i(\operatorname{sgn}(\xi))\frac{\pi}{4}} \frac{(1+|\xi|^\alpha)^{1/2}}{(1+|\xi|^2)^{\beta/2}} e^{-i\frac{t\xi}{1+|\xi|^\alpha}}\,,
$$

we clearly have

$$\tilde{A}(t,x,y) = \frac{c}{t^{1/2}} \int \tilde{a}_t(\xi) e^{i\lambda\xi}\, e^{i(y^2/4t)\xi|\xi|^\alpha} d\xi\,.$$

LEMMA 3.2. *Let us fix $y \in \mathbb{R}$ and $t > 0$. Set*

$$F_1(\lambda) := \int \tilde{a}_t(\xi) e^{i\lambda\xi}\, e^{i(y^2/4t)\xi|\xi|^\alpha} d\xi\,.$$

Then F_1 is a continuous function such that

$$\lim_{|\lambda|\to\infty} F_1(\lambda) = 0\,.$$

Proof. It suffices to apply the Riemann–Lebesgue lemma since $\tilde{a}_t \in L^1(\mathbb{R})$. ∎

The proof of Theorem 3.1 is now straightforward. ∎

3.2. The nonlinear case. We investigate the Cauchy problem

$$(u_t + u_x + uu_x + Lu_t)_x + u_{yy} = 0, \quad u(0,x,y) = \varphi(x,y)\,. \tag{3.2}$$

THEOREM 3.2. *Let $\alpha > 0$, $k > \frac{\alpha+3}{4}$. Assume that $(I - \partial_x^2)^k \varphi \in L^1(\mathbb{R}^2) \cap L^2(\mathbb{R}^2)$. Let u be a solution of (3.2) such that*

$$u \in C([0,T]\,;\, H^{2k+1,0}(\mathbb{R}^2))\,.$$

Then, for any $t \in (0,T]$, $u(t,x,y)$ is a continuous function in x and y and satisfies

$$\int_{-\infty}^{\infty} u(t,x,y)dx = 0 \quad \forall y \in \mathbb{R},\ \ \forall t \in (0,T]$$

in the sense of generalized Riemann integrals. In fact $u(t,x,y)$ is the derivative with respect to x of a C_x^1 continuous function which vanishes as $x \to \pm\infty$ for any fixed y and $t \in (0,T]$.

Proof. Again we use the Duhamel formula

$$u(t) = S(t)\varphi - \int_0^t S(t-s)u(s)u_x(s)ds,$$

where

$$S(t) = e^{it(I+L)^{-1}(\partial_x + \partial_x^{-1}\partial_y^2)}\,.$$

By Theorem 3.1, it suffices to consider the integral term in the Duhamel formula. We have

$$\int_0^t S(t-s)u(s)u_x(s)ds = \frac{1}{2}\int_0^t \frac{\partial}{\partial x}\Big(S(t-s)u^2(s)\Big)ds = \frac{1}{2}\frac{\partial}{\partial x}\int_0^t S(t-s)u^2(s)ds.$$

To justify the last equality, we have to check that $S(t-s)u(s)u_x(s)$ is dominated by a $L^1(0,t)$ function uniformly in (x,y). We write

$$S(t-s)(u(s)u_x(s)) = \tilde{A}(x,y,t-s) \star (I - \partial_x^2)^k u(s)u_x(s), \tag{3.3}$$

where

$$\tilde{A}(x,y,t-s) = \int_{\mathbb{R}^2} \frac{1}{(1+|\xi|^2)^k} e^{-\frac{i(t-s)}{1+|\xi|^\alpha}(\xi+\eta^2/\xi)} e^{ix\xi+iy\eta} d\xi d\eta \,.$$

Proceeding as in the beginning of the proof of Theorem 3.1, it follows that

$$\tilde{A}(x,y,t-s) = \frac{c}{(t-s)^{1/2}} \int_{\mathbb{R}} \frac{e^{-i(\mathrm{sgn}(\xi))\frac{\pi}{4}} |\xi|^{1/2}(1+|\xi|^\alpha)^{1/2}}{(1+\xi^2)^k} e^{-i\frac{\xi(t-s)}{1+|\xi|^\alpha}} e^{i\lambda\xi} e^{i(y^2/4(t-s))\xi|\xi|^\alpha} d\xi \,,$$

where $\lambda = x + y^2/4(t-s)$. Since $k > \frac{\alpha+3}{4}$, the integral in ξ defines a continuous bounded function in x, y, t, s by the Riemann–Lebesgue theorem. It follows that

$$|S(t-s)u(s)u_x(s)| \le \frac{c}{(t-s)^{1/2}} \|(I-\partial_x^2)^k(uu_x)\|_{L^1(\mathbb{R}^2)} \le \frac{c}{(t-s)^{1/2}}$$

since $u \in C([0,T]\,;\, H^{2k+1,0}(\mathbb{R}^2))$. Since the function

$$\frac{e^{-i(\mathrm{sgn}(\xi))\frac{\pi}{4}} |\xi|^{1/2}(1+|\xi|^\alpha)^{1/2}}{(1+\xi^2)^k} e^{-i\frac{\xi(t-s)}{1+\xi^\alpha}}$$

belongs to $L^1(\mathbb{R}_\xi)$, we can use the Riemann–Lebesgue lemma to obtain that for fixed y, t, and s the function $\tilde{A}(x,y,t-s)$ tends to zero as x tends to $\pm\infty$. Moreover, the absolute value of $\tilde{A}(x,y,t-s)$ is bounded by $c|t-s|^{-1/2}$. Thus as in the proof of Theorem 2.2, we can apply the Lebesgue dominated convergence theorem to conclude that

$$\lim_{x\to\pm\infty} \int_0^t S(t-s)u^2(s)ds = 0$$

for any fixed $y \in \mathbb{R}$ and $t \in (0,T]$. This achieves the proof of Theorem 3.2. $\square$

REMARK 3.2. *For large values of α, one can relax the assumptions on k in the hypothesis for u by simply using the H^s unitary property of $S(t)$.*

4. Extensions. With the price of some technicalities, one could consider symbols $c(\xi)$ in (1.2) which behave like $|\xi|^\alpha$ at infinity but which are not homogeneous.

Let us finally comment briefly on the three-dimensional case. For simplicity, we consider only the KP-type equations:

$$(u_t - Lu_x)_x + u_{yy} + u_{zz} = 0, \quad u(0,x,y,z) = \varphi(x,y,z) \tag{4.1}$$

with L given by (2.2). Following the lines of the proof of Theorem 2.1, we find that the fundamental solution G can be expressed as $G = \partial_x A$, where

$$A(t,x,y,z) = \frac{c}{t^{1+\frac{2}{\alpha+2}}} \int_{\mathbb{R}} \mathrm{sgn}(\xi)\, e^{-i(\mathrm{sgn}(\xi))\frac{\pi}{4}} e^{i\xi(x/t^{1/(\alpha+1)}+(y^2+z^2)/4t)} \, e^{i\xi|\xi|^\alpha} \, d\xi \,.$$

We first notice that, when $\alpha > 1$, G is a well-defined continuous function of (x,y,z). Actually the proof follows the same lines as the two-dimensional case. Let

$$F(\lambda) = \int_{\mathbb{R}} \mathrm{sgn}(\xi) e^{-i(\mathrm{sgn}(\xi))\frac{\pi}{4}} e^{i\lambda\xi} \, e^{i\xi|\xi|^\alpha} \, d\xi \,.$$

By a result of [15], $F(\lambda)$ is a continuous function which tends to zero as $|\lambda| \to \infty$, provided $\alpha > 1$, (notice that this excludes the case $\alpha = 1$ which would correspond to the three-dimensional generalizations of the Benjamin–Ono equation). We thus obtain the exact counterpart of Theorem 2.1 in the three-dimensional case when $\alpha > 1$ (this includes the three-dimensional usual KP equations).

TWO-SCALE HOMOGENIZATION FOR EVOLUTIONARY VARIATIONAL INEQUALITIES VIA THE ENERGETIC FORMULATION*

ALEXANDER MIELKE† AND AIDA M. TIMOFTE‡

Abstract. This paper is devoted to two-scale homogenization for a class of rate-independent systems described by the energetic formulation or equivalently by an evolutionary variational inequality. In particular, we treat the classical model of linearized elastoplasticity with hardening. The associated nonlinear partial differential inclusion has periodically oscillating coefficients, and the aim is to find a limit problem for the case in which the period tends to 0. Our approach is based on the notion of *energetic solutions*, which is phrased in terms of a stability condition and an energy balance of an energy-storage functional and a dissipation functional. Using the recently developed method of *weak and strong two-scale convergence* via *periodic unfolding*, we show that these two functionals have a suitable two-scale limit, but now involving the macroscopic variable in the physical domain as well as the microscopic variable in the periodicity cell. Moreover, relying on an abstract theory of Γ-convergence for the energetic formulation using so-called *joint recovery sequences*, it is possible to show that the solutions of the problem with periodicity converge to the energetic solution associated with the limit functionals.

Key words. weak two-scale convergence, strong two-scale convergence, two-scale Γ-limit, rate-independent evolution, energetic formulation, elastoplasticity with hardening

1. Introduction.

Our aim is to provide homogenization results for evolutionary variational inequalities of the following type:

$$\forall\, v \in \mathcal{Q}: \ \langle \mathcal{A}q - \ell(t), v - \dot{q} \rangle + \mathcal{R}(v) - \mathcal{R}(\dot{q}) \geq 0. \tag{1.1}$$

Here $\mathcal{Q}$ is a Hilbert space with dual $\mathcal{Q}^*$, and the continuous linear operator $\mathcal{A} : \mathcal{Q} \to \mathcal{Q}^*$ is symmetric and positive definite on the cone on which $\mathcal{R}$ is finite. The forcing ℓ lies in $\mathrm{C}^1([0,T], \mathcal{Q}^*)$, and the dissipation functional $\mathcal{R} : \mathcal{Q} \to [0, \infty)$ is convex, lower semicontinuous, and positively homogeneous of degree 1, i.e., $\mathcal{R}(\gamma q) = \gamma \mathcal{R}(q)$ for all $\gamma \geq 0$ and $q \in \mathcal{Q}$. The latter property of $\mathcal{R}$ leads to rate independence.

Problem (1.1) has many different equivalent formulations. We have chosen the *energetic formulation* for rate-independent hysteresis problems (cf. [MT99, MT04, Mie05]), since it is more flexible in treating general rate-independent energetic material models, including nonconvexities and strong nonlinearities; see [Mie03, Mie04, MT06, FM06]. We hope that our methods simplify and clarify the theory of two-scale convergence and thus provide ideas and tools for solving more general prob-

lems, including nonlinear elastic effects. A similar development was initiated in [Alb00, Alb03, Nes06, Nes07] based on the theory of monotone operators. This theory allows for rate-dependent effects, but is restricted to linearized elasticity.

The energetic formulation is based on the storage functional $\mathcal{E} : [0,T]\times\mathcal{Q} \to \mathbb{R}$ defined via $\mathcal{E}(t,q) = \frac{1}{2}\langle \mathcal{A}q, q\rangle - \langle \ell(t), q\rangle$ and the dissipation functional $\mathcal{R}$. Thus, homogenization of an evolutionary problem can be reduced to some extent to the homogenization of functionals. A function $q : [0,T] \to \mathcal{Q}$ is called an *energetic solution* associated with the functionals $\mathcal{E}$ and $\mathcal{R}$ if for all $t \in [0,T]$ it satisfies the *global stability condition* (S) and the *energy balance* (E):

$$\text{(S)} \quad \forall\, q \in \mathcal{Q} :\ \mathcal{E}(t,q(t)) \le \mathcal{E}(t,q) + \mathcal{R}(q{-}q(t));$$

$$\text{(E)} \quad \mathcal{E}(t,q(t)) + \int_0^t \mathcal{R}(\dot q(s))\,\mathrm{d}s = \mathcal{E}(0,q(0)) - \int_0^t \langle \dot\ell(s), q(s)\rangle\,\mathrm{d}s.$$

We also say that q solves the *energetic formulation* (S) and (E) associated with $\mathcal{E}$ and $\mathcal{R}$.

Note that rate-independent hysteresis phenomena occur in quite general systems like hyperbolic PDEs for electromagnetism; cf. [Vis94, BS96]. Then hysteresis operators are seen as constitutive relations and are coupled to general balance equations. Here, as a first step, we treat only purely rate-independent processes which are relevant in elastoplasticity and other material models.

In this paper we consider a family of energy functionals $(\mathcal{E}_\varepsilon)_\varepsilon$ and of dissipation functionals $(\mathcal{R}_\varepsilon)_\varepsilon$ which are defined as integrals over a domain $\Omega \subset \mathbb{R}^d$ and where the densities depend periodically on x with a period proportional to ε. More precisely, for a periodicity lattice Λ we denote by $\mathcal{Y} = \mathbb{R}^d/_{\Lambda}$ the periodicity torus. For a tensor-valued mapping $\mathbb{A} : \mathcal{Y} \to \mathrm{Lin}(\mathbb{R}^{d\times d}_{\mathrm{sym}}\times\mathbb{R}^m)$ and a function $\rho : \mathcal{Y}\times\mathbb{R}^m \to [0,\infty]$ we define the functionals

$$\mathcal{E}_\varepsilon(t,u,z) = \int_\Omega \frac{1}{2} \left\langle\!\!\left\langle \mathbb{A}\left(\frac{x}{\varepsilon}\right) \begin{pmatrix} \boldsymbol{e}(u) \\ z \end{pmatrix}, \begin{pmatrix} \boldsymbol{e}(u) \\ z \end{pmatrix} \right\rangle\!\!\right\rangle \mathrm{d}x - \langle \ell(t), u\rangle,$$
$$\mathcal{R}_\varepsilon(z) = \int_\Omega \rho\left(\frac{x}{\varepsilon}, z(x)\right) \mathrm{d}x$$

on the space $\mathcal{Q} = \mathrm{H}^1_{\Gamma_{\mathrm{Dir}}}(\Omega)^d\times\mathrm{L}^2(\Omega)^m$.

The task is now to describe the limiting behavior of the associated energetic solutions. Because of the nonsmoothness and the hysteretic behavior of the evolution of the systems, it will not be possible to find a homogenized limit equation in the classical sense. This would mean finding limiting functionals defined on Ω again. Instead we will need the so-called two-scale homogenization that decomposes solutions into macroscopic and microscopic behavior.

The classical notion of two-scale convergence was introduced by Nguetseng in 1989 [Ngu89] and further developed by Allaire in 1992 [All92]. It aimed for a better description of sequences of oscillating functions and thus for the derivation of a new homogenization method. In [LNW02], an overview of the main homogenization problems which have been studied by this technique is given. This concept is applied in a variety of quite different applications in continuum mechanics; see, e.g., [BM93, HJM94, Vis96, BLM96, Vis97, Alb00, EKK02, MS02]. Moreover, even in engineering this method is used extensively for numerical simulations. There the unit periodicity cell is usually called a “representative unit cell.”

To explain our results in some detail we introduce a few new notions. The two-scale method relies on a micro-macro-decomposition of points $x \in \mathbb{R}^d$ via

$$x = \mathcal{N}_\varepsilon(x) + \varepsilon \mathcal{R}_\varepsilon(x) \quad \text{with } \mathcal{N}_\varepsilon(x) = \varepsilon \left[\frac{x}{\varepsilon}\right]_\Lambda \text{ and } \mathcal{R}_\varepsilon(x) = \left\{\frac{x}{\varepsilon}\right\}_Y,$$

where $[\widetilde{x}]_\Lambda$ is the closest lattice point to $\widetilde{x}$ and $\{\widetilde{x}\}_Y$ is the remainder; see section 2.1 for the exact details. The decomposition of functions is then done by the so-called *periodic unfolding* introduced in [CDG02, CDD04, CDD06]:

$$(\mathcal{T}_\varepsilon u)(x, y) = u_{\text{ex}}(\mathcal{N}_\varepsilon(x) + \varepsilon y),$$

where u_{ex} is the extension of $u : \Omega \to \mathbb{R}$ by 0 to all of $\mathbb{R}^d$. Thus, functions in $\mathrm{L}^p(\Omega)$ are mapped to functions $U = \mathcal{T}_\varepsilon u \in \mathrm{L}^p(\mathbb{R}^d \times \mathcal{Y})$. Similar ideas, called "dilation operators," were used before in [ADH90]. See also [LSB99] for an application in electrical networks.

In section 2.2 we discuss this periodic unfolding operator together with a newly introduced *folding operator* $\mathcal{F}_\varepsilon : \mathrm{L}^p(\mathbb{R}^d \times \mathcal{Y}) \to \mathrm{L}^p(\Omega)$, which is a kind of pseudoinverse as well as the adjoint operator (when taking the conjugate exponent p). In particular, we give special care to the complications arising from the mismatch of Ω and a finite union of small cells of type $\varepsilon(\lambda + Y)$.

In section 2.3 we introduce our notion of *weak and strong two-scale convergences*:

$$u_\varepsilon \overset{\text{w2}}{\rightharpoonup} U \quad \Longleftrightarrow \quad \mathcal{T}_\varepsilon u_\varepsilon \rightharpoonup U_{\text{ex}} \ \text{ in } \mathrm{L}^p(\mathbb{R}^d \times \mathcal{Y}),$$
$$u_\varepsilon \xrightarrow{\text{s2}} U \quad \Longleftrightarrow \quad \mathcal{T}_\varepsilon u_\varepsilon \to U_{\text{ex}} \ \text{ in } \mathrm{L}^p(\mathbb{R}^d \times \mathcal{Y}).$$

This definition is an adaptation of the definitions in [Vis04] to the case that Ω has a boundary; see also [Vis06b]. Nevertheless, the convergences on the right-hand side are asked to occur in $\mathrm{L}^p(\mathbb{R}^d \times \mathcal{Y})$, since the support of $\mathcal{T}_\varepsilon u$ is in general not contained in $\Omega \times \mathcal{Y}$. We relate our definitions to the ones which are used in [Ngu89, All92, CD99, LNW02] and show that our strengthening makes many relations more natural. In particular, the notions of weak and strong two-scale convergences allow us to prove the convergence of scalar products, namely,

$$u_n \overset{\text{w2}}{\rightharpoonup} U, \ v_n \xrightarrow{\text{s2}} V \quad \Longrightarrow \quad \int_\Omega u_n v_n \, \mathrm{d}x \ \to \ \int_\Omega \int_{\mathcal{Y}} U(x, y) V(x, y) \, \mathrm{d}y \, \mathrm{d}x.$$

Using classical two-scale convergence on bounded domains only allows for a weaker statement (cf. [LNW02, Thm. 11]), since at the boundary losses may occur. Exactly this result will be crucial for our limit procedure in section 4.

In section 2.4 we recall known results on the two-scale limits of sequences of gradients and construct a *gradient folding operator* $\mathcal{G}_\varepsilon : \mathrm{H}^1_0(\Omega) \times \mathrm{L}^2(\Omega, \mathrm{H}^1_{\text{av}}(\mathcal{Y})) \to \mathrm{H}^1_0(\Omega)$ such that for all (u_0, U_1) we have $\nabla \mathcal{G}_\varepsilon(u_0, U_1) \xrightarrow{\text{s2}} \nabla_x u_0 + \nabla_y U_1$ and $\mathcal{G}_\varepsilon(u_0, U_1) \rightharpoonup u_0$ in $\mathrm{H}^1_0(\Omega)$. Based on these results we provide the relevant two-scale Γ-limit results for the functionals $\mathcal{E}_\varepsilon(t, \cdot)$ and $\mathcal{R}_\varepsilon$. Under simple additional assumptions, the two-scale limits are

$$\boldsymbol{E}(t, u_0, U_1, Z) = \int_{\Omega \times \mathcal{Y}} \frac{1}{2} \left\langle\!\!\left\langle \mathbb{A}(y) \begin{pmatrix} \boldsymbol{e}_x(u_0) + \boldsymbol{e}_y(U_1) \\ Z \end{pmatrix}, \begin{pmatrix} \boldsymbol{e}_x(u_0) + \boldsymbol{e}_y(U_1) \\ Z \end{pmatrix} \right\rangle\!\!\right\rangle \mathrm{d}y \, \mathrm{d}x - \langle \ell(t), u_0 \rangle$$
$$\boldsymbol{R}(Z) = \int_{\Omega \times \mathcal{Y}} \rho(y, Z(x, y)) \, \mathrm{d}y \, \mathrm{d}x.$$

The convergence of $\mathcal{E}_\varepsilon$ and $\mathcal{R}_\varepsilon$ to $\boldsymbol{E}$ and $\boldsymbol{R}$ can be seen as a type of two-scale Mosco convergence, i.e., Γ-convergence in the weak and in the strong topology; see [MRS07]. Recovery sequences (also called *realizing sequences* in [JKO94]) in the strong two-scale convergence sense are obtained via our explicit operators $\mathcal{F}_\varepsilon$ and $\mathcal{G}_\varepsilon$.

In section 3 we formulate our rate-independent evolution systems and provide existence and uniqueness theorems for energetic formulations associated with $\mathcal{E}_\varepsilon$ and $\mathcal{R}_\varepsilon$ on the one hand and with $\boldsymbol{E}$ and $\boldsymbol{R}$ on the other hand. We obtain uniform a priori Lipschitz bounds for the energetic solutions $q_\varepsilon = (u_\varepsilon, z_\varepsilon) : [0,T] \to \mathcal{Q}$. The solutions $Q = (u_0, U_1, Z) : [0,T] \to \boldsymbol{Q}$ are defined on the space $\boldsymbol{Q} = \boldsymbol{H}\times\boldsymbol{Z}$ with

$$\boldsymbol{H} = \mathrm{H}^1_{\Gamma_{\mathrm{Dir}}}(\Omega)^d\times\mathrm{L}^2(\Omega;\mathrm{H}^1_{\mathrm{av}}(\mathcal{Y}))^d, \quad \boldsymbol{Z} = \mathrm{L}^2(\Omega;\mathrm{L}^2(\mathcal{Y}))^m = \mathrm{L}^2(\Omega\times\mathcal{Y})^m,$$

with $\mathrm{H}^1_{\mathrm{av}}(\mathcal{Y}) = \{\, U \in \mathrm{H}^1(\mathcal{Y}) \mid \int_{\mathcal{Y}} U(y)\,\mathrm{d}y = 0\,\}$.

The final section, section 4, establishes the relation between the solutions q_ε and Q. The main result is Theorem 4.3, which states that if the initial data $q_\varepsilon(0)$ strongly two-scale cross-converge to Q^0, written as $q_\varepsilon(0) \xrightarrow{\text{s2c}} Q^0$ and defined as

$$\begin{aligned} &u_\varepsilon \rightharpoonup u_0 \text{ in } \mathrm{H}^1_{\Gamma_{\mathrm{Dir}}}(\Omega)^d, \qquad \nabla u_\varepsilon \xrightarrow{\text{s2}} \nabla_x u_0+\nabla_y U_1 \text{ in } \mathrm{L}^2(\Omega,\mathrm{H}^1_{\mathrm{av}}(\mathcal{Y})),\\ &z_\varepsilon \xrightarrow{\text{s2}} Z \text{ in } \mathrm{L}^2(\Omega\times\mathcal{Y}),\end{aligned}$$

then for all $t \in [0,T]$ we have $q_\varepsilon(t) \xrightarrow{\text{s2c}} Q(t)$, where Q is the unique energetic solution associated with $\boldsymbol{E}$ and $\boldsymbol{R}$ with the initial value $Q(0) = Q^0$. In terms of evolutionary variational inequalities this means that the solutions $q_\varepsilon = (u_\varepsilon, z_\varepsilon)$ of

$$\langle \mathrm{D}\mathcal{E}_\varepsilon(t,q_\varepsilon), v-\dot q_\varepsilon\rangle + \mathcal{R}_\varepsilon(v) - \mathcal{R}_\varepsilon(\dot q_\varepsilon) \geq 0 \quad \text{ for all } v \in \mathcal{Q}$$

strongly two-scale cross-converge to the solution $Q = (u_0, U_1, Z)$ of

$$\langle \mathrm{D}\boldsymbol{E}(t,Q), V-\dot Q\rangle + \boldsymbol{R}(V) - \boldsymbol{R}(\dot Q) \geq 0 \quad \text{ for all } V \in \boldsymbol{Q}$$

if the initial conditions satisfy $q_\varepsilon(0) \xrightarrow{\text{s2c}} Q(0)$ for $\varepsilon \to 0$.

The crucial tool for proving this convergence is the abstract Γ-convergence theory developed in [MRS07]. The main difficulty in the theory is to show that weak (two-scale) limits of stable states are again stable. In [MRS07, eqn. (2.16)] a sufficient condition is provided that asks for the existence of a *joint recovery sequence* $(\widetilde q_\varepsilon)_\varepsilon$ such that

$$\limsup_{\varepsilon\to 0} \mathcal{E}_\varepsilon(t,\widetilde q_\varepsilon)+\mathcal{R}_\varepsilon(\widetilde z_\varepsilon-z_\varepsilon)-\mathcal{E}_\varepsilon(t,q_\varepsilon) \leq \boldsymbol{E}(t,\widetilde Q)+\boldsymbol{R}(\widetilde Z-Z)-\boldsymbol{E}(t,Q) \ \text{ and } \ \widetilde q_\varepsilon \overset{\text{w2c}}{\rightharpoonup} \widetilde Q,$$

where q_ε is a given family of stable states with $q_\varepsilon \overset{\text{w2c}}{\rightharpoonup} Q$ and $\widetilde Q$ is an arbitrary test state; cf. Proposition 4.5. In our situation this condition can be fulfilled by exploiting the quadratic nature of the energies, which leads to some cancellation of differences of the energies, namely, $\mathcal{E}_\varepsilon(t,\widetilde q_\varepsilon) - \mathcal{E}_\varepsilon(t,q_\varepsilon)$ converges to $\boldsymbol{E}(t,\widetilde Q) - \boldsymbol{E}(t,Q)$ if $q_\varepsilon \overset{\text{w2c}}{\rightharpoonup} Q$ and $\widetilde q_\varepsilon - q_\varepsilon \xrightarrow{\text{s2c}} \widetilde Q - Q$ strong. Here it is important that our notion of weak and strong convergences allows us to conclude convergence of scalar products; see Proposition 2.4(d).

As far as we know, this is the first homogenization work for a nonlinear and nonsmooth evolutionary problems except for [Alb03, Nes06, Nes07] and [Vis06a]. The former works treat more general quasi-static evolution laws and are not restricted to the rate-independent setting; however, they are more restrictive in the constitutive laws and prove the convergence only in an averaged sense over microscopic phase shifts of the cells. The latter work considers hyperbolic systems coupled with hysteresis operators. Similar variational inequalities are treated in [BM93, CS04, Yos01], but with different constraints and without time dependence.

2. Two-scale convergence. We recall here the definition of the two-scale convergence and several important results concerning this notion (see [Ngu89, All92, CD99, LNW02]). In particular, the presented results are based on [CDG02, Vis04], where the notions of *periodic unfolding* (also called "two-scale decomposition" in the latter work) and *periodic folding*, which is called "averaging operator" in [CDG02, sect. 5]. In the following subsections we take special care of the problems that are associated with the fact that we want to work on a bounded domain Ω and that this is only approximately compatible with microscopic periodicity. This gives rise to a certain notational complication but allows us a very precise and efficient definition of weak and strong two-scale convergences in section 2.3. Note also Example 2.7, which shows that such special care is necessary to avoid problems at the boundary.

2.1. Basic definitions of the two-scale variables. Let $d \in \mathbb{N}$ be the space dimension. The periodicity in $\mathbb{R}^d$ is expressed by a d-dimensional periodicity lattice

$$\Lambda = \left\{ \lambda = \sum_{j=1}^{d} k_j b_j \;\middle|\; k = (k_1, k_2, \dots, k_d) \in \mathbb{Z}^d \right\},$$

where $\{b_1, \dots, b_d\}$ is an arbitrary basis in $\mathbb{R}^d$. The associated unit cell is $Y = \{\, x = \sum_1^d \gamma_j b_j \mid \gamma_j \in [-1/2, 1/2) \,\} \subset \mathbb{R}^d$, such that $\mathbb{R}^d$ is the disjoint union of the translated cells $\lambda + Y$ if λ runs through all of Λ. Following [Vis04], we distinguish the unit cell from the periodicity cell $\mathcal{Y}$, which is obtained by identifying the opposite faces of $\overline{Y}$, or we may set $\mathcal{Y} = \mathbb{R}^d/_\Lambda$. Thus, $\mathcal{Y}$ has the structure of a torus. For most applications one may assume that $\Lambda = \mathbb{Z}^d$, $Y = [-1/2, 1/2)^d$, and $\mathcal{Y} = \mathbb{R}^d/_{Z^d} = \mathbb{T}^d$, the d-dimensional standard torus. However, our theory covers the general case. Yet, we will be slightly inconsistent and use y to denote elements of Y and $\mathcal{Y}$ simultaneously by relying on the natural identification between $y + \Lambda \in \mathcal{Y}$ and $y \in Y$.

On $\mathbb{R}^d$ we define the mappings $[\,\cdot\,]_\Lambda$ and $\{\cdot\}_Y$ such that

$$[\,\cdot\,]_\Lambda : \mathbb{R}^d \to \Lambda, \quad \{\cdot\}_Y : \mathbb{R}^d \to Y, \quad x = [x]_\Lambda + \{x\}_Y \text{ for all } x \in \mathbb{R}^d.$$

We also use the notation $\{\,\cdot\,\}_\mathcal{Y}$ such that $\{x\}_\mathcal{Y} = x \bmod \Lambda \in \mathcal{Y}$. Obviously a function f defined on R^d is Λ-periodic if $f(x) = f(\{x\}_Y)$ for $x \in \mathbb{R}^d$, and we may identify f with a function $\widetilde{f}$ defined on $\mathcal{Y}$. Note that $\mathrm{L}^p(Y)$ and $\mathrm{L}^p(\mathcal{Y})$ may be identified in contrast to $\mathrm{C}^k(Y)$ and $\mathrm{C}^k(\mathcal{Y}) = \mathrm{C}^k_{\mathrm{per}}(\overline{Y})$. Similarly, we use $\mathrm{H}^1(\mathcal{Y}) = \mathrm{H}^1_{\mathrm{per}}(\overline{Y})$, which is different from $\mathrm{H}^1(Y)$. A nonstandard space, which we will need in what follows, is

$$\mathrm{H}^1_{\mathrm{av}}(\mathcal{Y}) := \left\{ f \in \mathrm{H}^1(\mathcal{Y}) \;\middle|\; \int_\mathcal{Y} f(y)\,\mathrm{d}y = 0 \right\}. \tag{2.1}$$

We now introduce a small length-scale parameter $\varepsilon > 0$ and want to study functions which have fast periodic oscillations on the microscopic periodicity cell εY. We *decompose* the points $x \in \Omega \subset \mathbb{R}^d$ such that

$$x = \mathcal{N}_\varepsilon(x) + \varepsilon \mathcal{R}_\varepsilon(x) \quad \text{with } \mathcal{N}_\varepsilon(x) = \varepsilon \left[\frac{x}{\varepsilon}\right]_\Lambda \text{ and } \mathcal{R}_\varepsilon(x) = \left\{\frac{x}{\varepsilon}\right\}_Y.$$

Thus, $\mathcal{N}_\varepsilon \in \varepsilon\Lambda$ denotes the macroscopic center of the small cell $\mathcal{N}_\varepsilon(x)+\varepsilon Y$ that contains x, and $\mathcal{R}_\varepsilon$ denotes the fine-scale part of x. With this we define a *decomposition map* $\mathcal{D}_\varepsilon$ and a *composition map* $\mathcal{S}_\varepsilon$ (cf. [Vis04]) as follows:

$$\mathcal{D}_\varepsilon : \begin{cases} \mathbb{R}^d & \to & \mathbb{R}^d\times\mathcal{Y}, \\ x & \mapsto & (\mathcal{N}_\varepsilon(x), \mathcal{R}_\varepsilon(x)), \end{cases} \qquad \mathcal{S}_\varepsilon : \begin{cases} \mathbb{R}^d\times\mathcal{Y} & \to & \mathbb{R}^d, \\ (x,y) & \mapsto & \mathcal{N}_\varepsilon(x)+\varepsilon y, \end{cases}$$

where in the last sum some $y \in \mathcal{Y}$ is identified with $y \in Y \subset \mathbb{R}^d$. For the construction of a periodic unfolding operator and a folding operator in the next subsection, the following simple properties of $\mathcal{D}_\varepsilon$ and $\mathcal{S}_\varepsilon$ are essential:

$$\mathcal{D}_\varepsilon(\mathcal{S}_\varepsilon(x,y)) = (\mathcal{N}_\varepsilon(x), y) \quad \text{and} \quad \mathcal{S}_\varepsilon(\mathcal{D}_\varepsilon(x)) = x \qquad \text{for all } (x,y) \in \mathbb{R}^d\times\mathcal{Y}. \tag{2.2}$$

If Ω does not coincide with $\mathbb{R}^d$, then certain technicalities arise from the fact that the image of $\mathcal{D}_\varepsilon$ is not contained in $\Omega\times\mathcal{Y}$. Similarly, we note that $\mathcal{S}_\varepsilon(\Omega\times\mathcal{Y})$ is not contained in Ω. To handle this, we introduce, for a fixed open domain Ω, the following subsets of Λ:

$$\Lambda_\varepsilon^- = \{\, \lambda \in \Lambda \mid \varepsilon(\lambda+Y) \subset \overline{\Omega} \,\} \quad \text{and} \quad \Lambda_\varepsilon^+ = \{\, \lambda \in \Lambda \mid \varepsilon(\lambda+Y) \cap \Omega \neq \emptyset \,\}.$$

Using this, we define the domains Ω_ε^- and Ω_ε^+ via $\Omega_\varepsilon^\pm = \operatorname{int}\big(\cup_{\lambda\in\Lambda_\varepsilon^\pm} \varepsilon(\lambda+Y)\big)$. Clearly, we have $\Omega_\varepsilon^- \subset \Omega \subset \Omega_\varepsilon^+$. Moreover, we have $[\Omega_\varepsilon^\pm]_\varepsilon^\pm = \Omega_\varepsilon^\pm$, $\Omega \subset N_{\varepsilon \operatorname{diam}(Y)}(\Omega_\varepsilon^-)$, and $\Omega_\varepsilon^+ \subset N_{\varepsilon \operatorname{diam}(Y)}(\Omega)$, where $\operatorname{diam}(Y)$ is the diameter of Y and $N_\delta(A)$ denotes the δ-neighborhood of the set A.

Moreover, we set $[\Omega\times\mathcal{Y}]_\varepsilon = \mathcal{S}_\varepsilon^{-1}(\Omega) = \{\, (x,y) | \mathcal{S}_\varepsilon(x,y) \in \Omega \,\}$ and note the relations

$$\Omega_\varepsilon^- \times\mathcal{Y} \subset [\Omega\times\mathcal{Y}]_\varepsilon \subset \overline{\Omega_\varepsilon^+}\times\mathcal{Y}, \tag{2.3}$$

which will significantly be used later on. From now on we will assume that Ω satisfies

$$\Omega \text{ is open and bounded} \quad \text{and} \quad |\partial\Omega| = 0. \tag{2.4}$$

This guarantees that $|\Omega\backslash\Omega_\varepsilon^-| + |\Omega_\varepsilon^+\backslash\Omega| \to 0$ for $\varepsilon \to 0$, which will be used later. To see this, denote by ϕ_ε the characteristic function of the set $N_{\varepsilon \operatorname{diam}(Y)}(\partial\Omega)$, then $\Omega\backslash\Omega_\varepsilon^- \cup \Omega_\varepsilon^+\backslash\Omega \subset N_{\varepsilon \operatorname{diam}(Y)}(\partial\Omega)$, and for all $x \notin \partial\Omega$ we have $\phi_\varepsilon(x) \to 0$ for $\varepsilon \to 0$. Hence, we conclude $|\Omega\backslash\Omega_\varepsilon^-| + |\Omega_\varepsilon^+\backslash\Omega| \leq |N_{\varepsilon \operatorname{diam}(Y)}(\partial\Omega)| = \int_{\mathbb{R}^d} \phi_\varepsilon \,\mathrm{d}x \to 0$ for $\varepsilon \to 0$. The second condition in (2.4) is certainly satisfied if Ω has a Lipschitz boundary.

2.2. Folding and periodic unfolding operators. The notion of two-scale convergence is intrinsically linked with a suitable "two-scale embedding" of the function space $\mathrm{L}^p(\Omega)$ into the two-scale space $\mathrm{L}^p(\Omega\times\mathcal{Y})$. Such a mapping will be called a *periodic unfolding operator*. Moreover, for a two-scale function U defined on $\Omega\times\mathcal{Y}$ it is desirable to find a function u_ε defined on Ω that has the corresponding microscopic behavior. A mapping from the two-scale space into the original function space $\mathrm{L}^p(\Omega)$ will be called a *folding operator*.

The natural candidate for the periodic unfolding operator was introduced in [CDG02] and reads

$$\mathcal{T}_\varepsilon : \mathrm{L}^p(\Omega) \to \mathrm{L}^p(\mathbb{R}^d\times\mathcal{Y});\ v \mapsto v_{\mathrm{ex}} \circ \mathcal{S}_\varepsilon, \tag{2.5}$$

where $v_{\mathrm{ex}} \in \mathrm{L}^p(\mathbb{R}^d)$ is obtained from v by extending it by 0 outside of Ω. By definition, we immediately have the product rule:

$$\frac{1}{p}+\frac{1}{q} = \frac{1}{r} \leq 1,\ u \in \mathrm{L}^p(\Omega),\ v \in \mathrm{L}^q(\Omega) \implies \mathcal{T}_\varepsilon(uv) = (\mathcal{T}_\varepsilon u)\,(\mathcal{T}_\varepsilon v) \in \mathrm{L}^r(\Omega\times\mathcal{Y}). \tag{2.6}$$

In general, the support of $\mathcal{T}_\varepsilon v$ is $\overline{[\Omega\times\mathcal{Y}]_\varepsilon}$, which is not contained in $\Omega\times\mathcal{Y}$. This discrepancy in support is the main reason why we repeat the definitions of the operators and the different versions of two-scale convergence in detail. Most previous work either deals with $\Omega = \mathbb{R}^d$ or is not very precise about the supports. However, as was noted in [LNW02] (see also our Examples 2.3 and 2.7), we need to be careful here.

A variant of $\mathcal{T}_\varepsilon$ that maps continuous functions u into continuous ones can be found in [Vis04].

For a function space F, to be specified later, simple choices for folding operators are given in the form

$$\widehat{F}_\varepsilon\colon \mathrm{F}(\Omega\times\mathcal{Y}) \to \mathrm{F}(\mathbb{R}^d);\ U \mapsto U\circ\mathcal{D}_\varepsilon \text{ and } F_\varepsilon\colon \mathrm{F}(\Omega\times\mathcal{Y}) \to \mathrm{F}(\mathbb{R}^d);\ U \mapsto U\circ D_\varepsilon, \tag{2.7}$$

where D_ε is the simple decomposition $D_\varepsilon : x \mapsto (x, \{\frac{x}{\varepsilon}\}_\mathcal{Y})$. Neither of these choices is suitable if for the function space "F" we choose L^p since the image of Ω under $\mathcal{D}_\varepsilon$ and D_ε, respectively, is a set of measure 0 in $\mathbb{R}^d\times\mathcal{Y}$. However, the folding operator F_ε is well-defined as a mapping from $\mathrm{C}^k(\mathbb{R}^d\times\mathcal{Y})$ into $\mathrm{C}^k(\mathbb{R}^d)$ and has the big advantage that the image of $\Omega\times\mathcal{Y}$ under D_ε is equal to Ω. In fact, this is the basis of the classical definition of two-scale convergence; see (2.9).

The main point in this subsection is that we use a very particular folding operator $\mathcal{F}_\varepsilon$ that is well adapted to the classical L^p-spaces, namely,

$$\mathrm{L}^p(\Omega\times\mathcal{Y}) = \mathrm{L}^p(\Omega;\mathrm{L}^p(\mathcal{Y})) = \mathrm{L}^p(\mathcal{Y};\mathrm{L}^p(\Omega)) \quad \text{for } p\in[1,\infty).$$

These are the relevant ones for elliptic PDEs and our aim is to avoid spaces involving continuous functions like $\mathrm{L}^p(\Omega,\mathrm{C}(\mathcal{Y}))$ (on which $\widehat{F}_\varepsilon$ is well-defined). Our folding operator is a variant of the averaging operator $\mathcal{U}_\varepsilon$ defined in [CDG02, sect. 5], since we take special care on the domain Ω.

On $\mathrm{L}^p(\mathbb{R}^d\times\mathcal{Y})$ we first define the classical projector to piecewise constant functions on each $\varepsilon(\lambda+Y)$ via

$$(\mathcal{P}_\varepsilon U)(x,y) = \fint_{\mathcal{N}_\varepsilon(x)+\varepsilon Y} U(\xi,y)\,\mathrm{d}\xi,$$

where $\fint_A$ denotes the average over A, i.e., $\fint_A g(a)\,\mathrm{d}a = \frac{1}{|A|}\int_A g(a)\,\mathrm{d}a$. Clearly $(\mathcal{P}_\varepsilon)^2 = \mathcal{P}_\varepsilon$, $\|\mathcal{P}_\varepsilon U\|_p \le \|U\|_p$, and $\mathcal{P}_\varepsilon U \to U$ in $\mathrm{L}^p(\Omega\times\mathcal{Y})$ for all $U\in\mathrm{L}^p(\Omega\times\mathcal{Y})$.

Our folding operator $\mathcal{F}_\varepsilon$ is now defined as follows:

$$\mathcal{F}_\varepsilon : \mathrm{L}^p(\mathbb{R}^d\times\mathcal{Y}) \to \mathrm{L}^p(\Omega);\ U \mapsto \big(\mathcal{P}_\varepsilon(\chi_\varepsilon U)\circ\mathcal{D}_\varepsilon\big)|_\Omega \quad \text{with } \chi_\varepsilon = \chi_{[\Omega\times\mathcal{Y}]_\varepsilon}. \tag{2.8}$$

Note that the folding operator is defined for functions on the full space $\mathbb{R}^d\times\mathcal{Y}$ and takes values in the functions on Ω. The construction with the characteristic function $\chi_\varepsilon : \mathbb{R}^d\times\mathcal{Y} \to \{0,1\}$ guarantees that $\chi_\varepsilon = \mathcal{P}_\varepsilon\chi_\varepsilon$ and $\mathrm{sppt}(\chi_\varepsilon\circ\mathcal{D}_\varepsilon) = \overline{\Omega}$, which follows from the definition of $[\Omega\times\mathcal{Y}]_\varepsilon$ and from (2.2).

The following proposition summarizes the properties of the folding operator and the periodic unfolding operator. We restrict ourselves to the case $p\in(1,\infty)$ and leave the generalizations for $p=1$ and $p=\infty$ to the reader. In fact, in our application we will only use $p=p'=2$, which is especially nice.

PROPOSITION 2.1. *Let $p\in(1,\infty)$ and $p'=p/(p-1)$. Then the folding operator $\mathcal{F}_\varepsilon : \mathrm{L}^p(\mathbb{R}^d\times\mathcal{Y}) \to \mathrm{L}^p(\Omega)$ and the periodic unfolding operators $\mathcal{T}_\varepsilon : \mathrm{L}^p(\Omega) \to \mathrm{L}^p(\mathbb{R}^d\times\mathcal{Y})$ and $\widetilde{\mathcal{T}}_\varepsilon : \mathrm{L}^{p'}(\Omega) \to \mathrm{L}^{p'}(\mathbb{R}^d\times\mathcal{Y})$ satisfy*

(a) $\|\mathcal{T}_\varepsilon u\|_{\mathrm{L}^{p'}(\mathbb{R}^d\times\mathcal{Y})} = \|u\|_{\mathrm{L}^{p'}(\Omega)}$ *and* $\mathrm{sppt}(\mathcal{T}_\varepsilon u) \subset \overline{[\Omega\times\mathcal{Y}]_\varepsilon}$ *for all* $u\in\mathrm{L}^{p'}(\Omega)$*;*

(b) $\|\mathcal{F}_\varepsilon U\|_{\mathrm{L}^p(\Omega)} \leq \|U\|_{\mathrm{L}^p(\mathbb{R}^d\times\mathcal{Y})}$ *for all* $U \in \mathrm{L}^p(\mathbb{R}^d\times\mathcal{Y})$;

(c) $\mathcal{F}_\varepsilon$ *is the adjoint of* $\widehat{\mathcal{T}}_\varepsilon$, *i.e.*, $\mathcal{F}_\varepsilon = \big(\widehat{\mathcal{T}}_\varepsilon\big)'$;

(d) $\mathcal{F}_\varepsilon \circ \mathcal{T}_\varepsilon = \mathrm{id}_{\mathrm{L}^p(\Omega)}$ *and* $(\mathcal{T}_\varepsilon \circ \mathcal{F}_\varepsilon)^2 = \mathcal{T}_\varepsilon \circ \mathcal{F}_\varepsilon = \chi_\varepsilon \mathcal{P}_\varepsilon$.

All these identities can be obtained by elementary calculations via decomposing $\mathbb{R}^d$ into $\cup_{\lambda\in\Lambda}\varepsilon(\lambda+Y)$.

2.3. Weak and strong two-scale convergences. Following [Ngu89, All92, CD99, LNW02], a family $(u_\varepsilon)_\varepsilon$ in $\mathrm{L}^p(\Omega)$ is called *two-scale convergent* to a function $U \in \mathrm{L}^p(\Omega\times\mathcal{Y})$ and write $u_\varepsilon \xrightharpoonup{2} U$ if for all test functions $\psi : \Omega\times\mathcal{Y} \to \mathbb{R}$ we have

$$\lim_{\varepsilon\to 0} \int_\Omega u_\varepsilon(x)\psi\left(x, \left\{\frac{x}{\varepsilon}\right\}_{\mathcal{Y}}\right) \mathrm{d}x = \int_\Omega \int_{\mathcal{Y}} U(x,y)\psi(x,y)\,\mathrm{d}y\,\mathrm{d}x \quad \text{for all } \psi \in \Psi. \tag{2.9}$$

The choice of the set of test functions Ψ is important here; cf. [LNW02]. The weakest notion occurs if we take $\Psi = \mathrm{C}_\mathrm{c}^\infty(\Omega\times\mathcal{Y})$, which corresponds to a kind of distributional convergence. If $p' = p/(p-1)$ denotes the dual exponent to $p \in (1,\infty)$, the choice $\Psi = \mathrm{L}^{p'}(\Omega, \mathrm{C}(\mathcal{Y}))$ is advocated in [LNW02], since it guarantees weak convergence of $(u_\varepsilon)_\varepsilon$ to $\int_{\mathcal{Y}} U(\cdot,y)\,\mathrm{d}y$ in $\mathrm{L}^p(\Omega)$. Note that two-scale convergence can also be defined using the folding operator F_ε defined in (2.7):

$$u_\varepsilon \xrightharpoonup{2} U \quad \iff \quad \langle u_\varepsilon, F_\varepsilon\psi\rangle_\Omega = \langle u_\varepsilon, \psi\circ D_\varepsilon\rangle_\Omega \to \langle U, \psi\rangle_{\Omega\times\mathcal{Y}}.$$

Here we follow some notions from [Vis04], but modify them to fit the case $\Omega \subsetneq \mathbb{R}^d$, for defining weak and strong two-scale convergences via the periodic unfolding operators $\mathcal{T}_\varepsilon$.

Definition 2.2. *Let* $(u_\varepsilon)_{\varepsilon\in(0,\varepsilon_0)}$ *be a family in* $\mathrm{L}^p(\Omega)$ *with* $p \in (1,\infty)$.

(a) *We say that* u_ε weakly two-scale converges *to* $U \in \mathrm{L}^p(\Omega\times\mathcal{Y})$ *and write "*$u_\varepsilon \xrightharpoonup{\mathrm{w2}} U$ *in* $\mathrm{L}^p(\Omega\times\mathcal{Y})$*" if* $\mathcal{T}_\varepsilon u_\varepsilon \rightharpoonup U_{\mathrm{ex}}$ *in* $\mathrm{L}^p(\mathbb{R}^d\times\mathcal{Y})$.

(b) *We say that* u_ε strongly two-scale converges *to* $U \in \mathrm{L}^p(\Omega\times\mathcal{Y})$ *and write "*$u_\varepsilon \xrightarrow{\mathrm{s2}} U$ *in* $\mathrm{L}^p(\Omega\times\mathcal{Y})$*" if* $\mathcal{T}_\varepsilon u_\varepsilon \to U_{\mathrm{ex}}$ *(strongly) in* $\mathrm{L}^p(\mathbb{R}^d\times\mathcal{Y})$.

As the supports of $\mathcal{T}_\varepsilon u_\varepsilon$ are contained in $\overline{[\Omega\times\mathcal{Y}]_\varepsilon} \subset \overline{\Omega_\varepsilon^+}\times\mathcal{Y}$, it is clear that any possible accumulation point U of $(\mathcal{T}_\varepsilon)_\varepsilon$ has its support in $\overline{\Omega}\times\mathcal{Y}$. Because of $|\partial\Omega| = 0$ we have $\mathrm{L}^p(\Omega\times\mathcal{Y}) = \mathrm{L}^p(\overline{\Omega}\times\mathcal{Y})$, and hence accumulation points of $(\mathcal{T}_\varepsilon u_\varepsilon)_\varepsilon$ can be uniquely described by elements in $\mathrm{L}^p(\Omega\times\mathcal{Y})$. Nevertheless, it is important that our definition involves a convergence statement in $\mathrm{L}^p(\mathbb{R}^d\times\mathcal{Y})$; i.e., we need to consider functions outside of $\Omega\times\mathcal{Y}$. If the convergence was asked only for the restrictions on $\Omega\times\mathcal{Y}$, then different notions would occur.

Example 2.3. *We choose* $\Omega = (0,1)$ *and* $Y = [0,1)$. *Along the sequence* $\varepsilon_k = (k^3-1)/k^4 \to 0$ *we consider the functions*

$$u_{\varepsilon_k}(x) = a_k \text{ for } x \in (1-1/k^2, 1) \qquad \text{and } 0 \text{ otherwise},$$

which satisfy $\|u_{\varepsilon_k}\|_{\mathrm{L}^2(\Omega)} = |a_k|/k$. *The periodic unfolding* $U_k = \mathcal{T}_{\varepsilon_k}u_{\varepsilon_k} \in \mathrm{L}^2(\mathbb{R}\times\mathcal{Y})$ *reads*

$$U_k(x,y) = a_k \text{ if } \big(x \in (1-1/k^2, 1+(k-1)/k^2) \text{ and } y \in (0,1/k)\big) \qquad \text{and } 0 \text{ otherwise}.$$

The support of U_k *has only a small part in* $\Omega\times\mathcal{Y}$, *while the main part is in* $(\Omega_{\varepsilon_k}^+\setminus\Omega)\times\mathcal{Y}$. *Hence,* $U_k\big|_{\Omega\times Y}$ *has a much smaller norm, namely,* $\|U_k\big|_{\Omega\times\mathcal{Y}}\|_{\mathrm{L}^2(\Omega\times\mathcal{Y})} = |a_k|/k^{3/2}$. *Thus, for* $a_k = o(k^{3/2})$ *we have* $U_k\big|_{\Omega\times Y} \to 0$ *strongly in* $\mathrm{L}^2(\Omega\times\mathcal{Y})$, *which implies* $u_k \xrightharpoonup{2} 0$ *in* $\mathrm{L}^2(\Omega\times\mathcal{Y})$.

However, $u_{\varepsilon_k} \overset{\mathrm{w2}}{\rightharpoonup} U$ *holds if and only if* $a_k = O(k)$ *and then* $U \equiv 0$*. Moreover,* $u_{\varepsilon_k} \xrightarrow{\mathrm{s2}} U$ *if and only if* $a_k = o(k)$ *and* $U \equiv 0$ *then. (A similar example is given in* [Gri05, p. 15]*.)*

Using the fact that the folding operator is the adjoint of the periodic unfolding operator, we may equivalently define weak two-scale convergence in a way similar to the classical definition (2.9), namely,

$$\begin{aligned} (2.10) \qquad & u_\varepsilon \overset{\mathrm{w2}}{\rightharpoonup} U \text{ in } \mathrm{L}^p(\Omega\times\mathcal{Y}) \\ & \iff \quad \forall V \in \mathrm{L}^{p'}(\Omega\times\mathcal{Y}): \int_\Omega u_\varepsilon\, \mathcal{F}_\varepsilon V \,\mathrm{d}x \to \int_\Omega \int_{\mathcal{Y}} U\, V \,\mathrm{d}y\,\mathrm{d}x. \end{aligned}$$

Note that we have simply replaced the folding operator $F_\varepsilon : U \mapsto U \circ D_\varepsilon$ by the more sophisticated version $\mathcal{F}_\varepsilon$, which allows us to take general L^p functions. Moreover, the test functions V are allowed to have a support bigger than $\overline{\Omega}\times\mathcal{Y}$. As we are interested in $\varepsilon \to 0$, it suffices to consider $V \in \mathrm{L}^{p'}(N_\delta(\Omega)\times\mathcal{Y})$ for any $\delta > 0$, whereas $\delta = 0$ will lead to a strictly weaker notion of convergence.

The definitions of weak and strong two-scale convergences are obtained by transferring convergence to the classical weak and strong convergences in the classical space $\mathrm{L}^p(\Omega\times\mathcal{Y})$.

PROPOSITION 2.4. *Let* $p \in (1,\infty)$ *and* $p' = p/(p-1)$ *and assume that* Ω *satisfies* (2.4)*.*

(a) *If* $u_\varepsilon \overset{\mathrm{w2}}{\rightharpoonup} U$ *in* $\mathrm{L}^p(\Omega\times\mathcal{Y})$*, then* $\|u_\varepsilon\|_{\mathrm{L}^p(\Omega)}$ *is bounded for* $\varepsilon \to 0$*.*

(b) *If* $u_\varepsilon \overset{\mathrm{w2}}{\rightharpoonup} U$ *in* $\mathrm{L}^p(\Omega\times\mathcal{Y})$*, then* $u_\varepsilon \overset{2}{\rightharpoonup} U$*. (The reverse implication is in general not true.)*

(c) $\big(u_\varepsilon \overset{\mathrm{w2}}{\rightharpoonup} U$ *and* $\|u_\varepsilon\|_{\mathrm{L}^p(\Omega)} \to \|U\|_{\mathrm{L}^p(\Omega\times\mathcal{Y})}\big) \iff u_\varepsilon \xrightarrow{\mathrm{s2}} U$*.*

(d) *If* $u_\varepsilon \overset{\mathrm{w2}}{\rightharpoonup} U$ *in* $\mathrm{L}^p(\Omega\times\mathcal{Y})$ *and* $v_\varepsilon \xrightarrow{\mathrm{s2}} V$ *in* $\mathrm{L}^{p'}(\Omega\times\mathcal{Y})$*, then* $\langle u_\varepsilon, v_\varepsilon\rangle_\Omega \to \langle U, V\rangle_{\Omega\times\mathcal{Y}}$*.*

(e) *For each* $U \in \mathrm{L}^p(\Omega\times\mathcal{Y})$ *there exists a family* $(u_\varepsilon)_\varepsilon$ *such that* $u_\varepsilon \xrightarrow{\mathrm{s2}} U$ *in* $\mathrm{L}^p(\Omega\times\mathcal{Y})$ *(simply take* $u_\varepsilon = \mathcal{F}_\varepsilon U_{\mathrm{ex}}$*).*

(f) *For each* $w \in \mathrm{L}^p(\Omega)$ *we have* $\mathcal{T}_\varepsilon w \xrightarrow{\mathrm{s2}} Ew$ *in* $\mathrm{L}^p(\Omega\times\mathcal{Y})$*, where* $E : \mathrm{L}^p(\Omega) \to \mathrm{L}^p(\Omega\times\mathcal{Y})$ *is defined via* $Ev(x,y) = v(x)$*.*

(g) *For* $p \in (1,\infty)$*,* $q \in (1,\infty]$*, and* $\frac{1}{p} + \frac{1}{q} = \frac{1}{r} \le 1$*, let* $u_\varepsilon \overset{\mathrm{w2}}{\rightharpoonup} U$ *in* $\mathrm{L}^p(\Omega\times\mathcal{Y})$ *and* $v_\varepsilon \xrightarrow{\mathrm{s2}} V$ *in* $\mathrm{L}^q(\Omega\times\mathcal{Y})$*; then* $u_\varepsilon v_\varepsilon \overset{\mathrm{w2}}{\rightharpoonup} UV$ *in* $\mathrm{L}^r(\Omega\times\mathcal{Y})$*. If additionally* $u_\varepsilon \xrightarrow{\mathrm{s2}} U$ *in* $\mathrm{L}^p(\Omega\times\mathcal{Y})$*, then* $u_\varepsilon v_\varepsilon \xrightarrow{\mathrm{s2}} UV$ *in* $\mathrm{L}^r(\Omega\times\mathcal{Y})$*.*

Note that our definition of weak and strong convergences implies an equivalence in part (c). The corresponding result in [Gri05, Prop. 1.8] using convergence of $\mathcal{T}_\varepsilon u_\varepsilon$ in $\mathrm{L}^p(\Omega\times\mathcal{Y})$ (instead of convergence in $\mathrm{L}^p(\mathbb{R}^d\times\mathcal{Y})$) only allows for the implication "$\Rightarrow$"; see the counterexample [Gri05, p. 15].

Proof. Parts (a), (c), (d), and (g) are immediate consequences of the corresponding results of weak and strong convergences in $\mathrm{L}^p(\Omega\times\mathcal{Y})$.

Property (b) will be a consequence of Proposition 2.5 below.

Property (e) follows as the projector $\mathcal{P}_\varepsilon$ on $\mathrm{L}^p(\Omega\times\mathcal{Y})$ satisfies $\mathcal{P}_\varepsilon U \to U$ and the characteristic function χ_ε (cf. (2.8)) converges pointwise a.e. to $\chi_{\Omega\times\mathcal{Y}}$.

For property (f) we use that the unfolding operators $\mathcal{T}_\varepsilon$ have norm 1 and that for $w \in \mathrm{C}^1(\overline{\Omega})$ some calculation gives $\|\mathcal{T}_\varepsilon w - Ew\|_{\mathrm{L}^p(\Omega\times\mathcal{Y})} \le 2\,\mathrm{diam}Y\,\varepsilon\,|\Omega|^{1/p}\|\nabla w\|_{\mathrm{L}^\infty}$. Because of (2.4) the smooth functions are dense and the assertion follows. ∎

In fact, the difference between $\overset{2}{\rightharpoonup}$ and $\overset{\mathrm{w2}}{\rightharpoonup}$ disappears if we a priori impose boundedness of the sequence.

PROPOSITION 2.5. *Let $(u_\varepsilon)_\varepsilon$ be a bounded family in* $\mathrm{L}^p(\Omega)$ *with* $p \in (1,\infty)$. *Then the following statements are equivalent:*

$$\text{(i) } u_\varepsilon \overset{2}{\rightharpoonup} U \text{ in } \mathrm{L}^p(\Omega\times\mathcal{Y}), \qquad \text{(ii) } \mathcal{T}_\varepsilon u_\varepsilon\big|_{\Omega\times\mathcal{Y}} \rightharpoonup U \text{ in } \mathrm{L}^p(\Omega\times\mathcal{Y}),$$
$$\text{(iii) } u_\varepsilon \overset{\mathrm{w}2}{\rightharpoonup} U \text{ in } \mathrm{L}^p(\Omega\times\mathcal{Y}).$$

Proof. For the equivalence between (i) and (ii) see [CDG02]. The definition of $\overset{\mathrm{w}2}{\rightharpoonup}$ shows that (iii) implies (ii). Moreover, using (2.10) and the boundedness of $(u_\varepsilon)_\varepsilon$, it is sufficient to show $\int_\Omega u_\varepsilon \mathcal{F}_\varepsilon V \,\mathrm{d}x \to \int_\Omega \int_\mathcal{Y} UV \,\mathrm{d}y \,\mathrm{d}x$ on the dense subset $\Psi = \mathrm{C}^\infty_\mathrm{c}(\Omega\times\mathcal{Y})$. However, on Ψ we have $\|\mathcal{F}_\varepsilon\psi - F_\varepsilon\psi\|_{\mathrm{L}^p(\Omega)} = O(\varepsilon)$, and thus (i) implies (iii). ∎

The next result provides an improvement of part (g) in Proposition 2.4.

PROPOSITION 2.6. *Let* $p \in [1,\infty)$ *and let* $(u_\varepsilon)_\varepsilon \overset{\mathrm{s}2}{\longrightarrow} U$ *in* $\mathrm{L}^p(\Omega\times\mathcal{Y})$. *Moreover, consider a bounded sequence* $(m_\varepsilon)_\varepsilon$ *in* $\mathrm{L}^\infty(\Omega)$ *such that* $\mathcal{T}_\varepsilon m_\varepsilon(x,y) \to M(x,y)$ *for a.e.* $x \in \Omega\times\mathcal{Y}$. *Then* $m_\varepsilon u_\varepsilon \overset{\mathrm{s}2}{\longrightarrow} MU$ *in* $\mathrm{L}^p(\Omega\times\mathcal{Y})$.

Proof. By the assumption, $U_\varepsilon = \mathcal{T}_\varepsilon u_\varepsilon$ is bounded in $\mathrm{L}^p(\Omega\times\mathcal{Y})$, and hence there is a subsequence and a majorant $g \in \mathrm{L}^p(\Omega\times\mathcal{Y})$ such that $|U_{\varepsilon_k}(x,y)| \le g(x,y)$ and $U_{\varepsilon_k}(x,y) \to U(x,y)$ a.e. in $\Omega\times\mathcal{Y}$. Because of the assumptions on m_ε we find that $\mathcal{T}_{\varepsilon_k}(m_{\varepsilon_k}U_{\varepsilon_k}) = \mathcal{T}_{\varepsilon_k}m_{\varepsilon_k}\,\mathcal{T}_{\varepsilon_k}U_{\varepsilon_k}$ also has a joint majorant and converges pointwise a.e. From this we conclude $\mathcal{T}_{\varepsilon_k}m_{\varepsilon_k}U_{\varepsilon_k} \rightharpoonup MU$ in $\mathrm{L}^p(\Omega\times\mathcal{Y})$. Since the limit of all subsequences is the same, the usual contradiction argument provides the convergence of the whole family. ∎

The following example shows that the statement in Proposition 2.4(d) is not true if we do not insist on the convergence of $\mathcal{T}_\varepsilon u_\varepsilon$ and $\mathcal{T}_\varepsilon v_\varepsilon$ in $\mathrm{L}^p(\mathbb{R}^d\times\mathcal{Y})$. In [LNW02, Thm. 11] a related result to (c) is proved, namely, $\int_\Omega \tau u_\varepsilon v_\varepsilon \,\mathrm{d}x \to \int_\Omega \tau \int_\mathcal{Y} UV \,\mathrm{d}y \,\mathrm{d}x$ for all $\tau \in \mathrm{C}^\infty_\mathrm{c}(\Omega)$, where the cut-off function τ that is 0 near the boundary $\partial\Omega$ is needed to compensate for the usage of the weaker notion of two-scale convergence $\overset{2}{\rightharpoonup}$ defined in (2.9). In [LNW02, Thm. 11] strong two-scale convergence is implicitly defined by two-scale convergence $\overset{2}{\rightharpoonup}$ and additional norm convergence; see Proposition 2.4(c).

EXAMPLE 2.7. *We take* $\Omega = (0,1)$, $Y = [0,1)$, ε_k, *and* u_{ε_k} *as in Example* 2.3. *Moreover, we let* $a_k = k$ *and* $v_{\varepsilon_k} = u_{\varepsilon_k}$. *Obviously, we have* $\int u_{\varepsilon_k} v_{\varepsilon_k} \,\mathrm{d}x = \|u_{\varepsilon_k}\|^2_{\mathrm{L}^2(\Omega)} = 1$. *However, as shown above we have* $\mathcal{T}_{\varepsilon_k}u_{\varepsilon_k}\big|_{\Omega\times\mathcal{Y}} \to U_\Omega \equiv 0$ *in* $\mathrm{L}^2(\Omega\times\mathcal{Y})$. *Hence, Proposition* 2.4(d) *does not hold for the limits* U_Ω *and* V_Ω *defined in* $\mathrm{L}^p(\Omega\times\mathcal{Y})$ *only.*

2.4. Two-scale convergence of gradients. We now deal with bounded sequences in $\mathrm{W}^{1,p}(\Omega)$. The two-scale convergence for the associated gradients provides an additional structure. To formulate the result we define

$$\mathrm{W}^{1,p}_{\mathrm{av}}(\mathcal{Y}) = \left\{ w \in \mathrm{W}^{1,p}(\mathcal{Y}) \;\middle|\; \int_\mathcal{Y} w(y)\,\mathrm{d}y = 0 \right\}$$

and note that $\mathrm{L}^p(\Omega;\mathrm{W}^{1,p}_{\mathrm{av}}(\mathcal{Y}))$ is the set of functions V in $\mathrm{L}^p(\Omega\times\mathcal{Y}) = \mathrm{L}^p(\Omega;\mathrm{L}^p(\Omega))$ such that $\int_\mathcal{Y} V(x,y)\,\mathrm{d}y = 0$ for a.a. $x \in \Omega$ and that $\nabla_y V$ (in the sense of distributions) lies again in $\mathrm{L}^p(\Omega\times\mathcal{Y})$.

THEOREM 2.8. *Let $(v_\varepsilon)_\varepsilon$ be a sequence in* $\mathrm{W}^{1,p}(\Omega)$ *such that* $v_\varepsilon \rightharpoonup v_0$ *weakly in* $\mathrm{W}^{1,p}(\Omega)$, *where* $p \in (1,\infty)$. *Then* $v_\varepsilon \overset{\mathrm{s}2}{\longrightarrow} Ev_0$ *in* $\mathrm{L}^p(\Omega\times\mathcal{Y})$, *and there exist a subsequence* $(v_{\varepsilon'})_{\varepsilon'}$ *and a function* $V_1 \in \mathrm{L}^p(\Omega;\mathrm{W}^{1,p}_{\mathrm{av}}(\mathcal{Y}))$ *such that*

$$\nabla v_{\varepsilon'} \overset{\mathrm{w}2}{\rightharpoonup} E\nabla_x v_0 + \nabla_y V_1.$$

Proof. Using $v_\varepsilon \rightharpoonup v_0$ weakly in $\mathrm{W}^{1,p}(\Omega)$ gives by the compact embedding that $v_\varepsilon \to v_0$ (strongly) in $\mathrm{L}^p(\Omega)$. Employing by Propositions 2.1(a) and 2.4 we now have $\|\mathcal{T}_\varepsilon v_\varepsilon - Ev_0\|_p \le \|\mathcal{T}_\varepsilon(v_\varepsilon - v_0)\|_p + \|\mathcal{T}_\varepsilon v_0 - Ev_0\|_p \to 0$. Thus, $v_\varepsilon \xrightarrow{\mathrm{s2}} Ev_0$ is established.

The weak two-scale convergence of the gradients along a subsequence can be deduced by exploiting the corresponding result from the classical two-scale convergence; see [Ngu89, All92]. Since weak convergence in $\mathrm{W}^{1,p}(\Omega)$ implies boundedness of the gradients, the desired result follows using Proposition 2.5. ∎

As for the strong two-scale convergence for functions, we also need a density result for gradients converging in the two-scale sense. These results will be used to construct recovery sequences for the Γ-limits below. We first provide an explicit construction that is based on a smoothing procedure using the heat kernels for $\mathbb{R}^d$ and $\mathcal{Y}$. After that we provide a second construction based on ideas in [Vis04] involving the solutions of elliptic problems.

PROPOSITION 2.9. *Let $p \in (1,\infty)$ and $\Omega \subset \mathbb{R}^d$ as above. Then for every function $(u_0, U_1) \in \mathrm{W}^{1,p}(\Omega) \times \mathrm{L}^p(\Omega; \mathrm{W}^{1,p}_{\mathrm{av}}(\mathcal{Y}))$ there exists a family $(u_\varepsilon)_\varepsilon$ in $\mathrm{W}^{1,p}(\Omega)$ such that $u_\varepsilon \rightharpoonup u_0$ in $\mathrm{W}^{1,p}(\Omega)$ and that $\nabla u_\varepsilon \xrightarrow{\mathrm{s2}} E\nabla u_0 + \nabla_y U_1$.*

Proof. It is sufficient to prove the result for $u_0 \equiv 0$, since we may shift any sequence by u_0. Note that by Proposition 2.4(f) we have $\mathcal{T}_\varepsilon \nabla u_0 \xrightarrow{\mathrm{s2}} E\nabla u_0$.

Hence it suffices to find for each $V_1 \in \mathrm{L}^p(\Omega; \mathrm{W}^{1,p}_{\mathrm{av}}(\mathcal{Y}))$ a family $(v_\varepsilon)_\varepsilon$ such that

$$v_\varepsilon \rightharpoonup 0 \text{ in } \mathrm{W}^{1,p}(\Omega) \quad \text{and} \quad \nabla v_\varepsilon \xrightarrow{\mathrm{s2}} \nabla_y V_1 \text{ in } \mathrm{L}^p(\Omega \times \mathcal{Y}).$$

For this we use the heat kernels $H_{\mathbb{R}^d}$ and $H_{\mathcal{Y}}$ defined via

$$H_{\mathbb{R}^d}(t,\xi) = \frac{1}{(4\pi t)^{d/2}} \exp\big(|\xi|^2/(4t)\big) \quad \text{and} \quad H_{\mathcal{Y}}(t,\eta) = \sum_{\lambda \in \Lambda} H_{\mathbb{R}^d}(t, \eta + \lambda).$$

For $t > 0$ we now define the functions

$$V(t,x,y) = \int_{\mathbb{R}^d} \int_{\mathcal{Y}} H_{\mathbb{R}^d}(t, x-\xi) H_{\mathcal{Y}}(t, y-\eta) (V_1)_{\mathrm{ex}}(\xi,\eta) \,\mathrm{d}\eta \,\mathrm{d}\xi. \tag{2.11}$$

The classical semigroup theory for the parabolic equation $\partial_t V = \Delta_{\mathbb{R}^d} V + \Delta_{\mathcal{Y}} V$ implies $V(t,\cdot) \in \mathrm{C}^\infty(\mathbb{R}^d \times \mathcal{Y})$ for $t > 0$ and

$$\begin{aligned}
&\forall\, \alpha, \beta \in \mathbb{N}_0^d \;\exists\, C_{\alpha,\beta} > 0 \;\forall\, t > 0: \quad \|\mathrm{D}_x^\alpha \mathrm{D}_y^\beta V(t,\cdot)\|_{\mathrm{L}^p(\mathbb{R}^d \times \mathcal{Y})} \le C \,/\, t^{(|\alpha|+|\beta|)/2},\\
&\delta(t) = \|\nabla_y V(t,\cdot) - \nabla_y V_1\|_{\mathrm{L}^p(\mathbb{R}^d \times \mathcal{Y})} \to 0 \;\text{ for } t \searrow 0.
\end{aligned}$$

We define the two-scale function $v(\varepsilon,t,\cdot) \in \mathrm{W}^{1,p}(\Omega)$ via $v(\varepsilon,t,x) = \varepsilon\, V(t,x,\{\frac{x}{\varepsilon}\}_{\mathcal{Y}})$. We will choose $t = t_\varepsilon$ suitably to define $v_\varepsilon = v(\varepsilon, t_\varepsilon, \cdot)$. As a first result we obtain

$$\|v_\varepsilon\|_{\mathrm{L}^p(\Omega)} \le \varepsilon |\Omega|^{1/p} \|V(t_\varepsilon,\cdot)\|_{\mathrm{C}^0(\Omega \times \mathcal{Y})} \le \varepsilon C_{\mathrm{Sob}} \|V(t_\varepsilon,\cdot)\|_{\mathrm{W}^{k,p}(\Omega \times \mathcal{Y})} \le C \varepsilon t_\varepsilon^{-k/2},$$

where $k > (d+d)/p$ and C_{Sob} is the corresponding embedding constant for $\mathrm{W}^{k,p}(\Omega \times \mathcal{Y})$ into $\mathrm{C}^0(\Omega \times \mathcal{Y})$. Below we will choose t_ε such that $\varepsilon\, t_\varepsilon^{-k/2} \to 0$ for $\varepsilon \to 0$, and thus we conclude $v_\varepsilon \to 0$ in $\mathrm{L}^p(\Omega)$.

For the gradients we obtain $\nabla v_\varepsilon(\varepsilon,x) = \varepsilon \nabla_x V(t_\varepsilon, x, \{\frac{x}{\varepsilon}\}_{\mathcal{Y}}) + \nabla_y V(t_\varepsilon, x, \{\frac{x}{\varepsilon}\}_{\mathcal{Y}})$. Using $\|\mathcal{T}_\varepsilon \nabla v_\varepsilon - \nabla_y V_1\|_{\mathrm{L}^p(\Omega \times \mathcal{Y})} \le \|\mathcal{T}_\varepsilon v_\varepsilon - \nabla_y V(t_\varepsilon,\cdot)\|_{\mathrm{L}^p(\Omega \times \mathcal{Y})} + \delta(t_\varepsilon)$ with $\delta(t_\varepsilon) \to 0$

and recalling $\mathcal{T}_\varepsilon u(x,y) = (u\circ S_\varepsilon)(x,y) = u(\mathcal{N}_\varepsilon(x){+}\varepsilon y)$, it suffices to estimate

$$\begin{aligned}&|(\mathcal{T}_\varepsilon \nabla v_\varepsilon)(x,y) - V(t_\varepsilon,x,y)|\\ &\le \varepsilon|\nabla_x V(t_\varepsilon,\mathcal{N}_\varepsilon(x),y)| + |\nabla_y V(t_\varepsilon,\mathcal{N}_\varepsilon(x),y) - \nabla_y V(t_\varepsilon,x,y)|\\ &\le \varepsilon\|\nabla_x V(t_\varepsilon,\cdot)\|_{\mathrm{C}^0(\Omega\times\mathcal{Y})} + \varepsilon\mathrm{diam}(Y)\|\nabla_x\nabla_y V(t_\varepsilon,\cdot)\|_{\mathrm{C}^0(\Omega\times\mathcal{Y})}\\ &\le C_1\varepsilon C_{\mathrm{Sob}}\|V(t_\varepsilon,\cdot)\|_{\mathrm{W}^{k+2,p}(\Omega\times\mathcal{Y})} \le C_2\varepsilon\, t_\varepsilon^{-(k+2)/2}.\end{aligned}$$

Letting $t_\varepsilon = \varepsilon^\gamma$ with $\gamma \in (0, 2/(2{+}k))$ we obtain $\mathcal{T}_\varepsilon v_\varepsilon \rightharpoonup V_1$ in $\mathrm{L}^p(\Omega{\times}\mathcal{Y})$, and the result is proved. $\square$

The second construction is more direct and allows us to do unfolding and folding as well. It is based on [Vis04, Thm. 6.1], but we take care of the problems with the boundary $\partial\Omega$. For simplicity, we restrict ourselves to the case $p = 2$ and assume Dirichlet boundary conditions. We define the intermediate space $\mathcal{L} = \mathrm{L}^2(\Omega){\times}\mathrm{L}^2(\mathbb{R}^d{\times}\mathcal{Y})^d$, the two-scale Hilbert space $\mathcal{H} = \mathrm{H}^1_0(\Omega){\times}\mathrm{L}^2(\mathbb{R}^d, \mathrm{H}^1_{\mathrm{av}}(\mathcal{Y}))$, and the two norm-preserving linear operators

$$\mathbb{T}_\varepsilon : \begin{cases} \mathrm{H}^1_0(\Omega) & \to \quad \mathcal{L},\\ u & \mapsto \quad (u, \mathcal{T}_\varepsilon\nabla u),\end{cases} \qquad \mathbb{F}_\varepsilon : \begin{cases} \mathcal{H} & \to \quad \mathcal{L},\\ (u_0,U_1) & \mapsto \quad (u_0, (E\nabla_x u_0{+}\nabla_y U_1)_{\mathrm{ex}}).\end{cases}$$

For norm-preservation of $\mathbb{F}_\varepsilon$ we choose the norm $\|U_1\|^2_{\mathrm{H}^1_{\mathrm{av}}(\mathcal{Y})} = \|\nabla_y U_1\|_{\mathrm{L}^2(\mathcal{Y})}$.

In particular the images $\mathcal{X}^\varepsilon_{\mathbb{T}} := \mathbb{T}_\varepsilon \mathrm{H}^1(\Omega)$ and $\mathcal{X}^\varepsilon_{\mathbb{F}} = \mathbb{F}_\varepsilon\mathcal{H}$ are closed subspaces of $\mathrm{L}^2_{\mathrm{av}}(\mathcal{Y})$. We let $\mathbb{Q}^\varepsilon_{\mathbb{T}}$ and $\mathbb{Q}^\varepsilon_{\mathbb{F}}$ be the orthogonal projections onto $\mathcal{X}^\varepsilon_{\mathbb{T}}$ and $\mathcal{X}^\varepsilon_{\mathbb{F}}$, respectively. Then we are able to define a *gradient unfolding operator* $\mathcal{T}^{(1)}_\varepsilon = \mathbb{F}_\varepsilon^{-1}\mathbb{Q}^\varepsilon_{\mathbb{F}}\mathbb{T}_\varepsilon : \mathrm{H}^1_0(\Omega) \to \mathcal{H}$ and a *gradient folding operator* $\mathcal{G}_\varepsilon$ via

$$\mathcal{G}_\varepsilon : \begin{cases} \mathcal{H} & \to \quad \mathrm{H}^1_0(\Omega),\\ (u_0,U_1) & \mapsto \quad \mathbb{T}_\varepsilon^{-1}\Big(\mathbb{Q}^\varepsilon_{\mathbb{T}}\big(\mathbb{F}_\varepsilon(u_0,U_1)\big)\Big).\end{cases} \tag{2.12}$$

As the operators $\mathcal{T}^{(1)}_\varepsilon$ and $\mathcal{G}_\varepsilon$ are compositions of norm-preserving operators and orthogonal projections, they have a norm not exceeding 1. The following result shows that the definition of $\mathcal{G}_\varepsilon$ is such that it relates to solving an auxiliary elliptic problem and that it provides a recovery sequence with strongly two-scale convergent gradients.

PROPOSITION 2.10. *For given $(u_0,U_1) \in \mathcal{H}$ the function $\mathcal{G}_\varepsilon(u_0,U_1)$ is uniquely characterized as the solution $v \in \mathrm{H}^1_0(\Omega)$ of the weak elliptic problem*

$$\int_\Omega (v-u_0)\,w + \big(\nabla v - \mathcal{F}_\varepsilon(E\nabla_x u_0{+}\nabla_y U_1)\big)\cdot\nabla w\,\mathrm{d}x = 0 \quad \textit{for all } w \in \mathrm{H}^1_0(\Omega). \tag{2.13}$$

Moreover, for $\varepsilon \to 0$, we have the convergences

$$\begin{aligned} \mathcal{G}_\varepsilon(u_0,U_1) &\rightharpoonup u_0 &&\textit{in } \mathrm{H}^1_0(\Omega),\\ \nabla\mathcal{G}_\varepsilon(u_0,U_1) &\xrightarrow{\mathrm{s2}} E\nabla_x u_0 + \nabla_y U_1 &&\textit{in } \mathrm{L}^2(\Omega{\times}\mathcal{Y}).\end{aligned} \tag{2.14}$$

Proof. At first, we fix ε and let $v = \mathcal{G}_\varepsilon(u_0,U_1)$ such that $\mathbb{T}_\varepsilon v$ is the orthogonal projection of $\mathbb{F}_\varepsilon(u_0,U_1)$ onto $\mathcal{X}^\varepsilon_{\mathbb{T}} = \mathbb{T}_\varepsilon\mathrm{H}^1(\Omega)$. Denoting by $\langle\cdot,\cdot\rangle_{\mathcal{L}}$ the scalar product in $\mathcal{L}$, this means that for all $w \in \mathrm{H}^1_0(\Omega)$ we have

$$\begin{aligned}
0 &= \langle\, \mathbb{T}_\varepsilon v - \mathbb{F}_\varepsilon(u_0, U_1)\,, \mathbb{T}_\varepsilon w \rangle_{\mathcal{L}} \\
&= \int_\Omega (v-u_0)\, w \,\mathrm{d}x + \int_{\mathbb{R}^d\times\mathcal{Y}} (\mathcal{T}_\varepsilon(\nabla v) - \nabla_x u_0 - \nabla_y U_1)\cdot \mathcal{T}_\varepsilon(\nabla w)\,\mathrm{d}y\,\mathrm{d}x \\
&= \int_\Omega (v-u_0)\, w \,\mathrm{d}x + \int_\Omega (\nabla v)\cdot(\nabla w)\,\mathrm{d}x - \int_\Omega \mathcal{F}_\varepsilon(\nabla_x u_0 + \nabla_y U_1)\cdot \nabla w\,\mathrm{d}x.
\end{aligned}$$

Here we use the definitions of $\mathbb{T}_\varepsilon$ and $\mathbb{F}_\varepsilon$ as well as the properties of $\mathcal{T}_\varepsilon$ in Proposition 2.1(a) and (c). Clearly the last line gives (2.13).

To show the desired convergence we recall that the operators $\mathcal{G}_\varepsilon : \mathcal{H} \to \mathrm{H}^1(\Omega)$ have a norm bounded by 1. Hence, it suffices to prove the desired convergence on a dense subset, namely, $\mathcal{C} = \mathrm{C}^2_\mathrm{c}(\Omega)\times\mathrm{C}^2_\mathrm{c}(\Omega\times\mathcal{Y})$. For $(u_0, U_1) \in \mathcal{C}$ we write $u_\varepsilon = (\mathcal{G}_\varepsilon(u_0, U_1))$ in the form

$$u_\varepsilon(x) = v_\varepsilon(x) + g_\varepsilon(x) \quad \text{with } v_\varepsilon(x) = u_0(x) + \varepsilon\, U_1\left(x, \left\{\frac{x}{\varepsilon}\right\}_{\mathcal{Y}}\right),$$

where g_ε is the solution of the weak elliptic problem

$$\begin{aligned}
&\int_\Omega g_\varepsilon w + \nabla g_\varepsilon \cdot \nabla w \,\mathrm{d}x = \ell_\varepsilon(w) \quad \text{for all } w \in \mathrm{H}^1_0(\Omega), \\
&\text{where } \ell_\varepsilon(w) = \int_\Omega (u_0 - v_\varepsilon) w + \big(\mathcal{F}_\varepsilon(E\nabla_x u_0 + \nabla_y U_1) - \nabla v_\varepsilon\big)\cdot \nabla w\,\mathrm{d}x.
\end{aligned} \tag{2.15}$$

Clearly, the family $(v_\varepsilon)_{\varepsilon\in(0,1)}$ is bounded in $\mathrm{H}^1_0(\Omega)$. Moreover, we have $\|u_0 - v_\varepsilon\|_{\mathrm{L}^\infty} \le C_1\varepsilon$, which implies $v_\varepsilon \rightharpoonup u_0$ in $\mathrm{H}^1_0(\Omega)$. Using $\nabla v_\varepsilon(x) = \nabla u_0(x) + \nabla_y U_1(x, \{\frac{x}{\varepsilon}\}_{\mathcal{Y}}) + \varepsilon \nabla_x U_1(x, \{\frac{x}{\varepsilon}\}_{\mathcal{Y}})$ and $(u_0, U_1) \in \mathcal{C}$, we have $\|\mathcal{T}_\varepsilon \nabla v_\varepsilon - (E\nabla_x u_0 - \nabla_y U_1)_{\mathrm{ex}}\|_{\mathrm{L}^2(\mathbb{R}^d\times\mathcal{Y})} \le C_2\varepsilon$, i.e., $\nabla v_\varepsilon \xrightarrow{\mathrm{s2}} E\nabla_x u_0 - \nabla_y U_1$ in $\mathrm{L}^2(\Omega\times\mathcal{Y})$.

Hence, it suffices to show $\|g_\varepsilon\|_{\mathrm{H}^1(\Omega)} \to 0$, as this implies $\nabla g_\varepsilon \xrightarrow{\mathrm{s2}} 0$ in $\mathrm{L}^2(\Omega\times\mathcal{Y})$. From (2.15) we have

$$\begin{aligned}
\|g_\varepsilon\|^2_{\mathrm{H}^1(\Omega)} &\le \|(u_0 - v_\varepsilon, \mathcal{F}_\varepsilon(E\nabla_x u_0 + \nabla_y U_1) - \nabla v_\varepsilon)\|^2_{\mathcal{L}} \\
&= \|u_0 - v_\varepsilon\|^2_{\mathrm{L}^2(\Omega)} + \|E\nabla_x u_0 + \nabla_y U_1) - \mathcal{T}_\varepsilon \nabla\|^2_{\mathrm{L}^2(\mathbb{R}^d\times\mathcal{Y})} \;\le\; C_3\varepsilon^2.
\end{aligned}$$

This finishes the proof of the convergence result (2.14). ∎

Finally, let us note that we may extend the construction to functions $u, u_0 \in \mathrm{H}^1(\Omega)$, namely, without Dirichlet boundary conditions. In fact, for $u_0 \in \mathrm{H}^1(\Omega)$ we obtain a recovery sequence $u_\varepsilon = u_0 + \mathcal{G}_\varepsilon(0, U_1)$ by simply employing the above result and Proposition 2.4(f).

2.5. Two-scale Γ-limits. We now discuss the question of how functionals behave under two-scale convergence. This relates strongly to the question of homogenization. The two-scale convergence results we present here are well known in the literature, but often they are not easily accessible. Thus, we repeat here some simple versions which can be easily deduced by our theory and which are sufficient for our application in the next section. For more advanced results we refer to [All92, CD99, CDD06, Vis07].

Let $W : \mathcal{Y}\times\mathbb{R}^m \to \mathbb{R}_\infty := \mathbb{R}\cup\{\infty\}$ be a normal integrand, which means that for each $u \in \mathbb{R}^m$ the function $y \mapsto W(y, u)$ is measurable and that for a.e. $y \in \mathcal{Y}$ the function $u \mapsto W(y,u)$ is lower semicontinuous. Recalling our definitions of $\mathcal{T}_\varepsilon$, $\mathcal{F}_\varepsilon$, and $[\Omega\times\mathcal{Y}]_\varepsilon$ (cf. the line above (2.3)), we obtain the following central formulas:

$$\int_\Omega W\left(\left\{\frac{x}{\varepsilon}\right\}_{\mathcal{Y}}, u(x)\right)\mathrm{d}x = \int_{[\Omega\times\mathcal{Y}]_\varepsilon} W(y, \mathcal{T}_\varepsilon u\,(x,y))\,\mathrm{d}y\,\mathrm{d}x \quad \text{for all } u\in \mathrm{L}^p(\Omega). \tag{2.16}$$

This identity follows by a simple decomposition of Ω_ε^+ into small cells $\mathcal{N}_\varepsilon(\xi)+\varepsilon Y$ and using the definition of $\mathcal{T}_\varepsilon$.

The next two lemmas are the basis of the two-scale Γ-convergence for the functionals

$$\mathcal{W}_\varepsilon : \begin{cases} \mathrm{L}^p(\Omega) \ \to \ \mathbb{R}_\infty, \\ u \ \mapsto \ \int_\Omega W(\left\{\frac{x}{\varepsilon}\right\}_{\mathcal{Y}}, u(x))\,\mathrm{d}x \end{cases} \quad \text{and} \quad \boldsymbol{W} : \begin{cases} \mathrm{L}^p(\Omega\times\mathcal{Y}) \to \ \mathbb{R}_\infty, \\ U \ \mapsto \ \int_{\Omega\times\mathcal{Y}} W(y, U(x,y))\,\mathrm{d}y\,\mathrm{d}x. \end{cases}$$

LEMMA 2.11. *Assume that $p\in(1,\infty)$, that Ω is as above, and that $W : \mathcal{Y}\times\mathbb{R}^m \to \mathbb{R}_\infty$ is a convex normal integrand, i.e., $W(y,\cdot) : \mathbb{R}^m \to \mathbb{R}_\infty$ is convex for a.e. $y\in\mathcal{Y}$. Moreover, let W be bounded from below by $W(y,u) \geq -h(y)$ for a.e. $y\in\mathcal{Y}$ with $h\in\mathrm{L}^1(\Omega)$. Then*

$$u_\varepsilon \overset{\mathrm{w2}}{\rightharpoonup} U \text{ in } \mathrm{L}^p(\Omega\times\mathcal{Y}) \quad \Longrightarrow \quad \boldsymbol{W}(U) \leq \liminf_{\varepsilon\to 0} \mathcal{W}_\varepsilon(u_\varepsilon).$$

Proof. We choose an increasing sequence A_k, $k\in\mathbb{N}$, of open subsets of Ω such that $A_k \subset A_{k+1} \Subset \Omega$ and $|\Omega\backslash A_k| \to 0$ for $k\to\infty$. Then for each k there exists ε_0 such that $A_k\times\mathcal{Y} \subset \Omega_\varepsilon^-\times\mathcal{Y} \subset [\Omega\times\mathcal{Y}]_\varepsilon$ for $\varepsilon\in(0,\varepsilon_0)$.

Now consider a family with $u_\varepsilon \overset{\mathrm{w2}}{\rightharpoonup} U$. Using (2.16) and $W\geq 0$ we find

$$\mathcal{W}_\varepsilon(u_\varepsilon) = \int_{[\Omega\times\mathcal{Y}]_\varepsilon} W(y, \mathcal{T}_\varepsilon u_\varepsilon(x,y))\,\mathrm{d}y\,\mathrm{d}x \geq \int_{A_k\times\mathcal{Y}} W(y, \mathcal{T}_\varepsilon u_\varepsilon(x,y))\,\mathrm{d}y\,\mathrm{d}x - \int_{\Omega\backslash A_k} h(y)\,\mathrm{d}y.$$

On the right-hand side we may pass to the limit inferior for $\varepsilon\to 0$, as $\mathcal{T}_\varepsilon u_\varepsilon \rightharpoonup U$ in $\mathrm{L}^p(\Omega\times\mathcal{Y})$ and as W is a convex normal integrand. We obtain

$$\liminf_{\varepsilon\to 0} \mathcal{W}_\varepsilon(u_\varepsilon) \geq \int_{A_k\times\mathcal{Y}} W(y, U(x,y))\,\mathrm{d}y\,\mathrm{d}x \ - \int_{\Omega\backslash A_k} h(y)\,\mathrm{d}y.$$

Since k was arbitrary, we may consider now the limit $k\to\infty$. The second term tends to 0 as $|\Omega\backslash A_k| \to 0$, whereas the first term converges to $\boldsymbol{W}(U)$. ∎

LEMMA 2.12. *Assume that $p\in(1,\infty)$ and that Ω is as above.*

(a) *Let $W : \mathcal{Y}\times\mathbb{R}^m \to \mathbb{R}$ be a Carathéodory function, i.e., $W(y,\cdot)$ is continuous for a.e. $y\in\mathcal{Y}$ and $W(\cdot,u)$ is measurable for each $u\in\mathbb{R}^d$. Moreover, assume that there is a function $h\in\mathrm{L}^1(\mathcal{Y})$ and a constant $C>0$ such that $|W(y,u)| \leq h(y) + C(1+|u|)^p$ for all $u\in\mathbb{R}^m$ and a.e. $y\in\mathcal{Y}$. Then*

$$u_\varepsilon \xrightarrow{\mathrm{s2}} U \text{ in } \mathrm{L}^p(\Omega\times\mathcal{Y}) \quad \Longrightarrow \quad \boldsymbol{W}(U) = \lim_{\varepsilon\to 0} \mathcal{W}_\varepsilon(u_\varepsilon).$$

In particular, this implies that $\mathcal{W}_\varepsilon(\mathcal{F}_\varepsilon U_{\mathrm{ex}}) \to \boldsymbol{W}(U)$.

(b) *Let $W : \mathcal{Y}\times\mathbb{R}^m \to \mathbb{R}_\infty$ be a normal integrand such that for a.e. $y\in\mathcal{Y}$ the function $W(y,\cdot)$ is convex and that $|W(y,0)| \leq h(y)$ for some $h\in\mathrm{L}^1(\mathcal{Y})$. Then*

$$\boldsymbol{W}(U) = \lim_{\varepsilon\to 0} \mathcal{W}_\varepsilon(\mathcal{F}_\varepsilon U_{\mathrm{ex}}) \quad \text{for all } U\in\mathrm{L}^p(\Omega\times\mathcal{Y}).$$

Proof. (a) We let $U_\varepsilon = \mathcal{T}_\varepsilon u_\varepsilon$; then formula (2.16) gives

$$\mathcal{W}_\varepsilon(u_\varepsilon) = \int_{[\Omega\times\mathcal{Y}]_\varepsilon} W(y, U_\varepsilon(x,y))\,\mathrm{d}y\,\mathrm{d}x = \boldsymbol{W}(U) + I_1^\varepsilon + I_\varepsilon^2$$

with

$$I_1^\varepsilon = \int_{\Omega\times\mathcal{Y}} \big[W(y,U_\varepsilon(x,y)) - W(y,U(x,y))\big]\,\mathrm{d}y\,\mathrm{d}x = \boldsymbol{W}(U_\varepsilon) - \boldsymbol{W}(U),$$
$$I_2^\varepsilon = \int_{[\Omega\times\mathcal{Y}]_\varepsilon} W(y,U_\varepsilon(x,y))\,\mathrm{d}y\,\mathrm{d}x - \int_{\Omega\times\mathcal{Y}} W(y,U_\varepsilon(x,y))\,\mathrm{d}y\,\mathrm{d}x.$$

We have $I_1^\varepsilon \to 0$ because of $U_\varepsilon \to U_{\mathrm{ex}}$ in $\mathrm{L}^p(\mathbb{R}^d\times\mathcal{Y})$ and the strong continuity of the functional $\boldsymbol{R}$. For the later property we use the continuity of $W(y,\cdot)$ and the growth restrictions; cf. [Dac89, Val88].

For $I_2^\varepsilon \to 0$ we note that both integrals have the same integrand. Moreover, the difference of the domains $\Omega\times\mathcal{Y}$ and $[\Omega\times\mathcal{Y}]_\varepsilon$ is contained in $B_\varepsilon = \big(\overline{\Omega_\varepsilon^+\backslash\Omega_\varepsilon^-}\big)\times\mathcal{Y}$. By condition (2.4) the Lebesgue measure of this set tends to 0, whence $I_2^\varepsilon \to 0$ and we conclude

$$|I_2^\varepsilon| \le \int_{B_\varepsilon} h(y) + C(1+|U_\varepsilon(x,y)|)^p\,\mathrm{d}y\,\mathrm{d}x \to 0,$$

where again $U_\varepsilon \to U$ is used to obtain the equi-integrability of $|U_\varepsilon|^p$.

(b) We again use (2.16) for $u = \mathcal{F}_\varepsilon U_{\mathrm{ex}}$ and note that $\mathcal{T}_\varepsilon\mathcal{F}_\varepsilon U_{\mathrm{ex}} = \chi_\varepsilon \mathcal{P}_\varepsilon U_{\mathrm{ex}}$ by Proposition 2.1(d). With this we find

$$\begin{aligned}\mathcal{W}_\varepsilon(\mathcal{F}_\varepsilon U_{\mathrm{ex}}) &= \int_{[\Omega\times\mathcal{Y}]_\varepsilon} W(y,\mathcal{P}_\varepsilon U_{\mathrm{ex}}(x,y))\,\mathrm{d}y\,\mathrm{d}x = \int_{\mathbb{R}^d\times\mathcal{Y}} \chi_\varepsilon(x,y) W(y,\mathcal{P}_\varepsilon U_{\mathrm{ex}}(x,y))\,\mathrm{d}y\,\mathrm{d}x\\
&\le_{(1)} \int_{\mathbb{R}^d\times\mathcal{Y}} \chi_\varepsilon(x,y) \fint_{\mathcal{N}_\varepsilon(x)+\varepsilon Y} W(y,U_{\mathrm{ex}}(y,\xi))\,\mathrm{d}\xi\;\mathrm{d}y\,\mathrm{d}x\\
&=_{(2)} \int_{\mathbb{R}^d\times\mathcal{Y}} \chi_\varepsilon(\xi,y) W(y,U_{\mathrm{ex}}(y,\xi))\,\mathrm{d}y\,\mathrm{d}\xi \;\le_{(3)}\; \boldsymbol{W}(U) + \int_{(\Omega_\varepsilon^+\backslash\Omega)\times\mathcal{Y}} h(y)\,\mathrm{d}y\,\mathrm{d}x.\end{aligned}$$

For $\le_{(1)}$ we have used the convexity of $W(y,\cdot)$ and Jensen's inequality. The equality $=_{(2)}$ uses the fact that the integrand is piecewise constant in x on each $\mathcal{N}_\varepsilon(x)+\varepsilon Y$. For $\le_{(3)}$ we use $\chi_\varepsilon \le \chi_{\Omega\times\mathcal{Y}} + \chi_{(\Omega_\varepsilon^+\backslash\Omega)\times\mathcal{Y}}$ and $U_{\mathrm{ex}} = 0$ outside of $\Omega\times\mathcal{Y}$. Using $h \in \mathrm{L}^1(\mathcal{Y})$ and (2.4) we find $\limsup_\varepsilon \mathcal{W}_\varepsilon(\mathcal{F}_\varepsilon U_{\mathrm{ex}}) \le \boldsymbol{W}(U)$. The opposite inequality $\liminf_\varepsilon \mathcal{W}_\varepsilon(\mathcal{F}_\varepsilon U_{\mathrm{ex}}) \ge \boldsymbol{W}(U)$ was established in Lemma 2.11. ∎

The following result states that the two-scale functional $\boldsymbol{W}$ can be considered as the two-scale Γ-limit of the functionals $\mathcal{W}_\varepsilon$ in the sense of Mosco; i.e., it is the two-scale Γ-limit in the weak as well as in the strong topology.

COROLLARY 2.13. *Let $p \in (1,\infty)$ and let Ω be as above. Moreover, let $W : \mathcal{Y}\times\mathbb{R}^m \to \mathbb{R}$ be a convex, normal integrand satisfying the bounds $W(y,u) \ge -h(y)$ and $W(y,0) \le h(y)$ for all $u \in \mathbb{R}^m$ and a.a. $y \in \mathcal{Y}$ with $h \in \mathrm{L}^1(\mathcal{Y})$. Then we have the following:*

(i) *Lower estimate: $u_\varepsilon \xrightarrow{\mathrm{w2}} U$ in $\mathrm{L}^p(\Omega\times\mathcal{Y}) \implies \boldsymbol{W}(U) \le \liminf_{\varepsilon\to 0} \mathcal{W}_\varepsilon(u_\varepsilon)$.*

(ii) *Recovery sequence: $\forall U \in \mathrm{L}^p(\Omega\times\mathcal{Y})\ \exists (u_\varepsilon)_\varepsilon :\ u_\varepsilon \xrightarrow{\mathrm{s2}} U$ and $\boldsymbol{W}(U) = \lim_{\varepsilon\to 0} \mathcal{W}_\varepsilon(u_\varepsilon)$.*

REMARK 2.14. *It is possible to generalize the above results to the case that the density W also depends on the macroscopic variable $x \in \Omega$. The central identity* (2.16) *is easily generalized to*

$$\int_\Omega W_\varepsilon(x, u(x))\,\mathrm{d}x = \int_{[\Omega\times\mathcal{Y}]_\varepsilon} W_\varepsilon(\mathcal{S}_\varepsilon(x,y), \mathcal{T}_\varepsilon u(x,y))\,\mathrm{d}y\,\mathrm{d}x \quad \textit{for all } u \in \mathrm{L}^p(\Omega).$$

Thus, if we want to realize a general Carathéodory function $W : \Omega\times\mathcal{Y}\times\mathbb{R}^m \to \mathbb{R}_\infty$ in the two-scale limit functional $\boldsymbol{W}$, we define $\mathcal{W}_\varepsilon$ via the approximate energy density,

$$W_\varepsilon(x,u) = \widehat{W}_\varepsilon\left(x, \left\{\frac{x}{\varepsilon}\right\}_{\mathcal{Y}}, u\right) \quad \textit{with } \widehat{W}_\varepsilon(x,y,u) = \fint_{\mathcal{N}_\varepsilon(x)+\varepsilon Y} W(\xi, y, u)\,\mathrm{d}\xi,$$

instead of the traditionally used $W(x, \left\{\frac{x}{\varepsilon}\right\}_{\mathcal{Y}}, u)$. Note that W_ε satisfies $W_\varepsilon(\mathcal{S}_\varepsilon(x,y),u) = \widehat{W}_\varepsilon(x,y,u) \to W(x,y,u)$ a.e. for $\varepsilon \to 0$.

Under some mild additional conditions it is then possible to pass to the limit as in Lemmas 2.11 *and* 2.12*; see also Proposition* 2.6*. This also resolves the difficulties addressed in* [CDG02, Thm. 2]*. This will be the subject of future research.*

2.6. Two-scale cross-convergence. Finally we present a result concerning a functional involving gradients. For families $((u_\varepsilon, z_\varepsilon))_\varepsilon$ in $\mathrm{W}^{1,p}(\Omega)\times\mathrm{L}^p(\Omega)$ we define the notions of *weak* and *strong two-scale cross-convergences* as follows:

$$(u_\varepsilon, z_\varepsilon) \overset{\mathrm{w2c}}{\rightharpoonup} (u_0, U_1, Z) \text{ in } \boldsymbol{X}_p \quad \Longleftrightarrow \quad \begin{cases} u_\varepsilon \rightharpoonup u_0 & \text{in } \mathrm{W}^{1,p}(\Omega), \\ \nabla u_\varepsilon \overset{\mathrm{w2}}{\rightharpoonup} E\nabla u_0 + \nabla_y U_1 & \text{in } \mathrm{L}^p(\Omega\times\mathcal{Y}), \\ z_\varepsilon \overset{\mathrm{w2}}{\rightharpoonup} Z & \text{in } \mathrm{L}^p(\Omega\times\mathcal{Y}), \end{cases}$$

$$(u_\varepsilon, z_\varepsilon) \xrightarrow{\mathrm{s2c}} (u_0, U_1, Z) \text{ in } \boldsymbol{X}_p \quad \Longleftrightarrow \quad \begin{cases} u_\varepsilon \rightharpoonup u_0 & \text{in } \mathrm{W}^{1,p}(\Omega), \\ \nabla u_\varepsilon \xrightarrow{\mathrm{s2}} E\nabla u_0 + \nabla_y U_1 & \text{in } \mathrm{L}^p(\Omega\times\mathcal{Y}), \\ z_\varepsilon \xrightarrow{\mathrm{s2}} Z & \text{in } \mathrm{L}^p(\Omega\times\mathcal{Y}), \end{cases}$$

where $\boldsymbol{X}_p = \mathrm{W}^{1,p}(\Omega)\times\mathrm{L}^p(\Omega;\mathrm{W}^{1,p}_{\mathrm{av}}(\mathcal{Y}))\times\mathrm{L}^p(\Omega\times\mathcal{Y})$. The final result on two-scale Γ-convergence now provides relations between the functionals

$$\Phi_\varepsilon(u,z) = \int_\Omega \phi\left(\left\{\frac{x}{\varepsilon}\right\}_{\mathcal{Y}}, u(x), \nabla u(x), z(x)\right)\mathrm{d}x,$$

$$\boldsymbol{\Phi}_\varepsilon(u_0, U_1, Z) = \int_{\Omega\times\mathcal{Y}} \phi(y, u_0(x), \nabla u_0(x){+}\nabla_y U_1(x,y), Z(x,y))\,\mathrm{d}x.$$

PROPOSITION 2.15. *Let $p \in (1,\infty)$ and let $\Omega \subset \mathbb{R}^d$ be a bounded domain with Lipschitz boundary. Assume that $\phi : \mathcal{Y}\times\mathbb{R}^k\times\mathbb{R}^{k\times d}\times\mathbb{R}^m \to \mathbb{R}$ is a Carathéodory function (measurable in $y \in \mathcal{Y}$ and continuous in $(u,F,z) \in \mathbb{R}^k\times\mathbb{R}^{k\times d}\times\mathbb{R}^m \to \mathbb{R}$) satisfying the bound $|\phi(y,u,A,z)| \le h(y) + C(1{+}|u|{+}|A|{+}|z|)^p$ for $h \in \mathrm{L}^1(\mathcal{Y})$. Then we have*

$$(u_\varepsilon, z_\varepsilon) \xrightarrow{\mathrm{s2c}} (u_0, U_1, Z) \textit{ in } \boldsymbol{X}_p \quad \Longrightarrow \quad \Phi_\varepsilon(u_\varepsilon, z_\varepsilon) \to \boldsymbol{\Phi}(u_0, U_1, Z).$$

Moreover, if $\phi(y,\cdot)$ is convex for a.a. $y \in \mathcal{Y}$, we also have

$$(u_\varepsilon, z_\varepsilon) \overset{\mathrm{w2c}}{\rightharpoonup} (u_0, U_1, Z) \textit{ in } \boldsymbol{X}_p \quad \Longrightarrow \quad \boldsymbol{\Phi}(u_0, U_1, Z) \le \liminf_{\varepsilon\to 0} \Phi_\varepsilon(u_\varepsilon, z_\varepsilon).$$

The proof is a direct consequence of combining Lemmas 2.11 and 2.12(a).

3. Existence and uniqueness of solution.

3.1. Abstract result. For the convenience of the reader we recall the standard existence and uniqueness results for evolutionary variational inequalities; see, e.g., [BS96, Vis94, Mie05]. We start with a Hilbert space $\mathcal{Q}$ with dual $\mathcal{Q}^*$ and dual pairing $\langle\cdot,\cdot\rangle : \mathcal{Q}^*\times\mathcal{Q} \to \mathbb{R}$ and a positive semidefinite operator $\mathcal{A} \in \mathrm{Lin}(\mathcal{Q},\mathcal{Q}^*)$, i.e., $\mathcal{A} = \mathcal{A}^*$ and $\langle \mathcal{A}q, q\rangle \geq 0$ for all $q \in \mathcal{Q}$. For a function $\ell \in \mathrm{C}^1([0,T],\mathcal{Q}^*)$ we define the energy functional

$$\mathcal{E}(t,q) = \frac{1}{2}\langle \mathcal{A}q, q\rangle - \langle \ell(t), q\rangle.$$

Moreover, let a dissipation functional $\mathcal{R} : \mathcal{Q} \to [0,\infty]$ be given that is convex, lower semicontinuous, and positively homogeneous of degree 1, viz.,

$$\mathcal{R}(\gamma q) = \gamma\mathcal{R}(q) \quad \text{ for all } \gamma \geq 0 \text{ and } q \in \mathcal{Q}.$$

The *energetic formulation* (S) and (E) of the rate-independent hysteresis problem associated with $\mathcal{E}$ and $\mathcal{R}$ is based on the *global stability condition* (S) and the *energy balance* (E):

$$\text{(S)} \qquad \mathcal{E}(t,q(t)) \leq \mathcal{E}(t,\widetilde{q}) + \mathcal{R}(\widetilde{q}-q(t)) \quad \text{for every } \widetilde{q} \in \mathcal{Q},$$

$$\text{(E)} \qquad \mathcal{E}(t,q(t)) + \mathrm{Diss}_{\mathcal{R}}(q;[0,t]) = \mathcal{E}(0,q(0)) + \int_0^t \partial_s\mathcal{E}(s,q(s))\,\mathrm{d}s,$$

where $\mathrm{Diss}_{\mathcal{R}}(q;[r,s]) = \int_r^s \mathcal{R}(\dot{q}(t))\,\mathrm{d}t$ and $\partial_s\mathcal{E}(s,q(s)) = -\langle\dot{\ell}(s), q(s)\rangle$. We call $q : [0,T] \to \mathcal{Q}$ satisfying (S) and (E) for all $t \in [0,T]$ an *energetic solution* associated with $(\mathcal{E},\mathcal{R})$.

The stability condition can be formulated in terms of the *sets of stable states*

$$\mathcal{S}(t) = \{\, q \in \mathcal{Q} \mid \mathcal{E}(t,q) \leq \mathcal{E}(t,\widehat{q}) + \mathcal{R}(\widehat{q}-q) \text{ for every } \widehat{q} \in \mathcal{Q}\,\}.$$

Now, (S) just means $q(t) \in \mathcal{S}(t)$.

There are several equivalent formulation for (S) and (E), for instance, the subdifferential inclusion $0 \in \partial\mathcal{R}(\dot{q}(t)) + \mathrm{D}_q\mathcal{E}(t,q(t))$ or the variational inequality

$$\text{(3.1)} \qquad \langle \mathcal{A}q(t)-\ell(t), v-\dot{q}(t)\rangle + \mathcal{R}(v) - \mathcal{R}(\dot{q}(t)) \geq 0 \quad \text{for every } v \in \mathcal{Q}.$$

For these equivalences, we refer to [MT04, Mie05], where also a proof of the following existence and uniqueness result can be found.

THEOREM 3.1. *Let $\ell \in \mathrm{C}^1([0,T],\mathcal{Q}^*)$ and $q_0 \in \mathcal{S}(0)$. Moreover, assume that the following coercivity condition holds:*

$$\text{(3.2)} \qquad \exists\, \alpha > 0\ \forall\, v \in \mathcal{Q} \text{ with } \mathcal{R}(v) < \infty : \quad \langle Av, v\rangle \geq \alpha\|v\|^2.$$

Then the energetic problem (S) *and* (E) *has a unique solution $q \in \mathrm{C}^{\mathrm{Lip}}([0,T],\mathcal{Q})$ with*

$$\|q(t) - q(s)\|_{\mathcal{Q}} \leq \frac{\mathrm{Lip}_{\mathcal{Q}^*}(\ell)}{\alpha}|t-s| \quad \textit{for all } s,t \in [0,T].$$

For the reader's convenience we repeat the main argument for the a priori estimate. Assume that for t the derivative $\dot{q}(t)$ exists. Using (3.1) with $v = 0$ we find $\langle \mathcal{A}q(t) - \ell(t), -\dot{q}(t)\rangle - \mathcal{R}(\dot{q}(t)) \leq 0$. For a sequence $t_n \to t$ where (3.1) holds we test with $v = \mu\dot{q}(t)$, divide by μ, and consider the limit $\mu \to \infty$. Using 1-homogeneity of

$\mathcal{R}$ we obtain $\langle \mathcal{A}q(t_n) - \ell(t_n), \dot{q}(t)\rangle + \mathcal{R}(\dot{q}(t)) \leq 0$. Adding this to the above estimate gives

$$\langle \big(\mathcal{A}q(t_n) - \ell(t_n)\big) - \big(\mathcal{A}q(t) - \ell(t)\big), \dot{q}(t)\rangle \leq 0.$$

Assuming $t_n > t$ we may divide the above inequality and pass to the limit to find $\langle \mathcal{A}\dot{q}(t) - \dot{\ell}(t), \dot{q}(t)\rangle \leq 0$. For $t_n < t$ we find the opposite inequality. Since we may approach t by sequences from both sides, this implies $\langle \mathcal{A}\dot{q}(t), \dot{q}(t)\rangle = \langle \dot{\ell}(t), \dot{q}(t)\rangle$. Now, (3.2) leads to the desired result $\alpha\|\dot{q}(t)\| \leq \|\dot{\ell}(t)\|_*$.

3.2. Elastoplasticity with periodic coefficients. In this section we formulate the continuum mechanics that describes the rate-independent evolution of an elastoplastic body under prescribed loading. This model is the classical one introduced by Moreau and is still used in many engineering applications; cf. [Mor76, HR99].

The body occupies a domain $\Omega \subset \mathbb{R}^d$, which is assumed to be a nonempty connected bounded open set with Lipschitz boundary $\partial\Omega$. As above we have a length scale parameter ε and a periodicity lattice Λ with unit cell $Y \subset \mathbb{R}^d$. With $u : \Omega \to \mathbb{R}^d$ we denote the displacement of the body, and $z : \Omega \to \mathbb{R}^m$ denotes a vector of internal variables which will account for inelastic effects due to plastic strains and plastic hardening.

The material properties are assumed to be periodic with respect to the microscopic lattice $\varepsilon\Lambda$, which leads to the dependence on $\left\{\frac{x}{\varepsilon}\right\}_{\mathcal{Y}}$. The energy functional $\mathcal{E}_\varepsilon$ is based on a stored-energy density $W : \mathcal{Y}\times\mathbb{R}^{d\times d}_{\mathrm{sym}}\times\mathbb{R}^m \to \mathbb{R}; (y, \boldsymbol{e}, z) \mapsto W(y, \boldsymbol{e}, z)$, where $\mathbb{R}^{d\times d}_{\mathrm{sym}} = \{\, A \in \mathbb{R}^{d\times d} \mid A = A^{\mathsf{T}} \,\}$ and $\boldsymbol{e} = \boldsymbol{e}(u) = \frac{1}{2}(\nabla u + \nabla u^{\mathsf{T}}) \in \mathbb{R}^{d\times d}_{\mathrm{sym}}$ is the linearized strain tensor. With this, $\mathcal{E}_\varepsilon$ takes the form

$$\mathcal{E}_\varepsilon(t, u, z) = \int_\Omega W\left(\left\{\frac{x}{\varepsilon}\right\}_{\mathcal{Y}}, \boldsymbol{e}(u)(x), z(x)\right) \mathrm{d}x - \langle \ell(t), u\rangle$$

$$\text{with } \langle \ell(t), u\rangle = \int_\Omega u(x)\cdot f_{\mathrm{ap}}(t,x)\,\mathrm{d}x + \int_{\partial\Omega} u(\xi)\cdot g_{\mathrm{ap}}(t,\xi)\,\mathrm{d}\xi,$$

where f_{ap} and g_{ap} are the applied, time-dependent loading in the volume and on the surface, respectively. We assume that they satisfy $f_{\mathrm{ap}} \in \mathrm{C}^1([0,T], \mathrm{L}^2(\Omega;\mathbb{R}^d))$ and $g_{\mathrm{ap}} \in \mathrm{C}^1([0,T], \mathrm{L}^2(\partial\Omega;\mathbb{R}^d))$, such that $\ell \in \mathrm{C}^1([0,T], \mathrm{H}^1(\Omega;\mathbb{R}^d)^*)$.

For the stored energy W we assume that it is a quadratic form in $(\boldsymbol{e}, z)$, namely,

$$W(y, \boldsymbol{e}, z) = \frac{1}{2}\left\langle\!\!\left\langle \mathbb{A}(y)\begin{pmatrix}\boldsymbol{e}\\ z\end{pmatrix}, \begin{pmatrix}\boldsymbol{e}\\ z\end{pmatrix}\right\rangle\!\!\right\rangle,$$

where $\mathbb{A}(y) : \mathbb{R}^{d\times d}_{\mathrm{sym}}\times\mathbb{R}^m \to \mathbb{R}^{d\times d}_{\mathrm{sym}}\times\mathbb{R}^m$ is a positive semidefinite linear operator and $\langle\!\langle \binom{\boldsymbol{e}}{z}, \binom{\widetilde{\boldsymbol{e}}}{\widetilde{z}} \rangle\!\rangle = \sum_{i,j=1}^d \boldsymbol{e}_{ij}\widetilde{\boldsymbol{e}}_{ij} + \sum_{k=1}^m z_k\widetilde{z}_k$ is the scalar product on $\mathbb{R}^{d\times d}_{\mathrm{sym}}\times\mathbb{R}^m$.

The dissipation potential $\mathcal{R}_\varepsilon$ is defined via a dissipation density $\rho : \mathcal{Y}\times\mathbb{R}^m \to [0,\infty]$, i.e., $\mathcal{R}_\varepsilon(\dot{z}) = \int_\Omega \rho(\left(\left\{\frac{x}{\varepsilon}\right\}_{\mathcal{Y}}\right), \dot{z}(x))\,\mathrm{d}x$. Rate-independence is imposed by assuming that $\rho(y,\cdot)$ is positively homogeneous of degree 1 (for short, 1-homogeneous). Note that ρ is not assumed to be symmetric (i.e., $\rho(y,-\dot{z}) \neq \rho(y,\dot{z})$ is allowed), since this freedom is necessary to model hardening.

Our precise assumptions on the material data $\mathbb{A}$ and ρ are

(3.3a) $\mathbb{A} \in \mathrm{L}^\infty(\mathcal{Y}, \mathrm{Lin}(\mathbb{R}^{d\times d}_{\mathrm{sym}}\times\mathbb{R}^m))$ with $\mathbb{A}(y) = \mathbb{A}(y)^\mathsf{T} \geq 0$,

(3.3b) $\rho : \mathcal{Y} \to [0,\infty]$ is a convex, normal integrand and $\rho(y,\cdot)$ is 1-homogeneous,

(3.3c)
$$\exists\, \widehat{\alpha} > 0\ \forall_{a.a.} y \in \mathcal{Y}\ \forall \begin{pmatrix} \boldsymbol{e} \\ z \end{pmatrix} \in \mathbb{R}^{d\times d}_{\mathrm{sym}}\times\mathbb{R}^m \text{ with } \rho(y,z) < \infty\ :$$
$$\left\langle\!\!\left\langle \mathbb{A}(y)\begin{pmatrix} \boldsymbol{e} \\ z \end{pmatrix}, \begin{pmatrix} \boldsymbol{e} \\ z \end{pmatrix} \right\rangle\!\!\right\rangle \geq \widehat{\alpha} \left| \begin{pmatrix} \boldsymbol{e} \\ z \end{pmatrix} \right|^2.$$

Remark 3.2. *Here we describe the exact setting for the linearized theory of elastoplasticity which is the motivation of this work. However, in the remainder of the paper we do not rely on the further specifications given here.*

The basis of linearized elastoplasticity is the additive split of the strain into an elastic part $\boldsymbol{e}_{\mathrm{el}} = \boldsymbol{e}(u) - \boldsymbol{p}$ *and a plastic part* $\boldsymbol{p} = \mathbb{B}(y)z$, *where* $\mathbb{B}(y) : \mathbb{R}^m \to \mathbb{R}^{d\times d}_{\mathrm{sym}}$ *is a linear mapping. Then* W *is taken in the form*

$$W(y,\boldsymbol{e},z) = \big\langle \mathbb{C}(y)(\boldsymbol{e}-\mathbb{B}(y)z), \boldsymbol{e}-\mathbb{B}(y)z \big\rangle_{d\times d} + \langle \mathbb{H}(y)z, z\rangle_m,$$

where $\mathbb{C}(y) : \mathbb{R}^{d\times d}_{\mathrm{sym}} \to \mathbb{R}^{d\times d}_{\mathrm{sym}}$ *is the symmetric (fourth order) elasticity tensor and* $\mathbb{H}(y)$ *denotes the hardening tensor. This means* $\mathbb{A}$ *has the block structure* $\big(\begin{smallmatrix} \mathbb{C} & \mathbb{C}\mathbb{B} \\ -\mathbb{B}^*\mathbb{C} & \mathbb{H}+\mathbb{B}^*\mathbb{C}\mathbb{B} \end{smallmatrix}\big)$.

The typical case of isotropic hardening may be written in the way that $z = (\boldsymbol{p}, h)$, *where* $\boldsymbol{p} \in (\mathbb{R}^{d\times d}_{\mathrm{sym}})_0 = \{\, A \in \mathbb{R}^{d\times d}_{\mathrm{sym}} \mid \operatorname{tr} A = 0 \,\}$ *is the (deviatoric) plastic strain (i.e.,* $\mathbb{B}(y)(\boldsymbol{p},h) = \boldsymbol{p}$*),* $h \in \mathbb{R}$ *is the isotropic hardening parameter, and* $\mathbb{H}(y)$ *is taken as* $\kappa(y) > 0$. *Moreover,* ρ *is assumed to have the form*

$$\rho(y,(\dot{\boldsymbol{p}},\dot{h})) = \begin{cases} r(y)\dot{h} & \text{for } \dot{h} \geq 0 \text{ and } \dot{\boldsymbol{p}} \in \dot{h}\,\Sigma(y), \\ \infty & \text{otherwise}, \end{cases}$$

where $r(y) > 0$ *and* $\Sigma(y) \subset (\mathbb{R}^{d\times d}_{\mathrm{sym}})^*_0$ *is the compact and convex elastic domain (with* $\partial\Sigma(y)$ *being the yield surface) at the point* $y \in \mathcal{Y}$ *for the the initial hardening state* $h = 1$.

The coercivity assumption (3.3c)*, which is essential for our analysis, then follows if we assume that there exist positive constants* c *and* C *such that for a.a.* $y \in \mathcal{Y}$ *we have the estimates*

$$\kappa(y) \geq c, \quad \langle \mathbb{C}(y)\boldsymbol{e},\boldsymbol{e}\rangle \geq c|\boldsymbol{e}|^2 \quad \text{for all } \boldsymbol{e}, \qquad |\boldsymbol{\sigma}| \leq C \quad \text{for all } \boldsymbol{\sigma} \in \Sigma(y).$$

Note that the restriction $\rho(y,(\boldsymbol{p},h)) < \infty$ *implies* $|\boldsymbol{p}| \leq Ch$. *Without the coercivity postulated in* (3.3c) *the analysis would be significantly more difficult due to strain localization; see, e.g.,* [DDM06].

Finally, we fix the function spaces by prescribing Dirichlet boundary conditions $u = 0$ along the part Γ_{Dir} of $\partial\Gamma$. This defines the underlying Hilbert space

$$\mathcal{Q} = \mathrm{H}^1_{\Gamma_{\mathrm{Dir}}}(\Omega)^d\times\mathrm{L}^2(\Omega)^m \quad \text{with } \mathrm{H}^1_{\Gamma_{\mathrm{Dir}}}(\Omega) = \{\, u \in \mathrm{H}^1(\Omega) \mid u_{\Gamma_{\mathrm{Dir}}} = 0 \,\}.$$

The domain Ω and the Dirichlet boundary part Γ_{Dir} are specified further in the next result to guarantee coercivity of the energy $\mathcal{E}_\varepsilon$.

Proposition 3.3 (Korn's inequality). *Let* $\Omega \subset \mathbb{R}^d$ *be a connected, open, bounded set with Lipschitz boundary* Γ. *Moreover, let* Γ_{Dir} *be a measurable subset of* Γ, *such that* $\int_{\Gamma_{\mathrm{Dir}}} 1\,\mathrm{d}a > 0$. *Then there exists a constant* $C_{\mathrm{Korn}} > 0$, *such that*

$$\int_\Omega |\boldsymbol{e}(u)|^2\,\mathrm{d}x \geq C_{\mathrm{Korn}}\|u\|^2_{\mathrm{H}^1(\Omega)} \quad \textit{for all } u \in \mathrm{H}^1_{\Gamma_{\mathrm{Dir}}}(\Omega)^d. \tag{3.4}$$

Clearly, we may write $\mathcal{E}_\varepsilon(t,\boldsymbol{e},z) = \frac{1}{2}\langle\!\langle \mathcal{A}_\varepsilon\binom{u}{z},\binom{u}{z}\rangle\!\rangle - \langle\widetilde{\ell}(t),\binom{\boldsymbol{e}}{z}\rangle$, where $\mathcal{A}_\varepsilon : \mathcal{Q}\to\mathcal{Q}^*$ is symmetric and positive semidefinite. Moreover, combining assumption (3.3c) and Korn's inequality, we find for all $\binom{\boldsymbol{e}}{z}\in\mathcal{Q}$ with $\mathcal{R}_\varepsilon(z)<\infty$ the coercivity estimate

(3.5)
$$\left\langle\!\!\left\langle \mathcal{A}_\varepsilon\begin{pmatrix}u\\ z\end{pmatrix},\begin{pmatrix}u\\ z\end{pmatrix}\right\rangle\!\!\right\rangle \ge \widehat{\alpha}\left\|\begin{pmatrix}\boldsymbol{e}(u)\\ z\end{pmatrix}\right\|^2_{\mathrm{L}^2(\Omega)} \ge \alpha\left\|\begin{pmatrix}u\\ z\end{pmatrix}\right\|^2_{\mathcal{Q}} \quad \text{with } \alpha=\widehat{\alpha}\min\{1,C_{\mathrm{Korn}}\}.$$

We call $q_\varepsilon=(u_\varepsilon,z_\varepsilon):[0,T]\to\mathcal{Q}$ an *energetic solution* associated with $(\mathcal{E}_\varepsilon,\mathcal{R}_\varepsilon)$ if for all $t\in[0,T]$ the *stability condition* (S^ε) and the *energy balance* (E^ε) hold:

(3.6)
$$(\mathrm{S}^\varepsilon)\quad \mathcal{E}_\varepsilon(t,u_\varepsilon(t),z_\varepsilon(t)) \le \mathcal{E}_\varepsilon(t,\widetilde{u},\widetilde{z}) + \mathcal{R}_\varepsilon(\widetilde{z}-z_\varepsilon(t)) \quad \text{for every } (\widetilde{u},\widetilde{z})\in\mathcal{Q},$$
$$(\mathrm{E}^\varepsilon)\quad \mathcal{E}_\varepsilon(t,u_\varepsilon(t),z_\varepsilon(t)) + \int_0^t \mathcal{R}_\varepsilon(\dot{z}_\varepsilon(s))\,\mathrm{d}s = \mathcal{E}_\varepsilon(0,u_\varepsilon(0),z_\varepsilon(0)) - \int_0^t \langle\dot{\ell}(s),u(s)\rangle\,\mathrm{d}s.$$

Applying the abstract Theorem 3.1 we immediately obtain the following existence and uniqueness result, which contains an a priori Lipschitz bound that is independent of $\varepsilon>0$.

PROPOSITION 3.4. *Let $\ell\in\mathrm{C}^{\mathrm{Lip}}([0,T],(\mathrm{H}^1_{\Gamma_{\mathrm{Dir}}}(\Omega)^d)^*)$. Then for all $\varepsilon>0$ and all stable $(u^0_\varepsilon,z^0_\varepsilon)\in\mathcal{Q}$ there exists a unique solution $(u_\varepsilon,z_\varepsilon)\in\mathrm{C}^{\mathrm{Lip}}([0,T],\mathcal{Q})$ of* (S^ε) *and* (E^ε) *with $(u_\varepsilon(0),z_\varepsilon(0))=(u^0_\varepsilon,z^0_\varepsilon)$. Moreover, all these solutions satisfy*

$$(3.7)\quad \|(u_\varepsilon(t),z_\varepsilon(t))-(u_\varepsilon(s),z_\varepsilon(s))\|_{\mathcal{Q}} \le \frac{\mathrm{Lip}_{\mathcal{Q}^*}((\ell,0))}{\alpha}\,|t-s| \quad \textit{for all } t,s\in[0,T],$$

where α is defined in (3.5) *and is independent of ε.*

3.3. The two-scale homogenized problem. Instead of the functionals $\mathcal{E}_\varepsilon$ and $\mathcal{R}_\varepsilon$ we may consider their two-scale limits. As the energy storage functional depends on the gradient of u, we use the notion of two-scale cross-convergence introduced in section 2.6 on the space

$$\boldsymbol{Q}=\boldsymbol{H}\times\boldsymbol{Z} \quad \text{with } \boldsymbol{H}=\mathrm{H}^1_{\Gamma_{\mathrm{Dir}}}(\Omega)^d\times\mathrm{L}^2(\Omega,\mathrm{H}^1_{\mathrm{av}}(\mathcal{Y}))^d \text{ and } \boldsymbol{Z}=\mathrm{L}^2(\Omega\times\mathcal{Y})^m.$$

We use $U=(u_0,U_1)$ for the elements in $\boldsymbol{H}$ and Z for the internal elements lying in $\boldsymbol{Z}$. The functionals $\boldsymbol{E}$ and $\boldsymbol{R}$ are defined via

$$\boldsymbol{E}(t,U,Z) = \int_{\Omega\times\mathcal{Y}} \frac{1}{2}\left\langle\!\!\left\langle \mathbb{A}(y)\begin{pmatrix}\widehat{\boldsymbol{e}}(U)\\ Z\end{pmatrix},\begin{pmatrix}\widehat{\boldsymbol{e}}(U)\\ Z\end{pmatrix}\right\rangle\!\!\right\rangle - \langle\ell(t),u_0\rangle,$$
$$\boldsymbol{R}(Z) = \int_{\Omega\times\mathcal{Y}} \rho(y,Z(x,y))\,\mathrm{d}y\,\mathrm{d}x,$$

where

$$\widehat{\boldsymbol{e}}(U) = \boldsymbol{e}_x(u_0)+\boldsymbol{e}_y(U_1) = \frac{1}{2}(\nabla_x u_0+(\nabla_x u_0)^{\mathsf{T}}) + \frac{1}{2}(\nabla_y U_1+(\nabla_y U_1)^{\mathsf{T}}).$$

Again we define the energetic formulation for $\boldsymbol{E}$ and $\boldsymbol{R}$ on $\boldsymbol{Q}$ via the global stability condition (**S**) and the energy balance (**E**). As above, a mapping $(U,Z):[0,T]\to\boldsymbol{H}\times\boldsymbol{Z}=\boldsymbol{Q}$ is called an energetic solution associated with $\boldsymbol{E}$ and $\boldsymbol{R}$ if for all $t\in[0,T]$ we have

(3.8)
$$(\mathbf{S})\quad \boldsymbol{E}(t,U(t),Z(t)) \le \boldsymbol{E}(t,\widetilde{U},\widetilde{Z}) + \boldsymbol{R}(\widetilde{Z}-Z(t)) \quad \text{for all } (\widetilde{U},\widetilde{Z})\in\boldsymbol{H}\times\boldsymbol{Z},$$
$$(\mathbf{E})\quad \boldsymbol{E}(t,U(t),Z(t)) + \int_0^t \boldsymbol{R}(\dot{Z}(s))\,\mathrm{d}s = \boldsymbol{E}(0,U(0),Z(0)) - \int_0^t \langle\dot{\ell}(s),u_0(s)\rangle\,\mathrm{d}s.$$

Using abstract existence Theorem 3.1 we again obtain the following result as soon as we have established the coercivity assumption (3.2) for the energy $\boldsymbol{E}$.

PROPOSITION 3.5. *Let* $\ell \in \mathrm{C}^{\mathrm{Lip}}([0,T],(\mathrm{H}^1_{\Gamma_{\mathrm{Dir}}}(\Omega)^d)^*)$. *Then for all stable* $Q^0 = (U^0,Z^0) \in \boldsymbol{Q}$, *problem* (**S**) *and* (**E**) *has a unique solution* $Q=(U,Z) \in \mathrm{C}^{\mathrm{Lip}}([0,T],\boldsymbol{Q})$ *with* $Q(0)=Q^0$.

Proof. It remains to prove that $\boldsymbol{A}:\boldsymbol{Q}\to\boldsymbol{Q}^*$, which is defined via $\boldsymbol{E}(t,U,Z) = \frac{1}{2}\langle \boldsymbol{A}\binom{U}{Z},\binom{U}{Z}\rangle_{\boldsymbol{Q}} - \langle \ell(t),u_0\rangle_{\mathrm{H}^1}$, satisfies (3.2):

$$\exists\,\alpha>0\ \forall\,(U,Z)\in\boldsymbol{Q} \text{ with } \boldsymbol{R}(Z)<\infty: \quad \left\langle \boldsymbol{A}\begin{pmatrix}U\\Z\end{pmatrix},\begin{pmatrix}U\\Z\end{pmatrix}\right\rangle_{\boldsymbol{Q}} \geq \alpha\|(U,Z)\|^2_{\boldsymbol{Q}}. \tag{3.9}$$

By our assumption (3.3c), we immediately obtain the lower estimate

$$\left\langle \boldsymbol{A}\begin{pmatrix}U\\Z\end{pmatrix},\begin{pmatrix}U\\Z\end{pmatrix}\right\rangle_{\boldsymbol{Q}} \geq \widehat{\alpha}\|(\widehat{\boldsymbol{e}}(U),Z)\|^2_{\mathrm{L}^2(\Omega\times\mathcal{Y})} \quad \text{for all } (U,Z)\in\boldsymbol{Q}. \tag{3.10}$$

Next, we use an orthogonality condition for the two-scale limit of gradients. If $\nabla u_\varepsilon \stackrel{\mathrm{w2}}{\rightharpoonup} E\nabla_x u_0 + \nabla_y U_1$ in $\mathrm{L}^2(\Omega\times\mathcal{Y})$, then

$$\int_{\Omega\times\mathcal{Y}} |\nabla_x u_0(x)+\nabla_y U_1(x,y)|^2\,\mathrm{d}y\,\mathrm{d}x = \int_\Omega |\nabla u_0(x)|^2\,\mathrm{d}x + \int_{\Omega\times\mathcal{Y}} |\nabla_y U_1(x,y)|^2\,\mathrm{d}y\,\mathrm{d}x.$$

The mixed terms drop out, since $E\nabla u_0(x,\cdot)$ is constant on $\mathcal{Y}$, while $\nabla_y U_1(x,\cdot)$ has average 0 as it is a derivative of a periodic function. For the symmetric strains we similarly obtain

$$\|\widehat{\boldsymbol{e}}((u_0,U_1))\|^2_{\mathrm{L}^2(\Omega\times\mathcal{Y})} = \|\boldsymbol{e}(u_0)\|^2_{\mathrm{L}^2(\Omega)} + \|\boldsymbol{e}_y(U_1)\|^2_{\mathrm{L}^2(\Omega\times\mathcal{Y})}.$$

With $K_{\mathcal{Y}} = 2\pi^2 \min\{\,|\lambda|^2 \mid 0\neq\lambda\in\Lambda\,\}$ we have the Korn–Poincaré-type inequalities:

$$\forall\,V\in\mathrm{H}^1_{\mathrm{av}}(\mathcal{Y}): \quad \|\boldsymbol{e}_y(V)\|^2_{\mathrm{L}^2(\mathcal{Y})} \geq K_{\mathcal{Y}}\|V\|^2_{\mathrm{L}^2(\mathcal{Y})} \ \text{ and } \ \|\boldsymbol{e}_y(V)\|^2_{\mathrm{L}^2(\mathcal{Y})} \geq \frac{1}{2}\|\nabla_y V\|^2_{\mathrm{L}^2(\mathcal{Y})}.$$

This follows easily by writing $V(y) = \sum_\Lambda V_\lambda \mathrm{e}^{2\mathrm{i}\pi\lambda\cdot y}$ and using Plancherel's identity. Inserting these estimates into (3.10) and employing Korn's inequality for u_0 we obtain

$$\left\langle \boldsymbol{A}\begin{pmatrix}U\\Z\end{pmatrix},\begin{pmatrix}U\\Z\end{pmatrix}\right\rangle_{\boldsymbol{Q}} \geq \widehat{\alpha}\left(C_{\mathrm{Korn}}\|u_0\|^2_{\mathrm{H}^1(\Omega)} + \frac{K_{\mathcal{Y}}}{1+2K_{\mathcal{Y}}}\int_\Omega \|U_1(x,\cdot)\|^2_{\mathrm{H}^1(\mathcal{Y})}\,\mathrm{d}x + \|Z\|^2_{\mathrm{L}^2(\Omega\times\mathcal{Y})}\right),$$

which provides the desired estimate (3.9). ∎

4. Convergence results. This final section addresses the question of under which conditions the solutions $(u_\varepsilon,z_\varepsilon)$ of (S^ε) and (E^ε) have a two-scale limit (U,Z) which is a solution of (**S**) and (**E**). The convergence is taken in the sense of two-scale cross-convergence, and we can build on our theory in section 4.3. In particular, the results of section 2.5 state that $\boldsymbol{E}$ and $\boldsymbol{R}$ are the Γ-limits of the families $(\mathcal{E}_\varepsilon)_\varepsilon$ and $(\mathcal{R}_\varepsilon)_\varepsilon$, respectively, in the Mosco sense.

PROPOSITION 4.1. *Let* $\Omega\subset\mathbb{R}^d$ *be bounded with Lipschitz boundary. Moreover, let* $\mathcal{E}_\varepsilon$, $\mathcal{R}_\varepsilon$, $\boldsymbol{E}$, *and* $\boldsymbol{R}$ *be defined as above such that* (3.3) *and* $\ell\in\mathrm{C}^0([0,T],(\mathrm{H}^1_{\Gamma_{\mathrm{Dir}}}(\Omega)^d)^*)$

hold. Then for each $t \in [0,T]$ we have the convergences

$$\text{(4.1a)} \quad (u_\varepsilon, z_\varepsilon) \overset{\text{w2c}}{\rightharpoonup} (u_0, U_1, Z) \in \boldsymbol{Q} \implies \left\{ \begin{array}{c} \boldsymbol{E}(t, u_0, U_1, Z) \leq \liminf_{\varepsilon\to 0} \mathcal{E}_\varepsilon(t, u_\varepsilon, z_\varepsilon), \\ \boldsymbol{R}(Z) \leq \liminf_{\varepsilon\to 0} \mathcal{R}_\varepsilon(z_\varepsilon); \end{array} \right.$$

$$\text{(4.1b)} \quad \begin{array}{l} \forall\, (u_0, U_1, Z) \in \boldsymbol{Q}\ \exists\, ((u_\varepsilon, z_\varepsilon))_\varepsilon : \\ (u_\varepsilon, z_\varepsilon) \xrightarrow{\text{s2c}} (u_0, U_1, Z) \textit{ in } \boldsymbol{Q} \quad \textit{and} \end{array} \left\{ \begin{array}{c} \mathcal{E}_\varepsilon(t, u_\varepsilon, z_\varepsilon) \to \boldsymbol{E}(t, u_0, U_1, Z), \\ \mathcal{R}_\varepsilon(z_\varepsilon) \to \boldsymbol{R}(Z), \end{array} \right.$$

where for the recovery sequence in (4.1b) *we may take* $(u_\varepsilon, z_\varepsilon) = (u_0 + \mathcal{G}_\varepsilon(0, U_1), \mathcal{F}_\varepsilon Z)$ *with* $\mathcal{F}_\varepsilon$ *and* $\mathcal{G}_\varepsilon$ *as defined in* (2.8) *and* (2.12)*, respectively.*

Here it is important that $\mathcal{G}_\varepsilon$ maps into $\mathrm{H}^1_0(\Omega)$, such that $u_0 + \mathcal{G}_\varepsilon(0, U_1) \in \mathrm{H}^1_{\Gamma_{\mathrm{Dir}}}(\Omega)^d$.

Our convergence result for the solutions $(u_\varepsilon, z_\varepsilon) \in \mathrm{C}^{\mathrm{Lip}}([0,T], \mathcal{Q})$ of (S^ε) and (E^ε) to the solution $(U, Z) \in \mathrm{C}^{\mathrm{Lip}}([0,T], \boldsymbol{Q})$ will be an adapted and simplified variant of the two abstract Theorems 3.1 and 3.3 in [MRS07]. The abstract theory is formulated on one single space $\widehat{\mathcal{Q}}$, but in fact the results there are easily generalized to the setting needed here. The following remark gives the alternative way of embedding everything into one big function space $\widehat{\mathcal{Q}}$.

REMARK 4.2. *To show that our situation is included exactly in this setting, we choose*

$$\widehat{\mathcal{Q}} = \widehat{\mathcal{H}} \times \widehat{\mathcal{Z}} \quad \textit{with } \widehat{\mathcal{H}} = \mathrm{H}^1_{\Gamma_{\mathrm{Dir}}}(\Omega)^d \times \mathrm{L}^2(\mathbb{R}^d; \mathrm{H}^1_{\mathrm{av}}(\mathcal{Y})) \textit{ and } \widehat{\mathcal{Z}} = \mathrm{L}^2(\mathbb{R}^d \times \mathcal{Y})$$

and define an ε-dependent embedding $(u, z) \mapsto (\mathcal{Q}_\varepsilon u, \mathcal{U}_\varepsilon u, \mathcal{T}_\varepsilon z)$, where the $\mathcal{Q}_\varepsilon : \mathrm{H}^1_{\Gamma_{\mathrm{Dir}}}(\Omega)^d \to \mathrm{H}^1_{\Gamma_{\mathrm{Dir}}}(\Omega)^d$ and $\mathcal{U} : \mathrm{H}^1_{\Gamma_{\mathrm{Dir}}}(\Omega)^d \to \mathrm{L}^2(\mathbb{R}^d; \mathrm{H}^1_{\mathrm{av}}(\mathcal{Y}))$ can be defined as indicated in [CDG02]. *Define H_ε as the subspace of $\mathrm{H}^1_{\Gamma_{\mathrm{Dir}}}(\Omega)^d$ containing the functions u such that $\fint_{\varepsilon(\lambda+Y)} u(x)\, \mathrm{d}x = 0$ for all $\lambda \in \Lambda^-_\varepsilon$; see section* 2.1. *Then let $\mathcal{Q}_\varepsilon$ be the orthogonal projection to the orthogonal complement of H_ε and set $\mathcal{U}_\varepsilon u = \frac{1}{\varepsilon}(\mathrm{id} - \mathcal{Q}_\varepsilon)u$. Finally, we define the functionals in $\widehat{\mathcal{Q}}$ via*

$$\widehat{\mathcal{E}}_\varepsilon(t, u_0, \widehat{U}_1, \widehat{Z}) = \left\{ \begin{array}{cl} \mathcal{E}_\varepsilon(t, u, z) & \textit{if } (u_0, \widehat{U}_1, \widehat{Z}) = (u, \mathcal{Q}_\varepsilon u, \mathcal{T}_\varepsilon z), \\ \infty & \textit{else,} \end{array} \right.$$

$$\widehat{\mathcal{E}}_0(t, u_0, \widehat{U}_1, \widehat{Z}) = \left\{ \begin{array}{cl} \boldsymbol{E}(t, u_0, U_1, Z) & \textit{if } \operatorname{sppt}(\widehat{U}_1, \widehat{Z}) \subset \overline{\Omega} \times \mathcal{Y}, \\ \infty & \textit{else,} \end{array} \right.$$

$$\widehat{\mathcal{R}}_\varepsilon(\widehat{Z}) = \left\{ \begin{array}{cl} \mathcal{R}_\varepsilon(z) & \textit{if } \widehat{Z} = \mathcal{T}_\varepsilon z, \\ \infty & \textit{else,} \end{array} \right. \qquad \widehat{\mathcal{R}}_0(Z) = \left\{ \begin{array}{cl} \boldsymbol{R}(Z) & \textit{if } \operatorname{sppt}(Z) \subset \overline{\Omega} \times \mathcal{Y}, \\ \infty & \textit{else.} \end{array} \right.$$

Hence, under the additional assumption that for all considered functions the corresponding functionals have finite values, we have concluded that weak and strong convergences in $\widehat{\mathcal{Q}}$ are equivalent to weak or strong two-scale convergence of families $(u_\varepsilon, z_\varepsilon)_\varepsilon$ in $\mathcal{Q}$ towards a limit $(u_0, U_1, Z) \in \boldsymbol{Q}$.

Now we are able to formulate the main result of this paper. It states that the solutions $(u_\varepsilon, z_\varepsilon)_\varepsilon$ of the ε-periodic problem (S^ε) and (E^ε) strongly two-scale cross-converge to a solution (U, Z) of the two-scale homogenized problem (**S**) and (**E**) under the sole assumption that the initial conditions strongly two-scale cross-converge.

THEOREM 4.3. *Let $(u_\varepsilon, z_\varepsilon) : [0,T] \to \mathcal{Q}$ be the solution for (S^ε) and (E^ε) as obtained in Proposition* 3.4. *Assume that the initial data satisfy*

$$(u_\varepsilon(0), z_\varepsilon(0)) \xrightarrow{\text{s2c}} Q^0 = (u^0, U^0, Z^0) \textit{ in } \boldsymbol{Q}.$$

Then Q^0 is stable (i.e., $Q^0 \in \boldsymbol{S}(0)$) and

$$\forall\, t \in [0,T]: \quad (u_\varepsilon(t), z_\varepsilon(t)) \xrightarrow{\text{s2c}} Q(t) = (u_0(t), U_1(t), Z(t)) \text{ in } \boldsymbol{Q},$$

where $Q : [0,T] \to \boldsymbol{Q}$ is the unique solution of (**S**) *and* (**E**) *with initial condition $Q(0) = Q^0$ as provided in Proposition* 3.5.

Recall the definition of the stable sets

$$\begin{aligned}
&\mathcal{S}_\varepsilon(t) = \{\, (u,z) \in \mathcal{Q} \mid \text{for all } (\widetilde{u},\widetilde{z}) \in \mathcal{Q}\text{: } \mathcal{E}_\varepsilon(t,\widetilde{u},\widetilde{z}) \le \mathcal{E}_\varepsilon(0,\widetilde{u},\widetilde{z}) - \mathcal{R}_\varepsilon(\widetilde{z}-z) \,\},\\
&\boldsymbol{S}(t) = \{\, (U,Z) \in \boldsymbol{Q} \mid \text{for all } (\widetilde{U},\widetilde{Z}) \in \boldsymbol{Q}\text{: } \boldsymbol{E}(t,\widetilde{U},\widetilde{Z}) \le \boldsymbol{E}(0,\widetilde{U},\widetilde{Z}) - \boldsymbol{R}(\widetilde{Z}-Z) \,\}.
\end{aligned}$$

REMARK 4.4. *In* [MRS07] *the convergence of the initial condition and of the solutions is formulated in terms of the underlying topology, which in the present setting means weak two-scale cross-convergence. However, the abstract theory assumes convergence of the initial energies and proves convergence of the energies $\mathcal{E}_\varepsilon(t, u_\varepsilon(t), z_\varepsilon(t)) \to \boldsymbol{E}(t, U(t), Z(t))$. Because of uniform convexity (cf.* (3.9)*) we see that weak convergence and energy convergence imply strong convergence. The details of this argument are worked out at the end of the proof of Theorem* 4.3. *See also* [Vis84] *for general arguments of this type.*

The main difficulty in the proof of the desired result is proving that the weak limit of stable states is again stable. In [MRS07] this property is reduced to a property which postulates the existence of suitable *joint recovery sequences* for a combination of $\mathcal{E}_\varepsilon$ and $\mathcal{R}_\varepsilon$. In our setting this reads as follows.

PROPOSITION 4.5. *For $t \in [0,T]$ assume that $(u_\varepsilon, z_\varepsilon) \in \mathcal{S}_\varepsilon(t)$ and $(u_\varepsilon, z_\varepsilon) \overset{\text{w2c}}{\rightharpoonup} (u_0, U_1, Z)$ in $\boldsymbol{Q}$.*

(a) *Then for each $(\widetilde{u}_0, \widetilde{U}_1, \widetilde{Z}) \in \boldsymbol{Q}$ there exists a joint recovery family $(\widetilde{u}_\varepsilon, \widetilde{z}_\varepsilon)_\varepsilon$ with $(\widetilde{u}_\varepsilon, \widetilde{z}_\varepsilon) \overset{\text{w2c}}{\rightharpoonup} (\widetilde{u}_0, \widetilde{U}_1, \widetilde{Z})$ in $\boldsymbol{Q}$ such that*

$$\begin{aligned}
&\limsup_{\varepsilon\to 0} \big[\mathcal{E}_\varepsilon(t,\widetilde{u}_\varepsilon,\widetilde{z}_\varepsilon) + \mathcal{R}_\varepsilon(\widetilde{z}_\varepsilon - z_\varepsilon) - \mathcal{E}_\varepsilon(t,u_\varepsilon,z_\varepsilon)\big]\\
&\le \boldsymbol{E}(t,\widetilde{U},\widetilde{Z}) + \boldsymbol{R}(\widetilde{Z}-Z) - \boldsymbol{E}(t,U,Z).
\end{aligned} \tag{4.2}$$

(b) *As a consequence $(u_0, U_1, Z) \in \boldsymbol{S}(t)$.*

Proof. (a) We give the joint recovery sequence explicitly in the form

$$(\widetilde{u}_\varepsilon, \widetilde{z}_\varepsilon) = (u_\varepsilon, z_\varepsilon) + (\widetilde{u}_0 - u_0 + \mathcal{G}_\varepsilon(0, \widetilde{U}_1 - U_1)\,,\ \mathcal{F}_\varepsilon(\widetilde{Z} - Z)).$$

Note that the arguments for $\mathcal{G}_\varepsilon$ and $\mathcal{F}_\varepsilon$ do not depend on ε. Hence, by Propositions 2.10 and 2.4 we obtain the important relation

$$(\widetilde{u}_\varepsilon, \widetilde{z}_\varepsilon) - (u_\varepsilon, z_\varepsilon) = (\widetilde{u}_0 - u_0 + \mathcal{G}_\varepsilon(0, \widetilde{U}_1 - U_1)\,,\ \mathcal{F}_\varepsilon(\widetilde{Z} - Z)) \xrightarrow{\text{s2c}} (\widetilde{u}_0 - u_0, \widetilde{U}_1 - U_1, \widetilde{Z} - Z). \tag{4.3}$$

In turn, this implies the obvious convergence $(\widetilde{u}_\varepsilon, \widetilde{z}_\varepsilon) \overset{\text{w2c}}{\rightharpoonup} (\widetilde{u}_0, \widetilde{U}_1, \widetilde{Z})$.

From (4.3) and Lemma 2.12(b) we obtain $\mathcal{R}_\varepsilon(\widetilde{z}_\varepsilon - z_\varepsilon) \to \boldsymbol{R}(\widetilde{Z} - Z)$.

For the energies we use the quadratic nature and obtain

$$\begin{aligned}
&\mathcal{E}_\varepsilon(t,\widetilde{u}_\varepsilon,\widetilde{z}_\varepsilon) - \mathcal{E}_\varepsilon(t,u_\varepsilon,z_\varepsilon)\\
&= \frac{1}{2}\int_\Omega \left\langle\!\!\left\langle \mathbb{A}\left(\left\{\frac{x}{\varepsilon}\right\}_{\mathcal{Y}}\right) \begin{pmatrix} \boldsymbol{e}(\widetilde{u}_\varepsilon - u_\varepsilon) \\ \widetilde{z}_\varepsilon + z_\varepsilon \end{pmatrix}, \begin{pmatrix} \boldsymbol{e}(\widetilde{u}_\varepsilon - u_\varepsilon) \\ \widetilde{z}_\varepsilon + z_\varepsilon \end{pmatrix} \right\rangle\!\!\right\rangle \mathrm{d}x - \langle \ell(t), \widetilde{u}_\varepsilon - u_\varepsilon \rangle.
\end{aligned}$$

The last term obviously converges to $\langle \ell(t), \widetilde{u}_0{-}u_0\rangle$ by the usual weak convergence in $\mathrm{H}^1_{\Gamma_{\mathrm{Dir}}}(\Omega)^d$. Under the integral we have a quadratic form, where the right factor weakly two-scale converges to $\binom{\widetilde{\mathbf{e}}(\widetilde{U}+U)}{\widetilde{Z}+Z}$ in $\mathrm{L}^2(\Omega{\times}\mathcal{Y})$. The left-hand factor is a product of the matrix $m_\varepsilon = \mathbb{A}(\{\frac{\cdot}{\varepsilon}\}_{\mathcal{Y}})$ and a strongly two-scale convergent sequence with limit $\binom{\widetilde{\mathbf{e}}(\widetilde{U}-U)}{\widetilde{Z}-Z}$ in $\mathrm{L}^2(\Omega{\times}\mathcal{Y})$. As $\mathcal{T}_\varepsilon m_\varepsilon(x,y) = \mathbb{A}(y)$ Proposition 2.6 implies

$$\mathbb{A}\left(\left\{\frac{\cdot}{\varepsilon}\right\}_{\mathcal{Y}}\right)\begin{pmatrix}\boldsymbol{e}(\widetilde{u}_\varepsilon{-}u_\varepsilon)\\ \widetilde{z}_\varepsilon{+}z_\varepsilon\end{pmatrix} \xrightarrow{\mathrm{s2}} \mathbb{A}\begin{pmatrix}\widetilde{\boldsymbol{e}}(\widetilde{U}{-}U)\\ \widetilde{Z}{-}Z\end{pmatrix} \text{ in } \mathrm{L}^2(\Omega{\times}\mathcal{Y}).$$

Since a scalar product of a weakly and a strongly converging sequence converges (see Proposition 2.4(d)), we conclude

$$\mathcal{E}_\varepsilon(t,\widetilde{u}_\varepsilon,\widetilde{z}_\varepsilon){-}\mathcal{E}_\varepsilon(t,u_\varepsilon,z_\varepsilon) \to \boldsymbol{E}(t,\widetilde{U},\widetilde{Z}){-}\boldsymbol{E}(t,U,Z).$$

Thus, we have established (4.2) in the stronger version that the limsup is a limit and the "$\leq$" is "$=$".

(b) This is a direct consequence of part (a). Let (U,Z) be the limit of stable states and take any test state $(\widetilde{U},\widetilde{Z}) \in \boldsymbol{Q}$. Now take the joint recovery sequence obtained in part (a) and insert $(\widetilde{u}_\varepsilon,\widetilde{z}_\varepsilon)$ into the stability condition for $(u_\varepsilon,z_\varepsilon)$, namely,

$$0 \leq \mathcal{E}_\varepsilon(t,\widetilde{u}_\varepsilon,\widetilde{z}_\varepsilon) + \mathcal{R}_\varepsilon(\widetilde{z}_\varepsilon{-}z_\varepsilon) - \mathcal{E}_\varepsilon(t,u_\varepsilon,z_\varepsilon).$$

As the right-hand side converges we conclude $0 \leq \boldsymbol{E}(t,\widetilde{U},\widetilde{Z}){+}\boldsymbol{R}(\widetilde{Z}{-}Z){-}\boldsymbol{E}(t,U,Z)$ and stability is established as $(\widetilde{U},\widetilde{Z})$ was arbitrary. $\square$

Proof of Theorem 4.3. By Proposition 3.4 we know that the family $(u_\varepsilon,z_\varepsilon)_\varepsilon$ is uniformly bounded in $\mathrm{C}^{\mathrm{Lip}}([0,T],\mathcal{Q})$. As closed balls in $\mathcal{Q}$ are weakly compact and have a metrizable topology, the Arzelà–Ascoli theorem can be applied in $\mathrm{C}^0([0,T],\mathcal{Q}_{\mathrm{weak}})$, and we find a subsequence $(\varepsilon_k)_{k\in\mathbb{N}}$ with $0<\varepsilon_k\to 0$ such that

$$\forall\, t\in[0,T]: \quad (u_{\varepsilon_k}(t),z_{\varepsilon_k}(t)) \stackrel{\mathrm{w2c}}{\rightharpoonup} (U(t),Z(t)) \text{ in } \boldsymbol{Q}.$$

By the lower semicontinuity of the norm, we have $(U,Z) \in \mathrm{C}^{\mathrm{Lip}}([0,T],\boldsymbol{Q})$ and it remains to show that (U,Z) is a solution of (**S**) and (**E**). As the initial condition (U^0,Z^0) is known, the solution is unique, and we even conclude that the whole family converges (by the standard argument via contradiction).

By Proposition 4.5 we know that $(U(t),Z(t))$ is stable for all $t\in[0,T]$, and hence (**S**) is satisfied and we have to establish the energy balance (**E**) in (3.8). For this, we pass to the limit $\varepsilon\to 0$ in (E^ε); cf. (3.6). The first term on the right-hand side converges, as the energy $\mathcal{E}_\varepsilon(0,u_\varepsilon(0),z_\varepsilon(0))$ converges applying the strong two-scale cross-convergence and Proposition 2.15. The second term converges by Lebesgue's dominated convergence theorem as the integrands are uniformly bounded and converge pointwise.

To treat the left-hand side of (E^ε) we let $e_\varepsilon(t) = \mathcal{E}_\varepsilon(t,u_\varepsilon(t),z_\varepsilon(t))$ and $d_\varepsilon(t) = \int_0^t \mathcal{R}_\varepsilon(z_\varepsilon(s))\,\mathrm{d}s$. By the above, we know that $r_\varepsilon(t) = e_\varepsilon(t)+d_\varepsilon(t)$ converges to $r_0(t)$, which is the limit of the right-hand side. We let $e^*(t) = \limsup_{\varepsilon\to 0} e_\varepsilon(t)$ and $d_*(t) = \liminf_{\varepsilon\to 0} d_\varepsilon(t)$ and conclude $e^*(t)+d_*(t) = r_0(t)$. Now we use the lower estimates for the functionals. For the stored energy we use (4.1a) to obtain

$$\boldsymbol{E}(t,U(t),Z(t)) \leq \liminf_{\varepsilon\to 0} e_\varepsilon(t) \leq \limsup_{\varepsilon\to 0} e_\varepsilon(t) = e^*(t).$$

For the dissipation integral we use $\int_0^t \boldsymbol{R}(\dot Z(s))\,\mathrm{d}s = \sup \sum_{j=1}^N \boldsymbol{R}(Z(t_j){-}Z(t_{j-1}))$, where the supremum is taken over all finite partitions of $[0,t]$. Again by (4.1a) we find

$$\begin{aligned}\sum_{j=1}^N \boldsymbol{R}(Z(t_j){-}Z(t_{j-1})) &\le \liminf_{\varepsilon\to 0} \sum_{j=1}^N \mathcal{R}_\varepsilon(z_\varepsilon(t_j){-}z_\varepsilon(t_{j-1}))\\ &\le \liminf_{\varepsilon\to 0}\int_0^t \mathcal{R}_\varepsilon(\dot z_\varepsilon(s))\,\mathrm{d}s = d_*(t).\end{aligned}\tag{4.4}$$

Thus, recalling $e^*+d_*=r_0$ we proved the lower energy estimate

$$\boldsymbol{E}(t,U(t),Z(t)){+}\int_0^T \boldsymbol{R}(\dot Z(s))\,\mathrm{d}s \le e^*(t){+}d_*(t) = \boldsymbol{E}(0,U(0),Z(0)){-}\int_0^t \langle \ell(s),u_0(s)\rangle\,\mathrm{d}s.$$

The upper energy estimate (just replace "$\le$" by "$\ge$") follows from the already established stability of (U,Z); see [MTL02, Thm. 2.5] or [MM05, Thm. 4.4]. Thus, (**E**) holds and, moreover, we also conclude that the inequality in (4.4) must be an equality. This in turn implies that $\boldsymbol{E}(t,U(t),Z(t)) = e^*(t) = \lim_{\varepsilon\to 0}\mathcal{E}_\varepsilon(t,u_\varepsilon(t),z_\varepsilon(t))$.

As the value of $t\in[0,T]$ is kept from now on, we omit it in the rest of the proof. From the above and using the weak two-scale convergence $q_\varepsilon=(u_\varepsilon,z_\varepsilon)\overset{\mathrm{w2c}}{\rightharpoonup} Q = (u_0,U_1,Z)$, we want to conclude $q_\varepsilon \xrightarrow{\mathrm{s2c}} Q$.

For this, we define $\widehat q_\varepsilon = (u_0+\mathcal{G}_\varepsilon(0,U_1),\mathcal{F}_\varepsilon Z)\in \mathcal{Q}$, which satisfies $\widehat q_\varepsilon \xrightarrow{\mathrm{s2c}} Q$. Moreover, we have

$$\begin{aligned}&\frac{\alpha}{2}\|\widehat q_\varepsilon{-}q_\varepsilon\|^2_{\mathcal{Q}} \le \frac12 \big\langle\!\big\langle \mathcal{A}_\varepsilon(\widehat q_\varepsilon{-}q_\varepsilon),(\widehat q_\varepsilon{-}q_\varepsilon)\big\rangle\!\big\rangle\\ &= \mathcal{E}_\varepsilon(t,q_\varepsilon)-\mathcal{E}_\varepsilon(t,\widehat q_\varepsilon) + \big\langle\!\big\langle \mathcal{A}_\varepsilon\widehat q_\varepsilon{-}\ell, q_\varepsilon{-}\widehat q_\varepsilon\big\rangle\!\big\rangle\\ &\to e^*(t)-\boldsymbol{E}(t,Q)+0=0.\end{aligned}$$

For the convergence note that the first term was treated above, that the second term converges because of "$\xrightarrow{\mathrm{s2c}}$" and Proposition 2.15, and that the third term converges as a scalar product, since the left-hand term is strongly convergent and while the right-hand term weakly converges to 0; see Proposition 2.4(d). Finally, we conclude by noting that

$$\begin{aligned}&\|(\mathcal{T}_\varepsilon(\nabla u_\varepsilon),z_\varepsilon)-(E\nabla_x u_0{+}\nabla_y U_1,Z)\|_{\mathrm{L}^2(\mathbb{R}^d\times\mathcal{Y})}\\ &\le \|(\mathcal{T}_\varepsilon(\nabla u_\varepsilon{-}\nabla\widehat u_\varepsilon),z_\varepsilon{-}\widehat z_\varepsilon)\|_{\mathrm{L}^2(\mathbb{R}^d\times\mathcal{Y})}+\delta_\varepsilon \;\le\; \|(u_\varepsilon,z_\varepsilon){-}(\widehat u_\varepsilon,\widehat z_\varepsilon)\|_{\mathcal{Q}}+\delta_\varepsilon\to 0\end{aligned}$$

with $\delta_\varepsilon = \|(\mathcal{T}_\varepsilon(\nabla\widehat u_\varepsilon),\widehat z_\varepsilon)-(E\nabla_x u_0{+}\nabla_y U_1,Z)\|_{\mathrm{L}^2(\mathbb{R}^d\times\mathcal{Y})}\to 0$ because of $\widehat q_\varepsilon\xrightarrow{\mathrm{s2c}} Q$. This establishes $q_\varepsilon\xrightarrow{\mathrm{s2c}} Q$ and we are done. ∎

A SUFFICIENT CONDITION OF REGULARITY FOR AXIALLY SYMMETRIC SOLUTIONS TO THE NAVIER–STOKES EQUATIONS*

G. SEREGIN† AND W. ZAJACZKOWSKI‡

Abstract. In the present paper, we prove a sufficient condition of local regularity for suitable weak solutions to the Navier–Stokes equations having axial symmetry. Our condition is an axially symmetric analogue of the so-called $L_{3,\infty}$-case in the general local regularity theory.

Key words. Navier–Stokes equations, axial symmetry, suitable weak solutions, backward uniqueness

AMS subject classifications. 35K, 76D

1. Introduction. In the present paper, we address the problem of regularity for axisymmetric solutions to the Navier–Stokes equations. In contrast to many others (see, for example, [7], [21], [9], [11], [12], [22], [23], and [24]), we study this problem in a local setting.

Our work is motivated by the results of two different papers, [2] and [4]. To explain that, we need the following simple notation. Let e_1, e_2, e_3 be an orthogonal basis of the Cartesian coordinates x_1, x_2, x_3, and let e_ϱ, e_φ, e_3 be an orthogonal basis of the cylindrical coordinates ϱ, φ, x_3 chosen so that

$$e_\varrho = \cos\varphi e_1 + \sin\varphi e_2, \quad e_\varphi = -\sin\varphi e_1 + \cos\varphi e_2, \quad e_3 = e_3.$$

Then, for any vector-valued field v, we have the representations

$$v = v_i e_i = v_1 e_1 + v_2 e_2 + v_3 e_3 = v_\varrho e_\varrho + v_\varphi e_\varphi + v_3 e_3.$$

The classical Navier–Stokes equations, which are invariant with respect to transformation of coordinates, have the form

$$\partial_t v + v\cdot\nabla v - \Delta v + \nabla p = 0, \qquad \mathrm{div} v = 0 \tag{1.1}$$

and are satisfied in some space-time domain. Here, as usual, v and p stand for the velocity field and the pressure field, respectively.

In our considerations, we always assume that v_ϱ, v_φ, v_3, and p are independent of the polar angle φ. In [2], Chae and Lee consider the Cauchy problem for the Navier–Stokes equations under the above assumption on axial symmetry. In addition to usual conditions on the initial data, the authors of [2] assume that velocity field v obeys

$$\int_0^T dt\Big(\int_{\mathbb{R}^3} |v|^\gamma d\varrho d\varphi dx_3\Big)^{\frac{\alpha}{\gamma}} < +\infty, \tag{1.2}$$

with $1/\alpha + 1/\gamma \leq 1/2$, $2 < \gamma < +\infty$, $2 < \alpha \leq +\infty$, and prove the regularity of solutions to the Cauchy problem for (1.1) on time interval $]0, T[$. In fact, they prove even more: their statement is still true if $|v|$ is replaced with $\sqrt{v_\varrho^2 + v_\varphi^2}$. However, it remains unclear whether or not the regularity takes place in the marginal case $\gamma = 2$ and $\alpha = +\infty$. In our opinion, the case cannot be treated by methods developed in [2] because, in a sense, it is an analogue of the so-called $L_{3,\infty}$-case studied in [4]. In turn, the $L_{3,\infty}$-case is marginal to the so-called Ladyzhenskaya–Prodi–Serrin condition; see [13], [19], [6], [20], [5], [16], and [17]. It seems quite reasonable to interpret the result of [2] (see [2, Theorem 3]) as the Ladyzhenskaya–Prodi–Serrin condition for axially symmetric problems. To treat $L_{3,\infty}$-solutions in a generic setting, one needs a new technique based on backward uniqueness for the heat operator with variable lower order terms. In this paper, we wish to extend this method to the axially symmetric case.

To formulate our main result, we introduce the additional notation:

$$\mathcal{C}(x_0, R) = \{x \in \mathbb{R}^3 \parallel x = (x', x_3),\ x' = (x_1, x_2),$$

$$|x' - x_0'| < R,\ |x_3 - x_{03}| < R\}, \quad \mathcal{C}(R) = \mathcal{C}(0, R), \quad \mathcal{C} = \mathcal{C}(1);$$

$$z = (x, t), \quad z_0 = (x_0, t_0), \quad Q(z_0, R) = \mathcal{C}(x_0, R) \times]t_0 - R^2, t_0[,$$
